THE VARIATIONAL FORMULATION OF THE FOKKER–PLANCK EQUATION*

RICHARD JORDAN†, DAVID KINDERLEHRER‡, AND FELIX OTTO§

In memory of Richard Duffin

Abstract. The Fokker–Planck equation, or forward Kolmogorov equation, describes the evolution of the probability density for a stochastic process associated with an Ito stochastic differential equation. It pertains to a wide variety of time-dependent systems in which randomness plays a role. In this paper, we are concerned with Fokker–Planck equations for which the drift term is given by the gradient of a potential. For a broad class of potentials, we construct a time discrete, iterative variational scheme whose solutions converge to the solution of the Fokker–Planck equation. The major novelty of this iterative scheme is that the time-step is governed by the Wasserstein metric on probability measures. This formulation enables us to reveal an appealing, and previously unexplored, relationship between the Fokker–Planck equation and the associated free energy functional. Namely, we demonstrate that the dynamics may be regarded as a gradient flux, or a steepest descent, for the free energy with respect to the Wasserstein metric.

1. Introduction and overview.

The Fokker–Planck equation plays a central role in statistical physics and in the study of fluctuations in physical and biological systems [7, 22, 23]. It is intimately connected with the theory of stochastic differential equations: a (normalized) solution to a given Fokker–Planck equation represents the probability density for the position (or velocity) of a particle whose motion is described by a corresponding Ito stochastic differential equation (or Langevin equation). We shall restrict our attention in this paper to the case where the drift coefficient is a gradient. The simplest relevant physical setting is that of a particle undergoing diffusion in a potential field [23].

It is known that, under certain conditions on the drift and diffusion coefficients, the stationary solution of a Fokker–Planck equation of the type that we consider here satisfies a variational principle. It minimizes a certain convex free energy functional over an appropriate admissible class of probability densities [12]. This free energy functional satisfies an H-theorem: it decreases in time for any solution of the Fokker–Planck equation [22]. In this work, we shall establish a deeper, and apparently previously unexplored, connection between the free energy functional and the Fokker–Planck dynamics. Specifically, we shall demonstrate that the solution of the

Fokker–Planck equation follows, at each instant in time, the direction of steepest descent of the associated free energy functional.

The notion of a steepest descent, or a gradient flux, makes sense only in context with an appropriate metric. We shall show that the required metric in the case of the Fokker–Planck equation is the Wasserstein metric (defined in section 3) on probability densities. As far as we know, the Wasserstein metric cannot be written as an induced metric for a metric tensor (the space of probability measures with the Wasserstein metric is not a Riemannian manifold). Thus, in order to give meaning to the assertion that the Fokker–Planck equation may be regarded as a steepest descent, or gradient flux, of the free energy functional with respect to this metric, we switch to a discrete time formulation. We develop a discrete, iterative variational scheme whose solutions converge, in a sense to be made precise below, to the solution of the Fokker–Planck equation. The time-step in this iterative scheme is associated with the Wasserstein metric. For a different view on the use of implicit schemes for measures, see [6, 16].

For the purpose of comparison, let us consider the classical diffusion (or heat) equation

$$\frac{\partial \rho(t,x)}{\partial t} = \Delta \rho(t,x)\,, \quad t \in (0,\infty)\,, \quad x \in \mathbb{R}^n\,,$$

which is the Fokker–Planck equation associated with a standard n-dimensional Brownian motion. It is well known (see, for example, [5, 24]) that this equation is the gradient flux of the Dirichlet integral $\frac{1}{2}\int_{R^n} |\nabla \rho|^2 \, dx$ with respect to the $L^2(\mathbb{R}^n)$ metric. The classical discretization is given by the scheme

$$\left.\begin{array}{l} \text{Determine } \rho^{(k)} \text{ that minimizes} \\ \frac{1}{2}\,\|\rho^{(k-1)} - \rho\|^2_{L^2(R^n)} \;+\; \frac{h}{2}\displaystyle\int_{R^n} |\nabla \rho|^2 \, dx \end{array}\right\}$$

over an appropriate class of densities ρ. Here, h is the time step size. On the other hand, we derive as a special case of our results below that the scheme

$$\left.\begin{array}{l} \text{Determine } \rho^{(k)} \text{ that minimizes} \\ \frac{1}{2}\, d(\rho^{(k-1)}, \rho)^2 \;+\; h \displaystyle\int_{\mathbb{R}^n} \rho \log \rho \, dx \\ \text{over all } \rho \in K\,, \end{array}\right\} \tag{1}$$

where K is the set of all probability densities on $\mathbb{R}^n$ having finite second moments, is also a discretization of the diffusion equation when d is the Wasserstein metric. In particular, this allows us to regard the diffusion equation as a steepest descent of the functional $\int_{\mathbb{R}^n} \rho \log \rho \, dx$ with respect to the Wasserstein metric. This reveals a novel link between the diffusion equation and the Gibbs–Boltzmann entropy $(-\int_{R^n} \rho \log \rho \, dx)$ of the density ρ. Furthermore, this formulation allows us to attach a precise interpretation to the conventional notion that diffusion arises from the tendency of the system to maximize entropy.

The connection between the Wasserstein metric and dynamical problems involving dissipation or diffusion (such as strongly overdamped fluid flow or nonlinear diffusion equations) seems to have first been recognized by Otto in [19]. The results in [19] together with our recent research on variational principles of entropy and free energy type for measures [12, 11, 15] provide the impetus for the present investigation. The work in [12] was motivated by the desire to model and characterize metastability

and hysteresis in physical systems. We plan to explore in subsequent research the relevance of the developments in the present paper to the study of such phenomena. Some preliminary results in this direction may be found in [13, 14].

The paper is organized as follows. In section 2, we first introduce the Fokker–Planck equation and briefly discuss its relationship to stochastic differential equations. We then give the precise form of the associated stationary solution and of the free energy functional that this density minimizes. In section 3, the Wasserstein metric is defined, and a brief review of its properties and interpretations is given. The iterative variational scheme is formulated in section 4, and the existence and uniqueness of its solutions are established. The main result of this paper—namely, the convergence of solutions of this scheme (after interpolation) to the solution of the Fokker–Planck equation—is the topic of section 5. There, we state and prove the relevant convergence theorem.

2. The Fokker–Planck equation, stationary solutions, and the free energy functional. We are concerned with Fokker–Planck equations having the form

$$\frac{\partial \rho}{\partial t} = \operatorname{div}\left(\nabla \Psi(x)\rho\right) + \beta^{-1}\Delta\rho\,, \quad \rho(x,0) = \rho^0(x), \tag{2}$$

where the potential $\Psi(x) : \mathbb{R}^n \to [0,\infty)$ is a smooth function, $\beta > 0$ is a given constant, and $\rho^0(x)$ is a probability density on $\mathbb{R}^n$. The solution $\rho(t,x)$ of (2) must, therefore, be a probability density on $\mathbb{R}^n$ for almost every fixed time t. That is, $\rho(t,x) \geq 0$ for almost every $(t,x) \in (0,\infty)\times\mathbb{R}^n$, and $\int_{\mathbb{R}^n} \rho(t,x)\,dx = 1$ for almost every $t \in (0,\infty)$.

It is well known that the Fokker–Planck equation (2) is inherently related to the Ito stochastic differential equation [7, 22, 23]

$$dX(t) = -\nabla\Psi(X(t))dt + \sqrt{2\beta^{-1}}\,dW(t)\,, \quad X(0) = X^0\,. \tag{3}$$

Here, $W(t)$ is a standard n-dimensional Wiener process, and X^0 is an n-dimensional random vector with probability density ρ^0. Equation (3) is a model for the motion of a particle undergoing diffusion in the potential field Ψ. $X(t) \in \mathbb{R}^n$ then represents the position of the particle, and the positive parameter β is proportional to the inverse temperature. This stochastic differential equation arises, for example, as the Smoluchowski–Kramers approximation to the Langevin equation for the motion of a chemically bound particle [23, 4, 17]. In that case, the function Ψ describes the chemical bonding forces, and the term $\sqrt{2\beta^{-1}}\,dW(t)$ represents white noise forces resulting from molecular collisions [23]. The solution $\rho(t,x)$ of the Fokker–Planck equation (2) furnishes the probability density at time t for finding the particle at position x.

If the potential Ψ satisfies appropriate growth conditions, then there is a unique stationary solution $\rho_s(x)$ of the Fokker–Planck equation, and it takes the form of the Gibbs distribution [7, 22]

$$\rho_s(x) = Z^{-1}\exp(-\beta\Psi(x)), \tag{4}$$

where the partition function Z is given by the expression

$$Z = \int_{\mathbb{R}^n} \exp(-\beta\Psi(x))\,dx.$$

Note that, in order for equation (4) to make sense, Ψ must grow rapidly enough to ensure that Z is finite. The probability measure $\rho_s(x)\,dx$, when it exists, is the unique

invariant measure for the Markov process $X(t)$ defined by the stochastic differential equation (3).

It is readily verified (see, for example, [12]) that the Gibbs distribution ρ_s satisfies a variational principle—it minimizes over all probability densities on $\mathbb{R}^n$ the free energy functional

$$F(\rho) = E(\rho) + \beta^{-1} S(\rho), \tag{5}$$

where

$$E(\rho) := \int_{\mathbb{R}^n} \Psi \rho \, dx \tag{6}$$

plays the role of an energy functional, and

$$S(\rho) := \int_{\mathbb{R}^n} \rho \log \rho \, dx \tag{7}$$

is the negative of the Gibbs–Boltzmann entropy functional.

Even when the Gibbs measure is not defined, the free energy (5) of a density $\rho(t, x)$ satisfying the Fokker–Planck equation (2) may be defined, provided that $F(\rho^0)$ is finite. This free energy functional then serves as a Lyapunov function for the Fokker–Planck equation: if $\rho(t, x)$ satisfies (2), then $F(\rho(t, x))$ can only decrease with time [22, 14]. Thus, the free energy functional is an H-function for the dynamics. The developments that follow will enable us to regard the Fokker–Planck dynamics as a gradient flux, or a steepest descent, of the free energy with respect to a particular metric on an appropriate class of probability measures. The requisite metric is the Wasserstein metric on the set of probability measures having finite second moments. We now proceed to define this metric.

3. The Wasserstein metric. The Wasserstein distance of order two, $d(\mu_1, \mu_2)$, between two (Borel) probability measures μ_1 and μ_2 on $\mathbb{R}^n$ is defined by the formula

$$d(\mu_1, \mu_2)^2 = \inf_{p \in \mathcal{P}(\mu_1, \mu_2)} \int_{R^n \times R^n} |x - y|^2 \, p(dxdy), \tag{8}$$

where $\mathcal{P}(\mu_1, \mu_2)$ is the set of all probability measures on $\mathbb{R}^n \times \mathbb{R}^n$ with first marginal μ_1 and second marginal μ_2, and the symbol $|\cdot|$ denotes the usual Euclidean norm on $\mathbb{R}^n$. More precisely, a probability measure p is in $\mathcal{P}(\mu_1, \mu_2)$ if and only if for each Borel subset $A \subset \mathbb{R}^n$ there holds

$$p(A \times \mathbb{R}^n) = \mu_1(A), \;\; p(\mathbb{R}^n \times A) = \mu_2(A).$$

Wasserstein distances of order q with q different from 2 may be analogously defined [10]. Since no confusion should arise in doing so, we shall refer to d in what follows as simply the Wasserstein distance.

It is well known that d defines a metric on the set of probability measures μ on R^n having finite second moments: $\int_{\mathbb{R}^n} |x|^2 \mu(dx) < \infty$ [10, 21]. In particular, d satisfies the triangle inequality on this set. That is, if μ_1, μ_2, and μ_3 are probability measures on $\mathbb{R}^n$ with finite second moments, then

$$d(\mu_1, \mu_3) \leq d(\mu_1, \mu_2) + d(\mu_2, \mu_3)\,. \tag{9}$$

We shall make use of this property at several points later on.

We note that the Wasserstein metric may be equivalently defined by [21]

$$d(\mu_1, \mu_2)^2 = \inf \mathbf{E}|X - Y|^2 \,, \tag{10}$$

where $\mathbf{E}(U)$ denotes the expectation of the random variable U, and the infimum is taken over all random variables X and Y such that X has distribution μ_1 and Y has distribution μ_2. In other words, the infimum is over all possible couplings of the random variables X and Y. Convergence in the metric d is equivalent to the usual weak convergence plus convergence of second moments. This latter assertion may be demonstrated by appealing to the representation (10) and applying the well-known Skorohod theorem from probability theory (see Theorem 29.6 of [1]). We omit the details.

The variational problem (8) is an example of a Monge–Kantorovich mass transference problem with the particular cost function $c(x, y) = |x-y|^2$ [21]. In that context, an infimizer $p^* \in \mathcal{P}(\mu_1, \mu_2)$ is referred to as an optimal transference plan. When μ_1 and μ_2 have finite second moments, the existence of such a p^* for (8) is readily verified by a simple adaptation of our arguments in section 4. For a probabilistic proof that the infimum in (8) is attained when μ_1 and μ_2 have finite second moments, see [10]. Brenier [2] has established the existence of a *one-to-one* optimal transference plan in the case that the measures μ_1 and μ_2 have bounded support and are absolutely continuous with respect to Lebesgue measure. Caffarelli [3] and Gangbo and McCann [8, 9] have recently extended Brenier's results to more general cost functions c and to cases in which the measures do not have bounded support.

If the measures μ_1 and μ_2 are absolutely continuous with respect to the Lebesgue measure, with densities ρ_1 and ρ_2, respectively, we will write $\mathcal{P}(\rho_1, \rho_2)$ for the set of probability measures having first marginal μ_1 and second marginal μ_2. Correspondingly, we will denote by $d(\rho_1, \rho_2)$ the Wasserstein distance between μ_1 and μ_2. This is the situation that we will be concerned with in what follows.

4. The discrete scheme. We shall now construct a time-discrete scheme that is designed to converge in an appropriate sense (to be made precise in the next section) to a solution of the Fokker–Planck equation. The scheme that we shall describe was motivated by a similar scheme developed by Otto in an investigation of pattern formation in magnetic fluids [19]. We shall make the following assumptions concerning the potential Ψ introduced in section 2:

$$\Psi \in C^\infty(\mathbb{R}^n);$$

$$\Psi(x) \;\geq\; 0 \;\text{ for all } x \in \mathbb{R}^n \,; \tag{11}$$

$$|\nabla \Psi(x)| \;\leq\; C\,(\Psi(x) + 1) \;\text{ for all } x \in \mathbb{R}^n \tag{12}$$

for some constant $C < \infty$. Notice that our assumptions on Ψ allow for cases in which $\int_{R^n} \exp(-\beta\Psi)\, dx$ is not defined, so the stationary density ρ_s given by (4) does not exist. These assumptions allow us to treat a wide class of Fokker–Planck equations. In particular, the classical diffusion equation $\frac{\partial \rho}{\partial t} = \beta^{-1}\Delta\rho$, for which $\Psi \equiv$ const., falls into this category. We also introduce the set K of admissible probability densities:

$$K \;:=\; \left\{ \rho \colon \mathbb{R}^n \to [0, \infty) \text{ measurable} \;\middle|\; \int_{\mathbb{R}^n} \rho(x)\, dx = 1 \,, M(\rho) < \infty \right\} ,$$

where

$$M(\rho) = \int_{\mathbb{R}^n} |x|^2\, \rho(x)\, dx \,.$$

With these conventions in hand, we now formulate the iterative discrete scheme:

$$\left.\begin{array}{l} \text{Determine } \rho^{(k)} \text{ that minimizes} \\ \frac{1}{2}\, d(\rho^{(k-1)}, \rho)^2 \;+\; h\, F(\rho) \\ \text{over all } \;\rho \in K\,. \end{array}\right\} \tag{13}$$

Here we use the notation $\rho^{(0)} = \rho^0$. The scheme (13) is the obvious generalization of the scheme (1) set forth in the Introduction for the diffusion equation. We shall now establish existence and uniqueness of the solution to (13).

PROPOSITION 4.1. *Given $\rho^0 \in K$, there exists a unique solution of the scheme (13).*

Proof. Let us first demonstrate that S is well defined as a functional on K with values in $(-\infty, +\infty]$ and that, in addition, there exist $\alpha < 1$ and $C < \infty$ depending only on n such that

$$S(\rho) \;\geq\; -C\,(M(\rho)+1)^{\alpha} \quad \text{for all } \rho \in K\,. \tag{14}$$

Actually, we shall show that (14) is valid for any $\alpha \in (\frac{n}{n+2}, 1)$. For future reference, we prove a somewhat finer estimate. Namely, we demonstrate that there exists a $C < \infty$, depending only on n and α, such that for all $R \geq 0$, and for each $\rho \in K$, there holds

$$\int_{R^n - B_R} |\min\{\rho \log \rho, 0\}|\, dx \;\leq\; C \left(\frac{1}{R^2+1}\right)^{\frac{(2+n)\,\alpha - n}{2}} (M(\rho)+1)^{\alpha}\,, \tag{15}$$

where B_R denotes the ball of radius R centered at the origin in $\mathbb{R}^n$. Indeed, for $\alpha < 1$ there holds

$$|\min\{z \log z, 0\}| \;\leq\; C\, z^{\alpha} \quad \text{for all } z \geq 0.$$

Hence by Hölder's inequality, we obtain

$$\begin{aligned} &\int_{R^n - B_R} |\min\{\rho \log \rho, 0\}|\, dx \\ &\leq C \int_{R^n - B_R} \rho^{\alpha}\, dx \\ &\leq C \left(\int_{R^n - B_R} \left(\frac{1}{|x|^2+1}\right)^{\frac{\alpha}{1-\alpha}}\, dx \right)^{1-\alpha} (M(\rho)+1)^{\alpha}\,. \end{aligned}$$

On the other hand, for $\frac{\alpha}{1-\alpha} > \frac{n}{2}$, we have

$$\int_{R^n - B_R} \left(\frac{1}{|x|^2+1}\right)^{\frac{\alpha}{1-\alpha}}\, dx \;\leq\; C \left(\frac{1}{R^2+1}\right)^{\frac{\alpha}{1-\alpha} - \frac{n}{2}}\,.$$

Let us now prove that for given $\rho^{(k-1)} \in K$, there exists a minimizer $\rho \in K$ of the functional

$$K \ni \rho \mapsto \tfrac{1}{2}\, d(\rho^{(k-1)}, \rho)^2 \;+\; h\, F(\rho)\,. \tag{16}$$

Observe that S is not bounded below on K and hence F is not bounded below on K either. Nevertheless, using the inequality

$$M(\rho_1) \;\le\; 2\,M(\rho_0) \,+ 2\,d(\rho_0,\rho_1)^2 \quad \text{for all } \rho_0,\rho_1 \in K \tag{17}$$

(which immediately follows from the inequality $|y|^2 \le 2|x|^2 + 2|x-y|^2$ and from the definition of d) together with (14) we obtain

$$\begin{aligned} &\tfrac{1}{2}\,d(\rho^{(k-1)},\rho)^2 \;+\; h\,F(\rho) \\ &\overset{(17)}{\ge}\; \tfrac{1}{4}\,M(\rho) \;-\; \tfrac{1}{2}\,M(\rho^{(k-1)}) \;+\; h\,S(\rho) \\ &\overset{(14)}{\ge}\; \tfrac{1}{4}\,M(\rho) \;-\; C\,(M(\rho)+1)^{\alpha} \;-\; \tfrac{1}{2}\,M(\rho^{(k-1)}) \quad \text{for all } \rho \in K\,, \end{aligned} \tag{18}$$

which ensures that (16) is bounded below. Now, let $\{\rho_\nu\}$ be a minimizing sequence for (16). Obviously, we have that

$$\{S(\rho_\nu)\}_\nu \quad \text{is bounded above}\,, \tag{19}$$

and according to (18),

$$\{M(\rho_\nu)\}_\nu \quad \text{is bounded}\,. \tag{20}$$

The latter result, together with (15), implies that

$$\left\{ \int_{\mathbb{R}^n} |\min\{\rho_\nu \,\log \rho_\nu, 0\}|\; dx \right\}_\nu \quad \text{is bounded}\,,$$

which combined with (19) yields that

$$\left\{ \int_{\mathbb{R}^n} \max\{\rho_\nu \,\log \rho_\nu, 0\}\; dx \right\}_\nu \quad \text{is bounded}\,.$$

As $z \mapsto \max\{z\log z, 0\}, z \in [0,\infty)$, has superlinear growth, this result, in conjunction with (20), guarantees the existence of a $\rho^{(k)} \in K$ such that (at least for a subsequence)

$$\rho_\nu \overset{w}{\rightharpoonup} \rho^{(k)} \quad \text{in } L^1(\mathbb{R}^n)\,. \tag{21}$$

Let us now show that

$$S(\rho^{(k)}) \;\le\; \liminf_{\nu\uparrow\infty} S(\rho_\nu)\,. \tag{22}$$

As $[0,\infty) \ni z \mapsto z\log z$ is convex and $[0,\infty) \ni z \mapsto \max\{z\log z, 0\}$ is convex and nonnegative, (21) implies that for any $R < \infty$,

$$\int_{B_R} \rho^{(k)} \,\log \rho^{(k)}\; dx \;\le\; \liminf_{\nu\uparrow\infty} \int_{B_R} \rho_\nu \,\log \rho_\nu \; dx\,, \tag{23}$$

$$\int_{\mathbb{R}^n - B_R} \max\{\rho^{(k)} \log \rho^{(k)}, 0\}\, dx \;\le\; \liminf_{\nu\uparrow\infty} \int_{\mathbb{R}^n - B_R} \max\{\rho_\nu \log \rho_\nu, 0\}\, dx. \tag{24}$$

On the other hand we have according to (15) and (20)

$$\limsup_{R\uparrow\infty} \sup_{\nu\in\mathbb{N}} \int_{\mathbb{R}^n - B_R} |\min\{\rho_\nu \,\log \rho_\nu, 0\}|\; dx \;=\; 0\,. \tag{25}$$

Now observe that for any $R < \infty$, there holds

$$S(\rho^{(k)}) \;\le\; \int_{B_R} \rho^{(k)}\,\log\rho^{(k)}\;dx \;+\; \int_{R^n - B_R} \max\{\rho^{(k)}\,\log\rho^{(k)}, 0\}\;dx\,,$$

which together with (23), (24), and (25) yields (22).

It remains for us to show that

$$E(\rho^{(k)}) \le \liminf_{\nu\uparrow\infty} E(\rho_\nu)\,, \tag{26}$$

$$d(\rho^{(k-1)}, \rho^{(k)})^2 \le \liminf_{\nu\uparrow\infty} d(\rho^{(k-1)}, \rho_\nu)^2\,. \tag{27}$$

Equation (26) follows immediately from (21) and Fatou's lemma. As for (27), we choose $p_\nu \in \mathcal{P}(\rho^{(k-1)}, \rho_\nu)$ satisfying

$$\int_{R^n\times R^n} |x-y|^2\,p_\nu(dx\,dy) \;\le\; d(\rho^{(k-1)}, \rho_\nu)^2 \;+\; \tfrac{1}{\nu}.$$

By (20) the sequence of probability measures $\{\rho_\nu\,dx\}_{\nu\uparrow\infty}$ is tight, or relatively compact with respect to the usual weak convergence in the space of probability measures on $\mathbb{R}^n$ (i.e., convergence tested against bounded continuous functions) [1]. This, together with the fact that the density $\rho^{(k-1)}$ has finite second moment, guarantees that the sequence $\{p_\nu\}_{\nu\uparrow\infty}$ of probability measures on $\mathbb{R}^n\times\mathbb{R}^n$ is tight. Hence, there is a subsequence of $\{p_\nu\}_{\nu\uparrow\infty}$ that converges weakly to some probability measure p. From (21) we deduce that $p \in \mathcal{P}(\rho^{(k-1)}, \rho^{(k)})$. We now could invoke the Skorohod theorem [1] and Fatou's lemma to infer (27) from this weak convergence, but we prefer here to give a more analytic proof. For $R < \infty$ let us select a continuous function $\eta_R\colon \mathbb{R}^n \to [0,1]$ such that

$$\eta_R \;=\; 1 \;\text{ inside of } B_R \quad\text{and}\quad \eta_R \;=\; 0 \;\text{ outside of } B_{2R}\,.$$

We then have

$$\left.\begin{aligned} &\int_{R^n\times R^n} \eta_R(x)\,\eta_R(y)\,|x-y|^2\,p(dx\,dy) \\ &\quad= \lim_{\nu\uparrow\infty} \int_{R^n\times R^n} \eta_R(x)\,\eta_R(y)\,|x-y|^2\,p_\nu(dx\,dy) \\ &\quad\le \liminf_{\nu\uparrow\infty} d(\rho^{(k-1)}, \rho_\nu)^2 \end{aligned}\right\} \tag{28}$$

for each fixed $R < \infty$. On the other hand, using the monotone convergence theorem, we deduce that

$$\begin{aligned} d(\rho^{(k-1)}, \rho^{(k)})^2 &\le \int_{R^n\times R^n} |x-y|^2\,p(dx\,dy) \\ &= \lim_{R\uparrow\infty} \int_{R^n\times R^n} \eta_R(x)\,\eta_R(y)\,|x-y|^2\,p(dx\,dy)\,, \end{aligned}$$

which combined with (28) yields (27).

To conclude the proof of the proposition we establish that the functional (16) has at most one minimizer. This follows from the convexity of K and the strict convexity of (16). The strict convexity of (16) follows from the strict convexity of S, the linearity of E, and the (obvious) convexity over K of the functional $\rho \mapsto d(\rho^{(k-1)}, \rho)^2$. □

Remark. One of the referees has communicated to us the following simple estimate that could be used in place of (14)–(15) in the previous and subsequent analysis: for any $\Omega \subset \mathbb{R}^n$ (in particular, for $\Omega = \mathbb{R}^n - B_R$) and for all $\rho \in K$ there holds

$$\int_\Omega |\min\{\rho \log \rho, 0\}|\, dx \le C \int_\Omega \mathrm{e}^{-\frac{|x|}{2}}\, dx + \epsilon M(\rho) + \frac{1}{4\epsilon} \int_\Omega \rho\, dx \tag{29}$$

for any $\epsilon > 0$. To obtain the inequality (29), select $C > 0$ such that for all $z \in [0,1]$, we have $z|\log z| \le C\sqrt{z}$. Then, defining the sets $\Omega_0 = \Omega \cap \{\rho \le \exp(-|x|)\}$ and $\Omega_1 = \Omega \cap \{\exp(-|x|) < \rho \le 1\}$, we have

$$\begin{aligned}\int_\Omega |\min\{\rho \log \rho, 0\}|\, dx &= \int_{\Omega_0} \rho |(\log \rho)_-|\, dx + \int_{\Omega_1} \rho |(\log \rho)_-|\, dx \\ &\le C \int_\Omega \mathrm{e}^{-\frac{|x|}{2}}\, dx + \int_\Omega |x| \rho\, dx\,.\end{aligned}$$

The desired result (29) then follows from the inequality $|x| \le \epsilon |x|^2 + 1/(4\epsilon)$ for $\epsilon > 0$.

5. Convergence to the solution of the Fokker–Planck equation. We come now to our main result. We shall demonstrate that an appropriate interpolation of the solution to the scheme (13) converges to the unique solution of the Fokker–Planck equation. Specifically, the convergence result that we will prove here is as follows.

THEOREM 5.1. *Let $\rho^0 \in K$ satisfy $F(\rho^0) < \infty$, and for given $h > 0$, let $\{\rho_h^{(k)}\}_{k \in \mathbb{N}}$ be the solution of* (13)*. Define the interpolation $\rho_h \colon (0,\infty) \times \mathbb{R}^n \to [0,\infty)$ by*

$$\rho_h(t) \;=\; \rho_h^{(k)} \quad \textit{for } t \in [k\,h, (k+1)\,h) \;\; \textit{and } \; k \in \mathbb{N} \cup \{0\}.$$

Then as $h \downarrow 0$,

$$\rho_h(t) \;\rightharpoonup\; \rho(t) \quad \textit{weakly in } L^1(\mathbb{R}^n) \quad \textit{for all } \; t \in (0,\infty)\,, \tag{30}$$

where $\rho \in C^\infty((0,\infty) \times \mathbb{R}^n)$ is the unique solution of

$$\frac{\partial \rho}{\partial t} \;=\; \mathrm{div}(\rho \nabla \Psi) \;+\; \beta^{-1} \Delta \rho\,, \tag{31}$$

with initial condition

$$\rho(t) \;\to\; \rho^0 \quad \textit{strongly in } \; L^1(\mathbb{R}^n) \quad \textit{for} \quad t \downarrow 0 \tag{32}$$

and

$$M(\rho),\, E(\rho) \;\in\; L^\infty((0,T)) \quad \textit{for all } \; T < \infty\,. \tag{33}$$

Remark. A finer analysis reveals that

$$\rho_h \;\to\; \rho \quad \textit{strongly in } L^1((0,T) \times \mathbb{R}^n) \quad \textit{for all } \; T < \infty\,.$$

Proof. The proof basically follows along the lines of [19, Proposition 2, Theorem 3]. The crucial step is to recognize that the first variation of (16) with respect to the independent variables indeed yields a time-discrete scheme for (31), as will now be demonstrated. For notational convenience only, we shall set $\beta \equiv 1$ from here on in. As will be evident from the ensuing arguments, our proof works for any positive β. In

fact, it is not difficult to see that, with appropriate modifications to the scheme (13), we can establish an analogous convergence result for time-dependent β.

Let a smooth vector field with bounded support, $\xi \in C_0^\infty(\mathbb{R}^n, \mathbb{R}^n)$, be given, and define the corresponding *flux* $\{\Phi_\tau\}_{\tau \in R}$ by

$$\partial_\tau \, \Phi_\tau \;=\; \xi \circ \Phi_\tau \;\text{ for all } \tau \in \mathbb{R} \quad \text{and} \quad \Phi_0 \;=\; \mathrm{id}\,.$$

For any $\tau \in \mathbb{R}$, let the measure $\rho_\tau(y)\,dy$ be the *push forward* of $\rho^{(k)}(y)\,dy$ under Φ_τ. This means that

$$\int_{R^n} \rho_\tau(y)\,\zeta(y)\,dy \;=\; \int_{R^n} \rho^{(k)}(y)\,\zeta(\Phi_\tau(y))\,dy \quad \text{for all } \zeta \in C_0^0(\mathbb{R}^n)\,. \tag{34}$$

As Φ_τ is invertible, (34) is equivalent to the following relation for the densities:

$$\det \nabla \Phi_\tau \; \rho_\tau \circ \Phi_\tau \;=\; \rho^{(k)}\,. \tag{35}$$

By (16), we have for each $\tau > 0$

$$\tfrac{1}{\tau} \, \Big(\Big(\tfrac{1}{2}\, d(\rho^{(k-1)}, \rho_\tau)^2 + h\, F(\rho_\tau) \Big) - \Big(\tfrac{1}{2}\, d(\rho^{(k-1)}, \rho^{(k)})^2 + h\, F(\rho^{(k)}) \Big) \Big) \;\geq\; 0, \tag{36}$$

which we now investigate in the limit $\tau \downarrow 0$. Because Ψ is nonnegative, equation (34) also holds for $\zeta = \Psi$, i.e.,

$$\int_{R^n} \rho_\tau(y)\,\Psi(y)\,dy \;=\; \int_{R^n} \rho^{(k)}(y)\,\Psi(\Phi_\tau(y))\,dy\,.$$

This yields

$$\tfrac{1}{\tau} \, \Big(E(\rho_\tau) - E(\rho^{(k)}) \Big) \;=\; \int_{R^n} \tfrac{1}{\tau} \, \big(\Psi(\Phi_\tau(y)) - \Psi(y) \big) \; \rho^{(k)}(y)\,dy\,.$$

Observe that the difference quotient under the integral converges uniformly to $\nabla\Psi(y)\cdot\xi(y)$, hence implying that

$$\tfrac{\mathrm{d}}{\mathrm{d}\,\tau} \, [E(\rho_\tau)]_{\tau=0} \;=\; \int_{R^n} \nabla\Psi(y)\cdot\xi(y)\,\rho^{(k)}(y)\,dy\,. \tag{37}$$

Next, we calculate $\frac{\mathrm{d}}{\mathrm{d}\,\tau} \, [S(\rho_\tau)]_{\tau=0}$. Invoking an appropriate approximation argument (for instance approximating log by some function that is bounded below), we obtain

$$\begin{aligned}
&\int_{R^n} \rho_\tau(y) \, \log(\rho_\tau(y))\,dy \\
&\overset{(34)}{=} \int_{R^n} \rho^{(k)}(y) \, \log(\rho_\tau(\Phi_\tau(y)))\,dy \\
&\overset{(35)}{=} \int_{R^n} \rho^{(k)}(y) \, \log\left(\frac{\rho^{(k)}(y)}{\det\nabla\Phi_\tau(y)} \right) \, dy\,.
\end{aligned}$$

Therefore, we have

$$\tfrac{1}{\tau} \, \Big(S(\rho_\tau) - S(\rho^{(k)}) \Big) \;=\; -\int_{R^n} \rho^{(k)}(y) \, \tfrac{1}{\tau} \, \log(\det \nabla\Phi_\tau(y))\,dy\,.$$

Now using

$$\tfrac{\mathrm{d}}{\mathrm{d}\tau}[\det\nabla\Phi_\tau(y)]_{\tau=0} \;=\; \mathrm{div}\xi(y)\,,$$

together with the fact that $\Phi_0 = \mathrm{id}$, we see that the difference quotient under the integral converges uniformly to $\mathrm{div}\xi$, hence implying that

$$\tfrac{\mathrm{d}}{\mathrm{d}\,\tau}\;[S(\rho_\tau)]_{\tau=0} \;=\; -\int_{\mathbb{R}^n}\rho^{(k)}\,\mathrm{div}\xi\;dy\,. \tag{38}$$

Now, let p be optimal in the definition of $d(\rho^{(k-1)},\rho^{(k)})^2$ (see section 3). The formula

$$\int_{R^n\times R^n}\zeta(x,y)\,p_\tau(dx\,dy) = \int_{R^n\times R^n}\zeta(x,\Phi_\tau(y))\,p(dx\,dy)\;,\zeta\in C_0^0(\mathbb{R}^n\times\mathbb{R}^n)$$

then defines a $p_\tau\in\mathcal{P}(\rho^{(k-1)},\rho_\tau)$. Consequently, there holds

$$\begin{aligned}&\tfrac{1}{\tau}\;\Big(\tfrac12\,d(\rho^{(k-1)},\rho_\tau)^2\;-\;\tfrac12\,d(\rho^{(k-1)},\rho^{(k)})^2\Big)\\ &\leq\;\int_{R^n\times R^n}\tfrac{1}{\tau}\;\big(\tfrac12\,|\Phi_\tau(y)-x|^2\;-\tfrac12\,|y-x|^2\big)\;p(dx\,dy)\,,\end{aligned}$$

which implies that

$$\begin{aligned}&\limsup_{\tau\downarrow0}\,\tfrac{1}{\tau}\;\Big(\tfrac12\,d(\rho^{(k-1)},\rho_\tau)^2\;-\;\tfrac12\,d(\rho^{(k-1)},\rho^{(k)})^2\Big)\\ &\leq\;\int_{R^n\times R^n}(y-x)\cdot\xi(y)\,p(dx\,dy)\,.\end{aligned} \tag{39}$$

We now infer from (36), (37), (38), and (39) (and the symmetry in $\xi\to-\xi$) that

$$\left.\begin{aligned}&\int_{R^n\times R^n}(y-x)\cdot\xi(y)\,p(dx\,dy)\;+\;h\int_{R^n}\left(\nabla\Psi\cdot\xi-\mathrm{div}\xi\right)\,\rho^{(k)}\,dy\;=\;0\\ &\text{for all }\xi\in C_0^\infty(\mathbb{R}^n,\mathbb{R}^n)\,.\end{aligned}\right\} \tag{40}$$

Observe that because $p\in\mathcal{P}(\rho^{(k-1)},\rho^{(k)})$, there holds

$$\begin{aligned}&\left|\int_{R^n}(\rho^{(k)}-\rho^{(k-1)})\,\zeta\;dy\;-\;\int_{R^n\times R^n}(y-x)\cdot\nabla\zeta(y)\,p(dx\,dy)\right|\\ &=\;\left|\int_{R^n\times R^n}(\zeta(y)-\zeta(x)\;+\;(x-y)\cdot\nabla\zeta(y))\,p(dx\,dy)\right|\\ &\leq\;\tfrac12\,\sup_{R^n}|\nabla^2\zeta|\,\int_{R^n\times R^n}|y-x|^2\,p(dx\,dy)\\ &=\;\tfrac12\,\sup_{R^n}|\nabla^2\zeta|\,d(\rho^{(k-1)},\rho^{(k)})^2\end{aligned}$$

for all $\zeta\in C_0^\infty(\mathbb{R}^n)$. Choosing $\xi=\nabla\zeta$ in (40) then gives

$$\begin{aligned}&\left|\int_{R^n}\left\{\tfrac{1}{h}\,(\rho^{(k)}-\rho^{(k-1)})\,\zeta+(\nabla\Psi\cdot\nabla\zeta-\Delta\zeta)\;\rho^{(k)}\right\}\,dy\right|\\ &\qquad\leq\tfrac12\sup_{R^n}|\nabla^2\zeta|\;\tfrac{1}{h}\,d(\rho^{(k-1)},\rho^{(k)})^2\;\text{ for all }\;\zeta\in C_0^\infty(\mathbb{R}^n)\,.\end{aligned} \tag{41}$$

We wish now to pass to the limit $h \downarrow 0$. In order to do so we will first establish the following a priori estimates: for any $T < \infty$, there exists a constant $C < \infty$ such that for all $N \in \mathbb{N}$ and all $h \in [0,1]$ with $N\,h \le T$, there holds

$$M(\rho_h^{(N)}) \le C\,, \tag{42}$$

$$\int_{R^n} \max\{\rho_h^{(N)}\,\log\rho_h^{(N)}, 0\}\,dx \le C\,, \tag{43}$$

$$E(\rho_h^{(N)}) \le C\,, \tag{44}$$

$$\sum_{k=1}^{N} d(\rho_h^{(k-1)}, \rho_h^{(k)})^2 \le C\,h\,. \tag{45}$$

Let us verify that the estimate (42) holds. Since $\rho_h^{(k-1)}$ is admissible in the variational principle (13), we have that

$$\tfrac{1}{2}\,d(\rho_h^{(k-1)}, \rho_h^{(k)})^2 \;+\; h\,F(\rho_h^{(k)}) \;\le\; h\,F(\rho_h^{(k-1)})\,,$$

which may be summed over k to give

$$\sum_{k=1}^{N} \tfrac{1}{2\,h}\,d(\rho_h^{(k-1)}, \rho_h^{(k)})^2 \;+\; F(\rho_h^{(N)}) \;\le\; F(\rho^0)\,. \tag{46}$$

As in Proposition 4.1, we must confront the technical difficulty that F is not bounded below. The inequality (42) is established via the following calculations:

$$\begin{aligned}
M(\rho_h^{(N)}) &\overset{(17)}{\le} 2\,d(\rho^0, \rho_h^{(N)})^2 \;+\; 2\,M(\rho^0) \\
&\le\; 2\,N \sum_{k=1}^{N} d(\rho_h^{(k-1)}, \rho_h^{(k)})^2 \;+\; 2\,M(\rho^0) \\
&\overset{(46)}{\le} 4\,h\,N\,\Big(F(\rho^0) - F(\rho_h^{(N)})\Big) \;+\; 2\,M(\rho^0) \\
&\overset{(14)}{\le} 4\,T\,\Big(F(\rho^0) + C\,(M(\rho_h^{(N)}) + 1)^\alpha\Big) \;+\; 2\,M(\rho^0)\,,
\end{aligned}$$

which clearly gives (42). To obtain the second line of the above display, we have made use of the triangle inequality for the Wasserstein metric (see equation (9)) and the Cauchy–Schwarz inequality. The estimates (43), (44), and (45) now follow readily from the bounds (14) and (15), the estimate (42), and the inequality (46), as follows:

$$\begin{aligned}
\int_{R^n} \max\{\rho_h^{(N)}\,\log\rho_h^{(N)}, 0\}\,dx \;&\le\; S(\rho_h^{(N)}) \;+\; \int_{R^n} |\min\{\rho_h^{(N)}\,\log\rho_h^{(N)}, 0\}|\,dx \\
&\overset{(15)}{\le} S(\rho_h^{(N)}) \;+\; C\,(M(\rho_h^{(N)}) + 1)^\alpha \\
&\le\; F(\rho_h^{(N)}) \;+\; C\,(M(\rho_h^{(N)}) + 1)^\alpha \\
&\overset{(46)}{\le} F(\rho^0) \;+\; C\,(M(\rho_h^{(N)}) + 1)^\alpha\,;
\end{aligned}$$

$$\begin{aligned}
E(\rho_h^{(N)}) \;&=\; F(\rho_h^{(N)}) \;-\; S(\rho_h^{(N)}) \\
&\overset{(14)}{\le} F(\rho_h^{(N)}) \;+\; C\,(M(\rho_h^{(N)}) + 1)^\alpha \\
&\overset{(46)}{\le} F(\rho^0) \;+\; C\,(M(\rho_h^{(N)}) + 1)^\alpha\,;
\end{aligned}$$

$$\sum_{k=1}^{N} d(\rho_h^{(k-1)}, \rho_h^{(k)})^2 \overset{(46)}{\leq} 2\,h\,\Big(F(\rho^0)\;-\;F(\rho_h^{(N)})\Big)$$
$$\overset{(14)}{\leq} 2\,h\,\Big(F(\rho^0)\;+\;C\,(M(\rho_h^{(N)})+1)^{\alpha}\Big)\,.$$

Now, owing to the estimates (42) and (43), we may conclude that there exists a measurable $\rho(t,x)$ such that, after extraction of a subsequence,

$$\rho_h \;\rightharpoonup\; \rho \quad \text{weakly in } L^1((0,T)\times\mathbb{R}^n) \quad \text{for all } T<\infty\,. \tag{47}$$

A straightforward analysis reveals that (42), (43), and (44) guarantee that

$$\begin{aligned} &\rho(t)\in K \quad \text{for a.e. } t\in(0,\infty)\,,\\ &M(\rho),\,E(\rho)\in L^\infty((0,T)) \quad \text{for all } T<\infty\,. \end{aligned} \tag{48}$$

Let us now improve upon the convergence in (47) by showing that (30) holds. For a given finite time horizon $T<\infty$, there exists a constant $C<\infty$ such that for all $N,N'\in\mathbb{N}$ and all $h\in[0,1]$ with $N\,h\leq T$, and $N'\,h\leq T$, we have

$$d(\rho_h^{(N')},\rho_h^{(N)})^2 \;\leq\; C\,|N'\,h-N\,h|\,.$$

This result is obtained from (45) by use of the triangle inequality (9) for d and the Cauchy–Schwarz inequality. Furthermore, for all $\rho,\rho'\in K\,, p\in\mathcal{P}(\rho,\rho')$, and $\zeta\in C_0^\infty(\mathbb{R}^n)$, there holds

$$\begin{aligned} \left|\int_{R^n}\zeta\,\rho'\,dx\;-\;\int_{R^n}\zeta\,\rho\,dx\right| &= \left|\int_{R^n\times R^n}(\zeta(x)\;-\;\zeta(y))\,p(dx\,dy)\right|\\ &\leq \sup_{R^n}|\nabla\zeta|\int_{R^n\times R^n}|x-y|\,p(dx\,dy)\\ &\leq \sup_{R^n}|\nabla\zeta|\left(\int_{R^n\times R^n}|x-y|^2\,p(dx\,dy)\right)^{\frac12}\,, \end{aligned}$$

so from the definition of d we obtain

$$\left|\int_{R^n}\zeta\,\rho'\,dx\;-\;\int_{R^n}\zeta\,\rho\,dx\right| \;\leq\; \sup_{R^n}|\nabla\zeta|\,d(\rho,\rho') \;\text{ for } \rho,\rho'\in K \text{ and } \zeta\in C_0^\infty(\mathbb{R}^n)\,.$$

Hence, it follows that

$$\left.\begin{aligned} &\left|\int_{R^n}\zeta\,\rho_h(t')\,dx\;-\;\int_{R^n}\zeta\,\rho_h(t)\,dx\right| \;\leq\; C\sup_{R^n}|\nabla\zeta|\;(|t'-t|+h)^{\frac12}\\ &\text{for all } t,t'\in(0,T),\text{ and } \zeta\in C_0^\infty(\mathbb{R}^n)\,. \end{aligned}\right\} \tag{49}$$

Let $t\in(0,T)$ and $\zeta\in C_0^\infty(\mathbb{R}^n)$ be given, and notice that for any $\delta>0$, we have

$$\begin{aligned} &\left|\int_{R^n}\zeta\,\rho_h(t)\,dx\;-\;\int_{R^n}\zeta\,\rho(t)\,dx\right|\\ &\leq\;\left|\int_{R^n}\zeta\,\rho_h(t)\,dx\;-\;\tfrac{1}{2\,\delta}\int_{t-\delta}^{t+\delta}\int_{R^n}\zeta\,\rho_h(\tau)\,dx\,d\tau\right|\\ &+\;\left|\tfrac{1}{2\,\delta}\int_{t-\delta}^{t+\delta}\int_{R^n}\zeta\,\rho_h(\tau)\,dx\,d\tau\;-\;\tfrac{1}{2\,\delta}\int_{t-\delta}^{t+\delta}\int_{R^n}\zeta\,\rho(\tau)\,dx\,d\tau\right|\\ &+\;\left|\tfrac{1}{2\,\delta}\int_{t-\delta}^{t+\delta}\int_{R^n}\zeta\,\rho(\tau)\,dx\,d\tau\;-\;\int_{R^n}\zeta\,\rho(t)\,dx\right|\,. \end{aligned}$$

According to (49), the first term on the right-hand side of this equation is bounded by

$$C \sup_{R^n} |\nabla\zeta| \, (\delta + h)^{\frac{1}{2}} \, ,$$

and owing to (47), the second term converges to zero as $h \downarrow 0$ for any fixed $\delta > 0$. At this point, let us remark that from the result (47) we may deduce that ρ is smooth on $(0,\infty)\times\mathbb{R}^n$. This is the conclusion of assertion (a) below, which will be proved later. From this smoothness property, we ascertain that the final term on the right-hand side of the above display converges to zero as $\delta \downarrow 0$. Therefore, we have established that

$$\int_{R^n} \zeta \, \rho_h(t) \, dx \; \to \; \int_{R^n} \zeta \, \rho(t) \, dx \quad \text{for all } \zeta \in C_0^\infty(\mathbb{R}^n) \, . \tag{50}$$

However, the estimate (42) guarantees that $M(\rho_h(t))$ is bounded for $h \downarrow 0$. Consequently, (50) holds for any $\zeta \in L^\infty(\mathbb{R}^n)$, and therefore, the convergence result (30) does indeed hold.

It now follows immediately from (41), (45), and (47) that ρ satisfies

$$\left.\begin{aligned} -\int_{(0,\infty)\times R^n} \rho \, (\partial_t\zeta - \nabla\Psi\cdot\nabla\zeta + \Delta\zeta) \; dx \, dt \; &= \; \int_{R^n} \rho^0 \, \zeta(0) \; dx \, , \\ \text{for all } \zeta \in C_0^\infty(\mathbb{R}\times\mathbb{R}^n) \, . & \end{aligned}\right\} \tag{51}$$

In addition, we know that ρ satisfies (33). We now show that

(a) any solution of (51) is smooth on $(0,\infty)\times\mathbb{R}^n$ and satisfies equation (31);
(b) any solution of (51) for which (33) holds satisfies the initial condition (32);
(c) there is at most one smooth solution of (31) which satisfies (32) and (33).

The corresponding arguments are, for the most part, fairly classical.

Let us sketch the proof of the regularity part (a). First observe that (51) implies

$$\begin{aligned} \int_{R^n} \rho(t_1) \, \zeta(t_1) \; dx - \int_{(t_0,t_1)\times R^n} \rho \, (\partial_t\zeta - \nabla\Psi\cdot\nabla\zeta + \Delta\zeta) \; dx \, dt \\ = \int_{R^n} \rho(t_0) \, \zeta(t_0) \; dx \end{aligned} \tag{52}$$

$$\text{for all } \; \zeta \in C_0^\infty(\mathbb{R}\times\mathbb{R}^n) \; \text{ and a.e. } \; 0 \le t_0 < t_1 \, .$$

We fix a function $\eta \in C_0^\infty(\mathbb{R}^n)$ to serve as a cutoff in the spatial variables. It then follows directly from (52) that for each $\zeta \in C_0^\infty(\mathbb{R}\times\mathbb{R}^n)$ and for almost every $0 \le t_0 < t_1$, there holds

$$\left.\begin{aligned} \int_{R^n} \eta \, \rho(t_1) \, \zeta(t_1) \, dx \; - \quad & \int_{(t_0,t_1)\times R^n} \eta \, \rho \, (\partial_t\zeta + \Delta\zeta) \; dx \, dt \\ = \; & \int_{(t_0,t_1)\times R^n} \rho \; (\Delta\eta - \nabla\Psi\cdot\nabla\eta) \; \zeta \, dx \, dt \\ + \; & \int_{(t_0,t_1)\times R^n} \rho \; (2\,\nabla\eta - \eta\nabla\Psi)\cdot\nabla\zeta \, dx \, dt \\ + \quad & \int_{R^n} \eta \, \rho(t_0) \, \zeta(t_0) \, dx \, . \end{aligned}\right\} \tag{53}$$

Notice that for fixed $(t_1, x_1) \in (0,\infty)\times\mathbb{R}^n$ and for each $\delta > 0$, the function

$$\zeta_\delta(t,x) \; = \; G(t_1 + \delta - t, x - x_1)$$

is an admissible test function in (53). Here G is the heat kernel

$$G(t,x) \;=\; t^{-\frac{n}{2}}\, g(t^{-\frac{1}{2}}x) \quad \text{with} \quad g(x) \;=\; (2\pi)^{-\frac{n}{2}} \exp(-\tfrac{1}{2}\,|x|^2). \tag{54}$$

Inserting ζ_δ into (53) and taking the limit $\delta \downarrow 0$, we obtain the equation

$$\left.\begin{aligned}(\rho\,\eta)(t_1) = &\int_{t_0}^{t_1} [\rho(t)\,(\Delta\eta - \nabla\Psi{\cdot}\nabla\eta)] * G(t_1-t)\,dt\\ +\;&\int_{t_0}^{t_1} [\rho(t)\,(2\,\nabla\eta - \eta\,\nabla\Psi)] * \nabla G(t_1-t)\,dt\\ &+ (\rho\,\eta)(t_0) * G(t_1-t_0) \quad \text{for a.e. } 0 \le t_0 < t_1\,,\end{aligned}\right\} \tag{55}$$

where $*$ denotes convolution in the x-variables. From (55), we extract the following estimate in the L^p-norm:

$$\begin{aligned}\|(\rho\,\eta)(t_1)\|_{L^p} = &\int_{t_0}^{t_1} \|\rho(t)\,(\Delta\eta - \nabla\Psi{\cdot}\nabla\eta)\|_{L^1}\, \|G(t_1-t)\|_{L^p}\,dt\\ +\;&\int_{t_0}^{t_1} \|\rho(t)\,(2\,\nabla\eta - \eta\,\nabla\Psi)\|_{L^1}\, \|\nabla G(t_1-t)\|_{L^p}\,dt\\ &+ \|(\rho\,\eta)(t_0)\|_{L^1}\, \|G(t_1-t_0)\|_{L^p} \quad \text{for a.e. } 0 \le t_0 < t_1\,.\end{aligned}$$

Now observe that

$$\begin{aligned}\|G(t)\|_{L^p} &= t^{(\frac{1}{p}-1)\,\frac{n}{2}}\, \|g\|_{L^p}\,,\\ \|\nabla G(t)\|_{L^p}, &= t^{\frac{1}{p}\,\frac{n}{2}-\frac{n+1}{2}}\, \|\nabla g\|_{L^p}\,,\end{aligned}$$

which leads to

$$\begin{aligned}&\|(\rho\,\eta)(t_1)\|_{L^p}\\ &= \operatorname*{ess\,sup}_{t\in(t_0,t_1)} \|\rho(t)\,(\Delta\eta - \nabla\Psi{\cdot}\nabla\eta)\|_{L^1} \int_0^{t_1-t_0} t^{(\frac{1}{p}-1)\,\frac{n}{2}}\, \|g\|_{L^p}\,dt\\ &+ \operatorname*{ess\,sup}_{t\in(t_0,t_1)} \|\rho(t)\,(2\,\nabla\eta - \eta\,\nabla\Psi)\|_{L^1} \int_0^{t_1-t_0} t^{\frac{1}{p}\,\frac{n}{2}-\frac{n+1}{2}}\, \|\nabla g\|_{L^p}\,dt\\ &+ \|(\rho\,\eta)(t_0)\|_{L^1}\, \|G(t_1-t_0)\|_{L^p} \quad \text{for a.e. } 0 \le t_0 < t_1\,.\end{aligned}$$

For $p < \frac{n}{n-1}$ the t-integrals are finite, from which we deduce that

$$\rho \;\in\; L^p_{\mathrm{loc}}((0,\infty){\times}\mathbb{R}^n)\,.$$

We now appeal to the L^p-estimates [18, section 3, (3.1), and (3.2)] for the potentials in (55) to conclude by the usual bootstrap arguments that any derivative of ρ is in $L^p_{\mathrm{loc}}((0,\infty){\times}\mathbb{R}^n)$, from which we obtain the stated regularity condition (a).

We now prove assertion (b). Using (55) with $t_0 = 0$, and proceeding as above, we obtain

$$\begin{aligned}&\|(\rho\,\eta)(t_1) \;-\; (\rho^0\,\eta) * G(t_1)\|_{L^1}\\ &= \operatorname*{ess\,sup}_{t\in(0,t_1)} \|\rho(t)\,(\Delta\eta - \nabla\Psi{\cdot}\nabla\eta)\|_{L^1} \int_0^{t_1} \|g\|_{L^1}\,dt\\ &+ \operatorname*{ess\,sup}_{t\in(0,t_1)} \|\rho(t)\,(2\,\nabla\eta - \eta\,\nabla\Psi)\|_{L^1} \int_0^{t_1} t^{-\frac{1}{2}}\, \|\nabla g\|_{L^1}\,dt \quad \text{for all } t_1 > 0\end{aligned}$$

and therefore,

$$(\rho\,\eta)(t) \;-\; (\rho^0\,\eta) * G(t) \;\to\; 0 \quad \text{in } L^1(\mathbb{R}^n) \quad \text{for } t \downarrow 0\,.$$

On the other hand, we have

$$(\rho^0\,\eta) * G(t) \;\to\; \rho^0\,\eta \quad \text{in } L^1(\mathbb{R}^n) \quad \text{for } t \downarrow 0\,,$$

which leads to

$$(\rho\,\eta)(t) \;\to\; \rho^0\,\eta \quad \text{in } L^1(\mathbb{R}^n) \quad \text{for } t \downarrow 0\,.$$

From this result, together with the boundedness of $\{M(\rho(t))\}_{t\downarrow 0}$, we infer that (32) is satisfied.

Finally, we prove the uniqueness result (c) using a well-known method from the theory of elliptic–parabolic equations (see, for instance, [20]). Let ρ_1, ρ_2 be solutions of (32) which are smooth on $(0,\infty)\times\mathbb{R}^n$ and satisfy (32), (33). Their difference ρ satisfies the equation

$$\frac{\partial \rho}{\partial t} \;-\; \operatorname{div}\left[\rho\,\nabla\Psi + \nabla\rho\right] \;=\; 0.$$

We multiply this equation for ρ by $\phi_\delta'(\rho)$, where the family $\{\phi_\delta\}_{\delta\downarrow 0}$ is a convex and smooth approximation to the modulus function. For example, we could take

$$\phi_\delta(z) \;=\; (z^2+\delta^2)^{\frac{1}{2}}\,.$$

This procedure yields the inequality

$$\begin{aligned}
&\partial_t[\phi_\delta(\rho)] \;-\; \operatorname{div}\left[\phi_\delta(\rho)\,\nabla\Psi + \nabla[\phi_\delta(\rho)]\right] \\
&= \;-\phi_\delta''(\rho)\,|\nabla\rho|^2 \;+\; \left(\phi_\delta'(\rho)\,\rho - \phi_\delta(\rho)\right)\,\Delta\Psi \\
&\le \;\left(\phi_\delta'(\rho)\,\rho - \phi_\delta(\rho)\right)\,\Delta\Psi,
\end{aligned}$$

which we then multiply by a nonnegative spatial cutoff function $\eta \in C_0^\infty(\mathbb{R}^n)$ and integrate over $\mathbb{R}^n$ to obtain

$$\begin{aligned}
\frac{d}{dt}\left[\int_{R^n} \phi_\delta(\rho(t))\,\eta\,dx\right] + \int_{R^n} \phi_\delta(\rho(t))\,\left(\nabla\Psi\cdot\nabla\eta - \Delta\eta\right)\,dx \\
\le \int_{R^n} \left(\phi_\delta'(\rho)\,\rho - \phi_\delta(\rho)\right)\,\Delta\Psi\,\eta\,dx\,.
\end{aligned}$$

Integrating over $(0,t)$ for given $t \in (0,\infty)$, we obtain with help of (32)

$$\begin{aligned}
\int_{R^n} \phi_\delta(\rho(t))\,\eta\,dx \;+ \int_{(0,t)\times R^n} \phi_\delta(\rho(t))\,\left(\nabla\Psi\cdot\nabla\eta - \Delta\eta\right)\,dx\,dt \\
\le \int_{(0,t)\times R^n} \left(\phi_\delta'(\rho)\,\rho - \phi_\delta(\rho)\right)\,\Delta\Psi\,\eta\,dx\,dt\,.
\end{aligned}$$

Letting δ tend to zero yields

$$\int_{R^n} |\rho(t)|\,\eta\,dx \;+ \int_{(0,t)\times R^n} |\rho(t)|\,\left(\nabla\Psi\cdot\nabla\eta - \Delta\eta\right)\,dx\,dt \;\le\; 0\,. \tag{56}$$

According to (12) and (33), ρ and $\rho\nabla\Psi$ are integrable on the entire $\mathbb{R}^n$. Hence, if we replace η in (56) by a function η_R satisfying

$$\eta_R(x) \;=\; \eta_1\left(\frac{x}{R}\right)\,, \quad \text{where } \eta_1(x) = 1 \text{ for } |x| \le 1\,,\;\; \eta_1(x) = 0 \text{ for } |x| \ge 2\,,$$

and let R tend to infinity, we obtain $\int_{R^n} |\rho(t)|\,dx = 0$. This produces the desired uniqueness result. □

STABILITY OF A RELAXATION MODEL WITH A NONCONVEX FLUX*

HAILIANG LIU†, JINGHUA WANG‡, AND TONG YANG§

Abstract. In this paper, we study the nonlinear stability of travelling wave solutions with shock profile for a relaxation model with a nonconvex flux, which is proposed by Jin and Xin [*Comm. Pure Appl. Math.*, 48 (1995), pp. 555–563] to approximate an original hyperbolic system numerically under the subcharacteristic condition introduced by T. P. Liu [*Comm. Math. Phys.*, 108 (1987), pp. 153–175]. The travelling wave solutions with strong shock profile are shown to be asymptotically stable under small disturbances with integral zero using an elementary but technical energy method. Proofs involve detailed study of the error equation for disturbances using the same weight function introduced in [*Comm. Math. Phys.*, 165 (1994), pp. 83–96].

Key words. relaxation model, stability, travelling wave

1. Introduction.

Relaxation occurs when the underlying material is in nonequilibrium and usually takes the form of hyperbolic conservation laws with source terms. Relaxation is often stiff when the relaxation rate is much shorter than the scales of other physical quantities.

The relaxation limit for nonlinear systems of the following form was first studied by Liu [4]:

$$\begin{cases} \partial_t u + \partial_x f(u,v) &= 0, \\ \partial_t v + \partial_x g(u,v) &= \frac{v_*(u)-v}{\tau(u)}, \end{cases} \tag{1.0}$$

provided that the travelling waves are weak and $f(u, v_*(u))$ is a convex function. And the subcharacteristic condition for stability was formulated in [4]. The dissipative entropy condition was formulated for general nonlinear relaxation systems later by Chen, Levermore, and Liu [1].

Recently, a class of relaxation models were proposed by Jin and Xin [10] to approximate the original conservation laws numerically. The special structure of these relaxation systems enables one to solve them numerically with underresolved stable discretization without using either Riemann solvers spatially or nonlinear systems of algebraic equations solvers temporally.

In this paper, we study the following relaxation model introduced in [10]:

$$\begin{cases} u_t + v_x = 0, \quad x \in R^1, \\ v_t + a u_x = -\frac{1}{\varepsilon}(v - f(u)), \end{cases} \tag{1.1}$$

with the initial data

$$(u,v)(x,0) = (u_0,v_0)(x) \to (u_\pm, v_\pm) \ \ as x \to \pm\infty, \quad v_\pm = f(u_\pm), \tag{1.2}$$

where a is a positive constant satisfying

$$-\sqrt{a} < f'(u) < \sqrt{a} \tag{1.3}$$

for all u under consideration. (1.3) is the *subcharacteristic condition* introduced by Liu [4]. We will show that the travelling wave solutions are stable as $\epsilon \to 0$.

In the relaxation limit, $\varepsilon \to 0^+$, the leading order of the relaxation system (1.1) is

$$\begin{aligned} v &= f(u), \\ u_t + f(u)_x &= 0. \end{aligned} \tag{1.4}$$

In fact, (1.1) was the prototype of the relaxation model introduced in [10] to solve (1.4) using a local relaxation approximation.

Using Chapman–Enskog expansion [4], the first-order approximation to (1.1) is

$$\begin{aligned} v &= f(u) - \varepsilon(a - f'(u)^2)u_x, \\ u_t + f(u)_x &= \varepsilon((a - f'(u)^2)u_x)_x. \end{aligned} \tag{1.5}$$

Since (1.5) is dissipative provided that condition (1.3) is satisfied, then similar to the diffusion, the relaxation term has smoothing and dissipative effects for the hyperbolic conservation laws. The stability of the viscous travelling waves with nonconvex flux was investigated by many authors, cf. [2], [5], [7], [8], etc. Using a weight function introduced in [7], we study the stability of strong travelling waves for the relaxation model (1.1) with a nonconvex flux. The behavior of solutions as $\varepsilon \to 0$ when subcharacteristic condition is violated was investigated by R. Leveque and J. Wang [3] under the assumption that the relaxation term is linear.

Under the scaling $(x,t) \to (\varepsilon x, \varepsilon t)$, equation (1.1) becomes

$$\begin{cases} u_t + v_x = 0, \quad x \in R^1, \\ v_t + a u_x = f(u) - v. \end{cases} \tag{1.6}$$

The behavior of the solution (u,v) of (1.1) and (1.2) at any fixed time t as $\varepsilon \to 0^+$ is equivalent to the long time behavior of (u,v) of (1.6) as $t \to \infty$.

In section 2, we will show that there exist travelling wave solutions with shock profile for (1.6), i.e.,

$$(u,v)(x,t) = (U,V)(x-st) \equiv (U,V)(z), \quad (U,V)(z) \to (u_\pm, v_\pm) \ \text{ as } \ z \to \pm\infty,$$

if the shock speed s lies between $-\sqrt{a}$ and $\sqrt{a}$ and (u_-, u_+) is an admissible shock of (1.4), that is, the constants $u_\pm$ and s (shock speed) satisfy the Rankine–Hugoniot condition

$$-s(u_+ - u_-) + f(u_+) - f(u_-) = 0 \tag{1.7}$$

and the entropy condition

$$Q(u) \equiv f(u) - f(u_\pm) - s(u - u_\pm) \begin{cases} < 0 & \text{for } \ u_+ < u < u_-, \\ > 0 & \text{for } \ u_- < u < u_+. \end{cases} \tag{1.8}$$

Note that the U component of a travelling wave solution of (1.6) is a travelling wave solution of the viscous conservation law

$$u_t + f(u)_x = \mu u_{xx} \tag{1.9}$$

with $\mu = a - s^2$. This also gives another justification of the dynamic subcharacteristic condition $s^2 < a$ [4].

The purpose of this paper is to show the stability of the strong travelling wave satisfying $s^2 < a$ for any nonconvex flux f which satisfies the entropy condition (1.7) and (1.8); our result also gives a justification of relaxation schemes introduced in [4] for the case of scalar nonconvex conservation laws.

Notation. Hereafter, C denotes a generic positive constant. L^2 denotes the space of square integrable functions on R with the norm

$$||f|| = \left(\int_R |f|^2 dx \right)^{1/2}.$$

Without any ambiguity, the integral region R will be omitted. $H^j (j > 0)$ denotes the usual jth-order Sobolev space with the norm

$$||f||_{H_j} = ||f||_j = \left(\sum_{k=0}^{j} ||\partial_x^k f||^2 \right)^{1/2}.$$

For a weight function $w > 0$, L^2_w denotes the space of measurable functions f satisfying $\sqrt{w} f \in L^2$ with the norm

$$|f|_w = \left(\int w(x) |f(x)|^2 dx \right)^{1/2}.$$

2. Preliminaries and theorem. We first state the existence of the travelling wave solution with shock profile for the system (1.6). Substituting

$$(u, v)(x, t) = (U, V)(z), \quad z = x - st,$$

into (1.6), we have

$$\begin{cases} -sU_z + V_z = 0, \\ -sV_z + aU_z = f(U) - V, \end{cases} \tag{2.1}$$

hence

$$(a - s^2) U_z = f(U) - V. \tag{2.2}$$

Integrating the first equation of (2.1) over $(\pm\infty, z)$ and using $(U, V)(\pm\infty) = (u_\pm, v_\pm)$ and $v_\pm = f(u_\pm)$ yields

$$-sU + V = -su_\pm + v_\pm = -su_\pm + f(u_\pm). \tag{2.3}$$

Combining (2.2) and (2.3), we obtain

$$U_z = \frac{Q(U)}{a - s^2}, \tag{2.4}$$

where $Q(U) \equiv f(U) - f(u_\pm) - s(U - u_\pm)$ and

$$s = \frac{v_+ - v_-}{u_+ - u_-} = \frac{f(u_+) - f(u_-)}{u_+ - u_-}.$$

Since (2.4) is a scalar ordinary differential equation of U, the trajectories satisfying boundary conditions $U(\pm\infty) = u_\pm$ necessarily connect adjacent equilibria u_- and u_+. It is easy to check that there is a trajectory from u_- to u_+ if and only if condition $(u_+ - u_-)\frac{Q(U)}{a-s^2} > 0$ that holds for u lies strictly between u_+ and u_-. By virtue of $s^2 < a$, this implies

$$Q(u)(u_+ - u_-) > 0$$

for u that lies strictly between u_+ and u_-, i.e., if and only if

$$u = \begin{cases} u_-, x - st < 0, \\ u_+, x - st > 0 \end{cases}$$

is an admissible shock for (1.4).

Without loss of generality, we study only the following case:

$$u_+ < u_- \quad \text{and} \quad U_z < 0. \tag{2.5}$$

Then the ordinary differential equation (2.4) with boundary condition $U(\pm\infty) = u_\pm$ has a unique smooth solution. Moreover, if $f'(u_+) < s < f'(u_-)$ or $Q'(u_\pm) \neq 0$, then $Q(U) \sim -|U-u_\pm|$ as $U \to u_\pm$. Hence $|(U-u_\pm, V-v_\pm)(z)| \sim \exp(-c_\pm|z|)$ as $z \to \pm\infty$ for some constants $c_\pm > 0$. While if $s = f'(u_+)$ or $Q'(u_+) = 0$, $|(U-u_+, V-v_+)(z)| \sim z^{-\frac{1}{k_+}}$ as $z \to +\infty$ provided $Q(U) \sim -|U-u_+|^{1+k_+}$ for $k_+ > 0$. Note $k_+ = n$ if $Q'(u_+) = \cdots = Q^{(n)}(u_+) = 0$ and $Q^{(n+1)}(u_+) \neq 0$.

Thus we have the existence of travelling wave solutions.

LEMMA 2.1. *Assume that $Q(U) < 0$ for $U \in (u_+, u_-)$, $s = \frac{f(u_+)-f(u_-)}{u_+-u_-}$, $v_\pm = f(u_\pm)$, and $|Q(U)| \sim |U-u_+|^{1+k_+}$ as $U \to u_+$ with $k_+ \geq 0$. Then there exists a travelling wave solution $(U,V)(x-st)$ of (1.1) with $(U,V)(\pm\infty) = (u_\pm, v_\pm)$, which is unique up to a shift and the speed satisfies*

$$s^2 < a. \tag{2.6}$$

Moreover, it holds as $z \to \pm\infty$

$$|(U-u_\pm, V-v_\pm)(z)| \sim \exp(-c_\pm|z|) \quad \text{if } f'(u_+) < s < f'(u_-);$$

$$|(U-u_+, V-v_+)(z)| \sim z^{-\frac{1}{k_+}} \quad \text{if } s = f'(u_+).$$

For the initial disturbance, without loss of generality, we assume

$$\int_{-\infty}^{+\infty} (u_0 - U)(x)dx = 0. \tag{2.7}$$

For a pair of travelling wave solutions given by Lemma 2.1, we let

$$(\phi_0, \psi_0)(x) = \left(\int_{-\infty}^{x} (u_0 - U)(y)dy, (v_0 - V)(x) \right). \tag{2.8}$$

Our goal is to show that the solution $(u,v)(x,t)$ of (1.6), (1.2) will approach the travelling wave solution $(U,V)(x-st)$ as $t \to \infty$; the main theorem is as follows.

THEOREM 2.2 (stability). *Suppose that (1.7)–(1.8) hold and $f'(u)^2 < a$, where $a > 0$ is a suitably large constant and $f(u)$ is a smooth function. Let $(U,V)(x-st)$ be a travelling wave solution determined by (2.7) with speed $s^2 < a$, and assume that*

$u_0 - U$ is integrable on R and $\phi_0 \in H^3, \psi_0 \in H^2$. Then there exists a constant $\varepsilon_0 > 0$ independent of $(u_\pm, v_\pm)$ such that if

$$N(0) \equiv ||u_0 - U, v_0 - V||_2 + ||\phi_0, \psi_0|| < \varepsilon_0,$$

the initial value problem (1.6), (1.2) *has a unique global solution $(u, v)(x, t)$ satisfying*

$$(u - U, v - V) \in C^0(0, \infty; H^2) \cap L^2(0, \infty; H^2).$$

Furthermore, the solution satisfies

$$\sup_{x \in R} |(u, v)(x, t) - (U, V)(x - st)| \to 0 \quad \text{as} \quad t \to +\infty. \tag{2.9}$$

3. Reformulation of the problem. The proof of Theorem 2.2 is based on L^2 energy estimates. We first rewrite the problem (1.6), (1.2) using the moving coordinate $z = x - st$. Under the assumption of (2.7), we will look for a solution of the following form:

$$(u, v)(x, t) = (U, V)(z) + (\phi_z, \psi)(z, t), \tag{3.1}$$

where (ϕ, ψ) is in some space of integrable functions which will be defined later.

We substitute (3.1) into (1.6), by virtue of (2.1), and integrate the first equation once with respect to z; the perturbation (ϕ, ψ) satisfies

$$\begin{cases} \phi_t - s\phi_z + \psi = 0, \\ \psi_t - s\psi_z + a\phi_{zz} = f(U + \phi_z) - f(U) - \psi. \end{cases} \tag{3.2}$$

The first equation of (3.2) gives

$$\psi = -(\phi_t - s\phi_z). \tag{3.3}$$

Substituting (3.3) into the second equation of (3.2), we get a closed equation for ϕ:

$$L(\phi) \equiv (\phi_t - s\phi_z)_t - s(\phi_t - s\phi_z)_z - a\phi_{zz} + \phi_t + \lambda\phi_z = -F(U, \phi_z), \tag{3.4}$$

where $F(U, \phi_z) = f(U + \phi_z) - f(U) - f'(U)\phi_z = O(1)(\phi_z^2)$ is a higher order term and $\lambda = Q'(U) = f'(U) - s$.

The corresponding initial data for (3.4) becomes

$$\phi(z, 0) = \phi_0(z), \;\; \phi_t(z, 0) = s\phi_0'(z) - \psi_0 = \phi_1(z). \tag{3.5}$$

The asymptotic stability of the profile (U, V) means that the perturbation (ϕ_z, ψ) decays to zero as $t \to \infty$. The left-hand side of (3.4) contains a first-order term with speed λ which plays the essential role of governing the large-time behavior of the solution.

Now, we introduce the solution space of the problem (3.4), (3.5) as follows:

$$X(0, T) = \{\phi(z, t) : \;\; \phi \in C^0([0, T); H^3) \cap C^1(0, T; H^2), \;\; (\phi_z, \phi_t) \in L^2(0, T; H^2)\},$$

with $0 < T \leq +\infty$. By virtue of (3.3), we have

$$\psi \in C^0([0, T); H^2) \cap L^2(0, T; H^2).$$

By the Sobolev embedding theorem, if we let

$$N(t) = \sup_{0 \leq \tau \leq t} \{||\phi(\tau)||_3 + ||\phi_t(\tau)||_2\},$$

then

$$\sup_{z\in R}\{|\phi|,|\phi_z|,|\phi_{zz},|\phi_t|,|\phi_{tz}|\}\le CN(t). \tag{3.6}$$

Thus Theorem 2.2 is a consequence of the following theorem.

THEOREM 3.1. *Under the conditions of Theorem* 2.2, *there exists a positive constant* δ_1 *such that if*

$$N(0)=||\phi_0||_3+||\phi_1||_2\le\delta_1, \tag{3.7}$$

then the problem (3.4), (3.5) *has a unique global solution* $\phi\in X(0,+\infty)$ *satisfying*

$$||\phi(t)||_3^2+||\phi_t||_2^2+\int_0^t||(\phi_t,\phi_z)(\tau)||_2^2d\tau\le CN(0)^2 \tag{3.8}$$

for $t\in[0,+\infty)$. *Furthermore,*

$$\sup_{z\in R}|(\phi_z,\phi_t)(z,t)|\to 0\quad as\ \ t\to\infty. \tag{3.9}$$

For the solution ϕ in the above theorem, we define (ϕ,ψ) by (3.3). Then it becomes a global solution of the problem (3.2) with $(\phi,\psi)(z,0)=(\phi_0,\psi_0)(z)$, and consequently we have the desired solution of the problem (1.6), (1.2) through the relation (3.1). On the other hand the solution of (1.6) is unique in the space $C^0(0,T;H^2)$. Therefore Theorem 2.2 follows from Theorem 3.1. Global existence for ϕ will be derived from the following local existence theorem for ϕ combined with an a priori estimate. (3.8) gives

$$||\phi_t,\phi_z||_1^2\to 0\quad \text{as}\ \ t\to\infty, \tag{3.10}$$

from which we have

$$\begin{aligned}\phi_t^2+\phi_z^2 &= \int_{-\infty}^{z}(2\phi_t\phi_{tz}+2\phi_z\phi_{zz})(y,t)dy\\ &\le \left(\int_{-\infty}^{+\infty}(\phi_t^2+\phi_z^2)dy\right)^{1/2}\left(\int_{-\infty}^{+\infty}(\phi_{tz}^2+\phi_{zz}^2)dy\right)^{1/2}\to 0,\ \ \text{as}\ \ t\to\infty.\end{aligned}$$

PROPOSITION 3.2 (local existence). *For any* $\delta_0>0$, *there exists a positive constant* T_0 *depending on* δ_0 *such that if* $\phi_0\in H^3$ *and* $\phi_1\in H^2$, *with* $N(0)<\delta_0/2$, *then the problem* (3.4), (3.5) *has a unique solution* $\phi\in X(0,T_0)$ *satisfying*

$$N(t)<2N(0) \tag{3.11}$$

for any $0\le t\le T_0$.

PROPOSITION 3.3 (a priori estimate). *Let* $\phi\in X(0,T)$ *be a solution for a positive constant* T; *then there exists a positive constant* δ_2 *independent of* T *such that if*

$$N(t)<\delta_2,\ \ t\in[0,T],$$

then ϕ *satisfies* (3.8) *for any* $0\le t\le T$.

Proposition 3.2 can be proved in the standard way, so we omit the proof; cf. [9]. To prove Proposition 3.3 is our main task in the following section.

Here we prove Theorem 3.1 by the continuation arguments based on Proposition 3.2 and Proposition 3.3.

Proof of Theorem 3.1. By the definition of $N(t)$, we have

$$N(t)^2 \le 2 \sup_{0\le\tau\le t} [||\phi(\tau)||_3^2 + ||\phi_t(\tau)||_2^2]. \tag{3.12}$$

Then the inequality (3.8) implies

$$N(t) < \sqrt{2C}N(0). \tag{3.13}$$

Choose δ_1 such that $\delta_1 = \min\{\frac{\delta_2}{2}, \frac{\delta_2}{2\sqrt{2C}}\}$; then the local solution of (3.4) can be continued globally in time, provided the smallness condition $N(0) \le \delta_1$ is satisfied. In fact we have $N(0) < \delta_1 \le \delta_2/2$. Therefore, by Proposition 3.2, there is a positive constant $T_0 = T_0(\delta_2)$ such that a solution exists on $[0, T_0]$ and satisfies $N(t) < 2N(0) \le \delta_2$ for $t \in [0, T_0]$.

Hence we can apply Proposition 3.3 with $T = T_0$ and get the estimate (3.8), that is, $N(t) \le \sqrt{2C}N(0) \le \frac{\delta_2}{2}$ for $t \in [0, T_0]$. Then we apply Proposition 3.2 by taking $t = T_0$ as the new initial time. We have a solution on $[T_0, 2T_0]$ with the estimate $N(t) \le 2N(T_0) \le \delta_2$ for $t \in [T_0, 2T_0]$. Therefore $N(t) \le \delta_2$ holds on $[0, 2T_0]$. Hence this again gives the estimate (3.8) for $t \in [0, 2T_0]$. In the same way we can extend the solution to the interval $[0, nT_0]$ successively, $n = 1, 2, \ldots$, and get a global solution ϕ. This completes the proof of Theorem 3.1. ∎

4. Energy estimates. In this section, we will complete the proof of our stability theorem. We establish the basic L^2 estimate as follows.

LEMMA 4.1. *There are positive constants C such that if*

$$-\sqrt{a} < f'(u) < \sqrt{a}, \quad u \in (u_+, u_-),$$

and a is sufficiently large, then

$$\begin{aligned} &||\phi(t)||_1^2 + ||\phi_t(t)||^2 + \int_0^t ||(\phi_t, \phi_z)(\tau)||^2 d\tau + \int_0^t \int_R |U_z|\phi^2 dz d\tau \\ &\le C\{||\phi_0||_1^2 + ||\phi_1||^2 + \int_0^t \int_R |F|(|\phi| + |(\phi_t, \phi_z)|) dz d\tau\} \end{aligned} \tag{4.1}$$

holds for $t \in [0, T]$.

Proof. When f is a nonconvex function, the standard energy method used in [6] does not work for our problem (3.4), (3.5). To overcome this difficulty, we use a weight function $w(U)$ introduced in [7] depending on the shock profile U.

First, by multiplying (3.4) by $2w(U)\phi$, we obtain

$$2w(U)\phi \cdot L(\phi) = -2Fw(U)\phi. \tag{4.2}$$

The left-hand side of (4.2) can be reduced to

(4.3)

$$\begin{aligned} &2[(\phi_t - s\phi_z)_t - s(\phi_t - s\phi_z)_z - a\phi_{zz}]w\phi + 2(\phi_t + \lambda\phi_z)w\phi \\ &= [2w\phi(\phi_t - s\phi_z)]_t - 2w\phi_t(\phi_t - s\phi_z) - 2s[w\phi(\phi_t - s\phi_z)]_z \\ &\quad + 2sw_z\phi(\phi_t - s\phi_z) + 2sw\phi_z(\phi_t - s\phi_z) - 2a(w\phi\phi_z)_z + 2aw\phi_z^2 \\ &\quad + (aw_z\phi^2)_z - aw_{zz}\phi^2 + (w\phi^2)_t + (\lambda w\phi^2)_z - \phi^2(\lambda w)_z \\ &= [w\phi^2 + 2w\phi(\phi_t - s\phi_z)]_t - 2w(\phi_t - s\phi_z)^2 + 2aw\phi_z^2 - aw_{zz}\phi^2 \\ &\quad - (\lambda w)_z\phi^2 + sw_z(\phi^2)_t - s^2\{w_z(\phi^2)\}_z + s^2w_{zz}\phi^2 \\ &\quad + \{-2sw\phi(\phi_t - s\phi_z) - 2aw\phi\phi_z + aw_z\phi^2 + \lambda w\phi^2\}_z \\ &= [w\phi^2 + 2w\phi(\phi_t - s\phi_z) + sw_z\phi^2]_t - 2w(\phi_t - s\phi_z)^2 + 2aw\phi_z^2 + A\phi^2 + \{\cdots\}_z; \end{aligned}$$

here $A = (s^2 - a)w_{zz} - (\lambda w)_z$, $\{\cdots\}_z$ denotes the terms which will disappear after integration with respect to $z \in R$.

Secondly, we calculate

$$2(\phi_t - s\phi_z)w \cdot L(\phi) = -2F(\phi_t - s\phi_z)w. \tag{4.4}$$

The left-hand side of (4.4) is

$$\begin{aligned}
&2[(\phi_t - s\phi_z)_t - s(\phi_t - s\phi_z)_z - a\phi_{zz}]w(\phi_t - s\phi_z)\\
&\quad +2w(\phi_t - s\phi_z)(\phi_t - s\phi_z + f'(U)\phi_z)\\
&= [w(\phi_t - s\phi_z)^2]_t - s[w(\phi_t - s\phi_z)^2]_z + sw_z(\phi_t - s\phi_z)^2\\
&\quad -2a[w\phi_z(\phi_t - s\phi_z)]_z + 2aw_z\phi_z(\phi_t - s\phi_z) + 2aw\phi_z(\phi_t - s\phi_z)_z\\
&\quad +2w(\phi_t - s\phi_z)^2 + 2wf'(U)\phi_z(\phi_t - s\phi_z)\\
&= [w(\phi_t - s\phi_z)^2]_t + (2w + sw_z)(\phi_t - s\phi_z)^2 + 2aw_z\phi_z(\phi_t - s\phi_z)\\
&\quad +2wf'(U)\phi_z(\phi_t - s\phi_z) + [aw\phi_z^2]_t - [asw\phi_z^2]_z + asw_z\phi_z^2\\
&\quad -[sw(\phi_t - s\phi_z)^2 + 2aw\phi_z(\phi_t - s\phi_z)]_z\\
&= [aw\phi_z^2 + w(\phi_t - s\phi_z)^2]_t + (2w + sw_z)(\phi_t - s\phi_z)^2\\
&\quad +saw_z\phi_z^2 + 2f'(U)w\phi_z(\phi_t - s\phi_z) + 2aw_z\phi_z(\phi_t - s\phi_z)\\
&\quad -[sw(\phi_t - s\phi_z)^2 + 2aw\phi_z(\phi_t - s\phi_z) + asw\phi_z^2]_z.
\end{aligned} \tag{4.5}$$

Hence, the combination (4.2) $\times\mu+$ (4.4) with a positive constant μ yields

$$\begin{aligned}
&\{E_1(\phi, (\phi_t - s\phi_z)) + E_3(\phi_z)\}_t + E_2(\phi_z, (\phi_t - s\phi_z)) + E_4(\phi) + \{\cdots\}_z\\
&\quad = -2Fw\{\mu\phi + (\phi_t - s\phi_z)\},
\end{aligned} \tag{4.6}$$

where

$$\begin{aligned}
E_1(\phi, (\phi_t - s\phi_z)) &= w(\phi_t - s\phi_z)^2 + 2\mu w\phi(\phi_t - s\phi_z) + \mu(w + sw_z)\phi^2,\\
E_3(\phi_z) &= aw\phi_z^2,\\
E_2(\phi_z, (\phi_t - s\phi_z)) &= (2w + sw_z - 2\mu w)(\phi_t - s\phi_z)^2\\
&\quad +2(f'(U)w + aw_z)\phi_z(\phi_t - s\phi_z) + a(2\mu w + sw_z)\phi_z^2,\\
E_4(\phi) &= \mu A\phi^2.
\end{aligned} \tag{4.7}$$

Due to $(a - s^2)U_z = Q(U)$ and $w = w(U)$, we have

$$\begin{aligned}
A &= -\{(a - s^2)w'(U)U_z + \lambda w\}_z\\
&= -\{w'(U)Q(U) + Q'(U)w\}_z\\
&= -\{wQ\}''U_z.
\end{aligned} \tag{4.8}$$

The monotonicity of the shock profile U implies $U_z < 0$; thus we need to choose $w \in C^2[u_+, u_-]$ such that

$$(wQ)'' \geq \nu > 0. \tag{4.9}$$

On the other hand, we need to choose a constant $\mu > 0$ and w such that the discriminants of E_i $(i = 1, 2)$ are negative; that is, the inequalities

$$\sup_j D_j < 0, \quad j = 1, 2, \tag{4.10}$$

hold uniformly in $(u_\pm, v_\pm)$, where D_j is the discrimant of the functions $E_j (j = 1, 2)$, respectively.

$$D_1 = 4\mu w[(\mu - 1)w - sw_z],$$

$$D_2 = 4\{(f'w + aw_z)^2 - a(2\mu w + sw_z)(2w + sw_z - 2\mu w)\},$$

and $2\mu w + sw_z > 0$. For this choice of μ and w, there exist positive constants c and C such that

$$\left\{ \begin{array}{lllll} c\{\phi^2 + (\phi_t - s\phi_z)^2\} & \le & E_1 & \le & C\{\phi^2 + (\phi_t - s\phi_z)^2\}, \\ c\{\phi_z^2 + (\phi_t - s\phi_z)^2\} & \le & E_2. & & \end{array} \right. \tag{4.11}$$

On the other hand, (4.8) and $a > 0$ gives

$$\left\{ \begin{array}{lllll} 0 & \le & E_3 & = & aw\phi_z^2, \\ & & E_4 & \ge & \mu\nu|U_z|\phi^2 \ge 0. \end{array} \right. \tag{4.12}$$

Thus the equality (4.6) together with the estimates (4.11)–(4.12) give the desired estimate (4.1) after integration with respect to t and z.

It remains to check conditions (4.8)–(4.10). First we choose the weight function $w(U)$ introduced in [7] for the scalar viscous conservation laws with nonconvex flux

$$w(U) = \frac{(U - u_+)(U - u_-)}{Q(U)}. \tag{4.13}$$

Then $w \in C^2[u_+, u_-]$ and (4.8) holds, i.e., $(wQ)'' = \nu = 2$. Furthermore, choosing $\mu = \frac{1}{2}$, the two inequalities in (4.10) are equivalent to

$$1 + 2s\frac{w_z}{w} > 0, \tag{4.14}$$

$$\left(f' + a\frac{w_z}{w}\right)^2 < a\left(1 + s\frac{w_z}{w}\right)^2, \tag{4.15}$$

since

$$\frac{w_z}{w} = \frac{w'}{w}\frac{Q}{a - s^2} = \frac{O(1)}{a - s^2},$$

which is small provided a is suitably large. This fact, together with $f'^2 < a$, gives us (4.14) and (4.15); thus conditions (4.8) and (4.10) are satisfied. This completes the proof of Lemma 4.1. □

Next we estimate the higher derivatives of ϕ, multiplying the derivative of (3.4) with respect to z by ϕ_z and $(\phi_t - s\phi_z)_z$, respectively; we have

$$2\partial_z L(\phi) \cdot \phi_z = -2F_z\phi_z,$$

$$2\partial_z L(\phi) \cdot (\phi_t - s\phi_z)_z = -2F_z(\phi_t - s\phi_z)_z.$$

Letting $\phi_z = \Phi$, then

$$\begin{array}{rcl} \partial_z L(\phi) & = & (\phi_{zt} - s\phi_{zz})_t - s(\phi_{zt} - s\phi_{zz})_z - a\phi_{zzz} + \phi_{zt} + \lambda\phi_{zz} + \lambda_z\phi_z \\ & = & L(\phi_z) + \lambda_z\phi_z = L(\Phi) + \lambda_z\Phi. \end{array} \tag{4.16}$$

By a similar argument to obtain (4.3) and (4.5) with $w = 1$, we have

$$\begin{aligned}[\Phi^2 + 2\Phi(\Phi_t - s\Phi_z)]_t + 2a\Phi_z^2 - 2(\Phi_t - s\Phi_z)^2 - \lambda_z\Phi^2 + 2\lambda_z\Phi^2 + \{\cdots\}_z \\ = -2F_z\Phi,\end{aligned} \tag{4.17}$$

and

$$\begin{aligned}[(\Phi_t - s\Phi_z)^2 + a\Phi_z^2]_t + 2(\Phi_t - s\Phi_z)^2 + 2f'(U)\Phi_z(\Phi_t - s\Phi_z) \\ +2\lambda_z\Phi(\Phi_t - s\Phi_z) + \{\cdots\}_z \\ = -2F_z(\Phi_t - s\Phi_z).\end{aligned} \tag{4.18}$$

The combination (4.17)$\times\frac{1}{2}$+(4.18) yields

$$\begin{aligned}\{E_1(\Phi, (\Phi_t - s\Phi_z)) + E_2(\Phi_z)\}_t + E_3(\Phi_z, (\Phi_t - s\Phi_z)) + G + \{\cdots\}_z \\ = -F_z\{\Phi + 2(\Phi_t - s\Phi_z)\},\end{aligned} \tag{4.19}$$

where

$$\begin{aligned} G &= \tfrac{\lambda_z}{2}\Phi^2 + 2\lambda_z\Phi(\Phi_t - s\Phi_z), \\ E_1(\Phi, (\Phi_t - s\Phi_z)) &= (\Phi_t - s\Phi_z)^2 + \Phi(\Phi_t - s\Phi_z) + \tfrac{1}{2}\Phi^2, \\ E_2(\Phi_z) &= a\Phi_z^2, \\ E_3(\Phi_z, (\Phi_t - s\Phi_z)) &= (\Phi_t - s\Phi_z)^2 + 2f'(U)\Phi_z(\Phi_t - s\Phi_z) + a\Phi_z^2. \end{aligned} \tag{4.20}$$

After integration with respect to t and z, (4.19) together with (4.20) gives the following estimate:

(4.21)

$$\begin{aligned}&||\Phi(t)||_1^2 + ||\Phi_t(t)||^2 + \int_0^t ||(\Phi_t, \Phi_z)(\tau)||^2 d\tau \\ &\quad \le C\left\{||\Phi_0||_1^2 + ||\Phi_1||^2 + \int_0^t \int |G| dz d\tau + \int_0^t \int_R |F_z|(|\Phi| + |(\Phi_t, \Phi_z)|) dz d\tau\right\};\end{aligned}$$

here $\Phi_0 = \phi_0'$ and $\Phi_1 = \phi_1'$.

Using the estimate (4.1), we obtain

(4.22)

$$\begin{aligned}\int_0^t \int |G| dz d\tau &\le \int_0^t \int \left[\frac{|\lambda_z|}{2}\Phi^2 + 2|\lambda_z|^2\Phi^2 + \frac{1}{2}\Phi_t^2 + 2s^2|\lambda_z|^2\Phi^2 + \frac{1}{2}\Phi_z^2\right] dz d\tau \\ &\le \frac{1}{2}\int_0^t ||(\Phi_t, \Phi_z)(\tau)||^2 d\tau + C\int_0^t \int \Phi^2 dz d\tau \\ &\le \frac{1}{2}\int_0^t ||(\Phi_t, \Phi_z)(\tau)||^2 d\tau \\ &\quad + C\left\{||\phi_0||_1^2 + ||\phi_1||^2 + \int_0^t \int |F|(|\phi| + |(\phi_t, \phi_z)|) dz d\tau\right\},\end{aligned}$$

where we have used Lemma 4.1 and the boundness of $|\lambda_z|$.

Substituting (4.22) into (4.21) and replacing Φ by $\partial_z\phi$, we have the following lemma.

LEMMA 4.2. *There are positive constants C such that if*

$$-\sqrt{a} < f'(u) < \sqrt{a} \ \text{ for } \ u \in (u_+, u_-),$$

then

$$
\begin{aligned}
&||\partial_z\phi(t)||_1^2+||\partial_z\phi_t||^2+\frac{1}{2}\int_0^t||(\partial_z\phi_t,\partial_z\phi_z)(\tau)||^2d\tau\\
&\quad\le C\left\{||\phi_0||_2^2+||\phi_1||_1^2+\int_0^t\int|F_z|(|\partial_z\phi|+|(\partial_z\phi_t,\partial_z\phi_z)|)dzd\tau\right.\\
&\quad\left.+\int_0^t\int|F|(|\phi|+|(\phi_t,\phi_z)|)dzd\tau\right\}
\end{aligned}
\tag{4.23}
$$

holds for $t\in[0,T]$.

Next we calculate the equality

$$\partial_z^2\phi\cdot\partial_z^2L(\phi)+2\partial_z^2(\phi_t-s\phi_z)\cdot\partial_z^2L(\phi)=-\partial_z^2F\{\partial_z^2\phi+2\partial_z^2(\phi_t-s\phi_z)\}$$

in the same way as for the proof of Lemma 4.2; it is easy to get the following equality for $\Psi=\partial_z^2\phi$:

(4.24)

$$
\begin{aligned}
&\left[(\Psi_t-s\Psi_z)^2+a\Psi_z^2+\Psi(\Psi_t-s\Psi_z)+\frac{1}{2}\Psi^2\right]_t+(\Psi_t-s\Psi_z)^2+2f'(U)\Psi_z(\Psi_t-s\Psi_z)\\
&\quad+a\Psi_z^2+4\lambda_z\Psi(\Psi_t-s\Psi_z)+\frac{3}{2}\lambda_z\Psi^2+\lambda_{zz}\Psi\phi_z+2\lambda_{zz}\phi_z(\Psi_t-s\Psi_z)+\{\cdots\}_z\\
&=-F_{zz}[\Psi+2(\Psi_t-s\Psi_z)].
\end{aligned}
$$

Thus, noting $\Psi=\phi_{zz}$, we have from (4.24) that

(4.25)

$$
\begin{aligned}
&||\partial_z^2\phi(t)||_1^2+||\partial_z^2\phi_t||^2+\frac{1}{3}\int_0^t||(\partial_z^2\phi_t,\partial_z^2\phi_z)(\tau)||^2d\tau-C\int_0^t\{||\partial_z^2\phi||^2+||\phi_z||^2\}d\tau\\
&\quad\le C\left\{||\phi_0||_3^2+||\phi_1||_2^2+\int_0^t\int|F_{zz}|(|\partial_z^2\phi|+|(\partial_z^2\phi_t,\partial_z^2\phi_z)|)dzd\tau\right\},
\end{aligned}
$$

where we have used the fact that $\lambda_z,\ \ \lambda_{zz}$ are smooth bounded functions and the Young inequality for the terms $4\lambda_z\Psi(\Psi_t-s\Psi_z)$ and $2\lambda_{zz}\phi_z(\Psi_t-s\Psi_z)$. Combining successively the estimates (4.1), (4.23), and (4.25), we have

(4.26)

$$
\begin{aligned}
&||\phi(t)||_3^2+||\phi_t(t)||_2^2+\int_0^t\int|\lambda_z|\phi^2dzd\tau+\int_0^t||(\phi_t,\phi_z)||_2^2d\tau\\
&\quad\le C\left\{||\phi_0||_3^2+||\phi_1||_2^2+\int_0^t\int\{|F|(|\phi|+|(\phi_t,\phi_z)|)+|F_z|(|\partial_z\phi|+|(\partial_z\phi_t,\partial_z\phi_z)|)\right.\\
&\qquad\left.+|F_{zz}|(|\partial_z^2\phi|+|(\partial_z^2\phi_t,\partial_z^2\phi_z)|)\}dzd\tau\right\}.
\end{aligned}
$$

Since $F=f(U+\phi_z)-f'(U)\phi_z-f(U)$, we have

$$|F|=O(1)(\phi_z^2),\quad |F_z|=O(1)(\phi_z^2+\phi_{zz}^2),$$

$$|F_{zz}|=O(1)(\phi_z^2+\phi_{zz}^2+|\phi_z\phi_{zzz}|).$$

By virtue of (3.6), the integral on the right-hand side of (4.26) is majored by

$$CN(t)\int_0^t||(\phi_t,\phi_z)||_2^2d\tau;$$

then we have

$$N^2(t) + \int_0^t ||(\phi_t, \phi_z)||_2^2 d\tau + \int_0^t \int |\lambda_z| \phi^2 dz d\tau \le N(0)^2 + CN(t) \int_0^t ||(\phi_t, \phi_z)||_2^2 d\tau.$$

Therefore, by assuming $N(T) \le \frac{1}{2C}$, we obtain the desired estimate

$$N^2(t) + \int_0^t ||(\phi_t, \phi_z)||_2^2 d\tau \le CN(0)^2 \quad \text{for} \quad t \in [0, T].$$

Thus the proof of Proposition 3.3 is completed. □

Remark. When $s = f'(u_+)$ or $s = f'(u_-)$, we need a weight of the order $\langle x \rangle = \sqrt{1 + x^2}$ as $x \to +\infty$ or $-\infty$ for a stability theorem. The stability analysis for ϕ in this case can be investigated similarly using the weighted function space

$$X_w(0, T) = \{\phi(z, t) : \quad \phi \in C^0([0, T); H^3 \cap L^2_{w(U)}) \cap C^1(0, T; H^2 \cap L^2_{w(U)}), \\ (\phi_z, \phi_t) \in L^2(0, T; H^2 \cap L^2_{w(U)})\},$$

where $w(U(z)) \sim \langle z \rangle$ as $z \to \pm\infty$ by virtue of Lemma 2.1 and the definition of $w(U)$ in (4.13).

Acknowledgment. The authors are grateful to Prof. M. Slemrod for stimulating discussions.

A CONDENSATION–EVAPORATION PROBLEM IN KINETIC THEORY*

L. ARKERYD† AND A. NOURI‡

Abstract. A linear Boltzmann model is used for studying a condensation–evaporation problem in a bounded domain. First the time asymptotic limit is derived, which solves the associated stationary problem. Then the Milne problem is discussed for the boundary layer. Finally a fluid approximation is obtained in the small mean free path limit with initial and boundary layers of zeroth order.

Key words. boundary layer, condensation, evaporation, hydrodynamic limit, initial layer, Milne problem, time asymptotics

Introduction. The kinetic description of a rarefied gas can be given through the Boltzmann equation for the density function $f(t,x,v)$ of particles with velocity v at position x and time t. A coarser theory consists of describing the gas as a continuous fluid with local density $\rho(t,x)$, velocity $u(t,x)$, and temperature $T(t,x)$ satisfying the Euler or Navier–Stokes equations. In the limit of small mean free path, the fluid dynamic equations may be derived from the Boltzmann equation through either a Hilbert or Chapman–Enskog expansion; see, e.g., [2, 8, 9, 12]. However, the fluid dynamic limits fail near shocks and for general indata near spatial or temporal boundaries.

Among the many studies of the boundary layer structure let us mention the following. In [3], the steady nonlinear Boltzmann equation for a gas with zero bulk velocity between two plates at two different temperatures is solved for a small mean free path, using a Chapman–Enskog expansion between the two plates. Here the fluid part of the solution contains Fourier's law for heat conduction which can be made to satisfy different temperature values at the two plates. This is why the boundary layer terms only need to be of first order with respect to the mean free path. An analogous study also including the initial layer is performed in [16] for the linear semiconductor case where further references in the field may also be found. For more results in the area see also [5, 10, 13, 19].

The present paper addresses the added presence of condensation–evaporation on the boundary. In this context a formal analysis and numerical computations are carried out in [17, 18] for a rarefied gas with varying temperatures and condensation–evaporation on the boundaries. On the basis of the linearized Boltzmann equation for hard sphere molecules, zeroth-order boundary layer terms are needed for solving the problem. Our paper considers the same problem for a rarefied solute in a solvent gas, and with varying temperatures on the boundary. The linear Boltzmann equation is used as a model for the solute. We prove that a fluid approximation in the interior together with initial and boundary layer structures are available to describe the solute

gas. Here the fluid approximation is derived from the boundary layer analysis. Indeed, like [17, 18] this boundary layer structure requires zeroth-order terms with respect to the mean free path.

In the first section an existence and uniqueness result for the initial boundary value problem with given indata in a bounded region is recalled. We then determine the solution to the stationary boundary value problem from the time asymptotics of the initial boundary value solution. The approach is designed for prospective future use in the nonlinear case. For another approach to the nonlinear stationary problem see [1]. Section 2 is devoted to the solution of the Milne problem. For indepth discussions and bibliography see [4, 6]. Depending on the sign of the normal velocity of the solvent gas, two kinds of solutions are of interest for the following boundary layer analysis. In the last section we perform in the slab case a fluid approximation with respect to the mean free path by splitting the solution into a zeroth-order initial layer term together with a stationary boundary value contribution having a fluid part with zeroth-order boundary layer terms and a first order remainder term.

1. The initial boundary value problem and its time asymptotic behavior. The linear Boltzmann equation models the interaction between a solvent gas and a solute gas. The solute gas is rarefied enough so that collisions with itself are negligible in comparison with collisions with the solvent gas. Both gases are located in a bounded convex domain $\Omega \subset \mathbb{R}^3$. The distribution function $f(t,x,v)$ of the solute gas satisfies the linear Boltzmann equation

$$\partial_t f + v \cdot \nabla_x f = Q(f), \tag{1.1}$$

where

$$Q(f)(t,x,v) = \int B(\theta, w)(f'F'_* - fF_*)dv_* d\theta d\epsilon = Q^+(f) - \nu f.$$

Here

$$\begin{gathered} f' = f(t,x,v'), \quad F'_* = F(t,x,v'_*), \\ f = f(t,x,v), \quad F_* = F(t,x,v_*), \\ w = |v - v_*|, \quad v' = v - \frac{2}{1+\kappa}((v-v_*)\cdot e)e, \\ v'_* = v_* + \frac{2\kappa}{1+\kappa}((v-v_*)\cdot e)e, \quad e \in S^2. \end{gathered}$$

F is the solvent distribution function, assumed to be known, and κ is the ratio between the solute molecular mass m and the solvent molecular mass m_*.

Assuming that the collisions between the two gases are governed by a cut-off inverse power law interaction potential $U(\rho) = c\rho^{-k+1}, k > 2$ depending on the distance ρ of two colliding particles, the weight function B is $B(\theta, w) = w^\gamma b(\theta)$, $0 \le \theta < \frac{\pi}{2}$, $w > 0$ (cf. [7]), where $\gamma = \frac{k-5}{k-1}$ and b is a nonnegative L^1-function defined on $[0, \frac{\pi}{2}]$, with $\int_0^{\frac{\pi}{2}} b(\theta)d\theta > 0$. We assume hard interactions, i.e., $k > 5$ or $0 < \gamma < 1$. A principle of detailed balance only holds [14], when F is a Maxwellian,

$$F(v) = \left(\frac{2\pi T}{m_*}\right)^{-\frac{3}{2}} \exp\left(-m_* \frac{(v-U)^2}{2T}\right).$$

This is also assumed throughout the paper.

The collision frequency $\nu(v)$ is bounded from above and below by a positive multiple of $(1+|v|)^\gamma$. The choice of the bulk velocity $U=(u,0,0)\in\mathbb{R}^3$ in connection with the given boundary temperature follows from the boundary value problem for the solvent gas. The present study of the solute holds for any U and boundary temperature. The solute Maxwellian with the same bulk velocity U and temperature T is $M(v)=(\frac{2\pi T}{m})^{-\frac{3}{2}}\exp(-m\frac{(v-U)^2}{2T})$. It satisfies

$$F_*M=F'_*M'. \tag{1.2}$$

(1.1) is complemented with an initial condition

$$f(0,x,v)=f_i(x,v) \tag{1.3}$$

and given indata on the boundary

$$f(t,x,v)=f_b(x,v),\quad x\in\partial\Omega,\quad v\cdot n(x)>0. \tag{1.4}$$

Here $n(x)$ denotes the inward normal at x. Let $(\partial\Omega\times\mathbb{R}^3)^+$ and $(\partial\Omega\times\mathbb{R}^3)^-$ denote the sets of $(x,v)\in\partial\Omega\times\mathbb{R}^3$ such that $v\cdot n(x)>0$ and $v\cdot n(x)<0$, respectively.

For $\partial\Omega$ sufficiently smooth, say C^1, the existence and uniqueness approach of [15] can be used to prove the following theorem.

THEOREM 1.1. *If $(1+|v|)^\gamma f_i$ and $(1+|v|)^\gamma f_b$ belong to $L^1(\Omega\times\mathbb{R}^3)$ and $L^1_{v\cdot n(x)}((\partial\Omega\times\mathbb{R}^3)^+)$, respectively, then there exists a unique solution f of (1.1)–(1.3–1.4) with $f(t)(1+|v|)^\gamma\in L^1(\Omega\times\mathbb{R}^3)$ for $t>0$. Moreover, f is nonnegative whenever f_i and f_b are nonnegative.*

Let us next discuss the collisions and the collision operator in velocity space. The momentum and energy conservations imply

$$\begin{aligned} mv+m_*v_*&=mv'+m_*v'_*,\\ m|v|^2+m_*|v_*|^2&=m|v'|^2+m_*|v'_*|^2. \end{aligned}$$

A transformation to the equal mass situation $m=m_*$ is given by

$$\tilde v=v-\frac{\alpha}{2}(v-v_*),\quad \tilde v_*=v_*-\frac{\alpha}{2}(v-v_*),$$

where $\alpha=\frac{m_*-m}{m_*+m}$. Hence

$$\begin{aligned} \tilde v+\tilde v_*&=\tilde v'+\tilde v'_*,\\ |\tilde v|^2+|\tilde v_*|^2&=|\tilde v'|^2+|\tilde v'_*|^2. \end{aligned}$$

Denote by $\tilde f$, $\tilde Q^+(\tilde f)$, and $\tilde Q(\tilde f)$

$$\tilde f=f\sqrt{\frac{\nu}{M}},\quad \tilde Q^+(\tilde f)=\frac{1}{\sqrt{\nu M}}\,Q^+(f),\quad \tilde Q(\tilde f)=\tilde Q^+(\tilde f)-\tilde f.$$

By (1.2)

$$\tilde Q^+(\tilde f)=\int B\sqrt{\frac{F'_*F_*}{\nu'\nu}}\;\tilde f'dv_*d\theta d\epsilon.$$

Let $(\,,\,)$ denote the scalar product in $L^2(\mathbb{R}^3)$.

LEMMA 1.2. *Every $\tilde{f} \in L^2(\mathbb{R}^3)$ can uniquely be written*

$$\tilde{f} = c_f\sqrt{\nu M} + \tilde{w}_f, \tag{1.5}$$

with $(\sqrt{\nu M},\ \tilde{w}_f) = 0$. Moreover

$$|(\tilde{Q}^+\tilde{w}_f, \tilde{w}_f)| \le (1-\sigma)\|\tilde{w}_f\|^2_{L^2} \tag{1.6}$$

for some constant σ such that $0 < \sigma < 1$.

Proof. $\tilde{Q}^+$ satisfies Grad's conditions [12], so $\tilde{Q}^+$ is a compact operator in $L^q_s := L^q(\mathbb{R}^3, 1+|v|^s)$, $1 \le q < \infty$, $s \in \mathbb{R}$. Moreover, $\tilde{Q}^+$ is symmetric in L^2. Hence its eigenvector spaces span L^2 and are finite dimensional for nonzero eigenvalues. Then

$$|(\tilde{Q}^+\tilde{f}, \tilde{f})| = \int B\sqrt{\frac{F'_*}{\nu'}}\ \tilde{f}'\ \overline{\sqrt{\frac{F_*}{\nu}}\ \tilde{f}} \le \int B\frac{F_*}{\nu}|\tilde{f}|^2 = \int |\tilde{f}|^2,$$

so $-\tilde{Q}$ is positive in L^2 and $\|\tilde{Q}^+\| \le 1$. The $\tilde{Q}^+$-eigenvalue 1 is simple. Indeed, $\tilde{Q}^+\tilde{f} = \tilde{f}$ implies $(\tilde{Q}\tilde{f}, \tilde{f}) = 0$, which can be written

$$\int B\left(\sqrt{\frac{F'_*}{\nu'}}\ \tilde{f}' - \sqrt{\frac{F_*}{\nu}}\tilde{f}\right)^2 dvdv_*\ d\theta d\epsilon = 0.$$

Hence

$$\sqrt{\frac{F'_*}{\nu'}}\ \tilde{f}' = \sqrt{\frac{F_*}{\nu}}\ \tilde{f},$$

or $\frac{f'}{M'} = \frac{f}{M}$ by (1.2). It follows (see [14]) that $\tilde{f} = c\sqrt{\nu M}$, where c is a constant. Now -1 is not an eigenvalue of $\tilde{Q}^+$. Otherwise, $\tilde{Q}^+\tilde{f} = -\tilde{f}$ for some $\tilde{f}$ implies

$$\int B\left(\sqrt{\frac{F'}{\nu'}}\ \tilde{f}' + \sqrt{\frac{F_*}{\nu}}\ \tilde{f}\right)^2 dvdv_*\ d\theta d\epsilon = 0,$$

so $\frac{f'}{M'} = -\frac{f}{M}$. Varying v_* and the angular coordinate for v fixed gives that f has a constant sign. Hence $\tilde{f} = 0$. Since $\tilde{Q}^+$ is compact and symmetric, $\|\tilde{Q}^+\| \le 1$, -1 is not an eigenvalue, and the eigenspace of 1 is $c\sqrt{\nu M}$, it follows that every $\tilde{f} \in L^2$ can be uniquely written as

$$\tilde{f} = c_f\sqrt{\nu M} + \tilde{w}_f, \quad \text{with } (\sqrt{\nu M}, \tilde{w}_f) = 0$$

and

$$|(\tilde{Q}^+\tilde{w}_f, \tilde{w}_f)| \le (1-\sigma)\|\tilde{w}_f\|^2_{L^2}, \quad 0 < \sigma < 1. \qquad \square$$

Let us next describe the time asymptotics for the solution of the initial boundary value problem (1.1)–(1.3–1.4).

THEOREM 1.3. *Let f_i and f_b be functions belonging to $L^2_{\frac{1}{M}}(\Omega \times \mathbb{R}^3)$ and $L^2_{\frac{v\cdot n(x)}{M}}((\partial\Omega \times \mathbb{R}^3)^+)$. When t tends to infinity, the solution to the initial boundary value problem (1.1)–(1.3–1.4) converges in $L^1(\Omega \times \mathbb{R}^3)$ to the unique stationary solution g of the linear stationary Boltzmann equation*

$$v \cdot \nabla_x g = Q(g), \tag{1.7}$$

with $\tilde{g} \in L^2$, complemented with the boundary condition

$$g(x,v) = f_b(x,v), \quad (x,v) \in (\partial\Omega \times \mathbb{R}^3)^+. \tag{1.8}$$

Proof. Due to the linearity of (1.1), f can be split into the sum of the solution to (1.1) with initial condition f_i and zero boundary condition, and the solution to (1.1) with a zero initial condition and f_b boundary condition. Again by linearity it is enough to consider nonnegative initial and boundary values. Let us first prove that the first part tends to zero in $L^1_{x,v}$ when t tends to infinity. Let $d\alpha(x)$ denote the measure on the boundary $\partial\Omega$. The Green formula applied to (1.1), together with (1.6), implies

$$\begin{aligned}
&\int_{\Omega\times\mathbb{R}^3} \frac{|\tilde f(t,x,v)|^2}{\nu(v)}dxdv \\
&+\int_0^t\int_{(\partial\Omega\times\mathbb{R}^3)^-} \frac{|v\cdot n(x)|}{\nu(v)}|\tilde f(s,x,v)|^2 dsd\alpha(x)dv \\
&+\sigma\int_0^t\int_{\Omega\times\mathbb{R}^3}|\tilde w(s,x,v)|^2 dsdxdv \le \int_{\Omega\times\mathbb{R}^3} \frac{|\tilde f(t,x,v)|^2}{\nu(v)}dxdv \\
&+\int_0^t\int_{(\partial\Omega\times\mathbb{R}^3)^-} \frac{|v\cdot n(x)|}{\nu(v)}|\tilde f(s,x,v)|^2 dsd\alpha(x)dv \\
&-\int_0^t\int_\Omega (\tilde Q\tilde w,\tilde w)(s,x)dsdx = \int_{\Omega\times\mathbb{R}^3} \frac{|\tilde f_i(x,v)|^2}{\nu(v)}dxdv. \qquad (1.9)
\end{aligned}$$

It follows that $\int_{\Omega\times\mathbb{R}^3}\frac{1}{\nu(v)}|\tilde f(t,x,v)|^2dxdv$ decreases with time. Moreover, there is a sequence t_j tending to infinity and a function $\tilde f^\infty$ such that $\tilde f(t_j+t)$ tends weakly to $\tilde f^\infty$ in $L^2_{\frac{1}{\nu}}$, and $\int_0^t\int_{\Omega\times\mathbb{R}^3}|\tilde w(t_j+t,x,v)|^2\ dtdxdv$ and $\int_0^1\int_{(\partial\Omega\times\mathbb{R}^3)^-}\frac{|v\cdot n(x)|}{\nu(v)}|\tilde f(t_j+t,x,v)|^2\,dtd\alpha(x)dv$ tend to zero when j tends to infinity. The function f^∞ is a weak solution to the equation (1.1) with zero boundary condition and $\tilde w_{f^\infty}=0$. It follows that $f^\infty = c^\infty M$ for some constant c^∞. The null boundary conditions imply that $c^\infty = 0$. Hence $\tilde f(t)$ weakly converges to zero in $L^2_{\frac{1}{v}}$. Since

$$\|f(t)\|_{L^1_{x,v}} = \int_\Omega\int_{\mathbb{R}^3}\sqrt{\frac{M(v)}{\nu(v)}}\ \tilde f(t,x,v)dxdv,$$

$f(t)$ tends to zero strongly in $L^1_{x,v}$, when t tends to infinity.

Let us prove that the solution to the initial boundary value problem (1.1)–(1.3–1.4) with null initial condition and boundary condition f_b tends to a stationary solution g to (1.7–1.8). In view of possible future applications we prefer not to give a proof based on the existence of stationary solutions being known but instead to deduce their existence from the long time behavior. By translation invariance in time, the solution at time $t+s$ is the sum of the solution at time t and the contribution at time s carried forward with zero boundary values to $t+s$. So $f(t,x,v)$ is increasing with time and converges pointwise in x,v to a measurable function f^∞, when t tends to infinity. Let us prove that $\tilde f^\infty$ belongs to L^2. For any set $\Gamma\subset\Omega\times\mathbb{R}^3$, multiplying (1.1) by $\tilde f$ and using Green's formula leads to

$$\begin{aligned}
&\int_{\Gamma^c}\frac{1}{\nu(v)}(|\tilde f(t+s)|^2-|\tilde f(t)|^2)dxdv+\int_\Gamma\frac{1}{\nu(v)}|\tilde f(t+s)|^2dxdv \\
&+\sigma\int_t^{t+s}\int_{\Omega\times\mathbb{R}^3}|\tilde w(\tau,x,v)|^2d\tau dxdv
\end{aligned}$$

$$+\int_t^{t+s}\int_{(\partial\Omega\times\mathbb{R}^3)^-}\frac{|v\cdot n(x)|}{\nu(v)}|\tilde f(\tau,x,v)|^2 d\tau d\alpha(x)dv$$

$$\leq \int_\Gamma \frac{1}{\nu(v)}|\tilde f(t)|^2 dxdv + sc, \tag{1.10}$$

where

$$c := \int_{(\partial\Omega\times\mathbb{R}^3)^+}\frac{v\cdot n(x)}{\nu(v)}\,|\tilde f_b(x,v)|^2 d\alpha(x)dv.$$

Let $\Gamma_{s\epsilon}\subset\Omega\times\mathbb{R}^3$ be the set of (y,v) such that $|v|\leq\frac{1}{\epsilon}$ and the characteristic starting at (t,y,v), namely, $\{(t+\tau,y+\tau v,v);\,\tau\geq 0\}$, reaches $(\partial\Omega\times\mathbb{R}^3)^-$ at a time smaller than $t+s$. Then from the exponential form of the equation

$$\int_t^{t+s}\int_{(\partial\Omega\times\mathbb{R}^3)^-}\frac{|v\cdot n(x)|}{\nu(v)}\,|\tilde f(\tau,x,v)|^2 d\tau d\alpha(x)dv$$

$$\geq\ c(s,\epsilon)\int_{\Gamma_{s\epsilon}}\frac{1}{\nu(v)}\,|\tilde f(t,x,v)|^2 dxdv$$

for some $c(s,\epsilon)\in(0,1)$. Hence by (1.10)

$$\int_{\Gamma_{s\epsilon}}\frac{1}{\nu}|\tilde f(t+s)|^2 dxdv \leq (1-c(s,\epsilon))\int_{\Gamma_{s\epsilon}}\frac{1}{\nu}|\tilde f(t)|^2 dxdv + sc.$$

It follows that

$$\sup_{t>0}\int_{\Gamma_{s\epsilon}}\frac{1}{\nu(v)}\,|\tilde f(t,x,v)|^2 dxdv$$

is finite. Then by (1.10)

$$\sup_{t>0}\int_0^{\frac{3}{2}}\int_{\Omega\times\mathbb{R}^3}|\tilde w(t+s,x,v)|^2 dsdxdv$$

is finite. Hence, by the previous two lines,

$$\sup_{t>0}\int_0^{\frac{3}{2}}\int_{\Gamma_{s\epsilon}}|c_f(t+s,x)|^2 M(v)dsdxdv$$

is bounded. Since Ω is bounded and convex, it follows that (for ϵ small)

$$\inf_{x\in\Omega}\int_{(x,v)\in\Gamma_{\frac{1}{2}\epsilon}}\nu(v)M(v)dv > c\int_{\mathbb{R}^3}\nu(v)M(v)dv.$$

This implies that

$$\sup_{t>0}\int_{\frac{1}{2}}^{\frac{3}{2}}\int_{\Omega\times\mathbb{R}^3}|c_f(t+s,x)|^2\nu(v)M(v)dsdxdv<\infty.$$

And so

$$\sup_{t>0}\int_0^1\int_{\Omega\times\mathbb{R}^3}|c_f(t+s,x)|^2\nu(v)M(v)dsdxdv$$

is bounded. Finally

$$\sup_{t>0} \int_0^1 \int_{\Omega\times\mathbb{R}^3} |\tilde{f}(t+s,x,v)|^2 dsdxdv$$

and (since $\tilde{f}$ is an increasing function of time)

$$\sup_{t>0} \int_{\Omega\times\mathbb{R}^3} |\tilde{f}(t,x,v)|^2 dxdv$$

are bounded. Hence $\tilde{f}^\infty$ belongs to $L^2(\Omega\times\mathbb{R}^3)$. Moreover, f^∞ solves the stationary problem (1.7–1.8), and $\tilde{f}(t)$ tends to $\tilde{f}^\infty$ in $L^2(\Omega\times\mathbb{R}^3)$, when t tends to infinity. Finally the solution of the stationary problem is unique in the class of functions g such that $\tilde{g}\in L^2$. Indeed, let us prove that if a function g such that $\tilde{g}\in L^2$ satisfies

$$v\cdot\nabla_x g = Q(g), \tag{1.11}$$

$$g(x,v)=0, \quad (x,v)\in(\partial\Omega\times\mathbb{R}^3)^+, \tag{1.12}$$

then $g=0$. We notice that

$$\int Q^+(g)\mathrm{sign}(g)dv - \int \nu|g|dv \le \int Q^+(|g|)dv - \int \nu|g|dv = 0.$$

So, multiplying (1.11) by $\mathrm{sign}(g)$ and integrating implies that

$$\int_{(\partial\Omega\times\mathbb{R}^3)^-} v\cdot n|g| = 0.$$

Hence

$$g(x,v)=0, \quad (x,v)\in\partial\Omega\times\mathbb{R}^3. \tag{1.13}$$

$\tilde{g}$ belongs to L^2 and can be expressed by (1.5) as

$$\tilde{g} = c\sqrt{M\nu} + \tilde{w}. \tag{1.14}$$

It satisfies

$$\frac{1}{\nu(v)}\, v\cdot\nabla_x\tilde{g} = \tilde{Q}\tilde{w}. \tag{1.15}$$

Integrating (1.15) with respect to x and v using (1.6) implies by (1.13) that $\tilde{w}$ is equal to zero. Then $\tilde{g}=0$ follows from (1.11–1.12). □

2. The Milne problem. Write the velocity as $v=(\xi,v')$ with ξ the velocity component in the x-direction and v' the orthogonal velocity component. We consider the Milne problem

$$\frac{\xi}{\nu}\,\partial_x\tilde{f} = \tilde{Q}\tilde{f}, \quad x>0, \quad v\in\mathbb{R}^3, \tag{2.1}$$

$$\tilde{f}(0,v)=\tilde{\varphi}(v), \quad \xi>0. \tag{2.2}$$

THEOREM 2.1. *Let $\tilde{\varphi}\in L^2_{\frac{\xi}{\nu}}(\mathbb{R}_+\times\mathbb{R}^2)$. There is a solution to* (2.1–2.2) *in the set $\{\tilde{f};\exists c_\infty\in\mathbb{R},\ \tilde{f}-c_\infty\sqrt{\nu M}\in L^2(\mathbb{R}_+\times\mathbb{R}^3)\}$, which satisfies $\int\xi f(x,v)dv = c_\infty u$ for all $x\ge 0$. For $u<0$, this holds with $c_\infty=0$, i.e., $\int\xi f(x,v)dv=0$ for all $x\ge 0$.*

Proof. There is—by the approach of Theorem 1.3—a unique solution $\tilde{f}^a \in L^2([0,a]\times\mathbb{R}^3)$ of

$$\frac{\xi}{\nu}\,\partial_x \tilde{f}^a = \tilde{Q}\tilde{f}, \quad x\in[0,a], \quad v\in\mathbb{R}^3,$$

together with (2.2) and boundary conditions at $x=a$ suitable for our purpose. For $u\geq 0$, we take

$$\tilde{f}^a(a,\xi,v') = \tilde{f}^a(a,-\xi+2u,v'), \quad \xi<0, \tag{2.3}$$

whereas for $u<0$,

$$\tilde{f}^a(a,v) = \frac{\sqrt{M(v)\nu(v)}}{\int_{\xi<0}|\xi|M(v)dv}\int_{\xi>0}\xi f^a(a,v)dv, \quad \xi<0. \tag{2.4}$$

Remark. The boundary condition (2.3) can only be used for $u>0$. A desired nonnegativity (2.9) would not be obtained from the boundary condition (2.4) for $u>0$.

Clearly $\int \xi f^a(x,v)dv$ is constant in both cases, moreover equal to zero for $u\leq 0$. Denote by uc_a this constant and bound it for $u>0$ from above and below. First

$$uc_a = \int \xi f^a(0,v)dv \leq \int_{\xi>0}\xi\varphi(v)dv. \tag{2.5}$$

Let $\tilde{f}^a(x,v) = c^a(x)\sqrt{\nu(v)M(v)}+\tilde{w}^a(x,v)$ be the decomposition of $\tilde{f}^a$ from section 1. By orthogonality

$$-(\tilde{Q}\tilde{f}^a,\tilde{f}^a) = -(\tilde{Q}\tilde{w}^a,\tilde{w}^a) \geq \sigma(\tilde{w}^a,\tilde{w}^a). \tag{2.6}$$

Multiplying (2.1) by $\tilde{f}^a$ and integrating over $\mathbb{R}^3_v$ leads to

$$\partial_x\int\frac{\xi}{\nu}\,|\tilde{f}^a|^2(x,v)dv = 2(\tilde{Q}\tilde{f}^a,\tilde{f}^a) \leq -2\sigma\|\tilde{w}^a\|^2 \leq 0. \tag{2.7}$$

Hence for $u\geq 0$,

$$\begin{aligned}\int\frac{\xi}{\nu}\,|\tilde{f}^a|^2(x,v)dv &\geq \int\frac{\xi}{\nu}\,|\tilde{f}^a|^2(a,v)dv \\ &\geq \int_{\xi<0}\frac{\xi}{\nu}\,|\tilde{f}^a|^2(a,v)dv + \int_{\xi>2u}\frac{\xi}{\nu}\,|\tilde{f}^a|^2(a,v)dv \\ &= 2u\int_{\xi>2u}\frac{1}{\nu}\,|\tilde{f}^a|^2(a,v)dv \geq 0,\end{aligned} \tag{2.8}$$

whereas for $u<0$,

$$\begin{aligned}\int\frac{\xi}{\nu}\,|\tilde{f}^a|^2(x,v)dv &\geq \int\frac{\xi}{\nu}\,|\tilde{f}^a|^2(a,v)dv \\ &\geq \left(1-\frac{\int_{\xi>0}\xi M}{\int_{\xi<0}|\xi|M}\right)\int_{\xi>0}\frac{\xi}{\nu}\,|\tilde{f}^a|^2(a,v)dv \geq 0.\end{aligned} \tag{2.9}$$

Indeed, using (2.4)

$$\int_{\xi<0} \frac{|\xi|}{\nu(v)}\ |\tilde f^a|^2(a,v)dv = \frac{1}{\int_{\xi<0}|\xi|M}\ \left(\int_{\xi>0}\xi f^a(a,v)dv\right)^2$$

$$\leq\ \frac{\int_{\xi>0}\xi M}{\int_{\xi<0}|\xi|M}\ \int_{\xi>0}\frac{\xi}{\nu(v)}\ |\tilde f^a|^2(a,v)dv.$$

But $\frac{\int_{\xi>0}\xi M(v)dv}{\int_{\xi<0}|\xi|M(v)dv} < 1$ for $u<0$ and so (2.9) follows. Finally by (2.8)

$$uc_a \geq \int_{\xi<0}\xi f^a(0,v)dv$$

$$=\ -\int_{\xi<0}|\xi|\ \sqrt{\frac{M(v)}{\nu(v)}}\ \tilde f^a(0,v)dv$$

$$\geq\ -\left(\int_{\xi<0}|\xi|M(v)dv\int_{\xi<0}\ \frac{|\xi|}{\nu}\ |\tilde f^a|^2(0,v)dv\right)^{\frac12}$$

$$\geq\ -\left(\int_{\xi<0}|\xi|M(v)dv\int_{\xi>0}\ \frac{\xi}{\nu(v)}\ \tilde\varphi^2(v)dv\right)^{\frac12}. \tag{2.10}$$

In the case $u=0$ the theorem can from here be derived using, e.g., [2] or [16]. So let us only detail the case when $u\neq 0$. First $\tilde w^a$ is bounded in $L^2([0,a]\times\mathbb{R}^3)$ uniformly with respect to a. Indeed by (2.8), (2.9)

$$\sigma\int_0^a\int|\tilde w^a|^2(x,v)dxdv$$

$$\leq\ -\int_0^a(\tilde Q\tilde f^a,\tilde f^a) = -\int_0^a\int\ \frac{\xi}{\nu(v)}\ \tilde f^a\partial_x\tilde f^a dxdv$$

$$=\ \frac12\left(\int\frac{\xi}{\nu(v)}\ |\tilde f^a|^2(0,v)dv - \int\frac{\xi}{\nu}\ |\tilde f^a|^2(a,v)dv\right) \tag{2.11}$$

$$\leq\ \frac12\int_{\xi>0}\ \frac{\xi}{\nu(v)}\ \tilde\varphi^2(v)dv.$$

Since $f^a(x,v) = c^a(x)M(v) + w^a(x,v)$,

$$|c_a - c^a(x)| = \frac{1}{|u|}\ \left|\int\xi w^a(x,v)dv\right|$$

$$\leq\ \frac{1}{|u|}\left(\int\xi^2\ \frac{M(v)}{\nu(v)}\ dv\int|\tilde w^a|^2(x,v)dv\right)^{\frac12}$$

so that

$$\int_0^a\int\left|\tilde f^a(x,v) - c_a\sqrt{M(v)\nu(v)}\ \right|^2 dxdv \leq c\int_0^a\int|\tilde w^a|^2(x,v)dxdv. \tag{2.12}$$

By (2.5), (2.11), and (2.12), there exist a sequence (a_j) tending to infinity, a number c_∞, and a function $\tilde f$ such that c_{a_j} tends to c_∞ and $\tilde f^{a_j} - c_{a_j}\sqrt{\nu M}$ converges weakly

in L^2 to $\tilde{f} - c_\infty\sqrt{\nu M}$. One can then check that $\tilde{f}$ is a solution to the Milne problem (2.1–2.2) with the desired properties. ∎

For the boundary layer study in section 3, some decay of $\tilde{g} := \tilde{f} - c_\infty\sqrt{\nu M}$ is needed.

PROPOSITION 2.2. *Assume that*

$$\sup_{v\in\mathbb{R}^3_+} |\tilde{\varphi}(v)|(1+|v|)^s < \infty, \quad s \in \mathbb{R}_+. \tag{2.13}$$

Then for $s \in \mathbb{R}_+$, $\int \frac{|\xi|}{\nu(v)}|\tilde{g}(x,v)|^2 dv \le cx^{-s}, \quad x > 0.$

This result can essentially be found in [11]. For the convenience of the reader we give their proof with the differences introduced by the nonzero bulk velocity of the Maxwellian. The proof is based on the entropy method introduced by Bardos, Santos, and Sentis [2], and uses the following decay properties of $\tilde{g}$, pointwise in v and integral in x.

LEMMA 2.3. *Under* (2.13) *for* $s \in \mathbb{R}_+$,

$$\sup_{x>0, v\in\mathbb{R}^3} (1+|v|)^s|\tilde{g}(x,v)| \le c_1, \tag{2.14}$$

$$\int_0^\infty \int_{\mathbb{R}^3} x^s|\tilde{g}(x,v)|^2 dxdv \le c_2. \tag{2.15}$$

The constants c_1, c_2 *depend on* φ *and* s.

Proof of Proposition 2.2. Write

$$\int_{\mathbb{R}^3} \frac{|\xi|}{\nu}\,|\tilde{g}(x,v)|^2 dv \le \int_{|\xi|\le r} \frac{|\xi|}{\nu}\,|\tilde{g}(x,v)|^2 dv$$
$$+ \int_{|\xi|>r, |v|\le\rho} \frac{|\xi|}{\nu}\,|\tilde{g}(x,v)|^2 dv + \int_{|v|\ge\rho} \frac{|\xi|}{\nu}\,|\tilde{g}(x,v)|^2 dv$$
$$:= a + b + c.$$

By (2.14), $a(r)$ and $c(\rho)$ satisfy

$$a(r) \le cr \int_{|\xi|\le r} (1+|v|)^{-2s-\gamma} dv \le cr \quad \text{for } s > \frac{3}{2} - \frac{\gamma}{2}, \tag{2.16}$$

$$c(\rho) \le c \int_{|v|\ge\rho} (1+|v|)^{-2s+1-\gamma} dv \le c\rho^{-1} \quad \text{for } s > \frac{5}{2} - \frac{\gamma}{2}. \tag{2.17}$$

Evidently

$$b(r,\rho) \le cr^{-1}\rho^\gamma \int_{\mathbb{R}^3} \left|\frac{\xi\tilde{g}(x,v)}{\nu(v)}\right|^2 dv.$$

Now

$$\frac{\xi}{\nu}\,(\tilde{g}(y,v) - \tilde{g}(x,v)) = \int_x^y \tilde{Q}(\tilde{w}_g)(z,v)dz,$$

and so by (2.15)

$$\int_{|\xi|>r, |v|\le\rho} \left|\frac{\xi}{\nu}\,(\tilde{g}(y,v) - \tilde{g}(x,v))\right|^2 dv \le c\left(\int_x^y \left(\int_{\mathbb{R}^3} |\tilde{w}_g(z,v)|^2 dv\right)^{\frac{1}{2}} dz\right)^2$$
$$\le\ cx^{-s+1}\int_x^y \int_{\mathbb{R}^3} z^s|\tilde{g}(z,v)|^2 dvdz \le cx^{-s+1}.$$

Since $\tilde{g} \in L^2(\mathbb{R}_+ \times \mathbb{R}^3)$, a sequence $y_j \to \infty$ can be chosen so that $\lim_{j\to\infty} \tilde{g}(y_j, .) = 0$ in $L^2(\mathbb{R}^3)$. It follows that

$$\int_{|\xi|>r, |v|\le\rho} \left| \frac{\xi}{\nu} \tilde{g}(x,v) \right|^2 dv \le c x^{-s+1}$$

and so

$$b(r,\rho) \le c r^{-1} \rho^\gamma x^{-s+1}.$$

The choice $r = x^{-\frac{s}{3}}$, $\rho = x^{\frac{s}{3}}$ in (2.16–2.17) gives the desired result. □

Proof of (2.14). By [11, Prop. 4.3]

$$\sup_{x>0} \|\tilde{g}(x, .)\|_{L^2(\mathbb{R}^3)} \le c, \tag{2.18}$$

where c depends on $\tilde{\varphi}$ in the $L^2 \cap L^\infty$ sense. Also

$$\tilde{Q}^+(\tilde{g})(x,v) = \int_{\mathbb{R}^3} k(v, v_1) \tilde{g}(x, v_1) dv_1 \tag{2.19}$$

with

$$|k(v, v_1)| \le (1 + |v| + |v_1|)^{-1+\gamma} (1 + |v_1|)^{-\frac{\gamma}{2}} \phi(v, v_1)$$

and

$$\int_{\mathbb{R}^3} \phi^2(v, v_1) dv_1 \le c(1 + |v|)^{-1-\gamma}.$$

Hence

$$(1 + |v|)^{\frac{3}{2}-\frac{\gamma}{2}} |\tilde{Q}^+ \tilde{g}(x,v)| \le c \|\tilde{g}(x, .)\|_{L^2(\mathbb{R}^3)}.$$

The exponential form of (2.1–2.2) gives

$$\begin{aligned} (1 + |v|)^{\frac{3}{2}-\frac{\gamma}{2}} |\tilde{g}(x,v)| \le{}& |\tilde{\varphi}(v)| (1 + |v|)^{\frac{3}{2}-\frac{\gamma}{2}} \chi_{\xi>0} \\ &+ c \sup_{x>0} \|\tilde{g}(x, .)\|_{L^2(\mathbb{R}^3)}. \end{aligned} \tag{2.20}$$

Here $\chi_{\xi>0}$ is the characteristic function of the set $\{v \in \mathbb{R}^3;\ \xi > 0\}$. By (2.18) the right-hand side is finite. Also

$$\int_{\mathbb{R}^3} (1 + |v|)^{s+1} (1 + |v_1|)^{-s} k(v, v_1) dv_1 < \infty, \quad s \in \mathbb{R}_+.$$

Using this together with (2.20), a direct estimate in the exponential form of (2.1–2.2) gives (2.14). □

Proof of 2.15. By (2.11), which also holds for $\tilde{w}_g$, there is a sequence $y_j \to \infty$ such that

$$\int |\tilde{w}_g(y_j, v)|^2 dv \to 0. \tag{2.21}$$

It follows from Theorem 2.1 that $\int_{\mathbb{R}^3} \xi g(x,v)dv = 0$, $x \in \mathbb{R}_+$, and so the orthogonal decomposition $\tilde{g}(x,v) = c^\infty(x)\sqrt{\nu(v)M(v)} + \tilde{w}_g(x,v)$ gives

$$|uc^\infty(x)| = \left| \int \xi w_g(v) dv \right|$$

$$\leq \left(\frac{\xi^2 M(v)}{\nu(v)} dv \int |\tilde{w}_g(x,v)|^2 dv \right)^{\frac{1}{2}}. \tag{2.22}$$

In particular

$$\lim_{j\to\infty} c^\infty(y_j) = 0. \tag{2.23}$$

Now the proof is based on a study of the entropy flux

$$H(x) = \int \frac{\xi}{\nu} \, |\tilde{g}(x,v)|^2 dv.$$

Using the orthogonal decomposition of $\tilde{g}$ and splitting the domain of integration we get

$$\lim_{j\to\infty} H(y_j) \leq \lim_{j\to\infty} Cc(y_j)^2 + \lim_{j\to\infty} C \int_{\mathbb{R}^3} \tilde{w}_g(y_j,v)^2 dv$$
$$+ \lim_{j\to\infty} C \int_{|v|\geq\rho} \frac{\xi}{\nu(v)} \, \tilde{g}(y_j,v)^2 dv.$$

By (2.21) and (2.23) the first two of these limits are zero. By (2.14) the third one is bounded by

$$c \int_{|v|\geq\rho} \frac{|\xi|}{\nu(v)} \, (1+|v|)^{-5} dv \leq \frac{c}{\rho}.$$

It follows that $\lim_{j\to\infty} H(y_j) = 0$. A multiplication of (2.1) by $\tilde{g}$ and v-integration show that $H(x)$ is nonincreasing. And so

$$0 \leq H(x) \leq H(0) \leq \int_{\xi>0} \frac{\xi}{\nu} \, \tilde{\varphi}(v)^2 dv. \tag{2.24}$$

Since $\tilde{g} \in L^2(\mathbb{R}_+ \times \mathbb{R}^3)$, it is enough for (2.15) to consider

$$\int_1^\infty \int_{\mathbb{R}^3} x^s \tilde{g}(x,v)^2 dx dv.$$

A multiplication of (2.1) by $x^s\tilde{g}$ and integration gives

$$H(y)y^s + \int_1^y \left(x^s \int_{\mathbb{R}^3} \tilde{w}_g(x,v)^2 dv - s x^{s-1} H(x) \right) dx$$
$$\leq H(1) \leq \int_{\xi>0} \frac{\xi}{\nu} \, \tilde{\varphi}(v)^2 dv. \tag{2.25}$$

The positivity of $H(y)$ implies that

$$\int_1^y \left(x^s \int_{\mathbb{R}^3} \tilde{w}_g(x,v)^2 dv - s x^{s-1} H(x) \right) dx \leq H(1).$$

Now

$$\int_{|v|\le\rho} \frac{|\xi|}{\nu}\, \tilde g(x,v)^2 dv \le c\rho^{1-\gamma}\|\tilde g(x,.)\|^2_{L^2(\mathbb{R}^3)},$$

and by (2.14), for any $\lambda \in \mathbb{R}_+$,

$$\int_{|v|\ge\rho} \frac{|\xi|}{\nu}\, \tilde g(x,v)^2 dv \le c_\lambda \rho^{-\lambda}.$$

This together with (2.22) and (2.25) implies for some $\alpha > 0$ that

$$\int_1^y x^s \left(\int \tilde g(x,v)^2 dv\right)\left(\alpha - \frac{c\rho^{1-\gamma}}{x}\right) dx \le H(1) + c_\lambda \int_1^y \rho^{-\lambda} s x^{s-1} dx.$$

The choice $\rho(x) = (\frac{\alpha x}{2c})^{\frac{1}{1-\gamma}}, \lambda > s(1-\gamma)$ yields

$$\int_1^\infty x^s \int \tilde g(x,v)^2 dv dx \le c_s. \qquad \square$$

3. The fluid approximation with initial and boundary layers for nonzero bulk velocity. Introduce the mean free path $\epsilon > 0$ and take $u > 0$. This section considers the slab problem

$$\partial_t f_\epsilon + \frac{1}{\epsilon^2}\xi \partial_x f_\epsilon = \frac{1}{\epsilon^3} Q(f_\epsilon), \quad t > 0, \quad x \in (0,1), \quad v \in \mathbb{R}^3, \tag{3.1}$$

together with the initial condition

$$f_\epsilon(0,x,v) = f_i(x,v), \quad x \in (0,1), \quad v \in \mathbb{R}^3, \tag{3.2}$$

and the boundary conditions

$$f_\epsilon(t,0,v) = f_0(v), t > 0, \xi > 0; \qquad f_\epsilon(t,1,v) = f_1(v), \quad t > 0, \quad \xi < 0. \tag{3.3}$$

After an initial layer, the unique solution satisfies the stationary problem

$$\xi \partial_x g_\epsilon = \frac{1}{\epsilon} Q(g_\epsilon), \quad x \in (0,1), \quad v \in \mathbb{R}^3, \tag{3.4}$$

together with the boundary conditions

$$g_\epsilon(0,v) = f_0(v), \quad \xi > 0; \quad g_\epsilon(1,v) = f_1(v), \quad \xi < 0, \tag{3.5}$$

if one disregards the error term from the initial layer. Moreover, g_ϵ can be split into a fluid part cM in the interior of the domain together with boundary layers and with the error term tending to zero strongly in L^1, when ϵ tends to zero.

THEOREM 3.1. *Let f_i, f_0, f_1 be given with $\tilde f_i \in L^2_{\frac{1}{\nu}}((0,1)\times\mathbb{R}^3)$, $\tilde f_0 \in L^2_{\frac{\xi}{\nu}}(\mathbb{R}^\xi_+ \times \mathbb{R}^2)$, $\tilde f_1 \in L^2_{\frac{|\xi|}{\nu}}(\mathbb{R}^\xi_- \times \mathbb{R}^2)$. Denote by f_ϵ and g_ϵ the unique solutions of* (3.1–3.3)*, respectively,* (3.4–3.5) *with these given initial and boundary values. Then for $t > 0$*

$$\lim_{\epsilon\to 0} f_\epsilon(t,.) - g_\epsilon(.) = 0$$

strongly in $L^1((0,1)\times\mathbb{R}^3)$.

THEOREM 3.2. *Under the same hypotheses there are a constant c, boundary layer terms $l_\epsilon(x,v) = l^0(\frac{x}{\epsilon}, v)$, and $r_\epsilon(x,v) = r^0(\frac{x-1}{\epsilon}, v)$, with $\tilde{l}^0$ and $\tilde{r}^0$, respectively, belonging to $L^2(\mathbb{R}_+ \times \mathbb{R}^3)$ and $L^2(\mathbb{R}_- \times \mathbb{R}^3)$ such that*

$$g_\epsilon = cM + l_\epsilon + r_\epsilon + S_\epsilon. \tag{3.6}$$

Here the terms $\tilde{l}^0$ and $\tilde{r}^0$ have the decay properties of Proposition 2.2, and the remainder term S_ϵ tends to 0 in $L^1((0,1) \times \mathbb{R}^3_v)$, when ϵ tends to 0.

The proof of Theorem 3.1 is based on the following lemma.

LEMMA 3.3. *Let f_i be given with $0 \le \tilde{f}_i \in L^2_{\frac{1}{\nu}}((0,1) \times \mathbb{R}^3)$. Denote by $f_\epsilon(t,x,v)$ the solution of (3.1–3.3) with f_i as initial value and boundary values $f_0 = f_1 = 0$. For $s > 0$, $f_\epsilon(s,.,.)$ converges strongly in $L^1((0,1) \times \mathbb{R}^3)$ to zero, when ϵ tends to zero.*

Proof. After scaling $t \to \frac{t}{\epsilon^2}$, the solution (still denoted f_ϵ) satisfies

$$(\partial_t + \xi\partial_x) f_\epsilon = \frac{1}{\epsilon}\, Q(f_\epsilon), \quad t \in \mathbb{R}_+, \quad x \in (0,1), \quad v \in \mathbb{R}^3,$$
$$f_\epsilon(0,.) = f_i(.),$$
$$f_\epsilon(t,0,v) = 0, \quad t > 0, \quad \xi > 0, \quad f_\epsilon(t,1,v) = 0, \quad t > 0, \quad \xi < 0.$$

Green's formula implies that mass and entropy

$$\int_0^1 \int_{\mathbb{R}^3} f_\epsilon(t,x,v)\,dxdv, \quad \int_0^1 \int_{\mathbb{R}^3} \frac{\tilde{f}_\epsilon(t,x,v)^2}{\nu(v)}\,dxdv$$

are decreasing with time. Suppose that the lemma does not hold. Then for some $s > 0$, there is a sequence (ϵ_j) with $\lim_{j\to\infty} \epsilon_j = 0$ such that

$$\inf_j \int_0^1 \int_{\mathbb{R}^3} f_{\epsilon_j}(t_j,x,v)\,dxdv > 0.$$

Here $t_j = \frac{s}{\epsilon_j^2}$. The lemma follows if for a subsequence of (t_j) (still denoted (t_j)) there is a sequence (t'_j) with $0 \le t'_j \le t_j$ such that

$$\lim_{j\to\infty} \int_0^1 \int_{\mathbb{R}^3} f_{\epsilon_j}(t'_j,x,v)\,dxdv = 0.$$

With $\tilde{f}_{\epsilon_j} := \tilde{f}_j, \tilde{w}_{\epsilon_j} := \tilde{w}_j$, (1.9) gives

$$\int_0^1 \int_{\mathbb{R}^3} \frac{\tilde{f}_j(t_j,x,v)^2}{\nu(v)}\,dxdv + \frac{\sigma}{\epsilon_j} \int_0^{t_j} \int_0^1 \int_{\mathbb{R}^3} \tilde{w}_j(\tau,x,v)^2 d\tau dxdv \le \int_0^1 \int_{\mathbb{R}^3} \frac{\tilde{f}_i(x,v)^2}{\nu(v)}\,dxdv := \sigma c_1.$$

If each of the $s\epsilon_j^{-\frac{3}{2}}$ intervals $[l\epsilon_j^{-\frac{1}{2}}, (l+1)\epsilon_j^{-\frac{1}{2}}]$ of $[0,t_j]$ has

$$\frac{1}{\epsilon_j} \int_{l\epsilon_j^{-\frac{1}{2}}}^{(l+1)\epsilon_j^{-\frac{1}{2}}} \int_0^1 \int_{\mathbb{R}^3} \tilde{w}_j(\tau,x,v)^2 d\tau dxdv > \epsilon_j^{\frac{3}{2}}\, \frac{c_1}{s},$$

then

$$\frac{\sigma}{\epsilon_j}\int_0^{t_j}\int_0^1\int_{\mathbb{R}^3}\tilde{w}_j(\tau,x,v)^2 d\tau dxdv > c_1\sigma.$$

This contradiction implies that for some interval $I_j \subset [0,t_j]$ and of length $\epsilon_j^{-\frac{1}{2}}$

$$\frac{1}{\epsilon_j}\int_{I_j}\int_0^1\int_{\mathbb{R}^3}\tilde{w}_j(\tau,x,v)^2 d\tau dxdv \le e_j^{\frac{3}{2}}\ \frac{c_1}{s}.$$

In particular

$$\lim_{j\to\infty}\epsilon_j^{-2}\int_{I_j}\int_0^1\int_{\mathbb{R}^3}\tilde{w}_j(\tau,x,v)^2 d\tau dxdv = 0.$$

With $I_j = (t_j', t_j'')$ it follows that for $t \ge 0$ (and some subsequence of the j's)

$$\tilde{f}_j(t_j'+t,x,v) \rightharpoonup \tilde{f}_\infty(t,x,v)$$

weakly in $L^2_{\frac{1}{\nu}}((0,1)\times\mathbb{R}^3)$. Here

$$\int_0^1\int_{\mathbb{R}^3}\frac{\tilde{f}_\infty(t,x,v)^2}{\nu(v)}\ dxdv \le \sigma c_1.$$

By the equicontinuity in t, it is enough to prove the above weak L^2-convergence for rational t's. Using (1.9) we have for t fixed and j large enough that

$$\int_0^1\int_{\mathbb{R}^3}\frac{1}{\nu(v)}\ f_j(t_j'+t,x,v)^2 dxdv \le \sigma c_1.$$

So a subsequence of $\tilde{f}_j(t_j'+t)$ converges weakly when $j\to 0$. We conclude with a Cantor diagonalization argument.

Also for a.e. $t>0$,

$$\tilde{w}_j(t_j'+t,x,v)\to 0$$

strongly in $L^2((0,1)\times\mathbb{R}^3)$, and so

$$\tilde{f}_\infty(t,x,v) = c_\infty(t,x,)\sqrt{\nu(v)M(v)}.$$

But $\tilde{f}_\infty$ satisfies

$$(\partial_t+\xi\partial_x)\tilde{f}_\infty = 0, \quad t>0, \quad x\in(0,1), \quad v\in\mathbb{R}^3,$$
$$\tilde{f}_\infty(t,0,v) = 0, \quad t>0, \quad \xi>0; \quad \tilde{f}_\infty(t,1,v) = 0, \quad t>0, \quad \xi<0,$$

and so $\tilde{f}_\infty \equiv 0$. In particular $\lim_{j\to\infty}\tilde{f}_j(t_j',.,.) = 0$ weakly in $L^2_{\frac{1}{\nu}}((0,1)\times\mathbb{R}^3)$. It follows that

$$0 \le \lim_{j\to\infty}\int_0^1\int_{\mathbb{R}^3} f_j(t_j,x,v)dxdv$$
$$\le \lim_{j\to\infty}\int_0^1\int_{\mathbb{R}^3} f_j(t_j',x,v)dxdv = \lim_{j\to\infty}\int_0^1\int_{\mathbb{R}^3}\sqrt{\frac{M(v)}{\nu(v)}}\ \tilde{f}_j(t_j',x,v)dxdv$$
$$= 0.$$

This completes the proof of the lemma. □

Proof of Theorem 3.1. The function $f_\epsilon - g_\epsilon$ satisfies (3.1–3.3) with initial value $f_i - g_i$ and boundary value zero. By linearity it is enough to prove the theorem when the boundary values are zero and $f_i - g_i \geq 0$, and this case is contained in Lemma 3.3. □

Proof of Theorem 3.2. Essentially by section 1, there is a unique solution $g_\epsilon(x,v)$ with $\tilde{g}_\epsilon \in L^2$ to

$$\begin{aligned} \xi \partial_x g_\epsilon &= \frac{1}{\epsilon}\, Q(g_\epsilon), \\ g_\epsilon(0,v) &= f_0(v), \quad \xi > 0, \\ g_\epsilon(1,v) &= f_1(v), \quad \xi < 0. \end{aligned}$$

From the results on the Milne problem in Theorem 2.1, there is a constant c such that

$$\begin{aligned} \frac{\xi}{\nu(v)}\, \partial_x \tilde{q}(x,v) = \tilde{Q}\tilde{q}(x,v), \quad x > 0, \quad v \in \mathbb{R}^3, \\ \tilde{q}(0,v) = \tilde{f}_0(v), \quad \xi > 0 \end{aligned}$$

has a solution $\tilde{q} = c\sqrt{\nu M} + \tilde{l}$, with $\tilde{l} \in L^2(\mathbb{R}^+ \times \mathbb{R}^3_v)$. Define l^0 by

$$l^0(y,v) = \sqrt{\frac{M(v)}{\nu(v)}}\, \tilde{l}(y,v).$$

Also by Theorem 2.1 the Milne problem

$$\begin{aligned} \frac{\xi}{\nu(v)}\, \tilde{r}_x(x,v) = \tilde{Q}\tilde{r}(x,v), \quad x < 0, \quad v \in \mathbb{R}^3, \\ \tilde{r}(0,v) = \tilde{f}_1(v) - c\sqrt{\nu(v)M(v)}, \quad \xi < 0 \end{aligned}$$

has a solution $\tilde{r} \in L^2(\mathbb{R}_- \times \mathbb{R}^3_v)$. Indeed for $u > 0$, looking for a solution defined in $\mathbb{R}_-$ corresponds to considering $u < 0$ in the $\mathbb{R}_+$ situation. Define r^0 by

$$r^0(y,v) = \sqrt{\frac{M(v)}{\nu(v)}}\, \tilde{r}(y,v).$$

$S_\epsilon := g_\epsilon - cM - l_\epsilon - r_\epsilon$ satisfies

$$\begin{aligned} \xi \partial_x S_\epsilon = \frac{1}{\epsilon}\, Q(S_\epsilon), \quad x \in (0,1), \quad v \in \mathbb{R}^3, \\ S_\epsilon(0,v) = -r^0\left(-\frac{1}{\epsilon}, v\right), \quad \xi > 0, \\ S_\epsilon(1,v) = -l^0\left(\frac{1}{\epsilon}, v\right), \quad \xi < 0. \end{aligned} \tag{3.7}$$

Introduce as above the orthogonal decomposition

$$\tilde{S}_\epsilon(x,v) = c^\epsilon(x)\sqrt{\nu M} + \tilde{w}_\epsilon.$$

It follows from (3.4), Green's formula, and (1.6) that

$$\int_{\xi<0} \frac{|\xi|}{\nu}\ |\tilde{S}_\epsilon(0,v)|^2 dv + \int_{\xi>0} \frac{\xi}{\nu}\ |\tilde{S}_\epsilon(1,v)|^2 dv$$

$$+ \frac{\sigma}{\epsilon}\int_0^1 \int_{\mathbb{R}^3} |\tilde{w}_\epsilon(x,v)|^2 dx dv$$

$$\leq \int_{\xi>0} \frac{\xi}{\nu}\ \left|\tilde{r}^0\left(-\frac{1}{\epsilon},v\right)\right|^2 dv + \int_{\xi<0} \frac{|\xi|}{\nu}\ \left|\tilde{l}^0\left(\frac{1}{\epsilon},v\right)\right|^2 dv. \tag{3.8}$$

By Proposition 2.2 the right-hand side tends superalgebraically to zero, when ϵ tends to zero. By (3.4)

$$uc_\epsilon = \int \xi S_\epsilon(x,v) dv$$

is independent of x. Multiplying (3.7) with $\mathrm{sign} S_\epsilon$ and integrating we get

$$\int_{\xi<0} |\xi|\ |S_\epsilon(0,v)| dv + \int_{\xi>0} \xi |S_\epsilon(1,v)| dv$$

$$\leq \int_{\xi>0} \xi \left|r^0\left(-\frac{1}{\epsilon},v\right)\right| dv + \int_{\xi<0} \left|\xi l^0\left(\frac{1}{\epsilon},v\right)\right| dv.$$

Thus

$$|c_\epsilon| \leq \frac{1}{u}\int |\xi| S_\epsilon(0,v) dv$$

$$\leq \frac{c}{u}\left(\int_{\xi>0} \frac{\xi}{\nu}\ \left|\tilde{r}^0\left(-\frac{1}{\epsilon},v\right)\right|^2 dv + \int_{\xi<0} \frac{|\xi|}{\nu}\ \left|\tilde{l}^0\left(\frac{1}{\epsilon},v\right)\right|^2 dv\right), \tag{3.9}$$

which tends to zero superalgebraically, when ϵ tends to zero. As in (2.12)

$$\int_0^1 \int_{\mathbb{R}^3} \left|\tilde{S}_\epsilon(x,v) - c_\epsilon \sqrt{\nu(v) M(v)}\ \right|^2 dx dv$$

$$\leq c \int_0^1 \int_{\mathbb{R}^3} |\tilde{w}_\epsilon(x,v)|^2 dx dv. \tag{3.10}$$

By (3.5–3.7)

$$\int_0^1 \int_{\mathbb{R}^3} |\tilde{S}_\epsilon(x,v)|^2 dx dv$$

tends to zero superalgebraically, when ϵ tends to zero. □

Remark. The evaporation at $x = 0$ determines the (fluid dynamic) mass flux term cM through the boundary layer analysis. At the condensation boundary $x = 1$ this term is removed from the boundary layer correction.

Remark. It follows from this proof that the solution of the Milne problem in Theorem 2.1 is unique. It also follows that the convergence to zero of the error term in Theorem 3.2 is superalgebraic.

A VARIATIONAL PROBLEM RELATED TO THE GINZBURG–LANDAU MODEL OF SUPERCONDUCTIVITY WITH NORMAL IMPURITY INCLUSION*

SHIJIN DING†, ZUHAN LIU‡, AND WANGHUI YU†

Abstract. A variational problem related to the Ginzburg–Landau model of superconductivity with normal impurity inclusion is considered. A standing feature of this problem is the vortex-pinning effect (i.e., the zeros of solutions are attracted to the region occupied by the normal impurities) as some parameters are sufficiently small. Asymptotic behaviors of the solutions of this problem as these parameters tend to zero is studied, and the vortex-pinning effect is proved.

Key words. Ginzburg–Landau model, superconductivity, normal impurities, asymptotic behavior, vortex-pinning effect

1. Introduction.

Let Ω_n and $\Omega(\Omega_n \subset\subset \Omega)$ be two bounded domains in $\mathbb{R}^2$, $g : \partial\Omega \to S^1$ be a smooth map with $\deg(g, \partial\Omega) > 0$. Set $\Omega_s \equiv \Omega\backslash\overline{\Omega_n}$. Consider the following variational problem: find a function $u \in H_g^1(\Omega)$ such that

$$E(u, \Omega) = \min_{v \in H_g^1(\Omega)} E(v, \Omega), \tag{1.1}$$

where

$$E(v, \Omega) \equiv \frac{1}{2}\int_\Omega |\nabla v|^2 + \frac{1}{4\varepsilon^2}\int_{\Omega_s}(1 - |v|^2)^2 + \frac{1}{2\mu^2}\int_{\Omega_n}|v|^2, \tag{1.2}$$

$$H_g^1(\Omega) \equiv \{v : \Omega \to \mathcal{C} | v \in H^1(\Omega), \quad v = g \text{ on } \partial\Omega\}, \tag{1.3}$$

and ε, μ are small positive constants.

This problem is related to the Ginzburg–Landau model of superconductivity with normal impurity inclusion such as superconducting-normal junctions (cf. [1]). Ω_s and Ω_n represent the domains occupied by superconducting materials and normal conducting materials, respectively. The solution u is the Ginzburg–Landau complex order parameter. Zeros of u are known as Ginzburg–Landau vortices which are of significance in the theory of superconductivity. When the vortices move, resistance to the current is produced and causes loss of superconductivity. One way to prevent the movement of the vortices is to add some impurities such as normal conducting materials into the superconducting materials to provide pinning sites for the vortices. In this setting, a simplified Ginzburg–Landau's Gibbs free energy is given by (1.2) (cf. [1], [2]).

This paper is devoted to the study of asymptotic behaviors of the solution u as ε, μ, and diam Ω_n tend to zero as well as the vortex-pinning effect of (1.1)–(1.3). For simplicity, we shall let $\varepsilon = \mu$, $\Omega = B_1$, $\Omega_n = B_\rho$, and $\Omega_s = B_1\backslash\overline{B_\rho}$. Here $0 < \rho < \frac{1}{4}$

and B_r is the disc in $\mathbb{R}^2$ centered at the origin with radius r. Then our problem becomes

$$E(u, B_1) = \min_{v \in H_g^1(B_1)} E(v, B_1), \tag{1.4}$$

where

$$E(v, B_1) \equiv \frac{1}{2}\int_{B_1} |\nabla v|^2 + \frac{1}{4\varepsilon^2}\int_{B_1 \setminus B_\rho} (1 - |v|^2)^2 + \frac{1}{2\varepsilon^2}\int_{B_\rho} |v|^2 \tag{1.5}$$

and

$$H_g^1(B_1) \equiv \{v : B_1 \to \mathcal{C} | v \in H^1(B_1),\ v = g \text{ on } \partial B_1\}. \tag{1.6}$$

Our main result is the following theorem.

THEOREM. *Suppose that $g \in C^2(\partial B_1, S^1)$ and $deg(g, \partial B_1) = d > 0$. Given any sequence $\{\varepsilon_n, \rho_n\}_{n=1}^{+\infty}$ satisfying $\varepsilon_n \to 0$ and $\rho_n \to 0$ as $n \to +\infty$, let u_n be a solution of (1.4)–(1.6) with $\varepsilon = \varepsilon_n$ and $\rho = \rho_n$. Then, by passing to an appropriate subsequence, we have*

$$u_n \to u_* \text{ in } C^1_{\text{loc}}\left(\overline{B_1} \setminus \bigcup_{i=0}^{m} \{a_i\}\right) \quad \text{as } n \to +\infty,$$

where $a_0, a_1, \ldots, a_m$ are $m+1$ distinct points in B_1, $a_0 = 0$, $0 \le m \le d$ and u_* is a harmonic map in $\overline{B_1} \setminus (\cup_{j=0}^{m}\{a_j\})$ such that $deg(u_*, a_j) = 1 (j = 1, 2, \ldots, m)$, $deg(u_*, 0) = d - m$, and $u_* = g$ on ∂B_1.

Moreover, there is a constant $\mu \ge 1$ depending only on g such that

1° $\deg(u_*, 0) < k$ if $\lim\limits_{n \to +\infty} \dfrac{\varepsilon_n}{\rho_n^{2k-1}} \ge \mu,\ (k = 2, \ldots, d)$,

2° $\deg(u_*, 0) > k$ if $\overline{\lim\limits_{n \to +\infty}} \dfrac{\varepsilon_n}{\rho_n^{2k+1}} \le \dfrac{1}{\mu}, (k = 0, 1, \ldots, d-1)$.

In particular, we have the following vortex-pinning effect:

3° $\deg(u_*, 0) \ge 1$ if $\lim\limits_{n \to +\infty} \dfrac{\varepsilon_n}{\rho_n} = 0$,

4° $\deg(u_*, 0) = k$ if $\lim\limits_{n \to +\infty} \dfrac{\varepsilon_n}{\rho_n^{2k-1}} = 0$ and $\lim\limits_{n \to +\infty} \dfrac{\varepsilon_n}{\rho_n^{2k+1}} = +\infty$

$(k = 1, 2, \ldots, d-1)$,

5° $\deg(u_*, 0) = d$ if $\lim\limits_{n \to +\infty} \dfrac{\varepsilon_n}{\rho_n^{2d-1}} = 0$.

One can easily see from the arguments in the following sections that, if $\lim\limits_{n \to +\infty} \rho_n = \rho_0 > 0$, the theorem also holds with a_0 replaced by B_{ρ_0} and $\deg(u_*, 0)$ by $\deg(u_*, B_{\rho_0})$. Hence 5° implies $\deg(u_*, B_{\rho_0}) = d$ and $m = 0$. Note that our arguments can be applied for more general domains Ω and Ω_n.

We shall show some energy estimates in section 2 and prove the first part of the theorem above (i.e., the convergence of the solution u_n to u_* in $C^1_{\rm loc}(\overline{B_1}\setminus \cup_{j=0}^m \{a_j\})$ as $n \to +\infty$) in section 3. In the last section, i.e., section 4, we shall study the degrees of the singular points $\{a_0, a_1, \ldots, a_m\}$ and complete the proof of the theorem.

Throughout this paper, $x = (x_1, x_2) \equiv x_1 + ix_2$ denotes both a complex number and a point in $\mathbb{R}^2$, (r, θ) is the polar coordinate of $\mathbb{R}^2$, and the capital letter "C" denotes various constants which depend only on g. Moreover, for any domain $\Omega \subset \mathbb{R}^2$, we shall let

$$E(v, \Omega) \equiv \frac{1}{2}\int_{B_1\cap\Omega} |\nabla v|^2 + \frac{1}{4\varepsilon^2}\int_{(B_1\setminus B_\rho)\cap\Omega} (1-|v|^2)^2 + \frac{1}{2\varepsilon^2}\int_{B_\rho\cap\Omega} |v|^2. \tag{1.7}$$

2. Some energy estimates. By the standard theory of variational problems, (1.4)–(1.6) has at least one solution $u_{\varepsilon,\rho} \in C^1(\overline{B_1}) \cap C^2(\overline{B_1\setminus B_\rho}) \cap C^2(\overline{B_\rho})$ satisfying

$$-\Delta u = \frac{1}{\varepsilon^2} u(1-|u|^2) \quad \text{in } B_1\setminus B_\rho, \tag{2.1}$$

$$-\Delta u = -\frac{1}{\varepsilon^2} u \qquad \text{in } B_\rho, \tag{2.2}$$

$$u \text{ and } \nabla u \text{ are continuous across } \partial B_\rho, \tag{2.3}$$

and

$$u = g \qquad \text{on } \partial B_1. \tag{2.4}$$

It follows from (2.1)–(2.4) that

$$0 \le |u| \le 1 \quad \text{in } B_1 \tag{2.5}$$

and

$$|\nabla u| \le \frac{C}{\varepsilon} \qquad \text{in } B_1. \tag{2.6}$$

In fact, (2.5) can be proved by the maximum principle, and the proof of (2.6) can be found in [3] (see the Appendix in [3]).

In this section we shall show some energy estimates for the solution u which will be used in the next section.

LEMMA 2.1.

$$E(u, B_1) \le \pi j \log\frac{1}{\varepsilon} + \pi(d-j)^2 \log\frac{1}{\rho} + C\left[1 + \frac{\rho}{\varepsilon}\right] \tag{2.7}_j$$

for $j = 0, 1, \ldots, d$.

Proof. We can assume $\varepsilon < \frac{1}{4}$ by (2.5) and (2.6). For any integer $j (0 \le j \le d)$, choose j disjoint discs in $B_1\setminus B_{\frac{1}{2}}$: $\{B_{R_0}(x_k)\}_{k=0}^j$. Here R_0 is a small constant and $B_{R_0}(x_0) \equiv \phi$. Define a comparison function $v(x)$ in $\overline{B_1}$ by the following:

1° v is the harmonic map in $(B_1\setminus B_{\frac{1}{2}})\setminus(\bigcup_{k=0}^j B_{R_0}(x_k))$ satisfy

$$v\,|_{\partial B_1} = g, \quad v|_{\partial B_{\frac{1}{2}}} = e^{i(d-j)\theta}, \text{ and}$$

$$v|_{\partial B_{R_0}(x_k)} = \frac{x - x_k}{|x - x_k|}, \qquad k = 0, 1, \ldots, j,$$

2° $v = \dfrac{x - x_k}{|x - x_k|}$ in $B_{R_0}(x_k)\backslash B_{\varepsilon R_0}(x_k)$, $\qquad k = 0, 1, \ldots, j,$

3° v is a minimizer of the functional $E(v, B_{\varepsilon R_0}(x_k))$ in $H^1(B_{\varepsilon R_0}(x_k))$ with the boundary condition

$$v = \frac{x - x_k}{|x - x_k|} \text{ on } \partial B_{\varepsilon R_0}(x_k), \qquad k = 0, 1, \ldots, j,$$

where $E(v, B_{\varepsilon R_0}(x_k))$ is defined in (1.7).

4° $v = e^{i(d-j)\theta}$ in $B_{\frac{1}{2}}\backslash B_{\rho+\varepsilon}$,

5° $v = \dfrac{r - \rho}{\varepsilon} e^{i(d-j)\theta}$ in $B_{\rho+\varepsilon}\backslash B_\rho$,

6° $v \equiv 0$ in B_ρ.

Obviously, $v \in H^1_g(B_1)$. So $E(u, B_1) \le E(v, B_1)$.

It is easy to verify that

$$E(v, D) \le \pi j \log \frac{1}{\varepsilon} + C, \tag{2.8}$$

where $D \equiv (B_1\backslash B_{\frac{1}{2}})\backslash(\cup_{k=0}^{j} B_{\varepsilon R_0}(x_k))$,

$$E(v, B_{\frac{1}{2}}\backslash B_{\rho+\varepsilon}) \le \pi(d - j)^2 \log \frac{1}{\rho + \varepsilon} + C \tag{2.9}$$

and

$$E(v, B_{\rho+\varepsilon}) \le \pi(d - j)^2 \log \frac{\rho + \varepsilon}{\rho} + C\left[\frac{\rho}{\varepsilon} + 1\right]. \tag{2.10}$$

Set $x - x_k = \varepsilon y$ and $\widehat{v}(y) = v(x_k + \varepsilon y)$. Then

$$E(v, B_{\varepsilon R_0}(x_k)) = \int_{B_{R_0}} \left[\frac{1}{2}|\nabla \widehat{v}|^2 + (1 - |\widehat{v}|^2)^2\right] dy.$$

Hence, we have from the minimality of v (see the definition 3°) that

$$E(v, B_{\varepsilon R_0}(x_k)) \le C, \quad k = 0, 1, \ldots, j. \tag{2.11}$$

Thus (2.7) follows from (2.8)–(2.11). □

LEMMA 2.2.

$$E(u, B_{\gamma\rho}) \le \frac{C}{1 - \gamma}\left[1 + \frac{\varepsilon}{\rho} + \frac{\varepsilon}{\rho}\log\frac{1}{\rho}\right] \quad (0 < \gamma < 1). \tag{2.12}$$

Proof. It is easy to see from $(2.7)_0$ that there is a constant $\widehat{\gamma} \in (\gamma, 1)$ such that

$$\int_0^{2\pi} \left[|\nabla u(\widehat{\gamma}\rho, \theta)|^2 + \frac{1}{2\varepsilon^2}|u(\widehat{\gamma}\rho, \theta)|^2\right] d\theta \le \frac{C}{\rho^2(1 - \gamma^2)}\left[1 + \frac{\rho}{\varepsilon} + \log\frac{1}{\rho}\right]. \tag{2.13}$$

Multiplying (2.2) by u^* (the complex conjugate function of u) and then integrating over $B_{\widehat{\gamma}\rho}$, we find that

$$\int_{B_{\widehat{\gamma}\rho}} \left[|\nabla u|^2 + \frac{1}{\varepsilon^2}|u|^2\right] = \int_{\partial B_{\widehat{\gamma}\rho}} \frac{\partial u}{\partial n} u^*$$

$$\leq \left(\int_{\partial B_{\widehat{\gamma}\rho}} |\nabla u|^2\right)^{1/2} \left(\int_{\partial B_{\widehat{\gamma}\rho}} |u|^2\right)^{1/2}$$

$$\leq \frac{C\widehat{\gamma}\rho\varepsilon}{(1-\gamma^2)\rho^2}\left[\log\frac{1}{\rho} + \frac{\rho}{\varepsilon} + 1\right]$$

$$\leq \frac{C}{1-\gamma^2}\left[1 + \frac{\varepsilon}{\rho} + \frac{\varepsilon}{\rho}\log\frac{1}{\rho}\right].$$

Hence (2.12) follows. □

LEMMA 2.3.

$$E(u, B_1\backslash B_{\gamma\rho}) \leq \pi j \log\frac{1}{\varepsilon} + \pi(d-j)^2\log\frac{1}{\rho} + C_\gamma\left(1 + \log\frac{1}{\rho}\right), \tag{2.14}_j$$
$$\left(j = 0, 1, \ldots, d, \quad \gamma > 1, \quad \gamma\rho < \frac{1}{4}\right),$$

where $C_\gamma \equiv C(\frac{1}{\gamma^2-1} + \log\gamma + 1)$.

Proof. In the case $2\varepsilon \geq \rho$, (2.14) follows directly from (2.7). So we only need to prove (2.14) for $2\varepsilon < \rho < \frac{1}{4}$. Let

$$\bar{u}(r) = \left\{\frac{1}{2\pi}\int_0^{2\pi} |u(r,\theta)|^2 d\theta\right\}^{1/2} \quad \text{for } r \in [0,1]. \tag{2.15}$$

One can easily verify that

$$|\bar{u}(r)|^2 = \frac{1}{2\pi}\int_0^{2\pi} |u(r,\theta)|^2 d\theta \text{ for } r \in [0,1], \tag{2.16}$$

$$(1 - |\bar{u}(r)|^2)^2 \leq \frac{1}{2\pi}\int_0^{2\pi} (1 - |u(r,\theta)|^2)^2 d\theta, \qquad r \in [0,1], \tag{2.17}$$

and

$$\left|\frac{\partial\bar{u}(r)}{\partial r}\right|^2 \leq \frac{1}{2\pi}\int_0^{2\pi}\left|\frac{\partial u(r,\theta)}{\partial r}\right|^2 d\theta \text{ for a.e. } r \in [0,1]. \tag{2.18}$$

Since $(2.7)_0$ implies that there exists a constant $\widehat{\gamma} \in (1,\gamma)$ such that

$$\int_0^{2\pi}\left[\frac{1}{2}|\nabla u(\widehat{\gamma}\rho,\theta)|^2 + \frac{1}{4\varepsilon^2}(1 - |u(\widehat{\gamma}\rho,\theta)|^2)^2\right] d\theta$$

$$\leq \frac{C}{(\gamma^2-1)\rho^2}\left[\log\frac{1}{\rho} + \frac{\rho}{\varepsilon} + 1\right], \tag{2.19}$$

we have from (2.17) and (2.19) that

$$(1-|\bar{u}(\widehat{\gamma}\rho)|^2)^2 \le \frac{C}{\gamma^2-1}\left[\frac{\varepsilon}{\rho}+\frac{\varepsilon^2}{\rho^2}+\frac{\varepsilon^2}{\rho^2}\log\frac{1}{\rho}\right]. \tag{2.20}$$

Now define a function $\tilde{v}$ in $\overline{B_1}$ by the following:

1° $\tilde{v}=v\in\overline{B_1}\backslash B_{\frac{1}{2}}$,

where v is defined in the proof of Lemma 2.1.

2° $\tilde{v}=e^{i(d-j)\theta}$ in $\overline{B_{\frac{1}{2}}}\backslash B_\varepsilon$,

3° $\tilde{v}=\frac{r}{\varepsilon}e^{i(d-j)\theta}$ in B_ε.

It is obvious that

$$E(\tilde{v},B_{\frac{1}{2}}\backslash B_{\widehat{\gamma}\rho})\le \pi(d-j)^2\log\frac{1}{\rho}+C\log\gamma, \tag{2.21}$$

$$|\nabla\tilde{v}|\le\frac{C}{\rho},|\nabla^2\tilde{v}|\le\frac{C}{\rho^2}\text{ in }B_{\frac{1}{2}}\backslash B_{\frac{1}{2}\rho}, \tag{2.22}$$

and

$$|\tilde{v}|\le 1,|\nabla\tilde{v}|\le\frac{C}{\varepsilon}\text{ in }B_{\frac{1}{2}}. \tag{2.23}$$

Moreover, (2.8) and (2.11) give

$$E(\tilde{v},B_1\backslash B_{\frac{1}{2}})\le\pi j\log\frac{1}{\varepsilon}+C. \tag{2.24}$$

Set

$$w(x)=\begin{cases}\tilde{v} & \text{in } B_1\backslash B_{\widehat{\gamma}\rho+\varepsilon},\\ \left[\dfrac{1-\bar{u}(\widehat{\gamma}\rho)}{\varepsilon}(r-\widehat{\gamma}\rho)+\bar{u}(\widehat{\gamma}\rho)\right]\tilde{v} & \text{in } B_{\widehat{\gamma}\rho+\varepsilon}\backslash B_{\widehat{\gamma}\rho},\\ \bar{u}\tilde{v} & \text{in } B_{\widehat{\gamma}\rho}.\end{cases} \tag{2.25}$$

Then $w(x)\in H_g^1(B_1)$, and, consequently,

$$\begin{aligned}&E(u,B_1)\le E(w,B_1)\\ &=E(\tilde{v},B_1\backslash B_{\widehat{\gamma}\rho+\varepsilon})+E(w,B_{\widehat{\gamma}\rho+\varepsilon}\backslash B_{\widehat{\gamma}\rho})+E(w,B_{\widehat{\gamma}\rho}).\\ &E(w,B_{\widehat{\gamma}\rho+\varepsilon}\backslash B_{\widehat{\gamma}\rho})\le C\int_{B_{\widehat{\gamma}\rho+\varepsilon}\backslash B_{\widehat{\gamma}\rho}}\left[|\nabla\tilde{v}|^2+\frac{1}{\varepsilon^2}(1-\bar{u}(\widehat{\gamma}\rho))^2\right].\end{aligned} \tag{2.26}$$

By (2.20) and (2.22), we get after simple calculations that

$$E(w,B_{\widehat{\gamma}\rho+\varepsilon}\backslash B_{\widehat{\gamma}\rho})\le\frac{C}{\gamma^2-1}\left(1+\log\frac{1}{\rho}\right). \tag{2.27}$$

$$
\begin{aligned}
E(w, B_{\widehat{\gamma}\rho}) &= \int_{B_{\widehat{\gamma}\rho}} \frac{1}{2}|\tilde{v}\nabla\bar{u} + \bar{u}\nabla\tilde{v}|^2 + \frac{1}{4\varepsilon^2}\int_{B_{\widehat{\gamma}\rho}\setminus B_\rho}(1-|\bar{u}|^2)^2 \\
&\quad + \frac{1}{2\varepsilon^2}\int_{B_\rho}|\tilde{v}\bar{u}|^2 \\
&\le E(\bar{u}, B_{\widehat{\gamma}\rho}) + \frac{1}{2}\int_{B_{\widehat{\gamma}\rho}}|\bar{u}|^2|\nabla\tilde{v}|^2 \\
&\quad + \frac{1}{2}\int_{B_{\widehat{\gamma}\rho}}[\tilde{v}\bar{u}\nabla\bar{u}\cdot\nabla\tilde{v}^* + \tilde{v}^*\bar{u}\nabla\bar{u}\cdot\nabla\tilde{v}] \\
&\equiv E(\bar{u}, B_{\widehat{\gamma}\rho}) + I.
\end{aligned}
$$

Integrating by parts and using (2.22) and (2.23), we have

$$
\begin{aligned}
|I| &\le C\left\{\int_{B_{\widehat{\gamma}\rho}\setminus B_{\frac{1}{2}\rho}}|\Delta\tilde{v}| + \int_{\partial B_{\widehat{\gamma}\rho}\cup\partial B_{\frac{1}{2}\rho}}|\nabla\tilde{v}|\right. \\
&\quad \left. + \int_{B_{\widehat{\gamma}\rho}}|\bar{u}|^2|\nabla\tilde{v}|^2 + \int_{B_{\frac{1}{2}\rho}}|\nabla\bar{u}|^2\right\} \\
&\le C\left\{1 + \int_{B_{\widehat{\gamma}\rho}\setminus B_{\frac{1}{2}\rho}}|\nabla\tilde{v}|^2 + \int_{B_{\frac{1}{2}\rho}}\left[|\nabla\bar{u}|^2 + \frac{1}{\varepsilon^2}|\bar{u}|^2\right]\right\} \\
&\le C\left\{1 + \int_{B_{\frac{1}{2}\rho}}\left[|\nabla\bar{u}|^2 + \frac{1}{\varepsilon^2}|\bar{u}|^2\right]\right\}.
\end{aligned}
$$

By (2.15), (2.18), and Lemma 2.2, we get $|I| \le C$, therefore,

$$
E(w, B_{\widehat{\gamma}\rho}) \le E(\bar{u}, B_{\widehat{\gamma}\rho}) + C. \tag{2.28}
$$

Combining (2.26)–(2.28), (2.21), (2.24), and (2.16)–(2.18), we yield

$$
\begin{aligned}
E(u, B_1) &\le \pi j\log\frac{1}{\varepsilon} + \pi(d-j)^2\log\frac{1}{\rho} \\
&\quad + C\left(\frac{1}{\gamma^2-1} + \log\gamma + 1\right)\left(1 + \log\frac{1}{\rho}\right) + E(u, B_{\widehat{\gamma}\rho}).
\end{aligned}
$$

Hence, (2.14) follows. □

LEMMA 2.4.

$$
\frac{1}{\varepsilon^2}\int_{B_1\setminus B_{\gamma\rho\alpha}}(1-|u|^2) \le \frac{C}{1-\alpha}\left(\log\gamma + \frac{1}{\gamma^2-1} + 1\right), \tag{2.29}
$$

where $\gamma > 1$, $\gamma\rho < \frac{1}{4}$, $0 < \alpha < 1$.

Proof. Multiplying (2.1) by $x \cdot \nabla u^*$ and then integrating over $B_1 \backslash B_r (\rho < r < 1)$, after some elementary calculations we get

$$\begin{aligned} &\frac{1}{2}\int_{\partial B_1}\left|\frac{\partial u}{\partial \nu}\right|^2 + \frac{r}{2}\int_{\partial B_r}\left|\frac{\partial u}{\partial \tau}\right|^2 \\ &\quad + \frac{1}{4\varepsilon^2}\int_{B_1\backslash B_r}(1-|u|^2)^2 + \frac{r}{4\varepsilon^2}\int_{\partial B_r}(1-|u|^2)^2 \\ &= \frac{1}{2}\int_{\partial B_1}\left|\frac{\partial u}{\partial \tau}\right|^2 + \frac{r}{2}\int_{\partial B_r}\left|\frac{\partial u}{\partial \nu}\right|^2 + \frac{1}{4\varepsilon^2}\int_{\partial B_1}(1-|u|^2)^2 \\ &\qquad\qquad (\rho < r < 1), \end{aligned} \tag{2.30}$$

where ν is the unit normal vector and τ is the unit tangential vector (for details, see [2, Theorem III 2, p. 45]).

By Lemma 2.3 and the inequality

$$\frac{1}{2}\int_{\gamma\rho}^{\gamma\rho^\alpha}\frac{1}{r}\left(r\int_{\partial B_r}|\nabla u|^2\right)dr = \frac{1}{2}\int_{B_{\gamma\rho^\alpha}\backslash B_{\gamma\rho}}|\nabla u|^2 \le E(u, B_1\backslash B_{\gamma\rho}),$$

we can find a $\widehat{\gamma} \in (\gamma\rho, \gamma\rho^\alpha)$ such that

$$\widehat{\gamma}\int_{\partial B_{\widehat{\gamma}}}|\nabla u|^2 \le \frac{E(u, B_1\backslash B_{\gamma\rho})}{(1-\alpha)|\log\rho|} \le \frac{C}{1-\alpha}\left(\frac{1}{\gamma^2-1} + \log\gamma + 1\right). \tag{2.31}$$

Thus (2.29) follows from (2.30) and (2.31). □

Given any constant $\eta \in (0, \frac{1}{2})$, consider the following variational problem: find a function $\phi \in H_u^1(B_\eta\backslash B_\xi)$, subject to (s.t.)

$$E(\phi, B_\eta\backslash B_\xi) = \min_{v\in H_u^1(B_\eta\backslash B_\xi)} E(v, B_\eta\backslash B_\xi), \tag{2.32}$$

where $\xi = 2\max\{\rho, \varepsilon\}$, $\xi < \eta/2$, u is a solution of (1.4)–(1.6), $E(v, B_\eta\backslash B_\xi)$ is defined in (1.7), i.e.,

$$E(v, B_\eta\backslash B_\xi) \equiv \int_{B_\eta\backslash B_\xi}\left[\frac{1}{2}|\nabla v|^2 + \frac{1}{4\varepsilon^2}(1-|v|^2)^2\right], \tag{2.33}$$

and

$$H_u^1(B_\eta\backslash B_\xi) \equiv \{v : \overline{B_\eta\backslash B_\xi} \to \mathcal{C} | v \in H^1(B_\eta\backslash B_\xi), v = u \text{ on } \partial B_\eta\}. \tag{2.34}$$

By the standard theory, (2.32) has at least one solution $\phi \in C^2(\overline{B_\eta\backslash B_\xi})$ satisfying

$$-\Delta\phi = \frac{1}{\varepsilon^2}\phi(1-|\phi|^2) \quad \text{in } B_\eta\backslash B_\xi, \tag{2.35}$$

$$\phi = u \qquad \text{on } \partial B_\eta, \tag{2.36}$$

$$\frac{\partial\phi}{\partial\nu} = 0 \qquad \text{on } \partial B_\xi. \tag{2.37}$$

LEMMA 2.5. *Let ϕ be a solution of* (2.32); *then*

$$E(\phi, B_\eta \backslash B_\xi) \le C \log \frac{1}{\xi} \le C \log \frac{1}{\varepsilon}, \tag{2.38}$$

$$|\phi| \le 1 \qquad \text{in } B_\eta \backslash B_\xi, \tag{2.39}$$

$$|\nabla \phi| \le \frac{C}{\varepsilon} \qquad \text{in } B_\eta \backslash B_\xi, \tag{2.40}$$

and

$$\frac{1}{\varepsilon^2} \int_{B_{\xi^\alpha} \backslash B_\xi} (1 - |\phi|^2)^2 \le \frac{C}{1-\alpha} (0 < \alpha < 1,\ \xi^\alpha < \eta). \tag{2.41}$$

Moreover, if

$$\frac{1}{2} \int_{\partial B_\eta} |\nabla u|^2 + \frac{1}{4\varepsilon^2} \int_{\partial B_\eta} (1 - |u|^2)^2 \le \frac{C}{\eta} \log \frac{1}{\xi}, \tag{2.42}$$

then

$$\frac{1}{\varepsilon^2} \int_{B_{\varepsilon^\alpha}(x_0) \cap (B_\eta \backslash B_\xi)} (1 - |\phi|^2)^2 \le \frac{C}{\alpha(1-\alpha)} \tag{2.43}$$

for $0 < \alpha < 1$, $\quad x_0 \in \overline{B_\eta \backslash B_\xi}$, $\quad$ *and* $\quad \varepsilon^{\alpha/2} \le \eta$.

Proof. Since $\xi = 2 \max\{\varepsilon, \rho\}$, (2.38) follows from Lemmas 2.1 and 2.3 and the minimality of ϕ. (2.39) follows from (2.35)–(2.37), (2.5), and the maximum principle.

Set $\widehat{\phi}(y) = \phi(\varepsilon y)$. Then $\widehat{\phi}$ solves

$$\begin{cases} -\Delta \widehat{\phi} = \phi(1 - |\phi|^2) & \text{for } \dfrac{\xi}{\varepsilon} < |y| < \dfrac{\eta}{\varepsilon}, \\ \dfrac{\partial \widehat{\phi}}{\partial \nu} = 0 & \text{on } \ |y| = \dfrac{\xi}{\varepsilon}, \\ |\widehat{\phi}| \le 1 & \text{for } \dfrac{\xi}{\varepsilon} \le |y| \le \dfrac{\eta}{\varepsilon}. \end{cases}$$

Noting that $\frac{\xi}{\varepsilon} \ge 2$ and $\frac{\eta}{\varepsilon} - \frac{\xi}{\varepsilon} \ge \frac{\xi}{\varepsilon} \ge 2$, we can apply the local estimates of elliptic equations to $\widehat{\phi}$ in the set $\{\frac{\xi}{\varepsilon} \le |y| \le \frac{\xi}{\varepsilon} + 1\}$ and obtain

$$|\nabla \widehat{\phi}| \le C \ \text{ for } \ \frac{\xi}{\varepsilon} \le |y| \le \frac{\xi}{\varepsilon} + 1. \tag{2.44}$$

Similarly, set $\widetilde{\phi}(y) = \widehat{\phi}(y) - u(\varepsilon y)$. Then $\widetilde{\phi}$ satisfies

$$\begin{cases} -\Delta \widetilde{\phi} = -u(1 - |u|^2) + \phi(1 - |\phi|^2) \equiv f, & \dfrac{\xi}{\varepsilon} < |y| < \dfrac{\eta}{\varepsilon}, \\ \widetilde{\phi} = 0 & \text{for } |y| = \dfrac{\eta}{\varepsilon}, \\ |\widetilde{\phi}| \le 2, |f| \le 2 & \text{for } \dfrac{\xi}{\varepsilon} \le |y| \le \dfrac{\eta}{\varepsilon}. \end{cases}$$

By applying local estimates of elliptic equations to $\widetilde{\phi}$ in $\frac{\eta}{\varepsilon} - 1 \le |y| \le \frac{\eta}{\varepsilon}$, we get

$$|\nabla \widetilde{\phi}| \le C \qquad \text{for } \frac{\eta}{\varepsilon} - 1 \le |y| \le \frac{\eta}{\varepsilon},$$

which, together with (2.6), gives

$$|\nabla\widehat{\phi}| \le C \quad \text{for } \frac{\eta}{\varepsilon} - 1 \le |y| \le \frac{\eta}{\varepsilon}. \tag{2.45}$$

Now by (2.44), (2.45), and the interior estimates of elliptic equations, we yield

$$|\nabla\widehat{\phi}| \le C \quad \text{for } \frac{\xi}{\varepsilon} \le |y| \le \frac{\eta}{\varepsilon}. \tag{2.46}$$

Recalling $\widehat{\phi}(y) = \phi(\varepsilon y)$, we get (2.40).

(2.41) can be proved in terms of (2.37), (2.38), and an argument similar to that in the proof of Lemma 2.4.

If (2.42) holds, then, for any $x_0 \in \overline{B_\eta \backslash B_\xi}$,

$$(x - x_0)\cdot\nu \ge 0 \qquad \text{on } \partial B_\eta$$

and

$$\int_{\partial B_\eta \cap B_{\varepsilon^\alpha}(x_0)} |x - x_0| \cdot \left[\frac{1}{2}\left|\frac{\partial u}{\partial \tau}\right|^2 + \frac{1}{4\varepsilon^2}(1 - |u|^2)^2\right] dS$$

$$\le \frac{C\varepsilon^\alpha}{\eta}\log\frac{1}{\xi} \le C\varepsilon^{\frac{\alpha}{2}}\log\frac{1}{\varepsilon} \le \frac{C}{\alpha}.$$

Thus an argument similar to that in the proof of Lemma 2.4 gives (2.43) when $B_{\varepsilon^\alpha}(x_0) \cap \partial B_\eta \ne \emptyset$ (see [4]). Notice that (2.43) follows directly from (2.41) when $B_{\varepsilon^\alpha}(x_0) \cap \partial B_\xi \ne \emptyset$. Hence (2.43) is proved. □

LEMMA 2.6. *Assume* (2.42),

$$|u| \ge \frac{1}{2} \quad \textit{in } B_{2\eta}\backslash B_\eta, \tag{2.47}$$

and

$$|\deg(u, \partial B_\eta| \le C. \tag{2.48}$$

Then there are finite integers $\delta_0, \delta_1, \ldots, \delta_N$ *and a positive constant* $\varepsilon_0 = \varepsilon_0(\eta)$ *such that*

$$\sum_{k=0}^{n} \delta_k = \deg(u, \partial B_\eta), \tag{2.49}$$

$$0 \le N \le C, \quad |\delta_k| \le C \quad (k = 0, 1, \ldots, N), \tag{2.50}$$

and

$$E(u, B_{2\eta}\backslash B_\xi) \equiv \int_{B_{2\eta}\backslash B_\xi}\left[\frac{1}{2}|\nabla u|^2 + \frac{1}{4\varepsilon^2}(1 - |u|^2)^2\right]$$

$$\ge \pi\delta_0^2 \log\frac{\eta}{\xi} + \pi\left(\sum_{k=1}^{N}\delta_k^2\right)\log\frac{1}{\varepsilon} - C \qquad \textit{for } \varepsilon \le \varepsilon_0, \tag{2.51}$$

where u *is a solution of* (1.4)–(1.6), $\xi = 2\max\{\varepsilon, \rho\}$, *and* $\xi \le \eta/2$.

Proof. In terms of Lemma 2.5 and the arguments in [2, Chapter IV] and in [4], there are a positive constant $\lambda(\lambda \le C)$ and a finite collection of disjoint discs $\{B_{\lambda\varepsilon}(x_k)\}_{k=1}^N$ satisfying

$$x_k \in \overline{B_\eta \backslash B_\xi}, \quad k = 1, 2, \ldots, N, \quad N \le C, \tag{2.52}$$

$$|x_i - x_j| \ge 8\lambda\varepsilon, \quad 1 \le i < j \le N, \tag{2.53}$$

$$|\phi(x_k)| < \frac{1}{2}, \quad k = 1, 2, \ldots, N, \tag{2.54}$$

$$|\phi(x)| \ge \frac{1}{2} \qquad \text{in } (B_\eta \backslash B_\xi) \left\backslash \left(\bigcup_{k=1}^N B_{\lambda\varepsilon}(x_k) \right) \right., \tag{2.55}$$

and

$$|\kappa_k| \le C, \quad \kappa_k \equiv \deg(\phi, \partial B_{\lambda\varepsilon}(x_k)), \quad k = 1, \ldots, N. \tag{2.56}$$

Because of $N \le C$ and $\varepsilon \le \frac{\xi}{2}$, we can assume without loss of generality that

$$|x_k| \ge 8\xi \quad k = 1, 2, \ldots, N. \tag{2.57}$$

By (2.48) and (2.55)–(2.57), $\kappa_0 \equiv \deg(\phi, \partial B_\xi)$ is well defined and

$$\sum_{k=0}^N \kappa_k = \deg(u, \partial B_\eta), \quad |\kappa_k| \le C, \quad k = 0, 1, \ldots, N. \tag{2.58}$$

Extend ϕ to B_1 by $\phi = u$ in $B_1 \backslash B_\eta$ and let

$$\phi_0 \equiv \sum_{k=0}^N \left(\frac{x - x_k}{|x - x_k|} \right)^{\kappa_k}. \tag{2.59}$$

Combining the arguments in [2, Appendix IV, Theorem A.6] and [5], we can deduce from Lemma 2.5, (2.47), (2.48), and (2.52)–(2.57) that

$$\int_\Omega |\nabla\phi|^2 \ge \int_\Omega |\nabla\phi_0|^2 - C, \tag{2.60}$$

where $\Omega \equiv B_{2\eta} \backslash (\bigcup_{k=1}^N B_{\lambda\varepsilon}(x_k) \cup B_\xi)$. For the convenience of our readers, we shall prove (2.60) in the Appendix of this paper.

Without loss of generality, suppose $\deg(u, \partial B_\eta) \ge 0$ (otherwise, one can replace $u(r, \theta)$ by $u(r, -\theta)$). By repeating the proof of Theorem II.1 in [2], we have from Corollary II.1 in [2] that

$$\frac{1}{2} \int_\Omega |\nabla\phi_0|^2 \ge \pi \min_{(\delta_0, \delta_1, \ldots, \delta_N) \in P} \left\{ \delta_0^2 \log \frac{\eta}{\xi} + \left(\sum_{k=1}^N \delta_k^2 \right) \log \frac{1}{\varepsilon} \right\} - C, \tag{2.61}$$

where

$$P \equiv \left\{ (\delta_0, \delta_1, \ldots, \delta_N) \,|\, \delta_k \text{ is an integer}, \quad k = 0, 1, \ldots, N, \right.$$

$$\left. 0 \le \delta_k \le \frac{1}{2} \left(|\kappa_k| + \kappa_k \right), \quad k = 0, 1, \ldots, N, \sum_{k=0}^N \delta_k = \deg(u, \partial B_\eta) \right\}.$$

Now (2.51) follows from (2.60), (2.61), and the inequality $E(u, B_{2\eta}\backslash B_\xi) \geq E(\phi, B_{2\eta}\backslash B_\xi)$. □

3. Convergence of the solutions. Owing to (2.5), (2.6), Lemma 2.4, and the argument in [2, Chapter IV], there is a finite collection of disjoint discs $\{B_{\lambda\varepsilon}(x_k)\}_{k=0}^{\widehat{m}}$; $B_{\lambda\varepsilon}(x_0) \equiv \emptyset$; $x_k \in B_1\backslash B_{3\xi^{\frac{1}{2}}}$, $k = 1, 2, \ldots, \widehat{m}$, where $\xi = 2\max\{\varepsilon, \rho\}$; and λ is a positive constant depending only on g such that

$$|u(x_k)| < \frac{1}{2}, \quad k = 1, 2, \ldots, \widehat{m}, \tag{3.1}$$

$$|u(x)| \geq \frac{1}{2} \quad \text{in } (B_1\backslash B_{3\xi^{\frac{1}{2}}}) \left\backslash \left(\bigcup_{k=0}^{\widehat{m}} B_{\lambda\varepsilon}(x_k) \right) \right., \tag{3.2}$$

$$0 \leq \widehat{m} \leq C, \quad |\deg(u, \partial B_{\lambda\varepsilon}(x_k))| \leq C, \quad k = 1, \ldots, \widehat{m}. \tag{3.3}$$

For any sequence $\{\varepsilon_n, \rho_n\}_{n=1}^{+\infty}$, $\varepsilon_n \to 0$, $\rho_n \to 0$ as $n \to +\infty$, by passing to an appropriate subsequence, we can assume that the limit set of $\{x_k\}_{k=0}^{\widehat{m}}(x_k \equiv x_k(n)$, $\widehat{m} \equiv \widehat{m}(n))$ in $\overline{B_1}\backslash\{0\}$ as $n \to +\infty$ is given by $\{a_1, a_2, \ldots, a_m\} 0 \leq m \leq C$ (by $m = 0$ denote the limit set is empty).

Let $a_0 = 0$ and $0 < \eta \leq \frac{1}{4} \min\limits_{0 \leq i \leq j \leq m} |a_i - a_j|$. Then it follows from (3.2) that

$$|u_n| \geq \frac{1}{2} \text{ in } B_1 \left\backslash \left(\bigcup_{k=0}^{m} B_\eta(a_k) \right) \right. \tag{3.4}$$

for n large enough, where u_n is a solution of (1.4)–(1.6) with $\varepsilon = \varepsilon_n$ and $\rho = \rho_n$. Thus $d_k \equiv \deg(u_n, \partial B_\eta(a_k))(k = 0, 1, \ldots, m)$ are well defined and, by (3.3),

$$|d_k| \leq C, \quad k = 0, 1, \ldots, m, \sum_{k=0}^{m} d_k = d, \tag{3.5}$$

where $d \equiv \deg(g, \partial B_1) > 0$. Therefore, by passing to a further subsequence, we can assume d_k $(k = 0, 1, \ldots, m)$ are independent of n.

LEMMA 3.1.

$$E(u_n, B_{\gamma\rho_n}) \leq C(1 + \log\gamma)\left(\frac{\rho_n}{\varepsilon_n} + 1\right) (\gamma > 1, \quad \gamma\rho_n < 4\eta). \tag{3.6}$$

Proof. By Lemmas 2.1 and 2.3, we can find a constant $\widehat{\eta} \in [\frac{1}{2}\ \eta, \eta]$ such that

$$\frac{1}{2}\int_{\partial B_{\widehat{\eta}}} |\nabla u_n|^2 + \frac{1}{4\varepsilon^2}\int_{\partial B_{\widehat{\eta}}} (1 - |u_n|^2) \leq \frac{C}{\widehat{\eta}} \log\frac{1}{\xi}, \tag{3.7}$$

where $\xi = 2\max\{\varepsilon_n, \rho_n\}$. So it follows from Lemma 2.6 that

$$E(u_n, B_{2\eta}\backslash B_{\gamma\xi}) \geq \pi\delta_0^2 \log\frac{\eta}{\xi} + \pi\left(\sum_{k=1}^{N} \delta_k^2\right) \log\frac{\eta}{\varepsilon_n} - C(\log\gamma + 1) \tag{3.8}$$

for some integers $\delta_0, \delta_1, \ldots, \delta_N$ with $\sum_{k=0}^{N} \delta_k = d_0$ and $0 \leq \delta_k \leq C(k = 0, 1, \ldots, N)$.

By Lemma 2.4 and (3.4) we have

$$E(u_n, B_{2\eta}(a_k)) \geq \pi|d_k| \log\ \frac{\eta}{\varepsilon_n} - C, \quad k = 1, \ldots, m, \tag{3.9}$$

(see [2, Theorem V.2, p. 53]).

Now we yield from (3.8), (3.9), and Lemma 2.1 that

$$\begin{aligned} &E(u_n, B_{\gamma\xi}) \\ &\le \pi j \log\frac{1}{\varepsilon_n} + \pi(d-j)^2 \log\frac{1}{\rho_n} + C\left(1+\frac{\rho_n}{\varepsilon_n}\right) \\ &\quad -\pi\left(\sum_{k=1}^{m}|d_k|\right)\log\frac{\eta}{\varepsilon_n} - \pi\left(\sum_{k=1}^{N}\delta_k^2\right)\log\frac{\eta}{\varepsilon_n} \\ &\quad -\pi\delta_0^2\log\frac{\eta}{\xi} + C(1+\log\gamma). \end{aligned} \tag{3.10}$$

Suppose $\varepsilon_n \ge \rho_n$. Then $\xi = 2\varepsilon_n$. Letting $j = d$ in (3.10), we get

$$\begin{aligned} E(u_n, B_{\gamma\xi}) &\le \pi\left(d - \sum_{k=1}^{m}|d_k| - \sum_{k=0}^{N}\delta_k^2\right)\log\frac{1}{\varepsilon_n} \\ &\quad +\pi\left(\sum_{k=0}^{N}\delta_k^2 + \sum_{k=1}^{m}|d_k|\right)\log\frac{1}{\eta} + C(1+\log\gamma)\left(1+\frac{\rho_n}{\varepsilon_n}\right). \end{aligned} \tag{3.11}$$

Since

$$d - \left(\sum_{k=1}^{m}|d_k| + \sum_{k=0}^{N}\delta_k^2\right) \le d - \sum_{k=0}^{m} d_k = d - d = 0,$$

we yield (3.6) for $\varepsilon_n \ge \rho_n$ by taking $\eta = \eta_0 \equiv \frac{1}{4}\min_{0\le i\le j\le m}|a_i - a_j|$.

Suppose $\varepsilon_n \le \rho_n$. Then $\xi = 2\rho_n$. If $|\delta_0| > d$, let $j = 0$ in (3.10); if $|\delta_0| \le d$, let $j = d - |\delta_0|$ in (3.10). In both cases, we can get (3.6) for $\varepsilon_n \ge \rho_n$. □

LEMMA 3.2.

$$\begin{aligned} &E(u_n, B_1\backslash B_{\gamma\rho_n}) \le \pi j\log\frac{1}{\varepsilon_n} + \pi(d-j)^2\log\frac{1}{\rho_n} + \frac{C}{\gamma^2-1}(1+\log\gamma) \\ &\qquad (j = 0, 1, \dots, d, \gamma > 1). \end{aligned} \tag{3.12}$$

Proof. Obviously, we can suppose $\gamma\rho_n < 4\eta$. There is a constant $\widehat{\gamma} \in (1, \gamma)$ from (3.6) such that

$$\begin{aligned} &\int_0^{2\pi}\left[\frac{1}{2}|\nabla u_n(\widehat{\gamma}\rho,\theta)|^2 + \frac{1}{4\varepsilon_n^2}(1-|u_n(\widehat{\gamma}\rho,\theta)|^2)\right]d\theta \\ &\le \frac{C(1+\log\gamma)}{(\gamma^2-1)\rho^2}\left(1+\frac{\rho_n}{\varepsilon_n}\right). \end{aligned} \tag{3.13}$$

Replacing (2.19) by (3.13) and repeating the proof of Lemma 2.3, we can deduce (3.12). □

LEMMA 3.3.

$$E\left(u_n, B_1\backslash\bigcup_{k=0}^{m}B_{2\eta}(a_k)\right) \le \pi\left(\sum_{k=0}^{N}\delta_k^2 + \sum_{k=1}^{m}|d_k|\right)\log\frac{1}{\eta} + C, \tag{3.14}$$

where $0 < \eta \le \frac{1}{4}\min_{0\le i\le j\le m}|a_i - a_j|$.

Proof. (3.14) follows from (3.8), (3.9), and (3.12) in terms of the argument used in the proof of Lemma 3.1. □

From (3.14) and a result in [3] there exists a harmonic function u_* defined in $\overline{B_1}\backslash\bigcup_{k=0}^m\{a_k\}$ such that

$$u_n \to u_* \quad \text{in } C^1_{\text{loc}}\left(\overline{B_1}\backslash\bigcup_{k=0}^m\{a_k\}\right) \qquad \text{as } n\to+\infty. \tag{3.15}$$

4. The degrees of the singular points.

LEMMA 4.1.

$$d_0 \geq 0, \quad 0\leq m\leq d, \tag{4.1}$$

$$d_k = 1, \quad a_k\in B_1\backslash\{0\}, \qquad k=1,2,\dots,m \quad \text{if } m\geq 1. \tag{4.2}$$

Proof. Because $\sum_{k=0}^N \delta_k^2\leq C$, we can assume $\sum_{k=1}^N\delta_k^2$ and δ_0 are independent of n (by passing to a further subsequence).

Since $a_k(k=1,2,\dots,m)$ are the limit points of $\{x_k\}_{k=1}^{\widehat{m}}(x_k\equiv x_k(n),\ \widehat{m}=\widehat{m}(n))$ as $n\to+\infty$, (3.1) and (3.14) imply

$$d_k\neq 0, \quad k=1,\dots,m, \tag{4.3}$$

(see [2, Step 1 of the proof of Theorem VI. 2, p. 61]).

It follows from (3.14) and (3.15) that

$$d_k = \deg(u_*,\partial B_\eta), \quad k=0,1,\dots,m, \tag{4.4}$$

and

$$\frac{1}{2}\int_{B_1\backslash\bigcup_{k=0}^m B_\eta(a_k)}|\nabla u_*|^2\leq \pi\left(\sum_{k=0}^N\delta_k^2+\sum_{k=1}^m|d_k|\right)\log\frac{1}{\eta}+C, \tag{4.5}$$

where $0<\eta\leq\frac{1}{8}\min\limits_{0\leq i<j\leq m}|a_i-a_j|$.

Set $I\equiv\{k|0\leq k\leq m, a_k\in\partial B_1\}$ and $I'=\{0,1,\dots,m\}\backslash I$. Then we have from [2, Lemma VI.1, p. 63 and Corollary II.2, p. 33] that

$$\frac{1}{2}\int_{(B_1\cap B_{\eta_0}(a_k))\backslash B_\eta(a_k)}|\nabla u_*|^2\geq 2\pi|d_k|\log\frac{1}{\eta}-C \quad \text{for } k\in I \tag{4.6}$$

and

$$\frac{1}{2}\int_{B_{\eta_0}(a_k)\backslash B_\eta(a_k)}|\nabla u_*|^2\geq\pi|d_k|^2\log\frac{1}{\eta}-C \qquad \text{for } k\in I'; \tag{4.7}$$

here, $\eta_0\equiv\frac{1}{4}\min\limits_{0\leq i<j<m}|a_i-a_j|$.

Combining (4.5)–(4.7), we have

$$\left(2\sum_{k\in I}|d_k|+\sum_{k\in I'}|d_k|^2\right)\log\frac{1}{\eta}\leq\left(\sum_{k=0}^N\delta_k^2+\sum_{k=1}^m|d_k|\right)\log\frac{1}{\eta}+C. \tag{4.8}$$

Taking η so small that $C/\log\frac{1}{\eta} \le \frac{1}{2}$, we get from (4.8) that

$$2\sum_{k\in I}|d_k| + \sum_{k\in I'}|d_k|^2 \le \sum_{k=0}^{N}\delta_k^2 + \sum_{k=1}^{m}|d_k|. \tag{4.9}$$

It is obvious from (3.8), (3.9), and Lemma 3.2 that

$$\begin{aligned}&\left(\sum_{k=1}^{m}|d_k| + \sum_{k=1}^{N}\delta_k^2\right)\log\frac{1}{\varepsilon_n} + \delta_0^2\log\frac{1}{\xi}\\ &\le j\log\frac{1}{\varepsilon_n} + (d-j)^2\log\frac{1}{\rho_n} + C, \quad j = 0,1,\dots,d.\end{aligned} \tag{4.10}$$

Suppose $\xi \equiv 2\max\{\varepsilon_n,\rho_n\} = 2\varepsilon_n \ge 2\rho_n$. Then we get from (4.9) and (4.10) for $j = d$ that

$$\left(2\sum_{k\in I}|d_k| + \sum_{k\in I'}|d_k|^2 - \sum_{k=0}^{m}d_k\right) \le \frac{C}{|\log\varepsilon_n|};$$

therefore, for n large enough,

$$\sum_{k\in I}(2|d_k| - d_k) + \sum_{k\in I'}(|d_k|^2 - d_k) \le 0, \tag{4.11}$$

which, together with (4.3), gives $I = \emptyset$, $0 \le d_0 \le 1$, and $d_k = 1 (k = 1,2,\dots,m)$. Thus (4.1) and (4.2) are true if $\varepsilon_n \ge \rho_n$.

Suppose $\xi \equiv 2\max\{\varepsilon_n,\rho_n\} = 2\rho_n \ge 2\varepsilon_n$. Then we find by taking $j = d$ in (4.10) and letting $n \to +\infty$ that

$$\sum_{k=1}^{m}|d_k| \le d; \tag{4.12}$$

consequently,

$$d_0 = d - \sum_{k=1}^{m}d_k \ge d - \sum_{k=1}^{m}d_k \ge 0. \tag{4.13}$$

Let $j = \sum_{k=1}^{m}|d_k|$; then $0 \le j \le d$ and, by (4.10),

$$\sum_{k=0}^{N}\delta_k^2 \le \left(d - \sum_{k=1}^{m}|d_k|\right)^2 \le d_0^2.$$

In particular, we have

$$|\delta_0| \le d_0. \tag{4.14}$$

So we can let $j = d - |\delta_0|$ in (4.10), and by noting (4.9) we get

$$2\sum_{k\in I}|d_k| + \sum_{k\in I'}|d_k|^2 - \delta_0^2 \le d - |\delta_0|,$$

that is,

$$\begin{aligned}\sum_{k\in I}(2|d_k|-d_k)+\sum_{k\in I'\setminus\{0\}}(|d_k|^2-d_k)&\\ \le\ \delta_0^2-d_0^2+d_0-|\delta_0|&\\ =\ (d_0-|\delta_0|)(1-d_0-|\delta_0|)\le 0;&\end{aligned}$$

consequently, $I=\phi$ and $d_k=1$ $(k=1,2,\dots,m)$. Thus (4.1) and (4.2) are also true when $\varepsilon_n\le\rho_n$ for n large enough. □

LEMMA 4.2. *There is a constant $\mu\ge 1$, depending only on g, such that for n large enough*

$$d_0<k \quad \text{if } \varepsilon_n\ge\mu\rho_n^{2k-1} \quad (k=2,\dots,d) \tag{4.15}$$

and

$$d_0>k \quad \text{if } \varepsilon_n\le\frac{1}{\mu}\rho_n^{2k+1} \quad (k=0,1,\dots,d-1). \tag{4.16}$$

In particular, for n large enough,

$$d_0\ge 1 \quad \text{if } \varepsilon_n\le\frac{1}{\mu}\rho_n, \tag{4.17}$$

$$d_0=k \quad \text{if } \mu\rho_n^{2k+1}\le\varepsilon_n\le\frac{1}{\mu}\rho_n^{2k-1} \quad (k=1,2,\dots,d-1), \tag{4.18}$$

and

$$d_0=d \quad \text{if } \varepsilon_n\le\frac{1}{\mu}\rho_n^{2d-1}. \tag{4.19}$$

Proof. Suppose $\varepsilon_n\ge\rho_n$ for n large enough. Then $0\le d_0\le 1$ by (4.11) and, therefore, (4.15) holds. Note that the condition of (4.16) does not hold when $\varepsilon_n\ge\rho_n$ for n large enough.

Suppose $\varepsilon_n\le\rho_n$ for n large enough. Then by (4.9) and (4.10) we have

$$(d-d_0)\log\frac{1}{\varepsilon_n}+d_0^2\log\frac{1}{\rho_n}<j\log\frac{1}{\varepsilon_n}+(d-j)^2\log\frac{1}{\rho_n}+\log\mu,$$

where $\mu=e^C$. Hence

$$(d_0-d+j)(d_0+d-j)\log\frac{1}{\rho_n}<(d_0-d+j)\log\frac{1}{\varepsilon_n}+\log\mu. \tag{4.20}$$

Suppose $d_0\ge k$ for $k=2,\dots,d$. Letting $j=d-d_0+1$ in (4.20), we find

$$(2d_0-1)\log\frac{1}{\rho_n}<\log\frac{1}{\varepsilon_n}+\log\mu,$$

which is followed by

$$(2k-1)\log\frac{1}{\rho_n}<\log\frac{1}{\varepsilon_n}+\log\mu,$$

that is

$$\varepsilon_n < \mu\rho_n^{2k-1}.$$

Thus (4.15) is true.

Suppose $d_0 \le k$ for $k = 0, 1, \ldots, d-1$. Letting $j = d - d_0 - 1$ in (4.20), then

$$(2d_0+1)\log\frac{1}{\rho_n} > \log\frac{1}{\varepsilon_n} - \log\mu,$$

which is followed by

$$\varepsilon_n > \frac{1}{\mu}\rho_n^{2d_0+1} \ge \frac{1}{\mu}\rho_n^{2k+1}.$$

So, (4.16) is also true.

(4.17)–(4.19) are direct consequences of (4.15) and (4.16). □

Now the proof of the theorem stated in section 1 is completed.

Appendix. Let B_R be the disc of radius R centered at 0. Let $p_1, p_2, \ldots, p_m$ be points in B_R such that

$$4R_1 \le |p_j| \le R/2, \quad j = 1, 2, \ldots, m, \tag{A.1}$$

and

$$|p_j - p_k| \ge 4R_0, \quad 1 \le k < j \le m, \quad 0 < R_0 \le R_1 \le 1. \tag{A.2}$$

Set

$$\Omega \equiv B_R \backslash \left(\bigcup_{j=1}^{m} B_{R_0}(p_j) \cup B_{R_1} \right). \tag{A.3}$$

Let u be a smooth map from Ω to $\mathcal{C}$ and assume

$$0 < a \le |u| \le 1 \quad \text{in } \Omega, \tag{A.4}$$

$$\frac{1}{R_0^2}\int_\Omega (|u|^2 - 1)^2 \le K \log\frac{1}{R_1}, \tag{A.5}$$

$$\frac{1}{R_0^2}\int_{\Omega \cap B_{R_0^{\frac{1}{2}}}(p_j)} (|u|^2 - 1)^2 \le K, \tag{A.6}$$

and

$$\frac{1}{R_1^2}\int_{B_{R_1^{\frac{1}{2}}}} (|u|^2 - 1)^2 \le K. \tag{A.7}$$

Set

$$u_0(x) = \prod_{j=0}^{m} \left(\frac{x - p_j}{|x - p_j|} \right)^{d_j},$$

where $p_0 = 0$, $d_0 = \deg(u, \partial B_{R_1})$, and $d_j = \deg(u, \partial B_{R_0}(p_j))$, $j = 1, 2, \ldots, m$.

THEOREM A. *Assume* (1)–(7)*; then*

$$\int_\Omega |\nabla u|^2 \geq \int_\Omega |\nabla u_0|^2 - C, \tag{A.8}$$

where C depends only on a, m, K, and d_j $(j = 0, 1, \ldots, m)$.

Proof. Set $\rho = |u|$. There is a well-defined single-valued function $\psi : B_R \to \mathbb{R}$ such that

$$u = \rho u_0 e^{i\psi} \quad \text{in } \Omega \tag{A.9}$$

and

$$\int_{B_R} |\nabla \psi|^2 \leq C \int_\Omega |\nabla \psi|^2, \tag{A.10}$$

where C is some universal constant (see [2, Appendix IV, Lemma A.1]). Write

$$u_0 = e^{i\varphi_0}, \varphi_0 = \sum_{j=0}^{m} d_j \theta_j, \quad \theta_j = \operatorname{Arg}\left(\frac{x - p_j}{|x - p_j|}\right). \tag{A.11}$$

Let $r_j = |x - p_j|$. Then

$$\nabla \theta_j = \frac{V_j}{r_j}, \quad j = 0, 1, \ldots, m, \tag{A.12}$$

where $V_j(x)$ is the unit vector tangent to the circle of radius $|x - p_j|$, centered at p_j.

We have from (9) that

$$|\nabla u|^2 = |\nabla \rho|^2 + \rho^2 |\nabla \varphi_0 + \nabla \psi|^2 \tag{A.13}$$

and consequently

$$\int_\Omega |\nabla u|^2 \geq \int_\Omega |\nabla \rho|^2 + \int_\Omega |\nabla u_0|^2 + \int_\Omega a^2 |\nabla \psi|^2 - X, \tag{A.14}$$

where

$$\begin{aligned} X &= \int_\Omega (1 - \rho^2) |\nabla \varphi_0|^2 + 2 \int_\Omega (1 - \rho^2) \nabla \varphi_0 \cdot \nabla \psi - 2 \int_\Omega \nabla \varphi_0 \nabla \psi \\ &\equiv X_1 + X_2 + X_3. \end{aligned} \tag{A.15}$$

Estimate of X_1.

$$|X_1| \leq C \int_\Omega (1 - \rho^2) \left(\sum_{j=0}^{m} d_j^2 |\nabla \theta_j|^2 \right) = C \sum_{j=0}^{m} d_j^2 \int_\Omega (1 - \rho^2) |\nabla \theta_j|^2.$$

For $j = 1, 2, \ldots, m$, we compute

$$\begin{aligned} \int_\Omega (1 - \rho^2) |\nabla \theta_j| &\leq \int_\Omega (1 - \rho^2) \frac{1}{r_j^2} \\ &= \left(\int_{\Omega \setminus B_{R_0^{\frac{1}{2}}}(p_j)} + \int_{\Omega \cap B_{R_0^{\frac{1}{2}}}(p_j)} \right) \frac{(1 - \rho^2)}{r_j^2} \\ &\equiv I_1 + I_2, \end{aligned}$$

$$
\begin{aligned}
I_1 &\le \left\{ \int_{\Omega \setminus B_{R_0^{\frac{1}{2}}}(p_j)} (1-\rho^2)^2 \right\}^{1/2} \left\{ \int_{\Omega \setminus B_{R_0^{\frac{1}{2}}}(p_j)} \frac{1}{r_j^4} \right\}^{1/2} \\
&\le \left(K R_0^2 \log \frac{1}{R_1} \right)^{1/2} \left(\frac{2\pi}{3} \right)^{\frac{1}{2}} \left(\frac{1}{R_0} - \frac{1}{R^2} \right)^{1/2} \\
&\le C \left(R_0 \log \frac{1}{R_1} \right)^{1/2} \\
&\le C \left(R_1 \log \frac{1}{R_1} \right)^{1/2} \le C.
\end{aligned}
$$

Here we have used (5) in the second inequality.

Similarly, using (6), we have

$$
\begin{aligned}
I_2 &\le \left\{ \int_{\Omega \cap B_{R_0^{\frac{1}{2}}}(p_j)} (1-\rho^2)^2 \right\}^{1/2} \left\{ \int_{\Omega \cap B_{R_0^{\frac{1}{2}}}(p_j)} \frac{1}{r_j^4} \right\}^{1/2} \\
&\le (K R_0^2)^{1/2} \left(\frac{2\pi}{3} \right)^{1/2} \left(\frac{1}{R_0^2} - \frac{1}{R_0} \right)^{1/2} \le C.
\end{aligned}
$$

Hence

$$
\int_\Omega (1-\rho^2) |\nabla \theta_j|^2 \le C, \quad j = 1, 2, \ldots, m.
$$

We can also show by the same method as above that

$$
\int_\Omega (1-\rho^2) |\nabla \theta_0|^2 \le C.
$$

Hence, we yield

$$
|X_1| \le C. \tag{A.16}
$$

Estimate of X_2.

$$
|X_2| \le \mu \int_\Omega |\nabla \psi|^2 + \frac{C}{\mu} \int_\Omega (1-\rho^2)^2 |\nabla \varphi_0|^2 \le \mu \int_\Omega |\nabla \psi|^2 + \frac{C}{\mu} X_1.
$$

So (1.6) gives

$$
|X_2| \le \mu \int_\Omega |\nabla \psi|^2 + \frac{C}{\mu} \quad (\mu > 0). \tag{A.17}
$$

Estimate of X_3.

$$
X_3 \equiv -2 \int_\Omega \nabla \varphi_0 \nabla \psi = -2 \sum_{j=0}^{m} d_j \int_\Omega \nabla \theta_j \cdot \nabla \psi = -2 \sum_{j=0}^{m} d_j \int_\Omega \frac{V_j}{r_j} \nabla \psi.
$$

For $j = 1, 2, \ldots, m$,

$$\int_\Omega \frac{V_j}{r_j}\nabla\psi = \int_{\Omega\setminus B_{R_0}(p_j)} \frac{V_j}{r_j}\nabla\psi - \sum_{\substack{k\neq j\\ k\neq 0}} \int_{B_{R_0}(p_k)} \frac{V_j}{r_j}\nabla\psi - \int_{B_{R_1}} \frac{V_j}{r_j}\nabla\psi$$
$$\equiv J_1 + J_2 + J_3.$$

Let $\rho_j = R - |p_j|$ $(j = 1, 2, \ldots, m)$. Then $\frac{R}{2} \leq \rho_j \leq R$ by (1). Since

$$\int_{\partial B_r(p_j)} V_j \nabla\psi = \int_{\partial B_r(p_j)} \frac{\partial\psi}{\partial\tau} = 0 \quad \text{for } 0 < r < \rho_j, j = 0, 1, \ldots, m,$$

we have

$$\int_{B_{\rho_j(p_j)}\setminus B_{R_0(p_j)}} \frac{V_j\nabla\psi}{r_j} = 0 \quad j = 0, 1, \ldots, m.$$

So

$$|J_1| \leq \frac{1}{\rho_j}\int_{\Omega\setminus B_{\rho_j}(p_j)} |\nabla\psi|$$
$$\leq \frac{|\Omega|^{1/2}}{\rho_j}\left(\int_\Omega |\nabla\psi|^2\right)^{1/2}$$
$$\leq \mu\int_\Omega |\nabla\psi|^2 + \frac{C}{\mu} \quad (\mu > 0).$$

The assumption (2) implies $r_j = |x - p_j| \geq |p_k - p_j| - R_0 \geq 3R_0$ for $x \in B_{R_0}(p_k)(k \neq j)$. Therefore

$$|J_2| \leq \frac{1}{3R_0}\int_{B_{R_0}(p_k)} |\nabla\psi|$$
$$\leq C\left\{\int_{B_{R_0}(p_k)} |\nabla\psi|^2\right\}^{1/2}$$
$$\leq \mu\int_\Omega |\nabla\psi|^2 + \frac{C}{\mu}.$$

Here we have used (10).

Similarly,

$$|J_3| \leq \mu\int_\Omega |\nabla\psi|^2 + \frac{C}{\mu}.$$

Hence

$$\left|\int_\Omega \frac{V_j}{r_j}\nabla\psi\right| \leq \mu\int_\Omega |\nabla\psi|^2 + \frac{C}{\mu}, \quad j = 1, 2, \ldots, m.$$

We can also deduce by the same method that

$$\left|\int_\Omega \frac{V_0}{r_0}\nabla\psi\right| \leq \mu\int_\Omega |\nabla\psi|^2 + \frac{C}{\mu}.$$

Thus

$$|X_3| \le \mu \int_\Omega |\nabla\psi|^2 + \frac{C}{\mu}. \tag{A.18}$$

Now, by combining (14)–(18), we yield

$$\int_\Omega |\nabla u|^2 \ge \int_\Omega |\nabla\rho|^2 + \int_\Omega |\nabla u_0|^2 + a^2 \int_\Omega |\nabla\psi|^2 - 3\mu \int_\Omega |\nabla\psi|^2 - \frac{C}{\mu} - C;$$

therefore, Theorem A is proved if we take $\mu = \frac{a^2}{6}$. □

ASYMPTOTIC BEHAVIOR OF THE SOLUTIONS TO A LANDAU–GINZBURG SYSTEM WITH VISCOSITY FOR MARTENSITIC PHASE TRANSITIONS IN SHAPE MEMORY ALLOYS*

JÜRGEN SPREKELS†, SONGMU ZHENG‡, AND PEICHENG ZHU‡

Abstract. In this paper, we investigate the system of partial differential equations governing the dynamics of martensitic phase transitions in shape memory alloys under the presence of a (possibly small) viscous stress. The corresponding free energy is assumed in Landau–Ginzburg form and nonconvex as a function of the order parameter. Results concerning the asymptotic behavior of the solution as time tends to infinity are proved, and the compactness of the orbit is shown.

1. Introduction.

In the present paper, we study the asymptotic behavior of the solutions to a system that arises in the thermomechanical developments in a one-dimensional heat-conducting viscous solid of constant mass density ϱ (assumed to be normalized to unity, i.e., $\varrho = 1$). The solid is subjected to heating and loading. We think of metallic solids that not only respond to a change of the strain ε by a (possibly nonlinear) elastic stress $\sigma = \sigma(\varepsilon)$, but also to a change of the curvature of their metallic lattice by a couple stress $\mu = \mu(\varepsilon_x)$.

We assume that the Helmholtz free energy density F is a potential of Landau–Ginzburg form, i.e.,

$$F = F(\varepsilon, \varepsilon_x, \theta), \tag{1.1}$$

where θ denotes the absolute temperature. To cover systems modelling first-order, stress-induced, and temperature-induced solid–solid phase transitions accompanied by hysteresis phenomena, we do not assume that F is a convex function of the order parameter ε.

A particular class of materials, in which both stress-induced and temperature-induced first-order phase transitions leading to a rather spectacular hysteretic behavior occur, are the so-called *shape memory alloys*. In these materials the metallic lattice is deformed by shear, and the assumption of a constant density is justified. The shape memory effect itself is due to martensitic phase transitions between different configurations of the crystal lattice, namely, austenite and martensitic twins. For an account of the physical properties of shape memory alloys, we refer the reader to Chapter 5 in the monograph [4]. In a series of papers (cf., for instance, [7], [8]), Falk has proposed a Landau–Ginzburg theory that uses the shear strain ε as order

parameter in order to explain the occurrence of the martensitic transitions in shape memory alloys. In this connection, we also refer to the works of Müller (cf., [1], [14]).

The simplest form for the free energy density F that accounts quite well for the experimentally observed behavior and that takes couple stresses into account is (see Falk [7], [8]) given by

$$F(\varepsilon, \varepsilon_x, \theta) = F_0(\theta) + F_1(\varepsilon)\theta + F_2(\varepsilon) + \frac{\delta}{2}\varepsilon_x^2\,, \tag{1.2}$$

where

$$F_1(\varepsilon) = \alpha_1\varepsilon^2, \quad F_2(\varepsilon) = \alpha_3\varepsilon^6 - \alpha_2\varepsilon^4 - \alpha_1\theta_1\varepsilon^2\,, \tag{1.3}$$

$$F_0(\theta) = -C_V\theta\log\left(\frac{\theta}{\theta_2}\right) + C_V\theta + \tilde{C}\,, \tag{1.4}$$

with positive physical constants $\theta_1, \delta, \alpha_1, \alpha_2, \alpha_3, \theta_2, C_V, \tilde{C}$. The constant C_V denotes the specific heat. Observe that in the interesting range of temperatures, for θ close to θ_1, F is not a convex function of the shear strain ε. In fact, $F(\cdot, \varepsilon_x, \theta)$ may have up to three minima that correspond to the austenitic and the two martensitic phases.

We want to forecast the dynamics of the phase transitions in the one-dimensional situation. To this end, let $\Omega = (0,1)$, and, for $t > 0$, $\Omega_t = \Omega \times (0,t)$. Then the balance laws of linear momentum and internal energy read

$$u_{tt} - \sigma_x + \mu_{xx} = 0, \quad \text{in} \quad \Omega_\infty\,, \tag{1.5}$$

$$U_t + q_x - \sigma\varepsilon_t - \mu\varepsilon_{xt} = 0, \quad \text{in} \quad \Omega_\infty\,. \tag{1.6}$$

The second law of thermodynamics is expressed by the Clausius–Duhem inequality

$$S_t + \left(\frac{q}{\theta}\right)_x \geq 0, \quad \text{in} \quad \Omega_\infty\,. \tag{1.7}$$

Here, u, σ, μ, U, q, ε, S, and θ denote displacement, shear stress, couple stress, internal energy density, heat flux, shear strain, entropy density, and absolute temperature, in that order.

For one-dimensional homogeneous thermoviscoelastic materials, we have the constitutive relations

$$\varepsilon = u_x, \quad \sigma = \frac{\partial F}{\partial \varepsilon} + \gamma\varepsilon_t, \quad \mu = \frac{\partial F}{\partial \varepsilon_x}, \quad S = -\frac{\partial F}{\partial \theta}, \quad U = F + \theta S\,, \tag{1.8}$$

where $\gamma > 0$ is the viscosity. For the heat flux q, we assume Fourier's law

$$q = -k\theta_x, \tag{1.9}$$

where $k > 0$ is the heat conductivity (assumed constant). Obviously, this assumption implies the validity of (1.7), so the second law of thermodynamics is automatically satisfied.

Inserting the constitutive relations in the balance laws (1.5)–(1.6), we obtain the system of partial differential equations

$$u_{tt} - (f_1\theta + f_2)_x - \gamma\varepsilon_{xt} + \delta u_{xxxx} = 0, \quad \text{in} \quad \Omega_\infty, \tag{1.10}$$

$$C_V\theta_t - k\theta_{xx} - f_1\theta\varepsilon_t - \gamma\varepsilon_t^2 = 0, \quad \text{in} \quad \Omega_\infty, \tag{1.11}$$

$$\varepsilon = u_x, \quad \text{in} \quad \Omega_\infty, \tag{1.12}$$

where

$$f_1 = f_1(\varepsilon) = F_1'(\varepsilon), \quad f_2 = f_2(\varepsilon) = F_2'(\varepsilon). \tag{1.13}$$

In addition, we prescribe the initial and boundary conditions

$$u|_{x=0} = \varepsilon_x|_{x=0} = 0, \quad \varepsilon|_{x=1} = (\gamma u_{xt} - \delta u_{xxx} + \sigma_1)|_{x=1} = 0, \tag{1.14}$$

with

$$\sigma_1 = f_1\theta + f_2, \tag{1.15}$$

as well as

$$\theta_x|_{x=0,\,1} = 0, \tag{1.16}$$

$$u(x,0) = u_0(x), \quad u_t(x,0) = u_1(x), \quad \theta(x,0) = \theta_0(x) > 0, \ x \in \ \overline{\Omega}. \tag{1.17}$$

The physical meaning of the boundary conditions is clear; for instance, the second condition at $x = 1$ describes the stress-free situation.

Next, we employ an idea of Andrews [2] and Pego [17] to simplify the problem by introducing the *velocity potential*

$$p(x,t) = \int_1^x u_t(y,t)\,dy\,. \tag{1.18}$$

Then,

$$\varepsilon_t = p_{xx}, \quad \text{in} \quad \Omega_\infty, \tag{1.19}$$

and (1.10)–(1.11) can be rewritten as

$$p_t - \gamma p_{xx} + \delta\varepsilon_{xx} - \sigma_1 = 0, \quad \text{in} \quad \Omega_\infty, \tag{1.20}$$

$$C_V\theta_t - k\theta_{xx} - f_1\theta p_{xx} - \gamma p_{xx}^2 = 0, \quad \text{in} \quad \Omega_\infty. \tag{1.21}$$

Accordingly, the initial and boundary conditions (1.14), (1.16), (1.17) become

$$p_x|_{x=0} = p_{xxx}|_{x=0} = \varepsilon_x|_{x=0} = 0, \tag{1.22}$$

$$p|_{x=1} = p_{xx}|_{x=1} = \varepsilon|_{x=1} = 0, \tag{1.23}$$

$$\varepsilon(x,0) = \varepsilon_0 = u_{0x}, \quad p(x,0) = p_0(x) = \int_1^x u_1(y)\,dy, \quad \theta(x,0) = \theta_0, \ \ x \in \overline{\Omega}\,. \tag{1.24}$$

It is easy to see that if (u, v, θ) is a smooth solution to (1.10)–(1.17), then (ε, p, θ) is a smooth solution to (1.19)–(1.24), and vice versa. Therefore, it suffices to consider the problem (1.19)–(1.24). In what follows, we assume without loss of generality that $C_V = 1$.

Before stating and proving our results, let us first recall some related results in the literature. In the case $\delta = 0$, Dafermos [5], Dafermos and Hsiao [6], Chen and Hoffmann [9], and Jiang [11] proved the global existence of a classical solution

to the system of (1.10)–(1.12) with various boundary conditions for a class of solid-like materials. However, an analysis of the asymptotic behavior as $t \to \infty$ was not performed in these papers. Recently, on the basis of Dafermos [5] and Dafermos and Hsiao [6], Luo [13] further investigated the asymptotic behavior of smooth solutions as time tends to infinity for a special class of solid-like materials in which $e = C_V\,\theta$, $F_2 = 0$, and $\delta = 0$. Racke and Zheng [18] obtained global existence, uniqueness, and the asymptotic behavior of weak solutions to (1.10)–(1.12) for $\delta = 0$ if both ends of the rod are insulated and if at least one end is stress-free.

In the case $\delta > 0$, we refer to Sprekels and Zheng [20] if $\delta > 0, \gamma = 0$, and to Hoffmann and Zochowski [10] if $\delta > 0, \gamma > 0$, for global existence and uniqueness results for Falk's Landau–Ginzburg model of shape memory alloys. However, the a priori estimates for the solution obtained in these papers depend on t, and hence the asymptotic behavior of the solution for $t \to \infty$ could not be treated there.

We also refer to the works of Andrews [2], Andrews and Ball [3], and Pego [17] for the isothermal and purely viscoelastic case.

The purpose of our contribution is to study the asymptotic behavior as $t \to \infty$ of the solutions to the system (1.19)–(1.24) and to prove the compactness of the orbit. Next, we state the main result of this paper.

THEOREM 1.1. *Suppose that $\varepsilon_0, p_0 \in H^3$, and $\theta_0 \in H^1$ are given functions that satisfy the compatibility conditions* $p_{0x}|_{x=0} = \varepsilon_{0x}|_{x=0} = 0$, $p_0|_{x=1} = p_{xx}|_{x=1} = \varepsilon_x|_{x=1} = 0$, *and suppose that $\theta_0 > 0$ in $[0,1]$. Then the following results hold.*

(i) *The problem admits a unique global solution (ε, p, θ) satisfying*

$$\varepsilon \in C(\mathbb{R}^+; H^3), \quad \varepsilon_t \in C(\mathbb{R}^+; H^1) \cap L^2(\mathbb{R}^+; H^2);$$

$$p \in C(\mathbb{R}^+; H^3) \cap L^2(\mathbb{R}^+; H^4), \quad p_t \in C(\mathbb{R}^+; H^1) \cap L^2(\mathbb{R}^+; H^2);$$

$$\theta \in C(\mathbb{R}^+; H^1), \quad \theta_x \in L^2(\mathbb{R}^+; H^1), \quad \theta_t \in L^2(\mathbb{R}^+; L^2),$$

$$\theta(x,t) > 0 \ \ \forall\, (x,t) \in \ [0,1] \times \mathbb{R}^+. \tag{1.25}$$

(ii) *As $t \to \infty$, it holds that*

$$\|p(\cdot,t)\|_{H^3} \to 0, \quad \|p_t(\cdot,t)\|_{H^1} \to 0, \tag{1.26}$$

$$\|\delta\varepsilon_{xx}(\cdot,t) - \sigma_1(\cdot,t)\|_{H^1} \to 0, \quad \|\varepsilon_t(\cdot,t)\|_{H^1} \to 0, \quad \|\theta_x(\cdot,t)\| \to 0. \tag{1.27}$$

(iii) *For all $\nu > 0$,*

$$\varepsilon \in C([\nu, +\infty); H^4), \quad p \in C([\nu, +\infty); H^4), \quad \theta \in C([\nu, +\infty); H^3); \tag{1.28}$$

i.e., the orbit is compact in $H^3 \times H^3 \times H^1$.

(iv)

$$(\varepsilon(\cdot,t), p(\cdot,t), \theta(\cdot,t)) \to (\overline{\varepsilon}, 0, \overline{\theta}), \quad \textit{as} \ \ t \to \infty, \ \ \textit{in} \ \ H^3 \times H^3 \times H^1\,, \tag{1.29}$$

where $(\overline{\varepsilon},\ \overline{\theta})$ is one of the equilibria for the corresponding stationary problem.

The main difficulties in proving Theorem 1.1 are due to the higher degree of nonlinearity inherent in the system (1.19)–(1.21) and to the higher order derivative arising for $\delta > 0$. The presence of this higher order derivative makes the problem in two ways significantly different from the problem with $\delta = 0, \gamma > 0$: it renders the

orbit compact (while discontinuities of strain will persist in the case $\delta = 0, \gamma > 0$, as shown in [18]), and the technique needed to obtain the asymptotic behavior differs considerably from that used in the case $\delta = 0, \gamma > 0$. One of the main ingredients of the proof in this paper is to bound the norms of ε, p, as well as their derivatives, in terms of expressions of the form

$$1 + \sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty}^{\alpha} + \left(\int_0^t \|\theta_t(\tau)\|^2 \, d\tau\right)^{\beta}, \tag{1.30}$$

where $0 \le \alpha \le \frac{3}{2}$, $0 \le \beta \le \frac{1}{2}$. This makes it possible to reduce the degree of nonlinearity via interpolation techniques. To study the asymptotic behavior, we will make repeated use of a basic lemma in analysis proved in Shen and Zheng [19]. In section 2, we will prove the uniform a priori estimates and the compactness of the orbit. In section 3, the asymptotic behavior is investigated.

The notation in this paper will be as follows: L^p, $1 \le p \le \infty$, $W^{m,\infty}$, $m \in \mathbb{N}$, $H^1 \equiv W^{1,2}$, and $H_0^1 = W_0^{1,2}$, respectively, denote the usual Lebesgue and Sobolev spaces on (0,1). By $(\cdot,\cdot)$, we denote the inner product in L^2, and $\|\cdot\|_B$ denotes the norm in the space B. We use the abbreviation $\|\cdot\| := \|\cdot\|_{L_2}$, and $C^k(I,B)$, $k \in \mathbb{N}_0$, denotes the space of k-times continuously differentiable functions from $I \subset \mathbb{R}$ into a Banach space B. The spaces $L^p(I,B)$, $1 \le p \le \infty$, are defined analogously. Finally, ∂_t or $\frac{d}{dt}$ or a subscript t and, likewise, ∂_x or a subscript x, denote the partial derivatives with respect to t and x, respectively.

2. Uniform a priori estimates. The general framework to prove global existence and uniqueness of solution has been established in earlier papers, for instance, in Sprekels and Zheng [20] and Hoffmann and Zochowski [10]. The setting will become more apparent soon during the derivation of uniform a priori estimates. Therefore, we can focus our attention on the study of the asymptotic behavior and on the compactness of the orbit. In order to get the asymptotic behavior of the solution as $t \to \infty$, we shall prove uniform a priori estimates on ε, p, and θ with respect to t. From now on, we will always denote by C a universal positive constant that may depend on the initial data, but not on t.

LEMMA 2.1. *For any $t > 0$, the following estimates hold.*

$$\|\varepsilon(t)\| + \|\varepsilon(t)\|_{L^6} + \|p_x(t)\| + \|\varepsilon_x(t)\| + \|\theta(t)\|_{L^1} \le C, \tag{2.1}$$

$$\|p(t)\|_{L^\infty} + \|\varepsilon(t)\|_{L^\infty} \le C, \tag{2.2}$$

$$\theta(x,t) > 0 \quad \forall\, (x,t) \in [0,1] \times \mathbb{R}^+. \tag{2.3}$$

Proof. First, applying the maximum principle to (1.21), we find that

$$\theta(x,t) > 0 \quad \forall\, (x,t) \in [0,1] \times \mathbb{R}^+ . \tag{2.4}$$

Next, multiplying (1.20) by $-p_{xx}$, adding the result to (1.21), and integrating with respect to x over Ω, we arrive at

$$\frac{d}{dt}\int_0^1 \left(\theta + F_2(\varepsilon) + \frac{1}{2}p_x^2 + \frac{\delta}{2}\varepsilon_x^2\right)(t)\, dx = 0. \tag{2.5}$$

Thus,

$$\int_0^1 \left(\theta + F_2(\varepsilon) + \frac{1}{2}p_x^2 + \frac{\delta}{2}\varepsilon_x^2\right)(t)\, dx = E_1 , \tag{2.6}$$

where E_1 is a constant depending only on the initial data.

Using Young's inequality, we see that

$$F_2(\varepsilon) \geq C_1\varepsilon^6 - C_2\,, \tag{2.7}$$

and thus,

$$\|\varepsilon(t)\| + \|p_x(t)\| + \|\varepsilon_x(t)\| + \|\varepsilon(t)\|_{L^6} + \|\theta(t)\|_{L^1} \leq C. \tag{2.8}$$

By virtue of the boundary conditions and of Poincaré's inequality, we find

$$\|p(t)\|_{L^\infty} + \|\varepsilon(t)\|_{L^\infty} \leq C\,, \tag{2.9}$$

from which the assertion follows. □

LEMMA 2.2. *For any $t > 0$, the following estimates hold.*

$$\int_0^t \int_0^1 \left(\frac{\theta_x^2}{\theta^2} + \frac{p_{xx}^2}{\theta}\right) dx\, d\tau \leq C, \tag{2.10}$$

$$\int_0^t \|p_x(\tau)\|^2 d\tau \leq \int_0^t \|p_x(\tau)\|_{L^\infty}^2 d\tau \leq C, \quad \int_0^t \|p(\tau)\|_{L^\infty}^2 d\tau \leq C\,, \tag{2.11}$$

$$\int_0^t \|p_x(\tau)\|^{n+2} d\tau \leq C \quad \forall \quad n \geq 0. \tag{2.12}$$

Proof. Multiplication of (1.21) by θ^{-1} and integration with respect to x over Ω yield

$$\frac{d}{dt}\int_0^1 \big(\log\theta - F_1(\varepsilon)\big)(t)\, dx - \int_0^1 \left(\frac{k\theta_x^2}{\theta^2} + \frac{\gamma p_{xx}^2}{\theta}\right)(t)\, dx = 0. \tag{2.13}$$

Since $\log\theta \leq \theta - 1$ for all $\theta > 0$, we obtain

$$\int_0^t \int_0^1 \left(\frac{k\theta_x^2}{\theta^2} + \frac{\gamma p_{xx}^2}{\theta}\right) dx\, d\tau \leq C. \tag{2.14}$$

From $p_x|_{x=0} = 0$ it follows that

$$p_x(x,t) = p_x(0,t) + \int_0^x p_{xx}(y,t)\, dy = \int_0^x p_{xx}(y,t)\, dy. \tag{2.15}$$

Hence,

$$\begin{aligned}
&\int_0^t \|p_x(\tau)\|_{L^\infty}^2 d\tau \leq \int_0^t \Big(\int_0^1 |p_{xx}(x,\tau)|\, dx\Big)^2 d\tau \\
&\leq \int_0^t \left(\int_0^1 \sqrt{\theta}\, \frac{|p_{xx}|}{\sqrt{\theta}}\, dx\right)^2 d\tau \leq \int_0^t \Big(\int_0^1 \theta\, dx\Big)\Big(\int_0^1 \frac{p_{xx}^2}{\theta}\, dx\Big)\, d\tau \\
&\leq C\int_0^t \int_0^1 \frac{p_{xx}^2}{\theta}\, dx\, d\tau \leq C.
\end{aligned} \tag{2.16}$$

Thus,

$$\int_0^t \|p_x(\tau)\|^2 d\tau \leq \int_0^t \|p_x(\tau)\|_{L^\infty}^2 d\tau \leq C. \tag{2.17}$$

Combining (2.11) with (2.8), a simple induction yields that to any $n \in \mathbb{N}$ there is some $C = C(n)$ such that

$$\int_0^t \|p_x(\tau)\|^{n+2} d\tau \le C\,. \tag{2.18}$$

The proof of the assertion is complete. □

In what follows we will see that (2.18) is very useful for reducing the degree of nonlinearity. To get further estimates, we will now derive estimates for the derivatives of the norms of ε, p by expressions of the form (1.30).

LEMMA 2.3. *For any $t > 0$, the following estimates hold.*

$$\int_0^t (\|\varepsilon_t(\tau)\|^2 + \|p_{xx}(\tau)\|^2)\, d\tau \le C \sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty}, \tag{2.19}$$

$$\int_0^t \|\theta_x(\tau)\|^2 d\tau \le C \sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty}^2. \tag{2.20}$$

Proof. Using Lemma 2.2, we obtain

$$\begin{aligned}\int_0^t \|p_{xx}(\tau)\|^2 d\tau &= \int_0^t \left\| \sqrt{\theta} \frac{p_{xx}}{\sqrt{\theta}}(\tau) \right\|^2 d\tau \\ &\le \sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty} \int_0^t \left\| \frac{p_{xx}}{\sqrt{\theta}}(\tau) \right\|^2 d\tau \\ &\le C \sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty}. \end{aligned} \tag{2.21}$$

Similarly, we have

$$\int_0^t \|\theta_x(\tau)\|^2 d\tau \le C \sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty}^2. \tag{2.22}$$

The proof is complete. □

We can now show further estimates.

LEMMA 2.4. *For any $t > 0$, the following estimates hold.*

$$\begin{aligned}&\|p_{xt}(t)\|^2 + \|p_{xxx}(t)\|^2 + \int_0^t (\|p_{xxt}(\tau)\|^2 + \|\varepsilon_{tt}(\tau)\|^2)\, d\tau \\ &\le C \left(1 + \sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty}^3 + \int_0^t \|\theta_t(\tau)\|^2\, d\tau \right), \end{aligned} \tag{2.23}$$

$$\begin{aligned}&\|\varepsilon_{xt}(t)\|^2 + \int_0^t (\|p_{xxxx}(\tau)\|^2 + \|\varepsilon_{xxt}(\tau)\|^2)\, d\tau \\ &\le C \left(1 + \sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty}^3 + \int_0^t \|\theta_t(\tau)\|^2\, d\tau \right). \end{aligned} \tag{2.24}$$

Proof. First, differentiating (1.20) with respect to t, multiplying the result by $-\varepsilon_{tt}$, and integrating with respect to x over Ω, we obtain

$$\begin{aligned}0 &= (p_{tt}(t), -p_{xxt}(t)) + \gamma \|\varepsilon_{tt}(t)\|^2 + (\delta\varepsilon_{xt}(t), \varepsilon_{xtt}(t)) + \int_0^1 \sigma_{1t}(t)\, \varepsilon_{tt}(t)\, dx \\ &= (p_{xtt}(t), p_{xt}(t)) + \gamma \|\varepsilon_{tt}(t)\|^2 + \delta(\varepsilon_{xt}(t), \varepsilon_{xtt}(t)) \\ &\quad + \int_0^1 \big(f_1'(\varepsilon)\, \varepsilon_t\, \theta + f_2'(\varepsilon)\, \varepsilon_t + f_1(\varepsilon)\, \theta_t \big)(t)\, \varepsilon_{tt}(t)\, dx. \end{aligned} \tag{2.25}$$

Combination with (2.9) yields

$$\frac{1}{2}\frac{d}{dt}(\|p_{xt}(t)\|^2+\delta\|\varepsilon_{xt}(t)\|^2)+\gamma\|\varepsilon_{tt}(t)\|^2 \le \frac{\gamma}{2}\|\varepsilon_{tt}(t)\|^2+C\int_0^1 \big(\theta^2\varepsilon_t^2+\varepsilon_t^2+\theta_t^2\big)(t)\,dx. \tag{2.26}$$

Integrating (2.26) with respect to t and applying Lemma 2.3, we arrive at

$$\begin{aligned}
&\|p_{xt}(t)\|^2 + \|\varepsilon_{xt}(t)\|^2 + \int_0^t \|\varepsilon_{tt}(\tau)\|^2 d\tau \\
&\le C + C\int_0^t (\|\theta(\tau)\,\varepsilon_t(\tau)\|^2 + \|\varepsilon_t(\tau)\|^2 + \|\theta_t(\tau)\|^2)\,d\tau \\
&\le C + C\sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}^2 \int_0^t \|\varepsilon_t(\tau)\|^2\,d\tau + C\int_0^t (\|\varepsilon_t(\tau)\|^2 + \|\theta_t(\tau)\|^2)\,d\tau \\
&\le C\Big(1+\sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}^3 + \int_0^t \|\theta_t(\tau)\|^2 d\tau\Big). \qquad (2.27)
\end{aligned}$$

Here, we have used Young's inequality in the form $a \le Ca^3 + C'$.

Next, we differentiate (1.20) with respect to t, then multiply by ε_{xxt}, and integrate the result with respect to x over Ω to obtain

$$\begin{aligned}
0 &= (p_{tt}(t),\varepsilon_{xxt}(t)) - \gamma(\varepsilon_{tt}(t),\varepsilon_{xxt}(t)) + \delta\|\varepsilon_{xxt}(t)\|^2 - \int_0^1 \varepsilon_{xxt}(t)\,\sigma_{1t}(t)\,dx \\
&= (p_{xxtt}(t),\varepsilon_t(t)) + \gamma(\varepsilon_{xtt}(t),\varepsilon_{xt}(t)) + \delta\|\varepsilon_{xxt}(t)\|^2 - \int_0^1 \varepsilon_{xxt}(t)\,\sigma_{1t}(t)\,dx \\
&= \frac{d}{dt}(p_{xxt}(t),\varepsilon_t(t)) - \|p_{xxt}(t)\|^2 + \frac{\gamma}{2}\frac{d}{dt}\|\varepsilon_{xt}(t)\|^2 + \delta\|\varepsilon_{xxt}(t)\|^2 \\
&\quad - \int_0^1 \varepsilon_{xxt}(t)\,\sigma_{1t}(t)\,dx. \qquad (2.28)
\end{aligned}$$

However, by integration by parts, we have

$$(p_{xxt}(t),\varepsilon_t(t)) = -(p_{xt}(t),\varepsilon_{xt}(t)). \tag{2.29}$$

Combining this with (2.28), and using (2.23) and Young's inequality, we find

$$\begin{aligned}
&\frac{\gamma}{4}\|\varepsilon_{xt}(t)\|^2 + \delta\int_0^t \|\varepsilon_{xxt}(\tau)\|^2 d\tau \\
&\le C + \frac{\delta}{2}\int_0^t \|\varepsilon_{xxt}(\tau)\|^2 d\tau + C\Big(\|p_{xt}(t)\|^2 + \int_0^t (\|\sigma_{1t}(\tau)\|^2 + \|p_{xxt}(\tau)\|^2)\,d\tau\Big) \\
&\le C\Big(1+\sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}^3 + \int_0^t \|\theta_t(\tau)\|^2 d\tau\Big) + \frac{\delta}{2}\int_0^t \|\varepsilon_{xxt}(\tau)\|^2 d\tau\,. \qquad (2.30)
\end{aligned}$$

The proof of the lemma is complete. □

In what follows, we will find that the above lemma plays a crucial role in reducing the degree of nonlinearity.

LEMMA 2.5. *For any $t > 0$, the following estimates hold.*

$$\|\theta_x(t)\|^2 + \int_0^t \|\theta_t(\tau)\|^2 d\tau \le C. \tag{2.31}$$

$$\sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty} \le C. \tag{2.32}$$

Proof. Multiplying (1.21) by θ_t and integrating with respect to x over Ω, we obtain

$$\begin{aligned}
&\frac{k}{2}\frac{d}{dt}\|\theta_x(t)\|^2 + \|\theta_t(t)\|^2 \;=\; \int_0^1 \big(f_1(\varepsilon)\,\theta\,\theta_t\,p_{xx} + \gamma\,\theta_t\,p_{xx}^2\big)(t)\,dx \\
&\le C\left(\|\theta(t)\,p_{xx}(t)\|\,\|\theta_t(t)\| + \Big(\int_0^1 p_{xx}^4(t)\,dx\Big)^{\frac12}\|\theta_t(t)\|\right) \\
&\le C\left(\|\theta(t)\|_{L^\infty}^{\frac12}\,\|p_{xx}(t)\|_{L^\infty}\Big(\int_0^1 \theta(t)\,dx\Big)^{\frac12}\|\theta_t(t)\| \;+\; \|p_{xx}(t)\|_{L^4}^2\,\|\theta_t(t)\|\right). \qquad (2.33)
\end{aligned}$$

Therefore, integration with respect to t yields

$$\begin{aligned}
&\|\theta_x(t)\|^2 + \int_0^t \|\theta_t(\tau)\|^2 d\tau \\
&\le C\left(\sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}^{\frac12}\Big(\int_0^t \|p_{xx}(\tau)\|_{L^\infty}^2 d\tau\Big)^{\frac12}\Big(\int_0^t \|\theta_t(\tau)\|^2 d\tau\Big)^{\frac12}\right. \\
&\qquad \left. + \Big(\int_0^t \|p_{xx}(\tau)\|_{L^4}^4 d\tau\Big)^{\frac12}\Big(\int_0^t \|\theta_t(\tau)\|^2 d\tau\Big)^{\frac12} \;+\; 1\right) \\
&= C\,(I_1 + I_2 + 1)\,. \qquad (2.34)
\end{aligned}$$

We now estimate the terms I_1, I_2. By virtue of Nirenberg's inequality and the boundary conditions, we obtain

$$\|p_{xx}(t)\|_{L^\infty} \le C\,\|p_{xxxx}(t)\|^{\frac12}\;\|p_x(t)\|^{\frac12}, \qquad (2.35)$$

$$\|p_{xx}(t)\|_{L^4} \le C\,\|p_{xxxx}(t)\|^{\frac{5}{12}}\;\|p_x(t)\|^{\frac{7}{12}}. \qquad (2.36)$$

Hence,

$$\begin{aligned}
I_1 &= C\left(\sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}\int_0^t \|\theta_t(\tau)\|^2 d\tau \int_0^t \|p_{xx}(\tau)\|_{L^\infty}^2 d\tau\right)^{\frac12} \\
&\le C\left(\sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}\int_0^t \|\theta_t(\tau)\|^2 d\tau \int_0^t \|p_{xxxx}(\tau)\|\,\|p_x(\tau)\|\,d\tau\right)^{\frac12} \\
&\le C\left(\sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}\int_0^t \|\theta_t(\tau)\|^2 d\tau\right)^{\frac12}\left(\int_0^t \|p_{xxxx}(\tau)\|^2 d\tau \int_0^t \|p_x(\tau)\|^2 d\tau\right)^{\frac14}. \qquad (2.37)
\end{aligned}$$

Using Lemmas 2.2 and 2.4 and Young's inequality, we conclude that

$$\begin{aligned}
I_1 &\le C\left(\sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}\int_0^t \|\theta_t(\tau)\|^2 d\tau\right)^{\frac12}\left(\int_0^t \|p_{xxxx}(\tau)\|^2 d\tau\right)^{\frac14} \\
&\le C\left(\sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}\int_0^t \|\theta_t(\tau)\|^2 d\tau\right)^{\frac12}\left(1 + \sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}^3 + \int_0^t \|\theta_t(\tau)\|^2 d\tau\right)^{\frac14} \\
&\le \frac14\int_0^t \|\theta_t(\tau)\|^2 d\tau + C\left(1 + \sup_{0\le\tau\le t}\|\theta(\tau)\|_{L^\infty}^{\frac52}\right). \qquad (2.38)
\end{aligned}$$

Next, owing to Schwarz's inequality and (2.36), we have

$$\begin{aligned} I_2 &= C\left(\int_0^t \|\theta_t(\tau)\|^2 d\tau \int_0^t \|p_{xx}(\tau)\|_{L^4}^4 d\tau\right)^{\frac{1}{2}} \\ &\le C\left(\int_0^t \|\theta_t(\tau)\|^2 d\tau \int_0^t \|p_{xxxx}(\tau)\|^{\frac{5}{3}} \, \|p_x(\tau)\|^{\frac{7}{3}} d\tau\right)^{\frac{1}{2}} \\ &\le C\left(\int_0^t \|\theta_t(\tau)\|^2 d\tau\right)^{\frac{1}{2}} \left(\int_0^t \|p_{xxxx}(\tau)\|^2 d\tau\right)^{\frac{5}{12}} \left(\int_0^t \|p_x(\tau)\|^{14} d\tau\right)^{\frac{1}{12}}. \end{aligned} \tag{2.39}$$

Applying (2.18) with $n = 12$ and Lemma 2.4, we get

$$\begin{aligned} I_2 &\le C\left(\int_0^t \|\theta_t(\tau)\|^2 d\tau\right)^{\frac{1}{2}} \left(\int_0^t \|p_{xxxx}(\tau)\|^2 d\tau\right)^{\frac{5}{12}} \\ &\le C\left(\int_0^t \|\theta_t(\tau)\|^2 d\tau\right)^{\frac{1}{2}} \left(1 + \sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty}^3 + \int_0^t \|\theta_t(\tau)\|^2 d\tau\right)^{\frac{5}{12}} \\ &\le \frac{1}{4}\int_0^t \|\theta_t(\tau)\|^2 d\tau + C \sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty}^{\frac{5}{2}} + C. \end{aligned} \tag{2.40}$$

Owing to Nirenberg's inequality and (2.1), we have

$$\|\theta(t)\|_{L^\infty} \le C\,\|\theta_x(t)\|^{\frac{2}{3}} \, \|\theta(t)\|_{L^1}^{\frac{1}{3}} + C\,\|\theta(t)\|_{L^1} \le C\,\|\theta_x(t)\|^{\frac{2}{3}} + C. \tag{2.41}$$

Combining (2.38)–(2.40) with (2.34) and (2.41) and applying Young's inequality, we find

$$\begin{aligned} \|\theta_x(t)\|^2 + \int_0^t \|\theta_t(\tau)\|^2 d\tau &\le \frac{1}{2}\int_0^t \|\theta_t(\tau)\|^2 d\tau + C\Big(1 + \sup_{0\le\tau\le t} \|\theta_x(\tau)\|^{\frac{5}{3}}\Big) \\ &\le C + \frac{1}{2}\left(\int_0^t \|\theta_t(\tau)\|^2 d\tau + \sup_{0\le\tau\le t} \|\theta_x(\tau)\|^2\right). \end{aligned} \tag{2.42}$$

Taking the supremum with respect to t in (2.42) yields

$$\sup_{0\le\tau\le t} \|\theta_x(\tau)\|^2 + \int_0^t \|\theta_t(\tau)\|^2 d\tau \le \frac{1}{2}\Big(\int_0^t \|\theta_t(\tau)\|^2 d\tau + \sup_{0\le\tau\le t} \|\theta_x(\tau)\|^2\Big) + C. \tag{2.43}$$

Hence,

$$\sup_{0\le\tau\le t} \|\theta_x(\tau)\|^2 + \int_0^t \|\theta_t(\tau)\|^2 d\tau \le C. \tag{2.44}$$

Thus, using (2.41),

$$\sup_{0\le\tau\le t} \|\theta(\tau)\|_{L^\infty}^2 \le C\,, \tag{2.45}$$

which concludes the proof of the assertion. □

Combining Lemmas 2.3–2.5 and using the system equations, we immediately conclude with the following lemma.

LEMMA 2.6. *For any $t > 0$, the following estimates hold.*

$$\int_0^t (\|p_{xx}(\tau)\|^2 + \|\varepsilon_t(\tau)\|^2 + \|\theta_x(\tau)\|^2_{H^1})\, d\tau \le C, \tag{2.46}$$

$$\int_0^t (\|p_{xxt}(\tau)\|^2 + \|\varepsilon_{tt}(\tau)\|^2 + \|p_{xxxx}(\tau)\|^2 + \|\varepsilon_{xxt}(\tau)\|^2)\, d\tau \le C, \tag{2.47}$$

$$\|p_{xt}(t)\|^2 + \|p_{xxx}(t)\|^2 + \|\varepsilon_{xt}(t)\|^2 + \|\varepsilon_{xxx}(t)\|^2 \le C. \tag{2.48}$$

LEMMA 2.7. *For any $t > 0$, the following estimates hold.*

$$\int_0^t (\|p_t(\tau)\|^2 + \|p_t(\tau)\|^2_{L^\infty} + \|p_{xt}(\tau)\|^2 + \|p_{xt}(\tau)\|^2_{L^\infty})\, d\tau \le C, \tag{2.49}$$

$$\int_0^t (\|\delta\varepsilon_{xx}(\tau) - \sigma_1(\tau)\|^2 d\tau + \|(\delta\varepsilon_{xx} - \sigma_1)_t(\tau)\|^2)\, d\tau \le C, \tag{2.50}$$

$$\int_0^t (\|p_{xx}(\tau)\|^2_{L^\infty} + \|p_{xxx}(\tau)\|^2 + \|p_{xxx}(\tau)\|^2_{L^\infty} + \|p_{tt}(\tau)\|^2)\, d\tau \le C, \tag{2.51}$$

$$\|p_t(t)\|^2 + \|p_{xx}(t)\|^2 + \|p_t(t)\|^2_{L^\infty} + \|p_x(t)\|^2_{L^\infty} + \|p_{xx}(t)\|^2_{L^\infty} \le C. \tag{2.52}$$

Proof. These estimates can easily be derived from the system equations and from Lemmas 2.5 and 2.6. □

Now we proceed to investigate the compactness of the orbit of the solution for $t > 0$ in $H^3 \times H^3 \times H^1$. For the time being, we assume that the initial data are so smooth that the solution will have enough smoothness to carry out the following argument: if the initial data belonged just to $H^3 \times H^3 \times H^1$, we could approximate them by smooth functions and then pass to the limit.

Differentiating (1.20) twice with respect to t, we find that

$$p_{ttt} - \gamma p_{xxtt} + \delta\varepsilon_{xxtt} - \sigma_{1tt} = 0\,. \tag{2.53}$$

A straightforward calculation yields

$$\sigma_{1tt} = f_1'(\varepsilon)\,\varepsilon_{tt}\,\theta + 2\,f_1'(\varepsilon)\,\varepsilon_t\,\theta_t + f_1(\varepsilon)\,\theta_{tt} + f_2''(\varepsilon)\,\varepsilon_t^2 + f_2'\varepsilon)\,\varepsilon_{tt}. \tag{2.54}$$

Multiplying (2.53) by p_{tt} and integrating with respect to x over Ω, we find

$$\begin{aligned} 0 &= \frac{1}{2}\frac{d}{dt}\|p_{tt}(t)\|^2 - \gamma(p_{xxtt}(t), p_{tt}(t)) + \delta(\varepsilon_{xxtt}(t), p_{tt}(t)) - (\sigma_{1tt}(t), p_{tt}(t)) \\ &= \frac{1}{2}\frac{d}{dt}\|p_{tt}(t)\|^2 + \gamma\|p_{xtt}(t)\|^2 + \delta(\varepsilon_{tt}(t), p_{xxtt}(t)) - (\sigma_{1tt}(t), p_{tt}(t)) \\ &= \frac{1}{2}\frac{d}{dt}\Big(\|p_{tt}(t)\|^2 + \delta\|\varepsilon_{tt}(t)\|^2\Big) + \gamma\|p_{xtt}(t)\|^2 - (\sigma_{1tt}(t), p_{tt}(t))\,. \end{aligned} \tag{2.55}$$

Multiplying (2.55) by t^2 and using (2.32), as well as Lemmas 2.6 and 2.7, we obtain that

$$\begin{aligned} &\frac{1}{2}\frac{d}{dt}\Big(t^2\|p_{tt}(t)\|^2 + t^2\delta\|\varepsilon_{tt}\|^2\Big) - t\,(\|p_{tt}(t)\|^2 + \delta\|\varepsilon_{tt}(t)\|^2) + \gamma t^2\|p_{xtt}(t)\|^2 \\ &\le t^2\|p_{tt}(t)\|^2 + Ct^2\|\sigma_{1tt}(t)\|^2 \\ &\le t^2\|p_{tt}(t)\|^2 + Ct^2(\|\varepsilon_{tt}(t)\|^2 + \|\theta_t(t)\|^2 + \|\theta_{tt}(t)\|^2 + \|\varepsilon_t(t)\|^2)\,. \end{aligned} \tag{2.56}$$

Hence, it follows from (2.31), (2.46), and (2.47) that

$$t^2(\|p_{tt}(t)\|^2+\delta\|\varepsilon_{tt}(t)\|^2)+\int_0^t \tau^2\|p_{xtt}(\tau)\|^2 d\tau \le C_1+Ct^2+C\int_0^t \tau^2\|\theta_{tt}(\tau)\|^2 d\tau\,, \tag{2.57}$$

where $C_1 = C(\|\varepsilon_0\|_{H^3}, \|p_0\|_{H^3}, \|\theta_0\|_{H^1})$.

On the other hand, differentiating (1.21) with respect to t, we get

$$\theta_{tt} - k\theta_{xxt} - (f_1(\varepsilon)\theta p_{xx} + \gamma p_{xx}^2)_t = 0. \tag{2.58}$$

Multiplying by θ_{tt} and integrating with respect to x, we arrive at

$$\begin{aligned} \frac{k}{2}\frac{d}{dt}\|\theta_{xt}(t)\|^2 + \|\theta_{tt}(t)\|^2 &\le \frac{1}{2}\|\theta_{tt}(t)\|^2 + \frac{1}{2}\|(f_1(\varepsilon)\theta p_{xx} + \gamma p_{xx}^2)_t(t)\|^2 \\ &\le \frac{1}{2}\|\theta_{tt}(t)\|^2 + C\left(\|p_{xx}(t)\|^2 + \|\theta_t(t)\|^2 + \|p_{xxt}(t)\|^2\right). \end{aligned} \tag{2.59}$$

Multiplication of (2.59) by t^2 yields

$$\frac{k}{2}\frac{d}{dt}(t^2\|\theta_{xt}(t)\|^2) - kt\|\theta_{xt}(t)\|^2 + \frac{t^2}{2}\|\theta_{tt}(t)\|^2 \le Ct^2(\|p_{xx}(t)\|^2+\|\theta_t(t)\|^2+\|p_{xxt}(t)\|^2). \tag{2.60}$$

In order to estimate $\int_0^t \tau\|\theta_{xt}(\tau)\|^2 d\tau$, we multiply (2.58) by θ_t and then integrate with respect to x over Ω to obtain

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|\theta_t(t)\|^2 + k\|\theta_{xt}(t)\|^2 &\le \frac{1}{2}\|\theta_t(t)\|^2 + \frac{1}{2}\|(f_1(\varepsilon)\theta p_{xx} + \gamma p_{xx}^2)_t(t)\|^2 \\ &\le \frac{1}{2}\|\theta_t(t)\|^2 + C\left(\|\varepsilon_t(t)\|^2 + \|\theta_t(t)\|^2 + \|p_{xxt}(t)\|^2\right). \end{aligned} \tag{2.61}$$

Multiplying (2.61) by t, we find

$$\frac{1}{2}\frac{d}{dt}(t\|\theta_t(t)\|^2) + kt\|\theta_{tx}(t)\|^2 \le C\left(\|\theta_t(t)\|^2 + t\|\theta_t(t)\|^2 + t\left(\|\varepsilon_t(t)\|^2+\|\theta_t(t)\|^2+\|p_{xxt}(t)\|^2\right)\right). \tag{2.62}$$

Therefore,

$$t\|\theta_t(t)\|^2 + \int_0^t \tau\|\theta_{xt}(\tau)\|^2 d\tau \le Ct + C_2\,, \tag{2.63}$$

where $C_2 = C(\|\varepsilon_0\|_{H^3}, \|p_0\|_{H^3}, \|\theta_0\|_{H^1})$.

Combination of (2.63) with (2.60) yields

$$\int_0^t \tau^2\|\theta_{tt}(\tau)\|^2 d\tau \le C_3 + Ct^2\,, \tag{2.64}$$

with $C_3 = C(\|\varepsilon_0\|_{H^3}, \|p_0\|_{H^3}, \|\theta_0\|_{H^1})$.

Thus, it follows from (2.57) that

$$\|p_{tt}(t)\|^2 + \|\varepsilon_{tt}(t)\|^2 \le C_4 t^{-2} + C. \tag{2.65}$$

Also, using (2.63) and (2.60),

$$\|\theta_t(t)\|^2 \le C + C_4 t^{-1}, \quad \|\theta_{xt}(t)\|^2 \le C_4 t^{-2} + C\,, \tag{2.66}$$

with C_4 depending only on $\|\varepsilon_0\|_{H^3}, \|p_0\|_{H^3}, \|\theta_0\|_{H^1}$.

Thus, it easily follows from equations (1.19) to (1.21) that for any initial data in $H^3 \times H^3 \times H^1$, the following holds:

$$(\varepsilon(\cdot,t), p(\cdot,t), \theta(\cdot,t)) \in H^4 \times H^4 \times H^3 \quad \forall\, t > 0. \tag{2.67}$$

Moreover, we can infer from Lemmas 2.5 to 2.7, and from (2.55), (2.59), and (2.61), that for any $\nu > 0$ the triple (ε, p, θ) is bounded in $C([\nu, +\infty); H^4 \times H^4 \times H^3)$. From this the compactness of the orbit in $H^3 \times H^3 \times H^1$ follows. □

3. Asymptotic behavior. In this section, we will prove the results on the asymptotic behavior of the solution given in Theorem 1.1. In what follows, a convergence symbol "$\to$" is always to be understood as $t \to \infty$. We will make use of the following basic lemma from Shen and Zheng [19].

LEMMA 3.1. *Suppose that y and h are nonnegative functions on $(0,\infty)$ such that y' is locally integrable and such that y, h satisfy*

$$\forall t \ge 0: \quad y'(t) \le A_1 y^2(t) + A_2 + h(t), \tag{3.1}$$

$$\forall T > 0: \quad \int_0^T y(\tau)d\tau \le A_3, \quad \int_0^T h(\tau)d\tau \le A_4, \tag{3.2}$$

where A_1, A_2, A_3, A_4 denote positive constants which are independent of t and T. Then, for any $r > 0$,

$$\forall t \ge 0: \quad y(t+r) \le \left(\frac{A_3}{r} + A_2 r + A_4\right) e^{A_1 A_2}. \tag{3.3}$$

Moreover,

$$\lim_{t\to\infty} y(t) = 0. \tag{3.4}$$

LEMMA 3.2. *It holds that*

$$\|p(t)\|_{H^3} \to 0, \quad \|p_t(t)\|_{H^1} \to 0, \tag{3.5}$$

$$\|\varepsilon_t(t)\|_{H^1} \to 0, \quad \|(\delta\varepsilon_{xx} - \sigma_1)(t)\|_{H^1} \to 0, \tag{3.6}$$

$$\|u_t(t)\|_{H^2} \to 0. \tag{3.7}$$

Proof. It follows from (2.26) and (2.32) that

$$\begin{aligned} &\frac{d}{dt}(\|p_{xt}(t)\|^2 + \delta\|\varepsilon_{xt}(t)\|^2) + \gamma\|\varepsilon_{tt}(t)\|^2 \\ &\le C\,(\|\theta(t)\,\varepsilon_t(t)\|^2 + \|\varepsilon_t(t)\|^2 + \|\theta_t(t)\|^2) \\ &\le C\,(\|\varepsilon_t(t)\|^2 + \|\theta_t(t)\|^2). \end{aligned} \tag{3.8}$$

Combining (3.8) with (2.51), (2.46), (2.49), (2.31) and applying Lemma 3.1, we arrive at

$$\|p_{xt}(t)\|^2 + \|\varepsilon_{xt}(t)\|^2 \to 0. \tag{3.9}$$

Hence, $\|p_{xxx}(t)\|^2 \to 0$, and thus $\|u_t\|_{H^2} \to 0$.

Next, we differentiate (1.20) with respect to t, then multiply by $\delta\varepsilon_{xx} - \sigma_1$, and integrate with respect to x over Ω. It follows that

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|\delta\varepsilon_{xx}(t) - \sigma_1(t)\|^2 &= -(p_{tt}(t) - \gamma\varepsilon_{tt}(t), \delta\varepsilon_{xx}(t) - \sigma_1(t)) \\ &\le \frac{1}{2}\|\delta\varepsilon_{xx}(t) - \sigma_1(t)\|^2 + C(\|p_{tt}(t)\|^2 + \|\varepsilon_{tt}(t)\|^2). \end{aligned} \tag{3.10}$$

Combining (3.10) with (2.50), (2.51), (2.47) and applying Lemma 3.1, we conclude that

$$\|\delta\varepsilon_{xx}(t) - \sigma_1(t)\|^2 \to 0. \tag{3.11}$$

From (1.20) and (3.9), we also get

$$\|(\delta\varepsilon_{xx} - \sigma_1)_x(t)\|^2 \to 0. \tag{3.12}$$

The assertions of Lemma 3.2 now follow from the above estimates and from Poincaré's inequality. □

LEMMA 3.3. *It holds that*

$$\|\theta_x(t)\| \to 0\,. \tag{3.13}$$

Proof. We multiply (1.21) by θ_t and integrate with respect to x over Ω to get

$$\begin{aligned} \frac{k}{2}\frac{d}{dt}\|\theta_x(t)\|^2 + \|\theta_t(t)\|^2 &= \int_0^1 \Big(\gamma\, p_{xx}^2\, \theta_t \,+\, f_1(\varepsilon)\, \theta\, \theta_t\, p_{xx}\Big)(t)\, dx \\ &\le \frac{1}{2}\|\theta_t(t)\|^2 + \|\theta(t)\, p_{xx}(t)\|^2 + \|p_{xx}^2(t)\|^2. \end{aligned} \tag{3.14}$$

Combining (3.14) with (2.32) and (2.52), we see that

$$k\frac{d}{dt}\|\theta_x(t)\|^2 + \|\theta_t(t)\|^2 \le C\|p_{xx}(t)\|^2. \tag{3.15}$$

Hence, we can infer from (2.46) and Lemma 3.1 that

$$\|\theta_x(t)\|^2 \to 0\,,$$

which concludes the proof. □

Concerning the convergence of ε, u, θ, we have the following result.

LEMMA 3.4. *It holds that*

$$(\varepsilon(\cdot,t), p(\cdot,t), \theta(\cdot,t)) \to (\overline{\varepsilon}, 0, \overline{\theta}), \quad \textit{in} \;\; H^3 \times H^3 \times H^1\,, \tag{3.16}$$

$$u(\cdot,t) \to \overline{u}\,, \quad \textit{in} \quad H^4\,, \quad \textit{with} \;\; \overline{u}(x) = \int_0^x \overline{\varepsilon}(y)\, dy \quad \forall\, x \in [0,1]\,, \tag{3.17}$$

where $(\overline{\varepsilon}, \overline{\theta})$ *is one of the equilibria for the corresponding stationary problem*

$$\delta\varepsilon_{xx} - f_1(\varepsilon)\theta - f_2(\varepsilon) = 0, \tag{3.18}$$

$$\varepsilon_x|_{x=0} = 0, \quad \varepsilon|_{x=1} = 0, \tag{3.19}$$

$$\theta = \text{Const.}, \tag{3.20}$$

$$\int_0^1 \Big(\theta + F_2(\varepsilon) + \frac{\delta}{2}\varepsilon_x^2\Big)\, dx = E_1. \tag{3.21}$$

Proof. It is easy to see from (2.4) and (2.12) that, for any $0 < \nu < 1$,

$$\begin{aligned} &\frac{d}{dt}\int_0^1 \Big(\theta - \nu\,\log\theta + F_2(\varepsilon) + \nu F_1(\varepsilon) + \frac{1}{2}p_x^2 + \frac{\delta}{2}\varepsilon_x^2\Big)(t)\, dx \\ &\qquad +\nu\int_0^1 \left(\frac{k\theta_x^2}{\theta^2} + \frac{\gamma p_{xx}^2}{\theta}\right)(t)\, dx = 0. \end{aligned} \tag{3.22}$$

Thus the system (1.19)–(1.21) has a Lyapunov function of the form

$$\int_0^1 \Big(\theta - \nu\,\log\theta + F_2(\varepsilon) + \nu F_1(\varepsilon) + \frac{1}{2}p_x^2 + \frac{\delta}{2}\varepsilon_x^2\Big)(t)\, dx\,.$$

Since the orbit is compact, as proved in previous section, it follows from the standard theory of dynamical systems that the ω-limit set is connected, compact, and consists of equilibria. Since the corresponding stationary problem admits only a finite number of solutions (see Zhou [22], and also Luckhaus and Zheng [12], Novick-Cohen and Zheng [16], Zheng [21]), (3.16) follows. In view of the boundary condition $u|_{x=0} = 0$, we also get (3.17). Therefore, the proof is complete. □

A NONLOCAL REGULARIZATION OF SOME OVER-DETERMINED BOUNDARY-VALUE PROBLEMS I*

D. E. EDMUNDS† AND N. I. POPIVANOV‡

Abstract. Some three-dimensional analogues of the plane Darboux problems for hyperbolic equations with degeneracy are investigated. In 1954, Protter initiated the study of such three-dimensional problems, and it is now well known that for an infinite number of smooth right-hand sides these problems have solutions with a strong power-type singularity on the characteristic cone. This effect appears even for small perturbations of certain C_0^∞ right-hand sides. Using Friedrichs' theory of symmetric positive operators, we find and investigate a nonlocal problem which is a regularizer, in some sense, of these ill-posed problems.

Key words. ill-posed problems, regularization methods, boundary-value problems, nonlocal problems, degenerate hyperbolic equations

1. Introduction.

To set the scene we denote points of $\mathbb{R}^3$ by $x = (x_1, x_2, t)$ and put $\rho = \sqrt{x_1^2 + x_2^2}$, $\varphi = \arctan(x_2/x_1)$. Let $K : [0, \infty) \to \mathbb{R}$ be of class C^1 and such that $K(0) = 0, K'(0) > 0$ with $K(t) > 0$, and $K'(t) > 0$ if $t > 0$. Let G be the domain

$$G = \left\{ x \in \mathbb{R}^3 : 0 < t < d,\ \int_0^t \sqrt{K(\tau)}d\tau < \rho < 1 - \int_0^t \sqrt{K(\tau)}d\tau \right\},$$

where d is the (unique) solution of the equation $2\int_0^d \sqrt{K(\tau)}d\tau = 1$. The boundary of G is $\partial G = S_0 \cup S_1 \cup S_2$, where S_0 is the disc $S_0 = \{x : t = 0, 0 \le \rho \le 1\}$ and

$$S_1 = \left\{ 0 \le t \le d, \rho = 1 - \int_0^t \sqrt{K(\tau)}d\tau \right\}, S_2 = \left\{ 0 \le t \le d, \rho = \int_0^t \sqrt{K(\tau)}d\tau \right\}.$$

We shall consider the equation

$$Lu := K(t)\left(u_{x_1x_1} + u_{x_2x_2}\right) - u_{tt} \equiv K(t)\left\{\rho^{-1}\left(\rho u_\rho\right)_\rho + \rho^{-2}u_{\varphi\varphi}\right\} - u_{tt} = f, \tag{1.1}$$

where f is a prescribed function; S_1 and S_2 are characteristics of (1.1).

Problem P. Is there a solution of (1.1) in G, which satisfies the condition

$$u = 0 \quad \text{on} \quad S_0 \cup S_1? \tag{1.2}$$

Problem P*. Is there a solution of (1.1) in G, which satisfies the condition

$$u = 0 \quad \text{on} \quad S_0 \cup S_2? \tag{1.3}$$

Protter [28, 29] formulated these adjoint problems as multidimensional analogues of the Darboux problem in the plane. He worked with the wave equation corresponding to $K(t) = 1$ and also investigated (1.1) in a domain which contained G in its

hyperbolic part and contained a set G' in which (1.1) is elliptic. For equation (1.1), which is of changing type in $G \cup G' \cup S_0$, he formulated certain other problems, which are three-dimensional analogues of a plane problem examined by Morawetz [20] and Lax and Phillips [17].

When equation (1.1) is of changing type, Protter's problem given in Protter [29] was studied by Aziz and Schneider [6], Bitsadze [7], Didenko [10], Salzman and Schneider [31], Papadakis [21], and others. Problems P and P* for (1.1) in the domain G were considered by Didenko [10] in the case of the Tricomi equation (in which $K(t) \equiv t$). In the same case, after the paper of Kan Cher [8], Popivanov showed in 1986 that the homogeneous Problem P* has infinitely many classical solutions v_n $(n = 4, 5, ...)$, where

$$v_n(t, \rho, \varphi) = t\rho^{-n} \left(\rho^2 - 4t^3/9\right)^{n-4/3} \ (a_n \cos n\varphi + b_n \sin n\varphi) \tag{1.4}$$

and a_n, b_n are arbitrary constants. This corresponds to the result of Kwang-Chang [16] for the wave equation and implies that for classical solvability of Problem P an infinite number of conditions of the form $f \perp v_n \quad (n = 4, 5, ...)$ are necessary.

Some interesting results concerning Protter's problems for equation (1.1), both in changing-type domains and in G, are provided by Sorokina [32, 33]; we discuss these in section 7. For further work on the problem (1.1), (1.2), see Aldashev [1, 2, 3], Kan Cher [8], Popivanov and Schneider [26, 27], and the references cited in these works.

Popivanov and Schneider [26] proceeded in another way, being interested in the question: why does Problem P not have a classical solution when $f = v_n$ (v_n as in (1.4))? They introduced a new class of "generalized solutions" of Problem P and proved that some kind of "generalized solution" exists and is unique but that it is unstable and has a very strong singularity on the characteristic cone S_2. More precisely, they showed that given any $\ell \in \mathbb{N}$, there is a function $f_\ell \in C^\ell\left(\overline{G}\right)$ such that the corresponding "generalized solution" $u_\ell \in C\left(\overline{G} \setminus S_2\right)$ of Problem P exists, is unique, and satisfies the estimate

$$\int_{S_{2,\varepsilon}} |u_\ell| \, ds \geq \varepsilon^{-\ell}, \quad 0 < \varepsilon < 1, \tag{1.5}$$

where $S_{2,\varepsilon} = \{x \in G : \rho = \varepsilon + \int_0^t \sqrt{K(\tau)} d\tau\}$.

This situation can be interpreted in terms of improperly posed (or ill-posed) problems: we recall that these are problems which fail to have a unique global solution which depends continuously on the data. For investigations of such problems for partial differential equations we refer to the monographs of Payne [22], Tikhonov and Arsenin [34], and Lavrentiev, Romanov, and Shishatskii [19]; the book by Lattès and Lions [18] describes a regularization method for approximating solutions to ill-posed problems. We also refer to the papers by Ames, Levine, and Payne [5], Ames [4], as well as to the many references cited in these works; and to Tikhonov and Arsenin [34] for numerous regularization methods.

In Problem P, the position is the following:

(i) According to the results of Popivanov and Schneider cited above, there are infinitely many distinct right-hand sides f_n $(n \in \mathbb{N})$ of (1.1) for which there is a generalized solution with a strong singularity, of at least power-type (see (1.5)).

(ii) Let $u_0 \in C_0^\infty(G)$ be fixed and suppose that $K(t) \equiv t$. Then $f_0 := Lu_0 \in C_0^\infty(G)$ and for any right-hand side

$$f_{n,\delta} := f_0 + \delta f_n \qquad (n \in \mathbb{N}, \delta \neq 0) \tag{1.6}$$

there is a generalized solution with a strong singularity (see (1.5)) and there is no classical solution. This shows that the Problem P for the Tricomi equation is very unstable, even though $f_0 \in C_0^\infty(G)$, because a small perturbation (1.6) in an infinite number of directions has such a strong effect.

With this in mind, and having regard to the work on ill-posed problems which was mentioned earlier, it is appropriate to consider a new problem which regularizes Protter's problem. This new problem should be such that its solutions are free of the singularity, typified by (1.5), which appears on the characteristic cone S_2. This suggests connecting points from G with ones on the cone S_2, and so to investigate Problems P and P* we introduce a new, nonlocal problem. Let α be a small positive parameter. Given any t_0, ρ_0 and with $C = \{t_0 + \alpha\rho_0/(\alpha+1)\}\rho_0^\alpha$, let $(p_\alpha(t_0,\rho), q_\alpha(t_0,\rho_0))$ be the point of intersection of the curves

$$\rho = \int_0^t \sqrt{K(\tau)}d\tau, \quad t = C\rho^{-\alpha} - \alpha\rho/(\alpha+1).$$

Problem A. Is there a solution $\omega(t,\rho,\varphi)$ of the equation

$$(L\omega)(t,\rho,\varphi) - \rho^{-2}K(t)\omega_{\varphi\varphi}(p_\alpha(t,\rho), q_\alpha(t,\rho),\varphi) = f(t,\rho,\phi) \tag{1.7}$$

in G which satisfies the boundary conditions (1.2), i.e., $\omega = 0$ on $S_0 \cup S_1$?

Equation (1.7) is nonlocal because it involves points with coordinates (t,ρ,φ) and $(p_\alpha(t,\rho), q_\alpha(t,\rho),\varphi)$. We remark here merely that in our nonlocal Problem A, in the additional term

$$\rho^{-2}K(t)\omega_{\varphi\varphi}(p_\alpha(t,\rho), q_\alpha(t,\rho),\varphi)$$

of (1.7), the point $(p_\alpha, q_\alpha, \varphi)$ lies just on the characteristic cone S_2, where the big singularity shown by (1.5) appears in the "generalized solution" of the original Problem P. The derivative $\omega_{\varphi\varphi}$ is tangential to S_2 at that point.

Unlike [26], where the "generalized solution" belongs to a weighted space of smooth functions, we work here in a weighted Sobolev space. Following the work of Morawetz [20] and Lax and Phillips [17] in the two-dimensional case and Sorokina [32] in the multidimensional case, we introduce the weighted Sobolev space

$$\widetilde{W}_2^1(G) := \left\{\omega : \|\omega\|_{\widetilde{W}_2^1(G)} = \left(\int_G \left(\omega^2 + \omega_t^2 + r\left(\omega_{x_1}^2 + \omega_{x_2}^2\right)\right)dx\right)^{1/2} < \infty\right\}, \tag{1.8}$$

where $r = \sqrt{x_1^2 + x_2^2 + t^2}$. (The weight in Sorokina [33] is different.) In this space we establish existence, uniqueness, and an a priori estimate of a generalized solution of Problem A for every $f \in L_2(G)$. We also prove the infinite smoothness of the solution with respect to φ. We remark that analogous results were given, without proofs, for the Tricomi equation in G in Popivanov [25] and concerning the wave equation in Popivanov [24].

What is the connection between Problems P and A? We note that Garabedian [15] proved uniqueness of a classical solution of Problem P for the wave equation; an analogous result for the equation (1.1) follows from [26]. But in both cases we do not know whether or not the unique solution depends continuously on f. Following Didenko [11], we investigate another problem.

Problem P$_\varphi$. Is there a solution u of Problem P which satisfies the extra condition $\partial u/\partial\varphi = 0$ on S_2?

We prove that its solution u_f (when it exists) coincides with the solution ω_f of the Problem A, i.e., $u_f \equiv \omega_f$. Accordingly we can say that Problem A is a "nonlocal regularizer" of the strongly over-determined Problems P_φ and P. Using the results about Problem A we prove that the solution u_f of Problem P_φ depends continuously on f. For the adjoint Problem P^* (with $\dim KerP^* = \infty$) we find some additional conditions, under which we prove the uniqueness of solutions in $\widetilde{W}_2^1(G)$.

The plan of the paper is simple. Influenced by the works of Friedrichs [14], Morawetz [20], Lax and Phillips [17], and Sorokina [32], we investigate in section 2 a system of partial differential equations which is connected with Problem P and formulate corresponding boundary-value problems. In section 3 we examine the problem of coincidence of weak and strong solutions of these problems; sections 4, 5, and 6 are concerned with the proof of the existence, uniqueness, and smoothness (in φ) of the generalized solution of Problem A. The final section, section 7, deals with the connection between Problems P, P*, and the nonlocal Problem A. It is shown that, under appropriate conditions on f, the solutions of Problem P coincide with those of Problem A.

2. Investigation of a related system of equations. Given a vector-valued function $\hat{u} = (u_1, u_2, u_3)$ we introduce the formal notation

$$u_\rho := (x_1 u_1 + x_2 u_2)/\rho, \quad u_\varphi := x_1 u_2 - x_2 u_1, \tag{2.1}$$

and the derivatives $\frac{\partial}{\partial\rho} = \frac{x_1}{\rho}\frac{\partial}{\partial x_1} + \frac{x_2}{\rho}\frac{\partial}{\partial x_2}$, $\frac{\partial}{\partial\varphi} = x_1\frac{\partial}{\partial x_2} - x_2\frac{\partial}{\partial x_1}$. We consider the system

$$\begin{cases} \dfrac{K}{\rho}\dfrac{\partial}{\partial\rho}(\rho u_\rho) + \dfrac{K}{\rho^2}\dfrac{\partial u_\varphi}{\partial\varphi} - \dfrac{\partial u_3}{\partial t} = f, \\ K\left\{\dfrac{a}{\rho}\left(\dfrac{\partial u_\varphi}{\partial t} - \dfrac{\partial u_3}{\partial\varphi}\right) - \left(\dfrac{\partial u_\varphi}{\partial\rho} - \dfrac{\partial u_\rho}{\partial\varphi}\right)\right\} = 0, \\ \dfrac{\partial u_\rho}{\partial t} - \dfrac{\partial u_3}{\partial\rho} = 0, \end{cases} \tag{2.2}$$

where $a = a(t, \rho, \varphi)$ is a function to be chosen later. In matrix form this becomes

$$\hat{L}_0\hat{u} := \left(A^1\frac{\partial}{\partial x_1} + A^2\frac{\partial}{\partial x_2} + A^3\frac{\partial}{\partial t}\right)\hat{u} = \hat{f}_1, \tag{2.3}$$

where $\hat{f}_1 = (f, 0, 0)$. We shall see that the equation (1.1) and the system (2.3) are not equivalent. In addition, for (2.3) we have a new characteristic, S_0; thus all the boundary surfaces S_0, S_1, and S_2 are characteristics. To use the Friedrichs [14] theory of positive systems we reduce (2.3) to symmetric form by left multiplication by

$$\Lambda := \begin{pmatrix} -x_1 & x_2/\rho & -Kax_1/\rho \\ -x_2 & -x_1/\rho & -Kax_2/\rho \\ a & 0 & \rho \end{pmatrix}. \tag{2.4}$$

This gives the symmetric system

$$\begin{aligned} \hat{L}\hat{u} \;:=\; & \begin{pmatrix} -Kx_1 & -Kx_2 & Ka \\ -Kx_2 & Kx_1 & 0 \\ Ka & 0 & -x_1 \end{pmatrix}\frac{\partial\hat{u}}{\partial x_1} + \begin{pmatrix} Kx_2 & -Kx_1 & 0 \\ -Kx_1 & -Kx_2 & Ka \\ 0 & Ka & -x_2 \end{pmatrix}\frac{\partial\hat{u}}{\partial x_2} \\ & + \begin{pmatrix} -Ka & 0 & x_1 \\ 0 & -Ka & x_2 \\ x_1 & x_2 & -a \end{pmatrix}\frac{\partial\hat{u}}{\partial t} = \begin{pmatrix} f_1 \\ f_2 \\ f_3 \end{pmatrix} := \hat{f}, \end{aligned} \tag{2.5}$$

where $f_1 = -x_1 f$, $f_2 = -x_2 f$, $f_3 = af$. We observe that $\det \Lambda = \rho^2 - Ka^2$; this leads us to impose the following condition on the function $a : \rho - a\sqrt{K(t)} > 0$ in G. Following the notation of Friedrichs we have

$$\left(\hat{u}, \hat{L}\hat{u}\right)_{L_2(G)} = (\hat{u}, \varkappa\hat{u})_{L_2(G)} + \frac{1}{2}\int_{\partial G} \hat{u} \cdot \beta\hat{u} ds; \tag{2.6}$$

here the boundary matrix β is given by $\beta(x) = \sum_{j=1}^{3} n_j(x)\Lambda(x)A^j(x)$, where $n(x) = (n_1(x), n_2(x), n_3(x))$ is the unit exterior normal vector at $x \in \partial G$, and the matrix $\varkappa$ is defined by

$$\varkappa = \begin{pmatrix} (Ka)_t & 0 & -Ka_{x_1} \\ 0 & (Ka)_t & -Ka_{x_2} \\ -Ka_{x_1} & -Ka_{x_2} & 2 + a_t \end{pmatrix}. \tag{2.7}$$

In the paper Friedrichs [14], the matrix corresponding to our matrix $\varkappa$ is positive in $\overline{G}$. To fit in with this we work in a suitably weighted Sobolev space and choose

$$a(t, \rho, \varphi) = \alpha(\rho + t) \text{ in } G, \tag{2.8}$$

where $d > 0$ is a parameter, as in Sorokina [32]. With this choice we have

$$\hat{u} \cdot \varkappa\hat{u} \geq \alpha K'(t)(\rho + t)\left(u_1^2 + u_2^2\right) + (2 + \alpha - \alpha K)u_3^2. \tag{2.9}$$

This leads us to impose the following two conditions on α :

(E1) $\rho - \alpha(\rho + t)\sqrt{K(t)} > 0$ in $\overline{G}\setminus\{(0,0,0)\}$,

(E2) $\alpha K(d) < 2 + \alpha$.

Remark. It easy to see that near the point $(0,0,0)$ the condition (E1) is equivalent to $0 < \alpha < 2/3$. Note that (E1) and (E2) are satisfied for every sufficiently small $\alpha > 0$. For example, if $K(t) = t$, then they hold if $0 < \alpha < 2/\left(3 + \sqrt[3]{6}\right)$.

According to the Friedrichs theory, the boundary conditions

$$\begin{cases} x_1u_1 + x_2u_2 = 0 \text{ on } S_0, \qquad x_1u_2 - x_2u_1 = 0 \text{ on } S_2; \\ \sqrt{K}\,(x_1u_1 + x_2u_2) - \rho u_3 = 0 \text{ on } S_1 \end{cases} \tag{2.10}$$

are admissible for $\hat{L}$. The adjoint boundary conditions are

$$\begin{cases} x_1v_1 + x_2v_2 - av_3 = 0 \text{ on } S_0, \qquad x_2v_1 - x_1v_2 = 0 \text{ on } S_1; \\ \sqrt{K}\,(x_1v_1 + x_2v_2) + \rho v_3 = 0 \text{ on } S_2, \end{cases} \tag{2.11}$$

and these are admissible for the adjoint operator $\hat{L}^*$. Following the work of Morawetz [20] and Lax and Phillips [17] in the two-dimensional case and Sorokina [32] in the multidimensional case, we introduce the weighted Lebesgue spaces

$$\begin{aligned} H^*(G) &:= \left\{\hat{u} : \|\hat{u}\|^* := \left(\int_G \left[r^{-1}\left(u_1^2 + u_2^2\right) + u_3^2\right] dx\right)^{1/2} < \infty\right\}, \\ H_*(G) &:= \left\{\hat{u} : \|\hat{u}\|_* := \left(\int_G \left[r\left(u_1^2 + u_2^2\right) + u_3^2\right] dx\right)^{1/2} < \infty\right\}, \end{aligned} \tag{2.12}$$

where $r = \sqrt{\rho^2 + t^2}$. By $(\cdot, \cdot)$ we shall mean the inner product in $L_2(G)$, and $\|\cdot\|$ will stand for the corresponding norm.

DEFINITION 2.1. *A function* $\hat{u} \in H_*(G)$ *is said to be a weak solution of the problem* (2.5), (2.10) *if*

$$\left(\hat{u}, \hat{L}^*\hat{v}\right) = \left(\hat{f}, \hat{v}\right) \tag{2.13}$$

for every $\hat{v} \in C^1\left(\overline{G}\right)$ *which satisfies the adjoint boundary conditions* (2.11) *and vanishes in some neighborhood of the point* $(0,0,0)$.

DEFINITION 2.2. *A function* $\hat{u} \in H_*(G)$ *is called a strong solution of the problem* (2.5), (2.10) *if, and only if, there are functions* $\hat{u}_m \in C^1\left(\overline{G}\right)$ $(m \in \mathbb{N})$ *each of which satisfies the boundary conditions* (2.10) *and vanishes in some neighborhood of* $(0,0,0)$ *such that*

$$\|\hat{u}_m - \hat{u}\|_* \to 0 \text{ and } \left\|\hat{L}\hat{u}_m - \hat{f}\right\|^* \to 0 \text{ as } m \to \infty. \tag{2.14}$$

From the Friedrichs theory and (2.9), standard procedures now show that the following theorem holds.

THEOREM 2.3. *Let* $\alpha > 0$ *be so small that* (E1) *and* (E2) *hold. Then for any* $\hat{f} \in H^*(G)$, *there exists a weak solution* $\hat{u} \in H_*(G)$ *of the problem* (2.5), (2.10). *If there is a strong solution, it is unique and satisfies the a priori estimate*

$$\|\hat{u}\|_* \le C_\alpha \left\|\hat{f}\right\|^*,$$

where C_α *is a constant which does not depend on* $\hat{u}$.

Every strong solution of (2.5), (2.10) is a weak solution. However, we also have the following theorem.

THEOREM 2.4. *Every weak solution is a strong solution.*

From this result (to be proved in the next section) and Theorem 2.3 it follows that given any $\hat{f} \in H^*(G)$, there are a unique weak solution and a unique strong solution, which coincide.

3. Proof of Theorem 2.4.

Proof. By partition of the unity argument it is enough to show that if the support of a weak solution $\hat{u}$ is concentrated in a small neighborhood of an arbitrary point of $\overline{G}$, then it is a strong solution; that is, there are functions $\hat{u}_m \in C^1\left(\overline{G}\right)$ satisfying the conditions of Definition 2.2. Far from $(0,0,0)$, the L_2-norm and the norms on $H^*(G)$ and $H_*(G)$ are equivalent. The point $(0,0,0)$ requires separate treatment. For each other point in G we use the method of mollifiers developed by Friedrichs [13], Lax and Phillips [17], Peyser [23], Rauch [30], and others. After suitable change of variables we look for an integral operator R_ε, which depends on a parameter $\varepsilon = (\varepsilon_1, \varepsilon_2, \varepsilon_3)$, such that $R_\varepsilon\hat{u}$ satisfies the boundary conditions (2.10), and with an adjoint R_ε^* such that $R_\varepsilon^*\hat{v}$ satisfies the adjoint boundary conditions (2.11) for every pair of functions $u, v \in L_2(G)$ with support in a small neighborhood of the point considered. The most difficult problem usually is to prove $\|\hat{L}R_\varepsilon\hat{u} - \hat{f}\| \to 0$ when $\varepsilon \to 0$ in a special way. Since $(\hat{L}R_\varepsilon^*)^*\hat{u} = R_\varepsilon\hat{f}$, we must show that

$$\left\|\left(\hat{L}^*R_\varepsilon^*\right)^*\hat{u} - \hat{L}R_\varepsilon\hat{u}\right\| \to 0 \quad \text{as} \quad \varepsilon \to 0. \tag{3.1}$$

If the kernel k_ε of the integral operator R_ε is $k_\varepsilon(x,y) = k_\varepsilon(x-y)$, then we have the integral representation

$$\left(\hat{L}^* R_\varepsilon^*\right)^* \hat{u}(y) - \hat{L} R_\varepsilon \hat{u}(y) = \int_G \left\{ \sum_{j=1}^{3} \frac{\partial}{\partial z_j} \left[A^j(y) k_\varepsilon(y-z) - k_\varepsilon(y-z) A^j(z) \right] \right. \tag{3.2}$$
$$\left. - \left[B(y) k_\varepsilon(y-z) - k_\varepsilon(y-z) B(z) \right] \right\} \hat{u}(z)\, dz.$$

We prove here local coincidence only in the case when the support of the solution lies in a small neighborhood of some point of $S_0 \cap S_1$. For the other cases we refer to Lax and Phillips [17], Peyser [23], Rauch [30], and Popivanov [24] for indications of how to proceed.

Let $P_0 \in S_0 \cap S_1$ and suppose that $u \in L_2(G)$ is a weak solution x of the boundary value problem (2.5), (2.10) with $u = 0$ in some neighborhood of S_2. Because the surface S_2 is not C^2 near P_0, we work with the variables (t, ρ, φ). Note that the system (2.5) in variables

$$\widetilde{u} = \begin{pmatrix} u_\rho \\ -\rho^{-1} u_\varphi \\ u_3 \end{pmatrix} = F_1 \hat{u} := \begin{pmatrix} x_1/\rho & x_2/\rho & 0 \\ x_2/\rho & -x_1/\rho & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} u_1 \\ u_2 \\ u_3 \end{pmatrix} \tag{3.3}$$

becomes

$$\hat{L}_1 \widetilde{u} := F_1 \hat{L} \hat{u} := F_1 \hat{L} F_1 \widetilde{u} \quad := \left[\begin{pmatrix} -Ka & 0 & \rho \\ 0 & -Ka & 0 \\ \rho & 0 & -a \end{pmatrix} \frac{\partial}{\partial t} \right.$$
$$+ \begin{pmatrix} -K\rho & 0 & Ka \\ 0 & K\rho & 0 \\ Ka & 0 & -\rho \end{pmatrix} \left. \frac{\partial}{\partial \rho} + A_2^\varphi \frac{\partial}{\partial \varphi} + B_2 \right] \widetilde{u} = \widetilde{f} \tag{3.4}$$

and that the boundary conditions (2.10) become

$$\sqrt{K}\widetilde{u}_1 - \widetilde{u}_3 = 0 \text{ on } S_1, \quad \widetilde{u}_1 = 0 \text{ on } S_0. \tag{3.5}$$

To diagonalize the matrix A^t we multiply the system (3.4) by the matrix $F_2 \in C^1$ (supp u), where

$$F_2 = \frac{1}{\rho^2 - Ka^2} \begin{pmatrix} a & 0 & \rho \\ 0 & \dfrac{Ka^2 - \rho^2}{a} & 0 \\ \rho & 0 & Ka \end{pmatrix}. \tag{3.6}$$

This gives the system

$$\hat{L}_2 \widetilde{u} := F_2 \hat{L}_1 \widetilde{u} \quad := \left[\begin{pmatrix} 1 & 0 & 0 \\ 0 & K(t) & 0 \\ 0 & 0 & 1 \end{pmatrix} \frac{\partial}{\partial t} \right.$$
$$+ \begin{pmatrix} 0 & 0 & -1 \\ 0 & -\dfrac{K\rho}{a} & 0 \\ -K & 0 & 0 \end{pmatrix} \left. \frac{\partial}{\partial \rho} + A_2^\varphi \frac{\partial}{\partial \varphi} + B_2 \right] \widetilde{u} = \widetilde{f}_1; \tag{3.7}$$

the boundary conditions (3.5) remain the same. The new adjoint conditions are

$$\widetilde{v}_2 = 0 \text{ on } S_1, \quad \widetilde{v}_3 = 0 \text{ on } S_0. \tag{3.8}$$

We define approximating functions by

$$R_\varepsilon \widetilde{u}(y) = \int_D k_\varepsilon(y-z)\widetilde{u}(z)dz \quad \left(y=(t,\rho,\varphi),\ z=\left(\overline{t},\overline{\rho},\overline{\varphi}\right)\right) \tag{3.9}$$

in the domain $D = \{(t,\rho,\varphi) : \frac{2}{3} < \rho < 1 - \int_0^t \sqrt{K(\tau)}\, d\tau, c_3 < \varphi < c_4 t\}$, where $0 < c_4 - c_3 < 2\pi$; as usual $j \in C^\infty(\mathbb{R}), j(s) = 0$ for $\mid s \mid > 1$, $\int j(s)ds = 1$, and

$$\begin{aligned} k_\varepsilon(y) := \quad & \operatorname{diag}\{J_1, J_2, J_3\} = \frac{1}{\varepsilon_1\varepsilon_2\varepsilon_3} j\left(\frac{\varphi}{\varepsilon_3}\right) \operatorname{diag}\left\{ j\left(\frac{t}{\varepsilon_1}-2\right) j\left(\frac{\rho}{\varepsilon_2}+E\right), \right. \\ & \left. j\left(\frac{t}{\varepsilon_1}+2\right) j\left(\frac{\rho}{\varepsilon_2}-E\right), j\left(\frac{t}{\varepsilon_1}+2\right) j\left(\frac{\rho}{\varepsilon_2}+E\right)\right\}, \end{aligned} \tag{3.10}$$

where $0 < \varepsilon_1 \le \varepsilon_2 \le \varepsilon_3$ and E is an appropriate constant.

The functions (3.9) satisfy the boundary conditions (3.5) on $t = 0$, while the functions $R_\varepsilon^* v$ satisfy the adjoint boundary conditions (3.8) on $t = 0$. On the surface S_1 we have $\rho = 1 - \int_0^t \sqrt{K(\tau)}\, d\tau$ and if $E \ge 2 + 3\sqrt{K(d)}$, then $R_\varepsilon \widetilde{u}$ satisfies the boundary condition (3.5) on S_1 and $R_\varepsilon^* v$ the adjoint conditions (3.8) on S_1. Then $(\hat{L}^* R_\varepsilon^*)^* \widetilde{u} = R_\varepsilon \widetilde{f}_1$ and we have to prove only the convergence (3.1). Using the representation (3.2) we must deal with the problems of convergence of the terms involving (a) $\partial/\partial t$, (b) $\partial/\partial\rho$, (c) $\partial/\partial\varphi$, (d) B_2.

It is easy to handle problem (a) because after the transformation (3.6), A^t depends only on t, and not on ρ or φ; we have estimates such as

$$\left|K(t) - K\left(\overline{t}\right)\right| \le M\left|t - \overline{t}\right| \le 3M\varepsilon_1 \text{ on } \operatorname{supp} k_\varepsilon. \tag{3.11}$$

The most interesting is problem (b), that is, to establish the convergence in $L_2(D)$ as $\varepsilon \to 0$ of the expression

$$I_\varepsilon = \int_D \frac{\partial}{\partial\overline{\rho}} \left\{A^\rho(z)k_\varepsilon(y-z) - k_\varepsilon(y-z)A^\rho(y)\right\} \widetilde{u}(z)dz. \tag{3.12}$$

Note that $A^\rho(z)K_\varepsilon(y-z) - K_\varepsilon(y-z)A^\rho(y) =$

$$\begin{pmatrix} 0 & 0 & J_1 - J_3 \\ 0 & \left\{a_1\left(\overline{t},\overline{\rho}\right) - a_1(t,\rho)\right\} J_2 & 0 \\ K\left(\overline{t}\right) J_3 - K(t) J_1 & 0 & 0 \end{pmatrix},$$

where $a_1(t,\rho) = \rho K(t)/a(t,\rho)$. We remark that S_1 is a characteristic surface and that we have some components which are simultaneously "free" for both the boundary and the adjoint boundary conditions. This fact is crucial and explains why we can choose the kernel of the mollifier in such a way that J_1 and J_3 depend in the same way on ρ.

Note that for any constant c and any $w \in L_2(D)$ with $w = 0$ in $\mathbb{R}^3 \backslash D$,

$$\left\| \int_{\mathbb{R}} \frac{1}{\varepsilon_1} j\left(\frac{t-\overline{t}}{\varepsilon_1} + c\right) w\left(\overline{t},\rho,\varphi\right) d\overline{t} - w(t,\rho,\varphi) \right\|_{L_2(D)} \to 0 \tag{3.13}$$

as $\varepsilon_1 \to 0$. In our case, we have

$$I'_\varepsilon := \left\| \left(\varepsilon_1 \varepsilon_2^2 \varepsilon_3\right)^{-1} \int_D \left\{ j\left(\frac{t-\bar{t}}{\varepsilon_1}+2\right) - j\left(\frac{t-\bar{t}}{\varepsilon_1}-2\right)\right\} j'\left(\frac{\rho-\overline{\rho}}{\varepsilon_2}+E\right) j\left(\frac{\varphi-\overline{\varphi}}{\varepsilon_3}\right) \widetilde{u}_3(z)dz \right\|_{L_2(D)} \to 0 \tag{3.14}$$

as $\varepsilon_1 \to 0$, ε_2 and ε_3 being fixed. In a similar way we find, using (3.13), that

$$I''_\varepsilon := \left\| \left(\varepsilon_1 \varepsilon_2^2 \varepsilon_3\right)^{-1} \int_D \left\{ K\left(\bar{t}\right) j\left(\frac{t-\bar{t}}{\varepsilon_1}+2\right) - K(t) j\left(\frac{t-\bar{t}}{\varepsilon_1}-2\right)\right\} j'\left(\frac{\rho-\overline{\rho}}{\varepsilon_2}+E\right) j\left(\frac{\varphi-\overline{\varphi}}{\varepsilon_3}\right) \widetilde{u}_1(z)dz \right\|_{L_2(D)} \to 0 \tag{3.15}$$

as $\varepsilon_1 \to 0$, ε_2 and ε_3 being fixed. We also have that

$$I'''_\varepsilon := \left\| \left(\varepsilon_1 \varepsilon_2 \varepsilon_3\right)^{-1} \int_D \frac{\partial}{\partial \overline{\rho}} \left\{ \left[a_1(\bar{t},\bar{\rho}) - a_1(t,\rho)\right] j\left(\frac{\rho-\overline{\rho}}{\varepsilon_2}-E\right)\right\} j\left(\frac{t-\bar{t}}{\varepsilon_1}+2\right) j\left(\frac{\varphi-\overline{\varphi}}{\varepsilon_3}\right) \widetilde{u}_2(z)dz \right\|_{L_2(D)} \to 0 \tag{3.16}$$

as $\varepsilon_1 \to 0$, $\varepsilon_2 \to 0$ with $0 < \varepsilon_1 \le \varepsilon_2$, and with ε_3 being fixed, since

$$\left|a_1\left(\bar{t},\overline{\rho}\right) - a_1(t,\rho)\right| \varepsilon_2^{-1} \le M\left\{\left|t-\bar{t}\right| + |\rho-\overline{\rho}|\right\}\varepsilon_2^{-1} \le M_1(\varepsilon_1\varepsilon_2^{-1}+1). \tag{3.17}$$

This completes the discussion of problem (b). Problems (c) and (d), involving A_2^φ and B_2 (see (3.2), (3.7)), are handled in a standard way. The investigation in a neighborhood of a point from $S_0 \cap S_1$ is finished. To deal with the point $(0,0,0)$ we follow the Lax–Phillips scheme [17] for the two-dimensional problem, but with some changes. We use a cut-off function $\psi \in C^\infty(\mathbb{R})$, with $\psi(s) = 0$ for $s \le 1$ and $\psi(s) = 1$ for $s \ge 2$, and for each $m \in \mathbb{N}$ define $\psi_m \in C^\infty\left(\overline{G}\right)$ by $\psi_m(t,\rho) = \psi\left(m\left(\rho + t^{3/2}\right)\right)$. Note that the function $\hat{u}_m := \psi_m \hat{u}$ is a weak solution of the system

$$\hat{L}\hat{u} = \hat{f}_m := \psi_m \hat{f} + m\left(\frac{x_1}{\rho}A^1 + \frac{x_2}{\rho}A^2 + \frac{3}{2}\sqrt{t}A^3\right)\psi'\left(m\left(\rho+t^{3/2}\right)\right)\hat{u}.$$

To finish the proof of Theorem 2.4 we need the next lemma, which follows in a standard way, using the fact that on $\mathrm{supp}\psi'$, we have $\rho \le 2/m$ and $t \le 2/m^{2/3}$.

LEMMA 3.1. *Let $\hat{u} \in H_*(G)$ and $\hat{f} \in H^*(G)$. Then*

$$\left\|\hat{f}_m - \hat{f}\right\|^* \to 0 \text{ as } m \to \infty. \tag{3.18}$$

The proof of Theorem 2.4 is complete. □

THEOREM 3.2. *Let $\hat{f} \in H^*(G)$ and suppose that $\hat{u} \in H_*(G)$ is a weak solution of the boundary-value problem* (2.5), (2.10). *Then it is a strong solution, it is unique, and it satisfies the a priori estimate*

$$\|\hat{u}\|_* \le C_\alpha \left\|\hat{f}\right\|^*. \tag{3.19}$$

Proof. We wish to use Theorems 2.3 and 2.4. For a weak solution $\hat{u}$ from Theorem 2.3 and for each $m \in \mathbb{N}$ define functions $\hat{u}_m = \psi_m \hat{u}$ as above. We know that $\hat{u}_m = 0$ in $G \cap \left\{\rho + t^{3/2} \le m^{-1}\right\}$. From the results above it follows that far from $(0,0,0)$ every weak solution is a strong solution. But $\hat{u}_m$ satisfies this condition. In view of this and Lemma 3.1 the proof is complete. □

4. The nonlocal problem: Existence of a generalized solution. Here we deal with Problem A. We recall that we consider the curve $t = C\rho^{-\alpha} - \alpha\rho/(\alpha+1)$, α being a small positive parameter, and that this curve contains the point (t_0, ρ_0) provided that $C = \{t_0 + \alpha\rho_0/(\alpha+1)\}\rho_0^{\alpha}$; under this condition we denote by $(p_\alpha(t_0,\rho_0), q_\alpha(t_0,\rho_0))$ the common point of the curve and the curve $\rho = \int_0^t \sqrt{K(\tau)}d\tau$ (for the details see section 7).

DEFINITION 4.1. *A function $\omega(t,\rho,\varphi)$ is called a generalized solution of Problem* A *if* (a) $\omega, \frac{\partial\omega}{\partial t}, \sqrt{r}\frac{\partial\omega}{\partial\rho} \in L_2(G)$; (b) $\sqrt{r}\rho^{-1}\frac{\partial\omega^1}{\partial\varphi} \in L_2(G)$, *where*

$$\omega^1(t,\rho,\varphi) := \omega(t,\rho,\varphi) - \omega\left(p_\alpha(t,\rho),\ q_\alpha(t,\rho),\varphi\right); \tag{4.1}$$

(c) $\omega = 0$ *on* $S_0 \cup S_1$; (d) *for any function* $v \in C^* := \{v \in C^1(\overline{G}) : v = 0$ *on* $S_0 \cup S_2$, *and in some neighborhood of* $(0,0,0)\}$, *the equality*

$$\int_G \left(\frac{\partial\omega}{\partial t}\frac{\partial v}{\partial t} - K(t)\frac{\partial\omega}{\partial\rho}\frac{\partial v}{\partial\rho} - \frac{K(t)}{\rho^2}\frac{\partial\omega^1}{\partial\varphi}\frac{\partial v}{\partial\varphi} - fv\right)\rho\, d\rho\, d\varphi\, dt = 0 \tag{4.2}$$

holds.

Remark. The trace in (4.1) exists because $p_\alpha, q_\alpha \in C^1(G)$ (see section 7).

THEOREM 4.2. *Suppose that the parameter $\alpha > 0$ is so small that conditions* (E1) *and* (E2) *are satisfied. Then for any $f \in L_2(G)$, there is a generalized solution of Problem* A.

Proof. Let $f \in L_2(G)$; then $\hat{f} = (-x_1 f, -x_2 f, \alpha(\rho+t)f) \in H^*(G)$. By Theorem 2.3, there exists a weak solution $\hat{u} = (u_1, u_2, u_3) \in H_*(G)$ of the problem (2.5), (2.10); by Theorem 2.4, it is a strong solution. Hence there are functions $\hat{u}_m = (u_{m1}, u_{m2}, u_{m3}) \in C^1\left(\overline{G}\right)$ $(m \in \mathbb{N})$ such that

$$\begin{aligned} &x_1 u_{m1} + x_2 u_{m2} = 0 \text{ on } S_0, \sqrt{K}\left(x_1 u_{m1} + x_2 u_{m2}\right) - \rho u_{m3} = 0 \text{ on } S_1, \\ &x_1 u_{m2} - x_2 u_{m1} = 0 \text{ on } S_2, \hat{u}_m = 0 \text{ in a neighborhood of } (0,0,0) \end{aligned} \tag{4.3}$$

and

$$\|\hat{u}_m - \hat{u}\|_* \to 0, \left\|\hat{L}\hat{u}_m - \hat{f}\right\|^* \to 0 \text{ as } m \to \infty. \tag{4.4}$$

Recalling that $\hat{L} = \Lambda L_0$ we put $u_{m\rho} = (x_1 u_{m1} + x_2 u_{m2})/\rho$, $u_{m\varphi} = x_1 u_{m2} - x_2 u_{m1}$,

$$\begin{cases} w_{m1} = L_0^1 \hat{u}_m := K(t)\left(\dfrac{\partial u_{m1}}{\partial x_1} + \dfrac{\partial u_{m2}}{\partial x_2}\right) - \dfrac{\partial u_{m3}}{\partial t}, \\ w_{m2} = (1/K(t))\, L_0^2 \hat{u}_m := \dfrac{a}{\rho}\left(\dfrac{\partial u_{m\varphi}}{\partial t} - \dfrac{\partial u_{m3}}{\partial\varphi}\right) - \left(\dfrac{\partial u_{m\varphi}}{\partial\rho} - \dfrac{\partial u_{m\rho}}{\partial\varphi}\right), \\ w_{m3} = L_0^3 \hat{u}_m := \dfrac{\partial u_{m\rho}}{\partial t} - \dfrac{\partial u_{m3}}{\partial\rho}. \end{cases} \tag{4.5}$$

Since $\det \Lambda = \rho^2 - a^2 K \geq c\left(\rho^2 + t^3\right)$ in G, $c > 0$, the second part of (4.4) gives

$$\left\| \left(\rho^2 + t^3\right)^{1/3} (w_{m1} - f) \right\|_{L_2(G)} \to 0, \|t w_{m2}\|_{L_2(G)} \to 0, \tag{4.6}$$

$$\left\| \left(\rho^2 + t^3\right)^{1/2} w_{m3} \right\|_{L_2(G)} \to 0. \tag{4.7}$$

Now we define functions $\omega_m \in C^1\left(\overline{G}\right)$ by

$$\omega_m(t, \rho, \varphi) = \int_0^t u_{m3}(\tau, \rho, \varphi)\, d\tau \quad (m \in \mathbb{N}). \tag{4.8}$$

In view of (4.4), there is a function $\omega \in L_2(G)$ such that

$$\|\omega_m - \omega\| \to 0, \left\| \frac{\partial u_m}{\partial t} - u_3 \right\| \to 0 \text{ as } m \to \infty, \tag{4.9}$$

and $\omega_t = u_3 \in L_2(G)$. From the boundary conditions (2.10) and from (4.7), for every $\delta > 0$ we obtain

$$\left\| \frac{\partial \omega_m}{\partial \rho} - (x_1 u_1 + x_2 u_2)/\rho \right\|_{L_2(G_\delta)} \to 0 \text{ as } m \to \infty, \tag{4.10}$$

where G_δ is the set of all those points of G with $\rho > \delta$. Hence

$$\frac{\partial \omega}{\partial \rho} = (x_1 u_1 + x_2 u_2)/\rho,\ \sqrt{r}\frac{\partial \omega}{\partial \rho} \in L_2(G).$$

The function ω satisfies the required boundary conditions (1.2) on $S_0 \cup S_1$. Thus ω satisfies conditions (a) and (c) of Definition 4.1.

We can now turn to the derivative with respect to φ. Put

$$Q_m := \frac{\partial \omega_m}{\partial \varphi} - u_{m\varphi} = \frac{\partial \omega_m}{\partial \varphi} - (x_1 u_{m2} - x_2 u_{m1}). \tag{4.11}$$

Use of the equations in system (2.2) and notation (4.5) shows that Q_m satisfies

$$\frac{a}{\rho}\frac{\partial Q_m}{\partial t} - \frac{\partial Q_m}{\partial \rho} = -w_{m2} + \frac{a}{\rho}\frac{\partial}{\partial \varphi}\int_0^t w_{m3}(\tau, \rho, \varphi) d\tau := -G_m(t, \rho, \varphi). \tag{4.12}$$

To integrate (4.12) we observe that $a = \alpha(\rho + t)$, make the change of variables $\xi = (t + \alpha\rho/(\alpha + 1))\rho^\alpha$, $s = \rho$, and write

$$\overline{Q}_m(\xi, s, \varphi) := Q_m\left(\xi s^{-\alpha} - \frac{\alpha}{\alpha + 1} s, s, \varphi\right), \tag{4.13}$$

with similar definition for $\overline{G}_m$. From (4.12) we have

$$\overline{Q}_m(\xi, s, \varphi) = F_m(\xi, \varphi) + \int_{s(\xi)}^s \overline{G}_m(\xi, \sigma, \varphi) d\sigma. \tag{4.14}$$

We choose $s(\xi_0)$ to be the ρ-coordinate of the point of intersection of S_2 and the curve $\xi = \xi_0$. Since $\overline{u}_{m\varphi}(\xi, s(\xi), \varphi) = 0$, by (4.3), then

$$\overline{Q}_m(\xi, s, \varphi) - \frac{\partial \overline{\omega}_m}{\partial \varphi}(\xi, s(\xi), \varphi) = \int_{s(\xi)}^s \overline{G}_m(\xi, \sigma, \varphi) d\sigma \tag{4.15}$$

and we finally have

$$\begin{aligned} Q_m(t,\rho,\varphi) \quad &- \frac{\partial\overline{\omega}_m}{\partial\varphi}\left(t\rho^\alpha + \frac{\alpha}{\alpha+1}\rho^{\alpha+1},\ s\left(t\rho^\alpha + \frac{\alpha}{\alpha+1}\rho^{\alpha+1}\right),\varphi\right) \\ &= \int_{s\left(t\rho^\alpha+\frac{\alpha}{\alpha+1}\rho^{\alpha+1}\right)}^{s} \overline{G}_m d\sigma. \end{aligned} \tag{4.16}$$

But this means that

$$\frac{\partial\omega_m^1}{\partial\varphi} - u_{m\varphi} = \int_{q_\alpha}^{\rho} \overline{G}_m(\xi,s,\varphi)ds \tag{4.17}$$

according to the notation (4.1). The integral

$$\int_{q_\alpha(t,\rho)}^{\rho} \overline{G}_m(\xi,s,\varphi)ds = \int_{q_\alpha(t,\rho)}^{\rho} G_m\left(\left(\frac{\rho}{s}\right)^\alpha\left(t+\frac{\alpha}{\alpha+1}\rho\right) - \frac{\alpha}{\alpha+1}s, s, \varphi\right)ds$$

can be split into two parts, by (4.12). For these we have the following estimates: for every $\delta > 0$,

$$\left\|\int_{q_\alpha}^{\rho} w_{m2}ds\right\|_{L^2(G^\delta)} \to 0, \quad \left\|\int_{q_\alpha}^{\rho}\int_0^t w_{m3}d\tau ds\right\|_{L^2(G^\delta)} \to 0, \tag{4.18}$$

as $m \to \infty$; here G^δ is the set of all those points of G with $t > \delta$. To prove this we need the properties of w_{m2} and w_{m3} given by (4.6) and (4.7), together with the fact that if some characteristic of the first-order partial differential equation (4.12) starts from a point on S_2 far from $(0,0,0)$, then it will remain far from $(0,0,0)$ at all times, so we have some uniformity. It should also be observed that the weight t in the estimate (4.6) for w_{m2} causes no difficulty in our case, because starting from a point in G we integrate along a curve through this point which goes to S_2 but remains away from $t = 0$. These considerations enable us to prove that for all $\psi \in C_0^\infty(G)$,

$$-\left(\omega^1, \frac{\partial\psi}{\partial\varphi}\right) = (u_\varphi, \psi), \tag{4.19}$$

that is, $\frac{\partial\omega^1}{\partial\varphi} = (-x_2u_1 + x_1u_2)$, $\frac{\sqrt{r}}{\rho}\frac{\partial\omega^1}{\partial\varphi} \in L_2(G)$, and the proof that ω satisfies condition (b) of Definition 4.1 is complete.

As for condition (d), let $v \in C^1(\overline{G})$ be such that $\frac{\partial v}{\partial\varphi} \in C^1(\overline{G})$ and v vanishes on S_2 and in some neighborhood of S_0. Then from (4.5), (4.6), and (4.7) it follows that

$$\left(K\frac{\partial u_{m1}}{\partial x_1} + K\frac{\partial u_{m2}}{\partial x_2} - \frac{\partial u_{m3}}{\partial t}, v\right) \to (f,v) \text{ as } m \to \infty. \tag{4.20}$$

Integrating by parts in view of the boundary conditions (4.3) and with the aid of the representations of derivatives of ω_m, it now follows that (4.2) holds, when v is restricted as stated above. That condition (d) is fulfilled for the given class of functions v results from a density argument. The proof of Theorem 4.2 is complete. □

5. Uniqueness of the generalized solution.

THEOREM 5.1. *Let $f \in L_2(G)$ and suppose that the positive parameter α is so small that it satisfies conditions* (E1) *and* (E2). *Then Problem* A *has at most one*

generalized solution, and there is a constant C such that if ω is a generalized solution it satisfies the a priori estimate

$$\|\omega\| + \left\|\frac{\partial\omega}{\partial t}\right\| + \left\|\sqrt{r}\frac{\partial\omega}{\partial\rho}\right\| + \left\|\frac{\sqrt{r}}{\rho}\frac{\partial\omega^1}{\partial\varphi}\right\| \le C\|f\|, \tag{5.1}$$

where we recall that $\|\cdot\|$ stands for $\|\cdot\|_{L^2(G)}$.

Proof. Suppose that ω is a generalized solution of Problem A. Put

$$\begin{aligned} &u_\rho = \frac{\partial\omega}{\partial\rho}, \quad u_3 = \frac{\partial\omega}{\partial t}, \quad u_\varphi = \frac{\partial\omega^1}{\partial\varphi}, \quad u_1 = x_1u_\rho\rho^{-1} - x_2u_\varphi\rho^{-2}, \\ &u_2 = x_2u_\rho\rho^{-1} + x_1u_\varphi\rho^{-2}. \end{aligned} \tag{5.2}$$

Then u_3, $\sqrt{r}u_1$, $\sqrt{r}u_2 \in L_2(G)$. We claim that the following result holds.

LEMMA 5.2. *The function $\hat{u} = (u_1, u_2, u_3)$ is a weak solution of problem* (2.5), (2.10) *for the function $\hat{f} = (-x_1f, -x_2f, \alpha(\rho+t)f) \in H^*(G)$.*

Assuming this for the moment, it follows from Theorem 3.2 that $\hat{u}$ is a strong solution of (2.5), (2.10), that it is unique, and that it satisfies the inequality (2.5), which in the notation (5.2) means

$$\|\omega_t\| + \left\|\sqrt{r}\omega_\rho\right\| + \left\|\sqrt{r}\rho^{-1}\omega^1_\varphi\right\| \le C\|f\|.$$

Since $\omega = 0$ on S_0 and $\omega = \int_0^t \omega_t(\tau,\rho,\varphi)d\tau$, the a priori estimate (5.1) follows.

To conclude the proof of Theorem 5.1 we establish Lemma 5.2. From (4.2) it follows that if $w_1 \in C^*$, i.e., $w_1 \in C^1(\overline{G})$, w_1 is zero on $S_0 \cup S_2$ and in a neighborhood of $(0,0,0)$, then (with $(\cdot,\cdot)$ denoting the inner product in $L_2(G)$)

$$\left(u_3, \frac{\partial w_1}{\partial t}\right) - \left(Ku_1, \frac{\partial w_1}{\partial x_1}\right) - \left(Ku_2, \frac{\partial w_1}{\partial x_2}\right) = (f, w_1). \tag{5.3}$$

If $w_3 \in C^2\left(\overline{G}\right)$ is zero on S_2 and in a neighborhood of $(0,0,0)$, then plainly

$$\left(u_\rho, \frac{\partial w_3}{\partial t}\right) - \left(u_3, \frac{1}{\rho}\frac{\partial}{\partial\rho}(\rho w_3)\right) = 0. \tag{5.4}$$

If $w_2 \in C^2\left(\overline{G}\right)$ is zero on S_1 and in a neighborhood of S_0, then we claim that

$$I(\omega) := \left(au_3 - \rho u_\rho, \frac{1}{\rho}\frac{\partial}{\partial\varphi}(Kw_2)\right) - \left(\frac{1}{\rho}u_\varphi, \frac{\partial}{\partial t}(aKw_2) - \frac{\partial}{\partial\rho}(\rho Kw_2)\right) = 0. \tag{5.5}$$

To verify this, observe that we may approximate the function $\omega(t,\rho,\varphi)$ by smooth functions $\omega_m(t,\rho,\varphi)$ in $W_2^1(\mathrm{supp}w_2)$. Using the notation ω_m^1 from (4.1) we see that $\omega_m^1 = 0$ on S_2, by definition of the functions p_α and q_α. Then $I(\omega_m) \to I(\omega)$ as $m \to \infty$; we see that $I(\omega_m) = 0$. This follows from the boundary conditions and because the functions $\omega_m(p_\alpha(t,\rho), q_\alpha(t,\rho), \varphi)$ depend actually only on φ and $\xi = t\rho^\alpha + \dfrac{\alpha}{\alpha+1}\rho^{\alpha+1}$. It is easy to check in that case that

$$\left\{\frac{\partial}{\partial\rho} - \frac{\alpha}{\rho}(t+\rho)\frac{\partial}{\partial t}\right\}\omega_m(p_\alpha(t,\rho), q_\alpha(t,\rho), \varphi) = 0. \tag{5.6}$$

From all this (5.5) follows. From (5.3), (5.4), (5.5), and the representation of the operator $\hat{L}_0$ we have

$$\left(\hat{u}, \hat{L}_0^*\hat{w}\right) = \left(\hat{f}_1, \hat{w}\right) = (f, w_1) \tag{5.7}$$

for every function $\hat{w} = (w_1, w_2, w_3)$ such that

$$\begin{cases} \hat{w} \in C^2\left(\overline{G}\right), \hat{w} = 0 \text{ in a neighborhood of } (0,0,0), \\ w_1 = 0 \text{ on } S_0 \cup S_2, w_2 = 0 \text{ on } S_1, w_3 = 0 \text{ on } S_2. \end{cases} \tag{5.8}$$

Recalling that $\hat{L} = \Lambda \hat{L}_0$, we are led to solve the equation $\hat{w} = \Lambda^* \hat{v}$. This gives

$$\begin{cases} w_1 = -\left(x_1 v_1 + x_2 v_2 - a v_3\right), \ w_2 = \left(x_2 v_1 - x_1 v_2\right)/\rho, \\ w_3 = \rho v_3 - Ka(x_1 v_1 + x_2 v_2)\rho^{-1}. \end{cases} \tag{5.9}$$

It is easy to see that for every $\hat{v} \in C^2\left(\overline{G}\right)$ which satisfies conditions (2.11) and the additional conditions

$$x_1 v_1 + x_2 v_2 = 0, \ v_3 = 0 \text{ on } S_2, \tag{5.10}$$

the corresponding function $\hat{w}$ given by (5.9) satisfies (5.8), and so the equality

$$\left(\hat{u}, \hat{L}^* \hat{v}\right) = \left(\hat{f}, \hat{v}\right), \ \hat{f} = (-x_1 f, -x_2 f, af)$$

holds for all such functions $\hat{v}$. Some density arguments remove the additional conditions (5.10) and thus show that $\hat{u}$ is a weak solution of problem (2.5), (2.10).

The proof of Lemma 5.2 is complete. □

6. Smoothness of the generalized solution. The matter investigated here is the smoothness with respect to φ of the generalized solution of the nonlocal Problem A. We begin with the following lemma.

LEMMA 6.1. *Suppose that the function ω satisfies all conditions from Definition* 4.1*, except that the equality* (4.2) *holds only for all functions $v \in C_0^\infty(G)$. Then ω is a generalized solution of Problem* A*.*

We omit this proof, because we shall not use this fact here.

THEOREM 6.2. *Suppose that the positive parameter α satisfies* (E1) *and* (E2)*, and let $f \in L_2(G)$ be such that $\frac{\partial^k f}{\partial \varphi^k} \in L_2(G)$ for $k = 1, \ldots, \ell$ for some $\ell \in \mathbb{N}$. Then there is a unique generalized solution ω of Problem* A *for which*

$$\frac{\partial^k \omega}{\partial \varphi^k} \in \widetilde{W}_2^1(G) \ (k = 0, \ldots, \ell - 1), \ \frac{\partial^{\ell+1} \omega}{\partial t \partial \varphi^\ell} \in L_2(G), \ \sqrt{r}\frac{\partial^{\ell+1} \omega}{\partial \rho \partial \varphi^\ell} \in L_2(G) \tag{6.1}$$

and

$$\sum_{k=0}^{\ell-1} \left\| \frac{\partial^k \omega}{\partial \varphi^k} \right\|_{\widetilde{W}_2^1(G)} + \left\| \frac{\partial^{\ell+1} \omega}{\partial t \partial \varphi^\ell} \right\|_{L_2(G)} + \left\| \sqrt{r}\frac{\partial^{\ell+1} \omega}{\partial \rho \partial \varphi^\ell} \right\|_{L_2(G)} \le C_\alpha \sum_{k=0}^{\ell} \left\| \frac{\partial^k f}{\partial \varphi^k} \right\|_{L_2(G)}. \tag{6.2}$$

Proof. First suppose that $g \in L_2(G)$ is such that $\partial g/\partial \varphi \in L_2(G)$. Let u be a generalized solution of Problem A, with $f = \partial g/\partial \varphi$; Theorem 4.2 ensures that such a solution exists. Then $u, \partial u/\partial t, \sqrt{r}\partial u/\partial \rho, \sqrt{r}\rho^{-1}\partial u^1/\partial \varphi \in L_2(G)$, $u = 0$ on $S_0 \cup S_1$, and

$$(u_t, v_t) - (Ku_\rho, v_\rho) - \left(K\rho^{-2}u_\varphi^1, v_\varphi\right) = (g_\varphi, v) = (g, v_\varphi) \tag{6.3}$$

for all $v \in C^*$. We have also in each set $G_\delta = G \cap \{\rho > \delta\}$ an approximation sequence $\{\omega_m\} \subset C^1(\bar{G}_\delta)$, as in Theorem 4.2.

Put $u_1(t,\rho,\varphi) = \int_0^{2\pi} u(t,\rho,\varphi)d\varphi$; then we have

$$\frac{\partial u_1}{\partial t} = \int_0^{2\pi} \frac{\partial u}{\partial t}(t,\rho,\varphi)d\varphi \in L_2(G), \frac{\partial u_1}{\partial \rho} = \int_0^{2\pi} \frac{\partial u}{\partial \rho}(t,\rho,\varphi)d\varphi, \frac{\partial u_1}{\partial \varphi} = 0. \tag{6.4}$$

Moreover, $u_1 = 0$ on $S_0 \cup S_1$. Let $v_1 \in C^*$ be independent of φ. Then from (6.3) we have

$$\int_\Delta \left(\frac{\partial u_1}{\partial t}\frac{\partial v_1}{\partial t} - K\frac{\partial u_1}{\partial \rho}\frac{\partial v_1}{\partial \rho} - \frac{K}{\rho^2}\frac{\partial u_1^1}{\partial \varphi}\frac{\partial v_1}{\partial \varphi} \right) \rho d\rho dt = 0, \tag{6.5}$$

where $\Delta = \{(t,\rho) : t > 0, \int_0^t \sqrt{K(\tau)}d\tau < \rho < 1 - \int_0^t \sqrt{K(\tau)}d\tau\}$.

Given $v \in C^*$, define $v_1 = \int_0^{2\pi} v d\varphi$; then (6.5) holds for this v_1 and we have

$$\int_G \left(\frac{\partial u_1}{\partial t}\frac{\partial v}{\partial t} - K\frac{\partial u_1}{\partial \rho}\frac{\partial v}{\partial \rho} - \frac{K}{\rho^2}\frac{\partial u_1^1}{\partial \varphi}\frac{\partial v}{\partial \varphi} \right) dx = 0 \tag{6.6}$$

for all $v \in C^*$. This shows that u_1 is a generalized solution of Problem A with $f = 0$. From the uniqueness part of Theorem 5.1 we have $u_1 = 0$ in G, that is, $\int_0^{2\pi} u(t,\rho,\varphi)d\varphi = 0$ for $(t,\rho) \in \Delta$.

Define

$$y(t,\rho,\varphi) = \int_0^\varphi u(t,\rho,\lambda)d\lambda. \tag{6.7}$$

Since $u_1 = 0$ in G, this function has a generalized φ-derivative $\frac{\partial y}{\partial \varphi} = u$, and by (6.3),

$$(y_t, v_{\varphi t}) - (Ky_\rho, v_{\varphi\rho}) - \left(K\rho^{-2}y_\varphi^1, v_{\varphi\varphi}\right) = (g, v_\varphi) \tag{6.8}$$

for all $v \in C^*$ such that $v_\varphi \in C^1\left(\overline{G}\right)$. Note that if $g \in L_2(G)$, there is a generalized solution ω of Problem A with $f = g$; for this solution (6.8) is also satisfied. With $z = \omega - y$ we then have

$$(z_t, v_{\varphi t}) - (Kz_\rho, v_{\varphi\rho}) - \left(K\rho^{-2}z_\varphi^1, v_{\varphi\varphi}\right) = 0 \tag{6.9}$$

for the same functions v. If $\psi \in C^2\left(\overline{G}\right) \cap C^*$, then

$$v_\varphi(t,\rho,\varphi) := \psi(t,\rho,\varphi) - \frac{1}{2\pi}\int_0^{2\pi} \psi(t,\rho,\varphi)d\varphi \tag{6.10}$$

can be substituted in (6.9), giving

$$\begin{aligned} \left(\left(z - \frac{1}{2\pi}\int_0^{2\pi} z d\varphi \right)_t, \psi_t \right) &- \left(K\left(z - \frac{1}{2\pi}\int_0^{2\pi} z d\varphi \right)_\rho, \psi_\rho \right) \\ &- \left(K\rho^{-2}\left(z - \frac{1}{2\pi}\int_0^{2\pi} z d\varphi \right)_\varphi^1, \psi_\varphi \right) = 0. \end{aligned} \tag{6.11}$$

It follows from Theorem 5.1 that

$$z(t,\rho,\varphi) - \frac{1}{2\pi}\int_0^{2\pi} z(t,\rho,\varphi)d\varphi = 0 \text{ in } G, \tag{6.12}$$

that is, $\omega_\varphi = u$ in G. The properties of the generalized solutions ω and u now lead to the conclusion of the theorem, once the estimate

$$\left\|\sqrt{r}\rho^{-1}\omega_\varphi\right\| \le C\,\|f_\varphi\| \tag{6.13}$$

has been established. To do this we use the fact that $\omega = 0$ in S_0 and the following lemma.

LEMMA 6.3. *For every* $w \in L_2(G)$,

$$\left\|\sqrt{r}\rho^{-1}\int_0^t w(\tau,\rho,\varphi)d\tau\right\| \le C\,\|w\|\,.$$

The proof of Theorem 6.2 is complete. □

7. Local and nonlocal problems, and their connection. We investigate here the connection between solutions of Problem P and those of Problem A.

DEFINITION 7.1. *A function* $u \in \tilde{W}_2^1(G)$ *is called a generalized solution of Problem* P *if, and only if,* $u = 0$ *on* $S_0 \cup S_1$ *and*

$$\int_G \left\{u_t v_t - K(t)u_\rho v_\rho - K(t)\rho^{-2}u_\varphi v_\varphi - fv\right\}dx = 0 \tag{7.1}$$

holds for all $v \in C^*$.

We shall also consider the following problem.

Problem P_φ. Is there a generalized solution of Problem P which satisfies the extra condition

$$u_\varphi = 0 \text{ on } S_2 \text{ in a weak sense,} \tag{7.2}$$

that is, $\int_{S_2} uv_\varphi\,ds = 0$ for all $v \in C_0^\infty(S_2)$?

For the Tricomi equation, Problem P_φ was formulated by Didenko [11].

Denote by H the set of all $f \in L_2(G)$ for which there exists a generalized solution u_f of Problem P; denote by H_φ the subspace of functions $f \in H$ for which the solution u_f satisfies (7.2). We know that in the case of the Tricomi equation, where $K(t) = t$,

$$\dim\left(L_2(G)/H\right) = \infty \tag{7.3}$$

since all the functions v_n given in (1.4) are orthogonal to H.

Remark. Sorokina [33] studied a variant of Problem P_φ: she called a function $u \in \tilde{W}_2^1(G)$ a "generalized solution" of this problem if, and only if, u is a solution of equation (1.1) in the sense of distributions (that is, (7.1) holds for every $v \in C_0^\infty(G)$), $u = 0$ on $S_0, u_\varphi = 0$ on S_2, and $u_\nu = 0$ on S_1 in a weak sense, where $u_\nu = K(n_1u_{x_1} + n_2u_{x_2}) - n_3u_{x_3}$ is the conormal derivative. Theorem 2 of Sorokina [33] states that given any $f \in L_2(G)$, there is a "generalized solution" of the problem, and any such solution is a strong solution. This result seems to us to be incorrect: the problem as formulated in Sorokina [33] appears to be strongly over determined (compare with (7.3) and Lemma 6.1).

We shall examine the uniqueness and continuous dependence on the data of solutions of Problem P_φ. The nonlocal Problem A will give some information about this.

THEOREM 7.2. *Let* $u \in \tilde{W}_2^1(G)$ *be a generalized solution of Problem* P_φ. *Then it is also a generalized solution of Problem* A *and so is unique and satisfies the a priori estimate*

$$\|u\|_{\tilde{W}_2^1(G)} \le C\,\|f\|_{L_2(G)}\,. \tag{7.4}$$

Proof. Let $v \in C^2(\overline{G})$ be zero in some neighborhoods of $S_1 \cap S_2$, $S_0 \cap S_1$, and $(0,0,0)$; suppose that $\alpha > 0$ is so small that conditions (E1) and (E2) hold. We investigate the nonlocal term in the integral equality (4.2):

$$\begin{aligned} I(v) := & \int_G K(t)\rho^{-2}u\left(p_\alpha(t,\rho), q_\alpha(t,\rho), \varphi\right) v_{\varphi\varphi}(t,\rho,\varphi)\rho d\rho dt d\varphi \\ = & \int_{S_2} u(s) w_\varphi(s) ds \end{aligned} \tag{7.5}$$

for some $w \in C_0^1(S_2)$, obtained by integration of v over the lines $t = C\rho^{-\alpha} - \alpha\rho/(\alpha+1)$. More precisely, let (t_0, ρ_0, φ) be a point in the domain G. This lies on the curve with equation $t = C\rho^{-\alpha} - \alpha\rho/(\alpha+1)$, where $C = (t_0 + \alpha\rho_0/(\alpha+1))\rho_0^\alpha$. This curve intersects $\rho = \int_0^t \sqrt{K(\tau)}d\tau$ in a point $(p_\alpha(t_0,\rho_0), q_\alpha(t_0,\rho_0), \varphi)$, where $t = p_\alpha(t_0,\rho_0)$ is a solution of the equation

$$F(t) := t\left[\int_0^t \sqrt{K(\tau)}d\tau\right]^\alpha + \frac{\alpha}{\alpha+1}\left[\int_0^t \sqrt{K(\tau)}d\tau\right]^{\alpha+1} = t_0\rho_0^\alpha + \alpha\rho_0^{\alpha+1}/(\alpha+1);$$

this exists because $F(t) > 0$ for $t > 0$ and $F(0) = 0$. Then

$$p_\alpha(t_0,\rho_0) = F^{-1}\left(t_0\rho_0^\alpha + \alpha\rho_0^{\alpha+1}/(\alpha+1)\right), \quad q_\alpha(t_0,\rho_0) = \int_0^{p_\alpha(t_0,\rho_0)} \sqrt{K(\tau)}d\tau.$$

We note here that $0 < p_\alpha(t_0,\rho_0) < d$; more precisely, the curve $t = C\rho^{-\alpha} - \alpha\rho/(\alpha+1)$ crosses every characteristic $\rho = \beta - \int_0^t \sqrt{K(\tau)}d\tau$ at least once, because at the common point (t_0,ρ_0) we have

$$t_1'(\rho_0) = -a(t_0,\rho_0)/\rho_0 > -1 \Big/ \sqrt{K(t_0)} = t_2'(\rho_0),$$

in view of condition (E1).

Let us denote by $(t,\psi_1(t))$ and $(t,\psi_2(t))$, $\psi_1(t) < \psi_2(t)$, the points of intersection of the curve $t = C\rho^{-\alpha} - \alpha\rho/(\alpha+1)$ and ∂G. We note here that $\psi_1 \in C^1(0,d)$, while $\psi_2 \in C^1((0,d)\backslash\{t'\})$, where $\psi_2(t') = 1$. Then the function $w(t,\varphi)$ in (7.5) will be given by

$$w(t,\varphi) = \frac{F'(t)}{\sqrt{1+K(t)}} \int_{\psi_1(t)}^{\psi_2(t)} (Kv_\varphi)\left(F(t)\rho^{-\alpha} - \alpha\rho/(\alpha+1), \rho, \varphi\right)\rho^{-1-\alpha}d\rho. \tag{7.6}$$

In view of condition (7.2) it follows that for every function v such that $w \in C_0^\infty(S_2)$, we have $I(v) = 0$. Thus $I(v) = 0$ for every $v \in C^*$. Comparison of (4.2) and (7.1) now shows that u is a generalized solution of Problem A. The rest of the proof now follows from Theorem 5.1. □

COROLLARY 7.3. *If $f \in H_\varphi$, then a generalized solution u_f of Problem P_φ exists and coincides with the generalized solution ω_f of Problem* A.

Theorems 6.2 and 7.2 also give information about the smoothness, with respect to φ, of generalized solutions of Problem P_φ.

COROLLARY 7.4. *If $f \in H_\varphi$ and $\partial^k f/\partial\varphi^k \in L_2(G)$ for $k = 0, ..., l$, then the conclusions of Theorem* 6.2 *hold for a generalized solution u_f of Problem P_φ.*

Of course, for $f \in H\backslash H_\varphi$ a generalized solution of Problem P need not coincide with the generalized solution ω_f of Problem A; and if $f \in L_2(G)\backslash H$, there is no

generalized solution of Problem P. Thus the nonlocal Problem A (for which Theorem 6.2 holds, ensuring uniqueness, existence, and differentiability with respect to φ) is, so to speak, a "regular continuation" of the strongly over determined Problem P_φ when $f \in L_2(G)\backslash H_\varphi$. In this sense, we may regard Problem A to be a "nonlocal regularization" of Problems P and P_φ. All this suggests the following procedure for tackling the ill-posed Problem P. For the given function $f \in L_2(G)$ we first try to solve the nonlocal Problem A. To do that, it is possible first to find the solution $\hat{u} = (u_1, u_2, u_3)$ of the local problem (2.5), (2.10) for the corresponding system of partial differential equations and then to find a solution ω_f of Problem A by integration of $u_3(t, \rho, \varphi)$. Then we check the value of the derivative $(\omega_f)_{\varphi\varphi}$ on the characteristic cone S_2 and if that value is very small, we might conclude that the solution u_f of the Problem P exists and is very close to the function ω_f already found.

Remark. Note that Eskin and Vishik solved the strongly overdetermined Cauchy problem for the Poisson equation $\Delta_n u = f$ (see Eskin [12]) by changing the equation to

$$\widehat{\Delta}_n u + G(v) = f,$$

where $G(v)$ is some potential with unknown density v which depends only on $(n-1)$ variables. They established existence and uniqueness results about the pair of functions (u, v); the addition of the potential $G(v)$ removed the overdeterminacy. In our approach we change equation (1.1) to (1.7), but our additional term depends only on the function ω, not on some new function.

We now return to Problem P^*, the homogeneous form of which has an infinite number of classical solutions. By introduction of additional conditions we seek to eliminate this nonuniqueness, and formulate the following nonlocal problem.

Problem $\tilde{\mathrm{P}}^*$. Is there a solution of the equation

$$K(t)\left(v_{x_1x_1} + v_{x_2x_2}\right) - v_{tt} = g \text{ in } G \tag{7.7}$$

which satisfies the boundary condition (1.3) and the additional nonlocal condition

$$\frac{\partial}{\partial\varphi}\int_{\psi_1(t)}^{\psi_2(t)} (Kv)(\tau(t,\rho),\rho,\varphi)\rho^{-1-\alpha}d\rho = 0 \quad (0 < \varphi < 2\pi, 0 < t < d)\,, \tag{7.8}$$

where $\tau(t,\rho) = F(t)\rho^{-\alpha} - \alpha\rho/(\alpha+1)$ (see (7.5) and (7.6) above)? The integration is over the intersection of G and the curve $(t + \frac{\alpha}{\alpha+1}\rho)\rho^\alpha = \text{constant}$, and it is assumed that the parameter α (> 0) satisfied conditions (E1) and (E2).

We must, of course, make precise the notion of a solution with which we shall be dealing. This leads to the following definition.

DEFINITION 7.5. *A function $v \in \tilde{W}_2^1(G)$ is called a generalized solution of Problem $\tilde{\mathrm{P}}^*$ if* (i) *$v = 0$ on $S_0 \cup S_2$;* (ii) *for every $u \in C_L := \{u \in C^1\left(\overline{G}\right) : u = 0$ on $S_0 \cup S_1$ and in some neighborhood of $(0,0,0)\}$, we have*

$$\int_G \left\{u_t v_t - K(t)u_\rho v_\rho - K(t)\rho^{-2}u_\varphi v_\varphi - ug\right\} dx = 0; \tag{7.9}$$

(iii) *for all $u \in C_0^\infty\left(S_2\right)$,*

$$\int_{S_2} u_\varphi(t,\varphi)\left\{\int_{\psi_1(t)}^{\psi_2(t)} (Kv)(\tau(t,\rho),\rho,\varphi)\rho^{-1-\alpha}d\rho\right\} dtd\varphi = 0. \tag{7.10}$$

For some functions, Problem $\tilde{\mathrm{P}}^*$ coincides with the problem adjoint to the nonlocal Problem A. This is the content of the following theorem.

THEOREM 7.6. *A function $v \in \tilde{W}_2^1(G)$ is a generalized solution of Problem $\tilde{\mathrm{P}}^*$ if, and only if, $v = 0$ on $S_0 \cup S_2$ and*

$$(7.11)\int_G \left\{u_t v_t - K(t)u_\rho v_\rho - K(t)\rho^{-2}[u_\varphi - u_\varphi\left(p_\alpha(t,\rho), q_\alpha(t,\rho), \varphi\right)]v_\varphi - ug\right\} dx = 0$$

for all $u \in C_L$.

Proof. Suppose that v satisfies (7.11), and let $u \in C_L$ be zero in some neighborhood of $S_1 \cap S_2$. Let $\psi \in C^\infty(\mathbb{R})$ be such that $\psi(s) = 0$ if $s \le 1$, $\psi(s) = 1$ if $s \ge 2$, and for each $m \in \mathbb{N}$ define

$$\psi_m(t,\rho) = \psi\left(m\left(\rho - \int_0^t \sqrt{K(\tau)}d\tau\right)\right);$$

$\psi_m u$ is zero in some neighborhood of S_2. Use of $\psi_m u$ in (7.11) gives

$$(7.12)\qquad \begin{aligned}(\psi_{mt}v_t - K\psi_{m\rho}v_\rho, u) \quad &+ (\psi_m u_t, v_t) - (\psi_m K u_\rho, v_\rho)\\ &- \left(\psi_m \rho^{-2} K u_\varphi, v_\varphi\right) = (\psi_m u, g)\end{aligned}$$

and by Hardy's inequality we see that the first term converges to zero. From this and (7.12) it follows that (7.9) holds, from which and (7.11) we obtain (7.10). Thus v is a generalized solution of Problem $\tilde{\mathrm{P}}^*$. The converse is immediate. ∎

THEOREM 7.7. *Problem $\tilde{\mathrm{P}}^*$ has at most one generalized solution.*

Proof. By Theorem 7.6, it is enough to prove that there is at most one generalized solution of the problem adjoint to Problem A. To do this, suppose that $v \in \tilde{W}_2^1(G)$, $v = 0$ on $S_0 \cup S_2$, and satisfies (7.11) with $g = 0$. Since $v \in L_2(G)$ and $\sqrt{r}\rho^{-1}v_\varphi \in L_2(G)$, by Theorem 6.2 there is a generalized solution ω of Problem A with $f = v$, such that $\omega \in \tilde{W}_2^1(G)$, $\frac{\partial^2\omega}{\partial t \partial\varphi} \in L_2(G)$, $\sqrt{r}\frac{\partial^2\omega}{\partial\rho\partial\varphi} \in L_2(G)$, and

$$(7.13)\qquad \int_G \left(\omega_t w_t - K\omega_\rho w_\rho - K\rho^{-2}\frac{\partial\omega^1}{\partial\varphi}w_\varphi - vw\right) dx = 0$$

for every $w \in C^*$.

We wish to put $w = v$ in (7.13). To justify this we use the function ψ employed in the proof of Theorem 7.6. Then (7.13) holds with $w = \psi(\rho m)v$, and so

$$\int_G \left(\omega_t v_t - K\omega_\rho v_\rho - K\rho^{-2}\frac{\partial\omega^1}{\partial\varphi}v_\varphi - v^2\right)\psi dx + m\int_G K\psi'(m\rho)\omega_\rho v dx = 0.$$

As $m \to \infty$, the second integral above converges to zero, since $|K(t)| \le Ct \le C_1\rho^{3/2}$ in G, and

$$m\left|\int_G K(t)\psi'(m\rho)\omega_\rho v dx\right| \le C\left\|\sqrt{r}\omega_\rho\right\|_{L_2(G_m)}\|v\|_{L_2(G_m)} \to 0,$$

where $G_m = G \cap \left\{(t,\rho,\varphi) : \rho \le 2m^{-1}\right\}$. Thus (7.11) with $g = 0$ and $u = w$ and (7.13) with $w = v$ show that $v = 0$ in G, and the proof is complete. ∎

We conjecture that for any $g \in \tilde{W}_2^1(G)$, there exists some kind of generalized solution of the Problem $\tilde{\mathrm{P}}^*$, possibly not belonging to $\tilde{W}_2^1(G)$. We feel that this should

follow from the uniqueness theorem relating to the general solution of the Problem A. Here we prove a weaker result.

THEOREM 7.8. *For every function $g \in L_2(G)$ there exists a weak solution of Problem* A**, that is, a function $v \in L_2(G)$ for which the equality*

$$\left(L\omega - K(t)\rho^{-2}\omega_{\varphi\varphi}\left(p_\alpha(t,\rho), q_\alpha(t,\rho), \varphi\right), v\right) = (\omega, g) \tag{7.14}$$

holds for every $\omega \in C_L \cap C^2\left(\overline{G}\right)$.

THEOREM 7.9. *This follows from the a priori estimate* (5.1)*, that is,*

$$\|\omega\|_{L_2(G)} \le C \left\|L\omega - K\rho^{-2}\omega_{\varphi\varphi}\left(p_\alpha, q_\alpha, \varphi\right)\right\|_{L_2(G)}.$$

Remark. Some other additional conditions relating to Problem P* for the wave equation (instead of equation (1.1)) were formulated by Kan Cher [9]. These conditions concern the boundedness of some integrals of Fourier-coefficients of solutions of Problem P*.

ON A CHARACTERIZATION OF THE KERNEL OF THE DIRICHLET-TO-NEUMANN MAP FOR A PLANAR REGION*

DAVID INGERMAN† AND JAMES A. MORROW†

Abstract. We will show that the Dirichlet-to-Neumann map Λ for the electrical conductivity equation on a simply connected plane region has an *alternating property*, which may be considered as a generalized maximum principle. Using this property, we will prove that the kernel, K, of Λ satisfies a set of inequalities of the form $(-1)^{\frac{n(n+1)}{2}} \det K(x_i, y_j) > 0$. We will show that these inequalities imply Hopf's lemma for the conductivity equation. We will also show that these inequalities imply the alternating property of a kernel.

1. Introduction. In this paper we will derive some properties of the Dirichlet-to-Neumann map for the electrical conductivity equation in $\mathbf{R}^2$. These properties are analogs of properties which characterize the Dirichlet-to-Neumann maps for electrical networks (see [1], [2], and [3]). We recall some definitions. Let Ω be a relatively compact, simply connected open set in $\mathbf{R}^2$ with C^2 boundary. Let $\gamma(p) > 0$ be a C^2 function on $\overline{\Omega}$. Let f be a function defined on $\partial\Omega$. Then there is a unique function u, defined on $\overline{\Omega}$, such that

$$\nabla(\gamma\nabla u) = 0 \tag{1.1}$$

and $u(p) = f(p)$ for $p \in \partial\Omega$. (Equation (1.1) is the electrical conductivity equation and a function, u, that satisfies (1.1) is called a γ-*harmonic function.*) Let $\frac{\partial u}{\partial n}(p)$ be the directional derivative of u in the direction of the outward pointing unit normal n at the point $p \in \partial\Omega$. Then the Dirichlet-to-Neumann map, Λ, is defined by the formula

$$\Lambda f(p) = \gamma(p)\frac{\partial u}{\partial n}(p). \tag{1.2}$$

The domain of Λ may be taken to be $H^{\frac{1}{2}}(\partial\Omega)$ and the image is in $H^{-\frac{1}{2}}(\partial\Omega)$. Λ is a pseudodifferential operator of order 1 and as such has a kernel, $K(x, y)$, defined as a distribution on $\partial\Omega \times \partial\Omega$. The kernel gives a representation of Λ by the formula

$$\Lambda f(x) = \int_{\partial\Omega} K(x, y)f(y)dy, \tag{1.3}$$

where x and y are arc length coordinates on $\partial\Omega$. For the pseudodifferential operator Λ, the kernel K is a symmetric function, $K(x, y) = K(y, x)$, and for a fixed $x \in \partial\Omega$, $\lim_{y\to x} |K(x, y)| = \infty$. More precisely,

$$K(x, y) = \frac{k(x, y)}{|x - y|^2} + D(x, y), \tag{1.4}$$

where k is continuous on $\partial\Omega \times \partial\Omega$, $k(x,y) = k(y,x)$, $k(x,x) \neq 0$, and D is a distribution supported on $\Delta = \{(x,x) : x \in \partial\Omega\}$. (In this formula, $|x-y|$ is the separation in arc length of points with arc length coordinates x and y and the continuous term in this expansion has been incorporated into the term $\frac{k(x,y)}{|x-y|^2}$.) If $x \notin \text{supp}(f)$, then the integral is an ordinary integral and there are no convergence questions. Since we will be interested in the behavior of $K(x,y)$ for $x \neq y$ we will ignore D and will pretend that $K(x,y) = \frac{k(x,y)}{|x-y|^2}$. The expansion (1.4) follows from Lemma 3.7 of [6] or Theorem 0.1 in [7]. The boundary, $\partial\Omega$, is a Jordan curve and hence is homeomorphic to a circle. Pick an orientation on $\partial\Omega$. We say that $(x_1, \ldots, x_n; y_1, \ldots, y_n)$ is a *circular pair* if there are points $p, q \in \partial\Omega$ which divide $\partial\Omega$ into two connected components, A, B such that $\{x_1, \ldots, x_n\} \subset A$, $\{y_1, \ldots, y_n\} \subset B$, and $x_1, \ldots, x_n, y_1, \ldots, y_n$ are in circular order on $\partial\Omega$. (Note that this definition is modified from the definition in [2].) The main theorem of this paper is the following theorem, which we prove to be equivalent to the alternating property stated in section 2.

THEOREM 1.1. *Let $(x_1, \ldots, x_n; y_1, \ldots, y_n)$ be a circular pair on $\partial\Omega$. Let $L = (l_{ij})$ be the $n \times n$ matrix with entries defined by $l_{ij} = K(x_i, y_j)$. Then*

$$(-1)^{\frac{n(n+1)}{2}} \det(L) > 0. \tag{1.5}$$

We consider this to be a generalization of a result in [2]. We will see how it implies the classical Hopf lemma for the conductivity equation in dimension 2.

2. The alternating property. We first restate and prove a result of [2]. Suppose that $\partial\Omega = I \cup J$, where I and J are disjoint connected arcs. Then we have the following theorem.

THEOREM 2.1. *Let f be a smooth function on $\partial\Omega$ such that $f = 0$ on I. Suppose there is a sequence of points $\{p_1, \ldots, p_n\} \subset I$ in circular order such that*

$$(-1)^{i+1} \Lambda f(p_i) > 0. \tag{2.1}$$

Then there is a sequence of points $\{q_1, \ldots, q_n\} \subset J$ in circular order such that

$$(-1)^n \Lambda f(p_i) f(q_i) > 0. \tag{2.2}$$

Proof. Equation (2.2) is equivalent to

$$\Lambda f(p_i) f(q_{n+1-i}) < 0. \tag{2.3}$$

We first describe how to pick the point q_n. Let u be the solution of (1.1) such that $u = f$ on $\partial\Omega$. By (2.1) $\frac{\partial u}{\partial n}(p_1) > 0$. Hence there is a small open line segment, α, such that $\alpha \subset \Omega$, p_1 is one end of α, and $u < 0$ on α. Let W be the connected component of $\{z \in \Omega \ : \ u(z) < 0\}$ that contains α. Suppose that $\overline{W} \cap J = \emptyset$. Then $u = 0$ on ∂W. But this contradicts the maximum principle since $u < 0$ in W and $W \neq \emptyset$. Thus $\overline{W} \cap J \neq \emptyset$. Now $u = 0$ at every point of ∂W that is in Ω. Using the maximum principle again we see that there is a $q_n \in \overline{W} \cap J$ such that $f(q_n) < 0$ and there is an open line segment $\beta \subset W$ such that q_n is an end point of β. Now we can connect the ends of α and β that are inside W by a smooth curve in W. Hence there is a smooth curve C_1 such that C_1 is diffeomorphic to a line segment, has end points p_1 and q_n, and $C_1 - p_1 - q_n \subset W$. Then $u(z) < 0$ for all $z \in C_1 - p_1$. We can repeat this argument to produce curves C_j such that C_j joins p_j to a point $q_{n+1-j} \in J$, $C_j - p_j - q_{n+1-j} \subset \Omega$, and $(-1)^j u(z) < 0$ for all $z \in C_j - p_j$. These curves cannot

intersect and by the Jordan curve theorem the points $p_1, \ldots, p_n, q_1, \ldots, q_n$ must be in circular order on $\partial\Omega$. It is easy to see that these points satisfy (2.3). □

We have referred to this property as the alternating property. Elsewhere [5] a similar property has been called the variation diminishing property. See also section 6 of this paper.

3. The weak inequality. We first prove the weaker statement.

THEOREM 3.1. *Let $(x_1, \ldots, x_n; y_1, \ldots, y_n)$ be a circular pair on $\partial\Omega$. Let $L = (l_{ij})$ be the $n \times n$ matrix with entries defined by $l_{ij} = K(x_i, y_j)$. Then*

$$(-1)^{\frac{n(n+1)}{2}} \det(L) \geq 0. \tag{3.1}$$

Proof. The proof is by induction on n. We first consider $n = 1$. The proof goes by contradiction. Suppose that there are points $p, q \in \partial\Omega$ with $p \neq q$ and $K(p, q) > 0$. Then there is an $\epsilon > 0$ such that $p \notin D_\epsilon = \{y : |y-q| < \epsilon\}$ and $K(p, y) > 0$ for $y \in D_\epsilon$. Let $f(y)$ be a continuous function on $\partial\Omega$ such that $\text{supp}(f) \subset D_\epsilon = \{y : |y - q| < \epsilon\}$, $f(q) > 0$, and $f(s) \geq 0$ for all $s \in \partial\Omega$. Then

$$\gamma(p)\frac{\partial u}{\partial n}(p) = \Lambda f(p) = \int_{D_\epsilon} K(p, y) f(y) dy > 0,$$

where u satisfies (1.1) and $u(s) = f(s),\ s \in \partial\Omega$. But then there must be a point z near p in Ω such that $u(z) < 0$. This contradicts the maximum principle.

Next we assume that the result is true for all $(n-1) \times (n-1)$ matrices and prove that it is true for $n \times n$ matrices. If the result is not true, then we have a circular pair $(x_1, \ldots, x_n; y_1, \ldots, y_n)$ such that

$$(-1)^{\frac{n(n+1)}{2}} \det(L) < 0. \tag{3.2}$$

Consider the matrix L^{-1} with entries (h_{ij}). Then

$$h_{ij} = (-1)^{i+j} \frac{\det(L_{ij})}{\det(L)}, \tag{3.3}$$

where L_{ij} is the (i, j) minor of L. By induction, (3.2), and (3.3),

$$(-1)^{i+j+\frac{n(n-1)}{2}+\frac{n(n+1)}{2}+1} h_{ij} = (-1)^{i+j+n+1} h_{ij} \geq 0. \tag{3.4}$$

Since L is nonsingular, for fixed i there must be some j for which

$$(-1)^{i+j+n+1} h_{ij} > 0. \tag{3.5}$$

Now let $w = [1, -1, 1, \ldots, (-1)^{n+1}]^T$ be an n-vector with alternating signs. Let $z = L^{-1}w$. Then using (3.4) and (3.5) it is easy to verify that

$$(-1)^{i+n} z_i > 0. \tag{3.6}$$

To summarize, we have a vector z such that

$$(-1)^{i+1} = w_i = \sum_{j=1}^{n} K(x_i, y_j) z_j \tag{3.7}$$

and

$$(-1)^{n+1} z_i w_i > 0. \tag{3.8}$$

Now, choose small intervals D_j around the points y_j such that the D_j are disjoint and do not contain any of the points x_i. Choose the D_j so small that

$$|K(x_i, y) - K(x_i, y_j)| < \epsilon,\ y \in D_j,\ i = 1, \ldots, n. \tag{3.9}$$

Also choose functions f_j such that

$$\operatorname{supp}(f_j) \subset D_j,\ z_j f_j(y) \geq 0, \text{and} \int_{D_j} f_j = z_j. \tag{3.10}$$

Let $f = \sum f_j$. Then

$$\begin{aligned} |\Lambda f(x_i) - w_i| &= \left| \int_{\partial\Omega} K(x_i, y) f(y) dy - \sum_{j=1}^{n} K(x_i, y_j) z_j \right| \\ &= \left| \int_{\partial\Omega} (K(x_i, y) - K(x_i, y_j)) f(y) dy \right| \\ &\leq \epsilon \sum_{j=1}^{n} |z_i|. \end{aligned} \tag{3.11}$$

Thus we conclude that for ϵ small enough $\Lambda f(x_i)$ has the same sign as w_i. By the alternating property, there would have to be a set of n points t_i in circular order such that

$$(-1)^n w_i f(t_i) > 0. \tag{3.12}$$

For such a set of points we would have to have $t_i \in D_i$ and hence $f(t_i)$ would have the same signs as z_i. This contradicts (3.8). □

4. The strong inequality. We now prove Theorem (1.1). We consider the cases $n = 1$ and $n > 1$ separately. Let us assume the arc length of $\partial\Omega$ is S and that points on $\partial\Omega$ are parametrized by the numbers in the interval $[0, S)$. When $n = 1$, suppose there is a pair of points x_1, y_1 with $0 \leq x_1 < y_1$ and $K(x_1, y_1) = 0$. By (1.4) there is no sequence of points z_j such that $x_1 < z_j < y_1$, $\lim_{j\to\infty} z_j = x_1$, and $\lim_{j\to\infty} K(x_1, z_j) = 0$. Hence there is a point η_2 with $x_1 < \eta_2 < y_1$ such that

$$K(x_1, \eta_2) = 0 \text{ and } K(x_1, \eta) < 0 \text{ for } x_1 < \eta < \eta_2.$$

Let x be any number such that $x_1 < x < \eta_2$ and choose η_1 so that $x < \eta_1 < \eta_2$. Then $(x_1, x; \eta_1, \eta_2)$ is a circular pair and hence

$$\begin{vmatrix} K(x_1, \eta_1) & K(x_1, \eta_2) \\ K(x, \eta_1) & K(x, \eta_2) \end{vmatrix} \leq 0. \tag{4.1}$$

Since

$$K(x_1, \eta_2) = 0,\ K(x, \eta_2) \leq 0,\ \text{and } K(x_1, \eta_1) < 0,$$

it follows that

$$K(x, \eta_2) = 0. \tag{4.2}$$

This shows that for *all* x, with $x_1 < x < \eta_2$, $K(x, \eta_2) = 0$. Hence we get the contradiction that $\lim_{x \to \eta_2} K(x, \eta_2) = 0$.

The proof for $n > 1$ makes use of the following result in [2]. It was later pointed out to us that Charles Dodgson (Lewis Carroll) used a version of this identity in [4]. Let $(x_1, \dots, x_n; y_1, \dots, y_n)$ be a circular pair. We assume that the coordinates on $\partial\Omega$ are chosen so that $0 \le x_1 < \cdots < x_n < y_1 < \cdots < y_n < S$. Let L be the matrix with i, j entry equal to $K(x_i, y_j)$. We will use the notation

$$\kappa(x_1, \dots, x_n; y_1, \dots, y_n) = \det(L). \tag{4.3}$$

LEMMA 4.1. *Let* $(a_1, \dots, a_{n+1}; b_1, \dots, b_{n+1})$ *be a circular pair. Then*

$$\begin{aligned} &\kappa(a_1, \dots, a_{n+1}; b_1, \dots, b_{n+1})\kappa(a_1, \dots, a_{n-1}; b_3, \dots, b_{n+1}) \\ &= \kappa(a_1, \dots, a_n; b_1, b_3, \dots, b_{n+1})\kappa(a_1, \dots, a_{n-1}, a_{n+1}; b_2, \dots, b_{n+1}) \\ &-\kappa(a_1, \dots, a_n; b_2, \dots, b_{n+1})\kappa(a_1, \dots, a_{n-1}, a_{n+1}; b_1, b_3, \dots, b_{n+1}). \end{aligned} \tag{4.4}$$

Assume that

$$\kappa(x_1, \dots, x_n; y_1, \dots, y_n) = 0 \tag{4.5}$$

for some circular pair. First we claim that there is no sequence of points z_j such that $x_n < z_j < y_1$, $\lim_{j \to \infty} z_j = x_n$, and $\lim_{j \to \infty} \kappa(x_1, \dots, x_n; z_j, y_2, \dots, y_n) = 0$. For this would imply that there are constants c_k (independent of j) so that

$$K(x_n, z_j) = \sum_{k<n} c_k K(x_k, z_j), \tag{4.6}$$

and hence

$$\lim_{j \to \infty} K(x_n, z_j) = \sum_{k<n} c_k K(x_k, x_n), \tag{4.7}$$

contradicting (1.4). Thus there is a number η_1 with $x_n < \eta_1 < y_1$ such that

$$\kappa(x_1, \dots, x_n; \eta_1, y_2, \dots, y_n) = 0 \text{ and} \tag{4.8}$$

$$\kappa(x_1, \dots, x_n; \eta, y_2, \dots, y_n) \neq 0 \text{ for } x_n < \eta < \eta_1. \tag{4.9}$$

Let x be such that $x_n < x < \eta_1$. Then there is an η such that $x < \eta < \eta_1$ and hence $(x_1, \dots, x_n, x; \eta, \eta_1, y_2, \dots, y_n)$ is a circular pair. By (4.4), (4.5), and (3.1),

$$\begin{aligned} 0 &\ge \kappa(x_1, \dots, x_n, x; \eta, \eta_1, y_2, \dots, y_n)\kappa(x_1, \dots, x_{n-1}; y_2, \dots, y_n) \\ &= \kappa(x_1, \dots, x_n; \eta, y_2, \dots, y_n)\kappa(x_1, \dots, x_{n-1}, x; \eta_1, y_2, \dots, y_n) \\ &\quad -\kappa(x_1, \dots, x_n; \eta_1, y_2, \dots, y_n)\kappa(x_1, \dots, x_{n-1}, x; \eta, y_2, \dots, y_n) \\ &= \kappa(x_1, \dots, x_n; \eta, y_2, \dots, y_n)\kappa(x_1, \dots, x_{n-1}, x; \eta_1, y_2, \dots, y_n) \ge 0. \end{aligned} \tag{4.10}$$

Using this and (4.9) we see that

$$\kappa(x_1, \dots, x_{n-1}, x; \eta_1, y_2, \dots, y_n) = 0 \text{ for } x_n < x < \eta_1. \tag{4.11}$$

As above, this contradicts (1.4) and proves the theorem.

5. The Hopf lemma. We now show how the fact that $K(x,y) < 0$ for $x \neq y$ implies the Hopf lemma (reference) for the conductivity equation.

THEOREM 5.1. *Let u be a nonconstant solution of $\nabla(\gamma\nabla u) = 0$, and let $p \in \partial\Omega$ be a point where u assumes a minimum. Then*

$$\frac{\partial u}{\partial n}(p) < 0. \tag{5.1}$$

Proof. We may assume that $u(p) = 0$. Let $f = u|_{\partial\Omega}$. Since u is not constant, $\mathrm{supp}(f)$ is not empty. Thus there is an interval D around p in $\partial\Omega$ such that $\mathrm{supp}(f) - D$ is not empty. Let ψ be a smooth function on $\partial\Omega$ such that $\psi = 1$ on $\mathrm{supp}(f) - D$, $\psi = 0$ on an interval around p, and $0 \leq \psi \leq 1$. Let $g = \psi f$ and let v be the solution of $\nabla(\gamma\nabla v) = 0$ with $v|_{\partial\Omega} = g$. Since $f \geq g$ it follows that $u \geq v$. It is also true that $g \geq 0$. Since $p \notin \mathrm{supp}(g)$ and $K(p,y) < 0$,

$$0 > \int_{\partial\Omega} K(p,y)g(y)dy = \gamma(p)\frac{\partial v}{\partial n}(p) \geq \gamma(p)\frac{\partial u}{\partial n}(p), \tag{5.2}$$

which proves the theorem. □

6. The variation diminishing property. We will use the following notation. Let $M(x,y)$ be a continuous function on $[c,d] \times [a,b]$. Let $c \leq x_1 < x_2 < \cdots < x_n \leq d$, $a \leq y_1 < y_2 < \cdots < y_n \leq b$. Let T be the $n \times n$ matrix with i,j entry equal to $M(x_i, y_j)$. Let

$$\mu(x_1, x_2, \ldots, x_n; y_1, y_2, \ldots, y_n) = \det(T).$$

The following lemma from [5] is sometimes paraphrased by saying that the kernel M has the *variation diminishing property*. It will be used to show that the inequalities (1.5) imply the alternating property.

LEMMA 6.1. *Let f be a continuous, not identically 0, function defined on the interval $[a,b]$ such that f changes its sign on this interval no more than $n-1$ times. Let $M(x,y)$, $x,y \in [c,d] \times [a,b]$, be a continuous kernel with the property that*

$$\mu(x_1, x_2, \ldots, x_n; y_1, y_2, \ldots, y_n) > 0, \tag{6.1}$$

whenever $c \leq x_1 < x_2 < \cdots < x_n \leq d$, $a \leq y_1 < y_2 < \cdots < y_n \leq b$. Then the function

$$g(x) = \int_a^b M(x,y)f(y)dy$$

vanishes in $[c,d]$ no more than $n-1$ times.

By saying that function f changes its sign k times on the interval $[a,b]$ we mean that there are $k+1$ points $x_1 < x_2 < \cdots < x_{k+1}$ in $[a,b]$ such that for $i = 1, 2, \ldots, k$

$$f(x_i)f(x_{i+1}) < 0. \tag{6.2}$$

Proof. By hypothesis there are points $a = s_0 < s_1 < s_2 < \cdots < s_{n-1} < s_n = b$ such that in each interval (s_{i-1}, s_i), $i = 1, 2, \ldots, n$ function f does not change its sign and is not identically 0. For $i = 1, 2, \ldots, n$ let

$$g_i(x) = \int_{s_{i-1}}^{s_i} M(x,y)f(y)dy. \tag{6.3}$$

Then

$$g(x) = \sum_{i=1}^{n} g_i(x). \tag{6.4}$$

For any $c \le x_1 < x_2 < \cdots < x_n \le d$ the determinant

$$\det(\{g_i(x_j\}) = \int_{s_{n-1}}^{s_n} \cdots \int_{s_0}^{s_1} \mu(x_1, x_2, \ldots, x_n; y_1, y_2, \ldots, y_n) f(y_1) \cdots f(y_n) dy_1 \cdots dy_n \tag{6.5}$$

is not 0 since the integrand is not identically zero and has constant sign. This shows that there is no nontrivial linear combination of g_i's vanishing at n points and hence that $g(x) = \sum_{i=1}^{n} g_i(x)$ cannot vanish at n points. □

We note that this proof only used the fact that $\mu(x_1, x_2, \ldots, x_n; y_1, y_2, \ldots, y_n)$ has constant sign. We need one more lemma before coming to the proof of the alternating principal.

Let $K(x, y)$ be a kernel on $\partial\Omega \times \partial\Omega$. We assume that $K(x, y)$ is continuous when $x \neq y$, but we don't assume anything about K on the diagonal of $\partial\Omega \times \partial\Omega$. Let $\kappa(x_1, \ldots, x_n; y_1, \ldots, y_n)$ be defined as in section 4.

LEMMA 6.2. *Suppose that $\kappa(x_1, \ldots, x_n; y_1, \ldots, y_n)$ is never zero and has constant sign for all circular n-pairs $(x_1, \ldots, x_n; y_1, \ldots, y_n)$. Let $\partial\Omega = I \cup J$ where I and J are disjoint connected arcs. Let f be a continuous function on $\partial\Omega$ with* $\operatorname{supp}(f) \subset J$. *Let*

$$g(x) = \int_{\partial\Omega} K(x, y) f(y) dy. \tag{6.6}$$

Then if there is a sequence of $n+1$ points in I in circular order at which g alternates in sign, then there is a sequence of at least $n+1$ points in J in circular order at which f alternates in sign.

Proof. If there is no sequence of $n + 1$ points of J at which f alternates in sign, then f can change its sign no more than $n-1$ times in J. By Lemma 6.1, g can vanish no more than $n - 1$ times in I. But we are assuming that g has $n + 1$ alternations of sign in I and hence at least n zeros in I. This contradiction proves the lemma. □

We now state and prove the theorem.

THEOREM 6.3. *Using the notation of Lemma* 6.2, *suppose that*

$$(-1)^{\frac{n(n+1)}{2}} \kappa(x_1, \ldots, x_n; y_1, \ldots, y_n) > 0 \tag{6.7}$$

for all $n > 0$ and all circular n-pairs $(x_1, \ldots, x_n; y_1, \ldots, y_n)$. Let f be a continuous function on $\partial\Omega$ with $\operatorname{supp}(f) \subset J$. *Let*

$$g(x) = \int_{\partial\Omega} K(x, y) f(y) dy. \tag{6.8}$$

Suppose there is a sequence of points $\{p_1, \ldots, p_n\} \subset I$ in circular order such that

$$(-1)^{i+1} g(p_i) > 0. \tag{6.9}$$

Then there is a sequence of points $\{q_1, \ldots, q_n\} \subset J$ in circular order such that

$$(-1)^n g(p_i) f(q_i) > 0. \tag{6.10}$$

Proof. By Lemma 6.2 there is a sequence of points in J at which f alternates in sign. If there is no sequence with the desired alteration property then J is a disjoint union of subintervals J_i, in circular order, such that

1. f is not identically 0 on $J_i,\ i = 1, \ldots, n$,
2. f does not change its sign on $J_i,\ i = 1, \ldots, n$,
3. for some $z_i \in J_i$,

$$(-1)^{n+i} f(z_i) > 0. \tag{6.11}$$

We use the idea of Lemma 6.1. For $i = 1, 2, \ldots, n$ let

$$g_i(x) = \int_{J_i} K(x, y) f(y) dy. \tag{6.12}$$

Then

$$g(x) = \sum_{i=1}^{n} g_i(x). \tag{6.13}$$

Let

$$G = \begin{bmatrix} g_1(x_1) & g_2(x_1) & \ldots & g_n(x_1) \\ g_1(x_2) & \ldots & & g_n(x_2) \\ \vdots & & & \vdots \\ g_1(x_n) & \ldots & & g_n(x_n) \end{bmatrix}. \tag{6.14}$$

Let u be the n-vector with $u_i = 1,\ i = 1, \ldots, n$. Then

$$Gu = \begin{bmatrix} g(x_1) \\ g(x_2) \\ \vdots \\ g(x_n) \end{bmatrix}. \tag{6.15}$$

Using (6.11) we will show that the signs of u are all negative. This contradiction will prove the theorem. We need to compute the signs of the entries of G^{-1}. Rather than get lost in a cloud of indices, we will give the proof in the case that $n = 3$ and leave the general proof to the reader. In this case the assumption (6.11) implies that $f(y) \geq 0$ in J_1, $f(y) \leq 0$ in J_2, and $f(y) \geq 0$ in J_3. As in section 3 we compute the signs of the cofactors of G. First we have

$$\det(G) = \int_{J_1} \int_{J_2} \int_{J_3} \kappa(x_1, x_2, x_3; y_1, y_2, y_3) f(y_1) f(y_2) f(y_3) dy_1 dy_2 dy_3 < 0. \tag{6.16}$$

We find that

$$\begin{vmatrix} g_2(x_2) & g_3(x_2) \\ g_2(x_3) & g_3(x_3) \end{vmatrix} = \int_{J_2} \int_{J_3} \kappa(x_2, x_3; y_2, y_3) f(y_2) f(y_3) dy_2 dy_3 > 0. \tag{6.17}$$

Hence $(G^{-1})_{11} < 0$. Next we compute that

$$(-1)^{1+2} \begin{vmatrix} g_1(x_2) & g_3(x_2) \\ g_1(x_3) & g_3(x_3) \end{vmatrix} = \int_{J_1} \int_{J_3} \kappa(x_2, x_3; y_1, y_3) f(y_1) f(y_3) dy_1 dy_3 > 0, \tag{6.18}$$

and thus $(G^{-1})_{21} < 0$. Continuing the calculation we find that the signs of G^{-1} are as follows:

$$G^{-1} = \begin{bmatrix} - & + & - \\ - & + & - \\ - & + & - \end{bmatrix}. \tag{6.19}$$

This yields the contradiction

$$\begin{bmatrix} - & + & - \\ - & + & - \\ - & + & - \end{bmatrix} \begin{bmatrix} + \\ - \\ + \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}. \tag{6.20}$$

□

7. Remarks and conjectures. We have not tried to state the most general hypotheses under which our results are valid, but have stated them in such a way that the essential ideas of the proofs are clear. We can also prove determinant inequalities for certain "blocks" in Dirichlet-to-Neumann kernels for multiply-connected plane domains. We can differentiate our inequalities to get a set of inequalities involving determinants of derivatives of the Dirichlet-to-Neumann kernel. These inequalities are equivalent to the set of inequalities (1.5). In our arguments we seem to need to assume that γ is in $C^2(\Omega)$; however, it is possible that weaker assumptions would suffice.

We would like to single out the following conjecture on characterizing the kernel of a Dirichlet-to-Neumann map.

CONJECTURE 1. *Let Ω be a relatively compact, simply connected region in the plane with C^2 boundary. Let $K(x,y) = \frac{k(x,y)}{|x-y|^2}$, where $(x,y) \in \partial\Omega \times \partial\Omega - \Delta$, k is continuous on $\partial\Omega \times \partial\Omega$, $k(x,x) \neq 0$, and K satisfies* (1.5). *Then there is a distribution $D(x,y)$ on $\partial\Omega \times \partial\Omega$, supported on the diagonal, Δ, and a regularization of K as a distribution on $\partial\Omega \times \partial\Omega$, so that $L = K + D$ is the kernel of the Dirichlet-to-Neumann map for some conductivity, γ, on Ω. The distribution D is determined by the property that*

$$\int_{\partial\Omega} L(x,y)dy = 0. \tag{7.1}$$

Equation (7.1) is analogous to the fact that the Dirichlet-to-Neumann matrix for an electrical network has row sums equal to zero. This implies that the diagonal is determined by the off-diagonal terms. This is true as well in the continuous case.

Acknowledgments. We have discussed these results with many people and their suggestions and advice have been of great benefit. Among these people are Ed Curtis, John Sylvester, and Gunther Uhlmann. The importance of the alternating property was recognized some time ago by Ed Curtis.

EXPONENTIALLY GROWING SOLUTIONS FOR NONSMOOTH FIRST-ORDER PERTURBATIONS OF THE LAPLACIAN*

CARLOS F. TOLMASKY†

Abstract. We construct exponentially growing solutions for first-order perturbations of the Laplacian which are not smooth. We apply this kind of solution to prove global uniqueness for an inverse boundary value problem for the Schrödinger equation in the presence of a magnetic field.

Key words. inverse boundary problems, Dirichlet–Neumann map, exponentially growing solutions

AMS subject classifications. 35J05, 35R30

1. Introduction.

The idea of using exponentially growing solutions in the context of inverse boundary value problems goes back to Calderón [C]. Motivated by Calderón's idea, Sylvester and Uhlmann [S-U] constructed exponentially growing solutions in order to prove global uniqueness for the conductivity of a body knowing the so-called Dirichlet-to-Neumann map.

The method of constructing exponentially growing solutions has been applied to other inverse problems like the inverse scattering problem at a fixed energy [N] and inverse spectral problems. However, Sylvester and Uhlmann's methods cannot be applied when we are in the presence of the first-order perturbation. Examples of this situation are given by the following:

(1) the problem of determining both the electrical conductivity and permitivity of a body and its magnetic permeability by measuring the tangential components of the electric field and the magnetic field at the boundary [O-P-S];

(2) the problem involving measurements at the boundary of an elastic medium, in which one measures displacements at the boundary and the corresponding stress at the boundary [N-U];

(3) the problem of determining both the electrical potential and the magnetic potential from boundary observations [Su], [N-Su-U].

This last problem is modeled by the Schrödinger equation in the presence of a magnetic field and it will be considered in this paper as an example of our techniques.

Let Ω be a bounded domain with smooth boundary in $\mathbb{R}^n$, $n \geq 3$; then the Schrödinger equation in the presence of a magnetic field is given by

$$H_{\vec{C},q} = \sum_{j=1}^{n} \left(-i\frac{\partial}{\partial x_j} + C_j(x) \right)^2 + q(x), \tag{1.1}$$

where $\vec{C} = (C_1, ..., C_n)$ is the magnetic potential and q is the electric potential. Assume $\vec{C} \in C^1(\overline{\Omega})$, $q \in L^\infty(\Omega)$ and both are real valued. If we assume further that zero is not a Dirichlet eigenvalue of (1.1) in Ω then we have that for any $f \in H^{1/2}(\Omega)$

*Received by the editors March 25, 1996; accepted for publication (in revised form) October 29, 1996.

†University of Washington, Department of Mathematics, Box 354350, Seattle, WA 98195-4350 (tolmasky@math.washington.edu).

there exists a unique $u \in H^1(\Omega)$ which solves

$$\begin{cases} H_{\vec{C},q} = 0 & \text{in } \Omega, \\ u|_{\partial\Omega} = f. \end{cases} \tag{1.2}$$

We define the Dirichlet-to-Neumann map by

$$\Lambda_{\vec{C},q} : f \longrightarrow \frac{\partial u}{\partial \eta}_{|\partial\Omega} + i(\vec{C}\cdot\eta)f, \tag{1.3}$$

where $f \in H^{1/2}(\Omega), u$ solves (1.2), and η is the unit outer normal to Ω.

The problem we consider is the one of recovering information about $\vec{C}$ and q given knowledge of the Dirichlet-to-Neumann map. It is well known (see [Su], [N-Su-U]) that the Dirichlet-to-Neumann map is invariant under gauge transformations in the magnetic potential. Consider $g \in C^1_\Omega$, where

$$C^s_\Omega = \{g \in C^s(\mathbb{R}^n) : \operatorname{supp} g \subset \Omega\}, \tag{1.4}$$

and consider the magnetic potential $\vec{C} + \nabla g$. Then $\Lambda_{\vec{C},q} = \Lambda_{\vec{C}+\nabla g,q}$. Therefore, we cannot hope to recover $\vec{C}$ from the Dirichlet-to-Neumann map. However, we can see that $rot(\vec{C})$ is invariant under a gauge transformation. It is then natural to wonder whether full knowledge of the Dirichlet-to-Neumann map gives full knowledge of $rot(\vec{C})$ and of q. This question has an affirmative answer given by Z. Sun in the case that the magnetic potential belongs to C^2_Ω and $q \in L^\infty(\Omega)$ provided that $rot(\vec{C})$ is small in the L^∞ topology [Su], and by Nakamura, Sun, and Uhlmann in the case that $\vec{C} \in C^\infty_\Omega$ and $q \in L^\infty(\Omega)$ under no assumptions on $rot(\vec{C})$ [N-Su-U]. In this paper we prove the following theorem.

THEOREM 1.1. *Let $\vec{C}_j \in C^1_\Omega, q_j \in L^\infty(\overline{\Omega})$, $j = 1, 2$. Assume that zero is not a Dirichlet eigenvalue for $H_{\vec{C}_j,q_j}$, $j = 1, 2$. If*

$$\Lambda_{\vec{C}_1,q_1} = \Lambda_{\vec{C}_2,q_2}$$

then

$$rot(\vec{C}_1) = rot(\vec{C}_2) \quad \textit{and} \quad q_1 = q_2 \quad \textit{in} \quad \Omega.$$

In [N-U], Nakamura and Uhlmann proved a result that enables us to find exponentially growing solutions to any smooth first-order perturbation of the Laplacian. In the same paper they used the solutions to prove global uniqueness for the inverse problem related to the elasticity system mentioned above.

In this paper we give a general method to construct exponentially growing solutions in the case that the first-order perturbation is not smooth. We note that the problem of global uniqueness in the case of a conductivity having less than two derivatives has been addressed by R. Brown in [Br]. Our method works by splitting the first-order term into a smooth part, with which we deal by following [N-U], and a nonsmooth one, for which we need estimates. Namely, we consider

$$S_{\vec{C}}(u) = (\Delta + \vec{C}\cdot\nabla)u = f$$

with $\vec{C} \in C^{2/3+\epsilon}(\overline{\Omega})$, $\epsilon > 0$. After conjugating by $e^{x\cdot\rho}$ ($\rho \in \mathbb{C}^n$, $\rho\cdot\rho = 0$) we get

$$S_{\vec{C},\rho} = \Delta_\rho u + \vec{C}\cdot\nabla_\rho u = f. \tag{1.5}$$

We can now decompose $\vec{C} \cdot \nabla_\rho$ into a pseudodifferential operator in the Shubin class (see [S]) plus a pseudodifferential operator with nonregular symbol depending on the parameter ρ for which we prove estimates.

The paper is organized as follows. In section 1 we define the spaces of symbols with limited regularity and we will show how to "smooth out" such symbols. The following section contains the proof of the dependence on the parameter ρ of the norm of the pseudodifferential operator associated with a symbol with limited regularity between Sobolev spaces. In section 3 we give the construction of the exponentially growing solutions for a generic perturbation of the Laplacian and in section 4 we prove Theorem 1.1.

2. Symbol smoothing. In this section we are going to smooth out nonregular symbols depending on a parameter. The ideas are similar as if we were working with no parameter at all (see [T, section 1.3]).

We recall now the definitions of the spaces $C^s(\mathbb{R}^n)$ and $C^s_*(\mathbb{R}^n)$.

DEFINITION 2.0.1. *Given* $0 < s < 1$, $C^s(\mathbb{R}^n)$ *is defined as the set of functions* u *such that*

$$|u(x+y) - u(x)| \leq C\ |y|^s.$$

For $k = 0, 1, 2, ...$, we take $C^k(\mathbb{R}^n)$ as the set of bounded continuous functions u so that $D^\beta u$ is bounded and continuous for any β such that $|\beta| \leq k$.

Then, if $s = k + r$, $0 \leq r \leq 1$, we define $C^s(\mathbb{R}^n)$ as the set of functions $u \in C^k(\mathbb{R}^n)$ so that $D^\beta u$ belongs to $C^r(\mathbb{R}^n)$ for $|\beta| = k$.

Let us consider the partition of unity

$$1 = \sum_{j=0}^{\infty} \psi_j(\xi)\ ,$$

where ψ_j is supported on $(1+|\xi|^2)^{1/2} \sim 2^j$ (by this we mean that there are constants M_1 and M_2 so that $(1+|\xi|^2)^{1/2} \leq M_1 2^j$ and $(1+|\xi|^2)^{1/2} \geq M_2 2^j$).

DEFINITION 2.0.2. *If* $s > 0$ *we say that* $u \in C^s_*(\mathbb{R}^n)$ *if and only if*

$$\sup_k\ 2^{ks} \|\psi_k(D)u\|_{L^\infty} < \infty,$$

and we define $\|\ \|_{C^s_*}$ *as the supremum of those numbers.*

A family of spaces $\{X^s : s \in \Sigma\}$ will be called a scale. We will be working with the spaces C^s and C^s_*, so in our case $\Sigma = (0, \infty)$.

We will introduce classes of symbols with limited regularity.

DEFINITION 2.0.3. *Let* $\delta \in [0, 1]$*:*

(a) $p_\rho(x, \xi) \in C^s_* S^m_{1,\delta,\rho}(\mathbb{R}^n)$ *if and only if*

$$|D^\alpha_\xi p_\rho(x, \xi)| \leq C_\alpha((1 + |\xi|^2 + |\rho|^2)^{\frac{1}{2}})^{m-|\alpha|}$$

and

$$\|D^\alpha_\xi p_\rho(\cdot, \xi)\|_{C^s_*} \leq C_\alpha\ ((1 + |\xi|^2 + |\rho|^2)^{\frac{1}{2}})^{m-|\alpha|+s\delta}$$

for any $\alpha \in \mathbf{Z}^n_+$.

(b) $p_\rho(x, \xi) \in C^s S^m_{1,\delta,\rho}(\mathbb{R}^n)$ *if the conditions on* (a) *are satisfied and, additionally,*

$$\|D^\alpha_\xi p_\rho(\cdot, \xi)\|_{C^j} \leq C_\alpha\ ((1 + |\xi|^2 + |\rho|^2)^{\frac{1}{2}})^{m-|\alpha|+j\delta}$$

for any $\alpha \in \mathbf{Z}^n_+$ *and* $0 \leq j \leq s, j \in \mathbf{N}$.

Our goal is to write a symbol $p_\rho(x,\xi) \in X^s S^s_{1,0,\rho}(\mathbb{R}^n)$ (where $X^s = C^s$ *or* C^s_*) as a sum of a smooth symbol and a reminder of lower order. We will find that the smooth part does not belong to $S^m_{1,0,\rho}$, but rather to one of the classes $S^m_{1,\delta,\rho}$.

We will need a partition of unity ψ^j_ρ of $\mathbb{R}^n$ such that

$$1 = \sum_{j=0}^{\infty} \psi^j_\rho(\xi),$$

where ψ^j_ρ is supported on $(1+|\xi|^2)^{1/2} \sim 2^j(1+|\rho|^2)^{1/2}$.

To construct such a partition we take $\psi^0_\rho(\xi)$ to be positive such that

$$\psi^0_\rho(\xi) = \begin{cases} 1 & \text{if } |\xi| \le (1+|\rho|^2)^{1/2}, \\ 0 & \text{if } |\xi| \ge 2(1+|\rho|^2)^{1/2}. \end{cases}$$

Finally, we set $\Psi^j_\rho(\xi) = \psi^0_\rho(2^{-j}\xi)$ and $\psi^j_\rho(\xi) = \Psi^j_\rho(\xi) - \Psi^{j-1}_\rho(\xi)$.

Now, given $p(x,\xi) \in X^s S^s_{1,0,\rho}$, choose $\delta \in (0,1]$ and set

$$p^\sharp_\rho(x,\xi) = \sum_{j=0}^{\infty} J_{\epsilon^j_\rho}\ p(x,\xi)\psi^j_\rho(\xi),$$

where

$$J_\epsilon f(x) = \theta(\epsilon D) f(x) \tag{2.1}$$

with $\theta \in C^\infty_0(R^n),\ \theta(\xi) = 1$ for $|\xi| \le 1$. We take

$$\epsilon^j_\rho = (2^{-j}(1+|\rho|^2)^{-1/2})^\delta. \tag{2.2}$$

We then define $p^b_\rho(x,\xi)$ to be $p_\rho(x,\xi) - p^\sharp_\rho(x,\xi)$, so our decomposition is

$$p_\rho(x,\xi) = p^\sharp_\rho(x,\xi) + p^b_\rho(x,\xi). \tag{2.3}$$

DEFINITION 2.0.4. *A scale X^s is called microlocalizable if, for $m \in \mathbf{R}$, $s, s+m \in \Sigma$,*

$$OPS^m_{1,0} : X^{s+m} \longrightarrow X^s.$$

Examples.

(1) The Sobolev spaces $H^{s,p}(\mathbb{R}^n)$ are microlocalizables provided $p \in (1,\infty)$.

(2) The property fails for the spaces C^s if s is an integer, but it turns out to be true for the Zygmund spaces C^s_*.

The following lemma will be useful to analyze the two terms in the decomposition (2.3); for the proof we refer to [T, Lemma 1.3.A].

LEMMA 2.1. *Let $\{X^s : s \in \Sigma\}$ be a microlocalizable scale; then, for $\epsilon \in (0,1]$,*

$$\|D^\beta_x J_\epsilon f\|_{X^s} \ \le\ C_\beta\ \epsilon^{-|\beta|}\|f\|_{X^s} \tag{2.4}$$

and

$$\|f - J_\epsilon f\|_{X^{s-t}} \ \le\ C\ \epsilon^t\ \|f\|_{X^s} \quad \textit{for } s, s-t \in \Sigma, \quad t \ge 0. \tag{2.5}$$

Using this, we derive the following proposition.

PROPOSITION 2.2. *If X^s is a microlocalizable scale and $p_\rho(x,\xi) \in X^s S^m_{1,0,\rho}$, then we have*

$$p^\sharp_\rho(x,\xi) \in S^m_{1,\delta,\rho} \tag{2.6}$$

and

$$p^b_\rho(x,\xi) \in X^{s-t} S^{m-t\delta}_{1,0,\rho} \quad if\ s, s-t \in \Sigma. \tag{2.7}$$

Proof. Let j be a nonnegative integer and suppose that $(1+|\xi|^2)^{1/2} \sim 2^j(1+|\rho|^2)^{1/2}$, i.e.,

$$(1+|\xi|^2)^{1/2} \leq C_1\, 2^j(1+|\rho|^2)^{1/2} \quad \text{and } 2^j(1+|\rho|^2)^{1/2} \leq C_2\,(1+|\xi|^2)^{1/2} \tag{2.8}$$

for some constants $C_1 > 0$ and $C_2 > 0$. Then

$$\begin{aligned} (1+|\xi|^2+|\rho|^2)^{1/2} &\leq (C_1^2\ 2^{2j}\ (1+|\rho|^2) + |\rho|^2)^{1/2} \\ &\leq (C_1^2\ 2^{2j} + 1)^{1/2}\ (1+|\rho|^2)^{1/2} \\ &\leq (C_1^2 + 1)^{1/2}\ 2^j\ (1+|\rho|^2)^{1/2} \end{aligned} \tag{2.9}$$

and

$$\begin{aligned} 2^j\ (1+|\rho|^2)^{1/2} &\leq C_2(1+|\xi|^2)^{1/2} \\ &\leq C_2(1+|\xi|^2+|\rho|^2)^{1/2}. \end{aligned} \tag{2.10}$$

From (2.9) and (2.10) we obtain that

$$(1+|\xi|^2)^{1/2} \sim 2^j(1+|\rho|^2)^{1/2} \iff (1+|\xi|^2+|\rho|^2)^{1/2} \sim 2^j(1+|\rho|^2)^{1/2}.$$

Let us analyze first the smooth part $p^\sharp_\rho(x,\xi)$. We fix j a nonnegative integer and ξ so that $(1+|\xi|^2)^{1/2} \sim 2^j(1+|\rho|^2)^{1/2}$. By (2.2), (2.4), (2.10), and $p_\rho(x,\xi) \in X^s S^m_{1,0,\rho}$ we have

$$\begin{aligned} \|D^\beta_x\, J_{\epsilon^j_\rho} p_\rho(\,\cdot\,,\xi)\|_{X^s} &\leq C_\beta\,(\epsilon^j_\rho)^{-|\beta|}\,\|p_\rho(\,\cdot\,,\xi)\|_{X^s} \\ &\leq C_\beta\,(2^j(1+|\rho|^2)^{1/2})^{\frac{\delta|\beta|}{2}}((1+|\xi|^2+|\rho|^2)^{1/2})^m \\ &\leq C_\beta\,((1+|\xi|^2+|\rho|^2)^{1/2})^{m+\delta|\beta|}. \end{aligned} \tag{2.11}$$

To prove (2.7) we first notice that derivatives in the x variable commute with the operators defined in (2.1); then it is enough to prove the estimates for $p^b_\rho(\,\cdot\,,\xi)$. Then, by (2.2), (2.5), (2.10), and $p_\rho(x,\xi) \in X^s S^m_{1,0,\rho}$ we have

$$\begin{aligned} \|p^b_\rho(\,\cdot\,,\xi)\|_{X^{s-t}} &\leq C\,(\epsilon^j_\rho)^t\,\|p_\rho(\,\cdot\,,\xi)\|_{X^s} \\ &\leq C\,(2^j(1+|\rho|^2)^{1/2})^{-\frac{\delta t}{2}}((1+|\xi|^2+|\rho|^2)^{1/2})^m \\ &\leq C\,((1+|\xi|^2+|\rho|^2)^{1/2})^{m-t\delta}. \end{aligned} \tag{2.12}$$

3. Continuity in $H^s(\mathbb{R}^n)$ of symbols in $C^r_* S^m_{1,0,\rho}(\mathbb{R}^n)$. The crucial step in the construction of the exponentially growing solutions is to know the dependence on ρ of the norm of operators with nonsmooth symbols. More specifically we will use the following result.

THEOREM 3.1. *Let $r > 0$ and $p_\rho(x,\xi) \in C^r_* S^m_{1,0,\rho}(\mathbb{R}^n)$. Then*

$$p_\rho(x,D): H^{s+m,p}(\mathbb{R}^n) \longrightarrow H^{s,p}(\mathbb{R}^n)$$

with

$$\|p_\rho(x,D)\|_{s+m,s} \le C\ ((1+|\rho|^2)^{\frac{1}{2}})^{s+m}$$

where $0 < s < r$, $p \in (1,\infty)$, and $\|\ \|_{s+m,s}$ denotes the operator norm between Sobolev spaces.

We will use the following results from the Littlewood–Paley theory.

LEMMA 3.2. *Let $f_k \in S'(\mathbb{R}^n)$ be such that, for some $A > 0$,*

$$supp\ \hat{f}_k \subset \{\xi\ ; A\,2^{k-1} \le |\xi| \le A\,2^{k+1}\}, \qquad k \ge 1,$$

and $\hat{f}_0$ has compact support. Then, for $p \in (1,\infty)$, $s \in \mathbb{R}$, we have

$$\left\| \sum_{k=0}^{\infty} f_k \right\|_{H^{s,p}} \sim \left\| \left\{ \sum_{k=0}^{\infty} 4^{ks}\ |f_k|^2 \right\}^{\frac{1}{2}} \right\|_{L^p}.$$

LEMMA 3.3. *Let $f_k \in S'(\mathbb{R}^n)$ be such that*

$$supp\ \hat{f}_k \subset \{\xi\ ;\ |\xi| \le A(1+|\rho|^2)^{\frac{1}{2}}\ 2^{k+1}\}, \qquad k \ge 0.$$

Then, for $p \in (1,\infty)$, $s > 0$, we have

$$\left\| \sum_{k=0}^{\infty} f_k \right\|_{H^{s,p}} \le C \left\| \left\{ \sum_{k=0}^{\infty} 4^{ks}\ (1+|\rho|^2)^{\frac{s}{2}}\ |f_k|^2 \right\}^{\frac{1}{2}} \right\|_{L^p}.$$

Proof of Theorem 3.1. The idea of the proof was taken from [T, Theorem 2.1.A] and it follows pioneering work of Coifman and Meyer [C-M]. See also Bourdaud [B]. By following [C-M] we can restrict ourselves to considering elementary symbols in $C^r_* S^m_{1,0,\rho}(\mathbb{R}^n)$. An elementary symbol in $C^r_* S^m_{1,0,\rho}(\mathbb{R}^n)$ can be written as

$$q_\rho(x,\xi) = \sum_{k=0}^{\infty} Q_k(x)\ \varphi^k_\rho(\xi)$$

with $supp\ \varphi^k_\rho$ on $(1+|\xi|^2)^{1/2} \sim 2^k\ (1+|\rho|^2)^{1/2}$.

So, by the definition of the class $C^r_* S^m_{1,0,\rho}(\mathbb{R}^n)$ we have that

$$\|Q_k(\cdot)\ \varphi^k_\rho(\xi)\ \|_{C^r_*} \le A\ ((1+|\xi|^2+|\rho|^2)^{1/2})^m. \tag{3.1}$$

We now consider a partition of unity ψ_j with $supp\ \psi_j$ on $(1+|\xi|^2)^{\frac{1}{2}} \sim 2^j$. Let $Q_{kj}(x) = \psi_j(D)\ Q_k(x)$ and $f_k = \varphi^k_\rho(D) f$.

Then

$$q_\rho(x,\xi) = \sum_{k=0}^{\infty} \left(\sum_{j=0}^{k-4} Q_{kj}(x) + \sum_{j=k-3}^{k+3} Q_{kj}(x) + \sum_{j=k+4}^{\infty} Q_{kj}(x) \right) \varphi^k_\rho(\xi)$$

$$= q^1_\rho(x,\xi) + q^2_\rho(x,\xi) + q^3_\rho(x,\xi). \tag{3.2}$$

We will work with each $q^i_\rho, i = 1,2,3$ separately.

Let us start with $q^1_\rho(x,D)$.
We have

$$\operatorname{supp}\left(\sum_{j=0}^{k-4} Q_{kj}\ f_k\right)\widehat{\ }$$

$$\subset\ \{\xi; 2^{k-1}(1+|\rho|^2)^{1/2} \leq |\xi| \leq 2^{k+1}(1+|\rho|^2)^{1/2}\} + \{\xi; |\xi| \leq 2^{k-3}\}$$

$$\subset \{\xi; 2^{k-1}(1+|\rho|^2)^{1/2} \leq |\xi| \leq 2^{k+1}(1+|\rho|^2)^{1/2}\} + \{\xi; |\xi| \leq 2^{k-3}(1+|\rho|^2)^{1/2}\}.$$

$$\subset \{\xi; A\ 2^{k-1}(1+|\rho|^2)^{1/2} \leq |\xi| \leq A\ 2^{k+1}(1+|\rho|^2)^{1/2}\}.$$

By Lemma 3.3 we get

$$\|q^1_\rho(x,D)f\|_{H^{s,p}}\ \leq\ C\ (1+|\rho|^2)^{s/2}\ \left\|\left\{\sum_{k=4}^{\infty}\ 4^{ks}\Big|\sum_{j=0}^{k-4} Q_{kj}\ f_k\ |^2\right\}^{\frac{1}{2}}\right\|_{L^p}. \tag{3.3}$$

From (3.1) and the definition of the spaces C^r_* we get

$$\|Q_{kj}(x)\|_\infty\ \leq\ B\ 2^{-jr}\ 2^{km}\ ((1+|\rho|^2)^{\frac{1}{2}})^m, \tag{3.4}$$

from which we obtain

$$\begin{aligned}\|q^1_\rho(x,D)f\|_{H^{s,p}} &\leq\ C_1\ \left\|\left(\sum_{k=4}^{\infty} 4^{k(s+m)}((1+|\rho|^2)^{\frac{1}{2}})^{s+m}|f_k|^2\right)^{1/2}\right\|_{L^p}\\ &\leq\ C_1\,\|f\|_{H^{s+m,p}}.\end{aligned} \tag{3.5}$$

We now make use of Lemma 3.2 to get

$$\left\|\left(\sum_{k=1}^{\infty}\ 4^{k(s+m)}\ ((1+|\rho|^2)^{1/2})^{s+m}|f_k\ |^2\right)^{\frac{1}{2}}\right\|_{L^p} \leq C\,\|f\|_{H^{s+m,p}},$$

which, combined with (3.5), gives

$$\|q^1_\rho(x,D)f\|_{H^{s,p}}\ \leq\ C_1\ \|f\|_{H^{s+m,p}}. \tag{3.6}$$

So, the result holds for $q^1_\rho(x,D)$. Let us proceed with $q^2_\rho(x,D)$.
In this case,

$$\operatorname{supp}\left(\sum_{j=k-3}^{k+3} Q_{kj}\ f_k\right)\widehat{\ }$$

$$\subset\ \{\xi; 2^{k-1}(1+|\rho|^2)^{1/2} \leq |\xi| \leq 2^{k+1}(1+|\rho|^2)^{1/2}\} + \{\xi; 2^{k-4} \leq |\xi| \leq 2^{k+4}\}$$

$$\subset \{\xi; 2^{k-1}(1+|\rho|^2)^{1/2} \leq |\xi| \leq 2^{k+1}(1+|\rho|^2)^{1/2}\} + \{\xi; |\xi| \leq 2^{k+4}(1+|\rho|^2)^{1/2}\}$$

$$\subset \{|\xi| \leq A\ 2^k(1+|\rho|^2)^{1/2}\}.$$

By Lemma 3.3,

$$\|q_\rho^2(x,D)f\|_{H^{s,p}} \;\le\; C\;(1+|\rho|^2)^{s/2}\;\left\|\left\{\sum_{k=0}^{\infty}\;4^{ks}\left|\sum_{j=k-3}^{k+3}\;Q_{kj}\;f_k\;\right|^2\right\}^{\frac12}\;\right\|_{L^p}.$$

Therefore, by (3.4), $|\sum_{j=k-3}^{k+3}\;Q_{kj}|\;\le\;C\;2^{km}\;((1+|\rho|^2)^{\frac12})^m$, and then we obtain

$$\|q_\rho^2(x,D)f\|_{H^{s,p}} \;\le\; C\;((1+|\rho|^2)^{1/2})^{s+m}\left\|\left\{\sum_{k=0}^{\infty}\;4^{k(s+m)}\;|f_k\;|^2\right\}^{\frac12}\;\right\|_{L^p}$$

$$\le\; C\;((1+|\rho|^2)^{1/2})^{s+m}\left\|\;|f_0|+\left(\sum_{k=1}^{\infty}\;4^{k(s+m)}\;|f_k\;|^2\right)^{\frac12}\;\right\|_{L^p}$$

$$\le\; C\;\left(((1+|\rho|^2)^{1/2})^{s+m}\|f_0\|_{L^p}+\left\|\left(\sum_{k=1}^{\infty}\;4^{k(s+m)}\;((1+|\rho|^2)^{1/2})^{s+m}|f_k\;|^2\right)^{\frac12}\;\right\|_{L^p}\right).$$

The estimate for q_ρ^2 follows if we notice that $\|f_0\|_{L^p}\le C\,\|f\|_{L^p}$ and that

$$\left\|\left(\sum_{k=1}^{\infty}\;4^{k(s+m)}\;((1+|\rho|^2)^{1/2})^{s+m}|f_k\;|^2\right)^{\frac12}\;\right\|_{L^p}\le C\,\|f\|_{H^{s+m,p}}.$$

Finally, we prove the result for $q_\rho^3(x,D)$.

$$supp\left(\sum_{k=0}^{j-4}\;Q_{kj}\;f_k\right)\widehat{\ }\subset\;\bigcup_{k=0}^{j-4}\;(\{\xi;2^{j-1}\le|\xi|\le 2^{j+1}\}$$

$$+\{\xi;2^{k-1}(1+|\rho|^2)^{1/2}\le|\xi|\le 2^{k+1}(1+|\rho|^2)^{1/2}\})$$

$$\subset\bigcup_{k=0}^{j-4}\;(\{\xi;|\xi|\le 2^{j+1}(1+|\rho|^2)^{1/2}\}+\{\xi;|\xi|\le 2^{k+1}(1+|\rho|^2)^{1/2}\})$$

$$\subset\{|\xi|\le A\;2^j(1+|\rho|^2)^{1/2}\}.$$

Applying once more Lemma 3.3 we obtain

$$\|q_\rho^3(x,D)f\|_{H^{s,p}} \;\le\; C\;(1+|\rho|^2)^{s/2}\;\left\|\left\{\sum_{j=4}^{\infty}\;4^{js}\;\left|\sum_{k=0}^{j-4}\;Q_{kj}\;f_k\;\right|^2\right\}^{\frac12}\;\right\|_{L^p}$$

$$\le\; C\;((1+|\rho|^2)^{1/2})^{s+m}\left\|\left(\sum_{j=4}^{\infty}\left|\sum_{k=0}^{j-4}\;2^{js}\;2^{-jr}\;2^{km}\;f_k\right|^2\right)^{1/2}\right\|_{L^p}$$

$$= C\ ((1+|\rho|^2)^{1/2})^{s+m} \left\| \left(\sum_{j=4}^{\infty} \left| \sum_{k=0}^{j-4} 2^{(k-j)(r-s)}\ 2^{k(s+m)}\ f_k \right|^2 \right)^{1/2} \right\|_{L^p},$$

where we used (3.4) and the fact that $2^{-kr} \leq C$. We now set

$$F_k = 2^{k(s+m)}|f_k|\ , \quad G_j = \sum_{k=0}^{j-4} 2^{(k-j)(r-s)}\ F_k.$$

Recalling that $0 < s < r$ we get, by using Young's inequality, that

$$\|q^3_\rho(x,D)f\|_{H^{s,p}} \ \leq\ C\ ((1+|\rho|^2)^{1/2})^{s+m} \left\| \left\{ \sum_{k=0}^{\infty} 4^{k(s+m)}\ |f_k\ |^2 \right\}^{\frac{1}{2}} \right\|_{L^p}$$

and we can now follow the steps from the previous case.

So, the theorem is proved by putting together the estimates for each one of the three pieces.

4. Constructing the solutions. Let us consider the equation

$$S_{\vec{C}}(\omega) = (\Delta + \vec{C}\cdot\nabla)\omega = f$$

with $\vec{C} \in C^{r+\epsilon}(\overline{\Omega})$, $\epsilon > 0$, and $r > 0$ to be determined.

Let $S_{\vec{C},\rho} = e^{-x\cdot\rho} S_{\vec{C}} e^{x\cdot\rho}$. Then

$$S_{\vec{C},\rho} = \Delta_\rho\omega\ +\ \vec{C}\cdot\nabla_\rho\omega = f, \tag{4.1}$$

where $\Delta_\rho = e^{-x\cdot\rho}\Delta e^{x\cdot\rho}$, $\nabla_\rho = e^{-x\cdot\rho}\nabla e^{x\cdot\rho}$, and $\rho \in \mathbb{C}^n$ with $\rho\cdot\rho = 0$.

In this section we prove the following proposition.

PROPOSITION 4.1. *Let $r = \frac{2}{3}$; then $S_{\vec{C},\rho}$ admits a bounded inverse $S^{-1}_{\vec{C},\rho} : L^2(\Omega) \longrightarrow H^1(\Omega)$. Moreover, if $f \in L^2(\Omega)$ and $\omega = S^{-1}_{\vec{C},\rho}(f)$ we have*

$$\|\omega\|_{L^2(\Omega)} \leq \frac{C}{|\rho|}\|f\|_{L^2(\Omega)}, \tag{4.2}$$

$$\|\omega\|_{H^1(\Omega)} \leq C\|f\|_{L^2(\Omega)}, \tag{4.3}$$

with C independent of ρ.

By the regularity assumed on $\vec{C}$ we get that $\vec{C}\cdot\nabla_\rho \in OPC^{r+\epsilon}S^1_{1,0,\rho}(\mathbb{R}^n)$.

Let us decompose $\vec{C}\cdot\nabla_\rho$ in two parts:

$$\vec{C}\cdot\nabla_\rho = N^\sharp_\rho(x,D)\ +\ N^b_\rho(x,D), \tag{4.4}$$

where

$$N^\sharp_\rho(x,D) \in OPS^1_{1,\delta,\rho}(\mathbb{R}^n)$$

and

$$N^b_\rho(x,D) \in OPC^{r+\epsilon-t}S^{1-t\delta}_{1,0,\rho}(\mathbb{R}^n)$$

for any $\delta \in (0,1)$, and $r < t < r+\epsilon$.

Now take $t = r + \frac{\epsilon}{2}$ and $t\delta > r$. Then we get that

$$N_\rho^b(x,D) \in OPC^{\frac{\epsilon}{2}} S^\eta_{1,0,\rho}(\mathbb{R}^n) \tag{4.5}$$

with $\eta = 1 - t\delta$.

So, in order to find solutions of (4.1), it would be enough to find solutions of

$$(\Delta_\rho \ + \ N_\rho^\sharp(x,D))\omega = f \tag{4.6}$$

and to use Theorem 3.1.

To solve (4.6) we make use of the following result due to Nakamura and Uhlmann.

LEMMA 4.2. *Let $N \in \mathbb{N}$. There exist operators $A_\rho(x,D)$ and $B_\rho(x,D)$ properly supported and belonging to $OPS^0_{1,\delta,\rho}(\mathbb{R}^n)$ such that for any $\phi_1 \in C_0^\infty(\mathbb{R}^n)$ there exist $\phi_2, \phi_3 \in C_0^\infty(\mathbb{R}^n)$, and $M > 0$ so that*

$$\phi_1(\Delta_\rho \ + \ N_\rho^\sharp(x,D))A_\rho(x,D)v = \phi_1 B_\rho(x,D)\ (\Delta_\rho + \phi_2 R_\rho^{-N(1-\delta)}(x,D)\phi_3)v, \tag{4.7}$$

where

$$\phi_2 R_\rho^{-N(1-\delta)}(x,D)\phi_3 : H^\alpha(\mathbb{R}^n) \longrightarrow H^\alpha(\mathbb{R}^n)$$

is a bounded linear operator with

$$\|\phi_2 R_\rho^{-N(1-\delta)}(x,D)\phi_3\|_{H^\alpha(\mathbb{R}^n), H^\alpha(\mathbb{R}^n)} \ \leq \ C\ ((1+|\rho|^2)^{1/2})^{-N(1-\delta)}$$

for $\rho \in Z, |\rho| \geq M$, and any $\alpha \in \mathbb{R}$. The functions ϕ_1, ϕ_2, ϕ_3 are taken to satisfy

$$\phi_1\phi_2 = \phi_1, \qquad \phi_1\phi_3 = \phi_1,$$

and

$$\phi_1 B_\rho(x,D)\phi_2 = \phi_1 B_\rho(x,D).$$

It is clear that we can assume that ϕ_1, ϕ_2, ϕ_3 also satisfy

$$\phi_1 N_\rho^b(x,D) = \phi_1 N_\rho^b(x,D)\phi_2, \qquad \phi_2 A_\rho(x,D)\phi_3 = \phi_2 A_\rho(x,D).$$

In terms of (4.1) we see that we would get

$$\begin{aligned} &\phi_1(S_{\vec{C},\rho})A_\rho(x,D)v \\ &= \phi_1 B_\rho(x,D)\ (\Delta_\rho + \phi_2 R_\rho^{-N(1-\delta)}(x,D)\phi_3)v + \phi_1 N_\rho^b(x,D)\phi_2 A_\rho(x,D)\phi_3 v. \end{aligned} \tag{4.8}$$

So, for any $f \in L^2(\mathbb{R}^n)$ it is enough to solve

$$\phi_1(B_\rho(x,D)\ (\Delta_\rho + \phi_2 R_\rho^{-N(1-\delta)}(x,D)\phi_3) + \phi_1 N_\rho^b(x,D)\phi_2 A_\rho(x,D)\phi_3)v \ = \ f \tag{4.9}$$

or, which is the same,

$$\begin{aligned} (\Delta_\rho + \phi_2 R_\rho^{-N(1-\delta)}(x,D)\phi_3 + \phi_1'(B_\rho(x,D))^{-1}\phi_1 N_\rho^b(x,D)\phi_2 A_\rho(x,D)\phi_3)v \\ = \ \phi_1'(B_\rho(x,D))^{-1}\phi_1(f). \end{aligned} \tag{4.10}$$

If we call

$$T_\rho = \phi_2 R_\rho^{-N(1-\delta)}(x,D)\phi_3 + \phi_1'(B_\rho(x,D))^{-1}\phi_1 N_\rho^b(x,D)\phi_2 A_\rho(x,D)\phi_3$$

we see that we need to study mapping properties for T_ρ. By Theorem (3.1) we know that

$$N^b_\rho(x,D) : H^{\eta+\frac{\epsilon}{2}\gamma}(\mathbb{R}^n) \longrightarrow H^{\frac{\epsilon}{2}\gamma}(\mathbb{R}^n) \tag{4.11}$$

with

$$\|N^b_\rho(x,D)\|_{H^{\eta+\frac{\epsilon}{2}\gamma}(\mathbb{R}^n),H^{\frac{\epsilon}{2}\gamma}(\mathbb{R}^n)} \leq C\ ((1+|\rho|^2)^{1/2})^{\eta+\frac{\epsilon}{2}\gamma} \tag{4.12}$$

for any $\gamma \in (0,1)$.

By [S, Theorem (9.1)] we know that

$$\phi_2 A_\rho(x,D)\phi_3 : H^{\eta+\frac{\epsilon}{2}\gamma}(\mathbb{R}^n) \longrightarrow H^{\eta+\frac{\epsilon}{2}\gamma}(\mathbb{R}^n)$$

with

$$\|\phi_2 A_\rho(x,D)\phi_3\|_{H^{\eta+\frac{\epsilon}{2}\gamma}(\mathbb{R}^n),H^{\eta+\frac{\epsilon}{2}\gamma}(\mathbb{R}^n)} \ \leq\ C\ ((1+|\rho|^2)^{1/2})^{\eta+\frac{\epsilon}{2}\gamma}$$

and that

$$\phi_1'(B_\rho(x,D))^{-1}\phi_1 : H^{\frac{\epsilon}{2}\gamma}(\mathbb{R}^n) \longrightarrow L^2(\mathbb{R}^n)$$

with

$$\|\phi_1'(B_\rho(x,D))^{-1}\phi_1\|_{H^{\frac{\epsilon}{2}\gamma}(\mathbb{R}^n),L^2(\mathbb{R}^n)} \ \leq\ C.$$

Putting all this together we obtain the following lemma.

LEMMA. *$T_\rho|_K : H^{\eta+\frac{\epsilon}{2}\gamma}(K) \longrightarrow L^2(K)$ for any compact set $K \supset \Omega$ and we have*

$$\|T_\rho|_K\|_{H^{\eta+\frac{\epsilon}{2}\gamma}(K),L^2(K)} \ \leq\ C\ ((1+|\rho|^2)^{\frac{1}{2}})^{2\eta+\epsilon\gamma} \tag{4.13}$$

with $\gamma \in (0,1)$ and C depending only on Ω.

We now compose $T_\rho|_\Omega$ with Δ_ρ^{-1} and make use of the fact that $\Delta_\rho^{-1} : L^2(\Omega) \longrightarrow H^s(\Omega)$ with

$$\|\Delta_\rho^{-1}\|_{L^2(\Omega),H^s(\Omega)} \ \leq\ \frac{C}{((1+|\rho|^2)^{\frac{1}{2}})^{1-s}} \tag{4.14}$$

for $s \in [0,1]$ and C depending only on Ω. We therefore get $T_\rho|_\Omega \ \circ\ \Delta_\rho^{-1} : L^2(\Omega) \longrightarrow L^2(\Omega)$ with

$$\|T_\rho|_\Omega \ \circ\ \Delta_\rho^{-1}\|_{L^2(\Omega),L^2(\Omega)} \ \leq\ C\ \frac{1}{((1+|\rho|^2)^{\frac{1}{2}})^{1-3\eta-2\epsilon\gamma}}. \tag{4.15}$$

So we see that, in order for this last expression to decay for $|\rho|$ big enough we need $\eta\ <\ \frac{1}{3}$. If we recall that $\eta = 1 - t\delta$ and that $t\delta > r$ we arrive at the conclusion that r must be at least $\frac{2}{3}$.

Then we can solve (4.10) on Ω with the following estimates:

$$\|\psi_1 v\|_{L^2(\mathbb{R}^n)} \ \leq\ \frac{C}{|\rho|}\ \|\tilde{f}\|_{L^2(\mathbb{R}^n)}, \tag{4.16}$$

where $\psi_1 \in C_0^\infty(\mathbb{R}^n)$ is taken so that

$$\phi_1(S_{\vec{C},\rho})A_\rho(x,D)\psi_1 = \phi_1(S_{\vec{C},\rho})A_\rho(x,D)$$

and

$$\tilde{f} = \begin{cases} f & \text{in } \Omega, \\ 0 & \text{in } \mathbb{R}^n \backslash \Omega. \end{cases} \tag{4.17}$$

So by now taking $\psi_2 \in C_0^\infty(\mathbb{R}^n)$ so that $\psi_2 \equiv 1$ on Ω and calling $\omega = \psi_2 A_\rho(x, D)\psi_1\, v$ we obtain, from (4.10), (4.16), and [S, Theorem 9.1],

$$S_{\vec{C},\rho}\, \omega \;=\; f \qquad \text{in} \quad \Omega. \tag{4.18}$$

For the estimate involving derivatives we are going to use the following standard interior estimate which we state without proof.

LEMMA 4.3. *Let $\omega \in H^1(\Omega)$ a solution of*

$$\Delta\omega \;=\; -F \qquad \textit{in} \;\; \Omega';$$

then

$$\|\omega\|_{H^1(\Omega)} \;\leq\; C\, \left(\|F\|_{H^{-1}(\Omega')} \;+\; \|\omega\|_{L^2(\Omega')}\right), \tag{4.19}$$

provided $\Omega \subset\subset \Omega'$.

Proof of (4.3). Without loss of generality we can assume that (4.18) holds in a slightly bigger domain Ω' and assume further that $\vec{C}$ is defined in Ω'. From the lemma we obtain

$$\|\omega\|_{H^1(\Omega)} \;\leq\; C\, (\| - 2\rho \cdot\; \nabla\omega - \vec{C}\cdot(\nabla + \rho)\omega + f\|_{H^{-1}(\Omega')} + \|\omega\|_{L^2(\Omega')}). \tag{4.20}$$

So the inequality follows by the fact that $\|\nabla\omega\|_{H^{-1}(\Omega')} \leq C\, \|\omega\|_{L^2(\Omega')}$ and by using (4.2) with Ω replaced by Ω' and f replaced by $\tilde{f}|_{\Omega'}$ (notice that $\|f\|_{L^2(\Omega)} = \|\tilde{f}\|_{L^2(\Omega')}$).

5. Application to the Schrödinger equation in a magnetic field. The purpose of this section is to apply the solutions we constructed to an inverse boundary value problem for the Schrödinger equation in the presence of a magnetic field.

Let Ω be a bounded domain in $\mathbb{R}^n, n \geq 3$, with smooth boundary. The equation we are going to study is given by

$$H_{\vec{C},q} = \sum_{j=1}^{n} \left(-i\frac{\partial}{\partial x_j} + C_j(x)\right)^2 + q(x), \tag{5.1}$$

where $\vec{C} = (C_1, ..., C_n) \in C^1(\overline{\Omega})$ is the magnetic potential and the scalar function $q \in L^\infty(\Omega)$ is the electric potential. We assume both to be real valued.

We assume further that zero is not a Dirichlet eigenvalue of (5.1) on Ω. Then the boundary value problem

$$\begin{cases} H_{\vec{C},q} u = 0 & \text{in } \Omega, \\ u|_{\partial\Omega} = f \;\in H^{1/2}(\partial\Omega) \end{cases} \tag{5.2}$$

has a unique solution $u \in H^1(\Omega)$. The usual computations give that the Dirichlet-to-Neumann map in this case is given by

$$\Lambda_{\vec{C},q} : f \longrightarrow \frac{\partial u}{\partial \nu} + i(\vec{C}\cdot\nu)f\;, \qquad f \;\in H^{1/2}(\partial\Omega), \tag{5.3}$$

where u is the unique solution to (5.2) and ν is the outer normal to $\partial\Omega$.

The question here is under what assumptions we can recover $\vec{C}$ and q.

It is well known that two magnetic potentials $\vec{C}$ and $\vec{C}+\nabla g$, where

$$g \in C^1_\Omega = \{f \in C^1(\mathbb{R}^n) : \operatorname{supp} f \subset \Omega\}, \tag{5.4}$$

produce the same Dirichlet-to-Neumann map [Su]. As $rot(\vec{C}) = rot(\vec{C}+\nabla g)$ it is natural to ask whether $rot(\vec{C})$ and q can be uniquely determined by $\Lambda_{\vec{C},q}$. Z. Sun [Su] proved that this is actually true in the case that the magnetic potential $\vec{C}$ belongs to C^2_Ω and the electric potential q is a bounded function on Ω provided $rot(\vec{C})$ is small in $L^\infty(\Omega)$. He proved the following theorem.

THEOREM 5.1 (Su). *Let $\vec{C}_j \in C^2_\Omega$ (see (1.4)), $q_j \in L^\infty(\Omega)$, $j=1,2$. Assume that zero is not a Dirichlet eigenvalue for $H_{\vec{C}_j,q_j}$, $j=1,2$. Then there exists a constant $\epsilon = \epsilon(\Omega) > 0$ such that if $\|rot(\vec{C}_j)\|_{L^\infty(\Omega)} \leq \epsilon$, $j=1,2$, and*

$$\Lambda_{\vec{C}_1,q_1} = \Lambda_{\vec{C}_2,q_2},$$

then

$$rot(\vec{C}_1) = rot(\vec{C}_2) \quad and \quad q_1 = q_2 \quad in \quad \Omega.$$

The restriction on $rot(\vec{C})$ was removed in the case that $\vec{C}$ is in the C^∞ class by Nakamura, Sun, and Uhlmann [N-Su-U]. They proved the following theorem.

THEOREM 5.2 (see [N-Su-U]). *Let $\vec{C}_j \in C^\infty_\Omega$ (see (1.4)), $q_j \in L^\infty(\Omega)$, $j=1,2$. Assume that zero is not a Dirichlet eigenvalue for $H_{\vec{C}_j,q_j}$, $j=1,2$. If*

$$\Lambda_{\vec{C}_1,q_1} = \Lambda_{\vec{C}_2,q_2}$$

then

$$rot(\vec{C}_1) = rot(\vec{C}_2) \quad and \quad q_1 = q_2 \quad in \quad \Omega.$$

Using the solution we have constructed already we are able to prove Sun's theorem without the restriction on $rot(\vec{C})$.

As we said before, recovering $rot(\vec{C})$ is the most we can expect from the Dirichlet-to-Neumann map. Therefore, this result appears to be optimal.

Remark. We could follow [Su] up to the point in which we use the solutions constructed in the previous section. However, by doing so we would get a weaker result; namely, we would end up needing $\vec{C}_j \in C^2_\Omega, i=1,2$. We sketch how to remove the condition on $rot(\vec{C}_j), j=1,2$ following Sun's proof.

Let us look for solutions of $H_{\vec{C},q}$ of the form

$$u(x,\rho) = e^{x\cdot\rho+\phi(x,\rho)}(1+\omega(x,\rho)), \tag{5.5}$$

where $\rho \in \mathbb{C}^n$ is a complex vector satisfying $\rho\cdot\rho = 0$ and $\omega(x,\rho)$ has decay properties that we will state. By plugging into the equation $H_{\vec{C},q}u(x,\rho) = 0$ we get the following couple of equations:

$$\rho\cdot\nabla\phi = -i\rho\cdot\vec{C}, \tag{5.6}$$

$$\Delta\omega + 2(\rho+\nabla\phi+i\vec{C})\cdot\nabla\omega - g\omega = g, \tag{5.7}$$

where

$$g = \vec{C}^2 - i\nabla \cdot \vec{C} + q - 2i\vec{C} \cdot \nabla\phi - \nabla\phi \cdot \nabla\phi - \Delta\phi. \tag{5.8}$$

We use (2.6) in [Su] to solve (5.6). We get that $\phi \in C^2(\overline{\Omega})$ and

$$\|\phi\left(\cdot, \frac{\rho}{|\rho|}\right)\|_{C^2(\overline{\Omega})} \leq C \|\vec{C}\|_{C^2_\Omega}. \tag{5.9}$$

From (5.8) and (5.9) it is clear that $\vec{C}_j \in C^2_\Omega, i = 1, 2$ cannot be lowered. We will come to this later. We can rewrite (5.7) as

$$\Delta_\rho \omega + \vec{D} \cdot \nabla\omega - h\omega = h, \tag{5.10}$$

where

$$\Delta_\rho = \Delta + 2\rho \cdot \nabla, \quad \vec{D} = 2(\nabla\phi + i\vec{C})\psi, \quad h = g\psi \tag{5.11}$$

and $\psi \in C_0^\infty(\mathbb{R}^n)$ with $\psi|_\Omega \equiv 1$.

By (5.9) and the regularity assumed on $\vec{C}$ we see that $\nabla\phi \in C^1(\overline{\Omega})$ and then $\vec{D} \in C^1(\overline{\Omega})$. By the results from the previous section we know that for any $f \in L^2(\Omega)$ we can find $w \in H^1(\Omega)$ so that

$$(\Delta_\rho + \vec{D} \cdot \nabla)w = f \quad \text{in } \Omega.$$

Moreover,

$$\|w\|_{L^2(\Omega)} \leq \frac{C}{|\rho|} \|f\|_{L^2(\Omega)}, \tag{5.12}$$

$$\|w\|_{H^1(\Omega)} \leq C \|f\|_{L^2(\Omega)}. \tag{5.13}$$

Therefore, it would not take much effort to prove Sun's theorem without the smallness condition. However, it pays off to take a slightly different path. By doing this we will be able to remove the smallness condition and also to sharpen the requirement on the regularity of the magnetic potential. We rewrite the Schrödinger equation as

$$H_{\vec{C},q} = -\Delta - 2\vec{C}(x) \cdot \nabla + G(x), \tag{5.14}$$

where $G = \vec{C}^2 - 2i\nabla \cdot \vec{C} + q$.

If we look for solutions of the form $e^{x\cdot\rho}(1 + \omega(x, \rho))$, we get

$$H_{\vec{C},q,\rho}\omega = (\Delta_\rho + 2\vec{C} \cdot \nabla_\rho + G(x))\omega = -G(x).$$

In the previous section we proved that $\Delta_\rho + 2\vec{C} \cdot \nabla_\rho$ is invertible as a map from $H^1(\Omega) \longrightarrow L^2(\Omega)$ and satisfies the usual estimates. We now prove that the same is true for $\Delta_\rho + 2\vec{C} \cdot \nabla_\rho + G(x)$.

LEMMA 5.3. *$H_{\vec{C},q,\rho}$ admits a bounded inverse $H^{-1}_{\vec{C},q,\rho} : L^2(\Omega) \longrightarrow H^1(\Omega)$. Moreover, if $g \in L^\infty(\Omega)$ we have*

$$\|H^{-1}_{\vec{C},q,\rho}(g)\|_{L^2(\Omega)} \leq \frac{C}{|\rho|}\|g\|_{L^2(\Omega)},$$

$$\|H^{-1}_{\vec{C},q,\rho}(g)\|_{H^1(\Omega)} \leq C\|g\|_{L^2(\Omega)},$$

with C independent of ρ.

Proof. Applying $(\Delta_\rho + 2\vec{C}\cdot\nabla_\rho)^{-1}$ to both sides, we get

$$(I+T)\omega = -(\Delta_\rho + 2\vec{C}\cdot\nabla_\rho)^{-1}(G), \tag{5.15}$$

where $T = (\Delta_\rho + 2\vec{C}\cdot\nabla_\rho)^{-1}\circ(G)$. By the regularity assumed on $\vec{C}$, $G \in L^\infty(\Omega)$ and then we obtain that $T : L^2(\Omega) \longrightarrow L^2(\Omega)$ with

$$\|T\|_{L^2(\Omega),L^2(\Omega)} \leq \frac{C}{|\rho|}\|G\|_{L^\infty}.$$

Therefore (5.15) has a unique solution provided $|\rho|$ is big enough. So the first estimate follows from $\|(\Delta_\rho+2\vec{C}\cdot\nabla_\rho)^{-1}(G)\|_{L^2(\Omega)} \leq \frac{C}{|\rho|}\|G\|_{L^2(\Omega)}$. We can now get the remaining estimate by writing

$$\omega = (\Delta_\rho + 2\vec{C}\cdot\nabla_\rho)^{-1}(G(1+\omega)).$$

We now turn to analyzing the behavior of the operator A_ρ when $|\rho| \longrightarrow \infty$.

LEMMA 5.4. *Let ϕ solve (5.6) and $\rho = s\rho_0$, with $s \in \mathbb{R}$ and $|\rho_0| = 1$. Then if $f \in C_0^\infty(\mathbb{R}^n)$ we have that*

$$\lim_{s\to\infty} A_\rho(x,D)f(x) = e^{\phi(x,\frac{\rho}{|\rho|})}f(x) \tag{5.16}$$

uniformly on compact sets.

Proof. Let us fix a compact set $K \subset \mathbb{R}^n$. By developing $a_\rho(x,\xi)$ (the full symbol of $A_\rho(x,D)$) in Taylor series in ξ we get:

$$a_\rho(x,\xi) = a_\rho(x,0) + \sum_{i=1}^n \xi_i \frac{\partial}{\partial\xi_i}a_\rho(x,0) + R_\rho(x,\xi,0), \tag{5.17}$$

where

$$R_\rho(x,\xi,0) = \sum_{i,j=1}^n \int_0^1 (1-t)\xi_i\xi_j \frac{\partial^2}{\partial\xi_i\partial\xi_j}a_\rho(x,t\xi)dt. \tag{5.18}$$

Now apply the operator given by (5.17) to $f \in C_0^\infty(\mathbb{R}^n)$. We need to prove that

$$\sum_{i=1}^n \frac{\partial}{\partial\xi_i}a_\rho(x,0)D_{x_i}(f) \quad\text{and}\quad \sum_{i,j=1}^n \int e^{ix\cdot\xi}\left(\int_0^1 (1-t)\frac{\partial^2}{\partial\xi_i\partial\xi_j}a_\rho(x,t\xi)dt\right)\xi_i\xi_j\hat{f}(\xi)d\xi$$

tend to 0 uniformly on K as $s\to\infty$. By the estimates on $a_\rho(x,\xi)$ it is easy to see this for the first term. For the second one we use

$$\left|\frac{\partial^2}{\partial\xi_i\partial\xi_j}a_\rho(x,t\xi)\right| \;\leq\; \frac{C_K}{1+|t\xi|^2+|\rho|^2} \;\leq\; \frac{C_K}{1+|\rho|^2},$$

which is valid for any $x \in K$. This proves that $|A_\rho(x,D)f(x) - a_\rho(x,0)f(x)| \longrightarrow 0$ as $s\to\infty$ uniformly on K.

Now, $a_\rho(x,0)$ solves the following equation:

$$\rho\cdot\nabla log(a_\rho(x,0)) = -iJ_{\epsilon_\rho^0}(\vec{C}(x)\cdot\rho).$$

Solving it we get

$$log(a_\rho(x,0)) = \frac{1}{(2\pi)^n}\int e^{-ix\eta}\frac{\rho\cdot\theta(\epsilon_\rho^0\eta)\vec{C}(\eta)}{\rho\cdot\eta}d\eta$$

or

$$log(a_\rho(x,0)) = \frac{1}{(2\pi)^n}\int e^{-ix\eta}\frac{\frac{\rho}{|\rho|}\cdot\theta(\epsilon_\rho^0\eta)\vec{C}(\eta)}{\frac{\rho}{|\rho|}\cdot\eta}d\eta.$$

As $s\to\infty, \epsilon_\rho^0\to 0$, so the last expression approaches

$$\frac{1}{(2\pi)^n}\int e^{-ix\eta}\frac{\frac{\rho}{|\rho|}\cdot\vec{C}(\eta)}{\frac{\rho}{|\rho|}\cdot\eta}d\eta$$

as $s\to\infty$ uniformly on compact sets which says that $\lim_{s\to\infty} log(a_\rho(x,0))$ satisfies (5.6).

We recall, without proof, the following identity proved in [S].

PROPOSITION 5.5. *Let $\vec{C}_j\in C^1_\Omega, q_j\in L^\infty(\overline{\Omega}),\ j=1,2$. Then*

$$i\int_\Omega(\vec{C}_1-\vec{C}_2)\cdot(u_1\nabla\overline{u_2}-\overline{u_2}\nabla u_1)dx+\int_\Omega(\vec{C}_1^2-\vec{C}_2^2+q_1-q_2)u_1\overline{u_2}dx$$

$$=-\int_{\partial\Omega}\overline{u_2}(\Lambda_{\vec{C}_1,q_1}-\Lambda_{\vec{C}_2,q_2})u_1ds$$

holds for the arbitrary u_j solution of $H_{\vec{C}_j,q_j}u_j=0, j=1,2$.

COROLLARY 5.6. *Assume the conditions from the previous proposition. If $\Lambda_{\vec{C}_1,q_1}=\Lambda_{\vec{C}_2,q_2}$ then*

$$i\int_\Omega(\vec{C}_1-\vec{C}_2)\cdot(u_1\nabla\overline{u_2}-\overline{u_2}\nabla u_1)dx+\int_\Omega(\vec{C}_1^2-\vec{C}_2^2+q_1-q_2)u_1\overline{u_2}dx=0 \tag{5.19}$$

holds for the arbitrary u_j solution of $H_{\vec{C}_j,q_j}u_j=0, j=1,2$.

Proof of Theorem 1.1. Let k,γ_1,γ_2 be three mutually orthogonal vectors $\in\mathbb{R}^n$ with $|\gamma_1|=|\gamma_2|=1$. Let $\zeta,\rho\in\mathbb{C}^n$ be given by

$$\zeta=\gamma_1+i\gamma_2,\qquad \rho=s\zeta+g(s,k)\gamma_1, \tag{5.20}$$

where s is a positive real parameter and

$$g(s,k)=2^{-1}|k|^2((|k|^2+4s^2)^{1/2}+4s)^{-1}. \tag{5.21}$$

Let $\rho_1,\rho_2\in\mathbb{C}^n$ be given by

$$\rho_1=i\frac{k}{2}+\rho,\qquad \overline{\rho_2}=i\frac{k}{2}-\rho. \tag{5.22}$$

We have

$$\rho_1\cdot\rho_1=\rho_2\cdot\rho_2=0,\qquad \rho_1+\overline{\rho_2}=ik,\qquad \rho_1-\overline{\rho_2}=2\rho, \tag{5.23}$$

$$\frac{\rho_1}{s} \to \zeta, \qquad \frac{\overline{\rho_2}}{s} \to -\zeta, \qquad \text{as } \ s \to \infty. \tag{5.24}$$

Let us construct solutions:

$$u_j(x,\rho_j) = e^{x\cdot\rho_j}\psi_2(x)A_{\rho_j}(x,D)\psi_1(x)(1+\omega_j(x,\rho_j)) \tag{5.25}$$

which is the solution of $H_{\vec{C}_j,q_j}u_j = 0, j = 1,2$ in Ω, $\psi_1,\psi_2 \in C_0^\infty(\mathbb{R}^n), \psi_j = 1$ in $\Omega, j = 1,2$, and $\omega_j, j = 1,2$ satisfying

$$\|\omega_j\|_{L^2(\Omega)} \leq \frac{C}{|\rho|} \quad \text{and} \qquad \|\nabla\omega_j\|_{H^1(\Omega)} \leq C \tag{5.26}$$

with C depending only on Ω, $\|\vec{C}_j\|_{C^1(\Omega)}$ and $\|q_j\|_{L^\infty(\Omega)}, j = 1,2$.

We now plug (5.25) into (5.19) to obtain

$$F + G + H + I + J + K + L = 0, \tag{5.27}$$

where F and G are functions of s, k, γ_1, γ_2, and they are defined by

$$F = -2i\int_\Omega e^{ix\cdot k}\rho\cdot(\vec{C}_1 - \vec{C}_2)A_{\rho_1}(x,D)(\psi_1)\overline{A_{\rho_2}(x,D)(\psi_1)}dx, \tag{5.28}$$

$$G = i\int_\Omega e^{ix\cdot k}A_{\rho_1}(x,D)(\psi_1)\overline{(\nabla(A_{\rho_2}(x,D)(\psi_1)) + \nabla(A_{\rho_2}(x,D)(\psi_1\omega_2)))}dx, \tag{5.29}$$

$$H = i\int_\Omega e^{ix\cdot k}A_{\rho_1}(x,D)(\psi_1\omega_1)\overline{(\nabla(A_{\rho_2}(x,D)(\psi_1)) + \nabla(A_{\rho_2}(x,D)(\psi_1\omega_2)))}dx, \tag{5.30}$$

$$I = -i\int_\Omega e^{ix\cdot k}\nabla(A_{\rho_1}(x,D)(\psi_1))\overline{(A_{\rho_2}(x,D)(\psi_1) + A_{\rho_2}(x,D)(\psi_1\omega_2))}dx, \tag{5.31}$$

$$J = -i\int_\Omega e^{ix\cdot k}\nabla(A_{\rho_1}(x,D)(\psi_1\omega_1))\overline{(A_{\rho_2}(x,D)(\psi_1) + A_{\rho_2}(x,D)(\psi_1\omega_2))}dx, \tag{5.32}$$

$$\begin{aligned} K = \int_\Omega e^{ix\cdot k}(&\vec{C_1}^{\,2} - \vec{C_2}^{\,2} \\ &+q_1 - q_2)A_{\rho_1}(x,D)(\psi_1)\overline{(A_{\rho_2}(x,D)(\psi_1) + A_{\rho_2}(x,D)(\psi_1\omega_2))}dx, \end{aligned} \tag{5.33}$$

$$\begin{aligned} L = \int_\Omega e^{ix\cdot k}(&\vec{C_1}^{\,2} - \vec{C_2}^{\,2} \\ &+q_1 - q_2)A_{\rho_1}(x,D)(\psi_1\omega_1)\overline{(A_{\rho_2}(x,D)(\psi_1) + A_{\rho_2}(x,D)(\psi_1\omega_2))}dx. \end{aligned} \tag{5.34}$$

We now apply (5.26) and Lemma (5.4) to get

$$\lim_{s\to\infty}\frac{G}{s} = \lim_{s\to\infty}\frac{H}{s} = \lim_{s\to\infty}\frac{I}{s} = \lim_{s\to\infty}\frac{J}{s} = 0 \lim_{s\to\infty}\frac{K}{s} = 0 \lim_{s\to\infty}\frac{L}{s} = 0 \tag{5.35}$$

and then

$$\lim_{s\to\infty}\frac{F}{s} = -2i\int_\Omega e^{ix\cdot k+\phi_1+\overline{\phi_2}}\zeta\cdot(\vec{C_1} - \vec{C_2})dx = 0, \tag{5.36}$$

where ϕ_j solves $\zeta\cdot\nabla\phi_1 = -i\zeta\cdot\vec{C}_1$ and $\zeta\cdot\nabla\overline{\phi_2} = i\zeta\cdot\vec{C}_2$.

(5.36) is all we need to end the proof of the theorem. The proof is finished following Sun's arguments. We refer to [Su] for details.

LOCAL AVERAGE LIAPUNOV FUNCTIONS AND PERSISTENCE IN POPULATION DYNAMICS*

W. H. RUAN†

Abstract. This paper is concerned with the problem of uniform persistence in population dynamics. We consider systems of reaction–diffusion equations which model ecosystems in bounded habitats with diffusion. It is shown that a system is persistent if every chain-recurrent set in the boundary of the positive cone does not attract trajectories from the interior of the positive cone, and this property can be determined by using localized average Liapunov functions. Some results on constructing local average Liapunov functions are given. A system describing a food chain model is discussed as an example.

Key words. population dynamics, average Liapunov functions, persistence

1. Introduction.

This paper is concerned with the uniform persistence of dynamical systems defined by systems of nonlinear partial differential equations of parabolic type. We consider the following initial-boundary value problem:

$$\begin{aligned} &\partial u_i/\partial t - L_i u_i = u_i f_i(u), && (x \in \Omega,\ t > 0), \\ &B_i u_i = 0, && (x \in \partial\Omega,\ t > 0), \quad (i = 1, \dots, N), \\ &u_i(x, 0) = u_i^0(x), && (x \in \Omega), \end{aligned} \tag{1.1}$$

where $\Omega \subset \mathbb{R}^n$ is a bounded domain with a smooth boundary $\partial\Omega$; $u = (u_1, \dots, u_N)$ is a vector function with each component nonnegative; L_i is a uniformly strongly elliptic operator having the divergence form

$$L_i u = \sum_{i,j=1}^{n} (a_{ij}(x) u_{x_i})_{x_j} + \sum_{i=1}^{n} b_i(x) u_{x_i}; \tag{1.2}$$

B_i is a boundary operator such that

$$B_i u(x) = \delta_i \frac{\partial u(x)}{\partial \nu(x)} + \beta_i(x) u, \tag{1.3}$$

where δ_i is either 0 (Dirichlet condition) or 1 (Neumann or Robin condition); β_i is a nonnegative function which is the constant 1 if $\delta = 0$; $\nu(x) = (\nu_1, \dots, \nu_n)$ is the outward conormal vector at $x \in \partial\Omega$ with

$$\nu_i = \sum_{j=1}^{n} a_{ij}(x) \zeta_j, \qquad i = 1, \dots, n;$$

and $\zeta = (\zeta_1, \dots, \zeta_n)$ is the outward normal vector at $x \in \partial\Omega$. It is assumed that $a_{ij},\ b_i \in C^1(\overline{\Omega})$, $\beta_i \in C^{1+\alpha}(\partial\Omega)$, $u_i^0 \in C(\overline{\Omega})$, $f_i \in C^1(\mathbb{R}^+)$, and $\partial\Omega \in C^{1+\alpha}$, where

$\alpha > 0$ is a constant. Such a system often arises in the study of population dynamics of ecological systems. Typically, Ω represents the habitat of several interacting species, u_i represents the density of the ith species (usually after scaling), f_i describes the effect of interaction among species on the growth rate of the ith species, and L_i and B_i account for diffusion and migration of the ith species in the interior and on the boundary of the habitat, respectively.

An important problem in ecology is to determine conditions under which all species survive in the long term. In mathematical language, it is the problem of persistence of the dynamical system. Let X_i be a Banach space such that $X_i = C_0(\Omega)$ if B_i is the Dirichlet condition and

$$X_i = \{u \in C^1(\overline{\Omega}) : \ B_i u = 0\}$$

if B_i is Neumann or Robin condition, and let X be the positive cone of the product space $\prod_{i=1}^N X_i$, i.e.,

$$X = \left\{ u \in \prod_{i=1}^N X_i : \ u_i \geq 0 \quad \text{for } i = 1, \ldots, N \right\}.$$

It is a consequence of the maximum principle that X is forwardly invariant for the semiflow π generated by system (1.1); that is, given any $\xi \in X$, the solution $u(\cdot, t)$ of (1.1) with $u^0 = \xi$ lies in X for all $t > 0$. Furthermore, by the uniqueness of solution, each face $S_i \equiv \{u \in X : u_i \equiv 0\}$ of the boundary of X is also forwardly invariant for the semiflow, and so is the total face $S \equiv \bigcup_{i=1}^N S_i$. The system (1.1), or equivalently the semiflow π, is called *persistent* if for all $\xi \in X \setminus S$, $\liminf_{t\to\infty} d(\xi\pi t, S) > 0$, and it is called *uniformly persistent* if there exists $\epsilon_0 > 0$ such that for all $\xi \in X \setminus S$, $\liminf_{t\to\infty} d(\xi\pi t, S) \geq \epsilon_0$ (cf. [4]). Here, $d(\cdot, \cdot)$ is the distance function in X defined by the norm, and $\xi\pi t$ is the solution $u(\cdot, t)$ of problem (1.1) with $u^0 = \xi$. In the case where the system is compact and point dissipative (the latter means there is a bounded nonempty set $B \subset X$ such that for any $\xi \in X$ there exists a $t_0 > 0$ such that $\xi\pi t \in B$ for all $t \geq t_0$), a result of Hale and Waltman [11] shows that persistence is equivalent to uniform persistent. This is true for many reaction–diffusion systems modeling ecosystems, and hence in this paper, we only discuss conditions for systems to be persistent.

The study of persistence of dynamical systems has attracted a considerable amount of attention in recent years (cf., e.g., [3, 4, 5, 6, 7, 9, 11, 13, 14, 17] and references therein). There are a number of important directions. One is to analyze the behavior of invariant sets on the boundary S and determine conditions for the maximal invariant set $I(S)$ in S to be repellent to trajectories in $X \setminus S$. Recall that a set in X is called invariant if it is a collection of full orbits, that is, orbits of solutions of (1.1) that are defined for all $t \in \mathbb{R}$. In view of Theorem 2.2 of [11], the maximal invariant set $I(S)$ in S exists and attracts all trajectories in S provided that the system is compact and point dissipative. It is found that if $I(S)$ has a finite covering by a family of isolated invariant sets such that there is no cycle in the family and each invariant set does not attract any trajectory from $X \setminus S$, then the system is persistent [3, 4, 9, 11]. Another direction is to use the so-called average Liapunov functions. An average Liapunov function is a continuous function $P : \ X \mapsto \mathbb{R}$ such that (i) $P(\xi) > 0$ for $\xi \in X \setminus S$, and (ii) for each $\xi \in I(S)$, there is $t > 0$ such that

$$\liminf_{\eta \in X\setminus S,\, \eta \to \xi} \frac{P(\eta\pi t)}{P(\eta)} > 1.$$

Whenever such a function exists, the system is persistent (cf. [13]). This method has been applied to several Lotka–Volterra-type ecological models in [5, 6, 7, 13]. Sufficient conditions for the systems to be persistent are obtained by constructing various such functions. It is the latter direction that we shall pursue mainly in this paper, although our approach is closely related to the former.

Generally, a difficulty in using average Liapunov functions arises from its "global" nature. To construct such a function, all the behavior of the semiflow on S must be taken into consideration simultaneously. Thus the larger the maximal invariant set $I(S)$ of S is, the more difficult it is to construct the function. When the semiflow has a complicated structure on S, the task of construction becomes overwhelming. Hence, it appears that the method would be much improved if average Liapunov functions can be used in a "local" sense, that is, not just one single global average Liapunov function but a number of local functions, one for each member of certain decomposition of $I(S)$, so that collectively, they ensure the persistence of the semiflow. The goal of this paper is to develop such a method. Let an average Liapunov function be defined only in a neighborhood of an isolated invariant set in S, i.e., an invariant set in S which is maximal in a neighborhood. We show that its existence ensures that the invariant set does not attract any trajectory from $X \setminus S$. Since the smaller the invariant set is, the easier the average Liapunov function can be constructed, the question becomes to determine the smallest invariant sets such that if each does not attract trajectories from $X \setminus S$, then neither does the entire face S. We show that the smallest of such invariant sets are the isolated connected chain-recurrent sets in S. Recall that an invariant set M is called chain recurrent if for each $x \in M$ and each $\varepsilon > 0$, there exist points $x = x_0, \ldots, x_n = x$ and times $t_1, \ldots, t_n \geq 1$ such that $d(x_i, x_{i-1}\pi t_i) < \varepsilon$ [8]. Our results show that if the system is not persistent, then any trajectory starting in $X \setminus S$ which is attracted to S is actually attracted to a chain-recurrent set in S. As a result, to show that the system is persistent, one needs to construct an average Liapunov function for each connected component of chain-recurrent sets in $I(S)$.

The paper is organized as follows. In section 2, we investigate the behavior of a trajectory of a general nonpersistent semiflow when it is attracted to S and show that the trajectory is actually attracted to a chain-recurrent set. In the case where the chain-recurrent set contains more than one equilibria, the trajectory will enter and exit any small neighborhood of each point of the set infinitely many times, with progressively slower pace. In section 3, we first show that for any isolated invariant set in S, the existence of an average Liapunov function in a neighborhood of the invariant set ensures that the invariant set does not attract any trajectory from $X \setminus S$. We then discuss the reaction–diffusion system (1.1) and show how the local average Liapunov functions can be constructed. As a result, we give sufficient conditions for isolated invariant sets in S not to attract trajectories from $X \setminus S$. The final section illustrates the techniques with a food chain model of Lotka–Volterra type.

2. Behavior of trajectories attracted to S. In this section, we consider nonpersistent systems and show that any trajectory attracted from $X \setminus S$ to S is necessarily attracted to a connected chain-recurrent set in S. As a result, we obtain sufficient conditions for the system to be persistent by requiring that each isolated connected chain-recurrent set in S repels trajectories in $X \setminus S$. We also give sufficient conditions for persistence in terms of Morse decompositions of the maximal invariant set $I(S)$ in S. Some other property of a trajectory when it is attracted to S in a nonpersistent system will also be given. The results in this section are valid for general dynamical systems.

Consider a semiflow π in the metric space (X, d). Let $S \subset X$ be a closed set such that both S and $X \setminus S$ are forwardly invariant for π. Let also $T(t) : X \mapsto X$ denote the semigroup defined by $T(t)x = x\pi t$ for $x \in X$ and $t \in \mathbb{R}^+$. We impose the following general assumptions:

(A) (i) The semiflow π is point dissipative in X [10].

(ii) There is a $t_0 > 0$ such that the semigroup $T(t)$ is compact in X for $t \geq t_0$.

In view of Theorem 2.2 of [11], the above condition (A) ensures that the semiflow π restricted to S has a compact nonempty global attractor $I(S)$ in S. We further assume the following:

(B) The maximal invariant set $I(S)$ in S is an isolated invariant set for π in X.

Let $M \subset S$ be an invariant set for π. We consider the situation when there is $x \in X \setminus M$ attracted to M. By x being attracted to (resp., repelled by) M we mean the ω-limit set $\omega(x)$ (resp., the α-limit set $\alpha(x)$) is nonempty and is enclosed in M (resp., $\alpha(x) \subset M$). Recall that $\omega(x)$ (resp., $\alpha(x)$) is the set of all $y \in X$ for which there is a sequence $t_n \to \infty$ (resp., $t \to -\infty$) as $n \to \infty$ such that $x\pi t_n \to y$. The set of all x attracted to (resp., repelled by) M is called the *stable* (resp., *unstable*) *set* of M and is denoted as $W^s(M)$ (resp., $W^u(M)$) (cf. [10]). For each $x \in X$, we let $\gamma^+(x) \equiv x\pi[0, T_{\max})$ and $\gamma^-(x) \equiv x\pi(T_{\min}, 0]$ denote the forward and backward semi-orbits, respectively. Here $T_{\max}$ (resp., $T_{\min}$) is the supreme of $t > 0$ (resp., infimum of $t \leq 0$) such that $x\pi t$ exists. One notes that for semiflows generated by the PDE (1.1), $\gamma^-(x)$ may not exist or may not be unique. Finally, let N be an open set of X; we say π does not explode in N if, whenever $x \in X$ and $x\pi[0, T_{\max}) \subset N$, $T_{\max} = \infty$. The next result from Rybakowski [15] plays an important role in our discussion.

PROPOSITION 2.1. *Let M be an isolated invariant set and N be a closed isolating neighborhood of M such that π does not explode in N. Let $x \in X$ be such that $\gamma^+(x)$ is bounded, $\omega(x) \cap M \neq \emptyset$, and $\omega(x) \setminus M \neq \emptyset$. Then there exist points x^s, $x^u \in \partial N \cap \omega(x)$ such that $\gamma^+(x^s) \subset N$ and all backward orbits $\gamma^-(x^u)$ through x^u are contained in N.*

Remark. By the invariance of ω-limit sets, through any point $y \in \omega(x)$ a full orbit $\gamma(y) \equiv y\pi\mathbb{R}$ exists. Hence by the compactness of $\omega(x)$, both $\omega(y)$ and $\alpha(y)$ are nonempty. Since, by definition, M is the maximal invariant set in N, it is clear that in the above proposition, $\omega(y^s) \subset M$ and $\alpha(y^u) \subset M$. That is, $y^s \in W^s(M)$ and $y^u \in W^u(M)$.

Using this proposition, we can show that if $x \in X \setminus S$ has an ω-limit point in S, then either x itself or some $y \in \omega(x) \setminus S$ is attracted to S.

COROLLARY 2.2. *Suppose conditions* (A) *and* (B) *hold. If $x \in X \setminus S$ has a bounded forward semi-orbit $\gamma^+(x)$, and $\omega(x) \cap S \neq \emptyset$, then either $\omega(x) \subset S$, or there is $y \in \omega(x) \setminus S$ such that $\omega(y) \subset S$.*

Proof. Since, by assumption, $\gamma^+(x)$ is bounded and $T(t)$ is compact, $\omega(x)$ is nonempty and contains only full orbits of the semiflow π. Hence $\omega(x) \cap S \subset I(S)$. Suppose $\omega(x) \not\subset S$. Then by assumption (B) and Proposition 2.1, for each isolating neighborhood N of $I(S)$, there is $y \in \omega(x) \cap \partial N$ such that the forward semi-orbit $\gamma^+(y) \subset N$. This implies that $\omega(y) \subset I(S)$ and there is a full orbit passing through y. Hence we must have $y \notin S$, because otherwise, by the invariance of S, the full orbit $\gamma(y)$ must be contained in S, and hence $y \in I(S)$, contradicting $y \in \partial N$. This proves the existence of $y \in \omega(x) \setminus S$ such that $\omega(y) \subset S$. □

The above result can be improved if we replace S by any isolated invariant set $M \subset S$, which is a repeller in S. Recall that an invariant set $M \subset S$ is called an

attractor if it attracts all elements in a neighborhood of itself, and an invariant set $M' \subset S$ is called a repeller dual to M if

$$M' = \{x \in I(S) : \omega(x) \cap M = \emptyset\}.$$

For an isolated invariant set M, an ordered finite collection of subsets $D = \{M_1, \ldots, M_n\}$ in M is called a Morse decomposition of M if each member M_i is invariant and if each $x \in M$ either lies in a set M_k or has its $\omega(x)$ and $\alpha(x)$ enclosed in two distinct sets M_i and M_j, respectively, with $i < j$. The members of D are called Morse sets (cf. [8]). The next theorem gives a result more general than Corollary 2.2. It shows that if a repeller M has the Morse decomposition $\{M_1, \ldots, M_n\}$, and if $x \in X \setminus S$ is such that $\omega(x) \cap M \neq \emptyset$, then either x or some $y \in \omega(x) \setminus S$ must be attracted to one of the Morse sets.

THEOREM 2.3. *Suppose conditions* (A) *and* (B) *hold. Let $M \subset S$ be an isolated invariant set of π which is a repeller in S (dual to an attractor). Suppose $\{M_1, \ldots, M_n\}$ is a Morse decomposition of M in S, and suppose that there is an $x \in X \setminus S$ having a bounded forward semi-orbit $\gamma^+(x)$ and $\omega(x) \cap M \neq \emptyset$. Then there is a Morse set M_i such that either x or some $y \in \omega(x) \setminus S$ is contained in $W^s(M_i)$.*

Proof. Assume by contradiction that such a Morse set does not exist. Let $z \in \omega(x) \cap M$. Then there is a Morse set M_k such that $\omega(z) \subset M_k$, and by the invariance of ω-limit sets, $\omega(x) \cap M_k \neq \emptyset$. Let j be the maximum of the subscripts k such that $\omega(x) \cap M_k \neq \emptyset$. Since, by assumption, $x \notin W^s(M_j)$, Proposition 2.1 shows that there is $y \in \omega(x)$ such that $y \notin M_j$ and $y \in W^s(M_j)$. Again by assumption, $y \notin X \setminus S$. Since $y \in \omega(x)$ implies that there is a full orbit passing through y, it follows that this orbit lies in S. Hence either $\alpha(y) \not\subset M$ or there is $i > j$ such that $\alpha(y) \subset M_i$. The former contradicts the fact that M is a repeller. The latter implies that $\omega(x) \cap M_i \supset \alpha(y) \cap M_i \neq \emptyset$, which contradicts the maximality of j. This completes the proof. □

Remark. Using a similar argument, one can show that the result of the theorem holds if $\omega(x) \subset M$ while M is not necessarily a repeller. The modification of the proof is straightforward.

It is known that given two Morse decompositions D_1, D_2 of an isolated invariant set M one can construct a third Morse decomposition D_3 finer than both D_1 and D_2. Let $M(D_i)$ denote the union of all the Morse sets in the decomposition D_i. Then necessarily, $M(D_3) \subset M(D_1) \cap M(D_2)$. It has been shown by Conley [8] that the intersection of the unions of Morse sets over all Morse decompositions is a chain recurrent set. This suggests that if there is $x \in X \setminus S$ which is attracted to S, then x is actually attracted to a chain recurrent set in S. We show this result in the next theorem.

THEOREM 2.4. *Suppose* (A) *and* (B) *hold and suppose $x \in X \setminus S$ has a bounded forward semi-orbit $\gamma^+(x)$ and satisfies $\omega(x) \cap S \neq \emptyset$. Then there is an invariant set $C \subset S$ which is connected and chain recurrent for π in S such that either x or some $y \in \omega(x) \cap (X \setminus S)$ is contained in $W^s(C)$.*

Proof. In view of Corollary 2.2, there exists $x^s \in X \setminus S$ such that $\omega(x^s) \subset S$, and x^s is either x itself or lies in $\omega(x)$. Let $R(S)$ be the maximal chain recurrent set of the semiflow π restricted in $I(S)$. According to [8], in every neighborhood of $R(S)$, there is a Morse decomposition D in S such that the union $M(D)$ of the Morse sets is in that neighborhood. Choose a decreasing sequence $\epsilon_n \to \infty$ and a corresponding sequence of Morse decompositions $\{D^n\}$ such that $M(D^n)$ lies in the ϵ_n-neighborhood of $R(S)$. By using intersections of Morse sets, we may assume without loss of generality that D^n becomes finer as n increases.

We select a decreasing sequence of Morse sets $M^n \in D^n$ and a precompact sequence of points $x_n \in X \setminus S$ such that $\omega(x_n) \subset M^n$ as follows. Let N be a fixed isolating neighborhood of $I(S)$ in X. By either reducing N or following the trajectory from x^s if necessary, we may assume $x^s \in \partial N$. Without loss of generality, we may also assume that $M(D^1) \subset N$. Applying Theorem 2.3 to x^s and D^1, we see that there is an $x_1 \in X \setminus S$ such that $\omega(x_1) \in M^1$ for some $M^1 \in D^1$, and x_1 is either x^s or lies in $\omega(x^s)$. We show that x_1 can be chosen on ∂N. Indeed, if $x_1 = x^s$, we already have $x_1 \in \partial N$. If $x_1 \in \omega(x^s)$, then by the invariance of ω-limit sets, there is a full orbit $\gamma(x_1)$ passing through x_1. Since $x_1 \notin S$ and since N is an isolating neighborhood of $I(S)$, it follows that $\gamma(x_1) \not\subset N$. Using the fact that $\omega(x_1) \subset M^1 \subset I(S)$, one sees that there exists $x_1' \in \gamma(x_1)$ such that $x_1' \in \partial N$ and $\omega(x_1') \in M^1$. We can then choose x_1' to replace x_1.

Next, assume that there exist Morse sets $M^k \in D^k$ and points $x_k \in \partial N \setminus S$, $k = 1, \ldots, n$, such that

$$M^1 \supset M^2 \supset \cdots \supset M^n$$

and $\omega(x_k) \subset M^k$. Assume also that each x_k is either x^s or lies in $\omega(x^s)$. It is easy to see that the intersections of M^n with the Morse sets of D^{n+1} constitute a Morse decomposition of M^n. Hence, in view of the remark following the proof of Theorem 2.3, there exist a Morse set $M^{n+1} \in D^{n+1}$ and a point $x_{n+1} \in X \setminus S$ such that $M^{n+1} \subset M^n$ and $\omega(x_{n+1}) \subset M^{n+1}$. Furthermore, x_{n+1} is either the same as x_n or lies in $\omega(x_n)$. By the transitivity of ω-limit sets, we see that x_{n+1} is either the same as x^s or lies in $\omega(x^s)$. Finally, using a similar argument in the preceding paragraph, x_{n+1} can be chosen to lie on ∂N. This completes the induction, and also the construction of sequences $\{M^n\}$ and $\{x_n\}$.

Let $C \equiv \bigcap_{n=1}^{\infty} M^n$. Then clearly, C is invariant and chain recurrent for π in S. By the compactness of $\omega(x^s)$, we see that there exists a convergent subsequence $\{x_{n'}\}$ of $\{x_n\}$ such that

$$\lim_{n' \to \infty} x_{n'} = y \in \partial N.$$

We show that $\omega(y) \subset C$ and y is either x itself or lies in $\omega(x) \setminus S$. First observe that by the construction of $\{x_n\}$, for each fixed n' and each $k \geq n'$, x_k is either $x_{n'}$ itself or lies in $\omega(x_{n'})$. Hence by the closedness of ω-limit sets, the same is true for y. This implies that $\omega(y) \subset M^{n'}$ for all n', which leads to $\omega(y) \subset C$. Next, since each x_n is either x^s itself or lies in $\omega(x^s)$, and x^s is either x itself or lies in $\omega(x)$, by the transitivity, the same is true for y. In the case where $y \in \omega(x)$, there is a full orbit passing through y. Since $y \in \partial N$ implies that $y \notin I(S)$, it follows that $y \notin S$. Finally, since $\omega(x)$ is connected, in case C is not, we may simply replace C by a component containing $\omega(x)$. This completes the proof. □

The above Theorems 2.3 and 2.4 lead to the following results for the persistence of the semiflow.

COROLLARY 2.5. *Let conditions* (A) *and* (B) *hold. Then the semiflow π is persistent if either* (i) *$I(S)$ has a Morse decomposition $\{M_1, \ldots, M_n\}$ such that $W^s(M_i) \cap (X \setminus S) = \emptyset$ for $i = 1, \ldots, n$, or* (ii) *each component $C \subset I(S)$ of the chain-recurrent set of π in S satisfies $W^s(C) \cap (X \setminus S) = \emptyset$.*

Proof. Suppose by contradiction that π is not persistent. Then there is $x \in X \setminus S$ such that $\gamma^+(x)$ is bounded and $\omega(x) \cap S \neq \emptyset$. In view of Corollary 2.2, we may assume $\omega(x) \subset S$ without loss of generality. Suppose $I(S)$ has a Morse decomposition $\{M_1, \ldots, M_n\}$. Then since $I(S)$ is a repeller in S (dual to $\emptyset$), Theorem 2.3 with

$M = I(S)$ asserts that there is a Morse set M_i attracting trajectories from $X \setminus S$. Hence condition (i) does not hold. Also, since by Theorem 2.4 there is at least one connected chain-recurrent set of π in S attracting trajectories from $X \setminus S$, we see that condition (ii) does not hold either. This completes the proof. □

By Theorem 2.4, if any $x \in X \setminus S$ is attracted to S it is actually attracted to a chain-recurrent set $C \subset S$ of the semiflow. In the case when $\omega(x)$ contains more than one equilibrium point, we can show that the trajectory through x will visit any neighborhood of each point of $\omega(x)$ infinitely many times, with increasingly slower pace, provided that each equilibrium itself does not attract any trajectory from $X \setminus S$. More generally, we have the following theorem.

THEOREM 2.6. *Suppose* (A) *and* (B) *hold and suppose $C \subset S$ is a connected chain-recurrent set of π in S such that for each equilibrium $e \in C$, $W^s(e) \cap (X \setminus S) = \emptyset$. Let $x \in W^s(C) \cap (X \setminus S)$, and let $y \in \omega(x)$. Suppose there exists an equilibrium $y' \neq y$ such that $y' \in \omega(x)$. Then for each $T > 0$ there exist constants $\varepsilon > 0$ and $T_3 > T_2 > T_1 > T_0 > 0$ such that $x\pi T_0 \in N_\varepsilon(y)$, $x\pi T_3 \in N_\varepsilon(y)$, $x\pi t \notin N_\varepsilon(y)$ for $t \in [T_1, T_2]$, and $T_2 - T_1 \geq T$.*

Proof. Let $\{t_n\}$ and $\{t'_n\}$ be sequences tending to ∞ such that $x\pi t_n \to y$, $x\pi t'_n \to y'$, where y' is an equilibrium. Choose ε sufficiently small so that the ε-neighborhoods $N_\varepsilon(y)$ and $N_\varepsilon(y')$ of y and y' are disjoint. Then for large n, $x\pi t_n \in N_\varepsilon(y)$ and $x\pi t'_n \in N_\varepsilon(y')$. By taking subsequences and relabeling them, we may assume that for all n, $t_n < t'_n < t_{n+1}$. Define

$$s_n = \sup\{t : \ t'_n < t < t_{n+1}, \ x\pi[t'_n, t) \subset N_\epsilon(y')\}.$$

It follows that $t_n < t'_n < s_n < t_{n+1}$, $x\pi[t'_n, s_n] \subset \overline{N_\varepsilon(y')}$ for all n, and $x\pi s_n \in \partial N_\varepsilon(y')$. In particular, $x\pi t \notin N_\varepsilon(y)$ for $t \in [t'_n, s_n]$. We assert that $s_n - t'_n \to \infty$ as $n \to \infty$. For if not, by choosing subsequences, we may assume without loss of generality that $s_n - t'_n \to c \in \mathbb{R}^+$ and $x\pi s_n \to y'' \in \partial N_\varepsilon(y')$ as $n \to \infty$. However, since y' is an equilibrium, it follows that $x\pi s_n = x\pi t'_n \pi(s_n - t'_n) \to y'\pi c = y'$. This contradicts $y'' \in \partial N_\varepsilon(y')$.

Now, choose n large so that $s_n - t'_n > T$. We see that for $T_0 = t_n$, $T_1 = t'_n$, $T_2 = s_n$ and $T_3 = t_{n+1}$, the conclusion of the theorem holds. □

3. Local average Liapunov functions. In view of Theorems 2.4 and 2.6, to determine the persistence of a semiflow π, we need to examine a family of subsets of $I(S)$ and show that each member of the family does not attract trajectories from $X \setminus S$. The family can be either a Morse decomposition of $I(S)$ or the collection of connected chain-recurrent sets of π in S. In this section, we show how the existence of an average Liapunov function defined in a neighborhood of an isolated invariant set in S ensures that the invariant set does not attract trajectories from $X \setminus S$. Our approach in this section follows that in Hutson [13].

Let $M \subset S$ be an isolated invariant set for π and let N be an isolating neighborhood of M in X. We say that a continuous function $P : \ N \mapsto \mathbb{R}$ is a (local) average Liapunov function in N with respect to S if

(i) $P(x) > 0$ for $x \in N \setminus S$,

(ii) for each $x \in M$ there is $t > 0$ such that $\liminf_{y \in N \setminus S; \ y \to x} P(y\pi t)/P(y) > 0$.

Define a function $Q(x, t)$ for $x \in N$ and $t \geq 0$ by

$$Q(x,t) = \begin{cases} P(x\pi t)/P(x) & x \in N \setminus S, \\ \liminf\limits_{y \in N \setminus S; \ y \to x} P(y\pi t)/P(y) & x \in N \cap S. \end{cases} \tag{3.1}$$

Then part (ii) of the definition of P is equivalent to saying that for each $x \in M$ there is $t > 0$ such that $Q(x,t) > 0$. It is easy to see that $Q(\cdot,t)$ is lower semicontinuous. This is obvious if $x \in N \setminus S$. Suppose $x \in N \cap S$. Let $\varepsilon > 0$. Then there is $\delta > 0$ such that

$$Q(y,t) \equiv P(y\pi t)/P(y) > Q(x,t) - \varepsilon$$

for all $y \in N \setminus S$, $d(x,y) < \delta$. Hence for any $z \in N \cap S$ with $d(z,x) < \delta$, we have $Q(z,t) \geq Q(x,t) - \varepsilon$. This proves the semicontinuity of $Q(\cdot,t)$ at x.

In the next theorem, we use functions P and Q to give a sufficient condition for M not to attract any trajectory from $X \setminus S$.

THEOREM 3.1. *Let the condition* (A)(ii) *hold. Suppose $M \subset S$ is an isolated invariant set of π in X, and suppose that there exists an average Liapunov function P defined in a neighborhood $N \supset M$ with respect to S. If for each $x \in M$ there is $t > 0$ such that $Q(x,t) > 1$, then $W^s(M) \cap (X \setminus S) = \emptyset$.*

Proof. Since the function $Q(x,t)$ is lower semicontinuous, it follows that for each $h > 0$ and $t > 0$, the set

$$U(h,t) = \{x \in N^\circ : \ Q(x,t) > h\} \tag{3.2}$$

is open. (Here N° is the interior of N in X.) Clearly $U(h,t)$ is monotone for any fixed t, i.e., $U(h_1,t) \supset U(h_2,t)$ if $h_1 < h_2$. Using the assumption that for each $x \in M$ there is $t > 0$ such that $Q(x,t) > 1$, we see that M is covered by the family $\{U(h,t) : \ h > 1, \ t > 0\}$. Since M is compact by the assumption (A), there exist $h_0 > 1$ and $t_1, \ldots, t_n > 0$ such that

$$M \subset U \equiv \bigcup_{i=1}^{n} U(h_0, t_i).$$

It is clear that $U \subset N$ and is open in X.

Suppose now by contradiction that there is $y \in X \setminus S$ such that $\omega(y) \subset M$. Then there exists $T > 0$ such that $y\pi t \in U$ for all $t \geq T$. Use a translation in t if necessary; we may assume that $y \in U$. Let $\bar{t} = \max(t_1, \ldots, t_n)$ and $\underline{t} = \min(t_1, \ldots, t_n)$. Then given any $t \geq 0$, there is $\underline{t} \leq \tau \leq \bar{t}$ such that

$$P(y\pi(t+\tau)) \geq h_0 P(y\pi t).$$

Repeated use of this inequality and the fact that $P(y) > 0$ shows that there is a sequence $\{\tau_n\} \to \infty$ such that $P(y\pi\tau_n) \to \infty$. However, since $\omega(y) \subset M$, by choosing a subsequence if necessary, we may assume that $\{y\pi\tau_n\}$ converges to a point in M. Hence by the continuity of P, the set $\{P(y\pi\tau_n)\}$ is bounded. This contradiction shows that such y does not exist. □

The conditions in Theorem 3.1 can be relaxed as follows. Let M_ω be the closure of the set $\bigcup_{x \in M} \omega(x)$. Then instead of requiring $Q(x,t) > 1$ for each $x \in M$ and a corresponding $t > 0$, it suffices to require that the inequality be satisfied in M_ω only. This is shown in the next theorem.

THEOREM 3.2. *The conclusion of Theorem* 3.1 *remains true if there exists an average Liapunov function P defined in a neighborhood $N \supset M$ with respect to S such that for each $x \in M_\omega$, there is $t > 0$ for which $Q(x,t) > 1$.*

Proof. We first show that for any $x \in M$ and any $t_0 > 0$ there is a $\tau > t_0$ such that $Q(x,\tau) > 0$. Let $U(h,t)$ be the open set defined in (3.2). Since P is an average

Liapunov function, it follows from part (ii) of the definition that for each $x \in M$ there is $t > 0$ such that $Q(x,t) > 0$. Hence M is covered by the family of open sets $\{U(h,t) : \ h > 0, t > 0\}$, and by the compactness of M, there exist $h_0 > 0$ and $t_1, \dots, t_n > 0$ such that

$$M \subset U \equiv \bigcup_{i=1}^{n} U(h_0, t_i) \subset N.$$

Clearly U is a neighborhood of M in X. Let $\bar{t} = \max(t_1, \dots, t_n)$ and $\underline{t} = \min(t_1, \dots, t_n)$. We choose an integer k such that $k\underline{t} \geq t_0$ and a neighborhood $N(x)$ such that $N(x)\pi[0, k\bar{t}] \subset U$. Then for any $y \in N(x) \setminus S$, there exist $0 = \tau_0 < \tau_1 < \cdots < \tau_k \leq k\bar{t}$ such that $\underline{t} \leq \tau_i \leq \bar{t}$ and $P(y\pi\tau_i) > h_0 P(y\pi\tau_{i-1})$ for $i = 1, \dots, k$. This implies that $P(y\pi\tau_k) > h_0^k P(y)$ for all $y \in N(x) \setminus S$. Hence $Q(x, \tau_k) \geq h_0^k > 0$. Since $\tau_k \geq k\underline{t} \geq t_0$, the assertion is proven with $\tau = \tau_k$.

We now show that the condition of Theorem 3.2 implies the condition of Theorem 3.1. That is, we show that for each $x \in M$ there is a $t > 0$ such that $Q(x,t) > 1$. It is clear that M_ω is a closed subset of the compact set M. Since by the assumption of the theorem M_ω is covered by $\bigcup_{h>1,t>0} U(h,t)$, it follows that there is a finite covering

$$M_\omega \subset U_1 \equiv \bigcup_{i=1}^{m} U(h_1, t_i),$$

where $h_1 > 1$ and $t_1, \dots, t_m$ are positive constants. Thus U_1 is an open neighborhood of M_ω in X. Let $t' = \max(t_1, \dots, t_m)$. Suppose $x \in M$. Then there exist t_0 and τ such that $t_0 \leq \tau$, $x\pi t \in U_1$ for all $t \geq t_0$, and $Q(x,\tau) = \delta > 0$. Choose an integer ν such that $h_1^\nu \delta/2 > 1$, and choose a neighborhood $N(x)$ of x such that $N(x)\pi[\tau, \tau + \nu t'] \subset U_1$ and

$$P(y\pi\tau)/P(y) > \delta/2 \qquad \text{for } y \in N(x). \tag{3.3}$$

Then for each $y \in N(x)$, we have $z \equiv y\pi\tau \in U_1$ and $z\pi[0, \nu t'] \subset U_1$. This implies that there exist $0 = \tau_0 < \tau_1 < \cdots < \tau_\nu \leq \nu t'$ such that $\tau_i \leq t'$ and $P(z\pi\tau_i) > h_1 P(z\pi\tau_{i-1})$ for $i = 1, \dots, \nu$. Therefore, by (3.3),

$$P(y\pi(\tau + \tau_\nu)) = P(z\pi\tau_\nu) > h_1^\nu P(z) = h_1^\nu P(y\pi\tau) > h_1^\nu (\delta/2) P(y).$$

This leads to $Q(x,t) \geq h_1^\nu \delta/2 > 1$ for $t = \tau + \tau_\nu$. The assertion is proven.

The conclusion of the theorem follows now from Theorem 3.1. □

In the remainder of this section, we consider the system (1.1) of parabolic partial differential equations. We present certain techniques of constructing local average Liapunov functions and use them to obtain conditions for an invariant set not to attract trajectories from $X \setminus S$. In the following, X is the positive cone of the product space $\prod_{i=1}^{N} X_i$ where $X_i = C_0(\Omega)$ if B_i is the Dirichlet condition and

$$X_i = \{u \in C^1(\overline{\Omega}) : \ B_i u = 0\}$$

if B_i is Neumann or Robin condition, and $S \equiv \bigcup_{i=1}^{N} S_i$ is the union of the faces $S_i \equiv \{u \in X : \ u_i \equiv 0\}$. It is clear from the uniqueness of the solution of (1.1) that each face S_i is forwardly invariant for the semiflow π generated by (1.1). Hence S is also forwardly invariant.

We first use eigenfunctions of adjoint operators to construct average Liapunov functions. For $i = 1, \dots, N$, let L_i^* and B_i^* be the adjoint operators corresponding to L_i and B_i given by (1.2) and (1.3), i.e.,

$$L_i^* u = \sum_{i,j=1}^{n} (a_{ij} u_{x_j})_{x_i} - \sum_{i=1}^{n} b_i u_{x_i} - u \sum_{i=1}^{n} (b_i)_{x_i},$$
$$B_i^* u = \delta_i \frac{\partial u(x)}{\partial \nu^*(x)} + \left(\delta_i \sum_{i=1}^{n} b_i \zeta_i + \beta \right) u,$$

where $\nu^* = (\nu_1^*, \dots, \nu_n^*)$ is the adjoint conormal vector at $x \in \partial\Omega$ with $\nu_j^* = \sum_{i=1}^{n} a_{ij} \zeta_i$. A simple computation shows that

$$\int_\Omega v L_i u \, dx = \int_\Omega u L_i^* v \, dx \quad \text{if } Bu = B^* v = 0. \tag{3.4}$$

Let ϕ be a positive function that satisfies the relation

$$L_i^* \phi = g(x)\phi \quad (x \in \Omega), \qquad B_i^* \phi = 0 \quad (x \in \partial\Omega) \tag{3.5}$$

for some function g. Define the function $P : X \mapsto \mathbb{R}$ by

$$P(\xi) = \int_\Omega \xi_i \phi \, dx. \tag{3.6}$$

Then $P(\xi) > 0$ for all $\xi \in X \setminus S_i$ and

$$\begin{aligned} \frac{P(\xi \pi t)}{P(\xi)} &= \exp\left(\ln \int_\Omega \phi u_i(x,t) \, dx - \ln \int_\Omega \phi u_i(x,0) \, dx \right) \\ &= \exp\left(\int_0^t \frac{\int_\Omega \phi u_{i,t}(x,\tau) \, dx}{\int_\Omega \phi u_i(x,\tau) \, dx} \, d\tau \right), \end{aligned} \tag{3.7}$$

where $u = (u_1, \dots, u_n)$ is the solution of (1.1) with $u(x,0) = \xi$ and $u_{i,t}$ is the partial derivative of u_i with respect to t. Since by (1.1) and (3.4),

$$\begin{aligned} \int_\Omega \phi u_{i,t} \, dx &= \int_\Omega \phi (L_i u_i + u_i f_i(u)) \, dx \\ &= \int_\Omega \phi u_i (g(x) + f_i(u(x,t))) \, dx \\ &\geq c_0 \int_\Omega \phi u_i \, dx, \end{aligned} \tag{3.8}$$

where $c_0 = \inf_{x \in \Omega} \{ g(x) + f_i(u(x,t)) \}$, it follows from the definition of $Q(x,t)$ in (3.1) that $Q(\xi, t) \geq \exp(c_0) > 0$ for all $\xi \in X$ and $t > 0$. This shows that P is a local average Liapunov function for π with respect to S_i. It is clear that for any constant $\alpha > 0$, the function P^α is also a local average Liapunov function with respect to S_i. Using this construction and Theorem 3.1 we obtain the following result.

THEOREM 3.3. *Let $M \subset S_i$ be an isolated invariant set of π. Suppose the semiflow defined by* (1.1) *satisfies the condition* (A)(ii), *and suppose that there exists a function $\phi > 0$ that satisfies the relation in* (3.5) *for some function g such that $g(x) > -f_i(\xi)$ for all $\xi \in M$ and $x \in \overline{\Omega}$. Then $W^s(M) \cap (X \setminus S_i) = \emptyset$.*

Proof. Let P be defined by (3.6). As it is shown above, P is a local average Liapunov function of π with respect to S_i. Let Q be the corresponding semicontinuous function defined by (3.1). Then by (3.5) and (3.7),

$$Q(\xi,t) = \liminf_{\eta\in X\setminus S_i;\,\eta\to\xi} P(\eta\pi t)/P(\eta) \geq e^{c_0 t} \qquad \text{for } \xi\in M,\ t>0,$$

where $c_0 = \inf_{x\in\Omega,\,\xi\in M}\{g(x)+f_i(\xi)\}$. Since by the assumption of the theorem $c_0>0$, it follows that $Q(\xi,t)>1$. The conclusion of the theorem now follows from Theorem 3.1. □

Remark. Since by the Fredholm alternative and the Krein–Rutman theorem problem (3.5) has a positive solution if and only if the problem

$$L_i\psi = g(x)\psi \quad (x\in\Omega), \qquad B_i\psi = 0 \quad (x\in\partial\Omega) \tag{3.9}$$

has a positive solution, the conclusion of Theorem 3.3 is valid if equation (3.5) is replaced by (3.9).

In the case when $M\equiv\{u^0\}\subset S_i$ is a singleton, the attractivity of u^0 to $X\setminus S$ is described by the eigenvalue problem:

$$L_i\psi + f_i(u^0)\psi = \lambda\psi \quad (x\in\Omega), \qquad B_i\psi = 0 \quad (x\in\partial\Omega). \tag{3.10}$$

As a special case of Theorem 3.3, we have the following result.

COROLLARY 3.4. *Let $u^0\in S$ be an isolated equilibrium of π which also constitutes an isolated invariant set of π in X. Then $W^s(u^0)\cap(X\setminus S)=\emptyset$ if problem* (3.10) *has a positive eigenvalue for some $i\in\{1,\dots,N\}$ such that $u^0\in S_i$.*

Proof. Suppose problem (3.10) has a positive solution ψ for some $\lambda>0$. Then the function $g(x)$ in (3.9) satisfies

$$g(x) = -f(u^0)+\lambda > -f(u^0).$$

Hence by Theorem 3.3, the conclusion follows. □

More complicated average Liapunov functions can be constructed as follows. Suppose P_1 and P_2 are two functions defined by

$$P_1(\xi) = \int_\Omega \xi_{i_1}\phi_1\,dx, \quad P_2(\xi) = \int_\Omega \xi_{i_2}\phi_2\,dx, \tag{3.11}$$

where $i_1,\ i_2\in\{1,\dots,n\}$ and $\phi_1,\ \phi_2$ satisfy the relation

$$\begin{aligned} L_{i_1}^*\phi_1 &= g_1(x)\phi_1 \quad (x\in\Omega), \qquad B_{i_1}^*\phi_1 = 0 \quad (x\in\partial\Omega),\\ L_{i_2}^*\phi_2 &= g_2(x)\phi_2 \quad (x\in\Omega), \qquad B_{i_2}^*\phi_2 = 0 \quad (x\in\partial\Omega), \end{aligned}$$

for some functions g_1 and g_2.

THEOREM 3.5. *Let P_1 and P_2 be defined by* (3.11) *and let α_1, α_2, δ_1, δ_2 be positive constants. Then* (i) *the function $P_1^{\alpha_1}P_2^{\alpha_2}$ is a local average Liapunov function of π with respect to $S_{i_1}\cup S_{i_2}$, and* (ii) *the function $\delta_1P_1^{\alpha_1}+\delta_2P_2^{\alpha_2}$ is a local average Liapunov function of π with respect to $S_{i_1}\cap S_{i_2}$.*

Proof. (i) Let $P=P_1^{\alpha_1}P_2^{\alpha_2}$. Then clearly, $P(\xi)>0$ for $\xi\notin S_{i_1}\cup S_{i_2}$. Let Q be the semicontinuous functions defined by (3.1) and let Q_1 and Q_2 be defined similarly with P replaced by P_1 and P_2, respectively. Then by taking limit-infimum, $Q\geq Q_1^{\alpha_1}Q_2^{\alpha_2}$. Since $Q_1(\xi,t)>0$ and $Q_2(\xi,t)>0$ for all $\xi\in K$ and $t>0$, the same is true for Q. This proves that P is a local average Liapunov function with respect to $S_{i_1}\cup S_{i_2}$.

(ii) Let $P = \delta_1 P_1^{\alpha_1} + \delta_2 P_2^{\alpha_2}$ and let $\xi \in K \setminus (S_{i_1} \cap S_{i_2})$. Suppose $u(t) = \xi\pi t$ for $t \geq 0$. Then, by computation,

$$P(\xi\pi t)/P(\xi) = \exp\left(\ln(P(\xi\pi t)) - \ln(P(\xi))\right) = \exp\left(\ln(P(u(t)) - \ln(P(u(0)))\right)$$
$$= \exp\left(\int_0^t \dot{P}(u(\tau))/P(u(\tau))\, d\tau\right),$$

where $\dot{P}$ is the derivative of $P(u(t))$ with respect to t along the trajectory. Using the definition of P_1 and P_2 in (3.11), we compute

$$\dot{P}(u(t)) = \delta_1\alpha_1 \int_\Omega \phi_1 u_{i_1,t}\, dx \left(\int_\Omega \phi_1 u_{i_1}\, dx\right)^{\alpha_1 - 1}$$
$$+ \delta_2\alpha_2 \int_\Omega \phi_2 u_{i_2,t}\, dx \left(\int_\Omega \phi_2 u_{i_2}\, dx\right)^{\alpha_2 - 1},$$

where $u_{i_1,t}$ and $u_{i_2,t}$ are the respective partial derivatives of u_{i_1} and u_{i_2} with respect to t. Following the derivation in (3.8), we have

$$\int_\Omega \phi_k u_{i_k,t}\, dx \geq c_k \int_\Omega \phi_k u_{i_k}\, dx$$

with the constants

$$c_k = \inf_{x\in\Omega}\{g_k(x) + f_{i_k}(u(x,t))\}, \qquad k = 1, 2.$$

Thus, by letting $c_0 = \min\{\alpha_1 c_1, \alpha_2 c_2\}$, it follows that

$$\dot{P}(u(t)) \geq \delta_1\alpha_1 c_1 \left(\int_\Omega \phi_1 u_{i_1}\, dx\right)^{\alpha_1} + \delta_2\alpha_2 c_2 \left(\int_\Omega \phi_2 u_{i_2}\, dx\right)^{\alpha_2} \geq c_0 P(u(t)).$$

Hence by dividing $P(u(t))$ and taking limit-infimum, we arrive at

$$Q(\xi, t) \geq e^{c_0 t} > 0 \qquad \text{for all } t > 0.$$

This proves the part (ii) of the theorem. □

In the case where $I_\omega(S)$, the closure of the set $\cup_{x\in S}\omega(x)$ is a finite set, we give a condition for the system to be persistent. It is clear that in this case, each member u^j of $I_\omega(S)$ is an equilibrium of the system, and there is $i \in \{1, \ldots, N\}$ such that $u^j \in S_i$. An equilibrium u^i is said to be chained to another equilibrium u^j if there exists a connecting orbit from u^i to u^j. A finite sequence $u^{i_1}, \ldots, u^{i_k}$ is called a cycle if $u^{i_1} = u^{i_k}$ and u^{i_j} is chained to $u^{i_{j+1}}$ for $j = 1, \ldots, k$. We show that the system is uniformly persistent if the following conditions are satisfied:

(C) (i) The set $I_\omega(S) = \{u^j\}$ contains no cycle.
(ii) At each equilibrium u^j, there is $i \in \{1, \ldots, N\}$ such that $u^j \in S_i$ and problem (3.10) has a positive eigenvalue.

THEOREM 3.6. *Suppose the system* (1.1) *satisfies conditions* (A) *and* (B) *and suppose that* $I_\omega(S) = \{u^j\}$ *is a finite set which satisfies condition* (C). *Then the system defined by* (1.1) *is uniformly persistent.*

Proof. Since $I_\omega(S)$ is a finite set and contains no cycle, its members constitute a Morse decomposition D for the invariant set $I(S)$. Rearranging the subscripts if

necessary, we may assume that $D = \{M_1, \dots, M_n\}$ with $M_j = \{u^j\}$ for $j = 1, \dots, n$. In view of Theorem 2.3, the semiflow π is uniformly persistent with respect to S if $W^s(u^j) \cap (X \setminus S) = \emptyset$ for each $j \in \{1, \dots, n\}$. This condition is ensured by the assumption (C)(ii) and Corollary 3.4. □

Finally, we comment that for the semiflow generated by the parabolic system (1.1), the condition (A) is the consequence of the following conditions:

(D) (i) *Uniform boundedness.* Given $\alpha > 0$, there exists a constant $B(\alpha)$ such that $||u^0||_\infty \le \alpha$ implies that the solution $u(x,t)$ of (1.1) satisfies $||u(\cdot,t)||_\infty < B(\alpha)$ for all $t > 0$.

(ii) *Dissipativity in L^∞.* There exists a positive constant γ such that for each $u^0 \in X$, there is a $t_0 > 0$ such that

$$||u(\cdot,t)||_\infty \le \gamma \qquad \text{for all } t \ge t_0.$$

Here $||\cdot||_\infty$ is the L^∞ norm. This result is essentially Theorem 3.3 in Cantrell, Cosner, and Hutson, [6], although in [6] the differential operators L_i are restricted to the type $\mu_i \Delta$, where μ_i are positive constants and Δ is the Laplacian, and the boundary conditions are either the homogeneous Dirichlet type or the homogeneous Neumann type. The proof is valid for the more general (1.1). Furthermore, condition (D) can often be deduced by the comparison principle and the method of upper and lower solutions, as the example in the next section shows.

4. A food chain model. In this final section, we discuss a Lotka–Volterra food chain model of three species as an illustration of the results obtained in the previous sections. For the sake of simplicity, we assume that the diffusion coefficients for all three species are identical and the interacting mechanisms are also identical. The analysis for the general case is similar, but lengthy. Our model has the form

$$\begin{aligned} &\partial u_1/\partial t - d\Delta u_1 = u_1(a - u_1 - bu_2 + cu_3) \\ &\partial u_2/\partial t - d\Delta u_2 = u_2(a + cu_1 - u_2 - bu_3) \qquad (x \in \Omega), \\ &\partial u_3/\partial t - d\Delta u_3 = u_3(a - bu_1 + cu_2 - u_3) \\ &\qquad Bu_1 = Bu_2 = Bu_3 = 0 \qquad (x \in \partial\Omega), \end{aligned} \tag{4.1}$$

where a, b, c and d are positive constants, $\Omega \subset \mathbb{R}^n$ is a bounded domain with a smooth boundary $\partial\Omega \in C^{1+\alpha}$ for some $\alpha > 0$, and

$$B = \delta \frac{\partial}{\partial \nu} + \beta(x),$$

where δ is either 0 or 1, $\beta \in C^{1+\delta}(\partial\Omega)$ is a nonnegative function such that $\beta \equiv 1$ if $\delta = 0$, and ν is the outward normal vector on $\partial\Omega$. We consider two cases. In the first case, the system has semitrivial solutions with two positive components. Hence, when one species is absent, the other two may coexist. In the second case, the system has no semitrivial solution with two positive components. Thus if one species is absent, one of the others cannot survive. We will see that in this case, the three semitrivial solutions (each has only one positive component) form a cycle. For each case, we use local average Liapunov functions to obtain conditions for the system to be persistent.

Our basic assumption for this section is

$$a > \lambda_0, \quad 0 < c < 1, \tag{4.2}$$

where λ_0 is the principal eigenvalue of the problem

$$-d\Delta\psi = \lambda\psi \quad (x \in \Omega), \qquad B\psi = 0 \quad (x \in \partial\Omega).$$

The next lemma gives the compactness and dissipativity of the semiflow.

LEMMA 4.1. *Suppose a, c, and d are positive constants, b is a nonnegative constant, and $c < 1$. Then the semiflow π generated by the system* (4.1) *satisfies condition* (A).

Proof. In view of the remark at the end of the preceding section, it suffices to verify condition (D). Let α be a positive constant, and let $u(x,t)$ be a solution of (4.1) with $||u^0||_\infty \le \alpha$. We choose the constant $M = \max\{\alpha, a/(1-c)\}$ and let $\mathbf{y} \equiv (y_1, y_2, y_3)$ be the solution of the system

$$\begin{aligned} y_1' &= y_1(a - y_1 + cy_3), \\ y_2' &= y_2(a + cy_1 - y_2), \\ y_3' &= y_3(a + cy_2 - y_3), \\ y_1(0) &= y_2(0) = y_3(0) = M. \end{aligned} \tag{4.3}$$

It is easy to see that the functions $\mathbf{y}$ and $\mathbf{0} \equiv (0,0,0)$ form a pair of ordered upper and lower solutions for the problem (4.1) (cf. [16, Chapter 8]). Hence

$$0 \le u_i(x,t) \le y_i(t) \qquad \text{for } (x,t) \in \Omega \times (0,\infty),\ i = 1,2,3. \tag{4.4}$$

On the other hand, due to the symmetry of (4.3), y_1, y_2, y_3 are identical and they solve the scalar problem

$$y' = y(a - (1-c)y), \quad y(0) = M.$$

Since by assumption $c < 1$ and $M \ge a/(1-c)$, it follows that y_i's are monotone nonincreasing in t and have the limit $a/(1-c)$. Thus by (4.4), $||u(\cdot,t)||_\infty \le M$ for all $t > 0$, and

$$\limsup_{t\to\infty} ||u(\cdot,t)||_\infty \le a/(1-c).$$

This proves the fulfillment of condition (D), and hence (A). □

We next identify the equilibria on the boundary of the positive cone. The system clearly has a trivial solution $\mathbf{0}$. A spectral analysis shows that it is unstable. Since by assumption $a > \lambda_0$, it is well known (cf. [2]) that the problem

$$-d\Delta\phi = \phi(a - \phi) \quad (x \in \Omega), \qquad B\phi = 0 \quad (x \in \partial\Omega) \tag{4.5}$$

has a unique positive solution ϕ. Hence problem (4.1) has three semitrivial solutions $\Phi_1 \equiv (\phi, 0, 0)$, $\Phi_2 \equiv (0, \phi, 0)$, and $\Phi_3 \equiv (0, 0, \phi)$. A spectral analysis shows that all are unstable. To determine the existence of a semitrivial solution with two positive components, we consider the two-component system

$$\begin{aligned} \partial u/\partial t - d\Delta u &= u(a - u - bv) \\ \partial v/\partial t - d\Delta v &= v(a + cu - v) \\ Bu = Bv &= 0 \end{aligned} \qquad \begin{aligned} &(x \in \Omega), \\ &\\ &(x \in \partial\Omega). \end{aligned} \tag{4.6}$$

Let $\lambda_0(p)$ denote the principal eigenvalue of the problem

$$-d\Delta\psi + p\psi = \lambda\psi \quad (x \in \Omega), \qquad B\psi = 0 \quad (x \in \partial\Omega), \tag{4.7}$$

where p is a continuous function. It is easy to see that whenever problem (4.6) has a positive steady-state solution (u_s, v_s), then $a > \lambda_0(bv_s)$ (see [2]). Since the principal eigenvalue $\lambda_0(p)$ is monotone increasing in p (which can be easily seen from the variational formulation of the principal eigenvalue), it follows that a necessary condition for the existence of a positive solution is $a > \lambda_0(0) \equiv \lambda_0$. The next lemma shows that another necessary condition is $b \leq 1$.

LEMMA 4.2. *Suppose $a > \lambda_0$ and $b > 1$. Then*

(i) *every solution (u, v) with $u(x, 0) \geq 0$, $u(x, 0) \not\equiv 0$, and $v(x, 0) \equiv 0$ converges to $(\phi, 0)$ as $t \to \infty$;*

(ii) *every solution (u, v) with $u(x, 0) \geq 0$, $v(x, 0) \geq 0$, and $v(x, 0) \not\equiv 0$ converges to $(0, \phi)$ as $t \to \infty$.*

In each case, the convergence is uniform for $x \in \overline{\Omega}$.

Proof. Consider the scalar problem

$$\partial z/\partial t - d\Delta z = z(a - p - z) \quad (x \in \Omega), \qquad Bz = 0 \quad (x \in \partial\Omega), \tag{4.8}$$

where p is a smooth function. It is well known that if $a \leq \lambda_0(p)$, then all nonnegative solutions converge uniformly to 0, and if $a > \lambda_0(p)$, then each solution $z(x, t)$ with $z(x, 0) \geq 0$, $z(x, 0) \not\equiv 0$ converges uniformly to the unique positive steady-state solution z_s (cf. e.g., [16, Chapter 8]). Part (i) of the lemma is a consequence of this result with $p = 0$ and $z_s = \phi$. We prove part (ii) of the lemma as follows.

We first show that the steady-state solution $(0, \phi)$ of (4.6) is asymptotically stable. The eigenvalue problem with respect to $(0, \phi)$ is

$$\begin{aligned} d\Delta\xi + (a - b\phi)\xi &= \lambda\xi \\ d\Delta\eta + c\phi\xi + (a - 2\phi)\eta &= \lambda\eta \\ B\xi = B\eta &= 0 \end{aligned} \qquad \begin{aligned} &(x \in \Omega), \\ &\\ &(x \in \partial\Omega). \end{aligned} \tag{4.9}$$

Since ϕ is a positive solution of (4.7) with $\lambda = a$ and $p = \phi$, it follows that $a = \lambda_0(\phi)$. Thus by the monotonicity of $\lambda_0(\cdot)$ and the assumption $b > 1$, we have $a < \lambda_0(b\phi)$ and $a < \lambda_0(2\phi)$. This implies that the first equation has a nontrivial solution only for some $\lambda < 0$, and so does the second equation with $\xi = 0$ to have a nontrivial solution. Hence all the eigenvalues of (4.9) are negative, which implies that $(0, \phi)$ is asymptotically stable.

Let ω_0 be the ω-limit set of the trajectory starting with $(u(\cdot, 0), v(\cdot, 0))$. It is well known for the Lotka–Volterra system (4.6) that any trajectory with a nonnegative initial condition has a connected, compact ω-limit set in the positive cone of the Banach space X^2, where $X = C_0(\Omega)$ if B is of Dirichlet type and $X = C^1(\overline{\Omega})$ if B is of Neumann or Robin type. To show that the solution $(u(\cdot, t), v(\cdot, t))$ converges to $(0, \phi)$, it suffices to show that $(0, \phi) \in \omega_0$. Because this would ensure that the trajectory will enter any small neighborhood of $(0, \phi)$ in finite time. Thus by the asymptotic stability, the trajectory must be attracted to $(0, \phi)$.

We first show that for each $(u^*, v^*) \in \omega_0$ the inequalities

$$u^*(x) \leq \phi(x), \quad v^*(x) \geq \phi(x) \qquad (x \in \Omega) \tag{4.10}$$

hold. To see this, let $\tilde{u}(x, t)$ and $\hat{v}(x, t)$ be solutions of (4.8) with $p = 0$ such that $\tilde{u}(x, 0) = u(x, 0)$ and $\hat{v}(x, 0) = v(x, 0)$. Then since u and v are nonnegative, it follows from the comparison principle (cf. e.g., [16, Theorem 2.3 of Chapter 4]) that $u(x, t) \leq \tilde{u}(x, t)$ and $v(x, t) \geq \hat{v}(x, t)$ for all $x \in \Omega$, $t > 0$. Since by the assumption

of the lemma $\lambda_0(0) < a < \lambda_0(b\phi)$ and $v(x,0) \not\equiv 0$, we have $\lim_{t\to\infty} \tilde{u}(\cdot,t) \le \phi$, and $\lim_{t\to\infty} \hat{v}(\cdot,t) = \phi$ uniformly in $\overline{\Omega}$. This proves (4.10).

Next, we let $(u^*(x,t), v^*(x,t))$ be a solution of (4.6) with $(u^*(\cdot,0), v^*(\cdot,0)) \in \omega_0$ and show that $(u^*(\cdot,t), v^*(\cdot,t)) \to (0,\phi)$ as $t \to \infty$. Once this is shown, then by the invariance of ω-limit sets, it is necessary that $(0,\phi) \in \omega_0$, which completes the proof of part (ii) of the lemma. Let $\tilde{u}(x,t)$ be a solution of (4.8) with $p = b\phi$ and $\tilde{u}(x,0) = u^*(x,0)$. Since by invariance $(u^*(\cdot,t), v^*(\cdot,t)) \in \omega_0$ for all $t > 0$, it follows from (4.10) that

$$u^*(x,t) \le \phi(x), \quad v^*(x,t) \ge \phi(x) \qquad \text{for all } x \in \Omega,\ t \ge 0. \tag{4.11}$$

Hence, by the comparison principle, $\tilde{u}(x,t) \ge u^*(x,t)$ for all $x \in \Omega$ and $t > 0$. Using the relation $a < \lambda_0(b\phi)$ we see that $\tilde{u}(\cdot,t) \to 0$ as $t \to \infty$, uniformly in $\overline{\Omega}$. Hence $u^*(\cdot,t) \to 0$. To find the limit of $v^*(\cdot,t)$, we observe that for any $\epsilon > 0$, there is $T > 0$ such that $cu^*(x,t) \le \varepsilon$ for all $x \in \Omega$ and $t \ge T$. Let $\hat{v}(x,t)$ be a solution of (4.8) with $p = -\varepsilon$ and $\tilde{v}(x,0) = v^*(x,T)$. Then by the comparison principle, $\tilde{v}(\cdot,t-T) \ge v^*(\cdot,t)$ for $t \ge T$. Since by the monotonicity of the principal eigenvalue $\lambda_0(\cdot)$,

$$a > \lambda_0(0) > \lambda_0(-\varepsilon),$$

it follows that $\tilde{v}(\cdot,t) \to \phi_\varepsilon$ as $t \to \infty$, where ϕ_ε is the positive solution of problem (4.5) with a replaced by $a + \varepsilon$. This leads to $v^*(x,t) \le \phi_\varepsilon(x)$ for t sufficiently large. Moreover, by the continuity of the solution of (4.5) with respect to a, $\phi_\varepsilon \to \phi$ as $\varepsilon \to 0^+$. Hence, we have

$$\limsup_{t\to\infty} v^*(x,t) \le \phi(x) \qquad \text{for all } x \in \Omega.$$

This, together with (4.11), shows that $v^*(\cdot,t) \to \phi$. The proof is complete. □

Remark. It can be shown using the degree theory that a sufficient condition for problem (4.6) to have a positive solution is $a > \lambda_0$ and $b < 1$.

Case 1*: when there exist semitrivial solutions with two positive components.* We show below that if $a > \lambda_0$, $c < 1$, and $b(1+c) < 1$ then the system is persistent. To prove this, we first find a priori bounds for the invariant sets of the system in S. This is done by using upper and lower solutions. Let $(\tilde{u}, \tilde{v})$ and $(\hat{u}, \hat{v})$ be smooth functions satisfying the inequalities

$$\tilde{u} \ge \hat{u} \ge 0, \qquad \tilde{v} \ge \hat{v} \ge 0,$$

and

$$\begin{aligned} -d\Delta\tilde{u} &\ge \tilde{u}(a - \tilde{u} - b\hat{v}), \quad -d\Delta\tilde{v} \ge \tilde{v}(a + c\tilde{u} - \tilde{v}), \\ -d\Delta\hat{u} &\le \hat{u}(a - \hat{u} - b\tilde{v}), \quad -d\Delta\hat{v} \le \hat{v}(a + c\hat{u} - \hat{v}), \qquad (x \in \Omega) \\ B\tilde{u} &\ge 0 \ge B\hat{u}, \quad B\tilde{v} \ge 0 \ge B\hat{v} \qquad (x \in \partial\Omega). \end{aligned}$$

It is well known that any solution (u,v) of (4.6) with the initial condition

$$\hat{u}(x) \le u(x,0) \le \tilde{u}(x), \quad \hat{v}(x) \le v(x,0) \le \tilde{v}(x) \qquad (x \in \Omega)$$

satisfies

$$\hat{u}(x) \le u(x,t) \le \tilde{u}(x), \quad \hat{v}(x) \le v(x,t) \le \tilde{v}(x) \qquad (x \in \Omega,\ t > 0).$$

Furthermore, there exist functions $(\overline{u}, \overline{v})$ and $(\underline{u}, \underline{v})$ satisfying the relations

$$\hat{u} \le \underline{u} \le \overline{u} \le \tilde{u}, \quad \hat{v} \le \underline{v} \le \overline{v} \le \tilde{v} \qquad \text{in } \Omega$$

such that

$$\begin{aligned} &\underline{u}(x) \le \liminf_{t\to\infty} u(x,t) \le \limsup_{t\to\infty} u(x,t) \le \overline{u}(x), \\ &\underline{v}(x) \le \liminf_{t\to\infty} v(x,t) \le \limsup_{t\to\infty} v(x,t) \le \overline{v}(x) \end{aligned} \qquad (x \in \Omega).$$

In fact, $(\overline{u}, \overline{v})$ and $(\underline{u}, \underline{v})$ form a "quasi-solution" of problem (4.6) in the sense that they satisfy

$$\begin{aligned} -d\Delta\overline{u} &= \overline{u}(a - \overline{u} - b\underline{v}), \quad -d\Delta\overline{v} = \overline{v}(a + c\overline{u} - \overline{v}), && (x \in \Omega) \\ -d\Delta\underline{u} &= \underline{u}(a - \underline{u} - b\overline{v}), \quad -d\Delta\underline{v} = \underline{v}(a + c\underline{u} - \underline{v}), && \\ B\overline{u} &= B\underline{u} = 0, \quad B\overline{v} = B\underline{v} = 0 && (x \in \partial\Omega) \end{aligned} \tag{4.12}$$

(see Theorem 4.2 of Chapter 8 in [16]). The next lemma gives upper and lower bounds of these functions.

LEMMA 4.3. *Suppose $a > \lambda_0$, $b(1+c) < 1$, $\hat{u} \not\equiv 0$, and $\hat{v} \not\equiv 0$. Then the inequalities*

$$(1 - b - bc)\phi \le \underline{u} \le \overline{u} \le \phi, \quad \phi \le \underline{v} \le \overline{v} \le (1 + c)\phi$$

hold for $x \in \Omega$.

Proof. Since by assumption $\hat{u}$ and $\hat{v}$ are nonnegative functions and none of them is identically zero, it follows from the maximum principle that $\underline{u}$ and $\underline{v}$ are both positive functions in Ω. Using the comparison principle to equations (4.5) and (4.12), we see that $\underline{v} \ge \phi$ and $\overline{u} \le \phi$. On the other hand, since the function $\xi = (1 + \mu)\phi$ satisfies

$$\begin{aligned} -d\Delta\xi &= \xi(a + \mu\phi - \xi) && (x \in \Omega), \\ B\xi &= 0 && (x \in \partial\Omega) \end{aligned}$$

for any $\mu \in \mathbb{R}$, it follows again from the comparison principle that $\overline{v} \le (1 + c)\phi$. Finally, since $\underline{u} > 0$ in Ω, by comparing the above equation with (4.12), we have $\underline{u} \ge (1 - b(1 + c))\phi$. This proves the lemma. □

Lemma 4.3 and Theorems 2.4 and 3.3 lead to the following persistence result.

THEOREM 4.4. *Suppose $a > \lambda_0$, $c < 1$, and $b(1 + c) < 1$. Then system (4.1) is uniformly persistent.*

Proof. Let M_1 be the maximal invariant set of the semiflow π in the region

$$\{u_1 = 0,\ (1 - b - bc)\phi \le u_2 \le \phi,\ \phi \le u_3 \le (1 + c)\phi\} \subset S_1.$$

We show that $W^s(M_1) \cap (X \setminus S) = \emptyset$. First observe that by assumption, $1 - b - bc > 0$; we have $M_1 \cap (S_2 \cup S_3) = \emptyset$. Thus the relation is equivalent to $W^s(M_1) \cap (X \setminus S_1) = \emptyset$. In view of Theorem 3.3, we need only to find a function $g(x)$ with the property that (1) $g(x) > -a + bu_2 - cu_3$ in Ω for all u_2 and u_3 such that $(0, u_2, u_3) \in M_1$, and (2) the problem

$$d\Delta\psi = g(x)\psi \quad (x \in \Omega), \qquad B\psi = 0 \quad (x \in \partial\Omega)$$

has a positive solution ψ. We choose g as follows. Since by assumption $b(1 + c) < 1$, it follows that $b < 1 < 1 + c$. Hence by the monotonicity of $\lambda_0(\cdot)$,

$$a = \lambda_0(\phi) > \lambda_0((b - c)\phi).$$

This ensures that for some sufficiently small ϵ, there is a positive solution ψ to the scalar problem

$$-d\Delta\psi = \psi(a - \varepsilon - (b-c)\phi - \psi) \quad (x \in \Omega), \qquad B\psi = 0 \quad (x \in \partial\Omega).$$

Choose $g = -a + \epsilon + (b-c)\phi + \psi$. Then

$$g(x) > -a + bu_2 - cu_3 \quad \text{if } u_2 \le \phi \text{ and } u_3 \ge \phi.$$

In particular, this holds if $(0, u_2, u_3) \in M_1$. The assertion $W^s(M_1) \cap (X \setminus S) = \emptyset$ thus follows from Theorem 3.3.

Define $M_2 \subset S_2$ and $M_3 \subset S_3$ analogously as the maximal invariant sets in the subregions

$$\{\phi \le u_1 \le (1+c)\phi,\ u_2 = 0,\ (1-b-bc)\phi \le u_3 \le \phi\}$$

and

$$\{(1-b-bc)\phi \le u_1 \le \phi,\ \phi \le u_2 \le (1+c)\phi,\ u_3 = 0\},$$

respectively. Then a similar proof shows that $W^s(M_i) \cap (X \setminus S) = \emptyset$ for $i = 1, 2$.

To show that the system (4.1) is persistent, we observe that the invariant set $I(S)$ has the Morse decomposition $\{M_1, M_2, M_3, \Phi_1, \Phi_2, \Phi_3, \mathbf{0}\}$. In view of Theorem 2.4, we need only show that each Morse set does not attract trajectories from $X \setminus S$. This has been done for M_i $(i = 1, 2, 3)$ in the preceding paragraphs. To see that the same is true for Φ_i and $\mathbf{0}$, we use Corollary 3.4. Consider Φ_1. It is clear that $\Phi_1 \in S_3$ and the eigenvalue problem (3.10) with $i = 3$ has the form

$$d\Delta\psi + (a - b\phi)\psi = \lambda\psi \quad (x \in \Omega), \qquad B\psi = 0 \quad (x \in \partial\Omega).$$

This problem has a positive solution if and only if $a - \lambda = \lambda_0(b\phi)$. Since $b < 1$, it follows that $a = \lambda_0(\phi) > \lambda_0(b\phi)$. Hence $\lambda > 0$, and by Corollary 3.4, $W^s(\Phi_1) \cap (X \setminus S) = \emptyset$. A similar argument gives the property for Φ_2 and Φ_3.

Finally, since $\mathbf{0} \in S_1$, its corresponding eigenvalue problem has the form

$$d\Delta\psi + a\psi = \lambda\psi \quad (x \in \Omega), \qquad B\psi = 0 \quad (x \in \partial\Omega).$$

Since by assumption $a > \lambda_0$, it certainly has a positive eigenvalue. Hence $W^s(\mathbf{0}) \cap (X \setminus S) = \emptyset$. This completes the proof. □

Case 2: when there exists no semitrivial solution with two positive components. Suppose $a > \lambda_0$ and $b > 1$. In view of Lemma 4.2, the system has no semitrivial solution with two positive components. The phase portrait of the semiflow in S is described in Figure 1. As can be seen, the maximal invariant set $I(S)$ has the Morse decomposition $\{M_1, M_2\}$, where M_1 consists of semitrivial solutions Φ_1, Φ_2, Φ_3, and the connecting orbits, and M_2 consists of the trivial solution $\mathbf{0}$. (Since each Φ_i has a one-dimensional unstable manifold as can be verified by examining the corresponding eigenvalue problem, the connecting orbit between each pair of semitrivial solutions is a one-dimensional manifold.) It is clear that M_1 is a chain-recurrent set in S. We consider the conditions for $W^s(M_i) \cap (X \setminus S) = \emptyset$ for $i = 1, 2$.

First consider $M_2 = \{\mathbf{0}\}$, which is a singleton. By Corollary 3.4, $W^s(M_2) \cap (X \setminus S) = \emptyset$ if for some $i \in \{1, 2, 3\}$, the problem

$$d\Delta\psi + a\psi = \lambda\psi \quad (x \in \Omega), \qquad B\psi = 0 \quad (x \in \partial\Omega)$$

has a positive eigenvalue. This is ensured by the assumption $a > \lambda_0$.

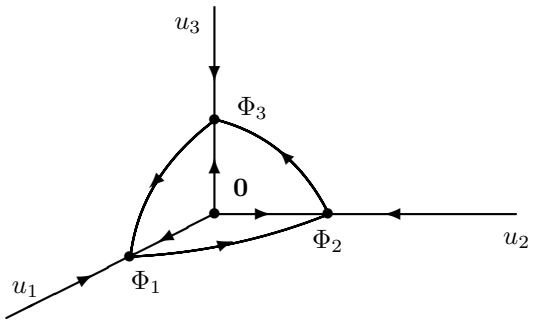

FIG. 1. *The boundary flow with a cycle.*

To obtain conditions for $W^s(M_1) \cap (X \setminus S) = \emptyset$, we construct the function P as follows. Let λ^* be the principal eigenvalue of the problem

$$d\Delta\varphi + (a + c\phi)\varphi = \lambda\varphi \quad (x \in \Omega), \qquad B\varphi = 0 \quad (x \in \partial\Omega). \tag{4.13}$$

Since by assumption and the monotonicity of principal eigenvalue,

$$a > \lambda_0(0) > \lambda_0(-c\phi),$$

it follows that $\lambda^* > 0$. Choose a positive eigenfunction φ and define

$$P(u) \equiv \prod_{i=1}^{3} \int_\Omega \varphi u_i \, dx.$$

In view of Theorem 3.5, P is a local average Liapunov function with respect to S. A direct computation shows that

$$\frac{P(\eta\pi t)}{P(\eta)} = \exp\left[\int_0^t \sum_{i=1}^{3} \frac{\int_\Omega \varphi u_{i,t}(x,\tau)\,dx}{\int_\Omega \varphi u_i(x,\tau)\,dx}\, d\tau\right] \quad \text{for } \eta \in X \setminus S, \tag{4.14}$$

where $u(\cdot,t) \equiv (u_1(\cdot,t), u_2(\cdot,t), u_3(\cdot,t)) = \eta\pi t$ and $u_{i,t} = \partial u_i/\partial t$. Since M_1 has the ω-limit set $M_{1,\omega} = \{\Phi_1, \Phi_2, \Phi_3\}$, it follows from Theorem 3.2 that $W^s(M_1) \cap (X \setminus S) = \emptyset$ provided that for each $j = 1, 2, 3$ there is a $t = t(j) > 0$ such that

$$Q(\Phi_j, t) = \liminf_{\eta \in X\setminus S,\, \eta \to \Phi_j} \frac{P(\eta\pi t)}{P(\eta)} > 1. \tag{4.15}$$

Once this holds, Theorem 2.4 ensures that the system is uniformly persistent. Such condition is given in the following theorem.

THEOREM 4.5. *Suppose* $a > \lambda_0$, $c < 1$, $b > 1$, *and*

$$2\lambda^* > (b + c)||\phi||_{C(\overline{\Omega})}. \tag{4.16}$$

Then the system (4.1) *is uniformly persistent.*

Proof. It suffices to show that for each $j = 1, 2, 3$, there is $t = t(j) > 0$ such that (4.15) holds. We only prove the assertion for $j = 1$. The proof for other values of j is similar. From equations (4.1) and (4.13) we see with the Green's identity that

$$\int_\Omega \varphi u_{1,t}(x,\tau)\,dx = \int_\Omega \varphi u_1(\lambda^* - u_1 - bu_2 - c(\phi - u_3))\,dx. \tag{4.17}$$

Since by the continuity of the solution of (4.1) with respect to the initial value $\lim_{\eta\to\Phi_1} u = \Phi_1$, it follows that the right side of (4.17) tends to $\int_\Omega \varphi\phi(\lambda^* - (c+1)\phi)\,dx$. Using (4.13) and the Green's identity, we have

$$\begin{aligned}\int_\Omega \varphi\phi(\lambda^* - (c+1)\phi)\,dx &= \int_\Omega (d\phi\Delta\varphi + (a+c\phi)\phi\varphi - (c+1)\phi^2\varphi)\,dx \\ &= \int_\Omega \varphi(d\Delta\phi + a\phi - \phi^2)\,dx,\end{aligned}$$

which is 0 by (4.5). Also using (4.13) and the Green's identity, we derive

$$\begin{aligned}\int_\Omega \varphi u_{2,t}(x,\tau)\,dx &= \int_\Omega \varphi u_2(\lambda^* - c(\phi - u_1) - u_2 - bu_3)\,dx, \\ \int_\Omega \varphi u_{3,t}(x,\tau)\,dx &= \int_\Omega \varphi u_3(\lambda^* - bu_1 - c(\phi - u_2) - u_3)\,dx.\end{aligned}$$

By the continuity of the solution u with respect to the initial value η, it follows that for any $\varepsilon > 0$ there is a constant $T > 0$ and a neighborhood $N(\Phi_1)$ such that

$$||c(\phi - u_1) + u_2 + bu_3||_{C(\overline{\Omega})} < \varepsilon, \quad ||bu_1 + c(\phi - u_2) + u_3||_{C(\overline{\Omega})} < ||(b+c)\phi||_{C(\overline{\Omega})} + \varepsilon$$

for $0 \le t \le T$. Hence in this neighborhood $N(\Phi_1)$,

$$\begin{aligned}\int_\Omega \varphi u_{2,t}(x,\tau)\,dx \Big/ \int_\Omega \varphi u_2(x,\tau)\,dx &\ge \lambda^* - \varepsilon, \\ \int_\Omega \varphi u_{3,t}(x,\tau)\,dx \Big/ \int_\Omega \varphi u_3(x,\tau)\,dx &\ge \lambda^* - (b+c)||\phi||_{C(\overline{\Omega})} - \varepsilon.\end{aligned}$$

Thus, using the assumption (4.16), we may choose $N(\Phi_1)$ sufficiently small such that

$$2\lambda^* - (b+c)||\phi||_{C(\overline{\Omega})} > 2\varepsilon.$$

This ensures that

$$\sum_{i=1}^{3} \frac{\int_\Omega \varphi u_{i,t}(x,\tau)\,dx}{\int_\Omega \varphi u_i(x,\tau)\,dx} > 0 \qquad \text{for } \eta \in N(\Phi_1) \text{ and } \tau \in (0,T].$$

Therefore, by (4.14),

$$\liminf_{\eta\in X\setminus S,\, \eta\to\Phi_1} \frac{P(\eta\pi t)}{P(\eta)} > 1 \qquad \text{for } t \in (0,T].$$

The proof is complete. □

Remark. In the case when the boundary operator B is of the Neumann type, we have $\phi = a$ and $\lambda^* = a(1+c)$. Hence condition (4.16) is reduced to $b < c + 2$.

EXPONENTIAL STABILITY OF A THERMOELASTIC SYSTEM WITH FREE BOUNDARY CONDITIONS WITHOUT MECHANICAL DISSIPATION*

GEORGE AVALOS† AND IRENA LASIECKA‡

Abstract. We show herein the uniform stability of a thermoelastic plate model with no added dissipative mechanism on the boundary (uniform stability of a thermoelastic plate with added boundary dissipation was shown in [J. LAGNESE, *Boundary Stabilization of Twin Plates*, SIAM Stud. Appl. Math. 10, SIAM, Philadelphia, PA, 1989], as was that of the analytic case—where rotational forces are neglected—in [Z. LIU and S. ZHENG, *Quarterly Appl. Math.*, 55 (1997), pp. 551–564]). The proof is constructive in the sense that we make use of a multiplier with respect to the coupled system involved so as to generate a fortiori the desired estimates; this multiplier is of an operator theoretic nature, as opposed to the more standard differential quantities used for related work. Moreover, the particular choice of our multiplier becomes clear only after recasting the PDE model into an associated abstract evolution equation.

Key words. thermoelastic plates, uniform stability, free boundary conditions

1. Introduction.

1.1. Statement of the problem. Let Ω be a bounded open subset of $\mathbb{R}^2$ with sufficiently smooth boundary $\Gamma = \Gamma_0 \cup \Gamma_1$, Γ_0 and Γ_1 both nonempty, and $\overline{\Gamma_0} \cap \overline{\Gamma_1} = \varnothing$. We consider here the following thermoelastic system taken from J. Lagnese's monograph [12]:

$$
\begin{cases}
\begin{cases} \omega_{tt} - \gamma\Delta\omega_{tt} + \Delta^2\omega + \alpha\Delta\theta = 0 \\ \beta\theta_t - \eta\Delta\theta + \sigma\theta - \alpha\Delta\omega_t = 0 \end{cases} & \text{on } (0,\infty)\times\Omega; \\
\omega = \dfrac{\partial\omega}{\partial\nu} = 0 \ \text{ on } (0,\infty)\times\Gamma_0; \\
\begin{cases} \Delta\omega + (1-\mu)B_1\omega + \alpha\theta = 0 \\ \dfrac{\partial\Delta\omega}{\partial\nu} + (1-\mu)\dfrac{\partial B_2\omega}{\partial\tau} - \gamma\dfrac{\partial\omega_{tt}}{\partial\nu} + \alpha\dfrac{\partial\theta}{\partial\nu} = 0 \end{cases} & \text{on } (0,\infty)\times\Gamma_1; \\
\dfrac{\partial\theta}{\partial\nu} + \lambda\theta = 0 \qquad \text{on } (0,\infty)\times\Gamma,\ \lambda \geq 0; \\
\omega(t=0) = \omega^0,\ \omega_t(t=0) = \omega^1,\ \theta(t=0) = \theta^0 \text{ on } \Omega.
\end{cases} \tag{1.1}
$$

Here, α, β, and η are strictly positive constants; positive constant γ is proportional to the thickness of the plate and assumed to be small with $0 < \gamma \leq M$; the constant $\sigma \geq 0$ and the boundary operators B_i are given by

$$B_1\omega \equiv 2\nu_1\nu_2\frac{\partial^2\omega}{\partial x\partial y} - \nu_1^2\frac{\partial^2\omega}{\partial y^2} - \nu_2^2\frac{\partial^2\omega}{\partial x^2};$$

(1.2)

$$B_2\omega \equiv (\nu_1^2 - \nu_2^2)\frac{\partial^2\omega}{\partial x\partial y} + \nu_1\nu_2\left(\frac{\partial^2\omega}{\partial y^2} - \frac{\partial^2\omega}{\partial x^2}\right);$$

the constant μ is the familiar Poisson's ratio $\in (0, \frac{1}{2})$, and $[\nu_1, \nu_2]$ denotes the outward unit normal to the boundary. The given model mathematically describes a Kirchoff plate, the displacement of which is represented by the function ω subjected to a thermal damping as quantified by θ. We are concerned here with the uniform stability of solutions $[\omega, \theta]$ to (1.1).

1.2. Preliminaries and abstract formulation. As a departure point for obtaining the proofs of well posedness and of exponential stability, we will consider the system (1.1) as an abstract evolution equation in a certain Hilbert space, for which we introduce the following definitions and notation:

- With $H^k_{\Gamma_0}(\Omega) \equiv \{\omega \in H^k(\Omega) : \frac{\partial^j\omega}{\partial\nu^j}|_{\Gamma_0} = 0 \text{ for } j = 0, ..., k-1\}$, we define $\mathring{\mathbf{A}}$: $L^2(\Omega) \supset D\left(\mathring{\mathbf{A}}\right) \to L^2(\Omega)$ to be $\mathring{\mathbf{A}} = \Delta^2$, with domain

$$D(\mathring{\mathbf{A}}) = \Bigg\{\omega \in H^4(\Omega) \cap H^2_{\Gamma_0}(\Omega) : \Delta\omega + (1-\mu)B_1\omega = 0 \text{ on } \Gamma_1 \text{ and}$$

(1.3)

$$\frac{\partial\Delta\omega}{\partial\upsilon} + (1-\mu)\frac{\partial B_2\omega}{\partial\tau} = 0 \text{ on } \Gamma_1\Bigg\}.$$

- $\mathring{\mathbf{A}}$ is then positive definite, self-adjoint, and consequently from [8] we have the characterizations

$$D(\mathring{\mathbf{A}}^{\frac{1}{4}}) = H^1_{\Gamma_0}(\Omega);$$

(1.4)

$$D(\mathring{\mathbf{A}}^{\frac{1}{2}}) = H^2_{\Gamma_0}(\Omega);$$

$$D(\mathring{\mathbf{A}}^{\frac{3}{4}}) = \left\{\omega \in H^3(\Omega) \cap H^2_{\Gamma_0}(\Omega) : \Delta\omega + (1-\mu)B_1\omega = 0 \text{ on } \Gamma_1\right\}.$$

Moreover, using the Green's formula in [12], we have that for ω, $\widehat{\omega}$ "smooth enough,"

$$\begin{aligned}\int_\Omega (\Delta^2\omega)\widehat{\omega}d\Omega &= a(\omega, \widehat{\omega}) \\ &+ \int_\Gamma \left[\frac{\partial\Delta\omega}{\partial\nu} + (1-\mu)\frac{\partial B_2\omega}{\partial\tau}\right]\widehat{\omega}d\Gamma \\ &- \int_\Gamma \left[\Delta\omega + (1-\mu)B_1\omega\right]\frac{\partial\widehat{\omega}}{\partial\nu}d\Gamma,\end{aligned} \tag{1.5}$$

where $a(\cdot,\cdot)$ is defined by

(1.6)

$$a(\omega, \widehat{\omega}) \equiv \int_\Omega \left[\omega_{xx}\widehat{\omega}_{xx} + \omega_{yy}\widehat{\omega}_{yy} + \mu\left(\omega_{xx}\widehat{\omega}_{yy} + \omega_{yy}\widehat{\omega}_{xx}\right) + 2(1-\mu)\omega_{xy}\widehat{\omega}_{xy}\right]d\Omega.$$

In particular, this formula and the second characterization in (1.4) give that for all ω, $\widehat{\omega} \in D(\mathring{\mathbf{A}}^{\frac{1}{2}})$,

$$\left\langle \mathring{\mathbf{A}}\omega, \widehat{\omega} \right\rangle_{\left[D(\mathring{\mathbf{A}}^{\frac{1}{2}})\right]' \times D(\mathring{\mathbf{A}}^{\frac{1}{2}})} = \left(\mathring{\mathbf{A}}^{\frac{1}{2}}\omega, \mathring{\mathbf{A}}^{\frac{1}{2}}\widehat{\omega}\right)_{L^2(\Omega)} = a\left(\omega, \widehat{\omega}\right)_{L^2(\Omega)}, \tag{1.7}$$

and in addition,

$$\|\omega\|^2_{D(\mathring{\mathbf{A}}^{\frac{1}{2}})} = \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} = a\left(\omega, \omega\right). \tag{1.8}$$

- We define $A_D : L^2(\Omega) \supset D\left(A_D\right) \to L^2(\Omega)$ to be $A_D = -\Delta$, with Dirichlet boundary conditions, viz.

$$D(A_D) = H^2(\Omega) \cap H^1_0(\Omega). \tag{1.9}$$

A_D is also positive definite, self-adjoint, and, by [8],

$$D(A_D^{\frac{1}{2}}) = H^1_0(\Omega). \tag{1.10}$$

- The space $L^2_{\sigma+\lambda}(\Omega)$ will be defined as

$$L^2_{\sigma+\lambda}(\Omega) \equiv \begin{cases} L^2(\Omega) & \text{if } \sigma + \lambda > 0, \\ \\ L^2_0(\Omega) & \text{if } \sigma + \lambda = 0, \end{cases} \tag{1.11}$$

where $L^2_0(\Omega) = \left\{\theta \in L^2(\Omega) \ni \int_\Omega \theta = 0\right\}$.

- We designate as $A_R : L^2(\Omega) \supset D\left(A_R\right) \to L^2(\Omega)$ the following second-order elliptic operator:

$$\begin{aligned} A_R &= -\Delta + \frac{\sigma}{\eta}\mathbf{I}, \\ D(A_R) &= \left\{\theta \in H^2(\Omega) : \frac{\partial \theta}{\partial \nu} + \lambda\theta = 0\right\}; \end{aligned} \tag{1.12}$$

A_R is self-adjoint, positive semidefinite on $L^2(\Omega)$, and, once more by [8],

$$D(A_R^{\frac{1}{2}}) = H^1(\Omega). \tag{1.13}$$

When $\lambda = \sigma = 0$, we shall denote the corresponding operator as A_N (instead of as A_R).

Furthermore, as the bilinear form $(\nabla\theta, \nabla\widetilde{\theta})_{L^2(\Omega)}$ is $H^1(\Omega)$-elliptic on $H^1(\Omega) \cap L^2_0(\Omega)$, we can define the norm-inducing inner product on $H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega)$ as

$$\left(\theta, \widetilde{\theta}\right)_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)} \equiv \left(\nabla\theta, \nabla\widetilde{\theta}\right)_{L^2(\Omega)} + \lambda\left(\theta, \widetilde{\theta}\right)_{L^2(\Gamma)} + \frac{\sigma}{\eta}\left(\theta, \widetilde{\theta}\right)_{L^2(\Omega)}. \tag{1.14}$$

- (γ_0, γ_1) will denote the Sobolev trace maps, which yield for $f \in C^\infty(\overline{\Omega})$

$$\gamma_0 f = f|_\Gamma\,; \gamma_1 f = \left.\frac{\partial f}{\partial \nu}\right|_\Gamma. \tag{1.15}$$

- We define the elliptic operators G_1, G_2, and D as thus:

$$G_1 h = v \Longleftrightarrow \begin{cases} \Delta^2 v = 0 \text{ in } (0,\infty)\times\Omega; \\ v = \dfrac{\partial v}{\partial \nu} = 0 \text{ on } (0,\infty)\times\Gamma_0; \\ \begin{cases} \Delta v + (1-\mu) B_1 v = h \\ \dfrac{\partial \Delta v}{\partial \nu} + (1-\mu)\dfrac{\partial B_2 v}{\partial \tau} = 0 \end{cases} \text{on } (0,\infty)\times\Gamma_1; \end{cases} \tag{1.16}$$

$$G_2 h = v \Longleftrightarrow \begin{cases} \Delta^2 v = 0 \text{ in } (0,\infty)\times\Omega; \\ v = \dfrac{\partial v}{\partial \nu} = 0 \text{ on } (0,\infty)\times\Gamma_0; \\ \begin{cases} \Delta v + (1-\mu) B_1 v = 0 \\ \dfrac{\partial \Delta v}{\partial \nu} + (1-\mu)\dfrac{\partial B_2 v}{\partial \tau} = h \end{cases} \text{on } (0,\infty)\times\Gamma_1; \end{cases} \tag{1.17}$$

$$Dh = v \Longleftrightarrow \begin{cases} \Delta v = 0 \text{ on } (0,\infty)\times\Omega; \\ v|_{\Gamma} = h \text{ on } (0,\infty)\times\Gamma. \end{cases} \tag{1.18}$$

The classic regularity results of [19, p. 152] then provide that for $s \in \mathbb{R}$,

$$\begin{cases} D \in \mathcal{L}\left(H^s(\Gamma), H^{s+\frac{1}{2}}(\Omega)\right); \\ G_1 \in \mathcal{L}\left(H^s(\Gamma_1), H^{s+\frac{5}{2}}(\Omega)\right); \\ G_2 \in \mathcal{L}\left(H^s(\Gamma_1), H^{s+\frac{7}{2}}(\Omega)\right). \end{cases} \tag{1.19}$$

With the operators $\mathring{\mathbf{A}}$ and G_i as defined above, one can readily show with the use of the Green's formula (1.5) that $\forall\ \omega \in D(\mathring{\mathbf{A}}^{\frac{1}{2}})$ the adjoints $G_i^* \mathring{\mathbf{A}} \in \mathcal{L}(D(\mathring{\mathbf{A}}^{\frac{1}{2}}), L^2(\Gamma))$ satisfy, respectively,

$$G_1^* \mathring{\mathbf{A}} \omega = \begin{cases} \left.\dfrac{\partial \omega}{\partial \nu}\right|_{\Gamma_1} & \text{on } (0,\infty)\times\Gamma_1; \\ 0 & \text{on } (0,\infty)\times\Gamma_0; \end{cases}$$

$$G_2^* \mathring{\mathbf{A}} \omega = \begin{cases} -\omega|_{\Gamma_1} & \text{on } (0,\infty)\times\Gamma_1; \\ 0 & \text{on } (0,\infty)\times\Gamma_0. \end{cases} \tag{1.20}$$

- We define the operator P_γ by

$$P_\gamma \equiv \mathbf{I} + \gamma A_N, \tag{1.21}$$

and make the following points:
(i) With the parameter $\gamma > 0$, we define a space $H^1_{\Gamma_0,\gamma}(\Omega)$ equivalent to $H^1_{\Gamma_0}(\Omega)$ with its inner product being

$$(\omega_1, \omega_2)_{H^1_{\Gamma_0,\gamma}(\Omega)} \equiv (\omega_1, \omega_2)_{L^2(\Omega)} + \gamma\,(\nabla\omega_1, \nabla\omega_2)_{L^2(\Omega)} \quad \forall\, \omega_1, \omega_2 \in H^1_{\Gamma_0}(\Omega), \tag{1.22}$$

and with its dual (pivotal with respect to L_2 inner product) denoted as $H^{-1}_{\Gamma_0,\gamma}(\Omega)$. After recalling that $H^1(\Omega) = D(A_N^{1/2})$, two extensions by continuity will then yield that

$$P_\gamma \in \mathcal{L}\left(H^1_{\Gamma_0,\gamma}(\Omega), H^{-1}_{\Gamma_0,\gamma}(\Omega)\right), \text{ with} \tag{1.23}$$

$$\langle P_\gamma \omega_1, \omega_2\rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega)\times H^1_{\Gamma_0,\gamma}(\Omega)} = (\omega_1,\omega_2)_{H^1_{\Gamma_0,\gamma}(\Omega)}. \tag{1.24}$$

Furthermore, the obvious $H^1_{\Gamma_0,\gamma}(\Omega)$-ellipticity of P_γ and Lax–Milgram give us that P_γ is boundedly invertible, i.e.,

$$P_\gamma^{-1} \in \mathcal{L}\left(H^{-1}_{\Gamma_0,\gamma}(\Omega), H^1_{\Gamma_0,\gamma}(\Omega)\right); \tag{1.25}$$

and moreover, P_γ being positive definite and self-adjoint as an operator $P_\gamma : L^2(\Omega) \supset D(P_\gamma) \to L^2(\Omega)$, the square root $P_\gamma^{1/2}$ is consequently well defined with $D(P_\gamma^{1/2}) = H^1_{\Gamma_0,\gamma}(\Omega)$ (using the interpolation theorem in [19, p. 10]; it then follows from (1.22) and (1.24) that for ω and $\widehat{\omega} \in H^1_{0,\gamma}(\Omega)$,

$$\left\|P_\gamma^{\frac12}\omega\right\|^2_{L^2(\Omega)} = \|\omega\|^2_{L^2(\Omega)} + \gamma\,\|\nabla\omega\|^2_{L^2(\Omega)} = \|\omega\|^2_{H^1_{\Gamma_0,\gamma}(\Omega)}; \tag{1.26}$$

$$\left(P_\gamma^{\frac12}\omega, P_\gamma^{\frac12}\widehat{\omega}\right)_{L^2(\Omega)} = (\omega,\widehat{\omega})_{H^1_{\Gamma_0,\gamma}(\Omega)}. \tag{1.27}$$

(ii) Finally, inasmuch as Green's formula yields for ω, $\widehat{\omega} \in D(\mathring{\mathbf{A}}^{\frac12})$,

$$\begin{aligned}&\gamma\left\langle\left(\Delta + \mathring{\mathbf{A}}G_2\gamma_1\right)\omega, \widehat{\omega}\right\rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega)\times H^1_{\Gamma_0,\gamma}(\Omega)}\\ &= -\gamma\,(\nabla\omega, \nabla\widehat{\omega})_{L^2(\Omega)} + \gamma\left(\frac{\partial\omega}{\partial\nu}, \widehat{\omega}\right)_{L^2(\Gamma_1)} + \gamma\left(\gamma_1\omega, G_2^*\mathring{\mathbf{A}}\widehat{\omega}\right)_{L^2(\Gamma_1)}\\ &= -\gamma\,(\nabla\omega, \nabla\widehat{\omega})_{L^2(\Omega)} = -\gamma\left\langle A_N\omega, \widehat{\omega}\right\rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega)\times H^1_{\Gamma_0,\gamma}(\Omega)},\end{aligned} \tag{1.28}$$

after using (1.20). We thus obtain after two extensions by continuity to $H^1_{\Gamma_0,\gamma}(\Omega)$ that

$$P_\gamma = \mathbf{I} - \gamma\left(\Delta + \mathring{\mathbf{A}}G_2\gamma_1\right) \text{ as elements of } \mathcal{L}\left(H^1_{\Gamma_0,\gamma}(\Omega), H^{-1}_{\Gamma_0,\gamma}(\Omega)\right). \tag{1.29}$$

In obtaining the equality above, we have used implicitly the fact that for every $\varpi^* \in H^{-1}_{\Gamma_0,\gamma}(\Omega)$ and $\varpi \in D(\mathring{\mathbf{A}}^{1/2})$,

$$\langle\varpi^*, \varpi\rangle_{H^{-1}_{\Gamma_0,\gamma}(\Omega)\times H^1_{\Gamma_0,\gamma}(\Omega)} = \langle\varpi^*, \varpi\rangle_{[D(\mathring{\mathbf{A}}^{\frac12})]'\times D(\mathring{\mathbf{A}}^{\frac12})}. \tag{1.30}$$

- We denote the Hilbert space $\mathbf{H}_\gamma$ to be

$$\mathbf{H}_\gamma \equiv D(\mathring{\mathbf{A}}^{\frac12}) \times H^1_{\Gamma_0,\gamma}(\Omega) \times L^2_{\sigma+\lambda}(\Omega), \tag{1.31}$$

with the inner product

$$\begin{aligned}&\left(\begin{bmatrix}\omega_1\\ \omega_2\\ \theta\end{bmatrix}, \begin{bmatrix}\widehat{\omega}_1\\ \widehat{\omega}_2\\ \widehat{\theta}\end{bmatrix}\right)_{\mathbf{H}_\gamma}\\ &= \left(\mathring{\mathbf{A}}^{\frac12}\omega_1, \mathring{\mathbf{A}}^{\frac12}\widehat{\omega}_1\right)_{L^2(\Omega)} + \left(P_\gamma^{\frac12}\omega_2, P_\gamma^{\frac12}\widehat{\omega}_2\right)_{L^2(\Omega)} + \beta\left(\theta,\widehat{\theta}\right)_{L^2(\Omega)}.\end{aligned} \tag{1.32}$$

- With the above definitions, we then set $\mathcal{A}_\gamma : \mathbf{H}_\gamma \supset D(\mathcal{A}_\gamma) \rightarrow \mathbf{H}_\gamma$ to be

(1.33)
$$\mathcal{A}_\gamma \equiv \begin{pmatrix} \mathbf{I} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & P_\gamma^{-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{I} \end{pmatrix} \begin{pmatrix} 0 & \mathbf{I} & 0 \\ -\mathring{\mathbf{A}} & 0 & (\clubsuit) \\ 0 & -\frac{\alpha}{\beta} A_D(\mathbf{I} - D\gamma_0) & -\frac{\eta}{\beta} A_R \end{pmatrix},$$

$$\text{where } (\clubsuit) \equiv \alpha \left(A_R - \frac{\sigma}{\eta} - \mathring{\mathbf{A}} G_1 \gamma_0 + \lambda \mathring{\mathbf{A}} G_2 \gamma_0 \right),$$

$$\text{with } D(\mathcal{A}_\gamma) = \Big\{ [\omega_1, \omega_2, \theta] \in D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times D(A_R) \cap L^2_{\sigma+\lambda}(\Omega)$$
$$\text{such that } \mathring{\mathbf{A}}\omega_1 + \alpha \mathring{\mathbf{A}} G_1 \gamma_0 \theta - \alpha\lambda \mathring{\mathbf{A}} G_2 \gamma_0 \theta \in H^{-1}_{\Gamma_0,\gamma}(\Omega)$$
$$\text{and } \alpha\, \Delta\omega_2 + \eta \Delta\theta \in L^2_{\sigma+\lambda}(\Omega) \Big\}.$$

If we take the initial data $\left[\omega^0, \omega^1, \theta^0\right]$ to be in $\mathbf{H}_\gamma$, then the coupled system (1.1) becomes the operator theoretic model

(1.34)
$$\frac{d}{dt} \begin{bmatrix} \omega \\ \omega_t \\ \theta \end{bmatrix} = \mathcal{A}_\gamma \begin{bmatrix} \omega \\ \omega_t \\ \theta \end{bmatrix},$$
$$\begin{bmatrix} \omega(0) \\ \omega_t(0) \\ \theta(0) \end{bmatrix} = \begin{bmatrix} \omega^0 \\ \omega^1 \\ \theta^0 \end{bmatrix}.$$

REMARK 1. *For initial data* $\left[\omega^0, \omega^1, \theta^0\right]$ *in* $D(\mathcal{A}_\gamma)$*, the two equations of* (1.1) *may be written pointwise as*

$$P_\gamma \omega_{tt} = -\mathring{\boldsymbol{A}}\omega - \alpha \mathring{\boldsymbol{A}} G_1 \gamma_0 \theta + \alpha\lambda \mathring{\boldsymbol{A}} G_2 \gamma_0 \theta - \alpha \Delta\theta \ \text{ in } H^{-1}_{\Gamma_0,\gamma}(\Omega); \tag{1.35}$$

$$\beta\theta_t = \eta\Delta\theta - \sigma\theta + \alpha\Delta\omega_t \ \text{ in } L^2_{\sigma+\lambda}(\Omega). \tag{1.36}$$

1.3. Previous literature. In recent years, questions related to the controllability and stabilization of thermoelastic plates have drawn considerable attention in the recent past (see [10], [12], [9], [21], [22], and [24]); we shall concentrate here on detailing results of strong and uniform stability related to the present model, that of the two-dimensional Kirchoff plate coupled with the heat equation. This particular model, associated with free boundary conditions, was introduced by J. Lagnese in [12]. In that work, he established the well posedness and exponential stability of (1.1) with γ strictly positive, and with the appropriately chosen feedback mechanisms $[\mathcal{F}_1(\omega_t), \mathcal{F}_2(\omega_t)]$ inserted into the natural boundary conditions of the Kirchoff plate component of the system, viz.

(1.37)
$$\begin{cases} \omega = \dfrac{\partial\omega}{\partial\nu} = 0 \text{ on } (0,\infty) \times \Gamma_0, \\ \\ \Delta\omega + (1-\mu) B_1 \omega + \alpha\theta = \mathcal{F}_1(\omega_t) \text{ on } (0,\infty) \times \Gamma_1, \\ \\ \dfrac{\partial \Delta\omega}{\partial\nu} + (1-\mu)\dfrac{\partial B_2 \omega}{\partial\tau} - \gamma \dfrac{\partial \omega_{tt}}{\partial\nu} + \alpha \dfrac{\partial\theta}{\partial\nu} = \mathcal{F}_2(\omega_t) \text{ on } (0,\infty) \times \Gamma_1; \end{cases}$$

the proof of Lagnese is based on the use of differential multipliers, and it exploits the fact that $\gamma > 0$. Since, from a physical point of view, the thermal effects present should induce some measure of energy dissipation (in fact, one can show the homogeneous system's strong stability by routine methods; see [12, Chap. 7], including the remark at the end of sect. 2.3 on p. 161), a natural question arising in this context is whether the system is actually (uniformly) stable without the boundary feedbacks $\mathcal{F}_1(\omega_t)$, $\mathcal{F}_2(\omega_t)$ in place, i.e., when there are no added mechanical forces. Indeed, in the case $\gamma = 0$ and with different boundary conditions than those in (1.1) imposed upon the system, the answer to the question is in the affirmative and has been provided by several authors. With $\gamma = 0$, J. Kim in [10] showed the uniform stability of (1.1) with the clamped boundary conditions $\omega = \frac{\partial \omega}{\partial \nu} = \theta = 0$ on Γ, as did J. Rivera and R. Racke in [25], who studied the coupled equation with the hinged boundary conditions $\omega = \Delta\omega = \theta = 0$. Also with $\gamma = 0$, Z. Liu and S. Zheng in [21] proved the exponential stability of (1.1) with the boundary conditions

$$\begin{cases} \omega = \dfrac{\partial \omega}{\partial \nu} = 0 \text{ on } (0,\infty) \times \Gamma_0, \\ \\ \omega = \Delta\omega + (1-\mu) B_1 \omega + \alpha\theta = 0 \text{ on } (0,\infty) \times \Gamma_1, \end{cases} \tag{1.38}$$

leaving the case of free boundary conditions as an open question, even in the case $\gamma = 0$. The proof of Liu and Zheng is indirect in the sense that it is based on a contradiction argument applied to the exponential decay stability criterion (due to L. Monauni, R. Nagel, and F. Huang), a criterion essentially dictating the uniform estimate for that part of the resolvent which lies on the imaginary axis. On the other hand, it is now known that the case $\gamma = 0$ is rather special as the corresponding system (at least for certain boundary conditions) generates an *analytic* semigroup (see [20]), a consequence of which will be the exponential stability of the system (recall that the system is strongly stable). Given these results, the question of interest now is whether the given thermoelastic system (without any additional boundary dissipation) is *uniformly* stable in the *nonanalytic* case, viz. $\gamma > 0$, with consequently the elastic part of the system being of hyperbolic character.

A partial answer to the question above was given by the present authors in [2], [3]: with $\gamma > 0$ in (1.1) and the boundary conditions

$$\begin{cases} \omega = (1-\chi) \dfrac{\partial \omega}{\partial \nu} = 0 \\ \\ \chi \left(\Delta\omega + (1-\mu)\, B_1 \omega \right) + \alpha\theta = 0 \end{cases} \qquad \text{on } (0,\infty) \times \Gamma \tag{1.39}$$

replacing the higher order ones for ω which are being considered in this work, where the parameter χ above is either 0 or 1, it is shown that the partial differential equation is uniformly stable with decay estimates which are "robust" with respect to the parameter γ. The proof of this stability result is through an implementation of the multiplier method (see [11] a for treatise of this technique), with an operator theoretic quantity taken as the particular multiplier of choice.

The main goal of the present paper is to provide an affirmative answer to the question of uniform stability of (1.1) with the free boundary conditions in place, again with $\gamma > 0$. The fact that the presence of these higher order boundary conditions greatly complicates the analysis was duly noted in [21], and the arguments employed in that work do not carry over for plates with free boundary conditions, even when $\gamma = 0$.

Like our earlier work in [2], [3], the proof of uniform decay here is "direct," based on pseudodifferential (or operator theoretic) multipliers, in contrast to the contradiction argument supplied in [21] for the case $\gamma = 0$ and clamped boundary conditions. In addition, our direct proof, making use as it does of the multiplier method, carries the advantage of providing explicit estimates of the decay rates. However, an application of the multiplier method alone is *not* enough to obtain the desired inequalities for the equation (1.1) in the case when free boundary conditions are present. Indeed, in proving the stability result (Theorem 1.3 below) we must couple the use of an operator theoretic multiplier with a decomposition of the solution ω into three separate components, and a subsequent and crucial invocation of recently derived trace regularity results to handle each of these in distinct fashion; in particular, we exploit the observation that the time derivative of one of these components (modulo a change of variable) solves a certain wave equation. This scrutiny of boundary traces for the hyperbolic component ω of the dynamics is a sine qua non for obtaining the necessary estimates for uniform decay. Finally, we must emphasize that the acute difficulty of the problem which necessitates the use of microlocally derived trace estimates is owing solely to the specific boundary conditions being considered here and does not appear for other combinations of lower order boundary conditions.

1.4. Statement of the results. We shall begin by giving preliminary results regarding the well posedness of the system (1.1) and the regularity of its solutions.

THEOREM 1.1 (well posedness). *Again with the parameter $\gamma > 0$, $\mathcal{A}_\gamma$, given by* (1.33)*, generates a C_0-semigroup of contractions $\left\{e^{\mathcal{A}_\gamma t}\right\}_{t\geq 0}$ on the energy space $\boldsymbol{H}_\gamma$; therefore for initial data $\left[\omega^0, \omega^1, \theta^0\right]$ in $\boldsymbol{H}_\gamma$, the solution $[\omega, \omega_t, \theta]$ to* (1.34)*, and consequently to* (1.1)*, is given by*

$$\left[\begin{array}{c} \omega \\ \omega_t \\ \theta \end{array}\right] = e^{\mathcal{A}_\gamma(\cdot)} \left[\begin{array}{c} \omega^0 \\ \omega^1 \\ \theta^0 \end{array}\right] \in C([0,T], \boldsymbol{H}_\gamma). \tag{1.40}$$

The following regularity result is needed to justify the computations performed below.

THEOREM 1.2. *For initial data $\left[\omega^0, \omega^1, \theta^0\right] \in D\left(\mathcal{A}_\gamma^2\right)$, we have the following:*

(i) *the solution $[\omega, \omega_t, \theta]$ to* (1.1) *is an element of $C([0,T]; H^4(\Omega) \times H^3(\Omega) \times H^2(\Omega))$.*

(ii) $\omega - \gamma G_2 \gamma_1 \omega_{tt} + \alpha G_1 \gamma_0 \theta - \alpha\lambda G_2 \gamma_0 \theta \in C([0,T];\, D(\boldsymbol{\mathring{A}}))$.

Our main result is as follows.

THEOREM 1.3 (uniform stability). *With $\gamma > 0$, the solution $[\omega, \omega_t, \theta]$ of* (1.1) *decays exponentially; that is to say, there exist constants $\delta > 0$ and $M_\delta \geq 1$ such that for all $t > 0$,*

$$\left\| \left[\begin{array}{c} \omega(t) \\ \omega_t(t) \\ \theta(t) \end{array}\right] \right\|_{\boldsymbol{H}_\gamma} \leq M_\delta e^{-\delta t} \left\| \left[\begin{array}{c} \omega^0 \\ \omega^1 \\ \theta^1 \end{array}\right] \right\|_{\boldsymbol{H}_\gamma}. \tag{1.41}$$

REMARK 2. *The estimates obtained in Theorem* 1.3 *are not uniform with respect to the parameter $\gamma > 0$. Indeed, the arguments used in the proof break down when $\gamma = 0$, and consequently the estimates leading to the statement in Theorem* 1.3 *blow up when $\gamma \to 0$. This is due to technicalities of the proof which rely on the strict hyperbolicity of the model (a property which is lost in the limit case $\gamma = 0$). On the other hand, in the case $\gamma = 0$, it has been recently shown in* [27] *that the thermoelastic*

system with free boundary conditions generates an analytic semigroup. Therefore, a posteriori (recalling the strong stability of the system), we conclude that uniform stability holds true also for the case $\gamma = 0$. However, these estimates cannot be reconstructed as a limiting case of the present problem when $\gamma > 0$. This is unlike the case of other boundary conditions associated with this model (see [3]*).*

2. Proofs. The proofs of well posedness and of regularity (Theorems 1.1 and 1.2) are by now fairly routine (see [12, Chap. 7] for related well posedness/regularity results). However, since these preliminaries are critical for our ultimate end of uniform stability, we provide their concise proofs for the sake of completeness.

2.1. Proof of Theorem 1.1. In establishing the semigroup generation of $\mathcal{A}_\gamma$, we will show that the conditions of the Lumer–Phillips theorem are satisfied; namely, we demonstrate here that $\mathcal{A}_\gamma$ is maximal dissipative.

To show the dissipativity of $\mathcal{A}_\gamma$: for $[\omega_1, \omega_2, \theta] \in D(\mathcal{A}_\gamma)$ we have

(2.1)
$$\left(\mathcal{A}_\gamma \begin{bmatrix} \omega_1 \\ \omega_2 \\ \theta \end{bmatrix}, \begin{bmatrix} \omega_1 \\ \omega_2 \\ \theta \end{bmatrix} \right)_{\mathbf{H}_\gamma}$$

$$= \left(\mathring{\mathbf{A}}^{\frac{1}{2}} \omega_2, \mathring{\mathbf{A}}^{\frac{1}{2}} \omega_1 \right)_{L^2(\Omega)}$$

$$+ \left(P_\gamma^{\frac{1}{2}} P_\gamma^{-1} \left(-\mathring{\mathbf{A}} \omega_1 + \alpha A_R \theta - \frac{\alpha\sigma}{\eta} \theta - \alpha \mathring{\mathbf{A}} G_1 \gamma_0 \theta + \alpha\lambda \mathring{\mathbf{A}} G_2 \gamma_0 \theta \right), P_\gamma^{\frac{1}{2}} \omega_2 \right)_{L^2(\Omega)}$$

$$-\alpha \left(A_D (\mathbf{I} - D\gamma_0) \omega_2, \theta \right)_{L^2(\Omega)} - \left(\eta A_R \theta, \theta \right)_{L^2(\Omega)};$$

using the characterizations in (1.4) and (1.20), along with the equality posted in (2.23), we have upon the taking of adjoints that

$$(2.1) = \left(\mathring{\mathbf{A}}^{\frac{1}{2}} \omega_2, \mathring{\mathbf{A}}^{\frac{1}{2}} \omega_1 \right)_{L^2(\Omega)} - \left\langle \mathring{\mathbf{A}} \omega_1, \omega_2 \right\rangle_{\left[D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \right]' \times D(\mathring{\mathbf{A}}^{\frac{1}{2}})}$$

$$+\alpha \left(A_R \theta - \frac{\sigma}{\eta} \theta, \omega_2 \right)_{L^2(\Omega)} - \alpha \left(\theta, \frac{\partial \omega_2}{\partial \nu} \right)_{L^2(\Gamma_1)} - \alpha\lambda \left(\theta, \omega_2 \right)_{L^2(\Gamma_1)}$$

$$-\alpha \left(A_D (\mathbf{I} - D\gamma_0) \omega_2, \theta \right)_{L^2(\Omega)} - \left(\eta A_R \theta, \theta \right)_{L^2(\Omega)}$$

$$= \left(\mathring{\mathbf{A}}^{\frac{1}{2}} \omega_2, \mathring{\mathbf{A}}^{\frac{1}{2}} \omega_1 \right)_{L^2(\Omega)} - \left(\mathring{\mathbf{A}}^{\frac{1}{2}} \omega_1, \mathring{\mathbf{A}}^{\frac{1}{2}} \omega_2 \right)_{L^2(\Omega)} - \alpha \left(\Delta\theta, \omega_2 \right)_{L^2(\Omega)}$$

$$-\alpha \left(\theta, \frac{\partial \omega_2}{\partial \nu} \right)_{L^2(\Gamma_1)} - \alpha\lambda \left(\theta, \omega_2 \right)_{L^2(\Gamma_1)} + \alpha \left(\Delta\omega_2, \theta \right)_{L^2(\Omega)} + \left(\eta\Delta\theta - \sigma\theta, \theta \right)_{L^2(\Omega)}$$

$$= \left(\mathring{\mathbf{A}}^{\frac{1}{2}} \omega_2, \mathring{\mathbf{A}}^{\frac{1}{2}} \omega_1 \right)_{L^2(\Omega)} - \left(\mathring{\mathbf{A}}^{\frac{1}{2}} \omega_1, \mathring{\mathbf{A}}^{\frac{1}{2}} \omega_2 \right)_{L^2(\Omega)} + \alpha \left(\nabla\theta, \nabla\omega_2 \right)_{L^2(\Omega)}$$

$$-\alpha \left(\nabla\omega_2, \nabla\theta \right)_{L^2(\Omega)} - \eta \left\| \nabla\theta \right\|^2_{L^2(\Omega)} - \lambda\eta \left\| \theta \right\|^2_{L^2(\Gamma)} - \sigma \left\| \theta \right\|^2_{L^2(\Omega)}$$

$$(2.2) \leq 0$$

(here, we are using the fact that $\frac{\partial\theta}{\partial\nu} = -\lambda\theta$); i.e., $\mathcal{A}_\gamma$ is dissipative.

To show the maximality of $\mathcal{A}_\gamma$: if for some $\xi > 0$ and arbitrary $[f_1, f_2, f_3] \in \mathbf{H}_\gamma$, $[\omega_1, \omega_2, \theta] \in D(\mathcal{A}_\gamma)$ solves the equation

$$(\xi \mathbf{I} - \mathcal{A}_\gamma) \begin{bmatrix} \omega_1 \\ \omega_2 \\ \theta \end{bmatrix} = \begin{bmatrix} f_1 \\ f_2 \\ f_3 \end{bmatrix}, \tag{2.3}$$

then this relation holds if and only if

(2.4)

$$\begin{cases} \xi\omega_1 - \omega_2 = f_1 \ \text{ in } D(\mathring{\mathbf{A}}^{\frac{1}{2}}), \\ \\ \xi\omega_2 + P_\gamma^{-1}\left(\mathring{\mathbf{A}}\omega_1 + \alpha\mathring{\mathbf{A}}G_1\gamma_0\theta - \alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\theta - \alpha A_R\theta + \dfrac{\alpha\sigma}{\eta}\theta\right) = f_2 \ \text{ in } H^1_{\Gamma_0,\gamma}(\Omega), \\ \\ \xi\theta + \dfrac{\alpha}{\beta}A_D(\mathbf{I} - D\gamma_0)\omega_2 + \dfrac{\eta}{\beta}A_R\theta = f_3 \ \text{ in } L^2_{\sigma+\lambda}(\Omega) \end{cases}$$

$$\Longleftrightarrow$$

(2.5)

$$\begin{cases} \xi^3 P_\gamma\omega_1 + \xi\mathring{\mathbf{A}}\omega_1 + \alpha\xi\mathring{\mathbf{A}}G_1\gamma_0\theta - \alpha\lambda\xi\mathring{\mathbf{A}}G_2\gamma_0\theta - \alpha\xi A_R\theta + \dfrac{\alpha\xi\sigma}{\eta}\theta \\ \qquad = \xi P_\gamma f_2 + \xi^2 P_\gamma f_1 \ \text{ in } H^{-1}_{\Gamma_0,\gamma}(\Omega), \\ \\ \alpha\xi A_D(\mathbf{I} - D\gamma_0)\omega_1 + \beta\xi\theta + \eta A_R\theta = \beta f_3 + \alpha A_D(\mathbf{I} - D\gamma_0)f_1 \text{ in } L^2(\Omega). \end{cases}$$

At this point we bring forth the following proposition.

PROPOSITION 2.1. *The operator* $\boldsymbol{F}$ *defined by*

$$\boldsymbol{F} \equiv \begin{bmatrix} \xi^3 P_\gamma + \xi\boldsymbol{\mathring{A}} & \alpha\xi\boldsymbol{\mathring{A}}G_1\gamma_0 - \alpha\lambda\xi\boldsymbol{\mathring{A}}G_2\gamma_0 - \alpha\xi A_R + \dfrac{\alpha\xi\sigma}{\eta}\boldsymbol{I} \\ \alpha\xi A_D(\boldsymbol{I} - D\gamma_0) & \beta\xi\boldsymbol{I} + \eta A_R \end{bmatrix} \tag{2.6}$$

is an element of $\mathcal{L}(D(\boldsymbol{\mathring{A}}^{1/2}) \times H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega), [D(\boldsymbol{\mathring{A}}^{1/2})]' \times [H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega)]')$ *and is boundedly invertible.*

Proof of Proposition 2.1. Easily, from the definitions of the operators which make up the components of $\mathbf{F}$, all of which are given in section 1.2, we deduce that $\mathbf{F}$ is bounded in the asserted topology. Moreover, we note by Green's theorem that for arbitrary $\theta \in D(A_R)$ and $\omega \in D(\mathring{\mathbf{A}}^{1/2})$,

$$\left\langle A_R\theta + \alpha\lambda\xi\mathring{\mathbf{A}}G_2\gamma_0, \omega \right\rangle_{[D(\mathring{\mathbf{A}}^{\frac{1}{2}})]' \times D(\mathring{\mathbf{A}}^{\frac{1}{2}})} = (\nabla\theta, \nabla\omega)_{L^2(\Omega)} + \frac{\sigma}{\eta}(\theta, \omega)_{L^2(\Gamma)}; \tag{2.7}$$

the characterization (1.13) and an extension by continuity will then have that (2.7) holds for all θ in $H^1(\Omega)$, and so for θ in $H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega)$. (2.7) in turn, when coupled with (2.23), (1.24), (1.14), (1.20), and Green's formula will provide the following coercivity inequality for all $[\omega, \theta] \in D(\mathring{\mathbf{A}}^{1/2}) \times H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega)$:

$$\begin{aligned} \left\langle \mathbf{F}\begin{bmatrix} \omega \\ \theta \end{bmatrix}, \begin{bmatrix} \omega \\ \theta \end{bmatrix} \right\rangle &= \xi^3 \|\omega\|^2_{L^2(\Omega)} + \xi^3\gamma \|\nabla\omega\|^2_{L^2(\Omega)} + \xi \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} \\ &\quad -\alpha\xi(\nabla\theta, \nabla\omega)_{L^2(\Omega)} + \alpha\xi(\nabla\theta, \nabla\omega)_{L^2(\Omega)} \\ &\quad +\eta\|\nabla\theta\|^2_{L^2(\Omega)} + \lambda\eta\|\theta\|^2_{L^2(\Gamma)} + (\sigma + \beta\xi)\|\theta\|^2_{L^2(\Omega)} \\ &\quad \text{(after noting the cancellation of boundary terms)} \\ &\geq C\left[\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} + \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}\right] \end{aligned} \tag{2.8}$$

(where $\langle\cdot,\cdot\rangle$ in (2.8) denotes the pairing between $D(\mathring{\mathbf{A}}^{1/2})\times H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)$ and its dual, and where the constant $C>0$). Thus, by Lax–Milgram, $\mathbf{F}^{-1}$ exists as an element of

$$\mathcal{L}\left(\left[D(\mathring{\mathbf{A}}^{\frac{1}{2}})\right]'\times\left[H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)\right]', D(\mathring{\mathbf{A}}^{\frac{1}{2}})\times H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)\right),$$

and the Proposition is proved.

To complete the proof of the maximality of $\mathcal{A}_\gamma$, we apply the inverse assured by Proposition 2.1 to both sides of (2.5) to obtain

$$\begin{cases}\begin{bmatrix}\omega_1\\ \theta\end{bmatrix}\equiv\mathbf{F}^{-1}\begin{bmatrix}\xi P_\gamma f_2+\xi^2 P_\gamma f_1\\ \beta f_3+\alpha A_D(\mathbf{I}-D\gamma_0)f_1\end{bmatrix},\\ \omega_2\equiv\xi\omega_1-f_1,\end{cases}\tag{2.9}$$

and a fortiori, one has, by using the second equation in (2.5), that

$$A_R\theta=-\frac{\beta\xi}{\eta}\theta-\frac{\alpha\xi}{\eta}A_D(\mathbf{I}-D\gamma_0)\omega_1+\frac{\beta}{\eta}f_3+\frac{\alpha}{\eta}A_D(\mathbf{I}-D\gamma_0)f_1\ \in L^2(\Omega),$$

viz. $\theta\in D(A_R)\cap L^2_{\sigma+\lambda}(\Omega)$. This additional regularity of θ, in conjunction with that implied in the first equation of (2.5) (namely, $\mathring{\mathbf{A}}\omega_1+\alpha\mathring{\mathbf{A}}G_1\gamma_0\theta-\alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\theta\in H^{-1}_{\Gamma_0,\gamma}(\Omega)$) and along with the third equation of (2.4), gives that our constructively acquired solution $[\omega_1,\omega_2,\theta]$ to (2.3) is in $D(\mathcal{A}_\gamma)$ as defined in (1.33). Hence, $\mathcal{A}_\gamma$ is maximal dissipative and the proof of Theorem 1.1 is complete.

2.2. Proof of Theorem 1.2. By definition, if $\left[\omega^0,\omega^1,\theta^0\right]\in D\left(\mathcal{A}_\gamma\right)$, then $\omega^1\in D(\mathring{\mathbf{A}}^{1/2})$ and $\theta^0\in D(A_R)$, and

$$\mathring{\mathbf{A}}\omega^0+\alpha\mathring{\mathbf{A}}G_1\gamma_0\theta^0-\alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\theta^0=g\in H^{-1}_{\Gamma_0,\gamma}(\Omega)=\left[D(\mathring{\mathbf{A}}^{\frac{1}{4}})\right]';\tag{2.10}$$

as $\mathring{\mathbf{A}}^{-1}:[D(\mathring{\mathbf{A}}^{1/4})]'\to D(\mathring{\mathbf{A}}^{3/4})\subset H^3(\Omega)$ (this containment deduced by the last characterization in (1.4)), we have after applying $\mathring{\mathbf{A}}^{-1}$ to (2.10), the use of trace theory and the regularity posted in (1.19) that

$$\omega^0=\mathring{\mathbf{A}}^{-1}g-\alpha G_1\gamma_0\theta^0+\alpha\lambda G_2\gamma_0\theta^0\in H^3(\Omega).\tag{2.11}$$

Thus for $\left[\omega^0,\omega^1,\theta^0\right]\in D\left(\mathcal{A}^2_\gamma\right)$,

(2.12)

$$\mathcal{A}_\gamma\begin{bmatrix}\omega^0\\ \omega^1\\ \theta^0\end{bmatrix}=\begin{bmatrix}\omega^1\\ P_\gamma^{-1}\left[-\mathring{\mathbf{A}}\omega^0-\alpha\mathring{\mathbf{A}}G_1\gamma_0\theta^0+\alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\theta^0+\alpha\left(A_R\theta^0-\frac{\sigma}{\eta}\theta^0\right)\right]\\ -\frac{\eta}{\beta}A_R\theta^0-\frac{\alpha}{\beta}A_D(\mathbf{I}-D\gamma_0)\omega^1\end{bmatrix}\in D\left(\mathcal{A}_\gamma\right),$$

and (2.12) coupled with (2.11) implies that

$$\omega^1\in H^3(\Omega).\tag{2.13}$$

Moreover, (2.12) also has that

$$P_\gamma^{-1}\left[\mathring{\mathbf{A}}\omega^0+\alpha\mathring{\mathbf{A}}G_1\gamma_0\theta^0-\alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\theta^0-\alpha\left(A_R\theta^0-\frac{\sigma}{\eta}\theta^0\right)\right]=g, \tag{2.14}$$

where $g\in D(\mathring{\mathbf{A}}^{1/2})$, or equivalently

$$\mathring{\mathbf{A}}\omega^0+\gamma\mathring{\mathbf{A}}G_2\gamma_1 g+\alpha\mathring{\mathbf{A}}G_1\gamma_0\theta^0-\alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\theta^0=g-\gamma\Delta g-\alpha\Delta\theta^0\in L^2(\Omega), \tag{2.15}$$

after using (1.29). A fortiori then, $\omega^0+\gamma G_2\gamma_1 g+\alpha G_1\gamma_0\theta^0-\alpha\lambda G_2\gamma_0\theta^0\in D(\mathring{\mathbf{A}})\subset H^4(\Omega)$. But trace theory and the smoothing specified in (1.19) give that $G_2\gamma_1 g$, $G_1\gamma_0\theta^0$ and $G_2\gamma_0\theta^0\in H^4(\Omega)$, and thus $D(\mathcal{A}_\gamma^2)\subset H^4(\Omega)\times H^3(\Omega)\times H^2(\Omega)$ with the inclusion being continuous. The solution $[\omega,\omega_t,\theta]$ will consequently have the asserted regularity upon consideration of the fundamental property that for $\xi\geq 0$, $\left[\omega^0,\omega^1,\theta^0\right]\in D\left(\mathcal{A}_\gamma^\xi\right)\Rightarrow$

$$\begin{bmatrix}\omega\\ \omega_t\\ \theta\end{bmatrix}=e^{\mathcal{A}_\gamma(\cdot)}\begin{bmatrix}\omega^0\\ \omega^1\\ \theta^0\end{bmatrix}\in C\left([0,T];D\left(\mathcal{A}_\gamma^\xi\right)\right)\ . \tag{2.16}$$

To prove (ii), we note that with $\left[\omega^0,\omega^1,\theta^0\right]\in D\left(\mathcal{A}_\gamma^2\right)$, $\omega_{tt}\in C([0,T];D(\mathring{\mathbf{A}}^{1/2}))$, so the solution $[\omega,\omega_t,\theta]$ to (1.1) satisfies

$$-\mathring{\mathbf{A}}\omega+\gamma\mathring{\mathbf{A}}G_2\gamma_1\omega_{tt}-\alpha\mathring{\mathbf{A}}G_1\gamma_0\theta+\alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\theta=\omega_{tt}-\gamma\Delta\omega_{tt}+\alpha\Delta\theta \tag{2.17}$$

in $C([0,T];\,L^2(\Omega))$, which establishes the result. □

REMARK 3. *Because of the regularity result posted in Theorem* 1.2 (ii)*, we have for sufficiently smooth initial data the valid pointwise representation*

$$\omega_{tt}+\Delta^2\omega-\gamma\Delta\omega_{tt}+\alpha\Delta\theta=0. \tag{2.18}$$

REMARK 4. *If either λ or $\sigma>0$, then for initial data $\left[\omega^0,\omega^1,\theta^0\right]\in D\left(\mathcal{A}_\gamma^2\right)$, we will also have that the solution component θ of* 1.1 *is in $C([0,T];H^3(\Omega))$. In fact, the last component on the right-hand side of* (2.12)*, the definition of $D\left(\mathcal{A}_\gamma\right)$, and* (2.13) *give that*

$$A_R\theta^0=h+\frac{\alpha}{\eta}\Delta\omega^1\in H^1(\Omega), \tag{2.19}$$

where $h\in H^2(\Omega)$. Applying ${A_R}^{-1}$ (which exists for λ or $\sigma>0$) to both sides of (2.19) *thus yields*

$$\theta^0\in H^3(\Omega), \tag{2.20}$$

and the result will follow from the semigroup property posted in (2.16).

2.3. Proof of Theorem 1.3. In proving Theorem 1.3, we begin with a preliminary energy identity.

LEMMA 2.2. *Again, with initial data $\left[\omega^0,\omega^1,\theta^0\right]\in\boldsymbol{H}_\gamma$, we have that the component θ of the solution of* (1.1) *is an element of $L^2\left(0,\infty;H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)\right)$; indeed, we have the following relation $\forall\ T>0$:*

$$-2\eta\int_0^T\|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}\,dt=E_\gamma(T)-E_\gamma(0), \tag{2.21}$$

where the "energy" $E_\gamma(t)$ is defined by

$$E_\gamma(t) \equiv \left\| \mathring{\boldsymbol{A}}^{\frac{1}{2}} \omega(t) \right\|^2_{L^2(\Omega)} + \left\| P_\gamma^{\frac{1}{2}} \omega_t(t) \right\|^2_{L^2(\Omega)} + \|\theta\|^2_{L^2_{\sigma+\lambda}(\Omega)}, \tag{2.22}$$

and where the norm of $H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega)$ is as defined in (1.14).

Proof. Starting with initial data in $D(\mathcal{A}_\gamma)$ which will provide $\forall\ T > 0$ that the solution $[\omega, \omega_t, \theta] \in C([0,T]; D(\mathcal{A}_\gamma))$ and $[\omega_t, \omega_{tt}, \theta_t] \in C([0,T]; \mathbf{H}_\gamma)$, we have pointwise on $(0,T)$

$$\frac{d}{dt} \left\| \begin{bmatrix} \omega(t) \\ \omega_t(t) \\ \theta(t) \end{bmatrix} \right\|^2_{\mathbf{H}_\gamma} = 2 \left(\mathcal{A}_\gamma \begin{bmatrix} \omega(t) \\ \omega_t(t) \\ \theta(t) \end{bmatrix}, \begin{bmatrix} \omega(t) \\ \omega_t(t) \\ \theta(t) \end{bmatrix} \right)_{\mathbf{H}_\gamma},$$

and for this special choice of initial data we will have the desired equality (2.21) upon integration and using the fact from (1.12) that

$$\begin{aligned} (A_R\theta, \theta)_{L^2(\Omega)} &= \left(-\Delta\theta + \frac{\sigma}{\eta}\theta, \theta \right)_{L^2(\Omega)} \\ &= \|\nabla\theta\|^2_{L^2(\Omega)} + \frac{\sigma}{\eta} \|\theta\|^2_{L^2(\Omega)} + \lambda \|\theta\|^2_{L^2(\Gamma)} \quad \text{for } \theta \in D(A_R). \end{aligned} \tag{2.23}$$

The asserted L^2-regularity follows immediately from (2.21), using the norm definition (1.14) for $H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega)$, and the fact that $\left\{ e^{\mathcal{A}_\gamma t} \right\}_{t \geq 0}$ is a contraction semigroup. A density argument concludes the proof. □

REMARK 5. *J. Lagnese in* [12] *first showed the dissipativity property* (2.21) *through a formal integration and a subsequent justification through variational arguments, and the alternate proof is included here as a simple consequence of contractive semigroups.*

We next derive a trace regularity result for the model under consideration here, a regularity which does not follow from the standard Sobolev trace theory, and which is critical in our estimates of uniform decay. We note that related trace regularity results for Euler–Bernoulli plates were proved in [18] and for Kirchoff plates in [14].

LEMMA 2.3. *One has the component ω of the solution $[\omega, \omega_t, \theta]$ of* (1.1) *satisfies $\Delta\omega|_{\Gamma_0} \in L^2(0,T; L^2(\Gamma_0))$ with the estimate*

$$\begin{aligned} \int_0^T \|\Delta\omega\|^2_{L^2(\Gamma_0)}\, dt \leq C \Bigg(\int_0^T \left[\left\| \mathring{\boldsymbol{A}}^{\frac{1}{2}} \omega \right\|^2_{L^2(\Omega)} + \left\| P_\gamma^{\frac{1}{2}} \omega_t \right\|^2_{L^2(\Omega)} + \|\theta\|^2_{H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega)} \right] dt \\ + E_\gamma(T) + E_\gamma(0) \Bigg), \end{aligned} \tag{2.24}$$

where C does not depend on the parameter γ.

Proof. If we take initial data $\left[\omega^0, \omega^1, \theta^0\right]$ in $D(\mathcal{A}_\gamma^2)$, then Theorem 1.2 provides that $[\omega, \omega_t, \theta]$ is a classical pointwise solution of (1.1). We will work to extract the desired estimate (2.24) in this special case—and consequently for all initial data after an extension by continuity—by multiplying the first equation of (1.1) by the quantity $h \cdot \nabla\omega$, where $h(x,y) \equiv [h_1(x,y), h_2(x,y)]$ is a $\left[C^2(\overline{\Omega})\right]^2$ vector field[1] which satisfies

$$h|_\Gamma = \begin{cases} [\nu_1, \nu_2] & \text{on } \Gamma_0, \\ 0 & \text{on } \Gamma_1, \end{cases} \tag{2.25}$$

[1]Here is where we use the fact that Γ_0 and Γ_1 are separated.

followed by an integration from 0 to T; i.e., we will work with the equation

$$\int_0^T \left(\omega_{tt} - \gamma\Delta\omega_{tt} + \Delta^2\omega + \alpha\Delta\theta, h\cdot\nabla\omega\right)_{L^2(\Omega)} dt = 0. \tag{2.26}$$

(i) First,

$$\begin{aligned}
&\int_0^T (\omega_{tt}, h\cdot\nabla\omega)_{L^2(\Omega)}\, dt = (\omega_t, h\cdot\nabla\omega)_{L^2(\Omega)}\Big|_0^T - \int_0^T (\omega_t, h\cdot\nabla\omega_t)_{L^2(\Omega)}\, dt \\
&= (\omega_t, h\cdot\nabla\omega)_{L^2(\Omega)}\Big|_0^T - \frac{1}{2}\int_0^T\int_\Omega \operatorname{div}\left(\omega_t^2 h\right) dtd\Omega \\
&\quad + \frac{1}{2}\int_0^T\int_\Omega \omega_t^2\left[h_{1x} + h_{2y}\right] dtd\Omega \\
&= (\omega_t, h\cdot\nabla\omega)_{L^2(\Omega)}\Big|_0^T + \frac{1}{2}\int_0^T\int_\Omega \omega_t^2\left[h_{1x} + h_{2y}\right] dtd\Omega,
\end{aligned} \tag{2.27}$$

after making use of the divergence theorem and the fact that $\omega_t = 0$ on Γ_0.

(ii) Next,

$$\begin{aligned}
&\int_0^T (-\Delta\omega_{tt}, h\cdot\nabla\omega)_{L^2(\Omega)}\, dt \\
&= (\nabla\omega_t, \nabla(h\cdot\nabla\omega))_{L^2(\Omega)}\Big|_0^T - \int_0^T (\nabla\omega_t, \nabla(h\cdot\nabla\omega_t))_{L^2(\Omega)}\, dt \\
&= (\nabla\omega_t, \nabla(h\cdot\nabla\omega))_{L^2(\Omega)}\Big|_0^T - \frac{1}{2}\int_0^T\int_\Omega \operatorname{div}\left(|\nabla\omega_t|^2 h\right) dtd\Omega \\
&\quad - \int_0^T\int_\Omega \left[\frac{\omega_{tx}^2 h_{1x}}{2} + \frac{\omega_{ty}^2 h_{2y}}{2}\right] dtd\Omega - \int_0^T\int_\Omega \left[\omega_{tx}\omega_{ty}h_{2x} + \omega_{tx}\omega_{ty}h_{1y}\right] dtd\Omega \\
&\quad + \int_0^T\int_\Omega \left[\frac{\omega_{tx}^2 h_{2y}}{2} + \frac{\omega_{ty}^2 h_{1x}}{2}\right] dtd\Omega \\
&= (\nabla\omega_t, h\cdot\nabla\omega)_{L^2(\Omega)}\Big|_0^T \\
&\quad + \int_0^T\int_\Omega \left[\frac{\omega_{tx}^2 h_{2y}}{2} + \frac{\omega_{ty}^2 h_{1x}}{2} - \frac{\omega_{tx}^2 h_{1x}}{2} - \frac{\omega_{ty}^2 h_{2y}}{2}\right] dtd\Omega \\
&\quad - \int_0^T\int_\Omega \left[\omega_{tx}\omega_{ty}h_{2x} + \omega_{tx}\omega_{ty}h_{1y}\right] dtd\Omega,
\end{aligned} \tag{2.28}$$

after again using the divergence theorem and the fact that

$$\int_\Omega \operatorname{div}\left(|\nabla\omega_t|^2 h\right) d\Omega = \int_{\Gamma_0} |\nabla\omega_t|^2\, d\Gamma_0 = 0 (\text{as } \omega_t(t) \in H^2_{\Gamma_0}(\Omega)).$$

(iii) To handle the fourth-order term, we use Green's theorem (1.5), the given boundary conditions of (1.1), (2.25), and the fact that $\omega \in H^2_{\Gamma_0}(\Omega)$ to obtain

(2.29)
$$\int_0^T \left(\Delta^2\omega, h\cdot\nabla\omega\right)_{L^2(\Omega)} dt = \int_0^T a\left(\omega, h\cdot\nabla\omega\right) dt$$
$$+\alpha\int_0^T\int_{\Gamma_1} \theta\cdot\frac{\partial h\cdot\nabla\omega}{\partial\nu}\, d\Gamma_1 dt \;-\int_0^T\int_{\Gamma_0}\left(\Delta\omega + (1-\mu)B_1\omega\right)\frac{\partial^2\omega}{\partial\nu^2}\, d\Gamma_0 dt.$$

We note at this point that we can rewrite the first term on the right-hand side of (2.29) as

(2.30)
$$\int_0^T a\left(\omega, h\cdot\nabla\omega\right) dt = \frac{1}{2}\int_0^T\int_\Omega h\cdot\nabla\left[\omega_{xx}^2+\omega_{yy}^2+2\mu\omega_{xx}\omega_{yy}+2(1-\mu)\omega_{xy}^2\right] dtd\Omega$$
$$+\mathcal{O}\left(\int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} dt\right),$$

where $\mathcal{O}(\int_0^T \|\mathring{\mathbf{A}}^{1/2}\omega\|^2_{L^2(\Omega)}dt)$ denotes a series of terms which can be majorized by the $L^2(0,T;D(\mathring{\mathbf{A}}^{1/2}))$-norm of ω; we consequently have by the divergence theorem that

$$\int_0^T a\left(\omega, h\cdot\nabla\omega\right) dt =$$
$$\frac{1}{2}\int_0^T\int_\Omega h\cdot\nabla\left[\omega_{xx}^2+\omega_{yy}^2+2\mu\omega_{xx}\omega_{yy}+2(1-\mu)\omega_{xy}^2\right] dtd\Omega$$
$$+\mathcal{O}\left(\int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} dt\right)$$
$$= \frac{1}{2}\int_0^T\int_\Omega \text{ div }\left\{h\left[\omega_{xx}^2+\omega_{yy}^2+2\mu\omega_{xx}\omega_{yy}+2(1-\mu)\omega_{xy}^2\right]\right\}$$
(2.31)
$$+\,\mathcal{O}\left(\int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} dt\right)$$
$$= \frac{1}{2}\int_0^T\int_{\Gamma_0}\left[\omega_{xx}^2+\omega_{yy}^2+2\mu\omega_{xx}\omega_{yy}+2(1-\mu)\omega_{xy}^2\right] dtd\Gamma_0$$
$$+\mathcal{O}\left(\int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} dt\right)$$
$$= \frac{1}{2}\int_0^T\int_{\Gamma_0}(\Delta\omega)^2\, dt + \mathcal{O}\left(\int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} dt\right),$$

where in the last step above, we have used the fact (as reasoned in [12, Ch. 4] that $\omega|_{\Gamma_0} = \frac{\partial\omega}{\partial\nu}|_{\Gamma_0} = 0$ implies that $\omega_{xx}^2+\omega_{yy}^2+2\mu\omega_{xx}\omega_{yy}+2(1-\mu)\omega_{xy}^2 = (\Delta\omega)^2$ on Γ_0.

To handle the last term on the right-hand side of (2.29), we note that $B_1\omega = 0$ on Γ_0, which implies that

$$\Delta\omega = \Delta\omega + (1-\mu)B_1\omega = \frac{\partial^2\omega}{\partial\nu^2} \text{ on } \Gamma_0 \ ; \tag{2.32}$$

we consequently have upon the insertion of (2.31) into (2.29), as well as by the consideration of (2.32), that

$$\begin{aligned}\int_0^T \left(\Delta^2\omega, h\cdot\nabla\omega\right)_{L^2(\Omega)} dt &= -\frac{1}{2}\int_0^T \|\Delta\omega\|^2_{L^2(\Gamma_0)}\, dt \\ +\alpha\int_0^T\int_{\Gamma_1} \theta\cdot\frac{\partial h\cdot\nabla\omega}{\partial\nu}\, d\Gamma_1 dt &+ \mathcal{O}\left(\int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} dt\right).\end{aligned} \tag{2.33}$$

(iv) To handle the last term on the left-hand side of equation (2.26), we again use Green's theorem and the boundary conditions posted in (1.1) to obtain

$$\int_0^T (\Delta\theta, h\cdot\nabla\omega)_{L^2(\Omega)}\, dt = -\int_0^T (\nabla\theta, \nabla\,(h\cdot\nabla\omega))_{L^2(\Omega)}\, dt. \tag{2.34}$$

To finish the proof, we rewrite (2.26) by collecting the relations given above in (2.27), (2.28), (2.33), and (2.34) to attain the desired inequality (2.24), upon the taking of norms and a subsequent majorization. □

In showing the exponential decay of the semigroup $\left\{e^{\mathcal{A}_\gamma t}\right\}_{t\geq 0}$ (Theorem 1.3) it will suffice as usual, to prove that there exists a time $0 < T < \infty$ which satisfies for all initial data in $\mathbf{H}_\gamma$,

$$E_\gamma(T) \leq \xi E_\gamma(0) \text{ with } \xi < 1. \tag{2.35}$$

By a density argument, it will then be enough by Lemma 2.2 *to show the existence of a time* T, $0 < T < \infty$, *and a positive constant* C_T *(independent of* γ*) for initial data in* $\left[\omega^0, \omega^1, \theta^0\right] \in D\left(\mathcal{A}_\gamma^2\right)$ *such that*

$$E_\gamma(T) \leq C_T \int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}\, dt, \tag{2.36}$$

to which end we will proceed to work.

2.4. Proof of inequality (2.36). Because of Theorem 1.2, we have for initial data $\left[\omega^0, \omega^1, \theta^0\right] \in D\left(\mathcal{A}_\gamma^2\right)$ a classical pointwise solution $[\omega, \omega_t, \theta]$ of (1.1); we can thus multiply the first equation in (1.1) by $A_D^{-1}\theta$ and integrate in time and space to obtain

$$\int_0^T \left(\omega_{tt} - \gamma\Delta\omega_{tt} + \Delta^2\omega + \alpha\Delta\theta, A_D^{-1}\theta\right)_{L^2(\Omega)} dt = 0; \tag{2.37}$$

the bulk of the work from here on out will be the scrutiny of the left-hand side of this equation.

(A.1) *Dealing with* $\int_0^T \left(\omega_{tt} - \gamma\Delta\omega_{tt}, A_D^{-1}\theta\right)_{L^2(\Omega)} dt$. Using an integration by parts, the second differential equation of (1.1) and the fact that $A_R\theta = -\Delta\theta + \frac{\sigma}{\eta}\theta = -\Delta\theta +$

$\Delta D\gamma_0\theta + \frac{\sigma}{\eta}\theta = A_D(\mathbf{I} - D\gamma_0)\theta + \frac{\sigma}{\eta}\theta$ produce

$$
\begin{aligned}
&\int_0^T \left(\omega_{tt} - \gamma\Delta\omega_{tt}, A_D^{-1}\theta\right)_{L^2(\Omega)} dt \\
&= \left(\omega_t, A_D^{-1}\theta\right)_{L^2(\Omega)}\Big|_0^T + \gamma\left(\nabla\omega_t, \nabla A_D^{-1}\theta\right)_{L^2(\Omega)}\Big|_0^T \\
&\quad - \int_0^T \left[\left(\omega_t, A_D^{-1}\theta_t\right)_{L^2(\Omega)} + \gamma\left(\nabla\omega_t, \nabla A_D^{-1}\theta_t\right)_{L^2(\Omega)}\right] dt \\
&= \alpha\beta^{-1}\int_0^T \left[\|\omega_t\|^2_{L^2(\Omega)} + \gamma\|\nabla\omega_t\|^2_{L^2(\Omega)}\right] dt \\
&\quad -\alpha\beta^{-1}\int_0^T \left[\left(\omega_t, D\gamma_0\omega_t\right)_{L^2(\Omega)} + \gamma\left(\nabla\omega_t, \nabla D\gamma_0\omega_t\right)_{L^2(\Omega)}\right] dt \\
&\quad +\eta\beta^{-1}\int_0^T \left[\left(\omega_t, (\mathbf{I} - D\gamma_0)\theta\right)_{L^2(\Omega)} + \gamma\left(\nabla\omega_t, \nabla(\mathbf{I} - D\gamma_0)\theta\right)_{L^2(\Omega)}\right] dt \\
&\quad +\sigma\beta^{-1}\int_0^T \left[\left(\omega_t, A_D^{-1}\theta\right)_{L^2(\Omega)} + \gamma\left(\nabla\omega_t, \nabla A_D^{-1}\theta\right)_{L^2(\Omega)}\right] dt \\
&\quad + \left(\omega_t, A_D^{-1}\theta\right)_{L^2(\Omega)}\Big|_0^T + \gamma\left(\nabla\omega_t, \nabla A_D^{-1}\theta\right)_{L^2(\Omega)}\Big|_0^T .
\end{aligned}
\tag{2.38}
$$

A further integration by parts, an application of Green's theorem (1.5) to the term $\int_0^T (\nabla\omega_t, \nabla D\gamma_0\omega_t)_{L^2(\Omega)}\, dt$, and a consideration of the boundary conditions posted in (1.1) yield

$$
\begin{aligned}
&-\gamma\int_0^T (\nabla\omega_t, \nabla D\gamma_0\omega_t)_{L^2(\Omega)}\, dt \\
&= -\gamma\left(\nabla\omega_t, \nabla D\gamma_0\omega\right)_{L^2(\Omega)}\Big|_0^T + \gamma\int_0^T \left(\nabla\omega_{tt}, \nabla D\gamma_0\omega\right)_{L^2(\Omega)} dt \\
&= -\gamma\left(\nabla\omega_t, \nabla D\gamma_0\omega\right)_{L^2(\Omega)}\Big|_0^T - \gamma\int_0^T \left(\Delta\omega_{tt}, D\gamma_0\omega\right)_{L^2(\Omega)} dt \\
&\quad +\gamma\int_0^T \left(\frac{\partial\omega_{tt}}{\partial\nu}, \gamma_0\omega\right)_{L^2(\Gamma_1)} dt \\
&= -\gamma\left(\nabla\omega_t, \nabla D\gamma_0\omega\right)_{L^2(\Omega)}\Big|_0^T - \int_0^T \left(\omega_{tt} + \Delta^2\omega + \alpha\Delta\theta, D\gamma_0\omega\right)_{L^2(\Omega)} dt \\
&\quad +\gamma\int_0^T \left(\frac{\partial\omega_{tt}}{\partial\nu}, \gamma_0\omega\right)_{L^2(\Gamma_1)} dt \\
&= -\gamma\left(\nabla\omega_t, \nabla D\gamma_0\omega\right)_{L^2(\Omega)}\Big|_0^T - \left(\omega_t, D\gamma_0\omega\right)_{L^2(\Omega)}\Big|_0^T + \int_0^T \left(\omega_t, D\gamma_0\omega_t\right)_{L^2(\Omega)} dt \\
&\quad - \int_0^T a\left(D\gamma_0\omega, \omega\right) dt - \int_0^T \left(\alpha\theta, \frac{\partial D\gamma_0\omega}{\partial\nu}\right)_{L^2(\Gamma_1)} dt - \int_0^T \left(\Delta\omega, \frac{\partial D\gamma_0\omega}{\partial\nu}\right)_{L^2(\Gamma_0)} dt \\
&\quad +\alpha\int_0^T \left(\nabla\theta, \nabla D\gamma_0\omega\right)_{L^2(\Omega)} dt.
\end{aligned}
\tag{2.39}
$$

Given that $D\gamma_0 \in \mathcal{L}(H^s(\Omega))$ for all real s and further using the fact that A_D^{-1} is "smoothing," viz. $\left\|A_D^{-1}\theta\right\|_{H^2(\Omega)} \leq C\left\|\theta\right\|_{L^2(\Omega)}$, we have the following estimates for the solution $[\omega, \omega_t, \theta]$ of (1.1) corresponding to arbitrary initial data in $\mathbf{H}_\gamma$:

$$\left\|(I - D\gamma_0)\theta\right\|_{L^2(\Omega)} + \left\|A_D^{-1}\theta\right\|_{L^2(\Omega)} \leq C\left\|\theta\right\|_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}; \tag{2.40}$$

$$\left\|\nabla(I - D\gamma_0)\theta\right\|_{L^2(\Omega)} + \left\|\nabla A_D^{-1}\theta\right\|_{L^2(\Omega)} \leq C\left\|\theta\right\|_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}; \tag{2.41}$$

$$\left\|\nabla D\gamma_0\omega\right\|_{L^2(\Omega)} \leq C\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|_{L^2(\Omega)}; \tag{2.42}$$

$$\left\|\frac{\partial D\gamma_0\omega}{\partial\nu}\right\|_{H^{\frac{1}{2}}(\Gamma)} \leq C\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|_{L^2(\Omega)}. \tag{2.43}$$

Thus a substitution of (2.39) into (2.38) and a subsequent majorization which makes use of the inequalities (2.40)–(2.43) will give the estimate

(2.44)

$$\begin{aligned}
&\left|\int_0^T \left(\omega_{tt} - \gamma\Delta\omega_{tt}, A_D^{-1}\theta\right)_{L^2(\Omega)} dt - \alpha\beta^{-1}\int_0^T \left[\left\|\omega_t\right\|^2_{L^2(\Omega)} + \gamma\left\|\nabla\omega_t\right\|^2_{L^2(\Omega)}\right] dt\right| \\
&\leq C\int_0^T \left[\left\|\omega_t\right\|_{L^2(\Omega)}\left\|\theta\right\|_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)} + \gamma\left\|\nabla\omega_t\right\|_{L^2(\Omega)}\left\|\theta\right\|_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}\right] dt \\
&\quad + C\left[E_\gamma(0) + E_\gamma(T)\right] + \left|\int_0^T a\left(D\gamma_0\omega, \omega\right) dt\right| \\
&\quad + \left|\int_0^T \left(\Delta\omega, \frac{\partial D\gamma_0\omega}{\partial\nu}\right)_{L^2(\Gamma_0)} dt\right| \\
&\leq \epsilon\int_0^T \left[\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} + \left\|\omega_t\right\|^2_{L^2(\Omega)} + \gamma\left\|\nabla\omega_t\right\|^2_{L^2(\Omega)}\right] dt + C_\epsilon\int_0^T \left\|\theta\right\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)} dt \\
&\quad + C\left[E_\gamma(0) + E_\gamma(T)\right] + \frac{\alpha}{\beta}\left|\int_0^T a\left(D\gamma_0\omega, \omega\right) dt\right| \\
&\quad + \frac{\alpha}{\beta}\left|\int_0^T \left(\Delta\omega, \frac{\partial D\gamma_0\omega}{\partial\nu}\right)_{L^2(\Gamma_0)} dt\right|,
\end{aligned}$$

where the constants C and C_ϵ do not depend on γ, $0 < \gamma \leq M$.

(A.2) *Dealing with* $\int_0^T \left(\Delta^2\omega, A_D^{-1}\theta\right) dt$. Yet another application of Green's theorem in (1.5) and the use of the enforced boundary conditions in (1.1) give

$$\begin{aligned}
\int_0^T \left(\Delta^2\omega, A_D^{-1}\theta\right) dt &= \int_0^T a\left(\omega, A_D^{-1}\theta\right) dt - \int_0^T \left(\Delta\omega, \frac{\partial A_D^{-1}\theta}{\partial\nu}\right)_{L^2(\Gamma_0)} dt \\
&\quad + \alpha\int_0^T \left(\theta, \frac{\partial A_D^{-1}\theta}{\partial\nu}\right)_{L^2(\Gamma_1)} dt.
\end{aligned} \tag{2.45}$$

Estimating the right-hand side of (2.45) yields, after the use of trace theory, elliptic regularity and the mean inequality,

$$\begin{aligned}
&\left|\int_0^T \left(\Delta^2\omega, A_D^{-1}\theta\right) dt\right| \\
&\leq C_0 \int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|_{L^2(\Omega)} \|\theta\|_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)} dt \\
&\quad + \frac{\epsilon}{2C}\int_0^T \|\Delta\omega\|^2_{L^2(\Gamma_0)} dt + C_\epsilon \int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)} dt \\
&\quad \text{(where the inverted } C \text{ is the same constant present in (2.24))} \\
&\leq\ C_0 \int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|_{L^2(\Omega)} \|\theta\|_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)} dt \\
&\quad + \frac{\epsilon}{2}\left[\int_0^T \left(\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} + \left\|P_\gamma^{\frac{1}{2}}\omega_t\right\|^2_{L^2(\Omega)}\right) dt + \right. \\
&\quad \left. + E_\gamma(0) + E_\gamma(T)\right] + C_\epsilon \int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)} dt \\
&\quad \text{(by Lemma 2.3)} \\
&\leq \epsilon \int_0^T \left[\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} + \left\|P_\gamma^{\frac{1}{2}}\omega_t\right\|^2_{L^2(\Omega)}\right] dt \\
&\quad + C\left[E_\gamma(0) + E_\gamma(T)\right] + C_\epsilon \int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)} dt, \qquad (2.46)
\end{aligned}$$

after the use of the mean inequality.

(A.3) *Dealing with* $\int_0^T \left(\alpha\Delta\theta, A_D^{-1}\theta\right)_{L^2(\Omega)} dt$. Finally, for the last term of (2.37), again using the fact that $A_R\theta = A_D(\mathbf{I} - D\gamma_0)\theta + \frac{\sigma}{\eta}\theta$, we have easily

$$\begin{aligned}
&\alpha\int_0^T \left(A_D(\mathbf{I} - D\gamma_0)\theta + \frac{\sigma}{\eta}\theta, A_D^{-1}\theta\right)_{L^2(\Omega)} dt \\
&\quad = \alpha\int_0^T \left[\|\theta\|^2_{L^2(\Omega)} - (D\gamma_0\theta, \theta)_{L^2(\Omega)} + \left(\frac{\alpha\sigma}{\eta}A_D^{-1}\theta, \theta\right)_{L^2(\Omega)}\right] dt \qquad (2.47) \\
&\quad \leq C\int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}\,.
\end{aligned}$$

(A.4) *Combining* (2.37), (2.44), (2.46)*, and* (2.47) *thus results in the following.* For $\epsilon > 0$ small enough there exists a constant $C > 0$ (independent of γ) such that the solution $[\omega, \omega_t, \theta]$ of (1.1) satisfies

$$\begin{aligned}
&\left(\frac{\alpha}{\beta} - 2\epsilon\right)\int_0^T \left[\|\omega_t\|^2_{L^2(\Omega)} + \gamma\|\nabla\omega_t\|^2_{L^2(\Omega)}\right] dt \\
&\leq C\left[\int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)} dt + E_\gamma(T) + E_\gamma(0)\right] \\
&\quad + 2\epsilon\int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} dt + \frac{\alpha}{\beta}\left|\int_0^T a\left(D\gamma_0\omega, \omega\right) dt\right| \\
&\quad + \frac{\alpha}{\beta}\left|\int_0^T \left(\Delta\omega, \frac{\partial D\gamma_0\omega}{\partial\nu}\right)_{L^2(\Gamma_0)} dt\right|, \qquad (2.48)
\end{aligned}$$

where the noncrucial dependence of C upon ϵ has not been noted.

(A.5) *Estimating the residual terms* $|\int_0^T a(D\gamma_0\omega,\omega)dt|$ and $|\int_0^T(\Delta\omega,\frac{\partial D\gamma_0\omega}{\partial\nu})_{L^2(\Gamma_0)}dt|$.[2] At this point we will find it advantageous to consider a decomposition of the solution component $[\omega,\omega_t]$ into $\omega=\omega^{(1)}+\omega^{(2)}+\omega^{(3)}$ (again with the corresponding initial data $[\omega_0,\omega_1]\in D(\mathcal{A}_\gamma^2)$), where the $\omega^{(i)}$ solve, respectively,

$$\begin{cases} -\gamma\Delta\omega_{tt}^{(1)}+\Delta^2\omega^{(1)}=-\alpha\Delta\theta \ \text{ on } (0,\infty)\times\Omega, \\ \omega^{(1)}=\dfrac{\partial\omega^{(1)}}{\partial\nu}=0 \ \text{ on } (0,\infty)\times\Gamma_0, \\ \begin{cases} \Delta\omega^{(1)}+(1-\mu)B_1\omega^{(1)}+\alpha\theta=0 \\ \dfrac{\partial\Delta\omega^{(1)}}{\partial\nu}+(1-\mu)\dfrac{\partial B_2\omega^{(1)}}{\partial\tau}-\gamma\dfrac{\partial\omega_{tt}^{(1)}}{\partial\nu}=0 \end{cases} \text{on } (0,\infty)\times\Gamma_1, \\ \omega^{(1)}(t=0)=\omega_t^{(1)}(t=0)=0; \end{cases} \tag{2.49}$$

$$\begin{cases} -\gamma\Delta\omega_{tt}^{(2)}+\Delta^2\omega^{(2)}=-\omega_{tt} \ \text{ on } (0,\infty)\times\Omega; \\ \omega^{(2)}=\dfrac{\partial\omega^{(2)}}{\partial\nu}=0 \ \text{ on } (0,\infty)\times\Gamma_0; \\ \begin{cases} \Delta\omega^{(2)}+(1-\mu)B_1\omega^{(2)}=0 \\ \dfrac{\partial\Delta\omega^{(2)}}{\partial\nu}+(1-\mu)\dfrac{\partial B_2\omega^{(2)}}{\partial\tau}-\gamma\dfrac{\partial\omega_{tt}^{(2)}}{\partial\nu}+\alpha\dfrac{\partial\theta}{\partial\nu}=0 \end{cases} \text{on } (0,\infty)\times\Gamma_1; \\ \omega^{(2)}(t=0)=\omega_t^{(2)}(t=0)=0. \end{cases} \tag{2.50}$$

$$\begin{cases} -\gamma\Delta\omega_{tt}^{(3)}+\Delta^2\omega^{(3)}=0 \ \text{ on } (0,\infty)\times\Omega; \\ \omega^{(3)}=\dfrac{\partial\omega^{(3)}}{\partial\nu}=0 \ \text{ on } (0,\infty)\times\Gamma_0; \\ \begin{cases} \Delta\omega^{(3)}+(1-\mu)B_1\omega^{(3)}=0 \\ \dfrac{\partial\Delta\omega^{(3)}}{\partial\nu}+(1-\mu)\dfrac{\partial B_2\omega^{(3)}}{\partial\tau}-\gamma\dfrac{\partial\omega_{tt}^{(3)}}{\partial\nu}=0 \end{cases} \text{on } (0,\infty)\times\Gamma_1; \\ \omega^{(3)}(0)=\omega^0; \ \ \omega_t^{(3)}(0)=\omega^1. \end{cases} \tag{2.51}$$

Through a semigroup formulation, the well posedness of (2.50) and (2.51) can be handled just as easily as the entire system (1.1); to wit, defining on the state space

[2]Notice that at this point, one might be tempted to straightaway majorize $\int_0^T a\,(D\gamma_0\omega,\omega)\,dt$ so as to obtain something like $|\int_0^T a(D\gamma_0\omega,\omega)|dt\le C\int_0^T\|\mathbf{\mathring{A}}^{1/2}\omega(t)\|^2_{L^2(\Omega)}dt$. However, this will not suffice as we do not have control over the constant C (C may not be small $<<1$). Therefore, we need a different, more complex argument which will culminate in the estimate (2.72) below; likewise for the term $|\int_0^T(\Delta\omega,\frac{\partial D\gamma_0\omega}{\partial\nu})_{L^2(\Gamma_0)}dt|$.

$D(\mathring{\mathbf{A}}^{1/2}) \times H^1_{\Gamma_0,\gamma}(\Omega)$ the operator $\widetilde{\mathcal{A}}_\gamma$ as

$$\widetilde{\mathcal{A}}_\gamma \equiv \begin{pmatrix} 0 & \mathbf{I} \\ -\widetilde{P}_\gamma^{-1}\mathring{\mathbf{A}} & 0 \end{pmatrix} \tag{2.52}$$

$$(\text{where } \widetilde{P}_\gamma \equiv \gamma A_N \in \mathcal{L}(H^1_{\Gamma_0,\gamma}(\Omega), H^{-1}_{\Gamma_0,\gamma}(\Omega))) \tag{2.53}$$

$$\text{with domain } D(\widetilde{\mathcal{A}}_\gamma) = \left\{ [\omega_1, \omega_2] \in D(\mathring{\mathbf{A}}^{\frac{3}{4}}) \times D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \right\}; \tag{2.54}$$

then with the same degree of effort as in the proof of Theorem 1.1, we can show that $\widetilde{\mathcal{A}}_\gamma$ generates a unitary C_0-group $\{e^{\widetilde{\mathcal{A}}_\gamma t}\}_{t\geq 0}$ on $D(\mathring{\mathbf{A}}^{1/2}) \times H^1_{\Gamma_0,\gamma}(\Omega)$ (note we are using the knowledge that $\widetilde{P}_\gamma^{-1}$ exists, inasmuch as A_N is elliptic on $H^1_{\Gamma_0,\gamma}(\Omega)$, and that $\widetilde{P}_\gamma = \gamma\left(\Delta + \mathring{\mathbf{A}}G_2\gamma_1\right)$ from (1.29)). Consequently we have that $\omega^{(2)} \in C([0,T]\,; D(\mathring{\mathbf{A}}^{1/2}) \times H^1_{\Gamma_0,\gamma}(\Omega))$, with this unique solution of (2.50) written explicitly as

$$\begin{bmatrix} \omega^{(2)}(t) \\ \omega_t^{(2)}(t) \end{bmatrix} = \int_0^t e^{\widetilde{\mathcal{A}}_\gamma(t-s)} \begin{bmatrix} 0 \\ \widetilde{P}_\gamma^{-1}\left(-\omega_{tt}(s) + \alpha\lambda\mathring{\mathbf{A}}G_2\gamma_0\theta(s)\right) \end{bmatrix} ds, \tag{2.55}$$

where again ω_{tt} is the second time derivative of the solution component ω. Recall that we are taking the initial data $\left[\omega^0, \omega^1, \theta^0\right]$ to be in $D(\mathcal{A}_\gamma^2)$, and so $\omega_{tt} \in C\left([0,T]\,; H^1_{\Gamma_0,\gamma}(\Omega)\right)$. Moreover, for arbitrary initial data, $\theta \in L^2(0,T; H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega))$, by Lemma 2.2, and this regularity, coupled with the facts contained in (1.17), (1.19), and (1.4), provide that $\mathring{\mathbf{A}}G_2\gamma_0\theta(t) \in L^2(0,T; H^{-1}_{\Gamma_0,\gamma}(\Omega))$. Hence the formula (2.55) is well defined. Likewise, $\omega^{(3)} \in C([0,T]\,; D(\mathring{\mathbf{A}}^{1/2}) \times H^1_{\Gamma_0,\gamma}(\Omega))$ with

$$\omega^{(3)}(t) = e^{\widetilde{\mathcal{A}}_\gamma t} \begin{bmatrix} \omega^0 \\ \omega^1 \end{bmatrix}. \tag{2.56}$$

Regarding the well posedness of the system (2.49), we have the following result from [14] and [13].

REGULARITY THEOREM. *For arbitrary initial data* $[\omega_0, \omega_1] \in D(\mathring{\mathbf{A}}^{1/2}) \times H^1_{\Gamma_0,\gamma}(\Omega)$, *parameter* $\xi \geq 0$, $f \in L^2(0,T; H^{-1}_{\Gamma_0,\gamma}(\Omega))$, *and* $g \in L^2(0,T; H^{1/2}(\Gamma_1))$, *the following system is well posed*:

$$\begin{cases} \xi\omega_{tt} - \gamma\Delta\omega_{tt} + \Delta^2\omega = f \ \text{ on } (0,\infty)\times\Omega; \\ \omega = \dfrac{\partial\omega}{\partial\nu} = 0 \ \text{ on } (0,\infty)\times\Gamma_0; \\ \begin{cases} \Delta\omega + (1-\mu)B_1\omega = g \\ \dfrac{\partial\Delta\omega}{\partial\nu} + (1-\mu)\dfrac{\partial B_2\omega}{\partial\tau} - \gamma\dfrac{\partial\omega_{tt}}{\partial\nu} = 0 \end{cases} \text{on } (0,\infty)\times\Gamma_1; \\ \omega(0) = \omega_0, \ \ \omega_t(0) = \omega_1, \end{cases} \tag{2.57}$$

with the solution $[\omega, \omega_t] \in C([0,T]\,; D(\mathring{\mathbf{A}}^{1/2}) \times H^1_{\Gamma_0,\gamma}(\Omega))$.

To make use of the above theorem for the resolution of (2.49) with arbitrary θ in $H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega)$ subject to Robin boundary conditions, we note that $-\Delta =$

$A_R - \frac{\sigma}{\eta} \in \mathcal{L}(H^1(\Omega), \left[H^1(\Omega)\right]')$ and consequently $\Delta\theta \in L^2(0,T; H^{-1}_{\Gamma_0,\gamma}(\Omega))$; moreover, $\theta|_\Gamma \in L^2(0,T; H^{1/2}(\Gamma))$ by the trace theorem, and so the regularity theorem will give us that

$$\omega^{(1)} \in C([0,T]\,; D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)), \tag{2.58}$$

with the pointwise estimate

$$\begin{aligned} \left\| \begin{array}{c} \omega^{(1)}(t) \\ \omega^{(1)}_t(t) \end{array} \right\|^2_{D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)} &\leq C \left[\int_0^T \|\Delta\theta(t)\|^2_{H^{-1}_{\Gamma_0,\gamma}(\Omega)}\, dt + \alpha \int_0^T \|\theta(t)\|^2_{H^{\frac{1}{2}}(\Gamma_1)}\, dt \right] \\ &\leq C \int_0^T \|\theta(t)\|^2_{H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega)}\, dt. \end{aligned} \tag{2.59}$$

A simple uniqueness argument which makes use of the regularity theorem verifies that indeed the solution component $\omega \equiv \omega^{(1)} + \omega^{(2)} + \omega^{(3)}$. Moreover, concerning the explicit representation (2.55), an integration by parts has that

$$\begin{aligned} &\int_0^t e^{\widetilde{\mathcal{A}}_\gamma (t-s)} \left[\begin{array}{c} 0 \\ \widetilde{P}^{-1}_\gamma \omega_{tt}(s) \end{array} \right] ds = e^{\widetilde{\mathcal{A}}_\gamma (t-s)} \left[\begin{array}{c} 0 \\ \widetilde{P}^{-1}_\gamma \omega_t(s) \end{array} \right] \Big|_0^t \\ &+ \int_0^t e^{\widetilde{\mathcal{A}}_\gamma (t-s)} \widetilde{\mathcal{A}}_\gamma \left[\begin{array}{c} 0 \\ \widetilde{P}^{-1}_\gamma \omega_t(s) \end{array} \right] ds \\ &= e^{\widetilde{\mathcal{A}}_\gamma (t-s)} \left[\begin{array}{c} 0 \\ \widetilde{P}^{-1}_\gamma \omega_t(s) \end{array} \right] \Big|_0^t - \int_0^t e^{\widetilde{\mathcal{A}}_\gamma (t-s)} \left[\begin{array}{c} \widetilde{P}^{-1}_\gamma \omega_t(s) \\ 0 \end{array} \right] ds, \end{aligned} \tag{2.60}$$

where the last equality above makes sense pointwise in $[D(\widetilde{\mathcal{A}_\gamma}^*)]' = [D(\mathring{\mathbf{A}}^{\frac{3}{4}})]' \times [D(\mathring{\mathbf{A}}^{1/2})]'$; hence upon majorizing (2.55) with the expression (2.60) in mind (and using the contraction of the semigroup $\{e^{\widetilde{\mathcal{A}}_\gamma (t)}\}_{t \geq 0}$), we have

$$\left\| \begin{array}{c} \omega^{(2)}(t) \\ \omega^{(2)}_t(t) \end{array} \right\|^2_{D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)} \leq C_T \left[\|\theta\|^2_{L^2(0,T; H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega))} + \|\omega_t\|^2_{C([0,T]; L^2(\Omega))} \right]. \tag{2.61}$$

Thus, using (2.59), (2.61), and the explicit representation (2.56), we have

$$\left\| \left[\begin{array}{c} \omega^{(1)}(t) + \omega^{(2)}(t) \\ \omega^{(1)}(t) + \omega^{(2)}_t(t) \end{array} \right] \right\|^2_{D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)}$$

$$\leq C_T \left[\|\theta\|^2_{L^2(0,T; H^1(\Omega) \cap L^2_{\sigma+\lambda}(\Omega))} + \|\omega_t\|^2_{C([0,T]; L^2(\Omega))} \right]; \tag{2.62}$$

$$\left\| \left[\begin{array}{c} \omega^{(3)}(t) \\ \omega^{(3)}_t(t) \end{array} \right] \right\|^2_{D(\mathring{\mathbf{A}}^{\frac{1}{2}}) \times H^1_{\Gamma_0,\gamma}(\Omega)} \leq E_\gamma(0). \tag{2.63}$$

Further analyzing $\omega^{(3)}$, if we make the substitution $z \equiv \Delta\omega^{(3)}$, we then note that z solves the wave equation

$$\gamma z_{tt} = \Delta z, \tag{2.64}$$

with $[z, z_t] \in C([0,T]; L^2(\Omega) \times H^{-1}(\Omega))$. Consequently, the recent regularity result of [26] (specifically, apply Theorem 3 therein together with Remark 2.3 and the remark after Theorem 9 in [26]) reveals that z has a "trace" on Γ with a positive constant $C(T,\gamma)$ and a $\rho > 0$ such that the following estimate holds:[3]

$$\| z|_\Gamma \|_{L^2(0,T;H^{-\frac{1}{2}+\rho}(\Gamma))} \le C(T,\gamma) \, \| [z, z_t] \|_{C([0,T];L^2(\Omega)\times H^{-1}(\Omega))}; \tag{2.65}$$

and as pointwise we have

$$\|z(t)\|^2_{L^2(\Omega)} + \|z_t(t)\|^2_{H^{-1}(\Omega)} \le C E_\gamma(0) \tag{2.66}$$

(from the estimate (2.63)), we end up with

$$\left\| \Delta\omega^{(3)}\Big|_\Gamma \right\|^2_{L^2(0,T;H^{-\frac{1}{2}+\rho}(\Gamma))} \le C(T,\gamma) E_\gamma(0). \tag{2.67}$$

Recall that $\omega^{(3)}$, as the solution of (2.51), satisfies

$$\Delta\omega^{(3)} - (1-\mu)\frac{\partial^2 \omega^{(3)}}{\partial \tau^2} = (1-\mu)\kappa \frac{\partial \omega^{(3)}}{\partial \nu} \quad \text{on } (0,T)\times\Gamma_1, \tag{2.68}$$

where κ denotes the curvature, and so (2.68), coupled with the estimates (2.67) and

$$\left\| \frac{\partial \omega^{(3)}}{\partial \nu} \right\|_{C([0,T];H^{\frac{1}{2}}(\Gamma_1))} \le C \left\| \omega^{(3)} \right\|_{C([0,T];H^2(\Omega))} \le C(T) E_\gamma(0),$$

gives that $\dfrac{\partial^2 \omega^{(3)}}{\partial \tau^2} \in L^2(0,T; H^{-\frac{1}{2}+\rho}(\Gamma_1))$ with

$$\left\| \frac{\partial^2 \omega^{(3)}}{\partial \tau^2} \right\|_{L^2(0,T;H^{-\frac{1}{2}+\rho}(\Gamma_1))} \le C(T,\gamma) E_\gamma(0), \tag{2.69}$$

and (2.69) is in turn equivalent to

$$\left\| \gamma_0 \omega^{(3)} \right\|_{L^2(0,T;H^{\frac{3}{2}+\rho}(\Gamma_1))} \le C(T,\gamma) E_\gamma(0). \tag{2.70}$$

REMARK 6. *The estimate in* (2.70) *can also be derived independently of Tataru's result in* [26] *by decomposing problem* (2.51) *microlocally into respective elliptic and hyperbolic parts. In the elliptic sector, we can use standard elliptic regularity and the boundary conditions on* Γ_1 *to deduce the regularity of the trace* $\gamma_0\omega^{(3)}$ *in* $H^2(0, T\times\Gamma_1)$. *In the hyperbolic sector, we apply the transformation* $z \equiv \Delta\omega^{(3)}$, *and we are subsequently led to the study of the wave equation with its forcing term in* $L^2(0,T;H^{-1}(\Omega))$ *(due to microlocalization). The arguments presented in* [16] *and* (*see also* [17]) *apply to the hyperbolic sector specifically and provide the estimate* (2.70) *valid in that sector. Combining elliptic and hyperbolic estimates yields* (2.70) *with the value of* ρ *being at least* $\frac{1}{10}$. *Instead, the estimate obtained by using Tataru's result* [26] *leads to the optimal value of* $\rho = \frac{1}{6}$.

[3] We note that the value of ρ depends on the geometry; however, we *always* have $\rho > 0$.

Given this extra regularity for the trace of $\omega^{(3)}\big|_{\Gamma_1}$, we can hence invoke a classical PDE interpolation inequality to finally obtain

(2.71)

$$\left\|\gamma_0\omega^{(3)}\right\|^2_{L^2(0,T;H^{\frac{3}{2}}(\Gamma_1))} \leq C(T,\gamma)^{-1}\left\|\gamma_0\omega^{(3)}\right\|^2_{L^2(0,T;H^{\frac{3}{2}+\rho}(\Gamma_1))}$$

$$+C_{T,\gamma}\left\|\gamma_0\omega^{(3)}\right\|^2_{L^2(0,T;H^{\frac{1}{2}}(\Gamma_1))}$$

(where $C(T,\gamma)$ is as in (2.70), and $C_{T,\gamma}$ denotes another positive constant depending on T and γ)

$$\leq E_\gamma(0) + C_{T,\gamma}\left\|\omega^{(3)}\right\|^2_{L^2(0,T;H^1(\Omega))}$$

(after using the estimate (2.70) and trace theory)

$$\leq E_\gamma(0) + C_{T,\gamma}\left\|\omega\right\|^2_{L^2(0,T;H^1(\Omega))} + C_{T,\gamma}\left\|\omega^{(1)}+\omega^{(2)}\right\|^2_{L^2(0,T;H^1(\Omega))}$$

(after using the decomposition $\omega = \omega^{(1)}+\omega^{(2)}+\omega^{(3)}$)

$$\leq E_\gamma(0) + C_{T,\gamma}\left[\|\theta\|^2_{L^2(0,T;H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega))} + \|\omega\|^2_{L^2(0,T;H^1(\Omega))} + \|\omega_t\|^2_{C([0,T];L^2(\Omega))}\right],$$

after using the inequality (2.62).

With the decomposition of ω in hand, along with its accompanying norm estimates, particularly that of the trace $\gamma_0\omega^{(3)}$ in (2.71), we can now deal with the recalcitrant terms $|\int_0^T a\left(D\gamma_0\omega,\omega\right)dt|$ and $|\int_0^T(\Delta\omega,\frac{\partial D\gamma_0\omega}{\partial\nu})_{L^2(\Gamma_0)}dt|$:

(A5.i) *Dealing with* $\left|\int_0^T a\left(D\gamma_0\omega,\omega\right)dt\right|$:

$$\left|\int_0^T a\left(D\gamma_0\omega,\omega\right)dt\right|$$

$$= \left|\int_0^T a\left(D\gamma_0\left(\omega^{(1)}+\omega^{(2)}+\omega^{(3)}\right),\omega\right)dt\right|$$

$$\leq \int_0^T C\left\|D\gamma_0\left(\omega^{(1)}+\omega^{(2)}+\omega^{(3)}\right)\right\|_{H^2(\Omega)}\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|_{L^2(\Omega)}dt$$

(after using the fact that $D\gamma_0\in\mathcal{L}(H^2(\Omega))$)

$$\leq \epsilon\int_0^T\left\|\mathring{\mathbf{A}}\omega\right\|^2_{L^2(\Omega)}dt + C_{T,\gamma}\left[\int_0^T\|\theta\|^2_{H^1(\Omega)\cap L^2(\Omega)}\,dt + \|\omega\|^2_{L^2(0,T;H^1(\Omega))}\right.$$

$$\left.+\|\omega_t\|^2_{C([0,T];L^2(\Omega))}\right]$$

$$+C\left[E_\gamma(T)+E_\gamma(0)\right], \tag{2.72}$$

after using the boundedness of the Dirichlet map D followed by the standard mean inequality as well as the crucial estimates (2.71) and (2.62) (here we have not noted the noncrucial dependence of ϵ in the constant $C_{T,\gamma}$).

(A.5ii) *Dealing with* $|\int_0^T(\Delta\omega,\frac{\partial D\gamma_0\omega}{\partial\nu})_{L^2(\Gamma_0)}dt|$. By Lemma 2, $\Delta\omega|_{\Gamma_0}\in L^2(0,T;L^2(\Gamma_0))$, and so with this bit of information we have

$$\left|\int_0^T\left(\Delta\omega,\frac{\partial D\gamma_0\omega}{\partial\nu}\right)_{L^2(\Gamma_0)}dt\right|$$

$$\leq C\int_0^T\|\Delta\omega\|_{L^2(\Gamma_0)}\|D\gamma_0\omega\|_{H^2(\Omega)}\,dt$$

(by the trace theorem)

$$
\begin{aligned}
&= C\int_0^T \|\Delta\omega\|_{L^2(\Gamma_0)} \left\| D\gamma_0\left(\omega^{(1)}+\omega^{(2)}+\omega^{(3)}\right)\right\|_{H^2(\Omega)} dt \\
&\le \frac{\epsilon}{C}\int_0^T \|\Delta\omega\|^2_{L^2(\Gamma_0)}\, dt + C_{T,\gamma}\left[\int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2(\Omega)}\, dt + \|\omega\|^2_{L^2(0,T;H^1(\Omega))}\right. \\
&\quad \left. + \|\omega_t\|^2_{C([0,T];L^2(\Omega))}\right] \\
&\quad +C\left[E_\gamma(T)+E_\gamma(0)\right] \\
&\quad \text{(again using the mean inequality followed by (2.71) and (2.62),} \\
&\quad \text{and where the inverted positive constant } C \text{ is that in (2.24))} \\
&\le \epsilon\int_0^T \left[\left\|\mathring{\mathbf{A}}^{\frac12}\omega\right\|^2_{L^2(\Omega)} + \int_0^T \left\|P_\gamma^{\frac12}\omega\right\|^2_{L^2(\Omega)}\right] dt + C_{T,\gamma}\left[\int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2(\Omega)}\, dt\right. \\
&\quad \left. + \|\omega\|^2_{L^2(0,T;H^1(\Omega))} + \|\omega_t\|^2_{C([0,T];L^2(\Omega))}\right] + C\left[E_\gamma(0)+E_\gamma(T)\right]. \qquad (2.73)
\end{aligned}
$$

Combining (2.48), (2.72), and (2.73), we finally have

$$
\begin{aligned}
&\left(\frac{\alpha}{\beta}-3\epsilon\right)\int_0^T \left[\|\omega_t\|^2_{L^2(\Omega)} + \gamma\|\nabla\omega_t\|^2_{L^2(\Omega)}\right] dt \\
&\le 3\epsilon\int_0^T \left\|\mathring{\mathbf{A}}^{\frac12}\omega\right\|^2_{L^2(\Omega)} dt + C_{T,\gamma}\left[\int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}\, dt\right. \\
&\quad \left. + \|\omega\|^2_{L^2(0,T;H^1(\Omega))} + \|\omega_t\|^2_{C([0,T];L^2(\Omega))}\right] \\
&\quad +C\left[E_\gamma(0)+E_\gamma(T)\right]. \qquad (2.74)
\end{aligned}
$$

(B) *Conclusion of the Proof of Theorem* 3. To majorize the norm of the component ω, we multiply (1.35) by ω, integrate from 0 to T and employ Green's theorem to obtain (after accounting for the boundary conditions and using (1.20))

$$
\begin{aligned}
&\left(P_\gamma^{\frac12}\omega_t, P_\gamma^{\frac12}\omega\right)_{L^2(\Omega)}\Big|_0^T - \int_0^T \left\|P_\gamma^{\frac12}\omega_t\right\|^2_{L^2(\Omega)} dt \\
&= -\int_0^T \left\|\mathring{\mathbf{A}}^{\frac12}\omega\right\|^2_{L^2(\Omega)} dt - \alpha\int_0^T \left(\theta, \frac{\partial\omega}{\partial\nu}\right)_{L^2(\Gamma_1)} dt \\
&\quad +\alpha\int_0^T (\nabla\theta, \nabla\omega)_{L^2(\Omega)}\, dt; \qquad (2.75)
\end{aligned}
$$

since by the trace theorem we have pointwise

$$
\begin{aligned}
&\left|\left(\theta, \frac{\partial\omega}{\partial\nu}\right)_{L^2(\Gamma_1)}\right| + \left|(\nabla\theta, \nabla\omega)_{L^2(\Omega)}\right| \\
&\le C\left[\|\theta\|_{H^{\frac12}(\Gamma)}\left\|\frac{\partial\omega}{\partial\nu}\right\|_{H^{\frac12}(\Gamma_1)} + \|\theta\|_{H^1(\Omega)}\|\omega\|_{H^1(\Omega)}\right] \\
&\le C\|\theta\|_{H^1(\Omega)}\|\omega\|_{H^2(\Omega)} \le \epsilon\left\|\mathring{\mathbf{A}}^{\frac12}\omega\right\|^2_{L^2(\Omega)} + C_\epsilon\|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}, \qquad (2.76)
\end{aligned}
$$

we thus arrive at the following.

There exists a constant $C > 0$ such that for $\epsilon > 0$ small enough, the solution $[\omega, \omega_t, \theta]$ of (1.1) satisfies

$$(1-\epsilon)\int_0^T \left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} dt \leq C\int_0^T \left[\|\omega_t\|^2_{L^2(\Omega)} + \gamma\|\nabla\omega_t\|^2_{L^2(\Omega)}\right] dt$$

$$+C\left(\int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}\, dt + E_\gamma(T) + E_\gamma(0)\right), \tag{2.77}$$

where the noncrucial dependence of C upon ϵ has not been noted.

Thus, if ϵ is small enough, we then have, upon combining (2.74) and (2.77), the existence of constants C and $C_{T,\gamma}$ such that

$$\int_0^T \left[\left\|\mathring{\mathbf{A}}^{\frac{1}{2}}\omega\right\|^2_{L^2(\Omega)} + \|\omega_t\|^2_{L^2(\Omega)} + \gamma\|\nabla\omega_t\|^2_{L^2(\Omega)} + \|\theta\|^2_{L^2(\Omega)}\right] dt$$

$$\leq C_{T,\gamma}\int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}\, dt + C\left[E_\gamma(T) + E_\gamma(0)\right]$$

$$+C_{T,\gamma}\left[\|\omega\|^2_{L^2(0,T;H^1(\Omega))} + \|\omega_t\|^2_{C([0,T];L^2(\Omega))}\right]. \tag{2.78}$$

From here, we apply the relation (2.21) and its inherent dissipativity property (that is, $E_\gamma(T) \leq E_\gamma(t)\ \forall\ 0 \leq t \leq T$) to (2.78) to finally attain the preliminary inequality; namely, for $T > 2C$ (with C as in (2.78) independent of T),

$$E_\gamma(T) \leq \frac{C_{T,\gamma} + 2C\eta}{T - 2C}\int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}\, dt$$

$$+C_{T,\gamma}\left[\|\omega\|^2_{L^2(0,T;H^1(\Omega))} + \|\omega_t\|^2_{C([0,T];L^2(\Omega))}\right]. \tag{2.79}$$

A straightforward compactness–uniqueness argument similar to that employed in [15] and [1] will subsequently eliminate the lower order terms in (2.79), viz. we have the following proposition.

PROPOSITION 2.4. *The presence of the inequality* (2.79) *implies that there exists a constant* C_T *which satisfies*

$$\|\omega\|^2_{L^2(0,T;H^1(\Omega))} + \|\omega_t\|^2_{C([0,T];H^2(\Omega))}\, dt \leq C_T\int_0^T \|\theta\|^2_{H^1(\Omega)\cap L^2_{\sigma+\lambda}(\Omega)}\, dt. \tag{2.80}$$

Hence, the inequalities (2.79) and (2.80) give the desired estimate (2.36) (and consequently (2.35)), and so the proof of Theorem 1.3 is now complete.

Note added in proof. As one reads through the arguments in the present paper, he or she gathers the understanding that the key ingredient in our stability proof is the selection of the "right" multiplier $A_D^{-1}\theta$ (which is novel when compared to the standard differential multipliers used in plate theory). This multiplier was first devised in our paper [3] (which initially considered the easier case of the thermoelastic plate with lower order "clamped" or "hinged" boundary conditions), and we have since invoked it in later problems (see [4], [13], [6], [5]. In particular, [4] is a preliminary version

of our present paper). In our present paper, it is this particular choice of multiplier which allows us to obtain sharp results on the uniform stabilization of thermoelastic plates with the higher order "free" boundary conditions in place, results which include the attainment of explicit decay rates.

Related work on this problem includes that of E. Bisognin, V. Bisognin, P. Menzala, and E. Zuazua in [7], who employed an alternative and indirect argument for the stabilization of the nonlinear thermoelastic plate in the case of *clamped/hinged* boundary conditions *only*. This method, even in the case of linear models, yielded weaker results than those posted in [2], [3]. (We assume that at the time of their work the four authors were unaware of [3].) Indeed, the indirect (proof by contradiction) method in [7] has the following shortcomings:

(i) The method requires two different treatments of the problem, corresponding to the respective cases $\gamma > 0$ and $\gamma = 0$. This dichotomy is necessitated by the fact that the accompanying decay rates they obtain blow up as $\gamma \downarrow 0$.

(ii) The decay rates they obtain are not explicit.

(iii) In the specific case $\gamma = 0$, the analyticity of the underlying semigroup is used in an essential way, which precludes the possibility that their indirect method can be adjusted so as to give a unified treatment of the problem for *all* cases $\gamma \geq 0$ (recall that $\gamma > 0$ corresponds to hyperbolic-like dynamics).

In contrast, the paper [3] (which is critical and constitutes a basis for the present paper) obtains decay estimates which are *uniform* in the parameter $\gamma \geq 0$, this being accomplished via the use of the multiplier $A_D^{-1}\theta$. As the authors of [7] were apparently informed much before the date of submission of [23] of this comparison between their work and that in [3] (this is a documented fact), one may then view as perplexing the subsequent appearance of the paper [23], which now claims for itself the right (and much improved with respect to [7]) result using the *very same* techniques and ideas as in [3] (which again are radically different from those in [7]). In particular, [23] uses the same multiplier and the same trace result, the latter being proclaimed therein as "hidden regularity." Perhaps adding to the perplexity is the fact that the two authors in [23], while freely addressing the aforementioned shortcomings of [7], make neither acknowledgment nor reference to [3]. Our main point here is to stress the fact that the critical multiplier and the resulting technique for proving uniform decay rates for thermoelastic plates takes its origin in [2], [3], and not in [23].

STABILITY OF N-FRONTS BIFURCATING FROM A TWISTED HETEROCLINIC LOOP AND AN APPLICATION TO THE FITZHUGH–NAGUMO EQUATION*

BJÖRN SANDSTEDE†

Abstract. In this article, existence and stability of N-front travelling-wave solutions of partial differential equations on the real line is investigated. The N-fronts considered here arise as heteroclinic orbits bifurcating from a twisted heteroclinic loop in the underlying ordinary differential equation describing travelling-wave solutions. It is proved that the N-front solutions are linearly stable provided the fronts building the twisted heteroclinic loop are linearly stable. The result is applied to travelling waves arising in the FitzHugh–Nagumo equation.

Key words. heteroclinic orbits, stability, FitzHugh–Nagumo equation

1. Introduction.

In this article, existence and stability of N-front solutions of parabolic equations

$$U_t = A\,U + F(U,\epsilon), \qquad x \in \mathbb{R} \tag{1.1}$$

on the real line is investigated. Here, the differential operator A generates a C^0-semiflow on $BU(\mathbb{R},\mathbb{R}^m)$—the space of bounded, uniformly continuous functions from $\mathbb{R}$ to $\mathbb{R}^m$—and F is a superposition operator—that is, $F(U,\epsilon)(x)$ depends only on the values of U and possibly derivatives of U at the point x—defined on the same space. Fronts and backs are travelling-wave solutions $U(\xi) = U(x + c\,t)$ which are asymptotically constant for $\xi \to \pm\infty$. Transforming (1.1) into a moving coordinate frame $(x,t) \mapsto (x + c\,t, t) = (\xi, t)$ yields

$$U_t = A\,U - c\,U_\xi + F(U,\epsilon), \qquad \xi \in \mathbb{R}. \tag{1.2}$$

Then fronts and backs of (1.1) with wave speed c correspond to equilibria of (1.2) solving

$$\begin{aligned} A\,U - c\,U_\xi + F(U,\epsilon) &= 0, \\ \lim_{\xi\to\pm\infty} U(\xi) &= U_\pm. \end{aligned} \tag{1.3}$$

Stability of a front U is often determined by the spectrum of the linearized operator

$$L(U)\,V = A\,V - c\,V_\xi + D_U F(U,\epsilon)\,V. \tag{1.4}$$

A front or back is called linearly stable if the spectrum of L is contained in the left half-plane with the exception of a simple eigenvalue at zero which is inevitable due

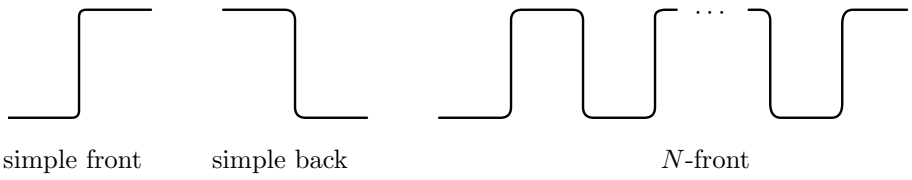

FIG. 1. *N-front solutions consist of* $2N+1$ *concatenated copies of a simple front and back.*

to translational invariance. Under rather general assumptions on A, linear stability implies nonlinear stability; see [Hen81] or [BJ89].

Suppose now that for $(c,\epsilon) = (c_0,\epsilon_0)$ linearly stable front and back waves do exist simultaneously. Then, upon varying $\mu := (c,\epsilon)$, other front solutions may arise. In particular, so-called N-fronts which are formed by alternately concatenating $2N+1$ copies of the simple front and back may bifurcate; see Figure 1. A natural and interesting question is whether the bifurcating N-fronts U_N inherit the linear stability from the simple front and back. For a fairly general class of operators A, it follows from [AGJ90] that the spectrum of $L(U_N)$ is bounded to the left of the imaginary axis except for $2N+1$ eigenvalues near zero. It therefore suffices to calculate these critical eigenvalues, that is, solutions (λ, V) of

$$A\,V - c_N\,V_\xi + D_U F(U_N,\epsilon_N)\,V = \lambda V \tag{1.5}$$

for λ close to zero, where U_N is the N-front existing for $(c,\epsilon) = (c_N,\epsilon_N)$.

Notice that the steady-state equation (1.3) and the eigenvalue problem (1.5) are ordinary differential equations in the time variable ξ. As such they can be written as first-order systems

$$\dot u = f(u,\mu), \qquad \mu = (c,\epsilon), \tag{1.6}$$

$$\dot v = (D_u f(u,\mu) + \lambda B)\,v, \tag{1.7}$$

respectively. Simple fronts and backs of (1.3) correspond to heteroclinic solutions $q_1(\xi)$ and $q_2(\xi)$ of (1.6) connecting two equilibria p_1 and p_2.

In this article, we investigate the existence and stability of N-fronts (and N-backs) under the assumption that the simple heteroclinic orbits q_1 and q_2 form a twisted heteroclinic loop; see Figure 2. Under certain generic assumptions, we prove existence of N-fronts of (1.6) for any $N \geq 1$ and determine all eigenvalues λ of (1.7) with $|\lambda|$ small. The N-fronts are either all stable or all unstable depending only on conditions on the simple front and back solution. The proof relies on a geometric reduction of the flow onto a two-dimensional invariant manifold containing the heteroclinic loop; see [Hom96], [San93], and [San95]. The reduction allows for a smooth linearization of the vector field near both equilibria. The existence of N-fronts is then proved using the Lyapunov–Schmidt reduction for the resulting vector field in $\mathbb{R}^2$ in the spirit of [Lin90] and [San93]. Finally, the critical eigenvalues of the operator (1.5) are calculated using [San96].

Deng [Den91a] proved the existence of N-fronts bifurcating from a twisted heteroclinic loop under the additional assumption that the stable manifolds of the relatively contractive equilibria p_1 and p_2 are one-dimensional using topological methods; see [Den91a, section 7(a)]. Shashkov [Sha92] asserts the existence of N-fronts for two-dimensional vector fields of class C^3, however, without giving a proof.

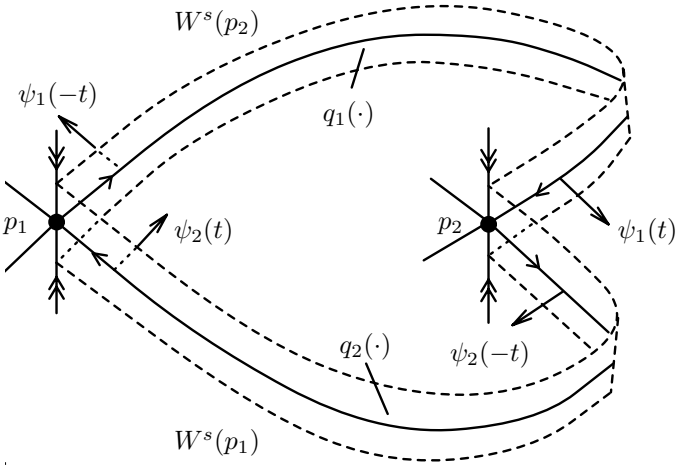

FIG. 2. *A twisted heteroclinic loop. The dashed curves indicate the stable manifolds of the equilibria continued backward in time.*

Finally, we apply the stability result to the FitzHugh–Nagumo equation

$$\begin{aligned} u_t &= u_{xx} + f(u) - w, \\ w_t &= \epsilon(u - \gamma w). \end{aligned}$$

Deng [Den91b] showed that the hypotheses of his existence result [Den91a] are satisfied, while Yanagida [Yan89] proved that the simple front and back are both linearly stable. Nii [Nii95b] proved linear stability of the 1-front provided f is linear near both equilibria. We show that in fact all N-fronts are linearly stable. Recently, Nii (personal communication) announced an extension of his result to N-fronts under the same restrictive hypothesis on f using topological methods.

The paper is organized as follows. In section 2, we state the basic assumptions and the main results about existence and stability of N-front solutions. The existence theorem is proved in section 3, the stability result in section 4. Finally, in section 5, the application to the FitzHugh–Nagumo system is given.

2. Main results. Consider the equation

$$\dot{u} = f(u, \mu), \qquad (u, \mu) \in \mathbb{R}^n \times \mathbb{R}^2, \tag{2.1}$$

where $f : \mathbb{R}^n \times \mathbb{R}^2 \to \mathbb{R}^n$ is C^2. We assume that equation (2.1) possesses two hyperbolic equilibria $p_1(\mu)$ and $p_2(\mu)$ for all μ. Moreover, the spectrum $\sigma(D_u f(p_k(\mu), \mu))$ for $k = 1, 2$ of the linearized vector field at these equilibria decomposes as follows.

(H1) *We assume that* $\dim W^s(p_1(0), 0) = \dim W^s(p_2(0), 0)$ *and*

$$\sigma(D_u f(p_k(\mu), \mu)) = \sigma_k^{ss} \cup \{-\alpha_k^s(\mu), \alpha_k^u(\mu)\} \cup \sigma_k^{uu}, \qquad 0 < \alpha_k^s(\mu) < \alpha_k^u(\mu)$$

hold with $\operatorname{Re}\sigma_k^{ss} < -\alpha_k^s(\mu)$, $\operatorname{Re}\sigma_k^{uu} > \alpha_k^u(\mu)$ *for* $k = 1, 2$ *and all* μ. *Moreover,* $-\alpha_k^s(\mu)$ *and* $\alpha_k^u(\mu)$ *are simple eigenvalues for* $k = 1, 2$. *We define* $\alpha_k(\mu) = \alpha_k^u(\mu)/\alpha_k^s(\mu) > 1$. *Also, let* $\alpha_k := \alpha_k(0)$ *and* $\alpha_k^i := \alpha_k^i(0)$ *for* $i = s, u$ *and* $k = 1, 2$.

We choose coordinates such that the equilibria do not depend on μ. Suppose that for $\mu = 0$ there exist two heteroclinic orbits $q_1(t)$ and $q_2(t)$ connecting p_1 to p_2 and vice versa; see (H2).

(H2) *The solution* $q_1(t)$ *satisfies* $\lim_{t\to-\infty} q_1(t) = p_1$ *and* $\lim_{t\to\infty} q_1(t) = p_2$ *while* $q_2(t)$ *satisfies* $\lim_{t\to-\infty} q_2(t) = p_2$ *and* $\lim_{t\to\infty} q_2(t) = p_1$.

Due to hypothesis (H1), the next assumption is met for generic vector fields.

(H3) *The heteroclinic solutions* $q_1(t)$ *and* $q_2(t)$ *are nondegenerate, that is,*

$$\begin{aligned} T_{q_1(0)}W^u(p_1,0) \cap T_{q_1(0)}W^s(p_2,0) &= \mathbb{R}\dot{q_1}(0), \\ T_{q_2(0)}W^u(p_2,0) \cap T_{q_2(0)}W^s(p_1,0) &= \mathbb{R}\dot{q_2}(0) \end{aligned}$$

hold.

Due to (H3), there exist two unique (up to constant multiples) bounded solutions $\psi_k(t)$ of the adjoint variational equation

$$\dot{w} = -D_u f(q_k(t),0)^*\, w$$

evaluated at $q_k(t)$ for $k = 1, 2$, respectively. As a matter of fact, they satisfy

$$\psi_k(t) \perp \big(T_{q_k(t)}W^u(p_k,0) + T_{q_k(t)}W^s(p_{k+1},0)\big). \tag{2.2}$$

Here, the index k is taken modulo two. Upon changing the parameter μ, the heteroclinic solutions $q_k(t)$ should break up. This is made precise in the next hypothesis.

(H4) *The Melnikov integrals*

$$N_k := \int_{-\infty}^{\infty} \langle \psi_k(t), D_\mu f(q_k(t),0)\rangle\, dt \in \mathbb{R}^2, \qquad k = 1, 2$$

are linearly independent (and in particular nonzero).

We need to assume that $q_k(t)$ and $\psi_k(t)$ converge along the leading directions to the equilibria and zero, respectively.

(H5) *Assume that the limits*

$$\begin{aligned} \lim_{t\to-\infty} e^{-\alpha_k^u t}\,\dot{q}_k(t) &=: v_k^-, & \lim_{t\to\infty} e^{\alpha_{k+1}^s t}\,\dot{q}_k(t) &=: v_{k+1}^+, \\ \lim_{t\to-\infty} e^{-\alpha_k^s t}\,\psi_k(t) &=: w_k^+, & \lim_{t\to\infty} e^{\alpha_{k+1}^u t}\,\psi_k(t) &=: w_{k+1}^- \end{aligned}$$

are nonzero for $k = 1, 2$*; see Figure* 2*. Again, the index* k *is taken modulo two.*

Then $v_k^\pm$ and $w_k^\pm$ are right and left eigenvectors of $D_u f(p_k, 0)$ for the eigenvalues $\alpha_k^{s,u}$. Due to (2.2), hypothesis (H5) is equivalent to the strong inclination property. Finally, we suppose that both heteroclinic orbits are twisted.

(H6) *Suppose that the scalar products* $\langle w_k^-, v_k^-\rangle > 0$ *and* $\langle w_k^+, v_k^+\rangle > 0$ *are positive for* $k = 1, 2$*; see Figure* 2*. Note that the scalar products do not vanish according to hypotheses* (H1) *and* (H5).

Choose two sections Σ_k transverse to the vector field and placed at $q_k(0)$ for $k = 1, 2$. We call the heteroclinic solutions $q_1(t)$ and $q_2(t)$ simple fronts and backs, respectively. An N-front solution is a heteroclinic orbit connecting p_1 to p_2 and intersecting Σ_2 N-times; see Figure 3. In other words, it follows the heteroclinic loop $N+\frac{1}{2}$ times and hits the set $\Sigma_1 \cup \Sigma_2$ $2N+1$ times. Similarly, N-backs are defined connecting p_2 to p_1.

Associated with each N-front are $2N$ return times T_j for $j = 0, \ldots, 2N-1$. With $l = 0, \ldots, N-1$, the numbers T_{2l} are the times consecutively spent between Σ_1 and Σ_2, that is, near the equilibrium p_2, while T_{2l+1} are the times spent between Σ_2 and Σ_1, that is, near the equilibrium p_1.

We remark that, on account of hypothesis (H4), there is a change of parameters of class C^2 such that the Melnikov integrals coincide with the coordinate axes

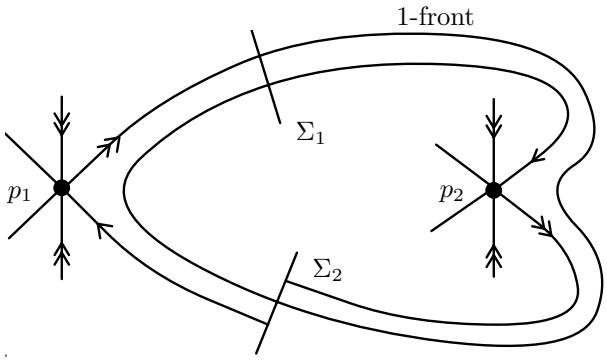

FIG. 3. *An N-front solution for $N = 1$. There are two return times T_0 and T_1 associated with the 1-front. T_0 is the time spent between Σ_1 and Σ_2, while T_1 is the time spent between Σ_2 and Σ_1.*

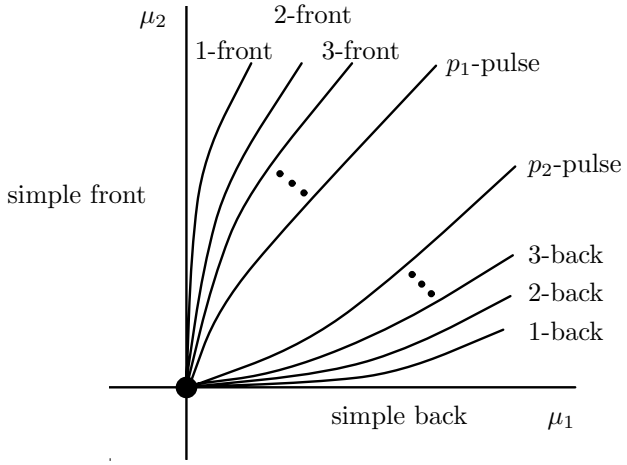

FIG. 4. *The bifurcation diagram. The parameters have been transformed such that a simple front (back) exists precisely when $\mu_1 = 0$ ($\mu_2 = 0$) and such that the Melnikov integrals are given by $N_1 = (1, 0)$ and $N_2 = (0, 1)$. The twisted heteroclinic loop exists for $\mu = 0$.*

in $\mathbb{R}^2$, that is, $N_1 = (1, 0)$ and $N_2 = (0, 1)$, and that simple fronts (backs) exist precisely when $\mu_1 = 0$ ($\mu_2 = 0$); see Figure 4. We refer to section 3.2 for the proof.

The first result is an extension of the existence theorem proved by Deng [Den91a], who assumed that the unstable manifolds are one-dimensional.

THEOREM 2.1. *Assume that* (H1)–(H6) *are satisfied. Then, for each $N \geq 1$, there exists a unique curve $\bar{\mu}_N(r)$ in parameter space defined for $r \in [0, r_0)$ with $\bar{\mu}_N(0) = 0$ such that* (2.1) *has an N-front solution (u, μ) if and only if there exists an r such that $\mu = \bar{\mu}_N(r)$. The N-fronts are unique and the curves $\bar{\mu}_N$ are of class C^1. The return times (as defined right before this theorem) of the N-fronts are given by*

$$
\begin{aligned}
T_{2l} &= -\tfrac{1}{\alpha_2^s}\,(1 + \mathrm{o}(1))\,\ln r, && \text{time spent near } p_2,\\
T_{2l+1} &= -\tfrac{\alpha_2+\theta_{N-l}}{\alpha_1^s}\,(1 + \mathrm{o}(1))\,\ln r, && \text{time spent near } p_1
\end{aligned}
\tag{2.3}
$$

for $l = 0, \dots, N-1$ as $r \to 0$. Here, the sequence θ_l is defined recursively by $\theta_1 = 0$, $\theta_2 = \alpha_1\alpha_2 - 1 > 0$, and $\theta_{l+1} := \alpha_1\theta_l + \theta_2 > \theta_l$. Different choices of the sections Σ_k do not change the leading order term in (2.3)*. Analogous results hold for N-backs.*

Now, assume in addition that parameters have been transformed according to the remark stated right before this theorem. Then the curves $\bar\mu_N$ satisfy

$$\bar\mu_N(r) = (r^{\alpha_2}(1 + \mathrm{o}(1)), r)$$

as $r \to 0$, and the bifurcation diagram is given in Figure 4*.*

Next we describe the bounded solutions $v \in C^1(\mathbb{R}, \mathbb{R}^n)$ of the equation

$$\dot v = \big(D_u f(q_N(r)(t), \bar\mu_N(r)) + \lambda B(t)\big)v \tag{2.4}$$

for $\lambda \in \mathbb{C}$ with $|\lambda|$ small, where $q_N(r)$ denotes the N-front existing for $\mu = \bar\mu_N(r)$. Here, B is a bounded, continuous, and matrix-valued function. Equation (2.4) is a generalized eigenvalue problem of the form

$$Lv = \lambda Bv.$$

Generalized eigenfunctions of (2.4) corresponding to an eigenvalue λ are functions v_i satisfying

$$Lv_i = \lambda Bv_i + Bv_{i-1}$$

with $v_0 = 0$. The algebraic multiplicity of eigenvalues can be defined in the usual way. We assume a nondegeneracy assumption with respect to λ.

(H7) *Suppose that the Melnikov integrals*

$$M_k := \int_{-\infty}^{\infty} \langle \psi_k(t), B(t)\,\dot q_k(t)\rangle\, dt \neq 0$$

are nonzero for $k = 1, 2$, where ψ_k is chosen according to hypothesis (H6)*.*

The next theorem—which is the main result of the present paper—describes the set of $\lambda \in \mathbb{C}$ with $|\lambda|$ small for which (2.4) possesses a bounded solution v.

THEOREM 2.2. *Suppose that the assumptions* (H1)–(H7) *are satisfied. Then there exists a $\delta > 0$ independent of N such that the following holds. For any $N \geq 1$ and $r_0 = r_0(N) > 0$ sufficiently small there exist precisely $2N+1$ solutions $(\lambda_j, v_j) \in \mathbb{C} \times C^1(\mathbb{R}, \mathbb{R}^n)$ of* (2.4) *with $|\lambda| < \delta$. The eigenvalues are counted with multiplicity and are given by*

$$\begin{aligned} \lambda_{2l-1} &= (c_{2l-1} + \mathrm{o}(1))\, r, \\ \lambda_{2l} &= (c_{2l} + \mathrm{o}(1))\, r^{\alpha_2 + \theta_{N+1-l}}, \\ \lambda_{2N+1} &= 0 \end{aligned}$$

for $l = 1, \dots, N$ as $r \to 0$, where the exponents θ_{N+1-l} have been defined in Theorem 2.1*.*

The constants c_j are nonzero and satisfy $\operatorname{sign} c_{2l} = \operatorname{sign} M_1$ *and* $\operatorname{sign} c_{2l-1} = \operatorname{sign} M_2$*. In particular, the eigenvalues λ_j are contained in the left half-plane for $j = 1, \dots, 2N$ provided $M_1, M_2 < 0$ are negative. Analogous results hold for N-backs.*

The second theorem establishes stability of the N-front solutions with respect to the underlying partial differential equation; see section 5 for an example.

Notice that there exist precisely two pulses converging to p_1 and p_2, respectively; see Figure 4. The existence proof is implicitly contained in section 3.3. As far as their stability is concerned, the same statement as for the N-fronts holds. This follows from [Nii95a] or section 4 of the present article.

3. Existence. In order to prove existence of N-fronts, a geometric reduction onto a two-dimensional invariant manifold in phase space is employed. The manifold is diffeomorphic to an annulus. Next, a system of $2N+1$ equations is derived using the Lyapunov–Schmidt reduction applied to the flow on the invariant manifold. In the final section, this system is being solved for using an implicit function theorem.

Throughout we assume that hypotheses (H1)–(H6) are met.

3.1. Center-manifold reduction. We have the following lemma.

LEMMA 3.1. *There exists a two-dimensional, locally invariant, and normally hyperbolic manifold $W^c_{hom} \subset \mathbb{R}^n$ of class $C^{1,\rho}$ jointly in (u,μ) for some $\rho > 0$. All solutions staying near the heteroclinic loop for all times and for parameter values close to zero are contained in W^c_{hom}. The manifold is homeomorphic to an annulus.*

Moreover, the flow restricted to W^c_{hom} is C^1-conjugated to the flow of an appropriate vector field $g(u,\mu)$ of class C^1 defined on $\mathbb{R}^2$. The hypotheses (H1)–(H6) *are still satisfied for g and, in addition, g is linear locally near both equilibria.*

Proof. The existence of W^c_{hom} is an application of [San95, Theorem 1]. We shall verify the assumptions of that theorem using the decomposition

$$\sigma(D_u f(p_k,0)) = \sigma_k^{ss} \cup \sigma_k^c \cup \sigma_k^{uu}, \qquad \sigma_k^c = \{-\alpha_k^s, \alpha_k^u\}.$$

Then [San95, (H1), ($\widetilde{\text{H3}}$)] are satisfied due to (H1) and (H5), while [San95, (H4)] is void. It remains to verify [San95, ($\widetilde{\text{H2}}$)] which reads

$$\begin{aligned} T_{q_1(0)}W^{uu}(p_1) \oplus T_{q_1(0)}W^{u,s,ss}(p_2) &= \mathbb{R}^n, \\ T_{q_1(0)}W^{s,u,uu}(p_1) \oplus T_{q_1(0)}W^{ss}(p_2) &= \mathbb{R}^n, \end{aligned}$$

and the analogous condition for $q_2(t)$. Here, $W^{u,s,ss}(p_2)$ denotes an invariant manifold tangent to the generalized eigenspace $E^{u,s,ss}$ associated with $\sigma_2^{ss} \cup \sigma_2^c$ at p_2 and similarly for $W^{s,u,uu}(p_1)$. On account of (H1), it suffices to prove that

$$\begin{aligned} T_{q_1(0)}W^{uu}(p_1) \cap T_{q_1(0)}W^{u,s,ss}(p_2) &= \{0\}, \\ T_{q_1(0)}W^{s,u,uu}(p_1) \cap T_{q_1(0)}W^{ss}(p_2) &= \{0\}. \end{aligned} \tag{3.1}$$

We have

$$T_{q_1(0)}W^{u,s,ss}(p_2) = T_{q_1(0)}W^{s}(p_2) \oplus \mathbb{R}v^u$$

for some nonzero v^u. On account of (H3) and (H5), the intersection

$$T_{q_1(0)}W^{uu}(p_1) \cap T_{q_1(0)}W^{s}(p_2) = \{0\}$$

is trivial. Therefore, if the first equation of (3.1) does not hold, there exists a vector $w \in T_{q_1(0)}W^s(p_2)$ such that

$$v^u + w \in T_{q_1(0)}W^{uu}(p_1) \cap T_{q_1(0)}W^{u,s,ss}(p_2).$$

Let $v^u(t)$ and $w(t)$ be the solutions of the variational equation along $q_1(t)$ satisfying $v^u(0) = v^u$ and $w(0) = w$. Choose $q_1(0)$ close to p_2, so that $T_{q_1(0)}W^{u,s,ss}(p_2)$ is close to $E^{u,s,ss}$. Then, due to (H5), $\langle \psi_1(0), v^u \rangle \neq 0$. However, the solution $v^u(t) + w(t) \in T_{q_1(t)}W^{uu}(p_1)$ decays exponentially to zero for $t \to -\infty$, while

$$\langle \psi_1(t), v^u(t) + w(t) \rangle \overset{(2.2)}{=} \langle \psi_1(t), v^u(t) \rangle = \langle \psi_1(0), v^u(0) \rangle \neq 0$$

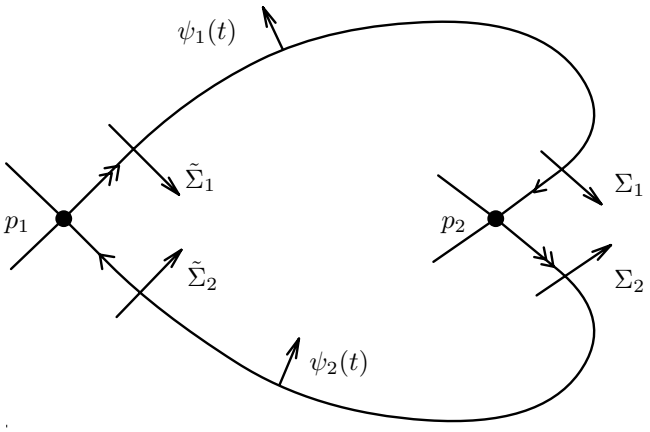

FIG. 5. *The choice of the sections in* $\mathbb{R}^2$. *The arrows denote the positive direction once sections are identified with intervals in* $\mathbb{R}$.

is independent of t as $\psi_1(t)$ solves the adjoint equation. This is a contradiction to $\psi_1(t)$ being bounded; thus

$$T_{q_1(0)}W^{uu}(p_1) \cap T_{q_1(0)}W^{u,s,ss}(p_2) = \{0\}.$$

The argument for the second equation of (3.1) is similar. Thus we can apply [San95, Theorem 1] to conclude the existence of an invariant manifold W^c_{hom}. Moreover, by the construction in [San95], W^c_{hom} is homeomorphic to an annulus owing to (H6). That the flow on W^c_{hom} is C^1-conjugated to the flow of a C^1-vector field in $\mathbb{R}^2$ follows from [San95, section 3.5]. The statement about the smooth linearization is proved in [Hom96, Proposition A.1.1]. □

Hence we can restrict the analysis to a C^1-vector field g in $\mathbb{R}^2$ satisfying ($\widetilde{\text{H1}}$), (H2)–(H6), and being linear locally near both equilibria, where hypothesis ($\widetilde{\text{H1}}$) is given by the following.

($\widetilde{\text{H1}}$) *We assume that* $\dim W^s(p_1, 0) = \dim W^s(p_2, 0) = 1$ *and*

$$\sigma(D_u f(p_k(\mu), \mu)) = \{-\alpha^s_k(\mu), \alpha^u_k(\mu)\}, \qquad 0 < \alpha^s_k(\mu) < \alpha^u_k(\mu)$$

hold for $k = 1, 2$. *We define* $\alpha_k(\mu) = \alpha^u_k(\mu)/\alpha^s_k(\mu) > 1$.

3.2. Lin's method in $\mathbb{R}^2$. According to the last section, it suffices to consider a vector field

$$\dot{u} = g(u, \mu), \qquad (u, \mu) \in \mathbb{R}^2 \times \mathbb{R}^2, \tag{3.2}$$

with $g \in C^1$ such that ($\widetilde{\text{H1}}$) and (H2) up to (H6) are satisfied and the flow near the equilibria p_k for $k = 1, 2$ is linear. Choose Poincaré sections Σ_k and $\tilde{\Sigma}_k$ for $k = 1, 2$ as in Figure 5. All sections are chosen inside the regions near the equilibria p_k where the flow is linear. Moreover, we shall identify the one-dimensional sections with intervals in $\mathbb{R}$ as shown in Figure 5. Next, we compute various Poincaré maps. Denoting the time spent between Σ_1 and Σ_2 by T, the map from Σ_1 to Σ_2 is given by

$$\begin{array}{ccc} \Sigma_1 & \to & \Sigma_2, \\ e^{-\alpha^u_2(\mu)T} & \mapsto & e^{-\alpha^s_2(\mu)T}, \end{array} \tag{3.3}$$

using the fact that the vector field is linear. Similarly, the map from $\tilde{\Sigma}_2$ to $\tilde{\Sigma}_1$ equals

$$\begin{array}{ccc} \tilde{\Sigma}_2 & \to & \tilde{\Sigma}_1, \\ e^{-\alpha_1^u(\mu)\tau} & \mapsto & e^{-\alpha_1^s(\mu)\tau}. \end{array} \tag{3.4}$$

The maps

$$\begin{array}{rccl} \tilde{\Pi}_k(u,\mu) & : & \tilde{\Sigma}_k & \to & \Sigma_k, \\ & & u & \mapsto & -\Pi_k(u,\mu) + d_k(\mu) \end{array} \tag{3.5}$$

are diffeomorphisms with $\Pi_k(u,\mu) \in C^1$, $\Pi_k(0,\mu) = 0$, and $D_u\Pi_k(0,\mu) > 0$ for $k = 1, 2$. The minus sign before the term $\Pi_k(u,\mu)$ appearing in (3.5) is a consequence of hypothesis (H6); see Figure 5. Due to hypothesis (H4), we may assume that $d_k(\mu) = \mu_k$ by a C^1-transformation of parameters. Indeed, with $u_k^u(\mu) \in W^u(p_k,\mu)$ and $u_k^s(\mu) \in W^s(p_k,\mu)$ chosen properly, and after possibly shifting time such that $q_k(0) \in \Sigma_k$, the separation function $d_k(\mu) = \langle \psi_k(0), u_k^u(\mu) - u_{k+1}^s(\mu)\rangle$ measures the signed distance of the one-dimensional stable and unstable manifolds of the equilibria at the section Σ_k; see, for instance, [Kok88], [Lin90], or [Den91b]. The integrals N_k appearing in (H4) are in fact the derivatives of $d_k(\mu)$ at $\mu = 0$. For consistency with the remark stated before Theorem 2.1, we note that parameters can be changed in the original system before applying the center-manifold reduction resulting in a C^2-transformation.

Summarizing the above, we obtain a map

$$\begin{array}{ccc} \Sigma_2 & \to & \Sigma_1, \\ -\Pi_2(e^{-\alpha_1^u(\mu)\tau},\mu) + \mu_2 & \mapsto & -\Pi_1(e^{-\alpha_1^s(\mu)\tau},\mu) + \mu_1. \end{array} \tag{3.6}$$

All solutions being mapped from Σ_2 to Σ_1 are captured by the above parametrization. The next step consists in formulating the Poincaré map by means of the return time with respect to the sections Σ_k instead of the one for $\tilde{\Sigma}_k$.

The times needed for initial points $u \in \tilde{\Sigma}_k$ to reach the sections Σ_k are given by functions $\Omega_k(u,\mu)$. Both functions $\Omega_k(u,\mu)$ are in C^1 and bounded uniformly in u. Thus the time T needed for the initial point

$$-\Pi_2(e^{-\alpha_1^u(\mu)\tau},\mu) + \mu_2 \in \Sigma_2$$

to reach

$$-\Pi_1(e^{-\alpha_1^s(\mu)\tau},\mu) + \mu_1 \in \Sigma_1$$

is given by

$$T = \tau + \Omega_1(e^{-\alpha_1^s(\mu)\tau},\mu) + \Omega_2(e^{-\alpha_1^u(\mu)\tau},\mu).$$

By the implicit function theorem, we can solve this equation with respect to τ yielding a C^1-function $\tau(T,\mu)$, with

$$\tau(T,\mu) = T - \Omega_1(e^{-\alpha_1^s(\mu)\,\tau(T,\mu)},\mu) - \Omega_2(e^{-\alpha_1^u(\mu)\,\tau(T,\mu)},\mu). \tag{3.7}$$

Therefore, we obtain the following lemma.

LEMMA 3.2. *The Poincaré maps from Σ_1 to Σ_2 and vice versa are given by*

$$\begin{array}{ccc} \Sigma_1 & \to & \Sigma_2, \\ e^{-\alpha_2^u(\mu)T} & \mapsto & e^{-\alpha_2^s(\mu)T} \end{array} \tag{3.8}$$

and

$$\begin{array}{ccc} \Sigma_2 & \to & \Sigma_1, \\ -\Pi_2(e^{-\alpha_1^u(\mu)\,\tau(T,\mu)},\mu)+\mu_2 & \mapsto & -\Pi_1(e^{-\alpha_1^s(\mu)\,\tau(T,\mu)},\mu)+\mu_1, \end{array} \tag{3.9}$$

respectively. The C^1-function $\tau(T,\mu)$ defined in (3.7) *satisfies*

$$\Big|\frac{d}{dT}\tau(T,\mu)-1\Big| \ll 1,$$

and the C^1-maps $\Omega_k(u,\mu)$ are bounded uniformly in u. Moreover, $\Pi_k(u,\mu)\in C^1$, $\Pi_k(0,\mu)=0$, and $D_u\Pi_k(0,\mu)>0$ for $k=1,2$. Up to this point, the construction looks pretty much like using Shilnikov variables. However, in order to describe solutions following the original heteroclinic loop several times, we shall adopt a boundary-value-point-of-view. That is, we are not going to iterate the Poincaré maps given in the previous lemma, but shall derive matching conditions in the sections.

Using Lemma 3.2, the existence of N-front solutions is equivalent to the existence of return times $T_j<\infty$ for $j=0,\dots,2N-1$ and parameter values μ such that

$$\begin{array}{rcll} e^{-\alpha_2^u(\mu)T_0} &=& \mu_1, & \\ e^{-\alpha_2^s(\mu)T_{2j}} &=& -\Pi_2(e^{-\alpha_1^u(\mu)\,\tau(T_{2j+1},\mu)},\mu)+\mu_2, & j=0,\dots,N-1, \\ e^{-\alpha_2^u(\mu)T_{2j}} &=& -\Pi_1(e^{-\alpha_1^s(\mu)\,\tau(T_{2j-1},\mu)},\mu)+\mu_1, & j=1,\dots,N-1, \\ 0 &=& -\Pi_1(e^{-\alpha_1^s(\mu)\,\tau(T_{2N-1},\mu)},\mu)+\mu_1 & \end{array} \tag{3.10}$$

holds. Indeed, then the various pieces of solutions defined in between the sections will fit together. Moreover, the first and last equation assert that the solution is contained in the unstable and stable manifolds of the equilibria p_1 and p_2, respectively. In fact, T_{2j+1} and T_{2j} are the times spent near the equilibria p_1 and p_2, respectively. Define

$$\begin{array}{rclcrcl} a_{2j+1}\,s &=& e^{-\alpha_1^s(\mu)\,\tau(T_{2j+1},\mu)}, & & s &=& e^{-\alpha_1^s(\mu)\,\tau(T_{2N-1},\mu)}, \\ a_{2j}\,r &=& e^{-\alpha_2^s(\mu)T_{2j}}, & & r &=& e^{-\alpha_2^s(\mu)T_0} \end{array} \tag{3.11}$$

for $j=0,\dots,N-1$ such that $a_0=a_{2N-1}=1$ and $a_1,\dots,a_{2N-2}$ are bounded. In the new variables a_j, r, and s, equation (3.10) reads

$$\begin{array}{rcll} r^{\alpha_2(\mu)}-\mu_1 &=& 0, & \\ r+\Pi_2((a_1 s)^{\alpha_1(\mu)},\mu)-\mu_2 &=& 0, & \\ (a_{2j}r)^{\alpha_2(\mu)}+\Pi_1(a_{2j-1}s,\mu)-\mu_1 &=& 0, & j=1,\dots,N-1, \\ a_{2j}r+\Pi_2((a_{2j+1}s)^{\alpha_1(\mu)},\mu)-\mu_2 &=& 0, & j=1,\dots,N-1, \\ \Pi_1(s,\mu)-\mu_1 &=& 0 & \end{array} \tag{3.12}$$

with $\alpha_k(\mu)=\alpha_k^u(\mu)/\alpha_k^s(\mu)>1$. Whenever (a_j,r,s) solve (3.12) such that $a_j>0$ and $r,s>0$, we obtain associated return times $T_j<\infty$ which solve (3.10) by using (3.11). Indeed, we have

$$\begin{array}{rcl} \tau(T_{2j+1},\mu) &=& -\frac{1}{\alpha_1^s(\mu)}\ln(a_{2j+1}s), \\ T_{2j} &=& -\frac{1}{\alpha_2^s(\mu)}\ln(a_{2j}r), \end{array} \tag{3.13}$$

and Lemma 3.2 implies that $\tau(T,\mu)$ is invertible with respect to T. Hence, it suffices to consider (3.12) keeping in mind that only positive solutions of this system correspond to solutions of the original problem.

3.3. Existence of N-fronts bifurcating from a twisted heteroclinic cycle. We shall solve (3.12). Note that the functions Π_1 and Π_2 are in C^1. By convention, for $\alpha > 1$, define x^α to be zero for negative values of x yielding a C^1-function, too. Then (3.12) is defined for all a_j bounded and r, s small including negative values. Throughout this section, the range of the index j is $j = 1, \dots, N-1$.

First, solve

$$\begin{aligned} \mu_1 &= r^{\alpha_2(\mu)}, \\ \Pi_1(s,\mu) &= r^{\alpha_2(\mu)} \end{aligned} \tag{3.14}$$

with respect to (μ_1, s) near $(r, s, \mu) = 0$ by the implicit function theorem using Lemma 3.2. Denote the solutions by $\mu_1(\mu_2, r)$ and $s(\mu_2, r)$, both of which are of class C^1. Observe that, owing to $\Pi_1(0, \mu) = 0$, the estimates

$$|s(\mu_2, r)|, |D_{\mu_2} s(\mu_2, r)| \le C_\delta\, r^{\alpha_2 - \delta} \tag{3.15}$$

hold for arbitrary small positive δ. Using the ansatz $\mu_2 = \epsilon r$, the second equation in (3.12) reads

$$r + \Pi_2((a_1 s)^{\alpha_1(\mu)}, \mu) - \mu_2 = r + \Pi_2\big((a_1 s(\epsilon r, r))^{\alpha_1(\epsilon r, r)}, \mu_1(\epsilon r, r), \epsilon r\big) - \epsilon r = 0. \tag{3.16}$$

Here and in the following, we will be a bit sloppy concerning the dependence of $\alpha_k(\mu)$ and Π_k on ϵ and r to avoid unnecessary complicated notation. Dividing (3.16) by r yields

$$1 + r^{-1}\Pi_2\big((a_1 s(\epsilon r, r))^{\alpha_1(\epsilon r, r)}, \mu_1(\epsilon r, r), \epsilon r\big) - \epsilon = 0, \tag{3.17}$$

which is C^1 in (ϵ, a_1) for $r \ge 0$ owing to (3.15) and since the dependence on ϵ is due to $\mu_2 = \epsilon r$. Using (3.15), we can solve (3.17) with respect to ϵ near $\epsilon = 1$, $r = 0$, and arbitrary bounded a_1 yielding a C^1-function

$$\epsilon = \epsilon(a_1, r) = 1 + r^{-1}\Pi_2\big((a_1 \tilde{s}(a_1, r))^{\tilde{\alpha}_1(a_1, r)}, \tilde{\mu}_1(a_1, r), \epsilon(a_1, r) r\big), \tag{3.18}$$

where

$$\begin{aligned} \tilde{s}(a_1, r) &= s(\epsilon(a_1, r) r, r), \\ \tilde{\alpha}_k(a_1, r) &= \alpha_k(\epsilon(a_1, r) r, r), \\ \tilde{\mu}_1(a_1, r) &= \mu_1(\epsilon(a_1, r) r, r). \end{aligned}$$

Notice that the dependence of all these functions on a_1 is due to terms of the form $\epsilon(a_1, r) r$. It remains to solve the system

$$\begin{aligned} \Pi_1\big(a_{2j-1}\tilde{s}(a_1, r), \tilde{\mu}(a_1, r)\big) + (a_{2j} r)^{\tilde{\alpha}_2(a_1, r)} - \tilde{\mu}_1(a_1, r) &= 0, \\ a_{2j} r + \Pi_2\big((a_{2j+1}\tilde{s}(a_1, r))^{\tilde{\alpha}_1(a_1, r)}, \tilde{\mu}(a_1, r)\big) - \epsilon(a_1, r) r &= 0 \end{aligned}$$

for $j = 1, \dots, N-1$. Dividing by $r^{\tilde{\alpha}_2(a_1, r)}$ and r, respectively, yields

$$\begin{aligned} r^{-\tilde{\alpha}_2(a_1, r)}\, \Pi_1\big(a_{2j-1}\tilde{s}(a_1, r), \tilde{\mu}(a_1, r)\big) + a_{2j}^{\tilde{\alpha}_2(a_1, r)} - 1 &= 0, \\ a_{2j} + r^{-1}\Pi_2\big((a_{2j+1}\tilde{s}(a_1, r))^{\tilde{\alpha}_1(a_1, r)}, \tilde{\mu}(a_1, r)\big) - \epsilon(a_1, r) &= 0. \end{aligned} \tag{3.19}$$

The functions

$$\begin{aligned} &r^{-\tilde{\alpha}_2(a_1, r)}\, \Pi_1\big(a_{2j-1}\tilde{s}(a_1, r), \tilde{\mu}(a_1, r)\big), \\ &r^{-1}\Pi_2\big((a_{2j-1}\tilde{s}(a_1, r))^{\tilde{\alpha}_1(a_1, r)}, \tilde{\mu}(a_1, r)\big) \end{aligned}$$

are C^1 in (a_{2j-1}, a_1) up to $r = 0$ owing to (3.14) and the above comment about the dependence on a_1. Moreover, the derivative with respect to a_{2j-1} at $r = 0$ equals one for the first and zero for the second function. Therefore, $a_{2j} = 1$ and $a_{2j-1} = 0$ for $j = 1, \ldots, N-1$ solve (3.19) with $r = 0$, and we can use the implicit function theorem to obtain solutions $a_{2j}(r)$ and $a_{2j-1}(r)$ for positive r.

It remains to show that $a_{2j-1}(r) > 0$ is positive for $r > 0$. Define constants γ_j recursively by

$$\begin{aligned} \gamma_N &:= 0, \\ \gamma_{N-1} &:= \alpha_1\alpha_2 - 1 > 0, \\ \gamma_{j-1} &:= \alpha_1\gamma_j + \gamma_{N-1} > \gamma_j \end{aligned} \tag{3.20}$$

for $j = 1, \ldots, N-1$. These constants are related to the numbers θ_j via

$$\gamma_j = \theta_{N+1-j}. \tag{3.21}$$

We will, however, work with the γ_j in order to keep the notation simpler. Let

$$\begin{aligned} a_{2j-1} &= b_{2j-1}\, r^{\gamma_j}, \\ a_{2j} &= 1 - b_{2j}\, r^{\gamma_j} \end{aligned} \tag{3.22}$$

for $j = 1, \ldots, N-1$, and set $b_{2N-1} = 1$. Substituting these expressions together with (3.18) into equation (3.19) yields

$$\begin{aligned} 0 &= r^{-\hat\alpha_2(b_1,r)}\,\Pi_1\big(b_{2j-1}r^{\gamma_j}\,\hat s(b_1,r), \hat\mu(b_1,r)\big) - 1 + (1 - b_{2j}r^{\gamma_j})^{\hat\alpha_2(b_1,r)}, \\ 0 &= b_{2j}r^{\gamma_j} + r^{-1}\big(\Pi_2\big((b_1r^{\gamma_1}\hat s(b_1,r))^{\hat\alpha_1(b_1,r)}, \hat\mu(b_1,r)\big) \\ &\quad -\Pi_2\big((b_{2j+1}r^{\gamma_{j+1}}\hat s(b_1,r))^{\hat\alpha_1(b_1,r)}, \hat\mu(b_1,r)\big)\big), \end{aligned}$$

where

$$\begin{aligned} \hat s(b_1,r) &= s(\epsilon(b_1r^{\gamma_1},r)r,r), \\ \hat\alpha_k(b_1,r) &= \alpha_k(\epsilon(b_1r^{\gamma_1},r)r,r), \\ \hat\mu_1(b_1,r) &= \mu_1(\epsilon(b_1r^{\gamma_1},r)r,r), \\ \hat\mu_2(b_1,r) &= \epsilon(b_1r^{\gamma_1},r)r. \end{aligned} \tag{3.23}$$

Dividing these equations by r^{γ_j} reads

$$\begin{aligned} 0 &= r^{-(\hat\alpha_2(b_1,r)+\gamma_j)}\,\Pi_1\big(b_{2j-1}r^{\gamma_j}\,\hat s(b_1,r), \hat\mu(b_1,r)\big) \\ &\quad + r^{-\gamma_j}\big((1 - b_{2j}r^{\gamma_j})^{\hat\alpha_2(b_1,r)} - 1\big), \\ 0 &= b_{2j} + r^{-(1+\gamma_j)}\big(\Pi_2\big((b_1r^{\gamma_1}\hat s(b_1,r))^{\hat\alpha_1(b_1,r)}, \hat\mu(b_1,r)\big) \\ &\quad -\Pi_2\big((b_{2j+1}r^{\gamma_{j+1}}\hat s(b_1,r))^{\hat\alpha_1(b_1,r)}, \hat\mu(b_1,r)\big)\big). \end{aligned} \tag{3.24}$$

As before, using the recursive relations (3.20), it is tedious but straightforward to see that the functions appearing in (3.24) are C^1 up to $r = 0$. Moreover, for $r = 0$, (3.24) boils down to

$$\begin{aligned} b_{2i-1} - \alpha_2\, b_{2i} &= 0, && i = 1, \ldots, N-1, \\ b_{2i} - D_u\Pi_2(0,0)\, D_u\Pi_1(0,0)^{-\alpha_1}\, b_{2i+1}^{\alpha_1} &= 0, && i = 1, \ldots, N-2, \\ b_{2N-2} - D_u\Pi_2(0,0)\, D_u\Pi_1(0,0)^{-\alpha_1} &= 0 \end{aligned} \tag{3.25}$$

owing to (3.14). It is straightforward to check that the Jacobian of (3.25) with respect to (b_j) is upper triangular with nonzero diagonal elements. Equation (3.24) can therefore be solved near

$$\begin{aligned} b_{2N-2} &= D_u\Pi_2(0,0)\, D_u\Pi_1(0,0)^{-\alpha_1}, \\ b_{2i-1} &= \alpha_2\, b_{2i}, && i = 1,\dots,N-1, \\ b_{2i-2} &= b_{2N-2}\, b_{2i-1}^{\alpha_1}, && i = 2,\dots,N-1 \end{aligned} \tag{3.26}$$

by invoking an implicit function theorem. This proves that

$$\begin{aligned} a_{2j-1} &= (b_{2j-1} + \mathrm{o}(1))\, r^{\gamma_j}, \\ a_{2j} &= 1 - (b_{2j} + \mathrm{o}(1))\, r^{\gamma_j} \end{aligned} \tag{3.27}$$

holds for $j = 1,\dots,N-1$. In particular, $a_{2j-1}(r) > 0$ is positive for $r > 0$ thanks to (3.26) and Lemma 3.2.

The expansion (2.3) of the return times is now an easy consequence of (3.13) and (3.27) using the relation (3.21) of γ_j and θ_j.

Finally, we prove the claim about the ordering of the bifurcation curves in Figure 4. Summarizing the results obtained thus far and using the exponents θ_j instead of γ_j, the bifurcation curve $\bar\mu_N(r)$ for N-fronts is given by

$$\begin{aligned} \mu_1(r) &= r^{\alpha_2(\mu_1(r),\mu_2(r))}, \\ \mu_2(r) &= r + (C_N + \mathrm{o}(1))\, r^{\alpha_1(\alpha_2+\theta_N)} =: r + \rho_N(r) \end{aligned} \tag{3.28}$$

for some positive constant C_N. Indeed, the first equation is (3.14), while the second is obtained by substituting (3.27) for $j = 1$ and the solution $s(\mu_2, r)$ of (3.14) into (3.16). Define the function $\hat\mu_1(r)$ by solving

$$\hat\mu_1 = r^{\alpha_2(\hat\mu_1, r)}$$

with respect to $\hat\mu_1$. This definition allows us to separate the parts of $\bar\mu_N(r)$ which are independent of N from those which are not. Write

$$(\mu_1, \mu_2)(r) = (\hat\mu_1(r) + \sigma_N, r + \rho_N(r)).$$

Then, using (3.28), a straightforward calculation shows that

$$\sigma_N(r) = \mathrm{O}(r^{\alpha_2(\hat\mu_1(r),r)}\, r^{\alpha_1(\alpha_2+\theta_N)-\delta}),$$

where $\delta > 0$ can be chosen as small as we wish. Thus, the bifurcation curve $\bar\mu_N(r)$ for N-fronts is given by

$$\begin{aligned} \mu_1(r) &= r^{\alpha_2(\hat\mu_1(r),r)}(1 + \mathrm{O}(r^{\alpha_1(\alpha_2+\theta_N)-\delta})), \\ \mu_2(r) &= r + (C_N + \mathrm{o}(1))\, r^{\alpha_1(\alpha_2+\theta_N)}. \end{aligned}$$

As the exponent $\alpha_1(\alpha_2 + \theta_N)$ is larger than one, it is possible to write r as a function of μ_2:

$$r(\mu_2) = \mu_2 - (C_N + \mathrm{o}(1))\, \mu_2^{\alpha_1(\alpha_2+\theta_N)}$$

for $\mu_2 \ge 0$. Therefore, using that $\delta > 0$ can be chosen smaller than one, we obtain

$$\begin{aligned} \mu_1 &= \mu_2^{\hat\alpha_2(\mu_2)} \Big(1 - (C_N + \mathrm{o}(1))\, \mu_2^{\alpha_1(\alpha_2+\theta_N)-1}\Big)^{\hat\alpha_2(\mu_2)} \Big(1 + \mathrm{O}(\mu_2^{\alpha_1(\alpha_2+\theta_N)-\delta})\Big) \\ &= \mu_2^{\hat\alpha_2(\mu_2)} \Big(1 - \hat\alpha_2(\mu_2)\, C_N\, \mu_2^{\alpha_1(\alpha_2+\theta_N)-1} + \mathrm{O}(\mu_2^{\alpha_1(\alpha_2+\theta_N)-\delta})\Big) \end{aligned}$$

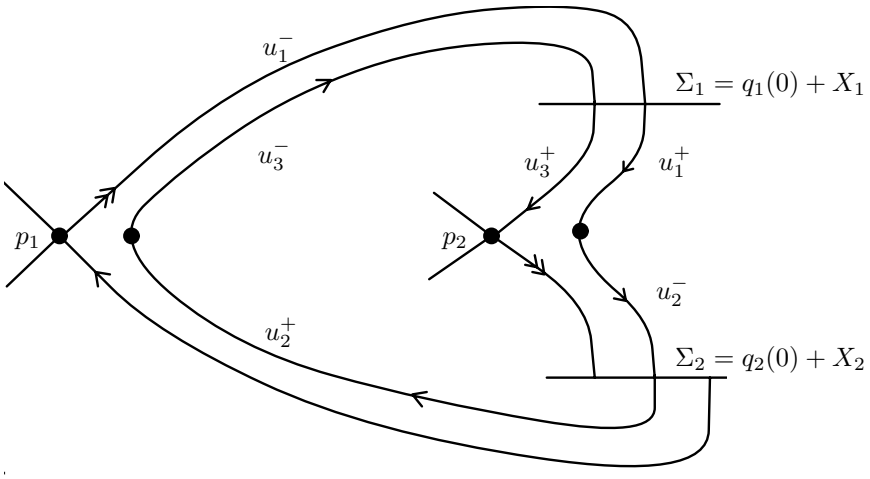

FIG. 6. *Description of N-front solutions for $N = 1$.*

with $\hat{\alpha}_2(\mu_2) := \alpha_2(\hat{\mu}_1(r(\mu_2)), r(\mu_2))$. Now, the claim about the ordering of the curves $\bar{\mu}_N(r)$ is an easy consequence of the fact that θ_N is strictly increasing in N.

Hence the proof of Theorem 2.1 is complete. ∎

4. Stability. This section is devoted to the proof of Theorem 2.2. The basic technique used is Lin's method applied to the eigenvalue problem (2.4). We shall use the abstract results from [San96] together with certain modifications needed in the present situation. As for the concrete bifurcation investigated here, we are again going to exploit the reduction to a two-dimensional invariant manifold. Finally, the eigenvalues of the resulting tridiagonal matrix are calculated.

Throughout we suppose that hypotheses (H1)–(H7) are met.

Convention. Throughout this section, we use the convention that the ranges of the indices i and j are $i = 1, \dots, 2N+1$ and $j = 1, \dots, 2N$ unless stated otherwise. Moreover, we define $i \bmod 2 \in \{1, 2\}$ by convention. The Landau symbol $o(1)$ is taken with respect to $r \to 0$.

4.1. Abstract reduction of the eigenvalue problem. We consider equation (2.1) and (2.4) in $\mathbb{R}^n$ keeping in mind that the N-fronts are actually contained in the invariant C^1-manifold W^c_{hom}. We also extend the sections Σ_k for $k = 1, 2$ to sections in $\mathbb{R}^n$ without changing notation.

Any solution with initial point in Σ_k and end point in Σ_{k+1} is uniquely described by the associated return time T. In particular, any N-front $q_N(t)$ is determined by $2N$ return times T_j for $j = 0, \dots, 2N-1$; see Theorem 2.1 and the proof in the last section. Define $u_i^{\pm}(t)$ by

$$q_N\Big(t + \sum_{j=0}^{i-2} T_j\Big) = \begin{cases} u_i^-(t) & \text{for } t \in [-\frac{1}{2}T_{i-2}, 0], \\ u_i^+(t) & \text{for } t \in [0, \frac{1}{2}T_{i-1}] \end{cases} \tag{4.1}$$

for $i = 1, \dots, 2N+1$ and with $T_{-1} = T_{2N} = \infty$; see Figure 6. As $q_N(t)$ is a solution of (2.1), the functions $u_i^{\pm}$ satisfy

$$\begin{aligned} u_i^+(0) &= u_i^-(0), && i = 1, \dots, 2N+1, \\ u_j^+(\tfrac{1}{2}T_{j-1}) &= u_{j+1}^-(-\tfrac{1}{2}T_{j-1}), && j = 1, \dots, 2N. \end{aligned} \tag{4.2}$$

The eigenvalue problem (2.4)

$$\dot v = \big(D_u f(q_N(t), \bar\mu_N) + \lambda B(t)\big) v, \qquad\qquad t \in \mathbb{R}$$

can be written as

$$\begin{array}{rcll} \dot v_i^- & = & (D_u f(u_i^-(t), \bar\mu_N) + \lambda B(t))\, v_i^- & \text{for } t \in (-\frac12 T_{i-2}, 0), \\ \dot v_i^+ & = & (D_u f(u_i^+(t), \bar\mu_N) + \lambda B(t))\, v_i^+ & \text{for } t \in (0, \frac12 T_{i-1}), \\ v_i^+(0) & = & v_i^-(0), & \\ v_j^+(\frac12 T_{j-1}) & = & v_{j+1}^-(-\frac12 T_{j-1}), & \end{array} \tag{4.3}$$

considered as equations over the complex field. Exploiting the fact that $\dot q_N(t)$ solves (2.4) for $\lambda = 0$ and using (4.1), we take the ansatz

$$v_i^\pm(t) = \dot u_i^\pm(t)\, d_i + w_i^\pm(t),$$

with $d_i \in \mathbb{R}$. On account of [San96, section 3.1] and (4.2), equation (4.3) is then equivalent to

$$\begin{array}{rcl} \dot w_i^\pm & = & (D_u f(u_i^\pm(t), \bar\mu_N) + \lambda B(t))\, w_i^\pm + \lambda\, B(t)\, \dot u_i^\pm(t)\, d_i \\ & & \text{for } t \in (-\frac12 T_{i-2}, 0) \text{ and } t \in (0, \frac12 T_{i-1}), \text{ respectively,} \\ w_i^+(0) & = & w_i^-(0), \\ w_i^\pm(0) & \in & X_{i \bmod 2}, \\ w_j^+(\frac12 T_{j-1}) & = & w_{j+1}^-(-\frac12 T_{j-1}) + \dot u_{j+1}^-(-\frac12 T_{j-1})(d_{j+1} - d_j), \end{array} \tag{4.4}$$

where the (complexified) subspaces X_k are defined by $\Sigma_k = q_k(0) + X_k$ for $k = 1, 2$. Following [San96], we shall investigate the system

$$\begin{array}{rcl} \dot w_i^\pm & = & (D_u f(u_i^\pm(t), \bar\mu_N) + \lambda B(t))\, w_i^\pm + \lambda\, B(t)\, \dot u_i^\pm(t)\, d_i \\ & & \text{for } t \in (-\frac12 T_{i-2}, 0) \text{ and } t \in (0, \frac12 T_{i-1}), \text{ respectively,} \\ w_i^+(0) - w_i^-(0) & \in & \mathbb{C} T_{u_i^+(0)} W^c_{hom}(\bar\mu_N) \cap X_{i \bmod 2} \;\cong\; \mathbb{C}, \\ w_i^\pm(0) & \in & X_{i \bmod 2}, \\ w_j^+(\frac12 T_{j-1}) & = & w_{j+1}^-(-\frac12 T_{j-1}) + \dot u_{j+1}^-(-\frac12 T_{j-1})(d_{j+1} - d_j). \end{array} \tag{4.5}$$

Define the signed distances

$$\xi_i := \langle \psi_{i \bmod 2}(0), w_i^+(0) - w_i^-(0) \rangle \in \mathbb{C}; \tag{4.6}$$

see Figure 5. Then we have the following lemma.

LEMMA 4.1. *Equation* (4.5) *possesses a unique bounded solution* $w = W(\lambda)d$ *linear in* d *and analytic in* λ. *Moreover,* w *solves* (4.4) *if and only if*

$$\xi = S(\lambda)\, d = \big(A(r) - \lambda\,(M + \mathrm{o}(1)) + \mathrm{O}(|\lambda|^2)\big)\, d = 0 \tag{4.7}$$

for some analytic, matrix-valued function $S(\lambda)$ *and*

$$M = \mathrm{diag}(M_1 K_1, M_2 K_2, \ldots, M_1 K_1)$$

with $K_1, K_2 > 0$ *positive. The matrix* $A(r)$ *is determined by* (4.5) *with* $\lambda = 0$. *Any solution of* (2.4) *with* $|\lambda|$ *small is given by the above function* $W(\lambda)$. *In particular,* $d = (1, \ldots, 1)$ *solves* $S(0)\, d = 0$.

With the equivalence of (2.4) and (4.1) as well as Lemma 4.1 at hand, it therefore remains to solve the reduced equation

$$\det S(\lambda) = 0. \tag{4.8}$$

Proof. The proof of the lemma is essentially contained in [San96], where the analysis was done for N-pulses. We will briefly mention the changes needed here.

The hypotheses (H1) and (H3) ensure that the technique developed in [San96] works in the present context. The only difference is that the linearized flows for the heteroclinic solutions are used instead of linearizing along a single homoclinic orbit. The major change made here in comparison with [San96] is that we allow for jumps in

$$w_i^+(0) - w_i^-(0) \in \mathbb{C}T_{u_i^+(0)}W^c_{hom}(\bar\mu_N) \cap X_{i \bmod 2} \cong \mathbb{C}$$

compared with jumps in $\mathbb{C}\psi(0)$

$$w_i^+(0) - w_i^-(0) \in \mathbb{C}\psi_{i \bmod 2}(0),$$

where $\psi_k(t)$ are the unique bounded solutions of the adjoint equation; see section 2. However, the only property of $\mathbb{C}\psi_k(0)$ used in [San96] is the transversality condition

$$\mathbb{R}\psi_k(0) \oplus \mathbb{R}\dot q_k(0) \oplus T_{q_k(0)}W^{uu}(p_k) \oplus T_{q_k(0)}W^{ss}(p_{k+1}) = \mathbb{R}^n$$

for $k = 1, 2$; see [San96, Lemma 3.5]. The corresponding relations

$$\big(T_{u_i^+(0)}W^c_{hom}(\bar\mu_N) \cap X_k\big) \oplus \mathbb{R}\dot q_k(0) \oplus T_{q_k(0)}W^{uu}(p_k) \oplus T_{q_k(0)}W^{ss}(p_{k+1}) = \mathbb{R}^n$$

are satisfied where $k = i \bmod 2$. Indeed, this is a consequence of (2.2) and the proof of Lemma 3.1. The statement about the matrix M follows from [San96, Lemma 3.6] and the above discussion. Indeed, taking the limit $r \to 0$ is equivalent to computing the matrix M by investigating the eigenvalue problem (2.4) for the primary heteroclinic orbits $q_k(t)$ for $k = 1, 2$ as $u_i \to q_{i \bmod 2}$ for $r \to 0$ in the sup-norm. The positive factors K_1 and K_2 stem from the projection of $\psi_k(0)$ onto the tangent spaces$T_{q_k(0)}W^c_{hom}$ for $k = 1, 2$. ∎

4.2. Determining the reduced problem using center-manifolds. In order to solve (4.8)

$$\det S(\lambda) = \det\big(A(r) - \lambda\,(M + \mathrm{o}(1)) + \mathrm{O}(|\lambda|^2)\big) = 0,$$

we have to determine the matrix $A(r)$. By definition, with $\lambda = 0$,

$$\xi = (\langle \psi_{i \bmod 2}(0), w_i^+(0) - w_i^-(0)\rangle)_{i=1,\dots,2N+1} = A(r)\,d,$$

where $w = W(0)\,d$ solves (4.5) with $\lambda = 0$; that is,

$$\begin{aligned}
&\text{(i)} && \dot w_i^\pm && = && D_u f(u_i^\pm, \bar\mu_N)\, w_i^\pm, \\
& && && && \text{for } t \in (-\tfrac12 T_{i-2}, 0) \text{ and } t \in (0, \tfrac12 T_{i-1}), \text{ respectively,} \\
&\text{(ii)} && w_i^+(0) - w_i^-(0) && \in && \mathbb{C}T_{u_i^+(0)}W^c_{hom}(\bar\mu_N) \cap X_{i \bmod 2}, \\
&\text{(iii)} && w_i^\pm(0) && \in && X_{i \bmod 2}, \\
&\text{(iv)} && w_j^+(\tfrac12 T_{j-1}) && = && w_{j+1}^-(-\tfrac12 T_{j-1}) + \dot u_{j+1}^-(-\tfrac12 T_{j-1})(d_{j+1} - d_j).
\end{aligned} \tag{4.9}$$

Therefore, the solutions w_i have to solve the variational equation along the N-front. Since W^c_{hom} is locally invariant and C^1, its continuous tangent bundle is invariant under the linearized flow. Since $\dot u_i \in T_{q_N} W^c_{hom}$ and the jumps of w_i are required to be in $T_{q_N} W^c_{hom}$, too, we expect that the solutions $w_i \in T_{q_N} W^c_{hom}$ are contained in the tangent bundle as well. By uniqueness of w as stated in Lemma 4.1, it is therefore sufficient to prove that we can solve (4.9) with $w_i \in T_{u_i} W^c_{hom}$. Since the linearized flow is still C^0-conjugated to the linearized flow in $\mathbb{R}^2$, see Lemma 3.1, it suffices to consider (4.9) for the vector field in $\mathbb{R}^2$ investigated in section 3—note that we do not need any differentiability further on.

Hence consider $w \in \mathbb{R}^2$ from now on. Denote the evolution of

$$\dot w = D_u f(u_i^\pm(t), \bar\mu_N)\, w$$

by $\Phi_i^\pm(t,s)$, then $w_i^\pm(t) = \Phi_i^\pm(t,0)\, w_i^\pm(0)$ solves (4.9)(i) and (iii) for arbitrary $w_i^\pm(0) \in X_k$. Note that (4.9)(ii) is then satisfied, too, as the subspaces $X_k \subset \mathbb{R}^2$ are one-dimensional. We shall solve (4.9)(iv)

$$w_j^+(\tfrac12 T_{j-1}) = w_{j+1}^-(-\tfrac12 T_{j-1}) + \dot u_{j+1}^-(-\tfrac12 T_{j-1})(d_{j+1} - d_j) \tag{4.10}$$

for given $d = (d_i)_{i=1,\dots,2N+1}$ and $j = 1, \dots, 2N$. Observe that these equations decouple as we can choose $w_i^\pm(0) \in X_k$ arbitrarily.

First, consider (4.10) for odd $j = 2l+1$ for $l = 0, \dots, N-1$. Then

$$\Phi^+_{2l+1}(t,0) = \Phi^-_{2l+2}(t,0) = \begin{pmatrix} e^{-\alpha_2^s(\mu)t} & 0 \\ 0 & e^{\alpha_2^u(\mu)t} \end{pmatrix}$$

as the flow is linear. Also,

$$\dot u^-_{2l+2}(-\tfrac12 T_{2l}) = (-\alpha_2^s(\mu)\, e^{-\frac12 \alpha_2^s(\mu) T_{2l}}, \alpha_2^u(\mu)\, e^{-\frac12 \alpha_2^u(\mu) T_{2l}})$$

and

$$\begin{aligned} w^+_{2l+1}(\tfrac12 T_{2l}) &= (0, e^{\frac12 \alpha_2^u(\mu) T_{2l}}\, w^+_{2l+1}(0)), \\ w^-_{2l+2}(-\tfrac12 T_{2l}) &= (e^{\frac12 \alpha_2^s(\mu) T_{2l}}\, w^-_{2l+2}(0), 0), \end{aligned}$$

identifying the subspaces X_k with $\mathbb{R}$ as in Figure 5. Thus, we conclude that

$$\begin{aligned} w^+_{2l+1}(0) &= \alpha_2^u(\mu)\, e^{-\alpha_2^u(\mu) T_{2l}}\, (d_{2l+2} - d_{2l+1}) = \mathrm{o}(r)\, (d_{2l+2} - d_{2l+1}), \\ w^-_{2l+2}(0) &= \alpha_2^s(\mu)\, e^{-\alpha_2^s(\mu) T_{2l}}\, (d_{2l+2} - d_{2l+1}) \\ &= \alpha_2^s\, (1 + \mathrm{o}(1))\, r\, (d_{2l+2} - d_{2l+1}), \end{aligned} \tag{4.11}$$

using (3.7) and (3.27).

Next, consider (4.10) for even $j = 2l$ for $l = 1, \dots, N$. Then

$$\begin{aligned} \Phi^+_{2l}(t,0) &= \begin{pmatrix} e^{-\alpha_1^s(\mu)(t-\Omega_2)} & 0 \\ 0 & e^{\alpha_1^u(\mu)(t-\Omega_2)} \end{pmatrix} \Phi^+_{2l}(\Omega_2, 0), \\ \Phi^-_{2l+1}(-t,0) &= \begin{pmatrix} e^{-\alpha_1^s(\mu)(-t+\Omega_1)} & 0 \\ 0 & e^{\alpha_1^u(\mu)(-t+\Omega_1)} \end{pmatrix} \Phi^+_{2l+1}(-\Omega_1, 0) \end{aligned}$$

for $t > 0$ large and with

$$\begin{aligned} \Omega_1 &= \Omega_1(e^{-\alpha_1^s(\mu)\, \tau(T_{2l-1}, \mu)}, \mu), \\ \Omega_2 &= \Omega_2(e^{-\alpha_1^u(\mu)\, \tau(T_{2l-1}, \mu)}, \mu); \end{aligned}$$

see section 3.2. Therefore, we obtain

$$\begin{aligned} w^+_{2l}(\tfrac{1}{2}T_{2l-1}) &= (e^{\alpha_1^s(\mu)(-\frac{1}{2}T_{2l-1}+\Omega_2)}\,\pi^s_{2l}, e^{\alpha_1^u(\mu)(\frac{1}{2}T_{2l-1}-\Omega_2)}\,\pi^u_{2l})\,w^+_{2l}(0),\\ w^-_{2l+1}(-\tfrac{1}{2}T_{2l-1}) &= (e^{\alpha_1^s(\mu)(\frac{1}{2}T_{2l-1}-\Omega_1)}\,\pi^s_{2l+1}, e^{\alpha_1^u(\mu)(-\frac{1}{2}T_{2l-1}+\Omega_1)}\,\pi^u_{2l+1})\,w^-_{2l+1}(0) \end{aligned}$$

for some constants π^k_{2l}, π^k_{2l+1} uniformly bounded in T_{2l-1} for $k = s, u$ such that

$$\pi^u_{2l}, \pi^s_{2l+1} < -\delta < 0 \tag{4.12}$$

for some δ owing to the sign convention for the sections—we identify the subspaces X_k with $\mathbb{R}$ in the same way as we did for Σ_k; see Figure 5. The time derivative is given by

$$\dot{u}^-_{2l+1}(-\tfrac{1}{2}T_{2l-1}) = (-\alpha_1^s(\mu)\,e^{-\alpha_1^s(\mu)(\frac{1}{2}T_{2l-1}-\Omega_2)}, \alpha_1^u(\mu)\,e^{-\alpha_1^u(\mu)(\frac{1}{2}T_{2l-1}-\Omega_1)}).$$

Thus, (4.10) reads

$$\begin{pmatrix} -e^{\alpha_1^s(\mu)(\frac{1}{2}T_{2l-1}-\Omega_1)}\,\pi^s_{2l+1} & e^{\alpha_1^s(\mu)(-\frac{1}{2}T_{2l-1}+\Omega_2)}\,\pi^s_{2l} \\ -e^{\alpha_1^u(\mu)(-\frac{1}{2}T_{2l-1}+\Omega_1)}\,\pi^u_{2l+1} & e^{\alpha_1^u(\mu)(\frac{1}{2}T_{2l-1}-\Omega_2)}\,\pi^u_{2l} \end{pmatrix} \begin{pmatrix} w^-_{2l}(0) \\ w^+_{2l+1}(0) \end{pmatrix}$$
$$= \begin{pmatrix} -\alpha_1^s(\mu)\,e^{-\alpha_1^s(\mu)(\frac{1}{2}T_{2l-1}-\Omega_2)} \\ \alpha_1^u(\mu)\,e^{-\alpha_1^u(\mu)(\frac{1}{2}T_{2l-1}-\Omega_1)} \end{pmatrix} (d_{2l+1}-d_{2l}),$$

and it is straightforward to calculate that for some $\delta > 0$

$$\begin{aligned} w^+_{2l}(0) &= \alpha_1^u(\mu)\,e^{-\alpha_1^u(\mu)(T_{2l-1}-\Omega_1-\Omega_2)}\,\pi^u_{2l}\,(1+\mathrm{O}(e^{-\delta T_{2l-1}}))\,(d_{2l+1}-d_{2l})\\ &= \alpha_1^u(\mu)\,e^{-\alpha_1^u(\mu)\,\tau(T_{2l-1})}\,\pi^u_{2l}\,(1+\mathrm{O}(e^{-\delta\tau(T_{2l-1})}))\,(d_{2l+1}-d_{2l})\\ &= \mathrm{o}(r^{\alpha_2+\gamma_l})\,(d_{2l+1}-d_{2l}),\\ w^-_{2l+1}(0) &= \alpha_1^s(\mu)\,e^{-\alpha_1^s(\mu)(T_{2l-1}-\Omega_1-\Omega_2)}\,\pi^s_{2l+1}\,(1+\mathrm{O}(e^{-\delta T_{2l-1}}))\,(d_{2l+1}-d_{2l})\\ &= \alpha_1^s(\mu)\,e^{-\alpha_1^s(\mu)\,\tau(T_{2l-1})}\,\pi^s_{2l+1}\,(1+\mathrm{O}(e^{-\delta\tau(T_{2l-1})}))\,(d_{2l+1}-d_{2l})\\ &= \alpha_1^s\,(b_{2l-1}+\mathrm{o}(1))\,\pi^s_{2l+1}\,r^{\alpha_2+\gamma_l}\,(d_{2l+1}-d_{2l}); \end{aligned} \tag{4.13}$$

see again (3.7) and (3.27). It is convenient to check the signs appearing in (4.11) and (4.13) by inspecting Figures 5 and 6.

Thus, the differences of $w^\pm_i(0)$ for $i = 1, \ldots, 2N+1$ with $\lambda = 0$ are given by

$$\begin{aligned} w^+_{2l}(0) - w^-_{2l}(0) &= \mathrm{o}(r^{\alpha_2+\gamma_l})\,(d_{2l+1}-d_{2l}) - \alpha_2^s\,(1+\mathrm{o}(1))\,r\,(d_{2l}-d_{2l-1}),\\ w^+_{2l+1}(0) - w^-_{2l+1}(0) &= \mathrm{o}(r)\,(d_{2l+2}-d_{2l+1})\\ &\quad -\alpha_1^s\,(b_{2l-1}+\mathrm{o}(1))\,\pi^s_{2l+1}\,r^{\alpha_2+\gamma_l}\,(d_{2l+1}-d_{2l}), \end{aligned}$$

and the jumps ξ_i read

$$\begin{aligned} \xi_{2l} &= \langle \psi_2(0), w^+_{2l}(0) - w^-_{2l}(0)\rangle\\ &= r\big(\mathrm{o}(r^{\alpha_2+\gamma_l-1})\,(d_{2l+1}-d_{2l}) + \alpha_2^s\,(1+\mathrm{o}(1))\,(d_{2l}-d_{2l-1})\big),\\ \xi_{2l+1} &= \langle \psi_1(0), w^+_{2l+1}(0) - w^-_{2l+1}(0)\rangle\\ &= r\big(\mathrm{o}(1)\,(d_{2l+2}-d_{2l+1})\\ &\quad -\alpha_1^s\,(b_{2l-1}+\mathrm{o}(1))\,\pi^s_{2l+1}\,r^{\alpha_2+\gamma_l-1}\,(d_{2l+1}-d_{2l})\big). \end{aligned} \tag{4.14}$$

Notice that the sign changes in the first equation since $\psi_2(0)$ points in the negative direction of X_2; see Figure 5. We rewrite (4.14) according to

$$\begin{aligned}\xi_{2l} &= r\,(-\kappa_{2l-1}\,d_{2l-1} + (\kappa_{2l-1} - \tilde\kappa_{2l})\,d_{2l} + \tilde\kappa_{2l}\,d_{2l+1}),\\ \xi_{2l+1} &= r\,(-\kappa_{2l}\,d_{2l} + (\kappa_{2l} - \tilde\kappa_{2l+1})\,d_{2l+1} + \tilde\kappa_{2l+1}\,d_{2l+2}),\end{aligned}$$

using the definitions

$$\begin{array}{llll}\kappa_{2l-1} &:= c_{2l-1} + \mathrm{o}(1) &:= \alpha_2^s\,(1+\mathrm{o}(1)),\\ \tilde\kappa_{2l-1} &:= \mathrm{o}(1),\\ \kappa_{2l} &:= (c_{2l} + \mathrm{o}(1))\,r^{\beta_l} &:= -\alpha_1^s\,(b_{2l-1} + \mathrm{o}(1))\,\pi_{2l+1}^s\,r^{\alpha_2+\gamma_l-1},\\ \tilde\kappa_{2l} &:= \mathrm{o}(r^{\beta_l}) &:= \mathrm{o}(r^{\alpha_2+\gamma_l-1})\end{array} \tag{4.15}$$

for $l = 1, \dots, N$ and

$$\kappa_0 = \tilde\kappa_0 = \kappa_{2N+1} = \tilde\kappa_{2N+1} = 0.$$

The exponents β_l and the constants c_j satisfy

$$\begin{array}{ll}\beta_l := \alpha_2 + \gamma_l - 1, & l = 1, \dots, N,\\ 0 < \alpha_2 - 1 = \beta_N < \beta_l < \beta_{l-1}, & l = 2, \dots, N-1,\\ c_j > 0, & j = 1, \dots, 2N,\end{array} \tag{4.16}$$

due to (3.20), (3.26), and (4.12).

Therefore, we end up with computing solutions of

$$\det\left(r\tilde A(r) - M\lambda + \mathrm{O}(|\lambda|(|\lambda| + \mathrm{o}(1)))\right) = 0, \tag{4.17}$$

where

$$M = \mathrm{diag}(M_1K_1, M_2K_2, \dots, M_1K_1)$$

for some positive constants $K_1, K_2 > 0$ and

$$\tilde A(r) = \begin{pmatrix} -\tilde\kappa_1 & \tilde\kappa_1 & & & & \\ -\kappa_1 & \kappa_1 - \tilde\kappa_2 & \tilde\kappa_2 & & & \\ & -\kappa_2 & \kappa_2 - \tilde\kappa_3 & \tilde\kappa_3 & & \\ & & \ddots & \ddots & & \\ & & & & -\kappa_{2N} & \kappa_{2N} \end{pmatrix}. \tag{4.18}$$

As we are mainly interested in stable N-front solutions, we assume

$$\operatorname{sign} M_1 = \operatorname{sign} M_2 = -1$$

from now on, and, by rescaling the solutions $\psi_k(t)$, we obtain

$$M = -\operatorname{id}.$$

The other cases can be handled similarly.

4.3. Solving the reduced eigenvalue problem. Thus we shall solve (4.17). By Rouché's theorem, there exist precisely $2N+1$ solutions of (4.17), since $S(\lambda)$ is analytic in λ and

$$\det S(\lambda) = \lambda^{2N+1} + \mathrm{o}(1)$$

near $\lambda = 0$.

One of these solutions is equal to zero,

$$\lambda_{2N+1} = 0, \tag{4.19}$$

due to translational invariance. By construction, the associated eigenvector is given by $v = (1, \dots, 1)$; see Lemma 4.1.

Substituting $\lambda = \nu r$ and $M = -\mathrm{id}$ into (4.17) and dividing by r^{2N+1} yields

$$\det\left(\tilde{A}(r) + \nu\,(\mathrm{id} + \mathrm{o}(1))\right) = 0. \tag{4.20}$$

There are another N eigenvalues which can be computed easily. Indeed, setting $r = 0$ in (4.20), we obtain

$$\det(\tilde{A}(0) + \nu\,\mathrm{id}) = \nu^{N+1} \prod_{l=1}^{N} (c_{2l-1} + \nu).$$

Hence, again by Rouché's theorem, there exist precisely N solutions $\nu_{2l-1}(r)$ of (4.20) counted with multiplicity and continuous in r such that

$$\nu_{2l-1}(0) = -c_{2l-1} < 0.$$

They correspond to N eigenvalues $\lambda_{2l-1}(r)$ of (4.17) given by

$$\lambda_{2l-1}(r) = \nu_{2l-1}(r)\, r = -(c_{2l-1} + \mathrm{o}(1))\, r < 0, \qquad l = 1, \dots, N. \tag{4.21}$$

It remains to calculate the remaining N eigenvalues of (4.20). The columns of the matrix $S(\nu, r) = \tilde{A}(r) + \nu\,(\mathrm{id} + \mathrm{o}(1))$ are given by

$$\begin{aligned}
C_1 &= (-\tilde{\kappa}_1 + \nu, -\kappa_1, 0, \dots, 0) + \mathrm{o}(1)\nu, \\
C_j &= \Big(0, \dots, 0, \tilde{\kappa}_{j-1}, \underbrace{\kappa_{j-1} - \tilde{\kappa}_j + \nu}_{j\text{th}}, -\kappa_j, 0, \dots, 0\Big) + \mathrm{o}(1)\nu, \qquad j = 2, \dots, 2N, \\
C_{2N+1} &= (0, \dots, 0, \tilde{\kappa}_{2N}, \kappa_{2N} + \nu) + \mathrm{o}(1)\nu;
\end{aligned}$$

see (4.18). Adding successively the jth column C_j to C_{j-1} for $j = 2N+1, \dots, 2$ yields a matrix with columns

$$\begin{aligned}
C_1 &= (\nu, \dots, \nu) + \mathrm{o}(1)\nu, \\
C_j &= \Big(0, \dots, 0, \tilde{\kappa}_{j-1}, \underbrace{\kappa_{j-1} + \nu}_{j\text{th}}, \nu, \dots, \nu\Big) + \mathrm{o}(1)\nu, \qquad j = 2, \dots, 2N, \\
C_{2N+1} &= (0, \dots, 0, \tilde{\kappa}_{2N}, \kappa_{2N} + \nu) + \mathrm{o}(1)\nu.
\end{aligned}$$

Note that this transformation does not change the determinant. Moreover, recall from (4.15) that

$$\begin{aligned}
\kappa_{2l-1} &= c_{2l-1} + \mathrm{o}(1), & \tilde{\kappa}_{2l-1} &= \mathrm{o}(1) = \mathrm{o}(\kappa_{2l-1}), \\
\kappa_{2l} &= (c_{2l} + \mathrm{o}(1))\, r^{\beta_l}, & \tilde{\kappa}_{2l} &= \mathrm{o}(r^{\beta_l}) = \mathrm{o}(\kappa_{2l})
\end{aligned}$$

for positive constants $c_j > 0$ and exponents $\beta_l > 0$ strictly decreasing in l; see (4.16). For fixed k satisfying $1 \le k \le N$, we make the ansatz

$$\nu = r^{\beta_k}\,\eta.$$

Substituting it into the matrix yields

$$\begin{aligned}
C_1 &= \big[(\eta,\dots,\eta) + \mathrm{o}(1)\big]\, r^{\beta_k},\\
C_{2l} &= \left[\left(0,\dots,0,\underbrace{c_{2l-1}}_{(2l)\mathrm{th}},0\dots,0\right) + \mathrm{o}(1)\right],\\
C_{2l+1} &= \begin{cases}
\left[\left(0,\dots,0,\underbrace{\eta}_{(2l+1)\mathrm{th}},\eta,\dots,\eta\right) + \mathrm{o}(1)\right] r^{\beta_k}, & l < k,\\
\left[\left(0,\dots,0,\underbrace{c_{2k}+\eta}_{(2k+1)\mathrm{th}},\eta,\dots,\eta\right) + \mathrm{o}(1)\right] r^{\beta_k}, & l = k,\\
\left[\left(0,\dots,0,\underbrace{c_{2l}}_{(2l+1)\mathrm{th}},0,\dots,0\right) + \mathrm{o}(1)\right] r^{\beta_l}, & l > k
\end{cases}
\end{aligned}$$

for $l = 1,\dots,N$. Thus, factorizing the powers of r multiplying each column, the determinant of the matrix $S(r^{\beta_k}\eta, r)$ equals

$$\det\, S(r^{\beta_k}\,\eta, r) = \big(\det\, \tilde{S}(\eta, r)\big)\, r^{(k+1)\beta_k} \prod_{l=k+1}^{N} r^{\beta_l},$$

where the columns of $\tilde{S}(\eta, r)$ are given by

$$\begin{aligned}
C_1 &= \big[(\eta,\dots,\eta) + \mathrm{o}(1)\big],\\
C_{2l} &= \left[\left(0,\dots,0,\underbrace{c_{2l-1}}_{(2l)\mathrm{th}},0\dots,0\right) + \mathrm{o}(1)\right],\\
C_{2l+1} &= \begin{cases}
\left[\left(0,\dots,0,\underbrace{\eta}_{(2l+1)\mathrm{th}},\eta,\dots,\eta\right) + \mathrm{o}(1)\right], & l < k,\\
\left[\left(0,\dots,0,\underbrace{c_{2k}+\eta}_{(2k+1)\mathrm{th}},\eta,\dots,\eta\right) + \mathrm{o}(1)\right], & l = k,\\
\left[\left(0,\dots,0,\underbrace{c_{2l}}_{(2l+1)\mathrm{th}},0,\dots,0\right) + \mathrm{o}(1)\right], & l > k.
\end{cases}
\end{aligned}$$

As we are interested in zeroes for $r > 0$, it suffices to solve

$$\det\, \tilde{S}(\eta, r) = 0. \tag{4.22}$$

This matrix, however, is upper triangular up to terms of order o(1). Its determinant is therefore given by

$$\begin{aligned}\det \tilde{S}(\eta, r) &= \det \tilde{S}(\eta, 0) + \mathrm{o}(1) \\ &= \eta^k \big(\textstyle\prod_{l=k+1}^{N} c_{2l} \big)(\eta + c_{2k}) \big(\textstyle\prod_{l=1}^{N} c_{2l-1} \big) + \mathrm{o}(1).\end{aligned}$$

Again by Rouché's theorem, there is a unique solution $\eta_{2l}(r)$ of (4.22) satisfying

$$\eta_{2l}(0) = -c_{2l}$$

for $l = 1, \dots, N$. The corresponding solution $\lambda_{2l}(r)$ of (4.17) is given by

$$\begin{aligned}\lambda_{2l}(r) = \nu_{2l}(r)\, r = \eta_{2l}(r)\, r^{1+\beta_l} &= -(c_{2l} + \mathrm{o}(1))\, r^{1+\beta_l} \\ &= -(c_{2l} + \mathrm{o}(1))\, r^{\alpha_2 + \gamma_{N+1-l}}\end{aligned} \tag{4.23}$$

for $l = 1, \dots, N$; see (4.16) for the last identity. Note that these solutions are not the same for different values of l owing to (4.16). Moreover, they converge faster to zero than the eigenvalues λ_{2l-1} obtained in (4.21).

Summarizing the facts obtained above, we have calculated $2N+1$ solutions λ_j of (4.17) appearing in (4.19), (4.21), and (4.23). According to the remark above, they are pairwise distinct, from which we have found all solutions. This proves Theorem 2.2. □

5. Application to the FitzHugh–Nagumo equation. Consider the FitzHugh–Nagumo equation

$$\begin{aligned}u_t &= u_{xx} + f(u) - w, \\ w_t &= \epsilon(u - \gamma w)\end{aligned} \tag{5.1}$$

for $x \in \mathbb{R}$ with $f(u) = u(1-u)(u-a)$ and $a \in (0, \frac{1}{2})$ fixed. This equation is a simplification of the Hodgkin–Huxley equation modeling the propagation of impulses in nerve axons. Being interested in travelling waves $(u, w)(x, t) = (u, w)(x + ct)$, we introduce new variables $(\xi, t) = (x + ct, t)$ in which (5.1) takes the form

$$\begin{aligned}u_t &= u_{\xi\xi} - c u_\xi + f(u) - w, \\ w_t &= -c w_\xi + \epsilon(u - \gamma w).\end{aligned} \tag{5.2}$$

The existence of fronts travelling with wave speed c boils down to investigating heteroclinic orbits of the ordinary differential equation

$$\begin{aligned}\dot{u} &= v, \\ \dot{v} &= cv - f(u) + w, \\ \dot{w} &= \tfrac{\epsilon}{c}(u - \gamma w),\end{aligned} \tag{5.3}$$

which is the steady-state equation corresponding to (5.2). Here $\dot{} = d/d\xi$. Linearized stability of equilibria (u, w) of (5.2) is determined by the spectrum of the linear operator

$$L(U, W) = \begin{pmatrix} U_{\xi\xi} - c\, U_\xi + D_u f(u) U - W \\ -c\, W_\xi + \epsilon(U - \gamma W) \end{pmatrix}. \tag{5.4}$$

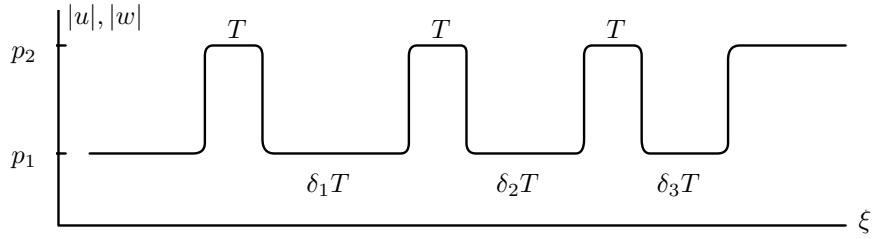

FIG. 7. *The N-front wave solution for $N = 3$. The distances of the layers are given by T and $\delta_j T = \frac{\alpha_2^u + \alpha_2^s \theta_{N+1-j}}{\alpha_1^s} T$ with $\theta_{N+1-j} > 0$ strictly decreasing in j; see Theorem* 2.1.

In particular, eigenvalues λ with corresponding eigenfunction (U, W) of L are given by bounded solutions of

$$\begin{aligned} \dot{U} &= V, \\ \dot{V} &= cV - D_u f(u)U + W + \lambda U, \\ \dot{W} &= \tfrac{\epsilon}{c}(U - \gamma W) - \tfrac{\lambda}{c} W. \end{aligned} \tag{5.5}$$

Deng proved in [Den91b] that there is a curve $(\gamma(\epsilon), c(\epsilon))$ for all $\epsilon > 0$ sufficiently small such that the FitzHugh–Nagumo equation (5.3) possesses a twisted heteroclinic loop for these values of parameters. In particular, he concluded the existence of N-fronts for any $N \geq 1$ using his result [Den91a]. Theorem 2.1 of the present article provides the distance of the layers; see Figure 7. Yanagida proved in [Yan89] that the simple fronts $q_1(t)$ and $q_2(t)$ building the heteroclinic loop are linearly stable with respect to the partial differential equation; that is, the spectrum of the linearized operator (5.4) is contained in the left half-plane except for a simple eigenvalue at zero. Finally, Nii [Nii95b] proved that the 1-fronts are linearly stable, too, using topological methods—however, he had to assume that the flow of (5.3) is linear near both equilibria. The next result asserts that in fact all N-fronts are linearly stable and provides asymptotic expansions of the critical eigenvalues.

THEOREM 5.1. *The N-fronts (and N-backs) of* (5.1) *proved to exist by Deng [Den*91*b] are linearly stable for all N. The $2N+1$ critical eigenvalues near zero are given by Theorem* 2.2. Note that linear stability implies nonlinear stability by [BJ89].

Proof. We shall use Theorem 2.2 to conclude linear stability of the N-fronts. First note that the hypotheses (H1)–(H6) needed in that theorem are met by [Den91b]. Moreover, by the results in [AGJ90] and the stability of the simple fronts proved in [Yan89], it is sufficient to calculate eigenvalues of the linearized operator (5.4) near zero; see for example [Nii95b] for a discussion. Indeed, the spectrum of (5.4) does not contain eigenvalues with nonnegative real part and large modulus; see [Eva75]. Comparing the eigenvalue problem (5.5) and the travelling wave equation (5.3) with equations (2.1) and (2.4), we see that they are of the same form by taking B according to

$$B = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & -\frac{1}{c} \end{pmatrix}.$$

Hence it suffices to prove that the Melnikov integrals

$$\int_{-\infty}^{\infty} \langle \psi_k(t), B\dot{q}_k(t) \rangle \, dt < 0 \tag{5.6}$$

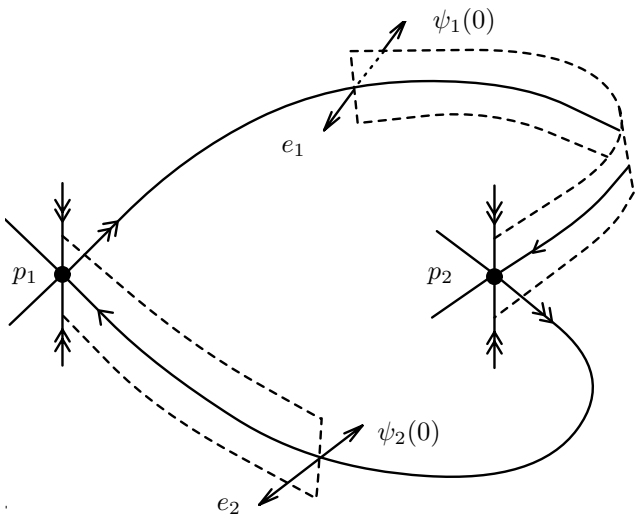

FIG. 8. *Conventions used by Deng and the present article.*

are negative for $k = 1, 2$, where $\psi_k(t)$ are chosen according to hypothesis (H6); see Figures 2 or 8. Indeed, then the statement of the theorem follows immediately from Theorem 2.2.

In order to do so, notice that for any solution (u, v, w) of (5.3)

$$B \begin{pmatrix} \dot{u} \\ \dot{v} \\ \dot{w} \end{pmatrix} = \begin{pmatrix} 0 \\ \dot{u} \\ -\frac{1}{c}\dot{w} \end{pmatrix} = \begin{pmatrix} 0 \\ v \\ -\frac{\epsilon}{c^2}(u - \gamma w) \end{pmatrix} = D_c F(u, v, w, c)$$

holds, where F denotes the right-hand side of (5.3). In particular, we obtain

$$\int_{-\infty}^{\infty} \langle \psi_k(t), B\dot{q}_k(t) \rangle \, dt = \int_{-\infty}^{\infty} \langle \psi_k(t), D_c F(q_k(t), c) \rangle \, dt. \tag{5.7}$$

The second integral in the above formula is the derivative with respect to c of the signed distance of unstable and unstable manifolds measured in the direction $\psi_k(0)$, that is,

$$\int_{-\infty}^{\infty} \langle \psi_k(t), D_c F(q_k(t), c) \rangle \, dt = \frac{d}{dc} \langle \psi_k(0), p_k^u(c) - p_{k+1}^s(c) \rangle, \tag{5.8}$$

where $p_k^u(c) \in W^u(p_k, c)$ and $p_k^s(c) \in W^s(p_k, c)$; see, for instance, [Kok88], [Lin90], or [Den91b]. Here, and in the following, the index k is taken modulo two. The last quantity appearing in (5.8) has been computed in [Den91b]. What is actually computed therein is

$$\frac{d}{dc} Q_k = \frac{d}{dc} \langle e_k, p_{k+1}^s(c) - p_k^u(c) \rangle < 0; \tag{5.9}$$

see [Den91b, eq. (3.1)] for the definition and [Den91b, eqs. (5.3a), (5.4a)] for the actual computation. Moreover, the vectors e_k appearing in (5.9) above are chosen in [Den91b, pp. 1641 and 1644] such that

$$e_k = -\psi_k(0); \tag{5.10}$$

see Figure 8. Summarizing, we obtain from (5.7) and (5.8) that the Melnikov integrals

$$\int_{-\infty}^{\infty} \langle \psi_k(t), B\dot{q}_k(t) \rangle \, dt \overset{(5.7),(5.8)}{=} \frac{d}{dc} \langle \psi_k(0), p_k^u(c) - p_{k+1}^s(c) \rangle$$

$$\overset{(5.10)}{=} \frac{d}{dc} \langle -e_k(0), p_k^u(c) - p_{k+1}^s(c) \rangle$$

$$\overset{(5.9)}{=} \frac{d}{dc} Q_k \; < \; 0$$

are indeed negative. Thus the theorem is proved. □

Acknowledgments. I am very grateful to Sanjeeva Balasuriya, Christopher K.R.T. Jones, and Daniela Peterhof for helpful discussions. Moreover, I wish to thank Hiroshi Kokubu and Shunsaku Nii for informing me about their related work.

MONOTONICITY OF PHASELOCKED SOLUTIONS IN CHAINS AND ARRAYS OF NEAREST-NEIGHBOR COUPLED OSCILLATORS*

LIWEI REN† AND G. BARD ERMENTROUT†

Abstract. The existence of phaselocked solutions in chains of weakly coupled oscillators is proven rigorously. The solutions show interesting monotonicity which plays an important role for the existence proofs. Under some conditions, we show that two-dimensional arrays can be decomposed into two one-dimensional problems. With this theory of decomposition, target patterns can be explained. Numerical results are provided to illustrate the theorems on the chain problem and to show traveling waves in the chains and arrays.

Key words. coupled oscillators, target patterns, phaselocking, neurons

1. Introduction.

Coupled oscillators play an increasingly important role in our understanding of various types of repetitive activity in the nervous system. There have been numerous analytic and numerical studies of the behavior of systems of coupled oscillators. These range from models of cognitive processing and binding [1] to attempts to model locomotor patterns [2]. Several connection topologies have been explored primarily due to their mathematical tractability. The simplest topology is a one-dimensional chain of oscillators. Mathematically, the case in which the two ends are connected is the easiest to analyze, but in realistic applications, this rarely arises. However, the chain topology is quite natural for models of systems such as the lamprey swim central pattern generator [2] or the central pattern generator of the leech [3]. The behavior of weakly coupled oscillators in a chain has been the object of extensive work by several authors [4, 5, 6, 7, 8].

Two-dimensional arrays of oscillators have been subject to far less mathematical analysis; most work deals exclusively with numerical simulations. They arise more naturally than chains in attempts to understand oscillatory neural behavior in neural tissue which is typically arranged in distinct two-dimensional sheets. Furthermore, there are many phenomena that can occur in two- and three-dimensional systems of oscillators that are not possible in one dimension.

It was shown in [5] that the phaselocked behavior of a sufficiently long chain of weakly coupled oscillators can be described by the solutions of a singularly perturbed two-point boundary value problem. The point of this reduction is that the analysis of phaselocking and the behavior of the chain in the presence of inhomogeneities and anisotropic coupling is much easier for the continuum model than for its discrete analogue. In this paper, we will use another approach to investigate the phaselocked behavior with *any number of oscillators*. That is, we do not require the length of the chain to tend to infinity.

Coupled oscillators present an almost impossible problem to analyze in any generality. Thus, we will restrict our attention to a class of so-called phase models that

*Received by the editors February 14, 1996; accepted for publication (in revised form) October 17, 1996. This work was supported by NIH grant NIMH-47150 and NSF grant DMS 96-26728.

†Department of Mathematics, University of Pittsburgh, Pittsburgh, PA 15260 (bard@math.pitt.edu).

arise when oscillatory elements are weakly coupled. As was the case in [5], we will restrict our attention in this paper to nearest-neighbor coupling. In a later paper, we investigate coupling with greater spread. We first consider one-dimensional chains of oscillators. Then, we turn our attention to two-dimensional arrays. Under the condition that the distribution of intrinsic frequencies is a sum of two stripe distributions: one with constant frequencies along each row and another with constant frequencies along each column, we are able to decompose the two-dimensional problem into a set of one-dimensional problems and from this gain insight into the global phaselocked behavior. The techniques for two-dimensional arrays can be generalized in an obvious fashion to three- and higher dimensional arrays.

The equations to be considered have the form

$$\theta_i' = \omega_i + H^+(\theta_{i+1} - \theta_i) + H^-(\theta_{i-1} - \theta i), \tag{1.1}$$

where $i = 1, \ldots, n+1$, both H^+ and H^- are smooth 2π-periodic functions of their arguments, and ω_i is the frequency for each oscillator. Note that (1.1) is a nearest-neighbor coupled system. The term H^- (respectively, H^+) will be ignored for $i = 1$ (respectively, $i = n+1$). Equation (1.1) arises naturally in systems of weakly coupled oscillators. We assume that without coupling, each component of the chain has an asymptotically stable limit cycle. Thus, without coupling, each oscillator is described by a single coordinate, the phase, θ_i. The phase space of the $n+1$ oscillators then lies in an $n+1$ torus. If the oscillators interact weakly, then this invariant torus persists, and it follows from averaging theory that the equations for the phases of the $n+1$ oscillators is exactly equation (1.1). (For details on the derivation of these equations, see, e.g., [4].) The interaction functions $H^{\pm}$ are easily computed once the uncoupled oscillation is known and a formula is given for the interaction between the oscillators.

We point out that if two oscillators are coupled by diffusion, then the interaction functions $H^{\pm}$ vanish at 0. Thus, if there are no local differences in the oscillators (ω_i is independent of i) then the synchronous state $\theta_i(t) = \omega t$ is one possible solution. However, if the coupling between oscillators is based on chemical transmission then one does not expect that $H^{\pm}(0)$ will vanish. Because oscillators on the boundary (at the ends in one dimension, on the edges in two dimensions, etc.) receive less synaptic input than oscillators in the interior, this sets up a natural frequency difference between the oscillators. This makes it possible to induce a pattern of relative phases such as a traveling wave in one dimension and target patterns in two dimensions. In [5] we analyzed chains of oscillators in which there is an intrinsic anisotropy in the coupling so that H^+ and H^- are not necessarily the same. This was exploited in order to suggest a mechanism for the uniform traveling wave of electrical activity in the lamprey spinal cord. In this paper, we are mainly concerned with couplings for which $H^{\pm}$ are identical. In [7] the behavior of the chain is understood by letting n get very large and converting to a continuum equation. Here we do not restrict the size of n; the results hold for both small and large n. The main reason that we first analyze the one-dimensional chain is that we can then use these results to analyze a class of solutions in two and higher dimensions.

In section 2, we shall take the technique used in [9] to prove the existence of phaselocked solutions for several general cases. The monotonicity of the phaselocked solutions is also obtained. The monotonicity does not have any specific implication for traveling wave, but it does play a critical role in the existence proof of the phaselocked solutions.

In section 3, we shall investigate the two-dimensional arrays of weakly coupled oscillators based on the existence results of section 2. As in the one-dimensional case,

we restrict our attention to nearest-neighbor coupling, but the coupling in each of the four directions need not be the same. Under some conditions on the frequencies ω_{ij}, we can reduce this problem to two independent chain problems such that we can apply the results obtained from section 2 to describe the behavior of two-dimensional arrays of weakly coupled oscillators. One of the main results is that with isotropic "synaptic coupling," target patterns spontaneously form and synchrony cannot occur. This is due to the effects of boundaries in synaptically coupled cells.

Finally, we discuss some other two-dimensional solutions as well as how small chains can qualitatively differ from very long chains.

2. Chains of oscillators. For convenience, the equations (1.1) are written in the form

$$\begin{aligned} \theta_1' &= \omega_1 + H^+(\theta_2 - \theta_1), \\ \theta_i' &= \omega_i + H^-(\theta_{i-1} - \theta_i) + H^+(\theta_{i+1} - \theta_i), \\ \theta_{n+1}' &= \omega_{n+1} + H^-(\theta_n - \theta_{n+1}). \end{aligned} \tag{2.1}$$

We take $\phi_i = \theta_{i+1} - \theta_i, \beta_i = \omega_{i+1} - \omega_i, i = 1, \ldots, n$. Also, we define two functions f and g related to H^+ and H^- as $f(\phi) + g(\phi) = H^+(\phi)$ and $f(\phi) - g(\phi) = H^-(-\phi)$. In (2.1), if the ith equation is subtracted from the $(i+1)$th one, we have

$$\begin{aligned} \phi_1' &= \beta_1 + f(\phi_2) + g(\phi_2) - 2g(\phi_1), \\ \phi_i' &= \beta_i + f(\phi_{i+1}) - f(\phi_{i-1}) + g(\phi_{i+1}) - 2g(\phi_i) + g(\phi_{i-1}), \\ & \qquad i = 2, \ldots, n-1, \\ \phi_n' &= \beta_n - f(\phi_{n-1}) - 2g(\phi_n) + g(\phi_{n-1}). \end{aligned} \tag{2.2}$$

Two numbers ϕ_L and ϕ_R need to be considered. They are defined as $f(\phi_L) = g(\phi_L)$, i.e., $H^-(-\phi_L) = 0$, and $f(\phi_R) = -g(\phi_R)$, i.e., $H^+(\phi_R) = 0$.

We assume some hypotheses on f and g in a sufficiently large interval J around $\phi = 0$:

(H1) $g'(\phi) > |f'(\phi)|$ *for* $\phi \in J$;

(H2) *There exists a unique solution* ϕ_L *(respectively,* ϕ_R*) to* $f = g$ *(respectively,* $f = -g$*) for* $\phi \in J$.

These conditions are proposed in [5] with other conditions. Note that $\phi_R < 0 < \phi_L$ if $f(0) > |g(0)|$ and $\phi_L < 0 < \phi_R$ if $f(0) < -|g(0)|$.

2.1. Isotropic case with $\beta_i = 0, i = 1, \ldots, n$. We investigate the case with $H^+ = H^-$ and $\beta_i = 0, i = 0, \ldots, n$. In this case, f is an even function and g an odd one. And we have $\phi_L = -\phi_R$. Then (2.2) can be rewritten as

$$\begin{aligned} \phi_1' &= f(\phi_2) + g(\phi_2) - 2g(\phi_1), \\ \phi_i' &= f(\phi_{i+1}) - f(\phi_{i-1}) + g(\phi_{i+1}) - 2g(\phi_i) + g(\phi_{i-1}), \\ & \qquad i = 2, \ldots, n-1, \\ \phi_n' &= -f(\phi_{n-1}) - 2g(\phi_n) + g(\phi_{n-1}). \end{aligned} \tag{2.3}$$

First of all, let's look at the initial value problem (IVP) (2.1) with $\theta_i(0) = c$ where c is any real number. Then by the facts that $H^+ = H^-$ and $\omega_i \equiv \omega$ (since $\beta_i = 0$, $i = 1, \ldots, n$), we have $\theta_i(t) = \theta_{n+2-i}(t)$ for $t \geq 0, i = 1, \ldots, n+1$. Then the IVP (2.3) with $\phi_i(0) = 0$ shall yield $\phi_i(t) \equiv -\phi_{n+1-i}(t)$. That inspires us to study the system including only half the number of equations of (2.3).

LEMMA 2.1. *Let $n = 2m - 1$. Assume that f and g satisfy the conditions* (H1), (H2), *and $f(0) > 0$; then the IVP* (2.3) *with $\phi_i(0) = 0, i = 1, \dots, n$, has the following monotonicity along the trajectory:*

$$\phi_L > \phi_1(t) > \phi_2(t) > \cdots > \phi_{m-1}(t) > \phi_m(t) \equiv 0 \tag{2.4}$$

and

$$\phi_i'(t) > 0, i = 1, \dots, m-1 \tag{2.5}$$

for $0 < t < \hat{t}$, where $\hat{t}$ is such that $\phi_i'(\hat{t}) = 0$, $i = 1, \dots, m$, or $\hat{t} = +\infty$.

Remark. The fixed point always happens at $t = +\infty$ for an autonomous system. So we should have $\hat{t} = +\infty$ here. But a finite positive $\hat{t}$ does not affect our results. Hence we define $\hat{t}$ in the above way for the convenience of proof.

Proof. As we mentioned, $\phi_m(t) = -\phi_{n+1-m}(t) = -\phi_m(t)$ for $t \geq 0$. Then $\phi_m(t) \equiv 0$ is obvious. Since we only use half the number of equations (2.3), we restate them as

$$\begin{aligned} \phi_1' &= f(\phi_2) + g(\phi_2) - 2g(\phi_1), \\ \phi_i' &= f(\phi_{i+1}) - f(\phi_{i-1}) + g(\phi_{i+1}) - 2g(\phi_i) + g(\phi_{i-1}), \\ &\quad i = 2, \dots, m-2, \\ \phi_{m-1}' &= f(0) - f(\phi_{m-2}) - 2g(\phi_{m-1}) + g(\phi_{m-2}). \end{aligned} \tag{2.6}$$

Therefore $\phi_1'(0) = f(0) > 0, \phi_i'(0) = 0, i = 2, \dots, m-1$ (where we use the fact that $g(0) = 0$ since g is odd).

Furthermore, one can show by induction that

$$\begin{aligned} \phi_1'(0) &> 0, \\ \phi_i'(0) = \cdots = \phi_i^{(i-1)}(0) &= 0, \\ \phi_i^{(i)}(0) = g'(0)\phi_{i-1}^{(i-1)}(0) &> 0, \quad i = 2, \dots, m-1. \end{aligned} \tag{2.7}$$

Remark. By (H1), $g'(0) > 0$ such that $\phi_i^{(i)}(0) = [g'(0)]^{i-1}\phi_1'(0) > 0$.

So there exists small $\delta > 0$ such that (2.4) and (2.5) hold for $0 < t < \delta$ if one applies the Taylor's expansion for $\phi_i(t)$ and $\phi_i'(t)$ around $t = 0$. Starting with this result, we need to show that (2.4) and (2.5) are always true for $t > 0$.

By contradiction, suppose that there is a first place t_0 where (2.4) and (2.5) break down. Then we need to study the following cases.

CASE 1. $\phi_L = \phi_1(t_0) \geq \phi_2(t_0) \geq \cdots \geq \phi_{m-1}(t_0) > \phi_m(t_0) \equiv 0$ *and* $\phi_i'(t_0) \geq 0$, $i = 1, \dots, m-1$.

Then

$$\begin{aligned} 0 \leq \phi_1'(t_0) &= f(\phi_2(t_0)) + g(\phi_2(t_0)) - 2g(\phi_1(t_0)) \\ &= f(\phi_2(t_0)) + g(\phi_2(t_0)) - 2g(\phi_L) \\ &= f(\phi_2(t_0)) + g(\phi_2(t_0)) - f(\phi_L) - g(\phi_L) \\ &= [f'(\xi) + g'(\xi)](\phi_2(t_0) - \phi_L) \\ &\leq 0, \end{aligned}$$

where $\xi \in (\phi_2(t_0), \phi_L)$ by the mean value theorem and $(f' + g')(\xi) > 0$ by (H1). This leads to $\phi_2(t_0) = \phi_L$.

By induction on i, we shall gain $\phi_i(t_0) = \phi_L$, $i = 2, \ldots, m-1$.

Then we have

$$\begin{aligned} 0 &\le f(0) - f(\phi_L) - g(\phi_L) \\ &= f(0) + g(0) - f(\phi_L) - g(\phi_L) \\ &= (f' + g')(\xi)(0 - \phi_L), \end{aligned}$$

which implies $\phi_L \le 0$. This leads to contradiction since $\phi_L > 0$. Therefore *Case* 1 *is impossible.*

CASE 2. $\phi_L > \phi_1(t_0) > \cdots > \phi_j(t_0) = \phi_{j+1} \ge \cdots \ge \phi_{m-1}(t_0) > \phi_m(t_0) = 0$ *for some* $j \in \{1, 2, \ldots, m-2\}$ *and* $\phi_i'(t_0) \ge 0$ $\forall i \in \{1, \ldots, m-1\}$.

Then

$$\begin{aligned} 0 \le \phi_{j+1}'(t_0) &= f(\phi_{j+2}(t_0)) - f(\phi_j(t_0)) + g(\phi_{j+2}(t_0)) - 2g(\phi_{j+1}(t_0)) + g(\phi_j(t_0)) \\ &= f(\phi_{j+2}(t_0)) - f(\phi_{j+1}(t_0)) + g(\phi_{j+2}(t_0)) - g(\phi_{j+1}(t_0)) \\ &= [f' + g'](\xi)(\phi_{j+2}(t_0) - \phi_{j+1}(t_0)) \\ &\le 0, \end{aligned}$$

which implies $\phi_{j+2}(t_0) = \phi_{j+1}(t_0)$ (since $f' + g' > 0$ in J and $\phi_{j+1}(t_0) \ge \phi_{j+2}(t_0)$).

By induction, we have $\phi_L > \phi_1(t_0) > \cdots > \phi_j(t_0) = \phi_{j+1}(t_0) = \cdots = \phi_{m-1}(t_0) > \phi_m(t_0) = 0$.

Then

$$\begin{aligned} 0 \le \phi_{m-1}'(t_0) &= f(0) - f(\phi_{m-1}(t_0)) - g(\phi_{m-1}(t_0)) \\ &= f(0) + g(0) - f(\phi_{m-1}(t_0)) - g(\phi_{m-1}(t_0)) \\ &= [f' + g'](\xi)(0 - \phi_{m-1}(t_0)), \end{aligned}$$

which implies $\phi_{m-1}(t_0) \le 0$: a contradiction!

Therefore we *eliminate the possibility of Case* 2.

CASE 3. $\phi_L > \phi_1(t_0) > \cdots > \phi_{m-1}(t_0) > \phi_m(t_0) = 0$ *and* $\phi_i'(t_0) \ge 0$ $\forall i$ *and* $\phi_j'(t_0) = 0$ *for some* $j \in \{1, \ldots, m-1\}$.

First of all, if $j = 1$, i.e., $\phi_1'(t_0) = 0$, then we must have $\phi_2'(t_0) = 0$. Otherwise $\phi_2'(t_0) > 0$; then for $\varepsilon > 0$ small enough, we have

$$\begin{aligned} \phi_1'(t_0 - \varepsilon) &= \phi_1'(t_0) - \phi_1''(t_0)\varepsilon + o(\varepsilon^2) \\ &= \phi_1'(t_0) - [f'(\phi_2(t_0)) + g'(\phi_2(t_0))]\phi_2'(t_0)\varepsilon + 2g'(\phi_1(t_0))\phi_1'(t_0)\varepsilon + o(\varepsilon^2) \\ &= -[f'(\phi_2(t_0)) + g'(\phi_2(t_0))]\phi_2'(t_0)\varepsilon + o(\varepsilon^2) \\ &< 0. \end{aligned}$$

This is a contradiction since t_0 is the first place where (2.4) and (2.5) break down.

Furthermore, we can get $\phi_i'(t_0) = 0, i = 2, \ldots, m-1$ by using the techniques of induction and contradiction. Taking $\hat{t} = t_0$, we are done with the proof.

Secondly, assume that $\phi_i'(t_0) > 0, i = 1, \ldots, j-1$, and $\phi_j'(t_0) = 0$ for some $j \in \{2, \ldots, m-1\}$. Then by applying the same technique above and noting that $g' - f' > 0$ in J, we will obtain $\phi_{j-1}'(t_0) = 0$, which is a contradiction. Hence *we eliminate Case* 3.

Now by getting rid of Cases 1–3, we can conclude that either there exists a $\hat{t} > 0$ such that (2.4) and (2.5) hold for $0 < t < \hat{t}$ and $\phi_i'(\hat{t}) = 0, i = 1, \ldots, m$, or the first place t_0 where (2.4) and (2.5) break down does not exist. The proof is completed. □

Remark 1. In the proof of Lemma 2.1, the monotonicity of solution along the trajectory plays an important role. In order to get monotonicity at the start of the trajectory, we need the initial vector $\phi_i(0) = 0, i = 1, \ldots, n$. For other initial vectors, monotonicity fails.

Remark 2. Throughout this paper, we always start from $\phi_i(0) = 0$. As we can see in the following sections, if the monotonicity fails on the trajectory, we cannot continue the proof theoretically. But numerical experiments show that the solution trajectory of (2.2) always converges to the same equilibrium for any initial vector. It seems that the basin of attraction is infinitely large.

LEMMA 2.2. *Let $n = 2m$. Assume that f and g satisfy the conditions* (H1), (H2), *and $f(0) > 0$; then the IVP* (2.3) *with $\phi_i(0) = 0, i = 1, \ldots, n$, has the following monotonicity along the trajectory:*

$$\phi_L > \phi_1(t) > \phi_2(t) > \cdots > \phi_{m-1}(t) > \phi_m(t) > 0 \tag{2.8}$$

and

$$\phi_i'(t) > 0, \quad 0 < t < \hat{t}, \quad i = 1, \ldots, m, \tag{2.9}$$

where $\hat{t}$ is such that $\phi_i'(\hat{t}) = 0$, $i = 1, \ldots, m$, or $\hat{t} = +\infty$.

Proof. The proof is similar to the proof of Lemma 2.1. The difference is that we should restate the equations of (2.3) as

$$\begin{aligned} \phi_1' &= f(\phi_2) + g(\phi_2) - 2g(\phi_1), \\ \phi_i' &= f(\phi_{i+1}) - f(\phi_{i-1}) + g(\phi_{i+1}) - 2g(\phi_i) + g(\phi_{i-1}), \\ &\qquad i = 2, \ldots, m-1, \\ \phi_m' &= f(\phi_m) - f(\phi_{m-1}) - 3g(\phi_m) + g(\phi_{m-1}). \end{aligned} \tag{2.10}$$

All the techniques from Lemma 2.1 can be applied here so we ignore the details. ∎

THEOREM 2.3. *Assume f and g satisfy the same conditions as in Lemmas* 2.1 *and* 2.2; *then the IVP* (2.3) *with $\phi_i(0) = 0$, $i = 1, \ldots, n$ has the following properties:*

(i) *For each $i \in \{1, \ldots, n\}$, there exists $\bar{\phi}_i$ such that $\lim_{t \to \hat{t}} \phi_i(t) = \bar{\phi}_i$;*

(ii) *$(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ is the fixed point of the system* (2.3);

(iii) *$\phi_L > \bar{\phi}_1 > \bar{\phi}_2 > \cdots > \bar{\phi}_{n-1} > \bar{\phi}_n > \phi_R$;*

(iv) *$\bar{\phi}_i = -\bar{\phi}_{n+1-i}$, $i = 1, \ldots, n$.*

Proof. By the results of Lemmas 2.1 and 2.2, (i), (ii), and (iv) are easy to check. Also we have $\phi_L \geq \bar{\phi}_1 \geq \bar{\phi}_2 \geq \cdots \geq \bar{\phi}_{n-1} \geq \bar{\phi}_n \geq \phi_R$. We need to show that all the inequalities are strict. By contradiction, suppose $\phi_L = \bar{\phi}_1$. Then we have

$$\begin{aligned} 0 &= f(\bar{\phi}_2) + g(\bar{\phi}_2) - 2g(\bar{\phi}_1) \\ &= f(\bar{\phi}_2) + g(\bar{\phi}_2) - 2g(\phi_L) \\ &= f(\bar{\phi}_2) + g(\bar{\phi}_2) - [f(\phi_L) + g(\phi_L)] \\ &= [f' + g'](\xi)(\bar{\phi}_2 - \phi_L), \end{aligned}$$

which implies $\bar{\phi}_2 = \phi_L$.

Then we would have $\bar{\phi}_i = \phi_L$, $i = 1, \ldots, n$ by induction on i.

And $0 = -f(\phi_L) - 2g(\phi_L) + g(\phi_L) = -f(\phi_L) - g(\phi_L)$ by the last equation of (2.3) such that $f(\phi_L) = -g(\phi_L)$ which leads to $\phi_L = \phi_R$. This contradicts $\phi_L = -\phi_R$ since $\phi_L > 0$. Hence $\phi_L > \bar{\phi}_1$ must hold.

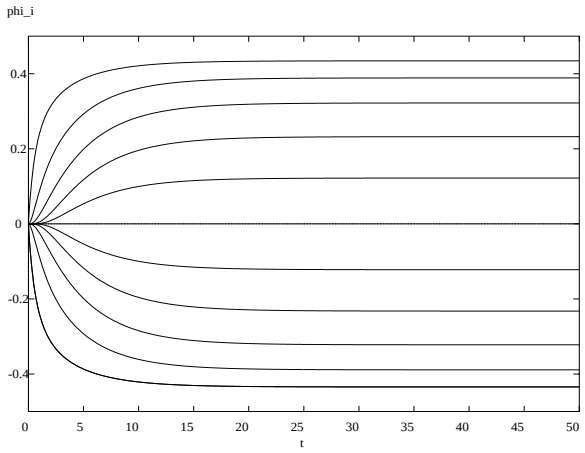

FIG. 2.1. *The isotropic case with* $H^+(\phi) = H^-(\phi) = H(\phi) = .5\cos\phi + \sin\phi$, $n = 11$, *and* $\beta_i = 0.0$.

Suppose $\bar{\phi}_1 = \bar{\phi}_2$; then $0 = f(\bar{\phi}_2) + g(\bar{\phi}_2) - 2g(\bar{\phi}_1)$ by (2.3). This is $0 = f(\bar{\phi}_1) - g(\bar{\phi}_1)$, which implies $\bar{\phi}_1 = \phi_L$. So we must have $\phi_L > \bar{\phi}_1 > \bar{\phi}_2$. By the symmetry, we have $\phi_R < \bar{\phi}_n < \bar{\phi}_{n-1}$.

Suppose i is the first index such that $\bar{\phi}_i = \bar{\phi}_{i+1}$; then

$$\begin{aligned} 0 &= f(\bar{\phi}_{i+1}) - f(\bar{\phi}_{i-1}) + g(\bar{\phi}_{i+1}) - 2g(\bar{\phi}_i) + g(\bar{\phi}_{i-1}) \\ &= f(\bar{\phi}_i) - f(\bar{\phi}_{i-1}) - g(\bar{\phi}_i) + g(\bar{\phi}_{i-1}) \\ &= f(\bar{\phi}_i) - g(\bar{\phi}_{i-1}) - g(\bar{\phi}_i) + g(\bar{\phi}_{i-1}) \\ &= (g' - f')(\xi)(\bar{\phi}_{i-1} - \bar{\phi}_i), \end{aligned}$$

which implies $\bar{\phi}_{i-1} = \bar{\phi}_i$, a contradiction.

Hence $\phi_L > \bar{\phi}_1 > \bar{\phi}_2 > \cdots > \bar{\phi}_{n-1} > \bar{\phi}_n > \phi_R$. ∎

In Figure 2.1 we illustrate the theory of Lemma 2.1 and Theorem 2.3 with a numerical example. Here we take $H^+(\phi) = H^-(\phi) = 0.5\cos\phi + \sin\phi$. Then $\phi_L = -\phi_R = \arctan(0.5) \approx 0.464$ and $J = (-\arctan 2, \arctan 2) \approx (-1.107, 1.107)$ for the conditions (H1) and (H2). We implemented the numerical computation by using the interactive package **XPPAUT** which was developed by B. Ermentrout. From the top to the bottom, the curves are $\phi_1(t), \ldots, \phi_{11}(t)$ ($n = 11$), respectively. Note $\phi_6(t) \equiv 0$ is on the x-axis. The figure shows the monotonicity and symmetry of solution $(\phi_1(t), \ldots, \phi_n(t))$ along the trajectory.

In Lemmas 2.1 and 2.2 and Theorem 2.3, we have the condition $f(0) > 0$. For $f(0) < 0$, the results and the proofs are very similar. We just state Theorem 2.4 without proof.

THEOREM 2.4. *Assume* f *and* g *satisfy* (H1), (H2), *and* $f(0) < 0$; *then the IVP* (2.3) *with* $\phi_i(0) = 0$, $i = 1, \ldots, n$ *has the following properties:*

(i) *For each* $i \in \{1, \ldots, n\}$, *there exists* $\bar{\phi}_i$ *such that* $\lim_{t\to\hat{t}} \phi_i(t) = \bar{\phi}_i$;

(ii) $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ *is the fixed point of the system* (2.3);

(iii) $\phi_L < \bar{\phi}_1 < \bar{\phi}_2 < \cdots < \bar{\phi}_{n-1} < \bar{\phi}_n < \phi_R$;

(iv) $\bar{\phi}_i = -\bar{\phi}_{n+1-i}$, $i = 1, \ldots, n$.

We turn our attention back to the system (2.1). Notice that we have

$$\omega + H^+(\bar{\phi}_1) = \omega + H^-(-\bar{\phi}_{i-1}) + H^+(\bar{\phi}_i) = \omega + H^-(-\bar{\phi}_n), i = 2, \ldots, n-1.$$

We take $\Omega = \omega + H^-(-\bar{\phi}_{i-1}) + H^+(\bar{\phi}_i)$; then $\theta_1 = \Omega t$, $\theta_i = \Omega t + \sum_{k=1}^{i-1} \bar{\phi}_k$, $i = 2, \ldots, n+1$, is the phaselocked solution of (2.1). Before showing that this phaselocked solution is stable, we state a general stability result due to Ermentrout [10].

THEOREM 2.5 (Ermentrout, 1992). *Consider the equations*

$$d\theta_k/dt = H_k(\theta_1 - \theta_k, \ldots, \theta_M - \theta_k), \quad k = 1, \ldots, M. \tag{2.11}$$

Let $\theta_k = \Omega t + \bar{\psi}_k$ be a phaselocked solution and let

$$a_{jk} = \partial H_k(z_1, \ldots, z_M)/\partial z_j \tag{2.12}$$

evaluated at $z_j = \bar{\psi}_j - \bar{\psi}_k$. Suppose that $a_{jk} \geq 0$ and the graph of the matrix (a_{jk}) is complete. Then the phaselocked solution is orbitally asymptotically stable in the sense that there is a simple zero eigenvalue corresponding to translation in time and all other eigenvalues have negative real parts.

Due to (H1), we have $g' \pm f' > 0$ in J. Then the phaselocked solution $\theta_1 = \Omega t$, $\theta_i = \Omega t + \sum_{k=1}^{i-1} \bar{\phi}_k$, $i = 2, \ldots, n+1$, satisfies the nonnegativity assumption in Theorem 2.5. The graph of (a_{jk}) is complete since $a_{i,i+1} > 0$ and $a_{i+1,i} > 0$ for $i = 1, \ldots, n$. So we have shown that the phaselocked solution is asymptotically stable. This result is summarized in the following theorem.

THEOREM 2.6. *Under the conditions of Theorem* 2.3 *or* 2.4, $\theta_1 = \Omega t$, $\theta_i = \Omega t + \sum_{k=1}^{i-1} \bar{\phi}_k$, $i = 2, \ldots, n+1$, *is the phaselocked solution of* (2.1), *orbitally asymptotically stable in the sense that there is a simple zero eigenvalue corresponding to translation in time and other eigenvalues have negative real parts.*

As a matter of fact, in Theorem 2.6, all the n nonzero eigenvalues with negative real parts are actually the eigenvalues of the system (2.3) linearized around the equilibrium $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$.

COROLLARY 2.7. *Under the conditions of Theorems* 2.3 *or* 2.4, $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ *is an asymptotically stable steady state of* (2.3) *and all the eigenvalues of the system* (2.3) *linearized around it have negative real parts.*

2.2. Isotropic case with $\beta_i = \beta \neq 0, i = 1, \ldots, n$. Throughout this section, without loss of generality, we assume $\beta < 0$. If $\beta > 0$, you can subtract the consecutive equations of (2.1) in another direction such that the frequency difference is less than zero. In this case, we still have $H^+ = H^-$, which implies that f is even and g odd such that $\phi_L = -\phi_R$. We restate (2.2) in the form

$$\begin{aligned} \phi_1' &= \beta + f(\phi_2) + g(\phi_2) - 2g(\phi_1), \\ \phi_i' &= \beta + f(\phi_{i+1}) - f(\phi_{i-1}) + g(\phi_{i+1}) - 2g(\phi_i) + g(\phi_{i-1}), \\ &\qquad i = 2, \ldots, n-1, \\ \phi_n' &= \beta - f(\phi_{n-1}) - 2g(\phi_n) + g(\phi_{n-1}). \end{aligned} \tag{2.13}$$

For $\beta = 0$, we have that $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ is the asymptotically stable steady state of (2.13) following Corollary 2.7. Then if $|\beta|$ is small enough, we should get an asymptotically stable steady state $\bar{\phi}_i(\beta)$, $i = 1, \ldots, n$ near $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ by the implicit function theorem. We denote the trajectory by $\phi_i(t, \beta)$, $i = 1, \ldots, n$ for the IVP (2.13) with $\phi_i(0) = 0$. By continuity, $\phi_i(t, \beta)$ should have the monotonicity and boundedness as in Lemmas 2.1 and 2.2, and $\phi_i(t, \beta) \to \bar{\phi}_i(\beta)$ as $t \to +\infty$ if $|\beta|$ is small enough. We summarize this fact in Theorem 2.8

THEOREM 2.8. *Assume that f and g satisfy* (H1) *and* (H2). *Let $|\beta|$ be small enough; then the IVP* (2.13) *with $\phi_i(0) = 0$ satisfies that*

(i) *if* $f(0) > 0$, *then*

$$\phi_L > \phi_1(t,\beta) > \cdots > \phi_n(t,\beta) > \phi_R; \tag{2.14}$$

(ii) *if* $f(0) < 0$, *then*

$$\phi_L < \phi_1(t,\beta) < \cdots < \phi_n(t,\beta) < \phi_R. \tag{2.15}$$

Also $\phi_i(t,\beta) \to \bar{\phi}_i(\beta)$ *as* $t \to +\infty$ *for* $i = 1,\ldots,n$, *where* $(\bar{\phi}_1(\beta),\ldots,\bar{\phi}_n(\beta))$ *is the asymptotically stable steady state of* (2.13) *near* $(\bar{\phi}_1,\ldots,\bar{\phi}_n)$.

Theorem 2.8 is not a particularly strong result. To keep the monotonicity and boundedness, $|\beta|$ has to be assumed very small. We would like to know when the monotonicity breaks down. This leads to the following theorem.

THEOREM 2.9. *Assume that* f *and* g *satisfy* (H1), (H2), *and* $f(0) > 0$. *Let* $|\beta|$ *be small enough that* $\phi_{n-1}(t) \geq \phi_R$, $t > 0$ *for the IVP* (2.13) *with* $\phi_i(0) = 0$, $i = 1,\ldots,n$. *Then we have the following properties along the trajectory:*

(i) *there is a sequence* $\{t_k\}_{k=1}^{\infty}$ *(it could be a finite sequence) such that* $0 = t_1 < t_2 < \cdots < t_k < \cdots < \hat{t}$, *and for each* k, *there is* $l_k \in \{1,\ldots,n\}$ *so that*

$$\phi_i'(t) > 0, \quad i = 1,\ldots,l_k, \quad t_k < t < t_{k+1},$$

$$\phi_j'(t) < 0, \quad j = l_k+1,\ldots,n, \quad t_k < t < t_{k+1}, \tag{2.16}$$

$$l_{k+1} \in \{0, l_k - 1, l_k, l_k + 1, n\}, \tag{2.17}$$

$$\text{either } \phi_{l_k}'(t_{k+1}) = 0 \text{ or } \phi_{l_k+1}'(t_{k+1}) = 0 \text{ (not both)}, \tag{2.18}$$

$$\phi_L > \phi_1(t) > \cdots > \phi_{n-1}(t) > \phi_n(t) > \phi_\beta, \quad t_k < t \leq t_{k+1} \tag{2.19}$$

where $\hat{t}$ *is such that* $\phi_i'(\hat{t}) = 0$, $i = 1,\ldots,n$ *or* $\hat{t} = +\infty$, *and* $\phi_\beta \in J$ *is such that* $f(\phi_\beta) + g(\phi_\beta) = \beta$ *(note that* $\phi_\beta < \phi_R$*).*

(ii) *for each* $i \in \{1,\ldots,n\}$, *there exists* $\bar{\phi}_i$ *such that*

$$\lim_{t \to \hat{t}} \phi_i(t) = \bar{\phi}_i, \tag{2.20}$$

$$\phi_L > \bar{\phi}_1 > \cdots > \bar{\phi}_n > \phi_\beta, \tag{2.21}$$

and $(\bar{\phi}_1,\ldots,\bar{\phi}_n)$ *is a fixed point of* (2.13).

Remark. The condition $\phi_{n-1}(t) \geq \phi_R, t > 0$ means that ϕ_{n-1} cannot cross ϕ_R along the trajectory. It is weaker than the condition in Theorem 2.8 since it allows ϕ_n to cross ϕ_R. It holds when $|\beta|$ is small enough (but not as small as in Theorem 2.8) according to the results of section 2.1.

The proof of the theorem is very long. We put it in the Appendix for interested readers.

Figure 2.2 is a numerical solution illustrating Theorem 2.9. Here $H^+(\phi) = H^-(\phi) = 0.5\cos\phi + \sin\phi$ and $\beta = -0.005$. The figure shows monotonicity of solution along the trajectory.

For the case $f(0) < 0$, we have results parallel to Theorem 2.9.

THEOREM 2.10. *Assume that* f *and* g *satisfy* (H1), (H2), *and* $f(0) < 0$. *Let* $|\beta|$ *be small enough that* $\phi_2(t) \geq \phi_L$, $t > 0$ *for the IVP* (2.13) *with* $\phi_i(0) = 0$, $i = 1,\ldots,n$. *Then we have the following properties along the trajectory:*

(i) *there is a sequence* $\{t_k\}_{k=1}^{\infty}$ *(it could be a finite sequence) such that* $0 = t_1 < t_2 < \cdots < t_k < \cdots < \hat{t}$ *and for each* k, *there is* $l_k \in \{1,\ldots,n\}$ *so that*

$$\phi_i'(t) < 0, \quad i = 1,\ldots,l_k, \quad t_k < t < t_{k+1},$$

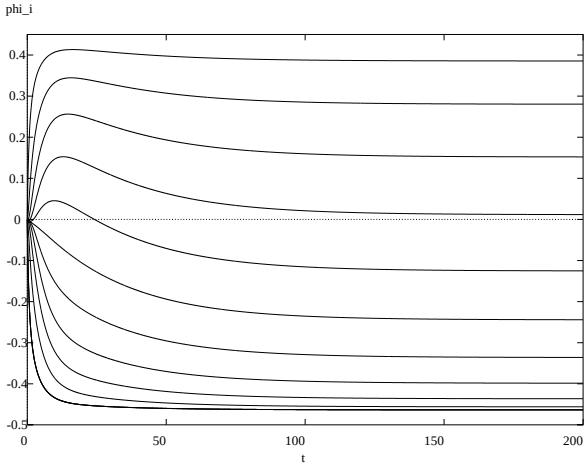

FIG. 2.2. *The isotropic case with* $H^+(\phi) = H^-(\phi) = H(\phi) = .5\cos\phi + \sin\phi$, $n = 11$, *and* $\beta_i = \beta = -0.005$.

$$\phi_j'(t) > 0, \quad j = l_k + 1, \dots, n, \quad t_k < t < t_{k+1}, \tag{2.22}$$

$$l_{k+1} \in \{0, l_k - 1, l_k, l_k + 1, n\}, \tag{2.23}$$

$$\text{either } \phi_{l_k}'(t_{k+1}) = 0 \text{ or } \phi_{l_k+1}'(t_{k+1}) = 0 \text{ (not both)}, \tag{2.24}$$

$$\phi_\beta < \phi_1(t) < \cdots < \phi_{n-1}(t) < \phi_n(t) < \phi_R, \quad t_k < t \le t_{k+1}, \tag{2.25}$$

where $\hat{t}$ *is such that* $\phi_i'(\hat{t}) = 0$, $i = 1, \dots, n$ *or* $\hat{t} = +\infty$, *and* $\phi_\beta \in J$ *is such that* $-f(\phi_\beta) + g(\phi_\beta) = \beta$ *(note that* $\phi_\beta < \phi_L$*).*

(ii) *for each* $i \in \{1, \dots, n\}$, *there exists* $\bar{\phi}_i$ *such that*

$$\lim_{t \to \hat{t}} \phi_i(t) = \bar{\phi}_i, \tag{2.26}$$

$$\phi_\beta < \bar{\phi}_1 < \cdots < \bar{\phi}_n < \phi_R, \tag{2.27}$$

and $(\bar{\phi}_1, \dots, \bar{\phi}_n)$ *is a fixed point of* (2.13).

As we did in section 2.1, if we let $\theta_1(t) = \Omega t$, $\theta_i(t) = \Omega t + \sum_{k=1}^{i-1} \bar{\phi}_k$, $i = 1, \dots, n+1$, where $(\bar{\phi}_1, \dots, \bar{\phi}_n)$ is the fixed point of (2.13) which we obtained in Theorems 2.9 and 2.10, then Theorem 2.5 assures us that $(\theta_1(t), \dots, \theta_{n+1}(t))$ is an orbitally asymptotically stable phaselocked solution of (2.1).

2.3. Nonisotropic case with $\beta_i = 0, i = 1, \dots, n$. In this case, we have $H^+ \neq H^-$ which implies that f is not even and g is not odd anymore. So $\phi_L \neq -\phi_R$ in general. And we would like to restate (2.2) in the form

$$\begin{aligned} \phi_1' &= f(\phi_2) + g(\phi_2) - 2g(\phi_1), \\ \phi_i' &= f(\phi_{i+1}) - f(\phi_{i-1}) + g(\phi_{i+1}) - 2g(\phi_i) + g(\phi_{i-1}), \\ &\qquad i = 2, \dots, n-1, \\ \phi_n' &= -f(\phi_{n-1}) - 2g(\phi_n) + g(\phi_{n-1}). \end{aligned} \tag{2.28}$$

THEOREM 2.11. *Assume that* f *and* g *satisfy* (H1), (H2), *and* $f(0) > |g(0)|$. *Then the IVP* (2.28) *with* $\phi_i(0) = 0$, $i = 1, \dots, n$ *has the following properties along the trajectory:*

(i) *There is a sequence* $\{t_k\}_{k=1}^{\infty}$ *(it could be a finite sequence) such that* $0 = t_1 < t_2 < \cdots < t_k < \cdots < \hat{t}$ *and for each* k*, there is* $l_k \in \{1, \ldots, n\}$ *so that*

$$\phi_i'(t) > 0, \quad i = 1, \ldots, l_k, \quad t_k < t < t_{k+1},$$

$$\phi_j'(t) < 0, \quad j = l_k + 1, \ldots, n, \quad t_k < t < t_{k+1}, \tag{2.29}$$

$$l_{k+1} \in \{0, l_k - 1, l_k, l_k + 1, n\}, \tag{2.30}$$

$$\text{either } \phi_{l_k}'(t_{k+1}) = 0 \text{ or } \phi_{l_k+1}'(t_{k+1}) = 0 \text{ (not both)}, \tag{2.31}$$

$$\phi_L > \phi_1(t) > \cdots > \phi_{n-1}(t) > \phi_n(t) > \phi_R, \quad t_k < t \le t_{k+1}, \tag{2.32}$$

where $\hat{t}$ *is such that* $\phi_i'(\hat{t}) = 0$*,* $i = 1, \ldots, n$*, or* $\hat{t} = +\infty$*.*

(ii) *For each* $i \in \{1, \ldots, n\}$*, there exists* $\bar{\phi}_i$ *such that*

$$\lim_{t \to \hat{t}} \phi_i(t) = \bar{\phi}_i, \tag{2.33}$$

$$\phi_L > \bar{\phi}_1 > \cdots > \bar{\phi}_n > \phi_R, \tag{2.34}$$

and $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ *is a fixed point of* (2.28)*.*

Proof. Note that $f(0) > |g(0)|$; then

$$\begin{aligned} \phi_1'(0) &= f(0) - g(0) > 0, \\ \phi_i'(0) &= 0, \quad i = 2, \ldots, n-1, \\ \phi_n'(0) &= -f(0) - g(0) < 0. \end{aligned} \tag{2.35}$$

Then by (2.28) and (2.35), we have

$$\begin{aligned} \phi_2''(0) &= [g'(0) - f'(0)][f(0) - g(0)] > 0, \\ \phi_{n-1}''(0) &= [g'(0) + f'(0)][-f(0) - g(0)] < 0. \end{aligned} \tag{2.36}$$

By induction on i, we can get that for $i = 3, \ldots, m-1$

$$\begin{aligned} \phi_i^{(k)}(0) &= 0, \quad k = 1, \ldots, i-1, \\ \phi_i^{(i)}(0) &= [g'(0) - f'(0)]^{i-1}[f(0) - g(0)] > 0, \\ \phi_{n-i+1}^{(k)}(0) &= 0, \quad k = 1, \ldots, i-1, \\ \phi_{n-i+1}^{(i)}(0) &= [g'(0) - f'(0)]^{i-1}[-f(0) + g(0)] < 0 \end{aligned} \tag{2.37}$$

whenever $n = 2m-1$ or $2m-2$. And when $n = 2m-1$, we have extra terms

$$\phi_m^{(k)}(0) = 0, \quad k = 1, \ldots, m. \tag{2.38}$$

Assume $\phi_m^{(m+1)}(0) \neq 0$ (otherwise we can figure out $\phi_m^{(M)}(0) \neq 0$ and $\phi_m^{(k)}(0) = 0, k = 1, \ldots, M-1$).

Without loss of generality, we assume $\phi_m^{m+1}(0) > 0$ when $n = 2m-1$.

Then we have $t_1 = 0, l_1 = m-1$ when $n = 2m-2$, and $t_1 = 0, l_1 = m$ when $n = 2m-1$. And the rest of the proof just mimics all the steps of proving Theorem 2.9 ∎

Again in Figure 2.3 we show the results of Theorem 2.11. Here $H^+(\phi) = H(\phi)$ and $H^-(\phi) = 0.2H(\phi)$ where $H(\phi) = 0.5\cos\phi + \sin\phi$. And $\phi_L = -\phi_R = \arctan(0.5)$ and $J = (-\arctan 2, \arctan 2)$. The monotonicity of the solution along the trajectory can be seen from the figure. Also we see that the solution converges to a fixed point.

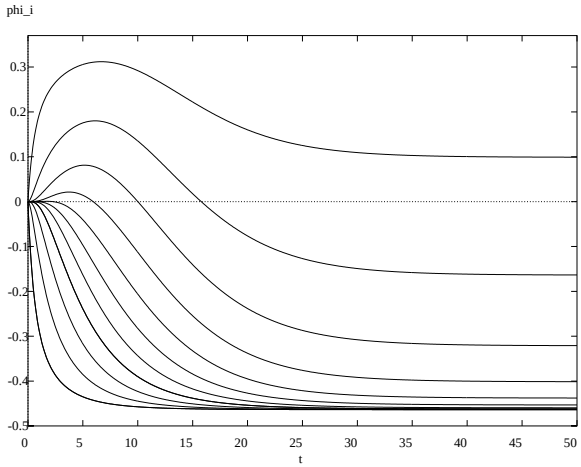

FIG. 2.3. *The nonisotropic case with* $H^+(\phi) = H(\phi), H^-(\phi) = 0.2H(\phi), H(\phi) = .5\cos\phi + \sin\phi$, $n = 11$, *and* $\beta_i = \beta = 0$.

THEOREM 2.12. *Assume that* f *and* g *satisfy* (H1), (H2), *and* $f(0) < -|g(0)|$. *Then the IVP* (2.28) *with* $\phi_i(0) = 0$, $i = 1, \ldots, n$ *has the following properties along the trajectory:*

(i) *there is a sequence* $\{t_k\}_{k=1}^{\infty}$ *(it could be a finite sequence) such that* $0 = t_1 < t_2 < \cdots < t_k < \cdots < \hat{t}$ *and for each* k, *there is* $l_k \in \{1, \ldots, n\}$ *so that*

$$\phi_i'(t) < 0, \quad i = 1, \ldots, l_k, \quad t_k < t < t_{k+1},$$

$$\phi_j'(t) > 0, \quad j = l_k + 1, \ldots, n, \quad t_k < t < t_{k+1}, \tag{2.39}$$

$$l_{k+1} \in \{0, l_k - 1, l_k, l_k + 1, n\}, \tag{2.40}$$

$$\text{either } \phi_{l_k}'(t_{k+1}) = 0 \text{ or } \phi_{l_k+1}'(t_{k+1}) = 0 \text{ (not both)}, \tag{2.41}$$

$$\phi_L < \phi_1(t) < \cdots < \phi_{n-1}(t) < \phi_n(t) < \phi_R, t_k < t \le t_{k+1}, \tag{2.42}$$

where $\hat{t}$ *is such that* $\phi_i'(\hat{t}) = 0$, $i = 1, \ldots, n$ *or* $\hat{t} = +\infty$.

(ii) *for each* $i \in \{1, \ldots, n\}$, *there exists* $\bar{\phi}_i$ *such that*

$$\lim_{t \to \hat{t}} \phi_i(t) = \bar{\phi}_i, \tag{2.43}$$

$$\phi_L < \bar{\phi}_1 < \cdots < \bar{\phi}_n < \phi_R, \tag{2.44}$$

and $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ *is a fixed point of* (2.28).

2.4. Nonisotropic case with $\beta_i = \beta \neq 0, i = 1, \ldots, n$. Throughout this section, without loss of generality, we assume $\beta < 0$. If $\beta > 0$, you can subtract the consecutive equations of (2.1) in another direction such that the frequency difference is less than zero. In this case, like in section 2.2, we have $H^+ \neq H^-$ which implies f is not even and g not odd such that $\phi_L \neq -\phi_R$. And we would like to restate (2.2) in the form

$$\begin{aligned} \phi_1' &= \beta + f(\phi_2) + g(\phi_2) - 2g(\phi_1), \\ \phi_i' &= \beta + f(\phi_{i+1}) - f(\phi_{i-1}) + g(\phi_{i+1}) - 2g(\phi_i) + g(\phi_{i-1}), \\ &\quad i = 2, \ldots, n-1, \\ \phi_n' &= \beta - f(\phi_{n-1}) - 2g(\phi_n) + g(\phi_{n-1}). \end{aligned} \tag{2.45}$$

THEOREM 2.13. *Assume that f and g satisfy* (H1), (H2), *and $f(0) > |g(0)|$. Let $|\beta|$ be small enough that $\phi_{n-1}(t) \geq \phi_R$, $t > 0$ for the IVP* (2.45) *with $\phi_i(0) = 0$, $i = 1, \ldots, n$. Then we have the following properties along the trajectory:*

(i) *there is a sequence $\{t_k\}_{k=1}^{\infty}$ (it could be a finite sequence) such that $0 = t_1 < t_2 < \cdots < t_k < \cdots < \hat{t}$ and for each k, there is $l_k \in \{1, \ldots, n\}$ so that*

$$\phi_i'(t) > 0, \quad i = 1, \ldots, l_k, \quad t_k < t < t_{k+1},$$

$$\phi_j'(t) < 0, \quad j = l_k + 1, \ldots, n, \quad t_k < t < t_{k+1}, \tag{2.46}$$

$$l_{k+1} \in \{0, l_k - 1, l_k, l_k + 1, n\}, \tag{2.47}$$

$$\text{either } \phi_{l_k}'(t_{k+1}) = 0 \text{ or } \phi_{l_k+1}'(t_{k+1}) = 0 \text{ (not both)}, \tag{2.48}$$

$$\phi_L > \phi_1(t) > \cdots > \phi_{n-1}(t) > \phi_n(t) > \phi_\beta, \quad t_k < t \leq t_{k+1}, \tag{2.49}$$

where $\hat{t}$ is such that $\phi_i'(\hat{t}) = 0$, $i = 1, \ldots, n$ or $\hat{t} = +\infty$, and $\phi_\beta \in J$ is such that $f(\phi_\beta) + g(\phi_\beta) = \beta$ (note that $\phi_\beta < \phi_R$).

(ii) *for each $i \in \{1, \ldots, n\}$, there exists $\bar{\phi}_i$ such that*

$$\lim_{t \to \hat{t}} \phi_i(t) = \bar{\phi}_i, \tag{2.50}$$

$$\phi_L > \bar{\phi}_1 > \cdots > \bar{\phi}_n > \phi_\beta, \tag{2.51}$$

and $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ is a fixed point of (2.13).

Figures 2.4(a) and 2.4(b) are numerical illustrations of Theorem 2.13. Here $H^+(\phi) = H(\phi)$ and $H^-(\phi) = 0.2H(\phi)$, where $H(\phi) = 0.5\cos\phi + \sin\phi$. And $\phi_L = -\phi_R = \arctan(0.5)$ and $J = (-\arctan 2, \arctan 2)$. Note that in Fig. 2.4(b), $\phi_{n-1}(t)$ crosses ϕ_R somewhere so that the monotonicity is destroyed. However, the trajectory still converges to a fixed point. Hence the monotonicity is not necessary for the convergence of the solution. In Fig. 2.4(a) the monotonicity is preserved since the $|\beta|$ is so small that $\phi_{n-1}(t)$ does not cross ϕ_R.

THEOREM 2.14. *Assume that f and g satisfy* (H1), (H2), *and $f(0) < -|g(0)|$. Let $|\beta|$ be small enough that $\phi_2(t) \geq \phi_L$, $t > 0$ for the IVP* (2.45) *with $\phi_i(0) = 0$, $i = 1, \ldots, n$. Then we have the following properties along the trajectory:*

(i) *there is a sequence $\{t_k\}_{k=1}^{\infty}$ (it could be a finite sequence) such that $0 = t_1 < t_2 < \cdots < t_k < \cdots < \hat{t}$ and for each k, there is $l_k \in \{1, \ldots, n\}$ so that*

$$\phi_i'(t) < 0, \quad i = 1, \ldots, l_k, \quad t_k < t < t_{k+1},$$

$$\phi_j'(t) > 0, \quad j = l_k + 1, \ldots, n, \quad t_k < t < t_{k+1}, \tag{2.52}$$

$$l_{k+1} \in \{0, l_k - 1, l_k, l_k + 1, n\}, \tag{2.53}$$

$$\text{either } \phi_{l_k}'(t_{k+1}) = 0 \text{ or } \phi_{l_k+1}'(t_{k+1}) = 0 \text{ (not both)}, \tag{2.54}$$

$$\phi_\beta < \phi_1(t) < \cdots < \phi_{n-1}(t) < \phi_n(t) < \phi_R, \quad t_k < t \leq t_{k+1}, \tag{2.55}$$

where $\hat{t}$ is such that $\phi_i'(\hat{t}) = 0$, $i = 1, \ldots, n$ or $\hat{t} = +\infty$, and $\phi_\beta \in J$ is such that $-f(\phi_\beta) + g(\phi_\beta) = \beta$ (note that $\phi_\beta < \phi_L$).

(ii) *for each $i \in \{1, \ldots, n\}$, there exists $\bar{\phi}_i$ such that*

$$\lim_{t \to \hat{t}} \phi_i(t) = \bar{\phi}_i, \tag{2.56}$$

$$\phi_\beta < \bar{\phi}_1 < \cdots < \bar{\phi}_n < \phi_R, \tag{2.57}$$

and $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ is a fixed point of (2.45).

By Theorem 2.5, the fixed points $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ from the two theorems above are asymptotically stable steady state of (2.45).

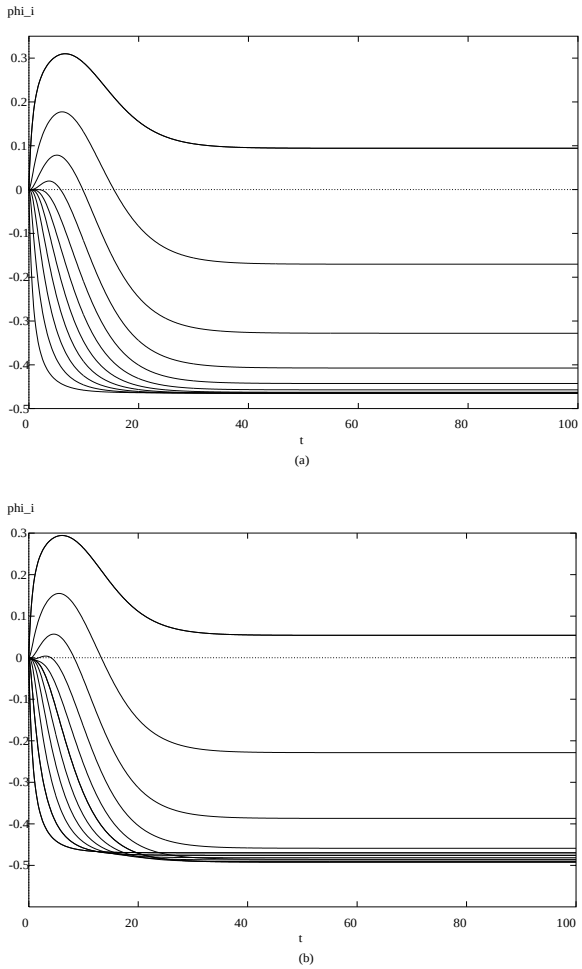

FIG. 2.4. *The nonisotropic case with* $H^+(\phi) = H(\phi), H^-(\phi) = 0.2H(\phi), H(\phi) = .5\cos\phi + \sin\phi$, $n = 11$, (a) $\beta_i = \beta = -0.0005$, (b) $\beta_i = \beta = -0.005$.

3. Arrays of oscillators. In this section, we consider a two-dimensional array of coupled oscillators. The equations to be considered have the form

$$\begin{aligned}\theta'_{ij} &= \omega_{ij} + H^{+X}(\theta_{i+1,j} - \theta_{ij}) + H^{-X}(\theta_{i-1,j} - \theta_{ij}) \\ &\quad + H^{+Y}(\theta_{i,j+1} - \theta_{ij}) + H^{-Y}(\theta_{i,j-1} - \theta_{ij}), \\ &\quad i, j = 1, \ldots, n+1, \end{aligned} \tag{3.1}$$

where H^{+X}, H^{+Y}, H^{-X}, and H^{-Y} are smooth 2π-periodic functions of the arguments and ω_{ij} is the frequency for each oscillator.

Note that in (3.1), each oscillator is coupled with its four nearest neighbors. The term H^{-X} (respectively, H^{+X} or H^{-Y} or H^{+Y}) is ignored for $i = 1$ (respectively, $i = n+1$ or $j = 1$ or $j = n+1$). We take

$$\begin{aligned}\phi_{ij} &= \theta_{i+1,j} - \theta_{ij}, \quad i = 1, \ldots, n, \quad j = 1, \ldots, n+1, \\ \psi_{ij} &= \theta_{i,j+1} - \theta_{ij}, \quad i = 1, \ldots, n+1, \quad j = 1, \ldots, n,\end{aligned}$$

$$\alpha_{ij} = \omega_{i+1,j} - \omega_{ij}, \quad i = 1, \dots, n, \quad j = 1, \dots, n+1,$$
$$\beta_{ij} = \omega_{i,j+1} - \omega_{ij}, \quad i = 1, \dots, n+1, \quad j = 1, \dots, n$$

and define the functions f, g, p, and q as

$$\begin{aligned} f(\phi) + g(\phi) &= H^{+X}(\phi), \\ f(\phi) - g(\phi) &= H^{-X}(-\phi), \\ p(\psi) + q(\psi) &= H^{+Y}(\psi), \\ p(\psi) - q(\psi) &= H^{-Y}(-\psi). \end{aligned} \tag{3.2}$$

Then in (3.1), if we subtract the (i,j)th equation from the $(i+1,j)$th one and the $(i,j+1)$th one, respectively, we have

$$\begin{aligned} \phi'_{ij} = {} & \alpha_{ij} + f(\phi_{i+1,j}) - f(\phi_{i-1,j}) + g(\phi_{i+1,j}) - 2g(\phi_{ij}) + g(\phi_{i-1,j}) \\ & + p(\psi_{i+1,j}) + p(\psi_{i+1,j-1}) - p(\psi_{ij}) - p(\psi_{i,j-1}) \\ & + q(\psi_{i+1,j}) - q(\psi_{i+1,j-1}) - q(\psi_{ij}) + q(\psi_{i,j-1}), \\ & i = 1, \dots, n, j = 1, \dots, n+1, \end{aligned}$$

$$\begin{aligned} \psi'_{ij} = {} & \beta_{ij} + p(\psi_{i,j+1}) - p(\psi_{i,j-1}) + q(\psi_{i,j+1}) - 2q(\psi_{ij}) + q(\psi_{i,j-1}) \\ & + f(\phi_{i,j+1}) + f(\phi_{i-1,j+1}) - f(\phi_{ij}) - f(\phi_{i-1,j}) \\ & + g(\phi_{i,j+1}) - g(\phi_{i-1,j+1}) - g(\phi_{ij}) + g(\phi_{i-1,j}) \\ & i = 1, \dots, n+1, j = 1, \dots, n. \end{aligned} \tag{3.3}$$

Note that the index (i,j) for ϕ_{ij} should satisfy $1 \le i \le n$ and $1 \le j \le n+1$ and the index (i,j) for ψ_{ij} should satisfy $1 \le i \le n+1$, $1 \le j \le n$. Hence if (i,j) is out of range for ϕ_{ij} or ψ_{ij}, the corresponding terms on the right-hand sides of (3.3) are ignored.

Again we define several constants related to f, g, p, and q. We define

- ϕ_L as $f(\phi_L) = g(\phi_L)$, i.e., $H^{-X}(-\phi_L) = 0$;
- ϕ_R as $f(\phi_R) = -g(\phi_R)$, i.e., $H^{+X}(\phi_R) = 0$;
- ψ_L as $p(\psi_L) = q(\psi_L)$, i.e., $H^{-Y}(-\psi_L) = 0$;
- ψ_R as $p(\psi_R) = -q(\psi_R)$, i.e., $H^{+Y}(\psi_R) = 0$.

We assume some hypotheses on f, g, p, and q in sufficiently large intervals J_X and J_Y around $\phi = 0$ and $\psi = 0$, respectively:

(HX1) *$g'(\phi) > |f'(\phi)|$ for $\phi \in J_X$;*

(HX2) *there exists a unique ϕ_L (respectively, ϕ_R) to $f = g$ (respectively, $f = -g$) for $\phi \in J_X$;*

(HY1) *$q'(\psi) > |p'(\psi)|$ for $\psi \in J_Y$;*

(HY2) *there exists a unique ψ_L (respectively, ψ_R) to $p = q$ (respectively, $p = -q$) for $\psi \in J_Y$.*

Note that (HX1), (HX2), (HY1), and (HY2) are the assumptions extended from the chain model.

Our goal is to apply the results obtained from the chain model to this array model. In order to achieve this task, let us first consider a very special system of equations:

$$\begin{aligned} \phi'_{ij} &= F_{ij}(\Phi) + G_{ij}(\Psi), \quad i = 1, \dots, n, \quad j = 1, \dots, n+1, \\ \psi'_{ij} &= P_{ij}(\Psi) + Q_{ij}(\Phi), \quad i = 1, \dots, n+1, \quad j = 1, \dots, n, \end{aligned} \tag{3.4}$$

where

$$\Phi = (\phi_{ij})_{n\times(n+1)} = [\Phi_1, \ldots, \Phi_{n+1}]$$

with

$$\Phi_j = \begin{bmatrix} \phi_{1j} \\ \vdots \\ \phi_{nj} \end{bmatrix}, \quad j = 1, \ldots, n+1$$

and

$$\Psi = (\psi_{ij})_{(n+1)\times n} = \begin{bmatrix} \Psi_1 \\ \vdots \\ \Psi_{n+1} \end{bmatrix}$$

with

$$\Psi_i = [\psi_{i1}, \ldots, \psi_{in}], \quad i = 1, \ldots, n+1$$

and F_{ij}, P_{ij}, G_{ij}, and Q_{ij} satisfy the following assumptions:

(i) *if* $\Phi_1 = \Phi_2 = \cdots = \Phi_{n+1}$ *(i.e.,* ϕ_{ij} *is independent of the index* j*), then*

$$F_{i1}(\Phi) = F_{i2}(\Phi) = \cdots = F_{i,n+1}(\Phi), \quad i = 1, \ldots, n, \tag{3.5}$$

$$Q_{ij}(\Phi) = 0, i = 1, \ldots, n+1, \quad j = 1, \ldots, n; \tag{3.6}$$

(ii) *if* $\Psi_1 = \Psi_2 = \cdots = \Psi_{n+1}$ *(i.e.,* ψ_{ij} *is independent of the index* i*), then*

$$P_{1j}(\Psi) = P_{2j}(\Psi) = \cdots = P_{n+1,j}(\Psi), \quad j = 1, \ldots, n, \tag{3.7}$$

$$G_{ij}(\Psi) = 0, \quad i = 1, \ldots, n, \quad j = 1, \ldots, n+1. \tag{3.8}$$

Remark. The special form of (3.4) is a generalization of the system (3.3). We will see this later. The conditions on F_{ij}, G_{ij}, P_{ij}, and Q_{ij} reflect a homogeneity requirement for the two-dimensional domain. That is, the phase lags between left and right neighbors are the same for each row. Similarly, the lags between top and bottom neighbors are the same for each column.

LEMMA 3.1. *The set* $S = \{(\Phi, \Psi) | \Phi_1 = \Phi_2 = \cdots = \Phi_{n+1}$ *and* $\Psi_1 = \Psi_2 = \cdots = \Psi_{n+1}\}$ *is an invariant set for the system* (3.4).

Proof. We only need to show that if $(\Phi(0), \Psi(0)) \in S$, then $\Phi_1'(0) = \cdots = \Phi_{n+1}'(0)$ and $\Psi_1'(0) = \cdots = \Psi_{n+1}'(0)$, i.e.,

$$\phi_{i1}'(0) = \phi_{i2}'(0) = \cdots = \phi_{i,n+1}'(0) \quad \text{for} \quad i = 1, \ldots, n, \tag{3.9}$$

$$\psi_{1j}'(0) = \psi_{2j}'(0) = \cdots = \psi_{n+1,j}'(0) \quad \text{for} \quad j = 1, \ldots, n. \tag{3.10}$$

By (3.4), (3.5), and (3.8), we have that for each $i \in \{1, \ldots, n\}$,

$$\begin{aligned} \phi_{ij}'(0) &= F_{ij}(\Phi(0)) + G_{ij}(\Psi(0)) \\ &= F_{ik}(\Phi(0)) + G_{ik}(\Psi(0)) \\ &= \phi_{ik}'(0). \end{aligned}$$

Hence (3.9) is proven. Also, we can prove (3.10) in the same way. ∎

LEMMA 3.2. *In the system* (3.3), *if we assume*

$$\alpha_{ij} = \alpha_i \text{ and } \beta_{ij} = \beta_j \tag{3.11}$$

then (3.3) *is a system of the type* (3.4).

Proof. (3.3) is a special case of (3.4) where

$$\begin{aligned}
F_{ij}(\Phi) &= \alpha_{ij} + f(\phi_{i+1,j}) - f(\phi_{i-1,j}) + g(\phi_{i+1,j}) - 2g(\phi_{ij}) + g(\phi_{i-1,j}),\\
G_{ij}(\Psi) &= p(\psi_{i+1,j}) + p(\psi_{i+1,j-1}) - p(\psi_{ij}) - p(\psi_{i,j-1})\\
&\quad + q(\psi_{i+1,j}) - q(\psi_{i+1,j-1}) - q(\psi_{ij}) + q(\psi_{i,j-1}),\\
P_{ij}(\Psi) &= \beta_{ij} + p(\psi_{i,j+1}) - p(\psi_{i,j-1}) + q(\psi_{i,j+1}) - 2q(\psi_{ij}) + q(\psi_{i,j-1}),\\
Q_{ij}(\Phi) &= f(\phi_{i,j+1}) + f(\phi_{i-1,j+1}) - f(\phi_{ij}) - f(\phi_{i-1,j})\\
&\quad + g(\phi_{i,j+1}) - g(\phi_{i-1,j+1}) - g(\phi_{ij}) + g(\phi_{i-1,j}).
\end{aligned}$$

Since we have (3.11), α_{ij} is independent of j and β_{ij} is independent of i. Then if ϕ_{ij} is independent of j and ψ_{ij} is independent of i, (3.5)–(3.8) are satisfied. The proof is completed. ∎

Remark. (3.11) means that the distribution of intrinsic frequencies is a sum of two stripe distributions: one with constant frequencies along each row, and another with constant frequencies along each column. Hence ω_{ij} is in the form of $\omega_{ij} = \omega_i^X + \omega_j^Y$.

LEMMA 3.3. *If the system* (3.3) *satisfies* (3.11), *then the IVP* (3.3) *with*

$$\phi_{ij}(0) = 0, \quad i = 1, \dots, n, \quad j = 1, \dots, n+1, \tag{3.12}$$

$$\psi_{ij}(0) = 0, \quad i = 1, \dots, n+1, \quad j = 1, \dots, n \tag{3.13}$$

has the following identity property:

$$\phi_{i1}(t) = \phi_{i2}(t) = \cdots = \phi_{i,n+1}(t), \quad i = 1, \dots, n, \tag{3.14}$$

$$\psi_{1j}(t) = \psi_{2j}(t) = \cdots = \psi_{n+1,j}(t), \quad j = 1, \dots, n \tag{3.15}$$

for $t \geq 0$.

Proof. This is an immediate result of Lemmas 3.1 and 3.2. ∎

Hence the IVP (3.3), (3.12), and (3.13) satisfying (3.11) is reduced to two independent systems of chain model, i.e.,

$$\begin{aligned}
\phi_1' &= \alpha_1 + f(\phi_2) + g(\phi_2) - 2g(\phi_1),\\
\phi_i' &= \alpha_i + f(\phi_{i+1}) - f(\phi_{i-1}) + g(\phi_{i+1}) - 2g(\phi_i) + g(\phi_{i-1}),\\
&\quad i = 2, \dots, n-1,\\
\phi_n' &= \alpha_n - f(\phi_{n-1}) - 2g(\phi_n) + g(\phi_{n-1})
\end{aligned} \tag{3.16}$$

and

$$\begin{aligned}
\psi_1' &= \beta_1 + p(\psi_2) + q(\psi_2) - 2q(\psi_1),\\
\psi_j' &= \beta_j + p(\psi_{j+1}) - p(\psi_{j-1}) + q(\psi_{j+1}) - 2q(\psi_j) + q(\psi_{j-1}),\\
&\quad j = 2, \dots, n-1,\\
\psi_n' &= \beta_n - p(\psi_{n-1}) - 2q(\psi_n) + q(\phi_{n-1}),
\end{aligned} \tag{3.17}$$

where $\phi_i = \phi_{i1} = \cdots = \phi_{i,n+1}$ and $\psi_j = \psi_{1j} = \cdots = \psi_{n+1,j}$.

Note that both (3.16) and (3.17) are exactly in the form of (2.2).

THEOREM 3.4. *If the trajectories of the IVP* (3.16) *with* $\phi_i(0) = 0$ *and the IVP with* (3.17) *with* $\psi_j(0) = 0$ *converge to the fixed point* $(\bar{\phi}_1, \ldots, \bar{\phi}_n)$ *of* (3.16) *and the fixed point* $(\bar{\psi}_1, \ldots, \bar{\psi}_n)$ *of* (3.17) *respectively, then the trajectory of the IVP* (3.3) *with* (3.12) *and* (3.13) *goes to* $((\bar{\phi}_{ij})_{n\times(n+1)}, (\bar{\psi}_{ij})_{(n+1)\times n})$ *which is the fixed point of* (3.3), *where*

$$\bar{\phi}_{ij} = \bar{\phi}_i, \quad i = 1, \ldots, n, \quad j = 1, \ldots, n+1$$

and

$$\bar{\psi}_{ij} = \bar{\psi}_j, \quad i = 1, \ldots, n+1, \quad j = 1, \ldots, n.$$

Also, $\Omega \equiv \omega_{ij} + H^{+X}(\bar{\phi}_{ij}) + H^{-X}(-\bar{\phi}_{i-1,j}) + H^{+Y}(\bar{\psi}_{ij}) + H^{-Y}(-\bar{\psi}_{i,j-1})$ *(*$i, j = 1, \ldots, n+1$*) is the locked frequency of* (3.1).

Proof. This is a straightforward result of Lemma 3.3. □

Now if we let $\theta_{1,1}(t) = \Omega t$, $\theta_{ij}(t) = \Omega t + \sum_{k=1}^{i-1} \bar{\phi}_k + \sum_{k=1}^{j-1} \bar{\psi}_k$, $\{\theta_{ij}(t)\}$ is the phaselocked solution of (3.1). And it is orbitally asymptotically stable by Theorem 2.5.

Therefore, all the results which we obtained in section 2 can be extended to this system.

Remark 3. If the condition (3.11) is not satisfied, we will not achieve the reduction. But if $\omega_{ij} = \omega_i^X + \omega_j^Y + o(\varepsilon)$ for small ε, we still get a stable phaselocked solution by the implicit function theorem.

Remark 4. The reduction technique could be applied to three-dimensional arrays of oscillators as long as ω_{ijk} is in the form of $\omega_{ijk} = \omega_i^X + \omega_j^Y + \omega_k^Z$. And the array models could be reduced to three independent chain models.

The following are some numerical results for the two-dimensional arrays of oscillators (3.1) and the reduced chains (3.16) and (3.17). For all cases, $\omega_{ij} = \omega_i^X + \omega_j^Y$ is assumed. A basic function $H(\phi) = 0.5\cos\phi + \sin\phi$ is assumed.

Example 1. Let $H^{+X} = H^{-X} = H^{+Y} = H^{-Y} = H$ and $\omega_{ij} \equiv \omega > 0$. Then (HX1), (HX2), (HY1), and (HY2) are satisfied with $J_X = J_Y = (-\arctan 2, \arctan 2)$ and $\phi_L = -\phi_R = \psi_L = -\psi_R = \arctan(0.5)$. Also, $f = p$ and $g = q$. Since $\omega_{ij} \equiv \omega$, the condition (3.11) holds so that the array system (3.3) can be reduced to the two chain systems (3.16) and (3.17) by Lemma 3.3. And (3.16) and (3.17) have asymptotically stable equilibria following the results in section 2.1. Then (3.3) has an asymptotically stable equilibrium. Noting that $f = p$, $g = q$, and $\alpha_i = \beta_j = 0$, the solutions of (3.16) and (3.17) are the identical. So we only study the solution $\bar{\phi}_i$ of (3.16). Figure 3.1(a) is the plot for $\bar{\phi}_i$ where $(i/(n+1), \bar{\phi}_i)$ are the coordinates. We can see that there is a wave traveling outward in both directions from the midpoint of the chain [5, 11]. The wave speed is almost constant except near the middle. By Theorem 3.4, $\bar{\phi}_{ij} = \bar{\phi}_i$ and $\bar{\psi}_{ij} = \bar{\psi}_j$. Then for the array, we have a wave traveling outward from the midpoint of the array. Figure 3.1b shows this observation by plotting the relative phases. As we mentioned in the introduction, with isotropic "synaptic coupling" target patterns are the generic phaselocked behavior. (See the remarks at the end of this section for a discussion about other stable patterns.)

Example 2. Let $H^{+X} = H^{+Y} = 1.5H$, $H^{-X} = H^{-Y} = 0.5H$, and $\omega_{ij} \equiv \omega > 0$. Then (HX1), (HX2), (HY1), and (HY2) hold with $J_X = J_Y = (-\arctan 2, \arctan 2)$ and $\phi_L = -\phi_R = \psi_L = -\psi_R = \arctan(0.5)$. Also, $f = p$ and $g = q$. The reduction from an array to two chains is then obtained. These two chains are identical according to our choice of coupling functions. Figure 3.2 shows the results for the reduced chains and the array. There is a wave traveling from the left of chain to the right. Thus there is a wave traveling from the southwest corner to the northeast corner of the array.

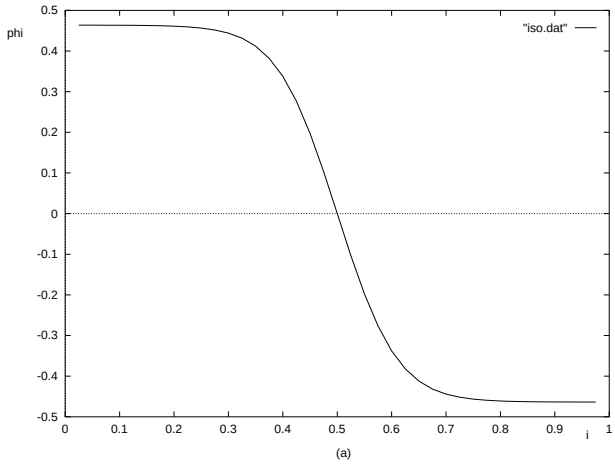

FIG. 3.1. $n+1=40$. (a) *Phase lags of the reduced chains. There is a wave traveling outward in both directions from the midpoint of the chain. The wave speed is almost constant except near the middle.* (b) *Relative phases of the array. There is a wave traveling outward from the midpoint of the array.*

Example 3. The coupling functions are the same as in Example 2. We choose $\omega_{ij} = 2\omega + 0.1[1 - i/(n+1)] + 0.1[1 - j/(n+1)]$ which is in the form $\omega_{ij} = \omega_i^X + \omega_j^Y$, where $\omega_i^X = \omega + 0.1[1 - i/(n+1)]$ and $\omega_j^X = \omega + 0.1[1 - j/(n+1)]$. Then the solutions of the two chain systems (3.16) and (3.17) are the same. Figure 3.3 shows the numerical solutions for the reduced chains and the array.

Example 4. In this example, we show how the size of the chain can apparently affect the qualitative features of the phases in one- and two-dimensional arrays. In Fig. 3.4(a), we show the results of a simulation with a 50×50 array of oscillators with no frequency gradient and all of the interactions functions identical and given by $H(\phi) = \sin\phi + 0.05\cos\phi + 0.8$. The phases give the appearance of a circularly symmetric target pattern, quite different from the rectangular-looking patterns of Figure 3.1. This effect can be understood by looking at the behavior of the chain. In Figure 3.4b, the phase-shifts between successive oscillators are shown for a chain with $n = 50$ and $n = 500$ oscillators. In the case of $n = 50$ the phase-difference

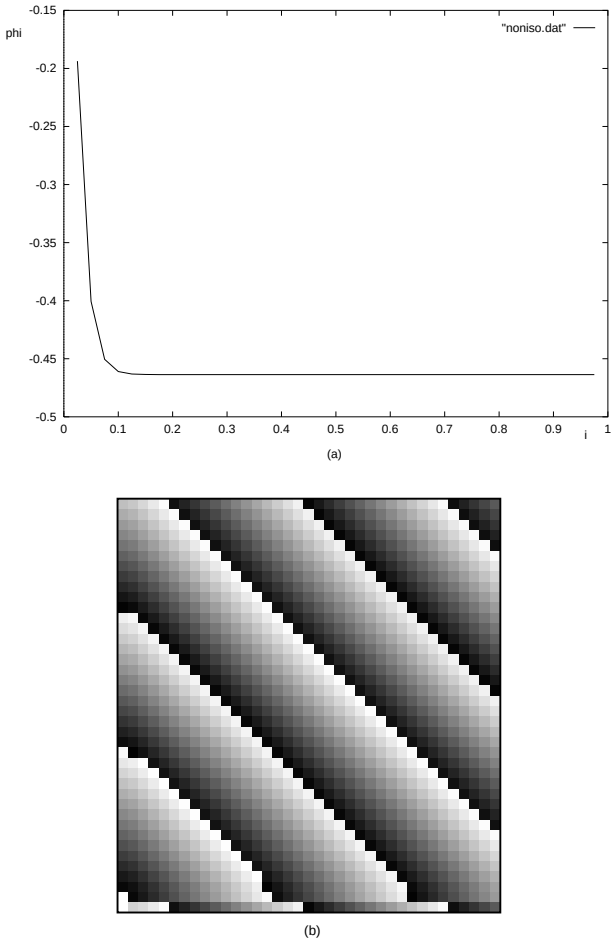

FIG. 3.2. $n + 1 = 40$. (a) *Phase lags of the reduced chains. There is a wave traveling from the left of chain to the right.* (b) *Relative phases of the array. There is a wave traveling from the southwest corner to the northeast corner.*

is nearly a straight line so that the relative phases (which are the "integral" of the phase differences) are quadratic. Since the results of this section show that the array behaves like two orthogonal chains, it is now clear why the relative phases in the square array have apparently circular contours; the relative phase along any axes of the array are nearly quadratic. This is actually an artifact of the chain size. For, as n increases, Figure 3.4(b) shows that the phase differences become piecewise constant and so the relative phases will be linear and, in the array, will look like Figure 3.1. This is also what is predicted by the continuum theory in [5]. However, due to the small size of the cosine coefficient, n must be very large before there is qualitative similarity to the continuum approximation.

3.1. Some remarks on the stability of the patterns. In one-dimensional chains with "synaptic coupling" the traveling wave solutions described in section 2 appear to be the only stable solutions. That is, no matter what the initial conditions, solutions converge to the monotone solutions described in section 2. On the other hand, if the one-dimensional chain has a ring geometry so that the two ends are

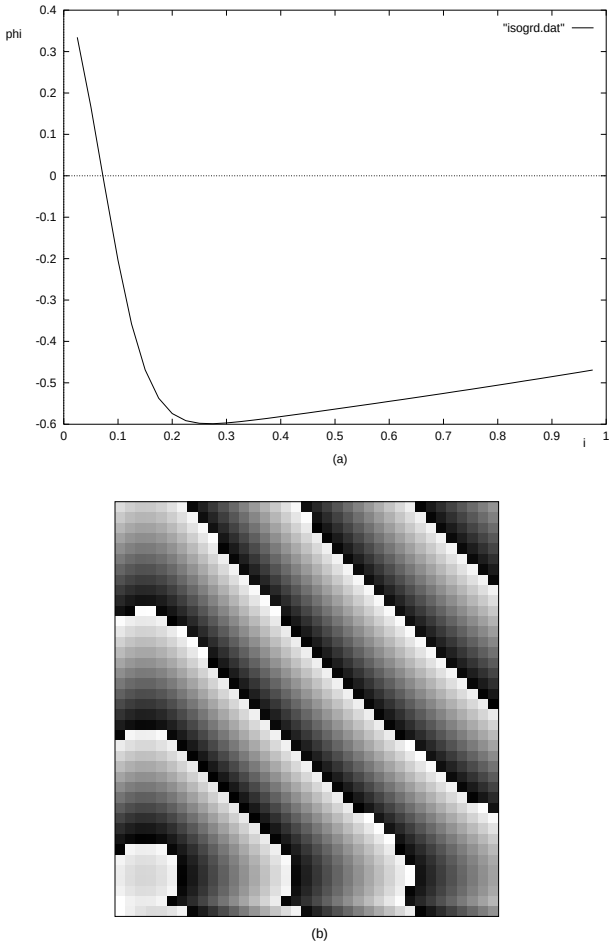

FIG. 3.3. $n+1=40$. (a) *Phase lags of the reduced chains.* (b) *Relative phases of the array.*

identified, then, there are several stable solutions that correspond to synchrony and traveling waves. Thus, the domain of attraction of any given solution varies and does not constitute the entire phase space. In particular, the larger the chain, the more different types of stable solutions are possible.

In two-dimensional systems, everything gets worse; there are many stable phaselocked patterns possible and a characterization of all of them remains a topic of current research. Finding domains of stability is even harder. Consider an $N \times N$ array where the coupling functions $H^{\pm X}, H^{\pm Y}$ are of the form

$$H(\phi) = \lambda \cos\phi + \sin\phi.$$

When $\lambda = 0$ one stable phaselocked solution is synchrony. As λ increases away from 0, the resulting phaselocked solution perturbs to the target-like patterns that we have discussed here. For $\lambda = 0$ Paullet and Ermentrout [9] have proven that there are also stable solutions analogous to spiral waves. Since these are stable, they persist for small λ and thus represent another phaselocked solution distinct from the target patterns described in this paper. Random initial data (rather than initial data identically 0)

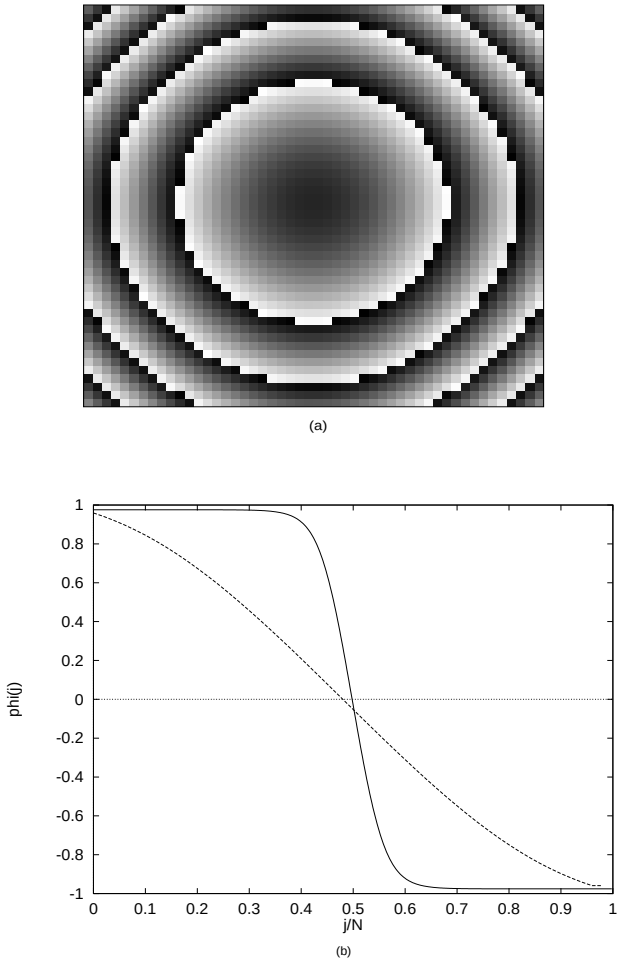

FIG. 3.4. *Relative phases in an array with almost circular symmetry and their analogue in a chain.* (a) *Relative phase for a* 50×50 *array.* (b) *A chain of length* 50 *and* 500 *showing how the almost quadratic behavior of the phase shifts for* $n = 50$ *becomes the piecewise linear phases for* $n = 500$ *as is predicted by the continuum equations.*

converge on phaselocked solutions, but sometimes they are not targets but rather are related to the spiral patterns. For small arrays, random initial data converge mainly to the target patterns but on larger arrays (e.g., 40×40) the tendency is to converge to series of broken spiral-like patterns. Thus, target patterns are "homotopes" of synchrony and have essentially the same global stability behavior. They are not unique phaselocked patterns, unlike their analogue in one dimension.

Appendix. Proof of Theorem 2.9.

(i) We prove it by applying induction on $k \in N$. Let $k = 1$. Note that $|\beta|$ is small; we have $f(0) + \beta > 0$. Then

$$\begin{aligned} \phi_1'(0) &= f(0) + \beta > 0, \\ \phi_i'(0) &= \beta < 0, \quad i = 2, \ldots, n-1, \\ \phi_n'(0) &= -f(0) + \beta < 0. \end{aligned} \tag{A.1}$$

Then by (2.13) and (A.1), we have

$$\begin{aligned} \phi_2''(0) &= g'(0)f(0), \\ \phi_{n-1}''(0) &= -g'(0)f(0). \end{aligned} \tag{A.2}$$

By induction on i, we can get that for $i = 3, \dots, m-1$

$$\begin{aligned} \phi_i'(0) = \beta, \phi_i^{(k)}(0) = 0, \quad k = 2, \dots, i-1, \\ \phi_i^{(i)}(0) = [g'(0)]^{i-1} f(0) > 0, \\ \phi_{n-i+1}'(0) = \beta, \phi_{n-i+1}^{(k)}(0) = 0, \quad k = 2, \dots, i-1, \\ \phi_{n-i+1}^{(i)}(0) = -[g'(0)]^{i-1} f(0) < 0, \end{aligned} \tag{A.3}$$

where $n = 2m-1$ or $n = 2m-2$ and

$$\phi_m'(0) = \beta, \phi_m''(0) = \cdots = \phi_m^{(m)}(0) = 0, \tag{A.4}$$

where $n = 2m-1$.

Hence by (A.1)–(A.4) and the fact that $\phi_i(0) = 0, i = 1, \dots, n$, one can apply the Taylor's formula to $\phi_i(t)$ and $\phi_i'(t)$. Then we have

$$\phi_1'(t) > 0, \phi_i'(t) < 0, \quad i = 2, \dots, n \tag{A.5}$$

and

$$\phi_L > \phi_1(t) > \cdots > \phi_n(t) > \phi_\beta \tag{A.6}$$

in $(0, \delta)$ for $\delta > 0$ small enough. Therefore $t_1 = 0$ and $l_1 = 1$.

CLAIM 1. *From $t = 0$, as long as* (A.5) *holds, we always have* (A.6).

Suppose that there is some first place t^* such that $\phi_L = \phi_1(t^*) \geq \phi_2(t^*) \geq \cdots \geq \phi_n(t^*) \geq \phi_\beta$. Then

$$\begin{aligned} \phi_1'(t^*) &= \beta + f(\phi_2(t^*)) + g(\phi_2(t^*)) - 2g(\phi_L), \\ &= \beta + f(\phi_2(t^*)) + g(\phi_2(t^*)) - f(\phi_L) - g(\phi_L), \\ &= \beta + [f'(\xi) + g'(\xi)](\phi_2(t^*) - \phi_L), \\ &\leq \beta. \end{aligned}$$

This is a contradiction since $\phi_1'(t^*) > 0$.

Now suppose that there is a first place t^* such that for some $i \in \{1, \dots, n-2\}$

$$\phi_L > \phi_1 > \phi_2 > \cdots > \phi_i = \phi_{i+1} \geq \cdots \geq \phi_{n-1} \geq \phi_n \geq \phi_\beta$$

at t^*. Then at this point t^*,

$$\begin{aligned} \phi_i' &= \beta + f(\phi_i) - f(\phi_{i-1}) + g(\phi_i) - 2g(\phi_i) + g(\phi_{i-1}) \\ &= \beta + f(\phi_i) - g(\phi_i) - f(\phi_{i-1}) + g(\phi_{i-1}) \\ &= \beta + [g' - f'](\xi_1)(\phi_{i-1} - \phi_i) \\ &> \beta \end{aligned}$$

and

$$\begin{aligned} \phi_{i+1}' &= \beta + f(\phi_{i+2}) - f(\phi_i) + g(\phi_{i+2}) - 2g(\phi_i) + g(\phi_i) \\ &= \beta + f(\phi_{i+2}) - f(\phi_i) + g(\phi_{i+2}) - g(\phi_i) \\ &= \beta + [g' - f'](\xi_2)(\phi_{i+2} - \phi_i) \\ &\leq \beta, \end{aligned}$$

so $\phi_i'(t^*) > \phi_{i+1}'(t^*)$. Therefore in a small neighborhood $(t^* - \delta, t^*)$ of t^* $(t^* > 0)$, we have $\phi_{i+1}(t) > \phi_i(t)$ since $\phi_i(t^*) = \phi_{i+1}(t^*)$. This leads to a contradiction.

Hence we can conclude that $\phi_L > \phi_1(t) > \phi_2(t) > \cdots > \phi_{n-1}(t) \geq \phi_n(t) \geq \phi_\beta$.

Suppose $\phi_L > \phi_1(t) > \phi_2(t) > \cdots > \phi_{n-1}(t) \geq \phi_n(t) = \phi_\beta$ at a first place t^*; then

$$\begin{aligned}\phi_n' &= \beta - f(\phi_{n-1}) + g(\phi_{n-1}) - 2g(\phi_\beta)\\ &= f(\phi_\beta) - g(\phi_\beta) - f(\phi_{n-1}) + g(\phi_{n-1})\\ &= [g' - f'](\xi)(\phi_{n-1} - \phi_\beta)\\ &\geq 0.\end{aligned}$$

This is a contradiction since we have $\phi_n'(t) < 0$ so far.

Hence $\phi_L > \phi_1(t) > \phi_2(t) > \cdots > \phi_{n-1}(t) \geq \phi_n(t) > \phi_\beta$.

Now suppose $\phi_L > \phi_1(t) > \phi_2(t) > \cdots > \phi_{n-1}(t) = \phi_n(t) > \phi_\beta$ at a first place t^*; then at t^*

$$\begin{aligned}\phi_n' &= \beta - f(\phi_n) + g(\phi_{n-1}) - 2g(\phi_n)\\ &= \beta - [f(\phi_{n-1}) + g(\phi_{n-1})]\end{aligned}$$

and

$$\begin{aligned}\phi_{n-1}' &= \beta + f(\phi_n) - f(\phi_{n-2}) + g(\phi_n) - 2g(\phi_{n-1}) + g(\phi_{n-2})\\ &= \beta + f(\phi_n) - f(\phi_{n-2}) - g(\phi_n) + g(\phi_{n-2})\\ &= \beta + [g' - f'](\xi_1)(\phi_{n-2} - \phi_n).\\ &> \beta.\end{aligned}$$

Since $\phi_{n-1}(t) \geq \phi_R$ for $t > 0$ by the assumption of the theorem,

$$\begin{aligned}f(\phi_{n-1}) + g(\phi_{n-1}) &= f(\phi_{n-1}) + g(\phi_{n-1}) - [f(\phi_R) + g(\phi_R)]\\ &= [f' + g'](\xi_2)(\phi_{n-1} - \phi_R)\\ &\geq 0\end{aligned}$$

at t^*. So $\phi_n'(t^*) < \phi_{n-1}'(t^*)$. Hence in a small neighborhood $(t^* - \delta, t^*)$ of t^*, we have $\phi_n(t) > \phi_{n-1}(t)$ which is a contradiction. Therefore Claim 1 is proven.

Suppose (A.5) breaks down at some first place $t_2 > 0$ (otherwise the proof is finished with $\hat{t} = +\infty$) and $\phi_i'(t_2) \neq 0$ for some $i \in \{1, \ldots, n\}$ (otherwise the proof is finished with $\hat{t} = t_2$). Then we have six cases to consider.

CASE 1. *There is some $l > 2$ such that $\phi_1'(t_2) \geq 0$, $\phi_{l-1}'(t_2) < 0$, $\phi_l'(t_2) = 0$, and $\phi_i'(t_2) \leq 0$ for $i \in \{2, \ldots, n\} - \{l-1, l\}$.*

CASE 2. *There is some $l \in \{3, \ldots, n-1\}$ such that $\phi_1'(t_2) \geq 0$, $\phi_i'(t_2) = 0$ for $i = 2, \ldots, l$ and $\phi_{l+1}'(t_2) < 0$, $l \in \{3, \ldots, n-1\}$.*

CASE 3. *$\phi_1'(t_2) = \phi_2'(t_2) = 0$ and $\phi_3'(t_2) < 0$, $\phi_i'(t_2) \leq 0$, $i = 4, \ldots, n$.*

CASE 4. *$\phi_1'(t_2) = 0$ and $\phi_i'(t_2) < 0$, $i = 2, \ldots, n$.*

CASE 5. *$\phi_1'(t_2) > 0$, $\phi_2'(t_2) = 0$ and $\phi_i'(t_2) < 0$, $i = 3, \ldots, n$.*

CASE 6. *$\phi_1'(t_2) > 0$ and $\phi_i'(t_2) = 0$, $i = 2, \ldots, n$.*

Assume Case 1 is true. Then we have

$$\begin{aligned}\phi_l'(t_2 - \varepsilon) = \beta &+ f(\phi_{l+1}(t_2 - \varepsilon)) - f(\phi_{l-1}(t_2 - \varepsilon))\\ &+ g(\phi_{l+1}(t_2 - \varepsilon)) - 2g(\phi_l(t_2 - \varepsilon)) + g(\phi_{l-1}(t_2 - \varepsilon))\end{aligned}$$

$$\begin{aligned}
&= \phi_l'(t_2) - f'(\phi_{l+1}(t_2))\phi_{l+1}'(t_2)\varepsilon + f'(\phi_{l-1}(t_2))\phi_{l-1}'(t_2)\varepsilon \\
&\quad - g'(\phi_{l+1}(t_2))\phi_{l+1}'(t_2)\varepsilon + 2g'(\phi_l(t_2))\phi_l'(t_2)\varepsilon \\
&\quad - g'(\phi_{l-1}(t_2))\phi_{l-1}'(t_2)\varepsilon + o(\varepsilon^2) \\
&= -\phi_{l+1}'(t_2)[g' + f'](\phi_{l+1}(t_2))\varepsilon \\
&\quad - \phi_{l-1}'(t_2)[g' - f'](\phi_{l-1}(t_2))\varepsilon + o(\varepsilon^2) \\
&> 0
\end{aligned}$$

for $\varepsilon > 0$ small enough (since $g' \pm f' > 0$ in J). This is a contradiction! So *Case* 1 *is eliminated in our concern.*

Assume Case 2 is true. Then

$$\begin{aligned}
\phi_l'(t_2 - \varepsilon) &= -\phi_{l+1}'(t_2)[g' + f'](\phi_{l+1}(t_2))\varepsilon + o(\varepsilon^2) \\
&> 0
\end{aligned}$$

for $\varepsilon > 0$ small enough. This is a contradiction! So *Case* 2 *is also eliminated.*

Case 3 *can be eliminated in the same way as Case* 2.

Hence we have Cases 4–6 left.

If case 4 is true, then

$$\begin{aligned}
\phi_1'(t_2 + \varepsilon) &= \phi_2'(t_2)[g' + f'](\phi_2(t_2))\varepsilon + o(\varepsilon^2) \\
&< 0
\end{aligned}$$

for small $\varepsilon > 0$. Then $l_2 = 0$ such that $l_2 = l_1 - 1$.

If Case 5 is true, then we have that for small $\varepsilon > 0$, either $\phi_2'(t) > 0$ in $(t_2, t_2 + \varepsilon)$ or $\phi_2'(t) < 0$ in $(t_2, t_2 + \varepsilon)$ (note that $\phi_2'(t) \equiv 0$ in $(t_2, t_2 + \varepsilon)$ cannot be true). Hence $l_2 = 2$, i.e., $l_2 = l_1 + 1$ or $l_2 = 1$, i.e., $l_2 = l_1$.

If Case 6 is true, then we can show that

$$\begin{aligned}
&\phi_2''(t_2) > 0, \\
&\phi_i^{(j)}(t_2) \;=\; 0, \quad j = 2, \ldots, i-1, \\
&\phi_i^{(i)}(t_2) \;>\; 0, \quad i = 3, \ldots, n
\end{aligned}$$

such that $\phi_i'(t) > 0$ $(i = 2, \ldots, n)$ in $(t_2, t_2 + \varepsilon)$ for ε small enough. Then $l_2 = n$.

And for Cases 4–6, we can prove by using the same techniques as above that

$$\phi_L > \phi_1(t_2) > \cdots > \phi_n(t_2) > \phi_\beta.$$

So we are done with $k = 1$.

Now suppose (2.16)–(2.19) hold for $1, 2, \ldots, k-1$ with $l_1, \ldots, l_k$, and $t_1 < t_2 < \ldots < t_k$.

Then for $t \in (t_k, t_k + \delta)$ ($\delta > 0$ is small)

$$\begin{aligned}
&\phi_i'(t) > 0, \quad i = 1, \ldots, l_k, \\
&\phi_j'(t) < 0, \quad j = l_k + 1, \ldots, n.
\end{aligned}$$

Claim 2. *From t_k, as long as*

$$\phi_i'(t) > 0, \quad i = 1, \ldots, l_k,$$

(A.7)

$$\phi_j'(t) < 0, \quad j = l_k + 1, \ldots, n,$$

we always have (A.6).

The proof is similar to Claim 1; we just ignore it here.

Suppose (A.7) breaks down at a first place $t_{k+1} > t_k$ and $\phi_i'(t_{k+1}) \neq 0$ for some $i \in \{1, \ldots, n\}$; then several cases should be considered carefully.

CASE 1. *There is $l < l_k$ such that $\phi_l'(t_{k+1}) \leq 0$, $\phi_{l+1}'(t_{k+1}) > 0$, $\phi_i'(t_{k+1}) \geq 0$ for $i \in \{1, \ldots, l_k\} - \{l, l+1\}$, and $\phi_j'(t_{k+1}) = 0$ for $j = l_k + 1, \ldots, n$.*

CASE 2. *There is $l > l_k + 1$ such that $\phi_i'(t_{k+1}) \geq 0$, $i = 1, \ldots, l_k$, $\phi_{l-1}'(t_{k+1}) < 0$, $\phi_l'(t_{k+1}) = 0$, and $\phi_j'(t_{k+1}) \leq 0$ for $j \in \{l_k + 1, \ldots, n\} - \{l-1, l\}$.*

CASE 3. *There is some $l \in \{2, \ldots, l_k - 1\}$ such that $\phi_i'(t_{k+1}) \geq 0$ for $i \in \{1, \ldots, l-2\}$, $\phi_{l-1}'(t_{k+1}) > 0, \phi_j'(t_{k+1}) = 0$ for $j \in \{l, \ldots, l_k\}$, and $\phi_j'(t_{k+1}) \leq 0$ for $j \in \{l_k + 1, \ldots, n\}$.*

CASE 4. *There is $l \in \{l_k + 2, \ldots, n-1\}$ such that $\phi_j'(t_{k+1}) \geq 0$ for $i \in \{1, \ldots, l_k\}$, $\phi_j'(t_{k+1}) = 0$ for $j \in \{l_k + 1, \ldots, l\}$, $\phi_{l+1}'(t_{k+1}) < 0$, and $\phi_j'(t_{k+1}) \leq 0$ for $j \in \{l + 2, \ldots, n\}$.*

CASE 5. *$\phi_i'(t_{k+1}) \geq 0$ for $i \in \{1, \ldots, l_k - 2\}$, $\phi_{l_k-1}'(t_{k+1}) > 0, \phi_{l_k}'(t_{k+1}) = \phi_{l_k+1}'(t_{k+1}) = 0$, and $\phi_i'(t_{k+1}) \leq 0$ for $i \in \{l_k + 2, \ldots, n\}$.*

CASE 6. *$\phi_i'(t_{k+1}) \geq 0$, $i \in \{1, \ldots, l_k - 1\}$, $\phi_{l_k}'(t_{k+1}) = \phi_{l_k+1}'(t_{k+1}) = 0$, $\phi_{l_k+2}'(t_{k+1}) < 0$, $\phi_j'(t_{k+1}) \leq 0$ for $j \in \{l_k + 3, \ldots, n\}$.*

CASE 7. *$\phi_i'(t_{k+1}) > 0$ for $i \in \{1, \ldots, l_k - 1\}$, $\phi_{l_k}'(t_{k+1}) = 0$, $\phi_j'(t_{k+1}) < 0$ for $j \in \{l_k + 1, \ldots, n\}$.*

CASE 8. *$\phi_i'(t_{k+1}) > 0$ for $i \in \{1, \ldots, l_k\}$, $\phi_{l_k+1}'(t_{k+1}) = 0$, and $\phi_j'(t_{k+1}) < 0$ for $j \in \{l_k + 2, \ldots, n\}$.*

CASE 9. *$\phi_i'(t_{k+1}) = 0$ for $i \in \{1, \ldots, l_k\}$, and $\phi_j'(t_{k+1}) < 0$ for $j \in \{l_k + 1, \ldots, n\}$.*

CASE 10. *$\phi_i'(t_{k+1}) > 0$ for $i \in \{1, \ldots, l_k\}$, and $\phi_j'(t_{k+1}) = 0$ for $j \in \{l_k + 1, \ldots, n\}$.*

By the techniques which we used in the case of $k = 1$, Cases 1–6 can be eliminated. Hence only Cases 7–10 are possible.

If Case 7 is true, then we have that for $\varepsilon > 0$ small enough, either $\phi_{l_k}'(t) > 0$ in $(t_{k+1}, t_{k+1} + \varepsilon)$ or $\phi_{l_k}' < 0$ in $(t_{k+1}, t_{k+1} + \varepsilon)$. Then $l_{k+1} = l_k$ or $l_{k+1} = l_k - 1$.

If Case 8 is true, then for $\varepsilon > 0$ small enough, either $\phi_{l_k+1}'(t) > 0$ in $(t_{k+1}, t_{k+1} + \varepsilon)$ or $\phi_{l_k+1}' < 0$ in $(t_{k+1}, t_{k+1} + \varepsilon)$. Then $l_{k+1} = l_k + 1$ or $l_{k+1} = l_k$.

If Case 9 is true, then for $\varepsilon > 0$ small enough, we can prove that $\phi_i'(t) < 0$ in $(t_{k+1}, t_{k+1} + \varepsilon)$ for $i = 1, \ldots, n$. Then $l_{k+1} = 0$.

If Case 10 is true, then for $\varepsilon > 0$ small enough, we can prove that $\phi_i'(t) > 0, i = 1, \ldots, n$; then $l_{k+1} = n$.

And for Cases 7–10, we can show that $\phi_L > \phi_1(t_{k+1}) > \cdots > \phi_n(t_{k+1}) > \phi_\beta$ always holds. Hence the proof is completed for this part.

(ii).

CLAIM 3. *Both $\phi_1'(t)$ and $\phi_n'(t)$ can change sign at most once. And if $\phi_1'(t)$ changes sign once, $\phi_n'(t)$ never changes sign. If $\phi_n'(t)$ changes sign once, $\phi_1'(t)$ never changes sign. That is,*

(a) *if $\phi_i'(t) < 0$, $i = 1, \ldots, n$ for $t \in (t_k, t_k + \varepsilon)$, then $\phi_i'(t) < 0$, $i = 1, \ldots, n$ for $t \in (t_k, \hat{t})$;*

(b) *if $\phi_i'(t) > 0$, $i = 1, \ldots, n$ for $t \in (t_k, t_k + \varepsilon)$, then $\phi_i'(t) > 0$, $i = 1, \ldots, n$ for $t \in (t_k, \hat{t})$.*

Claim 3 can be shown by contradiction. We ignore the proof here.

Hence by Claim 3, without loss of generality, we assume $\phi_1'(t)$ never changes sign; then we always have that $\phi_1'(t) > 0$ for $0 < t < \hat{t}$. So $\phi_1(t)$ increases as t increases. Since $\phi_L > \phi_1(t) > \cdots > \phi_n(t) > \phi_\beta$, $\phi_1(t)$ is bounded above by ϕ_L such that

$\lim_{t\to\hat{t}}\phi_1(t)=\bar{\phi}_1$ for some $\bar{\phi}_1\in[\phi_\beta,\phi_L]$. Also we have $\lim_{t\to\hat{t}}\phi_1'(t)=0$ such that

$$0=\beta+\lim_{t\to\hat{t}}[f+g](\phi_2(t))-2g(\bar{\phi}_1).$$

Then $\lim_{t\to\hat{t}}\phi_2(t)=\lim_{t\to\hat{t}}[f+g]^{-1}[f+g](\phi_2(t))$ exists. Let $\bar{\phi}_2=\lim_{t\to\hat{t}}\phi_2(t)$. By the boundedness, $\phi_L\geq\bar{\phi}_2\geq\phi_\beta$.

By induction we can show $\lim_{t\to\hat{t}}\phi_i(t)=\bar{\phi}_i$, where $\bar{\phi}_i\in[\phi_\beta,\phi_L]$. Since $\phi_L>\phi_1(t)>\cdots>\phi_n(t)>\phi_\beta$ for $t>0$, then $\phi_L\geq\bar{\phi}_1\geq\cdots\geq\bar{\phi}_n\geq\phi_\beta$.

If we apply the argument in the proof of Theorem 2.3, we also can show $\phi_L>\bar{\phi}_1>\cdots>\bar{\phi}_n>\phi_\beta$.

Remark. If we recall the proof of Claims 1 and 2, we need to assume $\phi_{n-1}\geq\phi_R$ along the trajectory. If this condition breaks down somewhere, the monotonicity may be destroyed.

REFINABLE FUNCTION VECTORS*

ZUOWEI SHEN†

Abstract. Refinable function vectors are usually given in the form of an infinite product of their refinement (matrix) masks in the frequency domain and approximated by a cascade algorithm in both time and frequency domains. We provide necessary and sufficient conditions for the convergence of the cascade algorithm. We also give necessary and sufficient conditions for the stability and orthonormality of refinable function vectors in terms of their refinement matrix masks. Regularity of function vectors gives smoothness orders in the time domain and decay rates at infinity in the frequency domain. Regularity criteria are established in terms of the vanishing moment order of the matrix mask.

Key words. refinable function vectors, stable basis, cascade algorithm, regularity

1. Introduction.

This paper presents a complete characterization of the convergence of the cascade algorithm and the stability and orthonormality of compactly supported refinable function vectors in terms of their refinement matrix masks. Regularity criteria for refinable function vectors are also established in terms of the vanishing moment order of the matrix mask.

We start with a finite set of compactly supported functions $\Phi \subset L_2(\mathbb{R}^s)$. The *FSI space* (finitely generated shift invariant; see [2]) $S(\Phi)$ generated by Φ is the smallest (closed) shift invariant subspace of $L_2(\mathbb{R}^s)$ containing Φ. Here we recall that a space is *shift invariant* if it is invariant under all *shifts*, i.e., invariant under all integer translations.

It is very convenient to discuss the shift invariant space in the frequency domain by using Gramian analysis. For a given set of functions Φ, the *pre-Gramian* matrix at $\omega \in \mathbb{T}^s$ is defined as a $\mathbb{Z}^s \times \Phi$ matrix by

$$J(\omega) := J_\Phi(\omega) := (\widehat{\varphi}(\omega + 2\pi\alpha))_{\alpha,\varphi},$$

where $\widehat{\varphi}$ is the Fourier transform of the function φ. Its adjoint matrix

$$J^*(\omega) := J_\Phi^*(\omega) := (\overline{\widehat{\varphi}(\omega + 2\pi\alpha)})_{\varphi,\alpha}$$

is a $\Phi \times \mathbb{Z}^s$ matrix. The *Gramian matrix* of functions Φ is a $\Phi \times \Phi$ matrix defined as the product of J^* and J, i.e., $J_\Phi^*(\omega) J_\Phi(\omega)$. The pre-Gramian matrix was first introduced in [22]; the basic properties of the pre-Gramian and its roles in the Gramian analysis for shift invariant spaces (not necessarily an FSI space) can be found in [22]. In this paper, we will often use the matrix $\overline{J^*J} =: G_\Phi =: G$ instead of J^*J. Since the properties of the Gramian matrix J^*J in which we are interested do not change when the conjugation is taken, we also call G_Φ the Gramian matrix of Φ.

This paper uses functions that are defined on $\mathbb{T}^s$, the s-dimensional torus. These can be viewed as 2π-periodic functions, via the standard transformation $\mathbb{R}^s \ni \omega \mapsto$

$e^{i\omega} := (e^{i\omega_1}, ..., e^{i\omega_s}) \in \mathbb{T}^s$. Though we may refer to such functions as defined on $\mathbb{T}^s$, we always treat their arguments as *real*. Thus, "multiplying a function defined on $\mathbb{T}^s$ by a function defined on $\mathbb{R}^s$" simply means "multiplying a 2π-periodic function by ...." Following this slight abuse of language, we write "$\Omega \subset \mathbb{T}^s$" to mean "$\Omega \subset [-\pi, \pi]^s$."

The functions Φ used in this paper are solutions to functional equations of the type

$$\Phi = \sum_{\alpha \in \mathbb{Z}^s} P_\alpha \Phi(2 \cdot -\alpha), \tag{1.1}$$

where the "coefficients" P_α are $\Phi \times \Phi$ matrices and Φ is a $\#\Phi$-dimensional column refinable function vector. We assume throughout that the refinement matrix masks are supported in $[0, N]^s$. Here we use Φ to denote both the set of functions Φ and the column function vector Φ.

Define

$$\mathbf{P} := 2^{-s} \sum_{\alpha \in \mathbb{Z}^s} P_\alpha \exp(-i\alpha \cdot).$$

Then, $\mathbf{P}$ is a $\Phi \times \Phi$ matrix, so each entry is a trigonometric polynomial such that their Fourier coefficients are supported in $[0, N]^s$. The functional equations (1.1) can be written as

$$\widehat{\Phi} := \mathbf{P}(\cdot/2)\widehat{\Phi}(\cdot/2). \tag{1.2}$$

Equations of the type (1.2) are called *vector refinement equations*; the matrix $\mathbf{P}$ is called the *refinement (matrix) mask*, and Φ is a ($\mathbf{P}$-) *refinable function vector*.

Since each entry of $\mathbf{P}$ is a trigonometric polynomial, the function matrix $\mathbf{P}$ satisfies

$$\|\mathbf{P}(\cdot) - \mathbf{P}(0)\| \le \text{const}\|\cdot\|,$$

where for any $d \times d$ matrix M, $\|M\| := \max_{\|\mathbf{v}\|=1} \|M\mathbf{v}\|/\|\mathbf{v}\|$, with $\|\mathbf{v}\|$ the Euclidean norm of the column vector $\mathbf{v} \in \mathbb{R}^d$.

If $\lim_{n\to\infty} \mathbf{P}(0)^n$ exists and is nontrivial, then the infinite product

$$\mathbf{P}^\infty := \prod_{k=1}^{\infty} \mathbf{P}(2^{-k}\cdot)$$

converges uniformly on compact sets. Further, $\widehat{\Phi} = \mathbf{P}^\infty \mathbf{a}$ is a solution of (1.2), where $\mathbf{a}$ is a right eigenvector of $\mathbf{P}(0)$ (see [12], [11] for the univariate case and [15] for the multivariate one). The functions Φ are compactly supported distributions with $\text{supp}(\Phi) \subset [0, N]^s$. We further remark that the existence of a solution $\widehat{\Phi}$ of (1.2) only requires the convergence of $\prod_{j=1}^n \mathbf{P}(2^{-j}\cdot)\mathbf{a}$, where $\mathbf{a}$ is a right eigenvector of $\mathbf{P}(0)$ corresponding to the eigenvalue 1 (see [12] and [4]). It has been shown in [4] that $\prod_{j=1}^n \mathbf{P}(2^{-j}\cdot)\mathbf{a}$ converges if $\rho(\mathbf{P}(0)) < 2$ (see also [12]).

We say that a matrix M (or linear operator) satisfies the condition on eigenvalues, or *Condition E* for short, if the spectral radius $\rho(M) \le 1$, 1 is required to be the only eigenvalue on the unit circle and must be a simple eigenvalue. Condition E is a useful concept in the wavelet theory and applications (see [3], [23], [24], and [18]).

Assume that $\mathbf{P}(0)$ satisfies Condition E. Then, there is a nonsingular matrix U so that $U\mathbf{P}(0)U^{-1}$ has the form

$$\begin{pmatrix} 1 & \mathbf{0} \\ \mathbf{0} & \Lambda \end{pmatrix}, \tag{1.3}$$

where

$$\Lambda := \begin{pmatrix} \lambda_2 & \mu_2 & 0 & 0 & \dots & 0 & 0 \\ 0 & \lambda_3 & \mu_3 & 0 & \dots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \dots & 0 & \lambda_{\#\Phi} \end{pmatrix}$$

with $|\lambda_i| < 1$, and $\mu_i = 1$, or 0, $i = 2, \dots, \#\Phi$. Define $\mathbf{P}_1 = U\mathbf{P}U^{-1}$; then $\Phi^1 := U\Phi$ satisfies the refinement equations

$$\widehat{\Phi}^1 = \mathbf{P}_1(\cdot/2)\widehat{\Phi}^1(\cdot/2), \tag{1.4}$$

where Φ is a solution of (1.2).

The stability, regularity, and convergence of the cascade algorithm discussed in the paper do not change, even if we consider the refinement equation (1.4) instead of (1.1). Furthermore, as we will see in section 3, the problem of checking the orthonormality of Φ can be reduced to that of checking the stability of Φ^1. Therefore, we can always assume that $\mathbf{P}(0)$ has the form given in (1.3), without losing anything.

In this case the vector $\mathbf{i}_1^T := (1, 0, \dots, 0)$ is a left eigenvector and $\mathbf{i}_1$ is a right eigenvector of $\mathbf{P}(0)$ corresponding to eigenvalue 1. We further require that $\mathbf{P}$ have vanishing moments of at least order 1, that is, equivalent to the fact that

$$\mathbf{i}_1^T\mathbf{P}(\pi\nu) = \delta_\nu \mathbf{i}_1^T, \quad \nu \in \mathbb{Z}^s/2\mathbb{Z}^s.$$

This implies that

$$\mathbf{i}_1^T\widehat{\Phi}(2\pi\alpha) = \delta_\alpha,\ \alpha \in \mathbb{Z}^s.$$

Altogether, we assume, throughout this paper, that the mask $\mathbf{P}$ satisfies the following conditions.

BASIC CONDITIONS 1.5. *We say that* $\mathbf{P}$ *satisfies the basic conditions if*

(i) $\mathbf{P}(0)$ *has the form of* (1.3)*, and*

(ii) $\mathbf{i}_1^T\mathbf{P}(\pi\nu) = \delta_\nu \mathbf{i}_1^T, \quad \nu \in \mathbb{Z}^s/2\mathbb{Z}^s$.

It has further been shown in [15] (see also [12]) that if the basic conditions 1.5 hold for $\mathbf{P}$, then

$$\mathbf{P}^\infty = \prod_{j=1}^{\infty} \mathbf{P}(\cdot/2^j) = \begin{pmatrix} \widehat{\Phi} & \mathbf{0} & \mathbf{0} & \cdots & \mathbf{0} \end{pmatrix}.$$

In particular, if $\widehat{\Phi}(0) \neq \mathbf{0}$, the solution Φ is determined uniquely up to a constant factor. In fact, $\widehat{\Phi} = c\mathbf{P}^\infty\mathbf{b}$, where $\mathbf{b}$ is an arbitrary vector satisfying $\mathbf{i}_1^T\mathbf{b} = 1$.

The functions Φ can be approximated by the following *cascade algorithm*: starting with a function vector Φ_0 which satisfies

$$\sum_{\alpha\in\mathbb{Z}^s} \mathbf{i}_1\Phi_0(\cdot - \alpha) = 1,$$

the function vector Φ_n is defined inductively by

$$\Phi_n := \sum_{\alpha\in\mathbb{Z}^s} P_\alpha \Phi_{n-1}(2\cdot - \alpha). \tag{1.5}$$

The cascade algorithm can be iterated in the frequency domain by taking the Fourier transform of (1.5):

$$\widehat{\Phi}_n = \mathbf{P}(\cdot/2)\widehat{\Phi}_{n-1}(\cdot/2). \tag{1.6}$$

It is clear that the sequence $(\Phi_n)_n$ converges in the L_2-norm if and only if the sequence $(\widehat{\Phi}_n)_n$ does. (We say $(\Phi_n)_n$ converges to Φ in the L_2-norm if each component of $(\Phi_n)_n$ converges to the corresponding component of Φ in the L_2-norm.) A sufficient condition for the convergence of the cascade algorithm is given in [4], under the assumption that Φ and its shifts are linearly independent; $s = 1$ and $\widehat{\Phi}_0 = \chi_{[-\pi,\pi]}\mathbf{a}$, where $\mathbf{a}$ is a right eigenvector of $\mathbf{P}(0)$ corresponding to eigenvalue 1. If the sequence $(\Phi_n)_n$ defined by (1.5) converges, then $\Phi \subset L_2(\mathbb{R}^s)$.

Define

$$S^k := S^k(\Phi) := \{f(2^k\cdot) : f \in S(\Phi)\}. \tag{1.7}$$

Then,

$$S^k \subset S^{k+1}. \tag{1.8}$$

It is proven in [14] that if

$$\cup_{k\in\mathbb{Z}} \cup_{\varphi\in\Phi} \operatorname{supp} \widehat{\varphi}(2^k\cdot) = \mathbb{R}^s \tag{1.9}$$

holds up to a null set and (1.8) holds, then $\cup_{k\in\mathbb{Z}} S^k$ is dense in $L_2(\mathbb{R}^s)$. If the refinable function vector Φ is compactly supported, (1.9) is always true. It has further been shown in [14] that if $\Phi \subset L_2(\mathbb{R}^s)$, then $\cap_{k\in\mathbb{Z}} S^k = \{0\}$. Altogether, we have the following result.

RESULT 1.1. *Let Φ be the compactly supported $\mathbf{P}$-refinable function vector. If $\Phi \subset L_2$, then*

$$\overline{\cup_{k\in\mathbb{Z}} S^k} = L_2(\mathbb{R}^s) \quad \textit{and} \quad \cap_{k\in\mathbb{Z}}\, S^k = \{0\}. \tag{1.10}$$

We say that a set of functions Φ is *stable* if Φ and their shifts form a Riesz basis of $S(\Phi)$, and a set of functions Φ is *orthonormal* if Φ and their shifts form an orthonormal basis of $S(\Phi)$.

A set of functions $\Phi \subset L_2(\mathbb{R}^s)$ is stable if and only if

$$0 < C_1 \le \|\lambda\|_\infty \le \|\Lambda\|_\infty \le C_2 < \infty, \quad \text{a.e.} \quad \omega \in \mathbb{T}^s,$$

where $\lambda(\omega)$ and $\Lambda(\omega)$ are the smallest and largest eigenvalues of the Gramian matrix $G_\Phi(\omega)$. If the set of functions Φ is compactly supported, then Φ is stable if and only if $\det G(\omega) \neq 0$ for all $\omega \in \mathbb{T}^s$. The set of functions Φ is orthonormal if and only if $G(\omega) = I$, a.e. $\omega \in \mathbb{T}^s$, where I is the identity matrix. The proofs of these results can be found in many articles (see, e.g., [13], [2], [9], [7], [22], [5], and [15]).

Once the set of functions $\Phi \subset L_2(\mathbb{R}^s)$ is stable (or orthonormal), it would be advantageous to know the regularity of Φ in order to make better use of Φ. An estimation of the regularity of Φ ($s = 1$) in terms of $\mathbf{P}$ has been given in [4], under the assumption that the refinable function vector Φ and its shifts are linearly independent.

By the above discussion, if the refinable function vector $\Phi \subset L_2(\mathbb{R}^s)$ is stable, or orthonormal, the sequence of subspaces $(S^k)_k$, $k \in \mathbb{Z}$ of $L_2(\mathbb{R}^s)$ forms a multiresolution; recall that a sequence $(S^k)_k$ forms a *multiresolution* if the sequence $(S^k)_k$ satisfies (1.10) and is refinable ($S^k \subset S^{k+1}$, $k \in \mathbb{Z}$) and if the refinable function vector Φ is stable or orthonormal.

The multiresolution generated by several functions was first introduced by [10], [9] (see also [1] and [6]). Result 1.1 is due to [14]. The first set of examples of orthonormal refinable function vectors Φ were given in [8], [7], and [6]. Examples of stable refinable function vectors Φ were given in [9]. Compactly supported wavelets and prewavelets from these examples were constructed in [7], [8], [25], and [16] (see also [5]).

It is of particular interest to construct compactly supported wavelets and prewavelets from compactly supported refinable function vectors and the refinement matrix masks. An algorithmic method in the construction of compactly supported wavelets and prewavelets from an arbitrarily given $\mathbf{P}$ refinable function vector Φ was obtained in [16], where $s = 1$. The problem of wavelet constructions is much more challenging in higher dimensions even when $\#\Phi = 1$ (see [13] and [14]). However, in dimensions no greater than 3, a method for the case $\#\Phi = 1$ has been provided in [19] and [20], under a mild condition on refinement masks.

Since the solutions Φ of (1.1) are defined via their Fourier transform by the refinement matrix mask $\mathbf{P}$, and since in practice only the refinement matrix mask is available for checking, it is useful to transfer the characterization of the stability and orthonormality of Φ by the Gramian matrix of Φ to characterization in terms of the mask. Similarly, it is necessary to characterize the convergence of the cascade algorithm defined by (1.6) and set criteria for the regularity of refinable function vectors in terms of the refinable matrix mask $\mathbf{P}$.

For this, we introduce the transition operator defined on $\mathbb{H}$, the space of all $\Phi \times \Phi$ matrices whose entries are trigonometric polynomials such that their Fourier coefficients are supported in $[-N, N]^s$. Here, we recall that the refinement mask $(P_\alpha)_\alpha$ is supported in $[0, N]^s$. The *transition operator* $\mathbf{T}_\Phi := \mathbf{T}$ is defined by

$$\mathbf{T}H := \sum_{\nu \in \mathbb{Z}^s/2\mathbb{Z}^s} \mathbf{P}(\cdot/2 + \pi\nu)H(\cdot/2 + \pi\nu)\mathbf{P}^*(\cdot/2 + \pi\nu), \quad H \in \mathbb{H}.$$

Then, $\mathbf{T}$ is a linear operator on $\mathbb{H}$.

Denote by $\mathbb{H}_M$ the space of all $\Phi \times \Phi$ matrices whose entries are trigonometric polynomials such that their Fourier coefficients are supported in $[-M, M]^s$. Then, if $M \geq N$, the transition operator $\mathbf{T}$ can be defined as an operator on $\mathbb{H}_M$. Further, since if $M > N$, $\mathbf{T}$ is a Fourier coefficient support reduced operator on $\mathbb{H}_M$, any eigenmatrix of nonzero eigenvalues of $\mathbf{T}_{|\mathbb{H}_M}$ is in $\mathbb{H}$. Therefore, all results of this paper can be stated in terms of the transition operator $\mathbf{T}$ on $\mathbb{H}_M$ for $M > N$, although they are stated in terms of the transition operator $\mathbf{T}$ on $\mathbb{H}$.

If the functions Φ are the solutions of refinable equations (1.1), and if one writes $J(\omega)$ as a column block matrix by

$$J(\omega) = (\widehat{\varphi}(\omega + 2\pi\nu + 4\pi\alpha))_{(\nu,\alpha)\times\varphi \in (\mathbb{Z}^s/2\mathbb{Z}^s \times \mathbb{Z}^s)\times\Phi},$$

then

$$\overline{J^*}(\omega) = (\mathbf{P}(\omega/2 + \pi\nu)\overline{J^*}(\omega/2 + \pi\nu))_{\nu \in \mathbb{Z}^s/2\mathbb{Z}^s}.$$

Hence

$$G(\omega) = \overline{J^*}(\omega)\overline{J}(\omega) = \sum_{\nu \in \mathbb{Z}^s/2\mathbb{Z}^s} \mathbf{P}(\omega/2 + \pi\nu)G(\omega/2 + \pi\nu)\mathbf{P}^*(\omega/2 + \pi\nu). \tag{1.11}$$

Therefore, the Gramian matrix $G_\Phi \in \mathbb{H}$ is an eigenmatrix of eigenvalue 1 of the transition operator $\mathbf{T}$.

Equation (1.11) also leads to the following result, which was proven by [10], [9], [8], [5], and [15].

RESULT 1.2. *If the compactly supported refinable function vector Φ is orthonormal, then*

$$I = \sum_{\nu\in\mathbb{Z}^s/2\mathbb{Z}^s} \mathbf{P}(\omega/2+\pi\nu)\mathbf{P}^*(\omega/2+\pi\nu), \quad \omega\in\mathbb{T}^s. \tag{1.12}$$

If the refinable function vector Φ is stable, then the matrix

$$\sum_{\nu\in\mathbb{Z}^s/2\mathbb{Z}^s} \mathbf{P}(\omega/2+\pi\nu)\mathbf{P}^*(\omega/2+\pi\nu)$$

is not singular for all $\omega\in\mathbb{T}^s$.

A mask $\mathbf{P}$ satisfying (1.12) is called a *conjugate quadrature filter*, or CQF.

Since $\mathbb{H}$ is a finite dimensional space, the operator $\mathbf{T}$ can be represented by a finite order matrix with respect to some fixed basis of $\mathbb{H}$. The matrix is also denoted by $\mathbf{T}$, and we will identify the operator $\mathbf{T}$ with the matrix $\mathbf{T}$.

We say that the cascade algorithm defined in (1.5) *converges*, if Φ_n defined by (1.5) converges to Φ with $\widehat{\Phi}(0)=\mathbf{i}_1$ for all Φ_0 which satisfy

$$\sum_{\alpha\in\mathbb{Z}^s} \mathbf{i}_1^T\Phi_0(\cdot-\alpha)=1, \quad \text{and} \quad G_{\Phi_0}\in\mathbb{H}. \tag{1.13}$$

We note that if $\mathbf{P}$ satisfies the basic conditions (1.5) and Φ_0 satisfies (1.13), then the Φ_n defined by the cascade algorithm (1.5) always converges to Φ with $\widehat{\Phi}(0)=\mathbf{i}_1$ in the distribution sense.

The rest of the paper is organized as follows. In section 2, we will prove that the cascade algorithm converges if and only if the transition operator $\mathbf{T}$ satisfies Condition E. In section 3, we will prove that Φ is stable if and only if the transition operator $\mathbf{T}$ satisfies Condition E and the corresponding eigenmatrix is nonsingular on $\mathbb{T}^s$. Consequently, we show that if Φ is stable, then the cascade algorithm converges; if $\mathbf{P}$ is a CQF mask, then Φ is orthonormal if and only if it is stable. Regularity criteria in terms of mask are established in section 4. We also remark that most of the results in this paper can be generalized to a general dilation matrix easily.

Finally, we remark that the corresponding results for the case $\#\Phi=1$ were obtained in [18] (convergence of the cascade algorithm), [17] (stability and orthonormality), and [21] (regularity).

2. Convergence of cascade algorithms. In this section we present a complete characterization of the convergence of the cascade algorithm defined by (1.5).

In what follows, we will identify the matrix $H\in\mathbb{H}$ with the corresponding unique sequence $(h_B^H)_{B\in\mathbb{B}}$ for a fixed basis $\mathbb{B}$, where

$$H=\sum_{B\in\mathbb{B}} h_B^H B.$$

We use the standard basis

$$\begin{aligned}\mathbb{B}_{st} :=&\{B_{i,j}^\alpha=(b_{l,l'}^\alpha)_{1\le l,l'\le\#\Phi}\in\mathbb{H}:\\ &b_{i,j}^\alpha=\exp(-i\alpha\cdot); \quad b_{l,l'}^\alpha=0, \quad (l,l')\ne(i,j); \quad \alpha\in[-N,N]^s\}\end{aligned}$$

in the proof of the sufficiency part of the next theorem.

We also note that a sequence of matrices $(\mathbf{T}^n)$ generated by a finite order matrix $\mathbf{T}$ converges to a nontrivial matrix if and only if the spectral radius $\rho(\mathbf{T}) \le 1$, and 1 is the only eigenvalue on the unit circle and is nondegenerate. Furthermore the sequence $(\mathbf{T}^n)$ converges if and only if for all $H \in \mathbb{H}$, the sequence $(\mathbf{T}^n H)$ converges. Here the convergence of the sequence $(\mathbf{T}^n H)$ is equivalent to the convergence of the sequence $(h_B^{\mathbf{T}^n H})_n$ for a fixed basis $\mathbb{B}$. Since $\mathbf{T}(\lim_n \mathbf{T}^{n-1} H) = \lim_n \mathbf{T}^n H$, the matrix $\lim_n \mathbf{T}^n H$ is an eigenmatrix of $\mathbf{T}$ corresponding to the eigenvalue 1. In particular, if $\mathbf{T}$ satisfies Condition E, then, for arbitrary $H \in \mathbb{H}$, $\lim_n \mathbf{T}^n H = \text{const} G_\Phi$.

A special basis of $\mathbb{H}$ is needed in the proof of the necessity part of the next theorem. The basis $\mathbb{B}_{sp}$ chosen is the one such that for each $B \in \mathbb{B}_{sp}$, there are Φ_0 and Ψ_0 satisfying (1.13) and $B = \overline{J^*_{\Phi_0} J_{\Psi_0}}$.

Define $\mathbb{D} = \mathbb{D}_1 \cup \mathbb{D}_2$, where

$$\begin{aligned}\mathbb{D}_1 := \{&D^\alpha_{1,1} = (d^\alpha_{l,l'})_{1\le l,l'\le \#\Phi} \in \mathbb{H}: \\ &d^\alpha_{1,1} = \exp(-i\alpha\cdot), \quad d^\alpha_{l,l'} = 0, \quad (l,l') \ne (1,1); \quad \alpha \in [-N,N]^s\};\end{aligned}$$

and

$$\begin{aligned}\mathbb{D}_2 :=\{&D^\alpha_{i,i} = (d^\alpha_{l,l'})_{1\le l,l'\le \#\Phi} \in \mathbb{H}: \quad d^\alpha_{1,1} = 1, \quad d^\alpha_{i,i} = \exp(-i\alpha\cdot), \quad 1 < i, \\ &d^\alpha_{1,i} = \exp(-i\alpha\cdot), \quad d_{i,1} = 1, \\ &d^\alpha_{l,l'} = 0, \quad \text{if } (l,l') \ne (i,i), (1,1),\ (i,1), \text{ and } (1,i);\ \alpha \in [-N,N]^s\}.\end{aligned}$$

Then define $\mathbb{E} = \mathbb{E}_1 \cup \mathbb{E}_2 \cup \mathbb{E}_3$, where

$$\begin{aligned}\mathbb{E}_1 :=\{&E^\alpha_{i,j} = (e^\alpha_{l,l'})_{1\le l,l'\le \#\Phi} \in \mathbb{H}: \\ &e^\alpha_{1,1} = 1, \quad e^\alpha_{i,j} = \exp(-i\alpha\cdot),\ 1 < i,j\ i \ne j, \\ &e^\alpha_{i,1} = 1, \quad e^\alpha_{1,j} = \exp(-i\alpha\cdot), \\ &e^\alpha_{l,l'} = 0, \text{ if } (l,l') \ne (1,1), (i,1), (1,j), \text{and } (i,j); \quad \alpha \in [-N,N]^s\};\end{aligned}$$

$$\begin{aligned}\mathbb{E}_2 :=\{&E^\alpha_{1,j} = (e^\alpha_{l,l'})_{1\le l,l'\le \#\Phi} \in \mathbb{H}: \quad e^\alpha_{1,1} = 1, \quad e^\alpha_{1,j} = \exp(-i\alpha\cdot), 1 < j, \\ &e^\alpha_{l,l'} = 0, \text{ otherwise}; \quad \alpha \in [-N,N]^s\};\end{aligned}$$

and

$$\mathbb{E}_3 := \{B^T : B \in \mathbb{E}_2\}.$$

Then, the set $\mathbb{B}_{sp} := \mathbb{D} \cup \mathbb{E}$ is a basis of $\mathbb{H}$.

For function vectors Φ_0 and Ψ_0 satisfying (1.13), define function vectors

$$\Phi_n = (\varphi^i_n)^T_{1\le i\le \#\Phi} \quad \text{and} \quad \Psi_n = (\psi^i_n)_{1\le i\le \#\Phi}$$

via their Fourier transform as

$$\widehat{\Phi}_n := \mathbf{P}(\cdot/2)\widehat{\Phi}_{n-1}(\cdot/2), \quad \text{and} \quad \widehat{\Psi}_n := \mathbf{P}(\cdot/2)\widehat{\Psi}_{n-1}(\cdot/2).$$

Let $G_n = \overline{J^*_{\Phi_n} J_{\Psi_n}}$. Then

$$\mathbf{T}G_{n-1} = \sum_{\nu\in\mathbb{Z}^s/2\mathbb{Z}^s} \mathbf{P}(\cdot/2+\pi\nu)\overline{J^*_{\Phi_{n-1}}}(\cdot/2+\pi\nu)\overline{J_{\Psi_{n-1}}}(\cdot/2+\pi\nu)\mathbf{P}^*(\cdot/2+\pi\nu) = G_n.$$

If the cascade algorithm converges in the L_2-norm, then each entry of G_n converges to the corresponding entry of G_Φ in the L_1-norm. This implies G_n converges to G_Φ in the $\|\cdot\|_1$-norm on $\mathbb{H}$, where for $H(\omega) := (h_{i,j}(\omega))_{1\le i,j\le \#\Phi}$,

$$\|H\|_1 := \sum_{1\le i,j\le \#\Phi} \|h_{i,j}(\cdot)\|_1.$$

For a fixed $\mathbb{B}$, let

$$G_n = \sum_{B\in\mathbb{B}} a_B^n B \quad \text{and} \quad G_\Phi = \sum_{B\in\mathbb{B}} a_B B.$$

Then, the convergence of the cascade algorithm implies that the sequence of the sequences $(a^n)_n$ converges to the sequence a.

Finally, we note that for any $\Phi := (\varphi^l)^T$ and $\Psi := (\psi^{l'})^T$, the $(\varphi^l, \psi^{l'})$th entry of $\overline{J_\Phi^* J_\Psi}$ can be written as

$$\sum_{\beta\in\mathbb{Z}^s} \widehat{\varphi^l}(\cdot + 2\pi\beta)\overline{\widehat{\psi^{l'}}(\cdot + 2\pi\beta)} = \sum_{\alpha\in\mathbb{Z}^s} (\varphi^l * \overline{\psi^{l'}(-\cdot)})(\alpha)\exp(-i\alpha\cdot). \tag{2.1}$$

We are ready to prove the following theorem.

THEOREM 2.1. *If the basic conditions* 1.5 *hold for* $\mathbf{P}$*, then the cascade algorithm converges if and only if the transition operator* $\mathbf{T}$ *satisfies Condition* E.

Proof. "$\Longrightarrow$" Since $\mathbf{T}$ satisfies Condition E, the sequence of linear operators $\mathbf{T}^n$ converges. Let Φ_n be a sequence of function vectors generated by the cascade algorithm (1.5) with Φ_0 satisfying (1.13). Then $G_{\Phi_n} = \mathbf{T}^n G_{\Phi_0}$ converges. Since for each fixed l, $\|\varphi_n^l\|$ is the coefficient of $B_{l,l}^0 \in \mathbb{B}_{st}$, if we express G_{Φ_n} by $\mathbb{B}_{st}$, and since $\mathbb{H}$ is a finite dimensional space, Φ_n is bounded in the L_2-norm. Hence any subsequence of Φ_n contains a weakly convergent subsubsequence of Φ_n. Since Φ_n converges to Φ in the distribution sense, and since weak convergence is stronger than convergence in the distribution sense, Φ_n converges to Φ weakly. Therefore, to show that Φ_n converges strongly to Φ, it remains to show that the L_2-norm of Φ_n converges to that of Φ. Since G_Φ is an eigenmatrix of $\mathbf{T}$ corresponding to the eigenvalue 1 and since $\mathbf{T}$ satisfies Condition E, G_Φ is the unique eigenmatrix of $\mathbf{T}$. Therefore,

$$\lim_{n\to\infty} \mathbf{T}^n G_{\Phi_0} = \lim_{n\to\infty} G_{\Phi_n} = \text{const} G_\Phi.$$

Since $\mathbf{i}_1^T G_{\Phi_0}(0)\mathbf{i}_1 = \mathbf{i}_1^T G_{\Phi_n}(0)\mathbf{i}_1 \neq 0$ for all n, we have

$$0 \neq \mathbf{i}_1^T G_{\Phi_0}(0)\mathbf{i}_1 = \lim_{n\to\infty} \mathbf{i}_1^T \mathbf{T}^n G_{\Phi_0}(0)\mathbf{i}_1$$

$$= \lim_{n\to\infty} \mathbf{i}_1^T G_{\Phi_n}(0)\mathbf{i}_1 = \mathbf{i}_1^T G_\Phi(0)\mathbf{i}_1 = \text{const}\mathbf{i}_1^T G_\Phi(0)\mathbf{i}_1.$$

Hence const $= 1$, and

$$\lim_{n\to\infty} \mathbf{T}^n G_{\Phi_0} = \lim_{n\to\infty} G_{\Phi_n} = G_\Phi.$$

Since for each fixed l, $\|\varphi_n^l\|$ is the coefficient of $B_{l,l}^0 \in \mathbb{B}_{st}$ and since $\mathbb{H}$ is a finite dimensional space, we must have $\lim_n \|\varphi_n^l\| = \|\varphi^l\|$. Hence, Φ_n converges to Φ strongly in the L_2-norm.

"$\Longleftarrow$" We first prove that for any element $B \in \mathbb{B}_{sp}$, there is a proper choice of $\Phi_0 := (\varphi^{l'})^T$ and $\Psi_0 := (\psi^l)^T$ satisfying (1.13) so that $\overline{J^*_{\Phi_0} J_{\Psi_0}} = B$.

For this, let $f := \chi_{[-1/2,1/2]^s}$.

First, if $B = D^\alpha_{1,1} \in \mathbb{D}_1$, then define $\Phi_0 = (\varphi^l_0)^T$ and $\Psi_0 = (\psi^{l'}_0)^T$ so that $\varphi^1_0 = f$, $\psi^1_0 = f(\cdot - \alpha)$, $\varphi^l_0 = 0$, and $\psi^{l'}_0 = 0$ if $l, l' \neq 1$. Then Φ_0 and Ψ_0 satisfy (1.13) and $\overline{J^*_{\Phi_0} J_{\Psi_0}} = D^\alpha_{1,1} \in \mathbb{D}_1$ by (2.1). For $E^\alpha_{i,j} \in \mathbb{E}_1$ (or $D^\alpha_{i,i} \in \mathbb{D}_2$), define $\Phi_0 = (\varphi^l_0)^T$ and $\Psi_0 = (\psi^{l'}_0)^T$ to be the function vectors such that $\varphi^1_0 = \psi^1_0 = f$ and $\varphi^i_0 = f$ and $\psi^j_0 = f(\cdot - \alpha)$, $\varphi^l_0 = 0$, $l \neq 1, i$, and $\psi^{l'}_0 = 0$ $l' \neq 1, j$. Then the function vectors Φ_0 and Ψ_0 satisfy (1.13). Further, the matrix $\overline{J^*_{\Phi_0} J_{\Psi_0}} = E^\alpha_{i,j} \in \mathbb{E}_1$ if $i \neq j$ (and $D_{i,i} \in \mathbb{D}_2$ if $i = j$) by (2.1). For $E^\alpha_{i,j} \in \mathbb{E}_2$, define $\Phi_0 = (\varphi^l_0)^T$ and $\Psi_0 = (\psi^{l'}_0)^T$ so that $\varphi^1_0 = \psi^1_0 = f$, and $\varphi^j_0 = 0$ and $\psi^j_0 = f(\cdot - \alpha)$ and $\varphi^l_0 = \psi^{l'}_0 = 0$ if $l, l' \neq 1, j$. Then Φ_0 and Ψ_0 satisfy (1.13) and $\overline{J^*_{\Phi_0} J_{\Psi_0}} = E^\alpha_{i,j} \in \mathbb{E}_2$ by (2.1).

Since the cascade algorithm converges, $\mathbf{T}^n B$ converges to G_Φ for all $B \in \mathbb{B}_{sp}$. Thus for any $H \in \mathbb{H}$, $\lim_{n\to\infty} \mathbf{T}^n H = \text{const} G_\Phi$; consequently, the sequence of matrices $(\mathbf{T}^n)$ converges. Therefore, the spectral radius $\rho(\mathbf{T}) \leq 1$ and 1 is the only eigenvalue of $\mathbf{T}$ on the unit circle. Further, 1 is a nondegenerate eigenvalue of $\mathbf{T}$. To prove that $\mathbf{T}$ satisfies Condition E, it remains to show that G_Φ is the only eigenmatrix of eigenvalue 1. Let $E \in \mathbb{H}$ so that $\mathbf{T}E = E$; then

$$\lim_{n\to\infty} \mathbf{T}^n E = E = \text{const} G_\Phi.$$

Hence, G_Φ is the only eigenmatrix (up to a constant multiple) of $\mathbf{T}$ corresponding to eigenvalue 1. □

3. Stability, orthonormality, and biorthonormality. In this section we will discuss the stability of refinable function vectors. We first give here a sufficient condition in terms of the eigenvalue of the transition operator $\mathbf{T}$ under which the function vector Φ is stable. Then, we will show that this condition is also necessary.

PROPOSITION 3.1. *Suppose that the basic conditions* (1.5) *hold for* $\mathbf{P}$ *and* $\Phi \subset L_2(\mathbb{R}^s)$. *If* 1 *is a simple eigenvalue of the transition operator* $\mathbf{T}$ *on* $\mathbb{H}$ *and the corresponding eigenmatrix nonsingular on* $\mathbb{T}^s$, *then the* $\mathbf{P}$*-refinable function vector* Φ *is stable.*

Proof. Since G_Φ is an eigenmatrix of $\mathbf{T}$ of the eigenvalue 1, the hypothesis of the theorem implies that the matrix $G_\Phi(\omega)$ is nonsingular on $\mathbb{T}^s$. Hence, the function vector Φ is stable. □

We note that if Φ is stable, the simplicity of the eigenvalue 1 of $\mathbf{T}$ implies that the corresponding eigenmatrix of the eigenvalue 1 of $\mathbf{T}$ is nonsingular on $\mathbb{T}^s$, since in this case G_Φ is the only eigenmatrix of $\mathbf{T}$. Therefore, to show that the condition in the above theorem is necessary, one only requires to show that if Φ is stable, then 1 is a simple eigenvalue of $\mathbf{T}$.

Define

$$V_1 := \{H \in \mathbb{H} : (\mathbf{i}_1^T H \mathbf{i}_1)(0) = 0\}.$$

Since for any $H \in \mathbb{H}$, $H = \sum_{B\in\mathbb{B}_{sp}} h_B B$, where the set $\mathbb{B}_{sp}$ is the basis defined in the previous section, a matrix $H \in V_1$ if and only if $\sum_{B\in\mathbb{B}_{sp}} h_B = 0$ by the structure of the element of $\mathbb{B}_{sp}$. Hence, the space V_1 has codimension 1. Since $(\mathbf{i}_1^T G_\Phi \mathbf{i}_1)(0) \neq 0$, $G_\Phi \notin V_1$. Since $\mathbf{P}$ satisfies the basic condition (1.5), for any $H \in V_1$,

$$(\mathbf{i}_1^T (\mathbf{T}H) \mathbf{i}_1)(0) = \sum_{\nu\in\mathbb{Z}^s/2\mathbb{Z}^s} \mathbf{i}_1^T \mathbf{P}(\pi\nu) H(\pi\nu) \mathbf{P}^*(\pi\nu) \mathbf{i}_1 = 0.$$

Hence, V_1 is a $\mathbf{T}$-invariant subspace of $\mathbb{H}$.

The proofs of the following two propositions (Propositions 3.2 and 3.3) were originally in our earlier drafts. Before completing the paper, we received a preprint of [15], which contains the same results (Proposition 3.3 and Theorems 5.1 and 5.2 in there) with similar proofs. Thus, we will only provide an outline of the proofs here.

PROPOSITION 3.2. *Let $H_1(\omega)$ and $H_2(\omega)$ be matrices so that each entry is a continuous function on $\mathbb{T}^s$. Then,*

$$\int_{\mathbb{T}^s} H_1(\omega)(\mathbf{T}^n H_2)(\omega)d\omega = \int_{\mathbb{R}^s} H_1(\omega)\Pi_n(\omega)H_2(2^{-n}w)\Pi_n^*(\omega)d\omega, \tag{3.1}$$

where

$$\Pi_n(\omega) := \chi_{2^n\mathbb{T}^s}(\omega)\prod_{j=1}^{n}\mathbf{P}(\omega/2^j);\ n = 1, 2, \ldots. \tag{3.2}$$

Here we define the transition operator as an operator on the space of the all $\Phi \times \Phi$ matrices whose entries are continuous functions on $\mathbb{T}^s$.

Proof. One can easily show that for any such H

$$\mathbf{T}^n H = \sum_{\alpha\in\mathbb{Z}^s} \Pi_n(\cdot + 2\pi\alpha)H(2^{-n}(\cdot + 2\pi\alpha))\Pi_n^*(\cdot + 2\pi\alpha),$$

by induction. Replacing H by H_2, multiplying by H_1, and integrating both sides of the above identity lead to the fact that for any H_1 and H_2, (3.1) holds. □

PROPOSITION 3.3. *Assume that the $\mathbf{P}$-refinable function vector Φ is stable and its mask $\mathbf{P}$ satisfies basic conditions* (1.5). *Then,*

(i) *for any $H_1 \in \mathbb{H}$ and $H_2 \in V_1$,*

$$\lim_{n\to\infty}\int_{\mathbb{R}^s} H_1(\omega)\Pi_n(\omega)H_2(2^{-n}\omega)\Pi_n^*(\omega)d\omega$$

$$= \int_{\mathbb{R}^s}\lim_{n\to\infty} H_1(\omega)\Pi_n(\omega)H_2(2^{-n}\omega)\Pi_n^*(\omega)d\omega = \mathbf{0};$$

(ii) *the transition operator $\mathbf{T}$ restricted to V_1 has spectral radius < 1.*

Proof. Since Φ is stable, $G_\Phi \geq cI$, with $c > 0$. This leads to the fact that the sequence $(\Pi_n\Pi_n^*)$ is uniformly integrable (details in the proof of Theorem 5.2 of [15]). Recall that the sequence

$$(\Pi_n(\omega)\Pi_n^*(\omega)), \quad n = 0, 1, \ldots,$$

is uniformly integrable if for an arbitrary $\varepsilon > 0$ there exist a finite measure set F and $\delta > 0$ so that

$$\int_{\mathbb{R}^s\setminus F} \Pi_n(\omega)\Pi_n^*(\omega)d\omega \leq \varepsilon$$

and

$$\int_D \Pi_n(\omega)\Pi_n^*(\omega)d\omega \leq \varepsilon$$

hold for all n for any measurable set D with the measure of $D \leq \delta$.

That the sequence $(\Pi_n(\omega)\Pi_n^*(\omega))_n$ is uniformly integrable implies that the sequence $(H_1(\omega)\Pi_n(\omega)H_2(2^{-n}\omega)\Pi_n^*(\omega))$ is uniformly integrable for any $H_1 \in \mathbb{H}$ and $H_2 \in V_1$. This implies that

$$\lim_{n\to\infty}\int_{\mathbb{R}^s} H_1(\omega)\Pi_n(\omega)H_2(2^{-n}\omega)\Pi_n^*(\omega)d\omega = \int_{\mathbb{R}^s}\lim_{n\to\infty} H_1(\omega)\Pi_n(\omega)H_2(2^{-n}\omega)\Pi_n^*(\omega)d\omega.$$

Since $(\mathbf{i}_1^T H_2\mathbf{i}_1)(0) = 0$ and since $\mathbf{P}^\infty = \begin{pmatrix}\widehat{\Phi} & \mathbf{0} & \cdots & \mathbf{0}\end{pmatrix}$,

$$\lim_{n\to\infty} H_1(\omega)\Pi_n(\omega)H_2(2^{-n}\omega)\Pi_n^*(\omega) = H_1(\omega)\mathbf{P}^\infty(\omega)H_2(0)\mathbf{P}^{*\infty}(\omega) = \mathbf{0}.$$

Hence, the first statement holds.

For the second statement, assume that λ is an eigenvalue of $\mathbf{T}$ restricted to V_1 and $H \in V_1$ is the corresponding nontrivial eigenmatrix. Then

$$\lambda^n\int_{\mathbb{T}^s} H^*(\omega)H(\omega)d\omega = \int_{\mathbb{R}^s} H^*(\omega)\Pi_n(\omega)H(2^{-n}\omega)\Pi_n^*(\omega)d\omega.$$

Hence, (i) implies that

$$\lim_{n\to\infty}\int_{\mathbb{R}^s} H^*(\omega)\Pi_n(\omega)H(2^{-n}\omega)\Pi_n^*(\omega)d\omega = \int_{\mathbb{R}^s}\lim_{n\to\infty} H^*(\omega)\Pi_n(\omega)H(2^{-n}\omega)\Pi_n^*(\omega)d\omega = \mathbf{0}.$$

This gives

$$\lim_{n\to\infty}\lambda^n\int_{\mathbb{T}^s} H^*(\omega)H(\omega)d\omega = 0.$$

Therefore $|\lambda| < 1$ by the fact

$$\int_{\mathbb{T}^s} H^*(\omega)H(\omega)d\omega \neq 0. \qquad \square$$

From the two propositions above, we obtain the following result.

LEMMA 3.4. *Assume that* $\mathbf{P}$ *satisfies basic conditions* (1.5) *and the corresponding refinable function vector* Φ *is stable; then the transition operator* $\mathbf{T}$ *satisfies Condition* E. *In particular,* 1 *is a simple eigenvalue of the transition operator* $\mathbf{T}$.

Proof. Let $\mathbb{B}_0$ be a basis of V_1. Since G_Φ is not in V_1 and V_1 has codimension 1, $G_\Phi \cup \mathbb{B}_0$ is a basis of $\mathbb{H}$. Therefore, an arbitrary $H \in \mathbb{H}$ can be written uniquely as

$$H = aG_\Phi + H_0, \quad H_0 \in V_1.$$

Let H be the eigenmatrix of the eigenvalue λ of $\mathbf{T}$,

$$\lambda aG_\Phi + \lambda H_0 = \mathbf{T}H = a\mathbf{T}G_\Phi + \mathbf{T}H_0 = aG_\Phi + \mathbf{T}H_0.$$

If $\lambda \neq 1$, then $a = 0$. Thus, $H = H_0 \in V_1$ is an eigenmatrix of λ. This implies $|\lambda| < 1$ by Proposition 3.3. If $\lambda = 1$, then $H_0 \in V_1$ is also the eigenmatrix of $\mathbf{T}$ corresponding to the eigenvalue 1; thus $H_0 = 0$ again by Proposition 3.3. Hence, $\rho(\mathbf{T}) \leq 1$ and 1 is the unique eigenvalue on the unit circle. Further, G_Φ is the only eigenmatrix of eigenvalue 1 up to a constant multiple.

Finally we need to show that 1 is a simple eigenvalue of $\mathbf{T}$. If not, it must be a degenerate eigenvalue with only one eigenmatrix. In this case, there exists a matrix $H \in \mathbb{H}$ such that $\mathbf{T}H = G_\Phi + H$. Let $H_1 = cG_\Phi + H$ so that $H_1 \in V_1$. Then

$$\int_{\mathbb{T}^s}(\mathbf{T}^n H_1)(\omega)d\omega = \int_{\mathbb{R}^s}\Pi_n(\omega)H_1(2^{-n}\omega)\Pi_n^*(\omega)d\omega = \int_{\mathbb{T}^s}((c+n)G_\Phi(\omega) + H(\omega))d\omega.$$

The left-hand side tends to 0 by the stability of the vector function Φ and (i) of Proposition 3.3, while the right-hand side tends to ∞, which is a contradiction. □

An immediate consequence of this lemma is the following corollary.

COROLLARY 3.5. *Assume that* $\mathbf{P}$ *satisfies the conditions* (1.5). *If the refinable vector function* Φ *is stable, then the cascade algorithm converges.*

The next theorem, the main result of this section, follows directly from Proposition 3.1 and Lemma 3.4.

THEOREM 3.6. *Assume that* $\mathbf{P}$ *satisfies the basic conditions* (1.5). *The* $\mathbf{P}$*-refinable function vector* Φ *is stable if and only if the corresponding transition operator* $\mathbf{T}$ *satisfies Condition* E *and the eigenmatrix of eigenvalue* 1 *is nonsingular on* $\mathbb{T}^s$.

Proof. If the transition operator satisfies Condition E, then the cascade algorithm converges and $\Phi \subset L_2(\mathbb{R}^s)$. Therefore, Φ is stable by Proposition 3.1. If Φ is stable, then Lemma 3.4 implies that the transition operator satisfies Condition E. G_Φ is the eigenmatrix of a simple eigenvalue 1 of $\mathbf{T}$ which is nonsingular on $\mathbb{T}^s$. □

REMARK 3.7. *If the transition operator* $\mathbf{T}$ *satisfies Condition* E *and if eigenvalue* 1 *has an eigenmatrix which is nonsingular on* $\mathbb{T}^s$, *then the compactly supported* $\mathbf{P}$*-refinable functions* $\Phi \subset L_2(\mathbb{R}^s)$ *by the fact that the corresponding cascade algorithm converges. Hence the sequence* $(S^k(\Phi))$ *forms a multiresolution of* $L_2(\mathbb{R}^s)$ *with the functions* Φ *and their shifts forming a Riesz basis of* $S(\Phi)$ *by Result* 1.1 *and Theorem* 3.6.

If $\mathbf{P}$ is CQF, the identity matrix I is an eigenmatrix of the transition operator $\mathbf{T}$ corresponding to eigenvalue 1. A consequence of Theorem 3.6 is as follows.

THEOREM 3.8. *Suppose that* $\mathbf{P}$ *is a CQF matrix mask which satisfies the basic conditions* (1.5)*; then the following statements are equivalent:*

(i) *the refinable function vector* Φ *is orthonormal,*

(ii) *the transition operator* $\mathbf{T}$ *satisfies Condition* E*,*

(iii) *the refinable function vector* Φ *is stable, and*

(iv) *the corresponding cascade algorithm converges.*

Remark 3.7 gives the following corollary.

COROLLARY 3.9. *Suppose that* $\mathbf{P}$ *is a CQF matrix mask which satisfies the basic conditions* (1.5). *If the corresponding transition operator* $\mathbf{T}$ *satisfies Condition* E*, then the sequence of spaces* $(S^k(\Phi))_k$ *forms a multiresolution of* $L_2(\mathbb{R}^s)$ *with the functions* Φ *and their shifts forming an orthonormal basis of* $S(\Phi)$.

In the rest of this section, we discuss the biorthonormality of two refinable function vectors Φ and Ψ. Let $\mathbf{P}_\Phi$ and $\mathbf{P}_\Psi$ be the refinement masks of functions Φ and Ψ satisfying the basic conditions (1.5) and the condition

$$\sum_{\nu \in \mathbb{Z}^s/2\mathbb{Z}^s} \mathbf{P}_\Phi(\cdot/2 + \pi\nu)\mathbf{P}_\Psi^*(\cdot/2 + \pi\nu) = I. \tag{3.3}$$

We say that Φ and Ψ are *biorthonormal* if both function vectors Φ and Ψ are stable and

$$\overline{J_\Phi^*}(\omega)\overline{J_\Psi}(\omega) = I, \quad \in \mathbb{T}^s.$$

Here again we are interested in characterizing the biorthonormality in terms of the matrix masks $\mathbf{P}_\Phi$ and $\mathbf{P}_\Psi$. The following result was shown in [15, Theorem 5.3], which is the main result of [15].

RESULT 3.10. *Let* $\mathbf{P}_\Phi$ *and* $\mathbf{P}_\Psi$ *be the refinement masks of refinable function vectors* Φ *and* Ψ *satisfying the basic conditions* (1.5) *and* (3.3). *Assume that* $G_\Phi(0) \geq \text{const}I$

and $G_\Psi(0) \geq \text{const} I$. *Then* Φ *and* Ψ *are biorthonormal if both* $\mathbf{T}_\Phi$ *and* $\mathbf{T}_\Psi$ *have the spectrum radius* < 1 *on* V_1.

We note that if the Φ and Ψ are stable, then by Proposition 3.3 (ii) the conditions in the above result are satisfied.

THEOREM 3.11. *Let* $\mathbf{P}_\Phi$ *and* $\mathbf{P}_\Psi$ *be the refinement matrix masks of* Φ *and* Ψ *which satisfy the basic conditions* (1.5) *and condition* (3.3). *Then the following statements are equivalent:*

(i) *the refinable function vectors* Φ *and* Ψ *are biorthonormal;*

(ii) *both* Φ *and* Ψ *are stable; and*

(iii) *the transition operators* $\mathbf{T}_\Phi$ *and* $\mathbf{T}_\Psi$ *satisfy Condition* E, *and the corresponding eigenmatrices of eigenvalue* 1 *of* $\mathbf{T}_\Phi$ *and* $\mathbf{T}_\Psi$ *are nonsingular on* $\mathbb{T}^s$.

Proof. The equivalence of (ii) and (iii) follows from Theorem 3.6. Since if Φ and Ψ are stable, the conditions in Result 3.10 are satisfied; (ii) implies (i) by that result. Finally, (i) implies (ii) by the definition of the biorthonormality of Φ and Ψ. □

4. Regularity of refinable function vectors. In this section, we establish some criteria for the regularity of refinable function vectors.

We say that the mask $\mathbf{P}$ satisfying the basic conditions (1.5) has *vanishing moment order* r if conditions

$$D^\beta(A^*(2\omega)\mathbf{P}(\omega))_{|\omega=\pi\nu} = i^{-|\beta|}(D^\beta A^*)(0)\delta_\nu, \quad \nu \in \mathbb{Z}^s/2\mathbb{Z}^s, \quad |\beta| \leq r-1, \tag{4.1}$$

hold for some

$$A = \sum_{|\beta|\leq r-1} \mathbf{a}_\beta^T \exp(-i\beta\cdot),$$

where $\mathbf{a}_\beta \in \mathbb{R}^{\#\Phi}$.

As we did in [21] for the case $\#\Phi = 1$, we will connect this vanishing moment order to the regularity of Φ.

We say that $\Phi := (\varphi^l)^T \in C^\gamma$ if each component $\varphi^l \in C^\gamma$. Recall that a function $\varphi \in C^\gamma$ for $n \leq \gamma < n+1$ provided that $\varphi \in C^n$ and

$$|D^\beta\varphi(x+t) - D^\beta\varphi(x)| \leq \text{const}|t|^{\gamma-n} \text{ for all } |\beta| = n \text{ and } |t| \leq 1$$

for some constant independent of x. This number is related to

$$\kappa_2 := \sup\left\{\kappa : \int_{\mathbb{R}^s} (1+|w|^2)^\kappa |\widehat{\varphi}(\omega)|^2 d\omega < \infty\right\}$$

by the inequality $\gamma \geq \kappa_2 - s/2$.

Define

$$V_r := \{H \in \mathbb{H} : (D^\beta(A^*(\omega)H(\omega))_{|\omega=0})^T = D^\beta(H(\omega)A(\omega))_{|\omega=0}, = \mathbf{0}, \quad |\beta| \leq r-1\}.$$

In the case that $r-1 > N$, we replace $\mathbb{H}$ by $\mathbb{H}_{r-1}$ in the above definition of V_r.

Since

$$D^\beta(A^*(2\omega)\mathbf{P}(\omega))_{|_{\omega=\pi\nu}} = i^{-|\beta|}(D^\beta A^*)(0)\delta_\nu, \quad \nu \in \mathbb{Z}^s/2\mathbb{Z}^s,\ |\beta| \le r-1, \tag{4.2}$$

we have that

$$(D^\beta(A^*(\omega)\mathbf{T}H(\omega))_{|_{\omega=0}})^T = D^\beta(\mathbf{T}H(\omega)A(\omega))_{|_{\omega=0}} = \mathbf{0}, \text{ for all } H \in V_r, |\beta| \le r-1.$$

Hence, the space V_r is an invariant subspace of the transition operator $\mathbf{T}$.

In the case $r = 1$, the space V_1 defined here is an invariant subspace of V_1 defined in section 3, since $A^*(0)$ is the left eigenvector of $\mathbf{P}$.

For each $H(\omega) := (h_{i,j}(\omega))_{1\le i,j\le \#\Phi} \in V_r$, define

$$\|H\|_F := \sum_{1\le i,j\le \#\Phi} \|h_{i,j}(\cdot)\|_\infty.$$

If H is a constant matrix, this norm is the sum of the modulus of all entries.

Then the operator norm $\|\mathbf{T}_{|_{V_r}}\| := \sup_{H\in V_r\setminus\{0\}} \frac{\|\mathbf{T}H\|_F}{\|H\|_F}$ on V_r satisfies

$$\lim_{n\to\infty} \|\mathbf{T}^n_{|_{V_r}}\|^{1/n} = \rho,$$

where ρ is the spectral radius of $\mathbf{T}_{|_{V_r}}$. Hence, there exists $N_{\mathbf{T}}$ such that for any $H \in V_r$ and for all $n > N_{\mathbf{T}}$,

$$\|\mathbf{T}^n H\|_F \le \|\mathbf{T}^n\|\|H\|_F \le \text{const}(\rho+\varepsilon)^n\|H\|_F, \tag{4.3}$$

where ε is arbitrarily small.

The proof of the following proposition is carried out by modifying the proofs of Proposition 3.6 of [21] and Theorem 5.2 of [15].

PROPOSITION 4.1. *Suppose* $\mathbf{P}$ *satisfies the basic conditions* 1.5 *and conditions* (4.1). *Then for the* $\mathbf{P}$*-refinable function* $\Phi := (\varphi^l)^T$, *there exists a constant* C *such that*

$$\int_{\mathbb{F}_n} \left|\widehat{\varphi}^l(\omega)\right|^2 d\omega \le C(\rho+\varepsilon)^{n+1},$$

where $\mathbb{F}_n := 2^n\mathbb{T}^s\backslash 2^{n-1}\mathbb{T}^s$ *for all* $n > N_{\mathbf{T}}$ *and* ε *is arbitrarily small.*

Proof. It follows from (4.3) for any $H \in V_r$,

$$\left\|\int_{\mathbb{F}_n} \mathbf{T}^n H(\omega)d\omega\right\|_F \le \text{const}(\rho+\varepsilon)^n\|H\|_F.$$

Since none of the choices of the constants in this proof depend on n, for simplicity we denote all constants by "const" even though the value of this may change with each occurrence.

Let $H(\omega) := (\sum_{\ell=1}^s (1-\cos w(\ell))^{r-1})I$. Since

$$(D^\beta(A^*(\omega)H(\omega))_{|_{\omega=0}})^T = D^\beta(H(\omega)A(\omega))_{|_{\omega=0}} = \mathbf{0}, \quad |\beta| \le r-1,$$

we have $H \in V_r$ and $H \ge I$ for all $\omega \in \mathbb{T}^s\backslash(1/2\mathbb{T}^s)$. Since $\|\mathbf{P}(\omega)-\mathbf{P}(0)\| \le \text{const}\|\omega\|$, the function $\widehat{\Phi}$ is bounded on $\mathbb{T}^s$.

We also note that

$$\widehat{\Phi}(\omega) = \Pi_n(\omega)\widehat{\Phi}(2^{-(n+1)}\omega).$$

Hence we have

$$\begin{aligned}\int_{\mathbb{F}_n} |\widehat{\varphi}^l(\omega)|^2 d\omega &= \int_{\mathbb{F}_n} \mathbf{i}_l^T \widehat{\Phi}(\omega)\widehat{\Phi}^*(\omega)\mathbf{i}_l d\omega \\ &= \int_{\mathbb{F}_n} \mathbf{i}_l^T \Pi_n(\omega)\widehat{\Phi}(2^{-(n+1)}\omega)\widehat{\Phi}^*(2^{-(n+1)}\omega)\Pi_n^*(\omega)\mathbf{i}_l d\omega \\ &\le \text{const} \int_{\mathbb{F}_n} \mathbf{i}_l^T \Pi_n(\omega) H(2^{-(n+1)}\omega)\Pi_n^*(\omega)\mathbf{i}_l d\omega \\ &\le \text{const} \int_{2^n\mathbb{T}^s} \mathbf{i}_l^T \Pi_n(\omega) H(2^{-(n+1)}\omega)\Pi_n^*(\omega)\mathbf{i}_l d\omega \\ &\le \text{const} \| \int_{2^n\mathbb{T}^s} \Pi_n(\omega) H(2^{-(n+1)}\omega)\Pi_n^*(\omega) d\omega \|_F \\ &= \text{const} \| \int_{\mathbb{T}^s} (\mathbf{T}^{(n+1)} H)(\omega) d\omega \|_F \\ &\le \text{const}(\rho+\varepsilon)^{n+1},\end{aligned}$$

where $\mathbf{i}_l$ is the $\Phi \times 1$ column vector whose lth entry is 1 and all others are 0. ∎

This proposition together with the usual Littlewood–Paley technique leads to the following estimate of the regularity of the refinable function vector Φ.

THEOREM 4.2. *Suppose* $\mathbf{P}$ *satisfies the basic conditions* 1.5 *and the conditions* (4.1)*, and let* ρ *be the spectral radius of* $\mathbf{T}_{|V_r}$*. Then the function* $\Phi = (\varphi^l)^T$ *is in* $C^{\gamma-\varepsilon}$ *for any* $\varepsilon > 0$ *and* $\gamma = -\log\rho/(2\log 2) - s/2$.

Proof. Since when $n > N_{\mathbf{T}}$,

$$\int_{\mathbb{F}_n} |\widehat{\varphi}^l(\omega)|^2 d\omega \le \text{const}\rho^{n+1},$$

and since the function $\widehat{\varphi}^l$ is bounded on $2^{N_T}\mathbb{T}^s$,

$$\int_{\mathbb{R}^s} (1+|w|^2)^\kappa |\widehat{\varphi}^l(\omega)|^2 d\omega \le \text{const}\left(1 + \sum_{n=1}^{\infty} 2^{2n\kappa}\rho^{n+1}\right).$$

Hence $\varphi^l \in C^{\gamma-\varepsilon}$ where $\gamma = -\log\rho/(2\log 2) - s/2$. That is, $\Phi \in C^{\gamma-\varepsilon}$. ∎

ORTHOGONALITY OF SIEVED RANDOM WALK POLYNOMIALS FROM A NONSIEVED ANALOGUE*

BLAISE DESESA†

Abstract. The continuous component of the orthogonality relation for sieved random walk polynomials is derived in general from the orthogonality relation of another nonsieved random walk sequence called the companion polynomials. Conditions are stated on the three-term recurrence relation between the two polynomial sequences for a linear difference equation to hold. Results from Ismail are used to find the Stieltjes transform of the orthogonality measure of the sieved polynomials. The linear difference equation allows for the Stieltjes transform to be inverted. The theory is applied to the sieved associated ultraspherical polynomials, and in general to random walk polynomials with linear birth and death rates of $\beta_n = c\,n + a$ and $\delta_n = c\,n + b$, respectively.

Key words. associated ultraspherical polynomials, birth and death process, companion polynomials, orthogonal polynomials, random walk polynomials, sieved polynomials, Stieltjes transform

1. Introduction.

In this paper we will study sieved orthogonal polynomials and derive their orthogonality from a nonsieved random walk analogue. Random walk polynomials arise from a special stationary Markov process known as a birth and death process (BDP). Here the state space $\{X(t) : t \geq 0\}$ is the set of nonnegative integers. The transition probabilities $P_{m,n}(t)$ are the probabilities that the system goes from state m to state n in time t. The transition probabilities satisfy

$$\begin{aligned} &P_{n,n+1}(t) = \beta_n t + o(t), \\ &P_{n,n-1}(t) = \delta_n t + o(t), \\ &P_{n,n}(t) = 1 - \delta_n t - \beta_n t + o(t), \\ &o(t) \text{ otherwise, as } t \to 0^+. \end{aligned} \tag{1}$$

The β_n and δ_n are called the birth and death rates of the process at state n, and they satisfy the requirements $\beta_n > 0$, $\delta_{n+1} > 0$ for $n \geq 0$, and $\delta_0 > 0$.

The random walk polynomials of the BDP are defined as

$$\begin{aligned} &R_{-1}(x) = 0, \qquad R_0(x) = 1, \\ &xR_n(x) = B_n R_{n+1}(x) + D_n R_{n-1}(x), \quad n \geq 0, \end{aligned} \tag{2}$$

where

$$B_n = \frac{\beta_n}{\beta_n + \delta_n}, \qquad D_n = \frac{\delta_n}{\beta_n + \delta_n}. \tag{3}$$

Another set of orthogonal polynomials associated with a BDP is the birth and death polynomials $\{Q_n(x)\}$, generated by

$$\begin{aligned} &Q_0(x) = 1, \qquad Q_1(x) = \frac{\lambda_0 + \mu_0 - x}{\lambda_0}, \\ &-xQ_n(x) = \lambda_n Q_{n+1}(x) + \mu_n Q_{n-1}(x) - (\lambda_n + \mu_n)Q_n(x), \quad n > 0. \end{aligned}$$

*Received by the editors January 29, 1996; accepted for publication (in revised form) September 30, 1996.

†Mathematics Department, Allentown College of Saint Francis de Sales, 2755 Station Avenue, Center Valley, PA 18034-9568.

Most of the BDP and their random walk polynomials that have been studied have birth and death rates as linear functions of n. If $\beta_n = an + b$ and $\delta_n = cn + d$, then interpreting the states of the process as populations, "an" and "cn" represent the growth and decline of the population due to its current size, while "b" and "d" represent external forces.

Given a random walk sequence of polynomials, we may define the sieved random walk polynomials. Charris and Ismail in [6, 7] outlined this process and defined the sieved random walk polynomials of the first and second kinds in general. An original random walk polynomial sequence $\{R_n(x)\}$ is given, defined by the recursion (2). Next, another random walk sequence $\{S_n(x)\}$, called the dual sequence, is defined by the recursion

$$\begin{aligned} &S_{-1}(x) = 0, \qquad S_0(x) = 1, \\ &xS_n(x) = D_nS_{n+1}(x) + B_nS_{n-1}(x), \quad n \geq 0. \end{aligned} \tag{4}$$

The sieved random walk polynomials of the first kind, written $r_n(x;k)$, are next defined by

$$\begin{aligned} &r_0(x;k) = 1, \qquad r_1(x;k) = x, \\ &xr_n(x;k) = d_{n-1}r_{n+1}(x;k) + b_{n-1}r_{n-1}(x;k), \quad n > 0, \end{aligned} \tag{5}$$

where

$$\begin{aligned} &b_n = d_n = \frac{1}{2} \text{ if } n+1 \neq mk, \\ &b_{mk-1} = B_{m-1}, d_{mk-1} = D_{m-1}, m = 1, 2, \ldots. \end{aligned} \tag{6}$$

The sieved random walks of the second kind, $s_n(x;k)$, are defined similarly by

$$\begin{aligned} &s_0(x;k) = 1, \qquad s_1(x;k) = 2x, \\ &xs_n(x;k) = b_ns_{n+1}(x;k) + d_ns_{n-1}(x;k), \quad n > 0. \end{aligned} \tag{7}$$

The first sieved polynomials studied were the sieved analogues of the ultraspherical polynomials $C_n^{\lambda}(x)$ by Al-Salam, Allaway, and Askey [1, 2]. These were studied as special limiting cases of the q-continuous ultraspherical polynomials $C_n(x;\beta|q)$.

Explicit representations of the sieved polynomials of the first and second kind were established by Charris and Ismail [6] in terms of the random walk polynomials $R_n(x)$ and the Tchebyshev polynomials of the first and second kinds, $T_n(x)$ and $U_n(x)$, respectively. These formulas allowed Charris and Ismail to find the Stieltjes transform of the measure of orthogonality of the sieved polynomials of the first kind. The absolutely continuous component of the measure of orthogonality of the sieved polynomials of the first and second kind have been related to each other in Ismail [11].

2. Mathematical preliminaries. Given a distribution function $\mu(x)$, there is a sequence of polynomials $\{P_n(x)\}$, where $P_n(x)$ is of exact degree n, such that

$$\int_{-\infty}^{\infty} P_n(x)P_m(x)d\mu(x) = \lambda_n\delta_{nm}, \quad \lambda_n > 0 \tag{8}$$

(see Chihara [8, p. 14]). The sequence $\{P_n(x)\}$ is called an orthogonal polynomial sequence (OPS).

Given the distribution function $\mu(x)$, then the OPS $\{P_n(x)\}$ always satisfies a three-term recurrence relation

$$P_{n+1}(x) = (A_n x + B_n)P_n(x) - C_n P_{n-1}(x), \quad n = 1, 2, \ldots, \tag{9}$$

where the coefficients A_n, B_n, C_n are real and such that $A_{n-1}A_nC_n > 0$, $n = 1, 2, \ldots$, which is the positivity condition to ensure that the polynomials are orthogonal with respect to a positive measure [8, p. 19].

From the orthogonality condition (8) and the three-term recurrence (9), we obtain

$$\lambda_n = \frac{A_0}{A_n} \prod_{k=1}^{n} C_k. \tag{10}$$

The vth associated polynomials of $P_n(x)$, written $P_n^{(v)}(x)$, are defined by the recursion

$$\begin{aligned} &P_{-1}^{(v)}(x) = 0, \qquad P_0^{(v)}(x) = 1, \\ &P_{n+1}^{(v)}(x) = (A_{n+v}x + B_{n+v})P_n^{(v)}(x) - C_{n+v}P_{n-1}^{(v)}(x). \end{aligned} \tag{11}$$

These polynomials are orthogonal by Favard's theorem [8]. The numerator polynomials of $P_n(x)$ are defined as

$$P_n^*(x) = A_0 P_{n-1}^{(1)}(x). \tag{12}$$

The Stieltjes transform of a distribution function $\mu(t)$ is defined as the function

$$\chi(z) = \int_{-\infty}^{\infty} \frac{d\mu(t)}{z - t} \tag{13}$$

for wherever the integral is convergent. Markov's theorem asserts that when the support of $\mu(x)$ is compact, with $[\xi_1, \eta_1]$ being the smallest closed interval containing the support of $\mu(x)$, then $\chi(z)$ is an analytic function for $z \notin [\xi_1, \eta_1]$, and

$$\chi(z) = \lim_{n\to\infty} \frac{P_n^*(z)}{P_n(z)} = \lim_{n\to\infty} \frac{A_0 P_{n-1}^{(1)}(z)}{P_n(z)}. \tag{14}$$

(See Askey and Ismail [3] and Wall [19].) For random walk polynomials, the interval $[\xi_1, \eta_1]$ is always $[-1, 1]$ (see Karlin and McGregor [13, 14]).

Once the Stieltjes transform of a distribution function is known from Markov's theorem, we will want to recover $d\mu_1(x)$, the absolutely continuous component of the measure induced by the distribution function $\mu(x)$. To this end we employ a corollary to the Stieltjes inversion formula. If $\mu(x)$ is of bounded variation on $(-\infty, \infty)$, then

$$d\mu_1(t) = \frac{1}{2\pi i} \lim_{\varepsilon\to 0^+} [\chi(t - i\varepsilon) - \chi(t + i\varepsilon)], \quad t \in \text{supp } (\mu(t)). \tag{15}$$

(See Widder [20].)

Another method of finding the measure $d\mu(x)$ for an OPS $\{P_n(x)\}$ is given by the theorem of Nevai: let $P_n(x)$ be defined by the recursion (9), and let $\tilde{P}_n(x) = P_n(x)/\sqrt{\lambda_n}$ be the corresponding orthonormal series. If in (9) we have

$$\sum_{n=0}^{\infty} \left\{ |B_n A_n^{-1}| + \left| C_{n+1}^{1/2} A_n^{-1/2} A_{n+1}^{-1/2} - \frac{\gamma}{2} \right| \right\} < \infty \tag{16}$$

for some γ, then

$$d\mu(x) = d\mu_1(x) + d\mu_2(x), \tag{17}$$

where $d\mu_1(x)$ is continuous and a positive measure in $(-\gamma, \gamma)$, $\text{supp}(d\mu) = [-\gamma, \gamma]$ is the smallest closed interval containing the support of $\mu(x)$, and $\mu_2(x)$ is a step function that is constant in $(-\gamma, \gamma)$. Further,

$$\limsup_{n\to\infty} \left\{ d\mu_1(x)\sqrt{\gamma^2 - x^2}\ \tilde{P}_n^2(x) \right\} = \frac{2}{\pi} \tag{18}$$

holds almost everywhere (a.e.) in $\text{supp}(d\mu)$. (See Nevai [15, Corollary 36, p. 141 and Theorem 40, p. 143].)

A theorem useful for finding the isolated jumps in the distribution function $\mu(x)$ is due to Shohat and Tamarkin [18, Corollary 26, pp. 45–46]. Let $\{\tilde{P}_n(x)\}$ be the orthonormal polynomials with respect to the distribution function $\mu(x)$. Let

$$[\rho(x)]^{-1} = \sum_{n=0}^{\infty} \tilde{P}_n^2(x). \tag{19}$$

When the corresponding Hamburger moment problem is determined, then $\rho(x) = 0$ at all points of continuity of $\mu(x)$ and equals the jump of $\mu(x)$ at a point of discontinuity.

Let $\sigma_1(x)$ be the distribution function for the polynomials $r_n(x;k)$ and $\chi_1(x;k) = \int_{-1}^{1} \frac{d\sigma_1(t)}{x-t}$ be the Stieltjes transform for $r_n(x;k)$. Charris and Ismail [6] proved the result

$$\chi_1(x;k) = \lim_{m\to\infty} \frac{a_{mk} U_{k-1}(x) S_{m-1}(T_k(x))}{R_m(T_k(x)) - R_{m-2}(T_k(x))}, \quad x \notin [-1, 1], \tag{20}$$

where

$$a_{mk} = \{D_0 D_1 \cdots D_{m-2}\}/\{B_0 B_1 \cdots B_{m-1}\}, \quad m > 1. \tag{21}$$

Further, if $\sigma_2(x)$ is the distribution function for $s_n(x;k)$, then

$$d\sigma_2(x) = c(1 - x^2) d\sigma_1(x), \tag{22}$$

c is a constant. (See Ismail [11].)

In the first part of this paper conditions will be developed that allow for the difference $R_n(x) - R_{n-2}(x)$ that occur in the denominator of (20) to be expressed as a linear combination of another random walk polynomial $P_n(x)$, called the companion polynomials to $R_n(x)$. It will then be shown that if the orthogonality relationship for the companion polynomials is known, then by using (20), it will be possible to invert the Stieltjes transform for the sieved polynomials of the first kind of $R_n(x)$ and obtain its absolutely continuous component of the measure of orthogonality.

In the second section, this general theory will be applied to the random walk polynomials $R_n(x; a, b, c)$ having linear birth and death rates given by $\beta_n = cn + a$, $\delta_n = cn + b$. This will lead to a mixed recursion relation with interesting special cases. The orthogonality for the sieved polynomials of the first kind of $R_n(x; a, b, c)$ will be discussed after this.

We will use the usual notation for the Gaussian hypergeometric series, writing

$${}_2F_1(a, b; c; z) = {}_2F_1\left(\begin{matrix} a, b \\ c \end{matrix} ; z \right) = \sum_{k=0}^{\infty} \frac{(a)_k (b)_k}{(c)_k} \frac{z^k}{k!}, \tag{23}$$

where

$$(a)_k = a(a+1)\cdots(a+k-1) = \Gamma(a+k)/\Gamma(a), \quad k = 1, 2, \ldots, \tag{24}$$
$$(a)_0 = 1.$$

3. A linear difference relation for sieved polynomials. In this section we seek a linear representation of the difference $R_n(x) - R_{n-2}(x)$ of a random walk polynomial in terms of another random walk polynomial. To this end we formulate the problem as follows. Let $R_n(x)$ and its dual $S_n(x)$ be given as defined by (2) and (4). These are the random walk polynomials whose sieved analogues we are trying to determine an orthogonality relationship for. We want to know under what conditions are there constants θ_n, ϕ_n, and ω_n, and another random walk sequence $\{P_n(x)\}$, such that

$$S_n(x) = \theta_n P_n^{(1)}(x), \quad n \geq 0, \tag{25}$$

$$R_n(x) - R_{n-2}(x) = \phi_n P_n(x) + x\omega_n P_{n-1}^{(1)}(x), \quad n \geq 1. \tag{26}$$

The polynomials $P_n(x)$ will be called the companion polynomials to $R_n(x)$, and $P_n^{(1)}(x)$ are the associated polynomials $P_n^{(v)}(x)$ with parameter $v = 1$. The companion polynomials are defined recursively by

$$P_{-1}(x) = 0, \qquad P_0(x) = 1, \tag{27}$$
$$xP_n(x) = \overline{B}_n P_{n+1}(x) + \overline{D}_n P_{n-1}(x), \quad n \geq 0,$$
$$\overline{B}_n + \overline{D}_n = 1, \quad n \geq 1.$$

The Stieltjes transform $\chi_P(x)$ for $P_n(x)$ will be assumed known, as well as the absolutely continuous component of the measure of orthogonality, $d\mu_P(x)$.

We state the following theorem.

THEOREM 1. *If*

$$B_n(1 - B_{n-1}) = \overline{B}_n(1 - \overline{B}_{n+1}), \quad n \geq 1, \tag{28}$$

then (25) *and* (26) *hold, with the constants* θ_n, ϕ_n, *and* ω_n *given by*

$$\theta_0 = 1, \qquad \theta_n = \frac{\overline{B}_1\overline{B}_2\cdots\overline{B}_n}{D_0 D_1 \cdots D_{n-1}}, \quad n \geq 1,$$
$$\phi_1 = \frac{1}{\overline{D}_1}, \qquad \phi_n = \frac{\overline{B}_1\overline{B}_2\cdots\overline{B}_{n-1}}{\overline{D}_1 B_1 B_2 \cdots B_{n-1}}, \quad n \geq 2, \tag{29}$$
$$\omega_n = \overline{D}_1\left(\frac{1}{B_0} - \frac{1}{\overline{B}_1\overline{D}_1}\right)\phi_n, \quad n \geq 1.$$

Proof. We shall proceed by induction on n. First, note (28) is equivalent to $\overline{B}_n\overline{D}_{n+1} = B_n D_{n-1}$, $n \geq 1$. The recurrence relation for $P_n^{(1)}(x)$ is

$$P_{-1}^{(1)}(x) = 0, P_0^{(1)}(x) = 1,$$
$$xP_n^{(1)}(x) = \overline{B}_{n+1}P_{n+1}^{(1)}(x) + \overline{D}_{n+1}P_{n-1}^{(1)}(x), \quad n \geq 0. \tag{30}$$

Thus $P_1^{(1)}(x) = \frac{1}{B_1}x$. Let $Q_n(x) = \theta_n P_n^{(1)}(x)$, $n \geq 0$, $Q_{-1}(x) = 0$. It is clear that $Q_n(x) = S_n(x)$ for $n = 0, 1$. Multiplying (30) throughout by θ_n, we obtain

$$xQ_n(x) = D_nQ_{n+1}(x) + \frac{\overline{D}_{n+1}\overline{B}_n}{D_{n-1}}Q_{n-1}(x) = D_nQ_{n+1}(x) + B_nQ_{n-1}(x), \quad n \geq 1.$$

Thus, $Q_n(x)$ has the same recursion and initial conditions as the dual polynomials $S_n(x)$ do. This establishes (25).

When $n = 1$, (26) becomes $R_1(x) = \phi_1 P_1(x) + x\omega_1$, which is easily verified as true. Likewise, using the recursion for $R_2(x)$, $P_2(x)$, and the definitions for ϕ_2 and ω_2, along with the fact that $B_1 + D_1 = 1$, it is routine to verify that (26) is true for $n = 2$.

Now assume (26) is true for $n \geq 2$ in general. Multiply both sides of (26) by x, then use the recursion relations for $R_n(x)$, $P_n(x)$, and $P_n^{(1)}(x)$. This yields

$$\begin{aligned} &B_nR_{n+1}(x) + (D_n - B_{n-2})R_{n-1}(x) - D_{n-2}R_{n-3}(x) \\ &= \phi_n[\overline{B}_nP_{n+1}(x) + \overline{D}_nP_{n-1}(x)] + x\omega_n[\overline{B}_nP_n^{(1)}(x) + \overline{D}_nP_{n-2}^{(1)}(x)]. \end{aligned} \tag{31}$$

Since $B_n + D_n = 1$ for $n \geq 0$, then $D_n - B_{n-2} = D_{n-2} - B_n$ for $n \geq 2$. Thus the left side of (31) becomes $B_n[R_{n+1}(x) - R_{n-1}(x)] + D_{n-2}[R_{n-1}(x) - R_{n-3}(x)]$. Applying the induction hypothesis to $R_{n-1}(x) - R_{n-3}(x)$ with $n \to n - 1$ and simplifying, we obtain

$$\begin{aligned} B_n[R_{n+1}(x) - R_{n-1}(x)] &= \phi_n\overline{B}_nP_{n+1}(x) + (\phi_n\overline{D}_n - \phi_{n-1}D_{n-2})P_{n-1}(x) \\ &+ x[\omega_n\overline{B}_nP_n^{(1)}(x) + (\omega_n\overline{D}_n - \omega_{n-1}D_{n-2})P_{n-2}^{(1)}(x)]. \end{aligned} \tag{32}$$

To simplify the above, first note that $\phi_{n+1} = \frac{\overline{B}_n}{B_n}\phi_n$, $\omega_{n+1} = \frac{\overline{B}_n}{B_n}\omega_n$, $n \geq 1$. Therefore $\phi_n\overline{D}_n = \frac{\overline{B}_{n-1}\overline{D}_n}{B_{n-1}}\phi_{n-1}$, $n \geq 2$. But $\overline{D}_n = \frac{B_{n-1}D_{n-2}}{\overline{B}_{n-1}}$, $n \geq 2$, so $\phi_n\overline{D}_n - \phi_{n-1}D_{n-2} = 0$, $n \geq 2$. Similarly, $\omega_n\overline{D}_n - \omega_{n-1}D_{n-2} = 0$, $n \geq 2$. Therefore, (32) simplifies to

$$R_{n+1}(x) - R_{n-1}(x) = \phi_{n+1}P_{n+1}(x) + x\omega_{n+1}P_n^{(1)}(x).$$

This is (26) with $n \to n + 1$, so the theorem is proved by induction. □

Once a suitable set of companion polynomials are selected, we may proceed to find $d\sigma_1(x; k)$, the absolutely continuous component of orthogonality for $r_n(x; k)$, the sieved polynomials of the first kind of $R_n(x)$, and the Stieltjes transform $\chi_1(x; k)$ of this measure.

By Theorem 1, $\frac{S_{n-1}(x)}{R_n(x)-R_{n-2}(x)} = \frac{\theta_{n-1}P_{n-1}^{(1)}(x)/P_n(x)}{\phi_n+x\omega_nP_{n-1}^{(1)}(x)/P_n(x)}$. Substituting the values in Theorem 1 for θ_n, ϕ_n, ω_n, and the values in (21) for a_{nk}, we have, after simplification and the use of Markov's theorem,

$$\lim_{n\to\infty} \frac{a_{n\,k}S_{n-1}(x)}{R_n(x) - R_{n-2}(x)} = \frac{\overline{B}_0}{B_0} \frac{\chi_P(x)}{\frac{1}{\overline{D}_1} + \overline{B}_0\left(\frac{1}{B_0} - \frac{1}{\overline{B}_0\overline{D}_1}\right)x\chi_P(x)}, \tag{33}$$

$x \notin [-1, 1]$. Since $x \in [-1, 1] \Leftrightarrow T_k(x) \in [-1, 1]$, replacing x by $T_k(x)$ in the above, and using (20), we have the following theorem.

THEOREM 2.

$$\chi_1(x;k)=\frac{\overline{B}_0}{B_0}\ \frac{U_{k-1}(x)\chi_P(T_k(x))}{\dfrac{1}{\overline{D}_1}+\overline{B}_0\left(\dfrac{1}{B_0}-\dfrac{1}{\overline{B}_0\overline{D}_1}\right)T_k(x)\chi_P(T_k(x))},\ x\notin[-1,1]. \tag{34}$$

To use the Stieltjes inversion formula on $\chi_1(x;k)$ to recover $d\mu_1(x;k)$, it is first necessary to mention a special case of a theorem due to Geronimo and Van Assche. If μ_0 is a probability measure with Stieltjes transform $\chi(z,\mu_0)$ and μ is another measure whose Stieltjes transform is given by $\chi(z,\mu)=U_{k-1}(z)\chi(T_k(z),\,\mu_0)$, where $T_k(x)$ and $U_k(x)$ are the Tchebyshev polynomials of the first and second kind, then the absolutely continuous components of the measures μ and μ_0 satisfy the relation $d\mu(x)=|U_{k-1}(x)|d\mu_0(T_k(x))$. (See Geronimo and Van Assche [10].)

If we let

$$\chi(x,\rho)=\lim_{n\to\infty}\frac{a_{nk}S_{n-1}(x)}{R_n(x)-R_{n-2}(x)},\quad x\notin[-1,1],$$

be the Stieltjes transform for some measure ρ, then $\chi_1(x;k)=U_{k-1}(x)\chi(T_k(x),\rho)$. Using (15), the corollary to the Stieltjes inversion formula, then (33) becomes

$$d\rho(x)=\frac{\overline{B}_0}{B_0\overline{D}_1}\ \frac{d\mu_P(x)}{\left|\dfrac{1}{\overline{D}_1}+\overline{B}_0\left(\dfrac{1}{B_0}-\dfrac{1}{\overline{B}_0\overline{D}_1}\right)x\chi_P(x)\right|^2},\quad x\in(-1,1). \tag{35}$$

Here the Stieltjes transform for the companion polynomials,

$$\chi_P(x)=\text{p.v.}\int_{-1}^{1}\frac{d\mu_P(t)}{x-t},\quad x\in(-1,1),$$

is understood to be a Cauchy principal value integral. Now applying the theorem of Geronimo and Van Assche to (35), we obtain the following theorem.

THEOREM 3.

$$d\sigma_1(x;k)=\frac{\overline{B}_0}{B_0\overline{D}_1}\ \frac{|U_{k-1}(x)|d\mu_P(T_k(x))}{\left|\dfrac{1}{\overline{D}_1}+\overline{B}_0\left(\dfrac{1}{B_0}-\dfrac{1}{\overline{B}_0\overline{D}_1}\right)T_k(x)\chi_P(T_k(x))\right|^2},\quad x\in(-1,1). \tag{36}$$

It is always possible to find companion polynomials $P_n(x)$ such that the formula $B_nD_{n-1}=\overline{B}_n\overline{D}_{n+1}$, $n\geq 1$, is satisfied. Choose $\overline{B}_n=D_{n-1}$ and $\overline{D}_n=B_{n-1}$. The requisite equation (28) is satisfied, and so is the random walk condition $\overline{B}_n+\overline{D}_n=1$, $n\geq 1$ for $P_n(x)$. These are called the natural companion polynomials and are defined as

$$\begin{aligned}&xP_n(x)=D_{n-1}P_{n+1}(x)+B_{n-1}P_{n-1}(x),\quad n\geq 1,\\ &P_{-1}(x)=0,\qquad P_0(x)=1,\qquad P_1(x)=\frac{x}{\overline{B}_0}.\end{aligned} \tag{37}$$

Here $\overline{B}_0$ and $\overline{D}_0$ need not be specified, since $\overline{D}_0$ plays no role as $P_{-1}(x)=0$. With this selection for $P_n(x)$, we see $P_n^{(1)}(x)=S_n(x)$. The constants θ_n, ϕ_n, and ω_n in

Theorem 1 become

$$\begin{aligned} &\theta_n = 1, \quad n \geq 0, \\ &\phi_1 = \frac{1}{B_0}, \qquad \phi_n = a_{nk}, \quad n \geq 2, \\ &\omega_1 = \frac{1}{B_0}\left(1 - \frac{1}{\overline{B}_0}\right), \qquad \omega_n = a_{nk}\left(1 - \frac{1}{\overline{B}_0}\right), \quad n \geq 2. \end{aligned} \tag{38}$$

Theorem 1 becomes

$$R_n(x) - R_{n-2}(x) = a_{nk}\left[P_n(x) + \left(1 - \frac{1}{\overline{B}_0}\right) x P^{(1)}_{n-1}(x)\right], \quad n \geq 2. \tag{39}$$

The formulas for the Stieltjes transform and measure of orthogonality for $r_n(x;k)$ become

$$\chi_1(x;k) = \frac{\overline{B}_0 U_{k-1}(x)\chi_P(T_k(x))}{1 + (\overline{B}_0 - 1)T_k(x)\chi_P(T_k(x))}, \quad x \notin [-1,1], \tag{40}$$

$$d\sigma_1(x;k) = \frac{\overline{B}_0 |U_{k-1}(x)| d\mu_P(T_k(x))}{|1 + (\overline{B}_0 - 1)T_k(x)\chi_P(T_k(x))|^2}, \quad x \in (-1,1). \tag{41}$$

4. Orthogonality of the associated ultraspherical polynomials. In this section we will study the random walk polynomials $R_n(x;a,b,c)$, or simply $R_n(x)$ when the dependence on the parameters is not necessary to state, with linear birth and death rates given by $\beta_n = cn + a$, $\delta_n = cn + b$. This will give us the background to then select a companion random walk polynomial sequence to $R_n(x)$ and to study the sieved analogues in the next section.

These polynomials satisfy the recursion

$$\begin{aligned} &R_{-1}(x) = 0, \qquad R_0(x) = 1, \\ &(cn + a)R_{n+1}(x) = (2cn + a + b)xR_n(x) - (cn + b)R_{n-1}(x), \quad n \geq 0. \end{aligned} \tag{42}$$

The case of $c = 0$ is seen to be the Tchebyshev polynomials $R_n(x) = (\frac{b}{a})^{n/2} U_n(\frac{a+b}{2\sqrt{ab}}x)$. Dispensing with this case, we may divide the recursion (42) by c, replace a by $\frac{a}{c}$ and b by $\frac{b}{c}$, thereby scaling c to 1. This leaves the recursion to the simplified form

$$(n + a)R_{n+1}(x;a,b) = (2n + a + b)xR_n(x;a,b) - (n + b)R_{n-1}(x;a,b), \quad n \geq 0. \tag{43}$$

These are seen to be the associated ultraspherical polynomials $C_n^{(\gamma)}(x;\beta) = R_n(x;\gamma+1, 2\beta+\gamma-1)$. The ultraspherical polynomials are $C_n^{\lambda}(x) = R_n(x;1,2\lambda-1)$.

The corresponding birth and death polynomials when $\beta_n = n+\alpha+c+1$, $\delta_n = n+c$, $n \geq 0$, are the associated Laguerre polynomials $L_n^{\alpha}(x;c)$. These have been studied in Askey and Wimp [4] and Ismail, Letessier, and Valent [12].

The positivity condition on the measure for $R_n(x)$ is found from (43) to be

$$\frac{(2n + a + b)(2n + a + b - 2)(n + b)}{(n + a)^2(n + a - 2)} > 0, \quad n = 1, 2, \ldots.$$

The intersection of these inequalities for $n = 1, 2, \ldots$, is found to be $a > 1, b > -1$.

Let $G(x,t)=\sum_{n=0}^{\infty}R_n(x;a,b)t^n$ be the generating function for the polynomials $R_n(x;a,b)$. Note that $G(x,0)=1$. Multiplying (43) by t^{n+1} and summing from $n=0$ to ∞, we obtain the differential equation

$$t(t-\alpha)(t-\beta)\frac{\partial G(x,t)}{\partial t}=-(1+b)(t-p)(t-q)G(x,t)+(a-1).$$

Here α,β are the roots of the equation $t^2-2tx+1=0$, with $|\alpha|\le|\beta|$. We note that $\alpha+\beta=2x$, $\alpha\beta=1$, and $|\alpha|=|\beta|\Leftrightarrow|x|\le 1$. Also, p,q are the roots of $-(1+b)t^2+(a+b)xt+(1-a)=0$. We have $p+q=\frac{a+b}{1+b}x$, $pq=\frac{a-1}{b+1}$. Let $A=1-a$, $B=\frac{a-b}{2}-1$. Solving the above differential equation, we obtain

$$G(x,t)=(a-1)t^A(1-2xt+t^2)^B\quad\int_0^t u^{-A-1}(1-2xu+u^2)^{-B-1}du.$$

For the integral to converge, we must have $A<0$, or $a>1$, which is implied from the positivity condition.

We may use the method of Darboux (see Olver [16, section 8.9]) to obtain asymptotic estimates for $R_n(x)$. Analyzing $x\notin[-1,1]$ first, we find a comparison function to be

$$\lim_{t\to\alpha}\left(1-\frac{t}{\alpha}\right)^{-B}G(x,t)=(a-1)\alpha^A\left(1-\frac{\alpha}{\beta}\right)^B\int_0^{\alpha}u^{-A-1}\left(1-\frac{u}{\alpha}\right)^{-B-1}\left(1-\frac{u}{\beta}\right)^{-B-1}du,$$

$B\neq 0,1,\ldots$. The above integral is a Hadamard integral (see Askey and Ismail [3, Chapter 5]). Using the binomial theorem for $(1-\frac{t}{\alpha})^B=\sum_{n=0}\frac{(-B)_n}{n!}\frac{t^n}{\alpha^n}$, and Stirling's asymptotic estimate $\frac{(-B)_n}{n!}\alpha^{-n}\sim\frac{\alpha^{-n}}{\Gamma(-B)}n^{-B-1}$, we obtain the asymptotic estimate

$$R_n(x)\sim(a-1)\alpha^A\left(1-\frac{\alpha}{\beta}\right)^B\frac{\alpha^{-n}}{\Gamma(-B)}n^{-B-1}\int_0^{\alpha}u^{-A-1}\left(1-\frac{u}{\alpha}\right)^{-B-1}\left(1-\frac{u}{\beta}\right)^{-B-1}du,$$

$x\in[-1,1]$.

To evaluate the above integral, we may use the binomial theorem on the factor $(1-\frac{u}{\beta})^{-B-1}$ inside the integral, reverse order of summation and integration, and use the definition of beta integrals to obtain after simplification the result

$$\begin{aligned}R_n(x;a,b)\sim{}&\frac{\Gamma(a)}{\Gamma\left(\frac{a+b}{2}\right)}\left(1-\frac{\alpha}{\beta}\right)^{\frac{a-b}{2}-1}\\&\times{}_2F_1\left(a-1,\frac{a-b}{2};\ \frac{a+b}{2};\ \frac{\alpha}{\beta}\right)\alpha^{-n}n^{(b-a)/2},\\&n\to\infty,x\notin[-1,1].\end{aligned}\tag{44}$$

There is no need to separately consider the case where $B=0,1,2,\ldots$, since the factor $\Gamma(-B)$ has cancelled.

For $x\in(-1,1)$, $|\alpha|=|\beta|$. Due to the two singularities of the generating function $G(x,t)$ that are equidistant from the origin, a comparison function to use in the method of Darboux in this case is

$$(a-1)\alpha^A\left(1-\frac{\alpha}{\beta}\right)^B\int_0^{\alpha}u^{-A-1}\left(1-\frac{u}{\alpha}\right)^{-B-1}\left(1-\frac{u}{\beta}\right)^{-B-1}du$$

$+$ complex conjugate.

Letting $x = \cos\theta$, $\alpha = e^{i\theta}$, $\beta = e^{-i\theta}$, we obtain the asymptotic estimate

$$\begin{aligned} R_n(x;a,b) &\sim 2\frac{\Gamma(a)}{\Gamma\left(\dfrac{a+b}{2}\right)}\ |1-e^{2i\theta}|^{(\frac{a-b}{2})-1} \\ &\times \left|{}_2F_1\left(\frac{a-b}{2}, a-1; \frac{a+b}{2}; e^{2i\theta}\right)\right| n^{(\frac{b-a}{2})}\cos(-n\theta+\phi), \\ &n\to\infty, \quad x\in(-1,1), \end{aligned} \tag{45}$$

where $\phi = \arg[(1-e^{2i\theta})^{(\frac{a-b}{2})-1}\ {}_2F_1\ (\frac{a-b}{2}, a-1; \frac{a+b}{2}; e^{2i\theta})]$.

To obtain the asymptotics at $x = 1$, we find the differential equation of the generating function $G(x,t)$ of $R_n(x)$ at $x = 1$ to be

$$t(t-1)^2\frac{\partial G(1,t)}{\partial t} = [-(b+1)t^2 + (a+b)t + 1 - a]G(1,t) + (a-1).$$

Solving this we obtain

$$G(1,t) = (a-1)t^{1-a}(1-t)^{a-b-2}\int_0^t u^{a-2}(1-u)^{b-a}du, \quad a>1.$$

A comparison function in the method of Darboux is

$$(a-1)(1-t)^{a-b-2}\int_0^1 u^{a-2}(1-u)^{b-a}du, \quad b-a\neq -1,-2,\ldots.$$

Evaluating the above Hadamard integral and using the binomial theorem and Stirling's asymptotic estimate, we obtain after simplification

$$\begin{aligned} R_n(1) &\sim \frac{1}{\Gamma(-a+b+2)}\ {}_2F_1(a-b, a-1; a; 1)n^{-a+b+1}, \\ &n\to\infty, \qquad b-a\neq -1,-2,\ldots. \end{aligned} \tag{46}$$

Since the recursion for $R_n(x)$ is symmetric, then $R_n(-1) = (-1)^n R_n(1)$, and therefore this case need not be considered separately (Chihara [8, p. 21]).

The numerator polynomials are defined in terms of the associated polynomials with parameter $v = 1$. We see that $R_n^{(1)}(x;a,b) = R_n(x;a+1,b+1)$. Therefore, by (44), we obtain the asymptotic estimate

$$\begin{aligned} R_n^{(1)}(x;a,b) &\sim \frac{\Gamma(a+1)}{\Gamma\left(\dfrac{a+b}{2}+1\right)}\ \left(1-\frac{\alpha}{\beta}\right)^{\frac{a-b}{2}-1} \\ &\times {}_2F_1\left(a, \frac{a-b}{2}; \frac{a+b}{2}+1; \frac{\alpha}{\beta}\right)\alpha^{-n}n^{(b-a)/2}, \\ &n\to\infty, \quad x\notin[-1,1]. \end{aligned} \tag{47}$$

The Stieltjes transform of the distribution function for the polynomials $R_n(x;a,b)$ can be obtained next. Let the orthogonality be written as

$$\int_{-1}^1 R_n(x;a,b)R_m(x;a,b)d\mu(x) = \lambda_n\delta_{mn}.$$

Let $\chi(x) = \int_{-1}^{1} \frac{d\mu(t)}{x-t}, x \notin [-1,1]$, be the Stieltjes transform. Applying Markov's theorem to asymptotic estimates (44) and (47), we obtain after simplification

$$\chi(x) = 2\alpha \frac{{}_2F_1\left(a, \frac{a-b}{2}; \frac{a+b}{2}+1; \frac{\alpha}{\beta}\right)}{{}_2F_1\left(a-1, \frac{a-b}{2}, \frac{a+b}{2}; \frac{\alpha}{\beta}\right)}, \quad x \notin [-1,1]. \tag{48}$$

Now that the asymptotic estimates for $R_n(x;a,b)$ are known for $x \in (-1,1)$, we may use the theorem of Nevai to obtain $d\mu(x)$, the continuous component of the measure of orthogonality. The hypotheses of the theorem are seen to be satisfied by a routine order estimation of the recursion coefficients. Using formula (10) and Stirling's formula, we have

$$\lambda_n = \frac{a+b}{a} \frac{(n+a)}{(2n+a+b)} \frac{(b+1)_n}{(a+1)_n} \sim \frac{a+b}{2b} \frac{\Gamma(a)}{\Gamma(b)} n^{b-a}. \tag{49}$$

Letting $x = \cos\theta$, we then have $\sqrt{1-x^2} = |\sin\theta|$, and $|1-e^{2i\theta}| = 2|\sin\theta|$. Therefore, using (45) and (49), we can write

$$\begin{aligned} d\mu(x) &= \limsup_{n\to\infty} \frac{2}{\pi} \frac{1}{\sqrt{1-x^2}} \frac{\lambda_n}{R_n^2(x,a,b)} \\ &= \frac{1}{\pi} 2^{b-a} \frac{a+b}{b} \frac{\Gamma^2\left(\frac{a+b}{2}\right)}{\Gamma(a)\Gamma(b)} |\sin\theta|^{b-a+1} \left| {}_2F_1\left(a-1, \frac{a-b}{2}; \frac{a+b}{2}; e^{2i\theta}\right)\right|^{-2} dx, \end{aligned} \tag{50}$$

$x \in (-1,1)$.

A partial analysis of mass points in the distribution function $\mu(x)$ may be obtained using (19). From asymptotic estimates (46) and (49), we have $\widetilde{R}_n^2(1) = \frac{R_n^2(1)}{\lambda_n} = O n^{-a+b+2}$. Therefore, if $a-b>3$, then $\sum_{n=0}^{\infty} \widetilde{R}_n^2(1)$ is divergent, and $\mu(x)$ does not have a mass point at $x=1$. The same analysis holds at $x=-1$.

The dual polynomials are defined by the recursion

$$(2n+a+b)xS_n(x;a,b) = (n+b)S_{n+1}(x;a,b) + (n+a)S_{n-1}(x;a,b), \tag{51}$$

with the usual initial conditions. By showing that the same recurrence and initial conditions are satisfied, we can make the following identifications:

$$S_n(x\colon a,b) = R_n(x\colon b,a) = R_n^{(1)}(x\colon b-1, a-1). \tag{52}$$

From asymptotic formula (44), we therefore have

$$S_n(x;a,b) \sim \left(1-\frac{\alpha}{\beta}\right)^{\frac{b-a}{2}-1} \frac{\Gamma(b)}{\Gamma\left(\frac{a+b}{2}\right)} {}_2F_1\left(b-1, \frac{b-a}{2}; \frac{a+b}{2}; \frac{\alpha}{\beta}\right) \alpha^{-n} n^{(a-b)/2}, \tag{53}$$

$n \to \infty, \quad x \notin [-1,1]$.

5. The sieved associated ultraspherical polynomials. We now have the background material to study the companion polynomials and the various sieved polynomials of $R_n(x)$. Let $r_n(x;k)$ be the sieved polynomials of the first kind of $R_n(x)$. From the birth and death rates $\beta_n = n + a$, $\delta_n = n + b$ of $R_n(x)$, we identify the coefficients

$$B_n = \frac{n+a}{2n+a+b}, \quad D_n = \frac{n+b}{2n+a+b}. \tag{54}$$

Therefore, the coefficients a_{mk} in (21) are given by

$$a_{mk} = (a+b+2m-2)\frac{(b)_{m-1}}{(a)_n} \sim \frac{2\Gamma(a)}{\Gamma(b)}\, m^{b-a}. \tag{55}$$

Let $\sigma_1(x;k)$ be the distribution function that the polynomials $r_n(x;k)$ are orthogonal with respect to, and let $\chi_{\ 1}(x;k)$ be the Stieltjes transform of $\sigma_1(x;k)$. Asymptotic estimates (44), (53), and (55) allow us to write

$$\lim_{m\to\infty} \frac{a_{mk} S_{m-1}(x;a,b)}{R_m(x;a,b) - R_{m-2}(x;a,b)} = \frac{2}{\beta-\alpha}\, \left(1-\frac{\alpha}{\beta}\right)^{(b-a)}\, \frac{{}_2F_1\left(b-1, \frac{b-a}{2}; \frac{a+b}{2}; \frac{\alpha}{\beta}\right)}{{}_2F_1\left(a-1, \frac{a-b}{2}; \frac{a+b}{2}; \frac{\alpha}{\beta}\right)},$$

$x \notin [-1,1]$.

Now let x be replaced everywhere by $T_k(x)$, the Tchebyshev polynomial of the first kind. Then α, β are replaced by

$$\alpha_k, \beta_k = T_k(x) \pm \sqrt{T_k^2(x) - 1}. \tag{56}$$

The statement $x \notin [-1,1]$ becomes $T_k(x) \notin [-1,1]$, which is identical to $x \notin [-1,1]$. By (20) we have

$$\chi_{\ 1}(x;k) = \frac{2}{\beta_k - \alpha_k}\, U_{k-1}(x)\, \left(1-\frac{\alpha_k}{\beta_k}\right)^{(b-a)}\, \frac{{}_2F_1\left(b-1, \frac{b-a}{2}; \frac{a+b}{2}; \frac{\alpha_k}{\beta_k}\right)}{{}_2F_1\left(a-1, \frac{a-b}{2}; \frac{a+b}{2}; \frac{\alpha_k}{\beta_k}\right)}, \tag{57}$$

$x \notin [-1,1]$.

5.1. The companion polynomials. We next study the companion polynomials for the $R_n(x;a,b)$ defined by the recursion $xP_n(x;a,b) = \overline{B}_n P_{n+1}(x;a,b) + \overline{D}_n P_{n-1}(x;a,b)$, with the usual initial conditions, and where

$$\overline{B}_n = \frac{n+a}{2n+a+b-2}, \qquad \overline{D}_n = \frac{n+b-2}{2n+a+b-2}, \quad n \geq 0. \tag{58}$$

We see the relation $\overline{B}_n \overline{D}_{n+1} = B_n D_{n-1}$ holds for $n \geq 1$, so the $P_n(x)$ are companion polynomials to $R_n(x)$, but these are not the natural companion polynomials of $R_n(x)$. The above companion polynomials were selected since they will furnish some interesting results. We first note the identities

$$\begin{aligned} P_n(x;a,b) &= R_n(x,a,b-2), \\ P_n^{(1)}(x;a,b) &= R_n(x;a+1,b-1). \end{aligned} \tag{59}$$

From (29), we identify the coefficients θ_n, ϕ_n, ω_n as

(60)
$$\theta_n = \frac{(a+1)_n}{(b)_n}, \quad \phi_n = \frac{a+b+2(n-1)}{b-1}, \quad \omega_n = \frac{1-a}{a}\ \frac{a+b+2(n-1)}{b-1}, \quad n \geq 1.$$

Using identities (59) and (60), formulas (25) and (26) become

$$S_n(x;a,b) = \frac{(a+1)_n}{(b)_n}\ R_n(x;a+1,b-1), \quad n \geq 0, \tag{61}$$

$$\begin{aligned} &R_n(x;a,b) - R_{n-2}(x;a,b) = \frac{a+b+2(n-1)}{b-1}, \\ &\times\ \left[R_n(x;a,b-2) + \frac{1-a}{a}\ x\ R_{n-1}(x;a+1,b-1)\right], \quad n \geq 1. \end{aligned} \tag{62}$$

In terms of the associated ultraspherical polynomials, formula (62) becomes the mixed recursion relation

$$\begin{aligned} &C_n^{(\gamma)}(x;\beta) - C_{n-2}^{(\gamma)}(x;\beta) = \\ &\frac{2(n+\beta+\gamma-1)}{2\beta+\gamma-2}\ \left[C_n^{(\gamma)}(x;\beta-1) - \frac{\gamma x}{\gamma+1}\ C_{n-1}^{(\gamma+1)}(x;\beta-1)\right]. \end{aligned} \tag{63}$$

The case of $\gamma = 0$ are the ultraspherical polynomials, written $C_n^{\lambda}(x)$, where λ is replacing β. Formula (63) reduces to

$$C_n^{\lambda}(x) - C_{n-2}^{\lambda}(x) = \frac{\lambda+n-1}{\lambda-1}\ C_n^{\lambda-1}(x),$$

a known result. (See Rainville [17, p. 283, eq. (39)].) Charris and Ismail [7] use this relation, along with the known weight function for the ultraspherical polynomials, to invert the Stieltjes transform for the sieved ultraspherical polynomials of the first kind, and thereby obtain the orthogonality relation for these polynomials.

The derivation of formula (63) was done originally in DeSesa [9, pp. 139–142]. First an expression for $C_n^{(\gamma)}(x;\beta)$ in terms of the Legendre functions of the first and second kinds was used. (See Bustoz and Ismail [5].) Then properties of the Legendre functions established (63). This was used to invert the Stieltjes transform for the sieved associated ultraspherical polynomials of the first kind. (See DeSesa [9, Chapter 4].)

The Stieltjes transform $\chi_P(z)$ for the companion polynomials is easily obtained by making the substitution $b \to b-2$ in formula (48), as justified by identity (59). Similarly, $d\mu_p(x)$, the absolutely continuous component for the measure of orthogonality of the companion polynomials, is found by using the same substitution in (50).

5.2. The sieved polynomials of the first kind. For $r_n(x;k)$, the sieved polynomials of the first kind, where B_n and D_n are given by (54), we note first

$$B_0 = \frac{a}{a+b}, \qquad \overline{B}_0 = \frac{a}{a+b-2}, \qquad \overline{D}_1 = \frac{b-1}{a+b}. \tag{64}$$

Using (64) and the substitution $b \to b-2$ in (48) for $\chi_P(x)$ in Theorem 2, formula (34), we obtain a second expression for $\chi_1(x;k)$ given by

$$\chi_1(x;k) = \frac{2(b-1)U_{k-1}(x)\alpha_k F_1}{(a+b-2)F_2 + 2(1-a)T_k(x)\alpha_k F_1}, \quad x \notin [-1,1], \tag{65}$$

where

$$F_1 = {}_2F_1\left(\begin{matrix} a, \dfrac{a-b}{2}+1 \\ \dfrac{a+b}{2} \end{matrix}; \frac{\alpha_k}{\beta_k}\right), \qquad F_2 = {}_2F_1\left(\begin{matrix} a-1, \dfrac{a-b}{2}+1 \\ \dfrac{a+b}{2}-1 \end{matrix}; \frac{\alpha_k}{\beta_k}\right),$$

and α_k, β_k are given by (56). The equivalence of (65) and (57) may be established more directly from a sequence of Kummer transformations and contiguous parameter identities of the Gaussian hypergeometric function.

To obtain the formula for $d\sigma_1(x;k)$, substitute the expressions found for $d\mu_P(x)$ and $\chi_P(x)$ into Theorem 3, formula (36). Note that when x is replaced by $T_k(x)$ for $x \in (-1,1)$, $\theta = \cos^{-1}(x)$ is replaced by $k\theta$, $\alpha_k = e^{ik\theta}$, and $\beta_k = e^{-ik\theta}$. This yields

$$d\sigma_1(x;k) = \frac{\dfrac{2^{b-a}}{\pi}(a+b)(b-1)\ \dfrac{\Gamma^2\left(\dfrac{a+b}{2}\right)}{\Gamma(a)\Gamma(b)}\ |\sin k\theta|^{b-a-1}|U_{k-1}(x)|}{|(a+b-2)^2F_3 + 2[(a+b)(b-2)-(a+b-2)^2]T_k(x)e^{ik\theta}F_4|^2}\ dx, \tag{66}$$

$x = \cos\theta,$

where

$$F_3 = {}_2F_1\left(\begin{matrix} a-1, \dfrac{a-b}{2}+1 \\ \dfrac{a+b}{2}-1 \end{matrix}; e^{2ik\theta}\right), \ F_4 = {}_2F_1\left(\begin{matrix} a, \dfrac{a-b}{2}+1 \\ \dfrac{a+b}{2} \end{matrix}; e^{2ik\theta}\right).$$

FRAMES CONTAINING A RIESZ BASIS AND PRESERVATION OF THIS PROPERTY UNDER PERTURBATIONS*

PETER G. CASAZZA† AND OLE CHRISTENSEN‡

Abstract. Aldroubi has shown how one can construct any frame $\{g_i\}_{i=1}^{\infty}$ starting with one frame $\{f_i\}_{i=1}^{\infty}$,using a bounded operator U on the space of square summable sequences $\ell^2(N)$. We study the overcompleteness of the frames in terms of properties of U. We also discuss perturbation of frames in the sense that two frames are "close" if a certain operator is compact. In this way we obtain an equivalence relation with the property that frames in the same equivalence class have the same overcompleteness. On the other hand we show that perturbation in the Paley–Wiener sense does not have this property.

Finally we construct a frame which is norm bounded below but which does not contain a Riesz basis. The construction is based on the delicate difference between the unconditional convergence of the frame representation and the fact that a convergent series in the frame elements need not converge unconditionally.

Key words. frames, Riesz bases, perturbations, overcompleteness

AMS subject classifications. 42C99, 46C99

1. Introduction. The introduction of frames for a Hilbert space $\mathcal{H}$ goes back to the paper [9] from 1952, where they are used in nonharmonic Fourier analysis. A frame is a family $\{f_i\}_{i\in I}$ of elements in $\mathcal{H}$ which can be considered as an "overcomplete basis": every element in $\mathcal{H}$ can be written as a linear combination of the frame elements f_i, with square integrable coefficients, which do not need to be unique. A natural theoretical question (which is also important for applications, e.g., representation of an operator using a basis) is how far frames are away from bases, i.e., one may ask questions like (1) does a frame contain a Riesz basis? (2) which conditions imply that a frame consists of a Riesz basis plus finitely many elements? (3) what happens with the overcompleteness if the frame elements are perturbed? The reason for the interest in Riesz bases and not just bases is that frames and Riesz bases are closely related: a Riesz bases is just a frame $\{f_i\}_{i=1}^{\infty}$, where the elements are ω-*independent*, i.e.,

$$\sum_{i\in I} c_i f_i = 0, \quad \{c_i\}_{i=1}^{\infty} \in \ell^2(I) \Rightarrow c_i = 0 \quad \forall i \in I.$$

Some answers have been found by Holub [10], who concentrates on the second question. Here we go one step further, in that we are mainly interested in frames which just contain a Riesz basis. For such frames one defines the *excess* as the number of elements one should take away to obtain a Riesz basis.

In the first part of the paper we apply a result of Aldroubi [1], explaining how one can map a frame onto another using a bounded operator U on ℓ^2. Our results

concern the relation between the frames involved and properties of U. Independent of that we construct a norm-bounded frame not containing a Riesz basis.

In section 3 we concentrate on the third question. We introduce the concept "compact perturbation." This leads to an equivalence relation on the set of frames, with the property that frames in the same equivalence class have the same overcompleteness properties; this means that if a frame contains a Riesz basis then all members in the class contain a Riesz basis, and all those frames have the same excess.

Finally we show that perturbation in the Paley–Wiener sense [7] does not have this pleasant property.

2. Frames containing a Riesz basis. Let $\mathcal{H}$ be a separable Hilbert space. A family $\{f_i\}_{i\in I}$ is called a *frame* for $\mathcal{H}$ if

$$\exists A, B > 0 : \ A||f||^2 \leq \sum_{i\in I} |\langle f, f_i\rangle|^2 \leq B||f||^2 \quad \forall f \in \mathcal{H}.$$

A and B are called *frame bounds*. The frame is *tight* if we can choose $A = B$. A *Riesz basis* is a family of elements which is the image of an orthonormal basis by a bounded invertible operator. Frequently we will use an equivalent characterization [16]: $\{f_i\}_{i\in I}$ is a Riesz basis if there exist numbers $A, B > 0$ such that

$$A\sum |c_i|^2 \leq \left\|\sum c_i f_i\right\|^2 \leq B\sum |c_i|^2 \tag{1}$$

for all finite sequences $\{c_i\}$.

Also, a basis $\{f_i\}_{i\in I}$ is a Riesz basis if and only if it is unconditional (meaning that if $\sum c_i f_i$ converges for some coefficients $\{c_i\}$, then it actually converges unconditionally) and $0 < \inf_i ||f_i|| \leq \sup_i ||f_i|| < \infty$.

There is a close connection between frames and Riesz bases:

$$\{f_i\}_{i\in I} \text{ is a Riesz basis}$$

$$\Updownarrow$$

$$\left[\{f_i\}_{i\in I} \text{ is a frame and } \sum_{i\in I} c_i f_i = 0, \{c_i\}_{i\in I} \in \ell^2(I) \Rightarrow c_i = 0 \quad \forall i\right].$$

In words: a Riesz basis is a frame, where the elements are ω-independent. If $\{f_i\}_{i\in I}$ is a Riesz basis, then the numbers A, B appearing in (1) are actually frame bounds. If $\{f_i\}_{i\in I}$ is a frame (or if only the upper frame condition is satisfied) then we define the *preframe operator* as an operator from the space of square summable sequences with index set I into $\mathcal{H}$:

$$T : \ell^2(I) \to \mathcal{H}, \quad T\{c_i\} := \sum_{i\in I} c_i f_i.$$

The operator T is bounded. Composing T with its adjoint

$$T^* : \mathcal{H} \to \ell^2(I), \quad T^* f = \{\langle f, f_i\rangle\}_{i\in I},$$

we get the *frame operator*

$$S = TT^* : \mathcal{H} \to \mathcal{H}, \quad Sf := \sum_{i\in I} \langle f, f_i\rangle f_i,$$

which is a bounded and invertible operator. This immediately leads to the *frame decomposition*; every $f \in \mathcal{H}$ can be written as

$$f = \sum_{i \in I} \langle f, S^{-1} f_i \rangle f_i,$$

where the series converges unconditionally. So a frame has a property similar to a basis: every element in $\mathcal{H}$ can be written as a linear combination of the frame elements. For more information about basic properties of frames we refer to the original paper [9] and the research tutorial [12]. The main difference between a frame $\{f_i\}_{i \in I}$ and a basis is that a frame can be overcomplete, so it might happen that $f \in \mathcal{H}$ has a representation $f = \sum_{i \in I} c_i f_i$ for some coefficients c_i which are different from the *frame coefficients* $\langle f, S^{-1} f_i \rangle$. In applications one might wish not to have "too much redundancy." In that spirit Holub [10] discusses *near-Riesz bases*, i.e., frames $\{f_i\}_{i \in I}$ consisting of a Riesz basis $\{f_i\}_{i \in I - \sigma}$ plus finitely many elements $\{f_i\}_{i \in \sigma}$. The number of elements in σ is called the *excess*. Let us denote the kernel of the operator T by N_T. If $\{f_i\}_{i \in I}$ is a frame, then

$$\{f_i\}_{i \in I} \text{ is a near-Riesz basis,}$$

$$\Updownarrow$$

$$N_T \text{ has finite dimension,}$$

$$\Updownarrow$$

$$\{f_i\}_{i \in I} \text{ is unconditional.}$$

The first of the above bi-implications is due to Holub [10], who also proves the second under the assumption that the frame is norm bounded below. The generalization above is proved by the authors in [4]. If the conditions above are satisfied, then the excess is equal to $\dim(N_T)$.

If $\dim(N_T) = \infty$, two things can happen: $\{f_i\}_{i \in I}$ consists of a Riesz basis plus infinitely many elements (in which case we will say that $\{f_i\}_{i \in I}$ has infinite excess) or $\{f_i\}_{i \in I}$ does not contains a Riesz basis at all. In the present paper we concentrate on frames which contain a Riesz basis. Every frame can be mapped onto such a frame (in fact, onto an arbitrary frame) using a construction of Aldroubi [1], which we now shortly describe.

For convenience, we will index our frames by the natural numbers. Let $\{f_i\}_{i=1}^{\infty}$ be a frame and $U : \ell^2(\mathbf{N}) \to \ell^2(\mathbf{N})$ a bounded operator. Let $\{u_{i,j}\}_{i,j \in N}$ be the matrix for U with respect to some basis. Define the family $\{g_i\}_{i=1}^{\infty} \in \mathcal{H}$ by

$$g_i = \sum_{j=1}^{\infty} u_{i,j} f_j. \tag{2}$$

By an abuse of notation we will sometimes write $\{g_i\}_{i=1}^{\infty} = U\{f_i\}_{i=1}^{\infty}$. A result of Aldroubi (differently formulated) states that

$$\{g_i\}_{i=1}^{\infty} \text{ is a frame} \Leftrightarrow \exists \gamma > 0 : ||UT^* f|| \geq \gamma \cdot ||T^* f|| \ \ \forall f \in \mathcal{H}.$$

It is important that *every* frame $\{g_i\}_{i=1}^{\infty}$ can be generated in this way; i.e., given the frame $\{g_i\}_{i=1}^{\infty}$ we just have to find the operator U mapping $\{f_i\}_{i=1}^{\infty}$ to $\{g_i\}_{i=1}^{\infty}$.

In connection with Aldroubi's construction there are (at least) two natural questions related to Holub's work: how is the excess of $\{g_i\}_{i=1}^\infty$ related to that of $\{f_i\}_{i=1}^\infty$, and which conditions imply that $\{g_i\}_{i=1}^\infty$ actually is a Riesz basis? We shall give answers to both questions in this section.

The definition of $\{g_i\}_{i=1}^\infty$ immediately shows that

$$\{\langle g_i, f\rangle\} = U\{\langle f_i, f\rangle\} \quad \forall f \in \mathcal{H};$$

this is true whether or not $\{g_i\}_{i=1}^\infty$ builds a frame. The formula leads to an expression for the preframe operator associated with $\{g_i\}_{i=1}^\infty$. We let U^T denote the transpose of U and $\overline{U}$ be the operator corresponding to the matrix where all entries in the matrix of U are complex conjugated. It is easy to prove that

$$\sum_{i=1}^\infty c_i g_i = TU^T\{c_i\}_{i=1}^\infty \quad \forall \{c_i\}_{i=1}^\infty \in \ell^2(\mathbf{N}).$$

So if $\{g_i\}_{i=1}^\infty$ contains a Riesz basis, then its excess is equal to $\dim(N_{TU^T})$. For the calculation of this number we need a lemma, the proof of which we leave to the reader. Corresponding to an operator V we denote its range by R_V.

LEMMA 2.1. *Let X, Y be vector spaces and $V : X \to Y$ a linear mapping. Given a subspace $Z \subseteq Y$, define $V^{-1}(Z) := \{x \in X \mid Vx \in Z\}$. Then*

$$\dim(V^{-1}(Z)) = \dim(Z \cap R_V) + \dim(N_V).$$

THEOREM 2.2. $\dim(N_{TU^T}) = \dim(R_{U^T} \cap N_T) + \dim(R_U^\perp)$.

Proof. Theorem 2.2 is an easy consequence of Lemma 2.1 and the calculation

$$\{\{c_i\}_{i=1}^\infty \mid TU^T\{c_i\}_{i=1}^\infty = 0\} = \{\{c_i\}_{i=1}^\infty \mid U^T\{c_i\}_{i=1}^\infty \in N_T\} = (U^T)^{-1}(N_T). \qquad \square$$

So if $\{g_i\}_{i=1}^\infty$ actually is a frame containing a Riesz basis, then Theorem 2.2 gives a recipe for calculation of the excess. In particular, if $\{f_i\}_{i=1}^\infty$ is a near-Riesz basis and R_U has finite codimension, then $\{g_i\}_{i=1}^\infty$ is also a near-Riesz basis. Observe that in the special case where $\{f_i\}_{i=1}^\infty$ is a Riesz basis, the excess of $\{g_i\}_{i=1}^\infty$ is equal to $\dim({R_U}^\perp) = \dim(N_{U^*})$.

Example 1. Let $\{f_i\}_{i=1}^\infty = \{e_i\}_{i=1}^\infty$ be an orthonormal basis for $\mathcal{H}$ and define

$$g_1 := e_1, \qquad g_i = e_{i-1} + \frac{1}{i}e_i, \quad i \geq 2.$$

According to (2), we have

$$U = \begin{pmatrix} 1 & 0 & 0 & . & . & . \\ 1 & 1/2 & 0 & 0 & . & . \\ 0 & 1 & 1/3 & 0 & 0 & . \\ . & . & . & . & . & . \\ . & . & . & . & . & . \end{pmatrix},$$

which certainly defines a bounded operator from $\ell^2(N)$ into $\ell^2(N)$. Since $\{f_i\}_{i=1}^\infty$ is an orthonormal basis, $R_{T^*} = \ell^2(N)$, so $\{g_i\}_{i=1}^\infty$ is a frame if and only if

$$\exists \gamma > 0 : \ ||U\{c_i\}_{i=1}^\infty|| \geq \gamma \cdot ||\{c_i\}_{i=1}^\infty|| \quad \forall \{c_i\}_{i=1}^\infty \in \ell^2(N).$$

But

$$||U\{c_i\}_{i=1}^{\infty}|| = \left\| \left(c_1, c_1 + \frac{1}{2}c_2, c_2 + \frac{1}{3}c_3, ... \right) \right\|$$

$$\geq ||(c_1, c_1, c_2, c_3, ...)|| - \left\| \left(0, \frac{c_2}{2}, \frac{c_3}{3}, ... \right) \right\| \geq \frac{1}{2}||\{c_i\}_{i=1}^{\infty}|| \quad \forall \{c_i\}_{i=1}^{\infty} \in \ell^2(N).$$

Now, since

$$U^* = \begin{pmatrix} 1 & 1 & 0 & . & . & . \\ 0 & 1/2 & 1 & 0 & . & . \\ 0 & 0 & 1/3 & 1 & 0 & . \\ . & . & . & . & . & . \\ . & . & . & . & . & . \end{pmatrix},$$

$N_{U^*} = \text{span}\{(1, -1, \frac{1}{2!}, \frac{-1}{3!}, ...)\}$. We conclude that $\{g_i\}_{i=1}^{\infty}$ has excess one.

Concerning Riesz bases we have another result, which can be proved by the interested reader.

PROPOSITION 2.3. *$\{g_i\}_{i=1}^{\infty}$ is a Riesz basis $\Leftrightarrow$ $\overline{U} : R_{T^*} \to \ell^2(N)$ is surjective.*

More generally one may wish that the frame at least contain a Riesz basis. As shown in [6], this is the case for a *Riesz frame*, which is a frame with the property that every subfamily is a frame for its closed linear span, with a common lower bound (see [4] for an extension.)

It is easy to construct a frame which does not contain a Riesz basis if one allows a subsequence of the frame elements to converge to 0 in norm. We now present an example showing that the same can be the case for a frame which is norm bounded below. Our approach is complementary to a work by Seip [14], who proves that there exist frames of complex exponentials for $L^2(-\pi, \pi)$ which do not contain a Riesz basis. While Seip relies on the theory for sampling and interpolation our approach is more elementary, just using functional analysis. Furthermore our construction puts focus on a different point, namely the difference between convergence and unconditional convergence of an expansion in the frame elements.

PROPOSITION 2.4. *There exists a tight frame for $\mathcal{H}$ which is norm bounded below but which does not contain a Riesz basis.*

The proof needs several lemmas, so let us shortly explain the basic idea. As we have seen, $\sum_{i \in I} c_i f_i$ converges unconditionally for every set of frame coefficients $\{c_i\}_{i \in I}$. But nothing guarantees that convergence of $\sum_{i \in I} c_i f_i$ implies unconditional convergence for general coefficients $\{c_i\}_{i \in I}$. Our proof consists of a construction of a frame where no total subset is unconditional, and hence not a Riesz basis. Technically the first step is to decompose $\mathcal{H}$ into a direct sum of finite dimensional subspaces of increasing dimension. The idea behind the proof might be useful in other situations as well.

LEMMA 2.5. *Let $\{e_i\}_{i=1}^{n}$ be an orthonormal basis for a finite dimensional space $\mathcal{H}_n$. Define*

$$f_j = e_j - \frac{1}{n} \sum_{i=1}^{n} e_i \quad \text{for } j = 1, \ldots, n,$$

$$f_{n+1} = \frac{1}{\sqrt{n}} \sum_{i=1}^{n} e_i.$$

Then

$$\sum_{j=1}^{n+1} |\langle f, f_j\rangle|^2 = ||f||^2 \quad \forall f \in \mathcal{H}_n.$$

Proof. Given $f \in \mathcal{H}_n$, write $f = \sum_{i=1}^n a_i e_i,\ a_i = \langle f, e_i\rangle$. If we let P denote the orthogonal projection onto the unit vector $\frac{1}{\sqrt{n}} \sum_{i=1}^n e_i$, then

$$Pf = \frac{1}{n} \left\langle f, \sum_{i=1}^n e_i \right\rangle \sum_{i=1}^n e_i = \frac{\sum_{i=1}^n a_i}{\sqrt{n}} \frac{1}{\sqrt{n}} \sum_{i=1}^n e_i.$$

Therefore

$$||Pf||^2 = \frac{|\sum_{i=1}^n a_i|^2}{n} = |\langle f, f_{n+1}\rangle|^2.$$

Also

$$||(I-P)f||^2 = ||f - Pf||^2 = \left\| \sum_{i=1}^n a_i e_i - \frac{\sum_{j=1}^n a_j}{n} \sum_{i=1}^n e_i \right\|^2$$
$$= \left\| \sum_{i=1}^n \left(a_i - \frac{\sum_{j=1}^n a_j}{n} \right) e_i \right\|^2 = \sum_{i=1}^n \left| a_i - \frac{\sum_{j=1}^n a_j}{n} \right|^2 = \sum_{i=1}^n |\langle f, f_i\rangle|^2.$$

Putting the two results together we obtain

$$||f||^2 = ||Pf||^2 + ||(I-P)f||^2 = \sum_{i=1}^{n+1} |\langle f, f_i\rangle|^2,$$

and the proof is complete. □

Given a sequence $\{g_i\}_{i\in I} \subseteq \mathcal{H}$, its *unconditional basis constant* is defined as the number

$$\sup \left\{ \left\| \sum_{i\in I} \sigma_i c_i g_i \right\| \Big| \left\| \sum_{i\in I} c_i g_i \right\| = 1 \text{ and } \sigma_i = \pm 1 \quad \forall i \right\}.$$

As shown in [15], a total family $\{g_i\}_{i\in I}$ consisting of nonzero elements is an unconditional basis for $\mathcal{H}$ if and only if it has finite unconditional basis constant.

LEMMA 2.6. *Define* $\{f_1, ..., f_{n+1}\}$ *as in Lemma* 2.5. *Any subset of* $\{f_1, f_2, ..., f_{n+1}\}$ *which spans* $\mathcal{H}_n$ *has unconditional basis constant greater than or equal to* $\sqrt{n-1} - 1$.

Proof. Since $\sum_{i=1}^n f_i = 0$, any subset of $\{f_1, ..., f_{n+1}\}$ which spans $\mathcal{H}_n$ must contain $n-1$ elements from $\{f_1, ..., f_n\}$ plus f_{n+1}. By the symmetric construction it is enough to consider the family $\{f_1, ..., f_{n-1}, f_{n+1}\}$. We have

$$\left\| \sum_{i=1}^{n-1} f_i \right\| = \left\| \sum_{i=1}^{n-1} e_i - \frac{n-1}{n} \sum_{i=1}^n e_i \right\|$$
$$= \left\| (1 - \frac{n-1}{n}) \sum_{i=1}^{n-1} e_i - \frac{n-1}{n} e_n \right\|$$
$$= \left\| \frac{1}{n} \sum_{i=1}^{n-1} e_i - \frac{n-1}{n} e_n \right\|$$
$$= \sqrt{\frac{n-1}{n^2} + \frac{(n-1)^2}{n^2}}$$
$$= \frac{1}{n} \sqrt{n(n-1)} \leq 1.$$

Now consider $||\sum_{i=1}^{n-1}(-1)^n f_i||$; if n is odd this number is equal to $||\sum_{i=1}^{n-1}(-1)^n e_i|| = \sqrt{n-1}$, and if n is even it is equal to

$$\left\|\sum_{i=1}^{n-1}(-1)^i e_i - \frac{1}{n}\sum_{i=1}^{n} e_i\right\| \geq \left\|\sum_{i=1}^{n-1}(-1)^i e_i\right\| - \left\|\frac{1}{n}\sum_{i=1}^{n} e_i\right\| \geq \sqrt{n-1} - \frac{\sqrt{n}}{n} \geq \sqrt{n-1} - 1.$$

That is, in all cases,

$$\left\|\sum_{i=1}^{n-1}(-1)^n f_i\right\| \geq \sqrt{n-1} - 1.$$

Combining this with the norm estimate $||\sum_{i=1}^{n-1} f_i|| \leq 1$, it follows that the unconditional basis constant of $\{f_1, ..., f_{n-1}\}$ is greater than or equal to $\sqrt{n-1}-1$, so clearly the same is true for $\{f_1, ..., f_{n-1}, f_{n+1}\}$. □

Now we are ready to do the construction for Proposition 2.4. Let $\{e_i\}_{i=1}^{\infty}$ be an orthonormal basis for $\mathcal{H}$ and define

$$\mathcal{H}_n := \text{span}\{e_{\frac{(n-1)n}{2}+1}, e_{\frac{(n-1)n}{2}+2}, ..., e_{\frac{(n-1)n}{2}+n}\}.$$

So $\mathcal{H}_1 = \text{span}\{e_1\}$, $\mathcal{H}_2 = \text{span}\{e_2, e_3\}, \mathcal{H}_3 = \text{span}\{e_4, e_5, e_6\}, ...$ By construction,

$$\mathcal{H} = \left(\sum_{n=1}^{\infty}\bigoplus \mathcal{H}_n\right)_{\mathcal{H}}.$$

That is, $g \in \mathcal{H} \Leftrightarrow g = \sum_{n=1}^{\infty} g_n, g_n \in \mathcal{H}_n$, and $||g||^2 = \sum_{n=1}^{\infty} ||g_n||^2$. We refer to [13] for details about such decompositions. For each space $\mathcal{H}_n$ we construct the sequence $\{f_i^n\}_{i=1}^{n+1}$ as in Lemma 2.5, starting with the orthonormal basis $\{e_{\frac{(n-1)n}{2}+1}, ..., e_{\frac{(n-1)n}{2}+n}\}$. Specifically, given $n \in N$,

$$f_i^n = e_{\frac{(n-1)n}{2}+i} - \frac{1}{n}\sum_{j=1}^{n} e_{\frac{(n-1)n}{2}+j}\ , \quad 1 \leq i \leq n,$$

$$f_{n+1}^n = \frac{1}{\sqrt{n}}\sum_{j=1}^{n} e_{\frac{(n-1)n}{2}+j}.$$

LEMMA 2.7. *$\{f_i^n\}_{i=1,n=1}^{n+1,\infty}$ is a frame for $\mathcal{H}$, with bounds $A = B = 1$.*

Proof. Write $g \in \mathcal{H}$ as $g = \sum_{n=1}^{\infty} g_n$, $g_n \in \mathcal{H}_n$. Given $n \in N$ it is clear that

$$\langle g, f_i^n\rangle = \langle g_n, f_i^n\rangle \text{ for } i = 1, ..., n+1.$$

From this calculation it follows that

$$\sum_{n=1}^{\infty}\sum_{i=1}^{n+1} |\langle g, f_i^n\rangle|^2 = \sum_{n=1}^{\infty}\sum_{i=1}^{n+1} |\langle g_n, f_i^n\rangle|^2 = \sum_{n=1}^{\infty} ||g_n||^2 = ||g||^2,$$

where we have used Lemma 2.5. □

LEMMA 2.8. *No subsequence of $\{f_i^n\}_{i=1,n=1}^{n+1,\infty}$ is a Riesz basis for $\mathcal{H}$.*

Proof. Any subsequence of $\{f_i^n\}_{i=1,n=1}^{n+1,\infty}$ which spans $\mathcal{H}$ must contain n elements from $\{f_i^n\}_{i=1}^{n+1}$ and so by Lemma 2.6, its unconditional basis constant is greater than or equal to $\sqrt{n-1}-1$ for every n. That is, the unconditional basis constant is infinite, hence the subsequence cannot be an unconditional basis for $\mathcal{H}$. □

Lemmas 2.7 and 2.8 prove Proposition 2.4. It would be interesting to determine whether Proposition 2.4 still holds if one only considers classes of frames with a special structure, for example Weyl–Heisenberg frames, wavelet frames, or frames consisting of translates of a single function.

Remark. Corresponding to a subfamily $\{f_i\}_{i=1}^n$ of a frame $\{f_i\}_{i=1}^\infty$, we define the frame operator by

$$S_n : \operatorname{span}\{f_i\}_{i=1}^n \to \operatorname{span}\{f_i\}_{i=1}^n, \quad S_n f = \sum_{i=1}^n \langle f, f_i\rangle f_i.$$

The orthogonal projection of $\mathcal{H}$ onto $\operatorname{span}\{f_i\}_{i=1}^n$ is given by

$$P_n f = \sum_{i=1}^n \langle f, {S_n}^{-1} f_i\rangle f_i.$$

According to [5, 6], we say that the *projection method* works if

$$\langle f, {S_n}^{-1} f_i\rangle \to \langle f, S^{-1} f_i\rangle \text{ for } n \to \infty \ \forall f \in \mathcal{H}, \ \forall i \in N.$$

The "block structure" of the frame $\{f_i^n\}_{i=1,n=1}^{n+1,\infty}$ constructed here shows that the projection method can be used. As shown in [6] the method can also be used for every Riesz basis. The more general questions whether a frame contains a Riesz basis and whether the projection method works do not seem to be strongly related.

3. Excess preserving perturbation. At several places in the following we need results for perturbation of frames and Riesz bases. We denote the frames by $\{f_i\}_{i=1}^\infty, \{g_i\}_{i=1}^\infty$, usually with the convention that $\{f_i\}_{i=1}^\infty$ is the frame we begin with, and $\{g_i\}_{i=1}^\infty$ is the perturbed family. Common to all these results is that they can be formulated using the *perturbation operator* K mapping a sequence $\{c_i\}$ of numbers to $\sum c_i(f_i - g_i)$.

THEOREM 3.1. *Let $\{f_i\}_{i=1}^\infty, \{g_i\}_{i=1}^\infty \subseteq \mathcal{H}$.*

(a) *If $\{f_i\}_{i=1}^\infty$ is a frame for $\mathcal{H}$ and K is compact as an operator from $\ell^2(N)$ into $\mathcal{H}$, then $\{g_i\}_{i=1}^\infty$ is a frame for its closed linear span.*

(b) *Suppose $\{f_i\}_{i=1}^\infty$ is a frame for $\mathcal{H}$ with bounds A, B. If there exist numbers $\lambda, \mu \geq 0$ such that $\lambda + \frac{\mu}{\sqrt{A}} < 1$ and*

$$\left\| \sum c_i(f_i - g_i) \right\| \leq \lambda \cdot \left\| \sum c_i f_i \right\| + \mu \sqrt{\sum |c_i|^2}$$

for all finite sequences $\{c_i\}$, then $\{g_i\}_{i=1}^\infty$ is a frame for $\mathcal{H}$ with bounds $A(1 - (\lambda + \frac{\mu}{\sqrt{A}}))^2, B(1 + \lambda + \frac{\mu}{\sqrt{B}})^2$.

(c) *If $\{f_i\}_{i=1}^\infty$ is a Riesz basis for $\overline{\operatorname{span}}\{f_i\}_{i=1}^\infty$ and the perturbation condition in* (b) *is satisfied, then $\{g_i\}_{i=1}^\infty$ is a Riesz basis for $\overline{\operatorname{span}}\{g_i\}_{i=1}^\infty$.*

For the proofs we refer to [6, 7, 8]. As an easy consequence of (a) we have the following.

COROLLARY 3.2. *If $\{f_i\}_{i=1}^\infty$ is a frame and $\sigma \subseteq N$ is finite, then $\{f_i\}_{i \in N-\sigma}$ is a frame for $\overline{\operatorname{span}}\{f_i\}_{i \in N-\sigma}$.*

Our next result connects Theorem 3.1 with the question about overcompleteness of the involved frames.

THEOREM 3.3. *Suppose that $\{f_i\}_{i=1}^\infty$ is a frame containing a Riesz basis, that $\{g_i\}_{i=1}^\infty$ is total, and that K is compact as a mapping from $l^2(N)$ into $\mathcal{H}$. Then $\{g_i\}_{i=1}^\infty$ is a frame for $\mathcal{H}$ containing a Riesz basis, and the frames $\{f_i\}_{i=1}^\infty$ and $\{g_i\}_{i=1}^\infty$ have the same excess.*

Proof. First assume that $\{f_i\}_{i=1}^{\infty}$ has finite excess equal to n. By changing the index set we may write $\{f_i\}_{i=1}^{\infty} = \{f_i\}_{i=1}^{n} \cup \{f_i\}_{i=n+1}^{\infty}$, where $\{f_i\}_{i=n+1}^{\infty}$ is a Riesz basis for $\mathcal{H}$. Let A be a lower frame bound for $\{f_i\}_{i=n+1}^{\infty}$ and choose $\mu < \sqrt{A}$. By compactness there exists a number $m > n$ such that

$$\left\| \sum_{i=m+1}^{\infty} c_i(f_i - g_i) \right\| \leq \mu \sqrt{\sum_{i=m+1}^{\infty} |c_i|^2}$$

for all sets of sequences $\{c_i\} \subseteq l^2(N)$. So by the remark after Theorem 3.1, $\{g_i\}_{i=m+1}^{\infty}$ is a Riesz basis for $\overline{\text{span}}\{g_i\}_{i=m+1}^{\infty}$. If we define the operator T on $\mathcal{H}$ by

$$Tf_i = f_i, \ n < i \leq m, \quad Tf_i = g_i, \quad i \geq m+1$$

(extended by linearity), then we have an invertible operator on $\mathcal{H}$. The argument is that every $f \in \mathcal{H}$ has a representation $f = \sum_{i=n+1}^{\infty} c_i f_i$, leading to

$$||(I-T)f|| = \left\| \sum_{i=m+1}^{\infty} c_i(f_i - g_i) \right\|$$

$$\leq \mu \sqrt{\sum_{i=m+1}^{\infty} |c_i|^2} \leq \frac{\mu}{\sqrt{A}} \left\| \sum_{i=m+1}^{\infty} c_i f_i \right\| \leq \frac{\mu}{\sqrt{A}} \cdot ||f||.$$

As a consequence,

$$\text{codim}(\overline{\text{span}}\{g_i\}_{i=m+1}^{\infty}) = \ \text{codim}(\overline{\text{span}}\{f_i\}_{i=m+1}^{\infty}) = m - n.$$

Take $m-n$ independent elements $\{g_{i_k}\}_{k=1}^{m-n}$ outside $\overline{\text{span}}\{g_i\}_{i=m+1}^{\infty}$. Then $\{g_{i_k}\}_{k=1}^{m-n} \cup \{g_i\}_{i=m+1}^{\infty}$ is a frame for $\overline{\text{span}}\{\{g_{i_k}\}_{k=1}^{m-n} \cup \{g_i\}_{i=m+1}^{\infty}\} = \mathcal{H}$, since only finitely many elements have been taken away from the frame $\{g_i\}_{i=1}^{\infty}$. If $\sum_{k=1}^{m-n} c_k g_{i_k} + \sum_{i=m+1}^{\infty} c_i g_i = 0$ now, then all coefficients are zero; first,

$$\sum_{k=1}^{m-n} c_k g_{i_k} = -\sum_{i=m+1}^{\infty} c_i g_i = 0$$

(if the sums were not equal to zero we could delete an element g_{i_k} and still have a frame for $\mathcal{H}$ contradicting the fact that $\text{codim}(\overline{\text{span}}\{g_i\}_{i=m+1}^{\infty}) = m - n$) and since $\{g_{i_k}\}_{k=1}^{m-n}$ is an independent set and $\{g_i\}_{i=m+1}^{\infty}$ a Riesz basis, all coefficients must be zero. So $\{g_{i_k}\}_{k=1}^{m-n} \cup \{g_i\}_{i=m+1}^{\infty}$ is a Riesz basis, i.e., $\{g_i\}_{i=1}^{\infty}$ also has excess n.

Now suppose that $\{f_i\}_{i=1}^{\infty}$ has infinite excess. Let $\{f_i\}_{i\in I}$ be a subset which is a Riesz basis. Then the corresponding set $\{g_i\}_{i\in I}$ spans a space of finite codimension, i.e., $\text{codim}(\overline{\text{span}}\{g_i\}_{i\in I}) < \infty$. This follows by the same compactness argument as we used in the finite excess case, which shows that there exist finitely many $f_i, i \in I$ with the property that if we take them away then we obtain a family which spans a space with the same codimension as the corresponding space of g_i's. Now take a finite family $\{g_i\}_{i\in J}$ such that $\{g_i\}_{i\in I\cup J}$ is total. Since $\{f_i\}_{i\in I\cup J}$ is a frame with finite excess, the finite excess result gives that $\{g_i\}_{i\in I\cup J}$ is a frame containing a Riesz basis, implying that $\{g_i\}_{i=1}^{\infty}$ has infinite excess. □

We can express the result in the following way: define an equivalence relation $\sim$ on the set of frames for $\mathcal{H}$ by

$$\{f_i\}_{i=1}^{\infty} \sim \{g_i\}_{i=1}^{\infty} \Leftrightarrow K \text{ is compact as an operator from } l^2(N) \text{ into } \mathcal{H}.$$

The equivalence relation partitions the set of frames into equivalence classes. If a frame contains a Riesz basis, then every frame in its equivalence class contains a Riesz basis, and the frames have the same excess.

Let us go back to Theorem 3.3. If $\{g_i\}_{i=1}^{\infty}$ is not total, we still know (from Theorem 3.1) that $\{g_i\}_{i=1}^{\infty}$ is a frame for its closed span. By checking the proof of Theorem 3.3 we obtain the following corollary.

COROLLARY 3.4. *Suppose that $\{f_i\}_{i=1}^{\infty}$ is a frame containing a Riesz basis and that K is compact as a mapping from $\ell^2(N)$ into $\mathcal{H}$. Then $\{g_i\}_{i=1}^{\infty}$ is a frame for its closed linear span, and it contains a Riesz basis for this space. The excess referring to $\overline{\text{span}}\{g_i\}_{i=1}^{\infty}$ is equal to the excess of $\{f_i\}_{i=1}^{\infty}$ referring to $\mathcal{H}$, plus the dimension of the orthogonal complement of $\overline{\text{span}}\{g_i\}_{i=1}^{\infty}$ in $\mathcal{H}$.*

Now we want to study the excess property of perturbations in the sense of Theorem 3.1 (b). We need a result, which might be interesting in itself. To motivate it, consider a near-Riesz basis $\{f_i\}_{i=1}^{\infty}$ containing a Riesz basis $\{f_i\}_{i\in I}$. Unfortunately, the lower bound for $\{f_i\}_{i\in I}$ can be arbitrarily small compared to the lower bound A of $\{f_i\}_{i=1}^{\infty}$. Our result states that if we are willing to delete sufficiently (still finitely) many elements, then we can obtain a family which is a Riesz basis for its closed span and which has a lower bound as close to A as we want.

PROPOSITION 3.5. *Let $\{f_i\}_{i=1}^{\infty}$ be a near-Riesz basis with lower bound A. Given $\epsilon > 0$, there exists a finite set $J \subseteq N$ such that $\{f_i\}_{i\in N-J}$ is a Riesz basis for its closed span, with lower bound $A-\epsilon$.*

Proof. As in the proof of Theorem 3.3, write $\{f_i\}_{i=1}^{\infty} = \{f_i\}_{i=1}^{n} \cup \{f_i\}_{i=n+1}^{\infty}$, where $\{f_i\}_{i=n+1}^{\infty}$ is a Riesz basis for $\mathcal{H}$. Let $d(\cdot,\cdot)$ denote the distance inside $\mathcal{H}$ (i.e., $d(f,E) = \inf_{g\in E}||f-g||$ for $f \in \mathcal{H}, E \subseteq \mathcal{H}$) and choose a number $m > n$ such that

$$d(f_j,\ \text{span}\{f_i\}_{i=n+1}^{m}) < \sqrt{\frac{\epsilon}{n}},\quad j = 1, ..., n.$$

We want to show that $\{f_i\}_{i=m+1}^{\infty}$ is a Riesz basis for its closed span, with lower bound $A-\epsilon$. Let P denote the orthogonal projection onto $\overline{\text{span}}\{f_i\}_{i=n+1}^{m}$. Since $||\sum c_i f_i|| \geq ||\sum c_i(I-P)f_i||$ for all sequences, it suffices to show that $\{(I-P)f_i\}_{i=m+1}^{\infty}$ satisfies the lower Riesz basis condition with bound $A-\epsilon$. Let $f \in (I-P)\mathcal{H}$. Then

$$\sum_{i=m+1}^{\infty} |\langle f, (I-P)f_i\rangle|^2 = \sum_{i=1}^{\infty} |\langle f, (I-P)f_i\rangle|^2 - \sum_{i=1}^{n} |\langle f, (I-P)f_i\rangle|^2$$
$$\geq A||f||^2 - \sum_{i=1}^{n} ||f||^2 \cdot ||(I-P)f_i||^2 \geq (A-\epsilon)||f||^2.$$

To conclude that $\{(I-P)f_i\}_{i=m+1}^{\infty}$ has lower Riesz basis bound $A-\epsilon$, we only have to show that $\{(I-P)f_i\}_{i=m+1}^{\infty}$ is ω-independent. But if $\sum_{i=m+1}^{\infty} c_i(I-P)f_i = 0$, then $\sum_{i=m+1}^{\infty} c_i f_i = P\sum_{i=m+1}^{\infty} c_i f_i$, implying that both sides are equal to zero, since $P\sum_{i=m+1}^{\infty} c_i f_i \in \text{span}\{f_i\}_{i=n+1}^{m}$ and $\{f_i\}_{i=n+1}^{\infty}$ is ω-independent. Therefore $c_i = 0$ for all i. ∎

THEOREM 3.6. *Let $\{f_i\}_{i=1}^{\infty}$ be a frame for $\mathcal{H}$ with bounds A, B. Let $\{g_i\}_{i=1}^{\infty} \subseteq \mathcal{H}$ and assume that there exist $\lambda, \mu \geq 0$ such that $\lambda + \frac{\mu}{\sqrt{A}} < 1$ and*

$$\left\|\sum c_i(f_i - g_i)\right\| \leq \lambda \cdot \left\|\sum c_i f_i\right\| + \mu \cdot \sqrt{\sum |c_i|^2}$$

for all finite sequences $\{c_i\}$. Then

$$\{f_i\}_{i=1}^{\infty} \text{ is a near-Riesz basis} \Leftrightarrow \{g_i\}_{i=1}^{\infty} \text{ is a near-Riesz basis},$$

in which case $\{f_i\}_{i=1}^{\infty}$ and $\{g_i\}_{i=1}^{\infty}$ have the same excess.

Proof. First assume that $\{f_i\}_{i=1}^{\infty}$ is a near-Riesz basis with excess n. Let m be chosen as in the proof of Proposition 3.5, corresponding to an ϵ satisfying the condition $\lambda + \frac{\mu}{\sqrt{A-\epsilon}} < 1$. Let Q denote the orthogonal projection onto $\overline{\text{span}}\{f_i\}_{i=m+1}^{\infty}$. Then every element $f \in \mathcal{H}$ can be written $f = (I-Q)f + Qf = (I-Q)f + \sum_{i=m+1}^{\infty} c_i f_i$ for some coefficients c_i. Now define an operator $T : \mathcal{H} \to \mathcal{H}$ by

$$Tf = f, \ f \in \overline{\text{span}}\{f_i\}_{i=m+1}^{\infty}{}^{\perp}, \ \ Tf_i = g_i, \ i \geq m+1.$$

T is bounded. Given $f \in \mathcal{H}$ we choose a representation as above. Then

$$||(I-T)f|| = \left\| \sum_{i=m+1}^{\infty} c_i(f_i - g_i) \right\| \leq \lambda \cdot \left\| \sum_{i=m+1}^{\infty} c_i f_i \right\| + \mu \cdot \sqrt{\sum_{i=m+1}^{\infty} |c_i|^2}$$

$$\leq (\lambda + \frac{\mu}{\sqrt{A-\epsilon}}) \left\| \sum_{i=m+1}^{\infty} c_i f_i \right\| = \left(\lambda + \frac{\mu}{\sqrt{A-\epsilon}} \right) ||Qf|| \leq \left(\lambda + \frac{\mu}{\sqrt{A-\epsilon}} \right) ||f||.$$

It follows that T is an isomorphism of $\mathcal{H}$ onto $\mathcal{H}$. So $\{g_i\}_{i=m+1}^{\infty}$ is a Riesz basis for its closed span, and

$$\dim(\overline{\text{span}}\{g_i\}_{i=m+1}^{\infty}{}^{\perp}) = \dim(\overline{\text{span}}\{f_i\}_{i=m+1}^{\infty}{}^{\perp}).$$

As a consequence, $\{f_i\}_{i=1}^{\infty}$ and $\{g_i\}_{i=1}^{\infty}$ have the same excess.

Now assume that $\{g_i\}_{i=1}^{\infty}$ is a near-Riesz basis. By reindexing we may again assume that $\{g_i\}_{i=n+1}^{\infty}$ is a Riesz basis for $\mathcal{H}$. Define a bounded operator $W : \mathcal{H} \to \mathcal{H}$ by $Wf := \sum_{i=1}^{\infty} \langle f, S^{-1}f_i \rangle g_i$. Then as in the original proof from [7], one proves that W is an isomorphism of $\mathcal{H}$ onto $\mathcal{H}$. If we define $W_n : \mathcal{H} \to \mathcal{H}$ by $W_n f = \sum_{i=n+1}^{\infty} \langle f, S^{-1}f_i \rangle g_i$, then this operator has a range with finite codimension in $\mathcal{H}$, which we will write as

$$\text{codim}_{\mathcal{H}}(R_{W_n}) < \infty.$$

Now let $\{e_i\}_{i=1}^{\infty}$ be the natural basis for $l^2(N)$; i.e., e_i is the sequence with 1 in the ith entry, otherwise 0. There exists a bounded invertible operator $V : \mathcal{H} \to \overline{\text{span}}\{e_i\}_{i=n+1}^{\infty}$ such that $Vg_i = e_i$ for $i \geq n+1$, and clearly

$$\text{codim}_{\overline{\text{span}}\{e_i\}_{i=n+1}^{\infty}}(R_{VW_n}) < \infty.$$

Observe that $VW_n f = \sum_{i=n+1}^{\infty} \langle f, S^{-1}f_i \rangle e_i = \{\langle f, S^{-1}f_i \rangle\}_{i=n+1}^{\infty}$. So

$$(VW_n)^*\{c_i\} = \sum_{i=n+1}^{\infty} c_i S^{-1} f_i = S^{-1} \sum_{i=n+1}^{\infty} c_i f_i.$$

Since $R_{VW_n}^{\perp} = N_{(VW_n)^*}$ has finite dimension, $\{c_i\}_{i=n+1}^{\infty} \longmapsto \sum_{i=n+1}^{\infty} c_i f_i$ also has a finite dimensional kernel. Therefore

$$T : \ell^2(N) \to \mathcal{H}, \ \ T\{c_i\}_{i=1}^{\infty} = \sum_{i=1}^{\infty} c_i f_i$$

has a finite dimensional kernel, and now the theorem of Holub implies that $\{f_i\}_{i=1}^{\infty}$ is a near-Riesz basis. By the first part of the theorem the two frames $\{f_i\}_{i=1}^{\infty}$ and $\{g_i\}_{i=1}^{\infty}$ now have the same excess, and the proof is complete. □

Example 2. Let us use Theorem 3.6 to give another argument in Example 1. We consider $\{g_i\}_{i=1}^{\infty}$ as a perturbation of the frame $\{f_i\}_{i=1}^{\infty}$, where

$$f_1 = e_1, \qquad f_i = e_{i-1}, \quad i \geq 2.$$

$\{f_i\}_{i=1}^{\infty}$ is a frame with excess 1 and bounds $A = 1, B = 2$. Since

$$\left\|\sum_{i=1}^{\infty} c_i(f_i - g_i)\right\| = \left\|\sum_{i=2}^{\infty} c_i \frac{1}{i} e_i\right\| \le \frac{1}{2}\left[\sum_{i=1}^{\infty} |c_i|^2\right]^{1/2} \quad \forall \{c_i\}_{i=1}^{\infty} \in \ell^2(N),$$

we conclude by Theorems 3.1 and 3.6 that $\{g_i\}_{i=1}^{\infty}$ is a frame with bounds $(1 - \frac{1}{2})^2 = \frac{1}{4}$, $2(1 + \frac{1}{2\sqrt{2}})^2$, and excess 1.

Unfortunately, the requirement that $\{f_i\}_{i=1}^{\infty}$ has finite excess is needed in Theorem 3.6. In fact we are able to construct examples, where $\{f_i\}$ is a tight frame with infinite excess and $\{g_i\}$ does not contain a Riesz basis but where the perturbation condition is satisfied. Let us shortly describe how one can do this. Define $\{f_i^n\}_{i=1,n=1}^{n+1,\infty}$ as in Lemma 2.7. Given $\epsilon > 0$, let

$$g_i^n = e_{\frac{(n-1)n}{2}+i} - \frac{1-\epsilon}{n}\sum_{j=1}^{n} e_{\frac{(n-1)n}{2}+j}, \quad 1 \le i \le n,$$

$$g_{n+1}^n = \frac{1}{\sqrt{n}}\sum_{j=1}^{n} e_{\frac{(n-1)n}{2}+j}.$$

Now, given a sequence $\{c_i^n\}$ we have

$$\left\|\sum c_i^n(f_i^n - g_i^n)\right\| = \epsilon \cdot \left\|\sum_{n=1}^{\infty}\left[\sum_{i=1}^{n} c_i^n\right]\frac{1}{n}\sum_{j=1}^{\infty} e_{\frac{(n-1)n}{2}+j}\right\|$$

$$\le \epsilon\sqrt{\sum_{n=1}^{\infty}\left|\sum_{i=1}^{n} c_i^n \frac{1}{\sqrt{n}}\right|^2} \le \epsilon\sqrt{\sum |c_i^n|^2}. \tag{3}$$

By Lemma 2.5, $\{f_i^n\}_{i=1,n=1}^{n,\infty}$ is a frame with bounds 1. If we choose $\epsilon < 1$, then the perturbation condition is satisfied with $\lambda = 0, \mu = \epsilon$, implying that $\{g_i^n\}_{i=1,n=1}^{n+1,\infty}$ is a frame with bounds $(1-\epsilon)^2, (1+\epsilon)^2$.

Claim. $\{g_i^n\}_{i=1,n=1}^{n,\infty}$ is a Riesz basis for $\mathcal{H}$. We only need to prove that $\{g_i^n\}_{i=1,n=1}^{n,\infty}$ satisfies the lower Riesz basis condition. Given a sequence $\{c_i^n\}$ we have

$$\left\|\sum_{n=1}^{\infty}\sum_{i=1}^{n} c_i^n g_i^n\right\| \ge \left\|\sum_{n=1}^{\infty}\sum_{i=1}^{n} c_i^n e_{\frac{(n-1)n}{2}+i}\right\| - (1-\epsilon)\left\|\sum_{n=1}^{\infty}\left(\sum_{i=1}^{n} c_i^n\right)\frac{1}{n}\sum_{i=1}^{n} e_{\frac{(n-1)n}{2}+i}\right\|$$

$$\ge \sqrt{\sum |c_i^n|^2} - (1-\epsilon)\sqrt{\sum_{n=1}^{\infty}|\sum_{i=1}^{n} c_i^n \frac{1}{\sqrt{n}}|^2} \ge \epsilon\sqrt{\sum |c_i^n|^2}.$$

So actually we have an example where $\{f_i^n\}_{i=1,n=1}^{n+1,\infty}$ does not contain a Riesz basis but the perturbed family does. To obtain the example we were looking for, we use the fact that $\{g_i^n\}$ has the lower bound $(1-\epsilon)^2$. By (3) above we can consider $\{f_i^n\}$ as a perturbation of $\{g_i^n\}$ if $\frac{\epsilon}{1-\epsilon} < 1$, i.e., if $\epsilon < \frac{1}{2}$. So we get our example by choosing $\epsilon < 1/2$ and switching the roles of $\{f_i^n\}$ and $\{g_i^n\}$.

Example 3. A Weyl–Heisenberg frame is a frame for $L^2(R)$ of the form

$$\{f_{m,n}\}_{m,n\in Z} = \{e^{imbx} f(x - na)\}_{m,n\in Z},$$

where $f \in L^2(R),\ a, b > 0$. It is well known that $\{f_{m,n}\}_{m,n\in Z}$ is a frame for $L^2(R)$ if f has support in an interval of length $1/b$ and

$$\exists A, B > 0 :\ A \leq \sum_{n\in Z} |f(x - na)|^2 \leq B,\ \text{a.e.}$$

This can only be satisfied if $ab \leq 1$. The case $ab = 1$ implies that $\{f_{m,n}\}_{m,n\in Z}$ is a Riesz basis, cf. [2, 3]. Heil [11, p. 139] has shown that if $ab < 1$, then there exist finite sets $F \subseteq Z\times Z$ of arbitrarily large cardinality such that $\{f_{m,n}\}_{(m,n)\in Z^2-F}$ is a frame. That is, if $\{f_{m,n}\}_{m,n\in Z}$ contains a Riesz basis, then $\{f_{m,n}\}_{m,n\in Z}$ has infinite excess.

Acknowledgments. The second author would like to thank Chris Heil for fruitful discussions on the subject.

1. Problem statement. In this article, we give a class of optimally stable solutions to Tietze's extension problem in general, metrically convex compact metric spaces. The extensions which solve this problem are the unique stationary states of nonlinear processes of regularization. The title is suggested by the formal analogy between the processes that we describe and the process of harmonic regularization (the classical process of diffusion). This analogy is briefly indicated at the end of this section and in section 4 of the paper.

Let (E, d) denote any metric space, and let f be any scalar-valued continuous function whose domain is a closed nonempty subset of E. Since Tietze's original result, which produced a continuous extension $\mathcal{E}(f)$ of f, several solutions have been proposed to improve the quality of the extension. Kakutani (in separable metric spaces) and Dugundji [2] (in a more general case than the metric case) have proposed linear and positive schemes $f \mapsto \mathcal{E}(f)$. These schemes are optimally data-value stable (DV-stable); that is,

$$\|\mathcal{E}(f) - \mathcal{E}(g)\|_{\infty,E} \leq D\|f - g\|_{\infty,A},$$

with $D = 1$, for any pair of scalar-valued continuous functions f, g with common domain A. Here the symbol $\|.\|_\infty$ denotes the usual supremum norm. When $E = \mathbb{R}^n$, linear optimally DV-stable schemes exist which are, moreover, Ω-stable. That is, they satisfy

$$\hat{\omega}(\mathcal{E}(f)) \leq C\hat{\omega}(f),$$

where C denotes a constant which does not depend on f and $\hat{\omega}(g)$ denotes the concave modulus of continuity of g. These schemes are obtained [1] by both improving the original construction of Whitney [7] and a result of Glaeser [3]. It is well known that, in the multidimensional case ($n > 1$), these linear schemes cannot be optimally Ω-stable ($C > 1$).

By improving a scheme of Mc Shane [5], we have obtained an optimally Ω-stable ($C = 1$) extension scheme $\mathcal{E}$, which is, moreover, DV-stable with $D \leq 3$, and also data-site stable [4]. Let us recall that $\mathcal{E}$ is defined by $\mathcal{E}(f)(x) := \sup_{a \in dom(f)}(f(a) - \hat{\omega}(f; d(x, a)))$. It can be shown that this scheme $\mathcal{E}$ is self-reproducing. That is,

$\mathcal{E}(\mathcal{E}(f)|B) = \mathcal{E}(f)$ for any f as above and any closed subset B of E containing $\mathrm{dom}(f)$ (the symbol "|" denotes restriction to). This scheme is not a local scheme because the modulus of continuity of a function is not a local notion. The concept of locality, which is, in smooth spaces, closely related to PDE (see section 4), has the following simple formulation: an extension scheme $\mathcal{E}$ is said to be *local* if $\mathcal{E}(\mathcal{E}(f)|\partial B)|B = \mathcal{E}(f)|B$ for any f as above and for any closed and bounded subset B of E with boundary ∂B such that the interior of B does not intersect $\mathrm{dom}(f)$.

In this paper, we produce, when (E, d) is any metrically convex compact metric space, a class of extension schemes which are both optimally Ω-stable and optimally DV-stable. Moreover, we establish (Proposition 3.9) the quasi-data-site stability, the quasi-locality, and the quasi-self-reproduction of some schemes of this class. For each extension scheme $\mathcal{K}$ of our class, the extension $\mathcal{K}(f)$ of f is obtained as follows. Starting with any continuous extension f_0 of f (Tietze's theorem ensures that such an extension exists), we define inductively a sequence $(f_n)_{n\in\mathbb{N}}$ of continuous extensions of f by

$$f_{n+1}(x) := \tilde{f}_n(x) := \frac{1}{2}\sup_{u\in D(x)} f_n(u) + \frac{1}{2}\inf_{u\in D(x)} f_n(u), x \in E,$$

where $D(x) :=$ ball centered at x of radius $r(x)$ satisfying $r(x) = 0 \iff x \in \mathrm{dom}(f)$; $|r(x) - r(y)| \le d(x, y), x, y \in E$.

The extension $\mathcal{K}(f)$ of f is the limit of this sequence, that is, the stationary state of the process of regularization $g \to \tilde{g}$. This stationary state does not depend on the initial state f_0.

Let us note, when E is a Euclidean space, the formal analogy between the process $g \mapsto \tilde{g}$ and the process of harmonic regularization $g \mapsto \hat{g}$ defined by

$$\hat{g}(x) = \int_{y\in D(x)} g(y)dy \Big/ \int_{y\in D(x)} dy, x \in E,$$

for which it is known [6] that the stationary states are harmonic functions.[1] It is this analogy which has led us to call the processes $g \mapsto \tilde{g}$ processes of harmonious regularization. It does not seem impossible to us that the processes of harmonious regularization, which regularize by ordering (the processes of harmonic regularization regularize by homogenizing) could occur in some model of the morphogenesis of ordered states of materials.

From a technical point of view, we prove the existence of harmonious extensions with the help of Ascoli's theorem and of Schauder's fixed point theorem. The nonlinearity of the harmonious extension schemes makes the proof of the uniqueness more difficult than in the harmonic case (see Theorem 3.3). Schauder's theorem is insufficient to prove the convergence of our processes to their stationary states: our proof needs an analysis of the story of the processes of harmonious regularization (see Theorem 3.5).

2. Preliminaries. Let us first recall some definitions. We call *concave modulus of continuity* any mapping $\omega : \mathbb{R}^+ \to \mathbb{R}^+$ which satisfies the following:

(i) $\omega(0) = 0$ and ω is continuous at 0;

(ii) ω is increasing: $h_1 \le h_2 \Rightarrow \omega(h_1) \le \omega(h_2)$;

[1] We are indebted to Prof. Y. Guivarc'h, who brought the result of W.A. Veech to our attention.

(iii) ω is concave: $\forall(\lambda_i)_{i=1,\dots,n}, 0 \le \lambda_i \le 1, \sum_{i=1}^n \lambda_i = 1$,

$$\forall(h_i)_{i=1,\dots,n}, \sum_{i=1}^n \lambda_i \omega(h_i) \le \omega\left(\sum_{i=1}^n \lambda_i h_i\right).$$

Let (E,d) be any metric space and let f be any function from E to $\mathbb{R}$. We say that f is Ω-continuous if there exists a concave modulus of continuity ω such that, for any $x, y \in E$,

$$|f(y) - f(x)| \le \omega(d(x,y)).$$

For such a function f, the lower bound of those concave moduli of continuity which satisfy the inequality above is still a concave modulus of continuity which satisfies this inequality. We denote it by $\hat{\omega}(f)$.

Any Ω-continuous function is uniformly continuous. Any bounded and uniformly continuous function is Ω-continuous. Therefore, any continuous function from a compact metric space to $\mathbb{R}$ is Ω-continuous.

A metric space (E,d) is said to be *metrically convex* if, for any $x, y \in E$ and for any real r, $0 \le r \le d(x,y)$, there exists some $z \in E$ such that $d(x,z) = r$ and $d(x,z) + d(z,y) = d(x,y)$.

Moreover, let us recall the following formulas:

$$\sup_{i\in I} x_i - \sup_{j\in J} y_j = \sup_{i\in I} \inf_{j\in J} (x_i - y_j); \tag{1}$$

$$\inf_{i\in I} x_i - \inf_{j\in J} y_j = \sup_{j\in J} \inf_{i\in I} (x_i - y_j); \tag{2}$$

$$\sup_{i\in I} x_i - \sup_{i\in I} y_i \le \sup_{i\in I} (x_i - y_i); \tag{3}$$

$$\inf_{i\in I} x_i - \inf_{i\in I} y_i \le \sup_{i\in I} (x_i - y_i). \tag{4}$$

The main results of this paper are contained in Theorems 3.3 and 3.5 below. From now on, (E,d) denotes any metrically convex compact metric space, A any closed nonempty subset of E, and r any mapping from E to $\mathbb{R}^+$ which satisfies the following:

(i) $r(x) = 0$ iff $x \in A$;

(ii) $|r(x) - r(y)| \le d(x,y), x, y \in E$.

Let us note here that such mappings r exist:

(i) $r(x) := \rho d(x,A), 0 < \rho \le 1$;

(ii) $r(x) := \inf(h, d(x,A)), h > 0$.

We denote by $D(x)$ the ball of center x, radius $r(x)$:

$$D(x) := \{y \in E : d(x,y) \le r(x)\}.$$

We start with a geometrical lemma.

LEMMA 2.1. *For any $x, y \in E$, we have*

$$\frac{1}{2} \sup_{u\in D(x)} \inf_{v\in D(y)} d(u,v) + \frac{1}{2} \sup_{v\in D(y)} \inf_{u\in D(x)} d(u,v) \le d(x,y).$$

Proof. Let us first establish that, for any $x, v \in E$ such that $d(x,v) \geq r(x)$, we have

$$\inf_{u \in D(x)} d(u,v) = d(x,v) - r(x).$$

To prove this inequality, we note that, by convexity, there exists $z \in E$ such that $d(x,z) = r(x)$ and $d(z,v) = d(x,v) - r(x)$. Thus we have $z \in D(x)$. Moreover, for any $u \in D(x)$, we have, by the triangle inequality,

$$d(x,v) \leq d(x,u) + d(u,v) \leq r(x) + d(u,v).$$

We infer that $d(u,v) \geq d(x,v) - r(x) = d(z,v)$ and, therefore, that

$$\inf_{u \in D(x)} d(u,v) = d(z,v) = d(x,v) - r(x),$$

which is the stated equality.

Now let $x, y \in E$ be such that there exists $v \in D(y)$, $d(x,v) \geq r(x)$. Using the equality above, the triangle inequality, and the definition of $D(y)$, we have

$$\begin{aligned} \sup_{v \in D(y)} \inf_{u \in D(x)} d(u,v) &\leq \sup_{v \in D(y)} d(x,v) - r(x) \\ &\leq \sup_{v \in D(y)} (d(x,y) + d(y,v)) - r(x) \\ &\leq d(x,y) + r(y) - r(x). \end{aligned}$$

We are now ready to prove the inequality of Lemma 2.1.

First case: $D(x) \subset D(y)$. In this case we have

$$\sup_{u \in D(x)} \inf_{v \in D(y)} d(u,v) = 0$$

and, by the inequality just established,

$$\sup_{v \in D(y)} \inf_{u \in D(x)} d(u,v) \leq d(x,y) + r(y) - r(x).$$

The result follows in this case since, by hypothesis, we have $|r(x) - r(y)| \leq d(x,y)$.

Second case: $D(y) \subset D(x)$. This case is similar to the first one.

Third case: $D(y) \not\subset D(x)$ and $D(x) \not\subset D(y)$. In this case we can apply twice the inequality previously established:

$$\begin{aligned} \frac{1}{2} \sup_{u \in D(x)} \inf_{v \in D(y)} d(u,v) + \frac{1}{2} \sup_{v \in D(y)} \inf_{u \in D(x)} d(u,v) &\leq \frac{1}{2}(d(x,y) + r(y) - r(x)) \\ &\quad + \frac{1}{2}(d(x,y) + r(x) - r(y)) \\ &\leq d(x,y), \end{aligned}$$

which is the stated result. ∎

3. Main results.

DEFINITION 3.1. *For any bounded function f from E to $\mathbb{R}$ we define a new bounded function $\tilde{f}$ from E to $\mathbb{R}$, called the harmonious regularization of f, by*

$$\tilde{f}(x) = \frac{1}{2}\sup_{u\in D(x)} f(u) + \frac{1}{2}\inf_{u\in D(x)} f(u), x \in E.$$

PROPOSITION 3.2. (i) *For any uniformly continuous function f from E to $\mathbb{R}$, we have*

$$\hat{\omega}(\tilde{f}) \leq \hat{\omega}(f);$$

(ii) *For any bounded functions f, g from E to $\mathbb{R}$, we have*

$$\|\tilde{f} - \tilde{g}\|_{\infty,E} \leq \|f - g\|_{\infty,E}.$$

Proof. (i) Let $x, y \in E$. We have

$$\begin{aligned}
\tilde{f}(x) - \tilde{f}(y) &= \frac{1}{2}\left(\sup_{u\in D(x)} f(u) + \inf_{u\in D(x)} f(u)\right) - \frac{1}{2}\left(\sup_{v\in D(y)} f(v) + \inf_{v\in D(y)} f(v)\right) \\
&= \frac{1}{2}\sup_{u\in D(x)}\inf_{v\in D(y)}(f(u) - f(v)) + \frac{1}{2}\sup_{v\in D(y)}\inf_{u\in D(x)}(f(u) - f(v)) \\
&\leq \frac{1}{2}\sup_{u\in D(x)}\inf_{v\in D(y)}\hat{\omega}(f; d(u,v)) + \frac{1}{2}\sup_{v\in D(y)}\inf_{u\in D(x)}\hat{\omega}(f; d(u,v)) \\
&\leq \frac{1}{2}\hat{\omega}\left(f; \sup_{u\in D(x)}\inf_{v\in D(y)} d(u,v)\right) + \frac{1}{2}\hat{\omega}\left(f; \sup_{v\in D(y)}\inf_{u\in D(x)} d(u,v)\right) \\
&\leq \hat{\omega}\left(f; \frac{1}{2}\sup_{u\in D(x)}\inf_{v\in D(y)} d(u,v) + \frac{1}{2}\sup_{v\in D(y)}\inf_{u\in D(x)} d(u,v)\right) \\
&\leq \hat{\omega}(f; d(x,y)).
\end{aligned}$$

The first equality is a consequence of the definition of $\tilde{f}$, and the second comes from formulas (1) and (2). The first inequality follows from the definition of $\hat{\omega}(f)$, the second from the monotonicity of $\hat{\omega}(f)$, the third from the concavity of $\hat{\omega}(f)$, and the last from Lemma 2.1 and from the monotonicity of $\hat{\omega}(f)$. We finish the proof by an exchange of the roles of x and y.

(ii) This assertion follows immediately from formulas (3) and (4). □

We are now ready to establish the following theorem.

THEOREM 3.3. *Any continuous function f from A to $\mathbb{R}$ has a unique continuous extension $\mathcal{K}(f)$ from E to $\mathbb{R}$ which satisfies the functional equation*

$$g(x) = \frac{1}{2}\sup_{u\in D(x)} g(u) + \frac{1}{2}\inf_{u\in D(x)} g(u). \tag{5}$$

Proof. Existence: let $\mathcal{C}^0(E,\mathbb{R})$ be the Banach space of all continuous mappings from E to $\mathbb{R}$ with the norm $\|.\|_{\infty,E}$ of the uniform convergence. Let

$$K := \{g \in \mathcal{C}^0(E,\mathbb{R}) : g \text{ extends } f, \|g\|_{\infty,E} \leq \|f\|_{\infty,A}, \hat{\omega}(g) \leq \hat{\omega}(f)\}.$$

Using the result of Mc Shane ([5, Theorem 2 and Corollary 2]), K is a nonempty subset of $\mathcal{C}^0(E,\mathbb{R})$. Let $g_1, g_2 \in K, 0 \leq \lambda \leq 1, g := (1-\lambda)g_1 + \lambda g_2$. It is immediate that g is a continuous extension of f and that

$$\|g\|_{\infty,E} \leq \|f\|_{\infty,A}.$$

Moreover, for any $x, y \in E$, we have

$$|g(x) - g(y)| \leq (1-\lambda)\hat{\omega}(g_1; d(x,y)) + \lambda\hat{\omega}(g_2; d(x,y)) \leq \hat{\omega}(f; d(x,y));$$

that is, $\hat{\omega}(g) \leq \hat{\omega}(f)$. We infer that K is a convex subset of $\mathcal{C}^0(E,\mathbb{R})$. This set K is closed and, by Ascoli's theorem, it is, moreover, a compact subset of $\mathcal{C}^0(E,\mathbb{R})$. Using Proposition 3.2, we have $\|\tilde{g}\|_{\infty,E} \leq \|g\|_{\infty,E}$ and $\hat{\omega}(\tilde{g}) \leq \hat{\omega}(g)$. Therefore, the operator $g \mapsto \tilde{g}$ maps K into K. Using Proposition 3.2 (ii), this operator is a continuous mapping. The proof of the existence follows now from Schauder's fixed point theorem.

Uniqueness: let g and h be two continuous extensions of f which satisfy the functional equation (5). Let us set

$$\Delta := \sup_{x\in E}(g(x) - h(x)), \quad F := \{x \in E : g(x) - h(x) = \Delta\},$$

$$M := \sup_{x\in F} g(x), \quad G := \{x \in F : g(x) = M\}.$$

The set G is nonempty because E is compact and because g and h are continuous mappings. Let us first show that $D(x) \subset F$ for any $x \in G$. Let us assume, by way of a contradiction, that there exists $x \in G$ such that $D(x) \not\subset F$. Since $G \subset F$ and since g and h are two extensions of f which satisfy (5), we have

$$\Delta = g(x) - h(x) = \frac{1}{2}\sup_{z\in D(x)} g(z) - \frac{1}{2}\sup_{z\in D(x)} h(z) + \frac{1}{2}\inf_{z\in D(x)} g(z) - \frac{1}{2}\inf_{z\in D(x)} h(z).$$

Since, by formula (4) and by definition of Δ we have

$$\inf_{z\in D(x)} g(z) - \inf_{z\in D(x)} h(z) \leq \sup_{z\in D(x)} (g(z) - h(z)) \leq \Delta,$$

we infer that

$$\Delta \leq \sup_{z\in D(x)} g(z) - \sup_{z\in D(x)} h(z). \tag{6}$$

Then let $y \in D(x)$ such that $g(y) = \sup_{z\in D(x)} g(z)$. Since $g(x) = M$ and $x \in D(x)$, we infer that $g(y) \geq M$.

First case: $g(y) > M$. In this case, we have $y \notin F$ because, by definition of F and M, we have $g(z) \leq M$ for any $z \in F$. But by (6), we also have

$$\Delta \leq g(y) - \sup_{z\in D(x)} h(z) \leq g(y) - h(y) \leq \Delta,$$

that is, $\Delta = g(y) - h(y)$, from which we infer $y \in F$, a contradiction.

Second case: $g(y) = M$. In this case, as g extends f and satisfies (5), we have

$$g(x) = \frac{1}{2} \sup_{z \in D(x)} g(z) + \frac{1}{2} \inf_{z \in D(x)} g(z).$$

As $x \in G$, we have $g(x) = M$. Therefore, $\inf_{z \in D(x)} g(z) = M$, and it follows that for any $z \in D(x)$ we have $g(z) = M$. Since, by hypothesis, $D(x)$ is not contained in F, let $t \in D(x)$, $t \notin F$. We have $g(t) = M$. Applying (6) again, we obtain

$$\Delta \leq g(t) - \sup_{z \in D(x)} h(z) \leq g(t) - h(t) \leq \Delta.$$

Now, as in the first case, we obtain $\Delta = g(t) - h(t)$; therefore, $t \in F$, a contradiction.

We have therefore proved that, for any $x \in G$, $D(x)$ is a subset of F. Hence, for any $u \in D(x)$, we have $g(u) \leq M$. Applying (5) again, we infer that $g(u) = M$ for any $u \in D(x)$. In other words, for any $x \in G$, $D(x)$ is a subset of G.

Now let us show that $G \bigcap A \neq \emptyset$. Let us assume, again by way of contradiction, that the distance $d(G, A)$ from G to A is strictly positive, and let $x \in G$, $a \in A$ such that $d(x, a) = d(G, A) > 0$. Using the hypotheses on the mapping r, we have $r(a) = 0$, $r(x) > 0$, and $r(x) \leq d(x, A) \leq d(x, a)$. By convexity of (E, d), there exists $z \in E$ such that

(i) $d(x, z) = r(x)$;

(ii) $d(z, a) = d(x, a) - r(x)$.

From (i), we have $z \in D(x)$. Since $D(x)$ is a subset of G, we infer that $z \in G$. From (ii), we have $d(z, a) < d(G, A)$, a contradiction.

Now, as $G \subset F$, we also have $F \bigcap A \neq \emptyset$. As g and h are both extensions of f, we infer that $\Delta = 0$, that is, $g \leq h$. By exchanging the roles of g and h , we obtain $g = h$, which is the stated result. □

Remark 3.4. (1) A corollary of the proof of Theorem 3.3 (uniqueness) is that the harmonious extension schemes $\mathcal{K}$ satisfy the maximum principle.

(i) $\sup_{z \in E} \mathcal{K}(f)(z) = \sup\{f(a) : a \in \mathrm{dom}(f)\}$.

(ii) If there exists x belonging to $E - \mathrm{dom}(f)$ such that

$$\mathcal{K}(f)(x) = \sup_{z \in E} \mathcal{K}(f)(z),$$

then $\mathcal{K}(f)$ is constant in a neighborhood of x. Here, as usual, f denotes any scalar-valued continuous function whose domain is a closed nonempty subset of E.

(2) Another corollary of the proof of Theorem 3.3 is that

$$\hat{\omega}(\mathcal{K}(f)) \leq \hat{\omega}(f).$$

The properties of stability of the extension scheme $\mathcal{K}$ are formulated in Theorem 3.5 below. Hypotheses and notations are those of Theorem 3.3.

THEOREM 3.5. (i) *For any continuous function f_0 from E to $\mathbb{R}$ which extends f, the sequence $(f_n)_{n \in \mathbb{N}}$ inductively defined by $f_{n+1} = \tilde{f}_n$ converges to $\mathcal{K}(f)$.*

(ii) *If g is any continuous function from A to $\mathbb{R}$, then we have*

$$\|\mathcal{K}(f) - \mathcal{K}(g)\|_{\infty, E} \leq \|f - g\|_{\infty, A}.$$

Proof. To show (i), it is sufficient to prove that $\lim_{n \to \infty} D_n = 0$, where $D_n := \sup_{x \in E} |f_{n+1}(x) - f_n(x)|$.

Indeed, by definition of the harmonious regularization and from Proposition 3.2, the sequence $(f_n)_{n\in\mathbb{N}}$ is equicontinuous and equibounded. Therefore, by Ascoli's theorem, there exists a subsequence $(f_{\varphi(n)})_{n\in\mathbb{N}}$ which converges to a continuous extension of f denoted by g. Since, by Proposition 3.2(ii), the operator of harmonious regularization is continuous, we infer that

$$\lim_{n\to\infty} \tilde{f}_{\varphi(n)} = \tilde{g}.$$

Now, as $\tilde{f}_{\varphi(n)} = f_{\varphi(n)+1}$, the convergence to 0 of sequence D_n implies that

$$\lim_{n\to\infty} f_{\varphi(n)} = \lim_{n\to\infty} \tilde{f}_{\varphi(n)},$$

that is, $\tilde{g} = g$. From Theorem 3.3, we have $g = \mathcal{K}(f)$.

If the sequence $(f_n)_{n\in\mathbb{N}}$ did not converge to $\mathcal{K}(f)$, there would exist $\epsilon > 0$ and a subsequence $(f_{\psi(n)})_{n\in\mathbb{N}}$ such that $\|f_{\psi(n)} - \mathcal{K}(f)\|_{\infty,E} > \epsilon$ for any $n \in \mathbb{N}$. Using Proposition 3.2 and Ascoli's theorem again, we could, by the same argument, obtain a new subsequence converging to a continuous extension of f satisfying (5) and distinct from $\mathcal{K}(f)$, contradicting Theorem 3.3.

To prove that $\lim_{n\to\infty} D_n = 0$, we set

$$\Delta_n^+ := \sup_{x\in E}(f_{n+1}(x) - f_n(x)),$$

$$\Delta_n^- := \sup_{x\in E}(f_n(x) - f_{n+1}(x)).$$

We notice that the sequences $(\Delta_n^+)_{n\in\mathbb{N}}$ and $(\Delta_n^-)_{n\in\mathbb{N}}$ are positive because the functions f_n are extensions of f.

As $0 \le D_n \le \sup(\Delta_n^+, \Delta_n^-)$, it is sufficient to prove that $\lim_{n\to\infty} \Delta_n^+ = 0$ and $\lim_{n\to\infty} \Delta_n^- = 0$.

Let us show that these sequences are decreasing. From the definition of f_{n+1} and f_{n+2}, we have

$$\Delta_{n+1}^+ = \sup_{x\in E}\left(\frac{1}{2}\sup_{z\in D(x)} f_{n+1}(z) - \frac{1}{2}\sup_{z\in D(x)} f_n(z) + \frac{1}{2}\inf_{z\in D(x)} f_{n+1}(z) - \frac{1}{2}\inf_{z\in D(x)} f_n(z)\right).$$

Therefore, by formulas (3) and (4), we have

$$\sup_{z\in D(x)} f_{n+1}(z) - \sup_{z\in D(x)} f_n(z) \le \Delta_n^+$$

and

$$\inf_{z\in D(x)} f_{n+1}(z) - \inf_{z\in D(x)} f_n(z) \le \Delta_n^+.$$

It follows that $\Delta_{n+1}^+ \le \Delta_n^+$. The proof is similar for the sequence $(\Delta_n^-)_{n\in\mathbb{N}}$.

Now the proof of $\lim_{n\to\infty} D_n = 0$ and, therefore, the proof of (i) will be an immediate consequence of the following two lemmas.

LEMMA 3.6. *Let $\delta > 0$ and let $(u_n)_{n\in\mathbb{N}}$ be a decreasing sequence of positive numbers satisfying, for any integer n and for any strictly positive integer p,*

$$u_{n+p} \le 2^{-p}((2^p - p)u_n + \delta).$$

Then

$$\lim_{n\to\infty} u_n = 0.$$

From now on, we set $\delta := \hat{\omega}(f_0; \operatorname{diam}(E))$, where $\operatorname{diam}(E)$ denotes the diameter of the compact metric space E. Using Proposition 3.2(i), we have

$$|f_n(x) - f_n(y)| \le \delta$$

for any $n \in \mathbb{N}$, $x, y \in E$. □

LEMMA 3.7. *For any integer n and any strictly positive integer p, we have*

(i) $\Delta^+_{n+p} \le 2^{-p}((2^p - p)\Delta^+_n + \delta)$,

(ii) $\Delta^-_{n+p} \le 2^{-p}((2^p - p)\Delta^-_n + \delta)$.

Proof of Lemma 3.6. Let $p > 0$ and $a_p = 1 - 2^{-p}p$. By a recursive application of the hypothesis, we obtain, for any $k \in \mathbb{N}$, $k > 0$,

$$\begin{aligned} u_{kp} &\le a_p u_{(k-1)p} + \delta 2^{-p} \\ &\quad \cdots \\ &\le (a_p)^k u_0 + (1 + \cdots + (a_p)^{k-1})\delta 2^{-p} \\ &\le (a_p)^k u_0 + (1/(1 - a_p))\delta 2^{-p}. \end{aligned}$$

That is,

$$u_{kp} \le (a_p)^k u_0 + \delta/p.$$

The sequence $(u_n)_{n\in\mathbb{N}}$ is positive and decreasing and therefore converges. Thus its subsequence $(u_{kp})_{k\in\mathbb{N}}$ also converges to the same limit. Since $0 \le a_p < 1$, the inequality above shows that this limit is positive and smaller than δ/p. Lemma 3.6 follows since p can be chosen arbitrarily large. □

Proof of Lemma 3.7. The proofs of (i) and (ii) are similar. Let us show (i).

Let $n \in \mathbb{N}$ and $x_0 \in E$ such that $f_{n+1}(x_0) - f_n(x_0) = \Delta^+_n$. We define inductively two sequences $(x_k)_{k=0,\dots,n}$ and $(y_k)_{k=0,\dots,n-1}$ of elements of E by

(a) $y_0 := x_0$,

(b) x_{k+1} is chosen in $D(x_k)$ such that $f_{n-k}(x_{k+1}) = \sup_{z\in D(x_k)} f_{n-k}(z)$,

(c) y_{k+1} is chosen in $D(y_k)$ such that $f_{n-k-1}(y_{k+1}) = \inf_{z\in D(y_k)} f_{n-k-1}(z)$.

Now let p, k be integers, $1 \le p \le n$, $0 \le k \le p - 1$.

By definition of f_{n-k+1}, x_k, and x_{k+1}, we have

$$f_{n-k+1}(x_k) = \frac{1}{2}(f_{n-k}(x_{k+1}) + \inf_{z\in D(x_k)} f_{n-k}(z)).$$

Using this equality inductively for $k = 0, \dots, p - 1$, we obtain

$$f_{n+1}(x_0) = 2^{-p}\left(f_{n+1-p}(x_p) + \sum_{k=0}^{p-1} 2^{p-1-k} \inf_{z\in D(x_k)} f_{n-k}(z)\right).$$

Similarly, we also have

$$f_n(y_0) = 2^{-p}\left(f_{n-p}(y_p) + \sum_{k=0}^{p-1} 2^{p-1-k} \sup_{z\in D(y_k)} f_{n-k-1}(z)\right).$$

Now we write Δ_n^+ in the following form:

$$\Delta_n^+ = 2^{-p}\left(f_{n+1-p}(x_p) - f_{n-p}(y_p) + \inf_{z\in D(x_0)} f_n(z) - \sup_{z\in D(x_0)} f_{n-1}(z) + R_1 + S_1\right),$$

where

$$R_1 := \sum_{i=1}^{p-1} 2^{p-1-i} \inf_{z\in D(x_i)} f_{n-i}(z) - (2^{p-1}-1) \sup_{z\in D(x_0)} f_{n-1}(z),$$

$$S_1 := (2^{p-1}-1) \inf_{z\in D(y_0)} f_n(z) - \sum_{i=1}^{p-1} 2^{p-1-i} \sup_{z\in D(y_i)} f_{n-1-i}(z).$$

By the definitions of Δ_{n-p}^+ and δ, we have

$$\begin{aligned} f_{n+1-p}(x_p) - f_{n-p}(y_p) &= f_{n+1-p}(x_p) - f_{n-p}(x_p) + f_{n-p}(x_p) - f_{n-p}(y_p) \\ &\le \Delta_{n-p}^+ + \delta. \end{aligned}$$

Moreover, using $x_0 \in D(x_0)$ and the definition of f_n, we have

$$\begin{aligned} \inf_{z\in D(x_0)} f_n(z) - \sup_{z\in D(x_0)} f_{n-1}(z) &\le f_n(x_0) - \sup_{z\in D(x_0)} f_{n-1}(z) \\ &\le \frac{1}{2} \sup_{z\in D(x_0)} f_{n-1}(z) + \frac{1}{2} \inf_{z\in D(x_0)} f_{n-1}(z) - \sup_{z\in D(x_0)} f_{n-1}(z) \\ &\le \frac{1}{2}\left(\inf_{z\in D(x_0)} f_{n-1}(z) - \sup_{z\in D(x_0)} f_{n-1}(z)\right) \\ &\le 0. \end{aligned}$$

Therefore,

$$\Delta_n^+ \le 2^{-p}(\Delta_{n-p}^+ + \delta + R_1 + S_1). \tag{7}$$

Now it remains to bound R_1 and S_1. They are the first terms of sequences $(R_k)_{k=1,\dots,p-1}$ and $(S_k)_{k=1,\dots,p-1}$ defined by

$$R_k := \sum_{i=k}^{p-1} 2^{p-1-i} \inf_{z\in D(x_i)} f_{n-i}(z) - (2^{p-k}-1) \sup_{z\in D(x_{k-1})} f_{n-k}(z),$$

$$S_k := (2^{p-k}-1) \inf_{z\in D(y_{k-1})} f_{n+1-k}(z) - \sum_{i=k}^{p-1} 2^{p-1-i} \sup_{z\in D(y_i)} f_{n-1-i}(z).$$

Sublemma. *We have* (i)

$$R_k \le \left(2^{p-1-k} - \frac{1}{2}\right)\Delta_{n-1-k}^+ + R_{k+1}, k = 1, \dots, p-2, \tag{8}$$

$$R_{p-1} \le 0, \tag{9}$$

and (ii)

$$S_k \le \left(2^{p-1-k} - \frac{1}{2}\right)\Delta^+_{n-1-k} + S_{k+1}, k = 1, \dots, p-2, \tag{10}$$

$$S_{p-1} \le \frac{1}{2}\Delta^+_{n-p}. \tag{11}$$

Using part (i) of this sublemma, we have, therefore,

$$R_1 \le \left(2^{p-2} - \frac{1}{2}\right)\Delta^+_{n-2} + \left(2^{p-3} - \frac{1}{2}\right)\Delta^+_{n-3} + \cdots + \left(2 - \frac{1}{2}\right)\Delta^+_{n+1-p}.$$

Since sequence Δ^+_n is decreasing, we infer that

$$R_1 \le \left(2^{p-2} - \frac{1}{2} + 2^{p-3} - \frac{1}{2} + \cdots + 2 - \frac{1}{2}\right)\Delta^+_{n+1-p};$$

that is,

$$R_1 \le \left(2^{p-1} - \frac{p}{2} - 1\right)\Delta^+_{n-p}. \tag{12}$$

Similarly, using (10) and (11), we obtain

$$S_1 \le \left(2^{p-1} - \frac{p}{2} - \frac{1}{2}\right)\Delta^+_{n-p}. \tag{13}$$

Combining (7), (12) and (13), we arrive at

$$\Delta^+_n \le 2^{-p}((2^p - p)\Delta^+_{n-p} + \delta).$$

The stated result follows by the translation of n to $n + p$.

Proof of the sublemma. First let us show (8). Since $x_k \in D(x_{k-1})$, we have

$$\begin{aligned} -\sup_{z\in D(x_{k-1})} f_{n-k}(z) &\le -f_{n-k}(x_k) \\ &\le -\frac{1}{2}\sup_{z\in D(x_k)} f_{n-k-1}(z) - \frac{1}{2}\inf_{z\in D(x_k)} f_{n-k-1}(z). \end{aligned}$$

Using this inequality, we can bound R_k as follows:

$$\begin{aligned} R_k \le R_{k+1} &+ \left(2^{p-1-k} - \frac{1}{2}\right)\left[\inf_{z\in D(x_k)} f_{n-k}(z) - \inf_{z\in D(x_k)} f_{n-k-1}(z)\right] \\ &+ \frac{1}{2}\left(\inf_{z\in D(x_k)} f_{n-k}(z) - \sup_{z\in D(x_k)} f_{n-k-1}(z)\right). \end{aligned}$$

The expression in square brackets in this last inequality is directly bounded by Δ^+_{n-k-1}, and the last term is negative (by the argument used to prove inequality (7)).

Therefore, we obtain

$$R_k \le R_{k+1} + \left(2^{p-1-k} - \frac{1}{2}\right)\Delta^+_{n-k-1},$$

which is the stated inequality (8).

Moreover, since $x_{p-1} \in D(x_{p-1})$, we have

$$\begin{aligned} R_{p-1} &= \inf_{z \in D(x_{p-1})} f_{n-p+1}(z) - \sup_{z \in D(x_{p-2})} f_{n-p+1}(z) \\ &\leq f_{n-p+1}(x_{p-1}) - \sup_{z \in D(x_{p-2})} f_{n-p+1}(z). \end{aligned}$$

As, by construction, we have $x_{p-1} \in D(x_{p-2})$, we infer inequality (9).

The proof of (10) is similar to that of (8). It remains to bound S_{p-1}. We have

$$S_{p-1} = \inf_{z \in D(y_{p-2})} f_{n-p+2}(z) - \sup_{z \in D(y_{p-1})} f_{n-p}(z).$$

As $y_{p-1} \in D(y_{p-2})$, we have

$$S_{p-1} \leq f_{n-p+2}(y_{p-1}) - \sup_{z \in D(y_{p-1})} f_{n-p}(z).$$

Using the definition of $f_{n-p+2}(y_{p-1})$, we can write

$$\begin{aligned} S_{p-1} &\leq \frac{1}{2} \left(\sup_{z \in D(y_{p-1})} f_{n-p+1}(z) - \sup_{z \in D(y_{p-1})} f_{n-p}(z) \right) \\ &\quad + \frac{1}{2} \left(\inf_{z \in D(y_{p-1})} f_{n-p+1}(z) - \sup_{z \in D(y_{p-1})} f_{n-p}(z) \right) \\ &\leq \frac{1}{2} \Delta^+_{n-p} + \frac{1}{2} \left(f_{n-p+1}(y_{p-1}) - \sup_{z \in D(y_{p-1})} f_{n-p}(z) \right). \end{aligned}$$

Using now the definition of $f_{n-p+1}(y_{p-1})$, we have

$$\begin{aligned} f_{n-p+1}(y_{p-1}) &= \frac{1}{2} \sup_{z \in D(y_{p-1})} f_{n-p}(z) + \frac{1}{2} \inf_{z \in D(y_{p-1})} f_{n-p}(z) \\ &\leq \sup_{z \in D(y_{p-1})} f_{n-p}(z). \end{aligned}$$

Finally, we have $S_{p-1} \leq (1/2)\Delta^+_{n-p}$, which is inequality (11).

We have now finished the proof of the sublemma, of Lemma 3.2, and, therefore, of part (i) of Theorem 3.5.

Proof of Theorem 3.5(ii). Using a result of Dugundji [2], let f_0 and g_0 be two continuous functions from E to $\mathbb{R}$ which extend, respectively, f and g and are such that $\|f_0 - g_0\|_{\infty,E} \leq \|f - g\|_{\infty,A}$. Using Proposition 3.2, we have $\|f_n - g_n\|_{\infty,E} \leq \|f - g\|_{\infty,A}$, $n \in \mathbb{N}$. We obtain the stated result by letting n tend to ∞. □

Remark 3.8. By Theorem 3.5(i), we have a new proof of the existence of a continuous solution of functional equation (5) which extends f. This proof gives some information on the speed of convergence of the process of harmonious regularization.

From now on, we shall consider only those harmonious extension schemes $\mathcal{K}$ for which the radius $r(x)$ of the ball $D(x)$ used in the description of $\mathcal{K}$ has the following form: $r(x) = \inf(h, d(x, A))$, $h > 0$, h independent of x. As the set A of data sites will not remain fixed, we shall use $r(A, x)$, $D(A, x)$ instead of $r(x)$, $D(x)$. As outlined in section 1, we prove in Proposition 3.9 below further properties of those $\mathcal{K}$. We shall denote by δ the usual Hausdorff distance between compact nonempty subsets of E.

PROPOSITION 3.9. *For any scalar-valued continuous function f whose domain* $\mathrm{dom}(f)$ *is a nonempty closed subset of E, we have the following properties:*

(i) *for any closed subset B of E whose interior does not intersect* $\mathrm{dom}(f)$*, we have*

$$\|\mathcal{K}(\mathcal{K}(f)|\partial B) - \mathcal{K}(f)\|_{\infty,B} \leq 2\hat{\omega}(f;h),$$

where ∂B denotes the boundary of B;

(ii) *for any closed subset A of E containing* $\mathrm{dom}(f)$*, we have*

$$\|\mathcal{K}(\mathcal{K}(f)|A) - \mathcal{K}(f)\|_{\infty,E} \leq 2\hat{\omega}(f;h);$$

(iii) *for any closed nonempty closed subsets A,B of* $\mathrm{dom}(f)$*, we have*

$$\|\mathcal{K}(f|A) - \mathcal{K}(f|B)\|_{\infty,E} \leq 4(\hat{\omega}(f;\delta(A,B)) + \hat{\omega}(f;h)).$$

Proof. Let us show (i). For convenience, let us set $f_1 := \mathcal{K}(\mathcal{K}(f)|\partial B)$, $f_2 := \mathcal{K}(f)$, $D_1(x) := D(\partial B, x)$, $D_2(x) := D(\mathrm{dom}(f), x)$, and let us denote by $r_j(x)$ the radius of $D_j(x)$. Note that, as the interior of B does not intersect $\mathrm{dom}(f)$, we have $D_1(x) \subset D_2(x)$ for any $x \in B$. Setting

$$\Delta_{12} := \sup_{x\in B}(f_1(x) - f_2(x)), \quad \Delta_{21} := \sup_{x\in B}(f_2(x) - f_1(x)),$$

we must show that Δ_{12} and Δ_{21} are smaller than $2\hat{\omega}(f;h)$. As these two cases are similar, let us show, without loss of generality, that $\Delta_{12} \leq 2\hat{\omega}(f;h)$. First of all, let us show that Δ_{12} is attained in the strip $K := \{x \in B : d(x,\partial B) \leq h\}$. This result is immediate if $B = K$. Otherwise, we note that, by definition of the function r, $D_1(y) = D_2(y)$ for any $y \in B\backslash K$. From this, the proof of the uniqueness of the harmonious extension in Theorem 3.3 shows that Δ_{12} is attained for an element x of B such that $d(x,\partial B) = h$, that is, for an element x of K. Now, as $\mathcal{K}$ is a harmonious extension scheme, we can write, for such an $x \in K$,

$$\Delta_{12} := f_1(x) - f_2(x) = \frac{1}{2}Q_1 + \frac{1}{2}Q_2,$$

where

$$Q_1 := \sup_{z\in D_1(x)} f_1(z) - \inf_{z\in D_2(x)} f_2(z), \quad Q_2 := \inf_{z\in D_1(x)} f_1(z) - \sup_{z\in D_2(x)} f_2(z).$$

As $x \in K$, we have $D_1(x) \cap \partial B \neq \emptyset$, since $r_1(x) = d(x,\partial B)$ in this case. Choosing $c \in D_1(x) \cap \partial B$, we obtain $Q_2 \leq \mathcal{K}(\mathcal{K}(f)|\partial B)(c) - \mathcal{K}(f)(c)$ and, therefore, $Q_2 \leq 0$, because $\mathcal{K}$ is an extension scheme. On the other hand, we can write $Q_1 = R_1 + S_1$, where

$$R_1 := \sup_{z\in D_1(x)} f_1(z) - \inf_{z\in D_2(x)} f_1(z), \quad S_1 := \inf_{z\in D_2(x)} f_1(z) - \inf_{z\in D_2(x)} f_2(z).$$

We immediately have $S_1 \leq \Delta_{12}$. Using the optimal Ω-stability of $\mathcal{K}$ (and $D_1(x) \subset D_2(x)$), we have also $R_1 \leq \hat{\omega}(f;2r_2(x))$. Since, by the definition of the function r, we have $r_2(x) \leq h$, we obtain

$$\Delta_{12} \leq \frac{1}{2}(2\hat{\omega}(f;h) + \Delta_{12}),$$

that is, $\Delta_{12} \leq 2\hat{\omega}(f;h)$, which is the desired inequality. The proofs of (ii) and (iii) use similar arguments. ∎

4. Final remark.

Remark 4.1. It is known that the processes of harmonic regularization are, in Euclidean space $\mathbb{R}^N$, associated with the heat equation

$$\frac{\partial u}{\partial t} = \sum_{i=1}^{N} \frac{\partial^2 u}{\partial x_i^2}.$$

An elementary calculation shows that the process of harmonious regularization considered in Proposition 3.9 above, for infinitesimal h, is possibly connected with the following PDE:

$$\frac{\partial u}{\partial t} = \left(\sum_{i,j=1}^{N} \frac{\partial u}{\partial x_i} \frac{\partial u}{\partial x_j} \frac{\partial^2 u}{\partial x_i \partial x_j} \right) / \sum_{i=1}^{N} \left(\frac{\partial u}{\partial x_i} \right)^2.$$

Acknowledgment. The authors would like to gratefully acknowledge the referees for their comments and suggestions.

BEHAVIORS OF SOLUTIONS FOR THE BURGERS EQUATION WITH BOUNDARY CORRESPONDING TO RAREFACTION WAVES*

TAI-PING LIU†, AKITAKA MATSUMURA‡, AND KENJI NISHIHARA§

Abstract. We investigate the asymptotic behaviors of solutions of the initial-boundary value problem to the generalized Burgers equation $u_t + f(u)_x = u_{xx}$ on the half-line with the conditions $u(0,t) = u_-, \quad u(\infty,t) = u_+$, where the corresponding Cauchy problem admits the rarefaction wave as an asymptotic state. In the present problem, because of the Dirichlet boundary, the asymptotic states are divided into five cases dependent on the signs of the characteristic speeds $f'(u_\pm)$ of the boundary state $u_- = u(0)$ and the far field state $u_+ = u(\infty)$. In all cases both global existence of the solution and the asymptotic behavior are shown without smallness conditions. New wave phenomena are observed. For instance, when $f'(u_-) < 0 < f'(u_+)$, the solution behaves as the superposition of (a part of) a viscous shock wave as boundary layer and a rarefaction wave propagating away from the boundary.

Key words. rarefaction wave, viscous shock wave, asymptotic behavior

1. Introduction. We consider the initial-boundary value problem (IBVP) on the half-line $\mathbf{R}_+ = (0,\infty)$ for scalar viscous conservation laws:

$$\text{(IBVP)} \qquad \begin{cases} u_t + f(u)_x = u_{xx}, \quad x \in \mathbf{R}_+, \quad t > 0, \\ u(0,t) = u_-, \quad t > 0, \\ u(x,0) = u_0(x) = \begin{cases} = u_- & x = 0, \\ \to u_+ & x \to \infty, \end{cases} \end{cases}$$

where $u_\pm$ are given constants. Here, we study the case that the corresponding Riemann problem

$$\begin{cases} u_t + f(u)_x = 0, \quad x \in \mathbf{R}, \quad t > 0, \\ u(x,0) = u_0^R(x) := \begin{cases} u_- & x < 0, \\ u_+ & x > 0 \end{cases} \end{cases} \tag{1.1}$$

yields the rarefaction wave solution

$$r^R(x/t) = \begin{cases} u_- & x \le f'(u_-)t, \\ (f')^{-1}(x/t) & f'(u_-)t \le x \le f'(u_+)t, \\ u_+ & x \ge f'(u_+)t. \end{cases} \tag{1.2}$$

This is the case when either

$$f''(u) > 0 \quad \text{for} \quad u \quad \text{under consideration, and} \quad u_- < u_+ \tag{1.3}$$

or

$$f''(u) < 0 \quad \text{for} \quad u \quad \text{under consideration, and} \quad u_- > u_+.$$

Without loss of generality we assume (1.3). The problem where the corresponding Cauchy problem has a viscous shock wave has been investigated by Yu [13], Liu and Yu [7], and Liu and Nishihara [6].

Since the solution of (IBVP) has a boundary at $x = 0$, the signs of the characteristic speeds $f'(u_\pm)$ divide the asymptotic state into five cases:

$$\begin{array}{ll} (1) & f'(u_-) < f'(u_+) < 0, \\ (2) & f'(u_-) < f'(u_+) = 0, \\ (3) & f'(u_-) < 0 < f'(u_+), \\ (4) & 0 = f'(u_-) < f'(u_+), \\ (5) & 0 < f'(u_-) < f'(u_+). \end{array}$$

We also assume

$$f(0) = f'(0) = 0 \tag{1.4}$$

without loss of generality. Then, the graph of f in each case is shown in Figure 1.1.

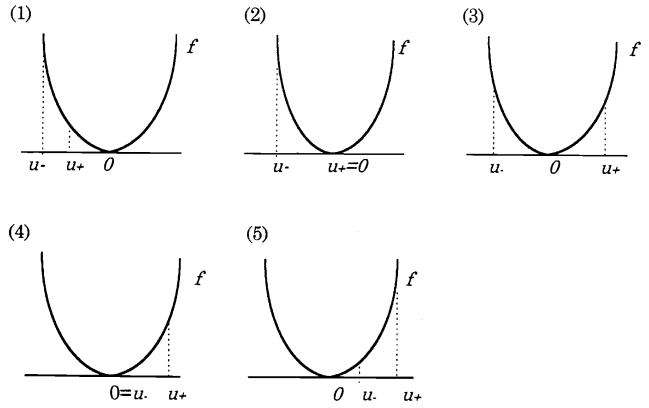

FIG. 1.1.

In the cases (1) and (2), the IBVP has a stationary solution $\phi = \phi_i(x), i = 1, 2$, respectively.

LEMMA 1.1. *Suppose that $f \in C^2$, and* (1.3) *and* (1.4) *hold. When* (1) $f'(u_-) < f'(u_+) < 0$ *or* (2) $f'(u_-) < f'(u_+) = 0$, *the boundary value problem of the ordinary differential equation*

$$\begin{cases} f(\phi)_x = \phi_{xx}, \quad x \in \mathbf{R}_+, \\ \phi(0) = u_-, \quad \phi(+\infty) = u_+ \end{cases} \tag{1.5}$$

has a unique solution $\phi_i \in C^3([0, \infty))(i = 1, 2)$, respectively, which satisfies

$$\phi_i'(x) > 0, \quad i = 1, 2, \tag{1.6}$$

$$\begin{cases} |\phi_1(x) - u_+| \le C_1 \exp(-|f'(u_+)|x) \\ |\phi_2(x) - u_+| \le C_2(1+x)^{-1} \end{cases} \tag{1.7}$$

for some constants C_1 *and* C_2.

Remark 1.1. If we take the extension $\hat{f}$ of f as Figure 1.2, then there is a unique viscous shock wave $\hat{\phi}_i(x+x_0)$ up to a shift such that

$$\begin{cases} \hat{f}(\hat{\phi})_x = \hat{\phi}_{xx}, \quad x \in \mathbf{R}, \\ \hat{\phi}(-\infty) = u_*, \quad \hat{\phi}(+\infty) = u_+. \end{cases}$$

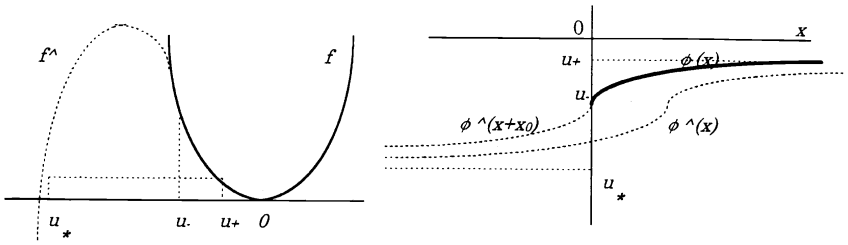

FIG. 1.2.

In fact, both the Rankine–Hugoniot condition $\frac{\hat{f}(u_+)-\hat{f}(u_*)}{u_+-u_*} = s = 0$ and the Oleinik entropy condition $-s(\hat{\phi}-u_+)+\hat{f}(\hat{\phi})-\hat{f}(u_+) < 0$ for $u_* < \hat{\phi} < u_+$ hold. Therefore, we can take $\phi_i(x) = \hat{\phi}(x+x_0)|_{\mathbf{R}_+}$, the unique profile with $\hat{\phi}(x_0) = u_-$. We also note that $\phi_i(x)(i=1,2)$ is, respectively, a part of a viscous shock wave which is nondegenerate in the case (1), degenerate in the case (2). For the details, see Liu and Nishihara [6].

Denoting the usual Lebesgue space and Sobolev space by $L^2 = L^2(\mathbf{R}_+)$ and $H^1 = H^1(\mathbf{R}_+)$, respectively, we have the first main theorem.

THEOREM 1.2 (in the case of $f'(u_-) < f'(u_+) \le 0$). *Suppose that* (1.3) *and* (1.4) *hold and that* $u_0 - \phi \in H^1$, *where* $\phi = \phi_i(i=1,2)$ *is a stationary solution obtained in Lemma* 1.1. *Then there exists a unique global solution* u *of* IBVP *such that*

$$u - \phi \in C([0,\infty); H^1), \quad (u-\phi)_x \in L^2(0,\infty; H^1)$$

and, moreover,

$$\sup_{\mathbf{R}_+} |u(x,t) - \phi(x)| \to 0 \quad as \quad t \to \infty.$$

Decay rates of $u - \phi$ are also obtained in the next section.

Next, we consider the cases (4) and (5) where the asymptotic state $\psi^R(x,t)$ is the restriction to $\mathbf{R}_+$ of the rarefaction wave $r^R(x/t)$ given by (1.2):

$$\psi^R(x,t) = r(x/t)|_{\mathbf{R}_+}. \tag{1.8}$$

THEOREM 1.3 (in the case of $0 \le f'(u_-) < f'(u_+)$). *Suppose that* (1.3) *and* (1.4) *hold and that* $u_0 - \psi^R(\cdot,0) \in H^1$. *Then, the IBVP has a unique global solution* $u(x,t)$ *which satisfies*

$$u - \psi^R \in C([0,\infty); H^1), \quad (u-\psi^R)_x, u_{xx} \in L^2(\mathbf{R}_+ \times \mathbf{R}_+),$$

and

$$\sup_{\mathbf{R}_+} |u(x,t) - \psi^R(x,t)| \to 0 \quad as \quad t \to \infty.$$

Finally, consider the case (3), which is the combination of both the cases (2) and (4). The asymptotic state is the superposition of $\phi = \phi_2(x)$ and $\psi^R = \psi_4^R(x,t)$, where ϕ_2 is the stationary solution connecting $u_-(<0)$ to 0 and ψ_4^R is the rarefaction wave connecting 0 to $u_+(>0)$. See Figure 1.3.

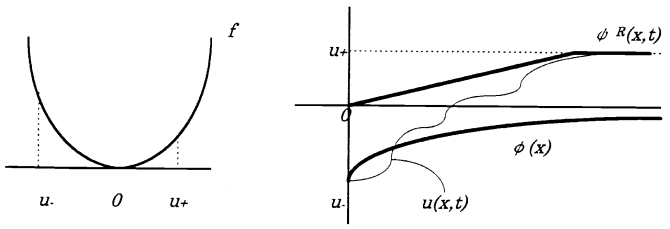

FIG. 1.3.

The following is our main theorem.

THEOREM 1.4 (in the case of $f'(u_-) < 0 < f'(u_+)$). *Suppose that* (1.3) *and* (1.4) *hold and that* $u_0 - \phi_2(\cdot) - \psi_4(\cdot,0) \in H^1$. *Then, there exists a unique global solution* $u(x,t)$ *of* (IBVP) *such that*

$$u - \phi_2 - \psi_4^R \in C([0,\infty); H^1),$$

$$(u - \phi_2 - \psi_4^R)_x, (u - \phi_2)_{xx} \in L^2(\mathbf{R}_+ \times \mathbf{R}_+),$$

and

$$\sup_{\mathbf{R}_+} |u(x,t) - \phi_2(x) - \psi_4^R(x,t)| \to 0 \quad as \quad t \to \infty.$$

Remark 1.2. As noted in Remark 1.1, ϕ_2 is a part of a viscous shock wave. Hence, the superposition of the viscous shock wave and the rarefaction wave constitutes our asymptotic state. As far as the authors know, there are few results on the stability of the superposition of different types of nonlinear waves (cf. Liu [5] for another example of such a superposition, but in an entirely different setting). In the Cauchy problem there is the question of determining the location of viscous shock waves. In the present case, the location is uniquely determined by the boundary.

Remark 1.3. Since $\phi_2(x), \psi_4^R(x,t)|_{x=t^\alpha} \to 0$ as $t \to \infty$ for $0 < \alpha < 1$, the solution $u(x,t)$ in Theorem 1.3 behaves like

$$u(x,t) \sim \begin{cases} \phi_2(x), & 0 < x \le Ct^\alpha, \\ \psi_4^R(x,t), & x \ge Ct^\alpha, \end{cases}$$

as $t \to \infty$. The asymptotic rate we will obtain is optimal when $\alpha = 1/2$.

Our plan of this paper is as follows. After stating the notation, in section 2 we investigate the cases (1) and (2), which correspond to the viscous shock waves. The cases (4) and (5) corresponding to the rarefaction waves are investigated in section 3. In the final section, we consider the case (3), which is the main part of this paper.

Notation. By $c_i, C_i (i \in \mathbf{Z}_+)$, or simply c, C, we denote several positive constants without confusion, where $\mathbf{Z}_+$ is a set of positive integers. We also denote $f(x) \sim g(x)$ as $x \to a$ when $C^{-1}g < f < Cg$ in a neighborhood of a. For function spaces, as stated above, $L^2 = L^2(\mathbf{R}_+)$ and $H^1 = H^1(\mathbf{R}_+)$ denote the usual Lebesgue space and Sobolev space with norms $||\cdot||$ and $||\cdot||_1$, respectively. For the weight function $w(x)$, L^2_w denotes the space of measurable functions f satisfying $\sqrt{w}f \in L^2$ with the norm $|f|_w = (\int_0^\infty w(x)|f(x)|^2dx)^{1/2}$. In the present paper we will use the weight function $w(x) = \langle x\rangle^\beta = (1+x^2)^{\beta/2}$, $x \geq 0$. The space $L^2_{\langle x\rangle^\beta}$ is written simply by L^2_β with norm $||\cdot||_\beta$.

2. Convergence to a viscous shock wave.

2.1. Reformulation of problem. We restate our problem

$$\text{(IBVP)} \qquad \begin{cases} u_t + f(u)_x = u_{xx}, \quad x \in \mathbf{R}_+, \quad t > 0, \\ \\ u(0,t) = u_-, \quad t > 0, \\ u(x,0) = u_0(x) = \begin{cases} = u_- & x = 0, \\ \to u_+ & x \to +\infty, \end{cases} \end{cases}$$

with $f''(u) > 0$ and $u_- < u_+ \leq 0$.

The stability theorem for the viscous shock waves to the equivalent problem has been obtained by Liu and Nishihara [5], in which the flux function f is not necessarily assumed to be convex or concave. Here, because of the convexity of f, we will obtain sharper results.

Putting $\phi = \phi_i(x)(i = 1, 2)$ and

$$u(x,t) = \phi(x) + v(x,t), \tag{2.1}$$

(IBVP) can be reformulated as

$$\begin{cases} v_t + (f(\phi+v) - f(\phi))_x = v_{xx}, \quad x \in \mathbf{R}_+, \quad t > 0, \\ \\ v(0,t) = 0, \\ \\ v(x,0) = v_0(x) := u_0(x) - \phi(x). \end{cases} \tag{2.2}$$

THEOREM 2.1 (in the case of $f'(u_-) < f'(u_+) \leq 0$). *Assume that the same conditions as those in Theorem* 1.1 *hold and that* $v_0 \in H^1$*; then there exists a unique solution* v *of* (2.2) *which satisfies*

$$v \in C([0,\infty); H^1), \quad v_x \in L^2(0,\infty; H^1),$$

$$\sup_{\mathbf{R}_+} |v(x,t)| \to 0 \quad \textit{as} \quad t \to \infty.$$

Theorem 1.1 is a direct consequence of Theorem 2.1. The combination of the local existence and a priori estimates proves Theorem 2.1.

We define the solution space by

$$X(0,T) = \{v \in C([0,T); H^1); \quad v_x \in L^2(0,T; H^1) \quad \text{with}$$

$$\partial_x^m v(x,t)|_{x=0} < +\infty \quad \text{for} \quad t \in (0,T) \quad \text{and} \quad m \in \mathbf{Z}_+\}.$$

PROPOSITION 2.2 (local existence). *For any $v_0 \in H^1$ with $||v_0||_1 \le M$, there exists a positive time T_0 and a unique solution $v \in X(0,T_0)$ of (2.2) satisfying $\sup_{0<\tau<T_0} ||v(\cdot,t)||_1 \le 2M$.*

The equation (2.2) is rewritten as an integral equation

$$v(x,t) = \int_0^\infty G(x,y;t)v_0(y)dy + \int_0^t \int_0^\infty G(x,y;t-\tau)(f(\phi+v)-f(\phi))_y dyd\tau, \tag{2.3}$$

where

$$G(x,y;t) = \frac{1}{\sqrt{4\pi t}}\left(e^{-\frac{(x-y)^2}{4t}} - e^{-\frac{(x+y)^2}{4t}}\right).$$

Making use of (2.3), Proposition 2.2 is proved in a standard way.

PROPOSITION 2.3 (a priori estimate). *Suppose that v is a solution of (2.2) in $X(0,T)$ for a positive constant T. Then, there exists a positive constant $C = C(||v_0||_1)$, independent of T, such that the solution v satisfies the estimate*

$$\sup_{0<\tau<t} ||v(\tau)||_1^2 + \int_0^t (||\sqrt{\phi_x}v(\tau)||^2 + ||v_x(\tau)||_1^2)d\tau \le C||v_0||_1^2. \tag{2.4}$$

2.2. A priori estimate. We devote ourselves to the proof of Proposition 2.2.

Let v be a solution of (2.2) in $X(0,T)$. First, multiply $(2.2)_1$ by v; then we have a divergence form

$$\begin{aligned}&(\tfrac{1}{2}v^2)_t + \left\{(f(\phi+v)-f(\phi))v - \left(\int_\phi^{\phi+v} f(s)ds - f(\phi)v\right) - v_x v\right\}_x \\ &\quad +(f(\phi+v)-f(\phi)-f'(\phi)v)\phi_x + v_x^2 = 0.\end{aligned} \tag{2.5}$$

Since $v_0 \in H^1$, $\sup_{\mathbf{R}_+} |v_0(x)| \le C_0$, and so

$$\sup_{\mathbf{R}_+} |v(x,t)| \le C_0, \quad 0 \le t < T, \tag{2.6}$$

due to the maximum principle of the parabolic equation. Hence,

$$(f(\phi+v)-f(\phi)-f'(\phi)v)\phi_x \ge \frac{c_0}{2}\phi_x v^2, \tag{2.7}$$

where $c_0 := \min_{u_- - C_0 \le u \le u_+ + C_0} f''(u) > 0$. Integrating (2.5) over $\mathbf{R}_+ \times (0,t)$ and using (2.7), we have

$$||v(t)||^2 + \int_0^t (||\sqrt{\phi_x}v(\tau)||^2 + ||v_x(\tau)||^2)d\tau \le C||v_0||^2. \tag{2.8}$$

Next, differentiate (2.2) in x and multiply the resultant equation by v_x to obtain

$$\begin{aligned}&(\tfrac{1}{2}v_x^2)_t + \{(f'(\phi+v)-f'(\phi))\phi_x v_x + \tfrac{1}{2}f'(\phi+v)v_x^2 - v_{xx}v_x\}_x \\ &\quad -(f'(\phi+v)-f'(\phi))\phi_x v_{xx} + \tfrac{1}{2}f''(\phi+v)(\phi_x+v_x)v_x^2 + v_{xx}^2 = 0.\end{aligned} \tag{2.9}$$

The integration of (2.9) over $\mathbf{R}_+ \times (0,t)$ yields

$$\begin{aligned} &\tfrac{1}{2}||v_x(t)||^2 + \int_0^t \left\{ \left(-\frac{f'(u_-)}{2} v_x^2 + v_{xx} v_x \right) |_{x=0} + ||v_{xx}(\tau)||^2 \right\} d\tau \\ &\le \tfrac{1}{2}||v_{0x}||^2 + C \int_0^t \int_0^\infty (\phi_x |v v_{xx}| + v_x^2 + |v_x|^3) dx d\tau. \end{aligned} \tag{2.10}$$

Here we have used (2.6). Since the equation (2.2) implies

$$f'(u_-) v_x(0,t) = v_{xx}(0,t), \tag{2.11}$$

we can estimate the integral on the boundary as follows:

$$\begin{aligned} &\left| \int_0^t \left(-\frac{f'(u_-)}{2} v_x^2 + v_{xx} v_x \right) \right|_{x=0} d\tau \le C \int_0^t v_x(0,\tau)^2 d\tau \\ &\le \tfrac{1}{4}||v_{xx}(\tau)||^2 d\tau + C \int_0^t ||v_x(\tau)||^2 d\tau. \end{aligned} \tag{2.12}$$

The last term of (2.10) is estimated as follows:

$$\begin{aligned} &C \int_0^t \int_0^\infty |v_x|^3 dx d\tau \le C \int_0^t ||v_{xx}(\tau)||^{1/2} ||v_x(\tau)||^{5/2} d\tau \\ &\le \tfrac{1}{2} \int_0^t ||v_{xx}(\tau)||^2 + C \sup_{0<\tau<t} ||v_x(\tau)||^{4/3} \cdot \int_0^t ||v_x(\tau)||^2 d\tau. \end{aligned} \tag{2.13}$$

It follows from (2.10)–(2.13) and (2.8) that

$$\sup_{0<\tau<t} ||v_x(\tau)||^2 + \int_0^t ||v_{xx}(\tau)||^2 d\tau \le C||v_0||_1^2 + C||v_0||^2 \cdot \sup_{0<\tau<t} ||v_x(\tau)||^{4/3},$$

which yields

$$\sup_{0<\tau<t} ||v_x(\tau)||^2 + \int_0^t ||v_{xx}(\tau)||^2 d\tau \le C||v_0||_1^2. \tag{2.14}$$

The combination (2.8) with (2.14) proves the estimate (2.4).

2.3. Convergence rates to viscous shock wave. First, consider the case (1), that is, the nondegenerate shock case. Note that $f'(u) \le -c_1 < 0$ for $u_+ \le u \le u_- < 0$. By Theorem 1.2

$$\sup_{\mathbf{R}_+} |v(x,t)| \to 0 \quad \text{as} \quad t \to \infty,$$

and hence, for any $\varepsilon > 0$, there is a positive time $t_1 = t_1(\varepsilon)$ such that

$$\sup_{\mathbf{R}_+} |v(x,t)| \le \varepsilon \quad \text{for} \quad t \ge t_1. \tag{2.15}$$

Multiplying (2.5) by $\langle x\rangle^\beta = (1+x)^{\beta/2}$, we have

$$
\begin{aligned}
&(\tfrac{\langle x\rangle^\beta}{2}v^2)_t + (\langle x\rangle^\beta\{\cdots\})_x \\
&-\beta x\langle x\rangle^{\beta-2}\left\{(f(\phi+v)-f(\phi))v - \left(\int_\phi^{\phi+v} f(s)ds - f(\phi)v\right) - v_x v\right\} \qquad (2.16)\\
&+\langle x\rangle^\beta(f(\phi+v)-f(\phi)-f'(\phi)v)\phi_x + \langle x\rangle^\beta v_x^2 = 0.
\end{aligned}
$$

By virtue of (2.15), for sufficiently small $\varepsilon_0 > 0$ and $t \ge t_1(\varepsilon_0)$,

$$
\begin{aligned}
&-\left\{(f(\phi+v)-f(\phi))v - \left(\int_\phi^{\phi+v} f(s)ds - f(\phi)v\right)\right\} \qquad (2.17)\\
&= -(f'(\phi+\theta_1 v) - \tfrac{1}{2}f'(\phi+\theta_2 v))v^2 \ge \tfrac{c_1}{2}v^2, \quad \text{where} \quad |\theta_i| < 1, \quad i = 1,2.
\end{aligned}
$$

The integration of (2.16) over $(0,\infty)\times(0,t)$, $t \le t_1(\varepsilon_0)$, gives

$$
\begin{aligned}
&\int_0^\infty \langle x\rangle^\beta v(x,t)^2 dx + \int_0^t\int_0^\infty \langle x\rangle^\beta(\phi_x v^2 + v_x^2)dxd\tau \qquad (2.18)\\
&\le C\left(\int_0^\infty \langle x\rangle^\beta v_0(x)^2 dx + \int_0^t\int_0^\infty \langle x\rangle^{\beta-1}(v^2 + |vv_x|)dxd\tau\right),
\end{aligned}
$$

and hence

$$
|v(t)|_\beta^2 + \int_0^t |v_x(\tau)|_\beta^2 d\tau \le C(t_1)|v_0|_\beta^2, \quad t \le t_1(\varepsilon_0). \qquad (2.19)
$$

Multiplying (2.16) by $(1+t-t_1)^\gamma$ and integrating the resultant equation over $(0,\infty)\times[t_1,t)$, we have

$$
\begin{aligned}
&(1+t-t_1)^\gamma|v(t)|_\beta^2 + \int_{t_1}^t (1+t-t_1)^\gamma(\beta|v(\tau)|_{\beta-1}^2 + |v_x(\tau)|_\beta^2)d\tau \\
&\le C(|v(t_1)|_\beta^2 + \gamma\int_{t_1}^t (1+\tau-t_1)^{\gamma-1}|v(\tau)|_\beta^2 d\tau) \qquad (2.20)\\
&+C\int_{t_1}^t (1+\tau-t_1)^\gamma\int_0^\infty \langle x\rangle^{\beta-1}|vv_x|dxd\tau.
\end{aligned}
$$

The final term of (2.20) is estimated as follows:

$$
\begin{aligned}
&C\int_{t_1}^t (1+\tau-t_1)^\gamma\int_0^\infty \langle x\rangle^{\beta-1}|vv_x|dxd\tau \qquad (2.21)\\
&\le \tfrac{\beta}{2}\int_{t_1}^t (1+\tau-t_1)^\gamma|v(\tau)|_{\beta-1}^2 d\tau + C\int_{t_1}^t (1+\tau-t_1)^\gamma\left(\int_0^R + \int_R^\infty\right)\langle x\rangle^{\beta-1}v_x^2 dxd\tau \\
&\le \tfrac{1}{2}\int_{t_1}^t (1+\tau-t_1)^\gamma(\beta|v(\tau)|_{\beta-1}^2 + |v_x(\tau)|_\beta^2)d\tau + C_R\int_{t_1}^t (1+\tau-t_1)^\gamma||v_x(\tau)||^2 d\tau
\end{aligned}
$$

for sufficiently large R. Combining (2.19)–(2.21), we have

$$
\begin{aligned}
&(1+t-t_1)^\gamma |v(t)|_\beta^2 + \int_{t_1}^t (1+\tau-t_1)^\gamma (\beta |v(\tau)|_{\beta-1}^2 + |v_x(\tau)|_\beta^2) d\tau \\
&\le C(|v_0|_\beta^2 + \gamma \int_{t_1}^t (1+\tau-t_1)^{\gamma-1} |v(\tau)|_\beta^2 d\tau + \int_{t_1}^t (1+\tau-t_1)^\gamma ||v_x(\tau)||^2 d\tau).
\end{aligned} \tag{2.22}
$$

This basic weighted energy estimate leads to the following lemma, using the procedure of reduction of Kawashima and Matsumura [2] and Matsumura and Nishihara [10].

LEMMA 2.4. *Suppose* (1.3), (1.4), *and* $f'(u_-) < f'(u_+) < 0$. *If* $v_0 \in H^1 \cap L^2_\alpha$, *then the solution* v *of* (2.2) *satisfies*

$$
(1+t)^\gamma ||v(t)||^2 + \int_0^t (1+\tau)^\gamma ||v_x(\tau)||^2 d\tau \le C|v_0|_\alpha^2 \tag{2.23}
$$

for any $\gamma \le \alpha$ *(*α*:integer) or* $\gamma < \alpha$ *(*α*:noninteger).*

For the derivative of v in x, we can easily show the similar estimate. Thus we obtain the following theorem.

THEOREM 2.5 (rate of asymptotics for $f'(u_-) < f'(u_+) < 0$). *Suppose that* (1.3) *and* (1.4) *hold and that* $f'(u_-) < f'(u_+) < 0$. *If* $u_0 - \phi_1 \in H^1 \cap L^2_\alpha$, *then the solution* $u(x,t)$ *of* (IBVP) *satisfies*

$$
\sup_{\mathbf{R}_+} |u(x,t) - \phi_1(x)| \le C_\varepsilon (1+t)^{-\frac{\alpha}{2}+\varepsilon} (||u_0 - \phi_1||_1 + |u_0 - \phi_1|_\alpha), \tag{2.24}
$$

where $\varepsilon = 0$ *if* α *is integer and* $\varepsilon > 0, C_\varepsilon \to \infty (\varepsilon \to 0)$ *if* α *is not integer.*

Remark 2.1. Nishikawa [12] has recently improved the result of Matsumura and Nishihara [10], so we can take $\varepsilon = 0$ even for noninteger α by the same method as his.

Remark 2.2. If $V_0 := \int_0^x v_0(y)dy = \int_0^x (u_0(y) - \phi_1(y))dy \in H^2$ is sufficiently small, then the reformulated problem

$$
\begin{cases}
V_t + f'(\phi_1)V_x - V_{xx} = -(f(\phi_1 + V_x) - f(\phi_1) - f'(\phi_1)V_x), \quad x \in \mathbf{R}_+, \quad t > 0, \\
V(x,0) = V_0(x), \\
V_x(0,t) = 0
\end{cases}
$$

has a unique global solution $V(x,t) \in C([0,\infty); H^2)$ satisfying

$$
\sup_{\mathbf{R}_+} |V_x(x,t)| = \sup_{\mathbf{R}_+} |u(x,t) - \phi_1(x)| \to 0 \quad \text{as} \quad t \to \infty \tag{2.25}
$$

(see Liu and Nishihara [6]). Moreover, if $V_0 \in L^2_\alpha$, then they conclude

$$
\sup_{\mathbf{R}_+} |u(x,t) - \phi_1(x)| \le C_\varepsilon (1+t)^{-\frac{\alpha}{2}+\varepsilon}. \tag{2.26}
$$

Here, ε and C_ε are same as those in Theorem 2.1. In the present case the assumptions $V_0 \in L^2_\alpha$ and $V_{0x} \in L^2_{\alpha+1}$, which seem to be reasonable, improve the rate of asymptotics as

$$
\sup_{\mathbf{R}_+} |u(x,t) - \phi_1(x)| \le C_\varepsilon (1+t)^{-\frac{\alpha+1}{2}+\varepsilon}. \tag{2.27}
$$

See also Nishihara and Rajopadhye [11].

Remark 2.3. If $\int_0^\infty e^{\delta x}|u_0(x)-\phi_1(x)|^2dx<+\infty$ for some $\delta>0$, then it also holds that the solution $u(x,t)$ of (IBVP) satisfies

$$\sup_{\mathbf{R}_+}|u(x,t)-\phi_1(x)|\le Ce^{-\delta' t}$$

for some positive constant δ'.

Similar considerations for the degenerate shock case (2) corresponding to Remark 2.2 are still available. However, since $f'(\phi_2(x)+v(x,t))$ is not uniformly negative, the procedure for the case (1) in this section is not directly applicable. Without going into the details we obtain the following decay properties for small data in the case (2) by the same arguments as in [10].

THEOREM 2.6 (rate of asymptotics for $f'(u_-)<f'(u_+)=0$). *Suppose that* (1.3) *and* (1.4) *hold and that* $f'(u_-)<f'(u_+)=0$. *If* $V_0:=\int_0^x(u_0(y)-\phi_2(y))dy\in H^2\cap L^2_\alpha$ *and* $V_{0x}\in L^2_{\alpha+1}$ *for* $\alpha<2$ *are small, then the solution* $u(x,t)$ *of* (IBVP) *satisfies*

$$\sup_{\mathbf{R}_+}|u(x,t)-\phi_2(x)|\le C_\varepsilon(1+t)^{-\frac{\alpha+2}{4}+\varepsilon},$$

where $\varepsilon>0$ *and* $C_\varepsilon\to\infty$ *as* $\varepsilon\to\infty$.

3. Convergence to rarefaction wave.

3.1. Reformulated problem in the case of $0\le f'(u_-)<f'(u_+)$. In this section we consider the cases (4) and (5), that is, $0\le f'(u_-)<f'(u_+)$. Since the asymptotic state $\psi^R(x,t)=r^R(x/t)|_{\mathbf{R}_+}$ is not smooth, we construct the smooth approximation $\psi=\psi_i(x,t)(i=4,5)$.

For the case (4) we prepare the following lemma.

LEMMA 3.1. *Suppose that* (1.3) *and* (1.4) *hold and that* $0=f'(u_-)<f'(u_+)$. *Let* $w(x,t)$ *be a unique smooth solution of the Cauchy problem*

$$\text{(3.1)}\qquad \begin{cases} w_t+ww_x=0, \quad x\in\mathbf{R}, \quad t>0,\\ \\ w(x,0)=w_{40}(x)=w_+\cdot\kappa_q\displaystyle\int_0^x(1+y^2)^{-q}dy, \quad q>1/2, \end{cases}$$

where $w_+=f'(u_+)>0$ *and* $\kappa_q\int_0^\infty(1+y^2)^{-q}dy=1$. *Then,* $\psi=\psi_4(x,t):=(f')^{-1}(w(x,t))|_{\mathbf{R}_+}$ *satisfies*

$$\text{(3.2)}\qquad \begin{cases} \psi_t+f(\psi)_x=0, \quad x\in\mathbf{R}_+, \quad t>0,\\ \\ \psi(0,t)=0(=u_-),\\ \psi(x,0)=\psi_{40}(x):=(f')^{-1}(w_{40}(x))=\begin{cases} =0, & x=0,\\ \to u_+, & x\to+\infty \end{cases} \end{cases}$$

and the following:

(i) $0=u_-\le\psi(x,t)<u_+, \quad \psi_x(x,t)>0, \quad (x,t)\in\mathbf{R}_+\times(0,\infty)$.

(ii) *For any* $1\le p\le\infty$ *there exists a constant* $C_{p,q}$ *such that*
$||\psi_x(t)||_{L^p}\le C_{p,q}\min(u_+,u_+^{1/p}t^{-1+\frac{1}{p}})$,
$||\psi_{xx}(t)||_{L^p}\le C_{p,q}\min(u_+,u_+^{-\frac{p-1}{2pq}}t^{-1-\frac{p-1}{2pq}})$.

(iii) $\lim_{t\to\infty}\sup_{\mathbf{R}_+}|\psi(x,t)-\psi_4^R(x,t)|=0$.

The proof of Lemma 3.1 is given by the characteristic curve method. See Matsumura and Nishihara [8], [9].

Set

$$u(x,t) = \psi_4(x,t) + v(x,t); \tag{3.3}$$

then the perturbation v satisfies

$$\begin{cases} v_t + (f(\psi_4 + v) - f(\psi_4))_x - v_{xx} = \psi_{4xx}, \quad x \in \mathbf{R}_+, \quad t > 0, \\ \\ v(0,t) = 0, \\ \\ v(x,0) = v_0(x) := v_0(x) - \psi_{40}(x). \end{cases} \tag{3.4}$$

Our theorem for the case (4) is the following.

THEOREM 3.2 (in the case of $0 = f'(u_-) < f'(u_+)$). *Suppose that* (1.3) *and* (1.4) *hold and that* $0 = f'(u_-) < f'(u_+)$. *If* $v_0 \in H^1$, *then there exists a unique solution* v *of* (3.4) *such that*

$$v \in C([0,\infty); H^1), \quad v_x \in L^2(0,\infty; H^1) \tag{3.5}$$

and, moreover,

$$\sup_{\mathbf{R}_+} |v(x,t)| \to 0 \quad \textit{as} \quad t \to \infty. \tag{3.6}$$

Theorem 1.2, in the case of $0 = f'(u_-) < f'(u_+)$, is a direct consequence of Theorem 3.2, Lemma 3.1 (iii), and (3.3).

In the case of $0 < f'(u_-) < f'(u_+)$, we prepare the following lemma in place of Lemma 3.1.

LEMMA 3.3. *Suppose that* (1.3) *and* (1.4) *hold and that* $0 < f'(u_-) < f'(u_+)$. *Let* $w(x,t)$ *be a unique global solution of the Cauchy problem*

$$\begin{cases} w_t + ww_x = 0, \quad x \in \mathbf{R}, \quad t > 0, \\ \\ w(x,0) = w_{50}(x) := \frac{w_+ + w_-}{2} + \frac{w_+ - w_-}{2}\kappa_q \displaystyle\int_0^x (1+y^2)^{-q} dy, \quad q > 3/2, \end{cases} \tag{3.7}$$

where $w_\pm = f'(u_\pm) > 0$ *and* $\kappa_q \int_0^\infty (1+y^2)^{-q} dy = 1$. *Then,* $\psi = \psi_5(x,t) := (f')^{-1}(w(x,t))|_{\mathbf{R}_+}$ *satisfies*

$$\begin{cases} \psi_t + f(\psi)_x = 0, \quad x \in \mathbf{R}_+, \quad t > 0, \\ \\ \psi(x,0) = \psi_{50}(x) := (f')^{-1}(w_{50}(x)), \end{cases} \tag{3.8}$$

and the following:

(i) $0 < u_- < \psi(x,t) < u_+, \quad \psi_x(x,t) > 0, \quad (x,t) \in \mathbf{R}_+ \times (0,\infty)$.

(ii) *For any* $1 \le p \le \infty$ *there exists a constant* $C_{p,q}$ *such that*
$||\psi_x(t)||_{L^p} \le C_{p,q} \min(|u_+ - u_-|, |u_+ - u_-|^{1/p} t^{-1+\frac{1}{p}})$,
$||\psi_{xx}(t)||_{L^p} \le C_{p,q} \min(|u_+ - u_-|, |u_+ - u_-|^{-\frac{p-1}{2pq}} t^{-1-\frac{p-1}{2pq}})$.

(iii) *For some constant* C_q
$|\psi(0,t) - u_-| \le C_q |u_+ - u_-| (1 + (|u_+ - u_-|t)^2)^{-q/3}$,
$|\psi_x(0,t)| \le C_q |u_+ - u_-| (1 + (|u_+ - u_-|t)^2)^{-q/2}$.

(iv) $\lim_{t\to\infty} \sup_{\mathbf{R}_+} |\psi(x,t) - \psi_5^R(x,t)| = 0$.

For the proof see Matsumura and Nishihara [8], [9].

The main difference between Lemmas 3.1 and 3.3 is the boundary value $\psi(0,t)$. The perturbation

$$v(x,t) = u(x,t) - \psi_5(x,t) \tag{3.9}$$

has a "boundary layer $u_- - \psi_5(0,t)$" at $x = 0$:

$$\begin{cases} v_t + (f(\psi_5 + v) - f(\psi_5))_x - v_{xx} = \psi_{5xx}, \quad x \in \mathbf{R}_+, \quad t > 0, \\ v(0,t) = u_- - \psi_5(0,t), \\ v(x,0) = v_0(x) := u_0(x) - \psi_{50}(x). \end{cases} \tag{3.10}$$

However, Lemma 3.3 (iii) shows that $u_- - \psi_5(0,t) \in L^1(\mathbf{R}_+)$ and $\psi_{5x}(0,t) \in L^1(\mathbf{R}_+)$ in t, from which we have the following theorem.

THEOREM 3.4 (in the case of $0 < f'(u_-) < f'(u_+)$). *Suppose that* (1.3) *and* (1.4) *hold and that* $0 < f'(u_-) < f'(u_+)$. *If* $v_0 \in H^1$, *then there exists a unique solution* v *of* (3.10) *such that*

$$v \in C([0,\infty); H^1), \quad v_x \in L^2(0,\infty; H^1) \tag{3.11}$$

and, moreover,

$$\sup_{\mathbf{R}_+} |v(x,t)| \to \infty \quad \textit{as} \quad t \to \infty. \tag{3.12}$$

We note that (3.12), together with Lemma 3.3 (iii) and (iv), yields that $\sup_{\mathbf{R}_+} |u(x,t) - \psi_5^R(x,t)| \to 0$ as $t \to \infty$. Hence, Theorem 1.2 in the case of $0 < f'(u_-) < f'(u_+)$ follows from Theorem 3.2.

In the next section we devote ourselves to the proof of Theorem 3.2. The proof of Theorem 3.4 is a little bit more complicated than that of Theorem 3.2. However, it is along the same line and is omitted.

3.2. Proof of Theorem 3.2. We can easily show the local existence of the solution of (3.4) in the solution space

$$X_4(0,T) = \{v \in C([0,T]; H^1), \quad v_x \in L^2(0,T; H^1) \quad \text{and}$$

$$\partial_x^m v(x,t)|_{x=0} < +\infty \quad \text{for} \quad t \in (0,T] \quad \text{and} \quad m \in \mathbf{Z}_+\}.$$

It remains to show the a priori estimates.

PROPOSITION 3.5 (a priori estimate). *Suppose* v *is a solution of* (3.4) *in* $X_4(0,T)$. *Then there exists a positive constant* C, *independent of* T, *satisfying*

$$||v(t)||_1^2 + \int_0^t (||\sqrt{\psi_4(\tau)}v(\tau)||^2 + ||v_x(\tau)||_1^2)d\tau \le C(||v_0||_1^2 + 1). \tag{3.13}$$

Remark 3.1. By virtue of (3.13) we note that

$$\int_0^t v_x(0,\tau)^2 d\tau \le C \int_0^t ||v_x(\tau)||||v_{xx}(\tau)||d\tau \le C(||v_0||_1^2 + 1).$$

Proof. Multiplying (3.4) by v and integrating the resultant equation over $\mathbf{R}_+ \times (0,t)$, we have

$$\begin{aligned}&\tfrac{1}{2}||v(t)||^2 + \int_0^t \left\{ \int_0^\infty (f(\psi_4+v) - f(\psi_4) - f'(\psi_4)v)\psi_{4x}dx + ||v_x(\tau)||^2 \right\} d\tau \\ &\qquad \le \tfrac{1}{2}||v_0||^2 + \int_0^t ||\psi_{4xx}(\tau)||||v(\tau)||d\tau.\end{aligned} \tag{3.14}$$

The maximum principle for v and the Gronwall inequality with (3.14) yield

$$||v(t)||^2 + \int_0^t (||\sqrt{\psi_4(\tau)}v(\tau)||^2 + ||v_x(\tau)||^2)d\tau \le C(||v_0||^2 + 1). \tag{3.15}$$

Next, to estimate the derivative of v, we have the relation at the boundary

$$v_{xx}(0,t) = -\psi_{xx}(0,t) \tag{3.16}$$

from the equation (3.4). With (3.16) we calculate $\int_0^t \int_0^\infty \frac{\partial}{\partial x}(3.4)_1 \cdot v_x dx d\tau$ and obtain

$$\begin{aligned}&\tfrac{1}{2}||v_x(t)||^2 + \int_0^t ||v_{xx}(\tau)||^2 d\tau \\ &\le \tfrac{1}{2}||v_{0x}||^2 + C\int_0^t \int_0^\infty |\psi_{4x}vv_{xx} + v_xv_{xx} + \psi_{4xx}v_{xx}|dxd\tau \\ &\qquad + \int_0^t (-v_{xx}(0,\tau) - \psi_{4xx}(0,\tau))v_x(0,\tau)d\tau \\ &\le C\left(||v_{0x}||^2 + 1 + \int_0^t (||\sqrt{\psi_4(\tau)}v(\tau)||^2 + ||v_x(\tau)||^2)d\tau \right).\end{aligned} \tag{3.17}$$

Combining (3.15) with (3.17), we conclude (3.13). □

4. Asymptotics to superposition of nonlinear waves.

4.1. Reformulation of the problem. Referring to the preceding sections, we take

$$\Phi_3(x,t) := \phi_2(x) + \psi_4(x,t) \tag{4.1}$$

as an asymptotic state at $t = \infty$, instead of $\phi_2(x) + \psi_4^R(x,t)$, where ϕ_2 and ψ_4 are, respectively, given in Lemmas 1.1 and 3.1.

The perturbation

$$v(x,t) = u(x,t) - \Phi_3(x,t) = u(x,t) - \phi_2(x) - \psi_4(x,t) \tag{4.2}$$

satisfies the reformulated problem

$$\begin{cases} v_t + (f(\Phi_3 + v) - f(\Phi_3))_x - v_{xx} = F, \\ v(0,t) = 0, \\ v(x,0) = v_0(x) := u_0(x) - \phi_2(x) - \psi_4(x,0), \end{cases} \tag{4.3}$$

where

$$F = -(f'(\phi_2+\psi_4)-f'(\phi_2))\phi_{2x} - (f'(\phi_2+\psi_4)-f'(\psi_4))\psi_{4x} + \psi_{4xx}. \tag{4.4}$$

Our final theorem is the following.

THEOREM 4.1 (in the case of $f'(u_-) < 0 < f'(u_+)$). *Suppose that* (1.3) *and* (1.4) *hold and that* $f'(u_-) < 0 < f'(u_+)$. *If* $v_0 \in H^1$, *then there exists a unique solution* v *of* (4.3) *which satisfies*

$$v \in C([0,\infty); H^1), \quad v_x \in L^2(0,\infty; H^1), \tag{4.5}$$

and

$$\sup_{\mathbf{R}_+} |v(x,t)| \to 0 \quad \textit{as} \quad t \to \infty. \tag{4.6}$$

The main Theorem 1.3 is a direct consequence of Theorem 4.1. As for the above theorems, Theorem 4.1 is proved by the local existence theorem with the a priori estimates. The solution space is

$$X_3(0,T) = \{v \in C([0,T]; H^1); v_x \in L^2(0,T; H^1) \quad \text{and}$$

$$\partial_x^m v(x,t)|_{x=0} < +\infty \quad \text{for} \quad t \in (0,T] \quad \text{and} \quad m \in \mathbf{Z}_+\}.$$

We will devote ourselves to the a priori estimates in the next section.

PROPOSITION 4.2 (a priori estimates). *Suppose that* $v \in X_3(0,T)$ *is a solution of* (4.3). *Then there exists a positive constant* C, *independent of* T, *satisfying*

$$||v(t)||_1^2 + \int_0^t (||\sqrt{\Phi_3(\tau)}v(\tau)||^2 + ||v_x(\tau)||_1^2)d\tau \le C(||v_0||_1^2 + 1). \tag{4.7}$$

4.2. Proof of Proposition 4.2. Multiplying $(4.3)_1$ by v and integrating the resultant equation over $\mathbf{R}_+$, we have

$$\frac{1}{2}\frac{d}{dt}||v(t)||^2 + \int_0^\infty (f(\Phi+v) - f(\Phi) - f'(\Phi)v)\Phi_x dx + ||v_x(t)||^2 = \int_0^\infty Fv dx. \tag{4.8}$$

(We drop the suffices "2", "3", and "4".) Since $\Phi_x = \phi_x + \psi_x > 0$ and $f''(\Phi+v) \ge c_0 > 0$ by the maximum principle, (4.8) gives

$$\frac{d}{dt}||v(t)||^2 + ||\sqrt{\Phi_x(t)}v(t)||^2 + ||v_x(t)||^2 \le C\left|\int_0^\infty Fv dx\right|. \tag{4.9}$$

We estimate the last term of (4.9) using (4.4). First,

$$\begin{aligned} &C|-\int_0^\infty (f'(\phi+\psi)-f'(\phi))\phi_x v dx| \\ &\le C\int_0^\infty \psi\phi_x|v|dx = \int_0^{f'(u_+)t} + \int_{f'(u_+)t}^\infty := I_1 + I_2. \end{aligned} \tag{4.10}$$

By virtue of $\phi < 0, \psi > 0$, and Lemmas 1.1 and 3.1(ii), we have

$$
\begin{aligned}
I_1 &\le C \sup_{\mathbf{R}_+} |v| \cdot \{[\phi\psi]_0^{f'(u_+)t} + \int_0^{f'(u_+)t} (-\phi)\psi_x dx\} \\
&\le C||v(t)||^{1/2}||v_x(t)||^{1/2}(1+t)^{-1} \int_0^{f'(u_+)t} \frac{dx}{1+x} \\
&\le \tfrac{1}{8}||v_x(t)||^2 + C\{(1+t)^{-1}\log(2+t)\}^{4/3}(||v(t)||^2+1),
\end{aligned} \tag{4.11}
$$

and

$$
\begin{aligned}
I_2 &\le C \sup_{\mathbf{R}_+} \cdot u_+ \int_{f'(u_+)t}^{\infty} \phi_x(x)dx \le C||v(t)||^{1/2}||v_x(t)||^{1/2}(1+t)^{-1} \\
&\le \tfrac{1}{8}||v_x(t)||^2 + C(1+t)^{-4/3}(||v(t)||^2+1).
\end{aligned} \tag{4.12}
$$

Secondly, in a similar fashion to (4.11) and (4.12),

$$
\begin{aligned}
&C|-\int_0^{\infty} (f'(\phi+\psi)-f'(\psi))\psi_x v dx| \\
&\le \tfrac{1}{4}||v_x(t)||^2 + C\{(1+t)^{-4/3} + ((1+t)^{-1}\log(1+t))^{4/3}\}(||v(t)||^2+1).
\end{aligned} \tag{4.13}
$$

Thirdly,

$$
\left|\int_0^{\infty} \psi_{xx} v dx\right| \le ||\psi_{xx}(t)||||v(t)||. \tag{4.14}
$$

Substituting (4.10)–(4.14) into (4.9) and integrating it over $(0,t)$, we have the desired estimate

$$
||v(t)||^2 + \int_0^t (||\sqrt{|\Phi_x(\tau)|}v(\tau)||^2 + ||v_x(\tau)||^2)d\tau \le C(||v_0||^2+1). \tag{4.15}
$$

Here we have used the Gronwall inequality.

Next, differentiate $(4.4)_1$ in x:

$$
v_{xt} + (f'(\Phi+v)v_x)_x - v_{xxx} = F_x - \{(f'(\Phi+v)-f'(\Phi))\Phi_x\}_x. \tag{4.16}
$$

By the equation (4.3) with (4.4) we have the relation at the boundary

$$
-f'(u_-)v_x(0,t) + v_{xx}(0,t) = f'(u_-)\psi_x(0,t) - \psi_{xx}(0,t). \tag{4.17}
$$

Multiplying (4.16) by v_x and integrating it over $(0,\infty)$, we have

$$
\begin{aligned}
&\tfrac{1}{2}\tfrac{d}{dt}||v_x(t)||^2 + (-\tfrac{1}{2}f'(u_-)v_x^2 + v_{xx}v_x)|_{x=0} + ||v_{xx}(t)||^2 \\
&\le (f'(u_-)\psi_x(0,t) - \psi_{xx}(0,t))v_x(0,t) \\
&\quad + C\int_0^{\infty} \{(1+|v_x|)v_x^2 + (|F| + \Phi_x|v|)|v_{xx}|\}dx.
\end{aligned} \tag{4.18}
$$

By virtue of (4.17) and $v_x(0,t)^2 \le C||v_x(t)||||v_{xx}(t)||$, the integration of (4.18) over $(0,t)$ yields

$$||v_x(t)||^2 + \int_0^t ||v_{xx}(\tau)||^2 d\tau$$

$$\le \{||v_{0x}||^2 + 1 + \int_0^\infty (||\sqrt{\Phi_x(\tau)}v(\tau)||^2 + ||v_x(\tau)||^2)d\tau\}$$

$$+C\int_0^\infty ||v_x(0,\tau)||^2 d\tau \cdot \sup_{0<\tau<t} ||v_x(0,\tau)||^{4/3}$$

and hence, by (4.15),

$$\sup_{0<\tau<t} ||v_x(\tau)||^2 + \int_0^t ||v_{xx}(\tau)||^2 d\tau \le C(||v_0||_1^2 + 1). \tag{4.19}$$

The combination of (4.15) and (4.19) gives a desired estimate (4.7), which completes the proof of Proposition 4.2.

SOME OVERDETERMINED BOUNDARY VALUE PROBLEMS WITH ELLIPTICAL FREE BOUNDARIES*

ANTOINE HENROT† AND GÉRARD A. PHILIPPIN‡

Abstract. In this paper we study three different overdetermined boundary value problems in $\mathbf{R}^2$: a problem of torsion, a problem of electrostatic capacity, and a problem of polarization. In each case we prove that a solution exists if and only if the free boundary is an ellipse. The techniques we use rely on classical complex function theory, maximum principle, and some topological argument.

Key words. overdetermined partial differential equation, free boundary, conformal map, ellipse

1. Introduction.

In his reference book on potential theory, O. D. Kellogg [Ke] has established that the density of charge at any point of an ellipsoid is proportional to the distance from the center to the tangent plane at that point.

The above mentioned property may also be formulated as follows:

$$|\nabla u| = \text{const.}h \quad \text{on } \partial\Omega, \tag{1}$$

where u is the electrostatic potential of the ellipsoid

$$\Omega := \left\{ \mathbf{x} = (x, y, z) \in \mathbf{R}^3 \,\middle|\, \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} < 1 \right\},$$

defined as the solution of the boundary value problem

$$\Delta u = 0 \quad \text{in } \mathbf{R}^3 \backslash \bar{\Omega}, \tag{2}$$

$$u = 1 \quad \text{on } \partial\Omega, \tag{3}$$

$$u = O\left(\frac{1}{r}\right) \text{ as } r \to \infty, \tag{4}$$

and $h = \mathbf{x}.\mathbf{n}$ is the scalar product of $\mathbf{x}$ with the exterior normal vector of $\partial\Omega$. This property leads to the following question: is the overdetermined boundary value problem (1)–(4) solvable only if Ω is an ellipsoid?

We note that the standard methods of investigation in the topics of overdetermined problems, such as, e.g., Serrin's moving plane method [Se] or even the maximum principle approach (see, e.g., [We]), may not be appropriate to characterize ellipsoids!

In this paper we are not going to investigate such challenging overdetermined problems in $\mathbf{R}^3$. However we shall analyze similar problems in $\mathbf{R}^2$, in order to take advantage of such powerful tools as the conformal mapping techniques.

‡Département de Mathématiques et de Statistique, Université Laval, Québec G1K 7P4, Canada (gphilip@mat.ulaval.ca).

The second section of the paper deals with some overdetermined Saint-Venant problems. The third section is dedicated to the analogue of problem (1)–(4) in $\mathbf{R}^2$, and the fourth section to some overdetermined polarization problem. In the fifth section, we collect some related open problems with ellipsoidal free boundaries in higher dimension.

2. An overdetermined Saint-Venant problem. Let u be the solution of the Saint-Venant problem

$$\Delta u = -2 \quad \text{in } \Omega, \tag{5}$$

$$u = 0 \quad \text{on } \partial\Omega, \tag{6}$$

where Ω is a simply connected bounded domain in $\mathbf{R}^2$. Assuming Ω convex, Makar-Limanov in 1971 [Ma-Li] has established the convexity of the level lines $\{u = \text{const.}\}$ of problem (5), (6). His method is based on the auxiliary function

$$M := u_{,ij}u_{,i}u_{,j} - |\nabla u|^2\Delta u + u[(\Delta u)^2 - u_{,ij}u_{,ij}]. \tag{7}$$

In (7) and in the rest of the paper a comma followed by indices indicates partial differentiation, and we adopt the usual summation convention on repeated indices. Using an identity derived in [Ph-Po] we compute

$$M_{,k} = u_{,ijk}u_{,i}u_{,j} - 2uu_{,ij}u_{,ijk} \quad \text{in } \Omega, \tag{8}$$

$$\Delta M = -2uu_{,ijk}u_{,ijk} \le 0 \quad \text{in } \Omega. \tag{9}$$

Moreover, we have on $\partial\Omega$

$$M = K|\nabla u|^3, \tag{10}$$

where K is the curvature of $\partial\Omega$. It follows from (9), (10) that M is positive in Ω if Ω is convex, which implies the convexity of the level lines $\{u = \text{const.}\}$.

Another consequence of (9) is that M is constant in Ω if and only if Ω is an ellipse. Indeed we have equality in (9) if and only if $u_{,ijk} = 0,\ i, j, k = 1, 2$, i.e., if and only if u is a quadratic polynomial in the two variables (x, y).

This section deals with problem (5), (6) overdetermined by the further boundary condition

$$K|\nabla u|^3 = c = \text{const.} > 0 \text{ on } \partial\Omega. \tag{11}$$

From the above remark we infer that (11) is satisfied if Ω is an ellipse. The next statement asserts that ellipses are the only domains for which condition (11) is satisfied.

THEOREM 1. *The overdetermined problem* (5), (6), (11) *is solvable only if* Ω *is an ellipse.*

Obviously we have to show the following implication:

$$M = \text{const. on } \partial\Omega \Longrightarrow M = \text{const. throughout } \Omega. \tag{12}$$

Let us assume that (11) is satisfied, i.e., that $M = \text{const.}$ on $\partial\Omega$. The outward normal derivative $\frac{\partial M}{\partial n}$ must be everywhere nonpositive on $\partial\Omega$ since M takes its minimum there. The conclusion of Theorem 1 would then follow if we succeed to construct a point $P \in \partial\Omega$ at which $\frac{\partial M}{\partial n} = 0$ in view of Hopf's second maximum principle [Pr-We]. On the other hand if the conclusion of Theorem 1 is incorrect, there would exist a

domain Ω for which $\frac{\partial M}{\partial n} < 0$ everywhere on $\partial\Omega$. Our proof of Theorem 1 will consist of showing that the two conditions $M = \text{const.}$ on $\partial\Omega$, $\frac{\partial M}{\partial n} < 0$ on $\partial\Omega$ lead to a contradiction.

Let $\mathbf{n} := (n_1, n_2) = (\cos\theta, \sin\theta)$, $\theta \in [0, 2\pi)$ be the exterior normal vector on $\partial\Omega$. Let s denote the arc length on $\partial\Omega$ oriented in the anticlockwise direction. Using the relations

$$u_{xxx} = -u_{xyy}, \qquad u_{yyy} = -u_{xxy}, \tag{13}$$

$$\mathbf{n} = -\frac{\nabla u}{|\nabla u|}, \tag{14}$$

and (8), we compute

$$\begin{aligned} \frac{\partial M}{\partial n} &= \mathbf{n}\cdot\nabla M = -|\nabla u|^{-1} u_{,ijk} u_{,i} u_{,j} u_{,k} \\ &= |\nabla u|^{-1}\left\{u_{xxy}u_y[u_y^2 - 3u_x^2] + u_{xyy}u_x[u_x^2 - 3u_y^2]\right\}, \end{aligned} \tag{15}$$

$$\begin{aligned} \frac{\partial M}{\partial s} &= 0 = -M_x n_2 + M_y n_1 \\ &= |\nabla u|^{-1}\left\{u_{xxy}u_x[u_x^2 - 3u_y^2] + u_{xyy}u_y[3u_x^2 - u_y^2]\right\}. \end{aligned} \tag{16}$$

The overdetermined condition (11) implies that Ω is strictly convex with a smooth boundary $\partial\Omega$. It follows then that the angle θ between $\mathbf{n}$ and the x-axis is strictly increasing as a function of s on $\partial\Omega$. Let $(x(\theta), y(\theta))$ be a parametric representation of $\partial\Omega$. From (14), (11) we compute

$$\begin{aligned} (x'(s), y'(s)) &= (\dot{x}(s), \dot{y}(s))\frac{ds}{d\theta} = (\dot{x}(s), \dot{y}(s))K^{-1} \\ &= (u_{y,}, -u_x)|\nabla u|^{-1}K^{-1} = |\nabla u|^2 c^{-1}(u_{y,}, -u_x), \end{aligned} \tag{17}$$

where a prime stands for $\frac{d}{d\theta}$, a dot stands for $\frac{d}{ds}$.

Let us now consider the pair of periodic functions $\varphi_1(\theta), \varphi_2(\theta)$ defined on $\partial\Omega$ as

$$\varphi_1(\theta) := u_{xx}(x(\theta), y(\theta)), \tag{18}$$

$$\varphi_2(\theta) := -u_{xy}(x(\theta), y(\theta)), \tag{19}$$

$\theta \in [0, 2\pi)$. Using (13), (17) we compute

$$\varphi_1'(\theta) = u_{xxx}x' + u_{xxy}y' = -\frac{|\nabla u|^2}{c}\{u_{xxy}u_x + u_{xyy}u_y\}, \tag{20}$$

$$\varphi_2'(\theta) = -u_{xyx}x' - u_{xyy}y' = -\frac{|\nabla u|^2}{c}\{u_{xxy}u_y - u_{xyy}u_x\}. \tag{21}$$

Using the identities

$$\cos 2\theta = \cos^2\theta - \sin^2\theta = |\nabla u|^{-2}(u_x^2 - u_y^2), \tag{22}$$

$$\sin 2\theta = 2\sin\theta\cos\theta = 2|\nabla u|^{-2}u_x u_y\ , \tag{23}$$

together with (20), (21) we obtain

$$\varphi_1'\cos 2\theta - \varphi_2'\sin 2\theta = \frac{1}{c}\{u_{xxy}u_x(3u_y^2 - u_x^2) + u_{xyy}u_y(u_y^2 - 3u_x^2)\}, \tag{24}$$

$$\varphi_1'\sin 2\theta + \varphi_2'\cos 2\theta = \frac{1}{c}\{u_{xxy}u_y(u_y^2 - 3u_x^2) + u_{yyx}u_x(u_x^2 - 3u_y^2)\}. \tag{25}$$

Using (15), (16), and assuming $M = \text{const.}$ on $\partial\Omega$, $\frac{\partial M}{\partial n} < 0$ on $\partial\Omega$, we can rewrite (24), (25) as

$$(\varphi_1'(\theta), \varphi_2'(\theta)) = a(\theta)(\sin 2\theta, \cos 2\theta), \tag{26}$$

with

$$a(\theta) := \frac{1}{c}|\nabla u|\frac{\partial M}{\partial n} < 0 \qquad \forall \theta \in [0, 2\pi). \tag{27}$$

From (26), (27) we conclude that the closed curve Γ given by the parametric representation $(\varphi_1(\theta), \varphi_2(\theta)), \theta \in [0, 2\pi)$ has its tangent which makes two revolutions around the origin in the negative direction.

In other words we have

$$\text{turn } (\Gamma) = -2, \tag{28}$$

where turn (Γ) is the turning number associated with Γ. We refer to [Be-Go] for a precise definition of turn (Γ) as the degree of the unit tangent map of Γ.

We shall now compute turn (Γ) using a different approach and obtain a contradiction. To this purpose we consider the auxiliary complex-valued function $f(z)$ defined in Ω as

$$f(z) := u_{xx} - iu_{xy}, \tag{29}$$

with $z := x + iy \in \bar{\Omega}$. We note that u_{xx} and $-u_{xy}$ are harmonic conjugate functions in view of (5), (13); i.e., $f(z)$ is analytic and maps $\partial\Omega$ onto Γ. Let the unit disc $|\zeta| < 1$ in the complex ζ-plane be mapped conformally onto Ω and denote by $z = \phi(\zeta)$ the univalent function associated to this mapping. We obtain a parametric representation of Γ in terms of $\psi \in [0, 2\pi)$ by setting

$$\varphi_1(\psi) + i\varphi_2(\psi) = f(\phi(e^{i\psi})). \tag{30}$$

The hodograph of Γ given by the analytic function

$$\frac{d}{d\psi}(\varphi_1 + i\varphi_2) = ie^{i\psi}\phi'(e^{i\psi})f'(\phi(e^{i\psi})) \tag{31}$$

is a closed curve homotopic to the unit tangent map of Γ (parametrized by $\psi \mapsto \frac{ie^{i\psi}\phi'(e^{i\psi})f'(\phi(e^{i\psi}))}{|\phi'(e^{i\psi})f'(\phi(e^{i\psi}))|}$) that does not go through the origin since we have

$$f'(z) = u_{xxx} - iu_{xxy} = -(u_{xyy} + iu_{xxy}) \neq 0 \qquad \forall z \in \partial\Omega \tag{32}$$

by assumption, and since $\phi'(\zeta) \neq 0$ in $\{|\zeta| < 1\}$ by conformality. The number turn (Γ) may therefore be evaluated by the integral

$$\text{turn } (\Gamma) = \frac{1}{2i\pi}\int_{|\zeta|=1} \frac{F'(\zeta)d\zeta}{F(\zeta)} \tag{33}$$

with

$$F(\zeta) := i\zeta\phi'(\zeta)f'(\phi(\zeta)); \tag{34}$$

turn (Γ) coincides therefore with the number of zeros (counted with their multiplicity) of $F(\zeta)$ in the disc $|\zeta| < 1$ and is therefore ≥ 1, in contradition to (28). This achieves the proof of Theorem 1.

3. An overdetermined boundary value problem for the electrostatic potential in $\mathbf{R}^2$. Let K be a simply connected bounded domain in $\mathbf{R}^2$, and let u be the solution of the following boundary value problem:

$$\Delta u = 0 \quad \text{in } \Omega := \mathbf{R}^2 \backslash \bar{K}, \tag{35}$$

$$u = 1 \quad \text{on } \partial K, \tag{36}$$

$$\lim_{r\to\infty} \frac{u}{\log r} = 1, \tag{37}$$

where $r := \sqrt{x^2+y^2}$ is the distance from the point (x,y) to the origin $O \in K$. We note that u takes its minimum value on ∂K. Moreover, if K is an ellipse, $u(x,y)$ can be computed in terms of elliptic functions and the following two relations hold on $\partial\Omega$:

$$x|\nabla u| = \epsilon\, n_1, \tag{38}$$

$$|\nabla u| = \delta h, \tag{39}$$

where ϵ is a negative constant, δ is a positive constant, $\mathbf{n} := (n_1, n_2)$ denotes the normal vector on ∂K oriented inside K, and $h := -x_i n_i$ is the distance from the tangent of ∂K to the origin $O \in K$. In this section we establish the following result.

THEOREM 2. *The boundary value problem* (35)–(37) *overdetermined either by* (38) *or by* (39) *is solvable only if K is an ellipse.*

Let $\hat{\Omega}$ be the exterior of the unit disc $|\zeta| < 1$ of the complex ζ-plane. This domain $\hat{\Omega}$ can be mapped conformally onto Ω by means of a univalent complex-valued function $\zeta \to z = \phi(\zeta)$ of the following form:

$$\phi(\zeta) = a\zeta + \sum_{n=0}^{\infty} b_n \zeta^{-n}, \tag{40}$$

where a can be chosen real positive. Let $\hat{u}$ be the solution of problem (35)–(37) associated with $\hat{\Omega}$. We have obviously

$$\hat{u}(\zeta) = 1 + \log \rho, \tag{41}$$

with $\rho := |\zeta|$, $\zeta := \rho e^{i\psi} \in \hat{\Omega}$. We then obtain the solution $u(z)$ of (35)–(37) in Ω by conformal transplantation of $\hat{u}(\zeta)$. This leads to

$$\begin{aligned} u(z) &:= \hat{u}(\phi^{-1}(z)) = \hat{u}(\zeta) = 1 + \log|\zeta| \\ &= 1 + Re \log \zeta = 1 + Re\{\log \phi^{-1}(z)\}. \end{aligned} \tag{42}$$

The complex gradient $\nabla u := u_x + iu_y$ is then given by

$$\nabla u = \overline{(\log \phi^{-1}(z))'} = 1/\ \overline{\phi^{-1}(z)\phi'(\phi^{-1}(z))}. \tag{43}$$

Moreover, the complex unit normal vector $n := n_1 + in_2$ is obtained by differentiating the parametric representation $\phi(e^{i\psi})$ of $\partial\Omega$ with respect to the parameter ψ. This leads to

$$n = n_1 + in_2 = -e^{i\psi} \frac{\phi'(e^{i\psi})}{|\phi'(e^{i\psi})|}. \tag{44}$$

Combining (43) and (44), we obtain the following expression for the normal derivative $\frac{\partial u}{\partial n}$ on $\partial\Omega$ in terms of the mapping function $\phi(\zeta)$:

$$\left.\frac{\partial u}{\partial n}\right|_{\partial\Omega} = Re\left[(u_x - iu_y)(n_1 + in_2)\right] = -\frac{1}{|\phi'(e^{i\psi})|}. \tag{45}$$

Since $u = 1$ on $\partial\Omega$, we have

$$|\nabla u|_{\partial\Omega} = -\left.\frac{\partial u}{\partial n}\right|_{\partial\Omega} = \frac{1}{|\phi'(e^{i\psi})|}. \tag{46}$$

With (46) we can rewrite the overdetermined conditions (38) and (39) as follows:

$$Re\{\phi(e^{i\psi})\} = -\epsilon Re\{e^{i\psi}\phi'(e^{i\psi})\}, \quad \psi \in [0, 2\pi), \tag{47}$$

and

$$Re\left\{e^{i\psi}\phi'(e^{i\psi})\,\overline{\phi(e^{i\psi})}\right\} = \frac{1}{\delta} > 0. \tag{48}$$

In the next step we shall show that either (47) or (48) implies separately that ϕ has the form

$$\phi(\zeta) = a\zeta + b_0 + b_1\zeta^{-1}, \tag{49}$$

from which we conclude that K must be an ellipse.

First case (47). Obviously we can select $b_0 = 0$ in (40) since this choice affects the mapping by a translation only. Making use of (40) with $b_n = \beta_n + i\gamma_n$, $n = 1, 2, \ldots$, condition (47) gives

$$\begin{aligned} &a\cos\psi + \sum_1^\infty (\beta_n \cos n\psi + \gamma_n \sin n\psi) \\ &\qquad = -\epsilon\left\{a\cos\psi - \sum_1^\infty n(\beta_n \cos n\psi + \gamma_n \sin n\psi)\right\}, \end{aligned} \tag{50}$$

from which we obtain

$$\beta_1 = \frac{a(1+\epsilon)}{\epsilon - 1}, \quad \beta_n = 0 \quad \forall n \geq 2, \tag{51}$$

$$\gamma_n = 0 \qquad \forall n \geq 1. \tag{52}$$

This leads to the desired form (49) of $\phi(\zeta)$.

Second case (48). The analysis of this case is more complicated. The condition (48) may be rewritten under the form

$$e^{i\psi}\,\overline{\phi(e^{i\psi})}\phi'(e^{i\psi}) + e^{-i\psi}\phi(e^{i\psi})\,\overline{\phi'(e^{i\psi})} = \text{const}. \tag{53}$$

Again we write

$$\phi(\zeta) := a\zeta + \sum_1^\infty b_n\zeta^{-n} \tag{54}$$

without loss of generality. Let us now introduce the associated function

$$\tilde{\phi}(\zeta) := \overline{\phi\left(1/\bar{\zeta}\right)} = a\zeta^{-1} + \sum_{1}^{\infty} \overline{b_n}\zeta^n. \tag{55}$$

With

$$\tilde{\phi}(e^{i\psi}) = \overline{\phi(e^{i\psi})}, \tag{56}$$

$$\tilde{\phi}'(\zeta) = -\frac{1}{\zeta^2}\overline{\phi'\left(1/\bar{\zeta}\right)}, \tag{57}$$

the condition (53) may be rewritten as

$$e^{i\psi}\tilde{\phi}(e^{i\psi})\phi'(e^{i\psi}) - e^{i\psi}\phi(e^{i\psi})\tilde{\phi}'(e^{i\psi}) = \text{const.} = c. \tag{58}$$

Moreover, we know a priori that the overdetermined condition implies that the boundary $\partial\Omega$ is analytic. This follows from Theorem 1.4 in Chapter 2 of Friedman's book [Fr]. The function ϕ analytic in $|\zeta| > 1$ may therefore be analytically extended inside the unit disc in a neighborhood of $|\zeta| = 1$, and the function $\tilde{\phi}$ analytic in $|\zeta| < 1$ may be analytically extended outside the unit disc in a neighborhood of $|\zeta| = 1$. There exists therefore a two-sided neighborhood $\omega := \{1 - \epsilon < |\zeta| < 1 + \epsilon\}$ of the unit circle in which ϕ and $\tilde{\phi}$ are analytic. In ω we have the identity

$$\tilde{\phi}(\zeta)\phi'(\zeta) - \tilde{\phi}'(\zeta)\phi(\zeta) = \frac{c}{\zeta} \tag{59}$$

in view of (58). Differentiating (59) we obtain

$$\tilde{\phi}\phi'' - \tilde{\phi}''\phi = -\frac{c}{\zeta^2}. \tag{60}$$

Combining (59) and (60) leads to

$$\tilde{\phi}\phi' - \tilde{\phi}'\phi + \zeta(\tilde{\phi}\phi'' - \tilde{\phi}''\phi) = 0, \tag{61}$$

which may be rewritten as

$$\zeta\,\frac{\phi' + \zeta\phi''}{\phi} = \zeta\,\frac{\tilde{\phi}' + \zeta\tilde{\phi}''}{\tilde{\phi}} \quad \text{in } \omega, \tag{62}$$

where the factors ζ on both sides of (62) make the right-hand side analytic at the origin since we have

$$\lim_{\zeta\to 0} \zeta\,\frac{\tilde{\phi}' + \zeta\tilde{\phi}''}{\tilde{\phi}} = 1 \tag{63}$$

as a consequence of (55), and the left-hand side bounded at infinity since we have

$$\lim_{\zeta\to\infty} \zeta\,\frac{\phi' + \zeta\phi''}{\phi} = 1 \tag{64}$$

as a consequence of (54). The identity (62) shows in fact that the function defined by $\zeta\frac{\phi'+\zeta\phi''}{\phi}$ outside the unit disc and by $\zeta\frac{\tilde{\phi}'+\zeta\tilde{\phi}''}{\tilde{\phi}}$ inside the closed unit disc is analytic

and bounded in the whole complex ζ-plane. It then follows from the classical theorem of Liouville that this function is constant (and equal to one, thanks to (64)). This fact leads to the following differential equation for $\phi(\zeta)$:

$$\zeta^2\phi'' + \zeta\phi' - \phi = 0 \qquad \forall|\zeta| > 1. \tag{65}$$

The differential equation (65) has the general solution

$$\phi(\zeta) = a\zeta + b\zeta^{-1}. \tag{66}$$

This achieves the proof of Theorem 2.

4. An overdetermined polarization problem. Let K be a simply connected bounded domain in $\mathbf{R^2}$. We consider the polarization problem in the x direction defined in $\Omega := \mathbf{R}^2\backslash\bar{K}$ as

$$\Delta u = 0 \quad \text{in } \Omega := \mathbf{R}^2\backslash\bar{K}, \tag{67}$$

$$u = x + b \quad \text{on } \partial\Omega, \tag{68}$$

$$u = O(r^{-1}) \quad \text{as } r := \sqrt{x^2+y^2} \to \infty. \tag{69}$$

In (68), b is a constant that is uniquely determined by the condition (69). In this section we establish the following result.

THEOREM 3. *Let u be the solution of problem* (67)–(69). *Assume moreover that u satisfies the further boundary condition*

$$\frac{\partial u}{\partial n} = cn_1 \quad \text{on } \partial\Omega, \tag{70}$$

where $\mathbf{n} := (n_1, n_2)$ is the unit normal vector on $\partial\Omega$ directed inside K and where c is a constant. Then K must be an ellipse whose axes are parallel to the axes of coordinates.

Before proving Theorem 3 we note that the constant c in (70) cannot be given arbitrarily. In fact c depends only on the geometry of K and is given by

$$c = -\frac{\int_{\partial\Omega} n_2^2\, \mathbf{x}.\mathbf{n}\, ds}{\int_{\partial\Omega} n_1^2\, \mathbf{x}.\mathbf{n}\, ds} < 0. \tag{71}$$

For the proof of (71) we compute

$$\int_\Omega |\nabla u|^2 dx = \int_{\partial\Omega} u\frac{\partial u}{\partial n} ds = c\int_{\partial\Omega} x n_1 ds = -cA, \tag{72}$$

where A is the area of K. (72) implies that c is negative. Moreover, from (70) we have

$$\frac{\partial(u-x)}{\partial n} = (c-1)n_1 \quad \text{on } \partial\Omega. \tag{73}$$

Inserting (72), (73) into Rellich's identity

$$\int_\Omega |\nabla u|^2 dx + A = -\frac{1}{2}\int_{\partial\Omega} \left(\frac{\partial(u-x)}{\partial n}\right) \mathbf{x}.\mathbf{n}\, ds \tag{74}$$

that is also derived in [Pa-Ph], we obtain (71).

For the proof of Theorem 3 we proceed again by conformal transplantation. Let $\hat{\Omega}$ be the exterior of the unit disc $|\zeta| < 1$ of the complex ζ-plane; $\hat{\Omega}$ may be mapped conformally onto Ω by means of a univalent complex-valued function $\zeta \to z = \phi(\zeta)$ of the following form:

$$\phi(\zeta) = a\zeta + \sum_{n=0}^{\infty} b_n \zeta^{-n}, \tag{75}$$

where a may be chosen real positive without loss of generality. Let $\hat{u}(\zeta)$ be the transplanted function defined in $\hat{\Omega}$ as

$$\hat{u}(\zeta) := u(\phi(\zeta)). \tag{76}$$

This function $\hat{u}(\zeta)$ satisfies the following boundary value problem:

$$\Delta \hat{u} = 0 \quad \text{in } \hat{\Omega}, \tag{77}$$

$$\hat{u}(e^{i\psi}) = u(\phi(e^{i\psi})) = Re(\phi(e^{i\psi})) + b, \quad \psi \in [0, 2\pi], \tag{78}$$

$$\hat{u} = O\left(\frac{1}{|\zeta|}\right) \text{ as } |\zeta| \to \infty. \tag{79}$$

In (78) we have used the notation $\zeta = \rho e^{i\psi}$. From (79) we see that $b = -Re(b_0)$. The solution of (77)–(79) is easily computable. We find

$$\begin{aligned} \hat{u}(\zeta) &= \hat{u}(\rho e^{i\psi}) \\ &= \frac{1}{2}\left\{ \frac{\bar{a} + b_1}{\rho} e^{-i\psi} + \frac{a + \bar{b}_1}{\rho} e^{i\psi} + \sum_{2}^{\infty} \frac{b_n e^{-in\psi} + \bar{b}_n e^{in\psi}}{\rho^n} \right\}. \end{aligned} \tag{80}$$

Since we have $a = \bar{a}$, (80) may be rewritten as

$$\hat{u}(\zeta) = Re\left(\frac{a}{\zeta}\right) + Re\left(\sum_{1}^{\infty} b_n \zeta^{-n}\right) = Re\left\{\frac{a}{\zeta} + \phi(\zeta) - a\zeta - b_0\right\} \tag{81}$$

in view of (75), from which we compute

$$u(z) = \hat{u}(\phi^{-1}(z)) = Re\left\{\frac{a}{\phi^{-1}(z)} + z - a\phi^{-1}(z) - b_0\right\}. \tag{82}$$

Using the identity $\nabla\{Re\, f(z)\} = \overline{f'(z)}$ with $f(z)$ analytic, we compute from (82)

$$\overline{\nabla u(z)} = u_x - iu_y = 1 - \frac{a}{\phi'(\phi^{-1}(z))[\phi^{-1}(z)]^2} - \frac{a}{\phi'(\phi^{-1}(z))}\,. \tag{83}$$

The complex-valued normal vector $n := n_1 + in_2$ of $\partial\Omega$ may also be expressed in terms of the parametrization $\psi \to \phi(e^{i\psi})$, $\psi \in [0, 2\pi)$ of $\partial\Omega$. We obtain

$$n = n_1 + in_2 = -e^{i\psi}\, \frac{\phi'(e^{i\psi})}{|\phi'(e^{i\psi})|}. \tag{84}$$

From (83), (84) we compute

$$\begin{aligned} \frac{\partial u(\phi(e^{i\psi}))}{\partial n} &= Re\{\overline{\nabla u}.n\} \\ &= Re\left\{-\frac{e^{i\psi}\phi'(e^{i\psi})}{|\phi'(e^{i\psi})|} + \frac{a}{|\phi'(e^{i\psi})|e^{i\psi}} + \frac{ae^{i\psi}}{|\phi'(e^{i\psi})|}\right\}. \end{aligned} \tag{85}$$

The overdetermined condition (70) may therefore be rewritten as

$$Re\{e^{i\psi}\phi'(e^{i\psi}) - ae^{-i\psi} - ae^{i\psi}\} = Re\{ce^{i\psi}\phi'(e^{i\psi})\}. \tag{86}$$

From (75) we compute

$$e^{i\psi}\phi'(e^{i\psi}) = ae^{i\psi} - \sum_{1}^{\infty} nb_n e^{-in\psi}. \tag{87}$$

From (86), (87) we obtain by identification

$$\begin{aligned} &-a\cos\psi - Re(b_1)\cos\psi - Im(b_1)\sin\psi \\ &= c(a\cos\psi - Re(b_1)\cos\psi - Im(b_1)\sin\psi) \end{aligned} \tag{88}$$

and

$$Re(nb_n e^{-in\psi}) = cRe(nb_n e^{-in\psi}), \quad n \geq 2. \tag{89}$$

Equation (88) gives

$$b_1 = \frac{c+1}{c-1}\, a. \tag{90}$$

Since $c \neq 1$, we obtain from (89)

$$b_n = 0, \quad n \geq 2. \tag{91}$$

The above computation shows that the mapping function $\phi(\zeta)$ must have the particular form

$$\phi(\zeta) = a\zeta + b_0 + \frac{c+1}{c-1}\,\frac{a}{\zeta}, \tag{92}$$

which implies the desired result. We finally note that K is a disc if $c = -1$.

5. Some open problems. In this section, we want to indicate some open problems which generalize in three dimensions the problems studied in the previous sections. In what follows, Ω_0 will denote the ellipsoid

$$\Omega_0 = \left\{ \mathbf{x} = (x,y,z) \,\Big/\, \frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} < 1 \right\},$$

with $a \geq b \geq c > 0$. The distance h from the tangent plane of $\partial\Omega_0$ to the origin is given by

$$h = \mathbf{x}.\mathbf{n} = \left(\frac{x^2}{a^4} + \frac{y^2}{b^4} + \frac{z^2}{c^4} \right)^{-1/2}, \tag{93}$$

and the Gaussian curvature G of $\partial\Omega_0$ is given by

$$G = h^4/a^2b^2c^2. \tag{94}$$

Of course, the problems described below have analogous N-dimensional versions which could easily be formulated.

The Saint-Venant problem. Let u be the solution of the Saint-Venant problem (5), (6) in Ω_0. We have

$$u(x,y,z) = A\left(\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} - 1\right), \tag{95}$$

$$|\nabla u|^2 = 4A^2\left(\frac{x^2}{a^4} + \frac{y^2}{b^4} + \frac{z^2}{c^4}\right), \tag{96}$$

with $A = -2(\frac{2}{a^2} + \frac{2}{b^2} + \frac{2}{c^2})^{-1}$. It follows from (94), (96) that

$$|\nabla u|^4\, G = \text{const.} \quad \text{on } \partial\Omega_0. \tag{97}$$

It is then natural to state the following problem.

Open problem 1. Let u be the solution of the Saint-Venant problem (5), (6) in Ω, where Ω is a regular bounded, simply connected domain in $\mathbf{R}^3$. Assume moreover that the overdetermined condition (97) is satisfied where G is the Gaussian curvature of $\partial\Omega$. Then prove that Ω is an ellipsoid.

The electrostatic potential problem. Let u be the electrostatic potential of the ellipsoid Ω_0, i.e., the solution of the boundary value problem

$$\Delta u = 0 \quad \text{in } \Omega := \mathbf{R}^3 \backslash \bar{\Omega}_0, \tag{98}$$

$$u = 1 \quad \text{on } \partial\Omega_0, \tag{99}$$

$$|\nabla u| = O(r^{-2}) \quad \text{as } r \to \infty. \tag{100}$$

Using ellipsoidal coordinates, we are able to write u explicitly as

$$u(x,y,z) = \int_\lambda^\infty \frac{dt}{\{(a^2+t)(b^2+t)(c^2+t)\}^{1/2}}, \tag{101}$$

where λ is the largest root of the equation

$$\frac{x^2}{a^2+\lambda} + \frac{y^2}{b^2+\lambda} + \frac{z^2}{c^2+\lambda} = 1.$$

We refer to [Ke] for the derivation of (101). From (101), it follows that

$$x|\nabla u| = \epsilon\, n_1, \tag{102}$$

$$|\nabla u| = \delta h \tag{103}$$

on $\partial\Omega_0$ as in the 2-dimensional case, where ϵ and δ are constants. Therefore, we can state the following problem.

Open problem 2. Let K be a regular simply connected compact set in $\mathbf{R}^3$. Let u be the electrostatic potential defined as the solution of (98)–(100) in $\mathbf{R}^3 \setminus K$. Assume moreover that u satisfies either the overdetermined condition (102) or (103). Then, prove that K is an ellipsoid.

The polarization problem. Let u be the solution of the polarization problem for the ellipsoid

$$\Delta u = 0 \quad \text{in } \Omega := \mathbf{R}^3 \backslash \bar{\Omega}_0, \tag{104}$$

$$u = x + b \quad \text{on } \partial\Omega_0, \tag{105}$$

$$|\nabla u| = O(r^{-3}) \quad \text{as } r \to \infty. \tag{106}$$

Using ellipsoidal coordinates, we are again able to write u explicitly as (see [Sc-Sz])

$$u(x,y,z) = \frac{2x}{p}\int_{\lambda}^{\infty} \frac{dt}{(a^2+t)\{(a^2+t)(b^2+t)(c^2+t)\}^{1/2}}, \tag{107}$$

where p is a constant determined by the boundary condition. It follows from (107) that

$$\frac{\partial u}{\partial n} = \text{const.} n_1 \tag{108}$$

on $\partial\Omega_0$ as in the 2-dimensional case.

Open problem 3. Let K be a regular, simply connected compact set in $\mathbf{R}^3$. Let u be the solution of the polarization problem (104)–(106) in $\mathbf{R}^3 \setminus K$. Assume moreover that u satisfies the overdetermined condition (108). Then, prove that K is an ellipsoid.

ON A FOURTH-ORDER DEGENERATE PARABOLIC EQUATION: GLOBAL ENTROPY ESTIMATES, EXISTENCE, AND QUALITATIVE BEHAVIOR OF SOLUTIONS*

ROBERTA DAL PASSO†, HARALD GARCKE‡, AND GÜNTHER GRÜN§

Abstract. By means of energy and entropy estimates, we prove existence and positivity results in higher space dimensions for degenerate parabolic equations of fourth order with nonnegative initial values. We discuss their asymptotic behavior for $t \to \infty$ and give a counterexample to uniqueness.

Key words. fourth-order degenerate parabolic equations, existence, regularity, long-time behavior, thin films

1. Introduction. In this paper we will present new results on existence, (non) uniqueness, positivity, and asymptotic behavior in higher space dimensions of weak solutions to degenerate parabolic equations of fourth order of the form

$$\begin{aligned} u_t + \operatorname{div}\big(m(u)\nabla\Delta u\big) &= 0 \quad \text{in } \Omega \times (0,T), \\ \frac{\partial u}{\partial \nu} = \frac{\partial}{\partial \nu}\Delta u &= 0 \quad \text{on } \partial\Omega \times [0,T], \\ u(0,\cdot) &= u_0(\,\cdot\,) \quad \text{in } \Omega. \end{aligned} \tag{1.1}$$

We assume that the nonnegative diffusion coefficient m vanishes at zero and has at most polynomial growth. We denote by n its growth exponent near zero.
Equation (1.1) can be seen as the archetype of a class of parabolic equations of higher order which appear in material sciences and fluid dynamics. For instance, in lubrication theory (cf. [3], [8] and the references therein), u describes the height of a viscous droplet spreading on a plain, solid surface; in the Cahn–Hilliard model of phase separation for binary mixtures, u plays the role of the concentration of one component (cf. [10]), and in a plasticity model (cf. [13] and the references therein) u stands for the density of dislocations.

Crucial for these applications is the fact that it is possible to construct solutions of (1.1) which preserve nonnegativity as has been proved for space dimension $N = 1$ by Bernis and Friedman [6] and for higher space dimensions in the papers by Grün [13] and by Elliott and Garcke [10]. This behavior is in strong contrast to that of classical solutions to linear parabolic equations of fourth order which in general become

negative even in the case of strictly positive initial values. Moreover, the publications of Beretta, Bertsch, and Dal Passo [2] and of Bertozzi and Pugh [8], who study this equation in space dimension $N = 1$, reveal a rich structure of qualitative behavior of solutions depending on the diffusion growth exponent n. To put it concisely, the larger n is, the stronger is the tendency of solutions to stay positive and the weaker is the regularity at the boundary of the set where u vanishes.

Recently Bernis [4], [5] showed for the special case $m(u) = u^n$ with $0 < n < 3$ that in space dimension $N = 1$ solutions to (1.1) have the property of finite speed of propagation. More precisely, this means that the interface separating the regions where u is positive and where u is equal to zero moves with finite velocity as time progresses. To obtain these results Bernis used local versions of entropy estimates first derived in [2].

While in the case of higher space dimensions existence results up to now were restricted to the cases $1 \le n < 2$ if $u_0 \ge 0$ arbitrary, and $n \ge 1$ if u_0 is strictly positive (cf. [13] and [10]), the results presented here will overcome this restriction and assure the existence for $\frac{1}{8} < n < 3$ and arbitrary nonnegative initial values u_0. It turns out that in general we cannot expect solutions to have $L^2(0,T;H^2(\Omega))$-regularity. In previous works (cf. [13] and [10]), this property has been a major ingredient in the definition of solution. Thus, we are forced to introduce a new solution concept that—to put in concisely—differs from the previous one in such a way that in the corresponding weak formulation of (1.1) derivatives of u of higher order than 1 do not appear. For the technical details, we refer the reader to the statement of Definition 3.1.

Let us point out that the growth exponent $n = 3$ seems to be a border case in the theory of degenerate fourth-order parabolic equations. This already has been indicated by results of Bernis, Peletier, and Williams [7], who showed that source-type solutions with finite mass only exist for $0 < n < 3$.

Technically, the restriction to values of $n < 3$ in this paper is due to the fact that entropy estimates for compactly supported initial data are not achievable if $n \ge 3$. For similar reasons the results of [4], [5] and many of the results of [2] and [8] are restricted to $n < 3$.

Our work will be based upon a refinement of those entropy estimates which have been used in [13] and [10]; they generalize results of the papers [2] or [8] to space dimensions $N = 2, 3$, which are the relevant ones for applications. Since in the case of higher space dimensions it is still not known whether solutions of (1.1) are in $L^\infty(\Omega_T)$ or whether they are strictly bounded away from zero in case of positive initial values, a more careful approximation process has to be applied than for space dimension $N = 1$.

Another important ingredient in the higher dimensional case which may be of independent interest is the generalization of the formula of integration by parts

$$\int_0^1 f'(u)u_x^2 u_{xx}\,dx = -\tfrac{1}{3}\int_0^1 f''(u)u_x^4\,dx$$

for appropriately smooth functions with $u_x(0) = u_x(1) = 0$ to higher space dimensions, which will be essential in order to obtain the entropy estimates (cf. Lemma 2.3).

Confining ourselves at the moment to entropy estimates global in space, in a forthcoming paper we wish to derive local versions of the entropy estimates and we hope to show results analogous to those of Bernis [4], [5] in higher space dimensions.

Let us briefly describe the outline of this paper.

In section 2 we state the refined entropy estimate first for auxiliary problems with positive initial values and sufficiently large diffusion growth exponents n. In a second step, we extend this result to arbitrary positive values of n by use of an appropriate approximation method.

Section 3 contains the main results of this paper. In Definition 3.1 we introduce the solution concept, in the framework of which we can prove existence of solutions for $\frac{1}{8} < n < 3$ and arbitrary, nonnegative initial values $u_0 \in H^1(\Omega)$ (cf. Theorem 3.2). As a consequence of the a priori estimates derived so far we improve the results of [13] about positivity of solutions (cf. Theorem 3.4) and show convergence to the mean value for $t \to \infty$ with respect to the H^1-norm (cf. Theorem 3.5). The latter result can be used in order to discuss the problem of uniqueness in the framework of the solution concept. By constructing steady state solutions with compact support which do not satisfy the entropy estimates but nevertheless solve the equation in the sense of the solution concept, it becomes evident that we cannot expect uniqueness of solutions without imposing regularity properties at the boundary of the set where u vanishes. Whether these regularity properties are already sufficient for uniqueness still remains an open problem.

Notation. In the whole paper we assume that $\Omega \subset \mathbb{R}^N$ ($N \in \{2, 3\}$) is an open and bounded domain with boundary of class $C^{1,1}$ (or $C^{0,1}$ if Ω is convex) which is piecewise smooth. We denote by I the time interval $(0, T)$, and Ω_T stands for the space-time cylinder $\Omega \times (0, T)$. We denote by ν the unit outer normal vector to $\partial\Omega$, and $II(.)$ is the second fundamental form of $\partial\Omega$. By $H^2_*(\Omega)$ we denote $\{u \in H^2(\Omega) : \frac{\partial}{\partial\nu} u = 0 \text{ on } \partial\Omega\}$. We will use as abbreviation the notation $u \in L^{p-}(\Omega)$ to indicate that $u \in L^q(\Omega)$ for all $q < p$. Furthermore, $\mathcal{L}^N$ denotes the N-dimensional Lebesgue measure and $\mathcal{H}^{N-1}$ denotes the $(N-1)$-dimensional Hausdorff measure. For vectors $v, w \in \mathbb{R}^N$ and symmetric matrices $A \in \mathbb{R}^{N\times N}$, we write $\langle v, A, w\rangle$ instead of $\sum_{i,j} v_i A_{ij} w_j$, and $\langle \cdot, \cdot \rangle$ stands for the standard scalar product on $\mathbb{R}^N$.

2. Entropy estimates. In this section we will present the entropy estimates essential for the qualitative results. For mainly technical reasons we shall confine ourselves at first to a special case of problem (1.1) that is characterized by the following additional conditions on the diffusion coefficient m and on the initial data u_0.

(A1) The diffusivity $m \in C^1(\mathbb{R}^+_0) \cap W^{1,\infty}(\mathbb{R}^+_0)$ can be written as $m(\tau) = \tau^n \cdot f(\tau)$ ($\tau \in \mathbb{R}^+_0$) with a positive function f such that $\|f\|_{C^{1,1}(\mathbb{R}^+_0, \mathbb{R}^+_0)} < \infty$. Furthermore, we assume that m is uniformly bounded from below by a positive constant for sufficiently large values of τ.

(A2) The growth exponent n satisfies

$$n > \begin{cases} 4 & \text{if } N = 2, \\ 8 & \text{if } N = 3. \end{cases}$$

(A3) The initial data $u_0 \in H^1(\Omega)$ are strictly positive; i.e., there exists a constant $\delta > 0$ such that $u_0 \geq \delta > 0$.

In [10] and [13], it has been proved that under the assumptions (A1)–(A3) there exists a pair of functions

$$(u, J) \in H^1\big(I; (H^1(\Omega))'\big) \cap L^\infty\big(I; H^1(\Omega)\big) \cap L^2\big(I; H^2_*(\Omega)\big) \times L^2(\Omega_T, \mathbb{R}^N)$$

which solves (1.1) in the following weak sense:

$$u_t = -\operatorname{div} J \quad \text{in } L^2\big(0, T; (H^1(\Omega))'\big) \tag{2.1}$$

and

$$\int_{\Omega_T} J \cdot \eta = -\int_{\Omega_T} \Delta u \, \mathrm{div}(m(u)\eta) \tag{2.2}$$

for all $\eta \in L^2(0,T;H^1(\Omega,\mathbb{R}^n)) \cap L^\infty(\Omega_T,\mathbb{R}^n)$.

Moreover, for a positive constant C the following estimate holds true:

$$\int_\Omega u(T)^{2-n} dx + \int_{\Omega_T} |\Delta u|^2 \, dxdt \le C \int_\Omega u_0^{2-n} dx \,. \tag{2.3}$$

In particular, this implies that u is strictly positive for almost every $t \in I$ (cf. [13]). This positivity property is the key to the following lemma assuring that under the assumptions (A1)–(A3) $\nabla\Delta u(t) \in L^2(\Omega)$ for almost every $t \in I$, and therefore $J(t) = m(u(t))\nabla\Delta u(t)$ in $L^2(\Omega)$ for these t. As a further consequence, we show that the L^2-norm of ∇u is monotonically decreasing, which will be important to obtain our results regarding asymptotic behavior.

LEMMA 2.1. *Assume* (A1)–(A3) *and let* u *be the weak solution of* (1.1) *constructed as described above. Then for almost all* $t \in [0,T]$ *we have* $u(t) \in C^\beta(\Omega)$ *(for* $\beta > 0$ *appropriately small),* $u(t)$ *is strictly positive, and*

$$J(t,\cdot) = m\big(u(t,\cdot)\big)\nabla\Delta u(t,\cdot) \in L^2(\Omega). \tag{2.4}$$

In addition, for almost every $t_1, t_2 \in I$ *the following estimate is true:*

$$\frac{1}{2}\int_\Omega |\nabla u(t_2)|^2 \, dx + \int_{t_1}^{t_2}\int_\Omega m(u)\,|\nabla\Delta u|^2 \, dxdt \le \frac{1}{2}\int_\Omega |\nabla u(t_1)|^2 \, dx \,. \tag{2.5}$$

The proof of Lemma 2.1 is contained in the Appendix at the end of this paper.

We now state the main entropy estimate. As in papers [2] and [8], we define the entropy to be $G_\alpha(t) = \int_A^t \int_A^s \frac{\tau^{\alpha+n-1}}{m(\tau)} \, d\tau ds$. Here, A is an arbitrary but fixed positive constant.

PROPOSITION 2.2. *Assume* (A1)–(A3) *and let* u *be the weak solution of* (1.1) *constructed by the method of* [10] *and* [13]. *Let* α *and* γ *be real numbers satisfying* $\frac{1}{2} < \alpha + n < 2$,

$$\frac{t+1-\sqrt{(t-2)(1-2t)}}{3} \le \gamma \le \frac{t+1+\sqrt{(t-2)(1-2t)}}{3} \qquad \text{with } \ t := \alpha + n \tag{2.6}$$

and $\gamma \in (\frac{1}{3}, 1)$ *if* $\alpha + n < 1$. *Then we have*

$$\begin{aligned} \int_\Omega G_\alpha\big(u(T)\big)\, dx + C_1^{-1}\int_{\Omega_T} u^{\alpha+n-3}\,|\nabla u|^4 \, dxdt \\ + C_1^{-1}\int_{\Omega_T} u^{\alpha+n+1-2\gamma}\left\{\tfrac{2}{3}\left|D^2 u^\gamma\right|^2 + \tfrac{1}{3}\,|\Delta u^\gamma|^2\right\} dxdt \\ \le \int_\Omega G_\alpha(u_0)\, dx + C_2\int_{\Omega_T} u^{\alpha+n+1}\, dxdt. \end{aligned} \tag{2.7}$$

Here, C_1 *and* C_2 *are constants only depending on the domain* Ω*; in particular,* C_2 *becomes zero if* Ω *is convex.*

Proof. The proof essentially consists of three parts. In the first one we introduce regularized versions of $G'_\alpha(u)$ which we use as test functions in the weak formulation of

equation (1.1). The main difficulty is to control the term containing spatial derivatives which we will henceforth call "elliptic part." To estimate this elliptic part, we at first only formulate a key inequality which allows to pass to the limit with some regularizing parameters (cf. part 2) and thus to establish the result. The last part will be devoted to the detailed verification of that particular inequality.

Part 1. Consider for positive parameters A, σ the functions

$$g^-_{\alpha\sigma}(s) := \int_A^s \frac{(\tau+\sigma)^{\alpha+n-1}}{m(\tau)}\,d\tau \tag{2.8}$$

and

$$g^+_{\alpha\sigma}(s) := \int_A^s \frac{\tau^{\alpha+n-1}}{m(\tau)(1+\sigma\tau^{\alpha+n-1})}\,d\tau\ . \tag{2.9}$$

If $\alpha+n<1$, we choose $g^-_{\alpha\sigma}(u+\varepsilon)$ as the test function in (2.1), (2.2); otherwise we choose $g^+_{\alpha\sigma}(u+\varepsilon)$ and obtain, using Lemma 2.1,

$$\int_0^T \left\langle u_t, g^\pm_{\alpha\sigma}(u+\varepsilon)\right\rangle\,dt = \int_0^T\int_\Omega \big(m(u)\nabla\Delta u, \nabla g^\pm_{\alpha\sigma}(u+\varepsilon)\big)\,dxdt. \tag{2.10}$$

The nonnegativity of u, the shift by ε, and the $L^\infty\big(I;H^1(\Omega)\big)\cap L^2\big(I;H^2(\Omega)\big)$-regularity of u guarantee the admissibility of these test functions. We notice that the functions $G^\pm_{\alpha\sigma}$, defined by

$$G^\pm_{\alpha\sigma}(s) := \int_A^s g^\pm_{\alpha\sigma}(\tau)\,d\tau, \tag{2.11}$$

are nonnegative and convex, that for fixed $\varepsilon>0$ their derivative $g^\pm_{\alpha\sigma}$ has at most linear growth on $[\varepsilon,\infty)$, and that for this reason we obtain (cf. [13, Lemma 2.6])

$$\int_0^T \left\langle u_t, g^\pm_{\alpha\sigma}(u+\varepsilon)\right\rangle\,dt = \int_\Omega G^\pm_{\alpha\sigma}(u+\varepsilon)(T,x)\,dx - \int_\Omega G^\pm_{\alpha\sigma}(u_0+\varepsilon)(x)\,dx. \tag{2.12}$$

In what follows, we shall make the calculations explicit only for $g^-_{\alpha\sigma}$ (i.e., $\alpha+n<1$). But by minor modifications the same strategy will work also in the case $\alpha+n\ge 1$.

Part 2. For almost all $t\in I$ the following inequality offers an estimate for the elliptic part (we set $\beta_{\varepsilon\sigma}(u) := (u+\varepsilon+\sigma)^{\alpha+n-1}$ for short):

(2.13)

$$\begin{aligned}
&-\int_\Omega m(u)\nabla\Delta u\nabla g^-_{\alpha\sigma}(u+\varepsilon)\\
&\ge \int_\Omega S_1(u)\left[D^2\big((u+\varepsilon)^\gamma\big)\right]^2 + \int_\Omega S_2(u)\left[\Delta\big((u+\varepsilon)^\gamma\big)\right]^2 + \int_\Omega S_3(u)\,|\nabla u|^4\\
&\quad -\int_\Omega\Big((\delta_1+\delta_3)(u+\varepsilon+\sigma)^{\alpha+n-3}\,|\nabla u|^4 + \delta_2(u+\varepsilon+\sigma)^{\alpha+n-1}(u+\varepsilon)^{-2}|\nabla u|^4\Big)\\
&\quad -\delta_3\int_\Omega\left|D^2(u+\varepsilon+\sigma)^{\frac{\alpha+n+1}{2}}\right|^2 - \frac{C}{\delta_1}\int_\Omega \beta_{\varepsilon\sigma}(u)\left(\frac{m(u)}{m(u+\varepsilon)}-1\right)|\Delta u|^2\\
&\quad -\frac{C}{\delta_2}\int_\Omega \beta_{\varepsilon\sigma}(u)|\Delta u|^2\left(\frac{\varepsilon}{u+\varepsilon}\right)^2 - C_{\delta_3}\int_\Omega (u+\varepsilon+\sigma)^{\alpha+n+1}\\
&\quad = \mathrm{I}+\mathrm{II}+\cdots+\mathrm{VIII}
\end{aligned}$$

with $\delta_i > 0$ arbitrary, $C > 0$ independent of t, and

$$\begin{aligned}
S_1(u) &= \tfrac{2}{3}\gamma^{-2}\beta_{\varepsilon\sigma}(u)\cdot(u+\varepsilon)^{2-2\gamma},\\
S_2(u) &= \tfrac{1}{3}\gamma^{-2}\beta_{\varepsilon\sigma}(u)\cdot(u+\varepsilon)^{2-2\gamma},\\
S_3(u) &= (1-\gamma)\left(\gamma-\tfrac{1}{3}\right)(u+\varepsilon+\sigma)^{\alpha+n-1}\cdot(u+\varepsilon)^{-2}\\
&\quad -\tfrac{1}{3}(\alpha+n-1)(\alpha+n-2)(u+\varepsilon+\sigma)^{\alpha+n-3}\\
&\quad +\tfrac{2}{3}(1-\gamma)(1-\alpha-n)\frac{(u+\varepsilon+\sigma)^{\alpha+n-2}}{(u+\varepsilon)}.
\end{aligned}$$

Before we prove the above inequality in part 3, we show that this inequality gives the assertion of Proposition 2.2.

Consequences of inequality (2.13). Observing that the first and third term in $S_3(u)$ are positive and that $\sigma > 0$, we have that $S_3(u) > 0$ if

$$c(\alpha,n,\gamma) := (1-\gamma)\left(\gamma-\tfrac{1}{3}\right) - \tfrac{1}{3}(\alpha+n-1)(\alpha+n-2) + \tfrac{2}{3}(1-\gamma)(1-\alpha-n)$$

is positive, i.e., if (2.6) is true.

Then, choosing $\delta_1, \delta_2, \delta_3$ sufficiently small, the terms IV and V in (2.13) can be absorbed in I, II, and III. In addition, we have the following:

- The integrand on the left-hand side is in $L^1(\Omega_T)$.
- As a consequence of the $L^2(I;H^2(\Omega))$-regularity of u, the integrands in the terms VI, VII, and VIII are uniformly bounded in $L^1(\Omega_T)$.
- The integrands in the terms I, II, and III are nonnegative.

This allows us to integrate over the whole space-time cylinder and to obtain from (2.10), (2.12), and (2.13) the existence of positive constants $\tilde{C}_1$ and $\tilde{C}_2$ independent of ε and σ such that

(2.14)
$$\begin{aligned}
&\int_\Omega G_{\alpha\sigma}(u+\varepsilon)_{|T} + \tilde{C}_1^{-1}\int_{\Omega_T}(u+\varepsilon+\sigma)^{\alpha+n-3}\,|\nabla u|^4\\
&\qquad + \tilde{C}_1^{-1}\int_{\Omega_T}\beta_{\varepsilon\sigma}(u)\cdot(u+\varepsilon)^{2-2\gamma}\left\{\tfrac{2}{3}\left|D^2\big((u+\varepsilon)^\gamma\big)\right|^2 + \tfrac{1}{3}\left|\Delta\big((u+\varepsilon)^\gamma\big)\right|^2\right\}\\
&\qquad \le \int_\Omega G_{\alpha\sigma}(u_0+\varepsilon) + \tilde{C}_2\Bigg\{\int_{\Omega_T}(u+\varepsilon+\sigma)^{\alpha+n+1}\\
&\qquad\qquad + \int_{\Omega_T}\beta_{\varepsilon\sigma}(u)\,|\Delta u|^2\left\{\frac{m(u)}{m(u+\varepsilon)} - 1 + \left(\frac{\varepsilon}{u+\varepsilon}\right)^2\right\}\Bigg\}.
\end{aligned}$$

Passage to the limit $\varepsilon \to 0$ *in inequality* (2.14). From the $L^2(I;H^2(\Omega))\cap L^\infty(I;H^1(\Omega))$-regularity of u, the uniform boundedness of $\beta_{\varepsilon\sigma}(u)$, and Lebesgue's theorem, we infer that the second term on the right-hand side converges to $\int_{\Omega_T} u^{\alpha+n+1}$ and that the last term on the right-hand side tends to zero. Since $u_0 \ge \delta > 0$ and $u_0 \in H^1(\Omega)$, a further application of Lebesgue's theorem gives that $\int_\Omega G_{\alpha\sigma}(u_0+\varepsilon)$ converges to $\int_\Omega G_{\alpha\sigma}(u_0)$ for $\varepsilon \to 0$.

Since the third term on the left-hand side can also be written in the form $\int_{\Omega_T}|\nabla(u+\varepsilon+\sigma)^{\frac{\alpha+n+1}{4}}|^4$, it is obvious that $\int_{\Omega_T}|\nabla(u+\sigma)^{\frac{\alpha+n+1}{4}}|^4$ is dominated by $\liminf_{\varepsilon\to 0}\int_{\Omega_T}(u+\varepsilon+\sigma)^{\alpha+n-3}\,|\nabla u|^4$. Similarly, the second term on the left-hand side can be handled,

and by use of Fatou's lemma we derive

(2.15)
$$\int_\Omega G_{\alpha\sigma}\big(u(T)\big)\,dx + C_1^{-1}\int_{\Omega_T}(u+\sigma)^{\alpha+n-1}\cdot u^{2-2\gamma}\left\{\tfrac{2}{3}\left|D^2u^\gamma\right|^2+\tfrac{1}{3}\left|\Delta u^\gamma\right|^2\right\}dxdt$$
$$+C_1^{-1}\int_{\Omega_T}(u+\sigma)^{\alpha+n-3}\left|\nabla u\right|^4\,dxdt$$
$$\le\int_\Omega G_{\alpha\sigma}(u_0)\,dx + C_2\int_{\Omega_T}(u+\sigma)^{\alpha+n+1}\,dxdt\,.$$

Passage to the limit $\sigma\to 0$ in inequality (2.15). An application of Fatou's lemma, the monotone convergence theorem, and the same methods to estimate limits of gradients of powers of u as used before gives the following result:

(2.16)
$$\int_\Omega G_{\alpha}\big(u(T)\big)\,dx + C_1^{-1}\int_{\Omega_T}u^{\alpha+n+1-2\gamma}\left\{\tfrac{2}{3}\left|D^2u^\gamma\right|^2+\tfrac{1}{3}\left|\Delta u^\gamma\right|^2\right\}dxdt$$
$$+C_1^{-1}\int_{\Omega_T}u^{\alpha+n-3}\left|\nabla u\right|^4\,dxdt$$
$$\le\int_\Omega G_{\alpha}(u_0)\,dx\,+C_2\int_{\Omega_T}u^{\alpha+n+1}\,dxdt\,.$$

Part 3. (Proof of inequality (2.13)). Integrating by parts and using $\frac{\partial u}{\partial\nu}=0$ on $\partial\Omega$, we obtain

$$-\int_\Omega m(u)\,\nabla\Delta u\,\nabla g^-_{\alpha\sigma}(u+\varepsilon)\,dx=\int_\Omega \operatorname{div}\left(\frac{m(u)}{m(u+\varepsilon)}\,\beta_{\varepsilon\sigma}(u)\,\nabla u\right)\Delta u\,dx$$
$$=\int_\Omega\left(\frac{m(u)}{m(u+\varepsilon)}\,\beta_{\varepsilon\sigma}(u)\right)\left|\Delta u\right|^2\,dx+\int_\Omega\left(\frac{m(u)}{m(u+\varepsilon)}\,\beta_{\varepsilon\sigma}(u)\right)_u\left|\nabla u\right|^2\,\Delta u\,dx=:I_1+I_2\,.$$

For I_1 and I_2 we calculate

$$I_1=\int_\Omega\beta_{\varepsilon\sigma}(u)\left|\Delta u\right|^2\,dx+\int_\Omega\beta_{\varepsilon\sigma}(u)\left(\frac{m(u)}{m(u+\varepsilon)}-1\right)\left|\Delta u\right|^2\,dx=I_1^1+I_1^2,$$
$$I_2=\int_\Omega\left\{\left(\frac{m'(u)}{m(u+\varepsilon)}-\frac{m(u)m'(u+\varepsilon)}{m(u+\varepsilon)^2}\right)\beta_{\varepsilon\sigma}(u)\right.$$
$$\left.+\frac{m(u)}{m(u+\varepsilon)}(\alpha+n-1)(u+\varepsilon+\sigma)^{\alpha+n-2}\right\}\left|\nabla u\right|^2\Delta u\,dx$$
$$=I_2^1+I_2^2.$$

Observing the existence of a constant C independent of ε with the property

$$\left|\frac{m'(u)}{m(u+\varepsilon)}-\frac{m(u)m'(u+\varepsilon)}{m(u+\varepsilon)^2}\right|\le C\cdot\left(\frac{u}{u+\varepsilon}\right)^{n-1}\frac{\varepsilon}{(u+\varepsilon)^2},$$

the term I_2^1 can be estimated as follows:

$$I_2^1\ge -C\int_\Omega\beta_{\varepsilon\sigma}(u)(u+\varepsilon)^{-1}\cdot\left|\nabla u\right|^2\cdot\left|\Delta u\right|\frac{\varepsilon}{u+\varepsilon}\,dx$$
$$\ge-\delta_2\int_\Omega\beta_{\varepsilon\sigma}(u)(u+\varepsilon)^{-2}\cdot\left|\nabla u\right|^4\,dx-\frac{\tilde C}{\delta_2}\int_\Omega\beta_{\varepsilon\sigma}(u)\left|\Delta u\right|^2\cdot\left(\frac{\varepsilon}{u+\varepsilon}\right)^2\,dx.$$

We now write I_2^2 as

$$\begin{aligned} I_2^2 &= (\alpha+n-1)\int_\Omega (u+\varepsilon+\sigma)^{\alpha+n-2}\,|\nabla u|^2\,\Delta u\,dx \\ &\quad +(\alpha+n-1)\int_\Omega (u+\varepsilon+\sigma)^{\alpha+n-2}\left(\frac{m(u)}{m(u+\varepsilon)}-1\right)|\nabla u|^2\,\Delta u\,dx \\ &= R_1+R_2. \end{aligned}$$

R_2 can be estimated as

$$\begin{aligned} R_2 \geq &-\delta_1\int_\Omega (u+\varepsilon+\sigma)^{\alpha+n-3}\,|\nabla u|^4\,dx \\ &-\frac{C}{\delta_1}\int_\Omega (u+\varepsilon+\sigma)^{\alpha+n-1}\left(\frac{m(u)}{m(u+\varepsilon)}-1\right)^2|\Delta u|^2\,dx. \end{aligned}$$

To proceed further it will be worthwhile to state a formula of integration by parts that generalizes the one-dimensional formula

$$\int_0^1 f'(u)\cdot u_x^2\cdot u_{xx}\,dx = -\tfrac{1}{3}\int_0^1 f''(u)\cdot u_x^4\,dx \qquad \text{if } u_x(0)=u_x(1)=0$$

to higher space dimensions.

LEMMA 2.3. *Let $f\in W^{2,\infty}(\mathbb{R})$ and $u\in H^2_*(\Omega)$. Then we have*

$$\begin{aligned} \int_\Omega f'(u)\,|\nabla u|^2\,\Delta u\,dx = &-\tfrac{1}{3}\int_\Omega f''(u)\,|\nabla u|^4\,dx \\ &+\tfrac{2}{3}\left(\int_\Omega f(u)\left|D^2u\right|^2\,dx-\int_\Omega f(u)\,|\Delta u|^2\,dx\right) \\ &+\tfrac{2}{3}\int_{\partial\Omega} f(u)II\big(\nabla u\big)\,d\mathcal{H}^{N-1}. \end{aligned}$$

Here, $II(\cdot)$ denotes the second fundamental form of $\partial\Omega$.

For a proof of Lemma 2.3 we refer to the Appendix.

Now, setting $f(u)=\beta_{\varepsilon\sigma}(u)$ and using the identity

$$D_{x_ix_j}v = \gamma^{-1}v^{1-\gamma}\,D_{x_ix_j}v^\gamma-(\gamma-1)\,v^{-1}\,D_{x_i}v\,D_{x_j}v$$

for $v=u+\varepsilon$, R_1 reads as

$$\begin{aligned} R_1 = &-\tfrac{1}{3}\int_\Omega \beta''_{\varepsilon\sigma}(u)\,|\nabla u|^4+\tfrac{2}{3}\gamma^{-2}\int_\Omega \beta_{\varepsilon\sigma}(u)\,(u+\varepsilon)^{2-2\gamma}\left\{\left[D^2(u+\varepsilon)^\gamma\right]^2-\left[\Delta(u+\varepsilon)^\gamma\right]^2\right\} \\ &+2(\gamma-1)\int_\Omega \beta_{\varepsilon\sigma}(u)\,(u+\varepsilon)^{-1}\,\Delta u\,|\nabla u|^2+\tfrac{2}{3}(\gamma-1)\int_\Omega\left((u+\varepsilon)^{-1}\,\beta_{\varepsilon\sigma}(u)\right)_u|\nabla u|^4 \\ &+\tfrac{2}{3}\int_{\partial\Omega}\beta_{\varepsilon\sigma}(u)\,II\big(\nabla u\big)\,d\mathcal{H}^{N-1}. \end{aligned}$$

For I_1^1 we obtain

$$\begin{aligned} I_1^1 = &\gamma^{-2}\int_\Omega \beta_{\varepsilon\sigma}(u)\,(u+\varepsilon)^{2-2\gamma}\left[\Delta\big((u+\varepsilon)^\gamma\big)\right]^2-2(\gamma-1)\int_\Omega \beta_{\varepsilon\sigma}(u)\,(u+\varepsilon)^{-1}\,\Delta u\,|\nabla u|^2 \\ &-(\gamma-1)^2\int_\Omega \beta_{\varepsilon\sigma}(u)\,(u+\varepsilon)^{-2}\,|\nabla u|^4\ . \end{aligned}$$

Summing up, we finally arrive at

$$
\begin{aligned}
I_1^1 + R_1 = &\int_\Omega S_1(u) \left[D^2\big((u+\varepsilon)^\gamma\big)\right]^2 \, dx + \int_\Omega S_2(u) \left[\Delta\big((u+\varepsilon)^\gamma\big)\right]^2 \, dx \\
&+ \int_\Omega S_3(u) \, |\nabla u|^4 \, dx + \tfrac{2}{3} \int_{\partial\Omega} \beta_{\varepsilon\sigma}(u) \, II\big(\nabla u\big) \, d\mathcal{H}^{N-1}
\end{aligned} \tag{2.17}
$$

with $S_1(u), S_2(u)$, and $S_3(u)$ as in (2.13). Collecting all the terms, (2.13) will be established, provided we can estimate the boundary term accordingly.

Let us remark that convexity of Ω implies the nonnegativity of the last term on the right-hand side in (2.17). Hence in this case we can neglect it for our a priori estimates, and in particular the last term on the right-hand side of (2.13) cancels out. Let us now concentrate on the case that Ω is not convex. First we state an interpolation inequality that easily can be proved by contradiction using the compactness of the imbedding $H^1(\Omega) \to L^2(\partial\Omega)$ which holds true for domains with Lipschitz boundary.

LEMMA 2.4. *Let Ω be of class $C^{0,1}$. For each $\varepsilon > 0$ there exists a constant $C_\varepsilon < \infty$ such that we have, for all $v \in H^2(\Omega)$,*

$$
\|\nabla v\|_{L^2(\partial\Omega)} \le \varepsilon \left\|D^2 v\right\|_{L^2(\Omega)} + C_\varepsilon \|v\|_{L^2(\Omega)} .
$$

Since $\partial\Omega$ is of class $C^{1,1}$ we can conclude that the second fundamental form of $\partial\Omega$ is uniformly bounded. Thus we have to estimate $\int_{\partial\Omega} \beta_{\varepsilon\sigma}(u) \, |\nabla u|^2 \, d\mathcal{H}^{N-1}$. Choosing a function $\Phi_{\varepsilon\sigma} : \mathbb{R} \to \mathbb{R}$ with $\Phi'_{\varepsilon\sigma} = \sqrt{\beta_{\varepsilon\sigma}}$ and applying Lemma 2.4, we obtain, after straightforward calculations,

$$
\int_{\partial\Omega} \beta_{\varepsilon\sigma}(u) \, |\nabla u|^2 \, d\mathcal{H}^{N-1} \le \delta_3 \int_\Omega \left|D^2 \Phi_{\varepsilon\sigma}(u)\right|^2 \, dx + C_{\delta_3} \int_\Omega |\Phi_{\varepsilon\sigma}(u)|^2 \, dx.
$$

Using the relation $\Phi_{\varepsilon\sigma}(u) = \text{const} \cdot (u + \varepsilon + \sigma)^{\frac{\alpha+n+1}{2}}$, we end up with

$$
\begin{aligned}
-\int_{\partial\Omega} \beta_{\varepsilon\sigma}(u) \, |\nabla u|^2 \, d\mathcal{H}^{N-1} \ge &- \delta_3 \int_\Omega \left|D^2 (u+\varepsilon+\sigma)^{\frac{\alpha+n+1}{2}}\right|^2 \, dx \\
&- C_{\delta_3} \int_\Omega |u+\varepsilon+\sigma|^{\alpha+n+1} \, dx.
\end{aligned}
$$

This proves estimate (2.13) and therefore Proposition 2.2. ∎

Our next goal is to establish entropy estimates in the spirit of Proposition 2.2 for diffusion coefficients m which are bounded from below by positive constants for large values of τ. We distinguish two cases:

(i)

$$
m \in C^1(\mathbb{R}^+) \cap W^{1,\infty}(1,\infty) \text{ with } n > 0 \text{ arbitrary} \tag{2.18}
$$

and (ii)

$$
\begin{aligned}
m(\tau) = |\tau|^n \cdot f(\tau) \qquad &\text{with } n > 0 \text{ arbitrary if } N = 2, \\
&0 < n < 4 \qquad \text{if } N = 3,
\end{aligned} \tag{2.19}
$$

$$
f \in C^2(\mathbb{R}, \mathbb{R}^+) \cap L^\infty(\mathbb{R}, \mathbb{R}^+). \tag{2.20}
$$

We shall proceed as follows: for a special choice of mobilities $(m_\delta)_{\delta>0}$ which approach m from below we obtain entropy estimates by use of Proposition 2.2.

A compactness lemma which offers all the convergence properties necessary for passing to the limit with $\delta \searrow 0$ will be crucial. It reads as follows.

LEMMA 2.5. *Let $(u_\delta, J_\delta)_{\delta\searrow 0}$ be a family of pairs of functions having the following properties:*

(i) $(u_\delta)_t = -\operatorname{div} J_\delta$ *in* $L^2(I;(W^{1,q}(\Omega))')$ $\quad \forall q > \frac{4N}{2N+(2-N)\cdot n}$,

(ii) $(J_\delta)_{\delta\searrow 0}$ *is uniformly bounded in* $L^2\big(I;L^{q'}(\Omega)\big)$ $\quad \forall q' < \frac{4N}{2N+(N-2)\cdot n}$,

(iii) $(u_\delta)_{\delta\searrow 0}$ *are nonnegative and for a number* $\beta \in \big(\frac{3}{4},\frac{3}{2}\big)$ *we have* $(u_\delta^\beta)_{\delta\searrow 0}$ *is uniformly bounded in* $L^2\big(I;H^2(\Omega)\big)$,

(iv) $(u_\delta)_{\delta\searrow 0}$ *is uniformly bounded in* $L^\infty\big(I;H^1(\Omega)\big)$.

Under the assumption that $q < \frac{2N}{N-2}$, the family $(u_\delta^\beta)_{\delta\searrow 0}$ is relatively compact in $L^2\big(I;H^1(\Omega)\big)$.

Remark. In dimension $N = 2$ there exists for every $n > 0$ a real number q in agreement with (i) which satisfies $q < \frac{2N}{N-2}$. In dimension $N = 3$ we need the condition $n < 4$, unless $(J_\delta)_{\delta\searrow 0}$ is uniformly bounded in $L^2(\Omega_T)$. The assumption $\beta \in (\frac{3}{4},\frac{3}{2})$ is not the most general condition one could impose, but it is nevertheless sufficient for our applications.

Proof of Lemma 2.5. It mainly consists of three steps.

(1) There is a constant $C > 0$ independent of $\delta > 0$ such that

$$\int_0^{T-h}\int_\Omega \big(u_\delta^\beta(t+h,x)-u_\delta^\beta(t,x)\big)\big(u_\delta(t+h,x)-u_\delta(t,x)\big)\,dxdt \le C\cdot h. \tag{2.21}$$

To prove this assertion we choose as the test function in the weak formulation of $(u_\delta)_t = -\operatorname{div} J_\delta$ the function $\phi(t,x) = \big(u_\delta^\beta(s+h,x)-u_\delta^\beta(s,x)\big)\cdot\chi_{[s,s+h]}(t)$ which is admissible. Integrating over $[0,T]$ with respect to t and over $[0,T-h]$ with respect to s, we arrive at

$$\begin{aligned}
&\left|\int_0^{T-h}\int_\Omega \big(u_\delta^\beta(s+h,x)-u_\delta^\beta(s,x)\big)\big(u_\delta(s+h,x)-u_\delta(s,x)\big)\,dsdx\right| \\
&\le \left|\int_0^{T-h}\int_s^{s+h}\int_\Omega J_\delta(t,x)\cdot\nabla\big(u_\delta^\beta(s+h,x)-u_\delta^\beta(s,x)\big)\,dxdtds\right| \\
&\le \int_0^{T-h}\int_0^h \|J_\delta(s+\tau,\cdot)\|_{q'}\cdot\Big\|\nabla\big(u_\delta^\beta(s+h,.)-u_\delta^\beta(s,.)\big)\Big\|_q\,d\tau\,ds \\
&\le 2\int_0^h \|J_\delta\|_{L^2(L^{q'})}\cdot\big\|\nabla u^\beta\big\|_{L^2(L^q)}\,d\tau \;\le 2\cdot C\cdot h.
\end{aligned}$$

(2) A subsequence of $(u_\delta^\beta)_{\delta\searrow 0}$ converges to u^β strongly in $L^1(\Omega_T)$.

In order to derive (2) we observe that

(a) $u_\delta \rightharpoonup u$ in $L^2\big(I;H^1(\Omega)\big)$ according to (iv),

(b) $(u_\delta^{\beta+1})_{\delta\searrow 0}$ is uniformly bounded in $L^\infty\big(I;L^1(\Omega)\big)$ (cf. iv),

(c) (2.21) holds true.

With the notation $b(u) = u^\beta$ and $B(u) = \frac{\beta}{\beta+1}u^{\beta+1}$ we can apply the following lemma (for a proof, see Alt and Luckhaus [1, Lemma 1.9]) in order to establish the result.

LEMMA. *Suppose that $(u_\delta)_{\delta\searrow 0}$ is a sequence which converges weakly to u in the*

space $L^r((0,T);W^{1,r}(\Omega))$ *and satisfies the estimates*

$$\frac{1}{h}\int_0^{T-h}\int_\Omega (b(u_\delta(t+h))-b(u_\delta(t)))(u_\delta(t+h)-u_\delta(t))dt \le C$$

and

$$\int_\Omega B(u_\delta(t)) \le C \quad \textit{for } 0<t<T,$$

uniformly with respect to δ. *Then* $b(u_\delta)\to b(u)$ *in* $L^1(\Omega_T)$ *and* $B(u_\delta)\to B(u)$ *almost everywhere.*

Let us remark that in the case $q=2$ this convergence result could have been deduced directly by using $u_t \in L^2(I;(H^1(\Omega))')$ and $u\in L^\infty(I;H^1(\Omega))$.

(3) From Fréchet–Kolmogorov's theorem and (2) we infer that

$$\lim_{h\to 0}\left\|u_\delta^\beta(\cdot+h,\cdot)-u_\delta^\beta(\cdot,\cdot)\right\|_{L^1\left((0,T-h),L^1(\Omega)\right)}=0$$

uniformly for $\delta>0$.

We then apply the following theorem due to J. Simon.

THEOREM (see [14, p. 84]). *Let* $X\subset B\subset Y$ *with compact imbedding* $X\hookrightarrow B$ *and* $1\le p\le\infty$.

If $F\subset L^p(I;X)$ *is bounded and* $\|f(\cdot+h,\cdot)-f(\cdot)\|_{L^p(0,T-h,Y)}\to 0$ *uniformly for* $f\in F$ *as* $h\to 0$, *then* F *is relatively compact in* $L^p(I;B)$.

With the choice $p=1$, $X=H^2(\Omega)$, $B=H^1(\Omega)$, and $Y=L^1(\Omega)$, we obtain at first that $(u_\delta^\beta)_{\delta\searrow 0}$ is relatively compact in $L^1\big(I;H^1(\Omega)\big)$, and then with (iv) we immediately obtain the assertion. □

Let us now specify the auxiliary diffusion coefficients m_δ which we want to use in order to obtain entropy estimates analogous to Proposition 2.2. We consider two cases. At first we study the case when m is bounded, but we allow the growth exponent near zero to be arbitrary. Having shown convergence of approximating solutions in this case, we are in a position to investigate situations where m has polynomial growth at infinity. Thus, the auxiliary diffusion coefficients read as follows.

(1) If m is bounded (like in (2.18)), we choose

$$m_\delta^{(1)}(\tau)=\frac{\tau^s m(\tau)}{\delta m(\tau)+\tau^s}\ , \tag{2.22}$$

with sufficiently large s to apply Proposition 2.2.

(2) If m has polynomial growth, i.e.,

$$m(\tau)=|\tau|^n\cdot f(\tau) \qquad \text{with } n\in\begin{cases}(0,\infty) & \text{if } N=2,\\ (0,4) & \text{if } N=3,\end{cases} \tag{2.23}$$

and f as in (2.20), then we choose

$$m_\delta^{(2)}(\tau)=\frac{\tau^n}{1+\delta\,|\tau|^n}\cdot f(\tau).$$

This leads to the following auxiliary problems:

$$P_\delta^i\begin{cases}(u_\delta^{(i)})_t+\operatorname{div}\big(m_\delta^{(i)}(u_\delta^{(i)})\nabla\Delta u_\delta^{(i)}\big)=0 & \text{in } \Omega_T,\\ \frac{\partial}{\partial\nu}u_\delta^{(i)}=\frac{\partial}{\partial\nu}\Delta u_\delta^{(i)}=0 & \text{on } \partial\Omega\times[0,T],\\ u_{\delta 0}^{(i)}=u_0+\delta^{\Theta_i} & \text{in } \Omega,\end{cases} \tag{2.24}$$

with $0 < \Theta_1 < \frac{1}{s-\alpha-n-1}$ and $0 < \Theta_2$.

Using the notation

$$
\begin{aligned}
G^{(i)}_{\alpha\delta}(t) &:= \int_A \int_A \frac{\tau^{\alpha+n-1}}{m^{(i)}_\delta(\tau)}\, d\tau ds \qquad \text{and} \\
G^{(i)}_{\alpha}(t) &:= \int_A \int_A \frac{\tau^{\alpha+n-1}}{m^{(i)}(\tau)}\, d\tau ds,
\end{aligned} \tag{2.25}
$$

we have the following proposition.

PROPOSITION 2.6. *Let $n_i > 0$ be the growth exponent of $m^{(i)}_\delta$ near zero and let $q_i > \frac{4N}{2N+(2-N)n_i}$. Assume that there exist constants $C_i > 0$ and α_i with $\frac{1}{2} < \alpha_i + n_i < 2$ such that $\int_\Omega G^{(i)}_\alpha(u_0)\, dx < C_i$. In the case $i = 2$ we furthermore require that the pair (N, n_2) satisfy the conditions in (2.23). Then for a subsequence $(u^{(i)}_\delta)_{\delta \searrow 0}$ of solutions to the auxiliary problems P^i_δ the following convergence properties hold true:*

(i) $u^{(i)}_\delta \overset{*}{\rightharpoonup} u^{(i)}$ *in* $L^\infty\big(I; H^1(\Omega)\big)$,

(ii) $J^{(i)}_\delta \rightharpoonup J^{(i)}$ *in* $L^2\big(I; L^2(\Omega)\big)$ *if* $i = 1$ *or*
in $L^2\big(I; L^{q_i'}(\Omega)\big)$ *if* $i = 2$, *respectively*,

(iii) $\big(u^{(i)}_\delta\big)_t \rightharpoonup \big(u^{(i)}\big)_t$ *in* $L^2\big(I; \big(H^1(\Omega)\big)'\big)$ *if* $i = 1$ *or*
in $L^2\big(I; \big(W^{1,q_i}(\Omega)\big)'\big)$ *if* $i = 2$, *respectively*,

(iv) $\big(u^{(i)}_\delta\big)^{\frac{\alpha+n+1}{2}} \rightharpoonup \big(u^{(i)}\big)^{\frac{\alpha+n+1}{2}}$ *in* $L^2\big(I; H^2(\Omega)\big)$,

(v) $\big(u^{(i)}_\delta\big)^{\frac{\alpha+n+1}{4}} \rightharpoonup \big(u^{(i)}\big)^{\frac{\alpha+n+1}{4}}$ *in* $L^4\big(I; W^{1,4}(\Omega)\big)$,

(vi) $\big(u^{(i)}_\delta\big)^{\frac{\alpha+n+1}{2}} \to \big(u^{(i)}\big)^{\frac{\alpha+n+1}{2}}$ *strongly in* $L^2\big(I; H^1(\Omega)\big)$,

where q_i' denotes the conjugate exponent to q_i.

For the limiting function $u^{(i)}$ the following estimate is valid with constants C_1 and C_2 which only depend on the domain Ω (in particular, C_2 is zero if Ω is convex):

$$
\begin{aligned}
\sup_{t\in[0,T]} \int_\Omega G^{(i)}_\alpha\big(u^{(i)}(t)\big) &+ C_1^{-1} \int_{\Omega_T} \Big| D^2 (u^{(i)})^{\frac{\alpha+n+1}{2}} \Big|^2 + C_1^{-1} \int_{\Omega_T} \Big| \nabla (u^{(i)})^{\frac{\alpha+n+1}{4}} \Big|^4 \\
&\le \int_\Omega G^{(i)}_\alpha(u_0) + C_2 \int_{\Omega_T} (u^{(i)})^{\alpha+n+1}\,.
\end{aligned} \tag{2.26}
$$

Proof. We present it in detail only for the case $i = 1$, drop here the superscript (i) and indicate the main modification necessary for the other case. For a given α satisfying $\frac{1}{2} < \alpha + n < 2$ we choose $\tilde\alpha := \alpha + (n - s)$ and apply Proposition 2.2 with $\frac{1}{2} < \tilde\alpha + s < 2$ to u_δ. This gives after rewriting in terms of α and n:

$$
\begin{aligned}
\sup_{t\in[0,T]} \int_\Omega G_{\alpha\delta}\big(u_\delta(t,x)\big) &+ C_1^{-1} \int_{\Omega_T} u_\delta^{\alpha+n+1-2\gamma} \big| D^2 u_\delta^\gamma \big|^2 + C_1^{-1} \int_{\Omega_T} u_\delta^{\alpha+n-3} \big| \nabla u_\delta \big|^4 \\
&\le \int_\Omega G_{0\delta}\big(u_{0\delta}(x)\big) + C_2 \int_{\Omega_T} u_\delta^{\alpha+n+1}\,.
\end{aligned} \tag{2.27}
$$

Using now the identity

$$
D_{x_i x_j} u^\gamma = \gamma(\gamma-1)\, u^{\gamma-2} D_{x_i} u D_{x_j} u + \gamma u^{\gamma-1} D_{x_i x_j} u
$$

and Young's inequality, we observe after straightforward calculations the existence of a new constant C_1 independent of δ, γ such that

$$\begin{aligned}\sup_{t\in[0,T]}\int_\Omega G_{\alpha\delta}\big(u_\delta(t,x)\big) &+ C_1^{-1}\int_{\Omega_T}\Big|D^2 u_\delta^{\frac{\alpha+n+1}{2}}\Big|^2 + C_1^{-1}\int_{\Omega_T}\Big|\nabla u_\delta^{\frac{\alpha+n+1}{4}}\Big|^4 \\ &\le \int_\Omega G_{\alpha\delta}\big(u_{0\delta}(x)\big) + C_2\int_{\Omega_T} u_\delta^{\alpha+n+1}\ .\end{aligned} \tag{2.28}$$

From estimate (2.5) we infer the validity of (i), (ii), and (iii). Combining these results with the inequality

$$\int_\Omega G_{\alpha\delta}\big(u_{0\delta}(x)\big)\,dx \le \int_\Omega G_\alpha\big(u_0(x)\big)\,dx + o_\delta(1),$$

we obtain by use of Lemma 2.5 the validity of (iv)–(vi). Writing

$$G_{\alpha\delta}(t) = \int_A^t\int_A^s G_\alpha(\tau)d\tau ds + \delta\int_A^t\int_A^s \tau^{\alpha+n-s-1}d\tau ds,$$

observing that the second term on the right is nonnegative, and using both Fatou's lemma and the convergence of u_δ to u pointwise almost everywhere, we end up with (2.26).

For the case $i = 2$ we only have to convince ourselves that J_δ is uniformly bounded in $L^2\big(I; L^{q'}(\Omega)\big)$ for $q' < \frac{4N}{2N+(N-2)n}$. This can be seen by use of Hölder's inequality and the uniform boundedness of the quantities

$$\int_{\Omega_T}\big(m_\delta(u_\delta^\varepsilon)+\varepsilon\big)\,|\nabla\Delta u_\delta^\varepsilon|^2\,dxdt$$

which occur during the proof of existence of solutions to degenerate problems by use of nondegenerate auxiliary problems (cf. [13], [10]). □

Remark. For $N = 3$ the Sobolev imbedding theorem implies that the limit u from Proposition 2.6 belongs to $L^\infty\big(I; L^6(\Omega)\big)$. Using the fact that $\nabla u^{\frac{\alpha+n+1}{4}} \in L^4(\Omega_T)$, we can apply interpolation theory (cf. DiBenedetto [9, Proposition 3.2]) to get L^p-regularity of u for all $p \le \alpha + n + 9$.

As a further consequence of Proposition 2.6 we obtain the following corollary.

COROLLARY 2.7. *Under the same assumptions as in Proposition* 2.6*, for a subsequence of* $(u_\delta^{(i)})_{\delta\searrow 0}$ *the following is true:*

$$\nabla(u_\delta^{(i)})^{\frac{\alpha+n+1}{4}} \longrightarrow \nabla(u^{(i)})^{\frac{\alpha+n+1}{4}} \ \textit{strongly in } L^{4-}\big([u^{(i)}>0]\big) \textit{ and pointwise a.e.}, \tag{2.29}$$

$$\nabla u_\delta^{(i)} \longrightarrow \nabla u^{(i)} \ \textit{strongly in } L^2(\Omega_T). \tag{2.30}$$

Proof. With the help of Vitali's theorem, relation (2.29) follows from point (v) of Proposition 2.6 and the convergence pointwise almost everywhere of $(\nabla(u_\delta^{(i)})^{\frac{\alpha+n+1}{2}})_{\delta\searrow 0}$ on the set $[u^{(i)} > 0]$.

Concerning the convergence behavior of $(\nabla u_\delta^{(i)})_{\delta\searrow 0}$, we observe—combining (2.29), the identity $|\nabla v|^2 = (\frac{4}{\alpha+n+1})^2 v^{\frac{3-\alpha-n}{2}} |\nabla v^{\frac{\alpha+n+1}{4}}|^2$, and the points (v) and (vi) of Proposition 2.6—that for δ tending to zero $||u_\delta^{(i)}||_{L^2(\Omega_T)}$ converges to $||u^{(i)}||_{L^2(\Omega_T)}$.

Now we recall the following well-known lemma.

LEMMA. *Assume that a sequence $(u_n)_{n\in\mathbb{N}}$ weakly converges to u in a Hilbert space X. If additionally $(\|u_n\|_X)_{n\in\mathbb{N}}$ converges to $\|u\|_X$, then $(u_n)_{n\in\mathbb{N}}$ strongly converges to u in X.* □

Hence, (2.30) can easily be established.

3. Existence, qualitative behavior, and (non)uniqueness of solutions. In this section we improve the existence results obtained previously in [13] and [10]. In particular, it will be possible to treat initial values with compact support in the case $2 \le n < 3$ which is important in lubrication theory. Moreover, we are able to extend the range of allowed diffusion growth exponents beneath 1 to $\frac{1}{8}$ and we propose a solution concept also for diffusion coefficients with polynomial growth.

Let us begin with the following assumption (A4) which basically requires that m (m', m'', respectively) have at most polynomial growth with the exponents n ($n-1, n-2$, respectively).

(A4) The diffusion coefficient m and the first two derivatives can be written as $m(\tau) = \tau^n \cdot f_0(\tau)$, $m'(\tau) = \tau^{n-1}\cdot f_1(\tau)$, and $m''(\tau) = \tau^{n-2}\cdot f_2(\tau) (\tau \in \mathbb{R}_0^+, i = 0,1,2)$ with functions f_i such that $\|f_i\|_{C^{2-i}(\mathbb{R}_0^+,\mathbb{R}_0^+)} < \infty$ $(i = 0,1,2)$. Furthermore, we assume that f_0 is positive and that m is bounded from below by a positive constant for large values of τ.

Let us present our concept of solution.

DEFINITION 3.1. *Let $N \ge 2$, $n > 0$, and m satisfy* (A4). *Let (u, J) be the element of $L^\infty(I; H^1(\Omega)) \cap H^1(I; (W^{1,q}(\Omega))') \times L^2(I; L^{q'}(\Omega; \mathbb{R}^N))$ where q satisfies one of the following properties:*

(i) *$q = 2$ if $m \in L^\infty(\mathbb{R})$,*

(ii) *$q > \frac{4N}{2N+(2-N)n}$ (and $n < \frac{2N}{N-2}$ if $N \ge 3$).*

We call the pair (u, J) the solution of (1.1) *if*

$$u_t = -\operatorname{div} J \quad \text{in } L^2\big(I; \big(W^{1,q}(\Omega)\big)'\big)\ , \tag{3.1}$$

$m''(u)\,|\nabla u|^3$ is in $L^1([u > 0])$, and J satisfies the relation $J = m(u)\nabla\Delta u$ in the following weak sense:

$$\begin{aligned}\int_{\Omega_T} J\cdot\eta\,dxdt = {}& \tfrac{1}{2}\int_{[u>0]} m''(u)\ |\nabla u|^2\ \nabla u\eta + \tfrac{1}{2}\int_{[u>0]} m'(u)\ |\nabla u|^2\ \operatorname{div}\eta \\ &+ \int_{[u>0]} m'(u)\big\langle \nabla u, D\eta, \nabla u\big\rangle + \int_{\Omega_T} m(u)\,\nabla u\nabla\operatorname{div}\eta \\ &\forall \eta \in L^\infty\big(I; W^{2,\infty}(\Omega;\mathbb{R}^N)\big) \text{ such that } \eta\cdot\nu = 0 \text{ on } \partial\Omega\ .\end{aligned} \tag{3.2}$$

(Here, q' denotes the conjugate exponent to q.)

Remark. Property (ii) is only necessary as long as there does not exist a positive result about boundedness of solutions.

Our main existence result reads as follows.

THEOREM 3.2 (existence of regular solutions). *Assume that the diffusion coefficient satisfies* (A4) *and that the initial value $u_0 \in H^1(\Omega)$ is nonnegative and satisfies*

$$\int_\Omega G_\alpha(u_0)\,dx < \infty$$

for a certain constant $\alpha \in (\frac{1}{2}-n, 2-n)$. *If one of the following combinations is true,*

(i) $N = 2$ *and* $n > \frac{1}{8}$,

(ii) $N = 3$, $m \in L^\infty(\mathbb{R})$, *and* $n > \frac{1}{8}$,

(iii) $N = 3$, $\frac{1}{8} < n < 4$, *and* $\alpha > -2$,

then there exists a solution (u, J) *to equation* (1.1) *in the sense of Definition* 3.1.

In particular, u *has the following additional regularity properties:*

$$u^{\frac{\alpha+n+1}{4}} \in L^4(I; W^{1,4}(\Omega)),$$
$$u^{\frac{\alpha+n+1}{2}} \in L^2(I; H^2(\Omega)).$$

Remark.

(i) For diffusion growth coefficients $0 < n < 3$, it is always possible to find a real number $\alpha_0 \in (\frac{1}{2}-n, 2-n)$ such that $\alpha_0 + 1 > 0$. Thus $\int_\Omega G_{\alpha_0}(u_0)dx < \infty$ for arbitrary nonnegative initial data $u_0 \in H^1(\Omega)$, i.e., for arbitrary $n \in (\frac{1}{8}, 3)$ and arbitrary nonnegative initial data $u_0 \in H^1(\Omega)$, a regular solution to (1.1) does exist.

(ii) Let us emphasize that in order to give a meaning to the first three integrands on the right-hand side of (3.2), we make essential use of the identities $u^{n-2}|\nabla u|^3 = \big(\frac{4}{\alpha+n+1}\big)^3 u^{\frac{n+1-3\alpha}{4}} \Big|\nabla u^{\frac{\alpha+n+1}{4}}\Big|^3$ and $u^{n-1}|\nabla u|^2 = \big(\frac{4}{\alpha+n+1}\big)^2 u^{\frac{n+1-\alpha}{2}} \Big|\nabla u^{\frac{\alpha+n+1}{4}}\Big|^2$.

Proof of Theorem 3.2. Let us begin with the case $m \in L^\infty(\mathbb{R})$ and $N = 2$ or 3. For the ease of presentation we now drop the superscript (i). From Proposition 2.6 and Corollary 2.7 we infer the following convergence behavior for a subsequence $(u_\delta, J_\delta)_{\delta\to 0}$ of solutions to the auxiliary problems P_δ^1:

(i) $u_{\delta t} \rightharpoonup u_t$ in $L^2\big(I; \big(H^1(\Omega)\big)'\big)$,

(ii) $\nabla u_\delta \longrightarrow \nabla u$ strongly in $L^2(\Omega_T)$,

(iii) $J_\delta \rightharpoonup J$ in $L^2(\Omega_T)$,

(iv) $\nabla u_\delta^{\frac{\alpha+n+1}{4}} \rightharpoonup \nabla u^{\frac{\alpha+n+1}{4}}$ in $L^4(\Omega_T)$,

(v) $\nabla u_\delta^{\frac{\alpha+n+1}{4}} \longrightarrow \nabla u^{\frac{\alpha+n+1}{4}}$ strongly in $L^{4-}\big([u > 0]\big)$ and pointwise a.e.

From (i) and (iii) relation (3.1) follows immediately. To proceed with the identification of J, we use the formula

$$\begin{aligned}\int_\Omega m_\delta(u_\delta)\,\nabla\Delta u_\delta \eta \;=\; &\tfrac{1}{2}\int_\Omega m_\delta''(u_\delta)\;|\nabla u_\delta|^2\;\nabla u_\delta\,\eta \;+\; \tfrac{1}{2}\int_\Omega m_\delta'(u_\delta)\;|\nabla u_\delta|^2\;\operatorname{div}\eta \\ &+ \int_\Omega m_\delta'(u_\delta)\langle\nabla u_\delta, D\eta, \nabla u_\delta\rangle \;+\; \int_\Omega m_\delta(u_\delta)\,\nabla u_\delta\nabla\operatorname{div}\eta,\end{aligned} \tag{3.3}$$

which is valid for $m_\delta \in C^2(\mathbb{R}) \cap W^{2,\infty}(\mathbb{R})$, $u_\delta \in H^2_*(\Omega)$ with $\nabla\Delta u_\delta \in L^2(\Omega)$ and $\eta \in W^{2,\infty}(\Omega)$ with $\eta \cdot \nu \equiv 0$ on $\partial\Omega$ as will be proved in the Appendix.

By our choice of m_δ we can identify $J_\delta(t)$ for a.e. $t \in I$ with $m_\delta(u_\delta)\,\nabla\Delta u_\delta$; thus J_δ can be related to $m_\delta(u_\delta)\,\nabla\Delta u_\delta$ in the sense of (3.2). Let us now pass to the limit $\delta \searrow 0$ on the right-hand side of (3.3). As the third term on the right-hand side of (3.3) qualitatively shows the same behavior as the second one and as the fourth term can easily be handled by using convergence property (ii), we will discuss in detail only the first and the second term. Writing $m_\delta'(\tau)$, $m_\delta''(\tau)$ as

$$m_\delta'(\tau) = \tau^{n-1} f_{1,\delta}(\tau) \text{ and } m_\delta''(\tau) = \tau^{n-2} f_{2,\delta}(\tau),$$

we observe after straightforward calculations that $f_{i,\delta}$ are uniformly bounded in $L^\infty(\mathbb{R}_0^+)$ $(i=1,2)$ and that on each compact subset of $(0,\infty)$, $f_{i,\delta}$ converges to f_i uniformly. For α with $\frac{1}{2} < \alpha + n < 2$ we write $\int_{\Omega_T} m_\delta''(u_\delta)\,|\nabla u|^2\,\nabla u \eta\,dxdt$ as

$$\int_{\Omega_T} u_\delta^{\frac{n+1-3\alpha}{4}} \left|\nabla u_\delta^{\frac{\alpha+n+1}{4}}\right|^2 \nabla u_\delta^{\frac{\alpha+n+1}{4}} \cdot f_{2,\delta}(u_\delta)\,\eta\,dxdt.$$

Condition $n > \frac{1}{8}$ ensures that α can be modified in such a way that $\frac{n+1-3\alpha}{4}$ is positive, and in addition $\int_\Omega G_\alpha(u_0)dx$ is bounded.

Using the properties of $f_{2,\delta}$, the regularity of u_δ, and $n > 1/8$, we observe that the term in u_δ converges weakly in $L^{1+\sigma}(\Omega_T)$ (for values of σ sufficiently small) to a function $\tilde{\beta}$. From (v) and the pointwise convergence of $f_{2,\delta}(u_\delta)$ we infer $\tilde{\beta} = m''(u)\,|\nabla u|^2 \cdot \nabla u$ on the set $[u>0]$.

On the set $[u=0]$ we argue as follows: for each $\varepsilon > 0$ we find by Egorov's theorem a set $S_\varepsilon \subset [u=0]$ with $\mathcal{L}^{N+1}(S_\varepsilon) < \varepsilon$ such that u_δ uniformly converges to u on the subset $[u=0] \setminus S_\varepsilon$. Thus we can estimate:

$$\begin{aligned}
&\left|\int_{[u=0]} m_\delta''(u_\delta)\,|\nabla u_\delta|^2\,\nabla u_\delta \cdot \eta\,dxdt\right| \\
&\quad\le \int_{S_\varepsilon \cup \left([u=0]\setminus S_\varepsilon\right)} u_\delta^{\frac{n+1-3\alpha}{4}} \cdot \left|\nabla u_\delta^{\frac{\alpha+n+1}{4}}\right|^3 \cdot |f_{2,\delta}(u_\delta)| \cdot |\eta|\;dxdt \\
&\quad\le o_\delta(1) \int_{[u=0]\setminus S_\varepsilon} \left|\nabla u_\delta^{\frac{\alpha+n+1}{4}}\right|^3 dxdt \\
&\qquad + \left(\int_{S_\varepsilon} u_\delta^{n+1-3\alpha}\,dxdt\right)^{\frac{1}{4}} \left(\int_{S_\varepsilon} \left|\nabla u_\delta^{\frac{\alpha+n+1}{4}}\right|^4 dxdt\right)^{\frac{3}{4}} \|f_{2,\delta}\|_\infty \cdot \|\eta\|_\infty .
\end{aligned} \tag{3.4}$$

By Vitali's theorem the second term in (3.4) converges to zero when $\mathcal{L}^{N+1}(S_\varepsilon) \to 0$. This gives the convergence of the first term on the right-hand side of (3.3).

For the second term on the right-hand side of (3.3) we write

$$\int_{\Omega_T} u_\delta^{\frac{-\alpha+n+1}{2}} \left|\nabla u_\delta^{\frac{\alpha+n+1}{4}}\right|^2 \cdot f_{1,\delta}(u_\delta) \cdot \operatorname{div}\eta\,dxdt$$

and use exactly the same technique as before in order to identify the limit. Putting everything together, the validity of (3.2) is established for m bounded. Eventually, we remark that the case of an unbounded diffusivity m which grows at most polynomially can be handled similarly, provided we use the restrictions on n in order to guarantee applicability of Hölder's inequality in the analogue to (3.4). Using the remark at the end of the first section, we see that this is possible if $\alpha > -2$. □

Let us point out that the regularity properties of u stated in Theorem 3.2 imply the following result about the behavior of the normal derivative of a solution at the boundary of $\operatorname{supp}(u)$.

COROLLARY 3.3 (regularity at the free boundary). *Let* $\hat{P} := \{t \in I : ||u(t,.)^{\frac{\alpha+n+1}{4}}||_{W^{1,4}(\Omega)} < \infty\}$ *with* α *as in Theorem* 3.2. *Then the following results are true:*

(i) *Under the assumption that* $\partial[supp(u(t,.)]$ *is an* $(N-1)$*-rectifiable set, we have for* $t \in \hat{P}$ *and for* $\mathcal{H}^{N-1}$*−almost every* $x \in \partial[supp(u(t,.))]$ *that the normal derivative* $\frac{\partial}{\partial \nu} u(t,x)$ *exists and that it is equal to zero.*

(ii) *If $N = 2$ and $n < 2$, then for arbitrary $t \in \hat{P}$ and for all $x \in [u(t,.) = 0]$ we have that $\nabla u(t,x)$ vanishes.*

Proof. Let us begin with the proof of (i). Assuming first that $\partial[\mathrm{supp}(u(t,.))]$ consists of finitely many portions of hyperplanes, the result follows from the $W^{1,4}$-regularity of $u^{\frac{\alpha+n+1}{4}}$, the nonnegativity of u, and the fact that $W^{1,p}$-functions are absolutely continuous along almost all line segments (cf. Theorem 2.1.4 of [15]). By flattening each $C^{0,1}-$portion of $\partial[\mathrm{supp}(u(t,.)]$, the general case can be established by straightforward calculations.

In order to prove (ii), we observe that if $N = 2$ and $x \in [u(t,.) = 0]$, there exists a positive constant C depending only on Ω and the $W^{1,4}(\Omega)$-norm of $u(t,.)$ such that for all $y \in \Omega$ we have $u(t,y) \le C\,|y-x|^{\frac{2}{\alpha+n+1}}$. If $n < 2$, α can be chosen in such a way that $\frac{2}{\alpha+n+1} > 1$. This completes the proof. □

The strengthened entropy estimates also enable us to improve results concerning positivity properties of solutions. Combining (2.26) and the techniques of ([13, Theorems 1.2 and 1.3]), we arrive at the following theorem.

THEOREM 3.4 (positivity properties). *Let u be a solution of* (1.1) *in the sense of Theorem* 3.2 *and assume the initial value satisfies $\int_\Omega u_0^{3/2-n}\,dx < \infty$.*

(i) *If $n \ge 3/2$ there does not exist a subset $E \subset \Omega$ with $\mathcal{L}^N(E) > 0$ and a time t_0 such that $\int_E u(x,t_0)\,dx = 0$.*

(ii) *If $N = 2$ and $n > 3$ or if $N = 3$ and $n > 6$, the solution u is for almost every $t \in [0,T]$ strictly positive in Ω.*

Let us now discuss the asymptotic behavior of a function u which solves (1.1) in the sense of Theorem 3.2 and in particular satisfies a priori estimate (2.26). We obtain the following theorem.

THEOREM 3.5 (convergence to the mean value). *Let $n > \frac{1}{8}$ be the diffusion growth exponent. Suppose Ω is convex and u solves* (1.1) *in the sense of Theorem* 3.2 *and satisfies the a priori estimate* (2.26) *for an α with $\alpha + n > 1$.*

Then

$$\lim_{t\to\infty} u(t) = \frac{1}{|\Omega|}\int_\Omega u_0(x)\,dx \qquad \text{in } H^1(\Omega).$$

Proof. Note that for convex Ω the constant C_2 in Proposition 2.2 is equal to zero. Thus there is an increasing sequence $(t_k)_{k\in\mathbb{N}}$ tending to infinity with the property

(i) $\int_\Omega \left|D^2 u^{\frac{\alpha+n+1}{2}}\right|^2 (t_k)\,dx \searrow 0,$

(ii) $\int_\Omega \left|\nabla u^{\frac{\alpha+n+1}{4}}\right|^4 (t_k)\,dx \searrow 0,$

which implies that both $\left(\nabla u^{\frac{\alpha+n+1}{2}}(t_k)\right)_{k\in\mathbb{N}}$ and $\left(u^{\frac{\alpha+n+1}{4}}(t_k)\right)_{k\in\mathbb{N}}$ converge to a constant in the corresponding norms. Hence $u^{\frac{\alpha+n+1}{2}}$ also converges to a constant with respect to the L^2-norm and thus

$$\int_\Omega \left|\nabla u^{\frac{\alpha+n+1}{2}}(t_k)\right|^2 dx \searrow 0\ .$$

Therefore,

$$\begin{aligned}\int_\Omega |\nabla u|^2 (t_k)\,dx &\le \int_{[u\ge 1]} u^{\alpha+n-1}\,|\nabla u|^2 (t_k)\,dx + \int_{[u<1]} u^{\frac{\alpha+n-3}{2}}\,|\nabla u|^2 (t_k)\,dx \\ &= o_k(1)\ .\end{aligned}$$

Now using the monotonicity formula (2.5) and the strong convergence of ∇u_δ to ∇u with respect to the $L^2(\Omega_T)$-norm (cf. (2.30)), we infer for almost every $t_1, t_2 \in I$

$$\int_\Omega |\nabla u(t_2)|^2 \, dx - \int_\Omega |\nabla u(t_1)|^2 \, dx \leq -2 \liminf_{\delta \to 0} \int_{t_1}^{t_2} \int_\Omega m(u_\delta) \, |\nabla \Delta u_\delta|^2 \, dxdt;$$

i.e., $\int_\Omega |\nabla u(t,x)|^2 \, dx$ is nonincreasing in t. Thus the result follows just by application of Poincaré's inequality for functions with mean value zero. □

Remark. (1) If $\frac{1}{8} < n < 3$ we get that for all nonnegative initial data $u_0 \in H^1(\Omega)$ there exists an α such that $\alpha + n > 1$ and such that the a priori estimate (2.26) is satisfied. This means that in particular all solutions with compactly supported initial data converge to the mean.

(2) If $n \geq 3$ the same convergence behavior holds true if we impose an additional condition on the initial value; namely, there is a number $\sigma > n - 3$ such that

$$\int_\Omega u_0^{-\sigma} \, dx < \infty \ .$$

This implies that $\int_\Omega G_\alpha(u_0)$ is bounded for an α with $\alpha + n > 1$.

(3) If Ω is not convex, the second term on the right-hand side of (2.26) cannot be neglected any longer, and thus the method of proof above cannot be applied. Nevertheless, by using the boundedness of

$$\int_0^\infty \int_\Omega |\Delta u|^2 \, dxdt$$

the result still can be established if a priori estimate (2.3) holds true, i.e., if $n < 2$ or if $n \geq 2$ and the initial value is strictly positive. Whether it is also true in the case when $n \geq 2$ and initial values have compact support still remains an open question.

Let us now construct steady state solutions with compact support which solve (1.1) in the sense of equations (3.1) and (3.2) for $n > 1$. In Theorem 3.5 we have already proved that for arbitrary, nonnegative initial values $u_0 \in H^1(\Omega)$ with compact support there exist solutions which converge for $t \to \infty$ to the mean value with respect to the H^1-norm. This illustrates in particular that for values of $n \in (1,3)$ we cannot expect results on uniqueness without imposing additional regularity properties at the free boundary in the spirit of estimate (2.26).

LEMMA 3.6 (steady state solutions with compact support). *Let $\Omega' \subset\subset \Omega$ be a subdomain with smooth boundary. Let $\hat{u}$ be the solution of*

$$\begin{aligned} -\Delta \hat{u} &= 1 \ \text{in } \Omega', \\ \hat{u} &= 0 \ \text{on } \partial\Omega'. \end{aligned}$$

Combining the function u defined by

$$u = \begin{cases} \hat{u} \ \text{in } \Omega', \\ 0 \ \text{in } \Omega \setminus \Omega' \end{cases}$$

with $J \equiv 0$, we obtain a weak solution to (1.1) *for values of $n > 1$ in the sense of Definition* 3.1.

Proof. From elliptic regularity theory (cf. Gilbarg and Trudinger [12, Chapter 8]) we infer

$$\hat{u} \in H^2(\Omega') \cap C^\infty(\Omega') \cap W^{1,\infty}(\Omega')$$

and

$$(*) \qquad \int_{\Omega'} \nabla\hat{u}\,\nabla\psi = \int_{\Omega'} \psi \qquad \forall \psi \in W_0^{1,1+\varepsilon}(\Omega').$$

In addition $\hat{u}$ is positive in Ω' (cf. [12, Theorem 8.19]).

Since J is equal to zero on Ω, it will be sufficient to prove that the right-hand side in (3.2) vanishes. We have

$$\begin{aligned} RHS &= \tfrac{1}{2}\int_{\Omega'\times I} m''(\hat{u})\,|\nabla\hat{u}|^2\,\nabla\hat{u}\,\eta + \int_{\Omega'\times I} m'(u)\langle\nabla\hat{u}, D\eta, \nabla\hat{u}\rangle \\ &\quad -\tfrac{1}{2}\int_{\Omega'\times I} m'(\hat{u})\,\operatorname{div}\eta\,\nabla\hat{u}\,\nabla\hat{u} + \int_{\Omega'\times I} \nabla\underbrace{\big(m(\hat{u})\,\operatorname{div}\eta\big)}_{\in W_0^{1,1+\varepsilon}(\Omega')}\cdot\nabla\hat{u} \\ &= I + II + III + IV. \end{aligned}$$

(Since $\hat{u} \in H^2(\Omega') \cap W^{1,\infty}(\Omega')$ and $n > 1$, the boundedness of all the integrals in the equation above is a simple consequence of Hölder's inequality.)

Let ν' be the unit outer normal vector on $\partial\Omega'$. Using the relation $(*)$, we obtain

$$\begin{aligned} IV &= \int_{\Omega'\times I} m(\hat{u})\,\operatorname{div}\eta = -\int_{\Omega'_T} \nabla m(\hat{u})\,\eta + \int_{\partial\Omega'\times I} \underbrace{m(\hat{u})\eta\cdot\nu'\,d\mathcal{H}^N}_{=0} \\ &= -\int_{\Omega'_T} m'(u)\,\nabla u\eta \overset{(*)}{=} -\int_{\Omega'_T} \nabla\big(m'(u)\nabla u\,\eta\big)\cdot\nabla u \\ &= -\int_{\Omega'_T} m''(u)\,|\nabla u|^2\,\eta\,\nabla u - \int_{\Omega'_T} m'(u)\langle\nabla u, D\eta, \nabla u\rangle - \int_{\Omega'_T} m'(u)\langle\eta, D^2u, \nabla u\rangle \\ &= IV_1 + IV_2 + IV_3. \end{aligned}$$

For IV_3 we compute:

$$\begin{aligned} IV_3 &= -\tfrac{1}{2}\int_{\Omega'_T} m'(u)\eta\cdot\nabla\,|\nabla u|^2 \\ &= \tfrac{1}{2}\int_{\Omega'_T} \operatorname{div}\big(m'(u)\,\eta\big)\cdot|\nabla u|^2 - \tfrac{1}{2}\underbrace{\int_{\partial\Omega'\times I} m'(u)\,|\nabla u|^2\,\eta\cdot\nu'\,d\mathcal{H}^N}_{=0 \text{ (since } m'(u)=0 \text{ on } \partial\Omega')} \\ &= \tfrac{1}{2}\int_{\Omega'_T} m''(u)\,|\nabla u|^2\,\eta\,\nabla u + \tfrac{1}{2}\int_{\Omega'_T} m'(u)\,\operatorname{div}\eta\,|\nabla u|^2\,. \end{aligned}$$

Summing up, we obtain $I + II + III = -IV$, which proves the claim. □

Remark. By linearity it is clear that we can adjust $\hat{u}$ in such a way that each positive mean value can be reached. We just take

$$\begin{aligned} \Delta\hat{u} &= \alpha \qquad \text{in } \Omega', \\ \hat{u} &= 0 \qquad \text{on } \partial\Omega', \end{aligned}$$

with $\alpha > 0$ arbitrary.

Appendix.

A. Proof of Lemma 2.1 (*proof of* (2.4)). Let $(u_\varepsilon)_{\varepsilon\searrow 0}$ be a sequence of solutions to auxiliary problems with nondegenerate mobility $m_\varepsilon(\tau) = m(\tau) + \varepsilon$ and initial value u_0 (cf. [13] and [10]). Combining the Aubin–Lions lemma and the uniform boundedness of u_ε (or of $(u_\varepsilon)_t$) in $L^2\big(I; H^2(\Omega)\big)$ (or in $L^2\big(I; (H^1(\Omega))'\big)$, respectively), we notice that a subsequence $(u_\varepsilon)_{\varepsilon\searrow 0}$ strongly converges to u in $L^2\big(I; C^\beta(\Omega)\big)$ for sufficiently small, positive β and that we can extract a subsequence such that $u_\varepsilon(t) \to u(t)$ in $C^\beta(\Omega)$ for almost all $t \in I$. Using the positivity result in Theorem 1.3 of [13], we observe that there is a set $P \subset I$ with $\mathcal{L}^1(I \setminus P) = 0$ such that for all $t \in P$, $u(t)$ is in $C^\beta(\Omega)$ and is strictly positive on Ω.

It will be sufficient to show that the one-dimensional measure of the set

$$E = \left\{ t \in P : \liminf_{\varepsilon\to 0} \int m_\varepsilon\big(u_\varepsilon(t)\big) \left|\nabla \Delta u_\varepsilon\right|^2 (t)\, dx = \infty \right\}$$

vanishes. Defining $K_\varepsilon(t) := \int_\Omega m_\varepsilon\big(u_\varepsilon(t)\big) \left|\nabla\Delta u_\varepsilon(t)\right|^2 dx$ and

$$[A]_n = \begin{cases} A & \text{if } A < n, \\ n & \text{otherwise} \end{cases}$$

and using the positivity of $u(t,\cdot)$ for almost every t, we have, by Lebesgue's theorem,

$$C \geq \int_E \int_\Omega m_\varepsilon\big(u_\varepsilon(t,x)\big) \left|\nabla\Delta u_\varepsilon(t,x)\right|^2 dxdt \geq \int_E [K_\varepsilon(t)]_n \, dt \overset{\varepsilon\to 0}{\longrightarrow} n \cdot |E| .$$

As n can be chosen arbitrarily, this implies $\mathcal{L}^1(E) = 0$. For fixed $t \in P \setminus E$ we can select a subsequence of $(\nabla\Delta u_\varepsilon(t,.))_{\varepsilon\to 0}$ which weakly converges in $L^2(\Omega)$. Then (2.2) implies that $J(t) = m(u(t))\nabla\Delta u(t) \quad$ in $L^2(\Omega)$ for all $t \in P \setminus E$.

Proof of (2.5). Choosing $\psi(t,x) = \chi_{[t_1,t_2]}\Delta u_\varepsilon$ as the test function in the weak formulation

$$\int_0^T \langle (u_\varepsilon)_t, \psi\rangle dt - \int_{\Omega_T} m_\varepsilon(u_\varepsilon)\nabla\Delta u_\varepsilon \nabla\psi dxdt = 0,$$

$$\psi \in L^2(I; H^1(\Omega)) \text{ arbitrary}$$

for auxiliary problems with nondegenerate mobility as described above, we immediately obtain for almost all $t_1, t_2 \in I$

$$\frac{1}{2}\int_\Omega |\nabla u_\varepsilon(t_2)|^2 dx + \int_{t_1}^{t_2}\int_\Omega m_\varepsilon(u_\varepsilon) \left|\nabla\Delta u_\varepsilon\right|^2 dxdt \leq \frac{1}{2}\int_\Omega |\nabla u_\varepsilon(t_1)|^2 dx.$$

Now observing that ∇u_ε converges to ∇u strongly in $L^{\frac{2N+4}{N}-}(\Omega_T)$ (cf., e.g., [13, Lemma 2.8]) and that $m_\varepsilon^{\frac{1}{2}}(u_\varepsilon)\nabla\Delta u_\varepsilon$ in $L^2(\Omega_T)$ weakly converges to a function β which for almost every $t \in I$ can be identified with $m(u)\nabla\Delta u$, the result follows by the lower semicontinuity of the norm under weak convergence.

B. Proof of Lemma 2.3 and (3.3). The following result will be essential.

LEMMA B.1. *Let $\Omega \subset \mathbb{R}^N$ be a domain with piecewise smooth boundary of class $C^{0,1}$. For every vector field $\eta \in H^2(\Omega;\mathbb{R}^N)$ which is tangential on $\partial\Omega$ we have*

$$(D\eta \cdot \nu)_{\|} = -d\nu \cdot \eta \tag{B.1}$$

a.e. on $\partial\Omega$. Here, $(\cdot)_{\|}$ denotes the tangential component of a vector field.

Proof. Since $\eta \cdot \nu = 0$, we have for arbitrary smooth curves $c:\,[0,1]\longrightarrow\partial\Omega$

$$0 = \frac{d}{dt}\left\langle \eta_{|c(t)}, \nu_{|c(t)}\right\rangle = \langle D\eta_{|c(t)}\dot c(t), \nu_{|c(t)}\rangle + \left\langle \eta_{|c(t)}, d\nu_{|c(t)}\cdot \dot c(t)\right\rangle$$

for almost every $x = c(t) \in \partial\Omega$. As $d\nu : T_{c(t)}S\longrightarrow T_{c(t)}S$ is a self-adjoint, linear mapping (cf. [11, Chapter V]), we obtain

$$\left\langle \eta_{|c(t)}, d\nu_{|c(t)}\cdot \dot c(t)\right\rangle = \left\langle d\nu_{|c(t)}\cdot \eta_{|c(t)}, \dot c(t)\right\rangle,$$

which proves the lemma. □

Proof of Lemma 2.3. We assume $\nabla\Delta u \in L^2(\Omega)$. The result for functions with weaker regularity can be proved by an approximation argument. Successive integration by parts gives

$$\begin{aligned}\int_\Omega f'(u)\,|\nabla u|^2\,\Delta u &= -\int_\Omega f(u)\,|\Delta u|^2 - \int_\Omega f(u)\,\nabla\Delta u\,\nabla u\\ &= -\int_\Omega f(u)\,|\Delta u|^2 + \int_\Omega f'(u)\langle\nabla u, D^2u, \nabla u\rangle + \int_\Omega f(u)\,\left|D^2u\right|^2\\ &\qquad - \int_{\partial\Omega} f(u)\langle\nabla u, D^2u, \nu\rangle\, d\mathcal{H}^{N-1}.\end{aligned}$$

Using now the identity $\langle\nabla u, D^2u, \nabla u\rangle = \frac12\langle\nabla\,|\nabla u|^2, \nabla u\rangle$, we obtain ($\frac{\partial}{\partial\nu}u = 0$ on $\partial\Omega$!):

$$\int_\Omega f'(u)\langle\nabla u, D^2u, \nabla u\rangle = -\frac12\int_\Omega f''(u)\,|\nabla u|^4 - \frac12\int_\Omega f'(u)\,|\nabla u|^2\,\Delta u.$$

Putting everything together and using formula (B.1), the result can be established easily. □

Proof of (3.3). Integration by parts shows

$$\begin{aligned}\int_\Omega m(u)\,\nabla\Delta u\,\eta\,dx &= \tfrac12\int_\Omega m''(u)\,|\nabla u|^2\,\nabla u\eta\,dx + \tfrac12\int_\Omega m'(u)\,|\nabla u|^2\,\mathrm{div}\,\eta\,dx\\ &\quad + \int_\Omega m'(u)\langle\nabla u, D\eta, \nabla u\rangle\,dx + \int_\Omega m(u)\,\nabla u\nabla\,\mathrm{div}\,\eta\,dx\\ &\quad - \int_{\partial\Omega} m(u)\big\{\langle\nabla u, D\eta, \nu\rangle - \langle\eta, D^2u, \nu\rangle\big\}\,d\mathcal{H}^{N-1}.\end{aligned}$$

Since both η and ∇u are tangential vector fields on $\partial\Omega$, we can apply (B.1) twice and obtain the result. □

Acknowledgments. It is a pleasure to thank Michiel Bertsch for deep and fruitful discussions.

BOUNDARY LAYERS IN THE HOMOGENIZATION OF A SPECTRAL PROBLEM IN FLUID–SOLID STRUCTURES*

GRÉGOIRE ALLAIRE† AND CARLOS CONCA‡

Abstract. This paper is devoted to the asymptotic analysis of the spectrum of a mathematical model that describes the vibrations of a coupled fluid–solid periodic structure. In a previous work [*Arch. Rational Mech. Anal.*, 135 (1996), pp. 197–257] we proved by means of a Bloch wave homogenization method that, in the limit as the period goes to zero, the spectrum is made of three parts: the macroscopic or homogenized spectrum, the microscopic or Bloch spectrum, and a third component, the so-called *boundary layer spectrum*. While the two first parts were completely described as the spectrum of some limit problem, the latter was merely defined as the set of limit eigenvalues corresponding to sequences of eigenvectors concentrating on the boundary. It is the purpose of this paper to characterize explicitly this boundary layer spectrum with the help of a family of limit problems revealing the intimate connection between the periodic microstructure and the boundary of the domain. We therefore obtain a "completeness" result, i.e., a precise description of all possible asymptotic behaviors of sequences of eigenvalues, at least for a special class of polygonal domains.

Key words. homogenization, Bloch waves, spectral analysis, boundary layers, fluid–solid structures

1. Introduction.

1.1. Setting of the problem. This paper is devoted to the study of some boundary layer phenomena which arise in the asymptotic analysis of the spectrum of a mathematical model describing the vibrations of a coupled periodic system of solid tubes immersed in a perfect incompressible fluid. This simple model is due to Planchard, who studied it intensively (see [31], [32]). Since we introduced it at length in section 1.2 of our previous work [3] we content ourselves with briefly recalling the statement of this problem.

We consider a periodic bounded domain Ω_ϵ obtained from a fixed bounded open set Ω in $\mathbb{R}^N$ by removing a collection of identical, periodically distributed holes $(T_p^\epsilon)_{1\le p\le n(\epsilon)}$. The distance between adjacent holes as well as their size are both of the order of ϵ, the size of the period which is a small parameter going to zero. Correspondingly, the number of holes $n(\epsilon)$ is of the order of ϵ^{-N}, where N is the spatial dimension. More precisely, let us first define the standard unit cell $Y = (0;1)^N$ which, upon rescaling to size ϵ, becomes the period in Ω. Let T be a smooth, simply connected, closed subset of Y, assumed to be *strictly included* in Y (i.e., T does not touch the boundary of Y). The set T represents the reference tube (or rod) and the unit fluid cell is defined as

$$Y^* = Y \setminus T.$$

For each value of the small positive parameter ϵ, the fluid domain Ω_ϵ is obtained from the reference domain Ω by removing a periodic arrangement of tubes ϵT with period ϵY. Denoting by (T_p^ϵ) the family of all translates of ϵT by vectors ϵp (where p is a multi-index in $\mathbb{Z}^N$) and by (Y_p^ϵ) the corresponding family of cells, we define

$$\Omega_\epsilon = \Omega \setminus \bigcup_{p=1}^{n(\epsilon)} T_p^\epsilon. \tag{1}$$

Although p is a multi-index in $\mathbb{Z}^N$, for simplicity we denote its range by $1 \le p \le n(\epsilon)$. To obtain the fluid domain Ω_ϵ in (1), we remove from the original domain Ω only those tubes T_p^ϵ which belong to a cell Y_p^ϵ completely included in Ω. This has the effect that no tube meets the boundary $\partial\Omega$. Analogously, (Γ_p^ϵ) denotes the family of tubes boundaries (∂T_p^ϵ).

We are interested in the following spectral problem in Ω: find the eigenvalues λ_ϵ and the corresponding normalized eigenvectors u_ϵ, solutions of

$$\begin{cases} -\Delta u_\epsilon = 0 & \text{in } \Omega_\epsilon, \\ \lambda_\epsilon \frac{\partial u_\epsilon}{\partial n} = \epsilon^{-N} \vec{n} \cdot \displaystyle\int_{\Gamma_p^\epsilon} u_\epsilon \vec{n} ds & \text{on } \Gamma_p^\epsilon \text{ for } 1 \le p \le n(\epsilon), \\ u_\epsilon = 0 & \text{on } \partial\Omega, \end{cases} \tag{2}$$

where $\vec{n}$ denotes the exterior unit normal to Ω_ϵ.

The homogenization of this model has already attracted the attention of several authors (see [1], [14], [16], [17]). Even though it is a spectral problem involving the Laplace operator, it is easily seen to admit only finitely many eigenvalues, exactly $Nn(\epsilon)$ (the number of tubes times the number of degrees of freedom in their displacements). To this end, a finite-dimensional operator S_ϵ is introduced, which acts on the family of tube displacements $\vec{s} = (\vec{s}_p)_{1 \le p \le n(\epsilon)}$ with $\vec{s}_p \in \mathbb{R}^N$,

$$\begin{aligned} S_\epsilon \,:\, \mathbb{R}^{Nn(\epsilon)} &\longrightarrow \mathbb{R}^{Nn(\epsilon)}, \\ (\vec{s}_p)_{1 \le p \le n(\epsilon)} &\mapsto \left(\frac{1}{\epsilon^N} \int_{\Gamma_p^\epsilon} u_\epsilon \vec{n} ds \right)_{1 \le p \le n(\epsilon)}, \end{aligned} \tag{3}$$

where the fluid potential u_ϵ is now the unique solution in $H^1(\Omega_\epsilon)$ of

$$\begin{cases} -\Delta u_\epsilon = 0 & \text{in } \Omega_\epsilon, \\ \frac{\partial u_\epsilon}{\partial n} = \vec{s}_p \cdot \vec{n} & \text{on } \Gamma_p^\epsilon \text{ for } 1 \le p \le n(\epsilon), \\ u_\epsilon = 0 & \text{on } \partial\Omega. \end{cases} \tag{4}$$

According to [17], S_ϵ is self-adjoint, positive definite, and its spectrum, denoted by $\sigma(S_\epsilon)$, coincides with the set of eigenvalues of (2). Of course, since S_ϵ acts in a finite-dimensional space, $\sigma(S_\epsilon)$ is made up of $Nn(\epsilon)$ real numbers. It has been further proved that all eigenvalues of S_ϵ are uniformly bounded away from zero and from infinity (see, e.g., Proposition 1.2.1 and Lemma 1.2.2 in [3]). As the period ϵ goes to zero, $\sigma(S_\epsilon)$, considered as a subset of $\mathbb{R}^+$, converges to a limit set σ_∞ which, by definition, is the set of all cluster points of (sub)sequences of eigenvalues of S_ϵ

$$\sigma_\infty = \{\lambda \in \mathbb{R}^+ \mid \exists \text{ a subsequence } \lambda_{\epsilon'} \in \sigma(S_{\epsilon'}) \text{ such that } \lambda_{\epsilon'} \to \lambda\}.$$

Finding an adequate characterization of the limit set σ_∞ was the main goal of our previous paper [3]. A positive answer to this problem is given in the present article for a special class of polygonal domains.

1.2. Survey of the previous results. The characterization of σ_∞ amounts to studying the asymptotic behavior of the spectral problem (2), or, in other words, to homogenize (2) as the parameter ϵ goes to zero. To our knowledge, this can be done, at least, using two different approaches: the classical *homogenization process* for periodic structures (see, e.g., the reference books [7], [8], [24], [28], [35]) or the so-called *Bloch wave method* (also called the *nonstandard homogenization procedure* in [16]; see [8], [33], [34], [36] for an introduction to Bloch waves in spectral analysis). The former naturally yields the *homogenized or macroscopic spectrum* of (2), while the latter is associated with the so-called *Bloch or microscopic spectrum*.

Historically the second approach was the first applied to problem (2) by C. Conca, M. Vanninathan, and their coworkers [1], [15], [16], [17]. The key point in this method is to rescale the ϵ-network of tubes to size 1 and, therefore, as ϵ goes to zero, to obtain an infinite limit domain containing a periodic array of unit tubes. Then, the limit problem is amenable to the celebrated Bloch wave decomposition (also known as the Floquet decomposition; see the original work of F. Bloch [11] or the first mathematical papers [19], [30], [36] or the books [8], [33]). The spectrum of this limit problem is called the *Bloch spectrum*.

Although it seems the easiest to apply, the first approach (i.e., the classical homogenization) has only been recently applied to problem (2) in our previous article [3]. By homogenizing the operator S_ϵ with the help of the *two-scale convergence* (see [2], [29]), a homogenized equation is obtained in the domain Ω. Its spectrum is called the *homogenized spectrum*. It turns out that the homogenized spectrum is completely different from the Bloch spectrum, and therefore both approaches are complementary. This is possible since in neither case the underlying sequences of linear operators converge uniformly to their limit which are noncompact operators. In addition to this homogenization result, our paper [3] provides a unified theory for both approaches that we called the *Bloch wave homogenization* method. We refer to [3] for more details (see also [4], [5]), and we simply recall our main results.

The homogenization of model (2) amounts to analyzing the convergence of the sequence of operators S_ϵ. Since these operators are defined on a space which varies with ϵ, we extend them to the fixed space $[L^2(\Omega)^N]^{K^N}$, where K is an arbitrary positive integer. Denoting by S_ϵ^K this extension, it will be amenable to a standard asymptotic analysis, while keeping essentially the same spectrum as S_ϵ. Following the lead of Planchard [32], the reference cell of our homogenization procedure is KY instead of simply Y (this technique is referred to as homogenization by packets in [32]). To give a precise definition of S_ϵ^K we introduce two linear maps: a projection P_ϵ^K from $[L^2(\Omega)^N]^{K^N}$ into $\mathbb{R}^{Nn(\epsilon)}$ and an extension E_ϵ^K from $\mathbb{R}^{Nn(\epsilon)}$ into $[L^2(\Omega)^N]^{K^N}$ such that $S_\epsilon^K = E_\epsilon^K S_\epsilon P_\epsilon^K$. To do so, some notation is required concerning the two indices p (indexing constant vectors in $\mathbb{R}^{Nn(\epsilon)}$) and j (indexing vector functions in $[L^2(\Omega)^N]^{K^N}$).

DEFINITION 1.1. *Let KY be the reference cell $(0,K)^N$ which is made of K^N subcells Y_j of the type $(0,1)^N$ containing a single tube T_j. The multi-integer $j = (j_1,\dots,j_N)$ which enumerates all the tubes in KY takes its values in $\{0,1,\dots,K-1\}^N$ (we use the notation $0 \le j \le K-1$). Let $p = (p_1,\dots,p_N)$ be the multi-integer which enumerates all the tubes in Ω_ϵ (see (1)). We define a third multi-integer $\ell = (\ell_1,\dots,\ell_N)$ which enumerates all the periodic reference cells $\epsilon(KY)$ in Ω_ϵ (its range is denoted by $1 \le \ell \le n_K(\epsilon)$). These three indices are assumed to be related by the*

following one-to-one map:

$$\ell_m = E\left(\frac{p_m}{K}\right), \quad j_m = p_m - K\ell_m \quad \forall m = 1, ..., N, \tag{5}$$

where $E(\cdot)$ denotes the integer-part function.

Then, P_ϵ^K and E_ϵ^K are defined by

$$\begin{aligned} P_\epsilon^K : [L^2(\Omega)^N]^{K^N} &\longrightarrow \mathbb{R}^{Nn(\epsilon)}, \\ (\vec{s}_j(x))_{0\le j\le K-1} &\longrightarrow \left(\vec{s}_p = \tfrac{1}{|\epsilon(KY)_\ell|}\int_{\epsilon(KY)_\ell} \vec{s}_j(x)dx\right)_{1\le p\le n(\epsilon),} \end{aligned} \tag{6}$$

$$\begin{aligned} E_\epsilon^K : \mathbb{R}^{Nn(\epsilon)} &\longrightarrow [L^2(\Omega)^N]^{K^N}, \\ (\vec{s}_p)_{1\le p\le n(\epsilon)} &\longrightarrow \left(\vec{s}_j(x) = \sum_\ell \chi_{\epsilon(KY)_\ell}(x)\vec{s}_p\right)_{0\le j\le K-1,} \end{aligned} \tag{7}$$

where p is related to (ℓ, j) by formula (5). One can easily check that the adjoint $(P_\epsilon^K)^*$ of P_ϵ^K is nothing but $(\epsilon K)^{-N}E_\epsilon^K$ and that $P_\epsilon^K E_\epsilon^K$ is equal to the identity in $\mathbb{R}^{Nn(\epsilon)}$. Therefore, S_ϵ^K is also self-adjoint compact and its spectrum is exactly that of S_ϵ, plus the new eigenvalue 0 which has infinite multiplicity.

The homogenization of the extended operator S_ϵ^K is now amenable to the two-scale convergence method [2], [29]. However, the limit operator S^K has a complicated form which can be simplified by using the following discrete Bloch wave decomposition (see [1]).

LEMMA 1.2. *For any family $(\vec{s}_j)_{0\le j\le K-1}$ of vectors in $\mathbb{C}^N$, let $\vec{s}(y)$ be the following KY-periodic function, piecewise constant in each subcell Y_j:*

$$\vec{s}(y) = \sum_{j=0}^{K-1} \vec{s}_j \chi_{Y_j}(y) \quad \forall y \in KY.$$

There exists a unique family of constant vectors $(\vec{t}_j)_{0\le j\le K-1}$ in $\mathbb{C}^N$ such that

$$\vec{s}(y) = \sum_{j=0}^{K-1} \vec{t}_j e^{2\pi\imath \frac{j}{K}\cdot E(y)} \quad \forall y \in KY, \tag{8}$$

where $E(\cdot)$ denotes the integer-part function. Moreover, the Bloch wave decomposition operator $\mathcal{B}$, defined by $\mathcal{B}(\vec{s}_j) = K^{N/2}(\vec{t}_j)$, is an isometry on $(\mathbb{C}^N)^{K^N}$.

The first main result in [3] (see Theorem 3.2.1) is the following theorem.

THEOREM 1.3. *The sequence $S_\epsilon^K = E_\epsilon^K S_\epsilon P_\epsilon^K$ converges strongly to a limit S^K; i.e., for any family $(\vec{s}_j(x))_{0\le j\le K-1}$, $S_\epsilon^K(\vec{s}_j)$ converges strongly to $S^K(\vec{s}_j)$ in $[L^2(\Omega)^N]^{K^N}$. Furthermore, the limit operator S^K is given by*

$$S^K = \mathcal{B}^* T^K \mathcal{B}, \text{ with } T^K = \operatorname{diag}\left[(T_j^K)_{0\le j\le K-1}\right], \tag{9}$$

where the entries T_j^K are self-adjoint continuous but noncompact operators in $L^2(\Omega)^N$, defined by

$$T_j^K \vec{t}_j = \begin{cases} (A(0) - I)\nabla u - (A(0) - |Y^*|I)\vec{t}_0 & \text{if } j = 0, \\ A(\frac{j}{K})\vec{t}_j & \text{if } j \neq 0, \end{cases} \tag{10}$$

where I is the identity matrix and u is the unique solution of the homogenized problem

$$\begin{cases} -\mathrm{div}(A(0)\nabla u) = \mathrm{div}((I - A(0))\vec{t}_0) & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{11}$$

and, for $\theta \in [0,1]^N$, $A(\theta)$ is the Bloch homogenized matrix with components $(A_{mm'}(\theta))_{1\le m,m'\le N}$ defined by

$$\bar{A}_{mm'}(\theta) = \int_{Y^*} \nabla w_m^\theta(y) \cdot \nabla \bar{w}_{m'}^\theta(y) dy, \tag{12}$$

where $(w_m^\theta)_{1\le m\le N}$ are solutions of the so-called cell problem at the Bloch frequency θ:

$$\begin{cases} -\Delta w_m^\theta = 0 & \text{in } Y^*, \\ (\nabla w_m^\theta - \vec{e}_m)\cdot \vec{n} = 0 & \text{on } \partial T, \\ y \to e^{-2\pi\imath\theta\cdot y} w_m^\theta(y) \ Y^*\text{-periodic.} \end{cases} \tag{13}$$

The first component T_0^K of the limit operator T^K is the same for all K and is denoted by S in what follows. It is called the macroscopic or homogenized limit of S_ϵ ((11) is also called the homogenized equation). The spectrum $\sigma(S)$ is essential and has been explicitly characterized in Theorems 2.1.4 and 2.1.5 of [3]. The other components of T^K are simple linear multiplication operators that represent the microscopic or Bloch limit behavior of the sequence S_ϵ^K.

According to Proposition 3.2.6 in [3], the matrix $A(\theta)$ is Hermitian and positive definite for any value of θ. Furthermore, it is a continuous function of θ, except at the origin $\theta = 0$. Nevertheless, it is continuous at the origin along rays of constant direction (see Proposition 3.4.4 in [3]). Denoting by $0 < \lambda_1(\theta) \le \lambda_2(\theta) \le \cdots \le \lambda_N(\theta)$ its eigenvalues, we can define the so-called *Bloch spectrum* by

$$\sigma_{Bloch} = \bigcup_{m=1}^{N} \overline{\lambda_m(]0,1[^N)},$$

where $\overline{\lambda_m(]0,1[^N)}$ denotes the closure of the image of $]0,1[^N$ under the maps $\lambda_m(\cdot)$. We deduce our second main result.

THEOREM 1.4. *The strong convergence of S_ϵ^K to the limit operator S^K implies the lower semicontinuity of the spectrum*

$$\sigma(S^K) \subset \lim_{\epsilon\to 0} \sigma(S_\epsilon^K).$$

By letting K go to infinity, we obtain

$$\sigma(S) \cup \sigma_{Bloch} \subset \lim_{\epsilon\to 0} \sigma(S_\epsilon). \tag{14}$$

REMARK 1.5. *As a matter of fact, the Bloch spectrum σ_{Bloch} and the homogenized spectrum $\sigma(S)$ do not coincide. Therefore, both type of limit problems (macroscopic* (11) *and microscopic* (13)*) are complementary. As already mentioned, the Bloch spectrum has already been characterized by C. Conca and M. Vanninathan in* [17] *by means of a different method, the so-called nonstandard homogenization procedure (see also the book* [16]*).*

The question is now to see whether the inclusion in (14) is actually an equality, i.e., if our asymptotic analysis is complete. It turns out that the homogenized and the Bloch spectra are usually not enough to describe σ_∞ because the interaction between the boundary $\partial\Omega$ and the microstructure is not taken into account in our analysis. More precisely, there may well exist sequences of eigenvectors of (2) which concentrate near the boundary $\partial\Omega$ of Ω. They behave as *boundary layers* in the sense that they converge strongly to zero locally inside the domain. Clearly the oscillations of these eigenvectors cannot be captured by the usual homogenization method; neither are they filtered in the Bloch spectrum which is insensitive to the boundary.

Nevertheless, the third main result of our previous paper [3] shows that for any other type of sequences of eigenvectors (not concentrating on the boundary), the limits of the corresponding sequences of eigenvalues belong to $\sigma(S) \cup \sigma_{Bloch}$. More exactly, introducing the subset of σ_∞

$$\begin{aligned} \sigma_{boundary} = \quad & \{\lambda \in \mathbb{R} \mid \exists(\lambda_{\epsilon'}, \vec{s}^{\epsilon'}) \text{ such that } S^1_{\epsilon'}\vec{s}^{\epsilon'} = \lambda_{\epsilon'}\vec{s}^{\epsilon'},\ \lambda_{\epsilon'} \to \lambda, \\ & \|\vec{s}^{\epsilon'}\|_{L^2(\Omega)^N} = 1, \text{ and } \forall\omega \text{ with } \overline{\omega} \subset \Omega,\ \|\vec{s}^{\epsilon'}\|_{L^2(\omega)^N} \to 0\}, \end{aligned} \tag{15}$$

where ϵ' is a subsequence of ϵ and S^1_ϵ is the extension to $L^2(\Omega)^N$ of S_ϵ, we proved the following theorem (see Theorem 3.2.9 in [3]).

THEOREM 1.6. *The limit set of the spectrum of the operator S_ϵ is precisely made of three parts; the homogenized, the Bloch, and the boundary layer spectrum*

$$\lim_{\epsilon\to 0} \sigma(S_\epsilon) = \sigma_\infty = \sigma(S) \cup \sigma_{Bloch} \cup \sigma_{boundary}.$$

The proof of this *completeness result* is the focus of section 3.4 in [3]. It involves a new type of default measure for weakly converging sequences of eigenvectors of S_ϵ, the so-called *Bloch measures* which quantify its amplitude and direction of oscillations.

Of course the definition of $\sigma_{boundary}$ is not satisfactory, since it does not characterize that part of the limit set σ_∞ as the spectrum of some limit operator associated with the boundary $\partial\Omega$. In particular, it is not clear whether $\sigma_{boundary}$ is empty or included in $\sigma(S) \cup \sigma_{Bloch}$. It is the purpose of the present paper to characterize explicitly $\sigma_{boundary}$, at least for special rectangular domains Ω and associated sequences of parameters ϵ.

REMARK 1.7. *By their very definitions, the limit spectrum σ_∞ and the boundary layer spectrum $\sigma_{boundary}$ depend a priori on the choice of the sequence of small parameters ϵ. On the contrary, the homogenized spectrum $\sigma(S)$ and the Bloch spectrum σ_{Bloch} are independent of the sequence ϵ. We believe that $\sigma_{boundary}$ is actually strongly dependent on the sequence ϵ. In particular, we shall characterize it only for a specific sequence ϵ. We thank C. Castro and E. Zuazua for clarifying discussions on this topic* [12].

1.3. Presentation of the main new results. There are mainly two new results in this paper which correspond to the next two sections. First, in section 2 we introduce a new class of limit problems involving the interaction between the tubes array and the domain boundary. We assume that the domain Ω is cylindrical;

$$\Omega = \Sigma\times]0; L[, \tag{16}$$

where Σ is an open bounded set in $\mathbb{R}^{N-1}$ and $L > 0$ is a positive length. A generic point x in $\mathbb{R}^N$ is denoted by $x = (x', x_N)$ with $x' \in \mathbb{R}^{N-1}$ and $x_N \in \mathbb{R}$ (x_N is the coordinate along the axis of Ω). Let us define a semi-infinite band

$$G = Y'\times]0; +\infty[,$$

where $Y' =]0,1[^{N-1}$ is the unit cell in $\mathbb{R}^{N-1}$. This new "boundary layer" limit problem takes place in the fluid part of G, denoted by G^* and defined by

$$G^* \;=\; G \setminus \bigcup_{q\geq 1} T_q,$$

where (T_q) is the infinite collection of tubes periodically disposed in G. With each tube T_q is associated a displacement $\vec{s}_q \in \mathbb{R}^N$. We denote by ℓ^2 the space of families $(\vec{s}_q)_{q\geq 1}$ such that $\sum_{q\geq 1} |\vec{s}_q|^2$ is finite. Introducing a Bloch parameter $\theta' \in [0,1]^{N-1}$, we define a "boundary layer" operator $d_{\theta'}$ by

$$\begin{aligned} & d_{\theta'} \,:\, \ell^2 \longrightarrow \ell^2, \\ & (\vec{s}_q)_{q\geq 1} \;\mapsto\; \left(\int_{\Gamma_q} u_{\theta'} \vec{n} ds \right)_{q\geq 1}, \end{aligned} \tag{17}$$

where $u_{\theta'}(y)$ is the unique solution of

$$\begin{cases} -\Delta u_{\theta'} = 0 & \text{in } G^*, \\ \frac{\partial u_{\theta'}}{\partial n} = \vec{s}_q \cdot \vec{n} & \text{on } \Gamma_q,\ q \geq 1, \\ u_{\theta'} = 0 & \text{if } y_N = 0, \\ y' \mapsto e^{-2\pi\imath\theta'\cdot y'} u_{\theta'}(y', y_N) & Y'\text{-periodic.} \end{cases}$$

Our first result (see Theorem 2.18) is concerned with the continuity of the spectrum of $d_{\theta'}$, considered as a subset of $\mathbb{R}$, with respect to the Bloch parameter θ'.

THEOREM 1.8. *For all $\theta' \in [0,1]^{N-1}$, $d_{\theta'}$ is a self-adjoint continuous but non-compact operator in ℓ^2. Its spectrum $\sigma(d_{\theta'})$ depends continuously on θ', except at $\theta' = 0$. Defining the* boundary layer spectrum *associated with the surface Σ*

$$\sigma_\Sigma \stackrel{\text{def}}{=} \bigcup_{\theta' \in]0,1[^{N-1}} \sigma(d_{\theta'}) \cup \sigma(d_0),$$

we have

$$\sigma_\Sigma \subset \lim_{\epsilon \to 0} \sigma(S_\epsilon).$$

In general, $\sigma(d_{\theta'})$ is not included in the previously found limit spectrum $\sigma(S) \cup \sigma_{Bloch}$ (see Proposition 2.17). Therefore, the new class of limit problems defined by (17) is not redundant with the homogenized or the Bloch limit problems. Our main tool for proving this theorem is a variant of the two-scale convergence adapted to boundary layers, using test functions which oscillate periodically in the directions parallel to the boundary Σ and decay asymptotically fast in the normal direction to Σ (see section 2.1). Remark that the above result holds for any cylindrical domain of the type (16) and for any sequence of periods ϵ going to zero.

Section 3 is devoted to our second main result which requires additional assumptions on the geometry of the domain and on the sequence of periods ϵ. More precisely, we now assume that Ω is a rectangle with integer dimensions

$$\Omega \;=\; \prod_{i=1}^{N}]0; L_i[\quad \text{and} \quad L_i \in \mathbb{N}^* \tag{18}$$

and that the sequence ϵ is exactly

$$\epsilon_n \;=\; \frac{1}{n},\; n \in \mathbb{N}^*.$$

These assumptions imply that, for any ϵ_n, the domain Ω is the union of a finite number of *entire* cells of size ϵ_n. Then, the above analysis of the boundary layer spectrum σ_Σ can be achieved for any face Σ of the rectangle Ω. Of course a completely similar analysis can be done for all the lower dimensional manifolds (edges, corners, etc.) of which the boundary of Ω is made up. For each type of manifold, a different family of limit problems arise which are straightforward generalizations of (17). For example, in two space dimensions, the corners of Ω give rise to a limit problem in the quarter of space $\mathbb{R}^+ \times \mathbb{R}^+$ filled with a periodic array of tubes (see section 3.3). Finally, we prove a completeness result (see Theorem 3.1).

THEOREM 1.9. *The limit set of the spectrum of the operator S_{ϵ_n} is precisely made of three parts; the homogenized, the Bloch, and the union of all boundary layer spectra, as defined in Theorem* 1.8*,*

$$\lim_{\epsilon_n \to 0} \sigma(S_{\epsilon_n}) = \sigma(S) \cup \sigma_{Bloch} \cup \sigma_{\partial\Omega},$$

with the notation

$$\sigma_{\partial\Omega} \;=\; \bigcup_{\Sigma \subset \partial\Omega} \sigma_\Sigma,$$

where the union is over all hypersurfaces and lower dimensional manifolds composing the boundary $\partial\Omega$.

REMARK 1.10. *The difference between the above completeness theorem and Theorem* 1.6 *is that, here, the boundary layer spectrum $\sigma_{\partial\Omega}$ is explicitly defined for the specific sequence of parameters ϵ_n as the spectrum of a family of limit operators, while, in our previous result, the boundary layer spectrum $\sigma_{boundary}$ was indirectly defined for any sequence ϵ but not explicitly characterized.*

We conclude this introduction by giving a few references to related works on boundary layers in homogenization and by a short discussion on numerical studies concerning problem (2). Apart from the classical books [7, Chapter 7] and [26], we refer mainly to the papers [6], [9], [10], and [27]. Planchard's model has already been studied numerically. The Bloch eigenvalues $\lambda_i(\theta)$ were computed by F. Aguirre in a two-dimensional example. A brief account of his work is given in [1]. On the other hand, direct numerical computations of the entire spectrum $\sigma(S_\epsilon)$ (for a fixed value of ϵ, and without using homogenization) have been reported in [23]. To our knowledge, these are the only available numerical results concerning a large tube array (see also [21], [22]). Of course, these results are consistent with Theorem 1.9 describing the asymptotic behavior of $\sigma(S_\epsilon)$. In particular, some vibration modes displayed in [23] are numerical evidence that $\sigma_{\partial\Omega}$ is not empty; i.e., there exist eigenvectors which are localized near the boundary or the corners of Ω.

2. Boundary layer homogenization. In this section we assume that Ω is a cylindrical bounded open set in $\mathbb{R}^N$ in the sense that it is defined by

$$\Omega = \Sigma \times]0; L[, \tag{19}$$

where Σ is an open bounded set in $\mathbb{R}^{N-1}$ and $L > 0$ is a positive length. With no loss of generality, we assume that the axis of the cylindrical domain Ω is parallel to the Nth

canonical direction. Therefore, a generic point x in Ω is denoted by $x = (x', x_N)$ with $x' \in \Sigma$ and $x_N \in]0; L[$. The goal of this section is to analyze the asymptotic behavior of that part of the spectrum $\sigma(S_\epsilon)$ which corresponds to eigenvectors concentrating on the boundary $\Sigma \times \{0\}$, under the sole geometric assumption (19) (in particular, no restrictions are made on the sequence ϵ which goes to zero).

2.1. Two-scale convergence for boundary layers. We begin by adapting the classical two-scale convergence method of Allaire [2] and Nguetseng [29] to the case of boundary layers, that is, sequences of functions in Ω which concentrate near the boundary $\Sigma \times \{0\}$. This method of "two-scale convergence for boundary layers" will allow us to understand this phenomenon of concentration of oscillations near the boundary. The usual two-scale convergence relies on periodically oscillating test functions with a unit period $Y =]0,1[^N$. Here, we use test functions which oscillate only in the directions parallel to the boundary Σ (with period $Y' =]0,1[^{N-1}$) and which simply decay in the Nth direction orthogonal to Σ.

Let us define a semi-infinite band $G = Y' \times]0; +\infty[$, where $Y' =]0,1[^{N-1}$ is the unit cell in $\mathbb{R}^{N-1}$. A generic point y is denoted by $y = (y', y_N)$ with $y' \in Y'$ and $y_N \in]0; +\infty[$. We introduce the space $L^2_\#(G)$ of square integrable functions in G which are periodic in the $(N-1)$ first variables, i.e.,

$$L^2_\#(G) = \{\phi(y) \in L^2(G) \mid y' \mapsto \phi(y', y_N) \text{ is } Y'\text{-periodic}\}.$$

We also denote by $C(\overline{\Sigma})$ the space of continuous functions on the closure of Σ, a compact set in $\mathbb{R}^{N-1}$.

Combining the concentration effect in y_N and the periodic oscillations in Y', the following convergence result is obtained for a sequence $\phi(\frac{x}{\epsilon})$ when ϕ belongs to $L^2_\#(G)$ (further modulated by $x' \in \Sigma$).

LEMMA 2.1. *Let $\varphi(x', y) \in L^2_\#\left(G; C(\overline{\Sigma})\right)$. Then*

$$\lim_{\epsilon \to 0} \frac{1}{\epsilon} \int_\Omega \left|\varphi\left(x', \frac{x}{\epsilon}\right)\right|^2 dx = \frac{1}{|Y'|} \int_\Sigma \int_G |\varphi(x', y)|^2 dx' dy.$$

REMARK 2.2. *Remark that, in the left-hand side of the above equation, the second argument of φ is x/ϵ and not only x'/ϵ. This implies that there is a concentration effect near 0 in the x_N variable since φ is not periodic in this direction. This, in turn, explains the $1/\epsilon$ scaling in front of the left-hand side, in order to get a nonzero limit.*

As usual in the context of two-scale convergence, the above result is not specific to the space $L^2_\#\left(G; C(\overline{\Sigma})\right)$, which could be replaced, for example, by $L^2\left(\Sigma; C_{c\#}(\bar{G})\right)$, where $C_{c\#}(\bar{G})$ is the space of continuous functions in G, periodic in y' of period Y', and with bounded support in y_N.

In view of Lemma 2.1, we define a notion of "two-scale convergence for boundary layers."

DEFINITION 2.3. *Let $(u_\epsilon)_{\epsilon>0}$ be a sequence in $L^2(\Omega)$. It is said to* two-scale converge in the sense of boundary layers *on Σ if there exists $u_0(x', y) \in L^2(\Sigma \times G)$ such that*

$$\lim_{\epsilon \to 0} \frac{1}{\epsilon} \int_\Omega u_\epsilon(x) \varphi\left(x', \frac{x}{\epsilon}\right) dx = \frac{1}{|Y'|} \int_\Sigma \int_G u_0(x', y) \varphi(x', y) dx' dy$$

for all smooth functions $\varphi(x', y)$ defined in $\Sigma \times G$ such that $y' \mapsto \varphi(x', y', y_N)$ is Y'-periodic and φ has a bounded support in $\Sigma \times G$.

This definition makes sense because of the following compactness theorem which generalizes the usual two-scale convergence compactness theorem in [2], [29].

THEOREM 2.4. *Let $(u_\epsilon)_{\epsilon>0}$ be a sequence in $L^2(\Omega)$ such that there exists a constant C, independent of ϵ, for which*

$$\frac{1}{\sqrt{\epsilon}}\|u_\epsilon\|_{L^2(\Omega)} \le C.$$

There exists a subsequence, still denoted by ϵ, and a limit function $u_0(x',y) \in L^2(\Sigma \times G)$ such that

$$\lim_{\epsilon\to 0}\frac{1}{\epsilon}\int_\Omega u_\epsilon(x)\varphi\left(x',\frac{x}{\epsilon}\right)dx = \frac{1}{|Y'|}\int_\Sigma\int_G u_0(x',y)\varphi(x',y)dx'dy \tag{20}$$

for all functions $\varphi(x',y) \in L^2_\#\left(G;C(\overline{\Sigma})\right)$.

Remark that Theorem 2.4 does not apply to sequences which are merely bounded in $L^2(\Omega)$ but also converge strongly to zero in $L^2(\Omega)$ as the square root of ϵ. Of course, this is the case for a sequence of the type $\varphi(x',\frac{x}{\epsilon})$, where $\varphi(x',y)$ is as in Lemma 2.1; then, the limit is nothing but $\varphi(x',y)$ itself.

It is not difficult to check that the L^2-norm is weakly lower semicontinuous with respect to the two-scale convergence (see Proposition 1.6 in [2]); i.e., in the present situation

$$\lim_{\epsilon\to 0}\frac{1}{\sqrt{\epsilon}}\|u_\epsilon\|_{L^2(\Omega)} \ge \frac{1}{|Y'|^{1/2}}\|u_0\|_{L^2(\Sigma\times G)}.$$

The next proposition asserts a corrector-type result when the above inequality is actually an equality.

PROPOSITION 2.5. *Let $(u_\epsilon)_{\epsilon>0}$ be a sequence in $L^2(\Omega)$ which two-scale converges in the sense of boundary layers to a limit $u_0(x',y) \in L^2(\Sigma\times G)$. Assume further that it two-scale converges* strongly*, that is,*

$$\lim_{\epsilon\to 0}\frac{1}{\sqrt{\epsilon}}\|u_\epsilon\|_{L^2(\Omega)} = \frac{1}{|Y'|^{1/2}}\|u_0\|_{L^2(\Sigma\times G)}.$$

Then,

(i) *for any sequence $(v_\epsilon)_{\epsilon>0}$ in $L^2(\Omega)$ which two-scale converges in the sense of boundary layers to a limit $v_0(x',y) \in L^2(\Sigma\times G)$, one has*

$$\lim_{\epsilon\to 0}\frac{1}{\epsilon}\int_\Omega u_\epsilon v_\epsilon dx = \frac{1}{|Y'|}\int_\Sigma\int_G u_0(x',y)v_0(x',y)dx'dy;$$

(ii) *if $u_0(x',y)$ is smooth, say $u_0 \in L^2_\#\left(G;C(\overline{\Sigma})\right)$, then*

$$\lim_{\epsilon\to 0}\frac{1}{\sqrt{\epsilon}}\left\|u_\epsilon(x) - u_0\left(x',\frac{x}{\epsilon}\right)\right\|_{L^2(\Omega)} = 0.$$

In order to investigate the convergence of sequences of functions in $H^1_0(\Omega)$, we first have to define adequate functional spaces for the two-scale limit. Let $C^\infty_{c\#}(G)$ be the space of smooth functions in $\overline{G}$ which are Y'-periodic in y' and have a compact support in y_N (i.e., they vanish for sufficiently large and small y_N but not necessarily on the whole ∂G). Let $H^1_{0\#}(G)$ be the Sobolev space obtained by completion of $C^\infty_{c\#}(G)$ with

respect to the $H^1(G)$-norm. We denote by $H^1_{0\#,loc}(G)$ the space of functions which are "locally" in $H^1_{0\#}(G)$, i.e., which coincide with a function of $H^1_{0\#}(G)$ in any compact set of $\overline{G}$. We define a Deny–Lions-type space (cf. [18]) $D^1_{0\#}(G)$ as the completion of $C^\infty_{c\#}(G)$ with respect to the $L^2(G)^N$-norm of the gradient

$$D^1_{0\#}(G) = \Big\{\psi(y) \in H^1_{0\#,loc}(G) \mid \exists \quad \psi_n \in C^\infty_{c\#}(G) \quad \text{such that} \quad \lim_{n\to+\infty} \|\nabla(\psi-\psi_n)\|_{L^2(G)^N} = 0\Big\}. \tag{21}$$

It is easily seen that a function in $D^1_{0\#}(G)$ vanishes when $y_N = 0$ but does not necessarily go to 0 when y_N goes to infinity since $D^1_{0\#}(G)$ contains functions which grow like y_N^α at infinity with $\alpha < 1/2$. We are now in a position to state our next result.

PROPOSITION 2.6. *Let $(u_\epsilon)_{\epsilon>0}$ be a sequence in $H^1_0(\Omega)$ such that there exists a constant C, independent of ϵ, for which*

$$\frac{1}{\sqrt{\epsilon}}\left(\|u_\epsilon\|_{L^2(\Omega)} + \|\nabla u_\epsilon\|_{L^2(\Omega)^N}\right) \le C.$$

Then, there exists a subsequence, still denoted by ϵ, and a limit $u_0(x',y) \in L^2(\Sigma; D^1_{0\#}(G))$ such that

$$\lim_{\epsilon\to 0}\frac{1}{\epsilon}\int_\Omega u_\epsilon(x)\varphi\left(x',\frac{x}{\epsilon}\right)dx = 0,$$

$$\lim_{\epsilon\to 0}\frac{1}{\epsilon}\int_\Omega \nabla u_\epsilon(x)\cdot\psi\left(x',\frac{x}{\epsilon}\right)dx = \frac{1}{|Y'|}\int_\Sigma\int_G \nabla_y u_0(x',y)\cdot\psi(x',y)dx'dy$$

for any functions $\varphi \in L^2_\#\left(G; C(\overline{\Sigma})\right)$ and $\psi \in L^2_\#\left(G; C(\overline{\Sigma})^N\right)$.

Remark that, in Proposition 2.6, the two-scale limit $u_0(x',y)$ does not belong to $L^2(\Sigma; H^1(G))$ as could be expected. The reason is that only $\nabla_y u_0 \in L^2(\Sigma\times G)$, while u_0 itself has no reason to belong to $L^2(\Sigma\times G)$. Since the proofs of the above results are very similar to those of the usual two-scale convergence theory, we simply sketch the proofs of Lemma 2.1, Theorem 2.4, and Proposition 2.6.

Proof of Lemma 2.1. Let us first assume that $\varphi(x',y) \in L^2_\#\left(G; C(\overline{\Sigma})\right)$ has bounded support in y_N; i.e., there exists $M > 0$ such that

$$\varphi(x',y) = 0 \text{ if } y_N \ge M.$$

Then, by the change of variables $y_N = x_N/\epsilon$ and for sufficiently small ϵ, we have

$$\begin{aligned}\tfrac{1}{\epsilon}\textstyle\int_\Omega |\varphi(x',\frac{x}{\epsilon})|^2dx &= \tfrac{1}{\epsilon}\textstyle\int_0^L\int_\Sigma |\varphi(x',\frac{x'}{\epsilon},\frac{x_N}{\epsilon})|^2dx'dx_N\\ &= \textstyle\int_0^{L/\epsilon}\int_\Sigma |\varphi(x',\frac{x'}{\epsilon},y_N)|^2dx'dy_N\\ &= \textstyle\int_0^{M}\int_\Sigma |\varphi(x',\frac{x'}{\epsilon},y_N)|^2dx'dy_N.\end{aligned} \tag{22}$$

The usual convergence result for oscillating functions in $\mathbb{R}^{N-1}$ (see, e.g., [2] and references therein) yields that for almost everywhere $y_N \in (0;M)$

$$\lim_{\epsilon\to 0}\int_\Sigma\left|\varphi\left(x',\frac{x'}{\epsilon},y_N\right)\right|^2dx' = \frac{1}{|Y'|}\int_\Sigma\int_{Y'}|\varphi(x',y',y_N)|^2dx'dy'$$

and that

$$\int_\Sigma \left|\varphi\left(x', \frac{x'}{\epsilon}, y_N\right)\right|^2 dx' \le |\Sigma| \int_{Y'} \max_{x'\in\overline{\Sigma}} |\varphi(x', y', y_N)|^2 dy'.$$

Therefore, applying the Lebesgue theorem, we deduce that

$$\lim_{\epsilon\to 0} \int_0^M \int_\Sigma \left|\varphi\left(x', \frac{x'}{\epsilon}, y_N\right)\right|^2 dx' dy_N = \frac{1}{|Y'|} \int_\Sigma \int_G |\varphi(x', y', y_N)|^2 dx' dy.$$

The density of such functions $\varphi(x', y)$ in $L^2_\#\left(G; C(\overline{\Sigma})\right)$ implies the desired result for any function in $L^2_\#\left(G; C(\overline{\Sigma})\right)$.

Proof of Theorem 2.4. Using the assumed uniform bound on u_ϵ, by the Schwarz inequality we obtain

$$\left|\frac{1}{\epsilon}\int_\Omega u_\epsilon(x)\varphi\left(x', \frac{x}{\epsilon}\right) dx\right| \le C\Big(\frac{1}{\epsilon}\int_\Omega \Big|\varphi\Big(x', \frac{x}{\epsilon}\Big)\Big|^2 dx\Big)^{\frac{1}{2}}.$$

Passing to the limit, up to a subsequence, which may depend on φ in the left-hand side and using Lemma 2.1 in the right-hand side, yield

$$\left|\lim_{\epsilon\to 0} \frac{1}{\epsilon}\int_\Omega u_\epsilon(x)\varphi\left(x', \frac{x}{\epsilon}\right) dx\right| \le C\Big(\int_\Sigma \int_G |\varphi(x', y)|^2 dx' dy\Big)^{\frac{1}{2}}. \tag{23}$$

Since $L^2_\#\left(G; C(\overline{\Sigma})\right)$ is separable, varying φ over a dense countable subset, by a standard diagonalization process, we can extract a subsequence of ϵ such that (23) is valid for all functions φ in this subset. By density, we conclude that the limit in the left side of (23), as a function of φ, defines a continuous linear form in $L^2(\Sigma\times G)$. Then, the classical Riesz representation theorem immediately implies the existence of a function $u_0(x, y) \in L^2(\Sigma\times G)$ which satisfies (20). This finishes the proof of Theorem 2.4.

Proof of Proposition 2.6. By application of Theorem 2.4, up to a subsequence, there exist two limits $u(x', y) \in L^2(\Sigma\times G)$ and $\xi^0(x', y) \in L^2(\Sigma\times G)^N$ such that u_ϵ and ∇u_ϵ two-scale converge in the sense of boundary layers to these respective limits; i.e.,

$$\lim_{\epsilon\to 0} \frac{1}{\epsilon}\int_\Omega u_\epsilon(x)\varphi\left(x', \frac{x}{\epsilon}\right) dx = \frac{1}{|Y'|}\int_\Sigma \int_G u(x', y)\varphi(x', y) dx' dy, \tag{24}$$

$$\lim_{\epsilon\to 0} \frac{1}{\epsilon}\int_\Omega \nabla u_\epsilon(x)\cdot\psi\left(x', \frac{x}{\epsilon}\right) dx = \frac{1}{|Y'|}\int_\Sigma \int_G \xi_0(x', y)\cdot\psi(x', y) dx' dy \tag{25}$$

for any functions $\varphi \in L^2_\#\left(G; C(\overline{\Sigma})\right)$ and $\psi \in L^2_\#\left(G; C(\overline{\Sigma})^N\right)$. Integrating by parts in (25), we obtain

$$\lim_{\epsilon\to 0} \frac{1}{\epsilon}\int_\Omega u_\epsilon(x)\mathrm{div}_y\psi\left(x', \frac{x}{\epsilon}\right) dx = 0.$$

In view of (24), this implies that

$$\frac{1}{|Y'|}\int_\Sigma \int_G u(x', y)\mathrm{div}_y\psi(x', y) dx' dy = 0.$$

Another integration by parts yields that $u(x', y)$ does not depend on y. On the other hand, it belongs to $L^2(\Sigma \times G)$ and G is unbounded. Since the only constant which belongs to $L^2(G)$ is zero, we deduce that $u = 0$. Now, specializing (25) to test functions ψ such that $\mathrm{div}_y \psi = 0$ and integrating by parts, we also obtain that

$$\frac{1}{|Y'|} \int_\Sigma \int_G \xi_0(x', y) \cdot \psi(x', y) dx' dy = 0.$$

As is well known, the orthogonal of divergence-free fields is exactly the set of gradients (see Proposition 1.14 in [2] for a precise statement and references). Therefore, there exists a function $u_0(x', y)$ in $L^2(\Sigma; D^1_{0\#}(G))$ such that $\xi_0 = \nabla_y u_0$ (we use the space $D^1_{0\#}(G)$ since u_0 has no reason to belong to $L^2(\Sigma \times G)$).

2.2. Convergence analysis. Recall that the original operator S_ϵ, defined by (3), acts in the space $\mathbb{R}^{Nn(\epsilon)}$ which depends on ϵ and that our strategy was to extend S_ϵ to a fixed space where a convergence analysis is possible. So far, the domain $\Omega = \Sigma \times]0, L[$ was considered periodic of period ϵY. Nevertheless, from now on, Ω is seen as a periodic domain with a new period G^K_ϵ defined by

$$G^K_\epsilon \stackrel{\text{def}}{=}]0; \epsilon K[^{N-1} \times]0; L[,$$

with K an integer larger than 1. We shall construct an extension of S_ϵ well suited for the previous two-scale convergence "in the sense of boundary layers" with such a period G^K_ϵ.

REMARK 2.7. *As already mentioned, we make no special hypothesis on the sequence of small parameters ϵ. However, the periodic arrangement of tubes in Ω is required to be aligned with Σ in such a way that the first row of periodic cells ϵY has a boundary which coincides with $\Sigma \times \{0\}$. In other words, the first layer of tubes close to Σ is at a fixed distance $\frac{\epsilon}{2}$ of $\Sigma \times \{0\}$ (see Figure 1).*

By a rescaling of ratio ϵ, this new period G^K_ϵ corresponds to a finite length truncation of the new reference cell

$$G^K \stackrel{\text{def}}{=} KG =]0; K[^{N-1} \times]0; +\infty[= KY' \times]0; +\infty[.$$

In the reference cell G^K (see Figure 2) we put infinitely many layers of tubes in the Nth direction, each layer being made of K^{N-1} tubes. The tubes in G^K are denoted by T_j, where $j = (j', j_N)$ is a multi-index such that $j_N \geq 1$ is an integer, which labels the corresponding layer in G^K, and j' is a multi-integer in $\{0, 1, \ldots, K-1\}^{N-1}$, which locates the tube T_j in its layer j_N. The fluid part in G^K is denoted by G^{*K}, i.e.,

$$G^{*K} \;=\; G^K \setminus \bigcup_{\substack{0 \leq j' \leq K-1 \\ 1 \leq j_N}} T_j.$$

To each tube T_j in G^K we associate the subcell Y_j and the fluid subcell $Y^*_j = Y_j \setminus T_j$ analogous to Y and Y^*, respectively (see Figure 2). The main idea is to attach to each tube T_j in G^K a different displacement function $\vec{s}(x')$, depending only on the variable $x' \in \Sigma$, such that the family $(\vec{s}_j(x'))_{\substack{0 \leq j' \leq K-1 \\ 1 \leq j_N}}$ belongs to the space $L^2(\Sigma; \ell^2_K)$, where ℓ^2_K is the Hilbert space defined by

$$\ell^2_K = \left\{ (\vec{s}_j)_{\substack{0 \leq j' \leq K-1 \\ 1 \leq j_N}} \;\middle|\; \vec{s}_j \in \mathbb{C}^N, \quad \sum_{\substack{0 \leq j' \leq K-1 \\ 1 \leq j_N}} |\vec{s}_j|^2 < +\infty \right\}.$$

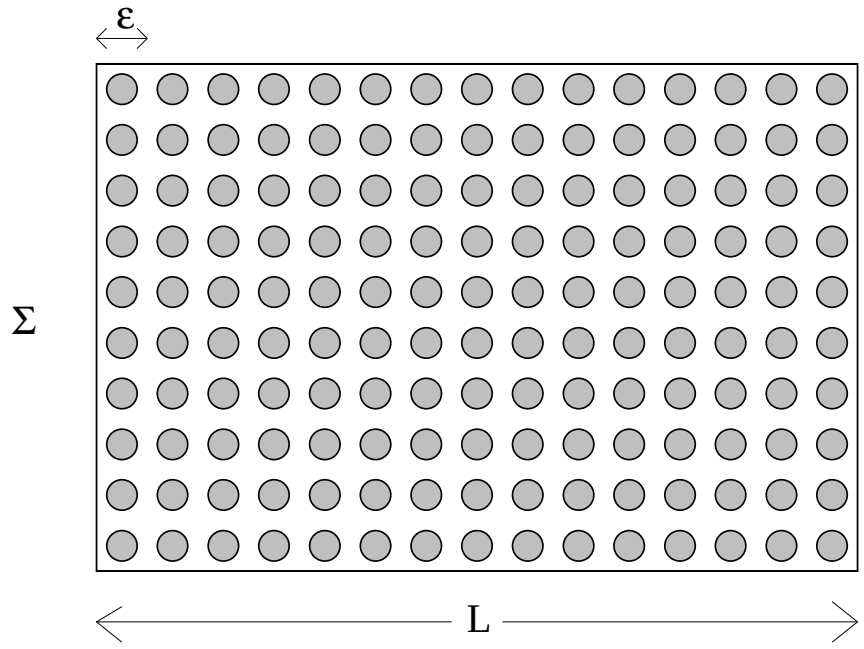

FIG. 1. *Cylindrical domain* $\Omega = \Sigma \times (0, L)$.

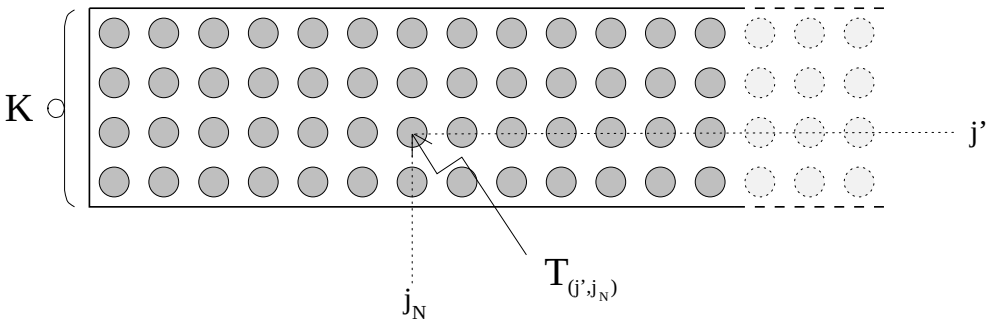

FIG. 2. *Reference cell* G^K.

Remark that this definition of ℓ^2_K implies a decay of the displacement function $\vec{s}_j$ as j_N goes to $+\infty$. Note also that each family $(\vec{s}_j(x')) \in L^2(\Sigma; \ell^2_K)$ can be identified with a function $\vec{s}(x', y) \in L^2(\Sigma \times G^K)$ which is constant in each subcell Y_j.

We now introduce the extended operator B^K_ϵ defined in $L^2(\Sigma; \ell^2_K)$ by

$$B^K_\epsilon = E^K_\epsilon S_\epsilon P^K_\epsilon,$$

where P^K_ϵ and E^K_ϵ are, respectively, projection and extension operators between $\mathbb{R}^{Nn(\epsilon)}$ and $L^2(\Sigma; \ell^2_K)$. To define precisely P^K_ϵ and E^K_ϵ we need the following notation.

DEFINITION 2.8. *Let $j = (j', j_N)$ denote the multi-index which enumerates all tubes in the periodic reference cell G^K. We use the notation $0 \le j' \le K - 1$ to indicate that j' varies in $\{0, 1, \ldots, K-1\}^{N-1}$ and $j_N \ge 1$ to indicate that j_N takes any positive integer value. Let $p = (p_1, \ldots, p_N)$ be the multi-integer which enumerates all the tubes in Ω (see Definition 1). The index p is such that the tube T^ϵ_p is located*

in the cell whose origin lies at the point $\epsilon p \in \Omega$. To describe its range we use the notation $1 \leq p \leq n(\epsilon)$, where $n(\epsilon)$ is the total numbers of tubes in Ω. We define a third multi-integer $\ell' = (\ell_1, \ldots, \ell_{N-1})$ which enumerates all the periodic reference cells $G^K_{\epsilon,\ell'}$ covering Ω (each being identical, up to a translation, to G^K_ϵ). For simplicity its range is denoted by $1 \leq \ell' \leq n_K(\epsilon)$. These three indices are assumed to be related by the following one-to-one relationship:

$$\left\{ \begin{array}{l} \ell_m = E(\frac{p_m}{K}), \quad j_m = p_m - K\ell_m \quad \textit{for} \quad 1 \leq m \leq N-1, \\ j_N = p_N, \end{array} \right. \tag{26}$$

where E denotes the integer-part function. This yields a one-to-one map between the tubes (T^ϵ_p) and their location in the cell $G^K_{\epsilon,\ell'}$ at the position j' in the layer j_N.

Then, we define a projection

$$\begin{array}{rcl} P^K_\epsilon \,:\, L^2(\Sigma; \ell^2_K) & \longrightarrow & \mathbb{R}^{Nn(\epsilon)}, \\ (\vec{s}_j(x'))_{\substack{0 \leq j' \leq K-1 \\ 1 \leq j_N}} & \mapsto & (\vec{s}_p)_{1 \leq p \leq n(\epsilon)} \end{array} \tag{27}$$

given by

$$\vec{s}_p = \frac{1}{|\epsilon K Y'|} \int_{(\epsilon K Y')_{\ell'}} \vec{s}_j(x') dx',$$

where (p, j, ℓ') are related by formula (26) and $(\epsilon K Y')_{\ell'}$ is the cross section of the cell $G^K_{\epsilon,\ell'}$.

We also define an extension

$$\begin{array}{rcl} E^K_\epsilon \,:\, \mathbb{R}^{Nn(\epsilon)} & \longrightarrow & L^2(\Sigma; \ell^2_K), \\ (\vec{s}_p)_{1 \leq p \leq n(\epsilon)} & \mapsto & (\vec{s}_j(x'))_{\substack{0 \leq j' \leq K-1 \\ 1 \leq j_N}} \end{array} \tag{28}$$

given by

$$\vec{s}_j(x') = \sum_{\ell'} \chi_{(\epsilon K Y')_{\ell'}}(x') \vec{s}_p,$$

where (p, j, ℓ') are related by formula (26) and $\chi_{(\epsilon K Y')_{\ell'}}(x')$ is the characteristic function of $(\epsilon K Y')_{\ell'}$. By convention, $\vec{s}_p$ is taken equal to 0 if the values of j and ℓ' correspond to a cell truncated by the boundary $\partial\Omega$ which therefore contains no tube.

One can easily check that P^K_ϵ and E^K_ϵ are adjoint operators (up to a multiplicative constant) and that the product $P^K_\epsilon E^K_\epsilon$ is nothing but the identity in $\mathbb{R}^{Nn(\epsilon)}$. Therefore, the spectrum of B^K_ϵ consists of that of S_ϵ and zero as an eigenvalue of infinite multiplicity. We summarize these results in the next lemma, the proof of which is safely left to the reader.

LEMMA 2.9. *The operators P^K_ϵ and E^K_ϵ satisfy the following properties;*

1. $(P^K_\epsilon)^\star = (\epsilon K)^{-(N-1)} E^K_\epsilon$,
2. $(E^K_\epsilon)^\star = (\epsilon K)^{(N-1)} P^K_\epsilon$,
3. $P^K_\epsilon E^K_\epsilon = Id_{\mathbb{R}^{Nn(\epsilon)}}$.

Therefore, the extended operator $B^K_\epsilon = E^K_\epsilon S_\epsilon P^K_\epsilon$ is self-adjoint and compact in $L^2(\Sigma; \ell^2_K)$. Its spectrum is

$$\sigma(B^K_\epsilon) = \sigma(S_\epsilon) \bigcup \{0\}.$$

The convergence analysis of this sequence of extended operators B_ϵ^K is amenable to the two-scale convergence method in the sense of boundary layers (as introduced in the previous section). It turns out that the corresponding limit operator B^K has a complicated form which can be considerably simplified by introducing the so-called Bloch wave decomposition. However, we emphasize that this decomposition will affect only the $(N-1)$ first variables and not the last one, orthogonal to the boundary Σ.

LEMMA 2.10. *Given a family $(\vec{s}_j)_{\substack{0\le j'\le K-1\\ 1\le j_N}}$ in ℓ^2_K, there exists a unique family $(\vec{t}_j)_{\substack{0\le j'\le K-1\\ 1\le j_N}}$ in ℓ^2_K such that, for any fixed j_N,*

$$\sum_{0\le j'\le K-1} \vec{s}_j \chi_{Y_{j'}}(y') = \sum_{0\le j'\le K-1} \vec{t}_j e^{2\pi\imath \frac{j'}{K}\cdot E(y')},$$

where $E(\cdot)$ denotes the integer part function and $(Y_{j'})_{0\le j'\le K-1}$ is the family of subcells of KY'. Moreover, Parseval's identity holds true; i.e., for any fixed j_N,

$$\sum_{0\le j'\le K-1} |\vec{s}_j|^2 \;=\; K^{N-1} \sum_{0\le j'\le K-1} |\vec{t}_j|^2.$$

The proof of Lemma 2.10 is standard (see, e.g., [1]). Remark that ℓ^2_K is isomorphic to $(\ell^2_1)^{K^{N-1}}$ by identifying an element $(\vec{s}_j)_{\substack{0\le j'\le K-1\\ 1\le j_N}}$ of ℓ^2_K as a collection of K^{N-1} elements $(\vec{s}_{(j',j_N)})_{j_N\ge 1}$ of ℓ^2_1. Therefore, in Lemma 2.10, one could replace ℓ^2_K by $(\ell^2_1)^{K^{N-1}}$. Let us define a linear map $\mathcal{B}'$

$$\begin{array}{rccl} \mathcal{B}' : & \ell^2_K & \longrightarrow & (\ell^2_1)^{K^{N-1}}, \\ & (\vec{s}_j) & \mapsto & (K^{\frac{N-1}{2}}\vec{t}_{(j',j_N)}), \end{array} \tag{29}$$

where the vectors $\vec{s}_j$ and $\vec{t}_j$ are related as in Lemma 2.10. This Bloch decomposition $\mathcal{B}'$ (the prime indicates that it concerns only the first $(N-1)$ variables) is easily seen to be an isometry from ℓ^2_K to $(\ell^2_1)^{K^{N-1}}$; namely, $(\mathcal{B}')^\star = (\mathcal{B}')^{-1}$.

We are now in a position to state the main result on the asymptotic behavior of B_ϵ^K.

THEOREM 2.11. *For each fixed $K\ge 1$, as ϵ goes to 0, the sequence B_ϵ^K converges strongly to a limit B^K into $L^2(\Sigma;\ell^2_K)$; i.e., for any function $\vec{s}(x')\in L^2(\Sigma;\ell^2_K)$ we have*

$$B_\epsilon^K \vec{s}(x') \longrightarrow B^K \vec{s}(x') \quad \text{in } L^2(\Sigma;\ell^2_K) \text{ strongly.}$$

By using the Bloch decomposition $\mathcal{B}'$ defined in (29)*, the operator B^K can be diagonalized*

$$B^K = (\mathcal{B}')^\star D^K \mathcal{B}' \quad \text{with} \quad D^K = \operatorname{diag}(D^K_{j'})_{0\le j'\le K-1},$$

where the entries $D^K_{j'}$ are self-adjoint continuous (but not compact) operators in $L^2(\Sigma;\ell^2_1)$ defined, for any $(\vec{s}_{j_N}(x'))_{j_N\ge 1}\in L^2(\Sigma;\ell^2_1)$, by

$$D^K_{j'}(\vec{s}_{j_N}(x')) = \left(\int_{\Gamma_{j_N}} u_{j'}\vec{n}ds\right)_{j_N\ge 1},$$

where $u_{j'}(y)$ is the unique solution of

$$(30)\qquad \begin{cases} -\Delta_y u_{j'} = 0 & \text{in } G^*, \\ \frac{\partial u_{j'}}{\partial n} = \vec{s}_{j_N} \cdot \vec{n} & \text{on } \Gamma_{j_N},\ j_N \geq 1, \\ u_{j'} = 0 & \text{on } y_N = 0, \\ y' \mapsto e^{-2\pi\imath \frac{j'}{K}\cdot y'} u_{j'}(y', y_N) & Y' - \text{periodic}, \end{cases}$$

where G^* is the fluid part of the semi-infinite band G (see Figure 2).

REMARK 2.12. *Of course, the solution $u_{j'}$ of* (30) *depends also on the variable $x' \in \Sigma$ since each displacement $\vec{s}_{j_N}(x')$ depends on x'. Nevertheless, x' plays the role of a parameter, since* (30) *is a partial differential equation in the variable y only. The limit problem* (30) *admits a unique solution $u_{j'}(x', y)$ in the space $L^2(\Sigma; D^1_{j',\#}(G^*))$, where $D^1_{j',\#}(G^*)$ is a Deny–Lions-type space. More precisely, it is defined as $D^1_{0\#}(G)$ in* (21)*, the only difference being that functions in $D^1_{j',\#}(G^*)$ satisfy a $(e^{2\pi\imath \frac{j'}{K}}, Y')$ periodicity condition in y', instead of the usual Y' periodicity. Recall that a function $w(y)$ satisfying the periodicity condition of the limit problem* (30) *is said to be $(e^{2\pi\imath \frac{j'}{K}}, Y')$-periodic in y' because such a function also satisfies the following (generalized) periodicity condition:*

$$w(y + (k', 0)) = e^{2\pi\imath \frac{j'\cdot k'}{K}} w(y) \quad \forall y = (y', y_N) \text{ and } \forall k' \in \mathbb{Z}^{N-1}.$$

For more details on this class of functions, we refer to [1], [16].

The key of the proof of Theorem 2.11 is the following homogenization result for the fluid potential when the displacements of the tubes are given in terms of the projection operator P^K_ϵ. Remark that, in view of definition (27) of P^K_ϵ, such a family of displacements concentrates near the boundary $\Sigma \times \{0\}$ as ϵ goes to 0.

PROPOSITION 2.13. *For any $\vec{s}(x') \in L^2(\Sigma; \ell^2_K)$ let us define $u_\epsilon = u_\epsilon(\vec{s})$ as the unique solution in $H^1(\Omega_\epsilon)$ of*

$$(31)\qquad \begin{cases} -\Delta u_\epsilon = 0 & \text{in } \Omega_\epsilon, \\ \frac{\partial u_\epsilon}{\partial n} = \left(P^K_\epsilon \vec{s}(x')\right)_p \cdot \vec{n} & \text{on } \Gamma^\epsilon_p,\ 1 \leq p \leq n(\epsilon), \\ u_\epsilon = 0 & \text{on } \partial\Omega. \end{cases}$$

Then, u_ϵ two scale converges in the sense of boundary layers to 0 and ∇u_ϵ two-scale converges in the sense of boundary layers to $\nabla_y u_0(x', y)$, where $u_0(x', y)$ is the unique solution in $L^2(\Sigma, D^1_{0\#}(G^{*K}))$ of

$$(32)\qquad \begin{cases} -\Delta_y u_0 = 0 & \text{in } G^{*K}, \\ \frac{\partial u_0}{\partial n} = \vec{s}_j \cdot \vec{n} & \text{on } \Gamma_j, \\ u_0 = 0 & \text{if } y_N = 0, \\ y' \mapsto u_0(x', y', y_N) & KY'\text{-periodic}, \end{cases}$$

and ∇u_ϵ two-scale converges strongly, i.e.,

$$(33)\qquad \lim_{\epsilon\to 0} \frac{1}{\epsilon} \int_{\Omega_\epsilon} |\nabla u_\epsilon|^2 dx = \frac{1}{|KY'|} \int_\Sigma \int_{G^K} |\nabla_y u_0|^2 dx' dy.$$

Moreover, if $\vec{s}^\epsilon(x')$ is a sequence which converges weakly to a limit $\vec{s}(x')$ in $L^2(\Sigma; \ell^2_K)$, then the sequence of associated solutions $u_\epsilon(\vec{s}^\epsilon)$ two-scale converges in the sense of boundary layers to 0 and $\nabla u_\epsilon(\vec{s}^\epsilon)$ two-scale converges in the sense of boundary layers to $\nabla u_0(x', y)$, where u_0 is still the solution of (32).

REMARK 2.14. *A priori, the solution u_ϵ of* (31) *is defined only in the fluid domain Ω_ϵ which is a varying set as ϵ goes to* 0. *However, it is a standard matter (see* [13]*) to build an extension operator X_ϵ acting from $H^1(\Omega_\epsilon)$ into $H^1(\Omega)$ such that, for any $v \in H^1(\Omega_\epsilon)$,*

$$X_\epsilon v = v \text{ in } \Omega_\epsilon \text{ and } \|X_\epsilon v\|_{H^1(\Omega)} \le C\|v\|_{H^1(\Omega_\epsilon)},$$

where C is a positive constant independent of ϵ. In what follows, we shall always identify functions in $H^1(\Omega_\epsilon)$ (as u_ϵ) with their extension in $H^1(\Omega)$ (as $X_\epsilon u_\epsilon$).

To prove Proposition 2.13 we need two technical lemmas.

LEMMA 2.15. *The extension and projection operators E_ϵ^K and P_ϵ^K satisfy the following estimates:*

(i) $\|P_\epsilon^K \vec{s}(x')\|_{\mathbb{R}^{Nn(\epsilon)}} \le C\epsilon^{-\frac{N-1}{2}} \|\vec{s}(x')\|_{L^2(\Sigma;\ell^2_K)}$,

(ii) $\|E_\epsilon^K(\vec{s}_p)\|_{L^2(\Sigma;\ell^2_K)} \le C\epsilon^{\frac{N-1}{2}} \|(\vec{s}_p)_{1\le p\le n(\epsilon)}\|_{\mathbb{R}^{Nn(\epsilon)}}$,

where C is a constant independent of ϵ and the norms are defined by

$$\|(\vec{s}_p)_{1\le p\le n(\epsilon)}\|^2_{\mathbb{R}^{Nn(\epsilon)}} = \sum_{1\le p\le n(\epsilon)} |\vec{s}_p|^2,$$

$$\|\vec{s}(x')\|^2_{L^2(\Sigma;\ell^2_K)} = \int_\Sigma \sum_{\substack{0\le j'\le K-1\\ 1\le j_N}} |\vec{s}_j(x')|^2 dx'.$$

Proof. Let us prove (i) (the other inequality (ii) has a similar proof). By definition of P_ϵ^K,

$$\|P_\epsilon^K \vec{s}(x')\|^2_{\mathbb{R}^{Nn(\epsilon)}} = \sum_{1\le p\le n(\epsilon)} \Big(\frac{1}{|\epsilon KY'|}\int_{(\epsilon KY')_{\ell'}} \vec{s}_j(x')dx'\Big)^2,$$

where (p, j, ℓ') are related by formula (26). Applying the Cauchy–Schwarz inequality and summing over ℓ' yield

$$\begin{aligned} \|P_\epsilon^K \vec{s}(x')\|^2_{\mathbb{R}^{Nn(\epsilon)}} &\le \sum_{1\le p\le n(\epsilon)} \tfrac{1}{|\epsilon KY'|}\textstyle\int_{(\epsilon KY')_{\ell'}} |\vec{s}_j(x')|^2 dx' \\ &\le \tfrac{1}{(K\epsilon)^{N-1}}\textstyle\int_\Sigma \sum_j |\vec{s}_j(x')|^2 dx', \end{aligned} \tag{34}$$

which is the desired result.

LEMMA 2.16. *Let $\vec{s}^\epsilon(x')$ be a sequence of functions which converges weakly to $\vec{s}(x')$ in $L^2(\Sigma;\ell^2_K)$. Define a piecewise constant function*

$$\vec{a}^\epsilon(x) = \sum_{\ell'}\sum_j \Big(\frac{1}{|\epsilon KY'|}\int_{(\epsilon KY')_{\ell'}} \vec{s}^\epsilon_j(x')dx'\Big)\chi_{Y^\epsilon_{j\ell'}}(x),$$

where $\chi_{Y^\epsilon_{j\ell'}}(x)$ is the characteristic function of the jth subcell of the periodic cell $G^K_{\epsilon,\ell'}$. Then, $\vec{a}^\epsilon$ two-scale converges in the sense of boundary layers to a limit $\vec{a}^0(x,y) \in L^2(\Sigma \times G^K)$ defined by

$$\vec{a}^0(x,y) = \sum_j \vec{s}_j(x')\chi_{Y_j}(y),$$

where $\chi_{Y_j}(y)$ *is the characteristic function of the jth subcell of the reference cell* G^K. *Moreover, if* $\vec{s}^\epsilon(x')$ *converges* strongly *to* $\vec{s}(x')$ *in* $L^2(\Sigma;\ell^2_K)$, *then* $\vec{a}^\epsilon$ *two-scale converges* strongly *to* $\vec{a}^0$ *in the sense of boundary layers, i.e.,*

$$\lim_{\epsilon\to 0}\frac{1}{\sqrt{\epsilon}}\|\vec{a}^\epsilon(x)\|_{L^2(\Omega)}=\frac{1}{K^{\frac{N-1}{2}}}\|\vec{a}^0(x',y)\|_{L^2(\Sigma\times G^K)}.$$

Proof. The proof is very similar to that of Lemma 3.3.2 in our previous work [3], so we briefly sketch it. Let $\vec{\varphi}(x',y)$ be a suitable smooth test function defined on $\Sigma\times G^K$ with values in $\mathbb{R}^N$ such that $y'\to\vec{\varphi}(x',y',y_N)$ is KY'-periodic and $\vec{\varphi}$ vanishes for sufficiently large y_N. We check the definition of two-scale convergence:

$$\begin{aligned}&\tfrac{1}{\epsilon}\textstyle\int_\Omega \vec{a}^\epsilon(x)\cdot\vec{\varphi}(x',\frac{x}{\epsilon})dx\\&=\tfrac{1}{\epsilon}\sum_{\ell,j}\Big(\tfrac{1}{(\epsilon K)^{N-1}}\textstyle\int_{\epsilon(KY')_{\ell'}}\vec{s}^\epsilon_j(x')dx'\Big)\cdot\int_{Y^\epsilon_{j\ell'}}\vec{\varphi}(x',\tfrac{x}{\epsilon})dx\\&=\tfrac{1}{K^{N-1}}\textstyle\sum_j\int_\Sigma\vec{s}^\epsilon_j(x')\cdot\Big[\sum_{\ell'}\Big(\tfrac{1}{\epsilon^N}\int_{Y^\epsilon_{j\ell'}}\vec{\varphi}(x',\tfrac{x}{\epsilon})dx\Big)\chi_{\epsilon(KY')_{\ell'}}(x')\Big]dx'.\end{aligned}$$

It is easily seen that for each fixed j the term between brackets converges strongly to $\int_{Y_j}\vec{\varphi}(x',y)dy$ in $L^2(\Sigma)^N$. Remark that the sum in j is finite since $\vec{\varphi}$ has a bounded support in G^K. Thus we can pass to the limit and obtain the desired result

$$\frac{1}{K^{N-1}}\sum_j\int_\Sigma\vec{s}_j(x')\cdot\left(\int_{Y_j}\vec{\varphi}(x',y)dy\right)dx'.$$

If $\vec{s}^\epsilon_j$ converges strongly to $\vec{s}_j$, the strong two-scale convergence of $\vec{a}^\epsilon(x)$ is obtained by a similar proof, replacing in the above computation the test function $\vec{\varphi}$ by $\vec{a}^\epsilon(x)$.

Proof of Proposition 2.13. Multiplying (31) by u_ϵ and integrating by parts, we get

$$\begin{aligned}\textstyle\int_{\Omega_\epsilon}|\nabla u_\epsilon|^2dx&=\sum_{1\le p\le n(\epsilon)}\big(P^K_\epsilon\vec{s}\big)_p\cdot\textstyle\int_{\Gamma^\epsilon_p}u_\epsilon\vec{n}ds\\&\le\|\big(P^K_\epsilon\vec{s}\big)\|_{\mathbb{R}^{Nn(\epsilon)}}\left\|\Big(\textstyle\int_{\Gamma^\epsilon_p}u_\epsilon\vec{n}ds\Big)\right\|_{\mathbb{R}^{Nn(\epsilon)}}.\end{aligned}\tag{35}$$

An easy calculation (see Lemma 2.2.3 in [3] if necessary) shows that

$$\left\|\Big(\int_{\Gamma^\epsilon_p}u_\epsilon\vec{n}ds\Big)\right\|^2_{\mathbb{R}^{Nn(\epsilon)}}\le C\epsilon^N\|\nabla u_\epsilon\|^2_{L^2(\Omega_\epsilon)^N},$$

and hence, using Lemma 2.15 we conclude that

$$\int_{\Omega_\epsilon}|\nabla u_\epsilon|^2dx\le C\epsilon\|\vec{s}(x')\|^2_{L^2(\Sigma;\ell^2_K)}.$$

A standard Poincaré inequality in Ω yields the same estimate for u_ϵ in $L^2(\Omega_\epsilon)$:

$$\int_{\Omega_\epsilon}|u_\epsilon|^2dx\le C\epsilon\|\vec{s}(x')\|^2_{L^2(\Sigma;\ell^2_K)}.$$

We now apply the method of two-scale convergence for the asymptotic analysis of the sequence u_ϵ, using test functions with G^K as the periodic cell (since we decided to consider G^K to be the reference cell and not G). By virtue of Proposition 2.6 there exists a subsequence of u_ϵ and a limit function $u_0(x', y)$ in $L^2(\Sigma; D^1_{0\#}(G^K))$ such that $(u_\epsilon, \nabla u_\epsilon)$ two-scale converge in the sense of boundary layers to $(0, \nabla_y u_0)$. Let $\varphi(x', y)$ be a smooth function in $L^2(\Sigma; D^1_{0\#}(G^K))$. Multiplying the equation (31) by $\varphi(x', \frac{x}{\epsilon})$ we obtain

$$\frac{1}{\epsilon}\int_\Omega \chi_{\Omega_\epsilon}(x)\nabla u_\epsilon \cdot \nabla_y \varphi\left(x', \frac{x}{\epsilon}\right) dx + \int_\Omega \chi_{\Omega_\epsilon}(x)\nabla u_\epsilon \nabla_{x'}\varphi\left(x', \frac{x}{\epsilon}\right) dx$$

$$= \sum_{1\le p\le n(\epsilon)} \left(P^K_\epsilon \vec{s}\right)_p \cdot \int_{\Gamma^\epsilon_p} \varphi\left(x', \frac{x}{\epsilon}\right)\vec{n} ds$$

$$= \frac{1}{\epsilon}\int_\Omega \left(\chi_{\Omega_\epsilon}(x) - 1\right)\vec{a}^\epsilon(x) \cdot \left(\nabla_y\varphi\left(x', \frac{x}{\epsilon}\right) + \epsilon\nabla_{x'}\varphi\left(x', \frac{x}{\epsilon}\right)\right) dx,$$

where $\chi_{\Omega_\epsilon}(x)$ is the periodic characteristic function of Ω_ϵ and $\vec{a}^\epsilon(x)$ is a piecewise constant function defined as in Lemma 2.16 by

$$\vec{a}^\epsilon = \sum_{\ell'}\sum_j \Big(\frac{1}{|\epsilon KY'|}\int_{(\epsilon KY')_{\ell'}} \vec{s}_j(x')dx'\Big)\chi_{Y^\epsilon_{j\ell'}}(x).$$

Remark that both terms involving $\nabla_{x'}\varphi$ go to zero with ϵ. Applying Lemma 2.16, we pass to the two-scale limit in the remaining terms to get

$$\frac{1}{|KY'|}\int_\Sigma\int_{G^{*K}} \nabla_y u_0(x', y)\cdot\nabla_y\varphi(x', y)dx'dy = \frac{-1}{|KY'|}\int_\Sigma\sum_j\int_{T_j}\vec{s}_j(x')\cdot\nabla_y\varphi(x', y)dx'dy$$

which is nothing but the variational formulation of the limit equation (32). A standard application of the Lax–Milgram lemma yields uniqueness of the solution u_0 in $L^2(\Sigma; D^1_{0\#}(G^K))$. Thus the entire sequence u_ϵ converges to the same limit u_0.

The proof of the energy convergence (33) is standard by passing to the two-scale limit in the right-hand side of (35) since $\vec{a}^\epsilon$ two-scale converges strongly in the sense of Proposition 2.5 (see Proposition 2.2.4 in [3]).

To prove the two-scale convergence of $u_\epsilon(\vec{s}^\epsilon)$ to u_0, when $\vec{s}^\epsilon$ converges weakly to $\vec{s}$ in $L^2(\Sigma; \ell^2_K)$, it suffices to repeat the same above arguments since Lemma 2.16 asserts that $\vec{a}^\epsilon$ two-scale converges to $\vec{a}^0$ even if $\vec{s}^\epsilon$ converges weakly. Note that in this case we do not have the energy convergence.

Proof of Theorem 2.11. Let $\vec{s}(x') \in L^2(\Sigma; \ell^2_K)$ and $\vec{t}^\epsilon$ be a sequence which converges weakly to $\vec{t}$ in $L^2(\Sigma; \ell^2_K)$. Our goal is to prove that

$$\lim_{\epsilon\to 0}\left\langle B^K_\epsilon \vec{s}(x'), \vec{t}^\epsilon(x')\right\rangle_{L^2(\Sigma;\ell^2_K)} = \left\langle B^K\vec{s}(x'), \vec{t}(x')\right\rangle_{L^2(\Sigma;\ell^2_K)}.$$

By definition of B_ϵ^K, we have

$$\begin{aligned}\left\langle B_\epsilon^K \vec{s}(x'), \vec{t^\epsilon}(x')\right\rangle_{L^2(\Sigma;\ell^2_K)} &= \left\langle E_\epsilon^K S_\epsilon P_\epsilon^K \vec{s}(x'), \vec{t^\epsilon}(x')\right\rangle_{L^2(\Sigma;\ell^2_K)} \\ &= (\epsilon K)^{N-1}\left\langle S_\epsilon P_\epsilon^K \vec{s}(x'), P_\epsilon^K \vec{t^\epsilon}(x')\right\rangle_{\mathbb{R}^{Nn(\epsilon)}} \\ &= (\epsilon K)^{N-1}\sum_{1\le p\le n(\epsilon)} \tfrac{1}{\epsilon^N}\left(\textstyle\int_{\Gamma_p^\epsilon} u_\epsilon(\vec{s})\vec{n}ds\right)\cdot (P_\epsilon^K \vec{t^\epsilon})_p \\ &= \tfrac{K^{N-1}}{\epsilon}\textstyle\int_{\Omega_\epsilon} \nabla u_\epsilon(\vec{s})\cdot\nabla u_\epsilon(\vec{t^\epsilon})dx.\end{aligned}$$

By Proposition 2.13 we know that $\nabla u_\epsilon(\vec{s})$ two-scale converges *strongly* in the sense of boundary layers to $\nabla_y u_0(\vec{s})$ while $\nabla u_\epsilon(\vec{t^\epsilon})$ two-scale converges weakly to $\nabla_y u_0(\vec{t})$. By virtue of Proposition 2.5 we can pass to the limit in the product and we get

$$\lim_{\epsilon\to 0}\left\langle B_\epsilon^K \vec{s}(x'), \vec{t^\epsilon}(x')\right\rangle_{L^2(\Sigma;\ell^2_K)} = \int_\Sigma\int_{G^{*K}} \nabla_y u_0(\vec{s})\cdot\nabla_y u_0(\vec{t})dx'dy,$$

where $u_0(\vec{s})$ and $u_0(\vec{t})$ are solutions of the homogenized problem (32) with $\vec{s}$ and $\vec{t}$, respectively, as the right-hand side. A simple integration by parts shows that

$$\int_\Sigma\int_{G^{*K}} \nabla_y u_0(\vec{s})\cdot\nabla_y u_0(\vec{t})dx'dy \;=\; \left\langle B^K \vec{s}(x'), \vec{t}(x')\right\rangle_{L^2(\Sigma;\ell^2_K)},$$

where the limit operator B^K is defined by

$$B^K\vec{s}(x') = \left(\int_{\Gamma_j} u_0(\vec{s})\vec{n}ds\right)_{\substack{0\le j'\le K-1\\ 1\le j_N}}. \tag{36}$$

This proves the strong convergence of B_ϵ^K to B^K on $L^2(\Sigma;\ell^2_K)$. Obviously, B^K is self-adjoint and continuous but not compact since x' plays the role of a parameter in the definition of B^K.

It remains to diagonalize B^K with the help of the Bloch decomposition $\mathcal{B}'$. This diagonalization process has already been exposed in section 3.3 of our previous paper [3] in a slightly different context. For the sake of brevity, we do not repeat this standard argument here. Let us simply indicate the three main steps of this Bloch diagonalization. First, we apply the operator $\mathcal{B}'$ to $\vec{s}(x') = (\vec{s}_j(x'))_{\substack{0\le j'\le K-1\\ j_N\ge 1}}$ which gives the Bloch decomposition of $\vec{s}(x')$ with respect to the multi-index j' (not including j_N). Secondly, plugging this Bloch decomposition in the limit equation (32) (which holds in G^{*K}) and using a similar Bloch decomposition of $u_0(\vec{s})$, we decompose (32) in a family of K^{N-1} equations defined in a single reference cell G^*. In a third step, applying again the Bloch decomposition $\mathcal{B}'$ to formula (36) yields the desired diagonalization of B^K.

2.3. Analysis of the limit spectrum. In this section we analyze the spectrum of the limit operator B^K and, from the strong convergence of B_ϵ^K to B^K, we deduce the lower semicontinuous convergence of the spectrum $\sigma(S_\epsilon)$ to the limit spectrum $\sigma(B^K)$. Recall that for any $K\ge 1$, the extended operator B_ϵ^K has a spectrum given by

$$\sigma(B_\epsilon^K) = \sigma(S_\epsilon)\cup\{0\}.$$

Since B_ϵ^K converges strongly to B^K in $L^2(\Sigma;\ell_K^2)$, by virtue of Proposition 2.1.11 in [3], we have

$$\sigma(B^K) \subset \sigma_\infty = \lim_{\epsilon\to 0} \sigma(S_\epsilon).$$

From Rellich's theorem, the strong convergence of the spectral family associated with B_ϵ^K to that of B^K is also easily deduced (see Theorem 3.2.5 in [3]). This gives some (partial) information on the convergence of eigenvectors that we shall not use below.

In view of Theorem 2.11,

$$B^K = (\mathcal{B}')^{-1} D^K \mathcal{B}' \quad \text{with} \quad D^K = \operatorname{diag}(D_{j'}^K)_{0\le j'\le K-1},$$

where each $D_{j'}^K$ is a self-adjoint continuous operator in $L^2(\Sigma;\ell_1^2)$. Since $\mathcal{B}'$ is an isometry, we have

$$\sigma(B^K) = \bigcup_{0\le j'\le K-1} \sigma(D_{j'}^K).$$

By the very definition of $D_{j'}^K$, the macroscopic variable $x' \in \Sigma$ plays the role of a parameter. Therefore, for any fixed value of x', $D_{j'}^K$ can be identified with an operator $d_{\frac{j'}{K}}$ acting in ℓ_1^2 which does not depend on x'. Introducing the Bloch parameter $\theta' = \frac{j'}{K} \in [0,1]^{N-1}$, this new operator $d_{\theta'}$ is defined by

$$\begin{aligned} &d_{\theta'} : \ell_1^2 \longrightarrow \ell_1^2, \\ &(\vec{s}_q)_{q\ge 1} \mapsto \left(\int_{\Gamma_q} u_{\theta'} \cdot \vec{n} ds \right)_{q\ge 1}, \end{aligned} \tag{37}$$

where $u_{\theta'}(y)$ is the unique solution of

$$\begin{cases} -\Delta u_{\theta'} = 0 & \text{in } G^*, \\ \frac{\partial u_{\theta'}}{\partial n} = \vec{s}_q \cdot \vec{n} & \text{on } \Gamma_q,\ q \ge 1, \\ u_{\theta'} = 0 & \text{if } y_N = 0, \\ y' \mapsto e^{-2\pi i \theta'\cdot y'} u_{\theta'}(y', y_N) & Y'\text{-periodic.} \end{cases}$$

In (37) the positive integer q is nothing but the index j_N introduced in Definition 2.8. Clearly, we have

$$\sigma(D_{j'}^K) = \sigma(d_{\frac{j'}{K}}).$$

As is well known, the spectrum of a self-adjoint operator can be decomposed in its *discrete* part, made of, at most, a countable number of isolated eigenvalues of finite multiplicities, and its *essential* part, for which the Weyl criterion applies (see, e.g., [25], [33], [34]). The next proposition characterizes the spectrum of $d_{\theta'}$.

PROPOSITION 2.17. *For all $\theta' \in [0,1]^{N-1}$, $d_{\theta'}$ is a self-adjoint continuous but noncompact operator in ℓ_1^2. Labeling the eigenvalues of the discrete spectrum $\sigma_{disc}(d_{\theta'})$ by decreasing order, each discrete eigenvalue is piecewise continuous in θ'. The essential spectrum is given by*

$$\sigma_{ess}(d_{\theta'}) = \bigcup_{\theta_N\in[0,1]} \sigma(A(\theta', \theta_N)),$$

where $A(\theta', \theta_N)$ is the Bloch homogenized matrix, defined by (12)*, which is continuous in $\theta \in]0,1[^N$ but discontinuous at $\theta = 0$. Moreover, the entire spectrum $\sigma(d_{\theta'})$, considered as a subset of $\mathbb{R}^+$, depends continuously on θ', except at $\theta' = 0$.*

Because we use the usual convenient labeling of the discrete eigenvalues by decreasing order, we can merely prove that they are piecewise continuous. This is due to the fact that, when θ' varies, an analytical branch (if any) of discrete eigenvalues may merge into the essential spectrum: this yields a "jump" in the labeling of discrete eigenvalues. Therefore, one cannot hope to prove a global continuity of these eigenvalues with such an ordering.

Let us postpone for a moment the proof of Proposition 2.17 and define the so-called *boundary layer spectrum* associated with the surface Σ:

$$\sigma_\Sigma \stackrel{\text{def}}{=} \bigcup_{\theta' \in]0,1[^{N-1}} \sigma(d_{\theta'}) \cup \sigma(d_0). \tag{38}$$

By virtue of Proposition 2.17, we have

$$\sigma_{Bloch} \subset \sigma_\Sigma. \tag{39}$$

Therefore σ_Σ also has a band structure since it includes the Bloch spectrum, but it may include new bands of eigenvalues of $\sigma_{disc}(d_{\theta'})$. It also contains the isolated eigenvalues of $\sigma_{disc}(d_0)$. Therefore σ_Σ can contain elements which are not included in the previous limit spectrum $\sigma(S) \cup \sigma_{Bloch}$ (see section 1.2). The continuity of $\sigma(d_{\theta'})$ with respect to θ' ensures that σ_Σ is the closure of the union of all spectra $\sigma(d_{\theta'})$ with θ' rational.

$$\overline{\bigcup_{K \geq 1} \bigcup_{0 \leq j' \leq K-1} \sigma(d_{\frac{j'}{K}})} = \sigma_\Sigma.$$

We summarize our results in the following theorem.

THEOREM 2.18. *The boundary layer spectrum associated to Σ is included in the limit spectrum*

$$\sigma_\Sigma \subset \sigma_\infty.$$

REMARK 2.19. *Of course σ_Σ is not the complete boundary layer spectrum since it is concerned only with that part of the spectrum concentrating near Σ. A completely similar analysis has to be done for all the $(N-1)$-dimensional surfaces and all other lower dimensional manifolds (edges, corners, etc.) of which the boundary of Ω is made up. Then, we shall prove in the next section that the union of all these contributions, the so-called boundary layer spectrum, plus the usual homogenized spectrum and the Bloch spectrum, is equal to σ_∞, at least when Ω is made up only of entire cells ϵY.*

Proof of Proposition 2.17. Let us first prove that the essential spectrum of $d_{\theta'}$ is included in the Bloch spectrum, and, more precisely,

$$\sigma_{ess}(d_{\theta'}) = \bigcup_{0 \leq \theta_N \leq 1} \sigma(A(\theta', \theta_N)),$$

where $A(\theta)$ is the usual Bloch homogenized matrix defined in (12). In particular, this proves that $\sigma_{ess}(d_{\theta'}) \neq \{0\}$, so $d_{\theta'}$ is not compact.

Let $\lambda(\theta)$ be an eigenvalue of $A(\theta)$ and $u(\theta)$ be the associated potential solution of

$$\begin{cases} -\Delta_y u(\theta) = 0 & \text{in } Y^*, \\ \frac{\partial u(\theta)}{\partial n} = \lambda^{-1}(\theta) \int\limits_{\Gamma} u(\theta)\vec{n} ds & \text{on } \Gamma, \\ y \mapsto e^{-2\pi\imath\theta\cdot y} u(\theta, y) & Y\text{-periodic.} \end{cases}$$

We construct a Weyl sequence u_n associated with the spectral value $\lambda(\theta)$ by

$$u_n = \frac{u(\theta)\psi_n}{\|u(\theta)\psi_n\|_{L^2(G^*)}},$$

where $\psi_n(y_N)$ is a cut-off function defined by

$$\begin{cases} \psi_n(y_N) = & y_N & \text{when } 0 \le y_N \le 1, \\ \psi_n(y_N) = & 1 & \text{when } 1 \le y_N \le n, \\ \psi_n(y_N) = & n+1-y_N & \text{when } n \le y_N \le n+1, \\ \psi_n(y_N) = & 0 & \text{when } y_N \ge n+1. \end{cases}$$

By definition, $\|u_n\|_{L^2(G^*)} = 1$ and $\lim_{n\to+\infty} \|u(\theta)\psi_n\|_{L^2(G^*)} = +\infty$. Then, it is easily checked that, for any $\varphi \in D^1_{0\#}(G)$ (the Deny–Lions-type space defined in (21)),

$$\int_{G^*} \nabla u_n \cdot \nabla\varphi dy = \frac{1}{\lambda(\theta)} \sum_{q\ge 1} \Big(\int_{\Gamma_q} u_n \vec{n} ds \Big) \cdot \Big(\int_{\Gamma_q} \varphi \vec{n} ds \Big) + \langle r_n, \varphi \rangle ,$$

where r_n is a negligible remainder term in the sense that

$$\lim_{n\to+\infty} \frac{\langle r_n, \varphi\rangle}{\|\nabla\varphi\|_{L^2(G^*)^N}} = 0.$$

Furthermore, $\vec{s}_n = (\int_{\Gamma_q} u_n \vec{n} ds)_{q\ge 1}$ converges weakly to 0 in ℓ^2_1 since

$$\lim_{n\to+\infty} \|u(\theta)\psi_n\|_{L^2(G^*)} = +\infty.$$

Therefore, $\vec{s}_n$ is a Weyl sequence associated with $\lambda(\theta)$ for the operator $d_{\theta'}$. This proves that $\lambda(\theta) \in \sigma_{ess}(d_{\theta'})$. To prove the converse inclusion,

$$\sigma_{ess}(d_{\theta'}) \subset \bigcup_{0\le\theta_N\le 1} \sigma(A(\theta', \theta_N)),$$

we consider a Weyl sequence $\vec{s}_n$ for a spectral value $\lambda \in \sigma_{ess}(d_{\theta'})$. Let u_n be the associated potential solution, i.e.,

$$\begin{cases} -\Delta u_n = 0 & \text{in } G^*, \\ \frac{\partial u_n}{\partial n} = (\vec{s}_n)_q \cdot \vec{n} & \text{on } \Gamma_q,\ q \ge 0, \\ u_n = 0 & \text{if } y_N = 0, \\ y' \mapsto e^{-2\pi\imath\theta'\cdot y'} u_n(y', y_N) & Y'\text{-periodic.} \end{cases} \tag{40}$$

Since $\|\vec{s}_n\|_{\ell^2_1} = 1$ and $\vec{s}_n \rightharpoonup 0$ in ℓ^2_1 weakly, it is easily seen that u_n converges to 0 weakly in $H^1(G^*)$. Furthermore, since the weak convergence to 0 of $\vec{s}_n$ implies that its components $(\vec{s}_n)_q$ go to 0 for fixed q, it is not difficult to check that, for any compact set $\mathcal{K}$ of G^*, u_n converges strongly to 0 in $H^1(\mathcal{K})$ (multiply equation (40)

by ϕu_n where ϕ is equal to 1 in $\mathcal{K}$ and is compactly supported away from infinity). Introducing a sequence

$$v_n = \frac{\psi u_n}{\|\psi u_n\|_{L^2(G^*)}},$$

where $\psi(y_N)$ is a cut-off function defined by

$$\begin{cases} \psi(y_N) = & 0 & \text{for } y_N \leq 0, \\ \psi(y_N) = & y_N & \text{for } 0 \leq y_N \leq 1, \\ \psi(y_N) = & 1 & \text{for } y_N \geq 1, \end{cases}$$

it is straightforward to prove that

$$\int_{B^*} \nabla v_n \cdot \nabla \varphi dx = \frac{1}{\lambda} \sum_{q \in \mathbb{Z}} \Big(\int_{\Gamma_q} v_n \vec{n} ds \Big) \cdot \Big(\int_{\Gamma_q} \varphi \vec{n} ds \Big) + \langle r_n, \varphi \rangle$$

for any $\varphi \in D^1_{\#}(B^*)$, where B^* is the infinite band $Y' \times]-\infty; +\infty[$ perforated by the periodic arrangement of tubes $(T_q)_{q \in \mathbb{Z}}$, and r_n is another negligible remainder term such that

$$\lim_{n \to +\infty} \frac{\langle r_n, \varphi \rangle}{\|\nabla \varphi\|_{L^2(B^*)^N}} = 0.$$

Therefore,

$$\vec{t}_n = \left(\int_{\Gamma_q} v_n \vec{n} ds \right)_{q \in \mathbb{Z}}$$

is a Weyl sequence for an operator similar to $d_{\theta'}$ but defined in the whole infinite band B^* instead of the semi-infinite band G^*. A standard Bloch decomposition with respect to the variable y_N yields that λ belongs to $\bigcup_{0 \leq \theta_N \leq 1} \sigma(A(\theta', \theta_N))$.

To conclude the proof of Proposition 2.17, it remains to prove that the isolated eigenvalues of finite multiplicity $\lambda(\theta') \in \sigma_{disc}(d_{\theta'})$ are piecewise continuous with respect to θ'. Let θ'_n be a sequence converging to θ' in $]0,1[^{N-1}$. Obviously, the sequence of continuous operators $d_{\theta'_n}$ uniformly converges to $d_{\theta'}$ in ℓ^2_1. Now, let us invoke a classical theorem (see, e.g., Theorem 3.1., Chapter I.3 in [20]) which states that for any closed curve γ in the complex plane, which encloses a finite number of eigenvalues of $\sigma_{disc}(d_{\theta'})$ and does not intersect $\sigma(d_{\theta'})$, there exists n_0 such that for any $n \geq n_0$, the curve γ contains the same number of eigenvalues (including multiplicities) of $\sigma_{disc}(d_{\theta'_n})$ and does not intersect $\sigma(d_{\theta'_n})$. This is nothing but the local continuity of the eigenvalues of $\sigma_{disc}(d_{\theta'})$ (enumerated, for example, in decreasing order). Remark that the continuity of the pth eigenvalue of $\sigma_{disc}(d_{\theta'})$ breaks down only when one of the previous eigenvalues (with label between 1 and $p-1$) meets the essential spectrum $\sigma_{ess}(d_{\theta'})$ as θ' varies. In any case, since $\sigma_{ess}(d_{\theta'})$ depends continuously on $\theta' \neq 0$, this proves that the entire spectrum $\sigma(d_{\theta'})$ depends also continuously on $\theta' \neq 0$. The lack of continuity for $\sigma(d_{\theta'})$ at $\theta' = 0$ is a phenomenon already explained in our previous work (see Proposition 3.3.4 in [3]).

REMARK 2.20. *When the tube T is symmetric in Y (in other words, by reflexion with respect to the hyperplane $[y_N = 0]$, G^* yields the infinite periodic array of tubes B^*), it can readily be checked that there is no isolated eigenvalue of finite multiplicity*

for $d_{\theta'}$; i.e., $\sigma_{disc}(d_{\theta'}) = \emptyset$ for all $\theta' \in [0,1]^{N-1}$. If this were not the case, by symmetry an eigenvalue of $\sigma_{disc}(d_{\theta'})$ would also be an eigenvalue of finite multiplicity for a similar operator in the infinite band B^*, which is impossible since by translation there exists an infinite number of eigenvectors.

We conclude this section by proving that the eigenvectors corresponding to isolated eigenvalues of finite multiplicity of $d_{\theta'}$ are localized in the vicinity of the boundary $[y_N = 0]$ since they decay exponentially at infinity.

PROPOSITION 2.21. *Let λ be an eigenvalue in $\sigma_{disc}(d_{\theta'})$ and let $(\vec{s}_q)_{q\geq 1}$ be a corresponding eigenvector. There exists a positive constant $\alpha > 0$ such that $(e^{\alpha p}\vec{s}_q)_{q\geq 1}$ belongs to ℓ^2_1.*

Proof. The argument is by contradiction of the Weyl property for eigenvalues in the essential spectrum. For $\lambda \in \sigma_{disc}(d_{\theta'})$, let $\vec{s} = (\vec{s}_q)_{q\geq 1}$ be a corresponding normalized eigenvector and $u(y)$ the corresponding potential, solution of

$$\left\{\begin{array}{ll} -\Delta u = 0 & \text{in } G^*, \\ \frac{\partial u}{\partial n} = \vec{s}_q \cdot \vec{n} & \text{on } \Gamma_q,\ q \geq 1, \\ u = 0 & \text{if } y_N = 0, \\ y' \mapsto e^{-2\pi\imath\theta'\cdot y'} u(y', y_N) & Y'\text{-periodic.} \end{array}\right. \tag{41}$$

By definition, for all $q \geq 1$, it satisfies

$$\int_{\Gamma_q} u \cdot \vec{n} ds \ = \ \lambda \vec{s}_q.$$

Let us define a sequence $(\vec{s}^{\,n})_{n\geq 0}$ in ℓ^2_1 by

$$\vec{s}^{\,n} = (\vec{s}^{\,n}_q)_{q\geq 1} \text{ with } \vec{s}^{\,n}_q = \left\{\begin{array}{ll} 0 & \text{if } q < n, \\ \frac{\vec{s}_q}{\sqrt{\sum_{p=n}^{\infty} |\vec{s}_p|^2}} & \text{if } q \geq n. \end{array}\right.$$

It is easily seen that $\vec{s}^{\,n}$ converges weakly to 0 in ℓ^2_1 with $\|\vec{s}^{\,n}\|_{\ell^2_1} = 1$. However, since λ does not belong to the essential spectrum of $d_{\theta'}$, any subsequence of $\vec{s}^{\,n}$ cannot be a Weyl sequence for λ. This implies the existence of a positive constant C and an integer n_0 such that, for any $n \geq n_0$,

$$\|d_{\theta'}\vec{s}^{\,n} - \lambda \vec{s}^{\,n}\|_{\ell^2_1} \geq C > 0. \tag{42}$$

As usual $u_n(y)$ is the potential associated with $\vec{s}^{\,n}$ through an equation similar to (41). We introduce a smooth cut-off function $\psi_n(y_N)$ such that $\psi_n = 0$ on all tubes T_q for $q < n$, and $\psi_n = 1$ on all tubes T_q for $q \geq n$. Let us denote by ω_n the bounded support of $\nabla\psi_n$ which lies between T_{n-1} and T_n. Introducing an approximation v_n of the potential u_n, defined by

$$v_n(y) = \frac{\psi_n(y_N)\,(u(y) - c_n)}{\sqrt{\sum_{p=n}^{\infty} |\vec{s}_p|^2}} \text{ with } c_n = \frac{1}{|\omega_n|}\int_{\omega_n} u(y)dy,$$

we write

$$d_{\theta'}\vec{s}^{\,n} \ = \ \lambda \vec{s}^{\,n} + \left(\int_{\Gamma_q} (u_n - v_n)\cdot \vec{n} ds\right)_{q\geq 1}.$$

From (42) we deduce

$$\|\nabla(u_n - v_n)\|_{L^2(G^*)^N} \geq C > 0 \text{ for } n \geq n_0.$$

Using the equations for u and u_n, a simple computation yields

$$\int_{G^*} |\nabla(u_n - v_n)|^2 dy = \int_{G^*} \nabla\psi_n \cdot \frac{(u_n - v_n)\nabla u - (u - c_n)\nabla(u_n - v_n)}{\sqrt{\sum_{p=n}^{\infty} |\vec{s}_p|^2}}. \tag{43}$$

Remark that the integral in the right-hand side reduces to ω_n since $\nabla\psi_n$ has bounded support in ω_n. Applying the Poincaré–Wirtinger inequality in ω_n to $(u-c_n)$ and $(u_n - v_n)$ (this last term has not zero average in ω_n, but (43) is invariant by substraction of a constant to $(u_n - v_n)$), we obtain from (43)

$$\|\nabla(u_n - v_n)\|_{L^2(G^*)^N} \leq C \frac{\|\nabla u\|_{L^2(\omega_n)^N}}{\sqrt{\sum_{p=n}^{\infty} |\vec{s}_p|^2}},$$

which implies

$$\sum_{p=n}^{\infty} |\vec{s}_p|^2 \leq C \|\nabla u\|^2_{L^2(\omega_n)^N}. \tag{44}$$

On the other hand, multiplying equation (41) by $\psi_n(u - c_n)$ and integrating by parts gives

$$\int_{G^*} \psi_n |\nabla u|^2 dy + \int_{G^*} (u - c_n)\nabla u \cdot \nabla\psi_n dy = \lambda \sum_{p=n}^{\infty} |\vec{s}_p|^2.$$

Applying again the Poincaré–Wirtinger inequality in ω_n to $(u - c_n)$ yields

$$\int_{G^*} \psi_n |\nabla u|^2 dy \leq \lambda \sum_{p=n}^{\infty} |\vec{s}_p|^2 + C \|\nabla u\|^2_{L^2(\omega_n)^N}. \tag{45}$$

Let us denote by G_n the subset of G^* defined by $G_n = \{y \in G^* | y_N > n\}$. From (44) and (45) we deduce

$$\|\nabla u\|^2_{L^2(G_{n+1})^N} \leq C \|\nabla u\|^2_{L^2(\omega_n)^N} \leq C \left(\|\nabla u\|^2_{L^2(G_n)^N} - \|\nabla u\|^2_{L^2(G_{n+1})^N} \right),$$

which implies, for $n \geq n_0$,

$$\|\nabla u\|^2_{L^2(G_n)^N} \leq \left(\frac{C}{1 + C} \right)^{n - n_0} \|\nabla u\|^2_{L^2(G_{n_0})^N}. \tag{46}$$

It is easily seen that (46) implies the desired result.

3. Completeness of the boundary layer spectrum. In this section we assume that Ω is a rectangle with integer dimensions, i.e.,

$$\Omega = \prod_{i=1}^{N}]0; L_i[\quad \text{and} \quad L_i \in \mathbb{N}^*. \tag{47}$$

The sequence of small parameters ϵ is also assumed to be

$$\epsilon_n \;=\; \frac{1}{n},\; n \in \mathbb{N}^*. \tag{48}$$

Remark that all the previous results in this paper hold for any type of sequence ϵ going to zero. From now on, we restrict ourselves to the sequence ϵ_n since, for any $n \geq 1$, the domain Ω is the union of a finite number of *entire periodic cells* $Y_p^{\epsilon_n}$. However, to simplify the notation, we shall not indicate the dependence on n and simply denote by ϵ the particular sequence defined in (48).

Remark that the assumption on the geometry of Ω can be slightly relaxed. Any polygonal domain with faces parallel to the axis (i.e., the normal is everywhere one of the basis vectors) and having vertex with integer coordinates could equally be considered.

3.1. Presentation of the main result. This section is devoted to the so-called completeness of the limit spectrum. Recall that in our previous work [3] we proved that

$$\sigma_\infty \;=\; \sigma(S) \cup \sigma_{Bloch} \cup \sigma_{boundary}, \tag{49}$$

where $\sigma_{boundary}$ is defined in (15). In section 2, we proved that

$$\sigma_\infty \;\supset\; \sigma_\Sigma,$$

where σ_Σ is the boundary layer spectrum associated with the surface Σ, defined by (38). Remark that, *due to our hypotheses on the domain* Ω *and on the sequence* ϵ, the surface Σ can be any of the faces of Ω defined by

$$\prod_{\substack{j=1\\ j\neq i}}^{N}]0; L_j[\times\{0\} \quad \text{or} \quad \prod_{\substack{j=1\\ j\neq i}}^{N}]0; L_j[\times\{L_i\} \quad \text{for } 1 \leq i \leq N.$$

Of course, the analysis of section 2 can be repeated for any other lower dimensional manifolds (edges, corners, etc.) which compose the boundary of Ω. For $0 \leq m \leq N-1$, let us define the m-dimensional parts of $\partial\Omega$ as

$$\Sigma_{m,\tau} = \prod_{j=1}^{m}]0; L_{\tau(j)}[\times \prod_{j=m+1}^{N} \{x_{\tau(j)} = 0 \text{ or } L_{\tau(j)}\},$$

where τ is any permutation of the numbers $\{1, 2, \ldots, N\}$. There are $2^{N-m}C_N^{N-m}$ m-dimensional manifolds of the type $\Sigma_{m,\tau}$. A simple adaptation of the two-scale convergence in the sense of boundary layers for such manifolds allows us to prove that, for any m and τ,

$$\sigma_\infty \;\supset\; \sigma_{\Sigma_{m,\tau}},$$

where $\sigma_{\Sigma_{m,\tau}}$ is the spectrum of a family of limit problems posed, not in a semi-infinite band as in section 2, but rather in a periodic domain bounded in the variables $x_{\tau(1)}, \ldots, x_{\tau(m)}$ and unbounded with respect to the other variables (see section 3.3 for the case of corners in two space dimension). Eventually, defining the union of all these spectra

$$\sigma_{\partial\Omega} = \bigcup_{m,\tau} \sigma_{\Sigma_{m,\tau}}, \tag{50}$$

we deduce from Theorem 2.18 and from the geometric assumptions (47), (48) that

$$\sigma_\infty \supset \sigma_{\partial\Omega}. \tag{51}$$

Comparing our results (49) and (51), a completeness result amounts to link the two definitions of the boundary layer spectrum $\sigma_{\partial\Omega}$ and $\sigma_{boundary}$.

THEOREM 3.1. *For the sequence ϵ_n defined by* (48)*, the boundary layer spectrum satisfies*

$$\sigma_{boundary} \subset \sigma_{\partial\Omega}.$$

Therefore, the limit spectrum of the sequence S_{ϵ_n} is precisely made of three parts; the homogenized, the Bloch, and the boundary layer spectrum

$$\lim_{\epsilon_n \to 0} \sigma(S_{\epsilon_n}) = \sigma(S) \cup \sigma_{Bloch} \cup \sigma_{\partial\Omega},$$

where the boundary layer spectrum $\sigma_{\partial\Omega}$ is explicitly defined by (50).

REMARK 3.2. *Remark that Theorem* 3.1 *does not state that $\sigma_{boundary}$, defined by* (15)*, and $\sigma_{\partial\Omega}$ coincide. Indeed, we have shown in* (39) *that $\sigma_{\partial\Omega}$ contains the Bloch spectrum. It is not clear whether $\sigma_{boundary}$ contains the Bloch spectrum too. The comparison of $\sigma_{\partial\Omega}$ and $\sigma_{boundary}$ is definitely a very difficult question. We suspect that if the definition of $\sigma_{boundary}$ is modified in such a way that it contains only limit eigenvalues corresponding to sequences of eigenvectors which decay exponentially fast away from the boundary, then it may coincide with that part of $\sigma_{\partial\Omega}$ made of discrete eigenvalues (which also have exponentially decreasing corresponding eigenvectors).*

To prove this completeness result, we need an intermediate result in the spirit of section 2.

THEOREM 3.3. *As in section* 2*, let Ω be a domain defined by*

$$\Omega = \Sigma \times]0; L[,$$

with Σ a bounded open set in $\mathbb{R}^{N-1}$ and $L > 0$. Recall that S^1_ϵ is the extension of S_ϵ to $L^2(\Omega)^N$. Consider a sequence of eigenvalues λ_ϵ and eigenvectors $\vec{s}^\epsilon$ such that

$$S^1_\epsilon \vec{s}^\epsilon = \lambda_\epsilon \vec{s}^\epsilon \quad \textit{with} \quad \|\vec{s}^\epsilon\|_{L^2(\Omega)^N} = 1 \quad \textit{and} \quad \lim_{\epsilon \to 0} \lambda_\epsilon = \lambda.$$

Assume that for all subset ω such that $\overline{\omega} \subset \Omega$, we have

$$\lim_{\epsilon \to 0} \|\vec{s}^\epsilon\|_{L^2(\omega)^N} = 0. \tag{52}$$

Assume further that there exists an $(N-1)$-dimensional open set σ, with $\overline{\sigma} \subset \Sigma$, a positive number l, with $0 < l < L$, and a positive constant c such that

$$\lim_{\epsilon \to 0} \|\vec{s}^\epsilon\|_{L^2(\sigma \times]0,l[)^N} \geq c > 0. \tag{53}$$

Then, λ belongs to the boundary layer spectrum associated with the surface Σ

$$\lambda \in \sigma_\Sigma,$$

where σ_Σ is defined by (38).

The proof of Theorem 3.3 is the focus of the next section. If we admit it for the moment, as well as its generalizations concerning all other manifolds $\Sigma_{m,\tau}$ making up the boundary $\partial\Omega$, we are in a position to complete the following proof.

Proof of Theorem 3.1. Let $\lambda \in \sigma_{boundary}$. By definition there exists a subsequence (still denoted by ϵ), eigenvalues λ_ϵ, and eigenvectors $\vec{s}^\epsilon$ of S^1_ϵ such that

$$S^1_\epsilon \vec{s}^\epsilon = \lambda_\epsilon \vec{s}^\epsilon \quad \text{with} \quad \|\vec{s}^\epsilon\|_{L^2(\Omega)^N} = 1 \quad \text{and} \quad \lim_{\epsilon\to 0} \lambda_\epsilon = \lambda,$$

and, for all subset ω satisfying $\overline{\omega} \subset \Omega$,

$$\lim_{\epsilon\to 0} \|\vec{s}^\epsilon\|_{L^2(\omega)^N} = 0.$$

If there exists an $(N-1)$-dimensional open subset σ_i, compactly embedded in $\prod_{\substack{j=1\\ j\neq i}}^N]0; L_j[$, a positive length $0 < l_i < L_i$, a positive constant c, and another subsequence (still denoted by ϵ) such that

$$\lim_{\epsilon\to 0} \|\vec{s}^\epsilon\|_{L^2(\sigma_i\times]0,l_i[)^N} \geq c > 0 \quad \text{or} \quad \lim_{\epsilon\to 0} \|\vec{s}^\epsilon\|_{L^2(\sigma_i\times]l_i,L_i[)^N} \geq c > 0, \tag{54}$$

then, by application of Theorem 3.3, the limit eigenvalue belongs to $\sigma_{\partial\Omega}$ as desired.

If (54) does not hold true for any such σ_i, l_i, c, and subsequence ϵ, it implies that the L^2-norm of $\vec{s}^\epsilon$ concentrates near the lower dimensional edges of the rectangle Ω. In this case, we repeat the above argument with an $(N-2)$-dimensional open set included in one of the set $\Sigma_{N-2,\tau}$, and so on up to the 0-dimensional set made of one of the vertices of Ω. A tedious but simple induction argument on the dimension m shows that there exists at least a dimension $0 \leq m \leq N-1$, a permutation τ, positive lengths $(l_{\tau(j)})_{m+1\leq j\leq N}$, a positive constant c, and a subsequence ϵ such that

$$\lim_{\epsilon\to 0} \|\vec{s}^\epsilon\|_{L^2(\omega)^N} \geq c > 0,$$

with $\omega \subset \Omega$ of the type

$$\omega = \sigma \times \prod_{j=m+1}^N \big(]0, l_{\tau(j)}[\text{ or }]l_{\tau(j)}, L_{\tau(j)}[\big) \quad \text{and} \quad \overline{\sigma} \subset \prod_{j=1}^m]0; L_{\tau(j)}[.$$

Then, applying an adequate generalization of Theorem 3.3, this proves that the limit eigenvalue belongs to $\sigma_{\partial\Omega}$.

3.2. Proof of the completeness. This section is devoted to the proof of Theorem 3.3 which is divided in several lemmas and propositions. Let us begin by recalling the definition of the associated potential u_ϵ, solution of

$$\begin{cases} -\Delta u_\epsilon = 0 & \text{in } \Omega_\epsilon, \\ \frac{\partial u_\epsilon}{\partial n} = \vec{s}^\epsilon_p \cdot \vec{n} & \text{on } \Gamma^\epsilon_p, \quad 1 \leq p \leq n(\epsilon), \\ u_\epsilon = 0 & \text{on } \partial\Omega. \end{cases} \tag{55}$$

The spectral equation $\widetilde{S}_\epsilon \vec{s}^\epsilon = \lambda_\epsilon \vec{s}^\epsilon$ implies that

$$\left(\int_{\Gamma^\epsilon_p} u_\epsilon \vec{n} \right)_{1\leq p\leq n(\epsilon)} = \lambda_\epsilon \vec{s}^\epsilon_p. \tag{56}$$

By assumption (52), for all subsets ω such that $\overline{\omega} \subset \Omega$, we have

$$\lim_{\epsilon\to 0} \|\vec{s}^\epsilon\|_{L^2(\omega)^N} = 0.$$

In other words, all the energy of the eigenvectors $\vec{s}^\epsilon$ concentrates near the boundary $\partial\Omega$. This concentration effect has important consequences on the associated potential u_ϵ.

LEMMA 3.4. *The sequence u_ϵ defined in* (55) *converges to* 0 *in $H_0^1(\Omega)$ weakly and strongly in $L^2(\Omega)$. Furthermore, u_ϵ converges strongly to* 0 *in $H^1_{loc}(\Omega)$.*

Proof. Multiplying equation (55) by a test function $v \in H_0^1(\Omega)$ yields

$$\int_{\Omega_\epsilon} \nabla u_\epsilon \cdot \nabla v dx = \sum_{p=1}^{n(\epsilon)} \vec{s}_\epsilon^p \cdot \Big(\int_{\Gamma_p^\epsilon} v\vec{n} ds \Big) = \int_\Omega \vec{s}^\epsilon(x) \cdot \vec{z}^\epsilon(x) dx,$$

where

$$\vec{z}^\epsilon(x) = -\sum_{p=1}^{n(\epsilon)} \frac{1}{\epsilon^N} \Big(\int_{T_p^\epsilon} \nabla v(x) dx \Big) \chi_{Y_p^\epsilon}(x).$$

It is easily seen that $\vec{z}^\epsilon$ converges strongly to $-\frac{|T|}{|Y|}\nabla v(x)$ in $L^2(\Omega)^N$. Since $\vec{s}^\epsilon$ converges weakly to 0 in $L^2(\Omega)^N$ by virtue of (52), we deduce that u_ϵ converges to 0 weakly in $H_0^1(\Omega)$ and, by the Rellich theorem, strongly in $L^2(\Omega)$. Finally, for any open set ω such that $\overline{\omega} \subset \Omega$, let φ be a smooth function with compact support in Ω and equal to 1 on ω. Multiplying (55) by $\varphi^2 u_\epsilon$ and integrating by parts leads to

$$\int_{\Omega_\epsilon} \varphi^2 |\nabla u_\epsilon|^2 dx = -2 \int_{\Omega_\epsilon} \varphi u_\epsilon \nabla\varphi \cdot \nabla u_\epsilon dx + \sum_{p=1}^{n(\epsilon)} \vec{s}_p^\epsilon \cdot \Big(\int_{\Gamma_p^\epsilon} \varphi^2 u_\epsilon \vec{n} ds \Big). \tag{57}$$

Since u_ϵ converges weakly to 0 in $H_0^1(\Omega)$, the first term in the right-hand side of (57) goes to 0 with ϵ. In view of (56), the second term is bounded by

$$\|\varphi\|^2_{L^\infty(\Omega)} \|\vec{s}^\epsilon\|^2_{L^2(\mathrm{supp}(\varphi))},$$

which goes to 0 by virtue of the assumption (52). Therefore, we deduce from (57) that ∇u_ϵ converges strongly to 0 in $L^2(\omega)^N$. This concludes the proof of Lemma 3.4.

By assumption (53), there exists an $(N-1)$-dimensional open set σ, with $\overline{\sigma} \subset \Sigma$, such that the sequence of eigenvectors concentrates partly near σ. By translation, one can always assume that the origin lies inside σ. The strategy of the proof is to rescale the domain Ω by the change of variables $y = \frac{x}{\epsilon}$ and then to transform the sequence of eigenvectors $\vec{s}^\epsilon$ in a Weyl sequence for a limit operator. The limit domain will be $\mathbb{R}^N_+ = \{y \in \mathbb{R}^N | y_N > 0\}$ since we have carefully choose the origin to belong to σ. The limit fluid domain is denoted by $G^{*\infty}$, which is defined by

$$G^{*\infty} = \mathbb{R}^N_+ \setminus \bigcup_{j \in \mathbb{Z}^N_+} T_j,$$

where T_j denotes the tube j placed in the subcell Y_j (centered at the point $j = (j', j_N)$ with $j' \in \mathbb{Z}^{N-1}$ and $j_N \in \mathbb{Z}_+$). In this limit domain we define a limit operator B^∞, which acts from ℓ^∞_2 in itself, by

$$B^\infty \vec{s} = \left(\int_{\Gamma_j} u\vec{n} ds \right)_{j \in \mathbb{Z}^N_+} \qquad \forall \vec{s} \in \ell^\infty_2,$$

where $u(y)$ is the unique solution in $D_0^1(G^{*\infty})$ of

$$\left\{\begin{array}{ll} -\Delta u = 0 & \text{in } G^{*\infty}, \\ \frac{\partial u}{\partial n} = \vec{s}_j \cdot \vec{n} & \text{on } \Gamma_j,\ j \in \mathbb{Z}_+^N, \\ u = 0 & \text{on } \mathbb{R}^{N-1} \times \{0\}. \end{array}\right. \tag{58}$$

Recall that elements in $D_0^1(G^{*\infty})$ are restrictions to $G^{*\infty}$ of functions wnin $D_0^1(\mathbb{R}_+^N)$ which, in its turn, is the closure, with respect to the L^2-norm of the gradient, of smooth functions with compact support in $\mathbb{R}_+^N$.

REMARK 3.5. *The limit domain $G^{*\infty}$ is nothing but the limit as K goes to infinity of the domain G^{*K} defined in section* 2.2. *By the same token, the Hilbert space ℓ_2^∞ is the limit of ℓ_2^K (it is also equal to $\ell_2(\mathbb{Z}_+^N;\mathbb{C}^N)$). In some sense the limit operator B^∞ is also the limit of the operator B^K defined in Theorem* 2.11.

Let φ be a smooth function, equal to 1 in $\omega = \sigma\times]0, L[$, with compact support in $\Sigma\times]-L; L[$ (i.e., φ vanishes on all faces of Ω except on that defined by $x_N = 0$). We use φ to localize the sequence of eigenvectors $\vec{s}^\epsilon$ in a vicinity of ω. Let us define a sequence $\vec{t}^{\,\epsilon}$ by

$$\vec{t}^{\,\epsilon} = E_\epsilon^1 P_\epsilon^1(\varphi(x)\vec{s}^\epsilon(x)),$$

where $E_\epsilon^1 P_\epsilon^1$ is the projection operator in $L^2(\Omega)^N$ on piecewise constant functions (cf. their definitions (27) and (28)).

Remark that, by assumption (53), the sequence $\vec{t}^{\,\epsilon}$ satisfies

$$\lim_{\epsilon\to 0} \|\vec{t}^{\,\epsilon}\|_{L^2(\omega)^N} \geq c > 0.$$

Let us define $G_\epsilon^{*\infty}$ as $G^{*\infty}$ rescaled to size ϵ. Let v_ϵ be the potential in $G_\epsilon^{*\infty}$ associated with $\vec{t}^{\,\epsilon}$, defined by

$$\left\{\begin{array}{ll} -\Delta v_\epsilon = 0 & \text{in } G_\epsilon^{*\infty}, \\ \frac{\partial v_\epsilon}{\partial n} = \vec{t}_p^{\,\epsilon} \cdot \vec{n} & \text{on } \Gamma_p^\epsilon,\ p \in \mathbb{Z}_+^N, \\ v_\epsilon = 0 & \text{on } \mathbb{R}^{N-1} \times \{0\}. \end{array}\right. \tag{59}$$

LEMMA 3.6. *The sequence v_ϵ defined by* (59) *converges to zero in $D_0^1(\mathbb{R}_+^N)$ weakly and in $H_{loc}^1(\mathbb{R}_+^N)$ strongly.*

Proof. The argument is similar to that of Lemma 3.4, except that the Rellich theorem applies only for compact sets in $\overline{\mathbb{R}_+^N}$.

LEMMA 3.7. *The difference $w_\epsilon = v_\epsilon - \varphi u_\epsilon$ converges strongly to zero in $D_0^1(\mathbb{R}_+^N)$.*

Proof. A simple calculation provides the following key identity:

$$\int_{\mathbb{R}_+^N} |\nabla w_\epsilon|^2 = \int_{\mathbb{R}_+^N} \nabla v_\epsilon \cdot \nabla w_\epsilon - \int_{\mathbb{R}_+^N} \nabla u_\epsilon \cdot \nabla(\varphi w_\epsilon) - \int_{\mathbb{R}_+^N} \nabla\varphi \cdot (u_\epsilon \nabla w_\epsilon - w_\epsilon \nabla u_\epsilon). \tag{60}$$

By virtue of Lemmas 3.4 and 3.6, u_ϵ and w_ϵ converge to zero strongly in L^2 of the support of φ. Therefore, the last term in (60) goes to zero with ϵ. On the other hand, an integration by parts yields

$$\int_{G_{\epsilon\infty}^*} \nabla v_\epsilon \cdot \nabla w_\epsilon - \int_{\Omega_\epsilon} \nabla u_\epsilon \cdot \nabla(\varphi w_\epsilon) = \sum_{p=1}^{n(\epsilon)} \left[\vec{t}_p^{\,\epsilon} \cdot \Big(\int_{\Gamma_p^\epsilon} w_\epsilon \vec{n} \Big) - \vec{s}_p^{\,\epsilon} \cdot \Big(\int_{\Gamma_p^\epsilon} \varphi w_\epsilon \vec{n} \Big) \right].$$

Since $\vec{t}_p^{\,\epsilon} = \frac{1}{\epsilon^N}\int_{Y_p^\epsilon} \varphi \vec{s}^{\,\epsilon}_p dx$ and $|\varphi(x) - \varphi(x_p^\epsilon)| \le \epsilon \|\nabla\varphi\|_{L^\infty}$, where x_p^ϵ is the center of the cube Y_p^ϵ which contains x, we obtain

$$\left| \int_{G^*_{\epsilon\infty}} \nabla v_\epsilon \cdot \nabla w_\epsilon - \int_{\Omega_\epsilon} \nabla u_\epsilon \cdot \nabla(\varphi w_\epsilon) \right| \le \epsilon \|\nabla\varphi\|_{L^\infty} \|\vec{s}^{\,\epsilon}\|_{L^2(\Omega)^N} \|\nabla w_\epsilon\|_{L^2(\mathbb{R}^+_N)^N},$$

which gives the desired result.

LEMMA 3.8. *From Lemma* 3.7 *we deduce the following approximation result for the displacement vector* $\vec{t}^{\,\epsilon}$*:*

$$\lim_{\epsilon\to 0} \sum_{p\in\mathbb{Z}^N_+} \epsilon^N \left| \frac{1}{\epsilon^N} \int_{\Gamma_p^\epsilon} v_\epsilon \vec{n} ds - \lambda_\epsilon \vec{t}_p^{\,\epsilon} \right|^2 = 0.$$

Proof. We have

$$\begin{aligned} \epsilon^N \sum_{p\in\mathbb{Z}^N_+} \left| \tfrac{1}{\epsilon^N} \textstyle\int_{\Gamma_p^\epsilon} (v_\epsilon - \varphi u_\epsilon)\vec{n} ds \right|^2 &\le \sum_{p\in\mathbb{Z}^N_+} \|\nabla(v_\epsilon - \varphi u_\epsilon)\|^2_{L^2(T_p^\epsilon)^N} \\ &\le \|\nabla(v_\epsilon - \varphi u_\epsilon)\|^2_{L^2(\mathbb{R}^N_+)^N}, \end{aligned} \tag{61}$$

which goes to zero as $\epsilon \to 0$ by virtue of Lemma 3.7. Furthermore,

$$\epsilon^N \sum_{p\in\mathbb{Z}^N_+} \left| \frac{1}{\epsilon^N} \int_{\Gamma_p^\epsilon} \varphi u_\epsilon \vec{n} ds - \lambda_\epsilon \vec{t}_p^{\,\epsilon} \right|^2 \le \epsilon \|\nabla\varphi\|_{L^\infty} \|\nabla u_\epsilon\|_{L^2(\Omega)^N}$$

since, $\vec{s}^{\,\epsilon}$ being constant in each cell Y_p^ϵ,

$$\frac{1}{\epsilon^N} \int_{\Gamma_p^\varepsilon} \varphi u_\epsilon \vec{n} ds = \frac{1}{\varepsilon^N} \int_{\Gamma_p^\epsilon} \Big(\varphi(s) - \frac{1}{\varepsilon^N} \int_{Y_p^\epsilon} \varphi(t) dt \Big) u_\epsilon \vec{n} ds + \lambda_\epsilon (P^1_\epsilon \varphi \vec{s}^{\,\epsilon})_p.$$

Summing these two estimates yields the desired result.

Now, let us define a sequence $\vec{\tau}^{\,\epsilon}$ in ℓ^∞_2 by

$$\vec{\tau}^{\,\epsilon} = \epsilon^{N/2} (\vec{t}_p^{\,\epsilon})_{p\in\mathbb{Z}^N_+},$$

which plays the role of a Weyl sequence for the limit operator B^∞.

PROPOSITION 3.9. *The sequence* $\vec{\tau}^{\,\epsilon}$ *satisfies*

$$\lim_{\epsilon\to 0} \|\vec{\tau}^{\,\epsilon}\|_{\ell^\infty_2} \ge c > 0,$$

and

$$B^\infty \vec{\tau}^{\,\epsilon} = \lambda \vec{\tau}^{\,\epsilon} + \vec{r}^{\,\epsilon}, \tag{62}$$

where $\vec{r}^{\,\epsilon}$ *is a remainder term which goes to zero strongly in* ℓ^∞_2*.*

Proof. A simple rescaling in (59) shows that $\tilde{v}_\epsilon(y) = \epsilon^{\frac{N}{2}-1} v_\epsilon(\epsilon y)$ is the unique solution in $D^1_0(G^{*\infty})$ of

$$\begin{cases} -\Delta \widetilde{v}_\epsilon = 0 & \text{in } G^{*\infty}, \\ \frac{\partial \widetilde{v}_\epsilon}{\partial n} = \vec{\tau}_p^{\,\epsilon} \cdot \vec{n} & \text{on } \Gamma_p,\ p \in \mathbb{Z}^N_+, \\ \widetilde{v}_\epsilon = 0 & \text{on } \mathbb{R}^{N-1} \times \{0\}. \end{cases} \tag{63}$$

Furthermore, $\|\nabla_y \widetilde{v}_\epsilon\|_{L^2(G^{*\infty})^N} = \|\nabla_x v_\epsilon\|_{L^2(G_\epsilon^{*\infty})^N}$. By definition,

$$B^\infty \vec{\tau}^\epsilon = \left(\int_{\Gamma_p} \widetilde{v}_\epsilon \vec{n} ds \right)_{p \in \mathbb{Z}_+^N} = \epsilon^{-\frac{N}{2}} \left(\int_{\Gamma_p^\epsilon} v_\epsilon \vec{n} ds \right)_{p \in \mathbb{Z}_+^N}.$$

Defining $\vec{r}^\epsilon = (\vec{r}_p^\epsilon)_{p \in \mathbb{Z}_+^N}$ by

$$\vec{r}_p^\epsilon = \epsilon^{\frac{N}{2}} \left(\frac{1}{\epsilon^N} \int_{\Gamma_p^\epsilon} v_\epsilon \vec{n} ds - \lambda_\epsilon \vec{t}_p^\epsilon \right),$$

we get

$$B^\infty \vec{\tau}^\epsilon = \lambda_\epsilon \vec{\tau}^\epsilon + \vec{r}^\epsilon,$$

which, by virtue of Lemma 3.8, is the desired result.

To conclude the proof of Theorem 3.3, we remark that either $\vec{\tau}^\epsilon$ converges weakly in ℓ_2^∞ to a nonzero limit $\vec{\tau}$ (up to a subsequence) or $\vec{\tau}^\epsilon$ converges weakly to $\vec{0}$ in ℓ_2^∞. In the first case, passing to the limit as ϵ goes to 0, we obtain that $\vec{\tau} \neq \vec{0}$ is an eigenvector of B^∞ for λ (the limit of the sequence λ_ϵ). In the latter case, this proves that $\vec{\tau}^\epsilon$ is a Weyl sequence for the spectral value λ which belongs to the essential spectrum of B^∞. Now, it is a standard matter (see, e.g., [15], [16]) to show, by a Bloch wave decomposition analogous to that of section 2.3, that the spectrum of B^∞ is nothing but $\lim_{K \to +\infty} \sigma(B^K)$, i.e., the boundary layer spectrum associated with the face Σ of Ω.

REMARK 3.10. *Let us remark that Theorem* 3.3 *is valid for any choice of the sequence ϵ and not only for the particular sequence ϵ_n defined in* (48). *The interested reader will not fail to notice that the present proof of the completeness result is different from that of our previous work* [3]. *In this paper, we used the concept of Bloch measures in order to prove a similar completeness result by means of an energetic method. Here, we propose a new proof (in a slightly different context), based on a rescaling argument, which is simpler, although less precise, and which could equally be applied in* [3].

3.3. Analysis of the corner spectrum. In section 3.1 the boundary layer spectrum $\sigma_{\partial\Omega}$ was defined as the union of all spectra of the type σ_Σ, where Σ is any lower dimensional manifold composing the boundary $\partial\Omega$. When Σ is an $(N-1)$-dimensional hyperplane, a complete derivation of σ_Σ has been given in section 2. However, for lower dimensional manifold we have been a little cavalier in saying that the analysis of section 2 can be easily generalized to the case of edges, corners, and so on. The purpose of this section is to briefly indicate some details of this generalization when analyzing the *corner spectrum*. Since the physical problem of interest is truly two-dimensional, we restrict ourselves to the case of corners of the plane square domain Ω (this has the advantage of simplifying the exposition).

Therefore, our domain Ω is now a rectangle with integer dimensions, i.e.,

$$\Omega =]0; L_1[\times]0; L_2[.$$

We describe the limit spectrum associated with the corner located at the origin. We introduce the space ℓ_+^2 of displacements defined by

$$\ell_+^2 = \left\{ (\vec{s}_j)_{j=(j_1,j_2)\ j_1 \geq 1, j_2 \geq 1} \ \middle|\ \vec{s}_j \in \mathbb{R}^2, \quad \sum_{j_1,j_2=1}^{+\infty} |\vec{s}_{j_1,j_2}|^2 < +\infty \right\}.$$

Remark that this definition of ℓ^2_+ implies a decay of the displacement $\vec{s}_j$ as j_1 or j_2 goes to $+\infty$.

We extend the operator S_ϵ to the larger space ℓ^2_+ by the following formula:

$$C_\epsilon = E_\epsilon S_\epsilon P_\epsilon,$$

where P_ϵ and E_ϵ are, respectively, projection and extension operators between $\mathbb{R}^{Nn(\epsilon)}$ and ℓ^2_+. Their definition is very simple. Recall that a tube T^ϵ_j in Ω is located in a cell Y^ϵ_j whose origin is ϵj. We denote the range of all indices j such that T^ϵ_j is included in Ω by $1 \le j \le n(\epsilon)$. The projection is defined by

$$\begin{array}{lll} P_\epsilon : \ell^2_+ & \longrightarrow & \mathbb{R}^{Nn(\epsilon)}, \\ (\vec{s}_j)_{j=(j_1,j_2)\ j_1\ge 1, j_2\ge 1} & \mapsto & (\vec{s}_j)_{1\le j\le n(\epsilon)}, \end{array}$$

and the extension by

$$\begin{array}{lll} E_\epsilon : \mathbb{R}^{Nn(\epsilon)} & \longrightarrow & \ell^2_+, \\ (\vec{s}_j)_{1\le j\le n(\epsilon)} & \mapsto & (\vec{t}_j)_{j=(j_1,j_2)\ j_1\ge 1, j_2\ge 1}, \end{array}$$

with $\vec{t}_j = \vec{s}_j$ if $1 \le j \le n(\epsilon)$ and $\vec{t}_j = 0$ otherwise.

One can easily check that P_ϵ and E_ϵ are adjoint operators and that the product $P_\epsilon E_\epsilon$ is equal to the identity in $\mathbb{R}^{Nn(\epsilon)}$. Therefore, the spectrum of C_ϵ consists of that of S_ϵ and zero as an eigenvalue of infinite multiplicity.

The convergence analysis of C_ϵ is much simpler than that in section 2 because ℓ^2_+ is not a space of periodically oscillating displacements. There is no need to introduce any notion of two-scale convergence for corner boundary layers. A simple rescaling argument is enough. More precisely, denoting by Q_+ the first quadrant in the plane

$$Q_+ \ =]0;+\infty[\times]0;+\infty[,$$

we replace the two-scale convergence by the weak convergence in $L^2(Q_+)$: with each bounded sequence $u_\epsilon(x)$ in $L^2(\Omega)$, we associate the rescaled sequence $v_\epsilon(y)$ defined by

$$v_\epsilon(y) = \begin{cases} \epsilon^2 u_\epsilon(\epsilon y) & \text{if } \epsilon y \in \Omega, \\ 0 & \text{otherwise,} \end{cases}$$

which is also bounded in $L^2(Q_+)$.

Then, a similar analysis to that of section 2 shows that the sequence of operators C_ϵ converges strongly in $\mathcal{L}(\ell^2_+)$ to a limit operator C_∞ defined by

$$C_\infty : \ell^2_+ \longrightarrow \ell^2_+ \tag{64}$$

$$(\vec{s}_j)_{j=(j_1,j_2)\ j_1\ge 1, j_2\ge 1} \ \mapsto \ \left(\int_{\Gamma_j} u\vec{n} ds \right)_{j=(j_1,j_2)\ j_1\ge 1, j_2\ge 1}, \tag{65}$$

where $u(y)$ is the unique solution of

$$\begin{cases} -\Delta u = 0 & \text{in } Q^*_+ = Q_+ \setminus \bigcup_j T_j, \\ \frac{\partial u}{\partial n} = \vec{s}_j \cdot \vec{n} & \text{on } \Gamma_j,\ j_1 \ge 1, j_2 \ge 1, \\ u = 0 & \text{on } \partial Q_+, \\ \lim\limits_{|y|\to+\infty} u(y) = 0. \end{cases}$$

Clearly, C_∞ is a self-adjoint noncompact operator acting in ℓ^2_+. As in Proposition 2.17, one can prove that the essential spectrum of C_∞ is precisely the Bloch spectrum. However, the discrete spectrum of C_∞ may contain new eigenvalues which correspond to eigenvectors localized in the corner of Q_+.

Acknowledgments. The authors would like to thank one of the anonymous referees for several sharp comments which enabled them to improve and revise the original version.

SMOOTHNESS BETWEEN COEFFICIENTS AND BOUNDARY VALUES FOR THE WAVE EQUATION*

GANG BAO†

Abstract. In this work, a density determination problem of an acoustic medium from point source response is studied. The continuity and differentiability are examined for the *forward map* which maps the density to the pressure field. Estimates for both the Lipschitz continuity and the Frechét differentiability are obtained. The continuity of the *linearized* forward map is also obtained. These estimates are crucial for linearization of the nonlinear forward map.

Key words. density determination, regularity of the forward map, continuity of the linearized forward map, microlocal cut-off

AMS subject classifications. 35R30, 86A22

1. Introduction and statement of the results. Many wave propagation problems with a point energy source may be modeled by the following linear acoustic wave equation:

$$\left(\frac{1}{c^2}\frac{\partial^2}{\partial t^2} - \Delta - \nabla\sigma\cdot\nabla\right)u = \delta(x,t)\ , \tag{1.1}$$

$$u = 0, \quad t < 0\ , \tag{1.2}$$

where the mechanical properties of the medium are described by $\sigma = \sigma(x)$ the logarithm of the density, $c = c(x)$ the sound velocity of the medium, and $u = u(x,t)$ the excess pressure. This work deals with the simplest case where the velocity is assumed to be a fixed constant, say $c = 1$. Also, the problem is set in $\mathbf{R}^{n+1}$ for $n \geq 2$.

Define the *forward map* F as

$$F : \sigma \to (\phi u)\mid_{x_n=0}\ , \tag{1.3}$$

where $\phi \in C_0^\infty(\mathbf{R}^n)$ is supported inside the conoid $\{t > |x|\}$ and near$\{x_n = 0\}$. The cut-off function $\phi(x,t)$ insures that the restriction of distribution u to the hypersurface $\{x_n = 0\}$ is well defined even when the equation (1.1) has a singular right-hand side. It is easily seen that even though the governing equation is linear, the forward map is nonlinear. Thus, solving the inverse problem may be viewed as inverting the nonlinear functional relation F.

In this paper we continue our study of the forward map F. In its predecessor [4], we obtained an a priori upper bound for the linearized forward map with respect to a smooth reference density. Our goal in this work is to establish conditions under which the forward map F is continuous and differentiable and the linearized forward map is continuous. These aspects of forward map are crucial in the study of the inverse problem which arises in reflection seismology, oil exploration, ground-penetrating radar, etc. Here, the inverse problem of interest is to determine the coefficients σ from the measured data of the excess pressure u on a time-like hypersurface $\{x_n = 0\}$. specifically, given data $F_{data}(x', t)$ (point source response, $x = (x', x_n)$) obtained from many receivers on the earth, find the density $\sigma(x)$ so that

$$F(\sigma) = F_{data},$$

or minimize the error $(F_{data} - F(\sigma))$ in some suitable norm. Two questions arise immediately:

- Since the forward map F is nonlinear, one naturally considers its linearization. So far, most progress has been made through the study of the linearization. However, it seems that very little work has been done to justify this commonly used procedure. Does the linearization of F provide useful information in recovering the density?
- The large size of the typical data set demands a fast means of solving the minimization problem. A natural candidate would be some Gauss–Newton-like method. When can one formulate such an algorithm?

To answer either one of the above questions requires the understanding of regularity of the forward map. In addition, local properties of the inverse problem may be obtained by examining the differentiability of the forward map. Also, continuity properties are crucial in the study of the linearized forward map with respect to a nonsmooth reference density.

Questions on regularity of the forward map have been studied extensively for layered problems where c and σ depend only on x_n. For a similar problem with the impulse-response instead of point source, Symes showed in [15] (for the constant wave speed case) that the forward map is a C^1-*diffeomorphism* by applying the method of geometrical optics together with energy estimates; see [15] for other references. The situation becomes more difficult for the multidimensional (nonlayered) problems. See Symes [14, 16], Sacks and Symes [13], Rakesh [11], and Bao and Symes [4] for some partial results. The difficulties are essentially due to the ill-posed nature of the time-like hyperbolic Cauchy problem and the presence of nonsmooth coefficients. Recently, in the study of this class of inverse problems and other close related problems [2, 3, 4], we have employed nonsmooth microlocal analysis techniques to obtain the optimal time-like trace regularity under weaker hypotheses on the coefficients. In this work, using these techniques, we establish new estimates on the regularity of the forward map and the continuity of its linearization.

We next state the main results of this paper.

Let σ_1 and σ_0 be the densities corresponding to the excess pressure u_1 and u_0, respectively; we have from (1.1) and (1.2) that

$$\begin{aligned} (\Box - \nabla\sigma_1 \cdot \nabla)\tilde{u} &= \nabla\delta\sigma \cdot \nabla u_0 \ , \\ \tilde{u} &= 0, \quad t < 0 \ , \end{aligned} \tag{1.4}$$

where $\Box = \partial_t^2 - \Delta$, $\tilde{u} = u_1 - u_0$, and $\delta\sigma = \sigma_1 - \sigma_0$. Moreover,

$$(\phi\tilde{u})|_{x_n=0} = (\phi u_1)|_{x_n=0} - (\phi u_0)|_{x_n=0} \ .$$

For a real number α, we denote by $[\alpha]$ the smallest integer that is not smaller than α. In the following statements of theorems, we always assume that

$$[l + (n-1)/2] > 1 + n/2 \text{ and } \ \tau > [l + (n-1)/2] + [(n-1)/2] + n/2 + 2 \ .$$

Let $M_\tau > 0$ and define

$$\mathcal{M}_\tau = \{\sigma \in C_0^\infty\{x_n > 0\}, \ \ ||\sigma||_\tau < M_\tau\}.$$

We also assume that the density and its perturbations are supported in the half-space $\{x_n > 0\}$.

THEOREM 1.1. *There exists a constant C depending on M_τ and the support of ϕ so that for σ_1 and $\sigma_0 \in \mathcal{M}_\tau$,*

$$||F(\sigma_1) - F(\sigma_0)||_l \leq C||\sigma_1 - \sigma_0||_{[l+\frac{n-1}{2}]} \, . \tag{1.5}$$

The following results concern the differentiability of the forward map. The formal linearization DF of the forward map F, with respect to the reference state (σ_0, u_0), is defined by the linearized problem

$$\begin{array}{c} (\Box - \nabla\sigma_0 \cdot \nabla)\delta u = \nabla\delta\sigma \cdot \nabla u_0 \, , \\ \delta u = 0, \quad t < 0, \end{array} \tag{1.6}$$

and

$$DF(\sigma_0)\delta\sigma = (\phi\delta u)|_{x_n=0} \, . \tag{1.7}$$

Recall that $\tilde{u}$ solves (1.4) and

$$F(\sigma_1) - F(\sigma_0) = (\phi\tilde{u})|_{x_n=0} \, ; \tag{1.8}$$

then

$$F(\sigma_1) - F(\sigma_0) - DF(\sigma_0)\delta\sigma = (\phi(\tilde{u} - \delta u))|_{x_n=0} \, , \tag{1.9}$$

where

$$\begin{array}{c} (\Box - \nabla\sigma_1 \cdot \nabla)(\tilde{u} - \delta u) = \nabla\delta\sigma \cdot \nabla\delta u \, , \\ \tilde{u} - \delta u = 0, \quad t < 0 \, . \end{array} \tag{1.10}$$

THEOREM 1.2. *There exists a constant C depending on M_τ and the support of ϕ so that for σ_1 and $\sigma_0 \in \mathcal{M}_\tau$,*

$$||F(\sigma_1) - F(\sigma_0) - DF(\sigma_0)\delta\sigma||_l \leq C||\delta\sigma||_{\tau+1}||\delta\sigma||_{[l+\frac{n-1}{2}]} \, .$$

THEOREM 1.3. *There exists a constant C depending on $M_{\tau+1}$ and the support of ϕ so that for σ_1 and $\sigma_0 \in \mathcal{M}_{\tau+1}$,*

$$||F(\sigma_1) - F(\sigma_0) - DF(\sigma_0)\delta\sigma||_l \leq C||\delta\sigma||_\tau||\delta\sigma||_{[l+\frac{n-1}{2}]} \, .$$

Note that the results of Theorems 1.2 and 1.3 do not imply that of Theorem 1.1 since the estimates depend on higher norms of the coefficients.

Finally, we present a continuity estimate for the linearized forward map.

THEOREM 1.4. *There exists a constant C depending on $M_{\tau+1}$ and the support of ϕ so that for σ_1, $\sigma_0 \in \mathcal{M}_{\tau+1}$, and $\eta \in C_0^\infty\{x_n > 0\}$,*

$$||DF(\sigma_1)\eta - DF(\sigma_0)\eta||_l \leq C\left[||\sigma_1 - \sigma_0||_{[l+\frac{n-1}{2}]} \, ||\eta||_{\tau+1} + ||\eta||_{[l+\frac{n-1}{2}]} \, ||\sigma_1 - \sigma_0||_{\tau+1}\right] \, .$$

In particular, DF extends to a Lipschitz continuous map:

$$\begin{array}{c} \sigma \to DF(\sigma) \\ H^{\tau+1}_{comp}(\mathbf{R}^{n-1} \times [0,\infty)) \to \mathcal{L}[H^{\tau+1}_{comp}(\mathbf{R}^{n-1} \times [0,\infty)), \; H^l(\mathbf{R}^{n-1} \times [0,\infty)]. \end{array}$$

Remarks. Our techniques in the proofs are similar to those in [4], where we showed that the linearized forward map $DF(\sigma_0)$ is a bounded map for a smooth reference density σ_0 (Theorem 1.1 in [4]).

In this work, we only study the density determination problem. A more interesting problem is to study the dependence of the boundary values of the pressure field on the velocity c. At present, no regularity result for the multidimensional velocity inversion problem is available. In this case, additional difficulties will occur because of the nonsmooth principal parts in the wave equation. We believe the general ideas described here may be extended to study the velocity inversion problem. Some recent progress has been made in [3] by establishing results on trace regularity and propagation of singularities. The reader is referred to Lewis and Symes [10] for regularity results in the one-dimensional case.

We assume that the reader is familiar with the basic calculus of *pseudodifferential operators* (" ψ*.d.o.* ") as stated in Taylor [17]. Throughout, C serves as a generalized positive constant the precise value of which is not needed.

2. Preliminaries. We recapitulate some useful results in this section. Let us begin with the algebraic properties of the Sobolev spaces and microlocal Sobolev spaces. Here H^s is the standard L^2-type Sobolev space and H^s_{loc} is the corresponding local Sobolev space.

PROPOSITION 2.1 (generalized Schauder's lemma). *If $u \in H^{s_1}(\mathbf{R}^n)$ and $v \in H^{s_2}(\mathbf{R}^n)$, with $s_1 + s_2 \geq 0$, then*

$$uv \in H^{min(s_1, s_2, s_1+s_2-n/2+\delta)} \quad \textit{for any } \delta > 0 \, .$$

Here we also state an extended Rauch lemma established in [2].

LEMMA 2.2. *Suppose that $\Omega = \Omega_0 \times \Omega_1 \subset\subset \mathbf{R}^{n_0} \times \mathbf{R}^{n-n_0}$ $(1 \leq n_0 \leq n)$, $\Omega' \subset\subset \Omega$, $n_0/2 < s$, $0 \leq l \leq s$, q, and $q < l + s - n_0/2$. Suppose that $Q \in S^0(\Omega')$, $\tilde{Q} \in S^0(\Omega)$ elliptic on $ES(Q)$, and $Q_0 \in S^0(\Omega_0)$ satisfies that $(x, y, \xi, \eta) \in ES(\tilde{Q}), \xi \neq 0 \Longrightarrow (x, \xi) \in ES(Q_0)$. Then there exists a constant $C > 0$ so that for $u \in C_0^\infty(\Omega_0)$ and $v(x, y) \in C_0^\infty(\Omega)$,*

$$||Quv||_{q,\Omega'} \leq C(||u||_{s,\Omega_0} + ||Q_0 u||_{q,\Omega_0})(||v||_{l,\Omega} + ||\tilde{Q}v||_{q,\Omega}).$$

Remark. The lemma (for $n_0 = n$) implies the original Rauch lemma in [12].

Let u_0 solve the model problem (1.1) and (1.2) for $\sigma = \sigma_0$.

LEMMA 2.3 (see [4, Theorem 3.1]). *Suppose that $1 + n/2 < s$ and $\sigma_0 \in H^s(\mathbf{R}^n)$. Then for $l < s - n + 1/2$*

$$\partial_t^l u_0 \in L^2_{loc}(U) \, ,$$

where $U = \{\mathbf{R}^n \times (0, T_1)\} \cap \{t > |x|\}$ $(T_1 > 0)$. And for $\phi \in C_0^\infty(U)$, the following estimate holds:

$$||\phi \partial_t^l u_0|| \leq C \, , \tag{2.1}$$

where the constant C depends on ϕ and $||\sigma_0||_s$.

Remark. For an explicit construction of the operator B, we refer the reader to [4].

Let $\Pi : T^*(\Omega_0) \to \Omega_0$ denote the projection of $T^*(\Omega_0)$ onto its base space.

LEMMA 2.4 (see [4, Lemma 3.1]). *Suppose that ψ, $\phi \in C_0^\infty(\mathbf{R}^{n+1})$, $s > n/2$, $k < s + 2 - n/2$, $\sigma_0 \in H^{s+1}_{comp}(\mathbf{R}^n)$, β is a null bicharacteristic strip for $\Box$, and*

$\Omega \subset\subset \mathbf{R}^{n+1}$ *satisfies* $\Pi\beta \cap \bar{\Omega} = \emptyset$. *Then there exist* $B \in OPS^0$ *with* $ES(B)$ *supported in an arbitrarily small conic neighborhood of* β *and* $C > 0$ *so that any* $w \in H^1_{loc}(\mathbf{R}^{n+1})$ *vanishing for large* t *and satisfying*

$$\Box w - \nabla\sigma_0 \cdot \nabla w = f \in L^2(\Omega), \ \ \mathrm{supp}(f) \subset \Omega \ ,$$

satisfies in addition

$$||\psi B \phi w||_k \leq C||f||_0.$$

LEMMA 2.5 (see [4, Lemma 3.2]). *Suppose that* ψ, $\phi \in C_0^\infty(\mathbf{R}^{n+1})$, $s > n/2$, $k < s - n/2 + 2$, $\sigma_0 \in H^{s+1}_{comp}(\mathbf{R}^n)$, P *is a* ψ*.d.o. of order zero such that a conic neighborhood of its essential support* $(ES(P))$ *is contained in the microlocal elliptic region of* $\Box$, *and* $\Omega \subset\subset \mathbf{R}^{n+1}$ *satisfies* $\Pi ES(P) \cap \bar{\Omega} = \emptyset$. *Then there exists a constant* $C > 0$ *so that any* $w \in H^1_{loc}(\mathbf{R}^{n+1})$ *vanishing for large* t *and satisfying*

$$\Box w - \nabla\sigma_0 \cdot \nabla w = f \in L^2(\Omega)$$

satisfies

$$||\psi P \phi w||_k \leq C||f||_0,$$

where the constant C *depends on* σ_0, k, P, ϕ, *and* ψ, *but not on* w.

We need the anisotropic Sobolev spaces $\mathcal{H}^{m,s}(\mathbf{R}^{n+1})$ introduced originally by Hörmander [9]:

$$\mathcal{H}^{m,s}(\mathbf{R}^k) = \{f \in \mathcal{D}', \ D^\alpha_{x',x_k} f \in L^2(\mathbf{R}^k) \ \forall \ \alpha = (\alpha_1, \alpha_1, \ldots, \alpha_k), |\alpha| \leq m+s, \alpha_k \leq m\},$$

where $D^\alpha_{x',x_k} = D^{\alpha_1,\ldots,\alpha_{k-1}}_{x'} D^{\alpha_k}_{x_k}$.

PROPOSITION 2.6 (see [9]). *Suppose* $m > 1/2$ *and* $m + s > k/2$. *Then*

$$\mathcal{H}^{m,s} \subset L^\infty(\mathbf{R}^k) \cap C^0(\mathbf{R}^k) \ \ \textit{continuous inclusion} \, .$$

We also need a conormal regularity result for the wave equation in the following form:

$$\begin{aligned} &(\partial_t^2 - \Delta - \nabla\sigma_0 \cdot \nabla)u(x,t) = a(x)S(t - r(x)) \ , \\ &\quad u = 0, \quad t < 0 \ , \end{aligned} \tag{2.2}$$

where again $r(x) = |x|$.

Introduce the standard polar coordinates with variables $r = |x|$, θ_1, θ_2, $\ldots$, θ_{n-1}. Denote $T_1 = \partial_t + \partial_r$, $T_{i+1} = \partial_{\theta_i}$ for $i = 1, 2, \ldots, n-1$, and $T_{n+1} = \partial_t - \partial_r$. Then T_i $(i = 1, 2, \ldots, n)$ form a basis of the tangent space to the characteristic surface $\{t = |x|\}$.

LEMMA 2.7 (see [4, Theorem 5.1]). *Suppose that, in* (2.12), $S \in H^{m-1}_{loc}$ *and* $a(x)$ *is a smooth function. Suppose also that* $k \geq 0$, $p \geq m+k$, $p > k+n/2+1$, $q \geq m+k-1$, *and* $q > k + n/2$. *Then for* $\{i_1, \ldots, i_k\} \subset \{1, 2, \ldots, n\}$ *and* $\phi(x,t) \in C_0^\infty(\mathbf{R}^{n+1})$,

$$T_{i_1} \cdots T_{i_k} u \in H^m_{loc} \ \textit{or} \ \ u \in H^{m,k}_{loc}.$$

In addition,

$$||\phi T_{i_1} \cdots T_{i_k} u||_m \leq C||a||_q$$

with the constant C *depending on* $||\sigma_0||_p$.

3. Progressing wave expansion. Consider a problem related to the model problem (1.1)(1.2)

$$\begin{aligned} (\Box - \nabla\sigma_0 \cdot \nabla)v_0 &= \delta^{(-\frac{n-1}{2})}(t)\delta(x) \ , \\ v_0 &= 0, \quad t < 0 \ . \end{aligned} \tag{3.1}$$

Hadamard's construction leads to the progressing wave expansion for v_0,

$$v_0 = \sum_{k=0}^{m-1} b_k(x) S_k(t - r(x)) + R_m(x,t), \tag{3.2}$$

where $r(x) = |x|$, $S_0(\cdot) = H(\cdot)$ is the Heaviside function, $S_k' = S_{k-1}$ $(k \geq 1)$, and $\{b_k\}$ $(k = 1, \ldots, m-1)$ solve the transport equations

$$2\nabla r \cdot \nabla b_0 + (\Delta r + \nabla r \cdot \nabla\sigma_0) b_0 = 0, \tag{3.3}$$

$$2\nabla r \cdot \nabla b_k + (\Delta r + \nabla r \cdot \nabla\sigma_0) b_k = \Delta b_{k-1} + \nabla\sigma_0 \cdot \nabla b_{k-1} \ . \tag{3.4}$$

Moreover, the remainder term R_m satisfies

$$\begin{aligned} (\Box - \nabla\sigma_0 \cdot \nabla)R_m &= (\Delta + \nabla\sigma_0 \cdot \nabla) b_{m-1} S_{m-1}(t - r(x)) \ , \\ R_m &= 0 \ , \quad t < 0 \ . \end{aligned} \tag{3.5}$$

Away from the origin, R_m is more regular. We refer the reader to [8] or [7] for a general discussion on the method of progressing wave expansions.

Similarly, integrating (1.6) in t gives

$$\begin{aligned} (\Box - \nabla\sigma_0 \cdot \nabla)\delta v &= \nabla\delta\sigma \cdot \nabla v_0 \ , \\ \delta v &= 0, \quad t < 0 \ , \end{aligned} \tag{3.6}$$

where $\delta u = \partial_t^{\frac{n-1}{2}} \delta v$.

The progressing wave expansion for δv takes the following form:

$$\delta v = \sum_{k=0}^{m-1} h_k(x) S_k(t - r(x)) + R_m^\delta(x,t), \tag{3.7}$$

where

$$2\nabla r \cdot \nabla h_0 + (\Delta r + \nabla r \cdot \nabla\sigma_0) h_0 = -b_0 \nabla\delta\sigma \cdot \nabla r, \tag{3.8}$$

$$\begin{aligned} 2\nabla r \cdot \nabla h_k + (\Delta r + \nabla r \cdot \nabla\sigma_0) h_k = (\Delta + \nabla\sigma_0 \cdot \nabla) h_{k-1} \\ + \nabla\delta\sigma \cdot (\nabla b_{k-1} - b_k \nabla r) \end{aligned} \tag{3.9}$$

and

$$\begin{aligned} (\Box - \nabla\sigma_0 \cdot \nabla)R_m^\delta &= \nabla\delta\sigma \cdot \nabla R_m + [\nabla\delta\sigma \cdot \nabla b_{m-1} \\ &\quad + (\Delta + \nabla\sigma_0 \cdot \nabla) h_{m-1}] S_{m-1}(t - r(x)) \ , \\ R_m^\delta &= 0, \quad t < 0 \ . \end{aligned} \tag{3.10}$$

Let us first simplify the transport equations by introducing two functions α and α_0 such that

$$\nabla r \cdot \nabla\alpha_0 = \Delta r/2 \ \text{ and } \alpha = \sigma_0/2 + \alpha_0 \ .$$

It is obvious that away from the origin α is nothing more than a smooth perturbation of $\sigma_0/2$.

We can then rewrite the transport equations as

$$2\nabla r \cdot \nabla(b_0 e^{\alpha}) = 0, \tag{3.11}$$

$$2\nabla r \cdot \nabla(b_k e^{\alpha}) = e^{\alpha}(\Delta b_{k-1} + \nabla\sigma_0 \cdot \nabla b_{k-1}) \tag{3.12}$$

and

$$2\nabla r \cdot \nabla(h_0 e^{\alpha}) = -e^{\alpha} b_0 \nabla\delta\sigma \cdot \nabla r, \tag{3.13}$$

$$2\nabla r \cdot \nabla(h_k e^{\alpha}) = e^{\alpha}[(\Delta + \nabla\sigma_0 \cdot \nabla)h_{k-1} + \nabla\delta\sigma \cdot (\nabla b_{k-1} - b_k \nabla r)]\ . \tag{3.14}$$

Let V denote the vector field $\nabla r \cdot \nabla$ and $Char(\nabla r \cdot \nabla) = \{(x,\xi) \in T^*(\mathbf{R}^n),\ \nabla r \cdot \xi = 0\}$.

LEMMA 3.1 (see [4, Lemma 4.1]). *Assume that u is a smooth function with $\mathrm{supp}(u) \subset \{|x| > \delta\}$ for some $\delta > 0$. Assume also that $\phi \in C_0^{\infty}(\mathbf{R}^n)$ with $\phi = 1$ on Ω and $\mathrm{supp}(\phi) \subset\subset \Omega'$, where Ω and Ω' are bounded open sets in $\mathbf{R}^n$. Then there exist a $Q \in OPS^0$ which is elliptic on $Char(V)$, $[Q,V] \in OPS^{-\infty}$, and $\phi' \in C_0^{\infty}(\mathbf{R}^n)$, $\phi' > 0$ on $\mathrm{supp}(\phi)$, such that for $s \in \mathbf{R}$ the estimates*

$$||u||_{s,\Omega} \le C||Q\phi' V u||_{s,\Omega'} + C||Vu||_{s-1,\Omega'} + C||u||_{\tau,\Omega'}, \tag{3.15}$$

$$||Q\phi u||_{s,\Omega} \le C||Q\phi V u||_{s,\Omega} + C||u||_{\tau,\Omega'} \tag{3.16}$$

hold for any $\tau \in \mathbf{R}$, where the constants are independent of u.

PROPOSITION 3.2 (see [4, Theorem 4.1]). *Suppose Ω is a bounded open subset of $\mathbf{R}^n$. Then for $i = 0, 1, \ldots, m-1$,*

$$||b_i||_{k,\Omega} \le C_{i,k},$$

where the constants $C_{i,k}$ depend on $||\sigma_0||_{s_i+2i}$ with $s_i > n/2 + 1$, $s_i \ge k$.

LEMMA 3.3. *Suppose that Ω is a bounded open subset of $\mathbf{R}^n$. Then for $i = 0, 1, \ldots, m-1$,*

$$||h_i||_{k,\Omega} \le C||\delta\sigma||_{k+2i+1},$$

where the constant depends on $||\sigma_0||_{p+2i}$ with $p > n/2 + 1$ and $p \ge k$.

Remark. An alternative way to write the equation (3.13) is

$$\nabla r \cdot \nabla(2h_0 e^{\alpha} + e^{\alpha} b_0 \delta\sigma) = \nabla r \cdot \nabla(e^{\alpha} b_0)\delta\sigma.$$

Thus the right-hand side involves the first-order derivative of b_0 but no derivative of $\delta\sigma$. Using this fact, similar estimates will then yield that

$$||h_i||_{k,\Omega} \le C||\delta\sigma||_{k+2i},$$

but the constant C depends on $||\sigma_0||_{p+2i+1}$ with $p > n/2$ and $p \ge k$.

The proof of Lemma 3.3 may be given by applying Lemma 3.1 and the regularity result for b_i (Proposition 3.2) to the energy estimates of h_i by using the assumption that $\delta\sigma = 0$ near $\{x_n = 0\}$. We shall omit the proof.

4. On the differentiability. Here we shall prove Theorem 1.2. The proof of Theorem 1.3 may be given by repeating the same arguments and using the remark after Lemma 3.3. Also, we shall omit the proof of Theorem 1.1 since it also follows the same arguments.

Due to the consideration of the simple principal part in the progressing wave expansions, we integrate (1.10) in t to get

$$\begin{aligned} (\Box - \nabla\sigma_1 \cdot \nabla)(v - \delta v) &= \nabla\delta\sigma \cdot \nabla\delta v, \\ v - \delta v &= 0, \quad t < 0 \, , \end{aligned} \tag{4.1}$$

where $\tilde{u} = \partial_t^{\frac{n-1}{2}} v$, $\delta u = \partial_t^{\frac{n-1}{2}} \delta v$, and v_0 solves

$$\begin{aligned} (\Box - \nabla\sigma_0 \cdot \nabla)v_0 &= \delta^{(-\frac{n-1}{2})}(t)\delta(x) \, , \\ v_0 &= 0, \quad t < 0 \, . \end{aligned} \tag{4.2}$$

Then, for $l \in \mathbf{R}$,

$$\begin{aligned} ||F(\sigma_1) - F(\sigma_0) - DF(\sigma_0)\delta\sigma||_l &= ||(\phi(\tilde{u} - \delta u))\,|_{x_n=0}\,||_l \\ &\le C||(\phi(v - \delta v))\,|_{x_n=0}\,||_{l_1}, \end{aligned} \tag{4.3}$$

where l_1 denotes $[l + (n-1)/2]$. In this way, we have reduced the continuity analysis to a time-like trace regularity estimate for $v - \delta v$.

Since $\phi \in C_0^\infty$ is supported near the time-like trace surface $\{x_n = 0\}$, a trace regularity result [2, Theorem 3.1] implies that

$$||\phi(v - \delta v)|_{x_n=0}||_{l_1} \le C||\phi_0(v - \delta v)||_{l_1}, \tag{4.4}$$

where C depends on the H^{l_1+1}-norm of σ_1 and $\phi_0 \in C_0^\infty$ supported near $\mathrm{supp}(\phi)$. Thus the estimate of $||\phi(v-\delta v)|_{x_n=0}||_{l_1}$ may be reduced to estimating $||\phi_0(v-\delta v)||_{l_1}$.

Because of the assumptions that $\delta\sigma$ is supported away from $\{x_n = 0\}$ and ϕ_0 is supported near the time-like surface, a result in [4, Proposition 6.1] implies that it suffices to estimate the t-derivatives of $v - \delta v$. We study the regularity of $v - \delta v$ through a dual problem. It is then convenient to look at the symmetric form. For $\rho_1(x) = e^{-\sigma_1}$,

$$\begin{aligned} \Box_1(v - \delta v) = \left[\frac{1}{\rho_1}\partial_t^2 - \nabla \cdot \left(\frac{1}{\rho_1}\nabla\right)\right](v - \delta v) &= \frac{1}{\rho_1}\nabla\delta\sigma \cdot \nabla\delta v \, , \\ v - \delta v = 0, \quad t < 0 \, . \end{aligned} \tag{4.5}$$

Introduce a dual problem to (4.5)

$$\begin{aligned} \Box_1' w = \left[\frac{1}{\rho_1}\partial_t^2 - \nabla \cdot \left(\frac{1}{\rho_1}\nabla\right)\right] w &= \Psi \, , \\ w = 0, \quad t \gg T_0 \, , \end{aligned} \tag{4.6}$$

where $\Psi \in C_0^\infty(\Omega_0)$ with $\Omega_0 \subseteq \{|x_n| < \epsilon\} \cap \{t \in (0, T_0), t > |x| + \epsilon\}$ for some $\epsilon > 0$.

Thus to obtain

$$||\partial_t^{l_1}(v - \delta v)||_{0,\Omega_0} \le C||\delta\sigma||_{\tau+1}\,||\delta\sigma||_{l_1} \, , \tag{4.7}$$

it suffices to show that for any $\Psi \in C_0^\infty(\Omega_0)$

$$|(\partial_t^{l_1}(v - \delta v), \Psi)| \le C||\delta\sigma||_{\tau+1}||\delta\sigma||_{l_1}\,||\Psi||_0 \, . \tag{4.8}$$

Integration by parts gives

$$\begin{aligned}(\partial_t^{l_1}(v-\delta v),\Psi) &= (\rho_1^{-1}\nabla\delta\sigma\cdot\nabla\partial_t^{l_1}\delta v, w)\\ &= (\rho_1^{-1}\nabla\delta\sigma\cdot\nabla\delta v, \partial_t^{l_1}(\phi_1 w)),\end{aligned} \tag{4.9}$$

where $\phi_1 \in C_0^\infty(\mathbf{R}^{n+1})$, ϕ_1 is supported in a small neighborhood of $\mathrm{supp}(w) \cap \mathrm{supp}(\nabla\delta\sigma\cdot\nabla\partial_t^{l_1}\delta v)$, and $\phi_1 = 1$ on $\mathrm{supp}(w)\cap\mathrm{supp}(\nabla\delta\sigma\cdot\nabla\partial_t^{l_1}\delta v)$.

Construct Q_0, Q_1, and $Q_2 \in OPS^0$ such that

- $\mathrm{supp}(q_0)$ is strictly contained in the light cone $\{t \geq r(x)\}$; q_1 and q_2 are supported near the light cone;
- $ES(Q_1) \subseteq$ a conic neighborhood of $Char(\partial_t + \nabla r\cdot\nabla)$;
- $ES(Q_2) \subseteq \{\omega + \nabla r\cdot\xi \neq 0\}$;
- $Q_0 + Q_1 + Q_2 = I$.

Hence

$$\partial_t^{l_1}(\phi_1 w) = \partial_t^{l_1}Q_0(\phi_1 w) + \partial_t^{l_1}Q_1(\phi_1 w) + \partial_t^{l_1}Q_2(\phi_1 w)\ .$$

Therefore

$$(\partial_t^{l_1}(v-\delta v),\Psi) = E_0 + E_1 + E_2\ , \tag{4.10}$$

where $E_j = (\rho_1^{-1}\nabla\delta\sigma\cdot\nabla\delta v, \partial_t^{l_1}Q_j(\phi_1 w))$ for $j = 0, 1, 2$.

Integration by parts gives

$$\begin{aligned}|E_0| &= \left|\sum_{j=1}^n (\rho_1^{-1}\partial_{x_j}\delta\sigma\partial_{x_j}\delta v, \partial_t^{l_1}Q_0(\phi_1 w))\right|\\ &= \left|\left(\partial_t^{l_1}\delta v, \sum_{j=1}^n \partial_{x_j}\phi_2\rho_1^{-1}\partial_{x_j}\delta\sigma Q_0(\phi_1 w)\right)\right|\ ,\end{aligned}$$

where $\phi_2 \in C_0^\infty(\mathbf{R}^{n+1})$ is supported strictly inside the light cone and $\phi_2 = 1$ on $\mathrm{supp}(q_0)\cap\mathrm{supp}(\phi_1)$.

Introduce another dual problem

$$\begin{aligned}&\Box_0' U = \left[\frac{1}{\rho_0}\partial_t^2 - \nabla\cdot\left(\frac{1}{\rho_0}\nabla\right)\right]U = -\sum_{j=1}^n \partial_{x_j}\left[\phi_2\frac{1}{\rho_1}\partial_{x_j}\delta\sigma Q_0(\phi_1 w)\right]\ ,\\ &\quad U = 0\ ,\quad t \gg T_0\ .\end{aligned} \tag{4.11}$$

Then

$$|E_0| = |(\partial_t^{l_1}\delta v, \Box_0' U)| = |(\partial_t^{l_1}\delta v, \Box_0'\phi_3 U)|\ ,$$

where $\phi_3 \in C_0^\infty$ supported strictly inside the characteristic surface and $\phi_3 = 1$ on $\mathrm{supp}(\phi_2)$.

Using the equation for δv, we have by integration by parts

$$\begin{aligned}|E_0| &= |(\nabla\delta\sigma\cdot\nabla\partial_t^{l_1}v_0, \phi_3 U)|\\ &= \left|\left(\partial_t^{l_1}v_0, \sum_{j=1}^n \partial_{x_j}(\phi_3 U\partial_{x_j}\delta\sigma)\right)\right|\\ &\leq ||\partial_t^{l_1}v_0||\ \left\|\sum_{j=1}^n \partial_{x_j}(\phi_3 U\partial_{x_j}\delta\sigma)\right\|\ ,\end{aligned}$$

where the integral is over the set strictly inside the characteristic surface. It follows from Lemma 2.3 that $||\partial_t^{l_1} v_0|| \leq C$ with the constant C depending on $||\sigma_0||_s$ for $s > l_1 + n/2$.

Thus

$$|E_0| \leq C||\phi_3 U \nabla \delta\sigma||_1 \leq C||\phi_3 U||_1 \, ||\delta\sigma||_{s_1+1}$$

for some $s_1 > n/2$.

Applying the method of energy estimates to the second dual problem yields further that

$$\begin{aligned} ||\phi_3 U||_1 &\leq C||\phi_2 \rho_1^{-1} \nabla \delta\sigma Q_0(\phi_1 w)||_1 \\ &\leq C||\delta\sigma||_{s_1+1}||\phi_1 w||_1 \\ &\leq C||\delta\sigma||_{s_1+1}||\Psi|| \, , \end{aligned}$$

where the constant C depends on $||\rho_1||_{s_1}$.

Therefore

$$|E_0| \leq C||\delta\sigma||^2_{s_1+1}||\Psi|| \, . \tag{4.12}$$

We next estimate the term E_1. According to the progressing wave expansion (3.7),

$$\nabla\delta\sigma \cdot \nabla\delta v = -h_0 \nabla\delta\sigma \cdot \nabla r \; \delta(t-r) + \nabla\delta\sigma \cdot \nabla h_0 \; H(t-r) + \nabla\delta\sigma \cdot \nabla R_1^\delta \, , \tag{4.13}$$

where $R_1^\delta(x,t)$ solves

$$\begin{aligned} (\Box - \nabla\sigma_0 \cdot \nabla) R_1^\delta &= \nabla\delta\sigma \cdot \nabla R_1 + \nabla\delta\sigma \cdot \nabla b_0 + (\Delta + \nabla\sigma_0 \cdot \nabla) h_0 \; H(t - r(x)) \, , \\ R_1^\delta &= 0, \quad t < 0 \, . \end{aligned} \tag{4.14}$$

Consequently

$$\begin{aligned} E_1 = &(-\psi\rho_1^{-1} h_0 \nabla\delta\sigma \cdot \nabla r \; \delta(t-r) + \psi\rho_1^{-1} \nabla\delta\sigma \cdot \nabla h_0 \; H(t-r), \partial_t^{l_1} Q_1(\phi_1 w)) \\ &+(\phi_1 \rho_1^{-1} \nabla\delta\sigma \cdot \nabla R_1^\delta, \partial_t^{l_1} Q_1(\phi_1 w)), \end{aligned}$$

with $\psi \in C_0^\infty(\mathbf{R}^n)$, $\psi(x) = 1$ on the x-projection of $\text{supp}(\nabla\delta\sigma \cdot \nabla\delta v) \cap \text{supp}(\partial_t^{l_1} Q_1(\phi_1 w))$.

Hence

$$\begin{aligned} |E_1| \leq &|(-\psi\rho_1^{-1} h_0 \nabla\delta\sigma \cdot \nabla r, (\partial_t^{l_1} Q_1(\phi_1 w))_{t=r})| + |(\psi\rho_1^{-1} \nabla\delta\sigma \cdot \nabla h_0, (\partial_t^{l_1 - 1} Q_1(\phi_1 w))_{t=r})| \\ &+|(\phi_1 \rho_1^{-1} \nabla\delta\sigma \cdot \nabla R_1^\delta, \partial_t^{l_1} Q_1(\phi_1 w))| \, . \end{aligned}$$

An application of the trace theorem yields that

$$\begin{aligned} |E_1| \leq &||\psi h_0 \rho_1^{-1} \nabla\delta\sigma \cdot \nabla r|| \; ||Q_1(\phi_1 w)||_{l_1 + 1/2} + ||\psi\rho_1^{-1} \nabla\delta\sigma \cdot \nabla h_0|| \; ||Q_1(\phi_1 w)||_{l_1 - 1/2} \\ &+||\phi_1 \rho_1^{-1} \nabla\delta\sigma \cdot \nabla R_1^\delta|| \; ||Q_1(\phi_1 w)||_{l_1} \, . \end{aligned}$$

By the construction of Q_1, the results on propagation of singularities (Lemmas 2.4 and 2.5) give that

$$||Q_1 \phi_1 w||_{l_1 + 1/2} \leq C||\Psi||_0 \, ,$$

where C depends on $||\sigma_1||_p$ for $p > l_1 + (n-1)/2$. Hence

$$\begin{aligned}|E_1| &\le C(||\psi h_0 \nabla \delta\sigma \cdot \nabla r|| + ||\psi \nabla \delta\sigma \cdot \nabla h_0|| + ||\phi_1 \nabla \delta\sigma \cdot \nabla R_1^\delta||)\ ||\Psi|| \\ &\le C||\delta\sigma||_{l_1}||\psi h_0||_1||\Psi|| + C||\phi_1 \nabla \delta\sigma \cdot \nabla R_1^\delta||\ ||\Psi||,\end{aligned}$$

with C depending on $||\sigma_1||_s$, $s > l_1 + (n-1)/2$.

Thus the problem has been reduced to estimate

$$||\phi_1 \nabla \delta\sigma \cdot \nabla R_1^\delta|| \le C||\delta\sigma||_{l_1}||\tilde{\phi_1} R_1^\delta||_1$$

for some $\tilde{\phi_1} \in C_0^\infty(\mathbf{R}^{n+1})$.

From (4.14), the method of energy estimates gives

$$||\tilde{\phi_1} R_1^\delta||_1 \le C||\delta\sigma||_{s+1}\ ,$$

where $s > n/2$ and the constant C depends on $||\sigma_0||_{s+1}$.

Therefore

$$|E_1| \le C||\delta\sigma||_{s+1}||\delta\sigma||_{l_1}||\Psi||\ . \tag{4.15}$$

We now estimate the term E_2.

Since $\partial_t + \nabla r \cdot \nabla$ is elliptic on $ES(\partial_t^{l_1} Q_2)$, the calculus of $\psi.d.o.$ implies that there exists a $\psi.d.o.$ $\tilde{Q}_2$ of order zero such that

$$\partial_t^{l_1 - i} Q_2 = (\partial_t + \nabla r \cdot \nabla)^{l_1 - i} \tilde{Q}_2 + K_i \text{ for } i = 0, 1, 2\ , \tag{4.16}$$

where K_i are smoothing operators.

Once again, from the progressing wave expansion

$$\nabla \delta\sigma \cdot \nabla \delta v = \sum_{i=0}^{2} d_i(x) S_{i-1}(t - r(x)) + \nabla \delta\sigma \cdot \nabla R_2^\delta(x, t)\ , \tag{4.17}$$

where $S_{-1}(t - r(x)) = \delta(t - r(x))$, $S_0(t - r(x)) = H(t - r(x))$, $S_1' = H$, and

$$d_0 = -h_0 \nabla \delta\sigma \cdot \nabla r\ , \tag{4.18}$$

$$d_1 = \nabla \delta\sigma \cdot \nabla h_0 - h_1 \nabla \delta\sigma \cdot \nabla r\ , \tag{4.19}$$

$$d_2 = \nabla \delta\sigma \cdot \nabla h_1\ . \tag{4.20}$$

Here R_2^δ solves the equation (3.10) with $m = 2$.

Denote $T_1 = \partial_t + \nabla r \cdot \nabla$. We can then rewrite E_2 as, for some $\psi \in C_0^\infty(\mathbf{R}^n)$,

$$\begin{aligned}E_2 &= \sum_{i=0}^{2} (\psi \rho_1^{-1} d_i S_{i-1}, \partial_t^{l_1} Q_2(\phi_1 w)) + (\phi_1 \rho_1^{-1} \nabla \delta\sigma \cdot \nabla R_2^\delta, \partial_t^{l_1} Q_2(\phi_1 w)) \\ &= \sum_{i=0}^{2} (\psi \rho_1^{-1} d_i, (\partial_t^{l_1 - i} Q_2(\phi_1 w))_{t=r}) + (\phi_1 \rho_1^{-1} \nabla \delta\sigma \cdot \nabla R_2^\delta, \partial_t^{l_1} Q_2(\phi_1 w))\ .\end{aligned}$$

Notice that

$$(\partial_t^{l_1 - i} Q_2(\phi_1 w))_{t=r} = (\nabla r \cdot \nabla)^{l_1 - i} (\tilde{Q}_2(\phi_1 w))_{t=r}\ .$$

We may use (4.16) and integration by parts to get

$$
\begin{aligned}
|E_2| &\le \sum_{i=0}^{2} ||(\nabla r\cdot\nabla+\Delta r)^{l_1-i-1}\psi\rho_1^{-1}d_i||\ ||(T_1\tilde{Q}_2(\phi_1 w))_{t=r})|| \\
&\quad +||(T_1+\Delta r)^{l_1-1}\phi_1\rho_1^{-1}\nabla\delta\sigma\cdot\nabla R_2^{\delta}||\ ||T_1\tilde{Q}_2(\phi_1 w)|| \\
&\le C\sum_{i=0}^{2} ||\psi\rho_1^{-1}d_i||_{l_1-i-1}||\tilde{Q}_2(\phi_1 w)_{t=r}||_1 + ||(T_1+\Delta r)^{l_1-1}\phi_1\rho_1^{-1}\nabla\delta\sigma\cdot\nabla R_2^{\delta}||\ ||\phi_1 w||_1\ .
\end{aligned}
$$

Applying the generalized Schauder's lemma and the assumption that $l_1-1>n/2$ as well as Lemma 3.3, we have from (4.18)–(4.20) that

$$
\begin{aligned}
&||\psi\rho_1{}^{-1}d_0||_{l_1-1}\le C||\delta\sigma||_{l_1}||\psi_0 h_0||_{l_1-1}\le C_0||\delta\sigma||_{l_1}^2\ , \\
&||\psi\rho_1{}^{-1}d_1||_{l_1-2}\le C||\delta\sigma||_{l_1}(||\psi_1 h_0||_{l_1-1}+||\psi_1 h_1||_{l_1-2})\le C_1||\delta\sigma||_{l_1}^2\ , \\
&||\psi\rho_1{}^{-1}d_2||_{l_1-3}\le C||\delta\sigma||_{l_1}||\psi_2 h_1||_{l_1-2}\le C_1||\delta\sigma||_{l_1}^2\ ,
\end{aligned}
$$

where $\psi_i\in C_0^{\infty}(\mathbf{R}^n)$. By Lemma 3.3, the constants C_0 and C_1 depend on $||\sigma_0||_{s_0}$ and $||\sigma_0||_{s_1}$, respectively, where $s_0>n/2$, $s_1>2+n/2$ and $s_0\ge l_1-1$, $s_1\ge l_1$. The constants also depend on $||\sigma_1||_{l_1-1}$.

Since $ES(\tilde{Q}_2)\subset\{\omega+\nabla r\cdot\xi\neq 0\}$, a trace regularity result (Corollary 2 in [1]) implies the existence of a $\phi_1'\in C_0^{\infty}(\mathbf{R}^{n+1})$ such that

$$
||(\tilde{Q}_2\phi_1 w)_{t=r(x)}||_1\le C||\phi_1' w||_1\le C||\Psi||_0\ .
$$

Therefore

$$
|E_2|\le C||\delta\sigma||_{l_1}^2||\Psi||+C||(T_1+\Delta r)^{l_1-1}\phi_1\nabla\delta\sigma\cdot\nabla R_2^{\delta}||\ ||\Psi||\ . \tag{4.21}
$$

Thus it suffices to estimate $||(T_1+\Delta r)^{l_1-1}\phi_1\nabla\delta\sigma\cdot\nabla R_2^{\delta}||$ or essentially to estimate, for $\phi\in C_0^{\infty}(\mathbf{R}^{n+1})$,

$$
||\phi T_1^{l_1-1}\nabla\delta\sigma\cdot\nabla R_2^{\delta}||\ . \tag{4.22}
$$

By Lipschitz's formula, it is sufficient to estimate

$$
\begin{aligned}
&\sum_{i=0}^{l_1-1}||\phi T_1^{l_1-1-i}\nabla\delta\sigma\cdot T_1^{i}\nabla R_2^{\delta}|| \\
&\quad =||\phi\nabla\delta\sigma\cdot T_1^{l_1-1}\nabla R_2^{\delta}||+\sum_{i=0}^{l_1-2}||\phi T_1^{l_1-1-i}\nabla\delta\sigma\cdot T_1^{i}\nabla R_2^{\delta}||\ .
\end{aligned} \tag{4.23}
$$

Note that although $R_2^{\delta}\in H_{loc}^2$ from the progressing wave expansion, the terms on the right-hand side of the above expression are still well defined due to the conormal properties of R_2^{δ}. We have by using the assumption $l_1-1>n/2$ and Schauder's lemma

$$
||\phi\nabla\delta\sigma\cdot T_1^{l_1-1}\nabla R_2^{\delta}||\le C||\delta\sigma||_{l_1}||\phi T_1^{l_1-1}\nabla R_2^{\delta}||.
$$

An application of Lemmas 2.7 and 3.3 yields that $R_2^{\delta}\in H_{loc}^{1,l_1-1}$ and

$$
||\phi T_1^{l_1-1}\nabla R_2^{\delta}||\le C||\delta\sigma||_q
$$

with $q > l_1 + 4 + n/2$ and the constant C depending on $||\sigma_0||_{l_1+3}$.

Thus

$$||\phi\nabla\delta\sigma \cdot T_1^{l_1-1}\nabla R_2^\delta|| \le C||\delta\sigma||_q||\delta\sigma||_{l_1}.$$

To estimate the second term on the right-hand side of (4.24) requires a different approach. We shall show that $\phi T_1^i \nabla R_2^\delta$ $(0 \le i \le l_1 - 2)$ is bounded by $C||\delta\sigma||_{\tau+1}$. Indeed if this is the case, then

$$\begin{aligned}\sum_{i=0}^{l_1-2} ||\phi T_1^{l_1-1-i}\nabla\delta\sigma \cdot T_1^i\nabla R_2^\delta|| &\le C\sum_{i=0}^{l_1-2} ||T_1^{l_1-1-i}\nabla\delta\sigma||\ ||\delta\sigma||_{l_1} \\ &\le C||\delta\sigma||_{\tau+1}||\delta\sigma||_{l_1}.\end{aligned}$$

According to Proposition 2.6, it suffices to show that for some integer $s > (n-1)/2$

$$R_2^\delta \in H_{loc}^{2,s+l_1-2}\ .$$

This can be done by an application of Lemmas 2.7 and 3.3. In fact, by applying Lemma 2.7 and Proposition 2.6 to the equation (3.10) (for $m = 2$), the term $\phi T_1^i \nabla R_2^\delta$ is bounded by

$$C(||\phi\nabla\delta\sigma \cdot \nabla R_2||_q + ||\psi\nabla\delta\sigma \cdot \nabla b_1 + \psi(\Delta + \nabla\sigma_0 \cdot \nabla)h_1||_q),$$

where the constant depends on $||\sigma_0||_p$ with $p \ge s + l_1$ and $p > s + l_1 + n/2 - 1$, and $q \ge s + l_1 - 1$, $q > s + l_1 + n/2 - 2$ for $\phi, \psi \in C_0^\infty$. We then use Lemma 3.3 and the regularity result for b_1 (Proposition 3.2) to obtain that

$$|\phi T_1^i \nabla R_2^\delta| \le C||\delta\sigma||_{q+5},$$

where the constant depends on $||\sigma_0||_{q+4}$ with $q + 4 > l_1 + [(n-1)/2] + n/2 + 2$.

Combining the discussions above, we finally obtain

$$|E_2| \le C||\delta\sigma||_{\tau+1}||\delta\sigma||_{l_1}||\Psi|| \tag{4.24}$$

with the constant C depending on $||\sigma_0||_\tau$.

5. Continuity of the linearized map. We now sketch the proof of Theorem 1.4. From the definition of the linearized forward map (1.7), we have

$$[DF(\sigma_1) - DF(\sigma_0)](\eta) = (\phi(\delta u_1 - \delta u_0))|_{x_n=0}\ ,$$

where for $i = 0, 1$

$$\begin{aligned}(\Box - \nabla\sigma_i \cdot \nabla)\delta u_i &= \nabla\eta \cdot \nabla u_i\ , \\ \delta u_i &= 0 \quad t < 0\ .\end{aligned} \tag{5.1}$$

Thus

$$\begin{aligned}||[DF(\sigma_1) - DF(\sigma_0)](\eta)||_l &\le ||(\phi(\delta u_1 - \delta u_0))|_{x_n=0}||_l \\ &\le C||(\phi(\delta v_1 - \delta v_0))|_{x_n=0}||_{l_1}\ ,\end{aligned} \tag{5.2}$$

where $\delta u_i = \partial_t^{[(n-1)/2]}\delta v_i$,

$$\begin{aligned}(\Box - \nabla\sigma_i \cdot \nabla)\delta v_i &= \nabla\eta \cdot \nabla v_i\ , \\ \delta v_i &= 0, \quad t < 0\ ,\end{aligned} \tag{5.3}$$

and

$$(\Box - \nabla\sigma_i \cdot \nabla)v_i = \delta^{(-\frac{n-1}{2})}(t)\delta(x) \ , \quad v_i = 0, \quad t < 0 \ . \tag{5.4}$$

From (5.3), similar to (4.5), we have ($\rho_1(x) = e^{-\sigma_1}$)

$$\Box_1(\delta v_1 - \delta v_0) = \rho_1^{-1}\nabla\eta \cdot \nabla(\delta v_1 - \delta v_0) - \rho_1^{-1}\nabla(\sigma_1 - \sigma_0) \cdot \nabla\delta v_0 \ , \tag{5.5}$$

$$\delta v_1 - \delta v_0 = 0. \tag{5.6}$$

Once again, by considering the dual problem (4.6), we wish to estimate

$$|(\partial_t^{l_1}(\delta v_1 - \delta v_0), \Psi)|/||\Psi||_0 \ .$$

Formal integration by parts yields

$$\begin{aligned}(\partial_t^{l_1}(\delta v_1 - \delta v_0), \Psi) &= (\rho_1^{-1}\nabla\eta \cdot \partial_t^{l_1}(v_1 - v_0) - \rho_1^{-1}\nabla(\sigma_1 - \sigma_0) \cdot \nabla\partial_t^{l_1}\delta v_0, w) \\ &= (\rho_1^{-1}\nabla\eta \cdot \nabla(v_1 - v_0), \partial_t^{l_1}(\phi_1 w)) - (\rho_1^{-1}\nabla\eta \cdot \nabla\delta v_0, \partial_t^{l_1}(\phi_1 w)).\end{aligned} \tag{5.7}$$

It suffices to estimate the terms in (5.7). The second term may be estimated the same way as in section 4. We obtain

$$|(\rho_1^{-1}\nabla\eta \cdot \nabla\delta v_0, \partial_t^{l_1}(\phi_1 w))| \le C||\sigma_1 - \sigma_0||_{l_1} \ ||\eta||_{\tau+1} \ ||\Psi||_0 \ . \tag{5.8}$$

To estimate the first term, recall that $v_1 - v_0$ solves

$$(\Box - \nabla\sigma_1 \cdot \nabla)(v_1 - v_0) = \nabla(\sigma_1 - \sigma_0) \cdot \nabla v_0 \ , \quad v_1 - v_0 = 0, \quad t < 0 \ . \tag{5.9}$$

Hence similar estimates as in section 4 yield

$$|(\rho_1^{-1}\nabla\eta \cdot \nabla(v_1 - v_0), \partial_t^{l_1}(\phi_1 w))| \le C||\eta||_{l_1} \ ||\sigma_1 - \sigma_0||_{\tau+1} \ ||\Psi||_0 \ . \tag{5.10}$$

Theorem 1.4 may be proved by combining (5.7)–(5.10).

Acknowledgment. I thank Prof. William W. Symes for providing me with many useful ideas.

TIME-HARMONIC ELECTROMAGNETIC FIELDS IN THIN CHIRAL CURVED LAYERS*

H. AMMARI† AND J. C. NÉDÉLEC†

Abstract. In this paper, we prove existence and uniqueness of the solution to the diffraction problem of a plane electromagnetic field by a chiral curved layer covering a perfectly conducting object. Approximative impedance conditions are given for thin chiral curved layers and optimal error estimates are obtained.

Key words. integral equations, chiral media, approximative impedance conditions, Drude–Born–Fedorov equations, error estimates

1. Introduction.

The interaction of electromagnetic fields at microwave frequencies with the optically active chiral media has attracted the attention of the electromagnetic community due to its potential applications in the field of antennas, microwave devices, waveguide propagation, scattering, etc. The original investigations of optical activity, or the effect of chirality on the polarization of light, also date back to the nineteenth century. Arago [5], Biot [7], Cauchy [12], Pasteur [23], and Fresnel [15] all examined optical activity in solid and liquid chiral medium. The concept of chirality has also played an increasingly important role in chemistry (see Prelog [24]). Chiral media can be characterized by a generalized set of constitutive relations in which the electric and magnetic fields are coupled. The coupling strength is given by the magnitude of a quantity known as the chirality admittance which determines the bulk electromagnetic properties of these materials. In scattering applications it may be possible to use chiral material to coat a scatterer and thus control its scattering properties more efficiently than a dielectric coating due to the extra degree of freedom offered by the presence of chiral parameter. Antennas coated with chiral materials may have significantly interesting radiation characteristics, and surface-relief gratings constructed using chiral material may find application in integrated optics and holography, for instance.

In this paper, we prove uniqueness and existence of the solution to the diffraction problem by a layer of chiral material covering a perfectly conducting object. Assuming that the thickness of the layer is sufficiently small compared to the wavelength of the incident radiation, we derive impedance boundary conditions which can be used, along with the radiation condition, to compute the scattered field without requiring detailed modeling of the field quantities inside the chiral coating. This procedure permits accurate numerical calculations of the scattered wave for chiral coatings as in the achiral case [13]. The starting points of the present paper are the Maxwell equations and the constitutive relations for the chiral layer. Different expressions exist for the constitutive relations. The Drude–Born–Fedorov constitutive equations are used here. For an interesting explanation of these equations and various physical

aspects of the propagation inside chiral media, we refer to [14], [8], [9], [10], [6], [17], [18], [20], [21], [22], [25], [16], and the references therein. It is noted that this list of papers is by no means complete, but it is representative of the work that is presently being conducted in this area. All these papers have come from physicists and the engineering community. To our knowledge, the existence and the uniqueness of the solution to the diffraction problem by a chiral layer has never been established. The present paper is devoted to presenting some results and approaches dealing with the rigorous scattering by a chiral medium.

2. Chirality and reduction of scattering. Let δ be a strictly positive parameter. Let $\Omega^i \subset \mathbb{R}^3$ be an open bounded set of class $\mathcal{C}^\infty$, with $\Gamma = \partial\Omega^i$ its boundary, n the outward normal. Let Ω_1^δ be the chiral layer, $\Omega_2^\delta = \Omega^e \setminus \overline{\Omega_1^\delta}$, Γ^δ the interface between the chiral material Ω_1^δ and the exterior domain Ω_2^δ. We assume that Γ^δ is parallel to the curve Γ. Let $\Omega_{2,R}^\delta = \Omega_2^\delta \cap \{r < R\}$ and $\Sigma_R = \{r = R\}$. For $x \in \Omega^e = \mathbb{R}^3 \setminus \overline{\Omega^i}$ sufficiently close to Γ^δ, we denote by x_{Γ^δ} the orthogonal projection of x on Γ^δ, $s = -(x - x_{\Gamma^\delta}) \cdot n(x_{\Gamma^\delta})$, where $n(x_{\Gamma^\delta})$ is the outward normal to Γ^δ. (x_{Γ^δ}, s) is a parameterization of the neighborhood of Γ^δ:

$$x(x_{\Gamma^\delta}, s) = x_{\Gamma^\delta} + s\, n(x_{\Gamma^\delta}).$$

The curve Γ is such that

$$\Gamma = \Big\{ x_{\Gamma^\delta} - \delta n(x_{\Gamma^\delta}), x_{\Gamma^\delta} \in \Gamma^\delta \Big\}.$$

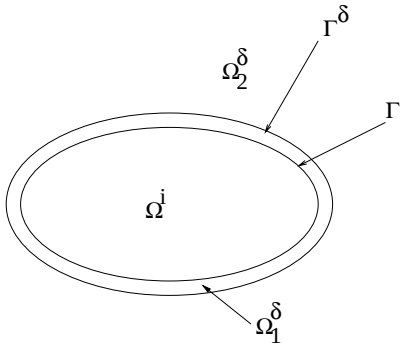

FIG. 2.1. *The chiral layer.*

We shall need some differential operators on the curve Γ^δ that we will introduce. The normal vector on Γ^δ is the opposite of the gradient of the function s. We use this property to define

$$n(x) = -\overrightarrow{\text{grad}}\, s(x) = n(x_{\Gamma^\delta}).$$

The mean curvature is defined as $2\, c(x_{\Gamma^\delta}) = \text{div}\, n$. We also introduce the family of parallel curves Γ_s^δ :

$$\Gamma_s^\delta = \Big\{ \text{ } x \in \Omega^e \text{ such that } x = x_{\Gamma^\delta} + s\, n(x_{\Gamma^\delta}) \text{ , } x_{\Gamma^\delta} \in \Gamma^\delta \text{ } \Big\}.$$

The vector field n is the field of the normal vectors to the curves Γ_s^δ. With any function f defined on the curve Γ^δ, we associate the function $\tilde{f}$ defined for x near Γ^δ

by

$$\tilde{f}(x) \,=\, f(x_{\Gamma^\delta}).$$

We also define $\tilde{u}$, for any smooth tangential vector field u on Γ^δ, as

$$\tilde{u}(x_{\Gamma^\delta} + sn(x_{\Gamma^\delta})) \,=\, u(x_{\Gamma^\delta}) - s\,\mathcal{R}\,u(x_{\Gamma^\delta}),$$

where $\mathcal{R}$ is the tensor of curvature at the point x_{Γ^δ}. It is defined as $\mathcal{R} \,=\, \overrightarrow{\operatorname{grad}}\, n$. The tangential gradient of the tangential field u is

$$\overrightarrow{\operatorname{grad}}_{\Gamma^\delta} u \,=\, \overrightarrow{\operatorname{grad}}\,\tilde{u}\,|_{\Gamma^\delta}\ .$$

This vector belongs to the tangent to the curve Γ^δ. For any smooth tangential vector field u on Γ^δ, let us define $\operatorname{div}_{\Gamma^\delta} u$ as

$$\operatorname{div}_{\Gamma^\delta} u \,=\, \operatorname{div}\tilde{u}\,|_{\Gamma^\delta}\ .$$

Let $\overrightarrow{\operatorname{curl}}_{\Gamma^\delta}$ denote the tangential rotational operator on Γ^δ. It is such that

$$\overrightarrow{\operatorname{curl}}_{\Gamma^\delta} u \,=\, \overrightarrow{\operatorname{grad}}_{\Gamma^\delta} u \,\wedge\, n$$

for any function u defined on the curve Γ^δ. The scalar tangential rotational operator is defined as

$$\operatorname{curl}_{\Gamma^\delta} u \,=\, \operatorname{curl}\tilde{u} \,\cdot\, n\,|_{\Gamma^\delta},$$

where u is a tangential vector to Γ^δ and $\tilde{u}(x) \,=\, u(x_{\Gamma^\delta})$. It is well known that

$$\operatorname{curl}_{\Gamma^\delta} u \,=\, \operatorname{div}_{\Gamma^\delta}(u \wedge n). \tag{2.1}$$

Finally, we recall the following formula.

LEMMA 2.1. *Let u be a smooth vectorial function defined in Ω; we have*

$$\tau_0(\operatorname{div} u) \,=\, \operatorname{div}_{\Gamma^\delta} u_{\Gamma^\delta} + 2\,c(x_{\Gamma^\delta})\; u \,\cdot\, n + \tau_1(u\,.\,n) \tag{2.2}$$

and

$$\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}(u \,\cdot\, n) \,=\, \tau_1(u_{\Gamma^\delta}) + n \wedge \operatorname{curl} u + \mathcal{R}(u_{\Gamma^\delta}), \tag{2.3}$$

where τ_0 and τ_1 are, respectively, the first and the second trace and u_{Γ^δ} is the tangential component of u.

Optical activity of the chiral layer Ω_1^δ of thickness δ can be explained by the direct substitution of the Drude–Born–Fedorov constitutive equations

$$\begin{cases} D^\delta &=& \varepsilon^\delta\Big(E^\delta + \beta^\delta \overrightarrow{\operatorname{curl}}\, E^\delta\Big), \\ B^\delta &=& \mu^\delta\Big(H^\delta + \beta^\delta \overrightarrow{\operatorname{curl}}\, H^\delta\Big) \end{cases} \tag{2.4}$$

into Maxwell's equations

$$\begin{cases} \overrightarrow{\operatorname{curl}}\, E^\delta &=& i\omega\, B^\delta, \\ \overrightarrow{\operatorname{curl}}\, H^\delta &=& -i\omega\, D^\delta. \end{cases} \tag{2.5}$$

It follows that the equivalent monochromatic constitutive relations

$$\left\{\begin{array}{rcl}\Big(1-(k^\delta\beta^\delta)^2\Big)\,D^\delta &=& \varepsilon^\delta E^\delta+\dfrac{i\beta^\delta}{\omega}(k^\delta)^2\,H^\delta,\\ \Big(1-(k^\delta\beta^\delta)^2\Big)\,B^\delta &=& \mu^\delta H^\delta-\dfrac{i\beta^\delta}{\omega}(k^\delta)^2\,E^\delta,\end{array}\right. \tag{2.6}$$

where the function ε^δ is the electric permittivity, μ^δ is the magnetic permeability, β^δ is the chirality admittance, and

$$k^\delta \,=\, \omega\sqrt{\varepsilon^\delta\,\mu^\delta} \tag{2.7}$$

is simply a shorthand notation and does not represent any wavenumber inside the chiral medium. Throughout what follows we assume that $|k^\delta\beta^\delta|\neq 1$. We also assume that $\varepsilon^\delta=\varepsilon_2,\mu^\delta=\mu_2$, and $\beta^\delta=0$ outside the chiral layer Ω_1^δ where ε_2 and μ_2 are two strictly positive constants. Now, combining (2.5) and (2.6) gives

$$\left\{\begin{array}{rcl}\overrightarrow{\rm curl}\,E^\delta &=& (\gamma^\delta)^2\,\beta^\delta E^\delta+i\omega\mu^\delta\left(\dfrac{\gamma^\delta}{k^\delta}\right)^2\,H^\delta,\\ \overrightarrow{\rm curl}\,H^\delta &=& (\gamma^\delta)^2\,\beta^\delta\,H^\delta-i\omega\varepsilon^\delta\left(\dfrac{\gamma^\delta}{k^\delta}\right)^2\,E^\delta.\end{array}\right. \tag{2.8}$$

In these equations, the parameter γ^δ is defined as

$$(\gamma^\delta)^2 \,=\, \frac{(k^\delta)^2}{1-(\,k^\delta\,\beta^\delta\,)^2}. \tag{2.9}$$

We are interested in the scattering problem for a plane incident field E^{in} defined as $E^{in}(x)=p\,e^{i\,\omega\,q\,.\,x}$, where the vectors $p,q\in\mathbb{R}^3$ must satisfy $q\,.\,q=\mu_2\varepsilon_2$ and $q\,.\,p=0$. Then the pair $(E^{in},\overrightarrow{\rm curl}E^{in}/i\omega\mu_2)$ satisfies the Maxwell equations in Ω_2^δ and our scattering problem can be formulated as follows.

$$\left\{\begin{array}{l}\overrightarrow{\rm curl}\,\dfrac{1}{\mu^\delta}\,(1-\omega^2\varepsilon^\delta\mu^\delta(\beta^\delta)^2)\,\overrightarrow{\rm curl}\,E^\delta-\omega^2\,\beta^\delta\varepsilon^\delta\overrightarrow{\rm curl}\,E^\delta-\omega^2\,\overrightarrow{\rm curl}\,(\beta^\delta\varepsilon^\delta)\,E^\delta\\ \qquad -\omega^2\,\varepsilon^\delta\,E^\delta\,=\,0\ \text{in}\ \Omega^e,\\ n\,\wedge\,E^\delta\,=\,0\quad\text{on}\ \Gamma,\\ E^\delta-E^{in}\ \text{satisfies the classical radiation condition.}\end{array}\right. \tag{2.10}$$

3. Uniqueness and existence results for the diffraction problem by the chiral layer. This section is devoted to proving the existence and uniqueness of a field E^δ satisfying the equations (2.10). We use the technique of boundary integral equations. We shall reduce the Drude–Born–Fedorov equations (2.10) to a boundary integral equation on $\Gamma^{\delta,h}=\{x=(x_{\Gamma^\delta},s=h)\}$. First, we consider the following boundary-value problems:

$$\left\{\begin{array}{l}\overrightarrow{\rm curl}\,\dfrac{1}{\mu^\delta}\,(1-\omega^2\varepsilon^\delta\mu^\delta(\beta^\delta)^2)\,\overrightarrow{\rm curl}\,e^\delta-\omega^2\,\beta^\delta\varepsilon^\delta\overrightarrow{\rm curl}\,e^\delta-\omega^2\,\overrightarrow{\rm curl}\,\beta^\delta\varepsilon^\delta\,e^\delta\\ \qquad -\omega^2\,\varepsilon^\delta\,e^\delta\,=\,0\ \text{in}\ \Omega_1^{\delta,h},\\ n\,\wedge\,e^\delta\,=\,0\quad\text{on}\ \Gamma,\\ n\,\wedge\,e^\delta\,=\,g^\delta\quad\text{on}\ \Gamma^{\delta,h}=\Big\{x=(x_{\Gamma^\delta},s=h)\Big\},\end{array}\right. \tag{3.1}$$

and

$$\text{(3.2)}\qquad \begin{cases} \overrightarrow{\text{curl}}\,\overrightarrow{\text{curl}} v^\delta - \omega^2\,\varepsilon_2\mu_2\,v^\delta \;=\; 0 \quad \text{in } \Omega_2^{\delta,h}, \\ n \wedge v^\delta \;=\; g^\delta \quad \text{on } \Gamma^{\delta,h} (=\partial\Omega_2^{\delta,h}), \\ v^\delta \text{ satisfies the outgoing radiation condition at infinity,} \end{cases}$$

where

$$g^\delta \in TH^{1/2}(\text{div}, \Gamma^{\delta,h}) = \left\{ \, c \in (H^{1/2}(\Gamma^{\delta,h}))^3, n \cdot c = 0 \text{ on } \Gamma^{\delta,h}, \text{div}_{\Gamma^{\delta,h}}\, c \in H^{1/2}(\Gamma^{\delta,h}) \, \right\}$$

is a known vector field. h is an arbitrarily strictly positive constant which must be small enough. $\Omega_1^{\delta,h}$ and $\Omega_2^{\delta,h}$ are given by $\Omega_1^{\delta,h} = \{(x_{\Gamma^\delta}, s), 0 < s < h\}$, and $\Omega_2^{\delta,h} = \mathbb{R}^3 \setminus \overline{\Omega_1^{\delta,h} \cup \Omega^i}$.

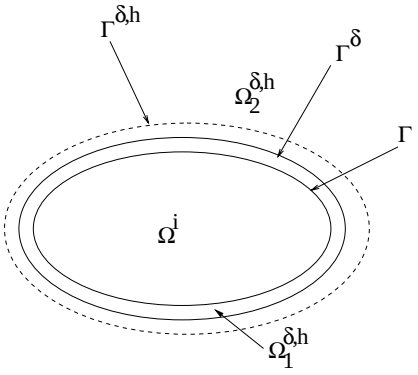

FIG. 3.1. *The chiral layer.*

The weak form of the Drude–Born–Fedorov equations (3.1) in a neighborhood of the interface Γ^δ gives the following jump relations on Γ^δ:

$$\text{(3.3)}\qquad \begin{cases} \left(e_1^\delta \,-\, e_2^\delta \right) \wedge n \;=\; 0, \\ \left(\overrightarrow{\text{curl}}\, e_1^\delta - \dfrac{\mu_1}{\mu_2} \overrightarrow{\text{curl}}\, e_2^\delta \right) \wedge n \;=\; 0, \end{cases}$$

where $e_1^\delta = e^\delta\,|_{\Omega_1^\delta}$ and $e_2^\delta = e^\delta\,|_{\Omega_1^{\delta,h} \setminus \overline{\Omega_1^\delta}}$, if we assume that the jump of β^δ across the interface Γ^δ is null.

Let

$$X^\delta = \left\{ \, H(\overrightarrow{\text{curl}}, \Omega_1^{\delta,h}), w^\delta \wedge n = 0 \text{ on } \partial\Omega_1^{\delta,h} = \Gamma \cup \Gamma^{\delta,h} \, \right\},$$

where

$$H(\overrightarrow{\text{curl}}, \Omega_1^{\delta,h}) = \left\{ \, w^\delta \in (L^2(\Omega_1^{\delta,h}))^3, \overrightarrow{\text{curl}}\, w^\delta \in (L^2(\Omega_1^{\delta,h})^3 \, \right\}.$$

Let $\tilde{g}^\delta$ be in $(H^1(\Omega_1^{\delta,h}))^3$ such that $n \wedge \tilde{g}^\delta = g^\delta$ on $\Gamma^{\delta,h}$ and $n \wedge \tilde{g}^\delta = 0$ on Γ. We define $\tilde{e}^\delta$ by

$$\tilde{e}^\delta = e^\delta - \tilde{g}^\delta.$$

It is easily seen that

$$
\begin{aligned}
&\overrightarrow{\operatorname{curl}}\,\frac{1}{\mu^\delta}\,(1-\omega^2\varepsilon^\delta\mu^\delta(\beta^\delta)^2)\,\overrightarrow{\operatorname{curl}}\,\tilde{e}^\delta-\omega^2\,\beta^\delta\varepsilon^\delta\overrightarrow{\operatorname{curl}}\,\tilde{e}^\delta-\omega^2\,\overrightarrow{\operatorname{curl}}\,\beta^\delta\varepsilon^\delta\,\tilde{e}^\delta-\omega^2\,\varepsilon^\delta\,\tilde{e}^\delta\\
&=-\overrightarrow{\operatorname{curl}}\,\frac{1}{\mu^\delta}\,(1-\omega^2\varepsilon^\delta\mu^\delta(\beta^\delta)^2)\,\overrightarrow{\operatorname{curl}}\,\tilde{g}^\delta+\omega^2\,\beta^\delta\varepsilon^\delta\overrightarrow{\operatorname{curl}}\,\tilde{g}^\delta+\omega^2\,\overrightarrow{\operatorname{curl}}\,\beta^\delta\varepsilon^\delta\,\tilde{g}^\delta\\
&+\omega^2\,\varepsilon^\delta\,\tilde{g}^\delta\ \text{in}\ (\mathcal{D}'(\Omega_1^{\delta,h}))^3,
\end{aligned}
\tag{3.4}
$$

where $\mathcal{D}'(\Omega_1^{\delta,h})$ is the space of all distributions in $\Omega_1^{\delta,h}$. If we multiply (3.4) by a test function $v^\delta\in X^\delta$, integrate over $\Omega_1^{\delta,h}$, and use integration by parts and the jump relations (3.3), we obtain

$$
\begin{aligned}
&\int_{\Omega_1^{\delta,h}}\frac{1}{\mu^\delta}\,(1-\omega^2\varepsilon^\delta\mu^\delta(\beta^\delta)^2)\,\overrightarrow{\operatorname{curl}}\,\tilde{e}^\delta\cdot\overrightarrow{\operatorname{curl}}\,v^\delta+\omega^2\int_{\Omega_1^{\delta,h}}\beta^\delta\varepsilon^\delta\overrightarrow{\operatorname{curl}}\,\tilde{e}^\delta\cdot v^\delta\\
&-\omega^2\int_{\Omega_1^{\delta,h}}\beta^\delta\varepsilon^\delta\,\tilde{e}^\delta\cdot\overrightarrow{\operatorname{curl}}\,v^\delta-\omega^2\int_{\Omega_1^{\delta,h}}\varepsilon^\delta\,\tilde{e}^\delta\cdot v^\delta\\
&=-\int_{\Omega_1^{\delta,h}}\frac{1}{\mu^\delta}\,(1-\omega^2\varepsilon^\delta\mu^\delta(\beta^\delta)^2)\,\overrightarrow{\operatorname{curl}}\,\tilde{g}^\delta\cdot\overrightarrow{\operatorname{curl}}\,v^\delta-\omega^2\int_{\Omega_1^{\delta,h}}\beta^\delta\varepsilon^\delta\overrightarrow{\operatorname{curl}}\,\tilde{g}^\delta\cdot v^\delta\\
&+\omega^2\int_{\Omega_1^{\delta,h}}\beta^\delta\varepsilon^\delta\,\tilde{g}^\delta\cdot\overrightarrow{\operatorname{curl}}\,v^\delta+\omega^2\int_{\Omega_1^{\delta,h}}\varepsilon^\delta\,\tilde{g}^\delta\cdot v^\delta.
\end{aligned}
\tag{3.5}
$$

Our variational problem is then to find the vector field $e^\delta\in H(\overrightarrow{\operatorname{curl}},\Omega_1^{\delta,h})$ such that (3.5) holds for all $v^\delta\in X^\delta$. Because the injection $X^\delta\hookrightarrow(L^2(\Omega^{\delta,h}))^3$ is not compact, we cannot apply the Fredholm theory to (3.5) to show the existence and uniqueness of a solution of this problem in X^δ. We shall prove Lemma 3.1 by using the generalized Lax–Milgram lemma of Babuška and Brezzi [11]. We discuss the unique solvability of (3.5) and (3.2). We may state and prove the following results.

LEMMA 3.1. *Assume that* (3.1) *has at most one solution. Then the variational problem* (3.5) *has a unique solution in* $H(\overrightarrow{\operatorname{curl}},\Omega_1^{\delta,h})$.

LEMMA 3.2. *The boundary-value problem* (3.2) *has a unique solution in* $H^{1,loc}(\Omega_2^{\delta,h})$.

It is well known that (3.2) has exactly one solution (cf. [2] for instance). Now, our aim is to sketch a proof of Lemma 3.1. By essentially the same arguments as in Abboud [1], we can establish the Fredholm alternative for the variational problem (3.5). We seek for $e^\delta\in H(\overrightarrow{\operatorname{curl}},\Omega_1^{\delta,h})$ and we decompose it into a field and a gradient:

$$
e^\delta=u^\delta+\overrightarrow{\operatorname{grad}}p^\delta+\tilde{g}^\delta,
\tag{3.6}
$$

where $u^\delta\in H(\overrightarrow{\operatorname{curl}},\Omega_1^{\delta,h})$ satisfies

$$
\operatorname{div}(\varepsilon^\delta\,u^\delta-\beta^\delta\,\varepsilon^\delta\,\overrightarrow{\operatorname{curl}}\,u^\delta)=0\quad\text{in}\ \Omega_1^{\delta,h},
\tag{3.7}
$$

$u^\delta\wedge n=0$ on $\Gamma\cup\Gamma^{\delta,h}$ and $p^\delta\in H_0^1(\Omega_1^{\delta,h})$. (3.5) will lead to a saddle point problem involving the form a^δ defined as

$$
\begin{aligned}
a^\delta(u^\delta,w^\delta)=&\int_{\Omega_1^{\delta,h}}\frac{1}{\mu^\delta}\,(1-\omega^2\varepsilon^\delta\mu^\delta(\beta^\delta)^2)\,\overrightarrow{\operatorname{curl}}\,u^\delta\cdot\overrightarrow{\operatorname{curl}}\,\overline{w}^\delta\\
&+\omega^2\int_{\Omega_1^{\delta,h}}\beta^\delta\,\varepsilon^\delta\,u^\delta\cdot\overrightarrow{\operatorname{curl}}\,\overline{w}^\delta\\
&-\omega^2\int_{\Omega_1^{\delta,h}}\beta^\delta\,\varepsilon^\delta\,\overrightarrow{\operatorname{curl}}\,u^\delta\cdot\overline{w}^\delta-\omega^2\int_{\Omega_1^{\delta,h}}\varepsilon^\delta\,u^\delta\cdot\overline{w}^\delta
\end{aligned}
$$

for all $w^\delta \in X^\delta$ and the form b^δ given as

$$\begin{aligned} b^\delta(w^\delta, q^\delta) &= a^\delta(\overrightarrow{\text{grad}} q^\delta, w^\delta) \\ &= \omega^2 \int_{\Omega_1^{\delta,h}} \beta^\delta \, \varepsilon^\delta \, \overrightarrow{\text{grad}} q^\delta \cdot \overrightarrow{\text{curl}}\, \overline{w}^\delta - \omega^2 \int_{\Omega_1^{\delta,h}} \varepsilon^\delta \, \overrightarrow{\text{grad}} q^\delta \cdot \overline{w}^\delta \end{aligned}$$

for all $w^\delta \in X^\delta$ and $q^\delta \in H_0^1(\Omega_1^{\delta,h})$. Now we show how to split the variational problem (3.5) into two distinct equations. First, by multiplying (3.7) by $q \in H_0^1(\Omega_1^{\delta,h})$ and integrating by parts over $\Omega_1^{\delta,h}$, we obtain

$$b^\delta(u^\delta, q^\delta) = 0 \quad \text{for all } q^\delta \in H_0^1(\Omega_1^{\delta,h}).$$

Second, multiplying (3.4) by $w \in X^\delta$ and integrating by parts over $\Omega_1^{\delta,h}$ give by using the decomposition (3.6) of the electric field e^δ

$$a^\delta(u^\delta, w^\delta) + b^\delta(w^\delta, p^\delta) = -a^\delta(\tilde{g}^\delta, w^\delta) \quad \text{for all } w^\delta \in X^\delta.$$

Then, we obtain

$$\text{(3.8)} \qquad \begin{cases} a^\delta(u^\delta, w^\delta) + b^\delta(w^\delta, p^\delta) = -a^\delta(\tilde{g}^\delta, w^\delta) & \text{for all } w^\delta \in X^\delta, \\ b^\delta(u^\delta, q^\delta) = 0 & \text{for all } q^\delta \in H_0^1(\Omega_1^{\delta,h}). \end{cases}$$

It is clear that there exist two strictly positive constants C_1 and C_2 such that

$$|a^\delta(u^\delta, u^\delta)| \geq C_1 \, ||\overrightarrow{\text{curl}}\, u^\delta||^2_{(L^2(\Omega_1^{\delta,h}))^3} - C_2 \, ||u^\delta||^2_{(L^2(\Omega_1^{\delta,h}))^3}.$$

It is easily shown that the form b^δ satisfies the inf-sup condition: for each q^δ in $H_0^1(\Omega_1^{\delta,h})$, it is clear that $\overrightarrow{\text{grad}}\, q^\delta$ satisfies $\overrightarrow{\text{grad}} q^\delta \wedge n = 0$ on $\Gamma \cup \Gamma^\delta$ and there exists a strictly positive constant C_3 such that

$$|b^\delta(\overrightarrow{\text{grad}} q^\delta, q^\delta)| \geq C_3 \; ||q^\delta||^2_{H_0^1(\Omega_1^{\delta,h})}.$$

On the other hand, if we assume that $\overrightarrow{\text{grad}}(\beta^\delta \varepsilon^\delta) \in (L^\infty(\Omega_1^{\delta,h}))^3$ then the imbedding $N^\delta \hookrightarrow (L^2(\Omega_1^{\delta,h}))^3$ is compact, where

$$N^\delta = \Big\{ u^\delta \in H(\overrightarrow{\text{curl}}, \Omega_1^{\delta,h}), \text{div}\,(\, \varepsilon^\delta \, u^\delta - \beta^\delta \, \varepsilon^\delta \, \overrightarrow{\text{curl}}\, u^\delta) = 0, u^\delta \wedge n = 0 \text{ on } \partial\Omega_1^{\delta,h} \Big\}$$

is the kernel of the form b^δ. Therefore, a^δ is a compact perturbation of a coercive form on the kernel N^δ of b^δ. It follows that the Fredholm alternative holds, and then uniqueness implies existence of the solution of (3.8). In order to complete the proof of Lemma 3.1 we should prove the following decomposition lemma which may be considered as a generalization of the Hodge decomposition.

LEMMA 3.3. *Let $\tilde{e}^\delta$ be in*

$$X^\delta = \Big\{ v^\delta \in H(\overrightarrow{\text{curl}}, \Omega_1^{\delta,h}), v^\delta \wedge n = 0 \text{ on } \partial\Omega_1^{\delta,h} = \Gamma^{\delta,h} \cup \Gamma \Big\}.$$

Then, there exist $u^\delta \in N^\delta$ and $p^\delta \in H_0^1(\Omega_1^{\delta,h})$ such that

$$\text{(3.9)} \qquad \tilde{e}^\delta = u^\delta + \nabla p^\delta \quad \text{in } \Omega_1^{\delta,h}.$$

Proof. We define f^δ by

$$f^\delta \;=\; \varepsilon^\delta \beta^\delta \,\overrightarrow{\mathrm{curl}}\,\tilde{e}^\delta - \varepsilon^\delta\,\tilde{e}^\delta.$$

$\tilde{e}^\delta \in H(\overrightarrow{\mathrm{curl}}, \Omega^{\delta,h})$ yields $f^\delta \in (L^2(\Omega^{\delta,h}))^3$. It is well known that the transmission problem

$$\begin{cases} \operatorname{div} \varepsilon^\delta \nabla \varphi^\delta_{c_1,c_2} \;=\; \operatorname{div} f^\delta \quad \text{in } \Omega_1^{\delta,h}, \\ \varphi^\delta_{c_1,c_2} \;=\; c_1 \quad \text{on } \Gamma^{\delta,h}, \\ \varphi^\delta_{c_1,c_2} \;=\; c_2 \quad \text{on } \Gamma \end{cases}$$

has a unique solution in $H^1(\Omega^{\delta,h})$ for any $(c_1, c_2) \in \mathbb{C} \times \mathbb{C}$. Let p^δ be defined by

$$p^\delta \;=\; \varphi^\delta_{0,0} \in H^1_0(\Omega_1^{\delta,h})$$

and u^δ given by

$$u^\delta \;=\; \tilde{e}^\delta - \nabla\,\varphi^\delta_{0,0}.$$

It is clear that u^δ is in N^δ; so, the decomposition (3.9) holds. □

Now, using Lemma 3.3, the uniqueness of a solution in $H(\overrightarrow{\mathrm{curl}}, \Omega_1^{\delta,h})$ to (3.1) gives the uniqueness of a solution to (3.8). The proof of Lemma 3.1 is then over.

Throughout what follows we assume that there exists $h > 0$ such that 0 is not an eigenvalue of the Drude–Born–Fedorov operator

$$\overrightarrow{\mathrm{curl}}\,\frac{1}{\mu^\delta}\,(1 - \omega^2 \varepsilon^\delta \mu^\delta (\beta^\delta)^2)\,\overrightarrow{\mathrm{curl}}\,\cdot - \omega^2\,\beta^\delta\,\varepsilon^\delta\,\overrightarrow{\mathrm{curl}}\,\cdot - \omega^2\,\overrightarrow{\mathrm{curl}}\,\beta^\delta\,\varepsilon^\delta\,\cdot - \omega^2\,\varepsilon^\delta\,\cdot \quad \text{in } \Omega_1^{\delta,h}$$

with the boundary condition $n \wedge \cdot = 0$ on $\Gamma^{\delta,h} \cup \Gamma$. The existence of such h can be verified, but it is not our purpose here.

Now, in order to reduce the diffraction problem by a chiral layer covering a perfectly conducting object to a boundary integral equation on $\Gamma^{\delta,h}$, we consider the two pseudodifferential operators on $\Gamma^{\delta,h}$ defined as

$$T_1(\beta,\omega)\;: g^\delta \in TH^{1/2}(\operatorname{div}, \Gamma^{\delta,h}) \longmapsto \overrightarrow{\mathrm{curl}}\, e^\delta \wedge n \in TH^{1/2}(\operatorname{div}, \Gamma^{\delta,h}), \tag{3.10}$$

where e^δ is the unique solution of (3.1), and

$$T_2(\omega)\;: g^\delta \in TH^{1/2}(\operatorname{div}, \Gamma^{\delta,h}) \longmapsto \overrightarrow{\mathrm{curl}}\, v^\delta \wedge n \in TH^{1/2}(\operatorname{div}, \Gamma^{\delta,h}), \tag{3.11}$$

where v^δ is the unique solution of (3.2) satisfying the radiation condition. We have to show that $T_1(\beta,\omega)\,(g^\delta)$ and $T_2(\omega)\,(g^\delta)$ are in $TH^{1/2}(\operatorname{div}, \Gamma^{\delta,h})$ for all g^δ in $TH^{1/2}(\operatorname{div}, \Gamma^{\delta,h})$. Let us define h^δ in $\Omega_1^{\delta,h}$ by

$$\overrightarrow{\mathrm{curl}}\, e^\delta \;=\; (\gamma^\delta)^2\,\beta^\delta\, e^\delta + i\omega\,\mu^\delta \left(\frac{\gamma^\delta}{k^\delta}\right)^2 h^\delta.$$

(3.1) yields a magnetic boundary-value problem for h^δ, and a solution can be found through a variational method similar to (3.5). e^δ and h^δ are in $(H^1(\Omega_1^{\delta,h} \cap \Omega_2^{\delta,h'}))^3$ for all $0 < h' < h$. By the trace theorem, we find that

$$\overrightarrow{\mathrm{curl}}\, e^\delta \wedge n \in TH^{1/2}(\Gamma^{\delta,h}),$$

and furthermore,

$$\begin{aligned}\mathrm{div}_{\Gamma^{\delta,h}}\left(\overrightarrow{\mathrm{curl}}\, e^\delta \wedge n\right) &= \overrightarrow{\mathrm{curl}}\,\overrightarrow{\mathrm{curl}}\, e^\delta \cdot n \\ &= \omega^2\varepsilon_2\mu_2\, e^\delta \cdot n\,|_{\Gamma^{\delta,h}} \in H^{1/2}(\Gamma^{\delta,h}).\end{aligned}$$

Similarly, we define w^δ by

$$\overrightarrow{\mathrm{curl}}\, v^\delta = i\omega\mu_2\, w^\delta.$$

w^δ is the unique outgoing solution of the Maxwell equations

$$\begin{cases} \overrightarrow{\mathrm{curl}}\,\overrightarrow{\mathrm{curl}}\, w^\delta - \omega^2\varepsilon_2\mu_2\, w^\delta = 0 \quad \text{in } \Omega_2^{\delta,h}, \\ i\omega\mu_2 w^\delta \cdot n = \mathrm{div}_{\Gamma^{\delta,h}}\, g^\delta \in H^{1/2}(\Gamma^{\delta,h}), \quad \text{on } \Gamma^{\delta,h}. \end{cases}$$

It is well known that, under the regularity assumption $g^\delta \in H^{1/2}(\Gamma^{\delta,h})$, v^δ and w^δ are in $(H^{1,loc}(\Omega_2^{\delta,h}))^3$. Thus we have

$$\overrightarrow{\mathrm{curl}}\, v^\delta \wedge n = i\omega\mu_2\, w^\delta \wedge n \in TH^{1/2}(\Gamma^{\delta,h})$$

and

$$\mathrm{div}_{\Gamma^{\delta,h}}\left(\overrightarrow{\mathrm{curl}}\, v^\delta \wedge n\right) = \omega^2\varepsilon_2\mu_2\, v^\delta \cdot n\,|_{\Gamma^{\delta,h}} \in H^{1/2}(\Gamma^{\delta,h}).$$

The jump relations lead to the boundary integral equation

$$T_1(\beta,\omega)(g^\delta) - T_2(\omega)(g^\delta) = g^{in} \quad \text{on } \Gamma^{\delta,h}, \tag{3.12}$$

where

$$g^{in} = T_2(\omega)(n \wedge E^{in}) - \overrightarrow{\mathrm{curl}}\, E^{in} \wedge n$$

and

$$g^\delta = n \wedge E^\delta;$$

E^δ satisfies (2.10). Using Lemmas 3.1 and 3.2, it is clear that the unique solvability of (2.8) is equivalent to the unique solvability of (3.12). To discuss existence and uniqueness of solutions of (3.12) let us introduce the following operators:

$$L_0 = T_1(\beta = 0, \omega) - T_2(\omega),$$

$$L_1 = T_1(\beta,\omega) - T_2(\omega),$$

and

$$L_t = t\, L_1 + (1-t)\, L_0 \quad \text{for all } 0 \le t \le 1.$$

The diffraction problem of Maxwell's equations by a layer of dielectric achiral material has a unique solution (cf. [2]). Therefore, we have the following result.

LEMMA 3.4. *The operator* $L_0 : TH^{1/2}(\mathrm{div}, \Gamma^{\delta,h}) \mapsto TH^{1/2}(\mathrm{div}, \Gamma^{\delta,h})$ *is an isomorphism.*

Proof. First we prove the injectivity of the operator L_0. Let $g \in TH^{1/2}(\Gamma^{\delta,h})$ be a solution to

$$L_0 g = 0. \tag{3.13}$$

Let E_1 be the unique solution of the Maxwell equations

$$\begin{cases} \overrightarrow{\text{curl}}\, \dfrac{1}{\mu^\delta}\, \overrightarrow{\text{curl}}\, E_1 - \omega^2 \varepsilon^\delta\, E_1 = 0 \quad \text{in } \Omega_1^{\delta,h}, \\ n \wedge E_1 = 0 \quad \text{on } \Gamma, \\ n \wedge E_1 = g \quad \text{on } \Gamma^{\delta,h}. \end{cases}$$

Let E_2 be given as the unique solution to the following problem:

$$\begin{cases} \overrightarrow{\text{curl}}\, \overrightarrow{\text{curl}}\, E_2 - \omega^2 \varepsilon_2 \mu_2\, E_2 = 0 \quad \text{in } \Omega_2^{\delta,h}, \\ n \wedge E_2 = g \quad \text{on } \Gamma^{\delta,h}, \\ E_2 \text{ satisfies the outgoing radiation condition at infinity.} \end{cases}$$

The field E_2 is in $(H^{1,loc}(\Omega_2^\delta))^3$. We define the field E by

$$E = \begin{cases} E_1 \quad \text{in } \Omega_1^{\delta,h}, \\ E_2 \quad \text{in } \Omega_2^{\delta,h}. \end{cases}$$

$L_0 g = 0$ implies that the jump of $\overrightarrow{\text{curl}}\, E \wedge n$ across $\Gamma^{\delta,h}$ is null. It follows that the field E satisfies the Maxwell equations

$$\begin{cases} \overrightarrow{\text{curl}}\, \dfrac{1}{\mu^\delta}\, \overrightarrow{\text{curl}}\, E - \omega^2 \varepsilon^\delta\, E = 0 \quad \text{in } \Omega^e, \\ n \wedge E = 0 \quad \text{on } \Gamma, \\ E \text{ satisfies the outgoing radiation condition at infinity,} \end{cases}$$

in a weak sense. We deduce from [2] that $E = 0$. Then, it follows that

$$g = n \wedge E|_{\Gamma^{\delta,h}} = 0.$$

Second, we verify the surjectivity of the operator L_0. Let g^{in} be in $TH^{1/2}(\text{div}, \Gamma^{\delta,h})$. Let $E^{in} \in (H^{1,loc}(\Omega_2^{\delta,h}))^3$ be defined as the unique solution of the following problem:

$$\begin{cases} \overrightarrow{\text{curl}}\, \overrightarrow{\text{curl}}\, E^{in} - \omega^2 \varepsilon_2 \mu_2\, E^{in} = 0 \quad \text{in } \Omega_2^{\delta,h}, \\ T_2(\omega)(n \wedge E^{in}) - \overrightarrow{\text{curl}}\, E^{in} \wedge n = g^{in} \quad \text{on } \Gamma^{\delta,h}, \\ E^{in} \text{ satisfies the downgoing radiation condition at infinity.} \end{cases}$$

The uniqueness of E^{in} follows from the fact that the boundary condition

$$T_2(\omega)(n \wedge E^{in}) - \overrightarrow{\text{curl}}\, E^{in} \wedge n = 0 \quad \text{on } \Gamma^{\delta,h}$$

implies (from the definition of the operator $T_2(\omega)$) that E^{in} satisfies the outgoing radiation condition. But it also satisfies the downgoing radiation condition, and then

it is a trivial solution. To show the existence of a solution, we make use of the boundary integral equation method. If we make an ansatz for E^{in} in the form

$$E^{in}(x) = -\omega\sqrt{\varepsilon_2\mu_2}\overrightarrow{\mathrm{curl}}\int_{\Gamma^{\delta,h}} a(y)\frac{e^{-i\omega\sqrt{\varepsilon_2\mu_2}|x-y|}}{4\pi|x-y|}ds(y) \quad \text{in } \Omega_2^{\delta,h},$$

where a is a vector in $TH^{1/2}(\mathrm{div},\Gamma^{\delta,h})$, we obtain that a satisfies the following integral equation on $\Gamma^{\delta,h}$:

$$-i\sqrt{\frac{\varepsilon_2}{\mu_2}}n\wedge\overrightarrow{\mathrm{curl}}\overrightarrow{\mathrm{curl}}\int_{\Gamma^{\delta,h}} a(y)\left(\frac{e^{-i\omega\sqrt{\varepsilon_2\mu_2}|x-y|}}{4\pi|x-y|}+\frac{e^{i\omega\sqrt{\varepsilon_2\mu_2}|x-y|}}{4\pi|x-y|}\right)ds(y) = \frac{1}{i\omega\mu_2}\,g^{in},$$

which is of Fredholm type. The existence of E^{in} follows then from the uniqueness. From [2], the Maxwell system

$$\begin{cases} \overrightarrow{\mathrm{curl}}\,E \;=\; i\omega\mu^{\delta}\,H \quad \text{in } \Omega^e, \\ \overrightarrow{\mathrm{curl}}\,H \;=\; -i\omega\varepsilon^{\delta}\,E \quad \text{in } \Omega^e, \\ E-E^{in} \text{ satisfies the outgoing radiation condition at infinity} \end{cases}$$

with the boundary condition $E\wedge n = 0$ on Γ has a unique solution

$$(E,H)\in\Big(H^{1,loc}(O)\Big)^3\times\Big(H^{1,loc}(O)\Big)^3 \quad \text{for all } \overline{O}\subset\Omega_2^{\delta,h}.$$

By construction, the tangential field $n\wedge E\in TH^{1/2}(\Gamma^{\delta,h})$ satisfies

$$L_0(n\wedge E) \;=\; -g^{in}.$$

In order to complete the proof of this lemma, we should verify that $\mathrm{div}_{\Gamma^{\delta,h}}(n\wedge E)$ is in $H^{1/2}(\Gamma^{\delta,h})$. Using the identity

$$\mathrm{div}_{\Gamma^{\delta,h}}(n\wedge E) \;=\; -n\cdot\overrightarrow{\mathrm{curl}}\,E|_{\Gamma^{\delta,h}},$$

we obtain

$$\mathrm{div}_{\Gamma^{\delta,h}}(n\wedge E) \;=\; -i\omega\mu_2\,n\cdot H\in H^{1/2}(\Gamma^{\delta,h}),$$

and then the proof is complete. □

Our next result plays an important role in the proof of the existence and uniqueness results for the Drude–Born–Fedorov equations (2.8).

LEMMA 3.5.

$$\Im m\,(L_t\,g, n\wedge g) \;=\; 0 \Longrightarrow g \;=\; 0 \quad \text{for all } t\in\,[0,1\,]. \tag{3.14}$$

Proof. Multiplying (3.1) by $\overline{e}^{\delta}$ and integrating by parts, we obtain

$$\Im m\,(T_1(\beta,\omega)\,g^{\delta}, n\wedge g^{\delta}) \;=\; 0.$$

Now, multiplying (3.2) by $\overline{v}^{\delta}$ and integrating by parts over $\Omega_{2,R}^{\delta,h} = \Omega_2^{\delta,h}\cap\{r<R\}$ yield

$$\Im m\,(T_2(\omega)\,g^{\delta}, n\wedge g^{\delta}) \;=\; \Im m\,\Big(T_R(\omega)(n\wedge(n\wedge v^{\delta})), n\wedge(n\wedge v^{\delta})\Big),$$

where $T_R(\omega)$ is the pseudodifferential operator on Σ_R given by

$$-n \wedge (n \wedge v^\delta)|_{\Sigma_R} \longmapsto \overrightarrow{\mathrm{curl}}\, v^\delta \wedge n|_{\Sigma_R}.$$

Here v^δ is the solution to the Maxwell equations on $\Omega_2^{\delta,h}$ satisfying the radiation condition. From the property (cf. Appendix A)

$$\Im m\,(T_R(\omega)(n \wedge (n \wedge v^\delta)), n \wedge (n \wedge v^\delta)) = 0 \Longrightarrow n \wedge v^\delta = 0$$

and by the Cauchy–Kowaleska uniqueness theorem, (3.14) holds for all t in $[0,1]$. □

We write the operator L_1 as

$$L_1 = L_0 + \Big(T_1(\beta,\omega) - T_1(\beta=0,\omega)\Big).$$

We show that equation (3.12) is uniquely solvable in $TH^{1/2}(\mathrm{div},\Gamma^{\delta,h})$.

LEMMA 3.6. *Assume that the Maxwell equations*

$$\begin{cases} \overrightarrow{\mathrm{curl}}\,\overrightarrow{\mathrm{curl}}\, u - \omega^2\,\varepsilon_2\,\mu_2\,u = 0 & \text{in } \Omega_1^{\delta,h}, \\ n \wedge u = 0 & \text{on } \Gamma, \\ n \wedge u = 0 & \text{on } \Gamma^{\delta,h} \end{cases}$$

have only the trivial solution in $(H^1(\Omega_1^{\delta,h}))^3$. *Then the operator* $T_1(\beta=0,\omega)-T_1(\beta,\omega)$ *is compact in* $TH^{1/2}(\mathrm{div},\Gamma^{\delta,h})$.

Proof. Let g be in $TH^{1/2}(\mathrm{div},\Gamma^{\delta,h})$. We define v_0 as the unique solution of Maxwell's equations

$$\begin{cases} \overrightarrow{\mathrm{curl}}\,\overrightarrow{\mathrm{curl}}\, v_0 - \omega^2\,\varepsilon_2\,\mu_2\,v_0 = 0 & \text{in } \Omega_1^{\delta,h}, \\ n \wedge v_0 = 0 & \text{on } \Gamma, \\ n \wedge v_0 = g & \text{on } \Gamma^{\delta,h} \end{cases}$$

and v_1 as the unique solution of the following boundary-value problem:

$$\begin{cases} \overrightarrow{\mathrm{curl}}\,\dfrac{1}{\mu^\delta}\,(1-\omega^2\varepsilon^\delta\mu^\delta(\beta^\delta)^2)\,\overrightarrow{\mathrm{curl}}\, v_1 - \omega^2\,\beta^\delta\,\varepsilon^\delta\,\overrightarrow{\mathrm{curl}}\, v_1 \\ -\omega^2\,\overrightarrow{\mathrm{curl}}\,\beta^\delta\,\varepsilon^\delta\,v_1 - \omega^2\,\varepsilon^\delta\,v_1 = 0 & \text{in } \Omega_1^{\delta,h}, \\ n \wedge v_1 = 0 & \text{on } \Gamma, \\ n \wedge v_1 = g & \text{on } \Gamma^{\delta,h}. \end{cases}$$

Therefore,

$$\Big(T_1(\beta=0,\omega) - T_1(\beta,\omega)\Big)\,g = \overrightarrow{\mathrm{curl}}\, v \wedge n,$$

where $v = v_0 - v_1$. v satisfies

$$\begin{cases} \overrightarrow{\mathrm{curl}}\,\overrightarrow{\mathrm{curl}}\, v - \omega^2\,\varepsilon_2\,\mu_2\,v = w & \text{in } \Omega_1^{\delta,h}, \\ n \wedge v = 0 & \text{on } \Gamma, \\ n \wedge v = 0 & \text{on } \Gamma^{\delta,h}, \end{cases}$$

where

$$w = \begin{cases} \omega^2 \varepsilon_2 \mu_2 v_1 - 2(\gamma_1)^2 \beta \overrightarrow{\text{curl}}\, v_1 - (\gamma_1)^2 v_1 & \text{in } \Omega_1^\delta, \\ 0 \quad \text{in } \Omega_1^{\delta,h} \setminus \overline{\Omega_1^\delta}. \end{cases}$$

Since $w = 0$ in a neighborhood of $\Gamma^{\delta,h}$, it follows under the regularity assumption of $\Gamma^{\delta,h}$ that

$$T_1(\beta = 0, \omega) = T_1(\beta, \omega) \bmod OPS^{-\infty}(\Gamma^{\delta,h})$$

(cf. [26]), so the proof of the lemma is over. □

Since the operator L_0 is invertible, the operator L_1 from $TH^{1/2}(\text{div}, \Gamma^{\delta,h})$ into itself satisfies then the Fredholm alternative. From the uniqueness Lemma 3.5, it follows that the mapping L_1 maps $TH^{1/2}(\text{div}, \Gamma^{\delta,h})$ onto $TH^{1/2}(\text{div}, \Gamma^{\delta,h})$. Thus, we have the following theorem.

THEOREM 3.7. *The boundary-value problem* (2.10) *has a unique solution.*

Proof. If E is a solution of (2.10) then $n \wedge E \in TH^{1/2}(\text{div}, \Gamma^{\delta,h})$ is a solution of the integral equation $L_1 u = g^{in}$. Conversely, let g be the unique solution of the above integral equation. Let E be defined by

$$E = \begin{cases} E_1 \quad \text{in } \Omega_1^{\delta,h}, \\ E_2 + E^{in} \quad \text{in } \Omega_2^{\delta,h}, \end{cases}$$

where E_1 is the unique solution of

$$\begin{cases} \overrightarrow{\text{curl}}\, \dfrac{1}{\mu^\delta} (1 - \omega^2 \varepsilon \mu^\delta (\beta^\delta)^2) \overrightarrow{\text{curl}}\, E_1 - \omega^2 \beta^\delta \varepsilon^\delta \overrightarrow{\text{curl}}\, E_1 \\ -\omega^2 \overrightarrow{\text{curl}}\, \beta^\delta \varepsilon^\delta E_1 - \omega^2 \varepsilon^\delta E_1 = 0 \quad \text{in } \Omega_1^{\delta,h}, \\ n \wedge E_1 = 0 \quad \text{on } \Gamma, \\ n \wedge E_1 = g \quad \text{on } \Gamma^{\delta,h}, \end{cases}$$

and E_2 is the unique solution of Maxwell's equations

$$\begin{cases} \overrightarrow{\text{curl}}\, \overrightarrow{\text{curl}} v^\delta - \omega^2 \varepsilon_2 \mu_2 E_2 = 0 \quad \text{in } \Omega_2^{\delta,h}, \\ n \wedge E_2 = g \quad \text{on } \Gamma^{\delta,h}, \\ E_2 \text{ satisfies the outgoing radiation condition at infinity.} \end{cases}$$

It follows that E satisfies equations (2.10); the proof of the theorem is over. □

4. Generalized impedance boundary conditions. In this section, we assume that Ω_1^δ and Ω_2^δ are filled with materials in such a way that the magnetic permeability μ^δ satisfies

$$\mu^\delta = \begin{cases} \mu_1 \quad \text{in } \Omega_1^\delta, \\ \mu_2 \quad \text{in } \Omega_2^\delta, \end{cases} \tag{4.1}$$

the dielectric coefficient ε^δ satisfies

$$\varepsilon^\delta = \begin{cases} \varepsilon_1 \quad \text{in } \Omega_1^\delta, \\ \varepsilon_2 \quad \text{in } \Omega_2^\delta, \end{cases} \tag{4.2}$$

and the chirality admittance β^δ satisfies

$$\beta^\delta = \begin{cases} \beta_1 = \beta & \text{in } \Omega_1^\delta, \\ \beta_2 = 0 & \text{in } \Omega_2^\delta, \end{cases} \tag{4.3}$$

where $\mu_1, \mu_2, \varepsilon_1, \varepsilon_2$ are positive constants such that $\mu_1 \neq \mu_2, \varepsilon_1 \neq \varepsilon_2$ and β is a real constant.

Setting

$$E_j^\delta = E^\delta|_{\Omega_j^\delta}, \quad (j = 1, 2),$$

the equations (2.8) yield

$$\overrightarrow{\operatorname{curl}}\,\overrightarrow{\operatorname{curl}} E_1^\delta - 2\gamma_1^2\,\beta\,\overrightarrow{\operatorname{curl}}\,E_1^\delta - \gamma_1^2\,E_1^\delta = 0 \quad \text{in } \Omega_1^\delta \tag{4.4}$$

and

$$\overrightarrow{\operatorname{curl}}\,\overrightarrow{\operatorname{curl}} E_2^\delta - \omega^2\,\varepsilon_2\,\mu_2\,E_2^\delta = 0 \quad \text{in } \Omega_2^\delta. \tag{4.5}$$

The weak form of the Maxwell equations in a neighborhood of Γ^δ gives the following jump relations on Γ^δ:

$$\begin{cases} \left(E_1^\delta - E_2^\delta\right) \wedge n = 0, \\ \left(\overrightarrow{\operatorname{curl}}\,E_1^\delta - \dfrac{1}{\mu_c}\overrightarrow{\operatorname{curl}}\,E_2^\delta\right) \wedge n = \beta\,(\gamma_1)^2\,E_1^\delta \wedge n, \end{cases} \tag{4.6}$$

where n is the normal to Γ^δ and μ_c defined by $\mu_c = \mu_2\,(1 - \omega^2\varepsilon_1\mu_1\beta^2)/\mu_1$.

The purpose of this section is to derive approximative impedance conditions useful to performing numerical calculations of the scattered field by the chiral layer. Our program is as follows. First, we derive these approximative impedance conditions. Then, we establish the existence and uniqueness of a solution $\mathcal{E}^\delta$ to the Maxwell equations in Ω_2^δ satisfying the radiation condition with these new boundary conditions on Γ^δ. Finally, by using a simple continuity argument, error estimates between $E_2^\delta - E^{in}$ and $\mathcal{E}^\delta$ are proved.

Using Lemma 2.1, it follows that

$$\overrightarrow{\operatorname{curl}}\,E_1^\delta \wedge n = \frac{\partial}{\partial s}E_{\Gamma_s^\delta}^\delta - \overrightarrow{\operatorname{grad}}_{\Gamma_s^\delta}(E_1^\delta \cdot n) + \mathcal{R}(E_{\Gamma_s^\delta}^\delta). \tag{4.7}$$

The remarkable identity (2.1) yields

$$\overrightarrow{\operatorname{curl}}\,H_1^\delta \cdot n = \operatorname{curl}_{\Gamma_s^\delta} H_{\Gamma_s^\delta}^\delta = \operatorname{div}_{\Gamma_s^\delta}(H_1^\delta \wedge n). \tag{4.8}$$

Since $E_1^\delta \wedge n = 0$ on Γ^δ, by integrating the identity (4.7) we obtain

$$E_{\Gamma^\delta}^\delta(x_{\Gamma^\delta}) = \int_{-\delta}^0 \overrightarrow{\operatorname{curl}}\,E_1^\delta \wedge n\,ds + \int_{-\delta}^0 \overrightarrow{\operatorname{grad}}_{\Gamma_s^\delta}(E_1^\delta \cdot n)\,ds - \int_{-\delta}^0 \mathcal{R}(E_{\Gamma_s^\delta}^\delta)\,ds. \tag{4.9}$$

(2.8) gives

$$\overrightarrow{\operatorname{curl}}\,E_1^\delta \wedge n = (\gamma_1)^2\,\beta\,E_1^\delta \wedge n + i\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2 H_1^\delta \wedge n. \tag{4.10}$$

Combining (4.9) and (4.10) gives

$$\begin{aligned} E^\delta_{\Gamma^\delta}(x_{\Gamma^\delta}) &= \delta\,(\gamma_1)^2\,\beta\,E^\delta_1 \wedge n + i\delta\,\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2 H^\delta_1 \wedge n \\ &\quad +\delta\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}(E^\delta_1(x_{\Gamma^\delta})\cdot n) + 0(\delta^2). \end{aligned} \tag{4.11}$$

Now, from

$$\operatorname{div}_{\Gamma^\delta}(H^\delta_1 \wedge n) = (\gamma_1)^2\beta\,H^\delta_1\cdot n - i\omega\varepsilon_1\left(\frac{\gamma_1}{k_1}\right)^2 E^\delta_1\cdot n \tag{4.12}$$

and

$$\operatorname{div}_{\Gamma^\delta}(E^\delta_1 \wedge n) = (\gamma_1)^2\beta\,E^\delta_1\cdot n + i\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2 H^\delta_1\cdot n, \tag{4.13}$$

it is easily seen that

$$E^\delta_1\cdot n = \frac{i}{\omega\varepsilon_1}\operatorname{div}_{\Gamma^\delta}(H^\delta_1\wedge n) - \beta\operatorname{div}_{\Gamma^\delta}(E^\delta_1\wedge n). \tag{4.14}$$

It follows that

$$\begin{aligned} -n\wedge(n\wedge E^\delta_2) &= i\delta\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2 H^\delta_2\wedge n + \frac{i\delta}{\omega\varepsilon_1}\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(H^\delta_2\wedge n) \\ &\quad -\delta\beta\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(E^\delta_2\wedge n) + 0(\delta^2). \end{aligned} \tag{4.15}$$

In the case of achiral thin layer of dielectric material, (4.15) is reduced to the impedance boundary condition obtained by Engquist and Nédélec [13]:

$$-n\wedge(n\wedge E^\delta_2) = i\delta\omega\mu_1\,H^\delta_2\wedge n + \frac{i\delta}{\omega\varepsilon_1}\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(H^\delta_2\wedge n) + 0(\delta^2). \tag{4.16}$$

Our aim is to prove the existence and uniqueness of $\mathcal{E}^\delta$ and $\mathcal{H}^\delta$ solutions to the Maxwell equations

$$\begin{cases} \overrightarrow{\operatorname{curl}}\,\mathcal{E}^\delta = i\omega\,\mu_2\,\mathcal{H}^\delta & \text{in } \Omega^\delta_2, \\ \overrightarrow{\operatorname{curl}}\,\mathcal{H}^\delta = -i\omega\,\varepsilon_2\,\mathcal{E}^\delta & \text{in } \Omega^\delta_2, \end{cases} \tag{4.17}$$

with the new boundary conditions given as

$$\begin{aligned} &n\wedge(n\wedge\mathcal{E}^\delta) + i\delta\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\mathcal{H}^\delta\wedge n + \frac{i\delta}{\omega\varepsilon_1}\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(\mathcal{H}^\delta\wedge n) \\ &-\delta\beta\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(\mathcal{E}^\delta\wedge n) = g^\delta \quad \text{on } \Gamma^\delta, \end{aligned} \tag{4.18}$$

where g^δ is a known smooth vector field and $\mathcal{E}^\delta$ and $\mathcal{H}^\delta$ satisfy the radiation condition at infinity. First, we prove the following uniqueness result.

LEMMA 4.1. *Assume $\beta = 0$. Then, the Maxwell system* (4.17) *with the boundary conditions* (4.18) *has at most one solution.*

Proof. Let $\mathcal{E}^\delta$ and $\mathcal{H}^\delta$ satisfy (4.17) with the following boundary conditions on Γ^δ:

$$n \wedge (n \wedge \mathcal{E}^\delta) + i\delta\omega\mu_1 \mathcal{H}^\delta \wedge n + \frac{i\delta}{\omega\varepsilon_1} \overrightarrow{\mathrm{grad}}_{\Gamma^\delta} \mathrm{div}_{\Gamma^\delta} (\mathcal{H}^\delta \wedge n) = 0 \quad \text{on } \Gamma^\delta, \tag{4.19}$$

and the radiation condition at infinity. Direct computation yields

$$\int_{\Omega^\delta_{2,R}} |\overrightarrow{\mathrm{curl}}\, \mathcal{E}^\delta|^2 - \omega^2 \varepsilon_2\mu_2 \int_{\Omega^\delta_{2,R}} |\mathcal{E}^\delta|^2 + \delta\omega^2\mu_1\,\mu_2 \int_{\Gamma^\delta} |\mathcal{H}^\delta \wedge n|^2$$
$$-\frac{\delta\,\mu_2}{\varepsilon_1} \int_{\Gamma^\delta} |\mathrm{div}_{\Gamma^\delta} (\mathcal{H}^\delta \wedge n)|^2 + i\omega\,\mu_2 \int_{\Sigma_R} (\mathcal{H}^\delta \wedge n) \cdot \overline{\mathcal{E}}^\delta = 0.$$

By taking the imaginary part in the above expression, we obtain

$$\Re e\Big(\int_{\Sigma_R} (\mathcal{H}^\delta \wedge n) \cdot \overline{\mathcal{E}}^\delta \Big) = 0. \tag{4.20}$$

Classical arguments, based on the Cauchy–Kowaleska uniqueness theorem and the well-known properties of the pseudodifferential operator $T_R(\omega)$ (cf. Appendix A), ensure that $\mathcal{E}^\delta = 0$ and $\mathcal{H}^\delta = 0$ in $\Omega^\delta_{2,R}$, and the proof of the uniqueness of a solution to (4.17) with the boundary conditions (4.19) is complete. □

Lemma 4.1 provides a proof of the uniqueness of the solution to the Maxwell system (4.17) with the approximative impedance condition written by Engquist and Nédélec.

LEMMA 4.2. *The Maxwell system* (4.17) *with the boundary conditions*

$$\begin{aligned} &n \wedge (n \wedge \mathcal{E}^\delta) + i\delta\omega\mu_1 \left(\frac{\gamma_1}{k_1}\right)^2 \mathcal{H}^\delta \wedge n + \frac{i\delta}{\omega\varepsilon_1} \overrightarrow{\mathrm{grad}}_{\Gamma^\delta} \mathrm{div}_{\Gamma^\delta} (\mathcal{H}^\delta \wedge n) \\ &-\delta\beta \overrightarrow{\mathrm{grad}}_{\Gamma^\delta} \mathrm{div}_{\Gamma^\delta} (\mathcal{E}^\delta \wedge n) = 0 \quad \text{on } \Gamma^\delta \end{aligned} \tag{4.21}$$

has nontrivial solutions only if μ_1 belongs to a countable set of exceptional values.

Proof. We introduce the scalar three-dimensional fundamental solution corresponding to ω as

$$\Phi(x,y) = \frac{e^{i\omega\sqrt{\varepsilon_2\mu_2}|x-y|}}{4\pi|x-y|}, \quad x \neq y.$$

Let

$$u^\delta = \mathcal{H}^\delta \wedge n.$$

The electric field $\mathcal{E}^\delta$ has the following integral representation:

$$\begin{aligned} \mathcal{E}^\delta(x) &= -\frac{i}{\omega\varepsilon_2} \overrightarrow{\mathrm{grad}} \int_{\Gamma^\delta} \Phi(x-y)\, \mathrm{div}_{\Gamma^\delta} u^\delta(y)\, d\gamma(y) \\ &\quad -i\omega\mu_2 \int_{\Gamma^\delta} \Phi(x-y)\, u^\delta(y)\, d\gamma(y) \\ &\quad + \overrightarrow{\mathrm{curl}} \int_{\Gamma^\delta} n(y) \wedge \mathcal{E}^\delta(y)\, \Phi(x-y)\, d\gamma(y). \end{aligned} \tag{4.22}$$

From

$$\begin{aligned}\overrightarrow{\mathrm{curl}}\,\mathcal{E}^\delta\cdot n &= -\mathrm{curl}_{\Gamma^\delta}\Big(n\wedge(n\wedge\mathcal{E}^\delta)\Big)\\ &= i\delta\,\omega\,\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\mathrm{curl}_{\Gamma^\delta}\,u^\delta,\end{aligned}$$

we deduce that

$$\begin{aligned}n\wedge\mathcal{E}^\delta &= i\delta\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2 n\wedge u^\delta+\frac{i\delta}{\omega\varepsilon_1}\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\mathrm{div}_{\Gamma^\delta}\,u^\delta\\ &\quad +i\delta^2\,\beta\,\omega\,\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\mathrm{curl}_{\Gamma^\delta}\,u^\delta,\end{aligned}\tag{4.23}$$

and then

$$\mathrm{div}_{\Gamma^\delta}\,(n\wedge\mathcal{E}^\delta)=i\delta\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\mathrm{div}_{\Gamma^\delta}\,(n\wedge u^\delta).$$

We rewrite the approximative impedance conditions (4.21) as

$$\begin{aligned}&n\wedge(n\wedge\mathcal{E}^\delta)+i\delta\,\omega\,\mu_1\left(\frac{\gamma_1}{k_1}\right)^2 u^\delta+\frac{i\delta}{\omega\varepsilon_1}\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\mathrm{div}_{\Gamma^\delta}\,(u^\delta)\\ &-i\delta^2\omega\mu_1\beta\left(\frac{\gamma_1}{k_1}\right)^2\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,(\mathrm{div}_{\Gamma^\delta}\,(u^\delta\wedge n))=0.\end{aligned}\tag{4.24}$$

Now, multiplying (4.24) by v^δ and integrating by parts on Γ^δ yields

$$\begin{aligned}&\int_{\Gamma^\delta}\mathcal{E}^\delta(x)\cdot v^\delta(x)\,d\gamma(x)=i\delta\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\int_{\Gamma^\delta}u^\delta(x)\cdot v^\delta(x)\,d\gamma(x)\\ &-\frac{i\delta}{\omega\varepsilon_1}\int_{\Gamma^\delta}\mathrm{div}_{\Gamma^\delta}u^\delta(x)\,\mathrm{div}_{\Gamma^\delta}\,v^\delta(x)\,d\gamma(x)\\ &+i\delta^2\,\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\beta\int_{\Gamma^\delta}\mathrm{div}_{\Gamma^\delta}\,v^\delta(x)\,\mathrm{div}_{\Gamma^\delta}\,(u^\delta(x)\wedge n(x))\,d\gamma(x).\end{aligned}$$

From the integral representation (4.22) it is easily seen that

$$\begin{aligned}&\frac12\int_{\Gamma^\delta}\mathcal{E}^\delta(x)\cdot v^\delta(x)\,d\gamma(x)=\frac{i}{\omega\varepsilon_2}\int_{\Gamma^\delta}\int_{\Gamma^\delta}\Phi(x-y)\,\mathrm{div}_{\Gamma^\delta}\,u^\delta(y)\,\mathrm{div}_{\Gamma^\delta}\,v^\delta(x)\,d\gamma(y)\,d\gamma(x)\\ &-i\omega\mu_2\int_{\Gamma^\delta}\int_{\Gamma^\delta}\Phi(x-y)\,u^\delta(y)\cdot v^\delta(x)\,d\gamma(y)\,d\gamma(x)\\ &+\int_{\Gamma^\delta}\Big(\overrightarrow{\mathrm{curl}}\int_{\Gamma^\delta}n(y)\wedge\mathcal{E}^\delta(y)\,\Phi(x-y)\,d\gamma(y)\Big)\cdot v^\delta(x)\,d\gamma(x).\end{aligned}\tag{4.25}$$

Then, we obtain that

$$
\begin{aligned}
&\frac{2i}{\omega\varepsilon_2}\int_{\Gamma^\delta}\int_{\Gamma^\delta}\Phi(x-y)\,\mathrm{div}_{\Gamma^\delta}\,u^\delta(y)\,\mathrm{div}_{\Gamma^\delta}\,v^\delta(x)\,d\gamma(y)\,d\gamma(x)\\
&-2i\omega\mu_2\int_{\Gamma^\delta}\int_{\Gamma^\delta}\Phi(x-y)\,u^\delta(y)\,\cdot\,v^\delta(x)\,d\gamma(y)\,d\gamma(x)\\
&+2\int_{\Gamma^\delta}\Big(\overrightarrow{\mathrm{curl}}\int_{\Gamma^\delta}n(y)\,\wedge\,\mathcal{E}^\delta(y)\,\Phi(x-y)\,d\gamma(y)\Big)\,\cdot\,v^\delta(x)\,d\gamma(x)\\
&=i\delta\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\int_{\Gamma^\delta}u^\delta(x)\,\cdot\,v^\delta(x)\,d\gamma(x)-\frac{i\delta}{\omega\varepsilon_1}\int_{\Gamma^\delta}\mathrm{div}_{\Gamma^\delta}u^\delta(x)\mathrm{div}_{\Gamma^\delta}\,v^\delta(x)\,d\gamma(x)\\
&+i\delta^2\,\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\beta\int_{\Gamma^\delta}\mathrm{div}_{\Gamma^\delta}\,v^\delta(x)\,\mathrm{div}_{\Gamma^\delta}\,(u^\delta(x)\,\wedge\,n(x))\,d\gamma(x).
\end{aligned}
\tag{4.26}
$$

We seek u^δ in $TH^1(\Gamma^\delta)\,=\,\{c\in(H^1(\Gamma^\delta))^3, c\,.\,n\,=\,0\,\}$ such that (4.26) holds for all tangential fields $v^\delta\,\in\,TH^1(\Gamma^\delta)$. We use the following decomposition of the space $TH^1(\Gamma^\delta)$.

LEMMA 4.3. $TH^1(\Gamma^\delta)\,=\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,H^2(\Gamma^\delta)\,\oplus\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,H^2(\Gamma^\delta)$.

The proof of this lemma is exactly the same as in [19] for the space

$$
TH^{-1/2}(\mathrm{div},\Gamma^\delta)\,=\Big\{c\in(H^{-1/2}(\Gamma^\delta))^3, c\,\cdot\,n=0, \mathrm{div}_{\Gamma^\delta}\,c\in H^{-1/2}(\Gamma^\delta)\Big\}.
$$

We decompose the tangential fields u^δ and v^δ as follows:

$$
\left\{\begin{array}{l}
u^\delta\;=\;\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi^\delta+\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\varphi^\delta,\\
v^\delta\;=\;\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi^\delta_t+\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\varphi^\delta_t.
\end{array}\right.
$$

(4.26) leads to the following equation:

$$
\begin{aligned}
&\frac{i\delta}{\omega\varepsilon_1}\int_{\Gamma^\delta}\Delta_{\Gamma^\delta}\,\psi^\delta(x)\,\Delta_{\Gamma^\delta}\,\psi^\delta_t(x)\,d\gamma(x)\\
&+\frac{2i}{\omega\varepsilon_2}\int_{\Gamma^\delta}\int_{\Gamma^\delta}\Phi(x-y)\,\Delta_{\Gamma^\delta}\,\psi^\delta(y)\,\Delta_{\Gamma^\delta}\,\psi^\delta_t(x)\,d\gamma(y)\,d\gamma(x)\\
&-2i\omega\mu_2\int_{\Gamma^\delta}\int_{\Gamma^\delta}\Phi(x-y)\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi^\delta(y)\,\cdot\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi^\delta_t(x)\,d\gamma(y)\,d\gamma(x)\\
&-2i\omega\mu_2\int_{\Gamma^\delta}\int_{\Gamma^\delta}\Phi(x-y)\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\varphi^\delta(y)\,\cdot\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi^\delta_t(x)\,d\gamma(y)\,d\gamma(x)\\
&+2\int_{\Gamma^\delta}(\mathcal{R}(x)-2c(x))\Big\{\int_{\Gamma^\delta}\Big(i\delta\omega\mu_1\,(-\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\psi^\delta(y)+\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\varphi^\delta(y))
\end{aligned}
$$

$$+\frac{i\delta}{\omega\varepsilon_1}\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\Delta_{\Gamma^\delta}\,\psi^\delta(y)\Big)\,\Phi(x-y)\,d\gamma(y)\,\wedge\,n(x)\Big\}\,\cdot\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi_t^\delta(x)\,d\gamma(x)$$

$$-i\delta^2\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\beta\int_{\Gamma^\delta}(\mathcal{R}(x)-2c(x))\Big(\int_{\Gamma^\delta}\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\Delta_{\Gamma^\delta}\,\varphi^\delta(y)$$

$$\Phi(x-y)\,d\gamma(y)\,\wedge\,n(x)\Big)\,\cdot\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi_t^\delta(x)\,d\gamma(x)$$

$$+i\delta\omega\mu_1\int_{\Gamma^\delta}\int_{\Gamma^\delta}\frac{\partial\Phi}{\partial n_x}(x-y)\,(-\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\psi^\delta(y)+\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\varphi^\delta(y))\,\cdot\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\psi_t^\delta(x)\,d\gamma(y)\,d\gamma(x)$$

$$+\frac{i\delta}{\omega\varepsilon_1}\int_{\Gamma^\delta}\int_{\Gamma^\delta}\frac{\partial\Phi}{\partial n_x}(x-y)\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\Delta_{\Gamma^\delta}\,\psi^\delta(y)\,\cdot\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\psi_t^\delta(x)\,d\gamma(y)\,d\gamma(x)$$

$$-i\delta^2\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\beta\int_{\Gamma^\delta}\int_{\Gamma^\delta}\frac{\partial\Phi}{\partial n_x}(x-y)\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\Delta_{\Gamma^\delta}\,\varphi^\delta(y)\,\cdot\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\psi_t^\delta(x)\,d\gamma(y)\,d\gamma(x)$$

$$+i\delta^2\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\beta\int_{\Gamma^\delta}\Delta_{\Gamma^\delta}\,\varphi^\delta(x)\,\Delta_{\Gamma^\delta}\,\psi_t^\delta(x)\,d\gamma(x)$$

$$-i\delta\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\int_{\Gamma^\delta}\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi^\delta(x)\,\cdot\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi_t^\delta(x)\,d\gamma(x)\,=\,0.$$

By multiplying (4.23) by $\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\varphi_t^\delta$, integrating by parts, and using (4.25), we obtain

$$i\delta^2\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\beta\int_{\Gamma^\delta}\Delta_{\Gamma^\delta}\,\varphi^\delta(x)\,\cdot\,\Delta_{\Gamma^\delta}\,\varphi_t^\delta(x)\,d\gamma(x)$$

$$-i\delta\omega\mu_1\int_{\Gamma^\delta}\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\varphi^\delta(x)\,\cdot\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\varphi_t^\delta(x)\,d\gamma(x)$$

$$=\frac{2i}{\omega\varepsilon_2}\int_{\Gamma^\delta}\int_{\Gamma^\delta}\Phi(x-y)\,\Delta_{\Gamma^\delta}\,\psi^\delta(y)\,\Delta_{\Gamma^\delta}\,\varphi_t^\delta(x)\,d\gamma(x)\,d\gamma(y)$$

$$-2i\omega\mu_2\int_{\Gamma^\delta}\int_{\Gamma^\delta}\Phi(x-y)\,(\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi^\delta(y)+\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\varphi^\delta(y))\,\cdot\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\varphi_t^\delta(x)\,d\gamma(x)\,d\gamma(y)$$

$$+2\int_{\Gamma^\delta}(\mathcal{R}(x)-2c(x))\Big\{\int_{\Gamma^\delta}\Big(i\delta\omega\mu_1\,(-\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\psi^\delta(y)+\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\varphi^\delta(y))$$

$$+\frac{i\delta}{\omega\varepsilon_1}\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\Delta_{\Gamma^\delta}\,\psi^\delta(y)\Big)\,\Phi(x-y)\,d\gamma(y)\,\wedge\,n(x)\Big\}\,\cdot\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\varphi_t^\delta(x)\,d\gamma(x)$$

$$-i\delta^2\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\beta\int_{\Gamma^\delta}(\mathcal{R}(x)-2c(x))\Big(\int_{\Gamma^\delta}\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\Delta_{\Gamma^\delta}\,\varphi^\delta(y)$$

$$\Phi(x-y)\,d\gamma(y)\,\wedge\,n(x)\Big)\,\cdot\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\varphi_t^\delta(x)\,d\gamma(x)$$

$$-i\delta\omega\mu_1\int_{\Gamma^\delta}\int_{\Gamma^\delta}\frac{\partial\Phi}{\partial n_x}(x-y)\,(-\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\psi^\delta(y)+\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\varphi^\delta(y))\,\cdot\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\varphi_t^\delta(x)\,d\gamma(y)\,d\gamma(x)$$

$$-\frac{i\delta}{\omega\varepsilon_1}\int_{\Gamma^\delta}\int_{\Gamma^\delta}\frac{\partial\Phi}{\partial n_x}(x-y)\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\Delta_{\Gamma^\delta}\,\psi^\delta(y)\,\cdot\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\varphi_t^\delta(x)\,d\gamma(y)\,d\gamma(x)$$

$$+i\delta^2\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\beta\int_{\Gamma^\delta}\int_{\Gamma^\delta}\frac{\partial\Phi}{\partial n_x}(x-y)\,\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\Delta_{\Gamma^\delta}\,\varphi^\delta(y)\,\cdot\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\varphi_t^\delta(x)\,d\gamma(y)\,d\gamma(x).$$

Straightforward computations give that the system of the above two equations leads

to a compact perturbation of the coercive form

$$\begin{pmatrix} \dfrac{1}{\omega\varepsilon_1}\displaystyle\int_{\Gamma^\delta} \Delta_{\Gamma^\delta}\,\psi^\delta(x)\,\Delta_{\Gamma^\delta}\,\psi_t^\delta(x)\,d\gamma(x) & \delta\omega\mu_1\left(\dfrac{\gamma_1}{k_1}\right)^2\beta\displaystyle\int_{\Gamma^\delta}\Delta_{\Gamma^\delta}\,\varphi^\delta(x)\,\Delta_{\Gamma^\delta}\,\psi_t^\delta(x)\,d\gamma(x) \\ 0 & \omega\mu_1\delta\left(\dfrac{\gamma_1}{k_1}\right)^2\beta\displaystyle\int_{\Gamma^\delta}\Delta_{\Gamma^\delta}\,\varphi^\delta(x)\,\Delta_{\Gamma^\delta}\,\varphi_t^\delta(x)\,d\gamma(x) \end{pmatrix}$$

on $H^2(\Gamma^\delta)/\mathbb{C}\times H^2(\Gamma^\delta)/\mathbb{C}$.

Now, we write the approximative impedance conditions (4.24) in the following form:

$$\begin{aligned} &n\wedge(n\wedge\mathcal{E}^\delta)+i\delta\,\omega\,u^\delta+\frac{i\delta}{\omega\varepsilon_1}\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(u^\delta)\\ &-\delta\beta\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\left(\overrightarrow{\operatorname{curl}}\,\mathcal{E}^\delta\cdot n\right)=-i\delta\,\omega\left(\mu_1\left(\frac{\gamma_1}{k_1}\right)^2-1\right)u^\delta. \end{aligned} \tag{4.27}$$

The above computations show that u^δ appears in (4.27) as an eigenvector of a compact perturbation of an invertible operator and

$$-i\delta\,\omega\left(\mu_1\left(\frac{\gamma_1}{k_1}\right)^2-1\right)$$

is its eigenvalue. Since the operator

$$\begin{aligned} &u^\delta\longmapsto n\wedge(n\wedge\mathcal{E}^\delta)+i\delta\,\omega\,u^\delta+\frac{i\delta}{\omega\varepsilon_1}\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(u^\delta)\\ &-\delta\beta\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\left(\overrightarrow{\operatorname{curl}}\,\mathcal{E}^\delta\cdot n\right) \end{aligned}$$

is independent of μ_1, the proof of the uniqueness Lemma 4.2 is then over. □

The proof of Lemma 4.2 also shows the existence of solutions to our boundary-value problem. Now, we use the boundary integral equation method to obtain optimal error estimates. We make an ansatz for $\mathcal{E}^\delta$ and $\mathcal{H}^\delta$ in the form

$$\begin{cases} \mathcal{E}^\delta(x)=\omega\sqrt{\varepsilon_2\mu_2}\,\overrightarrow{\operatorname{curl}}\displaystyle\int_{\Gamma^\delta}a(y)\,\Phi(x,y)\,ds(y) & \text{in } \Omega_2^\delta,\\ \mathcal{H}^\delta(x)=\dfrac{1}{i\omega\mu_2}\,\overrightarrow{\operatorname{curl}}\,\mathcal{E}^\delta(x) & \text{in } \Omega_2^\delta, \end{cases} \tag{4.28}$$

where a is a vector function in $TH^2(\Gamma^\delta)=\{c\in(H^2(\Gamma^\delta))^3, c\cdot n=0\}$. From the properties of Φ, we see that $(\mathcal{E}^\delta,\mathcal{H}^\delta)$ satisfy the Maxwell equations (4.17) and the radiation condition. The tangential components of $\mathcal{E}^\delta$ and $\mathcal{H}^\delta$ on Γ^δ take the form

$$\begin{aligned} n\wedge\mathcal{E}^\delta(x) &= \omega\sqrt{\varepsilon_2\mu_2}\,n\wedge\int_{\Gamma^\delta}\overrightarrow{\operatorname{curl}}_x(a(y)\,\Phi(x,y))\,ds(y)\\ &\quad+\tfrac{\omega}{2}\sqrt{\varepsilon_2\mu_2}\,a(x),\quad x\in\Gamma^\delta,\\ n\wedge\mathcal{H}^\delta(x) &= -i\sqrt{\frac{\varepsilon_2}{\mu_2}}\,n\wedge\overrightarrow{\operatorname{curl}}\,\overrightarrow{\operatorname{curl}}\int_{\Gamma^\delta}a(y)\,\Phi(x,y)\,ds(y),\quad x\in\Gamma^\delta. \end{aligned} \tag{4.29}$$

The boundary conditions (4.29) for $\mathcal{E}^\delta$ and $\mathcal{H}^\delta$ will lead to an integral equation on Γ^δ for the unknown vector a. In order to write it, we introduce the following boundary

operators:

$$
\begin{aligned}
Q(a)(x) &= n \wedge a(x), \quad x \in \Gamma^\delta,\\
M(a)(x) &= n \wedge \overrightarrow{\operatorname{curl}} \int_{\Gamma^\delta} a(y)\,\Phi(x,y)\,ds(y), \quad x \in \Gamma^\delta,\\
N(a)(x) &= n \wedge \int_{\Gamma^\delta} a(y)\,\Phi(x,y)\,ds(y), \quad x \in \Gamma^\delta,\\
P(a)(x) &= n \wedge \overrightarrow{\operatorname{curl}}\,\overrightarrow{\operatorname{curl}} \int_{\Gamma^\delta} a(y)\,\Phi(x,y)\,ds(y), \quad x \in \Gamma^\delta.
\end{aligned}
$$

Then, (4.18) leads to

$$
\begin{aligned}
&\frac{1}{2}\,\delta\,\beta\,\sqrt{\varepsilon_2\mu_2}\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} a - \frac{\delta}{\omega}\sqrt{\frac{\varepsilon_2}{\mu_2}}\,\frac{1}{\omega\varepsilon_1}\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} Pa\\
&+\delta\,\beta\,\sqrt{\varepsilon_2\mu_2}\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} Ma + \delta\,\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\sqrt{\frac{\varepsilon_2}{\mu_2}}\,Pa\\
&+\frac{\sqrt{\varepsilon_2\mu_2}}{2}\,Qa + \sqrt{\varepsilon_2\mu_2}\,QMa = g^\delta \in TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta),
\end{aligned}
\tag{4.30}
$$

where $TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta) = \{c \in (L^2(\Gamma^\delta))^3, c\cdot n = 0, \operatorname{curl}_{\Gamma^\delta} c \in H^1(\Gamma^\delta)\}$. Thus we have the following theorem.

THEOREM 4.4. *The vector function $a \in TH^2(\Gamma^\delta)$ is a solution of the integral equation* (4.30) *if and only if the fields $(\mathcal{E}^\delta,\mathcal{H}^\delta)$ satisfy the boundary conditions* (4.18).

In order to discuss the solvability of the integral equation (4.30), we compute $\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} P\,a, \overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} M\,a$, $\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} N\,a$, $\operatorname{curl}_{\Gamma^\delta} P\,a$ and $\operatorname{curl}_{\Gamma^\delta} QM\,a$. Direct computation yields

$$
\begin{aligned}
\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} P\,a &= \overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(a\wedge n) - \omega^2\sqrt{\varepsilon_2\mu_2}\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} N\,a,\\
&= \overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{curl}_{\Gamma^\delta} a - \omega^2\sqrt{\varepsilon_2\mu_2}\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} N\,a,
\end{aligned}
\tag{4.31}
$$

$$
\begin{aligned}
\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} M\,a &= -\frac{\partial}{\partial s}\Big(n\wedge\Big(n\wedge\overrightarrow{\operatorname{curl}}\overrightarrow{\operatorname{curl}}\int_{\Gamma^\delta} a\,\Phi\Big)\Big) + \omega^2\,\varepsilon_2\,\mu_2\,n\wedge\overrightarrow{\operatorname{curl}}\int_{\Gamma^\delta} a\,\Phi\\
&\quad -n\wedge\overrightarrow{\operatorname{curl}}\,a,\\
&= -i\sqrt{\frac{\mu_2}{\varepsilon_2}}\,\frac{\partial}{\partial s}\Big(n\wedge(n\wedge\mathcal{H}^\delta)\Big) + \omega\sqrt{\varepsilon_2\,\mu_2}\,n\wedge\mathcal{E}^\delta - n\wedge\overrightarrow{\operatorname{curl}}\,a,
\end{aligned}
\tag{4.32}
$$

$$
\begin{aligned}
\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta} N\,a &= \overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\Big(\overrightarrow{\operatorname{curl}}\int_{\Gamma^\delta} a\,\Phi\cdot n\Big),\\
&= \frac{1}{\omega\sqrt{\varepsilon_2\mu_2}}\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}(\mathcal{E}^\delta\cdot n),
\end{aligned}
\tag{4.33}
$$

$$
\begin{aligned}
\operatorname{curl}_{\Gamma^\delta} P\,a &= \operatorname{curl}_{\Gamma^\delta}\Big(n\wedge\Big(\mathcal{R} - 2c - \frac{\partial}{\partial n}\Big)\\
&\quad\Big\{-\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\Big(\int_{\Gamma^\delta} a(y)\cdot(n(x)-n(y))\Phi(x-y)\,ds(y)\Big)\\
&\quad -\mathcal{R}\Big(n\wedge\Big(n\wedge\int_{\Gamma^\delta} a\Phi\Big)\Big) + \frac{\partial}{\partial n}\Big(n\wedge\Big(n\wedge\int_{\Gamma^\delta} a\Phi\Big)\Big)\Big\}\Big)
\end{aligned}
\tag{4.34}
$$

$$\text{(4.35)}\quad \mathrm{curl}_{\Gamma^\delta} QM\,a \;=\; \mathrm{curl}_{\Gamma^\delta}\Big(n\wedge\int_{\Gamma^\delta}(\mathcal{R}-2c)(a\wedge n)\Phi-\int_{\Gamma^\delta} a\wedge n\frac{\partial\Phi}{\partial n_x}\Big).$$

Now, we write the integral equation (4.30) as follows:

$$\Big(L^\delta+K^\delta\Big)a\;=\;g^\delta, \tag{4.36}$$

where

$$L^\delta\,a\;=\;\frac{1}{2}\delta\,\beta\,\sqrt{\varepsilon_2\mu_2}\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\mathrm{div}_{\Gamma^\delta}\,a-\frac{\delta}{\omega}\sqrt{\frac{\varepsilon_2}{\mu_2}}\,\frac{1}{\omega\varepsilon_1}\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\mathrm{div}_{\Gamma^\delta}\,(a\wedge n) \tag{4.37}$$

and

$$\begin{aligned} K^\delta\,a \;&=\; \delta\,\frac{\varepsilon_2}{\varepsilon_1}\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\mathrm{div}_{\Gamma^\delta}\,N\,a+\delta\,\beta\,\sqrt{\varepsilon_2\mu_2}\,\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\mathrm{div}_{\Gamma^\delta}\,M\,a\\ &\quad+\sqrt{\varepsilon_2\mu_2}\,QM\,a+\delta\,\mu_1\,\left(\frac{\gamma_1}{k_1}\right)^2\sqrt{\frac{\varepsilon_2}{\mu_2}}\,P\,a+\frac{\sqrt{\varepsilon_2\mu_2}}{2}\,Q\,a. \end{aligned} \tag{4.38}$$

We treat this equation in the spaces

$$L^\delta+K^\delta\;:TH^2(\Gamma^\delta)\longmapsto TL^2(\mathrm{curl}_{\Gamma^\delta},\Gamma^\delta).$$

From (4.31)–(4.35), it is clear that $\mathrm{curl}_{\Gamma^\delta}\,K^\delta\,a\in H^2(\Gamma^\delta)$ and

$$K^\delta\,a\in TH^1(\Gamma^\delta)=\Big\{c\in(H^1(\Gamma^\delta))^3, c\cdot n=0\Big\}$$

for $a\in TH^2(\Gamma^\delta)$. The operator K^δ is then compact between these spaces. We show that the operator L^δ is an isomorphism from $TH^2(\Gamma^\delta)$ onto $TL^2(\mathrm{curl}_{\Gamma^\delta},\Gamma^\delta)$. By using the decomposition

$$a\;=\;\overrightarrow{\mathrm{curl}}_{\Gamma^\delta}\,\varphi+\overrightarrow{\mathrm{grad}}_{\Gamma^\delta}\,\psi,$$

the integral equation

$$L^\delta\,a\;=\;g^\delta$$

is equivalent to the following elliptic system:

$$\begin{cases} \dfrac{\sqrt{\varepsilon_2\mu_2}}{2}\,\Delta_{\Gamma^\delta}\,\psi\;=\;-\mathrm{curl}_{\Gamma^\delta}\,g^\delta\;\in H^1(\Gamma^\delta),\\ \sqrt{\dfrac{\varepsilon_2}{\mu_2}}\,\dfrac{\delta}{\omega^2\varepsilon_1}\,\Delta^2_{\Gamma^\delta}\,\varphi\;=\;-\dfrac{1}{2}\delta\,\beta\,\sqrt{\varepsilon_2\mu_2}\,\Delta^2_{\Gamma^\delta}\,\psi+\mathrm{div}_{\Gamma^\delta}\,g^\delta\;\in H^{-1}(\Gamma^\delta), \end{cases}$$

which has a unique solution $(\varphi,\psi)\in(H^3(\Gamma^\delta)/\mathbb{C})^2$. The integral equation $L^\delta\,a=g^\delta$ then has a unique solution in $TH^2(\Gamma^\delta)$.

Applying these results to (4.30) yields

$$a+(L^\delta)^{-1}\,K^\delta a\;=\;(L^\delta)^{-1}\,g^\delta, \tag{4.39}$$

which is a Fredholm equation of the second kind in $TH^2(\Gamma^\delta)$. Now, under the assumption that μ is not is the set of exceptional values introduced in Lemma 4.2, we can prove the following theorem.

THEOREM 4.5. *There exists a unique solution to the integral equation* (4.30) *in* $TH^2(\Gamma^\delta)$.

From Lemma 4.2 the boundary-value problem (4.17)–(4.18) itself has at most one solution. To show the uniqueness of the solution to the integral equation (4.30), let us consider $a \in TH^2(\Gamma^\delta)$ a solution of (4.30) and define

$$\mathcal{E}^\delta(x) = \omega \sqrt{\varepsilon_2 \mu_2}\, \overrightarrow{\operatorname{curl}} \int_{\Gamma^\delta} a(y)\, \Phi(x,y)\, ds(y) \quad \text{in } \Omega_2^\delta,$$
$$\mathcal{H}^\delta(x) = \frac{1}{i\omega\mu_2}\, \overrightarrow{\operatorname{curl}}\, \mathcal{E}^\delta(x) \quad \text{in } \Omega_2^\delta.$$

Standard arguments state that $\mathcal{E}^\delta$ and $\mathcal{H}^\delta$ are solutions of the boundary-value problem (4.17)–(4.18). Hence, there exists a unique solution to the integral equation (4.30) in $TH^2(\Gamma^\delta)$.

The uniform continuity of the operator $(\,(L^\delta)^{-1}\, K^\delta + I\,)^{-1}\,(L^\delta)^{-1}$ from $TL^2(\operatorname{curl}_{\Gamma^\delta}, \Gamma^\delta)$ onto $TH^2(\Gamma^\delta)$ with respect to δ gives the existence of a strictly positive constant C independent of δ such that the unique solution of the equation (4.39) satisfies the following estimate:

$$||a||_{TH^2(\Gamma^\delta)} \leq C\, ||g^\delta||_{TL^2(\operatorname{curl}_{\Gamma^\delta}, \Gamma^\delta)}.$$

From the integral representations (4.28), it is easily established that for each $O \subset\subset \Omega_2^\delta$, there exists a strictly positive constant C independent of δ such that

$$||\mathcal{E}^\delta||_{H(\overrightarrow{\operatorname{curl}}, O)} + ||\mathcal{H}^\delta||_{H(\overrightarrow{\operatorname{curl}}, O)} \leq C\, ||a||_{TH^2(\Gamma^\delta)}.$$

Therefore, we obtain the following result.

THEOREM 4.6. *For each* $O \subset\subset \Omega_2^\delta$, *there exists a positive constant* C *independent of* δ *such that*

$$||\mathcal{E}^\delta||_{H(\overrightarrow{\operatorname{curl}}, O)} + ||\mathcal{H}^\delta||_{H(\overrightarrow{\operatorname{curl}}, O)} \leq C\, ||g^\delta||_{TL^2(\operatorname{curl}_{\Gamma^\delta}, \Gamma^\delta)}. \tag{4.40}$$

Now, let $\mathcal{E}^\delta, \mathcal{H}^\delta$ be the solution of the Maxwell equations with the new boundary conditions corresponding to

$$g^\delta = n \wedge (n \wedge E^{in}) + i\delta\omega\mu_1 \left(\frac{\gamma_1}{k_1}\right)^2 H^{in} \wedge n + \frac{i\delta}{\omega\varepsilon_1}\, \overrightarrow{\operatorname{grad}}_{\Gamma^\delta} \operatorname{div}_{\Gamma^\delta} (H^{in} \wedge n)$$
$$-\delta\beta\, \overrightarrow{\operatorname{grad}}_{\Gamma^\delta} \operatorname{div}_{\Gamma^\delta} (E^{in} \wedge n)$$

in (4.18) ($H^{in} = -i\omega\, \varepsilon_2\, \overrightarrow{\operatorname{curl}}\, E^{in}$). By Theorem 4.4, we obtain the following error estimate.

THEOREM 4.7. *For each* $O \subset\subset \Omega_2^\delta$, *there exists a positive constant* C *independent of* δ *such that*

$$||\mathcal{E}^\delta - E_2^{sc,\delta}||_{H(\overrightarrow{\operatorname{curl}}, O)} + ||\mathcal{H}^\delta - H_2^{sc,\delta}||_{H(\overrightarrow{\operatorname{curl}}, O)} \leq C\, \delta^2, \tag{4.41}$$

where $E_2^{sc,\delta} = E_2^\delta - E^{in}$ *and* $H_2^{sc,\delta} = H_2^\delta - H^{in}$ *are the unique solutions of* (2.8) *in* Ω_2^δ *satisfying the radiation condition at infinity.*

Proof. We first recall that the tangential component of the electric field on Γ^δ is given by

$$\begin{aligned} E^\delta_{\Gamma^\delta}(x_{\Gamma^\delta}) &= (\gamma_1)^2\,\beta\int_{-\delta}^0 E_1^\delta\wedge n\,ds + i\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\int_{-\delta}^0 H_1^\delta\wedge n\,ds \\ &\quad + \frac{i}{\omega\varepsilon_1}\int_{-\delta}^0 \overrightarrow{\operatorname{grad}}_{\Gamma^\delta_s}\,\operatorname{div}_{\Gamma^\delta_s}(H_1^\delta\wedge n)\,ds - i\beta\int_{-\delta}^0 \overrightarrow{\operatorname{grad}}_{\Gamma^\delta_s}\,\operatorname{div}_{\Gamma^\delta_s}(E_1^\delta\wedge n)\,ds \\ &\quad - \int_{-\delta}^0 \mathcal{R}(E^\delta_{\Gamma^\delta_s})\,ds. \end{aligned}$$

Let us define

$$\begin{cases} e^\delta = \mathcal{E}^\delta - E_2^{sc,\delta}, \\ h^\delta = \mathcal{H}^\delta - H_2^{sc,\delta}. \end{cases}$$

It is clear that (e^δ, h^δ) satisfy the Maxwell equations

$$\begin{cases} \overrightarrow{\operatorname{curl}}\,e^\delta = i\omega\,\mu_2\,h^\delta \quad \text{in } \Omega_2^\delta, \\ \overrightarrow{\operatorname{curl}}\,h^\delta = -i\omega\,\varepsilon_2\,e^\delta \quad \text{in } \Omega_2^\delta, \end{cases}$$

with the boundary conditions given by

$$\begin{aligned} &n\wedge(n\wedge e^\delta) + i\delta\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2 h^\delta\wedge n + \frac{i\delta}{\omega\varepsilon_1}\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(h^\delta\wedge n) \\ &-\delta\beta\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(e^\delta\wedge n) = w^\delta \quad \text{on } \Gamma^\delta, \end{aligned}$$

where

$$\begin{aligned} w^\delta &= \frac{i}{\omega\varepsilon_1}\Big(\int_{-\delta}^0 \overrightarrow{\operatorname{grad}}_{\Gamma^\delta_s}\operatorname{div}_{\Gamma^\delta_s}(H_1^\delta\wedge n)\,ds - \delta\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(H_1^\delta(x_{\Gamma^\delta})\wedge n)\Big) \\ &\quad -i\beta\Big(\int_{-\delta}^0 \overrightarrow{\operatorname{grad}}_{\Gamma^\delta_s}\operatorname{div}_{\Gamma^\delta_s}(E_1^\delta\wedge n)\,ds - \delta\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(E_1^\delta(x_{\Gamma^\delta})\wedge n)\Big) \\ &\quad -\int_{-\delta}^0 \mathcal{R}(E^\delta_{\Gamma^\delta_s})\,ds + (\gamma_1)^2\beta\int_{-\delta}^0 E_1^\delta\wedge n\,ds \\ &\quad +i\omega\mu_1\left(\frac{\gamma_1}{k_1}\right)^2\Big(\int_{-\delta}^0 H_1^\delta\wedge n\,ds - \delta\,H_1^\delta\wedge n\Big). \end{aligned}$$

From Theorem 4.4, it follows that for each $O\subset\subset\Omega_2^\delta$, there exists a positive constant C independent of δ such that

$$||e^\delta||_{H(\overrightarrow{\operatorname{curl}},O)} + ||h^\delta||_{H(\overrightarrow{\operatorname{curl}},O)} \le C\,||w^\delta||_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)}. \tag{4.42}$$

Now, in order to prove the optimal error estimate (4.41), we should estimate the following quantities:

$$\Big|\int_{-\delta}^0 \overrightarrow{\operatorname{grad}}_{\Gamma^\delta_s}\operatorname{div}_{\Gamma^\delta_s}(H_1^\delta\wedge n)\,ds - \delta\,\overrightarrow{\operatorname{grad}}_{\Gamma^\delta}\operatorname{div}_{\Gamma^\delta}(H_1^\delta(x_{\Gamma^\delta})\wedge n)\Big|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)},$$

$$\left| \int_{-\delta}^{0} \overrightarrow{\operatorname{grad}}_{\Gamma_s^\delta} \operatorname{div}_{\Gamma_s^\delta} (E_1^\delta \wedge n)\, ds - \delta \overrightarrow{\operatorname{grad}}_{\Gamma^\delta} \operatorname{div}_{\Gamma^\delta} (E_1^\delta(x_{\Gamma^\delta}) \wedge n) \right|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)},$$

$$\left| \int_{-\delta}^{0} \mathcal{R}(E_{\Gamma_s^\delta}^\delta)\, ds \right|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)}, \left| \int_{-\delta}^{0} E_1^\delta \wedge n\, ds \right|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)},$$

and

$$\left| \int_{-\delta}^{0} H_1^\delta \wedge n\, ds - \delta\, H_1^\delta \wedge n \right|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)}.$$

We need the following lemma.

LEMMA 4.8. *Let u be a smooth vectorial function defined in Ω_1^δ. We have*

$$\left| \int_{-\delta}^{0} \overrightarrow{\operatorname{grad}}_{\Gamma_s^\delta} \operatorname{div}_{\Gamma_s^\delta} (u \wedge n)\, ds - \delta \overrightarrow{\operatorname{grad}}_{\Gamma^\delta} \operatorname{div}_{\Gamma^\delta} (u(x_{\Gamma^\delta}) \wedge n) \right|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)} \leq C\,\delta^2,$$

where C is a strictly positive constant independent of δ.

Formally, since the derivatives of the tangential components of the magnetic and the electric field are bounded uniformly with respect to δ, it follows that there exists a strictly positive constant C such that

$$\left| \int_{-\delta}^{0} \mathcal{R}(E_{\Gamma_s^\delta}^\delta)\, ds \right|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)} \leq C\,\delta^2,$$

$$\left| \int_{-\delta}^{0} E_1^\delta \wedge n\, ds \right|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)} \leq C\,\delta^2,$$

and

$$\left| \int_{-\delta}^{0} H_1^\delta \wedge n\, ds - \delta\, H_1^\delta \wedge n \right|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)} \leq C\,\delta^2.$$

Lemma 4.2 yields

$$\left| \int_{-\delta}^{0} \overrightarrow{\operatorname{grad}}_{\Gamma_s^\delta} \operatorname{div}_{\Gamma_s^\delta} (H_1^\delta \wedge n)\, ds - \delta \overrightarrow{\operatorname{grad}}_{\Gamma^\delta} \operatorname{div}_{\Gamma^\delta} (H_1^\delta(x_{\Gamma^\delta}) \wedge n) \right|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)} \leq C\,\delta^2,$$

$$\left| \int_{-\delta}^{0} \overrightarrow{\operatorname{grad}}_{\Gamma_s^\delta} \operatorname{div}_{\Gamma_s^\delta} (E_1^\delta \wedge n)\, ds - \delta \overrightarrow{\operatorname{grad}}_{\Gamma^\delta} \operatorname{div}_{\Gamma^\delta} (E_1^\delta(x_{\Gamma^\delta}) \wedge n) \right|_{TL^2(\operatorname{curl}_{\Gamma^\delta},\Gamma^\delta)} \leq C\,\delta^2.$$

The proof of the error estimate is then complete by using (4.42). ∎

Finally, we note that the present method for obtaining the approximative impedance conditions is quite general, and it is applicable to coatings with arbitrary constitutive relations, such as dielectric layers with tensor permittivity and nonreciprocal coatings. Multiple layers may also be handled in a systematic manner.

5. Conclusions. In this paper, the diffraction problem by a chiral layer is formulated. The existence and the uniqueness of a solution to this problem is proved except for a possible discrete set of frequencies. In the case of a thin chiral layer, approximative impedance conditions are derived. The well-posedness of the new boundary-value problem obtained from these equivalent boundary conditions is established, and optimal error estimates between the unique solution of this new boundary-value problem and the solution of the diffraction problem by the chiral layer are obtained.

Appendix A. Let $(Y_l^m)_{-l\leq m\leq l}$ be an orthonormal sequence of spherical harmonics of order l on the unit sphere Σ normalized such that

$$\int_\Sigma Y_l^m \cdot \overline{Y}_{l'}^{m'} = \delta_{l,l'}^{m,m'}.$$

The basis functions for tangential fields on Σ_R are then

$$G_l^m = \frac{1}{\sqrt{l(l+1)}}\overrightarrow{\mathrm{grad}}_\Sigma Y_l^m \text{ and } R_l^m = n \wedge G_l^m \quad \text{for } -l\leq m\leq l,\ l\geq 1.$$

The tangential vector fields G_l^m and G_l^m are an orthonormal basis on the unit sphere (in the L^2 inner product). The multipolar vector basis for Maxwell's equations

$$\text{(A.1)} \qquad \begin{cases} \overrightarrow{\mathrm{curl}}\, E = i\omega\,\mu_2\, H, \\ \overrightarrow{\mathrm{curl}}\, H = -i\omega\,\varepsilon_2\, E \end{cases}$$

are given by

$$\text{(A.2)} \qquad \begin{cases} M_{j,l}^m(x) = \overrightarrow{\mathrm{curl}}\Big(x\, h_l^{(j)}(k|x|)\, Y_l^m\Big(\dfrac{x}{|x|}\Big)\Big), \\ N_{j,l}^m(x) = \dfrac{1}{ik}\overrightarrow{\mathrm{curl}}\, M_{j,l}^m(x), \end{cases}$$

where $j\in\{1,2\}, m=-l,\dots,l, l\geq 1, k=\omega\sqrt{\varepsilon_2\mu_2}$. $h_l^{(j)}$ denotes the spherical Hankel functions of the j kind and order l. It is well known that any solution of Maxwell's equations $(A.1)$ satisfying the outgoing radiation condition can be written for $|x|>R$ in the form

$$\text{(A.3)} \qquad E(x) = \sum_{l\geq 1}\sum_{m=-l}^{l}\Big(\alpha_l^m N_{1,l}^m(x) + \beta_l^m M_{1,l}^m(x)\Big).$$

In this appendix, we shall prove that if $\Im m \int_{\Sigma_R}(\overrightarrow{\mathrm{curl}}\, E \wedge n)\cdot\overline{E} = 0$ then $E\equiv 0$ in $|x|>R$. We need to express

$$\Im m \int_{\Sigma_R}\Big(\overrightarrow{\mathrm{curl}}\, E\wedge n\Big)\cdot\overline{E},$$

where E is a solution to Maxwell's equations $(A.1)$ satisfying the outgoing radiation condition at infinity in terms of the coefficients of the expansions for E. Using the expansion $(A.3)$ we obtain

$$\begin{aligned} \overrightarrow{\mathrm{curl}}\, E\wedge n &= \sum_{l\geq 1}\sum_{m=-l}^{l}\Big(\sqrt{l(l+1)}\,\beta_l^m\, h_l^{(1)}(kR)\, G_l^m\Big(\frac{x}{R}\Big)\Big) \\ &\quad + \frac{i}{kR}\sum_{l\geq 1}\sum_{m=-l}^{l}\Big(\sqrt{l(l+1)}\,\alpha_l^m\Big\{ h_l^{(1)}(kR) + kR(h_l^{(1)})'(kR)\Big\} R_l^m\Big(\frac{x}{R}\Big)\Big) \end{aligned}$$

on Σ_R. Now, from the definitions of G_l^m and R_l^m, we show that

$$-n\wedge\Big(n\wedge N_{1,l}^m(x)\Big) \,=\, -\frac{i}{kR}\sqrt{l(l+1)}\,\Big(h_l^{(1)}(kR)+kR(h_l^{(1)})'(kR)\Big)\,G_l^m\Big(\frac{x}{R}\Big),\quad \text{on } \Sigma_R$$

and

$$-n\wedge\Big(n\,\wedge\,M_{1,l}^m(x)\Big) \,=\, -\sqrt{l(l+1)}\,h_l^{(1)}(kR)\,R_l^m\Big(\frac{x}{R}\Big)\quad \text{on } \Sigma_R.$$

Direct computation yields

$$\int_{\Sigma_R}\Big(\overrightarrow{\operatorname{curl}}\,E\wedge n\Big)\cdot\overline{E} \,=\, \sum_{l\geq 1}\sum_{m=-l}^{l} l(l+1)\,\Big(|\alpha_l^m|^2+|\beta_l^m|^2\Big)\,\Im m\,\Big(h_l^{(1)}(kR)\,(h_l^{(1)})'(kR)\Big).$$

From

$$\Im m\; h_l^{(1)}(kR)\,\overline{(h_l^{(1)})'}(kR) \,<\, 0\quad \text{for all } l\geq 1,$$

proved in [2], we obtain that

$$\Im m\,\int_{\Sigma_R}\Big(\overrightarrow{\operatorname{curl}}\,E\,\wedge\,n\Big)\,\cdot\,\overline{E}\,=\,0\,\Longrightarrow\,E\,\equiv 0 \text{ in } |x|>R.$$

Appendix B. For the convenience of the reader we summarize in this appendix the vector identities used in this paper. Let Ω be a bounded domain with a smooth boundary $\partial\Omega$. n denotes its outward normal. Let u and v be two sufficiently smooth vectorial functions defined in Ω and w on $\partial\Omega$ such that $n\cdot w=0$. We have

$$\int_\Omega \overrightarrow{\operatorname{curl}}\,u\,\cdot\,v\,=\,\int_\Omega u\,\cdot\,\overrightarrow{\operatorname{curl}}\,v-\int_{\partial\Omega}\Big(u\,\wedge\,n\Big)\cdot\Big(n\,\wedge\,(n\,\wedge\,v)\Big).$$

$$\overrightarrow{\operatorname{curl}}\,\overrightarrow{\operatorname{curl}}\,u\,=\,\overrightarrow{\operatorname{grad}}\,\operatorname{div}u-\Delta\,u.$$

$$\overrightarrow{\operatorname{curl}}\,\overrightarrow{\operatorname{grad}}\,u\,=\,0.$$

$$\operatorname{div}\overrightarrow{\operatorname{curl}}\,u\,=\,0.$$

$$\operatorname{div}_{\partial\Omega}(u\,\wedge\,n)\,=\,n\,\cdot\,\overrightarrow{\operatorname{curl}}\,u|_{\partial\Omega}.$$

$$\int_{\partial\Omega}\overrightarrow{\operatorname{grad}}_{\partial\Omega}\operatorname{div}_{\partial\Omega}(u\,\wedge\,n)\,\cdot\,(v\,\wedge\,n)\,=\,-\int_{\partial\Omega}\operatorname{div}_{\partial\Omega}(u\,\wedge\,n)\operatorname{div}_{\partial\Omega}(v\,\wedge\,n).$$

$$\operatorname{div}_{\partial\Omega}\overrightarrow{\operatorname{curl}}_{\partial\Omega}\,w\,=\,0.$$

$$-\operatorname{curl}_{\partial\Omega}\overrightarrow{\operatorname{curl}}_{\partial\Omega}\,w\,=\,\Delta_{\partial\Omega}\,w\,=\,\operatorname{div}_{\partial\Omega}\overrightarrow{\operatorname{grad}}_{\partial\Omega}\,w.$$

$$\operatorname{curl}_{\partial\Omega}\overrightarrow{\operatorname{grad}}_{\partial\Omega}\,w\,=\,0.$$

$$\mathrm{div}_{\partial\Omega}\,(w \wedge n) \;=\; \mathrm{curl}_{\partial\Omega}\, w.$$

$$\overrightarrow{\mathrm{curl}}\, u \;=\; \mathrm{curl}_{\partial\Omega}\, u_{\partial\Omega}\, n + \overrightarrow{\mathrm{curl}}_{\partial\Omega}(u \cdot n) + (\mathcal{R} - 2c)(u \wedge n) - \frac{\partial}{\partial s}(u \wedge n),$$

where

$$u_{\partial\Omega} \;=\; -n \wedge (n \wedge u).$$

$$\begin{aligned}\overrightarrow{\mathrm{curl}}\,\overrightarrow{\mathrm{curl}}\, u \;=\;& (\mathrm{curl}_{\partial\Omega}\,\overrightarrow{\mathrm{curl}}_{\partial\Omega}\,(u \cdot n))\, n + \mathrm{div}_{\partial\Omega}\,(\mathcal{R}\, u_{\partial\Omega})\, n + \mathrm{div}_{\partial\Omega}\,\Big(\frac{\partial}{\partial n}\, u_{\partial\Omega}\Big)\\ &+\overrightarrow{\mathrm{curl}}_{\partial\Omega}\,\mathrm{curl}_{\partial\Omega}\, u_{\partial\Omega} + \Big(\mathcal{R} - 2c - \frac{\partial}{\partial s}\Big)\Big(-\overrightarrow{\mathrm{grad}}_{\partial\Omega}(u \cdot n)\\ &+\mathcal{R}\, u_{\partial\Omega} + \frac{\partial}{\partial s}\, u_{\partial\Omega}\Big).\end{aligned}$$

BIFURCATION STRUCTURE OF STATIONARY SOLUTIONS OF A LOTKA–VOLTERRA COMPETITION MODEL WITH DIFFUSION*

YUKIO KAN-ON†

Abstract. In this paper, we consider a Lotka–Volterra competition model with diffusion which describes the dynamics of the population of two competing species, and establish the bifurcation structure of positive stationary solutions of the model. To do this, we shall employ the comparison principle and the bifurcation theory and study the spatial profile of positive stationary solutions.

Key words. Lotka–Volterra competition model, comparison principle, bifurcation theory

AMS subject classification. 35B32

PII. S0036141096305784

1. Introduction.

In order to understand the mechanism of phenomena which appear in various fields, we often use the system of reaction–diffusion equations

$$\begin{cases} \boldsymbol{u}_t = \varepsilon\, D\, \Delta \boldsymbol{u} + \boldsymbol{f}(\boldsymbol{u}), & x \in \Omega, \quad t > 0, \\ \frac{\partial}{\partial \nu} \boldsymbol{u} = 0, & x \in \partial\Omega, \quad t > 0, \end{cases} \tag{1.1}$$

with suitable initial condition, and discuss the existence of stationary solutions and their stability properties, where $\boldsymbol{u} \in \mathbf{R}^n$, ε is a positive constant, D is a diagonal matrix whose elements are positive, $\boldsymbol{f} : \mathbf{R}^n \to \mathbf{R}^n$ is a smooth function, Ω is a bounded domain in $\mathbf{R}^m$ with smooth boundary $\partial\Omega$, and ν is the outward unit normal vector on $\partial\Omega$.

When $n = 1$ holds, it is comparatively easy to study the existence of stationary solutions of (1.1) and their spatial profile by the analysis of motions in the phase plane, because the so-called *comparison principle* holds. Furthermore, it is well known that for suitable $f(u)$, the global attractor $\mathcal{A}$ of (1.1) is represented as $\mathcal{A} = \cup_{e \in \mathcal{E}} W^u(e)$, where $\mathcal{E}$ is the set of stationary solutions of (1.1) and $W^u(e)$ is an unstable manifold of (1.1) at $u = e$ (for example, see Chapter 4 in Hale [6]). This suggests that in order to understand the precise asymptotic behavior of solutions of (1.1), it is important to study the number of stationary solutions and their stability properties.

In general, the comparison principle does not always hold in case of $n \geq 2$. This leads to the considerable complexity for the study of the existence and stability of stationary solutions of (1.1). In this paper, to approach the problem for $n \geq 2$, we consider a Lotka–Volterra competition model with diffusion which describes the dynamics of the population $\boldsymbol{u} = (u, v)$ of two competing species, and assume the nonlinearity $\boldsymbol{f}(\boldsymbol{u}) = (f, g)(\boldsymbol{u})$ with

$$f(\boldsymbol{u}) = u\,(1 - u - c\,v), \quad g(\boldsymbol{u}) = v\,(a - b\,u - v),$$

which is most simple in the framework of Lotka–Volterra competition models, where a, b, and c are positive constants. We should note here that under the above nonlinearity,

†Department of Mathematics, Faculty of Education, Ehime University, Matsuyama 790, Japan (kanon@ed.ehime-u.ac.jp).

the comparison principle holds for (1.1) with respect to the order relation $\preceq_o$ which will be defined in the next section.

Many authors have studied the existence and stability of positive stationary solutions for a variety of Lotka–Volterra competition models including (1.1) (for instance, see Dancer [3] and Gui and Lou [5]). For the asymptotic behavior of solutions of (1.1), the following is well known (for example, see de Mottoni [4]):

(I) If $a < \min(b, 1/c)$, then $\lim_{t\to+\infty} \boldsymbol{u}(t,x) = (1,0)$.

(II) If $b < a < 1/c$, then

$$\lim_{t\to+\infty} \boldsymbol{u}(t,x) = \left(\frac{1-a\,c}{1-b\,c}, \frac{a-b}{1-b\,c}\right).$$

(III) If $1/c < a < b$, then both $(1,0)$ and $(0,a)$ are locally stable.

(IV) If $a > \max(b, 1/c)$, then $\lim_{t\to+\infty} \boldsymbol{u}(t,x) = (0,a)$.

Precisely speaking for case (III), Kishimoto and Weinberger [8] showed that any spatially inhomogeneous positive stationary solution is unstable if Ω is convex. On the other hand, Matano and Mimura [9] proved that there exist stable spatially inhomogeneous positive stationary solutions for suitably nonconvex domain Ω. (Along this line, we also refer to Mimura, Ei, and Fang [10] and Kan-on and Yanagida [7].) These results mean that there exist many positive stationary solutions of (1.1) and that their stability properties crucially depend on the shape of the domain Ω. We now address the following question: suppose that Ω is suitably fixed. How many positive stationary solutions does (1.1) have? In this paper, to answer this problem, we assume

$$\text{(A)} \qquad \Omega = (0,1), \quad D = I_2, \quad a = 1, \quad b = c > 1,$$

study the spatial profile of positive stationary solutions by employing the comparison principle and the bifurcation theory, and then establish the bifurcation structure of the positive stationary solutions of (1.1).

2. Statement of result. We set $X = \{\, \boldsymbol{u} \in C^2([0,1], \mathbf{R}^2) \mid \boldsymbol{u}_x(0) = 0,\ \boldsymbol{u}_x(1) = 0 \,\}$ and define the order relations $\preceq_s$ and $\preceq_o$ in the following manner:

$$(u_1, v_1) \preceq_s (u_2, v_2) \iff u_1 \le u_2,\ v_1 \le v_2,$$
$$(u_1, v_1) \preceq_o (u_2, v_2) \iff u_1 \le u_2,\ v_1 \ge v_2.$$

We denote by $\prec_s$ and $\prec_o$ the relations obtained from the above definition by replacing $\le$ with $<$. We shall say that $\boldsymbol{u}(x)$ is *positive* if $\boldsymbol{u}(x) \succ_s 0$ holds on $[0,1]$.

Setting $\bar{u} = 1/(1+b)$, $\bar{\boldsymbol{u}} = (\bar{u}, \bar{u})$, $\varepsilon_0 = +\infty$, and $\varepsilon_n = (b-1)/(n^2\,\pi^2\,(b+1))$ $(n \in \mathbf{N})$, we can easily check that spatially inhomogeneous positive stationary solutions of (1.1) bifurcate from $\boldsymbol{u} = \bar{\boldsymbol{u}}$ at $\varepsilon = \varepsilon_n$ for each $n \in \mathbf{N}$. In the next section, we shall study the geometrical position of the curve of such stationary solutions.

Here is the main result of this paper.

THEOREM 2.1. *Under the assumption* (A)*, the following holds for each* $n \in \mathbf{N}$*:*

(i) *For any* $\varepsilon \in (0, \varepsilon_n)$*, there exists a pair of spatially inhomogeneous positive stationary solutions* $\boldsymbol{u}_n^{\pm}(x,\varepsilon)$ *of* (1.1) *such that*

$$(-1)^j\, \boldsymbol{u}_{nx}^{-}(x,\varepsilon) \prec_o 0, \quad (-1)^j\, \boldsymbol{u}_{nx}^{+}(x,\varepsilon) \succ_o 0$$

are satisfied for each $0 \le j < n$ *and* $x \in (j/n, (j+1)/n)$*.*

(ii) *Both* $\boldsymbol{u}_n^{-}(.,\varepsilon)$ *and* $\boldsymbol{u}_n^{+}(.,\varepsilon)$ *are* C^1*-class functions from* $(0, \varepsilon_n)$ *to* X*.*

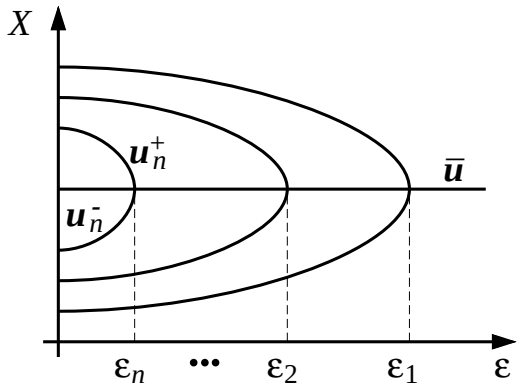

FIG. 1. *Bifurcation structure of positive stationary solutions.*

(iii) (1.1) *has no positive stationary solutions other than* $\bar{\boldsymbol{u}}$ *and* $\boldsymbol{u}_j^{\pm}(x,\varepsilon)$ $(1 \le j < n)$ *for any* $\varepsilon \in [\varepsilon_n, \varepsilon_{n-1})$.

Figure 1 indicates the bifurcation structure of positive stationary solutions of (1.1). We should note here that the secondary bifurcation of stationary solutions never occurs. In consideration of the result in Chafee and Infante [1], the above theorem means that the bifurcation structure of positive stationary solutions of (1.1) is similar to that of stationary solutions of

$$\begin{cases} u_t = \varepsilon\, u_{xx} + u\,(1-u^2), & x \in (0,1), \quad t > 0, \\ u_x = 0, & x = 0, 1, \quad t > 0. \end{cases}$$

We shall prove the above theorem in the following sections.

3. Bifurcation from spatially homogeneous solution. In this section, we calculate spatially inhomogeneous positive stationary solutions bifurcating from $\boldsymbol{u} = \bar{\boldsymbol{u}}$ at $\varepsilon = \varepsilon_n$ for each $n \in \mathbf{N}$. To do it, we set

$$\hat{\varepsilon}_n(\mu) = \varepsilon_n + \tilde{\varepsilon}_n(\mu)\,\mu^2, \quad \hat{\boldsymbol{u}}_n(x,\mu) = \bar{\boldsymbol{u}} + \mu\,\boldsymbol{e}\,\cos(n\,\pi\,x) + \mu^2\,\tilde{\boldsymbol{u}}_n(x,\mu), \tag{3.1}$$

where $\boldsymbol{e} = (1,-1)$ is an eigenvector of the 2×2-matrix $\boldsymbol{f}_{\boldsymbol{u}}(\bar{\boldsymbol{u}}) - \varepsilon_n\, n^2\, \pi^2\, I_2$ corresponding to the eigenvalue 0. Substituting $\varepsilon = \hat{\varepsilon}_n(\mu)$ and $\boldsymbol{u} = \hat{\boldsymbol{u}}_n(x,\mu)$ into (1.1), we have

$$\tilde{\varepsilon}_n(0) = -\frac{(11\,b-5)\,(b-1)}{2\,(5\,b-3)\,n^2\,\pi^2}$$

and then obtain $\tilde{\varepsilon}_n(0) < 0$ because of (A). We have the following by the bifurcation theory.

LEMMA 3.1 (see Crandall and Rabinowitz [2]). *For each* $n \in \mathbf{N}$, *there exist* $\delta_n > 0$, $\mu_n > 0$, *and* C^1*-class functions* $\hat{\varepsilon}_n(\mu)$, $\hat{\boldsymbol{u}}_n(.,\mu)$ *defined on* $(-\mu_n, \mu_n)$ *such that the following properties hold:*

(i) $\hat{\boldsymbol{u}}_n(x,\mu)$ *is a spatially inhomogeneous positive stationary solution of* (1.1) *with* $\varepsilon = \hat{\varepsilon}_n(\mu)$ *for each* $\mu \in (-\mu_n, 0) \cup (0, \mu_n)$.

(ii) $\hat{\varepsilon}_n(0) = \varepsilon_n$ *and* $\hat{\varepsilon}_n(\mu) < \varepsilon_n$ *for any* $\mu \in (-\mu_n, 0) \cup (0, \mu_n)$ *are satisfied.*

(iii) *Suppose that* $\boldsymbol{w}(x)$ *is a spatially inhomogeneous positive stationary solution of* (1.1) *for* $\varepsilon = \eta$. *If* $|\,\eta - \varepsilon_n\,| < \delta_n$ *and* $\|\,\boldsymbol{w} - \bar{\boldsymbol{u}}\,\|_X < \delta_n$ *hold, then there exists* $\rho \in (-\mu_n, \mu_n)$ *such that* $\eta = \hat{\varepsilon}_n(\rho)$ *and* $\boldsymbol{w} = \hat{\boldsymbol{u}}_n(.,\rho)$.

4. Property of positive stationary solutions. Let $\boldsymbol{u}_0(x) = (u_0, v_0)(x)$ be an arbitrary spatially inhomogeneous positive stationary solution of (1.1) for $\varepsilon > 0$. It is obvious from Lemma 3.1 that such a solution exists for some $\varepsilon > 0$. In this section, we study spatial profiles of $\boldsymbol{u}_0(x)$ which will be used in order to discuss the possibility of the secondary bifurcation in the next section.

By the boundary condition, we can regard $\boldsymbol{u}_0(x)$ as a periodic function with period 2 which satisfies $\boldsymbol{u}(x) = \boldsymbol{u}(-x)$ for any $x \in \mathbf{R}$. By the comparison principle, it is easy to show that $0 < u_0(x) + v_0(x)\,(\equiv K(x)) < 1$ holds for any $x \in \mathbf{R}$. Furthermore, we find that $H(x) = u_0(x) - v_0(x)$ satisfies

$$\begin{cases} 0 = \varepsilon\, H_{xx} + (1 - K(x))\, H, & x \in (0,1), \\ H_x(0) = 0, \quad H_x(1) = 0. \end{cases}$$

If $H(x) \gtrless 0$ holds for any $x \in [0,1]$, then we have

$$0 = \int_0^1 \{\, \varepsilon\, H_{xx}(x) + (1 - K(x))\, H(x) \,\}\, dx \gtrless 0.$$

This contradiction implies that there exists $x_0 \in [0,1]$ such that $H(x_0) = 0$ and $H(x) \neq 0$ for any $x \in [0, x_0)$.

We consider the case $x_0 = 0$. We obtain $H(x) = 0$ for any $x \in \mathbf{R}$ by virtue of uniqueness and then find that $u_0(x)$ satisfies

$$\begin{cases} 0 = \varepsilon\, u_{xx} + u\,\{\, 1 - (1+b)\, u \,\}, & x \in (0,1), \\ u_x(0) = 0, \quad u_x(1) = 0. \end{cases}$$

Since $u_0(x) > 0$ holds for any $x \in \mathbf{R}$, we obtain $u_0(x) = 1/(1+b)$ for any $x \in \mathbf{R}$. This contradicts that $\boldsymbol{u}_0(x)$ is spatially inhomogeneous. In a similar manner, we can derive a contradiction when $x_0 = 1$ holds. Hence we have $x_0 \in (0,1)$ and $H_x(x_0) \neq 0$. If $\varepsilon > 4\, x_0^2/\pi^2$ is satisfied, then we have

$$\begin{aligned} 0 &= \int_0^{x_0} \{\, \varepsilon\, H_{xx}(x) + (1 - K(x))\, H(x) \,\}\, \cos(\pi\, x/(2\, x_0))\, dx \\ &= \int_0^{x_0} \{\, 1 - K(x) - \varepsilon\, \pi^2/(4\, x_0^2) \,\}\, H(x)\, \cos(\pi\, x/(2\, x_0))\, dx \neq 0 \end{aligned}$$

because of integration by parts. This indicates that ε must satisfy $\varepsilon \leq 4\, x_0^2/\pi^2$.

We set

$$T = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix},$$

whose operation is the change of the role of u and v. Since $g(\boldsymbol{u}) = f(T\, \boldsymbol{u})$ is satisfied for any $\boldsymbol{u}$ because of (A), we find that $\boldsymbol{f}(T\, \boldsymbol{u}) = T\, \boldsymbol{f}(\boldsymbol{u})$ holds for any $\boldsymbol{u}$ and that $T\, \boldsymbol{u}_0(x)$ is a spatially inhomogeneous positive stationary solution of (1.1). Hence we see that

$$\boldsymbol{U}(x)\,(\equiv (U,V)(x)) = \boldsymbol{u}_0(x) - T\, \boldsymbol{u}_0(2\, x_0 - x)$$

is a periodic function with period 2 and that $\boldsymbol{U}(x)$ satisfies $\boldsymbol{U}(x_0) = 0$, $U_x(x_0) = V_x(x_0)$, and

$$0 = \varepsilon\, \boldsymbol{U}_{xx} + \boldsymbol{f}_{\boldsymbol{u}}^1(x)\, \boldsymbol{U}, \quad x \in \mathbf{R},$$

where

$$\boldsymbol{f}_{\boldsymbol{u}}^{1}(x)=\int_{0}^{1}\boldsymbol{f}_{\boldsymbol{u}}(\theta\,\boldsymbol{u}_{0}(x)+(1-\theta)\,T\,\boldsymbol{u}_{0}(2\,x_{0}-x))\,d\theta.$$

We assume that $U_x(x_0)\neq 0$ holds. It follows that there exists $x_1\in(x_0,x_0+2]$ such that $U(x_1)\,V(x_1)=0$ and $U(x)\,V(x)>0$ for any $x\in(x_0,x_1)$. If $U(x_1)=0$ is satisfied, then we have

$$\begin{aligned}0=\int_{x_0}^{x_1}(\varepsilon\,u_{0xx}(x)+f(\boldsymbol{u}_0(x)))\,v_0(2\,x_0-x)\,dx&=\varepsilon\,(u_0(x_1)\,U_x(x_1)-u_0(x_0)\,U_x(x_0))\\&\quad-\int_{x_0}^{x_1}(U(x)+b\,V(x))\,u_0(x)\,v_0(2\,x_0-x)\,dx\neq 0\end{aligned}$$

because of integration by parts. In a similar manner, we can derive a contradiction when $V(x_1)=0$ holds. Hence we have $\boldsymbol{U}_x(x_0)=0$. By uniqueness, we obtain $\boldsymbol{u}_0(x)=T\,\boldsymbol{u}_0(2\,x_0-x)$ for any $x\in\mathbf{R}$.

LEMMA 4.1. *Let $\boldsymbol{u}_0(x)=(u_0,v_0)(x)$ be an arbitrary spatially inhomogeneous positive stationary solution of (1.1) for $\varepsilon>0$. Then there exists a unique constant $x_0\in(0,1)$ such that $u_0(x)\neq v_0(x)$ for any $x\in[0,x_0)$ and*

$$\boldsymbol{u}_0(x)=\begin{cases}\boldsymbol{u}_0(r(x)) & \text{if } q(x)\equiv 0 \mod 4,\\ T\,\boldsymbol{u}_0(x_0-r(x)) & \text{if } q(x)\equiv 1 \mod 4,\\ T\,\boldsymbol{u}_0(r(x)) & \text{if } q(x)\equiv 2 \mod 4,\\ \boldsymbol{u}_0(x_0-r(x)) & \text{if } q(x)\equiv 3 \mod 4\end{cases}$$

for any $x\in\mathbf{R}$, where $q(x)\in\mathbf{Z}$ and $r(x)\in[0,x_0)$ are determined by $x=r(x)+q(x)\,x_0$.

The linearized operator $\mathcal{L}$ of (1.1) around $\boldsymbol{u}_0(x)$ can be represented as $\mathcal{L}\,\boldsymbol{u}=\varepsilon\,\boldsymbol{u}_{xx}+\boldsymbol{f}_{\boldsymbol{u}}(\boldsymbol{u}_0(x))\,\boldsymbol{u}$. Since $\boldsymbol{u}_{0x}(x)$ is a nontrivial solution of $\mathcal{L}\,\boldsymbol{u}=0$ with $\boldsymbol{u}(0)=0$, we obtain $\boldsymbol{u}_{0xx}(0)\neq 0$. We set

$$\begin{pmatrix}f_u^0 & f_v^0\\ g_u^0 & g_v^0\end{pmatrix}(x)=\boldsymbol{f}_{\boldsymbol{u}}(\boldsymbol{u}_0(x)).$$

From the functional form of $\boldsymbol{f}(\boldsymbol{u})$, we have $f_v^0(x)<0$ and $g_u^0(x)<0$ for any $x\in\mathbf{R}$.

LEMMA 4.2. *Let $(\varphi,\psi)(x)$ be an arbitrary solution of $\mathcal{L}\,\boldsymbol{u}=0$. Suppose that there exist x_2 and x_3 $(x_2<x_3)$ such that $\varphi(x_2)=0=\varphi(x_3)$ (resp., $\psi(x_2)=0=\psi(x_3)$) and $\varphi(x)>0$ (resp., $\psi(x)>0$) for any $x\in(x_2,x_3)$. Then $\psi(x)<0$ (resp., $\varphi(x)<0$) is satisfied for some $x\in(x_2,x_3)$.*

Proof. We only show the proof for the former case, because the latter can be proved in a similar manner. If $\psi(x)\geq 0$ holds for any $x\in(x_2,x_3)$, then we have

$$\begin{aligned}0=&\int_{x_2}^{x_3}(\varepsilon\,\varphi_{xx}(x)+f_u^0(x)\,\varphi(x)+f_v^0(x)\,\psi(x))\,u_0(x)\,dx\\=&\varepsilon\,(\varphi_x(x_3)\,u_0(x_3)-\varphi_x(x_2)\,u_0(x_2))-\int_{x_2}^{x_3}(\varphi(x)+b\,\psi(x))\,u_0(x)^2\,dx<0.\end{aligned}$$

This contradiction implies that the desired result holds. □

Since $\frac{d}{dx}(u_{0xx}\,v_{0xx})(0)=0$ and

$$\varepsilon\,\tfrac{d^2}{dx^2}(u_{0xx}\,v_{0xx})(0)=-f_v^0(0)\,v_{0xx}(0)^2-g_u^0(0)\,u_{0xx}(0)^2>0$$

hold if $u_{0xx}(0)\,v_{0xx}(0) = 0$ is satisfied, it follows from $\boldsymbol{u}_{0x}(2\,x_0) = 0$ that there exists $x_4 \in (0, 2\,x_0]$ such that $u_{0x}(x_4)\,v_{0x}(x_4) = 0$ and $u_{0x}(x)\,v_{0x}(x) \neq 0$ for any $x \in (0, x_4)$.

We consider the case $\boldsymbol{u}_{0x}(x_4) \neq 0$. It is obvious that

$$\boldsymbol{U}(x)\,(\equiv (U,V)(x)) = \boldsymbol{u}_0(x) - \boldsymbol{u}_0(2\,x_4 - x)$$

is a periodic function with period 2 and that $\boldsymbol{U}(x)$ satisfies $\boldsymbol{U}(x_4) = 0$, $\boldsymbol{U}_x(x_4) \neq 0$, $U_x(x_4)\,V_x(x_4) = 0$, $\boldsymbol{U}_{xx}(x_4) = 0$, and

$$\begin{aligned} \varepsilon\,U_{xxx}(x_4)\,V_x(x_4) &= -f_v^0(x_4)\,V_x(x_4)^2 > 0 \quad \text{if } U_x(x_4) = 0, \\ \varepsilon\,V_{xxx}(x_4)\,U_x(x_4) &= -g_u^0(x_4)\,U_x(x_4)^2 > 0 \quad \text{if } V_x(x_4) = 0. \end{aligned}$$

Hence we see that there exists $x_5 \in (x_4, x_4 + 2]$ such that $U(x_5)\,V(x_5) = 0$ and $U(x)\,V(x) > 0$ for any $x \in (x_4, x_5)$. We can derive a contradiction in the same manner as in the proof of Lemma 4.1. Therefore we obtain $\boldsymbol{u}_{0x}(x_4) = 0$. Since $\boldsymbol{u}_0(x) = \boldsymbol{u}_0(2\,x_4 - x)$ holds for any $x \in \mathbf{R}$, we find $H(2\,x_4 - x_0) = 0$. By Lemma 4.1, we have either $x_4 = x_0$ or $x_4 = 2\,x_0$. If $x_4 = x_0$ holds, then we obtain $H(x) = 0$ for any $x \in \mathbf{R}$ because of $H(x_0) = 0$ and $H_x(x_0) = 0$, which indicates that $\boldsymbol{u}_0(x)$ is a constant function. This contradiction implies that $x_4 = 2\,x_0$ holds. By Lemma 4.2 and the choice of x_4, we have $u_{0x}(x)\,v_{0x}(x) < 0$ for any $x \in (0, 2\,x_0)$.

LEMMA 4.3. *Let $\boldsymbol{u}_0(x) = (u_0, v_0)(x)$ be an arbitrary spatially inhomogeneous positive stationary solution of* (1.1) *for $\varepsilon > 0$, and let x_0 be the unique constant given in Lemma* 4.1. *Then there exists $\ell \in \mathbf{N}$ such that $2\,x_0\,\ell = 1$ holds. Furthermore, $u_{0x}(x)\,v_{0x}(x) < 0$ is satisfied for any $k \in \mathbf{Z}$ and $x \in (2\,k\,x_0, 2\,(k+1)\,x_0)$.*

For any spatially inhomogeneous positive stationary solution $\boldsymbol{u}(x)$ of (1.1), we denote by $\ell(\boldsymbol{u})$ the integer which is given by applying Lemma 4.3 to $\boldsymbol{u}(x)$.

COROLLARY 4.4. *Let $n \in \mathbf{N}$, and let $\hat{\boldsymbol{u}}_n(x,\mu) = (\hat{u}_n, \hat{v}_n)(x,\mu)$ be a C^1-class function given in Lemma* 3.1. *Then $\ell(\hat{\boldsymbol{u}}_n(.,\mu)) = n$ holds for any $\mu\,(\neq 0)$ in a neighborhood of $\mu = 0$.*

Proof. Since

$$(\hat{u}_n(x,\mu) - \hat{v}_n(x,\mu))/\mu = 2\,\cos(n\,\pi\,x) + O(\mu)$$

as $\mu \to 0$ by virtue of (3.1), we see from Lemmas 4.1 and 4.3 that the desired result holds. □

LEMMA 4.5. *Let $0 \leq \varepsilon_- < \varepsilon_+$, and let $\boldsymbol{u}(.,\varepsilon) = (u,v)(.,\varepsilon)$ be a continuous function on $(\varepsilon_-, \varepsilon_+)$ such that $\boldsymbol{u}(x,\varepsilon)$ is a spatially inhomogeneous positive stationary solution of* (1.1) *for each $\varepsilon \in (\varepsilon_-, \varepsilon_+)$. Then $\ell(\boldsymbol{u}(.,\varepsilon))$ is a constant function on $(\varepsilon_-, \varepsilon_+)$.*

Proof. We define $\ell_0 \in \mathbf{N}$ and $\eta_0 \in (\varepsilon_-, \varepsilon_+)$ by

$$\ell_0 = \ell(\boldsymbol{u}(.,\eta_0)) = \min_{\varepsilon \in (\varepsilon_-, \varepsilon_+)} \ell(\boldsymbol{u}(.,\varepsilon)).$$

By Lemma 4.3 and the continuity of $\boldsymbol{u}(.,\varepsilon)$, we find that for any $\kappa > 0$, there exists $\rho_1 > 0$ such that $u_x(x,\varepsilon)\,v_x(x,\varepsilon) < 0$ for any $\kappa \leq x \leq 1/\ell_0 - \kappa$ and $|\,\varepsilon - \eta_0\,| \leq \rho_1$. This means that $\ell(\boldsymbol{u}(.,\varepsilon)) = \ell_0$ holds for any ε in a neighborhood of $\varepsilon = \eta_0$. Hence we see that there is a maximal extended interval $J = (\hat{\varepsilon}_-, \hat{\varepsilon}_+)$ such that $\eta_0 \in \operatorname{Int} J$ and $\ell(\boldsymbol{u}(.,\varepsilon)) = \ell_0$ for any $\varepsilon \in J$. We assume $\varepsilon_- < \hat{\varepsilon}_-$. By the continuity of $\boldsymbol{u}(.,\varepsilon)$, we obtain $s_1\,\boldsymbol{u}_x(x,\hat{\varepsilon}_-) \succeq_o 0$ on $[0, 1/\ell_0]$ for some $s_1 \in \{\,-1, 1\,\}$ and $u_x(x_6,\hat{\varepsilon}_-)\,v_x(x_6,\hat{\varepsilon}_-) = 0$

for some $x_6 \in (0, 1/\ell_0)$. Since $f_v(\boldsymbol{u}(x, \hat{\varepsilon}_-)) < 0$ and $g_u(\boldsymbol{u}(x, \hat{\varepsilon}_-)) < 0$ are satisfied for any $x \in [0, 1]$, we have

$$u_{xx}(x_6, \hat{\varepsilon}_-) = 0, \quad 0 \le \hat{\varepsilon}_- \, s_1 \, u_{xxx}(x_6, \hat{\varepsilon}_-) = -f_v(\boldsymbol{u}(x_6, \hat{\varepsilon}_-)) \, s_1 \, v_x(x_6, \hat{\varepsilon}_-) \le 0$$

if $u_x(x_6, \hat{\varepsilon}_-) = 0$, and

$$v_{xx}(x_6, \hat{\varepsilon}_-) = 0, \quad 0 \ge \hat{\varepsilon}_- \, s_1 \, v_{xxx}(x_6, \hat{\varepsilon}_-) = -g_u(\boldsymbol{u}(x_6, \hat{\varepsilon}_-)) \, s_1 \, u_x(x_6, \hat{\varepsilon}_-) \ge 0$$

if $v_x(x_6, \hat{\varepsilon}_-) = 0$. These facts imply that $\boldsymbol{u}_x(x_6, \hat{\varepsilon}_-) = 0$ and $\boldsymbol{u}_{xx}(x_6, \hat{\varepsilon}_-) = 0$ hold. By uniqueness, we find that $\boldsymbol{u}(x, \hat{\varepsilon}_-)$ must be a constant function. This is a contradiction. Hence we obtain $\hat{\varepsilon}_- = \varepsilon_-$. Similarly, we can prove $\hat{\varepsilon}_+ = \varepsilon_+$. Therefore we have $\ell(\boldsymbol{u}(., \varepsilon)) = \ell_0$ for any $\varepsilon \in (\varepsilon_-, \varepsilon_+)$. □

5. Nonexistence of the eigenvalue 0. Let $\boldsymbol{u}_0(x) = (u_0, v_0)(x)$ be an arbitrary spatially inhomogeneous positive stationary solution of (1.1) for $\varepsilon > 0$, and let $\mathcal{L}$ be the linearized operator of (1.1) around $\boldsymbol{u} = \boldsymbol{u}_0(x)$. We denote by $\sigma(\mathcal{L})$ the set of spectra of $\mathcal{L}$ relative to X. In this section, we show that $0 \notin \sigma(\mathcal{L})$ holds.

We assume $0 \in \sigma(\mathcal{L})$ in order to derive a contradiction. Let $x_0 = 1/(2\,\ell(\boldsymbol{u}_0))$, and let $\phi(x) = (\phi^u, \phi^v)(x)$ be an arbitrary eigenfunction of $\mathcal{L}$ corresponding to the eigenvalue 0. By Lemma 4.1 and the boundary condition, we can regard $\phi(x)$ as a periodic function with period 2 which satisfies $\boldsymbol{u}(x) = \boldsymbol{u}(-x)$ for any $x \in \mathbf{R}$.

LEMMA 5.1. *Either* $\phi(2\,k\,x_0) \succ_o 0$, $\phi(2\,k\,x_0) = 0$, *or* $\phi(2\,k\,x_0) \prec_o 0$ *is satisfied for any* $k \in \mathbf{Z}$. *Furthermore if* $\phi^u(2\,k\,x_0) = 0$ *is satisfied for some* $k \in \mathbf{Z}$, *then* $\phi(x) = -\phi(4\,k\,x_0 - x)$ *holds for any* $x \in \mathbf{R}$.

Proof. We consider the case where both of $\phi^u(2\,k\,x_0)\,\phi^v(2\,k\,x_0) \ge 0$ and $\phi(2\,k\,x_0) \ne 0$ hold. We see from Lemma 4.1 that

$$\boldsymbol{U}(x)\,(\equiv (U, V)(x)) = \phi(x) + \phi(4\,k\,x_0 - x)$$

is a nontrivial solution of $\mathcal{L}\,\boldsymbol{u} = 0$ with period 2 and satisfies $U(2\,k\,x_0)\,V(2\,k\,x_0) \ge 0$, $\boldsymbol{U}(2\,k\,x_0) \ne 0$, and $\boldsymbol{U}_x(2\,k\,x_0) = 0$. Since $\frac{d}{dx}(U\,V)(2\,k\,x_0) = 0$ and

$$\varepsilon\,\tfrac{d^2}{dx^2}(U\,V)(2\,k\,x_0) = -f_v^0(2\,k\,x_0)\,V(2\,k\,x_0)^2 - g_u^0(2\,k\,x_0)\,U(2\,k\,x_0)^2 > 0$$

are satisfied if $U(2\,k\,x_0)\,V(2\,k\,x_0) = 0$, we find that there exists $x_7 \in (2\,k\,x_0,\, 2\,k\,x_0 + 2]$ such that the following properties hold:

(i) $U(x)\,V(x) > 0$ holds for any $x \in (2\,k\,x_0, x_7)$ and

(ii) $U(x_7)\,V(x_7) = 0$ is satisfied if $x_7 < 2\,k\,x_0 + 2$.

Since $\boldsymbol{u}_{0x}(2\,k\,x_0) = 0$ and $\boldsymbol{u}_{0x}(2\,k\,x_0 + 2) = 0$ are satisfied because of Lemma 4.1, we have

$$\begin{aligned} 0 =& \int_{2\,k\,x_0}^{x_7} (\varepsilon\,U_{xx}(x) + f_u^0(x)\,U(x) + f_v^0(x)\,V(x))\,u_0(x)\,dx \\ =& \varepsilon\,(U_x(x_7)\,u_0(x_7) - U(x_7)\,u_{0x}(x_7)) - \int_{2\,k\,x_0}^{x_7} (U(x) + b\,V(x))\,u_0(x)^2\,dx \ne 0 \end{aligned}$$

if $U(x_7) = 0$ or $x_7 = 2\,k\,x_0 + 2$, and

$$\begin{aligned} 0 =& \int_{2\,k\,x_0}^{x_7} (\varepsilon\,V_{xx}(x) + g_u^0(x)\,U(x) + g_v^0(x)\,V(x))\,v_0(x)\,dx \\ =& \varepsilon\,V_x(x_7)\,v_0(x_7) - \int_{2\,k\,x_0}^{x_7} (b\,U(x) + V(x))\,v_0(x)^2\,dx \ne 0 \end{aligned}$$

if $V(x_7) = 0$. These contradictions imply that the desired result holds. □

By the above lemma, we may assume $\phi^u(0) = 1$ and $\phi^v(0) < 0$ without loss of generality.

COROLLARY 5.2. *$\mathcal{N}(\mathcal{L}) = \mathrm{span}\{\,\phi\,\}$ is satisfied where $\mathcal{N}(\mathcal{L}) = \{\,\boldsymbol{u} \in X \mid \mathcal{L}\,\boldsymbol{u} = 0\,\}$.*

Proof. Let $\boldsymbol{u}(x) = (u, v)(x)$ be another eigenfunction of $\mathcal{L}$ corresponding to the eigenvalue 0. It is obvious that $\boldsymbol{U} = \boldsymbol{u} - u(0)\,\phi \in \mathcal{N}(\mathcal{L})$ holds. Applying the proof of Lemma 5.1 to $\boldsymbol{U}(x)$, we have $\boldsymbol{U}(0) = 0$. By uniqueness, we obtain $\boldsymbol{U}(x) = 0$ for any $x \in [0, 1]$, which implies that the desired result holds. □

LEMMA 5.3. *Let $\boldsymbol{u}(x) = (u, v)(x)$ be an arbitrary nontrivial solution of $\mathcal{L}\,\boldsymbol{u} = 0$ which satisfies $\boldsymbol{u}(x) = \boldsymbol{u}(x + 2)$ for any $x \in \mathbf{R}$. Then $u_x(\tau) \neq 0$ (resp., $v_x(\tau) \neq 0$) holds for any zero τ of $u(x)$ (resp., $v(x)$).*

Proof. We only show the proof for the former case, because the latter can be proved in a similar manner. We assume $u_x(\tau) = 0$ contrary to the conclusion.

We first consider the case $u_{xx}(\tau) = 0$. Then we obtain $v(\tau) = 0$ and

$$\varepsilon\, u_{xxx}(\tau)\, v_x(\tau) = -f_v^0(\tau)\, v_x(\tau)^2 > 0.$$

It follows from $\boldsymbol{u}(\tau) = 0$ that there exists $x_8 \in (\tau, \tau + 2]$ such that $u(x_8)\, v(x_8) = 0$ and $v_x(\tau)\, u(x) > 0$, $v_x(\tau)\, v(x) > 0$ for any $x \in (\tau, x_8)$. By Lemma 4.2, we see that there exists $x_9 \in (\tau, x_8)$ such that

$$v_x(\tau)\, v(x_9) < 0 \ \text{ if } u(x_8) = 0, \qquad v_x(\tau)\, u(x_9) < 0 \ \text{ if } v(x_8) = 0.$$

This contradiction implies that $u_{xx}(\tau) \neq 0$ holds. We see that there exist x_{10}^- and x_{10}^+ $(x_{10}^- < \tau < x_{10}^+)$ such that $u(x_{10}^\pm) = 0$ and $u_{xx}(\tau)\, u(x) > 0$ hold for any $x \in (x_{10}^-, \tau) \cup (\tau, x_{10}^+)$. By Lemma 4.2 and $v(\tau) = -\varepsilon\, u_{xx}(\tau)/f_v^0(\tau)$, it follows that there exist x_{11}^- and x_{11}^+ $(x_{10}^- < x_{11}^- < \tau < x_{11}^+ < x_{10}^+)$ such that $v(x_{11}^\pm) = 0$ and $u_{xx}(\tau)\, v(x) > 0$ for any $x \in (x_{11}^-, x_{11}^+)$. By Lemma 4.2, we have $u_{xx}(\tau)\, u(x) < 0$ for some $x \in (x_{11}^-, x_{11}^+)$. This contradiction implies that the desired result holds. □

We define $\{\,x_k^u\,\}_{k=1}^{\ell_u}$ (resp., $\{\,x_k^v\,\}_{k=1}^{\ell_v}$) by the set of zeros of $\phi^u(x)$ (resp., $\phi^v(x)$) on $(0, 1)$ which satisfy $x_k^u < x_{k+1}^u$ (resp., $x_k^v < x_{k+1}^v$) for each k. By Lemma 5.1, we obtain

$$0 < x_1^u < x_{\ell_u}^u < 1, \quad 0 < x_1^v < x_{\ell_v}^v < 1.$$

Setting $x_0^\nu = 0$ and $x_{\ell_\nu + 1}^\nu = 2 - x_{\ell_\nu}^\nu$ $(\nu = u,\, v)$, we have

$$(-1)^k\, \phi^u(x) > 0 \ \text{ on } (x_k^u, x_{k+1}^u), \quad (-1)^k\, \phi^v(x) < 0 \ \text{ on } (x_k^v, x_{k+1}^v) \tag{5.1}$$

for each k because of Lemma 5.3. By definition, it is obvious that

$$x_k^u \le x_k^v \le x_{k+1}^u \quad \text{or} \quad x_k^v \le x_k^u \le x_{k+1}^v \tag{5.2}$$

holds for $k = 0$. When $x_j^u \le x_j^v \le x_{j+1}^u$ holds, we have $x_{j+1}^u < x_{j+2}^v$ and $x_{j+1}^v < x_{j+2}^u$ by virtue of (5.1) and Lemma 4.2 and then obtain

$$\begin{aligned} &x_{j+1}^u \le x_{j+1}^v < x_{j+2}^u \quad \text{if } x_{j+1}^u \le x_{j+1}^v, \\ &x_{j+1}^v < x_{j+1}^u < x_{j+2}^v \quad \text{if } x_{j+1}^u > x_{j+1}^v, \end{aligned}$$

which implies that (5.2) holds for $k = j + 1$. In a similar manner, we can prove that (5.2) is satisfied for $k = j + 1$ when $x_j^v \le x_j^u \le x_{j+1}^v$ holds. By induction, we find that (5.2) holds for each $0 \le k \le \min(\ell_u, \ell_v)$. When $\ell_u < \ell_v$ is satisfied, we have

$$x_{\ell_u}^u \le x_{\ell_u+1}^v < x_{\ell_u+2}^v \le x_{\ell_v+1}^v \le x_{\ell_u+1}^u,$$

and then obtain $\phi^u(x)\,\phi^v(x) > 0$ for any $x \in (x^v_{\ell_u+1}, x^v_{\ell_u+2})$. This contradicts the fact of Lemma 4.2. In a similar manner, we can derive a contradiction when $\ell_v < \ell_u$ holds. Hence we have $\ell_u = \ell_v$.

We consider the case where there exists $k \in \mathbf{Z}$ such that $\phi^u(2\,k\,x_0) = 0$ holds. By Lemmas 5.1 and 5.3, we have $\phi(2\,k\,x_0) = 0$, $u_{0xx}(2\,k\,x_0) \neq 0$, and $\phi^u_x(2\,k\,x_0) \neq 0$. Setting

$$\boldsymbol{U}(x)\,(\equiv (U,V)(x)) = \boldsymbol{u}_{0x}(x) - \frac{u_{0xx}(2\,k\,x_0)}{\phi^u_x(2\,k\,x_0)}\,\phi(x),$$

we see that $\boldsymbol{U}(x)$ is a solution of $\mathcal{L}\,\boldsymbol{u} = 0$ and satisfies $\boldsymbol{U}(2\,k\,x_0) = 0$ and $U_x(2\,k\,x_0) = 0$. By Lemma 5.3, we obtain $\boldsymbol{U}(x) = 0$ for any $x \in \mathbf{R}$, which indicates $\phi(0) = 0$. This contradicts the fact $\phi^u(0) = 1$. Hence we have $\phi^u(2\,k\,x_0) \neq 0$ for any $k \in \mathbf{Z}$.

We consider the case where there exist j and k such that $2\,j\,x_0 < x^u_k < x^u_{k+1} < 2\,(j+1)\,x_0$. From Lemmas 4.2 and 4.3, we have $s_2\,\boldsymbol{u}_{0x}(x) \succ_o 0$ on $(2\,j\,x_0, 2\,(j+1)\,x_0)$ for some $s_2 \in \{-1, 1\}$, and $(-1)^k\,\phi^v(x_{12}) < 0$ for some $x_{12} \in (x^u_k, x^u_{k+1})$. Hence we see that there exists $0 \leq k' \leq \ell_v$ such that $x_{12} \in (x^v_{k'}, x^v_{k'+1})$ is satisfied. If $x^v_{k'} \leq 2\,j\,x_0$ holds, then we obtain $(-1)^k\,\phi^u(2\,j\,x_0) \geq 0$ by virtue of Lemma 5.1. By (5.1), we have $2\,j\,x_0 \leq x^u_{k-1}$ and $\phi^u(x)\,\phi^v(x) > 0$ for any $x \in (x^u_{k-1}, x^u_k)$. This contradicts the fact of Lemma 4.2. Therefore we obtain $2\,j\,x_0 < x^v_{k'}$. In a similar manner, we can prove $x^v_{k'+1} < 2\,(j+1)\,x_0$. Setting $x^-_{13} = \min(x^u_k, x^v_{k'})$ and $x^+_{13} = \max(x^u_{k+1}, x^v_{k'+1})$, we obtain

$$\begin{aligned}
&(-1)^k\,\phi^u(x) \leq 0 \quad \text{on } [x^-_{13}, x^u_k) \cup (x^u_{k+1}, x^+_{13}],\\
&(-1)^k\,\phi^v(x) \geq 0 \quad \text{on } [x^-_{13}, x^v_{k'}) \cup (x^v_{k'+1}, x^+_{13}]
\end{aligned}$$

because of Lemma 4.2. It follows that there exists $C_1 > 0$ such that

$$\boldsymbol{U}(x)\,(\equiv (U,V)(x)) = s_2\,\boldsymbol{u}_{0x}(x) - C_1\,(-1)^k\,\phi(x)$$

satisfies the following: (i) $\boldsymbol{U}(x)$ is a solution of $\mathcal{L}\,\boldsymbol{u} = 0$, (ii) $\boldsymbol{U}(x) \succeq_o 0$ holds for any $x \in [x^-_{13}, x^+_{13}]$, and (iii) there exists $x_{14} \in (x^-_{13}, x^+_{13})$ such that $U(x_{14})\,V(x_{14}) = 0$. Since $f^0_u(x) < 0$ and $g^0_u(x) < 0$ are satisfied for any $x \in \mathbf{R}$, we have

$$\begin{aligned}
&U_x(x_{14}) = 0, \quad 0 \leq \varepsilon\,U_{xx}(x_{14}) = -f^0_v(x_{14})\,V(x_{14}) \leq 0 \quad \text{if } U(x_{14}) = 0,\\
&V_x(x_{14}) = 0, \quad 0 \geq \varepsilon\,V_{xx}(x_{14}) = -g^0_u(x_{14})\,U(x_{14}) \geq 0 \quad \text{if } V(x_{14}) = 0.
\end{aligned}$$

These facts imply that $\boldsymbol{U}(x_{14}) = 0$ and $\boldsymbol{U}_x(x_{14}) = 0$ hold. By uniqueness, we obtain $\boldsymbol{U}(x) = 0$ for any $x \in \mathbf{R}$. This contradicts $U(0) = (-1)^{k+1}\,C_1 \neq 0$. Therefore we have

$$\#[\{\,x^u_k\,\}_{n=1}^{\ell_u} \cap (2\,j\,x_0, 2\,(j+1)\,x_0)] \leq 1$$

for any $0 \leq j < \ell(\boldsymbol{u}_0)$, where $\#A$ is the number of elements of the set A. In a similar manner, we can prove

$$\#[\{\,x^u_k\,\}_{n=1}^{\ell_u} \cap (2\,j\,x_0, 2\,(j+1)\,x_0)] \geq 1$$

for any $0 \leq j < \ell(\boldsymbol{u}_0)$. Hence we have

$$2\,j\,x_0 < x^u_{j+1} < 2\,(j+1)\,x_0 \tag{5.3}$$

for any $0 \le j < \ell(\boldsymbol{u}_0)$.

We see from Lemma 4.1 that $\boldsymbol{U}(x) = \phi(x + 4\,x_0) + \phi(4\,x_0 - x)$ is a solution of $\mathcal{L}\,\boldsymbol{u} = 0$ with $\boldsymbol{u}_x(0) = 0$. Since $\phi(x)$ is a periodic function with period 2, we obtain

$$\boldsymbol{U}(2 - x) = \phi(4\,x_0 - x + 2) + \phi(x + 4\,x_0 - 2) = \boldsymbol{U}(x)$$

for any $x \in \mathbf{R}$. Since $\boldsymbol{U} \in \mathcal{N}(\mathcal{L})$ holds because of $\boldsymbol{U}_x(1) = 0$, we find from Corollary 5.2 that there exists $C_2 \in \mathbf{R}$ such that $\boldsymbol{U}(x) = C_2\,\phi(x)$ for any $x \in \mathbf{R}$. Since $\phi^u(4\,k\,x_0) > 0$ and

$$2 \min_{0 \le j \le \ell(\boldsymbol{u}_0)} \phi^u(4\,j\,x_0) \le C_2\,\phi^u(4\,k\,x_0) \le 2 \max_{0 \le j \le \ell(\boldsymbol{u}_0)} \phi^u(4\,j\,x_0)$$

holds for any $0 \le k \le \ell(\boldsymbol{u}_0)$, we obtain $C_2 = 2$. By $\phi(x) = \phi(-x)$ for any $x \in \mathbf{R}$, we have

$$\begin{aligned}
\phi(4\,(k+2)\,x_0) - 2\,\phi(4\,(k+1)\,x_0) + \phi(4\,k\,x_0) = 0,\\
\phi_x(4\,(k+2)\,x_0) - 2\,\phi_x(4\,(k+1)\,x_0) + \phi_x(4\,k\,x_0) = 0
\end{aligned}$$

for any $k \in \mathbf{Z}$ and then obtain

$$\phi(4\,k\,x_0) = \phi(0) + k\,(\phi(4\,x_0) - \phi(0)), \quad \phi_x(4\,k\,x_0) = k\,\phi_x(4\,x_0)$$

for any $k \in \mathbf{Z}$. Since $\phi(x)$ is a periodic function, we have $\phi(4\,k\,x_0) = \phi(0)$ and $\phi_x(4\,k\,x_0) = 0$ for any $k \in \mathbf{Z}$. By uniqueness and Lemma 4.1, we obtain $\phi(x) = \phi(4\,x_0 - x)$ for any $x \in \mathbf{R}$. Hence we see that $\phi(x)$ is a nontrivial solution of

$$\begin{cases}
\mathcal{L}\,\boldsymbol{u} = 0, \quad x \in (0, 2\,x_0),\\
\boldsymbol{u}_x(0) = 0, \quad \boldsymbol{u}_x(2\,x_0) = 0.
\end{cases}$$

By Lemma 4.1 and $\boldsymbol{f}_{\boldsymbol{u}}(T\,\boldsymbol{u})T = T\,\boldsymbol{f}_{\boldsymbol{u}}(\boldsymbol{u})$ for any $\boldsymbol{u}$, we have $T\,\phi(2\,x_0 - .) \in \mathcal{N}(\mathcal{L})$. Hence it follows from Corollary 5.2 that there exists $C_3 \in \mathbf{R}$ such that $\phi(x) = C_3\,T\,\phi(2\,x_0 - x)$ for any $x \in \mathbf{R}$, which implies $\phi(x) = C_3^2\,\phi(x)$ for any $x \in \mathbf{R}$. Since $\phi(x)$ is nontrivial, we have either $C_3 = 1$ or $C_3 = -1$. Since $0 > \phi^u(2\,x_0) = -\phi^v(0) > 0$ holds if $C_3 = -1$, we obtain $C_3 = 1$, which implies $\phi^u(x) = \phi^v(2\,x_0 - x)$ for any $x \in \mathbf{R}$.

We may assume $H(x) > 0$ for any $x \in [0, x_0)$. (If not, we use the below argument by replacing $[0, 2\,x_0]$ and $\phi(x)$ with $[2\,x_0, 4\,x_0]$ and $-\phi(x)$, respectively.) By Lemma 4.1, we have $H(x) < 0$ for any $x \in (x_0, 2\,x_0]$. Setting $x_{15}^- = \min(x_1^u, x_1^v)$, $x_{15}^+ = \max(x_1^u, x_1^v)$, $\Phi(x) = \phi^u(x) + \phi^v(x)$, and $\Psi(x) = \phi^u(x) - \phi^v(x)$, we can easily check that $x_{15}^+ = 2\,x_0 - x_{15}^-$ holds and that $(\Phi, \Psi)(x)$ is a nontrivial solution of

$$\begin{cases}
\varepsilon\,\Phi_{xx} = a_{11}(x)\,\Phi + a_{12}(x)\,\Psi,\\
\varepsilon\,\Psi_{xx} = a_{21}(x)\,\Phi + a_{22}(x)\,\Psi, \quad x \in (0, 2\,x_0),\\
\Phi_x = 0, \quad \Psi_x = 0, \quad x = 0, 2\,x_0,
\end{cases}$$

where

$$\begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}(x) = \begin{pmatrix} (b+1)\,K - 1 & (1-b)\,H \\ H & K - 1 \end{pmatrix}(x).$$

Since $\phi^u(x) = \phi^v(2\,x_0 - x)$ holds for any $x \in \mathbf{R}$, we have $\Phi(x) = \Phi(2\,x_0 - x)$ and $\Psi(x) = -\Psi(2\,x_0 - x)$ for any $x \in \mathbf{R}$. By $\phi^v(0) < 0 < \phi^u(0)$, we obtain $\Psi(x) > 0$ for

any $x \in [0, x_{15}^-)$ and $\Psi(x) < 0$ for any $x \in (x_{15}^+, 2\,x_0]$. Furthermore if $\Phi(x_0) \neq 0$ holds, then we have $\Phi(x_0)\,\Phi(x) > 0$ for any $x \in [x_{15}^-, x_{15}^+]$. Since $K(x)$ satisfies $0 < K(x) < 1$ for any $x \in \mathbf{R}$ and

$$0 = \varepsilon\,K_{xx} + \left(1 - \frac{b+1}{2}\,K\right)K + \frac{b-1}{2}\,H^2, \quad x \in \mathbf{R},$$

we obtain $2/(b+1) \leq K(x) < 1$ for any $x \in \mathbf{R}$ by virtue of the comparison principle. Hence we have $a_{11}(x) > 0$ and $a_{22}(x) < 0$ for any $x \in \mathbf{R}$.

First of all, we consider the case $\Phi(x_0) > 0$. Suppose that $x_{16} < 2\,x_0$ holds, where

$$x_{16} = \sup\{\, y \in [x_0, 2\,x_0] \,|\, \Phi(x) \geq 0 \text{ for any } x \in [x_0, y]\,\}\,(> x_{15}^+).$$

Setting

$$x_{17} = \sup\{\, y \in [x_{16}, 2\,x_0] \,|\, \Phi(x) \leq 0 \text{ for any } x \in [x_{16}, y]\,\}\,(\leq 2\,x_0),$$

we have $\Phi_x(x_{17}) \geq 0$ because of $\Phi(2\,x_0) = 0$. Since $\Phi(x)$ satisfies $\Phi(x_{16}) = 0$, $\Phi_x(x_{16}) \leq 0$, and

$$\varepsilon\,\Phi_{xx}(x) = a_{11}(x)\,\Phi(x) + a_{12}(x)\,\Psi(x) < 0, \quad x \in [x_{16}, x_{17}],$$

we obtain $x_{17} > x_{16}$ and $\Phi_x(x_{17}) < 0$. This contradiction implies that $\Phi(x) \geq 0\,(\not\equiv 0)$ holds for any $x \in [0, 2\,x_0]$. Since $H(x)$ satisfies

$$\begin{cases} \varepsilon\,H_{xx} - a_{22}(x)\,H = 0, \quad x \in (0, 2\,x_0), \\ H_x(0) = 0, \quad H_x(2\,x_0) = 0, \end{cases}$$

we have

$$0 < \int_0^{2\,x_0} H(x)^2\,\Phi(x)\,dx = \int_0^{2\,x_0} (\varepsilon\,\Psi_{xx}(x) - a_{22}(x)\,\Psi(x))\,H(x)\,dx = 0$$

because of integration by parts. This is a contradiction.

We next consider the case $\Phi(x_0) < 0$. It is obvious that $\Phi(x) < 0$ holds for any $x \in [x_{15}^-, x_{15}^+]$. If there exist x_{18}^- and x_{18}^+ $(x_{15}^- \leq x_{18}^- < x_{18}^+ \leq x_0)$ such that $\Psi(x_{18}^\pm) = 0$ and $\Psi(x) \leq 0$ for any $x \in [x_{18}^-, x_{18}^+]$, then we have

$$\begin{aligned} 0 > \int_{x_{18}^-}^{x_{18}^+} H(x)^2\,\Phi(x)\,dx &= \int_{x_{18}^-}^{x_{18}^+} (\varepsilon\,\Psi_{xx}(x) - a_{22}(x)\,\Psi(x))\,H(x)\,dx \\ &= \varepsilon\,(\Psi_x(x_{18}^+)\,H(x_{18}^+) - \Psi_x(x_{18}^-)\,H(x_{18}^-)) \geq 0 \end{aligned}$$

because of $H(x_{18}^\pm) \geq 0$. This fact and $\Psi(x_0) = 0$ show that $\Psi(x) \geq 0$ holds for any $x \in [0, x_0]$. Since

$$\varepsilon\,\Phi_{xx}(x) = a_{11}(x)\,\Phi(x) + a_{12}(x)\,\Psi(x) < 0$$

holds if both of $\Phi(x) < 0$ and $0 \leq x < x_0$ are satisfied, we obtain $\Phi(x) < 0$ and $\Phi_x(x) > 0$ for any $0 \leq x < x_0$ because of $\Phi_x(x_0) = 0$. This contradicts $\Phi_x(0) = 0$.

Finally, we consider the case $\Phi(x_0) = 0$. We have $x_{15}^- = x_{15}^+ = x_0$ because of $\Phi(x_0) = 2\,\phi^u(x_0)$. Since $(\Phi, \Psi)(x)$ is nontrivial, we obtain $\Psi_x(x_0) < 0$ and

$$\varepsilon\,\Phi_{xxxx}(x_0) = 2\,(1-b)\,H_x(x_0)\,\Psi_x(x_0) < 0.$$

We can derive a contradiction in a similar manner with the proof for the case where $\Phi(x_0) < 0$.

The above contradictions show that the following lemma holds.

LEMMA 5.4. *$0 \notin \sigma(\mathcal{L})$ holds.*

6. Proof of Theorem 2.1. Let $n \in \mathbf{N}$ be arbitrarily fixed. It follows from Lemmas 3.1, 4.5, 5.4, and Corollary 4.4 that there exists a maximal extended interval $J_n = (\eta_n, \varepsilon_n)$ such that the following property is satisfied:

(i) There exists a pair of C^1-class functions $\boldsymbol{u}_n^{\pm}(.,\varepsilon) = (u_n^{\pm}, v_n^{\pm})(.,\varepsilon)$ defined on J_n such that fact (i) in Theorem 2.1 holds for any $\varepsilon \in J_n$.

(ii) $\boldsymbol{u}_n^{\pm}(.,\varepsilon_n(\mu)) = \hat{\boldsymbol{u}}_n(.,\pm\mu)$ hold for any $0 \le \mu < \mu_n$.

By (1.1), we can easily obtain

$$\int_0^1 f(\boldsymbol{u}_n^{\pm}(x,\varepsilon))\,dx = 0, \quad \int_0^1 g(\boldsymbol{u}_n^{\pm}(x,\varepsilon))\,dx = 0$$

for each $\varepsilon \in J_n$. Since $\boldsymbol{u}_n^{\pm}(x,\varepsilon) \in [0,1] \times [0,1]$ hold for any x and ε because of the comparison principle, we see from the Ascoli–Arzela theorem that there exist stationary solutions $\boldsymbol{w}_0^-(x)$ and $\boldsymbol{w}_0^+(x)$ of (1.1) such that $\boldsymbol{u}_n^{\pm}(.,\varepsilon) \to \boldsymbol{w}_0^{\pm}$ as $\varepsilon \to \eta_n$ in X. Furthermore, we also find that $\boldsymbol{w}_0^-(x) \succeq_s 0$ and $\boldsymbol{w}_0^+(x) \succeq_s 0$ are satisfied for any $x \in [0,1]$.

We consider the case where there exists $x_{19} \in [0,1]$ such that $w^u(x_{19}) = 0$ holds, where $\boldsymbol{w}_0^+(x) = (w^u, w^v)(x)$. By $w_x^u(x_{19}) = 0$, we have $w^u(x) = 0$ for any $x \in [0,1]$ because of uniqueness. Hence we see that $w^v(x)$ is a nonnegative solution of

$$\begin{cases} 0 = \eta_n\, v_{xx} + v\,(1-v), & x \in (0,1), \\ v_x(0) = 0, \quad v_x(1) = 0, \end{cases}$$

which implies either (a) $w^v(x) \equiv 0$ on $[0,1]$ or (b) $w^v(x) \equiv 1$ on $[0,1]$. Since

$$\frac{f(\boldsymbol{u}_n^+(.,\varepsilon))}{u_n^+(.,\varepsilon)} \to \begin{cases} 1 & \text{for the case (a)}, \\ 1-b\,(<0) & \text{for the case (b)} \end{cases}$$

as $\varepsilon \to \eta_n$ holds in X, we have

$$\int_0^1 f(\boldsymbol{u}_n^+(x,\varepsilon))\,dx \begin{cases} > 0 & \text{for the case (a)}, \\ < 0 & \text{for the case (b)} \end{cases}$$

in a neighborhood of $\varepsilon = \eta_n$. This contradiction implies that $w^u(x) > 0$ holds for any $x \in [0,1]$. In a similar manner, we can prove $w^v(x) > 0$ for any $x \in [0,1]$. Hence we see that $\boldsymbol{w}_0^+(x)$ is positive. Analogously we can show that $\boldsymbol{w}_0^-(x)$ is also positive.

We consider the case where $\eta_n > 0$. By Corollary 4.4 and Lemma 4.5, we have $\ell(\boldsymbol{u}_n^{\pm}(.,\varepsilon)) = n$ for any $\varepsilon \in J_n$. By Lemma 5.4 and the implicit function theorem, it follows that $\boldsymbol{w}_0^-(x)$ and/or $\boldsymbol{w}_0^+(x)$ must be spatially homogeneous. Lemma 3.1 leads to the fact that $\eta_n = \varepsilon_m$ holds for some $m > n$. By Corollary 4.4, we see that $\ell(\boldsymbol{u}_n^-(.,\varepsilon)) = m$ or $\ell(\boldsymbol{u}_n^+(.,\varepsilon)) = m$ holds in a neighborhood of $\varepsilon = \eta_n$. This is a contradiction. Hence we have $\eta_n = 0$.

Let $\eta > 0$, and let $\boldsymbol{u}_0(x)$ be an arbitrary spatial inhomogeneous positive stationary solution of (1.1) for $\varepsilon = \eta$. We find from Lemma 5.4 and the implicit function theorem that there exists a maximal extended interval $J = (\varepsilon_-, \varepsilon_+)$ such that the following properties hold:

(i) $\eta \in \operatorname{Int} J$ is satisfied.

(ii) There exists a C^1-class function $\boldsymbol{w}(.,\varepsilon)$ defined on J such that $\boldsymbol{w}(x,\varepsilon)$ is a spatially inhomogeneous positive stationary solution of (1.1) for each $\varepsilon \in J$ and satisfies $\boldsymbol{w}(.,\eta) = \boldsymbol{u}_0$.

By Lemma 4.5, we have $\ell(\boldsymbol{w}(.,\varepsilon)) = \ell(\boldsymbol{u}_0)$ for any $\varepsilon \in J$, which implies $\varepsilon_+ \leq 1/(\pi^2\,\ell(\boldsymbol{u}_0)^2)$. Lemma 5.4, the implicit function theorem, and the above argument show that the limit $\lim_{\varepsilon\to\varepsilon_+} \boldsymbol{w}(x,\varepsilon)$ must be spatially homogeneous and positive. By Lemma 3.1 and Corollary 4.4, we have $\varepsilon_+ = \varepsilon_{\ell(\boldsymbol{u}_0)}$ and then obtain $\boldsymbol{u}_0 = \boldsymbol{u}^{\nu}_{\ell(\boldsymbol{u}_0)}(.,\eta)$ for some $\nu \in \{+,-\}$. Thus the proof is completed. □

ON THE PROPERTIES OF SOME NONLINEAR EIGENVALUES*

ANGELO ALVINO†, VINCENZO FERONE†, AND GUIDO TROMBETTI†

Abstract. We consider the eigenvalue problem for a nonlinear equation involving the p-Laplacian with homogeneous Dirichlet conditions. We give some properties of the first eigenvalue and of the corresponding eigenfunction. In particular we prove inequalities similar to the well-known Payne–Rayner inequality, which holds in the linear case.

Key words. nonlinear eigenvalues, Payne–Rayner inequality, symmetrization

1. Introduction.

Let Ω be a bounded domain in $\mathbb{R}^n$, $n \geq 2$. It is well known that the first eigenvalue of the problem,

$$\begin{cases} -\Delta u = \lambda u & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

is positive and simple; that is, all the corresponding eigenfunctions are scalar multiples of each other. Furthermore, if λ is the first eigenvalue of (1.1) then

$$\lambda = \min_{\substack{u \in W_0^{1,2}(\Omega) \\ u \not\equiv 0}} \frac{\displaystyle\int_\Omega |\nabla u|^2 \, dx}{\displaystyle\int_\Omega |u|^2 \, dx}. \tag{1.2}$$

Various comparison results have been given for λ and the associated eigenfunction. For example, when $n = 2$, in [PR1] the following inequality has been proven:

$$\int_\Omega u^2 \, dx \leq \frac{\lambda}{4\pi} \left(\int_\Omega |u| \, dx \right)^2,$$

where u is any eigenfunction of (1.1) corresponding to the first eigenvalue. Such a result has been extended in various directions. For example in [KJ] (see also [PR2]) a similar inequality has been proven for any dimension n, and in [C1], [C2], it has been shown that for any $0 < q < r < \infty$ one has

$$\|u\|_r \leq K(r, q, n, \lambda) \, \|u\|_q, \tag{1.3}$$

where K is a suitable constant. We observe that the inequalities we are referring to are isoperimetric; that is, they hold as equalities if and only if Ω is a ball.

Our aim is to show that all the properties we have recalled about the first eigenvalue of (1.1) can be proven also for the first eigenvalue of the following nonlinear problem:

$$\begin{cases} -\Delta_p u = \lambda u|u|^{p-2} & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.4}$$

where Δ_p denotes the p-Laplacian, that is, $\Delta_p u = \operatorname{div}\big(|\nabla u|^{p-2}\nabla u\big)$. The properties of the first eigenvalue and of the corresponding eigenfunctions of problem (1.4) have been studied by various authors (see, e.g., [Th], [A], [Sa], [B1], [B2], [L1], [L2]). For example, they prove that the first eigenvalue of (1.4) is positive, simple, and isolated.

We will consider the more general problem

$$\begin{cases} -\operatorname{div}\big((A\nabla u, \nabla u)^{(p-2)/2} A\nabla u\big) = \lambda u|u|^{p-2} & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{1.5}$$

where $p > 1$ and $A = \{a_{ij}(x)\}$ is a symmetric matrix with measurable bounded coefficients satisfying an ellipticity condition. After having proven that the simplicity of the first eigenvalue of (1.5) is still true, by adapting the arguments of [L1], we give a Faber–Krahn inequality for the first eigenvalue λ_p of (1.5) (see [C1] for the case $p = 2$). In particular we will show that the first eigenvalue of (1.4) in a ball with the same measure as Ω is smaller or equal to λ_p and, furthermore, that equality holds if and only if Ω is a ball and $a_{ij}x_j = x_i$ for a.e. $x \in \mathbb{R}^n$, modulo translations.

It is well known that (see, e.g., [G]) any solution of (1.5) is bounded. In the last section of the paper we prove the following "reverse" inequality:

$$\|u\|_r \le \beta(r, q, p, n, \lambda_p)\, \|u\|_q, \tag{1.6}$$

where $0 < q < r \le \infty$. We remark that, as (1.3), the above inequality is isoperimetric. The proof of (1.6) is based on a comparison result between u and a suitable eigenfunction v of problem (1.4) defined in a ball B such that the corresponding first eigenvalue is equal to λ_p. This result is a consequence of a comparison result between solution and subsolutions of a one-dimensional problem of the following type:

$$\begin{cases} -\big(|\varphi'(s)|^{\gamma-2}\varphi'(s)\big)' = \lambda m(s)|\varphi(s)|^{\gamma-2}\varphi(s) & \text{in } (0, a), \\ \varphi(0) = \varphi(a) = 0, \end{cases}$$

where the weight $m(s)$ is a continuous function in the interval $(0, a)$ satisfying suitable assumptions. Obviously the comparison result between u and v is isoperimetric.

We finally recall that some estimates similar to (1.6) can be found also in [M].

2. General results about eigenvalues. Let Ω be a bounded domain in $\mathbb{R}^n$, $n \ge 2$. Let us consider the first eigenvalue λ_p of the problem

$$\begin{cases} -\operatorname{div}\big((A\nabla u, \nabla u)^{(p-2)/2} A\nabla u\big) = \lambda u|u|^{p-2} & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{2.1}$$

where $p > 1$ and $A = \{a_{ij}(x)\}$ is a symmetric matrix with measurable bounded coefficients satisfying the ellipticity condition

$$a_{ij}(x)\xi_j\xi_i \ge |\xi|^2, \quad \text{a.e. } x \in \Omega\, \forall \xi \in \mathbb{R}^n.$$

It is well known that λ_p is the minimum of the Rayleigh quotient

$$\lambda_p = \min_{\substack{u\in W_0^{1,p}(\Omega)\\ u\not\equiv 0}} \frac{\displaystyle\int_\Omega (A\nabla u,\nabla u)^{p/2}\,dx}{\displaystyle\int_\Omega |u|^p\,dx} \tag{2.2}$$

and that the above minimization problem is equivalent to the weak form of (2.1) with $\lambda=\lambda_p$, that is,

$$\int_\Omega \big(A\nabla u,\nabla u\big)^{(p-2)/2}\big(A\nabla u,\nabla\varphi\big)dx = \lambda_p\int_\Omega u|u|^{p-2}\varphi\,dx \quad \forall\varphi\in W_0^{1,p}(\Omega). \tag{2.3}$$

Furthermore, the existence of a first eigenfunction and of the first eigenvalue can be proven by standard tools.

Using the methods in [L1] it is also possible to prove the following property for the eigenfunctions of (2.1).

THEOREM 2.1. *The first eigenvalue of* (2.1) *is simple; that is, all the associated eigenfunctions u are scalar multiples of each other.*

The proof of the above theorem is based on the following lemma, whose proof will be given in the Appendix (see also [L1]).

LEMMA 2.2. *Let $A=\{a_{ij}\}$ be a symmetric matrix such that $a_{ij}\xi_j\xi_i \ge |\xi|^2$ $\forall\xi\in\mathbb{R}^n$. Then we have:*

(i) *if $p\ge 2$:*

$$\big(A\xi_2,\xi_2\big)^{p/2}\ge \big(A\xi_1,\xi_1\big)^{p/2}+p\big(A\xi_1,\xi_1\big)^{\frac{p-2}{2}}\big(A\xi_1,\xi_2-\xi_1\big)+\frac{\big(A(\xi_2-\xi_1),\xi_2-\xi_1\big)^{p/2}}{2^{p-1}-1}$$

for every $\xi_1,\xi_2\in\mathbb{R}^n$;

(ii) *if $1<p<2$:*

$$\big(A\xi_2,\xi_2\big)^{p/2}\ge \big(A\xi_1,\xi_1\big)^{p/2}+p\big(A\xi_1,\xi_1\big)^{\frac{p-2}{2}}\big(A\xi_1,\xi_2-\xi_1\big) + c(p)\frac{\big(A(\xi_2-\xi_1),\xi_2-\xi_1\big)}{\big(\sqrt{(A\xi_1,\xi_1)}+\sqrt{(A\xi_2,\xi_2)}\big)^{2-p}}$$

for every $\xi_1,\xi_2\in\mathbb{R}^n$, where $c(p)$ is a constant which depends only on p.

Proof of Theorem 2.1. First of all we observe that any solution of (2.1) is Hölder continuous (see, e.g., [G]). Furthermore, if u minimizes (2.2), then $|u|$ does also; that is, $|u|$ is also an eigenfunction. By Harnack's inequality (see, e.g., [Se], [Tr]) it follows that either $|u|>0$ or $|u|\equiv 0$ in Ω. This means that if u is an eigenfunction then $u>0$ or $u<0$ in Ω.

Suppose now that u and v are two positive eigenfunctions relative to the first eigenvalue of (2.1). Clearly both u and v satisfy (2.3). We will prove that u and v are proportional. Following the arguments of [L1] we put $u_\varepsilon=u+\varepsilon$ and $v_\varepsilon=v+\varepsilon$ for $\varepsilon>0$. Then we use the test functions $\varphi=\big(u_\varepsilon^p-v_\varepsilon^p\big)/u_\varepsilon^{p-1}$ in the equation satisfied by u and $\varphi=\big(v_\varepsilon^p-u_\varepsilon^p\big)/v_\varepsilon^{p-1}$ in the equation satisfied by v. Adding the obtained equalities we have

$$\lambda_p\int_\Omega\left[\frac{u^{p-1}}{u_\varepsilon^{p-1}}-\frac{v^{p-1}}{v_\varepsilon^{p-1}}\right](u_\varepsilon^p-v_\varepsilon^p)dx$$

$$= \int_\Omega \big(A\nabla u_\varepsilon, \nabla u_\varepsilon\big)^{p/2} \left[1 + (p-1)\frac{v_\varepsilon^p}{u_\varepsilon^p}\right] dx + \int_\Omega \big(A\nabla v_\varepsilon, \nabla v_\varepsilon\big)^{p/2} \left[1 + (p-1)\frac{u_\varepsilon^p}{v_\varepsilon^p}\right] dx$$
$$- \int_\Omega p\big(A\nabla u_\varepsilon, \nabla v_\varepsilon\big) \left[\big(A\nabla u_\varepsilon, \nabla u_\varepsilon\big)^{(p-2)/2} \frac{v_\varepsilon^{p-1}}{u_\varepsilon^{p-1}} + \big(A\nabla v_\varepsilon, \nabla v_\varepsilon\big)^{(p-2)/2} \frac{u_\varepsilon^{p-1}}{v_\varepsilon^{p-1}}\right] dx.$$

Observing that $\big(A\nabla u_\varepsilon, \nabla u_\varepsilon\big)/u_\varepsilon^2 = \big(A\nabla(\log u_\varepsilon), \nabla(\log u_\varepsilon)\big)$, from Lemma 2.2 it follows that

$$\lambda_p \int_\Omega \left[\frac{u^{p-1}}{u_\varepsilon^{p-1}} - \frac{v^{p-1}}{v_\varepsilon^{p-1}}\right] (u_\varepsilon^p - v_\varepsilon^p) dx \geq 0. \tag{2.4}$$

On the other hand we also have

$$\lim_{\varepsilon \to 0^+} \int_\Omega \left[\frac{u^{p-1}}{u_\varepsilon^{p-1}} - \frac{v^{p-1}}{v_\varepsilon^{p-1}}\right] (u_\varepsilon^p - v_\varepsilon^p) dx = 0. \tag{2.5}$$

Let us now consider $p \geq 2$. Lemma 2.2 and the ellipticity condition allow us to write also

$$\lambda_p \int_\Omega \left[\frac{u^{p-1}}{u_\varepsilon^{p-1}} - \frac{v^{p-1}}{v_\varepsilon^{p-1}}\right] (u_\varepsilon^p - v_\varepsilon^p) dx \tag{2.6}$$
$$\geq \frac{1}{2^{p-1}-1} \int_\Omega (u_\varepsilon^p + v_\varepsilon^p) \Big(A\big(\nabla(\log u_\varepsilon - \log v_\varepsilon)\big), \nabla(\log u_\varepsilon - \log v_\varepsilon)\Big)^{p/2} dx$$
$$= \frac{1}{2^{p-1}-1} \int_\Omega \left(\frac{1}{u_\varepsilon^p} + \frac{1}{v_\varepsilon^p}\right) \Big(A\big(v_\varepsilon \nabla u_\varepsilon - u_\varepsilon \nabla v_\varepsilon\big), v_\varepsilon \nabla u_\varepsilon - u_\varepsilon \nabla v_\varepsilon\Big)^{p/2} dx$$
$$\geq \frac{1}{2^{p-1}-1} \int_\Omega \left(\frac{1}{u_\varepsilon^p} + \frac{1}{v_\varepsilon^p}\right) |v_\varepsilon \nabla u_\varepsilon - u_\varepsilon \nabla v_\varepsilon|^p dx \geq 0.$$

Passing to the limit in (2.6) and using (2.5), one obtains that u is proportional to v in Ω.

In the case $1 < p < 2$ one can use similar arguments. Instead of (2.6), by Lemma 2.2 one gets

$$\lambda_p \int_\Omega \left[\frac{u^{p-1}}{u_\varepsilon^{p-1}} - \frac{v^{p-1}}{v_\varepsilon^{p-1}}\right] (u_\varepsilon^p - v_\varepsilon^p) dx$$
$$\geq c(p) \int_\Omega \left(\frac{1}{u_\varepsilon^p} + \frac{1}{v_\varepsilon^p}\right) \frac{|v_\varepsilon \nabla u_\varepsilon - u_\varepsilon \nabla v_\varepsilon|^2}{\big(v_\varepsilon \sqrt{(Au_\varepsilon, u_\varepsilon)} + u_\varepsilon \sqrt{(Av_\varepsilon, v_\varepsilon)}\big)^{2-p}} dx \geq 0,$$

which gives the same conclusion. □

Clearly the above results also hold true when $n = 1$, for example, for the following eigenvalue problem in an interval $(0, a)$:

$$\begin{cases} -\big(|\varphi'(s)|^{\gamma-2}\varphi'(s)\big)' = \lambda |\varphi(s)|^{\gamma-2}\varphi(s) & \text{in } (0,a), \\ \varphi(0) = \varphi(a) = 0, \end{cases} \tag{2.7}$$

where $\gamma > 1$ (see, e.g., [O1], [O2]). We give here a version of Theorem 2.1 for a problem slightly more general than (2.7). More precisely we consider the problem

$$\begin{cases} -\big(|\varphi'(s)|^{\gamma-2}\varphi'(s)\big)' = \lambda m(s) |\varphi(s)|^{\gamma-2}\varphi(s) & \text{in } (0,a), \\ \varphi(0) = \varphi(a) = 0, \end{cases} \tag{2.8}$$

where the weight $m(s)$ is a continuous function in $(0,a)$ satisfying the condition

$$0 < m(s) \le \frac{c}{\big(\sigma(s)\big)^{\gamma-\alpha}}, \tag{2.9}$$

with c a positive constant, $\alpha > 0$, $\sigma(s) = \min(s, a-s)$. Once again the first eigenvalue λ_γ of problem (2.8) can be found as minimum of the Rayleigh quotient

$$\lambda_\gamma = \min_{\substack{\varphi \in W_0^{1,\gamma}(0,a) \\ \varphi \not\equiv 0}} \frac{\displaystyle\int_0^a |\varphi'(s)|^\gamma \, ds}{\displaystyle\int_0^a m(s)|\varphi(s)|^\gamma \, ds}. \tag{2.10}$$

The existence of a first eigenfunction and of the first eigenvalue can be proven by standard tools also in this case. It is enough to observe that, under assumption (2.9), the embedding of $W_0^{1,\gamma}(0,a)$ in the weighted space $L^\gamma_m(0,a)$ is compact (see for example [N]).

Using the methods of Theorem 2.1 it is possible to prove the following theorem.

THEOREM 2.3. *The first eigenvalue of* (2.8) *is simple; that is, all the associated eigenfunctions u are scalar multiples of each other.*

Proof. All the arguments in the proof of Theorem 2.1 work in the same way for problem (2.8) and for the corresponding weak formulation. So, let $u > 0$, $v > 0$, two eigenfunctions of (2.8), relative to the first eigenvalue. We have to verify the analogue of (2.5), that is,

$$\lim_{\varepsilon \to 0^+} \int_0^a \left[\left(\frac{u(s)}{u_\varepsilon(s)} \right)^{\gamma-1} - \left(\frac{v(s)}{v_\varepsilon(s)} \right)^{\gamma-1} \right] \big(u_\varepsilon^\gamma(s) - v_\varepsilon^\gamma(s) \big) m(s) \, ds = 0,$$

where $u_\varepsilon = u + \varepsilon$ and $v_\varepsilon = v + \varepsilon$, $\varepsilon > 0$. The above result can be obtained by simply observing that for $\eta \in (0, a/2)$ we have

$$\int_0^a f_\varepsilon(s) \, ds = \int_0^\eta f_\varepsilon(s) \, ds + \int_{a-\eta}^a f_\varepsilon(s) \, ds + \int_\eta^{a-\eta} f_\varepsilon(s) \, ds,$$

where

$$f_\varepsilon(s) = \left[\left(\frac{u(s)}{u_\varepsilon(s)} \right)^{\gamma-1} - \left(\frac{v(s)}{v_\varepsilon(s)} \right)^{\gamma-1} \right] \big(u_\varepsilon^\gamma(s) - v_\varepsilon^\gamma(s) \big) m(s).$$

The last integral goes to zero as $\varepsilon \to 0^+$, while, using (2.9) and well-known embedding results (see [N]), the first two integrals can be made arbitrarily close to zero by suitably choosing η. The claim is then proven. □

We are interested in the case

$$m(s) = \begin{cases} s^{\alpha-\gamma} & \text{if } s \in (0, a/2), \\ (a-s)^{\alpha-\gamma} & \text{if } s \in (a/2, a), \end{cases} \tag{2.11}$$

where $\alpha > 0$. Using the symmetry of the problem, the Pólya–Szegö principle, and Hardy–Littlewood inequality, it is easy to show that any positive eigenfunction of (2.8) with $m(s)$ as in (2.11) is symmetric with respect to $s = a/2$, and it is increasing in $(0, a/2)$, decreasing in $(a/2, a)$.

In particular such a result allows us to obtain information about the following one-dimensional problem:

$$\begin{cases} -\big(|\varphi'(s)|^{\gamma-2}\varphi'(s)\big)' = \mu\, s^{\alpha-\gamma}|\varphi(s)|^{\gamma-2}\varphi(s) & \text{in } (0,b), \\ \varphi(0) = \varphi'(b) = 0. \end{cases} \tag{2.12}$$

The first eigenvalue of such a problem is given by

$$\mu_\gamma = \min_{\substack{\varphi\in W^{1,\gamma}(0,b)\\ \varphi\not\equiv 0,\ \varphi(0)=0}} \frac{\displaystyle\int_0^b |\varphi'(s)|^\gamma\, ds}{\displaystyle\int_0^b |\varphi(s)|^\gamma s^{\alpha-\gamma}\, ds}. \tag{2.13}$$

Indeed any function which realizes the minimum in (2.13) suitably extended by symmetry in $(0,2b)$ can be used as the test function vanishing in 0 and $2b$ in the Rayleigh quotient

$$\frac{\displaystyle\int_0^{2b} |\varphi'(s)|^\gamma\, ds}{\displaystyle\int_0^{2b} |\varphi(s)|^\gamma m(s)\, ds}.$$

Conversely, if $\varphi \in W_0^{1,\gamma}(0,2b)$ minimizes the above quotient in $W_0^{1,\gamma}(0,2b)$ then the restriction of φ to $(0,b)$ can be used as test function in (2.13). A simple consequence of the above considerations is the following.

THEOREM 2.4. *The first eigenvalue of* (2.12) *is simple; that is, all the associated eigenfunctions u are scalar multiples of each other. Furthermore every positive eigenfunction of* (2.12) *associated with the first eigenvalue is strictly increasing in* $(0,b)$.

Now we state a useful comparison lemma which can be seen as the "nonlinear" version of analogous "linear" results (see, e.g., [Ba]).

LEMMA 2.5. *Let μ_γ be the first eigenvalue of* (2.12) *and let φ be a positive eigenfunction associated with μ_γ. Suppose that, for $c > b$, $\psi \in W^{1,\gamma}(0,c)$ is a nonnegative increasing function such that $\big(\psi'(s)^{\gamma-1}\big)$ is absolutely continuous in $[\varepsilon, c]$ for every $\varepsilon > 0$, and*

$$\begin{cases} -\big((\psi'(s))^{\gamma-1}\big)' \le \mu_\gamma\, s^{\alpha-\gamma}(\psi(s))^{\gamma-1} & \text{a.e. in } (0,c), \\ \psi(0) = \psi'(c) = 0. \end{cases} \tag{2.14}$$

If there exists $s_1 \in (0,b)$ such that $\varphi'(s_1) = \psi'(s_1)$ then

$$\psi(s) \le \varphi(s), \qquad \forall s \in (0, s_1). \tag{2.15}$$

Proof. First of all we prove that $\psi(s_1) \le \varphi(s_1)$. Suppose, ab absurdo, that $\psi(s_1) > \varphi(s_1)$. We put $w(s) = \psi(s) - \varphi(s)$. We define

$$z(s) = \begin{cases} \psi(s) & \text{if } s \in (0, s_1), \\ \varphi(s) + w(s_1) & \text{if } s \in [s_1, b]. \end{cases} \tag{2.16}$$

By construction, $\big(z'(s)\big)^{\gamma-1}$ is absolutely continuous in $[\varepsilon, c]$ for every $\varepsilon > 0$, and $z(s)$ satisfies

$$\begin{aligned}
&\big(z'(s)\big)^{\gamma-1} = \big(\varphi'(s)\big)^{\gamma-1}, \qquad z(s) > \varphi(s), \qquad s \in (s_1, b),\\
&\big(z'(s)\big)^{\gamma-1} = \big(\psi'(s)\big)^{\gamma-1}, \qquad z(s) = \psi(s), \qquad s \in (0, s_1).
\end{aligned}$$

This means that $z(s)$ satisfies the inequality

$$-\big((z'(s))^{\gamma-1}\big)' \le \mu_\gamma\, s^{\alpha-\gamma}(z(s))^{\gamma-1}, \quad \text{a.e. in } (0,b).$$

Multiplying the above inequality by $z(s)$ and integrating we obtain

$$\int_0^b |z'(s)|^\gamma ds \le \mu_\gamma \int_0^b |z(s)|^\gamma s^{\alpha-\gamma} ds,$$

where, taking into account the continuity of the embedding of $W^{1,\gamma}(0,b)$ into $L^\gamma_{s^{-\gamma}}(0,b)$, we have used the following:

$$\lim_{\varepsilon\to 0^+} \big(z'(\varepsilon)\big)^{\gamma-1} z(\varepsilon) = 0.$$

We have then proven

$$\min_{\substack{\varphi\in W^{1,p}(0,b)\\ \varphi\not\equiv 0\ \varphi(0)=0}} \frac{\displaystyle\int_0^b |\varphi'(s)|^p}{\displaystyle\int_0^b |\varphi(s)|^\gamma s^{\alpha-\gamma} ds} \le \mu_\gamma. \tag{2.17}$$

Using (2.13) and Theorem 2.4 we have that in (2.17) the equality sign has to hold and that $z(s)$ is proportional to $\varphi(s)$. Then, by (2.16), it has to coincide with $\varphi(s)$. But this is a contradiction. The claim is then proven.

In order to completely prove the assertion we observe that, if $\psi(s) > \varphi(s)$ for some $s \in (0, s_1)$, then a positive maximum $\tilde{s} \in (0, s_1)$ of $w(s)$ would exist. But this is forbidden because one can repeat the above arguments with $\tilde{s}$ in place of s_1. □

Remark 2.1. The assumption $c > b$ in Lemma 2.5 takes into account the only nontrivial case. Indeed, if $c = b$, then a function ψ which satisfies (2.14) has to coincide with the eigenfunction associated to the first eigenvalue of (2.12). This means that the hypothesis $\varphi'(s_1) = \psi'(s_1)$, $s_1 \in (0, b)$, implies $\varphi(s) = \psi(s)$.

About the case $c < b$ it is simple to observe that under such an assumption no function $\psi \not\equiv 0$ satisfying (2.14) exists. In fact, the existence of such a function would imply that the first eigenvalue of problem (2.13) in the interval $(0, b)$ is bigger or equal to the first eigenvalue of the same problem in $(0, c)$. This contradicts the fact that the first eigenvalue is a strictly decreasing function of the measure of the interval.

Remark 2.2. If one retraces the proof of Lemma 2.5 it is evident that it is not necessary that ψ satisfies (2.14) in an interval $(0, c)$. One can simply suppose that for $s_1 \in (0, b)$ the following condition holds:

$$\begin{cases} -\big((\psi'(s))^{\gamma-1}\big)' \le \mu_\gamma\, s^{\alpha-\gamma}(\psi(s))^{\gamma-1} & \text{a.e. in } (0, s_1),\\ \psi(0) = 0, \quad \psi'(s_1) = \varphi'(s_1). \end{cases}$$

3. Faber–Krahn inequality. In this section we will prove the following comparison result for the first eigenvalue of problem (2.1).

THEOREM 3.1. *If λ_p is the first eigenvalue of problem* (2.1) *then*

$$\lambda_p \geq \lambda_p^{\#},$$

where $\lambda_p^{\#}$ is the first eigenvalue of the problem

$$\begin{cases} -\mathrm{div}\big(|\nabla v|^{p-2}\nabla v\big) = \lambda v|v|^{p-2} & \text{in } \Omega^{\#}, \\ v = 0 & \text{on } \partial\Omega^{\#}, \end{cases} \tag{3.1}$$

and $\Omega^{\#}$ is the ball centered at the origin such that $|\Omega^{\#}| = |\Omega|$, where, here and in the following, we denote by $|E|$ the measure of any measurable set $E \subset \mathbb{R}^n$. Furthermore, $\lambda_p = \lambda_p^{\#}$ if and only if $\Omega = \Omega^{\#}$ and $a_{ij}(x)x_j = x_i$, a.e. in Ω, modulo translations.

Remark 3.1. In the case $p = 2$, $n = 2$ the above result is known as the Faber–Krahn theorem. In such a case it can be stated as *the membrane with lowest principal frequency is the circular one.*

Remark 3.2. We observe explicitly that, if B is a ball centered at the origin, then ν_p is the first eigenvalue of problem (3.1) in B if and only if the one-dimensional problem

$$\begin{cases} -\big(|\varphi'(s)|^{\gamma-2}\varphi'(s)\big)' = \mu\, s^{-\gamma(1-1/n)}|\varphi(s)|^{\gamma-2}\varphi(s) & \text{in } (0,|B|), \\ \varphi(0) = \varphi'(|B|) = 0, \end{cases}$$

where $\gamma = p' = p/(p-1)$, has first eigenvalue

$$\mu_\gamma = \left(\frac{\nu_p^{1/p}}{nC_n^{1/n}}\right)^{p'}.$$

Such a claim follows from the symmetry of problem (3.1). Because of the simplicity of the first eigenvalue, any eigenfunction v associated with the first eigenvalue of problem (3.1) in a ball B is spherically symmetric. If we put $B_s = \{x : C_n|x|^n < s\}$ and $V(s) = \int_{B_s} v^{p-1}(x)\,dx$, where v is a positive eigenfunction, we have

$$\begin{cases} -\Big(\big(V'(s)\big)^{1/(p-1)}\Big)' = \frac{\nu_p^{1/(p-1)}}{(nC_n^{1/n}s^{1-1/n})^{p/(p-1)}}\big(V(s)\big)^{1/(p-1)} & \text{in } (0,|B|), \\ V(0) = V'(|B|) = 0, \end{cases}$$

and the assertion follows.

Before giving the proof of Theorem 3.1 we recall a few definitions about rearrangements (for more details see, e.g., [Ba], [Ta1], [Ta3]). If $\varphi : \Omega \to \mathbb{R}$ is a measurable function we define the decreasing rearrangement of φ

$$\varphi^*(s) = \sup\{t > 0 : |\{x \in \Omega : |\varphi(x)| > t\}| > s\}$$

and the spherically symmetric decreasing rearrangement of φ

$$\varphi^{\#}(x) = \varphi^*(C_n|x|^n),$$

where C_n denotes the measure of the unit ball in $\mathbb{R}^n$.

The following result proven in [BZ] will be useful in the proof of Theorem 3.1.

THEOREM 3.2. *Let u be a positive function in $W_0^{1,p}(\Omega)$, $1 < p < \infty$. Suppose that the equality sign holds in the Pólya–Szegö inequality, that is,*

$$\int_\Omega |\nabla u|^p \, dx = \int_{\Omega^\#} |\nabla u^\#|^p \, dx.$$

If $|\{x : \nabla u^\# = 0\} \cap {u^\#}^{-1}(0, \operatorname{ess\,sup} u)| = 0$, then $u = u^\#$ a.e., modulo translations.

Proof of Theorem 3.1. Clearly $\lambda_p^\#$ can be written as

$$\lambda_p^\# = \min_{v \in W_0^{1,p}(\Omega^\#)} \frac{\displaystyle\int_{\Omega^\#} |\nabla v|^p \, dx}{\displaystyle\int_{\Omega^\#} |v|^p \, dx}.$$

If $u > 0$ is an eigenfunction associated with the first eigenvalue of (2.1), using the ellipticity condition and Pólya–Szegö principle, we have

$$\lambda_p = \frac{\displaystyle\int_\Omega (A\nabla u, \nabla u)^{p/2} \, dx}{\displaystyle\int_\Omega |u|^p \, dx} \geq \frac{\displaystyle\int_\Omega |\nabla u|^p \, dx}{\displaystyle\int_\Omega |u|^p \, dx} \geq \frac{\displaystyle\int_{\Omega^\#} |\nabla u^\#|^p \, dx}{\displaystyle\int_{\Omega^\#} |u^\#|^p \, dx} \geq \lambda_p^\#, \tag{3.2}$$

that is, the first part of the theorem.

About the case of equality we observe that if $\lambda_p = \lambda_p^\#$ then inequality (3.2) implies that $u^\#$ is an eigenfunction of problem (3.1) corresponding to the first eigenvalue. Furthermore, the following equality holds:

$$\int_\Omega |\nabla u|^p \, dx = \int_{\Omega^\#} |\nabla u^\#|^p \, dx, \tag{3.3}$$

because $\|u\|_p = \|u^\#\|_p$. On the other hand, the fact that $u^\#$ is an eigenfunction of (3.1) implies that

$$|\{x : 0 < u^\#(x) < \sup u, \ \nabla u^\#(x) = 0\}| = 0.$$

By Theorem 3.2 (3.3) then gives:

$$u^\#(x) = u(x), \qquad \Omega = \Omega^\#, \quad \text{modulo translations.}$$

The assertion about the coefficients a_{ij} is a consequence of the following observation (see also [ALT1], [Ke]). The vector $\nabla u = \nabla u^\#$ points in the direction of x. This means that if equality holds in (3.2) then

$$a_{ij}(x) x_j x_i = |x|^2 \quad \text{a.e. in } \Omega.$$

But if A is a symmetric matrix whose first eigenvalue is greater or equal to 1, then x is an eigenvector corresponding to the eigenvalue 1; that is the assertion. □

4. Payne–Rayner-type inequalities. Let us consider a fixed eigenfunction $u \not\equiv 0$ of problem (2.1), corresponding to the first eigenvalue, that is a solution of the problem

$$\begin{cases} -\operatorname{div}\big((A\nabla u, \nabla u)^{(p-2)/2} A\nabla u\big) = \lambda_p u |u|^{p-2} & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega. \end{cases} \tag{4.1}$$

Let B be the ball centered at the origin such that the first eigenvalue of problem (3.1) in B is equal to λ_p, and let $v_q > 0$, $0 < q \le \infty$, be the corresponding eigenfunction such that

$$\|v_q\|_q = \|u\|_q. \tag{4.2}$$

In other words v_q satisfies (4.2) and solves the following problem:

$$\begin{cases} -\mathrm{div}\big(|\nabla v_q|^{p-2}\nabla v_q\big) = \lambda_p v_q |v_q|^{p-2} & \text{in } B, \\ \\ v_q = 0 & \text{on } \partial B. \end{cases} \tag{4.3}$$

A straightforward calculation shows that the ball B having the above properties is given by

$$B = \{x \in \mathbb{R}^n : |x| < (\kappa_p/\lambda_p)^{1/p}\},$$

where κ_p denotes the first eigenvalue of problem (4.3) in the unit ball. Making use of the characterization (2.2) and of Theorem 3.1 it is also clear that $|B| \le |\Omega|$.

We will prove the following comparison result between u and v_q.

THEOREM 4.1. *If u and v_q are defined as above we have*

(i) *if $0 < q < \infty$ then*

$$\int_0^s \big(u^*(t)\big)^q dt \le \int_0^s \big(v_q^*(t)\big)^q dt, \qquad s \in [0, |B|];$$

(ii) *if $q = \infty$ then*

$$u^*(s) \ge v_\infty^*(s), \qquad s \in [0, |B|].$$

If any of the above inequalities hold as equalities then $\Omega = B$, $u(x) = u^{\#}(x) = v_q(x)$ and $a_{ij}(x)x_j = x_i$, a.e. in Ω, modulo translations.

Before proving the theorem we quote a lemma whose proof is contained for example in [Ta1], [Ta2], [BFM].

LEMMA 4.2. *Let u be solution of* (4.1); *then the following inequality holds:*

$$-\big(u^*(s)\big)' \le \frac{\lambda_p^{1/(p-1)}}{(nC_n^{1/n}s^{1-1/n})^{p/(p-1)}} \left(\int_0^s \big(u^*(t)\big)^{p-1} dt\right)^{\frac{1}{p-1}} \qquad \text{a.e. in } (0, |\Omega|).$$

Proof of Theorem 4.1. If $|B| = |\Omega|$ then, because of Theorem 3.1, there is nothing to prove. So we will suppose $|B| < |\Omega|$.

Let us define

$$U(s) = \int_0^s \big(u^*(t)\big)^{p-1} dt, \qquad s \in [0, |\Omega|],$$

and

$$V(s) = \int_0^s \big(v_q^*(t)\big)^{p-1} dt, \qquad s \in [0, |B|].$$

Taking into account Lemma 4.2 and the definition of v_q we have that $U(s)$ and $V(s)$ satisfy the following conditions:

$$\begin{cases} -\Big(\big(U'(s)\big)^{1/(p-1)}\Big)' \le \frac{\lambda_p^{1/(p-1)}}{(nC_n^{1/n}s^{1-1/n})^{p/(p-1)}} \big(U(s)\big)^{1/(p-1)} & \text{a.e. in } (0, |\Omega|), \\ U(0) = U'(|\Omega|) = 0, \end{cases} \tag{4.4}$$

and

$$\text{(4.5)}\quad \begin{cases} -\Big(\big(V'(s)\big)^{1/(p-1)}\Big)' = \frac{\lambda_p^{1/(p-1)}}{(nC_n^{1/n}s^{1-1/n})^{p/(p-1)}}\big(V(s)\big)^{1/(p-1)} \text{ in } (0,|B|), \\ V(0) = V'(|B|) = 0. \end{cases}$$

We remark that (4.5) holds for every $0 < q \leq \infty$.

We start to consider the case $q = p-1$. First of all we observe that, by definition, (4.2) implies that $U(|B|) < U(|\Omega|) = V(|B|)$. We will prove that $U(s) \leq V(s)$ in $(0,|B|)$. Suppose ab absurdo that a positive maximum of $U(s) - V(s)$ exists in $s_1 \in (0,|B|)$. In such a point we have $U(s_1) > V(s_1)$ and $U'(s_1) = V'(s_1)$. Using (4.4), (4.5), and recalling Remark 3.2, we can apply Lemma 2.5 with $\varphi = V$, $\psi = U$, $b = |B|$, $c = |\Omega|$, $\gamma = p' = p/(p-1)$, $\mu_\gamma = \big(\lambda_p^{1/p}/nC_n^{1/n}\big)^{p'}$, $\alpha = p'/n$, obtaining a contradiction. The case $q = p-1$ is then proven.

In order to complete the proof of case (i) in theorem 4.1 we consider, for $0 < q < \infty$, the functions

$$U_q(s) = \int_0^s \big(u^*(t)\big)^q dt, \qquad s \in [0,|\Omega|],$$

and

$$V_q(s) = \int_0^s \big(v_q^*(t)\big)^q dt, \qquad s \in [0,|B|].$$

By definition (4.2) of v_q we have $U_q(|B|) < U_q(|\Omega|) = V_q(|B|)$. We will prove that $U_q(s) \leq V_q(s)$ in $(0,|B|)$. Suppose ab absurdo that a positive maximum of $U_q(s) - V_q(s)$ exists in $s_1 \in (0,|B|)$. In such a point we have $U_q(s_1) > V_q(s_1)$ and $U_q'(s_1) = V_q'(s_1)$; then $U'(s_1) = V'(s_1)$. Taking into account (4.4), (4.5), Remark 3.2, and Lemma 2.5, it follows that

$$\text{(4.6)}\qquad U(s) \leq V(s), \qquad s \in [0,s_1].$$

Now (4.4), (4.5), and (4.6) give

$$\text{(4.7)}\qquad u^*(s) \leq v_q^*(s) \qquad \text{a.e. in } (0,s_1).$$

Obviously (4.7) implies $U_q(s_1) \leq V_q(s_1)$; that is a contradiction. The proof of part (i) is then complete.

Part (ii) can be proven using similar arguments. We define

$$s_1 = \inf\{s \in (0,|B|) : u^*(t) \geq v_\infty^*(t) \quad \forall t \in (s,|B|]\}.$$

Taking into account the fact that $|B| < |\Omega|$ and $u^*(|B|) > v_\infty^*(|B|) = 0$, we have that s_1 is well defined and moreover $u^*(s_1) = v_\infty^*(s_1)$; that is, $U'(s_1) = V'(s_1)$ if $s_1 > 0$. Obviously in the case $s_1 = 0$ we immediately have the assertion. On the contrary, if ab absurdo $s_1 > 0$ then, by the above arguments, we have

$$\int_0^s \big(u^*(t)\big)^{p-1} dt \leq \int_0^s \big(v_\infty^*(t)\big)^{p-1} dt, \qquad s \in [0,s_1].$$

This inequality, together with (4.4) and (4.5), gives

$$-\big(u^*(s)\big)' \leq -\big(v_\infty^*(s)\big)' \qquad \text{a.e. in } (0,s_1).$$

Integrating between 0 and s and taking into account (4.2) we obtain

$$u^*(s) \geq v_\infty^*(s) \quad \text{in } (0, s_1),$$

which contradicts the assumption $s_1 > 0$.

Finally, the case of equality in (i) and (ii) follows immediately from Theorem 3.1. It is enough to observe that if, for example, equality holds in part (i), then $u^* = v_q^*$ and $|\Omega| = |B|$. This means that Theorem 3.1 applies. □

A consequence of Theorem 4.1 is the following reverse inequality.

THEOREM 4.3. *Let $u > 0$ be an eigenfunction of problem (4.1). Then, for $0 < q < r \leq \infty$, we have*

$$\|u\|_r \leq \beta(r, q, p, n, \lambda_p)\|u\|_q, \tag{4.8}$$

where $\beta(r, q, p, n, \lambda_p) = \frac{\|v\|_r}{\|v\|_q}$ and v is any nontrivial eigenfunction of (4.3). Furthermore, equality in (4.8) holds if and only if Ω is a ball centered at the origin, $u(x) = u^\#(x)$, and $a_{ij}(x)x_j = x_i$, a.e. in Ω, modulo translations.

Proof. Inequality (4.8) is an immediate consequence of Theorem 4.1. Indeed, choosing v_q as in (4.2) and defining $v_q^*(s) = 0$ for $s \in (|B|, |\Omega|)$, Theorem 4.1 implies that $u^q \in K(v_q^q)$, where, for $f \in L_+^1(\Omega)$ we denote by $K(f)$ the set of functions $\varphi \in L_+^1(\Omega)$ such that (see [ALT2])

$$\int_0^s \varphi^*(t)dt \leq \int_0^s f^*(t)dt \quad \forall s \in (0, |\Omega|), \qquad \text{and} \quad \int_0^{|\Omega|} \varphi^*(t)dt = \int_0^{|\Omega|} f^*(t)dt.$$

Using well-known properties about $K(f)$ (see, e.g., [ALT2]), one obtains

$$\|u\|_r \leq \|v_q\|_r = \frac{\|v_q\|_r}{\|v_q\|_q}\|u\|_q,$$

that is, the assertion.

About the case of equality in (4.8) it is clear that by Theorem 3.1 it will be sufficient to show that $|B| = |\Omega|$. We then suppose ab absurdo that $|B| < |\Omega|$. Let us first consider the case $r = \infty$. So we have

$$\|u\|_\infty = \frac{\|v\|_\infty}{\|v\|_q}\|u\|_q, \qquad 0 < q < \infty,$$

where v is a nontrivial eigenfunction of (4.3). In particular we can choose $v = v_q$ and then

$$\|u\|_\infty = \|v_q\|_\infty,$$

that is, $v_q = v_\infty$. Taking into account Theorem 4.1 we immediately have $u^*(s) = v_\infty^*(s)$, which gives the contradiction, again by Theorem 4.1.

The contradiction is achieved even in the case $0 < r < \infty$. Indeed, arguing as above, we have that equality in (4.8) implies

$$\|u\|_r = \|v_q\|_r.$$

We have already observed that, suitably defining $v_q^*(s)$ in $[|B|, |\Omega|]$, Theorem 4.1 says that $u^q \in K(v_q^q)$. The functional $F(\varphi) = \|\varphi\|_{r/q}$ is strictly convex on $K(v_q^q)$

and assumes its maximum $\|v_q^q\|_{r/q}$ on such a set. It is well known (see [ALT2]) that the maximum of $F(\varphi)$ is achieved only on extreme points of $K(v_q^q)$, that is, on rearrangements of v_q^q. This observation proves the assertion. □

Remark 4.1. As in [C2] one can observe that Lemma 4.2 holds for any solution of problem (2.1), not necessarily corresponding to the first eigenvalue. So the results stated in Theorems 4.1 and 4.3 hold true for every eigenfunction of problem (2.1).

Appendix.

Proof of Lemma 2.2. We start with the case $p \geq 2$. Let us put $\mathcal{A}(\xi) = \sqrt{(A\xi, \xi)}$. Simple arguments show that

$$\left|\mathcal{A}\left(\frac{\xi_1+\xi_2}{2}\right)\right|^p + \left|\mathcal{A}\left(\frac{\xi_1-\xi_2}{2}\right)\right|^p \leq \left[\mathcal{A}\left(\frac{\xi_1+\xi_2}{2}\right)^2 + \mathcal{A}\left(\frac{\xi_1-\xi_2}{2}\right)^2\right]^{p/2}$$

$$= \left[\frac{\mathcal{A}(\xi_1)^2 + \mathcal{A}(\xi_2)^2}{2}\right]^{p/2}.$$

By convexity of the function $f(t) = t^\alpha$, with $\alpha \geq 1$, we have the Clarkson-type inequality

$$\left|\mathcal{A}\left(\frac{\xi_1+\xi_2}{2}\right)\right|^p + \left|\mathcal{A}\left(\frac{\xi_1-\xi_2}{2}\right)\right|^p \leq \frac{\mathcal{A}(\xi_1)^p + \mathcal{A}(\xi_2)^p}{2}. \tag{A.1}$$

On the other hand the function $g(\xi) = \mathcal{A}(\xi)^p$ is strictly convex because $p \geq 2$ and $\mathcal{A}(\xi)^2$ is strictly convex. This means that

$$\mathcal{A}(\xi_2)^p \geq \mathcal{A}(\xi_1)^p + p\mathcal{A}(\xi_1)^{p-2}(A\xi_1, \xi_2 - \xi_1). \tag{A.2}$$

Using (A.1) and (A.2) we have

$$\mathcal{A}(\xi_2)^p \geq -\mathcal{A}(\xi_1)^p + 2\left|\mathcal{A}\left(\frac{\xi_1+\xi_2}{2}\right)\right|^p + 2\left|\mathcal{A}\left(\frac{\xi_1-\xi_2}{2}\right)\right|^p$$

$$\geq \mathcal{A}(\xi_1)^p + p\mathcal{A}(\xi_1)^{p-2}(A\xi_1, \xi_2 - \xi_1) + 2\left|\mathcal{A}\left(\frac{\xi_1-\xi_2}{2}\right)\right|^p.$$

We have then proven part (i) of Lemma 2.2 with the constant 2^{1-p} instead of $(2^{p-1}-1)^{-1}$. Using an iteration argument as in the appendix of [L1] one obtains the full claim.

In the case $1 < p < 2$ we consider the function

$$\phi(t) = \mathcal{A}(\xi_1 + t(\xi_2 - \xi_1))^p,$$

where $\mathcal{A}(\xi)$ is the previously defined function. If $\phi(t) = 0$ for some $t \in [0,1]$, then by ellipticity condition ξ_1 and ξ_2 are multiples of each other, with the possibility that one or both of them vanish. In such cases the claim of the lemma is evident. So we can suppose that $\phi(t) \neq 0$ in $[0,1]$. Then we can use the equality

$$\phi(1) = \phi(0) + \phi'(0) + \int_0^1 (1-t)\phi''(t)\,dt$$

to get

$$\mathcal{A}(\xi_1)^p = \mathcal{A}(\xi_1)^p + p\,\mathcal{A}(\xi_1)^{p-2}(A\xi_1, \xi_2 - \xi_1) + \int_0^1 (1-t)\phi''(t)\,dt. \tag{A.3}$$

A straightforward calculation gives

$$\begin{aligned}\phi''(t) = {} & p(p-2)\mathcal{A}(\xi_1 + t(\xi_2 - \xi_1))^{p-4}\big(A(\xi_1 + t(\xi_2 - \xi_1)), \xi_2 - \xi_1\big)^2 \\ & + p\mathcal{A}(\xi_1 + t(\xi_2 - \xi_1))^{p-2}\mathcal{A}(\xi_2 - \xi_1)^2.\end{aligned}$$

Now we observe that, because of the symmetry of the matrix A, we have, for every $\xi_1, \xi_2 \in \mathbb{R}^n$,

$$(A\xi_1, \xi_2)^2 \le (A\xi_1, \xi_1)(A\xi_2, \xi_2),$$

$$\mathcal{A}(\xi_1 + \xi_2) \le \mathcal{A}(\xi_1) + \mathcal{A}(\xi_2).$$

Using the above inequalities we obtain

$$\begin{aligned}\phi''(t) &\ge p(p-1)\mathcal{A}(\xi_1 + t(\xi_2 - \xi_1))^{p-2}\mathcal{A}(\xi_2 - \xi_1)^2 \\ &\ge p(p-1)\frac{\mathcal{A}(\xi_2 - \xi_1)^2}{\big(\mathcal{A}(\xi_1) + \mathcal{A}(\xi_2)\big)^{2-p}} \qquad t \in [0,1].\end{aligned}$$

This inequality and (A.3) give the assertion. □

LINEAR PARABOLIC STOCHASTIC PDEs AND WIENER CHAOS*

R. MIKULEVICIUS† AND B. ROZOVSKII‡

Abstract. We study Cauchy's problem for a second-order linear parabolic stochastic partial differential equation (SPDE) driven by a cylindrical Brownian motion. Existence and uniqueness of a generalized (soft) solution is established in Sobolev, Hölder, and Lipschitz classes. We make only minimal assumptions, virtually identical to those common to similar deterministic problems. A stochastic Feynman–Kac formula for the soft solution is also derived. It is shown that the soft solution allows a Wiener chaos expansion and that the coefficients of this expansion can be computed recursively by solving a simple system of parabolic PDEs.

Key words. stochastic PDEs, Wiener chaos, soft solution, Feynman–Kac formula

1. Introduction.

In this paper we study second-order linear SPDEs of the type

$$\begin{aligned} &du(t,x) = (\mathcal{L}u(t,x) + f(t,x))dt + (\mathcal{M}u(t,x) + g(t,x), dW_t)_Y, \\ &u(0,x) = \varphi(x),\ (t,x) \in (0,1] \times \mathbb{R}^d, \end{aligned} \tag{0.1}$$

where $\mathcal{L}u(t,x) = a^{ij}(t,x)u_{x_i,x_j} + b^i(t,x)u_{x_i} + c(t,x)u$, $\mathcal{M}u(t,x) = \sigma^i(t,x)u_{x_i} + h(t,x)u$, and W is a cylindrical Brownian motion in some Hilbert space Y. The coefficients of the operator $\mathcal{L}$ and $f(t,x)$ are real-valued functions while the coefficients of $\mathcal{M}$ and $g(t,x)$ are Y-valued. Equation (0.1) is assumed to be parabolic; i.e., the matrix (a^{ij}) is symmetric, and $A = (2a^{ij} - (\sigma^i, \sigma^j)_Y)$ is nonnegatively definite.

To motivate the study, we recall two important examples of equation (0.1).

1. *Backward diffusion equation* (see [11], [17], [29]). Let $X^{t,x}(s)$ be a diffusion process defined by the Ito equation

$$\begin{aligned} &dX^{t,x}(s) = b(X^{t,x}(s))ds + \sigma(X^{t,x}(s))dw_s, \quad s \in (t,1], \\ &X^{t,x}(t) = x, \quad x \in R^1, \text{ and } w_s \text{ is a one-dimensional Brownian motion.} \end{aligned}$$

It is well known (see, e.g., [29]) that assuming some smoothness of $b(x)$ and $\sigma(x)$ (which will be discussed later) one can show that the function $u(t,x) = X^{1-t,x}(1)$ is a solution of the equation

$$\begin{aligned} &du(t,x) = \left[\tfrac{1}{2}\sigma^2(x)u_{xx}(t,x) + b(x)u_x(t,x)\right]dt + \sigma(x)u_x(t,x)dw_1(t), \\ &u(0,x) = x\,, \text{ where } w_1(t) = w_1 - w_{1-t}. \end{aligned} \tag{0.2}$$

2. *Zakai equation* (see [32], [29]). Let us consider the nonlinear filtering problem in the following, rather common, setting. Assume that the signal process X_t is a diffusion process defined by the Ito equation

$$X_t = X_0 + \int_0^t b(X_s)ds + \int_0^t (\sigma(X_s)dw_s + \hat{\sigma}(X_s)d\hat{w}_s),$$

where w and $\hat{w}$ are one-dimensional Brownian motions and X_0 is a random variable with density function $p(x)$. The Brownian motions w and $\hat{w}$ and the random variable X_0 are defined on the probability space $(\Omega, \mathcal{F}, P)$ and are assumed to be independent. The observation process is given by

$$y_t = \int_0^t h(X_s)ds + w_t \ .$$

It is a standard fact that for every function ψ such that $E|\psi(x_t)|^2 < \infty$, the optimal mean square estimate for $\psi(X_t)$, given the past of the observations $\mathcal{F}_t^y = \sigma(y_s, s \le t)$, is of the form

$$\hat{\psi}_t = \frac{E_{\tilde{P}}\left[\psi(X_t)\zeta(t)|\mathcal{F}_t^y\right]}{E_{\tilde{P}}\left[\zeta(t)|\mathcal{F}_t^y\right]},$$

where $\zeta(t) = \exp\{\int_0^t h(X_s)dy_s - \frac{1}{2}\int_0^t |h(X_s)|^2 ds\}$ and $d\tilde{P} = \zeta(1)^{-1}dP$.

Assuming some smoothness of the coefficients b, σ, and h, one can show that

$$E_{\tilde{P}}[\psi(X_t)\zeta(t)|\mathcal{F}_t^y] = \int \psi(x)u(t,x)dx \ , \tag{0.3}$$

where $u(t,x)$, usually referred to as the unnormalized filtering density, is a solution of the Zakai equation

$$\begin{aligned} &du(t,x) = \left[\tfrac{1}{2}\left(\left(\sigma^2(x) + \hat{\sigma}^2(x)\right)u(t,x)\right)_{xx} - \left(b(x)u(t,x)\right)_x\right]dt \\ &+ \left[h(x)u(t,x) - \left(\sigma(x)u(t,x)\right)_x\right]dy_t, \quad t > 0 \ , \\ &u(0,x) = p(x) \ . \end{aligned} \tag{0.4}$$

Since y is a Brownian motion on $(\Omega, \mathcal{F}, \tilde{P})$, equation (0.4) is obviously a particular case of equation (0.1).

The Cauchy problem (0.1) has been studied by many authors [27], [14], [2], etc. In the superparabolic case (the matrix A is uniformly nondegenerate) there exists a quite complete theory for this problem in Sobolev spaces $W^{n,2}(R^d)$ (see [29] and references therein) and in the spaces of Bessel potentials $H_p^s(R^d)$ (see [13]).

On the other hand, the existent theory for this problem in Hölder spaces, as well as the $W^{n,2}(R^d)$-theory in the degenerate case ($A \ge 0$), is not completely satisfactory. For example, in the latter case the existence of solutions to (0.1) in $W^{1,2}(R^d)$ is known only if $a^{ij} \in C_b^2(\mathbb{R}^d)$ and the remaining coefficients are assumed to have bounded derivatives of the first order (in x). By applying this result to the backward diffusion equation (0.2) one can see that the assumptions needed to make these equations meaningful are substantially stronger than those that ensure the existence of the diffusion process itself. The same applies to the Zakai equation. Indeed, the conditional expectation in the left-hand part of (0.3) is well defined if the coefficients $b, \sigma, \hat{\sigma}$, and h are continuous and bounded and $\sigma^2 + \hat{\sigma}^2 \ge \delta > 0$ (see [9], [30]), while in order to ensure the existence of a $W^{1,2}$-solution to the Zakai equation, one needs to assume additionally that σ and $\hat{\sigma}$ are three times differentiable, b and h are twice differentiable, and all the derivatives are bounded. Even in the superparabolic case, the Zakai equation has a solution in $W^{1,p}(R^d), p \ge 2$, only if σ has bounded derivatives in x (see [13]).

The objective of this article is to study the Cauchy problem (0.1) with nonsmooth coefficients. In particular, we would like to avoid the assumption on differentiability

of the coefficients of the operator $\mathcal{M}$ and the function g and simultaneously relax the superparabolicity assumption ($A^{ij}\xi_i\xi_j \geq \delta|\xi|^2$ for some $\delta > 0$, where $A^{ij} = 2a^{ij} - (\sigma^i, \sigma^j)_Y$).

These goals are hardly achievable within the scope of the standard (variational or semigroup) approaches to SPDEs. This is why we extend the notion of a solution to (0.1) by using the Cameron–Martin–Ito theory of (homogeneous) Wiener chaos (see [1], [16]). In a way, we treat the Wiener process W as an (infinite-dimensional) variable and solve equation (0.1) by separating (t, x) and W. More specifically, we begin with the introduction of a "skeleton" equation associated with (0.1). This equation could be formally obtained from (0.1) by replacing dW_t by $l(t)dt$, where $l(t)$ is a Y-valued deterministic function. Then we define a soft solution of equation (0.1) as an appropriately measurable and integrable function $u(t, x)$ such that its S-transform (Laplace–Wiener transform)

$$S^l u(t, x) = Eu(t, x) \exp\left\{\int_0^t \langle l(s), dW_s\rangle_Y - \frac{1}{2}\int_0^t \|l(s)\|_Y^2 ds\right\}$$

solves the skeleton equation for a sufficiently rich class of functions l.

We prove (see Theorem 1) existence and uniqueness of a soft solution to (0.1) in Sobolev spaces $W^{2,p}$, Hölder spaces $C^{2+\beta}$, and the Lipschitz space L under minimal assumptions on the coefficients and free forces. In particular, in the case of Sobolev spaces, we do not require any differentiability of the coefficients. In the case of Hölder and Lipschitz spaces the coefficients are Hölder and Lipschitz continuous (respectively). In the first two cases the matrix a is assumed to be uniformly nondegenerate and continuous. The superparabolic assumption is not required at any point in our exposition.

Of course, if the coefficients and the free forces are smooth enough, the soft solution coincides with the generalized (variational) solution in the sense of [29]. In the nonsmooth case the soft solution can be approximated by solutions of similar equations with smooth coefficients (Theorem 2).

It turns out (see Theorem 1) that the S-transform is invertible under the same assumptions that guarantee the existence and uniqueness of the soft solution, and the inverse is none other than the stochastic "Feynman–Kac" formula (in the terminology of [29], averaging over characteristic formula) for a solution of (0.1). In particular, this result eliminates the aforementioned gap between the assumptions which ensure the existence of a solution to (0.1) and those needed just to define the Feynman–Kac functional.

The Feynman–Kac formula is not always a convenient representation for a solution of problem (0.1). For example, the whole purpose of the Zakai equation is to provide a convenient recursive way to "compute" the unnormalized filter in the left-hand side of (0.3). It is readily checked that the Feynman–Kac formula for the Zakai equation is equivalent to this functional. So in this case, the Feynman–Kac interpretation of a soft solution does not serve the same purpose as the Zakai equation.

With this in mind, we developed another representation for a soft solution of (0.1) based on the Wiener chaos expansion. Specifically, we prove (Theorem 3) that a soft solution of the Cauchy problem (0.1) admits the following expansion in $L_2(\Omega)$:

$$u(t, x) = \sum_{\alpha\in I} \frac{1}{\sqrt{\alpha!}}\varphi_\alpha(t, x)\xi_\alpha(W), \tag{0.5}$$

where I is the set of all multi-indices of finite length, $\xi_\alpha(W)$ are Wick polynomials

of Wiener integrals $\int_0^t m_k(s)d(W_s, e_j)_Y$, where $\{m_k\}_{k\geq 1}$ and $\{e_j\}_{j\geq 1}$ are complete orthonormal systems in $L_2(0,1)$ and Y, respectively, and $\varphi_\alpha(t,x)$ are the deterministic coefficients in the Cameron–Martin orthogonal decomposition of $u(t,x)$. In section 3 we prove that $\{\varphi_\alpha\}_{\alpha\in I}$ is a solution of a simple recursive parabolic system of Kolmogorov-like deterministic equations (see [24]), referred to below as the S-system.

We prove (Theorem 3) that the S-system has a unique solution in Sobolev, Hölder, and Lipschitz classes and the expansion (0.5) holds under essentially the same minimal assumptions which were used to prove the existence of the soft solution. In some sense, the Wiener chaos expansion (0.5) could serve as another definition of the soft solution.

Of course, using Ito's decomposition theorem [7], one could rewrite the expansion (0.5) in terms of multiple Wiener integrals (Corollary 4). This expansion, while formally equivalent to (0.5), is not as flexible as the former (see [25]).

The Wiener chaos expansion is of special importance in nonlinear filtering. For one, the expansion (0.5) and the associated S-system are well defined and functional in many cases where the Zakai equation for the nonnormalized filtering density is not. Even in the case of smooth coefficients, when the Zakai equation is also well defined, the Wiener chaos expansion has some computational advantages. For example, an important feature of expansion (0.5) is that it separates observations and parameters, in that the Wick polynomials are completely defined by the observations process y_t, while the coefficients $\varphi_\alpha(t,x)$ are determined only by the coefficients of the signal process and the observation function h. This allows one to shift off-line the time-consuming computation related to solving PDEs (for more detail see [20]). We would like to remark that the method of soft solutions has clear-cut limitations. For example, it is not applicable if the coefficients of the equations are functions of W.

We conclude this introduction with some historical remarks.

The idea of using multiple Wiener integral expansions for solving stochastic differential equations was championed by Veretennikov and Krylov [31]; see also Zvonkin and Krylov [33], Isobe and Sato [6], and Léandre and Meyer [19]. (These works address ordinary Ito equations which are equivalent to soft solutions of the backward diffusion equation (0.2)).

Kunita [16] developed a similar representation for the Zakai equation with smooth coefficients; see also a related work by Ocone [26].

The notion of a soft solution was introduced in [24]. Similar constructions have also been used by several authors within the scope of white noise analysis (see, e.g., [28], [5], and references therein). Loosely speaking, the goal in these works was to study an appropriate skeleton equation and to prove that its solution is an S-transform of some element in the space of Hida distributions. Then this element is declared to be a generalized solution of the original equation.

Various particular cases of the Feynman–Kac formula can be found in the literature (see e.g., [5], [12], [15], [28], and the references therein).

The Wiener chaos expansion (0.5) and the associated S-system were first introduced in [23]; see also [24]. For applications of these expansions to nonlinear filtering, see [20] and references therein.

2. Soft solutions of SPDEs. Let $(\Omega, \mathcal{F}, P)$ be a probability space, Y a separable Hilbert space, and W a cylindrical Wiener process in Y. The latter means that we have a family of continuous martingales $W_t(f), f \in Y$, such that

$$\langle W(f), W(g)\rangle_t = t(f,g)_Y \quad \forall f, g \in Y\ .$$

In the future we will assume that $Y = L^2(U, \mathcal{U}, \kappa)$, where $(U, \mathcal{U}, \kappa)$ is a separable

measure space, $\kappa \geq 0$. This assumption is not essential in any way and is made only for the sake of convenience of notation.

Ito's stochastic integral for a stochastic process f in $L^2(U,\mathcal{U},\kappa)$ will be denoted

$$\int_0^t \int_U f(s,\eta) W(ds,d\eta) \ .$$

We denote $H = [0,1] \times R^d$ and suppose that the following measurable functions are given:

$$a : H \to \mathbb{R}^{d^2}, \quad b : H \to \mathbb{R}^d, \quad \sigma : H \times U \to \mathbb{R}^d, \quad c : H \to \mathbb{R},$$
$$h : H \times U \to \mathbb{R}, \quad f : H \to \mathbb{R}, \quad g : H \times U \to \mathbb{R}, \quad \varphi : \mathbb{R}^d \to \mathbb{R}$$

such that

$$|a| + |b| + |c| + \int_U (|\sigma|^2 + h^2) d\kappa \leq K < \infty \ .$$

It is also assumed that f, $\int_U g^2 d\kappa$, and φ are locally integrable.

The main objective of this paper is to study the equation

$$\begin{aligned} du(t,x) &= [\mathcal{L}u(t,x) + f(t,x)]dt \\ &+ \int_U (\mathcal{M}_{t,\eta} u(t,x) + g(t,x,\eta)) W(dt,d\eta), \\ u(0,x) &= \varphi(x), \end{aligned} \tag{1}$$

where $\mathcal{L}u = a^{ij}(t,x) u_{x_i x_j} + b^i(t,x) u_{x_i} + c(t,x)u$ and

$$\mathcal{M}u = \mathcal{M}_{t,\eta} u = \sigma^i(t,x,\eta) u_{x_i} + h(t,x,\eta) u \ .$$

Note that the above assumptions imply that $\mathcal{M}_{t,\eta} v$ is a Hilbert–Schmidt operator from $L^2(U,\mathcal{U},\kappa)$ into $L^2(H)$ for any $v \in W^{1,2}(\mathbb{R}^d)$. The case of a non-Hilbert–Schmidt operator μ is addressed in [25].

Now we shall further specify the structure of the matrix a. For this purpose let us introduce a measurable function $\hat{\sigma} : H \times U \to \mathbb{R}^d$. Everywhere below we assume that

$$\begin{aligned} &a^{ij}(\bar{x}) = \tfrac{1}{2} \int_U (\sigma^i(\bar{x},\eta)\sigma^j(\bar{x},\eta) + \hat{\sigma}^i(\bar{x},\eta)\hat{\sigma}^j(\bar{x},\eta)) d\kappa, \\ &\bar{x} \in H \ . \end{aligned} \tag{P}$$

This assumption asserts that equation (1) is parabolic in the sense of [29].

Obviously the Zakai equation and the backward diffusion equation discussed in the introduction are particular cases of equation (1). In both cases $U = \{1, \dots, d_1\}$ and κ is the counting measure on U, i.e.,

$$\int_A d\kappa = \sum_{i=1}^{d_1} 1_A(i) \ .$$

Let $C^{2+\beta}(H)$, $\beta \in (0,1)$, be the space of all continuous functions v on H having the finite norm

$$|v|_{2,\beta} = \sup_{t,x} |v(t,x)| + |D_x^2 v|_\beta \ ,$$

where

$$|v|_\beta = \sup_{t,x} |v(t,x)| + \sup_{t,x\neq y} \frac{|v(t,x)-v(t,y)|}{|x-y|^\beta} .$$

Denote $W^{2,p}(H), p>1$, the Sobolev class of p-integrable functions v on H having generalized space derivatives up to the second order with the finite norm

$$|v|_{2,p} = |v|_p + |D_x^2 v|_p ,$$

where $|v|_p = (\int_H |v|^p dt\, dx)^{1/p}$.

Denote by $L(H)$ the set of continuous functions v on H with finite norm

$$|v|_L = \sup_{t,x} |v(t,x)| + \sup_{t,x\neq y} \frac{|v(t,x)-v(t,y)|}{|x-y|} .$$

Below we consider three different sets of assumptions on the coefficients of equation (1):

(L) (a) $|f|_L + |b|_L + |c|_L \le K$;

(b)

$$\int_U \left\{|\sigma(\bar{x},\eta)-\sigma(\bar{y},\eta)|^2 + |\hat{\sigma}(\bar{x},\eta)-\hat{\sigma}(\bar{y},\eta)|^2 + |h(\bar{x},\eta)-h(\bar{y},\eta)|^2 + |g(\bar{x},\eta)-g(\bar{y},\eta)|^2\right\} d\kappa \le K|x-y|^2 ,$$
$$\forall \bar{x} = (t,x), \quad \bar{y} = (t,y) \in H ;$$
$$tr\ a + \int_U (|h|+|g|)^2 d\kappa \le K .$$

(C) For $\beta \in (0,1), \delta > 0$

(a) $|f|_\beta + |b|_\beta + |c|_\beta \le K$;

(b) $a^{ij}\xi_i\xi_j \ge \delta|\xi|^2 \qquad \forall \xi \in \mathbb{R}^d$;

(c) $\forall \bar{x} = (t,x), \bar{y} = (t,y) \in H$

$$\int_U \left\{|\sigma(\bar{x},\eta)-\sigma(\bar{y},\eta)|^2 + |\hat{\sigma}(\bar{x},\eta)-\hat{\sigma}(\bar{y},\eta)|^2 + |h(\bar{x},\eta)-h(\bar{y},\eta)|^2 + |g(\bar{x},\eta)-g(\bar{y},\eta)|^2\right\} d\kappa \le K|x-y|^{2\beta} ,$$
$$tr\, a + \int_U (|h|+|g|)^2 d\kappa \le K ;$$

(d) $\varphi \in C^{2,\beta}(\mathbb{R}^d)$.

(W) (a) $\lim_{|x-x'|\to 0} \sup_t \int_U \left\{|\sigma(t,x,\eta)-\sigma(t,x',\eta)|^2 + |\hat{\sigma}(t,x,\eta)-\hat{\sigma}(t,x',\eta)|^2\right\} d\kappa = 0$ and (b) of (C) holds;

(b) for $p > d$, $f \in L^p(H) \cap L^{2p}(H)$, $(\int_U |g|^2 d\kappa)^{1/2} \in L^p(H) \cap L^{2p}(H)$ and $\varphi \in W^{2,p}(\mathbb{R}^d) \cap W^{2,2p}(\mathbb{R}^d)$.

Throughout what follows, we assume that at least one of the assumptions (L), (C), or (W) holds.

Let $\mathcal{F}^W = \mathcal{F}_1^W$ be a P-completion of $\sigma(W_s(f), f \in L^2(U,d\kappa),\ s \in [0,1])$ and $\mathcal{F}_t^W = \mathcal{F}_t$ be a σ-algebra generated by $\cap_{r>t}\sigma(W_s(f), f \in L^2(U,d\kappa), s \in [0,r])$ and negligible sets of $\mathcal{F}^W$. For $l \in L^2([0,1]\times U, dtd\kappa)$, we define $q_t(l)$ as the unique solution of the equation

$$\begin{cases} dq_t(l) = q_t(l) \int_U l(t,\eta) W(dt,d\eta), t \in [0,1], \\ q_0(l) = 1. \end{cases}$$

Let $\mathcal{D}$ be the class of all $l \in L^2([0,1]\times U, dt\,d\kappa)$ such that $\int_U l(t,\eta)^2 d\kappa$ is bounded. Let[1] $\tilde{\mathcal{F}} = \mathcal{B}(H)\otimes\mathcal{F}^W, \tilde{\mathcal{F}}_t = \mathcal{F}_t\otimes\mathcal{B}(\mathbb{R}^d)$. For an $\tilde{\mathcal{F}}$-measurable and $\tilde{\mathcal{F}}_t$-adapted function $u(t,x)$ such that $E|u(t,x)|^2$ is locally bounded, we define its S^l-transform by

$$S^l u(t,x) = Eu(t,x)q_t(l) = Eu(t,x)q_1(l),\ l \in \mathcal{D}\ .$$

Simple (informal) computations yield that $u^l(t,x) = S^l u(t,x)$ verifies the skeleton equation.

$$\begin{cases} \partial_t u^l = \mathcal{L}u^l + f + \displaystyle\int_U l(\mathcal{M}u^l + g)d\kappa, t \in [0,1], \\ u^l(0,x) = \varphi(x). \end{cases} \tag{2}$$

This equation is central for our construction. It will be studied below in Hölder, Sobolev, and Lipschitz classes. The notion of a solution for the former two classes is well known (see, e.g., [3], [18], etc.). $L(H)$-solution, a solution in the Lipschitz class $L(H)$, is understood in the following sense.

DEFINITION 1. *A function $u \in L(H)$ is said to be an $L(H)$-solution of the Cauchy problem*

$$\begin{cases} \partial_t u = \mathcal{L}_u + f \quad in \quad H, \\ u(0,\cdot) = \varphi \end{cases} \tag{3}$$

if for every $y(x) \in C_0^\infty(\mathbb{R}^d)$ and all $t \in [0,1]$,

$$\begin{aligned} \int_{\mathbb{R}^d} u(t,x)y(x)dx = \int_{\mathbb{R}^d} \varphi(x)y(x)dx + \int_0^t \int_{\mathbb{R}^d} \big\{ -a^{ij}(s,x)u_{x_i}(s,x)y_{x_j}(x) \\ +[(b^i(s,x) - a^{ij}_{x_j}(s,x))u_{x_i}(s,x) + c(s,x)u(s,x) + f(s,x)]y(x)\big\}dx\,ds\ . \end{aligned} \tag{4}$$

It is a standard fact that if a function v is Lipschitz continuous on $\mathbb{R}^d$,

$$|v(x) - v(y)| \le C|x-y| \qquad \forall x, y \in \mathbb{R}^d\ ,$$

then v is differentiable almost everywhere (a.e.) on $\mathbb{R}^d$ and $\operatorname{essup}_x|v_x| \le C$. So, the equality (4) is well defined.

DEFINITION 2. *Let (C) (respectively, (W) or (L)) be satisfied. An $\tilde{\mathcal{F}}$-measurable $\mathcal{F}_t$-adapted function u is a $C^{2+\beta}$-soft (respectively, $W^{2,p}$-soft, L-soft) solution for* (1) *if, for each $l \in \mathcal{D}$, $u^l(t,x) = \mathcal{S}^l u(t,x)$ is a solution in the class $C^{2+\beta}(H)$ (respectively, $W^{2,p}(H)$ or $L(H)$) of the equation* (2).

To formulate the main result of this section we shall introduce some additional notation.

Let $\hat{W}$ be a cylindrical Wiener process in $L^2(U,\mathcal{U},\kappa)$ independent of W. Let us fix a number $s \le 1$ and set for $t \in [0,s]$, $W_t^s = W_s - W_{s-t}$ and $\hat{W}_t^s = \hat{W}_s - \hat{W}_{s-t}$.

Let $\mathcal{G} = \mathcal{G}_1^1$ be a P-completion of $\sigma(W_r^s, \hat{W}_r^s, r \in [0,1])$ *and* $\mathcal{G}_t^s$ be a σ-algebra generated by $\cap_{r>u}\sigma(W_v^s, \hat{W}_v^s, v \le r)$ and P-negligible sets of $\mathcal{G}_1^1$. Let $\mathcal{X} = C_{[0,1]}(\mathbb{R}^d)$ be the space of continuous $\mathbb{R}^d$-valued trajectories on $[0,1]$, equipped with the canonical process $X_t = X_t(w) = w(t)$, $w \in \mathcal{X}$, the canonical σ-algebra $\mathcal{C}_1^1 = \sigma(X_s, s \in [0,1])$, and the filtration $\mathcal{C}_t^s = \sigma(X_{s-r}, r \le t)$. On the product space $\bar{\Omega} = \Omega \times \mathcal{X}$ we define

[1]Here and below $\mathcal{B}$ denotes the Borel σ-algebra.

σ-algebras $\bar{\mathcal{G}} = \mathcal{G}_1^1 \otimes \mathcal{C}_1^1$, $\bar{\mathcal{G}}_t^s = \cap_{r>t} \mathcal{G}_r^s \otimes \mathcal{C}_r^s$, $\bar{\mathbf{G}}^s = (\bar{\mathcal{G}}_t^s)$. Denote by $B_{mc}(\bar{\Omega})$ the set of all bounded measurable functions f on $\bar{\Omega}$ such that $f(w,\cdot)$ is continuous on $\mathcal{X}$ for all $w \in \Omega$. Let $M_{mc}^1(\bar{\Omega})$ be the set of probability measures μ on $(\bar{\Omega}, \bar{\mathcal{G}})$ with the property $\mu|_\Omega = P$. This space is assumed to be endowed with the topology generated by the maps

$$\mu \to \mu(f), \mu \in M_{mc}^1(\bar{\Omega}), f \in B_{mc}(\bar{\Omega})$$

(see [8]).

DEFINITION 3. *For $(s,x) \in H$ define*[2]

$$\begin{aligned}\mathcal{S}(s,x,\sigma,\hat{\sigma},b) = \big\{\mu \in M_{mc}^1(\bar{\Omega}) : \quad & \mu\text{-a.e. } X_u = x \quad \forall u \geq s, \\ -dX_t = \int_U (\sigma(t,X_t,\eta) W(\overleftarrow{dt}, d\eta) + \hat{\sigma}(t,X_t,\eta)\hat{W}(\overleftarrow{dt}, d\eta)) & \\ + b(t,X_t)dt, t < s\big\} &\end{aligned}$$

A measure $\mu \in \mathcal{S}(s,x,\sigma,\hat{\sigma},b)$ is called a solution to $(s,x,\sigma,\hat{\sigma},b)$.

Remark 1. Let $\bar{P} \in M_{mc}^1(\bar{\Omega})$. Using the Ito formula one can check easily that $\bar{P} \in \mathcal{S}(s,x,\sigma,\hat{\sigma},b)$ if and only if

$$\begin{aligned} M_t = X_{s-t} - x - \int_{s-t}^s b(r,X_r)dr \in \mathcal{M}_{loc}(\bar{\mathbf{G}}^s, \bar{P}) \ , \\ X_u = x \qquad \forall u \geq s \ , \qquad \bar{P}\text{-a.e.} \\ \langle M, W^s(h) + \hat{W}^s(\hat{h})\rangle_t = \int_{s-t}^s \int_U \{\sigma(r,X_r,\eta)h(\eta) \\ + \hat{\sigma}(r,X_r,\eta)\hat{h}(\eta)\big\} d\kappa\, dr \quad \forall h, \hat{h} \in L^2(E, d\kappa) \end{aligned}$$

and

$$\begin{aligned}\langle M^i, M^j\rangle_t = \int_{s-t}^s \int_U \big\{\sigma^i(r,X_r,\eta)\sigma^j(r,X_r,\eta) \\ + \hat{\sigma}^i(r,X_r,\eta)\hat{\sigma}^j(r,X_r,\eta)\big\}\, d\kappa dr \ .\end{aligned}$$

Indeed, let $N_t = M_t - \int_{s-t}^s \int_U \sigma(r,X_r,\eta) W(\overleftarrow{dr}, d\eta) - \int_{s-t}^s \int_U \hat{\sigma}(r,X_r,\eta)\hat{W}(\overleftarrow{dr}, d\eta)$. Then

$$\begin{aligned}&\langle N^i\rangle_t = \langle M^i\rangle_t - 2\int_{s-t}^s \int_U \sigma^i(r,X_r,\eta)^2 d\kappa dr \\ &-2\int_{s-t}^s \int_U \hat{\sigma}^i(r,X_r,\eta)^2 d\kappa dr + \int_{s-t}^s \int_U \sigma^i(r,X_r,\eta)^2 d\kappa, dr \\ &+ \int_{s-t}^s \int_U \hat{\sigma}^i(r,X_r,\eta)^2 d\kappa dr = 0, i = 1,\dots,d \ .\end{aligned}$$

This proves the remark.

For $l \in \mathcal{D}$, set $B_l(t,x) = b(t,x) + \int_U \sigma(t,x,\eta) l(t,\eta) d\kappa$ and denote $B(t,x) = b(t,x) - \int_U \sigma(t,x,\eta) h(t,x,\eta), d\kappa$.

---

[2]The backward stochastic integral with respect to the cylindrical Wiener process W can be defined by the formula

$$\int_r^t \int_U f(s,\eta) W(\overleftarrow{ds}, d\eta) = \int_{1-t}^{1-r} \int_U f(1-s,\eta) W(ds, d\eta) \ .$$

For details see, e.g., [15] and [29].

THEOREM 1. *Assume (C) (respectively, (W) or (L)). Then there is a $C^{2+\beta}$-soft (respectively, $W^{2,p}$-soft or L-soft) solution u of (1) such that u^l is continuous for each $l \in \mathcal{D}$. For each $(s,x) \in H$ any two soft solutions having this property are P-indistinguishable.*

In addition, there exists a unique measure $P^B_{s,x} \in S(s,x,\sigma,\hat{\sigma},B)$ so that the map $s,x \to P^B_{s,x}$ is continuous and for every s,x,

$$u(s,x) = P^B_{s,x}\left[\int_0^s f(t,X_t)\rho(s,t)dt\right.$$

$$\left.+\varphi(X_0)\rho(s,0) + \int_0^s \int_U g(t,X_t,\eta)\rho(s,t)W(\overleftarrow{dt},d\eta)|\mathcal{F}^W_s\right] \qquad \text{P-a.s.,} \tag{5}$$

where

$$\rho(s,t) = \exp\left\{\int_t^s c(r,X_r)dr + \int_t^s \int_U h(r,X_r,\eta)W(\overleftarrow{dr},d\eta)\right.$$
$$\left.-\tfrac{1}{2}\int_t^s \int_U h(r,X_r,\eta)^2 d\kappa, dr\right\}.$$

Before proceeding with the proof of this statement we shall present some important auxiliary results.

LEMMA 1 (see [4]). *Let $\xi \in L^2(\Omega,\mathcal{F}^W,P)$ and $Eq_1(h)\xi = 0$ for each $h \in L^2([0,1]\times U, dt\, d\kappa)$, where*

$$q_t(h) = \exp\left\{\int_0^t \int_U h(s,\eta)W(ds,d\eta) - \tfrac{1}{2}\int_0^t \int_U h(s,\eta)^2 d\kappa\, ds\right\}.$$

Then $\xi = 0$ P-a.e.; i.e., the linear subspace generated by $q_1(h), h \in L^2([0,1]\times U$, $dt\, d\kappa)$ is dense in $L^2(\Omega,\mathcal{F}^W,P)$.

We will need two "auxiliary" sets of assumptions:

(A) For each $\bar{x} = (t,x), \bar{y} = (t,y) \in H$

$$\int_U \{|\sigma(\bar{x},\eta) - \sigma(\bar{y},\eta)|^2 + |\hat{\sigma}(\bar{x},\eta) - \hat{\sigma}(\bar{y},\eta)|^2\}d\kappa$$
$$+|b(\bar{x}) - b(\bar{y})|^2 \le K|x-y|^2,$$
$$|b| + \int_U (|\sigma| + |\hat{\sigma}|)^2 d\kappa \le K\,.$$

(B) (a) For some $\delta > 0$,

$$a^{ij}\xi_i\xi_j \ge \delta|\xi|^2 \qquad \forall \xi \in \mathbb{R}^d;$$

(b) $\lim_{|x-x'|\to 0}\sup_t \int_U \left\{|\sigma(t,x,\eta) - \sigma(t,x',\eta)|^2 + |\hat{\sigma}(t,x,\eta) - \hat{\sigma}(t,x',\eta)|^2\right\} d\kappa = 0$;

(c) $|a| + |b| \le K$.

LEMMA 2 (see [18], [10], [21], [22]). *Let assumption* (B) *be satisfied and $p > d$. Then there exists a constant $N = N(\delta,K,d,p)$ such that for each $(s,x) \in H$ and $\bar{P} \in S(s,x,\sigma,\hat{\sigma},b)$,*

$$\bar{P}\int_s^1 f(t,X_t)dt \le N|f|_p \quad \textit{for all} \quad f \in L^p(H)\,.$$

PROPOSITION 1. *Let (at least) one of the assumptions* (A) *and* (B) *be satisfied. Then for each* $(s,x) \in H$ *there exists a unique* $P_{s,x} \in S(s,x,\sigma,\hat{\sigma},b)$ *and the map* $(s,x) \to P_{s,x} \in M^1_{mc}(\bar{\Omega})$ *is continuous.*

Proof. 1. Assume (A). In this case the proof can be carried out along familiar lines and we confine ourselves to a short outline.

Iterating and using (A) in a standard way, we find a unique strong solution $X_t = X_t^{s,x}$ of the equation

$$\begin{aligned} -dX_t &= \int_U \left\{ \sigma(t,X_t,\eta) W(\overleftarrow{dt}, d\eta) + \hat{\sigma}(t,X_t,\eta)\hat{W}(\overleftarrow{dt}, d\eta) \right\} \\ &+ b(t,X_t)dt\ , \\ X_t &= x \quad \forall t \geq s\ . \end{aligned}$$

In addition, it is readily checked that $E \sup_t |X_t^{s,x}|^2$ is locally bounded on H.

Now, using Gronwall's inequality, we derive that

$$E \sup_t |X_t^{s,x} - X_t^{s',x'}|^2 \longrightarrow 0 \text{ as } (s',x') \to (s,x)\ . \tag{6}$$

Define $P_{s,x}(d\omega, dw) = \delta_{X^{s,x}_{\cdot}}(dw) P(d\omega) \in M^1_{mc}(\bar{\Omega})$, where δ_w is a Dirac measure on $\mathcal{X}$ at point w. Then obviously $P_{s,x} \in \mathcal{S}(s,x,\sigma,\hat{\sigma},b)$ is a unique solution to $(s,x,\sigma,\hat{\sigma},b)$. The continuity of the map $(s,x) \to P_{s,x}$ follows from (6).

2. Assume (B). First we will prove that a solution of the martingale problem $(s,x,\sigma,\hat{\sigma},b)$ is unique. This follows from Lemma 3 below.

LEMMA 3. *Let* $\bar{P}, \bar{P}' \in \mathcal{S}(s,x,\sigma,\hat{\sigma},b)$. *Then for every partition* $0 \leq s_1 \leq \cdots \leq s_n \leq 1$ *and for each bounded continuous* $g : (\mathbb{R}^d)^n \to \mathbb{R}$,

$$\bar{P}[g(X_{s_1}, \ldots, X_{s_n})|\mathcal{G}] = \bar{P}'[g(X_{s_1}, \ldots, X_{s_n})|\mathcal{G}] \qquad \text{P-a.e.} \tag{7}$$

Proof. The proof will be carried out by induction. Obviously (7) holds if $n = 1$ and $s_1 = 1$.

Let us fix the partition, $0 < s_1 \leq \cdots \leq s_n \leq 1$, and assume that for this partition (**) holds. It is sufficient to prove that for any $h,\ \hat{h} \in L^2([0,1] \times U, dt\, d\kappa)$ and $f \in C_0^\infty(H)$,

$$\begin{aligned} &\bar{P}\left[g(X_{s_1}, \ldots, X_{s_n}) \int_0^{s_1} f(t,X_t) dt q_0(h,\hat{h}) \right] \\ &= \bar{P}'\left[g(X_{s_1}, \ldots, X_{s_n}) \int_0^{s_1} f(t,X_t) dt q_0(h,\hat{h}) \right]\ , \end{aligned} \tag{8}$$

where

$$\begin{aligned} q_t(h,\hat{h}) &= \exp\left\{ \int_t^1 \int_U [hW(ds,d\eta) + \hat{h}\hat{W}(ds,d\eta)] \right. \\ &\left. -\tfrac{1}{2} \int_t^1 \int_U (h^2 + \hat{h}^2) d\kappa\, ds \right\}\ . \end{aligned}$$

Since f and $h, \hat{h}$ are arbitrary, it would follow by Lemma 1 that for each $s_0 \in [0, s_1)$, and $v \in C_0^\infty(\mathbb{R}^d)$,

$$\begin{aligned} &\bar{P}[g(X_{s_1}, \ldots, X_{s_n}) v(X_{s_0})|\mathcal{G}] \\ &= \bar{P}'[g(X_{s_1}, \ldots, X_{s_n}) v(X_{s_0})|\mathcal{G}] \qquad \text{P-a.e.} \end{aligned}$$

Thus for each $\Gamma_0, \dots, \Gamma_n \in \mathcal{B}(\mathbb{R}^d)$, $0 \le s_0 \le \cdots \le s_n \le 1$ we would have

$$\begin{aligned}&\bar{P}[X_{s_0} \in \Gamma_0, \dots, X_{s_n} \in \Gamma_n | \mathcal{G}] \\ &= \bar{P}'[X_{s_0} \in \Gamma_0, \dots, X_{s_n} \in \Gamma_n | \mathcal{G}] \qquad \text{P-a.e.}\end{aligned}$$

In order to prove (8) we take a continuous function $v \in W^{2,d+1}(H)$ solving the Cauchy problem

$$\begin{cases} \partial_t u = \tilde{\mathcal{L}} u + \tilde{\mathcal{M}}_u + f, \\ u(0, \cdot) = 0, \end{cases}$$

where $\tilde{\mathcal{L}} u = a^{ij} u_{x_i x_j} + b^i u_{x_i}$, $\tilde{\mathcal{M}} u = (\int_U (\sigma^i h + \hat{\sigma}^i \hat{h}) d\kappa) u_{x_i}$.

Such a solution exists according to [21] and the Sobolev imbedding theorem. By the Ito formula for backward stochastic differentials (see [29]) and Lemma 2 we have (see [22])

$$\begin{aligned}\bar{P}[g(X_{s_1}, \dots, X_{s_n}) \;\; & v(s_1, X_{s_1}) q_0(h, \hat{h})] \\ &= \bar{P}\left[g(X_{s_1}, \dots, X_{s_n}) \int_0^{s_0} [\tilde{\mathcal{M}} v(t, X_t) + f(t, X_t)] dt q_0(h, \hat{h}) \right] \\ &- \bar{P}\left[g(X_{s_1}, \dots, X_{s_n}) \int_0^{s_1} v_{x_i}(t, X_t) (\sigma^i(t, X_t, \eta) W(\overleftarrow{dt}, d\eta) \right. \\ &\left. + \; \hat{\sigma}^i(t, X_t, \eta) \hat{W}(\overleftarrow{dt}, d\eta)) q_0(h, \hat{h}) \right] \\ &= \bar{P}\left[g(X_{s_1}, \dots, X_{s_n}) \int_0^{s_1} f(t, X_t) dt q_0(h, \hat{h}) \right] .\end{aligned}$$

Then the uniqueness follows.

Let $w \in C_0^\infty(\mathbb{R}^d)$, $w \ge 0$, $\int w \, dx = 1$, $\operatorname{supp} w \subset \{x : |x| < 1\}$, $\epsilon > 0$, $w_\epsilon(x) = \epsilon^d w(x/\epsilon)$, $\sigma_\epsilon(t, x, y) = \sigma(t, \cdot, y) * w_\epsilon(x)$, $\hat{\sigma}_\epsilon(t, x, y) = \hat{\sigma}(t, \cdot, y) * w_\epsilon(x)$, $b_\epsilon(t, x) = b(t, \cdot) * w_\epsilon(x)$.

To prove the existence let us choose $\epsilon_n \to 0$ such that $a_n^{ij}(\bar{x}) \xi_i \xi_i \ge \delta/2 |\xi|^2$, where

$$\begin{aligned}&a_n^{ij}(\bar{x}) = \int_U (\sigma_n^i(\bar{x}, \eta) \sigma_n^j(\bar{x}, \eta) + \hat{\sigma}_n^i(\bar{x}, \eta) \hat{\sigma}_n^j(\bar{x}, \eta)) d\kappa \, , \\ &\sigma_n^i = \sigma_{\epsilon_n}^i, \hat{\sigma}_n^i = \hat{\sigma}_{\epsilon_n}^i, b_n = b_{\epsilon_n}, \quad \text{and} \\ &b_n \to b, \quad \int (|\sigma_n - \sigma|^2 + |\hat{\sigma}_n - \hat{\sigma}|^2) d\kappa \to 0, \\ &dtdx\text{-a.e.}\end{aligned}$$

Let $(s_n, x_n) \to (s, x)$, $\bar{P}^n \in S(s_n, x_n, \sigma_n, \bar{\sigma}_n, b_n)$. In the first part ((A) is satisfied) we proved already that for every n, $\bar{P}^n$ exists and is unique. Obviously, the set of measures $\{\bar{P}^n \circ X^{-1}, n \ge 1\}$ on $\mathcal{X}$ is relatively compact. Thus the set $\{\bar{P}^n, n \ge 1\}$ is also relatively compact in $M_{mc}^1(\bar{\Omega})$. In fact, it is shown in [8] that the former is necessary and sufficient for the latter.

We can assume that $\bar{P}^n \to \bar{P}$ in $M_{mc}^1(\bar{\Omega})$. For $r < t$, let $\bar{f}$ be a $\mathcal{C}_r$-measurable bounded continuous function and $H \in \mathcal{G}_r$. Then

$$\bar{P}^n 1_H \bar{f} (M_t^n - M_r^n) = 0,$$

where $M_t^n = X_t - \int_t^s b^n(r, X_r) dr$.

For each $m, K > 0$

$$\bar{P}^n \int_0^1 |b^n(r, X_r) - b^m(r, X_r)|dr$$
$$\leq N|(b^n - b^m)1_{\{|x|\leq K\}}|_p + C \sup_n \bar{P}^n(\sup_t |X_t| > K) .$$

Thus

$$\bar{P}1_H \bar{f}(M_t - M_s) = 0 .$$

Similarly, using the characterization given in Remark 1 we derive in a standard way that $\bar{P} \in S(s, x, \sigma, \hat{\sigma}, b)$. Since we have already proved that $\bar{P}$ is unique, the statement follows.

Now we shall discuss basic properties of $L(H)$-solutions to (4).

Set $\psi(x) = (1 + |x|^2)^{-d}$, $\hat{b}^j = b^j - [2a^{ij}\psi_{x_i} + a^{ij}_{x_i}]$, $\hat{c} = c - [\mathcal{L}\psi - 2a^{ij}\psi_{x_i}\psi_{x_j}]/\psi$, and $\hat{f} = \psi f$.

LEMMA 4. *Let u be an $L(H)$-solution of the Cauchy problem* (3). *Set $\bar{u}(t, x) = \psi(x)u(t, x)$. Then $\bar{u}(t, x)$ is a continuous map from $[0, 1]$ into $L^2(R^d)$. In addition $\bar{u}(t, x) \in L^2((0, 1); W^{1,2}(\mathbb{R}^d))$ and satisfies the "energy" equality*

$$\int_{\mathbb{R}^d} |\bar{u}(t, x)|^2 dx = \int_{\mathbb{R}^d} |\bar{u}(0, x)|^2 dx + 2 \int_0^t \int_{\mathbb{R}^d} \Big\{ - a^{ij}(s, x)\bar{u}_{x_i}(s, x)\bar{u}_{x_j}(s, x)$$
$$+ \Big[\hat{b}^i(s, x)\bar{u}_{x_i}(s, x) + \hat{c}(s, x)\bar{u}(s, x) + \hat{f}(s, x)\Big] \bar{u}(s, x)\Big\} dx\, ds . \tag{9}$$

Proof. The inclusion $\bar{u} \in W^{1,2}(\mathbb{R}^d)$ is obvious. It is also readily checked that $\bar{u}$ is a $(W^{1,2}(\mathbb{R}^d))$ generalized solution of the Cauchy problem

$$\frac{\partial \bar{u}}{\partial t} = \hat{\mathcal{L}}\bar{u} + \hat{f} \ , \ \bar{u}(0) = \psi\varphi, \tag{10}$$

where $\hat{\mathcal{L}}\bar{u} = (a^{ij}\bar{u}_{x_i})_{x_j} + \hat{b}^i\bar{u}_{x_i} + \hat{c}\bar{u}$. It follows from (4) and (10) that

$$\frac{\partial \bar{u}}{\partial t} \in L^2((0, 1); W^{-1,2}(\mathbb{R}^d)). \tag{11}$$

By the standard imbedding theorem (see, e.g., [18]), (4) and (11) give that there exists a version of function $\bar{u}$ which is continuous from [0,1] into $L^2(\mathbb{R}^d)$. It is well known (see, e.g., [18] or [29]) that if a generalized solution of (10) belongs to $L^2((0, 1); W^{1,2}(\mathbb{R}^d)) \cap C([0, 1]; L^2(\mathbb{R}^d))$, then it satisfies equality (9).

PROPOSITION 2. *For each $\bar{x} = (t, x), \bar{y} = (t, y) \in H$, let*

$$\int_U \left\{|\sigma(\bar{x}, \eta) - \sigma(\bar{y}, \eta)|^2 + |\hat{\sigma}(\bar{x}, \eta) - \hat{\sigma}(\bar{y}, \eta)|^2\right\} d\kappa \leq K|x - y|^2$$

and $|b|_L + |c|_L + \int(|\sigma| + |\hat{\sigma}|)^2 d\kappa \leq K$.

Then for each f, φ such that $|f|_L + |\varphi|_L < \infty$ there exists a unique $u \in L(H)$ solving (3). *Moreover,*

$$u(s, x) = E\left[\int_0^s \exp\left\{\int_t^s c(r, X_r^{s,x})dr\right\} f(t, X_t^{s,x})dt\right.$$
$$\left. + \exp\left\{\int_0^s c(r, X_r^{s,x})dr\right\} \varphi(X_0^{s,x})\right] , \tag{12}$$

where $X_t = X_t^{s,x}$ is a strong solution of the equation

$$\begin{cases} -dX_t &= \int_U (\sigma(t,X_t,\eta)W(\overleftarrow{dt},d\eta) + \hat{\sigma}(t,X_t,\eta)\hat{W}(\overleftarrow{dt},d\eta)) \\ & \quad +b(t,X_t)dt, t<s\ . \\ X_t &= x \quad \forall t \geq s\ . \end{cases}$$

Proof. 1. *The uniqueness.* It is enough to prove that a function $v \in L(H)$ that satisfies (10) with $f = \varphi = 0$ is identically zero.

By (9) we have

$$\|v(t)\|_0^2 = 2\int_0^t \int_{R^d} \left\{-a^{ij}v_{x_i}v_{x_j} + \hat{b}^i v_{x_i} v + \hat{c}v^2\right\} ds\, dx, \tag{13}$$

where $\|\cdot\|_0$ stands for the norm in $L^2(\mathbb{R}^d)$. Integrating by parts we notice that

$$\begin{aligned} 2\int_{R^d} \hat{b}^i v_{x_i} v dx = -\int (b^i - 2a^{ij}\psi_{x_j}\psi^{-1})_{x_i} v^2 dx \\ +2\int a^{ij}_{x_j} v_{x_i} v dx\ . \end{aligned} \tag{14}$$

Owing to the boundedness of the coefficients a, b, c and their first derivatives (for $a.a.x$), we derive from (13) and (14) that for all t,

$$\begin{aligned} \|v(t)\|_0^2 \leq 2\int_0^t \int_{R^d} \left\{-a^{ij}v_{x_i}v_{x_j} + a^{ij}_{x_j} v_{x_i} v\right\} dx\ ds \\ +c\int_0^t \|v(s)\|_0^2 ds\ . \end{aligned} \tag{15}$$

Again integrating by parts we get

$$\begin{aligned} \int_{R^d}\int_U (\sigma^i(\eta)\sigma^j(\eta))_{x_j} v_{x_i} v d\kappa dx = \int_{R^d}\int_U \sigma^i(\eta)\sigma^j_{x_j}(\eta) v_{x_i} v d\kappa dx \\ + \tfrac{1}{2}\int_{R^d}\int_U \sigma^i_{x_j}(\eta)\sigma^j(\eta)(v^2)_{x_i} dx = \int_{R^d}\int_U \sigma^i(\eta)\sigma^j_{x_j}(\eta) v_{x_i} v d\kappa dx \\ - \tfrac{1}{2}\int_{R^d}\int_U \sigma^i_{x_j}(\eta)\sigma^j_{x_i}(\eta) v^2 d\kappa dx + \tfrac{1}{2}\int_{R^d}\int_U \sigma^i_{x_i}(\eta)\sigma^j_{x_j}(\eta) v^2 d\kappa dx \\ + \int_{R^d}\int_U \sigma^i_{x_i}(\eta)\sigma^j(\eta) v v_{x_j} d\kappa dx = I_1 + I_2 + I_3 + I_4. \end{aligned}$$

Obviously,

$$I_2 + I_3 \leq c\|v\|_0^2\ . \tag{16}$$

Applying the Hölder inequality and then the elementary inequality $2ab \leq a^2 + b^2$ we obtain

$$I_1 + I_4 \leq \int_{R^d}\int_U |\sigma^i(\eta) v_{x_i}|^2 d\kappa dx + c\|v\|_0^2\ . \tag{17}$$

Estimates (16) and (17) yield

$$\begin{aligned} \int_0^t \int_{R^d}\int_U (\sigma^i(\eta)\sigma^j(\eta))_{x_j} v_{x_i} v d\kappa dx ds \leq \int_0^t \int_{R^d}\int_U |\sigma^i(\eta) v_{x_i}|^2 d\kappa dx ds \\ +c\int_0^t \|v\|_0^2 ds\ . \end{aligned} \tag{18}$$

Similar arguments lead to the estimate

$$\int_0^t \int_{R^d} \int_U (\hat\sigma^i(\eta)\hat\sigma^j(\eta))_{x_j} v_{x_i} v d\kappa dx ds \le \int_0^t \int_{R^d} \int_U |\hat\sigma^i(\eta) v_{x_i}|^2 d\kappa dx ds + c\int_0^t \|v\|_0^2 ds\,. \tag{19}$$

Combining (18) and (19) we arrive at

$$2\int_0^t \int_{R^d} a^{ij}_{x_j} v_{x_i} v dx \le \int_0^t \int_{R^d} \int_U (|\sigma^i(\eta) v_{x_i}|^2 + |\hat\sigma^i(\eta) v_{x_i}|^2 + |\hat\sigma^i(\eta) v_{x_i}|^2) d\kappa dx ds + c\int_0^t \|v\|_0^2 ds = 2\int_0^t \int_{R^d} a^{ij} v_{x_i} v_{x_j} dx ds + c\int_0^t \|v\|_0^2 ds\,.$$

The latter inequality together with (15) gives

$$\|v(t)\|_0^2 \le c\int_0^t \|v(s)\|_0^2 ds\,,$$

and thus by the Gronwall lemma $\|v(t)\|_0 \equiv 0$.

2. *The existence.* Let $w \in C_0^\infty(\mathbb{R}^d)$, $w \ge 0$, $\mathrm{supp} w \subset \{x : |x| < 1\}$, $\int w dx = 1$, $w_\epsilon(x) = \epsilon^{-d} w(x/\epsilon)$. Define $b_\epsilon(t,\cdot) = b(t,\cdot) * w_\epsilon$, $c_\epsilon(t,\cdot) = c(t,\cdot) * w_\epsilon$, $\sigma_\epsilon(t,\cdot,\eta) = \sigma(t,\cdot,\eta) * w_\epsilon$, $\hat\sigma_\epsilon(t,\cdot,\eta) = \hat\sigma(t,\cdot,\eta) * w_\epsilon$, $f_\epsilon(t,\cdot) = f(t,\cdot) * w_\epsilon$, $\varphi_\epsilon = \varphi * w_\epsilon$. Consider the Cauchy problem

$$\begin{cases} -\partial_t u + \mathcal{L}^\epsilon u + f_\epsilon = 0 \text{ in } H, \\ u(0,\cdot) = \varphi_\epsilon, \end{cases} \tag{20}$$

where $\mathcal{L}^\epsilon$ is obtained by $\mathcal{L}$ by substituting $\sigma_\epsilon, \hat\sigma_\epsilon, b_\epsilon, c_\epsilon$ for $\sigma, \hat\sigma, b, c$. Then according to [29], we can find a unique smooth (with respect to x) solution u^ϵ to (20). For $(s,x) \in H$ denote by $X_t = X_t^{\epsilon,s,x}$ a solution to

$$\begin{cases} -dX_t &= \displaystyle\int_U (\sigma_\epsilon(t, X_t, \eta) W(\overleftarrow{dt}, d\eta) + \hat\sigma(t, X_t, \eta)\hat W(\overleftarrow{dt}, d\eta)) \\ &+ b(t, X_t) dt,\ t < s, \\ X_t &= x, \quad \forall t \ge s. \end{cases}$$

By the Ito formula we have

$$u^\epsilon(s,x) = E\left[\int_0^s \exp\left\{\int_t^s c_\epsilon(r, X_r^{\epsilon,s,x}) dr\right\} f_\epsilon(t, X_t^{\epsilon,s,x}) dt + \exp\left\{\int_0^s c_\epsilon(r, X_r^{\epsilon,s,x} dr\right\} \varphi_\epsilon(X_0^{\epsilon,s,x})\right]. \tag{21}$$

Now it is easy to see that

$$|u^\epsilon(s,x) - u^\epsilon(s',x))| \le C|s-s'|^{\frac{1}{2}} \tag{22}$$

$$|u^\epsilon(s,x) - u^\epsilon(s,x'))| \le C|x-x'|\,, \tag{23}$$

where the constant C does not depend on ϵ.

Thus we can find a sequence $\epsilon_k \downarrow 0$ such that $(u^k)(u^{\epsilon_k})$ converges to $u \in L(H)$ uniformly on compact subsets of H and (23) holds for u as well. So

$$|u_x^\epsilon| \le C, |u_x| \le C \ .$$

Since $u^k = u^{\epsilon_k}$ is a classical solution of (20) for every $y \in C_0^\infty(\mathbb{R}^d)$ we can rewrite (4) as

$$\int u^k(t,x)y(x)dx = \int \varphi_{\epsilon_k}(x)y(x)dx + \int_0^t \int \Big\{ - a^{ij}_{\epsilon_k}(s,x)u^k_{x_i}(s,x)y_{x_j}(x)$$

$$+[(b^i_{\epsilon_k}(s,x) - a^{ij}_{\epsilon_{k_{x_j}}}(s,x))u^k_{x_i}(s,x) + c_{\epsilon_k}(s,x)u^k(s,x) + f_{\epsilon_k}(s,x)]y(x)\Big\}dxds \ , \tag{24}$$

where

$$a^{ij}_{\epsilon_k}(s,x) = \tfrac{1}{2}\int_u (\sigma^i_{\epsilon_k}(s,x,\eta)\sigma^j_{\epsilon_k}(s,x,\eta) + \hat\sigma^i_{\epsilon_k}(s,x,\eta)\hat\sigma^j_{\epsilon_k}(s,x,\eta))d\kappa \ .$$

In order to pass to the limit as $h \to \infty$ we notice that for a bounded function $g(s,x)$ on H taking values in a Hilbert space V and any compact $K \subset \mathbb{R}^d$

$$\int_0^1 \int_K \|g_\epsilon(s,x) - g(s,x)\|^2 ds\, dx \overset{\epsilon \to 0}{\longrightarrow} 0 \ , \tag{25}$$

where $g_\epsilon(s,\cdot) = g(s,\cdot) * w_\epsilon$.

Also, if g_k, g are measurable functions on H such that $\sup_k |g_k| + \sup_k |g_k| \le C$ and for each compact K

$$\int_0^1 \int_K |g_k(s,x) - g(s,x)| \overset{k \to \infty}{\longrightarrow} 0 \ ,$$

then for every $\varphi \in C_0^\infty(\mathbb{R}^d)$,

$$\int_0^1 \int g_k(s,x)u^k_{x_l}(s,x)\varphi(x)dxds \overset{k \to \infty}{\longrightarrow} \int_0^1 \int g(s,x)u_{x_l}(s,x)\varphi(x)dxds \ . \tag{26}$$

Indeed, for each m

$$\overline{\lim}_k \left\{ \left| \int_0^1 |g_k(s,x)u^k_{x_l}(s,x)\varphi(x)ds\, dx - \int_0^1 \int g_m(s,x)u^k_{x_l}(s,x)\varphi(x)ds\, dx \right| \right.$$

$$\left. + \left| \int_0^1 \int g_k(s,x)u_{x_l}(s,x)\varphi(x)ds\, dx - \int_0^1 \int g_m(s,x)u_{x_l}(s,x)\varphi(x)d, dx \right| \right\}$$

$$\le c(m) \quad \text{and} \quad c(m) \overset{m \to \infty}{\longrightarrow} 0 \ .$$

On the other hand, for each m

$$\lim_k \int_0^1 \int g_m(s,x)u^k_{x_l}(s,x)\varphi(x)ds\, dx = -\lim_k \int_0^1 \int (g_m(s,x)\varphi(x))_{x_l}u^k(s,x)ds\, dx$$

$$= \int_0^1 \int (g_m(s,x)\varphi(x))_{x_l}u(s,x)ds\, dx = \int_0^1 \int g_m(s,x)\varphi(x)u_{x_l}(s,x)ds\, dx$$

and (26) follows.

Applying (25) for $V = L^2(U,\mathcal{U},d\kappa)$, $g = \sigma, \hat{\sigma}, \sigma_{x_l}, \hat{\sigma}_{x_l}$, we derive that for a compact $K \subset \mathbb{R}^d$

$$\int_0^1 \int_K (|a^{ij}_{\epsilon_k}(s,x) - a^{ij}(s,x)| + |a^{ij}_{\epsilon_k x_l}(s,x) - a^{ij}_{x_l}(s,x)|)ds\,dx \overset{k\to\infty}{\longrightarrow} 0\,.$$

Using the same argument for $V = \mathbb{R}$,

$$\int_0^1 \int_K (|c_{\epsilon_k}(s,x) - c(s,x)| + |\varphi_{\epsilon_k}(x) - \varphi(x)| + |f_{\epsilon_k}(s,x) - f(s,x)| \\ + |b^i_{\epsilon_k}(s,x) - b(s,x)|)ds\,dx \overset{k\to\infty}{\longrightarrow} 0\,.$$

Now using (26) we pass to the limit, as $k \to \infty$, in (24) and arrive at (4) for u, and (12) follows from (21). This completes the proof.

Proof of Theorem 1. 1. *The uniqueness.* The uniqueness is an immediate consequence of Lemma 1 and the corresponding uniqueness theorem for (2). For the class $L(H)$ the latter result follows from Proposition 1. Uniqueness of (2) in the classes $C^{2+\beta}(H)$ and $W^{2,p}(H)$ is well known; see, e.g., [3], [18], [21], [22], and a continuous version of a $W^{2,p}(H)$-solution exists by the Sobolev imbedding theorem.

Remark 2. Note that in the standard references (e.g., [3] or [18]) some smoothness of the coefficients of (3) in t is assumed. In fact this assumption is not necessary (see [21], [22]).

2. *The existence.* Obviously the assumption (L) implies (A) while (B) follows from either of the assumptions (C) or (W). This of course remains true if b in (A) and (B) is replaced by B or B^l for any $l \in \mathcal{D}$. So by Proposition 1 there exists a unique measure $P^B_{s,x} \in \mathcal{S}(s,x,\sigma,\hat{\sigma},B)$ and the map $(s,x) \to P^B_{s,x}$ is continuous. The right-hand part of (5) is well defined and we denote it by $v(s,x)$. Then $E|v(s,x)|^2$ is locally bounded by the Hölder inequality (and Lemma 2 if (W) is assumed). Fix $l \in \mathcal{D}$ and set $v^l(s,x) = Ev(s,x)q_s(l)$. Simple computation based on Girsanov's theorem shows that

$$v^l(s,x) = P^{B_l}_{s,x}\left[\int_0^s \exp\left\{\int_t^s \tilde{c}(r,X_r)dr\right\}(f(t,X_t) \right. \\ \left. + \int_U l(t,\eta)g(t,X_t,\eta)d\kappa)dt + \varphi(X_0)\exp\left\{\int_0^s \tilde{c}(r,X_r)dr\right\}\right], \tag{27}$$

where $\tilde{c}(t,x) = c(t,x) + \int_U l(t,\eta)h(t,x,\eta)d\kappa$ and $P^{B_l}_{s,x} \in \mathcal{S}(s,x,\sigma,\hat{\sigma},B^l)$.

Since the right-hand side of (27) solves equation (2) in the corresponding class and is continuous in (s,x) (see [3], [18], [21], [22] for $C^{2+\beta}(H)$, $W^{2,p}(H)$, and Proposition 1 for $L(H)$), we are done.

The following corollary is an obvious implication of (5) and the uniqueness property of soft solutions.

Corollary 1. *If $g = 0$, $f \geq 0$, and $\varphi \geq 0$ then the S-solution of equation* (1) *is nonnegative.*

Remark 3. Let the assumption (L) be satisfied. Then we can rewrite (5) as

$$u(s,x) = E\left[\int_0^s f(t,X^{s,x}_t)\tilde{\rho}(s,t)dt + \varphi(X^{s,x}_0)\tilde{\rho}(0,s) \right. \\ \left. + \int_0^s \int_U g(t,X^{s,x}_t,\eta)\tilde{\rho}(s,t)W(\overleftarrow{dt},d\eta)|\mathcal{F}^W_s\right], \tag{28}$$

where $X^{s,x}$ is a strong solution of the stochastic differential equation (SDE)

$$\begin{cases} -dX_t &= \int_U (\sigma(t,X_t,\eta)W(\overleftarrow{dt},d\eta)+\hat\sigma(t,X_t,\eta)\hat W(\overleftarrow{dt},d\eta)) \\ &+ B(t,X_t)dt, \quad t<s, \\ X_t &= x \quad \forall t\ge s\ , \end{cases}$$

and

$$\tilde\rho(s,t)=\exp\left\{\int_t^s c(r,X_r^{s,x})dr+\int_t^s\int_U h(r,X_r^{s,x},\eta)W(\overleftarrow{dr},d\eta)\right.$$
$$\left.-\tfrac12\int_t^s h(r,X_r^{s,x},\eta)^2 d\kappa\, dr\right\}\ .$$

Moreover, a simple computation shows that for each $p\ge 2$ there exists C such that

$$E|u(t,x)-u(t,y)|^p\le C|x-y|^p\ ,$$
$$E|u(t,x)-u(t',x)|^p\le C|t-t'|^{p/2}\ .$$

Now we will show that an S-solution can be obtained as a limit of strong solutions.

Let $w,\bar w\in C_0^\infty(\mathbb{R}^d), w\ge 0$, $0\le\bar w\le 1$, $\int w\,dx=1$, $\operatorname{supp} w\subset\{x:|x|<1\}$, and $\bar w(x)=1$ if $|x|\le 1$. Define $w_\epsilon(x)=\epsilon^{-d}w(x/\epsilon)$, $\bar w_\epsilon(x)=w(\epsilon x)$, $\sigma_\epsilon(t,\cdot,\eta)=\sigma(t,\cdot,\eta)*w_\epsilon, \hat\sigma_\epsilon(t,\cdot,\eta)=\hat\sigma(t,x\cdot,\eta)*w_\epsilon$, $b_\epsilon(t,\cdot)=b(t,\cdot)*w_\epsilon$, and $c_\epsilon(t,\cdot)=c(t,\cdot)*w_\epsilon$, $h_\epsilon(t,\cdot,\eta)=h(t,\cdot,\eta)*w_\epsilon$.

As before denote

$$\mathcal{L}^\epsilon u=a_\epsilon^{ij}u_{x_ix_j}+b_\epsilon^i u_{x_i}+c_\epsilon u\ ,$$
$$\mathcal{M}^\epsilon u=\mathcal{M}_\eta^\epsilon u=\sigma_\epsilon^i u_{x_i}+h_\epsilon u\ ,$$

where $a_\epsilon^{ij}=\frac12\int_U(\sigma_\epsilon^i\sigma_\epsilon^j+\hat\sigma_\epsilon^i\hat\sigma_\epsilon^j)d\kappa$.

Let $f^\epsilon(t,\cdot)=f(t,\cdot)*w_\epsilon\bar w_\epsilon, g^\epsilon(t,\cdot,\eta)=g(t,\cdot,\eta)*w_\epsilon\bar w_\epsilon$, $\varphi^\epsilon=\varphi*w_\epsilon\bar w_\epsilon$.

Consider the equation

$$\text{(29)}\quad\begin{cases} du(t,x)=(\mathcal{L}^\epsilon u(t,x)+f^\epsilon(t,x))dt+\int_U(\mathcal{M}_\eta^\epsilon u(t,x)+g^\epsilon(t,x))W(dt,d\eta), \\ u(0,\cdot)=\varphi^\epsilon\ . \end{cases}$$

If one of the conditions (C), (W), or (L) holds, then according to [29] (at this point the specific construction of approximations is used) there exists a unique classical solution $u=u^\epsilon$ to (29) and the following representation holds:

$$\text{(30)}\quad\begin{aligned} u^\epsilon(s,x)=E\Bigg[&\int_0^s f^\epsilon(t,X_t^{\epsilon,s,x})\rho_\epsilon(s,t)dt+\varphi^\epsilon(X_0^{\epsilon,s,x})\rho_\epsilon(0,s) \\ &+\int_0^s\int_U g^\epsilon(t,X_t^{\epsilon,s,x},\eta)\rho_\epsilon(s,t)W(\overleftarrow{dt},d\eta)|\mathcal{F}_s^W\Bigg]\ , \end{aligned}$$

where $X=X_t^{\epsilon,s,x}$ is a solution of

$$\begin{cases} -dX_t &= \int_U(\sigma_\epsilon(t,X_t,\eta)W(\overleftarrow{dt},d\eta)+\hat\sigma_\epsilon(t,X_t,\eta)\hat W(\overleftarrow{dt},d\eta)) \\ &+ B_\epsilon(t,X_t)dt, \\ X_t &= x \quad \forall t\ge s\ , \end{cases}$$

and

$$B_\epsilon = b_\epsilon - \int_U \sigma_\epsilon h_\epsilon d\kappa, \rho_\epsilon(s,t) = \exp\left\{\int_t^s c_\epsilon(r, X_r^{\epsilon,s,x})dr \right.$$
$$\left. + \int_t^s \int_U h_\epsilon(r, X_r^{\epsilon,s,x}, \eta) W(\overleftarrow{dr}, d\eta) - \tfrac{1}{2}\int_s^t \int_U h_\epsilon(r, X_r^{\epsilon,s,x}, \eta)^2 d\kappa dr \right\} .$$

THEOREM 2. (a) *Let (L) be satisfied and u be an L-soft solution of* (1). *Then for each $(s,x) \in H$, $u^\epsilon(s,x) \to u(s,x)$ in $L^2(\Omega, \mathcal{F}^W, P)$.*

(b) *Let (C) (respectively, (W)) be satisfied and u be a $C^{2+\beta}$-soft (respectively, $W^{2,p}$-soft) solution to* (1). *Then for each $(s,x) \in H$, $u^\epsilon(s,x) \to u(s,x)$ weakly in $L^2(\Omega, \mathcal{F}^W, P)$.*

Proof. Denote

$$\begin{aligned} F_\epsilon &= \int_0^s f_\epsilon(t, X_t^{\epsilon,s,x})\rho_\epsilon(s,t)dt \ , \\ G_\epsilon &= \int_0^s \int_U g^\epsilon(t, X_t^{\epsilon,s,x}, \eta)\rho_\epsilon(s,t) W(\overleftarrow{dt}, d\eta) \ , \\ \Phi_\epsilon &= \varphi^\epsilon(X_0^{\epsilon,s,x})\rho_\epsilon(0,s). \end{aligned}$$

Assume that f, $\int_E g^2 d\kappa, \varphi, D\varphi, D^2\varphi$ are bounded. Then for each $p \geq 1$

$$\sup_\epsilon E\left[|F_\epsilon|^p + |G_\epsilon|^p + |\Phi_\epsilon|^p\right] < \infty. \tag{31}$$

Let (L) be satisfied and $X_t = X_t^{s,t}$ be a solution of

$$\begin{cases} -dX_t = \displaystyle\int_U (\sigma(t, X_t, \eta) W(\overleftarrow{dt}, d\eta) + \hat{\sigma}(t, X_t, \eta)\hat{W}(\overleftarrow{dt}, d\eta)) \\ +B(t, X_t)dt, \\ X_t = x \qquad \forall\, t \geq s. \end{cases}$$

Then

$$E \sup_t |X_t^{\epsilon,s,x} - X_t^{s,x}|^2 \to 0 \ .$$

It is readily checked that for each $p \geq 1$

$$\sup_\epsilon E \sup_t \rho_\epsilon(s,t)^p < \infty \ .$$

Thus for $p \geq 1$,

$$E \sup_t |\rho_\epsilon(s,x) - \tilde{\rho}(s,x)|^p \overset{\epsilon \to}{\to} 0,$$

where $\tilde{\rho}(s,t) =$

$$= \exp\left\{\int_t^s c(r, X_r^{s,t})dr + \int_t^s \int_U h(r, X_r^{s,t}, \eta) W(\overleftarrow{dr}, d\eta) \right.$$
$$\left. -\tfrac{1}{2}\int_t^s \int_U h(r, X_r^{s,x}, \eta)^2 d\kappa, dr \right\}.$$

So for each $p \geq 1$ by (31)

$$E(|F_\epsilon - F|^p + |G_\epsilon - G|^p + |\Phi_\epsilon - \epsilon|^p) \overset{\epsilon \to}{\to} 0 \ ,$$

where

$$F = \int_0^s f(t, X_t^{s,x})\tilde{\rho}(s,t)dt\ ,$$
$$G = \int_0^s \int_U g(t, X_t^{s,x}, \eta)\tilde{\rho}(s,t)W(\overleftarrow{dt}, d\eta)\ ,$$
$$\Phi = \varphi(X_0^{s,x})\tilde{\rho}(0,s)\ .$$

Then $E[F_\epsilon + G_\epsilon + \Phi_\epsilon|\mathcal{F}_s^W] \to E[F + G + \Phi|\mathcal{F}_s^W]$ in $L^p(\Omega, \mathcal{F}^W, P)$. Thus passing to the limit in (30), we get (28) and the statement is proved in the (L) case.

Let (C) or (W) be satisfied and $f, \int g^2 d\kappa, \varphi, D\varphi, D^2\varphi$ be bounded. According to Lemma 1, there is a complete orthonormal system (CONS) in $L^2(\Omega, \mathcal{F}^W, P)$ consisting of linear combinations of $q_1(l), l \in \mathcal{D}$. Since $\sup_\epsilon E(|u^\epsilon(s,x)|^2 + |u(s,x)|^2) < \infty$, then in order to prove the weak convergence in $L^2(\Omega, \mathcal{F}^W, P)$ it is sufficient to demonstrate that

$$v_\epsilon^l(s,x) = Eu^\epsilon(s,x)q_1(l) \to Eu(s,x)q_1(l) = v^l(s,x)$$
$$\forall l \in \mathcal{D}\ .$$

Let $P_l^\epsilon \in \mathcal{S}(s,x,\sigma_\epsilon,\hat{\sigma}_\epsilon,B_l^\epsilon)$ and $P_l \in \mathcal{S}(s,x,\sigma,\hat{\sigma},B_l)$, where $B_l^\epsilon = b_\epsilon + \int_U \sigma_\epsilon l d\kappa$, $B_l = b + \int_U \sigma l d\kappa$. Then

$$v_\epsilon^l(s,x) = P_l^\epsilon \left[\int_0^s \exp\left\{\int_t^s \tilde{c}_\epsilon(r, X_r)dr\right\}(f^\epsilon(t, X_t)\right.$$
$$\left. + \int_U l(t,\eta)g^\epsilon(t, X_t, \eta)d\kappa)dt + \varphi^\epsilon(X_0)\exp\left\{\int_0^s \tilde{c}_\epsilon(t, X_t)dt\right\}\right]\ , \tag{32}$$

where $\tilde{c}_\epsilon = c_\epsilon + \int l h_\epsilon d\kappa$.

A similar formula holds for $v^l(s,x)$ if we omit ϵ everywhere.

Indeed, owing to Lemma 2 we can pass to the limit in (32). Indeed, let $\epsilon_n \to 0$. Then by [8] the set $\{P_l^{\epsilon_n}, n \geq 1\}$ is relatively compact. Assume that for some subsequence n_k, $P_l^{\epsilon_{n_k}} = P^k \to P_l$ as $k \to \infty$. Let $\tilde{c}_k = \tilde{c}_{\epsilon_{n_k}}, f^k = f^{\epsilon_{n_k}}$. Then for each m

$$A = P^k \int_0^s \exp\left\{\int_t^s \tilde{c}_k(r, X_r)dr\right\} f^k(t, X_t)dt$$
$$= P^k \int_0^s \exp\left\{\int_t^s \tilde{c}_m(r, X_r)dr\right\} f^m(t, X_t)dt$$
$$+ P^k \left[\int_0^s \exp\left\{\int_t^s \tilde{c}_k(r, X_r)dr\right\} f^k(t, X_t)dt\right.$$
$$\left. - \int_0^s \exp\left\{\int_t^s \tilde{c}_m(r, X_r)dr\right\} f^m(t, X_t)dt\right] = I_1 + I_2.$$

Now there exists a constant C such that

$$|I_2| \leq CP^k\left[\int_0^1 |\tilde{c}_k(r, X_r) - \tilde{c}_m(r, X_r)|dr\right.$$
$$\left. + \int_0^1 |f^k(r, X_r) - f^m(r, X_r)|dr\right] = I_{21} + I_{22}.$$

If (W) is satisfied, $I_{22} \le C'|f^k - f^m|_p \overset{k,m\to\infty}{\to} 0$. On the other hand, for each L

$$\begin{aligned} I_{21} &\le \bar{C}\Big(\sup_k P^k(\sup_t |X_t| > L) \\ &+P^k \int_0^1 |\tilde{c}_k(r, X_r) - \tilde{c}_m(r, X_r)|\bar{w}(X_r)dr \Big) \\ &\le \bar{c}\sup_k P^k(\sup_t |X_t| > L) \\ &+N|(\tilde{c}_k - \tilde{c}_m)\bar{w}_L|_p. \end{aligned}$$

Thus for each m, L,

$$\begin{aligned} B &= \lim_k \left| A - P_l \int_0^s \exp\left\{ \int_t^s \tilde{c}(r, X_r)dr \right\} f(t, X_t)dt \right| \\ &\le 2C'|f - f^m|_p + 2N|(\tilde{c} - \tilde{c}_m)\bar{w}_L|_p + C\sup_k P^k(\sup_t |X_t| \\ &> L) + P_l(\sup_t |X_t| > L) \ . \end{aligned}$$

Also $\overline{\lim_L}\ \overline{\lim_m} B = 0$. This proves that

$$\lim_k A = P_l \int_0^s \exp\left\{ \int_t^s \tilde{c}(r, X_r)dr \right\} f(t, X_t)dt \ .$$

Similarly

$$\begin{aligned} &P^k \left[\int_0^s \int_U l(t, \eta) g^{\epsilon_{n_k}}(t, X_t, \eta)d\kappa dt \right. \\ &\left. +\varphi^{\epsilon_{n_k}}(X_0) \exp\left\{ \int_0^s \tilde{c}_k(t, X_t)dt \right\} \right] \\ &\to P_l \left[\int_0^s \int_U l(t, \eta) g(t, X_t, \eta)d\kappa dt \right. \\ &\left. +\varphi(X_0) \exp\left\{ \int_0^s \tilde{c}_k(t, X_t)dt \right\} \right] \ . \end{aligned}$$

This completes the proof of the weak convergence in $L^2(\Omega, \mathcal{F}^W, P)$ given that either one of (C) and (W) is satisfied and f, $\int g^2 d\kappa, \varphi, D\varphi, D^2\varphi$ are bounded.

Now we drop the latter assumption and assume (W) in its original form. Define $f_n = f1_{\{|f|\le n\}}$, $g_n = g1_{\{\int g^2 d\kappa \le n\}}$, and take a sequence $\varphi_n \in C_0^\infty(\mathbb{R}^d)$ converging to φ in $W^{2,p}(\mathbb{R}^d)$. Let $u^{n,\epsilon}$ be a solution to problem (1) with f, g, φ replaced by f_n, g_n, φ_n. Then by Lemma 2

$$\lim_{n\to\infty} \sup_\epsilon E|u^{n,\epsilon}(s, x) - u^\epsilon(s, x)|^2 = 0 \ .$$

Let u^n be a solution of (1) with f, g, φ replaced by f_n, g_n, φ_n. Then we know already that for each n, $u^{n,\epsilon} \to u^n$ weakly in $L^2(\Omega, \mathcal{F}^W, P)$.

By Lemma 3

$$\lim_{n\to\infty} E|u^n(s, x) - u(s, x)|^2 = 0 \ .$$

3. Chaos expansions of soft solutions. Let us fix an arbitrary complete orthonormal system (m_k) in $L^2([0, 1] \times U, dtd\kappa)$ such that $m_k \in \mathcal{D} \quad \forall k \ge 1$. Let us also introduce random variables

$$\xi_k = \int_0^1 \int_U m_k(s, \eta) W(ds, d\eta)$$

and $H_n(\xi_k)$, where H_n is the nth Hermite polynomial[3] defined by

$$H_n(x) = (-1)^n \left(\frac{d^n}{dx^n} e^{-\frac{x^2}{2}} \right) e^{\frac{x^2}{2}}.$$

Let $\alpha = (\alpha_k)$ be an infinite multi-index, i.e., $\alpha_k \in \mathbb{N} = \{0, 1, 2, \ldots\}$, $k \geq 1$. We shall consider only such α that $|\alpha| = \sum_k \alpha_k < \infty$; i.e., only a finite number of α_k is not zero, and we denote by $\mathcal{J}$ the set of all such multi-indices. If $\alpha = (\alpha_k) \in \mathcal{J}$, the number $\alpha! = \Pi_k \alpha_k$ is well defined. Let $\xi_\alpha = \Pi_k H_{\alpha_k}(\xi_k)/\alpha!$, $\alpha = (\alpha_k) \in \mathcal{J}$. Now we recall the celebrated Cameron–Martin result.

THEOREM 3 (see [1], [4]). *The set $\{\xi_\alpha, \alpha \in \mathcal{J}\}$ is a CONS in $L^2(\Omega, \mathcal{F}^W, P)$; i.e., for each $\xi \in L^2(\Omega, \mathcal{F}^W, P)$,*

$$\xi = \sum_{\alpha \in \mathcal{J}} E[\xi \xi_\alpha] \xi_\alpha$$

and

$$E\xi^2 = \sum_{\alpha \in \mathcal{J}} (E[\xi \xi_\alpha])^2 \, .$$

Let $\mathcal{Z}$ be the set of real-valued sequences $z = (z_k)_{k \geq 1}$ such that only a finite number of z_k is not zero. For $\alpha = (\alpha_k) \in \mathcal{J}$, set $\partial^\alpha = \partial_z^\alpha = \Pi_k \frac{\partial^{\alpha_k}}{(\partial z_k)^{\alpha_k}}$ and $m = m_z = m(s, \eta, z) = \sum_k z_k m_k$ (obviously $m \in \mathcal{D}$). Set $p_t(z) = q_t(m_z)$.

COROLLARY 2. *If $\xi \in L^2(\Omega, \mathcal{F}_s^W, P)$ for some $s \in [0, 1]$, then*

(a) $\xi = \sum_{\alpha \in \mathcal{J}} \frac{1}{\sqrt{\alpha!}} \partial_z^\alpha E[\xi p_s(z)]|_{z=0} \xi_\alpha(s)$, *where* $\xi_\alpha(s) = \partial_z^\alpha p_s(z)|_{z=0}/\sqrt{\alpha!} = \Pi_k H_{\alpha_k}$ $(\int_0^s \int_U m_k(r, \eta) W(dr, d\eta))$;

(b) $E\xi^2 = \sum_{\alpha \in \mathcal{J}} \frac{1}{\alpha!} \left(\partial_z^\alpha E[\xi p_s(z)]|_{z=0} \right)^2$.

Proof. For $s = 1$, both (a) and (b) follow straightforwardly from Theorem 2 and the well-known formula

$$\xi_\alpha = \partial_z^\alpha p_1(z)|_{z=0}/\sqrt{\alpha!}$$

(see, e.g., [4]). Since $p_s(z)$ is an $\mathcal{F}_s^W$-martingale, it is readily checked that the general statement is a simple implication of the above special case $s = 1$.

Remark 4. If u is a soft solution to (1), we have by (2) the following equation for $u^z = u^{m_z} = S^{m_z} u$:

$$\begin{cases} \partial_t u^z = \mathcal{L} u^z + f + \displaystyle\int_U m_z (\mathcal{M} u^z + g) d\kappa, \\ u^z(0, \cdot) = \varphi \, . \end{cases} \tag{33}$$

Our objective is to expand a soft solution of (1) with respect to (ξ_α). In order to determine the coefficients of this expansion, we consider the recursive system of PDEs:

$$\begin{cases} \partial_t \varphi^\alpha = \mathcal{L} \varphi^\alpha + f 1_{\{|\alpha|=0\}} + \displaystyle\sum_k \alpha_k \int_U m_k (\mathcal{M} \varphi^{\alpha(k)} + g 1_{\{|\alpha|=1\}}) d\kappa, \\ \varphi^\alpha(0, x) = \varphi(x) 1_{\{|\alpha|=0\}}, \end{cases} \tag{34}$$

[3]The random variable $H_n(\xi_k)$ is often referred to as the Wick product (polynomial) and denoted $:(\xi_k)^n:$. This term and notation originated in physical literature (for more detail see [4], etc.).

where $\alpha = (\alpha_i) \in \mathcal{J}$ and by $\alpha(k)$ we denote a sequence $(\tilde{\alpha}_i)$ such that $\tilde{\alpha}_i = \alpha_i$ if $i \neq k$, and $\tilde{\alpha}_k = \max\{\alpha_k - 1, 0\}$. In other words one obtains the sequence $\alpha(k)$ by substituting $\max\{\alpha_k - 1, 0\}$ for α_k in α.

THEOREM 4. *Let (W) (respectively, (C), (L)) be satisfied. Then*

(a) *There exists a unique solution $\varphi^\alpha, \alpha \in \mathcal{J}$ of system (33) such that $\varphi^\alpha \in W^{2,p}(H) \cap W^{2,2p}(H)$ (respectively, $u^\alpha \in C^{2+\beta}(H)$, $L(H)$ for each $\alpha \in \mathcal{J}$).*

(b) *For each (s,x), the soft solution of (1) allows the Wiener chaos expansion:*

$$u(s,x) = \sum_{\alpha \in \mathcal{J}} u^\alpha(s,x)\xi_\alpha = \sum_{\alpha \in \mathcal{J}} u^\alpha(s,x)\xi_\alpha(s),$$

where $u^\alpha = \frac{1}{\sqrt{\alpha!}}\varphi^\alpha$.

Proof. Assume (L). In this case, the uniqueness follows from Proposition 1 by induction, and we only have to prove the existence.

Let u be a soft solution of (1) given by (5) or (28). We claim that $\varphi^\alpha = \partial_z^\alpha S^{m_z} u|_{z=0} = E[u\partial_z^\alpha p_1(z)|_{z=0}]$, $\alpha \in \mathcal{J}$, is a solution to (34). By Remark 3, $\varphi^\alpha \in L(H)$, $\alpha \in \mathcal{J}$. On the other hand, by definition (see Definition 1) (33) means that for each $\psi \in C_0^\infty(\mathbb{R}^d)$ and $t \in [0,s]$,

$$\begin{aligned}
&\int u^z(t,x)\psi(x)dx - \int \varphi(x)\psi(x)dx \\
&\quad = \int_0^t \int a^{ij}(r,x)u^z_{x_i}(r,x)\psi_{x_j}(x)dr\,dx \\
&\quad - \int_0^t \int a^{ij}_{x_j}(r,x)u^z_{x_i}(r,x)\psi(x)dx + \int_0^t \int c(r,x)u^z(r,x)\psi(x)dx\,dr \\
&\quad + \int_0^t \int b^i(r,x)u^z_{x_i}(r,x)\psi(x)dx\,dr + \int_0^t \int \int_U m_z(r,\eta)(\mathcal{M}u^z(r,x) \\
&\qquad + g(r,x,\eta))\psi(x)dx\,d\kappa\,dr\,.
\end{aligned} \tag{35}$$

Since according to Remark 3 we have Lipschitz estimates, it is possible to differentiate (35) with respect to z. Indeed, let (η_k) be a CONS in $L^2(\Omega, \mathcal{F}^W, P)$. Then $u(t,x) = \sum_k f^k(t,x)\eta_k$, $f^k(t,x) = E[u(t,x)\eta_k]$. Let

$$e_i = (\underbrace{0, \dots, 0}_{i-1}, 1, 0, \dots, 0).$$

Then by Remark 3 for each t, x, and positive h

$$\begin{aligned}
&\sum_k (f^k(t,x+he_i) - f^k(t,x))^2 = E|u(t,x+he_i) \\
&-u(t,x)|^2 \leq Ch^2.
\end{aligned}$$

Thus for each t, $f^k_{x_i}$ exists dx-a.e., is bounded, and coincides with the partial generalized derivative of f^k. Moreover, for each t

$$\lim_{h \to 0} \frac{f^k(t,x+he_i) - f^k(t,x)}{h} \to f^k_{x_i}(t,x)$$

dx-a.e. Let $u^n(t,x) = \sum_1^n f^k(t,x)\eta_k$. Then for each t dx-a.e.

$$\sum_1^n f^k_{x_i}(t,x)^2 = \lim_{h \to 0} \sum_1^n \frac{(f^k(t,x+he_i) - f^k(t,x))^2}{h^2} \leq C\,.$$

So for each t, dx-a.e.

$$\sum_1^\infty f^k_{x_i}(t,x)^2 \le C\ .$$

Therefore, for each t we have the following equalities dx-a.e. in $L^2(\Omega,\mathcal{F}^W,P)$:

$$\begin{aligned}&\lim_{h\to 0}\tfrac{u(t,x+he_i)-u(t,x)}{h}=\textstyle\sum_i f^k_{x_i}(t,x)\eta_k\\&=\lim_{n\to\infty}u^n_{x_i}(t,x);\end{aligned}$$

i.e., $u_{x_i}(t,x)$ exists in $L^2(\Omega,\mathcal{F}^W,P)$ for each t dx-a.e. and coincides with the generalized partial derivative. Moreover, $E|u_{x_i}(t,x)|^2\le K$ for each $t\,dx$-a.e. Thus

$$\begin{aligned}&u^z_{x_i}(t,x)=E[u_{x_i}(t,x)p_t(z)]\ ,\\&\partial^\alpha_z u^z_{x_i}(t,x)|_{z=0}=E[u_{x_i}(t,x)\partial^\alpha_z p_t(z)|_{z=0}]\ ,\end{aligned}$$

and

$$\varphi^\alpha_{x_i}(t,x)=E[u_{x_i}(t,x)\partial^\alpha_z p_t(z)|_{z=0}]$$

for each t dx-a.e.

It is readily checked now that by applying the differentiation operator $\partial^\alpha_z[\cdot]|_{z=0}$ to both sides of (35) we arrive at an integral equation equivalent to (34). This of course completes the proof of (a) in the class $L(H)$.

Since $u^\alpha(s,x)=\frac{1}{\sqrt{\alpha!}}\partial^\alpha_z E[u(s,x)p_s(z)]|_{z=0}$, part (b) of Theorem 4 follows from Corollary 2.

2. Now assume (W) or (C). In this case uniqueness follows by the same arguments as in 1.

Proof of the existence is also analogous to the one in 1. Only two steps require special justification. Specifically, one has to demonstrate that in this case, too, $\varphi^\alpha=\partial^\alpha_z S^{m_z}u|_{z=0}$, and also $\varphi^\alpha\in W^{2,p}(H)\cap W^{2,2p}(H)$ (respectively, $\varphi^\alpha\in C^{2+\beta}(H)$) for each $\alpha\in\mathcal{J}$. These two issues are addressed below.

If (W) or (C) is satisfied, by Remark 4 we have that u^z satisfies equation (33). Let $\mathcal{Z}_N=\{z=(z_k)\in\mathcal{Z}: z_k=0 \text{ if } k>N\}$, $\mathcal{J}_N=\{\alpha=(\alpha_k)\in\mathcal{J}:\alpha_k=0 \text{ if } k>N\}$, $N\ge 1$. Assume that for $|\alpha|=n$, $\partial^\alpha_z u^z=\partial^\alpha_z S^{m_z}u$ satisfies

$$\text{(36)}\qquad\begin{cases}\partial_t\partial^\alpha_z u^z=\mathcal{L}\partial^\alpha_z u^z+f1_{\{\alpha=0\}}\\+\displaystyle\int_U m_z\mathcal{M}\partial^\alpha_z u^z d\kappa+\int_U\alpha_k m_k(\mathcal{M}\partial^{\alpha(k)}_z u^z\\+g1_{\{|\alpha|=1\}})d\kappa\\\partial^\alpha u^z(0,x)=\varphi 1_{\{|\alpha|=0\}}\ .\end{cases}$$

If (W) is satisfied, we assume that

$$|\partial^\alpha_z u^z|_{2,p}\le C(N,R,|\alpha|)(|f|_p+|g|_p+|\varphi|_{2,p})\ ,$$

where $|\alpha|\le n$, $z\in\mathcal{Z}_N$, and $|z|\le R$, $\alpha\in\mathcal{J}_N$, $|g|_p=(\int_0^1\int_{\mathbb{R}^d}(\int_E g^2 d\kappa)^{\frac{p}{2}}dxdt)^{\frac{1}{p}}$.

If (C) is satisfied, we assume that

$$|\partial^\alpha_z u^z|_{2,\beta}\le C(N,R,\alpha)(|f|_\beta+|g|_\beta+|\varphi|_{2,\beta})\ ,$$

where $|\alpha| \le n$, $\alpha \in \mathcal{J}_N$, $z \in \mathcal{Z}_N$, $|z| \le R$,

$$|g|_\beta = \sup_{t,x} \left(\int |g|^2 d\kappa \right)^{\frac{1}{2}} + \sup_{t,x \ne y} \frac{\left(\int |g(t,x,\eta) - g(t,y,\eta)|^2 d\kappa \right)^{\frac{1}{2}}}{|x-y|^\beta} .$$

Let us fix $\alpha \in \mathcal{J}_N$ such that $\alpha = \alpha' + \gamma$, $|\alpha'| = n$, $|\gamma| = 1$, $\gamma = (\gamma_k)$, $\gamma_l \ne 0$.

So for $\partial_z^{\alpha'} u^z$ equation (36) is satisfied according to our assumption. Then we take $\epsilon > 0$ and consider

$$\Delta_\epsilon^{\alpha',\gamma} u^z = (\partial^{\alpha'} u^{z+\epsilon e_l} - \partial^{\alpha'} u^z)/\epsilon ,$$

where the lth component of e_l is 1 and the remaining components are zeros. Then using assumed estimates we can pass to the limit and obtain the equation (36) for $\partial_z^{\alpha'+\gamma} u^z$ and similar estimates for $|\alpha'| = n+1$. Thus our statement follows by induction if we start from $\alpha = 0$. If $|\alpha| = 0$, (36) follows from [21].

Remark 5. If (L) is assumed, the existence of $L(H)$-solutions of (34) can be proved in a more analytic way by approximating smoothly the "free forces" and the coefficients.

The rest of this section is dedicated to the derivation of a multiple Wiener integral version of the Wiener chaos expansion of Theorem 4.

First, we will demonstrate that a solution of the S-system (34) can be "explicitly solved" (represented as an integral of superpositions of the operators $\mathcal{M}_{s,\eta}$ and semigroups associated with the operator $\mathcal{L}$).

Denote by $T_{s,t} f$ the solution of the problem

$$\begin{cases} -\partial_t u + \mathcal{L} u = 0, \quad s \le t, \\ u(s,\cdot) = f. \end{cases}$$

Remark 6. If (C) or (W) are satisfied, then for each $(s,x) \in H$ there exists a unique $P_{s,x} \in \mathcal{S}(s,x,\sigma,\hat{\sigma},b)$ and by [22] for $f \in C^{2+\beta}$ or $W^{2,p}$, respectively,

$$T_{s,t} f(x) = P_{t,x} \exp\left\{ \int_s^t c(u, X_u) du \right\} f(X_s).$$

To each multi-index $\alpha = (\alpha_k) \in \mathcal{J}$ of length n (i.e., $|\alpha| = n$) we relate a set K_α. The elements of K_α are positive integers $k_i, i = 1, \dots, n$ such that each k is represented there by α_k-copies. This of course implies that if $\alpha_k = 0$ then k is not included in K_α. Let $\mathcal{P}^n$ be a permutation group of the set $\{1, \dots, n\}$, $s^n = (s_1, \dots, s_n)$, $\eta^n = (\eta_1, \dots, \eta_n)$, $ds^n = ds_1 \cdots ds_n, d\kappa^n = \kappa(d\eta_1) \cdots \kappa(d\eta_n)$, $U^n = U \times \cdots \times U$, n times.

PROPOSITION 3. *Let (C) or (W) be satisfied. Then for each multi-index $|\alpha| = n$, we have*

$$\begin{aligned} \varphi^\alpha(s,x) = \sum_{\sigma \in \mathcal{P}^n} \int_0^s \int_0^{s_n} \cdots \int_0^{s_2} \int_{U^n} T_{s_n,s} M_{s_n,\eta_n} \cdots \\ \cdots T_{s_1,s_2} (M_{s_1,\eta_1} \varphi^0(s_1,x) + g(s_1,x,\eta_1)) m_{k_{\sigma(n)}}(s_n,\eta_n) \cdots \\ \cdots m_{k_{\sigma(1)}}(s_1,\eta_1) ds^n d\kappa^n \qquad \text{if } n \ge 2 , \end{aligned} \tag{37}$$

and

$$\begin{aligned} \varphi^\alpha(s,x) = \int_0^s \int_U T_{t,s} m_{k_1}(t,\eta) (M_{t,\eta} \varphi^0(t,\eta) \\ + g(t,x,\eta)) dt\, d\kappa \quad \text{if } n = 1, \quad \text{where } K_\alpha = \{k_1, \dots, k_n\} . \end{aligned}$$

Proof. To begin with we have to check that all the integrals in (37) are well defined. This problem is addressed in Lemma 5 and Corollary 3 below.

LEMMA 5.

(a) *Let* (C) *be satisfied. Then there exists* C *such that for each* $s < t \leq 1$, $v \in C^{\beta}(\mathbb{R}^d)$.

$$\int_s^t \int_U T_{s,u}(\mathcal{M}_{u,\eta} T_{u,t} v)^2 d\kappa \, du \leq C T_{s,t} v^2 \, . \tag{38}$$

(b) *Let* (W) *be satisfied. Then there exists* C *such that for each* $s < t \leq 1$, $v \in L^p(\mathbb{R}^d) \cap L^{2p}(\mathbb{R}^d)$, *the estimate* (38) *holds.*

Proof. (a) Let $v \in C^{2,\beta}(\mathbb{R}^d)$. Then by [21] $l = T_{s,t} v \in C^{2+\beta}(H_t)$, where $H_t = [0,t] \times \mathbb{R}^d$. Fix $(s,x) \in H_t$, $s < t$. Let $P_{s,x} \in \mathcal{S}(s,x,\sigma,\hat{\sigma},b)$. Then $l^2 \in C^{2+\beta}(H_t)$. The needed estimate with some C independent of v follows readily from Remark 6 and the Ito formula for $l^2(t,X_t)\exp\{\int_s^t 2c(r,X_r)dr\}$. Using standard estimates for the fundamental solutions of parabolic equations (see [18, Ch. 1V, section 13], and [3]) we derive (38) for $v \in C^{\beta}(\mathbb{R}^d)$ by passing to the limit.

(b) Let $v \in W^{2,p}(\mathbb{R}^d) \cap W^{2,2p}(\mathbb{R}^d)$. Then $l = T_{s,t} v \in W^{2,p}(H_t) \cap W^{2,2p}(H_t)$ (see [21], [22]), and $l^2 \in W^{2,p}(H_t)$ $H_t = [0,t] \times \mathbb{R}^d$. Fix $(s,x) \in H_t$, $s < t$. Let $P_{s,x} \in \mathcal{S}(s,x,\sigma,\hat{\sigma},b)$. Inequality (37) with C independent of v follows by Remark 6 and the Ito formula for v^2 (see [22]). On the other hand, as shown in [31], there exists a constant $N_{s,t}$ such that $\sup_x |T_{s,t} f| \leq N_{s,t} |f|_p$. Thus we can derive (38) for general v by passing to the limit.

COROLLARY 3. *Let* (C) *or* (W) *be satisfied. Then for each* $(s,x) \in H$, $n > 2$.

$$\begin{aligned}
&\int_0^s \int_0^{s_n} \cdots \int_0^{s_2} \int_{U^n} \Big[T_{s_n,s} M_{s_n,\eta_n} \cdots T_{s_1,s_2} (M_{s_1,\eta_1} \varphi^0(s_1,x) \\
&+ g(s_1,x,\eta_1)) \Big]^2 ds_1 \cdots d_{s_n} \kappa(d\eta_1) \cdots \kappa(d\eta_n) \\
&+ \int_s^1 \int_U \Big[T_{t,s} (M_{t,\eta} \varphi^0(t,x) + g(t,x,\eta) \Big]^2 dt \kappa(d\eta) < \infty \, .
\end{aligned}$$

Proof. Applying Lemma 5 and using induction arguments one can see that it is sufficient to prove the inequality

$$\int_0^s T_{s,t} (M_{t,\eta} \varphi^0(t,x) + g(t,x))^2 dt \, d\kappa < \infty \, .$$

Obviously

$$\varphi^0(s,x) = T_{0,s} \varphi(x) + \int_0^s T_{s,t} f(t,x) dt \, ,$$

and the statement follows by Lemma 5 and the estimates in [21].

Now we can proceed with the derivation of formula (36).

By (34) we have

$$\begin{aligned}
\varphi^{\alpha}(s,x) = \int_s^1 \int_E \sum_k \alpha_k m_k(t,\eta) T_{s,t} (M_{t,\eta} \varphi^{\alpha(k)}(t,x) \\
+ g(t,x,\eta) 1_{|\alpha|=1}) dt \, d\kappa,
\end{aligned} \tag{39}$$

and the representation formula is obviously true for $|\alpha| = 1$. Assume that it is true for $|\alpha| = n$. Let $|\alpha| = n+1$, $K_\alpha = \{k_1, \dots, k_{n+1}\}$. If $\mathcal{P}_j^{n+1}$ is a permutation group of the set $\{1, \dots, n+1\} \setminus \{j\}$, it follows from (39) that

$$\varphi^\alpha(s,x) = \int_0^s \int_U \sum_{j=1}^{n+1} m_{k_j}(t,\eta) T_{t,s} \mathcal{M}_{t,\eta} \varphi^{\alpha(k_j)}(t,x) dt\, d\kappa$$

$$= \int_0^s \int_U \sum_{j=1}^{n+1} m_{k_j}(t,\eta) T_{t,s} \mathcal{M}_{t,\eta} \sum_{\sigma \in \mathcal{P}_j^{n+1}} \int_0^t \int_0^{s_{n+1}} \dots \int_0^{s_{j+1}} \int_0^{s_j} \dots$$

$$\int_0^{s_2} \int_{U^n} T_{s_{n+1},t} M_{s_{n+1},\eta_{n+1}} \cdots T_{s_{j-1},s_{j+1}} \mathcal{M}_{s_{j-1},\eta_{j-1}} \cdots T_{s_1,s_2}(g(s_1,x,\eta_1)$$

$$+ \mathcal{M}_{s_1,\eta_1} \varphi^0(s_1,x)) ds_j^{n+1} dt d\kappa_j^{n+1} ,$$

$$ds_j^{n+1} = ds_1 \cdots ds_{j-1} ds_{j+1} \cdots ds_{n+1} ,\ d\kappa_j^{n+1}$$
$$= \kappa(d\eta_1) \cdots \kappa(d\eta_{j-1}) \kappa(d\eta_{j+1}) \cdots \kappa(d\eta_{n+1}) .$$

By Corollary 3 all the integrals are well defined. Thus our statement follows by induction.

Remark 7. For $\alpha \in \mathcal{J}$, $|\alpha| = n$, $K_\alpha = \{k_1, \dots, k_n\}$, define

$$e_\alpha = \sum_{\sigma \in \mathcal{P}^n} m_{k_{\sigma(1)}} \otimes \cdots \otimes m_{k_{\sigma(n)}} / \sqrt{\alpha! |\alpha|!} .$$

Then we can rewrite (39) in the following way:

$$\varphi^\alpha(s,x) = \sqrt{\alpha! |\alpha|!} \int_0^s \int_0^{s_n} \dots \int_0^{s_2} \int_{U^n} T_{s_n,s} \mathcal{M}_{s_n,\eta_n} \dots$$

$$\dots T_{s_2,s_1}(\mathcal{M}_{s_1,\eta_1} \varphi^0(s_1,x) + g(s_1,x,\eta_1)) e_\alpha(s^n,\eta^n) ds^n d\kappa^n$$

$$= \sqrt{\alpha!} / \sqrt{|\alpha|!} \int_{([0,1]\times U)^n} G^n(s^n,\eta^n) ds^n d\kappa^n ,$$

where

$$G^n(s^n,\eta^n) = \textstyle\sum_{\sigma \in \mathcal{P}^n} T_{s_{\sigma(n)},s} \mathcal{M}_{s_{\sigma(n)},\eta_{\sigma(n)}} \dots$$

$$\dots T_{s_{\sigma(1)},s_{\sigma(2)}}(\mathcal{M}_{s_{\sigma(1)},\eta_{\sigma(1)}} \varphi^0(s_{\sigma(1)},x)$$

$$+ g(s_{\sigma(1)},x,\eta_{\sigma(1)}) 1_{\{s_{\sigma(1)} > \dots > s_{\sigma(n)} > s\}} .$$

The last equality here follows immediately from the fact that $(e_\alpha)_{|\alpha|=n}$ form a CONS for the symmetric part of $L^2(([0,1]\times U)^n, ds^n d\kappa^n)$.

COROLLARY 4. *For each $\alpha \in \mathcal{J}$ such that $|\alpha| = n$,*

$$\sum_{|\alpha|=n} \frac{1}{\sqrt{\alpha!}} \varphi^\alpha(s,x)\xi_\alpha = \int_0^s \int_0^{s_n} \dots \int_0^{s_2} \int_{U^n} T_{s_n,s} \mathcal{M}_{s_n,\eta_n} \cdots$$

$$T_{s_1,s_2}(\mathcal{M}_{s_1,\eta_1}\varphi^0(s_1,x) + g(s_1,x,\eta_1))W(ds_n,d\eta_n)\cdots W(ds_1,d\eta_1),$$

$$\sum_{|\alpha|=n} \frac{1}{\alpha!} \varphi^\alpha(s,x)^2 = \int_0^s \int_0^{s_n} \dots \int_0^{s_2} \int_{U^n} \{T_{s_n,s}\mathcal{M}_{s_n,\eta_n} \dots$$

$$\dots T_{s_1,s_2}(\mathcal{M}_{s_1,\eta_1}\varphi^0(s_1,x) + g(s_1,x,\eta_1))\}^2 \, ds^n d\kappa^n \quad \text{if } n > 2,$$

and

$$\sum_{|\alpha|=1} \frac{1}{\sqrt{\alpha!}} \varphi^\alpha(s,x)\xi_\alpha = \int_0^s \int_U T_{t,s}(\mathcal{M}_{t,\eta}\varphi^0(t,x) + g(t,x,\eta))W(dt,d\eta),$$

$$\sum_{|\alpha|=1} \frac{1}{\alpha!} \varphi^\alpha(s,x)^2 = \int_0^s \int_U T_{t,s}(\mathcal{M}_{t,\eta}\varphi^0(t,x) + g(t,x,\eta))^2 dt\, d\kappa\,.$$

Proof. It follows from Theorem 3.1 in [7] that for $|\alpha| = n$,

$$\xi_\alpha/\sqrt{\alpha!} = \int_0^1 \int_0^{s_n} \dots \int_0^{s_2} \int_{U^n} e_\alpha(s^n,\eta^n) W(ds_1,d\eta_1)\cdots W(ds_n,d\eta_n)$$

(e_α was defined in Remark 7). Since G^n is a symmetric function on $([0,1]\times U)^n$ we have the $L^2(([0,1]\times U)^n, ds^n d\kappa^n)$ expansion for G^n:

$$\begin{aligned} G^n &= \sum_{|\alpha|=n} e_\alpha \int_{([0,1]\times U)^n} G^n(s^n,\eta^n) e_\alpha(s^n,\eta_n) ds^n d\kappa^n \\ &= \sum_{|\alpha|=n} c_\alpha e_\alpha\,. \end{aligned}$$

Thus,

$$\sum_{|\alpha|=n} \frac{\varphi_\alpha(s,x)}{\sqrt{\alpha!}} \xi_\alpha = \sum_{|\alpha|=n} c_\alpha \int_0^1 \int_0^{s_n} \dots \int_0^{s_2} e_\alpha(s^n,\eta^n) W(ds_n,d\eta_n)\dots$$

$$\dots W(ds_1,d\eta_1) = \int_0^s \int_0^{s_n} \int_0^{s_i} \int_{U^n} (T_{s_n,s}\mathcal{M}_{s_n,\eta_n} \dots$$

$$\dots T_{s_1,s_2}(\mathcal{M}_{s_1,\eta_1}\varphi^0(s_1,x) + g(s_1,x,\eta_1)))W(ds_1,d\eta_1)\dots W(ds_n,d\eta_n)$$

The equality for $\sum_{|\alpha|=n} \frac{\varphi_\alpha(s,x)^2}{\alpha!}$ follows from the latter in a simple way.

CONSTRUCTION OF MULTISCALING FUNCTIONS WITH APPROXIMATION AND SYMMETRY*

G. PLONKA† AND V. STRELA‡

Abstract. This paper presents a new and efficient way to create multiscaling functions with given approximation order, regularity, symmetry, and short support. Previous techniques were operating in time domain and required the solution of large systems of nonlinear equations. By switching to the frequency domain and employing the latest results of the multiwavelet theory we are able to elaborate a simple and efficient method of construction of multiscaling functions. Our algorithm is based on a recently found factorization of the refinement mask through the two-scale similarity transform (TST). Theoretical results and new examples are presented.

Key words. approximation order, symmetry, multiscaling functions, multiwavelets

1. Introduction. This paper discusses the construction of *multiscaling functions* which generate a *multiresolution analysis* (MRA) and lead to *multiwavelets*. A standard (*scalar*) MRA assumes that there is only one scaling function $\phi(t)$ whose translates $\phi(t-k)$ $(k \in \mathbb{Z})$ constitute an L^2-stable basis of their span V_0 [D2, SN]. We move a step forward and allow several functions $\phi_0(t), \dots, \phi_{r-1}(t)$. The vector $\boldsymbol{\phi}(t) = [\phi_0(t) \cdots \phi_{r-1}(t)]^{\mathrm{T}}$ is called a *multiscaling function* if the integer translates $\phi_\nu(\cdot - k)$ $(k \in \mathbb{Z}, \nu = 0, \dots, r-1)$ form an L^2-stable basis of V_0 and if $\boldsymbol{\phi}(t)$ satisfies a *dilation equation*,

$$\boldsymbol{\phi}(t) = \sum_{n=0}^{N} \boldsymbol{P}_n \, \boldsymbol{\phi}(2t-n). \tag{1.1}$$

Here the coefficients $\boldsymbol{P}_n$ are $r \times r$ matrices instead of usual scalars. The multiscaling function $\boldsymbol{\phi}$ generates an MRA $\{V_j : j \in \mathbb{Z}\}$ of multiplicity r. The corresponding wavelet spaces W_j can be generated by a *multiwavelet* $\boldsymbol{w}(t) = [w_0(t) \cdots w_{r-1}(t)]^{\mathrm{T}}$ associated with $\boldsymbol{\phi}(t)$, satisfying a *wavelet equation*

$$\boldsymbol{w}(t) = \sum_{n=0}^{K} \boldsymbol{D}_n \, \boldsymbol{\phi}(2t-n). \tag{1.2}$$

Again, $\boldsymbol{D}_n$ are $r \times r$ matrices.

Multiwavelets naturally generalize the scalar wavelets. For $r = 1$, (1.1) is the well-studied refinement equation (see, e.g., [CDM, DL1, DL2]). However, multiwavelets have some completely new features arising from the matrix nature ($r > 1$) of the equation (1.1). They can simultaneously possess symmetry, orthogonality, and high approximation order which is not possible in the scalar case [SB, D2]. This suggests that in some applications multiwavelets may behave better than the scalar ones. The

results of first experiments [SHSTH, XGHS] confirm this conjecture and show that the multiwavelets are definitely worth studying.

One of the first multiwavelet constructions is due to Alpert and Rokhlin [AR]. They considered a multiscaling function whose components are polynomials of degree $r-1$ supported on $[0,1]$. The general theory of multiwavelets, based on the MRA of multiplicity r, is discussed in [GLT, GL].

Using fractal interpolation, Geronimo, Hardin, and Massopust succeeded to construct a continuous multiscaling function $\boldsymbol{\phi}(t) = [\phi_0(t)\ \phi_1(t)]^{\mathrm{T}}$ with short support, symmetry, and second approximation order [GHM]. The plot of this pair $\phi_0(t)$, $\phi_1(t)$ is presented in Figure 1.1.

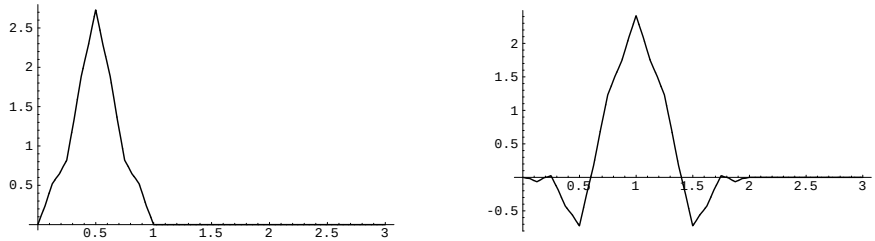

FIG. 1.1. *GHM symmetric orthogonal multiscaling function with approximation order* 2.

The results of [GHM] triggered many attempts to construct more examples [SS1, CL, DGHM] as well as the systematic study of multiscaling functions.

Properties of a refinable function can be formulated either in *time* or in *frequency* domain. In [SS2, HSS, L], conditions of orthogonality and approximation were established in the time domain. Also, a way to construct multiscaling functions with short support and low approximation order was found [SS1, HSS, CL]. Unfortunately, this method required the solution of a large system of nonlinear equations. We therefore switch to the frequency domain.

Working in the frequency domain, one faces the necessity of dealing with the Fourier transformation of (1.1),

$$\widehat{\boldsymbol{\phi}}(\omega) = \boldsymbol{P}\left(\frac{\omega}{2}\right)\,\widehat{\boldsymbol{\phi}}\left(\frac{\omega}{2}\right), \tag{1.3}$$

where $\widehat{\boldsymbol{\phi}} := [\widehat{\phi}_0, \ldots, \widehat{\phi}_{r-1}]^{\mathrm{T}}$, $\widehat{\phi}_\nu := \int_{-\infty}^{\infty} \phi_\nu(t)\, e^{-it\cdot}\, \mathrm{d}t$, and $\boldsymbol{P}(\omega)$ is the *refinement mask* corresponding to $\boldsymbol{\phi}(t)$,

$$\boldsymbol{P}(\omega) := \frac{1}{2}\sum_{n=0}^{N} \boldsymbol{P}_n\, e^{-i\omega n}. \tag{1.4}$$

In the scalar case, $P(\omega)$ is a *trigonometric polynomial*. In the vector case, $\boldsymbol{P}(\omega)$ becomes a *matrix of trigonometric polynomials*. To ensure certain approximation order, $\boldsymbol{P}(\omega)$ must satisfy necessary and sufficient conditions in the frequency domain. Those conditions were formulated and proved in [HSS, P3]. In [P3], it was also shown

that the vector $\boldsymbol{\phi}(t)$ can only provide approximation order m if the refinement mask $\boldsymbol{P}(\omega)$ can be factorized in the form

$$\boldsymbol{P}(\omega) = \frac{1}{2^m}\, \boldsymbol{C}_{m-1}(2\omega) \cdots \boldsymbol{C}_0(2\omega)\, \boldsymbol{P}^{(0)}(\omega)\, \boldsymbol{C}_0(\omega)^{-1} \cdots \boldsymbol{C}_{m-1}(\omega)^{-1}, \tag{1.5}$$

where $\boldsymbol{P}^{(0)}(\omega)$ is well defined and $\boldsymbol{C}_0(\omega), \ldots, \boldsymbol{C}_{m-1}(\omega)$ are matrices of a special form. The factorization (1.5) is not unique. With the help of the *two-scale similarity transformation* (TST), the whole set of possible factorizations can be described [S1].

The factorization (1.5) naturally generalizes the scalar case $r = 1$. As known, one scaling function with compact support and linearly independent integer translates provides approximation order m if and only if its refinement mask $P(\omega)$ has m zeros at $\omega = \pi$:

$$P(\omega) = \left(\frac{1 + e^{-i\omega}}{2}\right)^m q(\omega), \tag{1.6}$$

with $q(0) = 1$ and $q(\pi) \neq 0$. For $r = 1$, (1.6) coincides with (1.5) taking $\boldsymbol{P}^{(0)}(\omega) = q(\omega)$ and $\boldsymbol{C}_0(\omega) = \cdots = \boldsymbol{C}_{m-1}(\omega) = (1 - e^{i\omega})$. Daubechies connected the behavior of $q(\omega)$ in (1.6) with the decay properties of $\widehat{\phi}(\omega)$, and hence, she obtained estimates of smoothness of $\phi(t)$ [D1]. The factorization (1.5) plays the same role for a multiscaling function as (1.6) for a scalar one. In [CDP] and independently in [S1], it was shown how the factorization of the refinement mask $\boldsymbol{P}(\omega)$ leads to the decay of $\widehat{\boldsymbol{\phi}}(\omega)$. Similar results on regularity of refinable function vectors are presented in [Sh].

However, up to now, the factorization (1.5) has been shown to be necessary only. For the construction of multiscaling functions we need the sufficiency of a factorization (1.5) for approximation order m. In this paper, we show how, under mild conditions, the factorization of the refinement mask $\boldsymbol{P}(\omega)$ yields a solution of (1.1) with desired approximation properties. Using this result and the TST, a construction of multiscaling functions providing an arbitrary, fixed approximation order becomes simple. Description of the corresponding algorithm is our main purpose.

The outline of the paper is as follows. In section 2 we summarize previously known and new theoretical results on the symmetry of $\boldsymbol{\phi}(t)$, its approximation order, the factorization of the refinement mask $\boldsymbol{P}(\omega)$, and the TST. The main novelty of section 2 is the observation that the factorization of the refinement mask leads to the approximation order of the multiscaling functions (Theorem 2.6). Other remarkable new results are given in Theorems 2.7, 2.9, and Lemma 2.5.

In section 3, we present a new algorithm for the construction of a refinement mask $\boldsymbol{P}(\omega)$ with any given approximation order. We intensively study how the inner matrix $\boldsymbol{P}^{(0)}(\omega)$ and the transformation matrices $\boldsymbol{M}_{\boldsymbol{r}_n}(\omega)$ should be chosen in order to obtain a smooth, symmetric multiscaling function with compact support. Several examples are given.

Section 4 contains the proof of Theorem 2.6.

2. Old and new theoretical results. In this section, we are going to present the results needed for the construction of symmetric multiscaling functions with given approximation order.

Let us start with definitions and notation. For a measurable function f over $\mathbb{R}$ and $m \in \mathbb{N}$ let

$$\|f\|_2 := \left(\int_{-\infty}^{\infty} |f(t)|^2 \,\mathrm{d}t\right)^{1/2}, \qquad \|f\|_{m,2} := \sum_{k=0}^{m} \|\mathrm{D}^k f\|_2.$$

Here and below $D := d/d\omega$ denotes the differentiation operator with respect to ω.

Let $W_2^m(\mathbb{R})$ be the usual Sobolev space with norm $\|\cdot\|_{m,2}$. For a vector $\boldsymbol{\phi} = (\phi_\nu)_{\nu=0}^{r-1}$ of compactly supported functions, let $\mathcal{S} = \mathcal{S}(\boldsymbol{\phi})$ be the shift-invariant space spanned by the integer translates $\phi_\nu(t-k)$ $(\nu = 0,\dots,r-1,\ k \in \mathbf{Z})$. We say that $\boldsymbol{\phi}(t)$ provides *approximation order* m if for every $f \in W_2^m(\mathbb{R})$

$$\min\{\|f-s\| :\ s \in \mathcal{S}^h\} \le \mathrm{const}_{\mathcal{S}}\ h^m\, \|f\|_{W_2^m(\mathbb{R})},$$

where $\mathcal{S}^h$ is the scaled space $\mathcal{S}^h := \{s(\cdot/h) :\ s \in \mathcal{S}\}$.

A vector $\boldsymbol{v}$ of length r is said to be in $C_{2\pi}^m(\mathbb{R}^r)$ and, analogously, an $r \times r$ matrix $\boldsymbol{V}$ is in $C_{2\pi}^m(\mathbb{R}^{r\times r})$ if all its entries are 2π-periodic m times continuously differentiable functions.

2.1. Conditions of approximation. Assume that $\phi_\nu \in C(\mathbb{R}) \cap BV(\mathbb{R})$ $(\nu = 0,\dots,r-1)$ are compactly supported functions. Here $BV(\mathbb{R})$ denotes the set of functions of bounded variation. If the integer translates $\phi_\nu(\cdot - l)$ form a Riesz basis of $\mathcal{S}(\boldsymbol{\phi})$, then the following statements are equivalent (see [JL, P3]):

(i) The function vector $\boldsymbol{\phi}(t)$ provides approximation order m $(m \in \mathbb{N})$.

(ii) All algebraic polynomials of degree up to $m-1$ can be exactly reproduced by a linear combination of integer translates of $\phi_\nu(t)$.

(iii) $\boldsymbol{\phi}(t)$ satisfies the Strang–Fix conditions [SF] of order m; in other words, there is a finitely supported sequence of vectors $\{\boldsymbol{a}_l\}_{l\in\mathbb{Z}}$ such that $f(t) := \sum_{l\in\mathbb{Z}} \boldsymbol{a}_l^{\mathrm{T}}\, \boldsymbol{\phi}(t-l)$ satisfies the following conditions:

$$\widehat{f}(0) \ne 0; \qquad \mathrm{D}^n \widehat{f}(2\pi l) = 0 \quad (l \in \mathbb{Z}\setminus\{0\};\ n = 0,\dots,m-1).$$

Since condition (ii) yields vanishing moments for the corresponding multiwavelets it is often used in applications.

The approximation order of a refinable function vector $\boldsymbol{\phi}(t)$ satisfying (1.1) is intimately related with the properties of the refinement mask $\boldsymbol{P}(\omega)$ defined by (1.4). In the scalar case $(r = 1)$, when there is only one scaling function, $\boldsymbol{P}_n$ are real numbers and $P(\omega)$ is a scalar trigonometric polynomial. Then mth approximation order implies m zeros of $P(\omega)$ at $\omega = \pi$ [D2]. In the vector case, $\boldsymbol{P}(\omega)$ is a matrix, and the situation becomes more complicated. But still, similar conditions at the point $\omega = \pi$ hold.

THEOREM 2.1 (see [HSS, P3]). *Let $\boldsymbol{\phi} = (\phi_\nu)_{\nu=0}^{r-1}$ be a refinable vector of compactly supported functions ϕ_ν. Further, assume that the integer translates $\phi_\nu(t-l)$ $(l \in \mathbb{Z})$ form a Riesz basis of $\mathcal{S}(\boldsymbol{\phi})$. Then $\boldsymbol{\phi}(t)$ provides approximation order m if and only if the refinement mask $\boldsymbol{P}(\omega)$ of $\boldsymbol{\phi}$ satisfies the following conditions: there are vectors $\boldsymbol{y}_k \in \mathbb{R}^r$; $\boldsymbol{y}_0 \ne \mathbf{0}$ $(k = 0,\dots,m-1)$ such that for $n = 0,\dots,m-1$,*

$$\sum_{k=0}^{n} \binom{n}{k} (\boldsymbol{y}_k)^T\, (2i)^{k-n}\, (D^{n-k}\boldsymbol{P})(0) = 2^{-n}\, (\boldsymbol{y}_n)^T, \tag{2.1}$$

$$\sum_{k=0}^{n} \binom{n}{k} (\boldsymbol{y}_k)^T\, (2i)^{k-n}\, (D^{n-k}\boldsymbol{P})(\pi) = \mathbf{0}^T. \tag{2.2}$$

Here $\mathbf{0}$ denotes the zero vector.

If a matrix $\boldsymbol{P}(\omega) \in C_{2\pi}^{m-1}(\mathbb{R}^{r\times r})$ satisfies (2.1) and (2.2) for $n = 0,\dots,m-1$ with vectors $\boldsymbol{y}_0,\dots,\boldsymbol{y}_{m-1}$ $(\boldsymbol{y}_0 \ne \mathbf{0})$, then we shortly say that $\boldsymbol{P}(\omega)$ provides approximation order m with $\boldsymbol{y}_0,\dots,\boldsymbol{y}_{m-1}$. In order to prove that relations (2.1) and (2.2) imply

approximation order m, one only needs to assume that $\boldsymbol{y}_0^{\mathrm{T}}\,\widehat{\boldsymbol{\phi}}(0) \neq 0$. Riesz stability of integer translates $\phi_\nu(t-l)$ is *not* needed.

Remark. The result of Theorem 2.1 is a natural generalization of the scalar case. For $r = 1$, equations (2.1), (2.2) can be simplified to

$$P(0) = 1; \qquad \mathrm{D}^n P(\pi) = 0 \quad (n = 0, \ldots, m-1), \tag{2.3}$$

implying m zeros of $P(\omega)$ at $\omega = \pi$. Note that in the vector case, we need conditions in *two* points, $\omega = 0$ and $\omega = \pi$. Also, both eigenvalues and eigenvectors of $\boldsymbol{P}(0)$ and $\boldsymbol{P}(\pi)$ are important.

2.2. Two-scale similarity transform. A very useful research and construction tool in the theory of multiwavelets is the TST [S1]. We say that $\boldsymbol{Q}(\omega)$ is a TST of $\boldsymbol{P}(\omega)$ with the *transformation matrix* $\boldsymbol{M}(\omega) \in C_{2\pi}(\mathbb{R}^{r\times r})$ if

$$\boldsymbol{Q}(\omega) = \boldsymbol{M}(2\omega)\,\boldsymbol{P}(\omega)\,\boldsymbol{M}(\omega)^{-1}.$$

If $\boldsymbol{M}(\omega)$ is invertible for all $\omega \in \mathbb{R}$, then the TST is *nondegenerate*. It is easy to see that if $\boldsymbol{P}(\omega) \in C_{2\pi}(\mathbb{R}^{r\times r})$ is the refinement mask of $\boldsymbol{\phi} \in L^2(\mathbb{R}^r)$, then a nondegenerate TST with transformation matrix $\boldsymbol{M}(\omega) \in C_{2\pi}(\mathbb{R}^{r\times r})$ yields a matrix $\boldsymbol{Q}(\omega)$ which itself is a refinement mask of a refinable function vector $\boldsymbol{\psi} \in L^2(\mathbb{R}^r)$ such that $\widehat{\boldsymbol{\psi}}(\omega) = \boldsymbol{M}(\omega)\,\widehat{\boldsymbol{\phi}}(\omega)$:

$$\begin{aligned}\widehat{\boldsymbol{\psi}}(\omega) &= \boldsymbol{M}(\omega)\,\widehat{\boldsymbol{\phi}}(\omega) = \boldsymbol{M}(\omega)\,\boldsymbol{P}\left(\frac{\omega}{2}\right)\,\widehat{\boldsymbol{\phi}}\left(\frac{\omega}{2}\right)\\ &= \boldsymbol{M}(\omega)\,\boldsymbol{P}\left(\frac{\omega}{2}\right)\,\boldsymbol{M}\left(\frac{\omega}{2}\right)^{-1}\,\widehat{\boldsymbol{\psi}}\left(\frac{\omega}{2}\right) = \boldsymbol{Q}\left(\frac{\omega}{2}\right)\,\widehat{\boldsymbol{\psi}}\left(\frac{\omega}{2}\right).\end{aligned}$$

The following theorem shows that a nondegenerate TST preserves the approximation properties of a refinement mask.

THEOREM 2.2 (see [S1]). *Let a transformation matrix $\boldsymbol{M}(\omega) \in C_{2\pi}^{m-1}(\mathbb{R}^{r\times r})$ be invertible for all $\omega \in \mathbb{R}$. Assume that $\boldsymbol{P} \in C_{2\pi}^{m-1}(\mathbb{R}^{r\times r})$ provides approximation order m with vectors $\boldsymbol{y}_0, \ldots, \boldsymbol{y}_{m-1}$. Then $\boldsymbol{Q}(\omega) = \boldsymbol{M}(2\omega)\,\boldsymbol{P}(\omega)\,\boldsymbol{M}(\omega)^{-1}$ also provides approximation order m with vectors $\boldsymbol{u}_0, \ldots, \boldsymbol{u}_{m-1}$, given by*

$$\boldsymbol{u}_k^T := \sum_{l=0}^{k} \binom{k}{l} i^{l-k}\,\boldsymbol{y}_l^T\,(D^{k-l}\boldsymbol{M}^{-1})(0) \qquad (k = 0, \ldots, m-1).$$

For more properties of the TST and the proof of Theorem 2.2 see [S1, S2].

2.3. Factorizations of the refinement mask. In the scalar case, the conditions of approximation (2.3) lead to a factorization of $P(\omega)$. A zero at $\omega = \pi$ means that $P(\omega)$ has a factor $(1 + e^{-i\omega})$. So $P(\omega)$ factorizes as in (1.6). This factorization plays the key role in the construction of regular scalar scaling functions [D2].

In the vector case, the conditions of approximation (2.1), (2.2) are more complicated, but still they imply a factorization of the *matrix* refinement mask $\boldsymbol{P}(\omega)$. This factorization opens a constructive way toward the creation of new multiscaling functions. But before starting with the factorization, we need to review some notation.

Let $r \in \mathbb{N}$ be fixed, and let $\boldsymbol{y} \in \mathbb{R}^r$ be a vector of length r. To start, assume that $\boldsymbol{y}$ is of the form

$$\boldsymbol{y} = [y_0 \cdots y_{l-1}\ 0 \cdots 0]^{\mathrm{T}}, \tag{2.4}$$

with $1 \le l \le r$ and $y_\nu \neq 0$ for $\nu = 0, \dots, l-1$. We introduce the direct sum of square matrices $\boldsymbol{A} \oplus \boldsymbol{B} := \mathrm{diag}(\boldsymbol{A}, \boldsymbol{B})$ and define the matrix $\boldsymbol{C_y}$ by

$$\boldsymbol{C_y}(\omega) := \widetilde{\boldsymbol{C}}\boldsymbol{y}(\omega) \oplus \boldsymbol{I}_{r-l}. \tag{2.5}$$

Here $\boldsymbol{I}_{r-l}$ denotes the $(r-l)\times(r-l)$ unit matrix, and for $l > 1$, $\widetilde{\boldsymbol{C}}\boldsymbol{y}(\omega)$ is defined by

$$\widetilde{\boldsymbol{C}}\boldsymbol{y}(\omega) := \begin{bmatrix} y_0^{-1} & -y_0^{-1} & 0 & \dots & 0 \\ 0 & y_1^{-1} & -y_1^{-1} & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & 0 \\ 0 & \ddots & \ddots & y_{l-2}^{-1} & -y_{l-2}^{-1} \\ -e^{-i\omega}/y_{l-1} & 0 & \dots & 0 & y_{l-1}^{-1} \end{bmatrix}.$$

If $l = 1$, let $\widetilde{\boldsymbol{C}}\boldsymbol{y}(\omega) = (1 - e^{-i\omega})/y_0$.

For general $\boldsymbol{y} = [y_0 \cdots y_{r-1}]^{\mathrm{T}} \in \mathbb{R}^r$, $\boldsymbol{y} \neq \boldsymbol{0}$ we define $\boldsymbol{C_y} := (C_{j,k})_{j,k=0}^{r-1}$ by reshuffling rows and columns. More exactly, let $j_0 := \min\{j;\, y_j \neq 0\}$ and $j_1 := \max\{j; y_j \neq 0\}$. For all $j < j_1$ with $y_j \neq 0$ let $d_j := \min\{\mu :\, \mu > j,\, y_\mu \neq 0\}$. For $j_0 < j_1$, the entries of $\boldsymbol{C_y}$ are defined by

$$C_{j,k}(\omega) := \begin{cases} y_j^{-1} & y_j \neq 0 \quad \text{and} \quad j = k, \\ 1 & y_j = 0 \quad \text{and} \quad j = k, \\ -y_j^{-1} & y_j \neq 0 \quad \text{and} \quad d_j = k, \\ -e^{-i\omega}/y_{j_1} & j = j_1 \quad \text{and} \quad k = j_0, \\ 0 & \text{otherwise} \end{cases} \qquad (j,\, k = 0, \dots, r-1). \tag{2.6}$$

For $j_0 = j_1$, $\boldsymbol{C_y}$ is a diagonal matrix of the form

$$\boldsymbol{C_y}(\omega) := \mathrm{diag}(\underbrace{1, \dots, 1}_{j_0}, (1 - e^{-i\omega})/y_{j_0}, \underbrace{1, \dots, 1}_{r-1-j_0}). \tag{2.7}$$

It is easy to observe that $\boldsymbol{C_y}(\omega)$ is invertible for $\omega \neq 0$. In particular,

$$\det \boldsymbol{C_y}(\omega) = \left(\prod_{\substack{\nu=0 \\ y_\nu \neq 0}}^{r-1} y_\nu^{-1} \right) (1 - e^{-i\omega}). \tag{2.8}$$

Furthermore, $\boldsymbol{C_y}$ is chosen so that $\boldsymbol{y}^{\mathrm{T}} \boldsymbol{C_y}(0) = \boldsymbol{0}^{\mathrm{T}}$. We introduce

$$\boldsymbol{G_y}(\omega) := (1 - e^{-i\omega})\, \boldsymbol{C}_{\boldsymbol{y}}^{-1}(\omega)\ . \tag{2.9}$$

If $\boldsymbol{y}$ is of the form (2.4), then $\boldsymbol{G_y}(\omega) = \widetilde{\boldsymbol{G}}\boldsymbol{y}(\omega) \oplus (1 - e^{-i\omega})\, \boldsymbol{I}_{r-l}$ with

$$\widetilde{\boldsymbol{G}}\boldsymbol{y}(\omega) := \begin{bmatrix} y_0 & y_1 & y_2 & \dots & y_{l-1} \\ y_0 z & y_1 & y_2 & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & y_{l-1} \\ y_0 z & y_1 z & \ddots & y_{l-2} & y_{l-1} \\ y_0 z & y_1 z & \dots & y_{l-2} z & y_{l-1} \end{bmatrix} \qquad (z := e^{-i\omega})\ .$$

Finally, let $\boldsymbol{e} = (e_\nu)_{\nu=0}^{r-1}$ corresponding to $\boldsymbol{y} = (y_\nu)_{\nu=0}^{r-1}$ be defined by

$$e_\nu := \begin{cases} 1 & \text{for } y_\nu \neq 0, \\ 0 & \text{for } y_\nu = 0 \end{cases} \qquad (\nu = 0, \dots, r-1). \tag{2.10}$$

Now we can proceed with the factorization of $\boldsymbol{P}(\omega)$.

THEOREM 2.3 (see [P3]). *Let $m > 1$ be fixed. Assume that $\boldsymbol{P} \in C_{2\pi}^{m-1}(\mathbb{R}^{r\times r})$ provides approximation order m with vectors $\boldsymbol{y}_0, \dots, \boldsymbol{y}_{m-1}$ $(\boldsymbol{y}_0 \neq \boldsymbol{0})$. Then*

$$\widetilde{\boldsymbol{P}}(\omega) := 2\, \boldsymbol{C}_{\boldsymbol{y}_0}(2\omega)^{-1}\, \boldsymbol{P}(\omega)\, \boldsymbol{C}_{\boldsymbol{y}_0}(\omega), \tag{2.11}$$

with $\boldsymbol{C}_{\boldsymbol{y}_0}(\omega)$ defined by $\boldsymbol{y}_0$ via (2.6)–(2.7)*, provides approximation order at least $m-1$ with vectors $\widetilde{\boldsymbol{y}}_0, \dots, \widetilde{\boldsymbol{y}}_{m-2}$, given by*

$$(\widetilde{\boldsymbol{y}}_k)^T := \frac{1}{k+1} \sum_{\nu=0}^{k+1} \binom{k+1}{\nu} i^{\nu-k-1}\, (\boldsymbol{y}_\nu)^T\, (D^{k+1-\nu} \boldsymbol{C}_{\boldsymbol{y}_0})(0) \tag{2.12}$$

for $k = 0, \dots, m-2$. In particular $\widetilde{\boldsymbol{y}}_0 \neq \boldsymbol{0}$.

Moreover, if $\boldsymbol{e}$ corresponds to $\boldsymbol{y}_0$ in the sense of (2.10)*, then $\widetilde{\boldsymbol{P}}(\omega)$ in* (2.11) *satisfies $\widetilde{\boldsymbol{P}}(0)\, \boldsymbol{e} = \boldsymbol{e}$.*

Assume that $\boldsymbol{P} \in C_{2\pi}^{m-1}(\mathbb{R}^{r\times r})$ provides approximation order m; then repeated application of Theorem 2.3 yields the desired factorization of $\boldsymbol{P}(\omega)$:

$$\boldsymbol{P}(\omega) = \frac{1}{2^m} \boldsymbol{C}_{\boldsymbol{x}_{m-1}}(2\omega) \cdots \boldsymbol{C}_{\boldsymbol{x}_0}(2\omega)\, \boldsymbol{P}^{(0)}(\omega)\, \boldsymbol{C}_{\boldsymbol{x}_0}(\omega)^{-1} \cdots \boldsymbol{C}_{\boldsymbol{x}_{m-1}}(\omega)^{-1}. \tag{2.13}$$

Here $\boldsymbol{P}^{(0)}(\omega) \in C_{2\pi}^{m-1}(\mathbb{R}^{r\times r})$ and $\boldsymbol{x}_0, \dots, \boldsymbol{x}_{m-1} \in \mathbb{R}^r$ are defined recursively by (2.12) [P3]. In particular, $\boldsymbol{x}_{m-1} = \boldsymbol{y}_0$ and, by (2.8),

$$\det \boldsymbol{P}(\omega) = \left(\frac{1 + e^{-i\omega}}{2^r} \right)^m \det \boldsymbol{P}^{(0)}(\omega).$$

However, the factorization (2.13) is not unique. The following theorem is a generalization of Theorem 2.3.

THEOREM 2.4 (see [S1]). *Let $m \geq 1$ be fixed, and let $\boldsymbol{P} \in C_{2\pi}^{m-1}(\mathbb{R}^{r\times r})$ provide approximation order m with vectors $\boldsymbol{y}_0, \dots, \boldsymbol{y}_{m-1}$. Further, let $\boldsymbol{M} \in C_{2\pi}^{m-1}(\mathbb{R}^{r\times r})$ satisfy the following conditions:*

1. *$\boldsymbol{M}(\omega)$ is invertible for all $\omega \neq 0$.*
2. *$\boldsymbol{M}(0)$ has a simple eigenvalue 0 with a corresponding left eigenvector $\boldsymbol{y}_0$ and $D(\det \boldsymbol{M})(0) \neq 0$.*

Then,

$$\widetilde{\boldsymbol{P}}(\omega) = 2\, \boldsymbol{M}(2\omega)^{-1}\, \boldsymbol{P}(\omega)\, \boldsymbol{M}(\omega) \tag{2.14}$$

provides approximation order at least $m-1$ with vectors $\boldsymbol{u}_0, \dots, \boldsymbol{u}_{m-2}$ $(m > 1)$ defined by

$$\boldsymbol{u}_k^T := \frac{1}{k+1} \sum_{j=0}^{k+1} \binom{k+1}{j} i^{j-k-1}\, \boldsymbol{y}_j^T\, (D^{k+1-j} \boldsymbol{M})(0) \qquad (k = 0, \dots, m-2).$$

In particular, $\boldsymbol{u}_0 \neq 0$. If $\boldsymbol{P}$ exactly provides approximation order $m = 1$, then $\widetilde{\boldsymbol{P}}(0)$ has the eigenvalue 1, but there exists no vector $\boldsymbol{y} \neq \boldsymbol{0}$ such that $\widetilde{\boldsymbol{P}}(\omega)$ satisfies (2.1), (2.2) *for $n = 0$.*

In [S1], this result was obtained directly, using similar ideas as in the proof of Theorem 2.3 in [P3]. Here we would like to give another proof which clearly shows the connection between the particular factorization matrix $\boldsymbol{C}_{\boldsymbol{y}_0}$ and general factorization matrices $\boldsymbol{M}$.

LEMMA 2.5. *Let $\boldsymbol{y} \in \mathbb{R}^r$ be a fixed nonzero vector, and let $\boldsymbol{M} \in C_{2\pi}^{m-1}(\mathbb{R}^{r\times r})$ satisfy assumptions 1 and 2 of Theorem 2.4 (with $\boldsymbol{y}$ instead of $\boldsymbol{y}_0$). Further, let $\boldsymbol{C}_{\boldsymbol{y}}$ be an $r \times r$ matrix defined by $\boldsymbol{y}$ via (2.6)–(2.7). Then, there exists a matrix $\boldsymbol{M}_0(\omega) \in C_{2\pi}^{m-1}(\mathbb{R}^{r\times r})$ which is invertible for all $\omega \in \mathbb{R}$, and*

$$\boldsymbol{C}_{\boldsymbol{y}}(\omega)\, \boldsymbol{M}_0(\omega) = \boldsymbol{M}(\omega).$$

Proof. Let $\boldsymbol{G}_{\boldsymbol{y}}$ be the $r \times r$ matrix defined by $\boldsymbol{C}_{\boldsymbol{y}}$ via (2.9). Define $\boldsymbol{M}_0(\omega)$ as follows:

$$\boldsymbol{M}_0(\omega) := \begin{cases} \boldsymbol{C}_{\boldsymbol{y}}(\omega)^{-1}\, \boldsymbol{M}(\omega) & \text{for } \omega \neq 0, \\ (-i)\, \big((\mathrm{D}\boldsymbol{G}_{\boldsymbol{y}})(0)\, \boldsymbol{M}(0) + \boldsymbol{G}_{\boldsymbol{y}}(0)\, (\mathrm{D}\boldsymbol{M})(0)\big) & \text{for } \omega = 0. \end{cases}$$

Here, $\boldsymbol{M}_0(0)$ is found by the rule of l'Hospital from

$$M_0(0) = \lim_{\omega\to 0} \boldsymbol{C}_{\boldsymbol{y}}(\omega)^{-1}\, \boldsymbol{M}(\omega) = \lim_{\omega\to 0} \frac{1}{1-e^{-i\omega}}\, \boldsymbol{G}_{\boldsymbol{y}}(\omega)\, \boldsymbol{M}(\omega).$$

Since $\boldsymbol{C}_{\boldsymbol{y}}(\omega)$ is invertible for $\omega \neq 0$, the relation $\boldsymbol{C}_{\boldsymbol{y}}(\omega)\, \boldsymbol{M}_0(\omega) = \boldsymbol{M}(\omega)$ easily follows for $\omega \neq 0$. For $\omega = 0$, we find

$$\boldsymbol{C}_{\boldsymbol{y}}(0)\, \boldsymbol{M}_0(0) = (-i)\, \big(\boldsymbol{C}_{\boldsymbol{y}}(0)\, (\mathrm{D}\boldsymbol{G}_{\boldsymbol{y}})(0)\, \boldsymbol{M}(0) + \boldsymbol{C}_{\boldsymbol{y}}(0)\, \boldsymbol{G}_{\boldsymbol{y}}(0)\, (\mathrm{D}\boldsymbol{M})(0)\big)\,.$$

Observe that, by definition,

$$\boldsymbol{G}_{\boldsymbol{y}}(\omega)\, \boldsymbol{C}_{\boldsymbol{y}}(\omega) = \boldsymbol{C}_{\boldsymbol{y}}(\omega)\, \boldsymbol{G}_{\boldsymbol{y}}(\omega) = (1-e^{-i\omega})\, \boldsymbol{I}_r.$$

Hence,

$$\begin{aligned} \boldsymbol{C}_{\boldsymbol{y}}(0)\, \boldsymbol{G}_{\boldsymbol{y}}(0) &= \boldsymbol{0}_r, \\ (\mathrm{D}\boldsymbol{C}_{\boldsymbol{y}})(0)\, \boldsymbol{G}_{\boldsymbol{y}}(0) + \boldsymbol{C}_{\boldsymbol{y}}(0)\, (\mathrm{D}\boldsymbol{G}_{\boldsymbol{y}})(0) &= i\boldsymbol{I}_r. \end{aligned}$$

From the assumption $\boldsymbol{y}^{\mathrm{T}}\, \boldsymbol{M}(0) = \boldsymbol{0}^{\mathrm{T}}$ we have $\boldsymbol{G}_{\boldsymbol{y}}(0)\boldsymbol{M}(0) = \boldsymbol{0}_r$. Thus,

$$\boldsymbol{C}_{\boldsymbol{y}}(0)\, \boldsymbol{M}_0(0) = (-i)\, \big(i\boldsymbol{I}_r - (\mathrm{D}\boldsymbol{C}_{\boldsymbol{y}})(0)\, \boldsymbol{G}_{\boldsymbol{y}}(0)\big)\, \boldsymbol{M}(0) = \boldsymbol{M}(0).$$

We see that $\boldsymbol{C}_{\boldsymbol{y}}(\omega)\, \boldsymbol{M}_0(\omega) = \boldsymbol{M}(\omega)$ for all $\omega \in \mathbb{R}$. Since $\boldsymbol{C}_{\boldsymbol{y}}(\omega)$ and $\boldsymbol{M}(\omega)$ are invertible for $\omega \neq 0$, $\boldsymbol{M}_0(\omega)$ is also invertible for $\omega \neq 0$. Further, since $\mathrm{D}(\det \boldsymbol{C}_{\boldsymbol{y}})(0) \neq 0$ and $\mathrm{D}(\det \boldsymbol{M})(0) \neq 0$, it follows that

$$\det \boldsymbol{M}_0(0) = \lim_{\omega\to 0} \frac{\det \boldsymbol{M}(\omega)}{\det \boldsymbol{C}_{\boldsymbol{y}}(\omega)} = \frac{\mathrm{D}(\det \boldsymbol{M}(0))}{\mathrm{D}(\det \boldsymbol{C}_{\boldsymbol{y}}(0))} \neq 0.$$

Thus, $\boldsymbol{M}_0(0)$ is invertible. ∎

Proof of Theorem 2.4. Recall that by Theorem 2.2, a TST with an invertible transformation matrix does not change the approximation order of a refinement mask. Using the result of Lemma 2.5, we simply observe that a factorization step (2.14) with a matrix $\boldsymbol{M}(\omega)$ can be considered as a combination of factorization step (2.11) with $\boldsymbol{C}_{\boldsymbol{y}_0}(\omega)$ and a nondegenerate TST with the transform matrix $\boldsymbol{M}_0(\omega)$. ∎

While the matrices $\boldsymbol{C_y}$ are determined by a left eigenvector $\boldsymbol{y}$ of $\boldsymbol{C_y}(0)$ to the eigenvalue 0, we want to identify the matrices $\boldsymbol{M}$ with the help of right eigenvectors of $\boldsymbol{M}(0)$ to the eigenvalue 0. Letting $\boldsymbol{r}_0$ be a right eigenvector of $\boldsymbol{M}(0)$ in Theorem 2.4, we then have $\boldsymbol{M_{r_0}} := \boldsymbol{M}$. Hence, similar to (2.13), repeated application of Theorem 2.4 gives a general factorization of $\boldsymbol{P}(\omega)$:

$$\boldsymbol{P}(\omega) = \frac{1}{2^m} \boldsymbol{M_{r_{m-1}}}(2\omega) \cdots \boldsymbol{M_{r_0}}(2\omega)\, \boldsymbol{P}^{(0)}(\omega)\, \boldsymbol{M_{r_0}}(\omega)^{-1} \cdots \boldsymbol{M_{r_{m-1}}}(\omega)^{-1}. \tag{2.15}$$

2.4. Factorization implies approximation order. In this section we state the main theoretical results of the paper. First, let us again return for a moment to the scalar case ($r = 1$). In [St1], it was shown that the approximation order defines the number of factors $(1 + e^{-i\omega})$ in $P(\omega)$, and on the other hand each such factor increases the approximation order by one. Therefore, our next step is to prove the reverse of Theorems 2.3 and 2.4, or in other words, to show that the factorization (2.15) of the refinement mask yields approximation order m for the corresponding refinable function vector.

To this end, we need to introduce the "modified" Bernoulli numbers $\widetilde{B}_n$ ($n \in \mathbb{N}$), defined by the following relations:

$$\widetilde{B}_0 = 1, \qquad \sum_{l=0}^{n} \binom{n+1}{l} (-1)^l\, \widetilde{B}_l = 0, \tag{2.16}$$

or

$$\widetilde{B}_0 = 1, \qquad \widetilde{B}_n = \frac{(-1)^{n+1}}{n+1} \sum_{l=0}^{n-1} \binom{n+1}{l} (-1)^l\, \widetilde{B}_l \qquad (n \geq 1).$$

In particular,

$$\widetilde{B}_1 = \frac{1}{2}, \quad \widetilde{B}_2 = \frac{1}{6}, \quad \widetilde{B}_4 = -\frac{1}{30}.$$

Note that, apart from $\widetilde{B}_1$, the modified Bernoulli numbers coincide with the usual Bernoulli numbers B_n:

$$\widetilde{B}_n = B_n \quad (n \in \mathbb{N} \setminus \{1\}), \qquad \widetilde{B}_1 = -B_1.$$

This means that $\widetilde{B}_{2n+1} = B_{2n+1} = 0$ ($n \geq 1$), and we have

$$\sum_{l=0}^{n} \binom{n+1}{l} (-2)^l\, \widetilde{B}_l = \sum_{l=0}^{n} \binom{n+1}{l} 2^l\, B_l = \begin{cases} 1, & n = 0, \\ 2(-2^{n+1}+1)\, \widetilde{B}_{n+1}, & n \geq 1 \end{cases} \tag{2.17}$$

(see [AS]).

Now we are ready to state the main results of this section.

THEOREM 2.6. *Let $m \geq 1$ be a fixed integer and let $\widetilde{\boldsymbol{P}} \in C^m_{2\pi}(\mathbb{R}^{r\times r})$ be a refinement mask providing the approximation order m with $\widetilde{\boldsymbol{y}}_0, \ldots, \widetilde{\boldsymbol{y}}_{m-1} \in \mathbb{R}^r$ ($\widetilde{\boldsymbol{y}}_0 \neq \boldsymbol{0}$). Further, assume that there is a vector $\boldsymbol{e} \in \mathbb{R}^r$ ($\boldsymbol{e} \neq \boldsymbol{0}$), containing only the entries 0 or 1, such that $\widetilde{\boldsymbol{P}}(0)\, \boldsymbol{e} = \boldsymbol{e}$. Let $\boldsymbol{y} = (y_\nu)_{\nu=0}^{r-1} \in \mathbb{R}^r$ ($\boldsymbol{y} \neq \boldsymbol{0}$) be an arbitrary vector such that $\boldsymbol{e}$ corresponds to $\boldsymbol{y}$ in the sense of* (2.10). *Then the matrix $\boldsymbol{P}(\omega)$,*

$$\boldsymbol{P}(\omega) := \frac{1}{2}\, \boldsymbol{C_y}(2\omega)\, \widetilde{\boldsymbol{P}}(\omega)\, \boldsymbol{C_y}(\omega)^{-1}$$

with $\boldsymbol{C_y}$ defined by $\boldsymbol{y}$ via (2.6)–(2.7)*, provides approximation order at least $m+1$ with vectors $\boldsymbol{y}_0, \dots, \boldsymbol{y}_m$,*

$$\boldsymbol{y}_k^T := (-ik)\, \widetilde{\boldsymbol{y}}_{k-1}^T\, (D\boldsymbol{G_y})(0) + \sum_{l=0}^{k} \binom{k}{l} \widetilde{B}_{k-l}\, \widetilde{\boldsymbol{y}}_l^T\, \boldsymbol{G_y}(0) \quad (k = 0, \dots, m-1), \tag{2.18}$$

$$\begin{aligned} \boldsymbol{y}_m^T := (-im)\, \widetilde{\boldsymbol{y}}_{m-1}^T\, (D\boldsymbol{G_y})(0) + \sum_{l=0}^{m-1} \binom{m}{l} \widetilde{B}_{m-l}\, \widetilde{\boldsymbol{y}}_l^T\, \boldsymbol{G_y}(0) \\ - \frac{2^m}{2^m - 1} \sum_{k=0}^{m-1} \binom{m}{k} (2i)^{k-m}\, \widetilde{\boldsymbol{y}}_k^T\, (D^{m-k}\widetilde{\boldsymbol{P}})(0)\, \boldsymbol{G_y}(0), \end{aligned} \tag{2.19}$$

where $\widetilde{\boldsymbol{y}}_{-1} := \boldsymbol{0}$.

The proof of Theorem 2.6 is presented in section 4. In particular, we obtain from (2.18) that $\boldsymbol{y}_0^{\mathrm{T}} = \widetilde{\boldsymbol{y}}_0^{\mathrm{T}}\, \boldsymbol{G_y}(0) = (\sum_{\nu=0}^{r-1} \widetilde{y}_{0,\nu})\, \boldsymbol{y}^{\mathrm{T}}$ with $\widetilde{\boldsymbol{y}}_0 = (\widetilde{y}_{0,\nu})_{\nu=0}^{r-1}$. Observe that the technical assumption $\widetilde{\boldsymbol{P}}(0)\boldsymbol{e} = \boldsymbol{e}$ ensures that $\boldsymbol{C_y}$ has the same right eigenvector $\boldsymbol{e}$ to the eigenvalue 0 as $\widetilde{\boldsymbol{P}}(0)$ to the eigenvalue 1.

Again, we can generalize this result using the TST.

THEOREM 2.7. *Let $m \geq 1$ be a fixed integer and let $\widetilde{\boldsymbol{P}} \in C_{2\pi}^m(\mathbb{R}^{r\times r})$ be a refinement mask providing approximation order m with vectors $\widetilde{\boldsymbol{y}}_0, \dots, \widetilde{\boldsymbol{y}}_{m-1} \in \mathbb{R}^r$ $(\boldsymbol{y}_0 \neq \boldsymbol{0})$. Further, let $\boldsymbol{r}$ be a right eigenvector of $\widetilde{\boldsymbol{P}}(0)$ to the eigenvalue* 1*.*

Choose a matrix $\boldsymbol{M_r}(\omega) \in C_{2\pi}^m(\mathbb{R}^{r\times r})$ such that

1. *$\boldsymbol{M_r}(\omega)$ is invertible for all $\omega \in \mathbb{R},\ \omega \neq 0$.*
2. *$\boldsymbol{M_r}(0)$ has a simple eigenvalue* 0 *with $\boldsymbol{M_r}(0)\, \boldsymbol{r} = \boldsymbol{0}$.*
3. *$D(\det \boldsymbol{M_r})(0) \neq 0$.*

Let $\boldsymbol{u}$ be a left eigenvector of $\boldsymbol{M_r}(0)$ corresponding to the eigenvalue 0*. Then the matrix*

$$\boldsymbol{P}(\omega) := \frac{1}{2}\, \boldsymbol{M_r}(2\omega)\, \widetilde{\boldsymbol{P}}(\omega)\, \boldsymbol{M_r}(\omega)^{-1} \tag{2.20}$$

provides approximation order at least $m+1$ with vectors $\boldsymbol{u}_0, \dots, \boldsymbol{u}_m$, given by

$$\boldsymbol{u}_k^T := (-ik)\, \widetilde{\boldsymbol{u}}_{k-1}^T\, (D\boldsymbol{G_u})(0) + \sum_{l=0}^{k} \binom{k}{l} \widetilde{B}_{k-l}\, \widetilde{\boldsymbol{u}}_l^T\, \boldsymbol{G_u}(0) \qquad (k = 0, \dots, m-1),$$

$$\begin{aligned} \boldsymbol{u}_m^T := (-im)\, \widetilde{\boldsymbol{u}}_{m-1}^T\, (D\boldsymbol{G_u})(0) + \sum_{l=0}^{m-1} \binom{m}{l} \widetilde{B}_{m-l}\, \widetilde{\boldsymbol{u}}_l^T\, \boldsymbol{G_u}(0) \\ - \frac{2^m}{2^m - 1} \sum_{k=0}^{m-1} \binom{m}{k} (2i)^{k-m}\, \widetilde{\boldsymbol{u}}_k^T\, (D^{m-k}(\boldsymbol{M}_0(2\cdot)^{-1}\, \widetilde{\boldsymbol{P}}\, \boldsymbol{M}_0))(0)\, \boldsymbol{G_u}(0), \end{aligned}$$

where $\boldsymbol{M}_0(\omega)$ is an invertible matrix such that $\boldsymbol{C_u}(\omega)\, \boldsymbol{M}_0(\omega) = \boldsymbol{M_r}(\omega)$, $\widetilde{\boldsymbol{u}}_{-1} := \boldsymbol{0}$, and $\widetilde{\boldsymbol{u}}_k^T := \sum_{l=0}^{k} \binom{k}{l}\, i^{(l-k)}\, \widetilde{\boldsymbol{y}}_l^T\, (D^{k-l}\boldsymbol{M}_0^{-1})(0)$ for $k = 0, \dots, m-1$.

Proof. In [S1], it is shown that $\boldsymbol{P}(\omega)$ defined by (2.20) is in $C_{2\pi}^m(\mathbb{R}^{r\times r})$ and $\boldsymbol{P}(0)$ has a left eigenvector $\boldsymbol{u}$, corresponding to the eigenvalue 1:

$$\boldsymbol{u}^{\mathrm{T}}\, \boldsymbol{P}(0) = \boldsymbol{u}^{\mathrm{T}}.$$

Let $\boldsymbol{C_u}$ be defined by $\boldsymbol{u}$ via (2.6)–(2.7); then $\boldsymbol{u}^{\mathrm{T}}\,\boldsymbol{C_u}(0) = \boldsymbol{0}^{\mathrm{T}}$. By Lemma 2.5, there exists a regular matrix $\boldsymbol{M}_0 \in \boldsymbol{C}^m_{2\pi}(\mathbb{R}^{r\times r})$ such that

$$\boldsymbol{C_u}(\omega)\,\boldsymbol{M}_0(\omega) = \boldsymbol{M_r}(\omega).$$

Recall that the eigenvalue 0 of $\boldsymbol{C_u}(0)$ is simple, and we have $\boldsymbol{C_u}(0)\,\boldsymbol{e} = \boldsymbol{0}$, where $\boldsymbol{e}$ is connected with $\boldsymbol{u}$ via (2.10). Hence, from $\boldsymbol{M_r}(0)\,\boldsymbol{r} = \boldsymbol{0}$, it follows that $\boldsymbol{M}_0(0)\,\boldsymbol{r} = c\,\boldsymbol{e}$ with some constant $c \neq 0$. Since $\boldsymbol{M}_0(\omega)$ is invertible for all $\omega \in \mathbb{R}$, Theorem 2.2 implies that the matrix $\boldsymbol{M}_0(2\omega)\,\widetilde{\boldsymbol{P}}(\omega)\,\boldsymbol{M}_0(\omega)^{-1}$ also provides approximation order m. Furthermore,

$$\boldsymbol{M}_0(0)\,\widetilde{\boldsymbol{P}}(0)\,\boldsymbol{M}_0(0)^{-1}\,\boldsymbol{e} = \frac{1}{c}\,\boldsymbol{M}_0(0)\,\widetilde{\boldsymbol{P}}(0)\boldsymbol{r} = \frac{1}{c}\,\boldsymbol{M}_0(0)\boldsymbol{r} = \boldsymbol{e}.$$

Now, we are ready to apply Theorem 2.6 to the matrix $\boldsymbol{M}_0(2\omega)\,\widetilde{\boldsymbol{P}}(\omega)\,\boldsymbol{M}_0(\omega)^{-1}$, yielding that

$$\begin{aligned}\boldsymbol{P}(\omega) &= \frac{1}{2}\,\boldsymbol{M_r}(2\omega)\,\widetilde{\boldsymbol{P}}(\omega)\,\boldsymbol{M_r}(\omega)^{-1}\\ &= \frac{1}{2}\,\boldsymbol{C_u}(2\omega)\,\boldsymbol{M}_0(2\omega)\,\widetilde{\boldsymbol{P}}(\omega)\,\boldsymbol{M}_0(\omega)^{-1}\,\boldsymbol{C_u}(\omega)^{-1}\end{aligned}$$

provides approximation order at least $m+1$. The construction of $\boldsymbol{u}_k$ $(k = 0,\dots,m)$ follows from Theorems 2.6 and 2.2. □

Remarks. 1. Let us mention that a degenerate TST with $D(\det \boldsymbol{M})(0) \neq 0$ can change the approximation order only by one. This fact does not follow directly from Theorems 2.4 or 2.7. Only together do these theorems imply it.

2. In particular, we obtain that, in Theorem 2.7, the vector $\boldsymbol{u}_0$ is a multiple of $\boldsymbol{u}$, since $\boldsymbol{u}_0^{\mathrm{T}} = \widetilde{\boldsymbol{u}}_0^{\mathrm{T}}\,\boldsymbol{G_u}(0)$.

Repeated application of Theorem 2.7 yields the following corollary.

COROLLARY 2.8. *Suppose that a matrix $\boldsymbol{P}^{(0)}(\omega) \in C^{m-1}_{2\pi}(\mathbb{R}^{r\times r})$ is given. Moreover, let*

$$\boldsymbol{P}^{(0)}(0)\boldsymbol{r}_0 = \boldsymbol{r}_0, \quad \boldsymbol{x}_0^T\boldsymbol{P}^{(0)}(0) = \boldsymbol{x}_0^T, \quad \boldsymbol{x}_0^T\boldsymbol{P}^{(0)}(\pi) \neq 0$$

for some $\boldsymbol{x}_0, \boldsymbol{r}_0 \in \mathbb{R}^r$. For $n = 1,\dots,m$, construct the matrices

$$\boldsymbol{P}^{(n)}(\omega) := \frac{1}{2}\boldsymbol{M}_{\boldsymbol{r}_{n-1}}(2\omega)\boldsymbol{P}^{(n-1)}(\omega)\boldsymbol{M}^{-1}_{\boldsymbol{r}_{n-1}}(\omega).$$

Here $\boldsymbol{M}_{\boldsymbol{r}_{n-1}}(\omega)$ are chosen such that

1. *$\boldsymbol{M}_{\boldsymbol{r}_{n-1}}(\omega)$ is invertible for all $\omega \neq 0$ and $D(\det \boldsymbol{M}_{\boldsymbol{r}_{n-1}})(0) \neq 0$;*
2. *$\boldsymbol{M}_{\boldsymbol{r}_{n-1}}(0)$ has a simple eigenvalue 0 with a right eigenvector $\boldsymbol{r}_{n-1}$,*

$$\boldsymbol{M}_{\boldsymbol{r}_{n-1}}(0)\boldsymbol{r}_{n-1} = \boldsymbol{0},$$

where $\boldsymbol{r}_{n-1}$ is the 1-eigenvector of $\boldsymbol{P}^{(n-1)}(0)$, i.e., $\boldsymbol{P}^{(n-1)}(0)\boldsymbol{r}_{n-1} = \boldsymbol{r}_{n-1}$.

Then there exist vectors $\boldsymbol{y}_0,\dots,\boldsymbol{y}_{m-1}$ $(\boldsymbol{y}_0 \neq \boldsymbol{0})$ such that the matrix $\boldsymbol{P}^{(m)}$

$$\boldsymbol{P}^{(m)}(\omega) := \frac{1}{2^m}\,\boldsymbol{M}_{\boldsymbol{r}_{m-1}}(2\omega)\cdots\boldsymbol{M}_{\boldsymbol{r}_0}(2\omega)\,\boldsymbol{P}^{(0)}(\omega)\,\boldsymbol{M}_{\boldsymbol{r}_0}(\omega)^{-1}\cdots\boldsymbol{M}_{\boldsymbol{r}_{m-1}}(\omega)^{-1}$$

provides approximation order m with $\boldsymbol{y}_0,\dots,\boldsymbol{y}_{m-1}$.

Corollary 2.8 opens an easy way to construct multiscaling functions with given approximation order. We discuss it in section 3. Note that the bulky formulas in Theorems 2.6 and 2.7 for $\boldsymbol{y}_k$ and $\boldsymbol{u}_k$ are only of theoretical interest. They will be used for the proof, but they need not be computed during the construction.

2.5. Regularity of multiscaling functions. In the scalar case, the approximation properties of the refinement mask are closely related with regularity of the scaling function. What happens in the vector case? To give an answer to this question we recall results from [CDP, S1].

Let $\boldsymbol{v}$ be a right eigenvector of $\boldsymbol{P}(0)$ for the eigenvalue 1. We introduce the spectral radius of $\boldsymbol{P}(0)$,

$$\rho(\boldsymbol{P}(0)) := \max\{|\lambda| : \boldsymbol{P}(0)\,\boldsymbol{x} = \lambda\,\boldsymbol{x},\ \boldsymbol{x} \neq \boldsymbol{0}\}.$$

Suppose that $\rho(\boldsymbol{P}(0)) < 2$. Then

$$\widehat{\boldsymbol{\Upsilon}}(\omega) := \lim_{n\to\infty} \Pi_{j=1}^{n} \boldsymbol{P}\left(\frac{\omega}{2^j}\right) \boldsymbol{v} \tag{2.21}$$

converges pointwise for all ω, and the convergence is uniform on compact sets (see [CDP]). Moreover, the following theorem holds.

THEOREM 2.9 (see [CDP]). *Let $\boldsymbol{P}$ be an $r \times r$ matrix of the form*

$$\boldsymbol{P}(\omega) = \frac{1}{2^m}\,\boldsymbol{C}_{\boldsymbol{x}_{m-1}}(2\omega)\cdots\boldsymbol{C}_{\boldsymbol{x}_0}(2\omega)\,\boldsymbol{P}^{(0)}(\omega)\,\boldsymbol{C}_{\boldsymbol{x}_0}(\omega)^{-1}\cdots\boldsymbol{C}_{\boldsymbol{x}_{m-1}}(\omega)^{-1},$$

where $\boldsymbol{C}_{\boldsymbol{x}_k}$ are defined by the vectors $\boldsymbol{x}_k \neq \boldsymbol{0}$ $(k = 0,\dots,m-1)$ via (2.6)–(2.7) *and $\boldsymbol{P}^{(0)}(\omega)$ is an $r \times r$ matrix with trigonometric polynomials as entries. Suppose that $\boldsymbol{P}^{(0)}(0)\boldsymbol{e}_0 = \boldsymbol{e}_0$, where $\boldsymbol{e}_0$ is defined by $\boldsymbol{x}_0$ via* (2.10). *Further, suppose that $\rho(\boldsymbol{P}^{(0)}(0)) < 2$, and let, for $k \geq 1$,*

$$\gamma_k := \frac{1}{k}\,\log_2 \sup_{\omega} \left\|\boldsymbol{P}^{(0)}\left(\frac{\omega}{2}\right)\cdots\boldsymbol{P}^{(0)}\left(\frac{\omega}{2^k}\right)\right\|. \tag{2.22}$$

Then there exists a constant $C > 0$ such that for all $\omega \in \mathbb{R}$,

$$\|\widehat{\boldsymbol{\Upsilon}}(\omega)\| \leq C\,(1+|\omega|)^{-m+\gamma_k},$$

where $\|\widehat{\boldsymbol{\Upsilon}}(\omega)\|$ denotes the Euclidean norm of $\widehat{\boldsymbol{\Upsilon}}(\omega) := (\widehat{\Upsilon}_\nu(\omega))_{\nu=0}^{r-1}$. Hence, if $\gamma_k < m-d$ $(d \in \mathbb{N})$, then Υ_ν $(\nu = 0,\dots,r-1)$ are $d-1$ times continuously differentiable.

If the conditions of Theorem 2.9 are satisfied and $\inf_{k\geq 1}\gamma_k < m-1$, then a compactly supported continuous solution $\boldsymbol{\Upsilon}(t)$ of (1.1) is unique in a wide class of functions. Further, the uniform convergence of the cascade algorithm (in time domain) is ensured (see [CDP, Sh]). Using the techniques from [S1] we obtain the following result.

COROLLARY 2.10. *Assume that for $n = 1,\dots,m$, $\boldsymbol{P}^{(n)}(\omega)$ is of the form*

$$\boldsymbol{P}^{(n)}(\omega) = \frac{1}{2^n}\,\boldsymbol{M}_{\boldsymbol{r}_{n-1}}(2\omega)\cdots\boldsymbol{M}_{\boldsymbol{r}_0}(2\omega)\,\boldsymbol{P}^{(0)}(\omega)\,\boldsymbol{M}_{\boldsymbol{r}_0}(\omega)^{-1}\cdots\boldsymbol{M}_{\boldsymbol{r}_{n-1}}(\omega)^{-1}.$$

Let $\boldsymbol{P}^{(0)}(\omega)$, $\boldsymbol{P}^{(n)}(\omega)$ and $\boldsymbol{M}_{\boldsymbol{r}_{n-1}}(\omega)$ $(n = 1,\dots,m)$ satisfy the assumptions of Corollary 2.8. *Further, suppose that $\rho(\boldsymbol{P}^{(0)}(0)) < 2$ and $\inf_{k\geq 1}\gamma_k < m-d$ $(d \in \mathbb{N})$, where γ_k is defined in* (2.22). *Then, $\boldsymbol{\Upsilon}(t)$ is a compactly supported $d-1$ times continuously differentiable solution of* (1.1) *with refinement mask $\boldsymbol{P}^{(m)}(\omega)$ providing approximation order at least m.*

Similar to the scalar case, the regularity of multiscaling functions depends both on the approximation order and the behavior of the residual $\boldsymbol{P}^{(0)}(\omega)$. Roughly speaking,

each approximation order adds one more derivative to the corresponding function vector, but the starting number of the derivatives depends on the $\boldsymbol{P}^{(0)}(\omega)$.

LEMMA 2.11. *Let $\boldsymbol{P}(\omega)$ be the refinement mask of a compactly supported continuously differentiable function vector $\boldsymbol{\phi} \in C^1(\mathbb{R}^r)$ providing approximation order at least 1; i.e., there exists a vector $\boldsymbol{y} \in \mathbb{R}^r$, $\boldsymbol{y} \neq \boldsymbol{0}$, such that*

$$\boldsymbol{y}^T \boldsymbol{P}(0) = \boldsymbol{y}^T, \qquad \boldsymbol{y}^T \boldsymbol{P}(\pi) = \boldsymbol{0}^T.$$

Further, assume that $\boldsymbol{P}(0)$ has a spectrum of the form $\{1, \mu_1, \ldots, \mu_{r-1}\}$ with each $\mu_\nu < 1/2$. Let $\boldsymbol{M}(\omega) \in C^1_{2\pi}(\mathbb{R})$ be an $r \times r$ matrix satisfying assumptions 1, 2 of Theorem 2.4 (with $\boldsymbol{y}$ instead of $\boldsymbol{y}_0$). Then

$$\widetilde{\boldsymbol{P}}(\omega) := 2\, \boldsymbol{M}(2\omega)^{-1}\, \boldsymbol{P}(\omega)\, \boldsymbol{M}(\omega) \tag{2.23}$$

is the refinement mask of a continuous function vector $\boldsymbol{\psi} = (\psi_\nu)_{\nu=0}^{r-1} \in C(\mathbb{R}^r) \cap L^1(\mathbb{R})$ and there is a constant $c_0 \in \mathbb{R}$ such that

$$\widehat{\boldsymbol{\phi}}(\omega) = \frac{c_0}{i\omega}\, \boldsymbol{M}(\omega) \widehat{\boldsymbol{\psi}}(\omega).$$

In particular, if $\boldsymbol{M} = \boldsymbol{C_y} \boldsymbol{M}_0$, with $\boldsymbol{C_y}$ defined by $\boldsymbol{y}$ as in (2.6)–(2.7) and a constant invertible matrix $\boldsymbol{M}_0$, then $\boldsymbol{\psi}$ is also compactly supported.

Proof. 1. Let us start with the case when $\widetilde{\boldsymbol{P}}(\omega) := 2\, \boldsymbol{C_y}(2\omega)^{-1}\, \boldsymbol{P}(\omega)\, \boldsymbol{C_y}(\omega)$ and $\boldsymbol{C_y}$ is defined by $\boldsymbol{y}$ as in (2.6)–(2.7). The assumptions on the spectrum of $\boldsymbol{P}(0)$ and the results of [CDP, S1] imply that $\rho(\widetilde{\boldsymbol{P}}(0)) = 1$, and 1 is a simple eigenvalue of $\widetilde{\boldsymbol{P}}(0)$. Hence, we can represent $\hat{\boldsymbol{\phi}}$ and $\hat{\boldsymbol{\psi}}$ in the form

$$\widehat{\boldsymbol{\phi}}(\omega) := \prod_{j=1}^{\infty} \boldsymbol{P}\left(\frac{\omega}{2^j}\right) \boldsymbol{a}, \qquad \widehat{\boldsymbol{\psi}}(\omega) := \prod_{j=1}^{\infty} \widetilde{\boldsymbol{P}}\left(\frac{\omega}{2^j}\right) \boldsymbol{b}, \tag{2.24}$$

where $\boldsymbol{a}$ and $\boldsymbol{b}$ are right eigenvectors of $\boldsymbol{P}(0)$ and $\widetilde{\boldsymbol{P}}(0)$, respectively. The convergence of the products in (2.24) is ensured by Theorem 3.2 in [CDP]. The observations in [P3] imply that $\widetilde{\boldsymbol{P}}(\omega)$ is a matrix of trigonometric polynomials ensuring a compactly supported solution $\boldsymbol{\psi}(t)$ of (1.1). The solutions $\boldsymbol{\phi}$ and $\boldsymbol{\psi}$ are uniquely determined by (2.24) up to a constant factor [CDP, H, HC].

By the repeated substitution of (2.23) into (2.24) we get

$$\begin{aligned}
\widehat{\boldsymbol{\phi}}(\omega) &= \lim_{n\to\infty} \left(\prod_{j=1}^{n} \frac{1}{2}\, \boldsymbol{C_y}\left(\frac{2\omega}{2^j}\right) \widetilde{\boldsymbol{P}}\left(\frac{\omega}{2^j}\right) \boldsymbol{C_y}\left(\frac{\omega}{2^j}\right)^{-1} \right) \boldsymbol{a} \\
&= \boldsymbol{C_y}(\omega) \lim_{n\to\infty} \frac{1}{2^n} \left(\prod_{j=1}^{n} \widetilde{\boldsymbol{P}}\left(\frac{\omega}{2^j}\right) \right) \boldsymbol{C_y}\left(\frac{\omega}{2^n}\right)^{-1} \boldsymbol{a}.
\end{aligned}$$

Formula (2.9) gives

$$\widehat{\boldsymbol{\phi}}(\omega) = \lim_{n\to\infty} \frac{1}{2^n\,(1 - e^{-i\omega/2^n})}\, \boldsymbol{C_y}(\omega) \prod_{j=1}^{n} \widetilde{\boldsymbol{P}}\left(\frac{\omega}{2^j}\right) \boldsymbol{G_y}\left(\frac{\omega}{2^n}\right) \boldsymbol{a}.$$

2. Replacing $\boldsymbol{C_y}(\omega)$ and $\boldsymbol{C_y}(2\omega)^{-1}$ by $(1 - e^{-i\omega})\, \boldsymbol{G_y}(\omega)^{-1}$ and $(1 - e^{-2i\omega})^{-1}$ $\boldsymbol{G_y}(2\omega)$, respectively, we obtain from (2.23) (with $\boldsymbol{M} = \boldsymbol{C_y}$) that

$$\frac{1}{2}\,(1 + e^{-i\omega})\, \widetilde{\boldsymbol{P}}(\omega)\, \boldsymbol{G_y}(\omega) = \boldsymbol{G_y}(2\omega)\, \boldsymbol{P}(\omega).$$

In particular, for $\omega = 0$, it follows that $\widetilde{\boldsymbol{P}}(0)\,\boldsymbol{G_y}(0) = \boldsymbol{G_y}(0)\,\boldsymbol{P}(0)$. Hence, $\boldsymbol{G_y}(0)\,\boldsymbol{a}$ is a right eigenvector of $\widetilde{\boldsymbol{P}}(0)$, and there is a constant c_0 such that

$$\boldsymbol{G_y}(0)\,\boldsymbol{a} = c_0\,\boldsymbol{b}.$$

Observing that $\lim_{n\to\infty} 2^{-n}(1 - e^{-i\omega/2^n})^{-1} = (i\omega)^{-1}$, we get

$$\widehat{\boldsymbol{\phi}}(\omega) = \frac{c_0}{i\omega}\,\boldsymbol{C_y}(\omega) \prod_{j=1}^{\infty} \widetilde{\boldsymbol{P}}\left(\frac{\omega}{2^j}\right) \boldsymbol{b} = \frac{c_0}{i\omega}\,\boldsymbol{C_y}(\omega)\,\widehat{\boldsymbol{\psi}}(\omega).$$

Now take a refinement mask $\boldsymbol{P}(\omega)$ of a compactly supported function vector $\boldsymbol{\phi} \in C^1(\mathbb{R}^r)$ and an arbitrary matrix $\boldsymbol{M} \in \boldsymbol{C}^1_{2\pi}(\mathbb{R}^{r\times r})$ corresponding to $\boldsymbol{P}$ such that $\boldsymbol{M}$ satisfies conditions 1, 2 of Theorem 2.4 (with $\boldsymbol{y}$ instead of $\boldsymbol{y}_0$). Then, by Corollary 2.10,

$$\widetilde{\boldsymbol{P}}(\omega) = 2\,\boldsymbol{M}^{-1}_{\boldsymbol{y}}(2\omega)\,\boldsymbol{P}(\omega)\,\boldsymbol{M_y}(\omega)$$

is a refinement mask of a continuous function vector $\boldsymbol{\psi} \in C(\mathbb{R}^r)$. Using Lemma 2.5 we can prove the relation

$$\widehat{\boldsymbol{\phi}}(\omega) = \frac{c_0}{i\omega}\,\boldsymbol{M_y}(\omega)\,\widehat{\boldsymbol{\psi}}(\omega)$$

with an arbitrary chosen constant c_0 in the same manner as above. □

Using the spectral properties of transition operators, more results on regularity can be obtained [CDP, Sh, J].

2.6. Symmetry of multiscaling functions. In many applications, symmetry of the scaling functions is very desirable. Unfortunately, this property is very restrictive, and in the scalar case symmetry cannot be combined with orthogonality. In the vector case, there is more freedom, and the components of a refinable function vector can be symmetric and orthogonal at the same time. One such example was constructed in [GHM] and is shown in Figure 1.1. In this section we are going to discuss some results on symmetry of multiscaling functions. All details can be found in [S1].

We say that a refinable function vector $\boldsymbol{\phi} = (\phi_\nu)_{\nu=0}^{r-1}$ *is symmetric* if all its components $\phi_\nu(t)$ are symmetric or antisymmetric. Symmetry implies some restrictions on a refinement mask $\boldsymbol{P}(\omega)$.

THEOREM 2.12 (see [S1]). *If there is a diagonal matrix*

$$\boldsymbol{E}(\omega) := \operatorname{diag}\left(\pm e^{-i2T_0\omega}, \ldots, \pm e^{-i2T_{r-1}\omega}\right)$$

such that the refinement mask $\boldsymbol{P}(\omega)$ of a refinable function vector $\boldsymbol{\phi} = (\phi_\nu)_{\nu=0}^{r-1}$ satisfies

$$\boldsymbol{P}(\omega) = \boldsymbol{E}(2\omega)\boldsymbol{P}(-\omega)\boldsymbol{E}(\omega)^{-1}, \tag{2.25}$$

then $\boldsymbol{\phi}$ is symmetric. The constants T_ν occurring in $\boldsymbol{E}(\omega)$ are points of symmetry of the components $\phi_\nu(t)$, i.e., $\phi_\nu(T_\nu - t) = \pm\phi_\nu(T_\nu + t)$.

While constructing a vector of multiscaling functions using Corollary 2.8, it is reasonable to start with a symmetric one and try to preserve the symmetry at each step (see section 3). The following theorem specifies the factorization matrices $\boldsymbol{M}(\omega)$ which preserve the symmetry.

THEOREM 2.13 (see [S1]). *Suppose that all components $\widetilde{\phi}_\nu(t)$ of a refinable function vector $\widetilde{\boldsymbol{\phi}} = (\widetilde{\phi}_\nu)_{\nu=0}^{r-1}$ are symmetric (or antisymmetric) with points of symmetry $\widetilde{T}_\nu$ determining*

$$\widetilde{\boldsymbol{E}}(\omega) := \operatorname{diag}\left(\pm e^{-i2\widetilde{T}_0\omega}, \ldots, \pm e^{-i2\widetilde{T}_{r-1}\omega}\right). \tag{2.26}$$

Take a matrix $\boldsymbol{M}(\omega) \in C_{2\pi}(\mathbb{R}^{r\times r})$ satisfying assumptions 1, 2 of Theorem 2.4 and a matrix

$$\boldsymbol{E}(\omega) := \operatorname{diag}\left(\pm e^{-i2T_0\omega}, \ldots, \pm e^{-i2T_{r-1}\omega}\right) \tag{2.27}$$

such that

$$\boldsymbol{M}(\omega) = -\boldsymbol{E}(\omega)\boldsymbol{M}(-\omega)\widetilde{\boldsymbol{E}}^{-1}(\omega). \tag{2.28}$$

Then the new vector $\boldsymbol{\phi} = (\phi_\nu)_{\nu=0}^{r-1}$, determined by $\widehat{\boldsymbol{\phi}}(\omega) = \frac{c_0}{i\omega}\boldsymbol{M}(\omega)\widehat{\widetilde{\boldsymbol{\phi}}}(\omega)$, is also symmetric and T_ν, $\nu = 0, \ldots, r-1$ are points of symmetry of its components.

Remark. Let us mention that if ϕ_ν has finite support l_ν, starting at point $t_1 \geq 0$, and T_ν is the point of symmetry of ϕ_ν, then $l_\nu \leq 2T_\nu$.

3. Construction of multiscaling functions. Finally we have reached the point where we can show how to construct refinement masks which yield multiscaling functions with desirable properties.

In the scalar case, there is no problem finding a mask providing any given order of accuracy. One can start with a trigonometric polynomial $P(\omega)$ such that $P(0) = 1$ and multiply by a power of $\frac{1}{2}(1 + e^{-i\omega})$ (see, e.g., [St1]). In the vector case, a TST with transformation matrix $\boldsymbol{M}(\omega)$ (as described in Theorem 2.7) plays the role of the factor $(1 + e^{-i\omega})$.

An algorithm for the construction of refinement masks, yielding multiscaling functions with given approximation order, can be obtained as a consequence of Corollary 2.8.

ALGORITHM 3.1. *Start with a matrix trigonometric polynomial $\boldsymbol{P}^{(n)}(\omega)$ providing approximation order $n \in \mathbb{N}_0$ such that $\rho(\boldsymbol{P}^{(n)}(0)) < 2$. Further, let $\boldsymbol{P}^{(n)}(0)$ possess an eigenvalue 1 with corresponding right eigenvector $\boldsymbol{r}_n$, i.e., $\boldsymbol{P}^{(n)}(0)\boldsymbol{r}_n = \boldsymbol{r}_n$.*

1. *Choose $\boldsymbol{M}_{\boldsymbol{r}_n}(\omega)$ such that:*
   (a) $\det \boldsymbol{M}_{\boldsymbol{r}_n}(\omega) \neq 0$ *for* $\omega \neq 0$,
   (b) $D(\det \boldsymbol{M}_{\boldsymbol{r}_n})(0) \neq 0$,
   (c) $\boldsymbol{M}_{\boldsymbol{r}_n}(0)\boldsymbol{r}_n = \boldsymbol{0}$.
2. *Construct the matrix $\boldsymbol{P}^{(n+1)}(\omega)$:*

$$\boldsymbol{P}^{(n+1)}(\omega) := \frac{1}{2}\boldsymbol{M}_{\boldsymbol{r}_n}(2\omega)\boldsymbol{P}^{(n)}(\omega)\boldsymbol{M}_{\boldsymbol{r}_n}^{-1}(\omega).$$

3. *Find a right eigenvector $\boldsymbol{r}_{n+1}$ corresponding to the eigenvalue 1 of $\boldsymbol{P}^{(n+1)}(0)$.*
4. *Repeat steps 1, 2, 3 as many times as needed.*

By Theorem 2.7, the approximation order of $\boldsymbol{P}^{(n+1)}(\omega)$ is $n+1$, and $m-n$ cycles of Algorithm 3.1 are needed to get a refinement mask $\boldsymbol{P}^{(m)}$ providing approximation order m. In [S1], it was proven that $\boldsymbol{P}^{(n+1)}(0)$ has eigenvalue 1, so step 4 is consistent.

One can see that there are two matrices to be chosen in Algorithm 3.1, the starting matrix $\boldsymbol{P}^{(n)}(\omega)$ (only once in the beginning) and the transformation matrix $\boldsymbol{M}_{\boldsymbol{r}_n}(\omega)$ (one on each cycle of the algorithm).

Corollary 2.10 shows that the regularity of the final function vector (determined by the refinement mask $\boldsymbol{P}^{(m)}(\omega)$) is governed by its approximation order m and by the properties of the starting matrix $\boldsymbol{P}^{(n)}(\omega)$.

The approximation order n implies that $\boldsymbol{P}^{(n)}$ can be factored:

$$\boldsymbol{P}^{(n)}(\omega) = \frac{1}{2^n}\, \boldsymbol{C}_{\boldsymbol{x}_{n-1}}(2\omega) \cdots \boldsymbol{C}_{\boldsymbol{x}_0}(2\omega)\, \boldsymbol{P}^{(0)}(\omega)\, \boldsymbol{C}_{\boldsymbol{x}_0}(\omega)^{-1} \cdots \boldsymbol{C}_{\boldsymbol{x}_{n-1}}(\omega)^{-1},$$

where $\boldsymbol{C}_{\boldsymbol{x}_k}$ are defined by vectors $\boldsymbol{x}_k \neq \boldsymbol{0}$ via (2.6)–(2.7). Further, the spectral radii of $\boldsymbol{P}^{(0)}(\omega)$ and $\boldsymbol{P}^{(k)}(0)$,

$$\boldsymbol{P}^{(k)}(\omega) := \frac{1}{2^k}\, \boldsymbol{C}_{\boldsymbol{x}_{k-1}}(2\omega) \cdots \boldsymbol{C}_{\boldsymbol{x}_0}(2\omega)\, \boldsymbol{P}^{(0)}(\omega)\, \boldsymbol{C}_{\boldsymbol{x}_0}(\omega)^{-1} \cdots \boldsymbol{C}_{\boldsymbol{x}_{k-1}}(\omega)^{-1} \quad (k \le n),$$

are related as follows [CDP, S1]:

$$\rho(\boldsymbol{P}^{(k)}(0)) = \max\{1,\, 2^{-k}\, \rho(\boldsymbol{P}^{(0)}(0))\} \quad (k = 0, \dots, n).$$

Let k_0 $(0 \le k_0 \le n)$ be the smallest integer such that $\rho(\boldsymbol{P}^{(k_0)}(0)) < 2$. Then by Theorem 2.9, it follows that the Fourier transformed solution vector $\widehat{\boldsymbol{\phi}}_n$ of (1.3), determined by $\boldsymbol{P}^{(n)}$, satisfies

$$\|\widehat{\boldsymbol{\phi}}_n(\omega)\| \le C\, (1 + |\omega|)^{-n+k_0+K_0},$$

where $K_0 := \inf_{l \ge 1} \gamma_l$, $\gamma_l = \frac{1}{l} \log_2 \sup_\omega \|\boldsymbol{P}^{(k_0)}(\frac{\omega}{2}) \cdots \boldsymbol{P}^{(k_0)}(\frac{\omega}{2^l})\|$. Thus, $m - n$ cycles of Algorithm 3.1 yield $\boldsymbol{P}^{(m)}$ providing a solution vector $\widehat{\boldsymbol{\phi}}_m(\omega)$ such that

$$\|\hat{\boldsymbol{\phi}}_m(\omega)\| \le C\, (1 + |\omega|)^{-m+k_0+K_0}.$$

So, if we want to get a multiscaling function with approximation order at least m and p derivatives, we need to apply $m_0 - n$ cycles of Algorithm 3.1, where m_0 is chosen such that $m_0 \ge \max\{m,\, k_0 + K_0 + p + 1\}$.

3.1. How to choose the transformation matrices $\boldsymbol{M}_{\boldsymbol{r}_n}(\boldsymbol{\omega})$. In the scalar case, $\boldsymbol{M}_{\boldsymbol{r}_k}(\omega) = (1 - e^{-i\omega})$ is fixed. In the vector case, we are flexible in the choice of $\boldsymbol{M}_{\boldsymbol{r}_k} \in C_{2\pi}(\mathbb{R}^{r \times r})$. Actually, only one eigenvalue and one eigenvector are restricted in $\boldsymbol{M}_{\boldsymbol{r}_k}(\omega)$. We can use this freedom to obtain multiscaling functions with desired properties.

Finite support. A refinement mask $\boldsymbol{P}^{(n+1)}(\omega)$ corresponds to a finitely supported scaling vector if all components of $\boldsymbol{P}^{(n+1)}(\omega)$ are trigonometric polynomials (algebraic polynomials in $z = e^{-i\omega}$) [MRV]. But

$$\boldsymbol{P}^{(n+1)}(\omega) = \frac{1}{2} \boldsymbol{M}_{\boldsymbol{r}_n}(2\omega) \boldsymbol{P}^{(n)}(\omega) \boldsymbol{M}_{\boldsymbol{r}_n}^{-1}(\omega) \tag{3.1}$$

contains $\boldsymbol{M}_{\boldsymbol{r}_n}(2\omega)$ and $\boldsymbol{M}_{\boldsymbol{r}_n}^{-1}(\omega)$ which generally are not matrices of trigonometric polynomials at the same time.

LEMMA 3.2. *Assume that $\boldsymbol{P}^{(n)}(\omega)$ is a matrix of trigonometric polynomials. If $\boldsymbol{M}_{\boldsymbol{r}_n}(\omega)$ satisfies conditions* (a)–(c) *of Algorithm* 3.1, *$\boldsymbol{M}_{\boldsymbol{r}_n}(\omega)$ is a matrix of trigonometric polynomials, and $\det \boldsymbol{M}_{\boldsymbol{r}_n}(\omega)$ is linear in $z = e^{-i\omega}$, then the components of $\boldsymbol{P}^{(n+1)}(\omega)$ in* (3.1) *are trigonometric polynomials.*

Proof. Let us use a well-known formula for an inverse matrix:

$$\boldsymbol{M}_{\boldsymbol{r}_n}^{-1}(\omega) = \frac{1}{\det \boldsymbol{M}_{\boldsymbol{r}_n}(\omega)} \boldsymbol{N}_{\boldsymbol{r}_n}(\omega). \tag{3.2}$$

Here the (i,j) element of the matrix $\boldsymbol{N}_{\boldsymbol{r}_n}(\omega)$ is the minor for the (j,i) element of $\boldsymbol{M}_{\boldsymbol{r}_n}(\omega)$ (see [St2, p. 225]). In particular, $\boldsymbol{N}_{\boldsymbol{r}_n}(\omega)$ contains only trigonometric polynomials.

Since $\det \boldsymbol{M}_{\boldsymbol{r}_n}(\omega)$ is linear in z, and $\det \boldsymbol{M}_{\boldsymbol{r}_n}(0) = 0$, we have

$$\det \boldsymbol{M}_{\boldsymbol{r}_n}(\omega) = c_0(1 - e^{-i\omega}),$$

with a constant $c_0 \neq 0$, and according to (3.2),

$$\boldsymbol{P}^{(n+1)}(\omega) = \frac{1}{2\, c_0\, (1 - e^{-i\omega})} \boldsymbol{M}_{\boldsymbol{r}_n}(2\omega) \boldsymbol{P}^{(n)}(\omega) \boldsymbol{N}_{\boldsymbol{r}_n}(\omega). \tag{3.3}$$

It is easy to see that the components of $\boldsymbol{M}_{\boldsymbol{r}_n}(2\omega)\boldsymbol{P}^{(n)}(\omega)\boldsymbol{N}_{\boldsymbol{r}_n}(\omega)$ are trigonometric polynomials. In [S1], it was proven that $\boldsymbol{P}^{(n+1)}(0)$ is bounded. On the other hand, $(1 - e^{-i\omega})^{-1}$ is infinite at $\omega = 0$. Thus, all components of $\boldsymbol{M}_{\boldsymbol{r}_n}(2\omega)\boldsymbol{P}^{(n)}(\omega)\boldsymbol{N}_{\boldsymbol{r}_n}(\omega)$ must possess a root at $\omega = 0$ or, in other words, must be divisible by $(1 - e^{-i\omega})$. Hence, reducing $\boldsymbol{M}_{\boldsymbol{r}_n}(2\omega)\boldsymbol{P}^{(n)}(\omega)\boldsymbol{N}_{\boldsymbol{r}_n}(\omega)$ by $(1 - e^{-i\omega})$, we get a matrix trigonometric polynomial $\boldsymbol{P}^{(n+1)}(\omega)$. □

One way to choose $\boldsymbol{M}_{\boldsymbol{r}_n}(\omega)$ satisfying the conditions of Algorithm 3.1 and Lemma 3.2 is given by Lemma 2.5. Take an arbitrary vector $\boldsymbol{y}_n = (y_{n,\nu})_{\nu=0}^{r-1}$ corresponding to $\boldsymbol{r}_n = (r_{n,\nu})_{\nu=0}^{r-1}$ in the sense that $y_{n,\nu} \neq 0$ if and only if $r_{n,\nu} \neq 0$ for $\nu = 0, \ldots, r-1$. Put

$$\boldsymbol{M}_{\boldsymbol{r}_n}(\omega) := \boldsymbol{C}_{\boldsymbol{y}_n}(\omega)\, \boldsymbol{R}_n$$

with $\boldsymbol{C}_{\boldsymbol{y}_n}(\omega)$ defined by $\boldsymbol{y}_n$ as in (2.6)–(2.7) and an arbitrary constant $r \times r$ matrix $\boldsymbol{R}_n$ with the only restriction

$$\boldsymbol{R}_n\, \boldsymbol{r}_n = \boldsymbol{e}_n,$$

where $\boldsymbol{e}_n$ corresponds to $\boldsymbol{r}_n$ via (2.10). Then $\boldsymbol{M}_{\boldsymbol{r}_n}(\omega)$ is linear in $z = e^{-i\omega}$ by construction and, by (2.8), $\det \boldsymbol{M}_{\boldsymbol{r}_n}$ is of the desired form. Moreover, we have $\boldsymbol{M}_{\boldsymbol{r}_n}(0)\, \boldsymbol{r}_n = \boldsymbol{C}_{\boldsymbol{y}_n}(0)\, \boldsymbol{R}_n\, \boldsymbol{r}_n = \boldsymbol{C}_{\boldsymbol{y}_n}(0)\, \boldsymbol{e}_n = \boldsymbol{0}$. A simple $\boldsymbol{R}_n$ satisfying the relation above is $\boldsymbol{R}_n := \operatorname{diag}(\widetilde{r}_{n,0}, \ldots, \widetilde{r}_{n,r-1})$, where

$$\widetilde{r}_{n,\nu} := \begin{cases} 1/r_{n,\nu} & r_{n,\nu} \neq 0, \\ 1 & r_{n,\nu} = 0. \end{cases}$$

Symmetry. A reasonable way to get symmetric multiscaling functions with high approximation order is to start with $\boldsymbol{P}^{(n)}(\omega)$, yielding a symmetric function vector with low approximation order, and to preserve symmetry on each cycle of Algorithm 3.1. It is remarkable that after each cycle, the number of symmetric and antisymmetric components of the multiscaling function changes, independent of the choice of $\boldsymbol{M}_{\boldsymbol{r}_n}$:

LEMMA 3.3. *Suppose that $\boldsymbol{M}(\omega)$ satisfies conditions* (a)–(c) *of Algorithm* 3.1 *and a* TST *with transformation matrix $\boldsymbol{M}(\omega)$ preserves the symmetry; i.e., $\boldsymbol{\phi} = (\phi_\nu)_{\nu=1}^{r-1}$, $\widetilde{\boldsymbol{\phi}} = (\widetilde{\phi}_\nu)_{\nu=1}^{r-1}$ are two symmetric multiscaling functions connected by the relation*

$$\widehat{\boldsymbol{\phi}}(\omega) = \frac{c_0}{i\omega}\, \boldsymbol{M}(\omega)\, \widehat{\widetilde{\boldsymbol{\phi}}}(\omega). \tag{3.4}$$

Then, for even r, the difference in the number of antisymmetric components in $\widetilde{\boldsymbol{\phi}}$ and $\boldsymbol{\phi}$ is odd, and for odd r, this difference is even.

Proof. Let $\boldsymbol{P}^{(n)}(\omega)$ be the refinement mask of $\widetilde{\boldsymbol{\phi}}$ and $\boldsymbol{P}^{(n+1)}(\omega)$ the refinement mask of $\boldsymbol{\phi}$, and let $\boldsymbol{P}^{(n)}$ and $\boldsymbol{P}^{(n+1)}$ be related as in Algorithm 3.1, with $\boldsymbol{M}_{\boldsymbol{r}_n} := \boldsymbol{M}$. Then (3.4) is a consequence of Lemma 2.11. By Theorem 2.13 we have

$$\boldsymbol{M}(\omega) = -\boldsymbol{E}(\omega)\, \boldsymbol{M}(-\omega)\, \widetilde{\boldsymbol{E}}^{-1}(\omega), \tag{3.5}$$

where $\boldsymbol{E}(\omega)$, $\widetilde{\boldsymbol{E}}(\omega)$ are defined by the points of symmetry T_ν, $\widetilde{T}_\nu$ of ϕ_ν, $\widetilde{\phi}_\nu$ ($\nu = 0, \dots, r-1$) via (2.26), (2.27). Since $\boldsymbol{M}(\omega)$ satisfies the conditions of Algorithm 3.1, $\det \boldsymbol{M}(\omega)$ has a simple zero at $\omega = 0$ such that

$$f(e^{-i\omega}) := \det \boldsymbol{M}(\omega) = (1 - e^{-i\omega}) f_0(e^{-i\omega}), \quad f_0(1) \neq 0. \tag{3.6}$$

From (3.5), (2.26), and (2.27), it follows that

$$\begin{aligned} \det \boldsymbol{M}(\omega) = f(e^{-i\omega}) &= (-1)^r \det \boldsymbol{E}(\omega) \cdot \det \widetilde{\boldsymbol{E}}^{-1}(\omega) \cdot \det \boldsymbol{M}(-\omega) \\ &= e^{-2iT\omega} f(e^{i\omega}) (-1)^{N+r}, \end{aligned} \tag{3.7}$$

where $T = \sum_{\nu=0}^{r-1} (T_\nu - \widetilde{T}_\nu)$, and N is the difference in the number of antisymmetric functions in $\boldsymbol{\phi}$ and $\widetilde{\boldsymbol{\phi}}$. Let $z := e^{-i\omega}$; then by (3.6)

$$f(z) = (1 - z) f_0(z)$$

and by (3.7)

$$f(z) = z^{2T} (-1)^{N+r} f\left(\frac{1}{z}\right) = z^{2T} (-1)^{N+r} \left(1 - \frac{1}{z}\right) f_0\left(\frac{1}{z}\right).$$

Combining these two relations we find

$$(1 - z) f_0(z) = -(-1)^{N+r} z^{2T-1} (1 - z) f_0\left(\frac{1}{z}\right)$$

and hence

$$f_0(z) = (-1)^{N+r+1} z^{2T-1} f_0\left(\frac{1}{z}\right). \tag{3.8}$$

But (3.8) implies that, if $N + r + 1$ is odd, then $f_0(1) = 0$ and thus $D(\det \boldsymbol{M})(0) = 0$, which contradicts the assumptions. So $N + r + 1$ must be even and $N + r$ must be odd. ∎

3.2. Examples. In this final section, we employ Algorithm 3.1 for the construction of multiscaling functions with high approximation order and other desirable properties.

Example 1. In the first example, we are going to increase the approximation order of the refinement mask $\boldsymbol{P}^{(2)}(\omega)$ corresponding to the Geronimo–Hardin–Massopust (GHM) multiscaling function $\boldsymbol{\phi} := [\phi_0\ \phi_1]^{\mathrm{T}}$ (see Figure 1.1):

$$\boldsymbol{P}^{(2)}(\omega) = \frac{1}{20} \begin{bmatrix} 6 + 6e^{-i\omega} & 8\sqrt{2} \\ (-1 + 9e^{-i\omega} + 9e^{-2i\omega} - e^{-3i\omega})/\sqrt{2} & -3 + 10e^{-i\omega} - 3e^{-2i\omega} \end{bmatrix}.$$

The functions $\phi_0(t)$, $\phi_1(t)$ are continuous, symmetric, and provide second-order approximation. The integer translates $\phi_0(t-l)$, $\phi_1(t-l)$ ($l \in \mathbb{Z}$) are orthogonal. It is easy to see that a 1-eigenvector of $\boldsymbol{P}^{(2)}(0)$ is $\boldsymbol{r}_2 = [\sqrt{2}\ \ 1]^{\mathrm{T}}$:

$$\boldsymbol{P}^{(2)}(0)\boldsymbol{r}_2 = \frac{1}{20}\begin{bmatrix} 12 & 8\sqrt{2} \\ 8\sqrt{2} & 4 \end{bmatrix}\begin{bmatrix} \sqrt{2} \\ 1 \end{bmatrix} = \begin{bmatrix} \sqrt{2} \\ 1 \end{bmatrix}.$$

Let us apply one cycle of Algorithm 3.1 to $\boldsymbol{P}^{(2)}(\omega)$ with transformation matrix $\boldsymbol{M}_{\boldsymbol{r}_2}(\omega)$ preserving symmetry and ensuring short support. Then, $\boldsymbol{M}_{\boldsymbol{r}_2}(\omega)$ must satisfy the assumptions of Lemma 3.2 and the following relation:

$$\boldsymbol{M}_{\boldsymbol{r}_2}(\omega) = -\boldsymbol{E}(\omega)\,\boldsymbol{M}_{\boldsymbol{r}_2}(-\omega)\,\widetilde{\boldsymbol{E}}^{-1}(\omega) \tag{3.9}$$

(cf. Theorem 2.13). The first GHM scaling function is symmetric about $\widetilde{T}_0 = 1/2$, and the second is symmetric about $\widetilde{T}_1 = 1$; hence $\widetilde{\boldsymbol{E}}(\omega) = \operatorname{diag}(e^{-i\omega}, e^{-2i\omega})$. In order to get the supports of the new scaling functions as short as possible, we choose $T_0 = T_1 = 1$. Thus, let $\boldsymbol{E}(\omega) = \operatorname{diag}(-e^{-2i\omega}, e^{-2i\omega})$. We put

$$\boldsymbol{M}_{\boldsymbol{r}_2}(\omega) := \begin{bmatrix} 1+e^{-i\omega} & -2\sqrt{2} \\ 1-e^{-i\omega} & 0 \end{bmatrix};$$

then (3.9) is satisfied. Moreover,

$$\boldsymbol{M}_{\boldsymbol{r}_2}(0)\boldsymbol{r}_2 = \begin{bmatrix} 2 & -2\sqrt{2} \\ 0 & 0 \end{bmatrix}\begin{bmatrix} \sqrt{2} \\ 1 \end{bmatrix} = \boldsymbol{0},$$

$\det \boldsymbol{M}_{\boldsymbol{r}_2}(\omega) = 2\sqrt{2}(1-e^{-i\omega}) \neq 0$ for $\omega \neq 0$, $D(\det \boldsymbol{M}_{\boldsymbol{r}_2})(0) = i2\sqrt{2} \neq 0$, so $\boldsymbol{M}_{\boldsymbol{r}_2}(\omega)$ satisfies all conditions of Algorithm 3.1. $\boldsymbol{M}_{\boldsymbol{r}_2}(\omega)$ is a matrix of trigonometric polynomials and $\det \boldsymbol{M}_{\boldsymbol{r}_2}(\omega) = 2\sqrt{2}(1-e^{-i\omega})$ is linear in $z = e^{-i\omega}$, so by Lemma 3.2, finite support for the new scaling functions is ensured.

Now we perform step 3 of Algorithm 3.1 and compute $\boldsymbol{P}^{(3)}(\omega)$:

$$\begin{aligned}\boldsymbol{P}^{(3)}(\omega) &= \frac{1}{2}\boldsymbol{M}_{\boldsymbol{r}_2}(2\omega)\boldsymbol{P}^{(2)}(\omega)\boldsymbol{M}_{\boldsymbol{r}_2}^{-1}(\omega) \\ &= \frac{1}{40}\begin{bmatrix} -7+10e^{-i\omega}-7e^{-2i\omega} & 15(1-e^{-2i\omega}) \\ -4(1-e^{-2i\omega}) & 10(1+e^{-i\omega})^2 \end{bmatrix}.\end{aligned}$$

The resulting scaling functions are continuously differentiable and provide approximation order 3. They are plotted in Figure 3.1.

The mask $\boldsymbol{P}^{(3)}(\omega)$ corresponds to a dilation equation (1.1) with three matrix coefficients:

$$\boldsymbol{P}_0 = \frac{1}{40}\begin{bmatrix} -7 & 15 \\ -4 & 10 \end{bmatrix},\quad \boldsymbol{P}_1 = \frac{1}{40}\begin{bmatrix} 10 & 0 \\ 0 & 20 \end{bmatrix},\quad \boldsymbol{P}_2 = \frac{1}{40}\begin{bmatrix} -7 & -15 \\ 4 & 10 \end{bmatrix}.$$

We mention that the GHM dilation equation has four coefficients since GHM functions ϕ_0, ϕ_1 have different supports.

Observe that, in accordance with Lemma 3.3, one scaling function is symmetric and the other is antisymmetric. Moreover, the sum of the supports grows exactly by 1.

Unfortunately, the new functions are not orthogonal and for practical applications a biorthogonal multiscaling function should be constructed [DM, SS4].

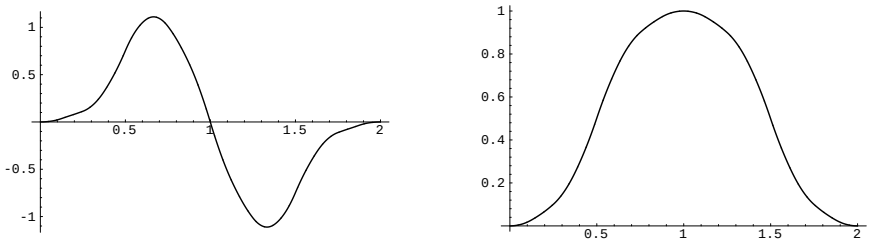

FIG. 3.1. *Symmetric multiscaling function with approximation order* 3.

Example 2. In the second example, we construct polynomial, symmetric multiscaling functions with two components, short support, and arbitrarily high approximation order. Let us start with the function vector $\boldsymbol{\phi}_2 := [\phi_{2,0}\ \phi_{2,1}]^{\mathrm{T}}$,

$$\phi_{2,0}(t) := \chi_{[0,1]}, \qquad \phi_{2,1}(t) := (1-2t)\,\chi_{[0,1]},$$

where $\chi_{[0,1]}$ denotes the characteristic function of $[0,\,1]$. The index 2 in $\boldsymbol{\phi}_2$ denotes the approximation order 2 provided by $\boldsymbol{\phi}_2$. Observe that both $\phi_{2,0}$ and $\phi_{2,1}$ are piecewise polynomials, but discontinuous; $\phi_{2,0}(1/2+t) = \phi_{2,0}(1/2-t)$ and $\phi_{2,1}(1/2+t) = -\phi_{2,1}(1/2-t)$. The vector $\boldsymbol{\phi}_2$ has the refinement mask

$$\boldsymbol{P}^{(2)}(\omega) := \frac{1}{4}\begin{bmatrix} 2+2z & 0 \\ 1-z & 1+z \end{bmatrix} \qquad (z := e^{-i\omega}),$$

with 1-eigenvector $\boldsymbol{r}_2 := [1\ \ 0]^{\mathrm{T}}$

$$\boldsymbol{P}^{(2)}(0)\,\boldsymbol{r}_2 = \frac{1}{4}\begin{bmatrix} 4 & 0 \\ 0 & 2 \end{bmatrix}\begin{bmatrix} 1 \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}.$$

We want to apply to $\boldsymbol{P}^{(2)}(\omega)$ one cycle of Algorithm 3.1 with a suitable transformation matrix $\boldsymbol{M}_{\boldsymbol{r}_2}(\omega)$ which preserves symmetry and short support. We try to find $\boldsymbol{M}_{\boldsymbol{r}_2}(\omega)$ satisfying the assumptions of Lemma 3.2 and such that

$$\boldsymbol{M}_{\boldsymbol{r}_2}(\omega) = -\operatorname{diag}(e^{-i\omega},\, e^{-2i\omega})\,\boldsymbol{M}_{\boldsymbol{r}_2}(-\omega)\,\operatorname{diag}(e^{-i\omega},\, -e^{-i\omega}).$$

Letting

$$\boldsymbol{M}_{\boldsymbol{r}_2}(\omega) := \begin{bmatrix} 0 & 2 \\ 1-z & -1-z \end{bmatrix} \quad (z = e^{-i\omega}),$$

we obtain, by applying Algorithm 3.1,

$$\boldsymbol{P}^{(3)}(\omega) = \frac{1}{2}\,\boldsymbol{M}_{\boldsymbol{r}_2}(2\omega)\,\boldsymbol{P}_2(\omega)\,\boldsymbol{M}_{\boldsymbol{r}_2}(\omega)^{-1} = \frac{1}{8}\begin{bmatrix} 2(1+z) & 2 \\ 2z(1+z) & 1+4z+z^2 \end{bmatrix}.$$

The corresponding compactly supported function vector $\boldsymbol{\phi}_3 = [\phi_{3,0}\ \phi_{3,1}]^{\mathrm{T}}$ provides approximation order 3, since $\boldsymbol{M}_{\boldsymbol{r}_2}(\omega)$ satisfies all assumptions of Theorem 2.7. We

easily observe that

$$\phi_{3,0}(t) = \begin{cases} 2t(1-t) & t \in [0,1], \\ 0 & \text{otherwise}, \end{cases}$$
$$\phi_{3,1}(t) = \begin{cases} t^2 & t \in [0,1], \\ (2-t)^2 & t \in [1,2], \\ 0 & \text{otherwise}. \end{cases}$$

In particular, $\phi_{3,0}$ and $\phi_{3,1}$ are continuous functions. (This can also be seen by Corollary 2.10.)

Now we apply a second cycle of Algorithm 3.1 to $\boldsymbol{P}^{(3)}(\omega)$ in order to get a symmetric vector $\boldsymbol{\phi}_4$ of scaling functions $\phi_{4,0}$, $\phi_{4,1}$ with short support and approximation order 4. Observe that $\boldsymbol{P}^{(3)}(0)\,\boldsymbol{r}_3 = \boldsymbol{r}_3$ with $\boldsymbol{r}_3 := [1 \quad 2]^{\mathrm{T}}$, so the transformation matrix

$$\boldsymbol{M}_{\boldsymbol{r}_3}(\omega) := 3 \begin{bmatrix} 1-z & 0 \\ 1+z & -1 \end{bmatrix} \quad (z = e^{-i\omega})$$

satisfies the assumptions of Lemma 3.2, and we have

$$\boldsymbol{M}_{\boldsymbol{r}_3}(\omega) = -\operatorname{diag}(e^{-2i\omega}, -e^{-2i\omega})\, \boldsymbol{M}_{\boldsymbol{r}_3}(-\omega)\, \operatorname{diag}(e^{-i\omega}, e^{-2i\omega}).$$

We construct

$$\begin{aligned} \boldsymbol{P}^{(4)}(\omega) &= \frac{1}{2}\, \boldsymbol{M}_{\boldsymbol{r}_3}(2\omega)\, \boldsymbol{P}^{(3)}(\omega)\, \boldsymbol{M}_{\boldsymbol{r}_3}(\omega)^{-1} \\ &= \frac{1}{16} \begin{bmatrix} 4(1+z)^2 & -2(1-z)(1+z) \\ 3(1-z)(1+z) & -1+4z-z^2 \end{bmatrix}. \end{aligned}$$

The corresponding (compactly supported) functions $\phi_{4,0}$ and $\phi_{4,1}$ are again piecewise polynomials:

$$\phi_{4,0}(t) = \begin{cases} (-2t^3+3t^2) & t \in [0,1), \\ (2-t)^2\,(2t-1) & t \in [1,2], \\ 0 & \text{otherwise}, \end{cases}$$
$$\phi_{4,1}(t) = \begin{cases} t^2(3t-3) & t \in [0,1), \\ (2-t)^2\,(-3t-3) & t \in [1,2], \\ 0 & \text{otherwise}. \end{cases}$$

The functions $\phi_{4,0}$ and $\phi_{4,1}$ are symmetric, continuously differentiable functions. Note that $\phi_{4,0}$, $\phi_{4,1}$ are finite element functions studied in [SS3]. They are presented in Figure 3.2. Obviously, functions $\phi_{4,0}$ and $\phi_{4,1}$ are not orthogonal. For the construction of dual scaling functions and wavelets see [DM, SS4].

The procedure can be repeated as follows. Take

$$\boldsymbol{M}_{\boldsymbol{r}_{2k}}(\omega) := \begin{bmatrix} 0 & 2 \\ 1-z & -1-z \end{bmatrix} \qquad (k \in \mathbb{N},\ z = e^{-i\omega})$$

and

$$\boldsymbol{M}_{\boldsymbol{r}_{2k+1}}(\omega) := (2k+1) \begin{bmatrix} (1-z)/k & 0 \\ (1+z)/k & -2/(k+1) \end{bmatrix} \qquad (k \in \mathbb{N},\ z = e^{-i\omega})$$

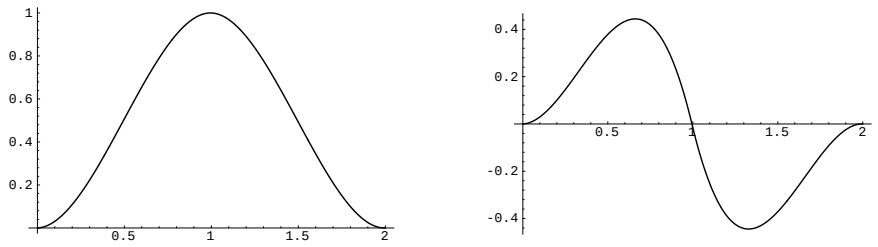

FIG. 3.2. *Polynomial multiscaling function with approximation order* 4.

and apply Algorithm 3.1 repeatedly with these transformation matrices. The refinement mask $\boldsymbol{P}^{(n)}$ ($n \in \mathbb{N}$; $n \geq 3$) then provides approximation order n; the corresponding multiscaling functions $\phi_{n,0}$ and $\phi_{n,1}$ are $(n-3)$-times continuously differentiable. If $n = 2k+1$ ($k \geq 1$), the corresponding multiscaling functions $\phi_{2k+1,0}$ and $\phi_{2k+1,1}$ are nothing but polynomial B-splines of order $2k+1$ with double knots, defined by the spline knots $0, 0, 1, 1, \ldots, k, k$ and $0, 1, 1, 2, 2, \ldots, k, k, k+1$, respectively. (This follows from a comparison with known recursion formulas for the refinement mask of B-splines vectors with multiple knots [P1, P2, P4]). In particular, $\operatorname{supp} \phi_{2k+1,0} = [0, k]$, $\operatorname{supp} \phi_{2k+1,1} = [0,\, k+1]$, and

$$\phi_{2k+1,0}(t) = \phi_{2k+1,0}(k-t), \qquad \phi_{2k+1,1}(t) = \phi_{2k+1,1}(k+1-t).$$

If $n = 2k$ ($k \geq 1$), the corresponding multiscaling functions $\phi_{2k,0}$ and $\phi_{2k,1}$ are nothing but polynomial B-splines of order $2k$, defined as the sum and the difference of the B-splines $N_{2k,0}$, $N_{2k,1}$ of order $2k$ with double knots, respectively. In other words, if $N_{2k,0}$ and $N_{2k,1}$ are defined by the spline knots $0, 0, \ldots, k-1, k-1, k$ and $0, 1, 1, \ldots, k-1, k, k$, then $\phi_{2k,0} = N_{2k,0} + N_{2k,1}$ and $\phi_{2k,1} = N_{2k,0} - N_{2k,1}$. In particular, $\operatorname{supp} \phi_{2k,0} = \operatorname{supp} \phi_{2k,1} = [0,\, k]$ and

$$\phi_{2k,0}(t) = \phi_{2k,0}(k-t), \qquad \phi_{2k,1}(t) = -\phi_{2k,1}(k-t).$$

Remark. For $r = 1$, the refinement mask $\boldsymbol{P}(\omega) = 2^{-m}(1+e^{-i\omega})^m$ determines the cardinal B-spline N_m of order m. Let $x_l := \lfloor l/r \rfloor$ ($l \in \mathbb{Z}$), where $\lfloor x \rfloor$ means the integer part of $x \in \mathbb{R}$. Then, the refinement mask

$$\boldsymbol{P}_m^r(\omega) := \frac{1}{2^m}\, \boldsymbol{C}_{\boldsymbol{x}_{m-1}}(2\omega) \cdots \boldsymbol{C}_{\boldsymbol{x}_0}(\omega)\, \boldsymbol{P}^{(0)}\, \boldsymbol{C}_{\boldsymbol{x}_0}(\omega)^{-1} \cdots \boldsymbol{C}_{\boldsymbol{x}_{m-1}}(\omega)^{-1}$$

with $\boldsymbol{C}_{\boldsymbol{x}_k}$ defined by the vector $\boldsymbol{x}_k := (x_{k+1}, \ldots, x_{k+r})^{\mathrm{T}}$ ($k = 0, \ldots m-1$) and

$$\boldsymbol{P}^{(0)} := \operatorname{diag}\left(2^{r-1}, \ldots, 2^0\right)$$

determines the vector of cardinal B-splines with r-fold knots [P1, P2, P4].

4. Proof of Theorem 2.6. Before starting the proof of Theorem 2.6 let us show some preliminary assertions. For a given $\widetilde{\boldsymbol{P}} \in C_{2\pi}^m(\mathbb{R}^{r\times r})$ and a nonzero vector $\boldsymbol{y} \in \mathbb{R}$, let the $r \times r$ matrix $\boldsymbol{P} \in C_{2\pi}^m(\mathbb{R}^{r\times r})$ be defined by

$$\boldsymbol{P}(\omega) = \frac{1}{2} \boldsymbol{C}_{\boldsymbol{y}}(2\omega)\, \widetilde{\boldsymbol{P}}(\omega)\, \boldsymbol{C}_{\boldsymbol{y}}(\omega)^{-1},$$

where $\boldsymbol{C_y}(\omega)$ is defined by $\boldsymbol{y}$ via (2.6)–(2.7). Hence, we have by (2.9)

$$(1-e^{-i\omega})\,\boldsymbol{G_y}(2\omega)\,\boldsymbol{P}(\omega)=\frac{1}{2}\,(1-e^{-2i\omega})\,\widetilde{\boldsymbol{P}}(\omega)\,\boldsymbol{G_y}(\omega),$$

i.e.,

$$\boldsymbol{G_y}(2\omega)\,\boldsymbol{P}(\omega)=\left(\frac{1+e^{-i\omega}}{2}\right)\,\widetilde{\boldsymbol{P}}(\omega)\,\boldsymbol{G_y}(\omega). \tag{4.1}$$

In the next lemma we compute $\boldsymbol{G_y}(2\omega)\,(\mathrm{D}^k\boldsymbol{P})(\omega)$ in terms of derivatives of $\widetilde{\boldsymbol{P}}(\omega)$ and lower derivatives of $\boldsymbol{P}(\omega)$.

LEMMA 4.1. *We have, for* $k\in\mathbb{N}$,

$$\begin{aligned}&\boldsymbol{G_y}(2\omega)\,(D^k\boldsymbol{P})(\omega)\\&=-\sum_{l=1}^{k}\binom{k}{l}2^l\,(D^l\boldsymbol{G_y})(2\omega)\,(D^{k-l}\boldsymbol{P})(\omega)+\left(\frac{1+e^{-i\omega}}{2}\right)\,(D^k\widetilde{\boldsymbol{P}})(\omega)\boldsymbol{G_y}(\omega)\\&+\frac{1}{2}\sum_{l=1}^{k}\binom{k}{l}(D^{k-l}\widetilde{\boldsymbol{P}})(\omega)\,(-i)^{l-1}\,\left([(2^l-1)e^{-i\omega}+1](D\boldsymbol{G_y})(\omega)-ie^{-i\omega}\,\boldsymbol{G_y}(\omega)\right).\end{aligned}$$

In particular,

$$\begin{aligned}\boldsymbol{G_y}(0)\,(D^k\boldsymbol{P})(0)&=-\sum_{l=1}^{k}\binom{k}{l}2^l\,(D^l\boldsymbol{G_y})(0)\,(D^{k-l}\boldsymbol{P})(0)+(D^k\widetilde{\boldsymbol{P}})(0)\,\boldsymbol{G_y}(0)\\&\quad+\frac{1}{2}\sum_{l=1}^{k}\binom{k}{l}(D^{k-l}\widetilde{\boldsymbol{P}})(0)\,(-i)^l\,[\boldsymbol{G_y}(0)+2^li(D\boldsymbol{G_y})(0)]\end{aligned}$$

and

$$\begin{aligned}\boldsymbol{G_y}(0)\,(D^k\boldsymbol{P})(\pi)&=-\sum_{l=1}^{k}\binom{k}{l}2^l\,(D^l\boldsymbol{G_y})(0)\,(D^{k-l}\boldsymbol{P})(\pi)\\&+\frac{1}{2}\sum_{l=1}^{k}\binom{k}{l}(D^{k-l}\widetilde{\boldsymbol{P}})(\pi)\,(-i)^l\,[-\boldsymbol{G_y}(\pi)-(2^l-2)i(D\boldsymbol{G_y})(\pi)].\end{aligned}$$

Proof. From (4.1) it follows by differentiation that

$$\begin{aligned}&\sum_{l=0}^{k}\binom{k}{l}2^l(\mathrm{D}^l\boldsymbol{G_y})(2\omega)\,(\mathrm{D}^{k-l}\boldsymbol{P})(\omega)\\&=\sum_{l=0}^{k}\binom{k}{l}(\mathrm{D}^{k-l}\widetilde{\boldsymbol{P}})(\omega)\,\mathrm{D}^l\left(\left(\frac{1+e^{-i\cdot}}{2}\right)\boldsymbol{G_y}\right)(\omega).\end{aligned} \tag{4.2}$$

Observing that

$$\mathrm{D}^s\left(\frac{1+e^{-i\cdot}}{2}\right)(\omega)=\begin{cases}\frac{1+e^{-i\omega}}{2} & \text{for } s=0,\\ \frac{(-i)^s}{2}\,e^{-i\omega} & \text{for } s\geq 1\end{cases}$$

and

$$(\mathrm{D}^s \boldsymbol{G_y})(\omega) = \begin{cases} \boldsymbol{G_y}(\omega) & \text{for } s = 0, \\ (-i)^{s-1}\,(\mathrm{D}\boldsymbol{G_y})(\omega) & \text{for } s \geq 1, \end{cases} \tag{4.3}$$

it follows for $l > 0$ that

$$\begin{aligned} &\mathrm{D}^l \left(\left(\frac{1+e^{-i\cdot}}{2} \right) \boldsymbol{G_y} \right)(\omega) = \sum_{s=0}^{l} \binom{l}{s} \mathrm{D}^s \left(\frac{1+e^{-i\cdot}}{2} \right)(\omega)\, (\mathrm{D}^{l-s}\boldsymbol{G_y})(\omega) \\ &= \left(\frac{1+e^{-i\omega}}{2} \right) (-i)^{l-1}\,(\mathrm{D}\boldsymbol{G_y})(\omega) + \frac{(-i)^l}{2}\, e^{-i\omega}\, \boldsymbol{G_y}(\omega) \\ &\quad + \frac{e^{-i\omega}}{2} \sum_{s=1}^{l-1} \binom{l}{s} (-i)^{l-1}\,(\mathrm{D}\boldsymbol{G_y})(\omega) \\ &= \frac{(-i)^{l-1}}{2}\,(\mathrm{D}\boldsymbol{G_y})(\omega)\, \left((1+e^{-i\omega}) + e^{-i\omega}(2^l-2) \right) + \frac{(-i)^l}{2}\, e^{-i\omega}\, \boldsymbol{G_y}(\omega) \\ &= \frac{(-i)^{l-1}}{2} \left((2^l-1)e^{-i\omega} + 1 \right) (\mathrm{D}\boldsymbol{G_y})(\omega) + \frac{(-i)^l}{2}\, e^{-i\omega}\, \boldsymbol{G_y}(\omega). \end{aligned}$$

Hence,

$$\begin{aligned} &\sum_{l=0}^{k} \binom{k}{l} (\mathrm{D}^{k-l}\widetilde{\boldsymbol{P}})(\omega)\, \mathrm{D}^l \left(\left(\frac{1+e^{-i\cdot}}{2} \right) \boldsymbol{G_y} \right)(\omega) \\ &= \left(\frac{1+e^{-i\omega}}{2} \right) (\mathrm{D}^k \widetilde{\boldsymbol{P}})(\omega)\, \boldsymbol{G_y}(\omega) \\ &\quad + \frac{1}{2} \sum_{l=1}^{k} \binom{k}{l} (\mathrm{D}^{k-l}\widetilde{\boldsymbol{P}})(\omega)\, (-i)^{l-1} \left([(2^l-1)e^{-i\omega}+1]\,(\mathrm{D}\boldsymbol{G_y})(\omega) - ie^{-i\omega}\, \boldsymbol{G_y}(\omega) \right). \end{aligned}$$

Together with (4.2) the assertion of Lemma 4.1 follows. □

Proof of Theorem 2.6. By (2.18) for $k = 0$ we have $\boldsymbol{y}_0^{\mathrm{T}} = \widetilde{\boldsymbol{y}}_0^{\mathrm{T}}\, \boldsymbol{G_y}(0) = \widetilde{\boldsymbol{y}}_0^{\mathrm{T}}\, \boldsymbol{e}\, \boldsymbol{y}^{\mathrm{T}}$, where $\boldsymbol{e}$ corresponds to $\boldsymbol{y}$ via (2.10). Further, note that $\widetilde{\boldsymbol{P}}(0)\, \boldsymbol{e} = \boldsymbol{e}$ implies

$$\widetilde{\boldsymbol{P}}(0)\, \boldsymbol{G_y}(0) = \boldsymbol{G_y}(0). \tag{4.4}$$

By assumption, $\widetilde{\boldsymbol{P}}$ satisfies the conditions (2.1)–(2.2) for $n = 0, \ldots, m-1$ with $\widetilde{\boldsymbol{y}}_0, \ldots, \widetilde{\boldsymbol{y}}_{m-1}$. Hence, we get

$$\begin{aligned} &\frac{2^k}{2^k-1} \sum_{l=0}^{k-1} \binom{k}{l} (2i)^{l-k}\, \widetilde{\boldsymbol{y}}_l^{\mathrm{T}}\, (\mathrm{D}^{k-l}\widetilde{\boldsymbol{P}})(0)\, \boldsymbol{G_y}(0) \\ &= \frac{2^k}{2^k-1} \left(\frac{1}{2^k}\, \widetilde{\boldsymbol{y}}_k^{\mathrm{T}}\, \boldsymbol{E}(0) - \widetilde{\boldsymbol{y}}_k^{\mathrm{T}}\, \widetilde{\boldsymbol{P}}(0)\, \boldsymbol{E}(0) \right) = -\widetilde{\boldsymbol{y}}_k^{\mathrm{T}}\, \boldsymbol{E}(0) \end{aligned}$$

such that $\boldsymbol{y}_k^{\mathrm{T}}$ defined in (2.18)–(2.19) can be represented for $k = 0, \ldots, m$ in the form

$$\begin{aligned} \boldsymbol{y}_k^{\mathrm{T}} &= (-ik)\widetilde{\boldsymbol{y}}_{k-1}^{\mathrm{T}}\, (\mathrm{D}\boldsymbol{G_y})(0) + \sum_{l=0}^{k-1} \binom{k}{l} \widetilde{B}_{k-l}\, \widetilde{\boldsymbol{y}}_l^{\mathrm{T}}\, \boldsymbol{G_y}(0) \\ &\quad - \frac{2^k}{2^k-1} \sum_{l=0}^{k-1} \binom{k}{l} (2i)^{l-k}\, \widetilde{\boldsymbol{y}}_l^{\mathrm{T}}\, (\mathrm{D}^{k-l}\widetilde{\boldsymbol{P}})(0)\, \boldsymbol{E}(0). \end{aligned} \tag{4.5}$$

1. We have to show that $\boldsymbol{P}(\omega)$ satisfies equations (2.1)–(2.2) for $n = 0, \dots, m$ with $\boldsymbol{y}_0, \dots, \boldsymbol{y}_m$. That means, by (2.18) and (4.5), we have to show that for $n = 0, \dots, m$

$$\boldsymbol{A}_n(0) + \boldsymbol{B}_n(0) + \boldsymbol{C}_n(0) + \boldsymbol{D}_n(0) = 2^{-n}\, \boldsymbol{y}_n^{\mathrm{T}}$$

and

$$\boldsymbol{A}_n(\pi) + \boldsymbol{B}_n(\pi) + \boldsymbol{C}_n(\pi) + \boldsymbol{D}_n(\pi) = \boldsymbol{0}^{\mathrm{T}}$$

are satisfied with

$$\begin{aligned}
\boldsymbol{A}_n(\omega) &:= \sum_{l=0}^{n} \binom{n}{l} (2i)^{l-n}\, (-il)\, \widetilde{\boldsymbol{y}}_{l-1}^{\mathrm{T}}\, (\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0)\, (\mathrm{D}^{n-l}\boldsymbol{P})(\omega),\\
\boldsymbol{B}_n(\omega) &:= \sum_{l=0}^{n-1} \binom{n}{l} (2i)^{l-n} \sum_{s=0}^{l} \binom{l}{s} \widetilde{B}_{l-s}\, \widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\, \boldsymbol{G}\boldsymbol{y}(0)\, (\mathrm{D}^{n-l}\boldsymbol{P})(\omega),\\
\boldsymbol{C}_n(\omega) &:= \sum_{s=0}^{n-1} \binom{n}{s} \widetilde{B}_{n-s}\, \widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\, \boldsymbol{G}\boldsymbol{y}(0)\, \boldsymbol{P}(\omega),\\
\boldsymbol{D}_n(\omega) &:= -\frac{2^n}{2^n - 1} \sum_{s=0}^{n-1} \binom{n}{s} (2i)^{s-n}\, \widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\, (\mathrm{D}^{n-s}\widetilde{\boldsymbol{P}})(0)\, \boldsymbol{G}\boldsymbol{y}(0)\, \boldsymbol{P}(\omega).
\end{aligned}$$

For $\omega = 0$ and $\omega = \pi$, we replace $\boldsymbol{G}\boldsymbol{y}(0)\, (\mathrm{D}^{n-l}\boldsymbol{P})(\omega)$ in $\boldsymbol{B}_n(\omega)$ by the corresponding expressions given in Lemma 4.1 and obtain

$$\boldsymbol{B}_n(\omega) = \boldsymbol{B}_n^0(\omega) + \boldsymbol{B}_n^1(\omega) + \boldsymbol{B}_n^2(\omega)$$

with

$$\begin{aligned}
\boldsymbol{B}_n^0(\omega) &:= -\sum_{l=0}^{n-1} \binom{n}{l} (2i)^{l-n} \sum_{s=0}^{l} \binom{l}{s} \widetilde{B}_{l-s}\, \widetilde{\boldsymbol{y}}_s^{\mathrm{T}} \sum_{r=1}^{n-l} \binom{n-l}{r} 2^r\, (\mathrm{D}^r \boldsymbol{G}\boldsymbol{y})(0)\\
&\quad \times (\mathrm{D}^{n-l-r}\boldsymbol{P})(\omega),\\
\boldsymbol{B}_n^1(\omega) &:= \left(\frac{1 + e^{-i\omega}}{2}\right) \sum_{l=0}^{n-1} \binom{n}{l} (2i)^{l-n} \sum_{s=0}^{l} \binom{l}{s} \widetilde{B}_{l-s}\, \widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\, (\mathrm{D}^{n-l}\widetilde{\boldsymbol{P}})(\omega)\, \boldsymbol{G}\boldsymbol{y}(\omega),\\
\boldsymbol{B}_n^2(\omega) &:= \frac{1}{2} \sum_{l=0}^{n-1} \binom{n}{l} (2i)^{l-n} \sum_{s=0}^{l} \binom{l}{s} \widetilde{B}_{l-s}\, \widetilde{\boldsymbol{y}}_s^{\mathrm{T}} \sum_{r=1}^{n-l} \binom{n-l}{r} (\mathrm{D}^{n-l-r}\widetilde{\boldsymbol{P}})(\omega)\, (-i)^{r-1}\\
&\quad \times \left([(2^r - 1)e^{-i\omega} + 1](\mathrm{D}\boldsymbol{G}\boldsymbol{y})(\omega) - ie^{-i\omega}\, \boldsymbol{G}\boldsymbol{y}(\omega) \right).
\end{aligned}$$

2. First we show that for $\omega = 0$ and $\omega = \pi$,

$$\boldsymbol{A}_n(\omega) + \boldsymbol{B}_n^0(\omega) = \boldsymbol{0}^{\mathrm{T}}.$$

Note that $\binom{n}{s}\binom{n-s}{l-s} = \binom{n}{l}\binom{l}{s}$. Changing the order of summation over l and s and putting $r' := n - l - r$, it follows that

$$\begin{aligned}
\boldsymbol{B}_n^0(\omega) &= (-i) \sum_{s=0}^{n-1} \binom{n}{s} \widetilde{\boldsymbol{y}}_s^{\mathrm{T}} \sum_{l=s}^{n-1} \binom{n-s}{l-s} (2i)^{l-n}\, \widetilde{B}_{l-s} \sum_{r=1}^{n-l} \binom{n-l}{r} 2^r\\
&\quad \times (\mathrm{D}^r \boldsymbol{G}\boldsymbol{y})(0)\, (\mathrm{D}^{n-l-r}\boldsymbol{P})(\omega)
\end{aligned}$$

$$= (-i)\sum_{s=0}^{n-1}\binom{n}{s}\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\sum_{l=s}^{n-1}\binom{n-s}{l-s}(2i)^{l-n}\,\widetilde{B}_{l-s}\sum_{r'=0}^{n-l-1}\binom{n-l}{r'}(-2i)^{n-l-r'}$$
$$\times(\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0)\,(\mathrm{D}^{r'}\boldsymbol{P})(\omega),$$

where we have used that $(\mathrm{D}^r\boldsymbol{G}\boldsymbol{y})(0) = (-i)^{r-1}\,(\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0) = (-i)^{n-l-r'+1}\,(\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0)$ (see (4.3)). Thus,

$$\begin{aligned}\boldsymbol{B}_n^0(\omega) &= (-i)\sum_{s=0}^{n-1}\binom{n}{s}\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\sum_{l=0}^{n-s-1}\binom{n-s}{l}(2i)^{l+s-n}\,\widetilde{B}_l\sum_{r=0}^{n-l-s-1}\binom{n-l-s}{r}\\ &\quad\times(-2i)^{n-l-s-r}\,(\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0)\,(\mathrm{D}^r\boldsymbol{P})(\omega)\\ &= (-i)\sum_{s=0}^{n-1}\binom{n}{s}\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\sum_{r=0}^{n-s-1}\binom{n-s}{r}(\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0)\,(\mathrm{D}^r\boldsymbol{P})(\omega)(2i)^{-r}(-1)^{n-s-r}\\ &\quad\times\sum_{l=0}^{n-r-s-1}\binom{n-r-s}{l}\widetilde{B}_l\,(-1)^l.\end{aligned}$$

Observe that, by (2.16),

$$\sum_{l=0}^{k-1}\binom{k}{l}\widetilde{B}_l\,(-1)^l = \begin{cases}0 & \text{for } k>1,\\ 1 & \text{for } k=1.\end{cases} \tag{4.6}$$

Hence, the last term in the last representation of $\boldsymbol{B}_n^0$ vanishes for $n-s-1\neq r$, and so

$$\boldsymbol{B}_n^0(\omega) = i\sum_{s=0}^{n-1}\binom{n}{s}(n-s)\,\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\,(\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0)\,(\mathrm{D}^{n-s-1}\boldsymbol{P})(\omega)\,(2i)^{-n+s+1}.$$

Shifting the summation index, we find for $\boldsymbol{A}_n(\omega)$ $(\omega = 0,\,\pi)$

$$\begin{aligned}\boldsymbol{A}_n(\omega) &= (-i)\sum_{l=0}^{n-1}\binom{n}{l+1}(2i)^{l+1-n}\,(l+1)\,\widetilde{\boldsymbol{y}}_l^{\mathrm{T}}\,(\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0)\,(\mathrm{D}^{n-l+1}\boldsymbol{P})(\omega)\\ &= (-i)\sum_{l=0}^{n-1}\binom{n}{l}(n-l)\widetilde{\boldsymbol{y}}_l^{\mathrm{T}}\,(\mathrm{D}\boldsymbol{E})(0)\,(\mathrm{D}^{n-l-1}\boldsymbol{P})(\omega)\,(2i)^{-n+l+1}.\end{aligned}$$

Hence, $\boldsymbol{B}_n^0(\omega)+\boldsymbol{A}_n(\omega) = \boldsymbol{0}^{\mathrm{T}}$ for $\omega = 0,\ \pi$.

3. Let us consider $\boldsymbol{B}_n^1(\omega)$. We easily observe that $\boldsymbol{B}_n^1(\pi) = \boldsymbol{0}^{\mathrm{T}}$. For $\omega = 0$, we find by changing the order of summations over l and s that

$$\begin{aligned}\boldsymbol{B}_n^1(0) &= \sum_{l=0}^{n-1}\binom{n}{l}(2i)^{l-n}\sum_{s=0}^{l}\binom{l}{s}\widetilde{B}_{l-s}\,\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\,(D^{n-l}\widetilde{\boldsymbol{P}})(0)\,\boldsymbol{G}\boldsymbol{y}(0)\\ &= \sum_{s=0}^{n-1}\binom{n}{s}\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\sum_{l=s}^{n-1}\binom{n-s}{l-s}(2i)^{l-n}\,\widetilde{B}_{l-s}\,(\mathrm{D}^{n-l}\widetilde{\boldsymbol{P}})(0)\,\boldsymbol{G}\boldsymbol{y}(0)\\ &= \sum_{s=0}^{n-1}\binom{n}{s}\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\sum_{l=0}^{n-s-1}\binom{n-s}{l}(2i)^{l+s-n}\,\widetilde{B}_l\,(\mathrm{D}^{n-s-l}\widetilde{\boldsymbol{P}})(0)\,\boldsymbol{G}\boldsymbol{y}(0)\\ &= \sum_{l=0}^{n-1}\binom{n}{l}\widetilde{B}_l\sum_{s=0}^{n-1-l}\binom{n-l}{s}(2i)^{-n+l+s}\,\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\,(\mathrm{D}^{n-l-s}\boldsymbol{P})(0)\,\boldsymbol{G}\boldsymbol{y}(0).\end{aligned}$$

On the other hand, for $l > 1$, the equations (2.1) for $\widetilde{\boldsymbol{P}}$ and $\widetilde{\boldsymbol{y}}_n$ $(n = 0, \dots, m-1)$ imply that

$$\begin{aligned}&\sum_{s=0}^{n-1-l} \binom{n-l}{s} (2i)^{-n+l+s}\, \widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\, (\mathrm{D}^{n-l-s}\widetilde{\boldsymbol{P}})(0)\, \boldsymbol{G}\boldsymbol{y}(0)\\ &= 2^{-n+l}\, \widetilde{\boldsymbol{y}}_{n-l}^{\mathrm{T}}\, \boldsymbol{G}\boldsymbol{y}(0) - \widetilde{\boldsymbol{y}}_{n-l}^{\mathrm{T}}\, \widetilde{\boldsymbol{P}}(0)\, \boldsymbol{G}\boldsymbol{y}(0) = (2^{-n+l}-1)\widetilde{\boldsymbol{y}}_{n-l}^{\mathrm{T}}\, \boldsymbol{G}\boldsymbol{y}(0),\end{aligned}$$

where we have used (4.4). Hence, we can write

$$\begin{aligned}\boldsymbol{B}_n^1(0) = &\sum_{l=1}^{n-1} \binom{n}{l} \widetilde{B}_l\, (2^{-n+l}-1)\, \widetilde{\boldsymbol{y}}_{n-l}^{\mathrm{T}}\, \boldsymbol{G}\boldsymbol{y}(0)\\ &+ \sum_{s=0}^{n-1} \binom{n}{s} \widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\, (2i)^{-n+s}\, (\mathrm{D}^{n-s}\widetilde{\boldsymbol{P}})(0)\, \boldsymbol{G}\boldsymbol{y}(0).\end{aligned} \tag{4.7}$$

4. Let us concentrate on $\boldsymbol{B}_n^2(\omega)$. Putting

$$\widetilde{\boldsymbol{E}}_r(\omega) := \frac{(-i)^{r-1}}{2}\, \left[[(2^r-1)e^{-i\omega}+1](\mathrm{D}\boldsymbol{G}\boldsymbol{y})(\omega) - ie^{-i\omega}\, \boldsymbol{G}\boldsymbol{y}(\omega)\right)$$

we obtain, for $\omega = 0, \pi$ by changing the order of summations and shifting the summation indices

$$\begin{aligned}\boldsymbol{B}_n^2(\omega) &= \sum_{l=0}^{n-1} \binom{n}{l} (2i)^{l-n} \sum_{s=0}^{l} \binom{l}{s} \widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\, \widetilde{B}_{l-s} \sum_{r=1}^{n-l} \binom{n-l}{r} (\mathrm{D}^{n-l-r}\widetilde{\boldsymbol{P}})(\omega)\, \widetilde{\boldsymbol{E}}_r(\omega)\\
&= \sum_{s=0}^{n-1} \binom{n}{s} \widetilde{\boldsymbol{y}}_s^{\mathrm{T}} \sum_{l=s}^{n-1} \binom{n-s}{l-s} (2i)^{l-n}\, \widetilde{B}_{l-s} \sum_{r=1}^{n-l} \binom{n-l}{r} (\mathrm{D}^{n-l-r}\widetilde{\boldsymbol{P}})(\omega)\, \widetilde{\boldsymbol{E}}_r(\omega)\\
&= \sum_{s=0}^{n-1} \binom{n}{s} \widetilde{\boldsymbol{y}}_s^{\mathrm{T}} \sum_{l=0}^{n-s-1} \binom{n-s}{l} (2i)^{l+s-n}\, \widetilde{B}_l \sum_{r=1}^{n-l-s} \binom{n-l-s}{r}\\
&\quad \times (\mathrm{D}^{n-l-s-r}\widetilde{\boldsymbol{P}})(\omega)\, \widetilde{\boldsymbol{E}}_r(\omega)\\
&= \sum_{l=0}^{n-1} \binom{n}{l} \widetilde{B}_l \sum_{s=0}^{n-l-1} \binom{n-l}{s} \widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\, (2i)^{l+s-n} \sum_{r=1}^{n-l-s} \binom{n-l-s}{r} (\mathrm{D}^{n-l-s-r}\widetilde{\boldsymbol{P}})(\omega)\, \widetilde{\boldsymbol{E}}_r(\omega)\\
&= \sum_{l=0}^{n-1} \binom{n}{l} \widetilde{B}_l \sum_{r=1}^{n-l} \binom{n-l}{r} \left(\sum_{s=0}^{n-l-r} \binom{n-l-r}{s} \widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\, (2i)^{-n+l+r+s}\, (\mathrm{D}^{n-l-r-s}\widetilde{\boldsymbol{P}})(\omega) \right)\\
&\quad \times (2i)^{-r}\, \widetilde{\boldsymbol{E}}_r(\omega).\end{aligned}$$

Application of (2.1)–(2.2) for $\widetilde{\boldsymbol{P}}$ in the sum over s implies that $\boldsymbol{B}_n^2(\pi) = 0$ and

$$\begin{aligned}\boldsymbol{B}_n^2(0) &= \sum_{l=0}^{n-1} \binom{n}{l} \widetilde{B}_l \sum_{r=1}^{n-l} \binom{n-l}{r} 2^{-n+l+r}\, \widetilde{\boldsymbol{y}}_{n-l-r}^{\mathrm{T}}\, (2i)^{-r}\, \widetilde{\boldsymbol{E}}_r(0)\\
&= \sum_{l=0}^{n-1} \binom{n}{l} \widetilde{B}_l \sum_{r=1}^{n-l} \binom{n-l}{r} 2^{-n+l-1}\, \widetilde{\boldsymbol{y}}_{n-l-r}^{\mathrm{T}}\, (-1)^r \left(i2^r(\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0) + \boldsymbol{G}\boldsymbol{y}(0)\right).\end{aligned}$$

Putting $r' := n-l-r$ and changing again the order of summation we get

$$\begin{aligned}\boldsymbol{B}_n^2(0) &= \sum_{l=0}^{n-1}\binom{n}{l}\widetilde{B}_l \sum_{r'=0}^{n-l-1}\binom{n-l}{r'} 2^{-n+l-1}\,\widetilde{\boldsymbol{y}}_{r'}^{\mathrm{T}}\,(-1)^{n-l-r'} \\ &\quad\times\Big(i2^{n-l-r'}(\mathrm{D}\boldsymbol{G}_{\boldsymbol{y}})(0)+\boldsymbol{G}_{\boldsymbol{y}}(0)\Big) \\ &= i\sum_{r=0}^{n-1}\binom{n}{r}\widetilde{\boldsymbol{y}}_r^{\mathrm{T}}\left(\sum_{l=0}^{n-r-1}\binom{n-r}{l}\widetilde{B}_l\,(-1)^l\right)2^{-r-1}\,(-1)^{n-r}\,(\mathrm{D}\boldsymbol{G}_{\boldsymbol{y}})(0) \\ &\quad+\sum_{r=0}^{n-1}\binom{n}{r}\widetilde{\boldsymbol{y}}_r^{\mathrm{T}}\left(\sum_{l=0}^{n-r-1}\binom{n-r}{l}\widetilde{B}_l\,(-2)^l\right)2^{-n-1}\,(-1)^{n-r}\,\boldsymbol{G}_{\boldsymbol{y}}(0).\end{aligned}$$

Using the identities (2.17) and (4.6) for Bernoulli numbers and observing that $(-1)^k\widetilde{B}_k=\widetilde{B}_k$ for $k>1$, it follows that

$$\begin{aligned}\boldsymbol{B}_n^2(0) &= \frac{-in}{2^n}\widetilde{\boldsymbol{y}}_{n-1}^{\mathrm{T}}\,(\mathrm{D}\boldsymbol{G}_{\boldsymbol{y}})(0)-\frac{n}{2^{n+1}}\,\widetilde{\boldsymbol{y}}_{n-1}^{\mathrm{T}}\,\boldsymbol{G}_{\boldsymbol{y}}(0) \\ &\quad+2^{-n}\sum_{r=0}^{n-2}\binom{n}{r}\widetilde{\boldsymbol{y}}_r^{\mathrm{T}}\,(-2^{n-r}+1)\widetilde{B}_{n-r}\,(-1)^{n-r}\boldsymbol{G}_{\boldsymbol{y}}(0) \\ &= \frac{-in}{2^n}\widetilde{\boldsymbol{y}}_{n-1}^{\mathrm{T}}\,(\mathrm{D}\boldsymbol{G}_{\boldsymbol{y}})(0)-\frac{n}{2^{n+1}}\,\widetilde{\boldsymbol{y}}_{n-1}^{\mathrm{T}}\,\boldsymbol{G}_{\boldsymbol{y}}(0) \\ &\quad+\sum_{r=0}^{n-2}\binom{n}{r}\widetilde{\boldsymbol{y}}_r^{\mathrm{T}}\,(2^{-n}-2^{-r})\widetilde{B}_{n-r}\,(-1)^{n-r}\boldsymbol{G}_{\boldsymbol{y}}(0) \\ &= \frac{-in}{2^n}\widetilde{\boldsymbol{y}}_{n-1}^{\mathrm{T}}\,(\mathrm{D}\boldsymbol{G}_{\boldsymbol{y}})(0)+\sum_{r=0}^{n-1}\binom{n}{r}\widetilde{\boldsymbol{y}}_r^{\mathrm{T}}\,(2^{-n}-2^{-r})\widetilde{B}_{n-r}\,\boldsymbol{G}_{\boldsymbol{y}}(0).\end{aligned}$$

5. Now let $\omega=\pi$. Recall that $\boldsymbol{B}_n^1(\pi)=\boldsymbol{B}_n^2(\pi)=\boldsymbol{A}_n(\pi)+\boldsymbol{B}_n^0(\pi)=\boldsymbol{0}^{\mathrm{T}}$. Further, by $\boldsymbol{G}_{\boldsymbol{y}}(0)\boldsymbol{P}(\pi)=\boldsymbol{0}$ we have $\boldsymbol{C}_n(\pi)=\boldsymbol{D}_n(\pi)=\boldsymbol{0}^{\mathrm{T}}$. Hence,

$$\boldsymbol{A}_n(\pi)+\boldsymbol{B}_n(\pi)+\boldsymbol{C}_n(\pi)+\boldsymbol{D}_n(\pi)=\boldsymbol{0}^{\mathrm{T}}.$$

6. Let $\omega=0$. By $\boldsymbol{G}_{\boldsymbol{y}}(0)\,\boldsymbol{P}(0)=\widetilde{\boldsymbol{P}}(0)\,\boldsymbol{G}_{\boldsymbol{y}}(0)=\boldsymbol{G}_{\boldsymbol{y}}(0)$ we obtain

$$\begin{aligned}\boldsymbol{C}_n(0) &= \sum_{s=0}^{n-1}\binom{n}{s}\,\widetilde{B}_{n-s}\,\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\,\boldsymbol{G}_{\boldsymbol{y}}(0), \\ \boldsymbol{D}_n(0) &= -\frac{2^n}{2^n-1}\sum_{s=0}^{n-1}\binom{n}{s}\,(2i)^{s-n}\,\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\,(\mathrm{D}^{n-s}\widetilde{\boldsymbol{P}})(0)\,\boldsymbol{G}_{\boldsymbol{y}}(0).\end{aligned}$$

Observing that by (4.7)

$$\begin{aligned}\boldsymbol{D}_n(0)+\boldsymbol{B}_n^1(0) &= \sum_{l=1}^{n-1}\binom{n}{l}\,\widetilde{B}_l\,(2^{-n+l}-1)\,\widetilde{\boldsymbol{y}}_{n-l}^{\mathrm{T}}\,\boldsymbol{G}_{\boldsymbol{y}}(0) \\ &\quad-\frac{1}{2^n-1}\sum_{s=0}^{n-1}\binom{n}{s}\,(2i)^{s-n}\widetilde{\boldsymbol{y}}_s^{\mathrm{T}}\,(\mathrm{D}^{n-s}\widetilde{\boldsymbol{P}})(0)\,\boldsymbol{G}_{\boldsymbol{y}}(0)\end{aligned}$$

and using the expression for $\boldsymbol{B}_n^2$ found in part 4, we obtain

$$\begin{aligned}
&\boldsymbol{D}_n(0) + \boldsymbol{B}_n^1(0) + \boldsymbol{B}_n^2(0) + \boldsymbol{C}_n(0) \\
&= -\frac{1}{2^n - 1} \sum_{s=0}^{n-1} \binom{n}{s} (2i)^{s-n} \widetilde{\boldsymbol{y}}_s^{\mathrm{T}} \, (\mathrm{D}^{n-s} \widetilde{\boldsymbol{P}})(0) \, \boldsymbol{G}\boldsymbol{y}(0) \\
&\quad + \sum_{l=0}^{n-1} \binom{n}{l} \widetilde{B}_{n-l} \, (2^{-l} - 1) \, \widetilde{\boldsymbol{y}}_l^{\mathrm{T}} \, \boldsymbol{G}\boldsymbol{y}(0) \\
&\quad - \frac{in}{2^n} \, \widetilde{\boldsymbol{y}}_{n-1}^{\mathrm{T}} \, (\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0) + \sum_{r=0}^{n-1} \binom{n}{r} \widetilde{\boldsymbol{y}}_r^{\mathrm{T}} \, (2^{-n} - 2^{-r}) \, \widetilde{B}_{n-r} \, \boldsymbol{G}\boldsymbol{y}(0) \\
&\quad + \sum_{s=0}^{n-1} \binom{n}{s} \widetilde{B}_{n-s} \, \widetilde{\boldsymbol{y}}_s^{\mathrm{T}} \, \boldsymbol{G}\boldsymbol{y}(0) \\
&= \frac{-in}{2^n} \, \widetilde{\boldsymbol{y}}_{n-1}^{\mathrm{T}} \, (\mathrm{D}\boldsymbol{G}\boldsymbol{y})(0) - \frac{1}{2^n - 1} \sum_{s=0}^{n-1} \binom{n}{s} (2i)^{s-n} \widetilde{\boldsymbol{y}}_s^{\mathrm{T}} \, (\mathrm{D}^{n-s} \widetilde{\boldsymbol{P}})(0) \, \boldsymbol{G}\boldsymbol{y}(0) \\
&\quad + \sum_{l=0}^{n-1} \binom{n}{l} \widetilde{B}_{n-l} \, \widetilde{\boldsymbol{y}}_l^{\mathrm{T}} \, \boldsymbol{G}\boldsymbol{y}(0) \, \left(2^{-l} - 1 + 2^{-n} - 2^{-l} + 1\right) = 2^{-n} \, \boldsymbol{y}_n^{\mathrm{T}}.
\end{aligned}$$

Recalling that $\boldsymbol{A}_n(0) + \boldsymbol{B}_n^0(0) = \boldsymbol{0}^{\mathrm{T}}$, the proof is complete. □

Acknowledgments. We would like to thank Ingrid Daubechies and Gilbert Strang for very useful discussions, advice, and comments.

THE LIFTING SCHEME: A CONSTRUCTION OF SECOND GENERATION WAVELETS*

WIM SWELDENS†

Abstract. We present the lifting scheme, a simple construction of second generation wavelets; these are wavelets that are not necessarily translates and dilates of one fixed function. Such wavelets can be adapted to intervals, domains, surfaces, weights, and irregular samples. We show how the lifting scheme leads to a faster, in-place calculation of the wavelet transform. Several examples are included.

Key words. wavelet, multiresolution, second generation wavelet, lifting scheme

AMS subject classification. 42C15

1. Introduction.

Wavelets form a versatile tool for representing general functions or data sets. Essentially we can think of them as data building blocks. Their fundamental property is that they allow for representations which are *efficient* and which can be computed *fast*. In other words, wavelets are capable of quickly capturing the essence of a data set with only a small set of coefficients. This is based on the fact that most data sets have correlation both in time (or space) and frequency. Because of the time-frequency localization of wavelets, efficient representations can be obtained. Indeed, building blocks which already reflect the correlation present in the data lead to more compact representations. This is the key to applications. Over the last decade wavelets have found applications in numerous areas of mathematics, engineering, computer science, statistics, physics, etc.

Wavelet functions $\psi_{j,m}$ are traditionally defined as the dyadic translates and dilates of one particular $L_2(\mathbf{R})$ function, the *mother wavelet* ψ: $\psi_{j,m}(x) = \psi(2^j x - m)$. We refer to such wavelets as *first generation wavelets*. In this paper we introduce a more general setting where the wavelets are not necessarily translates and dilates of each other but still enjoy all the powerful properties of first generation wavelets. These wavelets are referred to as *second generation wavelets*. We present the *lifting scheme*, a simple, but quite powerful, tool to construct second generation wavelets.

Before we consider the generalization to the second generation case, let us review the properties of first generation wavelets which we would like to preserve.

P1: Wavelets form a Riesz basis for $L_2(\mathbf{R})$ and an unconditional basis for a wide variety of function spaces $\mathcal{F}$, such as Lebesgue, Lipschitz, Sobolev, and Besov spaces. If we denote the wavelet basis by $\{\psi_{j,m} \mid j, m\}$, we can represent a general function f in $\mathcal{F}$ as $f = \sum_{j,m} \gamma_{j,m} \psi_{j,m}$, with unconditional convergence in the norm of $\mathcal{F}$. Simple characterizations of the $\mathcal{F}$-norm of f in terms of the absolute value of its wavelet coefficients $\gamma_{j,m}$ exist.

P2: One has explicit information concerning the coordinate functionals $\widetilde{\psi}_{j,m}$ where $\gamma_{j,m} = \widetilde{\psi}_{j,m}(f)$. The wavelets are either orthogonal or the dual (biorthogonal) wavelets are known.

P3: The wavelets and their duals are local in space and frequency. Some wavelets are even compactly supported. The frequency localization follows from the smoothness of the wavelets (decay towards high frequencies) and the fact that they have vanishing polynomial moments (decay towards low frequencies).

P4: Wavelets fit into the framework of multiresolution analysis. This leads to the *fast wavelet transform*, which allows us to pass between the function f and its wavelet coefficients $\gamma_{j,m}$ in linear time.

These properties result in the fact that, quoted from Donoho in [58], "*wavelets are optimal bases for compressing, estimating, and recovering functions in* $\mathcal{F}$." Roughly speaking, for a general class of functions, the essential information contained in a function is captured by a small fraction of the wavelet coefficients. Again this is the key to applications. Wavelets have proved to be useful in various application domains such as signal and image processing, data compression, data transmission, the numerical solution of differential and integral equations, and noise reduction.

Many first generation wavelet families have been constructed over the last ten years. We refer to the work of (in alphabetical order) Aldroubi and Unser [2, 3, 108, 107], Battle and Lemarié [13, 78], Chui and Wang [19, 25, 24, 23], Cohen and Daubechies [28], Cohen, Daubechies, and Feauveau [29], Daubechies [47, 49, 48], Donoho [57, 56], Frazier and Jawerth [65, 67, 66], Herley and Vetterli [73, 110], Kovačević and Vetterli [77, 111], Mallat [85, 84, 86], Meyer [87], and many more. Except for Donoho, they all rely on the Fourier transform as a basic construction tool. The reason is that translation and dilation become algebraic operations in the Fourier domain.

In fact, in the early 1980s, several years before the above developments, Strömberg discovered the first orthogonal wavelets with a technique based on spline interpolation which does not rely on the Fourier transform [103].

The construction as initiated by Daubechies and coworkers essentially consists of three stages. The *algebraic stage* involves constructing the filters that are used in the fast wavelet transform; more precisely, it consists of finding certain polynomials and assuring that the above property P4 is satisfied. In the *analytic stage*, one shows that wavelets associated with these filters exist, that they are localized (property P3), and that they form a basis for the proper function space (property P1). In the *geometrical stage*, one checks the smoothness of the basis functions (property P3). In this context, we mention the work of Collela and Heil [37, 38], Daubechies and Lagarias [50, 51], Eirola [63], Rioul [94], and Villemoes [113, 112].

Let us next consider applications which illustrate the need for generalizations of first generation wavelets.

G1: While first generation wavelets provided bases for functions defined on $\mathbf{R}^n$, applications such as data segmentation and the solution of partial differential and integral equations on general domains require wavelets that are defined on arbitrary, possibly nonsmooth, domains of $\mathbf{R}^n$, as well as wavelets adapted to "life" on curves, surfaces, or manifolds.

G2: Diagonalization of differential forms, analysis on curves and surfaces, and weighted approximation require a basis adapted to weighted measures; however, first generation wavelets typically provide bases only for spaces with translation invariant (Haar–Lebesgue) measures.

G3: Many real life problems require algorithms adapted to irregular sampled data, while first generation wavelets imply a regular sampling of the data.

A generalization of first generation wavelets to the settings G1–G3, while preserving the properties P1–P4, is needed. We refer to such wavelets as *second generation wavelets*. The key lies in the observations (A) that translation and dilation cannot be maintained in the settings G1–G3, and (B) that translation and dilation are not essential in obtaining the properties P1–P4. Giving up translation and dilation, however, implies that the Fourier transform can no longer be used as a construction tool. A proper substitute is needed.

Several results concerning the construction of wavelets adapted to some of the cases in G1–G3 already exist. For example, we have wavelets on an interval [8, 10, 18, 30, 31, 88], wavelets on bounded domains [27, 74], spline wavelets for irregular samples, [15, 7, 45], and weighted wavelets [11, 12, 104]. These constructions are tailored toward one specific setting. Other instances of second generation wavelets have been reported in the literature, e.g., the construction of scaling functions through subdivision [41], basis constructions [43], as well as the development of stability criteria [41, 42].

In this paper, we present the *lifting scheme*, a simple, general construction of second generation wavelets. The basic idea, which inspired the name, is to start with a very simple or trivial multiresolution analysis and gradually work one's way up to a multiresolution analysis with particular properties. The lifting scheme allows one to custom design the filters, needed in the transform algorithms, to the situation at hand. In this sense it provides an answer to the algebraic stage of a wavelet construction. Whether these filters actually generate functions which form a stable basis (analytic stage) or have smoothness (geometric stage) remains to be checked in each particular case. The lifting scheme also leads to a fast in-place calculation of the wavelet transform, i.e., an implementation that does not require auxiliary memory.

The paper is organized as follows. We start out by discussing related work in section 2. In sections 3, 4, 5, and 6 we generalize, respectively, multiresolution analysis, cascade algorithm, wavelets, and the fast wavelet transform to the second generation setting. With the notation introduced in section 7 we are able to state and prove the lifting scheme in section 8. Section 9 discusses the lifted fast wavelet transform, while section 10 covers the cakewalk construction, an enhanced version of the lifting scheme. Sections 11, 12, and 13 introduce three possible examples of an initial multiresolution analysis to start lifting: respectively, generalized Haar wavelets, the Lazy wavelet, and biorthogonal Haar wavelets. Finally, section 14 contains a discussion of applications and future research.

2. Related work. The idea of second generation wavelets and abandoning the Fourier transform as a construction tool for wavelets is not entirely new and, over the last few years, has been researched by several independent groups. In this section we discuss these developments and their relationship with lifting.

The lifting scheme was originally inspired by the work of Donoho on one side and Lounsbery, De Rose, and Warren on the other. In [56, 57], Donoho presents the idea of interpolating and average-interpolating wavelets, a construction of first generation wavelets which relies on polynomial interpolation and subdivision as construction tools rather than the Fourier transform. It thus can be generalized to interval constructions [59] or weighed wavelets [104]. Lounsbery, De Rose, and Warren [79, 80] construct wavelets for the approximation of polyhedral surfaces of arbitrary genus. The wavelets are constructed by orthogonalizing scaling functions in a local neighborhood. We will

show later how this can be seen as a special case of lifting.

The lifting scheme can also be used to construct first generation wavelets; see [105, 52]. Although in this setting, the lifting will never come up with wavelets which could not have been found using the Cohen–Daubechies–Feauveau machinery in [29], it leads to two new insights: a custom-design construction of wavelets and a faster, in-place implementation of existing wavelet transforms [52]. In the first generation setting, lifting has many contacts with certain filter design algorithms used in signal processing. Those connections are pointed out in [105, 52].

Over the last few years Donovan, Hardin, Geronimo, and Massopust have developed techniques to construct wavelets based on fractal interpolation functions [60, 61, 62, 70]. They also introduced the concept of several generating functions (multiwavelets). As this technique does not rely on the Fourier transform either, it too potentially can be used to construct second generation wavelets.

Several spatial constructions of spline wavelets on irregular grids have been proposed [15, 7]. In [45], Dahmen and Micchelli propose a spatial construction of compactly supported wavelets that generate complementary spaces in a multiresolution analysis of univariate irregular knot splines.

Dahmen already made use of a technique related to lifting in the first generation setting [40] and later introduced a multiscale framework related to second generation wavelets [41].

Finally, after finishing this work, the author learned of two other very similar techniques developed independent of each other and of lifting. Harten and Abgrall developed a general multiresolution approximation framework based on prediction [71, 1], while Dahmen and co-workers [17, 46] developed a mechanism to characterize *all* stable biorthogonal decomposition. We will come back to this toward the end of the paper.

3. Multiresolution analysis. In this section we present the second generation version of multiresolution analysis. We keep most of the terminology and symbols of the first generation case, although their meaning can be quite different. For example, we maintain the name scaling function although it can be a little misleading since the scaling function can no longer be written as linear combinations of scaled versions of itself.

Consider a general function space $\mathrm{L}_2 = \mathrm{L}_2(X, \Sigma, \mu)$, with $X \subset \mathbf{R}^n$ being the spatial domain, Σ a σ-algebra, and μ a nonatomic measure on Σ. We do not require the measure to be translation invariant, so weighted measures are allowed. We assume (X, d) is a metric space.

DEFINITION 3.1. *A* multiresolution analysis $\mathbf{M}$ *of* L_2 *is a sequence of closed subspaces* $\mathbf{M} = \{V_j \subset \mathrm{L}_2 \mid j \in \mathcal{J} \subset \mathbf{Z}\}$ *so that*

1. $V_j \subset V_{j+1}$,
2. $\bigcup_{j\in\mathcal{J}} V_j$ *is dense in* L_2,
3. *for each* $j \in \mathcal{J}$, V_j *has a Riesz basis given by* scaling functions $\{\varphi_{j,k} \mid k \in \mathcal{K}(j)\}$.

One can think of $\mathcal{K}(j)$ as a general index set. We assume that $\mathcal{K}(j) \subset \mathcal{K}(j+1)$. We consider two cases:

I: $\mathcal{J} = \mathbf{N}$: This means there is one coarsest level V_0. This is the case if $\mu(X) < \infty$.

II: $\mathcal{J} = \mathbf{Z}$: We have a fully bi-infinite setting. This is typical when $\mu(X) = \infty$.

We then add the condition that

$$\bigcap_{j\in\mathcal{J}} V_j = \{\mathbf{0}\}\,.$$

A *dual multiresolution analysis* $\widetilde{\mathbf{M}} = \{\widetilde{V}_j \mid j \in \mathcal{J}\}$ consists of spaces $\widetilde{V}_j$ with Riesz bases given by *dual scaling functions* $\widetilde{\varphi}_{j,k}$. These dual scaling functions are biorthogonal with the scaling functions in the sense that

$$\langle\, \varphi_{j,k}, \widetilde{\varphi}_{j,k'} \,\rangle \;=\; \delta_{k,k'} \quad \text{for} \quad k,\, k' \in \mathcal{K}(j)\,. \tag{3.1}$$

For $f \in \mathrm{L}_2$, define the coefficients $\lambda_{j,k} \;=\; \langle\, f, \widetilde{\varphi}_{j,k} \,\rangle$ and consider the projections

$$P_j\, f \;=\; \sum_{k\in\mathcal{K}(j)} \lambda_{j,k}\, \varphi_{j,k}.$$

If the projection operators P_j are uniformly bounded in L_2, then

$$\lim_{j\to\infty} \|f - P_j\, f\| = 0.$$

First generation scaling functions reproduce polynomials up to a certain degree. To generalize this, consider a set of $\mathcal{C}^\infty$ functions on X, $\{P_p \mid p = 0, 1, 2, \ldots\}$, with $P_0 \equiv 1$ and so that the restrictions of a finite number of these functions to any ϵ-ball are linearly independent. We then say that the *order of the multiresolution analysis* is N if for all $j \in \mathcal{J}$, each P_p with $0 \le p < N$ can be represented pointwise as a linear combination of the $\{\varphi_{j,k} \mid k \in \mathcal{K}(j)\}$,

$$P_p(x) \;=\; \sum_{k\in\mathcal{K}(j)} c^p_{j,k}\, \varphi_{j,k}(x)\,.$$

We let $\widetilde{N}$ be the order of the dual multiresolution analysis, where we use a similar set of functions $\widetilde{P}_p$. In case X is a domain in $\mathbf{R}^n$, the functions P_p typically will be polynomials; in case X is a manifold, the functions P_p can, e.g., be parametric images of polynomials. However, in a practical situation one often has no explicit knowledge of the parameterization. This is why we use a very general definition of the order. Our definition obviously depends on the choice of P_p, but we do not include this dependency in the notation to avoid overloading. Most of the examples only have $N = 1$ in which case there is no dependency as $P_0 = 1$.

We assume that the dual functions are integrable and normalize them as

$$\int_X \widetilde{\varphi}_{j,k}\, d\mu \;=\; 1\,. \tag{3.2}$$

This implies that if $N > 0$,

$$\sum_{k\in\mathcal{K}(j)} \varphi_{j,k}(x) \;=\; 1\,. \tag{3.3}$$

4. Cascade algorithm. A question which immediately arises is how to construct scaling functions and dual scaling functions. As in the first generation case, there is often no analytic expression for them, and they are only defined through an iterative procedure, the *cascade algorithm*. In this section we present the second

generation version of the cascade algorithm. To do so we need two things: a *set of partitionings* and a *filter*.

Let us start by defining a filter. The definition of multiresolution analysis implies that for every scaling function $\varphi_{j,k}$ ($j \in \mathcal{J}$, $k \in \mathcal{K}(j)$), coefficients $\{h_{j,k,l} \mid l \in \mathcal{K}(j+1)\}$ exist so that formally

$$\varphi_{j,k} = \sum_{l \in \mathcal{K}(j+1)} h_{j,k,l}\, \varphi_{j+1,l}\,. \tag{4.1}$$

We refer to this equation as a *refinement relation*. Each scaling function can be written as a linear combination of scaling functions on the next finer level. To ensure that the summation in (4.1) is well defined we need to clearly state the definition of a *filter*. In this paper we only consider finite filters.

DEFINITION 4.1. *A set of real numbers* $\{h_{j,k,l} \mid j \in \mathcal{J}, k \in \mathcal{K}(j), l \in \mathcal{K}(j+1)\}$ *is called a* finite filter *if*

1. *For each* j *and* k *only a finite number of coefficients* $h_{j,k,l}$ *are nonzero, and thus the set*

$$\mathcal{L}(j,k) = \{l \in \mathcal{K}(j+1) \mid h_{j,k,l} \neq 0\}$$

   is finite.
2. *For each* j *and* l *only a finite number of coefficients* $h_{j,k,l}$ *are nonzero, and thus the set*

$$\mathcal{K}(j,l) = \{k \in \mathcal{K}(j) \mid h_{j,k,l} \neq 0\}$$

   is finite.
3. *The size of sets* $\mathcal{L}(j,k)$ *and* $\mathcal{K}(j,l)$ *is uniformly bounded for all* j, k, *and* l.

Note that in the first generation case $h_{j,k.l} = h_{l-2k}$, so if $\{h_k \mid k\}$ is a finite sequence, the filter is finite according to the above definition. We will always choose our indices consistently so that $j \in \mathcal{J}$, $k \in \mathcal{K}(j)$, and $l \in \mathcal{K}(j+1)$, even though it will not always be explicitly mentioned. The above defined index sets indicate which elements are nonzero on each row (respectively, column) of the (possibly infinite) matrix $\{h_{j,k,l} \mid k \in \mathcal{K}(j), l \in \mathcal{K}(j+1)\}$. We can think of them as adjoints of each other as

$$\mathcal{K}(j,l) = \{k \in \mathcal{K}(j) \mid l \in \mathcal{L}(j,k)\}\,.$$

The dual scaling functions satisfy refinement relations with coefficients $\{\widetilde{h}_{j,k,l}\}$. We can define similar index sets (denoted with a tilde).

A set of partitionings $\{S_{j,k}\}$ can be thought of as the replacement for the dyadic intervals on the real line in the first generation case. Again each scaling function $\varphi_{j,k}$ is associated with exactly one set $S_{j,k}$. We use the following definition.

DEFINITION 4.2. *A set of measurable subsets* $\{S_{j,k} \in \Sigma \mid j \in \mathcal{J}, k \in \mathcal{K}(j)\}$ *is called a* set of partitionings *if*

1. $\forall j \in \mathcal{J}$: $\operatorname{clos} \bigcup_{k \in \mathcal{K}(j)} S_{j,k} = X$ *and the union is disjoint,*
2. $\mathcal{K}(j) \subset \mathcal{K}(j+1)$,
3. $S_{j+1,k} \subset S_{j,k}$,
4. *For a fixed* $k \in \mathcal{K}(j_0)$, $\bigcap_{j > j_0} S_{j,k}$ *is a set which contains one point. We denote this point with* x_k.

The purpose now is to use a filter and a set of partitionings to construct scaling functions that satisfy (4.1). Assume we want to synthesize φ_{j_0,k_0}. First define a Kronecker sequence $\{\lambda_{j_0,k} = \delta_{k,k_0} \mid k \in \mathcal{K}(j_0)\}$. Then, generate sequences $\{\lambda_{j,k} \mid k \in \mathcal{K}(j)\}$ for $j > j_0$ by recursively applying the formula

$$\lambda_{j+1,l} \;=\; \sum_{k \in \mathcal{K}(j,l)} h_{j,k,l}\, \lambda_{j,k}\,.$$

Next we construct the functions

$$f^{(j)}_{j_0,k_0} \;=\; \sum_{k \in \mathcal{K}(j)} \lambda_{j,k}\, \chi_{S_{j,k}}, \qquad j \geq j_0\,. \tag{4.2}$$

These functions satisfy, for $j > j_0$,

$$f^{(j)}_{j_0,k_0} \;=\; \sum_{l} h_{j_0,k_0,l}\, f^{(j)}_{j_0+1,l}\,. \tag{4.3}$$

If $\lim_{j\to\infty} f^{(j)}_{j_0,k_0}$ converges to a function in L_2, we define this function to be φ_{j_0,k_0}. This procedure is called the *cascade algorithm*. The limit functions satisfy

$$\lim_{j\to\infty} \lambda_{j,k} \;=\; \varphi_{j_0,k_0}(x_k) \quad \text{a.e.}$$

If the cascade algorithm converges for all j_0 and k_0, we get a set of scaling functions that satisfies the refinement equation (4.1). This can be seen by letting j go to infinity in (4.3). Note how the resulting functions depend both on the filter and the set of partitionings. If the scaling functions generate a multiresolution analysis, the cascade algorithm started with a sequence $\{\lambda_{j_0,k} \mid k \in \mathcal{K}(j)\}$ that belongs to $\ell^2(\mathcal{K}(j))$ converges to

$$\sum_k \lambda_{j_0,k}\, \varphi_{j_0,k}\,.$$

The dual scaling functions are constructed similarly starting from a finite filter $\widetilde{h}$, the same set of partitionings, and an initial Kronecker sequence $\{\lambda_{j_0,k} = \delta_{k,k_0}/\mu(S_{j_0,k_0}) \mid k \in \mathcal{K}(j_0)\}$. The normalization of the initial sequences assures that $\langle\, \widetilde{\varphi}_{j,k}, \varphi_{j,k}\,\rangle = 1$.

An interesting question is now whether the biorthogonality condition (3.1) can be related back to the filters h and $\widetilde{h}$. By writing out the refinement relations we see that the biorthogonality (3.1) implies that

$$\sum_l h_{j,k,l}\, \widetilde{h}_{j,k',l} \;=\; \delta_{k,k'} \quad \text{for} \quad j \in \mathcal{J},\, k, k' \in \mathcal{K}(j)\,, \tag{4.4}$$

but the converse is not immediately true. More precisely, if the filter coefficients satisfy (4.4) and the cascade algorithm for the primal and dual scaling functions converges, then the resulting scaling functions are biorthogonal. This follows from the fact that (4.4) assures that the intermediate functions of the form $f^{(j)}_{j_0,k_0}$ in (4.2) (which converge to the scaling functions) are biorthogonal at each stage j.

It is important to note that not every filter corresponds to a set of scaling functions; i.e., the convergence of the cascade algorithm is not guaranteed. We would like to have a condition which relates convergence of the cascade algorithm and the Riesz basis property back to the filter coefficients, similar to the Cohen criterion in the first generation case [26] or the Cohen–Daubechies–Feauveau theorem [29] or [48, Theorem 8.3.1]. This result is part of the analysis phase of the construction. As we mentioned earlier, this paper is mostly concerned with the algebraic phase and the generation of the filter coefficients.

5. Wavelets. First generation wavelets are defined as basis functions for spaces complementing V_j in V_{j+1}. The same idea remains in the second generation case. This leads to the following definition.

DEFINITION 5.1. *A set of functions* $\{\psi_{j,m} \mid j \in \mathcal{J},\, m \in \mathcal{M}(j)\}$, *where* $\mathcal{M}(j) = \mathcal{K}(j+1) \setminus \mathcal{K}(j)$, *is a* set of wavelet functions *if*

1. *The space* $W_j = \operatorname{clos}\operatorname{span}\{\psi_{j,m} \mid m \in \mathcal{M}(j)\}$ *is a complement of* V_j *in* V_{j+1} *and* $W_j \perp \widetilde{V}_j$.
2. *If* $\mathcal{J} = \mathbf{Z}$, *the set* $\{\psi_{j,m}/\|\psi_{j,m}\| \mid j \in \mathcal{J}, m \in \mathcal{M}(j)\}$ *is a Riesz basis for* L_2. *If* $\mathcal{J} = \mathbf{N}$, *the set* $\{\psi_{j,m}/\|\psi_{j,m}\| \mid j \in \mathcal{J}, m \in \mathcal{M}(j)\} \cup \{\varphi_{0,k}/\|\varphi_{0,k}\| \mid k \in \mathcal{K}(0)\}$ *is a Riesz basis for* L_2.

We always assume that the index m belongs to the set $\mathcal{M}(j)$. The dual basis is given by *dual wavelets* $\widetilde{\psi}_{j,m}$, which are biorthogonal to the wavelets

$$\langle\, \psi_{j,m}, \widetilde{\psi}_{j',m'} \,\rangle \;=\; \delta_{m,m'}\, \delta_{j,j'}\,. \tag{5.1}$$

The dual wavelets span spaces $\widetilde{W}_j$ which complement $\widetilde{V}_j$ in $\widetilde{V}_{j+1}$ and $\widetilde{W}_j \perp V_j$. For $f \in \mathrm{L}_2$, define the coefficients $\gamma_{j,m} \;=\; \langle\, f, \widetilde{\psi}_{j,m} \,\rangle$. Then

$$f \;=\; \sum_{j,m} \gamma_{j,m}\, \psi_{j,m}\,.$$

Their definition implies that the wavelets satisfy refinement relations of the form

$$\psi_{j,m} \;=\; \sum_{l} g_{j,m,l}\, \varphi_{j+1,l}\,. \tag{5.2}$$

We assume that $g = \{g_{j,m,l} \mid j \in \mathcal{J}, m \in \mathcal{M}(j), l \in \mathcal{K}(j+1)\}$ is a finite filter according to Definition 4.1 with k substituted by m. This leads to the definition of the uniformly bounded finite sets

$$\mathcal{M}(j,l) \;=\; \{m \in \mathcal{M}(j) \mid g_{j,m,l} \neq 0\} \quad \text{and} \quad \mathcal{L}(j,m) \;=\; \{l \in \mathcal{K}(j+1) \mid m \in \mathcal{M}(j,l)\}\,.$$

The dual wavelets satisfy refinement relations with a finite filter $\widetilde{g}$.

Also, since $\varphi_{j+1,l} \in V_j \oplus W_j$, it holds that

$$\varphi_{j+1,l} \;=\; \sum_{k} \widetilde{h}_{j,k,l}\, \varphi_{j,k} + \sum_{m} \widetilde{g}_{j,m,l}\, \psi_{j,m}\,.$$

The biorthogonality (5.1) combined with (3.1) implies the following relations between the filters:

$$\begin{aligned} \sum_l g_{j,m,l}\, \widetilde{g}_{j,m',l} &= \delta_{m,m'}\,, & \sum_l h_{j,k,l}\, \widetilde{g}_{j,m,l} &= 0\,, \\ \sum_l h_{j,k,l}\, \widetilde{h}_{j,k',l} &= \delta_{k,k'}\,, & \sum_l g_{j,m,l}\, \widetilde{h}_{j,k,l} &= 0\,. \end{aligned} \tag{5.3}$$

DEFINITION 5.2. *A set of filters* $\{h, \widetilde{h}, g, \widetilde{g}\}$ *is a* set of biorthogonal *filters if condition* (5.3) *is satisfied.*

Now given a set of biorthogonal filters and a set of partitionings and assuming that the cascade algorithm converges, the resulting scaling functions, wavelets, dual

scaling functions, and dual wavelets are biorthogonal in the sense that

$$\begin{aligned} \langle\, \widetilde{\varphi}_{j,k}, \varphi_{j,k'} \,\rangle &= \delta_{k,k'}\,, \\ \langle\, \widetilde{\psi}_{j,m}, \psi_{j,m'} \,\rangle &= \delta_{m,m'}\,, \\ \langle\, \widetilde{\varphi}_{j,k}, \psi_{j,m} \,\rangle &= 0\,, \\ \langle\, \widetilde{\psi}_{j,m}, \varphi_{j,k} \,\rangle &= 0\,. \end{aligned}$$

Next we need to generalize the notion of vanishing polynomial moments. We therefore use the (nonpolynomial) functions P_p defined in section 3. If the scaling functions $\varphi_{j,k}$ with $k \in \mathcal{K}(j)$ reproduce P_p, then

$$\int_X P_p\, \widetilde{\psi}_{j,m}\, d\mu \;=\; 0 \quad \text{for} \quad 0 \le p < N,\ j \in \mathcal{J},\ m \in \mathcal{M}(j)\,.$$

We say that the dual wavelets have N vanishing moments. Similarly, the wavelets have $\widetilde{N}$ vanishing moments.

6. Fast wavelet transform. The basic idea of a wavelet transform is the same as in the first generation case. Given the set of coefficients $\{\lambda_{n,k} \mid k \in \mathcal{K}(n)\}$, calculate the $\{\gamma_{j,m} \mid n_0 \le j < n,\, m \in \mathcal{M}(j)\}$ and $\{\lambda_{n_0,k} \mid k \in \mathcal{K}(n_0)\}$. From the refinement relation of the dual scaling functions and wavelets, we see that a fast forward wavelet transform is given by recursive application of

$$\lambda_{j,k} = \sum_{l \in \widetilde{\mathcal{L}}(j,k)} \widetilde{h}_{j,k,l}\, \lambda_{j+1,l} \quad \text{and} \quad \gamma_{j,m} = \sum_{l \in \widetilde{\mathcal{L}}(j,m)} \widetilde{g}_{j,m,l}\, \lambda_{j+1,l}\,.$$

Similarly, the inverse transform follows from the recursive application of

$$\lambda_{j+1,l} \;=\; \sum_{k \in \mathcal{K}(j,l)} h_{j,k,l}\, \lambda_{j,k} \;+\; \sum_{m \in \mathcal{M}(j,l)} g_{j,m,l}\, \gamma_{j,m}\,.$$

The major difference with the first generation fast wavelet transform, and thus with traditional subband transforms, is that the filter coefficients are different for every coefficient. One has to be careful analyzing the complexity of the second generation fast wavelet transform. For general filters the complexity need not be linear as the number of terms in the above summation, albeit finite, can grow from level to level. This is precisely why Definition 4.1 of a finite filter requires the sizes of the index sets $\mathcal{L}$, $\mathcal{K}$, and $\mathcal{M}$ to be *uniformly* bounded. This leads to the following corollary.

COROLLARY 6.1. *In case the filters h, g, $\widetilde{h}$, and $\widetilde{g}$ are finite, the second generation fast wavelet transform is a linear time algorithm.*

Note that in a computer implementation the data structure for the filters can become much more complex than in the first generation case and therefore has to be designed carefully.

In case the wavelets form an unconditional basis, the condition number of the wavelet transform is bounded independent of the number of levels. Consequently the propagation of numerical round-off error in floating point calculations will be bounded. As we mentioned before, lifting does not guarantee stability and bounded condition numbers. However, in a practical situation involving spherical wavelets [99] we numerically estimated the condition number and found it to vary little with the number of levels. For a spherical wavelet transform involving roughly $650,000$ coefficients we found the condition number to be approximately 8.

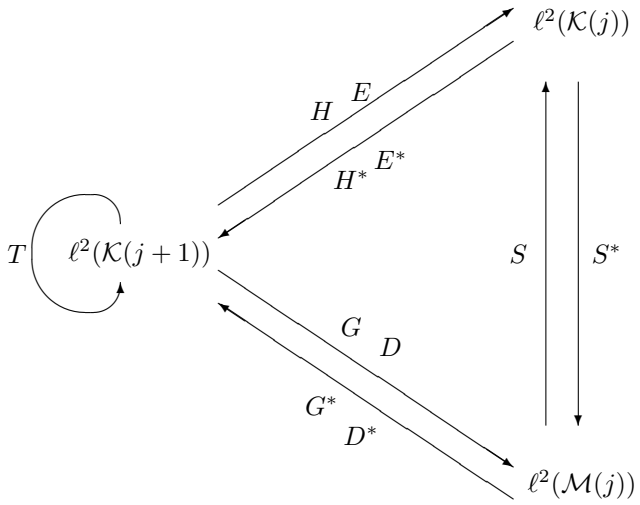

FIG. 7.1. *Schematic representation of operators, their domain, and range. This scheme can be used to verify that the order in which operators are applied is correct and which operators can be added.*

7. A word on notation. So far we have been using a notation involving the filter coefficients $h_{j,k,l}$ and $g_{j,m,l}$. As one can see this leads to expressions involving many indices. We will refer to it as the *index notation*. In this section we introduce a new notation, which we refer to as the *operator notation*. The advantage is that both the statement and the proof of some results become more elegant. Statements in the operator notation will also formally look the same as in the first generation case. In this way it helps to shed light on why things work. The disadvantage is that the operator notation is not practical and that it obscures implementation. Therefore we always state results in the index notation as well.

First consider the spaces $\ell^2(\mathcal{K}(j+1))$, $\ell^2(\mathcal{K}(j))$, and $\ell^2(\mathcal{M}(j))$, with their usual norm and inner product. We denote elements of these spaces by, respectively, a, b, and c so that

$$a \;=\; \{a_l \mid l \in \mathcal{K}(j+1)\} \in \ell^2(\mathcal{K}(j+1))\,,$$

and, similarly, mutatis mutandis, for $b \in \ell^2(\mathcal{K}(j))$ and $c \in \ell^2(\mathcal{M}(j))$. We always denote the identity operator on these spaces with 1. It should be clear from the context which one is meant. Next we introduce two operators (see also Figure 7.1):

1. $H_j : \ell^2(\mathcal{K}(j+1)) \to \ell^2(\mathcal{K}(j))$, where $b = H_j\, a$ means that

$$b_k \;=\; \sum_{l \in \mathcal{K}(j+1)} h_{j,k,l}\, a_l\,.$$

2. $G_j : \ell^2(\mathcal{K}(j+1)) \to \ell^2(\mathcal{M}(j))$, where $c = G_j\, a$ means that

$$c_m \;=\; \sum_{l \in \mathcal{K}(j+1)} g_{j,m,l}\, a_l\,.$$

The operators $\widetilde{H}_j$ and $\widetilde{G}_j$ are defined similarly. We refer to these operators as *filter operators* or sometimes simply as filters.

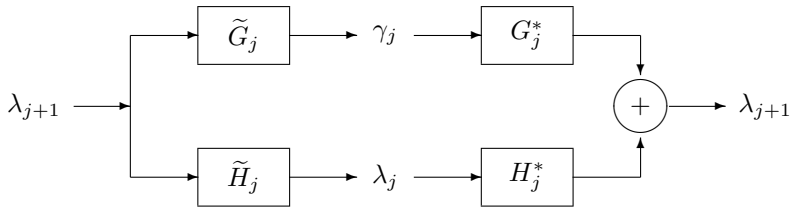

FIG. 7.2. *The fast wavelet transform. The major difference with the first generation fast wavelet transform is that the filters potentially are different for each coefficient. Observe that the subsampling is absorbed into the filters.*

We can now write the fast wavelet transform in operator notation. Define the sequences $\lambda_j = \{\lambda_{j,k} \mid k\}$ and $\gamma_j = \{\gamma_{j,k} \mid m\}$. Then one step in the forward transform is given by

$$\lambda_j \;=\; \widetilde{H}_j\, \lambda_{j+1} \quad \text{and} \quad \gamma_j \;=\; \widetilde{G}_j\, \lambda_{j+1}\,,$$

and one step in the inverse transform is given by

$$\lambda_{j+1} \;=\; H_j^*\, \lambda_j + G_j^*\, \gamma_j\,.$$

One step of the transform is depicted as a block diagram in Figure 7.2. We use here a scheme similar to a subband transform. Note how the traditional subsampling is absorbed into the filter operators.

The conditions on the filter operators for exact reconstruction now readily follow:

$$\widetilde{H}_j\, H_j^* \;=\; \widetilde{G}_j\, G_j^* \;=\; 1\,, \qquad\qquad \widetilde{G}_j\, H_j^* \;=\; \widetilde{H}_j\, G_j^* \;=\; 0\,,$$

and

$$H_j^*\, \widetilde{H}_j + G_j^*\, \widetilde{G}_j \;=\; 1\,.$$

These we can write in matrix form as

$$\text{(7.1)} \quad \begin{bmatrix} \widetilde{H}_j \\ \widetilde{G}_j \end{bmatrix} \begin{bmatrix} H_j^* & G_j^* \end{bmatrix} \;=\; \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} H_j^* & G_j^* \end{bmatrix} \begin{bmatrix} \widetilde{H}_j \\ \widetilde{G}_j \end{bmatrix} \;=\; 1\,.$$

DEFINITION 7.1. *The set of filter operators* $\{H_j, \widetilde{H}_j, G_j, \widetilde{G}_j\}$ *is a* set of biorthogonal filter operators *if condition* (7.1) *is satisfied.*

With slight abuse of notation, i.e., by letting the operators work on sequences of functions, we can write the refinement relations. Define $\varphi_j = \{\varphi_{j,k} \mid k \in \mathcal{K}(j)\}$ and $\psi_j = \{\psi_{j,m} \mid m \in \mathcal{M}(j)\}$. Then

$$\varphi_j \;=\; H_j\, \varphi_{j+1} \quad \text{and} \quad \psi_j \;=\; G_j\, \varphi_{j+1}\,.$$

In the other direction we have

$$\varphi_{j+1} \;=\; \widetilde{H}_j^*\, \varphi_j + \widetilde{G}_j^*\, \psi_j\,.$$

Armed with this operator notation, we now can state the lifting scheme.

8. The lifting scheme. In this section we state and prove the lifting scheme and show how it can be used to construct second generation wavelets.

THEOREM 8.1 (lifting). *Take an initial set of biorthogonal filter operators* $\{H_j^{\text{old}}, \widetilde{H}_j^{\text{old}}, G_j^{\text{old}}, \widetilde{G}_j^{\text{old}}\}$. *Then a new set of biorthogonal filter operators* $\{H_j, \widetilde{H}_j, G_j, \widetilde{G}_j\}$ *can be found as*

$$\begin{aligned} H_j &= H_j^{\text{old}}\,, \\ \widetilde{H}_j &= \widetilde{H}_j^{\text{old}} + S_j\,\widetilde{G}_j^{\text{old}}\,, \\ G_j &= G_j^{\text{old}} - S_j^*\,H_j^{\text{old}}\,, \\ \widetilde{G}_j &= \widetilde{G}_j^{\text{old}}\,, \end{aligned}$$

where S_j *is an operator from* $\ell^2(\mathcal{M}(j))$ *to* $\ell^2(\mathcal{K}(j))$.

Proof. We write the lifting scheme in matrix notation:

$$\begin{bmatrix} \widetilde{H}_j \\ \widetilde{G}_j \end{bmatrix} = \begin{bmatrix} 1 & S \\ 0 & 1 \end{bmatrix} \begin{bmatrix} \widetilde{H}_j^{\text{old}} \\ \widetilde{G}_j^{\text{old}} \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} H_j \\ G_j \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ -S^* & 1 \end{bmatrix} \begin{bmatrix} H_j^{\text{old}} \\ G_j^{\text{old}} \end{bmatrix}.$$

If we think of the biorthogonality conditions (7.1) in the matrix notation, the proof simply follows from the fact that

$$\begin{bmatrix} 1 & S \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & -S \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}. \qquad \square$$

One can use Figure 7.1 to assert that the order of the operators H, G, and S is correct. The theorem in the index notation reads as follows.

THEOREM 8.2 (lifting in index notation). *Take an initial set of biorthogonal filters* $\{h^{\text{old}}, \widetilde{h}^{\text{old}}, g^{\text{old}}, \widetilde{g}^{\text{old}}\}$; *then a new set of biorthogonal filters* $\{h, \widetilde{h}, g, \widetilde{g}\}$ *can be constructed as*

$$\begin{aligned} h_{j,k,l} &= h_{j,k,l}^{\text{old}}\,, \\ \widetilde{h}_{j,k,l} &= \widetilde{h}_{j,k,l}^{\text{old}} + \sum_m s_{j,k,m}\,\widetilde{g}_{j,m,l}^{\text{old}}\,, \\ g_{j,m,l} &= g_{j,m,l}^{\text{old}} - \sum_k s_{j,k,m}\,h_{j,k,l}^{\text{old}}\,, \\ \widetilde{g}_{j,m,l} &= \widetilde{g}_{j,m,l}^{\text{old}}\,. \end{aligned}$$

After lifting, the filters h and $\widetilde{g}$ remain the same, while the filters $\widetilde{h}$ and g change. As h remains the same, so do the primal scaling functions. The dual scaling functions and primal wavelets change since $\widetilde{h}$ and g change. The dual wavelets also change because the dual scaling functions, from which they are built, change. However, the coefficients $\widetilde{g}$ of the refinement equation of the dual wavelet remain the same. More precisely, we have

$$\begin{aligned} \varphi_j &= \varphi_j^{\text{old}}\,, \\ \widetilde{\varphi}_j &= \widetilde{H}_j^{\text{old}}\widetilde{\varphi}_{j+1} + S_j\,\widetilde{G}_j^{\text{old}}\,\widetilde{\varphi}_{j+1} \;=\; \widetilde{H}_j^{\text{old}}\widetilde{\varphi}_{j+1} + S_j\,\widetilde{\psi}_j\,, \\ \psi_j &= G_j^{\text{old}}\,\varphi_{j+1} - S_j^*\,H_j^{\text{old}}\varphi_{j+1} \;=\; \psi_j^{\text{old}} - S_j\,\varphi_j^{\text{old}}\,, \\ \widetilde{\psi}_j &= \widetilde{G}_j^{\text{old}}\,\widetilde{\varphi}_j\,, \end{aligned}$$

or

$$\varphi_{j,k} = \varphi^{\text{old}}_{j,k}\,,$$

$$\widetilde{\varphi}_{j,k} = \sum_l \widetilde{h}^{\text{old}}_{j,k,l}\,\widetilde{\varphi}_{j+1,l} + \sum_m s_{j,k,m}\,\widetilde{\psi}_{j,m}\,, \tag{8.1}$$

$$\psi_{j,m} = \psi^{\text{old}}_{j,m} - \sum_k s_{j,k,m}\,\varphi^{\text{old}}_{j,k}\,, \tag{8.2}$$

$$\widetilde{\psi}_{j,m} = \sum_l \widetilde{g}^{\text{old}}_{j,k,m}\,\widetilde{\varphi}_{j+1,l}\,. \tag{8.3}$$

Although formally similar, the expressions in (8.2) and (8.1) are quite different. The difference lies in the fact that in (8.2) the scaling functions on the right-hand side did not change after lifting, while in (8.1) the functions on the right-hand side did change after lifting. Indeed, the dual wavelets on the right-hand side of (8.1) already are the new ones.

The power behind the lifting scheme is that through the operator S we have full control over all wavelets and dual functions that can be built from a particular set of scaling functions. This means we can start from a simple or trivial multiresolution analysis and use (8.2) to choose S so that the wavelets after lifting have particular properties. This allows custom design of the wavelet, and it is the motivation behind the name "lifting scheme."

The fundamental idea behind the lifting scheme is that instead of using scaling functions on the *finer* level to build a wavelet, as in (5.2), we use an old, simple wavelet and scaling functions on the *same* level to synthesize a new wavelet; see (8.2). Thus instead of using "sister" scaling functions, we use "aunt" scaling functions of the family tree to build wavelets. As we will point out later, the "aunt" property is fundamental when building adaptive wavelets. The advantage of using (8.2) as opposed to (5.2) for the construction of $\psi_{j,m}$ is that in the former we have total freedom in the choice of S. Once S is fixed, the lifting scheme assures that all filters are biorthogonal. If we use (5.2) to construct ψ, we would have to check the biorthogonality separately.

Equation (8.2) is also the key to finding the S operator, since functions on the right-hand side do not change. Conditions on $\psi_{j,m}$ thus immediately translate into conditions on S. For example, we can choose S to increase the number of vanishing moments of the wavelet or choose S so that $\psi_{j,m}$ resembles a particular shape.

If the original filters and S are finite filters, then the new filters will be finite as well. In such case define the (adjoint) sets

$$\mathcal{K}(j,m) \;=\; \{k \mid s_{j,k,m} \neq 0\} \quad \text{and} \quad \mathcal{M}(j,k) \;=\; \{m \mid k \in \mathcal{K}(j,m)\}\,.$$

If we want the wavelet to have vanishing moments, the condition that the integral of a wavelet multiplied with a certain function P_p is zero leads to

$$\int_X P_p\,\psi_{j,m}\,d\mu \;=\; 0 \;\Rightarrow\; \int_X P_p\,\psi^{\text{old}}_{j,m}\,d\mu \;=\; \sum_{k\in\mathcal{K}(j,m)} s_{j,k,m} \int_X P_p\,\varphi^{\text{old}}_{j,k}\,d\mu\,.$$

For fixed indices j and m, the latter is a linear equation in the unknowns $\{s_{j,k,m} \mid k \in \mathcal{K}(j,m)\}$. All coefficients only depend on the old multiresolution analysis. If we choose the number of unknown coefficients $s_{j,k,m}$ equal to the number of equations, we simply need to solve a linear system for each j and m. Remember that the functions

P_p had to be independent, so if the functions $\varphi_{j,k}^{\text{old}}$ are independent as well, the system will be full rank.

Notes.

1. Other constraints than vanishing moments can be used for the choice of S. For example one can custom design the shape of the wavelet for use in feature recognition. Given the scaling functions, choose S so that $\psi_{j,m}$ resembles the particular feature we want to recognize. The magnitude of the wavelet coefficients is now proportional to how much the original signal at the particular scale and place resembles the feature. This has important applications in automated target recognition and medical imaging. Other ideas are fixing the value of the wavelet or the value of the derivative of the wavelet at a certain location. This is useful to accommodate boundary conditions.
2. In general it is not possible to use lifting to build orthogonal or semi-orthogonal wavelets using only finite lifting filters. In the semi-orthogonal case, the condition that a new wavelet $\psi_{j,m}$ is orthogonal to the V_j typically will require using all $\varphi_{j,k}$ scaling functions of level j in the lifting (8.2). In [80] this was bypassed by *pseudo-orthogonalization,* a scheme where $\psi_{j,m}$ is only required to be orthogonal to the (interpolating) scaling functions in a certain neighborhood. As mentioned in the introduction, part of the inspiration of the lifting scheme came from generalizing this idea to a fully biorthogonal setting.
3. In [17] several examples, including splines with nonuniform knot sequences, are given where semi-orthogonal wavelets are constructed. This construction uses all possible degrees of freedom for the construction of the wavelet, which is more than what lifting allows, but does not lead to finite primal and dual filters.
4. One of the appealing features of using the lifting scheme in the construction of second generation wavelets is that one gets the filters for the scaling functions *and* the wavelets together. Other constructions, such as nonstationary subdivision, only give the filters for the scaling functions; see for example [104, Chapter 5]. One then needs to use a technical trick to find the wavelet filters with the right biorthogonality properties. There is no guarantee that this is always possible.

9. Fast lifted wavelet transform. In this section we show how the lifting scheme can be used to facilitate and accelerate the implementation of the fast wavelet transform. The basic idea is to never explicitly form the new filters but only work with the old filter, which can be trivial, and the S filter.

For the forward transform we get

$$\lambda_j \;=\; \widetilde{H}_j\,\lambda_{j+1} \;=\; \widetilde{H}_j^{\text{old}}\lambda_{j+1} + S_j\,\gamma_j\,.$$

In index notation this becomes

$$\lambda_{j,k} \;=\; \sum_l \widetilde{h}_{j,k,l}^{\text{old}}\,\lambda_{j+1,l} + \sum_m s_{j,k,m}\,\gamma_{j,m}\,.$$

This implies that if we first calculate the wavelet coefficients γ_j as $\widetilde{G}_j^{\text{old}}\lambda_{j+1}$, we can later *reuse* them in the calculation of the λ_j coefficients. The λ_j are first calculated as $\widetilde{H}_j^{\text{old}}\,\lambda_{j+1}$ and later updated (lifted) with the γ_j coefficients. This way we never have to form the (potentially large) filter $\widetilde{H}_j$. In other words, the lifting scheme makes

optimal use of the similarities between the $\widetilde{H}$ and $\widetilde{G}$ filter. This both facilitates and accelerates the implementation.

For the inverse transform we find that

$$\lambda_{j+1} \;=\; H_j^*\,\lambda_j + G_j^*\,\gamma_j \;=\; H_j^{\mathrm{old}\,*}(\lambda_j - S_j\,\gamma_j) + G_j^{\mathrm{old}\,*}\gamma_j\,.$$

In index notation this becomes

$$\lambda_{j+1,l} \;=\; \sum_k h^{\mathrm{old}}_{j,k,l}\left(\lambda_{j,k} - \sum_m s_{j,k,m}\gamma_{j,m}\right) + \sum_m g^{\mathrm{old}}_{j,m,l}\gamma_{j,m}\,.$$

The inverse transform thus first undoes the lifting (between the parentheses) and then does an inverse transform with the old filters.

This leads to the following algorithm for the *fast lifted wavelet transform* depicted in Figure 9.1. On each level the forward transform consists of two stages. Stage I is simply the forward transform with the old filters while stage II is the lifting. In the inverse transform, stage I simply undoes the lifting and stage II is an inverse transform with the old filters. In pseudo code this becomes

Forward wavelet transform	Inverse wavelet transform

`For j = n-1 downto 0`
`  Forward I(j)`
`  Forward II(j)`
	`For level = 0 to n-1`
	`  Inverse I(j)`
	`  Inverse II(j)`

`Forward I(j)`: Calculate the $\gamma_{j,m}$ and first stage of $\lambda_{j,k}$

$$\forall k \in \mathcal{K}(j)\,:\,\lambda_{j,k} := \sum_{l\in\widetilde{\mathcal{L}}(j,k)} \widetilde{h}^{\mathrm{old}}_{j,k,l}\,\lambda_{j+1,l}$$

$$\forall m \in \mathcal{M}(j)\,:\,\gamma_{j,m} := \sum_{l\in\widetilde{\mathcal{L}}(j,m)} \widetilde{g}^{\mathrm{old}}_{j,m,l}\,\lambda_{j+1,l}$$

`Forward II(j)`: Lift the $\lambda_{j,k}$ using the $\gamma_{j,m}$ calculated in Stage I

$$\forall k \in \mathcal{K}(j)\,:\,\lambda_{j,k} \mathrel{+}= \sum_{m\in\mathcal{M}(j,k)} s_{j,k,m}\,\gamma_{j,m}$$

`Inverse I(j)`: Undo the lifting

$$\forall k \in \mathcal{K}(j)\,:\,\lambda_{j,k} \mathrel{-}= \sum_{m\in\mathcal{M}(j,k)} s_{j,k,m}\,\gamma_{j,m}$$

`Inverse II(j)`: Calculate the $\lambda_{j+1,l}$ using the $\lambda_{j,k}$ from Stage I:

$$\forall l \in \mathcal{K}(j+1)\,:\,\lambda_{j+1,l} := \sum_{k\in\mathcal{K}(j,l)} h^{\mathrm{old}}_{j,k,l}\,\lambda_{j,k} + \sum_{m\in\mathcal{M}(j,l)} g^{\mathrm{old}}_{j,m,l}\,\gamma_{j,m}$$

As noted in [100], there are always two possibilities to implement these sums. For example, take the sum in the `Forward I` routine. We can either implement this as (after assigning 0 to $\gamma_{j,m}$)

$$\forall m \in \mathcal{M}(j)\,:\,\forall l \in \mathcal{L}(j,m)\,:\,\gamma_{j,m} \mathrel{+}= \widetilde{g}^{\mathrm{old}}_{j,m,l}\,\lambda_{j+1,l}$$

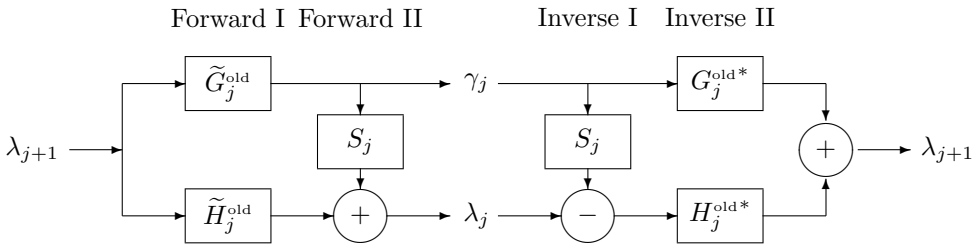

FIG. 9.1. *The fast lifted wavelet transform: the basic idea is to first perform a transform with the old, simple filters and later "lift" the scaling function coefficients with the help of wavelet coefficients. The inverse transform first undoes the lifting and then performs an inverse transform with the old filters.*

or as

$$\forall l \in \mathcal{K}(j+1) \,:\, \forall m \in \mathcal{M}(j,l) \,:\, \gamma_{j,m} \mathrel{+}= \widetilde{g}^{\text{old}}_{j,m,l}\, \lambda_{j+1,l}\,.$$

The first option loops over all m, for each $\gamma_{j,m}$ identifies the $\lambda_{j+1,l}$ that determine its value, then calculates the linear combination and assigns it into $\gamma_{j,m}$. The second option loops over all l, identifies the $\gamma_{j,m}$ which are influenced by $\lambda_{j+1,l}$, and then adds on the right amount to each $\gamma_{j,m}$. Both options are theoretically equivalent, but often one of the two is much easier to implement than the other; see for example [100]. There one of the index sets always contains the same number of elements, while the cardinality of the other can vary depending on the mesh.

10. Cakewalk construction. In this section we discuss how one can iterate the lifting scheme to bootstrap one's way up to a multiresolution analysis with desired properties.

We first introduce the *dual lifting scheme*. The basic idea is the same as for the lifting scheme except that we now leave the dual scaling function and the $\widetilde{H}$ and G filters untouched. The H and $\widetilde{G}$ filters and the dual wavelet, scaling function, and wavelet (by refinement) change. We can use the dual lifting scheme to custom design the dual wavelet. If we denote the operator involved with $\widetilde{S}_j$, the new set of biorthogonal filter operators is given by

$$\begin{aligned}
H_j &= H_j^{\text{old}} + \widetilde{S}_j\, G_j^{\text{old}}\,,\\
\widetilde{H}_j &= \widetilde{H}_j^{\text{old}}\,,\\
G_j &= G_j^{\text{old}}\,,\\
\widetilde{G}_j &= \widetilde{G}_j^{\text{old}} - \widetilde{S}_j^*\, \widetilde{H}_j^{\text{old}}\,,
\end{aligned}$$

where $\widetilde{S}_j$ is an operator from $\ell^2(\mathcal{M}(j))$ to $\ell^2(\mathcal{K}(j))$. Relationships like (8.2) and (8.1) can be obtained by simply toggling the tildes. In the second stage of the fast wavelet transform, the γ_j coefficients are now lifted with the help of the λ_j coefficients calculated in the first stage.

We now can alternate lifting and dual lifting. For example, after increasing the number of vanishing moments of the wavelet with the lifting scheme, one can use the dual lifting scheme to increase the number of vanishing moments of the dual wavelet. By iterating lifting and dual lifting, one can bootstrap one's way up to a multiresolution analysis with desired properties on primal and dual wavelets. This is the basic idea behind the *cakewalk* construction.

There is one issue that remains to be checked to allow cakewalk constructions. Suppose we first use dual lifting to increase the number of vanishing moments of the dual wavelet. How do we know that this will not be ruined by later lifting? Remember that lifting changes the dual scaling function and thus, by refinement, the dual wavelet. The answer is given by the following theorem.

THEOREM 10.1. *Consider a multiresolution analysis with order N. After lifting, the first N moments of the dual scaling function and dual wavelet do not change.*

Proof. The primal scaling functions do not change after lifting. This means that

$$P_p \;=\; \sum_k \langle\, P_p, \widetilde{\varphi}^{\,\mathrm{old}}_{j,k} \,\rangle\, \varphi_{j,k} \;=\; \sum_k \langle\, P_p, \widetilde{\varphi}_{j,k} \,\rangle\, \varphi_{j,k} \quad \text{for} \quad 0 \le p < N\,.$$

This implies that the first N moments of the dual scaling functions do not change after lifting. Since the coefficients of the refinement relations of the dual wavelets do not change (8.3), neither do their moments. ∎

Thus lifting does not alter the number of vanishing moments of the dual wavelet obtained by prior lifting.

Suppose we use dual lifting to increase the number of dual vanishing moments from N^{old} to N. This involves solving a linear system of size N, independent of how many vanishing moments the old dual wavelets already had. This means that if we use a cakewalk construction the linear systems to be solved become larger and larger, and so do the S filters. Therefore we present a scheme which allows us to exploit the fact that the dual wavelets already have N^{old} moments and thus only solve a system of size $N - N^{\mathrm{old}}$. The basic idea is to lift an old dual wavelet ($\widetilde{\psi}^{\,\mathrm{old}}_{j,m}$) not with old dual *scaling functions* on the same level ($\widetilde{\varphi}^{\,\mathrm{old}}_{j,k}$) but with old dual *wavelets* on the coarser level ($\widetilde{\psi}^{\,\mathrm{old}}_{j-1,n}$). This leads to a new dual wavelet of the form

$$\widetilde{\psi}_{j,m} \;=\; \widetilde{\psi}^{\,\mathrm{old}}_{j,m} - \sum_{n \in \mathcal{M}(j-1)} \widetilde{t}_{j,n,m}\, \widetilde{\psi}^{\,\mathrm{old}}_{j-1,n}\,.$$

Here the $\widetilde{t}_{j,n,m}$ are the coefficients of a filter operator $\widetilde{T}_j : \ell^2(\mathcal{M}(j)) \to \ell_2(\mathcal{M}(j-1))$. We always assume that the index n belongs to $\mathcal{M}(j-1)$. Note that the new dual wavelets independent of $\widetilde{T}$ immediately have at least as many vanishing moments as the old ones (N^{old}). Expressing that the new dual wavelets have N vanishing moments leads to only $N - N^{\mathrm{old}}$ equations in the unknowns $\{\widetilde{t}_{j,n,m} \mid n\}$.

Let us try to find a fast wavelet transform associated with this. In operator notation we have

$$\widetilde{\psi}_j \;=\; \widetilde{\psi}^{\,\mathrm{old}}_j - \widetilde{T}^*_j\, \widetilde{\psi}^{\,\mathrm{old}}_{j-1} \;=\; \widetilde{\psi}^{\,\mathrm{old}}_j - \widetilde{T}^*_j\, \widetilde{G}^{\,\mathrm{old}}_{j-1}\, \widetilde{\varphi}^{\,\mathrm{old}}_j\,.$$

This construction thus corresponds to letting $\widetilde{S}^*_j = \widetilde{T}^*_j\, \widetilde{G}^{\,\mathrm{old}}_{j-1}$. The basic idea is to use only the old filters and the filter $\widetilde{T}$ and never construct the $\widetilde{S}$ filter or any of the new filters explicitly. The forward transform takes three stages:

- I: Given the sequence λ_{j+1} calculate the forward transform with the old filters: $\lambda_j := \widetilde{H}^{\,\mathrm{old}}_j\, \lambda_{j+1}$ and $\gamma_j := \widetilde{G}^{\,\mathrm{old}}_j\, \lambda_{j+1}$.
- II: Calculate another level with the old filters: $\lambda_{j-1} := \widetilde{H}^{\,\mathrm{old}}_{j-1}\, \lambda_j$ and $\gamma_{j-1} := \widetilde{G}^{\,\mathrm{old}}_{j-1}\, \lambda_j$.
- III: Lift the γ_j with the γ_{j-1}: $\gamma_j - = \widetilde{T}^*_j\, \gamma_{j-1}$.

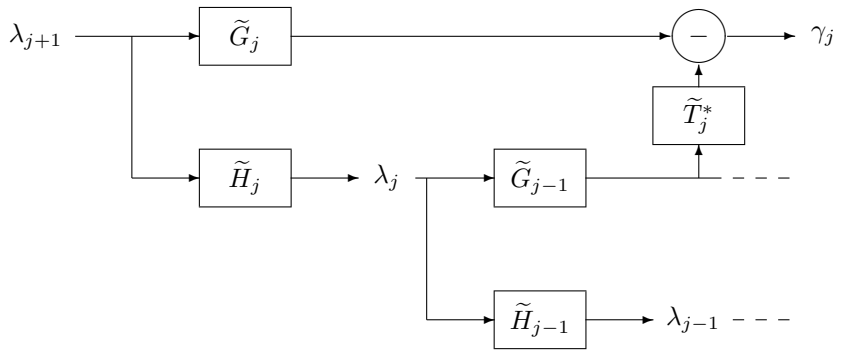

FIG. 10.1. *Part of a cakewalk construction. The basic idea is to lift the wavelet coefficients with wavelet coefficients on the coarser level. This way the fact that the old dual wavelets already have N^{old} vanishing moments can be exploited.*

Note that the second stage on level j coincides with the first stage on level $j-1$; see Figure 10.1 for a block diagram. The inverse transform in a first stage undoes the lifting and then applies an inverse transform with the old filters.

We have seen how the lifting scheme can pass between an old and a new multiresolution analysis. To start the construction of second generation wavelets we therefore need an initial multiresolution analysis. In the following sections we will give three examples of an initial multiresolution analysis to start the lifting scheme.

11. Orthogonal Haar wavelets. In this section we present the generalized orthogonal Haar wavelets, which form a first example of an initial multiresolution analysis to start the lifting scheme. The idea was first introduced by Coifman, Jones, and Semmes for dyadic cubes in [33], generalized for Clifford-valued measures in [9, 91], and later generalized for arbitrary partitionings in [68].

We first introduce the notion of a *nested set of partitionings*.

DEFINITION 11.1. *A set of measurable subsets $\{X_{j,k} \mid j,k\}$ is a* nested set of partitionings *if it is a set of partitionings and if, for every j and k, $X_{j,k}$ can be written as a finite disjoint union of at least two sets $X_{j+1,l}$:*

$$X_{j,k} = \bigcup_{l \in \mathcal{L}(j,k)} X_{j+1,l}\,.$$

Note that because of the partition property ($X_{j,k} \subset X_{j+1,k}$) we have that $k \in \mathcal{L}(j,k)$. Let $\varphi_{j,k} = \chi_{X_{j,k}}$ and $\widetilde{\varphi}_{j,k} = \chi_{X_{j,k}}/\mu(X_{j,k})$ according to our normalization (3.2). Define the $V_j \subset \mathrm{L}_2$ as

$$V_j \;=\; \operatorname{clos}\operatorname{span}\{\varphi_{j,k} \mid k \in \mathcal{K}(j)\}\,.$$

The spaces V_j generate a multiresolution analysis of L_2; see, e.g., [68] for a proof. As the scaling functions are orthogonal, we let W_j be the orthogonal complement of V_j in V_{j+1} so that $\widetilde{V}_j = V_j$.

Now fix a scaling function $\varphi_{j,k}$. For the construction of the Haar wavelets, we only need to consider the set $X_{j,k}$. First we assume without loss of generality that $\mathcal{L}(j,k)$ contains either two or three elements. Indeed, if $\mathcal{L}(j,k)$ contains more elements, we can split them into two groups whose numbers of elements differ by at most one. For each group we can introduce (implicitly) a new corresponding $X_{j',k'}$. We can continue

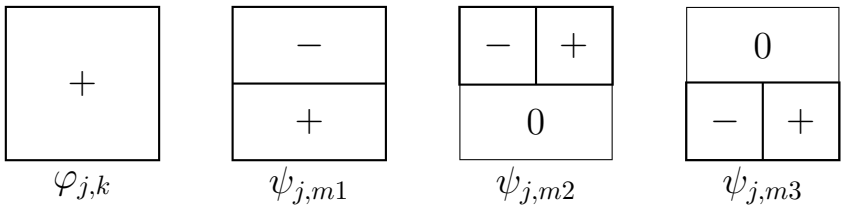

FIG. 11.1. *The generalized orthogonal Haar wavelets for square partitionings. The wavelets are piecewise constant and have a vanishing integral. The sign is indicated in the support. The orthogonality follows immediately from the support and the vanishing integral of the wavelets. Similar constructions apply to arbitrary partitionings.*

to do this until the number of elements is either 2 or 3. In case $\mathcal{L}(j,k) = \{k, m\}$ we let the wavelet $\psi_{j,m}$ be

$$\psi_{j,m} \;=\; \frac{\varphi_{j+1,k}}{2\,\mu(X_{j+1,k})} - \frac{\varphi_{j+1,m}}{2\,\mu(X_{j+1,m})}\,. \tag{11.1}$$

In case $\mathcal{L}(j,k) = \{k, m, m'\}$ we keep $\psi_{j,m}$ as above and let

$$\psi_{j,m'} \;=\; \frac{\varphi_{j+1,k} + \varphi_{j+1,m}}{2\,\mu(X_{j+1,k}) + 2\,\mu(X_{j+1,m})} - \frac{\varphi_{j+1,m'}}{2\,\mu(X_{j+1,m'})}\,.$$

In case $\mathcal{L}(j,k) = \{k, m1, m2, m3\}$, we need two stages. Each stage involves two sets and a wavelet of the form (11.1); see Figure 11.1. The Haar wavelets are constructed so that

$$\int_X \psi_{j,m}\,d\mu \;=\; 0 \quad \text{and} \quad \int_X |\psi_{j,m}|\,d\mu \;=\; 1\,.$$

They are orthogonal to $\varphi_{j,k}$ because they have a vanishing integral. Two different wavelets are orthogonal, since either their supports are disjoint or one is constant on the support of the other.

These wavelets form an orthogonal basis for L_2. In fact, they also form an unconditional basis for L_p.

THEOREM 11.2 (see [68]). *The generalized orthogonal Haar wavelets* $\{\psi_{j,m} \mid j, m\}$ *form an unconditional basis for* L_p *with* $1 < p < \infty$*, with unconditional basis constant* $p^* - 1$*, where* $1/p + 1/p^* = 1$.

This construction allows for Haar wavelets adapted to the settings G1–G3 mentioned in the introduction. Their advantage is their generality. Their disadvantages are that they are nonsmooth and that they have only one vanishing moment. However, they form a perfect example of an initial multiresolution analysis to start the lifting scheme with. With the lifting scheme we can build wavelets with more vanishing moments and/or more smoothness.

In the case of the real line and the classical Haar wavelet, the dual lifting scheme corresponds to a technique called *average interpolation* introduced by Donoho in [56]. Here $\widetilde{\varphi}$ is the indicator function on $[0,1]$, while φ is constructed through a subdivision scheme which ensures that polynomials up to a certain order can be reproduced with the scaling functions. This condition is precisely the same as the vanishing moment condition of the dual wavelet as used in dual lifting. The average interpolating technique can be generalized to a second generation setting; see, e.g., [104] for the construction of weighted wavelets. It generates primal and dual scaling functions which

are biorthogonal. However, it is not immediately clear what the wavelets and dual wavelets are. In other words there is no immediate generalization for the quadrature mirror filter construction where one takes $\widetilde{g}_k = (-1)^k h_{1-k}$. The dual lifting scheme provides a very simple solution to this problem. Again, the idea is to *first* construct the dual wavelets and later check what happens to the scaling functions using the cascade algorithm.

12. Interpolating scaling functions and wavelets. In this section we introduce the Lazy wavelet, another candidate to start the lifting scheme with, which is even simpler than the Haar wavelets. We show how it is connected with interpolating scaling functions.

12.1. The Lazy wavelet. One way to look at the general index sets $\mathcal{K}(j)$ and $\mathcal{M}(j)$ is to think of $\mathcal{K}(j)$ (respectively, $\mathcal{M}(j)$) as the generalization of the even (respectively, odd) indices. This inspires us to define two *subsampling operators* E (**e**ven) and D (o**d**d) as follows:

$E : \ell^2(\mathcal{K}(j+1)) \to \ell^2(\mathcal{K}(j))$, where $b = E\,a$ means $b_k = a_k$ for $k \in \mathcal{K}(j)$.

$D : \ell^2(\mathcal{K}(j+1)) \to \ell^2(\mathcal{M}(j))$, where $c = D\,a$ means $c_m = a_m$ for $m \in \mathcal{M}(j)$.

Although these operators depend on the level j we will not supply them with an extra subscript, since no confusion is possible. These operators provide a trivial orthogonal splitting, as

$$\begin{bmatrix} E \\ D \end{bmatrix} \begin{bmatrix} E^* & D^* \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} E^* & D^* \end{bmatrix} \begin{bmatrix} E \\ D \end{bmatrix} = 1\,.$$

We can now decompose any operator $W : \ell^2(\mathcal{K}(j)) \to \ell^2(\mathcal{K}(j))$ as

$$W = W_e\,E + W_d\,D\,, \quad \text{with} \quad W_e = W\,E^* \quad \text{and} \quad W_d = W\,D^*\,. \tag{12.1}$$

The filter operators of the *Lazy wavelet* are precisely these subsampling operators

$$H_j^{\text{Lazy}} = \widetilde{H}_j^{\text{Lazy}} = E \quad \text{and} \quad G_j^{\text{Lazy}} = \widetilde{G}_j^{\text{Lazy}} = D\,.$$

The Lazy wavelet transform thus is an orthogonal transform that essentially does nothing. It only resamples the coefficients into two groups for each step and thus can be seen as the generalization of the polyphase transform to the second generation setting. However, it is important to consider since it is connected with interpolating scaling functions. The operators E and D are crucial when implementing the lifting scheme. Although they are mathematically trivial, the data structure in the program has to be designed carefully to make them easy to implement. With such a data structure, the implementation of the lifting scheme is straightforward.

Given a set of partitionings, one can formally associate scaling functions and dual scaling functions with the Lazy wavelet. By using the cascade algorithm pointwise and respecting the normalization, one can see that $\widetilde{\varphi}_{j,k} = \delta(\cdot - x_k)$ and that $\varphi_{j,k}$ is zero everywhere except at x_k where it is one. Formally they are biorthogonal, but in the L_2 setting, $\widetilde{\varphi}_{j,k}$ does not belong to the space while $\varphi_{j,k}$ is zero. The wavelets and dual wavelets are given by $\psi_{j,m} = \varphi_{j+1,m}$ and $\widetilde{\psi}_{j,m} = \varphi_{j+1,m}$, and $N = \widetilde{N} = 0$.

12.2. Interpolating scaling functions. Next, we generalize the notion of an interpolating scaling function. We first need a *set of interpolation points* $\{x_k \mid j \in \mathcal{J}, k \in \mathcal{K}(j)\}$. Remember that such a set can be defined by a set of partitionings. In

the other direction, we can associate a set of partitionings with a set of interpolating points as follows. Assume that

$$\forall k \; : \; \inf_{j \in \mathcal{J},\, k' \in \mathcal{K}(j)} \; d(x_k, x_{k'}) = 0$$

for all k. Then let

$$S_{j,k} = \{x \in X \mid d(x, x_k) < d(x, x_{k'}) \text{ for } k' \in \mathcal{K}(j), k \neq k'\}\,.$$

The sets $S_{j,k}$ are the *Voronoi cells* of the set of points $\{x_k \mid k \in \mathcal{K}(j)\}$.

DEFINITION 12.1. *A set of scaling functions* $\{\varphi_{j,k} \mid j,k\}$ *is* interpolating *if a set of interpolation points* x_k *exists so that* $\varphi_{j,k}(x_{k'}) = \delta_{k,k'}$ *for* $k, k' \in \mathcal{K}(j)$.

As in the first generation case, the interpolating property can be characterized by means of the coefficients of the refinement relation. We state and prove the result in the index notation.

LEMMA 12.2. *If a set of second generation scaling functions is interpolating, then*

$$\forall\, k, k' \in \mathcal{K}(j) : h_{j,k,k'} \;=\; \delta_{k,k'}\,. \tag{12.2}$$

Proof.

$$\delta_{k,k'} = \varphi_{j,k}(x_{k'}) = \sum_m h_{j,k,l}\, \varphi_{j+1,l}(x_{k'}) = \sum_m h_{j,k,l}\, \delta_{l,k'} \;=\; h_{j,k,k'}\,. \qquad \square$$

Note that this lemma can be seen as a special case of Remark 4.2 in [41]. A filter h is called an *interpolating filter* if condition (12.2) holds. This condition can be written in operator notation as

$$H_j^{\text{int}}\, E^* \;=\; 1\,.$$

Note that this is the generalization of an *à trous* filter in the first generation case.

If we have an interpolating scaling function, we can always take Dirac functions as a formal dual

$$\widetilde{\varphi}_{j,k}^{\text{int}} \;=\; \delta(\cdot - x_k)\,.$$

The biorthogonality follows immediately from the interpolation property. The filter corresponding to the dual scaling function is

$$\widetilde{H}^{\text{int}} \;=\; E\,.$$

Now define $\widetilde{S}_j$ as $H_j^{\text{int}}\, D^*$. Then it follows from (12.1) that any interpolating filter can be written as $H_j^{\text{int}} = E + \widetilde{S}_j\, D$. But this expression can be seen as the result of applying the dual lifting scheme to the Lazy wavelet. We can then write a set of biorthogonal filters as

$$\begin{aligned}
H_j^{\text{int}} &= E + \widetilde{S}_j\, D\,,\\
\widetilde{H}_j^{\text{int}} &= E\,,\\
G_j^{\text{int}} &= D\,,\\
\widetilde{G}_j^{\text{int}} &= D - \widetilde{S}_j^*\, E\,.
\end{aligned}$$

We have thus shown the following theorem.

THEOREM 12.3. *The set of filters resulting from interpolating scaling functions, and Diracs as their formal dual, can be seen as a dual lifting of the Lazy wavelet.*

In index notation the filters become

$$\begin{aligned}
h^{\text{int}}_{j,k,l} &= \begin{cases} \delta_{k,l} & \text{if } l \in \mathcal{K}(j)\,, \\ \widetilde{s}_{j,k,l} & \text{if } l \in \mathcal{M}(j)\,, \end{cases} \\
\widetilde{h}^{\text{int}}_{j,k,l} &= \delta_{k,l}\,, \\
g^{\text{int}}_{j,m,l} &= \delta_{m,l}\,, \\
\widetilde{g}^{\text{int}}_{j,m,l} &= \begin{cases} -\widetilde{s}_{j,l,m} & \text{if } l \in \mathcal{K}(j)\,, \\ \delta_{m,l} & \text{if } l \in \mathcal{M}(j)\,. \end{cases}
\end{aligned}$$

Formally the dual wavelets are given by

$$\widetilde{\psi}_{j,m} \;=\; \delta(\cdot - x_m) - \sum_k h_{j,k,m}\delta(\cdot - x_k)\,.$$

The primal wavelets are $\psi_{j,m} \;=\; \varphi_{j+1,m}$. We have $\widetilde{N} = 0$ and N possibly > 0. These filters do not correspond to a multiresolution analysis of L_2, as the dual functions are Dirac distributions which do not even belong to L_2. In the case of linear interpolation, this example corresponds to what is known in finite elements as "hierarchical basis functions" [116].

We next apply the lifting scheme to find wavelets which have $\widetilde{N} > 0$. This leads to new filters of the form

$$\begin{aligned}
H_j = H^{\text{int}}_j \;&=\; E + \widetilde{S}_j\, D\,, \\
\widetilde{H}_j = \widetilde{H}^{\text{int}}_j + S_j\, \widetilde{G}^{\text{int}}_j \;&=\; (1 - S_j\, \widetilde{S}^*_j)\, E + S_j\, D\,, \\
G_j = G^{\text{int}}_j - S^*_j\, H^{\text{int}}_j \;&=\; -S^*_j\, E + (1 - S^*_j\, \widetilde{S}_j)\, D\,, \\
\widetilde{G}_j = \widetilde{G}^{\text{int}}_j \;&=\; -\widetilde{S}^*_j\, E + D\,.
\end{aligned}$$

This can be verified using Figure 12.1. For example, to find $\widetilde{H}_j$, follow the paths from λ_{j+1} to λ_j. There are three: one direct through E, one through D and then down through S_j, and one through E then up through $\widetilde{S}^*_j$ and down through S_j. Consequently $\widetilde{H}_j = (1 - S_j\, \widetilde{S}^*_j)\, E + S_j\, D$. In index notation this becomes

$$\widetilde{h}_{j,k,l} = \delta_{k,l} + \sum_m s_{j,k,m}\, \widetilde{g}_{j,m,l},$$

$$g_{j,m,l} = \delta_{m,l} - \sum_k s_{j,k,m}\, h_{j,k,l}\,.$$

The new wavelet can be written as

$$\psi_{j,m} \;=\; \varphi_{j+1,m} - \sum_{k \in \mathcal{K}(j,m)} s_{j,m,k}\, \varphi_{j,k}. \tag{12.3}$$

One can find the $s_{j,k,m}$ in the same way as described above.

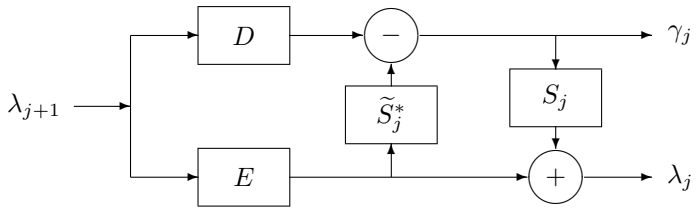

FIG. 12.1. *The fast wavelet transform for wavelets built from interpolating scaling functions. First apply a Lazy wavelet transform, then a dual lifting, and finally a regular lifting.*

12.3. Algorithm. The algorithm for the wavelet transform associated with the wavelets constructed in the previous section consists of three stages. First a Lazy wavelet transform, then a dual lifting, and finally a primal lifting; see Figure 12.1. The inverse transform can be derived immediately by simply inverting each step of the forward transform.

```
Forward(j):
```

$$\begin{aligned}
\forall k \in \mathcal{K}(j): \quad & \lambda_{j,k} \;:=\; \lambda_{j+1,k} \\
\forall m \in \mathcal{M}(j): \quad & \gamma_{j,m} \;:=\; \lambda_{j+1,m} \\
\forall m \in \mathcal{M}(j): \quad & \gamma_{j,m} \;-\!=\; \sum_{k \in \widetilde{\mathcal{K}}(j,m)} \widetilde{s}_{j,k,m}\, \lambda_{j,k} \\
\forall k \in \mathcal{K}(j): \quad & \lambda_{j,k} \;+\!=\; \sum_{m \in \mathcal{M}(j,k)} s_{j,k,m}\, \gamma_{j,m}
\end{aligned}$$

```
Inverse(j):
```

$$\begin{aligned}
\forall k \in \mathcal{K}(j): \quad & \lambda_{j,k} \;-\!=\; \sum_{m \in \mathcal{M}(j,k)} s_{j,k,m}\, \gamma_{j,m} \\
\forall m \in \mathcal{M}(j): \quad & \gamma_{j,m} \;+\!=\; \sum_{k \in \widetilde{\mathcal{K}}(j,m)} \widetilde{s}_{j,k,m}\, \lambda_{j,k} \\
\forall m \in \mathcal{M}(j): \quad & \lambda_{j+1,m} \;:=\; \gamma_{j,m} \\
\forall k \in \mathcal{K}(j): \quad & \lambda_{j+1,k} \;:=\; \lambda_{j,k}
\end{aligned}$$

One of the nice properties of the fast lifted wavelet transform is that all calculations can be done in place, i.e., without auxiliary memory. It is sufficient to provide storage locations only for the coefficients $\lambda_{n,k}$ of the finest levels. No additional auxiliary memory is needed. A coefficient $\lambda_{j,k}$ with $j < n$ can be stored in the same location as $\lambda_{n,k}$, while a wavelet coefficient $\gamma_{j,m}$ with $j < n$ can be stored in the same location as $\lambda_{n,m}$. The Lazy wavelet transform now simply requires blinking your eyes. Lifting will only require updates with local neighboring coefficients (typically $+=$ or $-=$ operators in the implementation) and thus does not need extra storage.

13. Biorthogonal Haar wavelets. In this section we introduce a third example of an initial multiresolution analysis: the biorthogonal Haar wavelets. They were first used in triangular subdivision in [99]. On triangles, biorthogonal Haar wavelets have more symmetry than orthogonal Haar wavelets. We here show how the biorthogonal Haar wavelets themselves can be seen as a result of lifting from the Lazy wavelet.

Take a set of nested partitionings $X_{j,k}$. Note that this defines the index sets $\mathcal{L}(j,k)$. Consider the Lazy scaling function and wavelet

$$\widetilde{\varphi}_{j,k}^{\text{Lazy}} \;=\; \delta(\cdot - x_k) \quad \text{and} \quad \widetilde{\psi}_{j,m}^{\text{Lazy}} \;=\; \delta(\cdot - x_m)\,.$$

Let us first apply dual lifting and denote the resulting functions with a superscript (1). Fix a $k^* \in \mathcal{K}(j)$ and let $\mathcal{M}(j,k^*) = \mathcal{L}(j,k^*)\backslash\{k^*\}$. In order for the new wavelet $\widetilde{\psi}_{j,m}^{(1)}$ with $m \in \mathcal{M}(j,k^*)$ to have one vanishing moment, we let

$$\widetilde{\psi}_{j,m}^{(1)} \;=\; \delta(\cdot - x_m) - \delta(\cdot - x_{k^*}) \;=\; \widetilde{\varphi}_{j+1,m}^{(1)} - \widetilde{\varphi}_{j+1,k^*}^{(1)}$$

so that $\mathcal{K}(j,m) = \{k^*\}$ and $\widetilde{s}_{j,k,m} = \delta_{k,k^*}$. This implies that the scaling function satisfies

$$\varphi_{j,k^*}^{(1)} = \varphi_{j+1,k^*}^{(1)} + \sum_{m\in\mathcal{M}(j,k^*)} \widetilde{s}_{j,k,m}\,\varphi_{j+1,m}^{(1)} = \sum_{l\in\mathcal{L}(j,k^*)} \varphi_{j+1,l}^{(1)} \tag{13.1}$$

which yields that $\varphi_{j,k}^{(1)} = \chi_{X_{j,k}}$ and thus $\psi_{j,m}^{(1)} = \chi_{X_{j+1,m}}$. We now have $N = 1$ and $\widetilde{N} = 0$ and could call this a *half-Haar basis*. Note that this half-Haar wavelet is used in the interlaced GIF format which is currently quite popular on the World Wide Web.

Next we use lifting to obtain a primal wavelet with a vanishing moment. We choose

$$\psi_{j,m} = \psi_{j,m}^{(1)} - s_{j,k^*,m}\,\varphi_{j,k*}^{(1)} \quad \text{with} \quad k^* \in \mathcal{K}(j,m)\,,$$

where $s_{j,k,m} = \mu(X_{j+1,m})/\mu(X_{j,k})$ if $m \in \mathcal{M}(j,k)$ and zero otherwise. In this way $\psi_{j,m}$ has one vanishing moment. The new dual scaling function becomes

$$\begin{aligned}
\widetilde{\varphi}_{j,k} &= \widetilde{\varphi}_{j+1,k} + \sum_{m\in\mathcal{M}(j,k)} \mu(X_{j+1,m})/\mu(X_{j,k})\,\widetilde{\psi}_{j,m} \\
&= \widetilde{\varphi}_{j+1,k} + \sum_{m\in\mathcal{M}(j,k)} \mu(X_{j+1,m})/\mu(X_{j,k})\,(\widetilde{\varphi}_{j+1,m} - \widetilde{\varphi}_{j+1,k}) \quad \text{(see (13.1))} \\
&= \sum_{m\in\mathcal{M}(j,k)} \mu(X_{j+1,m})/\mu(X_{j,k})\,\widetilde{\varphi}_{j+1,m} \\
&\qquad + \left(1 - \sum_{m\in\mathcal{M}(j,k)} \mu(X_{j+1,m})/\mu(X_{j,k})\right)\,\widetilde{\varphi}_{j+1,k} \\
&= \sum_{l\in\mathcal{L}(j,k)} \mu(X_{j+1,l})/\mu(X_{j,k})\,\widetilde{\varphi}_{j+1,l} \\
&= \chi_{X_{j,k}}/\mu(X_{j,k})\,.
\end{aligned}$$

Summarizing, we have the following basis functions, which generate the *biorthogonal Haar* multiresolution analysis:

$$\begin{aligned}
&\varphi_{j,k} = \chi_{X_{j,k}}\,, \\
&\widetilde{\varphi}_{j,k} = \chi_{X_{j,k}}/\mu(X_{j,k})\,, \\
&\psi_{j,m} = \varphi_{j+1,m} - \mu(X_{j+1,m})/\mu(X_{j,k^*})\,\varphi_{j,k^*} \quad \text{with} \quad \{k^*\} = \mathcal{K}(j,m)\,, \\
&\widetilde{\psi}_{j,m} = \widetilde{\varphi}_{j+1,m} - \widetilde{\varphi}_{j+1,k^*}\,.
\end{aligned}$$

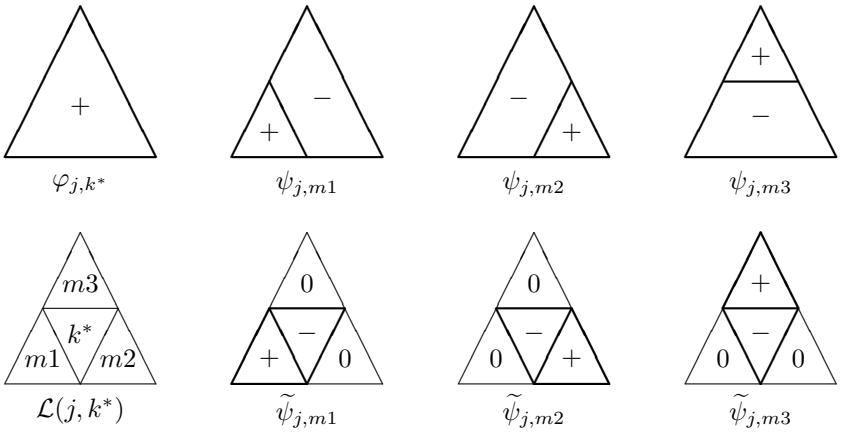

FIG. 13.1. *The biorthogonal Haar wavelets on triangles. Biorthogonality follows from the support and the vanishing integral of wavelets and dual wavelets. On triangles the biorthogonal Haar wavelets are more symmetric than the orthogonal Haar. This is another example to start the lifting scheme with.*

Figure 13.1 shows the biorthogonal Haar wavelets for a triangular partitioning. Given that the scaling function and dual scaling function are multiples of each other, we actually have a semi-orthogonal setting. This means that the V_j and $\widetilde{V}_j$ spaces coincide. Consequently wavelets on different levels are orthogonal, but within one level the wavelets are not orthogonal. The biorthogonal Haar multiresolution analysis is another example of an initial multiresolution analysis with $N = \widetilde{N} = 1$. Here we actually showed how it can be constructed by twice lifting the Lazy wavelet.

The algorithm for the biorthogonal Haar transform is given below. Again all calculations can be done in place.

`Forward(j):`

$$\forall m \in \mathcal{M}(j): \quad \gamma_{j,m} := \lambda_{j+1,m} - \lambda_{j+1,k} \qquad (\{k^*\} = \mathcal{K}(j,m))$$
$$\forall k \in \mathcal{K}(j): \quad \lambda_{j,k} := \lambda_{j+1,k} + \sum_{m \in \mathcal{M}(j,k)} s_{j,k,m}\, \gamma_{j,m}$$

`Inverse(j):`

$$\forall k \in \mathcal{K}(j): \quad \lambda_{j+1,k} := \lambda_{j,k} - \sum_{m \in \mathcal{M}(j,k)} s_{j,k,m}\, \gamma_{j,m}$$
$$\forall m \in \mathcal{M}(j): \quad \lambda_{j+1,m} := \gamma_{j,m} + \lambda_{j+1,k} \qquad (\{k^*\} = \mathcal{K}(j,m))$$

14. Applications and future research. Now that we understand the machinery of the lifting scheme, we can start to apply it in the settings described in the introduction. We discuss a few cases in more detail.

14.1. Wavelets on an interval. As pointed out in the introduction, many wavelet constructions on the interval already exist. They all involve modifying the wavelets and scaling functions close to the end point of the interval, which leads to special boundary filters. The derivation of the boundary filters is actually quite technical and it is not immediately clear to the user why they work. With the aid of the lifting scheme, the construction of interval wavelets and the implementation of

the associated transform become much more transparent. The Haar and Lazy wavelet can be trivially defined on the interval. Lifting then only requires pulling in the right aunts (scaling functions on the coarser level) at the boundary of the interval. All calculations can be done in place. For details we refer to [106].

A software package, `LIFTPACK`, to calculate the wavelet transformation of images is currently available [64]. Its properties are in-place calculation, correct treatment of boundaries, arbitrary size images (not only powers of two), and a faster implementation of existing biorthogonal wavelet filters (speedup can be a factor of two).

14.2. Weighted wavelets. Let X be $\mathbf{R}$ and consider the weight function $w(x) = d\mu/dx$, where dx stands for the Lebesgue measure. The wavelets constructed with the lifting scheme are orthogonal with respect to a weighted inner product, where $w(x)$ is the weight function. We refer to them as weighted wavelets. They are useful for the approximation of functions with singularities. If a function f contains a singularity, then the approximation with first generation wavelets will be slow, independent of the number of dual vanishing moments N. If we can now choose a weight function w so that $w \cdot f$ is a smooth function, then the approximation with weighted wavelets will again be of the order of the number of vanishing moments. An example of this behavior is given in [106].

Weighted wavelets are also useful in the solution of boundary value ODEs; see [75, 104]. If the operator is of the form $-DaD$, then operator wavelets defined as the antiderivative of weighted wavelets with weight function $w(x) = \sqrt{a(x)}$ diagonalize the operator. The solution algorithm is thus simply a forward and inverse wavelet transform. Future research involves the incorporation of the operator wavelets construction directly into the lifting scheme.

14.3. Wavelets on curves, surfaces, and manifolds. The only thing needed to construct wavelets on manifolds is either a set of interpolating points to define a Lazy wavelet or a set of nested partitionings to define Haar wavelets. Lifting will take care of the rest. The resulting wavelets are defined intrinsically on the manifold and do not depend on any parameterization or atlas.

In [99] the lifting scheme is used to construct wavelets on a sphere. Partitionings of the sphere were obtained by starting from a Platonic solid and alternating triangular subdivision and projection out to the sphere. This is known as a geodesic sphere construction. The Lazy wavelet is the starting point for a family of vertex-based wavelets, while the biorthogonal Haar wavelets lead to a family of face-based wavelets. In [100] these wavelets were used for the processing of spherical images. Current research involves the generalization of the construction and the applications to arbitrary surfaces.

14.4. Adaptive wavelets. The idea of adaptive wavelets was introduced in [69, 97, 98] in the context of the numerical solution of integral equations for illumination computations. The idea is the following. Assume the solution can be approximated with sufficient accuracy in a linear space V_n of dimension M. We know that out of the M^2 matrix entries representing the integral operator in the wavelet basis, only a fraction $\mathcal{O}(M)$ is relevant. If we have these entries, solving the matrix equation can be done in linear ($\mathcal{O}(M)$) time.

However, calculating all wavelet coefficients of the kernel from the finest level n to the coarsest level 0 with the fast wavelet transform requires $\mathcal{O}(M^2)$ operations and is thus a waste of CPU time and memory. Indeed the majority of all computations and memory use will be in vain. If we want an algorithm with linear complexity we can

only afford to calculate the wavelet coefficients which we actually need or a slightly larger set.

Gortler, Schröder, et al. [69] achieve this with the use of an *oracle* function. This function predicts, in a conservative fashion and based upon knowledge of the kernel of the integral equation, which wavelet coefficients need to be calculated. They were able to implement this with the use of what they call *tree wavelets*. Tree wavelets have the property that each wavelet of level j is supported within the support of only one scaling function of level j. Haar wavelets and Alpert wavelets [4, 5, 6] have this property. The advantage is that subdividing the support of a scaling function on level j, and thus constructing the wavelets of level j associated with it, does not imply subdividing any other support sets on level j. This way they can calculate the wavelet coefficients from the *coarsest* level to the *finest* level, thereby only subdividing (adding wavelets) where the oracle tells them to.

With traditional (nontree) wavelets, subdividing a support set S on level j and constructing the wavelets associated with it (whose support may reach outside of S) will imply subdividing a neighboring set of S and dragging in the wavelets associated with that set. This process cascades out and would imply subdividing the *whole* level j and thus makes adaptive constructions awkward.

Tree wavelets are discontinuous and this is a drawback in many applications. As shown in [99], lifting provides a solution here. Indeed, because of the "aunt" property, subdividing a set S on level j only requires its neighbors to exist; it does not necessarily require them to be subdivided as well. The mesh only needs to satisfy a restriction criterion in the sense that neighboring sets only differ by at most one level. This does not cascade out. Lifting thus opens the door to smooth adaptive wavelets. Current research involves the incorporation of these wavelets in illumination computations.

A word of caution is needed here. In [46, 96] it is shown that adaptive wavelet algorithms require wavelets on manifolds satisfying specific conditions concerning stability, regularity, and norm equivalence. As pointed out earlier, lifting does not guarantee these conditions and they have to be verified in each particular case.

14.5. Recursive wavelets. The principle of *recursive wavelets* is explained in [8, 56]. The basic idea is not to use the cascade algorithm ad infinitum to construct the scaling functions, but instead fix the scaling functions on an arbitrary finest level n. This can be generalized easily to the second generation case. Consider a set of partitionings and let

$$\varphi_{n,k} \;=\; \chi_{S_{n,k}} \quad \text{for} \quad k \in \mathcal{K}(n)\,.$$

Next consider a general filter h (not necessarily a Haar filter) and define the scaling functions on the coarser level ($\varphi_{j,k}$ with $j < n$) through recursive applications of the refinement relation (4.1). By definition all scaling functions $\varphi_{j,k}$ are piecewise constant on the sets $\{S_{n,k} \mid k \in \mathcal{K}(n)\}$. This is precisely the advantage of recursive wavelets; no need to go through an infinite limit process to find the scaling functions, instead apply the refinement relation a finite number of times.

One can choose other functions than indicator functions as scaling functions on the finest level. The advantage of indicator functions is their generality; the disadvantage is that they are not smooth. If the topology admits it, smoother choices are piecewise linear (hat) functions or B/box-splines.

In the setting of recursive wavelets, there are L_2 functions associated with the Lazy wavelet. Indeed

$$\psi^{\text{Lazy}}_{j,m} \;=\; \varphi^{\text{Lazy}}_{j+1,m} \;=\; \varphi^{\text{Lazy}}_{n,m} \;=\; \chi_{S_{n,m}}\,.$$

In this paper, we have always assumed that the measure is nonatomic. This restriction, however, is not fundamental. Recursive wavelets allow for atomic measures. Indeed, there is no reason why any of the subsets of $S_{n,k}$ should be measurable. As is shown in [68], it is possible to build Haar wavelets on fully discrete sets such as the integers, or on sets which are of mixed continuous/discrete nature. Also the lifting scheme remains valid.

The idea of recursive wavelets can also be combined with the idea of adaptive wavelets of the previous section. Instead of fixing the scaling function on one finest level n, one can let the notion of finest level depend on the location. Indeed, the oracle of the previous section typically leads to finer subdivisions in certain locations and coarser subdivisions in other. The finest level $n(k)$ thus depends on the location k. We then fix the scaling functions

$$\varphi_{n(k),k} \;=\; \chi_{S_{n(k),k}}\,,$$

where

$$X = \bigcup_k S_{n(k),k}\,.$$

In other words, we are using an adaptive mesh.

It is important to note that even though recursive wavelets only use a finite number of levels, the stability issue does not go away but rather manifests itself as a problem concerning ill-conditioning.

14.6. Wavelet packets. *Wavelet packets* were introduced by Coifman, Meyer, and Wickerhauser [34, 35, 114, 115]. The idea is to also further split the W_j spaces with the help of the h and g filters. This way one obtains a better frequency localization. The splitting leads to a full binary tree of wavelet packets, which form a redundant set. For a given function, one can choose the *best basis* with respect to a criterion such as the entropy of the basis coefficients. A fast tree algorithm to find the best basis was introduced in [36]; see also [115].

This idea again carries over into the second generation setting and can be combined with lifting. The conditions for exact reconstruction have exactly the same algebraic structure as in the wavelet case. One can start with defining a Lazy wavelet packet or a generalized Haar wavelet packet (which could be called generalized Walsh functions). A new wavelet packet is now defined as an old wavelet packet plus a linear combination of wavelet packets that live on a coarser level. From a practical point of view, one extra index comes in, and proper data structures need to be designed to incorporate the new filters.

14.7. M-band wavelets. The idea of *M-band wavelets*, or *p-adic wavelets*, a name more common in the mathematical literature, is to split a space V_{j+1} into M (as opposed to 2) subspaces: $V_j \oplus W_j^1 \oplus \cdots \oplus W_j^{M-1}$. For each subspace a different filter is used. Several constructions were introduced in [72, 81, 102, 109]. In some sense the second generation wavelet setting already incorporates this. Indeed, it even allows for different filters for each individual wavelet. However, thinking of lifting combined with M-band wavelets can lead to new constructions. Let us start with the Lazy wavelet. An M-band Lazy wavelet is easily defined and again is the standard polyphase transform [109]. Now one can define a new wavelet as an old wavelet plus a linear combination of scaling functions on the coarser level. This would be ordinary lifting. But we could also define a new wavelet as an old wavelet plus a

linear combination of scaling functions on a coarser level plus *wavelets belonging to another (lower index) subband*. This allows more flexibility in the construction. It requires that the M subband be calculated in ascending index order in the transform. In the extreme case one can let each subband contain precisely one wavelet. A new wavelet is now an old wavelet plus previously constructed new wavelets. This requires an ordering within the wavelets of one level. This way we can construct noncompactly supported wavelets with only finite filters.

14.8. Nonseparable wavelets in $\mathbf{R}^n$. As mentioned earlier, the lifting scheme also leads to new insights in the construction of first generation wavelets. This was shown in the one-dimensional case in [105]. Higher dimensional wavelets can always be constructed using tensor products, but this leads to severe axial directional dependencies. Instead one prefers to work with nonseparable wavelets which have more axial symmetry and which do not necessarily use a product lattice; see, for example, [22, 28, 32, 76, 77, 89, 90, 92, 93].

Here too lifting can help. Each lattice allows for the immediate definition of a Lazy wavelet or a Haar wavelet, either 2-band or M-band. Polynomial cancelation then leads to the filter coefficients. Whether lifting will actually lead to new wavelets in this context or rather provide faster implementations of already existing filters as in the one-dimensional case remains a topic for further study.

14.9. Wavelets on bounded domains and wavelet probing. One of the important application domains of wavelets is the solution of partial differential equations. In [44] it is shown that one can use wavelets to build multilevel preconditioners which result in stiffness matrices with uniformly bounded condition numbers. This leads to linear solution algorithms. To solve real life problems one needs wavelets constructed on nonsmooth (Lipschitz) domains in $\mathbf{R}^n$. In [27, 74] such a construction is presented. In both cases, tensor product wavelets are used in the interior of the domain while at the boundary specially adapted wavelets are constructed. In this sense these constructions are the natural generalization of the interval constructions to higher dimensions. With the lifting scheme one can build nonseparable wavelets adapted to general domains. Again the only thing needed is a set of partitionings. One nice property here is that lifting allows for adaptive meshes.

Already in the simple case of the Laplace equation and a nonsmooth domain it was recently shown that one cannot obtain an $\mathcal{O}(M^{-2})$ accuracy (where M is the number of elements) unless one uses nonlinear approximation [39]. The underlying reason is that the solution does not belong to the second-order Sobolev space but rather to a second-order Besov space. In other words, one has to use adaptive grids to obtain the correct convergence order.

There is another important application of wavelets on domains. It is a technique called *wavelet probing* introduced independently in [59] and [8, 53]. Let us discuss the idea first on the real line. Consider a function which is smooth except for jump discontinuities at isolated points. We know that the decay of the wavelet coefficients is fast away from the jumps, and slow in the neighborhood of the jumps. Increasing the number of dual vanishing moments leads to faster decay away from the jumps but also to a larger set of coefficients affected by the jumps because of the larger support. It is thus not possible to obtain more efficient approximations and thus better compression by simply increasing the number of dual vanishing moments.

Suppose now we know the location of the jumps. If we use interval wavelets on each interval between two jumps and thus segment the signal accordingly, we would get fast convergence *everywhere*. Wavelet probing is a technique which allows us to

locate the jumps. It simply tries every location between two samples and checks whether it would pay off to segment at this location. The payoff can be measured, e.g., with the entropy of the wavelet coefficients. Probing one location only requires altering $\log M$ coefficients where M is the number of samples. The whole algorithm thus has a complexity of $M \log M$.

Wavelet probing has important applications in image compression. Indeed it allows quick localization of the edges in an image, and then builds wavelets on the segments defined by those edges. Considerably higher compression ratios can be obtained this way. Wavelet probing thus provides an alternative for the zero crossing representation introduced by Mallat and Zhong [82, 83]. The advantage is that no iterative reconstruction is needed. Wavelet probing interacts easily with lifting and the adaptive wavelets mentioned above.

14.10. Wavelets adapted to irregular samples. As we mentioned in the introduction, one of the motivations for the generalization to second generation wavelets was the processing of irregularly sampled data. Let us discuss this first on the real line. Assume we are given irregular samples of a function $f(x)$: $\lambda_{n,k} = f(x_k)$ with $k \in \mathcal{K}(n)$. We first need to define a Lazy wavelet; i.e., we need the sets $\mathcal{K}(j)$ with $j < n$ (the coarser levels) and the sets $\mathcal{M}(j)$ with $j \geq n$, together with the x_m for $m \in \mathcal{M}(j)$ (the finer levels). For the coarser levels we only need to decide *which* sample locations to retain, while for the finer levels we also have to decide *where* to put the new locations. Coarser levels are needed in the wavelet transform, finer in the cascade algorithm. A simple strategy, which was used in [106], is to retain every other sample on the coarser level and put a new sample in the middle of two old samples on the finer levels. Once a Lazy wavelet is defined, dual lifting provides interpolating scaling functions, and lifting yields wavelets with vanishing moments. The dual lifting can be seen as an instance of irregular Deslauriers–Dubuc subdivision [54, 55]. Current research involves the study of more advanced choices for the Lazy wavelet. One of the strategies is to choose the sample locations so that the ratio of the largest versus the smallest interval of a level becomes closer and closer to one on both the finer ($j > n$) and the coarser ($j < n$) levels. Future research also involves the study of these schemes in higher dimensions.

14.11. Integer to integer wavelet transforms. In [16] lifting is used to build reversible wavelets which map integers to integers for applications to lossless image coding. The idea is to introduce a nonlinear round-off in each lifting step. This way the result is guaranteed to be integer while the lifting assures that the transform is invertible. The exact same idea works in the second generation setting, and using this in second generation compression applications is another line of future research.

14.12. Conclusion. In this paper we presented the lifting scheme, a construction tool for wavelets adapted to general settings. We showed how one can start from a trivial multiresolution analysis and use lifting to work one's way up to a multiresolution analysis with particular properties. As we mentioned in the introduction, the lifting scheme provides an answer to the algebraic phase of a wavelet construction. For each of the applications mentioned in this section, one still has to verify whether the cascade algorithm converges, whether the resulting wavelets form a Riesz basis (analytic phase), and what their smoothness is (geometric phase).

Note. As mentioned in the introduction, we learned after finishing this work that Dahmen and collaborators independently obtained a construction of multiscale bases with a technique very similar to lifting [17]. Here we go into more detail comparing

the two approaches. Recall from Theorem 8.1 that the lifting involved an operator which can be written in matrix location as

$$\begin{bmatrix} 1 & S \\ 0 & 1 \end{bmatrix}.$$

The main advantage of this operator is that, independent of the choice of S, it is guaranteed to be invertible and the inverse can be found by flipping the sign on S. In the setting of [17] a more general operator of the form

$$\begin{bmatrix} 1 & S \\ 0 & K \end{bmatrix}$$

is used (which for $K = I$ becomes lifting). This operator is invertible if and only if K is invertible. The inverse is then given by

$$\begin{bmatrix} 1 & -SK^{-1} \\ 0 & K^{-1} \end{bmatrix}.$$

This setting is more general and allows us to explore *all* the degrees of freedom one has to generate new biorthogonal filters. In section 3.3 of [17] a $K \neq I$ is constructed which generates orthogonal decompositions. Section 4.1 of [17] discusses the case of compactly supported semi-orthogonal spline wavelets on irregular knot sequences. However, these settings do not allow both K and K^{-1} to be sparse.

There are certain advantages to the lifting ($K = I$) approach. One problem with the more general approach ($K \neq I$) is that it involves taking the inverse of K and does not guarantee that all primal and dual filters are finite. Infinitely supported filters are less useful practically and do not necessarily lead to fast transforms. Moreover, K^{-1} might be difficult to compute numerically. Many of the attractive features of lifting such as in-place computation, no need for inverting operators, and adaptive transforms using "aunt" functions disappear when allowing a general $K \neq I$.

In the first generation setting it was shown recently [52] that in case of finite filters no generality is lost when restricting oneself to the lifting setting: all finite filters can be obtained using multiple alternate primal and dual lifting steps.

On several occasions in this paper we mentioned that lifting does not guarantee stable bases or convergence of the associated subdivision scheme. In fact, many of these issues have been addressed carefully in [17, 41, 42] and we refer to those papers for details.

Acknowledgments. While this paper was being written (spring 1995), the author worked in close collaboration with Peter Schröder on the application of the lifting scheme to the construction of spherical wavelets [99, 100] and on a tutorial paper [106]. The feedback from the numerous and stimulating discussions with Peter was a tremendous help in writing this paper and has led to several new insights. Peter also helped by improving the exposition in this paper considerably. Also special thanks to Jelena Kovačević for pointing out the connection between the Lazy wavelet and the polyphase transform and to Thomas Barregren, Maurits Malfait, and Geert Uytterhoeven for carefully proofreading the text. Finally, the author would like to thank the two referees for their thorough reports and for pointing out oversights in the original submission. Their constructive comments have led to a much improved paper.

THE SHAPE OF THE TALLEST COLUMN*

STEVEN J. COX† AND C. MAEVE MCCARTHY†

Abstract. The height at which an unloaded column will buckle under its own weight is the fourth root of the least eigenvalue of a certain Sturm–Liouville operator. We show that the operator associated with the column proposed by Keller and Niordson [*J. Math. Mech.*, 16 (1966), pp. 433–446] *does not* possess a discrete spectrum. This calls into question their formal use of perturbation theory, so we consider a class of designs that permits a tapered summit yet still guarantees a discrete spectrum. Within this class we prove that the least eigenvalue increases when one replaces a design with its decreasing rearrangement. This leads to a very simple proof of the existence of a tallest column.

Key words. buckling load, self-weight, continuous spectrum, rearrangement

1. Introduction.

Euler [4], [5] posed and solved the problem of buckling of prismatic columns under self-weight. He found that a column, clamped at its base and free at its summit, could be built to a height of

$$H_c = \left(\frac{9EI}{4\rho A} j_{-1/3}^2\right)^{1/3}$$

before buckling under its own weight. Here E denotes Young's modulus, ρ denotes weight density, A and I denote cross-sectional area and its second moment, and $j_{-1/3} \approx 1.8663$ is the least positive root of the Bessel function of order $-1/3$. To take a particular instance, the critical height of a circular cylinder of volume V is

$$H_c = \left(\frac{9EV}{16\pi\rho} j_{-1/3}^2\right)^{1/4}.$$

Almost two hundred years elapsed before Keller and Niordson [9] asked what height one could reach if, while fixing V, the overall volume, one was permitted to taper the column by varying A, and hence I, from point to point. Keller and Niordson formulated the Euler problem of critical height in terms of an eigenvalue problem for an ordinary differential operator and proceeded to maximize its least eigenvalue over a large class of shapes. In the spirit of Keller's previous attacks on buckling problems, [8] and [14], it was supposed that this least eigenvalue varied smoothly over the admissible class of shapes. This approach led Keller and Niordson to propose a shape that is so severely tapered at its summit that we are able to show that the associated differential operator *does not* possess a discrete spectrum. As this calls into doubt their method, if not their result, we argue that the problem merits reconsideration. Indeed, though the literature on column buckling is vast, see, e.g., Gajewski and Zyczkowski [7], the tallest column problem appears to have started and ended with the work of Keller and Niordson!

In section 2 we recall Keller and Niordson's formulation of the problem, their proposed tallest column, and present a proof that the associated spectrum is not discrete. In section 3 we isolate an admissible class of designs that permits tapered ends and guarantees a discrete spectrum. Within this class we prove, in section 4, the intuitively obvious, though technically elusive, fact that the least eigenvalue increases when one replaces a shape with its decreasing rearrangement. This leads to a very simple proof, in section 5, of the existence of a tallest column.

2. The work of Keller and Niordson. Tapered cross sections appear through the dependence of A on z, the distance from the clamped base. Assuming simply connected, geometrically similar cross sections, we find $I(z) = \alpha A^2(z)$, where α is a geometric constant. If $y(z)$ is the lateral deflection, from vertical, of the cross section at z and $EI(z)y''(z)$ is the associated bending moment then a balance of moments brings

$$E\alpha A^2(z)y''(z) = \int_z^H \rho A(\tilde{z})[y(\tilde{z}) - y(z)]\,d\tilde{z}, \quad 0 < z < H, \tag{2.1}$$

where H is the height of the column. Clamping the column at its base is synonymous with $y(0) = y'(0) = 0$. With V denoting the column's volume, Keller and Niordson introduce the dimensionless variables

$$x = z/H, \quad a(x) = HA(xH)/V, \quad \eta(x) = y(xH)/H, \quad \lambda = \rho H^4/\alpha EV$$

and so arrive at

$$a^2(x)\eta'' = \lambda \int_x^1 a(\tilde{x})[\eta(\tilde{x}) - \eta(x)]\,d\tilde{x}, \quad \eta(0) = \eta'(0) = 0, \tag{2.2}$$

and the area normalization

$$\int_0^1 a\,dx = 1. \tag{2.3}$$

Differentiating (2.2) with respect to x and calling $u(x) = \eta'(x)$, they finally obtain

$$-(a^2(x)u'(x))' = \lambda \left(\int_x^1 a(t)\,dt \right) u(x), \quad 0 < x < 1, \quad u(0) = a^2(1)u'(1) = 0. \tag{2.4}$$

We shall refer to this eigenvalue problem as the Euler problem and denote by $\lambda_1(a)$ its least eigenvalue. Keller and Niordson took up the problem of maximizing $\lambda_1(a)$ over those nonnegative a satisfying the volume constraint, (2.3). Supposing the existence of an optimal design, formal perturbation theory led them to a candidate $\tilde{a}$ for which

$$\tilde{a}(x) = \begin{cases} O(1), & \text{as } x \to 0, \\ c(1-x)^3 + O((1-x)^4), & \text{as } x \to 1, \end{cases} \tag{2.5}$$

where c is a positive constant. We shall now argue that the spectrum of the Euler problem is not discrete for such a design.

Following Friedrichs [6], we consider

$$\frac{1}{Z(x)} \equiv 4\tilde{a}^2(x) \left(\int_x^1 \tilde{a}(t)\,dt \right) \left(\int_0^x \tilde{a}(t)^{-2}\,dt \right)^2 \tag{2.6}$$

and recall [6, Criteria II & III] that if

$$\lambda_* \equiv \lim_{x\to 1} Z(x)$$

exists and

$$\lambda_* \le \liminf_{x\to 0} Z(x)$$

then the spectrum of (2.4) is discrete below λ_* and nondiscrete above λ_*. On substituting (2.5) into (2.6) we find, near $x = 1$, that

$$\begin{aligned}\frac{1}{Z(x)} &= 4\left(c^2(1-x)^6 + O((1-x)^7)\right)\left(\frac{c(1-x)^4}{4} + O((1-x)^5)\right)\\ &\qquad\times\left(\frac{1}{5c^2(1-x)^5} + \frac{1}{O((1-x)^4)}\right)^2\\ &= \frac{1}{25c} + O(1-x)\end{aligned}$$

and so $\lambda_* = 25c$. As $\tilde{a}$ is well behaved near $x = 0$, it follows easily that

$$\liminf_{x\to 0} Z(x) = +\infty.$$

We have just established the following proposition.

PROPOSITION 2.1. *The spectrum of the Euler problem,* (2.4), *with the Keller–Niordson design,* $\tilde{a}$, *is discrete below* $25c$ *and nondiscrete above* $25c$.

We note that the result states that *if* (2.4) has spectrum below $25c$ then this spectrum is discrete. It remains to see whether any such design produces eigenvalues below $25c$. Keller and Niordson's calculation of $c = \lambda_1/24$ suggests that their design indeed gives rise to an isolated eigenvalue, $\lambda_1 = 24c$, just below the continuous spectrum. Their result however was predicated on the false assumption that (2.4) possessed a purely discrete spectra. Nevertheless, we now construct a concrete design of unit volume that satisfies (2.5) and possesses at least one eigenvalue below $25c$. Again, the main idea lies with Friedrichs [6]; if there exists a function u for which $u(0) = 0$ and

$$\int_0^1 \tilde{a}^2|u'|^2\,dx < \lambda_* \int_0^1 \left(\int_x^1 \tilde{a}(t)\,dt\right) u^2\,dx < \infty$$

then (2.4) possesses at least one eigenvalue below λ_*. We shall apply this to

$$\tilde{a}(x) = 5(1-x)^3 - (5/4)(1-x)^4 \quad \text{and} \quad u(x) = \frac{x}{(1-x)^2}.$$

This $\tilde{a}$ is clearly positive away from $x = 1$ and satisfies the volume constraint (2.3). These choices produce $\lambda_* = 125$,

$$\int_0^1 \tilde{a}^2|u'|^2\,dx = \frac{1145}{24}, \quad \text{and} \quad \int_0^1 \left(\int_x^1 \tilde{a}(t)\,dt\right) u^2\,dx = \frac{19}{48},$$

and so this design has an eigenvalue below

$$\frac{1145/24}{19/48} \approx 120.5263.$$

Although one may easily generalize this example we have not been able to produce an exact characterization of those $\tilde{a}$ that satisfy (2.5) *and* possess at least one isolated eigenvalue. In other words, we have not been able to formulate a (large) class of admissible designs that accommodate Keller and Niordson's belief in cubic taper and presence of discrete spectra. In the interest of rigorously establishing the existence of a tallest column we have been compelled to exclude the possibility of cubic taper.

3. The Green's function. When the Green's function associated with the Euler problem is square integrable, the associated Green's operator is compact on $L^2(0,1)$ and therefore in possession of a discrete spectrum.

Following the standard recipe, see, e.g., Porter and Stirling [12, Example 6.13], the Green's function associated with the Euler problem (2.4) is

$$g(x,y;a) = \sqrt{w(x)w(y)} \int_0^{x\wedge y} \frac{dt}{a^2(t)},$$

where $x \wedge y = \min\{x, y\}$ and

$$w(x) \equiv \int_x^1 a(t)\, dt.$$

We now isolate a class of a that is rich enough to describe a large number of columns yet narrow enough to guarantee purely discrete spectra. On physical grounds it seems apparent that the tallest columns will be those that taper at their summit. We control the degree of taper by asking the cross-sectional area to lie in

$$ad_p \equiv \{a : k_1(1-x)^p \le a(x) \le k_2(1-x)^p\}$$

for some positive values of $k_1,\ k_2$, and p. It follows immediately that for such a

$$g^2(x,y;a) \le \frac{k_2^2}{k_1^2(1+p)^2(1-2p)^2}(1-x)^{1+p}(1-y)^{1+p}(1+(1-x\wedge y)^{2-4p}).$$

This being integrable over $(0,1)\times(0,1)$ so long as $0 \le p < 3$, we find the following proposition.

PROPOSITION 3.1. *If $a \in ad_p$ and $0 \le p < 3$ then the spectrum of the Euler problem is discrete.*

Proof. As $g(\cdot,\cdot;a) \in L^2((0,1)\times(0,1))$, it follows from [12, Theorem 3.4] that the Green's operator

$$G(a)\phi(x) \equiv \int_0^1 g(x,y;a)\phi(y)\, dy$$

is a compact operator on $L^2(0,1)$. This operator is also self-adjoint and positive and so, see, e.g., [12, Theorem 4.15], its spectrum is composed solely of a discrete sequence of nonnegative real numbers. □

We remark that $\tilde{a}$, the design of Keller and Niordson, remains just out of our reach. We next invoke [12, Lemma 5.1] in the variational characterization

$$\frac{1}{\lambda_1(a)} = \max_{\|\phi\|=1} \langle G(a)\phi, \phi\rangle, \tag{3.1}$$

where $\langle\cdot,\cdot\rangle$ denotes the standard $L^2(0,1)$ inner product and $\|\cdot\|$ denotes the associated norm. The maximum is attained at $\phi_1 = \sqrt{w}u_1$, where u_1 is the first eigenfunction of

(2.4). As the boundary conditions on (2.4) are separated, the standard oscillation theory implies that $\lambda_1(a)$ is simple and that u_1 may be assumed everywhere nonnegative. Our first application of (3.1) is the following proposition.

PROPOSITION 3.2. *If $a \in ad_p$ and $0 \le p < 3$ and a satisfies the volume constraint* (2.3) *then*

$$\lambda_1(a) \le \frac{720}{k_1}.$$

Proof. Choosing $\phi \equiv 1$ in (3.1) brings

$$\frac{1}{\lambda_1(a)} \ge \int_0^1 \int_0^1 g(x,y;a)\,dx\,dy,$$

so we proceed to establish a pointwise lower bound for g.

$$\begin{aligned} g(x,y;a) &\ge \frac{k_1}{4}(1-x)^2(1-y)^2(x\wedge y)\left(\frac{1}{x\wedge y}\int_0^{x\wedge y} a^{-2}(t)\,dt\right) \\ &\ge \frac{k_1}{4}(1-x)^2(1-y)^2(x\wedge y)\left(\frac{1}{x\wedge y}\int_0^{x\wedge y} a(t)\,dt\right)^{-2} \\ &\ge \frac{k_1}{4}(1-x)^2(1-y)^2(x\wedge y)^3 \\ &\equiv g_0(x,y). \end{aligned}$$

The first inequality stems from $a(x) \ge k_1(1-x)^3$, the second is Jensen's inequality, while the third uses the nonnegativity of a and the volume constraint (2.3). As

$$\int_0^1 \int_0^1 g_0(x,y)\,dx\,dy = \frac{k_1}{720},$$

our result follows. □

Our second application of (3.1) states that the eigenvalues depend continuously on the Green's function.

PROPOSITION 3.3. *If a_1 and a_2 each lie in ad_p for $p < 3$ then*

$$\left|\frac{1}{\lambda_1(a_1)} - \frac{1}{\lambda_1(a_2)}\right| \le \|g(\cdot,\cdot;a_1) - g(\cdot,\cdot;a_2)\|.$$

Proof. Set $d(a_1,a_2) \equiv \|g(\cdot,\cdot;a_1) - g(\cdot,\cdot;a_2)\|$. Hölder's inequality provides

$$\langle G(a_2)\phi,\phi\rangle - d(a_1,a_2) \le \langle G(a_1)\phi,\phi\rangle \le \langle G(a_2)\phi,\phi\rangle + d(a_1,a_2),$$

when $\|\phi\| = 1$. Applying (3.1) throughout now gives

$$\frac{1}{\lambda_1(a_2)} - d(a_1,a_2) \le \frac{1}{\lambda_1(a_1)} \le \frac{1}{\lambda_1(a_2)} + d(a_1,a_2). \qquad \square$$

As preparation for our result on rearrangements we express (3.1) in a form reminiscent of that invoked by Alvino & Trombetti [1].

PROPOSITION 3.4. *If $a \in ad_p$ with $p < 3$ then*

$$\frac{1}{\lambda_1(a)} = \max_{\|\phi\|=1} \int_0^1 \frac{1}{a^2(x)}\left(\int_x^1 \sqrt{w(y)}\phi(y)\,dy\right)^2 dx.$$

Proof. This follows directly from

$$\langle G(a)\phi,\phi\rangle = \int_0^1\int_0^1 \sqrt{w(x)w(y)}\int_0^{x\wedge y}\frac{dt}{a^2(t)}\phi(x)\phi(y)\,dy\,dx$$
$$= \int_0^1 \sqrt{w(x)}\phi(x)\left(\int_0^x \sqrt{w(y)}\phi(y)\int_0^y \frac{dt}{a^2(t)}\,dy + \int_x^1 \sqrt{w(y)}\phi(y)\int_0^x \frac{dt}{a^2(t)}\,dy\right)dx.$$

Integrating by parts brings

$$\int_0^x \sqrt{w(y)}\phi(y)\int_0^y \frac{dt}{a^2(t)}\,dy = -\int_0^x \frac{dt}{a^2(t)}\int_x^1 \sqrt{w(t)}\phi(t)\,dt + \int_0^x \frac{1}{a^2(y)}\int_y^1 \sqrt{w(t)}\phi(t)\,dt\,dy,$$

so

$$\langle G(a)\phi,\phi\rangle = \int_0^1 \sqrt{w(x)}\phi(x)\int_0^x\int_y^1 \sqrt{w(t)}\phi(t)\,dt\frac{dy}{a^2(y)}\,dx.$$

Integrating this by parts, we arrive at the final form

$$\langle G(a)\phi,\phi\rangle = \int_0^1 \frac{1}{a^2(x)}\left(\int_x^1 \sqrt{w(t)}\phi(t)\,dt\right)^2 dx. \qquad \square$$

4. Increasing height via decreasing rearrangement. Expecting that the most efficient use of material will start from a large base and suffer a gradual diminution, we here show that replacing a by its decreasing rearrangement can but increase $\lambda_1(a)$. We follow a line of reasoning which, in our context, goes back to Krein [10] and Beesack & Schwarz [2]. The former considered the effect of the rearrangement of mass density while the latter addressed the rearrangement of a potential term. Our problem, with the design variable appearing in a nonlinear fashion in the highest order term and in a nonlocal fashion in the lowest order term, is considerably more cumbersome. Our contribution amounts to striking upon a variational characterization of $\lambda_1(a)$ which permits the application of the methods of [10] and [2].

Recall that the decreasing rearrangement of a nonnegative function, f, on $(0,1)$ is simply

$$f^*(x) \equiv \sup\{t>0 : \mu_f(t) > x\},$$

where

$$\mu_f(t) = |\{x\in(0,1) : f(x) > t\}|$$

is the measure of the set on which f exceeds t. The increasing rearrangement of f is simply $f_*(x)\equiv f^*(1-x)$. It is not difficult to show that

$$\int_0^1 f\,dx = \int_0^1 f^*\,dx = \int_0^1 f_*\,dx. \tag{4.1}$$

Regarding integrals of products, we recall the following propposition.

PROPOSITION 4.1. *Let f,ξ, and η be nonnegative functions, with ξ increasing and η decreasing. Then*

$$\int_0^1 f^*\xi\,dx \le \int_0^1 f\xi\,dx \quad \textit{and} \quad \int_0^1 f_*\eta\,dx \le \int_0^1 f\eta\,dx. \tag{4.2}$$

Proof. These are both special cases of inequalities established in Pólya and Szegö [11, p. 153]. □

As final preparation we recall the increasing rearrangement of a certain composition.

PROPOSITION 4.2. *If ψ is decreasing on the range of f then $(\psi \circ f)_* = \psi \circ f^*$.*

Proof. This is a special case of Cox [3, Theorem 1]. □

PROPOSITION 4.3. *If $a \in ad_p$ and $p < 3$ then $\lambda_1(a) \le \lambda_1(a^*)$.*

Proof. Denote by v the eigenfunction of $G(a^*)$ corresponding to $\lambda_1(a^*)$. As previously remarked, v is nonnegative. Now

$$\begin{aligned}
\frac{1}{\lambda_1(a)} &\ge \int_0^1 \frac{1}{a^2(x)} \left(\int_x^1 \left(\int_y^1 a(t)\,dt \right)^{1/2} v(y)\,dy \right)^2 dx \\
&\ge \int_0^1 \frac{1}{a^2(x)} \left(\int_x^1 \left(\int_y^1 a^*(t)\,dt \right)^{1/2} v(y)\,dy \right)^2 dx \\
&\ge \int_0^1 \left(\frac{1}{a^2(x)} \right)_* \left(\int_x^1 \left(\int_y^1 a^*(t)\,dt \right)^{1/2} v(y)\,dy \right)^2 dx \\
&= \int_0^1 \frac{1}{(a^*)^2(x)} \left(\int_x^1 \left(\int_y^1 a^*(t)\,dt \right)^{1/2} v(y)\,dy \right)^2 dx \\
&= \frac{1}{\lambda_1(a^*)}.
\end{aligned}$$

The first inequality is a direct consequence of Proposition 3.4. The second inequality comes from the first in (4.2) with ξ being the characteristic function of $(x, 1)$. The third inequality follows from the second in (4.2) with

$$\eta(x) = \left(\int_x^1 \left(\int_y^1 a^*(t)\,dt \right)^{1/2} v(y)\,dy \right)^2.$$

We remark that the nonnegativity of v leads to the nonincreasing of η. The first equality is a consequence of Proposition 4.2 with $\psi(t) = t^{-2}$. The final equality follows directly from the definition of v. □

5. Existence of a tallest column. Let us denote by ad_p^1 the collection of $a \in ad_p$ obeying the integral constraint (2.3). For $p < 3$ it follows from Proposition 3.2 that λ_1 is bounded on ad_p^1 and so

$$\lambda_1^{(p)} \equiv \sup_{a \in ad_p^1} \lambda_1(a)$$

is finite. That this sup is attained will follow directly from the following proposition.

PROPOSITION 5.1 (Helly's selection theorem, [13, p. 167]). *If $\{f_n\}$ is a sequence of nonnegative nonincreasing functions on $[0, 1]$ then there exists a subsequence $\{f_{n_k}\}$ and a function f such that $f_{n_k}(x) \to f(x)$ as $k \to \infty$ for each $x \in [0, 1]$.*

PROPOSITION 5.2. *If $p < 3$ then $a \mapsto \lambda_1(a)$ attains its maximum on $a \in ad_p^1$.*

Proof. As $\lambda_1^{(p)} < \infty$ there exists a maximizing sequence $\{a_n\} \subset ad_p^1$ for which $\lambda_1(a_n) \to \lambda_1^{(p)}$. By (4.1) and Proposition 4.3 we may assume that each a_n is nonincreasing and hence, by Helly's selection theorem, that there exists an $\hat{a}$ and a subsequence (that we neglect to relabel) such that $a_n \to \hat{a}$ pointwise. It follows by the

dominated convergence theorem (Rudin [13, Theorem 11.32]) that

$$\int_x^1 a_n(t)\,dt \to \int_x^1 \hat{a}(t)\,dt \quad \text{and} \quad \int_0^{x\wedge y} \frac{dt}{a_n^2(t)} \to \int_0^{x\wedge y} \frac{dt}{\hat{a}^2(t)}$$

for each x and y. In particular,

$$\int_0^1 a_n\,dx \to \int_0^1 \hat{a}\,dx \quad \text{and} \quad g(x,y;a_n) \to g(x,y;\hat{a}).$$

By the dominated convergence theorem it follows that $g(\cdot,\cdot,a_n) \to g(\cdot,\cdot,\hat{a})$ in $L^2((0,1)\times(0,1))$. This implies, via Proposition 3.3, that $\lambda_1(a_n) \to \lambda_1(\hat{a})$. But, by construction, $\lambda_1(a_n) \to \lambda_1^{(p)}$, and so $\lambda_1(\hat{a}) = \lambda_1^{(p)}$. □

SLOW DYNAMICS OF INTERFACES IN THE ALLEN–CAHN EQUATION ON A STRIP-LIKE DOMAIN*

SHIN-ICHIRO EI† AND EIJI YANAGIDA ‡

Abstract. The dynamics of interfaces in the Allen–Cahn equation is studied. If a domain in $\boldsymbol{R^2}$ has constant width along a smooth curve, it is called a strip-like domain. We derive an equation which describes the motion of a straight interface intersecting the boundary of the strip-like domain. The equation shows that the motion is slower than the mean curvature flow, but faster than the very slow dynamics.

Key words. dynamics of interfaces, Allen–Cahn equation, super- and subsolutions

1. Introduction.

Recently, the dynamics of interfaces appearing in various reaction diffusion equations has received much attention. Among them, the motion of interfaces in the Allen–Cahn equation

$$\begin{cases} u_t = \varepsilon^2 \Delta u + f(u), & x \in \Omega, \\ \dfrac{\partial}{\partial n} u = 0, & x \in \partial\Omega, \end{cases} \tag{1.1}$$

has been most extensively studied, where $\varepsilon > 0$ is a sufficiently small parameter, Ω a (bounded or unbounded) domain in $\boldsymbol{R}^N$ with boundary $\partial\Omega$, Δ the Laplace operator, $\partial/\partial n$ the outer normal derivative. The nonlinearity f is given by $f = u(1-u^2)$, although we can extend our results to more general nonlinearities. In fact, we may assume that f is a sufficiently smooth cubic-like odd function which is derived from double-well potential with equal depth.

Given initial data, the solution u of (1.1) behaves in the following way. Since $\varepsilon > 0$ is small, the diffusion term is negligible in the first stage so that the solution approaches $+1$ or -1 depending only on the sign of the initial value. Thus, after some time, there must appear an inner layer (or an interface) in which the value of u rapidly changes from -1 to $+1$. At this stage, the diffusion term is not negligible near the interface, and the interface begins to move slowly.

In the case where $N = 1$ and Ω is a compact interval, the dynamics of interfaces was precisely investigated by Carr and Pego [3] and Fusco and Hale [7]. They showed that the motion of interfaces is governed by the *very slow dynamics*. More precisely, it moves with the speed $O(e^{-A/\varepsilon})$ for some positive constant A.

In higher dimension, it is known (see, e.g., [2, 4, 5, 6, 12]) that the motion of interfaces is approximately described by the *mean curvature flow*

$$V = -\varepsilon^2 (N-1)k, \quad x \in \Gamma. \tag{1.2}$$

Here $\Gamma = \Gamma(t)$ is a hypersurface in $\boldsymbol{R}^N$ which represents the location of an interface,

and V and k stand for the normal velocity and the mean curvature of Γ, respectively. When Γ intersects $\partial\Omega$, it must be orthogonal to $\partial\Omega$ (cf. [8, 11]).

If Γ is a minimal surface (i.e., $k = 0$), then it is a steady state of (1.2) so that the interface does not move under the dynamics (1.2). However, if Ω is a cylindrical domain and Γ is a plane, the interface may move with a slower time scale. In fact, if a solution is constant in the transectional direction, then the solution behaves exactly in the same manner as in the one-dimensional case so that the motion of the interface is governed by the very slow dynamics.

Recently, Alikakos, Fusco, and Kowalczyk [1] dealt with (1.1) on a domain in $\boldsymbol{R}^2$ which consists of a rectangle and other parts. When Γ is a line segment inside the rectangle, they showed that the motion of Γ depends on the shape of Ω and the speed is $O(e^{-A/\varepsilon})$. Namely, the motion of Γ is governed by the very slow dynamics. It seems that this result can be extended to Ω which consists of a part of an annulus and other parts [9].

In this paper, we show that in a certain kind of domain, there may appear a motion with the speed $O(\varepsilon^4)$, which we will call the *slow dynamics*. Let $C(s), 0 < s < L$, be a smooth curve in $\boldsymbol{R}^2$ with its length L, where s is the arclength parameter. We define a strip-like domain Ω in $\boldsymbol{R}^2$ along $C(s)$ with its width $2d$ by

$$\Omega = \{C(s) + z\nu(s) \mid 0 < s < L,\ -d < z < d\},$$

where $\nu(s)$ is a unit normal vector of $C(s)$ (see Fig. 1.1). We assume that the curvature $\kappa(s)$ of $C(s)$ satisfies

$$d \sup_{0<s<L} |\kappa(s)| \le \delta \tag{1.3}$$

for some $0 < \delta < 1$. We also assume that Ω is simply connected and any point in Ω corresponds one-to-one to (s, z) by the relation

$$(x, y) = C(s) + z\nu(s).$$

Let Γ be a line segment intersecting $\partial\Omega$ orthogonally. Then Γ stands still under the dynamics (1.2). However, the interface may move in a slower time scale by keeping its shape straight, because the line segment can be translated freely along $C(s)$.

Our results assert that any straight interface moves with the speed $O(\varepsilon^4)$ toward the direction where C is less curved. More precisely, let $s = S(t)$ represent the s coordinate of the position of Γ. Then $S(t)$ is approximately governed by

$$\frac{d}{dt}S(t) = \varepsilon^4 H(S(t)), \tag{1.4}$$

where

$$H(s) = -\frac{M}{\{1 - d^2\kappa(s)^2\}^2\ \left\{1 + \frac{1}{3}d^2\kappa(s)^2\right\}}\ \kappa(s)\kappa_s(s),$$

$$M = \frac{\displaystyle\int_{-\infty}^{+\infty} \eta^2\varphi_\eta(\eta)^2 d\eta}{\displaystyle\int_{-\infty}^{+\infty} \varphi_\eta(\eta)^2 d\eta} > 0,$$

and φ is a unique solution of

$$\begin{cases} \varphi_{\eta\eta} + f(\varphi) = 0, \quad -\infty < \eta < \infty, \\ \varphi(0) = 0, \quad \varphi(\pm\infty) = \pm 1. \end{cases}$$

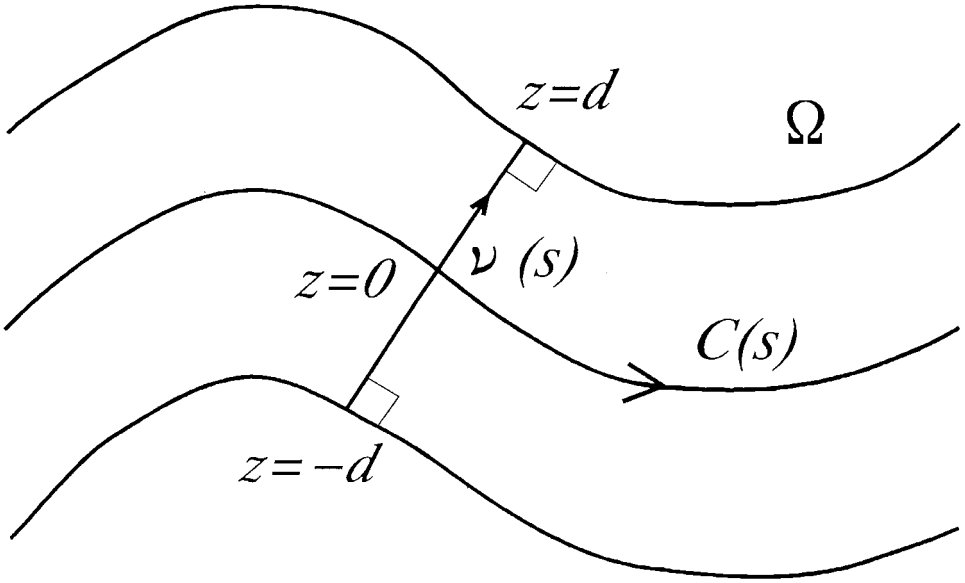

FIG. 1.1. *A strip-like domain* Ω.

Under our assumption on f, the solution φ is a sufficiently smooth function which is monotone increasing and odd symmetric with respect to η. Since $H(s)$ can be represented as

$$H(s) = -A(s)\{\kappa(s)^2\}_s$$

for some positive function $A(s)$, (1.4) implies that the interface moves toward a minimal point of $|k(s)|$. In Fig. 1.2, we present some numerical results which demonstrate this slow dynamics of interfaces.

When $\kappa(s)$ is constant, then $H(s) \equiv 0$, which means that the interface moves in slower dynamics. On the other hand, if $\kappa(s)$ is constant, then the domain must be a rectangle or a part of annulus. In this case, the motion of interface is governed by the very slow dynamics as mentioned previously. Thus, for a domain in $\boldsymbol{R}^2$, there are three kinds of dynamics, that is, the mean curvature flow, the slow dynamics, and the very slow dynamics.

This paper is organized as follows. In section 2, we give some definitions and our main results. In section 3, we state several important propositions. In section 4, we give proofs of the main results by using these propositions. Sections 5 and 6 are devoted to proofs of the propositions.

2. Definitions and results. Before stating our main results, we list our notation.

$\kappa(s)$: the curvature of $C(s)$ measured in the direction of $\nu(s)$.

$l(s)$: the straight line segment through $C(s)$ intersecting $\partial\Omega$ orthogonally, that is,

$$l(s) = \{C(s) + z\nu(s)\ ;\ -d < z < d\}.$$

C^z : the curve defined by

$$C^z = \{C(s) + z\nu(s)\ ;\ 0 < s < L\}.$$

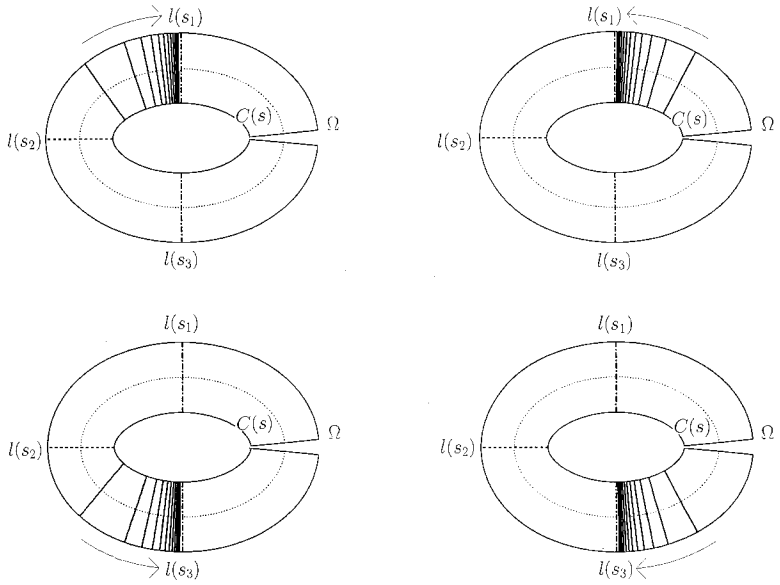

FIG. 1.2. *The dynamics of interfaces in a strip-like domain Ω whose center curve (a dotted curve) is a part of an ellipse. An arrow indicates the direction of movement of an interface. Broken lines denote the line segments $l(s_1), l(s_2), l(s_3)$, where s_1, s_3 are the values of s corresponding to the minima of $|\kappa(s)|$, while s_2 is the value of maximum of $|\kappa(s)|$.*

$\mathrm{Dist}\{(x,y), l(s)\}$: the signed distance between the point $(x,y) \in \Omega$ and the line segment $l(s)$ measured along C^z, that is,

$$\mathrm{Dist}\{(x,y), l(s)\} = (1 - z\kappa(s))(r - s) \quad \text{for } (x,y) = C(r) + z\nu(r).$$

$\Pi(P, Q, s)$: the set of functions satisfying the conditions

$$\begin{array}{rcccccccccc} -1-Q & \le & u(x,y) & \le & -1+Q & \text{if} & -\infty & \le & \mathrm{Dist}\{(x,y),l(s)\} & \le & -P, \\ -1-Q & \le & u(x,y) & \le & +1+Q & \text{if} & -P & \le & \mathrm{Dist}\{(x,y),l(s)\} & \le & +P, \\ +1-Q & \le & u(x,y) & \le & +1+Q & \text{if} & +P & \le & \mathrm{Dist}\{(x,y),l(s)\} & \le & +\infty, \end{array}$$

where $P > 0$ and $Q > 0$.

T : the time scale $\varepsilon^4 t$.

$\langle \cdot, \cdot \rangle_\eta$: the inner product of $L^2(\boldsymbol{R})$ with respect to η.

In the time scale $T = \varepsilon^4 t$, (1.4) can be written as

$$\frac{d}{dT} S(T) = H(S(T)), \quad T > 0. \tag{2.1}$$

In the following theorems, we denote a solution of (1.1) by $u(t,x,y)$.

THEOREM 2.1. *Let $S(T)$ be a solution of* (2.1) *defined for $T \in [0, T^*]$ for some $T^* < \infty$. Then for any $m \in (0,1)$, there exist positive constants P_1, Q_1, P_2, Q_2, and ε_0 such that if $0 < \varepsilon < \varepsilon_0$ and*

$$u(0,x,y) \in \Pi(P_1\varepsilon^m, Q_1\varepsilon^{m+3}, S(0)),$$

then

$$u(t,x,y) \in \Pi(P_2\varepsilon^m, Q_2\varepsilon^{m+3}, S(\varepsilon^4 t))$$

for $t \in [0, T^*/\varepsilon^4]$.

Let S^* be an equilibrium of (2.1). We say that S^* is exponentially stable if S^* satisfies $H'(S^*) < 0$.

THEOREM 2.2. *Suppose that a solution $S(T)$ of (2.1) converges to an exponentially stable equilibrium S^*. Then for any $m \in (0,1)$, there exist positive constants P_1, Q_1, P_2, Q_2, and ε_0 such that if $0 < \varepsilon < \varepsilon_0$ and*

$$u(0,x,y) \in \Pi(P_1\varepsilon^m, Q_1\varepsilon^{m+3}, S(0)),$$

then

$$u(t,x,y) \in \Pi(P_2\varepsilon^m, Q_2\varepsilon^{m+3}, S(\varepsilon^4 t))$$

for all $t \in [0,\infty)$.

THEOREM 2.3. *Let S^* be an exponentially stable equilibrium of (2.1). Then for any $m \in (0,1)$, there exist positive constants P, Q, and ε_0 such that if $0 < \varepsilon < \varepsilon_0$, (1.1) possesses a stable stationary solution $u^*(x,y)$ satisfying*

$$u^*(x,y) \in \Pi(P\varepsilon^m, Q\varepsilon^{m+3}, S^*).$$

Remark. It is easily seen from proofs of the above theorems that if Ω consists of a strip-like domain and other parts, similar results hold as long as a straight interface remains in the strip-like domain.

In (2.1), $H(s)$ is expressed as

$$H(s) = -A(s)\{\kappa(s)^2\}_s$$

for some positive function $A(s)$ as mentioned in section 1. This implies that the exponentially stable equilibrium S^* of (2.1) corresponds to a minimal point of $|\kappa(s)|$. Also Theorems 2.2 and 2.3 imply that the straight interface moves toward a minimal point of $|\kappa(s)|$ and converges to a stable stationary solution u^* with its inner layer near the line segment $l(S^*)$.

3. Preliminaries. In this section, we give several propositions as preliminaries for the subsequent sections. Throughout this paper, we let m be an arbitrarily fixed constant satisfying $0 < m < 1$. Also, we denote by A_j $(j = 0,1,2,\ldots)$ positive constants independent of t, $(x,y) \in \Omega$, sufficiently small $\varepsilon > 0$, and u.

In order to prove the theorems, we will employ the comparison method. We say that $u^+(t,x,y)$ $(t \in [0,t_0], (x,y) \in \Omega)$ is a supersolution of (1.1) if u^+ satisfies

$$u_t^+ \geq \Delta u^+ + f(u^+), \quad t \in [0,t_0],\ (x,y) \in \Omega,$$

and the Neumann boundary condition. Similarly, we say that $u^-(t,x,y)$, $(t \in [0,t_0], (x,y) \in \Omega)$ is a subsolution of (1.1) if u^- satisfies

$$u_t^- \leq \Delta u^- + f(u^-), \quad t \in [0,t_0],\ (x,y) \in \Omega,$$

and the Neumann boundary condition.

The following two propositions are well known (see, e.g., [10]).

PROPOSITION 3.1. *Let $u(t,x,y)$ be a solution of (1.1). If $u^+(t,x,y)$, $t \in [0,t_0]$, is a supersolution satisfying $u^+(0,x,y) \geq u(0,x,y)$ for $(x,y) \in \Omega$, then $u^+(t,x,y) \geq u(t,x,y)$ for $t \in [0,t_0], (x,y) \in \Omega$. Similarly, if $u^-(t,x,y)$, $t \in [0,t_0]$, is a subsolution satisfying $u^-(0,x,y) \leq u_0(x,y)$ for $(x,y) \in \Omega$, then $u^-(t,x,y) \leq u(t,x,y)$ for $t \in [0,t_0], (x,y) \in \Omega$.*

PROPOSITION 3.2. *If $u^+(x,y)$ and $u^-(x,y)$ are, respectively, super- and subsolutions independent of t satisfying*

$$u^-(x,y) \le u^+(x,y), \quad (x,y) \in \Omega,$$

then there exists a stable stationary solution $u^*(x,y)$ of (1.1) satisfying

$$u^-(x,y) \le u^*(x,y) \le u^+(x,y), \quad (x,y) \in \Omega.$$

The following two propositions are easily shown.

PROPOSITION 3.3. *For small $|q|$, there exist smooth functions $\alpha^\pm(q)$ such that $f(\alpha^\pm(q))+q=0$ and $\alpha^\pm(q) = \pm 1 + M_0 q + O(q^2)$, where $M_0 = -\frac{1}{f'(1)} = -\frac{1}{f'(-1)} > 0$.*

Here we define

$$|v(\eta)|_{C^h(\eta)} = \sum_{j=0}^{h} \left| \frac{d^j}{d\eta^j} v(\eta) \right|,$$
$$|v(\eta)|_{D^h(\eta)} = |v(\eta)|_{C^h(\eta)} - |v(\eta)|$$

for $v \in C^h$, the set of h times continuously differentiable functions.

PROPOSITION 3.4. *There exist positive constants a_0, A_0, and β_0 such that*

$$a_0 e^{-\beta_0|\eta|} \le |\varphi(\eta)+1| \le A_0 e^{-\beta_0|\eta|} \quad \text{for } \eta < 0,$$
$$a_0 e^{-\beta_0|\eta|} \le |\varphi(\eta)-1| \le A_0 e^{-\beta_0|\eta|} \quad \text{for } \eta > 0,$$

and for any positive integer h,

$$|\varphi(\eta)|_{D^h(\eta)} = O(e^{-\beta_0|\eta|}) \text{ as } |\eta| \to \infty.$$

Let $S^\pm(T)$ be solutions of

$$S_T^\pm = H^\pm(S^\pm) \tag{3.1}$$

with $S^\pm(0) = S(0) \mp \varepsilon^m$, where

$$H^\pm(s) = H(s) \mp \frac{2 - d\kappa(s)}{M_1\{1 + \frac{1}{3}d^2\kappa^2(s)\}}\varepsilon^m$$

and $M_1 = \langle\, \varphi, \varphi \,\rangle_\eta$. We assume that a solution $S(T)$ of (2.1) exists and is bounded for $T \in [0, T^*]$ for some $T^* \in (0, \infty]$. Then, we can construct super- and subsolutions as stated in the following proposition.

PROPOSITION 3.5. *Let $\gamma^\pm(T)$ be arbitrary smooth functions of $T \in [0, T^*]$, and set*

$$\eta^\pm = \{1 - z\kappa(S^\pm(T))\}\left(\frac{s - S^\pm(T)}{\varepsilon} - \gamma^\pm(T)\right)$$

with $(x,y) = C(s) + z\nu(s)$. Then for small $\varepsilon > 0$, there exist super- and subsolutions $u^\pm$ of (1.1) of the form

$$u^\pm(t,x,y) = \varphi(\eta^\pm) + \varepsilon\Phi^\pm(t,z,\eta^\pm;\varepsilon) \pm M_0\varepsilon^{m+3} + \varepsilon^4 R^\pm(t,x,y;\varepsilon), \tag{3.2}$$

where $\Phi^\pm$ satisfy

$$|\Phi^\pm(t,z,\eta;\varepsilon)|_{C^2(\eta)} \le A_1 e^{-\beta|\eta|}, \quad (t,z,\eta) \in [0, T^*/\varepsilon^4] \times (-d,d) \times (-\infty,\infty) \tag{3.3}$$

with some positive constants A_1 and $\beta \in (\frac{3}{4}\beta_0, \beta_0)$, and $R^\pm(t,x,y;\varepsilon)$ are uniformly bounded in $t \in [0, T^*/\varepsilon^4]$ and $(x,y) \in \Omega$.

A proof of this proposition will be given in section 5. All theorems in section 2 are derived from this proposition.

4. Proofs of theorems. In this and the following sections, B denotes a generic positive constant independent of sufficiently small ε and the solution u which may vary from line to line.

Let $S^{\pm}(T)$ be solutions of (3.1) with $S^{\pm}(0) = S(0) \mp \varepsilon^m$, respectively. Then there exists $B > 0$ such that

$$S^+(T) + B\varepsilon^m \le S(T) \le S^-(T) - B\varepsilon^m \tag{4.1}$$

uniformly in $T \in [0, T^*]$. For such $S^{\pm}(T)$, let $u^{\pm}(t, x, y)$ be, respectively, super- and subsolutions given in Proposition 3.5, and set

$$v^{\pm}(t, z, s) = u^{\pm}(t, C(s) + z\nu(s)).$$

LEMMA 4.1. *If $\varepsilon > 0$ is sufficiently small, then*

$$v^+(t, z, s) > v^-(t, z, s) + \frac{5}{3} M_0 \varepsilon^{m+3}, \quad (t, z, s) \in [0, T^*/\varepsilon^4] \times (-d, d) \times (0, L). \tag{4.2}$$

Proof. Let $\mu^{\pm} = \frac{s - S^{\pm}(T)}{\varepsilon}$ and let $\gamma^{\pm}(T)$ be a function as in Proposition 3.5. Then $v^{\pm}$ satisfy (3.2). Therefore it suffices to show (4.2) for $s > S^+(T) + \varepsilon\gamma^+(T)$.

First we consider the case where $S^+(T) + \varepsilon\gamma^+(T) < s < S^-(T) + \varepsilon\gamma^-(T)$. In this case, we have $\eta^+ > 0$, $\eta^- < 0$, and

$$\begin{aligned}
\eta^+ - \eta^- &= (\mu^+ - \mu^-) - (\gamma^+ - \gamma^-) - z\kappa^+(\mu^+ - \gamma^+) + z\kappa^-(\mu^- - \gamma^-) \\
&\ge (\mu^+ - \mu^-) - (\gamma^+ - \gamma^-) - \delta(\mu^+ - \mu^- - \gamma^+ + \gamma^-) \\
&= (1 - \delta)(\mu^+ - \mu^- - \gamma^+ + \gamma^-) \\
&= (1 - \delta)\left(\frac{S^- - S^+}{\varepsilon} - \gamma^+ + \gamma^-\right) \\
&\ge (1 - \delta)\left(\frac{2B}{\varepsilon^{1-m}} - \gamma^+ + \gamma^-\right) \\
&\ge \frac{B}{\varepsilon^{1-m}}
\end{aligned}$$

by noting $\mu^+ - \gamma^+ \ge 0$, $\mu^- - \gamma^- \le 0$, and (4.1). Hence the monotonicity of φ yields

$$\varphi(\eta^+) - \varphi(\eta^-) \ge \varphi(\eta^+) - \varphi\left(\eta^+ - \frac{B}{\varepsilon^{1-m}}\right).$$

Here, if $0 \le \eta^+ \le \frac{B}{2\varepsilon^{1-m}}$, we have

$$\begin{aligned}
\varphi(\eta^+) - \varphi\left(\eta^+ - \frac{B}{2\varepsilon^{1-m}}\right) &\ge \varphi(\eta^+) - \varphi\left(-\frac{B}{2\varepsilon^{1-m}}\right) \\
&\ge \varphi(\eta^+) + 1 - \exp\left(-\frac{\beta_0 B}{2\varepsilon^{1-m}}\right) \\
&\ge 1 - \exp\left(-\frac{\beta_0 B}{2\varepsilon^{1-m}}\right) \\
&\ge \frac{1}{2},
\end{aligned}$$

which means (4.2) by (3.2) and (3.3). Also, for $\eta^+ \ge \frac{B}{2\varepsilon^{1-m}}$, we can show

$$\varphi(\eta^+) - \varphi(\eta^-) \ge \frac{1}{2}$$

in quite a similar manner. Thus, (4.2) holds when $S^+(T)+\varepsilon\gamma^+(T) < s < S^-(T)+\varepsilon\gamma^-(T)$.

Next we consider the case where $s > S^-(T)+\varepsilon\gamma^-(T)$. Since $\eta^\pm \geq 0$ in this case, we see from Proposition 3.4, (3.2), and (3.3) that

$$v^+(t,z,s) \geq 1 - A_0 e^{-\beta_0|\eta^+|} - \varepsilon A_1 e^{-\beta|\eta^+|} + M_0\varepsilon^{m+3} - B\varepsilon^4, \tag{4.3}$$

$$v^-(t,z,s) \leq 1 - a_0 e^{-\beta_0|\eta^-|} + \varepsilon A_1 e^{-\beta|\eta^-|} - M_0\varepsilon^{m+3} + B\varepsilon^4. \tag{4.4}$$

Here $\eta^+ \geq \frac{B}{\varepsilon^{1-m}}$ holds. Hence, in view of (4.3) and (4.4), it suffices to show that

$$1 + M_0\varepsilon^{m+3} - B\varepsilon^4 \geq 1 - a_0 e^{-\beta_0|\eta^-|} + \varepsilon A_1 e^{-\beta|\eta^-|} - M_0\varepsilon^{m+3} + B\varepsilon^4 + \frac{5}{3}M_0\varepsilon^{m+3},$$

that is,

$$a_0 e^{-\beta_0|\eta^-|} - \varepsilon A_1 e^{-\beta|\eta^-|} \geq -\frac{1}{3}M_0\varepsilon^{m+3} + B\varepsilon^4. \tag{4.5}$$

Noting $\eta^- \geq 0$, we let

$$\sigma(\eta) = a_0 e^{-\beta_0\eta} - \varepsilon A_1 e^{-\beta\eta}.$$

By

$$\sigma'(\eta) = e^{-\beta_0\eta}\left(-a_0\beta_0 + \varepsilon A_1\beta e^{(\beta_0-\beta)\eta}\right),$$

$\sigma(\eta)$ has a minimum at $\eta = \eta^*$, where

$$\eta^* = \frac{1}{\beta_0-\beta}\log\left(\frac{a_0\beta_0}{\varepsilon A_1\beta}\right)$$

satisfies $\sigma'(\eta^*) = 0$. Substituting η^*, we have

$$\sigma(\eta^*) = A_1\left(\frac{A_1\beta}{a_0\beta_0}\right)^{\frac{\beta}{\beta_0-\beta}}\left(1-\frac{\beta_0}{\beta}\right)\varepsilon^{\frac{\beta_0}{\beta_0-\beta}} < 0.$$

Since $\frac{3}{4}\beta_0 < \beta < \beta_0$ and $0 < m < 1$, the inequality $\frac{\beta_0}{\beta_0-\beta} > m+3$ holds, which implies (4.5) for sufficiently small $\varepsilon > 0$. □

LEMMA 4.2. *There exist positive constants P_1 and Q_1 such that*

$$\Pi(P_1\varepsilon^m, Q_1\varepsilon^{m+3}, s_0) \subset \Pi^* \tag{4.6}$$

for sufficiently small $\varepsilon > 0$, where $s_0 = S(0)$ and

$$\Pi^* = \{w(z,s);\ v^-(0,z,s) \leq w(z,s) \leq v^+(0,z,s)\}.$$

Proof. Suppose $|\mathrm{Dist}\{(x,y), l(s_0)\}| \leq P_1\varepsilon^m$. This is equivalent to

$$|(1-z\kappa(s_0))(s-s_0)| \leq P_1\varepsilon^m,$$

where $(x,y) = C(s) + z\nu(s)$. Hence, we have

$$\left|\frac{s-s_0}{\varepsilon}\right| \leq \frac{P_1}{(1-z\kappa(s_0))\varepsilon^{1-m}} \leq \frac{P_1}{(1-\delta)\varepsilon^{1-m}}$$

and

$$\begin{aligned}\frac{s-S^+(0)}{\varepsilon} &= \frac{s-s_0}{\varepsilon}+\frac{s_0-S^+(0)}{\varepsilon}\\ &\geq -\frac{P_1}{(1-\delta)\varepsilon^{1-m}}+\frac{1}{\varepsilon^{1-m}}\\ &\geq \frac{B}{\varepsilon^{1-m}}\end{aligned}$$

for appropriately small constant $P_1>0$, and similarly

$$\frac{s-S^-(0)}{\varepsilon}\leq -\frac{B}{\varepsilon^{1-m}}.$$

Therefore, it follows that

$$\begin{aligned}\eta^+ &= (1-z\kappa^+)\left(\frac{s-S^+(0)}{\varepsilon}-\gamma^+(0)\right)\\ &\geq (1-\delta)\left(\frac{B}{\varepsilon^{1-m}}-\gamma^+(0)\right)\\ &\geq \frac{B}{\varepsilon^{1-m}},\end{aligned}\tag{4.7}$$

and similarly

$$\begin{aligned}\eta^- &= (1-z\kappa^-)\left(\frac{s-S^-(0)}{\varepsilon}-\gamma^-(0)\right)\\ &\leq -\frac{B}{\varepsilon^{1-m}}.\end{aligned}\tag{4.8}$$

By the inequalities (3.2), (3.3), (4.3) and (4.7), (4.8), we get

$$v^+(0,z,s)\geq 1+B\varepsilon^{m+3},\tag{4.9}$$

and similarly

$$v^-(0,z,s)\leq -1-B\varepsilon^{m+3}\tag{4.10}$$

for sufficiently small $\varepsilon>0$.

Next, suppose $\mathrm{Dist}\{(x,y),l(s_0)\}\geq P_1\varepsilon^m$. In this range, (4.7) and (4.9) also hold. On the other hand, (3.2) and (4.7) imply

$$v^+(0,z,s)\leq 1+\frac{4}{3}M_0\varepsilon^{m+3}$$

for sufficiently small $\varepsilon>0$. Hence, by Lemma 4.1, we obtain

$$v^-(0,z,s)\leq 1-\frac{1}{3}M_0\varepsilon^{m+3}.$$

Thus,

$$v^-(0,z,s)\leq 1-\frac{1}{3}M_0\varepsilon^{m+3}\leq 1+B\varepsilon^{m+3}\leq v^+(0,z,s)\tag{4.11}$$

holds for $\mathrm{Dist}\{(x,y),l(s_0)\}\geq P_1\varepsilon^m$.

The case that $\mathrm{Dist}\{(x,y), l(s_0)\} \leq -P_1\varepsilon^m$ can be treated in quite a similar manner.

Taking $0 < Q_1 \leq \min\{B, \frac{1}{3}M_0\}$, the proof is complete. □

Now let us complete the proofs of Theorems 2.1–2.3.

Proof of Theorem 2.1. Let $u(t,x,y)$ be the solution of (1.1) with

$$u(0,\cdot) \in \Pi(P_1\varepsilon^m, Q_1\varepsilon^{m+3}, s_0).$$

Then the inequalities

$$v^-(t,z,s) \leq u(t,x,y) \leq v^+(t,z,s)$$

hold for $(t,z,s) \in [0,T^*/\varepsilon^4] \times (-d,d) \times (0,L)$ by Lemma 4.2, where $(x,y) = C(s) + z\nu(s)$. On the other hand, we have

$$S(T) - B\varepsilon^m < S^+(T) < S(T) < S^-(T) < S(T) + B\varepsilon^m$$

for some B uniformly in $T \in [0,T^*]$. Therefore, we have

$$v^\pm(t,z,s) \in \Pi(P_2\varepsilon^m, Q_2\varepsilon^{m+3}, S(\varepsilon^4 t))$$

for certain positive constants P_2, Q_2 by a similar argument to the above. Thus the proof is complete. □

Proof of Theorem 2.2. Since S^* is an exponentially stable equilibrium of (2.1), the equation (3.1) also has exponentially stable equilibria $S^*_\pm$, respectively, satisfying

$$S^* - B\varepsilon^m < S^*_+ < S^* < S^*_- < S^* + B\varepsilon^m \tag{4.12}$$

for some B. Let $S^\pm(T)$ be solutions of (3.1) with $S^\pm(0) = S(0) \mp \varepsilon^m$. Then, for sufficiently small $\varepsilon > 0$, $S^\pm(T)$ converge to $S^*_\pm$ as $T \to \infty$, respectively, and the inequalities

$$S(T) - B\varepsilon^m < S^+(T) < S(T) < S^-(T) < S(T) + B\varepsilon^m$$

hold uniformly in $T \geq 0$. Therefore, we can prove Theorem 2.2 by quite a similar manner to Theorem 2.1. □

Proof of Theorem 2.3. Let $S^\pm(T)$ be solutions of (3.1) with $S^\pm(0) = S^*_\pm$, respectively. Then we see that $S^\pm(T) \equiv S^*_\pm$ and (4.12) hold. Since $v^\pm(t,z,s)$ corresponding to $S^\pm(T)$ are independent of t, the proof of Theorem 2.3 is complete by Proposition 3.2. □

5. Proof of Proposition 3.5.

5.1. Preliminaries. Now let us explain the way to construct a suitable supersolution $u^+(t,x,y)$. We consider the equation

$$u_t = \varepsilon^2\Delta u + f(u) + \varepsilon^{m+3}, \quad t > 0,\ (x,y) \in \Omega. \tag{5.1}$$

Suppose that a function u^+ approximates (5.1) up to $O(\varepsilon^n)$ for some $n > m+3$. More precisely, suppose that u^+ satisfies

$$\varepsilon^2\Delta u^+ + f(u^+) + \varepsilon^{m+3} - u^+_t = O(\varepsilon^n)$$

uniformly in $t \in [0,T^*/\varepsilon^4]$ and $(x,y) \in \Omega$. Then u^+ must be a supersolution for sufficiently small $\varepsilon > 0$, because

$$\varepsilon^2\Delta u^+ + f(u^+) - u^+_t = -\varepsilon^{m+3} + O(\varepsilon^n) < 0.$$

Similarly, we consider the equation

$$u_t = \varepsilon^2 \Delta u + f(u) - \varepsilon^{m+3}, \quad t > 0,\ (x,y) \in \Omega. \tag{5.2}$$

If a function u^- approximates (5.2) up to $O(\varepsilon^n)$ for some $n > m+3$, then u^- becomes a subsolution for sufficiently small $\varepsilon > 0$. Thus, it is sufficient to find approximate functions u^+ and u^-.

Along the above argument, the following proposition gives the direct proof of Proposition 3.5.

PROPOSITION 5.1. *Let $\gamma^{\pm}(T)$ be arbitrary smooth functions of $T \in [0, T^*]$, and set*

$$\eta^{\pm} = \{1 - z\kappa(S^{\pm}(T))\} \left(\frac{s - S^{\pm}(T)}{\varepsilon} - \gamma^{\pm}(T) \right)$$

with $(x,y) = C(s) + z\nu(s)$. Then for small $\varepsilon > 0$, there exist a number $n \in (m+3, 4)$ and functions $u^{\pm}(t,x,y)$ of the form

$$u^{\pm}(t,x,y) = \varphi(\eta^{\pm}) + \varepsilon \Phi^{\pm}(t,z,\eta^{\pm};\varepsilon) \pm M_0 \varepsilon^{m+3} + \varepsilon^4 R^{\pm}(t,x,y;\varepsilon) \tag{5.3}$$

which satisfy (5.1) and (5.2) up to $O(\varepsilon^n)$ uniformly in $t \in [0, T^*/\varepsilon^4]$ and $(x,y) \in \Omega$ together with the Neumann boundary condition, where $\Phi^{\pm}$ satisfy

$$|\Phi^{\pm}(t,z,\eta;\varepsilon)|_{C^2(\eta)} \le A_1 e^{-\beta|\eta|}, \quad (t,z,\eta) \in [0, T^*/\varepsilon^4] \times (-d,d) \times (-\infty, \infty) \tag{5.4}$$

with some positive constants A_1 and $\beta \in (\frac{3}{4}\beta_0, \beta_0)$, and $R^{\pm}(t,x,y;\varepsilon)$ are uniformly bounded in $t \in [0, T^*/\varepsilon^4]$ and $(x,y) \in \Omega$.

In order to prove this proposition, we need some preliminary results.

PROPOSITION 5.2. *For any $\beta \in (0, \beta_0)$ and any nonnegative integer h, the equation*

$$v_{\eta\eta} + f'(\varphi(\eta))v = g(\eta), \quad -\infty < \eta < \infty, \tag{5.5}$$

has a unique solution v^* satisfying $|v^*(\eta)|_{C^{h+2}(\eta)} = O\left(e^{-\beta|\eta|}\right)$ as $|\eta| \to \infty$ and $\langle\, v^*, \varphi_\eta \,\rangle_\eta = 0$ if and only if $g \in C^h$ satisfies $|g(\eta)|_{C^h(\eta)} = O\left(e^{-\beta|\eta|}\right)$ as $|\eta| \to \infty$ and the solvability condition

$$\langle\, g, \varphi_\eta \,\rangle_\eta = 0. \tag{5.6}$$

Moreover, any bounded solution of (5.5) is written as

$$v(\eta) = v^*(\eta) + \gamma \varphi_\eta \tag{5.7}$$

for some constant $\gamma \in \boldsymbol{R}$.

Here we define

$$|v(r,\eta)|_{C^{h,k}(r,\eta)} = \sum_{\substack{0 \le i \le h,\ 0 \le j \le k \\ 0 \le i+j \le \max\{h,k\}}} \left| \frac{\partial^{i+j}}{\partial r^i \eta^j} v(r,\eta) \right|,$$

$$|v(r,\eta)|_{D^{h,k}(r,\eta)} = |v(r,\eta)|_{C^{h,k}(r,\eta)} - |v(r,\eta)|$$

for $v \in C^{h,k}$, the set of functions such that the partial derivatives in the right-hand side are defined and continuous.

PROPOSITION 5.3. *There exists a positive constant b_0 such that for any $b \in (0, b_0)$ and $\beta \in (\frac{3}{4}\beta_0, \beta_0)$, if $g \in C^{0,0}$ satisfies $|g(r,\eta)| \le A_2 \min\{e^{-br}, e^{-\beta|\eta|}\}$ for some A_2 and the solvability condition*

$$\int_0^\infty \langle\, g, \varphi_\eta \,\rangle_\eta \, dr = 0, \tag{5.8}$$

then the equation

$$v_{rr} + v_{\eta\eta} + f'(\varphi(\eta))v = g(r,\eta), \quad 0 < r < \infty,\ -\infty < \eta < \infty, \tag{5.9}$$

has a solution v satisfying $v_r(0,\eta) = 0$ and $|v(r,\eta)|_{C^{2,2}(r,\eta)} \le A_3 \min\{e^{-b'r}, e^{\beta'|\eta|}\}$ for some $b' \in (0,b)$, $\beta' \in (\frac{3}{4}\beta_0, \beta)$ and A_3.

Proposition 5.2 is a well-known fact. A proof of Proposition 5.3 will be given in section 6. By using these propositions, we will prove Proposition 5.1 in the following.

Let us construct u^+. By changing the variables from (x,y) to (z,s), (5.1) is rewritten as

$$v_t = \varepsilon^2 \left\{ v_{zz} - \frac{\kappa}{1-\kappa z} v_z + \frac{1}{1-\kappa z}\left(\frac{1}{1-\kappa z} v_s\right)_s \right\} + f(v) + \varepsilon^{m+3}, \tag{5.10}$$

$$t > 0,\ -d < z < d,\ 0 < s < L,$$

with the boundary conditions

$$v_z(t, \pm d, s) = 0, \tag{5.11}$$

where $\kappa = \kappa(s)$ and $v(t,z,s) = u^+(t, C(s) + z\nu(s))$.

First, we pay our attention to a neighborhood of the inner layer of v. Let $s = S^+$ be the position of the inner layer of u^+ and transform s into μ by $s = S^+ + \varepsilon\mu$. Then (5.10) is rewritten as

$$v_t - \frac{S_t^+}{\varepsilon} v_\mu = \varepsilon^2 \left(v_{zz} - \frac{\kappa}{1-\kappa z} v_z \right) + \frac{1}{1-\kappa z}\left(\frac{1}{1-\kappa z} v_\mu\right)_\mu + f(v) + \varepsilon^{m+3}. \tag{5.12}$$

We solve this equation under the conditions

$$v(t, z, \pm\infty) = \alpha^\pm(\varepsilon^{m+3}). \tag{5.13}$$

Here we assume that v and S^+ are functions of T, where $T = \varepsilon^4 t$, that is, $v = v(T,z,\mu)$ and $S^+ = S^+(T)$. Then (5.12) takes the form

$$\varepsilon^4 v_T = F^\varepsilon(v), \tag{5.14}$$

where

$$F^\varepsilon(v) = \varepsilon^2 \left(v_{zz} - \frac{\kappa}{1-\kappa z} v_z \right) + \frac{1}{1-\kappa z}\left(\frac{1}{1-\kappa z} v_\mu\right)_\mu + f(v) + \varepsilon^{m+3} + \varepsilon^3 S_T^+ v_\mu.$$

We expand $v(T,z,\mu)$ and $F^\varepsilon(v)$ as

$$v(T,z,\mu) = v^0(T,z,\mu) + \varepsilon v^1(T,z,\mu) + \cdots, \tag{5.15}$$

$$F^\varepsilon(v) = F^0(v) + \varepsilon F^1(v) + \cdots. \tag{5.16}$$

Noting that

$$\begin{aligned}\kappa &= \kappa(S^+ + \varepsilon\mu)\\ &= \kappa^+ + \varepsilon\mu\kappa_s^+ + \frac{1}{2}\varepsilon^2\mu^2\kappa_{ss}^+ + \frac{1}{6}\varepsilon^3\mu^3\kappa_{sss}^+ + O((\varepsilon\mu)^4),\end{aligned}$$

where $\kappa^+ = \kappa(S^+(T))$, we have

$$F^0(v) = \frac{1}{(1-z\kappa^+)^2}v_{\mu\mu} + f(v), \tag{5.17}$$

$$F^1(v) = F^1(z,\mu)v = \frac{\kappa_s^+ z}{(1-z\kappa^+)^2}(v_\mu + 2\mu v_{\mu\mu}), \tag{5.18}$$

$$\begin{aligned}F^2(v) &= F^2(z,\mu)v\\ &= v_{zz} - \frac{\kappa^+}{1-z\kappa^+}v_z + \frac{z}{(1-z\kappa^+)^3}\left(\kappa_{ss}^+ + \frac{3z{\kappa_s^+}^2}{1-z\kappa^+}\right)(\mu v_\mu + \mu^2 v_{\mu\mu}),\end{aligned} \tag{5.19}$$

$$F^3(v) = F^3(z,\mu)v + S_T^+ v_\mu + \varepsilon^m, \tag{5.20}$$

where

$$\begin{aligned}F^3(z,\mu)v = &-\frac{\kappa_s^+}{(1-z\kappa^+)^2}\mu v_z\\ &+\frac{z}{(1-z\kappa^+)^3}\left\{\frac{1}{3}\kappa_{sss}^+ + \frac{3z\kappa_s^+\kappa_{ss}^+}{1-z\kappa^+} + \frac{4z^2{\kappa_s^+}^3}{(1-z\kappa^+)^2}\right\}\left(\frac{3}{2}\mu^2 v_\mu + \mu^3 v_{\mu\mu}\right).\end{aligned}$$

Define

$$|\mu|_h = \sum_{j=0}^{h}|\mu|^j.$$

Then it is obvious that

$$\left|F^\varepsilon(v) - \sum_{j=0}^{3}\varepsilon^j F^j(v)\right| \le B\varepsilon^4|\mu|_4|v(z,\mu)|_{D^{1,2}(z,\mu)}. \tag{5.21}$$

Substituting (5.15) into (5.14) and equating coefficients of the same power of ε, we have

$$0 = F^0(v^0), \tag{5.22}$$

$$0 = F_v^0(v^0)v^1 + F^1(z,\mu)v^0, \tag{5.23}$$

$$0 = F_v^0(v^0)v^2 + \frac{1}{2}F_{vv}^0(v^0)v^1\cdot v^1 + F^1(z,\mu)v^1 + F^2(z,\mu)v^0, \tag{5.24}$$

$$\begin{aligned}0 = &F_v^0(v^0)v^3 + F_{vv}^0(v^0)v^1\cdot v^2 + \frac{1}{6}F_{vvv}^0(v^0)(v^1)^3\\ &+F^1(z,\mu)v^2 + F^2(z,\mu)v^1 + F^3(z,\mu)v^0 + S_T^+ v_\mu^0 + \varepsilon^m.\end{aligned} \tag{5.25}$$

We solve these equations to find $v^0,\dots,v^3$. We note that by (5.13) and Proposition 3.3, v^j must satisfy

$$v^0(t,z,\pm\infty) = \pm 1, \tag{5.26}$$

$$v^j(t,z,\pm\infty) = 0 \quad (j=1,2), \tag{5.27}$$

$$v^3(t,z,\pm\infty) = M_0\varepsilon^m. \tag{5.28}$$

First we can obtain v^0 from (5.22), (5.17), and (5.26) as

$$v^0(T,z,\mu)=\varphi((1-z\kappa^+)(\mu-\gamma^+)) \tag{5.29}$$

for a certain function $\gamma^+=\gamma^+(T,z)$. However, this does not satisfy (5.11). This implies that we have to consider boundary layers. We will consider only the boundary layer in the neighborhood of $z=-d$ here, because the neighborhood of $z=d$ is treated in the same manner.

We set $z=-d+\varepsilon r$ near $z=-d$. Then (5.14) is written as

$$\varepsilon^4\tilde{v}_T=\widetilde{F}^\varepsilon(\tilde{v}) \tag{5.30}$$

with the boundary conditions

$$\tilde{v}(T,r,\pm\infty)=\alpha^\pm(\varepsilon^{m+3}),\quad \tilde{v}_r(T,0,\mu)=0, \tag{5.31}$$

where

$$\tilde{v}(T,r,\mu)=v(T,-d+\varepsilon r,\mu) \tag{5.32}$$

and

$$\widetilde{F}^\varepsilon(\tilde{v})=\tilde{v}_{rr}-\varepsilon\frac{\kappa}{1-\kappa z}\tilde{v}_r+\frac{1}{1-\kappa z}\left(\frac{1}{1-\kappa z}\tilde{v}_\mu\right)_\mu+f(\tilde{v})+\varepsilon^{m+3}+\varepsilon^3S_T^+\tilde{v}_\mu.$$

We expand $\tilde{v}(T,r,\mu)$ and $\widetilde{F}^\varepsilon(\tilde{v})$ as

$$\begin{aligned}\tilde{v}(T,r,\mu)&=\tilde{v}^0(T,r,\mu)+\varepsilon\tilde{v}^1(T,r,\mu)+\cdots,\\ \widetilde{F}^\varepsilon(\tilde{v})&=\widetilde{F}^0(\tilde{v})+\varepsilon\widetilde{F}^1(\tilde{v})+\cdots.\end{aligned}$$

Then, by the same way as in the case of F^ε, we have

$$\widetilde{F}^0(\tilde{v})=\tilde{v}_{rr}+\frac{1}{(1+d\kappa^+)^2}\tilde{v}_{\mu\mu}+f(\tilde{v}), \tag{5.33}$$

$$\begin{aligned}\widetilde{F}^1(\tilde{v})&=\widetilde{F}^1(r,\mu)\tilde{v}\\ &=-\frac{\kappa^+}{1+d\kappa^+}\tilde{v}_r+\frac{2\kappa^+}{(1+d\kappa^+)^3}r\tilde{v}_{\mu\mu}-\frac{d\kappa_s^+}{(1+d\kappa^+)^3}(\tilde{v}_\mu+2\mu\tilde{v}_{\mu\mu}),\end{aligned} \tag{5.34}$$

$$\begin{aligned}\widetilde{F}^2(\tilde{v})&=\widetilde{F}^2(r,\mu)\tilde{v}\\ &=-\frac{\kappa_s^+\mu+(\kappa^+)^2r}{(1+d\kappa^+)^2}\tilde{v}_r+\frac{r}{(1+d\kappa^+)^3}\left(\kappa_s^+-\frac{3d\kappa^+\kappa_s^+}{1+d\kappa^+}\right)(2\mu\tilde{v}_{\mu\mu}+\tilde{v}_\mu)\\ &\quad+\frac{3(\kappa^+)^2r^2}{(1+d\kappa^+)^4}\tilde{v}_{\mu\mu}-\frac{d}{(1+d\kappa^+)^3}\left(\kappa_{ss}^+\mu-\frac{3d(\kappa_s^+)^2}{1+d\kappa^+}\right)(\mu^2\tilde{v}_{\mu\mu}+\mu\tilde{v}_\mu).\end{aligned} \tag{5.35}$$

On the other hand, $v(T,-d+\varepsilon r,\mu)$ is expanded as

$$\begin{aligned}&v(T,-d+\varepsilon r,\mu)\\ &=v^0(T,-d+\varepsilon r,\mu)+\varepsilon v^1(T,-d+\varepsilon r,\mu)+\varepsilon^2v^2(T,-d+\varepsilon r,\mu)+\cdots\\ &=v^0(T,-d,\mu)+\varepsilon\left\{v_z^0(T,-d,\mu)r+v^1(T,-d,\mu)\right\}\\ &\qquad+\varepsilon^2\left\{\frac{1}{2}v_{zz}^0(T,-d,\mu)r^2+v_z^1(T,-d,\mu)r+v^2(T,-d,\mu)\right\}\\ &\qquad+\varepsilon^3\left\{\frac{1}{6}v_{zzz}^0(T,-d,\mu)r^3+\frac{1}{2}v_{zz}^1(T,-d,\mu)r^2\right.\\ &\qquad\qquad\left.+v_z^2(T,-d,\mu)r+v^3(T,-d,\mu)\right\}+\cdots,\end{aligned}$$

which must be equal to $\tilde{v}(T,r,\mu)$ by (5.32). Hence we have as $r \to \infty$

$$\tilde{v}^0(T,r,\mu) = \widetilde{W}^0(T,\mu) + o(1), \tag{5.36}$$

$$\tilde{v}^1(T,r,\mu) = \widetilde{W}^1(T,r,\mu) + o(1), \tag{5.37}$$

$$\tilde{v}^2(T,r,\mu) = \widetilde{W}^2(T,r,\mu) + o(1), \tag{5.38}$$

$$\tilde{v}^3(T,r,\mu) = \widetilde{W}^3(T,r,\mu) + o(1), \tag{5.39}$$

where

$$\begin{aligned}
\widetilde{W}^0(T,\mu) &= v^0(T,-d,\mu),\\
\widetilde{W}^1(T,r,\mu) &= v^0_z(T,-d,\mu)r + v^1(T,-d,\mu),\\
\widetilde{W}^2(T,r,\mu) &= \frac{1}{2}v^0_{zz}(T,-d,\mu)r^2 + v^1_z(T,-d,\mu)r + v^2(T,-d,\mu),\\
\widetilde{W}^3(T,r,\mu) &= \frac{1}{6}v^0_{zzz}(T,-d,\mu)r^3 + \frac{1}{2}v^1_{zz}(T,-d,\mu)r^2\\
&\qquad + v^2_z(T,-d,\mu)r + v^3(T,-d,\mu).
\end{aligned}$$

We will find $\tilde{v}^j$ $(j = 0,\dots,3)$ which satisfy (5.36)–(5.39) up to the second derivative with respect to r.

Similar to (5.22)–(5.28), the following equalities must hold:

$$0 = \widetilde{F}^0(\tilde{v}^0), \tag{5.40}$$

$$0 = \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\tilde{v}^1 + \widetilde{F}^1(z,\mu)\tilde{v}^0, \tag{5.41}$$

$$0 = \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\tilde{v}^2 + \frac{1}{2}\widetilde{F}^0_{\tilde{v}\tilde{v}}(\tilde{v}^0)\tilde{v}^1\cdot\tilde{v}^1 + \widetilde{F}^1(z,\mu)\tilde{v}^1 + \widetilde{F}^2(z,\mu)\tilde{v}^0, \tag{5.42}$$

$$\begin{aligned}
0 = {}& \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\tilde{v}^3 + \widetilde{F}^0_{\tilde{v}\tilde{v}}(\tilde{v}^0)\tilde{v}^1\cdot\tilde{v}^2 + \frac{1}{6}\widetilde{F}^0_{\tilde{v}\tilde{v}\tilde{v}}(\tilde{v}^0)(\tilde{v}^1)^3\\
&+\widetilde{F}^1(z,\mu)\tilde{v}^2 + \widetilde{F}^2(z,\mu)\tilde{v}^1 + \widetilde{F}^3(z,\mu)\tilde{v}^0 + S^+_T\tilde{v}^0_\mu + \varepsilon^m,
\end{aligned} \tag{5.43}$$

and

$$\begin{aligned}
\tilde{v}^0(t,z,\pm\infty) &= \pm 1,\\
\tilde{v}^j(t,z,\pm\infty) &= 0 \ (j=1,2),\\
\tilde{v}^3(t,z,\pm\infty) &= M_0\varepsilon^m.
\end{aligned} \tag{5.44}$$

We remark here that (5.40)–(5.43) hold when $\tilde{v}^j = \widetilde{W}^j$ $(j = 0,1,2,3)$.

By (5.29), (5.33) and (5.36), (5.40), (5.44), we immediately have

$$\begin{aligned}
\tilde{v}^0(T,r,\mu) &= \widetilde{W}^0(T,\mu)\\
&= \varphi((1+d\kappa^+)(\mu-\gamma^+(T,-d))),
\end{aligned} \tag{5.45}$$

which is independent of r.

5.2. Constructions of v^j and $\tilde{v}^j$ $(j = 1,2,3)$. First, let us consider v^1 and $\tilde{v}^1$.

LEMMA 5.4. *There exists a function v^1 satisfying* (5.23) *and* (5.27).

Proof. By (5.29) and the transformation $\eta = (1-z\kappa^+)(\mu-\gamma^+)$, (5.23) is equivalent to

$$0 = v^1_{\eta\eta} + f'(\varphi(\eta))v^1 + g^1, \tag{5.46}$$

where

$$g^1 = \frac{z\kappa_s^+}{(1-z\kappa^+)^2}\left\{2\eta\varphi_{\eta\eta} + \varphi_\eta + 2\gamma^+(1-z\kappa^+)\varphi_{\eta\eta}\right\}.$$

Since we can easily see that $|g^1(\eta)|_{C^3(\eta)} \le Be^{-\beta_1|\eta|}$ for constants $\beta_1 \in (\frac{3}{4}\beta_0, \beta_0)$ and B and that the solvability condition

$$\langle\, g^1, \varphi_\eta \,\rangle_\eta = 0$$

holds, there exists a unique function $V^1(T,z,\eta)$ satisfying (5.46),

$$\langle\, V^1, \varphi_\eta \,\rangle_\eta = 0, \tag{5.47}$$

and

$$|V^1(T,z,\eta)|_{C^5(\eta)} \le Be^{-\beta_1|\eta|} \tag{5.48}$$

by Proposition 5.2 and the smoothness of φ. Here we used the oddness of φ and

$$\langle\, \eta\varphi_{\eta\eta}, \varphi_\eta \,\rangle_\eta = -\frac{1}{2}M_1. \tag{5.49}$$

Hence, from (5.7), v^1 is given by

$$\begin{aligned} v^1(T,z,\mu) = V^1(T,z,(1-z\kappa^+)(\mu-\gamma^+(T,z)) \\ +\gamma^1(T,z)\varphi_\eta((1-z\kappa^+)(\mu-\gamma^+(T,z))) \end{aligned} \tag{5.50}$$

for some function γ^1. □

In general, we may assume

$$|V^1(T,z,\eta)|_{C^{5,5}(z,\eta)} \le Be^{-\beta_1|\eta|}. \tag{5.51}$$

LEMMA 5.5. *There exists a function $\tilde{v}^1$ satisfying* (5.31), (5.37) *and* (5.41), (5.44) *if and only if*

$$\gamma_z^+(T,-d) = 0. \tag{5.52}$$

Proof. In this proof, we simply express $V^1(T,-d,\eta)$, $\gamma^+(T,-d)$, and $\gamma_z^+(T,-d)$ as $V^1(\eta)$, γ^+, and γ_z^+, respectively.

By (5.34), (5.41), and (5.45), the equality (5.41) is represented as

$$0 = \tilde{v}^1_{rr} + \tilde{v}^1_{\eta\eta} + f'(\varphi)\tilde{v}^1 + \tilde{h}^1, \tag{5.53}$$

where $\eta = (1+d\kappa^+)(\mu-\gamma^+)$ and

$$\tilde{h}^1 = \frac{2\kappa^+}{(1+d\kappa^+)}r\varphi_{\eta\eta} - \frac{d\kappa_s^+}{(1+d\kappa^+)^2}\left\{\varphi_\eta + 2\eta\varphi_{\eta\eta} + 2\gamma^+(1+d\kappa^+)\varphi_{\eta\eta}\right\}.$$

Now it follows from (5.29) and (5.50) that

$$\widetilde{W}^1(T,r,\mu) = -\left\{\frac{\kappa^+}{1+d\kappa^+}\eta + (1+d\kappa^+)\gamma_z^+\right\}\varphi_\eta r + V^1(\eta) + \gamma^1\varphi_\eta,$$

where $\gamma^1 = \gamma^1(T, -d)$. Denote the right-hand side of this equation by $W^1 = W^1(T, r, \eta)$ and set $w^1 = \tilde{v}^1 - W^1$. Then w^1 satisfies

$$\begin{cases} w^1_{rr} + w^1_{\eta\eta} + f'(\varphi)w^1 = 0, \\ w^1_r(T, 0, \eta) = \left(\dfrac{\kappa^+}{1 + d\kappa^+}\eta + (1 + d\kappa^+)\gamma^+_z \right) \varphi_\eta, \\ w^1(T, \infty, \eta) = 0, \end{cases} \tag{5.54}$$

because $V^1(\eta)$, φ_η, respectively, satisfy (5.46) at $z = -d$ and the equation

$$0 = (\varphi_\eta)_{\eta\eta} + f'(\varphi)\varphi_\eta$$

and $U^{1,1} = -\eta\varphi_\eta$ satisfies

$$0 = U^{1,1}_{\eta\eta} + f'(\varphi)U^{1,1} + 2\varphi_{\eta\eta}. \tag{5.55}$$

Let $\chi(r)$ be a smooth function satisfying

$$\chi_r(0) = 1, \quad |\chi(r)|_{C^2(r)} \le Be^{-b_0 r},$$

and let

$$\tilde{w}^1 = w^1 - \chi(r) \left(\frac{\kappa^+}{1 + d\kappa^+}\eta + (1 + d\kappa^+)\gamma^+_z(T, -d) \right) \varphi_\eta.$$

Then, by (5.55), the equation for $\tilde{w}^1$ becomes

$$\begin{aligned} &\tilde{w}^1_{rr} + \tilde{w}^1_{\eta\eta} + f'(\varphi)\tilde{w}^1 + \tilde{g}^1 = 0, \\ &\tilde{w}^1_r(T, 0, \eta) = 0, \end{aligned} \tag{5.56}$$

where

$$\tilde{g}^1 = \frac{\kappa^+}{1 + d\kappa^+} \left\{ -\chi_{rr}U^{1,1} + 2\chi\varphi_{\eta\eta} \right\} + \chi_{rr}(1 + d\kappa^+)\gamma^+_z\varphi_\eta.$$

Since $|\tilde{g}^1(T, r, \eta)| \le O\left(e^{-(b_0 r + \beta_1|\eta|)}\right)$, Proposition 5.3 implies that there exists a function $\tilde{w}^1$ satisfying (5.56) and $|\tilde{w}^1|_{C^{2,2}(r,\eta)} \le O(\min\{e^{-b_1 r}, e^{-\beta_2|\eta|}\})$ for $b_1 \in (0, b_0)$ and $\beta_2 \in (\frac{3}{4}\beta_0, \beta_1)$ if and only if

$$\begin{aligned} 0 &= \int_0^\infty \langle\, \tilde{g}^1, \varphi_\eta \,\rangle_\eta \, dr \\ &= \int_0^\infty \chi_{rr}(1 + d\kappa^+)\gamma^+_z \langle\, \varphi_\eta, \varphi_\eta \,\rangle_\eta \, dr \\ &= M_1(1 + d\kappa^+)\gamma^+_z[\chi_r]_0^\infty \\ &= -M_1(1 + d\kappa^+)\gamma^+_z. \end{aligned}$$

This is equivalent to (5.52). Now, we set

$$\widetilde{V}^1 = \tilde{w}^1 + \chi(r) \left(\frac{\kappa^+}{1 + d\kappa^+}\eta + (1 + d\kappa^+)\gamma^+_z \right) \varphi_\eta + W^1. \tag{5.57}$$

Then, by (5.52) and the definition of W^1, we have

$$\begin{aligned} \widetilde{V}^1 &= \tilde{w}^1 + \chi(r)\frac{\kappa^+}{1 + d\kappa^+}\eta\varphi_\eta + W^1 \\ &= \tilde{w}^1 + \frac{(\chi - r)\kappa^+}{1 + d\kappa^+}\eta\varphi_\eta + V^1(\eta) + \gamma^1\varphi_\eta. \end{aligned}$$

Thus the function $\widetilde{V}^1$ satisfies (5.53) and

$$|\widetilde{V}^1(T,r,\eta) - W^1(T,r,\eta)|_{C^{2,2}(r,\eta)} \le B\min\{e^{-b_1 r}, e^{-\beta_2|\eta|}\}, \tag{5.58}$$

and $\tilde{v}^1$ is given by

$$\tilde{v}^1(T,r,\mu) = \widetilde{V}^1(T,r,(1+d\kappa^+)(\mu-\gamma^+)). \qquad \square \tag{5.59}$$

In quite a similar way, we can show that

$$\gamma_z^+(T,d) = 0 \tag{5.60}$$

is a necessary and sufficient condition for the existence of $\tilde{v}^1$ in a neighborhood of $z = d$.

Next we consider (5.24) in order to obtain v^2. A condition so that v^2 exists in (5.24) is given by

$$0 = \left\langle \frac{1}{2}F^0_{vv}(v^0)v^1\cdot v^1 + F^1(z,\mu)v^1 + F^2(z,\mu)v^0, v^0_\mu \right\rangle_\mu, \tag{5.61}$$

which is easily found by Proposition 5.2 and the transformation of μ into $\eta = (1 - z\kappa^+)(\mu - \gamma^+(T,z))$.

LEMMA 5.6. *The equality*

$$0 = \left\langle \frac{1}{2}F^0_{vv}(v^0)v^1\cdot v^1 + F^1(z,\mu)v^1, v^0_\mu \right\rangle_\mu \tag{5.62}$$

holds.

Proof. By differentiating (5.23) with respect to μ, we have

$$0 = F^0_{vv}(v^0)v^0_\mu\cdot v^1 + F^0_v(v^0)v^1_\mu + \frac{\partial}{\partial\mu}F^1v^0. \tag{5.63}$$

Hence, noting that $F^0_v(v^0)$ is self-adjoint, we see

$$\begin{aligned} 0 &= \left\langle F^0_{vv}(v^0)v^0_\mu\cdot v^1 + F^0_v(v^0)v^1_\mu + \frac{\partial}{\partial\mu}F^1v^0, v^1 \right\rangle_\mu \\ &= \langle\, F^0_v(v^0)v^1 - F^1v^0, v^1_\mu \,\rangle_\mu + \langle\, F^0_{vv}(v^0)v^1\cdot v^1, v^0_\mu \,\rangle_\mu \\ &= -2\langle\, F^1v^0, v^1_\mu \,\rangle_\mu + \langle\, F^0_{vv}(v^0)v^1\cdot v^1, v^0_\mu \,\rangle_\mu . \end{aligned} \tag{5.64}$$

Substituting (5.64) into the right-hand side of (5.62), we have

$$\left\langle \frac{1}{2}F^0_{vv}(v^0)v^1\cdot v^1 + F^1v^1, v^0_\mu \right\rangle_\mu = \langle\, F^1v^0, v^1_\mu \,\rangle_\mu + \langle\, F^1v^1, v^0_\mu \,\rangle_\mu . \tag{5.65}$$

Here it follows in general that, by a simple calculation,

$$\langle\, F^1v, w_\mu \,\rangle_\mu = -\langle\, F^1w, v_\mu \,\rangle_\mu . \tag{5.66}$$

From (5.65) and (5.66), the proof of this lemma is complete. $\square$

Lemma 5.6 implies that (5.61) is equivalent to

$$0 = \langle\, F^2(z,\mu)v^0, v^0_\mu \,\rangle_\mu . \tag{5.67}$$

LEMMA 5.7. *The equality* (5.67) *holds if and only if*

$$\gamma^+ = \gamma^+(T) \tag{5.68}$$

is independent of z.

Proof. From (5.29), we have

$$v_z^0 = -\left\{\frac{\kappa^+}{1-z\kappa^+}\eta + (1-z\kappa^+)\gamma_z^+\right\}\varphi_\eta,$$
$$v_{zz}^0 = \left\{\frac{\kappa^+}{1-z\kappa^+}\eta + (1-z\kappa^+)\gamma_z^+\right\}^2 \varphi_{\eta\eta} + \{2\kappa^+\gamma_z^+ - (1-z\kappa^+)\gamma_{zz}^+\}\varphi_\eta.$$

Noting

$$\langle\, \eta^2\varphi_{\eta\eta}, \varphi_\eta \,\rangle_\eta = 0,$$
$$\langle\, \varphi_{\eta\eta}, \varphi_\eta \,\rangle_\eta = 0,$$
$$\langle\, \eta\varphi_{\eta\eta}, \varphi_\eta \,\rangle_\eta = -\frac{1}{2}M_1,$$

we see

$$\begin{aligned}
&\left\langle v_{zz}^0 - \frac{\kappa^+}{1-z\kappa^+}v_z^0, v_\mu^0\right\rangle_\mu \qquad (5.69)\\
&= \langle\, v_{zz}^0, v_\mu^0 \,\rangle_\mu - \frac{\kappa^+}{1-z\kappa^+}\langle\, v_z^0, v_\mu^0 \,\rangle_\mu\\
&= \left(\frac{\kappa^+}{1-z\kappa^+}\right)^2 \langle\, \eta^2\varphi_{\eta\eta}, \varphi_\eta \,\rangle_\eta + 2\kappa^+\gamma_z^+ \langle\, \eta\varphi_{\eta\eta}, \varphi_\eta \,\rangle_\eta\\
&\qquad +(1-z\kappa^+)^2(\gamma_z^+)^2 \langle\, \varphi_{\eta\eta}, \varphi_\eta \,\rangle_\eta\\
&\qquad +\{2\kappa^+\gamma_z^+ - (1-z\kappa^+)\gamma_{zz}^+\}\langle\, \varphi_\eta, \varphi_\eta \,\rangle_\eta\\
&\qquad -\frac{\kappa^+}{1-z\kappa^+}\left(-\frac{\kappa^+}{1-z\kappa^+}\langle\, \eta\varphi_\eta, \varphi_\eta \,\rangle_\eta - (1-z\kappa^+)\gamma_z^+\langle\, \varphi_\eta, \varphi_\eta \,\rangle_\eta\right)\\
&= -M_1\kappa^+\gamma_z^+ + M_1\{2\kappa^+\gamma_z^+ - (1-z\kappa^+)\gamma_{zz}^+\}\\
&\qquad -\frac{\kappa^+}{1-z\kappa^+}\cdot\{-M_1(1-z\kappa^+)\gamma_z^+\}\\
&= 2M_1\kappa^+\gamma_z^+ - M_1(1-z\kappa^+)\gamma_{zz}^+.
\end{aligned}$$

On the other hand, we have

$$\begin{aligned}
&\langle\, \mu v_\mu^0 + \mu^2 v_{\mu\mu}^0, v_\mu^0 \,\rangle_\mu \qquad (5.70)\\
&= \left\langle\left(\frac{\eta}{1-z\kappa^+} + \gamma^+\right)(1-z\kappa^+)\varphi_\eta, \varphi_\eta\right\rangle_\eta\\
&\qquad +\left\langle\left(\frac{\eta}{1-z\kappa^+} + \gamma^+\right)^2(1-z\kappa^+)^2\varphi_{\eta\eta}, \varphi_\eta\right\rangle_\eta\\
&= \langle\, \eta\varphi_\eta, \varphi_\eta \,\rangle_\eta + (1-z\kappa^+)\gamma^+M_1 + \langle\, \eta^2\varphi_{\eta\eta}, \varphi_\eta \,\rangle_\eta\\
&\qquad +2\gamma^+(1-z\kappa^+)\langle\, \eta\varphi_{\eta\eta}, \varphi_\eta \,\rangle_\eta + (\gamma^+)^2(1-z\kappa^+)^2\langle\, \varphi_{\eta\eta}, \varphi_\eta \,\rangle_\eta\\
&= (1-z\kappa^+)\gamma^+M_1 - (1-z\kappa^+)\gamma^+M_1\\
&= 0.
\end{aligned}$$

By (5.69), (5.70), and (5.67), $\gamma^+(T,z)$ must satisfy

$$\gamma^+_{zz} - \frac{2\kappa^+}{1-z\kappa^+}\gamma^+_z = 0, \quad -d < z < d, \tag{5.71}$$

in order that (5.67) holds. Thus, by (5.71) with (5.52), (5.60), we obtain (5.68). □

By Lemma 5.7, we can show the existence of v^2 satisfying (5.24) if and only if (5.68) holds.

Next, let us consider $\tilde{v}^2$ of (5.42).

LEMMA 5.8. *The equality*

$$\left\langle \frac{1}{2}\widetilde{F}^0_{\tilde{v}\tilde{v}}(\tilde{v}^0)\tilde{v}^1\cdot\tilde{v}^1 + \widetilde{F}^1\tilde{v}^1, \tilde{v}^0_\mu \right\rangle_\mu = -\frac{\kappa^+}{1+d\kappa^+}\langle\, \tilde{v}^1_r, \tilde{v}^0_\mu \,\rangle_\mu + \langle\, \tilde{v}^1_{rr}, \tilde{v}^1_\mu \,\rangle_\mu \tag{5.72}$$

holds.

Proof. By differentiating (5.41) with respect to μ, we have

$$\widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\tilde{v}^1_\mu + \widetilde{F}^0_{\tilde{v}\tilde{v}}(\tilde{v}^0)\tilde{v}^0_\mu\cdot\tilde{v}^1 + \frac{\partial}{\partial\mu}(\widetilde{F}^1\tilde{v}^0) = 0,$$

and taking an inner product with $\tilde{v}^1$, we also have

$$\langle\, \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\tilde{v}^1_\mu, \tilde{v}^1 \,\rangle_\mu + \langle\, \widetilde{F}^0_{\tilde{v}\tilde{v}}(\tilde{v}^0)\tilde{v}^1\cdot\tilde{v}^1, \tilde{v}^0_\mu \,\rangle_\mu - \langle\, \widetilde{F}^1\tilde{v}^0, \tilde{v}^1_\mu \,\rangle_\mu = 0. \tag{5.73}$$

Since

$$\widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\tilde{v} = \tilde{v}_{rr} + F^0_v(\tilde{v}^0)\tilde{v} \tag{5.74}$$

and $F^0_v(\tilde{v}^0)$ is self-adjoint in $L^2(\boldsymbol{R}^1)$, it follows that

$$\begin{aligned}\langle\, \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\tilde{v}^1_\mu, \tilde{v}^1 \,\rangle_\mu &= \langle\, (\tilde{v}^1_\mu)_{rr}, \tilde{v}^1 \,\rangle_\mu + \langle\, F^0_v(\tilde{v}^0)\tilde{v}^1_\mu, \tilde{v}^1 \,\rangle_\mu \\ &= -\langle\, \tilde{v}^1_{rr}, \tilde{v}^1_\mu \,\rangle_\mu + \langle\, \tilde{v}^1_\mu, F^0_v(\tilde{v}^0)\tilde{v}^1 \,\rangle_\mu \\ &= \langle\, \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\tilde{v}^1, \tilde{v}^1_\mu \,\rangle_\mu - 2\langle\, \tilde{v}^1_{rr}, \tilde{v}^1_\mu \,\rangle_\mu .\end{aligned} \tag{5.75}$$

On the other hand, we have

$$\begin{aligned}&\langle\, \widetilde{F}^1\tilde{v}^0, \tilde{v}^1_\mu \,\rangle_\mu \\ &= -\frac{2\kappa^+ r}{(1+d\kappa^+)^3}\langle\, \tilde{v}^1_{\mu\mu}, \tilde{v}^0_\mu \,\rangle_\mu + \frac{d\kappa^+_s}{(1+d\kappa^+)^3}\langle\, \tilde{v}^1_\mu + 2\mu\tilde{v}^1_{\mu\mu}, \tilde{v}^0_\mu \,\rangle_\mu \\ &= -\langle\, \widetilde{F}^1\tilde{v}^1, \tilde{v}^0_\mu \,\rangle_\mu - \frac{\kappa^+}{1+d\kappa^+}\langle\, \tilde{v}^1_r, \tilde{v}^0_\mu \,\rangle_\mu\end{aligned} \tag{5.76}$$

by (5.34), (5.45), and the same equality as (5.66). Substituting (5.75) and (5.76) into (5.73) and using (5.41), we complete the proof. □

LEMMA 5.9. *The unique solution V^1 of* (5.46) *with* (5.47) *is explicitly obtained as*

$$V^1(T,z,\eta) = \zeta^{1,1}(T,z)U^{1,1}(\eta) + \zeta^{1,2}(T,z)U^{1,2}(\eta), \tag{5.77}$$

where

$$\begin{aligned}\zeta^{1,1}(T,z) &= \frac{\gamma^+(T)\kappa^+_s z}{1-z\kappa^+}, \\ U^{1,1}(\eta) &= -\eta\varphi_\eta(\eta), \\ \zeta^{1,2}(T,z) &= \frac{z\kappa^+_s}{(1-z\kappa^+)^2}, \\ U^{1,2}(\eta) &= -\frac{1}{2}\eta^2\varphi_\eta(\eta) + \frac{M_2}{2M_1}\varphi_\eta(\eta)\end{aligned}$$

and $M_2 = \langle\, \eta\varphi_\eta, \eta\varphi_\eta \,\rangle_\eta$.

Proof. We have equalities

$$\langle\, U^{1,1}, \varphi_\eta \,\rangle_\eta = \langle\, U^{1,2}, \varphi_\eta \,\rangle_\eta = 0.$$

Moreover, $U^{1,1}$ and $U^{1,2}$ satisfy (5.55) and

$$U^{1,2}_{\eta\eta} + F'(\varphi)U^{1,2} + \varphi_\eta + 2\eta\varphi_\eta = 0.$$

Thus the proof is complete. □

LEMMA 5.10. *There exists a function $\tilde{v}^2$ satisfying* (5.38), (5.42), *and* (5.44) *if and only if*

$$\gamma^1_z(T,-d) + \frac{\kappa^+}{1+d\kappa^+}\gamma^1(T,-d) + \frac{M_2\kappa^+}{M_1(1+d\kappa^+)}\zeta^{1,2}(T,-d) = 0. \tag{5.78}$$

Proof. Let

$$\tilde{h}^2 = \frac{1}{2}\widetilde{F}^0_{\tilde{v}\tilde{v}}(\tilde{v}^0)\tilde{v}^1\cdot\tilde{v}^1 + \widetilde{F}^1\tilde{v}^1 + \widetilde{F}^2\tilde{v}^0$$

and $w^2 = \tilde{v}^2 - \widetilde{W}^2$. Then w^2 satisfies

$$\begin{aligned} &0 = \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)w^2 + \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\widetilde{W}^2 + \tilde{h}^2,\\ &w^2_r(T,0,\mu) = -v^1_z(T,-d,\mu),\\ &w^2(T,r,\mu)\to 0 \ \text{ as } \ |\mu|,\ r\to\infty, \end{aligned} \tag{5.79}$$

because $\widetilde{W}^2_r(T,0,\mu) = v^1_z(T,-d,\mu)$. Putting

$$\tilde{w}^2 = w^2 + \chi(r)v^1_z$$

and

$$\tilde{g}^2 = -\widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\chi v^1_z + \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\widetilde{W}^2 + \tilde{h}^2,$$

where $v^1_z = v^1_z(T,-d,\mu)$, we get

$$\begin{aligned} &0 = \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\tilde{w}^2 + \tilde{g}^2,\\ &\tilde{w}^2_r(T,0,\mu) = 0,\\ &w^2(T,r,\mu)\to 0 \ \text{ as } \ |\mu|,\ r\to\infty. \end{aligned} \tag{5.80}$$

Here we have

$$\widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\widetilde{W}^2 + \frac{1}{2}\widetilde{F}^0_{\tilde{v}\tilde{v}}(\tilde{v}^0)\widetilde{W}^1\cdot\widetilde{W}^1 + \widetilde{F}^1\widetilde{W}^1 + \widetilde{F}^2\widetilde{W}^0 = 0. \tag{5.81}$$

Moreover (5.36) and (5.37) hold with the exponential order $O(e^{-b_1 r})$ from (5.45), (5.58), and (5.59). Hence

$$|\tilde{g}^2| \le O(\min\{e^{-b_1 r}, e^{-\beta_2|\eta|}\}),$$

where $\eta = (1+d\kappa^+)(\mu-\gamma^+)$. Therefore, by Proposition 5.3, there exists $\tilde{w}^2$ of (5.80) if and only if

$$\int_0^\infty \langle\, \tilde{g}^2, \tilde{v}^0_\mu \,\rangle_\mu \, dr = 0. \tag{5.82}$$

Here we note that $\langle\, \tilde{g}^2, \varphi_\eta \,\rangle_\eta = \langle\, \tilde{g}^2, \tilde{v}^0_\mu \,\rangle_\mu$ with $\eta = (1+d\kappa^+)(\mu-\gamma^+)$.

We will calculate (5.82). From (5.74), we have

$$\tilde{g}^2 = -\chi_{rr} v_z^1 - \chi F_v^0(\tilde{v}^0) v_z^1 + \widetilde{F}_{\tilde{v}}^0(\tilde{v}^0)\widetilde{W}^2 + \tilde{h}^2. \tag{5.83}$$

Since

$$\begin{aligned} \langle\, F_v^0(\tilde{v}^0) v_z^1, \tilde{v}_\mu^0 \,\rangle_\mu &= \langle\, F_v^0(\widetilde{W}^0) v_z^1, \widetilde{W}_\mu^0 \,\rangle_\mu \\ &= \langle\, v_z^1, F_v^0(\widetilde{W}^0)\widetilde{W}_\mu^0 \,\rangle_\mu \\ &= 0, \end{aligned}$$

it suffices to calculate

$$-\int_0^\infty \chi_{rr} \langle\, v_z^1, \tilde{v}_\mu^0 \,\rangle_\mu \, dr \tag{5.84}$$

and

$$\int_0^\infty \langle\, \widetilde{F}_{\tilde{v}}^0(\tilde{v}^0)\widetilde{W}^2 + \tilde{h}^2, \tilde{v}_\mu^0 \,\rangle_\mu \, dr. \tag{5.85}$$

In (5.84), $v_z^1 = v_z^1(T, -d, \mu)$ and $\tilde{v}_\mu^0$ are independent of r. Hence we have

$$\begin{aligned} -\int_0^\infty \chi_{rr} \langle\, v_z^1, \tilde{v}_\mu^0 \,\rangle_\mu \, dr &= -[\chi_r]_0^\infty \langle\, v_z^1, \tilde{v}_\mu^0 \,\rangle_\mu \\ &= \langle\, v_z^1, \tilde{v}_\mu^0 \,\rangle_\mu . \end{aligned} \tag{5.86}$$

On the other hand, (5.49) and (5.50) imply

$$\begin{aligned} &\langle\, v_z^1, \tilde{v}_\mu^0 \,\rangle_\mu \\ &= \left\langle V_z^1 - \frac{\kappa^+}{1+d\kappa^+}\eta V_\eta^1 + \gamma_z^1 \varphi_\eta - \gamma^1 \frac{\kappa^+}{1+d\kappa^+}\eta\varphi_{\eta\eta}, \varphi_\eta \right\rangle_\eta \\ &= M_1\gamma_z^1 + \langle\, V_z^1, \varphi_\eta \,\rangle_\eta - \frac{\kappa^+}{1+d\kappa^+}\left(\langle\, \eta V_\eta^1, \varphi_\eta \,\rangle_\eta - \frac{1}{2} M_1 \gamma^1 \right) \end{aligned} \tag{5.87}$$

at $z = -d$. Here, by Lemma 5.9, we have

$$\begin{aligned} \langle\, \eta V_\eta^1, \varphi_\eta \,\rangle_\eta &= \zeta^{1,2} \langle\, \eta U_\eta^{1,2}, \varphi_\eta \,\rangle_\eta \\ &= -\frac{1}{2} M_2 \zeta^{1,2}, \end{aligned}$$

because $U^{1,1}(\eta)$ and $U^{1,2}(\eta)$ are, respectively, odd and even. Hence

$$\begin{aligned} &\langle\, v_z^1, \tilde{v}_\mu^0 \,\rangle_\mu \\ &= M_1\gamma_z^1(T,-d) - \frac{\kappa^+}{1+d\kappa^+}\left(-\frac{1}{2} M_2\zeta^{1,2}(T,-d) - \frac{1}{2} M_1\gamma^1(T,-d) \right) \\ &= M_1\gamma_z^1(T,-d) + \frac{\kappa^+}{2(1+d\kappa^+)}\left(M_2\zeta^{1,2}(T,-d) + M_1\gamma^1(T,-d) \right). \end{aligned} \tag{5.88}$$

Next we calculate (5.85). From Lemma 5.8, we have

$$\begin{aligned} &\left\langle \frac{1}{2}\widetilde{F}_{\tilde{v}\tilde{v}}^0(\widetilde{W}^0)\widetilde{W}^1 \cdot \widetilde{W}^1 + \widetilde{F}^1\widetilde{W}^1, \widetilde{W}_\mu^0 \right\rangle_\mu \\ &= -\frac{\kappa^+}{1+d\kappa^+} \langle\, \widetilde{W}_r^1, \widetilde{W}_\mu^0 \,\rangle_\mu + \langle\, \widetilde{W}_{rr}^1, \widetilde{W}_\mu^1 \,\rangle_\mu , \end{aligned} \tag{5.89}$$

since $\widetilde{W}^j$ $(j=0,1,2)$ satisfy the same equations as (5.40) $\sim$ (5.42) and $\tilde{v}^0=\widetilde{W}^0$. In (5.89), it is obvious that

$$\begin{aligned}\langle\, \widetilde{W}^1_r, \widetilde{W}^0_\mu \,\rangle_\mu &= \langle\, v^0_z(T,-d,\mu), v^0_\mu(T,-d,\mu)\,\rangle_\mu \\ &= -\frac{\kappa^+}{1+d\kappa^+}\,\langle\, \eta\varphi_\eta, \varphi_\eta\,\rangle_\eta \\ &= 0,\end{aligned} \tag{5.90}$$

$$\langle\, \widetilde{W}^1_{rr}, \widetilde{W}^1_\mu \,\rangle_\mu = 0. \tag{5.91}$$

Hence, by (5.89), (5.90), and (5.91), we have

$$\left\langle \frac{1}{2}\widetilde{F}^0_{\tilde{v}\tilde{v}}(\widetilde{W}^0)\widetilde{W}^1\cdot\widetilde{W}^1 + \widetilde{F}^1\widetilde{W}^1, \widetilde{W}^0_\mu \right\rangle_\mu = 0. \tag{5.92}$$

In order to use (5.72), we calculate the right-hand side of (5.72). By (5.59), we have

$$\langle\, \tilde{v}^1_r, \tilde{v}^0_\mu \,\rangle_\mu = \langle\, \widetilde{V}^1_r, \varphi_\eta\,\rangle_\eta\,, \tag{5.93}$$

$$\langle\, \tilde{v}^1_{rr}, \tilde{v}^1_\mu \,\rangle_\mu = \langle\, \widetilde{V}^1_{rr}, \widetilde{V}^1_\eta\,\rangle_\eta\,. \tag{5.94}$$

Since $\tilde{w}^1$ is odd with respect to η due to (5.52) and (5.56), it follows from (5.57) that

$$\begin{aligned}\langle\, \widetilde{V}^1_r, \varphi_\eta\,\rangle_\eta &= \langle\, \tilde{w}^1_r, \varphi_\eta\,\rangle_\eta - (\chi_r+1)\frac{\kappa^+}{1+d\kappa^+}\,\langle\, \eta\varphi_\eta, \varphi_\eta\,\rangle_\eta \\ &= 0.\end{aligned} \tag{5.95}$$

Therefore, (5.93) and (5.95) imply

$$\langle\, \tilde{v}^1_r, \tilde{v}^0_\mu \,\rangle_\mu = 0. \tag{5.96}$$

Similarly, (5.94) becomes

$$\begin{aligned}&\langle\, \widetilde{V}^1_{rr}, \widetilde{V}^1_\eta\,\rangle_\eta \\ &= \left\langle \tilde{w}^1_{rr} + \frac{\kappa^+}{1+d\kappa^+}\chi_{rr}\eta\varphi_\eta\ ,\ \tilde{w}^1_\eta + \frac{\kappa^+}{1+d\kappa^+}(\chi-r)(\eta\varphi_\eta)_\eta + V^1_\eta + \gamma^1\varphi_{\eta\eta}\right\rangle_\eta \\ &= \langle\, \tilde{w}^1_{rr}, V^1_\eta\,\rangle_\eta + \frac{\kappa^+}{1+d\kappa^+}\chi_{rr}\,\langle\, \eta\varphi_\eta, V^1_\eta + \gamma^1\varphi_{\eta\eta}\,\rangle_\eta \\ &= \langle\, \tilde{w}^1_{rr}, V^1_\eta\,\rangle_\eta - \frac{\kappa^+}{2(1+d\kappa^+)}\chi_{rr}(M_2\zeta^{1,2}+M_1\gamma^1),\end{aligned} \tag{5.97}$$

where $V^1=V^1(T,-d,\eta)$, $\zeta^{1,2}=\zeta^{1,2}(T,-d)$, and $\gamma^1=\gamma^1(T,-d)$. Since

$$\langle\, \widetilde{F}^2\tilde{v}^0, \tilde{v}^0_\mu\,\rangle_\mu = 0$$

by (5.35), (5.45), (5.49), and the oddness of φ, it follows from (5.72), (5.92) and (5.96), (5.97) that

$$\begin{aligned}&\langle\, \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\widetilde{W}^2 + \tilde{h}^2, \tilde{v}^0_\mu\,\rangle_\mu \\ &= \langle\, \widetilde{F}^0_{\tilde{v}}(\tilde{v}^0)\widetilde{W}^2\ ,\ \tilde{v}^0_\mu\,\rangle_\mu + \left\langle \frac{1}{2}\widetilde{F}^0_{\tilde{v}\tilde{v}}(\tilde{v}^0)\tilde{v}^1\cdot\tilde{v}^1 + \widetilde{F}^1\tilde{v}^1\ ,\ \tilde{v}^0_\mu\right\rangle_\mu \\ &= -\left\langle \frac{1}{2}\widetilde{F}^0_{\tilde{v}\tilde{v}}(\widetilde{W}^0)\widetilde{W}^1\cdot\widetilde{W}^1 + \widetilde{F}^1\widetilde{W}^1\ ,\ \tilde{v}^0_\mu\right\rangle_\mu \\ &\qquad + \langle\, \tilde{w}^1_{rr}, V^1_\eta\,\rangle_\eta - \frac{\kappa^+}{2(1+d\kappa^+)}\chi_{rr}(M_2\zeta^{1,2}+M_1\gamma^1).\end{aligned}$$

Therefore, (5.85) is equal to

$$\begin{aligned}(5.98)\qquad &\int_0^\infty \left(\langle\, \tilde{w}^1_{rr}, V^1_\eta \,\rangle_\eta - \frac{\kappa^+}{2(1+d\kappa^+)}\chi_{rr}(M_2\zeta^{1,2}+M_1\gamma^1)\right) dr\\ &= \langle\, \tilde{w}^1_r(T,\infty,\eta) - \tilde{w}^1_r(T,0,\eta), V^1_\eta \,\rangle_\eta\\ &\qquad -\frac{\kappa^+}{2(1+d\kappa^+)}(M_2\zeta^{1,2}+M_1\gamma^1)(\chi_r(\infty)-\chi_r(0))\\ &= \frac{\kappa^+}{2(1+d\kappa^+)}(M_2\zeta^{1,2}+M_1\gamma^1).\end{aligned}$$

It follows from (5.82), (5.88), and (5.98) that

$$\begin{aligned}(5.99)\qquad 0 &= \int_0^\infty \langle\, \tilde{g}^2, \tilde{v}^0_\mu \,\rangle_\mu\, dr\\ &= \left(M_1\gamma^1_z + \frac{\kappa^+}{2(1+d\kappa^+)}(M_2\zeta^{1,2}+M_1\gamma^1)\right)\\ &\qquad +\frac{\kappa^+}{2(1+d\kappa^+)}(M_2\zeta^{1,2}+M_1\gamma^1)\\ &= M_1\gamma^1_z + \frac{M_1\kappa^+}{1+d\kappa^+}\gamma^1 + \frac{M_2\kappa^+}{1+d\kappa^+}\zeta^{1,2}\end{aligned}$$

at $z=-d$. This shows (5.78). □

Similarly, $\tilde{v}^2$ exists in a neighborhood of $z=d$ if and only if

$$(5.100)\qquad \gamma^1_z(T,d) + \frac{\kappa^+}{1-d\kappa^+}\gamma^1(T,d) + \frac{M_2\kappa^+}{M_1(1-d\kappa^+)}\zeta^{1,2}(T,d) = 0.$$

Finally, we consider v^3 of (5.25). Put $w = v^3 - M_0\varepsilon^m$. Then w satisfies

$$\begin{aligned}(5.101)\qquad 0 &= F^0_v(v^0)w + F^0_{vv}(v^0)v^1\cdot v^2 + \frac{1}{6}F^0_{vvv}(v^0)(v^1)^3 + F^1(z,\mu)v^2\\ &\quad +F^2(z,\mu)v^1 + F^3(z,\mu)v^0 + S^+_T v^0_\mu + (M_0f'(v^0)+1)\varepsilon^m\end{aligned}$$

with

$$w(T,z,\mu)\to 0 \ as\ |\mu|\to\infty.$$

Hence the condition for the existence of w in (5.101) is

$$\begin{aligned}(5.102)\qquad 0 = \Big\langle & F^0_{vv}(v^0)v^1\cdot v^2 + \frac{1}{6}F^0_{vvv}(v^0)(v^1)^3 + F^1(z,\mu)v^2\\ &+F^2(z,\mu)v^1 + F^3(z,\mu)v^0 + S^+_T v^0_\mu + (M_0f'(v^0)+1)\varepsilon^m, v^0_\mu \Big\rangle_\mu.\end{aligned}$$

LEMMA 5.11. *The condition* (5.102) *is equivalent to*

$$(5.103)\qquad 0 = \langle\, F^2v^0, v^1_\mu \,\rangle_\mu + \langle\, F^2v^1, v^0_\mu \,\rangle_\mu + \langle\, F^3v^0, v^0_\mu \,\rangle_\mu + M_1(1-z\kappa^+)S^+_T + 2\varepsilon^m.$$

Proof. It is easily shown that

$$\begin{aligned}(5.104)\qquad &\langle\, S^+_T v^0_\mu + (M_0f'(v^0)+1)\varepsilon^m, \tilde{v}^0_\mu \,\rangle_\mu\\ &= \langle\, (1-z\kappa^+)S^+_T\varphi_\eta + (M_0f'(\varphi)+1)\varepsilon^m, \varphi_\eta \,\rangle_\eta\\ &= M_1(1-z\kappa^+)S^+_T + 2\varepsilon^m.\end{aligned}$$

So we consider the remaining terms of (5.103).

By (5.63), we have

$$0 = \left\langle F^0_{vv}(v^0)v^0_\mu \cdot v^1 + F^0_v(v^0)v^1_\mu + \frac{\partial}{\partial\mu}F^1v^0, v^2 \right\rangle_\mu \tag{5.105}$$
$$= \langle\, F^0_{vv}(v^0)v^1 \cdot v^2, v^0_\mu \,\rangle_\mu + \langle\, F^0_v(v^0)v^2, v^1_\mu \,\rangle_\mu - \langle\, F^1v^0, v^2_\mu \,\rangle_\mu .$$

Here

$$-\langle\, F^1v^0, v^2_\mu \,\rangle_\mu = \langle\, F^1v^2, v^0_\mu \,\rangle_\mu$$

holds by (5.66). Hence (5.105) is written as

$$0 = \langle\, F^0_{vv}(v^0)v^1 \cdot v^2 + F^1v^2, v^0_\mu \,\rangle_\mu + \langle\, F^0_v(v^0)v^2, v^1_\mu \,\rangle_\mu . \tag{5.106}$$

On the other hand, it follows from (5.24) that

$$0 = -\langle\, F^0_v(v^0)v^2, v^1_\mu \,\rangle_\mu + \frac{1}{2}\langle\, F^0_{vv}(v^0)v^1 \cdot v^1, v^1_\mu \,\rangle_\mu \tag{5.107}$$
$$+ \langle\, F^1v^1, v^1_\mu \,\rangle_\mu + \langle\, F^2v^0, v^1_\mu \,\rangle_\mu .$$

Now we have

$$\begin{aligned}\frac{1}{2}\langle\, F^0_{vv}(v^0)v^1 \cdot v^1, v^1_\mu \,\rangle_\mu &= -\frac{1}{2}\langle\, (F^0_{vv}(v^0)v^1 \cdot v^1)_\mu, v^1 \,\rangle_\mu \\ &= -\frac{1}{2}\langle\, F^0_{vvv}(v^0)v^1 \cdot v^1 \cdot v^0_\mu + 2F^0_{vv}(v^0)v^1 \cdot v^1_\mu, v^1 \,\rangle_\mu \\ &= -\frac{1}{2}\langle\, F^0_{vvv}(v^0)(v^1)^3, v^0_\mu \,\rangle_\mu - \langle\, F^0_{vv}(v^0)(v^1)^2, v^1_\mu \,\rangle_\mu ,\end{aligned}$$

so

$$\langle\, F^0_{vv}(v^0)(v^1)^2, v^1_\mu \,\rangle_\mu = -\frac{1}{3}\langle\, F^0_{vvv}(v^0)(v^1)^3, v^0_\mu \,\rangle_\mu . \tag{5.108}$$

Substituting (5.108) into (5.107), we obtain

$$0 = \langle\, F^0_v(v^0)v^2, v^1_\mu \,\rangle_\mu - \frac{1}{6}\langle\, F^0_{vvv}(v^0)(v^1)^3, v^0_\mu \,\rangle_\mu \tag{5.109}$$
$$+ \langle\, F^1v^1, v^1_\mu \,\rangle_\mu + \langle\, F^2v^0, v^1_\mu \,\rangle_\mu .$$

Hence, by (5.106), (5.109), and the equality $\langle\, F^1v^1, v^1_\mu \,\rangle_\mu = 0$, we have

$$\begin{aligned}&\left\langle F^0_{vv}(v^0)v^1 \cdot v^2 + \frac{1}{6}F^0_{vvv}(v^0)(v^1)^3 + F^1(z,\mu)v^2 + F^2(z,\mu)v^1 + F^3(z,\mu)v^0, v^0_\mu \right\rangle_\mu \\ &= \langle\, F^1v^1, v^1_\mu \,\rangle_\mu + \langle\, F^2v^0, v^1_\mu \,\rangle_\mu + \langle\, F^2v^1, v^0_\mu \,\rangle_\mu + \langle\, F^3v^0, v^0_\mu \,\rangle_\mu \\ &= \langle\, F^2v^0, v^1_\mu \,\rangle_\mu + \langle\, F^2v^1, v^0_\mu \,\rangle_\mu + \langle\, F^3v^0, v^0_\mu \,\rangle_\mu ,\end{aligned}$$

which completes the proof. □

LEMMA 5.12. *The equality*

$$\langle\, F^2v^0, v^1_\mu \,\rangle_\mu + \langle\, F^2v^1, v^0_\mu \,\rangle_\mu = M_1\gamma^1_{zz} + \frac{M_2(1+z\kappa^+)}{(1-z\kappa^+)^4}\kappa^+\kappa^+_s \tag{5.110}$$

holds.

Proof. Put $F^2v = F^{2,1}v + F^{2,2}v$, where

$$F^{2,1}v = v_{zz} - \frac{\kappa^+}{1-z\kappa^+}v_z,$$
$$F^{2,2}v = \frac{z}{(1-z\kappa^+)^3}\left(\kappa^+_{ss} + \frac{3z\kappa^{+2}_s}{1-z\kappa^+}\right)(\mu v_\mu + \mu^2 v_{\mu\mu}).$$

First we note that

$$\langle\, F^{2,2}v, w_\mu \,\rangle_\mu = -\langle\, v_\mu, F^{2,2}w \,\rangle_\mu$$

holds in general. Therefore, we have

$$\langle\, F^2v^0, v^1_\mu \,\rangle_\mu + \langle\, F^2v^1, v^0_\mu \,\rangle_\mu = \langle\, F^{2,1}v^0, v^1_\mu \,\rangle_\mu + \langle\, F^{2,1}v^1, v^0_\mu \,\rangle_\mu . \tag{5.111}$$

Let $\eta = (1-z\kappa^+)(\mu - \gamma^+)$. Then $F^{2,1}$ is expressed as

$$\begin{aligned} F^{2,1}v &= v_{zz} - \frac{2\kappa^+}{1-z\kappa^+}\eta v_{z\eta} + \left(\frac{\kappa^+}{1-z\kappa^+}\right)^2 \eta^2 v_{\eta\eta} \\ &\quad - \frac{\kappa^+}{1-z\kappa^+}\left(v_z - \frac{\kappa^+}{1-z\kappa^+}\eta v_\eta\right) \\ &= v_{zz} - \frac{2\kappa^+}{1-z\kappa^+}\eta v_{z\eta} - \frac{\kappa^+}{1-z\kappa^+}v_z \\ &\quad + \left(\frac{\kappa^+}{1-z\kappa^+}\right)^2 (\eta v_\eta + \eta^2 v_{\eta\eta}), \end{aligned} \tag{5.112}$$

and v^0 and v^1 are already obtained as

$$v^0 = \varphi(\eta), \tag{5.113}$$
$$v^1 = V^1(T,z,\eta) + \gamma^1(T,z)\varphi_\eta(\eta) \tag{5.114}$$

by (5.29) and (5.50). Since $d\eta = (1-z\kappa^+)d\mu$ and

$$v^0_\mu = (1-z\kappa^+)\varphi_\eta,$$
$$v^1_\mu = (1-z\kappa^+)\{V^1 + \gamma^1\varphi_\eta\}_\eta$$

by (5.113) and (5.114), the right-hand side of (5.111) is written as

$$\begin{aligned} &\langle\, F^{2,1}v^0, v^1_\mu \,\rangle_\mu + \langle\, F^{2,1}v^1, v^0_\mu \,\rangle_\mu \\ &= \langle\, F^{2,1}\varphi, (V^1 + \gamma^1\varphi_\eta)_\eta \,\rangle_\eta + \langle\, F^{2,1}(V^1 + \gamma^1\varphi_\eta), \varphi_\eta \,\rangle_\eta . \end{aligned} \tag{5.115}$$

Let $F^{2,1}v = F^*v + F^{**}v$ with

$$F^*v = v_{zz} - \frac{2\kappa^+}{1-z\kappa^+}\eta v_{z\eta} - \frac{\kappa^+}{1-z\kappa^+}v_z,$$
$$F^{**}v = \left(\frac{\kappa^+}{1-z\kappa^+}\right)^2 (\eta v_\eta + \eta^2 v_{\eta\eta}).$$

Since F^{**} also satisfies $\langle\, F^{**}v, w_\eta \,\rangle_\eta = -\langle\, v_\eta, F^{**}w \,\rangle_\eta$ in general, we have

$$\begin{aligned} &\langle\, F^{2,1}\varphi, (V^1 + \gamma^1\varphi_\eta)_\eta \,\rangle_\eta + \langle\, F^{2,1}(V^1 + \gamma^1\varphi_\eta), \varphi_\eta \,\rangle_\eta \\ &= \langle\, F^*\varphi, (V^1 + \gamma^1\varphi_\eta)_\eta \,\rangle_\eta + \langle\, F^*(V^1 + \gamma^1\varphi_\eta), \varphi_\eta \,\rangle_\eta . \end{aligned} \tag{5.116}$$

Since $F^*\varphi = 0$, it follows from (5.111), (5.115), and (5.116) that

$$\langle F^2 v^0, v_\mu^1 \rangle_\mu + \langle F^2 v^1, v_\mu^0 \rangle_\mu = \langle F^*(V^1 + \gamma^1 \varphi_\eta), \varphi_\eta \rangle_\eta . \tag{5.117}$$

We will show

$$\langle F^*(\gamma^1 \varphi_\eta), \varphi_\eta \rangle_\eta = M_1 \gamma_{zz}^1. \tag{5.118}$$

Since $\langle \eta\varphi_\eta, \varphi_{\eta\eta} \rangle_\eta = -\frac{1}{2} M_1$ and

$$F^*(\gamma^1 \varphi_\eta) = \gamma_{zz}^1 \varphi_\eta - \frac{2\kappa^+}{1 - z\kappa^+} \eta \gamma_z^1 \varphi_{\eta\eta} - \frac{\kappa^+}{1 - z\kappa^+} \gamma_z^1 \varphi_\eta,$$

we have

$$\begin{aligned} \langle F^*(\gamma^1 \varphi_\eta), \varphi_\eta \rangle_\eta &= M_1 \gamma_{zz}^1 + \frac{M_1 \kappa^+}{1 - z\kappa^+} \gamma_z^1 - \frac{M_1 \kappa^+}{1 - z\kappa^+} \gamma_z^1 \\ &= M_1 \gamma_{zz}^1. \end{aligned}$$

This shows (5.118).

Next, we will show

$$\langle F^* V^1, \varphi_\eta \rangle_\eta = \frac{M_2 (1 + z\kappa^+)}{(1 - z\kappa^+)^4} \kappa^+ \kappa_s^+. \tag{5.119}$$

Substituting (5.77), we have

$$F^* V^1 = \sum_{j=1}^{2} \left(\zeta_{zz}^{1,j} U^{1,j} - \frac{2\kappa^+}{1 - z\kappa^+} \eta \zeta_z^{1,j} U_\eta^{1,j} - \frac{\kappa^+}{1 - z\kappa^+} \zeta_z^{1,j} U^{1,j} \right).$$

Since $\langle U^{1,j}, \varphi_\eta \rangle_\eta = 0$ $(j = 1, 2)$, the left-hand side of (5.119) satisfies the equality

$$\langle F^* V^1, \varphi_\eta \rangle_\eta = -\frac{2\kappa^+}{1 - z\kappa^+} \sum_{j=1}^{2} \zeta_z^{1,j} \langle \eta U_\eta^{1,j}, \varphi_\eta \rangle_\eta . \tag{5.120}$$

Since both $U_\eta^{1,1}$ and φ_η are even functions, it follows from (5.120) that

$$\begin{aligned} \langle F^* V^1, \varphi_\eta \rangle_\eta &= -\frac{2\kappa^+}{1 - z\kappa^+} \zeta_z^{1,2} \langle \eta U_\eta^{1,2}, \varphi_\eta \rangle_\eta \\ &= -\frac{2\kappa^+}{1 - z\kappa^+} \left(\frac{z\kappa_s^+}{(1 - z\kappa^+)^2} \right)_z \langle \eta U_\eta^{1,2}, \varphi_\eta \rangle_\eta \\ &= -\frac{2(1 + z\kappa^+)}{(1 - z\kappa^+)^4} \kappa^+ \kappa_s^+ \langle \eta U_\eta^{1,2}, \varphi_\eta \rangle_\eta . \end{aligned} \tag{5.121}$$

Here, by Lemma 5.9, we have

$$\begin{aligned} \langle \eta U_\eta^{1,2}, \varphi_\eta \rangle_\eta &= -\left\langle \eta\varphi_\eta + \frac{1}{2}\eta^2 \varphi_{\eta\eta} - \frac{M_2}{2M_1} \varphi_{\eta\eta}, \eta\varphi_\eta \right\rangle_\eta \\ &= -M_2 - \frac{1}{2} \langle \eta^3 \varphi_{\eta\eta}, \varphi_\eta \rangle_\eta + \frac{M_2}{2M_1} \langle \varphi_{\eta\eta}, \eta\varphi_\eta \rangle_\eta \\ &= -M_2 - \frac{1}{4} \langle \eta^3, (\varphi_\eta{}^2)_\eta \rangle_\eta + \frac{M_2}{2M_1} \left(-\frac{1}{2} M_1 \right) \\ &= -M_2 + \frac{3}{4} M_2 - \frac{1}{4} M_2 \\ &= -\frac{1}{2} M_2. \end{aligned} \tag{5.122}$$

Thus, (5.121) and (5.122) show (5.119).

By (5.117), (5.118), and (5.119), the proof is complete. □

LEMMA 5.13. *The equality*

$$\langle\, F^3 v^0, v^0_\mu \,\rangle_\mu = \frac{M_2}{(1-z\kappa^+)^4}\kappa^+\kappa^+_s \tag{5.123}$$

holds.

Proof. First it is easily shown that

$$\left\langle \frac{3}{2}\mu^2 v^0_\mu + \mu^3 v^0_{\mu\mu}, v^0_\mu \right\rangle_\mu = 0.$$

Hence

$$\langle\, F^3 v^0, v^0_\mu \,\rangle_\mu = -\frac{\kappa^+_s}{(1-z\kappa^+)^2}\,\langle\, \mu v^0_z, v^0_\mu \,\rangle_\mu\,. \tag{5.124}$$

Since

$$\mu v^0_z = \left(\frac{\eta}{1-z\kappa^+} + \gamma^0\right)\left(-\frac{\kappa^+}{1-z\kappa^+}\right)\eta\varphi_\eta$$

by (5.29) and (5.68), we have

$$\begin{aligned}
\langle\, \mu v^0_z, v^0_\mu \,\rangle_\mu &= \langle\, \mu v^0_z, \varphi_\eta \,\rangle_\eta \\
&= -\frac{\kappa^+}{1-z\kappa^+}\left(\frac{1}{1-z\kappa^+}\,\langle\, \eta^2\varphi_\eta, \varphi_\eta \,\rangle_\eta + \gamma^0\,\langle\, \eta\varphi_\eta, \varphi_\eta \,\rangle_\eta\right) \\
&= -\frac{\kappa^+}{1-z\kappa^+}\times\frac{1}{1-z\kappa^+}M_2 \\
&= -\frac{\kappa^+}{(1-z\kappa^+)^2}.
\end{aligned}$$

Substituting this into (5.124), we complete the proof. □

By (5.102) and Lemmas 5.11–5.13, there exists v^3 satisfying (5.25) and (5.28) if and only if

$$\begin{aligned}
0 &= M_1\gamma^1_{zz} + \frac{M_2(1+z\kappa^+)}{(1-z\kappa^+)^4}\kappa^+\kappa^+_s + \frac{M_2}{(1-z\kappa^+)^4}\kappa^+\kappa^+_s \\
&\qquad + M_1(1-z\kappa^+)S^+_T + 2\varepsilon^m \\
&= M_1\gamma^1_{zz} + \frac{M_2(2+z\kappa^+)}{(1-z\kappa^+)^4}\kappa^+\kappa^+_s + M_1(1-z\kappa^+)S^+_T + 2\varepsilon^m.
\end{aligned} \tag{5.125}$$

LEMMA 5.14. *There exists* γ^1 *satisfying* (5.125) *with* (5.78) *and* (5.100) *if and only if*

$$S^+_T = H^+(S^+). \tag{5.126}$$

Proof. Set

$$\begin{aligned}
K(z) &= \frac{1}{M_1}\left(\frac{M_2(2+z\kappa^+)}{(1-z\kappa^+)^4}\kappa^+\kappa^+_s + M_1(1-z\kappa^+)S^+_T + 2\varepsilon^m\right), \\
\omega^\pm &= \frac{\kappa^+}{1\mp d\kappa^+}, \\
\lambda^\pm &= \frac{M_2\kappa^+}{M_1(1\mp d\kappa^+)}\zeta^{1,2}(T, \pm d) \\
&= \pm\frac{M_2 d}{M_1(1\mp d\kappa^+)^3}\kappa^+\kappa^+_s.
\end{aligned}$$

Then (5.125) with (5.100) and (5.78) is expressed as

$$\left\{ \begin{array}{l} \gamma^1_{zz} + K = 0, \quad -d < z < d, \\ \gamma^1_z + \omega^{\pm}\gamma^1 + \lambda^{\pm} = 0, \quad z = \pm d. \end{array} \right. \tag{5.127}$$

Let $\gamma^{1,\pm} = \gamma^1(\pm d)$. Then by integrating (5.127) over $(-d, d)$, we have

$$-\omega^+\gamma^{1,+} - \lambda^+ + \omega^-\gamma^{1,-} + \lambda^- + K_1 = 0, \tag{5.128}$$

where

$$K_1 = \int_{-d}^{d} K(z)dz.$$

On the other hand, by integrating (5.127) over $(-d, d)$ twice, we have

$$\gamma^{1,+} - \gamma^{1,-} + 2(\omega^-\gamma^{1,-} + \lambda^-)d + K_2 = 0, \tag{5.129}$$

where

$$K_2 = \int_{-d}^{d}\int_{-d}^{z} K(t)dtdz.$$

Set

$$D = \begin{pmatrix} -\omega^+ & \omega^- \\ 1 & 2d\omega^- - 1 \end{pmatrix}, \quad \boldsymbol{b} = \begin{pmatrix} K_1 - \lambda^+ + \lambda^- \\ K_2 + 2d\lambda^- \end{pmatrix}.$$

Then the equalities (5.128) and (5.129) are expressed as

$$D\begin{pmatrix} \gamma^{1,+} \\ \gamma^{1,-} \end{pmatrix} + \boldsymbol{b} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}. \tag{5.130}$$

The determinant of D is computed as

$$\begin{aligned} \det\ D &= -\omega^+(2d\omega^- - 1) - \omega^- \\ &= -2d\omega^+\omega^- + \omega^+ - \omega^- \\ &= -2d\frac{\kappa^+}{1 - d\kappa^+} \times \frac{\kappa^+}{1 + d\kappa^+} + \frac{\kappa^+}{1 - d\kappa^+} - \frac{\kappa^+}{1 + d\kappa^+} \\ &= 0. \end{aligned}$$

Hence $\boldsymbol{b}$ must be orthogonal to the eigenfunction

$$\boldsymbol{x} = \begin{pmatrix} 2d\omega^- - 1 \\ -\omega^- \end{pmatrix}$$

of ${}^tD$ (the transposed matrix of D) in order that $(\gamma^{1,+}, \gamma^{1,-})$ exists. Namely

$$(2d\omega^- - 1)(K_1 - \lambda^+ + \lambda^-) - \omega^-(K_2 + 2d\lambda^-) = 0 \tag{5.131}$$

must be satisfied. Here we have

$$K_1 = \frac{4M_2 d(1 + d^2(\kappa^+)^2)}{M_1(1 - d\kappa^+)^3(1 + d\kappa^+)^3}\kappa^+\kappa_s^+ + 2dS_T^+ + \frac{4dp}{M_1}\varepsilon^m,$$

$$K_2 = \frac{M_2 d}{M_1}\left(\frac{1+d^2(\kappa^+)^2}{\kappa^+(1-d\kappa^+)^2(1+d\kappa^+)^2} - \frac{1-d\kappa^+}{\kappa^+(1+d\kappa^+)^3}\right)\kappa^+\kappa_s^+ + 2d^2\left(\frac{1}{3}d\kappa^+ + 1\right)S_T^+ + \frac{2d^2 p}{M_1}\varepsilon^m.$$

Substituting these into (5.131), we complete the proof. □

Let $S^+(T)$ be the solution of (5.126) defined for $T \in [0, T^*]$. Then we can construct $v^0, \dots, v^3$ and $\tilde{v}^0, \dots, \tilde{v}^2$ as we have seen so far. In quite a similar manner, we can show the existence of $\tilde{v}^3$ satisfying (5.39), (5.31) and (5.43), (5.44). We will roughly explain it and omit the details.

By Proposition 5.2 and Lemma 5.7, v^2 is expressed as

$$v^2 = V^2 + \gamma^2\varphi_\eta$$

for certain functions $V^2 = V^2(T, z, \eta)$ and $\gamma^2 = \gamma^2(T, z)$, where $\eta = (1 - z\kappa^+)(\mu - \gamma^+)$. Then the solvability condition for the existence of $\tilde{v}^3$ gives boundary conditions of γ^2 at $z = -d$ as (5.41) and (5.42) give (5.52) and (5.78), respectively. On the other hand, the equation of γ^2 for $z \in (-d, d)$ is derived from the solvability condition of v^4 as (5.71) and (5.125) are derived from (5.24) and (5.25), respectively. However we need not consider v^4 here, because the complete properties of γ^2, except that v^2 satisfies (5.24), and (5.27), are not necessary. Therefore, we can give an adequate boundary value of γ^2 such that $\tilde{v}^3$ exists.

5.3. Construction of the approximate function v^+. We will show the existence of a positive constant $n \in (m+3, 4)$ such that there exists a function $v^+(t, z, s)$ approximating (5.10) up to $O(\varepsilon^n)$ uniformly in $t \in [0, \leq T^*/\varepsilon^4]$ and $(z, s) \in (-d, d) \times (0, L)$. We note that v^j and $\tilde{v}^j$ $(j = 0, \dots, 3)$ are represented as functions of (T, z, η_z) and (T, r, η_{-d}), respectively, with $\eta_z = (1 - z\kappa^+)(\mu - \gamma^+(T))$ and $\eta_{-d} = (1 + d\kappa^+)(\mu - \gamma^+(T))$. Hence we can write v^j and $\tilde{v}^j$ $(j = 0, \dots, 3)$ as $v^j(T, z, \eta_z)$ and $\tilde{v}^j(T, r, \eta_{-d})$ $(j = 0, \dots, 3)$, respectively, and expand

$$v^\varepsilon(T, z, \eta) = \sum_{j=0}^{3} \varepsilon^j v^j(T, z, \eta),$$

$$\tilde{v}^\varepsilon(T, r, \eta) = \sum_{j=0}^{3} \varepsilon^j \tilde{v}^j(T, r, \eta).$$

Also $\widetilde{W}^j$ $(j = 0, \dots, 3)$ are represented as functions of (T, r, η_{-d}). Hence we write those as $\widetilde{W}^j(T, r, \eta_{-d})$ $(j = 0, \dots, 3)$ and expand

$$\widetilde{W}^\varepsilon(T, r, \eta) = \sum_{j=0}^{3} \varepsilon^j \widetilde{W}^j(T, r, \eta).$$

Then v^ε and $\tilde{v}^\varepsilon$ satisfy

$$|v^\varepsilon(T, z, \eta) - (\pm 1 + M_0\varepsilon^{m+3})|_{C^{5,5}(z,\eta)} \leq Be^{-\beta|\eta|}, \tag{5.132}$$

$$|\tilde{v}^\varepsilon(T, r, \eta) - \widetilde{W}^\varepsilon(T, r, \eta)|_{C^{2,2}(r,\eta)} \leq B\min\{e^{-br}, e^{-\beta|\eta|}\}, \tag{5.133}$$

respectively, for $b \in (0, b_1)$, $\beta \in (\frac{3}{4}\beta_0, \beta_2)$ by (5.51) and so on. Furthermore, it follows from the definition of $\widetilde{W}^j$ and (5.132) that

$$\begin{aligned} |\widetilde{W}^\varepsilon(T, r, \eta_{-d})|_{C^{2,2}(r,\mu)} &\leq B|\varepsilon r|_3(1 + |\eta_{-d}|^3)|v^\varepsilon(T, z, \eta_{-d})|_{C^{3,5}(z,\eta)} \\ &\leq B|\varepsilon r|_3 e^{-\beta'|\eta_{-d}|} \end{aligned} \tag{5.134}$$

for $r > 0$ and some $\beta' \in (\frac{3}{4}\beta_0, \beta_0)$.

Let $\rho(\eta)$ be a smooth function satisfying $0 \le \rho(\eta) \le 1$, $\rho(\eta) = 0$ for $\eta \le -1$, and $\rho(\eta) = 1$ for $\eta \ge 1$, and let

$$\hat{v}(t,z,\mu) = \left\{1 - \rho\left(\frac{r - 2q|\log\varepsilon|}{q|\log\varepsilon|}\right)\right\}\tilde{v}^\varepsilon(T,r,\eta_{-d}) + \rho\left(\frac{r-2q|\log\varepsilon|}{q|\log\varepsilon|}\right)v^\varepsilon(T,z,\eta_z),$$

where $T = \varepsilon^4 t$, $r = \frac{z+d}{\varepsilon}$ and q is a positive constant with $bq \ge 4$.

LEMMA 5.15. *For any fixed $n \in (m+3, 4)$, $\hat{v}$ satisfies*

$$\hat{v}_z(t,-d,\mu) = 0 \tag{5.135}$$

and

$$F^\varepsilon(\hat{v}) - \hat{v}_t = O(\varepsilon^n) \tag{5.136}$$

uniformly in $(t,z,\mu) \in [0, T^*/\varepsilon^4] \times (-d,d) \times (-\infty,\infty)$.

Proof. From the definition of $\hat{v}$, we may write it by $\hat{v}(T,z,\mu)$, and (5.135) obviously holds. Therefore, it suffices to show that

$$F^\varepsilon(\hat{v}) = O(\varepsilon^n) \tag{5.137}$$

uniformly in $(t,z,\mu) \in J$, where $J = [0,T^*] \times (-d,d) \times (-\infty,\infty)$.

First, let us consider (5.137) in the range of $0 \le r \le q|\log\varepsilon|$, that is, $-d \le z \le -d + q\varepsilon|\log\varepsilon|$. In this range, $\hat{v}(T,z,\mu) = \tilde{v}^\varepsilon(T,r,\eta_{-d})$ holds. Now it follows from (5.21) that

$$\left|\widetilde{F}^\varepsilon(\tilde{v}) - \sum_{j=0}^{3}\varepsilon^j\widetilde{F}^j(\tilde{v})\right| \le B\varepsilon^4 r^4 |\mu|_4 |\tilde{v}(r,\mu)|_{D^{1,2}(r,\mu)} \tag{5.138}$$

for $r > 1$. Hence, by (5.133) and inequalities $m+3 < n < 4$, $0 < \beta' < \beta$, we have

$$\begin{aligned}
&|\widetilde{F}^\varepsilon(\tilde{v}^\varepsilon)| \\
&\le \left|\sum_{j=0}^{3}\varepsilon^j\widetilde{F}^j(\tilde{v}^\varepsilon)\right| + B\varepsilon^4 r^4|\mu|_4|\tilde{v}^\varepsilon(T,r,\mu)|_{D^{1,2}(r,\mu)} \\
&\le B\varepsilon^4 r^4\left|\frac{\eta_{-d}}{1+d\kappa^+} + \gamma^+\right|_4 |\tilde{v}^\varepsilon(T,r,\eta_{-d})|_{C^{1,2}(r,\eta)} \\
&\le B\varepsilon^4 r^4\left|\frac{\eta_{-d}}{1+d\kappa^+} + \gamma^+\right|_4 \left\{|\widetilde{W}^\varepsilon(T,r,\eta_{-d})|_{C^{1,2}(r,\eta)} + B\min\{e^{-br}, e^{\beta|\eta_{-d}|}\}\right\} \\
&\le B\varepsilon^4 r^4\left|\frac{\eta_{-d}}{1+d\kappa^+} + \gamma^+\right|_4 \left\{B|\varepsilon r|_3 e^{-\beta|\eta_{-d}|} + B\min\{e^{-br}, e^{-\beta|\eta_{-d}|}\}\right\} \\
&\le B\varepsilon^4 r^4(|\varepsilon r|_3 + 1)\left|\frac{\eta_{-d}}{1+d\kappa^+} + \gamma^+\right|_4 e^{\beta|\eta_{-d}|} \\
&\le B\varepsilon^4 r^4 \\
&\le B(q\varepsilon|\log\varepsilon|)^4 \\
&\le B\varepsilon^n
\end{aligned}$$

for $1 < r \le q|\log\varepsilon|$, where $\tilde{v}^\varepsilon(T,r,\mu) = \tilde{v}^\varepsilon(T,r,\eta_{-d})$. For $0 \le r \le 1$, the inequality $|\widetilde{F}^\varepsilon(\tilde{v}^\varepsilon)| \le B\varepsilon^n$ obviously holds. Thus, we have

$$|\widetilde{F}^\varepsilon(\tilde{v}^\varepsilon)| \le B\varepsilon^n \tag{5.139}$$

uniformly in $(T,r,\mu) \in [0,T^*] \times [0, q|\log\varepsilon|] \times (-\infty,\infty)$.

Next, consider (5.137) in the range of $r \geq 3q|\log\varepsilon|$, that is, $z \geq -d + 3q\varepsilon|\log\varepsilon|$. In this range of r, $\hat{v}(T,z,\mu) = v^\varepsilon(T,z,\eta_z)$ holds. By

$$\frac{\partial}{\partial z} v(z,\eta_z) = v_z - \frac{\eta_z}{1-z\kappa^+} v_\eta,$$

we have

$$|v(z,\eta_z)|_{D^{1,2}(z,\mu)} \leq B(1+|\eta_z|)|v(z,\eta_z)|_{D^{1,2}(z,\eta)}.$$

Hence, by (5.21) and (5.132), we have

$$\begin{aligned}(5.140)\quad |F^\varepsilon(v^\varepsilon)| &\leq \left|\sum_{j=0}^{3} \varepsilon^j F^j(v^\varepsilon)\right| \\ &\qquad + B\varepsilon^4 \left|\frac{\eta_z}{1-z\kappa^+} + \gamma^+\right|_4 (1+|\eta_z|)|v^\varepsilon(T,z,\eta_z)|_{D^{1,2}(z,\eta)} \\ &\leq B\varepsilon^4(1+|\eta_z|)^5 e^{-\beta|\eta_z|} \\ &\leq B\varepsilon^4\end{aligned}$$

uniformly in $(T,z,\mu) \in J$.

Finally, consider (5.137) in the range of $q|\log\varepsilon| \leq r \leq 3q|\log\varepsilon|$, that is, $-d + q\varepsilon|\log\varepsilon| \leq z \leq -d + 3q\varepsilon|\log\varepsilon|$. In this range of r, we have

$$\begin{aligned}(5.141)\qquad \left|\sum_{j=0}^{3} \varepsilon^j F^\varepsilon(\widetilde{W}^\varepsilon)\right| &\leq B|\varepsilon r|^4 e^{-\beta|\eta|} \\ &\leq B(\varepsilon|\log\varepsilon|)^4 e^{-\beta|\eta|}\end{aligned}$$

uniformly in $(T,r,\eta) \in [0,T^*] \times [q|\log\varepsilon|, 3q|\log\varepsilon|] \times (-\infty,\infty)$. Furthermore, we have

$$\begin{aligned}(5.142)\qquad |\tilde{v}^\varepsilon(T,r,\eta) - \widetilde{W}^\varepsilon(T,r,\eta)|_{C^{2,2}(r,\eta)} &\leq B\min\{e^{-br}, e^{-\beta|\eta|}\} \\ &\leq B\min\{\varepsilon^{bq}, e^{-\beta|\eta|}\} \\ &\leq B\min\{\varepsilon^4, e^{-\beta|\eta|}\}\end{aligned}$$

by (5.133) and the inequalities $bq \geq 4$, $q|\log\varepsilon| \leq r \leq 3q|\log\varepsilon|$. Then the inequalities

$$(5.143)\qquad \begin{cases} |v^\varepsilon(T,z,\eta_z) - \sum_{j=0}^{3} \varepsilon^j \widetilde{W}^j(T,r,\eta_{-d})|_{C^{0,2}(z,\mu)} \\ \qquad \leq B\,|z+d|^4(e^{-\beta|\eta_z|} + e^{-\beta|\eta_{-d}|}), \\ \left|v^\varepsilon(T,z,\eta_z) - \displaystyle\sum_{j=0}^{3} \varepsilon^j \widetilde{W}^j(T,r,\eta_{-d})\right|_{C^{2,2}(z,\mu)} \\ \qquad \leq B\,|z+d|^2\left((1+|\eta_z|^2)e^{-\beta|\eta_z|} + e^{-\beta|\eta_{-d}|}\right) \\ \qquad \leq B\,|z+d|^2(e^{-\beta'|\eta_z|} + e^{-\beta|\eta_{-d}|}) \end{cases}$$

hold for $(T,z,\mu) \in J$ and $\beta' \in (\frac{3}{4}\beta_0, \beta)$. Therefore, by (5.142) and (5.143), $\hat{v}(T,z,\mu)$ is expressed as

$$\begin{aligned}(5.144)\qquad &\hat{v}(T,z,\mu) \\ &= (1-\rho)\cdot(\widetilde{W}^\varepsilon + a(T,r,\eta_{-d})) + \rho\cdot(\widetilde{W}^\varepsilon + b(T,z,\eta_z,\eta_{-d})) \\ &= \widetilde{W}^\varepsilon + c(T,z,\eta_z,\eta_{-d}),\end{aligned}$$

where

$$\widetilde{W}^\varepsilon = \widetilde{W}^\varepsilon(T, r, \eta_{-d}),$$
$$\rho = \rho\left(\frac{r - 2q|\log\varepsilon|}{q|\log\varepsilon|}\right),$$
$$c(T, z, \eta_z, \eta_{-d}) = (1-\rho)a\left(T, \frac{z+d}{\varepsilon}, \eta_{-d}\right) + \rho \cdot b(T, z, \eta_z, \eta_{-d}),$$

and $a(T, r, \eta_{-d}), b(T, z, \eta_z, \eta_{-d})$ satisfy

$$|a(T, r, \eta_{-d})|_{C^{2,2}(r,\mu)}, |b(T, z, \eta_z, \eta_{-d})|_{C^{0,2}(z,\mu)} \le B(|z+d|^4 + \varepsilon^4)(e^{-\beta'|\eta_z|} + e^{-\beta|\eta_{-d}|}),$$

$$|b(T, z, \eta_z, \eta_{-d})|_{C^{2,2}(z,\mu)} \le B(|z+d|^2 + \varepsilon^4)(e^{-\beta'|\eta_z|} + e^{-\beta|\eta_{-d}|}).$$

Since $q\varepsilon|\log\varepsilon| \le z + d \le 3q\varepsilon|\log\varepsilon|$,

$$\begin{aligned} |c(T, z, \eta_z, \eta_{-d})|_{C^{2,2}(z,\mu)} &\le B(\varepsilon|\log\varepsilon|)^2(e^{-\beta|\eta_z|} + e^{-\beta|\eta_{-d}|}), \\ |c(T, z, \eta_z, \eta_{-d})|_{C^{0,2}(z,\mu)} &\le B(\varepsilon|\log\varepsilon|)^4(e^{-\beta|\eta_z|} + e^{-\beta|\eta_{-d}|}) \end{aligned} \tag{5.145}$$

hold. Therefore, by (5.21), (5.134), (5.141) and (5.142), (5.144), (5.145), we have

$$\begin{aligned} |F^\varepsilon(\hat{v})| &\le \left|\sum_{j=0}^{3} \varepsilon^j F^j(\hat{v})\right| + B\varepsilon^4|\mu|_4|\hat{v}|_{D^{1,2}(z,\mu)} \\ &\le \left|\sum_{j=0}^{3} \varepsilon^j F^j(\widetilde{W}^\varepsilon + c)\right| \\ &\qquad + B\varepsilon^4|\mu|_4(|\widetilde{W}^\varepsilon|_{D^{1,2}(z,\mu)} + |c(T, z, \eta_z, \eta_{-d})|_{D^{1,2}(z,\mu)}) \\ &\le \left|\sum_{j=0}^{3} \varepsilon^j F^j(\widetilde{W}^\varepsilon)\right| + B|c(T, z, \eta_z, \eta_{-d})| + \left|\sum_{j=1}^{3} \varepsilon^j F^j c\right| \\ &\qquad + B\varepsilon^4|\mu|_4(|\varepsilon r|_3 + (\varepsilon|\log\varepsilon|)^2)(e^{-\beta'|\eta_z|} + e^{-\beta'|\eta_{-d}|}) \\ &\le B(\varepsilon|\log\varepsilon|)^4 e^{-\beta'|\eta_{-d}|} + B(\varepsilon|\log\varepsilon|)^4(e^{-\beta'|\eta_z|} + e^{-\beta'|\eta_{-d}|}) \\ &\qquad + \varepsilon|F^1 c| + \left|\sum_{j=2}^{3} \varepsilon^j F^j c\right| + B\varepsilon^4|\mu|_4(e^{-\beta'|\eta_z|} + e^{-\beta'|\eta_{-d}|}) \\ &\le B\varepsilon^n|\mu|_4(e^{-\beta'|\eta_z|} + e^{-\beta'|\eta_{-d}|}) + B\varepsilon|c(T, z, \eta_z, \eta_{-d})|_{C^{0,2}(z,\mu)} \\ &\qquad + B\varepsilon^2|c(T, z, \eta_z, \eta_{-d})|_{C^{2,2}(z,\mu)} \\ &\le B\varepsilon^n + B\varepsilon(\varepsilon|\log\varepsilon|)^4(e^{-\beta'|\eta_z|} + e^{-\beta'|\eta_{-d}|}) \\ &\qquad + B\varepsilon^2(\varepsilon|\log\varepsilon|)^2(e^{-\beta'|\eta_z|} + e^{-\beta'|\eta_{-d}|}) \\ &\le B\varepsilon^n \end{aligned} \tag{5.146}$$

uniformly in $(T, z, \mu) \in [0, T^*] \times [q|\log\varepsilon|, 3q|\log\varepsilon|] \times (-\infty, \infty)$. Here we note that F^1 does not contain any terms differentiated with respect to z.

Thus, it follows from (5.139), (5.140), and (5.146) that

$$F^\varepsilon(\hat{v}) \le B\varepsilon^n \tag{5.147}$$

uniformly in $(T, z, \mu) \in J$. □

In the vicinity of $z = d$, we can treat it by quite a similar way, and consequently we can construct $\hat{v}(t, z, \mu)$ satisfying (5.136), (5.135),

$$\hat{v}_z(t, d, \mu) = 0, \tag{5.148}$$

and the inequality

$$|\hat{v}(T, z, \mu) - (1 + M_0\varepsilon^m)|_{C^{2,2}(z,\mu)} \le Be^{-\beta|\eta_z|}$$

for some $\beta > 0$. Now, we may assume q is sufficiently large so that $bq, \beta q \ge 4$.

Let $\bar{\gamma} = \max_{0\le T\le T^*} |\gamma^+(T)|$ and $\bar{q} = \frac{q}{1-\delta} + \bar{\gamma}$. Define

$$v^+(t, z, s) = \begin{cases} (1-\rho)\hat{v}(t, z, \mu) + (1 + M_0\varepsilon^{m+3})\rho, & \mu > \bar{q}|\log\varepsilon|, \\ \hat{v}(t, z, \mu), & -\bar{q}|\log\varepsilon| \le \mu \le \bar{q}|\log\varepsilon|, \\ \rho\hat{v}(t, z, \mu) + (1-\rho)(-1 + M_0\varepsilon^{m+3}), & \mu < -\bar{q}|\log\varepsilon|, \end{cases}$$

where

$$\rho = \rho\left(\frac{\mu - 2\bar{q}|\log\varepsilon|}{\bar{q}|\log\varepsilon|}\right), \quad \mu = \frac{s - S^+(T)}{\varepsilon}.$$

It is obvious from the manner of construction of v^+ that $v^+(t, z, s) = u^+(t, C(s) + z\nu(s))$ satisfies (5.3) and (5.4).

LEMMA 5.16. *$v^+(t, z, s)$ satisfies* (5.11) *and*

$$\varepsilon^2\left\{v_{zz} - \frac{\kappa}{1-\kappa z}v_z + \frac{1}{1-\kappa z}\left(\frac{1}{1-\kappa z}v_s\right)_s\right\} + f(v) + \varepsilon^{m+3} - v_t = O(\varepsilon^n) \tag{5.149}$$

uniformly in $(t, z, s) \in [0, T^*/\varepsilon^4] \times (-d, d) \times (0, L)$.

Proof. It suffices to consider only the case $\mu > \bar{q}|\log\varepsilon|$.

Since $\mu > \bar{q}|\log\varepsilon|$ implies

$$\begin{aligned} \eta_z &\ge (1-\delta)(\bar{q}|\log\varepsilon| - \bar{\gamma}) \\ &\ge (1-\delta)(\bar{q} - \bar{\gamma})|\log\varepsilon| \\ &= q|\log\varepsilon|, \end{aligned}$$

$\hat{v}$ satisfies

$$\begin{aligned} |\hat{v}(T, z, \mu) - (1 + M_0\varepsilon^{m+3})|_{C^{2,2}(z,\mu)} &\le Be^{-\beta|\eta_z|} \\ &\le Be^{-\beta q|\log\varepsilon|} \\ &\le B\varepsilon^4 \end{aligned} \tag{5.150}$$

by (5.132). Hence v^+ is represented as

$$\begin{aligned} v^+(t, z, s) &= (1-\rho)(1 + M_0\varepsilon^{m+3} + d(T, z, \mu)) + \rho(1 + M_0\varepsilon^{m+3}) \\ &= (1 + M_0\varepsilon^{m+3}) + (1-\rho)d(T, z, \mu). \end{aligned}$$

Here (5.150) implies

$$|d(T, z, \mu)|_{C^{2,2}(z,\mu)} \le B\varepsilon^4, \tag{5.151}$$

$$|(1-\rho)d(T, z, \mu)|_{C^{2,2}(z,\mu)} \le B\varepsilon^4. \tag{5.152}$$

Hence, by (5.151), (5.152), and Proposition 3.3, we obtain

$$\begin{aligned}|F^\varepsilon(v^+) - v_t^+| &\le B\varepsilon^4 + |f(1+M_0\varepsilon^{m+3}) + \varepsilon^{m+3}| + \varepsilon^4|v_T^+| \\ &\le B\varepsilon^4 + O(\varepsilon^{2(m+3)}) \\ &\le B\varepsilon^4.\end{aligned}$$

This completes the proof. □

Quite similarly, we can construct v^- satisfying (5.3), (5.4), and (5.11), and

$$\begin{aligned}\varepsilon^2\left\{v_{zz} - \frac{\kappa}{1-\kappa z}v_z + \frac{1}{1-\kappa z}\left(\frac{1}{1-\kappa z}v_s\right)_s\right\} \\ +f(v) - \varepsilon^{m+3} - v_t = O(\varepsilon^n)\end{aligned} \tag{5.153}$$

uniformly in $(t,z,s) \in [0, T^*/\varepsilon^4] \times (-d,d) \times (0,L)$ if $S^-(T)$ is a solution of

$$S_T^- = H^-(S^-). \tag{5.154}$$

6. Proof of Proposition 5.3. Suppose $|g(r,\eta)| \le \min\{e^{-br}, e^{-\beta|\eta|}\}$ for certain $b > 0$ and $\beta \in (\frac{3}{4}\beta_0, \beta_0)$. Let

$$\begin{aligned}\theta(r) &= \langle v, \varphi_\eta\rangle_\eta, \\ \psi(r,\eta) &= v - \langle v, \varphi_\eta\rangle_\eta\varphi_\eta,\end{aligned}$$

and

$$\begin{aligned}g^\theta(r) &= \langle g, \varphi_\eta\rangle_\eta, \\ g^\psi(r,\eta) &= g - \langle g, \varphi_\eta\rangle_\eta\varphi_\eta.\end{aligned}$$

Then (5.9) is equivalent to the equations

$$\theta_{rr} = g^\theta, \tag{6.1}$$

$$\psi_{rr} + E\psi = g^\psi, \tag{6.2}$$

with $|\theta(r)|, |\psi(r,\eta)| \to 0$ as $r, |\eta| \to +\infty$, where

$$E\psi = \psi_{\eta\eta} + f'(\varphi)\psi$$

for

$$\psi \in D(E) = \{\psi \in H^2(\boldsymbol{R}^1);\ \langle\psi, \varphi_\eta\rangle_\eta = 0\}.$$

Let $\|v\|_\eta = \sqrt{\langle v, v\rangle_\eta}$. First, we obtain θ from (6.1) as

$$\theta(r) = \int_0^r\int_0^q g^\theta(s)dsdq - \int_0^\infty\int_0^r g^\theta(q)dqdr.$$

LEMMA 6.1. *The inequality*

$$|\theta(r)|_{C^2(r)} \le Be^{-b'r} \tag{6.3}$$

holds for $b' \in (0,b)$.

Proof. Since $\|\varphi_\eta\|_\eta^2 = M_1$ and

$$
\begin{aligned}
|g^\theta(r)| &\le \| g(r,\cdot) \|_\eta \cdot \| \varphi_\eta \|_\eta \\
&\le \sqrt{M_1} \left(\int_{-\infty}^{\infty} (\min\{e^{-br}, e^{-\beta|\eta|}\})^2 d\eta \right)^{\frac{1}{2}} \\
&= \sqrt{M_1} \left(\frac{2br+1}{\beta} \right)^{\frac{1}{2}} e^{-br} \\
&\le B e^{-b'r}
\end{aligned} \tag{6.4}
$$

for $b' \in (0, b)$, we have the inequality

$$
|\theta_{rr}(r)| \le B e^{-b'r} \tag{6.5}
$$

directly from (6.1) and (6.4).

On the other hand, θ_r is estimated as

$$
\begin{aligned}
|\theta_r(r)| &= \left| \int_0^r g^\theta(r) dr \right| \\
&= \left| \int_r^\infty g^\theta(r) dr \right| \\
&\le \int_r^\infty |g^\theta(r)| dr \\
&\le B e^{-b'r}
\end{aligned} \tag{6.6}
$$

by using (5.8) and (6.4). Therefore, by (6.6), we have

$$
\begin{aligned}
|\theta(r)| &= \left| \int_0^r \theta_r(r) dr + \theta(0) \right| \\
&= \left| \int_0^r \theta_r(r) dr - \int_0^\infty \theta_r(r) dr \right| \\
&\le \int_r^\infty |\theta_r(r)| dr \\
&\le B e^{-b'r}.
\end{aligned} \tag{6.7}
$$

Inequalities (6.5), (6.6), and (6.7) complete the proof. □

Next, consider the equation (6.2). Let $\beta' \in (\frac{3}{4}\beta_0, \beta)$, and let $\omega(\eta)$ be a positive smooth function satisfying

$$
\begin{aligned}
&\omega(\eta) = e^{\beta'|\eta|}, \ |\eta| \ge A_4, \\
&\omega(\eta) \ge A_5, \ \eta \in \boldsymbol{R}^1
\end{aligned}
$$

for some positive constants A_4 and A_5. Define the Banach space X with a weighted sup-norm by

$$
X = \left\{ \psi \in C^0(\boldsymbol{R}^1) \cap D(E) \ ; \ \| \psi \|_\infty = \sup_\eta |\psi(\eta)\omega(\eta)| < \infty \right\}.
$$

Let $\mathcal{F}$ be the Fourier transformation on $(0, \infty)$ defined by

$$
(\mathcal{F}\psi)(\xi) = \sqrt{\frac{2}{\pi}} \int_0^\infty \cos \xi r \psi(r) dr.
$$

LEMMA 6.2. *The equation* (6.2) *has a solution* $\psi(r,\eta)$ *satisfying*

$$|\psi(r,\eta)|_{C^{0,2}(r,\eta)} \le Be^{-\beta'|\eta|}. \tag{6.8}$$

Proof. Operating $\mathcal{F}$ on both sides of (6.2), we have

$$(E-\xi^2)(\mathcal{F}\psi) = \mathcal{F}g^{\psi}. \tag{6.9}$$

Since

$$\begin{aligned} |g^{\psi}(r,\eta)| &\le |g(r,\eta)| + |g^{\theta}(r)||\varphi_{\eta}(\eta)| \\ &\le \min\{e^{-br}, e^{-\beta|\eta|}\} + Be^{-b'r}e^{-\beta_0|\eta|} \end{aligned} \tag{6.10}$$

by (6.4), we have

$$\begin{aligned} |(\mathcal{F}g^{\psi}(\xi,\cdot))(\eta)| &\le \int_0^{\infty} |g^{\psi}(r,\eta)|dr \\ &\le \int_0^{\infty} \left(\min\{e^{-br}, e^{-\beta|\eta|}\} + Be^{-b'r}e^{-\beta_0|\eta|}\right) dr \\ &\le \frac{\beta|\eta|+1}{b}e^{-\beta|\eta|} + Be^{-\beta_0|\eta|} \\ &\le Be^{-\beta'|\eta|}. \end{aligned}$$

Hence $\mathcal{F}g^{\psi}(\xi,\cdot) \in X$ and the equation (6.9) is solvable with respect to $\mathcal{F}\psi(\xi,\cdot)$ in X with $\| \frac{\partial^j}{\partial\eta^j}\mathcal{F}\psi(\xi,\cdot) \|_{\infty} \le \frac{B}{1+\xi^2}$ $(j=0,1,2)$. This implies the existence of ψ satisfying

$$|\psi(r,\eta)|_{C^{0,2}(r,\eta)} \le Be^{-\beta'|\eta|}, \tag{6.11}$$

because $\mathcal{F}(\mathcal{F}\psi) = \psi$. □

Let

$$L^2_{\varphi_\eta} = \left\{\psi \in L^2(\boldsymbol{R}^1)\ ;\ \langle\ \psi, \varphi_\eta\ \rangle_\eta = 0\right\}$$

with the norm $\|\psi\|_\eta = \sqrt{\langle\psi,\psi\rangle_\eta}$. Then E is self-adjoint in $L^2_{\varphi_\eta}$ and there exists $\underline{\lambda} > 0$ such that the spectrum of $-E$ is contained in $[\underline{\lambda}, \infty)$. Therefore, there exists a partition of unity $\{E(\lambda)\}$ with respect to $-E$ such that E is represented as

$$E = -\int_{\underline{\lambda}}^{\infty} \lambda dE(\lambda).$$

Let

$$g(\lambda; r)(\cdot) = E(\lambda)g^{\psi}(r,\cdot),$$

and let

$$\begin{aligned} \psi(\lambda; r) = \frac{1}{2}e^{-\Lambda r}\psi^0(\lambda) &- \frac{1}{2\Lambda}e^{\Lambda r}\int_r^{\infty} e^{-\Lambda s}g(\lambda; s)ds \\ &- \frac{1}{2\Lambda}e^{-\Lambda r}\int_0^{r} e^{\Lambda s}g(\lambda; s)ds, \end{aligned} \tag{6.12}$$

$$\psi(r,\cdot) = \int_{\underline{\lambda}}^{\infty} d\psi(\lambda; r) \tag{6.13}$$

for $\lambda \geq \underline{\lambda}$, where

$$\psi^0(\lambda) = -\frac{1}{\Lambda}\int_0^\infty e^{-\Lambda s} g(\lambda; s) ds$$

and $\Lambda = \sqrt{\lambda}$. Then ψ defined in (6.13) satisfies (6.2) because $g^\psi(r)(\cdot) = \int_{\underline{\lambda}}^\infty dg(\lambda; r)$ and the equation

$$\frac{d^2}{dr^2}\psi(\lambda; r) - \lambda\psi(\lambda; r) = g(\lambda; r) \quad (\lambda \geq \underline{\lambda}) \tag{6.14}$$

are satisfied.

In the following, we will estimate $\psi(r, \eta)$ given in (6.13). Note that

$$|g^\psi(r, \eta)|^2 \leq B(1 + r)e^{-2br} \tag{6.15}$$

by (6.4) and (6.10). Since the inequality $b' < b$ holds, it follows from (6.15) that

$$\begin{aligned} \langle\, e^{b'r} g^\psi(r, \cdot), e^{b'r} g^\psi(r, \cdot)\,\rangle_\eta &= e^{2b'r}\,\langle\, g^\psi(r, \cdot), g^\psi(r, \cdot)\,\rangle_\eta \\ &= e^{2b'r} B(1 + r)e^{-2br} \\ &\leq Be^{-2(b''-b')r} \end{aligned}$$

for some $b'' \in (b', b)$. Hence

$$\begin{aligned} \langle\, e^{b'r} g^\psi(r, \cdot), e^{b'r} g^\psi(r, \cdot)\,\rangle_\eta &= \|\bar{g}(r)\|_\eta^2 \\ &= \int_{\underline{\lambda}}^\infty d\,\langle\, E(\lambda)\bar{g}, \bar{g}\,\rangle_\eta \\ &= \int_{\underline{\lambda}}^\infty d\|\bar{g}(\lambda; r)\|_\eta^2 \\ &\leq Be^{-2(b''-b')r}, \end{aligned} \tag{6.16}$$

where $\bar{g}(r)(\cdot) = e^{b'r} g^\psi(r, \cdot)$ and $\bar{g}(\lambda; r) = E(\lambda)\bar{g}(r)(\cdot)$. Here we fix a constant b_0 with

$$0 < b_0 < \underline{\Lambda},$$

where $\underline{\Lambda} = \sqrt{\underline{\lambda}}$, and suppose the inequalities $0 < b' < b < b_0$.

LEMMA 6.3. *The inequality*

$$\|\,\psi(r, \cdot)\,\|_{H^1(\boldsymbol{R}^1)} \leq Be^{-b'r} \tag{6.17}$$

holds.

Proof. By (6.12) and (6.16) $d\psi(\lambda; r)$ is estimated as

$$\begin{aligned} &d\,\langle\, E(\lambda)\psi, \psi\,\rangle_\eta = d\|\psi(\lambda; r)\|_\eta^2 \\ &\leq B\left\{e^{-2\Lambda r} d\|\psi^0(\lambda; r)\|_\eta^2 + \frac{1}{\Lambda^2} e^{2\Lambda r}\left(\int_r^\infty e^{-\Lambda s} d\|g(\lambda; s)\|_\eta ds\right)^2\right. \\ &\qquad\left. + \frac{1}{\Lambda^2} e^{-2\Lambda r}\left(\int_0^r e^{\Lambda s} d\|g(\lambda; s)\|_\eta ds\right)^2\right\} \end{aligned}$$

$$
\begin{aligned}
&\le B\left\{e^{-2\Lambda r}\cdot\frac{1}{\Lambda^2}\int_0^\infty e^{-2\Lambda s}ds\int_0^\infty d\|g(\lambda;s)\|_\eta^2 ds\right.\\
&\qquad\qquad +\frac{1}{\Lambda^2}e^{2\Lambda r}\int_r^\infty e^{-2\Lambda s}ds\int_r^\infty d\|g(\lambda;s)\|_\eta^2 ds\\
&\qquad\qquad \left.+\frac{1}{\Lambda^2}e^{-2\Lambda r}\int_0^r e^{2(\Lambda-b')s}ds\int_0^r d\|\bar g(\lambda;s)\|_\eta^2 ds\right\}\\
&=\frac{B}{\Lambda^2}\left\{\frac{1}{2\Lambda}e^{-2\Lambda r}\int_0^\infty d\|g(\lambda;s)\|_\eta^2 dr+\frac{1}{2\Lambda}\int_r^\infty d\|g(\lambda;s)\|_\eta^2 ds\right.\\
&\qquad\qquad \left.+\frac{1}{2(\Lambda-b')}\left(e^{-2b'r}-e^{-2\Lambda r}\right)\int_0^r d\|\bar g(\lambda;s)\|_\eta^2 ds\right\}\\
&\le\frac{B}{\lambda}\left\{\frac{1}{2\underline{\Lambda}}e^{-2\underline{\Lambda}r}\int_0^\infty d\|g(\lambda;s)\|_\eta^2 ds+\frac{1}{2\underline{\Lambda}}\int_r^\infty d\|g(\lambda;s)\|_\eta^2 ds\right.\\
&\qquad\qquad \left.+\frac{1}{2(\underline{\Lambda}-b')}e^{-2b'r}\int_0^r d\|\bar g(\lambda;s)\|_\eta^2 ds\right\}
\end{aligned}
$$

for some B, where we used the relation $g^\psi(r)=e^{-b'r}\bar g(r)$. Thus, by (6.16), we have

$$
\begin{aligned}
&\langle -E\psi(r,\cdot),\psi(r,\cdot)\rangle_\eta\\
&=\int_{\underline{\lambda}}^\infty \lambda d\langle E(\lambda)\psi,\psi\rangle_\eta\\
&=\int_{\underline{\lambda}}^\infty \lambda d\|\psi(\lambda;r)\|_\eta^2\\
&\le B\left\{e^{-2\underline{\Lambda}r}\int_0^\infty\int_{\underline{\lambda}}^\infty d\|g(\lambda;s)\|_\eta^2 ds+\int_r^\infty\int_{\underline{\lambda}}^\infty d\|g(\lambda;s)\|_\eta^2 ds\right.\\
&\qquad\qquad \left.+e^{-2b'r}\int_0^r\int_{\underline{\lambda}}^\infty d\|\bar g(\lambda;s)\|_\eta^2 ds\right\}\\
&\le B\left(e^{-2\underline{\Lambda}r}\int_0^\infty\|g^\psi(s)\|_\eta^2 ds+\int_r^\infty\|g^\psi(s)\|_\eta^2 ds+e^{-2b'r}\int_0^r\|\bar g(s)\|_\eta^2 ds\right)\\
&\le B\left(e^{-2\underline{\Lambda}r}\int_0^\infty e^{-2b''s}ds+\int_r^\infty e^{-2b''s}ds+e^{-2b'r}\int_0^r e^{-2(b''-b')s}ds\right)\\
&\le B\left(e^{-2\underline{\Lambda}r}+e^{-2b''r}+e^{-2b'r}\right)\\
&\le Be^{-2b'r}.
\end{aligned}
$$

Since

$$\langle -E\psi(r,\cdot),\psi(r,\cdot)\rangle_\eta\ge\underline{\lambda}\,\|\,\psi(r,\cdot)\,\|_\eta^2,$$

the above inequality yields (6.17). □

It follows from Lemma 6.3 that

$$|\psi(r,\eta)|\le Be^{-b'r}.$$

Hence, by Lemma 6.2, we get

$$|\psi(r,\eta)|\le B\min\{e^{-b'r},e^{-\beta'|\eta|}\}$$

for some B. Thus the inequalities (6.3) and (6.8) imply that a solution $v(r,\eta) = \theta\varphi_\eta + \psi$ of (5.9) satisfies

$$|v(r,\eta)| \le B\min\{e^{-b'r}, e^{-\beta'|\eta|}\}. \tag{6.18}$$

By using the inequalities (6.18) and (6.8) again, we get

$$|v_{rr}(r,\eta)| \le Be^{-\beta'|\eta|} \tag{6.19}$$

by using (5.9).

On the other hand, equation (5.9) is rewritten as

$$v_{rr} + v_{\eta\eta} + f'(\varphi(r))v = h(r,\eta), \tag{6.20}$$

where

$$h(r,\eta) = f'(\varphi(r))v(r,\eta) - f'(\varphi(\eta))v(r,\eta) + g(r,\eta).$$

We can estimate h as

$$|h(r,\eta)| \le B\min\{e^{-b'r}, e^{-\beta'|\eta|}\} \tag{6.21}$$

by (6.18). Hence we can apply the same argument as above to (6.20) by exchanging the role of r and η. Consequently, we obtain

$$\begin{array}{rcl} |v(r,\eta)|_{C^{2,0}(r,\eta)} & \le & Be^{-b'''r}, \\ |v_{\eta\eta}(r,\eta)| & \le & Be^{-b'''r} \end{array} \tag{6.22}$$

for some $b''' \in (0,b')$.

Thus, we have

$$\begin{array}{rcl} |v(r,\eta)|_{C^{2,0}(r,\eta)} & \le & B\min\{e^{-b'''r}, e^{-\beta''|\eta|}\}, \\ |v(r,\eta)|_{C^{0,2}(r,\eta)} & \le & B\min\{e^{-b'''r}, e^{-\beta''|\eta|}\} \end{array} \tag{6.23}$$

for some $\beta'' \in (\frac{3}{4}\beta_0, \beta')$ by using (6.3), (6.8), (6.18) and (6.19), (6.22) and the same argument as (6.6). The rest of the proof is easily obtained by using the Poisson Kernel on the upper half-plane. □

AN EXTENSION OF MARCHIORO'S BOUND ON THE GROWTH OF A VORTEX PATCH TO FLOWS WITH L^p VORTICITY*

M. C. LOPES FILHO† AND H. J. NUSSENZVEIG LOPES†

Abstract. We observe that C. Marchioro's cubic-root bound in time on the growth of the diameter of a patch of vorticity [*Comm. Math. Phys*, 164 (1994), pp. 507–524] can be extended to incompressible two-dimensional Euler flows with compactly supported initial vorticity in L^p, $p > 2$, and with a distinguished sign.

Key words. L^p vorticity, two-dimensional incompressible flow, support of vorticity

AMS subject classifications. 35Q35, 76C05

PII. S0036141096310910

Let $\omega_0 \in L^p_c(\mathbb{R}^2)$, $p \geq 1$, be a compactly supported function. It was first shown by A. Majda (see [2] and references therein) that a weak solution to the two-dimensional inviscid, incompressible vorticity equation with ω_0 as initial data exists if $p > 4/3$. An extension of this result to all $p \geq 1$ is a consequence of the work of J.-M. Delort in [1], as was observed by S. Schochet in [4]. There are, however, very few results on weak solutions to two-dimensional Euler beyond existence.

The purpose of this note is to extend to a nonnegative initial vorticity ω_0 in L^p_c, $p > 2$, the $\mathcal{O}(t^{1/3})$ bound on the diameter of the support of $\omega(\cdot, t)$ obtained previously by C. Marchioro [3] for $\omega_0 \in L^\infty$. The exponent $p = 2$ is precisely the exponent for which velocity is no longer a priori bounded.

Our strategy is as follows. Fix $p > 2$ and $\omega_0 \in L^p_c$ a nonnegative, compactly supported function. Assume that $\operatorname{supp}(\omega_0) \subset\subset B_{R_0}$, the ball of radius R_0, centered at the origin. Let $\omega_0^\varepsilon \in C^\infty_c$ be a sequence of nonnegative functions, obtained by regularizing ω_0, so that $\operatorname{supp}(\omega_0^\varepsilon) \subset\subset B_{R_0}$. Let $\omega^\varepsilon = \omega^\varepsilon(x,t)$ be the sequence of smooth solutions of the two-dimensional vorticity equation, with initial data ω_0^ε. By the results proven in [1], [2], [4] there exists a subsequence of ω^ε converging weakly to a weak solution. Let $\omega = \omega(x,t)$ be a global weak solution obtained as the weak limit of such a subsequence. We will show that the support of ω^ε is contained in the disk of radius $r_t = (R_0^3 + b_1 t)^{1/3}$ for some positive constant b_1, independent of ε, thereby implying that the support of ω is contained in the same disk. Our result has the nature of an a priori estimate on any weak solution obtained by the process of regularization of initial data as described above. Hereafter we will omit the superscript ε.

Let $u = u(x,t)$ be the incompressible velocity field induced by the vorticity ω, given by $u = K * \omega$, the Biot–Savart law. We show below that, although the velocity field is only locally $W^{1,p}$, a simple estimate gives a global L^∞ bound. We will denote $p' = p/(p-1)$, the conjugate Lebesgue exponent, throughout.

LEMMA 1. *We have* $\|u\|_{L^\infty} \leq C_p \|\omega_0\|_{L^p} + (2\pi)^{-1} \int \omega_0$.

Proof. We estimate directly

$$|u(x,t)| \leq \int_{|x-y|\leq 1} (2\pi)^{-1} |x-y|^{-1} \omega(y,t)dy + \int_{|x-y|>1} (2\pi)^{-1} |x-y|^{-1} \omega(y,t)dy$$

$$\leq \|\omega(\cdot,t)\|_{L^p(B_1(x))} \, \| \, |y|^{-1} \, \|_{L^{p'}(B_1(0))} + (2\pi)^{-1} \int \omega_0.$$

Take $C_p = \| \, |y|^{-1} \, \|_{L^{p'}(B_1(0))} < \infty$, since $p > 2$. The estimate follows, since the L^p-norm of vorticity is conserved. □

Before we state and prove our theorem, some comments on Marchioro's proof of the L^∞ result are in order. The basic issue in the proof of Theorem 2.1 in [3] is to carefully estimate the radial velocity field at a point far from the center of motion. This is performed by decomposing velocity into the portions generated by neighboring vorticity, referred to as near-field velocity, and by vorticity remaining near the center of motion, the far-field velocity. The difficult part of this problem is to estimate the near-field.

The heart of Marchioro's argument is to obtain exponential decay of the mass of vorticity relevant for the near-field estimate; this is encoded in [3, eq. (2.64)]. Nevertheless, this estimate is still a far-field calculation, which means that it is insensitive to the unboundedness of vorticity. Finally, the near-field estimate is performed using the technique in [3, eq. (2.29)]. It is this final step that needs modification in order to extend Marchioro's result to unbounded vorticities. We will use Lemma 2 to estimate the near-field. As in [3], $m_t(r)$ denotes the mass of vorticity outside the disk of radius r at time t.

LEMMA 2. *Let $\beta \in (p'/2, 1)$. Then there exists a constant C such that*

$$\left| \int_{|y| \geq R} K(x-y)\, \omega(y,t) dy \right| \leq C (m_t(R))^{1-\beta} \|\omega_0\|_{L^p}^{\beta}.$$

Moreover, C depends only on β, p, and the Lebesgue measure of the support of the initial vorticity, $|supp\ (\omega_0)|$. In addition, $C = \mathcal{O}(1/(p-2))$ as p approaches 2.

Proof. Let B_R^c denote the set $\{|y| \geq R\}$. Write $\omega = \omega^{1-\beta}\omega^{\beta}$ and estimate directly

$$\left| \int_{B_R^c} K(x-y)\, \omega(y,t) dy \right| \leq (m_t(R))^{1-\beta} \left(\int_{B_R^c} |K(x-y)|^{1/\beta}\, \omega(y,t) dy \right)^{\beta}$$

$$\leq (m_t(R))^{1-\beta} \|\omega_0\|_{L^p}^{\beta} \left(\int_{\text{supp } (\omega(\cdot,t))} |K(x-y)|^{p'/\beta} dy \right)^{\beta/p'}.$$

Above, we have used Hölder's inequality twice and the conservation of the L^p-norm of vorticity.

The proof is concluded once we find an upper bound for

$$\left(\int_{\text{supp } (\omega(\cdot,t))} |K(x-y)|^{p'/\beta} dy \right)^{\beta/p'}. \tag{1}$$

The condition $p'/2 < \beta < 1$ is used to guarantee that (1) is finite.

By incompressibility, $|\text{supp } (\omega(\cdot,t))|$ is constant and equal to $|\text{supp } (\omega_0)|$. We adapt the idea in [3, eqs. (2.29),(2.30)] to obtain

$$(1) \leq \left(\frac{1}{2\pi} \int_{B_\eta} \left(\frac{1}{|z|} \right)^{p'/\beta} dz \right)^{\beta/p'}.$$

The radius η is chosen so that $\pi\eta^2 = |\text{supp }(\omega_0)|$. Denote $q = 2\beta(p-1) - p$.

Hence, (1) is bounded above by

$$\eta^{q/p}\left(\frac{\beta(p-1)}{q}\right)^{\beta/p'} \equiv C(\beta, p, |\text{supp }(\omega_0)|),$$

and, clearly, this constant C is $\mathcal{O}(1/(p-2))$ as $p \to 2$, as we wanted. □

THEOREM 3. *There exists a constant $b_1 = b_1(p, R_0, \|\omega_0\|_{L^p}) > 0$ such that the diameter of the support of $\omega(\cdot, t)$ is at most $2(R_0^3 + b_1 t)^{1/3}$ for $t \geq 0$.*

Proof. In this proof we will mention only those portions of the proof of Theorem 2.1 in [3] which need to be changed.

We begin by using Lemma 1 to ensure the existence of $t^* > 0$ so that the support of vorticity is contained in the disk of radius $r_t = (R_0^3 + b_1 t)^{1/3}$, for $0 \leq t \leq t^*$, for some positive b_1.

All subsequent arguments and estimates in Marchioro's proof are far-field estimates up to [3, eq. (2.64)] and can be adapted to the L^p case in a straightforward manner: simply substitute $K(x-y)$ by $K(x-y)\omega(y,t)$ whenever it appears.

Marchioro's argument consists of estimating the radial velocity at a point x, with $|x| = r_t$. This is done by decomposing the disk of radius r_t into a union of annuli: $\{a_{k-1} \leq |y| < a_k\}$, $1 \leq k \leq k^*$, and $\{a_{k^*} \leq |y| < r_t\}$. Here, $a_0 = 0$, $a_1 = R_0$, $a_k = 2a_{k-1}$, and k^* is chosen so that $a_{k^*+1} \leq r_t < a_{k^*+2}$. We restrict our attention to the near-field velocity, generated by vorticity outside the disk of radius a_{k^*}. Recall that $n = 2^{k^*-1} - 1$ and fix $\beta \in (p'/2, 1)$.

Substitute estimate [3, eq. (2.65)] by the following:

$$m_t(a_{k^*}) < C^n b_1^{-n} < \bar{C} n^{-2M}, \tag{2}$$

where $M = (1-\beta)^{-1}$. This is possible by choosing b_1 sufficiently large. Observe that b_1 blows up exponentially as $p \to 2$. Thus,

$$m_t(a_{k^*}) \leq C a_{k^*}^{-2M} \leq C r_t^{-2M}. \tag{3}$$

Finally, consider estimate [3, eq. (2.66)]. This is Marchioro's near-field estimate, which we substitute by Lemma 2, at $R = a_{k^*}$:

$$\left|\int_{|y|\geq a_{k^*}} K(x-y)\,\omega(y,t)dy\right| \leq C(m_t(a_{k^*}))^{1-\beta}\|\omega_0\|_{L^p}^{\beta} \leq \tilde{C} r_t^{-2M(1-\beta)} = \tilde{C} r_t^{-2}.$$

This concludes the proof. □

This result raises the question of what happens with more singular vorticity, such as L^p-vorticity, $1 \leq p \leq 2$ or even vortex sheets, keeping the distinguished sign restriction. Since velocity is no longer bounded, it could happen that the support of vorticity escapes to infinity instantly. This will be the object of forthcoming work.

Acknowledgments. The authors are grateful to S. Schochet for helpful comments. The authors also thank the referee for pointing out a substantial simplification of our original argument.

NONLINEAR INSTABILITY OF A PRECESSING BODY WITH A CAVITY FILLED BY AN IDEAL FLUID*

ANDREI A. LYASHENKO† AND SUSAN J. FRIEDLANDER‡

Abstract. A sufficient condition is derived for the nonlinear instability of a rotating body with a fluid-filled cavity. This condition is given in terms of quantities completely determined by the shape of the body/cavity and the relative density of the fluid and the body. It is shown, for example, that such a system with a prolate ellipsoidal cavity of appropriate ellipticity is nonlinearly unstable.

Key words. nonlinear instability, precession, rotating ideal fluids

Introduction. We consider the stability of a rigid body with a cavity completely filled with an inviscid, incompressible fluid. The entire system initially rotates with constant angular velocity about an axis through its center of mass. The angular velocity of the rigid body is free to vary with time (i.e., the body may precess) and the fluid moves under the constraints of incompressibility and is subject to the condition that there are no velocity components normal to the boundary of the cavity. Such a system gives a model for an astronomical body with a rigid crust surrounding a liquid core, and there is a long history of examining the mathematics of such fluid-body systems (eg., [6, 5, 12]). More recent studies have been inspired by the question of stability of projectiles with fuel-filled cavities and the mathematical theory of rotating fluids (eg., [14, 15, 4]). In this present paper we give a sufficient condition for nonlinear instability of such a fluid-body system.

Recently Friedlander, Strauss, and Vishik [3] proved the following theorem for rather general nonlinear evolution partial differential equations (PDEs). It is shown that, under appropriate conditions, instability of the linearized operator implies nonlinear instability. The crucial idea underlying this theorem is to use two Banach spaces: a large space Z where the spectrum of the linearized operator is studied and a "small" space $X \hookrightarrow Z$ where a local existence theorem for the nonlinear equation can be proved. The method of proof of this theorem utilizes a projection onto the subspaces of growing and decaying modes. Such a decomposition requires the existence of a suitable "gap" in the spectrum of the linearized operator. This spectral gap condition may be hard to verify for a PDE where the unstable spectrum of the linearized operator has both continuous and discrete parts (eg., the Euler equations for an ideal fluid perturbed about an arbitrary steady state). However, any problem for which the unstable spectrum is nonempty and purely discrete automatically satisfies the spectral gap condition.

For the equations governing the motion of a precessing body with a fluid-filled cavity Ω, we verify the conditions of the nonlinear instability theorem of [3]. We prove

a local existence theorem with the functional space X being $X_s \times \mathbb{R}^3$, where X_s is the space of divergence-free vectors, tangential to the boundary of Ω with components in the Sobolev space H^s, $s > 5/2$. We note that the "infinite dimensional" contribution to the nonlinearity comes from the nonlinearity in the fluid equation and the method of proof of local existence follows the lines of well-known proofs of local existence for the Euler equation (see, for example, [16]). We consider the spectrum in a space Z of the operator obtained from the equations linearized about a state of uniform rotation. The space Z is taken to be $J_0(\Omega) \times \mathbb{R}^3$, where $J_0(\Omega)$ is the space of divergence-free square integrable vectors tangential to the boundary of Ω. We study the unstable spectrum under the simplifying assumption that the body and the cavity have 4-fold symmetry about the axis of rotation (see [14, 10]). We obtain an explicit formula for the unstable eigenvalues of the linearized operator in terms of the zeros of an analytic function. It follows from this formula that

(1) all the unstable eigenvalues are discrete and for any $\epsilon > 0$ there exist at most a finite number of spectral points λ satisfying $|\mathrm{Re}\lambda| \geq \epsilon$;
(2) we have a necessary and sufficient condition for linear instability and a bound on $|\lambda|$ explicitly given in terms of the geometry of the configuration and the relative densities of the liquid and the body.

Since the unstable spectrum is purely discrete, it is straightforward to apply the nonlinear instability theorem. Hence we obtain the result that any fluid-body configuration for which the sufficient condition for linear instability holds is nonlinearly unstable in X. To our knowledge this is the first nonlinear instability result for this system.

We note that the property of discreteness of the unstable spectrum follows from the nature of the linearized operator and is valid independent of any geometrical symmetry constraints. Hence the nonlinear instability theorem of [3] can be invoked to show that any configuration that is linearly unstable is also nonlinearly unstable. The constraint of 4-fold symmetry is used to obtain the explicit formulas for the unstable eigenvalues. As a particular example, in the final section we use these formulas to compute necessary and sufficient conditions for linear instability for the case of an ellipsoidal cavity. We show, for example, that a spinning body with a prolate ellipsoidal cavity of appropriate ellipticity is nonlinearly unstable.

1. Equations of motion. We consider a rigid body G with a cavity Ω entirely filled with a homogeneous incompressible inviscid fluid. It is assumed that the boundary $\partial\Omega$ is smooth and that G and Ω satisfy a condition of 4-fold symmetry (following [14], a domain is said to satisfy a condition of k-fold symmetry if it is symmetric with respect to turning through an angle of $2\pi/k$ about the axis of symmetry). Let O be the center of mass of the entire "body+fluid" system and let Ox_1, x_2, x_3 be an orthogonal system rigidly connected with the body (Ox_3 is the axis of 4-fold symmetry). With respect to the center of mass O, the motion of the system is completely described by seven scalar functions: the fluid velocity,

$$\mathbf{u}(\mathbf{r}, t) = (u_1(\mathbf{r}, t), u_2(\mathbf{r}, t), u_3(\mathbf{r}, t)), \quad \mathbf{r} \in \Omega,\ t \geq 0,$$

the fluid "pressure" term,

$$p(\mathbf{r}, t), \quad \mathbf{r} \in \Omega,\ t \geq 0,$$

and the angular velocity of the body,

$$\mathbf{W}(t) = (W_1(t), W_2(t), W_3(t)), \quad t \geq 0.$$

The position vector $\mathbf{r}$ of a fluid particle in Ω has components (x_1, x_2, x_3). By the "pressure" we consider the scalar potential for the conservative forces acting on the fluid.

The motion is governed by the coupled system of equations: the Euler equations for the motion of the fluid in Ω and the equations for conservation of angular momentum of the entire "body+fluid" system. Following [7, 10], the equations of motion are written in the form

$$\frac{\partial \mathbf{u}}{\partial t} + (\mathbf{u}\cdot\nabla)\mathbf{u} + 2\mathbf{W}\times\mathbf{u} + \frac{d\mathbf{W}}{dt}\times\mathbf{r} = -\nabla p, \tag{1.1}$$

$$\frac{d}{dt}\left(J\mathbf{W} + \int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega\right) + \mathbf{W}\times\left(J\mathbf{W} + \int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega\right) = 0, \tag{1.2}$$

$$\nabla\cdot\mathbf{u} = 0, \tag{1.3}$$

$$\mathbf{u}\cdot\mathbf{n}|_{\partial\Omega} = 0, \tag{1.4}$$

where

$$\begin{cases} J = \mathrm{Diag}(a, a, b), \\ a = \displaystyle\int_\Omega (x_1^2 + x_3^2)\,d\Omega + \mu\int_G (x_1^2 + x_3^2)\,dG \\ b = 2\displaystyle\int_\Omega x_1^2\,d\Omega + 2\mu\int_G x_1^2\,dG, \end{cases} \tag{1.5}$$

and μ is the ratio of the body density to the fluid density.

The solenoidality condition of (1.3) can be replaced by writing (1.1) in operator form:

$$\frac{\partial \mathbf{u}}{\partial t} + B(\mathbf{u},\mathbf{u}) + 2P_0(\mathbf{W}\times\mathbf{u}) + P_0\left(\frac{d\mathbf{W}}{dt}\times\mathbf{r}\right) = 0, \tag{1.6}$$

where $P_0 : L^2(\Omega) \to L^2(\Omega)$ is the Weyl orthogonal projection onto the subspace $J_0(\Omega)$ of solenoidal vectors satisfying $\mathbf{u}\cdot\mathbf{n}|_{\partial\Omega} = 0$ and $B(\mathbf{u},\mathbf{v}) = P_0(\mathbf{u}\cdot\nabla)\mathbf{v}$.

We consider perturbations of the steady state of rigid body rotation about the axis Ox_3 with angular velocity $\omega_0 > 0$:

$$\mathbf{u}_0 = \mathbf{0}, \quad \mathbf{W}_0 = \omega_0\mathbf{e}_3; \quad \mathbf{W} = \mathbf{w} + \omega_0\mathbf{e}_3,$$

where $\mathbf{e}_3 = (0, 0, 1)$. The system (1.2), (1.6) is then written as follows:

$$\frac{\partial}{\partial t}\big(\mathbf{u} + P_0(\mathbf{w}\times\mathbf{r})\big) + 2i\omega_0 T\mathbf{u} + B(\mathbf{u},\mathbf{u}) + 2P_0(\mathbf{w}\times\mathbf{u}) = 0, \tag{1.7}$$

$$\begin{aligned} &\frac{d}{dt}\left(J\mathbf{w} + \int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega\right) + \omega_0\mathbf{e}_3\times J\mathbf{w} + \omega_0 b\mathbf{w}\times\mathbf{e}_3 + \omega_0\mathbf{e}_3\times\int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega \\ &\qquad + \mathbf{w}\times J\mathbf{w} + \mathbf{w}\times\int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega = 0, \end{aligned} \tag{1.8}$$

where $T\mathbf{u} = iP_0(\mathbf{u} \times \mathbf{e}_3)$ is a self-adjoint operator with spectrum $\sigma(T) = [-1, 1]$. Equations (1.7), (1.8) can be written in the form

$$\frac{\partial}{\partial t} K\mathbf{V} + \omega_0 L\mathbf{V} + N(\mathbf{V}) = 0, \tag{1.9}$$

where $\mathbf{V} = \binom{\mathbf{u}}{\mathbf{w}}$,

$$K\mathbf{V} = \begin{pmatrix} \mathbf{u} + P_0(\mathbf{w} \times \mathbf{r}) \\ J\mathbf{w} + \displaystyle\int_\Omega \mathbf{r} \times \mathbf{u}\, d\Omega \end{pmatrix}, \tag{1.10}$$

$$L\mathbf{V} = \begin{pmatrix} 2iT\mathbf{u} \\ \mathbf{e}_3 \times J\mathbf{w} + b\mathbf{w} \times \mathbf{e}_3 + \mathbf{e}_3 \times \displaystyle\int_\Omega \mathbf{r} \times \mathbf{u}\, d\Omega \end{pmatrix}, \tag{1.11}$$

$$N(\mathbf{V}) = \begin{pmatrix} B(\mathbf{u}, \mathbf{u}) + 2P_0(\mathbf{w} \times \mathbf{u}) \\ \mathbf{w} \times J\mathbf{w} + \mathbf{w} \times \displaystyle\int_\Omega \mathbf{r} \times \mathbf{u}\, d\Omega \end{pmatrix}. \tag{1.12}$$

In the Hilbert space $Z = J_0(\Omega) \times \mathbb{R}^3$ with the inner product

$$(\mathbf{V}_1, \mathbf{V}_2)_Z = \int_\Omega \mathbf{u}_1 \cdot \mathbf{u}_2\, d\Omega + \mathbf{w}_1 \cdot \mathbf{w}_2, \tag{1.13}$$

the operator K is self-adjoint and satisfies

$$c_1 \|\mathbf{V}\|_Z^2 \le (K\mathbf{V}, \mathbf{V})_Z \le c_2 \|\mathbf{V}\|_Z^2 \tag{1.14}$$

for some positive constants $c_1, c_2 > 0$ (see [7]). Hence the operator K is bounded and K^{-1} exists. Therefore (1.9) can be written in the form

$$\frac{\partial}{\partial t}\mathbf{V} + \omega_0 K^{-1} L\mathbf{V} + K^{-1} N(\mathbf{V}) = 0. \tag{1.15}$$

We will prove that, under appropriate conditions on Ω and μ, the steady state $\mathbf{V}_0 = \mathbf{0}$ (i.e., rigid body rotation $\mathbf{u}_0 = 0$, $\mathbf{W}_0 = \omega_0 \mathbf{e}_3$) is nonlinearly unstable.

2. General nonlinear instability theorem. Let us fix a pair of Banach spaces $X \hookrightarrow Z$ with a dense embedding. Consider a nonlinear evolution equation of the form

$$\frac{d}{dt}\mathbf{v} = L\mathbf{v} + N(\mathbf{v}), \quad \mathbf{v}(0) = \mathbf{v}_0, \tag{2.1}$$

where L is the generator of a C_0-group of operators $\mathcal{L}(Z)$, e^{Lt} leaves X invariant for $t \in \mathbb{R}$, $X \subset D(L)$, and N is a nonlinear operator

$$N : X \to Z. \tag{2.2}$$

We assume that the nonlinear term N satisfies the inequality

$$\begin{aligned} &\|N(\mathbf{v})\|_Z \le c_0 \|\mathbf{v}\|_X \|\mathbf{v}\|_Z \quad \text{for } \mathbf{v} \in X \text{ with} \\ &\|\mathbf{v}\|_X < \rho \text{ for some } \rho > 0. \end{aligned} \tag{2.3}$$

We assume that a local existence theorem holds for the nonlinear equation (2.1). This means that for any $\mathbf{v}_0 \in X$ there exists $T > 0$ and a unique

$$\mathbf{v}(t) \in L^\infty((0,T);X) \cap C([0,T];Z), \tag{2.4}$$

which is a solution to (2.1) in the following sense: for any $\phi \in D(0,T)$

$$\int_0^T \{\mathbf{v}(\tau)\phi'(\tau) + [L\mathbf{v}(\tau) + N(\mathbf{v}(\tau))]\phi(\tau)\}\, d\tau = 0. \tag{2.5}$$

The initial condition is assumed in the sense of strong convergence in Z:

$$\lim_{t\to 0^+} \|\mathbf{v}(t) - \mathbf{v}_0\|_Z = 0.$$

We consider the following definition of nonlinear stability/instability. The trivial solution $\mathbf{v}_0 = 0$ of equation (1.1) is called nonlinearly stable in X (i.e., Lyapunov stable) if no matter how small $\epsilon > 0$ is, there exists a $\delta > 0$ such that $\|\mathbf{v}(0)\|_X < \delta$ implies

(a) we can choose $T = \infty$ in (2.4) and

(b) $\|\mathbf{v}(t)\|_X < \epsilon$ for a.e. $t \in [0,\infty)$.

The trivial solution $\mathbf{v}_0 = 0$ is called nonlinearly unstable if it is not nonlinearly stable.

Remark. By this definition we regard a "blowing up" solution (i.e., there exists a maximal finite $T > 0$ in (2.4)) as a particular case of nonlinear instability.

The following theorem is proved by Friedlander, Strauss, and Vishik [3].

THEOREM 2.1. *Let the nonlinear equation* (2.1) *admit a local existence theorem as described above with N satisfying* (2.3). *Let the spectrum σ of $e^{Lt} \in \mathcal{L}(Z)$ be of the following structure:*

$$\sigma = \sigma(e^{Lt}) = \sigma_+ \cup \sigma_-, \quad \sigma_+ \neq \emptyset,$$

where

$$\sigma_+ \subset \{z \in \mathbb{C} \mid e^{Mt} < |z| < e^{\Lambda t}\},$$
$$\sigma_- \subset \{z \in \mathbb{C} \mid e^{\lambda t} < |z| < e^{\mu t}\}$$

with $-\infty < \lambda < \mu < M < \Lambda < \infty$ and $M > 0$. Then the trivial solution $\mathbf{v}_0 = 0$ to equation (2.1) *is nonlinearly unstable in X.*

We remark that any operator L for which the unstable spectrum is nonempty and purely discrete automatically satisfies the "spectral gap" condition stated above which is utilized in the proof of Theorem 2.1.

We will apply Theorem 2.1 to the nonlinear equation for the coupled fluid-body system given by (1.15). We choose the following spaces for X and Z:

$$X = X_s \times \mathbb{R}^3, \text{ where } X_s = \{\mathbf{u} \in (H^s(\Omega))^3 \mid \operatorname{div}\mathbf{u} = 0 \text{ in } \Omega;\ \mathbf{u}\cdot\mathbf{n}|_{\partial\Omega} = 0\},$$
$$Z = J_0(\Omega) \times \mathbb{R}^3, \text{ where } J_0(\Omega) = \{\mathbf{u} \in (L^2(\Omega))^3 \mid \operatorname{div}\mathbf{u} = 0 \text{ in } \Omega;\ \mathbf{u}\cdot\mathbf{n}|_{\partial\Omega} = 0\}.$$

In section 3 we will show that the nonlinear equation (1.15) admits a local existence theorem in X and that the operator $(K^{-1}N)$ given by (1.10), (1.12) satisfies the inequality (2.3). In section 4 we study the spectrum of the linear operator $(K^{-1}L)$ given by (1.10), (1.11). We prove that the unstable spectrum is purely discrete and we obtain a necessary and sufficient condition for the existence of an unstable eigenvalue. It therefore follows from Theorem 2.1 that geometries for which this condition holds are nonlinearly unstable.

3. General conditions. Let s be an integer with $s > 5/2$ and consider the pair of Hilbert spaces

$$Z = J_0(\Omega) \times \mathbb{R}^3, \quad (\mathbf{V}_1, \mathbf{V}_2)_Z = (\mathbf{u}_1, \mathbf{u}_2)_{\mathbf{L}^2} + \mathbf{w}_1 \cdot \mathbf{w}_2,$$
$$X = X_s \times \mathbb{R}^3, \quad (\mathbf{V}_1, \mathbf{V}_2)_X = (\mathbf{u}_1, \mathbf{u}_2)_{\mathbf{H}^s} + \mathbf{w}_1 \cdot \mathbf{w}_2,$$

where from now on we use the notations $\mathbf{L}^2 = (L^2(\Omega))^3$ and $\mathbf{H}^s = (H^s(\Omega))^3$.

PROPOSITION 3.1. *The operator $K^{-1}N$ given by* (1.10) *and* (1.12) *satisfies*

$$\|K^{-1}N(\mathbf{V})\|_Z \le \text{const}\, \|\mathbf{V}\|_X \|\mathbf{V}\|_Z \qquad \textit{for all } \mathbf{V} \in X.$$

Proof. Because of (1.10), (1.12), and (1.14),

$$\|K^{-1}N(\mathbf{V})\|_Z^2 \le \text{const}\, \|N(\mathbf{V})\|_Z^2$$
$$= \text{const} \left(\|P_0(\mathbf{u} \cdot \nabla)\mathbf{u} + 2P_0(\mathbf{w} \times \mathbf{u})\|_{\mathbf{L}^2}^2 + \left| \mathbf{w} \times J\mathbf{w} + \mathbf{w} \times \int_\Omega \mathbf{r} \times \mathbf{u}\, d\Omega \right|^2 \right)$$
$$\le \text{const} \left(\|(\mathbf{u} \cdot \nabla)\mathbf{u}\|_{\mathbf{L}^2}^2 + \|\mathbf{V}\|_Z^4 \right) \le \text{const}\, \|\mathbf{V}\|_X^2 \|\mathbf{V}\|_Z^2$$

due to the Sobolev embedding theorem ($s > 1 + 3/2$). ∎

In the proof of the following local existence theorem we follow the lines of Temam (see [16]).

THEOREM 3.1. *For any $\mathbf{V}_0 \in X$ there exist $T > 0$ and unique $\mathbf{V}(t) \in L^\infty((0,T); X) \cap C([0,T]; Z)$ satisfying* (1.15) *and $V(0) = V_0$.*

Proof. It suffices to prove this local existence result for the original problem (1.1)–(1.4). Following Temam [16] we first derive a priori estimates. Assume that $\mathbf{u}$, p, and $\mathbf{W}$ are sufficiently regular real-valued solutions to (1.1)–(1.4). Taking the $\mathbf{L}^2$-scalar product of (1.1) with $\mathbf{u}$ and adding it to the $\mathbb{R}^3$-scalar product of (1.2) with $\mathbf{W}$ we obtain

$$\frac{d}{dt} \left(\frac{1}{2} \|\mathbf{u}(t)\|_{\mathbf{L}^2}^2 + \frac{1}{2} J\mathbf{W}(t) \times \mathbf{W}(t) + \left(\int_\Omega \mathbf{r} \times \mathbf{u}(t)\, d\Omega \right) \cdot \mathbf{W}(t) \right) = 0. \tag{3.1}$$

It is easy to see that

$$\|\mathbf{u}\|_{\mathbf{L}^2}^2 + J\mathbf{W} \times \mathbf{W} + 2 \left(\int_\Omega \mathbf{r} \times \mathbf{u}\, d\Omega \right) \cdot \mathbf{W} = (K\mathbf{V}, \mathbf{V})_Z, \quad \mathbf{V} = \begin{pmatrix} \mathbf{u} \\ \mathbf{W} \end{pmatrix} \in Z. \tag{3.2}$$

Thus (3.1) and (3.2) imply

$$\frac{d}{dt} (K\mathbf{V}(t), \mathbf{V}(t))_Z = 0. \tag{3.3}$$

It follows from (1.14) and (3.3) that

$$\|\mathbf{V}(t)\|_Z^2 \le \frac{1}{c_1} (K\mathbf{V}(t), \mathbf{V}(t))_Z = \frac{1}{c_1} (K\mathbf{V}_0, \mathbf{V}_0)_Z \le \frac{c_2}{c_1} \|\mathbf{V}_0\|_Z^2. \tag{3.4}$$

We apply $D^\alpha_{\mathbf{r}}$ to (1.1), take the $\mathbf{L}^2$-scalar product with $D^\alpha_{\mathbf{r}}\mathbf{u}$, and sum for $|\alpha| = \alpha_1 + \alpha_2 + \alpha_3 = s$. Since s is an integer satisfying $s > 5/2$, we obtain

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|\mathbf{u}(t)\|_s^2 &= -[\nabla p, \mathbf{u}]_s - \sum_{|\alpha|=s} \left(D^\alpha_{\mathbf{r}}((\mathbf{u}\cdot\nabla)\mathbf{u}), D^\alpha_{\mathbf{r}}\mathbf{u}\right)_{\mathbf{L}^2} \\ &= -[\nabla p, \mathbf{u}]_s - \sum_{|\alpha|=s} \left(D^\alpha_{\mathbf{r}}((\mathbf{u}\cdot\nabla)\mathbf{u}) - (\mathbf{u}\cdot\nabla)D^\alpha_{\mathbf{r}}\mathbf{u}, D^\alpha_{\mathbf{r}}\mathbf{u}\right)_{\mathbf{L}^2},\end{aligned}$$

where

$$\|\mathbf{u}\|_s^2 = \sum_{|\alpha|=s} \|D^\alpha_{\mathbf{r}}\mathbf{u}\|^2_{\mathbf{L}^2}, \quad [\mathbf{u},\mathbf{v}]_s = \sum_{|\alpha|=s} (D^\alpha_{\mathbf{r}}\mathbf{u}, D^\alpha_{\mathbf{r}}\mathbf{v})_{\mathbf{L}^2}.$$

Therefore, by (1.14) of [16],

$$\frac{1}{2}\frac{d}{dt}\|\mathbf{u}(t)\|_s^2 \le \|\nabla p(t)\|_{\mathbf{H}^s}\|\mathbf{u}(t)\|_s + \text{const}\,\|\mathbf{u}(t)\|_s^3. \tag{3.5}$$

In order to estimate $\|\nabla p(t)\|_{\mathbf{H}^s}$ we use (1.1). Applying div to (1.1), we obtain

$$\Delta p = -\sum_{i,j=1}^3 D_{x_i}u_j D_{x_j}u_i + 2(\nabla\times\mathbf{u})\cdot\mathbf{W}.$$

Taking the $\mathbb{R}^3$-inner product of the trace of (1.1) with the normal vector $\mathbf{n}$ we obtain

$$\begin{aligned}\frac{\partial p}{\partial \mathbf{n}} &= -2\mathbf{W}\cdot(\mathbf{u}\times\mathbf{n}) - \frac{d\mathbf{W}}{dt}\cdot(\mathbf{r}\times\mathbf{n}) - ((\mathbf{u}\cdot\nabla)\mathbf{u})\cdot\mathbf{n} \\ &= -2\mathbf{W}\cdot(\mathbf{u}\times\mathbf{n}) - \frac{d\mathbf{W}}{dt}\cdot(\mathbf{r}\times\mathbf{n}) + \sum_{i,j=1}^3 u_i u_j \frac{D_{x_i x_j}\phi}{|\nabla\phi|},\end{aligned}$$

where locally $\partial\Omega = \{\phi(x_1,x_2,x_3) = 0\}$. By the results of Agmon, Douglis, and Nirenberg [1],

$$\begin{aligned}&\|\nabla p\|_{\mathbf{H}^s} \le \|p\|_{H^{s+1}(\Omega)} \le \text{const}\left(\|\Delta p\|_{H^{s-1}(\Omega)} + \left\|\frac{\partial p}{\partial\mathbf{n}}\right\|_{H^{s-1/2}(\partial\Omega)}\right) \\ &\le \text{const}\left[\sum_{i,j=1}^3 \left(\|D_{x_i}u_jD_{x_j}u_i\|_{H^{s-1}} + \|u_ju_i\|_{H^s}\right) + |\mathbf{W}|\,\|\mathbf{u}\|_{\mathbf{H}^s} + \left|\frac{d\mathbf{W}}{dt}\right|\right] \\ &\le \text{(by (1.13) of [16])} \\ &\le \text{const}\left(\|\mathbf{u}\|^2_{\mathbf{H}^s} + |\mathbf{W}|^2 + \left|\frac{d\mathbf{W}}{dt}\right|\right).\end{aligned}$$

Therefore

$$\|\nabla p(t)\|_{\mathbf{H}^s} \le \text{const}\left(\|\mathbf{V}(t)\|_X^2 + \left|\frac{d\mathbf{W}}{dt}(t)\right|\right). \tag{3.6}$$

Denote

$$\mathbf{a}_j = P_0(\mathbf{e}_j\times\mathbf{r}), \quad j = 1,2,3.$$

It is shown in Lyashenko [11] that

$$\begin{cases} (\mathbf{a}_j, \mathbf{a}_i)_{\mathbf{L}^2} = 0, \quad i \neq j; \quad \|\mathbf{a}_1\|_{\mathbf{L}^2} = \|\mathbf{a}_2\|_{\mathbf{L}^2}, \\ \displaystyle\int_\Omega \mathbf{r} \times \mathbf{u}\, d\Omega = \big((\mathbf{u}, \mathbf{a}_1)_{\mathbf{L}^2}, (\mathbf{u}, \mathbf{a}_2)_{\mathbf{L}^2}, (\mathbf{u}, \mathbf{a}_3)_{\mathbf{L}^2}\big), \quad \mathbf{u} \in J_0(\Omega). \end{cases} \tag{3.7}$$

We have

$$\|\mathbf{a}_1\|^2_{\mathbf{L}^2} = \|\mathbf{a}_2\|^2_{\mathbf{L}^2} \le \|\mathbf{e}_1 \times \mathbf{r}\|^2_{\mathbf{L}^2} = \int_\Omega x_1^2 + x_3^2\, d\Omega < \int_\Omega x_1^2 + x_3^2\, d\Omega + \mu \int_G x_1^2 + x_3^2\, dG = a,$$

$$\|\mathbf{a}_3\|^2_{\mathbf{L}^2} \le \|\mathbf{e}_3 \times \mathbf{r}\|^2_{\mathbf{L}^2} = 2\int_\Omega x_1^2\, d\Omega < 2\int_\Omega x_1^2\, d\Omega + 2\mu \int_G x_1^2\, dG = b.$$

Therefore

$$\|\mathbf{a}_1\|^2_{\mathbf{L}^2} = \|\mathbf{a}_2\|^2_{\mathbf{L}^2} < a, \quad \|\mathbf{a}_3\|^2_{\mathbf{L}^2} < b. \tag{3.8}$$

Denote

$$\mathbf{U}(t) = (U_1(t), U_2(t), U_3(t)) = \big((\mathbf{u}(t), \mathbf{a}_1)_{\mathbf{L}^2}, (\mathbf{u}(t), \mathbf{a}_2)_{\mathbf{L}^2}, (\mathbf{u}(t), \mathbf{a}_3)_{\mathbf{L}^2}\big).$$

Because of (1.5) and (3.7), equation (1.2) can be written as follows:

$$\begin{cases} \dfrac{d}{dt}(aW_1 + U_1) + (b-a)W_3W_2 + W_2U_3 - W_3U_2 = 0, \\ \dfrac{d}{dt}(aW_2 + U_2) - (b-a)W_3W_1 + W_3U_1 - W_1U_3 = 0, \\ \dfrac{d}{dt}(bW_3 + U_3) + W_1U_2 - W_2U_1 = 0. \end{cases} \tag{3.9}$$

Taking the $\mathbf{L}^2$-inner product of (1.1) with $\mathbf{a}_j$, $j = 1, 2, 3$ and using

$$\left(\frac{d\mathbf{W}}{dt} \times \mathbf{r}, \mathbf{a}_j\right)_{\mathbf{L}^2} = \sum_{k=1}^3 \frac{dW_k}{dt}(\mathbf{e}_k \times \mathbf{r}, \mathbf{a}_j)_{\mathbf{L}^2} = \sum_{k=1}^3 \frac{dW_k}{dt}(\mathbf{a}_k, \mathbf{a}_j)_{\mathbf{L}^2} = \frac{dW_j}{dt}\|\mathbf{a}_j\|^2_{\mathbf{L}^2},$$

we obtain

$$\frac{d}{dt}\big(\|\mathbf{a}_j\|^2_{\mathbf{L}^2} W_j + U_j\big) = (\mathbf{u}, (\mathbf{u} \cdot \nabla)\mathbf{a}_j)_{\mathbf{L}^2} - 2(\mathbf{W} \times \mathbf{u}, \mathbf{a}_j)_{\mathbf{L}^2}, \quad j = 1, 2, 3. \tag{3.10}$$

Because of (3.8), equations (3.9) and (3.10) imply

$$\left|\frac{d\mathbf{W}}{dt}(t)\right| \le \text{const}\,(\|\mathbf{u}(t)\|^2_{\mathbf{L}^2} + |\mathbf{W}(t)|^2) = \text{const}\,\|\mathbf{V}(t)\|^2_Z. \tag{3.11}$$

Estimates (3.5), (3.6), and (3.11) yield

$$\frac{d}{dt}\|\mathbf{u}(t)\|_s \le \text{const}\,\|\mathbf{V}(t)\|^2_X. \tag{3.12}$$

Taking the $\mathbf{L}^2$-inner product of (1.1) with $\mathbf{u}$ we obtain

$$\frac{1}{2}\frac{d}{dt}\|\mathbf{u}(t)\|^2_{\mathbf{L}^2} = -\left(\frac{d\mathbf{W}}{dt}(t) \times \mathbf{r}, \mathbf{u}(t)\right)_{\mathbf{L}^2},$$

which implies

$$\frac{d}{dt}\|\mathbf{u}(t)\|_{\mathbf{L}^2} \le \text{const}\,\|\mathbf{V}(t)\|_Z^2. \tag{3.13}$$

Thus estimates (3.11)–(3.13) yield

$$\frac{d}{dt}\|\mathbf{V}(t)\|_X \le \text{const}\,\|\mathbf{V}(t)\|_X^2, \tag{3.14}$$

where the constant does not depend on t.

Following Temam [16], we consider the following singular perturbation to the system (1.1)–(1.4):

$$\frac{\partial \mathbf{u}}{\partial t} + \epsilon[(-\Delta)^s\mathbf{u} + \mathbf{u}] + (\mathbf{u}\cdot\nabla)\mathbf{u} + 2\mathbf{W}\times\mathbf{u} + \frac{d\mathbf{W}}{dt}\times\mathbf{r} = -\nabla p, \tag{3.15}$$

$$\frac{d}{dt}\left(J\mathbf{W} + \int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega\right) + \mathbf{W}\times\left(J\mathbf{W} + \int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega\right) = 0, \tag{3.16}$$

$$\nabla\cdot\mathbf{u} = 0, \tag{3.17}$$

$$\mathbf{u}\cdot\mathbf{n}|_{\partial\Omega} = 0, \tag{3.18}$$

$$\Delta^j\mathbf{u}|_{\partial\Omega} = 0, \quad \frac{s}{2} \le j \le s-1, \quad s \text{ even}; \quad \frac{s+1}{2} \le j \le s-1, \quad s \text{ odd}, \tag{3.19}$$

$$\frac{\partial\Delta^j\mathbf{u}}{\partial\mathbf{n}}|_{\partial\Omega} = 0, \quad \frac{s}{2} \le j \le s-2, \quad s \text{ even}; \quad \frac{s-1}{2} \le j \le s-2, \quad s \text{ odd}, \tag{3.20}$$

$$\frac{\partial\Delta^{s-1}\mathbf{u}}{\partial\mathbf{n}} = \left(\frac{\partial\Delta^{s-1}\mathbf{u}}{\partial\mathbf{n}}\cdot\mathbf{n}\right)\mathbf{n}. \tag{3.21}$$

It is easy to see (cf. [9, 17]) that for any $\epsilon > 0$ fixed there exists $T > 0$ and unique $\mathbf{u}_\epsilon(t) \in L^2((0,T);X_s)\cap L^\infty((0,T);J_0(\Omega))$, $\mathbf{W}_\epsilon(t) \in (L^\infty(0,T))^3$ satisfying (3.15)–(3.21) and $\mathbf{u}_\epsilon(0) = \mathbf{u}_0$, $\mathbf{W}(0) = \mathbf{W}_0$. Applying the same arguments as in deriving (3.14) and using the additional boundary conditions (3.19)–(3.21), we obtain the following a priori estimates:

$$\frac{1}{2}\frac{d}{dt}\|\mathbf{u}_\epsilon(t)\|_{\mathbf{H}^s}^2 + \epsilon\|(-\Delta)^s\mathbf{u}_\epsilon(t) + \mathbf{u}_\epsilon(t)\|_{\mathbf{L}^2}^2 \le \text{const}\,\|\mathbf{u}_\epsilon(t)\|_{\mathbf{H}^s}\|\mathbf{V}_\epsilon(t)\|_X^2, \tag{3.22}$$

$$\left|\frac{d\mathbf{W}}{dt}(t)\right| \le \text{const}\,(\|\mathbf{V}_\epsilon(t)\|_Z^2 + \epsilon\|\mathbf{u}_\epsilon(t)\|_{\mathbf{H}^s}) \tag{3.23}$$

which imply

$$\frac{d}{dt}\|\mathbf{V}_\epsilon(t)\|_X \le \text{const}\,\|\mathbf{V}_\epsilon(t)\|_X^2. \tag{3.24}$$

Standard passage to the limit $\epsilon \to 0$ (cf. [16]) proves existence of a solution to the system (1.1)–(1.4). Uniqueness follows from (3.4). The inclusion $\mathbf{V}(t) \in C([0,T];Z)$ follows from (3.11) and (3.13). □

4. The unstable spectrum of the linearized operator. In the present section we study the spectrum of the linear part $\omega_0 K^{-1}L$ of equation (1.15). We show that the unstable spectrum is purely discrete and we obtain a necessary and sufficient condition for the existence of an unstable eigenvalue. Thus, for configurations where this condition is satisfied, the general theorem described in section 2 implies nonlinear instability of the uniform rotation of the fluid+body system. Since ω_0 is a positive constant, it is sufficient to discuss the spectral properties of the operator $K^{-1}L$.

PROPOSITION 4.1. *If $\lambda \in \mathbb{C}$ is a spectral point of $K^{-1}L$ satisfying $\operatorname{Re}\lambda \neq 0$ then λ is an eigenvalue of finite multiplicity.*

Proof. Let $\operatorname{Re}\lambda \neq 0$. Using (1.14) and the self-adjointness of K we obtain

$$\begin{aligned}(K^{-1}L - \lambda I) &= K^{-1/2}\left(iK^{-1/2}L_1K^{-1/2} + K^{-1/2}L_2K^{-1/2} - \lambda I\right)K^{1/2}\\ &= K^{-1/2}\left(iK^{-1/2}L_1K^{-1/2} - \lambda I\right)\\ &\qquad\cdot\left(I + (iK^{-1/2}L_1K^{-1/2} - \lambda I)^{-1}K^{-1/2}L_2K^{-1/2}\right)K^{1/2},\end{aligned}$$

where

$$L_1\mathbf{V} = \begin{pmatrix}2T\mathbf{u}\\ 0\end{pmatrix}, \qquad \mathbf{V} = \begin{pmatrix}\mathbf{u}\\ \mathbf{w}\end{pmatrix},$$

and

$$L_2 = L - iL_1$$

is a finite-dimensional operator. Since $K^{-1/2}L_1K^{-1/2}$ is a self-adjoint operator then λ is a spectral point of $K^{-1}L$ if and only if (-1) is an eigenvalue of the finite-dimensional operator

$$(iK^{-1/2}L_1K^{-1/2} - \lambda I)^{-1}K^{-1/2}L_2K^{-1/2}.$$

Therefore any spectral point λ of $K^{-1}L$ satisfying $\operatorname{Re}\lambda \neq 0$ is an eigenvalue of finite multiplicity. □

Remark. We note that the above arguments do not make use of the condition of 4-fold symmetry. Therefore Proposition 4.1 is valid independent of any geometrical symmetry constraints.

Consider the spectral problem

$$K^{-1}L\mathbf{V} = \lambda\mathbf{V}, \quad \mathbf{V} \in Z. \tag{4.1}$$

Because of (1.5), (1.10), and (1.11) it can be written as follows:

$$2iT\mathbf{u} = \lambda(\mathbf{u} + P_0(\mathbf{w}\times\mathbf{r})), \tag{4.2}$$

$$\mathbf{e}_3 \times \left((a-b)\mathbf{w} + \int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega\right) = \lambda\left(J\mathbf{w} + \int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega\right). \tag{4.3}$$

It is easy to see that $\lambda = 0$ is always an eigenvalue of (4.2), (4.3). Henceforth we assume that $\lambda \neq 0$. Then (4.3) can be solved for $\mathbf{w}$ (cf. [11]):

$$\mathbf{w} = C(\lambda)\int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega, \tag{4.4}$$

where

$$C(\lambda) = \begin{pmatrix} \dfrac{(b-a)-\lambda^2 a}{(b-a)^2+\lambda^2 a^2} & -\lambda b & 0 \\ \lambda b & \dfrac{(b-a)-\lambda^2 a}{(b-a)^2+\lambda^2 a^2} & 0 \\ 0 & 0 & -\dfrac{1}{b} \end{pmatrix}.$$

Using the notation of section 3

$$\mathbf{a}_j = P_0(\mathbf{e}_j \times \mathbf{r}), \quad j = 1, 2, 3,$$

and formulas (3.7) one can verify that (cf. [11])

$$P_0\left(\left(C(\lambda)\int_\Omega \mathbf{r}\times\mathbf{u}\,d\Omega\right)\times\mathbf{r}\right) = -m\left[\frac{\lambda+i}{\lambda+ik}P_{\mathbf{c}_1}\mathbf{u} + \frac{\lambda-i}{\lambda-ik}P_{\mathbf{c}_2}\mathbf{u} + dP_{\mathbf{c}_3}\mathbf{u}\right], \tag{4.5}$$

where

$$\begin{cases} m = \dfrac{\|\mathbf{a}_1\|^2_{\mathbf{L}^2}}{a}, \quad k = \dfrac{a-b}{a}, \quad d = \dfrac{a}{b}\dfrac{\|\mathbf{a}_3\|^2_{\mathbf{L}^2}}{\|\mathbf{a}_1\|^2_{\mathbf{L}^2}}, \\ P_{\mathbf{c}_j}\mathbf{u} = \dfrac{(\mathbf{u},\mathbf{c}_j)_{\mathbf{L}^2}}{\|\mathbf{c}_j\|^2_{\mathbf{L}^2}}\mathbf{c}_j, \quad j = 1,2,3, \\ \mathbf{c}_1 = \mathbf{a}_1 + i\mathbf{a}_2, \quad \mathbf{c}_2 = \mathbf{a}_1 - i\mathbf{a}_2, \quad \mathbf{c}_3 = \mathbf{a}_3. \end{cases} \tag{4.6}$$

Thus (4.4), (4.5) imply that for $\lambda \neq 0$ system (4.2), (4.3) is equivalent to the following spectral problem:

$$2iT\mathbf{u} + m\lambda D(\lambda, k, d)\,\mathbf{u} = \lambda\mathbf{u}, \tag{4.7}$$

where

$$D(\lambda,k,d) = \frac{\lambda+i}{\lambda+ik}P_{\mathbf{c}_1} + \frac{\lambda-i}{\lambda-ik}P_{\mathbf{c}_2} + dP_{\mathbf{c}_3}$$

is a three-dimensional operator in $J_0(\Omega)$. It follows from (3.7), (4.6) that

$$(\mathbf{c}_j, \mathbf{c}_n)_{\mathbf{L}^2} = 0\,, \quad j \neq n; \quad \|\mathbf{c}_1\|_{\mathbf{L}^2} = \|\mathbf{c}_2\|_{\mathbf{L}^2}. \tag{4.8}$$

Therefore $P_{\mathbf{c}_j}$, $j = 1, 2, 3$ are pair-wise orthogonal one-dimensional projections. It is easy to see that (1.5), (4.6), and (3.8) imply

$$0 < m < 1, \quad 0 < md < 1, \quad -1 < k < 1. \tag{4.9}$$

Since T is a self-adjoint operator then for any λ with $\operatorname{Re}\lambda \neq 0$ spectral problem (4.1) is equivalent to

$$\mathbf{u} + m\lambda\,(2iT - \lambda I)^{-1}\,D\,(\lambda,k,d)\,\mathbf{u} = 0. \tag{4.10}$$

PROPOSITION 4.2. *If there exists an eigenvalue λ of $K^{-1}L$ satisfying $\operatorname{Re}\lambda \neq 0$ then $k = (a-b)/a > 0$.*

Proof. Let $\lambda \in \mathbb{C}$, $\operatorname{Re}\lambda \neq 0$ be an eigenvalue of $K^{-1}L$ and $\mathbf{u}$ be a corresponding eigenfunction. Taking the real part of the $\mathbf{L}^2$-inner product of (4.7) with $\mathbf{u}$ we obtain

$$\begin{aligned}\operatorname{Re}\lambda\, k(1-k)\, m \left[\frac{\|P_{\mathbf{c}_1}\mathbf{u}\|^2_{\mathbf{L}^2}}{|\lambda+ik|^2} + \frac{\|P_{\mathbf{c}_2}\mathbf{u}\|^2_{\mathbf{L}^2}}{|\lambda-ik|^2}\right] \\ = \operatorname{Re}\lambda \left(\|\mathbf{u}\|^2_{\mathbf{L}^2} - m\|P_{\mathbf{c}_1}\mathbf{u}\|^2_{\mathbf{L}^2} - m\|P_{\mathbf{c}_2}\mathbf{u}\|^2_{\mathbf{L}^2} - md\|P_{\mathbf{c}_3}\mathbf{u}\|^2_{\mathbf{L}^2}\right).\end{aligned} \tag{4.11}$$

Because of (4.8),(4.9) and $\operatorname{Re}\lambda \neq 0$, equality (4.11) implies $k > 0$. □

Corollary. *Condition*

$$a - b = \int_\Omega x_3^2 - x_1^2\, d\Omega + \mu \int_G x_3^2 - x_1^2\, dG > 0 \tag{4.12}$$

is a necessary condition for $K^{-1}L$ to have an eigenvalue λ satisfying $\operatorname{Re}\lambda < 0$.

Remark. The physical meaning of (4.12) is that the axis of rotation is the axis of the least moment of inertia of the entire system body+liquid. This necessary condition for the linear instability is known in the literature (cf. [14]).

Denote

$$P_3 = P_{\mathbf{c}_1} + P_{\mathbf{c}_2} + P_{\mathbf{c}_3}$$

an orthogonal projection onto $span\{\mathbf{c}_1, \mathbf{c}_2, \mathbf{c}_3\}$ by virtue of (4.8). Since $D(\lambda,k,d)P_3 = D(\lambda,k,d)$ then (4.10) is equivalent to the following system:

$$P_3\mathbf{u} + m\lambda P_3 \left(2iT - \lambda I\right)^{-1} D\left(\lambda,k,d\right) P_3\mathbf{u} = 0, \tag{4.13}$$

$$(I - P_3)\mathbf{u} + m\lambda(I - P_3) \left(2iT - \lambda\right)^{-1} D\left(\lambda,k,d\right) P_3\mathbf{u} = 0. \tag{4.14}$$

Thus $(I-P_3)\mathbf{u}$ is uniquely determined by $P_3\mathbf{u}$. Hence $\lambda \in \mathbb{C}$, $\operatorname{Re}\lambda \neq 0$ is an eigenvalue of $K^{-1}L$ if and only if (4.13) admits a nontrivial solution. Since

$$P_3 + m\lambda P_3(2iT - \lambda I)^{-1} D(\lambda,k,d) P_3$$

is a three-dimensional linear operator in $P_3 J_0(\Omega) = span\{\mathbf{c}_1, \mathbf{c}_2, \mathbf{c}_3\}$ then (4.13) admits a nontrivial solution if and only if

$$\det\left[(\mathbf{c}_j, \mathbf{c}_n)_{\mathbf{L}^2} + m\lambda \left(\left(2iT - \lambda I\right)^{-1} D\left(\lambda,k,d\right)\mathbf{c}_j, \mathbf{c}_n\right)_{\mathbf{L}^2}\right] = 0. \tag{4.15}$$

It was shown in [11] that

$$((2iT - \lambda I)^{-1}\mathbf{c}_j, \mathbf{c}_n)_{\mathbf{L}^2} = 0, \quad j \neq n,\ \operatorname{Re}\lambda \neq 0. \tag{4.16}$$

Because of (4.16), equation (4.15) can be written as follows:

$$f_1(\lambda,m,k) \cdot f_2(\lambda,m,k) \cdot f_3(\lambda,md,k) = 0, \tag{4.17}$$

where

$$\begin{aligned} f_1(\lambda,m,k) &= \|\mathbf{c}_1\|^2_{\mathbf{L}^2} + m\lambda\frac{\lambda+i}{\lambda+ik}((2iT - \lambda I)^{-1}\mathbf{c}_1, \mathbf{c}_1)_{\mathbf{L}^2}, \\ f_2(\lambda,m,k) &= \|\mathbf{c}_2\|^2_{\mathbf{L}^2} + m\lambda\frac{\lambda-i}{\lambda-ik}((2iT - \lambda I)^{-1}\mathbf{c}_2, \mathbf{c}_2)_{\mathbf{L}^2}, \\ f_3(\lambda,m,k) &= \|\mathbf{c}_3\|^2_{\mathbf{L}^2} + m\lambda((2iT - \lambda I)^{-1}\mathbf{c}_3, \mathbf{c}_3)_{\mathbf{L}^2} \end{aligned}$$

are functions that are analytic in $\lambda \in \mathbb{C} \setminus \{\alpha i \mid \alpha \in [-2,2]\}$. Thus we have verified the following criterion.

THEOREM 4.1. *$\lambda \in \mathbb{C}$, $\operatorname{Re}\lambda \neq 0$ is an eigenvalue of $K^{-1}L$ if and only if (4.17) holds.*

COROLLARY. *For any $\epsilon > 0$ there exist at most a finite number of spectral points λ of $K^{-1}L$ satisfying $|\operatorname{Re}\lambda| \geq \epsilon$.*

Proof. It is easy to see that

$$\lim_{\lambda\to\infty} f_j(\lambda, m, k) = \|\mathbf{c}_j\|^2_{\mathbf{L}^2}(1-m) \neq 0, \quad j = 1,2,3.$$

Therefore there exist $R_j(m,k) > 0$, $j = 1,2,3$ such that

$$f_j(\lambda, m, k) \neq 0, \quad |\lambda| > R_j(m,k)\,,\ j = 1,2,3.$$

Then the statement of the corollary follows from Proposition 4.1, Theorem 4.1, and the analyticity of $f_j(\lambda, m, k)$, $j = 1,2,3$. □

Now we are going to simplify the criterion presented in Theorem 4.1 by showing that $f_3(\lambda, md, k) \neq 0$, $\operatorname{Re}\lambda \neq 0$, and $\overline{f_1(\lambda, m, k)} = f_2(\bar\lambda, m, k)$.

LEMMA 4.1. *For any $\mathbf{a} \in J_0(\Omega)$, $\mathbf{a} \neq 0$, $m \in (0,1)$, $\lambda \in \mathbb{C}$, $\operatorname{Re}\lambda \neq 0$ we have*

$$\|\mathbf{a}\|^2_{\mathbf{L}^2} + m\lambda\left((2iT - \lambda I)^{-1}\mathbf{a}\,,\,\mathbf{a}\right)_{\mathbf{L}^2} \neq 0.$$

Proof. Let E_γ be the resolution of identity corresponding to the self-adjoint operator T. Since $\sigma(T) = [-1,1]$, then for any $\epsilon > 0$

$$\begin{aligned}\|\mathbf{a}\|^2_{\mathbf{L}^2} + m\lambda\left((2iT - \lambda I)^{-1}\mathbf{a}\,,\,\mathbf{a}\right)_{\mathbf{L}^2} &= \int_{-1}^{1+\epsilon}\left(1 + \frac{m\lambda}{2i\gamma - \lambda}\right) d(E_\gamma\mathbf{a},\mathbf{a})_{\mathbf{L}^2} \\ &= \int_{-1}^{1+\epsilon}\frac{|2i\gamma-\lambda|^2 - m|\lambda|^2}{|2i\gamma-\lambda|^2}\, d(E_\gamma\mathbf{a},\mathbf{a})_{\mathbf{L}^2} - 2m\lambda i\int_{-1}^{1+\epsilon}\frac{\gamma}{|2i\gamma-\lambda|^2}\, d(E_\gamma\mathbf{a},\mathbf{a})_{\mathbf{L}^2}.\end{aligned}$$

Assume there exists $\lambda \in \mathbb{C}$, $\operatorname{Re}\lambda \neq 0$ such that $\|\mathbf{a}\|^2_{\mathbf{L}^2} + m\lambda\left((2iT - \lambda I)^{-1}\mathbf{a},\mathbf{a}\right)_{\mathbf{L}^2} = 0$. Then from the formula above it follows that

$$\int_{-1}^{1+\epsilon}\frac{\gamma}{|2i\gamma-\lambda|^2}\, d(E_\gamma\mathbf{a},\mathbf{a})_{\mathbf{L}^2} = 0,$$

$$\begin{aligned}0 = \int_{-1}^{1+\epsilon}\frac{|2i\gamma-\lambda|^2 - m|\lambda|^2}{|2i\gamma-\lambda|^2}\, d(E_\gamma\mathbf{a},\mathbf{a})_{\mathbf{L}^2} &= \int_{-1}^{1+\epsilon}\frac{4\gamma^2 + (1-m)|\lambda|^2}{|2i\gamma-\lambda|^2}\, d(E_\gamma\mathbf{a},\mathbf{a})_{\mathbf{L}^2} \\ &> \frac{(1-m)|\lambda|^2}{(\operatorname{Re}\lambda)^2}\int_{-1}^{1+\epsilon} d(E_\gamma\mathbf{a},\mathbf{a})_{\mathbf{L}^2} = \frac{(1-m)|\lambda|^2}{(\operatorname{Re}\lambda)^2}\|\mathbf{a}\|^2_{\mathbf{L}^2} > 0.\end{aligned}$$

The obtained contradiction proves the lemma. □

COROLLARY. *From Lemma 4.1 and $\mathbf{c}_3 = P_0(-x_2, x_1, 0) \neq 0$ it follows that*

$$f_3(\lambda, m, k) \neq 0, \quad \operatorname{Re}\lambda \neq 0\,,\ m \in (0,1).$$

Let $\mathbf{v} \in J_0(\Omega) \cap \mathbf{H}^1$, $\lambda \in \mathbb{C}$, $\mathrm{Re}\lambda \neq 0$, and

$$\mathbf{u} = (2iT - \lambda I)^{-1}\mathbf{v}. \tag{4.18}$$

Then

$$\mathbf{v} = (2iT - \lambda I)\mathbf{u} = 2P_0(\mathbf{e}_3 \times \mathbf{u}) - \lambda\mathbf{u} = 2(-u_2, u_1, 0) - \lambda(u_1, u_2, u_3) - \nabla p \tag{4.19}$$

for some $p(x) \in H^1(\Omega)$. Therefore

$$\begin{cases} u_1 = \dfrac{2v_2 - \lambda v_1 + 2p_{x_2} - \lambda p_{x_1}}{\lambda^2 + 4}, \\ u_2 = -\dfrac{2v_1 + \lambda v_2 + 2p_{x_1} + \lambda p_{x_2}}{\lambda^2 + 4}, \\ u_3 = -\dfrac{v_3 + p_{x_3}}{\lambda}. \end{cases} \tag{4.20}$$

Since $\mathbf{u}, \mathbf{v} \in J_0(\Omega)$ then

$$0 = \operatorname{div}\mathbf{u} = \frac{1}{\lambda(\lambda^2+4)}\Big(-\lambda^2\Delta p - 4p_{x_3x_3} + 2\lambda(v_{2x_1} - v_{1x_2}) - 4v_{3x_3}\Big),$$

$$0 = \mathbf{u}\cdot\mathbf{n} = \frac{-\lambda^2\nabla p\cdot\mathbf{n} + 2\lambda(p_{x_2}n_1 - p_{x_1}n_2) - 4p_{x_3}n_3 + 2\lambda(v_2n_1 - v_1n_2) - 4v_3n_3}{\lambda(\lambda^2+4)}.$$

Hence $p(x)$ satisfies

$$\left(-\frac{\lambda}{2}\right)^2 \Delta p + p_{x_3x_3} = -\left(-\frac{\lambda}{2}\right)(v_{2x_1} - v_{1x_2}) - v_{3x_3}, \tag{4.21}$$

$$\begin{aligned} \left(-\frac{\lambda}{2}\right)^2 \nabla p\cdot\mathbf{n} + \left(-\frac{\lambda}{2}\right)(p_{x_2}n_1 - p_{x_1}n_2) + p_{x_3}n_3\big|_{\partial\Omega} \\ = -\left(-\frac{\lambda}{2}\right)(v_2n_1 - v_1n_2) - v_3n_3\big|_{\partial\Omega}. \end{aligned} \tag{4.22}$$

Remark. If $\mathbf{v} = 0$ then (4.21), (4.22) is the spectral problem corresponding to the second mixed problem for the Poincaré–Sobolev equation (cf. [18]).

Applying the standard arguments (cf. [13, 2]), one obtains the following result.

LEMMA 4.2 (see [10]). *Let $\lambda \in \mathbb{C}$, $\mathrm{Re}\,\lambda \neq 0$, $s \in \mathbb{N}\cup\{0\}$, $\mathbf{v} \in X_{s+1}$, $\partial\Omega \in C^{4+s}$. Then there exists unique $p \in H^{s+2}(\Omega)$ satisfying* (4.21), (4.22), *and $\int_\Omega p\,d\Omega = 0$.*

Denote by $p(x, \lambda, \mathbf{v})$ the unique solution of (4.21), (4.22) satisfying $\int_\Omega p\,d\Omega = 0$. From (4.21), (4.22) it follows that

$$\overline{p(x, \lambda, \mathbf{v})} = p(x, \bar\lambda, \bar{\mathbf{v}}). \tag{4.23}$$

Let $\mathrm{Re}\lambda \neq 0$, $\mathbf{v} = (v_1, v_2, v_3) \in J_0(\Omega) \cap \mathbf{H}^1$. Then using (4.18), (4.19) we obtain

(4.24)

$$\begin{aligned} &g(\mathbf{v}, \lambda) \stackrel{\text{def}}{=} \big((2iT - \lambda I)^{-1}\mathbf{v}, \mathbf{v}\big)_{\mathbf{L}^2} \\ &= \frac{1}{\lambda(\lambda^2+4)}\int_\Omega \big(2\lambda(v_2\bar v_1 - v_1\bar v_2) - \lambda^2|\mathbf{v}|^2 - 4|v_3|^2 + 2\lambda(p_{x_2}\bar v_1 - p_{x_1}\bar v_2) - 4p_{x_3}\bar v_3\big)\,d\Omega, \end{aligned}$$

where $p = p(x, \lambda, \mathbf{v})$. Since $\overline{\mathbf{c}_1} = \mathbf{c}_2$ then (4.23), (4.24) imply

$$\overline{\left((2iT - \lambda I)^{-1}\mathbf{c}_1\,,\,\mathbf{c}_1\right)_{\mathbf{L}^2}} = \left((2iT - \bar{\lambda} I)^{-1}\mathbf{c}_2\,,\,\mathbf{c}_2\right)_{\mathbf{L}^2}.$$

Hence

$$\overline{f_1(\lambda, m, k)} = f_2(\bar{\lambda}, m, k).$$

Thus, Theorem 4.1 can be rewritten as follows.

THEOREM 4.2. *$\lambda \in \mathbb{C}$, $\operatorname{Re}\lambda \neq 0$ is an eigenvalue of $K^{-1}L$ if and only if*

$$\left[\|\mathbf{c}_1\|^2_{\mathbf{L}^2} + m\lambda\frac{\lambda + i}{\lambda + ik}g(\mathbf{c}_1, \lambda)\right] \cdot \left[\|\mathbf{c}_1\|^2_{\mathbf{L}^2} + m\bar{\lambda}\frac{\bar{\lambda} + i}{\bar{\lambda} + ik}g(\mathbf{c}_1, \bar{\lambda})\right] = 0, \tag{4.25}$$

where $g(\mathbf{v}, \lambda)$ is defined by (4.24).

To conclude this section we derive a representation of $p(x, \lambda, \mathbf{v})$ in the form of a power series in $1/\lambda$. It follows from (4.18), (4.19) that

$$\nabla p(x, \lambda, \mathbf{v}) = (I - P_0)2(-u_2, u_1, 0) = 2(I - P_0)(\mathbf{e}_3 \times (2iT - \lambda I)^{-1}\mathbf{v}).$$

Since $\|T\| = 1$ then for any $\lambda \in \mathbb{C}$, $|\lambda| > 2$ we have

$$(2iT - \lambda I)^{-1}\mathbf{v} = -\frac{1}{\lambda}\sum_{j=0}^{\infty}\left(\frac{2}{\lambda}\right)^j (iT)^j\mathbf{v}.$$

Therefore

$$\nabla p(x, \lambda, \mathbf{v}) = \sum_{j=1}^{\infty}\frac{1}{\lambda^j}\left[-2^j(I - P_0)(\mathbf{e}_3 \times (iT)^{j-1}\mathbf{v})\right].$$

Due to the Weyl decomposition of $\mathbf{L}^2$, for any $j \in \mathbb{N}$ there exists a unique $p_j(x, \mathbf{v}) \in H^1(\Omega)$ such that $\int_\Omega p_j\, d\Omega = 0$ and

$$\nabla p_j(x, \mathbf{v}) = -2^j(I - P_0)(\mathbf{e}_3 \times (iT)^{j-1}\mathbf{v}).$$

Hence we have

$$p(x, \lambda, \mathbf{v}) = \sum_{j=1}^{\infty}\frac{1}{\lambda^j}p_j(x, \mathbf{v})\,, \quad \lambda \in \mathbb{C} \setminus \{i\alpha \mid \alpha \in [-2, 2]\}. \tag{4.26}$$

Substituting (4.26) into (4.21), (4.22) we obtain that $p_j(x, \mathbf{v})$, $j \in \mathbb{N}$ satisfy the following system:

(4.27)
$$\begin{cases} \Delta p_1 = 2(v_{2x_1} - v_{1x_2}), & \nabla p_1 \cdot \mathbf{n}\big|_{\partial\Omega} = 2(v_2 n_1 - v_1 n_2)\big|_{\partial\Omega}, \\ \Delta p_2 = -4v_{3x_3}, & \nabla p_2 \cdot \mathbf{n}\big|_{\partial\Omega} = 2(p_{1x_2}n_1 - p_{1x_1}n_2) - 4v_3 n_3\big|_{\partial\Omega}, \\ \Delta p_{j+2} = -4p_{jx_3x_3}, & \nabla p_{j+2} \cdot \mathbf{n}\big|_{\partial\Omega} = 2(p_{j+1x_2}n_1 - p_{j+1x_1}n_2) - 4p_{jx_3}n_3\big|_{\partial\Omega}. \end{cases}$$

It is easy to see that the system of Neumann problems (4.27) is compatible and the functions $p_j(x, \mathbf{v})$, $j \in \mathbb{N}$ are uniquely determined by (4.27) and the condition $\int_\Omega p_j\, d\Omega = 0$.

The following theorem summarizes the obtained results regarding the spectrum of the operator $K^{-1}L$.

THEOREM 4.3.

(1) *All the spectral points* λ *of* $K^{-1}L$ *satisfying* $\operatorname{Re}\lambda \neq 0$ *are eigenvalues of finite multiplicity;*
(2) *For any* $\epsilon > 0$ *there exist at most a finite number of spectral points* λ *of* $K^{-1}L$ *satisfying* $|\operatorname{Re}\lambda| \geq \epsilon$*;*
(3) $\lambda \in \mathbb{C}$, $\operatorname{Re}\lambda \neq 0$ *is an eigenvalue of* $K^{-1}L$ *if and only if* (4.25) *holds, where* $g(\mathbf{v}, \lambda)$ *is defined by* (4.24) *and* $p = p(x, \lambda, \mathbf{v})$ *is given by* (4.26), (4.27).

Thus the spectral gap condition of Theorem 2.1 holds whenever there exists a $\lambda \in \mathbb{C}$, $\operatorname{Re}\lambda < 0$ satisfying (4.25) and the linear instability of uniform rotation of the entire body+liquid system implies nonlinear instability.

5. Ellipsoidal cavity. To demonstrate that Theorem 4.3 gives an effective condition for nonlinear instability, we consider the example of a body with an ellipsoidal cavity Ω. We calculate the geometric quantities occuring in equation (4.25). We obtain an explicit quadratic equation for the spectral parameter λ and demonstrate that for cavities of appropriate ellipticity there exists an eigenvalue with $\operatorname{Re}\lambda < 0$. In fact either the unstable spectrum is empty or there exist exactly two pairs of eigenvalues $\pm\operatorname{Re}\lambda + i\operatorname{Im}\lambda$ and $\pm\operatorname{Re}\lambda - i\operatorname{Im}\lambda$ (the volume preserving nature of the fluid motion dictates that a growing mode is matched by a decaying mode). The growth rate $|\operatorname{Re}\lambda|$ of the instability is given by an explicit function of the geometry and the relative fluid/body density.

For any $r, R \in (0, \infty)$ we consider the following ellipsoid of revolution:

$$\Omega = \Omega_{r,R} = \{x \in \mathbb{R}^3 \mid r^2(x_1^2 + x_2^2) + x_3^2 < R^2\}.$$

Then

$$\mathbf{n}(x) = \frac{(r^2 x_1, r^2 x_2, x_3)}{\sqrt{r^2(R^2 - x_3^2) + x_3^2}}$$

is the outer normal to $\Omega_{r,R}$. Denote

$$\tilde{\mathbf{n}}(x) = (r^2 x_1, r^2 x_2, x_3).$$

Consider $\mathbf{a}_k = P_0(\mathbf{e}_k \times \mathbf{r})$, $k = 1, 2, 3$, $\mathbf{r} = (x_1, x_2, x_3)$. We have

$$\begin{aligned}
&\mathbf{a}_1 = (0, -x_3, x_2) - \nabla p^1, \quad \nabla p^1 \cdot \tilde{\mathbf{n}}\big|_{\partial\Omega} = -x_3\tilde{n}_2 + x_2\tilde{n}_3\big|_{\partial\Omega} = (1 - r^2)x_2x_3,\\
&\mathbf{a}_2 = (x_3, 0, -x_1) - \nabla p^2, \quad \nabla p^2 \cdot \tilde{\mathbf{n}}\big|_{\partial\Omega} = x_3\tilde{n}_1 - x_1\tilde{n}_3\big|_{\partial\Omega} = (r^2 - 1)x_1x_3,\\
&\mathbf{a}_3 = (-x_2, x_1, 0) - \nabla p^3, \quad \nabla p^3 \cdot \tilde{\mathbf{n}}\big|_{\partial\Omega} = -x_2\tilde{n}_1 + x_1\tilde{n}_2\big|_{\partial\Omega} = 0,
\end{aligned}$$

$$\Delta p^j(x) = 0, \qquad j = 1, 2, 3.$$

Assuming $\int_\Omega p^j \, d\Omega = 0$ we obtain

$$p^1(x) = \frac{1 - r^2}{1 + r^2}x_2x_3, \quad p^2(x) = \frac{r^2 - 1}{1 + r^2}x_1x_3, \quad p^3(x) = 0.$$

Therefore

$$\mathbf{a}_1 = \frac{2}{1 + r^2}(0, -x_3, r^2x_2), \quad \mathbf{a}_2 = \frac{2}{1 + r^2}(x_3, 0, -r^2x_1), \quad \mathbf{a}_3 = (-x_2, x_1, 0).$$

According to (4.6),

$$\mathbf{c}_1 = \mathbf{a}_1 + i\mathbf{a}_2 = \frac{2}{1+r^2}(ix_3, -x_3, r^2(x_2 - ix_1)),$$
$$\mathbf{c}_2 = \mathbf{a}_1 - i\mathbf{a}_2 = \frac{2}{1+r^2}(-ix_3, -x_3, r^2(x_2 + ix_1)),$$
$$\mathbf{c}_3 = \mathbf{a}_3 = (-x_2, x_1, 0).$$

By (4.26), (4.27),

$$p(x, \lambda, \mathbf{c}_1) = \sum_{j=1}^{\infty} \frac{1}{\lambda^j} p_j(x, \mathbf{c}_1),$$

where $p_j(x, \mathbf{c}_1)$, $j \in \mathbb{N}$ satisfy

$$\Delta p_1 = 0, \qquad \nabla p_1 \cdot \tilde{\mathbf{n}}\big|_{\partial\Omega} = -4i\frac{r^2}{1+r^2} x_3(x_2 - ix_1),$$
$$\Delta p_2 = 0, \qquad \nabla p_2 \cdot \tilde{\mathbf{n}}\big|_{\partial\Omega} = 2(p_{1_{x_2}}\tilde{n}_1 - p_{1_{x_1}}\tilde{n}_2) - 8\frac{r^2}{1+r^2} x_3(x_2 - ix_1),$$
$$\Delta p_{j+2} = -4p_{j_{x_3x_3}}, \quad \nabla p_{j+2} \cdot \tilde{\mathbf{n}}\big|_{\partial\Omega} = 2(p_{j+1_{x_2}}\tilde{n}_1 - p_{j+1_{x_1}}\tilde{n}_2) - 4p_{j_{x_3}}\tilde{n}_3.$$

Since $\nabla(x_3(x_2 - ix_1)) \cdot \tilde{\mathbf{n}}(x) = (r^2+1)x_3(x_2 - ix_1)$ then one can easily verify that

$$p_1(x, \mathbf{c}_1) = -4i\frac{r^2}{(1+r^2)^2} x_3(x_2 - ix_1),$$

$$p_{j+1}(x, \mathbf{c}_1) = -\frac{2i}{1+r^2} p_j(x, \mathbf{c}_1), \quad j \in \mathbb{N}.$$

Therefore

$$p(x, \lambda, \mathbf{c}_1) = \sum_{j=1}^{\infty} \frac{1}{\lambda^j} p_j(x, \mathbf{c}_1) = -4i\frac{r^2}{1+r^2} \cdot \frac{x_3(x_2 - ix_1)}{\lambda(1+r^2) + 2i}.$$

According to (4.24) we have

$$g(\mathbf{c}_1, \lambda) = \frac{1}{\lambda(\lambda^2+4)(1+r^2)^2} \left[16i\lambda \int_\Omega x_3^2 \, d\Omega - 8\lambda^2 \int_\Omega (x_3^2 + r^4 x_1^2) \, d\Omega \right.$$
$$\left. -32r^4 \int_\Omega x_1^2 \, d\Omega + \frac{32ir^2}{\lambda(1+r^2) + 2i} \left(i\lambda \int_\Omega x_3^2 \, d\Omega + 2r^2 \int_\Omega x_1^2 \, d\Omega \right) \right].$$

Since

$$\int_{\Omega_{r,R}} x_3^2 \, d\Omega = \frac{4\pi}{15} R^5 \frac{1}{r^2}, \quad \int_{\Omega_{r,R}} x_1^2 \, d\Omega = \frac{4\pi}{15} R^5 \frac{1}{r^4},$$

we obtain

$$g(\mathbf{c}_1, \lambda) = -\frac{32\pi}{15} R^5 \frac{1}{r^2(\lambda(1+r^2) + 2i)}.$$

Therefore

$$\begin{aligned} f_1(\lambda,m,k) &= \|\mathbf{c}_1\|^2_{\mathbf{L}^2} + m\lambda\frac{\lambda+i}{\lambda+ik}g(\mathbf{c}_1,\lambda) \\ &= 2\left(\frac{2}{1+r^2}\right)^2\int_\Omega (x_3^2+r^4x_1^2)\,d\Omega - \frac{32\pi}{15}R^5 m\lambda\frac{\lambda+i}{\lambda+ik}\cdot\frac{1}{r^2(\lambda(1+r^2)+2i)} \\ &= \frac{32\pi}{15}R^5\frac{(1+r^2)(1-m)\lambda^2+((1+r^2)(k-m)+2)i\lambda-2k}{r^2(r^2+1)(\lambda+ik)(\lambda(1+r^2)+2i)}. \end{aligned}$$

Thus, from Theorem 4.2 it follows that $K^{-1}L$ has an unstable eigenvalue λ if and only if the roots of the numerator have the form

$$\lambda = \frac{\pm\sqrt{\Delta} - i((1+r^2)(k-m)+2)}{2(1+r^2)(1-m)}$$

with

$$\Delta(r,m,k) = 8(1+r^2)(1-m)k - ((1+r^2)(k-m)+2)^2 > 0. \tag{5.1}$$

The quantities m and k occurring in the instability condition (5.1) are defined in (4.6) and (1.5) and involve only the shape of the body/cavity and the relative density μ of the body/fluid. For configurations such that $\Delta > 0$ the linearized operator has an eigenfunction whose growth rate is given by $\sqrt{\Delta}$ and such a configuration is nonlinearly unstable.

Remark. Condition (5.1) reproduces the linear instability condition obtained by Sobolev [14] using a different approach.

Consider the limit case of the weightless body. Then the ratio μ of the body density to the fluid density is zero and we have

$$m = \frac{4r^2}{(1+r^2)^2}, \quad k = \frac{r^2-1}{r^2+1}.$$

Therefore, in this case

$$\Delta = \frac{(r^2-1)^3}{(1+r^2)^2}(9-r^2).$$

Thus we have verified the following result: in the case of weightless body with ellipsoidal cavity $\Omega_{r,R}$ the uniform rotation is linearly unstable if and only if $r \in (1,3)$. This is a classical result known to Kelvin (see, for example, [8]).

Since m, k depend continuously on $\mu \in [0,\infty)$ and $\Delta(r,m,k)$ depends continuously on m, k then from the above arguments it follows that for any $r \in (1,3)$, $R \in (0,\infty)$ there exists $\mu_0 > 0$ such that for any $\mu \in (0,\mu_0)$ uniform rotation of the entire system body+liquid is unstable in the case $\Omega = \Omega_{r,R}$.

Remark. For general geometries the two separate problems,

(i) free oscillations of a uniformly rotating fluid in a bounded domain (the so-called inertial modes of the Poincaré problem for rotating fluids),

(ii) free oscillations of a solid spinning body with no cavity,

both give rise to purely stable spectrum. (This is easily seen by setting (i) $\mathbf{W} = \omega_0\mathbf{e}_3$ or (ii) $\mathbf{u}(\mathbf{r},t) = 0$). However, as we have proved, under certain conditions on shape and relative density the coupled fluid-body system is (nonlinearly) unstable.

ON THE CHAPMAN–JOUGUET LIMIT FOR A COMBUSTION MODEL*

BERNARD HANOUZET†, ROBERTO NATALINI‡, AND ALBERTO TESEI§

Abstract. We study the limiting behavior of solutions to a simple model for combustion waves when the reaction rate tends to infinity. First we establish strong convergence for locally uniformly bounded sequences of solutions. Next we show the uniform boundedness with respect to the reaction rate of piecewise smooth solutions, both for detonation and for deflagration waves.

Key words. small combustion, detonation, deflagration, Chapman–Jouguet limit, conservation laws with source, shock waves

1. Introduction.

In this paper we investigate the qualitative behavior of solutions to the following simple model for combustion waves:

$$\partial_t(u+v) + \partial_x f(u) = 0 \ , \tag{1.1}$$

$$\partial_t v = -k\varphi(u)v \qquad (k>0) \tag{1.2}$$

for $(x,t) \in \mathbb{R} \times (0,\infty)$, with initial conditions

$$u(x,0) = u_0(x) \ , \quad v(x,0) = v_0(x) \qquad (x \in \mathbb{R}). \tag{1.3}$$

Throughout the paper the functions f and φ are smooth given functions. We also assume that

$$\varphi \text{ is monotone increasing, } \ \varphi(u) \equiv 0 \text{ for } u \le 0. \tag{1.4}$$

The model (1.1)–(1.2) has been proposed independently by Fickett [Fi] and Majda [Ma1] as a simple mathematical analogous for the equations describing one-dimensional compressible flows in a chemically reacting fluid. Existence, uniqueness, and stability of the (entropy) solutions to the Cauchy problem (1.1)–(1.3) have been first established in [TY1]; further results can be found in [TY2], [Le], [HN]. A slightly different model, yet with the same viscous travelling waves of model (1.1)–(1.2), was considered in [MR] and [L1], [L2].

The main purpose of this paper is to investigate the limit of solutions to (1.1)–(1.3) as the reaction rate k diverges. Our approach can be described as follows. Denote by (u^k, v^k) the solution of (1.1)–(1.3) for any fixed $k > 0$. Consider the following Chapman–Enskog-type expansion with respect to the small parameter $1/k$:

$$u^k = u^\infty + \frac{1}{k}\tilde{u} + 0\left(\frac{1}{k}\right), \ v^k = v^\infty + \frac{1}{k}\tilde{v} + 0\left(\frac{1}{k}\right) \ . \tag{1.5}$$

§Dipartimento di Matematica, Università degli Studi di Roma "La Sapienza," P. le A. Moro 5, I-00185 Roma, Italy (tesei@mat.uniroma1.it).

Introducing (1.5) into the system (1.1)–(1.2) gives, up to terms of order $\frac{1}{k}$,

$$\partial_t(u^\infty + v^\infty) + \partial_x f(u^\infty) = 0 \ , \tag{1.6}$$

$$\partial_t v^\infty \le 0 \ , \qquad v^\infty \ge 0 \ , \tag{1.7}$$

$$\varphi(u^\infty)v^\infty = 0 \ . \tag{1.8}$$

It is natural to try to give a rigorous justification of the above formal argument. This is made in section 3, assuming that the sequence $\{u^k\}$ is locally uniformly bounded in the supremum norm. Under this assumption, by compensated compactness arguments we prove that any sequence $\{(u^k, v^k)\}$ of entropy solutions of (1.1)–(1.3) contains a subsequence that converges to a weak solution (u^∞, v^∞) of problem (1.6)–(1.8) (see Theorem 3.1). Let us observe that this convergence result is far from obvious, since no stability condition—as, for example, the subcharacteristic condition in the case of relaxation problems; see [CLL], [Na]—is satisfied in the present case. In fact, the technical tools of [CLL] have partially inspired our convergence proof; however, an important difference is given by the intrinsic instability of the present problem (see [LZ]).

The remainder of the paper is devoted to investigating the uniform boundedness of the sequence $\{u^k\}$, at least for some classes of initial data.

In section 4 we deal with simple detonation waves; these waves are in general nonmonotone, so usual comparison arguments (like those used, e.g., for relaxation phenomena) are not expedient in this case. On the other hand, using energy methods seems cumbersome for the present problem, due to the lack of regularity of solutions. In our approach, the crucial remark is that the dissipative character of the shock wave affects the reaction mechanism in equation (1.1); hence the absorption effect of equation (1.2) is able to make the solution uniformly bounded. In this connection, let us observe that the uniform boundedness depends in an essential way on the nonlinear character of the flux function $f = f(u)$ (see section 4 for a counterexample when the flux function is linear). A careful study of propagation along characteristics of the above mechanism allows us to extend elementary arguments of the space clamp situation to the general detonation case.

Finally, in section 5 we study deflagration waves using a fixed-point approach. Then we generalize previous results in [TY1], both for more general data and for unbounded reaction rates.

Before proceeding, it is important to motivate our interest in the present problem. Let us recall that two different mathematical theories are widely used to describe the propagation of combustion waves in reacting flows: the Chapman–Jouguet (CJ) theory and the Zeldovich-Von Neumann-Döring (ZND) theory (see [CF], [Wi], [Ma2]). The CJ theory assumes that the reaction rate is *infinitely large* or, equivalently, that the reaction region is *infinitely thin*; on the contrary, the ZND theory makes the assumption that the reaction rate is *finite*. Both theories disregard the effects of viscosity and heat conduction; in fact, they are formulated starting from the classical Euler equations for gas dynamics, which in Lagrangian coordinates for the one-dimensional case read

$$\begin{cases} \partial_t \tau - \partial_x w = 0, \\ \partial_t w + \partial_x P = 0, \\ \partial_t(E) + \partial_x(wP) = 0 \ . \end{cases} \tag{1.9}$$

Here τ is the specific volume, w is the fluid velocity, P is the pressure, and E is the total specific energy—namely, $E = e + q_0 z + \frac{1}{2}w^2$, the quantity e being the specific internal energy, while q_0 denotes the amount of heat released by the chemical reaction and z is the mass fraction of the reactant. The internal energy e and the temperature T are given through state equations $e = e(\tau, P),\ T = T(\tau, P)$, which depend on the gas mixture under consideration.

To make the above system well defined, an equation for the mass fraction z must be provided. This is where the difference between the theories occurs. To specify the variable z, the CJ theory introduces the following relation:

$$z(x,t) = \begin{cases} 0 & \text{if } \sup\limits_{0\le s\le t} T(x,s) > T_i, \\ z(x,0) & \text{if } \sup\limits_{0\le s\le t} T(x,s) \le T_i\ , \end{cases} \tag{1.10}$$

where T_i is a given ignition temperature. On the contrary, in the ZND theory the Ansatz (1.10) is replaced by the following:

$$\partial_t z = -k\varphi(T)z\ , \tag{1.11}$$

where the rate function $\varphi(T)$ has the form

$$\varphi(T) = \begin{cases} 0 & \text{if } T < T_i, \\ T^\alpha \exp\left\{-\frac{A}{T-T_i}\right\} & \text{if } T \ge T_i\ . \end{cases} \tag{1.12}$$

Here T_i is again the ignition temperature, A is the activation energy, and k is the reaction rate ($T_i, A, k > 0$); as for α, this is a dimensionless parameter in the range $(-1, 2]$.

It is natural to ask whether the CJ system (1.9)–(1.10) is in some sense the limit as $k \to \infty$ of the ZND system (1.9), (1.11) (with $\varphi(T)$ as in (1.12)). Observe that this is formally the case, as it is apparent from the equality

$$z(x,t) = z(x,0)e^{-k\int_0^t \varphi(T(x,s))ds}\ .$$

This remark led some authors (see [LZ]) to investigate the equation (1.1) supplemented by the equalities

$$v(x,t) = \begin{cases} 0 & \text{if } \sup\limits_{0\le s\le t} u(x,s) > 0, \\ v(x,0) & \text{if } \sup\limits_{0\le s\le t} u(x,s) \le 0\ . \end{cases} \tag{1.13}$$

Then the system (1.1), (1.13) can be regarded as a simplified version of the CJ model (1.9)–(1.10), while the system (1.1)–(1.2) is the counterpart of the ZND system (1.9), (1.11). The unknown u plays a role similar to that of density, velocity, and temperature in (1.9), while v represents the mass fraction of the unburnt gas. The function φ can be chosen as in (1.12), with $T = u$ and $T_i = 0$.

The reason to consider these simpler models is apparent, due to the complexity, e.g., of (1.9), (1.11). Let us mention that local existence of solutions to the Cauchy problem for this system was proved in [DH] for initial data of small bounded variation (see also [YW]); however, global existence—even for the Riemann problem—seems to be still an open problem.

The Riemann problem for system (1.1), (1.13) was investigated in [LZ] (see also [Zh], where an interesting survey on the whole theory is given). In particular, in [LZ] the authors found up to four distinct configurations for some given initial data to exist. Therefore they proposed to consider as physically eligible those (piecewise smooth, self-similar) solutions for which the number of combustion waves is as small as possible. It was proved in [TY1] that these admissible solutions are the limit of solutions to the Riemann problem (1.1)–(1.3) as the reaction rate k diverges, the limit as $k \to \infty$ was taken by using the explicit structure of the combustion waves (both for detonation and for deflagration) of the Riemann problem, under suitable assumptions on the function φ.

Although the above results are very interesting in themselves, it can be observed that the very mathematical formulation of the limiting problem (1.1), (1.13) is meaningless for generic discontinuous solutions. This seems a strong argument to advocate the use of (1.6)–(1.8) instead of (1.1), (1.13) as the limit of (1.1)–(1.2) when $k \to \infty$. Observe that the solutions of (1.1), (1.13) considered in [LZ] satisfy almost everywhere equation (1.8) (with φ as in (1.12)).

2. Preliminaries. In this section we shall recall some basic definitions and results concerning entropy solutions of the Cauchy problem (1.1)–(1.3). First let us fix some notation. Throughout the paper Σ_T denotes the strip $\mathbb{R} \times (0,T)$ $(T > 0)$, $\Sigma = \Sigma_\infty$. Let us recast the problem (1.1)–(1.2) in a more general way. Consider the weakly coupled first-order quasilinear hyperbolic 2×2 system

$$\partial_t u_i + \partial_x f_i(u_i) = g_i(U) \ , \qquad i = 1,2 \ , \tag{2.1}$$

$$U(x,0) = U^0(x) \ , \tag{2.2}$$

where $U = (u_1, u_2)$ and $U^0 = (u_1^0, u_2^0)$. Here $F(U) = (f_1(u_1), f_2(u_2))$, $G(U) = (g_1(U), g_2(U))$ are given smooth functions.

Let us define the entropy solutions of (2.1)–(2.2) as follows (see [HN]; see also [Kr] for the scalar case).

DEFINITION 2.1. *A vector-valued function $U \in L^\infty(\Sigma_T)^2$ is said to be an entropy solution of* (2.1)–(2.2) *in Σ_T if, for any $\Psi \in C_0^\infty(\Sigma_T)^2$, $\Psi = (\psi_1, \psi_2)$, $\psi_i \geq 0$ $(i = 1,2)$, and any l_1, $l_2 \in \mathbb{R}$, we have*

$$\sum_{i=1}^{2} \iint_{\Sigma_T} \{|u_i - l_i| \, \partial_t \psi_i + \operatorname{sgn}(u_i - l_i)(f(u_i) - f(l_i))\partial_x \psi_i + g_i(U)\psi\} \, dx \, dt \geq 0 \tag{2.3}$$

and, for any interval I,

$$\lim_{T \to 0^+} \frac{1}{T} \int_0^T \int_I |u_i(x,t) - u^0(x)| dx = 0 \ . \tag{2.4}$$

Remark 2.2. Observe that U verifies the condition (2.3) if and only if for any convex function η, setting $q_i := \int^u \eta'(s) f_i'(s) ds$, we have

$$\partial_t \eta(u^i) + \partial_x q_i(u^i) \leq \eta'(u^i) g_i(U)$$

in $\mathcal{D}'$. The pair (η, q_i) is called an entropy pair for the ith equation in (2.1) $(i = 1,2)$.

The following results were proved in [HN].

THEOREM 2.3. (a) *For any $U^\circ \in L^\infty(\mathbb{R})^2$ and $T > 0$ there exists at most one entropy solution U to the Cauchy problem* (2.1)–(2.2) *in* Σ_T.

(b) *For any $U^0 \in L^\infty(\mathbb{R})^2$ there is $T > 0$ (depending only on $\|U_0\|_\infty$) such that in Σ_T there exists an entropy solution U of* (2.1)–(2.2) *and $U \in C([0,T], L^1_{loc}(\mathbb{R})^2)$. Moreover, only two possibilities occur: either $U \in L^\infty(\Sigma_T)^2$ for all $T > 0$, or there exists $T^* < +\infty$ such that U is defined for all $T < T^*$ and*

$$\lim_{T \to T^*_-} \|U\|_{L^\infty(\Sigma_T)^2} = +\infty \ .$$

Concerning our problem (1.1)–(1.2), the following statement can be proved by using the comparison tools in [HN] (see also [TY1], [TY2], [Le]).

THEOREM 2.4. *Let φ verify* (1.4); *assume that φ is Lipschitz continuous and sublinear*; *namely, there is a constant $C > 0$ such that*

$$0 \le \varphi(u) \le Cu \qquad \text{for all } u \ge 0 \ . \tag{2.5}$$

Then for any u_0, $v_0 \in L^\infty(\mathbb{R})$, $v_0 \ge 0$, there is a unique entropy solution (u, v) to the Cauchy problem (1.1)–(1.2). *Moreover, the following global estimates hold true for almost every $(x,t) \in \Sigma$:*

$$0 \le v(x,t) \le v_0(x) \ , \tag{2.6}$$

$$-\|u_0\|_\infty \le u(x,t) \le \|u_0\|_\infty e^{Ck\|v_0\|_\infty t} \ . \tag{2.7}$$

3. The Chapman–Jouguet limit. In this section we are dealing with the limit as $k \to \infty$ of globally defined entropy solutions (u^k, v^k) to problem (1.1)–(1.2) (see Theorem 2.4).

We assume the sequence $\{u^k\}$ to be uniformly locally bounded in L^∞; namely,

$$\begin{cases} \text{for any compact set } B \subseteq \overline{\Sigma} \text{ there exists} \\ \text{a constant } C_B > 0 \text{ such that, for any } k > 0 \ , \\ \qquad \|u^k\|_{L^\infty(B)} \le C_B \ . \end{cases} \tag{3.1}$$

Then we have the following result.

THEOREM 3.1. *Assume that the function f is not affine on any interval. Let the hypotheses of Theorem* 2.4 *and* (3.1) *hold. Then there exist a subsequence (also denoted $\{(u^k, v^k)\}$) of solutions to* (1.1)–(1.2) *and a couple $(\overline{u}, \overline{v}) \in L^\infty_{loc}(\Sigma)$ such that*

$$u^k \longrightarrow \overline{u} \qquad \text{in } L^p_{loc}(\Sigma) \quad (1 \le p < +\infty) \ , \tag{3.2}$$

$$v^k \rightharpoonup \overline{v} \qquad \text{in } L^\infty\text{-weak}^* \ . \tag{3.3}$$

Moreover, for any $\psi \in C^\infty_0(\overline{\Sigma})$ the following holds:

$$\iint (\overline{u} + \overline{v})\partial_t \psi + f(\overline{u})\partial_x \psi \ dx\, dt + \int (u_0(x) + v_0(x))\psi(x,0)dx = 0 \ ; \tag{3.4}$$

$$\overline{v} \ge 0 \ ; \tag{3.5}$$

$$\varphi(\overline{u})\overline{v} = 0 \quad \text{for almost every } (x,t) \in \Sigma; \tag{3.6}$$

$$\partial_t \overline{v} \le 0 \qquad \text{in } \mathcal{D}' \ . \tag{3.7}$$

To prove the above theorem we shall use the following results.

PROPOSITION 3.2 (see [Ta]). *Let $f \in C^1$ and $\Omega \subseteq \mathbb{R}^n$ be a bounded open set. Let $\{u^k\}$ be a sequence of functions satisfying $u^k \rightharpoonup u$ in $L^\infty(\Omega)$–weak*. Suppose that for any convex function η*

$$\partial_t \eta(u^k) + \partial_x q(u^k) \in (\text{compact set of } H^{-1}(\Omega)), \tag{3.8}$$

where $q' = \eta' f'$. Then, if no interval exists on which f is affine,

$$u^k \longrightarrow u \qquad \text{in } L^p(\Omega) \tag{3.9}$$

for any $p \in [1,\infty)$.

LEMMA 3.3 (see [Mu]). *Let Ω be a bounded open set of $\mathbb{R}^n$ and $p \in (1,\infty)$. Let $\{u^k\}$ be any sequence such that $\{u^k\} \in$ (bounded set of $W^{-1,p}(\Omega)$) and $u^k \ge 0$. Then $\{u^k\} \in$ (compact set of $W^{-1,q}(\Omega)$) for all $1 < q < p$.*

LEMMA 3.4 (see [DCL]). *Let Ω be a bounded open set of $\mathbb{R}^n$ and $1 < p \le q < r < +\infty$. Let $\{u^k\}$ be a sequence such that $\{u^k\} \in$ (compact set of $W^{-1,p}(\Omega) \cap$ (bounded set of $W^{-1,r}(\Omega)$. Then $\{u^k\} \in$ (compact set of $W^{-1,q}(\Omega)$).*

Proof of Theorem 3.1. Let $\psi \in C_0^\infty(\mathbb{R})$, $\psi \ge 0$. From the second equation in (1.1) we have, for all $t \ge 0$ and $k > 0$,

$$\partial_t \int v^k(x,t)\psi(x)dx + k \int \varphi(u^k(x,t))v^k(x,t)\psi(x)dx = 0 \ .$$

Then, for any $T > 0$,

$$0 \le \int_0^T \int \varphi(u^k(x,t))v^k(x,t)\psi(x)dx\,dt \le \frac{\|v_0\|_\infty \|\psi\|_{L^1}}{k} \ . \tag{3.10}$$

Now let (η, q) be an entropy pair; namely, η is convex and $q' = \eta' f'$. Then, in view of Remark 2.2, we have, for all $k > 0$,

$$\partial_t \eta(u^k) + \partial_x q(u^k) \le k\eta'(u^k)\varphi(u^k)v^k \qquad \text{in } \mathcal{D}' \ .$$

Setting

$$I^k := k\eta'(u^k)\varphi(u^k)v^k,$$

we have, by (3.1) and (3.10),

$$\|I^k\psi\|_{L^1(\Sigma_T)} \le C \sup_{(0,T)\times(\text{supp}\psi)} |\eta'(u^k)| \le \overline{C} \ ,$$

where $\overline{C}$ depends only on $\|v_0\|_\infty$, η, ψ, and T.

Then the function I^k is in a bounded set of L^1_{loc} for any $k > 0$. Hence by the Sobolev embedding lemma

$$I^k \in \ (\text{compact set in } W^{-1,p_1}_{loc}) \tag{3.11}$$

with $p_1 < 2$. Moreover,

$$\Lambda^k := \partial_t \eta(u^k) + \partial_x q(u^k) - I^k \leq 0,$$

Λ^k being in a bounded subset in W^{-1,p_1}_{loc}. In view of Lemma 3.3 we have

$$\Lambda^k \in (\text{compact set in } W^{-1,p}_{loc}) \tag{3.12}$$

for all $1 \leq p < p_1$. Hence by (3.11)–(3.12), there holds

$$\partial_t \eta(u^k) + \partial_x q(u^k) \in \ (\text{compact set of } W^{-1,p}_{loc}) \ , \tag{3.13}$$

which by assumption (3.1) implies

$$\partial_t \eta(u^k) + \partial_x q(u^k) \in \ (\text{bounded set of } W^{-1,\infty}_{loc}) \ .$$

Then, using Lemma 3.4, we get

$$\partial_t \eta(u^k) + \partial_x q(u^k) \in \ (\text{compact set of } H^{-1}_{loc}) \ .$$

By Proposition 3.2 there exists $\overline{u} \in L^\infty_{loc}(\Sigma)$ and a subsequence (also denoted u^k) such that

$$u^k \longrightarrow \overline{u} \qquad \text{in } L^p_{loc}(\Sigma) \ .$$

Moreover, there exists $\overline{v} \in L^\infty(\Omega)$ and a further subsequence v^k such that

$$v^k \rightharpoonup \overline{v} \ , \ \varphi(u^k) v^k \rightharpoonup \varphi(\overline{u})\overline{v} \ ,$$

both convergences being in the L^∞-weak* sense. On the other hand, using (3.10), we obtain

$$\varphi(u^k) v^k \longrightarrow 0 \qquad \text{in } L^1_{loc} \ ,$$

which implies (3.6). The proof of (3.4), (3.5), and (3.7) is now easy. Hence the conclusion follows. □

4. Simple detonations. In this section we establish a uniform bound in the supremum norm for the solutions of (1.1)–(1.2) in the case where the flow is piecewise smooth with finitely many noninteracting detonation waves. According to the results of section 3, this estimate is of fundamental importance to prove the convergence of the sequence $\{u^k, v^k\}$ as $k \to \infty$.

For simplicity we concentrate on the case where the solution contains only a single detonation; the general case easily follows by similar arguments.

Let us make the following definition.

DEFINITION 4.1. *An entropy solution* (u, v) *of problem* (1.1)–(1.2) *is a* simple detonation *if:*

(i) *the initial data* $(u_0, v_0) \in L^\infty(\mathbb{R}) \cap C^1(\mathbb{R}\backslash\{0\})$;

(ii) $v \in C^1(\mathbb{R}\backslash\{0\})$;

(iii) u *is a* C^1 *function away from a shock curve* $t = \theta(x)$*, which has the following properties:* θ *is defined for* $x > 0$ *and is monotonically increasing;* $\theta(0) = 0$, $\lim_{x\to\infty} \theta(x) = +\infty$;

(iv) *for $x < 0$ and any $t > 0$, u is bounded, uniformly with respect to k. For $x \geq 0$, $t \geq \theta(x)$, u is decreasing in time and is nonnegative. For $x > 0$, $0 < t < \theta(x)$, u is nonpositive.*

Notice that, due to the entropy conditions, the function θ satisfies both the Rankine–Hugoniot condition and the Oleinik entropy condition.

Examples of simple detonations which exhibit the above structure are given in [TY1, Theorem 3] (see also [Le]); there the function φ is increasing such that $\varphi(u) \equiv 1$ if $u \geq \beta > 0$.

Let us assume the following:

(H_1) the function f is C^2 and convex, with $f(0) = f'(0) = 0$. Moreover, there exist $\delta \in (1/2, 1)$ and $M > 0$ such that

$$\frac{uf'(\delta u)}{f(u)} \geq M + 1 \qquad \text{for all } u > 0 \ . \tag{4.1}$$

If $f(u) = Au^\beta$ for $u > 0$ ($A > 0$, $\beta > 1$), assumption (H_1) is satisfied with $\delta^{\beta-1} \geq \frac{M+1}{\beta}$;

(H_2) the function φ is Lipschitz continuous, satisfies (1.4), and there holds $\varphi(u) > 0$ for $u > 0$. Moreover, there exists $\alpha \geq 0$ such that

$$\varphi(u) = 0(u^\alpha) \quad \text{as } u \to +\infty \ .$$

Among the above assumptions the convexity of f is important, as the following example shows.

Example 4.2. Consider the following semilinear problem ($f(u) \equiv u$ in (1.1)):

$$\begin{cases} \partial_t u + \partial_x u = k\varphi(u)v \ , \\ \partial_t v = -k\varphi(u)v \ , \end{cases}$$

with $u_0(x) = H(-x)$ and $v_0(x) = H(x)$, where H is the Heaviside function. It is easily seen that

$$v(x,t) = v_0(x)e^{-k\int_0^t \varphi(u(x,\tau))d\tau} \ ;$$

in particular,

$$v(x,t) \equiv 1 \qquad \text{for } 0 \leq t \leq x.$$

On the other hand, on the characteristic $x = t$ the function u verifies

$$u(t^-,t) = k\int_0^t \varphi(u(\tau^-,\tau))v\,d\tau + 1 \geq k\varphi(1)t + 1 \ .$$

It is clear from the above inequality that condition (3.1) is not satisfied in the present case.

Let us prove the following result.

THEOREM 4.3. *Let (u^k, v^k) be a simple detonation; let assumptions (H_1)–(H_2) be satisfied. Then there exists a constant $C > 0$ (only depending on f, φ, $\|u_0\|_\infty$, $\|v_0\|_\infty$) such that*

$$u^k(x,t) \leq C$$

for all $x > 0$, $t > \theta^k(x)$.

Proof. By the change of variable $\tilde{x} = \frac{x}{k}$, $\tilde{t} = \frac{t}{k}$ it suffices to consider the case $k = 1$, since all the involved quantities do not depend on the scaling; hence we omit the index k in the following. Assume $x \geq 0$, $t \geq \theta(x)$. Fix $x_0 > 0$ and $t_0 = \theta(x_0)$; also set

$$\overline{u} = \max_{x \in [0, x_0]} u(x^-, \theta(x)) \ .$$

Let $\overline{x}$ be such that $\overline{u} = u(\overline{x}^-, \theta(\overline{x}))$; set $\overline{t} = \theta(\overline{x})$.

Observe that by Definition 4.1 (iv) we have

$$\overline{u} = \max_{\substack{\theta(x) \leq t \leq t_0 \\ 0 \leq x \leq x_0}} u(x,t) \ .$$

Consider now the backward characteristic $(X(t), U(t))$ issued from the point $(\overline{x}, \overline{t})$. There holds

$$\begin{cases} \dot{X} = f'(U) \ , \\ \dot{U} = v_0(X(t))\varphi(U) e^{-\int_{\theta(X(t))}^{t} \varphi(u(X(t),\tau))d\tau} \ , \end{cases} \tag{4.2}$$

with $x(\overline{t}) = \overline{x}$, $U(\overline{t}) = \overline{u}$. Let $\overline{\gamma} \in [0, \overline{t}]$ be such that $x(\overline{\gamma}) = 0$, $\overline{\alpha} := u(0, \overline{\gamma})$; set

$$I(t) := \int_t^{\overline{t}} v_0(x(s))\varphi(u(s)) e^{-\int_{\theta(x(s))}^{s} \varphi(u(x(s),\tau))d\tau} ds \tag{4.3}$$

for all $t \in [\overline{\gamma}, \overline{t}]$. Then

$$U(t) + I(t) = \overline{u} \tag{4.4}$$

for all $t \in [\overline{\gamma}, \overline{t}]$. In particular,

$$\overline{\alpha} + I(\overline{\gamma}) = \overline{u} \ . \tag{4.5}$$

If $I(\overline{\gamma}) \leq \frac{1}{2}\overline{u}$, then $\overline{u} \leq 2\overline{\alpha}$. Otherwise we have $\overline{u} > 2u(0, \overline{\gamma})$. For any fixed $\delta \in \left(\frac{1}{2}, 1\right)$ there exists $t_\delta \in (\overline{\gamma}, \overline{t})$ such that $U(t_\delta) = \delta\overline{u}$, from which $I(t_\delta) = (1-\delta)\overline{u}$. Therefore the following estimate holds:

$$\overline{u} \leq \frac{1}{1-\delta} \|v_0\|_\infty \varphi(\overline{u}) \int_{t_\delta}^{\overline{t}} e^{-\int_{\theta(x(s))}^{s} \varphi(u(x(s),\tau))d\tau} ds \ . \tag{4.6}$$

To estimate the integral on the right-hand side we observe that, since $u_t \leq 0$ for $t \geq \theta(x)$, there holds

$$\varphi(u(x(s),\tau)) \geq \varphi(U(s)) \geq \varphi(U(t_\delta)) = \varphi(\delta\overline{u}) \ .$$

Then

$$-\int_{\theta(x(s))}^{s} \varphi(u(x(s),\tau))d\tau \leq -\varphi(\delta\overline{u})(s - \theta(x(s))) \tag{4.7}$$

for $s \in [t_\delta, \overline{t}]$.

Due to the mean value theorem, there exists $\xi \in (x(s), \overline{x})$ and $\tau \in (s, \overline{t})$ such that

$$s - \theta(x(s)) = (s - \overline{t}) \left(1 - \frac{d\theta}{dx}(\xi) f'(U(\tau))\right) \ . \tag{4.8}$$

On the other hand, by the Rankine–Hugoniot condition we have

$$\frac{d\theta}{dx}(\xi) = \frac{u(\xi^-, \theta(\xi)) - u(\xi^+, \theta(\xi))}{f(u(\xi^-, \theta(\xi))) - f(u(\xi^+, \theta(\xi)))} \ ,$$

where $u(\xi^-, \theta(\xi))$ and $u(\xi^+, \theta(\xi))$ are the left, respectively, the right, limit of u on the shock curve. Since θ is monotone increasing, we have $\frac{d\theta}{dx} \geq 0$. Moreover, the function f is convex, $f(0) = f'(0) = 0$, and

$$u(\xi^+, \theta(\xi)) \leq 0 \leq u(\xi^-, \theta(\xi)) \leq \overline{u} \ .$$

It follows that

$$\frac{d\theta}{dx}(\xi) \geq \frac{\overline{u}}{f(\overline{u})}$$

for all $\xi \geq 0$.

On the other hand $U(\tau) \geq \delta\overline{u}$. Combined with (4.8), this gives

$$\begin{aligned} s - \theta(x(s)) &\geq (\overline{t} - s)\left(\frac{\overline{u}}{f(\overline{u})} f'(\delta\overline{u}) - 1\right) \\ &\geq (\overline{t} - s)M \end{aligned} \tag{4.9}$$

by assumption (H_1). Now the inequality (4.6) yields

$$\begin{aligned} \overline{u} &\leq \frac{1}{1-\delta}\|v_0\|_\infty \varphi(\overline{u}) \int_{t_\delta}^{\overline{t}} e^{-\varphi(\delta\overline{u})M(\overline{t}-s)} ds \\ &\leq \frac{1}{1-\delta}\|v_0\|_\infty \frac{\varphi(\overline{u})}{\varphi(\delta\overline{u})M} \ . \end{aligned} \tag{4.10}$$

Then by assumption (H_2) there exist $\alpha \geq 0$, $\tilde{C} > 0$ such that

$$\overline{u} \leq \tilde{C}\frac{\delta^{-\alpha}}{1-\delta}\|v_0\|_\infty \ ,$$

where $\tilde{C}$ depends only on φ, f. Hence the conclusion follows choosing

$$C \geq \max\left(2\overline{\alpha}, \tilde{C}\frac{\delta^{-\alpha}}{1-\delta}\|v_0\|_\infty\right) \ . \qquad \square$$

5. Deflagrations. Deflagration waves are analogous to the rarefaction waves of the nonreactive case. This section is devoted to a detailed investigation of their structure.

Let (u, v) be a solution of problem (1.1)–(1.3) with initial data

$$(u_0(x), v_0(x)) = \begin{cases} (\alpha_1, 0) & \text{if } x < 0 \ , \\ (\alpha_2, \beta_2) & \text{if } x > 0 \ . \end{cases} \tag{5.1}$$

As usual the function φ satisfies condition (1.4), while concerning the function f we make the following assumption:

(H_3) $f(0) = f'(0) = 0$; there exists a constant $\nu > 0$ such that $f''(u) \geq \nu > 0$ for all $u \geq 0$.

Due to the convexity of f, we say that a deflagration wave is generated if

$$0 < \alpha_1 < \alpha_2 \ , \qquad \beta_2 > 0 \ . \tag{5.2}$$

Even in this case it is enough to consider the case $k = 1$. The main result of this section is given in the following theorem, which provides a (global) uniform L^∞ bound for the solution (u, v), as required by Theorem 3.1.

THEOREM 5.1. *Let the assumption* (H_3) *hold and the initial data satisfy* (5.1)–(5.2). *Then the problem* (1.1)–(1.3) *has a unique global entropy solution* (u, v) *such that*

$$\alpha_1 \le u(x,t) \le \alpha_2 + \beta_2 \ , \tag{5.3}$$

$$0 \le v(x,t) \le \beta_2 \tag{5.4}$$

for almost every $(x, t) \in \mathbb{R} \times (0, \infty)$.

Observe that, by contrast with Theorem 2.4, no growth assumption is made here on the function φ. In fact, we shall assume, without loss of generality,

$$\varphi(u) = \varphi(\alpha_2 + \beta_2) \quad \text{for } u \ge \alpha_2 + \beta_2 \ . \tag{H_4}$$

Let us introduce for any $\alpha, \beta \ge 0$ the solution $(\tilde u, \tilde v) = (\tilde u, \tilde v)(\alpha, \beta)$ of the ordinary differential system

$$\begin{cases} \dot{\tilde u} = \varphi(\tilde u)\tilde v, \\ \dot{\tilde v} = -\varphi(\tilde u)\tilde v, \end{cases} \tag{5.5}$$

with Cauchy data $\tilde u(0) = \alpha,\ \tilde v(0) = \beta$. It is easily seen that

$$\tilde u + \tilde v = \alpha + \beta, \quad 0 \le \tilde v \le \beta, \quad \alpha \le \tilde u \le \alpha + \beta \ .$$

Set

$$\tilde x(t) = \int_0^t f'(\tilde u(\tau))d\tau \qquad (t > 0) \ ; \tag{5.6}$$

then the half-plane Σ is the union of the following regions:

$$\begin{aligned} I &:= \{(x,t) \,|\, x \le 0 \ ,\ t > 0\} \ ; \\ II &:= \{(x,t) \,|\, 0 < x \le \tilde x(t) \ ,\ t > 0\} \ ; \\ III &:= \{(x,t) \,|\, x > \tilde x(t) \ ,\ t > 0\} \ . \end{aligned}$$

Since $\dot{\tilde x} = f'(\tilde u) \ge 0$ and $\ddot{\tilde x} = f''(\tilde u)\dot{\tilde u} = f''(\tilde u)\varphi(\tilde u)\tilde v \ge 0$, the curve $x = \tilde x(t)$ is strictly increasing and convex for $t > 0$.

Now we can state the following result, which completely describes the structure of deflagration waves.

THEOREM 5.2. *Let the assumption* (H_3)–(H_4) *hold and the initial data satisfy* (5.1)–(5.2). *Then there exists a unique global entropy solution* (u, v) *to problem* (1.1)–(1.3) *such that* $u \in \mathrm{Lip}_{loc}(\overline{\Sigma} \setminus (0,0))$. *Moreover,*

$$(u, v) = (\alpha_1, 0) \quad \text{in region } I \ , \tag{5.7}$$

$$(u, v) = (\tilde u, \tilde v)(\alpha_2, \beta_2) \quad \text{in region } III \tag{5.8}$$

and there exists $\overline{M} > 0$ *such that*

$$0 \le \partial_x u \le \overline{M} \max\left(\frac{1}{t}, 1\right) \ , \tag{5.9}$$

$$-\frac{\overline{M}}{t} \le \partial_t u \le 0 \quad \text{in region } II \ . \tag{5.10}$$

It is easily seen that Theorem 5.1 follows from the above result; hence the remainder of the paper is devoted to the proof of the latter.

For this purpose, observe that (1.2)–(1.3) (with $k = 1$) entail

$$v(x,t) = v_0(x) e^{-\int_0^t \varphi(u(x,s))ds} \ . \tag{5.11}$$

Then it is natural to investigate the integro-differential problem

$$\partial_t u + \partial_x f(u) = \varphi(u) v_0(x) e^{-\int_0^t \varphi(u(x,s))ds} \ , \tag{5.12}$$

$$u(x,0) = u_0(x) \ . \tag{5.13}$$

Let us introduce the space $\mathcal{A}^M(\Sigma)$, as the space of $w \in \mathrm{Lip}_{loc}(\overline{\Sigma} \setminus (0,0))$ such that

$$\alpha_1 \le w \le \alpha_2 + \beta_2; \tag{P_1}$$

$$w = \alpha_1 \quad \text{in region } I; \tag{P_2}$$

$$w = \tilde{u}(\alpha_2, \beta_2) \quad \text{in region } III; \tag{P_3}$$

(P_4) there exists $M > 0$ such that

$$0 \le \partial_x w \le M \max\left(\frac{1}{t}, 1\right) \quad \text{in } \Sigma;$$

(P_5) there exists $M > 0$ such that

$$-\frac{M}{t} \le \partial_t w \le 0 \quad \text{in region } II \ .$$

For any $w \in \mathcal{A}^M(\Sigma)$ we define a map $u = \Lambda(w)$ by considering the (unique) entropy solution of the problem

$$\partial_t u + \partial_x f(u) = \varphi(u) v_0(x) e^{-\int_0^t \varphi(w(x,s))ds} \ , \tag{5.14}$$

$$u(x,0) = u_0(x) \ . \tag{5.15}$$

This solution exists by classical results (see section 2), in view of the assumption (H_4).

The first step in the proof of Theorem 5.2 is given in the following proposition.

PROPOSITION 5.3. *There exists* $M > 0$ *such that, for any* $w \in \mathcal{A}^M(\Sigma)$*, there holds* $\Lambda(w) \in \mathcal{A}^M(\Sigma)$.

The proof of Proposition 5.3 will be given after two preliminary lemmas (see Lemmas 5.4–5.5 below). Set

$$v(x,t) = v_0(x) e^{-\int_0^t \varphi(w(x,s))ds} \ , \tag{5.16}$$

where $v_0 \equiv 0$ for $x \le 0$, $v_0 \equiv \beta_2$ for $x > 0$. Then $u \equiv \alpha_1$ for $x \le 0$. To deal with the case $x > 0$ we solve the system for the characteristics of equation (5.14), namely,

$$\dot{X} = f'(U),\ \dot{U} = \varphi(U)V\ , \tag{5.17}$$

where $X = X(t),\ U = U(t),\ V(t) = v(X(t), t)$. Since $\dot{X} > 0$, the function X is invertible; denote by $T = T(x)$ its inverse function for $x > 0$. Then the system (5.17) is equivalent to

$$\frac{dT}{dx} = \frac{1}{f'(U)}, \quad \frac{dU}{dx} = \frac{\varphi(U)}{f'(U)}V\ , \tag{5.18}$$

where $U(x) = U(T(x))$ and $V(x) = V(T(x))$.

We supplement (5.18) with two different sets of initial data, namely,

$$(T(0), U(0)) = (\gamma, \alpha_1) \qquad \text{for } \gamma \ge 0, \tag{5.19}$$

or, respectively,

$$(T(0), U(0)) = (0, \alpha) \qquad \text{for } \alpha \in [\alpha_1, \alpha_2]\ . \tag{5.20}$$

Due to the above assumptions (in particular (H_4)), it is easily seen that the solutions of system (5.18) with initial conditions (5.19) or (5.20) are globally defined for $x > 0$. The following holds.

LEMMA 5.4. *Characteristic curves (T, U) corresponding to different values of the parameter γ or α do not intersect themselves for $x > 0$. The following inequalities hold:*

(i) $\frac{\partial U}{\partial \gamma}(x, \gamma) < 0,\ \frac{\partial T}{\partial \gamma}(x, \gamma) \ge 1\ (x > 0, \gamma \ge 0)$;

(ii) $\frac{\partial U}{\partial \alpha}(x, \alpha) > 0,\ \frac{\partial T}{\partial \alpha}(x, \alpha) < 0\ (x > 0, \alpha \in [\alpha_1, \alpha_2])$.

Moreover, the families $\{T(x, \gamma), \gamma \ge 0\}$ and $\{T(x, \alpha), \alpha \in [\alpha_1, \alpha_2]\}$ cover the entire region II.

Proof. Let us only consider (5.18)–(5.19), since problem (5.18), (5.20) can be dealt with by similar arguments. Let $0 \le \gamma_1 < \gamma_2$; set

$$\tilde{T}(x) = T_2(x) - T_1(x)\ ,\ \tilde{U}(x) = U_2(x) - U_1(x)\ ,$$

with obvious meaning of the symbols. An elementary calculation shows that

$$\tilde{T}(0) > 0\ , \qquad \frac{d\tilde{T}}{dx}(0) = 0\ , \qquad \frac{d^2\tilde{T}}{dx^2}(0) > 0\ , \tag{5.21}$$

$$\frac{d\tilde{T}}{dx} = -\frac{(\int_0^1 f''(\theta U_1 + (1-\theta)U_2)d\theta)\tilde{U}}{f'(U_1)f'(U_2)} \qquad (x > 0)\ , \tag{5.22}$$

$$\frac{d\tilde{U}}{dx} = \frac{\varphi(U_2)V(x, \gamma_2)}{f'(U_2)} - \frac{\varphi(U_1)V(x, \gamma_1)}{f'(U_1)} \qquad (x > 0). \tag{5.23}$$

By (5.22) there is a right neighborhood of $x = 0$ where $\tilde{T} > 0$, $\frac{d\tilde{T}}{dx} > 0$. Let $x_1 > 0$ exist such that $\tilde{T}(x) > 0$ for $x \in (0, x_1)$, $\tilde{T}(x_1) = 0$. Then there is $x_0 \in (0, x_1)$ such that $\frac{d\tilde{T}}{dx} > 0$ in $(0, x_0)$ and $\frac{d\tilde{T}}{dx}(x_0) = 0$. Hence by (5.22), $\tilde{U} < 0$ in $(0, x_0)$, $\tilde{U}(x_0) = 0$, which gives $\frac{d\tilde{U}}{dx}(x_0) \ge 0$. On the other hand, since $\tilde{T}(x_0) > 0$ we have

$$\begin{aligned} &V(x_0, \gamma_2) - V(x_0, \gamma_1) \\ &\quad = \beta_2 \left\{ e^{-\int_0^{T(x,\gamma_2)} \varphi(w(x_0,s))ds} - e^{-\int_0^{T(x,\gamma_1)} \varphi(w(x_0,s))ds} \right\} < 0\ . \end{aligned}$$

It follows from (5.23) that $\frac{d\tilde{U}}{dx}(x_0) < 0$; the contradiction proves the claim.

Inequalities (i) and (ii) are proved by similar arguments. To prove the last claim it suffices to show that $T(x, \alpha_2) = \tilde{t}(x)$ $(x \geq 0)$, where $\tilde{t}(\cdot)$ denotes the inverse function of $\tilde{x}(\cdot)$. Observe first that $(X(t, \alpha_2), U(t, \alpha_2))$ satisfies the equations

$$\dot{X} = U,\ \dot{U} = \varphi(U)V\ ,$$

with $X(0) = 0$, $U(0) = \alpha_2$, and $V(t) = \beta_2\, e^{-\int_0^t \varphi(w(X(t),s))ds}$. On the other hand, setting $X(t) = \tilde{x}(t)$ in the expression for $V(t)$ gives $V(t) = \tilde{v}(t)$. Since the couple $(\tilde{u}, \tilde{v}) = (\tilde{u}, \tilde{v})(\alpha_2, \beta_2)$ verifies

$$\dot{\tilde{x}} = \tilde{u},\ \dot{\tilde{u}} = \varphi(\tilde{u})\tilde{v} = \varphi(\tilde{u})V\ ,$$

and $\tilde{x}(0) = 0$, $\tilde{u}(0) = \alpha_2$, the conclusion follows by the uniqueness theorem for ordinary differential equations. □

Set

$$II_a = \{(x,t) \in II \,|\, t > T(x, \alpha_1)\}\ ;$$
$$II_b = \{(x,t) \in II \,|\, T(x, \alpha_2) < t \leq T(x, \alpha_1)\}\ .$$

For any $(x,t) \in II_a$, there exists a unique value $\gamma = \gamma(x,t) > 0$ such that $t = T(x, \gamma)$. In the same way, for any $(x,t) \in II_b$, there exists a unique $\alpha = \alpha(x,t) \in [\alpha_1, \alpha_2)$ such that $t = T(x, \alpha)$. Hence we can define, in region II,

$$\lambda(x,t) = \begin{cases} \gamma(x,t) & \text{if } (x,t) \in II_a, \\ \alpha(x,t) & \text{if } (x,t) \in II_b\ . \end{cases} \tag{5.24}$$

The function λ is invertible and differentiable. Define a function $u : \Sigma \to [\alpha_1, \infty)$ as follows:

$$u(x,t) = \begin{cases} \alpha_1 & \text{in region } I \setminus (0,0), \\ U(x, \lambda, (x,t)) & \text{in region } II, \\ \tilde{u}(t) & \text{in region } III\ . \end{cases} \tag{5.25}$$

The elementary proof of the following result is omitted.

LEMMA 5.5. *The function u given by* (5.25) *is in $C^1(\overline{\Sigma} \setminus \{(0,0)\})$ and solves problem* (5.12)–(5.13).

Proof of Proposition 5.3. Let $u = \Lambda w$ as defined by (5.25). First let us show that

$$\partial_x u \geq 0 \quad \text{in } \Sigma,\ \partial_t u < 0 \quad \text{in region } II\ .$$

In region I or region III, $\partial_x u \equiv 0$. On the other hand $u(x,t) = U(x, \lambda(x,t))$ in region II; hence $\partial_t u < 0$ by Lemma 5.4. Also, $f'(u)\partial_x u = -\partial_t u + \varphi(u)v > 0$. Since $\tilde{u}(t) \leq \alpha_2 + \beta_2$ in region III and $\partial_t u < 0$ in region II, we have

$$u(x,t) \leq \alpha_2 + \beta_2 \qquad \text{in region } II\ .$$

Hence properties (P_1), (P_2), (P_3) of the space $\mathcal{A}^M(\Sigma)$ are satisfied. We must check that there exists $M > 0$ such that, if $w \in \mathcal{A}^M(\Sigma)$, (P_4) and (P_5) are verified for u. Set $p = \partial_x u$ and differentiate equation (5.12). We have

$$\partial_t p + f'(u)\partial_x p + p^2 = \varphi'(u)vp + \varphi(u)\partial_x v\ . \tag{5.26}$$

For $x = 0$, it follows from the equation that

$$p(0,\gamma) = (\partial_x u)(0,\gamma) = \frac{\varphi(\alpha_1)}{\alpha_1}\beta_2 e^{-\varphi(\alpha_1)\gamma} \ . \tag{5.27}$$

Let $M_1 = \beta_2 \max(\sup_{u\in(\alpha_1,\alpha_2+\beta_2)} \varphi'(u), \frac{\varphi(\alpha_1)}{\alpha_1})$. Then $\overline{p} := M_1$ is a supersolution for problem (5.26)–(5.27) in region II_a. By standard comparison arguments on the characteristic curves we have

$$0 \le \partial_x u \le M_1 \tag{5.28}$$

and

$$\begin{aligned} 0 \le -\partial_t u &= u\partial_x u - \varphi(u)v \\ &\le (\alpha_2+\beta_2)M_1 \quad \text{for all } (x,t) \in II_a \ . \end{aligned} \tag{5.29}$$

To estimate the derivatives of u in region II_b we set

$$P(t,\alpha) = p(X(t,\alpha),t) = (\partial_x u)(X(t,\alpha),t) \ .$$

Using (5.18), (5.20), this yields

$$P(t,\alpha) = \frac{\varphi(U)}{f'(U)}V - \frac{1}{f'(U)}\ \frac{\partial U/\partial\alpha}{\partial T/\partial\alpha} \ .$$

Then

$$\lim_{t\to 0^+} t\ P(t,\alpha) = -\lim_{t\to 0^+} \frac{1}{f'(U)}\ \frac{\partial U}{\partial\alpha}\ \frac{t}{\frac{\partial T}{\partial\alpha}(X(t,\alpha),\alpha)} \ .$$

By elementary arguments it easy to show that

$$\lim_{t\to 0^+} t\ P(t,\alpha) = \frac{1}{f''(\alpha)} \ . \tag{5.30}$$

Observe now that P is a solution of the ordinary differential equation

$$\dot{P} = P^2 + \varphi'(U)VP + \varphi(U)v_x(X(t,\alpha),t). \tag{5.31}$$

Then

$$P(t,\alpha) \le \frac{M_2}{t} \ ,$$

where

$$M_2 = \max\left(\frac{1}{f''(\alpha)}, 1 + \left[\sup_{\alpha_1\le u\le\alpha_2+\beta_2} \varphi'(U)\right]\frac{\beta_2}{\varphi(\alpha_1)}\right) \ ,$$

since $\overline{P} = \frac{M_2}{t}$ is a supersolution of (5.31)–(5.30). Choosing $M = \max(M_1, M_2)$, the conclusion follows easily. □

The second step in the proof of Theorem 5.2 is given by the following fixed point result.

PROPOSITION 5.6. *Let M be given by Proposition* 5.3. *Then the map* $\Lambda : \mathcal{A}^M(\Sigma) \to \mathcal{A}^M(\Sigma)$ *has a fixed point.*

Proof. We shall use the Schauder theorem in the space

$$\mathcal{A}(Q) = \mathcal{A}^M(\Sigma)|_Q \ ,$$

where $Q = [0,T] \times [-R,R]$ $(T > 0, R > 0)$. Set also

$$B(\Sigma) = t\mathcal{A}^M(\Sigma), \ B(Q) = t\mathcal{A}(Q) \ .$$

Step 1. For any fixed R, T, the set $B(Q)$ is obviously a convex, bounded subset of $L^1(Q)$. Moreover, due to the properties (P_4)–(P_5) of the space $\mathcal{A}^M$, for any $z \in B(Q)$, $\partial_t z, \partial_x z \in L^\infty(Q)$. Next we claim that $B(Q)$ is a closed subset of $L^1(Q)$. In fact, let $\{z_n\} \subset B(Q)$ such that

$$z_n \longrightarrow z \qquad \text{in } L^1(Q) \ .$$

Then for any multi-index $\alpha = (\alpha_1, \alpha_2)$,

$$D^\alpha z_n \rightharpoonup D^\alpha x \qquad \text{in } \mathcal{D}(Q) \ ,$$

where D^α denotes any partial derivative with respect to the (x,t)-variables. Since $D^\alpha z_n$ is in a bounded set of $L^\infty(Q)$ for any α with $|\alpha| = 1$, there exist $\xi^\alpha \in L^\infty(Q)$ and a subsequence of $\{z_n\}$, say $\{z_{n_k}\}$, such that

$$D^\alpha z_{n_k} \rightharpoonup \xi^\alpha \qquad \text{in } L^\infty - \text{weak}^* \ .$$

Hence $D^\alpha z = \xi^\alpha \in L^\infty(Q)$ and the claim follows. Then the compact embedding of $B(Q)$ in $L^1(Q)$ follows, since $B(Q) \subseteq W^{1,\infty}(Q)$.

Step 2. To define a continuous map from $B(Q)$ in itself, fix $t \le T$ and $R > \tilde{x}(T)$. For $w_1, w_2 \in \mathcal{A}(Q)$, let $u_1 = \Lambda w_1$ and $u_2 = \Lambda w_2$. By the Gauss–Green formula applied to equation (5.12) we have

$$\begin{aligned}
&\int_{-R}^{R} |u_2(x,t) - u_1(x,t)|dx \\
&\quad = -\int_0^t [f(u_2) - f(u_1)](\tau, R)d\tau + \int_0^t [f(u_2) - f(u_1)](\tau, -R)d\tau \\
&\quad + \int_0^t \int_{-R}^{R} |\varphi(u_2)v_2 - \varphi(u_1)v_1|d\tau\, dx \\
&\quad \le \int_0^t \int_{-R}^{R} |\varphi(u_2)v_2 - \varphi(u_1)v_1|d\tau\, dx.
\end{aligned} \tag{5.32}$$

Since v_i is bounded, φ is Lipschitz continuous and by (5.16)

$$\begin{aligned}
&\int_0^t |v_2(x,\tau) - v_1(x,\tau)|d\tau \\
&\quad = \beta_2 \int_0^t \left| e^{-\int_0^\tau \varphi(w_2(x,s))ds} - e^{-\int_0^\tau \varphi(w_1(x,s))ds} \right| d\tau \\
&\quad \le \overline{C}_1 \int_0^t |w_2(x,\tau) - w_1(x,\tau)|d\tau \ ,
\end{aligned}$$

there exists a constant $\overline{C} > 0$ (depending only on T, φ, α_1, α_2, β_2, M) such that

$$\begin{aligned}\int_0^t \int_{-R}^R |\varphi(u_1)v_1 - \varphi(u_2)v_2| dx\, d\tau \\ \leq \overline{C} \int_0^t \int_{-R}^R [\,|u_1(x,\tau) - u_2(x,\tau)| \\ + |w_1(x,\tau) - w_2(x,\tau)|\,] dx\, d\tau\ .\end{aligned} \tag{5.33}$$

Due to (5.32)–(5.33), by the Gronwall inequality there exists a constant $C > 0$ (which depends on T, φ, α_1, α_2, β_2, M) such that

$$\int_{-R}^R |u_2(x,t) - u_1(x,t)| dx \leq C \int_0^t \int_{-R}^R |w_2(x,\tau) - w_1(x,\tau)| dx\, d\tau\ . \tag{5.34}$$

Now define a map $\mathcal{T} : B(Q) \to B(Q)$ setting

$$\mathcal{T}(z) = t\Lambda\left(\frac{1}{t}z\right) \quad \text{for all } z \in B(Q)\ . \tag{5.35}$$

Step 3. Let us prove that the map $\mathcal{T}$ defined in (5.35) is continuous in the L^1 topology. Set $z_i = tw_i$ $(i = 1, 2)$. Then (5.34) yields

$$\begin{aligned}\|\mathcal{T}z_1 - \mathcal{T}z_2\|_{L^1(Q)} &= \int_0^T \int_{-R}^R t|u_1(x,\tau) - u_2(x,\tau) dx\, d\tau \\ &\leq T \int_0^T \int_{-R}^R |u_1(x,\tau) - u_2(x,\tau)| dx\, d\tau \\ &\leq CT \int_0^T dt \int_0^t \int_{-R}^R \frac{1}{\tau}|z_1(x,\tau) - z_2(x,\tau)| dx\, d\tau \\ &\leq C' \int_0^T \int_{-R}^R \frac{1}{\tau}|z_1(x,\tau) - z_1(x,\tau)| dx\, d\tau\ .\end{aligned}$$

Fix $\varepsilon > 0$. Since $z_i = tw_i$ and $\alpha_1 \leq w_i \leq \alpha_2 + \beta_2$ $(1 = 1, 2)$, there exists $t_\varepsilon > 0$ such that

$$\int_0^{t_\varepsilon} \int_{-R}^R \frac{1}{\tau}|z_1(x,\tau) - z_2(x,\tau)| dx\, d\tau \leq \varepsilon\ .$$

On the other hand,

$$\int_{t_\varepsilon}^T \int_{-R}^R \frac{1}{\tau}|z_1(x,\tau) - z_2(x,\tau)| dx\, d\tau \leq \frac{1}{t_\varepsilon}\|z_1 - z_2\|_{L^1(Q)}\ .$$

Therefore, for any $\varepsilon > 0$ there is $\delta > 0$ such that if $\|z_1 - z_2\|_{L^1(Q)} < \delta$, then $\|\mathcal{T}z_1 - \mathcal{T}z_2\|_{L^1(Q)} < \varepsilon$. Hence the continuity of the map $\mathcal{T}$ is proved.

Due to Steps 1–3 above, for any fixed rectangle Q there is a fixed point of the map $\mathcal{T}$ in $B(Q)$. Let $\overline{z}$ be this fixed point. Then, the function $\overline{u} = \frac{1}{z}\overline{z}$ is a fixed point of Λ in $B(Q)$ and the conclusion follows. □

Proof of Theorem 5.2. It follows by Propositions 5.3 and 5.6. □

ON MAXWELL'S EQUATIONS IN AN ELECTROMAGNETIC FIELD WITH THE TEMPERATURE EFFECT*

HONG-MING YIN†

Abstract. This paper deals with Maxwell's equations coupled with a nonlinear heat equation. The system models an induction heating process for a conductive material in which the electrical conductivity strongly depends on the temperature. It is shown that the evolution system has a global weak solution if the electrical conductivity is bounded. For the case of one space dimension, the existence of a global classical solution is established. Moreover, for a quasi-stationary state field it is proved that the temperature will blow up in finite time if the electric conductivity satisfies certain growth conditions.

1. Introduction.

Induction heating is commonly used in industrial operations such as metal hardening and preheating for forging operations (see [5, 14]). The investigation of an induction heating system usually relies upon a series of expensive, long, and complicated experiments. The mathematical analysis and numerical simulation for induction heating play an important role in the designing process. In this paper we shall investigate how a conductive material is heated up by using electromagnetic waves.

The mathematical model of induction heating consists of Maxwell's equations coupled with a nonlinear heat equation (see section 2). The analysis of this full system is quite complicated. The common method in the previous study of induction heating is to assume that the electric field $\mathbf{E}$ is given by certain special time-harmonic form. With this assumption for $\mathbf{E}$, one can decouple Maxwell's equations from the nonlinear heat equation and then study the heat equation alone (see [4, 5, 8, 9, 10, 14, 16] for example). This method is a good approximation of the full system when the electrical conductivity of the targeted material is not sensitive with respect to the change of the temperature. The microwave cooking is partly based on this approximation (see [14]), since the electric conductivity of most water-like foodstuffs has only a small change with respect to the change of temperature. However, the electric field $\mathbf{E}$ is much more complicated than the guessed form if the electric conductivity strongly depends on the temperature. One must take into account the effect of the temperature and investigate the full Maxwell equations along with the nonlinear heat equation.

This paper is devoted to the investigation of the full Maxwell equations coupled with a nonlinear heat equation. We show that the full evolution system has a global solution in some weak sense. The existence proof is based on a standard fixed point argument. The technical difficulty is to show that the mapping is continuous in applying Schauder's fixed point theorem. This difficulty is resolved from the help of the boundedness assumption on the electric conductivity. For a special case where an electrical field depends only one space variable, Maxwell's equation becomes a wave equation with a nonlinear damping which depends on the temperature. For the

†Department of Mathematics, University of Notre Dame, Notre Dame, IN 46656 (hong-ming.yin.3@nd.edu).

damped wave equation, we are able to derive the a priori L^∞-bound of the electric field. With this a priori bound, we establish the existence of a global solution in the classical sense.

The paper is organized as follows. In section 2, we formulate the mathematical model for completeness. The existence of a global weak solution is established in section 3. In section 4, we consider a special case where the electrical field depends only on one space variable and show that the full system has a unique global solution in the classical sense. In section 5, we present a blowup result for temperature in a quasi-stationary field.

2. The mathematical model. For completeness, we shall formulate the mathematical model of an induction heating process. Let a certain conductive material occupy a bounded domain $\Omega \subset R^3$. Let $\mathbf{E}(x,t)$ and $\mathbf{H}(x,t)$ denote the electric and magnetic fields in Ω (hereafter, a bold letter means a vector in R^3). Let $\mathbf{D}(x,t)$ and $\mathbf{B}(x,t)$ be the electric displacement and magnetic induction in Ω, respectively.

Then the classical Maxwell equations hold in Ω (see [11]):

$$\nabla \times \mathbf{E} + \mathbf{B}_t = 0 \qquad \text{(Faraday's law)},$$
$$\nabla \times \mathbf{H} = \mathbf{J} + \mathbf{D}_t \qquad \text{(generalized Ampere's law)},$$

where $\mathbf{J}$ represents the electric current and $\nabla = (\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z})$.

Moreover, we will assume the following constitutive relations [11]:

$$\mathbf{D} = \varepsilon \mathbf{E}, \qquad \mathbf{B} = \mu \mathbf{H}, \qquad \mathbf{J} = \sigma \mathbf{E} \qquad \text{(Omh's law)},$$

where ε, μ, and σ are electric permittivity, the magnetic permeability, and the electric conductivity of the medium, respectively.

Let $u(x,t)$ denote the temperature in Ω. Due to the complexity of the dynamical process, we shall only study how the temperature through the electric conductivity, $\sigma = \sigma(u)$, affects the electromagnetic field in the conductive material. Therefore, we shall normalize the physical constants ε and μ and set $\varepsilon = \mu = 1$.

Note that the local Joule heat generated by the current equals

$$\mathbf{E} \cdot \mathbf{J} = \mathbf{E} \cdot [\sigma(u)\mathbf{E}] = \sigma(u)|\mathbf{E}|^2.$$

Eliminating $\mathbf{D}$ and $\mathbf{B}$ and applying Fourier's law and the conservation of energy for the temperature $u(x,t)$, we obtain the following evolution system for $\mathbf{E}$(x,t), $\mathbf{H}(x,t)$, and $u(x,t)$:

$$\mathbf{E}_t + \sigma(u)\mathbf{E} = \nabla \times \mathbf{H}, \qquad (x,t) \in Q_T, \tag{2.1}$$
$$\mathbf{H}_t + \nabla \times \mathbf{E} = 0, \qquad (x,t) \in Q_T, \tag{2.2}$$
$$u_t - \nabla[k(u)\nabla u] = \sigma(u)|\mathbf{E}|^2, \qquad (x,t) \in Q_T, \tag{2.3}$$

where $Q_T = \Omega \times (0,T]$ with $T > 0$, $\sigma(u)$ and $k(u)$ denote the electrical and the thermal conductivity, respectively, and other physical parameters have been normalized.

When a conductive material is heated up by using induction heating, the mechanism in the material for the electric field $\mathbf{E}$, the magnetic field $\mathbf{H}$, and the temperature u will be determined by the coupled system (2.1)–(2.3) subject to appropriate initial and boundary values.

The system (2.1)–(2.3) has certain similarity to the well-known Maxwell–Vlasov system which has been studied by many authors (see [6, 7] and the references therein). However, to the best of the author's knowledge, little is known about the evolution

system (2.1)–(2.3). This paper is the first attempt to answer some mathematical questions such as the well-posedness of the system (2.1)–(2.3) subject to appropriate initial and boundary conditions. We shall prescribe the following initial-boundary conditions:

$$\nu \times \mathbf{E} = 0,\ u = 0, \qquad (x,t) \in \partial\Omega, \quad t > 0, \tag{2.4}$$

$$\mathbf{E}(x,0) = \mathbf{E}_0(x), \qquad \mathbf{H}(x,0) = \mathbf{H}_0(x), \qquad u(x,0) = u_0(x), \qquad x \in \Omega. \tag{2.5}$$

In some industrial applications (see [3] for example), the electrical displacement $\mathbf{D}$ is negligible. This field is often referred to as quasi-stationary in physics. Since $\mathbf{D} = \varepsilon\mathbf{E}$, we see that $\mathbf{E}_t = 0$. In this case, Maxwell's equations (2.1)–(2.2) reduce to

$$\mathbf{H}_t + \nabla \times [r(u)\nabla \times \mathbf{H}] = 0,$$

where $r(u) = \frac{1}{\sigma(u)}$ is the resistivity of the material. This system was studied in [19]. A global weak solution was obtained in [19], and regularity of the weak solution was studied in [20]. In this paper we shall show that the certain growth condition $r(u)$ is necessary in order to avoid the thermal runaway phenomenon.

3. Global existence of weak solutions. For the reader's convenience, we recall some standard notation.

Let B be a Banach space and $1 \le p < \infty$, and let

$$L^p(0,T;B) = \left\{ f | f : [0,T] \to B \text{ with the norm } ||f||_{L^p(0,T;B)} < \infty \right\},$$

where

$$||f||_{L^p(0,T;B)} = \left[\int_0^T ||f||_B^p dt \right]^{\frac{1}{p}}.$$

The spaces $W^{m,p}(\Omega), H_0^1(\Omega), W_p^{2,1}(Q_T)$, and $C^{1+\alpha,\frac{1+\alpha}{2}}(\bar{Q}_T), C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)$, etc. are the usual Sobolev and classical spaces.

Let

$$C^\infty_{curl}(\bar{\Omega}, R^3) = \left\{ \mathbf{F}(x) : \Omega \to R^3 \text{ is smooth, } \nu \times \mathbf{F} = 0 \text{ on } \partial\Omega \right\},$$

$$H_*(\Omega) = \left\{ \mathbf{F}(x) \in H^1(\Omega; R^3) : \nabla \times \mathbf{F} \in L^2(\Omega; R^3), \nu \times \mathbf{F} = 0 \text{ a.e. on } \partial\Omega \right\}.$$

DEFINITION 3.1. *A bounded domain $\Omega \subset R^3$ is said to be cylindrical if $\Omega = (l_1, l_2) \times \Omega_1$ for some l_1, l_2 and a bounded domain Ω_1 in R^2.*

PROPOSITION 3.2 (see [13]). *Let Ω be a cylinder-type domain in R^3; then $H_*(\Omega)$ is a separable Hilbert space. Moreover, $C^\infty_{curl}(\bar{\Omega}; R^3)$ is dense in $H_*(\Omega)$. Hence, the trace operator*

$$Tr : \mathbf{F}(x) \in H_*(\Omega) \to H^{1/2}(\partial\Omega)$$

is well defined.

From now on, we shall always assume that the domain Ω is a cylinder-type one in R^3.

Consider the following linear Maxwell's equations:

$$\mathbf{E}_t + \sigma(x,t)\mathbf{E} = \nabla \times \mathbf{H}, \qquad (x,t) \in Q_T, \tag{3.1}$$

$$\mathbf{H}_t + \nabla \times \mathbf{E} = 0, \qquad (x,t) \in Q_T, \tag{3.2}$$

$$\nu \times \mathbf{E} = 0, \qquad (x,t) \in \partial\Omega \times (0,T], \tag{3.3}$$

$$\mathbf{E}(x,0) = \mathbf{E}_0(x), \qquad \mathbf{H}(x,0) = \mathbf{H}_0(x), \qquad x \in \Omega. \tag{3.4}$$

H(3.1). Assume that $\mathbf{E}_0(x)$ and $\mathbf{H}_0(x)$ are in $L^2(\Omega; R^3)$.

LEMMA 3.3. *Let the assumption* (3.1) *hold and let the function* $\sigma(x,t)$ *be measurable, nonnegative, and bounded. Then the problem* (3.1)–(3.4) *has a unique weak solution* $(\mathbf{E}, \mathbf{H}) \in L^\infty(0,T; L^2(\Omega; R^3))^2$ *in the following sense:*

$$\int_0^T \int_\Omega \left[-\mathbf{E}\cdot\mathbf{\Phi}_t + \sigma\mathbf{E}\cdot\mathbf{\Phi} - \mathbf{H}\cdot(\nabla\times\mathbf{\Phi})\right] dxdt = \int_\Omega E_0(x)\cdot\mathbf{\Phi}(x,0)dx; \tag{3.5}$$

$$\int_0^T \int_\Omega \left[-\mathbf{H}\cdot\mathbf{\Psi}_t + \mathbf{H}\cdot(\nabla\times\mathbf{\Psi})\right] dxdt = \int_\Omega \mathbf{H}_0(x)\cdot\mathbf{\Psi}(x,0)dx \tag{3.6}$$

for any vector test functions $\mathbf{\Phi}, \mathbf{\Psi} \in H^1(0,T; H^1_*(\Omega; R^3))$.

Moreover, the following energy estimate holds:

$$\int_\Omega \left[|\mathbf{E}|^2 + |\mathbf{H}|^2\right] dx + \int_0^t \int_\Omega \sigma|\mathbf{E}|^2 dxdt = \int_\Omega \left[|\mathbf{E}_0|^2 + |\mathbf{H}_0|^2\right] dx. \tag{3.7}$$

Proof. Since the domain Ω is a cylinder-type one in R^3, the Hilbert space $H_*(\Omega)$ is separable. We can use the finite element method to prove the existence when $\sigma(x,t)$ is only a function of the space variables and belongs to $W^{1,\infty}(\Omega)$; this was done in [13, Theorem 3.1]. For the current case, one can follow the same argument to establish the existence. However, we must clarify how a weak solution takes the initial and boundary value since $(\mathbf{E}, \mathbf{H})$ only belongs to $L^\infty(0,T; L^2(\Omega; R^3))^2$. Introduce a new function

$$\mathbf{W}(x,t) = \int_0^t \mathbf{E}(x,\tau)d\tau.$$

Then the system (3.1)–(3.2) becomes

$$\mathbf{W}_{tt} + \sigma(x,t)\mathbf{W}_t = \nabla\times[\mathbf{H}_0 - \nabla\times\mathbf{W}], \qquad (x,t) \in Q_T, \tag{3.8}$$

$$\nu\times\mathbf{W}_\mathbf{t} = 0, \qquad (x,t) \in \partial\Omega\times(0,T], \tag{3.9}$$

$$\mathbf{W}(x,0) = 0,\ \mathbf{W}_t(x,0) = \mathbf{E}_0(x), \qquad x \in \Omega. \tag{3.10}$$

Now we can easily show that $\mathbf{W} \in H^1(0,T; L^2(\Omega; R^3)) \bigcap L^2(0; T; H_*(\Omega))$ by using the energy method. Moreover, by Lemma 4.1 in Chapter 3 of [12] $\mathbf{W}_t$ is strongly continuous in t in the norm of $L^2(\Omega; R^3)$. It follows that the initial condition (3.10) for $\mathbf{W}$ makes sense. On the other hand, by Proposition 2.1 of [12], the trace of $\mathbf{W}$ on $\partial\Omega$ makes sense. Consequently we can uniquely define the value of $\mathbf{W}_t$ on the boundary $\partial\Omega$ as follows:

$$\nu\times\mathbf{W}_t = 0 \text{ if and only if } \quad \nu\times\mathbf{W} = 0 \qquad \text{on } \partial\Omega\times(0,T].$$

To derive the energy estimate, we note that, for any smooth vector fields $\mathbf{E}(x,t)$ and $\mathbf{H}(x,t)$ with $\nu\times\mathbf{E} = 0$ on $\partial\Omega\times(0,T]$,

$$\int_\Omega (\nabla\times\mathbf{H})\cdot\mathbf{E}dx = \int_\Omega \mathbf{H}\cdot(\nabla\times\mathbf{E})dx.$$

By taking the inner production to (2.1) with $\mathbf{E}$ and to (2.2) with $\mathbf{H}$, respectively, we obtain

$$\frac{d}{dt}\int_\Omega \frac{1}{2}\left[|\mathbf{E}|^2 + |\mathbf{H}|^2\right] dx + \int_\Omega \sigma|\mathbf{E}|^2 dx = 0.$$

Integration over $[0,t]$ yields the desired identity (3.7). The uniqueness of the solution is obvious from the identity (3.7).

The following lemma is elementary, but important, in the proof of the main result.

LEMMA 3.4. *Assume that a uniformly bounded sequence* $\{\sigma_n(x,t)\}$ *converges to* $\sigma(x,t)$ *in* $L^2(Q_T)$. *Let* $(\mathbf{E}_n,\mathbf{H}_n)$ *and* $(\mathbf{E},\mathbf{H})$ *be the corresponding solutions to the system* (3.1)–(3.4). *Then* $\mathbf{E}_n$ *and* $\mathbf{H}_n$ *converge to* $\mathbf{E}$ *and* $\mathbf{H}$, *respectively, in* $L^2(Q_T)$ *as* $n\to\infty$.

Proof. To prove the convergence, we define

$$\hat{\mathbf{E}}_n=\mathbf{E}_n-\mathbf{E},\qquad \hat{\mathbf{H}}_n=\mathbf{H}_n-\mathbf{H}.$$

Then, we have

$$\int_0^T\int_\Omega\Big[-\hat{\mathbf{E}}_n\cdot\mathbf{\Phi}_t-\hat{\mathbf{H}}_n\cdot(\nabla\times\mathbf{\Phi})\Big]\,dxdt=\int\int_{Q_T}[\sigma_n\mathbf{E}_n-\sigma\mathbf{E}]\cdot\mathbf{\Phi}dxdt,$$
$$\int_0^T\int_\Omega\Big[-\hat{\mathbf{H}}_n\cdot\mathbf{\Psi}_t+\hat{\mathbf{E}}_n\cdot(\nabla\times\mathbf{\Psi})\Big]\,dxdt=0.$$

By using Steklov averaging and standard approximation if necessary, we may choose $\mathbf{\Phi}=\hat{\mathbf{E}}_n(x,t)$, $\mathbf{\Psi}=\hat{\mathbf{H}}_n(x,t)$ as test functions to obtain

$$\begin{aligned}&\sup_{0\le t\le T}\int_\Omega[|\hat{\mathbf{E}}_n|^2+|\hat{\mathbf{H}}_n|^2]dx\\&\le\int\int_{Q_T}\Big[\sigma_n|\hat{\mathbf{E}}_n|^2+|\sigma_n-\sigma|\cdot|\mathbf{E}|\cdot|\hat{\mathbf{E}}_n|\Big]\,dxdt\\&\le C\int\int_{Q_T}|\hat{\mathbf{E}}_n|^2dxdt+\int\int_{Q_T}|\sigma_n-\sigma|^2\cdot|\mathbf{E}|^2dxdt\end{aligned}$$

since $0\le\sigma(s)\le\sigma_0$.

Gronwall's inequality implies

$$\sup_{0\le t\le T}\int_\Omega[|\hat{\mathbf{E}}_n|^2+|\hat{\mathbf{H}}_n|^2]dx\le C\int\int_{Q_T}|\sigma_n-\sigma|^2\cdot|\mathbf{E}|^2dxdt.$$

Since σ_n converges to σ in $L^2(Q_T)$, there exists a subsequence, say, σ_{n_k} which converges to σ a.e. on Q_T. By Lebesgue's dominated convergence theorem, it follows that

$$\int\int_{Q_T}|\sigma_{n_k}-\sigma|^2\cdot|\mathbf{E}|^2dxdt\to 0$$

as $n_k\to\infty$. Consequently, we have

$$\sup_{0\le t\le T}\int_\Omega[|\hat{\mathbf{E}}_{n_k}|^2+|\hat{\mathbf{H}}_{n_k}|^2]dx\to 0$$

as $n_k\to\infty$.

On the other hand, since the solution to the problem (3.1)–(3.4) is unique, the whole sequence $(\mathbf{E}_n,\mathbf{H}_n)$ must converge to $(\mathbf{E},\mathbf{H})$ in $L^2(Q_T)$.

Without essential difference, we shall assume that $k(u)=1$ in (2.3) for simplicity.

DEFINITION 3.5. *We say a triple of functions* $\mathbf{E}(x,t),\mathbf{H}(x,t)$, *and* $u(x,t)$ *is a weak solution of the system* (2.1)–(2.5) *if*

$$\mathbf{E},\mathbf{H}\in L^\infty(0,T;L^2(Q_T))\ \textit{and}\ u(x,t)\in L^q(0,T;W_0^{1,q}(\Omega))\ \textit{for some}\ q\in(1,\tfrac{5}{4}),$$

which satisfy

$$\int_0^T \int_\Omega \left[-\mathbf{E}\cdot\mathbf{\Phi}_t + \sigma\mathbf{E}\cdot\mathbf{\Phi} - \mathbf{H}\cdot(\nabla\times\mathbf{\Phi})\right] dxdt = \int_\Omega \mathbf{E}_0(x)\cdot\mathbf{\Phi}(x,0)dx,$$
$$\int_0^T \int_\Omega \left[-\mathbf{H}\cdot\mathbf{\Psi}_t + \mathbf{H}\cdot(\nabla\times\mathbf{\Psi})\right] dxdt = \int_\Omega \mathbf{H}_0(x)\cdot\mathbf{\Psi}(x,0)dx,$$
$$\int_0^T \int_\Omega u[\phi_t + \Delta\phi]dxdt = \int_0^T \int_\Omega \sigma(u)|\mathbf{E}|^2\phi dxdt$$

for any vector functions $\mathbf{\Phi}, \mathbf{\Psi} \in H^1(0,T;H_*(\Omega,R^3))$ *and for any* $\phi(x,t) \in C_0^\infty(Q_T)$. *Moreover, the limit of* $u(x,t)$ *as* t *tends to 0 is* $u_0(x)$ *in the sense of Lebesgue measure.*

Now we study the full evolution system (2.1)–(2.5).

H(3.2). (a) Let $\sigma(s)$ be bounded and uniformly Lipschitz continuous in $[0,\infty)$.

(b) $u_0(x) \in L^2(\Omega)$ with $u_0(x) \geq 0$.

THEOREM 3.6. *Under the assumptions* **H**(3.1)–**H**(3.2), *the problem* (2.1)–(2.5) *has a global weak solution.*

Proof. We shall use Schauder's fixed point theorem to prove the desired result. Let T be an arbitrary fixed number. Let

$$K = \{u(x,t) \in L^{1+\varepsilon_0}(Q_T) : ||u||_{L^{1+\varepsilon_0}(Q_T)} \leq K_0\},$$

where $\varepsilon_0 \in (0, \frac{1}{4})$ is a fixed number and K_0 will be determined later.

For any $v(x,t) \in K$, we solve Maxwell's equations:

$$\mathbf{E}_t + \sigma(v)\mathbf{E} = \nabla\times\mathbf{H}, \qquad (x,t) \in Q_T, \tag{3.11}$$
$$\mathbf{H}_t + \nabla\times\mathbf{E} = 0, \qquad (x,t) \in Q_T, \tag{3.12}$$
$$\nu\times\mathbf{E} = 0, \qquad (x,t) \in \partial\Omega\times(0,T], \tag{3.13}$$
$$\mathbf{E}(x,0) = \mathbf{E}_0(x), \mathbf{H}(x,0) = \mathbf{H}_0(x), \qquad x \in \Omega. \tag{3.14}$$

By Lemma 3.3, the system (3.11)–(3.14) has a unique weak solution $(\mathbf{E},\mathbf{H}) \in L^\infty(0,T;L^2(\Omega;R^3))^2$ with

$$\sup_{0\leq t\leq T}\int_\Omega \left[|\mathbf{E}|^2 + |\mathbf{H}|^2\right] dx + \int_0^T\int_\Omega \sigma(v)|\mathbf{E}|^2 dxdt \leq C_0,$$

where C_0 depends only on known data and the bound of $\sigma(s)$, but not on K_0.

Now we define a mapping $\mathcal{M} : v \in K \to u(x,t) = M[v] \in L^{1+\varepsilon_0}(Q_T)$ as follows. For any $v(x,t) \in K$, we define $\mathcal{M}[v] = u(x,t)$ to be the weak solution of the parabolic problem

$$u_t - \Delta u = \sigma(v)|\mathbf{E}|^2, \qquad (x,t) \in Q_T, \tag{3.15}$$
$$u(x,t) = 0, \qquad (x,t) \in \partial\Omega\times(0,T], \tag{3.16}$$
$$u(x,0) = u_0(x), \qquad x \in \Omega, \tag{3.17}$$

where $\mathbf{E}(x,t)$ is the solution of the system (3.11)–(3.14).

Since $\sigma(v)|\mathbf{E}|^2 \in L^1(Q_T)$, the result of Theorem 4 in [2] implies that the parabolic problem (3.15)–(3.17) has a weak solution:

$$u(x,t) \in L^\infty(0,T;L^1(\Omega))\bigcap L^q(0,T;W_0^{1,q}(\Omega))$$

for any $q \in (0, \frac{5}{4})$ (recall the space dimension of Ω is 3). Moreover, there exists a constant C_1 such that for any $q \in (1, \frac{5}{4})$

$$\sup_{0\le t\le T}\int_\Omega |u|dxdt + \int\int_{Q_T} |\nabla u|^q dxdt \le C_1,$$

where C_1 depends only on known data and the bound of $\sigma(s)$, but not on K_0.

Hence, the mapping $\mathcal{M}$ is well defined if we choose $q \in (1+\varepsilon_0, \frac{5}{4})$ and from K to itself if we choose $K_0 = C_1$.

Next we show that $\mathcal{M}$ is continuous. Let $\{v_n(x,t)\} \subset K \subset L^{1+\varepsilon_0}(Q_T)$ be a sequence which converges to $v(x,t)$ in $L^{1+\varepsilon_0}(Q_T)$. Let $(\mathbf{E}_n, \mathbf{H}_n)$ and $(\mathbf{E}, \mathbf{H})$ be the weak solutions of the system (3.11)–(3.14) corresponding to $v_n(x,t)$ and $v(x,t)$, respectively. It is clear by using the same argument that the following energy estimates hold:

$$\sup_{0\le t\le T}\int_\Omega \left[|\mathbf{E}_n|^2 + |\mathbf{H}_n|^2\right] dx + \int_0^T\int_\Omega \sigma(v_n)|\mathbf{E}_n|^2 dxdt \le C_0,$$

$$\sup_{0\le t\le T}\int_\Omega \left[|\mathbf{E}|^2 + |\mathbf{H}|^2\right] dx + \int_0^T\int_\Omega \sigma(v)|\mathbf{E}|^2 dxdt \le C_0.$$

We claim that $\mathbf{E}_n \to \mathbf{E}$ and $\mathbf{H}_n(x,t) \to \mathbf{H}$ in $L^2(Q_T)$ as $n \to \infty$. Indeed, since $v_n \to v$ in $L^{1+\varepsilon_0}(Q_T)$ and $\sigma(s)$ is bounded and uniformly Lipschitz continuous, then

$$\int_{Q_T} |\sigma(v_n) - \sigma(v)|^2 dx \le C\int_{Q_T} |\sigma(v_n) - \sigma(v)|^{1+\varepsilon_0} dxdt \le C\int_{Q_T} |v_n - v|^{1+\varepsilon_0} dxdt \to 0,$$

as $n \to \infty$. The claim follows from Lemma 3.3.

Since the L^1-bound of $\sigma(u_n)|\mathbf{E}|^2$ is independent of n, we have by [2] that, for any $q \in (1, \frac{5}{4})$,

$$||u_n||_{L^q(0,T;W_0^{1,q}(\Omega))} \le C_1,$$

where C_1 depends only on C_0 and known data, but not on n.

From a compactness result of [15], we see that there exists a subsequence of u_n (still denoted by $u_n(x,t)$) such that, for any $q \in (1+\varepsilon_0, \frac{5}{4})$,

$$\begin{aligned} &u_n \to u(x,t), && \text{weakly in } L^q(0,T;W_0^{1,q}(\Omega)) \ ; \\ &u_n \to u(x,t), && \text{strongly in } L^q(Q_T). \end{aligned}$$

Now we show that $u(x,t)$ is the only limit point of the sequence $\{u_n(x,t)\}$ in $L^q(Q_T)$. Assume that $u^*(x,t)$ is a limit point of $\{u_n(x,t)\}$ in $L^q(Q_T)$. Then we can extract a subsequence, denoted by $v_{n_k}(x,t)$, of $\{v_n(x,t)\}$ such that $v_{n_k}(x,t) \to v(x,t)$ a.e. in Q_T.

Now, by Green's representation,

$$u_{n_k}(x,t) = \int_\Omega G(x,y,t,0)u_0(y)dy + \int_0^t\int_\Omega G(x,y;t,\tau)f_{n_k}(y,\tau)dyd\tau,$$

where

$$f_{n_k}(x,t) = \sigma(v_{n_k})|\mathbf{E}_{n_k}|^2$$

and $G(x,y;t,\tau)$ is Green's function of the heat operator with homogeneous Dirichlet boundary conditions. It follows (see [19]) that

$$\sup_{0\le t\le T}\int_\Omega |u_{n_k} - u|dx + \int_0^T\int_\Omega |\nabla u_{n_k} - \nabla u|dxdt \le C||f_{n_k} - f||_{L^1(Q_T)}. \tag{3.18}$$

Since $\mathbf{E}_{n_k}$ converges to $\mathbf{E}$ in $L^2(Q_T)$, it follows that $|\mathbf{E}_{n_k}|^2$ converges to $|\mathbf{E}|^2$ in $L^1(Q_T)$. On the other hand, since $\sigma(s)$ is bounded and v_{n_k} converges to v a.e. in Q_T, it follows that $f_{n_k}(x,t)$ converges to $f(x,t)$ in $L^1(Q_T)$.

Consequently, taking the limit in (3.18), we obtain

$$\sup_{0\le t\le T}\int_\Omega |u^*-u|dx+\int_0^T\int_\Omega |\nabla u^*-\nabla u|dxdt\le 0,$$

i.e., $u^*(x,t)=u(x,t)$ a.e. in Q_T. Therefore, the mapping $\mathcal{M}$ is continuous.

In order to apply Schauder's fixed point theorem, we need to show that the mapping $\mathcal{M}$ is compact. It is clear that $W^{1,1}(\Omega)\subset BV(\Omega)$, where $BV(\Omega)$ denotes the space of functions with bounded total variations in Ω. On the other hand, the embedding from $BV(\Omega)$ to $L^q(\Omega)$ with $q\in(1,\frac{3}{2})$ (recall the space dimension of Ω is 3) is compact. Moreover, since $\nabla u\in L^q(Q_T)$ for any $q\in(1,5/4)$ and $\sigma(v)|\mathbf{E}|^2\in L^1(Q_T)$, it follows that from the equation (3.15),

$$u_t\in L^1(Q_T)+L^1(0,T;W^{-1,q'}(\Omega)),$$

where $q'=\frac{q}{q-1}$.

It follows by [15] that the mapping $\mathcal{M}$ is also compact. Finally, by Schauder's fixed point theorem, we know that the mapping $\mathcal{M}$ has a fixed point, denoted by $u(x,t)$. This fixed point $u(x,t)$ along with the solution $(\mathbf{E},\mathbf{H})$ of (3.11)–(3.14) consists of a weak solution of (2.1)–(2.5). □

The temperature $u(x,t)$ satisfied (2.3) only in the sense of distribution. However, we can improve the regularity of $u(x,t)$ if some additional condition is imposed on $\sigma(u)$.

COROLLARY 3.7. *In addition to the assumptions* **H**(3.1)–**H**(3.2), *assume that there exists a constant* σ_1 *such that*

$$s^p\sigma(s)\le\sigma_1\qquad\text{for } s\ge 0 \text{ and some } p>0;$$

then $v(x,t)=u(x,t)^{\frac{p}{2}}\in L^\infty(0,T;L^2(\Omega))\bigcap L^2(0,T;H_0^1(\Omega))$.

Proof. By choosing $\psi=u^p$ as a test function,

$$\int\int_{Q_T}u^p\sigma(u)|\mathbf{E}|^2dxdt\le C_0\int\int_{Q_T}|\mathbf{E}|^2dxdt\le C,$$

where C is a constant depending only upon the known constants.

Set $v(x,t)=u^{p/2}(x,t)$. Then from (2.3) we easily derive

$$\int_\Omega v^2dx+\int\int_{Q_T}|\nabla v|^2dxdt\le C,$$

where C depends only on the known data and p. We can choose the set K as a subset of the space such that

$$u(x,t)^{\frac{p}{2}}\in L^\infty(0,T;L^2(\Omega))\bigcap L^2(0,T;H_0^1(\Omega)).$$

By the same argument as in the proof of Theorem 3.6, we can obtain the desired result. □

4. One-dimension problem. In this section we consider a special case where the electrical field is parallel to the y-axis; that is, $\mathbf{E}(x,t) = \{0, g(x,t), 0\}$. Then $\mathbf{H}$ must have the form $\mathbf{H} = \{0, 0, h(x,t)\}$. For this special case, the system (2.1)–(2.5) becomes

$$g_t + \sigma(u)g = -h_x, \qquad 0 < x < 1, \quad t > 0, \tag{4.1}$$

$$h_t + g_x = 0, \qquad 0 < x < 1, \quad t > 0, \tag{4.2}$$

$$u_t - (k(u)u_x)_x = \sigma(u)g^2, \qquad 0 < x < 1, \quad t > 0, \tag{4.3}$$

$$g(i,t) = u(i,t) = 0, \qquad t > 0, \quad i = 0, 1, \tag{4.4}$$

$$g(x,0) = g_0(x), h(x,0) = h_0(x), u(x,0) = u_0(x) \geq 0, \qquad 0 \leq x \leq 1. \tag{4.5}$$

H(4.1). (a) Let $\sigma(s)$ and $k(s)$ be C^2 functions and

$$0 \leq \sigma(s) \leq \sigma_0, \quad 0 < k_0 \leq k(s) \leq k_1 < \infty.$$

(b) Let $g_0(x)$ and $h_0(x)$ be $C^3[0,1]$. Moreover, $g_0(x)$ and $h_{0x}(x)$ can be extended as odd functions about $x = 0$ and $x = 1$, and the extended functions are in $C^2(R)$. Furthermore, the following consistency conditions hold:

$$\begin{aligned}
&\sigma(0)g_0(0) = h_0^{'}(0),\ \sigma(0)g_0(1) = h_0^{'}(1),\ g_0^{''}(0) = g_0^{''}(1) = 0,\\
&u_0(0) = u_0(1) = 0,\\
&-[k(0)u_0^{''}(0) + k'(0)u_0^{'}(0)^2] = \sigma(0)g_0(0)^2,\\
&-[k(0)u_0^{''}(1) + k'(0)u_0^{'}(1)^2] = \sigma(0)g_0(1)^2.
\end{aligned}$$

THEOREM 4.1. *Under the assumption* **H**(4.1), *the problem* (4.1)–(4.5) *has a unique global solution in the classical sense:* $g, h \in C^{1+1,1+1}(\mathbf{Q}_T)$ *and* $u(x,t) \in C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)$.

Proof. Introduce

$$w(x,t) = \int_0^t g(x,\tau)d\tau, \qquad (x,t) \in Q_T.$$

Then it is easy to see that $w(x,t)$ satisfies

$$w_{tt} - w_{xx} + \sigma(u)w_t = h_{0x}, \qquad (x,t) \in Q_T, \tag{4.6}$$

$$u_t - (k(u)u_x)_x = \sigma(u)w_t^2, \qquad 0 < x < 1, t > 0, \tag{4.7}$$

$$w(i,t) = u(i,t) = 0, \qquad 0 \leq t \leq T, i = 0, 1, \tag{4.8}$$

$$w(x,0) = 0, w_t(x,0) = g_0(x), u(x,0) = u_0(x), \qquad 0 \leq x \leq 1. \tag{4.9}$$

By the assumption **H**(4.1), we see that a classical solution $g(x,t), h(x,t)$, and $u(x,t)$ exists in Q_{T_0} for a small $T_0 > 0$, which can be done by a standard argument (see [17] for example). To extend the local solution to an arbitrary interval $[0,T]$, we only need to derive an a priori estimate in the classical space.

Since we are deriving a priori estimates, we can always assume that h, g, and u are smooth. We will use C to denote a generic constant which depends only on known data.

By the assumption, we extend the function $g_0(x)$ as an odd function about $x = 0$ and $x = 1$ and the extended function $g_0(x) \in C^2(R)$. By considering $F(x,t) = h_{0x}(x) - \sigma(u)w_t$ as an inhomogeneous term in (4.6), the solution $w(x,t)$ will be an odd function as long as the inhomogeneous term $h_{0x}(x) - \sigma(u)w_t$ is an odd function.

Note that $\sigma(u(x,t)) \geq 0$ is an even function if $u(x,t)$ is an even function about $x=0$ and $x=1$. If we extend $u_0(x)$ as an even function about $x=0$ or $x=1$, then $u(x,t)$ will be an even function since $\sigma(u)w_t^2 \geq 0$. Now it is clear that $w(x,t)$ and $w_t(x,t)$ have the same sign when the space variable x is replaced by $-x$ or $1-x$; it follows that the solution $w(x,t)$ can be represented by the following formula (see [18]):

$$\begin{aligned} w(x,t) &= \frac{1}{2}\int_{x-t}^{x+t} g_0(\xi)d\xi + \frac{1}{2}\int_0^t \int_{x-(t-\tau)}^{x+(t-\tau)} [h_{0y}(y) - \sigma(u(y,\tau))w_\tau(y,\tau)]dyd\tau \\ &= \frac{1}{2}\int_{x-t}^{x+t} g_0(\xi)d\xi + \frac{1}{2}\int_0^t [h_0(x+t-\tau) - h_0(x-t+\tau)]d\tau \\ &\quad -\frac{1}{2}\int_0^t \int_{x-(t-\tau)}^{x+t-\tau} \sigma(u(y,\tau))w_\tau(y,\tau)dyd\tau. \end{aligned} \tag{4.10}$$

Then

$$\begin{aligned} w_t(x,t) &= \frac{1}{2}[g_0(x+t) - g_0(x-t)] + \frac{1}{2}\int_0^t h_0^{'}(x+t-\tau) + h_0^{'}(x-t+\tau)]d\tau \\ &\quad -\frac{1}{2}\int_0^t \sigma(u(y,\tau))w_\tau(y,\tau)\,|_{y=x-t+\tau}^{y=x+t-\tau}\, d\tau. \end{aligned} \tag{4.11}$$

Since $\sigma(s)$ is bounded by σ_0, we have

$$||w_t(\cdot,t)||_{L^\infty(0,1)} \leq ||g_0||_{L^\infty(0,1)} + T||h_0^{'}||_{L^\infty(0,1)} + \sigma_0 \int_0^t ||w_\tau||_{L^\infty(0,1)}d\tau.$$

Gronwall's inequality yields

$$||w_t||_{L^\infty(0,1)} \leq C,$$

where C depends only on σ_0, T, and $||g_0||_{L^\infty(0,1)} + ||h_0||_{L^\infty(0,1)}$.

From the classical theory of parabolic equations, we know from (4.7) that for any $p > 1$,

$$||u||_{W_p^{2,1}(Q_T)} \leq C||\sigma(u)w_t^2||_{L^p(Q_T)} \leq C,$$

where C depends only on p, σ_0, and known data.

Sobolev's embedding implies that for any $\alpha \in (0,1)$,

$$||u||_{C^{1+\alpha,\frac{1+\alpha}{2}}(\bar{Q}_T)} \leq C.$$

Note that

$$\begin{aligned} &\frac{d}{dx}\int_0^t \sigma(u(x+t-\tau,\tau)w_\tau(x+t-\tau,\tau))d\tau \\ &= \int_0^t [\sigma'(u(y,\tau))u_x(y,\tau)w_\tau(y,\tau) + \sigma(u(y,\tau))w_{\tau y}(y,\tau)]_{y=x+t-\tau}\, d\tau. \end{aligned}$$

We can differentiate (4.11) with respect to x and use the boundedness of u_x and w_t to obtain

$$||w_{tx}||_{L^\infty(0,1)} \leq C + C\int_0^t ||w_{\tau x}||_{L^\infty(0,1)}d\tau,$$

which gives the $L^\infty(0,1)$-bound of w_{tx} by Gronwall's inequality. Moreover, the $L^\infty(0,1)$-bound of w_{tx} depends only on known data.

Next, we differentiate (4.11) with respect to t again, after some routine calculations, to obtain

$$||w_{tt}||_{L^\infty(0,1)} \le C + C\int_0^t ||w_{tx}||_{L^\infty(0,1)} d\tau \le C.$$

Set $v(x,t) = u_t(x,t)$. Then it is easy to see that $v(x,t)$ solves the following initial-boundary value problem:

$$\begin{aligned} &v_t - k(u)v_{xx} - k''(u)u_x^2 v - 2k'(u)v_x u_x - k'(u)u_{xx}v \\ &= \sigma'(u)vw_t^2 + 2\sigma(u)w_t w_{tt}, \qquad (x,t) \in Q_T, \end{aligned} \tag{4.12}$$

$$v(0,t) = v(1,t) = 0, \qquad 0 \le t \le T, \tag{4.13}$$

$$v(x,0) = v_0(x), \qquad 0 \le x \le 1, \tag{4.14}$$

where

$$v_0(x) = k(u_0)u_0''(x) + k'(u_0)u_0'(x)^2 + \sigma(u_0)g_0(x)^2.$$

By the $W_p^{2,1}(Q_T)$-estimate for parabolic equations, we see

$$||v||_{W_p^{2,1}(Q_T)} \le C + ||v||_{L^{2p}(Q_T)} + ||u_{xx}||_{L^{2p}(Q_T)} + C||w_{tt}||_{L^p(Q_T)} \le C,$$

where C depends only on known data.

Again, Sobolev's embedding theorem implies that for any $\alpha \in (0,1)$

$$||u_t||_{C^{1+\alpha,\frac{1+\alpha}{2}}(\bar{Q}_T)} \le C.$$

Similarly, by differentiating the equation (4.7) with respect to x we can easily derive that

$$||u_x||_{C^{1+\alpha,\frac{1+\alpha}{2}}(\bar{Q}_T)} \le C.$$

Now we take the derivative with respect to x twice in (4.11) and then use the boundedness of u_{xx} and w_t to deduce

$$||w_{txx}||_{L^\infty(0,1)} \le C + C\int_0^t ||w_{\tau xx}||_{L^\infty(0,1)} d\tau,$$

which yields an a priori bound of $||w_{txx}||_{L^\infty(0,1)}$. Finally, from the definition of w and the system (4.1)–(4.2) we see

$$g(x,t), h(x,t) \in C^{1+1,1+1}(\bar{Q}_T), \qquad u(x,t) \in C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T),$$

and

$$||g||_{C^{1+1,1+1}(\bar{Q}_T)} + ||h||_{C^{1+1,1+1}(\bar{Q}_T)} + ||u||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)} \le C,$$

where $\alpha \in (0,1)$ is arbitrary and C depends only on known data.

With the above a priori estimate, we can use the method of continuity to extend a local solution to an arbitrary interval $[0,T]$. □

5. Maxwell's equations in quasi-stationary fields. In this section we study an electromagnetic field with a negligible electric displacement $\mathbf{D}$. When $\mathbf{D}_t = 0$, then $\mathbf{E}_t = 0$. It follows that the system (2.1)–(2.3) becomes

$$\mathbf{H}_t + \nabla \times [r(u)\nabla \times \mathbf{H}] = 0, \qquad (x,t) \in Q_T, \tag{5.1}$$

$$u_t - \nabla[k(u)\nabla u] = r(u)|\nabla \times \mathbf{H}|^2, \qquad (x,t) \in Q_T, \tag{5.2}$$

where $r(u) = \frac{1}{\sigma(u)}$.

We shall prescribe the following initial-boundary conditions for $\mathbf{H}$ and $u(x,t)$:

$$\mathbf{H}(x,t) = \mathbf{F}(x,t),\ u_\nu(x,t) = 0, \qquad (x,t) \in S_T = \partial\Omega \times (0,T], \tag{5.3}$$

$$\mathbf{H}(x,0) = \mathbf{H}_0(x), u(x,0) = u_0(x), \qquad x \in \Omega, \tag{5.4}$$

where u_ν denotes the outward normal derivative to $\partial\Omega$.

$\mathbf{H}(5.1)$. (a) Let $r(u)$ and $k(u)$ be $C^{1+\alpha}(R)$ functions. There exists a constant $a_0 > 0$ such that

$$r(u) \geq a_0, k(u) \geq a_0.$$

(b) Let $u_0(x) \geq 0, u_0(x) \in C^{2+\alpha}(\bar{\Omega})$, and $\mathbf{H}_0 \in C^{2+\alpha}(\bar{\Omega})^3, \mathbf{F}(x,t) \in C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)^3$. The following consistency conditions hold:

$$\begin{aligned}
&\nabla \cdot \mathbf{H}_0(x) = 0, && x \in \Omega,\\
&u_{0\nu}(x) = 0, \mathbf{F}(x,0) = \mathbf{H}_0(x), && \text{on } \partial\Omega,\\
&\mathbf{F}_t(x,0) + \nabla \times [r(u_0(x))\nabla \times \mathbf{H}_0] = 0, && \text{on } \partial\Omega.
\end{aligned}$$

LEMMA 5.1. *Under the assumption* $\mathbf{H}(5.1)$ *the evolution system* (5.1)–(5.4) *has a classical solution* $\mathbf{H}(x,t) \in C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)^3, u(x,t) \in C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)$ *for some* $T > 0$.

Proof. The proof is quite standard. We shall only outline the main steps. For simplicity, we take $k(u) = 1$. It will be seen that the general case can be handled similarly. We also assume that $T \leq 1$ since we are only concerned with the local existence.

Let

$$K = \{u(x,t) \in C^{\alpha,\frac{\alpha}{2}}(\bar{Q}_T) : u(x,t) \geq 0, ||u||_{C^{1+\alpha,\frac{1+\alpha}{2}}(\bar{Q}_T)} \leq K_0\},$$

where K_0 is a constant to be specified later. It is clear that K is a bounded convex subset of $C^{2,1}(\bar{Q}_T)$. Given $u^*(x,t) \in K$, we consider the following evolution system:

$$\mathbf{H}_t + \nabla \times [r(u^*)\nabla \times \mathbf{H}] = 0, \qquad (x,t) \in Q_T, \tag{5.5}$$

$$\mathbf{H}(x,t) = \mathbf{F}(x,t), \qquad (x,t) \in \partial\Omega \times (0,T]; \tag{5.6}$$

$$\mathbf{H}(x,0) = \mathbf{H}_0(x), \qquad x \in \Omega. \tag{5.7}$$

Observe that

$$\nabla \times [r(u^*)\nabla \times \mathbf{H}] = -r(u^*)\Delta\mathbf{H} + r'(u^*)\nabla u^* \times (\nabla \times \mathbf{H}).$$

By the results of parabolic systems (see [12]), there exists a unique classical solution $\mathbf{H}(x,t)$ for some $T > 0$. Moreover, there exists a constant $C(K_0)$ such that

$$||\mathbf{H}||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)} \leq C(K_0),$$

where $C(K_0)$ depends only on K_0 and the known data but is independent of the lower bound of T.

Now we define a mapping as follows:

$$M : u^*(x,t) \in K \to u(x,t) = M[u^*],$$

where $u(x,t)$ is the solution to the following problem:

$$u_t - \Delta u = r(u^*)|\nabla \times \mathbf{H}|^2, \qquad (x,t) \in Q_T, \tag{5.8}$$

$$u_\nu = 0, \qquad (x,t) \in \partial\Omega \times (0,T], \tag{5.9}$$

$$u(x,0) = u_0(x), \qquad x \in \Omega, \tag{5.10}$$

where $\mathbf{H}$ is the solution to the system (5.5)–(5.7).

The classical theory of parabolic equations ensures that the above parabolic problem has a unique classical solution on $[0,T]$. Moreover,

$$||u||_{C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)} \le C(K_0),$$

where $C(K_0)$ depends on known data and K_0, but not on the lower bound of T. We know that the mapping M is well defined. The continuity of the mapping M is quite standard since $u^* \in C^{1+\alpha,\frac{1+\alpha}{2}}(\bar{Q}_T)$. The compactness of the mapping M is clear since $u(x,t) = M[u^*] \in C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)$ and the embedding operator from $C^{2+\alpha,1+\frac{\alpha}{2}}(\bar{Q}_T)$ to $C^{2,1}(\bar{Q}_T)$ is compact.

Now we show that the mapping M is from K into K. Indeed,

$$\begin{aligned} ||u||_{C^{1+\alpha,\frac{1+\alpha}{2}}(\bar{Q}_T)} &\le \sum_{|k|\le 2} \sup_{Q_T} |D^k u| + \sup_{Q_T} |u_t| \\ &\le [T^\alpha + T^{\alpha/2}]C(K_0) + ||u_0||_{C^2(\bar{\Omega})} \\ &\le 1 + ||u_0||_{C^2(\bar{\Omega})}, \end{aligned}$$

provided that we restrict T such that $TC(K_0) \le 1$.

By Schauder's fixed point theorem, the mapping M has a fixed point. This fixed point $u(x,t)$ along $\mathbf{H}$ obtained from (5.5)–(5.8) consists of a solution to the system (5.1)–(5.4). The uniqueness is clear since the solution is classical.

H(5.2). (a) The function $r(s)$ satisfies

$$\int_{a_0}^{\infty} \frac{1}{r(s)} ds < \infty$$

for some constant $a_0 > 0$.

(b) The initial and boundary data $u_0(x)$ and $\mathbf{F} = (F_1, F_2, F_3)$ satisfy the following inequality:

$$u_0(x) \ge a_0, \int_\Omega \int_{u_0(x)}^{\infty} \frac{1}{r(s)} ds dx < \frac{1}{C_0} \sum_{i=1}^{3} \int_0^\infty \int_S |F_i - (F_i)_s|^2 ds dt,$$

where C_0 is the best constant from the trace inequality

$$\sum_{i=1}^{3} \int_S |F_i - (F_i)_s|^2 ds \le C_0 \sum_{i,j=1}^{3} \int_\Omega |H_{ix_j}|^2 dx,$$

$$\mathbf{H} = (H_1, H_2, H_3),\ (F_i)_s = \frac{1}{|S|} \int_S F_i ds, i = 1,2,3,$$

while ds represents the surface element and $|S|$ denotes the $(n-1)$-dimension Lebesgue measure.

Now we can state the following blowup result.

THEOREM 5.2. *Let the assumptions* $\mathbf{H}(5.1)$–$\mathbf{H}(5.2)$ *hold. Then* $u(x,t)$ *will blow up in finite time.*

Proof. The argument below follows the idea from [1]. It is clear from the assumption and the maximum principle that $u(x,t) \geq a_0$ whenever the solution exists. Suppose the problem (5.1)–(5.4) has a smooth solution for any $T > 0$. Define

$$A(t) = \int_\Omega \int_{u(x,t)}^{\infty} \frac{1}{r(s)} ds dx.$$

Then $A(t)$ is well defined for all $t < \infty$. By using (5.2) and performing the integration by parts, we see

$$\begin{aligned} A'(t) &= -\int_\Omega \frac{u_t}{r(u)} dx \\ &= -\int_\Omega \frac{\nabla[k(u)\nabla u]}{r(u)} dx - \int_\Omega |\nabla \times \mathbf{H}|^2 dx \\ &= -\int_\Omega \frac{r'(u)k(u)|\nabla u|^2}{r(u)^2} dx - \int_\Omega |\nabla \times \mathbf{H}|^2 dx \\ &\leq -\int_\Omega |\nabla \times \mathbf{H}|^2 dx. \end{aligned}$$

It follows that

$$0 \leq A(t) \leq A(0) - \int_0^t \int_\Omega |\nabla \times \mathbf{H}|^2 dx dt.$$

Since $\nabla \cdot \mathbf{H}_t(x,t) = 0$ from (5.1), it follows that

$$\nabla \cdot \mathbf{H}(x,t) = \nabla \cdot \mathbf{H}_0(x) = 0.$$

Performing integration by parts, we obtain

$$\begin{aligned} &\int_\Omega |\nabla \times \mathbf{H}|^2 dx \equiv \int_\Omega [|\nabla \cdot \mathbf{H}|^2 + |\nabla \times \mathbf{H}|^2] dx \\ &= \sum_{i,j=1}^{3} \int_\Omega |H_{ix_j}|^2 dx. \end{aligned}$$

It follows that

$$0 \leq A(t) \leq A(0) - \sum_{i,j=1}^{3} \int_0^t \int_\Omega |H_{ix_j}|^2 dx dt.$$

Now the trace inequality implies

$$\sum_{i=1}^{3} \int_S |F_i - (F_i)_s|^2 ds \leq C_0 \sum_{i,j=1}^{3} \int_\Omega |H_{ix_j}|^2 dx,$$

where C_0 is a constant depending only upon the space dimension n and the boundary $S = \partial\Omega$. In particular, C_0 does not depend on t. Consequently,

$$0 \leq A(t) \leq A(0) - \frac{1}{C_0} \int_0^t \int_S |F - (F)_s|^2 ds$$

will become negative for large t by the assumption $\mathbf{H}(5.2)$, a contradiction.

It follows that $u(x,t)$ will become unbounded in finite time. ∎

Acknowledgment. The author would like to thank Professor Bei Hu for many helpful discussions.

ALL-TIME EXISTENCE OF CLASSICAL SOLUTIONS FOR SLIGHTLY COMPRESSIBLE FLOWS*

THOMAS HAGSTROM† AND JENS LORENZ†

Abstract. In two space dimensions and under periodic boundary conditions, the solution of the incompressible Navier–Stokes equations is known to remain smooth for all time. In this paper we consider the system of equations describing isentropic, compressible flow and show a similar result if the Mach number is sufficiently small and the initial data are almost incompressible. It is not assumed that the initial data are small. To the leading order, the solution consists of the corresponding incompressible flow plus a highly oscillatory part describing sound waves.

Key words. Navier–Stokes equations, compressible flows, all-time existence, multiple scales

PII. S0036141097315312

1. Introduction. In this paper we consider the Navier–Stokes equations for isentropic, compressible flows of a polytropic gas:

$$\begin{aligned} &u_t + (u\cdot\nabla)u + (1+\varepsilon^2\rho)^{\gamma-2}\nabla\rho \\ &\qquad = (1+\varepsilon^2\rho)^{-1}\left(\nu\Delta u + \eta\nabla\nabla\cdot u\right), \quad \nu>0, \quad \eta+\nu>0, \end{aligned} \tag{1.1}$$

$$\varepsilon^2\left(\rho_t + (u\cdot\nabla)\rho\right) + (1+\varepsilon^2\rho)\nabla\cdot u = 0\ . \tag{1.2}$$

The scalings and assumptions leading to these equations are given in the Appendix, where it also is explained that ρ describes the scaled fluctuations of the density. If the parameter ε, which represents the Mach number, is formally set to zero, we obtain the equations for incompressible flow,

$$U_t + (U\cdot\nabla)U + \nabla P = \nu\Delta U, \quad \nu>0, \tag{1.3}$$

$$\nabla\cdot U = 0\ . \tag{1.4}$$

We restrict the discussion to two space variables

$$(x,y)\in(\mathbb{R}\mathrm{mod}2\pi)^2 =: T^2;$$

i.e., we assume that the functions

$$u(x,y,t),\ \rho(x,y,t),\ U(x,y,t),\ P(x,y,t)$$

are 2π-periodic in x and in y. (We comment below on the three-dimensional case.)

For $\varepsilon > 0$, the equations (1.1), (1.2) form a coupled parabolic–hyperbolic system, for which we give initial conditions

$$u = u_0(x,y), \quad \rho = \rho_0(x,y) \qquad \text{at} \quad t = 0\ . \tag{1.5}$$

For simplicity,[1] we assume that $u_0, \rho_0 \in C^\infty(T^2)$ and that they have mean zero:

$$\int_{T^2} u_0 dxdy\ , \quad \int_{T^2} \rho_0 dxdy = 0. \tag{1.6}$$

(Note that these assumptions on the mean are without essential loss of generality, as they may be imposed by a Galilean transformation and by choosing the reference density to be the mean initial density.) For the incompressible equations (1.3), (1.4), one can only prescribe an initial velocity field $U_0(x,y)$, which must be divergence-free, to obtain a classical solution,

$$U = U_0(x,y) \qquad \text{at} \quad t = 0\ . \tag{1.7}$$

Here we assume $U_0 \in C^\infty$, $\int_{T^2} U_0 = 0$, $\nabla \cdot U_0 = 0$. To eliminate the free (time-dependent) constant in the incompressible pressure, we impose the side condition

$$\int_{T^2} P(x,y,t)dxdy = 0, \quad t \geq 0\ . \tag{1.8}$$

It is well known that the incompressible problem (1.3), (1.4), (1.7), (1.8) has a unique classical solution $(U,P) \in C^\infty(T^2 \times [0,\infty))$, and this solution—together with all its derivatives—tends to zero at an exponential rate as $t \to \infty$. (See, e.g., [5, Chap. 9] and extensions of the arguments therein.)

The aim of this paper is to show all-time existence also for the compressible problem (1.1), (1.2), (1.5) provided that $\varepsilon > 0$ is sufficiently small and the initial data u_0, ρ_0 are *almost incompressible.* A precise statement is given in the next section.

Under the assumptions of our theorem, the compressible solution $u = u^\varepsilon, \rho = \rho^\varepsilon$ consists of leading order of the incompressible flow U, P, and it is essential for our proof that U, P decays to zero as $t \to \infty$. Thus, at present it is not clear if our result generalizes to Euler flow ($\nu = \eta = 0$) or to the forced equation

$$u_t + (u \cdot \nabla)u + (1+\varepsilon^2\rho)^{\gamma-2}\nabla\rho = (1+\varepsilon^2\rho)^{-1}\left(\nu\Delta u + \eta\nabla\nabla\cdot u + F(x,y,t)\right),$$

$$\varepsilon^2\left(\rho_t + (u\cdot\nabla)\rho\right) + (1+\varepsilon^2\rho)\nabla\cdot u = 0$$

with $F \in C^\infty$. In both cases, the solution U, P is C^∞ for $0 \leq t < \infty$, but generally does not tend to zero.

A generalization of our result to three-dimensional flow is straightforward, however, if we assume that the initial incompressible velocity field $U_0(x,y,z)$ leads to a classical solution U, P for $0 \leq t < \infty$, which—together with all its derivatives—tends to zero as $t \to \infty$.

Our approach can also be used to establish an asymptotic expansion result for $u^\varepsilon, \rho^\varepsilon$. Leading order corrections to U, P consist of fast oscillations of the pressure and the dilatation, $\nabla \cdot u^\varepsilon$. These corrections are solutions of the damped wave equation

$$w_{tt} = \frac{1}{\varepsilon^2}\Delta w + (\nu+\eta)\Delta w_t\ .$$

[1] Only a finite number of derivatives will be used. We work with C^∞-functions so that we do not have to keep track of the exact number of derivatives required at every step.

We will not elaborate on this here, however, since corresponding asymptotic expansions in finite time intervals have already been derived in [3, 4, 6].

There has been much recent work on weak solutions of the equations of compressible flow. Hoff (see [2] and references therein) has considered discontinuous initial data in one space dimension. Lions [7, 8, 9] has developed a multidimensional theory of weak solutions for the isentropic system we consider and has established connections with the theory of weak solutions for the incompressible case. Results on classical solutions for small data are also known. See [1] for a proof using the techniques of this paper and for references to earlier work.

2. Notations and statement of main theorem. The Euclidean inner product and norm on $\mathbb{C}^n$ (and $\mathbb{R}^n$) are denoted by

$$\langle u, v\rangle = \sum_{j=1}^{n} \bar{u}_j v_j, \quad |u| = \langle u, u\rangle^{1/2} .$$

Also, if $A \in \mathbb{C}^{n\times n}$ is an $n\times n$ matrix, then $|A|$ denotes the corresponding matrix norm. If $H_1, H_2 \in \mathbb{C}^{n\times n}$ are Hermitian matrices, then we write $H_1 \le H_2$ iff $u^* H_1 u \le u^* H_2 u$ for all $u \in \mathbb{C}^n$. For functions $u, v \in L_2 = L_2(T^2, \mathbb{R}^n)$, the L_2-inner product and norm are defined by

$$(u, v) = \int_{T^2} \langle u(x, y), v(x, y)\rangle dxdy, \quad \|u\| = (u, u)^{1/2} .$$

We recall Parseval's relation,

$$(u, v) = \sum_{k\in\mathbb{Z}^2} \langle \hat{u}(k), \hat{v}(k)\rangle,$$

where

$$\hat{u}(k) = \frac{1}{2\pi} \int_{T^2} e^{-i(k_1 x + k_2 y)} u(x, y) dxdy .$$

For spatial differential expressions we use multi-index notation,

$$D^\alpha = \frac{\partial^{|\alpha|}}{\partial x^{\alpha_1} \partial y^{\alpha_2}}, \quad |\alpha| = \alpha_1 + \alpha_2 .$$

We partially order multi-indices by

$$\beta < \alpha \iff \beta_1 \le \alpha_1, \quad \beta_2 \le \alpha_2, \quad \beta \ne \alpha.$$

The Sobolev inner products and norms, based on L_2, are

$$(u, v)_j = \sum_{|\alpha|\le j} (D^\alpha u, D^\alpha v) , \quad \|u\|_j = (u, u)_j^{1/2} , \quad j = 1, 2, \ldots .$$

We write $H^j = H^j(T^2, \mathbb{R}^n)$ for the corresponding Sobolev space. The sup-norm of any bounded function u is denoted by $|u|_\infty$.

In our main theorem formulated next, let $U_0 \in C^\infty(T^2)$ denote an incompressible velocity field and let $P_0 = P_0(x, y)$ denote the corresponding pressure at $t = 0$; i.e., if U, P is the solution of (1.3), (1.4), (1.7), (1.8), then $P_0(x, y) = P(x, y, 0)$.

THEOREM 2.1. *Consider the compressible problem,* (1.1), (1.2), (1.5), (1.6), *with* $u_0, \rho_0 \in C^\infty(T^2)$, $\nu > 0, \varepsilon > 0$, $\eta + \nu > 0$. *There is* $\varepsilon_0 = \varepsilon_0(U_0, \nu, \eta) > 0$ *and* $\delta_0 = \delta_0(U_0, \nu, \eta) > 0$ *so that the following holds. If* $0 < \varepsilon \le \varepsilon_0$ *and*

$$\|u_0 - U_0\|_3^2 + \varepsilon^2 \|\rho_0 - P_0\|_3^2 \le \delta_0^2 \ , \tag{2.1}$$

then the solution u, ρ *is in* $C^\infty(T^2 \times [0, \infty))$ *and approaches a uniform state* $(\bar{u}'_\infty, 0)$ *as* $t \to \infty$.

A main point of the theorem is that the radius, given by δ_0, of the ball about incompressible data can be chosen independently of the singular perturbation parameter $0 < \varepsilon < \varepsilon_0$. We note that the bounded derivative principle (in finite time intervals) is valid for the system (1.1), (1.2); see [6]. Thus, a highly oscillatory part of the solution could be suppressed by proper initialization. We emphasize that our theorem does *not* require such an initialization; i.e., a highly oscillatory part (sound waves) is generally present in the solution. The amplitude of the sound waves is initially controlled by δ_0.

An outline of the proof follows. If we subtract the incompressible solution U, P from u, ρ, then we obtain equations for the differences $u' = u - U, \rho' = \rho - P$ with a forcing term of order $\mathcal{O}(\varepsilon^2)$. The details are carried out in section 3. The 3-vector

$$w = (u', \varepsilon\rho')^T$$

satisfies a coupled parabolic–hyperbolic system, where the large hyperbolic part is symmetrized. This symmetrization is the reason for multiplying ρ' by ε. The system satisfied by w is central for our discussion.

General results on coupled parabolic–hyperbolic systems (see, for example, [1]) imply that w is C^∞ in some maximal interval $0 \le t < t_\varepsilon$, and if t_ε is finite, then

$$\sup_{0 \le t < t_\varepsilon} \|w(\cdot, t)\|_3 = \infty \ .$$

(In N space dimensions, the crucial degree of smoothness is given by the smallest integer $s > \frac{N}{2} + 1$. For $N = 2$ we have $s = 3$.) Thus it suffices to show that $\|w(\cdot, t)\|_3$ remains bounded in order to obtain all-time existence and C^∞ smoothness.

Standard L_2-estimates for w and its space derivatives are not good enough to imply all-time existence. A crucial step is the construction of a new norm $\|\cdot\|_H$, in which the solution of the linearized constant coefficient problem decays exponentially. The construction of this new norm is carried out in section 4. A main technical difficulty is to obtain ε-independent bounds for the related symmetrizer.

3. Equations for the perturbed variables. The solution u, ρ of (1.1), (1.2), (1.5) consists of a slow part and a part which is highly oscillatory in time. Following [6], we first subtract the slow part of the solution in order to obtain an equation with small initial data for the remainder.

If U, P denotes the solution of the incompressible problem (1.3), (1.4), (1.7), (1.8), then we define new variables u', ρ' by

$$u = U + u', \quad \rho = P + \rho' \ .$$

A lengthy but straightforward computation yields

$$\begin{aligned} &u'_t + (U \cdot \nabla)u' + (u' \cdot \nabla)U + (u' \cdot \nabla)u' + \nabla\rho' + \varepsilon^2(P + \rho')\Pi(0, \varepsilon^2(P + \rho'))\nabla\rho' \\ &\quad + \varepsilon^2\rho' F(P, U, \rho', \varepsilon) = (1 + \varepsilon^2 P + \varepsilon^2\rho')^{-1} (\nu\Delta u' + \eta\nabla\nabla \cdot u') + \varepsilon^2 g_1 \ , \end{aligned} \tag{3.1}$$

$$\varepsilon^2 (\rho'_t + (U \cdot \nabla)\rho' + (u' \cdot \nabla)P + (u' \cdot \nabla)\rho') + (1 + \varepsilon^2 P + \varepsilon^2\rho')\nabla \cdot u' = \varepsilon^2 g_2 \tag{3.2}$$

with

$$\Pi(a,b) = (\gamma-2)\int_0^1 (1+a+bz)^{\gamma-3}dz,$$
$$F = \Pi(\varepsilon^2 P, \varepsilon^2\rho')\nabla P + \nu(1+\varepsilon^2 P)^{-1}(1+\varepsilon^2 P+\varepsilon^2\rho')^{-1}\Delta U,$$
$$g_1 = -P\Pi(0,\varepsilon^2 P)\nabla P - \nu P(1+\varepsilon^2 P)^{-1}\Delta U,$$
$$g_2 = -(P_t + (U\cdot\nabla)P).$$

The variables u', ρ' satisfy initial conditions

$$u' = u_0'(x,y), \quad \rho' = \rho_0'(x,y) \qquad \text{at} \quad t=0\ , \tag{3.3}$$

where $u_0' = u_0 - U_0, \rho_0' = \rho_0 - P_0$, and therefore

$$\|u_0'\|_3^2 + \varepsilon^2\|\rho_0'\|_3^2 \le \delta_0^2 \tag{3.4}$$

by assumption (2.1). We note that the incompressible solution satisfies estimates

$$\|U(\cdot,t)\|_j + \|P(\cdot,t)\|_j \le C_j e^{-c_j t}, \quad t\ge 0, \quad j=0,1,\dots \tag{3.5}$$

with $C_j > 0$ and $c_j > 0$ independent of t. Corresponding estimates for time derivatives follow from the differential equation. (We will use the following convention: C, C_j, etc. denote sufficiently large constants which may depend on U_0 and the viscosities ν, η. Similarly, c, c_j, etc. denote sufficiently small positive constants which may depend on U_0 and ν, η. All constants are independent of $u_0, \rho_0, t, \varepsilon$, and the wave vector k used below. At different appearances, the constants may have different meanings.)

The inhomogeneous terms $\varepsilon^2 g_1$, $\varepsilon^2 g_2$ in (3.1), (3.2) can be reduced to higher order by constructing additional terms in the expansion of the "slow" part of the solution [6], but this is unnecessary for our purposes.

We also note that the nonlinearities in (3.1), (3.2) are smooth only under some restrictions on the arguments. To be specific, we must have $(1+\varepsilon^2 P), (1+\varepsilon^2\rho'), (1+\varepsilon^2 P+\varepsilon^2\rho') > 0$. As we derive time-uniform bounds on the solution valid for all ε sufficiently small, we can guarantee that the arguments remain in the appropriate domains by further restricting ε_0 if necessary.

To motivate a scaling that we use below, we first consider the linear constant coefficient system obtained from (3.1), (3.2) by setting the incompressible solution, (U,P) to zero and ignoring nonlinearities:

$$u_t' + \nabla\rho' = \nu\Delta u' + \eta\nabla\nabla\cdot u', \tag{3.6}$$

$$\varepsilon^2\rho_t' + \nabla\cdot u' = 0\ . \tag{3.7}$$

For $\nu = \eta = 0$ this system is hyperbolic, but unsymmetric, and in fact strongly unbalanced for $0 < \varepsilon \ll 1$. To symmetrize this underlying hyperbolic system, we use the variable $\varepsilon\rho'$ instead of ρ'. Thus we introduce the 3-vector

$$w = \begin{pmatrix} u' \\ \varepsilon\rho' \end{pmatrix}.$$

Returning to the full system (3.1), (3.2) and dividing (3.2) by ε, we obtain the following system for w:

$$w_t + ((U+u')\cdot\nabla)w = A_\varepsilon w + \varepsilon G + Q. \tag{3.8}$$

Here A_ε is the constant coefficient operator (compare with (3.6), (3.7))

$$A_\varepsilon = -\frac{1}{\varepsilon}\begin{pmatrix} 0 & 0 & \partial_x \\ 0 & 0 & \partial_y \\ \partial_x & \partial_y & 0 \end{pmatrix} + \begin{pmatrix} \nu\Delta + \eta\frac{\partial^2}{\partial x^2} & \eta\frac{\partial^2}{\partial x \partial y} & 0 \\ \eta\frac{\partial^2}{\partial x \partial y} & \nu\Delta + \eta\frac{\partial^2}{\partial y^2} & 0 \\ 0 & 0 & 0 \end{pmatrix}, \tag{3.9}$$

G is the inhomogeneous term

$$G = \begin{pmatrix} \varepsilon g_1 \\ g_2 \end{pmatrix}, \tag{3.10}$$

and the remaining terms Q are given by

$$Q = Q_1 + Q_2, \tag{3.11}$$

$$Q_1 = \begin{pmatrix} \frac{(\varepsilon w^{(3)} + \varepsilon^2 P)}{(1+\varepsilon w^{(3)} + \varepsilon^2 P)}\,(\nu\Delta u' + \eta\nabla\nabla\cdot u') - (w^{(3)} + \varepsilon P)\Pi(0, \varepsilon w^{(3)} + \varepsilon^2 P)\nabla w^{(3)} \\ 0 \end{pmatrix}, \tag{3.12}$$

$$Q_2 = \begin{pmatrix} -(u'\cdot\nabla)U - \varepsilon w^{(3)} F \\ -\varepsilon(u'\cdot\nabla)P - (w^{(3)} + \varepsilon P)\nabla\cdot u' \end{pmatrix}. \tag{3.13}$$

The initial condition for w is

$$w = w_0(x,y) := \begin{pmatrix} u_0' \\ \varepsilon\rho_0' \end{pmatrix} \quad \text{at} \quad t = 0;$$

thus

$$\|w_0\|_3 \le \delta_0. \tag{3.14}$$

In the next section we consider the constant coefficient system $w_t = A_\varepsilon w$.

4. Decay estimates for $w_t = A_\varepsilon w$. Let $w = w(x,y,t)$ denote a solution of the linear constant coefficient system $w_t = A_\varepsilon w$ with A_ε given by (3.9). The standard L_2-estimate reads

$$\begin{aligned} \frac{d}{dt}\|w\|^2 &= 2(w, w_t) \\ &= -2\nu\sum_{j=1}^{2}\|Dw^{(j)}\|^2 - 2\eta\|\nabla\cdot u'\|^2 \ \le\ 0\ . \end{aligned}$$

Here, $\|Dv\|^2 = \|v_x\|^2 + \|v_y\|^2$. Clearly, the third component of w does not appear on the right side (since the third component of (3.9) does not contain the viscosity terms), and therefore we cannot obtain exponential decay of w in the L_2-norm. This is the fundamental reason for the difficulty in proving our main theorem. We will, however, construct a new norm, which is equivalent to the L_2 norm, in which we have exponential decay, except for the spatial averages of w. (The spatial averages of the solutions of $w_t = A_\varepsilon w$ remain constant in time. For the full system (3.8), they will require a separate consideration, with bounds following from the conservation of mass and momentum.)

To construct the new norm, we use Fourier expansion in space. The Fourier representation of w is

$$w(x,y,t) = \frac{1}{2\pi}\sum_{k\in\mathbb{Z}^2} e^{ik_1x+ik_2y}\hat{w}(k,t)$$

with

$$\hat{w}(k,t) = \frac{1}{2\pi}\int_{T^2} e^{-ik_1x-ik_2y}w(x,y,t)dxdy\ ,$$

and the system $w_t = A_\varepsilon w$ transforms to

$$\hat{w}_t(k,t) = \hat{A}_\varepsilon(k)\hat{w}(k,t), \quad k\in\mathbb{Z}^2\ . \tag{4.1}$$

Here

$$\hat{A}_\varepsilon(k) = -\frac{i}{\varepsilon}\begin{pmatrix} 0 & 0 & k_1\\ 0 & 0 & k_2\\ k_1 & k_2 & 0\end{pmatrix} - \begin{pmatrix} \nu|k|^2+\eta k_1^2 & \eta k_1k_2 & 0\\ \eta k_1k_2 & \nu|k|^2+\eta k_2^2 & 0\\ 0 & 0 & 0\end{pmatrix} \tag{4.2}$$

is the symbol of A_ε; see (3.9). We first show that the eigenvalues of $\hat{A}_\varepsilon(k)$ have negative real parts for all $k\neq 0$.

LEMMA 4.1. *Let $\lambda_j = \lambda_j(\nu,\eta,\varepsilon,k)$ denote the eigenvalues of $\hat{A}_\varepsilon(k)$. Then we have*

$$\operatorname{Re}\lambda_j \le \max\left\{-\nu, -\frac{\nu+\eta}{2}, -\frac{1}{(\nu+\eta)\varepsilon^2}\right\} < 0, \quad j=1,2,3$$

for all $\nu>0, \nu+\eta>0, \varepsilon>0, k\in\mathbb{Z}^2, k\neq 0$.

Proof. For

$$\phi_1 = \frac{1}{|k|}\begin{pmatrix} -k_2\\ k_1\\ 0\end{pmatrix}$$

we have

$$\hat{A}_\varepsilon(k)\phi_1 = -\nu|k|^2\phi_1;$$

thus $\lambda_1 = -\nu|k|^2$. Next let ϕ_2,ϕ_3, which span the subspace of $\mathbb{R}^3$ orthogonal to ϕ_1, be given by

$$\phi_2 = \frac{1}{|k|}\begin{pmatrix} k_1\\ k_2\\ 0\end{pmatrix}\ , \qquad \phi_3 = \begin{pmatrix} 0\\ 0\\ 1\end{pmatrix}\ .$$

Then we have

$$\hat{A}_\varepsilon(k)\phi_2 = -(\nu+\eta)|k|^2\phi_2 - \frac{i}{\varepsilon}|k|\phi_3,$$
$$\hat{A}_\varepsilon(k)\phi_3 = -\frac{i}{\varepsilon}|k|\phi_2.$$

This implies that the eigenvalues $\lambda_{2,3}$ of $\hat{A}_\varepsilon(k)$ are the eigenvalues of

$$B = \begin{pmatrix} -(\nu+\eta)|k|^2 & -\frac{i}{\varepsilon}|k|\\ -\frac{i}{\varepsilon}|k| & 0\end{pmatrix}\ , \tag{4.3}$$

and we obtain that

$$\lambda_{2,3} = -\frac{(\nu+\eta)|k|^2}{2}\left\{1 \pm \sqrt{1 - \frac{4}{(\nu+\eta)^2\varepsilon^2|k|^2}}\right\}. \tag{4.4}$$

If $4 > (\nu+\eta)^2\varepsilon^2|k|^2$, then the root is purely imaginary; thus

$$\operatorname{Re}\lambda_{2,3} = -\frac{(\nu+\eta)|k|^2}{2} \le -\frac{\nu+\eta}{2}\ .$$

If $(\nu+\eta)^2\varepsilon^2|k|^2 \ge 4$, then $\lambda_{2,3}$ are real, and we have

$$\lambda_2 \le \lambda_3 = -\frac{r}{2} + \frac{r}{2}\sqrt{1 - \frac{4}{(\nu+\eta)\varepsilon^2 r}} \tag{4.5}$$

with $r = (\nu+\eta)|k|^2$. Clearly, $\lambda_3 \to -\frac{1}{(\nu+\eta)\varepsilon^2}$ as $r \to \infty$. Furthermore, the function of r on the right side of (4.5) is monotonically increasing. Therefore,

$$\lambda_2 \le \lambda_3 \le -\frac{1}{(\nu+\eta)\varepsilon^2}\ ,$$

and the lemma is proved. □

Remarks. 1. Let S denote the orthogonal matrix containing as columns the vectors ϕ_j defined in the proof of the previous lemma,

$$S = \frac{1}{|k|}\begin{pmatrix} -k_2 & k_1 & 0 \\ k_1 & k_2 & 0 \\ 0 & 0 & |k| \end{pmatrix}\ . \tag{4.6}$$

Then the proof shows that

$$\hat{A}_\varepsilon(k)S = S\begin{pmatrix} -\nu|k|^2 & 0 & 0 \\ 0 & b_{11} & b_{12} \\ 0 & b_{21} & b_{22} \end{pmatrix}, \tag{4.7}$$

where B is given in (4.3).

2. In the three-dimensional case, let $\psi_1, \psi_2 \in \mathbb{R}^3$ denote vectors so that ψ_1, ψ_2, $k/|k|$ form an orthonormal system of $\mathbb{R}^3$. Setting $\phi_j = (\psi_j, 0)^T$, we obtain

$$\hat{A}_\varepsilon(k)\phi_j = -\nu|k|^2\phi_j, \quad j = 1, 2\ .$$

Furthermore, let

$$\phi_3 = \frac{1}{|k|}(k_1, k_2, k_3, 0)^T, \quad \phi_4 = (0, 0, 0, 1)^T\ .$$

Computation of $\hat{A}_\varepsilon(k)\phi_j, j = 3, 4$, shows that the same matrix B as given in (4.3) determines the eigenvalues $\lambda_{3,4}$ of $\hat{A}_\varepsilon(k)$. Thus, Lemma 4.1 generalizes directly to the three-dimensional case.

Since the matrices $\hat{A}_\varepsilon(k)$ in (4.1) all have their eigenvalues in the left half-plane, all solutions $\hat{w}(k,t), k \ne 0$, tend to zero as $t \to \infty$. We need to quantify this decay. For clarity, consider first any ODE system

$$\frac{dy}{dt} = Ay, \quad y(t) \in \mathbb{C}^n, \tag{4.8}$$

where A is a constant $n \times n$ matrix with eigenvalues $\lambda_1, \ldots, \lambda_n, \operatorname{Re}\lambda_j \le -c_0 < 0$. One can construct a norm, based on an inner product, in which all solutions of (4.8) decay exponentially. In particular, we can construct a positive definite Hermitian matrix H satisfying

$$HA + A^*H \le -c_0 H. \tag{4.9}$$

The positive definite Hermitian matrix H defines an inner product and a norm on $\mathbb{C}^n$,

$$\langle u, v\rangle_H = u^*Hv, \quad |u|_H = \langle u, u\rangle_H^{1/2} .$$

For any solution $y(t)$ of (4.8) we have

$$\begin{aligned}\frac{d}{dt}|y|_H^2 &= \langle y, y'\rangle_H + \langle y', y\rangle_H \\ &= \langle y, Ay\rangle_H + \langle Ay, y\rangle_H \\ &= \langle y, HAy\rangle + \langle y, A^*Hy\rangle \\ &\le -c_0|y|_H^2.\end{aligned}$$

The last inequality follows from the crucial property $HA + A^*H \le -c_0 H$ of the matrix H. Therefore, for all solutions $y(t)$ of (4.8), the expression $|y(t)|_H$ decays exponentially. The matrix $H = H^* > 0$ is called a symmetrizer for the system (4.8) since—in $|\cdot|_H$—A acts like a matrix with negative definite symmetric part.

For the family of systems (4.1) we need additional properties of the symmetrizer $H = H(\nu, \eta, \varepsilon, k)$, namely some uniform estimates. As we will see, it suffices to consider the matrices B given in (4.3). Recall that, by Lemma 4.1, the eigenvalues $\lambda_{2,3}$ of B satisfy

$$\operatorname{Re}\lambda_{2,3} \le -c_0 < 0 , \quad c_0 = c_0(\nu + \eta) \tag{4.10}$$

for all $0 < \varepsilon \le 1, k \in \mathbb{Z}^2, k \ne 0$, and any fixed $\nu + \eta > 0$.

LEMMA 4.2. *For fixed $\nu + \eta > 0$, consider the family of matrices B given in* (4.3) *for $k \in \mathbb{Z}^2, k \ne 0$. There are positive constants $c_0, c_1, C_1, C_2, \varepsilon_0$, depending only on $\nu + \eta$, and there are Hermitian matrices $H = H(\nu + \eta, \varepsilon, k) \in \mathbb{C}^{2\times 2}$ for $0 < \varepsilon \le \varepsilon_0$ with the following properties:*

$$0 < (1 - C_1\varepsilon)I \le H \le (1 + C_1\varepsilon)I \tag{4.11}$$

$$q^*(HB + B^*H)q \le -c_0 q^*Hq - c_1|k|^2|q_1|^2 \quad \forall q \in \mathbb{C}^2, \tag{4.12}$$

$$|H - I| \le C_2\frac{\varepsilon}{|k|}. \tag{4.13}$$

Proof. We seek H in the form

$$H = \begin{pmatrix} 1 & i\frac{\varepsilon\mu}{|k|} \\ -i\frac{\varepsilon\mu}{|k|} & 1 \end{pmatrix}, \tag{4.14}$$

which, for fixed $\mu > 0$, clearly satisfies (4.11) and (4.13). To check (4.12) we directly compute $HB + B^*H$ and obtain

$$\begin{aligned} HB + B^*H &= \begin{pmatrix} -2(\nu+\eta)|k|^2 + 2\mu & -i\mu\varepsilon(\nu+\eta)|k| \\ i\mu\varepsilon(\nu+\eta)|k| & -2\mu \end{pmatrix} \\ &= \begin{pmatrix} -c_1|k|^2 & 0 \\ 0 & 0 \end{pmatrix} + R, \end{aligned} \tag{4.15}$$

where we choose $c_1 = \nu + \eta$. We must only show that R is negative definite and that its largest eigenvalue is bounded above by $-\bar{c}_0 < 0$ independent of $|k|$ and ε sufficiently small. Then (4.15) combined with (4.11) will imply (4.12). To that end we compute

$$\det(R) = \mu(\nu+\eta)|k|^2 \left(2 - \mu(\nu+\eta)\varepsilon^2 - 4\frac{\mu}{(\nu+\eta)|k|^2}\right), \tag{4.16}$$

$$\operatorname{tr}(R) = -(\nu+\eta)|k|^2. \tag{4.17}$$

Clearly, the trace is negative and the determinant positive for ε, μ sufficiently small. For 2×2 Hermitian matrices this implies negative definiteness. Choosing, for example,

$$\mu = \frac{\nu+\eta}{8}, \quad \varepsilon_0 < \frac{2}{\nu+\eta}, \tag{4.18}$$

we also have the bound

$$\bar{c}_0 \geq -\frac{\det(R)}{\operatorname{tr}(R)} > \frac{\nu+\eta}{8}. \tag{4.19}$$

This completes the proof. □

Combining this lemma with Remark 1 above we obtain the following result for the systems (4.1).

LEMMA 4.3. *For fixed $\nu > 0$, $\nu + \eta > 0$, and ε_0 sufficiently small consider the family of matrices $\hat{A}_\varepsilon(k)$ given by (4.2) for $0 < \varepsilon \leq \varepsilon_0, k \in \mathbb{Z}^2, k \neq 0$. There are positive constants c_0, c_1, C_1, C_2, depending only on ν, η, and there are Hermitian matrices $H = H(\nu, \eta, \varepsilon, k) \in \mathbb{C}^{3\times 3}$ with the following properties:*

$$0 < (1 - C_1\varepsilon)I \leq H \leq (1 + C_1\varepsilon)I, \tag{4.20}$$

$$q^*(H\hat{A}_\varepsilon + \hat{A}_\varepsilon^* H)q \leq -c_0 q^* H q - c_1|k|^2(|q_1|^2 + |q_2|^2) \quad \forall q \in \mathbb{C}^3, \tag{4.21}$$

$$|H - I| \leq \frac{C_2\varepsilon}{|k|}. \tag{4.22}$$

Proof. Let $\tilde{H} \in \mathbb{C}^{2\times 2}$ denote the symmetrizer constructed in the proof of Lemma 4.2 for the matrices B. We set

$$H = S \begin{pmatrix} 1 & 0 \\ 0 & \tilde{H} \end{pmatrix} S^*,$$

where the orthogonal matrix S is given in (4.6). Then H clearly satisfies (4.20) and (4.22). Setting $p = S^*q$ we find

$$q^*(H\hat{A}_\varepsilon + \hat{A}_\varepsilon^* H)q = p^* \begin{pmatrix} -\nu|k|^2 & 0 \\ 0 & \tilde{H}B + B^*\tilde{H} \end{pmatrix} p \leq -c_0 p^* H p - c_1|k|^2(|p_1|^2 + |p_2|^2).$$

Inequality (4.21) follows from the orthogonality of S and its block structure, completing the proof. □

By the previous lemma, the symmetrizer $H = H(\nu, \eta, \varepsilon, k)$ of (4.1) is constructed for $\nu > 0$, $\nu + \eta > 0$, $0 < \varepsilon \leq \varepsilon_0$, $k \in \mathbb{Z}^2$, $k \neq 0$. For $k = 0$ we set $H = I$. Then we define a new inner product on $L_2 = L_2(T^2, \mathbb{R}^3)$ by

$$(w_1, w_2)_H = \sum_{k\in\mathbb{Z}^2} \hat{w}_1(k)^* H(\nu, \eta, \varepsilon, k)\hat{w}_2(k) \ .$$

The corresponding norm is denoted by $\|\cdot\|_H$, where the dependency on ν, η, and ε is suppressed in our notation. The following result is an easy consequence of Lemma 4.3 and Parseval's relation.

LEMMA 4.4.

(a) *For all* $w = (u', w^{(3)})^T \in L_2$,

$$(1 - C_1\varepsilon)\|w\|^2 \le \|w\|_H^2 \le (1 + C_1\varepsilon)\|w\|^2 \ ,$$

i.e., the norms $\|\cdot\|_H$ *are equivalent to the* L_2*-norm, and in fact are* ε*-close to it.*

(b) *If* $w = w(x, y)$ *is sufficiently regular (e.g.,* $w \in H^2$*) and* $\hat{w}(0) = 0$ *(i.e., the spatial averages of the components of* w *are zero), then*

$$(w, A_\varepsilon w)_H + (A_\varepsilon w, w)_H \le -c_0\|w\|_H^2 - c_1\|Du'\|^2 \ .$$

In this sense, A_ε *is negative definite, uniformly in* ε*, with "parabolic" estimates on the velocities.*

(c) *If* $w_1 \in L_2, w_2 \in H^1$*, then*

$$|(w_1, Dw_2)_H - (w_1, Dw_2)| \le \varepsilon C_2\|w_1\|\|w_2\| \ .$$

Here $D = \partial_x$ *or* $D = \partial_y$*. In this sense, we "gain" one derivative when comparing the* H*-inner product and the* L_2*-inner product, and the constant in the estimate is proportional to* ε*.*

(d) *If* $w_1, w_2 \in H^1$ *then*

$$(w_1, Dw_2)_H = -(Dw_1, w_2)_H \quad \textit{for} \quad D = \partial_x \textit{ or } D = \partial_y \ ,$$

i.e., the rule of integration by parts, $(w_1, Dw_2) = -(Dw_1, w_2)$*, is valid in the* H*-inner product.*

As a consequence of (b) we note the following: if $w = w(x, y, t)$ solves

$$w_t = A_\varepsilon w, \quad w = w_0(x, y) \quad \text{at} \quad t = 0,$$

and $\hat{w}_0(0) = 0$, then

$$\begin{aligned}\frac{d}{dt}\|w\|_H^2 &= (w, A_\varepsilon w)_H + (A_\varepsilon w, w)_H \\ &\le -c_0\|w\|_H^2 - c_1\|Du'\|_H^2 \ .\end{aligned}$$

Therefore, $\|w(\cdot, t)\|_H$ decays exponentially in time. The rate of decay is independent of $0 < \varepsilon \le \varepsilon_0$.

The following result will be useful when we estimate derivative terms in the sections below. We first show the result for the L_2-inner product, then for the H-inner product.

LEMMA 4.5. *Let* $w \in H^1(T^2, \mathbb{R}^3)$ *and let* $v \in C^1(T^2)$ *be a real valued function. Then we have*

$$|(w, vDw)| \le \frac{1}{2}|Dv|_\infty\|w\|^2 \tag{4.23}$$

for $D = \partial_x$ *or* $D = \partial_y$*.* The crucial point is that no derivative of w appears on the right side.

Proof. Integration by parts yields

$$(w, vDw) = (vw, Dw) = -((Dv)w, w) - (vDw, w) \ . \tag{4.24}$$

Therefore,

$$(w, vDw) = -\frac{1}{2}((Dv)w, w)$$

and (4.23) follows. □

Equation (4.24) is valid if v takes Hermitian matrices as values; the estimate corresponding to (4.23) is a standard tool for symmetric hyperbolic systems; see, e.g., [5]. Equation (4.24) is not valid, however, if the L_2-inner product is replaced by the H-inner product. For this case, we obtain the following slightly weaker result.

LEMMA 4.6. *Under the assumptions of Lemma* 4.5 *we have*

$$|(w, vDw)_H| \le C(\varepsilon|v|_\infty + |Dv|_\infty)\|w\|^2 \ . \tag{4.25}$$

Proof. We have

$$(w, vDw)_H = (w, D(vw))_H - T_1$$

with $T_1 = (w, (Dv)w)_H$; thus $|T_1| \le C|Dv|_\infty\|w\|^2$. By Lemma 4.4 it follows that

$$(w, D(vw))_H = (w, D(vw)) + T_2$$

with

$$|T_2| \le \varepsilon C\|w\|\|vw\| \le \varepsilon C|v|_\infty\|w\|^2.$$

Finally,

$$(w, D(vw)) = (w, vDw) + T_3$$

with $T_3 = (w, (Dv)w)$; thus $|T_3| \le |Dv|_\infty\|w\|^2$. Using the estimate of the previous lemma for (w, vDw), estimate (4.25) follows. □

5. Conservation laws and estimates of the mean. The results of the preceding section cannot be used directly to estimate the spatial averages of the perturbed quantities, $\hat{w}(0,t)$, as these are invariant for the linearized evolution. However, we can bound them using the basic conservation laws of mass and linear momentum.

First recall that $u' = u - U$, $\rho' = \rho - P$, $w = (u', \varepsilon\rho')^T$, and that total mass

$$s = \int_{T^2}(1 + \varepsilon^2\rho)dxdy$$

and total momentum

$$m = \int_{T^2}(1 + \varepsilon^2\rho)udxdy$$

are constant in time, as follows directly from (1.2) and (1.1). Moreover, we have assumed (see (1.6), (1.8)) that

$$\int_{T^2} u_0 dxdy = \int_{T^2} U_0 dxdy = 0, \quad \int_{T^2} \rho_0 dxdy = \int_{T^2} P dxdy = 0, \tag{5.1}$$

where u_0, U_0, and ρ_0 are the initial data for u, U, and ρ, respectively. Combining these we have the following lemma.

LEMMA 5.1. *If the initial data satisfy* (5.1) *and* w *is a solution of* (3.8), *we have,* $\forall t \geq 0$,

$$\hat{w}^{(3)}(0,t) = \varepsilon \hat{\rho}'(0,t) = 0. \tag{5.2}$$

Proof. By conservation of mass and (5.1),

$$0 = \int_{T^2} (\rho' + P) dxdy,$$

which implies, using (1.8),

$$\int_{T^2} \rho' dxdy = -\int_{T^2} P dxdy = 0,$$

completing the proof. ∎

We now consider conservation of momentum. Note that by (1.6) the momentum satisfies

$$m = \int_{T^2} (1 + \varepsilon^2 \rho_0) u_0 dxdy = \varepsilon^2 \int_{T^2} \rho_0 u_0 dxdy. \tag{5.3}$$

We then have the following lemma.

LEMMA 5.2. *Suppose the initial data satisfy* (5.1) *and that* w *is a solution of* (3.8). *Let*

$$\bar{u}' = (2\pi)^{-2} \int_{T^2} u' dxdy,$$

and let[2]

$$w^c = w - (\bar{u}', 0)^T.$$

Then, for some constants C, c *depending on* U_0 *and* ν *but independent of* u_0, ρ_0, ε, *and* $\forall t \geq 0$ *we have*

$$|\bar{u}'| \leq \varepsilon C \left(\delta_0 + \varepsilon + \|w^c\|_H (e^{-ct} + \|w^c\|_H) \right). \tag{5.4}$$

Proof. We have

$$m = \int_{T^2} (1 + \varepsilon^2 \rho' + \varepsilon^2 P)(u' + U) dxdy = \varepsilon^2 \int_{T^2} \rho_0 u_0 dxdy.$$

Recalling that ρ', U, and P all have mean zero and solving for $\bar{u}'$, we obtain

$$\bar{u}' = \varepsilon^2 (2\pi)^{-2} \int_{T^2} (\rho_0 u_0 - PU) dxdy - \varepsilon (2\pi)^{-2} \int_{T^2} \left(\varepsilon (\rho' + P)(u' - \bar{u}') + \varepsilon \rho' U \right) dxdy.$$

From (3.14) we conclude

$$\varepsilon \int_{T^2} |\rho_0 u_0 - PU| dxdy \leq \varepsilon \int_{T^2} |\rho_0 u_0 - P_0 U_0| dxdy + \varepsilon \int_{T^2} |P_0 U_0 - PU| dxdy \leq C\delta_0 + C\varepsilon.$$

[2]Here $\bar{u}'$ is the spatial average of u'. Also w^c is centered in the sense that its spatial mean is zero.

Using the Cauchy–Schwarz inequality on the remaining terms, the estimate readily follows. ∎

Noting that the decomposition into spatially constant and spatially centered components is orthogonal with respect to the H inner product we have, as an immediate corollary of these lemmas,

$$\|w^c\|_H^2 \geq \|w\|_H^2 - \varepsilon^2 C(\varepsilon^2 + \delta_0^2 + \|w^c\|_H^2(e^{-ct} + \|w^c\|_H^2)). \tag{5.5}$$

6. Proof of Theorem 2.1. We begin by estimating time derivatives of the H-norm of the solution, w, to (3.8) along with its first three space derivatives. Set

$$\phi^2(t) = \frac{1}{2}\sum_{|\alpha|\leq 3} \|D^\alpha w(\cdot,t)\|_H^2, \quad h^2(t) = \sum_{|\alpha|=4} \|D^\alpha u'(\cdot,t)\|^2. \tag{6.1}$$

Note that short-time existence of a solution is guaranteed by the standard theory of parabolic–hyperbolic systems [5]. Moreover, we assume a bound on ϕ, $\phi(t) \leq 1$, so that the various nonlinear functions appearing in the equations remain smooth and so that higher powers of ϕ can be bounded by lower ones. We then have the fundamental estimate.

LEMMA 6.1. *Under the assumptions of Theorem* 2.1 *and in an interval* $0 \leq t < t_\varepsilon$ *of existence of a smooth solution,* w*, with* $\phi(t) \leq 1$*, the function* $\phi^2(t)$ *satisfies*

$$\begin{aligned}\frac{d}{dt}\phi^2(t) \leq \left(Ce^{-ct} - 2\tilde{c}_0\right)\phi^2(t) + \left(\varepsilon^2 Ce^{-ct} - \frac{1}{2}c_1\right)h^2(t)\\ +\varepsilon^2 Ce^{-ct} + \varepsilon^4 C + \varepsilon^2\delta_0^2 C + C\phi^3(t) + \varepsilon C\phi(t)h^2(t),\end{aligned} \tag{6.2}$$

$$\phi^2(0) \leq \frac{1}{2}(1 + C_1\varepsilon)\delta_0^2. \tag{6.3}$$

(Here and throughout constants depend on ν*,* η*,* U_0 *but are independent of* ε *for* $0 < \varepsilon \leq \varepsilon_0(\nu,\eta,U_0)$*.)*

Proof. We have

$$\frac{d}{dt}\phi^2(t) = \operatorname{Re}\sum_{|\alpha|\leq 3}(D^\alpha w, D^\alpha w_t)_H, \tag{6.4}$$

where

$$D^\alpha w_t = -D^\alpha(((U+u')\cdot\nabla)w) + A_\varepsilon D^\alpha w + \varepsilon D^\alpha G + D^\alpha Q_1 + D^\alpha Q_2. \tag{6.5}$$

We bound the right-hand side of (6.4) term-by-term in a sequence of lemmas. We recall first some standard general results, specialized here to two space dimensions. Proofs of some can be found in the Appendix of [1]. See also [3]. We assume throughout that f, g are (possibly vector-valued) functions in the Sobolev space indicated, and for the chain rule we assume that Φ is in C^3. All constants are independent of f, g but may depend on Φ. The multi-index, α, satisfies $1 \leq |\alpha| \leq 3$.

Sobolev's inequality:

$$|f|_\infty \leq C\|f\|_3, \quad |Df|_\infty \leq C\|f\|_3, \quad |D^2 f|_\infty \leq C\|f\|_4. \tag{6.6}$$

Estimate based on the chain rule:

$$\|D^\alpha(\Phi\circ f)\| \leq C(1 + |f|_\infty)^{|\alpha|-1}\|f\|_{|\alpha|}. \tag{6.7}$$

Estimates based on Leibniz' rule:

$$\|D^\alpha(fg)\| \le C(|f|_\infty \|g\|_{|\alpha|} + |g|_\infty \|f\|_{|\alpha|}), \tag{6.8}$$

$$\|D^\alpha(fg) - fD^\alpha g\| \le C(|Df|_\infty \|g\|_{|\alpha|-1} + |g|_\infty \|f\|_{|\alpha|}). \tag{6.9}$$

We remark that by Lemma 4.4(a) the L_2-norms in the inequalities above can be replaced by H-norms.

LEMMA 6.2. *Under the assumptions of Lemma* 6.1 *and for* $|\alpha| \le 3$ *we have*

$$|(D^\alpha w, D^\alpha(((U+u')\cdot\nabla)w))_H| \le Ce^{-ct}\phi^2(t) + C\phi^3(t). \tag{6.10}$$

Proof. We have

$$(D^\alpha w, D^\alpha(((U+u')\cdot\nabla)w))_H = (D^\alpha w, ((U+u')\cdot\nabla)D^\alpha w)_H + T,$$

$$T = \sum_{\beta<\alpha} c_{\alpha\beta}(D^\alpha w, (((D^{\alpha-\beta}(U+u'))\cdot\nabla)D^\beta w))_H.$$

We estimate the first term using (4.25), (3.5), and Sobolev's inequality to conclude

$$|(D^\alpha w, ((U+u')\cdot\nabla)D^\alpha w)_H| \le C(\varepsilon|U+u'|_\infty + |D(U+u')|_\infty)\phi^2 \le Ce^{-ct}\phi^2 + C\phi^3.$$

To estimate T, we use the Cauchy–Schwarz inequality, (3.5), and (6.9) to conclude

$$\begin{aligned} |T| &\le C\phi\,(|D(U+u')|_\infty \|w\|_3 + |Dw|_\infty \|U+u'\|_3) \\ &\le Ce^{-ct}\phi^2 + C\phi^3, \end{aligned}$$

completing the proof. ∎

LEMMA 6.3. *Under the assumptions of Lemma* 6.1 *we have*

$$\begin{aligned} &\operatorname{Re}\sum_{|\alpha|\le 3}(D^\alpha w, A_\varepsilon D^\alpha w)_H \\ &\quad\le -2\tilde{c}_0\phi^2(t) - c_1h^2(t) + \varepsilon^4 C + \varepsilon^2\delta_0^2 C + \varepsilon^2 Ce^{-ct}\phi^2(t) + C\varepsilon^2\phi^4(t). \end{aligned} \tag{6.11}$$

Proof. Since $\hat{A}_\varepsilon(0) = 0$, Lemma 4.4(b) implies

$$\operatorname{Re}\sum_{|\alpha|\le 3}(D^\alpha w, A_\varepsilon D^\alpha w)_H \le -2\tilde{c}_0\left(\|w^c\|_H^2 + \sum_{1\le|\alpha|\le 3}\|D^\alpha w\|_H^2\right) - c_1h^2.$$

Using (5.5) to replace $\|w^c\|_H^2$ by $\|w\|_H^2$, we obtain the desired estimate. ∎

LEMMA 6.4. *Under the assumptions of Lemma* 6.1 *we have*

$$|(D^\alpha w, \varepsilon D^\alpha G)_H| \le Ce^{-ct}\phi^2(t) + \varepsilon^2 Ce^{-ct}. \tag{6.12}$$

Proof. The lemma follows directly from the Cauchy–Schwarz and Cauchy inequalities combined with (3.5). ∎

LEMMA 6.5. *Under the assumptions of Lemma* 6.1 *we have*

$$\sum_{|\alpha|\le 3}|(D^\alpha w, D^\alpha Q_1)_H| \le Ce^{-ct}(\phi^2(t)+\varepsilon^2h^2(t)) + C\phi^3(t) + C\phi^2(t)h(t) + \varepsilon C\phi(t)h^2(t). \tag{6.13}$$

Proof. Recall that

$$Q_1 = \begin{pmatrix} \tilde{Q}_1 \\ 0 \end{pmatrix},$$

$$\tilde{Q}_1 = \frac{\varepsilon w^{(3)} + \varepsilon^2 P}{1 + \varepsilon w^{(3)} + \varepsilon^2 P}(\nu \Delta u' + \eta \nabla \nabla \cdot u') - (w^{(3)} + \varepsilon P)\Pi(0, \varepsilon w^{(3)} + \varepsilon^2 P)\nabla w^{(3)}.$$

We split the quantity to be estimated into three parts:

$$\sum_{|\alpha| \le 3} (D^\alpha w, D^\alpha Q_1)_H = T_1 + T_2 + T_3,$$
$$T_1 = \sum_{|\alpha|=3} (D^\alpha u', D^\alpha \tilde{Q}_1),$$
$$T_2 = \sum_{|\alpha| \le 2} (D^\alpha u', D^\alpha \tilde{Q}_1),$$
$$T_3 = \sum_{|\alpha| \le 3} (D^\alpha w, D^\alpha Q_1)_H - (D^\alpha w, D^\alpha Q_1).$$

Integrating once by parts and applying the Cauchy–Schwarz inequality, we find

$$|T_1| \le Ch \|\tilde{Q}_1\|_2.$$

Estimating directly by Cauchy–Schwarz, we obtain

$$|T_2| \le C\phi \|\tilde{Q}_1\|_2.$$

Finally, from Lemma 4.4(c) we conclude

$$|T_3| \le \varepsilon C\phi \|\tilde{Q}_1\|_2.$$

It remains then to estimate $\|\tilde{Q}_1\|_2$. By first applying (6.8) we have

$$\|\tilde{Q}_1\|_2 \le C|\varepsilon w^{(3)} + \varepsilon^2 P|_\infty h + C|D^2 u'|_\infty \left\| \frac{\varepsilon w^{(3)} + \varepsilon^2 P}{1 + \varepsilon w^{(3)} + \varepsilon^2 P} \right\|_2$$
$$+ C|(w^{(3)} + \varepsilon P)\Pi|_\infty \phi + C|Dw^{(3)}|_\infty \|(w^{(3)} + \varepsilon P)\Pi\|_2.$$

By Sobolev's inequality and (3.5) we may bound the maximum norm terms:

$$|\varepsilon w^{(3)} + \varepsilon^2 P|_\infty \le \varepsilon C\phi + \varepsilon^2 C e^{-ct},$$

$$|(w^{(3)} + \varepsilon P)\Pi|_\infty \le C\phi + \varepsilon C e^{-ct},$$

$$|D^2 u'|_\infty \le Ch, \quad |Dw^{(3)}|_\infty \le \phi.$$

Using (6.7) in combination with Sobolev's inequality and (3.5) we obtain

$$\left\| \frac{\varepsilon w^{(3)} + \varepsilon^2 P}{1 + \varepsilon w^{(3)} + \varepsilon^2 P} \right\|_2 \le \varepsilon C(\phi + \varepsilon e^{-ct}),$$

$$\|(w^{(3)} + \varepsilon P)\Pi(0, \varepsilon w^{(3)} + \varepsilon^2 P)\|_2 \le C(\phi + \varepsilon e^{-ct}).$$

Combining these, we have

$$\|\tilde{Q}_1\|_2 \le C(\phi + \varepsilon h)(\phi + \varepsilon e^{-ct}).$$

According to the bounds on the T_j, the final estimate follows from multiplying the right-hand side by $C(\phi + h)$, yielding

$$|T_j| \le C(\phi + h)(\phi + \varepsilon h)(\phi + \varepsilon e^{-ct}).$$

Application of Cauchy's inequality completes the proof. ∎

LEMMA 6.6. *Under the assumptions of Lemma* 6.1 *we have*

$$\sum_{|\alpha|\le 3} |(D^\alpha w, D^\alpha Q_2)_H| \le Ce^{-ct}\phi^2(t) + \varepsilon^2 Ce^{-ct}h^2(t) + C\phi^2(t)h(t). \tag{6.14}$$

Proof. We directly estimate $\|Q_2\|_3$ and then use the equivalence of the H-norm to the L_2-norm in conjunction with the Cauchy–Schwarz inequality to obtain the estimate. We recall

$$Q_2 = \begin{pmatrix} -(u'\cdot\nabla)U - \varepsilon w^{(3)}F \\ -\varepsilon(u'\cdot\nabla)P - (w^{(3)} + \varepsilon P)\nabla\cdot u' \end{pmatrix}.$$

Using (6.8), (6.6), and (3.5) we obtain

$$\|Q_2\|_3 \le Ce^{-ct}\phi + (\varepsilon Ce^{-ct} + C\phi)(\phi + h) + \varepsilon C\phi\|F\|_3.$$

Now F is given by

$$F = \Pi(\varepsilon^2 P, \varepsilon w^{(3)})\nabla P + \nu(1+\varepsilon^2 P)^{-1}(1 + \varepsilon w^{(3)} + \varepsilon^2 P)^{-1}\Delta U.$$

Therefore, by (6.8), the chain rule estimate, (6.7), (6.6), and (3.5) we have

$$\begin{aligned}\|F\|_3 &\le Ce^{-ct}(\|\Pi(\varepsilon^2 P, \varepsilon w^{(3)})\|_3 + \|\nu(1+\varepsilon^2 P)^{-1}(1+\varepsilon w^{(3)} + \varepsilon^2 P)^{-1}\|_3) \\ &\le Ce^{-ct}(1 + \varepsilon\phi + \varepsilon^2 Ce^{-ct})^3 \le Ce^{-ct}.\end{aligned}$$

Combining these terms and multiplying by ϕ (by applying Cauchy–Schwarz) the bound becomes

$$Ce^{-ct}\phi^2 + \varepsilon Ce^{-ct}\phi h + C\phi^2 h.$$

Applying the Cauchy inequality to the second term yields the desired result. ∎

Substituting the estimates of Lemmas 6.2–6.6 into the right-hand side of (6.4) almost yields (6.2), with $-c_1$ multiplying h^2 (rather than $-(1/2)c_1$), and an additional term $C\phi^2 h$. The latter is approximated using Cauchy's inequality and the assumed bound on ϕ:

$$C\phi^2 h \le C\phi^3 + \frac{1}{2}c_1 h^2,$$

finally producing (6.2). Equation (6.3) follows from (3.14) and Lemma 4.4(a), thus completing the proof of Lemma 6.1. ∎

We are now in a position to prove Theorem 2.1. Assume that δ_0 and ε_0 are chosen so that $\phi(0) < 1$. Recall that the short-time existence theory of hyperbolic–parabolic

systems guarantees a maximal interval of existence, $0 \le t < T$, with $\phi(t) < 1$ and, if $T < \infty$,

$$\limsup_{t \to T^-} \phi^2(t) = 1. \tag{6.15}$$

Therefore, all-time existence is proved if we can bound $\phi^2(t) < 1$ in arbitrary intervals of existence. To that end, consider the scalar ordinary differential inequality

$$\frac{dy}{dt} \le \left(Ce^{-ct} - \tilde{c}_0\right) y + \varepsilon^2 C \left(e^{-ct} + \varepsilon^2 + \delta_0^2\right), \tag{6.16}$$

$$y(0) \le \frac{1}{2}(1 + C_1\varepsilon)\delta_0^2. \tag{6.17}$$

(For clarity, we now fix the constants C, $\tilde{c}_0$, c, C_1 to values appearing in Lemma 6.1.) We then have the following lemma.

LEMMA 6.7. *There exists K depending only on C, $\tilde{c}_0$, c, C_1 such that any solution, $y(t)$, of* (6.16)–(6.17) *satisfies*

$$y(t) < K^2(\varepsilon^2 + \delta_0^2), \quad 0 \le t < \infty, \tag{6.18}$$

$$\limsup_{t \to \infty} y(t) \le \varepsilon^2 K^2 (1 + \varepsilon^2 + \delta_0^2). \tag{6.19}$$

Proof. Set

$$\psi(t) = \int_0^t \left(Ce^{-cs} - \tilde{c}_0\right) ds = c^{-1}C(1 - e^{-ct}) - \tilde{c}_0 t \le c^{-1}C - \tilde{c}_0 t,$$

$$z(t) = e^{-\psi(t)} y(t), \quad z(0) = y(0).$$

Then

$$\frac{dz}{dt}(t) = e^{-\psi(t)} \left(\frac{dy}{dt} - (Ce^{-ct} - \tilde{c}_0) y\right) \le \varepsilon^2 C e^{-\psi(t)} \left(e^{-ct} + \varepsilon^2 + \delta_0^2\right).$$

Integrating, we obtain

$$y(t) = e^{\psi(t)} z(t) \le \frac{1}{2}(1 + C_1\varepsilon)\delta_0^2 e^{\psi(t)} + \varepsilon^2 C \int_0^t e^{\psi(t) - \psi(s)} \left(e^{-cs} + \varepsilon^2 + \delta_0^2\right) ds.$$

Note that $e^{\psi(t)}$ is uniformly bounded and decays exponentially to zero as $t \to \infty$. Moreover,

$$\int_0^t e^{\psi(t) - \psi(s)} ds \le \tilde{c}_0^{-1} e^{c^{-1}C}.$$

The inequalities (6.18) and (6.19) then follow, completing the proof. ∎

Now choose $\varepsilon_0(\nu, \eta, U_0)$ and $\delta_0(\nu, \eta, U_0)$ sufficiently small such that all previous lemmas hold and that

$$K\sqrt{\varepsilon_0^2 + \delta_0^2} \le 1, \tag{6.20}$$

$$2\left(\varepsilon_0^2 C + \varepsilon_0 C K \sqrt{\varepsilon_0^2 + \delta_0^2}\right) \le c_1, \tag{6.21}$$

$$CK\sqrt{\varepsilon_0^2 + \delta_0^2} \le \tilde{c}_0. \tag{6.22}$$

Our claim is that, given (6.20), (6.21), (6.22),

$$\phi^2(t) < K^2(\varepsilon^2 + \delta_0^2) \tag{6.23}$$

holds in any interval of existence. Suppose the contrary. Then for some time T we have (6.23) for $0 \le t < T$ and

$$\phi^2(T) = K^2(\varepsilon_0^2 + \delta_0^2).$$

However, inequalities (6.21), (6.22) combined with (6.2) imply, for $0 \le t \le T$,

$$\frac{d}{dt}\phi^2(t) \le \left(Ce^{-ct} - \tilde{c}_0\right)\phi^2(t) + \varepsilon^2 C\left(e^{-ct} + \varepsilon^2 + \delta_0^2\right).$$

Therefore (see (6.3)), ϕ^2 satisfies (6.16) and (6.17), so by (6.18)

$$\phi^2(T) < K^2(\varepsilon^2 + \delta_0^2).$$

We have thus reached a contradiction. Hence, (6.23) must hold and, by the remarks at the start of the proof, all-time existence is proved.

From (6.19) we may now conclude

$$\limsup_{t\to\infty} \phi^2(t) \le \varepsilon^2 K^2(1 + \varepsilon^2 + \delta_0^2). \tag{6.24}$$

To prove that a uniform state is attained, we derive an inequality analogous to (6.2) for

$$\frac{d}{dt}\sum_{|\alpha|\le 3} \|D^\alpha w^c\|_H^2 \equiv \phi_c^2$$

by essentially repeating the estimates in Lemmas 6.2–6.6, while being careful to keep track of terms which are bounded independent of the mean. (See, e.g., [1].) We thus obtain

$$\frac{d}{dt}\phi_c^2(t) \le \left(Ce^{-ct} - 2\bar{c}_0\right)\phi_c^2(t) + C\phi(t)\phi_c(t)\left(\phi_c(t) + e^{-ct}\right) + \varepsilon^2 Ce^{-ct}. \tag{6.25}$$

Using (5.5), we find that

$$\phi \le \phi_c + \varepsilon C(\varepsilon + \delta_0 + \phi_c^2 + \phi_c e^{-ct}). \tag{6.26}$$

Applying Cauchy's inequality and further restricting ε_0 and δ_0 if necessary, we find

$$\frac{d}{dt}\phi_c^2(t) \le \left(Ce^{-ct} - \bar{c}_0\right)\phi_c^2(t) + C\phi_c^3(t) + \varepsilon^2 Ce^{-ct}. \tag{6.27}$$

Choosing T sufficiently large and using (6.24), we finally conclude

$$\frac{d}{dt}\phi_c^2(t) \le -\frac{1}{2}\bar{c}_0\phi_c^2(t) + \varepsilon^2 Ce^{-ct}, \quad t \ge T. \tag{6.28}$$

Integrating (6.28), we find

$$\lim_{t\to\infty} \phi_c = 0,$$

at an exponential rate. This, in combination with the conservation of mass and momentum, implies

$$\lim_{t\to\infty} w = (\bar{u}'_\infty, 0)^T, \tag{6.29}$$

where

$$\bar{u}'_\infty = (2\pi)^{-2}\varepsilon^2 \int_{T^2} \rho_0 u_0 dxdy = (2\pi)^{-2} m. \tag{6.30}$$

That is, we approach the unique uniform flow field with mass and momentum equal to the initial mass and momentum. This completes the proof. □

Appendix. If entropy variations are neglected and the viscosity coefficients are assumed constant, the equations for compressible flow read

$$\begin{aligned} \rho\,(u_t + (u\cdot\nabla)u) + \nabla p &= \mu\Delta u + \xi\nabla(\nabla\cdot u), \\ \rho_t + \nabla\cdot(\rho u) &= 0, \\ p/p_* &= (\rho/\rho_*)^\gamma, \quad \gamma \geq 1\ . \end{aligned}$$

Here we have assumed a γ-gas law as equation of state for simplicity.

Let $x_*, t_*, u_*, p_*, \rho_*$ denote units of length, time, velocity, pressure, and density, respectively. We assume

$$u_* = \frac{x_*}{t_*}\ .$$

The sound speed a_* corresponding to the state ρ_*, p_* satisfies

$$\frac{dp}{d\rho}(\rho_*) = \frac{\gamma p_*}{\rho_*} = a_*^2\ ,$$

and

$$\varepsilon = \frac{u_*}{a_*}$$

is the Mach number. If we introduce dimensionless variables $\tilde{x}, \tilde{t}, \tilde{u}, \tilde{p}, \tilde{\rho}$ by $x = x_*\tilde{x}$, etc., the equations become

$$\begin{aligned} \rho\,(u_t + (u\cdot\nabla)u) + \frac{1}{\gamma\varepsilon^2}\nabla p &= \nu\Delta u + \eta\nabla(\nabla\cdot u), \\ \rho_t + \nabla\cdot(\rho u) &= 0, \\ p &= \rho^\gamma, \end{aligned}$$

where $\tilde{}$ is dropped in the notation. Here

$$\nu = \frac{\mu}{x_*\rho_* u_*}, \quad \eta = \frac{\xi}{x_*\rho_* u_*}\ .$$

Eliminating p and dividing the momentum equations by ρ, the system reads

$$\begin{aligned} u_t + (u\cdot\nabla)u + \frac{1}{\varepsilon^2}\rho^{\gamma-2}\nabla\rho &= \frac{\nu}{\rho}\Delta u + \frac{\eta}{\rho}\nabla(\nabla\cdot u), \\ \rho_t + (u\cdot\nabla)\rho + \rho\nabla\cdot u &= 0. \end{aligned}$$

Introduce a new variable $r = r(x,t)$ by

$$\rho = 1 + \varepsilon^2 r \ .$$

Then we obtain

$$u_t + (u\cdot\nabla)u + (1+\varepsilon^2 r)^{\gamma-2}\nabla r = \frac{\nu}{1+\varepsilon^2 r}\Delta u + \frac{\eta}{1+\varepsilon^2 r}\nabla(\nabla\cdot u),$$
$$\varepsilon^2(r_t + (u\cdot\nabla)r) + (1+\varepsilon^2 r)\nabla\cdot u = 0.$$

We obtain the equations (1.1), (1.2) if we write ρ instead of r.

The introduction of r can be motivated as follows. Assuming that u, ρ, and their derivatives are $\mathcal{O}(1)$, the first equation implies that ρ is constant in space, to leading order in ε. Then, if we assume $\rho = \rho_0(t) + \mathcal{O}(\varepsilon^2)$, the second equation implies $\rho_0(t) =$ constant. We take $\rho_0 = 1$. This is an assumption on the initial data and our choice of ρ_*.

THE SECOND STEKLOFF EIGENVALUE AND ENERGY DISSIPATION INEQUALITIES FOR FUNCTIONALS WITH SURFACE ENERGY*

ROBERT LIPTON†

Abstract. A functional with both bulk and interfacial surface energy is considered. It corresponds to the energy dissipated inside a two-phase electrical conductor in the presence of an electrical contact resistance at the two-phase interface. The effect of embedding a highly conducting particle into a matrix of lesser conductivity is investigated. We find the criterion that determines when the increase in surface energy matches or exceeds the reduction in bulk energy associated with the particle. This criterion is general and applies to any particle with Lipschitz continuous boundary. It is given in terms of the of the second Stekloff eigenvalue of the particle. This result provides the means for selecting energy-minimizing configurations.

1. Introduction.

We consider a suspension of electrically conducting particles embedded in a matrix with a lower electrical conductivity. The two-phase conductor fills out a domain $\Omega \subset R^3$ with Lipschitz continuous boundary $\partial\Omega$. The electric conductivity tensor associated with the particle is denoted by σ_r and that of the matrix by σ_m. Here, both conductors are assumed anisotropic, and σ_r, σ_m are given by 3×3 symmetric, positive definite matrices. The tensors satisfy the inequality $\sigma_r > \sigma_m$ in the sense of quadratic forms. We suppose that there is an interfacial contact resistance between the two phases. The contact resistance is characterized by a scalar β with dimensions of conductivity per unit length.

The region occupied by the better conductor is denoted by A_r, and the region occupied by the matrix is denoted by A_m. The interface separating them is assumed Lipschitz continuous and is denoted by Γ and $\Omega = A_r \cup A_m \cup \Gamma$. The resistivity tensor inside the composite is described by $\sigma^{-1}(x) = \sigma_r^{-1}\chi_{A_r} + \sigma_m^{-1}(1 - \chi_{A_r})$, where χ_{A_r} equals one in A_r and zero otherwise. For a prescribed current $g \in H^{-1/2}(\partial\Omega)$, such that $\int_{\partial\Omega} g ds = 0$, the thermal energy dissipated inside the composite is given by $E(A_r, g)$, where

$$E(A_r, g) = \min\{C(A_r, j) : j \in L^2(\Omega)^3, \operatorname{div} j = 0,\ j \cdot n = g \text{ on } \partial\Omega\} \tag{1.1}$$

and

$$C(A_r, j) = \int_\Omega \sigma^{-1}(x)\ j \cdot j dx + \beta^{-1} \int_\Gamma (j \cdot n)^2 ds. \tag{1.2}$$

†Department of Mathematical Sciences, Worcester Polytechnic Institute, 100 Institute Rd., Worcester, MA 01609 (lipton@wpi.edu).

Here div $j = 0$ holds in the sense of distributions, ds is the element of surface area, and the vector n is the unit normal pointing into the matrix phase. The first term of the functional $C(A_r, j)$ is associated with bulk energy dissipation, while the second term gives the energy dissipation at the two-phase interface. The minimizer j_{A_r} is precisely the current in the composite and is related to the potential u_{A_r} by the constituitive law: $j_{A_r} = \sigma(x)\nabla u_{A_r}$ and

$$\operatorname{div}(\sigma(x)\nabla u_{A_r}) = 0 \text{ in } A_r \cup A_m. \tag{1.3}$$

Across the interface one has

$$[j_{A_r} \cdot n] = 0 \text{ on } \Gamma, \tag{1.4}$$

and

$$j_{A_r} \cdot n_{|_2} = -\beta[u_{A_r}] \text{ on } \Gamma,\ \sigma_m \nabla u_{A_r} \cdot n = g \text{ on } \partial\Omega. \tag{1.5}$$

Here $u_{A_r} \in H^1(\Omega\backslash\Gamma)$ and $[u_{A_r}] = u_{A_r|_2} - u_{A_r|_1}$, where the subscripts indicate the side of the interface where the trace is taken. The requirement $\int_{\partial\Omega} g ds = 0$ is the solvability condition for the equation of state, and the potential u_{A_r} is determined uniquely up to a constant. To expedite the presentation we denote the subspace of all elements $g \in H^{-1/2}(\partial\Omega)$ such that $\int_{\partial\Omega} g ds = 0$ by $H^{-1/2}(\partial\Omega) \setminus R$.

The replacement of a region of matrix denoted by "Σ" with material of better conductivity amounts to a nonlocal perturbation of the functional $C(A_r, j)$. The region Σ is assumed to be compactly contained within the matrix (i.e., $\Sigma \subset A_m$ and $\partial\Sigma \cap \partial A_m = \emptyset$). The perturbed functional is written as

$$C(A_r \cup \Sigma, j) = \int_\Omega \tilde{\sigma}^{-1}(x)\ j \cdot j dx + \beta^{-1} \int_{\Gamma\cup\partial\Sigma} (j \cdot n)^2 ds, \tag{1.6}$$

where $\partial\Sigma$ is the reinforcement (or particle) boundary and

$$\tilde{\sigma}^{-1}(x) = \sigma_r^{-1}\chi_{A_r\cup\Sigma} + \sigma_m^{-1}(1 - \chi_{A_r\cup\Sigma}). \tag{1.7}$$

In this article we present the geometric criterion that determines when effects due to surface energy overcome the benefits of a highly conducting particle. This criterion is general and applies to any particle with Lipschitz continuous boundary. In order to give the criterion, we introduce the 3×3 symmetric matrix $\mathbf{R_{cr}}$ given by

$$\mathbf{R_{cr}} = \beta^{-\mathbf{1}}(\sigma_{\mathbf{m}}^{-\mathbf{1}} - \sigma_{\mathbf{r}}^{-\mathbf{1}})^{-\mathbf{1}}. \tag{1.8}$$

Here each element of $\mathbf{R_{cr}}$ has dimensions of length. This tensor provides a measure of the relative magnitude of the interfacial barrier resistance with respect to the mismatch between the resistivity tensors of the matrix and particle. For a given particle occupying the set "Σ," the geometric parameter of interest is its second Stekloff eigenvalue ρ_2. The second Stekloff eigenvalue has dimensions of conductivity per unit length and we write $\rho_2(\Sigma, \sigma_r)$ to indicate its dependence on the conductivity and geometry of the particle. When Σ has Lipschitz continuous boundary the variational formulation for the second Stekloff eigenvalue is given by

$$\rho_2(\Sigma, \sigma_r) = \min_{\operatorname{div}(\sigma_r\nabla\varphi)=0} \frac{\int_{\partial\Sigma}(\sigma_r\nabla\varphi \cdot n)^2 ds}{\int_\Sigma \sigma_r \nabla\varphi \cdot \nabla\varphi dx}; \tag{1.9}$$

cf. Kuttler and Sigillito [9] and Alessandrini and Magnanini [1]. Equality in (1.9) holds for the second Stekloff eigenfunction φ_2, where div $(\sigma_r \nabla \varphi_2) = 0$ in Σ, $\int_{\partial\Sigma} \varphi_2 ds = 0$, and

$$\sigma_r \nabla \varphi_2 \cdot n = \rho_2(\Sigma, \sigma_r)\varphi_2 \text{ on } \partial\Sigma. \tag{1.10}$$

The study of this eigenvalue problem was initiated in the work of Stekloff [17]. It is evident that the second Stekloff eigenvalue and boundary traces of the Stekloff eigenfunction correspond to the first nonzero eigenvalue and eigenfunction of the Dirichlet to Neumann map on $\partial\Sigma$.

Let $\mathrm{E}(\mathrm{A_r} \cup \Sigma, \mathrm{g})$ denote the associated energy dissipation obtained by replacing a region Σ compactly contained inside A_m with the better conductor. It is given by

$$\mathrm{E}(\mathrm{A_r} \cup \Sigma, \mathrm{g}) = \min\{C(A_r \cup \Sigma, j) : j \in L^2(\Omega)^3, \text{div } j = 0,\ j \cdot n = g \text{ on } \partial\Omega\} \tag{1.11}$$

We state the following theorem.

THEOREM 1.1 (energy dissipation inequality). *Let Σ be a set with Lipschitz continuous boundary that is compactly contained in A_m. If $\rho_2(\Sigma, \sigma_r)$ satisfies*

$$\mathbf{R_{cr}^{-1}} \leq \sigma_{\mathbf{r}}^{-\mathbf{1}} \rho_{\mathbf{2}}(\mathbf{\Sigma}, \sigma_{\mathbf{r}}), \tag{1.12}$$

then

$$E(A_r \cup \Sigma, g) \geq E(A_r, g) \tag{1.13}$$

for all $g \in H^{-1/2}(\partial\Omega) \setminus R$.

Here (1.12) holds in the sense of quadratic forms. No assumptions on the topological nature of the particle domain Σ is made. Indeed it can be a disjoint union of multiply-connected components. The proof of this theorem is provided in section 2. We emphasize that (1.13) holds for every current $g \in H^{-1/2}(\partial\Omega) \setminus R$.

When the particle is made from an isotropic conductor, one can readily compute ρ_2 for spheres and rectangular fibers; cf. Kuttler and Sigillito [9]. For starlike domains and domains with smooth boundary, isoperimetric inequalities bounding ρ_2 from below have been obtained in the work of Payne [15], Bramble and Payne [2]: see also the review article of Payne [16]. These observations are applied in section 3, where heat dissipation inequalities are given in terms of the physical dimensions of the reinforcement. Such *size effect* inequalities predict the existence of a critical particle dimension below which the particle will no longer reduce the total heat dissipated inside the composite. These results show that the size of the domain Ω must be taken into consideration. Indeed, if the domain is "too thin," then the particle will have to have dimensions below the critical value in order to fit inside it. For such domains, the addition of highly conducting particles will not reduce the energy.

Theorem 1.1 can be applied to problems of energy minimization over various classes of configurations. We consider mixtures of two isotropically conducting materials. For this case, the particle and matrix phases have scalar conductivities and we continue to denote them as σ_r and σ_m, respectively, where $\sigma_r > \sigma_m$. The admissible class is chosen to be all suspensions of spheres of conductivity σ_r suspended in a matrix of σ_m. Here we allow the suspension to contain spheres of different radii. This class of suspensions is referred to as the class of *polydisperse* suspensions of spheres. We assume that each suspension consists of a finite number of spheres and that the spheres do not intersect. It is emphasized that no lower bound is placed on the size

of the spheres appearing in the suspension. We suppose that the total amount of good conductor occupies no more than a prescribed volume fraction θ_r of the domain denoted by Ω. Theorem 4.1 shows that one needs only to consider suspensions of spheres with radii greater than or equal to $R_{cr} = \beta^{-1}(\sigma_m^{-1} - \sigma_r^{-1})^{-1}$ when looking for energy-minimizing configurations. This result rules out the appearance of fine scale mixtures of spheres (i.e., minimizing sequences of suspensions made with progressively smaller spheres). An existence proof of optimal designs within this class follows from a suitable Poincaré inequality together with the theory of Chenais [3], [4] for shape optimization problems over a restricted class of Lipschitz domains. This topic is pursued elsewhere and will appear in [10]. These results are in striking contrast to what is seen when there is perfect bonding between the two conductors. For this situation it is often the case that no optimal design exists. Instead, minimizing sequences of designs exhibit regions consisting of progressively finer mixtures of the two conductors; see Lurie and Cherkaev [13] and Murat and Tartar [14].

More generally, we consider Lipschitz domains A_r of good conductor compactly contained within the design domain Ω. As before, we place no constraints on the topological nature of the reinforcing set A_r. We show, subject to the resource constraint $\text{meas}(A_r) \leq \theta_r \text{ meas}(\Omega)$, that all energy minimizing configurations lie within a subclass of domains determined by bounds on $\rho_2(A_r, \sigma_r)$: see Theorem 4.2.

2. Energy dissipation inequalities. In this section we establish Theorem 1.1.

For any $g \in H^{-1/2}(\partial\Omega) \setminus R$ we write the difference $\Delta E = E(A_r \cup \Sigma, g) - E(A_r, g)$ as

$$\Delta E = C(A_r, \tilde{j}) - C(A_r, \hat{j}) + D(\Sigma, \tilde{j}), \tag{2.14}$$

where $\tilde{j} = \text{argmin}\{C(A_r \cup \Sigma, j)\}$, $\hat{j} = \text{argmin}\{C(A_r, j)\}$, and $D(\Sigma, \tilde{j})$ is given by

$$D(\Sigma, \tilde{j}) = \beta^{-1}\left\{\int_{\partial\Sigma} (\tilde{j} \cdot n)^2 ds - \int_\Sigma \beta(\sigma_m^{-1} - \sigma_r^{-1})\tilde{j} \cdot \tilde{j} dx\right\}. \tag{2.15}$$

Noting that the field $\tilde{j}$ is an admissible trial for the variational principle (1.1), we have

$$C(A_r, \tilde{j}) - C(A_r, \hat{j}) \geq 0. \tag{2.16}$$

Thus

$$\Delta E \geq D(\Sigma, \tilde{j}). \tag{2.17}$$

Now, the equations of state for the potential $\tilde{u} \in H^1(\Omega \backslash (\Gamma \cup \partial\Sigma))$ imply that $\tilde{j} = \sigma_r \nabla \tilde{u}$ in Σ, $[\sigma \nabla \tilde{u} \cdot n] = 0$ on $\partial\Sigma$, and $\tilde{j} \cdot n_{|_2} = \sigma_r \nabla \tilde{u} \cdot n_{|_2}$ on $\partial\Sigma$. Thus from (2.15) and (2.17) we obtain

$$\Delta \text{E} \geq \beta^{-1}\left\{\int_{\partial\Sigma} (\sigma_r \nabla \tilde{u} \cdot n)^2 ds - \int_\Sigma \beta(\sigma_m^{-1} - \sigma_r^{-1})\sigma_r \nabla \tilde{u} \cdot \sigma_r \nabla \tilde{u} dx\right\}. \tag{2.18}$$

From (1.9), it follows that

$$\int_{\partial\Sigma} (\sigma_r \nabla \varphi \cdot n)^2 ds - \rho_2(\Sigma, \sigma_r) \int_\Sigma \sigma_r \nabla \varphi \cdot \nabla \varphi dx \geq 0 \tag{2.19}$$

for all $\varphi \in H^{3/2}(\Sigma)$ such that $\text{div}(\sigma_r \nabla \varphi) = 0$ in Σ.

Comparing the right-hand side of (2.18) with (2.19), we discover that

$$\Delta E \geq 0 \tag{2.20}$$

for

$$\sigma_r \beta(\sigma_m^{-1} - \sigma_r^{-1})\sigma_r \leq \sigma_r \rho_2(\Sigma, \sigma_r), \tag{2.21}$$

and the theorem follows.

We observe that strict inequality in (2.20) follows from strict inequality in (2.21), provided that $\nabla \tilde{u}$ is not identically equal to zero on Σ.

3. The second Stekloff eigenvalue for simple shapes and size effects. The second Stekloff eigenvalue for a sphere of radius a filled with isotropic conductor σ_r is given by $\rho_2 = \sigma_r/a$. It follows immediately from Theorem 1.1 that if both conducting phases are isotropic and if Σ is a sphere of radius a, then we have the following theorem.

THEOREM 3.1 (size effect for spheres). *For any current flux $g \in H^{-1/2}(\partial\Omega) \setminus R$,*

$$E(A_r \cup \Sigma, g) \geq E(A_r, g) \tag{3.22}$$

if

$$a \leq R_{cr} = \beta^{-1}(\sigma_m^{-1} - \sigma_r^{-1})^{-1}. \tag{3.23}$$

Other size-effect theorems have been obtained in the context of effective properties for isotropic suspensions of isotropically conducting spheres in an isotropic matrix. In that context the results have focused on critical radii for monodisperse suspensions of spheres; see Lipton and Vernescu [11]. Here the critical radius is precisely R_{cr} and is that for which the conductivity of the composite equals that of the matrix.

Results involving various averages of sphere radii have been found in the context of isotropic polydisperse suspensions of spheres; see Lipton and Vernescu [12]. There it is shown that if the harmonic mean of the sphere radii lies above R_{cr}, then the effective conductivity is greater than the matrix conductivity. Moreover, the effective conductivity lies below that of the matrix when the arithmetic mean of the radii lies below R_{cr}.

For size effects in the context of isotropic dilute suspensions of spheres, see Chiew and Glandt [5]. Prediction of size effects for isotropic monodisperse suspensions of spheres, by way of micromodels such as the effective medium theory and differential effective medium theory, can be found in the work of Every, Tzou, Hasselman, and Raj [7], Hasselman and Johnson [8], and Davis and Artz [6].

More generally, we consider starlike inclusions Σ filled with isotropic conductor σ_r embedded in an isotropic matrix with conductivity σ_m. Fixing the origin inside Σ, we denote by h_m the minimum distance from the origin to a tangent plane on $\partial\Sigma$. The maximum and minimum distance from the origin to $\partial\Sigma$ are denoted by r_M and r_m, respectively. For such shapes, Bramble and Payne [2] show

$$\sigma_r^{-1}\rho_2(\Sigma, \sigma_r) \geq \frac{1}{r_M}\left[\left(\frac{r_m}{r_M}\right)^2 \frac{h_m}{r_M}\right]. \tag{3.24}$$

It is evident from (3.24) and Theorem 1.1 that we have the following size effect theorem for starlike reinforcements.

THEOREM 3.2 (size effect theorem for starlike particles). *If the reinforcement Σ is starlike with geometric parameters r_m, r_M, and h_m, then for any $g \in H^{-1/2}(\partial\Omega) \setminus R$, we have*

$$E(A_r \cup \Sigma, g) \geq E(A_r, g) \tag{3.25}$$

if

$$\left(\frac{1}{r_M} \left[\left(\frac{r_m}{r_M} \right)^2 \frac{h_m}{r_M} \right] \right)^{-1} \leq R_{cr}. \tag{3.26}$$

To fix ideas we apply this theorem to an ellipsoidal particle. Here we suppose that the half-lengths of the major and minor axes are specified by a and c, respectively. For this case Theorem 3.2 implies the following corollary.

COROLLARY 3.3 (size effect theorem for ellipsoidal particles). *Given an ellipsoidal particle Σ with major and minor axes specified by a and c, respectively, then for any current flux $g \in H^{-1/2}(\partial\Omega) \setminus R$*

$$E(A_r \cup \Sigma, g) \geq E(A_r, g) \tag{3.27}$$

if

$$a \left(\frac{a}{c} \right)^3 \leq R_{cr}. \tag{3.28}$$

We consider an ellipsoidal inclusion such that $c = a(1-\lambda)$ for $0 < \lambda < 1$. It follows from the corollary that the introduction of an ellipsoidal inclusion will not lower the energy dissipated inside the composite when a lies below $R_{cr}(1-\lambda)^3$.

4. Energy minimizing configurations. We consider the problem of minimizing the thermal energy dissipation over the class of polydisperse suspensions of spheres of good conductor immersed in a matrix of lesser conductivity. The matrix and spheres are made from isotropically conducting material with conductivities specified by σ_m and σ_r, respectively. Here the suspensions consist of a finite number of nonintersecting spheres and we assume no lower bound on the sphere radii. Denoting the ith sphere by B_i, we write $A_r = \cup B_i$. We suppose that the suspension takes up no more than a prescribed volume fraction θ_r of the total composite; i.e., $\text{meas}(A_r) \leq \theta_r$ meas(Ω). We denote this class of suspensions by $\mathcal{C}_{\theta_r}$. We consider the subclass $\mathcal{SC}_{\theta_r}$ of $\mathcal{C}_{\theta_r}$, defined to be all suspensions with minimum sphere radii greater than or equal to R_{cr}. For a prescribed heat flux $g \in H^{-1/2}(\partial\Omega) \setminus R$ on the boundary, we consider the problem

$$\min\{E(A_r, g) : A_r \in \mathcal{C}_{\theta_r}\}. \tag{4.29}$$

Theorem 4.1 follows from Theorem 3.1.

THEOREM 4.1. *If a minimizer of problem* (4.1) *exists, then it can be found in the class $\mathcal{SC}_{\theta_r}$ or $A_r = \emptyset$. Moreover, if Ω has dimensions for which $\mathcal{SC}_{\theta_r}$ is empty, then the minimum energy dissipation is given by $E(\emptyset, g)$.*

Proof. We consider any suspension in the class $\mathcal{C}_{\theta_r}$. If there exist spheres of radius less than R_{cr}, then Theorem 3.1 shows that there is no advantage to keeping them

in the suspension. When $\mathcal{SC}_{\theta_r}$ is empty, we see that no reinforcement is needed, and the minimum is attained for $A_r = \emptyset$. □

Next we consider energy minimization over a wide class of particle configurations. We suppose that σ_m and σ_r are anisotropic and let $\mathcal{CL}_{\theta_r}$ be the class of Lipschitz continuous sets A_r compactly contained inside Ω for which $\text{meas}(A_r) \leq \theta_r \text{ meas}(\Omega)$. Here we assume that A_r is the union of one or more components and we make no assumption on the topological nature of each component. For a given reinforcement set A_r, we denote its ith component by A_r^i. The subclass $\mathcal{SCL}_{\theta_r}$ of $\mathcal{CL}_{\theta_r}$ is defined to be all $A_r \in \mathcal{CL}_{\theta_r}$ for which every component A_r^i satisfies

$$\sigma_r^{-1}\rho_2(A_r^i, \sigma_r) \leq \mathbf{R_{cr}^{-1}}. \tag{4.30}$$

For $g \in H^{-1/2}(\partial\Omega) \setminus R$ we consider the problem

$$\min\{E(A_r, g) : A_r \in \mathcal{CL}_{\theta_r}\}. \tag{4.31}$$

Theorem 4.2 follows immediately from Theorem 1.1.

THEOREM 4.2. *If a minimizer of problem* (4.3) *exists, then it can be found in* $\mathcal{SCL}_{\theta_r}$ *or* $A_r = \emptyset$. *Moreover, if* Ω *has dimensions for which* $\mathcal{SCL}_{\theta_r}$ *is empty, then the minimum energy dissipation is given by* $E(\emptyset, g)$.

5. Conclusions. The second Stekloff eigenvalue associated with the reinforcement phase is shown to be a basic tool for the study of nonlocal perturbations of functionals with bulk and surface energies associated with imperfectly bonded composite conductors. The associated energy dissipation inequalities establish a means for selecting energy minimizing configurations. For the problem treated in section 4, it is found that fine scale oscillations are rendered superfluous due to the electrical contact resistance associated with the interface.

GLOBAL STABILITY IN CHEMOSTAT-TYPE EQUATIONS WITH DISTRIBUTED DELAYS*

XUE-ZHONG HE†, SHIGUI RUAN‡, AND HUAXING XIA§

Abstract. We consider a chemostat-type model in which a single species feeds on a limiting nutrient supplied at a constant rate. The model incorporates a general nutrient uptake function and two distributed (infinite) delays. The first delay models the fact that the nutrient is partially recycled after the death of the biomass by bacterial decomposition, and the second delay indicates that the growth of the species depends on the past concentration of the nutrient. By constructing appropriate Liapunov-like functionals, we obtain sufficient conditions for local and global stability of the positive equilibrium of the model. Quantitative estimates on the size of the delays for local and global stability are also obtained with the help of the Liapunov-like functionals. The technique we use in this paper may be used as well to study global stability of other types of physical models with distributed delays.

Key words. chemostat-type equations, distributed delay, Liapunov functionals, local and global stability, nutrient recycling

1. Introduction.

The effect of material (nutrient) recycling on ecosystem stability has been previously studied for closed systems (see Nisbet and Gurney [16], Nisbet, McKinstry, and Gurney [17], and Ulanowicz [22]). Powell and Richerson [18] and Nisbet and Gurney [16] regarded nutrient recycling as an instantaneous process, thus neglecting the time required to regenerate the nutrient from the dead biomass by bacterial decomposition. However, as pointed out in Whittaker [23], a delay in nutrient recycling is always present in a natural system and it increases when temperature decreases. To simulate the growth of planktonic communities of unicellular algae in the lakes, Beretta, Bischi, and Solimano [1] proposed an open system in which a single species feeds on a limiting nutrient supplied at a constant rate. They assumed that the nutrient is partially recycled after the death of the organisms and used a distributed delay to model nutrient recycling. Bischi [5] observed that the delay involved in nutrient recycling alone does not have a destabilizing effect on the equilibrium.

Evidence of delayed growth response has also been observed from chemostat experiments with microalgae *Chlamidomonas Reinhardii* even when the limiting nutrient is at undetectable small concentration (see Caperon [7]). Following Caperon [7], Ruan [19] introduced a discrete delay to the model of Beretta, Bischi, and Solimano [1] to describe the delayed growth response of the species to nutrient uptake. It is shown (see He and Ruan [11]) that the positive equilibrium is globally stable if the delays

are sufficiently small. However, there is a threshold value of the discrete delay involved in the growth response; when the discrete delay is increased and passes this critical value, the equilibrium may lose its stability and a Hopf bifurcation may occur (see Ruan [19]). Recently, Beretta and Takeuchi [2–4] used an additional distributed delay to model the delayed growth response. By assuming that the response function is either a Lotka–Volterra function or a Michaelis–Menten function, they studied the global stability of the positive equilibrium.

In this paper, we consider a chemostat-type model with (distributedly) delayed growth response and (distributedly) delayed nutrient recycling, namely, a system of two retarded functional differential equations with two distributed delays. This model was first proposed and studied by Beretta and Takeuchi [2]. However, their stability results are only local. Although global stability was also considered in [2–4] for similar models with an additional instantaneous negative feedback or without delayed growth response at all, the problem is more difficult to study when delayed growth response is introduced. By constructing appropriate Liapunov-like functionals, we study both local and global stability of the positive equilibrium of the model. It turns out that the positive equilibrium can be globally asymptotically stable if the mean delays are sufficiently small, and quantitative estimates on the size of these delays can be obtained with the help of the Liapunov-like functionals. Moreover, our approach to the local stability problem is slightly different than that used by Beretta and Takeuchi [2], and we improve their local stability result.

We remark that distributed (infinite) delay equations have been used in biological modeling since the work of Volterra (see Scudo and Ziegler [20]) and they are regarded to be more realistic than discrete (finite) delay equations (see Caperon [7]). The fundamental theory and some properties such as stability, existence of periodic solutions, etc. of distributed delay equations are well understood now and are discussed in the books of Burton [6], Hale and Verduyn Lunel [10], and Hino, Murakami and Naito [12]. The monographs of Cushing [8] and MacDonald [15] give excellent descriptions of distributed delay models and study the local stability, bifurcation, and periodic solutions of these models. Although global stability of some biological models with distributed delays has been studied (see Gopalsamy [9], Kuang [14], Wolkowicz, Xia, and Ruan [24] and the references cited therein), in general global results for models involving distributed delays are hard to obtain. The reason probably is that there are few methods available in investigating the global stability of infinite delay equations. The most powerful and most important method is perhaps the Liapunov function(al) method. However, there is no general procedure to follow in constructing a desirable Liapunov function(al), and completely different forms of Liapunov function(al)s are used for different kinds of equations. In the present paper, we try to construct the Liapunov-like functionals step by step so that the idea and technique can be easily followed. We believe that our technique can be used as well to study global stability of some other types of physical models with infinite delays.

The paper is organized as follows. In section 2 we describe the model equations. Local stability is studied in section 3 and global stability is discussed in section 4. Finally, a brief discussion is carried out in section 5.

2. The model. Let $N(t)$ denote the limiting nutrient concentration and $P(t)$ denote the plankton concentration at time t. Consider the following integrodifferential equations model of plankton–nutrient interaction with delayed growth response and delayed nutrient recycling:

$$\begin{aligned}\dot{N} =& D(N^0 - N) - aU(N)P + b\gamma \int_0^\infty f(s)P(t-s)\,ds \\ \dot{P} =& P\bigg[- (\gamma + D) + c\int_0^\infty g(s)U(N(t-s))\,ds\bigg],\end{aligned} \tag{2.1}$$

with initial value conditions

$$N(\theta) = \phi_1(\theta) \geq 0, \quad P(\theta) = \phi_2(\theta) \geq 0, \quad \theta \in (-\infty, 0], \tag{2.2}$$

where $\phi_1(\theta), \phi_2(\theta) \in BC(-\infty, 0]$, the Banach space of all continuous bounded functions, and all parameters are positive constants. N^0 is the input concentration of the limiting nutrient, a is the maximum uptake rate of nutrient, $c\,(\leq a)$ is the maximum specific growth rate of plankton, $b\,(0 < b < 1)$ is the fraction of the nutrient recycled by bacterial decomposition of the dead plankton, γ is the death rate of plankton, and D is the washout rate, so $\gamma + D$ represents the total loss rate of the plankton.

The function $U(N)$ describes the nutrient uptake rate of plankton. Throughout, we assume that $U(N)$ is nonnegative, increasing, and vanishes when there is no nutrient, and there is a saturation effect when the nutrient is very abundant. That is, we assume that $U(N)$ is a continuously differentiable function defined on $[0, \infty)$ and

$$U(0) = 0, \quad \frac{dU}{dN} > 0, \quad \lim_{N\to\infty} U(N) = 1. \tag{2.3}$$

These general hypotheses are satisfied by the Michaelis–Menten function (see [21])

$$U(N) = \frac{N}{L + N},$$

where $L > 0$ is the half-saturation constant or Michaelis–Menten constant.

The delay kernels $f(s)$ and $g(s)$ are nonnegative bounded functions defined on $[0, \infty)$. $f(s)$ describes the contribution of the plankton population dead in the past to the nutrient recycled and $g(s)$ describes the delayed growth response of plankton to nutrient uptake. The presence of the distributed time delays must not affect the equilibrium values, so we normalize the kernels such that

$$\int_0^\infty f(s)ds = \int_0^\infty g(s)ds = 1.$$

As in MacDonald [15], we define the average time delays as

$$T_f = \int_0^\infty sf(s)ds, \quad T_g = \int_0^\infty sg(s)ds.$$

Note that $E_0 = (N^0, 0)$ is always an equilibrium for system (2.1), and if

$$\gamma + D < c \quad \text{and} \quad U^{-1}\bigg(\frac{\gamma + D}{c}\bigg) < N^0, \tag{2.4}$$

system (2.1) has a positive interior equilibrium $E^* = (N^*, P^*)$ with

$$N^* = U^{-1}\bigg(\frac{\gamma + D}{c}\bigg), \quad P^* = \frac{D(N^0 - N^*)}{aU(N^*) - b\gamma}. \tag{2.5}$$

Throughout, we always assume that (2.4) is satisfied and T_f and T_g are finite.

Denote by $X(t,\phi) = (N(t,\phi), P(t,\phi))$ the solution of system (2.1) satisfying the initial value conditions (2.2), where $\phi = (\phi_1, \phi_2)$. We say that the positive equilibrium $E^* = (N^*, P^*)$ of (2.1) is *(locally) stable* if for any $\varepsilon > 0$ there exists $\delta = \delta(\varepsilon)$ such that $|X(t,\phi) - E^*| < \varepsilon$ for $t \geq 0$ and $\phi \in B(E^*, \delta)$, where $B(E^*, \delta)$ is an open δ-ball of E^*. E^* is said to be *(locally) asymptotically stable* if it is (locally) stable and there is a $\delta_o > 0$ such that $\phi \in B(E^*, \delta_o)$ implies $X(t,\phi) \to E^*$ as $t \to \infty$. E^* is said to be *globally asymptotically stable* if it is (locally) asymptotically stable, and for any positive solution $X(t,\phi)$ of (2.1) and (2.2), we have $X(t,\phi) \to E^*$ as $t \to \infty$.

System (2.1) was introduced and studied by Beretta and Takeuchi [2, 4]. It was shown there that all solutions of system (2.1) are nonnegative if the initial data chosen from $BC(-\infty, 0]$ are nonnegative. They also discussed stability of the positive equilibrium E^*. However, their stability results about system (2.1) are only local, and global stability results hold only for systems (similar to (2.1)) with an additional instantaneous negative feedback or without delayed growth response at all. The object of this paper is to improve their local stability result and investigate as well the global stability of the positive equilibrium.

3. Local asymptotic stability. We first study the local stability of the positive equilibrium $E^* = (N^*, P^*)$. Let

$$x_1 = N - N^*, \quad x_2 = P - P^*,$$

where $-N^* \leq x_1 < \infty$, $-P^* \leq x_2 < \infty$, and define

$$\xi(x_1) = U(N) - U(N^*) \tag{3.1}$$

so that $-U(N^*) \leq \xi(x_1) < 1 - U(N^*)$ by assumption (2.3). Then the linearized equations about E^* are

$$\begin{aligned} \dot{x}_1 &= -\big(D + aP^*U'(N^*)\big)x_1 - aU(N^*)x_2 + b\gamma \int_0^\infty f(s)x_2(t-s)ds, \\ \dot{x}_2 &= cP^*U'(N^*) \int_0^\infty g(s)x_1(t-s)ds. \end{aligned} \tag{3.2}$$

Note that the asymptotic stability of the trivial equilibrium $x_1 = x_2 = 0$ of (3.2) implies the local asymptotic stability of the positive equilibrium E^* of (2.1). For convenience, we define

$$A = D + aP^*U'(N^*), \quad B = acP^*U(N^*)U'(N^*), \quad C = b\gamma cP^*U'(N^*). \tag{3.3}$$

Then $B > C$, and system (3.2) becomes

$$\begin{aligned} \dot{x}_1 &= -Ax_1 - \frac{B}{C}b\gamma x_2 + b\gamma \int_0^\infty f(s)x_2(t-s)ds, \\ \dot{x}_2 &= \frac{C}{b\gamma} \int_0^\infty g(s)x_1(t-s)ds. \end{aligned} \tag{3.4}$$

Let $(x_1(t), x_2(t))$ be an arbitrary solution of system (3.4). We first consider the function $V_{11}(t) = x_1^2(t)$. It follows from (3.4) that

$$\begin{aligned}
\dot V_{11}(t) &= 2x_1(t)\dot x_1(t)\\
&= -2Ax_1^2(t) - 2b\gamma\tfrac{B}{C}x_1(t)x_2(t) + 2b\gamma x_1(t)x_2(t)\\
&\quad - 2b\gamma x_1(t)\int_0^t f(s)\int_{t-s}^t \dot x_2(u)\,du\,ds + I(t)\\
&= -2Ax_1^2(t) - 2b\gamma\big(\tfrac{B}{C}-1\big)x_1(t)x_2(t) + I(t)\\
&\quad - 2Cx_1(t)\int_0^t f(s)\int_{t-s}^t\int_0^\infty g(v)x_1(u-v)\,dv\,du\,ds\\
&\le -2Ax_1^2(t) - 2b\gamma\big(\tfrac{B}{C}-1\big)x_1(t)x_2(t) + I(t)\\
&\quad + C\int_0^\infty f(s)\int_{t-s}^t\int_0^\infty g(v)[x_1^2(t)+x_1^2(u-v)]\,dv\,du\,ds\\
&= -2Ax_1^2(t) - 2b\gamma\big(\tfrac{B}{C}-1\big)x_1(t)x_2(t) + CT_f x_1^2(t)\\
&\quad + C\int_0^\infty f(s)\int_{t-s}^t\int_0^\infty g(v)x_1^2(u-v)\,dv\,du\,ds + I(t),
\end{aligned}\tag{3.5}$$

where

$$I(t) = -2b\gamma x_1(t)\int_t^\infty f(s)\big(x_2(t)-x_2(t-s)\big)\,ds.\tag{3.6}$$

For technical reasons, we assume that $\int_0^\infty s^2 f(s)\,ds < \infty$. Then the function

$$V_{12}(t) = C\int_0^\infty f(s)\int_{t-s}^t\int_r^t\int_0^\infty g(v)x_1^2(u-v)\,dv\,du\,dr\,ds$$

is well defined, and by (3.5), we have

$$\begin{aligned}
\dot V_{11}(t) + \dot V_{12}(t) &\le -2Ax_1^2(t) - 2b\gamma\big(\tfrac{B}{C}-1\big)x_1(t)x_2(t) + CT_f x_1^2(t)\\
&\quad + C\int_0^\infty f(s)\int_{t-s}^t\int_0^\infty g(v)x_1^2(t-v)\,dv\,du\,ds + I(t)\\
&= -2Ax_1^2(t) - 2b\gamma\big(\tfrac{B}{C}-1\big)x_1(t)x_2(t) + CT_f x_1^2(t)\\
&\quad + CT_f\int_0^\infty g(s)x_1^2(t-s)\,ds + I(t).
\end{aligned}\tag{3.7}$$

We now consider the function

$$V_1(t) = V_{11}(t) + V_{12}(t) + CT_f\int_0^\infty g(s)\int_{t-s}^t x_1^2(u)\,du\,ds.$$

It follows from (3.7) that

$$\dot V_1(t) \le -2\big(A - CT_f\big)x_1^2(t) - 2b\gamma\big(\tfrac{B}{C}-1\big)x_1(t)x_2(t) + I(t).\tag{3.8}$$

On the other hand, by the second equation of (3.4), we have

$$\frac{d}{dt}\left[x_2 + \frac{C}{b\gamma}\int_0^\infty g(s)\int_{t-s}^t x_1(u)\,du\,ds\right] = \frac{C}{b\gamma}x_1(t).$$

Assume $\int_0^\infty s^2 g(s)ds < \infty$ and define

$$V_2(t) = \left[x_2 + \frac{C}{b\gamma}\int_0^\infty \int_{t-s}^t g(s)x_1(u)du\right]^2 + \left(\frac{C}{b\gamma}\right)^2 \int_0^\infty g(s)\int_{t-s}^t \int_v^t x_1^2(u)dudvds.$$

We find that

$$\dot{V}_2(t) \le \frac{2C}{b\gamma}x_1(t)x_2(t) + 2\left(\frac{C}{b\gamma}\right)^2 T_g x_1^2(t). \tag{3.9}$$

Therefore, for the function

$$V(t) = V_1(t) + \frac{(b\gamma)^2}{C}\left(\int_t^\infty f(s)\,ds + \frac{B}{C} - 1\right)V_2(t),$$

we have from (3.6), (3.8), and (3.9) that

$$\begin{aligned}
\dot{V}(t) \le & -2\left[A - CT_f - \left(C\int_t^\infty f(s)\,ds + B - C\right)T_g\right]x_1^2(t) \\
& + 2b\gamma x_1(t)x_2(t)\int_t^\infty f(s)\,ds + I(t) \\
= & -2\left[A - CT_f - \left(C\int_t^\infty f(s)\,ds + B - C\right)T_g\right]x_1^2(t) \\
& + 2b\gamma x_1(t)\int_t^\infty f(s)x_2(t-s)\,ds \\
\le & -2\left[A - CT_f - \left(C\int_t^\infty f(s)\,ds + B - C\right)T_g\right]x_1^2(t) \\
& + 2b\gamma|x_1(t)|\|\phi_2\|\int_t^\infty f(s)\,ds \\
\le & -2\left[A - CT_f - \left(C\int_t^\infty f(s)\,ds + B - C\right)T_g\right]x_1^2(t) \\
& + b\gamma x_1^2(t)\int_t^\infty f(s)\,ds + b\gamma\|\phi_2\|^2\int_t^\infty f(s)\,ds \\
= & -2\big[A - CT_f - (B-C)T_g\big]x_1^2(t) \\
& + \big(2CT_g + b\gamma\big)x_1^2(t)\int_t^\infty f(s)\,ds + b\gamma\|\phi_2\|^2\int_t^\infty f(s)\,ds,
\end{aligned} \tag{3.10}$$

where $\phi_2 \in BC(-\infty, 0]$ is the initial data of $x_2(t)$. By using (3.10), we now can prove the following local stability result.

THEOREM 3.1. *Assume that* $\int_0^\infty s^2 f(s)\,ds < \infty$ *and* $\int_0^\infty s^2 g(s)ds < \infty$. *If*

$$CT_f + (B-C)T_g < A, \tag{3.11}$$

then the positive equilibrium E^* *of system* (2.1) *is locally asymptotically stable.*

Proof. Let $(x_1(t), x_2(t))$ be an arbitrary solution of (3.4) with $\phi_2 \in BC(-\infty, 0]$ being the initial data for $x_2(t)$. By (3.11), we can find $\varepsilon > 0$ such that

$$Q(\varepsilon) \triangleq CT_f + (B-C)T_g + \left(CT_g + \frac{1}{2}b\gamma\right)\varepsilon < A.$$

Let $T = T(\varepsilon) > 0$ be such that $\int_t^\infty f(s)\,ds < \varepsilon$ for all $t \geq T$. It then follows from (3.10) that for all $t \geq T$,

$$\dot{V}(t) \leq -2\big(A - Q(\varepsilon)\big)x_1^2(t) + b\gamma\|\phi\|^2 \int_t^\infty f(s)\,ds.$$

Integrating $\dot{V}(t)$ from T to $t \geq T$ gives

$$\begin{aligned} x_1^2(t) + \frac{(b\gamma)^2}{C^2}\big(B - C\big)V_2(t) + 2\big(A - Q(\varepsilon)\big)\int_T^t x_1^2(s)\,ds \\ \leq V(t) + 2\big(A - Q(\varepsilon)\big)\int_T^t x_1^2(s)\,ds \\ \leq V(T) + b\gamma\|\phi_2\|^2 \int_T^t \int_s^\infty f(u)\,du ds \\ \leq V(T) + b\gamma\|\phi_2\|^2 \int_0^\infty s f(s)\,ds \\ = V(T) + b\gamma\|\phi_2\|^2 T_f < \infty. \end{aligned}$$

Therefore, $x_1(t)$ and $x_2(t)$ are bounded, and $x_1^2(t) \in L_1[0,\infty)$. By the mean value theorem and the equations in (3.4), $x_1(t)$, $x_2(t)$, and their derivative functions are thus uniformly continuous on $[0,\infty)$. Applying the Barbălat lemma (see Lemmas 1.2.2 and 1.2.3 in Gopalsamy [9]), we conclude that $\big(x_1(t), \dot{x}_1(t)\big) \to 0$ as $t \to \infty$. Therefore, from the first equation of (3.4), we must have

$$\lim_{t\to\infty}\left[-\frac{B}{C}x_2(t) + \int_0^\infty f(s)x_2(t-s)\,ds\right] = 0. \tag{3.12}$$

Let $\alpha = \liminf_{t\to\infty} x_2(t)$, $\beta = \limsup_{t\to\infty} x_2(t)$, and $\{t_m\} \uparrow \infty$ be a sequence such that $x_2(t_m) \to \beta$ as $m \to \infty$. Then $\beta < \infty$, and from (3.12) we obtain

$$\frac{B}{C}\,\beta = \lim_{m\to\infty}\int_0^\infty f(s)x_2(t_m - s)\,ds \leq \beta.$$

Since $B > C$, this implies that $\beta \leq 0$. A similar argument shows that $\alpha \geq 0$. Therefore $\alpha = \beta = 0$, and $\big(x_1(t), x_2(t)\big) \to (0,0)$ as $t \to \infty$ for every solution $\big(x_1(t), x_2(t)\big)$ of system (3.4).

Note that the characteristic equation of (3.4) is

$$\Delta(\lambda) = \lambda^2 + A\lambda + G(\lambda)\big(B - CF(\lambda)\big) = 0,$$

where

$$F(\lambda) = \int_0^\infty f(s)e^{-\lambda s}ds, \quad G(\lambda) = \int_0^\infty g(s)e^{-\lambda s}ds.$$

Since $B > C$ and every solution of (3.4) approaches zero as $t \to \infty$, $\Delta(\lambda)$ has no roots with $\mathrm{Re}(\lambda) \geq 0$. Therefore, all roots of $\Delta(\lambda)$ have negative real parts and E^* is thus locally asymptotically stable. This completes the proof. □

Remark 3.2. Beretta and Takeuchi [2, 4] observed that system (3.4) has the same characteristic equation as the following system:

$$\begin{aligned} \dot{y}_1 &= y_2, \\ \dot{y}_2 &= -Ay_2 - \int_0^\infty Bg(s)y_1(t-s)ds + C\int_0^\infty\int_0^\infty g(s-v)f(v)y_1(t-s)dvds. \end{aligned} \tag{3.13}$$

They then constructed a Liapunov functional for (3.13) and showed that the sufficient condition for the local stability of E^* is (Theorem 2 in [4])

$$CT_f + (B + C)T_g < A.$$

Our condition (3.11) improves the above condition.

4. Global asymptotic stability. To study the global stability of E^*, we consider any positive solution $X(t,\phi) = (N(t,\phi), P(t,\phi))$ of (2.1) and (2.2). We make the change of variables

$$x_1 = N - N^*, \quad x_2 = \ln(P/P^*), \tag{4.1}$$

and define $\xi(x_1)$ as in (3.1). Then

$$N = x_1 + N^*, \quad P = P^* \exp(x_2), \tag{4.2}$$

and $x_1\xi(x_1) > 0$ for any $x_1 \in [-N^*, +\infty)$; $x_1\xi(x_1) = 0$ if and only if $x_1 = 0$. Using (4.1), we rewrite system (2.1) as follows:

$$\begin{aligned}
\dot{x}_1(t) =& - Dx_1(t) - aP^* \exp(x_2(t))\xi(x_1(t)) - P^*G\big(\exp(x_2(t)) - 1\big) \\
& - b\gamma P^* \int_0^t \int_{t-s}^t f(s) \exp(x_2(u))\dot{x}_2(u) du\, ds + J(t), \\
\dot{x}_2(t) =& c \int_0^\infty g(s)\xi(x_1(t-s))ds,
\end{aligned} \tag{4.3}$$

where $G = aU(N^*) - b\gamma > 0$ and

$$J(t) = -b\gamma P^* \int_t^\infty f(s)\big[\exp(x_2(t)) - \exp(x_2(t-s))\big]\, ds. \tag{4.4}$$

Let $(x_1(t), x_2(t))$ be an arbitrary solution of system (4.3). We consider the function

$$V_{11}(t) = \int_0^{x_1(t)} \xi(s)\, ds.$$

Then upon using (4.3), we obtain

$$\begin{aligned}
\dot{V}_{11}(t) =& -Dx_1(t)\xi(x_1(t)) - aP(t)\xi^2(x_1(t)) - P^*G\big(\exp(x_2(t)) - 1\big)\xi(x_1(t)) \\
& - b\gamma P^*\xi(x_1(t)) \int_0^t \int_{t-s}^t f(s) \exp(x_2(u))\dot{x}_2(u) du ds + \xi(x_1(t))J(t) \\
=& -Dx_1(t)\xi(x_1(t)) - aP(t)\xi^2(x_1(t)) \\
& - P^*G\big(\exp(x_2(t)) - 1\big)\xi(x_1(t)) + \xi(x_1(t))J(t) \\
& - bc\gamma P^*\xi(x_1(t)) \int_0^t \int_{t-s}^t f(s) \exp(x_2(u)) \int_0^\infty g(v)\xi(x_1(u-v)) dv du ds \\
\le& -Dx_1(t)\xi(x_1(t)) - aP(t)\xi^2(x_1(t)) - P^*G\big(\exp(x_2(t)) - 1\big)\xi(x_1(t)) \\
& + \frac{1}{2}bc\gamma\bigg(\int_0^\infty \int_{t-s}^t f(s)P(u) du ds\bigg)\xi^2(x_1(t)) + \xi(x_1(t))J(t) \\
& + \frac{1}{2}bc\gamma \int_0^\infty \int_{t-s}^t f(s)P(u) \int_0^\infty g(v)\xi^2(x_1(u-v)) dv du ds.
\end{aligned} \tag{4.5}$$

Let us now consider the following two functions:

$$V_{12}(t) = \frac{1}{2}bc\gamma \int_0^\infty f(s) \int_{t-s}^t \int_w^t P(u) \int_0^\infty g(v)\xi^2(x_1(u-v))dvdudwds,$$
$$V_{13}(t) = \frac{1}{2}bc\gamma T_f \int_0^\infty g(s) \int_{t-s}^t P(u+s)\xi^2(x_1(u))duds.$$

We now assume that $\int_0^\infty s^2 f(s)\,ds < \infty$ so that V_{12} is well defined. To see the existence of V_{13}, we note from (2.1) that

$$\dot{P}(t) \le P(t)[c - (\gamma + D)] = kP(t) \tag{4.6}$$

with $k = c - (\gamma + D) > 0$. This implies

$$P(s) \le P(t)e^{k(s-t)} \qquad \text{for} \qquad s \ge t \ge 0. \tag{4.7}$$

Since $|\xi(x)| \le 1$, using (4.7), we have from the definition of V_{13} that

$$\begin{aligned} V_{13}(t) &\le \frac{1}{2}bc\gamma T_f P(t) \int_0^\infty g(s) \int_{t-s}^t e^{k(u+s-t)}duds \\ &= \frac{1}{2k}bc\gamma T_f P(t) \int_0^\infty g(s)[e^{ks} - 1]ds. \end{aligned} \tag{4.8}$$

It follows that if $\int_0^\infty g(s)[e^{ks} - 1]\,ds < \infty$, then $V_{13}(t)$ exists. Thus, for $V_1(t) = V_{11}(t) + V_{12}(t) + V_{13}(t)$, we obtain from (4.5) that

$$\begin{aligned} \dot{V}_1(t) \le{}& -Dx_1(t)\xi(x_1(t)) - aP(t)\xi^2(x_1(t)) - P^*G\big(\exp(x_2(t)) - 1\big)\xi(x_1(t)) \\ &+ \frac{1}{2}bc\gamma\xi^2(x_1(t)) \int_0^\infty \int_{t-s}^t f(s)P(u)duds \\ &+ \frac{1}{2}bc\gamma T_f\xi^2(x_1(t)) \int_0^\infty g(s)P(t+s)\,ds + \xi(x_1(t))J(t). \end{aligned} \tag{4.9}$$

Notice that from the second equation of system (2.1), we have $\dot{P}(t) \ge -(\gamma + D)P(t)$ for all $t > 0$. Thus

$$P(s) \le P(t)\exp\big[(\gamma + D)(t - s)\big] \quad \text{for } t \ge s \ge 0. \tag{4.10}$$

This implies that

$$\begin{aligned} \int_0^\infty \int_{t-s}^t f(s)P(u)\,duds &= \int_0^t \int_{t-s}^t f(s)P(u)\,duds + \int_t^\infty \int_0^t f(s)P(u)\,duds + K(t) \\ &\le P(t) \int_0^t \int_{t-s}^t f(s)\,\exp\big[(\gamma + D)(t-u)\big]duds \\ &\quad + P(t) \int_t^\infty \int_0^t f(s)\exp\big[(\gamma + D)(t-u)\big]duds + K(t) \\ &\le \frac{P(t)}{\gamma + D} \int_0^\infty f(s)\big(\exp[(\gamma + D)s] - 1\big)\,ds + K(t) \\ &= T_f^* P(t) + K(t), \end{aligned} \tag{4.11}$$

where

$$K(t) = \int_t^\infty f(s) \int_{t-s}^0 P(u)\, duds, \tag{4.12}$$

$$T_f^* = \frac{1}{\gamma + D} \int_0^\infty f(s)\big(\exp\big[(\gamma + D)s\big] - 1\big)\, ds. \tag{4.13}$$

Similarly, using (4.10), we have

$$\int_0^\infty g(s)P(t+s)ds \le P(t) \int_0^\infty g(s) \exp\big[ks\big] ds = \big(1 + kT_g^*\big)P(t), \tag{4.14}$$

where

$$T_g^* = \frac{1}{k} \int_0^\infty g(s)[e^{ks} - 1]ds < \infty. \tag{4.15}$$

Then (4.9), together with (4.11) and (4.14), implies that

$$\begin{aligned} \dot{V}_1(t) \le & -Dx_1(t)\xi(x_1(t)) - aP(t)\xi^2(x_1(t)) \\ & - P^*G\big(\exp(x_2(t)) - 1\big)\xi(x_1(t)) \\ & + \frac{1}{2}bc\gamma\big(T_f^* + T_f + kT_fT_g^*\big)P(t)\xi^2(x_1(t)) \\ & + \xi(x_1(t))J(t) + \frac{1}{2}bc\gamma\xi^2(x_1(t))K(t). \end{aligned} \tag{4.16}$$

On the other hand, from the second equation of system (4.3), we have

$$\frac{d}{dt}\left[x_2(t) + c\int_0^\infty g(s) \int_{t-s}^t \xi(x_1(u))duds\right] = c\xi(x_1(t)).$$

Let

$$y(t) = x_2(t) + c\int_0^\infty g(s) \int_{t-s}^t \xi(x_1(u))duds.$$

We define

$$V_{21}(t) = \int_0^{y(t)} \big[\exp(s) - 1\big] ds.$$

Then it follows that

$$\begin{aligned} \dot{V}_{21}(t) &= c\xi(x_1(t))\left\{ \exp\left[x_2(t) + c\int_0^\infty g(s) \int_{t-s}^t \xi(x_1(u))duds\right] - 1\right\} \\ &= c\xi(x_1(t))\big[\exp(x_2(t)) - 1\big] \\ &\quad + c\xi(x_1(t))\left\{ \exp\left[x_2(t) + c\int_0^\infty g(s) \int_{t-s}^t \xi(x_1(u))duds\right] - \exp(x_2(t))\right\} \\ &= c\xi(x_1(t))\big[\exp(x_2(t)) - 1\big] \\ &\quad + c\exp(x_2(t))\xi(x_1(t))\left\{ \exp\left[c\int_0^\infty g(s) \int_{t-s}^t \xi(x_1(u))duds\right] - 1\right\} \\ &= c\xi(x_1(t))\big[\exp(x_2(t)) - 1\big] \\ &\quad + c^2\exp(x_2(t))\xi(x_1(t))\exp(\alpha(t)) \int_0^\infty g(s) \int_{t-s}^t \xi(x_1(u))duds \end{aligned}$$

for some function $\alpha(t)$ between 0 and $c\int_0^\infty g(s)\int_{t-s}^t \xi(x_1(u))duds$. Since $|\xi(x_1)| \le 1$, we have

$$|\alpha(t)| \le c\int_0^\infty g(s)\int_{t-s}^t |\xi(x_1(u))|duds \le cT_g.$$

Therefore,

$$\begin{aligned}
\dot V_{21}(t) &\le c\xi(x_1(t))\big[\exp(x_2(t)) - 1\big] \\
&\quad + \frac{1}{2}c^2\exp(x_2(t))\exp(\alpha(t))\int_0^\infty\int_{t-s}^t g(s)\big[\xi^2(x_1(t)) + \xi^2(x_1(u))\big]duds \\
&= c\xi(x_1(t))\big[\exp(x_2(t)) - 1\big] \\
&\quad + \frac{1}{2}c^2\exp(x_2(t))\exp(\alpha(t))\left[T_g\xi^2(x_1(t)) + \int_0^\infty\int_{t-s}^t g(s)\xi^2(x_1(u))duds\right] \\
&\le c\xi(x_1(t))\big[\exp(x_2(t)) - 1\big] \\
&\quad + \frac{1}{2}c^2T_g\exp(x_2(t))\exp(cT_g)\xi^2(x_1(t)) \\
&\quad + \frac{1}{2}c^2\exp(x_2(t))\exp(cT_g)\int_0^\infty\int_{t-s}^t g(s)\xi^2(x_1(u))duds. \qquad (4.17)
\end{aligned}$$

We now define

$$V_{22}(t) = \frac{1}{2}c^2\exp(cT_g)\int_0^\infty g(s)\int_{t-s}^t \exp(x_2(v+s))\int_v^t \xi^2(x_1(u)dudvds.$$

Then, by using (4.7) and

$$\begin{aligned}
&\int_0^\infty g(s)\int_{t-s}^t P(v+s)\int_v^t du\,dv\,ds \\
&\qquad \le \int_0^\infty sg(s)\int_{t-s}^t P(v+s)\,dv\,ds \\
&\qquad \le P(t)\int_0^\infty sg(s)\int_{t-s}^t e^{k(v+s-t)}\,dv\,ds = \frac{1}{k}P(t)\int_0^\infty sg(s)[e^{ks}-1]ds,
\end{aligned}$$

we can see that, under the assumption that $\int_0^\infty sg(s)[e^{ks}-1]ds < \infty$, $V_{22}(t)$ exists. Let $V_2(t) = V_{21}(t) + V_{22}(t)$; we have from (4.17) that

$$\begin{aligned}
\dot V_2(t) &\le c\xi(x_1(t))\big[\exp(x_2(t)) - 1\big] \\
&\quad + \frac{1}{2}c^2T_g\exp(cT_g)\,\exp(x_2(t))\xi^2(x_1(t)) \\
&\quad + \frac{1}{2}c^2\exp(cT_g)\xi^2(x_1(t))\int_0^\infty g(s)\int_{t-s}^t \exp(x_2(u+s))duds.
\end{aligned}$$

Note that from (4.7) we have

$$\int_{t-s}^t \exp(x_2(u+s))du \le \frac{1}{k}[e^{ks}-1]\exp(x_2(t)).$$

Therefore,

$$\begin{aligned}\dot{V}_2(t) \le{}& c\xi(x_1(t))\big[\exp(x_2(t)) - 1\big] \\ &+ \frac{1}{2}c^2\exp(cT_g)\big(T_g + T_g^*\big)\exp(x_2(t))\xi^2(x_1(t)).\end{aligned} \tag{4.18}$$

We finally define the following function:

$$V(t) = V_1(t) + \frac{P^*}{c}\bigg(b\gamma\int_t^\infty f(s)\,ds + G\bigg)V_2(t).$$

It then follows from (4.16) and (4.18) that

$$\begin{aligned}\dot{V}(t) \le{}& -Dx_1(t)\xi(x_1(t)) - \frac{1}{2}\big(2a - L\big)P(t)\xi^2(x_1(t)) \\ &+ \frac{1}{2}bc\gamma P^*\exp(cT_g)\big(T_g + T_g^*\big)\exp(x_2(t))\xi^2(x_1(t))\int_t^\infty f(s)\,ds \\ &+ b\gamma P^*\xi(x_1(t))\int_t^\infty f(s)\big[\exp(x_2(t-s)) - 1\big]\,ds \\ &+ \frac{1}{2}bc\gamma\xi^2(x_1(t))K(t),\end{aligned} \tag{4.19}$$

where

$$L = bc\gamma\big(T_f^* + T_f + kT_fT_g^*\big) + cG\exp(cT_g)\big(T_g + T_g^*\big).$$

Notice that from (4.2), $P(u) = P^*\exp(\phi_2(u))$ for $u \le 0$ and $\exp(x_2(t-s)) = \exp(\phi_2(t-s))$ for $t \le s$, where $\phi_2 \in BC(-\infty, 0]$ is the initial data for $x_2(t)$. By (4.12), we have

$$\begin{aligned}&|K(t)| \le P^*\exp\big(\|\phi_2\|\big)\int_t^\infty sf(s)\,ds, \\ &\left|\int_t^\infty f(s)\big[\exp(x_2(t-s)) - 1\big]ds\right| \le \big[\exp\big(\|\phi_2\|\big) - 1\big]\int_t^\infty f(s)\,ds.\end{aligned}$$

Since $|\xi(x_1)| \le 1$, using the above inequalities, we obtain from (4.19) that

$$\begin{aligned}\dot{V}(t) \le{}& -Dx_1(t)\xi(x_1(t)) - \frac{1}{2}\big(2a - L\big)P(t)\xi^2(x_1(t)) \\ &+ \frac{1}{2}bc\gamma\exp(cT_g)\big(T_g + T_g^*\big)P(t)\xi^2(x_1(t))\int_t^\infty f(s)\,ds \\ &+ b\gamma P^*\big[\exp\big(\|\phi_2\|\big) - 1\big]\int_t^\infty f(s)\,ds \\ &+ \frac{1}{2}bc\gamma P^*\exp\big(\|\phi_2\|\big)\int_t^\infty sf(s)\,ds.\end{aligned} \tag{4.20}$$

The above analysis now leads to the following global stability result.

THEOREM 4.1. *Let $G = aU(N^*) - b\gamma$ and T_f^* and T_g^* be the constants defined in* (4.13) *and* (4.15), *respectively. Assume that $\int_0^\infty sg(s)[e^{ks} - 1]ds < \infty$ and*

$$L \triangleq bc\gamma\big(T_f^* + T_f + kT_fT_g^*\big) + cG\exp(cT_g)\big(T_g + T_g^*\big) < 2a \tag{4.21}$$

with $k = c - (\gamma + D) > 0$. Then the positive equilibrium E^* is globally asymptotically stable.

Proof. Let $(x_1(t), x_2(t))$ be an arbitrary solution of system (4.3) with $\phi_2 \in BC(-\infty, 0]$ being the initial data of $x_2(t)$. We choose $\varepsilon > 0$ such that

$$L(\varepsilon) \triangleq L + \frac{1}{2}bc\gamma \exp(cT_g)\big(T_g + T_g^*\big)\varepsilon < 2a$$

and find $T = T(\varepsilon) > 1$ such that $\int_t^\infty f(s)\,ds < \varepsilon$ for all $t \geq T$. Notice that $L < 2a$ and $\int_0^\infty s^2 g(s)[e^{ks} - 1]ds < \infty$, thus $V(t)$ is well defined and (4.20) holds. Therefore, for all $t \geq T$, we have

$$\begin{aligned}\dot{V}(t) \leq & - Dx_1(t)\xi(x_1(t)) - \frac{1}{2}\big(2a - L(\varepsilon)\big)P(t)\xi^2(x_1(t)) \\ & + \frac{1}{2}b\gamma P^*\big[(c+2)\exp\big(\|\phi_1\|\big) - 2\big]\int_t^\infty sf(s)\,ds \\ \leq & - Dx_1(t)\xi(x_1(t)) + M\int_t^\infty sf(s)\,ds,\end{aligned}$$

where $M = \frac{1}{2}b\gamma P^*\big[(c+2)\exp\big(\|\phi_1\|\big) - 2\big] > 0$. Integrating $\dot{V}(t)$ from T to $t \geq T$ now gives

$$\begin{aligned}& V_{11}(t) + \frac{P^*G}{C}V_2(t) + D\int_T^t x_1(s)\xi(x_1(s))\,ds \\ & \quad \leq V(t) + D\int_T^t x_1(s)\xi(x_1(s))\,ds \\ & \quad \leq V(T) + M\int_T^t\int_s^\infty uf(u)\,duds \\ & \quad \leq V(T) + M\int_0^\infty s^2 f(s)\,ds \\ & \quad \leq V(T) + 2(\gamma + D)MT_f^* < \infty.\end{aligned}$$

This implies that $x_1(t)$ and $x_2(t)$ are bounded, and $x_1(t)\xi(x_1(t)) \in L_1[0,\infty)$. Since ξ is uniformly continuous on $[0,\infty)$, it follows from the equations in system (4.3) and the boundedness of $x_1(t)$ and $x_2(t)$ that $x_1(t)\xi(x_1(t))$ is also uniformly continuous. Thus, by the Barbălat lemma (see Lemma 1.2.2 in [9]), $x_1(t)\xi(x_1(t)) \to 0$ as $t \to \infty$. This leads to $\lim_{t\to\infty} x_1(t) = 0$, so $\lim_{t\to\infty} N(t) = N^*$ by (4.2). Note further that $\dot{x}_1(t)$ is also uniformly continuous on $[0,\infty)$ by the equations in (4.3). Applying the Barbălat lemma (see Lemma 1.2.3 in [9]) once again gives $\lim_{t\to\infty}\dot{x}_1(t) = \lim_{t\to\infty}\dot{N}(t) = 0$. Now taking the limit $(t \to \infty)$ on both sides of (2.1), we obtain

$$\lim_{t\to\infty}\left(aU(N^*)P(t) - b\gamma\int_0^\infty f(s)P(t-s)\,ds\right) = D\big(N^0 - N^*\big). \tag{4.22}$$

Let $\alpha = \liminf_{t\to\infty} P(t)$, $\beta = \limsup_{t\to\infty} P(t)$, and $\{t_m\} \uparrow \infty$ be a sequence such that $\lim_{m\to\infty} P(t_m) = \beta$. Since $\beta < \infty$, it follows from (4.22) that

$$\begin{aligned}aU(N^*)\beta &= D\big(N^0 - N^*\big) + \lim_{m\to\infty} b\gamma\int_0^\infty f(s)P(t_m - s)\,ds \\ &\leq D\big(N^0 - N^*\big) + b\gamma\beta.\end{aligned}$$

Thus,

$$\beta \le \frac{D\big(N^0 - N^*\big)}{aU(N^*) - b\gamma} = P^*.$$

Similarly, we can show that $\alpha \ge P^*$. Therefore, $\lim_{t\to\infty} P(t) = P^*$. This proves the global attractivity of E^*.

On the other hand, we claim that $L < 2a$ implies (3.11). In fact,

$$CT_f + (B - C)T_g = cP^*U'(N^*)[b\gamma T_f + GT_g] \tag{4.23}$$

with $G = aU(N^*) - b\gamma > 0$. It is noticed that $T_f \le T_f^*$ and $T_g \le T_g^*$. Then, from $L < 2a$, we have

$$2a > bc\gamma(T_f^* + T_f) + cG(T_g + T_g^*) \ge 2c[b\gamma T_f + GT_g]$$

and hence

$$CT_f + (B - C)T_g \le P^*U'(N^*)a < A,$$

which shows that (3.11) holds. By Theorem 3.1, E^* is locally asymptotically stable. This, together with global attractivity, implies that E^* is globally asymptotically stable. □

5. Discussion. In this paper, we have considered a chemostat-type plankton model with nutrient recycling. We assumed that there are a (distributed) delay in the growth response of plankton to nutrient uptake and a (distributed) delay in nutrient recycling. We have obtained some sufficient conditions for both local and global stability of the positive equilibrium by constructing appropriate Liapunov-like functionals. It is known that the delay in the growth response of the populations to nutrient uptake can cause oscillations in population density (see Caperon [7] and Ruan [19]); our results indicate that one can still have global stability of the positive equilibrium if the delays are sufficiently small, and explicit estimates (see (3.11), (4.18), and (4.19)) on the size of these delays for local and global stability can also be obtained.

We should point out that model (2.1) and other related models have been studied by Beretta and Takeuchi [2–4], He and Ruan [11], and Kolmanovskii, Torelli, and Vermiglio [13]. For local stability, following the arguments of Kolmanovskii, Torelli, and Vermiglio [13], Beretta and Takeuchi [2, 4] chose a Liapunov functional for the equivalent system (3.13) and obtained some sufficient conditions. Our local stability conditions improve their conditions. For global stability, Beretta and Takeuchi [2, 4] considered the special cases of model (2.1) when the second delay does not appear, that is, the system (2.1) with Dirac delta function $g(s) = \delta(s)$. In [2], they assumed that the interaction between nutrient and biotic species is described by (no-delayed) Lotka–Volterra coupling (i.e., $U(N) = N$). In [4], they adopted a (no-delayed) Michaelis–Menten law (i.e., $U(N) = N/(L+K)$), which is better than the former to describe the interaction from the biological point of view. With this choice, they proved (Theorem 7 in [4]) that the positive equilibrium E^* is attractive if

$$\gamma T_f < \min\left\{\frac{1}{b}, \frac{2}{b}\sqrt{\frac{aDN^*}{c^2U(N^*)K}}\right\} \le \frac{1}{b}, \tag{5.1}$$

where $K = \max\{\beta, N^o/(1 - b\gamma T_f)\}$, $\beta = (1 + b\gamma T_f)H$, and H is the bound for initial functions. Hence, the attractivity of N^* is indeed for all the solutions whose initial

functions are bounded by H. Obviously, $\gamma T_f \to 0$ as $H \to \infty$. If we consider Beretta and Takeuchi's model in [4] as a special case of our system (2.1), then we have $T_g = T_g^* = 0$ and our global asymptotic stability condition in Theorem 4.1 becomes

$$bc\gamma[T_f^* + T_f] < 2a. \tag{5.2}$$

Condition (5.2) was also obtained in He and Ruan [11, Theorem 2.1] for the system (2.1) with $g(s) = \delta(s)$ and the general growth response $U(N)$. Rewrite (5.2) as

$$\gamma T_f + \frac{1}{2}\gamma[T_f^* - T_f] < \frac{a}{bc}. \tag{5.3}$$

Note that $c \le a$, so $a/bc \ge 1/b$. Compared with (5.1), we can see that (5.3) is more restrictive on the delay kernel function f but less restrictive on the initial functions. Since condition (5.1) depends on the bound of the initial values, basically it is not a global stability condition. Thus, our condition (5.3) complements Beretta and Takeuchi's results in [4] by providing really global stability results with a little more restriction on the delay. Furthermore, our global stability results hold for the general case when both distributed delays are present and the growth response function is a general function satisfying (2.3).

Acknowledgments. Conditions in Theorem 4.1 were improved by following the referees' suggestions. We thank both referees for their comments. We are also grateful to Wanbiao Ma for his careful reading of the original version of the paper and for his helpful comments and suggestions.
