RECOVERY OF SINGULARITIES OF A MULTIDIMENSIONAL SCATTERING POTENTIAL*

LASSI PÄIVÄRINTA† AND VALERI SEROV‡

Abstract. We prove that in multidimensional potential scattering the leading order singularities of the unknown potential are obtained exactly from the scattering amplitude by the linearized inversion method. The proof is based on the appropriate mapping properties of the fundamental solution in weighted L^p-spaces and on a homogeneity argument concerning the bilinear term.

Key words. Born approximation, Schrödinger scattering, inverse problem

AMS subject classifications. 35P25, 35R30

Introduction. A widely applied approximate method of estimating the potential from the scattering amplitude is to use the Born approximation for the scattering solution. The obvious advantage of this is that within the Born approximation, the scattering amplitude is simply the Fourier transform of the unknown potential. The weaker the potential, the better is this approximation. But even when the potential is not weak the Fourier transform of a scattering amplitude contains essential information of the potential as was shown in [PS] and [PSS] in two and three dimensions.

The purpose of this work is to generalize the results of the articles [PS], [PSS] to arbitrary dimensions. The assumptions on the potential for the Schrödinger operator are also reduced to allow stronger singularities. We recall that in the case of less singular potentials Sun and Uhlmann [SU1], [SU2] considered related problems in two dimensions with fixed energy data, while Greenleaf and Uhlmann [GU] considered related problems in $\mathbb{R}^n$ with backscattering data. The main result of this work is that the leading order singularity of the potential is obtained exactly from the scattering amplitude by the linearized inversion method (Born approximation). For a similar result in the one-dimensional case see [So], [No], and [ST].

1. Outline and results. Let $q(x)$ be a real valued potential in $\mathbb{R}^n (n \geq 3)$ appearing in the Schrödinger operator

$$H \equiv -\Delta + q(x). \tag{1.1}$$

Our basic assumption is that the potential $q(x)$ belongs to the weighted space $L^s_\sigma(\mathbb{R}^n)$ defined by the norm

$$\|q\|_{s,\sigma} = \left(\int_{\mathbb{R}^n} (1+|x|)^{\sigma s} |q(x)|^s dx \right)^{1/s} < \infty,$$

where

$$s > 2n, \quad \sigma > 1 + \frac{n}{s}. \tag{1.2}$$

Below we also use the following notation. The space $H^t,\ t \in \mathbb{R}$, denotes the usual L^2-based and W_s^t the L^s-based Sobolev space in $\mathbb{R}^n$.

Under the above assumptions on the potential $q(x)$, the operator H is a self-adjoint operator in $L^2(\mathbb{R}^n)$. The spectrum of this operator consists of an absolutely continuous spectrum, filling out the positive real axis, and a negative discrete spectrum of finite multiplicity with zero as the only possible accumulation point. In this case, for arbitrary $k \in \mathbb{R},\ k \neq 0$, we define the scattering solutions of the homogeneous Schrödinger equation

$$(H - k^2)u(x,k) = 0 \tag{1.3}$$

to be the unique solutions of the Lippmann–Schwinger equation

$$u(x,k,\theta) = e^{ik(x,\theta)} - \int\limits_{\mathbb{R}^n} G_k^+(|x-y|)q(y)u(y,k,\theta)dy, \tag{1.4}$$

where $\theta \in S^{n-1}$ and the outgoing fundamental solution of the Helmholtz equation G_k^+ is defined as

$$G_k^+(|x|) = \frac{i}{4}\left(\frac{|k|}{2\pi|x|}\right)^{\frac{n-2}{2}} H^{(1)}_{\frac{n-2}{2}}(|k||x|), \tag{1.5}$$

where $H^{(1)}_{\frac{n-2}{2}}$ is the Hankel function of the first kind and of order $\frac{n-2}{2}$. The function $G_k^+(x-y)$ is the kernel of the integral operator $(-\Delta - k^2)^{-1}$.

The solution $u(x,k,\theta)$ for $k > 0$ of the equation (1.3) admits asymptotically as $|x| \to +\infty$ the representation

$$u(x,k,\theta) = e^{ik(x,\theta)} + C_n \frac{e^{ik|x|}k^{\frac{n-3}{2}}}{|x|^{\frac{n-1}{2}}} A(k,\theta',\theta) + o\left(\frac{1}{|x|^{\frac{n-1}{2}}}\right). \tag{1.6}$$

Here $\theta \in S^{n-1},\ \theta' = \frac{x}{|x|} \in S^{n-1},\ C_n$ is a constant depending only on the dimension n, and the scattering amplitude $A(k,\theta',\theta)$ is defined by

$$A(k,\theta',\theta) = \int\limits_{\mathbb{R}^n} e^{-ik(\theta',y)}q(y)u(y,k,\theta)dy. \tag{1.7}$$

For $k < 0$ we set

$$(k,\theta',\theta) = \overline{A(-k,\theta',\theta)}$$

to obtain a well-defined scattering amplitude $A(k,\theta',\theta)$ for all $k \in \mathbb{R},\ k \neq 0,\ \theta',\theta \in S^{n-1}$. The inverse scattering problem is to recover the potential from the knowledge of $A(k,\theta',\theta)$.

To introduce the Born inversion scheme we proceed as in [PS] and define the manifolds M_0 and M by $M_0 = \mathbb{R} \times S^{n-1},\ M = M_0 \times S^{n-1}$ and the measures $d\mu_\theta(k,\theta')$ and $d\mu(k,\theta',\theta)$ over M_0 and M, correspondingly, as

$$d\mu_\theta(k,\theta') = \frac{1}{4}|k|^{n-1}dk|\theta - \theta'|^{n-1}d\theta',$$

$$d\mu(k,\theta',\theta) = \frac{1}{|S^{n-1}|}d\theta d\mu_\theta(k,\theta'), \tag{1.8}$$

where $|S^{n-1}| = 2\pi^{\frac{n}{2}}/\Gamma(n/2)$ is the area of the unit sphere S^{n-1} and $d\theta$ and $d\theta'$ denote the usual Lebesgue measures on S^{n-1}. We shall define the equivalent of the usual inverse Fourier transform on M_0 and M as

$$\left(\mathcal{F}_{M_0}^{-1}\phi_1\right)(x) = \frac{1}{(2\pi)^n}\int\limits_{M_0} e^{-ik(\theta-\theta',x)}\phi_1(k,\theta')d\mu_\theta(k,\theta'),$$

$$\left(\mathcal{F}_{M}^{-1}\phi_2\right)(x) = \frac{1}{(2\pi)^n}\int\limits_{M} e^{-ik(\theta-\theta',x)}\phi_2(k,\theta',\theta)d\mu(k,\theta',\theta). \tag{1.9}$$

If we write $\xi = k(\theta-\theta')$ then k and θ are obtained by

$$k = \frac{|\xi|}{2(\theta,\hat{\xi})},\ \theta' = \theta - 2(\theta,\hat{\xi})\hat{\xi},$$

$$\hat{\xi} = \frac{\xi}{|\xi|},\ (\theta,\hat{\xi}) \neq 0. \tag{1.10}$$

These formulas are found useful later on.

From (1.6), Proposition 1.4, and (1.7), it follows that

$$\left(\mathcal{F}q\right)(\xi) = \lim_{k\to\infty} A(k,\theta',\theta),\ \xi = k(\theta'-\theta), \tag{1.11}$$

where $\mathcal{F}$ is the usual Fourier transform in $\mathbb{R}^n$. This fact justifies the following definition.

DEFINITION. *The inverse Born approximation $q_B^\theta(x)$ and $q_B(x)$ of the potential $q(x)$ are defined as follows:*

$$q_B^\theta(x) = \left(\mathcal{F}_{M_0}^{-1}A\right)(x),\ q_B(x) = \left(\mathcal{F}_{M}^{-1}A\right)(x). \tag{1.12}$$

In this work we will prove the following three theorems.

THEOREM 1.1. *Assume that the potential $q(x)$ belongs to $L^s_\sigma(\mathbb{R}^n)$ $(n \geq 3)$ with conditions* (1.2) *fulfilled. Then the knowledge of $q_B^\theta(x)$ with θ restricted to an $(n-2)$-dimensional semisphere defines $q(x)$ uniquely.*

THEOREM 1.2. *Under the same assumptions for $q(x)$ as in Theorem* 1.1, *there exists $\varepsilon > 0$ such that*

$$q(x) - q_B(x) \in L^{s+\varepsilon}_{loc}(\mathbb{R}^n). \tag{1.13}$$

THEOREM 1.3. *Under the same assumptions for $q(x)$ as in Theorem* 1.1,

$$\lim_{k\to+\infty} k^{n-1}\int\limits_{S^{n-1}}\int\limits_{S^{n-1}} e^{-ik(\theta-\theta',x)}A(k,\theta',\theta)d\theta d\theta' = \frac{(2\pi)^n}{\pi}\int\limits_{\mathbb{R}^n}\frac{q(y)dy}{|x-y|^{n-1}}. \tag{1.14}$$

The following new estimates for the resolvent of the operator H (cf. [S]) on the continuous spectrum play the key role in the proofs of these theorems.

PROPOSITION 1.4. *Assume that the potential $q(x)$ is in $L^{\frac{p}{p-2}}_\sigma(\mathbb{R}^n)$ $(n \geq 3)$ for $2 \leq p < \frac{2n}{n-1/2}$, $\frac{1}{p}+\frac{1}{p'} = 1$, and $\sigma > 1 + n(1-\frac{2}{p})$. Then for all $k \in \mathbb{R}$, $k \neq 0$, the limit*

$$\mathbf{G}_q := \lim_{\varepsilon\to+0}(H - k^2 - i\varepsilon)^{-1} \tag{1.15}$$

exists in the uniform operator topology from $L^{p'}_{\sigma/2}(\mathbb{R}^n)$ to $L^p_{-\sigma/2}(\mathbb{R}^n)$.

Moreover, for large $|k|$

$$\|\mathbf{G}_q f\|_{L^p_{-\sigma/2}(\mathbb{R}^n)} \le \frac{C}{|k|^\alpha}\|f\|_{L^{p'}_{\sigma/2}(\mathbb{R}^n)}, \tag{1.16}$$

where $0 < \alpha < 1 - n(1 - \frac{2}{p})$.

The following well-known resolvent equation for the integral kernel $G_q(x, y, k)$ of the operator $\mathbf{G}_q$ in (1.15) will be useful in several points of the paper:

$$G_q(x, y, k) = G_k^+(|x - y|) - \int\limits_{\mathbb{R}^n} G_k^+(|x - z|)q(z)G_q(z, y, k)dz. \tag{1.17}$$

Finally, by $\mathbf{K}$ we denote the integral operator having the kernel

$$K(x, y) = |q(x)|^{1/2}G_k^+(|x - y|)q_{1/2}(y) \tag{1.18}$$

with $q_{1/2} = |q|^{1/2}\ \operatorname{sgn} q$. From Proposition 1.4 it follows that $\mathbf{K}$ is a bounded operator in $L^2(\mathbb{R}^n)$ with the norm estimate

$$\|\mathbf{K}\| \le \frac{C}{|k|^\alpha} \tag{1.19}$$

with α as in (1.16).

2. Reconstruction of L^p-singularities. This section is devoted to the proofs of Theorems 1.1 and 1.2.

Proof of Theorem 1.1. The beginning of the proof proceeds as in [PS]. For the readers' convenience we repeat the reasoning. The rest of the proof is concentrated on the right L^p-estimates.

The definition (1.9) of $q_B^\theta(x)$ together with formula (1.7) for the scattering amplitude $A(k, \theta', \theta)$ yields

$$q_B^\theta(x) = \frac{1}{(2\pi)^n}\int\limits_{M_0} e^{-ik(\theta-\theta',x)}A(k, \theta', \theta)d\mu_\theta(k, \theta')$$

$$= \frac{1}{(2\pi)^n}\int\limits_{M_0} d\mu_\theta(k, \theta')\int\limits_{\mathbb{R}^n} e^{-ik(\theta-\theta',x-y)}q(y)v(y, k, \theta)dy, \tag{2.1}$$

where $v(y, k, \theta) = e^{-ik(y,\theta)}u(y, k, \theta)$. After making the change of variables (1.10) in (2.1) we have

$$q_B^\theta(x) = \frac{1}{(2\pi)^n}\int\limits_{\mathbb{R}^n} d\xi \int\limits_{\mathbb{R}^n} e^{-i(\xi,x-y)}q(y)v\left(y, \frac{|\xi|}{2(\theta, \hat{\xi})}, \theta\right)dy.$$

Hence the usual Fourier transform of $q_B^\theta(x)$ is simply

$$\left(\mathcal{F}q_B^\theta\right)(\xi) = \left(\mathcal{F}(q)\right)(\xi) + \int\limits_{\mathbb{R}^n} e^{i(\xi,y)}q(y)\left[v\left(y, \frac{|\xi|}{2(\theta, \hat{\xi})}, \theta\right) - 1\right]dy.$$

This allows us to get the next inequality,

$$\left|\mathcal{F}(q_B^\theta - q)(\xi)\right| \le \int\limits_{\mathbb{R}^n} |q(y)| \left| v\left(y, \frac{|\xi|}{2(\theta,\hat{\xi})}, \theta\right) - 1 \right| dy. \tag{2.2}$$

Further, from the Lippmann–Schwinger equation (1.4) and the kernel equation (1.17) we have

$$v(y,k,\theta) - 1 = \tilde{\mathbf{G}}_q(q), \tag{2.3}$$

where $\tilde{\mathbf{G}}_q$ is the integral operator with the kernel $\tilde{G}_q(x,y,k) = e^{-ik(x-y,\theta)} G_q(x,y,k)$. Because the potential $q(x)$ satisfies the conditions (1.2), it is easy to check that $q(x)$ is in $L_{\sigma/2}^{\frac{2s}{s+1}}(\mathbb{R}^n)$, where s and σ satisfy (1.2). Thus, by (2.3) and Proposition 1.4 we get

$$\|v(y,k,\theta) - 1\|_{L_{-\sigma/2}^{\frac{2s}{s-1}}(\mathbb{R}^n)} \le \frac{C}{|k|^\alpha} \|q\|_{L_{\sigma/2}^{\frac{2s}{s+1}}(\mathbb{R}^n)}, \tag{2.4}$$

where $0 < \alpha < 1 - n/s$. Finally, from (2.2) and (2.4) we get

$$\left|\mathcal{F}(q_B^\theta - q)(\xi)\right| \le C \left(\frac{|(\hat{\xi},\theta)|}{|\xi|}\right)^\alpha \|q\|^2_{L_{\sigma/2}^{\frac{2s}{s+1}}(\mathbb{R}^n)}.$$

Clearly this implies

$$\mathcal{F}(q_B^\theta - q)(\xi) = 0 \text{ for } (\hat{\xi},\theta) = 0.$$

But the data $\{(\mathcal{F}f)(\xi) | (\hat{\xi},\theta) = 0\}$ when θ runs through an $(n-2)$-dimensional semisphere is enough for the complete recovery of f. □

For the proof of Theorem 1.2, we need some new definitions and lemmas.

For f in the Schwarz space S let v be the outgoing solution of the inhomogeneous Schrödinger equation

$$(H - k^2)v = f. \tag{2.5}$$

Then from (1.15) and (1.17) it follows that for v we have the following representation:

$$v(x) = \mathbf{G}_k^+(f - q \cdot \mathbf{G}_q(f))(x), \tag{2.6}$$

where $\mathbf{G}_k^+$ and $\mathbf{G}_q$ are the integral operators with kernels $G_k^+(|x-y|)$ and $G_q(x,y,k)$, correspondingly. This representation allows us to get the following asymptotic for $|x| \to +\infty$ behavior ($k > 0$):

$$v(x,k) = C_n \frac{e^{ik|x|} k^{\frac{n-3}{2}}}{|x|^{\frac{n-1}{2}}} A_f(k,\theta') + o(|x|^{\frac{1-n}{2}}), \tag{2.7}$$

where $\theta' = \frac{x}{|x|}$ and

$$A_f(k,\theta') = \int\limits_{\mathbb{R}^n} e^{-i(\theta',y)} (f(y) - q(y)\mathbf{G}_q(f)(y)) dy.$$

Below we will employ the following useful lemma.

LEMMA 2.1 (optical lemma). *For the function $A_f(k,\theta')$ the L^2-norm can be calculated by*

$$\int\limits_{S^{n-1}} |A_f(k,\theta')|^2 d\theta' = -\frac{1}{C_n^2 k^{n-2}} \operatorname{Im} \int\limits_{\mathbb{R}^n} f(x)\overline{v}(x,k)dx, \tag{2.8}$$

where C_n is the constant from (2.7).

The proof is the same as in [PS] with obvious modifications.

The function $A_f(k,\theta')$ is often called the "far field" of the equation (2.7). It satisfies the following equality:

$$A_f(k,\theta') = ((I - q\mathbf{G}_q)f, e^{ik(\theta',y)})_{L^2(\mathbb{R}^n)} = \int\limits_{\mathbb{R}^n} f(y)\overline{u(y,k,\theta')}dy, \tag{2.9}$$

where $u(y,k,\theta')$ is the solution of the Lippmann–Schwinger equation.

If a function $f : \mathbb{R}^n \to \mathbb{C}$ is decaying fast enough so that its Fourier transform has a trace on a unit sphere, then we can define the operator $A_0(k)$ as

$$(A_0(k)f)(\theta') = \int\limits_{\mathbb{R}^n} e^{-ik(\theta',y)} f(y)dy.$$

Similarly we define $A_q(k)$ as the trace of a generalized Fourier transform

$$(A_q(k)f)(\theta') = \int\limits_{\mathbb{R}^n} f(y)\overline{u(y,k,\theta')}dy, \tag{2.10}$$

whenever it exists.

The following lemma yields sufficient estimate for the existence of the above traces as well as k-dependent norm inequalities.

LEMMA 2.2. *Let the potential $q(x)$ satisfy the conditions* (1.2). *Then $A_q(k)$ and $A_0(k)$ are well defined bounded operators from $L^{\frac{2s}{s+1}}_{\sigma/2}(\mathbb{R}^n)$ to $L^2(S^{n-1})$ with the operator norm estimates*

$$\|A_0(k)\|,\ \|A_q(k)\| \le \frac{C}{|k|^{\frac{n-2}{2}+\frac{\alpha}{2}}}, \tag{2.11}$$

where s and σ are as in (1.2) *and $0 < \alpha < 1 - \frac{n}{s}$.*

Proof. By Lemma 2.1, we have

$$\|A_q(k)f\|^2_{L^2(S^{n-1})} = \int\limits_{S^{n-1}} |A_f(k,\theta')|^2 d\theta' \le \frac{C}{|k|^{n-2}} \|v\|_{L^{\frac{2s}{s-1}}_{-\sigma/2}(\mathbb{R}^n)} \|f\|_{L^{\frac{2s}{s+1}}_{\sigma/2}(\mathbb{R}^n)}.$$

Further, because $v = \mathbf{G}_q f$, from Proposition 1.4 and (1.16) we can get the estimate

$$\|A_q(k)f\|^2_{L^2(S^{n-1})} \le \frac{C}{|k|^{n-2+\alpha}} \|f\|_{L^{\frac{2s}{s+1}}_{\sigma/2}(\mathbb{R}^n)},$$

which proves the lemma. ∎

Now let $\Phi_0(k)$ and $\Phi(k)$ be the operators, defined for $f \in L^2(S^{n-1})$ as

$$\begin{aligned} \Phi_0(k)f(x) &= |q(x)|^{1/2} \int\limits_{S^{n-1}} e^{ik(\theta,x)} f(\theta)d\theta, \\ \Phi(k)f(x) &= |q(x)|^{1/2} \int\limits_{S^{n-1}} u(x,k,\theta)f(\theta)d\theta. \end{aligned} \tag{2.12}$$

It is readily seen that

$$\begin{aligned} \Phi_0(k)f(x) &= |q(x)|^{1/2}(A_0^*(k)f)(x), \\ \Phi(k)f(x) &= |q(x)|^{1/2}(A_q^*(k)f)(x), \end{aligned} \tag{2.13}$$

where A_q^* and A_0^* are the adjoint operators for A_q and A_0.

By Lemma 2.2 and (2.13) the operators $\Phi_0(k)$ and $\Phi(k)$ are bounded from $L^2(S^{n-1})$ to $L^2(\mathbb{R}^n)$ with the norm estimates

$$\|\Phi_0(k)\|,\ \|\Phi(k)\| \le \frac{C}{|k|^{\frac{n-2+\alpha}{2}}}. \tag{2.14}$$

A repeated use of the Lippmann–Schwinger equation yields the following representation for the scattering amplitude $A(k,\theta',\theta)$:

$$\begin{aligned} A(k,\theta',\theta) = \sum_{j=0}^{m} \int\limits_{\mathbb{R}^n} e^{-ik(\theta',y)} q_{1/2}(y)\mathbf{K}^j(|q|^{1/2}e^{ik(x,\theta)})(y)dy \\ + \int\limits_{\mathbb{R}^n} e^{-ik(\theta',y)} q_{1/2}(y)\mathbf{K}^{m+1}(|q|^{1/2}u(x,k,\theta))(y)dy, \end{aligned} \tag{2.15}$$

where $\mathbf{K}$ is the integral operator with kernel (1.18). This equality can be formulated in the sense of the integral operator in $L^2(S^{n-1})$:

$$\hat{A} = \sum_{j=0}^{m} \Phi_0^*(k)\ \operatorname{sgn} q\mathbf{K}^j\Phi_0(k) + \Phi_0^*(k)\ \operatorname{sgn} q\mathbf{K}^{m+1}\Phi(k), \tag{2.16}$$

where $\Phi_0^*(k)$ is the adjoint operator for $\Phi_0(k)$. Further, if we apply these formulas to the definition (1.12) of the Born approximation $q_B(x)$, we get

$$q_B(x) = \sum_{j=0}^{m} \mathcal{F}_M^{-1}[\Phi_0^*(k)\ \operatorname{sgn} q\mathbf{K}^j\Phi_0(k)] + \mathcal{F}_M^{-1}[\Phi_0^*(k)\ \operatorname{sgn} q\mathbf{K}^{m+1}\Phi(k)], \tag{2.17}$$

where the inverse Fourier transform is applied on the integral kernel of the corresponding integral operator. Let's rewrite the formula (2.17) as

$$q_B(x) = \sum_{j=0}^{m} q_j(x) + \tilde{q}_{m+1}(x). \tag{2.18}$$

By using this notation we have the following lemma.

LEMMA 2.3. *For any $j \ge 1$, $q_j(x)$ and $\tilde{q}_j x$ belong to the Sobolev space $H^t(\mathbb{R}^n)$ for any $t < \alpha(j+1) + \frac{n}{2} - 2$, where $0 < \alpha < 1 - \frac{n}{s}$.*

Proof. By the definition of the norm in the Sobolev space H^t and after the change of variables (1.10) we obtain

$$\|q_j\|^2_{H^t} = \|(1+|\xi|^2)^{t/2}\mathcal{F}(q_j)(\xi)\|^2_{L^2(\mathbb{R}^n)}$$

$$= \frac{1}{|S^{n-1}|}\int\limits_{\mathbb{R}^n}(1+|\xi|^2)^t d\xi \left| \int\limits_{S^{n-1}} [\Phi_0^*\ \operatorname{sgn} q\mathbf{K}^j\Phi_0] \left(\frac{|\xi|}{2(\theta,\hat{\xi})}, \theta - 2(\hat{\xi},\theta)\hat{\xi},\theta\right) d\theta \right|^2$$

$$\leq C\int\limits_0^\infty |k|^{n-1}(1+k^2)^t \|(\Phi_0^*\ \operatorname{sgn} q\mathbf{K}^j\Phi_0)(1)\|^2_{L^2(S^{n-1})}dk, \tag{2.19}$$

where $[\Phi_0^*\ \operatorname{sgn} q\mathbf{K}^j\Phi_0]$ denote the kernel of the integral operator inside and the integral operator applied to the function $f\equiv 1$ on S^{n-1} is denoted by $(\Phi_0^*\ \operatorname{sgn} q\mathbf{K}^j\Phi_0)(1)$. From estimates (1.18) and (2.14) we have, for $|k|>1$,

$$\|(\Phi_0^*\ \operatorname{sgn} q\mathbf{K}^j\Phi_0)(1)\|^2_{L^2(S^{n-1})} \leq C\|\Phi_0^*\|^2\|\Phi_0\|^2\|\mathbf{K}\|^{2j} \leq \frac{C}{|k|^{2\alpha(j+1)+2(n-2)}}.$$

Hence, for $q_j(x)$ we obtain the following estimate:

$$\|q_j\|_{H^t} \leq C\left(1+\int\limits_{|k|>1}\frac{|k|^{n-1+2t}d|k|}{|k|^{2\alpha(j+1)+2(n-2)}}\right)^{1/2}.$$

We leave it for the readers to check that the proof goes through for $\tilde{q}_j$ with obvious changes. Lemma 2.3 is thus proved. □

It is also easy to check that $q_0(x)$ in (2.18) is simply the potential $q(x)$ and hence we can rewrite (2.18) as

$$q_B(x) - q(x) = q_1(x) + \sum_{j=2}^m q_j(x) + \tilde{q}_{m+1}(x).$$

Here the first bilinear term $q_1(x)$ has the form

$$q_1(x) = \int\limits_{\mathbb{R}^n}\int\limits_{\mathbb{R}^n} F(y-x, z-x)q(y)q(z)dydz = (F*Q)(x,x),$$

where $Q = q\otimes q$ and F is a tempered distribution in $\mathbb{R}^{2n}$, given by

$$F(y,z) = \int\limits_{\mathbb{R}}\int\limits_{S^{n-1}}\int\limits_{S^{n-1}} e^{ik(\theta,y)-ik(\theta',z)}(|k||\theta-\theta'|)^{n-1}G_k^+(|y-z|)d\theta d\theta' dk. \tag{2.20}$$

LEMMA 2.4. *The Fourier transform $\hat{F}$ of the function F from* (2.20) *is homogeneous of degree -2 and the first nonlinear term $q_1(x)$ belongs to the Sobolev space W^1_s, where s satisfies the condition* (1.2).

Proof. See the Appendix.

Now we are ready to give the proof of Theorem 2.2.

Proof of Theorem 1.2. By Lemma 2.3 and (2.19), we obtain that

$$q_B(x) - q(x) - q_1(x) \in W_2^t(\mathbb{R}^n) = H^t \tag{2.21}$$

for any $t < 1 + \frac{n}{2} - \frac{3n}{s}$, where $s > 2n$. From the Sobolev embedding theorem we have

$$H^t \subset W_s^{t-n(1/2-1/s)}(\mathbb{R}^n).$$

But the number $t - n/2 + n/s$ can be chosen strictly positive since $1 + n/2 - 3n/s - n/2 + n/s = 1 - 2n/s > 0$ and $s > 2n$. This implies the existence of $\varepsilon > 0$ such that

$$q_B(x) - q(x) - q_1(x) \in L_{loc}^{s+\varepsilon}(\mathbb{R}^n). \tag{2.22}$$

By Lemma 2.4 we are through. □

3. Proof of Theorem 1.3. Theorem 1.3 generalizes the Saito formula to the case of singular potentials (cf. [Sa]). Again, Proposition 1.4 plays the main role for proving this theorem.

Proof of Theorem 1.3. By definition (1.7) of the scattering amplitude we have

$$\begin{aligned} & k^{n-1} \int\limits_{S^{n-1}} \int\limits_{S^{n-1}} A(k, \theta', \theta) e^{-ik(\theta-\theta', x)} d\theta d\theta' \\ & = k^{n-1} \int\limits_{\mathbb{R}^n} q(y) dy \int\limits_{S^{n-1}} \int\limits_{S^{n-1}} e^{ik(\theta-\theta', y-x)} d\theta d\theta' \\ & + k^{n-1} \int\limits_{\mathbb{R}^n} q(y) dy \int\limits_{S^{n-1}} \int\limits_{S^{n-1}} e^{-ik(\theta', y)} R(y, k, \theta) e^{-ik(\theta-\theta', x)} d\theta d\theta', \end{aligned} \tag{3.1}$$

where the function $R(y, k, \theta)$ is given by

$$R(y, k, \theta) = -\int\limits_{\mathbb{R}^n} G_k^+(|y - z|) q(z) u(z, k, \theta) dz. \tag{3.2}$$

Denote the right side of (3.1) as $I_1 + I_2$. Since

$$\int\limits_{S^{n-1}} \int\limits_{S^{n-1}} e^{ik(\theta-\theta', y-x)} d\theta d\theta' = \left| \int\limits_{S^{n-1}} e^{ik(\theta, y-x) d\theta} \right|^2$$

the integral I_1 from (3.1) rewrites as

$$I_1 = k^{n-1} \int\limits_{\mathbb{R}^n} q(y) dy \left| \int\limits_{S^{n-1}} e^{ik|y-x|(\theta, \omega)} d\theta \right|^2, \tag{3.3}$$

where $w = (y - x)/|y - x|$.

By the equality (cf. [W])

$$\int\limits_{S^{n-1}} e^{ik|y-x|(\theta, \omega)} d\theta = \frac{2\pi^{\frac{n-1}{2}}}{\Gamma\left(\frac{n-1}{2}\right)} \int\limits_0^\pi e^{ik|y-x| \cos\phi} (\sin\phi)^{n-2} d\phi,$$

we obtain

$$I_1 = (2\pi)^n k \int\limits_{\mathbb{R}^n} \frac{q(y)}{|x-y|^{n-2}} J^2_{\frac{n-2}{2}}(k|x-y|)dy. \tag{3.4}$$

We consider the cases $k|x-y|<1$ and $k|x-y|>1$ separately. In the first case we see by using Hölder's inequality that the integral over $\{y:\ k|x-y|<1\}$ can be estimated by

$$C_n k \int\limits_{|x-y|<\frac{1}{k}} \frac{|q(y)|(k|x-y|)^{n-2}}{|x-y|^{n-2}}dy \le C_n k^{\frac{n}{s}-1}\left(\int\limits_{|x-y|<\frac{1}{k}} |q(y)|^s dy\right)^{\frac{1}{s}}, \tag{3.5}$$

where $s>2n$. This means that for every fixed x the integral over $\{y:\ k|x-y|<1\}$ approaches zero as $k\to+\infty$. Hence we need only to estimate the integral (3.3) over $\{y:\ k|x-y|>1\}$. Here we have

$$\begin{aligned}
&(2\pi)^n k \int\limits_{|x-y|>\frac{1}{k}} \frac{|q(y)|}{|x-y|^{n-2}}\left[\sqrt{\frac{2}{\pi k|x-y|}}\cos\left(k|x-y|-\frac{\pi n}{4}+\frac{\pi}{4}\right)\right.\\
&\left.+O\left(\frac{1}{(k|x-y|)^{\frac{3}{2}}}\right)\right]^2 dy\\
&= (2\pi)^n k \int\limits_{|x-y|>\frac{1}{k}} \frac{|q(y)|}{|x-y|^{n-2}}\left[\frac{2}{\pi k|x-y|}\cos^2(k|x-y|+\phi_n)+O\left(\frac{1}{(k|x-y|)^2}\right)\right]dy\\
&= 2^n\pi^{n-1}\int\limits_{|x-y|>\frac{1}{k}} \frac{|q(y)|}{|x-y|^{n-1}} + 2^n\pi^{n-1}\int\limits_{|x-y|>\frac{1}{k}} \frac{|q(y)|}{|x-y|^{n-1}}\cos(2k|x-y|+2\phi_n)dy\\
&+\frac{O(1)}{k^{1-\delta}}\int\limits_{|x-y|>\frac{1}{k}} \frac{|q(y)|}{|x-y|^{N-\delta}},
\end{aligned} \tag{3.6}$$

with $0<\delta<1$. By Sobolev's inequality we have that the L^1-norm of the function $q(y)|x-y|^{n-1}$ is uniformly bounded with respect to x. Hence, it follows from the Riemann–Lebesque lemma that the second summand in the right-hand side of (3.6) approaches zero uniformly with respect to x. The same is true for the third term and thus we have

$$\lim_{k\to+\infty} I_1 = 2^n\pi^{n-1}\int\limits_{\mathbb{R}^n}\frac{q(y)dy}{|x-y|^{n-1}}. \tag{3.7}$$

Further, for the function $R(y,k,\theta)$ defined by (3.2) we have

$$R(y,k,\theta) = \mathbf{G}_q\left(qe^{ik(\theta,z)}\right) \tag{3.8}$$

and hence for the integral I_2 we obtain the following presentation:

$$I_2 = -k^{n-1}\int\limits_{\mathbb{R}^n} q(y)dy \int\limits_{S^{n-1}} e^{ik(\theta',x-y)}d\theta \mathbf{G}_q\left(q(z)\int\limits_{S^{n-1}} e^{ik(\theta,z-x)}d\theta\right)$$

$$= -k^{n-1}(2\pi)^{n-1}\int\limits_{\mathbb{R}^n} q(y)\frac{J_{\frac{n-2}{2}}(k|x-y|)}{(k|x-y|)^{\frac{n-2}{2}}}\mathbf{G}_q\left(q(z)\frac{J_{\frac{n-2}{2}}(k|z-x|)}{(k|x-z|)^{\frac{n-2}{2}}}\right)dy$$

$$= (2\pi)^n k\int\limits_{\mathbb{R}^n} q_{1/2}(y)\frac{J_{\frac{n-2}{2}}(k|x-y|)}{(k|x-y|)^{\frac{n-2}{2}}}|q(y)|^{1/2}\mathbf{K}\left(|q(z)|^{1/2}\frac{J_{\frac{n-2}{2}}(k|z-x|)}{(|z-x|)^{\frac{n-2}{2}}}dy\right), \tag{3.9}$$

where $\mathbf{K}$ is the integral operator with the kernel (cf. (1.18)):

$$K(x,y) = -|q(x)|^{1/2}G_q(x,y,k)q_{1/2}(y).$$

From Proposition 1.4 and Hölder's inequality it follows that

$$|I_2| \le (2\pi)^n k\int\limits_{\mathbb{R}^n} |q(y)|\frac{J^2_{\frac{n-2}{2}}(k|x-y|)}{|x-y|^{n-2}}dy\|\mathbf{K}\|_{L^2\to L^2} \le \frac{C}{|k|^\alpha}.$$

This proves the theorem. □

Remark. It is easy to see that the result of Theorem 1.3 in the three-dimensional case can be applied to any potential $q(x)$ which satisfies the following conditions:

1. $q \in L^p_{loc}(\mathbb{R}^3)$ for some $p > 3/2$;
2. $|q(x)| \le \frac{C}{|x|^{2+\delta}}$ for $|x| \to +\infty$, where $\delta > 0$ and fixed.

COROLLARY 3.1. *Assume that the potential $q(x)$ satisfies the same assumptions as in Theorem* 1.3. *Then the following formula is true:*

$$q(x) = \lim_{k\to+\infty}\frac{\Gamma\left(\frac{n-1}{2}\right)k^n}{2^{n+1}\pi^{\frac{3n-1}{2}}}\int\limits_{S^{n-1}}\int\limits_{S^{n-1}} A(k,\theta',\theta)|\theta-\theta'|e^{-ik(\theta-\theta',x)}d\theta d\theta'. \tag{3.10}$$

Proof. Denote the left-hand side of (1.14) by $f(x)$. Then the Fourier transform of f is given by

$$\hat{f}(\xi) = 2^n\pi^{n-1}\hat{q}(\xi)\int_{\mathbb{R}^n}|x|^{1-n}e^{ix\xi}dx. \tag{3.11}$$

Thus

$$q(x) = \frac{\Gamma\left(\frac{n-1}{2}\right)}{2^{n+1}\pi^{\frac{3n-1}{2}}}\mathcal{F}^{-1}(|\xi|\hat{f}(\xi))(x) \tag{3.12}$$

with $\mathcal{F}^{-1}$ the inverse Fourier transform. Further from (3.12) and (1.14) we get

$$q(x) = \frac{\Gamma\left(\frac{n-1}{2}\right)}{2^{n+1}\pi^{\frac{3n-1}{2}}}\lim_{k\to+\infty}k^{n-1}\int\limits_{S^{n-1}}\int\limits_{S^{n-1}} A(k,\theta',\theta)k|\theta-\theta'|F^{-1}\left(\delta(\xi-k(\theta-\theta'))\right)(x)d\theta d\theta'$$

$$= \frac{\Gamma\left(\frac{n-1}{2}\right)}{2^{n+1}\pi^{\frac{3n-1}{2}}}\lim_{k\to+\infty}k^{n}\int\limits_{S^{n-1}}\int\limits_{S^{n-1}} A(k,\theta',\theta)|\theta-\theta'|e^{-ik(\theta-\theta',x)}d\theta d\theta'. \qquad \square$$

Remark. A related theorem for measure potentials is proved in [F].

4. Appendix.

Proof of Lemma 2.4. From (2.20) it follows that the function $F(y,z)$ has the representation

$$F(y,z) = C_n \int\limits_k \int\limits_{\theta'} \int\limits_{\theta} e^{ik(\theta,z)-ik(\theta',y)} G_k^+(|z-y|)\,(|k||\theta-\theta'|)^{n-1}\,dk d\theta' d\theta. \tag{4.1}$$

For the $2n$-dimensional Fourier transform of the function $F(y,z)$ we obtain

$$\hat{F}(\xi_1,\xi_2) \tag{4.2}$$

$$= \int\limits_{\mathbb{R}} \int\limits_{S^{n-1}} \int\limits_{S^{n-1}} (|k||\theta-\theta'|)^{n-1}\,dk d\theta' d\theta \int\limits_{\mathbb{R}^n} e^{-i(k(\theta'-\theta)+\xi_1+\xi_2,y)} dy \int\limits_{\mathbb{R}^n} G_k^+(|s|) e^{-i(\xi_2-k\theta,s)} ds.$$

We approximate $\hat{F}$ by $\hat{F}_\varepsilon$ given by

$$\hat{F}_\varepsilon(\xi_1,\xi_2) = \int\limits_k \int\limits_{\theta'} \int\limits_{\theta} (|k||\theta-\theta'|)^{n-1}\,dk d\theta' d\theta \int\limits_{\mathbb{R}^n} e^{-i(k(\theta'-\theta)+\xi_1+\xi_2,y)} \frac{1}{\xi_2^2 - 2k(\theta,\xi_2) - i\varepsilon} dy. \tag{4.3}$$

Here we used the fact that

$$\hat{G_k^+}(\eta) = \lim_{\varepsilon\to+0} \frac{1}{|\eta|^2 - k^2 - i\varepsilon}.$$

By (4.3) we have

$$\hat{F}_\varepsilon(\xi_1,\xi_2) = C_n \int\limits_{S^{n-1}} \frac{g\theta'}{f\theta' - i\varepsilon g\theta'} d\theta', \tag{4.4}$$

where $g = \xi_1+\xi_2$ and $f = \xi_1^2(\xi_1+\xi_2) - \xi_1|\xi_1+\xi_2|^2$. Suppose T is the two-dimensional plane spanned by f and g (for ξ_1 and ξ_2 fixed):

$$T = \mathrm{span}\{f,g\}.$$

We denote by S^1 the circle

$$S^1 = T \cap S^{n-1}.$$

Then we claim

$$\hat{F}_\varepsilon(\xi_1,\xi_2) = C_n \int\limits_{S^1} \frac{g\omega}{f\omega - i\varepsilon g\omega} d\omega, \tag{4.5}$$

where the constant C_n depends only on n and not on ξ_1 and ξ_2. To prove (4.5) we introduce the usual n-dimensional polar coordinates ($n \geq 3$) :

$$\begin{cases} x_1 = \rho\cos\phi_1, \\ x_2 = \rho\sin\phi_1\cos\phi_2, \\ \dots \\ x_n = \rho\sin\phi_1\sin\phi_2\cdots\sin\phi_{n-1}, \end{cases}$$

$$\left|\frac{\partial x}{\partial\phi}\right| = \rho^{n-1}\sin^{n-2}\phi_1\cdots\sin\phi_{n-2},$$

where we have chosen the coordinate system so that x_1 and x_2 span the plane T. Of course, this is not the original coordinate system but we use it only to prove (4.5) from (4.4).

Clearly, from (4.4) we get for any Φ

$$\int_{S^{n-1}} \Phi(x_1, x_2) d\theta = C \int_0^{\pi} \int_0^{2\pi} \Phi(\cos\phi_1, \sin\phi_1 \cos\phi_2) \sin^{n-2}\phi_1 \sin^{n-3}\phi_2 d\phi_2 d\phi_1, \tag{4.6}$$

where again $n \geq 3$. From $x_1 = \cos\phi_1,\ x_2 = \sin\phi_1 \cos\phi_2$ we get

$$\left|\frac{\partial x}{\partial \phi}\right| = \begin{vmatrix} -\sin\phi_1 & 0 \\ \cos\phi_1 \cos\phi_2 & -\sin\phi_1 \sin\phi_2 \end{vmatrix} = \sin^2\phi_1 \sin\phi_2.$$

Further, note that

$$x_1^2 = 1 - \sin^2\phi_1,\ x_2^2 = \sin^2\phi_1(1 - \sin^2\phi_2)$$

or

$$\sin^2\phi_1 \sin^2\phi_2 = -x_2^2 + \sin^2\phi_1 = 1 - x_1^2 - x_2^2 = 1 - |x|^2.$$

This together with (4.4) and (4.6) yield

$$\hat{F}_\varepsilon(\xi_1, \xi_2) = C \int_D \frac{gx}{fx - i\varepsilon gx} (1 - |x|^2)^{\frac{n-4}{2}} dx, \tag{4.7}$$

where D is the unit disc on T. Introducing polar coordinates on D, we get

$$\hat{F}_\varepsilon(\xi_1, \xi_2) = C \int_0^1 \int_{S^1} \frac{g\omega}{f\omega - i\varepsilon g\omega} r(1 - r^2)^{\frac{n-4}{2}} dr d\omega, \tag{4.8}$$

which proves (4.5).

As in the proof of Lemma 3.5 in [PSS] we obtain, after a straightforward calculation,

$$\hat{F}(\xi_1, \xi_2) = C_n \frac{\phi(\hat{\xi}_1, \hat{\xi}_2)}{|\xi_1||\xi_2|}, \tag{4.9}$$

where $\hat{\xi}_i = |\xi_i|/|\xi_i|$, $i = 1, 2$ and

$$\phi(\theta, \theta') = (\theta, \theta') + i\sqrt{1 - (\theta, \theta')} = e^{i\alpha}. \tag{4.10}$$

Here α is the angle between θ and θ'.

We introduce Riesz potential I^{-1} and Riesz transform R [St] defined as

$$I^{-1} f(x) = \mathcal{F}^{-1}\left(\frac{1}{|\xi|} \hat{f}(\xi)\right)(x)$$

and

$$Rf(x) = \mathcal{F}^{-1}(\hat{\xi} \hat{f}(\xi))(x).$$

Next we claim that

$$I^{-1} : L^s_\sigma(\mathbb{R}^n) \to W^1_s(\mathbb{R}^n) \tag{4.11}$$

for $\sigma > 1 + n/s$ and $s > 2n$. To see this we first observe that $D_j I^{-1} = R_j$ is bounded in L^s for every $1 < s < \infty$ [St]. Hence we only need to show

$$I^{-1} : L^s_\sigma(\mathbb{R}^n) \to L^s(\mathbb{R}^n) \tag{4.12}$$

for $2 \le s \le \infty$. But f belongs to L^2_σ if and only if $\hat f$ belongs to H^σ. Thus $\hat f(\xi)/|\xi|$ is integrable at the origin and (4.12) holds for $s = 2$. Since for $f \in L^\infty_\sigma, \sigma > 1$,

$$|I^{-1} f(x)| = \left| C_n \int \frac{1}{|x-y|^{n-1}} f(y) dy \right| \le C_n \int \frac{1}{|x-y|^{n-1}} (1+|y|)^{-\sigma} dy,$$

the claim holds for $s = \infty$, too. The case of a general $2 \le s \le \infty$ follows now by interpolation [T].

We write

$$q_1(x) = C_n \int e^{i(x,\xi_1+\xi_2)} \phi(\hat\xi_1, \hat\xi_2) \hat h(\xi_1) \hat h(\xi_2) d\xi_1 d\xi_2, \tag{4.13}$$

where $h = I^{-1} q$. By using binomial series for the square root in (4.10) we obtain

$$q_1(x) = C_n \left((Rh)^2 + i \sum_{k=0}^\infty \binom{1/2}{k} \int e^{i(x,\xi_1+\xi_2)} (\hat\xi_1, \hat\xi_2)^{2k} \hat h(\xi_1) \hat h(\xi_2) d\xi_1 d\xi_2 \right).$$

Since the components R_j of R are bounded also in W^1_s [St] and W^1_s is a multiplication algebra, i.e., $W^1_s \cdot W^1_s \subset W^1_s$ for $s > n$ [T], we obtain for $\|h\|_{W^1_s} < 1/2n$ that q_1 belongs to W^1_s and that

$$\|q_1(x)\|_{W^1_s} \le C_n \left(\|h\|^2_{W^1_s} + \sum_{k=0}^\infty \binom{1/2}{k} n^{2k} \|h\|^2_{W^1_s} \right) \le C_n \|h\|^2_{W^1_s}. \tag{4.14}$$

By the bilinearity of (4.13) the inequality (4.14) holds also without assuming that $\|h\|_{W^1_s}$ is small. The lemma is thus proved. □

As a corollary we obtain for less singular potentials that $q - q_B$ is, indeed, Hölder continuous.

COROLLARY 4.1. *Assume that $q(x)$ belongs to $L^s_\sigma(\mathbb{R}^n)$ for $s > 3n$ and $\sigma > 1 + \frac{n}{s}$. Then $q - q_B \in C^\alpha$ for $0 < \alpha < 1 - 3n/s$.*

Proof. By Sobolev embedding $W^1 \hookrightarrow C^\alpha$ for $1 - n/s > \alpha$. As shown in the proof of Theorem 1.2, $q - q_B - q_1 \in H^t, t < 1 + n/2 - 3n/s$. On the other hand, $q_1 \in W^1_s$ and $H^t \hookrightarrow C^\alpha$ for $t > \alpha + n/2$. □

Finally we remark that the statement in Theorem 2.2 in [PSS] is not correct and should be replaced by Lemma 2.4 of the present article.

RADIAL SYMMETRY AND DECAY RATE OF VARIATIONAL GROUND STATES IN THE ZERO MASS CASE*

M. FLUCHER† AND S. MÜLLER‡

Abstract. P.-L. Lions raised the question whether variational ground state solutions of the semilinear Dirichlet problem

$$-\Delta w = f(w) \text{ in } \mathbb{R}^n,$$
$$w(x) \to 0 \text{ as } |x| \to \infty$$

are radial with constant sign. We consider the zero mass case $f(0) = f'(0) = 0$ without regularity assumptions for the nonlinearity. The celebrated symmetry result of Gidas, Ni, and Nirenberg and its refinements do not apply. Nevertheless we give an affirmative answer to the question of Lions. We prove that every variational ground state is either strictly positive or strictly negative. For positive nonlinearities positive solutions are radially symmetric with respect to some point and strictly decreasing in radial direction. For general nonlinearities we show that the same is true outside a compact set. This is a consequence of our main result, the second-order decay estimate

$$w(r) = c\, r^{2-n}(1 + O(r^{-2})) \text{ in the } C^1\text{-sense.}$$

In addition we obtain an integral representation for the constant c.

Key words. elliptic boundary value problem, ground state, symmetry, decay rate

AMS subject classifications. 35J20, 35B40

1. Introduction.

In this paper we derive exact decay estimates for variational ground state solutions of the semilinear Dirichlet problem

$$\begin{aligned} -\Delta w &= \lambda f(w) \ \text{ in } \ \mathbb{R}^n, \\ w(x) &\to 0 \ \text{ as } \ |x| \to \infty. \end{aligned} \tag{1.1}$$

We restrict our attention to the *zero mass case* $f(0) = 0$, $f'(0) = 0$. Variational ground state solutions are obtained by solving the variational problem for the *generalized Sobolev constant*

$$S^F := \sup \left\{ \int_{\mathbb{R}^n} F(u) \,:\, u \in D^{1,2}(\mathbb{R}^n),\ \|\nabla u\|_2 \le 1 \right\}$$

with $F' = f$. A *variational ground state* thus satisfies

$$\|\nabla w\|_2 = 1, \qquad \int_{\mathbb{R}^n} F(w) \ = \ S^F.$$

Lions [11, Remark II.6] raised the question whether for nonsymmetric integrands variational ground states are radial with constant sign. For $f \in C^{1,\alpha}$ with $f(0) = 0$ and $f'(0) < 0$, symmetry of positive solutions follows from the result of Gidas, Ni,

and Nirenberg [7]. Symmetry for Lipschitz continuous nonlinearities is due to Kaper, Kwong, and Li [8]. In section 2 (Lemma 2) we answer Lions' question for the zero mass case. Our symmetry result is obtained as a consequence of the second-order decay estimates of section 4 in combination with a result of Brothers and Ziemer [1]. Due to our variational technique no regularity is needed for the nonlinearity besides a mild growth condition for its antiderivative. The precise hypotheses are as follows:

(F) The integrand F satisfies the growth condition $0 \le F(t) \le c\,|t|^{2^*}$ for some constant c. It is upper semicontinuous and $F \not\equiv 0$ in the L^1 sense.

For smooth integrands every variational ground state is a solution of the Euler–Lagrange equation (1.1). The value of the Lagrange multiplier can be obtained as follows. The scaling $u^s(x) := u(x/s)$ with $s := \|\nabla u\|_2^{-\frac{2}{n-2}}$ leads to $\|\nabla u^s\|_2 = 1$ and

$$\int_{\mathbb{R}^n} F(u^s) = \|\nabla u^s\|_2^{-2^*} \int_{\mathbb{R}^n} F(u). \tag{1.2}$$

Thus variational ground states are critical points of the functional

$$J(u) := \frac{\int_{\mathbb{R}^n} F(u)}{\|\nabla u\|_2^{2^*}} \tag{1.3}$$

defined on $D^{1,2}(\mathbb{R}^n) \setminus \{0\}$. The gradient of this functional is

$$\begin{aligned} J'(w)\phi &= \frac{d}{dt} J(w + t\phi)\bigg|_{t=0} \\ &= \frac{d}{dt}\left(\int_{\mathbb{R}^n} F(w + t\phi) - S^F \frac{2^*}{2} \int_{\mathbb{R}^n} |\nabla(w + t\phi)|^2 \right)\bigg|_{t=0} \\ &= \int_{\mathbb{R}^n} f(w)\phi - 2^* S^F \int_{\mathbb{R}^n} \nabla w \cdot \nabla \phi \end{aligned}$$

by normalization of w and $\int_{\mathbb{R}^n} F(w) = S^F$. Hence

$$\lambda = \frac{1}{2^* S^F}. \tag{1.4}$$

Existence of variational ground states has been discussed in [4]. Uniqueness of radial ground states is an unsolved problem. Most results available deal with the positive mass case $f'(0) < 0$ or require a similar condition leading to exponential decay at infinity. Results of this type have been obtained by many authors including Kwong [9], Kwong and Zhang [10], Chen and Lin [2], and Yanagida [13]. The most general uniqueness results (together with an up-to-date survey of the literature) are due to Franchi, Lanconelli, and Serrin [5]. They consider general divergence operators of the form $\operatorname{div}(A(|\nabla u|)\nabla u)$ including the p-Laplacian and the mean curvature operator.

2. Symmetry. In the following u^* denotes the Schwarz symmetrization or decreasing rearrangement of a positive function u. It is well known that $\|\nabla u^*\|_2 \le \|\nabla u\|_2$ and $\int_{\mathbb{R}^n} F(u^*) = \int_{\mathbb{R}^n} F(u)$. If w is a variational ground state then so is w^* as follows from (1.2). This reduces the computation of the generalized Sobolev constant to a one-dimensional problem. Our symmetry result is based on the following lemma of Brothers and Ziemer and the strict decay property of radial extremals (Theorem 5).

LEMMA 1 (Brothers and Ziemer [1]). *If a positive function $u \in D^{1,2}(\mathbb{R}^n)$ satisfies $\|\nabla u^*\|_2 = \|\nabla u\|_2$ then $u = u^*$ up to translation or u has a plateau of positive volume which is below the top level.*

LEMMA 2 (basic properties of variational ground states). *Assume* (F) *and let w be an extremal for S^F. Then:*

1. *Either $w \geq 0$ or $w \leq 0$.*
2. *There is a ball $B^{r_0}_{x_0}$ (we assume $x_0 = 0$) such that $w = w^*$ outside this ball. If we suppose for normalization that $w \geq 0$ then the function $r \mapsto w(r)$ is strictly decreasing on (r_0, ∞). In particular $w > 0$ in $\mathbb{R}^n$.*

Proof.

1. If w changes sign we split $w = w_+ + w_-$ and we have $\|\nabla w_\pm\|_2 < 1$, $S_\pm := \int_{\mathbb{R}^n} F(w_\pm) < S^F$. Both functions belong to $D^{1,2}(\mathbb{R}^n)$. Normalization by means of (1.2) leads to the contradiction

$$\begin{aligned} S^F = S_+ + S_- &= \|\nabla w_+\|_2^{2^*} \int_{\mathbb{R}^n} F(w_+^{s_+}) + \|\nabla w_-\|_2^{2^*} \int_{\mathbb{R}^n} F(w_-^{s_-}) \\ &\leq S^F \left(\left(\int_{\mathbb{R}^n} |\nabla w_+|^2 \right)^{\frac{n}{n-2}} + \left(\int_{\mathbb{R}^n} |\nabla w_-|^2 \right)^{\frac{n}{n-2}} \right) < S^F \end{aligned}$$

   by definition of the generalized Sobolev constant and strict convexity of the function $t \mapsto t^{\frac{n}{n-2}}$ on $\mathbb{R}^+$. Thus $w \geq 0$ or $w \leq 0$.
2. By Theorem 5 below the symmetrized function w^* is strictly decreasing outside some ball $B_0^{r_0}$. We show that after translation $w = w^*$ in $\mathbb{R}^n \setminus B_0^{r_0}$. Assume the contrary. Then by Lemma 1 the function w^* has a doubly connected plateau $B_0^R \setminus B_0^r$ with $r > r_0$ in contradiction to the fact that w^* is strictly decreasing outside $B_0^{r_0}$. ∎

3. Euler–Lagrange equation corresponding to variations of the independent variable. Our integrands may be discontinuous. Hence we cannot use (1.1). Instead we use the Euler–Lagrange equation corresponding to variations of the independent variable.

If w is a radial function we write $r := |x|$ and $w(r) := w(|x|)$. The jump $[g(r)]$ denotes the difference of right and left limit of a function g at the point r. Moreover, $w'(r)$ denotes an arbitrary element of the subdifferential of w at r. The tensor product of two $1 \times n$-matrices $a \otimes b = a^T b$ is an $n \times n$-matrix. The scalar product of $n \times n$-matrices is defined by $A : B = Tr(A^T B)$.

LEMMA 3. *Every extremal for S^F satisfies*

$$\int_{\mathbb{R}^n} \left(2\nabla w \otimes \nabla w - |\nabla w|^2 \,\mathrm{Id} + 2\lambda F(w)\mathrm{Id} \right) : D\eta = 0 \tag{3.1}$$

for every test function $\eta \in C_c^\infty(\mathbb{R}^n, \mathbb{R}^n)$ with λ as in (1.4). *If w is a radial extremal for S^F then*

$$\int_0^\infty r^n \left(|w'|^2 + 2\lambda F(w) \right) \psi' - r^{n-1} \left((n-2)\,|w'|^2 - 2n\lambda F(w) \right) \psi = 0 \tag{3.2}$$

for every $\psi \in C_c^\infty(\mathbb{R}^+)$. In particular the jump condition $[|w'|^2] = -2\lambda[F(w)]$ holds at the discontinuities of F.

Proof. Consider the variations

$$\phi_t(x) := x + t\eta(x), \qquad w_t := w \circ \phi_t^{-1}$$

of the independent variable. Then

$$\begin{aligned}\frac{d}{dt}\int_{\mathbb{R}^n} F(w_t)\bigg|_{t=0} &= \frac{d}{dt}\int_{\mathbb{R}^n} F(w)\,\det D\phi_t\bigg|_{t=0}\\ &= \int_{\mathbb{R}^n} F(w)\,\mathrm{div}\,\eta \quad = \quad \int_{\mathbb{R}^n} F(w)\,\mathrm{Id} : D\eta.\end{aligned}$$

Similarly

$$\begin{aligned}\int_{\mathbb{R}^n} |\nabla w_t|^2 &= \int_{\mathbb{R}^n} \left|\nabla w (D\phi_t)^{-1}\right|^2 \det D\phi_t,\\ \frac{d}{dt}\int_{\mathbb{R}^n} |\nabla w_t|^2\bigg|_{t=0} &= \int_{\mathbb{R}^n} |\nabla w|^2\,\mathrm{Id} : D\eta \;- 2\int_{\mathbb{R}^n} \nabla w \otimes \nabla w : D\eta.\end{aligned}$$

Since w is a maximizer of the functional J defined in (1.3) we have

$$0 = \frac{d}{dt}J(w_t)\bigg|_{t=0} \quad = \quad \frac{d}{dt}\left(\int_{\mathbb{R}^n} F(w_t) - \frac{n}{n-2}S^F\int_{\mathbb{R}^n}|\nabla w_t|^2\right)\bigg|_{t=0}.$$

Inserting the above expressions for the variation of the individual terms yields (3.1). In the radial case set $\eta(x) = \psi(r)x$. □

For smooth integrands (3.2) is equivalent to

$$w'' + \frac{n-1}{r}w' + \lambda f(w) = 0,$$

i.e., to (1.1) at all points where w' is defined and nonzero. A similar identity leading to the same jump condition has been proposed by Franchi, Lanconelli, and Serrin [5, p. 179]. In our terms it assumes the form

$$\left(r\left(|w'|^2 + 2\lambda F(w)\right)^{\frac{1}{2(n-1)}}\right)' = 2\left(|w'|^2 + 2\lambda F(w)\right)^{-\frac{2n-3}{2(n-1)}} F(w).$$

Equation (3.2) is the radial component of

$$\mathrm{div}\left(|\nabla w|^2 x + 2\lambda F(w)x\right) + (n-2)\,|w'|^2 - 2n\lambda F(w) = 0$$

in the sense of distributions. Integration over $\mathbb{R}^n$ yields a special case of the Pohozaev identity, namely

$$\int_{\mathbb{R}^n} |\nabla w|^2 = 2^*\lambda \int_{\mathbb{R}^n} F(w).$$

This is the same as (1.4).

4. Decay estimates. Every radial $D^{1,2}$ function decays at least like $r^{-\frac{n-2}{2}}$ (Strauss [12]). We will see that variational ground states decay faster. In most applications F is nondecreasing on $\mathbb{R}^+$ and nonincreasing on $\mathbb{R}^-$ corresponding to $f \geq 0$ on $\mathbb{R}^+$ and $f \leq 0$ on $\mathbb{R}^-$, respectively. In this case every positive extremal is superharmonic in the sense of distributions. This can be seen as follows. For every positive test function ϕ and $t \geq 0$ we have $\int_{\mathbb{R}^n} F(w + t\phi) \geq \int_{\mathbb{R}^n} F(w)$ and therefore $\int_{\mathbb{R}^n} |\nabla(w + t\phi)|^2 \geq \int_{\mathbb{R}^n} |\nabla w|^2$ by definition of the generalized Sobolev constant. This

implies $\int_{\mathbb{R}^n} \nabla w \cdot \nabla \phi \geq 0$. On every subdomain a superharmonic function is pointwise bigger or equal to the harmonic function with the same boundary values. The properties listed below are consequences of this fact. Let

$$K(r) := \frac{1}{(n-2)\,|S^{n-1}|\,r^{n-2}}$$

denote the fundamental singularity of the Laplacian.

LEMMA 4 (monotone integrands). *Assume* (F) *and let w be a positive extremal for S^F. If F is nondecreasing on $\mathbb{R}^+$ then:*

1. *After translation $w = w^*$. We can assume that w is radial with respect to the origin.*
2. *The function $r \mapsto w(r)$ is strictly decreasing on $\{w < w(0)\}$.*
3. *The function $r \mapsto w(r)/K(r)$ is nondecreasing on $\mathbb{R}^+$.*
4. *The function $r \mapsto w'(r)/K'(r)$ is nondecreasing on $\mathbb{R}^+$. In particular every kink satisfies $[w'] \leq 0$.*
5. *The limit*

$$w_\infty := \lim_{r\to\infty} \frac{w(r)}{K(r)} \quad = \quad \lim_{r\to\infty} \frac{w'(r)}{K'(r)}$$

exists and $w_\infty > 0$. In particular $w(r) \leq w_\infty r^{2-n}$ and $F(w(r)) \leq c\, r^{-2n}$.

Proof. The symmetrized function w^* is also extremal. By weak superharmonicity of w^* outside the ball B_0^r we have

$$w^*(R) \geq \frac{w^*(r)}{K(r)} K(R)$$

for every $R \geq r$. In particular w^* is strictly decreasing below the top level and strictly positive. Lemma 1 implies $w = w^*$ up to translation. The above inequality also shows $w'/K' \geq w/K$. Weak superharmonicity of w implies that for every triple $r \leq s \leq R$ we have

$$w(s) \geq w(R) + \frac{K(s) - K(R)}{K(r) - K(R)} (w(r) - w(R)).$$

Therefore

$$w'(r) \geq K'(r) \frac{w(r) - w(R)}{K(r) - K(R)}, \qquad w'(R) \quad \leq \quad K'(R) \frac{w(r) - w(R)}{K(r) - K(R)},$$

which implies $w'(r)/K'(r) \leq w'(R)/K'(R)$. Thus the limit w_∞ exists in $(0, \infty]$. We are left to show that it is finite. This is trivial if $F = 0$ near 0. For general integrands we refer to Theorem 5. Also the last claim follows from weak superharmonicity of w. For every triple $r \leq s \leq R$ we have

$$w(s) \geq w(R) + \frac{K(s) - K(R)}{K(r) - K(R)} (w(r) - w(R)).$$

Therefore

$$w'(r) \geq K'(r) \frac{w(r) - w(R)}{K(r) - K(R)}, \qquad w'(R) \quad \leq \quad K'(R) \frac{w(r) - w(R)}{K(r) - K(R)}.$$

Thus $w'(r)/K'(r) \leq w'(R)/K'(R)$. ∎

The proof of our decay estimates involves an iteration technique that is common in elliptic regularity theory (see, e.g., Giaquinta [6, Chapter III, Lemma 2.1]).

THEOREM 5 (decay rate of variational ground states). *Assume* (F) *and let* $w = w^*$ *be a positive radial extremal for* S^F. *Then*

$$\begin{aligned} w_\infty K(r)\left(1 - O(r^{-2})\right) \le w(r) &\le w_\infty K(r), \\ w_\infty K'(r) \le w'(r) &\le w_\infty K'(r)\left(1 - O(r^{-2})\right) \end{aligned}$$

for $r \to \infty$, *where*

$$w_\infty^2 = \frac{2(n-1)}{nS^F} \int_{\mathbb{R}^n} \frac{F(w)}{K(|\cdot|)}.$$

In particular $w'(r) < 0$ *for* $r > r_0$ *with some* $r_0 \ge 0$, $w(r) \le c\, r^{2-n}$, $F(w(r)) \le c\, r^{-2n}$, *and*

$$\int_{\mathbb{R}^n \setminus B_0^R} |\nabla w|^2 \le c\, R^{2-n}, \quad \int_{\mathbb{R}^n \setminus B_0^R} F(w) \le c\, R^{-n}$$

for every $R > 0$. *The error terms depend only on the constant in the growth condition* (F).

Proof. With $\psi(r) = r^{n-2}\eta(r)$ equation (3.2) assumes the form

$$\int_0^\infty r^{2(n-1)} \left(|w'|^2 + 2\lambda F(w)\right) \eta' + 2(n-1) r^{2n-3} 2\lambda F(w)\eta = 0.$$

In terms of the auxiliary functions

$$\begin{aligned} a(r) &:= r^n \left(|w'(r)|^2 + 2\lambda F(w(r))\right), \\ b(r) &:= r^n 2\lambda F(w(r)), \end{aligned}$$

this can be written as

$$\left(r^{n-2} a(r)\right)' = 2(n-1) r^{n-3} b(r) \tag{4.1}$$

or

$$a'(r) = r^{n-1} \left(2n\lambda F(w) - (n-2)\,|w'|^2\right)$$

in the sense of distributions. The right-hand side is in $L^1(\mathbb{R}^+)$. Thus $\lim_{r\to\infty} a(r)$ exists. Together with

$$\int_0^\infty \frac{a(r)}{r} = \int_0^\infty r^{n-1} \left(|w'|^2 + 2\lambda F(w)\right) < \infty,$$

this shows that $\lim_{r\to\infty} a(R) = 0$. Also the decreasing envelope of a,

$$A(r) := \sup_{R \ge r} a(R),$$

tends to 0. In terms of this function we can estimate

$$w(r) = \int_\infty^r w' \le \int_r^\infty \left(\frac{a(R)}{R^n}\right)^{\frac{1}{2}} \le c\, A^{\frac{1}{2}}(r) r^{-\frac{n-2}{2}},$$

and therefore

$$b(r) \le c\, r^n w^{2^*} \quad \le \quad c\, A^{\frac{n}{n-2}}(r) \tag{4.2}$$

by (F). Integration of (4.1) over the interval (r, R) yields

$$a(R) - \left(\frac{r}{R}\right)^{n-2} a(r) \le c \left(1 - \left(\frac{r}{R}\right)^{n-2}\right) A^{\frac{n}{n-2}}(r) \quad \le \quad c\, A^{\frac{n}{n-2}}(r).$$

Since the larger radius appears in the denominator we can take the supremum over all $R' \ge R$ to obtain

$$A(R) \le \left(\left(\frac{r}{R}\right)^{n-2} + A^{\frac{2}{n-2}}(r)\right) A(r) \quad \text{for every} \quad R > r > 0. \tag{4.3}$$

Fix $\beta \in \left(\frac{n-2}{n}(n-2), n-2\right)$ and choose r such that

$$A(r)^{\frac{2}{n-2}} \le 2^{-\beta} - 2^{-(n-2)}.$$

This is possible because $A(r) \to 0$ as $r \to \infty$. Iterated application of (4.3) with $R = 2r$ and monotonicity of A yields

$$A(r) \le c r^{-\beta}, \quad b(r) \quad \le \quad c r^{-\frac{\beta n}{n-2}}$$

for every r by (4.2). Since $\frac{\beta n}{n-2} > n-2$, the right-hand side of (4.1) is integrable. In particular $a(r) \le c\, r^{2-n}$. Another application of (4.2) yields

$$b(r) \le c\, r^{-n}, \quad F(w(r)) \quad \le \quad c\, r^{-2n},$$

and $r^{n-3} b(r) \to 0$ as $r \to \infty$. Integration of (4.1) together with $a(0) = 0$ yields

$$\begin{aligned} r^{2(n-1)} \left(|w'|^2 + 2\lambda F(w)\right) \quad &\le \quad c_1^2 \quad \text{with} \\ c_1^2 \quad := \quad 2(n-1) \int_0^\infty r^{2n-3} 2\lambda F(w(r)) \quad &= \quad \frac{4(n-1)\lambda}{|S^{n-1}|} \int_{\mathbb{R}^n} |x|^{n-2} F(w) \end{aligned}$$

for every r with equality at infinity. Thus, in view of (1.4),

$$\begin{aligned} |w'(r)| \le c_1\, r^{1-n} \quad &= \quad w_\infty \left|K'(r)\right|, \\ w(r) \le \int_r^\infty |w'| \quad &\le \quad \frac{c_1}{(n-2) r^{n-2}} \quad = \quad w_\infty K(r) \end{aligned}$$

by integration. Again by (4.1)

$$\begin{aligned} R^{2(n-1)} \left(|w'|^2 + 2\lambda F(w)\right) &= c_1^2 - 2(n-1) \int_R^\infty r^{n-3} b(r) \\ &= c_1^2 - O(R^{-2}) \end{aligned}$$

since $b(r) \le c\, r^{-n}$. Together with $F(w(r)) \le c\, r^{-2n}$ we obtain

$$w'(r) = w_\infty K'(r) \left(1 + O(r^{-2})\right)$$

and the lower bound for w. □

The approximation formulas of Theorem 5 are second-order accurate. This is best possible as can be seen from the variational ground state

$$w(r) = \frac{c}{(1+r^2)^{\frac{n-2}{2}}} \quad = \quad w_\infty K(r)\left(1 + O(r^{-2})\right)$$

for the critical power $F(t) = |t|^{2^*}$. For $0 \le f(t) \le t^p$ with $p > \frac{n+2}{n-2}$, Egnell [3, Proposition C] found

$$w_\infty = \lambda \int_{\mathbb{R}^n} f(w).$$

Formally this follows by integration of (1.1) over a large ball.

L_∞ ESTIMATES ON THE SOLUTIONS OF NONSELFADJOINT ELLIPTIC AND PARABOLIC EQUATIONS IN BOUNDED DOMAINS*

ADRIAN T. HILL†

Abstract. This paper considers explicit upper bounds in L_∞ on the solution operator of a class of second-order parabolic Dirichlet problems defined in $(-1, 1)^N$. The elliptic part of the operator L is given by

$$Lu = -\sum_{i=1}^{N} a_i(x, t)\frac{\partial^2 u}{\partial x_i^2} + \sum_{i=1}^{N} b_i(x, t)\frac{\partial u}{\partial x_i},$$

where $a_i \geq d_i > 0$, $|b_i| \leq M_i$, $i = 1, \ldots, N$, uniformly across the domain.

Symmetry and the maximum principle are used to identify those coefficients, obeying these bounds, which result in the largest possible value for the norm of the solution operator in L_∞. The norm of this optimal case is found in terms of (d_i) and (M_i) and a family of constant coefficient problems in one space dimension. This representation is made quantitatively explicit by Laplace transform evaluation of the one-dimensional problems.

Similar sharp quantitative estimates on the resolvent $\|(\lambda I + L)^{-1}\|_\infty$, $\lambda \geq 0$, are obtained in $(-1, 1)^N$ as a corollary of the parabolic results. For comparison, a related, but direct, technique is used to derive optimal bounds on the resolvent of a slightly more general class of elliptic operators defined on the unit ball in $\mathbb{R}^N$.

1. Introduction.

Our objective in this paper is to obtain explicit sharp L_∞ estimates for a class of elliptic and parabolic operators, defined on a bounded subdomain of $\mathbb{R}^N$ with Dirichlet boundary conditions. Elsewhere, we consider L_1 bounds in bounded domains and in $\mathbb{R}^N$ [8, 9]. Such quantitative estimates are of use in the applied analysis of numerical algorithms, control systems, and biological models. Thus, our motivation differs from that of Agmon, Douglis, and Nirenberg [2] and Stewart [13], whose far more general estimates are of a qualitative nature.

On the domain $\Omega = (-1, 1)^N$, we investigate the parabolic equation

$$\frac{\partial u}{\partial t} + Lu \equiv \frac{\partial u}{\partial t} - \sum_{i=1}^{N} a_i(x, t)\frac{\partial^2 u}{\partial x_i^2} + \sum_{i=1}^{N} b_i(x, t)\frac{\partial u}{\partial x_i}, \qquad (x, t) \in \Omega \times (0, \infty), \tag{1.1}$$

subject to the Dirichlet boundary conditions

$$u(x, t) = 0 \qquad \text{for } (x, t) \in \partial\Omega \times (0, \infty),$$

with initial data u_0 taken to be in $L_\infty(\Omega)$.

It is assumed that $a_i \in C(\overline{\Omega} \times [0, \infty))$ satisfies

$$\inf_{(x, t) \in \Omega \times [0, \infty)} a_i(x, t) \geq d_i > 0; \tag{1.2}$$

*Received by the editors October 7, 1996; accepted for publication March 25, 1997.

also that $b(\cdot, t) = (b_i(\cdot, t)) \in L_\infty(\Omega)$ for $t \geq 0$, and

$$\text{ess. sup}_{(x,t)\in\overline{\Omega}\times[0,\infty)}|b_i(x, t)| \leq M_i, \qquad i = 1, \ldots, N. \tag{1.3}$$

Our objective is to derive sharp estimates for $\|u(t)\|_\infty/\|u_0\|_\infty$, for nonnull u_0, in terms of the bounds $d = (d_i)$ and $M = (M_i)$. This is rather similar to the work of Pucci [11] for elliptic equations, though we work with somewhat different assumptions on the coefficients. As in [11], we identify a maximizing operator, which here is given by

$$L_{d,M}u = -\sum_{i=1}^{N} d_i \frac{\partial^2 u}{\partial x_i^2} + \sum_{i=1}^{N} M_i \text{sign}[x_i] \frac{\partial u}{\partial x_i}. \tag{1.4}$$

$V(d, M; x, t)$, the solution of (1.1) when $L = L_{d,M}$ and $u_0(x) \equiv 1$, is symmetric about $x_i = 0$ and is therefore the solution of a constant coefficient equation in the octant $[0, 1]^N$ with Neumann boundary conditions at $x_i = 0$, $i = 1, \ldots, N$. As a result, we show that $V(d, M; x, t)$ may be written as the product of the solutions, $v(M_i/d_i; x_i, d_i t)$, of constant coefficient equations in one space dimension.

By analyzing the behavior of $v(M; x, t)$, for $M \geq 0$, $x \in [0, 1]$, we find that $V(d, M; x, t)$ also satisfies

$$u_t - \sum_{i=1}^{N} d_i \frac{\partial^2 u}{\partial x_i^2} - \sum_{i=1}^{N} M_i \left| \frac{\partial u}{\partial x_i} \right| = 0, \qquad (x, t) \in \Omega \times (0, \infty), \tag{1.5}$$

and is therefore an upper solution for any equation of the form (1.1), with initial data such that $\|u_0\|_\infty \leq 1$. Consequently, for nonnull $u_0 \in L_\infty$,

$$\frac{\|u(t)\|_\infty}{\|u_0\|_\infty} \leq \|V(d, M; \cdot, t)\|_\infty = V(d, M; 0, t) = \prod_{i=1}^{N} v(M_i/d_i; 0, d_i t). \tag{1.6}$$

The right-hand side is now explicitly computable via the Laplace transform.

In section 2, we establish the qualitative properties of v and V, leading to the proof of (1.6). As a corollary, we also deduce sharp upper bounds for the elliptic case in $(-1, 1)^N$, in terms of v. More quantitative properties of $v(M; 0, t)$ are obtained in section 3, following small and large time expansions of the Laplace transform. Explicitly computable estimates for both the parabolic and elliptic cases are derived as a consequence. In section 4, we consider elliptic boundary value problems defined on the unit ball in $\mathbb{R}^N$, under less restrictive assumptions on the form of the diffusion coefficients, and sharp estimates are obtained in L_∞ using a related, but direct, method.

We remark that our bounds are not confined exclusively to the special geometries we study here. Scaling easily extends all of our results on the cube to rectangular domains. More generally, it is known that the L_∞ norm of the parabolic solution operator and of the resolvent $(\lambda I + L)^{-1}$ are monotonically increasing with respect to domain inclusion; see Sattinger [12]. Thus, our bounds still hold, though less sharply, for operators defined on $\Omega' \subset \Omega$ whose coefficients can be extended to satisfy (1.2), (1.3) on Ω.

2. Qualitative bounds on the cube. In this section, we find bounds for the solutions of (1.1)–(1.3) in terms of the solution of a constant coefficient parabolic

problem in one space dimension. Subsequently, we extend our results to the elliptic case.

We begin with a detailed study of the properties of the solution of the following problem. For $M \in [0, \infty)$, we consider the initial boundary value problem

$$\begin{aligned} u_t + L_M u \equiv u_t - u_{xx} + M u_x = 0, &\qquad (x, t) \in (0, 1) \times (0, \infty), \\ u_x(0, t) = u(1, t) = 0, &\qquad t \in (0, \infty), \\ u(x, 0) = 1, &\qquad x \in (0, 1). \end{aligned} \tag{2.1}$$

Standard results imply that (2.1) possesses a solution $v(M)$, which is unique in $C[[0, \infty); L_2(0, 1)]$, and belongs to $C[[0, \infty) \times [0, 1)] \cap C^\infty[(0, \infty); C^\infty[0, 1]]$. There is a finite discontinuity of $v(M; x, t)$ at $(x, t) = (1, 0)$.

LEMMA 2.1. *For all $M \geq 0$, v satisfies*

$$v_t(M; x, t) < 0, \qquad (x, t) \in [0, 1) \times (0, \infty), \tag{2.2}$$

$$v_x(M; x, t),\ v_{xx}(M; x, t) < 0, \qquad (x, t) \in (0, 1] \times (0, \infty), \tag{2.3}$$

and $\|v(M; \cdot, t)\|_\infty = v(M; t)$ for $t \geq 0$, where

$$v(M; t) \equiv v(M; 0, t). \tag{2.4}$$

Proof. The initial data $u_0(x) \equiv 1$ is a strict upper solution for the elliptic boundary value problem corresponding to (2.1). Consequently, a monotonicity result of Sattinger [12, Lemma 3.5] now implies that (2.2) holds. Integrating e^{-Mx} times (2.1) with respect to x leads to the identity

$$v_x(M; x, t) = \int_0^x e^{M(x-y)} v_t(M; y, t)\, dy < 0, \qquad (x, t) \in (0, 1] \times (0, \infty). \tag{2.5}$$

This implies that, for all $t > 0$, $v(M; \cdot, t)$ has its maximum at $x = 0$. From (2.1),

$$v_{xx} = M v_x + v_t < 0, \qquad (x, t) \in (0, 1] \times (0, \infty).$$

(Here, $v_x(M; 1, t)$ and $v_{xx}(M; 1, t)$ are continuous limits as $x \to 1$.) ∎

The following theorem collects further results describing the qualitative behavior of $v(M; t)$, which is of use in studying the behavior of the upper bound (1.6). However, the remaining results of this section do not depend upon it.

THEOREM 2.2. *$v(M; t)$ increases strictly with M. For fixed $M \geq 0$, $v(M; t)$ satisfies*

$$-\lambda_1 < \frac{1}{v(M; t)} \frac{dv}{dt}(M; t) < 0, \qquad t > 0, \tag{2.6}$$

$$\frac{d}{dt}\left(\frac{1}{v(M; t)} \frac{dv}{dt}(M; t) \right) \leq 0, \qquad t > 0, \tag{2.7}$$

where λ_1 is the principal eigenvalue of the elliptic operator L_M, subject to the boundary conditions of (2.1).

Proof. For $M > 0$, (2.3) implies that, for any $\epsilon \in (0, 1]$, $v(M; x, t)$ is a strict upper solution for (2.1) when $M(1 - \epsilon)$ replaces M, and thus $v(M; t)$ is strictly increasing with M by parabolic monotonicity.

We now consider

$$p(M; x, t) = \frac{v_x(M; x, t)}{v(M; x, t)}, \qquad (x, t) \in [0, 1) \times (0, \infty).$$

Since v_x and v satisfy equation (2.1), p obeys

$$u_t - u_{xx} + (M - 2u)u_x = 0, \qquad (x, t) \in (0, 1) \times (0, \infty).$$

(2.3) states that $v_x(M; 1, t) < 0$ for $t > 0$. Since $v_t(M; 1, t) = 0$, $v_{xx}(M; 1, t) = Mv_x(M; 1, t)$ for $t > 0$. Hence, p satisfies the boundary conditions

$$u(0, t) = 0, \qquad \lim_{x \to 1} u(x, t) + \frac{1}{1 - x} = \frac{M}{2}.$$

We define $q^h(M; x, t) = (p(M; x, t + h) - p(M; x, t))/h$, $h > 0$. From the above considerations for p, we see that q^h satisfies

$$\begin{aligned} u_t - u_{xx} + (M - \overline{p})u_x - \overline{p}_x u = 0, &\qquad (x, t) \in (0, 1) \times (0, \infty), \\ u(0, t) = u(1, t) = 0, &\qquad t > 0, \end{aligned}$$

where $\overline{p}(x, t) = (p(M; x, t + h) + p(M; x, t))/2$. For $x \in [0, 1)$, (2.3) implies that $p(M; x, h) \le 0$, and so $q^h(M; x, 0) \le 0$. We note that $\overline{p}$ and $\overline{p}_x$ are unbounded as x tends to 1. However, one may argue by contradiction, using the usual maximum principle arguments and considering $e^{-Kt}q^h$ for sufficiently large positive values of K, to show that $q^h(M; x, t) \le 0$ for $(x, t) \in (0, 1) \times (0, \infty)$. Thus,

$$\frac{\partial}{\partial x}\left(\frac{v_t}{v}\right) = \frac{\partial^2 \log v}{\partial x \partial t} = \frac{\partial}{\partial t}\left(\frac{v_x}{v}\right) = \lim_{h \to 0} q^h \le 0, \qquad (x, t) \in (0, 1) \times (0, \infty). \tag{2.8}$$

Hence, for all $t > 0$,

$$-\frac{v_t(M; t)}{v(M; t)} = \inf_{x \in [0, 1)} -\frac{v_t}{v}(M; x, t) = \inf_{x \in [0, 1)} \frac{-v_{xx} + Mv_x}{v}(M; x, t) < \lambda_1,$$

where the last inequality is a consequence of a result of Protter and Weinberger [10], and hence (2.6) holds.

(2.8) also implies that for $(x, t) \in [0, 1) \times (0, \infty)$,

$$\frac{d}{dt}\left(\frac{v(M; x, t)}{v(M; t)}\right) = \left[\frac{v_t(M; x, t)}{v(M; x, t)} - \frac{v_t(M; t)}{v(M; t)}\right]\frac{v(M; x, t)}{v(M; t)} \le 0.$$

Thus for any $h > 0$,

$$0 \le \frac{v(M; t + h)}{v(M; t)} v(M; x, t) - v(M; x, t + h), \qquad (x, t) \in [0, 1) \times (0, \infty).$$

Considering the right-hand side as initial data for (2.1), over the time interval $[0, h]$, the maximum principle implies that

$$0 \le \frac{v(M; t + h)}{v(M; t)} v(M; x, t + h) - v(M; x, t + 2h), \qquad (x, t) \in [0, 1) \times (0, \infty).$$

Hence, letting $x = 0$, we conclude that

$$\begin{aligned} 0 &\ge \lim_{h \to 0} \frac{1}{h^2}\left[\frac{v(M; t + 2h) - v(M; t + h)}{v(M; t + h)} - \frac{v(M; t + h) - v(M; t)}{v(M; t)}\right] \\ &= \frac{d}{dt}\left(\frac{1}{v(M; t)}\frac{dv}{dt}(M; t)\right), \qquad t > 0, \end{aligned}$$

which implies (2.7). □

We now extend the definition of $v(M;\, x,\, t)$ to $x \in [-1,\, 0)$ by reflection:

$$v(M;\, x,\, t) \equiv v(M;\, -x,\, t), \qquad (x,\, t) \in [-1,\, 0) \times [0,\, \infty). \tag{2.9}$$

Since $v_x(M;\, 0,\, t) = 0$ and v is even in x, $v(M;\, \cdot,\, t) \in C^2[-1,\, 1]$, and v satisfies the equation

$$u_t - u_{xx} + M\text{sign}[x]u_x = 0, \qquad (x,\, t) \in (-1,\, 1) \times (0,\, \infty), \tag{2.10}$$

(with the convention that sign[0] = 0).

For $d = (d_i)$, $M = (M_i)$, and $\Omega = (-1,\, 1)^N$, we define

$$V(d,\, M;\, x,\, t) = \prod_{i=1}^{N} v(M_i/d_i;\, x_i,\, d_i t), \qquad (x,\, t) \in \overline{\Omega} \times [0,\, \infty). \tag{2.11}$$

From the foregoing analysis, we conclude that the following lemma is true.

LEMMA 2.3. *The function* $V(d,\, M;\, \cdot,\, \cdot) \in C^1[(0,\, \infty);\, C(\Omega)] \cap\, C\left[(0,\, \infty);\, C^2(\overline{\Omega})\right] \cap\, C[[0,\, \infty) \times \Omega]$ *is the solution of the problem*

$$\begin{aligned} u_t + L_{d,\, M} u &= 0, \qquad (x,\, t) \in \Omega \times (0,\, \infty), \\ u(x,\, t) &= 0, \qquad (x,\, t) \in \partial\Omega \times (0,\, \infty), \\ u(x,\, 0) &= 1, \qquad x \in \Omega. \end{aligned}$$

Furthermore,

$$\text{sign}\left[\frac{\partial V}{\partial x_i}\right] = -\,\text{sign}[x_i], \qquad \frac{\partial^2 V}{\partial x_i^2} \le 0, \qquad (x,\, t) \in [-1,\, 1] \times (0,\, \infty),$$

$V(d,\, M)$ *satisfies* (1.5), *and* $\|V(d,\, M;\, \cdot,\, t)\|_\infty = V(d,\, M;\, 0,\, t)$.

THEOREM 2.4. *Suppose that* $u(x,\, t)$ *is the solution of an initial boundary value problem of the form* (1.1)–(1.3), *for some* $d,\, M \in \mathbb{R}^N$, *and nonnull initial data* $u_0 \in L_\infty(\Omega)$. *Then,*

$$\frac{\|u(t)\|_\infty}{\|u_0\|_\infty} \le V(d,\, M;\, 0,\, t) = \prod_{i=1}^{N} v(M_i/d_i;\, d_i t). \tag{2.12}$$

This upper bound is attained when $a_i(x,\, t) = d_i$, $b_i = M_i\,\text{sign}[x_i]$, *and* $u_0(x)$ *is a nonzero constant.*

Proof. By linearity, we may assume without loss that $\|u_0\|_\infty = 1$. Now, Lemma 2.3 implies that for each $t > 0$, almost everywhere in Ω,

$$\begin{aligned} V_t + LV &= V_t - \sum_{i=1}^{N} a_i \frac{\partial^2 V}{\partial x_i^2} + \sum_{i=1}^{N} b_i \frac{\partial V}{\partial x_i} \\ &= -\sum_{i=1}^{N} (a_i - d_i) \frac{\partial^2 V}{\partial x_i^2} + \sum_{i=1}^{N} (b_i - M_i \text{sign}[x_i]) \frac{\partial V}{\partial x_i} \\ &\ge 0. \end{aligned}$$

Since V satisfies the boundary conditions and $V(d,\, M;\, x,\, 0) \ge u_0(x)$, V is an upper solution for the problem (1.1)–(1.3); similarly, $-V$ is a lower solution. The maximum principle now implies that

$$-V(d,\, M;\, x,\, t) \le u(x,\, t) \le V(d,\, M;\, x,\, t), \qquad (x,\, t) \in \overline{\Omega} \times [0,\, \infty).$$

Thus $\|u(t)\|_\infty \le \|V(d, M; \cdot, t)\|_\infty$. Lemma 2.3 implies that $\|V(d, M; \cdot, t)\|_\infty = V(d, M; 0, t)$. □

Since Laplace transform techniques will be used later to establish further properties of V, it is convenient to consider properties of the elliptic problem corresponding to the operator $L_{d,M}$. The boundary value problem

$$L_{d,M}u + \lambda u = 1, \quad x \in \Omega; \qquad u(x) = 0, \quad x \in \partial\Omega, \tag{2.13}$$

has a unique solution in $H_0^1(\Omega)$ for $\lambda \ge 0$ (see, e.g., Gilbarg and Trudinger [7, Chapter 8]), which we define as $W(d, M; x, \lambda)$.

LEMMA 2.5.

$$\begin{aligned} \overline{V}(d, M; x, \lambda) &\equiv \int_0^\infty e^{-\lambda t} V(d, M; x, t)\, dt \\ &= W(d, M; x, \lambda), \qquad (x, \lambda) \in [-1, 1]^N \times [0, \infty). \end{aligned} \tag{2.14}$$

Furthermore, $\operatorname{sign}[\partial W/\partial x_i] = -\operatorname{sign}[x_i]$ *and*

$$\|W(d, M; \lambda, \cdot)\|_\infty = W(d, M; \lambda, 0) = \int_0^\infty e^{-\lambda t} V(d, M; 0, t), dt. \tag{2.15}$$

Proof. Standard parabolic regularity implies that we may differentiate each term in (2.1) with respect to t for $t \ge 1$, say, so that $v_t(M; x, t)$ also satisfies (2.1), including the boundary conditions, for $t \ge 1$. We may now deduce from a result of Friedman [6, Chapter 6] that there are constants C, $\mu > 0$ such that

$$\|v_t(t)\|_\infty \le Ce^{-\mu t}, \qquad t \ge 1.$$

For fixed t, one may use (2.5) to express v, v_x, and v_{xx} in terms of v_t. Now, using the definition of $V(d, M; x, t)$ in terms of v, we conclude that, for each $x \in \Omega$, V and its first and second partial derivatives are absolutely integrable over the time interval $(0, \infty)$. Thus, by a standard result of calculus, x-differentiation commutes with Laplace transformation for $x \in \Omega$. Hence, $\overline{V}(d, M; \cdot, \lambda) \in H_0^1(\Omega)$ and satisfies (2.13) and so is equal to $W(d, M; \cdot, \lambda)$ by uniqueness.

Since $V(d, M; x, t)$ is nonnegative, with a maximum at $x = 0$ for each $t \ge 0$, $\overline{V}(d, M; x, \lambda)$ and therefore $W(d, M; x, \lambda)$ must also be nonnegative with a maximum at $x = 0$. Lastly, since the sign of $\partial V/\partial x_i$ is invariant for fixed x, $\partial W/\partial x_i$ takes the same sign, by the commutativity of x-differentiation and t-integration. □

3. Calculations of $v(M; t)$. In order to obtain practical bounds as a consequence of Theorem 2.4, it remains to explicitly compute the function $v(M; t)$ for $M, t \ge 0$. By a simple calculation one finds that the solution $w(M; x, \lambda)$ of the problem

$$(L_M + \lambda I)[u] = 1; \quad x \in (0, 1); \quad u_x(0) = u(1) = 0, \tag{3.1}$$

takes the following values at $x = 0$:

$$\left.\begin{aligned} &\frac{e^M - M - 1}{M^2}, && \lambda = 0, \\ &\frac{1}{\lambda} - \frac{2\gamma e^{-(M/2+\gamma)}}{\lambda(\gamma - M/2 + (\gamma + M/2)e^{-2\gamma})}, && \left[\gamma = (\lambda + M^2/4)^{1/2}\right], \quad \lambda > 0. \end{aligned}\right\} \tag{3.2}$$

Since Lemma 2.5 implies that $\overline{v}(M; 0, \lambda) = w(M; 0, \lambda)$, we calculate $v(M; t)$ by finding two expansions for the inverse Laplace transform of (3.2), one of which is rapidly convergent for large t and the other for small t.

3.1. Eigenmode expansion. Here, we apply the Mellin inversion and residue theorems directly to (3.2) to obtain an expansion suitable for small t, which is equivalent to an expansion in terms of the eigenfunctions of L_M. Extending the definition of $\overline{v}(M;\,\lambda)$ to complex λ, one sees that the function is single valued because it is even in γ. The singularity at $\lambda = 0$ is removable, and thus poles occur only when $\gamma = 0$ or $\tanh\gamma/\gamma = M/2$. The imaginary part of this last equation yields

$$b\sinh 2a = a\sin 2b \qquad \text{for } \gamma = a + bi, \quad a,\, b \in \mathbb{R},$$

but this can only be satisfied when either $a = 0$ or $b = 0$ since

$$\sinh x/x > 1 > \sin x/x \qquad \text{for } \ x \in \mathbb{R}\setminus\{0\}.$$

Hence poles only occur when γ is real or pure imaginary.

Negative γ is excluded, so when $b = 0$ we require solutions of

$$a\cosh a = M/2\sinh a, \qquad a \geq 0. \tag{3.3}$$

The solution $a = 0$ does not yield a pole, except when $M = 2$. For $M \in [0,\,2)$, (3.3) has no other solutions. When $M \in [2,\,\infty)$ there is exactly one solution, yielding a pole $\lambda = -\lambda_1$, where $\lambda_1 = M^2/4 - a^2$. λ_1 is the principal eigenvalue of the operator L_M, previously considered in Theorem 2.2.

The remaining poles occur when $\gamma = ib$, where b is a solution of

$$b\cos b = M/2\sin b, \qquad b > 0. \tag{3.4}$$

For all $M \geq 0$ there is exactly one solution b_n of (3.4) in every interval $((n-1)\pi,\,(n-1/2)\pi]$ for $n = 2,\,3,\,4,\,\ldots$. When $M \in [0,\,2)$ there is a further solution $b_1 \in (0,\,\pi/2]$. These solutions yield poles $\lambda = -\lambda_n$, where $\lambda_n = M^2/4 + b_n^2$. Hence, all poles are simple, real, and strictly negative.

An analysis similar to that of Carslaw and Jaeger [3, p. 96] demonstrates that $\overline{v}(M;\,\lambda)$ satisfies a version of Jordan's lemma on the sequence of contours $\Gamma_n = \partial\omega_n$, where

$$\omega_n = \left\{ z \in \mathbb{C} \;\middle|\; |z + M^2/4| < n^2\pi^2, \quad \mathrm{Re}[z] \leq 0 \right\}.$$

Thus,

$$v(M;\,t) = \frac{1}{2\pi i}\int_{-i\infty}^{i\infty} \overline{v}(M;\,\lambda)e^{\lambda t}\,d\lambda = \sum \mathrm{Res}[\overline{v}(M;\,\lambda)e^{\lambda t}].$$

A calculation shows that, for all $t \geq 0$,

$$v(M;\,t) = \sum_{n=1}^{\infty} c_n(M)\exp(-\lambda_n(M)t), \tag{3.5}$$

where

$$c_1(M) = \begin{cases} \frac{2e^{-M/2}(\lambda_1 - M^2/4)}{\lambda_1^{1/2}(\lambda_1 - M/2)} & M \in [0,\,\infty)\setminus\{2\}, \\ 3e^{-(1+t)} & M = 2, \end{cases}$$

$$c_n(M) = \frac{2(-1)^{n+1}e^{-M/2}(\lambda_n - M^2/4)}{\lambda_n^{1/2}(\lambda_n - M/2)}, \qquad n \geq 2.$$

We state some of the conclusions from the calculation as a theorem.

THEOREM 3.1. *The terms in the series* (3.5) *are alternating and decreasing,*

$$e^{-\lambda_1 t} \le v(M;\, t) \le \min\left[1,\, c_1(M)e^{-\lambda_1 t}\right], \tag{3.6}$$

and $v(M;\, t) \sim c_1(M)e^{-\lambda_1 t}$ *for large* t. $\lambda_1(M)$ *decreases with* M; $\lambda_1(0) = \pi^2/4$, $\lambda_1(2) = 1$, *and*

$$\lambda_1(M) = M^2 e^{-M} + 2M^2(M-1)e^{-2M} + o\left(e^{-(3-\epsilon)M}\right) \qquad \text{for any } \epsilon > 0, \tag{3.7}$$

for large M. $c_1(M)$ *also decreases with* M; $c_1(0) = 4/\pi$, $c_1(2) = 3/e$, *and, for large* M,

$$c_1(M) = 1 + (M-3)e^{-M} + o\left(e^{-(2-\epsilon)M}\right) \qquad \text{for any } \epsilon > 0. \tag{3.8}$$

Proof. Since $\lambda_n(M) \ge \max[M/2,\, M^2/4]$, except when $n = 1$ and $M > 2$, $(-1)^{n+1}c_n$ decreases with λ_n, and thus with n. Hence the sequence $(c_n e^{-\lambda_n t})$ is alternating and decreasing for $t \ge 0$. This implies $v(M;\, t) \le c_1(M)\exp(-\lambda_1(M)t)$. On the other hand, the maximum principle implies that $v(M;\, t) \le 1$. For the lower bound, we observe that if $\phi_1(x)$ is the first eigenmode of L_M, $u(x,\, t) = e^{-\lambda_1 t}\phi_1(x)$ is a solution of (2.1) such that $u_0 = \phi_1$. Thus, the last part of (3.6) follows from Theorem 2.4. Since $0 < \lambda_1 < \lambda_n$ for $n > 1$, (3.5) implies that $v(M;\, t) \sim c_1(M)e^{-\lambda_1 t}$. The values of $\lambda_1(M)$ and $c_1(M)$, and the asymptotic estimates for large M, are obtained by solving (3.3) and (3.4). ∎

A simple consequence of Theorems 2.4 and 3.1 is that the first eigenvalue of the operator $L_{d,\,M}$ attains the minimum possible value for an eigenvalue of an elliptic operator L (independent of t), of the form indicated by (1.1)–(1.3). As regards the behavior of $v(M;\, t)$ and the series (3.6), we postpone further comment until the end of the section.

3.2. Complementary error function expansion. We now consider expansions of $v(M;\, t)$ suitable for small t in terms of iterated complementary error functions. $\overline{v}(M;\, \lambda)$, given by (3.2), may be re-expressed as a convergent geometric series, provided λ is sufficiently small. Considering the nth partial sum of this series, we define

$$\overline{v}_n(M;\, \lambda) = \frac{1}{\lambda} - \frac{2\gamma e^{-(M/2+\gamma)}}{\lambda(\gamma - M/2)} \sum_{r=0}^{n} (-1)^r \left[\frac{(\gamma + M/2)e^{-2\gamma}}{\gamma - M/2}\right]^r \tag{3.9}$$

and set $v_n(M;\, t) \equiv \mathcal{L}^{-1}\{\overline{v}_n(M;\, \lambda)\}(t)$, where $\mathcal{L}$ is the Laplace transform operator. To obtain an explicit expression for $v_n(M;\, t)$, we apply the following theorem stated by Carslaw and Jaeger [3, Theorem XII, p. 259].

THEOREM 3.2. *If the transform of* $f(t)$ *is* $F(\lambda)$, $\lambda \ge \lambda_0$, *and that of* $K(t,\, u)$ *is* $\phi(\lambda)e^{-u\psi(\lambda)}$, *where* $\phi(\lambda)$ *and* $\psi(\lambda)$ *are independent of* u, *and* $\psi(\lambda) \ge \lambda_0$ *for* $\lambda \ge \lambda_1$, *then*

$$\mathcal{L}^{-1}\left\{\phi(\lambda)F(\psi(\lambda))\right\}(t) = \int_0^\infty K(t,\, u)f(u)\, du. \tag{3.10}$$

Here, we note that for $\phi(\lambda) = 1/\gamma(\lambda)$ and $\psi(\lambda) = \gamma(\lambda) - M/2$,

$$\frac{1}{\lambda} - \overline{v}_n(M;\, \lambda) = \phi(\lambda)F_n(\psi(\lambda)),$$

where

$$F_n(\lambda) = \frac{2(\lambda + M/2)^2 e^{-(M+\lambda)}}{\lambda^2(\lambda + M)} \sum_{r=0}^{n} (-1)^r \left(1 + \frac{M}{\lambda}\right)^r e^{-r(M+2\lambda)}. \tag{3.11}$$

Henceforth, for standard transform results we quote the tables of Erdélyi et al. [5], from where we deduce that

$$K(t,\, u) = \frac{1}{\sqrt{\pi t}} \exp\left(-\left(\frac{u}{2\sqrt{t}} - \frac{M\sqrt{t}}{2}\right)^2\right).$$

On the other hand, expanding (3.11),

$$F_n(\lambda) = \left(\frac{2}{\lambda} + \frac{M^2}{2\lambda^2(\lambda + M)}\right) \sum_{r=0}^{n} (-1)^r \sum_{s=0}^{r} \binom{r}{s} \frac{M^s e^{-(r+1)M} e^{-(2r+1)\lambda}}{\lambda^s}.$$

Using the tables [5], $f_n(t)$, the inverse of $F_n(\lambda)$, is given by

$$\begin{aligned}
&\sum_{r=0}^{n} (-1)^r \sum_{s=0}^{r} 2 \binom{r}{s} M^s e^{-(r+1)M} \frac{(t - (2r+1))^s}{s!} H(t - (2r+1)) \\
&+ \frac{1}{2}(e^{-Mt} - e^{-M} + Me^{-M}(t-1)) H(t-1) \\
&+ \sum_{r=1}^{n} \frac{(-1)^r}{2} \sum_{s=0}^{r-1} \binom{r-1}{s} M^{s+2} e^{-(r+1)M} \frac{(t - (2r+1))^{s+2}}{(s+2)!} H(t - (2r+1)),
\end{aligned}$$

where $H(t)$ is the Heaviside function. Evaluating (3.10), we find that

$$\begin{aligned}
&v_n(M;\, t) \\
&= 1 - \sum_{r=0}^{n} (-1)^r \sum_{s=0}^{r} 2 \binom{r}{s} e^{-(r+1)M} (2M\sqrt{t})^s \mathrm{i}^s \mathrm{erfc}\left(\frac{2r+1}{2\sqrt{t}} - \frac{M\sqrt{t}}{2}\right) \\
&- \frac{1}{2}\left(\mathrm{erfc}\left(\frac{1}{2\sqrt{t}} + \frac{M\sqrt{t}}{2}\right) - e^{-M} \mathrm{erfc}\left(\frac{1}{2\sqrt{t}} - \frac{M\sqrt{t}}{2}\right)\right) \\
&- Me^{-M}\sqrt{t}\,\mathrm{i}^1 \mathrm{erfc}\left(\frac{1}{2\sqrt{t}} - \frac{M\sqrt{t}}{2}\right) \\
&- \sum_{r=1}^{n} (-1)^r \sum_{s=0}^{r-1} \binom{r-1}{s} \frac{e^{-(r+1)M}}{2} (2M\sqrt{t})^{s+2} \mathrm{i}^{s+2} \mathrm{erfc}\left(\frac{2r+1}{2\sqrt{t}} - \frac{M\sqrt{t}}{2}\right),
\end{aligned} \tag{3.12}$$

where (see [1, Chapter 7]),

$$i^n \mathrm{erfc}(x) = \int_x^\infty \frac{(t-x)^n}{n!} e^{-t^2}\, dt, \quad n = 0,\, 1,\, 2,\, \ldots; \quad \mathrm{erfc}(x) \equiv \mathrm{i}^0 \mathrm{erfc}(x), \quad x \in \mathbb{R}$$

and $i^n \mathrm{erfc}(x)$ satisfies the recurrence relation

$$\mathrm{i}^n \mathrm{erfc}(x) = -\frac{x}{n} \mathrm{i}^{n-1} \mathrm{erfc}(x) + \frac{1}{2n} \mathrm{i}^{n-2} \mathrm{erfc}(x), \quad n \geq 1, \tag{3.13}$$

where $\mathrm{i}^{-1} \mathrm{erfc}(x) = (2/\sqrt{\pi}) \exp(-x^2)$.

THEOREM 3.3. *The sequence* $(v_n(M;\, t))$ *is such that, for* $n \geq 0$,

$$v_{2n}(M;\, t) \leq v(M;\, t) \leq v_{2n+1}(M;\, t), \qquad (M,\, t) \in [0,\, \infty) \times (0,\, \infty), \tag{3.14}$$

and for fixed $(M,\, t) \in [0,\, \infty) \times (0,\, \infty)$, $\lim_{n\to\infty} v_n(M;\, t) = v(M;\, t)$. *Furthermore, for small* t,

$$v(M;\, t) = 1 - \frac{2e^{-M/2}\sqrt{t}}{\sqrt{\pi}} \exp\left(-\frac{1}{4t}\right)[1 + 2M\sqrt{t} + O(t)]. \tag{3.15}$$

Proof. Subtracting (3.9) from (3.2), we obtain

$$\overline{v}(M;\, \lambda) - \overline{v}_n(M;\, \lambda) = (-1)^n \left[\frac{(\gamma + M/2)e^{-2\gamma}}{\gamma - M/2}\right]^{(n+1)} \left(\frac{1}{\lambda} - \overline{v}(M;\, \lambda)\right).$$

Applying the iterated product formula for inverse Laplace transforms and using the positivity of $\mathcal{L}^{-1}\{1/\lambda - \overline{v}(M;\, \lambda)\}(t)$ and $\mathcal{L}^{-1}\{(\gamma + M/2)e^{-2\gamma}/(\gamma - M/2)\}(t)$, we conclude that $(-1)^n(v(M;\, t) - v_n(M;\, t))$ is nonnegative, and (3.14) follows.

Consequently,

$$\begin{aligned}
&|v(M;\, t) - v_n(M;\, t)| \\
&\quad \leq |v_{n+1}(M;\, t) - v_n(M;\, t)| \\
&\quad \leq \sum_{s=0}^{n+1} 2 \begin{pmatrix} n+1 \\ s \end{pmatrix} e^{-(n+2)M} (2M\sqrt{t})^s \mathrm{i}^s \mathrm{erfc}\left(\frac{2n+3}{2\sqrt{t}} - \frac{M\sqrt{t}}{2}\right) \\
&\quad + \sum_{s=0}^{n} \begin{pmatrix} n \\ s \end{pmatrix} \frac{e^{-(n+2)M}}{2} (2M\sqrt{t})^{s+2} \mathrm{i}^{s+2} \mathrm{erfc}\left(\frac{2n+3}{2\sqrt{t}} - \frac{M\sqrt{t}}{2}\right),
\end{aligned} \tag{3.16}$$

where we have used (3.12).

When $2n + 3 \geq Mt + 2\sqrt{t}$, the estimate

$$i^n \mathrm{erfc}(x) < \frac{2}{\sqrt{\pi}} \frac{e^{-x^2}}{(2x)^{n+1}}, \quad x > 0, \quad n \geq 0,$$

implies that the right-hand side of (3.16) is bounded above by

$$\frac{2e^{-M/2}}{\sqrt{\pi}} (1 + M\sqrt{t})^{n+2} \exp\left(-\left(\frac{(2n+3)^2}{4t} + \frac{M^2 t}{4}\right)\right). \tag{3.17}$$

Hence, $\lim_{n\to\infty} v_n(M;\, t) = v(M;\, t)$.

When $Mt + 2\sqrt{t} \leq 3$, (3.17) implies that $v(M;\, t) = v_0(M;\, t) + O\left(e^{-9/(4t)}\right)$. Expanding the five terms comprising $v_0(M;\, t)$ and using the recurrence relation (3.13) and the asymptotic formula [1, p. 298],

$$\sqrt{\pi} x e^{x^2} \mathrm{erfc}(x) \sim 1 + \sum_{m=1}^{\infty} (-1)^m \frac{1 \cdot 3 \cdots (2m-1)}{(2x^2)^m}, \qquad \text{as } z \to \infty, \tag{3.18}$$

one obtains (3.15). ∎

3.3. The behavior of $v(M; t)$ and numerical analysis. Qualitatively, we know (Theorem 3.3) that $\lim_{t\to 0} v_t(M; t) = 0$, and (Theorems 2.2 and 3.1) that $v_t(M; t)/v(M; t)$ is a decreasing function of t, tending to $-\lambda_1$ as $t \to \infty$. The asymptotic behavior of $v(M; t)$ in t-neighborhoods of 0 and ∞ is given by Theorems 3.3 and 3.1, respectively. The nonpolynomially slow initial decay given by (3.15) is well known in the case $M = 0$; see, e.g., Carslaw and Jaeger [3]. For $M > 0$, we see that this is modified by the constant $e^{-M/2}$. For large times, Theorem 3.1 states that $v(M; t) \sim c_1(M)e^{-\lambda_1(M)t}$, which is also a familiar type of result for eigenmode expansions in the selfadjoint case. However, for large M, $\lambda_1(M) \sim M^2e^{-M}$. This is so small for large M that, even for $M = 50$, it is on the limit of double precision (16-digit decimal) arithmetic to detect the decay of $v(M; t)$ over any interval of the form $[t, t + 10]$. We also remark that the value of $1/\lambda_1$ is highly sensitive to changes in M.

In the t-range between these asymptotic estimates, the behavior of $v(M; t)$ is not so immediately apparent from either (3.5) or (3.12), and a numerical summation of a truncation of one of these expansions is required. Considering small t initially, we note that Theorems 2.2 and 3.3 imply

$$v(M; t) \geq v(0, t) \geq v_0(0; t) = 1 - 2\,\mathrm{erfc}(1/(2\sqrt{t})), \qquad (M, t) \in [0, \infty)^2.$$

We deduce that the decay of $v(M; t)$ is undetectable by double precision arithmetic for $t \leq 0.007$. So, there is no point in summing (3.5) on a computer for such t. However, in the case of (3.12), because 1 is the first term in the expansion, $1 - v(M; t)$ may be well approximated by $1 - v_0(M; t)$ over this t-range.

Without descending into too detailed an analysis, for $t \in (0.007, 0.1]$ and $M \in [0, 10]$, the decay in $v(M; t)$ becomes detectable, although obviously the precise values of t depend upon M. Loosely speaking, expansion (3.12) is at an advantage over (3.5) in this range, since the latter requires many terms for accuracy. The appropriate number of terms to take in (3.12) is indicated by the error estimate (3.16), since $3 > Mt + 2\sqrt{t}$ for this parameter range. We note that instructions on the numerical calculation of $\mathrm{i}^n\mathrm{erfc}(x)$ for $x > 0$ are given in [1, Chapter 7]. Essentially, this is cheap to evaluate, using a *backward* iteration of (3.13) (to avoid cancellation errors), once the values of $\mathrm{erfc}(x)$ and $(2/\sqrt{\pi})\exp(-x^2)$ are known. However, a recalculation must be performed for each value of t.

For $M > 10$, $1 - v(M; t)$ is much smaller for $t \in [0, 1]$, and (3.12) remains appropriate over this range. Considering (3.16) again, in the case where $2n + 3 \leq Mt + 2\sqrt{t}$, the crude estimate

$$i^n\mathrm{erfc}(x) \leq 2\exp(x_-), \qquad x \in \mathbb{R}, \;\; n = 0, 1, \ldots$$

implies that

$$|v(M; t) - v_n(M; t)| \leq 4(1 + 2M\sqrt{t})^{n+2}e^{-(n+2)M}e^{M\sqrt{t}/2}. \tag{3.19}$$

Thus for $t \in [0, 1]$, $v_3(M; t)$ suffices for $M = 10$, while for $M \geq 40$, $v_0(M; t)$ is good enough. We remark that $\mathrm{i}^n\mathrm{erfc}(x)$ should be evaluated by *forward* iteration of (3.13) when $x < 0$.

For $t > 0.1$ and $M \in [0, 10]$, a truncation to m terms of (3.5) becomes more competitive. We remark that λ_n and the coefficients of $e^{-\lambda_n t}$ may be quite cheaply calculated from (3.3) and (3.4) using a Newton–Raphson iteration and that, for fixed M, the same coefficients serve for all t. As stated in Theorem 3.1, the series (3.5) is

alternating and decreasing. Thus, the error in the truncation after m terms is less in magnitude than the $(m+1)$st term. For $n > 1$ and $\theta(M, n) \in (0, 1/2)$,

$$c_n(M)e^{-\lambda_n t} = (-1)^{n+1}\frac{2e^{-M/2}(n-\theta)^2\pi^2\exp(-((n-\theta)^2\pi^2 + M^2/4)t)}{((n-\theta)^2\pi^2 + M^2/4 - M/2)((n-\theta)^2\pi^2 + M^2/4)^{1/2}}.$$

Hence, to achieve an error of less than ϵ, it is sufficient that m satisfy

$$\sqrt{\frac{[\log(m\pi\epsilon/2) + M/2]_-}{\pi^2 t}} < m, \qquad \text{where } [x]_- \equiv (|x| - x)/2.$$

So, $m = 7$ suffices for all $t > 0.1$ if $\epsilon = 10^{-16}$. As t increases, successively fewer terms are needed.

Lastly, we note that for large M and $t \in [0, 1]$,

$$1 - c_1(M)\exp(-\lambda_1 t) \approx e^{-M}(M^2 t - (M-3)),$$
$$|c_2(M)|\exp(-\lambda_2 t) \approx \frac{2\pi^2 e^{-M/2}}{\sqrt{(\pi^2 + M^2/4)}(\pi^2 + M^2/4 - M/2)}e^{-(M^2/4+\pi^2)t}.$$

Thus, when $t \geq 3/M$, the second and subsequent terms in (3.5) are entirely negligible, and the behavior of $v(M; t)$ is essentially exponential decay. This indicates that increasing M has a more pronounced effect on the large time behavior than it does on the initial decay.

4. Elliptic bounds. Here, we initially consider means of calculating the L_∞ bound given by Lemma 2.5 for a cubical domain. Subsequently, we consider bounds in a spherical geometry for somewhat more general elliptic operators, under slightly different assumptions on the advection.

4.1. Problems on the unit cube. Here, in the domain $\Omega = (-1, 1)^N$, we consider the problem

$$Lu + \lambda u \equiv -\sum_{i=1}^{N} a_i(x)\frac{\partial^2 u}{\partial x_i^2} + \sum_{i=1}^{N} b_i\frac{\partial u}{\partial x_i} + \lambda u = f, \qquad x \in \Omega, \tag{4.1}$$
$$u(x) = 0, \qquad x \in \partial\Omega.$$

It is assumed that $\lambda \geq 0$, $a \in C(\overline{\Omega})$, b, $f \in L_\infty(\Omega)$,

$$\inf_{x\in\Omega} a_i(x) \geq d_i > 0, \qquad \|b_i(x)\|_\infty \leq M_i, \tag{4.2}$$

and that f is nonnull.

THEOREM 4.1. *Suppose that $u(x)$ is the solution of a boundary value problem of the form (4.1), for some $\lambda \geq 0$, where the coefficients satisfy the above assumptions. Then,*

$$\frac{\|u\|_\infty}{\|f\|_\infty} \leq W(d, M; 0, \lambda) = \int_0^\infty e^{-\lambda t}\prod_{i=1}^{N} v(M_i/d_i; d_i t)\, dt. \tag{4.3}$$

This upper bound is attained when $a_i(x) = d_i$, $b_i(x) = M_i \operatorname{sign}[x_i]$, and f is a nonzero constant.

Proof. Lemma 2.5 implies that $W(d,\, M;\, x,\, \lambda)$ satisfies the equation

$$-\sum_{i=1}^{N} d_i \frac{\partial^2 u}{\partial x_i^2} - \sum_{i=1}^{N} M_i \left| \frac{\partial u}{\partial x_i} \right| + \lambda u = 1.$$

The rest of the proof resembles that of Theorem 2.4 and is omitted. ∎

When $N = 1$, we have already found a simple explicit formula, given by (3.2). An explicit formula is also available for $W(d,\, M;\, 0,\, \lambda)$ for $N > 1$, using the eigenmode expansion (3.5). We begin by relabelling the coefficients of (3.5) as follows:

$$v(M_i/d_i;\, t) = \sum_{n=1}^{\infty} c_n^i \exp(-\lambda_n^i t), \qquad \lambda_n^i = \lambda_n(M_i/d_i), \quad c_n^i = c_n^i(M_i/d_i). \tag{4.4}$$

From (4.3) we obtain

$$W(d,\, M;\, \lambda) = \sum_{n_1=1}^{\infty} \sum_{n_2=1}^{\infty} \cdots \sum_{n_N=1}^{\infty} \frac{c_{n_1}^1 \cdots c_{n_N}^N}{\lambda + d_1 \lambda_{n_1}^1 + \cdots + d_n \lambda_{n_N}^N}. \tag{4.5}$$

However, (4.5) is a very slowly converging series, unsuitable for computation.

To obtain practical bounds, for $N > 1$ and λ not too small, probably the most numerically efficient way of evaluating the integral is to rescale the time variable to $\tau = \lambda t$ and then apply Gauss–Laguerre quadrature—see [1, p. 923], with the values of $v(M;\, t)$ approximated in the way indicated at the end of section 3. However, the error term for this quadrature method is very difficult to evaluate in practice, so sharp guaranteed error bounds are not usually available.

Alternatively, setting $d_0 = \min[d_1,\, \ldots,\, d_N]$, we approximate

$$\begin{aligned} v(M_i/d_i;\, d_i t) &\approx 1, \qquad d_0 t \in [0,\, t^*], \\ v(M_i/d_i;\, d_i t) &\approx \sum_{n_i=1}^{m^*} c_{n_i}^i \exp(-d_i \lambda_{n_i}^i t), \qquad d_0 t > t^*, \end{aligned}$$

for some $t^* > 0$ and m^* an odd integer. Integrating exactly, one obtains

$$\begin{aligned} W(d,\, M;\, 0,\, \lambda) &\approx \frac{1 - e^{-\lambda t^*/d_0}}{\lambda} \\ &+ \sum_{n_1=1}^{m^*} \cdots \sum_{n_N=1}^{m^*} \frac{c_{n_1}^1 \cdots c_{n_N}^N \exp(-(\lambda + d_1 \lambda_{n_1}^1 + \cdots + d_N \lambda_{n_N}^N) t^*/d_0)}{\lambda + d_1 \lambda_{n_1}^1 + \cdots + d_N \lambda_{n_N}^N}. \end{aligned} \tag{4.6}$$

Since m^* is odd, (4.6) is an upper bound for (4.5). The analysis of section 3 may be used to show that if $t^* = 0.007$, $m^* = 23$, and $N \leq 10$ then the absolute error of (4.6) is less than 10^{-16}. However, for very large λ, (4.6) is insufficiently accurate to give a good approximation of $1/\lambda - W(d,\, M;\, 0,\, \lambda)$, because this corresponds in an Abelian or Tauberian sense to the subtle behavior of $1 - V(d,\, M;\, 0,\, t)$ near $t = 0$.

We note that Nm^* transcendental equations of the form (3.3) or (3.4) must be solved for (4.6), which is perfectly feasible for the parameters suggested. The sum on the right-hand side contains $(m^*)^N$ different terms, which when $m^* = 23$ is not too many to compute for the usual physical dimensions, $N \leq 3$. However, for N much bigger than 7 this method becomes impractical.

4.2. Problems on the unit ball. On $B \equiv B(\mathbb{R}^N; 0, 1)$, the unit ball in $\mathbb{R}^N$, we consider

$$(L+\lambda)u \equiv -\sum_{i,j=1}^{N} a_{ij}(x)\frac{\partial^2 u}{\partial x_i x_j} + \sum_{i=1}^{N} b_i(x)\frac{\partial u}{\partial x_i} + \lambda u = f, \qquad |x| < 1,$$
$$u(x) = 0, \qquad |x| = 1. \tag{4.7}$$

It is assumed that $\lambda \geq 0$, $a \in C(\overline{B})$, b, $f \in L_\infty(B)$,

$$\inf_{x\in\Omega} \sup_{\xi\in B} a_{ij}(x)\xi_i\xi_j \geq 1, \qquad \left\| \sum_{i=1}^{N} b_i^2 \right\|_\infty \leq K^2, \tag{4.8}$$

and that f is nonnull.

For $K \geq 0$, we define

$$L_K u \equiv -\Delta u + K\frac{x}{|x|}.\nabla u, \quad x \neq 0; \qquad L_K u \equiv -\Delta u, \quad x = 0, \tag{4.9}$$

and set $w(K; x, \lambda)$ to be the solution of (4.7) when $L = L_K$ and $f(x) \equiv 1$.

LEMMA 4.2. *$w(K; x, \lambda) = v(K; |x|, \lambda)$, where v, the solution of the problem*

$$-u_{rr} - (N-1)u_r + Ku_r + \lambda u = 1, \quad r \in (0, 1); \qquad u'(0) = u(1) = 0, \tag{4.10}$$

satisfies

$$v_r(r) < 0, \qquad v_{rr}(r) - \frac{v_r(r)}{r} < 0, \quad r \in (0, 1). \tag{4.11}$$

Furthermore, for $M(\cdot, \cdot, \cdot)$, the confluent hypergeometric Kummer function of the first kind (see [1, p. 504]*), and $r \in (0, 1)$,*

$$v(K; r, 0) = \int_r^1 \int_0^s (t/s)^{N-1} e^{K(s-t)}\, dt\, ds,$$
$$v(K; r, \lambda) = \frac{1}{\lambda}\left(1 - e^{(\gamma - K/2)(1-r)}\frac{M((N-1)\delta, N-1, 2\gamma r)}{M((N-1)\delta, N-1, 2\gamma)}\right), \quad \lambda > 0,$$
$$\gamma \equiv \sqrt{K^2/4 + \lambda}, \qquad \delta \equiv (1/2 - (K/4\gamma)). \tag{4.12}$$

Proof. We define the nonnegative sequence (b_n) by $b_1 = 0$, $b_2 = 1$,

$$b_{n+2} = \frac{K(n+1)}{(N+n)(n+2)} b_{n+1} + \frac{\lambda b_n}{(N+n)(n+2)}, \quad n \geq 1. \tag{4.13}$$

Defining $C(N, K, \lambda) = \sum_{n=2}^{\infty} b_n$, we consider the sequence (a_n), where

$$a_0 = \frac{C(N, K, \lambda)}{\lambda C(N, K, \lambda) + 2N}, \quad a_1 = 0, \quad a_2 = -\frac{a_0}{C(N, K, \lambda)}, \tag{4.14}$$

and $a_n = a_2 b_n$ for $n \geq 3$. We observe that $\sum_{n=0}^{\infty} a_n r^n$ satisfies (4.10).

The relationship between the respective solutions of (4.9) and (4.10) is clear. Since $w(K; x, \lambda)$ is unique, so is $v(K; r, \lambda)$, and thus,

$$v(r) = \sum_{n=0}^{\infty} a_n r^n. \tag{4.15}$$

(Coddington and Levinson [4] present a general theory of ODEs, including (4.9).) We note that $a_n < 0$ for $n \geq 2$, and therefore

$$v_r(r) = \sum_{n=2}^{\infty} n a_n r^{n-1} < 0; \qquad v_{rr}(r) - \frac{v_r(r)}{r} = \sum_{n=2}^{\infty} n(n+2) a_{n+2} r^n < 0, \qquad r \in (0,\, 1).$$

For $\lambda = 0$, (4.13) is elementary. For $\lambda > 0$, we define

$$y(2\gamma r) \equiv e^{(\gamma - K/2)r} \left(\frac{1}{\lambda} - v(r) \right), \quad r \in [0,\, 1].$$

$y(x)$ satisfies the following version of Kummer's equation; see [1, p. 504]:

$$xy_{xx} + ((N-1) - x)y_x - (N-1)\delta y = 0, \qquad x \in (0,\, 2\gamma), \tag{4.16}$$
$$y_x(0) = \delta y(0), \qquad y(2\gamma) = \frac{e^{\gamma - K/2}}{\lambda}.$$

(4.12) now follows for $\lambda > 0$ from the properties of Kummer's functions. ∎

THEOREM 4.3. *Suppose that $u(x)$ is the solution of* (4.1)*, under the accompanying assumptions, including* (4.8) *for some $K \geq 0$. Then,*

$$\frac{\|u\|_\infty}{\|f\|_\infty} \leq \sum_{n=0}^{\infty} \frac{K^n (N-1)!}{(n+2)(N+n)!}, \qquad \lambda = 0, \tag{4.17}$$

$$\frac{\|u\|_\infty}{\|f\|_\infty} \leq \frac{1}{\lambda} \left(1 - \frac{e^{\gamma - K/2}}{M((N-1)\delta,\, (N-1),\, 2\gamma)} \right), \qquad \lambda > 0. \tag{4.18}$$

These bounds are attained when $L = L_K$ and f is a nonzero constant.

Proof. Assuming $\|f\|_\infty = 1$, (4.9) and (4.11) imply that

$$\begin{aligned}
(L+\lambda)w &= -\sum_{i,\,j=1}^{N} a_{ij}(x) \frac{\partial^2 W}{\partial x_i \partial x_j} + \sum_{i=1}^{N} b_i(x) \frac{\partial W}{\partial x_i} + \lambda W \\
&= -\left(v_{rr}(|x|) - \frac{v_r(|x|)}{|x|} \right) \sum_{i,\,j=1}^{N} a_{ij}(x) \frac{x_i x_j}{|x|^2} - \frac{v_r(|x|)}{|x|} \sum_{1=1}^{N} a_{ii}(x) \\
&\quad + v_r(|x|) \sum_{i=1}^{N} b_i(x) x_i + \lambda v(|x|) \\
&\geq -v_{rr} - \frac{N-1}{|x|} v_r + K v_r + \lambda v = 1 \geq f(x)
\end{aligned}$$

for almost every $x \in B$. The maximum principle therefore implies that $u(x) \leq w(x)$; similarly, $u(x) \geq -w(x)$. Thus, $\|u\|_\infty \leq \|w(K;\, \cdot,\, \lambda)\|_\infty = w(K;\, 0,\, \lambda)$. The right-hand sides of (4.17) and (4.18) come from evaluations of (4.13), (4.14), and (4.12), respectively. ∎

We note that, from a computational point of view, the right-hand side is relatively easily evaluated, using the power series representation of the function $M(\cdot,\, \cdot, \cdot)$; see [1]. Lastly, we remark that it should be possible to obtain quantitative bounds on a parabolic version of (4.7) provided that a suitable expansion of the inverse Laplace transform of (4.18) can be found.

Acknowledgment. The author wishes to thank Professor J. F. Toland for suggesting this problem.

ANALYSIS OF CONCENTRATION AND OSCILLATION EFFECTS GENERATED BY GRADIENTS*

IRENE FONSECA†, STEFAN MÜLLER‡, AND PABLO PEDREGAL§

Abstract. A general theorem characterizing the interaction of concentrations and oscillations effects associated with sequences of gradients bounded in L^p, $p > 1$, is proved. The oscillations are recorded in the Young measure while the concentrations are encoded in the varifold.

Key words. oscillations, concentrations, Young measures, varifolds, quasiconvexity

1. Introduction.

Oscillatory phenomena and the characterization of limits of nonlinear quantities of oscillating sequences have been successfully analyzed by means of Young measures. These measures were first introduced by Young [38] to study nonconvex problems in optimal control theory and to provide the appropriate framework for the description of generalized minimizers in the calculus of variations. Recently Young measures have become an important tool in the study of nonlinear partial differential equations [10], [12], [13], [31], [33], [34], [35], [37] and the analysis of oscillatory behavior in nonconvex variational principles that arise in models of solid–solid phase transitions [7], [8]. Characterizations of Young measures associated with minimizing sequences of such functionals as well as with general sequences of gradients bounded in $L^p(\Omega;\mathbf{M})$ have been found in [21] and [22] (see also [29]). Here Ω is an open, bounded subset of $\mathbf{R}^N$ and $\mathbf{M} = \mathbf{M}^{m\times N}$ is the set of $m \times N$ matrices.

One of the main drawbacks of Young measures is that they miss completely concentration effects. Indeed, sequences may share the same Young measure and yet one may exhibit concentrations while the other does not. Several ways of understanding and manipulating concentrations have been proposed. We refer the reader to [14], [15], [18], [19], [24], [25], [30], [36], and [37] for some of these methods. Another possibility is using varifolds or indicator measures following the works [3], [4], [17], [28]. This is the point of view that we will take here, and we will focus on sequences that are constrained to be gradients. A similar approach has been employed in [2] for unconstrained sequences that are bounded in L^1.

The notion of a varifold has been used to describe certain nonlinear limits of oscillating measures, and it plays a role complementary to that of the Young measure.

In fact, the Young measure associated with a sequence $\{f_j\}$, which is bounded in $L^p(\Omega;\mathbf{R}^d)$, describes the effect of oscillations on the limits of $\{\varphi(f_j)\}$ whenever the nonlinearity φ has growth of order strictly less than p, while the varifold describes the effect of concentrations on the limits of $\{\psi(f_j)\}$ when ψ grows asymptotically as the pth power. We will be more precise in section 3.

Our goal is to understand the relation between the varifold and the Young measure that are generated by a sequence of gradients which is bounded in $L^p(\Omega;\mathbf{M})$, $p>1$. We hope to address the case $p=1$ in a future work. A detailed description of Young measures generated by sequences of gradients bounded in $L^p(\Omega;\mathbf{M})$ was obtained in [22] (see Theorem 2.3 below).

To describe our main result we consider an open, bounded set $\Omega\subset\mathbf{R}^N$ and a sequence $\{f_j\}$ of functions bounded in $L^p(\Omega;\mathbf{R}^d)$ for some $p>1$. There exists a subsequence, still denoted $\{f_j\}$, and a family $\nu=\{\nu_x\}_{x\in\Omega}$ (called the *Young measure*) of probability measures ν_x on $\mathbf{R}^d$, as well as a nonnegative Radon measure Λ on $\Omega\times\mathcal{S}^{d-1}$ (called the *varifold*) with the following properties (see [6], [17], and section 3). For all continuous functions θ that vanish on $\partial\Omega$, $\theta\in\mathcal{C}_0(\Omega)$, all continuous functions φ on $\mathbf{R}^d$ with growth of order strictly less than p, i.e., $|\varphi(\xi)|\le C(1+|\xi|^r),\quad 1\le r<p$, and for all continuous functions ψ on $\mathbf{R}^d$ that are homogeneous of degree p, we have

$$\begin{aligned}\int_\Omega \theta(x)\varphi(f_j(x))\,dx &\to \int_\Omega \theta(x)\int_{\mathbf{R}^d}\varphi(\xi)\,d\nu_x(\xi)\,dx,\\ \int_\Omega \theta(x)\psi(f_j(x))\,dx &\to \int_{\Omega\times\mathcal{S}^{d-1}}\theta(x)\psi(\xi)\,d\Lambda(x,\xi)\\ &= \int_\Omega \theta(x)\int_{\mathcal{S}^{d-1}}\psi(\xi)\,d\lambda_x(\xi)\,d\pi(x).\end{aligned}$$

Here π is the projection of Λ onto Ω, λ_x are probability measures (for π-a.e. $x\in\Omega$), $\Lambda=\lambda\otimes\pi$, $\lambda=\{\lambda_x\}_{x\in\Omega}$ is the slicing decomposition of Λ [15], and $\mathcal{S}:=\mathcal{S}^{d-1}$ is the unit sphere in $\mathbf{R}^d$. In what follows, we will refer to (ν,Λ) as the *Young measure-varifold pair*.

If $\{u_j\}$ is a bounded sequence in $W^{1,p}(\Omega;\mathbf{R}^m)$, if $f_j=\nabla u_j$, and if the target space $\mathbf{R}^d$ is identified with the space $\mathbf{M}:=\mathbf{M}^{m\times N}$ of $m\times N$ matrices, we say that (ν,Λ) is a $W^{1,p}(\Omega)$-*Young measure-varifold pair*, and we abbreviate it by saying that (ν,Λ) is a YM-V pair. The Young measures that arise in such pairs (the so-called $W^{1,p}(\Omega)$ *Young measures*) were characterized in [22]. The following example shows that there are also restrictions Λ. Let $p=m=N$ and consider the N-homogeneous function $\psi(A):=\det A$. Then by the above

$$\int_\Omega \theta(x)\det\nabla u_j\,dx\to\int_\Omega\theta(x)\int_{\mathcal{S}}\det A\,d\lambda_x(A)\,d\pi(x).$$

On the other hand, we know that [5], [28] $\det\nabla u_j\overset{*}{\rightharpoonup}\det\nabla u$ in the sense of measures, where u is the weak limit of u_j in $W^{1,p}(\Omega;\mathbf{R}^N)$. We conclude that

$$(\det\nabla u)\,d\mathcal{L}^N=\left(\int_{\mathcal{S}}\det A\,d\lambda_x(A)\right)d\pi,$$

where $\mathcal{L}^N$ denotes the Lebesgue measure in $\mathbf{R}^N$. Therefore, if we write $\pi=\pi_a+\pi_s$, where π_a and π_s are, respectively, absolutely continuous and singular with respect to $\mathcal{L}^N$, we obtain that

$$\int_{\mathcal{S}} \det A \, d\lambda_x(A) = 0$$

for π_s a.e. $x \in \Omega$.

The main result of this paper is the following characterization theorem for YM-V pairs.

THEOREM 1.1. *Let $p > 1$. (ν, Λ) is a YM-V pair, where $\nu = \{\nu_x\}_{x\in\Omega}$, and $\Lambda = \{\lambda_x\}_{x\in\Omega} \otimes \pi$ if and only if*

1.

$$\nabla u(x) = \int_{\mathbf{M}} A \, d\nu_x(A), \quad \mathcal{L}^N \text{ a.e. } x \in \Omega,$$

for some $u \in W^{1,p}(\Omega; \mathbf{R}^m)$;

2.

$$\varphi(\nabla u(x)) \le \int_{\mathbf{M}} \varphi(A) \, d\nu_x(A), \quad \mathcal{L}^N \text{ a.e. } x \in \Omega,$$

for every quasiconvex φ for which the limit

$$\lim_{|A|\to\infty} \frac{\varphi(A)}{1 + |A|^p}$$

exists;

3.

$$\int_{\mathbf{M}} \psi(A) \, d\nu_x(A) \le \frac{d\pi}{d\mathcal{L}^N}(x) \int_{\mathcal{S}} \psi(A) \, d\lambda_x(A), \quad \mathcal{L}^N \text{ a.e. } x \in \Omega,$$

for every p-homogeneous, continuous function ψ such that $Q\psi(0) = 0$, where $Q\psi$ denotes the quasiconvexification of ψ;

4.

$$\int_{\mathcal{S}} \psi(A) \, d\lambda_x(A) \ge 0, \quad \pi_s \text{ a.e. } x \in \Omega,$$

for every p-homogeneous, continuous function ψ such that $Q\psi(0) = 0$, where π_s is the singular part of π with respect to $\mathcal{L}^N$.

We remind the reader (see [5], [11], [26]) that a function φ, defined on $\mathbf{M}$, is said to be *quasiconvex* if

$$\varphi(F) \le \frac{1}{|\Omega|} \int_\Omega \varphi(F + \nabla u(x)) \, d\mathcal{L}^N(x)$$

for all matrices F and all test functions $u \in W_0^{1,\infty}(\Omega; \mathbf{R}^m)$. If φ is not quasiconvex then its *quasiconvexification*, $Q\varphi$, is defined to be

$$Q\varphi(F) := \inf_u \frac{1}{|\Omega|} \int_\Omega \varphi(F + \nabla u(x)) \, dx$$

for all matrices F. The infimum is taken again over the set of functions u that belong to $W_0^{1,\infty}(\Omega; \mathbf{R}^m)$. In addition, if

$$|\varphi(\xi)| \le C \left(1 + |\xi|^p\right),$$

then

$$Q\varphi(F) = \inf_{u \in W_0^{1,p}(\Omega;\mathbf{R}^m)} \frac{1}{|\Omega|} \int_\Omega \varphi(F + \nabla u(x))\, dx.$$

Equivalently, $Q\varphi$ can be characterized as the largest quasiconvex function below φ [1], [11].

Parts 1 and 2 of Theorem 1.1, together with the integrability condition

$$\int_\Omega \int_{\mathbf{M}} |A|^p \, d\nu_x(A)\, dx < +\infty,$$

correspond to the characterization of the underlying Young measure and were proved in [21] and [22]. Part 3 provides the interaction between the Young measure and the absolutely continuous part of the varifold. Part 4 represents the restriction on the varifold in the set where the singular part π_s is concentrated. An interesting consequence of this result is that there are no restrictions on the singular measure π_s.

A key tool in the proof of the above theorem is the following decomposition result for sequences of gradients that are bounded in $L^p(\Omega;\mathbf{M})$ for some $p > 1$. It states, in particular, that every such sequence admits a subsequence that can be written as a sum of a sequence $\{\nabla z_j\}$ (of gradients!) whose pth power is equi-integrable and a remainder that converges to zero in measure (and hence almost uniformly). We may say that $\{\nabla z_j\}$ carries the oscillations, while the remainder accounts for the concentration effects.

LEMMA 1.2 (decomposition lemma). *Let $\Omega \subset \mathbf{R}^N$ be an open, bounded set and let $\{w_n\}$ be a bounded sequence in $W^{1,p}(\Omega;\mathbf{R}^m)$. There exists a subsequence, $\{w_j\}$, and a sequence $\{z_j\} \subset W^{1,p}(\Omega;\mathbf{R}^m)$ such that*

$$\mathcal{L}^N\left(\{z_j \neq w_j \text{ or } \nabla z_j \neq \nabla w_j\}\right) \to 0, \tag{1.1}$$

as $j \to \infty$, and $\{|\nabla z_j|^p\}$ is equi-integrable. If Ω is Lipschitz (or, more generally, an extension domain), then each z_j may be chosen to be a Lipschitz function.

Note that (1.1) implies that both sequences $\{\nabla z_j\}$ and $\{\nabla w_j\}$ generate the same Young measure.

Some remarks are in order. A similar result was derived independently by Kristensen [23]. The characterization of $W^{1,p}$-Young measures obtained in [22] (see Theorem 2.3) does not provide a way of identifying the oscillatory part and the concentrations on a given sequence $\{w_n\}$ bounded in $W^{1,p}(\Omega;\mathbf{R}^m)$; it asserts that a Young measure generated by $\{w_n\}$ will be generated also by a sequence $\{v_n\}$ with $\{|\nabla v_n|^p\}$ equi-integrable, but there is no direct relation between this and the former sequence. Also, the approach via [22] is rather indirect and implicitly relies on the lower semicontinuity results of Acerbi and Fusco [1]. In fact, once Lemma 1.2 is proved one can considerably shorten the arguments in [1] and [22] (see [27] for this point of view). Our proof of Lemma 1.2 (see section 4) still relies on essentially the same tools as [1], namely L^p estimates for maximal functions and Lipschitz extensions of $W^{1,p}$ functions off small sets, but we think that an approach that uses the decomposition result as a starting point might be more intuitive. Kristensen's proof [23], on the other hand, uses Iwaniec's estimates for perturbed Hodge decompositions. These estimates, however, in turn rely on L^p estimates involving the sharp maximal function. Finally, the result may be viewed as an L^p counterpart of a theorem by Zhang [39] which states that if $\{\nabla w_j\}$ is bounded in L^q for some $q > 1$ and generates a Young measure with

support contained in a ball $B = B(0,R) \subset \mathbf{M}$ (i.e., $\operatorname{supp}(\nu_x) \subset B$ for a.e. $x \in \Omega$) then there exists a sequence z_j with

$$|\nabla z_j| \le C(N)R \quad \text{and} \quad \mathcal{L}^N\left(\{z_j \neq w_j \text{ or } \nabla z_j \neq \nabla w_j\}\right) \to 0.$$

2. Preliminaries. For any number $p > 0$ consider the class

$$\mathcal{H}_p := \{f \in \mathcal{C}(\mathbf{M}) : f \text{ is positively homogeneous of degree } p\},$$

where $\mathcal{C}(\mathbf{M})$ is the set of continuous functions on $\mathbf{M}$. If $f \in \mathcal{H}_p$ then $f(tA) = t^p f(A)$ for all $A \in \mathbf{M}$ and $t > 0$. It is easy to show that homogeneity entails $Q\psi(0) = 0$ whenever $\psi \in \mathcal{H}_p$ and $Q\psi(0)$ is finite. Let X_p denote the set of continuous functions in $\mathbf{M}$ with growth of order at most p, i.e.,

$$X_p := \{\varphi \in \mathcal{C}(\mathbf{M}) : |\varphi(A)| \le C(1 + |A|^p)\}.$$

X_p is a Banach space under the natural norm

$$\|\varphi\| := \left\| \frac{\varphi(\cdot)}{1 + |\cdot|^p} \right\|_{L^\infty(\mathbf{M})}.$$

Finally, we consider the class

$$\mathcal{E}_p := \left\{ \varphi \in \mathcal{C}(\mathbf{M}) : \text{ there exists } f \in \mathcal{H}_p, \lim_{|A|\to\infty} \frac{\varphi(A) - f(A)}{|A|^p} = 0 \right\}.$$

Some properties of $\mathcal{E}_p$ are listed in the proposition below.

PROPOSITION 2.1.

1. *For every $\varphi \in \mathcal{E}_p$ there is a unique $f \in \mathcal{H}_p$ such that*

$$\lim_{|A|\to\infty} \frac{\varphi(A) - f(A)}{|A|^p} = 0.$$

The function f is the recession function of φ of degree p, φ_p^∞, defined by

$$\varphi_p^\infty(A) = \lim_{t\to\infty} \frac{\varphi(tA)}{t^p}.$$

2. *$\mathcal{E}_p$ is a closed, separable subspace of X_p and $\mathcal{H}_p$ is a closed subspace of $\mathcal{E}_p$.*
3. *If $f \in \mathcal{H}_p$ then*

$$\|f\| = \|f\|_{L^\infty(\mathcal{S})},$$

where $\mathcal{S}$ is the unit sphere in $\mathbf{M}$.

The proof of this proposition is elementary. The only fact that requires some comment is the separability of $\mathcal{E}_p$. Indeed, using the map

$$\mathcal{C}^\infty\left(\overline{B}(0,1)\right) \to \mathcal{E}_p,$$
$$\theta \to \left(A \mapsto \theta\left(\frac{A}{1+|A|}\right)\ |A|^p\right),$$

one can easily verify that $\mathcal{E}_p$ is isomorphic to the space of continuous functions on the unit ball of $\mathbf{M}$, equipped with the sup norm. This space is separable due to the

compactness of the unit ball. If we compare the space $\mathcal{E}_p$ with the space considered in [22],

$$E_p := \left\{ \varphi \in \mathcal{C}(\mathbf{M}) : \lim_{|A|\to\infty} \frac{\varphi(A)}{1+|A|^p} \text{ exists} \right\},$$

we see that $\mathcal{E}_p$ corresponds to the compactification of $\mathbf{M}$ by a sphere at ∞ while E_p corresponds to the one-point compactification. More general compactifications have been considered in [14], [29], [30], and [31].

We will use the following lemma, whose proof is elementary and left to the reader.

PROPOSITION 2.2. *If ψ is Lipschitz continuous on the unit sphere $\mathcal{S}$ and homogeneous of degree p, $p \geq 1$, then there is a constant $C > 0$ (depending on ψ) such that*

$$|\psi(A) - \psi(B)| \leq C \left(|A|^{p-1} + |B|^{p-1} \right) |A - B|$$

for any pair of matrices A, B.

A remark that will be used often in sections 5 and 6 is the following. Given a family of probability measures $\nu = \{\nu_x\}_{x\in\Omega}$ and a sequence of functions $\{f_j\}$ bounded in $L^p(\Omega; \mathbf{R}^d)$, it can be shown that if

$$\lim_{j\to\infty} \int_\Omega \theta(x) \varphi(f_j(x))\, dx = \int_\Omega \theta(x) \int_{\mathbf{R}^d} \varphi(\xi)\, d\nu_x(\xi)\, dx \tag{2.1}$$

for all $\theta \in \mathcal{C}_0(\Omega)$, $\varphi \in \mathcal{C}_0^\infty(\mathbf{R}^d)$, then (2.1) still holds for all $\varphi \in \mathcal{C}(\mathbf{R}^d)$ such that $\{\varphi(f_j)\}$ is equi-integrable and, in particular, for all φ on $\mathbf{R}^d$ which grow slower than $1 + |\xi|^p$. Therefore $\nu = \{\nu_x\}_{x\in\Omega}$ is *the* Young measure associated with $\{f_j\}$. We conclude that in order to identify the Young measure generated by $\{f_j\}$, it suffices to study the limits (2.1) for $\theta \in \mathcal{C}_0(\Omega)$ and $\varphi \in \mathcal{C}_0^\infty(\mathbf{R}^d)$. Also, it can be shown that

$$\int_\Omega \int_{\mathbf{R}^d} |\xi|^p \, d\nu_x(\xi)\, dx < \infty. \tag{2.2}$$

The main result in [22] is a characterization of $W^{1,p}$-Young measures in terms of Jensen's inequality for quasiconvex functions.

THEOREM 2.3. *Let $p > 1$. Then $\nu = \{\nu_x\}_{x\in\Omega}$ is a $W^{1,p}$-Young measure if and only if*

1.

$$\nabla u(x) = \int_{\mathbf{M}} A\, d\nu_x(A), \quad \mathcal{L}^N \text{ a.e. } x \in \Omega,$$

for some $u \in W^{1,p}(\Omega; \mathbf{R}^m)$;

2.

$$\varphi(\nabla u(x)) \leq \int_{\mathbf{M}} \varphi(A)\, d\nu_x(A), \quad \mathcal{L}^N \text{ a.e. } x \in \Omega,$$

for every quasiconvex φ for which the limit

$$\lim_{|A|\to\infty} \frac{\varphi(A)}{1+|A|^p}$$

exists;

3.

$$\int_\Omega \int_{\mathbf{M}} |A|^p \, d\nu_x(A)\, dx < \infty.$$

3. The representation formula. We introduced the space $\mathcal{E}_p$ in order to recover weak limits associated with sequences $\{\varphi(\nabla u_j)\}$ for $\varphi \in \mathcal{E}_p$ and any sequence $\{u_j\}$ that is bounded in $W^{1,p}(\Omega;\mathbf{R}^m)$. The representation of weak limits for such functions in terms of Young measures is only valid if one can rule out concentration effects (see [9]). To account for possible development of concentrations, we associate with $\{\nabla u_j\}$ a measure Λ on $\Omega \times \mathcal{S}$ called the *varifold associated with* $\{\nabla u_j\}$. We first recall that for an $\mathbf{M}$-valued Radon measure μ on an open set Ω the polar decomposition (see [17]) is given by $d\mu = \alpha\, d\lambda$, where λ is the total variation of μ and $\alpha : \Omega \to \mathcal{S}$ is the density of μ, i.e., the Radon–Nikodym derivative of μ with respect to its total variation λ (see [16]). A *varifold* is a nonnegative measure on $\Omega \times \mathcal{S}$. By slicing arguments (see [15]), every such measure Λ can be written in the form $\Lambda = \{\lambda_x\}_{x\in\Omega} \otimes \pi$, where π is a measure on Ω and λ_x are probability measures on $\mathcal{S}$. By the Radon–Nikodym theorem we may further write $\pi = \pi_a \mathcal{L}^N + \pi_s$, where $\pi_a := \frac{d\pi}{d\mathcal{L}^N}$ and π_s is singular with respect to $\mathcal{L}^N$. We first recall that every bounded sequence of $\mathbf{M}$-valued Radon measures has (up to a subsequence) a varifold limit (see [17]).

THEOREM 3.1. *Let $\{\mu_j\}$ be a sequence of $\mathbf{M}$-valued measures on Ω with polar decomposition $\alpha_j d\lambda_j$. Assume that $\mu_j \overset{*}{\rightharpoonup} \mu$ in the sense of measures. There exists a subsequence, still denoted $\{\mu_j\}$, and a nonnegative, finite, Radon measure $\Lambda = \{\lambda_x\}_{x\in\Omega} \otimes \pi$ on $\Omega \times \mathcal{S}$ such that for every $f \in \mathcal{C}_0(\Omega \times \mathbf{R}^d)$*

$$\begin{aligned}\lim_{j\to\infty} \int_\Omega f(x, \alpha_j(x))\, d\lambda_j(x) &= \int_{\Omega\times\mathcal{S}} f(x,y)\, d\Lambda(x,y)\\ &= \int_\Omega \int_{\mathcal{S}} f(x,y)\, d\lambda_x(y)\, d\pi(x).\end{aligned}$$

Given a sequence $\{u_n\}$, bounded in $W^{1,p}(\Omega;\mathbf{R}^m)$, we consider the bounded sequence of $\mathbf{M}$-valued Radon measures $\{|\nabla u_n|^{p-1}\, \nabla u_n \mathcal{L}^N\}$. According to Theorem 3.1, associated with a subsequence there exists a varifold, and this suggests the following definition.

DEFINITION 3.2. *A finite, Radon measure Λ supported on $\Omega \times \mathcal{S}$ is a $W^{1,p}$-varifold if there exists a bounded sequence in $W^{1,p}(\Omega;\mathbf{R}^m)$, $\{u_n\}$, such that for every $f \in \mathcal{C}_0(\Omega \times \mathbf{M})$*

$$\lim_{n\to\infty} \int_\Omega f\left(x, \frac{\nabla u_n}{|\nabla u_n|}\right) |\nabla u_n|^p\, dx = \int_{\Omega\times\mathcal{S}} f(x,A)\, d\Lambda(x,A).$$

In particular, if ψ is homogeneous of degree p and $\theta \in \mathcal{C}_0(\Omega)$ then

$$\begin{aligned}\lim_{n\to\infty} \int_\Omega \theta(x)\psi(\nabla u_n)\, dx &= \int_{\Omega\times\mathcal{S}} \theta(x)\psi(A)\, d\Lambda(x,A)\\ &= \int_\Omega \theta(x) \int_{\mathcal{S}} \psi(A)\, d\lambda_x(A)\, d\pi(x).\end{aligned}$$

In order to see how the YM-V pair determines the limits of $\{\varphi(\nabla u_n)\}$ for sequences $\{u_n\}$ bounded in $W^{1,p}(\Omega;\mathbf{R}^m)$ and having oscillatory and concentrating features, consider $\varphi \in \mathcal{E}_p$. By definition,

$$\lim_{|A|\to\infty} \frac{\varphi(A) - \varphi_p^\infty(A)}{|A|^p} = 0,$$

which implies that $\{\varphi(\nabla u_n) - \varphi_p^\infty(\nabla u_n)\}$ is weakly relatively compact in $L^1(\Omega)$. For this sequence, the representation in terms of the Young measure is valid. On the other hand, $\varphi_p^\infty \in \mathcal{H}_p$, and the limit for $\{\varphi_p^\infty(\nabla u_n)\}$ is therefore given by the varifold. Hence, we have the representation formula

$$\lim_{n\to\infty} \int_\Omega \theta(x)\varphi(\nabla u_n(x))\,dx = \int_\Omega \theta(x) \int_{\mathbf{M}} \left(\varphi(A) - \varphi_p^\infty(A)\right)\,d\nu_x(A)\,dx + \int_\Omega \theta(x) \int_{\mathcal{S}} \varphi_p^\infty(A)\,d\lambda_x(A)\,d\pi(x).$$

It is this formula that motivated our study of YM-V pairs.

Examples.

1. *Oscillations.*

Let $\Omega \subset \mathbf{R}^N$ be an open, bounded set, and let $p > 1$. Given $f \in W_0^{1,p}(Q;\mathbf{R}^m)$, we extend f to $\mathbf{R}^N$ periodically, with period $Q := (-1/2, 1/2)^N$. Fix $A \in \mathbf{M}$ and define

$$u_n(x) := Ax + \frac{1}{n} f(nx).$$

It is easy to check that $u_n \rightharpoonup Ax$ in $W^{1,p}(\Omega;\mathbf{R}^m)$, and the YM-V pair generated by this sequence is (ν, Λ), where

$$\langle \nu_x, \varphi\rangle := \int_Q \varphi(A + \nabla f(y))\,dy$$

for $\mathcal{L}^N$ a.e. $x \in \Omega$ and for all $\varphi \in C_0(\mathbf{M})$, and $\Lambda = \{\lambda_x\}_{x\in\Omega} \otimes \pi$ with $\pi := ||A + \nabla f||^p_{L^p(Q;\mathbf{M})}\,\mathcal{L}^N$ and

$$\langle \lambda_x, \psi\rangle := \frac{1}{||A + \nabla f||^p_{L^p(Q;\mathbf{M})}} \int_Q \psi\left(\frac{A + \nabla f(y)}{|A + \nabla f(y)|}\right) |A + \nabla f(y)|^p\,dy$$

for π a.e. $x \in \Omega$ and all $\psi \in C(\mathcal{S})$.

2. *Concentrations.*

We consider $f \in W_0^{1,p}(Q;\mathbf{R}^m)$ extended to $\mathbf{R}^N$ by zero, where $Q := (-1/2, 1/2)^N$. Fix $p > 1$, choose $x_0 \in \Omega$, and set

$$u_n(x) := n^{-1+N/p}\, f(n(x - x_0)).$$

Then $u_n \rightharpoonup 0$ in $W^{1,p}(\Omega;\mathbf{R}^m)$, and the YM-V pair generated by this sequence is (ν, Λ), where $\nu_x := \delta_0$ for $\mathcal{L}^N$ a.e. $x \in \Omega$, $\Lambda = \{\lambda_x\}_{x\in\Omega} \otimes \pi$, with $\pi := ||\nabla f||^p_{L^p(Q;\mathbf{M})}\,\delta_{x_0}$ and

$$\langle \lambda_x, \psi\rangle := \frac{1}{||\nabla f||^p_{L^p(Q;\mathbf{M})}} \int_Q \psi\left(\frac{\nabla f(y)}{|\nabla f(y)|}\right) |\nabla f(y)|^p\,dy$$

for π a.e. $x \in \Omega$ and all $\psi \in C(\mathcal{S})$.

Indeed, we claim that if $\varphi \in C_0(\mathbf{M})$ is such that $\varphi(0) = 0$ then

$$\lim_{n\to\infty} \int_\Omega \theta(x)\varphi(\nabla u_n(x))\,dx = 0$$

for all $\theta \in C_0(\Omega)$. Fix $\varepsilon > 0$ and $1 < q < p$. We may find $C(\varepsilon) > 0$ such that $|\varphi(A)| \le \varepsilon + C(\varepsilon)|A|^q$ for all $A \in \mathbf{M}$. Therefore,

$$\begin{aligned}\left|\int_\Omega \theta(x)\varphi(\nabla u_n(x))\,dx\right| &\le \varepsilon||\theta||_{L^\infty} + C(\varepsilon)||\theta||_{L^\infty} n^{Nq/p}\int_\Omega |\nabla f(n(x-x_0))|^q\,dx \\ &\le \varepsilon||\theta||_{L^\infty} + C(\varepsilon)||\theta||_{L^\infty} n^{N(q/p-1)}||\nabla f||^q_{L^q(Q;\mathbf{M})},\end{aligned}$$

and we conclude by letting $n \to \infty$ and then $\varepsilon \to 0$. Also, given $\psi \in C(\mathcal{S})$ and for n large enough we have

$$\begin{aligned}&\int_\Omega \theta(x)\psi\left(\frac{\nabla u_n(x)}{|\nabla u_n(x)|}\right)|\nabla u_n(x)|^p dx \\ &\qquad = \int_\Omega \theta(x)\psi\left(\frac{\nabla f(n(x-x_0))}{|\nabla f(n(x-x_0))|}\right) n^N |\nabla f(n(x-x_0))|^p\,dx \\ &\qquad = \int_Q \theta\left(x_0 + \frac{1}{n}y\right)\psi\left(\frac{\nabla f(y)}{|\nabla f(y)|}\right)|\nabla f(y)|^p\,dy.\end{aligned}$$

Letting $n \to \infty$, we deduce that

$$\int_\Omega \int_{\mathcal{S}} \theta(x)\psi(A)\,d\lambda_x(A)\,d\pi(x) = \theta(x_0)\int_Q \psi\left(\frac{\nabla f(y)}{|\nabla f(y)|}\right)|\nabla f(y)|^p\,dy.$$

3. *Generalized Solutions to PDEs.*

In the previous example it was clear that the behavior of the sequence was captured by the varifold, and little information was available through the Young measure $\nu_x = \delta_0$. Other cases where the varifold plays an important role include situations where one seeks the effective energy

$$\liminf \int_\Omega f(\nabla u_n)\,dx$$

associated with a sequence $\{u_n\}$ bounded in $W^{1,p}(\Omega;\mathbf{R}^m)$, with f nonconvex and behaving asymptotically at infinity as $C(1+|A|^p)$.

The first applications of Young measures to evolution equations, precisely to conservation laws where oscillations may be present, were provided by Tartar (see [33], [34], [35]). Later, the need to introduce a measure accounting for the development of concentrations (when L^∞ bounds are not available), possibly with conjunction with propagation of oscillations, was pointed out by Diperna and Majda (see [14]). They introduced the notion of generalized Young measure triplets (μ, ν^1, ν^2) associated with a (subsequence of a) sequence $\{v_n\}$ bounded in L^2. To establish the parallel between the YM-V (ν, Λ) and (μ, ν^1, ν^2), it suffices to set

$$\mu := \pi, \quad \nu^1 := \frac{1+|\cdot|^2}{1+\frac{d\pi}{d\mathcal{L}^N}}\,\nu_x, \quad \nu^2 := \lambda_x.$$

Diperna and Majda [14] proved that the generalized Young measure generated by a sequence of classical solutions of the two-dimensional Euler equation with uniformly bounded local kinetic energy is a measure-valued solution of the incompressible Euler equation.

4. Proof of the decomposition lemma. In this section we will prove Lemma 1.2. As mentioned in the introduction, our argument uses maximal functions and their properties, and we recall some well-known facts (see [32]).

Given a Borel measurable function $u : \mathbf{R}^N \to \mathbf{R}^d$, the *maximal function* of u is defined by

$$M(u)(x) := \sup_{r>0} \frac{1}{|B(x,r)|} \int_{B(x,r)} |u(y)|\, dy.$$

If $u \in W^{1,p}(\mathbf{R}^N; \mathbf{R}^m)$ then we set

$$M^*(u)(x) := M(u)(x) + M(\nabla u)(x),$$

and if $p > 1$, then

$$\|M^*(u)\|_{L^p(\mathbf{R}^N)} \le C(N,p) \|u\|_{W^{1,p}(\mathbf{R}^N;\mathbf{R}^m)}. \tag{4.1}$$

LEMMA 4.1. *Let $p > 1$ and let $w \in W^{1,p}(\mathbf{R}^N; \mathbf{R}^m)$. Given $\lambda > 0$ there exists a Lipschitz function z in $\mathbf{R}^N$ such that $w = z$ on $\{M(\nabla w) < \lambda\}$ and the Lipschitz constant for z is bounded by $C(N)\lambda$, where $C(N)$ is a constant depending only upon dimension.*

For the proof see, e.g., [16].

The proof of Lemma 1.2 will be divided into two steps. In the first step we consider an *extension domain* Ω, i.e., an open, bounded set Ω for which there exists an extension operator $T : W^{1,p}(\Omega; \mathbf{R}^m) \to W^{1,p}(\mathbf{R}^N; \mathbf{R}^m)$ such that

$$Tu(x) = u(x), \quad x \in \Omega, \qquad \|Tu\|_{W^{1,p}(\mathbf{R}^N;\mathbf{R}^m)} \le C \|u\|_{W^{1,p}(\Omega;\mathbf{R}^m)}.$$

In the second step we remove this restriction on Ω, generalizing the result for arbitrary open sets.

Proof of Lemma 1.2.

Step 1. Assume that Ω is an extension domain. Let $\{w_n\}$ be a bounded sequence in $W^{1,p}(\Omega; \mathbf{R}^m)$. In what follows, we identify w_n with its extension $Tw_n \in W^{1,p}(\mathbf{R}^N; \mathbf{R}^m)$.

By (4.1) the sequence $\{M(\nabla w_n)\}$ is bounded in $L^p(\mathbf{R}^n)$, so (see [6] and (2.2)) there exists a subsequence (not relabeled) and a parametrized measure $\mu = \{\mu_x\}_{x\in\Omega}$ such that

$$\int_\Omega \int_{\mathbf{R}} |s|^p \, d\mu_x(s)\, dx < \infty, \tag{4.2}$$

and whenever $\{f(M(\nabla w_n))\}$ converges weakly in $L^1(\Omega)$, its weak limit is given by

$$\overline{f}(x) := \langle \mu_x, f \rangle, \quad \mathcal{L}^N\text{a.e. } x \in \Omega.$$

Let $k \in \mathbf{N}$ and consider the truncation map $T_k : \mathbf{R} \to \mathbf{R}$ given by

$$T_k(x) := \begin{cases} x, & |x| \le k, \\ k\dfrac{x}{|x|}, & |x| > k. \end{cases}$$

Clearly $\{T_k(M(\nabla w_n))\}$ is a bounded sequence in $L^\infty(\Omega)$, therefore equi-integrable, and so given $a \in L^\infty(\Omega)$ we have

$$\begin{aligned} \lim_{k\to\infty} \lim_{n\to\infty} \int_\Omega a(x) |T_k(M(\nabla w_n))(x)|^p \, dx &= \lim_{k\to\infty} \int_\Omega a(x) \int_{\mathbf{R}} |T_k(s)|^p \, d\mu_x(s)\, dx \\ &= \int_\Omega \int_{\mathbf{R}} a(x) |s|^p \, d\mu_x(s)\, dx, \end{aligned} \tag{4.3}$$

where we have used (4.2) and the dominated convergence theorem. For every $k \in \mathbf{N}$, choose $n(k)$ with $n(k) > n(k-1)$ such that

$$\left| \lim_{n\to\infty} \int_\Omega |T_k(M(\nabla w_n))(x)|^p \, dx - \int_\Omega |T_k(M(\nabla w_m))(x)|^p \, dx \right| < \frac{1}{k}$$

whenever $m \geq n(k)$. Setting $a \equiv 1$, (4.3) reduces to

$$\lim_{k\to\infty} \int_\Omega \left|T_k(M(\nabla w_{n(k)}))(x)\right|^p \, dx = \int_\Omega \int_{\mathbf{R}} |s|^p \, d\mu_x(s)\, dx. \tag{4.4}$$

We claim that

$$\left|T_k(M(\nabla w_{n(k)}))\right|^p \rightharpoonup \overline{f} \text{ in } L^1(\Omega), \tag{4.5}$$

where

$$\overline{f}(x) := \int_{\mathbf{R}} |s|^p \, d\mu_x(s).$$

Indeed, fix $b \in L^\infty(\Omega)$, $l \in \mathbf{N}$, and let $k > l$. Clearly

$$\begin{aligned}\int_\Omega b(x) \left|T_k(M(\nabla w_{n(k)}))(x)\right|^p \, dx \leq \|b\|_{L^\infty(\Omega)} \int_\Omega \left|T_k(M(\nabla w_{n(k)}))(x)\right|^p \, dx \\ - \int_\Omega \Big(\|b\|_{L^\infty(\Omega)} - b(x)\Big) \left|T_l(M(\nabla w_{n(k)}))(x)\right|^p \, dx,\end{aligned}$$

and so, taking first the limit as $k \to \infty$, followed by the limit as $l \to \infty$, and by virtue of (4.3) and (4.4), we conclude that

$$\limsup_{k\to\infty} \int_\Omega b(x) \left|T_k(M(\nabla w_{n(k)}))(x)\right|^p \, dx \leq \int_\Omega \int_{\mathbf{R}} b(x)\, |s|^p \, d\mu_x(s)\, dx. \tag{4.6}$$

Similarly, (4.6) holds for $-b$ in place of b; hence

$$\lim_{k\to\infty} \int_\Omega b(x) \left|T_k(M(\nabla w_{n(k)}))(x)\right|^p \, dx = \int_\Omega b(x)\overline{f}(x)\, dx,$$

proving (4.5). Set

$$R_k := \left\{x \in \mathbf{R}^N : M(\nabla w_{n(k)})(x) \geq k\right\}.$$

By Lemma 4.1 there exist Lipschitz functions z_k such that

$$z_k = w_{n(k)} \quad \text{a.e. on } \mathbf{R}^N \setminus R_k, \qquad |\nabla z_k(x)| \leq C(N)k, \quad \text{a.e. } x \in \mathbf{R}^N.$$

Therefore, by (4.1) and because Ω is bounded,

$$\begin{aligned}\mathcal{L}^N\left(\Omega \cap \left\{z_k \neq w_{n(k)} \text{ or } \nabla z_k \neq \nabla w_{n(k)}\right\}\right) &\leq \mathcal{L}^N\left(R_k \cap \Omega\right) \\ &\leq \frac{1}{k^p} \int_\Omega \left|M(\nabla w_{n(k)})\right|^p \, dx,\end{aligned}$$

and this term tends to zero as $k \to \infty$. In addition, for $\mathcal{L}^N$ a.e. $x \in \Omega \setminus R_k$ we have (see [16, Theorem 3 in section 6.1] and [20, Lemma 7.7])

$$|\nabla z_k(x)| = \left|\nabla w_{n(k)}(x)\right| \leq \left|M(\nabla w_{n(k)})(x)\right| = \left|T_k(M(\nabla w_{n(k)})(x))\right|,$$

while if $x \in R_k$ then

$$|\nabla z_k(x)| \le C(N)k = C(N)\left|T_k(M(\nabla w_{n(k)})(x))\right|.$$

We conclude that

$$|\nabla z_k(x)|^p \le C\left|T_k(M(\nabla w_{n(k)})(x))\right|^p \quad \text{a.e. } x \in \Omega,$$

which, together with (4.5), yields equi-integrability of $\{|\nabla z_k|^p\}$.

Step 2. Let Ω be an open, bounded domain of $\mathbf{R}^N$, and let $\{w_j\}$ be a bounded sequence in $W^{1,p}(\Omega;\mathbf{R}^m)$. Without loss of generality we may assume that there exists $w_0 \in W^{1,p}(\Omega;\mathbf{R}^m)$ such that

$$w_j \rightharpoonup w_0 \quad \text{in } W^{1,p}(\Omega;\mathbf{R}^m), \quad w_j \to w_0 \quad \text{in } L^p_{loc}(\Omega;\mathbf{R}^m);$$

i.e., if $w_j := w_0 + \tilde{w}_j$,

$$\tilde{w}_j \rightharpoonup 0 \quad \text{in } W^{1,p}(\Omega;\mathbf{R}^m), \quad \tilde{w}_j \to 0 \quad \text{in } L^p_{loc}(\Omega;\mathbf{R}^m).$$

Let $\{\Omega_n\}$ be an increasing sequence of compactly contained subdomains of Ω, with $\mathcal{L}^N(\Omega \setminus \Omega_n) \to 0$, and choose cut-off functions $\eta_n \in \mathcal{C}_0^\infty(\Omega;[0,1])$ such that $\eta_n = 1$ if $x \in \Omega_n$. We have

$$\limsup_{n\to\infty}\limsup_{j\to\infty}\|\eta_n\tilde{w}_j\|_{L^p(\Omega;\mathbf{R}^m)} = 0$$

and

$$\begin{aligned}\limsup_{n\to\infty}\limsup_{j\to\infty}\|\nabla(\eta_n\tilde{w}_j)\|_{L^p(\Omega;\mathbf{M})} &= \limsup_{n\to\infty}\limsup_{j\to\infty}\|\tilde{w}_j\otimes\nabla\eta_n + \eta_n\nabla\tilde{w}_j\|_{L^p(\Omega;\mathbf{M})}\\ &\le \limsup_{j\to\infty}\|\nabla\tilde{w}_j\|_{L^p(\Omega;\mathbf{M})} < \infty.\end{aligned}$$

A standard diagonalization procedure yields a bounded subsequence in $W^{1,p}_0(\Omega;\mathbf{R}^m)$, $\{\eta_n\tilde{w}_{j(n)}\}$, which we extend by zero to $\mathbf{R}^N$. Now the argument used in Step 1 applies to this sequence, so we obtain a sequence $\{z_k\}$ of Lipschitz functions such that

$$\alpha_k := \mathcal{L}^N\left(\Omega \cap \left\{z_k \ne \eta_{n(k)}\tilde{w}_{j(n(k))} \text{ or } \nabla z_k \ne \nabla\left(\eta_{n(k)}\tilde{w}_{j(n(k))}\right)\right\}\right) \to 0,$$

as $k \to \infty$, and $\{|\nabla z_k|^p\}$ is equi-integrable. We conclude that $\{|\nabla(w_0+z_k)|^p\}$ is equi-integrable and

$$\mathcal{L}^N\left(\Omega \cap \left\{w_{j(n(k))} \ne w_0 + z_k \text{ or } \nabla w_{j(n(k))} \ne \nabla(w_0+z_k)\right\}\right) \le \alpha_k + \mathcal{L}^N\left(\Omega \setminus \Omega_{n(k)}\right)$$

and this term converges to zero as $k \to \infty$.

5. Characterization of YM-V: Necessary conditions. We devote this section to the proof of the necessity part of Theorem 1.1. We may assume that Ω is smooth as otherwise we can first consider smooth subsets of Ω and then exhaust Ω by such sets. Conditions 1 and 2 were established in [21] and [22]. To prove 3 and 4 we split Λ into a part, $P\nu$, that is determined by the Young measure and a remainder, $\tilde{\Lambda}$, that is related to pure concentration effects.

For $\psi \in \mathcal{C}(\mathcal{S})$ (with p-homogeneous extension $\tilde{\psi}$) and $\theta \in \mathcal{C}_0(\Omega)$, let

$$\langle P\nu_x, \psi\rangle := \langle \nu_x, \tilde{\psi}\rangle = \int_{\mathbf{M}} \tilde{\psi}(A)\, d\nu_x(A)$$

and $P\nu := \{P\nu_x\}_{x\in\Omega} \otimes \mathcal{L}^N$, i.e.,

$$\langle P\nu, \theta \otimes \psi\rangle := \int_\Omega \theta(x) \int_{\mathbf{M}} \tilde{\psi}(A)\, d\nu_x(A)\, dx.$$

Let $\tilde{\Lambda} := \Lambda - P\nu$. Suppose that $\{\nabla u_j\}$ generates the YM-V pair (ν, Λ). In Steps 2 and 3 below we will show that u_j can be decomposed as $u_j = z_j + v_j$ where $\{|\nabla z_j|^p\}$ is equi-integrable, $\{\nabla z_j\}$ generates the YM-V pair $(\nu, P\nu)$, and $\{\nabla v_j\}$ generates the YM-V pair $(\delta_0 \otimes \mathcal{L}^N, \tilde{\Lambda})$.

Step 1. *Reformulation of conditions* 3 *and* 4.

We claim that 3 and 4 are equivalent to requiring that

(i) $\tilde{\Lambda}$ is a nonnegative, finite Radon measure on $\Omega \times \mathcal{S}$;

(ii) if $\tilde{\Lambda} = \{\tilde{\lambda}_x\}_{x\in\Omega} \otimes \tilde{\pi}$ is the slicing decomposition of $\tilde{\Lambda}$, where $\tilde{\lambda}_x$ are probability measures on $\mathbf{M}$, then for $\tilde{\pi}$ a.e. $x \in \Omega$

$$\langle \tilde{\lambda}_x, \psi\rangle \geq 0 \tag{5.1}$$

for all $\psi \in \mathcal{H}_p$ such that $Q\psi(0) = 0$.

Assume first that 3 and 4 hold. Since Λ and $P\nu$ are finite, nonnegative Radon measures, it follows that $\tilde{\Lambda}$ is a finite Radon measure. In addition, if $\theta \in \mathcal{C}_0(\Omega)$, $\theta \geq 0$, and if $\psi \in \mathcal{C}(\mathcal{S})$, $\psi \geq 0$, then $Q\tilde{\psi}(0) = 0$ and we have, by 3 and 4,

$$\begin{aligned}\langle \tilde{\Lambda}, \theta \otimes \psi\rangle &= \int_\Omega \theta(x) \int_{\mathcal{S}} \psi(A)\, d\lambda_x(A)\, d\pi_s(x) \\ &\quad + \int_\Omega \theta(x) \left[\frac{d\pi}{d\mathcal{L}^N}(x) \int_{\mathcal{S}} \psi(A)\, d\lambda_x(A) - \int_{\mathbf{M}} \tilde{\psi}(A)\, d\nu_x(A)\right] dx \\ &\geq 0.\end{aligned} \tag{5.2}$$

Hence $\tilde{\Lambda} \geq 0$, proving (i).

In order to prove (ii), fix $\theta \in \mathcal{C}_0(\Omega)$, $\theta \geq 0$, $\psi \in \mathcal{H}_p$, $Q\psi(0) = 0$; using the slicing decomposition of $\tilde{\Lambda}$ and (5.2) we deduce that

$$\int_\Omega \theta(x) \langle \tilde{\lambda}_x, \psi\rangle\, d\tilde{\pi}(x) = \langle \tilde{\Lambda}, \theta \otimes \psi\rangle \geq 0. \tag{5.3}$$

The arbitrariness of θ yields the existence of a $\tilde{\pi}$-null set E_ψ such that if $x \in \Omega \setminus E_\psi$ then

$$\langle \tilde{\lambda}_x, \psi\rangle \geq 0.$$

Let $\{\psi_k\}$ be a countable, dense set in $\mathcal{H}_p$, and define

$$E := \bigcup_k \bigcup_{\{n\,:\, Q(\psi_k + (1/n)|A|^p)(0) = 0\}} E_{\psi_k + (1/n)|A|^p}. \tag{5.4}$$

It is clear that $\tilde{\pi}(E) = 0$. Fix $x \in \Omega \setminus E$, $\psi \in \mathcal{H}_p$, $Q\psi(0) = 0$, and choose a subsequence $\{\psi_{k_i}\}$ such that

$$\psi_{k_i} \to \psi \quad \text{in } L^\infty(\mathcal{S}), \qquad \|\psi_{k_i} - \psi\|_{L^\infty(\mathcal{S})} < \frac{1}{n_i},$$

where $n_i \to \infty$. Then

$$\begin{aligned}\psi_{k_i}(A) + \frac{1}{n_i}|A|^p &\geq \psi_{k_i}(A) + |A|^p \|\psi_{k_i} - \psi\|_{L^\infty(\mathcal{S})} \\ &\geq \psi_{k_i}(A) + |\psi_{k_i}(A) - \psi(A)| \\ &\geq \psi(A),\end{aligned}$$

and so

$$Q\left(\psi_{k_i} + \frac{1}{n_i}|\cdot|^p\right)(0) \geq Q\psi(0) = 0.$$

By homogeneity

$$Q\left(\psi_{k_i} + \frac{1}{n_i}|\cdot|^p\right)(0) = 0.$$

Finally, using the definition of E, $x \notin E_{\psi_{k_i}+(1/n_i)|\cdot|^p}$, therefore

$$0 \leq \lim_{i\to\infty} \left\langle \tilde{\lambda}_x, \psi_{k_i} + \frac{1}{n_i}|\cdot|^p \right\rangle = \langle \tilde{\lambda}_x, \psi\rangle, \tag{5.5}$$

concluding the proof of (ii).

Conversely, if (i) and (ii) hold, using (5.2), (5.3), and $\theta := \chi_{B(a,\rho)}$, $a \in \Omega$, $\rho > 0$, we have

$$\int_{B(a,\rho)} \langle \lambda_x, \psi\rangle \, d\pi_s + \int_{B(a,\rho)} \left(\frac{d\pi}{d\mathcal{L}^N}(x)\langle \lambda_x, \psi\rangle - \langle \nu_x, \psi\rangle \right) dx \geq 0$$

for $\psi \in \mathcal{H}_p$, $Q\psi(0) = 0$. Conditions 3 and 4 follow by virtue of the Radon–Nikodym theorem. Note that a priori the exceptional sets could depend on ψ, but the argument outlined for the definition of E above would entail the existence of π_s- and $\mathcal{L}^N$-negligible sets for which 3 and 4 hold for all $\psi \in \mathcal{H}_p$ such that $Q\psi(0) = 0$.

In light of Step 1, the rest of this section will be dedicated to proving (5.1).

Step 2. *Construction of* $\{z_j\}$.

By the decomposition lemma (Lemma 1.2) there exists a sequence of Lipschitz functions $\{z_j\}$ such that $\{|\nabla z_j|^p\}$ is equi-integrable in Ω and the set

$$R_j := \{x \in \Omega : z_j(x) \neq u_j(x), \nabla z_j(x) \neq \nabla u_j(x)\}$$

satisfies

$$\mathcal{L}^N(R_j) \to 0. \tag{5.6}$$

In particular, $\{\nabla z_j\}$ generates the YM-V pair $(\nu, P\nu)$.

Step 3. *Construction of* $\{v_j\}$.

Let $v_j := u_j - z_j$. We claim that $\{\nabla v_j\}$ generates the YM-V pair $(\delta_0 \otimes \mathcal{L}^N, \tilde{\Lambda})$. In particular, $\tilde{\Lambda} \geq 0$. The assertion regarding the Young measure follows from (5.6). To study the varifold generated by $\{\nabla v_j\}$ consider $\theta \in \mathcal{C}_0(\Omega)$ and $\psi \in \mathcal{H}_p$ such that $\psi|_{\mathcal{S}}$ is Lipschitz. In view of Proposition 2.2 and Hölder's inequality we have

$$\left| \int_\Omega \theta(x)\psi(\nabla v_j)\, dx - \int_\Omega \theta(x) \left(\psi(\nabla u_j) - \psi(\nabla z_j)\right) dx \right|$$

$$
\begin{aligned}
&= \left| \int_{R_j} \theta(x) \left(\psi(\nabla u_j - \nabla z_j) - \psi(\nabla u_j) + \psi(\nabla z_j) \right) dx \right| \\
&\le C \|\theta\|_\infty \int_{R_j} \left[\left(|\nabla u_j - \nabla z_j|^{p-1} + |\nabla u_j|^{p-1} \right) |\nabla z_j| + |\nabla z_j|^p \right] dx \\
&\le C \|\theta\|_\infty \left[\left(\int_{R_j} |\nabla z_j|^p \, dx \right)^{1/p} + \int_{R_j} |\nabla z_j|^p \, dx \right].
\end{aligned}
$$

Since $\mathcal{L}^N(R_j) \to 0$ as $j \to \infty$ and $\{|\nabla z_j|^p\}$ is equi-integrable, the last term goes to zero as $j \to \infty$ and thus, using Step 2, we conclude that

$$
\int_\Omega \theta(x) \psi(\nabla v_j) \, dx \to \langle \Lambda - P\nu, \theta \otimes \psi \rangle = \langle \tilde{\Lambda}, \theta \otimes \psi \rangle.
$$

By density, the result extends to all $\psi \in \mathcal{H}_p$ and the claim is proved.

Step 4. We prove that for $\tilde{\pi}$ a.e. $x \in \Omega$

$$
\langle \tilde{\lambda}_x, \psi \rangle \ge 0 \tag{5.7}
$$

for all $\psi \in \mathcal{H}_p$ with $Q\psi(0) = 0$.

We first make the additional assumption that ψ is Lipschitz on $\mathcal{S}$. Let $\theta \in \mathcal{C}_0^\infty(B(a,\rho))$, $0 \le \theta \le 1$. By the definition of $Q\psi$, Proposition 2.2, and Hölder's inequality, we have

$$
\begin{aligned}
0 &\le \int_{B(a,\rho)} \psi \left(\nabla(\theta v_j) \right) \\
&= \int_{B(a,\rho)} \psi \left(\theta \nabla v_j + v_j \otimes \nabla \theta \right) dx \\
&\le \int_{B(a,\rho)} \theta^p \psi(\nabla v_j) \, dx + C \int_{B(a,\rho)} \left(|\theta \nabla v_j|^{p-1} + |v_j \otimes \nabla \theta|^{p-1} \right) |v_j \otimes \nabla \theta| \, dx \\
&\le \int_{B(a,\rho)} \theta^p \psi(\nabla v_j) \, dx + C(\theta) \left[\left(\int_{B(a,\rho)} |v_j|^p \, dx \right)^{1/p} + \int_{B(a,\rho)} |v_j|^p \, dx \right].
\end{aligned}
$$

Now $v_j \rightharpoonup 0$ in $W^{1,p}(B(a,\rho))$ as $j \to \infty$, and thus $v_j \to 0$ in $L^p(B(a,\rho))$. By Step 3, the sequence $\{\nabla v_j\}$ generates the varifold $\tilde{\Lambda}$. Therefore taking the limit as $j \to \infty$ in the above inequality, we obtain

$$
0 \le \langle \tilde{\Lambda}, \theta^p \otimes \psi \rangle.
$$

The assertion follows (for $\psi \in \mathrm{Lip}(\mathcal{S})$) by taking an increasing sequence $\theta_i \to \chi_{B(a,\rho)}$ and applying the dominated convergence theorem. Hence

$$
\int_{B(a,\rho)} \langle \tilde{\lambda}_x, \psi \rangle \, d\tilde{\pi}(x) \ge 0,
$$

and the Radon–Nikodym theorem yields the existence of a set $E_\psi \subset \Omega$, $\tilde{\pi}(E_\psi) = 0$ such that (5.7) holds if $x \notin E_\psi$. Defining E as in (5.4) and following the argument (5.4)–(5.5), we finally remove the restriction that ψ be Lipschitz on $\mathcal{S}$ to conclude that (5.7) holds for $\psi \in \mathcal{H}_p$, $Q\psi(0) = 0$, proving (ii).

6. Characterization of YM-V: Sufficient conditions. Suppose that the pair (ν, Λ) satisfies the conditions of Theorem 1.1. We have to construct a sequence $\{u_j\}$, bounded in $W^{1,p}(\Omega; \mathbf{R}^m)$, such that (ν, Λ) is the YM-V pair generated by $\{\nabla u_j\}$.

As in the beginning of section 5, we write $\Lambda := P\nu + \tilde{\Lambda}$, where

$$\langle P\nu, \theta \otimes \psi \rangle := \int_\Omega \theta(x) \int_{\mathbf{M}} \tilde{\psi}(A)\, d\nu_x(A)\, dx$$

for $\theta \in \mathcal{C}_0(\Omega)$, $\psi \in \mathcal{C}(\mathcal{S})$, and with $\tilde{\psi}$ the p-homogeneous extension of ψ. From section 5, Step 1, we know that $\tilde{\Lambda}$ is a nonnegative, finite Radon measure and

$$\langle \tilde{\lambda}_x, \psi \rangle \geq 0 \tag{6.1}$$

for all $\psi \in \mathcal{H}_p$ with $Q\psi(0) = 0$, where $\{\tilde{\lambda}_x\}_{x\in\Omega} \otimes \tilde{\pi}$ denotes the slicing decomposition of $\tilde{\Lambda}$.

Step 1. We claim that it suffices to find $\{z_j\}$, $\{v_j\}$ bounded in $W^{1,p}(\Omega; \mathbf{R}^m)$ such that

$$\{|\nabla z_j|^p\} \text{ is equi-integrable}, \quad \{\nabla z_j\} \text{ generates the YM-V pair } (\nu, P\nu), \tag{6.2}$$

and

$$\{\nabla v_j\} \text{ generates the YM-V pair } (\delta_0 \otimes \mathcal{L}^N, \tilde{\Lambda}), \tag{6.3}$$

setting, as before, $u_j := z_j + v_j$. Indeed, note that since $p > 1$ then $\{|\nabla v_j|\}$ is equi-integrable, and so given $\lambda > 0$ and in view of (2.1)

$$\mathcal{L}^N\left(\{|\nabla v_j| > \lambda\}\right) \leq \frac{1}{\lambda} \int_\Omega |\nabla v_j|\, dx \to \frac{1}{\lambda} \langle \delta_0 \otimes \mathcal{L}^N, |\cdot| \rangle = 0. \tag{6.4}$$

Thus given $\theta \in \mathcal{C}_0(\Omega)$ and $\varphi \in \mathcal{C}_0^\infty(\mathbf{M})$ we have

$$\left| \int_\Omega \theta(x) \left[\varphi(\nabla u_j) - \varphi(\nabla z_j)\right] dx \right| \leq \|\theta\|_\infty C \int_\Omega |\nabla v_j|\, dx \to 0$$

as $j \to \infty$, and this implies that the Young measure associated with $\{\nabla u_j\}$ is also ν.

Similarly, if $\theta \in \mathcal{C}_0(\Omega)$, $\psi \in \mathcal{H}_p$, $\psi|_{\mathcal{S}}$ Lipschitz, by Proposition 2.2 for fixed $\lambda > 0$

$$\begin{aligned}
&\left| \int_\Omega \theta(x) \left(\psi(\nabla u_j) - \psi(\nabla z_j) - \psi(\nabla v_j)\right) dx \right| \\
&\leq C \int_{\{|\nabla v_j| \leq \lambda\}} \left(|\psi(\nabla u_j) - \psi(\nabla z_j)| + |\psi(\nabla v_j)|\right) dx \\
&\quad + C \int_{\{|\nabla v_j| \geq \lambda\}} \left(|\psi(\nabla u_j) - \psi(\nabla v_j)| + |\psi(\nabla z_j)|\right) dx \\
&\leq C \int_{\{|\nabla v_j| \leq \lambda\}} \left(|\nabla z_j|^{p-1} + |\nabla v_j|^{p-1}\right) |\nabla v_j|\, dx + C \int_{\{|\nabla v_j| \leq \lambda\}} |\nabla v_j|^p\, dx \\
&\quad + C \int_{\{|\nabla v_j| \geq \lambda\}} \left(|\nabla z_j|^{p-1} + |\nabla v_j|^{p-1}\right) |\nabla z_j|\, dx + C \int_{\{|\nabla v_j| \geq \lambda\}} |\nabla z_j|^p\, dx,
\end{aligned}$$

and so, using Hölder's inequality, (6.4), and the equi-integrability of $\{|\nabla z_j|^p\}$,

$$\limsup_{j\to\infty} \left| \int_\Omega \theta(x) \left[\psi(\nabla u_j) - \psi(\nabla z_j) - \psi(\nabla v_j)\right] dx \right| = O(\lambda).$$

Letting $\lambda \to 0^+$ and removing the regularity restrictions imposed on ψ as in (5.4)–(5.5), we conclude that the varifold associated with $\{\nabla u_j\}$ is $P\nu + \tilde{\Lambda} := \Lambda$.

Step 2. We introduce two sets of measures supported on the unit sphere $\mathcal{S}$ of M, namely

$$A := \{\mu \in \mathcal{M}(\mathcal{S}) : \mu \geq 0, \langle \mu, \psi \rangle \geq 0 \text{ if } \psi \in \mathcal{H}_p, Q\psi(0) = 0\},$$
$$H := \left\{ \overline{\delta_{\nabla u/|\nabla u|} \otimes |\nabla u|^p \, \mathcal{L}^N} : u \in W_0^{1,p}(B; \mathbf{R}^m) \right\},$$

where B is the unit ball in R^N, and the average measures of H are defined by

$$\langle \overline{\delta_{\nabla u/|\nabla u|} \otimes |\nabla u|^p \, \mathcal{L}^N}, \psi \rangle := \frac{1}{|B|} \int_B \psi \left(\frac{\nabla u}{|\nabla u|} \right) |\nabla u|^p \, dx$$

for $\psi \in \mathcal{C}(\mathcal{S})$. We do not distinguish henceforth a continuous function on $\mathcal{S}$ from its p-homogeneous extension. Note that, in view of (6.1), $\tilde{\lambda}_x \in A$ for $\tilde{\pi}$ a.e. $x \in \Omega$. It is clear that A is weak *-closed and $H \subset A$.

PROPOSITION 6.1. *A is the weak *-closure of H. Moreover, if $R > 0$ then $A \cap \{\|\mu\| \leq R\}$ is the weak *-closure of $H \cap \{\|\mu\| \leq R\}$.*

Remark. The second statement will be useful in Step 3 where we will use the fact that the weak *-topology of $\mathcal{M}(S)$ is metrizable on closed balls.

Proof of Proposition 6.1. The proof is a standard application of the Hahn–Banach theorem. We start by proving that H is convex. Fix $\theta \in (0,1)$ and let for $i = 1, 2$

$$\mu_i := \overline{\delta_{\nabla u_i/|\nabla u_i|} \otimes |\nabla u_i|^p \, \mathcal{L}^N}, \quad u_i \in W_0^{1,p}(B; \mathbf{R}^m).$$

Let $x_0 \in B$ be such that $|x_0| = 1/2$ and define

$$\tilde{u}_1(x) := k^{-1+N/p} u_1(kx), \quad \tilde{u}_2(x) := k^{-1+N/p} u_2(k(x - x_0)),$$

where $k \geq 4$. Clearly $\tilde{u}_i \in W_0^{1,p}(B; \mathbf{R}^m)$, $\tilde{u}_1$ and $\tilde{u}_2$ have disjoint supports, and a change of variables shows that $\tilde{\mu}_i = \mu_i$ for $i = 1, 2$. It follows that the function

$$\tilde{u} := \theta^{1/p} \tilde{u}_1 + (1-\theta)^{1/p} \tilde{u}_2 \in W_0^{1,p}(B; \mathbf{R}^m)$$

generates $\mu := \theta\mu_1 + (1-\theta)\mu_2$ and so $\mu \in H$.

We now show that A cannot be separated from H. Assume that $\psi \in \mathcal{C}(\mathcal{S})$ is such that $\langle \nu, \psi \rangle \geq a$ for all $\nu \in H$ and for some $a \in \mathbf{R}$. Hence, extending ψ as p-homogeneous,

$$Q\psi(0) = \inf_{u \in W_0^{1,p}(B; \mathbf{R}^m)} \frac{1}{|B|} \int_B \psi(\nabla u) \, dx \geq a,$$

and so $0 \geq Q\psi(0) \geq a$. We conclude that $Q\psi(0)$ is finite; thus $Q\psi(0) = 0$ by homogeneity, and $0 = Q\psi(0) \geq a$. By definition of A, we have that $\langle \mu, \psi \rangle \geq 0 \geq a$ for all $\mu \in A$. Hence A cannot be separated from H.

Next, we show that $A_R := A \cap \{\|\mu\| \leq R\}$ cannot be separated from $H_R := H \cap \{\|\mu\| \leq R\}$. Given $\rho > 0$ define $H_\rho := H \cap \{||\mu|| = \rho\} = H \cap \{\langle \mu, 1 \rangle = \rho\}$. We claim that

$$\overline{H_\rho} = \overline{H} \cap \{\langle \mu, 1 \rangle = \rho\}. \tag{6.5}$$

It is clear that $\overline{H_\rho} \subset \overline{H} \cap \{\langle \mu, 1\rangle = \rho\}$. Suppose that this inclusion is strict. Then there exists $\mu \in \overline{H}$ such that $\langle \mu, 1\rangle = \rho$ and $\mu \notin \overline{H_\rho}$. Since H_ρ is convex, using the Hahn–Banach theorem we may find $\psi \in C(\mathcal{S}), a \in \mathbf{R}$, such that

$$\langle \mu, \psi\rangle < a, \quad \langle \nu, \psi\rangle \geq a \quad \text{for all } \nu \in H_\rho.$$

Set $\bar{\psi} := \psi - a/\rho$. Clearly,

$$\langle \mu, \bar{\psi}\rangle = \langle \mu, \psi\rangle - \frac{a}{\rho}\langle \mu, 1\rangle < 0,$$

while $\langle \nu, \bar{\psi}\rangle \geq 0$ for all $\nu \in H_\rho$. Since H is a cone, we conclude that $\langle \nu, \bar{\psi}\rangle \geq 0$ for all $\nu \in H$; therefore $\langle \mu, \overline{\psi}\rangle \geq 0$. We have reached a contradiction, thus (6.5) is proved. Finally, since $A = \overline{H}$, it follows that $A_R \supset \overline{H_R}$, and by (6.5) we conclude that

$$\overline{H_R} = \overline{\bigcup_{0<\rho\leq R} H_\rho} \supset \bigcup_{0<\rho\leq R} \overline{H_\rho} = \bigcup_{0<\rho\leq R} \overline{H} \cap \{\langle \mu, 1\rangle = \rho\} = A \cap \{||\mu|| \leq R\}.$$

Step 3. *Construction of* $\{z_j\}$.

Using condition 3 in Theorem 1.1 with $\psi(A) := |A|^p$, we have

$$\int_\Omega \int_{\mathbf{M}} |A|^p \, d\nu_x(A)\, dx \leq \int_\Omega \frac{d\pi}{d\mathcal{L}^N}(x) \int_{\mathcal{S}} d\lambda_x(A)\, dx \leq \pi(\Omega) < \infty,$$

which, together with conditions 1 and 2 and by Theorem 2.3 (see [22] for the proof), implies that ν is a $W^{1,p}$-Young measure. Using the decomposition lemma (Lemma 1.2) (see also Step 2, Section 5) we find a sequence $\{z_j\}$ bounded in $W^{1,p}(\Omega; \mathbf{R}^m)$ and satisfying (6.2).

Step 4. *Construction of* $\{v_j\}$ *when*

$$\tilde{\Lambda} := \sum_{i=1}^{I} c_i \lambda_i \otimes \delta_{x_i}, \quad x_i \in \Omega, \lambda_i \in A, c_i > 0.$$

Here we search for a sequence $\{v_j\}$ bounded in $W_0^{1,p}(\Omega; \mathbf{R}^m)$ such that (6.3) holds, i.e., $\{\nabla v_j\}$ generates $(\delta_0 \otimes \mathcal{L}^N, \tilde{\Lambda})$ and, in addition,

$$\lim_{j\to\infty} \|\nabla v_j\|^p_{L^p(\Omega;\mathbf{M})} = \left\|\tilde{\Lambda}\right\|.$$

By Proposition 6.1 and the remark after it, there exist bounded sequences $\{w_j^{(i)}\}$ in $W_0^{1,p}(B; \mathbf{R}^m)$ such that

$$\lim_{j\to\infty} \frac{1}{|B|} \int_B \psi(\nabla w_j^{(i)})\, dx = \langle \lambda_i, \psi\rangle$$

for all $\psi \in \mathcal{H}_p$. In particular

$$\|\lambda_i\| = \lim_{j\to\infty} \frac{1}{|B|} \int_B \left|\nabla w_j^{(i)}\right|^p \, dx.$$

Now

$$v_j(x) := j^{-1+N/p} \frac{1}{|B|^{1/p}} \sum_{i=1}^{I} c_i^{1/p} w_j^{(i)}\left(j(x - x_i)\right)$$

has the desired properties.

Step 5. *Construction of* $\{v_j\}$ *in the general case.*

To obtain $\{v_j\}$ satisfying (6.3), we will use the following approximation lemma.

LEMMA 6.2. *Let* $\tilde{\Lambda}$ *be a nonnegative, finite, Radon measure on* $\Omega \times \mathcal{S}$ *with slicing decomposition* $\{\tilde{\lambda}_x\}_{x\in\Omega} \otimes \tilde{\pi}$*, let* A *be a convex set of the set of all nonnegative, finite Radon measures on* $\mathcal{S}$*, and suppose that*

$$\tilde{\lambda}_x \in A \text{ for } \tilde{\pi} \text{ a.e. } x \in \Omega.$$

Then $\tilde{\Lambda}$ *can be approximated in the weak *-topology by measures of the form*

$$\tilde{\Lambda}^{(k)} := \sum_{i=1}^{I_k} c_i^{(k)} \lambda_i^{(k)} \otimes \delta_{x_i^{(k)}}, \quad x_i^{(k)} \in \Omega, \lambda_i^{(k)} \in A, c_i^{(k)} > 0,$$

such that

$$\left\|\tilde{\Lambda}^{(k)}\right\| \le \left\|\tilde{\Lambda}\right\|.$$

Before proving the approximation lemma, we conclude the construction of $\{v_j\}$. By Lemma 6.2 we have

$$\tilde{\Lambda} = \text{ w-*-limit } \tilde{\Lambda}^{(k)}, \tilde{\Lambda}^{(k)} := \sum_{i=1}^{I_k} c_i^{(k)} \lambda_i^{(k)} \otimes \delta_{x_i^{(k)}}, \left\|\tilde{\Lambda}^{(k)}\right\| \le \left\|\tilde{\Lambda}\right\|.$$

Also, Step 4 yields the existence of sequences $\{v_j^{(k)}\}$ bounded in $W_0^{1,p}(\Omega;\mathbf{R}^m)$ generating the YM-V pair $(\delta_0 \otimes \mathcal{L}^N, \tilde{\Lambda}^{(k)})$ and such that

$$\lim_{j\to\infty} \left\|\nabla v_j^{(k)}\right\|_{L^p(\Omega;\mathbf{M})}^p = \left\|\tilde{\Lambda}^{(k)}\right\| \le \left\|\tilde{\Lambda}\right\|$$

for all k. Separability of $\mathcal{C}_0(\Omega)$, $\mathcal{C}_0(\mathbf{M})$ and $\mathcal{C}(\mathcal{S})$, and a standard diagonalization argument allow us to extract a diagonal subsequence $v_k := v_{j(k)}^{(k)}$ satisfying (6.3) and

$$\sup_k \|\nabla v_k\|_{L^p(\Omega;\mathbf{M})}^p \le \left\|\tilde{\Lambda}\right\| + 1.$$

It remains to prove Lemma 6.2.

Proof of Lemma 6.2. The result is well known to experts. We include a proof for the convenience of the reader. By Besicovitch's covering theorem, for each $k \in \mathbf{N}$ there exists a finite family of disjoint closed balls $B(x_i^{(k)}, r_i^{(k)})$ such that

$$\tilde{\pi}\left(\Omega \setminus \bigcup_{i\in I_k} B(x_i^{(k)}, r_i^{(k)})\right) < \frac{1}{k}, \quad r_i^{(k)} < \frac{1}{k}. \tag{6.6}$$

Set

$$\langle \lambda_i^{(k)}, \psi\rangle := \frac{1}{\tilde{\pi}\left(B(x_i^{(k)}, r_i^{(k)})\right)} \int_{B(x_i^{(k)}, r_i^{(k)})} \langle \tilde{\lambda}_x, \psi\rangle \, d\tilde{\pi}(x).$$

Since A is convex we have $\lambda_i^{(k)} \in A$, and we define

$$\tilde{\Lambda}^{(k)} := \sum_{i=1}^{I_k} c_i^{(k)} \lambda_i^{(k)} \otimes \delta_{x_i^{(k)}}, \quad c_i^{(k)} := \tilde{\pi}\left(B(x_i^{(k)}, r_i^{(k)})\right).$$

Then

$$\left\|\tilde{\Lambda}^{(k)}\right\| = \sum_{i=1}^{I_k} c_i^{(k)} \left\|\lambda_i^{(k)}\right\| \leq \sum_{i=1}^{I_k} \tilde{\pi}\left(B(x_i^{(k)}, r_i^{(k)})\right) \leq \tilde{\pi}(\Omega) = \left\|\tilde{\Lambda}\right\|.$$

For $\psi \in \mathcal{C}(\mathcal{S})$ and $\theta \in W_0^{1,\infty}(\Omega)$ with Lipschitz constant $\mathrm{Lip}(\theta)$ one has

$$\begin{aligned}
&\left|\langle \tilde{\Lambda}^{(k)} - \tilde{\Lambda}, \theta \otimes \psi\rangle\right| \\
&\quad = \left| \int_\Omega \langle \tilde{\lambda}_x, \psi\rangle \theta(x)\, d\tilde{\pi}(x) - \sum_{i=1}^{I_k} c_i^{(k)} \langle \lambda_i^{(k)}, \psi\rangle \theta(x_i^{(k)}) \right| \\
&\leq \left| \sum_{i=1}^{I_k} \int_{B(x_i^{(k)}, r_i^{(k)})} \langle \tilde{\lambda}_x, \psi\rangle \theta(x)\, d\tilde{\pi}(x) - \sum_{i=1}^{I_k} \int_{B(x_i^{(k)}, r_i^{(k)})} \langle \tilde{\lambda}_x, \psi\rangle\, d\tilde{\pi}(x) \theta(x_i^{(k)}) \right| \\
&\qquad + \int_{\Omega \setminus \cup B(x_i^{(k)}, r_i^{(k)})} \left|\langle \tilde{\lambda}_x, \psi\rangle\right| |\theta(x)|\, d\tilde{\pi}(x) \\
&\leq \frac{1}{k} \mathrm{Lip}(\theta) \int_\Omega \left|\langle \tilde{\lambda}_x, \psi\rangle\right| d\tilde{\pi}(x) + \|\psi\|_{L^\infty(\mathcal{S})} \|\theta\|_{L^\infty(\Omega)} \tilde{\pi}\left(\Omega \setminus \cup B(x_i^{(k)}, r_i^{(k)})\right),
\end{aligned}$$

and this expression tends to zero as $k \to \infty$. We have used (6.6). The assertion follows since test functions of the above type are dense and $\{\|\tilde{\Lambda}^{(k)}\|\}$ is bounded.

SOLUTIONS OF FINITELY SMOOTH NONLINEAR SINGULAR DIFFERENTIAL EQUATIONS AND PROBLEMS OF DIAGONALIZATION AND TRIANGULARIZATION*

HARRY GINGOLD† AND ALEXANDER TOVBIS‡

Abstract. It is known that existence of a formal power series solution $\hat{y}(x)$ to a system of nonlinear ordinary differential equations (ODEs) with analytic or infinitely smooth coefficients at an irregular singular point implies the existence of an actual solution $y(x)$, which possesses the asymptotic expansion $\hat{y}(x)$. In the present paper we extend this result for systems with finitely smooth coefficients. In this case one cannot speak about a formal power series solution $\hat{y}(x)$; it has therefore to be replaced by the requirement of existence of an "approximate" solution $y_0(x)$. The existence of a corresponding actual solution is a subject of certain conditions that link the smoothness of the system, the "accuracy" of the approximation $y_0(x)$, and the "degeneracy" of the system, linearized with respect to $y_0(x)$. As applications, problems of reduction of linear time dependent systems of ODEs into diagonal and triangular forms, as well as some other problems, are considered. In particular, the well-known theorem on integration of linear systems with irregular singularities is extended from analytical to finitely smooth systems. In one of the simplest cases, our result is simultaneously a consequence of the classical Levinson theorem.

Key words. irregular singularities, finitely smooth nonlinear equations, approximate solutions, diagonalization, triangularization

Introduction. In the present paper we study the existence of an actual solution to the nonlinear system of differential equations (or the vector equation)

$$\mathcal{N}y \equiv x^{1-r}y'(x) - f(x,y) = 0, \tag{0.1}$$

where $r \in \mathbb{N}$ and $x \geq x_0$ for some $x_0 \geq 0$. We assume that the entries of the n-dimensional vector-valued function $f(x,y)$ belong to the space

$$C[x_0,\infty) \times C^2(\mathcal{B}_\zeta)$$

and that $f(x,y)$ and its derivatives are bounded on $[x_0,\infty)$. Here $\mathcal{B}_\zeta$ denotes the open ball of the radius ζ in the Euclidean norm in $\mathbb{C}^n$, centered at the origin.

Similar to the analytic case, we call $x = +\infty$ an irregular singular point of (0.1) and the number r—the Poincaré rank of (0.1) at $x = +\infty$.

The classical result in the analytic case, i.e., when $f(x,y)$ is analytic at $(\infty,0) \in \bar{\mathbb{C}} \times \mathbb{C}^n$, states that the existence of a formal power series solution

$$\hat{y}(x) = \sum_{k=1}^{\infty} y_k x^{-k} \tag{0.2}$$

implies the existence of an analytic solution $y(x)$ such that

$$y(x) \sim \hat{y}(x), \quad x \to \infty,\ x \in S, \tag{0.3}$$

where S is some sector of the complex x-plane containing the positive real semiaxis (see, for example, [Hu], [Wa], [RS], [T2]). This result was extended to the C^∞-equations in [Ku]: suppose

$$f(x,y) = \sum_{|\alpha|=1}^{\infty} f_\alpha(x) y^\alpha, \tag{0.4}$$

where α is a multi-index, $|\alpha|$ denotes the length of α, all vector-valued functions $f_\alpha(x)$ are infinitely smooth on $[x_0, \infty)$ (with some positive x_0) and admit formal power series asymptotic expansions as $x \to +\infty$, and the series (0.4) is uniformly convergent for $x \in [x_0, \infty), \|y\| < \zeta$. Then the existence of the formal solution (0.2) implies the existence of a C^∞ solution $y(x)$ such that $y(x)$ satisfies (0.3), where the sector S shrinks to the positive real semiaxis. Naturally, these results are true if (0.2) is a series in fractional powers of x^{-1}.

We would like to mention here several observations that initiated our research. The first one is that the requirement of existence of a formal solution (0.2) is too strong. In fact, it suffices to show the existence of an approximate solution

$$y_N(x) = \sum_{k=1}^{N} y_k x^{-k} \tag{0.5}$$

such that

$$\mathcal{N} y_N = o(x^{-N}), \quad x \to \infty, \tag{0.6}$$

provided that N is large enough. The estimate on such N can be found in [T2].

Second, the existence of a formal solution (0.2), as shown by the following elementary example, is a luxury that sometimes cannot be afforded.

Example 0.1. Consider the Riccati equation

$$y'(x) = \frac{\theta}{x} + \frac{u(x)}{x^\beta} + \alpha y(x) + y^2(x) \tag{0.7}$$

at the singular point $x = \infty$, where θ, α are complex constants and $\beta > 0$. If one chooses $u(x)$ to be $\ln x$, $\sin x$, or any other function that does not admit a power series asymptotic expansion at $x = \infty$, then (0.7) cannot have formal power series solutions in x^{-1}, and so we are beyond the range of validity of the above mentioned results concerning the existence of an actual solution.

This example considerably restricts the range of validity of analytic methods, because it is intuitively clear that for large β the asymptotic behavior of solutions of (0.7) does not depend very much on whether $u(x) = x$ (a formal power series solution exists) or $u(x) = x \ln x$ (a formal power series solution does not exist).

Finally, it seems that a certain "gap" between the methods and results in the analytic and "nonanalytic" (i.e., finitely smooth or even L_p) theories of singular differential equations has become visible recently. This gap could be considered as a gap between formal algebraic and complex-analytic techniques on one hand, and a real-analysis technique on the other. (Compare, for example, the approach in [Wa] versus that in [Es].)

The main objective of this paper is to extend the algebraic methods used in the analytical and C^∞ cases to the finitely smooth case, i.e., to the case when the coefficients $f_\alpha(x)$ in (0.4) are only finitely smooth. Note that in this situation a formal

solution (0.2) to (0.1) cannot be defined. Therefore, the requirement of existence of (0.2) has to be replaced by the existence of an approximate solution (see Definition 0.1 below).

If the equation (0.1) is "sufficiently" smooth and if it possesses a "sufficiently" accurate approximate solution $y_0(x)$, then there exists an actual solution $y(x)$ of (0.1) that is "close" to $y_0(x)$. Theorem A below presents a rigorous formulation of this statement. However, much sharper estimates of the required amount of smoothness of (0.1) and amount of accuracy of $y_0(x)$ can be expressed in terms of "degeneracy" of the equation (0.1), linearized with respect to $y_0(x)$ (Theorem B). Theorem B, applied to Example 0.1, states that in the cases $\Re\alpha \neq 0, \beta \geq 0$ or $\Re\alpha = 0, \beta \geq 2$ the equation (0.7) possesses a smooth solution $y(x)$ such that $\lim_{x\to\infty} y(x) = 0$ for any $\theta \in \mathbb{C}$ and any smooth function $u(x)$ that is bounded at infinity.

In sections 1–3 the proof of Theorem B is given. It is also shown that Theorem A is a simple consequence of Theorem B. In section 4 these theorems are applied to problems of triangularization and of diagonalization of the $n \times n$ matrix linear differential equation

$$D_A Y \equiv x^{1-r} Y'(x) - A(x)Y(x) = 0. \tag{0.8}$$

The "amount" of smoothness of $A(x)$, which allows triangularization and diagonalization (under the additional assumption that $A(\infty)$ has n distinct eigenvalues) (0.8), has been estimated in Theorem 4.2 and Corollary 4.2, respectively. Theorems 4.1 and 4.3 contain corresponding statements for block triangularization and block diagonalization. Based on the triangularization theorem (Theorem 4.2), the classical theorem on asymptotic solution of a system of linear ODEs with irregular singularity (see, for example, [Wa, Theorem 19.1]) is extended (Corollary 4.1) to finitely smooth systems. One of the possible applications of the obtained results in the oscillation theory is discussed in Example 4.1.

DEFINITION 0.1. *For a given $m \in \mathbb{R}$ a function $y_0(x)$ is called an* m-approximate *solution of* (0.1) *if $y_0 \in C^1[x_0, \infty)$ and if there exists some $\delta > 0$ such that*

$$\mathcal{N} y_0 = O(x^{-m-\delta}) \quad as \quad x \to \infty. \tag{0.9}$$

DEFINITION 0.2. *For a given $k \in \mathbb{R}$ we say that a matrix-valued function $F(x) \in \mathcal{R}_k$ if $F(x)$ is continuous on $[x_0, \infty)$ and if there exists some $\delta > 0$ such that*

$$F(x) = A(x) + O(x^{-k-\delta}), x \to \infty, \tag{0.10}$$

where $A(x)$ is a polynomial in $\frac{1}{x}$.

We say that $F(x)$ is a C^{k+1} matrix-valued function on $[x_0, \infty]$ if $\Psi(\xi) = F(\frac{1}{\xi})$, where $\xi = \frac{1}{x}$, is a $C^{k+1}[0, x_0^{-1}]$ matrix-valued function. Then, according to the Taylor theorem,

$$\Psi(\xi) = \sum_{j=0}^{k} \Psi_j \xi^j + O(\xi^{k+1}), \quad \xi \to +0,$$

so $F(x) \in \mathcal{R}_k$. Thus, the requirement $F(x) \in \mathcal{R}_k$ is a requirement on smoothness of $F(x)$ at $x = \infty$.

THEOREM A. *Suppose there exists an m-approximate solution $y_0(x)$ of* (0.1) *such that $y_0(\infty) = 0$ and that $F(x) = \frac{\partial f}{\partial y}(x, y_0(x)) \in \mathcal{R}_k$ for some $k \in \mathbb{N}$. Then the conditions*

$$m \geq 2nr, \quad k \geq nr \tag{0.11}$$

imply the existence of an actual solution $y(x) \in C^1[\tilde{x}, \infty]$ *for some* $\tilde{x} \geq x_0$*, where*

$$y(x) - y_0(x) = o(x^{-m+nr}), \quad x \to \infty. \tag{0.12}$$

Remark 0.1. Theorem A is also valid in the case when $F(x)$ can be represented as a polynomial in fractional powers of $\frac{1}{x}$ plus a term of the order $O(x^{-k-\delta})$.

Remark 0.2. Conditions (0.11) in Theorem A guarantee the existence of an actual solution to (0.1) without any restriction on the Jacobian $F(x)$. However, these conditions can be weakened significantly if we make some assumptions about the Jacobian. For example, if all the eigenvalues of $F(\infty)$ have nonzero real parts, then the conditions (0.11) can be replaced by $m \geq 0, \quad k \geq 0$.

In what follows we introduce the notion of the *rank of degeneracy* $\nu(A)$ of the linear singular differential operator D_A defined by (0.8), where $r \in \mathbb{N}$ and $A(x)$ is an analytic matrix-valued function at $x = \infty$, and prove the following theorem.

THEOREM B. *Conditions* (0.11) *in Theorem* A *can be replaced by*

$$m \geq 2\nu(A), \quad k \geq \nu(A), \tag{0.13}$$

where the polynomial $A(x)$ (in $\frac{1}{x}$) *is defined by* $F(x)$ *according to* (0.10)*. Correspondingly,* (0.12) *becomes*

$$y(x) - y_0(x) = o(x^{-m+\nu(A)}), \ x \to \infty. \tag{0.14}$$

This theorem ties $\nu(A)$ with the values of m and k. Roughly speaking, it ties the degeneracy of the Jacobian of (0.1) with the "order" of approximation of $y_0(x)$ and with the amount of smoothness of the Jacobian $F(x)$ at $x = \infty$ in such a way that the existence of an actual solution $y(x)$, which is "close" to $y_0(x)$, is ensured. The rank of degeneracy for analytic equations was defined in [T2]. In section 1 we adjust this definition for equations of a real variable. It will follow immediately from this definition that Theorem A, as well as Remark 0.2, are particular cases of Theorem B. The latter case, in fact, coincides with Theorem 33.1 in [Wa].

Remark 0.3. In the case of equation (0.7) the rank of degeneracy $\nu(A) = 0$ if $\Re\alpha \neq 0$ and $\nu(A) = 1$ if $\Re\alpha = 0$. Correspondingly, we have to require $m = 0$ and $m = 2$. In the first case $y_0 \equiv 0$ is a 0-approximate solution provided $\beta > 0$ and $u(x)$ is bounded on $[x_0, \infty)$. In the second case the required 2-approximate solution is $y_0(x) = -\frac{\theta}{\alpha x} + \frac{\theta}{x^2\alpha^2}(1 - \frac{\theta}{\alpha})$ if $\alpha \neq 0$ and $y_0(x) = i\sqrt{\frac{\theta}{x}} - \frac{1}{4x} - \frac{3i}{32\sqrt{\theta}x^{3/2}}$ if $\alpha = 0$, provided $\beta > 2$ and $u(x)$ is bounded on $[x_0, \infty)$. It is easy to check that $F(x) \equiv \alpha + 2y_0(x)$, so the requirement on the Jacobian is satisfied in both cases.

Remark 0.4. The Riccati equation (0.7) appears in many applied problems, for example, in traveling wave solutions to the Burgers equation. The fundamental role of the latter equation in nonlinear wave phenomena is well recognized in the literature (see, for example, [Wh]). It may appear, though, that the Burgers equation is of limited value for modelling turbulence, since it is an integrable equation. One of the ways to introduce some chaos in the model is to consider a driven equation. That was done, for example, in [MK] to study shock-trains in the Burgers model (see also references there). Assuming that the driving term is time independent in some reference frame, after one integration we get the Riccati equation $y'(x) = y^2(x) + \alpha y(x) + h(x)$ for a traveling wave solution. Here $h(x)$ and α are determined by the driving term and speed of the wave, respectively. Assuming further that $h(x)$ is in the same form as in (0.7), we get conditions guaranteeing existence of a traveling wave, decaying at infinity, from Remark 0.3.

A similar question can be considered for driven nonlinear oscillators: under what conditions on the external force $g(x)$ is the oscillator

$$y'' + y = f(y) + g(x) \tag{0.15}$$

asymptotically stable at the origin? Here $f(y)$ contains only quadratic or higher order terms. It is easy to show that even in the linear case the decaying forcing $g(x) = O(x^{-1})$ does not guarantee stability. Indeed, the general solution of (0.15) with $f(y) \equiv 0,\ g(x) = \frac{\cos x}{x}$,

$$y(x) = c_1 \cos x + c_2 \sin x + \frac{1}{2} \sin x \ln x + \frac{1}{2} \int_{\infty}^{x} \frac{\sin(x-2t)}{t} dt,$$

is not bounded as $x \to \infty$ for any c_1, c_2. On the other hand, Theorem B guarantees the existence of a decaying solution if, for example, $y_0 \equiv 0$ is a 2-approximate solution to (0.15), that is, if $g(x) = O(x^{-2-\delta})$ with any $\delta > 0$. Indeed, as it follows from Definition 1.1, section 1, in the case of equation (0.15) $\nu(A) = \rho(A) = 1$, so $m \geq 2$ in Theorem B.

The proof of Theorem B is divided into

(1) preliminary normalization of the equation (0.1);

(2) contractibility of the corresponding integral operator;

(3) existence of $y(x)$ by the fixed point method.

1. Preliminary normalization.

1.1. Equation for the remainder term. Let $y_0(x)$ be an m-approximate solution of (0.1) with a corresponding $\delta > 0$ satisfying (0.9). Without loss of generality we assume that $F(x)$ satisfies (0.10) with the same δ. Then the substitution $y(x) = y_0(x) + z(x)$ yields the equation

$$x^{1-r} z'(x) = a(x) + F(x)z + h(x, z) \tag{1.1}$$

for the remainder $z(x)$, where

$$a(x) = f(x, y_0) - x^{1-r} y_0'(x) = O(x^{-m-\delta}), \quad x \to \infty; \tag{1.2}$$

$$F(x) = \frac{\partial f}{\partial y}(x, y_0) = \sum_{j=0}^{k} A_j x^{-j} + O(x^{-k-\delta}), \quad x \to \infty \tag{1.3}$$

(this follows from (0.10));

$$h(x, z) = f(x, y_0 + z) - f(x, y_0) - \frac{\partial f}{\partial y}(x, y_0) z. \tag{1.4}$$

Note that there exists some $x_1 \geq x_0$ such that

$$\|h(x, z)\| = O(\|z\|)^2 \quad \text{as} \quad z \to 0 \tag{1.5}$$

uniformly for $x \geq x_1$. Indeed, $y_0(\infty) = 0$ implies the existence of some $x_1 \geq x_0$ such that $\|y_0(x)\| < \zeta$ if $x \geq x_1$. Then (1.5) follows from the assumptions on $f(x, y)$ in (0.1).

1.2. Triangularization of linear differential operators. The problem of triangularization of holomorphic and continuous matrix-valued functions by means of similarity transformations was studied in [Br], [Lv], [Fr], [GH], [KT], [T1], and others. In the latter two papers it was shown how the triangularization of a matrix-valued function $A(x)$, analytic at $x = \infty$, can be extended to singular differential operators (0.8). We need the following statement.

THEOREM 1.1 (see [T1]). *Let the matrix-valued function $A(x)$ in* (0.8) *be analytic at $x = \infty$. Then there exists a number $p \in \mathbb{N}$ and a formal matrix series*

$$T(x) = T_0 + T_1 x^{-1/p} + T_2 x^{-2/p} + \cdots \tag{1.6}$$

(where T_j are matrices of complex numbers and T_0 is an invertible matrix) such that the transformation $Y(x) = T(x)Z(x)$ reduces the differential operator

$$D_A Y = x^{1-r}\frac{dY(x)}{dx} - A(x)Y(x) \tag{1.7}$$

into a triangular form (T-form)

$$D_B Z = x^{1-r}\frac{dZ(x)}{dx} - B(x)Z(x), \tag{1.8}$$

where $B(x)$ is an upper-triangular formal matrix series in $x^{-\frac{1}{p}}$. Moreover, the matrix $\operatorname{diag}B(x)$ *of diagonal entries of $B(x)$ is a polynomial in $x^{-1/p}$ of order not larger than pr. This matrix is invariant modulo $O(x^{-r})$ over all the T-forms of* (0.8).

Remark 1.1. Matrix $B(x)$ in (1.8) can be taken to be lower triangular as well.

Remark 1.2. The series (1.6) with an invertible matrix T_0 will be called a formal matrix series, holomorphic in $x^{-1/p}$. The series

$$V(x) = \sum_{\nu=\beta}^{\infty} V_\nu x^{\frac{-\nu}{p}},$$

where V_ν are matrices of complex numbers, $\beta \in \mathbb{Z}$, and $\det V(x) \not\equiv 0$, will be called a formal matrix series, meromorphic in $x^{-1/p}$.

Proof. The proof is based on two facts:

(a) There exists a formal matrix series $V(x)$, meromorphic in $x^{-1/p}$, that reduces (0.8) to its Jordan form D_J, where

$$J(x) = \begin{pmatrix} \lambda_1(x) & \delta_1 & 0 & \cdots & 0 \\ 0 & \lambda_2(x) & \delta_2 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & \lambda_{n-1}(x) & \delta_{n-1} \\ 0 & \cdots & \cdots & 0 & \lambda_n(x) \end{pmatrix}. \tag{1.9}$$

Here $\lambda_j(x)$ are polynomials in $x^{-1/p}$ of order not larger than pr and the numbers δ_j are either 0 or 1 (the latter is possible only when $\lambda_j(x) \equiv \lambda_{j+1}(x)$). The polynomials $\lambda_j(x)$ are defined uniquely modulo $O(x^{-r})$. The proof of this well-known statement can be found, in fact, in [Wa, section 19.5] (see also [BJL], [KT], [T1]);

(b) Given $V(x)$, a formal matrix series meromorphic in $x^{-1/p}$, it is well known that there exists a unique factorization

$$V(x) = T(x)P(x)(x^{1/p})^K,$$

where $T(x)$ is a formal matrix series holomorphic in $x^{-1/p}$, $P(x)$ is an upper-triangular matrix polynomial in $x^{1/p}$, $P(0) = \mathrm{diag}P(x) = I$, and K is a diagonal matrix of integer numbers. This factorization was known to G. Birkhoff and could be found, for example, in [BJL].

According to (a), the transformation $Y(x) = V(x)Z(x)$ reduces (1.6) to its Jordan form D_J, where J is given by (1.9). Then

$$J(x) = V^{-1}(x)A(x)V(x) - x^{1-r}V^{-1}(x)V'(x). \tag{1.10}$$

At the same time, according to (b),

$$V(x) = T(x)U(x), \tag{1.11}$$

where $U(x) = P(x)(x^{1/p})^K$ is an upper-triangular matrix. It follows now from (1.10)–(1.11) that

$$U(x)J(x)U^{-1}(x)+x^{1-r}U'(x)U^{-1}(x) = T^{-1}(x)A(x)T(x)-x^{1-r}T^{-1}(x)T'(x). \tag{1.12}$$

So, the transformation $Y(x) = T(x)Z(x)$, applied to (1.7), yields (1.8) with

$$B(x) = U(x)J(x)U^{-1}(x) + x^{1-r}U'(x)U^{-1}(x).$$

Now one can easily verify that the matrix $B(x)$ satisfies all the assertions of the theorem. □

COROLLARY 1.1. *For any $N \in \mathbb{N}$ the transformation $Y(x) = T_N(x)Z(x)$, where*

$$T_N(x) = T_0 + T_1x^{-1/p} + \cdots + T_{Np}x^{-N} \tag{1.13}$$

is the truncated series (1.6), *reduces the operator D_A to its N-approximate triangular form D_{B_N} (T_N-form), where the matrix-valued function $B_N(x)$ is holomorphic in $x^{-1/p}$ and the first Np Taylor coefficients of $B_N(x)$ (in $x^{-1/p}$) are upper-triangular matrices.*

Proof. The fact that the formal transformation $T(x)$ reduces D_A to its triangular form D_B can be represented as an infinite series of equations on the corresponding coefficients A_n, B_n, and T_n. Then the corollary follows from the fact that the first Np equations are satisfied by the coefficients of $T_N(x)$. □

1.3. Rank of degeneracy of D_A and $\tilde{R}$-diagonal forms. Given a T-form (1.8) of the operator D_A, let us define the matrix

$$\tilde{\Lambda}(x) = \mathrm{diag}(\lambda_1(x), \dots, \lambda_n(x)), \tag{1.14}$$

where $x^r\lambda_j(x)$ consists of several consequent leading terms of the jth diagonal polynomial of $x^rB(x)$ (it is a polynomial in $x^{1/p}$ of order not greater than pr) defined as the following: the smallest term $\lambda_j x^{r+\rho_j}$ of $x^r\lambda_j(x)$ satisfies either $\Re\lambda_j \neq 0$ or $\rho_j = -r$; the coefficients of all the other terms of $x^r\lambda_j(x)$ are purely imaginary numbers. According to Theorem 1.1, the numbers ρ_j do not depend on a particular T-form D_B. Let us denote $\rho(A) = -\min_{1\le j\le n}\rho_j$ and

$$\tilde{R} = \mathrm{diag}(\rho_1, \dots, \rho_n).$$

Our aim is to reduce D_B into $D_{\hat{A}}$ with

$$\hat{A}(x) = x^{\tilde{R}}(\Lambda(x) + \tilde{B}(x)), \tag{1.15}$$

where $\tilde{B}(x) = o(1)$, $x \to \infty$, and $x^{\tilde{R}}\Lambda(x) = \tilde{\Lambda}(x)$ modulo $O(x^{-r})$. This can be achieved by the transformation $Z(x) = S(x)\tilde{Z}(x)$, where

$$S(x) = \mathrm{diag}(x^{-m_1}, x^{-m_2-\varepsilon}, \dots, x^{-m_n-(n-1)\varepsilon}). \tag{1.16}$$

This transformation is called a shearing transformation (see [Wa]) and $S(x)$ is called a shearing matrix. (For some historical remarks about shearing transformations see [Va]). The rational numbers $m_n \geq m_{n-1} \geq \cdots \geq m_1 = 0$ and the small positive number ε are to be specified below.

The action of the transformation (1.16) on the entries of $B(x)$ can be roughly described as follows: it multiplies the (i,j)th entry $B_{i,j}(x)$ of $B(x)$ by $x^{m_i-m_j+(i-j)\varepsilon}$. So, while the diagonal entries remain invariant modulo $O(x^{-r})$, the degree of each of the upper-triangular entries decreases and the degree of each of the lower-triangular entries increases.

Here and henceforth the degree of a scalar or a matrix series $a(x)$ in negative powers of the variable x means the exponent of the highest power of x occurring in the series; it is denoted by $\deg a(x)$; we set $\deg a(x) = -\infty$ if $a(x) \equiv 0$. It follows from (1.16) that $\deg S^{-1}(x) = m_n + (n-1)\varepsilon$. One can check that the minimal numbers m_j that satisfy (1.15) are recurrently defined by

$$m_k = \max\{m_{k-1}, \deg B_{1,k} - \rho_1 + m_1, \dots, \deg B_{k-1,k} - \rho_{k-1} + m_{k-1}\}, \tag{1.17}$$

where $k = 2, \dots, n$. It can be verified directly that

$$\deg \tilde{B}(x) \leq -\varepsilon \quad \text{and} \quad m_k \leq (k-1)\rho(A). \tag{1.18}$$

DEFINITION 1.1. *The rank of degeneracy $\nu(A)$ of the differential operator D_A is the minimum of*

$$\nu = \rho(A) + \deg\, S^{-1}(x) \tag{1.19}$$

over all T-forms of D_A, where ε is put to be zero.

The definition of $\nu(A)$ depends on $\tilde{R}$, that is, on the manner to choose ρ_j. The choice of ρ_j could be different if, for example, we consider x varying along the negative real semiaxis. In order to avoid confusion, $\nu(A)$ is called the $\tilde{R}$-rank of degeneracy and is denoted sometimes by $\nu(A, \tilde{R})$. In what follows we assume that (1.16) minimizes (1.19).

DEFINITION 1.2. *The operator $D_{\hat{A}}$, where $\hat{A}$ is given by* (1.15), *is called the $\tilde{R}$-diagonal form of D_A, and the matrix* (1.16) *is called its reducing shearing matrix.*

The fact that $\nu(A) = 0$ if all the eigenvalues of $A(\infty)$ have nonzero real parts follows immediately. The estimate

$$\nu(A) \leq n\rho(A) \tag{1.20}$$

is a direct consequence of (1.18). So $\nu(A) \leq nr$. Thus Theorem B implies the statement of Remark 0.2 and Theorem A.

1.4. The prenormalized equation. Let $A(x)$ be a polynomial part of the Jacobian $F(x)$ defined by (1.3), let $T_k(x)$ be a polynomial in $x^{-1/p}$ reducing D_A to its T_k-form (1.8), and let the shearing matrix $S(x)$ be defined by (1.8) according to (1.16)–(1.17). Then the transformation $z(x) = S(x)T_k(x)u(x)$ reduces (1.1) to

$$u'(x) = x^{r-1}\tilde{b}(x) + x^{\tilde{R}+r-1}[\Lambda(x) + \tilde{B}(x)]u(x) + x^{r-1}\tilde{F}(x)u + x^{r-1}\tilde{g}(x,u), \tag{1.21}$$

where

(a) $\tilde{b}(x) = T_k^{-1}(x)S^{-1}(x)a(x)$;

(b) $\tilde{R}$ is defined above. In the case $\rho(A) < r$ we put $\Lambda(x) = x^{-\tilde{R}}\tilde{\Lambda}(x)$ as in (1.15). In the opposite case we add $(m_j + (j-1)\varepsilon)\frac{1}{x}$ to the jth entry of the diagonal matrix $x^{-\tilde{R}}\tilde{\Lambda}(x)$ for every j such that $\rho_j = -r$;

(c) $\tilde{F}(x) = T_k^{-1}(x)S^{-1}(x)[F(x) - A(x)]S(x)T_k(x)$;

(d) $\tilde{g}(x,u) = T_k^{-1}(x)S^{-1}(x)h(x, S(x)T_k(x)u(x))$.

Let R denote $\tilde{R}+(r-1)I_n$, where I_n denotes the $n\times n$ identity matrix. Rewriting (1.21) as

$$u' = x^R(b(x) + [\Lambda(x) + G(x)]u + g(x,u)) \tag{1.22}$$

and using deg $x^{-\tilde{R}}S^{-1}(x) = \nu(A) + (n-1)\varepsilon$, we obtain the following:

(a)

$$b(x) = x^{-\tilde{R}}\tilde{b}(x) = O(x^{-m-\delta+\nu(A)+(n-1)\varepsilon}), \quad x \to \infty; \tag{1.23}$$

according to (1.2) and (1.21)(a),

(b) $G(x) = \tilde{B}(x) + x^{-\tilde{R}}\tilde{F}(x)$. As it follows from (1.3) and (1.21)(c),

$$x^{-\tilde{R}}\tilde{F}(x) = O(x^{-k-\delta+\nu(A)+(n-1)\varepsilon}), \quad x \to \infty. \tag{1.24}$$

The choice $\varepsilon < \frac{\delta}{n}$ together with (0.13) and (1.18) implies $x^{-\tilde{R}}\tilde{F}(x) = O(x^{-\varepsilon}), \quad x \to \infty$, and

$$G(x) = O(x^{-\varepsilon}), \quad x \to \infty; \tag{1.25}$$

(c) $g(x,u) = x^{-\tilde{R}}\tilde{g}(x,u)$, so

$$\frac{\partial g}{\partial u}(x,u) = x^{r-1}S^{-1}(x)T_{k-1}^{-1}(x)\frac{\partial h}{\partial z}\big(x, T_{k-1}(x)S(x)u\big)T_{k-1}(x)S(x).$$

According to (1.4),

$$\frac{\partial h}{\partial z}(x,z) = \frac{\partial f}{\partial y}(x, y_0 + z) - \frac{\partial f}{\partial y}(x, y_0).$$

Thus, similar to (1.5), we get $\|\frac{\partial h}{\partial z}(x,z)\| = O(\|z\|), \ z \to 0$, uniformly in $x \geq x_1$. Then, there exist constants $\hat{g} > 0$ and $\rho > 0$ such that

$$\left\|\frac{\partial g}{\partial u}(x,u)\right\| \leq x^{\nu(A)+(n-1)\varepsilon}\hat{g}\|u\| \tag{1.26}$$

for all $x \geq x_1$ and $\|z\| < \rho$.

The equation (1.22) is called the prenormalized form of (0.1) with respect to the approximate solution $y_0(x)$.

2. Contractiveness of integral operators.

2.1. Integral equation. Consider the equation (1.22) as a perturbation of the linear equation

$$U'(x) = x^R \Lambda(x) U(x). \tag{2.1}$$

This equation has the fundamental matrix solution

$$U(x) = e^{Q(x)}, \tag{2.2}$$

where $Q'(x) = x^R \Lambda(x)$. The entries $q_j(x)$ of the diagonal matrix $Q(x)$ can be represented as

$$q_j(x) = \tilde{q}_j(x) + c_j \ln x, \tag{2.3}$$

where c_j is a complex constant and $\tilde{q}_j(x)$ is a polynomial in $x^{1/p}$ of order not more than pr and $\tilde{q}_j(0) = 0$. Note that according to the construction of $\Lambda(x)$, in the case $\rho_j > -r$ all but one coefficient of $\tilde{q}_j(x)$ are purely imaginary and $c_j = 0$, while in the case $\rho_j = -r$ all these coefficients are purely imaginary.

The equation (1.22) can be converted into the integral equation

$$u(x) = e^{Q(x)} \left[C + \int^x e^{-Q(t)} t^R (b(t) + G(t)u + g(t,u)) dt \right], \tag{2.4}$$

where $C \in \mathbb{C}^n$ is an arbitrary constant vector. We have a freedom to choose a lower limit of integration for each entry of the vector integrand in (2.4) independently on that of other entries.

2.2. The integral operator $\mathcal{I}_Q$. Let Φ_γ, $\gamma \in \mathbb{R}$, denote the linear space of n-dimensional vector-valued functions $v(x) \in C[x_0, \infty)$, which are majorized by

$$\|v(x)\| \le M x^{-\gamma}, \quad x \in [x_0, \infty), \tag{2.5}$$

where the constant M depends on $v(x)$.

The lower limits of integration $s = \{s_1, \dots, s_n\}$ of the integral operator

$$\mathcal{I}_Q v = e^{Q(x)} \int_s^x e^{-Q(t)} t^R v(t) dt, \tag{2.6}$$

which acts on Φ_γ, are defined by γ and by the matrix $Q(x)$ as follows:

(a) If $\Re[\tilde{q}_j(x)] \to +\infty$ as $x \to \infty$, then $s_j = \infty$;

(b) If $\Re[\tilde{q}_j(x)] \to -\infty$ as $x \to +\infty$, then $s_j = x_0$;

(c) If $\Re[\tilde{q}_j(x)] \equiv 0$, then $s_j = x_0$ if $-\gamma - \Re c_j > 0$ or $s_j = +\infty$ if $-\gamma - \Re c_j < 0$.

We can always assume that

$$-\gamma - \Re c_j \neq 0 \tag{2.7}$$

by making a small variation of γ, if necessary.

THEOREM 2.1. *For a given diagonal matrix $Q(x)$ with entries* (2.3) *and a given $\gamma \in \mathbb{R}$ satisfying* (2.7) *there exists a constant $K > 0$ such that for any $v(x) \in \Phi_\gamma$ and satisfying* (2.5),

$$\|\mathcal{I}_Q v\| \le K M x^{-\gamma}, \quad x \in [x_0, \infty).$$

Proof. Since $Q(x)$ is a diagonal matrix, it is sufficient to consider the scalar case $n = 1$. So, let $Q(x) = q(x) + c \ln x$, where $q(x)$ is a polynomial in $x^{1/p}$.

(a, b) Suppose $\Re q(x) \not\equiv 0$, so either case (a) or (b) in the definition of lower limit s holds. Then we need to estimate the integral

$$e^{q(x)} x^c \int_s^x e^{-q(t)} t^{\bar{r}-1} t^{-c} t^{-\gamma} dt, \tag{2.8}$$

where $\lambda x^{\bar{r}}$ is the only term in $q(x)$ with nonzero real part. Since all other terms of $q(x)$ have purely imaginary coefficients, we can disregard them while estimating (2.8) for real positive x. Then (2.8) becomes

$$x^c \int_s^x e^{\alpha(x^{\bar{r}} - t^{\bar{r}})} t^{\bar{r}-1} t^{-c-\gamma} dt. \tag{2.9}$$

The assertion of the theorem for such integrals is well known (see, for example, [Wa, section 14]; the desired estimate for integrals (2.9) was derived in the course of estimating the integral (14.25) in Lemma 14.2 there).

(c) If $\Re q(x) \equiv 0$ then $|e^{q(x)}| \equiv 1$, so

$$|\mathcal{I}_Q v| = \left| x^c \int_s^x t^{-c-1} v(t) dt \right| \le M x^{\Re c} \left| \int_s^x t^{-\Re c - 1 - \gamma} dt \right|.$$

Suppose $-\gamma - \Re c < 0$. Then $s = \infty$ and

$$|\mathcal{I}_Q v| \le \frac{M}{|\gamma + \Re c|} x^{-\gamma}.$$

Suppose $-\gamma - \Re c > 0$. Then $s = x_0$ and

$$|\mathcal{I}_Q v| \le M x^{\Re c} \left. \frac{t^{-\gamma - \Re c}}{-\gamma - \Re c} \right|_{x_0}^{x} \le \frac{2M}{|\gamma + \Re c|} x^{-\gamma},$$

since $(\frac{x_0}{x})^{-\gamma - \Re c} < 1$. The statement of the theorem in this case follows from the estimate of $|\mathcal{I}_Q v|$. □

3. Fixed point method.

3.1. Convergence of iterations. The integral equation (2.4) can now be put in the operator form

$$u(x) = e^{Q(x)} C + \mathcal{I}_Q [b(x) + G(x) u(x) + g(x, u(x))], \tag{3.1}$$

where C is an arbitrary constant vector. We assume $C = 0$ and define the iterations by $u_0 \equiv 0$,

$$u_{j+1}(x) = \mathcal{I}_Q [b(x) + G(x) u_j(x) + g(x, u_j(x))], \tag{3.2}$$

where $j = 0, 1, 2, \ldots$.

Let us denote $\Delta u_j(x) = u_j(x) - u_{j-1}(x)$ and

$$\gamma = m - \nu(A) + \delta - (n-1)\varepsilon. \tag{3.3}$$

LEMMA 3.1. *Under the conditions* (0.13) *there exist some* $\tilde{x} \geq x_1$ *and* $M > 0$ *such that for every* $x \in [\tilde{x}, \infty)$ *the series*

$$u(x) = \sum_{j=1}^{\infty} \Delta u_j(x)$$

converges absolutely and uniformly and

$$\|u(x)\| \leq Mx^{-\gamma}. \tag{3.4}$$

Proof. 1. *Introduction.* The asymptotics (1.23), (1.25) can be converted into the inequalities

$$\|b(x)\| \leq \frac{1}{2}\hat{b}x^{-\gamma} \tag{3.5}$$

and

$$\|G(x)\| \leq \hat{G}x^{-\varepsilon} \tag{3.6}$$

for the appropriate constants $\hat{b}$, $\hat{G} > 0$, and $x \geq x_1$. Decreasing slightly, if necessary, the constant δ defined by (1.2)–(1.3), we can apply Theorem 2.1, with Q defined as in (3.1) and γ defined by (3.3), to estimate $u_1 = \mathcal{I}_Q b$. Then

$$\|u_1(x)\| < \frac{1}{2}K\hat{b}x^{-\gamma} \tag{3.7}$$

for $x \in [x_1, \infty)$.

Let us assume

$$\|\Delta u_l(x)\| \leq \frac{K\hat{b}x^{-\gamma}}{2^l}, \quad x \in [\tilde{x}_0, \infty), \tag{3.8}$$

for $l = 1, \dots, j$ and prove (3.8) for $l = j + 1$. Then the statement of Lemma 3.1, where $M = K\hat{b}$, will follow from (3.8) by induction.

According to (3.2)

$$\Delta u_{j+1}(x) = \mathcal{I}_Q G(x)\Delta u_j(x) + \mathcal{I}_Q \Delta g(x, u_j(x)), \tag{3.9}$$

where $\Delta g(x, u_j(x)) = g(x, u_j(x)) - g(x, u_{j-1}(x))$.

2. *Estimate of the linear term in* (3.9). The constant K, defined in Theorem 2.1, depends on Q and Φ_γ. Without loss of generality we may assume that K is the same for Φ_γ and $\Phi_{\gamma+\varepsilon}$. Let $\tilde{x} \geq (4\hat{G}K)^{1/\varepsilon}$. Then, taking into account (3.5), (3.7), (3.8), and Theorem 2.1,

$$\|\mathcal{I}_Q G(x)\Delta u_j(x)\| \leq \frac{K\hat{b}}{2^j}\hat{G}\|\mathcal{I}_Q x^{-\gamma-\varepsilon}\| \leq \frac{K\hat{b}\hat{G}}{2^j}Kx^{-\gamma-\varepsilon} \leq \frac{1}{2}\frac{K\hat{b}}{2^{j+1}}x^{-\gamma}. \tag{3.10}$$

3. *Estimate of the nonlinear term in* (3.9). We use the well-known formula

$$g(y_2) - g(y_1) = \int_0^1 \frac{\partial g}{\partial y}(x, sy_2 + (1-s)y_1)ds \cdot (y_2 - y_1) \tag{3.11}$$

to estimate the nonlinear term in (3.9). According to (3.11) we get

$$\|\Delta g(x, u_j(x))\| \leq \left\| \int_0^1 \frac{\partial g}{\partial y}(x, su_j + (1-s)u_{j-1})ds \right\| \|\Delta u_j\|. \tag{3.12}$$

Without loss of generality we may assume that $\tilde{x}$ is so large that $K\hat{b}|\tilde{x}|^{-\gamma} < \rho$, where ρ was defined in (1.26). Then

$$\|su_j(x) + (1-s)u_{j-1}(x)\| \le K\hat{b}x^{-\gamma} < \rho \tag{3.13}$$

for $x \in [\tilde{x}, \infty)$. So, according to (1.26),

$$\left\| \frac{\partial g}{\partial u}(x, su_j(x) + (1-s)u_{j-1}(x)) \right\| \le \hat{g}x^{\nu(A)+(n-1)\varepsilon} K\hat{b}x^{-\gamma}. \tag{3.14}$$

In order to estimate the right-hand side of (3.14) by $\hat{g}K\hat{b}x^{-\varepsilon}$ we need

$$-m - \delta + 2\nu(A) + 2(n-1)\varepsilon \le -\varepsilon. \tag{3.15}$$

Due to (0.13), this inequality is satisfied if $\varepsilon < \frac{\delta}{(2n-1)}$. Then (3.14) yields

$$\|\Delta g(x, u_j(x))\| \le \hat{g}K\hat{b}x^{-\varepsilon}\|\Delta u_j\|.$$

Now one can repeat the arguments of (3.10) in order to get

$$\|\mathcal{I}_Q \Delta g(x, u_j)\| \le \frac{1}{2}\frac{K\hat{b}}{2^{j+1}}x^{-\gamma}.$$

This proves (3.8) for $l = j+1$. □

3.2. Theorem B. The solution $y(x)$ to the equation (0.1) can now be represented as

$$y(x) = y_0(x) + T_k(x)S(x)u(x), \tag{3.16}$$

where $u(x)$ is a solution of the differential equation (1.22) (or of the equivalent equation (3.1)). The asymptotics (0.14) follow from (3.4). The proof of Theorem B is completed.

Remark 3.1. Suppose the diagonal matrix $e^{Q(x)}$ contains $l \le n$ entries that decrease exponentially as $x \to \infty$. Then the arguments of Lemma 3.1 will keep valid for an arbitrary constant vector C in (3.1) chosen from the corresponding l-dimensional subspace of $\mathbb{C}^n$. In this case Theorem B asserts the existence of an l-parameter family of solutions to (0.1).

Remark 3.2. In the case when the equation (0.1) is a linear nonhomogeneous equation, conditions $m \ge 2nr$ and $m \ge 2\nu(A)$ in Theorems A and B can be replaced by $m \ge nr$ and by $m \ge \nu(A)$, respectively. Indeed, in this case there is no need to estimate the nonlinear term in (3.9), so inequality (3.15) for m can be replaced by the requirement that γ in (3.3) is nonnegative.

4. Simplification of finitely smooth linear systems.

4.1. Block-diagonalization. Setting of the problem. Consider an $n \times n$ matrix differential equation

$$x^{1-r}Y'(x) = A(x)Y(x), \tag{4.1}$$

where $r \in \mathbb{N}$ and the $n \times n$ matrix-valued function $A(x) \in \mathcal{R}_k$ for some $k \in \mathbb{N}$ and $x_0 \in \mathbb{R}$.

Suppose that the spectrum of $A(\infty)$ consists of two nonempty disjoint sets σ_1 and σ_2; we can therefore assume $A(\infty)$ to be a block-diagonal matrix

$$A(\infty) = \operatorname{diag}(A_0^1, A_0^2), \quad \text{where} \quad \sigma_1 \cap \sigma_2 = \emptyset. \tag{4.2}$$

Let $l > 0$ denote the dimension of the square matrix A_0^1. Then the natural question is whether the equation (4.1) can be completely decoupled into two equations of dimensions l and $n - l$. These problems are known as block-diagonalization problems for matrix linear differential equations. Problems of block-diagonalization and of block-triangularization for finitely smooth equations are discussed below. Recurrent applications of block simplification transformations can lead eventually to full diagonalization or full triangularization of a system. These problems are also considered below.

4.2. Reduction to nonlinear equation. Let us look for a linear transformation

$$Y(x) = P(x)Z(x) \tag{4.3}$$

that reduces (4.1) to the desired block-diagonal system

$$x^{1-r}Z'(x) = B(x)Z(x). \tag{4.4}$$

Here

$$B(x) = \operatorname{diag}(B^{11}(x), B^{22}(x)) \tag{4.5}$$

and $B^{11}(\infty) = A_0^1, B^{22}(\infty) = A_0^2$.

One can immediately check that the transformation (4.3) reduces (4.1) to (4.4) iff

$$x^{1-r}P'(x) = A(x)P(x) - P(x)B(x). \tag{4.6}$$

According to (4.2), we represent

$$A(x) = \begin{pmatrix} A^{11}(x) & A^{12}(x) \\ A^{21}(x) & A^{22}(x) \end{pmatrix},$$

where $A^{11}(\infty) = A_0^1,\ A^{22}(\infty) = A_0^2,\ A^{12}(\infty) = 0,\ A^{21}(\infty) = 0$. If we are looking for $P(x)$ in the form

$$P(x) = \begin{pmatrix} I_l & P^{12}(x) \\ P^{21}(x) & I_{n-l} \end{pmatrix}, \tag{4.7}$$

then the substitution of (4.7) into (4.6) together with (4.5) yields

$$\left\{ \begin{array}{c} 0 = A^{12}(x)P^{21}(x) + A^{11}(x) - B^{11}(x), \\ x^{1-r}\dfrac{dP^{12}(x)}{dx} = A^{11}(x)P^{12}(x) - P^{12}(x)B^{22}(x) + A^{12}(x), \\ x^{1-r}\dfrac{dP^{21}(x)}{dx} = A^{22}(x)P^{21}(x) - P^{21}(x)B^{11}(x) + A^{21}(x), \\ 0 = A^{21}(x)P^{12}(x) + A^{22}(x) - B^{22}(x) \end{array} \right\} \tag{4.8}$$

(see, for instance, [Wa, section 12]). This system can be split into two decoupled nonlinear equations

$$x^{1-r}\frac{dP^{12}(x)}{dx} = A^{12}(x)+A^{11}(x)P^{12}(x)-P^{12}(x)A^{22}(x)-P^{12}(x)A^{21}(x)P^{12}(x) \tag{4.9}$$

and into a similar equation for P^{21}.

We say that the transformation (4.3) block-triangularizes (4.1) if instead of a block-diagonal matrix $B(x)$ in (4.4) we get a block-triangular matrix, say,

$$B(x) = \begin{pmatrix} B^{11}(x) & 0 \\ B^{21}(x) & B^{22}(x) \end{pmatrix}. \tag{4.10}$$

One can check directly that the transformation

$$P(x) = \begin{pmatrix} I_l & P^{12}(x) \\ 0 & I_{n-l} \end{pmatrix} \tag{4.11}$$

reduces (4.1) to (4.4), (4.10) if $P^{12}(x)$ satisfies (4.9).

4.3. Finitely smooth block-triangularization. Let us first consider problems of block-triangularization. As we will see, we can carry out the block-triangularization of equation (4.1) regardless of the condition (4.2), so this condition will be abolished in this section.

In what follows we suppose that, according to Corollary 1.1, the equation (4.1) is reduced to its k-approximate triangular form. Taking into account Remark 1.1, we get

$$A^{12}(x) = O(x^{-k-\delta}), \quad x \to \infty, \tag{4.12}$$

for some $\delta > 0$, and, consequently, that $P_0^{12}(x) \equiv 0$ is a k-approximate solution of (4.9). The fact that $\frac{\partial f}{\partial y}(x,0) \in \mathcal{R}_k$ for (4.9) can be checked directly. Then Theorem A, applied to (4.9), yields the following statement.

Statement 4.1. If the coefficient $A(x)$ of (4.1) belongs to $\mathcal{R}_k$ with

$$k \geq 2(n-l)lr, \tag{4.13}$$

then there exists a transformation (4.3), (4.11), where $P^{12}(x) = o(x^{-k+(n-l)lr})$, that reduces (4.1) to (4.4), (4.10). In the other words, the transformation (4.3), (4.11) block-triangularizes (4.1).

For a given equation (4.1) the requirement (4.13) is very crude. The more refined statement of Theorem B estimates k via the rank of degeneracy $\nu(A^{11}, A^{22})$ of the linear operator $Tr_A X = A^{11}(x)X - XA^{22}(x)$. However, instead of computing $\nu(A^{11}, A^{22})$ directly, we prefer to improve the estimate (4.13) by studying equation (4.9) in the integral form and applying to it the same arguments as in the proof of Theorem B.

Let us denote $A(x) = \tilde{A}(x) + \tilde{G}(x)$, where $\tilde{A}(x)$ is a polynomial in $x^{-1/p}$ of order not greater than pk and $\tilde{G}(x) = O(x^{-k-\delta})$. We call $\tilde{A}(x)$ and $\tilde{G}(x)$ polynomial and small parts of $A(x)$, respectively. According to Theorem 1.1, the diagonal entries $\lambda_i(x)$ of $\tilde{A}(x)$ are polynomials in $x^{-1/p}$ of order not greater than pr. Let

$$\lambda_{ij}(x) = \lambda_i(x) - \lambda_j(x), \quad 1 \leq i \leq l,\ l+1 \leq j \leq n. \tag{4.14}$$

For polynomials $\lambda_{ij}(x)$ we define the numbers ρ_{ij} in the same manner as the numbers ρ_j were defined for polynomials (1.14): ρ_{ij} is either the order of the maximal term of $\lambda_{ij}(x)$ with a nonpurely imaginary coefficient or $\rho_{ij} = -r$ if such a term fails to exist. For $i = 1, \dots, l$ and $j = l+1, \dots, n$ we denote

(4.15)

$$\rho_i = \min_{l+1\le j\le n} \rho_{ij}, \quad \rho_j = \min_{1\le i\le l} \rho_{ij}, \quad \tilde{R}_1 = \operatorname{diag}(\rho_1, \dots, \rho_l), \quad \tilde{R}_2 = \operatorname{diag}(\rho_{l+1}, \dots, \rho_n)$$

and

$$\rho(A^{11}, A^{22}) = -\min_{1\le i\le l,\ l+1\le j\le n} \rho_{ij}. \tag{4.16}$$

To study (4.9) we need to introduce differential operators

$$D_A^T Y = x^{1-r}\frac{dY(x)}{dx} + Y(x)A(x)$$

that are adjoint to (1.7).

DEFINITION 4.1. *The operator $D^T_{\hat{A}^T}$ is called an $\tilde{R}$-diagonal form of D^T_A if*

$$\hat{A}^T = (\Lambda(x) + \tilde{B}(x))x^{\tilde{R}},$$

where $\Lambda, \tilde{B}$ are defined in the same way as in Definition 1.2. *The corresponding reducing shearing transformation is defined similarly.*

Let

$$\hat{A}_1 = x^{\tilde{R}_1}(\Lambda_1(x) + \tilde{B}_1(x)) \ \text{ and } \ \hat{A}_2^T = (\Lambda_2(x) + \tilde{B}_2(x))x^{\tilde{R}_2} \tag{4.17}$$

be $\tilde{R}_1$-diagonal and $\tilde{R}_2$-diagonal forms of the operators $D_{A^{11}}$ and $D^T_{A^{22}}$, respectively. Let also $m_1 = \deg S_1^{-1}(x)$, $m_2 = \deg S_2^{-1}(x)$, where S_1 and S_2 are the corresponding shearing matrices with $\varepsilon = 0$.

We define

$$\nu = 2\rho(A^{11}, A^{22}) + m_1 + m_2. \tag{4.18}$$

Then, similar to (1.20), we get

$$\nu \le n\rho(A^{11}, A^{22}). \tag{4.19}$$

THEOREM 4.1. *The condition* (4.13) *in Statement* 4.1 *can be replaced by*

$$k \ge \nu. \tag{4.20}$$

Moreover,

$$P^{12}(x) = o(x^{-\tilde{k}-\rho(A^{11},A^{22})}), \quad x \to \infty, \tag{4.21}$$

where $\tilde{k} = k - \nu$ and

$$B^{11}(x), B^{22}(x) \in \mathcal{R}_{\tilde{k}+\rho(A^{11},A^{22})}. \tag{4.22}$$

Proof. The transformation $P^{12}(x) = S_1(x)U(x)S_2(x)$ reduces (4.9) to

$$x^{1-r}U'(x) = S_1^{-1}A^{12}S_2^{-1} + x^{\tilde{R}_1}[\Lambda_1 + \tilde{B}_1]U - U[\Lambda_2 + \tilde{B}_2]x^{\tilde{R}_2} - US_2A^{21}S_1U.$$

It can be rewritten as

(4.23)

$$U = e^{Q_1}\left\{\int_s^x e^{-Q_1}[t^{r-1}S_1^{-1}A^{12}S_2^{-1} + t^{R_1}\tilde{B}_1U - U\tilde{B}_2t^{R_2} - t^{r-1}US_2A^{21}S_1U]e^{Q_2}dt\right\}e^{-Q_2},$$

where $Q_1' = x^{R_1}\Lambda_1$, $Q_2' = x^{R_2}\Lambda_2$, $R_1 = \tilde{R}_1 + (r-1)I_l$, and $R_2 = \tilde{R}_2 + (r-1)I_{n-l}$. This equation is an $l \times (n-l)$-dimensional vector equation of the type (2.4). The set of lower limits of integration s is chosen as in (2.6).

Remark 4.1. The statement of Theorem 2.1 is valid for both integral operators

$$\mathcal{I}_1V = e^{Q_1}\left\{\int_s^x e^{-Q_1}t^{R_1}Ve^{Q_2}dt\right\}e^{-Q_2},$$

$$\mathcal{I}_2V = e^{Q_1}\left\{\int_s^x e^{-Q_1}Vt^{R_2}e^{Q_2}dt\right\}e^{-Q_2},$$

where $V(x) \in \Phi_\gamma$.

Let us rewrite (4.23) again as

$$U = e^{Q_1}\left\{\int_s^x e^{-Q_1}[t^{R_1}(b + \tilde{B}_1U - t^{-\tilde{R}_1}UhU) - U\tilde{B}_2t^{R_2}]e^{Q_2}dt\right\}e^{-Q_2}, \tag{4.24}$$

where

$$b(x) = x^{-\tilde{R}_1}S_1^{-1}A^{12}S_2^{-1} = O(x^{-k-\delta+\nu-\rho(A^{11},A^{22})+(n-2)\varepsilon}), \quad x \to \infty, \tag{4.25}$$

and

$$h(x) = S_2A^{21}S_1 = O(1), \quad x \to \infty. \tag{4.26}$$

The rest of the proof follows as in Lemma 3.1 with $\gamma = k + \delta - \nu + \rho(A^{11}, A^{22}) - (n-2)\varepsilon$. Note, however, that according to (4.26), the estimate (3.15) is replaced by

$$-k - \delta + \nu - \rho(A^{11}, A^{22}) + (n-2)\varepsilon + \rho(A^{11}, A^{22}) \ \leq -\varepsilon. \tag{4.27}$$

This yields (4.20) provided $\varepsilon < \frac{\delta}{n-1}$. The second statement follows then from (4.25). Finally, the substitution of (4.10)–(4.11) into (4.6) yields

$$B^{11} = A^{11} - P^{12}A^{21}, \quad B^{22} = A^{22} + A^{21}P^{12}, \tag{4.28}$$

so (4.22) follows from (4.21). □

Theorem 4.1 shows that the required amount of smoothness for block-triangularization is of the order $O(n)$ instead of $O(n^2)$ as could be seen from Statement 4.1.

4.4. Complete triangularization. Solutions of k-smooth systems. Let us define $\tilde{\rho}(A)$ by modifying the definition (4.16) of $\rho(A^{11}, A^{22})$ as

$$\tilde{\rho}(A) = -\min_{1\le i<j\le n} \rho_{ij}.$$

It is clear that

$$\tilde{\rho}(A) \ge \rho(A^{11}, A^{22}). \tag{4.29}$$

Then, as a consequence of Theorem 4.1, we obtain the following theorem.

THEOREM 4.2. *If the coefficient $A(x)$ of (4.1) belongs to $\mathcal{R}_k$ with*

$$k \ge 2(n-1)\tilde{\rho}(A), \tag{4.30}$$

then there exists a transformation (4.3), where $P(x)$ is an upper-triangular matrix and $\operatorname{diag} P(x) \equiv I_n$, that reduces (4.1) to (4.4), where $B(x) \in \mathcal{R}_{\tilde{k}+\tilde{\rho}(A)}$, $\tilde{k} = k - 2(n-1)\tilde{\rho}(A)$, and $B(x)$ is a lower-triangular matrix. Moreover, $P(x) = I_n + U(x)$, where

$$U(x) = o(x^{-\tilde{k}-\tilde{\rho}(A)}),\ x \to \infty. \tag{4.31}$$

Proof. Let us prove Theorem 4.2 by induction. For $n = 2$ triangularization and block-triangularization coincide. Note that in this case the statements of Theorems 4.1 and 4.2 also coincide. Suppose the statement of the theorem is true for any $n \le 2^m$, $m \in \mathbb{N}$. Let us then prove it for any n such that $2^m < n \le 2^{m+1}$.

We start to block-triangularize (4.1) by (4.3), (4.11), choosing $l = \frac{n}{2}$ if n is even or $l = \frac{n+1}{2}$ otherwise. Then, according to (4.22), (4.29), $B^{11}, B^{22} \in \mathcal{R}_{k_1}$, where $k_1 \ge k - n\rho(A^{11}, A^{22}) + \rho(A^{11}, A^{22}) \ge k - (n-1)\tilde{\rho}(A)$. Note that (4.21), (4.28) imply $\tilde{\rho}(A^{11}) = \tilde{\rho}(B^{11})$, $\tilde{\rho}(A^{22}) = \tilde{\rho}(B^{22})$ so that $\tilde{\rho}(B^{11}), \tilde{\rho}(B^{22}) \le \tilde{\rho}(A)$. Then using (4.30) we obtain

$$k_1 \ge \tilde{k} + 2(n-1)\tilde{\rho}(A) - (n-1)\tilde{\rho}(A) \ge \tilde{k} + 2(l-1)\tilde{\rho}(A).$$

Now the assertion of the theorem follows by induction arguments. ∎

In section 1.2 we described reduction of a singular differential operator D_A to its Jordan form. As a consequence of this reduction, one can get the classical Hukuhara–Turritin theorem (see, for example, [Wa, section 19.5]), stating that if $A(x)$ is a matrix-valued function, holomorphic at ∞, then (4.1) possesses a formal solution

$$Y(x) = V(x) x^H e^{Q(x)}, \tag{4.32}$$

where $V(x)$ is a matrix-valued function, holomorphic in some sector S in the complex x-plane for sufficiently large values of $|x|$, that admits the asymptotic expansion

$$\hat{V} = \sum_{j=0}^{\infty} V_j x^{-j/p}$$

in S with some $p \in \mathbb{N}$; $\det V(x) = O(x^{-m})$ for some $m \in \mathbb{N}$; $Q(x)$ is a diagonal, polynomial in $x^{1/p}$ matrix with $Q(0) = 0$; and H is a constant matrix that commutes with $Q(x)$.

Theorem 4.2 extends this result to the case $A(x) \in \mathcal{R}_k$ in the following way.

COROLLARY 4.1. *Under the assumption (4.30) there exists a solution (4.32) to (4.1), where $V(x) \in \mathcal{R}_{\tilde{k}}$, $\det V(x) = O(x^{-m})$ for some $m \in \mathbb{N}$; $Q(x)$ is a diagonal matrix, $x^{-r} Q(x) \in \mathcal{R}_{\tilde{k}+\tilde{\rho}(A)}$; and H is a constant diagonal matrix.*

Proof. According to Theorem 4.2, we can assume that $A(x)$ is a lower triangular matrix and $A(x) \in \mathcal{R}_{\tilde{k}+\tilde{\rho}(A)}$ in the notations of the theorem. Next we apply the shearing transformation $S(x) = \mathrm{diag}(x^{-m_n}, \dots, x^{-m_1})$, where $0 = m_1 \le m_2 \le \dots \le m_n$, that reduces D_A to D_B, where B is lower triangular and off-diagonal entries of B are $O(x^{-\tilde{k}-\tilde{\rho}(A)-\delta})$. The matrix B can be decomposed as $B(x) = \Lambda(x) + \tilde{B}(x)$, where $\Lambda(x) = \mathrm{diag}B(x)$ and $\tilde{B}(x)$ is strictly lower triangular. Then the change of variables

$$Y(x) = (I + Z(x))e^{Q(x)},$$

where $Z(x)$ is a strictly lower triangular matrix and $x^{1-r}Q'(x) = \Lambda(x)$, reduces the equation $D_B Y = 0$ to

$$x^{1-r}Z' = \tilde{B} + BZ - Z\Lambda.$$

The latter equation is a linear nonhomogeneous equation with $\nu(\mathcal{A}) = \rho(\mathcal{A}) = \tilde{\rho}(A)$, where the linear operator $\mathcal{A}Z = BZ - Z\Lambda$. Then, according to Remark 3.2, there exists a solution $Z(x) = O(x^{-\tilde{k}-\delta})$. That completes the proof of the corollary. Note that $H = 0$ if $\tilde{\rho}(A) < r$. □

4.5. Diagonalization. Let us consider now the problem of block-diagonalization of (4.1) provided that (4.2) holds. Considering (4.9) as an $l \times (n-l)$ vector equation of the form (0.1), we see that the Jacobian matrix $\frac{\partial f}{\partial y}(\infty, 0)$ is invertible, because the matrices $A^{11}(\infty)$ and $A^{22}(\infty)$ have a disjoint spectrum.

If the matrix-valued function $A(x)$ is analytic at $x = \infty$, then, according to Theorem 33.1 in [Wa], the equation (4.9) possesses a solution $P^{12}(x)$ such that $\lim_{x\to+\infty} P^{12}(x) = 0$ and that $P^{12}(x)$ is an analytic function in the interval $(\tilde{x}, \infty)$ for some $\tilde{x} \ge x_0$. That implies the block-diagonalization of (4.1).

Suppose, however, that the analyticity of $A(x)$ is replaced by finite smoothness. Then, according to Remark 0.2, the Jacobian matrix $\frac{\partial f}{\partial y}(\infty, 0)$ has to have eigenvalues with nonzero real part in order to guarantee the existence of a solution to (4.9). Accordingly, the original condition (4.2) of disjointness of the spectrum of $A(\infty)$ in the equation (4.1) should be replaced by the following condition: the eigenvalues λ_j, $j = 1, \dots, n$, of the matrix $A(\infty)$ can be separated into two sets $\sigma_{1,2}$ so that the difference $\lambda_\alpha - \lambda_\beta$ between any $\lambda_\alpha \in \sigma_1$ and any $\lambda_\beta \in \sigma_2$ is not purely imaginary.

Under the latter assumption various results on block-diagonalization of the finitely-smooth equation (4.1) were obtained (see, e.g., [Gi], [Co], and references there). However, we have not come across any result that guarantees such block-diagonalization under the weaker condition of disjointedness (4.2). Theorem 4.1 enables us to partially fill this gap by the following statement.

THEOREM 4.3. *Suppose that in the equation* (4.1) $A(x) \in \mathcal{R}_k$, *where*

$$k \ge \nu - \rho(A^{11}, A^{22}), \tag{4.33}$$

and the matrix $A(\infty)$ *has a disjoint spectrum (i.e.,* $A(\infty)$ *can be represented by* (4.2)*). Then there exists a matrix* $P(x)$, *given by* (4.7), *such that* $P(x) - I_n = o(1)$, $x \to \infty$, *and that the transformation* $Y(x) = P(x)Z(x)$ *block-diagonalizes* (4.1) *(i.e., reduces* (4.1) *to* (4.4)–(4.5)*).*

Proof. A consequence of the condition (4.2) is that we can block-diagonalize $\tilde{A}(x)$, which is the polynomial part of $A(x)$. Then, in addition to (4.12) we get $A^{21} = O(x^{-k-\delta})$, $x \to \infty$. The proof of the theorem coincides with that of Theorem 4.1, except that instead of (4.26) we now have

$$h(x) = S_2 A^{21} S_1 = O(x^{-k-\delta}), \quad x \to \infty.$$

This changes (4.27) to

$$-2k - 2\delta + \nu + (n-2)\varepsilon \ \le -\varepsilon. \tag{4.34}$$

This inequality is a consequence of (4.33).

The estimate (4.33) follows from the requirement $P(x) - I_n = o(1),\ x \to \infty$, where, as in Theorem 4.1, $\gamma = k + \delta - \nu + \rho(A^{11}, A^{22}) - (n-2)\varepsilon$. □

COROLLARY 4.2. *Let $A(x) \in \mathcal{R}_k$ with*

$$k \ge \tilde{\rho}(A) \tag{4.35}$$

and let all eigenvalues of $A(\infty)$ be distinct. Then there exists a matrix $P(x)$ such that $P(x) = o(1),\ x \to \infty$, and that the transformation $Y(x) = (I_n + P(x))Z(x)$ reduces (4.1) to (4.4), where $B(x)$ is diagonal and $B(x) \in \mathcal{R}_k$.

Proof. Let us choose arbitrarily some blocks A_0^1, A_0^2 in (4.2). Let $\tilde{A}(x)$ denote the polynomial part of $A(x)$. As is well known, under the assumptions of the corollary, we can reduce the operator $D_{\tilde{A}}$ to D_Λ, where the matrix $\Lambda(x)$ is diagonal modulo $O(x^{-k-\delta})$. This implies that no shearing is needed to bring $\tilde{A}^{11}$ and $\tilde{A}^{22}$ to their $\tilde{R}$-diagonal forms. Therefore, (4.18) yields $\nu = 2\rho(A^{11}, A^{22})$.

According to (4.29) and (4.35), assumptions of Theorem 4.3 are satisfied, so (4.1) can be decoupled into (4.4)–(4.5) by the transformation (4.3), (4.7). Note that (4.8) implies $B^{11} = A^{11} + A^{12}P^{21},\ \ B^{22} = A^{22} + A^{21}P^{12}$ and that the off-diagonal blocks A^{12}, A^{21} are of the order $O(x^{-k-\delta})$. So $B^{11}, B^{22} \in \mathcal{R}_k$. Each of the matrices $B^{11}(\infty), B^{22}(\infty)$ has distinct eigenvalues, so the block-diagonalization process can be continued. The proof can be completed by induction arguments. □

Remark 4.2. In the case $r = 1$ we have $\tilde{\rho}(A) = 1$. Then Corollary 4.2 is a particular case of the Levinson theorem [CL, section 3.8].

Potentially, the obtained results on triangularization and diagonalization could have various applications in such areas as oscillations, control theory, singular perturbations and others. Within the limits of the paper we would like illustrate this with the following example in oscillation theory.

Example 4.1. Oscillatory properties of solutions of the linear differential equation

$$y^{(n)}(x) = p(x)y(x) \tag{4.36}$$

on the interval $[x_0, \infty)$, where $p \in C^2[x_0, \infty)$ and x_0 is sufficiently large, were considered in [EG1], [EG2] (see also references there). By means of certain linear transformations, this equation was reduced to the system $D_A Y = 0$ with $r = 0$ and

$$\begin{aligned} A(x) = \frac{x p^{\frac{1}{n}}(x)}{s(x)} &\begin{pmatrix} 0 & s(x) & 0 & \cdots & 0 \\ 0 & 1 & s(x) & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & n-2 & s(x) \\ 0 & \cdots & \cdots & 0 & n-1 \end{pmatrix} \\ &+ x[s(x) - s] \begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & 0 & 1 \\ 1 & \cdots & \cdots & 0 & 0 \end{pmatrix} \\ &= B(x) + \tilde{B}(x), \end{aligned}$$

where $B(x), \tilde{B}(x)$ denote the first and second matrix terms, respectively, $s(x) = \frac{-np^{1+1/n}(x)}{p'(x)}$, and $s = \lim_{x\to\infty} s(x)$ provided that the limit exists. One of the most interesting cases when $0 < |s| < \infty$ and when $B(\infty)$ has a multiple eigenvalue λ was considered in [EG2]. In this case it was demonstrated in [EG1] that the multiplicity of λ is exactly two. Analysis of [EG2] shows that under the additional assumption

$$x^n p(x) \text{ is analytic at } x = \infty, \tag{4.37}$$

the equation (4.36) possesses a two-dimensional subspace S of nonoscillatory solutions, i.e., that $y \in S$ and $y \not\equiv 0$ imply existence of some $x_1 \geq x_0$ such that sign $y =$ const. on $[x_1, \infty)$.

Direct computations show that assumption (4.37) implies $s(x) - s = O(x^{-2})$ and thus the equation $D_A Y = 0$ can be considered as a perturbation of $D_B Y = 0$ for large x. The leading term of the last equation can be split into a two-dimensional block B^{11} that corresponds to the eigenvalue λ and into the remaining $(n-2)$-dimensional block B^{22}. The proof of the above mentioned statement is based on the block-diagonalization of D_A determined by B^{11}, B^{22}.

Our point is that, based on Theorem 4.3, the assumption (4.37) in [EG2] can be replaced by the less restrictive assumption $x^{n+1}p'(x) \in \mathcal{R}_1$. Indeed, under this assumption $s(x) - s = O(x^{-2})$ is still valid and $A(x) \in \mathcal{R}_0$. It remains to note that equation $D_A Y = 0$ with regular singularity at infinity $\nu = 0$; thus Theorem 4.3 guarantees block-diagonalization.

ORTHOGONAL POLYNOMIALS AND CUBATURE FORMULAE ON SPHERES AND ON BALLS*

YUAN XU†

Abstract. Orthogonal polynomials on the unit sphere in $\mathbb{R}^{d+1}$ and on the unit ball in $\mathbb{R}^d$ are shown to be closely related to each other for symmetric weight functions. Furthermore, it is shown that a large class of cubature formulae on the unit sphere can be derived from those on the unit ball and vice versa. The results provide a new approach to study orthogonal polynomials and cubature formulae on spheres.

Key words. orthogonal polynomials in several variables, on spheres, on balls, spherical harmonics, cubature formulae

1. Introduction.

We are interested in orthogonal polynomials in several variables with emphasis on those orthogonal with respect to a given measure on the unit sphere S^d in $\mathbb{R}^{d+1}$. In contrast to orthogonal polynomials with respect to measures defined on the unit ball B^d in $\mathbb{R}^d$, there have been relatively few studies on the structure of orthogonal polynomials on S^d beyond the ordinary spherical harmonics which are orthogonal with respect to the surface (Lebesgue) measure (cf. [2, 3, 4, 5, 6, 8]). The classical theory of spherical harmonics is primarily based on the fact that the ordinary harmonics satisfy the Laplace equation. Recently Dunkl (cf. [2, 3, 4, 5] and the references therein) opened a way to study orthogonal polynomials on the spheres with respect to measures invariant under a finite reflection group by developing a theory of spherical harmonics analogous to the classical one. In this important theory the role of Laplacian operator is replaced by a differential-difference operator in the commutative algebra generated by a family of commuting first-order differential-difference operators (Dunkl's operators). Other than these results, however, we are not aware of any other method of studying orthogonal polynomials on spheres.

A closely related question is constructing cubature formulae on spheres and on balls. Cubature formulae with a minimal number of nodes are known to be related to orthogonal polynomials. Over the years, a lot of effort has been put into the study of cubature formulae for measures supported on the unit ball, or on other geometric domains with nonempty interior in $\mathbb{R}^d$. In contrast, the study of cubature formulae on the unit sphere has been more or less focused on the surface measure on the sphere; there is little work on the construction of cubature formulae with respect to other measures. This is partly due to the importance of cubature formulae with respect to the surface measure, which play a role in several fields in mathematics, and perhaps partly due to the lack of study of orthogonal polynomials with respect to a general measure on the sphere.

One main purpose of this paper is to provide an elementary approach towards the study of orthogonal polynomials on S^d for a large class of measures. This approach is

†Department of Mathematics, University of Oregon, Eugene, OR 97403-1222 (yuan@math.uoregon.edu).

based on a close connection between orthogonal polynomials on S^d and those on the unit ball B^d; a prototype of the connection is the following elementary example.

For $d = 1$, the spherical harmonics of degree n are given in the standard polar coordinates by

$$Y_n^{(1)}(x_1, x_2) = r^n \cos n\theta \quad \text{and} \quad Y_n^{(2)}(x_1, x_2) = r^n \sin n\theta. \tag{1.1}$$

Under the transform $x = \cos\theta$, the polynomials $T_n(x) = \cos n\theta$ and $U_n(x) = \sin n\theta / \sin\theta$ are the Chebyshev polynomials of the first and the second kind, orthogonal with respect to $1/\sqrt{1-x^2}$ and $\sqrt{1-x^2}$, respectively, on the unit ball $[-1, 1]$ in $\mathbb{R}$. Hence, the spherical harmonics on S^1 can be derived from orthogonal polynomials on B^1.

We shall show that for a large class of weight functions on $\mathbb{R}^{d+1}$ we can construct homogeneous orthogonal polynomials on S^d from the corresponding orthogonal polynomials on B^d in a similar way. This allows us to derive properties of orthogonal polynomials on S^d from those on B^d; the latter have been studied much more extensively. Although the approach is elementary and there is no differential or differential-difference operator involved, the result offers a new way to study the structure of orthogonal polynomials on S^d.

Our approach depends on an elementary formula that links the integration on B^d to the integration on S^d. The same formula yields an important connection between cubature formulae on S^d and those on B^d; the result states roughly that a large class of cubature formulae on S^d is generated by cubature formulae on B^d and vice versa. In particular, it allows us to shift our attention from the study of cubature formulae on the unit sphere to the study of cubature formulae on the unit ball; there has been much more understanding towards the structure of the latter one. Although the result is simple and elementary, its importance is apparent. It yields, in particular, many new cubature formulae on spheres and on balls. Because the main focus of this paper is on the relation between orthogonal polynomials and cubature formulae on spheres and those on balls, we will present examples of cubature formulae in a separate paper.

The paper is organized as follows. In section 2 we introduce notation and present the necessary preliminaries, where we also prove the basic lemma. In section 3 we show how to construct orthogonal polynomials on S^d from those on B^d. In section 4 we discuss the relation between cubature formulae on the unit sphere and those on the unit ball.

2. Preliminary and basic lemma. For $\mathbf{x}, \mathbf{y} \in \mathbb{R}^d$ we let $\mathbf{x} \cdot \mathbf{y}$ denote the usual inner product of $\mathbb{R}^d$ and $|\mathbf{x}| = (\mathbf{x} \cdot \mathbf{x})^{1/2}$ the Euclidean norm of $\mathbf{x}$. Let B^d be the unit ball of $\mathbb{R}^d$ and S^d be the unit sphere on $\mathbb{R}^{d+1}$; that is,

$$B^d = \{\mathbf{x} \in \mathbb{R}^d : |\mathbf{x}| \le 1\} \qquad \text{and} \qquad S^d = \{\mathbf{y} \in \mathbb{R}^{d+1} : |\mathbf{y}| = 1\}.$$

Polynomial spaces. Let $\mathbb{N}_0$ be the set of nonnegative integers. For $\alpha = (\alpha_1, \ldots, \alpha_d) \in \mathbb{N}_0^d$ and $\mathbf{x} = (x_1, \ldots, x_d) \in \mathbb{R}^d$ we write $\mathbf{x}^\alpha = x_1^{\alpha_1} \cdots x_d^{\alpha_d}$. The number $|\alpha|_1 = \alpha_1 + \cdots + \alpha_d$ is called the total degree of $\mathbf{x}^\alpha$. We denote by Π^d the set of polynomials in d variables on $\mathbb{R}^d$ and by Π_n^d the subset of polynomials of total degree at most n. We also denote by $\mathcal{P}_n^d$ the space of homogeneous polynomials of degree n on $\mathbb{R}^d$ and we let $r_n^d = \dim \mathcal{P}_n^d$. It is well known that

$$\dim \Pi_n^d = \binom{n+d}{n} \quad \text{and} \quad r_n^d = \binom{n+d-1}{n}.$$

Orthogonal polynomials on B^d. Let W be a nonnegative weight function on B^d and assume $\int_{B^d} W(\mathbf{x}) d\mathbf{x} < \infty$. It is known that for each $n \in \mathbb{N}_0$ the set of polynomials

of degree n that are orthogonal to all polynomials of lower degree forms a vector space $\mathcal{V}_n$ whose dimension is r_n^d. We denote by $\{P_k^n\}$, $1 \le k \le r_n^d$ and $n \in \mathbb{N}_0$, one family of orthonormal polynomials with respect to W on B^d that forms a basis of Π_n^d, where the superscript n means that $P_k^n \in \Pi_n^d$. The orthonormality means that

$$\int_{B^d} P_k^n(\mathbf{x}) P_j^m(\mathbf{x}) W(\mathbf{x}) d\mathbf{x} = \delta_{j,k}\delta_{m,n}.$$

A useful notation is $\mathbb{P}_n = (P_1^n, \ldots, P_{r_n^d}^n)^T$, which is a vector with P_j^n as components (cf. [22, 24]). For each $n \in \mathbb{N}_0$, the polynomials P_k^n, $1 \le k \le r_n^d$, form an orthonormal basis of $\mathcal{V}_n$. We note that there are many bases of $\mathcal{V}_n$; if Q is an invertible matrix of size r_n^d, then the components of $Q\mathbb{P}_n$ form another basis of $\mathcal{V}_n$ which is orthonormal if Q is an orthogonal matrix. For general results on orthogonal polynomials in several variables, including some of the recent development, we refer to the survey [24] and the references therein. One family of weight functions on B^d whose corresponding orthogonal polynomials have been studied in detail is $(1 - |\mathbf{x}|^2)^{\mu-1/2}$, $\mu \ge 0$, which we will refer to as classical orthogonal polynomials on B^d (cf. [1, 6, 25]).

Ordinary spherical harmonics. The harmonic polynomials on $\mathbb{R}^d$ are the homogeneous polynomials satisfying the Laplace equation $\Delta P = 0$, where

$$\Delta = \partial_1^2 + \cdots + \partial_d^2 \qquad \text{on} \quad \mathbb{R}^d$$

and ∂_i is the ordinary partial derivative with respect to the ith coordinate. They span a subspace $\mathcal{H}_n^d = \ker \Delta \cap \mathcal{P}_n^d$ of dimension $\dim \mathcal{P}_n^d - \dim \mathcal{P}_{n-2}^d$. The spherical harmonics are the restriction of harmonic polynomials on S^{d-1}. If $Y_n \in \mathcal{H}_n^d$, then Y_n is orthogonal to $Q \in \mathcal{P}_k^d$, $0 \le k < n$, with respect to the surface measure $d\omega$ on S^{d-1}.

Dunkl's h-harmonics. For a nonzero vector $\mathbf{v} \in \mathbb{R}^d$ we define the reflection $\sigma_{\mathbf{v}}$ by

$$\mathbf{x}\sigma_{\mathbf{v}} := \mathbf{x} - 2(\mathbf{x} \cdot \mathbf{v})\mathbf{v}/|\mathbf{v}|^2, \qquad \mathbf{x} \in \mathbb{R}^d.$$

Suppose that G is a finite reflection group on $\mathbb{R}^d$ with the set $\{\mathbf{v}_i : i = 1, 2, ..., m\}$ of positive roots; assume that $|\mathbf{v}_i| = |\mathbf{v}_j|$ whenever σ_i is conjugate to σ_j in G, where we write $\sigma_i = \sigma_{\mathbf{v}_i}$, $1 \le i \le m$. Then G is a subgroup of the orthogonal group generated by the reflections $\{\sigma_{\mathbf{v}_i} : 1 \le i \le m\}$.

The h-harmonics yield orthogonal polynomials on S^{d-1} with respect to $h_\alpha^2 d\omega$, where the weight function h_α is defined by

$$h_\alpha(\mathbf{x}) := \prod_{i=1}^m |\mathbf{x} \cdot \mathbf{v}_i|^{\alpha_i}, \qquad \alpha_i \ge 0, \tag{2.1}$$

with $\alpha_i = \alpha_j$ whenever σ_i is conjugate to σ_j in G. The function h_α is a positively homogeneous G-invariant function of degree $|\alpha|_1 = \alpha_1 + \cdots + \alpha_m$. The key ingredient of the theory is a family of commuting first-order differential-difference operators, $\mathcal{D}_i$ (Dunkl's operators), defined by

$$\mathcal{D}_i f(\mathbf{x}) := \partial_i f(\mathbf{x}) + \sum_{j=1}^m \alpha_j \frac{f(\mathbf{x}) - f(\mathbf{x}\sigma_j)}{\mathbf{x} \cdot \mathbf{v}_j} \mathbf{v}_j \cdot \mathbf{e}_i, \qquad 1 \le i \le d, \tag{2.2}$$

where $\mathbf{e}_1, \ldots, \mathbf{e}_d$ are the standard unit vectors of $\mathbb{R}^d$. The h-Laplacian is defined by (see [3])

$$\Delta_h = \mathcal{D}_1^2 + \cdots + \mathcal{D}_d^2, \tag{2.3}$$

which plays the role of Laplacian in the theory of the ordinary harmonics. In particular, the h-harmonics are the homogeneous polynomials satisfying the equation $\Delta_h Y = 0$; in other words, they are the elements of the polynomial subspace $\mathcal{H}_n^d(h^2) := \mathcal{P}_n^d \cap \ker \Delta_h$. The h-spherical harmonics are the restriction of h-harmonics on the sphere.

Basic lemma. We let $d\omega = d\omega_d$ denote the surface measure on S^d, and the surface area

$$\omega = \omega_d = \int_{S^d} d\omega_d = 2\pi^{(d+1)/2}/\Gamma((d+1)/2).$$

The standard change of variables from $\mathbf{x} \in \mathbb{R}^d$ to polar coordinates $r\mathbf{x}'$, $\mathbf{x}' \in S^{d-1}$, yields the following useful formula:

$$\int_{B^d} f(\mathbf{x}) W(\mathbf{x}) d\mathbf{x} = \int_0^1 r^{d-1} \int_{S^{d-1}} f(r\mathbf{x}') W(r\mathbf{x}') d\omega_{d-1} dr. \tag{2.4}$$

This formula connects the integral on B^d to S^{d-1} in a natural way. Our basic formula in the following establishes another relation between integrations over the unit sphere and over the unit ball.

LEMMA 2.1. *Let H be defined on $\mathbb{R}^{d+1}$. Assume that H is symmetric with respect to x_{d+1}; i.e., $H(\mathbf{x}, x_{d+1}) = H(\mathbf{x}, -x_{d+1})$, where $\mathbf{x} \in \mathbb{R}^d$. Then for any continuous function f defined on S^d,*

$$\begin{aligned}\int_{S^d} f(\mathbf{y}) H(\mathbf{y}) d\omega_d = \int_{B^d} \Big[f(\mathbf{x}, \sqrt{1-|\mathbf{x}|^2}) + f(\mathbf{x}, -\sqrt{1-|\mathbf{x}|^2}) \Big] \\ \times H(\mathbf{x}, \sqrt{1-|\mathbf{x}|^2}) d\mathbf{x} \Big/ \sqrt{1-|\mathbf{x}|^2}.\end{aligned} \tag{2.5}$$

Proof. For $\mathbf{y} \in S^d$, we write $\mathbf{y} = (\sqrt{1-t^2}\mathbf{x}, t)$, where $\mathbf{x} \in S^{d-1}$ and $-1 \le t \le 1$. Then it follows that (cf. [21, p. 436])

$$d\omega_d = (1-t^2)^{(d-2)/2} dt \, d\omega_{d-1}.$$

Starting from the change of variables $\mathbf{y} = (\sqrt{1-t^2}\mathbf{x}, t)$ in the integral, we get

$$\begin{aligned}\int_{S^d} f(\mathbf{y}) H(\mathbf{y}) d\omega_d &= \int_{-1}^1 \int_{S^{d-1}} f(\sqrt{1-t^2}\mathbf{x}, t) H(\sqrt{1-t^2}\mathbf{x}, t) d\omega_{d-1} (1-t^2)^{(d-2)/2} dt \\ &= \int_0^1 \int_{S^{d-1}} \Big[f(\sqrt{1-t^2}\mathbf{x}, t) + f(\sqrt{1-t^2}\mathbf{x}, -t) \Big] H(\sqrt{1-t^2}\mathbf{x}, t) d\omega_{d-1} (1-t^2)^{(d-2)/2} dt \\ &= \int_0^1 \int_{S^{d-1}} \Big[f(r\mathbf{x}, \sqrt{1-r^2}) + f(r\mathbf{x}, -\sqrt{1-r^2}) \Big] H(r\mathbf{x}, \sqrt{1-r^2}) d\omega_{d-1} r^{d-1} \frac{dr}{\sqrt{1-r^2}} \\ &= \int_{B^d} \Big[f(\mathbf{x}, \sqrt{1-|\mathbf{x}|^2}) + f(\mathbf{x}, -\sqrt{1-|\mathbf{x}|^2}) \Big] H(\mathbf{x}, \sqrt{1-|\mathbf{x}|^2}) \frac{d\mathbf{x}}{\sqrt{1-|\mathbf{x}|^2}},\end{aligned}$$

where in the second step we have used the symmetry of H with respect to x_{d+1}, in the third step we have changed the variable $t \mapsto \sqrt{1-r^2}$, and in the last step we have used (2.4). ∎

As a special case of this theorem, we notice that the Lebesgue measure on S^d is related to the Chebyshev weight function $1/\sqrt{1-|\mathbf{x}|^2}$ over B^d.

3. Orthogonal polynomials on spheres. Our main result in this section shows a connection between orthogonal polynomials on B^d and those on S^d, which is the surface of B^{d+1} by definition. To be more precise, we need some notation.

Throughout this section we fix the following notation: for $\mathbf{y} \in \mathbb{R}^{d+1}$, we write

$$\mathbf{y} = (y_1, \ldots, y_d, y_{d+1}) = (\mathbf{y}', y_{d+1}) = r\mathbf{x} = r(\mathbf{x}', x_{d+1}), \quad \mathbf{x} \in S^d, \quad \mathbf{x}' \in B^d, \tag{3.1}$$

where $r = |\mathbf{y}| = \sqrt{y_1^2 + \cdots + y_{d+1}^2}$ and $\mathbf{x}' = (x_1, \ldots, x_d)$.

DEFINITION 3.1. *A weight function H defined on $\mathbb{R}^{d+1}$ is called S-symmetric if it is symmetric with respect to y_{d+1} and centrally symmetric with respect to the variables $\mathbf{y}' = (y_1, \ldots, y_d)$; i.e.,*

$$H(\mathbf{y}', y_{d+1}) = H(\mathbf{y}', -y_{d+1}) \quad \textit{and} \quad H(\mathbf{y}', y_{d+1}) = H(-\mathbf{y}', y_{d+1}). \tag{3.2}$$

For examples of S-symmetric weight functions, we may take $H(\mathbf{y}) = W(\mathbf{y}')h(y_{d+1})$, where W is a centrally symmetric function on $\mathbb{R}^d$ and h is an even function on $\mathbb{R}$. There are many other examples of S-symmetric functions, including

$$H(\mathbf{y}) = \prod_{1 \le i < j \le d+1} |y_i^2 - y_j^2|^{\alpha_{ij}}, \qquad \alpha_{ij} \ge 0,$$

which becomes, when $\alpha_{ij} = \alpha$, an example of reflection invariant weight functions considered by Dunkl (associated with the octahedral group). We note that, however, the weight function $\prod_{i<j} |y_i - y_j|^\alpha$ associated with the symmetric group is not an S-symmetric function, since it is not symmetric with respect to y_{d+1}. Nevertheless, this function is centrally symmetric in $\mathbb{R}^{d+1}$. In fact, it is easy to see that S-symmetry implies central symmetry on $\mathbb{R}^{d+1}$, which we formally state in the following proposition.

PROPOSITION 3.2. *If H is an S-symmetric weight function on $\mathbb{R}^{d+1}$, then it is centrally symmetric on $\mathbb{R}^{d+1}$; that is, $H(\mathbf{y}) = H(-\mathbf{y})$ for all $\mathbf{y} \in \mathbb{R}^{d+1}$.*

In association with a weight function H on $\mathbb{R}^{d+1}$, we define a weight function W_H on B^d by

$$W_H(\mathbf{x}) = H(\mathbf{x}, \sqrt{1 - |\mathbf{x}|^2}), \qquad \mathbf{x} \in B^d. \tag{3.3}$$

If H is S-symmetric, then the assumption that H is centrally symmetric with respect to the first d variables implies that W is centrally symmetric on B^d. We denote by $\{P_k^n\}$ and $\{Q_k^n\}$ systems of orthonormal polynomials with respect to the weight functions

$$W_H^{(1)}(\mathbf{x}) = 2W_H(\mathbf{x})/\sqrt{1 - |\mathbf{x}|^2} \qquad \text{and} \qquad W_H^{(2)}(\mathbf{x}) = 2W_H(\mathbf{x})\sqrt{1 - |\mathbf{x}|^2}, \tag{3.4}$$

respectively, where we keep the convention that the superscript n means that P_k^n and Q_k^n are polynomials in Π_n^d, and the subindex k has the range $1 \le k \le r_n^d$. Keeping in mind the notation (3.1) we define

$$Y_{k,n}^{(1)}(\mathbf{y}) = r^n P_k^n(\mathbf{x}') \qquad \text{and} \qquad Y_{j,n}^{(2)}(\mathbf{y}) = r^n x_{d+1} Q_j^{n-1}(\mathbf{x}'), \tag{3.5}$$

where $1 \le k \le r_n^d$, $1 \le j \le r_{n-1}^d$, and we define $Y_{j,0}^{(2)}(\mathbf{y}) = 0$. These functions are, in fact, homogeneous polynomials in $\mathbb{R}^{d+1}$.

THEOREM 3.3. *Let H be an S-symmetric weight function defined on $\mathbb{R}^{d+1}$. Assume that W_H in (3.3) is a nonzero weight function on B^d. Then the functions $Y_{k,n}^{(1)}(\mathbf{y})$ and $Y_{k,n}^{(2)}(\mathbf{y})$ defined in (3.5) are homogeneous polynomials of degree n on $\mathbb{R}^{d+1}$ and*

$$\int_{S^d} Y_{k,n}^{(i)}(\mathbf{x}) Y_{l,m}^{(j)}(\mathbf{x}) H(\mathbf{x}) d\omega_d = \delta_{k,l}\delta_{n,m}\delta_{i,j}, \qquad i,j = 1,2.$$

Proof. From the definition of W_H in (3.3), it follows that both $W_H^{(1)}$ and $W_H^{(2)}$ in (3.4) are centrally symmetric weight functions on B^d. As a consequence, the polynomials P_k^n and Q_k^n are even functions if n is even and odd functions if n is odd. In fact, recall the notation $\mathbb{P}_n$ in section 2; it is known (cf. [22]) that there exist proper matrices $D_{n,i}$ and F_n such that

$$\mathbb{P}_{n+1} = \sum_{i=1}^{d} x_i D_{n,i}^T \mathbb{P}_n + F_n \mathbb{P}_{n-1},$$

from which this conclusion follows easily from induction (cf. [23, p. 20]). This allows us to write, for example,

$$P_k^{2n}(\mathbf{x}') = \sum_{j=0}^{n} \sum_{|\alpha|_1 = 2j} a_\alpha (\mathbf{x}')^\alpha, \qquad a_\alpha \in \mathbb{R}, \quad \mathbf{x}' \in B^d,$$

where $\alpha \in \mathbb{N}_0^d$, which implies that

$$Y_{k,2n}^{(1)}(\mathbf{y}) = r^n P_k^{2n}(\mathbf{x}') = \sum_{k=0}^{n} r^{2n-2k} \sum_{|\alpha|_1 = 2k} a_\alpha (\mathbf{y}')^\alpha.$$

Since $r^2 = y_1^2 + \cdots + y_{d+1}^2$ and $\mathbf{y}' = (y_1, \ldots, y_d)$, this shows that $Y_{k,2n}^{(1)}(\mathbf{y})$ is a homogeneous polynomial of degree $2n$ in $\mathbf{y}$. Similar proof can be adopted to show that $Y_{k,2n-1}^{(1)}$ is homogeneous of degree $2n-1$ and, using the fact $r x_{d+1} = y_{d+1}$, that $Y_{k,n}^{(2)}$ are homogeneous of degree n.

Since $Y_{k,n}^{(1)}$, when restricted to S^d, is independent of x_{d+1} and $Y_{k,2n}^{(1)}$ contains a single factor x_{d+1}, it follows that

$$\int_{S^d} Y_{k,n}^{(1)}(\mathbf{x}) Y_{l,m}^{(2)}(\mathbf{x}) H(\mathbf{x}) d\omega_d = \int_{S^d} x_{d+1} P_k^n(\mathbf{x}') Q_l^m(\mathbf{x}') H(\mathbf{x}) d\omega_d = 0$$

for any (k,n) and (l,m). By the basic formula (2.6),

$$\begin{aligned}\int_{S^d} Y_{k,n}^{(1)}(\mathbf{x}) Y_{l,m}^{(1)}(\mathbf{x}) H(\mathbf{x}) d\omega_d &= 2\int_{B^d} P_k^n(\mathbf{x}') P_l^m(\mathbf{x}') H(\mathbf{x}', \sqrt{1-|\mathbf{x}'|^2}) \frac{d\mathbf{x}'}{\sqrt{1-|\mathbf{x}'|^2}} \\ &= \int_{B^d} P_k^n(\mathbf{x}') P_l^m(\mathbf{x}') W_H^{(1)}(\mathbf{x}') d\mathbf{x}' = \delta_{k,l}\delta_{n,m}\end{aligned}$$

and similarly, using the fact that $x_{d+1}^2 = 1 - |\mathbf{x}'|^2$,

$$\begin{aligned}\int_{S^d} Y_{k,n}^{(2)}(\mathbf{x}) Y_{l,m}^{(2)}(\mathbf{x}) H(\mathbf{x}) d\omega_d &= 2\int_{B^d} (1-|\mathbf{x}'|^2) Q_k^{n-1}(\mathbf{x}') Q_l^{m-1}(\mathbf{x}') H(\mathbf{x}', \sqrt{1-|\mathbf{x}'|^2}) \\ &\quad \times \frac{d\mathbf{x}'}{\sqrt{1-|\mathbf{x}'|^2}} = \int_{B^d} Q_k^{n-1}(\mathbf{x}') Q_l^{m-1}(\mathbf{x}') W_H^{(2)}(\mathbf{x}') d\mathbf{x}' = \delta_{k,l}\delta_{n,m}.\end{aligned}$$

This completes the proof. □

The assumption that H is S-symmetry in Theorem 3.3 is necessary; it is used to show that $Y_{k,n}^{(1)}$ and $Y_{k,n}^{(2)}$ in (3.5) are indeed polynomials in $\mathbf{y}$.

Example 3.4. If $H(\mathbf{y}) = 1$, then $Y_{k,n}^{(1)}$ and $Y_{k,n}^{(2)}$ are orthonormal with respect to the surface measure $d\omega$; they are the ordinary spherical harmonics. According to Theorem 3.3, the harmonics are related to the orthogonal polynomials with respect to the radial weight functions $W_0(\mathbf{x}) = 1/\sqrt{1-|\mathbf{x}|^2}$ and $W_1(\mathbf{x}) = \sqrt{1-|\mathbf{x}|^2}$ on B^d, both of which belong to the family of weight functions $W_\mu(\mathbf{x}) = W_{\mu,d}(\mathbf{x}) = w_\mu(1-|\mathbf{x}|^2)^{\mu-\frac{1}{2}}$, $\mu > -1/2$, whose corresponding orthogonal polynomials have been studied in [1, 6, 25]. For $d = 1$, the spherical harmonics are given in the polar coordinates $(y_1, y_2) = r(x_1, x_2) = r(\cos\theta, \sin\theta)$ by the formula (1.1), which can be written as

$$Y_n^{(1)}(y_1, y_2) = r^n T_n(x_1) \quad \text{and} \quad Y_n^{(2)}(y_1, y_2) = r^n x_2 U_{n-1}(x_1),$$

where, with $t = \cos\theta$, $T_n(t) = \cos n\theta$ and $U_n(t) = \sin n\theta / \sin\theta$ are the Chebyshev polynomials of the first and the second kind, which are orthogonal with respect to $1/\sqrt{1-x^2}$ and $\sqrt{1-x^2}$, respectively. It is this example that motivates our present consideration. □

DEFINITION 3.5. *We define a subspace* $\mathcal{H}_n^{d+1}(H)$ *of* $\mathcal{P}_n^{d+1}$ *by*

$$\mathcal{H}_n^{d+1}(H) = \operatorname{span}\{Y_{k,n}^{(1)}, \quad 1 \le k \le r_n^d; \quad \textit{and} \quad Y_{j,n}^{(2)}, \quad 1 \le j \le r_{n-1}^d\}.$$

THEOREM 3.6. *Let* H *be an* S*-symmetric function on* $\mathbb{R}^{d+1}$*. For each* $n \in \mathbb{N}_0$*,*

$$\dim \mathcal{H}_n^{d+1}(H) = \binom{n+d}{d} - \binom{n+d-2}{d} = \dim \mathcal{P}_n^{d+1} - \dim \mathcal{P}_{n-2}^{d+1}.$$

Proof. From the orthogonality in Theorem 3.3, the polynomials in $\{Y_{k,n}^{(1)}, Y_{j,n}^{(2)}\}$ are linearly independent. Hence, it follows readily that

$$\dim \mathcal{H}_n^{d+1}(H) = r_n^d + r_{n-1}^d = \binom{n+d-1}{n} + \binom{n+d-2}{n-1},$$

where we use the convention that $\binom{k}{j} = 0$ if $j < 0$. Using the identity $\binom{n+m}{n} - \binom{n+m-1}{n} = \binom{n+m-1}{n-1}$, it is easy to verify that

$$\dim \mathcal{H}_n^{d+1}(H) = \binom{n+d}{d} - \binom{n+d-2}{d},$$

which is the desired result. □

THEOREM 3.7. *Let* H *be an* S*-symmetric function on* $\mathbb{R}^{d+1}$*. For* $n \in \mathbb{N}_0$*,*

$$\mathcal{P}_n^{d+1} = \bigoplus_{k=0}^{[n/2]} |\mathbf{y}|^{2k} \mathcal{H}_{n-2k}^{d+1}(H);$$

that is, if $P \in \mathcal{P}_n^{d+1}$*, then there is a unique decomposition*

$$P(\mathbf{y}) = \sum_{k=0}^{[n/2]} |\mathbf{y}|^{2k} P_{n-2k}(\mathbf{y}), \qquad P_{n-2k} \in \mathcal{H}_{n-2k}^{d+1}(H).$$

Proof. Since P is homogeneous of degree n, we can write $P(\mathbf{y}) = r^n P(\mathbf{x})$, where we use the notation in (3.1) again. According to the power of y_{d+1} being even or odd and using $x_{d+1}^2 = 1 - |\mathbf{x}'|^2$ whenever possible, we can further write

$$P(\mathbf{y}) = r^n P(\mathbf{x}) = r^n [p(\mathbf{x}') + x_{d+1} q(\mathbf{x}')],$$

where p and q are polynomials of degree at most n and $n-1$, respectively, in $\mathbf{x}' \in B^d$. Moreover, if n is even, then p is even and q is odd; if n is odd, then p is odd and q is even. Since both $\{P_k^n\}$ and $\{Q_k^n\}$ form a basis for Π_n^d and since the weight functions $W_H^{(1)}$ and $W_H^{(2)}$ in (3.4) are centrally symmetric, we have the unique expansions

$$p(\mathbf{x}') = \sum_{k=0}^{[n/2]} \sum_j a_{j,k} P_j^{n-2k}(\mathbf{x}') \quad \text{and} \quad q(\mathbf{x}') = \sum_{k=0}^{[(n-1)/2]} \sum_j b_{j,k} Q_j^{n-2k-1}(\mathbf{x}'),$$

where $1 \le j \le r_{n-2k}^d$. Therefore, by the definition of $Y_{k,n}^{(1)}$ and $Y_{k,n}^{(2)}$, we have

$$P(\mathbf{y}) = \sum_{k=0}^{[n/2]} r^{2k} \sum_j a_{j,k} Y_{j,n-2k}^{(1)}(\mathbf{y}) + \sum_{k=0}^{[(n-1)/2]} r^{2k-1} \sum_j b_{j,k} Y_{j,n-2k+1}^{(2)}(\mathbf{y}),$$

which is the desired decomposition. The uniqueness follows from the orthogonality in Theorem 3.3. □

For the spherical harmonics or h-harmonics, the above theorem is usually established using the differential or differential-difference operator (cf. [19, 2]). The importance of the results in this section lies in the fact that they provide an approach to studying orthogonal polynomials on S^d with respect to a large class of measures. For example, one of the essential ingredients in the recent work of orthogonal polynomials in several variables (cf. [22, 24]) is a three-term relation in a vector-matrix form,

$$x_i \mathbb{P}_n = A_{n,i} \mathbb{P}_{n+1} + B_{n,i} \mathbb{P}_n + A_{n-1,i}^T \mathbb{P}_{n-1},$$

where $A_{n,i}$ and $B_{n,i}$ are proper matrices, which also plays a decisive role in the study of common zeros of $\mathbb{P}_n$ and cubature formulae; the results in Theorem 3.3 show that the h-spherical harmonic polynomials that are even (or odd) in x_{d+1} also satisfy such a three-term relation.

It is worthwhile to point out that the relation between orthogonal polynomials on B^d and those on S^d goes both ways. In fact, the following result holds.

THEOREM 3.8. *Let H be a weight function defined on $\mathbb{R}^{d+1}$ which is symmetric with respect to y_{d+1}. Assume that W_H in (3.3) is a nonzero weight function on B^d. Let $Y_{k,n}^{(1)}$ be the orthonormal polynomials of degree n with respect to $H(\mathbf{y})d\omega$ on S^d that are even in y_{d+1}, and write the orthonormal polynomials that are odd in y_{d+1} as $y_{d+1} Y_{k,n-1}^{(2)}$. Then*

$$P_k^n(\mathbf{x}) = Y_{k,n}^{(1)}(\mathbf{x}, \sqrt{1-|\mathbf{x}|^2}) \quad \text{and} \quad Q_k^n(\mathbf{x}) = Y_{k,n}^{(2)}(\mathbf{x}, \sqrt{1-|\mathbf{x}|^2})$$

are orthonormal polynomials of degree n in $\mathbf{x} \in B^d$ with respect to $W_H^{(1)}$ and $W_H^{(2)}$ defined in (3.4), respectively.

Proof. The orthogonality follows easily from Lemma 2.1 as in the proof of Theorem 3.3. We show that the assumption on $Y_{k,n}^{(i)}$ is justified. Since H is symmetric

with respect to y_{d+1}, we can pick the orthogonal polynomials with respect to $Hd\omega$ on S^d as either even in y_{d+1} or odd in y_{d+1} (recall the nonuniqueness of orthonormal bases). Indeed, if Y_n is a polynomial of degree n orthogonal to lower degree polynomials with respect to $Hd\omega$, so is the polynomial $Y_n(\mathbf{y}', -y_{d+1})$ by the symmetry of H with respect to y_{d+1}. Hence, if n is even, then the polynomial $Y_n(\mathbf{y}) + Y_n(\mathbf{y}', -y_{d+1})$ is an orthogonal polynomial of degree n which is even in y_{d+1}; if n is odd, then we consider $Y_n(\mathbf{y}) - Y_n(\mathbf{y}', -y_{d+1})$ instead. Therefore, the polynomials P_k^n and Q_k^n are well defined on B^d. □

It should be noted that there is no need to assume that H is S-symmetric in the above theorem; consequently, there is no assurance that $Y_{k,n}^{(i)}$ are homogeneous.

In an effort to understand Dunkl's theory of h-harmonics, we study the orthogonal polynomials on S^d associated to $h(\mathbf{y}) = |y_1|^{\alpha_1} \cdots |y_{d+1}|^{\alpha_{d+1}}$ in detail in [26]. In particular, making use of the product structure of the measure, an orthonormal basis of h-harmonics is given in terms of the orthonormal polynomials of one variable with respect to the measure $(1-t^2)^\lambda |t|^{2\mu}$ on $[-1,1]$ (which in turn can be written in terms of Jacobi polynomials). By Theorem 3.8, we can then derive an explicit basis of orthogonal polynomials with respect to $W_H(\mathbf{x}) = |x_1|^{\alpha_1} \cdots |x_d|^{\alpha_d} (1 - |\mathbf{x}|^2)^{\alpha_{d+1}}$.

The theory of the h-harmonics developed by Dunkl recently is a rich one; it has found applications in a number of fields. For numerical work, one essential problem in dealing with h-harmonics is the construction of a workable orthonormal basis for $\mathcal{H}_n^{d+1}(h^2)$. So far, such a basis has been constructed only in the case of $h(\mathbf{y}) = |y_1|^{\alpha_1} \cdots |y_{d+1}|^{\alpha_{d+1}}$, associated to the reflection group $Z_2 \times \cdots \times Z_2$. Theorem 3.3 indicates that an explicit construction of such a basis may be difficult for the reflection invariant weight functions h associated with most of other reflection groups. We illustrate by the following example.

Example 3.9. Consider the weight function h on $\mathbb{R}^3$ defined by

$$h(y_1, y_2, y_3) = |(y_1^2 - y_2^2)(y_1^2 - y_3^2)(y_2^2 - y_3^2)|^\mu,$$

which is associated to the octahedral group; the group is generated by the reflections in $y_i = 0$, $1 \le i \le 3$, and $y_i \pm y_j = 0$, $1 \le i, j \le 3$; it is the Weyl group of type B_3. This weight function is one of the simplest nonproduct weight functions on S^2. According to Theorem 3.1, the h-harmonics associated to the function $H(\mathbf{y}) = h^2(\mathbf{y})$ are related to the orthogonal polynomials on the disc $B^2 \subset \mathbb{R}^2$ with respect to the weight function $W_H^{(1)}$ and $W_H^{(2)}$ in (3.4), where the weight function $W_H^{(1)}$ is given by

$$W_H^{(1)}(x_1, x_2) = 2|(x_1^2 - x_2^2)(1 - 2x_1^2 - x_2^2)(1 - x_1^2 - 2x_2^2)|^{2\mu} / \sqrt{1 - x_1^2 - x_2^2}, \quad (x_1, x_2) \in B^2.$$

An explicit basis for the h-harmonics will mean an explicit basis for orthogonal polynomials with respect to $W_H^{(1)}$ and vice versa. However, the form of $W_H^{(1)}$ given above indicates that it may be difficult to find a closed formula for such a basis. □

4. Cubature formula on spheres and on balls. In this section we discuss the connection between cubature formulae on spheres and on balls. For a given integral $\mathcal{L}(f) := \int f d\mu$, where $d\mu$ is a nonnegative measure with support set on B^d, a cubature formula of degree M is a linear functional

$$\mathcal{I}_M(f) = \sum_{k=1}^N \lambda_k f(\mathbf{x}_k) \ , \quad \lambda_k > 0, \quad \mathbf{x}_k \in \mathbb{R}^d,$$

defined on Π^d, such that $\mathcal{L}(f) = \mathcal{I}_M(f)$ whenever $f \in \Pi^d_M$, and $\mathcal{L}(f^*) \neq \mathcal{I}_M(f^*)$ for at least one $f^* \in \Pi^d_{M+1}$. When the measure is supported on S^d, we need to replace Π^d_M by $\bigcup_{k=0}^M \mathcal{P}_k^{d+1}$ in the above formulation and require $\mathbf{x}_k \in S^d$. The points $\mathbf{x}_1, \ldots, \mathbf{x}_N$ are called *nodes* and the numbers $\lambda_1, \ldots, \lambda_N$ are called *weights*. Such a formula is called minimal if N, the number of nodes, is minimal among all cubature formulae of degree M.

Cubature formulae on the unit sphere have important applications in numerical integration and in areas ranging from coding theory to isometric embeddings between classical Banach spaces (cf. [11, 15, 16] and the references therein). Over years, construction of cubature formulae on the unit sphere with respect to the surface measure $d\omega$ has attracted a lot of attention. For example, starting from the pioneer work of Sobolev (cf. [17]), the Russian school of mathematicians have constructed various cubature formulae on S^d that are invariant under finite groups (cf. [14, 10] and the references therein). There are also important studies on Chebyshev cubature formulae, which are formulae with equal weights (cf. [9, 11, 15] and the references therein). Nevertheless, the simple results we present below on the connection between cubature formula on balls and on spheres do not seem to have been noticed before.

THEOREM 4.1. *Let H defined on $\mathbb{R}^{d+1}$ be symmetric with respect to y_{d+1}. Suppose that there is a cubature formula of degree M on B^d for W_H defined in* (3.3)*,*

$$\int_{B^d} g(\mathbf{x}) W_H(\mathbf{x}) \frac{d\mathbf{x}}{\sqrt{1-|\mathbf{x}|^2}} = \sum_{i=1}^N \lambda_i g(\mathbf{x}_i), \qquad g \in \Pi^d_M, \tag{4.1}$$

whose N nodes lie inside the unit ball B^d; that is, $|\mathbf{x}_i| \le 1$. Then there is a cubature formula of degree M on the unit sphere S^d,

$$\begin{aligned} &\int_{S^d} f(\mathbf{y}) H(\mathbf{y}) d\omega \\ &\qquad = \sum_{i=1}^N \lambda_i \Big[f(\mathbf{x}_i, \sqrt{1-|\mathbf{x}_i|^2}) + f(\mathbf{x}_i, -\sqrt{1-|\mathbf{x}_i|^2}) \Big], \quad f \in \bigcup_{k=0}^M \mathcal{P}_k^{d+1}. \end{aligned} \tag{4.2}$$

Proof. Assuming (4.1), to prove (4.2) it suffices to prove, by Lemma 2.1, that

$$\begin{aligned} &\int_{B^d} \Big[f(\mathbf{x}, \sqrt{1-|\mathbf{x}|^2}) + f(\mathbf{x}, -\sqrt{1-|\mathbf{x}|^2}) \Big] W_H(\mathbf{x}) \frac{d\mathbf{x}}{\sqrt{1-|\mathbf{x}|^2}} \\ &\qquad = \sum_{i=1}^N \lambda_i \Big[f(\mathbf{x}_i, \sqrt{1-|\mathbf{x}_i|^2}) + f(\mathbf{x}_i, -\sqrt{1-|\mathbf{x}_i|^2}) \Big] \end{aligned} \tag{4.3}$$

for all polynomials $f \in \Pi^d_M$. We consider the basis of $\bigcup_{k=0}^M \mathcal{P}_k^{d+1}$ consisting of monomial $\{f_\alpha\}_{|\alpha|_1 \le M}$, where $f_\alpha(\mathbf{y}) = \mathbf{y}^\alpha$ and $\alpha \in \mathbb{N}^{d+1}$. If f_α is an odd function in y_{d+1}, then both the left side and the right side of (4.3) are zero, so the equality holds. If f_α is even in y_{d+1}, $|\alpha|_1 \le M$, then the function

$$f_\alpha(\mathbf{x}, \sqrt{1-|\mathbf{x}|^2}) = \mathbf{x}^{\alpha'} (1-|\mathbf{x}|^2)^{\alpha_{d+1}/2},$$

where we write $\alpha = (\alpha', \alpha_{d+1})$, is a polynomial of degree at most M in $\mathbf{x}$. Hence, it follows from the cubature formula (4.1) that

$$\int_{B^d} f(\mathbf{x}, \pm\sqrt{1-|\mathbf{x}|^2}) W_H(\mathbf{x}) \frac{d\mathbf{x}}{\sqrt{1-|\mathbf{x}|^2}} = \sum_{i=1}^N \lambda_i f(\mathbf{x}_i, \pm\sqrt{1-|\mathbf{x}_i|^2})$$

holds. Adding the above equations for $f(\mathbf{x}, \sqrt{1-|\mathbf{x}|^2})$ and for $f(\mathbf{x}, -\sqrt{1-|\mathbf{x}|^2})$ together proves (4.3). ∎

The theorem states that each cubature formula on the unit ball B^d leads to a cubature formula on the unit sphere S^d. The converse of this result is also true.

THEOREM 4.2. *Let H be a weight function on $\mathbb{R}^{d+1}$ which is symmetric with respect to x_{d+1}. Suppose that there is a cubature formula of degree M on the sphere S^d*

$$\int_{S^d} f(\mathbf{y}) H(\mathbf{y}) d\omega = \sum_{i=1}^N \lambda_i f(\mathbf{y}_i), \qquad f \in \bigcup_{k=0}^M \mathcal{P}_k^{d+1} \tag{4.4}$$

whose nodes are all located on S^d. Then there is a cubature formula of degree M on the unit ball B^d

$$2 \int_{B^d} g(\mathbf{x}) W_H(\mathbf{x}) \frac{d\mathbf{x}}{\sqrt{1-|\mathbf{x}|^2}} = \sum_{i=1}^N \lambda_i g(\mathbf{x}_i), \qquad g \in \Pi_M^d, \tag{4.5}$$

where $\mathbf{x}_i \in B^d$ are the first d components of $\mathbf{y}_i$; that is, $\mathbf{y}_i = (\mathbf{x}_i, x_{d+1,i})$.

Proof. By Lemma 2.1, the cubature formula (4.4) is equivalent to

$$\int_{B^d} \Big[f(\mathbf{x}, \sqrt{1-|\mathbf{x}|^2}) + f(\mathbf{x}, -\sqrt{1-|\mathbf{x}|^2}) \Big] W_H(\mathbf{x}) \frac{d\mathbf{x}}{\sqrt{1-|\mathbf{x}|^2}} = \sum_{i=1}^N \lambda_i f(\mathbf{y}_i). \tag{4.6}$$

If we write $\mathbf{y} = (\mathbf{x}, x_{d+1}) \in \mathbb{R}^{d+1}$, where $\mathbf{x} \in \mathbb{R}^d$, then for every monomial $g_\alpha(\mathbf{x}) = \mathbf{x}^\alpha \in \Pi_M^d$ the function f_α defined by $f_\alpha(\mathbf{y}) = g_\alpha(\mathbf{x})$ is a polynomial in $\mathcal{P}_k^{d+1}$, where $|\alpha|_1 = k \le M$. We can apply cubature formula (4.4) to it. Since f so defined is apparently even in x_{d+1}, the cubature (4.6) becomes cubature formula (4.5). ∎

Although these theorems are simple to state, they have important implications. They allow us to fit a large class of cubature formula on spheres into the structure of cubature formulae on balls, which suggests an alternative approach to study and construct cubature formulae.

Example 4.3. In the case $d = 1$, the formula (4.1) under the change of variable $x = \cos\theta$ becomes

$$\int_0^\pi g(\cos\theta) W_H(\cos\theta) d\theta = \sum_{i=1}^N \lambda_i g(\cos\theta_i).$$

On the other hand, we can write the integral over S^1 in the polar coordinates as

$$\int_{S^1} f(\mathbf{y}) H(\mathbf{y}) d\omega = \int_0^{2\pi} f(\cos\theta, \sin\theta) H(\cos\theta, \sin\theta) d\theta.$$

Since H is symmetric with respect to x_2, it follows that $W_H(\cos\theta) = H(\cos\theta, \sin\theta)$ in the notation of (3.3). Hence, (4.2) becomes

$$\int_0^{2\pi} f(\cos\theta, \sin\theta) W_H(\cos\theta) d\theta = \sum_{i=1}^N \lambda_i \Big[f(\cos\theta_i, \sin\theta_i) + f(\cos\theta_i, -\sin\theta_i) \Big].$$

From these formulae the relation between (4.1) and (4.2) is evident. ∎

In a separate paper we will present a number of examples on S^2 that are obtained using this approach. Here we concentrate on the theoretic side of the matter. What we are interested in is the minimal cubature formula, or cubature formula whose number of nodes is close to minimal.

We state the lower bounds on the number of nodes of cubature formulae, which are used to test whether a given cubature is minimal. Let us denote by N_{B^d} the number of nodes for a cubature formula on B^d, and by N_{S^d} the number of nodes for a cubature formula on S^d. It is well known (cf. [7, 18]) that

$$N_{B^d} \ge \dim \Pi_n^d = \binom{n+d}{n}, \qquad M = 2n \ \text{ or } \ M = 2n+1, \tag{4.7}$$

and

$$N_{S^d} \ge \sum_{k=0}^{n} \dim \mathcal{H}_k^{d+1} = \binom{n+d}{n} + \binom{n+d-1}{n-1}, \quad M = 2n \ \text{ or } \ M = 2n+1, \tag{4.8}$$

where the equal sign in (4.8) follows from the formula for $\dim \mathcal{H}_k^{d+1}$ (cf. Theorem 3.6 with $H = 1$) and simple computation. Moreover, for centrally symmetric weight functions there are improved lower bounds for cubature formula of odd degree, due to Möller for N_{B^d} and to Mysovskikh for N_{S^d} (cf. [13, 14]), which states that

$$N_{B^2} \ge \binom{n+2}{n} + \left[\frac{n+1}{2}\right], \qquad M = 2n+1, \tag{4.9}$$

and

$$N_{S^d} \ge 2\binom{n+d}{n}, \qquad M = 2n+1, \tag{4.10}$$

where, for simplicity, we have restricted the lower bound of N_{B^d} to the case $d = 2$.

Several characterizations of cubature formulas on B^d that attain the lower bound in (4.7), or (4.9), are known. For example, there is a cubature formula that attains the bound (4.7) for $M = 2n+1$ if, and only if, the corresponding orthogonal polynomials $P_1^{n+1}, \ldots, P_{r_{n+1}^d}^{n+1}$ of degree $n+1$ have $\dim \Pi_n^d$ many distinct real common zeros. The characterization for the case (4.7) with $M = 2n$ and the case (4.9) for centrally symmetric weight functions will involve common zeros of quasi-orthogonal polynomials. For these characterizations and extensions of them we refer to [12, 14, 23, 24] and the references therein. In view of the results in section 3, we see that when H is centrally symmetric, we can relate these characterizations to orthogonal polynomials on spheres.

Let us consider the number of nodes of the cubature formulae in (4.2) and (4.5).

Remark 4.4. In Theorem 4.1, the number of nodes in the cubature formula (4.2) may be less than $2N$, since if one of the nodes of (4.1), say $\mathbf{x}_i$, lies on the boundary $\partial B^d = S^{d-1}$, then $|\mathbf{x}_i| = 1$ and two nodes $(\mathbf{x}_i, \sqrt{1-|\mathbf{x}_i|^2})$ and $(\mathbf{x}_i, -\sqrt{1-|\mathbf{x}_i|^2})$ in (4.2) become one. That is,

$$\text{number of nodes of (4.2)} = 2N - \text{number of } \mathbf{x}_i \text{ on } S^{d-1}. \tag{4.11}$$

Similarly, in Theorem 4.2, the number of nodes in the cubature formula (4.5) may be less than N, since different $\mathbf{y}_i \in S^d$ may have the same first d components, which

happens when $\mathbf{y}_i$ and $\mathbf{y}_j$ form a *symmetric pair* with respect to the last component; i.e., $\mathbf{y}_i = (\mathbf{x}_i, x_{d+1})$ and $\mathbf{y}_j = (\mathbf{x}_i, -x_{d+1})$ with $x_{d+1} \neq 0$. We conclude that

(4.12) number of nodes of (4.5) = N − number of symmetric pairs among $\mathbf{y}_i$.

Clearly, the number of nodes in (4.5) satisfies a lower bound $N/2$, which is attained when the nodes of (4.4) consist of only symmetric pairs. □

It is important to remark that even if the cubature formula (4.1) on B^d in Theorem 4.1 attains the lower bound (4.7) or (4.9), the cubature formula (4.2) on S^d may not attain the lower bound (4.8) or (4.10), respectively. For example, when $d = 1$, the formula (4.1) for $M = 2n+1$ attains the lower bound (4.7) with $N_{B^1} = n+1$, which is the classical Gaussian quadrature formula. On the other hand, the corresponding formula in (4.2) attains the lower bound (4.8) with $N_{S^1} = 2n+1$ only when $x = 1$ or $x = -1$ is a node of (4.1), which does not hold in general since the nodes of a Gaussian quadrature formula on $[-1, 1]$ are zeros of orthogonal polynomials and are located in $(-1, 1)$.

As an immediate consequence of these lower bounds and Theorems 4.1 and 4.2, we formulate a corollary that seems to be of independent interest.

COROLLARY 4.5. *Let H be an S-symmetric weight function on $\mathbb{R}^3$. If there is a cubature formula of degree $2n+1$ with respect to H on S^2 that attains the lower bound in* (4.10)*, then it contains at least $2[(n+1)/2]$ nodes which are not symmetric with respect to x_3.*

Proof. Assume that a cubature formula with respect to H on S^2 exists which attains the lower bound in (4.10). Let E be the number of symmetric pairs among the nodes of the cubature. By Theorem 4.2 and (4.12), there is a cubature formula on B^2 with $N_{S^2} - E = 2\binom{n+2}{n} - E$ many nodes. Moreover, the weight function associated with the new cubature formula is centrally symmetric on B^2. Hence, by (4.9), we have the inequality that

$$N_{S^2} - E = 2\binom{n+2}{n} - E \geq \binom{n+2}{n} + \Big[\frac{n+1}{2}\Big],$$

from which we get an upper bound for E. Evidently, the number of nodes that do not contain symmetric pairs is equal to $N_{S^2} - 2E$. Hence, the upper bound for E leads to a lower bound on the number of nodes that are not symmetric with respect to x_3, which gives the desired result. □

In particular, if the cubature formula on S^2 is symmetric with respect to x_3, which means that the node of the cubature always contains the pair (x_1, x_2, x_3) and $(x_1, x_2, -x_3)$ whenever $x_3 > 0$, then there are at least $2[(n+1)/2]$ many nodes on the largest circle $x_1^2 + x_2^2 = 1$ which is perpendicular to x_3 axis. Results as such provide necessary conditions on the minimal cubature formulae; they may provide insight in the construction of the minimal formula or can be used to prove that such a formula does not exist. An analogue of Corollary 4.5 is as follows.

COROLLARY 4.6. *If there is a cubature formula on B^2 that attains the lower bound in* (4.9) *with all nodes in B^2, then it can have no more than $2[(n+1)/2]$ points on the boundary $\partial B^2 = S^1$.*

Proof. If a cubature formula on B^2 as stated exists which attains the lower bound (4.9), then by Theorem 4.1 and (4.11) there is a cubature formula on S^2 with

$$N_{S^2} = 2\binom{n+2}{n} + 2\Big[\frac{n+1}{2}\Big] - \text{number of nodes on } S^1.$$

The desired result then follows from the lower bound (4.10). ∎

We conclude this paper with another simple application dealing with Chebyshev cubature formulae, which are cubature formulae with equal weights. It is proved in [9] that the number of nodes of a Chebyshev cubature formula of degree M with respect to $1/\sqrt{1-|\mathbf{x}|^2}$on B^2 is of order $\mathcal{O}(M^3)$. Furthermore, it is conjectured there that the number of nodes of a Chebyshev cubature formula of degree M with respect to the surface measure on S^2 is of order $\mathcal{O}(M^2)$.

COROLLARY 4.7. *If there is a Chebyshev cubature formula of degree M with respect to the surface measure on S^2 whose number of nodes is of order $\mathcal{O}(M^2)$, then its nodes cannot all be symmetric with respect to a plane that contains one largest circle of S^2 and none of the nodes.*

Indeed, if such a cubature formula exists, we may assume that the plane is the coordinate plane perpendicular to the x_3 axis since the integral is invariant under rotation. Then there are an even number of nodes and all nodes form symmetric pairs. Therefore, by Theorem 4.2, there would be a Chebyshev cubature formula of degree M with respect to $1/\sqrt{1-|\mathbf{x}|^2}$ on B^2 with the number of nodes in the order of $\mathcal{O}(M^2)$, which leads to a contradiction.

Acknowledgment. The author thanks a referee for his careful review and helpful suggestions.

CONVOLUTIONS FOR ORTHOGONAL POLYNOMIALS FROM LIE AND QUANTUM ALGEBRA REPRESENTATIONS*

H. T. KOELINK† AND J. VAN DER JEUGT‡

Abstract. The interpretation of the Meixner–Pollaczek, Meixner, and Laguerre polynomials as overlap coefficients in the positive discrete series representations of the Lie algebra $\mathfrak{su}(1,1)$ and the Clebsch–Gordan decomposition lead to generalizations of the convolution identities for these polynomials. Using the Racah coefficients, convolution identities for continuous Hahn, Hahn, and Jacobi polynomials are obtained. From the quantized universal enveloping algebra for $\mathfrak{su}(1,1)$, convolution identities for the Al-Salam and Chihara polynomials and the Askey–Wilson polynomials are derived by using the Clebsch–Gordan and Racah coefficients. For the quantized universal enveloping algebra for $\mathfrak{su}(2)$, q-Racah polynomials are interpreted as Clebsch–Gordan coefficients, and the linearization coefficients for a two-parameter family of Askey–Wilson polynomials are derived.

Key words. orthogonal polynomials, convolution, Lie algebra, quantum algebra

1. Introduction.

The representation theory of Lie algebras and quantum algebras, or quantized universal enveloping algebras [9], is intimately linked to special functions of (basic) hypergeometric type; see, e.g., [35], [9]. In this paper we consider especially the Lie algebra $\mathfrak{su}(1,1)$ and its quantum analogue $U_q(\mathfrak{su}(1,1))$, and we derive convolution identities for certain orthogonal polynomials which occur as overlap coefficients. The idea, which is due to Granovskii and Zhedanov [15], [16], [17], see also [34], is to consider (generalized) eigenvectors of a suitable element of the Lie algebra which is a recurrence operator in an irreducible representation of this Lie algebra. Then there is a relation between these eigenvectors and the eigenvectors of this Lie algebra element in the n-fold tensor product of irreducible representations of the Lie algebra. From the tensor product decomposition in irreducible representations for $n = 2, 3$, we obtain identities for these eigenvectors involving Clebsch–Gordan and Racah coefficients. In particular, if the overlap coefficients are known in terms of special functions, we obtain identities for these special functions in this way.

For the Lie algebra $\mathfrak{su}(1,1)$ and the positive discrete series representations, a special case of this approach is contained in Granovskii and Zhedanov [16], but the result is not worked out in detail. Elaborating the method of Granovskii and Zhedanov, Van der Jeugt [34] obtains a generalization of the classical convolution identity for the Laguerre polynomials [13, section 10.12, eq. (41)]. Van der Jeugt [34] also considers the boson Lie algebra $\mathfrak{b}(1)$, a central extension of the oscillator algebra, leading to a generalization of the convolution identity for Hermite polynomials [13, section

10.13, eq. (38)]. The last identity follows from the previous one by a well-known limit transition of Laguerre polynomials to Hermite polynomials; see, e.g., [22].

Apart from the Laguerre and the Hermite polynomials, the Meixner–Pollaczek, Meixner, and Charlier polynomials, which all fit into the Askey scheme of hypergeometric orthogonal polynomials [5], [22], also satisfy a convolution identity of the same form. This is a straightforward consequence of the existence of a generating function of a special kind; see Al-Salam [1]. It is also known that the Meixner–Pollaczek and the Meixner polynomials can be interpreted as overlap coefficients in the positive discrete series representations of $\mathfrak{su}(1,1)$; see Masson and Repka [29]. In section 3 we show how the method of Granovskii and Zhedanov for the two-fold tensor product of positive discrete series representations of $\mathfrak{su}(1,1)$ leads to a generalization of the convolution identity for Meixner–Pollaczek polynomials, from which generalized convolution formulas for Meixner, Laguerre, Charlier, and Hermite polynomials can be obtained by substitution or by limit transitions. Next, using the three-fold tensor product representation, we obtain a very general convolution identity for continuous Hahn polynomials, and similarly for the Hahn and Jacobi polynomials. These identities can also be viewed as yielding connection coefficients between two sets of orthogonal polynomials in two variables with respect to the same orthogonality measure. With this point of view, this result coincides with Dunkl's results [11], [12]. Our derivation gives an intrinsic explanation for the occurrence of balanced ${}_4F_3$-series as connection coefficients; they are Racah coefficients. Actually, the interpretation as orthogonal polynomials in two variables works in general and is an intrinsic way to determine the S-functions in [16] and [34] in terms of orthogonal polynomials instead of reducing a triple sum to a single sum.

In section 4 we apply the same idea to the quantized universal enveloping algebra $U_q(\mathfrak{su}(1,1))$ and its positive discrete series representations. Due to the noncocommutativity of the comultiplication, which is needed to define the tensor product representation, the tensor product of eigenvectors is no longer an eigenvector in the tensor product representation. This can be solved if we restrict to operators related to so-called twisted primitive elements in $U_q(\mathfrak{su}(1,1))$; see, e.g., [28], [24]. Then the whole machinery works and we obtain a generalization of the Al-Salam and Chihara [2] convolution identity for the Al-Salam and Chihara polynomials by considering the Clebsch–Gordan coefficients in the two-fold tensor product. Going to the three-fold tensor product representations yields a very general convolution identity for Askey–Wilson polynomials also involving q-Racah polynomials, and Theorem 4.10 is the key result of this paper. Overlap coefficients are also considered in somewhat more generality in Klimyk and Kachurik [21], but we have to restrict ourselves to the twisted primitive elements in order to keep the action in the tensor product representations manageable.

It is interesting to note that in this derivation we have a natural interpretation of the continuous Hahn, Hahn, and Jacobi polynomials as Clebsch–Gordan coefficients for the Lie algebra $\mathfrak{su}(1,1)$. Similarly, we have an interpretation of the Askey–Wilson polynomials as Clebsch–Gordan coefficients for the quantized universal enveloping algebra $U_q(\mathfrak{su}(1,1))$. In section 5 we shortly discuss the corresponding result for the quantized universal enveloping algebra $U_q(\mathfrak{su}(2))$, where the q-Racah polynomials then occur as Clebsch–Gordan coefficients. This case can be obtained formally from the results for $U_q(\mathfrak{su}(1,1))$. Since in the dual Hopf $*$-algebra the so-called zonal spherical elements are known in terms of a two-parameter family of Askey–Wilson polynomials, cf. [28], we obtain the explicit linearization coefficients for this subfamily of the Askey–Wilson polynomials.

It should be remarked that there does not seem to be an appropriate q-analogue of the boson Lie algebra $\mathfrak{b}(1)$. Either the Hopf $*$-algebra structure is lacking, or, as in [19], the recurrence in the two-fold tensor product representation seems unmanageable.

Instead of using generalized eigenvectors we use the spectral theory of Jacobi matrices, which we recall briefly in section 2. In particular we use this theory to interpret certain recurrence operators in $\ell^2(\mathbb{Z}_+)^{\otimes n}$, $n = 1, 2, 3$, as multiplication operators in certain weighted L^2-spaces on $\mathbb{R}^n$. This approach exploits the theory of orthogonal polynomials; cf. Propositions 3.3 and 4.3.

The notation for (basic) hypergeometric series is the standard one as in Gasper and Rahman [14]. Unexplained notions for quantized universal enveloping algebras can be found in Chari and Pressley [9].

2. Jacobi matrices and orthogonal polynomials. We recall some of the results on the spectral theory of Jacobi matrices and the relation with orthogonal polynomials. For more information we refer to Berezanskiĭ [7, Chap. VII, section 1]; see also Masson and Repka [29] and Klimyk and Kachurik [21]. The operator J acting on the standard orthonormal basis $\{e_n \mid n \in \mathbb{Z}_+\}$ of $\ell^2(\mathbb{Z}_+)$ by

$$Je_n = a_n\, e_{n+1} + b_n\, e_n + a_{n-1}\, e_{n-1}, \qquad a_n > 0,\ b_n \in \mathbb{R}, \tag{2.1}$$

is called a Jacobi matrix. This operator is symmetric, and its deficiency indices are $(0,0)$ or $(1,1)$. In particular, if the coefficients a_n and b_n are bounded, J is a bounded operator on $\ell^2(\mathbb{Z}_+)$ and thus self-adjoint. J is a self-adjoint operator, possibly unbounded, if $\sum_{n=0}^{\infty} a_n^{-1} = \infty$ by Carleman's condition. Then e_0 is a cyclic vector for J; i.e., the span of finite linear combinations of the form $J^p e_0$, $p \in \mathbb{Z}_+$, is dense in $\ell^2(\mathbb{Z}_+)$. This is the case for all Jacobi matrices considered in this paper.

Assuming this, we can use the same coefficients a_n, b_n to generate polynomials $p_n(x)$ of degree n in x by the recurrence relation

$$xp_n(x) = a_n\, p_{n+1}(x) + b_n\, p_n(x) + a_{n-1}\, p_{n-1}(x), \qquad p_{-1}(x) = 0,\ p_0(x) = 1. \tag{2.2}$$

By Favard's theorem there exists a positive measure m on the real line such that the polynomials $p_n(x)$ are orthonormal;

$$\int_{\mathbb{R}} p_n(x) p_m(x)\, dm(x) = \delta_{n,m}.$$

The measure is obtained by $m(B) = \langle E(B)e_0, e_0\rangle$, B Borel set, where E denotes the spectral decomposition of the self-adjoint operator J.

We can represent the operator J as a multiplication operator M_x on $L^2(m)$, where $M_x f(x) = xf(x)$. For this we define

$$\Lambda\colon \ell^2(\mathbb{Z}_+) \to L^2(m), \qquad \big(\Lambda e_n\big)(x) = p_n(x);$$

then Λ is a unitary operator, since it maps an orthonormal basis onto an orthonormal basis. Note that we use here that the polynomials are dense in $L^2(m)$, since the self-adjointness of J implies that the corresponding moment problem is determined. From (2.1) and (2.2) it follows that $\Lambda \circ J = M_x \circ \Lambda$, so Λ intertwines the Jacobi matrix J on $\ell^2(\mathbb{Z}_+)$ with the multiplication operator M_x on $L^2(m)$.

3. The case $\mathfrak{su}(1,1)$. The Lie algebra $\mathfrak{su}(1,1)$ is given by

$$[H,B]=2B, \qquad [H,C]=-2C, \qquad [B,C]=H.$$

There is a $*$-structure by $H^*=H$ and $B^*=-C$.

The positive discrete series representations π_k of $\mathfrak{su}(1,1)$ are unitary representations labelled by $k>0$. The representation space is $\ell^2(\mathbb{Z}_+)$ equipped with orthonormal basis $\{e_n^k\}_{\{n\in\mathbb{Z}_+\}}$. The action is given by

$$\begin{aligned}\pi_k(H)\,e_n^k &= 2(k+n)\,e_n^k,\\ \pi_k(B)\,e_n^k &= \sqrt{(n+1)(2k+n)}\,e_{n+1}^k,\\ \pi_k(C)\,e_n^k &= -\sqrt{n(2k+n-1)}\,e_{n-1}^k.\end{aligned} \tag{3.1}$$

The tensor product of two positive discrete series representations decomposes as

$$\pi_{k_1}\otimes\pi_{k_2}=\bigoplus_{j=0}^{\infty}\pi_{k_1+k_2+j}. \tag{3.2}$$

The corresponding intertwining operator can be expressed by means of the Clebsch–Gordan coefficients

$$e_n^k=\sum_{n_1,n_2} C_{n_1,n_2,n}^{k_1,k_2,k}\,e_{n_1}^{k_1}\otimes e_{n_2}^{k_2}. \tag{3.3}$$

Later we also use the notation $e_n^{(k_1k_2)k}$ for e_n^k to stress the fact that this vector arises from the decomposition $\pi_{k_1}\otimes\pi_{k_2}$ into irreducible representations. The Clebsch–Gordan coefficients are nonzero only if $n_1+n_2=n+j$, $k=k_1+k_2+j$ for $j,n_1,n_2,n\in\mathbb{Z}_+$ by considering the action of H on both sides. We normalize the Clebsch–Gordan coefficients by $\langle e_0^k, e_0^{k_1}\otimes e_j^{k_2}\rangle>0$.

For the above results Vilenkin and Klimyk [35, section 8.7] can be consulted.

3.1. Clebsch–Gordan coefficients and orthogonal polynomials. The Meixner–Pollaczek polynomials are defined by

$$P_n^{(\lambda)}(x;\phi)=\frac{(2\lambda)_n}{n!}e^{in\phi}\,{}_2F_1\left(\begin{matrix}-n,\lambda+ix\\ 2\lambda\end{matrix};1-e^{-2i\phi}\right). \tag{3.4}$$

For $\lambda>0$ and $0<\phi<\pi$, these are orthogonal polynomials with respect to a positive measure on $\mathbb{R}$; see [22], [33, App.], and references therein. The orthonormal Meixner–Pollaczek polynomials

$$p_n(x)=p_n^{(\lambda)}(x;\phi)=\sqrt{\frac{n!}{\Gamma(n+2\lambda)}}P_n^{(\lambda)}(x;\phi)$$

satisfy the three-term recurrence relation

$$\begin{aligned}2x\,\sin\phi\,p_n(x) &= a_n\,p_{n+1}(x)-2(n+\lambda)\cos\phi\,p_n(x)+a_{n-1}\,p_{n-1}(x),\\ a_n &= \sqrt{(n+1)(n+2\lambda)}.\end{aligned}$$

The orthogonality measure for Meixner–Pollaczek polynomials is absolutely continuous. Define

$$w^{(\lambda)}(x;\phi)=\frac{(2\sin\phi)^{2\lambda}}{2\pi}e^{(2\phi-\pi)x}\left|\Gamma(\lambda+ix)\right|^2;$$

then

$$\int_{\mathbb{R}} p_n^{(\lambda)}(x;\phi)p_m^{(\lambda)}(x;\phi)\, w^{(\lambda)}(x;\phi)dx = \delta_{nm}.$$

Define the self-adjoint element in $\mathfrak{su}(1,1)$;

$$X_\phi = -\cos\phi\, H + B - C. \tag{3.5}$$

PROPOSITION 3.1. $\Lambda\colon \ell^2(\mathbb{Z}_+) \to L^2(\mathbb{R}, w^{(k)}(x;\phi)dx)$, $e_n^k \mapsto p_n^{(k)}(\cdot;\phi)$, *is a unitary mapping intertwining* $\pi_k(X_\phi)$ *acting in* $\ell^2(\mathbb{Z}_+)$ *with* $M_{2x\sin\phi}$ *on* $L^2(\mathbb{R}, w^{(k)}(x;\phi)dx)$.

Here, and elsewhere, M_g denotes multiplication by the function g, so $M_g f(x) = g(x)f(x)$.

Proof. Use (3.1) and (3.5) to see that $\pi_k(X_\phi)$ is a Jacobi matrix. Next compare the coefficients with the three-term recurrence relation for the orthonormal Meixner–Pollaczek polynomials to find the result as in section 2. □

Proposition 3.1 states that $v^k(x) = \sum_{n=0}^\infty p_n^{(k)}(x;\phi)\, e_n^k$ is a generalized eigenvector for $\pi_k(X_\phi)$ for the eigenvalue $2x\sin\phi$. Next we study the action of X_ϕ in the tensor product representation $\pi_{k_1}\otimes\pi_{k_2}$. Recall that $\Delta(X_\phi) = 1\otimes X_\phi + X_\phi\otimes 1$.

PROPOSITION 3.2. $\Upsilon\colon \ell^2(\mathbb{Z}_+)\otimes\ell^2(\mathbb{Z}_+) \to L^2(\mathbb{R}^2, w^{(k_1)}(x_1;\phi)w^{(k_2)}(x_2;\phi)dx_1dx_2)$, *defined by* $e_{n_1}^{k_1}\otimes e_{n_2}^{k_2} \mapsto p_{n_1}^{(k_1)}(x_1;\phi)p_{n_2}^{(k_2)}(x_2;\phi)$, *is a unitary mapping intertwining* $\pi_{k_1}\otimes\pi_{k_2}(\Delta(X_\phi))$ *with* $M_{2(x_1+x_2)\sin\phi}$.

Proof. This can be seen by using the mapping Λ of Proposition 3.1 in the second tensor factor and solving the resulting three-term recurrence in the first factor. □

Proposition 3.2 states that

$$v^{k_1,k_2}(x_1,x_2) = \sum_{n_1,n_2=0}^\infty p_{n_1}^{(k_1)}(x_1;\phi)p_{n_2}^{(k_2)}(x_2;\phi)\; e_{n_1}^{k_1}\otimes e_{n_2}^{k_2}$$

are generalized eigenvectors for $\pi_{k_1}\otimes\pi_{k_2}(\Delta(X_\phi))$ for the eigenvalue $2(x_1+x_2)\sin\phi$.

So Υ maps the basis $e_{n_1}^{k_1}\otimes e_{n_2}^{k_2}$ onto orthonormal polynomials in two variables. By the Clebsch–Gordan decomposition (3.2) there exists another orthonormal basis e_n^k for the tensor product representation space. So Υe_n^k gives another set of orthonormal polynomials in two variables in $L^2(\mathbb{R}^2, w^{(k_1)}(x_1;\phi)w^{(k_2)}(x_2;\phi)dx_1dx_2)$.

In order to formulate the result we need the continuous Hahn polynomials introduced by Atakishiyev and Suslov [6], for which we use Askey's [3] notation; see also [22], [23];

$$p_n(x;a,b,c,d) = i^n\frac{(a+c)_n(a+d)_n}{n!}\,{}_3F_2\left(\begin{matrix}-n, n+a+b+c+d-1, a+ix\\ a+c,\ a+d\end{matrix};1\right), \tag{3.6}$$

satisfying the orthogonality relations for $\Re(a,b,c,d) > 0$,

$$\frac{1}{2\pi}\int_{\mathbb{R}}\Gamma(a+ix)\Gamma(b+ix)\Gamma(c-ix)\Gamma(d-ix)\, p_n(x;a,b,c,d)p_m(x;a,b,c,d)\,dx$$
$$= \delta_{nm}\frac{\Gamma(n+a+c)\Gamma(n+a+d)\Gamma(n+b+c)\Gamma(n+b+d)}{n!\,(2n+a+b+c+d-1)\Gamma(n+a+b+c+d-1)}.$$

The orthogonality measure is positive for $a=\bar{c}$, $b=\bar{d}$.

PROPOSITION 3.3. *In* $L^2(\mathbb{R}^2, w^{(k_1)}(x_1;\phi)w^{(k_2)}(x_2;\phi)dx_1dx_2)$ *we have*

$$\Upsilon e_n^k(x_1,x_2) = p_n^{(k)}(x_1+x_2;\phi)\,\Upsilon e_0^k(x_1,x_2),$$
$$\Upsilon e_0^k(x_1,x_2) = Cp_j(x_1;k_1,k_2-i(x_1+x_2),k_1,k_2+i(x_1+x_2)),$$
$$C = (-2\sin\phi)^j\sqrt{\frac{j!\,(2j+2k_1+2k_2-1)\Gamma(j+2k_1+2k_2-1)}{\Gamma(2k_1+j)\Gamma(2k_2+j)}}.$$

Note that $\Upsilon e_0^k(x_1,x_2)$ is indeed a polynomial in x_1, x_2.

Proof. The first statement follows from use of the intertwining of Proposition 3.2 and the intertwining of (3.2);

$$2(x_1+x_2)\sin\phi\,\Upsilon e_n^k(x_1,x_2) = M_{2(x_1+x_2)\sin\phi}\Upsilon e_n^k(x_1,x_2) = \big(\Upsilon\pi_k(X_\phi)\,e_n^k\big)(x_1,x_2),$$

which gives a three-term recurrence relation for Υe_n^k with respect to n of the same form as in Proposition 3.1. Taking into account the initial conditions proves the first statement.

To prove the second statement we note that for $k=k_1+k_2+j$, $l=k_1+k_2+i$,

$$\delta_{ij}\delta_{mn} = \langle e_n^k, e_m^l\rangle = \langle \Upsilon e_n^k, \Upsilon e_m^l\rangle = \int\!\!\int_{\mathbb{R}^2} p_n^{(k)}(x_1+x_2;\phi)p_m^{(l)}(x_1+x_2;\phi)$$
$$\times\Big(\Upsilon e_0^k(x_1,x_2)\Upsilon e_0^l(x_1,x_2)\Big)w^{(k_1)}(x_1;\phi)w^{(k_2)}(x_2;\phi)\,dx_1dx_2$$

by the first statement and Proposition 3.2. Introduce $s=x_1+x_2$, $t=x_1$; then we find

$$\delta_{ij}\delta_{mn} = \int_{\mathbb{R}} p_n^{(k)}(s;\phi)p_m^{(l)}(s;\phi)\int_{\mathbb{R}}\Upsilon e_0^k(t,s-t)\Upsilon e_0^l(t,s-t)w^{(k_1)}(t;\phi)w^{(k_2)}(s-t;\phi)\,dtds.$$

In case $k=l$, or $i=j$, we see that the inner integral must equal the normalized orthogonality measure for the Meixner–Pollaczek polynomials $p_n^{(k)}(s;\phi)$, since the corresponding moment problem is determined. In case $k\neq l$, or $i\neq j$, we conclude that the inner integral integrated against any polynomial gives zero, so it must be zero since the polynomials are dense in $L^2(\mathbb{R}^2, w^{(k_1)}(x_1;\phi)w^{(k_2)}(x_2;\phi)dx_1dx_2)$. So we get

$$\delta_{ij}w^{(k)}(s;\phi) = e^{(2\phi-\pi)s}\frac{(2\sin\phi)^{2k_1+2k_2}}{4\pi^2}\int_{\mathbb{R}}\Upsilon e_0^k(t,s-t)\Upsilon e_0^l(t,s-t)$$
$$\times\,\Gamma(k_1+it)\Gamma(k_2-is+it)\Gamma(k_1-it)\Gamma(k_2+is-it)\,dt.$$

Apply Υ to (3.3) for $n=0$ to see that $\Upsilon e_0^k(t,s-t)$ is a polynomial of degree j in t. Hence, $\Upsilon e_0^k(t,s-t)$ is a multiple of a continuous Hahn polynomial of degree j with the parameters as in Proposition 3.3.

The value of the constant follows from comparing the squared norms up to a sign. The sign is determined from the condition on the Clebsch–Gordan coefficients. This implies $0<\langle\Upsilon e_0^k, \Upsilon e_0^{k_1}\otimes e_j^{k_2}\rangle$, and using the first two parts of Proposition 3.3 and Proposition 3.2 shows that the sign of C follows from the sign of a double integral of two orthogonal polynomials. Only the integral over x_2 is relevant, and the sign of C equals the sign of the leading coefficient of the continuous Hahn polynomials viewed as a polynomial in x_2, which is $(-1)^j$. ∎

So we can now apply Υ to (3.3) to find $k = k_1 + k_2 + j$,

$$\sum_{n_1+n_2=n+j} C^{k_1,k_2,k}_{n_1,n_2,n}\, p^{(k_1)}_{n_1}(x_1;\phi) p^{(k_2)}_{n_2}(x_2;\phi) = C p^{(k)}_n(x_1+x_2;\phi) \times p_j(x_1;k_1,k_2-i(x_1+x_2),k_1,k_2+i(x_1+x_2)). \tag{3.7}$$

The Clebsch–Gordan coefficients remain to be determined, and this can be done from this formula; see [34]. They can be expressed in terms of ${}_3F_2$-series, which are known as Hahn polynomials. Using the Hahn polynomials defined by

$$Q_n(x;a,b,N) = {}_3F_2\left(\begin{matrix} -n, n+a+b+1, -x \\ a+1,\ -N \end{matrix};1\right) \tag{3.8}$$

for $N \in \mathbb{Z}_+$, $0 \le n \le N$, we have, with $k = k_1 + k_2 + j$, $n_1 + n_2 = n + j$,

$$C^{k_1,k_2,k}_{n_1,n_2,n} = \sqrt{\frac{(2k_1)_{n_1}(2k_2)_{n_2}(2k_1)_j}{n!n_1!n_2!j!\,(2k_1+2k_2+2j)_n(2k_2)_j(2k_1+2k_2+j-1)_j}} \times (n+j)!\,Q_j(n_1;2k_1-1,2k_2-1;n+j);$$

see [35, section 8.7] for another proof.

Using this in (3.7) gives an identity in a weighted L^2-space, but since it is a polynomial identity it holds for all x_1, x_2. Simplifying proves the following theorem.

THEOREM 3.4. *With the notation for continuous Hahn, Meixner–Pollaczek, and Hahn polynomials as in* (3.4), (3.6), *and* (3.8), *the following convolution formula holds*:

$$\binom{n+j}{n} \sum_{l=0}^{n+j} Q_j(l;2k_1-1,2k_2-1,n+j)\, P^{(k_1)}_l(x_1;\phi)\, P^{(k_2)}_{n+j-l}(x_2;\phi) = \frac{(-2\sin\phi)^j}{(2k_1)_j}\, P^{(k_1+k_2+j)}_n(x_1+x_2;\phi)\, p_j(x_1;k_1,k_2-i(x_1+x_2),k_1,k_2+i(x_1+x_2)).$$

Remark 3.5. (i) The case $j = 0$ gives back the convolution identity for the Meixner–Pollaczek polynomials; see, e.g., [1, section 8], [2]. The case $n = 0$ gives another convolution identity for Meixner–Pollaczek polynomials, since the Hahn polynomial reduces to a summable ${}_2F_1$-series.

(ii) The polynomials on both sides of the formula in Theorem 3.4 are orthogonal polynomials in two variables for the space $L^2(\mathbb{R}^2, w^{(k_1)}(x_1;\phi)w^{(k_2)}(x_2;\phi)dx_1dx_2)$, so we have proved a connection coefficient formula for these polynomials. The dual connection coefficient formula follows from the orthogonality of the Clebsch–Gordan matrix, or equivalently, from the orthogonality relations for the dual Hahn polynomials.

(iii) Theorem 3.4 shows that the continuous Hahn polynomials have an interpretation as Clebsch–Gordan coefficients for $\mathfrak{su}(1,1)$. Using the generalized eigenvectors, we formally have, cf. (3.3),

$$v^{k_1,k_2}(x_1,x_2) = \sum_k C\, p_j(x_1;k_1,k_2-i(x_1+x_2),k_1,k_2+i(x_1+x_2))\, v^k(x_1+x_2),$$

with C as in Proposition 3.3. The dual relations can be written using the orthogonality measure for the continuous Hahn polynomials.

Recall the Laguerre polynomials $L_n^{(a)}(x) = (a+1)_n/n!\,{}_1F_1(-n;a+1;x)$, the Jacobi polynomials $P_n^{(a,b)}(x) = \frac{(a+1)_n}{n!}\,{}_2F_1(-n,n+a+b+1;a+1;(1-x)/2)$, and the Meixner polynomials $M_n(x;\beta;c) = {}_2F_1(-n,-x;\beta;1-c^{-1})$; see [1], [33].

COROLLARY 3.6 (see [34]). (i) *The Laguerre polynomials satisfy the following convolution identity:*

$$\sum_{l=0}^{n+j} Q_j(l;a,b,n+j)\,L_l^{(a)}(x_1)\,L_{n+j-l}^{(b)}(x_2) = \frac{(-1)^j n!\,j!}{(a+1)_j(n+j)!} \times L_n^{(a+b+1+2j)}(x_1+x_2)\,(x_1+x_2)^j P_j^{(a,b)}\left(\frac{x_2-x_1}{x_1+x_2}\right).$$

(ii) *The Meixner polynomials satisfy the following convolution identity:*

$$(c^{-1}-1)^{-j}\sum_{l=0}^{n+j}\frac{(a)_l(b)_{n+j-l}}{l!\,(n+j-l)!}Q_j(l;a-1,b-1,n+j)\,M_l(x_1;a;c)\,M_{n+j-l}(x_2;b;c)$$
$$= \frac{(a+b+2j)_n}{(n+j)!}\,M_n(x_1+x_2-j;a+b+2j;c)\,(-x_1-x_2)_j Q_j(x_1;a-1,b-1,x_1+x_2).$$

Proof. The first case follows from the limit transition of the Meixner–Pollaczek polynomials to the Laguerre polynomials; $\lim_{\phi\downarrow 0} P_n^{((a+1)/2)}(-2x/\phi;\phi) = L_n^{(a)}(x)$. In this limit transition the continuous Hahn polynomials tend to the Jacobi polynomials.

The second case follows from the substitution $\phi = \ln c/2i$ and replacing x_1 and x_2 by ik_1+ix_1 and ik_2+ix_2. For this substitution the continuous Hahn polynomials go over into the Hahn polynomials. □

Remark 3.7. (i) The case $j=0$ in both formulas gives back the convolution identities for the Laguerre and Meixner polynomials, see, e.g., [1], [2], [13, section 10.12, eq. (41)], and the case $n=0$ gives another convolution identity for the Laguerre and Meixner polynomials. Again these formulas can be viewed as connection coefficient formulas for orthogonal polynomials in two variables.

(ii) The identities of Corollary 3.6 can be obtained by considering the action of $X = -H+B-C$ in the representations π_k and $\pi_{k_1}\otimes\pi_{k_2}$ for the Laguerre case, see [34], and by considering the action of $X_c = -\big((1+c)/(2\sqrt{c})\big)H + B - C$, $0<c<1$, in the representations π_k and $\pi_{k_1}\otimes\pi_{k_2}$ for the Meixner case. The limit case $c\uparrow 1$ in the Meixner result gives the Laguerre result. In this case we can interpret the Jacobi and Hahn polynomials as Clebsch–Gordan coefficients; cf. Remark 3.5(iii).

(iii) Corollary 3.6(ii) is equivalent to Theorem 3.4 by the same substitution. Theorem 3.4 can also be obtained from Corollary 3.6(i) by a double application of the Mellin transform. For this we have to use the Laguerre polynomials that are mapped onto Meixner–Pollaczek polynomials, cf. [25, section 3], and the Jacobi polynomials that are mapped onto the continuous Hahn polynomials, cf. [23, eq. (3.4) with $\Gamma(\beta-i\lambda)$ replaced by $\Gamma(\beta+i\lambda)$].

The other hypergeometric orthogonal polynomials satisfying a convolution identity are the Charlier and Hermite polynomials; cf. [1], [2]. These identities can be obtained by taking the appropriate limits from the Meixner polynomials to the Charlier polynomials and from the Laguerre polynomials to the Hermite polynomials; cf., e.g., [22]. The Hahn polynomials tend to Krawtchouk polynomials and the Jacobi polynomials tend to Hermite polynomials. We use the notation $K_n(x;p,N) = {}_2F_1(-n,-x;-N;p^{-1})$ for Krawtchouk polynomials, $C_n(x;a) = {}_2F_0(-n,-x;-;a^{-1})$ for Charlier polynomials and $H_n(x) = (2x)^n\,{}_2F_0(-n/2,-(n-1)/2;-;-x^{-2})$ for the Hermite polynomials; see Szegő [33].

COROLLARY 3.8 (see [34]). (i) *The Hermite polynomials satisfy the following convolution identity:*

$$\sum_{l=0}^{n+j} K_j\left(l;\frac{a^2}{a^2+b^2},n+j\right)\frac{a^l}{l!}H_l(x)\frac{b^{n+j-l}}{(n+j-l)!}H_{n+j-l}(y)$$
$$=\frac{(a^2+b^2)^{(n+j)/2}}{(n+j)!}\left(\frac{b}{a}\right)^j H_n\left(\frac{ax+by}{\sqrt{a^2+b^2}}\right)H_j\left(\frac{ay-bx}{\sqrt{a^2+b^2}}\right).$$

(ii) *The Charlier polynomials satisfy the following convolution identity:*

$$\sum_{l=0}^{n+j}\binom{n+j}{l}\alpha^l\beta^{n+j-l}K_j\left(l;\frac{\alpha}{\alpha+\beta},n+j\right)C_l(x;\alpha)\,C_{n+j-l}(y;\beta)$$
$$=(-1)^j(\alpha+\beta)^nC_n(x+y-j;\alpha+\beta)\,(-x-y)_jK_j\left(x;\frac{\alpha}{\alpha+\beta},x+y\right).$$

Remark 3.9. (i) Again the case $j=0$ gives known convolution formulas; cf. [1, section 8], [2], [13, section 10.13, eq. (40)]. Corollary 3.8(ii) is derived in a different way in Vilenkin and Klimyk [35, section 8.6.5].

(ii) This time the identities have a similar interpretation, but now we have to use the Lie algebra $\mathfrak{b}(1)$, a central extension of the oscillator algebra; cf. [34]. In particular we can now interpret the Hermite and Charlier polynomials as Clebsch–Gordan coefficients.

3.2. Racah coefficients and orthogonal polynomials. In the tensor product of three positive discrete series representations $\pi_{k_1}\otimes\pi_{k_2}\otimes\pi_{k_3}$ of $\mathfrak{su}(1,1)$ we consider the following orthogonal bases:

$$e_n^{((k_1k_2)k_{12}k_3)k}=\sum_{n_{12},n_3}C^{k_{12},k_3,k}_{n_{12},n_3,n}\;e^{(k_1k_2)k_{12}}_{n_{12}}\otimes e^{k_3}_{n_3} \tag{3.9}$$

$$=\sum_{n_1,n_2,n_3,n_{12}}C^{k_1,k_2,k_{12}}_{n_1,n_2,n_{12}}C^{k_{12},k_3,k}_{n_{12},n_3,n}\;e^{k_1}_{n_1}\otimes e^{k_2}_{n_2}\otimes e^{k_3}_{n_3} \tag{3.10}$$

and

$$e_n^{(k_1(k_2k_3)k_{23})k}=\sum_{n_1,n_{23}}C^{k_1,k_{23},k}_{n_1,n_{23},n}\;e^{k_1}_{n_1}\otimes e^{(k_2k_3)k_{23}}_{n_{23}} \tag{3.11}$$

$$=\sum_{n_1,n_2,n_3,n_{23}}C^{k_2,k_3,k_{23}}_{n_2,n_3,n_{23}}C^{k_1,k_{23},k}_{n_1,n_{23},n}\;e^{k_1}_{n_1}\otimes e^{k_2}_{n_2}\otimes e^{k_3}_{n_3}. \tag{3.12}$$

Here we use the extended notation $e_n^{(k_1k_2)k}$ for the basis of the tensor product decomposition to keep track of how the decomposition is obtained.

These bases are connected by the Racah coefficients, which leads to an intertwiner for the action of $\mathfrak{su}(1,1)$. The Racah coefficients are defined by

$$e_n^{((k_1k_2)k_{12}k_3)k}=\sum_{k_{23}}U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}}\;e_n^{(k_1(k_2k_3)k_{23})k}. \tag{3.13}$$

In the previous formulas the following constraints hold:

(3.14)
$$k_{12}=k_1+k_2+j_{12},\qquad k_{23}=k_2+k_3+j_{23},$$
$$k=k_{12}+k_3+j=k_1+k_{23}+j',\qquad j_{12},j,j_{23},j'\in\mathbb{Z}_+,\ \text{and } j_{12}+j=j_{23}+j'.$$

Thus all above sums are finite sums.

Recall that $(1\otimes\Delta)(\Delta(X_\phi)) = 1\otimes 1\otimes X_\phi + 1\otimes X_\phi\otimes 1 + X_\phi\otimes 1\otimes 1$. The following proposition is proved as Proposition 3.2.

PROPOSITION 3.10. *Define the unitary mapping*

$$\Theta\colon \ell^2(\mathbb{Z}_+)\otimes\ell^2(\mathbb{Z}_+)\otimes\ell^2(\mathbb{Z}_+) \to L^2(\mathbb{R}^3, w^{(k_1)}(x_1;\phi)w^{(k_2)}(x_2;\phi)w^{(k_3)}(x_3;\phi)dx_1dx_2dx_3)$$

by

$$\Theta\colon e^{k_1}_{n_1}\otimes e^{k_2}_{n_2}\otimes e^{k_3}_{n_3} \mapsto p^{(k_1)}_{n_1}(x_1;\phi)p^{(k_2)}_{n_2}(x_2;\phi)p^{(k_3)}_{n_3}(x_3;\phi);$$

then Θ *intertwines* $\pi_{k_1}\otimes\pi_{k_2}\otimes\pi_{k_3}(1\otimes\Delta)(\Delta(X_\phi))$ *with* $M_{2(x_1+x_2+x_3)\sin\phi}$.

Remark 3.11. Let $\Lambda^{(k)} = \Lambda$ be the unitary mapping defined in Proposition 3.1 and $\Upsilon^{(k_1k_2)} = \Upsilon$ be the unitary mapping defined in Proposition 3.2. Using the identifications

$$\begin{aligned} &L^2(\mathbb{R}^3, w^{(k_1)}(x_1;\phi)w^{(k_2)}(x_2;\phi)w^{(k_3)}(x_3;\phi)dx_1dx_2dx_3)\\ &\quad= L^2(\mathbb{R}, w^{(k_1)}(x_1;\phi)dx_1)\otimes L^2(\mathbb{R}^2, w^{(k_2)}(x_2;\phi)w^{(k_3)}(x_3;\phi)dx_2dx_3)\\ &\quad= L^2(\mathbb{R}^2, w^{(k_1)}(x_1;\phi)w^{(k_2)}(x_2;\phi)dx_1dx_2)\otimes L^2(\mathbb{R}, w^{(k_3)}(x_3;\phi)dx_3), \end{aligned}$$

we have $\Theta = \Lambda^{(k_1)}\otimes\Upsilon^{(k_2k_3)} = \Upsilon^{(k_1k_2)}\otimes\Lambda^{(k_3)}$. Hence, for the orthogonal bases on the right-hand side of (3.9) and (3.12) we have

$$\begin{aligned} \Theta e^{(k_1k_2)k_{12}}_{n_{12}}\otimes e^{k_3}_{n_3} &= \left(\Upsilon^{(k_1k_2)}e^{(k_1k_2)k_{12}}_{n_{12}}\right)\left(\Lambda^{(k_3)}e^{k_3}_{n_3}\right),\\ \Theta e^{k_1}_{n_1}\otimes e^{(k_2k_3)k_{23}}_{n_{23}} &= \left(\Lambda^{(k_1)}e^{k_1}_{n_1}\right)\left(\Upsilon^{(k_2k_3)}e^{(k_2k_3)k_{23}}_{n_{23}}\right). \end{aligned}$$

And the right-hand sides are known from Propositions 3.1 and 3.2 in terms of Meixner–Pollaczek polynomials times continuous Hahn polynomials.

PROPOSITION 3.12. (i) *The following expressions hold:*

$$\begin{aligned} \Theta(e^{((k_1k_2)k_{12}k_3)k}_n)(x_1,x_2,x_3) &= p^{(k)}_n(x_1+x_2+x_3;\phi)\ \Theta(e^{((k_1k_2)k_{12}k_3)k}_0)(x_1,x_2,x_3),\\ \Theta(e^{((k_1k_2)k_{12}k_3)k}_0)(x_1,x_2,x_3) &= \Upsilon^{(k_1k_2)}e^{(k_1k_2)k_{12}}_0(x_1,x_2)\ \Upsilon^{(k_{12}k_3)}e^{(k_{12}k_3)k}_0(x_1+x_2,x_3). \end{aligned}$$

(ii) *The following expressions hold:*

$$\begin{aligned} \Theta(e^{(k_1(k_2k_3)k_{23})k}_n)(x_1,x_2,x_3) &= p^{(k)}_n(x_1+x_2+x_3;\phi)\ \Theta(e^{(k_1(k_2k_3)k_{23})k}_0)(x_1,x_2,x_3),\\ \Theta(e^{(k_1(k_2k_3)k_{23})k}_0)(x_1,x_2,x_3) &= \Upsilon^{(k_2k_3)}e^{(k_2k_3)k_{23}}_0(x_2,x_3)\ \Upsilon^{(k_1k_{23})}e^{(k_1k_{23})k}_0(x_1,x_2+x_3). \end{aligned}$$

Proof. Statement (ii) is proved analogously as statement (i). The first statement of (i) follows from Proposition 3.10 and the decomposition of the three-fold tensor product; cf. Proposition 3.3.

For the second statement we use (3.9), Remark 3.11, and Propositions 3.3 and 3.1 to find

$$\begin{aligned} &\Theta(e^{((k_1k_2)k_{12}k_3)k}_0)(x_1,x_2,x_3)\\ &\quad= \left(\Upsilon^{(k_1k_2)}e^{(k_1k_2)k_{12}}_0\right)(x_1,x_2)\sum_{n_{12}+n_3=j} C^{k_{12},k_3,k}_{n_{12},n_3,0}\ p^{(k_{12})}_{n_{12}}(x_1+x_2;\phi)p^{(k_3)}_{n_3}(x_3;\phi). \end{aligned}$$

The sum can be evaluated as $(\Upsilon^{(k_{12}k_3)}e^{(k_{12}k_3)k}_0)(x_1+x_2,x_3)$ by (3.7). ∎

Next we apply Θ to (3.13); then it follows from Proposition 3.12 that we can divide both sides by the Meixner–Pollaczek polynomial of degree n. Since Θ is unitary we obtain the Wigner–Eckart theorem [35, Chap. 8], stating that the Racah coefficients in (3.13) are independent of n. So we can restrict to the case $n = 0$ of (3.13) before applying Θ without loss of generality. We obtain

$$\begin{aligned}\sum_{j_{23}} U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}} \left(\Upsilon^{(k_2k_3)} e_0^{(k_2k_3)k_{23}}\right)(x_2,x_3) \left(\Upsilon^{(k_1k_{23})} e_0^{(k_1k_{23})k}\right)(x_1,x_2+x_3)\\ = \left(\Upsilon^{(k_1k_2)} e_0^{(k_1k_2)k_{12}}\right)(x_1,x_2) \left(\Upsilon^{(k_{12}k_3)} e_0^{(k_{12}k_3)k}\right)(x_1+x_2,x_3).\end{aligned} \tag{3.15}$$

The Racah coefficients remain to be determined, and this can actually be done from (3.15); see [34]. One can either copy the expression [34, eq. (4.8)] or use the limit $q \uparrow 1$ of the expression for the q-Racah coefficient given in Proposition 4.9. Both lead to the following expression of the Racah coefficients in terms of balanced ${}_4F_3$-series:

(3.16)

$$\begin{aligned}U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}} &= \begin{pmatrix} j+j_{12} \\ j_{23}\end{pmatrix} \frac{(2k_2)_{j_{12}}(2k_3)_j(2k_1+2k_2+2k_3+j+j_{12}-1)_{j_{23}}}{(2k_3,2k_2+2k_3+j_{23}-1)_{j_{23}}(2k_2+2k_3+2j_{23})_{j'}}\\ &\times \left(\frac{j'!(2k_1,2k_{23},2k_1+2k_{23}+j'-1)_{j'}\ j_{23}!(2k_2,2k_3,2k_2+2k_3+j_{23}-1)_{j_{23}}}{j!(2k_{12},2k_3,2k_{12}+2k_3+j-1)_j\ j_{12}!(2k_1,2k_2,2k_1+2k_2+j_{12}-1)_{j_{12}}}\right)^{1/2}\\ &\times {}_4F_3\left(\begin{matrix}2k_1+2k_2+j_{12}-1, 2k_2+2k_3+j_{23}-1, -j_{12}, -j_{23}\\ 2k_2, 2k_1+2k_2+2k_3+j+j_{12}-1, -j-j_{12}\end{matrix};1\right),\end{aligned}$$

with the convention (3.14).

The Racah coefficients can be rewritten in terms of the Racah polynomials defined by

$$R_n(\lambda(x);\alpha,\beta,\gamma,\delta) = {}_4F_3\left(\begin{matrix}-n, n+\alpha+\beta+1, -x, x+\gamma+\delta+1\\ \alpha+1,\ \beta+\delta+1,\ \gamma+1\end{matrix};1\right), \tag{3.17}$$

where $\lambda(x) = x(x+\gamma+\delta+1)$, one of the lower parameters equals $-N$, $N \in \mathbb{Z}_+$, and $0 \le n \le N$; see Wilson [36] or [22]. The orthogonality relations for the Racah polynomials follow from the fact that the Racah coefficients form a unitary matrix.

So we obtain the following theorem by simplifying (3.15) using $s = x_1+x_2+x_3$ and the explicit expression (3.16).

THEOREM 3.13. *The continuous Hahn polynomials satisfy the following convolution identity:*

$$\begin{aligned}&\sum_{l=0}^{n+j} \begin{pmatrix} j+n \\ n\end{pmatrix} \frac{(2k_2)_n(2k_3)_j(2k_1+2k_2+2k_3+j+n-1)_l}{(2k_3)_l(2k_2+2k_3+l-1)_l(2k_2+2k_3+2l)_{j+n-l}}\\ &\quad\times R_l(\lambda(n);2k_2-1,2k_3-1,-j-n-1,2k_1+2k_2+j+n-1)\\ &\quad\times p_{n+j-l}(x_1;k_1,k_2+k_3+l-is,k_1,k_2+k_3+l+is)\\ &\quad\times p_l(x_2;k_2,k_3-i(s-x_1),k_2,k_3+i(s-x_1))\\ &= p_n(x_1;k_1,k_2-i(x_1+x_2),k_1,k_2+i(x_1+x_2))\\ &\quad\times p_j(x_1+x_2;k_1+k_2+n,k_3-is,k_1+k_2+n,k_3+is),\end{aligned}$$

with the notation as in (3.6), (3.17).

Remark 3.14. (i) Theorem 3.13 can be considered as a connection coefficient formula between two systems of orthogonal polynomials for the absolutely continuous orthogonality measure with weight

$$\Gamma(k_1+ix_1)\Gamma(k_1-ix_1)\Gamma(k_2+ix_2)\Gamma(k_2-ix_2)\Gamma(k_3+i(s-x_1-x_2))\Gamma(k_3-i(s-x_1-x_2))$$

on $\mathbb{R}^2$. This follows from substituting $s = x_1 + x_2 + x_3$ in the weighted L^2-space of Proposition 3.10 and leaving out the integration with respect to s, which can be done by Proposition 3.12 and the Wigner–Eckart theorem.

(ii) Theorem 3.4 can be obtained as a limit case of Theorem 3.13 by letting $k_3 \to \infty$ and using the limit transition of the continuous Hahn polynomials to the Meixner–Pollaczek polynomials; see, e.g., [22]. Note that Theorem 3.4 is used in the derivation of Theorem 3.13.

(iii) Application of Θ to (3.9)–(3.12) gives results which are immediately derivable from Theorem 3.4.

COROLLARY 3.15 (see [34]). (i) *The Jacobi polynomials satisfy the convolution identity*

$$\begin{aligned}\sum_{l=0}^{n+j} \binom{j+n}{n} &\frac{(b+1)_n(c+1)_j(a+b+c+j+n+2)_l}{(c+1)_l(b+c+l+1)_l(b+c+2l+2)_{j+n-l}}\\ &\times R_l(\lambda(n);b,c,-j-n-1,a+b+j+n+1)\\ &\times P_{n+j-l}^{(a,b+c+2l+1)}(1-2x_1)\,(1-x_1)^l P_l^{(b,c)}\left(\frac{1-x_1-2x_2}{1-x_1}\right)\\ =\ &(x_1+x_2)^n P_n^{(a,b)}\left(\frac{x_2-x_1}{x_1+x_2}\right)\ P_j^{(a+b+2n+1,c)}(1-2(x_1+x_2)).\end{aligned}$$

(ii) *The Hahn polynomials satisfy the following convolution identity:*

$$\begin{aligned}\sum_{l=0}^{n+j} \binom{j+n}{l} &\frac{(a+1)_{n+j-l}(b+1)_l(b+1)_n(c+1)_j(a+b+c+j+n+2)_l}{(a+1)_n(c+1)_l(b+c+l+1)_l(b+c+2l+2)_{j+n-l}(a+b+2n+2)_j}\\ &\times R_l(\lambda(n);b,c,-j-n-1,a+b+j+n+1)\\ &\times (l-s)_{n+j-l}\,Q_{n+j-l}(x_1;a,b+c+2l+1,s-l)\,(x_1-s)_l\,Q_l(x_2;b,c,s-x_1)\\ =\ &(-x_1-x_2)_n\,Q_n(x_1;a,b,x_1+x_2)\,(n-s)_j\,Q_j(x_1+x_2-n;a+b+2n+1,c,s-n)\end{aligned}$$

with the notation (3.8), (3.17).

Proof. The first result follows from the limit transition of the continuous Hahn polynomials to the Jacobi polynomials. Replace x_i by sx_i and let $s \to \infty$. The second result follows by a similar substitution as in the proof of Corollary 3.6(ii). □

Remark 3.16. (i) Similar to Remark 3.7(iii) we have that Corollary 3.15(ii) and Theorem 3.13 can be obtained from each other by formal substitution. Theorem 3.13 can be obtained from Corollary 3.15(i) by a double application of the Mellin transform. Moreover, Corollary 3.15 can be proved as Theorem 3.13 by analyzing the action of X and X_c, cf. Remark 3.7(ii), in the three-fold tensor product.

(ii) Dunkl [11, Thm. 4.2, Prop. 5.4], [12, Thm. 1.7] has obtained Corollary 3.15, and hence Theorem 3.13, by a different method. Dunkl [11] obtains the two-variable Hahn polynomials by judiciously guessing solutions for a certain difference equation arising from the representation theory of the symmetric group. By symmetry considerations there are more solutions of this type, and the connection coefficients can

be calculated in terms of balanced ${}_4F_3$-series. The derivation in this paper gives an intrinsic explanation for the occurrence of the Racah polynomials as connection coefficients. See also Dunkl [11], [12] for the orthogonality relations for these two-variable Hahn and Jacobi polynomials for suitable restrictions on the parameters.

We do not obtain extensions of Corollary 3.8 in this way. For $k_1, k_2, k_3 \to \infty$ in Theorem 3.13 we obtain the same result. This is also explained by the fact that the Racah coefficients for the Lie algebra $\mathfrak{b}(1)$ are of the same form as the Clebsch–Gordan coefficients; cf. [34].

4. The case $U_q(\mathfrak{su}(1,1))$. Let $U_q(\mathfrak{sl}(2,\mathbb{C}))$ be the complex unital associative algebra generated by A, B, C, D subject to the relations

$$AD = 1 = DA, \quad AB = qBA, \quad AC = q^{-1}CA, \quad BC - CB = \frac{A^2 - D^2}{q - q^{-1}}. \tag{4.1}$$

It is a Hopf algebra. We are only concerned with the comultiplication, which is defined by

$$\begin{aligned} &\Delta(A) = A \otimes A, \quad \Delta(B) = A \otimes B + B \otimes D, \\ &\Delta(C) = A \otimes C + C \otimes D, \quad \Delta(D) = D \otimes D \end{aligned} \tag{4.2}$$

on the level of generators and extended as an algebra homomorphism. There are several possible $*$-structures on $U_q(\mathfrak{sl}(2,\mathbb{C}))$, and assuming $0 < q < 1$ we take

$$A^* = A, \quad B^* = -C, \quad C^* = -B, \quad D^* = D,$$

and the corresponding Hopf $*$-algebra is denoted by $U_q(\mathfrak{su}(1,1))$.

The positive discrete series representations π_k of $U_q(\mathfrak{su}(1,1))$ are unitary representations labelled by $k > 0$. They act in $\ell^2(\mathbb{Z}_+)$ and the action of the generators is given by

$$\begin{aligned} &\pi_k(A)\, e_n^k = q^{k+n}\, e_n^k, \qquad \pi_k(D)\, e_n^k = q^{-k-n}\, e_n^k, \\ &\pi_k(C)\, e_n^k = q^{1/2-k-n} \frac{\sqrt{(1-q^{2n})(1-q^{4k+2n-2})}}{q - q^{-1}}\, e_{n-1}^k, \\ &\pi_k(B)\, e_n^k = q^{-1/2-k-n} \frac{\sqrt{(1-q^{2n+2})(1-q^{4k+2n})}}{q^{-1} - q}\, e_{n+1}^k. \end{aligned} \tag{4.3}$$

Note that $\pi_k(D)$, $\pi_k(B)$, $\pi_k(C)$ are unbounded operators, but $\pi_k(A) \in \mathcal{B}(\ell^2(\mathbb{Z}_+))$. The operators that we consider are bounded.

Recall that the tensor product of two representations are defined by use of the comultiplication. The tensor product of two positive discrete series representation decomposes as for the Lie algebra $\mathfrak{su}(1,1)$;

$$\pi_{k_1} \otimes \pi_{k_2} \cong \bigoplus_{j=0}^{\infty} \pi_{k_1+k_2+j}. \tag{4.4}$$

So there exists a unitary matrix mapping the orthogonal basis $e_{n_1}^{k_1} \otimes e_{n_2}^{k_2}$ onto $e_n^{k_1+k_2+j}$ intertwining the action of $U_q(\mathfrak{su}(1,1))$. The matrix elements of this unitary mapping are the Clebsch–Gordan coefficients;

$$e_n^k = \sum_{n_1,n_2=0}^{\infty} C_{n_1,n_2,n}^{k_1,k_2,k}\, e_{n_1}^{k_1} \otimes e_{n_2}^{k_2}, \tag{4.5}$$

where $k = k_1 + k_2 + j$ for $j \in \mathbb{Z}_+$. The sum is finite; $n_1 + n_2 = n + j$. The Clebsch–Gordan coefficients are normalized by $\langle e_0^k, e_0^{k_1} \otimes e_j^{k_2} \rangle > 0$.

These results can be found in Burban and Klimyk [8] and Kalnins, Manocha, and Miller [19]. See Chari and Pressley [9] for general information on quantized universal enveloping algebras.

4.1. Clebsch–Gordan coefficients and orthogonal polynomials. For this section we need the Askey–Wilson polynomials and the Al-Salam and Chihara polynomials, which are a subclass of the Askey–Wilson polynomials. The Askey–Wilson polynomial is defined by

(4.6)
$$p_m(\cos\theta; a, b, c, d|q) = a^{-m}(ab, ac, ad; q)_m \, {}_4\varphi_3 \left(\begin{matrix} q^{-m}, abcdq^{m-1}, ae^{i\theta}, ae^{-i\theta} \\ ab,\ ac,\ ad \end{matrix} ; q, q \right),$$

and it is symmetric in its parameters a, b, c, and d; see [5]. The Al-Salam and Chihara polynomials, introduced originally in [2], are obtained by taking $c = d = 0$ in the Askey–Wilson polynomials;

(4.7)
$$s_m(\cos\theta; a, b|q) = p_m(\cos\theta; a, b, 0, 0|q) = a^{-m}(ab; q)_m \, {}_3\varphi_2 \left(\begin{matrix} q^{-m}, ae^{i\theta}, ae^{-i\theta} \\ ab,\ 0 \end{matrix} ; q, q \right).$$

Let $dm(\cdot; a, b, c, d|q)$ denote the normalized orthogonality measure for the Askey–Wilson polynomials, which is absolutely continuous on $[-1, 1]$ and has at most a finite number of discrete mass points outside $[-1, 1]$. We put $dm(\cdot; a, b|q) = dm(\cdot; a, b, 0, 0|q)$ for the normalized orthogonality measure for the Al-Salam and Chihara polynomials. Explicitly, let

$$w(z) = \frac{(z^2, z^{-2}; q)_\infty}{(az, a/z, bz, b/z, cz, c/z, dz, d/z; q)_\infty};$$

we use $w(z) = w(z; a, b, c, d|q)$ to stress the dependence on the parameters when needed. Let a, b, c, and d be real, or, if complex, appearing in conjugate pairs, and let all the pairwise products of a, b, c, and d not be greater than or equal to 1. Then the Askey–Wilson polynomials $p_n(x) = p_n(x; a, b, c, d|q)$ satisfy the orthogonality relations

$$\begin{aligned} &\frac{1}{2\pi h_0} \int_0^\pi p_n(\cos\theta) p_m(\cos\theta) w(e^{i\theta}) \, d\theta + \frac{1}{h_0} \sum_k p_n(x_k) p_m(x_k) w_k = \delta_{n,m} h_n, \\ &h_n = \frac{(1 - q^{n-1}abcd)}{(1 - q^{2n-1}abcd)} \frac{(q, ab, ac, ad, bc, bd, cd; q)_n}{(abcd; q)_n}, \\ &h_0 = \frac{(abcd; q)_\infty}{(q, ab, ac, ad, bc, bd, cd; q)_\infty}. \end{aligned} \tag{4.8}$$

The points x_k are of the form $\frac{1}{2}(eq^k + e^{-1}q^{-k})$ for e any of the parameters a, b, c, or d with absolute value greater than 1; the sum is over $k \in \mathbb{Z}_+$ such that $|eq^k| > 1$ and w_k is the residue of $z \mapsto w(z)$ at $z = eq^k$ minus the residue at $z = e^{-1}q^{-k}$. So the normalized orthogonality measure $dm(\cdot; a, b, c, d|q)$ can be read off from (4.8); see Askey and Wilson [5] or [14].

Let $S_m(x;a,b|q) = s_m(x;a,b|q)/\sqrt{(q,ab;q)_m}$ denote the orthonormal Al-Salam and Chihara polynomials, which satisfy the three-term recurrence relation

$$\begin{aligned} 2x\, S_n(x) &= a_{n+1}\, S_{n+1}(x) + q^n(a+b)\, S_n(x) + a_n\, S_{n-1}(x), \\ a_n &= \sqrt{(1-abq^{n-1})(1-q^n)}. \end{aligned} \tag{4.9}$$

We now define

$$Y_s = q^{1/2}B - q^{-1/2}C + \frac{s^{-1}+s}{q^{-1}-q}(A-D) \in U_q(\mathfrak{su}(1,1)). \tag{4.10}$$

Then Y_sA is a self-adjoint element in $U_q(\mathfrak{su}(1,1))$ for $s \in \mathbb{R}\backslash\{0\}$, or $s \in \mathbb{T}$. Y_s is a twisted primitive element, i.e., $\Delta(Y_s) = A \otimes Y_s + Y_s \otimes D$, meaning that Y_s is very much like a Lie algebra element.

We also use the notation $\mu(x) = (x+x^{-1})/2 = \mu(x^{-1})$ for $x \neq 0$ in this section.

PROPOSITION 4.1. *Let $\Lambda\colon \ell^2(\mathbb{Z}_+) \to L^2(\mathbb{R}, dm(\cdot;q^{2k}s,q^{2k}/s|q^2))$ be the unitary mapping defined by $\Lambda\colon e_n^k \mapsto S_n(\cdot;q^{2k}s,q^{2k}/s|q^2)$; then Λ intertwines $\pi_k(Y_sA)$ acting in $\ell^2(\mathbb{Z}_+)$ with $2(M_x-\mu(s))/(q^{-1}-q)$.*

Proof. The bounded self-adjoint operator $\pi_k(Y_sA)$ is a Jacobi matrix by (4.10) and (4.3), and the result follows upon comparing with the three-term recurrence (4.9) for the Al-Salam and Chihara polynomials as in section 2. □

Proposition 4.1 says that $v^k(x) = \sum_{n=0}^{\infty} S_n(\mu(x);q^{2k}s,q^{2k}/s|q^2)\, e_n^k$ is a generalized eigenvector of the self-adjoint operator $\pi_k(Y_sA)$ for the eigenvalue

$$\lambda_x = \frac{x+x^{-1}-s-s^{-1}}{q^{-1}-q} = 2\frac{\mu(x)-\mu(s)}{q^{-1}-q}.$$

Due to the fact that the comultiplication on $U_q(\mathfrak{su}(1,1))$ is less simple than for the Lie algebra $\mathfrak{su}(1,1)$, it takes a little more effort to determine the action of Y_sA in $\pi_{k_1} \otimes \pi_{k_2}$. The result can still be phrased using orthogonal polynomials in two variables.

PROPOSITION 4.2. *Define $\Upsilon\colon \ell^2(\mathbb{Z}_+) \otimes \ell^2(\mathbb{Z}_+) \to L^2(\mathbb{R}^2, dm(x_1,x_2))$, where*

$$dm(x_1,x_2) = dm(x_1;q^{2k_1}w_2,q^{2k_1}/w_2|q^2)\, dm(x_2;q^{2k_2}s,q^{2k_2}/s|q^2), \qquad x_2 = \mu(w_2),$$

by

$$\Upsilon\colon e_{n_1}^{k_1} \otimes e_{n_2}^{k_2} \mapsto S_{n_1}(x_1;q^{2k_1}w_2,q^{2k_1}/w_2|q^2)\, S_{n_2}(x_2;q^{2k_2}s,q^{2k_2}/s|q^2);$$

then Υ is a unitary mapping intertwining $\pi_{k_1}\otimes\pi_{k_2}(\Delta(Y_sA))$ with $2(M_{x_1}-\mu(s))/(q^{-1}-q)$ in $L^2(dm(x_1,x_2))$.

Note that $\Upsilon(e_{n_1}^{k_1} \otimes e_{n_2}^{k_2})$ forms a set of orthogonal polynomials in two variables x_1 and x_2 for $L^2(\mathbb{R}^2, dm(x_1,x_2))$, since the Al-Salam and Chihara polynomial is symmetric in its parameters.

Proposition 4.2 states that the vector

$$\begin{aligned} w(x_1;x_2) &= \sum_{n_1=0}^{\infty} S_{n_1}(\mu(x_1);q^{2k_1}x_2,q^{2k_1}/x_2|q^2)\, e_{n_1}^{k_1} \otimes v^{k_2}(x_2) \\ &= \sum_{n_1,n_2=0}^{\infty} S_{n_1}(\mu(x_1);q^{2k_1}x_2,q^{2k_1}/x_2|q^2)\, S_{n_2}(\mu(x_2);q^{2k_2}s,q^{2k_2}/s|q^2)\, e_{n_1}^{k_1} \otimes e_{n_2}^{k_2} \end{aligned}$$

is a generalized eigenvector of $\pi_{k_1} \otimes \pi_{k_2}(\Delta(Y_s A))$ for the eigenvalue λ_{x_1}. This last observation is essentially the way to obtain Proposition 4.2, since $\Delta(Y_s A) = A^2 \otimes Y_s A + Y_s A \otimes 1$ acts as a three-term recurrence operator in $e^{k_1}_{n_1} \otimes v^{k_2}(x_2)$.

Proof. We use $\Delta(Y_s A) = A^2 \otimes Y_s A + Y_s A \otimes 1$ and Proposition 4.1 to define for fixed x_2 the map $\Lambda_0 \colon \ell^2(\mathbb{Z}_+) \otimes \ell^2(\mathbb{Z}_+) \to \ell^2(\mathbb{Z}_+)$ by

$$\Lambda_0 \colon e^{k_1}_{n_1} \otimes e^{k_2}_{n_2} \mapsto S_{n_2}(x_2; q^{2k_2}s, q^{2k_2}/s|q^2)\, e^{k_1}_{n_1}$$

to obtain the recurrence in n_1

$$\begin{aligned}
&\Lambda_0\Big((q^{-1}-q)\big(\pi_{k_1} \otimes \pi_{k_2}\Delta(Y_s A)\big) + s + s^{-1}\Big)\, e^{k_1}_{n_1} \otimes e^{k_2}_{n_2} \\
&\quad = S_{n_2}(x_2; q^{2k_2}s, q^{2k_2}/s|q^2)\Big(q^{2n_1}\big((s+s^{-1})q^{2k_1} + \lambda_{w_2} q^{2k_1}(q^{-1}-q)\big)\, e^{k_1}_{n_1} \\
&\quad + \sqrt{(1-q^{2n_1+2})(1-q^{4k_1+2n})}\, e^{k_1}_{n_1+1} + \sqrt{(1-q^{2n_1})(1-q^{4k_1+2n_1-1})}\, e^{k_1}_{n_1-1}\Big).
\end{aligned}$$

Use the explicit expression for λ_{w_2} and the three-term recurrence relation (4.9) to obtain the result. ∎

We now calculate the action of $\Upsilon\, e^k_n$, which yields another set of orthonormal polynomials for $L^2(\mathbb{R}^2, dm(x_1, x_2))$.

PROPOSITION 4.3. *Let $k = k_1 + k_2 + j$ for $j \in \mathbb{Z}_+$ and $x_1 = \mu(w_1)$; then*

$$\begin{aligned}
\big(\Upsilon\, e^k_n\big)(x_1, x_2) &= S_n(x_1; q^{2k}s, q^{2k}/s|q^2)\, \big(\Upsilon\, e^k_0\big)(x_1, x_2), \\
\big(\Upsilon\, e^k_0\big)(x_1, x_2) &= C\, p_j(x_2; q^{2k_1}w_1, q^{2k_1}/w_1, q^{2k_2}s, q^{2k_2}/s|q^2), \\
C^{-1} = \big(C_j(k_1, k_2)\big)^{-1} &= \sqrt{(q^2, q^{4k_1}, q^{4k_2}, q^{4k_1+4k_2+2j-2}; q^2)_j}.
\end{aligned}$$

Proof. By Proposition 4.2, (4.4), and

$$2\frac{x_1 - \mu(s)}{q^{-1}-q}\, \Upsilon e^k_n(x_1, x_2) = \Upsilon(\pi_k(Y_s A)\, e^k_n)(x_1, x_2),$$

we obtain the three-term recurrence relation as in Proposition 4.1, but with different initial conditions. Hence, the first statement follows.

Since Υ is unitary we have the orthogonality relations $\delta_{nm}\delta_{kl} = \langle \Upsilon e^k_n, \Upsilon e^l_m \rangle =$

$$\int S_n(x_1; q^{2k}s, q^{2k}/s|q^2) S_m(x_1; q^{2l}s, q^{2l}/s|q^2) \int \Upsilon e^k_0(x_1, x_2) \Upsilon e^l_0(x_1, x_2)\, dm(x_1, x_2),$$

by our first observation. As in the proof of Proposition 3.3 we conclude $\Upsilon e^k_0(x_1, x_2) = p_j(x_2)$ is a polynomial of degree j, $k = k_1 + k_2 + j$, in x_2 satisfying the orthogonality relations

$$\int_{x_2} p_j(x_2) p_i(x_2)\, dm(x_1, x_2) = \delta_{ij} dm(x_1; q^{2k}s, q^{2k}/s|q^2)$$

as measures with respect to functions in the variable x_1.

We now assume for ease of presentation that $dm(x_1, x_2)$ is absolutely continuous. The general case can be proved similarly, or it can be obtained by analytic continuation with respect to s. The measure is absolutely continuous for $q^{2k_2} < |s| < q^{-2k_2}$, since $k_1, k_2 > 0$. Put $x_1 = \cos\theta$, $x_2 = \cos\psi$; then we obtain the explicit expression (4.8)

for the orthogonality measure;

$$\frac{1}{2\pi}\int_0^\pi p_i(\cos\psi)p_j(\cos\psi)\frac{(e^{\pm 2i\psi},e^{\pm 2i\theta};q^2)_\infty}{(q^{2k_2}se^{\pm i\psi},q^{2k_2}e^{\pm i\psi}/s,q^{2k_1}e^{\pm i\psi\pm i\theta};q^2)_\infty}d\psi$$
$$=\delta_{ij}\frac{(q^{4k_1+4k_2+4j};q^2)_\infty}{(q^2,q^{4k_1},q^{4k_2};q^2)_\infty}\frac{(e^{\pm 2i\theta};q^2)_\infty}{(q^{2k_1+2k_2+2j}se^{\pm i\theta},q^{2k_1+2k_2+2j}e^{\pm i\theta}/s;q^2)_\infty}$$

for almost all θ. The $\pm$ signs mean that we take all possible combinations in the infinite q-shifted factorials. Cancelling the $(e^{\pm 2i\theta};q^2)_\infty$ on both sides and comparing the result with (4.8), we see that p_j is a multiple of $p_j(\cdot;q^{2k_1}e^{i\theta},q^{2k_1}e^{-i\theta},q^{2k_2}s,q^{2k_2}/s|q^2)$. The constant in front follows up to a sign by comparing the squared norms. As in the proof of Proposition 3.3 the sign of C follows from the normalization of the Clebsch–Gordan coefficients, and now we obtain $C>0$. □

So we obtain a second set of orthonormal polynomials for $L^2(\mathbb{R}^2,dm(x_1,x_2))$ in terms of Al-Salam and Chihara polynomials and Askey–Wilson polynomials.

The convolution formula for the Al-Salam and Chihara polynomials is obtained by applying Υ to (4.5) using the results of Propositions 4.2 and 4.3. The results hold as an identity in a weighted L^2-space, but since it is a polynomial identity it holds for all x_1, x_2; with $x_1=\mu(w_1)$, $x_2=\mu(w_2)$, and $k=k_1+k_2+j$,

$$\sum_{n_1+n_2=n+j} C_{n_1,n_2,n}^{k_1,k_2,k}\,S_{n_1}(x_1;q^{2k_1}w_2,q^{2k_1}/w_2|q^2)\,S_{n_2}(x_2;q^{2k_2}s,q^{2k_2}/s|q^2)$$
$$=\frac{S_n(x_1;q^{2k}s,q^{2k}/s|q^2)p_j(x_2;q^{2k_1}w_1,q^{2k_1}/w_1,q^{2k_2}s,q^{2k_2}/s|q^2)}{\sqrt{(q^2,q^{4k_1},q^{4k_2},q^{4k_1+4k_2+2j-2};q^2)_j}}. \tag{4.11}$$

We have not yet calculated the Clebsch–Gordan coefficients explicitly, but we can now use (4.11) to determine $C_{n_1,n_2,n}^{k_1,k_2,k}$ by specializing to a generating function for the Clebsch–Gordan coefficients. The result is phrased in terms of q-Hahn polynomials, which are defined as follows (cf. [4]):

$$Q_n(q^{-x};a,b,N;q)={}_3\varphi_2\left(\begin{matrix}q^{-n},q^{-x},abq^{n+1}\\ aq,\ q^{-N}\end{matrix};q,q\right).$$

See, e.g., [19] for other derivations of the following lemma.

LEMMA 4.4. *With $n_1+n_2=n+j$ we get*

$$C_{n_1,n_2,n}^{k_1,k_2,k_1+k_2+j}=C\;Q_j(q^{-2n_1};q^{4k_1-2},q^{4k_2-2},n+j;q^2),$$

with the constant C given by

$$\frac{q^{2k_1(n-n_1)}(q^2;q^2)_{n+j}\sqrt{(q^{4k_1};q^2)_{n_1}(q^{4k_2};q^2)_{n_2}(q^{4k_1};q^2)_j}}{\sqrt{(q^2;q^2)_{n_1}(q^2;q^2)_{n_2}(q^2,q^{4k_1+4k_2+4j};q^2)_n(q^2,q^{4k_2},q^{4k_1+4k_2+2j-2};q^2)_j}}.$$

Proof. Observe that $C_{n_1,n_2,n}^{k_1,k_2,k}$ is independent of s, $x_1=\mu(w_1)$ and $x_2=\mu(w_2)$. Specialize $w_2=q^{2k_2}s$ and $w_1=q^{2k_1}/w_2=q^{2k_1-2k_2}/s$; then the Al-Salam and Chihara polynomials in the summand on the left-hand side of (4.11) can be evaluated explicitly, since the ${}_3\varphi_2$-series reduces to 1. For this choice the Askey–Wilson polynomial on the right-hand side can also be evaluated explicitly, and we obtain the generating function

for the Clebsch–Gordan coefficients

$$\sum_{n_1+n_2=n+j} C^{k_1,k_2,k}_{n_1,n_2,n}\, q^{2n_1(k_2-k_1)-2n_2k_2} s^{n_1-n_2} \frac{\sqrt{(q^{4k_1};q^2)_{n_1}(q^{4k_2};q^2)_{n_2}}}{\sqrt{(q^2;q^2)_{n_1}(q^2;q^2)_{n_2}}}$$
$$= \frac{q^{-2jk_2-2n(k_1+k_2+j)} s^{n-j} (q^{4k_1},q^{4k_2},q^{4k_2}s^2;q^2)_j}{\sqrt{(q^2,q^{4k_1},q^{4k_2},q^{4k_1+4k_2+2j-2};q^2)_j}} \sqrt{\frac{(q^{4k_1+4k_2+4j};q^2)_n}{(q^2;q^2)_n}}$$
$$\times\ {}_3\varphi_2\left(\begin{matrix} q^{-2n}, q^{4k_2+2j}, q^{4k_1+2j}/s^2 \\ q^{4k_1+4k_2+4j},\ 0 \end{matrix} ; q^2, q^2 \right).$$

This determines $C^{k_1,k_2,k}_{n_1,n_2,n}$, but it takes some work to find the expression in terms of q-Hahn polynomials. First, take n_1 as the summation parameter in the sum and multiply both sides by s^{n+j} to find that both sides are polynomials of degree $n+j$ in s^2. Apply [14, eq. (III.6)] to rewrite the ${}_3\varphi_2$-series as a polynomial in s^2 and the q-binomial theorem [14, eq. (II.3)] to write $(q^{4k_2}s^2;q^2)_j$ as a polynomial in s^2. Comparing next the coefficients on both sides gives an expression for the Clebsch–Gordan coefficients as a terminating ${}_3\varphi_2$-series. To put it into the required form in terms of q-Hahn polynomials, we need to apply some transformations for ${}_3\varphi_2$-series, namely [14, (III.13), (III.11)]. The constant follows by a straightforward calculation. □

Combining Lemma 4.4 with the unitarity of the intertwining operator consisting of the Clebsch–Gordan coefficients results in the orthogonality relations for the q-Hahn and dual q-Hahn polynomials; cf. [14, section 7.2].

We now have all ingredients to rewrite (4.11). Simplifying proves the following theorem.

THEOREM 4.5. *With the notation* (4.7) *and* (4.6) *for the Al-Salam and Chihara polynomials and Askey–Wilson polynomials and* $x_1=\mu(w_1)$, $x_2=\mu(w_2)$, $n,j\in\mathbb{Z}_+$, $k_1,k_2>0$ *we have*

$$(q^{4k_1};q^2)_j \sum_{l=0}^{n+j} q^{2k_1(n-l)} \begin{bmatrix} n+j \\ l \end{bmatrix}_{q^2} Q_j(q^{-2l};q^{4k_1-2},q^{4k_2-2},n+j;q^2)$$
$$\times\ s_l(x_1;q^{2k_1}w_2,q^{2k_1}/w_2|q^2)\, s_{n+j-l}(x_2;q^{2k_2}s,q^{2k_2}/s|q^2)$$
$$= s_n(x_1;q^{2k_1+2k_2+2j}s,q^{2k_1+2k_2+2j}/s|q^2)\, p_j(x_2;q^{2k_1}w_1,q^{2k_1}/w_1,q^{2k_2}s,q^{2k_2}/s|q^2).$$

Remark 4.6. (i) Theorem 4.5 is a connection coefficient formula for orthogonal polynomials in two variables, orthogonal for the same measure, where the connection coefficients are given by the q-Hahn polynomials. The dual connection coefficient problem follows from the orthogonality for the Clebsch–Gordan coefficients or, equivalently, from the orthogonality relations for the dual q-Hahn polynomials.

(ii) The case $j=0$ gives a simple convolution property for the Al-Salam and Chihara polynomials, since the q-Hahn and the Askey–Wilson polynomial reduce to 1. This was the motivation for Al-Salam and Chihara [2] to introduce the Al-Salam and Chihara polynomials as the most general set of orthogonal polynomials still satisfying a convolution property; see also Al-Salam [1, section 8]. The case $n=0$ is also of interest, since then the q-Hahn polynomial can be evaluated and the Al-Salam and Chihara polynomial on the right-hand side reduces to 1. In both cases we have a free parameter in the sum.

(iii) Formally, in the representation space $\ell^2(\mathbb{Z}_+)\otimes\ell^2(\mathbb{Z}_+)$ we have two bases of (generalized) eigenvectors for the action of Y_sA, namely $v^k(x)$ and $w(x_1;x_2)$. They

are connected by Clebsch–Gordan coefficients, which are now expressible as Askey–Wilson polynomials;

$$w(x_1;x_2)=\sum_{j=0}^{\infty}\frac{p_j(\mu(x_2);q^{2k_1}x_1,q^{2k_1}/x_1,q^{2k_2}s,q^{2k_2}/s|q^2)}{\sqrt{(q^2,q^{4k_1},q^{4k_2},q^{4k_1+4k_2+2j-2};q^2)_j}}\,v^{k_1+k_2+j}(x_1);$$

cf. [15, (23)] for the appropriate analogue in the case $U_q(\mathfrak{su}(2))$ in which the Askey–Wilson polynomials are replaced by q-Racah polynomials. The dual Clebsch–Gordan coefficient relation follows by integrating against the appropriate orthogonality measure for the Askey–Wilson polynomials.

4.2. Racah coefficients and orthogonal polynomials. In the tensor product of three positive discrete series representations $\pi_{k_1}\otimes\pi_{k_2}\otimes\pi_{k_3}$ of $U_q(\mathfrak{su}(1,1))$ we have the same orthogonal bases as in section 3.2 and we use the same notation as in (3.9)–(3.12). Similarly, we now have an intertwiner for the $U_q(\mathfrak{su}(1,1))$-action in terms of q-Racah coefficients;

$$e_n^{((k_1k_2)k_{12}k_3)k}=\sum_{k_{23}}U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}}\;e_n^{(k_1(k_2k_3)k_{23})k}. \tag{4.12}$$

Again the constraints (3.14) hold.

PROPOSITION 4.7. *Define* $\Theta\colon \ell^2(\mathbb{Z}_+)\otimes\ell^2(\mathbb{Z}_+)\otimes\ell^2(\mathbb{Z}_+)\to L^2(\mathbb{R}^3,dm(x_1,x_2,x_3))$ *by*

$$\begin{aligned}&\Theta\big(e^{k_1}_{n_1}\otimes e^{k_2}_{n_2}\otimes e^{k_3}_{n_3}\big)(x_1,x_2,x_3)\\&=S_{n_1}(x_1;q^{2k_1}w_2,q^{2k_1}/w_2|q^2)\,S_{n_2}(x_2;q^{2k_2}w_3,q^{2k_2}/w_3|q^2)\,S_{n_3}(x_3;q^{2k_3}s,q^{2k_3}/s|q^2),\end{aligned}$$

with the measure $dm(x_1,x_2,x_3)$ *given by*

$$dm(x_1;q^{2k_1}w_2,q^{2k_1}/w_2|q^2)\,dm(x_2;q^{2k_2}w_3,q^{2k_2}/w_3|q^2)\,dm(x_3;q^{2k_3}s,q^{2k_3}/s|q^2),$$

where $x_i=\mu(w_i)$. *Then* Θ *is a unitary map intertwining* $\pi_{k_1}\otimes\pi_{k_2}\otimes\pi_{k_3}(1\otimes\Delta)(\Delta(Y_sA))$ *with* $2(M_{x_1}-\mu(s))/(q^{-1}-q)$.

Proof. Observe that $(1\otimes\Delta)(\Delta(Y_sA))=A^2\otimes\Delta(Y_sA)+Y_sA\otimes\Delta(1)$. The proof now proceeds as the proof of Proposition 4.2. □

PROPOSITION 4.8. (i) *The following equality holds with* $x_i=\mu(w_i)$*:*

$$\begin{aligned}&\Theta\big(e_n^{((k_1k_2)k_{12}k_3)k}\big)(x_1,x_2,x_3)=C_j(k_{12},k_3)C_{j_{12}}(k_1,k_2)\,S_n\left(x_1;q^{2k}s,\frac{q^{2k}}{s}|q^2\right)\\&\times\,p_j\left(x_3;q^{2k_{12}}w_1,\frac{q^{2k_{12}}}{w_1},q^{2k_3}s,\frac{q^{2k_3}}{s}|q^2\right)p_{j_{12}}\left(x_2;q^{2k_1}w_1,\frac{q^{2k_1}}{w_1},q^{2k_2}w_3,\frac{q^{2k_2}}{w_3}|q^2\right).\end{aligned}$$

(ii) *The following equality holds with* $x_i=\mu(w_i)$:

$$\begin{aligned}&\Theta\big(e_n^{(k_1(k_2k_3)k_{23})k}\big)(x_1,x_2,x_3)=C_{j'}(k_1,k_{23})C_{j_{23}}(k_2,k_3)\,S_n\left(x_1;q^{2k}s,\frac{q^{2k}}{s}|q^2\right)\\&\times\,p_{j'}\left(x_2;q^{2k_1}w_1,\frac{q^{2k_1}}{w_1},q^{2k_{23}}s,\frac{q^{2k_{23}}}{s}|q^2\right)p_{j_{23}}\left(x_3;q^{2k_2}w_2,\frac{q^{2k_2}}{w_2},q^{2k_3}s,\frac{q^{2k_{23}}}{s}|q^2\right).\end{aligned}$$

The constant $C_j(k_1,k_2)$ *is defined in Proposition* 4.3.

The proof of Proposition 4.8 is slightly more complicated than the proof of its counterpart Proposition 3.12 due to the fact that we do not have a nice factorization for Θ as in Remark 3.11. This is a consequence of the noncocommutativity of the comultiplication for $U_q(\mathfrak{su}(1,1))$.

Note that the occurrence of $S_n(x_1;q^{2k}s,q^{2k}/s|q^2)$ on the right-hand side corresponds to the intertwining property of the Racah coefficients as in the proof of the first statement of Proposition 4.3.

Proof. The proof of (i) and (ii) is similar. To prove (i) we use (3.10) (for the $U_q(\mathfrak{su}(1,1))$-setting) and Proposition 4.7 to find

$$\begin{aligned}\Theta\big(e_n^{((k_1k_2)k_{12}k_3)k}\big)(x_1,x_2,x_3) &= \sum_{n_{12}+n_3=n+j} C^{k_{12},k_3,k}_{n_{12},n_3,n}\, S_{n_3}(x_3;q^{2k_3}s,q^{2k_3}/s|q^2)\\ &\times \sum_{n_1+n_2=n_{12}+j_{12}} C^{k_1,k_2,k_{12}}_{n_1,n_2,n_{12}}\, S_{n_1}(x_1;q^{2k_1}w_2,q^{2k_1}/w_2|q^2)\, S_{n_2}(x_2;q^{2k_2}w_3,q^{2k_2}/w_3|q^2)\\ = C_{j_{12}}(k_1,k_2)&p_{j_{12}}(x_2;q^{2k_1}w_1,q^{2k_1}/w_1,q^{2k_2}w_3,q^{2k_2}/w_3|q^2)\\ &\times \sum_{n_{12}+n_3=n+j} C^{k_{12},k_3,k}_{n_{12},n_3,n}\, S_{n_3}(x_3;q^{2k_3}s,q^{2k_3}/s|q^2)\, S_{n_{12}}(x_1;q^{2k_{12}}w_3,q^{2k_{12}}/w_3,|q^2)\end{aligned}$$

by (4.11). The last sum can be evaluated by another application of (4.11) leading to the result. □

The n-dependence in the right-hand sides of Proposition 4.8 is the same, so we obtain the Wigner–Eckhart theorem for the $U_q(\mathfrak{su}(1,1))$-setting by applying Θ to (4.12). So we can restrict to $n=0$ in (4.12) before applying Θ without loss of generality, and we obtain the following polynomial identity in x_2 and x_3 with w_1 as a parameter:

(4.13)

$$\begin{aligned}&C_j(k_{12},k_3)C_{j_{12}}(k_1,k_2)\,p_j(x_3;q^{2k_{12}}w_1,q^{2k_{12}}/w_1,q^{2k_3}s,q^{2k_3}/s|q^2)\\ &\times p_{j_{12}}(x_2;q^{2k_1}w_1,q^{2k_1}/w_1,q^{2k_2}w_3,q^{2k_2}/w_3|q^2)\\ &=\sum_{j_{23}=0}^{j_{12}+j} U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}}\, C_{j'}(k_1,k_{23})C_{j_{23}}(k_2,k_3)\,p_{j'}(x_2;q^{2k_1}w_1,q^{2k_1}/w_1,q^{2k_{23}}s,q^{2k_{23}}/s|q^2)\\ &\times p_{j_{23}}(x_3;q^{2k_2}w_2,q^{2k_2}/w_2,q^{2k_3}s,q^{2k_{23}}/s|q^2).\end{aligned}$$

Again we can use (4.13) in two ways. First, we specialize to a suitable formula from which the Racah coefficients can be determined explicitly. The Racah coefficients for the finite dimensional representations of $U_q(\mathfrak{sl}(2,\mathbb{C}))$, see section 5, are due to Kirillov and Reshetikhin [20]; see also [35, section 14.5]. Second, with the explicit expression for the Racah coefficients we derive a convolution identity for the Askey–Wilson polynomials.

PROPOSITION 4.9. *The Racah coefficients of* (4.12) *are given by*

$$U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}} = C\ {}_4\varphi_3\left(\begin{matrix} q^{4k_1+4k_2+2j_{12}-2}, q^{4k_2+4k_3+2j_{23}-2}, q^{-2j_{12}}, q^{-2j_{23}}\\ q^{4k_2}, q^{4k_1+4k_2+4k_3+2j+2j_{12}-2}, q^{-2j-2j_{12}}\end{matrix};q^2;q^2\right),$$

with the constant C given by

$$\frac{(q^2,q^{4k_1},q^{4k_{23}},q^{4k_1+4k_{23}+2(j+j_{12}-j_{23})-2};q^2)_{j+j_{12}-j_{23}}^{1/2}}{(q^2,q^{4k_{12}},q^{4k_3},q^{4k_{12}+4k_3+2j-2};q^2)_j^{1/2}}\frac{(q^2,q^{4k_2},q^{4k_3},q^{4k_2+4k_3+2j_{23}-2};q^2)_{j_{23}}^{1/2}}{(q^2,q^{4k_1},q^{4k_2},q^{4k_1+4k_2+2j_{12}-2};q^2)_{j_{12}}^{1/2}}$$
$$\times q^{2k_2(j-j_{23})}\begin{bmatrix} j+j_{12} \\ j_{23}\end{bmatrix}_{q^2}\frac{(q^{4k_3};q^2)_j(q^{4k_2};q^2)_{j_{12}}(q^{4k_1+4k_2+4k_3+2j+2j_{12}-2};q^2)_{j_{23}}}{(q^{4k_3},q^{4k_2+4k_3+2j_{23}-2};q^2)_{j_{23}}(q^{4k_2+4k_3+4j_{23}};q^2)_{j+j_{12}-j_{23}}}.$$

Proof. Take $w_1=s=1$ and $x_2=\mu(q^{2k_1})$ in (4.13) to find

$$\begin{aligned}&p_j(x_3;q^{2k_{12}},q^{2k_{12}},q^{2k_3},q^{2k_3}|q^2)(q^{2k_1+2k_2}w_3,q^{2k_1+2k_2}/w_3;q^2)_{j_{12}}\\&=\sum_{j_{23}}C_1U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}}p_{j_{23}}(x_3;q^{2k_1+2k_2},q^{2k_2-2k_1},q^{2k_3},q^{2k_3}|q^2)\end{aligned}$$

for C_1 an explicit constant depending upon $k_1,k_2,k_3,j_{12},j_{23}$, and j, since two Askey–Wilson polynomials can be evaluated for this choice. So the Racah coefficients occur as the coefficients when developing the polynomial of degree $j+j_{12}$ on the left-hand side into Askey–Wilson polynomials. Hence the Racah coefficients can be obtained from

$$\begin{aligned}&C_2U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}}\\&=\int p_{j_{23}}(x_3;q^{2k_1+2k_2},q^{2k_2-2k_1},q^{2k_3},q^{2k_3}|q^2)p_j(x_3;q^{2k_{12}},q^{2k_{12}},q^{2k_3},q^{2k_3}|q^2)\\&\qquad\times(q^{2k_1+2k_2}w_3,q^{2k_1+2k_2}/w_3;q^2)_{j_{12}}\,dm(x_3;q^{2k_1+2k_2},q^{2k_2-2k_1},q^{2k_3},q^{2k_3}|q^2),\end{aligned}$$

for some known constant C_2. Now observe that

$$\begin{aligned}&(q^{2k_1+2k_2}w_3,q^{2k_1+2k_2}/w_3;q^2)_{j_{12}}\,dm(x_3;q^{2k_1+2k_2},q^{2k_2-2k_1},q^{2k_3},q^{2k_3}|q^2)\\&\qquad=C_3\,dm(x_3;q^{2k_{12}},q^{2k_2-2k_1},q^{2k_3},q^{2k_3}|q^2)\end{aligned}$$

for some known constant C_3 by (3.14) and (4.8). Thus the Racah coefficients can be obtained by integration;

(4.14)
$$\begin{aligned}C_4\,U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}}&=\int p_{j_{23}}(x_3;q^{2k_1+2k_2},q^{2k_2-2k_1},q^{2k_3},q^{2k_3}|q^2)\\&\qquad\times p_j(x_3;q^{2k_{12}},q^{2k_{12}},q^{2k_3},q^{2k_3}|q^2)\,dm(w_3;q^{2k_{12}},q^{2k_2-2k_1},q^{2k_3},q^{2k_3}|q^2),\end{aligned}$$

with C_4 explicitly known. Observe that three out of four of the parameters of each of the Askey–Wilson polynomials in (4.14) coincide with the parameters of the Askey–Wilson measure in (4.14). Use the connection coefficient formula for Askey–Wilson polynomials with one different parameter, cf. Askey and Wilson [5, (6.4–5)] or see [14, (7.6.8–9) with the right-hand side of (7.6.9) multiplied by $(q;q)_n$], twice to rewrite the Askey–Wilson polynomials in terms of Askey–Wilson polynomials with the same parameters as the Askey–Wilson measure in (4.14). By orthogonality the integration is then easily performed and we are left with a single sum, which can be written as a very well poised ${}_8\varphi_7$-series. This can be transformed to a balanced ${}_4\varphi_3$-series by Watson's transformation [14, (III.17)], and another application of Sears's transformation [14, (III.15)] gives the form as in the statement of the proposition. The constant follows from bookkeeping. ∎

Recall the q-Racah polynomials, see Askey and Wilson [4] or [14, section 7.2], [22],

$$R_n(\nu(x);\alpha,\beta,\gamma,\delta;q) = {}_4\varphi_3\left(\begin{matrix} q^{-n}, \alpha\beta q^{n+1}, q^{-x}, \gamma\delta q^{x+1} \\ \alpha q,\ \beta\delta q,\ \gamma q \end{matrix}; q, q\right) \tag{4.15}$$

with $\nu(x) = q^{-x} + \gamma\delta q^{x+1}$, one of the lower parameters equals q^{-N}, $N \in \mathbb{Z}_+$, and $0 \le n \le N$. The ${}_4\varphi_3$-series in Proposition 4.9 can be written in terms of a q-Racah polynomial.

We can now rewrite (4.13) to arrive at the key result of this paper. For convenience we replace q^2 by q, $(a,b,c) = (q^{k_1}, q^{k_2}, q^{k_3})$, and we relabel w_1, j_{23}, and j_{12} by t, l, and n, and finally replace x_2, x_3 by x_1, x_2. We obtain the following q-analogue of Theorem 3.13 and Corollary 3.15.

THEOREM 4.10. *With $x_1 = \mu(w_1)$, $x_2 = \mu(w_2)$, $n, j \in \mathbb{Z}_+$, we have the convolution identity for the Askey–Wilson polynomials*

$$\begin{aligned}\sum_{l=0}^{n+j} b^{j-l} \begin{bmatrix} j+n \\ l \end{bmatrix}_q \frac{(b^2;q)_n (a^2b^2c^2q^{j+n-1};q)_l (c^2;q)_j}{(c^2, b^2c^2q^{l-1};q)_l (b^2c^2q^{2l};q)_{j+n-l}} \\ \times R_l(\nu(n); b^2/q, c^2/q, q^{-j-n-1}, a^2b^2q^{n+j-1}; q) \\ \times p_{j+n-l}(x_1; at, a/t, bcq^l s, bcq^l/s|q)\, p_l(x_2; bw_1, b/w_1, cs, c/s|q) \\ = p_n(x_1; at, a/t, bw_2, b/w_2|q)\, p_j(x_2; abq^n t, abq^n/t, cs, c/s|q),\end{aligned}$$

with the notation of (4.6), (4.15).

Remark 4.11. (i) Theorem 4.5 can be obtained as a special case of Theorem 4.10 by letting $c \to 0$.

(ii) Dunkl [10, section 3] obtains a special case of Theorem 4.10 in the same spirit as his proof [11] of Corollary 3.15; see Remark 3.16(ii). The symmetric group is now replaced by the general linear group over the field of q elements. This finite group of Lie type has the symmetric group as its Weyl group; see [10] for more information.

(iii) Theorem 4.10 leads to a kind of generating function for the q-Racah and q-Hahn polynomials. Choosing $w_1 = at$ and $w_2 = cs$ in Theorem 4.10 reduces all four Askey–Wilson polynomials to a single term. The remaining free parameters s and t appear only in the combination s/t. Replacing $bcs/(at)$ by u and (a^2, b^2, c^2) by (α, β, γ) gives

$$\begin{aligned}\sum_{l=0}^{n+j} \begin{bmatrix} j+n \\ l \end{bmatrix}_q \frac{(\alpha;q)_{j+n-l} (\beta;q)_n (\alpha\beta\gamma q^{j+n-1};q)_l}{(\alpha;q)_n (\beta\gamma q^{l-1};q)_l (\beta\gamma q^{2l};q)_{j+n-l}} u^{j-l} (\beta\gamma q^l/u;q)_{j+n-l} (u;q)_l \\ \times R_l(\nu(n); \beta/q, \gamma/q, q^{-j-n-1}, \alpha\beta q^{n+j-1}; q) = (\alpha q^n u;q)_j (\beta/u;q)_n.\end{aligned}$$

For $\gamma = 0$ we obtain a similar identity for q-Hahn polynomials:

$$\begin{aligned}\sum_{l=0}^{n+j} \begin{bmatrix} j+n \\ l \end{bmatrix}_q \frac{(\alpha;q)_{j+n-l} (\beta;q)_n}{(\alpha;q)_n} Q_n(q^{-l}; \beta/q, \alpha/q, n+j; q) u^{j-l} (u;q)_l \\ = (\alpha q^n u;q)_j (\beta/u;q)_n.\end{aligned}$$

(iv) Theorem 4.10 gives the connection coefficients for two sets of orthogonal polynomials with respect to the absolutely continuous measure

$$\frac{(w_1^{\pm 2}, w_2^{\pm 2};q)_\infty}{(taw_1^{\pm 1}, aw_1^{\pm 1}/t, csw_2^{\pm 1}, cw_2^{\pm 1}/s;q)_\infty} \frac{1}{(bw_1^{\pm 1} w_2^{\pm 1};q)_\infty} \frac{dw_1}{w_1} \frac{dw_2}{w_2}$$

on the torus $\mathbb{T}^2$ for $|t|^{-1} < |a| < |t|$, $|s|^{-1} < |c| < |s|$, and $|b| < 1$. Here all possible signs for $\pm$ have to be used. (Otherwise discrete masses at points and lines have to be added.) This weight function is invariant under simultaneously interchanging w_1 with w_2, t with s, and a with c. This transforms the orthogonal polynomials on the right-hand side of Theorem 4.10 to the ones occurring in the left-hand side.

In particular, note that for $s = t$, $a = c$, the weight function is invariant under the Weyl group for B_2, i.e., the group generated by $(w_1, w_2) \mapsto (w_2, w_1)$ and $(w_1, w_2) \mapsto (w_1, w_2^{-1})$. The corresponding Weyl group invariant orthogonal polynomials are

$$p_n(\mu(w_1); at, a/t, bw_2, b/w_2|q)\, p_j(\mu(w_2); abq^n t, abq^n/t, at, a/t|q) + p_n(\mu(w_2); at, a/t, bw_1, b/w_1|q)\, p_j(\mu(w_1); abq^n t, abq^n/t, at, a/t|q)$$

for $n \geq j \geq 0$. These orthogonal polynomials do not seem directly related to the Koornwinder–Macdonald orthogonal polynomials associated with root system BC_2, see [27], although the structure of the orthogonality measure is similar.

5. Linearization coefficients for Askey–Wilson polynomials. In the results of the previous section using $U_q(\mathfrak{su}(1,1))$, especially Theorems 4.5 and 4.10, we can use analytic continuation with respect to the parameters involved in finding similar identities but with the Al-Salam and Chihara polynomials and the Askey–Wilson polynomials replaced by the dual q-Krawtchouk polynomials and the q-Racah polynomials; cf. [15], [20], [28]. These identities can be obtained by the same procedure using $U_q(\mathfrak{su}(2))$ and its representation theory instead of using $U_q(\mathfrak{su}(1,1))$. In particular we can now give an interpretation for q-Racah polynomials as Clebsch-Gordan coefficients for $U_q(\mathfrak{su}(2))$; see [15, (23)]. In this case we also have some knowledge on the structure of the dual Hopf $*$-algebra and this can be used to obtain a linearization formula for a two-parameter family of Askey–Wilson polynomials. This is an application of the results of the previous section.

We first recall $U_q(\mathfrak{su}(2))$ and its representation theory; see, e.g., [9], [24], [28], [30]. The Hopf algebra structure on $U_q(\mathfrak{su}(2))$ is the same as the Hopf algebra structure on $U_q(\mathfrak{sl}(2,\mathbb{C}))$; cf. (4.1), (4.2). The $*$-operator making $U_q(\mathfrak{su}(2))$ into a Hopf $*$-algebra for $0 < q < 1$ is given by

$$A^* = A, \quad B^* = C, \quad C^* = B, \quad D^* = D.$$

There is precisely one irreducible unitary $U_q(\mathfrak{su}(2))$-module W_N of each dimension $N+1$ with highest weight vector v_+, i.e., $A\, v_+ = q^{N/2} v_+$, $B\, v_+ = 0$. The corresponding representation is denoted by t^N. With respect to the standard orthonormal basis e_n^N, $0 \leq n \leq N$, the action of the generators is given by $t^N(A)\, e_n^N = q^{n-N/2}\, e_d^N$ and

$$t^N(B)\, e_n^N = \frac{q^{(1-N)/2}}{1-q^2} \sqrt{(1-q^{2n+2})(1-q^{2N-2n})}\, e_{n+1}^N,$$

$$t^N(C)\, e_n^N = \frac{q^{(1-N)/2}}{1-q^2} \sqrt{(1-q^{2n})(1-q^{2N-2n+2})}\, e_{n-1}^N,$$

with the convention $e_{-1}^N = 0 = e_{N+1}^N$. So e_N^N is the highest weight vector. The representation t^N, considered as a representation of $U_q(\mathfrak{sl}(2,\mathbb{C}))$, can be obtained from the discrete series representation π_k of (4.3) by formally replacing k by $-N/2$.

The Clebsch–Gordan decomposition holds; as unitary $U_q(\mathfrak{su}(2))$-modules

$$W_{N_1} \otimes W_{N_2} = \bigoplus_{j=0}^{\min(N_1,N_2)} W_{N_1+N_2-2j}.$$

The matrix coefficients of the intertwining operator give the Clebsch–Gordan coefficients;

$$e_n^N = \sum_{n_1,n_2} C_{n_1,n_2,n}^{N_1,N_2,N}\ e_{n_1}^{N_1} \otimes e_{n_2}^{N_2}. \tag{5.1}$$

Of course, the Clebsch–Gordan coefficient is zero if $N \neq N_1 + N_2 - 2j$ for $0 \leq j \leq \min(N_1, N_2)$. By considering the action of A on both sides we see that the Clebsch–Gordan coefficient is zero unless $n_1 + n_2 = n + j$, so the sum is actually a single sum. The Clebsch–Gordan coefficients are normalized by $\langle e_0^N, e_j^{N_1} \otimes e_0^{N_2} \rangle > 0$ if $N = N_1 + N_2 - 2j$, $0 \leq j \leq \min(N_1, N_2)$.

We are particularly interested in the element

$$X_p = q^{1/2}B + q^{-1/2}C - \frac{p^{1/2} - p^{-1/2}}{q - q^{-1}}(A - D) \in U_q(\mathfrak{sl}(2, \mathbb{C})), \qquad p > 0.$$

Then X_pA is self-adjoint and $\Delta(X_pA) = A^2 \otimes X_pA + X_pA \otimes 1$. Koornwinder [28] has shown that in each module W_N the action of X_pA is completely diagonalizable. To formulate this result we introduce the orthonormal dual q-Krawtchouk polynomials; for $a > 0$,

$$r_n(q^{-x} - q^{x-N}/a; a, N; q) = (-1)^n a^{n/2} q^{n(n-1)/4} \left[\begin{array}{c} N \\ n \end{array} \right]_q^{1/2} R_n(q^{-x} - q^{x-N}/a; a, N; q)$$

for $N \in \mathbb{Z}_+$ and $0 \leq x, n \leq N$. The dual q-Krawtchouk polynomials are special cases of the q-Racah polynomials (4.15) and are defined by

$$R_n(q^{-x} - q^{x-N}/a; a, N; q) = {}_3\varphi_2 \left(\begin{array}{c} q^{-n}, q^{-x}, -q^{x-N}/a \\ q^{-N}, 0 \end{array} ; q, q \right).$$

The corresponding three-term recurrence relation is

$$\begin{aligned} (q^{-x} - q^{x-N}/a)\, r_n &= A_n\, r_{n+1} + q^{n-N}(1 - a^{-1})\, r_n + A_{n-1}\, r_{n-1}, \\ A_n &= a^{-1/2} q^{-N+n/2} \sqrt{(1 - q^{n+1})(1 - q^{N-n})} \end{aligned} \tag{5.2}$$

for $0 \leq x, n \leq N$, and $r_n = r_n(q^{-x} - q^{x-N}/a; a, N; q)$.

PROPOSITION 5.1 (see [28]). *There exists an orthogonal basis $\phi_f^N = \phi_f^N(p)$, $0 \leq f \leq N$, of W_N of eigenvectors of $t^N(X_pA)$ for the eigenvalue*

$$\lambda_f^N(p) = \frac{p^{1/2} q^{N-2f} - p^{-1/2} q^{2f-N} + p^{-1/2} - p^{1/2}}{q^{-1} - q}.$$

Moreover, $\phi_f^N(p) = \sum_{n=0}^N r_n(q^{-2f} - q^{2f-2N}/p; p, N; q^2)\, e_d^N$.

Proposition 5.1 is the analogue of Proposition 4.1, and we could have formulated it in a similar fashion using the finite discrete orthogonality measure for the dual q-Krawtchouk polynomials. Actually, replacing $e^{i\theta}$, k in $S_n(\cos\theta; q^{2k}s, q^{2k}/s|q^2)$ by q^{-2f+N}/s, $-N/2$ and next taking $s^2 = -p^{-1}$ gives $r_n(q^{-2f} - q^{2f-2N}/p; p, N; q^2)$. The analogue of Proposition 4.2 is the following.

PROPOSITION 5.2. *For $0 \leq f_1 \leq N_1$, $0 \leq f_2 \leq N_2$, define in $W_{N_1} \otimes W_{N_2}$ the vector*

$$\phi_{f_1,f_2}^{N_1,N_2} = \sum_{n_1=0}^{N_1} r_{n_1}(q^{-2f_1} - q^{2f_1-2N_1-2N_2+4f_2}/p; pq^{2N_2-4f_2}, N_1; q^2)\ e_{n_1}^{N_1} \otimes \phi_{f_2}^{N_2};$$

then $t^{N_1}\otimes t^{N_2}\big(\Delta(X_pA)\big)\,\phi^{N_1,N_2}_{f_1,f_2}=\lambda^{N_1+N_2}_{f_1+f_2}(p)\,\phi^{N_1,N_2}_{f_1,f_2}$. *Moreover,* $\phi^{N_1,N_2}_{f_1,f_2}$, $0\le f_1\le N_1$, $0\le f_2\le N_2$, *constitutes an orthogonal basis of* $W_{N_1}\otimes W_{N_2}$ *of eigenvectors of* $\Delta(X_pA)$.

Proof. From $\Delta(X_pA)=A^2\otimes X_pA+X_pA\otimes 1$ it follows that there is an eigenvector of the form $\sum_{n_1=0}^{N_1}p_{n_1}\,e^{N_1}_{n_1}\otimes\phi^{N_2}_{f_2}$ by solving a three-term recurrence relation for the p_{n_1}. Now (5.2) can be used to solve this.

There are $(N_1+1)(N_2+1)$ eigenvectors in $W_{N_1}\otimes W_{N_2}$, and $\langle\phi^{N_1,N_2}_{f_1,f_2},\phi^{N_1,N_2}_{g_1,g_2}\rangle$ equals zero if $f_2\ne g_2$ by Proposition 5.1. It also equals zero if $f_1+f_2\ne g_1+g_2$ by the self-adjointness of X_pA. □

The result of Proposition 5.2 can be obtained from Proposition 4.2 by substituting k_1, k_2 by $-N_1/2$, $-N_2/2$ and w_1, w_2 by $q^{N_1+N_2-2f_1-2f_2}/s$, $q^{N_2-2f_2}/s$ and s^2 by $-p^{-1}$.

PROPOSITION 5.3. *For* $N=N_1+N_2-2j$, $0\le j\le\min(N_1,N_2)$, *we have*

$$\langle\phi^{N_1,N_2}_{f_1,f_2},e^N_n\rangle=r_n(q^{2j-2f_1-2f_2}-q^{2f_1+2f_2-2j-2N}/p;p,N;q^2)\langle\phi^{N_1,N_2}_{f_1,f_2},e^N_0\rangle$$

if $0\le f_1+f_2-j\le N$, *and* $\langle\phi^{N_1,N_2}_{f_1,f_2},e^N_n\rangle=0$ *otherwise. If nonzero, then*

$$\langle\phi^{N_1,N_2}_{f_1,f_2},e^N_0\rangle=\begin{bmatrix}N_2\\ j\end{bmatrix}_{q^2}^{1/2}\frac{p^{j/2}q^{j(2N_1+N_2)}q^{-3j(j-1)/2}}{\sqrt{(q^{2N_1},q^{2N_1+2N_2-2j+2};q^{-2})_j}}(-p^{-1}q^{2f_1+2f_2-2N_1-2N_2};q^2)_j$$
$$\times(q^{-2f_1-2f_2};q^2)_j\,{}_4\varphi_3\left(\begin{matrix}q^{-2j},q^{2j-2-2N_1-2N_2},q^{-2f_2},-p^{-1}q^{2f_2-2N_2}\\ q^{-2N_2},q^{-2f_1-2f_2},-p^{-1}q^{2f_1+2f_2-2N_1-2N_2}\end{matrix};q^2,q^2\right).$$

Note that the ${}_4\varphi_3$-series is balanced and can be written in terms of q-Racah polynomials (4.15). The ${}_4\varphi_3$-series in Proposition 5.3 equals

$$R_j(q^{-2f_2}-p^{-1}q^{2f_2-2N_2};q^{-2N_2-2},q^{-2N_1-2},q^{-2f_1-2f_2-2},-p^{-1}q^{2f_1+2f_2-2N_2};q^2).$$

The proof of Proposition 5.3 is similar to the proof of Proposition 4.3. Proposition 5.3 can also be obtained from Proposition 4.3 using the substitutions as indicated earlier. It can also be obtained by using $e^N_0=\sum C^{N_1,N_2,N}_{n_1,n_2,0}\,e^{N_1}_{n_1}\otimes e^{N_2}_{n_2}$, Propositions 5.2 and 5.1, and the explicit value for the Clebsch–Gordan coefficients for $n=0$, $N=N_1+N_2-2j$,

$$C^{N_1,N_2,N}_{n_1,n_2,0}=(-1)^{n_2}q^{n_2(N_2-j-1)}\sqrt{\frac{(q^{2n_1+2};q^2)_{n_2}(q^{2N_1-2n_1};q^{-2})_{n_2}(q^{2N_2};q^{-2})_j}{(q^2;q^2)_{n_2}(q^{2N_2};q^{-2})_{n_2}(q^{2N_1+N_2-2j+2};q^2)_j}}.$$

See, e.g., [35, section 14.3], but this simple case can also be derived as follows. Apply C to both sides of (5.1) to obtain a three-term recurrence for the Clebsch–Gordan coefficients, which reduces to a two-term recurrence for $n=0$. This can easily be solved, with the initial condition following from the unitarity and the normalization; see [34] for a similar derivation. Then we have a sum involving the product of two dual q-Krawtchouk polynomials. Upon inserting the series representation we obtain a triple sum, and after interchanging summations we can use the q-binomial theorem and the q-Chu–Vandermonde sum, see [14], to obtain a single ${}_4\varphi_3$-series.

Remark 5.4. With Proposition 5.3 at hand it is straightforward to calculate the $U_q(\mathfrak{su}(2))$-counterparts of Theorems 4.5 and 4.10. The Al-Salam and Chihara, respectively, Askey–Wilson, polynomials have to be replaced by dual q-Krawtchouk, respectively, q-Racah, polynomials. The result can also be obtained from Theorems 4.5 and 4.10 by substitution as indicated earlier, so we do not give them explicitly. These formulas give an alternative for the formulas of Groza and Kachurik [18].

In the representation space $W_{N_1} \otimes W_{N_2}$ we have two bases of eigenvectors for the action of $X_p A$, namely ϕ_f^N and $\phi_{f_1,f_2}^{N_1,N_2}$, and the corresponding Clebsch–Gordan coefficients are given by Proposition 5.3, since, with $N = N_1 + N_2 - 2j$,

$$\begin{aligned}\phi_{f_1,f_2}^{N_1,N_2} &= \sum_{j=0}^{\min(N_1,N_2)} \sum_{n=0}^{N} \langle \phi_{f_1,f_2}^{N_1,N_2}, e_n^N \rangle \, e_n^N \\ &= \sum_{j=0}^{\min(N_1,N_2)} \langle \phi_{f_1,f_2}^{N_1,N_2}, e_0^N \rangle \sum_{n=0}^{N} r_n(q^{2j-2f_1-2f_2} - q^{2f_1+2f_2-2j-2N}/p; p, N; q^2)\, e_n^N \\ &= \sum_{j=0}^{\min(N_1,N_2)} \langle \phi_{f_1,f_2}^{N_1,N_2}, e_0^N \rangle \, \phi_{f_1+f_2-j}^N.\end{aligned}$$

Here we use the convention that $\phi_f^N = 0$ for $f > N$ or $f < 0$. So introducing the notation

$$\phi_{f_1,f_2}^{N_1,N_2} = \sum_{f,j} C_{f_1,f_2,f}^{N_1,N_2,N}(p)\ \phi_f^N, \tag{5.3}$$

we see that the Clebsch–Gordan coefficients are zero unless $f_1 + f_2 = f + j$, and then $C_{f_1,f_2,f}^{N_1,N_2,N}(p) = \langle \phi_{f_1,f_2}^{N_1,N_2}, e_0^N \rangle$. So, by Proposition 5.3 we have proved that the q-Racah polynomials occur as Clebsch–Gordan coefficients for $U_q(\mathfrak{su}(2))$. This is due to Granovskii and Zhedanov [15].

Using (5.3) in a special case we can obtain the linearization coefficients for the two parameter family of Askey–Wilson polynomials occurring as spherical functions on the quantum $SU(2)$ group; cf. [28]. We consider odd-dimensional representations; $N_1 = 2l_1$, $N_2 = 2l_2$, $l_1, l_2 \in \mathbb{Z}_+$. Then the kernel of $t^{2l_1}(X_p A)$ is one dimensional and spanned by $\phi_{l_1}^{2l_1}(p)$. Moreover, $\phi_{l_1,l_1}^{2l_1,2l_2}(p) = \phi_{l_1}^{2l_1}(p) \otimes \phi_{l_2}^{2l_2}(p)$. Next we consider matrix elements as linear functionals on $U_q(\mathfrak{su}(2))$ to find

$$\begin{aligned}&\sum_{(X)} \langle t^{2l_1}(X_{(1)})\phi_{l_1}^{2l_1}(p), \phi_{l_1}^{2l_1}(r)\rangle \, \langle t^{2l_2}(X_{(2)})\phi_{l_2}^{2l_2}(p), \phi_{l_2}^{2l_2}(r)\rangle \\ &= \langle t^{2l_1} \otimes t^{2l_2}(\Delta(X))\phi_{l_1,l_1}^{2l_1,2l_2}(p), \phi_{l_1,l_1}^{2l_1,2l_2}(r)\rangle \\ &= \sum_{l=|l_1-l_2|}^{l_1+l_2} C_{l_1,l_2,l}^{2l_1,2l_2,2l}(p) C_{l_1,l_2,l}^{2l_1,2l_2,2l}(r) \langle t^{2l}(X)\phi_l^{2l}(p), \phi_l^{2l}(r)\rangle,\end{aligned} \tag{5.4}$$

where $r > 0$ is another parameter and $\Delta(X) = \sum_{(X)} X_{(1)} \otimes X_{(2)}$.

The dual Hopf $*$-algebra $A_q(SU(2))$ generated by the matrix elements of the representations t^N, $N \in \mathbb{Z}_+$, of $U_q(\mathfrak{su}(2))$, is known in terms of generators and relations, cf. [9], [24], [28], [30]. Koornwinder [28] has given an explicit expression for the element in $A_q(SU(2))$ corresponding to the linear functionals considered in (5.4), which can be considered as a zonal spherical function on the quantum $SU(2)$ group.

$$\langle t^{2l}(X)\phi_l^{2l}(p), \phi_l^{2l}(r)\rangle = \frac{q^{-l}}{(q^{2l+2};q^2)_l} \left\langle X, p_l\left(\rho; q\sqrt{\frac{p}{r}}, q\sqrt{\frac{r}{p}}, \frac{-q}{\sqrt{pr}}, -q\sqrt{pr}|q^2\right)\right\rangle, \tag{5.5}$$

where $\rho \in A_q(SU(2))$ is some fixed simple element, which is, up to an affine scaling, the linear functional $X \mapsto \langle t^2(X)\phi_1^2(p), \phi_1^2(r)\rangle$, and the last $\langle \cdot, \cdot \rangle$ denotes the duality

between $U_q(\mathfrak{su}(2))$ and $A_q(SU(2))$. Since $A_q(SU(2))$ is the dual Hopf $*$-algebra, the left-hand side of (5.4) corresponds to the multiplication of the two linear functionals. So (5.4) leads to the following identity in $A_q(SU(2))$:

$$p_{l_1}(\rho)\,p_{l_2}(\rho) = \sum_{l=|l_1-l_2|}^{l_1+l_2} q^{l_1+l_2-l}\frac{(q^{2l_1+2};q^2)_{l_1}(q^{2l_2+2};q^2)_{l_2}}{(q^{2l+2};q^2)_l}C_{l_1,l_2,l}^{2l_1,2l_2,2l}(p)C_{l_1,l_2,l}^{2l_1,2l_2,2l}(r)\,p_l(\rho)$$

with $p_l(\cdot) = p_l(\cdot; q\sqrt{\frac{p}{r}}, q\sqrt{\frac{r}{p}}, \frac{-q}{\sqrt{pr}}, -q\sqrt{pr}|q^2)$.

The only information on $A_q(SU(2))$ needed is the existence of a family of one-dimensional representations sending ρ to $\cos\theta$. Thus, applying the one-dimensional representations of $A_q(SU(2))$ and using Proposition 5.3 proves the following linearization coefficient formula.

THEOREM 5.5. *Let $p_l(x) = p_l(x; q\sqrt{\frac{p}{r}}, q\sqrt{\frac{r}{p}}, \frac{-q}{\sqrt{pr}}, -q\sqrt{pr}|q^2)$, $p, r > 0$, be defined in terms of Askey–Wilson polynomials* (4.6)*. Then the coefficients in the linearization formula*

$$p_{l_1}(x)\,p_{l_2}(x) = \sum_{j=0}^{2\min(l_1,l_2)} c_j\,p_{l_1+l_2-j}(x)$$

are given by a product of two balanced terminating ${}_4\varphi_3$-series;

$$\begin{aligned} c_j = {} & q^{-j(j-1)}q^{j+4jl_1}(q^{2l_1+2};q^2)_{l_1-j}(q^{2l_2+2};q^2)_{l_2}\begin{bmatrix} 2l_2 \\ j \end{bmatrix}_{q^2} \\ & \times\frac{(q^{2l_1+2l_2};q^{-2})_j}{(q^{2l_1+2l_2+2};q^2)_{l_1+l_2-j}}\frac{1-q^{4l_1+4l_2-4j+2}}{1-q^{4l_1+4l_2-2j+2}} \\ & \times\, p^{j/2}(-p^{-1}q^{-2l_1-2l_2};q^2)_j\ {}_4\varphi_3\left(\begin{matrix} q^{-2j}, q^{-2l_2}, q^{2j-2-4l_1-4l_2}, -p^{-1}q^{-2l_2} \\ q^{-4l_2}, q^{-2l_1-2l_2}, -p^{-1}q^{-2l_1-2l_2} \end{matrix};q^2,q^2\right) \\ & \times\, r^{j/2}(-r^{-1}q^{-2l_1-2l_2};q^2)_j\ {}_4\varphi_3\left(\begin{matrix} q^{-2j}, q^{-2l_2}, q^{2j-2-4l_1-4l_2}, -r^{-1}q^{-2l_2} \\ q^{-4l_2}, q^{-2l_1-2l_2}, -r^{-1}q^{-2l_1-2l_2} \end{matrix};q^2,q^2\right). \end{aligned}$$

Remark 5.6. (i) In particular, for $p = r$ the linearization coefficients are positive. This can already be observed without the explicit knowledge of the linearization coefficients; see [24, section 8.3], [26, section 7].

(ii) For $p = r = 1$ the Askey–Wilson polynomials $p_l(x; q, q, -q, -q|q^2)$ are the continuous q-Legendre polynomials $C_l(x; q^2|q^4)$; see [5, section 4]. This is a special case of the continuous q-ultraspherical polynomials introduced by Rogers at the end of the 19th century. Rogers calculated the linearization coefficients for the continuous q-ultraspherical polynomials, see, e.g., [5, section 4], [14, section 8.5], and we can go from Theorem 5.5 to the special case of Rogers's result by using Andrew's summation formula; see [14, (II.17)].

(iii) Not only the zonal spherical elements on the quantum $SU(2)$ group are known in terms of Askey–Wilson polynomials in the generators of the dual Hopf algebra as in (5.5), but any matrix coefficient of t^N of the form $\langle t^N(X)\phi_f^N(p), \phi_g^N(r)\rangle$ can be written in terms of Askey–Wilson polynomials on the dual Hopf algebra. This is due to Noumi and Mimachi [31], [32], [30]; see [24] for a proof. The method described here to obtain a linearization formula only works for the zonal spherical functions, as in the group case.

Acknowledgment. We thank Tom Koornwinder for useful comments. We also thank Charles Dunkl for useful comments on the previous version and pointing out [10] and Alexei Zhedanov for pointing out [15], [17]. The first author thanks the Universiteit Gent for its hospitality.

QUASICONVEXIFICATION IN $W^{1,1}$ AND OPTIMAL JUMP MICROSTRUCTURE IN BV RELAXATION*

CHRISTOPHER J. LARSEN†

Abstract. An integral representation for the relaxation in $BV(\Omega;\mathbb{R}^p)$ of the functional

$$u \mapsto \int_\Omega W(\nabla u(x))dx + \mathcal{H}^{N-1}(S(u))$$

with respect to BV weak $*$ convergence is obtained. The bulk term in the integral representation reduces to the quasiconvexification of W, and we describe optimal behavior of approximating sequences along $S(u)$, for scalar valued u.

Key words. quasiconvex, lower semicontinuous, microstructure, bounded variation, relaxation

1. Introduction.

In this paper, we study the lower semicontinuity of the functional

$$E(u) := \int_\Omega W(\nabla u)dx + \mathcal{H}^{N-1}(S(u)),$$

where $\Omega \subset \mathbb{R}^N$ is open and bounded, $u \in BV(\Omega;\mathbb{R}^p)$, ∇u is the Radon–Nikodym derivative of Du with respect to $\mathcal{L}^N$, $S(u)$, the "jump set" of u, is the complement of the set of Lebesgue points of u, and $\mathcal{H}^{N-1}$ is the $N-1$-dimensional Hausdorff measure.

This functional can be viewed as modeling materials with fracture: if u represents a deformation, the energy density W penalizes elastic deformation, and $\mathcal{H}^{N-1}(S(u))$ penalizes fracture by the size of the fracture site.

As is typical in the study of such functionals, we consider the relaxed energy I, i.e., the lower semicontinuous envelope in L^1 of the original energy E. By studying why these energies might not agree, and in particular, why corresponding energy densities might not agree, one is led to investigate the local behavior of minimizing sequences and the onset of microstructure, i.e., the development in minimizing sequences of finer and finer oscillations of their gradients, jump sets, or a combination of the two. By optimal "jump microstructure," we mean optimal oscillations involving both the gradients and jump sets of a sequence of functions that occur along the jump set of the limit of that sequence.

The jump set $S(u)$ of any BV function u is known to be $N-1$-rectifiable, and so it has a normal, ν, $\mathcal{H}^{N-1}$ almost everywhere. Furthermore, we have the decomposition

$$Du = \nabla u\mathcal{L}^N + [u] \otimes \nu\mathcal{H}^{N-1}\lfloor S(u) + C(u),$$

This research was conducted while the author was at Carnegie Mellon University and at the Army Research Laboratory in Aberdeen, MD.

where $[u]$ is the jump in u, i.e., $u^+ - u^-$, where u^+ and u^- are the traces of u on either side of $S(u)$ (see, e.g., [10] and [17]), and $C(u)$ is the so-called *Cantor part*, which is singular with respect to the first two measures in the decomposition. If $C(u) = 0$, we say $u \in SBV(\Omega; \mathbb{R}^p)$, the space of *special functions of bounded variation* introduced in [9]. Since functions with $Du = C(u)$ are dense in L^1, if $\min W = W(0)$ then the relaxation of E would reduce to $\mathcal{L}^N(\Omega)W(0)$. We avoid this pathology by only considering sequences in SBV, which is equivalent to relaxing $E(\cdot)+\infty|C(\cdot)|(\Omega)$. This corresponds to allowing macroscopic states with Cantor part, but not microscopic states.

In [3], Ambrosio analyzed the energy functional on SBV given by

$$E(u) = \int_\Omega W(x, u, \nabla u)dx + \int_{S(u)} \phi(u^+, u^-, \nu)d\mathcal{H}^{N-1}(x),$$

under the hypotheses that W is Carathéodory and has superlinear growth in ∇u, and under conditions on ϕ that, in particular, allow ϕ to be any positive constant. A result is that if W is quasiconvex, and if certain assumptions on ϕ are met, then E is L^1_{loc} lower semicontinuous in SBV. The analysis of the relaxation in BV of the model where $\phi \equiv 1$ and W has superlinear growth was carried out in [11].

In this paper, we assume that W has linear growth and we take $\phi \equiv 1$. Physically, this last assumption corresponds to weighing jumps, or cracks, only by the size of the jump set $S(u)$, with no dependence on the orientation ν or size of the jump $[u]$. The linear growth of W allows interaction along the jump set: approximating sequences of u need not jump at $S(u)$, but might have much more complicated behavior consisting of combinations of smooth growth (gradients) and jumps. If W has superlinear growth, it is energetically impossible for optimal approximating sequences to develop concentrations of their gradients along the jump set of u, and so their behavior there is much simpler. The study of the case where W and ϕ both have linear growth was undertaken in [6] (see also [7]).

The main new contributions in this paper are the expressions for QW (the quasiconvexification of W) in section 3, a new method for showing the upper bound inequality for the jump density in section 4, Lemma 5.1 in section 5 which allows us to blow up in such a way that the rescaled variation measures do not lose mass as they converge weakly $*$, and finally a method for finding the optimal jump microstructure for scalar valued functions in section 6. This last result allows us to exhibit the optimal behavior of approximating sequences along $S(u)$. The method is applicable not only when the jump energy density is a constant, but also when it depends in a positive homogenous degree one way on the jump (see Theorem 6.5 and Remark 6.6).

This paper is organized as follows: in section 2 we discuss preliminaries and state the relaxation theorem, the essence of which is the integral representation

$$I(u) = \int_\Omega QW(\nabla u)dx + \int_{S(u)} h([u], \nu)d\mathcal{H}^{N-1} + \int_\Omega (QW)^\infty(dC(u)), \tag{1.1}$$

where QW is the quasiconvexification of W (see section 2), and h and $(QW)^\infty$ are defined in section 2.

In section 3 we show that, although QW is defined in terms of sequences in Sobolev spaces, there are equivalent definitions in terms of certain sequences in BV. An analogous lower semicontinuity result for superlinear W was obtained by Ambrosio in [3], Theorem 3.3.

In section 4, we show that $I(u) \leq$ the right-hand side of (1.1). We first prove that $I(u,\cdot)$ is a finite Borel regular measure, absolutely continuous with respect to $\mathcal{L}^N + |Du|$. This follows largely from [12]. The remaining issue in this section is the upper bound for $I(u,\cdot)\lfloor S(u)$, for which we introduce a new argument. There is some difficulty with this step because $\mathcal{H}^{N-1}\lfloor S(u)$ is, in general, not a Radon measure, and so taking derivatives with respect to $\mathcal{H}^{N-1}\lfloor S(u)$ is not possible. The usual method for showing upper bound inequalities for jump densities is based on [4] and [5], and involves approximating jump sets with boundaries of sets with finite perimeter. The technique here is based on looking at the intersection of the jump set with certain sets of finite perimeter. We consider level sets E_t of the components of u, such that E_t has finite perimeter and $|D_j u| := |Du|\lfloor S(u)$ concentrates on $S(u) \cap \partial_* E_t$ as we blow-up. We then see that the analysis on $S(u) \cap \partial_* E_t$ is much easier than on $S(u)$. The rest follows from constructing functions in a reasonable way, and by using a suitable covering argument.

Section 5 deals with the proof of the lower bound inequality $I(u) \geq$ the right-hand side of (1.1), which is a modified version of the corresponding argument in [6]. The changes include a lemma that allows us to choose the rescaling factors so that as the rescaled variation measures converge weakly $*$ on a cube, they do not lose any mass (see Lemma 5.1).

In section 6 we find optimal microstructure along the jump set of u, for scalar valued u. The proof relies on a coarea formula and an application of Jensen's inequality on boundaries of level sets. It turns out that the proof may be easily extended to the case where the energy density on jumps is a positive homogeneous degree one function of $[u]\nu$, and also when the energy density on jumps is just a function of the normal to $S(u)$.

2. Preliminaries and the relaxation theorem. We consider a bounded, open set $\Omega \subset \mathbb{R}^N$, and we define the Sobolev spaces $W^{1,1}(\Omega)$ and $W^{1,\infty}(\Omega)$, and the space of functions of bounded variation $BV(\Omega)$ in the usual way (see, e.g., [10] and [17]). We denote by ρ_m, or alternatively ρ_ϵ, the standard mollifier, and for $E \subset \Omega$, χ_E stands for the characteristic function of E. Given two sets A and B, we define the *symmetric difference* $A \triangle B := (A \backslash B) \cup (B \backslash A)$.

We say that a set $E \subset \Omega$ has *finite perimeter* in Ω if $\chi_E \in BV(\Omega)$. For such an E, the *measure theoretic boundary* in Ω, $\partial_* E$, is defined as

$$\left\{ x \in \Omega : \limsup_{\delta \to 0^+} \frac{\mathcal{L}^N(B(x,\delta) \cap E)}{\mathcal{L}^N(B(x,\delta))} > 0 \text{ and } \limsup_{\delta \to 0^+} \frac{\mathcal{L}^N(B(x,\delta) \backslash E)}{\mathcal{L}^N(B(x,\delta))} > 0 \right\}, \tag{2.1}$$

where $B(x,\delta)$ is the closed ball in $\mathbb{R}^N$ centered at x with radius δ. We denote by $\nu_E(x)$ the *measure theoretic normal* to E at $x \in \partial_* E$ (for properties of this normal, see [10] or [17]). The *reduced boundary* $\partial^* E$ is the set of $x \in \partial_* E$ such that x is a Lebesgue point for ν_E, with respect to the Radon measure $\mathcal{H}^{N-1}\lfloor \partial_* E$. Given a set E of finite perimeter, we define on $\partial_* E$ the following:

$$H(x) := \{ y \in \mathbb{R}^N : \nu_E(x) \cdot (y - x) = 0 \},$$
$$H^+(x) := \{ y \in \mathbb{R}^N : \nu_E(x) \cdot (y - x) \geq 0 \},$$

and

$$H^-(x) := \{ y \in \mathbb{R}^N : \nu_E(x) \cdot (y - x) \leq 0 \}.$$

For $u \in BV(\Omega;\mathbb{R}^p)$, we write $Du = D_{ac}u + D_s u$, where $D_{ac}u$ and $D_s u$ stand for, respectively, the absolutely continuous and singular part of Du with respect to $\mathcal{L}^N$. We also consider the set $S(u)$ of points which are not Lebesgue points for u, and recall that $S(u)$ is $N-1$-rectifiable, and so it has a normal, ν, $\mathcal{H}^{N-1}$-almost everywhere. We set $D_j u := D_s u \lfloor S(u)$ and use the representations $D_{ac}u = \nabla u \mathcal{L}^N$ and $D_j u = [u] \otimes \nu \mathcal{H}^{N-1} \lfloor S(u)$, so we have the decomposition

$$Du = \nabla u \mathcal{L}^N + [u] \otimes \nu \mathcal{H}^{N-1} \lfloor S(u) + C(u), \tag{2.2}$$

where $C(u) := D_s u - D_j u$, $[u]$ is the jump in u across $S(u)$, i.e., $[u] = u^+ - u^-$, where u^+ and u^- are the traces of u on either side of $S(u)$. If $C(u) = 0$, then we say u is a *special function of bounded variation*, and we write $u \in SBV(\Omega;\mathbb{R}^p)$. This space was introduced in [9].

We set $\mathbb{R}^+ := [0,\infty)$ and $\bar{\mathbb{R}} := \mathbb{R} \cup \{-\infty,\infty\}$. We denote the space of $p \times N$ matrices by $\mathbb{M}^{p\times N}$, and, for $W : \mathbb{M}^{p\times N} \to \mathbb{R}$, we define the *recession function* $W^\infty : \mathbb{M}^{p\times N} \to \bar{\mathbb{R}}$ by

$$W^\infty(F) := \limsup_{t\to\infty} \frac{W(tF)}{t}.$$

We recall that a function $f : \mathbb{M}^{p\times N} \to \mathbb{R}$ is *quasiconvex* if $f(F) \le \int_A f(\nabla\phi)dx$ for all $\phi \in Fx + C_0^\infty(A;\mathbb{R}^p)$ and all $F \in \mathbb{M}^{p\times N}$, where $A \subset \mathbb{R}^N$ is any open set with $\mathcal{L}^N(A) = 1$ (see [15]). We denote by QW the quasiconvex envelope of W and by CW the convex envelope, i.e.,

$$QW(F) := \sup\{f(F) : f \le W \text{ and } f \text{ is quasiconvex}\},$$
$$CW(F) := \sup\{f(F) : f \le W \text{ and } f \text{ is convex}\}.$$

It follows from a straightforward rescaling argument (see [13]; see also [1] and [8]) that for W satisfying (H2) below, we have

$$QW(F) = \inf\left\{ \liminf_{n\to\infty} \int_A W(\nabla u_n)dx : \{u_n\} \subset W^{1,1}(A;\mathbb{R}^p), u_n \to Fx \text{ in } L^1(A;\mathbb{R}^p)\right\} \tag{2.3}$$

for any open set A with $\mathcal{L}^N(A) = 1$.

For a unit vector $\nu \in \mathbb{R}^N$, we denote by Q_ν any open unit cube centered at 0 with two faces normal to ν, and S_ν is the set $\{x \in \mathbb{R}^N : |x\cdot\nu| < 1/2\}$.

If $f : \mathbb{M}^{p\times N} \to \mathbb{R}$ is positive homogeneous of degree one and μ is a $\mathbb{M}^{p\times N}$-valued measure, we use the notation

$$\int f(d\mu) := \int f\left(\frac{d\mu}{d|\mu|}\right) d|\mu|,$$

where $|\mu|$ is the total variation measure of μ.

We consider $W : \mathbb{M}^{p\times N} \to \mathbb{R}^+$, and for $u \in BV(\Omega;\mathbb{R}^p)$, we define

$$E(u) := \int_\Omega W(\nabla u)dx + \mathcal{H}^{N-1}(S(u)).$$

The relaxed functional I is defined by

$$I(u) := \inf\left\{ \liminf_{n\to\infty} E(u_n) : \{u_n\} \subset SBV(\Omega;\mathbb{R}^p), u_n \to u \text{ in } L^1(\Omega;\mathbb{R}^p)\right\},$$

and for $\xi \in \mathbb{R}^p, \nu \in S^{N-1}$, we define the following functional:

$$h(\xi,\nu) := \inf\Big\{ \int_{Q_\nu} W^\infty(\nabla v)dx + \mathcal{H}^{N-1}(S(v)) : v \in SBV(Q_\nu;\mathbb{R}^p), \quad v = \xi \text{ if } x \in \partial Q_\nu \text{ and } x\cdot\nu \geq 0, \text{ and } v = 0 \text{ if } x \in \partial Q_\nu \text{ and } x\cdot\nu < 0\Big\}. \tag{2.4}$$

As we will see below, $h([u],\nu)$ turns out to be the energy density of I on $S(u)$.

Before giving the relaxation theorem, we state the following hypotheses on the bulk density W:

(H1) $W:\mathbb{M}^{p\times N}\to\mathbb{R}^+$ is continuous,

(H2) for some $C_0, C_1 > 0$ and all $F \in \mathbb{M}^{p\times N}$, we have

$$C_0|F| - \frac{1}{C_0} \leq W(F) \leq C_1(1+|F|),$$

(H3) there exist $m \in (0,1), L > 0$, and $C > 0$ such that

$$\left|W^\infty(F) - \frac{W(tF)}{t}\right| \leq \frac{C}{t^m} \text{ for all } F \in \mathbb{M}^{p\times N} \text{ with } |F| = 1, \text{ and all } t > L.$$

THEOREM 2.1. *If $W:\mathbb{M}^{p\times N}\to\mathbb{R}^+$ satisfies* (H1), (H2), *and* (H3), *then*

$$I(u) = \int_\Omega QW(\nabla u)dx + \int_{S(u)} h([u],\nu)d\mathcal{H}^{N-1} + \int_\Omega (QW)^\infty(dC(u)). \tag{2.5}$$

The proof of this theorem will be carried out in sections 3, 4, and 5.

3. Characterizations of QW for sequences in BV. It is useful to consider the following bulk density, which is analogous to that considered in [6]. $G:\mathbb{M}^{p\times N}\to\mathbb{R}^+$ is defined by

$$G(F) := \inf\Big\{ \liminf_{n\to\infty} \int_Q W(\nabla u_n)dx : \{u_n\} \subset SBV(Q;\mathbb{R}^p), \quad u_n \to Fx \text{ in } L^1(Q;\mathbb{R}^p), \text{ and } \mathcal{H}^{N-1}(S(u_n)) \to 0\Big\}.$$

The goal of this section is to prove that $G = QW$. Recalling (2.3), we see that the admissible class for G is larger than that for QW. The point, then, is to show that if we insist that admissible sequences for G satisfy $\mathcal{H}^{N-1}(S(u_n)) \to 0$, we might as well require the sequences to be in $W^{1,1}$, as in (2.3). In fact, the lemma below indicates that $W^{1,1}$ can be weakened to BV, with the requirement that $|D_s u_n|(Q) \to 0$.

LEMMA 3.1. *Suppose that $W:\mathbb{M}^{p\times N}\to\mathbb{R}^+$ is a Borel measurable function such that* (H2) *holds. Then*

$$QW(F) = \inf\Big\{ \liminf_{n\to\infty} \int_Q W(\nabla u_n(x))dx : \{u_n\} \subset BV(Q;\mathbb{R}^p), \quad u_n \to Fx \text{ in } L^1(Q;\mathbb{R}^p) \text{ and } |D_s u_n|(Q) \to 0\Big\}$$

for all $F \in \mathbb{M}^{p\times N}$.

Proof. We need only show $QW(F) \leq$ the right-hand side above, since the admissible class of functions for the right-hand side is broader than that in (2.3). Let $\{u_n\}$ be an admissible sequence for the right-hand side. By Theorem 2.16 in [14], we know that for each u_n, we can choose a sequence $v_{n,k} \in W^{1,1}(Q;\mathbb{R}^p)$ such that $v_{n,k} \to u_n$ in L^1 as $k \to \infty$ and

$$\int_Q QW(\nabla v_{n,k})dx \to \int_Q QW(\nabla u_n)dx + C|D_s u_n|(Q)$$

as $k \to \infty$, for some $C > 0$. Since $|D_s u_n|(Q) \to 0$, we can take a diagonal subsequence $\{v_n\}$ such that $v_n \to Fx$ and

$$\liminf_{n\to\infty} \int_Q QW(\nabla v_n)dx = \liminf_{n\to\infty} \int_Q QW(\nabla u_n)dx.$$

The lemma follows from the fact that

$$QW(F) \leq \liminf_{n\to\infty} \int_Q QW(\nabla v_n)dx. \qquad \square$$

So, it remains only to show that requiring admissible sequences to satisfy

$$\mathcal{H}^{N-1}(S(u_n)) \to 0$$

is no less restrictive than requiring $|D_s u_n|(Q) \to 0$. If the former holds, since u_n are in SBV, it is enough if u_n are uniformly bounded in L^∞. In fact, it is enough if a little less is true. In the next lemma we see that we can truncate u_n in such a way that $\liminf_{n\to\infty} \int_Q W(\nabla u_n(x))dx$ is altered by an arbitrarily small amount. It is then straightforward to show $G = QW$.

LEMMA 3.2. *Let* $W : \mathbb{M}^{p\times N} \to \mathbb{R}^+$ *be a Borel measurable function satisfying* (H2)*, and let* $f \in L^\infty(Q;\mathbb{R}^p)$ *and* $\varepsilon > 0$ *be given. Then for every sequence* $\{u_n\} \subset SBV(Q;\mathbb{R}^p)$ *such that*

$$||u_n||_{L^1(Q;\mathbb{R}^p)} + |D_{ac}u_n|(Q) \leq R$$

for all $n \in \mathbb{N}$ *and some* $R > 0$*, there exists a sequence* $\{v_n\} \subset SBV(Q;\mathbb{R}^p)$ *uniformly bounded in* $L^\infty(Q;\mathbb{R}^p)$ *such that*

$$S(v_n) \subset S(u_n), \quad ||v_n - f||_{L^1(Q;\mathbb{R}^p)} \leq ||u_n - f||_{L^1(Q;\mathbb{R}^p)}, \text{ and}$$

$$\liminf_{n\to\infty} \int_Q W(\nabla v_n(x))dx \leq \liminf_{n\to\infty} \int_Q W(\nabla u_n(x))dx + \varepsilon.$$

Proof. The proof is a simpler version of the proof of Lemma 3.7 in [6], which relies on a truncation argument proposed by De Giorgi. Set $\lambda := [\ln(||f||_\infty + 1)] + 1$, where $[\cdot]$ is integer part, and fix $k \in \mathbb{N}$ with $k \geq \lambda$. Let $i \in \{\lambda, \dots, k\}$ be given. Define $\phi_i \in W^{1,\infty}(\mathbb{R}^p;\mathbb{R}^p)$ by

$$\phi_i(x) := \begin{cases} x & \text{if } |x| \leq e^i, \\ \frac{x}{e-1}\left(\frac{e^{i+1}}{|x|} - 1\right) & \text{if } e^i < |x| < e^{i+1}, \\ 0 & \text{if } |x| \geq e^{i+1}. \end{cases}$$

Set $u_{n,i} := \phi_i \circ u_n$. Then $||u_{n,i}||_\infty \le e^i$. Since $\mathrm{Lip}(\phi_i) = 1$, we have $u_{n,i} \in SBV(Q;\mathbb{R}^p)$, $|D_{ac}u_{n,i}|(Q) \le |D_{ac}u_n|(Q)$, and $S(u_{n,i}) \subset S(u_n)$ (see [3] and [16]). Furthermore, by the choice of λ we have

$$\begin{aligned} ||u_{n,i} - f||_{L^1(Q;\mathbb{R}^p)} &= \int_{\{|u_n|<e^i\}} |u_n(x) - f(x)|dx + \int_{\{|u_n|\ge e^i\}} |\phi_i(u_n(x)) - \phi_i(f(x))|dx \\ &\le ||u_n - f||_{L^1(Q;\mathbb{R}^p)}, \end{aligned}$$

where we used the fact that $\mathrm{Lip}(\phi_i) = 1$ and $\phi_i \circ f = f$. Now, fix $n \in \mathbb{N}$ and set

$$Q_i := \{x \in Q : |u_n(x)| < e^i\}.$$

Note that we have $\int_{Q\setminus Q_i} W(\nabla u_{n,i}(x))dx \le C_1(\mathcal{L}^N(Q\setminus Q_i) + |D_{ac}u_{n,i}|(Q\setminus Q_i))$, where $\mathcal{L}^N(Q\setminus Q_i) \le \frac{R}{e^i}$ and

$$\sum_{i=\lambda}^{k} |D_{ac}u_{n,i}|(Q\setminus Q_i) \le \sum_{i=\lambda}^{k} |D_{ac}u_{n,i}|(\{e^i \le |\tilde{u}_n(x)| < e^{i+1}\}) \le |D_{ac}u_n|(Q) \le R.$$

We now have that

$$\sum_{i=\lambda}^{k} \int_{Q\setminus Q_i} W(\nabla u_{n,i}(x))dx \le \sum_{i=\lambda}^{k} C_1\frac{R}{e^i} + C_1R \le C_1R\left(\frac{1}{e^{\lambda-1}(e-1)} + 1\right)$$

so that

$$\sum_{i=\lambda}^{k} \int_{Q} W(\nabla u_{n,i}(x))dx \le (k-\lambda+1)\int_{Q} W(\nabla u_n(x))dx + C_1R\left(\frac{1}{e^{\lambda-1}(e-1)} + 1\right),$$

and by the choice of λ,

$$\begin{aligned} \frac{1}{k-\lambda+1}\sum_{i=\lambda}^{k} \int_{Q} W(\nabla u_{n,i}(x))dx \le\ & \int_{Q} W(\nabla u_n(x))dx \\ & + \frac{C_1R}{k - [\ln(||f||_\infty + 1)]}\left(1 + \frac{1}{(||f||_\infty + 1)(e-1)}\right). \end{aligned}$$

Choosing k large enough so that

$$\frac{C_1R}{k - [\ln(||f||_\infty + 1)]}\left(1 + \frac{1}{(||f||_\infty + 1)(e-1)}\right) < \varepsilon,$$

we see that there must be an $i \in \{\lambda, \dots, k\}$ so that

$$\int_{Q} W(\nabla u_{n,i}(x))dx \le \int_{Q} W(\nabla u_n(x))dx + \varepsilon$$

with $||u_{n,i}||_\infty \le e^k$, where the above choice of k does not depend on n. Hence, this can be done for all $n \in \mathbb{N}$, giving the same L^∞ bound of e^k, and the proof is complete, choosing $v_n := u_{n,i}$. ∎

We now have the following proposition.

PROPOSITION 3.3. *Suppose that* $W:\mathbb{M}^{p\times N}\to\mathbb{R}^+$ *is a Borel measurable function satisfying* (H2). *Then*

$$QW = G.$$

Proof. We need only show that

$$QW(F) \le G(F), \tag{3.1}$$

since the admissible class of $\{u_n\}$ for $G(F)$ includes that for $QW(F)$, and so $QW(F) \ge G(F)$. Choose $\{u_n\} \subset SBV(Q;\mathbb{R}^p)$ such that $u_n \to Fx$ in $L^1(Q;\mathbb{R}^p)$, $\mathcal{H}^{N-1}(S(u_n)) \to 0$, and

$$\lim_{n\to\infty}\int_Q W(\nabla u_n(x))dx = G(F).$$

Since the sequence $\{u_n\}$ is convergent in L^1, it is bounded. Furthermore, since $W(\nabla u_n(x)) \ge C_0|\nabla u_n(x)| - \frac{1}{C_0}$, we deduce that

$$\begin{aligned}|D_{ac}u_n|(Q) &= \int_Q |\nabla u_n(x)|dx\\ &\le \frac{1}{C_0}\left(\int_Q W(\nabla u_n(x))dx + \frac{1}{C_0}\right)\\ &\to \frac{1}{C_0}\Big(G(F) + \frac{1}{C_0}\Big) < \infty,\end{aligned}$$

so $\sup_{n\in\mathbb{N}}|D_{ac}u_n|(Q) < \infty$. Let $\varepsilon > 0$ and consider Lemma 3.2 with $f := Fx$, $R := \sup_{n\in\mathbb{N}}(||u_n||_{L^1} + |D_{ac}u_n|(Q))$, and the above ε and $\{u_n\}$. We now have

$$\lim_{n\to\infty}\int_Q W(\nabla v_n(x))dx \le G(F) + \varepsilon$$

for some $\{v_n\}$ with the same properties as $\{u_n\}$ and, in addition, $||v_n||_\infty \le M < \infty$ for all $n \in \mathbb{N}$. Hence, $|D_s v_n|(Q) \le 2M\mathcal{H}^{N-1}(S(v_n)) \to 0$. By Lemma 3.1, we conclude that

$$QW(F) \le \lim_{n\to\infty}\int_Q W(\nabla v_n(x))dx \le G(F) + \varepsilon.$$

Since $\varepsilon > 0$ was arbitrary, we have (3.1). ∎

4. Upper bound. In this section, we prove an inequality leading to (2.5). Precisely,

$$I(u) \le \int_\Omega QW(\nabla u)dx + \int_{S(u)} h([u],\nu)d\mathcal{H}^{N-1} + \int_\Omega (QW)^\infty(dC(u)).$$

To do this, we first show that $I(u)$ can be considered a set function, and, in fact, a measure. For $A \subset \Omega$ open set

$$E(u,A) := \int_A W(\nabla u)dx + \mathcal{H}^{N-1}(S(u)\cap A)$$

and

$$I(u,A) := \inf\left\{\liminf_{n\to\infty} E(u_n,A) : \{u_n\} \subset SBV(A;\mathbb{R}^p), u_n \to u \text{ in } L^1(A;\mathbb{R}^p)\right\}.$$

Then we have the following proposition.

PROPOSITION 4.1. *Suppose that $u \in BV(A;\mathbb{R}^p)$, where A is a bounded, open subset of Ω. Then $I(u,\cdot)$ extends to a nonnegative, finite, Borel regular measure on A, which is absolutely continuous with respect to $\mathcal{L}^N + |Du|$.*

Proof. By an argument similar to that for Theorem 3.2 in [12], we know that $I(u,\cdot)$ is a Radon measure on A, and is, in fact, the weak $*$ limit of the measures $E(u_n,\cdot)$ for a minimizing sequence u_n. It remains to show that $I(u,\cdot)$ is finite and absolutely continuous with respect to $\mathcal{L}^N + |Du|$. Let $B \subset A$ be open. By Theorem 5.3.3 of [17] or Theorem 2 in section 5.2.2 of [10], we choose $u_n \in C^\infty(B;\mathbb{R}^p)$ such that $u_n \to u$ in $L^1(B;\mathbb{R}^p)$ and $|Du_n|(B) \to |Du|(B)$. Since the u_n are smooth, we have

$$\begin{aligned} I(u,B) &= \liminf_{n\to\infty} \int_B W(\nabla u_n)dx \\ &\le \liminf_{n\to\infty} \int_B C_1\Big[1 + |\nabla u_n|\Big]dx \\ &= C_1\Big[\mathcal{L}^N(B) + |Du|(B)\Big], \end{aligned}$$

which, in particular, implies that $I(u,A) < \infty$ for all $u \in BV(A;\mathbb{R}^p)$. ∎

Fix $A \subset \Omega$ open and $u \in BV(A;\mathbb{R}^p)$. Note that we have

$$I(u,A) \le \inf\left\{\liminf_{n\to\infty} \int_A W(\nabla u_n)dx : \{u_n\} \subset W^{1,1}(A;\mathbb{R}^p), u_n \to u \text{ in } L^1(A;\mathbb{R}^p)\right\},$$

so from [14] we know that

$$I(u,A) \le \int_A QW(\nabla u)dx + \int_{S(u)\cap A} (QW)^\infty(dD_j u) + \int_A (QW)^\infty(dC(u));$$

hence, it only remains to prove that

$$I(u,S(u)) \le \int_{S(u)} h([u](x),\nu(x))d\mathcal{H}^{N-1}(x). \tag{4.1}$$

The jump set $S(u)$ is, in general, not so easy to deal with. Indeed, there exist functions $u \in BV((0,1)^2)$ with jump set $\{(x,y) \in (0,1)^2 : x \in \mathbb{Q}\}$. Furthermore, although for such u one has $E(u) = \infty$, we know that $I(u) \le C_1[1+|Du|((0,1)^2)] < \infty$. However, measure theoretic boundaries of sets of finite perimeter are much easier to handle and, for our purposes, there are connections between $S(u)$ and certain sets of finite perimeter that we can exploit.

Let $u \in BV(\Omega)$ and let $D \subset \mathbb{R}$ be dense. Then,

$$S(u) = \bigcup_{t\in D} S(u) \cap \partial_* E_t = \bigcup_{\substack{t_1,t_2\in D \\ t_1\neq t_2}} \partial_* E_{t_1} \cap \partial_* E_{t_2},$$

where $E_t := \{x \in \Omega : u(x) > t\}$. If $u \in BV(\Omega;\mathbb{R}^p)$, we denote the t level set of u^i by E_t^i, or by E_t if it is clear that we mean the ith component. Also, if $u \in BV(\Omega)$, then E_t

has finite perimeter for $\mathcal{L}^1$ almost every t, and $\{x \in S(u) : u^-(x) < t < u^+(x)\} \subset \partial_* E_t$ (see, e.g., the proof of Theorem 1 in section 5.9 of [10]). We also point out that for $u \in BV(\Omega;\mathbb{R}^p)$, we have $S(u) = \bigcup_{i=1}^p S(u^i)$.

If $T \subset \Omega$ has finite perimeter, then $\mathcal{H}^{N-1}\lfloor\partial_* T$ is a Radon measure. Since $S(u)$ is $\mathcal{H}^{N-1}$ measurable, we conclude that $\chi_{S(u)} \in L^1(\Omega, \mathcal{H}^{N-1}\lfloor\partial_* T)$. So, for $\mathcal{H}^{N-1}$ almost every $x \in S(u) \cap \partial_* T$ we have

$$\begin{aligned}\lim_{\delta\to 0^+} \frac{\mathcal{H}^{N-1}(B(x,\delta)\cap S(u)\cap\partial_* T)}{\alpha(N-1)\delta^{N-1}} &= \lim_{\delta\to 0^+} \frac{\mathcal{H}^{N-1}(B(x,\delta)\cap S(u)\cap\partial_* T)}{\mathcal{H}^{N-1}(B(x,\delta)\cap\partial_* T)} \\ &= \lim_{\delta\to 0^+} \fint_{B(x,\delta)} \chi_{S(u)} d\mathcal{H}^{N-1}\lfloor\partial_* T = 1,\end{aligned}$$

where the first equality follows from Corollary 1 (ii) in section 5.7.2 of [10]. Hence, if $D \subset \mathbb{R}$ is countable and dense and such that E_t^i has finite perimeter for all $t \in D$ and all $i \in \{1,\dots,p\}$, then, fixing $i \in \{1,\dots,p\}$ and setting $E_t := E_t^i$, we have that for $\mathcal{H}^{N-1}$ almost every $x \in S(u)$, for all $t \in D \cap ((u^i)^-(x), (u^i)^+(x))$

(4.2)
$$\lim_{\delta\to 0^+} \frac{\mathcal{H}^{N-1}(B(x,\delta)\cap S(u)\cap\partial_* E_t)}{\alpha(N-1)\delta^{N-1}} = \lim_{\delta\to 0^+} \frac{\mathcal{H}^{N-1}(B(x,\delta)\cap S(u)\cap\partial_* E_t)}{\mathcal{H}^{N-1}(B(x,\delta)\cap\partial_* E_t)} = 1.$$

Furthermore, since $[u] \in L^1(\Omega, \mathcal{H}^{N-1}\lfloor(S(u)\cap\partial_* E_t))$, for $\mathcal{H}^{N-1}$ almost every $x \in S(u)$, for all $t \in D \cap ((u^i)^-(x), (u^i)^+(x))$ we have

$$\lim_{\delta\to 0^+} \fint_{B(x,\delta)\cap S(u)\cap\partial_* E_t} |[u](y) - [u](x)| d\mathcal{H}^{N-1}(y) = 0.$$

Note that the same is true if $B(x,\delta)$ is replaced by $Q(x,\delta) := x + \delta Q_{\nu(x)}$. Hence, for $\mathcal{H}^{N-1}$ almost every $x \in S(u)$, for all $t \in D \cap ((u^i)^-(x), (u^i)^+(x))$ we have

$$\lim_{\delta\to 0^+} \frac{1}{\delta^{N-1}} \int_{Q(x,\delta)\cap S(u)\cap\partial_* E_t} |[u](y)| d\mathcal{H}^{N-1}(y) = |[u](x)|. \tag{4.3}$$

On the other hand, for $\mathcal{H}^{N-1}$ almost every $x \in S(u)$,

$$\lim_{\delta\to 0^+} \frac{1}{\delta^{N-1}} \int_{Q(x,\delta)\cap S(u)} |[u](y)| d\mathcal{H}^{N-1}(y) = |[u](x)|,$$

which, together with (4.3), shows that for $\mathcal{H}^{N-1}$ almost every $x \in S(u)$, for all $t \in D \cap ((u^i)^-(x), (u^i)^+(x))$ we have

$$\lim_{\delta\to 0^+} \frac{|D_j u|(Q(x,\delta)\backslash\partial_* E_t)}{\delta^{N-1}} = 0. \tag{4.4}$$

Proof [Proof of (4.1)]. First, we note that $W^\infty(\xi\otimes\nu)$ is continuous since the limit W^∞ is attained uniformly (see (H3)), hence $h(\xi,\nu)$ is continuous. Note further that, for E_t as above, $[u]$ and ν are $\mathcal{H}^{N-1}\lfloor(S(u)\cap\partial_* E_t)$-measurable, and $h \le 1$, so

$$h([u](\cdot),\nu(\cdot)) \in L^1(\Omega, \mathcal{H}^{N-1}\lfloor(S(u)\cap\partial_* E_t)).$$

Let $x_0 \in S(u)\cap\Omega$ and $t \in \mathbb{R}$ be given such that $u_i^-(x_0) < t < u_i^+(x_0)$, E_t has finite perimeter,

$$\lim_{\delta\to 0^+} \frac{1}{\delta^{N-1}} \int_{Q(x_0,\delta)} |\nabla u| dx = 0, \quad \lim_{\delta\to 0^+} \frac{1}{\delta^{N-1}} |C(u)|(Q(x_0,\delta)) = 0, \tag{4.5}$$

(4.6)
$$\lim_{\delta\to 0^+}\frac{1}{\delta^{N-1}}|D_j u|(Q(x_0,\delta)\backslash\partial_* E_t)=0,\quad \lim_{\delta\to 0^+}\frac{\mathcal{H}^{N-1}(Q(x_0,\delta)\cap S(u)\cap\partial_* E_t)}{\delta^{N-1}}=1,$$

and

(4.7)
$$\lim_{\delta\to 0^+}\frac{1}{\delta^{N-1}}\int_{Q(x_0,\delta)\cap S(u)\cap\partial_* E_t}|h([u](x),\nu(x))-h([u](x_0),\nu(x_0))|d\mathcal{H}^{N-1}(x)=0.$$

Note that the above can be done for $\mathcal{H}^{N-1}$ almost every $x\in S(u)$ (the last three follow from (4.4) and (4.2)).

Since (4.1) is equivalent to

$$I(u,S(u))\le\int_{S(u)}\frac{h([u](x),\nu(x))}{|[u](x)|}|[u](x)|d\mathcal{H}^{N-1}(x),$$

and we know that

$$\lim_{\delta\to 0^+}\frac{I(u,Q(x_0,\delta))}{|D_j u|(Q(x_0,\delta))}=\lim_{\delta\to 0^+}\frac{I(u,Q(x_0,\delta))}{|[u](x_0)|\delta^{N-1}},$$

it is enough to show that

$$\limsup_{\delta\to 0^+}\frac{I(u,Q(x_0,\delta))}{\delta^{N-1}}\le h([u](x_0),\nu(x_0)).$$

Let $\varepsilon>0$ be given and choose $\delta_{x_0}\in(0,\varepsilon)$ such that if $\delta\in(0,\delta_{x_0})$, then (4.5), (4.6), and (4.7) hold to within ε. For $\delta\in(0,\delta_{x_0})$ we would like to find a sequence $\{v_n\}\subset SBV(Q(x_0,\delta);\mathbb{R}^p)$ such that $v_n\to u$ in $L^1(Q(x_0,\delta);\mathbb{R}^p)$ and

$$\liminf_{n\to\infty}\frac{E(v_n,Q(x_0,\delta))}{\delta^{N-1}}\le h([u](x_0),\nu(x_0))+O(\varepsilon).\tag{4.8}$$

Let $\delta\in(0,\delta_{x_0})$ and denote $Q(x_0,\delta)$ by Q. The idea is this: in Q, the set $S(u)\cap\partial_* E_t$ is close to the hyperplane $H(x_0)$, which has normal $\nu(x_0)$. Furthermore, on $H^+(x_0)$, u is close to the trace u^+, and on $H^-(x_0)$, u is close to u^-. Now, if $S(u)\cap\partial_* E_t$ were equal to the hyperplane $H(x_0)$, and if u were equal to its traces on each side of the hyperplane, we would do the following: choose w admissible for $h([u](x_0),\nu(x_0))$ such that

$$\int_{Q_{\nu(x_0)}}W^\infty(\nabla w)dx+\mathcal{H}^{N-1}(S(w))<h([u](x_0),\nu(x_0))+\varepsilon.\tag{4.9}$$

Extend w periodically and set

$$w_n(x):=w\Big(\frac{n}{\delta}x\Big)\in SBV_{\rm loc}\Big(\frac{\delta}{n}S_{\nu(x_0)};\mathbb{R}^p\Big).$$

Define

$$v_n(x):=\begin{cases}u^-(x_0)+w_n(x) & \text{if } x\in Q\cap(x_0+\dfrac{\delta}{n}S_{\nu(x_0)}),\\ u^+(x_0) & \text{if } x\in Q\cap H^+(x_0)\backslash(x_0+\dfrac{\delta}{n}S_{\nu(x_0)}),\\ u^-(x_0) & \text{if } x\in Q\cap H^-(x_0)\backslash(x_0+\dfrac{\delta}{n}S_{\nu(x_B)}).\end{cases}$$

Note that as $n \to \infty$, $v_n \to u$ in $L^1(Q;\mathbb{R}^p)$. Furthermore,

$$E(v_n, Q) = E\Big(v_n, Q \cap \Big(x_0 + \frac{\delta}{n} S_{\nu(x_0)}\Big)\Big) + \mathcal{L}^N\Big(Q \backslash \Big(x_0 + \frac{\delta}{n} S_{\nu(x_0)}\Big)\Big) W(0) \tag{4.10}$$

and

$$\begin{aligned} E\Big(v_n, Q \cap \Big(x_0 + \frac{\delta}{n} S_{\nu(x_0)}\Big)\Big) &= \int_{(\delta/n) S_{\nu(x_0)} \cap \delta Q_{\nu(x_0)}} W\Big(\frac{n}{\delta} \nabla w\Big(\frac{n}{\delta} x\Big)\Big) dx + \mathcal{H}^{N-1}(S(w_n) \cap Q) \\ &= \delta^{N-1} \int_{Q_{\nu(x_0)}} \frac{\delta}{n} W\Big(\frac{n}{\delta} \nabla w(x)\Big) dx + \delta^{N-1} \mathcal{H}^{N-1}(S(w)). \end{aligned}$$

By (H3),

$$\begin{aligned} \int_{Q_{\nu(x_0)}} \Big| \frac{\delta}{n} W\Big(\frac{n}{\delta} \nabla w(x)\Big) - W^\infty(\nabla w(x))\Big| dx \ &\le \int_{Q_{\nu(x_0)} \cap \{n | \nabla w| > \delta L\}} \frac{C\delta}{L^{m-1} n} dx \\ &\quad + \int_{Q_{\nu(x_0)} \cap \{n | \nabla w| \le \delta L\}} \frac{\delta}{n} C_1 [1 + L] dx \\ &\to 0 \end{aligned} \tag{4.11}$$

as $n \to \infty$. Using (4.9) and (4.10), we now have

$$\lim_{n \to \infty} \Big| E(v_n, Q) - \Big[\delta^{N-1} h([u](x_0), \nu(x_0)) + \delta^N W(0)\Big]\Big| \le \delta^{N-1} \varepsilon, \tag{4.12}$$

which gives (4.8).

We now need to consider the actual situation, where $S(u) \cap \partial_* E_t$ does not equal $H(x_0)$, and u does not equal its trace on each side of $H(x_0)$. The construction involved is quite messy, but it is a straightforward adaptation of what we have already done. Therefore, we give only an outline of the proof. Again, we need to find a sequence $\{v_n\}$ that approaches u in $L^1(Q;\mathbb{R}^p)$ such that (4.8) holds. Since u is some distance away from its trace on either side of $H(x_0)$, we cannot have a construction as simple as before. However, we can choose small disjoint balls, B, centered at points x_B in $S(u) \cap \partial_* E_t \cap Q$ that are Lebesgue points for $h([u](\cdot), \nu(\cdot))$. With a finite number of such balls, we can almost cover $S(u) \cap \partial_* E_t \cap Q$ (almost with respect to $\mathcal{H}^{N-1} \lfloor (S(u) \cap \partial_* E_t)$ and with respect to $|D_j u|$), and they can be chosen small enough so that in these balls, u is arbitrarily close to its traces on either side of $H(x_B)$. Outside them, we can take $v_n = u$, and inside, we can perform constructions of v_n as we did for x_0 above. We then need to add a transition layer around these balls, to connect v_n inside and outside the balls. There are then the two issues: i) does $v_n \to u$, and ii) does (4.8) hold?

i) This issue is easy since we can choose balls so small that essentially all of Q is outside of the balls, and we recall that there, $v_n = u$.

The real issue is ii). First, note that within each ball B, we perform a construction as we did for x_0, and so the energy there will be arbitrarily close to

$$\alpha(N-1) r_B^{N-1} h([u](x_B), \nu(x_B)) + \alpha(N) r_B^N W(0),$$

where r_B is the radius of ball B. By (4.7), we know that these energies sum to within order $\delta^{N-1}\varepsilon$ of $\delta^{N-1} h([u](x_0), \nu(x_0))$. Outside the balls, we know from (4.5), (4.6), and the choice of the balls that the energy is small. On the transition layers around

each ball, we smoothly connect v_n inside the ball to its value u outside the transition layer. There is arbitrarily small variation in the transition layers, since the balls were chosen so that $|D_j u|(Q\backslash \cup B)$ is small and in the transition layers u is close to its traces $u^+(x_B)$ and $u^-(x_B)$. Since W has linear growth, the energy in the transition layers is arbitrarily small. Therefore, (4.8) holds. □

5. Lower bound. In this section we prove that

$$I(u) \geq \int_\Omega QW(\nabla u)dx + \int_{S(u)} h([u],\nu)d\mathcal{H}^{N-1} + \int_\Omega (QW)^\infty(dC(u)).$$

As mentioned in the introduction, we rely heavily on [6], and we use the blow-up method introduced by Fonseca and Müller in [14].

Let $u_n \in SBV(\Omega;\mathbb{R}^p)$ be given such that $u_n \to u$ in $L^1(\Omega,\mathbb{R}^p)$ and

$$\begin{aligned}\liminf_{n\to\infty} &\left[\int_\Omega W(\nabla u_n)dx + \mathcal{H}^{N-1}(S(u_n))\right] \\ &= \lim_{n\to\infty}\left[\int_\Omega W(\nabla u_n)dx + \mathcal{H}^{N-1}(S(u_n))\right] < \infty.\end{aligned}$$

Define a sequence of Radon measures by $\mu_n := W(\nabla u_n)\mathcal{L}^N + \mathcal{H}^{N-1}\lfloor S(u_n)$. Since μ_n are uniformly bounded, there exists a subsequence (not relabeled) and a finite Radon measure μ such that $\mu_n \overset{*}{\rightharpoonup} \mu$. The Radon–Nikodym theorem and (2.2) allow us to write

$$\mu = d_{ac}\mathcal{L}^N + d_j|[u]|\mathcal{H}^{N-1}\lfloor S(u) + d_c|C(u)| + \mu_s,$$

where μ_s is singular with respect to the first three terms in the decomposition, and μ_s is nonnegative since μ is. In view of Proposition 3.3, we need only show that

a) $d_{ac}(x_0) \geq G(\nabla u(x_0))$ for $\mathcal{L}^N$ almost every $x_0 \in \Omega$,

b) $d_j(x_0) \geq \frac{h([u](x_0),\nu(x_0))}{|[u](x_0)|}$ for $\mathcal{H}^{N-1}$ almost every $x_0 \in S(u)$, and

c) $d_c(x_0) \geq G^\infty\left(\frac{dC(u)}{d|C(u)|}(x_0)\right)$ for $|C(u)|$ almost every $x_0 \in \Omega$.

The proofs of all three are straightforward adaptations of the corresponding arguments in [6], except that we introduce a significant simplification in the proof of c).

A complication in the proof in [6] is due to the fact that as a sequence of measures converges weakly $*$ on a cube, it might lose mass. However, the sequences we need to consider come from blowing up one particular measure. The lemma below shows that, almost everywhere, we don't have to worry about such sequences losing mass.

LEMMA 5.1. *Let λ be a Radon measure on $\Omega \subset \mathbb{R}^N$. Then, for λ almost every $x \in \Omega$, given any open, bounded convex set C containing the origin, there is a sequence $\delta_i \to 0^+$ and a Radon measure γ on C such that*

$$\lambda_{\delta_i}(\cdot) := \frac{\lambda(x+\delta_i\cdot)}{\lambda(x+\delta_i C)} \overset{*}{\rightharpoonup} \gamma \text{ on } C, \text{ and } \gamma(C) = 1.$$

Proof. We first show that for λ almost every $x \in \Omega$ we have

$$\liminf_{\delta \to 0^+} \frac{\lambda(x + \delta C)}{\delta^N} > 0 \tag{5.1}$$

for all C as in the statement of the lemma. It is sufficient to consider (5.1) for an open ball B containing the origin, since $\delta B \subset C$ for small enough δ. Put

$$A := \left\{ x \in \Omega : \liminf_{\delta \to 0^+} \frac{\lambda(x + \delta B)}{\delta^N} = 0 \right\}.$$

Let $\varepsilon > 0$ be given, and using Besicovitch's covering theorem, choose a countable family of disjoint balls $x_i + \delta_i B \subset \Omega$ such that $\lambda(A \backslash \cup (x_i + \delta_i B)) = 0$ and $\lambda(x_i + \delta_i B) < \varepsilon \delta_i^N$. It follows that $\lambda(A) < \varepsilon \frac{\mathcal{L}^N(\Omega)}{\mathcal{L}^N(B)}$, and so $\lambda(A) = 0$.

Fix $x \in \Omega$ for which (5.1) is satisfied. Without loss of generality, we can assume $x = 0$. Let $\eta \in (0, 1)$ be given and set $\delta_i := \eta^i$. Suppose that

$$\limsup_{i \to \infty} \lambda_{\delta_i}(\eta C) < \eta^N.$$

Then we can choose $j \in \mathbb{N}$ and $\alpha \in (0, \eta^N)$ such that if $i \geq j$, then

$$\frac{\lambda(\delta_i \eta C)}{\lambda(\delta_i C)} < \alpha.$$

We now have

$$\frac{\lambda(\delta_i C)}{\delta_i^N} \leq \frac{\lambda(\delta_j C)\alpha^{i-j}}{[\eta^{i-j}\delta_j]^N} \to 0$$

as $i \to \infty$, which contradicts (5.1). Hence, we may extract a subsequence, not relabeled, and choose a Radon measure γ so that $\lambda_{\delta_i} \overset{*}{\rightharpoonup} \gamma$ on C and $\lambda_{\delta_i}(\eta C) > \alpha$, where $\alpha < \eta^N$. Choose $\beta \in (\eta, 1)$ such that $\gamma(\partial \beta C) = 0$. Then, for a subsequence and a Radon measure $\bar{\gamma}$, $\lambda_{\beta\delta_i} \overset{*}{\rightharpoonup} \bar{\gamma}$ on C, and for any Borel set $A \subset C$ we have

$$\lambda_{\beta\delta_i}(A) = \frac{\lambda(\beta\delta_i A)}{\lambda(\beta\delta_i C)} < \frac{1}{\alpha} \frac{\lambda(\beta\delta_i A)}{\lambda(\delta_i C)} = \frac{1}{\alpha} \lambda_{\delta_i}(\beta A).$$

Let $\varepsilon > 0$ be given and let $D \subset C$ be an open neighborhood of $\partial \beta C$ such that $\gamma(\bar{D}) < \varepsilon$. Then,

$$\limsup_{\delta_i \to 0^+} \lambda_{\beta\delta_i}\left(\frac{\bar{D}}{\beta} \cap C\right) \leq \frac{1}{\alpha} \limsup_{\delta_i \to 0^+} \lambda_{\delta_i}(\bar{D}) \leq \frac{1}{\alpha} \gamma(\bar{D}) < \frac{\varepsilon}{\alpha}.$$

Hence,

$$\bar{\gamma}(C) \geq \bar{\gamma}\left(C \backslash \frac{D}{\beta}\right) \geq \limsup_{\delta_i \to 0^+} \lambda_{\beta\delta_i}\left(C \backslash \frac{D}{\beta}\right) \geq \liminf_{\delta_i \to 0^+} \lambda_{\beta\delta_i}\left(C \backslash \frac{\bar{D}}{\beta}\right) > 1 - \frac{\varepsilon}{\alpha}.$$

From the arbitrariness of ε, it follows that $\bar{\gamma}(C) = 1$. ∎

Proof [Proof of c]. Let $x_0 \in \Omega$ be given such that

$$\lim_{\delta \to 0^+} \frac{|Du|(Q(x_0, \delta))}{|C(u)|(Q(x_0, \delta))} = 1, \quad \lim_{\delta \to 0^+} \frac{|Du|(Q(x_0, \delta))}{\delta^{N-1}} = 0, \quad \lim_{\delta \to 0^+} \frac{|Du|(Q(x_0, \delta))}{\delta^N} = \infty,$$

$$A_0 := \lim_{\delta\to 0^+} \frac{Du(Q(x_0,\delta))}{|Du|(Q(x_0,\delta))} \text{ exists and } ||A_0|| = 1, A_0 = a\otimes\nu, \text{ and}$$

$$d_c(x_0) = \lim_{\delta\to 0^+} \frac{\mu(Q(x_0,\delta))}{|C(u)|(Q(x_0,\delta))} = \lim_{\delta\to 0^+} \frac{\mu(Q(x_0,\delta))}{|Du|(Q(x_0,\delta))} < \infty.$$

Note that the above hold for $|C(u)|$ almost every $x\in\Omega$, where the statements regarding A_0 are due to Alberti [2]. Without loss of generality, assume that $\nu = e_N$ and $|a| = 1$. Choose $\delta_k < \frac{1}{k}$ such that, setting

$$z_k(x) := \frac{\delta_k^{N-1}}{|Du|(Q(x_0,\delta_k))}\left[u(x_0+\delta_k x) - \frac{1}{\delta_k^N}\int_{Q(x_0,\delta_k)} u(y)dy\right],$$

the sequence $\{\delta_k\}$ is selected according to Lemma 5.1 so that, with $\lambda := |Du|$ and γ equal to the weak $*$ limit of $|Dz_k|$, we have $\gamma(Q) = \lim_{k\to\infty}|Dz_k|(Q) = 1$. Note that, using notations from the proof of Lemma 5.1, the δ_k chosen here are of the form $\beta\delta_i$. So, by choosing an appropriate β in the proof of Lemma 5.1, the δ_k can also be chosen such that $\mu(\partial Q(x_0,\delta_k)) = 0$ for all k. Then,

$$\begin{aligned} d_c(x_0) &= \lim_{k\to\infty}\frac{\mu(Q(x_0,\delta_k))}{|Du|(Q(x_0,\delta_k))} \\ &= \lim_{k\to\infty}\left[\frac{1}{|Du|(Q(x_0,\delta_k))}\lim_{n\to\infty}\int_{Q(x_0,\delta_k)} d\mu_n\right] \\ &= \lim_{k\to\infty}\left\{\frac{1}{|Du|(Q(x_0,\delta_k))}\lim_{n\to\infty}\left[\int_{Q(x_0,\delta_k)} W(\nabla u_n(x))dx \right.\right. \\ &\qquad \left.\left. +\mathcal{H}^{N-1}(Q(x_0,\delta_k)\cap S(u_n))\right]\right\}. \end{aligned} \tag{5.2}$$

Also,

$$\lim_{k\to\infty}\lim_{n\to\infty}\frac{\delta_k^{N-1}}{|Du|(Q(x_0,\delta_k))}\int_Q \left|u_n(x_0+\delta_k x) - \frac{1}{\delta_k^N}\int_{Q(x_0,\delta_k)} u_n(y)dy - \left[u(x_0+\delta_k x) - \frac{1}{\delta_k^N}\int_{Q(x_0,\delta_k)} u(y)dy\right]\right| dx = 0. \tag{5.3}$$

By (5.2) and (5.3), using a standard diagonalization argument, choose a subsequence $\{u_k\}$ such that

$$d_c(x_0) = \lim_{k\to\infty}\frac{1}{|Du|(Q(x_0,\delta_k))}\left[\int_{Q(x_0,\delta_k)} W(\nabla u_k(x))dx + \mathcal{H}^{N-1}(S(u_k)\cap Q(x_0,\delta_k))\right]$$

and

$$||\bar{u}_k - z_k||_{L^1(Q;\mathbb{R}^p)} \to 0, \tag{5.4}$$

where

$$\bar{u}_k(x) := \frac{\delta_k^{N-1}}{|Du|(Q(x_0,\delta_k))}\left[u_k(x_0+\delta_k x) - \frac{1}{\delta_k^N}\int_{Q(x_0,\delta_k)} u_k(y)dy\right],$$

$$z_k(x) := \frac{\delta_k^{N-1}}{|Du|(Q(x_0,\delta_k))}\left[u(x_0+\delta_k x) - \frac{1}{\delta_k^N}\int_{Q(x_0,\delta_k)} u(y)dy\right].$$

Setting $\quad t_k := \dfrac{|Du|(Q(x_0,\delta_k))}{\delta_k^N} \to \infty, \quad \theta_k := \dfrac{|Du|(Q(x_0,\delta_k))}{\delta_k^{N-1}} \to 0$

we conclude that

$$d_c(x_0) = \lim_{k\to\infty}\left[\frac{1}{t_k}\int_Q W(t_k\nabla\bar{u}_k(x))dx + \frac{1}{\theta_k}\mathcal{H}^{N-1}(S(\bar{u}_k)\cap Q)\right].$$

Since $d_c(x_0) < \infty$, we know

$$\mathcal{H}^{N-1}(S(\bar{u}_k)\cap Q) \to 0 \text{ (since } \theta_k \to 0^+) \tag{5.5}$$

and

$$d_c(x_0) \geq \limsup_{k\to\infty}\frac{1}{t_k}\int_Q W(t_k\nabla\bar{u}_k(x))dx = \limsup_{k\to\infty}\int_Q W^\infty(\nabla\bar{u}_k(x))dx \tag{5.6}$$

just as in (4.11). Since

$$\int_Q z_k(x)dx = \int_Q \bar{u}_k(x)dx = 0 \quad \text{and} \quad |D\bar{u}_k|(Q) = |Dz_k|(Q) = 1,$$

by (5.4) and Poincaré's inequality, there exist subsequences (not relabeled) $\{z_k\}, \{\bar{u}_k\}$, and there exists $u_0 \in BV(Q;\mathbb{R}^p)$ such that $z_k, \bar{u}_k \to u_0$ in $L^1(Q;\mathbb{R}^p)$.

Now,

$$Dz_k(Q) = \frac{Du(Q(x_0,\delta_k))}{|Du|(Q(x_0,\delta_k))} \to A_0 = a\otimes e_N$$

and $|Dz_k|(Q) = 1$ so, by Proposition A.1 of [14], it follows that

$$|Dz_k - (Dz_k\cdot A_0)A_0|(Q) \to 0,$$

from which we conclude that $|Dz_k\cdot e_i|(Q)\to 0$ for $i = 1,\dots,N-1$. Since

$$|Du_0\cdot e_i|(Q) \leq \liminf_{k\to\infty}|Dz_k\cdot e_i|(Q) = 0,$$

we obtain

$$u_0(x) = \hat{u}_0(x_N) \in BV\left(\left(-\frac{1}{2},\frac{1}{2}\right);\mathbb{R}^p\right).$$

Note that, in general, if $\mu_k \overset{*}{\rightharpoonup} \eta$, $|\mu_k| \overset{*}{\rightharpoonup} \gamma$, and $\gamma(Q) = \lim_{k\to\infty}|\mu_k|(Q)$, then $\eta(Q) = \lim_{k\to\infty}\mu_k(Q)$. Here we have $Dz_k \overset{*}{\rightharpoonup} \eta$ and $\gamma(Q) = \lim_{k\to\infty}|Dz_k|(Q)$, so that $\eta(Q) = A_0$. On the other hand, $z_k \to u_0$ in $L^1(Q;\mathbb{R}^p)$, which implies that $Du_0 = \eta$ in Q, and so $Du_0(Q) = A_0$. Thus, $u_0(x) - A_0(x) = p(x_N) + c$, where $p(-1/2) = p(1/2) = 0$, and $u_0(x) - A_0x$ can be extended periodically to $\mathbb{R}^N$. Without loss of generality, we can assume that the trace of $\bar{u}_k$ equals the trace of u_0, so that $\bar{u}_k - A_0x$ can be extended periodically, and we call this extension w_k. Set $v_k^j(x) := A_0x + \frac{1}{j}w_k(jx)$ and

note that, for $x \in Q_j := (-\frac{1}{2j}, \frac{1}{2j})^N$, we have $\nabla v_k^j(x) = \nabla \bar{u}_k(jx)$. By (5.5) we may choose $k(j) > j$ such that $\mathcal{H}^{N-1}(S(v^j_{k(j)}) \cap Q) < 1/j$, and we have

$$v_j := v^j_{k(j)} \to A_0 x \text{ in } L^1(Q; \mathbb{R}^p)$$

and

$$\mathcal{H}^{N-1}(S(v_j) \cap Q) \to 0.$$

Furthermore,

$$\int_Q W^\infty(\nabla v_j(x))dx = j^N \int_{Q_j} W^\infty(\nabla \bar{u}_{k(j)}(jx))dx = \int_Q W^\infty(\nabla \bar{u}_{k(j)}(x))dx$$

and so, by (5.6), we need only show that

$$G^\infty(A_0) \le \limsup_{j\to\infty} \int_Q W^\infty(\nabla v_j(x))dx.$$

By (H3) we have

$$\begin{aligned} G^\infty(A_0) &\le \limsup_{t\to\infty} \left[\frac{1}{t} \limsup_{j\to\infty} \int_Q W(t\nabla v_j(x))dx\right] \\ &\le \limsup_{t\to\infty} \limsup_{j\to\infty} \left\{ \int_{\{t|\nabla v_j|>L\}} \left[W^\infty(\nabla v_j(x)) + \frac{C}{L^{m-1}t}\right] dx \right. \\ &\qquad \left. + \int_{\{t|\nabla v_j|\le L\}} \frac{1}{t} C_1[1+L]dx \right\} \\ &\le \limsup_{j\to\infty} \int_Q W^\infty(\nabla v_j(x))dx. \qquad \square \end{aligned}$$

6. Optimal jump microstructure for scalar valued functions. We now ask the question, what behavior is it necessary to allow for admissible functions for h? That is, how do infimizing sequences behave? Below, we answer this question for scalar valued functions. The idea is based on level sets, and so it is not straightforward to extend the result to vector valued functions.

Looking at the definition of $h(\rho, \nu)$ (see (2.4)), we see that admissible functions may have both jumps and nonzero gradient. Is it possible that there is an admissible function v that jumps and has nonzero gradient, and the energy of v is below the infimum over functions that just jump, and below the infimum over functions in $W^{1,1}$? The answer to this question is "yes," and we will see that a natural example illustrates the behavior of infimizing sequences.

We first consider the two-dimensional case, and the square in Figure 6.2 represents Q_ν for $N = 2$. Suppose that $CW^\infty(\rho\nu) \gg 1$ and $W^\infty(\rho\mu) \ll 1$ for some $\rho \in \mathbb{R}^+$ and unit vectors $\nu, \mu \in \mathbb{R}^2$, where $\nu \cdot \mu > 0$. We then see that a function that is 0 below $\Gamma := \Gamma_1 \cup \Gamma_2$ and ρ above, with a jump across Γ_1 and affine growth across a narrow neighborhood of Γ_2, has lower energy than the infimum over functions that just jump (this infimum is 1), and the infimum over functions in $W^{1,1}$ (this infimum is $CW^\infty(\rho\nu)$). Note that this example fails if CW^∞ is isotropic. We show that this

behavior is optimal. The idea is this: first, we give a coarea formula which allows us to consider, for any admissible function for $h(\rho,\nu)$, the bulk energy as an integral over measure-theoretic boundaries of level sets. We may then choose a "good" level set. Next, we prove that it is energetically better for the jump part of the boundary, i.e., $S(u)$ intersected with the boundary, to be connected and flat. As we will show in Lemma 6.1, we can assume that W^∞ is convex without changing the infimum of the energy, in which case we will prove that the remainder of the boundary might as well be flat, and we conclude that Figure 6.1 captures the geometry of minimizing sequences.

We begin with the following lemma.

LEMMA 6.1. *In the scalar case,* $h_W = h_{CW}$.

Proof. Since $CW \le W$, it follows that $h_{CW} \le h_W$. Conversely, let u be an admissible function for h_{CW}. By the relaxation theorem (Theorem 2.1), we have

$$I(u,Q) \le \int_Q CW(\nabla u)dx + \mathcal{H}^{N-1}(S(u)\cap Q),$$

where we use the fact that $h \le 1$. It also follows from Theorem 2.1 that

$$I_{CW}(u,Q) = \int_Q CW(\nabla u)dx + \int_{S(u)\cap Q} h_{CW}([u],\nu)d\mathcal{H}^{N-1}.$$

By the lower semicontinuity of I, we have

$$\begin{aligned}\int_Q C\ W(\nabla u)dx &+ \int_{S(u)\cap Q} h_W([u],\nu)d\mathcal{H}^{N-1}\\ &\le \int_Q CW(\nabla u)dx + \int_{S(u)\cap Q} h_{CW}([u],\nu)d\mathcal{H}^{N-1},\end{aligned}$$

which implies $h_W \le h_{CW}$. ∎

LEMMA 6.2. *Let λ be a finite Borel regular measure on Q and let $f: Q \to \mathbb{R}^N$ be λ measurable with $||f||_\infty < \infty$. Then there is a sequence $\{f_n\} \subset C_0^\infty(Q;\mathbb{R}^N)$ such that $f_n \to f$ λ almost everywhere and $||f_n||_\infty \le ||f||_\infty$ for all n.*

We now recall some notation: for $u \in BV(Q)$, set $E_t := \{x \in Q : u(x) > t\}$. For $x \in \partial_* E_t \subset Q$ (see (2.1)), we denote by $\nu_{E_t}(x)$ the measure theoretic unit *inner* normal (see Theorem 1, section 5.8 of [10]), so that

$$\int_{E_t} \mathrm{div}\phi(x)dx = -\int_{\partial_* E_t} \phi(x)\cdot\nu_{E_t}(x)d\mathcal{H}^{N-1}(x)$$

for all $\phi \in C_0^1(Q;\mathbb{R}^N)$.

LEMMA 6.3 (Coarea formula). *Let $u \in BV(Q)$ be given, and let $f: Q\times\mathbb{M}^{1\times N}\to\mathbb{R}$ be a Carathéodory function, where measurability is Borel, and positive homogeneous of degree one in the last variable. Assume further that $f(x, \frac{dDu(x)}{d|Du|(x)}) \in L^\infty(Q,|Du|)$. Then*

$$\int_Q f(x,dDu(x)) = \int_{\mathbb{R}}\int_{\partial_* E_t} f(x,\nu_{E_t}(x))d\mathcal{H}^{N-1}(x)dt. \tag{6.1}$$

Proof. First we note that, as a consequence of Borel regularity and the coarea formula for BV functions (see Theorem 1 (ii) of section 5.5 of [10]), we have that for any set $A \subset \Omega$,

$$|Du|(A) = 0 \text{ implies } \mathcal{H}^{N-1}(A \cap \partial_* E_t) = 0 \text{ for } \mathcal{L}^1 \text{ almost every t.} \tag{6.2}$$

We know (see claim 1 in the proof of Theorem 1, section 5.5 in [10]) that

$$\int_Q u(x)\mathrm{div}\phi(x)dx = \int_{\mathbb{R}} \int_{E_t} \mathrm{div}\phi(x)dxdt$$

for all $\phi \in C_0^1(Q;\mathbb{R}^N)$. Hence,

$$\int_Q \phi(x)\cdot\sigma(x)d|Du|(x) = \int_{\mathbb{R}} \int_{\partial_* E_t} \phi(x)\cdot\nu_{E_t}(x)d\mathcal{H}^{N-1}(x)dt \tag{6.3}$$

for all $\phi \in C_0^1(Q;\mathbb{R}^N)$, where $\sigma(x) := \frac{dDu(x)}{d|Du|(x)}$.

We now show that for $\mathcal{L}^1$ almost every $t \in \mathbb{R}$, we have

$$\sigma(x) = \nu_{E_t}(x) \text{ for } \mathcal{H}^{N-1} \text{ almost every } x \in \partial_* E_t. \tag{6.4}$$

Using Lemma 6.2, choose $\sigma_n \in C_0^1(Q;\mathbb{R}^2)$ such that $\sigma_n(x) \to \sigma(x)$ $|Du|$ almost everywhere (and so, by (6.2), $\mathcal{H}^{N-1}\lfloor\partial_* E_t$ almost everywhere for $\mathcal{L}^1$ almost every t) and $|\sigma_n| \le 1$. Note that $\sigma_n \cdot \nu_{E_t}$ is $\mathcal{H}^{N-1}\lfloor\partial_* E_t$ measurable since ν_{E_t} is, and

$$t \mapsto \int_{\partial_* E_t} \sigma_n(x)\cdot\nu_{E_t}(x)d\mathcal{H}^{N-1}(x) = \int_{E_t} \mathrm{div}\sigma_n(x)dx$$

is $\mathcal{L}^1$ measurable (see, e.g., the proof of Lemma 1 in section 5.5 of [10]). Then, by (6.3) and the dominated convergence theorem,

$$\begin{aligned}
\int_{\mathbb{R}} \int_{\partial_* E_t} \sigma(x)\cdot\nu_{E_t}(x)d\mathcal{H}^{N-1}(x)dt &= \lim_{n\to\infty} \int_{\mathbb{R}} \int_{\partial_* E_t} \sigma_n(x)\cdot\nu_{E_t}(x)d\mathcal{H}^{N-1}(x)dt \\
&= \lim_{n\to\infty} \int_Q \sigma_n(x)\cdot\sigma(x)d|Du|(x) \\
&= \int_Q d|Du| \\
&= \int_{\mathbb{R}} \int_{\partial_* E_t} d\mathcal{H}^{N-1}(x)dt.
\end{aligned}$$

Since $\sigma \cdot \nu_{E_t} \le 1$, we have (6.4).

Using Lemma 6.2 once more, choose $\phi_n \in C_0^1(Q;\mathbb{R}^N)$ such that $\phi_n(x) \to f(x,\sigma(x))\sigma(x)$ $|Du|$ almost everywhere and $||\phi_n||_\infty \le ||f(\cdot,\sigma(\cdot))||_\infty$. Then, as above,

$$\begin{aligned}
\int_Q f(x, dDu(x)) &= \int_Q f(x,\sigma(x))d|Du|(x) \\
&= \lim_{n\to\infty} \int_Q \phi_n(x)\cdot\sigma(x)d|Du|(x) \\
&= \lim_{n\to\infty} \int_{\mathbb{R}} \int_{\partial_* E_t} \phi_n(x)\cdot\nu_{E_t}(x)d\mathcal{H}^{N-1}(x)dt \text{ (by (6.3))} \\
&= \int_{\mathbb{R}} \int_{\partial_* E_t} f(x,\nu_{E_t}(x))d\mathcal{H}^{N-1}(x)dt. \text{ (by (6.4))} \qquad \square
\end{aligned}$$

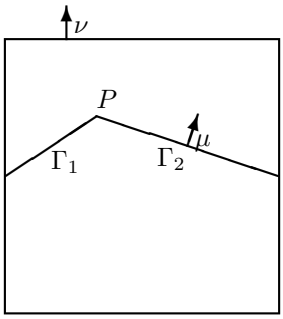

FIG. 6.1. *Admissible "function" for H.*

Now we introduce another infimum, similar to h, but which includes only very simple functions in its admissible class. Given $\nu \in S^{N-1}$, we consider the family $\mathcal{S}^2_\nu$ of squares with unit edge length, centered at zero, with two edges normal to ν (with ν in the plane of the square). Without loss of generality, we will assume $\nu = e_N$. Now consider the square $\mathcal{Q} \in \mathcal{S}^2_\nu$ with the remaining two edges having normal e_1 (in the plane of the square). We consider connected curves $\Gamma \subset \mathcal{Q}$ made up of two line segments such that Γ connects the midpoints of the edges that have normal e_1, i.e., $\Gamma = \Gamma_1 \cup \Gamma_2$, where Γ_1 is the line segment from $(-1/2, 0, \dots, 0)$ to some point P in the square, and Γ_2 is the line segment connecting P to $(1/2, 0, \dots, 0)$ (see Figure 6.1). For other $\mathcal{Q} \in \mathcal{S}^2_\nu$, with two edges not having normal e_1, we consider analogous $\Gamma \subset \mathcal{Q}$. Set

$$H(\rho, \nu) := \inf\{\mathcal{H}^1(\Gamma_1) + \rho\mathcal{H}^1(\Gamma_2) CW^\infty(\mu) : \\ \mathcal{Q} \in \mathcal{S}^2_\nu, \Gamma \subset \mathcal{Q} \text{ is as above, and } \mu \text{ is the unit normal to } \Gamma_2 \text{ so that } \mu \cdot \nu \geq 0\}.$$

REMARK 6.4. Note the following:

i) $H(\rho, \nu) \leq 1$ since we can take $\Gamma = \Gamma_1$.

ii) The infimum H is attained since CW^∞ is continuous.

iii) If CW^∞ is isotropic, then the minimizing Γ equals Γ_1 or Γ_2.

THEOREM 6.5. $h = H$.

Proof. By Lemma 6.1, we may assume that $W = (CW)^\infty$. Furthermore, note that $(CW)^\infty$ is convex. Hence, in the sequel we will take W to be convex and positive homogeneous of degree one.

Step 1. We show that $h \leq H$.

Case a. $N = 2$.

Fix $\mathcal{Q} \in \mathcal{S}^2_\nu$ and $\Gamma \subset \mathcal{Q}$ as in the definition of H, and consider functions in $SBV(\mathcal{Q}; \mathbb{R})$ that are zero below Γ, ρ above, jump at Γ_1, and are affine across a narrow neighborhood of Γ_2, with another jump connection near the intersection of the boundary with Γ_2, and we see that these functions are admissible for $h(\rho, \nu)$ and their energy E approaches $\mathcal{H}^1(\Gamma_1) + \rho\mathcal{H}^1(\Gamma_2) W(\mu)$ (see Figure 6.2).

Case b. $N > 2$.

First, we point out the following:

$$h(\xi, \nu) = \inf\Big\{ \int_{Q_\nu} W^\infty(\nabla v) dx + \mathcal{H}^{N-1}(S(v) \cap Q_\nu) : v \in SBV_{loc}(S_\nu; \mathbb{R}^p), \\ v(y) = 0 \text{ if } y \cdot \nu = -\frac{1}{2}, v(y) = \xi \text{ if } y \cdot \nu = \frac{1}{2} \\ v \text{ is 1-periodic in the directions } \nu_1, \dots, \nu_{N-1} \Big\}. \tag{6.5}$$

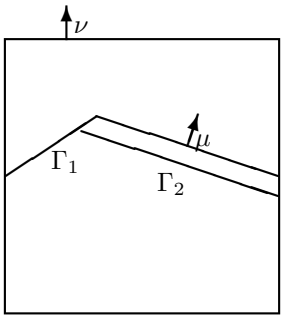

FIG. 6.2. $h \leq H$.

Clearly, $h \geq$ the right-hand side of (6) since admissible functions for h have the necessary periodicity. The other inequality follows from the fact that, after rescaling, an admissible function for the right-hand side of (6) will have the correct trace for h after altering it to jump on a set of arbitrarily small $\mathcal{H}^{N-1}$ measure.

Now, as in case a), let any $\mathcal{Q}$ and Γ as in the definition of H be given. Choose the cube Q_ν such that two sets of faces each have their normal in common with one of the faces of the square $\mathcal{Q}$. Extend Γ to Q_ν by $\bar{\Gamma} := \{x \in Q_\nu : \text{proj}(x) \text{ onto } \mathcal{Q} \in \Gamma\}$. We then construct functions as in the case $N = 2$, where there is a jump connection near the intersection of $\bar{\Gamma}_2$ with the face of Q_ν having the same normal as $\mathcal{Q}$. By (6), these functions have the necessary periodicity to be admissible for $h(\rho, \nu)$. Again, we see that the energy E approaches $\mathcal{H}^1(\Gamma_1) + \rho\mathcal{H}^1(\Gamma_2)W(\mu)$.

Step 2. We now show that $h \geq H$.

Let u be an admissible function for $h(\rho, \nu)$, i.e.,

$$u \in SBV(Q_\nu; \mathbb{R}), u = \rho \text{ if } x \in \partial Q_\nu \text{ and } x \cdot \nu \geq 0, \text{ and } u = 0 \text{ if } x \in \partial Q_\nu \text{ and } x \cdot \nu < 0.$$

For simplicity, we refer to Q_ν as Q. The goal is to find an appropriate curve $\Gamma = \Gamma_1 \cup \Gamma_2$ with H-energy no greater than the h-energy of u.

Step 2a. We first find a "good" level set. Applying Lemma 6.3 to

$$f(x, dDu(x)) := \chi_{Q \setminus S(u)}(x) W(dDu(x)),$$

so that $\left| f\left(x, \frac{dDu(x)}{d|Du|(x)}\right) \right| \leq C_1$, we get

$$\int_Q W(\nabla u(x)) dx = \int_{\mathbb{R}} \int_{\partial_* E_t \setminus S(u)} W(\nu_{E_t}(x)) d\mathcal{H}^{N-1}(x) dt.$$

Choose $t_0 \in (0, \rho)$ such that

$$\int_{\partial_* E_{t_0} \setminus S(u)} W(\nu_{E_{t_0}}(x)) d\mathcal{H}^{N-1}(x) \leq \frac{1}{\rho} \int_Q W(\nabla u(x)) dx. \tag{6.6}$$

Note that the coercivity of W guarantees that E_{t_0} has finite perimeter. Set

$$\beta := \mathcal{H}^{N-1}(\partial_* E_{t_0} \setminus S(u)) \text{ and } \bar{\nu} := \frac{1}{\beta} \int_{\partial_* E_{t_0} \setminus S(u)} \nu_{E_{t_0}}(x) d\mathcal{H}^{N-1}(x)$$

so that, by Jensen's inequality,

$$\beta W(\bar{\nu}) \leq \int_{\partial_* E_{t_0} \setminus S(u)} W(\nu_{E_{t_0}}(x)) d\mathcal{H}^{N-1}(x). \tag{6.7}$$

We can assume $\nu = e_N$ and $\bar{\nu} \cdot e_i = 0$ for $i \in \{2, \ldots, N-1\}$. Note that we can also assume that Q has e_1 normal to two of its faces, for the following reason: let Q_1 be a cube with normals e_N and e_1. We can rescale Q and u, and almost cover $\{x \in Q_1 : x_N = 0\}$ with the cubes $a_i + \delta Q$, where $a_i \in \{x \in Q_1 : x_N = 0\}$. Define $v \in SBV(Q_1)$ by

$$v(x) := \begin{cases} u\left(\dfrac{x - a_i}{\delta}\right) & \text{if } x \in a_i + \delta Q, \\ 0 & \text{if } x_N < 0 \text{ and } x \notin \cup(a_i + \delta Q), \\ \rho & \text{if } x_N \geq 0 \text{ and } x \notin \cup(a_i + \delta Q). \end{cases}$$

Using the homogeneity of W, we now have $E(v, Q_1) - E(u, Q) \leq \mathcal{H}^{N-1}(\{x \in Q_1 : x_N = 0\} \setminus \cup_i (a_i + \delta Q))$, yet $\bar{\nu}$, defined as for u, remains unchanged.

Step 2b. As suggested in our selection of t_0, we want to separate $\partial_* E_{t_0}$ into two pieces: its intersection with $S(u)$ and the rest. These will be turned into Γ_1 and Γ_2, respectively. By (6.6) and (6.7), it appears that a suitably long Γ_2 with normal in the direction $\bar{\nu}$ is energetically better than its counterpart, $\int_Q W(\nabla u) dx$. Referring to Figure 6.1, we see that the main issue is whether the segment Γ_1 needed to connect Γ_2 to the midpoint of the opposite edge has length larger than the $N-1$-dimensional area of $S(u)$, $\mathcal{H}^{N-1}(S(u))$. In fact, we can show that Γ_1 has length no larger than $\mathcal{H}^{N-1}(\partial_* E_{t_0} \cap S(u))$. What we first need to show is that $\partial_* E_{t_0}$ meets the midpoints of the opposing edges, and goes "all the way across" the cube. That is, we wish to show that

$$\int_{\partial_* E_{t_0}} \nu_{E_{t_0}}(x) \cdot e_1 d\mathcal{H}^{N-1}(x) = 0 \tag{6.8}$$

and

$$\int_{\partial_* E_{t_0}} \nu_{E_{t_0}}(x) \cdot e_N d\mathcal{H}^{N-1}(x) = 1. \tag{6.9}$$

From Theorem 1 (ii) of section 5.8 in [10], we know that if $E \subset \mathbb{R}^N$ has locally finite perimeter in $\mathbb{R}^N$, then

$$\int_E \mathrm{div}\phi(x) dx = -\int_{\partial_* E} \phi(x) \cdot \nu_E(x) d\mathcal{H}^{N-1}(x) \tag{6.10}$$

for all $\phi \in C_0^1(\mathbb{R}^N; \mathbb{R}^N)$, where, as before, ν_E is the *inner* unit normal. Define $E \subset \mathbb{R}^N$ by

$$E := E_{t_0} \cup \{x \in \mathbb{R}^N \setminus Q : x \cdot e_N > 0\}.$$

Then E is locally of finite perimeter in $\mathbb{R}^N$ and we claim that

$$\mathcal{H}^{N-1}([\partial_* E] \triangle C) = 0, \tag{6.11}$$

where $C := \partial_* E_{t_0} \cup \{x \in \mathbb{R}^N \backslash Q : x \cdot e_N = 0\}$. It is clear that $C \subset \partial_* E$ and that

$$(\partial_* E) \backslash C \subset \partial Q,$$

so the idea is to show that $\mathcal{H}^{N-1}(\partial Q \cap \partial_* E) = 0$. Let $x \in \partial Q$ be given such that $x \cdot e_N > 0$ and

$$\lim_{r \to 0} \fint_{B(x,r) \cap Q} |u(y) - \rho| dy = 0. \tag{6.12}$$

We need only show that

$$\limsup_{r \to 0} \frac{\mathcal{L}^N(B(x,r) \backslash E)}{r^N} = 0,$$

since then $x \notin \partial_* E$. We have

$$\begin{aligned} \limsup_{r \to 0} \frac{\mathcal{L}^N(B(x,r) \backslash E)}{r^N} &= \limsup_{r \to 0} \frac{1}{r^N} \mathcal{L}^N(B(x,r) \cap \{y \in Q : u(y) \leq t_0\}) \\ &\leq \limsup_{r \to 0} \frac{1}{r^N} \frac{1}{|\rho - t_0|} \int_{B(x,r) \cap Q} |u(y) - \rho| dy = 0. \end{aligned}$$

Since, by Theorem 2 of section 5.3 of [10], (6.12) holds $\mathcal{H}^{N-1}$ almost everywhere on the upper half of ∂Q, and, dealing with the case $x \cdot e_N < 0$ similarly, we find $\mathcal{H}^{N-1}(\partial Q \cap \partial_* E) = 0$.

Choose $\phi \in C_0^1(\mathbb{R}^N; \mathbb{R}^N)$ such that $\phi_i = 0$ for all $i \in \{2, \dots, N\}$, $\phi_1 = 1$ on Q. Clearly, $\mathrm{div}\phi = \partial \phi_1 / \partial x_1$, $\mathrm{div}\phi = 0$ on $\bar{Q}$, and $\nu_E = e_N$ on $\mathbb{R}^N \backslash \bar{Q}$. So, $\int_E \mathrm{div}\phi(x) dx = 0$. For example, we can take $\phi := \rho_{1/2} * \chi_{2Q} e_1$. By (6.10), (6.11), and the fact that E is locally of finite perimeter, we have

$$\begin{aligned} 0 &= \int_{\partial_* E} \phi(x) \cdot \nu_E(x) d\mathcal{H}^{N-1}(x) \\ &= \int_{\partial_* E_{t_0}} e_1 \cdot \nu_{E_{t_0}}(x) d\mathcal{H}^{N-1}(x) + \int_{\{x \cdot e_N = 0\} \backslash Q} \phi(x) \cdot e_N d\mathcal{H}^{N-1}(x) \\ &= \int_{\partial_* E_{t_0}} e_1 \cdot \nu_{E_{t_0}}(x) d\mathcal{H}^{N-1}(x), \end{aligned}$$

and we conclude (6.8).

Equation (6.9) follows by considering, for $\varepsilon > 0$, $\phi \in C_0^1((-1/2 - \varepsilon, 1/2 + \varepsilon)^N; \mathbb{R}^N)$ such that $\phi_i = 0$ for all $i < N$, $\phi = -e_N$ on Q and $-1 \leq \phi \cdot e_N \leq 0$. For example, take $\phi := -\rho_\varepsilon * \chi_{(-1/2-\varepsilon, 1/2+\varepsilon)^N} e_N$. By (6.10) and (6.11) we have

$$\int_E \mathrm{div}\phi(x) dx = \int_{\partial_* E_{t_0}} e_N \cdot \nu_{E_{t_0}}(x) d\mathcal{H}^{N-1}(x) - \int_{\{x \cdot e_N = 0\} \backslash Q} \phi(x) \cdot e_N d\mathcal{H}^{N-1}(x).$$

We see that

$$1 < \int_E \mathrm{div}\phi(x) dx < (1 + 2\varepsilon)^{N-1}$$

and

$$\left| \int_{\{x \cdot e_N = 0\} \setminus Q} \phi(x) \cdot e_N d\mathcal{H}^{N-1}(x) \right| < (1+2\varepsilon)^{N-1} - 1.$$

The arbitrariness of ε yields

$$\int_{\partial_* E_{t_0}} e_N \cdot \nu_{E_{t_0}}(x) d\mathcal{H}^{N-1}(x) = 1.$$

Step 2c. It remains to show that $\mathcal{H}^{N-1}(S(u))$ is larger than the length of Γ_1, which we construct below. The needed inequality is

$$\mathcal{H}^{N-1}(S(u)) \geq [(\beta\bar{\nu} \cdot e_1)^2 + (1 - \beta\bar{\nu} \cdot e_N)^2]^{1/2}, \tag{6.13}$$

which we now prove.

$$\begin{aligned}
\mathcal{H}^{N-1}(S(u)) &\geq \int_{\partial_* E_{t_0} \cap S(u)} |\nu_{E_{t_0}}(x)|^2 d\mathcal{H}^{N-1}(x) \\
&\quad \text{(since } |\nu_{E_{t_0}}| = 1 \ \ \mathcal{H}^{N-1} \text{ almost everywhere)} \\
&= \int_{\partial_* E_{t_0} \cap S(u)} \sum_{i=1}^{N} (\nu_{E_{t_0}}(x) \cdot e_i)^2 d\mathcal{H}^{N-1}(x) \\
&\geq \mathcal{H}^{N-1}(\partial_* E_{t_0} \cap S(u)) \left(\fint_{\partial_* E_{t_0} \cap S(u)} (\nu_{E_{t_0}}(x) \cdot e_1)^2 d\mathcal{H}^{N-1}(x) \right. \\
&\qquad \left. + \fint_{\partial_* E_{t_0} \cap S(u)} (\nu_{E_{t_0}}(x) \cdot e_N)^2 d\mathcal{H}^{N-1}(x) \right) \\
&\geq \mathcal{H}^{N-1}(\partial_* E_{t_0} \cap S(u)) \left(\left[\fint_{\partial_* E_{t_0} \cap S(u)} \nu_{E_{t_0}}(x) \cdot e_1 d\mathcal{H}^{N-1}(x) \right]^2 \right. \\
&\qquad \left. + \left[\fint_{\partial_* E_{t_0} \cap S(u)} \nu_{E_{t_0}}(x) \cdot e_N d\mathcal{H}^{N-1}(x) \right]^2 \right) \quad \text{(by Jensen's inequality)} \\
&= \mathcal{H}^{N-1}(\partial_* E_{t_0} \cap S(u))^{-1} \left(\left[\int_{\partial_* E_{t_0} \cap S(u)} \nu_{E_{t_0}}(x) \cdot e_1 d\mathcal{H}^{N-1}(x) \right]^2 \right. \\
&\qquad \left. + \left[\int_{\partial_* E_{t_0} \cap S(u)} \nu_{E_{t_0}}(x) \cdot e_N d\mathcal{H}^{N-1}(x) \right]^2 \right) \\
&= \mathcal{H}^{N-1}(\partial_* E_{t_0} \cap S(u))^{-1} \left([\beta\bar{\nu} \cdot e_1]^2 + [1 - \beta\bar{\nu} \cdot e_N]^2 \right), \\
&\qquad \text{(by (6.8) and (6.9))}
\end{aligned}$$

which gives (6.13).

Step 2d. We now construct Γ_1 and Γ_2. First, suppose that $\bar{\nu} \cdot e_N \leq 0$. Then (6.13) implies that $\mathcal{H}^{N-1}(S(u)) \geq 1$. Therefore, $E(u, Q) \geq 1 \geq H(\rho, \nu)$. Assume now

that $\bar{\nu} \cdot e_N > 0$. Consider the square in the e_1-e_N plane with normals e_1 and e_N and, suppressing e_i for $i \in \{2, \dots, N-1\}$, take $\Gamma = \Gamma_1 \cup \Gamma_2$, where Γ_2 is the line segment with right endpoint $(1/2, 0)$, unit normal $\bar{\nu}/|\bar{\nu}|$, and length $|\bar{\nu}|\beta$ (if $\beta\bar{\nu}\cdot e_N \geq 1$, redefine $\beta := (1-\varepsilon)/(\bar{\nu} \cdot e_N)$). Γ_1 is then the line segment from the left endpoint of Γ_2 to $(-1/2, 0)$. Note that the length of Γ_1 is $[(\beta\bar{\nu} \cdot e_1)^2 + (1 - \beta\bar{\nu} \cdot e_N)^2]^{1/2}$, and so, by (6.13), we have $\mathcal{H}^1(\Gamma_1) \leq \mathcal{H}^{N-1}(S(u))$. Finally, by (6.6) and (6.7), we conclude that

$$\begin{aligned} H(\rho, \nu) &\leq \rho|\bar{\nu}|\beta W\left(\frac{\bar{\nu}}{|\bar{\nu}|}\right) + \mathcal{H}^1(\Gamma_1) \\ &\leq \rho\beta W(\bar{\nu}) + \mathcal{H}^{N-1}(S(u)) \\ &\leq \int_Q W(\nabla u(x))dx + \mathcal{H}^{N-1}(S(u)). \end{aligned}$$

Due to the arbitrariness of u, we have $h \geq H$. □

We conclude with the following remark, which simply says that the above argument works for more general initial jump energy densities.

REMARK 6.6. Suppose that the energy of the admissible functions for h is given by

$$E(u, Q) = \int_Q W(\nabla u)dx + \int_{S(u)} \phi([u]\nu)d\mathcal{H}^{N-1},$$

where W and ϕ are convex and positive homogeneous of degree one. Then the conclusion of Theorem 6.5 holds. Taking

$$f(x, dDu) := \chi_{Q\setminus S(u)}W(dDu) + \chi_{S(u)}\phi(dDu)$$

we have

$$\int_Q f(x, dDu) = \int_Q W(\nabla u)dx + \int_{S(u)} \phi([u]\nu)d\mathcal{H}^{N-1} = E(u, Q),$$

and, by Lemma 6.3,

$$E(u, Q) = \int_{\mathbb{R}} \left[\int_{\partial_* E_t \setminus S(u)} W(\nu_{E_t}(x))d\mathcal{H}^{N-1} + \int_{\partial_* E_t \cap S(u)} \phi(\nu_{E_t}(x))d\mathcal{H}^{N-1} \right] dt.$$

The rest of the proof of Theorem 6.5 follows with the obvious alterations.

Acknowledgments. The author would like to thank Luigi Ambrosio and the referees for comments and suggestions on earlier versions.

A NOTE ON MATRIX REFINEMENT EQUATIONS*

THOMAS A. HOGAN†

Abstract. Refinement equations involving matrix masks are receiving much of attention these days. They can play a central role in the study of refinable finitely generated shift-invariant spaces, multiresolutions generated by more than one function, multiwavelets, splines with multiple knots, and matrix subdivision schemes—including Hermite-type subdivision schemes. Several recent papers on this subject begin with an assumption on the eigenstructure of the mask, pointing out that this assumption is heuristically "natural" or "preferred." In this note, we prove that stability of the shifts of the refinable function requires this assumption.

Key words. matrix refinement equation, matrix subdivision scheme, refinable function vector, stability, Riesz basis, multiwavelet, shift-invariant space, FSI space

1. Introduction.

Several desirable properties are not available with compactly supported orthogonal wavelets, e.g., symmetry and piecewise polynomial structure. Presently, multiwavelets seem to offer a satisfactory alternative (see, for example, [DGHM], [GL]). Multiwavelets are wavelets constructed from a refinable function vector Φ which satisfies a matrix refinement equation of the form

$$\Phi = \sum_{\alpha \in \mathbb{Z}^d} a(\alpha)\Phi(M^T \cdot -\alpha).$$

Here, each coefficient $a(\alpha)$ is a $\Phi \times \Phi$ matrix, and $M \in \mathbb{Z}^{d\times d}$. Refinable function vectors have also appeared in the study of matrix subdivision schemes, which play an important role in the analysis of multivariate subdivision schemes (cf. [D]).

As in the case of a single refinable function, it is often impossible to study a refinable function vector directly. In such a case, its properties are analyzed indirectly via the coefficient sequence $(a(\alpha))_{\alpha\in\mathbb{Z}^d}$ (see, for example, [CDP], [HC], [HSS], [H], [P], [S]). For example, the eigenstructure of the matrix

$$A(0) = \sum_{\alpha \in \mathbb{Z}^d} a(\alpha)$$

has played an important role in such analyses. In particular, it is assumed in [HSS] and [S], that 1 is a simple eigenvalue of $A(0)$ and that all other eigenvalues have modulus strictly less than 1. In this paper, we demonstrate that this is a very reasonable assumption by proving that without such an assumption, the refinable function vector Φ cannot possibly have stable shifts.

A slightly weaker statement has already been proved by Cohen, Dyn, and Levin in [CDL] for ℓ^∞-stability. In that paper, they assumed that $a(\alpha) = 0$ for all but finitely many α and that the associated subdivision scheme is C^0, i.e., convergent. In this paper we strengthen and extend their results.

†Department of Mathematical Sciences, University of Alberta, Edmonton, AB T6G 2G1, Canada (thogan@vega.math.ualberta.ca).

To present our results in a general setting, we recall the following definition from [JM]:

$$\mathcal{L}^p := \mathcal{L}^p(\mathbb{R}^d) := \left\{ \phi : \mathbb{R}^d \to \mathbb{C} \;\middle|\; |\phi|_p := \|\widetilde{\phi}\|_{L^p([0,1)^d)} < \infty \right\}$$

for $1 \le p \le \infty$, where $\widetilde{\phi} := \sum_{\alpha \in \mathbb{Z}^d} |\phi(\cdot - \alpha)|$. As pointed out in [JM], $\mathcal{L}^p$ is a Banach space with norm $|\cdot|_p$ and

$$\mathcal{L}^p \subset L^1 \cap L^p.$$

Now, let $M \in \mathbb{Z}^{d\times d}$ be an integer matrix satisfying $\lim_{k\to\infty} M^{-k} = 0$ and let $\phi_1, \dots, \phi_m \in \mathcal{L}^p$. We say that $\Phi := (\phi_j)_{j=1}^m$ is *M-refinable* if there exist sequences $a_{j,k} \in \ell^1(\mathbb{Z}^d) \quad (1 \le j,k \le m)$ such that

$$\phi_j = \sum_{k=1}^m \sum_{\alpha\in\mathbb{Z}^d} a_{j,k}(\alpha)\phi_k(M^T \cdot - \alpha), \qquad (j = 1, \dots, m).$$

Equivalently, Φ is refinable if

$$\widehat{\Phi}(M\xi) = A(\xi)\widehat{\Phi}(\xi) \quad \text{for all } \xi \in \mathbb{R}^d, \tag{1.1}$$

where the matrix $A := (A_{j,k})_{1\le j,k\le m}$ of (continuous 2π-periodic) functions is defined by

$$A_{j,k}(\xi) := \frac{1}{|\det M|} \sum_{\alpha\in\mathbb{Z}^d} a_{j,k}(\alpha) e^{-i\langle\alpha,\xi\rangle}.$$

The matrix A is referred to as the *(refinement) mask*.

It is already well known that equation (1.1) has only the trivial solution $\Phi = 0$ if the spectral radius $\rho(A(0)) < 1$. It is also well known that convergence of the infinite product

$$P := \prod_{j=1}^{\infty} A(M^{-j}\cdot) \tag{1.2}$$

requires that (i) $\rho(A(0)) \le 1$; (ii) 1 be the only eigenvalue of modulus 1; and (iii) the algebraic and geometric multiplicities of the eigenvalue 1 be the same. When this product does converge, the function Φ defined by $\widehat{\Phi}(\xi) = P(\xi)x$ is a solution to equation (1.1) for any $x \in \mathbb{C}^m$. Convergence of the matrix subdivision scheme associated with equation (1.1) requires similar assumptions on A (cf. [CDL]). Nonetheless, solutions to equation (1.1) may exist even without such assumptions (as pointed out in [HC] and [CDP]). However, the existence of solutions with stable shifts will require these assumptions and more.

The shifts of $\phi_1, \dots, \phi_m \in \mathcal{L}^p$ are said to be *ℓ^p-stable* if there exist constants $0 < c_1 \le c_2 < \infty$ such that

$$c_1 \sum_{j=1}^m \|a_j\|_{\ell^p} \le \| \sum_{j=1}^m \sum_{\alpha\in\mathbb{Z}^d} a_j(\alpha)\phi_j(\cdot - \alpha)\|_{L^p} \le c_2 \sum_{j=1}^m \|a_j\|_{\ell^p}$$

for any $a_1, \dots, a_m \in \ell^p(\mathbb{Z}^d)$. In [JM], Jia and Micchelli proved that the shifts of any $\phi_1, \dots, \phi_m \in \mathcal{L}^p$ are ℓ^p-stable if and only if the sequences

$$\left(\widehat{\phi}_j(\xi + 2\alpha\pi)\right)_{\alpha\in\mathbb{Z}^d}, \qquad (j = 1, \dots, m)$$

are linearly independent for every $\xi \in \mathbb{R}^d$. This will play the major role in our proofs.

In the statement of our theorems, we use the following terminology. An eigenvalue is *nondegenerate* if its algebraic and geometric multiplicities agree. A *simple* eigenvalue is a nondegenerate eigenvalue of multiplicity 1.

To facilitate our proofs, we define

$$V := \{\, v \in \mathbb{Z}^d \mid v = Mt \text{ for some } t \in [0,1)^d \,\}.$$

Then V is a complete set of representatives for the quotient group $\mathbb{Z}^d/M\mathbb{Z}^d$. In particular, $\mathbb{Z}^d$ is the disjoint union of the sets $v + M\mathbb{Z}^d$ ($v \in V$). We will actually only ever make use of the set $V' := V\backslash 0$.

2. Stability imposes structure.

THEOREM 2.1. *Let $\phi_1, \ldots, \phi_m \in \mathcal{L}^p$. Suppose $\Phi := (\phi_j)_{j=1}^m$ is M-refinable with mask A. If the shifts of $\phi_1, \ldots, \phi_m$ are ℓ^p-stable, then* 1 *is a simple eigenvalue of $A(0)$ and all other eigenvalues have modulus strictly less than* 1. *Moreover, $\widehat{\Phi}(0)$ is a right* 1*-eigenvector.*

Proof. We assume stability to demonstrate the eigenvalue assertions.

By the refinement equation (1.1), we have, for any $\xi \in \mathbb{R}^d$ and $n \in \mathbb{N}$,

$$\widehat{\Phi}(\xi) = \prod_{j=1}^{k} A(M^{-j}\xi)\widehat{\Phi}(M^{-k}\xi).$$

Since $M^{-k} \to 0$ (and since A and $\widehat{\Phi}$ are both continuous), $\rho(A(0)) < 1$ would imply that Φ is identically zero—contradicting the assumption that the shifts of Φ are stable. So, $\rho(A(0)) \geq 1$.

Now, suppose $y \in \mathbb{C}^m$ satisfies $y^T A(0) = \mu y^T \neq 0$ for some $\mu \in \mathbb{C}$ with $|\mu| \geq 1$. Then the refinement equation (1.1) implies that

$$\begin{aligned} y^T\widehat{\Phi}(2M^k(M\alpha + v)\pi) &= y^T A^k(0) A(2M^{-1}v\pi)\widehat{\Phi}(2M^{-1}v\pi + 2\alpha\pi) \\ &= \mu^k y^T A(2M^{-1}v\pi)\widehat{\Phi}(2M^{-1}v\pi + 2\alpha\pi) \end{aligned} \tag{2.1}$$

for any $k \in \mathbb{Z}_+$, $\alpha \in \mathbb{Z}^d$, $v \in V'$. Since $v \in V'$ (hence $M\alpha + v \neq 0$), our assumptions on M imply that $\lim_{k\to\infty} |M^k(M\alpha + v)| = \infty$. Since $y^T\Phi \in \mathcal{L}^p \subset L^1$, the left-hand side of equation (2.1) then tends to zero as k tends to infinity. And, since $|\mu| \geq 1$, this implies that

$$y^T A(2M^{-1}v\pi)\widehat{\Phi}(2M^{-1}v\pi + 2\alpha\pi) = 0$$

for every $\alpha \in \mathbb{Z}^d$ (which implies that $y^T A(2M^{-1}v\pi) = 0$ for every $v \in V'$, since the shifts of Φ are stable). Together with equation (2.1), this implies that $y^T\widehat{\Phi}(2\beta\pi) = 0$ for all $\beta \in \mathbb{Z}^d\backslash 0$, since every such β has a (unique) representation of the form $\beta = M^k(M\alpha + v)$ for some $k \in \mathbb{Z}_+$, $\alpha \in \mathbb{Z}^d$, $v \in V'$. The stability of the shifts of Φ then implies that $y^T\widehat{\Phi}(0) \neq 0$ and, a fortiori, $\widehat{\Phi}(0) \neq 0$. The refinement equation (1.1) then implies that $\widehat{\Phi}(0)$ is a right 1-eigenvector of $A(0)$.

Now, suppose that $y_1^T A(0) = \mu_1 y_1^T \neq 0$ and $y_2^T A(0) = \mu_2 y_2^T \neq 0$ with $|\mu_i| \geq 1$ ($i = 1, 2$). The above arguments imply that $y_i^T\widehat{\Phi}(2\beta\pi) = 0$ $\forall \beta \in \mathbb{Z}^d\backslash 0$ and $y_i^T\widehat{\Phi}(0) \neq 0$; without loss of generality, we may assume that $y_i^T\widehat{\Phi}(0) = 1$. Then $(y_2 - y_1)^T\widehat{\Phi}(2\beta\pi) = 0$ for every $\beta \in \mathbb{Z}^d$. The stability of the shifts of Φ now implies that $y_1 = y_2$.

We conclude that 1 is an eigenvalue of $A(0)$ of *geometric* multiplicity 1. It is the only eigenvalue outside of the open unit disc. Its (unique-up-to-multiplicity) right eigenvector is $\widehat{\Phi}(0)$ and its (unique-up-to-multiplicity) left eigenvector, y^T, satisfies $y^T\widehat{\Phi}(2\beta\pi) = 0$ for all $\beta \in \mathbb{Z}^d\backslash 0$. If the algebraic multiplicity of the eigenvalue 1 were greater than 1, then the (one-dimensional) left and right eigenspaces would be orthogonal one to the other (this follows easily by considering the Jordan canonical form of $A(0)$). That is, $y^T\widehat{\Phi}(0)$ would be zero—contradicting the assumption that the shifts of Φ are stable. □

Remark. The above proof in fact implies that the left eigenvector y^T of $A(0)$ actually satisfies the "sum rules"

$$y^T \sum_{\alpha\in\mathbb{Z}^d} a(\beta + M^T\alpha) = y^T \quad \forall\, \beta \in \mathbb{Z}^d,$$

as well as the so-called Strang–Fix conditions of order 1

$$y^T\widehat{\Phi}(0) \neq 0, \qquad y^T\widehat{\Phi}(2\beta\pi) = 0 \quad \forall\, \beta \in \mathbb{Z}^d\backslash 0.$$

So, stability implies accuracy of order 1 (or density) as expected.

3. Stability of matrix functions. A generalized stability notion for matrix functions has been recently considered in [CDL]. In the spirit of that paper, we will say that the shifts of any $m \times n$ matrix $\Phi = (\phi_{j,k})$ of $\mathcal{L}^p$-functions are *ℓ^p-stable* if there exist constants $0 < c_1 \le c_2 < \infty$ such that

$$c_1 \sum_{j=1}^m \|a_j\|_{\ell^p} \le \sum_{k=1}^n \left\| \sum_{j=1}^m \sum_{\alpha\in\mathbb{Z}^d} a_j(\alpha)\phi_{j,k}(\cdot - \alpha) \right\|_{L^p} \le c_2 \sum_{j=1}^m \|a_j\|_{\ell^p}$$

for any $a_1, \dots, a_m \in \ell^p(\mathbb{Z}^d)$.

Many of the results from [JM] can be generalized to cover this notion. To state some pertinent ones, we first recall some of their notation. We denote the d-dimensional torus

$$\left\{ (z_1, \dots, z_d) \in \mathbb{C}^d \;\middle|\; |z_1| = \cdots = |z_d| = 1 \right\}$$

by $\mathbb{T}^d$. Then, for any $f, g \in \mathcal{L}^2$, define

$$[f, g](z) := \sum_{\alpha\in\mathbb{Z}^d} \langle f, g(\cdot - \alpha)\rangle z^\alpha, \qquad (z \in \mathbb{T}^d),$$

where $\langle f, g\rangle := \int_{\mathbb{R}^d} f\overline{g}$ for $f, g \in L^2(\mathbb{R}^d)$. And, lastly, for $\phi_1, \dots, \phi_m \in \mathcal{L}^p$, define

$$\mathcal{S}^1(\phi_1, \dots, \phi_m) := \left\{ \sum_{j=1}^m \sum_{\alpha\in\mathbb{Z}^d} a_j(\alpha)\phi_j(\cdot - \alpha) \;\middle|\; a_j \in \ell^1(\mathbb{Z}^d) \text{ for } j = 1, \dots, m \right\}.$$

It is worth pointing out that $[f, g](z)$ is a continuous function of z on $\mathbb{T}^d$ and that $\mathcal{S}^1(\phi_1, \dots, \phi_m)$ is a subspace of $\mathcal{L}^p(\mathbb{R}^d)$.

A generalized statement of [JM, Theorem 4.1] follows.

THEOREM 3.1. *Let $\phi_{j,k} \in \mathcal{L}^2(\mathbb{R}^d)$, $(j = 1, \dots, m; k = 1, \dots, n)$. Then the shifts of $\Phi = (\phi_{j,k})$ are ℓ^2-stable if and only if one of the following conditions holds:*

(i) *For any* $\xi \in \mathbb{R}^d$, *the sequences* $(\widehat{\phi}_{j,k}(\xi + 2\alpha\pi))_{k=1,\alpha\in\mathbb{Z}^d}^n$ $(j = 1, \dots, m)$ *are linearly independent.*
(ii) *The matrix* $(\sum_{k=1}^n [\phi_{j,k}, \phi_{\ell,k}](z))_{1\le j,\ell\le m}$ *is positive definite for every* $z \in \mathbb{T}^d$.
(iii) *There exist* $g_{j,k} \in \mathcal{S}^1(\phi_{1,k}, \dots, \phi_{m,k})$ $(j = 1, \dots, m; k = 1, \dots, n)$ *such that*

$$\sum_{k=1}^{n} \langle g_{j,k}, \phi_{\ell,k}(\cdot - \alpha)\rangle = \delta_{j\ell}\delta_{0\alpha} \quad \text{for } 1 \le j, \ell \le m \quad \text{and } \alpha \in \mathbb{Z}^d,$$

and [JM, Theorem 4.2] is generalized as follows.

THEOREM 3.2. *Let* $\phi_{j,k} \in \mathcal{L}^p(\mathbb{R}^d)$, $(j = 1, \dots, m; k = 1, \dots, n)$. *Then the shifts of* $\Phi = (\phi_{j,k})$ *are* ℓ^p*-stable if and only if condition* (i) *of Theorem* 3.1 *holds.*

The proofs of these theorems are clear from the proofs of [JM, Theorems 3.3, 3.5, and 4.1]. We now state a generalization of Theorem 2.1. The proof is similar, so we provide only the major distinctions below.

THEOREM 3.3. *Let* $\phi_{j,k} \in \mathcal{L}^p(\mathbb{R}^d)$, $(j = 1, \dots, m; k = 1, \dots, n)$. *Suppose* $\Phi = (\phi_{j,k})$ *is* M*-refinable with mask* A. *If the shifts of* Φ *are* ℓ^p*-stable, then* 1 *is a nondegenerate eigenvalue of* $A(0)$*; its multiplicity is the rank of the matrix* $\widehat{\Phi}(0) = \big(\widehat{\phi}_{i,j}(0)\big)$, *and all other eigenvalues have modulus strictly less than* 1. *In particular, the columns of* $\widehat{\Phi}(0)$ *must span the right* 1*-eigenspace of* $A(0)$.

Proof. Define

$$W := \{\, y \in \mathbb{C}^m \mid y^T A(0) = \mu y^T \text{ for some } |\mu| \ge 1 \,\} \text{ and } X := \{\, x \in \mathbb{C}^m \mid A(0)x = x \,\}.$$

Then, $\operatorname{rank}\widehat{\Phi}(0) \le \dim X \le \dim W$, since every nonzero column of $\widehat{\Phi}(0)$ is a right 1-eigenvector of $A(0)$.

As in the proof of Theorem 1, if $y \in W$, then $y^T\widehat{\Phi}(2\beta\pi) = 0$ for all $\beta \in \mathbb{Z}^d\backslash 0$. If the shifts of Φ are stable, then $y^T\widehat{\Phi}(0) \ne 0$ for every $y \in W$. This implies that $\dim W \le \operatorname{rank}\widehat{\Phi}(0)$; hence both must equal the geometric multiplicity of the eigenvalue 1. In particular, all other eigenvalues have modulus strictly less than 1, and the columns of $\widehat{\Phi}(0)$ span the right 1-eigenspace.

If the algebraic multiplicity of the eigenvalue 1 is greater than its geometric multiplicity, then there exists a left 1-eigenvector y for which $y^T x = 0$ for all $x \in X$. Such y satisfies $y^T\widehat{\Phi}(2\alpha\pi) = 0$ for all $\alpha \in \mathbb{Z}^d$, and the shifts of Φ are not stable. □

We can say even more, under slightly more restrictive assumptions, on the sequences $(a_{j,k}(\alpha))_{\alpha\in\mathbb{Z}}$. Suppose, for example, that each of these sequences decays exponentially fast; then the entries of the matrix A are analytic functions. Now, if Φ is a matrix solution to the refinement equation (1.1) and the shifts of Φ are stable, then the arguments of [HC] (and the consequences of Theorem 3.3) imply that the infinite matrix product (1.2) is convergent and that the map $v \mapsto Pv$ is an isomorphism from the right 1-eigenspace of $A(0)$ onto the (vector) solution space of the refinement equation (1.1). Hence this solution space is already spanned by some N of the columns of Φ, where N is the multiplicity of the eigenvalue 1 of $A(0)$. This leads to the following theorem.

THEOREM 3.4. *Suppose some (matrix) solution of the refinement equation* (1.1) *has* ℓ^p*-stable shifts. Then a given solution* Φ *has* ℓ^p*-stable shifts if and only if the columns of* $\widehat{\Phi}(0)$ *span the right* 1*-eigenspace of* $A(0)$.

Acknowledgment. The author is grateful to Nira Dyn for discussions (at the *Program on Spline Functions and the Theory of Wavelets* in Montréal) which motivated this work.

ON THE REGULARIZATION OF FREDHOLM INTEGRAL EQUATIONS OF THE FIRST KIND *

ENRICO DE MICHELI†, NICODEMO MAGNOLI‡, AND GIOVANNI ALBERTO VIANO‡

Abstract. In this paper the problem of recovering a regularized solution of the Fredholm integral equations of the first kind with Hermitian and square-integrable kernels, and with data corrupted by additive noise, is considered. Instead of using a variational regularization of Tikhonov type, based on a priori global bounds, we propose a method of truncation of eigenfunction expansions that can be proved to converge asymptotically, in the sense of the L^2-norm, in the limit of noise vanishing. Here we extend the probabilistic counterpart of this procedure by constructing a probabilistically regularized solution without assuming any structure of order on the sequence of the Fourier coefficients of the data. This probabilistic approach allows us to use the statistical tools proper of time-series analysis, and in this way we attain a new regularizing algorithm, which is illustrated by some numerical examples. Finally, a comparison with solutions obtained by the means of the variational regularization exhibits how some intrinsic limits of the variational-based techniques can be overcome.

1. Introduction.

We consider the Fredholm integral equations of the first kind

$$(Af)(x) = \int_a^b K(x,y)f(y)\,dy = g(x) \qquad (a \le x \le b) \tag{1}$$

whose kernel $K(x,y)$ is supposed to be Hermitian and square integrable; i.e.,

$$K(x,y) = \overline{K(y,x)} \tag{2}$$

and

$$\int_a^b \left\{ \int_a^b |K(x,y)|^2 dx \right\} dy < \infty. \tag{3}$$

Then $A : L^2(a,b) \to L^2(a,b)$ is a self-adjoint compact operator.

For simplicity we shall suppose hereafter that the kernel K, the function g, and the unknown function f are real-valued functions; in addition, we assume that the interval $[a,b]$ is a bounded and closed subset of the real line.

The Hilbert–Schmidt theorem guarantees that the integral operator A admits a set of eigenfunctions $\{\psi_k\}_1^\infty$ and, accordingly, a countably infinite set of eigenvalues $\{\lambda_k\}_1^\infty$. The eigenfunctions form an orthonormal basis of the orthogonal complement of the null space of the operator A and therefore an orthonormal basis of $L^2(a,b)$ when A is injective. For the sake of simplicity only this case will be considered, although this assumption can be easily relaxed with slight technical modifications.

‡ Dipartimento di Fisica, Università di Genova, Istituto Nazionale di Fisica Nucleare, sez. di Genova, Via Dodecaneso 33, 16146 Genova, Italy (magnoli@ge.infn.it, viano@ge.infn.it).

The Hilbert–Schmidt theorem also guarantees that $\lim_{k\to\infty} \lambda_k = 0$. Furthermore, we shall suppose hereafter that the eigenvalues are ordered as follows: $\lambda_1 > \lambda_2 > \lambda_3 > \cdots$ In view of the Hilbert–Schmidt theorem we associate with the integral equation (1) the following eigenfunction expansion:

$$f(x) = \sum_{k=1}^{\infty} \left(\frac{g_k}{\lambda_k} \right) \psi_k(x), \tag{4}$$

where $g_k = (g, \psi_k)$, $((\cdot,\cdot)$ denoting the scalar product in $L^2(a,b))$. The series (4) converges in the sense of L^2.

Remark. If the support of the data does not coincide with that of the solutions, i.e., $A : L^2(a,b) \to L^2(c,d)$ with $[a,b]$ different from $[c,d]$, the problem can be worked out in terms of singular values and singular functions of the operator A [6], and all of the following results can be easily reformulated.

In view of the fact that there always exists some inherent noise in the data, instead of (1) we have to deal with the following equation:

$$Af + n = \overline{g} \qquad (\overline{g} = g + n), \tag{5}$$

where n represents the noise. Therefore, instead of expansion (4) we have to consider the following expansion:

$$\sum_{k=1}^{\infty} \left(\frac{\overline{g}_k}{\lambda_k} \right) \psi_k, \tag{6}$$

where $\overline{g}_k = (\overline{g}, \psi_k)$. Expansion (6) is generally diverging because $\overline{g}$ does not belong, in general, to the range of the operator A. This is precisely a manifestation of the ill-posed character of the Fredholm integral equation of the first kind.

Several methods of regularization have been proposed (see [10, 14, 16] and references therein); all of them modify one of the elements of the triplet $\{A, X, Y\}$, where A is the integral operator defined by (1), whereas X and Y are, respectively, the solution and the data space (in our case $X \equiv Y \equiv L^2(a,b)$). Among these methods the procedure, which is probably the most popular, consists in admitting only those solutions that belong to a compact subset of the solution space X. In particular the famous method of Tikhonov leads to the construction of "regularizing operators" by the minimization of "smoothing functionals." In this latter functional the smoothing term is obtained precisely by restricting the admitted solutions to a compact subset of the space X; then the continuity of A^{-1} follows from compactness. This restriction is realized by the use of a priori bounds which can be written assuming some prior knowledge of the solution. Therefore, in addition to the inequality

$$\|Af - \overline{g}\| \leq \epsilon \tag{7}$$

which corresponds to a bound on the noise ($\|\cdot\|$ denoting the norm in $L^2(a,b)$), one also considers an a priori bound on the solution of the following form:

$$\|Cf\|_{\mathcal{Z}} \leq E, \tag{8}$$

where $\mathcal{Z}$ denotes the "constraint space" and, accordingly, C is the "constraint operator." From the bounds (7) and (8) we are led to define the regularized solution as the minimum of the following functional:

$$\Phi(f) = \|Af - \overline{g}\|^2 + \alpha^2 \|Cf\|^2_{\mathcal{Z}}, \qquad \left(\alpha = \left(\frac{\epsilon}{E}\right)\right). \tag{9}$$

In spite of several significant merits, this procedure is not free from defects. Concerning the possibility of writing suitable a priori bounds on the solution, we want to remark strongly that two different types of problems must be distinguished:

a) synthesis problems,
b) inverse problems

and to note that both are frequently solved by the use of Fredholm integral equations of the first kind. In the first class of problems, that basically consists in finding the source that produces a prescribed effect (e.g., prescribed boundary values), the a priori bounds are intrinsic of the problem itself, whereas this is not always the case for the second class. As typical examples we can consider

a′) the antenna synthesis,
b′) the signal recovery.

The problem of the antenna synthesis consists in determining, within a certain degree of approximation, the current intensity that generates a desired radiation pattern. It can be formulated in terms of Fredholm equation of the first kind [18, 24] and, consequently, it presents the typical pathology of the ill-posed problems. In this problem the a priori bound on the ohmic losses associated with the current intensity is necessary and can be regarded as a natural constraint intrinsic of the problem. Conversely, in the case of the signal recovery problem, the a priori bounds can be written only if prior knowledge of the signal is assumed. Generally, it is possible to have some a priori information regarding, for instance, the support of the signal or requiring the function representing the signal to be nonnegative. But even in these cases the prior knowledge could be insufficiently specific to be peculiar of the function to be reconstructed, and arbitrary, though reasonable, constraints must be added to solve the problem. Strictly connected with this question there is the crux of the matter: the practical choice of the regularization parameter α (see formula (9)) for a fixed $\overline{g}$ when the a priori bound (8) is unknown or is not sufficiently precise.

Moreover, let us note that the functional (9) works as a filter whose action is smoothing the Fourier components $\overline{g}_k$ for high values of k. But it is easy to exhibit examples of signals whose Fourier components are small, or even zero, for low values of k, while the significant contributions of the signal are brought by those components at intermediate values of k, which are smoothed out by the action of the filter. In these situations the standard regularization method fails, showing that the only existence of the minimum of functional (9) does not guarantee the bulk of the signal has been really recovered. This delicate point will be illustrated with numerical examples in section 4.

We suggest a different approach which is based on the following observation: for the moment, suppose that the moduli of the noiseless Fourier coefficients $|g_k|$ are monotonically decreasing as k increases; then, although the formal series (6) diverges, nevertheless the effect of the error remains limited in the beginning of the expansion, and there exists a point (a certain value of k) where divergence sets in. Thus, the idea is to stop the expansion at the point where it turns to diverge. This rough and qualitative description can be put in rigorous form by proving that even if the series (6) diverges, nevertheless it converges (in the sense of L^2-norm) as ϵ (i.e., the bound on the noise) tends to zero. This result, which has been proved by two of us (see [17]), does not give (except in very particular cases) a practical numerical method for finding out the truncation point (i.e., the value of k) at which to stop expansion (6). However, here we prove a probabilistic generalization of the results presented in [17] by removing the quite restrictive assumption that the Fourier coefficients $|g_k|$ of the signal to be

recovered are monotonically decreasing. Compared to [17] the significance of the new results is relevant. First, the hypothesis made in [17] on the order of the coefficients $|g_k|$ leads to a regularization procedure that essentially works as an ideal low-pass filter, and, as previously discussed, this does not guarantee to recover correctly the signals whose bulk is localized at intermediate frequencies. Conversely, in this paper it will be shown how to construct a regularized solution without assuming any kind of order on the coefficients $|g_k|$ by exploiting the tools supplied by the information theory. This result will lead to a more effective regularizing algorithm which is based on a suitable statistical analysis of the data and whose main feature is indeed the frequency selectivity. Second, from the application point of view, the hypothesis on the order of the coefficients $|g_k|$ is too restrictive; thus, by removing it, a much larger class of real signals can be practically analyzed. These questions are precisely the contents of sections 3 and 4. We will prove, indeed, in section 3 that it is possible to split the noisy Fourier coefficients $\overline{g}_k$ into two classes:

i) the Fourier coefficients $\overline{g}_k$ from which a significant amount of information on $f_k = (f, \psi_k)$ can be extracted;
ii) the Fourier coefficients $\overline{g}_k$ that can be regarded as random numbers because the noise prevails on the coefficients g_k.

In section 4 it will be shown how it is possible to separate practically the coefficients $\overline{g}_k$ into these two classes by the use of statistical tools supplied by the so called "time-series" analysis. Therefore, we can practically construct an approximation which converges to the real solution, and furthermore we can have some confidence that the bulk of the function f has been effectively recovered.

The paper is organized as follows. In the first part of section 2 a short sketch of the variational method based on the minimization of functional (9) is given. This will be done in order to have explicitly the formulae which will be used in section 4, where our procedure and the variational one will be compared. The second part of section 2 is devoted to the probabilistic formulation of the regularization problem in a quite general setting. In section 3 we start illustrating the asymptotic convergence of the eigenfunction expansion (in the sense of L^2-norm) as ϵ tends to zero; then this result is reconsidered from the viewpoint of probability and information theory. Here a key role will be played by the Bayes formula: it will provide the various terms of our approximation, which will be proved to be a probabilistically regularized solution of (1). The first part of section 4 is devoted to the discussion of the statistical tools that are necessary for practically recovering the regularized solution from finite samples of noisy data. Finally, some numerical examples are given in the second part of section 4.

2. Variational and probabilistic regularization.

2.1. Variational regularization. After the classical book of Tikhonov and Arsenine [23] the literature on the theory and applications of the variational regularization has been rapidly growing (see, for instance, [14]). In order to compare our algorithm with this classical one, some formulae and results of the variational regularization will be recalled here (see [5, 6, 20, 23] for proofs and details).

Let us characterize, first of all, the constraint operator C and, accordingly, the constraint space $\mathcal{Z}$. Let us take a constraint operator C such that $C^\star C$ and $A^\star A$ commute (this assumption does not restrict the theory and the applications significantly [5, 18]). Then, the space $\mathcal{Z}$ is composed by those functions $f \in L^2(a, b)$ such

that $\|Cf\|_{\mathcal{Z}}$ is finite; i.e.,

$$\|Cf\|_{\mathcal{Z}}^2 = (C^\star Cf, f) = \sum_{k=1}^{\infty} c_k^2 |f_k|^2 < \infty. \tag{10}$$

Now we consider the ball $\mathcal{U}_{\mathcal{Z}} = \{f \in \mathcal{Z} \mid \sum_{k=1}^{\infty} c_k^2 |f_k|^2 \le E^2\}$ and the restriction A_0 of the operator A (see (1)) to the ball $\mathcal{U}_{\mathcal{Z}}$. Then, the following propositions can be proved.

PROPOSITION 2.1. *If* $\lim_{k\to\infty} c_k^2 = +\infty$, *the operator* A_0^{-1} *is continuous.*

PROPOSITION 2.2. *The functional* $\Phi(f)$, *with* $\alpha = (\epsilon/E)$, *has a unique minimum which is given by*

$$f_\star = [A^\star A + \left(\frac{\epsilon}{E}\right)^2 C^\star C]^{-1} A^\star \overline{g}. \tag{11}$$

By expanding $\overline{g}$ in terms of ψ_k (eigenfunctions of the operator A), we have

$$f_\star = \sum_{k=1}^{\infty} \frac{\lambda_k \overline{g}_k}{\lambda_k^2 + c_k^2 \left(\frac{\epsilon}{E}\right)^2} \psi_k. \tag{12}$$

Next, we have the following proposition.

PROPOSITION 2.3. *The following limit holds true for any function* f *satisfying the bounds* (7) *and* (8)*:*

$$\lim_{\epsilon\to 0} \|f - f_\star\| = 0 \qquad (E \ \textit{fixed}). \tag{13}$$

In numerical computations it is often convenient to use truncated approximations. For instance, one can derive from the smoothed solution (12) the following truncated approximation:

$$f_\star^{(1)} = \sum_{k=1}^{k_\alpha} \frac{\overline{g}_k}{\lambda_k} \psi_k, \tag{14}$$

where k_α is the largest integer such that

$$\lambda_k \ge \left(\frac{\epsilon}{E}\right) |c_k|. \tag{15}$$

PROPOSITION 2.4. *The following limit holds true for any function* f *satisfying bounds* (7) *and* (8)*:*

$$\lim_{\epsilon\to 0} \left\| f - f_\star^{(1)} \right\| = 0 \qquad (E \ \textit{fixed}). \tag{16}$$

In several problems a weaker a priori bound should be used by setting $C = I$ (the identity operator). Therefore, instead of bound (8), we have

$$\|f\| = \left(\sum_{k=1}^{\infty} |f_k|^2 \right)^{1/2} \le E. \tag{17}$$

In this case the unique minimum of functional (9) is given by

$$f_\star^{(2)} = \sum_{k=1}^{\infty} \frac{\lambda_k \overline{g}_k}{\lambda_k^2 + \left(\frac{\epsilon}{E}\right)^2} \psi_k, \tag{18}$$

and, accordingly, the following truncated approximation can be introduced:

$$f_\star^{(3)} = \sum_{k=1}^{k_\beta} \frac{\overline{g}_k}{\lambda_k} \psi_k, \tag{19}$$

where k_β is the largest integer such that

$$\lambda_k \geq \frac{\epsilon}{E}. \tag{20}$$

Both $f_\star^{(2)}$ and $f_\star^{(3)}$ converge to f as $\epsilon \to 0$ in a weak sense. In fact, as shown in [20, 21], the following proposition can be proved.

PROPOSITION 2.5. *For any function f which satisfies the bounds* (7) *and* (17)*, the following limits hold true:*

$$\lim_{\epsilon \to 0} \left| \left(\left[f - f_\star^{(2)} \right], v \right) \right| = 0 \qquad (\|v\| \leq 1,\ E \text{ fixed}), \tag{21}$$

$$\lim_{\epsilon \to 0} \left| \left(\left[f - f_\star^{(3)} \right], v \right) \right| = 0 \qquad (\|v\| \leq 1,\ E \text{ fixed}). \tag{22}$$

2.2. Probabilistic regularization. Here we want to reconsider (5) from a probabilistic point of view. With this in mind we rewrite (5) in the following form:

$$A\xi + \zeta = \eta, \tag{23}$$

where ξ, ζ, and η, which correspond to f, n, and $\overline{g}$, respectively, are Gaussian weak random variables (w.r.v.) in the Hilbert space $L^2(a, b)$ [2]. A Gaussian w.r.v. is uniquely defined by its mean element and its covariance operator; in the present case we denote by $R_{\xi\xi}$, $R_{\zeta\zeta}$, and $R_{\eta\eta}$ the covariance operators of ξ, ζ, and η, respectively. Next, we make the following assumptions:

I) ξ and ζ have zero mean; i.e., $m_\xi = m_\zeta = 0$;
II) ξ and ζ are uncorrelated; i.e., $R_{\xi\zeta} = 0$;
III) $R_{\zeta\zeta}^{-1}$ exists.

The third assumption is the mathematical formulation of the fact that all the components of the data function are affected by noise. As it is shown by Franklin (see formula (3.11) of [11]), if the signal and the noise satisfy assumptions I) and II), then

$$R_{\eta\eta} = A R_{\xi\xi} A^\star + R_{\zeta\zeta} \tag{24}$$

and the cross-covariance operator is given by

$$R_{\xi\eta} = R_{\xi\xi} A^\star. \tag{25}$$

We also assume that $R_{\zeta\zeta}$ will depend on a parameter ϵ that tends to zero when the noise vanishes; i.e.,

$$R_{\zeta\zeta} = \epsilon^2 N, \tag{26}$$

where N is a given operator (e.g., $N = I$ for the white noise).

Now we are faced with the following problem.

Problem. Given a value $\overline{g}$ of the w.r.v. η find an estimate of the w.r.v. ξ.

A linear estimate of ξ will be any w.r.v. $\xi_L = L\eta$, where $L : Y \to X$ is an arbitrary linear continuous operator. Then from a value $\overline{g}$ of η one obtains the linear estimate $L\overline{g}$ of the w.r.v. ξ. Now a measure of the reliability of the estimator L is given by

$$\delta^2(\epsilon, v; L) = \mathrm{E}\left\{|(\xi - L\eta, v)|^2\right\}, \quad (v \in X = L^2(a, b)), \tag{27}$$

where $\mathrm{E}\{\cdot\}$ denotes the expectation value. Then we have the following proposition.

PROPOSITION 2.6. *If the covariance operator $R_{\zeta\zeta}$ has a bounded inverse, then there exists a unique operator L_0 that minimizes $\delta^2(\epsilon, v; L)$ for any $v \in X$, and it is given by*

$$L_0 = R_{\xi\eta} R_{\eta\eta}^{-1} = R_{\xi\xi} A^\star \left[A R_{\xi\xi} A^\star + R_{\zeta\zeta}\right]^{-1}. \tag{28}$$

Proof. See [4, 5]. □

The w.r.v. $L_0\eta$ is called the best linear estimate of ξ, and, given a value $\overline{g}$ of η, the best linear estimate $f_\star^{(4)}$ for the value of ξ is

$$f_\star^{(4)} = \frac{R_{\xi\xi} A^\star}{A R_{\xi\xi} A^\star + R_{\zeta\zeta}} \overline{g}, \qquad (A^\star = A). \tag{29}$$

If ξ and $L\eta$ have finite variance, then the global mean-square error may be defined as follows:

$$\delta^2(\epsilon, L) = \mathrm{E}\left\{\|\xi - L\eta\|^2\right\}. \tag{30}$$

When the operator L_0 which minimizes (27) does exist, it also minimizes the global error (30) if $L_0\eta$ has finite variance; i.e., if $\mathrm{Tr}\,(L_0 R_{\eta\eta} L_0^\star) < \infty$, then the following proposition can be proved.

PROPOSITION 2.7. *If the assumptions*

i) *$R_{\xi\xi}$ is an operator of trace class*;

ii) *$R_{\zeta\zeta} = \epsilon^2 N$ has bounded inverse*;

iii) *the equation $Af = 0$, where $f \in$ Range $\left(R_{\xi\xi}^{1/2}\right)$, has only the trivial solution $f = 0$*

are satisfied, then the following limit holds true:

$$\lim_{\epsilon \to 0} \delta^2(\epsilon) = 0, \tag{31}$$

where $\delta^2(\epsilon) = \inf_L \delta^2(\epsilon; L)$.

Proof. See [4, 5]. □

Let us note that $\delta^2(\epsilon) = \delta^2(\epsilon; L_0)$ when L_0 does exist and is unique.

If we want to compare the probabilistic results obtained above with the variational ones, which have been obtained by the use of eigenfunction expansions, we must expand ξ and ζ in terms of the eigenfunctions of the operator A (i.e., $\{\psi_k\}_1^\infty$). Their Fourier components are the random variables $\xi_k = (\xi, \psi_k)$ and $\zeta_k = (\zeta, \psi_k)$, whose variances are given respectively by ρ_k^2 and $\epsilon^2 \nu_k^2$. Next, in addition to the assumptions I)–III) made before, we make the following hypothesis in spite of the fact that it turns out to be completely unrealistic (see section 4):

IV) the Fourier components of ξ are mutually uncorrelated as well as the Fourier components of ζ.

Therefore, if $R_{\zeta\zeta}^{-1}$ is bounded (i.e. $\sup_k(1/\epsilon^2\nu_k^2) < \infty$), then the operator L_0 exists and the best linear estimate (29) can be written as

$$f_\star^{(4)} = \sum_{k=1}^{\infty} \frac{\lambda_k \rho_k^2}{\lambda_k^2\rho_k^2 + \epsilon^2\nu_k^2} \overline{g}_k \psi_k. \tag{32}$$

Finally, the quantities $\delta^2(\epsilon, v; L_0)$ and $\delta^2(\epsilon)$ become

$$\begin{aligned} \delta^2(\epsilon, v; L_0) &= \mathrm{E}\left\{|(\xi - L_0\eta, v)|^2\right\} = \\ &= ([R_{\xi\xi} - L_0 R_{\eta\eta} L_0^\star]v, v) = \epsilon^2 \sum_{k=1}^{\infty} \frac{\rho_k^2\nu_k^2}{\lambda_k^2\rho_k^2 + \epsilon^2\nu_k^2} |v_k|^2 \end{aligned} \tag{33}$$

and

$$\delta^2(\epsilon) = \delta^2(\epsilon; L_0) = \mathrm{Tr}\,[R_{\xi\xi} - L_0 R_{\eta\eta} L_0^\star] = \epsilon^2 \sum_{k=1}^{\infty} \frac{\rho_k^2\nu_k^2}{\lambda_k^2\rho_k^2 + \epsilon^2\nu_k^2}, \tag{34}$$

and we have the following proposition.

PROPOSITION 2.8. *The following statements hold true:*

i) *for any* $v \in X$ $(X = L^2(a, b))$

$$\lim_{\epsilon \to 0} \delta^2(\epsilon, v; L_0) = 0, \tag{35}$$

ii) *if* $Tr\, R_{\xi\xi} < \infty$, *then*

$$\lim_{\epsilon \to 0} \delta^2(\epsilon) = 0. \tag{36}$$

3. Information theory and regularization.

3.1. Asymptotic convergence, in the L^2-norm, of the eigenfunction expansion. In the variational regularization, use is made of global a priori bounds (e.g., formulae (8) or (17)), which are the natural constraints in the case of synthesis problems where the variational approach is certainly appropriate. But these global bounds are not necessarily given in the case of inverse problems where the prior knowledge on the solution can be, in several cases, rather poor. Moreover, in the truncated solutions derived by the methods of variational regularization, the point at which to stop the expansion is obtained by comparing the eigenvalues λ_k with the ratio (ϵ/E) (i.e., formula (20)) or with $(\epsilon/E)|c_k|$ (see formula (15)). In both cases this approach appears quite unnatural from the viewpoint of the experimental or physical sciences, whose methodology would rather suggest to stop the expansions at the value k_0 of k such that for $k > k_0$ the Fourier coefficients g_k of the noiseless data are smaller or at most of the same order of magnitude of ϵ, and, consequently, it is impossible to extract information from the corresponding coefficients $\overline{g}_k$. With this in mind, and assuming that the noise is represented by a bounded and integrable function $n(x)$ which satisfies the following condition:

$$\sup |n(x)| \leq \epsilon, \qquad x \in [a, b], \tag{37}$$

the following results have been proved by two of us.

LEMMA 3.1. *The following statements hold true:*

$$\sum_{k=1}^{\infty}\left(\frac{g_k}{\lambda_k}\right)^2 = \|f\|^2 = C_1 \qquad (C_1 = \textit{constant}), \tag{38}$$

$$\sum_{k=1}^{\infty}\left(\frac{\overline{g}_k}{\lambda_k}\right)^2 = +\infty \qquad \textit{if } \overline{g} \notin \textit{Range}\,(A), \tag{39}$$

$$\lim_{\epsilon\to 0}\overline{g}_k = g_k \quad \forall k. \tag{40}$$

If $k_0(\epsilon)$ is defined by

$$k_0(\epsilon) = \max\left\{m \in \mathbb{N} : \sum_{k=1}^{m}\left(\frac{\overline{g}_k}{\lambda_k}\right)^2 \le C_1\right\}, \tag{41}$$

then

$$\lim_{\epsilon\to 0} k_0(\epsilon) = +\infty. \tag{42}$$

Proof. See [17]. □

Now we can introduce the following approximation:

$$f_0^{(\epsilon)} = \sum_{k=1}^{k_0(\epsilon)}\frac{\overline{g}_k}{\lambda_k}\psi_k \tag{43}$$

and prove the following theorem.

THEOREM 3.2. *The following equality holds true:*

$$\lim_{\epsilon\to 0}\left\|f - f_0^{(\epsilon)}\right\| = 0. \tag{44}$$

Proof. See [17]. □

If we consider a sequence of noisy data $\overline{g}$ which tends to g for $\epsilon \to 0$ in the sense of the L^2-norm (i.e., $\lim_{\epsilon\to 0}\|\overline{g}-g\| = 0$), then $f_0^{(\epsilon)}$ will tend to f as $\epsilon \to 0$ in the sense of the L^2-norm (i.e., $\lim_{\epsilon\to 0}\|f_0^{(\epsilon)} - f\| = 0$). In fact, since $\|\overline{g}-g\|^2 = \sum_{k=1}^{\infty}|\overline{g}_k - g_k|^2$, the $\lim_{\epsilon\to 0}\|\overline{g}-g\| = 0$ implies that for any k, $\lim_{\epsilon\to 0}\overline{g}_k = g_k$, and in view of Lemma 3.1 and Theorem 3.2 it can be concluded that $\lim_{\epsilon\to 0}\|f_0^{(\epsilon)} - f\| = 0$. Therefore, from approximation (43) we can derive an operator $\overline{B}$ defined by

$$\overline{B}\overline{g} = \sum_{k=1}^{k_0(\epsilon)}\frac{\overline{g}_k}{\lambda_k}\psi_k, \tag{45}$$

which continuously maps, (i.e., preserving the convergence) the data $\overline{g}$ into the solution space X. Thus, continuity has been restored without requiring compactness.

Two types of difficulties still remain:

a) how to determine numerically the truncation point $k_0(\epsilon)$ if the norm of the function f (i.e., the constant $C_1 = \|f\|^2$) is unknown;
b) in any case the convergence of approximation (43) is not sufficient to guarantee that the bulk of the unknown function f has been really recovered.

We can give a satisfactory answer to these questions only in very specific and peculiar cases, as we will explain below. Suppose that the moduli of the Fourier coefficients $|g_k|$ are monotonically decreasing for increasing values of k. Since $\overline{g}_k = g_k + n_k$, it turns out that at a certain value k_0 of k we have $|g_k| \simeq |n_k| \leq \epsilon$. The Fourier coefficients of the noiseless data are of the same order of magnitude as the Fourier components of the noise, and at this point we cannot extract any information from the noisy Fourier coefficients $\overline{g}_k$. Let us now introduce the function $M(m) = \sum_{k=1}^{m} (\overline{g}_k/\lambda_k)^2$, whose relevant properties are:

1) it is an increasing function of m;
2) if ϵ is sufficiently small and the values of $|g_k|$ are monotonically decreasing for increasing k, $M(m)$ presents a "plateau" when it reaches the value C_1. Indeed, from formula (42) in Lemma 3.1 it follows that $M(m)$ remains nearly constant when it attains the value C_1. An explicit numerical example of this "plateau" is given in Figure 1D in section 4.

This "plateau" corresponds to the order–disorder transition in the coefficients $\overline{g}_k$: for $k < k_0(\epsilon)$ the data g_k prevail on n_k whereas for $k > k_0(\epsilon)$ the noise components n_k are larger or, at least, of the same order of magnitude of the noiseless data. However, it must be remarked that in practical cases to single out the plateau which does really correspond to the order–disorder transition in the coefficients $\overline{g}_k$ can be made difficult by the presence of other spurious plateaux due to the erratic behavior of the noise. Furthermore, if the coefficients g_k are negligible for low values of k, and the actual bulk of information is located only at intermediate values of k, there could be no numerical evidence of such a plateau in spite of the fact that the convergence guaranteed by Theorem 3.2 remains true. Then we are forced to look for other methods that overcome these difficulties. This issue will be investigated by means of probabilistic methods, as will be illustrated in the next subsection.

3.2. Bayes formula, information theory, and regularization. Here our goal is to find a probabilistic extension of the result of Theorem 3.2 in which the assumption requiring the Fourier coefficients $|g_k|$ to be monotonically decreasing will be removed. In fact, we will show how to construct a regularizing solution from the noisy data, disregarding the order of the coefficients $|g_k|$. For this purpose, we turn (23) into an infinite sequence of one-dimensional equations by means of orthogonal projections:

$$\lambda_k \xi_k + \zeta_k = \eta_k, \quad (k = 1, 2, ...), \tag{46}$$

where $\xi_k = (\xi, \psi_k)$, $\zeta_k = (\zeta, \psi_k)$, $\eta_k = (\eta, \psi_k)$ are Gaussian random variables. Here we retain assumptions I)–III) made in section 2.2, but we remove assumption IV). In fact, there is no reason to assume that the basis $\{\psi_k\}_1^\infty$ which diagonalizes the operator A also diagonalizes the covariance operators $R_{\xi\xi}$, $R_{\zeta\zeta}$, $R_{\eta\eta}$ [19]. Therefore, we can introduce the variances $\rho_k^2 = (R_{\xi\xi}\psi_k, \psi_k)$, $\epsilon^2\nu_k^2 = (R_{\zeta\zeta}\psi_k, \psi_k)$, $\lambda_k^2\rho_k^2 + \epsilon^2\nu_k^2 = (R_{\eta\eta}\psi_k, \psi_k)$ without assuming that the Fourier components ξ_k of ξ (and analogously also for ζ_k and η_k) are mutually uncorrelated. In view of assumptions I) and III) the following probability densities for ξ_k and ζ_k can be assumed:

$$p_{\xi_k}(x) = \frac{1}{\sqrt{2\pi}\,\rho_k} \exp\left\{-\left(\frac{x^2}{2\rho_k^2}\right)\right\}, \quad (k = 1, 2, ...) \tag{47}$$

and

$$p_{\zeta_k}(x) = \frac{1}{\sqrt{2\pi}\,\epsilon\nu_k} \exp\left\{-\left(\frac{x^2}{2\epsilon^2\nu_k^2}\right)\right\}, \quad (k = 1, 2, ...). \tag{48}$$

By the use of the (46) we can also introduce the conditional probability density $p_{\eta_k}(y|x)$ of the random variable η_k for fixed $\xi_k = x$, which reads

$$\begin{aligned} p_{\eta_k}(y|x) &= \frac{1}{\sqrt{2\pi}\,\epsilon\nu_k} \exp\left\{-\frac{(y-\lambda_k x)^2}{2\epsilon^2\nu_k^2}\right\} \\ &= \frac{1}{\sqrt{2\pi}\,\epsilon\nu_k} \exp\left\{-\frac{\lambda_k^2}{2\epsilon^2\nu_k^2}\left(x - \frac{y}{\lambda_k}\right)^2\right\}. \end{aligned} \tag{49}$$

Now let us apply the Bayes formula that provides the conditional probability density of ξ_k given η_k through the following expression:

$$p_{\xi_k}(x|y) = \frac{p_{\xi_k}(x)p_{\eta_k}(y|x)}{p_{\eta_k}(y)}. \tag{50}$$

Thus, if a realization of the random variable η_k is given by $\overline{g}_k$ (see the formulation of the problem in section 2.2), formula (50) becomes

$$p_{\xi_k}(x|\overline{g}_k) = A_k \exp\left\{-\frac{x^2}{2\rho_k^2}\right\} \exp\left\{-\frac{\lambda_k^2}{2\epsilon^2\nu_k^2}\left(x - \frac{\overline{g}_k}{\lambda_k}\right)^2\right\} \quad (A_k = \text{const.}). \tag{51}$$

Now the amount of information on the variable ξ_k which is contained in the variable η_k can be evaluated. We have [13]

$$J(\xi_k, \eta_k) = -\frac{1}{2}\log(1 - r_k^2), \tag{52}$$

where

$$r_k^2 = \frac{|\mathrm{E}\{\xi_k\eta_k\}|^2}{\mathrm{E}\{|\xi_k|^2\}\,\mathrm{E}\{|\eta_k|^2\}} = \frac{(\lambda_k\rho_k)^2}{(\lambda_k\rho_k)^2 + (\epsilon\nu_k)^2}. \tag{53}$$

Thus,

$$J(\xi_k, \eta_k) = \frac{1}{2}\log\left(1 + \frac{\lambda_k^2\rho_k^2}{\epsilon^2\nu_k^2}\right). \tag{54}$$

From equality (54) it follows that $J(\xi_k, \eta_k) < \frac{1}{2}\log 2$ if $\lambda_k\rho_k < \epsilon\nu_k$. Thus, we are naturally led to introduce the following sets:

$$\mathcal{I}_k = \{k : \lambda_k\rho_k \geq \epsilon\nu_k\}, \tag{55}$$

$$\mathcal{N}_k = \{k : \lambda_k\rho_k < \epsilon\nu_k\}. \tag{56}$$

Reverting to the conditional probability density (51), it can be regarded as the product of two Gaussian probability densities: $p_1(x) = A_k^{(1)} \exp\{-x^2/2\rho_k^2\}$ and $p_2(x) = A_k^{(2)} \exp\{-(\lambda_k^2/2\epsilon^2\nu_k^2)(x - (\overline{g}_k/\lambda_k))^2\}$, $(A_k = A_k^{(1)} \cdot A_k^{(2)})$, whose variances are respectively given by ρ_k and $(\epsilon\nu_k/\lambda_k)$. Let us note that if $k \in \mathcal{I}_k$, the variance

associated with the density $p_2(x)$ is smaller than the corresponding variance of $p_1(x)$, and vice versa if $k \in \mathcal{N}_k$. Therefore, it is reasonable to consider as an acceptable approximation of $\langle \xi_k \rangle$ the mean value given by the density $p_2(x)$ if $k \in \mathcal{I}_k$, or the mean value given by the density $p_1(x)$ if $k \in \mathcal{N}_k$. We can write the following approximation:

$$\langle \xi_k \rangle = \begin{cases} \dfrac{\overline{g}_k}{\lambda_k} & (k \in \mathcal{I}_k), \\ 0 & (k \in \mathcal{N}_k). \end{cases} \tag{57}$$

Consequently, given the value $\overline{g}$ of the w.r.v. η, we are led to consider the following estimate of ξ:

$$\widehat{B}\overline{g} = \sum_{k \in \mathcal{I}_k} \frac{\overline{g}_k}{\lambda_k} \psi_k. \tag{58}$$

However, these are only heuristic considerations based on plausible arguments. They will become rigorous statements only if it will proved that they lead to a solution $\widehat{B}\overline{g}$ which is probabilistically regularized. For this purpose, the global mean-square error associated with the operator $\widehat{B}$, i.e., $\mathrm{E}\{\|\xi - \widehat{B}\eta\|^2\}$, must be evaluated, and we have the following proposition.

PROPOSITION 3.3.

i) *If* $\lim_{k\to\infty}(\lambda_k \rho_k/\nu_k) = 0$, *then the set* $\mathcal{I}_k$ *is finite for any fixed positive value of* ϵ;

ii) *assuming that the limit stated in* i) *holds true, and, in addition, that* $R_{\xi\xi}$ *is an operator of trace class, then the following relationship holds:*

$$E\left\{\|\xi - \widehat{B}\eta\|^2\right\} = \sum_{k \in \mathcal{N}_k} \rho_k^2 + \sum_{k \in \mathcal{I}_k} \frac{\epsilon^2 \nu_k^2}{\lambda_k^2} < \infty. \tag{59}$$

Proof. The proof of statement i) is obvious if we recall the definition of the set $\mathcal{I}_k$ (formula (55)). Statement ii) follows easily from the equality

$$\mathrm{E}\left\{\|\xi - \widehat{B}\eta\|^2\right\} = \mathrm{Tr}\,(R_{\xi\xi} - R_{\xi\xi}A^\star \widehat{B}^\star - \widehat{B}AR_{\xi\xi} + \widehat{B}R_{\eta\eta}\widehat{B}^\star) \tag{60}$$

and by the use of formulae (24), (26), and (58). □

In order to prove that approximation (58) is regularized, we need the following auxiliary lemma.

LEMMA 3.4. *Let* $k_\gamma(\epsilon)$ *be defined as follows:*

$$k_\gamma(\epsilon) = \max\left\{ m \in \mathbb{N} : \sum_{k=1}^{m} \left(\rho_k^2 + \frac{\epsilon^2 \nu_k^2}{\lambda_k^2} \right) \le \Gamma \right\}, \tag{61}$$

where $\Gamma = Tr\, R_{\xi\xi}$ *is finite. Then the following statements hold true:*

$$\text{i)} \quad \lim_{\epsilon \to 0} k_\gamma(\epsilon) = +\infty, \tag{62}$$

$$\text{ii)} \quad \lim_{\epsilon \to 0} \left\{ \sum_{k=1}^{k_\gamma} \frac{\epsilon^2 \nu_k^2}{\lambda_k^2} + \sum_{k=k_\gamma+1}^{\infty} \rho_k^2 \right\} = 0. \tag{63}$$

Proof. i) Let k_{γ_1} denote the sum $(k_\gamma + 1)$. Then suppose that the limit (62) does not hold. This latter assumption would imply that there exists a finite number M, which does not depend on ϵ, such that $k_{\gamma_1} < M$. Furthermore, this bound should remain true for any sequence ϵ_i tending to zero. Then we have the following inequalities:

$$\Gamma < \sum_{k=1}^{k_{\gamma_1}} \left(\rho_k^2 + \frac{\epsilon^2 \nu_k^2}{\lambda_k^2} \right) \leq \sum_{k=1}^{M} \left(\rho_k^2 + \frac{\epsilon^2 \nu_k^2}{\lambda_k^2} \right). \tag{64}$$

Now for any sequence ϵ_i tending to zero, we have

$$\Gamma < \sum_{k=1}^{M} \rho_k^2 \leq \sum_{k=1}^{\infty} \rho_k^2 = \Gamma, \tag{65}$$

which is contradictory. Then limit (62) holds.

ii) From $\sum_{k=1}^{\infty} \rho_k^2 = \operatorname{Tr} R_{\xi\xi} = \Gamma < \infty$, and in view of statement i), it follows that $\lim_{\epsilon \to 0} \sum_{k=k_{\gamma_1}}^{\infty} \rho_k^2 = 0$. Regarding the sum $\sum_{k=1}^{k_\gamma} (\epsilon^2 \nu_k^2 / \lambda_k^2)$, we can proceed as follows. From formula (61) we have

$$\sum_{k=1}^{k_\gamma} \frac{\epsilon^2 \nu_k^2}{\lambda_k^2} + \sum_{k=1}^{k_\gamma} \rho_k^2 \leq \Gamma. \tag{66}$$

Then

$$\sum_{k=1}^{k_\gamma} \frac{\epsilon^2 \nu_k^2}{\lambda_k^2} \leq \Gamma - \sum_{k=1}^{k_\gamma} \rho_k^2 = \sum_{k=k_{\gamma_1}}^{\infty} \rho_k^2, \tag{67}$$

but in view of the fact that $\lim_{\epsilon \to 0} \sum_{k=k_{\gamma_1}}^{\infty} \rho_k^2 = 0$, we have $\lim_{\epsilon \to 0} \sum_{k=1}^{k_\gamma} (\epsilon^2 \nu_k^2 / \lambda_k^2) = 0$, and statement ii) is proved. □

We can now prove the following theorem.

THEOREM 3.5. *If the covariance operator $R_{\xi\xi}$ is of trace class, and if the set $\mathcal{I}_k$ is finite (see Proposition* 3.3*), then the following limit holds true:*

$$\lim_{\epsilon \to 0} \delta^2(\epsilon, \widehat{B}) = \lim_{\epsilon \to 0} E\left\{ \|\xi - \widehat{B}\eta\|^2 \right\} = 0; \tag{68}$$

i.e., approximation (58) *is probabilistically regularized.*

Proof. In view of formula (59) in Proposition 3.3, the proof of equality (68) reduces to the proof of the following limit:

$$\lim_{\epsilon \to 0} \left\{ \sum_{k \in \mathcal{I}_k} \frac{\epsilon^2 \nu_k^2}{\lambda_k^2} + \sum_{k \in \mathcal{N}_k} \rho_k^2 \right\} = 0. \tag{69}$$

Regarding the first sum of (69), we divide the set $\mathcal{I}_k$ into two subsets defined by

$$\mathcal{I}_k^{(1)} = \{k \in \mathcal{I}_k \,:\, k \leq k_\gamma\}, \tag{70}$$

$$\mathcal{I}_k^{(2)} = \{k \in \mathcal{I}_k \,:\, k > k_\gamma\}; \qquad (\mathcal{I}_k = \mathcal{I}_k^{(1)} \cup \mathcal{I}_k^{(2)}). \tag{71}$$

Accordingly, we can write

$$\sum_{k\in\mathcal{I}_k}\frac{\epsilon^2\nu_k^2}{\lambda_k^2}=\sum_{k\in\mathcal{I}_k^{(1)}}\frac{\epsilon^2\nu_k^2}{\lambda_k^2}+\sum_{k\in\mathcal{I}_k^{(2)}}\frac{\epsilon^2\nu_k^2}{\lambda_k^2}. \tag{72}$$

Then $\sum_{k\in\mathcal{I}_k^{(1)}}(\epsilon^2\nu_k^2/\lambda_k^2)\le\sum_{k=1}^{k_\gamma}(\epsilon^2\nu_k^2/\lambda_k^2)$, and in view of Lemma 3.4 (where we proved that $\lim_{\epsilon\to0}\sum_{k=1}^{k_\gamma}(\epsilon^2\nu_k^2/\lambda_k^2)=0$) it follows that

$$\lim_{\epsilon\to0}\sum_{k\in\mathcal{I}_k^{(1)}}\frac{\epsilon^2\nu_k^2}{\lambda_k^2}=0. \tag{73}$$

Regarding the term $\sum_{k\in\mathcal{I}_k^{(2)}}(\epsilon^2\nu_k^2/\lambda_k^2)$, since $k\in\mathcal{I}_k$ then $\rho_k^2\ge(\epsilon^2\nu_k^2/\lambda_k^2)$ and therefore

$$\sum_{k\in\mathcal{I}_k^{(2)}}\frac{\epsilon^2\nu_k^2}{\lambda_k^2}\le\sum_{k=k_{\gamma_1}}^{\infty}\rho_k^2. \tag{74}$$

But, as we have seen in Lemma 3.4, $\lim_{\epsilon\to0}\sum_{k=k_{\gamma_1}}^{\infty}\rho_k^2=0$, and consequently

$$\lim_{\epsilon\to0}\sum_{k\in\mathcal{I}_k^{(2)}}\frac{\epsilon^2\nu_k^2}{\lambda_k^2}=0. \tag{75}$$

We can conclude that $\lim_{\epsilon\to0}\sum_{k\in\mathcal{I}_k}(\epsilon^2\nu_k^2/\lambda_k^2)=0$. Regarding the sum $\sum_{k\in\mathcal{N}_k}\rho_k^2$, we proceed in an analogous way by splitting the set $\mathcal{N}_k$ into two subsets defined by

$$\mathcal{N}_k^{(1)}=\{k\in\mathcal{N}_k\,:\,k\le k_\gamma\}, \tag{76}$$

$$\mathcal{N}_k^{(2)}=\{k\in\mathcal{N}_k\,:\,k>k_\gamma\};\qquad(\mathcal{N}_k=\mathcal{N}_k^{(1)}\cup\mathcal{N}_k^{(2)}). \tag{77}$$

Accordingly, we write

$$\sum_{k\in\mathcal{N}_k}\rho_k^2=\sum_{k\in\mathcal{N}_k^{(1)}}\rho_k^2+\sum_{k\in\mathcal{N}_k^{(2)}}\rho_k^2. \tag{78}$$

If $k\in\mathcal{N}_k^{(1)}$ and by the use of inequality $\rho_k^2<(\epsilon^2\nu_k^2/\lambda_k^2)$ (because $k\in\mathcal{N}_k$) we can write

$$\sum_{k\in\mathcal{N}_k^{(1)}}\rho_k^2\le\sum_{k=1}^{k_\gamma}\frac{\epsilon^2\nu_k^2}{\lambda_k^2}. \tag{79}$$

But in Lemma 3.4 we proved that $\lim_{\epsilon\to0}\sum_{k=1}^{k_\gamma}(\epsilon^2\nu_k^2/\lambda_k^2)=0$, and therefore we have $\lim_{\epsilon\to0}\sum_{k\in\mathcal{N}_k^{(1)}}\rho_k^2=0$. Regarding the second term on the right-hand side of formula (78), we have

$$\sum_{k\in\mathcal{N}_k^{(2)}}\rho_k^2\le\sum_{k=k_{\gamma_1}}^{\infty}\rho_k^2. \tag{80}$$

But, again, $\lim_{\epsilon\to 0}\sum_{k=k_{\gamma_1}}^{\infty}\rho_k^2 = 0$, and then $\lim_{\epsilon\to 0}\sum_{k\in\mathcal{N}_k^{(2)}}\rho_k^2 = 0$. □

Remarks. i) It is worth it to notice that the proof of Theorem 3.5 does not require any type of order in the sum (58). In fact, the only assumption that $\{\lambda_k\}$ is a strictly decreasing sequence does not evidently imply that the terms $(\lambda_k\rho_k/\epsilon\nu_k)$ have any type of monotonicity in k, and, consequently, the sum (58) cannot, in general, be regarded as an ordered sum of terms up to a certain maximum value of k. Thus, unlike the regularized solutions (12), (14), (18), (19), and also (45), $\widehat{B}\overline{g}$ features frequency selectivity, which is obtained by evaluating the information content of the noisy Fourier coefficients.

ii) Notice that the estimate (58) associated with the operator $\widehat{B}$ represents a probabilistically regularized solution, in the sense of the formula (68), even if, in general, it does not minimize the global mean-square error (30).

At this point in order to apply the results of this section, statistical methods that allow for splitting the coefficients $\overline{g}_k$ into the sets $\mathcal{I}_k$ and $\mathcal{N}_k$ must be investigated. These methods will be illustrated in the next section.

4. Numerical analysis: The regularizing algorithm.

4.1. The correlation function of the noisy data. The application of the results of the previous section to a Fredholm equation of the first kind would involve using statistical tools for the determination of the two sets $\mathcal{I}_k$ and $\mathcal{N}_k$. In this section this issue is discussed and the basic steps of a numerical algorithm for constructing the regularized solution $\widehat{B}\overline{g}$ from the noisy data $\overline{g}$ are outlined. For simplicity we shall work throughout only with data corrupted by white noise. However, provided the independence assumption between ξ and ζ, more general cases involving "colored" noise could be treated by using suitable methods, for instance, "prewhitening" transformations [7], whose discussion is beyond the scope of this section. Here our goal is to show that statistical estimates of the amount of information carried by the Fourier coefficients $\overline{g}_k$ can be sufficient to construct a satisfactory regularized solution. Furthermore, the direct comparison of the numerical results clearly evidentiates how some inherent limitations of the variational regularization scheme are overcome.

Following the analysis of the previous section, we are now faced with the problem of separating the Fourier coefficients $\overline{g}_k$ into two classes; one containing all the Fourier coefficients of the noisy data which are correlated, the other containing the $\overline{g}_k$ that can be regarded as random numbers. This task can be achieved by computing the correlation function of the random variables η_k; i.e., the probabilistic counterpart of the coefficients $\overline{g}_k$:

$$\Delta_\eta(k_1,k_2) = \frac{E\{[\eta_{k_1} - E\{\eta_{k_1}\}][\eta_{k_2} - E\{\eta_{k_2}\}]\}}{E\{[\eta_{k_1} - E\{\eta_{k_1}\}]^2\}^{1/2}E\{[\eta_{k_2} - E\{\eta_{k_2}\}]^2\}^{1/2}}. \tag{81}$$

In practice, just a finite realization $\{\overline{g}_k\}_1^N$ of the random variables η_k is available, from which estimates $\delta_{\overline{g}}$ of the autocorrelations can be obtained by regarding the data $\{\overline{g}_k\}_1^N$ as a finite length record of a stationary random normal series. In principle, the assumption of stationarity of the series $\{\eta_k\}$ is not correct because in general the moments of the random variables η_k will depend on k, but from the practical point of view this is usually the only possible chance. In fact, in many areas of application, it is difficult or even impossible to have multiple independent realizations $\{\overline{g}_k\}_1^N$ of the process $\{\eta_k\}$, so estimates of ensemble averages cannot be computed. Thus, we are forced to introduce the working hypothesis that the process $\{\eta_k\}$ is stationary in wide sense [9], that is, $\Delta_\eta(k_1,k_2) = \Delta_\eta(k_1 - k_2)$, and to compute the estimates

of the autocorrelation coefficients by means of the ergodic relation between ensemble and *time* (i.e., the index k in our case) averages. Of course, such a restriction can be removed whenever many independent sets of data $\{\overline{g}_k\}_1^N$ would be available for evaluating ensemble averages. Anyway, we will see later in the discussion of the algorithm how an ambiguity in the reconstruction of the regularized solution $\widehat{B}\overline{g}$ due to the assumed invariance for k-translation of $\{\eta_k\}$ will be removed.

A number of estimators of the autocorrelation function have been suggested by statisticians, and their properties are discussed in detail in [15]. An estimate which is widely used by statisticians, and in the following examples as well, is given by

$$\delta_{\overline{g}}(n) = \frac{\displaystyle\sum_{k=1}^{N-n} (\overline{g}_k - \langle \overline{g}_k \rangle)(\overline{g}_{k+n} - \langle \overline{g}_{k+n} \rangle)}{\left\{ \displaystyle\sum_{k=1}^{N-n} (\overline{g}_k - \langle \overline{g}_k \rangle)^2 \sum_{k=1}^{N-n} (\overline{g}_{k+n} - \langle \overline{g}_{k+n} \rangle)^2 \right\}^{1/2}}, \quad n = 0, ..., N-1, \tag{82}$$

where

$$\langle \overline{g}_k \rangle = \frac{1}{N-n} \sum_{k=1}^{N-n} \overline{g}_k \; ; \qquad \langle \overline{g}_{k+n} \rangle = \frac{1}{N-n} \sum_{k=1}^{N-n} \overline{g}_{k+n}. \tag{83}$$

Equation (82), which is based on the scatter diagram of $\overline{g}_{k+n}$ against $\overline{g}_k$ for $k = 1, \ldots, N-n$, represents the maximum likelihood estimate of the autocorrelation coefficients of two random variables η_k and η_{k+n} whose joint probability distribution function is bivariate normal.

In order to identify the structure of the series $\{\bar{g}_k\}_1^N$ so that we can separate correlated components from the random ones, it is necessary to have a crude test on whether $\delta_{\overline{g}}(n)$ is effectively zero. It has been shown by Anderson [1] that the distribution of an estimated autocorrelation coefficient, whose theoretical value is zero, is approximately normal. Thus, on the hypothesis that the theoretical autocorrelation $\Delta_\eta(n) = 0$, the estimate $\delta_{\overline{g}}(n)$ divided by its standard error $\sigma_\delta(n)$ will be approximately distributed as a unit normal deviate. This fact may be used to provide a rough guide as to whether theoretical autocorrelations are essentially zero. To this purpose it is usually sufficient to remember that, for normal distribution, deviations exceeding two standard errors in either direction have a probability of about 0.05, so that the 95% confidence interval of the estimate is approximately $\delta_{\overline{g}}(n) \pm 1.96\, \sigma_\delta(n)$.

Estimated autocorrelations can have rather large variances and can be highly correlated with each other [3, 12] so that care is required in the interpretation of individual autocorrelations. In particular, moderately large estimated autocorrelations can occur after the theoretical autocorrelation function has damped out, and, in any case, it must be considered that an estimated autocorrelation function always exhibits less damping than the theoretical one, as the estimated autocorrelations are inflated by sampling fluctuations (see also the following Example 1). Thus, in order to avoid a purely empirical analysis of the autocorrelations, it is necessary to assume a rough model of the series that allows us to evaluate the order of magnitude of the sampling errors $\sigma_\delta(n)$ associated with the autocorrelation estimator.

According to the discussion in section 3.2, since we expect to find the set $\mathcal{I}_k$ to be finite, we also expect that the autocorrelation function $\Delta_\eta(n)$ will vanish beyond a certain lag n_0. Thus, in what follows, it will be assumed that there exists an index n_0 such that $\Delta_\eta(n) = 0$ for $n > n_0$. In this case, if the record length N is

large enough (i.e., such that $O(1/N^2)$ terms can be neglected), use can be made of Bartlett's approximate expression for the variance of the estimated autocorrelations of a stationary normal process [3]:

$$\text{var}\,[\delta_{\overline{g}}(n)] \sim \frac{1}{N-n}\left\{1+2\sum_{v=1}^{n_0}\Delta_\eta^2(v)\right\} \quad \text{for} \quad n > n_0. \tag{84}$$

To use (84) in practice, the estimated autocorrelations $\delta_{\overline{g}}$ are substituted for the theoretical ones Δ_η, and in this case we shall refer to the square root of (84) as the *large-lag* standard error $\sigma_\delta(n; n_0)$ [7].

The index n_0 is actually recovered in a recursive way through a hypothesis generation-verification procedure. Starting from the assumption that the series is completely random, i.e., $n_0 = 0$, the standard error $\sigma_\delta(n; 0)$ is computed and the first index $\overline{n} > 0$ such that $|\delta_{\overline{g}}(\overline{n})| > 1.96\,\sigma_\delta(n; 0)$ is searched for. If there exists such an index $\overline{n}$, it becomes the new candidate to be n_0, i.e., we set $n_0 = \overline{n}$, $\sigma_\delta(n; n_0)$ is computed, and again it is tested whether the series is compatible with the hypothesis that $\Delta_\eta(n) = 0$ for $n > n_0$. The whole procedure is repeated until no new index $\overline{n}$ is found. Formally, n_0 is then defined as

$$n_0 = \max\{\overline{n} \geq 0 : \forall n \in (\overline{n}, N-1], \mid \delta_{\overline{g}}(n) \mid < 1.96\ \sigma_\delta(n, \overline{n})\}. \tag{85}$$

The set $\mathbf{Q}$ of the lags corresponding to autocorrelation values that are effectively different from zero and, consequently, indicating lack of randomness of the coefficients $\overline{g}_k$, is defined as

$$\mathbf{Q} = \{0 < n \leq n_0 : \mid \delta_{\overline{g}}(n) \mid > 1.96\ \sigma_\delta(n, 0)\}. \tag{86}$$

Let N_c be the number of elements of $\mathbf{Q}$.

As previously discussed, as a consequence of the inevitable assumption of stationarity of the process $\{\eta_k\}$, the Fourier coefficients $\overline{g}_k$ that are correlated cannot be determined in a unique way from the set $\mathbf{Q}$. In fact, an integer $n_i \in \mathbf{Q}$ just indicates a strong correlation between at least two Fourier coefficients n_i apart. This means that, in principle, any couple $(\overline{g}_{k_i}, \overline{g}_{k_i+n_i})$ for any integer $1 \leq k_i \leq (N - n_i)$ could have generated such a strong correlation at the lag n_i. Thus, from the set $\mathbf{Q}$ we can construct N_c families F_i defined as

$$F_i = \left\{(\overline{g}_{k_i}, \overline{g}_{k_i+n_i})\right\}_{k_i=1}^{(N-n_i)}, \quad i = 1, ..., N_c \tag{87}$$

from which the couples of coefficients $\overline{g}_k$ that are likely to be correlated can be selected. In theory, that is for $N \to \infty$, the N_c indices k_i and the N_c elements $n_i \in \mathbf{Q}$ are mutually dependent. In fact, any two coefficients $\overline{g}_{k_\alpha}, \overline{g}_{k_\beta}$ which are selected from the families F_i must satisfy the pairwise compatibility conditions requiring $|k_\alpha - k_\beta| \in \mathbf{Q}$. Or, in other words, it can be seen that, given the set $\mathbf{Q}$, the number $N_\mathcal{I}$ of admissible Fourier coefficients $\overline{g}_k$ is combinatorially constrained to be

$$\frac{1}{2}\,(1 + \sqrt{1 + 8N_c}) \leq N_\mathcal{I} \leq N_c + 1. \tag{88}$$

The left inequality in (88) follows directly from the observation that the maximum number of correlations among $N_\mathcal{I}$ coefficients is $\binom{N_\mathcal{I}}{2}$, then $N_c \leq \binom{N_\mathcal{I}}{2}$, whereas the

right inequality expresses that at least $(N_{\mathcal{I}}-1)$ distinct correlations can be computed among $N_{\mathcal{I}}$ coefficients (i.e., $N_c \geq N_{\mathcal{I}}-1$). For instance, if $N_c = 2$, we have from inequalities (88) that there need to be $N_{\mathcal{I}} = 3$ coefficients $\overline{g}_k$ to construct the set $\mathbf{Q}$, or, referring to (87), that the two indices k_1 and k_2 must coincide, i.e., $k_1 \equiv k_2 \geq 1$. In any case, the compatibility conditions are not sufficient to constrain in a unique way the selection of the coefficients $\overline{g}_k$ and, consequently, the construction of the regularized solution.

In practice, that is, when the record length N is finite and particularly when the signal-to-noise ratio (SNR) of the data $\overline{g}$ is small, the compatibility constraints cannot be assumed to be satisfied. In fact, because of the sampling fluctuations in the estimates $\delta_{\overline{g}}(n)$, some correlations which are actually different from zero could be incorrectly detected by the procedure discussed above. However, we shall see later in the discussion of the numerical examples how the compatibility constraints can provide us with a confidence check on the reliability of the regularized solution $\widehat{B}\overline{g}$.

In order to recover in a unique way from the set $\mathbf{Q}$ the Fourier coefficients that are likely to be correlated, we adopt the following criterion suggested by the definition itself of the autocorrelation function: for any $n_i \in \mathbf{Q}$, $i = 1, ..., N_c$, we select the pair $(\overline{g}_{k_i^\star}, \overline{g}_{k_i^\star + n_i})$ giving the maximum contribution to the autocorrelation estimate $\delta_{\overline{g}}(n_i)$; i.e., we define $k_i^\star$ as

$$k_i^\star = \arg \max_{k \in [1, N-n_i]} \{|\overline{g}_k \, \overline{g}_{k+n_i}|\}, \quad i = 1, ..., N_c, \tag{89}$$

and, accordingly, we can define the set of frequencies $\mathcal{I}_k$ exhibiting correlated Fourier coefficients as

$$\mathcal{I}_k = \{k_i^\star\}_1^{N_c} \cup \{k_i^\star + n_i\}_1^{N_c}, \tag{90}$$

where each element of $\mathcal{I}_k$ is counted only once.

4.2. Numerical examples. Throughout this section we shall consider as a sample problem the integral equation (1) with kernel

$$K(x,y) = \begin{cases} (1-x)\,y & \text{if} \quad 0 \leq y \leq x \leq 1, \\ x\,(1-y) & \text{if} \quad 0 \leq x \leq y \leq 1 \end{cases} \tag{91}$$

whose eigenfunctions and eigenvalues are, respectively,

$$\psi_k(x) = \sqrt{2}\,\sin(k\pi x), \tag{92}$$

$$\lambda_k = \frac{1}{k^2\pi^2}. \tag{93}$$

The data $g(x)$ have been noised by adding white noise $n(x)$, simulated by computer generated random numbers uniformly distributed in the interval $[-\epsilon, \epsilon]$ (see also [22] for a very preliminary numerical analysis of this problem). The examples shown hereafter differ for the choice of the input signal $f(x)$ and for the values of the noise boundary ϵ, whereas the performances of the algorithm are evaluated by direct comparison of the reconstructed signal with the true signal $f(x)$. In every example reported here, the approximations obtained through the variational scheme (see section 2.1) are computed by setting the constraint operator C such that $c_k = k$, $(k = 1, 2, ...)$, the parameter ϵ corresponding to the boundary on the noise equal to the dispersion of the noise D_ϵ (see (7)), and the boundary E on the solution equal to the norm of the unknown function, i.e., $E = \|f(x)\|$ (see (8)).

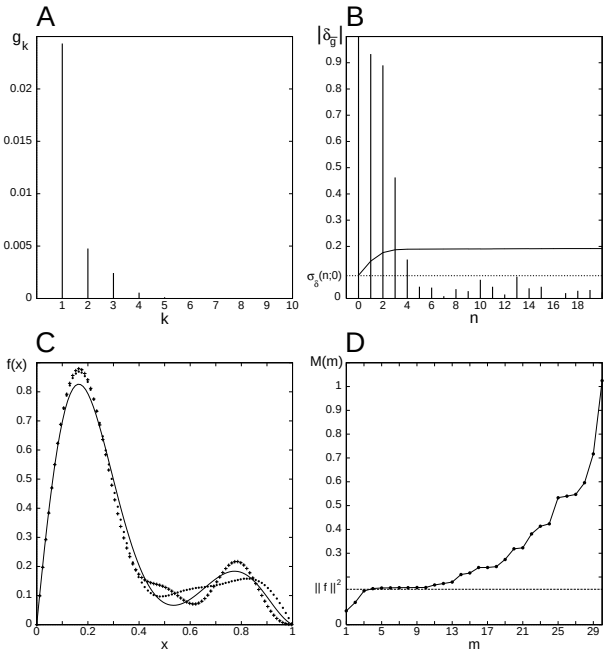

FIG. 1. *Example* 1: $f_1(x) = (1-x)\sin(3\sin(3x))$, $\epsilon = 10^{-4}$, *SNR* $\simeq 25.7dB$, $N = 512$. (A) *Noiseless Fourier coefficients* g_k. (B) *Modulus of the autocorrelation function. The horizontal dotted straight line indicates the* 95% *confidence limit* $1.96\,\sigma_\delta(n;0)$ *for a purely random sequence. The solid curved line indicates the confidence limit* $1.96\,\sigma_\delta(n;3)$, $n > 3$. *From the analysis of* $\delta_{\overline{g}}(n)$ *we have* $\mathbf{Q} = \{1,2,3\}$ *and* $\mathcal{I}_k = \{1,2,3,4\}$. (C) *Regularized solutions. The solid line represents the actual solution* $f_1(x)$. *The dots represent the reconstruction* $\widehat{B}\overline{g}$. *The crosses represent the variational solution* $f_\star^{(1)}$ *obtained by using* $c_k = k$; $k_\alpha = 8$ (*see equations* (14) *and* (15)). (D) *Plot of the function* $M(m) = \sum_{k=1}^{m} (\overline{g}_k/\lambda_k)^2$. *Notice that the value of* $M(m)$ *corresponding to its first plateau, i.e., approximately for* $4 \le m \le 10$, *is about the squared norm of the true solution.*

In Figure 1, the analysis of the sample function $f_1(x) = (1-x)\sin(3\sin(3x))$ with noise boundary $\epsilon = 10^{-4}$ is summarized. The global SNR, defined as the ratio of the mean power of the noiseless data to the noise variance, was SNR $\simeq 25.7$dB. The function $f_1(x)$ is characterized by having the bulk of information localized in the first few values of k (see the related noiseless coefficients g_k in Figure 1A) so that we expect that also a variational solution could provide a satisfactory reconstruction of the input signal. Figure 1B shows the behavior of the autocorrelation function $\delta_{\overline{g}}(n)$ along with the two lines indicating the statistical confidence limits we used to discriminate whether the autocorrelations are essentially null. The dashed horizontal straight line represents the threshold that we would have under the hypothesis of purely random sequence $\{\overline{g}_k\}$, whereas the solid line represents the threshold corresponding to the model of autocorrelation function of ideal damped type. In this example we found $n_0 = 3$, $\mathbf{Q} = \{1,2,3\}$, and the autocorrelation at $n = 4$ was rejected in spite of its quite large value (see formula (86)). The direct inspection of the values of $\epsilon\nu_k$ and g_k in repeated realizations showed that for $k = 5$ the noise was usually larger than the Fourier coefficient, confirming hence the result that the autocorrelation $\delta_{\overline{g}}(4)$ was abnormally inflated by the large autocorrelations at $n = 1,2,3$. According to the criteria (89) and (90), the set of frequencies whose corresponding Fourier coefficients

exhibit strong correlations is $\mathcal{I}_k = \{1, 2, 3, 4\}$. It is worth noticing that in this case the elements of $\mathcal{I}_k$ satisfy all the compatibility constraints; i.e., any difference between elements of $\mathcal{I}_k$ belongs to $\mathbf{Q}$, and $N_{\mathcal{I}}$ satisfies constraints (88). This complete cross consistency between $\mathbf{Q}$ and $\mathcal{I}_k$ gives a high level of confidence in the result of the whole analysis. In Figure 1C the true function f_1 (solid line), the regularized solution $\widehat{B}\overline{g}$ (crosses), and the regularized function $f_\star^{(1)}$ (dots) are compared. The truncation point of $f_\star^{(1)}$, obtained through the criterion (15), was $\alpha = 8$. Figure 1C shows how in this case both regularization methods lead to comparable results, which are quite satisfactory approximations of the "unknown" function f_1. The plot of the function $M(m)$, displayed in Figure 1D, confirms the correctness of the two approximations. In fact, it clearly exhibits a "plateau," ranging from about $m = 3$ to $m = 10$, that corresponds to the order–disorder transition of the coefficients $\overline{g}_k$. Then it could be argued that for any truncation point belonging to this "plateau" the truncated approximation will hold coefficients $\overline{g}_k$ whose information content is not completely obscured by the noise. In every example discussed here, the regularized solutions $f_\star^{(2)}$ and $f_\star^{(3)}$ (see (18) and (19)) have also been considered, providing in all cases worse results (not plotted).

The second and third examples, shown in Figure 2, are quite simple but a little tricky, and show the deep differences between our approach and the variational one. They consist of a finite linear combination of, respectively, 3 and 10 basis functions ψ_k (see the legend for numerical details), and, indeed, they have been chosen as typical signals in which the bulk of the information is not grouped in a single block of consecutive low frequencies. In these cases, setting global constraints on the solution, such as in the variational methods, leads inevitably to a failure, which is clearly evident from Figure 2C,F, since the lack of selectivity necessarily causes the regularized solution $f_\star^{(1)}$ to contain pure noisy components. On the contrary, the selectivity achieved through the analysis of the autocorrelation function overcomes this limit. In both examples the analysis of the autocorrelation function (see Figure 2A,D) led to the correct selection of the components that carry information in spite of the quite small SNR (in Example 2, SNR $\simeq 0.55$dB). Referring to the Example 2 depicted in Figure 2A,B,C, it can be observed that all the compatibility constraints are indeed satisfied; however, it is worth it to remark that, because of the sampling fluctuation of the estimates $\delta_{\overline{g}}(n)$, the autocorrelation $\delta_{\overline{g}}(6)$ was not always detected in different realizations of the noisy data $\{\overline{g}_k\}_1^N$. In these cases the set $\mathcal{I}_k$, computed from the set $\mathbf{Q} = \{4, 10\}$ missing $n = 6$, is still correct, i.e., $\mathcal{I}_k = \{3, 7, 13\}$, even though one compatibility constraint is not fulfilled.

A more complex example is shown in Figure 3. Following the trace of the previous example, here we have the input function f_4 which is characterized by having the significant Fourier components grouped in different ranges of the k axis. Consequently, the Fourier coefficients g_k that clearly emerge from the noise (in this example, $\epsilon = 10^{-4}$) are quite sparse in the range $1 \leq k \leq 12$ (see Figure 3A). The plot of the regularized solution $\widehat{B}\overline{g}$, obtained from the analysis of the autocorrelation function shown in Figure 3B, shows an acceptable agreement with the real solution f_4, even though the procedure failed in detecting the coefficient at $k = 5$. On the contrary, the "nontruncated" (in the sense that the sum runs up to N) solution $f_\star$ (see (12)), which is displayed in Figure 3D, yields a rather poor reconstruction either because the constraint operator C smooths out too many frequencies or because distortions are introduced by those coefficients which are essentially noise (e.g., $k = 2, 6, 7, 8, 9, 10$). Of course, the variational reconstruction could be considerably improved by choosing

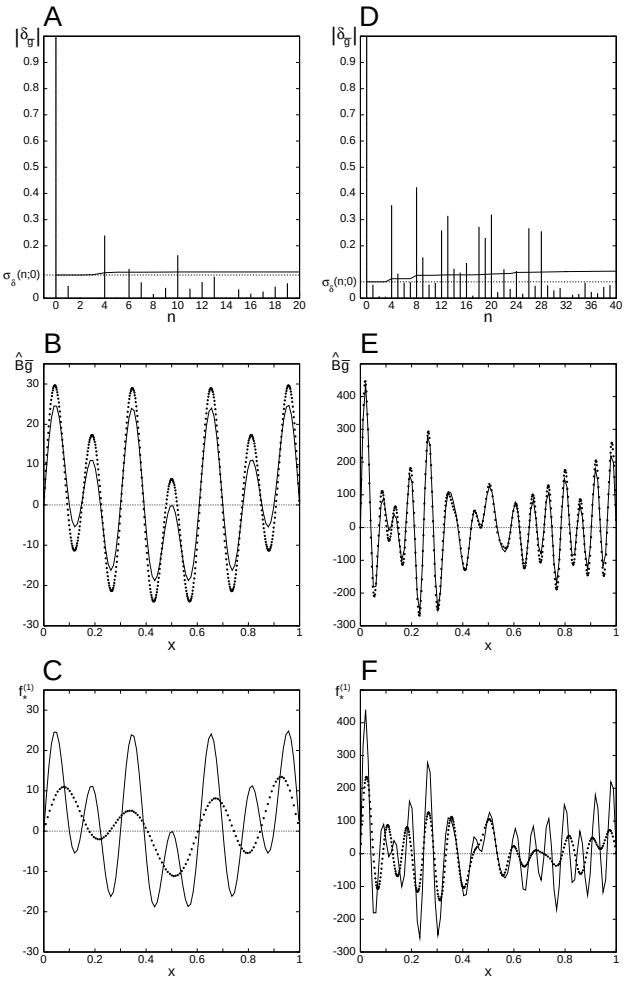

FIG. 2. *Example* 2: $f_2(x) = 5\sin(3\pi x)+10\sin(7\pi x)+15\sin(13\pi x)$, $\epsilon = 3\,10^{-3}$, $SNR \simeq 0.54dB$, $N = 512$. (A) *Modulus of the autocorrelation function.* $\mathbf{Q} = \{4, 6, 10\}$, $\mathcal{I}_k = \{3, 7, 13\}$. (B) *Comparison between the actual solution* $f_2(x)$ *(solid line) and the regularized solution* $\widehat{B\overline{g}}(x)$ *(dots).* (C) *Comparison between the actual solution* $f_2(x)$ *(solid line) and the approximated solution* $f_\star^{(1)}(x)$ *with* $k_\alpha = 9$ (*see criterion* (15)). (D) *Example* 3: *Modulus of the autocorrelation function.* $f_3(x) = \sum_{j=1}^{10} a_j \sin(k_j \pi x)$, *with* $a_j = \{17, 23, 27, 33, 43, 55, 68, 70, 77, 81\}$ *and* $k_j = \{5, 9, 13, 17, 18, 23, 24, 25, 31, 33\}$. $\epsilon = 10^{-3}$, $SNR \simeq 9.79dB$, $N = 1024$; $\mathbf{Q} = \{4, 5, 8, 9, 12, 13, 14, 15, 16, 18, 19, 20, 22, 24, 26, 28\}$, $\mathcal{I}_k = \{5, 9, 13, 17, 18, 23, 24, 25, 31, 33\}$. (E) *Comparison between the actual solution* $f_3(x)$ *(solid line) and the regularized solution* $\widehat{B\overline{g}}(x)$ *(dots).* (F) *Comparison between the actual solution* $f_2(x)$ *(solid line) and the approximated solution* $f_\star^{(1)}(x)$ *with* $k_\alpha = 27$.

a more appropriate operator C and different values for the parameters ϵ and E, but this would require more precise a priori knowledge on the actual solution.

In conclusion, some final remarks. The method of regularization based on the analysis of the correlation function of the data allows us to pick out the Fourier components of the noisy data which are likely to carry exploitable information on the unknown solution and, at the same time, for rejecting the ones dominated by the noise.

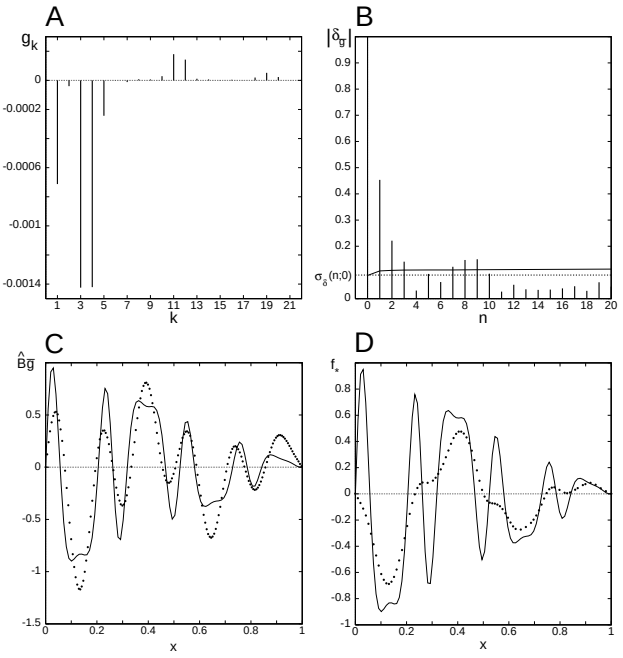

FIG. 3. *Example* 4: $f_4(x) = (1-x)\sin(5\sin(12x))$, $\epsilon = 10^{-4}$, $SNR \simeq 4.6dB$, $N = 512$. (A) *Noiseless Fourier coefficients* g_k. (B) *Modulus of the autocorrelation function.* $\mathbf{Q} = \{1,2,3,5,7,8,9\}$, $\mathcal{I}_k = \{1,3,4,9,11,12\}$. (C) *Comparison between the actual solution* $f_4(x)$ *(solid line) and the regularized solution* $\widehat{B}\overline{g}(x)$ *(dots).* (D) *Comparison between the actual solution* $f_4(x)$ *(solid line) and the variational solution* $f_\star(x)$ (*see* (12)).

Frequency selectivity is not featured by methods of regularization that basically work as low-pass filters, and we have seen this inherent limit through examples in which frequency selectivity is essential for a satisfactory reconstruction.

The regularized solution $\widehat{B}\overline{g}$ is founded only on a suitable analysis of the real data, that aims at holding only the data whose information content is significant. This approach naturally agrees with the methodology of the experimental physical science.

A moderate number of reasonable assumptions have been made in the construction of the regularized solution $\widehat{B}\overline{g}$ (see Theorem 3.5), and, more important, the solution itself does not depend on unknown parameters. Even in the variational approach, methods to reduce the dependence of the solution on free parameters have been widely investigated, and several practical strategies for choosing the regularization parameter α (see functional (9)) have been proposed (see, for instance, [8, 25] and references therein). Since the optimal parameter is impossible to determine because the exact solution is not known, many of these strategies can provide estimates of the asymptotically optimal rate of convergence of the regularized solution to the real solution when the noise vanishes.

The main difficulty of the method we have proposed regards the analysis of the correlation function. First, the correctness of the regularized solution depends on the capability of the correlation function to catch the information content of the data and to exhibit it in an effective way. Second, usually quite large data samples, i.e., N large, are necessary in order to limit sample fluctuations that could give rise to

incorrect interpretation of the correlation function itself.

"CHAOS GAMES" FOR ITERATED FUNCTION SYSTEMS WITH GREY LEVEL MAPS*

B. FORTE†, F. MENDIVIL‡, AND E. R. VRSCAY§

Abstract. Two random iteration algorithms, or "chaos games," for iterated function systems (IFS) on function spaces, namely IFS with grey level maps (IFSM), are described. The first algorithm can be interpreted as a "chaos game in code space" and is guaranteed to work only in the case of nonoverlapping IFS maps. In the second algorithm, applicable to IFSM with overlapping IFS maps but affine grey level maps, the (normalized) IFSM attractor function $\bar{u}$ serves as the density for an invariant measure $\bar{\mu}$ of an IFS with probabilities with condensation measure. As such, approximations to the attractor function of the IFSM are yielded by visitation histograms, as in the case of IFS with probabilities on measure spaces. Some computer results illustrating the convergence of this chaos game for a simple overlapping IFSM on [0,1] are also presented.

Key words. iterated function systems, chaos game, invariant measures, fractals

1. Introduction.

In this paper we formulate two *random iteration algorithms*, or "chaos games," for iterated function systems with grey level maps (IFSM). As in the case of iterated function systems with probabilities (IFSP) on probability measure spaces, the chaos game is a kind of "bin counting" algorithm which can be used to generate approximations to IFSM attractor functions. For both the IFSM and IFSP, such a random iteration algorithm represents an alternative to a *deterministic algorithm* for constructing such approximations.

In the remainder of this section, the basic definitions for IFSM are presented. In section 2, we outline a first kind of chaos game for IFSM, motivated by the chaos game for IFSP. (The important features of the latter are given in the appendix.) Its applicability in analyzing the IFSM attractor function $\bar{u}(x)$ is restricted to the case where the IFS contraction maps are "nonoverlapping." In this case, as expected, a sampling of function values by a random "chaos game" walk produces converging estimates of the average value of the attractor over a subset/pixel. The breakdown of the algorithm in the overlapping case can be understood by reformulating it as a chaos game over code space. A convergence result for this chaos game is provided by Elton's ergodic theorem. However, it can provide information about $\bar{u}(x)$ on X only in the nonoverlapping case. In section 3, we introduce another chaos game for affine IFSM in $\mathcal{L}^1$ in the general overlapping case. The (normalized) IFSM attractor function $\bar{u}$ is considered as the density of the invariant measure for an IFSP with condensation. The offset terms β_i in the affine grey level maps $\phi_i(t) = \alpha_i t + \beta_i$ will

play the role of the condensation measure θ, while the scaling terms α_i will contribute to mixing probabilities for these condensation measures. We conclude the paper with some computer results that illustrate the convergence of the chaos game for a simple overlapping IFSM on [0,1].

1.1. Basics of IFSM. Let (X, d) denote a complete metric space, the "base space," typically $[0, 1]$ or $[0, 1]^2$ with Euclidean metric. Let $\mathbf{w} = \{w_1, w_2, \ldots, w_N\}$ be a set of one-to-one contraction maps on (X, d) with contraction factors $c_i \in [0, 1)$. For simplicity, we assume that the IFS maps are affine. Associated with the IFS maps w_i is a set of grey level maps $\Phi = \{\phi_1, \phi_2, \ldots, \phi_N\}$, $\phi_i : \mathbf{R} \to \mathbf{R}$, assumed to be Lipschitz on $\mathbf{R}$ with Lipschitz constants K_i. The set of IFS maps $\mathbf{w}$ and associated grey level maps Φ comprises an IFSM on (X, d).

Associated with the N-map IFSM $(\mathbf{w}, \Phi)$ is a *fractal transform* operator $T : \mathcal{L}^p(X) \to \mathcal{L}^p(X)$, $p \in [1, \infty)$ [6, 7]. For $u \in \mathcal{L}^p(X)$,

$$(Tu)(x) \;=\; \sum_{k=1}^{N} f_k(x), \qquad x \in X, \tag{1.1}$$

where the *fractal components* $f_k(x)$ are given by

$$f_k(x) = \begin{cases} \phi_k(u(w_k^{-1}(x))), & x \in w_k(X), \\ 0, & x \notin w_k(X). \end{cases} \tag{1.2}$$

In other words, the kth fractal component $f_k(x)$ is a modification of the grey level value of u at the preimage $w_k^{-1}(x)$ (provided this preimage exists).

For $u, v \in \mathcal{L}^p(X)$, $p \in [1, \infty)$,

$$\| Tu - Tv \|_p \leq C_p \, \| u - v \|_p, \qquad C_p = \sum_{k=1}^{N} |J_k|^{1/p} K_k, \tag{1.3}$$

where $|J_k|$ is the Jacobian associated with the transformation $x = w_k(y)$. These bounds may be improved in the μ-nonoverlapping case, where the sets $X_i = w_i(X)$ overlap only on sets of zero Lebesgue measure on X (a common assumption in the literature):

$$\| Tu - Tv \|_p \leq \bar{C}_p \, \| u - v \|_p, \qquad \bar{C}_p = \left[\sum_{k=1}^{N} |J_k| K_k^p \right]^{1/p}. \tag{1.4}$$

If $C_p < 1$, then T is contractive in $(\mathcal{L}^p, d_p)$. From the Banach contraction mapping theorem, there exists a unique fixed point $\bar{u} \in \mathcal{L}^p(X)$, i.e., $T\bar{u} = \bar{u}$. Furthermore, for any $u \in \mathcal{L}^p(X)$, $d_p(T^n u, \bar{u}) \to 0$ as $n \to \infty$. This is the basis for the deterministic algorithm to generate approximations to $\bar{u}$.

In what follows it will be useful to consider the *code space* associated with the N-map IFS $\mathbf{w}$. Recall that there exists a unique compact set $A \subseteq X$, the *attractor* of the IFS, such that $A = \cup_{i=1}^{N} w_i(A)$. Define

$$\Sigma = \{\sigma = (\sigma_1, \sigma_2, \ldots,) \mid \sigma_i \in \{1, 2, \ldots, N\} \; \forall \; i \geq 1\}. \tag{1.5}$$

Then for any $x \in A$, there exists at least one code $\sigma \in \Sigma$ such that

$$x = \lim_{n \to \infty} w_{\sigma_1} \circ w_{\sigma_2} \circ, \ldots, \circ w_{\sigma_n}(y) \tag{1.6}$$

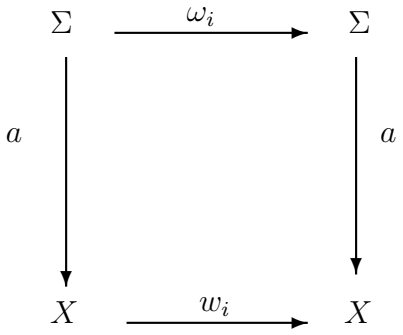

FIG. 1.1.

for any $y \in X$ [2, 1]. As well, for any $\sigma \in \Sigma$, there exists a unique point $x \in X$. We let $a : \Sigma \to X$ denote the *address map* so that $a(\sigma) = x$. If the sets $w_i(A)$ are disjoint, then a is one-to-one.

Finally, each IFS map w_i on X induces an equivalent action on Σ. The code space map corresponding to w_i is $\omega_i : (\sigma_1, \sigma_2, \dots,) \mapsto (i, \sigma_1, \sigma_2, \dots,)$. These actions are depicted schematically in Figure 1.1.

2. A simple chaos game.

2.1. Nonoverlapping sets $X_i = w_i(X)$. Let $P_K = \{B_k\}_{k=1}^K$ denote a partition of X into Borel subsets B_k. Associated with each set B_k is a "cumulative sum" S_k which will initially be set to 0. Let $(\mathbf{w}, \Phi)$ be an N-map IFSM on X satisfying the following properties:

1. The sets $X_i = w_i(X)$ cover X, i.e., $\bigcup_{k=1}^N X_i = X$.
2. As well, $m(X_i \cap X_j) = 0$ for $i \neq j$ ("nonoverlapping" sets).
3. The grey level maps ϕ_i are contractive on $\mathbf{R}$, i.e., $K_i \in [0, 1)$. (This implies that T is contractive on $\mathcal{L}^\infty(X)$ [3, 6].)

From the above assumptions, almost every point $x \in X$ (Lebesgue measure) has a unique code $\sigma = (\sigma_1, \sigma_2, \dots,) \in \Sigma$. If $\bar{u}$ is the attractor of the N-map IFSM $(\mathbf{w}, \Phi)$, then $\bar{u}(x) = \phi_{\sigma_1} \bar{u}(w_{\sigma_1}^{-1}(x))$, which may be iterated to obtain (using the contractivity of the ϕ_i)

$$\bar{u}(x) = \lim_{n \to \infty} \phi_{\sigma_1} \circ \phi_{\sigma_2} \circ, \dots, \circ \phi_{\sigma_n}(t_0), \tag{2.1}$$

where $t_0 \in \mathbf{R}$.

Let $\mathbf{p} = \{p_1, p_2, \dots, p_n\}$, $p_k > 0$, $\sum_{k=1}^N p_k = 1$ be a set of probabilities associated with each IFS grey level map pair (w_k, ϕ_k). The choice of the p_k — a crucial point — will be specified below. We now outline the first algorithm:

1. Initialize x_0 as the fixed point of w_1 (merely for convenience).
2. Initialize u_0 to be "close" to $u(x_0)$ by setting $u_0 = \phi_1^{\circ m}(1)$, where m is sufficiently large to obtain the desired accuracy. (Convergence is guaranteed by the contractiveness of the ϕ_k maps and the nonoverlapping property of the X_i.)
3. Initialize the sum $S_{j_0} = u_0$, where $x_0 \in B_{j_0}$.
4. Choose a pair $\{w_{\sigma_0}, \phi_{\sigma_0}\}$, $\sigma_0 \in \{1, 2, \dots, N\}$ according to the probabilities p_i.
5. Set $x_1 = w_{\sigma_0}(x_0)$ and $u_1 = \phi_{\sigma_0}(u_0)$.
6. Increment the sum S_{j_1} by u_1, where $x_1 \in B_{j_1}$.

7. Continue in this way by returning to 4 above, i.e.,

$$x_{n+1} = w_{\sigma_n}(x_n), \quad u_{n+1} = \phi_{\sigma_n}(u_n), \qquad \sigma_n \in \{1, 2, \ldots, N\}, \tag{2.2}$$

where the σ_k are chosen according to the probabilities p_i and then by updating the appropriate $S_{j_{n+1}}$.

PROPOSITION 2.1. *For each $k \in \{1, 2, \ldots, K\}$,*

$$\frac{S_k}{n} \to \int_{B_k} \bar{u}(x) d\bar{\mu}(x) \quad as \quad n \to \infty, \tag{2.3}$$

where $\bar{\mu}$ is the invariant measure of the IFSP $(\mathbf{w}, \mathbf{p})$. (See the appendix for the definition of IFSP.)

Proof. From the assumptions that (1) the ϕ_i maps are contractive and (2) the sets $w_i(X)$ are nonoverlapping, it follows that $u_n \approx \bar{u}(x_n)$. Let I_k denote the characteristic function of B_k. Then at the nth stage of this chaos game,

$$\frac{S_k}{n} \approx \frac{1}{n} \sum_{m=1}^{n} I_k(x_m) \bar{u}(x_m). \tag{2.4}$$

From Elton's theorem [5], in the limit $n \to \infty$ the right-hand side of the above expression becomes $\int_{B_k} \bar{u}(x) d\bar{\mu}(x)$. □

COROLLARY 2.2. *Define the probabilities to be $p_i = m(X_i)/\sum_k m(X_k)$. Then*

$$\begin{aligned} \lim_{n\to\infty} \frac{1}{n} \frac{S_k}{m(B_k)} &= \frac{1}{m(B_k)} \int_{B_k} \bar{u}(x) dm(x), \\ &= \bar{u}_{av}(B_k), \end{aligned} \tag{2.5}$$

the average value of $\bar{u}$ over B_k.

Proof. An easy calculation shows that the invariant measure for the IFSP $(\mathbf{w}, \mathbf{p})$ is $\mu = m$. From Eq. (2.4) the desired result follows. □

PROPOSITION 2.3. *Let $\mathcal{P}_n$ be a nested sequence of Borel partitions whose "sizes" go to zero as $n \to \infty$. Let $\bar{u}_n$ be the average value function of $\bar{u}$ associated with $\mathcal{P}_n$. Suppose that T is contractive in $\mathcal{L}^p(X, m)$ $(1 \le p < \infty)$ so that its fixed point $\bar{u} \in \mathcal{L}^p$. Then $\bar{u}_n$ converges to $\bar{u}$ in $\mathcal{L}^p$.*

Proof. Notice that $\bar{u}_n$ is the conditional expectation of $\bar{u}$ given $\mathcal{P}_n$. Thus, $\bar{u}_n$ forms a martingale sequence which is $\mathcal{L}^p$ bounded. The desired convergence then follows by the martingale convergence theorem [9]. □

Remarks. 1. The above implies that we may obtain an approximation to any accuracy (in the $\mathcal{L}^p$ sense) by using a sufficiently fine partition of X. In the particular case that $\bar{u} \in \mathcal{L}^1$, a stronger result follows from the martingale convergence theorem, namely, that $\bar{u}_n \to \bar{u}$ pointwise a.e.

2. In the general case of probabilities p_i, $\sum_i^N p_i = 1$, the limit in Corollary 2.2 becomes $\bar{u}_{av}(B_k, \bar{\mu})$, the $\bar{\mu}$-average value of $\bar{u}$ over B_k. Then Proposition 2.3 is generalized to convergence of $\bar{u}_n$ to $\bar{u}$ in $\mathcal{L}^p(\mu)$. The specific results of Corollary 2.2 and Proposition 2.3, i.e., convergence with respect to Lebesgue measure, are more relevant to computer approximations using the chaos game.

2.2. Overlapping $w_i(X)$ and a "chaos game in code space." In the case that the sets $X_i = w_i(X)$ overlap, i.e., $m(X_i \cap X_j) \neq 0$ for some pair (i, j), $i \neq j$, the chaos game of the previous section fails. One immediate consequence of overlapping

is that in Step 2 of the algorithm, it is not guaranteed that u_0 may be made "close" to $\bar{u}(x_0)$, since x_0 may have several preimages $w_i^{-1}(x_0)$. In order to further understand this problem, we formulate a chaos game algorithm on the code space Σ rather than on the base space X. This is possible from the equivalence of actions in both spaces as shown in Figure 1.1 at the end of section 1.1. Associated with the partition P_K of X into Borel subsets B_k is a partition of Σ into subsets defined by $T_k = a^{-1}(B_k)$ for all k, where $a : \Sigma \to X$ is the address map defined in section 1.1. To each T_k we now associate a cumulative sum S_k, initialized to zero.

Instead of considering functions $u : X \to \mathbf{R}$, as was done in the previous section, we consider the function $f : \Sigma \to \mathbf{R}$ defined as follows: for $\sigma \in \Sigma$, define

$$f(\sigma) = \lim_{n\to\infty} \phi_{\sigma_1} \circ \phi_{\sigma_2} \circ, \ldots, \circ \phi_{\sigma_n}(t_0), \tag{2.6}$$

where $t_0 \in \mathbf{R}$. The limit exists and is independent of t_0 by the assumption that the ϕ_i are contractive on $\mathbf{R}$. This is the "code space analogy" of the base space attractor function $\bar{u}$ as defined in Eq. (2.1).

We now modify the algorithm of the previous section to produce a chaos game on Σ instead of X. This is simply done by replacing B_{j_k} by T_{j_k}—the "bins" are now in the code space Σ instead of the base space X. Let $\sigma_1, \sigma_2, \ldots, \sigma_n, \ldots$, be the indices of the (w_i, ϕ_i) pairs chosen. Elton's ergodic theorem [5] guarantees the following result.

PROPOSITION 2.4. *For each $k \in \{1, 2, \ldots, K\}$,*

$$\frac{S_k}{n} \;\approx\; {\sum}' f(\tau_n) I_{T_j} \;\to\; \int_{T_k} f(\sigma) dP(\sigma), \quad \textit{as} \quad n \to \infty. \tag{2.7}$$

The prime indicates summation over codes $\tau_n = (\sigma_{n-l}, \sigma_{n-l+1}, \ldots, \sigma_n)$, where l is sufficiently large so that $f(\tau_n) \approx f(\sigma)$. As well, P denotes the invariant measure of the IFS with probabilities $(\mathbf{w}, \mathbf{p})$ on Σ.

In order to obtain an approximation to the IFSM attractor $\bar{u}(x)$ on X, it is necessary to interpret the above algorithm as acting on X. One may try to accomplish this by using the address map a to "push" the process onto X. From Eq. (2.7),

$$\frac{S_k}{n} \;\to\; \int_{T_k} f(\sigma) dP(\sigma). \tag{2.8}$$

This integral may involve a summation over different regions B_{k_i} which are mapped to T_k. In order to obtain a true approximation to $\bar{u}$ on X, however, we require the following quantity:

$$\int_{B_k} \left(\sum_{\sigma \in a^{-1}(x)} f(\sigma) \right) dP(a^{-1}(x)). \tag{2.9}$$

The quantities in Eqs. (2.8) and (2.9) are not necessarily identical. Equality is guaranteed only in the case that a is injective, i.e., the sets $X_i = w_i(X)$ are nonoverlapping. We illustrate the problem with the overlapping case by means of a simple example.

Example. $X = [0, 1]$ with

$$\begin{aligned} &w_1(x) = w_2(x) = \frac{1}{2}x, \quad w_3(x) = \frac{1}{2}x + \frac{1}{2}, \\ &\phi_1(t) = \phi_2(t) = \frac{1}{2}, \quad \phi_3(t) = 1. \end{aligned} \tag{2.10}$$

Then $\bar{u}(x) = 1$. Let $B_1 = [0, 1/2] = w_1(X)$ and $B_2 = [1/2, 1] = w_3(X)$. Consider the case $k = 1$ in Eqs. (2.8) and (2.9). Then $f = 1/2$ on T_1 because $\phi_1 = \phi_2 = 1/2$. The integral in Eq. (2.8) becomes

$$\begin{aligned} \int_{\sigma_1=1} \frac{1}{2} dP(\sigma) + \int_{\sigma_1=2} \frac{1}{2} dP(\sigma) &= \int_0^{\frac{1}{2}} \frac{1}{2} dP(a^{-1}(x)) \\ &= \frac{1}{2}(p_1 + p_2). \end{aligned} \tag{2.11}$$

The corresponding integral in Eq. (2.9) is

$$\begin{aligned} \int_{\sigma_1=1} \left(\frac{1}{2} + \frac{1}{2}\right) dP(\sigma) + \int_{\sigma_1=2} \left(\frac{1}{2} + \frac{1}{2}\right) dP(\sigma) &= \int_0^{\frac{1}{2}} \left(\frac{1}{2} + \frac{1}{2}\right) dP(a^{-1}(x)) \\ &= (p_1 + p_2). \end{aligned} \tag{2.12}$$

The two integrals are clearly not equal. The problem is due to the existence of "cross terms" in the integral of Eq. (2.9), which are not present in Eq. (2.8).

In the case that the address map a is injective, the integrals in Eqs. (2.8) and (2.9) are identical, and Proposition 2.1 of the previous section follows. The following generalization of Corollary 2.2 also follows:

$$\begin{aligned} \lim_{n\to\infty} \frac{1}{n} \frac{S_k}{\bar{\mu}(B_k)} &= \frac{1}{\bar{\mu}(B_k)} \int_{B_k} \bar{u}(x) d\bar{\mu}(x) \\ &= \bar{u}_{av}(B_k, \bar{\mu}), \end{aligned} \tag{2.13}$$

the $\bar{\mu}$-average of $\bar{u}$ over B_k. Approximations to this average value may be obtained by running the standard chaos game for the invariant measure $\bar{\mu}$ of the IFSP $(\mathbf{w}, \mathbf{p})$ simultaneously: simply include another set of accumulation variables m_k, $1 \le k \le K$, and increment the appropriate m_j by 1 at each step. Then $m_k/n \to \bar{\mu}(B_k)$ as $n \to \infty$ so that $S_k/m_k \to \bar{u}_{av}(B_k, \bar{\mu})$.

In summary, the simple "chaos game" algorithms outlined above — one in the base space X and the other in the code space Σ — are guaranteed to work only in the special case of nonoverlapping $w_i(X)$. We are unable to construct comparable algorithms for the more general case of overlapping $w_i(X)$.

This is not to say that the algorithms never work in the overlapping case. They may work in "nongeneric" situations, for example, when grey level maps ϕ_i corresponding to overlapping IFS maps are identically zero. These are special cases, however. Our simple example clearly illustrates that the algorithms are not universally applicable. This serves as a motivation for the work outlined in the next section, in which a chaos game based on IFS with probabilities and condensation measures is devised.

3. Chaos game using IFSP with condensation. In what follows we assume, for simplicity of notation, that $X = [0, 1]$. Let $(\mathbf{w}, \Phi)$ denote an N-map *affine* IFSM, i.e., both IFS and grey level maps are affine:

$$w_i(x) = s_i x + a_i, \quad \phi_i(t) = \alpha_i t + \beta_i, \quad 1 \le i \le N. \tag{3.1}$$

Note that the sets $w_i(X)$ are *not* assumed to be nonoverlapping. The associated fractal transform operator T has the form

$$(Tu)(x) = \sum_{k=1}^{N} \alpha_k u\left(\frac{x - a_k}{s_k}\right) I_{X_k}(x) \; + \; \sum_{k=1}^{N} \beta_k I_{X_k}(x), \tag{3.2}$$

where $X_k = w_k(X)$. We shall write the above operation symbolically as

$$T(u) = A(u) + b, \tag{3.3}$$

where $b(x)$ is defined by the second sum in Eq. (3.2). We also assume that $\alpha_i, \beta_i \geq 0$, and that

$$C_1 = \sum_{k=1}^{N} c_i \alpha_i < 1, \tag{3.4}$$

where $c_i = |s_i|$, i.e., T is contractive in $\mathcal{L}^1$. Then the fixed point $\bar{u} = T\bar{u}$ may be written as follows:

$$\begin{aligned} \bar{u} &= b + A(\bar{u}) \\ &= \sum_{n=0}^{\infty} A^n(b). \end{aligned} \tag{3.5}$$

The iterated application of A on the function b mimics the operation of "condensation" in IFSP with condensation measures (reviewed in the appendix). The nature of this condensation is clarified if we consider the (normalized) attractor $\bar{u}$ as the density function of a probability measure $\bar{\mu}$ on X.

From the relation $T\bar{u} = \bar{u}$, one may easily compute the following integral:

$$\langle \bar{u} \rangle = \int_X \bar{u}(x)dx = \frac{\sum_k c_k \beta_k}{1 - \sum_k c_k \alpha_k}. \tag{3.6}$$

(Note that the denominator does not vanish.) As well,

$$\langle b \rangle = \int_X b(x)dx = \sum_k c_k \beta_k. \tag{3.7}$$

We also have from the relation $T\bar{u} = \bar{u}$, for any Borel set $S \subset X$,

$$\int_S \bar{u}(x)dx = \sum_{k=1}^{N} \alpha_k c_k \int_{w_k^{-1}(S)} \bar{u}(x)dx \ + \ \int_S b(x)dx. \tag{3.8}$$

Define the normalized functions $\bar{u}_1(x) = \bar{u}(x)/\langle \bar{u} \rangle$ and $b_1(x) = b(x)/\langle b \rangle$ so that $\langle \bar{u}_1 \rangle = \langle b_1 \rangle = 1$. Rewrite Eq. (3.8) in terms of these normalized functions to obtain

$$\bar{\mu}(S) = \sum_{k=1}^{N} \alpha_k c_k \bar{\mu}(w_k^{-1}(S)) \ + \ \left[1 - \sum_{k=1}^{N} \alpha_k c_k \right] \theta(S), \tag{3.9}$$

where $\bar{\mu}(S) = \int_S \bar{u}_1(x)dx$ and $\theta(S) = \int_S b_1(x)dx$. Thus, the measure $\bar{\mu} \in \mathcal{M}(X)$, with density $\bar{u}_1$, is the invariant measure of an IFSP with condensation measure $\theta \in \mathcal{M}(X)$ with density $\bar{b}_1$; cf. Eq. (A.10) in the appendix. Let $p_i = \alpha_i c_i$, $1 \leq i \leq N$ be the probabilities associated with the IFS maps w_i and let $p_0 = 1 - \sum_i^N \alpha_i c_i$ be the probability associated with the condensation measure θ. Our chaos game for affine IFSM will now be based on a chaos game for IFSP with condensation.

As in the previous section, we assume that X is partitioned into Borel subsets B_k. The cumulative sums S_k associated with the sets B_k are again initialized to zero. Here, however, they will supply information only on the visitation of the sets B_k. The algorithm is as follows:

1. Initialize x_0 as the fixed point of w_1 (merely for convenience).
2. Set $S_{j_0} = 1$, where $x_{j_0} \in B_j$.
3. Choose a $\sigma_1 = i \in \{0, 1, 2, \ldots, N\}$ according to the probabilities p_i. If
    1. $\sigma_1 \geq 1$, then define $x_1 = w_i(x_0)$. Increment the sum S_{j_1} by one, where $x_1 \in B_{j_1}$;
    2. $\sigma_1 = 0$, then choose x_1 according to the distribution with b_1 as its density. Increment the sum S_{j_1} by one, where $x_1 \in B_{j_1}$;
    3. Continue in this way, choosing the next σ_n according to the probabilities p_i, either (a) setting $x_{n+1} = w_{\sigma_n}(x_n)$ or (b) sampling from b_1. Then increment the appropriate $S_{j_{n+1}}$ accordingly.

At the nth stage, the approximation to $\bar{u}$ on B_k yielded by the above algorithm will be given by

$$\bar{u}_{av}(B_k) \approx \frac{1}{n}\left(\frac{S_j}{m(B_j)}\right)\left(\frac{\sum_k \beta_k c_k}{1 - \sum_k \alpha_i c_i}\right). \tag{3.10}$$

PROPOSITION 3.1. *The above approximations converge to the average value of $\bar{u}$ over the set B_k as $n \to \infty$.*

Proof. By Proposition 6 in [4], we have $S_k/n \to \bar{\mu}(B_k)$, where $\bar{\mu}$ is the invariant measure for the IFSP with condensation $(\mathbf{w}, \mathbf{p})$. We write the IFSP Markov operator as

$$\begin{aligned}(M\nu)(B) &= \sum_{i=1}^{N} p_i \nu(w_i^{-1}(B)) + p_0\theta(B) \\ &= (\bar{A}\nu)(B) + p_0\theta(B). \end{aligned} \tag{3.11}$$

Thus,

$$\bar{\mu} = \sum_{n}^{\infty} \bar{A}^n(\theta). \tag{3.12}$$

This shows that $\bar{\mu}$ is absolutely continuous with respect to Lebesgue measure since each term $\bar{A}^n(\theta)$ is. Since $\bar{\mu}$ is invariant with respect to M, its Radon–Nikodým derivative (i.e., its density) must also be invariant with respect to M. By scaling, we obtain the desired result. ∎

In order for the connection between IFSM and IFSP with condensation to be possible, the IFSM must be affine so that the operator T may be written as in Eq. (3.3). However, some generalizations may be made:

1. The shift or "offset" terms β_i in the grey level maps may be generalized to nonconstant functions of $x \in X$. In other words, the function $b(x)$ in Eq. (3.3) need not be a piecewise constant function. In order to define a density function for the condensation measure θ (cf. Eqs. (3.8), (3.9)) it is sufficient that the $\beta_i \in \mathcal{L}^1(X)$. The nonnegativity condition on the β_i may also be relaxed, as shown below.

2. Consider the affine IFSM operator T in Eq. (3.3), with $b(x)$ negative but bounded from below on X. Now let c be a positive constant (or a nonnegative $\mathcal{L}^1$ function) such that $b + c \geq 0$ on X. Now define the affine IFSM operator T', where

$$T'(u) = A(u) + (b + c), \qquad u \in \mathcal{L}^1(X). \tag{3.13}$$

Then T' is contractive with fixed point $\bar{u}' \in \mathcal{L}^1(X)$ given by

$$\bar{u}' = \sum_{n=0}^{\infty} A^n(b + c) \tag{3.14}$$

$$= \sum_{n=0}^{\infty} A^n(b) \; + \; \sum_{n=0}^{\infty} A^n(c)$$
$$= \bar{u} \; + \; \bar{v},$$

where $\bar{v}$ is the fixed point for the IFSM operator T_c, where $T_c(u) = A(u)+c$. Therefore $\bar{u} = \bar{u}' - \bar{v}$. "IFSP with condensation" chaos games may now be run separately for the two operators T' and T_c since they both have nonnegative condensation functions. Two accumulation sums are now computed in the algorithm, and approximations to the attractor $\bar{u}$ may then be obtained by subtracting these sums.

Example. Consider the following 3-map affine IFSM on [0,1] with overlapping IFS maps:

$$\begin{aligned} &w_1(x) = 0.5x, && \phi_1(t) = 0.6t + 0.2, \\ &w_2(x) = 0.4x + 0.3, && \phi_2(t) = 0.25t + 0.25, \\ &w_3(x) = 0.6x + 0.4, && \phi_3(t) = 0.4t + 0.6. \end{aligned} \tag{3.15}$$

The IFSM operator T is contractive in $\mathcal{L}^1(X)$. A histogram approximation of the attractor $\bar{u}$ of this IFSM is shown in Figure 3.1. This approximation was obtained by using the deterministic algorithm on an equipartition of [0,1] using 2000 subintervals. A discrete version of the IFSM operator was then iterated until satisfactory convergence was obtained. (Twenty-five iterations required about 0.03 CPU sec. All calculations were performed on an IBM RISC 6000 Model 43P-100.) Figures 3.2, 3.3, and 3.4 show histogram approximations to $\bar{u}$ yielded by the chaos game after 250,000, 2,000,000 and 10,000,000 iterations, respectively. (Again, 2000 "bins" B_k were employed.) In all three cases, less than 0.01 CPU sec. was required. It is evident that the approximations yielded by the chaos game are converging.

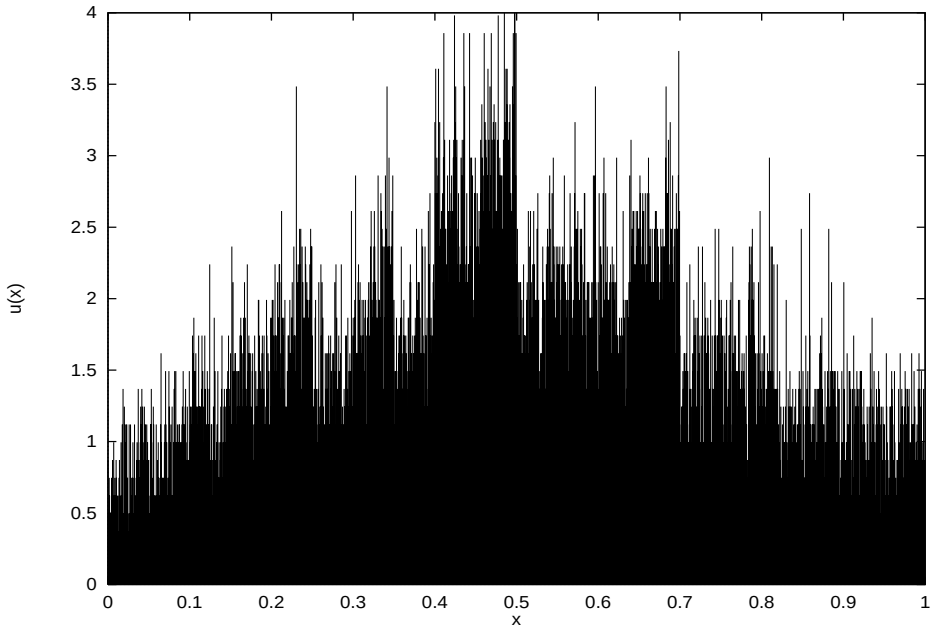

FIG. 3.2. *Chaos game approximation to* $\bar{u}$ *after* $250,000$ *iterations.*

Appendix.

IFSP and the "chaos game."

Let $(\mathbf{w}, \mathbf{p})$ be an N-map IFS with probabilities, i.e., $\mathbf{p} = \{p_1, p_2, ..., p_N\}$, $p_i \geq 0$. Let $\mathcal{B}(X)$ denote the σ-algebra of Borel subsets of X and $\mathcal{M}(X)$ the set of all probability measures on $\mathcal{B}(X)$. Associated with the N-map IFSP $(\mathbf{w}, \mathbf{p})$ is a (Markov) operator $M : \mathcal{M}(X) \to \mathcal{M}(X)$ such that for a $\mu \in \mathcal{M}(X)$ and any $S \in \mathcal{B}(X)$,

$$(M\mu)(S) = \sum_{i=1}^{N} p_i \mu(w_i^{-1}(S)). \tag{3.16}$$

M is contractive on $\mathcal{M}(X)$ [8],

$$d_H(M\mu, M\nu) \leq c d_H(\mu, \nu), \quad \forall \mu, \nu \in \mathcal{M}(X), \tag{3.17}$$

where $c = \max_{1 \leq i \leq N}\{c_i\}$ and d_H is the Monge–Kantorovich metric, referred to in the IFS literature as the "Hutchinson metric" due to its use in [8]. Thus, there exists a unique $\bar{\mu} \in \mathcal{H}(X)$ such that (1) $M\bar{\mu} = \bar{\mu}$ and (2) $d_H(M^n\mu, \bar{\mu}) \to 0$ as $n \to \infty$ for any $\mu \in \mathcal{M}(X)$. Moreover, $\text{supp}(\bar{\mu}) \subseteq A$, with the equality when all $p_i > 0$.

Given an $f \in C(X)$ and a $\mu \in \mathcal{M}(X)$, then

$$\int_X f(x) d(M\mu)(x) = \int_X (M^\dagger f) d\mu, \tag{3.18}$$

where the adjoint operator $M^\dagger : C(X) \to C(X)$ (referred to as T in [2]) is given by

$$(M^\dagger f)(x) = \sum_{k=1} p_k (f \circ w_k)(x). \tag{3.19}$$

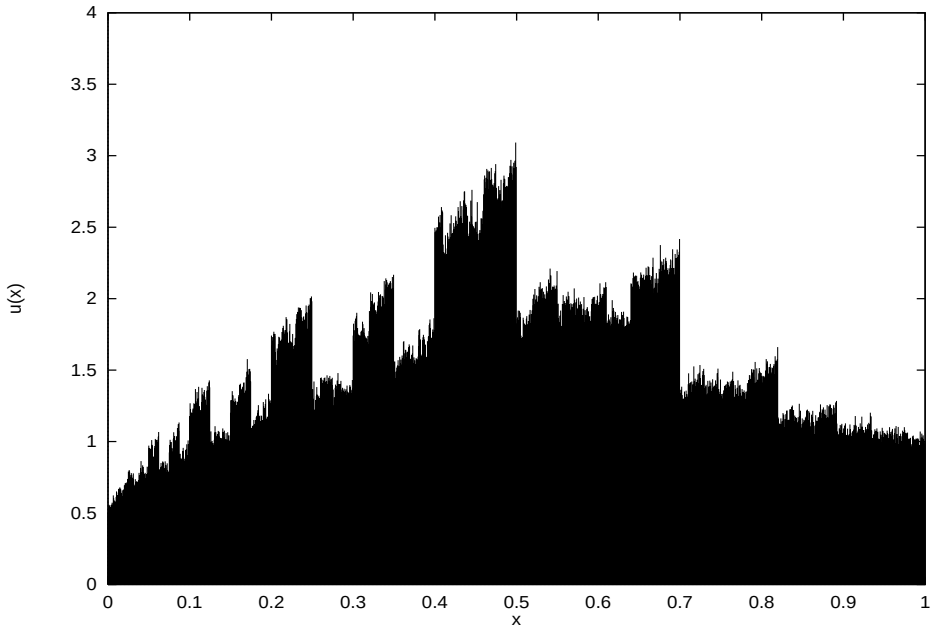

FIG. 3.3. *Chaos game approximation to* $\bar{u}$ *after* $2,000,000$ *iterations.*

The above procedure may be iterated to obtain, for $n = 1, 2, \ldots$,

$$\int_X f(x)d(M^n\mu)(x) = \sum_{i_1,\ldots,i_n}^{N} p_{i_1},\ldots,p_{i_n} \int_X (f \circ w_{i_1} \circ, \ldots, \circ w_{i_n})(x)d\mu(x). \tag{3.20}$$

Now set $\mu = \delta_{x_0}$, the Dirac unit mass at $x_0 \in X$ and $f(x) = I_S(x)$, where $S \subseteq X$, to give

$$\bar{\mu}(S) = \lim_{n\to\infty} \sum_{i_1,\ldots,i_n}^{N} p_{i_1},\ldots,p_{i_n} I_S(w_{i_1} \circ, \ldots, \circ w_{i_n}(x_0)). \tag{3.21}$$

The term involving I_S indicates whether or not the point $w_{i_1} \circ, \ldots, \circ w_{i_n}(x_0)$ lies in S. The quantity $p_{i_1}p_{i_2},\ldots,p_{i_n}$ represents the probability of choosing the finite sequence $\{\tau_{i_1}, \tau_{i_2}, \ldots, \tau_{i_n}\}$. Therefore, for each $n > 0$ the sum is equal to the probability that the point x_n lies in S.

There is a connection between Eq. (A.6) and the random iteration algorithm or "chaos game" [1], defined as follows: pick an $x_0 \in X$ and define the iteration sequence

$$x_{n+1} = w_{\tau_n}(x_n), \qquad n = 0, 1, 2, \ldots, \tag{3.22}$$

where the τ_n are chosen randomly and independently from the set $\{1, 2, \ldots, N\}$ with probabilities $P(\tau_n = i) = p_i$. A straightforward coding argument shows that for almost every code sequence $\tau = \{\tau_1, \tau_2, \ldots,)$ the orbit $\{x_n\}$ is dense on the attractor A of the IFS $\mathbf{w}$. As such, the chaos game can be used to generate computer approximations of A. However, it also provides approximations to the invariant measure $\bar{\mu}$ as a consequence of the following ergodic theorem for IFS [5]: for almost all code

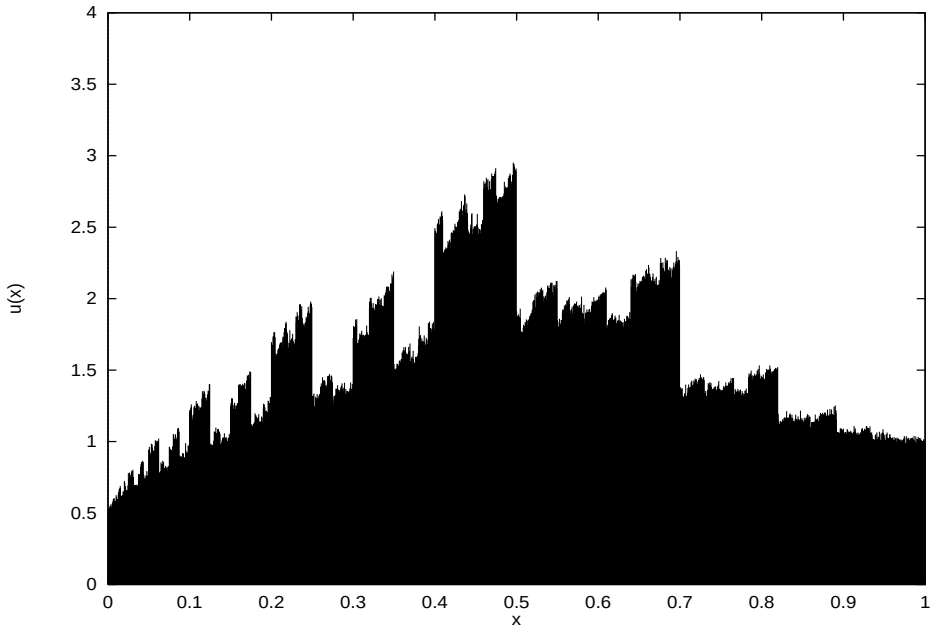

FIG. 3.4. *Chaos game approximation to* $\bar{u}$ *after* $10,000,000$ *iterations.*

sequences $\tau = (\tau_1, \tau_2, \dots,)$,

$$\lim_{n\to\infty} \frac{1}{n+1} \sum_{k=0}^{n} f(x_k) = \int_X f(x)\bar{\mu}(x) \tag{3.23}$$

for all continuous (and simple) functions $f : X \to \mathbf{R}$. By setting $f(x) = I_S(x)$ in Eq. (A.8) for an $S \subseteq X$, we obtain

$$\bar{\mu}(S) = \lim_{n\to\infty} \frac{1}{n+1} \sum_{k=0}^{n} I_S(x_k). \tag{3.24}$$

In other words, $\bar{\mu}(S)$ is the limit of the relative visitation frequency of S during the chaos game.

IFSP with condensation. Consider an N-map IFSP on (X, d) with a condensation measure $\theta \in \mathcal{M}(X)$, i.e.,

1. $w_i : X \to X$, $1 \le i \le N$, contractive IFS maps on (X, d), with associated probabilities p_i, $1 \le i \le N$;

2. a condensation measure $\theta \in \mathcal{M}(X)$ with support $L \in \mathcal{B}(X)$ such that $\theta(L) = 1$ and $\theta(B) = \theta(B \cap L)$ for $B \in \mathcal{B}(X)$.

The Markov operator $M : \mathcal{M}(X) \to \mathcal{M}(X)$ is given by

$$(M\mu)(S) = \sum_{i=1}^{N} p_i \mu(w_i^{-1}(S)) \ + \ p_0\theta(S), \qquad S \in \mathcal{H}(X). \tag{3.25}$$

Thus

$$\int_X f(x)d(M\mu)(x) = \sum_{i=1}^{N} p_i \int_X (f \circ w_i)(x)d\mu(x) \ + \ p_0 \int_X f(x)d\theta(x). \tag{3.26}$$

Following [2], define the IFSP $\{w_1, \ldots, w_N, \hat{p}_1, \ldots, \hat{p}_N\}$, where $\hat{p}_i = p_i/(1-p_0)$, with associated Markov operator $\hat{M} : \mathcal{M}(X) \to \mathcal{M}(X)$. Define the affine map $\bar{M}_c : \mathcal{M}(X) \to \mathcal{M}(X)$, where

$$M_c\mu = (1-p_0)\hat{M}\mu + p_0\theta, \qquad \mu \in \mathcal{M}(X). \tag{3.27}$$

M_c is contractive in the d_H metric. Hence, there exists a unique $\bar{\mu}_c \in \mathcal{M}(X)$ such that $M_c\bar{\mu}_c = \bar{\mu}_c$.

REARRANGEMENTS OF VECTOR VALUED FUNCTIONS, WITH APPLICATION TO ATMOSPHERIC AND OCEANIC FLOWS*

R. J. DOUGLAS†

Abstract. This paper establishes the equivalence of four definitions of two vector valued functions being rearrangements. Properties of the monotone rearrangement of a vector valued function are used to show existence and uniqueness of the minimizer of an energy functional arising from the semigeostrophic equations, a model for atmospheric and oceanic flow. At each fixed time solutions are shown to be equal to the gradient of a convex function, verifying the conjecture of Cullen, Norbury, and Purser [*SIAM J. Appl. Math.*, 51 (1991), pp. 20–31].

Key words. rearrangement of functions, semigeostrophic, variational problems, generalized solution

1. Introduction.

This paper studies properties of rearrangements of vector valued functions and gives an application to atmospheric and oceanic flow. We say that two vector valued functions $f, g \in L^p(\Omega \subset \mathbf{R}^n, \lambda, \mathbf{R}^d)$, where $1 \leq p < \infty$ and Ω is bounded, are *rearrangements* if

$$\lambda\left(f^{-1}(B)\right) = \lambda\left(g^{-1}(B)\right) \tag{1.1}$$

for each Borel subset B of $\mathbf{R}^d$. (We restrict our definition of rearrangement to functions defined on measure spaces (Ω, λ) with certain properties; see section 2.1.) This is equivalent to the definition of rearrangement for scalar valued functions when $d = 1$. Rearrangement can be viewed as an equivalence relation on the space of L^p functions; therefore we can define the set of rearrangements (or equivalence class) of a given vector valued function. For a prescribed f_0 we write $R(f_0)$ to denote the set of rearrangements of f_0.

Different definitions have been given for two vector valued functions being rearrangements. Brenier [2] defined vector valued functions f and g (belonging to $L^p(\Omega \subset \mathbf{R}^n, \lambda, \mathbf{R}^d)$) to be rearrangements if $\int_\Omega F(f) = \int_\Omega F(g)$ for each F in a subclass of continuous functions from $\mathbf{R}^d$ to $\mathbf{R}$. In contrast, Cullen, Norbury, and Purser [6] made a direct extension of the definition of scalar valued rearrangement, requiring that $\lambda\{x : f(x) \geq c\} = \lambda\{x : g(x) \geq c\}$ for each $c \in \mathbf{R}^d$, where the inequalities are calculated component by component. Section 2 unifies these concepts, establishing that both are equivalent to the definition in the opening paragraph. We establish a fourth equivalent property which yields a characterization for the set of rearrangements of a prescribed vector valued function. This is a vector valued extension of the real valued characterization of Eydeland, Spruck, and Turkington [7]. These results are stated in Theorem 2.2.

Section 3 studies a variational problem arising from a model for atmospheric and oceanic flow. The equations are the three-dimensional Boussinesq equations of semi-geostrophic flow, a standard model for slowly varying flows constrained by rotation and stratification. (They are recalled in section 3.2.) Cullen, Norbury, and Purser [6] interpreted solutions as a sequence of minimum energy states: at each time t, the particles arrange themselves so that geostrophic energy is minimized. The state of the fluid is known on particles; therefore we minimize geostrophic energy over the set of rearrangements of a possible state of the fluid at time t, a vector valued function. Cullen, Norbury, and Purser conjectured the existence of a unique minimizer, equal to the gradient of a convex function, which is the actual state of the fluid. We make the physically reasonable assumption that the fluid configuration belongs to L^p so that we may use the theory of monotone rearrangement of vector valued functions, which was developed by Brenier [2]. If the fluid configuration satisfies a nondegeneracy condition (see section 3.3), the Cullen–Norbury–Purser conjecture follows easily by the results of Brenier [2]. However, the nondegeneracy condition is severe, as it does not allow the function to have level sets of positive measure. Our main result is a proof of the Cullen–Norbury–Purser conjecture in Theorem 3.1; we make no restriction on the fluid configuration. We approximate functions that fail the nondegeneracy condition by a sequence of functions which satisfy it, and take appropriate limits. Uniqueness of the energy minimizer is recovered by properties of the monotone rearrangement.

The theory of rearrangements of vector valued functions is a new research area; recent advances have been made by Brenier [2]. In comparison, the theory of rearrangements of scalar valued functions is well developed; for example see Burton [3] and Alvino, Lions, and Trombetti [1]. Some results for scalar valued rearrangements do not have vector valued equivalents. For example, the monotone rearrangement of a vector valued function does not satisfy some of the inequalities which hold for the increasing rearrangement of a real valued function. (See Brenier [2] for details.) Moreover, scalar valued rearrangement of the components of a vector valued function does not imply vector valued rearrangement, although the converse is true. (See the appendix for details.)

2. Equivalent definitions of rearrangement of vector valued functions.

2.1. Introduction. In this section we establish four equivalent definitions of rearrangement for vector valued functions. We define rearrangement for vector valued functions on finite measure spaces (U, μ) which are isomorphic to $(0, \mu(U))$ endowed with Lebesgue measure λ. By isomorphic we mean there exists a measure preserving transformation $T : U \to (0, \mu(U))$. We recall the definition of measure preserving transformation in the next section. The restriction to finite measure spaces (U, μ) isomorphic to $(0, \mu(U))$ with Lebesgue measure is not severe; Royden [14] yields that any separable complete metric space U, equipped with a Borel measure μ such that $\mu(U) < \infty$ and $\mu(\{x\}) = 0$ for each $x \in U$, is isomorphic to $((0, \mu(U)), \lambda)$.

DEFINITION 2.1. *Let (U, μ) be a measure space which is isomorphic to $((0, \mu(U)), \lambda)$. Let $f, g \in L^p(U, \mu, \mathbf{R}^d)$ for $1 \le p < \infty$. Then f is a* rearrangement *of g if*

$$\mu\left(f^{-1}(B)\right) = \mu\left(g^{-1}(B)\right) \tag{2.1}$$

for every Borel subset B of $\mathbf{R}^d$.

We prove the following theorem.

THEOREM 2.2. *Let (U, μ) be as above. Let $f, g \in L^p(U, \mu, \mathbf{R}^d)$ for $1 \le p < \infty$. Then the following are equivalent.*

(i) *f is a rearrangement of g.*

(ii) *For each $F \in C(\mathbf{R}^d)$ such that $|F(\xi)| \leq K(1 + |\xi|_2^p)$ (where $|.|_2$ denotes Euclidean distance on $\mathbf{R}^d$, and K is a constant), the following equation is satisfied:*

$$\int_U F(f(x))d\mu(x) = \int_U F(g(x))d\mu(x). \tag{2.2}$$

(iii) *$\mu(f^{-1}(C)) = \mu(g^{-1}(C))$ for each set $C \in \{\prod_{i=1}^d [\alpha_i, \infty) : \alpha_i \in \mathbf{R}$ for each $i = 1, ..., d\} \bigcup \{\emptyset, \mathbf{R}^d\}$.*

(iv) *For each $\sigma \in \mathbf{R}^d$, $\alpha > 0$,*

$$\int_U (|g - \sigma|_\infty - \alpha)_+ d\mu = \int_U (|f - \sigma|_\infty - \alpha)_+ d\mu, \tag{2.3}$$

where $|.|_\infty$ denotes the infinity norm on $\mathbf{R}^d$, and the $+$ subscript denotes the positive part of the function.

Brenier [2] used property (ii) to define rearrangement of vector valued functions, while Cullen, Norbury, and Purser [6] used property (iii). This theorem shows that their definitions are equivalent. Property (iv) is a vector valued extension of the characterization of the set of rearrangements of a given real valued function by Eydeland, Spruck, and Turkington [7]. It may be shown that $R(f_0)$ is closed, and it follows from (iv) that for $w \in R(f_0)$, $\|w\|_p = \|f_0\|_p$, where

$$\|w\|_p = \left\{ \int_U |w|_\infty^p d\mu \right\}^{\frac{1}{p}}. \tag{2.4}$$

We omit the proofs, which are elementary.

2.2. Measure preserving mappings and transformations. We recall the concept of a measure preserving mapping.

DEFINITION 2.3. *A* measure preserving mapping *from a finite measure space (U, μ) to a measure space (V, ν) with $\mu(U) = \nu(V)$ is a mapping $s : U \to V$ such that for each ν-measurable set $A \subset V$, $\mu(s^{-1}(A)) = \nu(A)$.*

If a measure preserving mapping maps its domain to a measurable set, then it is surjective (up to a set of measure zero) but not necessarily injective. If a measure preserving mapping s is injective (up to a set of measure zero), and s maps μ-measurable sets to ν-measurable sets, then s^{-1} exists (almost everywhere) and is a measure preserving mapping. Such an s is called a *measure preserving transformation.*

2.3. A preliminary result.

LEMMA 2.4. *Let f, g be as in Theorem* 2.2. *Define*

$$\mathcal{M} = \{A \subset \mathbf{R}^d : \mu(f^{-1}(A)) = \mu(g^{-1}(A))\}, \tag{2.5}$$

$$H = \left\{ \prod_{i=1}^d [a_i, b_i] : a_i, b_i \in \mathbf{R}, a_i \leq b_i \text{ for } i = 1, ..., d \right\} \bigcup \{\emptyset, \mathbf{R}^d\}. \tag{2.6}$$

Suppose $H \subset \mathcal{M}$. Then $\mathcal{M}$ contains the Borel sets of $\mathbf{R}^d$.

Proof. Let $B_{cd}(H)$ denote the smallest family of sets which contains H that is closed under countable disjoint union and complementation (relative to $\mathbf{R}^d$). H is closed under finite intersection; therefore Kechris [11, page 65, Theorem 10.1(iii)]

yields that $B_{cd}(H)$ is a σ-algebra. H generates the Borel sets; therefore it follows that the Borel sets are contained in $B_{cd}(H)$. $\mathcal{M}$ is closed under countable disjoint union and complementation (relative to $\mathbf{R}^d$). Given that $H \subset \mathcal{M}$, we have $B_{cd}(H) \subset B_{cd}(\mathcal{M}) = \mathcal{M}$, so $\mathcal{M}$ contains the Borel sets. This completes the proof. □

2.4. Proof of Theorem 2.2. We begin by showing that (i) implies (ii). Let $F \in C(\mathbf{R}^d)$ satisfy $|F(\xi)| \leq K\{1 + |\xi|_2^p\}$ for each $\xi \in \mathbf{R}^d$, where K is some constant. We assume that F is nonnegative. (If not, we work with the positive and negative parts of F.) F is continuous; therefore we can choose a sequence of nonnegative functions (φ_n), each φ_n a finite linear combination of indicator functions of Borel sets, with $\varphi_n(\xi) \leq \varphi_{n+1}(\xi)$ and $\varphi_n(\xi) \to F(\xi)$ for each $\xi \in \mathbf{R}^d$. It follows from (i) that

$$\int_U \varphi_n(f(x))d\mu(x) = \int_U \varphi_n(g(x))d\mu(x) \tag{2.7}$$

for each $n \in \mathbf{N}$. Applying the dominated convergence theorem we obtain

$$\int_U F(f(x))d\mu(x) = \lim_{n\to\infty} \int_U \varphi_n(f(x))d\mu(x) \tag{2.8}$$

$$= \lim_{n\to\infty} \int_U \varphi_n(g(x))d\mu(x) \tag{2.9}$$

$$= \int_U F(g(x))d\mu(x). \tag{2.10}$$

This verifies (ii).

We show that (ii) implies (i). Let families of sets H and $\mathcal{M}$ be as in Lemma 2.4. Let $H_1 \in H$. There exists a sequence $(\varphi_n) \subset C(\mathbf{R}^d)$ such that $|\varphi_n(y)| \leq 1 + |y|_2^p$ for each $y \in \mathbf{R}^d$ and $n \in \mathbf{N}$, with $\varphi_n(y) \to 1_{H_1}(y)$ for each $y \in \mathbf{R}^d$. Noting that (ii) holds, we apply the dominated convergence theorem to obtain

$$\mu(f^{-1}(H_1)) = \int_U 1_{H_1} \circ f(x)d\mu(x) \tag{2.11}$$

$$= \lim_{n\to\infty} \int_U \varphi_n \circ f(x)d\mu(x) \tag{2.12}$$

$$= \lim_{n\to\infty} \int_U \varphi_n \circ g(x)d\mu(x) \tag{2.13}$$

$$= \int_U 1_{H_1} \circ g(x)d\mu(x) = \mu(g^{-1}(H_1)). \tag{2.14}$$

Thus $H_1 \in \mathcal{M}$. It follows that $H \subset \mathcal{M}$. Lemma 2.4 yields that $\mathcal{M}$ contains the Borel sets of $\mathbf{R}^d$; therefore f and g are rearrangements.

(i) implies (iii) is immediate. To see the converse, we show that $H \subset \mathcal{M}$, given that (iii) holds. We proceed by induction. Let $\mathcal{P}(k)$ be the proposition that all sets of the form $\prod_{i=1}^k [a_i, b_i] \times \prod_{i=k+1}^d [a_i, \infty) \in \mathcal{M}$, where $a_i, b_i \in \mathbf{R}$. We demonstrate $\mathcal{P}(1)$. Now

$$[a_1, b_1] \times \prod_{i=2}^d [a_i, \infty) = \prod_{i=1}^d [a_i, \infty) \Bigg\backslash \left(\bigcup_{n=1}^\infty \left([b_1 + 1/n, \infty) \times \prod_{i=2}^d [a_i, \infty) \right) \right), \tag{2.15}$$

and, noting that $\mathcal{M}$ is closed under countable increasing union and differences of two ordered elements (with respect to the partial order $\subset$), we obtain that $[a_1, b_1] \times$

$\prod_{i=2}^{d}[a_i,\infty) \in \mathcal{M}$. This shows $\mathcal{P}(1)$. We demonstrate that $\mathcal{P}(k+1)$ is true given that $\mathcal{P}(k)$ holds. We have that

(2.16)

$$\prod_{i=1}^{k+1}[a_i,b_i] \times \prod_{i=k+2}^{d}[a_i,\infty) = \prod_{i=1}^{k}[a_i,b_i] \times \prod_{i=k+1}^{d}[a_i,\infty) \setminus \left(\bigcup_{n=1}^{\infty} \left(\prod_{i=1}^{k}[a_i,b_i] \times [b_{k+1}+1/n,\infty) \times \prod_{i=k+2}^{d}[a_i,\infty) \right) \right).$$

We are given that $\mathcal{P}(k)$ holds; therefore $\prod_{i=1}^{k}[a_i,b_i] \times \prod_{i=k+1}^{d}[a_i,\infty) \in \mathcal{M}$, and $\prod_{i=1}^{k}[a_i,b_i] \times [b_{k+1}+1/n,\infty) \times \prod_{i=k+2}^{d}[a_i,\infty) \in \mathcal{M}$ for each $n \in \mathbf{N}$. It follows that $\prod_{i=1}^{k+1}[a_i,b_i] \times \prod_{i=k+2}^{d}[a_i,\infty) \in \mathcal{M}$. This verifies $\mathcal{P}(k+1)$. By induction $\mathcal{P}(d)$ holds, that is, all sets of the form $\prod_{i=1}^{d}[a_i,b_i] \in \mathcal{M}$ for $a_i, b_i \in \mathbf{R}$, $i = 1, ..., d$. It is immediate that $\emptyset, \mathbf{R}^d \in \mathcal{M}$; therefore $H \subset \mathcal{M}$. Lemma 2.4 yields that $\mathcal{M}$ contains the Borel sets of $\mathbf{R}^d$. This shows (i).

Let (iv) hold. The characterization of the set of rearrangements of a scalar valued function by Eydeland, Spruck, and Turkington [7] yields that $|g-\sigma|_\infty \in R(|f-\sigma|_\infty)$ in the scalar valued sense for each $\sigma \in \mathbf{R}^d$. It follows that $\mu(g^{-1}(C_\alpha(\sigma))) = \mu(f^{-1}(C_\alpha(\sigma)))$ for each $\alpha > 0$, where $C_\alpha(\sigma)$ denotes the open cube of side 2α about $\sigma \in \mathbf{R}^d$. Let K denote the set of all d-dimensional open cubes. We have shown that $K \subset \mathcal{M}$. We now demonstrate that this implies that all open subsets of $\mathbf{R}^d$ belong to $\mathcal{M}$. Recall that $\mathcal{M}$ is closed under countable decreasing intersections, increasing countable unions, and differences of ordered elements of $\mathcal{M}$. For $j = 0, \ldots, d$, every j-dimensional closed cube is a countable decreasing intersection of j-dimensional open cubes. Further, for $j = 1, \ldots, d$ every j-dimensional open cube with one $(j-1)$-dimensional open face attached is an increasing countable union of j-dimensional closed cubes. Now, for $j = 1, ..., d$, every $(j-1)$-dimensional open cube is the difference of a set of the type described in the preceding sentence and a j-dimensional open cube contained in it. It follows by induction that open and closed cubes of dimensions $0, \ldots, d$ belong to $\mathcal{M}$. Every open subset of $\mathbf{R}^d$ is a countable disjoint union of open cubes of dimensions $0, \ldots, d$; therefore such sets belong to $\mathcal{M}$. The methods of Lemma 2.4 (noting that the intersection of two open sets is open) yield that $\mathcal{M}$ contains the Borel sets. Thus (iv) implies (i). The converse follows because (i) implies that $\mu(g^{-1}(C_\alpha(\sigma))) = \mu(f^{-1}(C_\alpha(\sigma)))$ for each positive $\alpha \in \mathbf{R}$, $\sigma \in \mathbf{R}^d$. This completes the proof. □

3. Energy minimizing solutions of atmospheric and oceanic flow.

3.1. Introduction. This section studies a variational problem over the set of rearrangements of a prescribed vector valued function, which arises from an energy minimizing principle. We study the semigeostrophic equations (recalled in the next section), a standard model for slowly varying flows constrained by rotation and stratification, using the methods of Cullen, Norbury, and Purser [6]. At any given time, $\mathbf{X}$, which describes the state of the fluid, is known on particles. The *Cullen–Norbury–Purser* principle states that for a solution, the particles are arranged to minimize geostrophic energy. This yields a variational problem: minimize energy over the set of rearrangements of a prescribed fluid configuration. We verify the conjecture of

Cullen, Norbury, and Purser [6, section 5] that the energy minimum is uniquely attained and that the minimizer is equal to the gradient of a convex function. We prove the following theorem.

THEOREM 3.1. *Let Ω be a bounded, connected, closed subset of $\mathbf{R}^3$, with smooth boundary. Define, for $\mathbf{X} = (X, Y, Z) \in L^p(\Omega, \mu, \mathbf{R}^3)$, where $2 \le p < \infty$ and μ denotes three-dimensional Lebesgue measure,*

$$E(\mathbf{X}) = \frac{1}{2}\int_\Omega X^2 + x^2 + Y^2 + y^2 d\mu(\mathbf{x}) - \int_\Omega \mathbf{X}.\mathbf{x} d\mu(\mathbf{x}), \tag{3.1}$$

where $\mathbf{x} = (x, y, z) \in \Omega$. Suppose $\mathbf{X_0} \in L^p(\Omega, \mu, \mathbf{R}^3)$ for p as above. Then there exists $\mathbf{X_0}^* \in R(\mathbf{X_0})$ such that

(i) *$E(\mathbf{X_0}^*) < E(\mathbf{X})$ for each $\mathbf{X} \in R(\mathbf{X_0})\backslash\{\mathbf{X_0}^*\}$.*
(ii) *$\mathbf{X_0}^* = \nabla\Psi$ for some convex function $\Psi \in W^{1,p}(\Omega)$.*
(iii) *$\mathbf{X_0}^*$ is a cyclically monotone function.*

The functional E represents the geostrophic energy of the fluid. We define E and $\mathbf{X}$ in the next section. The unique energy minimizer is the monotone rearrangement of the prescribed function: this concept was introduced by Brenier [2] and is recalled in section 3.3. The proof uses an approximation argument, with the strict inequality following by the uniqueness of the monotone rearrangement.

3.2. The semigeostrophic equations, and the Cullen–Norbury–Purser principle. We state the three-dimensional Boussinesq equations of semigeostrophic theory on an f plane. These are a standard model for slowly varying flows constrained by rotation and stratification and are used to study front formation in meteorology. We state the equations in the form used by Hoskins [10].

$$\frac{Du_g}{Dt} - fv_{ag} = 0, \qquad \frac{Dv_g}{Dt} + fu_{ag} = 0, \tag{3.2}$$

$$\frac{D\theta}{Dt} = 0, \tag{3.3}$$

$$\nabla.\mathbf{u} = 0, \tag{3.4}$$

$$\nabla\phi = \left(fv_g, -fu_g, \frac{g\theta}{\theta_0}\right), \tag{3.5}$$

where

$$\begin{aligned} \mathbf{u} &\equiv (u, v, w) \equiv \mathbf{u_g} + \mathbf{u_{ag}}, \\ \mathbf{u_g} &\equiv (u_g, v_g, 0), \\ \frac{D}{Dt} &\equiv \frac{\partial}{\partial t} + \mathbf{u}.\nabla, \end{aligned} \tag{3.6}$$

f is the Coriolis parameter, assumed constant, g denotes the acceleration due to gravity, θ_0 is a reference value of the potential temperature θ, and ϕ is a pressure variable. Subscripts g and ag denote geostrophic and ageostrophic velocity (or wind) components, respectively, where the geostrophic velocity is defined to be the horizontal component of velocity in balance with the pressure gradient. This definition

is included in equation (3.5), as is the statement of hydrostatic balance. We solve the equations (for the velocity $\mathbf{u}$) in a closed, bounded, connected set $\Omega \subset \mathbf{R}^3$, with normal velocity $\mathbf{u}.\mathbf{n}$ given on $\partial\Omega$. For $\mathbf{x} = (x, y, z) \in \Omega$, by making the substitution

$$\mathbf{X} \equiv (X, Y, Z) \equiv (x + v_g/f, y - u_g/f, (g/f^2\theta_0)\theta), \tag{3.7}$$

it is shown in Purser and Cullen [13] that we may replace (3.2) and (3.3) by

$$\frac{D\mathbf{X}}{Dt} = \mathbf{u_g}. \tag{3.8}$$

We think of $\mathbf{X}$ as a function of the physical space coordinates $\mathbf{x}$. Rewriting in terms of $\mathbf{X}$ and $\mathbf{x}$, we have

$$\frac{DX}{Dt} = f(y - Y), \tag{3.9}$$

$$\frac{DY}{Dt} = f(X - x), \tag{3.10}$$

$$\frac{DZ}{Dt} = 0. \tag{3.11}$$

The geostrophic energy E is defined as

$$E = \int_\Omega \frac{1}{2}u_g^2 + \frac{1}{2}v_g^2 - \frac{g\theta z}{\theta_0} d\mu(\mathbf{x}) \tag{3.12}$$

$$= f^2\frac{1}{2}\int_\Omega X^2 + x^2 + Y^2 + y^2 d\mu(\mathbf{x}) - f^2\int_\Omega \mathbf{x}.\mathbf{X} d\mu(\mathbf{x}). \tag{3.13}$$

Henceforth we ignore the constant f^2. At any fixed time t, $\mathbf{X}$ is found on particles by predicting (X, Y, Z) on particles using equations (3.9), (3.10), and (3.11). The *Cullen–Norbury–Purser* principle states that for a solution, the particles are arranged to minimize geostrophic energy. Suppose one possible state of the fluid is described by values $\mathbf{X_0} = (X_0, Y_0, Z_0)$ which are known on particles. The Cullen–Norbury–Purser principle yields the energy minimization problem

$$\inf_{\mathbf{X}\in R(\mathbf{X_0})} E(\mathbf{X}), \tag{3.14}$$

where the energy minimizer (if it exists and is unique) gives the actual state of the fluid. In this way, solutions can be viewed as a sequence of minimum energy states.

We make some (physically reasonable) assumptions to enable us to use vector valued rearrangement theory. Let Ω be a closed, bounded, connected subset of $\mathbf{R}^3$, with smooth boundary. Suppose the possible fluid configuration $\mathbf{X_0} \in L^p(\Omega, \mu, \mathbf{R}^3)$, for $2 \le p < \infty$, where μ denotes three-dimensional Lebesgue measure. (Choosing $p \ge 2$ ensures finite geostrophic energy.)

3.3. Monotone rearrangement of vector valued functions. We recall the concept of the monotone rearrangement of a vector valued function: essentially, this is the vector valued analogue of the increasing rearrangement of a real valued function. Let Ω and μ be as in the last paragraph of the previous section. The following theorem is due to Brenier [2, section 1.2, Theorem 1.1].

THEOREM 3.2. *For each $u \in L^p(\Omega, \mu, \mathbf{R}^3)$, where $1 \le p < \infty$, there is a unique $u^* \in R(u)$ such that*

$$u^* \in \{\nabla\Psi : \Psi \in W^{1,p}(\Omega, \mu), \Psi \text{ convex}\}, \tag{3.15}$$

and the mapping $u \to u^*$ is continuous.

When Ω is not convex, Ψ is understood to be the restriction to Ω of a convex function defined on $\mathbf{R}^3$. We call u^* the *monotone rearrangement of* u. The name comes from the fact that u^* is a cyclically monotone function. We note that McCann [12] has generalized the first part of this result (concerning the existence of an essentially unique rearrangement equal to the gradient of a convex function) to more general measures than Lebesgue measure, and has removed the restriction that Ω must be closed, connected, and have smooth boundary.

DEFINITION 3.3. *A function $u \in L^p(\Omega, \mu, \mathbf{R}^3)$ is* nondegenerate *if $\mu(u^{-1}(E)) = 0$ for each set $E \subset \mathbf{R}^3$ with Lebesgue measure zero. We say that a function which fails to be nondegenerate is* degenerate.

Brenier established further properties of the monotone rearrangement of a nondegenerate function in the following theorem [2, section 1.2, Theorem 1.2]

THEOREM 3.4. *For each nondegenerate $u \in L^p(\Omega, \mu, \mathbf{R}^3)$, there exists a unique pair (u^*, s), where u^* is the monotone rearrangement of u and s is a measure preserving mapping from (Ω, μ) to (Ω, μ) such that*

(i) *$u = u^* \circ s$.*

(ii) *s is the unique measure preserving mapping that maximizes $\int_\Omega u(\mathbf{x}).s(\mathbf{x})d\mu(\mathbf{x})$.*

An elementary proof of the above result was found by Gangbo [8]. Note that Theorem 3.4 is not true if u has a level set of positive measure: the measure preserving mapping is not unique, nor do we have uniqueness in property (ii). Such a u is degenerate. The author is not aware of any corresponding result for degenerate functions.

3.4. Existence and uniqueness of an energy minimizer. Recall that we are studying the energy minimization problem

$$\inf_{\mathbf{X} \in R(\mathbf{X_0})} \frac{1}{2} \int_\Omega x^2 + X^2 + y^2 + Y^2 d\mu(\mathbf{x}) - \int_\Omega \mathbf{x}.\mathbf{X} d\mu(\mathbf{x}), \tag{3.16}$$

where $\mathbf{X_0} \in L^p(\Omega, \mu, \mathbf{R}^3)$ for $2 \le p < \infty$, and $\mathbf{X} = (X, Y, Z)$. We show that the first integral is conserved under rearrangements.

LEMMA 3.5. *Let $\mathbf{X_0}$ be as in Theorem* 3.1. *Let $\mathbf{X_1} \in R(\mathbf{X_0})$. Then*

$$\int_\Omega x^2 + X_1^2 + y^2 + Y_1^2 d\mu(\mathbf{x}) = \int_\Omega x^2 + X_0^2 + y^2 + Y_0^2 d\mu(\mathbf{x}), \tag{3.17}$$

where $\mathbf{X_0} = (X_0, Y_0, Z_0)$ and $\mathbf{X_1} = (X_1, Y_1, Z_1)$.

Proof. $\mathbf{X_1} \in R(\mathbf{X_0})$ implies that $X_1 \in R(X_0)$. It follows that

$$\int_\Omega X_1^2 d\mu(\mathbf{x}) = \int_\Omega X_0^2 d\mu(\mathbf{x}). \tag{3.18}$$

A similar result holds for Y_0 and Y_1. The result follows. □

To show that there is a unique energy minimizer, it remains to show that

$$\sup_{\mathbf{X} \in R(\mathbf{X_0})} \int_\Omega \mathbf{x}.\mathbf{X} d\mu(\mathbf{x}) \tag{3.19}$$

is uniquely attained. If $\mathbf{X_0}$ is nondegenerate, the result follows easily using Theorem 3.4. Our method of proof is to approximate degenerate functions with a sequence of nondegenerate functions. This shows that the monotone rearrangement is an energy

minimizer. We demonstrate that an energy minimizer is the gradient of a convex function: the monotone rearrangement is the unique such amongst the set of rearrangements; therefore the result follows.

LEMMA 3.6. *Let* $\mathbf{X} \in L^p(\Omega, \mu, \mathbf{R}^3)$ (*where* Ω, μ, *and* p *are as in section* 3.2). *Then there exists a sequence of nondegenerate functions* $(\mathbf{X_n})$ *such that* $\mathbf{X_n} \to \mathbf{X}$ *in* $L^p(\Omega, \mu, \mathbf{R}^3)$.

Proof. For each $n \in \mathbf{N}$, choose a simple function φ_n such that $\|\mathbf{X} - \varphi_n\|_p \leq 1/n$. Now for each $n \in \mathbf{N}$, define $\mathbf{X_n}$ by $\mathbf{X_n}(\mathbf{x}) = \varphi_n(\mathbf{x}) + (1/n)\mathbf{x}$ for $\mathbf{x} \in \Omega$. It is immediate that $\mathbf{X_n} \to \mathbf{X}$ in $L^p(\Omega, \mu, \mathbf{R}^3)$. It remains to show that $\mathbf{X_n}$ is nondegenerate for each $n \in \mathbf{N}$. Fix $n \in \mathbf{N}$. φ_n is a simple function; therefore it takes finitely many values which we enumerate $\{\mathbf{b_1}, \mathbf{b_2}, ..., \mathbf{b_m}\}$. Define $A_i = {\varphi_n}^{-1}(\mathbf{b_i})$ for each $i = 1, ..., m$. Write ${\mathbf{X_n}}^i$ for $\mathbf{X_n}|_{A_i}$. For a given i, ${\mathbf{X_n}}^i = \mathbf{b_i} + (1/n)\mathbf{x}$. Let E be a Lebesgue negligible subset of $\mathbf{R}^3$. Then

$$\mu\left(({\mathbf{X_n}}^i)^{-1}(E)\right) = \mu\left(A_i \bigcap (nE - n\mathbf{b_i})\right) \tag{3.20}$$

$$\leq \mu(nE - n\mathbf{b_i}) \tag{3.21}$$

$$= \mu(nE) = 0. \tag{3.22}$$

By way of explanation, we used translation invariance of Lebesgue measure to obtain the first equality in (3.22), and used properties of Lebesgue measure to obtain the second. This demonstrates that ${\mathbf{X_n}}^i$ is nondegenerate (as an element in $L^p(A_i, \mu, \mathbf{R}^3)$) for each $i = 1, ..., m$.

Let E be a Lebesgue negligible subset of $\mathbf{R}^3$. Then

$$\mu\left({\mathbf{X_n}}^{-1}(E)\right) = \mu\left(\bigcup_{i=1}^{m} ({\mathbf{X_n}}^i)^{-1}(E)\right) \tag{3.23}$$

$$= \sum_{i=1}^{m} \mu\left(({\mathbf{X_n}}^i)^{-1}(E)\right) = 0. \tag{3.24}$$

To obtain (3.24) we used the countable additivity of μ and the fact that ${\mathbf{X_n}}^i$ is nondegenerate for each $i = 1, ..., m$. This shows that $\mathbf{X_n}$ is nondegenerate and completes the proof. □

LEMMA 3.7. *Let* $\mathbf{X_0}$ *be as in Theorem* 3.1. *Then*

$$\int_\Omega {\mathbf{X_0}}^*(\mathbf{x}).\mathbf{x} d\mu(\mathbf{x}) \geq \int_\Omega \mathbf{X}(\mathbf{x}).s(\mathbf{x}) d\mu(\mathbf{x}) \tag{3.25}$$

for each $\mathbf{X} \in R(\mathbf{X_0})$ *and each* $s : \Omega \to \Omega$ *a measure preserving mapping.*

Proof. Let $\mathbf{X} \in R(\mathbf{X_0})$ and let $s : \Omega \to \Omega$ be a measure preserving mapping. From the previous lemma we may choose a sequence $(\mathbf{X_n})$ of nondegenerate functions such that $\mathbf{X_n} \to \mathbf{X}$ in $L^p(\Omega, \mu, \mathbf{R}^3)$. For each $n \in \mathbf{N}$, Theorem 3.4(i) yields the existence of a unique measure preserving mapping $s_n : \Omega \to \Omega$ such that $\mathbf{X_n} = {\mathbf{X_n}}^* \circ s_n$. Applying Theorem 3.2 we have ${\mathbf{X_n}}^* \to \mathbf{X}^* = {\mathbf{X_0}}^*$. Now

$$\int_\Omega {\mathbf{X_0}}^*(\mathbf{x}).\mathbf{x} d\mu(\mathbf{x}) = \lim_{n\to\infty} \int_\Omega {\mathbf{X_n}}^*(\mathbf{x}).\mathbf{x} d\mu(\mathbf{x}) \tag{3.26}$$

$$= \lim_{n\to\infty} \int_\Omega {\mathbf{X_n}}^* \circ s_n(\mathbf{x}).s_n(\mathbf{x}) d\mu(\mathbf{x}) \tag{3.27}$$

$$= \lim_{n\to\infty} \int_\Omega \mathbf{X_n}(\mathbf{x}).s_n(\mathbf{x}) d\mu(\mathbf{x}) \tag{3.28}$$

$$\geq \lim_{n\to\infty} \int_\Omega \mathbf{X_n}(\mathbf{x}).s(\mathbf{x})d\mu(\mathbf{x}) \tag{3.29}$$

$$= \int_\Omega \mathbf{X}(\mathbf{x}).s(\mathbf{x})d\mu(\mathbf{x}) \tag{3.30}$$

as required. By way of explanation, (3.27) holds because s_n is a measure preserving map, and (3.29) follows because Theorem 3.4(ii) yields that

$$\int_\Omega \mathbf{X_n}(\mathbf{x}).s_n(\mathbf{x})d\mu(\mathbf{x}) \geq \int_\Omega \mathbf{X_n}(\mathbf{x}).s(\mathbf{x})d\mu(\mathbf{x}) \tag{3.31}$$

for each measure preserving mapping $s : \Omega \to \Omega$ and for each $n \in \mathbf{N}$. This completes the proof. □

LEMMA 3.8. *Let* $\mathbf{X_0}$ *be as in Theorem* 3.1. *Then*

$$\int_\Omega \mathbf{X_0}^*(\mathbf{x}).\mathbf{x}d\mu(\mathbf{x}) > \int_\Omega \mathbf{X}(\mathbf{x}).\mathbf{x}d\mu(\mathbf{x}) \tag{3.32}$$

for each $\mathbf{X} \in R(\mathbf{X_0})\backslash\{\mathbf{X_0}^*\}$.

Proof. Applying the previous lemma for the identity mapping, we have

$$\int_\Omega \mathbf{X_0}^*(\mathbf{x}).\mathbf{x}d\mu(\mathbf{x}) \geq \int_\Omega \mathbf{X}(\mathbf{x}).\mathbf{x}d\mu(\mathbf{x}) \tag{3.33}$$

for each $\mathbf{X} \in R(\mathbf{X_0})\backslash\{\mathbf{X_0}^*\}$. It remains to show strict inequality. Suppose there exists $\mathbf{X_1} \in R(\mathbf{X_0})$ such that $\int_\Omega \mathbf{X_1}.\mathbf{x}d\mu = \int_\Omega \mathbf{X_0}^*.\mathbf{x}d\mu$. Applying the previous lemma to $\mathbf{X_1} \in R(\mathbf{X_0})$ we obtain

$$\int_\Omega \mathbf{X_1}(\mathbf{x}).\mathbf{x}d\mu(\mathbf{x}) = \int_\Omega \mathbf{X_0}^*(\mathbf{x}).\mathbf{x}d\mu(\mathbf{x}) \tag{3.34}$$

$$\geq \int_\Omega \mathbf{X_1}(\mathbf{x}).s(\mathbf{x})d\mu(\mathbf{x}) \tag{3.35}$$

for each measure preserving mapping $s : \Omega \to \Omega$. Brenier [2, Proposition 2.1] yields that $\mathbf{X_1} \in \{\nabla\Psi : \Psi \in W^{1,2}(\Omega), \Psi \text{ convex}\}$. However Theorem 3.2 states that $\mathbf{X_0}^*$ is the unique member of $R(\mathbf{X_0})$ belonging to $\{\nabla\Psi : \Psi \in W^{1,2}(\Omega), \Psi \text{ convex}\}$; therefore $\mathbf{X_1} = \mathbf{X_0}^*$. This completes the proof. □

Proof of Theorem 3.1. The proof follows from Lemmas 3.5 and 3.8. □

Note added in revision. We can rewrite an equivalent minimization problem

$$\inf_{\mathbf{X}\in R(\mathbf{X_0})} \int_\Omega |\mathbf{X}(\mathbf{x}) - \mathbf{x}|^2 d\mu(\mathbf{x}), \tag{3.36}$$

where $|\mathbf{X}(\mathbf{x}) - \mathbf{x}|^2 = (\mathbf{X}(\mathbf{x}) - \mathbf{x}).(\mathbf{X}(\mathbf{x}) - \mathbf{x})$, as a Monge mass transport problem as follows. Define $\nu(S) = \mu(\mathbf{X_0}^{-1}(S))$ for (Borel) subsets of $\mathbf{R}^3$, and rewrite (3.36) as

$$\inf_{s\in S} \int_\Omega c(\mathbf{x}, s(\mathbf{x}))d\mu(\mathbf{x}), \tag{3.37}$$

where S is the set of measure preserving mappings between (Ω, μ) and $(\mathbf{R}^3, \nu)$, and the *cost function* $c : \mathbf{R}^3 \times \mathbf{R}^3 \to \mathbf{R}$ is defined by $c(\mathbf{x}, \mathbf{y}) = |\mathbf{x} - \mathbf{y}|^2$. (Note that $\mathbf{X_0}$ is nondegenerate if and only if ν is absolutely continuous with respect to Lebesgue measure.) Gangbo and McCann [9] showed that (3.37) has a unique minimizer by proving the existence of a unique minimizer (which has a particular form) of an appropriate Monge–Kantorovich problem. An extensive review of Monge–Kantorovich problems may be found in Cuesta-Albertos et al. [4]. This paper, developed independently, does not use this approach.

Appendix. We consider the relationship between vector valued functions which are rearrangements and vector valued functions for which corresponding components are rearrangements in the scalar valued sense. Let f, g be as in the opening paragraph of the introduction. Define, for $i = 1, ..., d$, $\Pi_i : \mathbf{R}^d \to \mathbf{R}$ to be the projection of the ith component of an element of $\mathbf{R}^d$. Write $f = (f_1, ..., f_d)$ and $g = (g_1, ..., g_d)$, where $f_i = \Pi_i \circ f$, $g_i = \Pi_i \circ g$ for $i = 1, ..., d$. The definition of vector valued rearrangement yields that if $f \in R(g)$, we have $f_i \in R(g_i)$ for each $i = 1, ..., d$ in the scalar valued sense. However, the converse is false in general. Let $f : [0,1]^2 \to \mathbf{R}^2$ be defined by

$$f(x) = \begin{cases} (1,1) & \text{if } x \in [1/2,1] \times [1/2,1], \\ (0,0) & \text{if } x \notin [1/2,1] \times [1/2,1]. \end{cases}$$

Then

$$f_1(x) = f_2(x) = \begin{cases} 1 & \text{if } x \in [1/2,1] \times [1/2,1], \\ 0 & \text{if } x \notin [1/2,1] \times [1/2,1]. \end{cases}$$

Define

$$g(x) = \begin{cases} (1,0) & \text{if } x \in [1/2,1] \times [1/2,1], \\ (0,1) & \text{if } x \in [0,1/2] \times [1/2,1], \\ (0,0) & \text{otherwise.} \end{cases}$$

Then $g_1 = f_1$ and

$$g_2(x) = \begin{cases} 1 & \text{if } x \in [0,1/2] \times [1/2,1], \\ 0 & \text{if } x \notin [0,1/2] \times [1/2,1]. \end{cases}$$

It is easily seen that $f_i \in R(g_i)$ for $i = 1, 2$, but $f \notin R(g)$. Consequently, in general we cannot apply scalar valued rearrangement theorems to components of vector valued functions and hope to obtain results pertaining to vector valued rearrangements.

STABILIZATION OF VORTICES IN THE GINZBURG–LANDAU EQUATION WITH A VARIABLE DIFFUSION COEFFICIENT*

XU-YAN CHEN†, SHUICHI JIMBO‡, AND YOSHIHISA MORITA§

Abstract. We study equilibria of the Ginzburg–Landau equation with a variable diffusion coefficient on a bounded planar domain subject to the Neumann boundary condition. It has been previously shown that if the diffusion coefficient is constant and the ambient domain is convex, the system does not carry stable vortices in the sense that any stable equilibrium solution is a constant of modulus 1. In this article we shall prove that arbitrarily given a domain, an appropriate choice of inhomogeneous diffusion coefficient yields a stable equilibrium solution having vortices. We can even manage to make the configuration of stable vortices close to prescribed locations. Our method is to minimize the free energy functional in suitably constructed positive invariant regions for the time-dependent Ginzburg–Landau equation.

Key words. Ginzburg–Landau equation, variable diffusion, vortex, stable solution

1. Introduction.

The Ginzburg–Landau equation for a complex order parameter is a nonlinear partial differential equation arising in a macroscopic description of superconductivity (see [6]). One of the important phenomena explained particularly well by the model is the formation of topological defects or *vortices* (i.e., zeros of the complex order parameter); this has received extensive mathematical analysis in recent years (see [1, 2, 4, 14]).

In this article we are concerned with the next Ginzburg–Landau equation with a variable diffusion coefficient in a bounded domain Ω in $\mathbb{R}^2$ with the Neumann boundary condition

$$\begin{cases} \operatorname{div}(a(x)\nabla\Phi) + (1-|\Phi|^2)\Phi = 0 & \text{in} \quad \Omega, \\ \dfrac{\partial\Phi}{\partial\nu} = 0 & \text{on} \quad \partial\Omega, \end{cases} \tag{1.1}$$

where $a(x)$ is a positive smooth function, ν is the unit outward normal vector on $\partial\Omega$, and the unknown Φ is a complex valued function representing the order parameter in the superconductor model. A solution to this equation gives an equilibrium of the

evolution equation

$$\text{(1.2)}\qquad \begin{cases} \dfrac{\partial \Phi}{\partial t} = \operatorname{div}(a(x)\nabla\Phi) + (1-|\Phi|^2)\Phi & \text{in} \quad (0,\infty)\times\Omega, \\ \dfrac{\partial \Phi}{\partial \nu} = 0 & \text{on} \quad (0,\infty)\times\partial\Omega. \end{cases}$$

Equation (1.1) can also be considered as the Euler–Lagrange equation of the Ginzburg–Landau free energy functional

$$\text{(1.3)}\qquad \mathcal{E}(\Phi) := \int_\Omega \left\{ \frac{1}{2}a(x)|\nabla\Phi|^2 + \frac{1}{4}(1-|\Phi|^2)^2 \right\} dx.$$

In this connection, the parabolic equation (1.2) is the gradient flow of $\mathcal{E}$ (see [7]).

The purpose of this article is to construct stable solutions having vortices to (1.1) by appropriately choosing the diffusion coefficient $a(x)$. Here we say that a solution to (1.1) is stable if it is Lyapunov stable as an equilibrium solution to (1.2) (see [7, 9]). In terms of the variational structure, stable equilibria correspond to local minimizers of the energy functional (1.3) in most typical cases (although not always).

Most natural candidates of stable solutions of a variational problem are global minimizers. It is however rather easy to see that the global minimizers of the energy (1.3) are exactly the constant functions with modulus 1. Therefore the solutions we are seeking—the stable equilibria with zeros—have to lie on nonminimal energy level and are not accessible by the direct method in the calculus of variation. In the case where $a(x)$ is constant, it has been shown in [10, 11, 13] that the geometry of the ambient domain plays a crucial role in the stability of equilibria; more precisely, for convex domains of $\mathbb{R}^n$ the Ginzburg–Landau equation (1.1) with constant $a(x) = \lambda^{-1} > 0$ has no stable nonconstant solutions, while in an annulus or generally in a topologically nontrivial domain (a nonsimply connected domain if $n = 2, 3$; see [13]), the equation has stable nonconstant solutions for sufficiently large λ. Those stable solutions, however, have no zero points, i.e., no vortices. Taking into account this fact, let us give a crude description of the time evolution of zeros of a solution to (1.2) in a convex domain with the constant diffusivity a. Deliver a finite number of isolated points arbitrarily in the domain and take any function Φ_0 whose zeros are identified with those points. The zeros of the solution of (1.2) with the initial data Φ_0 represent the migrating vortices. Then by the instability result of [10], under a small perturbation of initial data, all of the vortices of the solution to (1.2) eventually disappear from the domain; every vortex either is absorbed by the boundary or is annihilated through merging with other vortices. An intuitive explanation of this phenomenon is as follows: higher energy of the potential term of (1.3) at vortices drives them moving in the direction of minimizing the energy functional until they disappear. Hence to stabilize each vortex, we have to create an energy barrier around the vortex, with the aid of an appropriate choice of the diffusion coefficient $a(x)$. This is roughly what we are going to do in this article.

Now we present our main theorem.

THEOREM 1.1. *Let Ω be a bounded domain in $\mathbb{R}^2$ with C^3 boundary $\partial\Omega$ and denote by $\overline{\Omega}$ the closure of Ω. Given arbitrarily a finite number of distinct points $\{a_j\}_{j=1}^N \subset \Omega$, a map $\phi \in C^0(\overline{\Omega}\setminus\{a_1,\dots,a_N\}; S^1)$, and a positive number ρ such that*

$$\text{(1.4)}\qquad 0 < \rho < \rho_0 := \min\left\{ \min_{1\le j<k\le N} \frac{1}{2}|a_j - a_k|, \min_{1\le j\le N} \operatorname{dist}(a_j, \partial\Omega) \right\},$$

there exists a C^∞ function $a(x) > 0$ such that the equation (1.1) *has a stable solution $\Phi(x)$ such that $\Phi(x) \neq 0$ for any $x \in \overline{\Omega} \setminus \cup_{j=1}^N B_\rho(a_j)$ and that moreover $\Phi/|\Phi|$ is homotopic to ϕ in $C^0(\overline{\Omega} \setminus \cup_{j=1}^N B_\rho(a_j); S^1)$.*

If we choose in the above theorem a ϕ with nonzero local topological degree d_j at a_j, for example,

$$\phi(z) = \prod_{j=1}^N \frac{(z-a_j)^{d_j}}{|z-a_j|^{d_j}}, \qquad z \in \overline{\Omega} \subset \mathbb{C}, z \neq a_1, \ldots, a_N$$

(where $\mathbb{R}^2$ is identified with $\mathbb{C}$), then our stable solution Φ satisfies that $\deg(\Phi; \partial B_\rho(a_j)) = d_j \neq 0$ and therefore must have at least one zero point within the (small) disk $B_\rho(a_j)$. This leads to the following corollary.

COROLLARY 1.2. *Let Ω be a bounded domain in $\mathbb{R}^2$ with C^3 boundary. Given arbitrarily a finite number of distinct points $\{a_j\}_{j=1}^N \subset \Omega$ and a positive number $\rho \in (0, \rho_0)$, there exists a C^∞ function $a(x) > 0$ such that the equation* (1.1) *has a stable solution $\Phi(x)$ whose zero set*

$$Z[\Phi] := \{x \in \overline{\Omega} |\, \Phi(x) = 0\}$$

is ρ-close to the prescribed configuration in the sense that

$$Z[\Phi] \subset \bigcup_{j=1}^N B_\rho(a_j), \quad Z[\Phi] \cap B_\rho(a_j) \neq \emptyset.$$

The result can be extended to a slightly modified equation of (1.1):

$$\begin{cases} \dfrac{1}{a(x)} \operatorname{div}(a(x) \nabla \Phi) + \lambda(1 - |\Phi|^2)\Phi = 0 & \text{in} \quad \Omega, \\ \dfrac{\partial \Phi}{\partial \nu} = 0 & \text{on} \quad \partial\Omega. \end{cases} \tag{1.5}$$

For details, see section 3.

The technique we use in the proof will be essentially the same as that in [12], where it is proved that for the constant diffusivity $a(x) = 1/\lambda$ in (1.1) there is a simply connected domain in $\mathbb{R}^3$ which allows a stable solution with vortices (for sufficiently large λ). Their methods, however, are not applicable to the 2-dimensional case with constant $a(x)$ (see also [3]). It remains an interesting open problem for the constant diffusivity whether there exists a 2-dimensional (nonconvex) domain which can carry a stable solution with a vortex.

We finally remark on the physical meaning of the variable diffusion briefly. In the Ginzburg–Landau theory for superconductivity, $a(x)$ represents the coherence length for superconducting electrons in a material. When a superconductor contains impurities, it is quite natural to consider the inhomogeneous coherence length in the equation, that is, the variable diffusion coefficient. On the other hand, equation (1.5) is a model describing another physical situation, that is, a thin superconducting film with variable thickness. Indeed it can be regarded as an approximate equation in a thin domain of $\mathbf{R}^3$,

$$D(\epsilon) = \{(x, x') \in \mathbf{R}^2 \times \mathbf{R} : x \in \Omega, 0 < x' < \epsilon a(x)\} \qquad (0 < \epsilon \ll 1),$$

where the function $a(x)$ represents the geometrical variation of the thin film. It is proved in [8] that as $\epsilon \to 0$, the averaging limit of the Laplacian in $D(\epsilon)$ is equal to $a(x)^{-1}\mathrm{div}(a(x)\nabla)$ in Ω in some sense. Hence, the Ginzburg–Landau equation with constant coherence length on 3-dimensional domains $D(\epsilon)$ is approximated by equation (1.5) with variable coefficient $a(x)$ on a planar domain Ω. We also note that when a vortex is trapped by some defect of the conductor, it is called the "pinning" effect in the literature of physics, which is just analytically realized in our main result.

2. Proof of the main theorem. Let Ω be a bounded domain of $\mathbb{R}^2$ with C^3 boundary $\partial\Omega$. We always identify the complex plane $\mathbb{C}$ with $\mathbb{R}^2$. So the function spaces $C^0(\overline{\Omega};\mathbb{C})$ and $L^2(\Omega;\mathbb{C})$ are the same as $C^0(\overline{\Omega};\mathbb{R}^2)$ and $L^2(\Omega;\mathbb{R}^2)$, respectively. We will also use the Sobolev space

$$H^1(\Omega;\mathbb{C}) \equiv H^1(\Omega;\mathbb{R}^2) = \{u \in L^2(\Omega;\mathbb{R}^2) : \partial u/\partial x_j \in L^2(\Omega;\mathbb{R}^2), j = 1,\dots,n\}.$$

We often abbreviate the above spaces as $C^0(\overline{\Omega})$, $L^2(\Omega)$, and $H^1(\Omega)$, respectively.

2.1. Stability of local minimizers. We first recall a result essentially due to L. Simon (see Corollary 2 of [15]).

A function $\Phi \in H^1(\Omega)$ is called a *local minimizer* of $\mathcal{E}$ if $\mathcal{E}(\Psi) \geq \mathcal{E}(\Phi)$ for any Ψ close to Φ in the H^1-norm. It is easily seen that a local minimizer has to satisfy (1.1). A solution of Φ of (1.1) is called a *stable equilibrium* of (1.2) if for any $\epsilon > 0$ there is a $\delta > 0$ such that any solution $\Phi(x,t)$ of (1.2) with $\|\Phi(\cdot,0) - \Phi\|_{C^0(\overline{\Omega})} \leq \delta$ satisfies $\|\Phi(\cdot,t) - \Phi\|_{C^0(\overline{\Omega})} \leq \epsilon$ for all $t \geq 0$.

LEMMA 2.1. *Φ is a local minimizer of $\mathcal{E}$ if and only if it is a stable equilibrium of* (1.2).

Thanks to this lemma, we only need to find local minimizers of $\mathcal{E}$ satisfying the required properties in Theorem 1.1. The proof of Lemma 2.1 uses an infinite dimensional version of the Łojasiewicz inequality, in whose derivation the real analyticity of the nonlinear term in the equation plays a role. We refer to [15] for more detail.

2.2. Minimizers on a domain with holes. Arbitrarily given N-points $\{a_k\}_{k=1}^N \subset \Omega$ and a positive number $\rho \in (0,\rho_0)$, where ρ_0 is as in (1.4), we define a subdomain of Ω by

$$\Omega_\rho := \Omega \setminus \bigcup_{j=1}^{N} \overline{B_{\rho/2}(a_j)}. \tag{2.1}$$

The problem (with constant diffusivity) on the domain Ω_ρ

$$\begin{cases} \lambda^{-1}\Delta\Phi + (1-|\Phi|^2)\Phi = 0 & \text{in} \quad \Omega_\rho, \\ \dfrac{\partial\Phi}{\partial\nu} = 0 & \text{on} \quad \partial\Omega_\rho \end{cases} \tag{2.2}$$

has been studied in [13] and [12], where nonconstant stable solutions are constructed within any nontrivial homotopy class of $C^0(\overline{\Omega_\rho};\mathbb{R}^2\setminus\{0\})$. The corresponding restricted energy functional over Ω_ρ is

$$\mathcal{E}_\rho(\Phi) := \int_{\Omega_\rho} \left\{ \frac{\lambda^{-1}}{2}|\nabla\Phi|^2 + \frac{1}{4}(1-|\Phi|^2)^2 \right\} dx. \tag{2.3}$$

Applying Theorem 2.1 of [13] and Lemma 2.3 of [12] to the above equation yields the next lemma.

LEMMA 2.2. *Consider equation* (2.2) *under the assumption that the boundary* $\partial\Omega$ *is* C^3. *Let* $\phi : \overline{\Omega_\rho} \to S^1$ *be continuous. Then*

(i) *there is a* $\lambda^* = \lambda^*(\Omega_\rho) > 0$ *such that for any* $\lambda > \lambda^*$ (2.2) *has a stable solution* $\Phi_\rho(x)$ *satisfying*

$$|\Phi_\rho(x)| > 0 \ (x \in \overline{\Omega_\rho}) \text{ and } \phi \text{ is homotopic to } \Phi_\rho/|\Phi_\rho| \text{ in } C^0(\overline{\Omega_\rho}; S^1). \tag{2.4}$$

(ii) *Moreover, for each* $\lambda > \lambda^*$ *and* $\eta > 0$, *there are positive numbers* δ_0 *and* μ_0 (*depending on* Ω, ρ, λ, *and* η) *such that for any* $\Psi \in H^1(\Omega_\rho) \cap C^0(\overline{\Omega_\rho})$ *with*

$$\|\Psi\|_{C^0(\overline{\Omega_\rho})} \le 1 + \eta, \qquad \inf_{0 \le c < 2\pi} \|e^{ic}\Phi_\rho - \Psi\|_{L^2(\Omega_\rho)} \le \delta_0,$$

the following inequality holds:

$$\mathcal{E}_\rho(\Psi) \ge \mathcal{E}_\rho(\Phi_\rho) + \mu_0 \inf_{0 \le c < 2\pi} \|e^{ic}\Phi_\rho - \Psi\|^2_{L^2(\Omega_\rho)}. \tag{2.5}$$

From now on, the continuous map $\phi : \overline{\Omega} \setminus \{a_1, \dots, a_N\} \to S^1$ and the numbers $0 < \rho < \rho_0, \lambda > \lambda^*$, and $\eta > 0$ are fixed. We shall also assume the C^∞ smoothness of ϕ without loss of generality. (If necessary, replace ϕ by a smooth map which is homotopic to ϕ in the topology of $C^0(\overline{\Omega} \setminus \{a_1, \dots, a_N\}; S^1)$.)

2.3. Fill the holes. For resolving the original problem on the whole domain $\overline{\Omega}$, we extend suitably the coefficient λ^{-1} and Φ_ρ onto functions $a(x)$ and $\Psi(x)$ over $\overline{\Omega}$. From the intuitive discussion in the introduction, a natural choice of $a(x)$ can be a positive function equal to λ^{-1} on $\overline{\Omega}$ but much smaller near a_j in order to produce appropriate energy barriers. The extension $\Psi(x)$ should make the energy integrals over the disks $B_{\rho/2}(a_j)$ sufficiently small. Such a Ψ will be our "approximate stable candidate," one of whose positively invariant neighborhood will finally provide a stable equilibrium.

The following lemma gives the precise conditions that a and Ψ should meet.

LEMMA 2.3. *Assume that the boundary* $\partial\Omega$ *is* C^3 *and let* Φ_ρ, μ_0, *and* δ_0 *be as in Lemma* 2.2. *Suppose that* $0 < a \in C^\infty(\overline{\Omega})$ *and* $\Psi \in C^0(\overline{\Omega}) \cap H^1(\Omega)$ *satisfy*

$$a|_{\overline{\Omega_\rho}} = \lambda^{-1}, \quad \Psi|_{\overline{\Omega_\rho}} = \Phi_\rho, \tag{2.6}$$

$$\|\Psi\|_{C^0(\overline{\Omega})} < 1 + \eta, \tag{2.7}$$

$$\sum_{j=1}^{N} \int_{B_{\rho/2}(a_j)} \left\{ \frac{1}{2} a(x) |\nabla\Psi|^2 + \frac{1}{4}(1 - |\Psi|^2)^2 \right\} dx < \mu_0\delta^2 - \gamma, \tag{2.8}$$

where $0 < \delta < \delta_0$ *and* $0 < \gamma < \mu_0\delta^2$ *are two positive numbers. Then,*

(i) *the set of functions defined by*

$$\begin{aligned} E(\gamma, \delta, a, \Psi) := \Big\{ & U \in H^1(\Omega) \cap C^0(\overline{\Omega}) : \|U\|_{C^0(\overline{\Omega})} \le 1 + \eta, \\ & \mathcal{E}(U) \le \mathcal{E}(\Psi) + \gamma, \\ & \inf_{0 \le c < 2\pi} \|U - e^{ic}\Phi_\rho\|_{L^2(\Omega_\rho)} \le \delta \Big\} \end{aligned} \tag{2.9}$$

has nonempty interior in the $C^0(\overline{\Omega}) \cap H^1(\Omega)$-topology and is positively invariant under the semiflow generated by the time-dependent Ginzburg–Landau equation (1.2);

(ii) *the energy functional $\mathcal{E}$ has a local minimizer Φ in the interior of $E(\gamma, \delta, a, \Psi)$.*

Proof. Part (i): By assumption, it is obvious that Ψ is an interior point of $E(\gamma, \delta, a, \Psi)$. Let $U \in E(\gamma, \delta, a, \Psi)$ and let $\Phi(x,t)$ be the solution of (1.2) with initial condition $\Phi(x,0) = U(x)$. We need to show that $\Phi(\cdot, t) \in E(\gamma, \delta, a, \Psi)$ for any $t > 0$. By the standard regularity theory for parabolic equations, we have $\Phi(\cdot, t) \in H^1(\Omega) \cap C^0(\overline{\Omega})$. The energy functional $\mathcal{E}$ in (1.3) is a Lyapunov function for the evolution equation (1.2); indeed

$$\frac{d}{dt}\mathcal{E}(\Phi(\cdot,t)) = -\int_\Omega \left|\frac{\partial \Phi}{\partial t}(x,t)\right|^2 dx.$$

Hence

$$\mathcal{E}(\Phi(\cdot,t)) \le \mathcal{E}(U) \le \mathcal{E}(\Psi) + \gamma, \qquad t > 0. \tag{2.10}$$

An application of the maximum principle gives

$$\|\Phi(\cdot,t)\|_{C^0(\overline{\Omega})} \le \max\left\{1, \|U\|_{C^0(\overline{\Omega})}\right\} (\le 1 + \eta), \qquad t > 0. \tag{2.11}$$

It remains to prove that $\inf_{0 \le c < 2\pi} \|\Phi(\cdot,t) - e^{ic}\Phi_\rho\|_{L^2(\Omega_\rho)} \le \delta$ for $t > 0$. Suppose by contradiction that there exists a $t_0 > 0$ such that

$$\delta < \inf_{0 \le c < 2\pi} \|\Phi(\cdot,t_0) - e^{ic}\Phi_\rho\|_{L^2(\Omega_\rho)} < \delta_0. \tag{2.12}$$

From (2.11) and (2.12) together with Lemma 2.2 (ii), we get a lower bound for the energy on the domain with holes:

$$\mathcal{E}_\rho(\Phi(\cdot,t_0)) > \mathcal{E}_\rho(\Phi_\rho) + \mu_0\delta^2. \tag{2.13}$$

Since the energy density is everywhere nonnegative, on the whole domain Ω, we have

$$\mathcal{E}_\rho(\Phi(\cdot,t_0)) \le \mathcal{E}(\Phi(\cdot,t_0)) \le \mathcal{E}(\Psi) + \gamma,$$

in view of (2.10). We thereby obtain

$$\mathcal{E}_\rho(\Phi_\rho) + \mu_0\delta^2 < \mathcal{E}(\Psi) + \gamma. \tag{2.14}$$

On the other hand, in view of the splitting

$$\mathcal{E}(\Psi) = \mathcal{E}_\rho(\Phi_\rho) + \sum_{j=1}^N \int_{B_{\rho/2}(a_j)} \left\{\frac{1}{2}a(x)|\nabla\Psi|^2 + \frac{1}{4}(1-|\Psi|^2)^2\right\} dx$$

and the assumption (2.8), we have $\mathcal{E}(\Psi) \le \mathcal{E}_\rho(\Phi_\rho) + \mu_0\delta^2 - \gamma$. This contradicts (2.14).

Part (ii): This part is very similar to the argument used in the proof of Theorem 3.1 of [12]. We only sketch it. One can look at the ω-limit set K of the positively invariant set $E := E(\gamma, \delta, a, \Psi)$ under the semiflow generated by (1.2). By the parabolic regularity theory, K is nonempty and compact. Moreover, by what we have seen in the proof of Part (i), K is contained in the interior of E. A minimizer of $\mathcal{E}$ on K will be a minimizer on the set E. ∎

2.4. Construction of extensions. In this section, we give an explicit construction of a family of $a(x)$ and $\Psi(x)$ satisfying the requirements in Lemma 2.3.

Let $\epsilon > 0$ be a small parameter. First prepare three auxiliary C^∞ functions $A_\epsilon(r)$, $\xi_\epsilon(r)$, and $\eta_\epsilon(r)$ on $[0,\infty)$, with the following properties, respectively:

$$A_\epsilon(r) = \begin{cases} \epsilon^3 & 0 \le r \le (\rho-\epsilon)/2, \\ \text{monotone increasing} & (\rho-\epsilon)/2 < r < \rho/2, \\ \lambda^{-1} & r \ge \rho/2, \end{cases}$$

$$\xi_\epsilon(r) = \begin{cases} r^2/(2\epsilon^2) & 0 \le r \le \epsilon, \\ \text{monotone increasing} & \epsilon < r < 2\epsilon, \\ 1 & 2\epsilon \le r \le (\rho-3\epsilon)/2, \\ \text{monotone decreasing} & (\rho-3\epsilon)/2 < r < (\rho-2\epsilon)/2, \\ 0 & r \ge (\rho-2\epsilon)/2. \end{cases}$$

$$\eta_\epsilon(r) = \begin{cases} 0 & 0 \le r \le (\rho-3\epsilon)/2, \\ \text{monotone increasing} & (\rho-3\epsilon)/2 < r < (\rho-2\epsilon)/2, \\ 1 & r \ge (\rho-2\epsilon)/2. \end{cases}$$

Moreover, we require that $\epsilon|\xi_\epsilon'(r)|$ and $\epsilon\eta_\epsilon'(r)$ are uniformly bounded by a constant independent of ϵ.

Now we define $a_\epsilon(x)$ and $\Psi_\epsilon(x)$. For $x \in \overline{\Omega_\rho}$, let

$$a_\epsilon(x) = \lambda^{-1}, \quad \Psi_\epsilon(x) = \Phi_\rho(x).$$

In the jth disk $B_{\rho/2}(a_j)$, for $x = a_j + r(\cos\theta, \sin\theta)$ with $0 \le r < \rho/2$, let

$$\begin{aligned} a_\epsilon(x) &= A_\epsilon(r), \\ \Psi_\epsilon(x) &= \xi_\epsilon(r)\phi\left(a_j + \frac{\rho}{2}(\cos\theta,\sin\theta)\right) + \eta_\epsilon(r)\Phi_\rho\left(a_j + \frac{\rho}{2}(\cos\theta,\sin\theta)\right). \end{aligned}$$

We claim the following lemma.

LEMMA 2.4. *There exists a constant β_0, independent of ϵ, δ, and γ, such that if $0 < \epsilon < \beta_0(\mu_0\delta^2 - \gamma)$, then the above chosen $a_\epsilon \in C^\infty(\overline{\Omega})$ and $\Psi_\epsilon \in C^0(\overline{\Omega}) \cap H^1(\Omega)$ satisfy the requirements* (2.6), (2.7), *and* (2.8) *in Lemma* 2.3.

Proof. All conditions can be verified straightforward. Let us only check (2.8). In the jth disk, use the polar coordinates $x - a_j = re^{i\theta}$ where $0 \le r \le \rho/2, \theta \in S^1$. Recall the identity

$$|\nabla f|^2 = \left|\frac{\partial f}{\partial r}\right|^2 + \frac{1}{r^2}\left|\frac{\partial f}{\partial \theta}\right|^2.$$

Now integrating the energy integrands $J_1 = \frac{1}{2}a_\epsilon(x)|\nabla\Psi_\epsilon(x)|^2$ and $J_2 = \frac{1}{4}(1-|\Psi_\epsilon|^2)^2$ over separated pieces of $B_{\rho/2}(a_j)$, we see

$$\begin{aligned} \int_{B_{\rho/2}(a_j)} J_1 dx &= \int_0^{(\rho-\epsilon)/2}\int_{S^1} J_1 \, r dr d\theta + \int_{(\rho-\epsilon)/2}^{\rho}\int_{S^1} J_1 \, r dr d\theta \\ &\le O\left(\epsilon^3 \cdot \epsilon^{-2}\right) + O(\epsilon) = O(\epsilon) \end{aligned}$$

and

$$\int_{B_{\rho/2}(a_j)} J_2 dx = \int_0^{2\epsilon}\int_{S^1} + \int_{2\epsilon}^{(\rho-3\epsilon)/2}\int_{S^1} + \int_{(\rho-3\epsilon)/2}^{\rho}\int_{S^1}$$
$$\leq O(\epsilon^2) + 0 + O(\epsilon) = O(\epsilon).$$

For small $\epsilon > 0$, (2.8) is satisfied. □

2.5. Convergence of local minimizers. For $0 < \epsilon < \beta_0(\mu_0\delta^2 - \gamma)$, the functions $a_\epsilon(x)$ and $\Psi_\epsilon(x)$ then provide a local minimizer $\Phi_{\gamma,\delta,\epsilon} \in E(\gamma, \delta, a_\epsilon, \Psi_\epsilon)$ by the last two lemmas. In this section, we let δ and γ depend on ϵ such that $\beta_0(\mu_0\delta^2 - \gamma) = 2\epsilon$ and $\gamma = \epsilon$ and investigate the asymptotic behavior of minimizers $\tilde{\Phi}_\epsilon := \Phi_{\gamma(\epsilon),\delta(\epsilon),\epsilon}$ as $\epsilon \downarrow 0$.

LEMMA 2.5. *Let $\tilde{\Phi}_\epsilon \in E(\gamma(\epsilon), \delta(\epsilon), a_\epsilon, \Psi_\epsilon)$ be local minimizers constructed above. Then we have*

$$\lim_{\epsilon\to 0}\left[\inf_{0\leq c<2\pi} \|e^{ic}\Phi_\rho - \tilde{\Phi}_\epsilon\|_{L^2(\Omega_\rho)}\right] = 0, \tag{2.15}$$

$$\lim_{\epsilon\to 0}\left[\inf_{0\leq c<2\pi} \|e^{ic}\Phi_\rho - \tilde{\Phi}_\epsilon\|_{C^1(\overline{\Omega_{2\rho}})}\right] = 0, \tag{2.16}$$

where

$$\overline{\Omega_{2\rho}} = \overline{\Omega} \setminus \bigcup_{j=1}^{N} B_\rho(a_j).$$

From the convergence (2.16), there is an $\epsilon_0 > 0$ such that for any $0 < \epsilon < \epsilon_0$, the map $\tilde{\Phi}_\epsilon/|\tilde{\Phi}_\epsilon|$ is homotopic to $e^{ic}\Phi_\rho/|\Phi_\rho|$ for some $c \in [0, 2\pi)$ (and hence for all $c \in [0, 2\pi)$), in $C^0(\overline{\Omega} \setminus \bigcup_{j=1}^N B_\rho(a_j); S^1)$. Combined with property (2.4) in Lemma 2.2, we find that $\tilde{\Phi}_\epsilon/|\tilde{\Phi}_\epsilon|$ is homotopic to ϕ. The main Theorem 1.1 is now completely proved.

Proof of Lemma 2.5. The L^2 convergence (2.15) follows from the definition (2.9) and the fact that $\delta = O(\epsilon^{1/2})$.

The C^1 convergence (2.16) follows from (2.15), once we show the relative compactness of $\tilde{\Phi}_\epsilon$ in $C^1(\overline{\Omega_{2\rho}})$. Since $\|\tilde{\Phi}_\epsilon\|_{C^0(\overline{\Omega})}$ is uniformly bounded, we obtain that $\mathrm{div}(a_\epsilon(x)\nabla\tilde{\Phi}_\epsilon)$ are also uniformly bounded in the L^∞ norm. In view of the fact that $a_\epsilon(x) = \lambda^{-1}$ is independent of ϵ on $\overline{\Omega_\rho}$, the elliptic L^p estimates ($p > 2$) give rise to a uniform upper bound for $\|\tilde{\Phi}_\epsilon\|_{W^{2,p}(\Omega_{3\rho/2})}$ (see [5]), which implies the required relative compactness. □

3. Remark. The arguments we used in the previous section are also applicable to other similar types of energy functionals. For instance, consider

$$\mathcal{F}(\Phi) := \int_\Omega \left\{\frac{1}{2}|\nabla\Phi|^2 + \frac{\lambda}{4}(1 - |\Phi|^2)^2\right\} a(x)dx \tag{3.1}$$

for $\Phi \in H^1(\Omega)$. One has the following analogue of Theorem 1.1.

THEOREM 3.1. *Let Ω be a bounded domain in $\mathbb{R}^2$ with C^3 boundary $\partial\Omega$ and denote by $\overline{\Omega}$ the closure of Ω. Given arbitrarily a finite number of distinct points $\{a_j\}_{j=1}^N \subset \Omega$, a map $\phi \in C^0(\overline{\Omega} \setminus \{a_1, \dots, a_N\}; S^1)$, and a positive number ρ such that*

$$0 < \rho < \rho_0 := \min \left\{ \min_{1 \le j < k \le N} \frac{1}{2}|a_j - a_k|, \min_{1 \le j \le N} \operatorname{dist}(a_j, \partial\Omega) \right\},$$

there exist a C^∞ function $a(x) > 0$ and a positive number $\lambda > 0$ such that the functional $\mathcal{F}$ has a local minimizer $\Phi(x)$ such that $\Phi(x) \neq 0$ for any $x \in \overline{\Omega} \setminus \cup_{j=1}^N B_\rho(a_j)$ and that moreover $\Phi/|\Phi|$ is homotopic to ϕ in $C^0(\overline{\Omega} \setminus \cup_{j=1}^N B_\rho(a_j); S^1)$.

Recall that by Simon's result (see Lemma 2.1), the local minimizers Φ in Theorem 3.1 are stable stationary solutions of the following time-dependent equation:

$$\begin{cases} c(x)\dfrac{\partial \Phi}{\partial t} = \operatorname{div}(a(x)\nabla\Phi) + \lambda a(x)(1 - |\Phi|^2)\Phi & \text{in} \quad (0,\infty) \times \Omega, \\ \dfrac{\partial \Phi}{\partial \nu} = 0 \qquad \text{on} \quad (0,\infty) \times \partial\Omega, \end{cases}$$

where $c(x)$ is an arbitrary positive smooth function. A special case, where $c(x) = a(x)$, i.e.,

$$\begin{cases} \dfrac{\partial \Phi}{\partial t} = \dfrac{1}{a(x)}\operatorname{div}(a(x)\nabla\Phi) + \lambda(1 - |\Phi|^2)\Phi & \text{in} \quad (0,\infty) \times \Omega, \\ \dfrac{\partial \Phi}{\partial \nu} = 0 \qquad \text{on} \quad (0,\infty) \times \partial\Omega, \end{cases}$$

is often encountered in applications.

The proof of Theorem 3.1 is very similar to that of Theorem 1.1. We replace Lemma 2.3 by the following slightly generalized version.

LEMMA 3.2. *Assume that the boundary $\partial\Omega$ is C^3 and let Φ_ρ, μ_0, and δ_0 be as in Lemma 2.2. Suppose that $0 < a \in C^\infty(\overline{\Omega})$, $0 \le b \in C^\infty(\overline{\Omega})$, and $\Psi \in C^0(\overline{\Omega}) \cap H^1(\Omega)$ satisfy*

$$a|_{\overline{\Omega_\rho}} = \lambda^{-1}, \quad b|_{\overline{\Omega_\rho}} = 1, \quad \Psi|_{\overline{\Omega_\rho}} = \Phi_\rho,$$

$$\|\Psi\|_{C^0(\overline{\Omega})} < 1 + \eta,$$

$$\sum_{j=1}^N \int_{B_{\rho/2}(a_j)} \left\{ \frac{1}{2}a(x)|\nabla\Psi|^2 + \frac{1}{4}b(x)(1 - |\Psi|^2)^2 \right\} dx < \mu_0\delta^2 - \gamma,$$

where $0 < \delta < \delta_0$ and $0 < \gamma < \mu_0\delta^2$ are two positive numbers. Let

$$\mathcal{G}(U) := \int_\Omega \left\{ \frac{1}{2}a(x)|\nabla\Phi|^2 + \frac{1}{4}b(x)(1 - |\Phi|^2)^2 \right\} dx. \tag{3.2}$$

Then

(i) *the set of functions defined by*

$$G(\gamma,\delta,a,b,\Psi) := \left\{ U \in H^1(\Omega)\cap C^0(\overline{\Omega}) : \|U\|_{C^0(\overline{\Omega})} \le 1+\eta, \ \mathcal{G}(U) \le \mathcal{G}(\Psi)+\gamma, \ \inf_{0\le c<2\pi} \|U - e^{ic}\Phi_\rho\|_{L^2(\Omega_\rho)} \le \delta \right\} \tag{3.3}$$

has nonempty interior in the $C^0(\overline{\Omega})\cap H^1(\Omega)$*-topology and is positively invariant under the semiflow generated by the following time-dependent Ginzburg–Landau equation*:

$$\begin{cases} \dfrac{\partial\Phi}{\partial t} = \operatorname{div}(a(x)\nabla\Phi) + b(x)(1-|\Phi|^2)\Phi \qquad \text{in} \quad (0,\infty)\times\Omega, \\ \dfrac{\partial\Phi}{\partial\nu} = 0 \qquad \text{on} \quad (0,\infty)\times\partial\Omega; \end{cases}$$

(ii) *the energy functional* $\mathcal{G}$ *has a local minimizer* Φ *in the interior of* $G(\gamma,\delta,a,b,\Psi)$.

The conditions in Lemma 3.2 are satisfied by $a_\epsilon(x)$ and $\Psi_\epsilon(x)$ chosen the same as in section 2.4 along with $b_\epsilon(x) := \lambda a_\epsilon(x)$. The proof of the convergences remains literally unchanged from section 2.5.

STATIONARY PARTICLE SYSTEMS APPROXIMATING STATIONARY SOLUTIONS TO THE BOLTZMANN EQUATION*

S. CAPRINO†, M. PULVIRENTI‡, AND W. WAGNER§

Abstract. We show that a regularized stationary Boltzmann equation with diffusive boundary conditions can be rigorously derived from a suitable stochastic N-particle system. To do this, we prove that the L_1-distance between the k-particle density and the k-fold product of the solution to the stationary Boltzmann equation is of order $1/N$.

Key words. stationary Boltzmann equation, diffusive boundary conditions, stochastic particle system, rate of convergence

AMS subject classifications. 60K35, 76P05, 82C40

1. Introduction.

Stochastic particle methods are widely used in the numerical simulation of rarefied flows. These are described at a mathematical level by the Boltzmann equation and hence, convergence results for such schemes are of practical interest. From a more fundamental point of view, in the study of these problems we are naturally led to tackle subtle difficulties related to the so-called propagation of chaos, which is an asymptotic (in the number of particles) statistical independence. Indeed, the convergence we want to establish is nothing else but a law of large numbers for (somehow weakly) dependent random variables. For this reason, results in this direction are also of interest in the field of limit theorems for large systems of interacting stochastic processes. We address the reader to [C], [BI], [LP], [W], [PWZ], [GM] for results concerning convergence of stochastic particle systems to solutions of (regularized) Boltzmann equations (see also [M], [P] for a review on these arguments and related results). Unfortunately the situation is far from being satisfactory for many reasons which we are going to illustrate.

The convergence results we mentioned above regard time-dependent problems. Namely, the empirical measure $\frac{1}{N}\sum_{i=1}^{N}\delta_{z_i(t)}(dz)$ (that is, a measure valued stochastic process), where $z_i(t)$ is the state of the ith particle at time t, is weakly converging in probability to $f(z,t)$, which is the solution of the Boltzmann equation with initial datum $f(z,0)=f_0(z)$, the distribution density of each particle at time zero, assuming also that all the particles are independently distributed. Such a convergence is not expected to hold uniformly in time. However, in most of the practical applications of these stochastic codes, we deal with stationary nonequilibrium situations, which we simulate in order to extract information on the macroscopic quantities such as profiles and fluxes. In other words, we are interested in nontrivial stationary solutions to the Boltzmann equation, but in this case the methods we have discussed so far are useless. In fact, even knowing the trend to a nonequilibrium stationary state for the Boltzmann

dynamics (which is, incidentally, not known except for simplified models), we could not conclude anything on the particle approximation of this asymptotic state, being that the two limits $N \to \infty$ and $t \to \infty$ are clearly not commutable.

The systematic error of some particle simulation scheme for a stationary model Boltzmann equation was studied in [B]. An alternative approach to the construction of particle schemes for the stationary Boltzmann equation has been proposed in [BS].

In this paper we face the above-mentioned problem for a gas in a bounded domain with diffusive boundary conditions at a possibly-not-constant temperature. We consider the unique stationary measure for the N-particle system and evaluate the distance between this and the measure given by the N-fold product of the unique solution to the stationary Boltzmann equation of cutoff type, with the same boundary conditions. We show that, if the mean free path inverse is sufficiently small, the L_1-difference between the k-particle distribution functions of such two measures vanishes in the limit $N \to \infty$, for any fixed k. To do this we use a technique which we call v-functions. Such a method is used in [CDPP] and [DP] for time-dependent problems related to stochastic particle systems in a lattice, in [CP] for a one-dimensional stationary problem for a model equation, and it is indeed very effective as we shall explain in section 3.

Let us conclude by criticizing the present result. As we said, it holds for small mean free path inverse. This is a consequence of the fact that we use a constructive perturbative technique. Also, the existence and uniqueness for stationary solutions of the Boltzmann equation is proven under the same smallness assumption. We do not even know whether recent approaches to the existence problem (see, for instance, [AN] for a Boltzmann equation in a slab) can be used to obtain at least the existence of solutions for our problem without this assumption. However, the uniqueness of such solutions, which should be preliminarily known for the convergence problem we set, seems at the moment hard to be proven, even for a regularized equation as the one we consider.

In the present paper, the Boltzmann equation enjoys two regularizations. The first, and more important, is a spatial smearing, which is standard in the above-quoted literature. Actually, the existence theory for the true Boltzmann equation is, up to now, too poor to allow us to approach the real problem. In [CP] a model equation without spatial smearing has been successfully attacked. However such model is one-dimensional—that is much easier to deal with. The second type of cutoff is on the set of possible velocities, which is assumed to be bounded away from 0. This assumption is made to take a full advantage by the ergodic property of the Knudsen flow. We absolutely need this as a consequence of our ignorance of qualitative properties of the invariant measure for the N-particle system, which we only know to exist uniquely. In fact, we think that the cutoff on large velocities (see (2.6)) is only technical: it allows us to avoid difficulties which could obscure the real essence of the approach.

2. Notations and results. Let $\Omega \subset R^d$, $d = 2, 3$ be an open set with sufficiently smooth boundary in the physical space, $V = \{v \in R^d : \|v\| \geq u_{\min} > 0\}$ the velocity space, and $[0, T]$ an interval on the real line. For $(x, v, t) \in \Omega \times V \times [0, T]$ consider the following Boltzmann equation of cutoff type

$$\partial_t p(x, v, t) + (v \cdot \nabla_x) p(x, v, t) = \lambda Q(p, p)(x, v, t) \tag{2.1}$$

with initial condition

$$p(x, v, 0) = p_0(x, v) \geq 0 \tag{2.2}$$

and boundary conditions ($n(x)$ is the outward normal in $x \in \partial\Omega$)

$$p(x,v,t) = J(x,t)M(x,v) \quad x \in \partial\Omega, \quad v \cdot n(x) \leq 0. \tag{2.3}$$

Here we used the following symbols: λ is a real parameter,

$$Q(p,p)(x,v,t) = \int_\Omega dy \int_V dv_1 \int_{S_+^{d-1}} deB(v,v_1,e)h_\beta(x,y)\chi((v^*,v_1^*) \in V \times V))$$

$$\times \{p(x,v^*,t)p(y,v_1^*,t) - p(x,v,t)p(y,v_1,t)\}, \tag{2.4}$$

e is the unit vector in R^d, χ is the characteristic function of its argument,

$$v^* = v + e \cdot (v_1 - v)e, \quad v_1^* = v_1 - e \cdot (v_1 - v)e, \tag{2.5}$$

S^{d-1} is the unit sphere, and $S_+^{d-1} = \{e \in S^{d-1} | e \cdot (v - v_1) \geq 0\}$.

Concerning the collision kernel $B : R^d \times R^d \times S^{d-1} \to \mathbb{R}^+$ we assume

$$B(v,v_1,e) \leq c_1 < \infty. \tag{2.6}$$

The function h_β, which acts as a spatial mollifier, is a symmetric function belonging to L_∞, vanishing for $|x-y| \geq \beta > 0$ and such that $\int h_\beta(x,y)dy = 1$. The incoming flux J at the point x is defined as

$$J(x,t) = \int_{v \cdot n(x) \geq 0} dv \quad v \cdot n(x)p(x,v,t). \tag{2.7}$$

Finally, M is a bounded positive function defined on the set

$$\{(x,v) | x \in \partial\Omega, v \in V, v \cdot n(x) \leq 0\},$$

which we require to satisfy the following normalization condition:

$$\int_{v \cdot n(x) \leq 0} dv \quad |v \cdot n(x)|M(x,v) = 1. \tag{2.8}$$

This last assumption, together with the well-known properties of Q, ensures the conservation of the quantity

$$m(t) = \int dx \int dv \quad p(x,v,t), \tag{2.9}$$

which we assume initially to be one so that we consider normalized solutions to problem (2.1)–(2.3).

From a physical point of view, equations (2.1)–(2.3) describe a rarefied gas in a vessel with diffusive boundary conditions at possibly-not-constant temperature on the boundary. The collision operator Q differs from the usual one for the cutoff on the velocities and for the presence of the smearing function h_β. The true Boltzmann equation is recovered by removing the two cutoffs, that is, letting $h_\beta \to \delta$ (δ is the δ-function centered at the origin) and assuming $V = \mathbb{R}^d$.

It will be useful in the following to deal with the mild version of the above problem:

$$p(t,x,v) = S(t)p_0(x,v) + \lambda \int_0^t ds \quad S(t-s)Q(p,p)(x,v,s), \tag{2.10}$$

where $S(t)$ is the **Knudsen semigroup**, that is the solution to the initial boundary value problem:

$$[\partial_t + (v \cdot \nabla_x)]S(t)p_0(x,v) = 0, \tag{2.11}$$

$$(S(t)p_0)(x,v) = J(x,t)M(x,v)\,, \quad x \in \partial\Omega\,, \quad v \cdot n(x) \leq 0\,. \tag{2.12}$$

There exists a unique solution to (2.10), thanks to the Lipschitz continuity in $L_1(x,v)$ of Q, due to the presence of the smearing function h_β and (2.6).

Here we are interested in the stationary equation

$$(v \cdot \nabla_x)g(x,v) = \lambda Q(g,g)(x,v), \tag{2.13}$$

with boundary conditions corresponding to the time-dependent case (2.3) and the normalization property

$$\int dx \int dv g(x,v) = 1.$$

Existence and uniqueness of a solution for a slightly different formulation for such a problem (under a suitable smallness assumption on λ) will be established in Theorem 2.2 below. For the moment, we need a preliminary property of the Knudsen flow expressed by the following theorem which will be proven in the appendix.

THEOREM 2.1. *There exists a unique probability density $\bar{g}$ which is stationary under the action of the Knudsen flow, i.e.,*

$$S(t)\bar{g} = \bar{g}\,, \quad \forall t \in \mathbb{R}^+\,. \tag{2.14}$$

Moreover, for any $\eta > 0$ there exists $T(\eta) > 0$ such that, for any $t \geq T(\eta)$ and for any probability density f, it is

$$\|S(t)f - \bar{g}\|_{L_1} \leq \eta. \tag{2.15}$$

Remark. We stress that the assumption for the velocities to stay bounded away from 0 implies the independence of $T(\eta)$ from the probability density f, which is of great importance to prove our main result.

We now also establish existence and uniqueness for the stationary solution of the boundary value problem (2.13).

THEOREM 2.2. *If λ is sufficiently small, then there exists a unique probability density g which is invariant for the flow* (2.10)*:*

$$g = S(t)g + \lambda \int_0^t ds \quad S(t-s)Q(g,g), \qquad t \in \mathbb{R}^+. \tag{2.16}$$

Moreover, it is globally attractive; that is,

$$\|p(t) - g\|_{L_1} \leq e^{-c\,t}\,,$$

where $p(t)$ is any solution to (2.10) *and c is some constant.*

The proof of this theorem, which is essentially perturbative, is given in the appendix.

Now we introduce the N-particle process which gives the approximation, in the limit $N \to \infty$, to problem (2.1)–(2.3). Let

$$Z_N = (z_1, ..., z_N), \quad z_i = (x_i, v_i), \quad i = 1, ..., N,$$

and for the sake of simplicity put

$$q(z_1, z_2, e) = h_\beta(x_1, x_2)B(v_1, v_2, e)\chi((v^*, v_2^*) \in V \times V). \tag{2.17}$$

We define the generator of the N-particle process, for any function Φ as

$$G_N(\Phi)(Z_N) = G_N^{free}(\Phi)(Z_N) + \frac{\lambda}{N} G_N^{jump}(\Phi)(Z_N), \tag{2.18}$$

where

$$G_N^{free}(\Phi)(Z_N) = \sum_{i=1}^{N} (v_i \cdot \nabla_{x_i})\Phi(Z_N) \tag{2.19}$$

(with diffusive boundary conditions to be specified; see equations (2.24)–(2.25)) and

$$G_N^{jump}(\Phi)(Z_N) = \sum_{1 \le i < j \le N} \int_{S_+^{d-1}} de[\Phi(Z_N^{(i,j)}) - \Phi(Z_N)]q(z_i, z_j, e) \tag{2.20}$$

being

$$Z_N^{(i,j)} = (z_1, \ldots, z_{i-1}, x_i, v_i^*, \ldots, z_{j-1}, x_j, v_j^*, \ldots, z_N). \tag{2.21}$$

Note that G_N^{free} is the generator of N-independent particles moving freely. The outgoing velocity v of each particle after a collision with the boundary at the point x is distributed according to the probability density given in (2.8). In other words, $\exp\{(G_N^{free})^* t\} = S_N(t)$, where $S_N(t)$ is the product of operators acting on a single particle, namely,

$$S_N(t) = \prod_{i=1}^{N} S_{\{i\}}(t), \tag{2.22}$$

where $S_{\{i\}}(t)$ is the Knudsen semigroup associated to the particle i. Therefore, the process described by the generator G_N consists of free motion (including the diffusive boundary conditions) of the N-particle system and random collisions. These collisions take place at random times, with random impact parameter e. The particles of the pair involved in the collision have mutual distance less than β, and their outgoing velocities after the interaction follow the deterministic law (2.5). This model, introduced in [C], is sometimes called the "soft balls" model.

If the system is initially distributed according to a probability density $f^N(Z_N)$, its time evolution is given by $f^N(t) = \exp\{(G_N)^* t\} f^N$. In other words,

$$\partial_t f^N(Z_N, t) + \sum_{i=1}^{N} (v_i \cdot \nabla_{x_i}) f^N(Z_N, t) = \frac{\lambda}{N} G_N^{jump} f^N(Z_N, t), \tag{2.23}$$

with initial conditions $f^N(Z_N,0)=f^N(Z_N)$ and with boundary conditions

(2.24)
$$f^N(z_1,\dots,z_i,\dots,z_N,t)=J_i^N(x_i,t,Z_N(i))M(x_i,v_i),\quad x_i\in\partial\Omega,\quad v_i\cdot n(x_i)\le 0$$

for all $i=1,\dots,N$, with $Z_N(i)=(z_1,\dots,z_{i-1},z_{i+1},\dots,z_N)$ and

$$J_i^N(x_i,t,Z_N(i))=\int_{v_i\cdot n(x_i)\ge 0} dv_i\quad v_i\cdot n(x_i)f^N(Z_N,t). \tag{2.25}$$

Condition (2.24) can easily be generalized to the case in which more than one particle stays on $\partial\Omega$, since those particles evolve independently. However, such events have vanishing probability for the N-particle system.

If we consider the stationary version of (2.23)–(2.24), that is,

$$\sum_{i=1}^N (v_i\cdot\nabla_{x_i})\tilde f^N(Z_N)=\frac{\lambda}{N}G_N^{jump}\tilde f^N(Z_N) \tag{2.26}$$

with the boundary conditions (2.24)–(2.25), we can state the following result, which is proven in the appendix.

THEOREM 2.3. *For all $N>0$ there exists a unique probability density $\tilde f^N=\tilde f^N(Z_N)$ which is invariant under the N-particle process.*

The main goal of this paper is to compare the stationary distribution $\tilde f^N$ with the one-particle stationary distribution g constructed in Theorem 2.2. To this purpose we introduce the k-particle distribution functions associated to the probability density $\tilde f^N$:

$$\tilde f_k^N(Z_k)=\int\cdots\int \tilde f^N(Z_N)dz_{k+1}\dots dz_N,\qquad k=1,\dots,N-1. \tag{2.27}$$

Introducing analogously the k-particle distribution functions for the time-dependent distribution $f^N(Z_N,t)$, we obtain from (2.23) and (2.24) the well-known BBGKY hierarchy of equations

$$\partial_t f_k^N(Z_k,t)+G_k^{free}f_k^N(Z_k,t)$$

$$=\frac{\lambda}{N}G_k^{jump}f_k^N(Z_k,t)+\lambda\frac{N-k}{N}C_{k,k+1}f_{k+1}^N(Z_k,t),\qquad k=1,\dots,N\,, \tag{2.28}$$

with boundary conditions

(2.29)
$$f_k^N(z_1,\dots,z_i,\dots,z_k,t)=J_i^N(x_i,t,Z_k(i))M(x_i,v_i),\quad x_i\in\partial\Omega,\quad v_i\cdot n(x_i)\le 0.$$

Here,

$$C_{k,k+1}f_{k+1}^N(Z_k,t)$$

$$=\sum_{i=1}^k\int\int_{S_+^{d-1}} dz_{k+1}de\quad q(z_i,z_{k+1},e)[f_{k+1}^N(Z_{k+1}^{(i,k+1)},t)-f_{k+1}^N(Z_{k+1},t)]. \tag{2.30}$$

Note that by Theorem 2.3 it follows that the unique solutions to the stationary version of problem (2.28) are those defined in (2.27).

Now we introduce the infinite Boltzmann hierarchy; that is, the (formal) limit as $N \to \infty$ of the BBGKY hierarchy, i.e.,

$$\partial_t f_k(Z_k,t) + G_k^{free} f_k(Z_k,t) = \lambda C_{k,k+1} f_{k+1}(Z_k,t), \qquad k = 1,2,\dots, \tag{2.31}$$

with initial and usual boundary conditions.

It is useful to consider the mild form of it, that is,

$$f_k(t) = S_k(t) f_k^0 + \lambda \int_0^t ds S_k(t-s) C_{k,k+1} f_{k+1}(s) \quad k = 1,2,\dots. \tag{2.32}$$

We denote by $P(t)$ the solution operator of the infinite hierarchy (2.32) that is $(P(t)f^0)_k = f_k(t)$. $P(t)$ acts on sequences $f^0 = \{f_k^0\}_{k=1,\dots,\infty}$, $f_k^0 \in L_1((\Omega \times V)^k)$.

Analogously we can define $(P^N(t)f^N)_k = f_k^N(t)$ to be the solution operator of the following finite hierarchy of equations (mild version of (2.28)):

(2.33)

$$\begin{aligned} f_k^N(t) = S_k(t) f_k^N &+ \frac{\lambda}{N} \int_0^t ds \quad S_k(t-s) G_k^{jump} f_k^N(s) \\ &+ \lambda \frac{N-k}{N} \int_0^t ds \quad S_k(t-s) C_{k,k+1} f_{k+1}^N(s), \qquad k = 1,2,\dots,N\,. \end{aligned}$$

Notice that (2.33) for $k = N$ is the mild version of (2.23).

Since (2.33) is a finite system of linear equations, it can easily be solved uniquely in $L_1((\Omega \times V)^k)$; namely, $f_k^N(t)$ are obtained by integrating $f^N(Z_N,t)$, a unique solution to (2.23).

By iterating formula (2.32), we arrive at the following formal series expansion:

$$(P(t)f^0)_k = f_k(t) = \sum_{n=0}^{\infty} \lambda^n a_{k,n}(t) f_k^0 \tag{2.34}$$

with

$$a_{k,n}(t) f_k^0 = \int_0^t \int_0^{t_1}, \dots, \int_0^{t_{n-1}} dt_1, \dots, dt_n$$

$$\times S_k(t-t_1) C_{k,k+1}, \dots, S_{k+n-1}(t_{n-1}-t_n) C_{k+n-1,k+n} S_{k+n}(t_n) f_{k+n}^0. \tag{2.35}$$

It is possible to show that the series in (2.34) converges in L_1 if the quantity λt is sufficiently small so that, under such a hypothesis, there exists a unique solution to (2.32). The method employed is the same as in [LP] and [PWZ], inspired by the well-known result due to Lanford (see [L] and [CIP]) in a L_∞-setup for the not regularized Boltzmann equation. Here we find the additional difficulty of the diffusive boundary conditions. However, working in L_1, this is not a problem, since the only property we need of the free flow is the isometry (see (2.36) below).

We will show the convergence of the series (2.34) as well as the asymptotic equivalence (for $N \to \infty$) of the operators $P^N(t)$ and $P(t)$.

Before stating Theorem 2.4 below, we stress two fairly evident estimates of the terms in the series (2.34):

$$\|S_k(t)f_k\|_{L_1} = \|f_k\|_{L_1} \tag{2.36}$$

and

$$\|C_{k,k+1}f_{k+1}\|_{L_1} \le ka\|f_{k+1}\|_{L_1}, \tag{2.37}$$

where

$$a = 2\sup_{z,z'} \int de\, q(z,z',e). \tag{2.38}$$

THEOREM 2.4. *Suppose $\lambda t < \frac{1}{8a}$. Then, given any sequence $\{f_k^0\}_{k=1,\dots,\infty}$ such that $\|f_k^0\|_{L_1} = 1$, the series (2.34) is absolutely convergent in $L_1((\Omega \times V)^k)$ for all $k \ge 1$. Moreover, given the sequence $f^N = \{f_k^N\}_{k=1,\dots,N}$ of k-particle densities, we have*

$$\|([P^N(t) - P(t)]f^N)_k\|_{L_1} \le \frac{8^k c_2}{N} \tag{2.39}$$

for some constant c_2 independent of f^N.

Remark. Since $P(t)$ has been defined as acting on infinite sequences, in (2.39) we mean $(P(t)f^N)_k = 0$ for $k > N$.

Proof. By (2.35), using (2.36) and (2.37) we have

$$\|a_{k,n}(t)f_k^0\|_{L_1} \le \frac{k(k+1),\dots,(k+n-1)}{n!}(ta)^n\|f_{k+n}^0\|_{L_1} \le 2^k(2ta)^n. \tag{2.40}$$

Therefore the series (2.34) converges for $2ta\lambda < 1$.

Let us define

$$D^N(t) = [P^N(t) - P(t)]f^N, \tag{2.41}$$

$$B_k^N(t) = \frac{\lambda}{N}\int_0^t dsS_k(t-s)G_k^{jump}(P^N(s)f^N)_k, \tag{2.42}$$

$$E_k^N(t) = -\frac{\lambda k}{N}\int_0^t dsS_k(t-s)C_{k,k+1}(P^N(s)f^N)_{k+1}. \tag{2.43}$$

By (2.32) and (2.33) we have

$$D_k^N(t) = B_k^N(t) + E_k^N(t) + \lambda\int_0^t dsS_k(t-s)C_{k,k+1}D_{k+1}^N(s), \qquad k = 1,2,\dots,N-1. \tag{2.44}$$

Iterating (2.44) $n-1$ times, with $n \le N-k$, we obtain

$$D_k^N(t) = \sum_{m=0}^{n-1}\lambda^m\int_0^t\int_0^{t_1},\dots,\int_0^{t_{m-1}} dt_1,\dots,dt_m$$

$$\times S_k(t-t_1)C_{k,k+1},\dots,S_{k+m-1}(t_{m-1}-t_m)C_{k+m-1,k+m}(B^N_{k+m}(t_m)+E^N_{k+m}(t_m))$$

$$+\lambda^n\int_0^t\int_0^{t_1},\dots,\int_0^{t_{n-1}}dt_1,\dots,dt_n$$

$$\times S_k(t-t_1)C_{k,k+1},\dots,S_{k+n-1}(t_{n-1}-t_n)C_{k+n-1,k+n}D^N_{k+n}(t_n). \tag{2.45}$$

By (2.34), (2.40), and the assumption $\lambda t<\frac{1}{8a}$, it follows from (2.41) that

$$\|D^N_{k+n}(t)\|_{L_1}\le 1+2^{k+n+1} \tag{2.46}$$

so that, after elementary calculation, we can bound the L_1-norm of the last term in the right-hand side of (2.45) by the quantity $4\cdot 4^k(\frac{1}{2})^n$.

Moreover we have

$$\|B^N_k(t)\|_{L_1}\le\frac{k^2\lambda ta}{N} \tag{2.47}$$

and

$$\|E^N_k(t)\|_{L_1}\le\frac{k^2\lambda ta}{N} \tag{2.48}$$

so that (2.45) implies

$$\|D^N_k(t)\|_{L_1}\le\frac{2^k}{N}\sum_{m\ge 0}(2a\lambda t)^{m+1}(k+m)^2+4\cdot 4^k\left(\frac{1}{2}\right)^n \tag{2.49}$$

$$\le\frac{4^k}{N}\frac{4a\lambda t}{1-4a\lambda t}+4\cdot 4^k\left(\frac{1}{2}\right)^n.$$

The thesis follows by putting $n=N-k$. □

Remark. The above result can be used to show the convergence of the solutions of the N-particle system to the solution of our Boltzmann equation. Indeed, Theorem 2.4 shows the existence and uniqueness of the solutions to hierarchy (2.32) for short times. Assume that the initial datum is factorizing, i.e., $f^N_k=f_0^{\otimes\, k}$, where f_0 is some one-particle probability density. Then it is easy to show that the unique solution of the hierarchy (2.32) we have constructed is of the form $f_k(t)=f^{\otimes\, k}(t)$, where $f(t)$ solves the Boltzmann equation (2.1) with initial datum f_0. This property is called propagation of chaos. Thus we have shown that $f^N_k(t)\to f^{\otimes\, k}(t)$ for all $k>0$, in L_1 and for short times. On the other hand, t must be smaller than a numerical constant independent of f^0 so that the procedure can be iterated in time to show that the convergence is global (see [LP], [PWZ], [P] for details).

Coming back to the stationary problem, we conclude this section by formulating the main result of this paper which will be proven in the next section. We recall that g denotes the stationary solution to the boundary value problem (2.13) constructed in Theorem 2.2 and we set

$$g_k(Z_k)=\prod_{i=1}^k g(z_i). \tag{2.50}$$

We also recall that $\tilde{f}_k^N$ denotes the k-particle distribution of the unique invariant measure of the N-particle system. We will prove the following result.

THEOREM 2.5. *There exists $\lambda_0 > 0$ such that for any $\lambda \le \lambda_0$ and any integer $k \ge 1$ it is*

$$\|\tilde{f}_k^N - g_k\|_{L_1} \le \frac{c^k}{N}, \qquad N > k,$$

for some constant c not depending on λ, k, N.

3. Proof of Theorem 2.5. We introduce a formalism which plays a very important role in what follows. Let $I \subset \mathbb{N}$ be a bounded set of indices and let $|I|$ represent its cardinality. We consider families of symmetric functions $\Phi = \{\Phi_I\}_{I\subset\mathbb{N}}$, where Φ acts on $[\Omega \times V]^{\mathbb{N}}$, and each Φ_I on $[\Omega \times V]^I$, respectively. Given two families $\Phi = \{\Phi_I\}_{I\subset\mathbb{N}}$ and $\Psi = \{\Psi_I\}_{I\subset\mathbb{N}}$, we give the following definition of **$*$-product**:

$$(\phi * \psi)_I(Z_I) = \sum_{J\subseteq I} \phi_J(Z_J)\psi_{I\setminus J}(Z_{I\setminus J}), \tag{3.1}$$

where we are using the notation $Z_I = \{z_i | i \in I\}$. Let us put

$$\phi_I^{\perp} = (-1)^{|I|}\phi_I \tag{3.2}$$

and finally, let us define

$$v_I^N = (g^{\perp} * \tilde{f}^N)_I, \tag{3.3}$$

where we set $\tilde{f}_I^N(Z_I) = \tilde{f}_k^N(Z_I)$ if $|I| = k$. We assume that

$$\tilde{f}_{\emptyset}^N = g_{\emptyset} = v_{\emptyset}^N = 1\,. \tag{3.4}$$

We want to stress that, if it were

$$\tilde{f}_I^N(Z_I) = \prod_{i\in I} f(z_i),$$

then

$$v_I^N(Z_I) = \prod_{i=1}^{|I|}[g(z_i) - f(z_i)]. \tag{3.5}$$

This means, in a sense, that the functions v^N represent the product of the differences rather than the difference of the products which we would have to deal with.

By (3.4) it follows that the definition (3.3) can be inverted to obtain

$$\tilde{f}_I^N = (g * v^N)_I, \tag{3.6}$$

and this implies, as it can be easily seen, that

$$\|\tilde{f}_k^N - g_k\|_{L_1} \le \sum_{J\subset I,\, J\neq\emptyset} \|v_J^N\|_{L_1}\,, \tag{3.7}$$

where $I = \{1, \dots, k\}$. Therefore we will prove Theorem 2.5 by estimating v^N.

As a consequence of Theorem 2.1, we have the following.

LEMMA 3.1. *For any $\eta > 0$ there exists a $T(\eta)$ such that, for $t > T(\eta)$ and $J \subset I$, the following estimate holds:*

$$\|S_J(t)v_I^N\|_{L_1} \le \eta^j \|v_I^N\|_{L_1}\,, \tag{3.8}$$

where $S_J(t) = \prod_{i\in J} S_{\{i\}}(t)$ and $j = |J|$.

Remark. Had we considered directly the difference $\tilde f_I^N - g_I$ in place of v_I^N; at the best we would have obtained $\|S_J(t)(\tilde f_I^N - g_I)\|_{L_1} \le \eta\|\tilde f_I^N - g_I\|_{L_1}$, and this is not sufficient for our purpose.

Proof. We first prove that, for all $\eta > 0$, there exists $T(\eta)$ such that, for $t > T(\eta)$, for all $u = u(z), u \in L_1$, satisfying $\int u dz = 0$, one has

$$\|S(t)u\|_{L_1} \le \eta\|u\|_{L_1}\,. \tag{3.9}$$

Indeed, denoting by u^+ and u^- the positive and negative part of u, respectively, setting

$$A = \int u^+ dz = \int u^- dz \tag{3.10}$$

we have by Theorem 2.1

$$\begin{aligned}\|S(t)u\|_{L_1} &= \|S(t)u^+ - S(t)u^-\|_{L_1}\\ &\le A\|S(t)\left(\frac{u^+}{A}\right) - \bar g\|_{L_1} + A\|S(t)\left(\frac{u^-}{A}\right) - \bar g\|_{L_1} \le 2A\eta = \eta\|u\|_{L_1}.\end{aligned} \tag{3.11}$$

Let $J = \{i_1, \dots, i_j\}$, and define the functions

$$r_k(Z_I) = S_{\{i_1,\dots,i_k\}}(t)\, v_I^N(Z_I)\,, \qquad k = 0, 1, \dots, j\,.$$

These functions satisfy

$$\int r_{k-1}(Z_I)\, dz_{i_k} = 0\,, \qquad k = 1, \dots, j,$$

since $\int v_I^N(Z_I)\, dz_i = 0\,,\ \forall i \in I\,,$ as a consequence of the definition of v^N. Thus, we obtain from (3.9) that

$$\int |r_k(Z_I)|\, dz_{i_k} = \int |S_{\{i_k\}}(t)\, r_{k-1}(Z_I)|\, dz_{i_k} \le \eta \int |r_{k-1}(Z_I)|\, dz_{i_k}$$

and $\|r_k\|_{L_1} \le \eta\, \|r_{k-1}\|_{L_1}\,,\ k = 1, \dots, j$, so that (3.8) follows immediately. □

We recall that $(P^N(t)\tilde f^N)_I = \tilde f_I^N$ for all I such that $0 < |I| \le N$ and $(P(t)g)_I = g_I$ for all I with $|I| > 0$. We extend this invariance property to the empty set; that is, (see (3.4))

$$(P^N(t)\tilde f^N)_\emptyset = 1\,, \qquad (P(t)g)_\emptyset = 1. \tag{3.12}$$

We also put

$$(P(t)\tilde f^N)_\emptyset = 1. \tag{3.13}$$

For any finite set of indices I, we have

$$v_I^N = (g^\perp * \tilde{f}^N)_I = (g^\perp * P^N(t)\tilde{f}^N)_I \tag{3.14}$$
$$= (g^\perp * P(t)\tilde{f}^N)_I + (g^\perp * [P^N(t) - P(t)]\tilde{f}^N)_I.$$

Before going on with the estimate of v^N, we introduce a suitable norm. Given an infinite sequence of L_1-functions $\phi = \{\phi_k\}$ and a real positive number α we set

$$\|\phi\|_\alpha = \sup_{k=1,2,\dots,} \|\phi_k\|_{L_1} e^{-\alpha k}. \tag{3.15}$$

Putting

$$R_I^N(t) = (g^\perp * [P^N(t) - P(t)]\tilde{f}^N)_I \tag{3.16}$$

by Theorem 2.4 and (3.12) and (3.13), it follows that for $\alpha \geq 2\log 3$ and $\lambda t < \frac{1}{8a}$, we have

$$\|R^N(t)\|_\alpha \leq \frac{c_2}{N}\,. \tag{3.17}$$

Indeed, suppose $|I| = k$,

$$\|R_I^N(t)\|_{L_1} \leq \sum_{h=1}^{k} \binom{k}{h} \|([P^N(t) - P(t)]\tilde{f}^N)_h\|_{L_1} \leq \frac{9^k c_2}{N} \tag{3.18}$$

so that (3.17) follows.

Since $(g^\perp * g)_I = 0$ if $|I| > 0$, we have by (3.4), (3.12), and (3.14) that

$$v_I^N = (g^\perp * P(t)(\tilde{f}^N - g))_I + R_I^N(t) := (g^\perp * P(t)\psi)_I + R_I^N(t) \tag{3.19}$$

where, by (3.6) we have put

$$\psi_I = \sum_{\substack{S\subset I \\ |S|>0}} v_S^N g_{I\setminus S}, \qquad \psi_\emptyset = 0. \tag{3.20}$$

We prove the following result.

LEMMA 3.2. *Let η be a positive real number and choose $T(\eta)$ as in Lemma* 3.1. *Then, for any integer $k > 0$ and $t > T(\eta)$, the following estimate holds:*

$$\|(P(t)\psi)_k - S_k(t)\psi_k\|_{L_1} \leq \frac{\delta_k}{1 - 2a\lambda t(e^\alpha + 1)} \|v^N\|_\alpha, \tag{3.21}$$

with $\delta_k = 2^k(1 + k2^{k-1}e^\alpha)(\frac{\eta}{2} + 2a\lambda t(e^\alpha + 1))$, provided that λ and η are so small to satisfy $e^\alpha[\frac{\eta}{2} + 2a\lambda t(e^\alpha + 1)] < 1$.

Proof. To prove the lemma, we write the expansion already introduced in (2.34)–(2.35). More precisely,

$$(P(t)\psi)_k = \sum_{n\geq 0} \lambda^n \int_0^t \int_0^{t_1} \cdots \int_0^{t_{n-1}} dt_1 \dots dt_n \sum_{i_1=1}^{k} \sum_{i_2=1}^{k+1} \cdots \sum_{i_n=1}^{k+n-1}$$

$$\times S_k(t - t_1) C_{k,k+1}^{i_1}, \dots, S_{k+n-1}(t_{n-1} - t_n) C_{k+n-1,k+n}^{i_n} S_{k+n}(t_n)\psi_{k+n}, \tag{3.22}$$

where

$$\sum_{i_r=1}^{k+r-1} C^{i_r}_{k+r-1,k+r} = C_{k+r-1,k+r}, \qquad r = 1, 2, \dots, n,$$

that is, $C^{i_r}_{k+r-1,k+r}$ is the contribution due to the collision of the i_rth particle (among the $k+r-1$ particles) with the $k+r$th. Let us indicate by I_r the set of indices $\{1, 2, \dots, r\}$ and by $I(k,n)$ the set $I_{k+n} \setminus I_k \equiv \{k+1, \dots, n\}$. Then by the definition of ψ it is

$$\psi_{k+n} = \sum_{S_1 \subseteq I_k} \sum_{S_2 \subseteq I(k,n)} v^N_{S_1 \cup S_2} g_{I_{k+n} \setminus (S_1 \cup S_2)} \chi(|S_1| + |S_2| > 0). \tag{3.23}$$

We now select among the particles in S_1 those which do not interact with any other particle. To this end, we consider the set $J = S_1 \setminus \{i_1, \dots, i_n\}$ and notice that

$$\sum_{i_1,\dots,i_n} \sum_{S_1 \subseteq I_k} \sum_{S_2 \subseteq I(k,n)} = \sum_{S_1 \subseteq I_k} \sum_{S_2 \subseteq I(k,n)} \sum_{J \subseteq S_1} \sum_{i_1,\dots,i_n} \prod_{r=1}^{n} \chi(i_r \notin J)\,. \tag{3.24}$$

Defining $n(s_1, j) = \max(s_1 - j, 1)$, (3.22) and (3.23) imply

$$(P(t)\psi)_k = S_k(t)\psi_k + \sum_{s_1=0}^{k} \sum_{\substack{S_1 \subseteq I_k \\ |S_1| = s_1}} \sum_{j=0}^{s_1} \sum_{\substack{J \subseteq S_1 \\ |J| = j}} \sum_{n > n(s_1,j)} \sum_{i_1,\dots,i_n} \lambda^n \tag{3.25}$$

$$\times \prod_{r=1}^{n} \chi(i_r \notin J) \sum_{s_2=0}^{n} \sum_{\substack{S_2 \subseteq I(n,k) \\ |S_2| = s_2}} \chi(s_1 + s_2 > 0) \int_0^t \int_0^{t_1} \cdots \int_0^{t_{n-1}} dt_1 \dots dt_n$$

$$\times S_{I_k \setminus J}(t - t_1) C^{i_1}_{k-j,k-j+1} S_{I_k \setminus J \cup \{i_1\}}(t_1 - t_2) \dots C^{i_n}_{k-j+n-1,k-j+n}$$

$$\times S_J(t) v^N_{S_1 \cup S_2} g_{I_{n+k} \setminus S_1 \cup S_2}.$$

Here we are using the notation $S_A(t) = \prod_{i \in A} S_{\{i\}}(t)$ and hence, $S_A(t)$ represents the Knudsen semigroup associated with the free motion of the particles with labels in A.

Formula (3.25) follows from the fact that we have selected J as the set of particles not interacting with the rest, and hence $S_J(t)$ commutes with all other operators.

By Lemma 3.1, for $\eta > 0$ and $t > T(\eta)$ we have

$$\|S_J(t) v^N_{S_1 \cup S_2}\|_{L_1} \le \eta^j \|v^N_{S_1 \cup S_2}\|_{L_1},$$

where $j = |J|$. Moreover,

$$\|g_{I_{n+k} \setminus S_1 \cup S_2}\|_{L_1} = 1.$$

Thus, using the equality

$$\sum_{i_1=1}^{k} \sum_{i_2=1}^{k+1} \cdots \sum_{i_n=1}^{k+n-1} \prod_{r=1}^{n} \chi(i_r \notin J) = \frac{(k-j+n-1)!}{(k-j-1)!},$$

by (2.37) we arrive at the formula

$$\|(P(t)\psi)_k - S_k(t)\psi_k\|_{L_1} \le \|v^N\|_\alpha \sum_{s_1=0}^{k} \binom{k}{s_1} \sum_{j=0}^{s_1} \binom{s_1}{j} \eta^j \sum_{n>n(s_1,j)} \sum_{s_2=0}^{n} \binom{n}{s_2}$$

$$\times \frac{(2a\lambda t)^n}{n!} \frac{(k-j+n-1)!}{(k-j-1)!} e^{\alpha(s_1+s_2)} \chi(s_1+s_2>0)\,. \tag{3.26}$$

Now we separate from the rest the term corresponding to $s_1 = 0$ and obtain

(3.27)

$$\|(P(t)\psi)_k - S_k(t)\psi_k\|_{L_1} \le \|v^N\|_\alpha 2^k \sum_{n\ge 1} (2a\lambda t)^n \sum_{s_2=1}^{n} \binom{n}{s_2} e^{\alpha s_2}$$
$$+ \|v^N\|_\alpha \sum_{s_1=1}^{k} \binom{k}{s_1} e^{\alpha s_1} \sum_{j=0}^{s_1} \binom{s_1}{j} \eta^j 2^{k-j} \sum_{n>n(s_1,j)} (2a\lambda t)^n \sum_{s_2=0}^{n} \binom{n}{s_2} e^{\alpha s_2}.$$

Since

$$\sum_{h=0}^{n} \binom{n}{h} a^h = (1+a)^n,$$

it follows that

(3.28)

$$\|(P(t)\psi)_k - S_k(t)\psi_k\|_{L_1} \le \|v^N\|_\alpha 2^k \sum_{n\ge 1} (2a\lambda t)^n (1+e^\alpha)^n$$
$$+ \|v^N\|_\alpha 2^k \sum_{s_1=1}^{k} \binom{k}{s_1} e^{\alpha s_1} \sum_{j=0}^{s_1} \binom{s_1}{j} \left(\frac{\eta}{2}\right)^j \sum_{n>n(s_1,j)} (2a\lambda t)^n (1+e^\alpha)^n.$$

By the hypothesis on λ, $2a\lambda t(1+e^\alpha) < 1$ so that we have

(3.29)

$$\|(P(t)\psi)_k - S_k(t)\psi_k\|_{L_1} \le \|v^N\|_\alpha 2^k \frac{2a\lambda t(1+e^\alpha)}{1-2a\lambda t(1+e^\alpha)}$$
$$+ \|v^N\|_\alpha \frac{2^k}{1-2a\lambda t(1+e^\alpha)} \sum_{s_1=1}^{k} \binom{k}{s_1} e^{\alpha s_1} \sum_{j=0}^{s_1} \binom{s_1}{j} \left(\frac{\eta}{2}\right)^j [2a\lambda t(1+e^\alpha)]^{s_1-j}.$$

After a few simple calculations, we arrive at

(3.30)

$$\|(P(t)\psi)_k - S_k(t)\psi_k\|_{L_1} \le \|v^N\|_\alpha \frac{2^k}{1-2a\lambda t(1+e^\alpha)}$$
$$\times \left\{ 2a\lambda t(1+e^\alpha) + \left[1 + e^\alpha \left(\frac{\eta}{2} + 2a\lambda t(1+e^\alpha)\right)\right]^k - 1 \right\}.$$

Using the elementary inequality

$$(1+x)^k - 1 \le k2^{k-1}x, \qquad x \in [0,1], \tag{3.31}$$

we obtain

$$\le \|v^N\|_\alpha \frac{2^k}{1-2a\lambda t(1+e^\alpha)} \left[2a\lambda t(1+e^\alpha) + k2^{k-1}e^\alpha \left(\frac{\eta}{2} + 2a\lambda t(1+e^\alpha)\right)\right] \tag{3.30}$$

$$\le \|v^N\|_\alpha \frac{2^k(1+k2^{k-1}e^\alpha)}{1-2a\lambda t(1+e^\alpha)} \left[\frac{\eta}{2} + 2a\lambda t(1+e^\alpha)\right], \tag{3.32}$$

and the lemma is proven. □

We have by Lemma 3.1 and (2.36), recalling the definition (3.20) of ψ,

$$\|S_k(t)\psi_k\|_{L_1} \le \sum_{j=1}^k \sum_{\substack{J\subseteq I_k \\ |J|=j}} \|S_k(t)v_J^N g_{I_k\setminus J}\|_{L_1}$$

$$\le \sum_{j=1}^k \sum_{\substack{J\subseteq I_k \\ |J|=j}} \eta^j \|v_J^N\|_{L_1} \le \|v^N\|_\alpha \sum_{j=1}^k \binom{k}{j} \eta^j e^{\alpha j}$$

$$= \|v^N\|_\alpha [(1+e^\alpha\eta)^k - 1] \le \|v^N\|_\alpha k2^{k-1}e^\alpha\eta \tag{3.33}$$

for $e^\alpha\eta \le 1$.

From Lemma 3.2 and (3.33) it finally follows that

$$\|(P(t)\psi)_k\|_{L_1} \le 2\frac{\delta_k}{1-2a\lambda t(1+e^\alpha)} \|v^N\|_\alpha . \tag{3.34}$$

Now the proof of the theorem is nearly complete. The estimate (3.34), together with the fact that $(P(t)\psi)_\emptyset = 0$, imply for $2a\lambda t(1+e^\alpha) < \frac{1}{2}$ that

$$\|(g^\perp * P(t)\psi)_k\|_{L_1} \le 4\|v^N\|_\alpha \sum_{j=1}^k \binom{k}{j} \delta_j$$

$$\le 4\|v^N\|_\alpha \left(\frac{\eta}{2} + 2a\lambda t(e^\alpha+1)\right) \sum_{j=1}^k \binom{k}{j} 2^j(1+j2^{j-1}e^\alpha)$$

$$\le 4\|v^N\|_\alpha(\eta + 2a\lambda t(e^\alpha+1))2e^\alpha \sum_{j=0}^k \binom{k}{j} 2^{3j}$$

$$\le 8\|v^N\|_\alpha(\eta + 2a\lambda t(e^\alpha+1))e^\alpha 9^k. \tag{3.35}$$

Thus

$$\|(g^\perp * P(t)\psi)_k\|_{L_1} e^{-\alpha k} \le 8\|v^N\|_\alpha(\eta + 2a\lambda t(e^\alpha+1))e^\alpha e^{(\log 9-\alpha)k}. \tag{3.36}$$

Now we can fix the parameters λ, T, η. We recall that $\alpha \geq 2\log 3$, and choose $\eta \leq \frac{1}{32e^{\alpha}}$. Consequently we fix $t = T(\eta)$ as in Lemma 3.1. Finally we choose λ in such a way that $e^{\alpha} 2a\lambda t(e^{\alpha}+1) \leq \frac{1}{32}$. Then we have

$$\|g^{\perp} * P(t)\psi\|_{\alpha} \leq \frac{1}{2}\|v^N\|_{\alpha} \tag{3.37}$$

and, by (3.19) and (3.37),

$$\|v^N\|_{\alpha} \leq 2\|R^N(t)\|_{\alpha}$$

so that (3.17) concludes the proof. □

Appendix.

Proof of Theorem 2.1. Consider $S(t)$ to be the Knudsen flow and $P_t(x', v'; x, v)$ to be the transition probability densities given by

$$\int P_t(x', v'; x, v) f(x', v') dx' dv' = S(t) f(x, v)$$

for $f \in L_1(\Omega \times V)$. For any final state (x, v), trace the backward trajectories $x - s\, v$ up to the instant (say t) of the collision with the boundary. Denote $y = y(x, v) = x - v\, t \in \partial\Omega$ as the point of the collision.

We introduce the set

$$\mathcal{M}(\beta) = \{(x, v) \in \Omega \times V : |v \cdot n(y)|\, M(y, v) \geq \beta\}, \qquad \beta > 0. \tag{A.1}$$

Note that for all $(x, v) \in \mathcal{M}(\beta)$, the transition $(y, v) \to (x, v)$ is performed with positive probability density (cf. (2.8)). Let

$$t_0 = \frac{4\, d_{\max}}{u_{\min}}, \tag{A.2}$$

where $u_{\min} > 0$ denotes the modulus of the smallest velocity, while $d_{\max}$ is the diameter of Ω.

We first show that

$$\inf_{x', v'} \inf_{(x,v) \in \mathcal{M}(\beta)} P_{t_0}(x', v'; x, v) \geq \gamma > 0. \tag{A.3}$$

Tracing the forward trajectory $x' + s\, v'$ up to the instant (say t') of the collision with the boundary, we denote by $y' = y'(x', v') = x' + v'\, t'$ the hitting point. So we still have to connect the points y' and y by some trajectory within the remaining time $t_0 - t - t'$. These trajectories should be such that both the upper bound for their length and the positive lower bound for their probability density are uniform in y, y'.

Assumption A (concerning Ω). For all $y, y' \in \partial\Omega$, there exists $y_1 \in \partial\Omega$ such that

$$\min(\|y_1 - y\|, \|y_1 - y'\|) \geq \varepsilon \tag{A.4}$$

and

$$|e(y', y_1) \cdot n(y')| \geq \varepsilon, \quad |e(y_1, y) \cdot n(y_1)| \geq \varepsilon, \quad |e(y, y_1) \cdot n(y)| \geq \varepsilon, \tag{A.5}$$

where $e(y, y_1) = \frac{y_1 - y}{\|y_1 - y\|}$, and $\varepsilon > 0$ does not depend on y, y', y_1.

Remark. This assumption is fulfilled if Ω has a smooth boundary, but it is also fulfilled in other cases. Note that, for simplicity, we assume Ω to be convex.

Assumption B (concerning M). There exists $u_0 > 0$ such that

$$M(x,v) \geq M_{\min} > 0, \quad \text{if} \quad u_0 \leq \|v\| \leq 4\,u_0. \tag{A.6}$$

Remark. This assumption is fulfilled if, e.g., M is a Maxwellian.

We first go from y' to $y_1 = y_1(y,y')$ provided by Assumption A, with a velocity satisfying (A.6), and then spend the rest of the time travelling between y_1 and y. The remaining time τ satisfies

$$\frac{d_{\max}}{u_{\min}} \leq \tau \leq \frac{4\,d_{\max}}{u_{\min}}, \tag{A.7}$$

since all flight times within Ω are bounded by $\frac{d_{\max}}{u_{\min}}$.

Note that, according to (A.7), one step from y_1 to y is not enough. Therefore, we choose some flight time $t^* \in (t_{\min}, t_{\max})$, where

$$t_{\min} = t_{\min}(y_1,y) = \frac{\|y-y_1\|}{4\,u_0}, \qquad t_{\max} = t_{\max}(y_1,y) = \frac{\|y-y_1\|}{u_0}, \tag{A.8}$$

and u_0 is provided by Assumption B. The velocities $v^* = \frac{y-y_1}{t^*}$ and $-v^*$ allow us to go both directions with probability density uniformly bounded from below. Indeed, according to (A.5) and (A.6), we have (cf. (2.8))

$$|v^* \cdot n(y_1)|\, M(y_1,v^*) = \|v^*\|\, |\frac{v^*}{\|v^*\|} \cdot n(y_1)|\, M(y_1,v^*) \geq u_0\,\varepsilon\, M_{\min}.$$

The same is true for y and $-v^*$.

We go in double steps before making the last one. Thus, we have to solve the equation

$$2\,l\,t^* + s = \tau, \tag{A.9}$$

for each τ satisfying (A.7), with respect to $s \in (t_{\min}, t_{\max})$ and $l = 0,1,\dots$. To this end, the intervals

$$(2\,l\,t^* + t_{\min}, 2\,l\,t^* + t_{\max}), \qquad l = 0,1,\dots, \tag{A.10}$$

should cover the interval given by (A.7). This is fulfilled if the intervals (A.10) overlap, i.e., one needs the condition

$$2\,l\,t^* + t_{\max} > 2\,(l+1)\,t^* + t_{\min} \qquad l = 0,1,\dots,$$

or $2\,(t^* - t_{\min}) < t_{\max} - 3\,t_{\min} = t_{\min}$, which is fulfilled provided that

$$t_{\min} < t^* < \frac{3}{2}\,t_{\min}.$$

Using (A.9), (A.7), and (A.8), the number l is estimated from above uniformly in y, y_1,

$$l \leq \frac{\tau}{2\,t^*} \leq \frac{8\,d_{\max}\,u_0}{u_{\min}\,\varepsilon},$$

where ε is from (A.4).

Now let $z = (x, v)$, $z' = (x', v')$ be states of the system and t_0 be defined in (A.2). We denote

$$P(z', z) = P_{t_0}(x', v'; x, v), \qquad Sf(z) = \int P(z', z)\, f(z')\, dz' = S(t_0) f(z), \tag{A.11}$$

$$\pi(z', Z';\, z) = \min\Big(P(z', z), P(Z', z)\Big) \tag{A.12}$$

and

$$\tilde{\pi}(z', Z') = \int \pi(z', Z';\, z)\, dz\,. \tag{A.13}$$

Note that $\pi \geq 0$ and $0 \leq \tilde{\pi}(z', Z') \leq 1$.

Define a transition probability

$$\hat{P}(z', Z';\, z, Z) \tag{A.14}$$

$$= \pi(z', Z';\, z)\, \delta(z - Z) + \frac{[P(z', z) - \pi(z', Z';\, z)]\, [P(Z', Z) - \pi(z', Z';\, Z)]}{1 - \tilde{\pi}(z', Z')}$$

and the operator

$$\hat{S}\, \Phi(z; Z) = \int\int \hat{P}(z', Z'; z, Z)\, \Phi(z', Z')\, dz'\, dZ'. \tag{A.15}$$

Note that

$$\int\int \hat{P}(z', Z';\, z, Z)\, dz\, dZ = \tilde{\pi}(z', Z') + \frac{[1 - \tilde{\pi}(z', Z')]\, [1 - \tilde{\pi}(z', Z')]}{1 - \tilde{\pi}(z', Z')} = 1.$$

The corresponding Markov chain behaves as follows.

With probability $\tilde{\pi}(z', Z')$, there is a transition from (z', Z') into (z, Z) according to

$$\frac{\pi(z', Z';\, z)}{\tilde{\pi}(z', Z')}\, \delta(z - Z),$$

i.e., z is distributed according to $\frac{\pi(z', Z';\, z)}{\tilde{\pi}(z', Z')}$ and $Z = z$.

With probability $1 - \tilde{\pi}(z', Z')$, there is a transition from (z', Z') into (z, Z) according to

$$\frac{[P(z', z) - \pi(z', Z';\, z)]\, [P(Z', Z) - \pi(z', Z';\, Z)]}{[1 - \tilde{\pi}(z', Z')]^2},$$

i.e., z, Z are independent and distributed according to $\frac{P(z', z) - \pi(z', Z';\, z)}{1 - \tilde{\pi}(z', Z')}$ and $\frac{P(Z', Z) - \pi(z', Z';\, Z)}{1 - \tilde{\pi}(z', Z')}$, respectively.

Note that if $z' = Z'$ then, according to (A.12) and (A.13), we have $\pi(z', Z';\, z) = P(z', z)$ and $\tilde{\pi}(z', Z') = 1$. Thus, z is distributed according to $P(z', z)$ and $Z = z$ so that the particles remain together.

LEMMA A.1. *Let R be a* **joint representation** *of f and g, i.e.,*

$$\int R(z,Z)\,dZ = f(z) \quad \textit{and} \quad \int R(z,Z)\,dz = g(Z),$$

and let $S, \hat{S}$ be defined in (A.11) *and* (A.15). *Then, for any $n \geq 1$,*

$$\|S^n f - S^n g\|_{L_1} \leq 2 \int\int \rho(z,Z)\,\hat{S}^n R(z,Z)\,dz\,dZ,$$

where ρ is the discrete distance, i.e., $\rho(z,Z) = 1$ if $z \neq Z$ and $\rho(z,Z) = 0$ if $Z = z$.

Proof. We first show that $\hat{S}^n R$ is a joint representation of $S^n f$ and $S^n g$, for any $n \geq 1$. From (A.15) and (A.14) we obtain

$$\int \hat{S}\,R(z,Z)\,dz$$

$$= \int\int \left[\pi(z',Z';\,Z) + \frac{[1-\tilde{\pi}(z',Z')]\,[P(Z',Z) - \pi(z',Z';\,Z)]}{1-\tilde{\pi}(z',Z')}\right] R(z',Z')\,dz'\,dZ'$$

$$= \int\int P(Z',Z)\,R(z',Z')\,dz'\,dZ' = \int P(Z',Z)\,g(Z')\,dZ' = S\,g(Z).$$

Analogously one shows that $\int \hat{S}\,R(z,Z)\,dZ = S\,f(z)$, so that $\hat{S}R$ is indeed a joint representation of Sf and Sg. The general case is established by induction.

The case $n = 1$ is now obtained from the estimate

$$\|S\,f - S\,g\|_{L_1}$$

$$= \int \left|\int \hat{S}R(z,Z)\,dZ - \int \hat{S}R(Z,z)\,dZ\right| dz \leq \int\int |\hat{S}R(z,Z) - \hat{S}R(Z,z)|\,dZ\,dz$$

$$= \int\int \rho(z,Z)\,|\hat{S}R(z,Z) - \hat{S}R(Z,z)|\,dZ\,dz \leq 2\int\int \rho(z,Z)\,\hat{S}R(z,Z)\,dZ\,dz.$$

In the general case we have

$$\|S^n f - S^n g\|_{L_1}$$

$$= \|S(S^{n-1}f) - S(S^{n-1}g)\|_{L_1} \leq 2\int\int \rho(z,Z)\,\hat{S}(\hat{S}^{n-1}R)(z,Z)\,dZ\,dz,$$

which completes the proof. □

LEMMA A.2. *Let $\hat{S}$ be defined in* (A.15) *and let R be a probability density function. Then there exists $\varepsilon > 0$ such that*

$$\int\int \rho(z,Z)\hat{S}^n R(z,Z)\,dz\,dZ \leq (1-\varepsilon)^n, \quad \forall n \geq 1.$$

Proof. According to (A.11), (A.12), and (A.13), we have

$$\tilde{\pi}(z', Z') = \inf_{x', v'; x, v} \int\int \min\Big(P_{t_0}(x', v'; y, w), P_{t_0}(x, v; y, w)\Big)\, dy\, dw\,.$$

Thus, using (A.3) we obtain

$$\tilde{\pi}(z', Z')$$

$$\geq \int\int \inf_{x', v'} P_{t_0}(x', v'; y, w)\, dy\, dw \geq \int\int \chi_{\mathcal{M}(\beta)}(y, w) \inf_{x', v'} P_{t_0}(x', v'; y, w)\, dy\, dw$$

$$\geq \inf_{x', v'} \inf_{(y,w)\in\mathcal{M}(\beta)} P_{t_0}(x', v'; y, w)\, \lambda(\mathcal{M}(\beta)) \geq \gamma\, \lambda(\mathcal{M}(\beta)),$$

where the symbol χ denotes the indicator function. Consequently, the estimate

$$1 \geq \tilde{\pi}(z', Z') \geq \varepsilon > 0 \tag{A.16}$$

holds, since the set $\mathcal{M}(\beta)$, defined in (A.1), has positive Lebesgue measure.

Consider a Markov chain (ξ_n, ζ_n) with the transition function (A.14). Let the random variables ξ_0, ζ_0 have the joint distribution R. Then the random variables ξ_n, ζ_n have the joint distribution $\hat{S}^n R$, and

$$\int\int \rho(z, Z)\, \hat{S}^n R(z, Z)\, dz\, dZ = P(\xi_n \neq \zeta_n), \tag{A.17}$$

where P denotes the probability. We obtain

$$P(\xi_n \neq \zeta_n) = P(\xi_n \neq \zeta_n \,|\, \xi_{n-1} = \zeta_{n-1})\, P(\xi_{n-1} = \zeta_{n-1})$$

$$+ \int\int \rho(z, Z)\, P(\xi_n \neq \zeta_n \,|\, \xi_{n-1} = z\,,\, \zeta_{n-1} = Z)\, \hat{S}^{n-1} R(z, Z)\, dz\, dZ$$

$$\leq \int\int \rho(z, Z)\, [1 - \tilde{\pi}(z, Z)]\, \hat{S}^{n-1} R(z, Z)\, dz\, dZ\,,$$

according to (A.14). Using (A.16) and (A.17), we get

$$P(\xi_n \neq \zeta_n) \leq (1 - \varepsilon) \int\int \rho(z, Z)\, \hat{S}^{n-1} R(z, Z)\, dz\, dZ = (1 - \varepsilon)\, P(\xi_{n-1} \neq \zeta_{n-1}),$$

and the result follows by iteration. ∎

From Lemmas A.1 and A.2 we get

$$\|S^n f - S^n g\|_{L_1} \leq 2\,(1 - \varepsilon)^n, \tag{A.18}$$

and, consequently,

$$\|S^{n+m} f - S^n f\|_{L_1} = \|S^n S^m f - S^n f\|_{L_1} \leq 2\,(1 - \varepsilon)^n.$$

Because of the completeness of L_1, this implies existence of some $\bar{g} = \lim_{n\to\infty} S^n f$, for which we have $S\bar{g} = \bar{g}$. Moreover, uniqueness of such $\bar{g}$ follows from (A.18).

Note that $\lim_{n\to\infty} f_n = \bar{g}, f_n \geq 0 \|f_n\|_{L_1} = 1$ imply $\bar{g} \geq 0$ and $\|\bar{g}\|_{L_1} = 1$, since $|\int \bar{g} - 1| \leq \int |\bar{g} - f_n|$.

Finally, from (A.18) we have, for $t \in [t_0\, n, t_0\, (n+1))$,

$$\|S(t)f - \bar{g}\|_{L_1} \leq \|S^n S(t - t_0\, n)f - S^n f\|_{L_1} + \|S^n f - \bar{g}\|_{L_1} \leq 4\,(1-\varepsilon)^n \leq 4\,(1-\varepsilon)^{\frac{t}{t_0}},$$

and (2.15) follows. Moreover, it follows from (A.18) that

$$\|S(t)\bar{g} - \bar{g}\|_{L_1} = \|S(t)S^n\bar{g} - S^n\bar{g}\|_{L_1} \leq 2\,(1-\varepsilon)^n\,, \quad \forall n,$$

which implies (2.14). □

Proof of Theorem 2.2. Let $p = p(x,v,t)$ and $l = l(x,v,t)$ be two solutions of the initial boundary value problem (2.1)–(2.3), with initial conditions p_0 and l_0, respectively. Writing the evolution equation in mild form (2.10), we have

$$p(t) - l(t) = S(t)(p_0 - l_0) + \lambda \int_0^t ds\, S(t-s)Q(p(s) + l(s), p(s) - l(s)),$$

where $Q(f,g)$ is the symmetrized collision operator (2.4).

By (3.9) we have that, if $h = h(x,v)$ has the property $\int h = 0$, then

$$\|S(t)h\|_{L_1} \leq e^{-bt}\|h\|_{L_1}.$$

Since $\int Q(f,g) = 0$ for any pair of functions f and g, we have (cf. (2.38))

$$\|p(t) - l(t)\|_{L_1} \leq e^{-bt}\|p_0 - l_0\|_{L_1} + 2a\lambda \int_0^t ds\, e^{-b(t-s)}\|p(s) - l(s)\|_{L_1},$$

so that, using the Gronwall lemma,

$$\|p(t) - l(t)\|_{L_1} \leq \|p_0 - l_0\|_{L_1} e^{-(b-2a\lambda)t}.$$

In particular, we obtain

$$\|p(t+\tau) - p(t)\|_{L_1} \leq \|p(\tau) - p_0\|_{L_1} e^{-(b-2a\lambda)t} \leq 2\, e^{-(b-2a\lambda)t}\,, \quad \forall \tau \geq 0.$$

Therefore, if $\lambda < \frac{b}{2a}$, there exists a probability density g which is the unique global attracting point for the flow described by (2.1) and also the unique invariant solution for such an evolution problem. □

Remark. It is not hard to show that g solves the stationary equation $(G^{free})^* g + \lambda Q(g,g) = 0$ and also solves the boundary value problem (2.13). In particular, the trace of g on the boundary does exist. These considerations are not relevant for the present analysis, so we do not go further.

Proof of Theorem 2.3. This theorem is easily proved using the same arguments as for the Knudsen flow. Indeed, it is enough to observe that for a fixed time t, the probability of each particle of the system to perform a collisionless motion is strictly positive. We remark that in [GLP] the same result has been obtained in a more difficult context.

ISOSPECTRAL SETS FOR FOURTH-ORDER ORDINARY DIFFERENTIAL OPERATORS*

LESTER F. CAUDILL, JR.†, PETER A. PERRY‡, AND ALBERT W. SCHUELLER§

Abstract. Let $L(p)u = D^4u - (p_1u')' + p_2u$ be a fourth-order differential operator acting on $L^2[0,1]$ with $p \equiv (p_1, p_2)$ belonging to $L^2_{\mathbb{R}}[0,1] \times L^2_{\mathbb{R}}[0,1]$ and boundary conditions $u(0) = u''(0) = u(1) = u''(1) = 0$. We study the isospectral set of $L(p)$ when $L(p)$ has simple spectrum. In particular we show that for such p, the isospectral manifold is a real-analytic submanifold of $L^2_{\mathbb{R}}[0,1] \times L^2_{\mathbb{R}}[0,1]$ which has infinite dimension and codimension. A crucial step in the proof is to show that the gradients of the eigenvalues of $L(p)$ with respect to p are linearly independent: we study them as solutions of a non-self-ajdoint fifth-order system, the *Borg system*, among whose eigenvectors are the gradients.

Key words. inverse spectral problem, ordinary differential equations

1. Introduction.

This paper initiates a study of isospectral sets of coefficients for self-adjoint, fourth-order ordinary differential operators, in Liouville–Green normal form, on the finite interval $[0,1]$. Such operators are labelled by a pair of coefficients $p = (p_1, p_2)$. Our motivation is twofold: first, we would like to understand the inverse spectral problem for fourth-order operators such as the Euler–Bernoulli operator of mechanics; second, we would like to develop techniques of analysis which are systematic in nature and are therefore likely to be useful in the study of other singular and higher order ordinary differential operators. Our goal is to understand the set of coefficients isospectral to a given pair $p = (p_1, p_2)$ as a Hilbert submanifold of a suitable Hilbert space of coefficients, in analogy to the analysis of the second-order Sturm–Liouville problem carried out by Trubowitz and his collaborators (see [11, 18, 19, 26, 27], and see [10] for more recent results).

As in the work of Trubowitz et. al., we use methods of global analysis to study the isospectral manifold as a level set of the direct spectral map from coefficients to spectra. For the class of operators we consider, the gradient $g_n(x;p)$ of a given eigenvalue $\lambda_n(p)$ is an ordered pair consisting of an eigenfunction square and the square of its derivative, and so the gradient of the mapping from coefficients to spectra is the infinite sequence of all such ordered pairs. A crucial part of the analysis is to show that these ordered pairs form a linearly independent set.

Our approach differs from the approach to the Sturm–Liouville problem taken in [11, 18, 19, 26, 27] in two respects. First of all, we use resolvent perturbation

techniques rather than integral equations and complex analysis to obtain the necessary eigenvalue and eigenfunction asymptotics: see the thesis of the third author [29], where these techniques are developed at greater length. Secondly, we study orthogonality properties of the gradients, not using special identities, but rather by studying an associated non-self-adjoint, fifth-order system, the *Borg system*, among whose eigenvectors are exactly the gradients $g_n(x,p)$. Our system is the analogue, for fourth-order differential operators, of a third-order non-self-adjoint eigenvalue problem introduced by Borg [9] in his study of completeness of eigenfunction squares in the Sturm–Liouville problem. We believe this technique to be a powerful one which admits generalization to other inverse spectral problems involving ordinary differential operators.

To describe our results in detail, we first specify the class of fourth-order operators which we will study. In order to study the isospectral set as a Hilbert manifold, we wish to study operators $L(p)$ where p ranges over a Hilbert space of coefficients; here $L(p)$ is the operator

$$L(p)u = D^4u - D(p_1Du) + p_2u \tag{1.1}$$

on $L^2[0,1]$, where $p = (p_1, p_2)$. In what follows, we will impose "double Dirichlet" boundary conditions $u(0) = u''(0) = u(1) = u''(1) = 0$, although our methods can be used to treat other separated, self-adjoint boundary conditions.

A natural choice for the Hilbert space of coefficients is $E \equiv L^2_{\mathbb{R}}[0,1] \times L^2_{\mathbb{R}}[0,1]$, where $L^2_{\mathbb{R}}[0,1]$ denotes real-valued, square-integrable, measurable functions on $[0,1]$. For such singular coefficients it is convenient to define the operator $L(p)$ by the method of sesquilinear forms (see, for example, Kato [17, Chapter 6]). Since we wish to study real analyticity of various maps on E, it will also be convenient to introduce $E_{\mathbb{C}} \equiv L^2_{\mathbb{C}}[0,1] \times L^2_{\mathbb{C}}[0,1]$ and define $L(p)$ for $p \in E_{\mathbb{C}}$. To this end, we introduce the sesquilinear form

$$q(u,v) = \int_0^1 u''(x)\overline{v''(x)} + p_1(x)u'(x)\overline{v'(x)} + p_2(x)u(x)\overline{v(x)}\,dx \tag{1.2}$$

with the form domain

$$\mathcal{Q}(q) = \{u \in H^2[0,1] : u(0) = u(1) = 0\}$$

for $p \in E_{\mathbb{C}}$. It is not difficult to see that the form q with $p = 0$ is a closed positive form. Using this fact and simple perturbative estimates, one can show that the form q with $0 \neq p \in E_{\mathbb{C}}$ is also closed and sectorial, i.e., that the set

$$\{q(u,u) : u \in \mathcal{Q}(q), \|u\|_{L^2[0,1]} = 1\}$$

is contained in a sector of the complex plane of the form $\Re(z) \geq -c$, $|\Im(z)| \leq (\Re(z)+c)$. Here c depends only on $\|p\|_E$; a complete proof is given in [29, section 5.2].

It follows from the form representation theorem (see, for example, Theorem VI.2.1 of [17]) that there is a unique sectorial operator $L(p)$, i.e., a unique closed operator with numerical range in a sector, associated with the sesquilinear form q. It follows from the same theorem that for all $p \in E_{\mathbb{C}}$, the domain of $L(p)$ is contained in the $H^3[0,1]$ functions with $u(0) = u''(0) = u(1) = u''(1) = 0$. Thus $L(p)$ is an operator with compact resolvent, and its spectrum consists of an infinite sequence, $\{\lambda_n(p)\}$, of discrete eigenvalues. Using the form representation theorem, one can also show

that if $p \in C^1([0,1];\mathbb{C}^2)$, then $L(p)$ is the operator (1.1). For more singular p the action of $L(p)$ may be understood in terms of the quasi-derivatives associated with the operator $L(p)$: see Naimark [25] for the general theory and Schueller [29, section 5.3] for its application to fourth-order operators.

We wish to study isospectral sets of $L(p)$ for $p = (p_1, p_2) \in E$. In order to apply techniques of global analysis, we need to realize the direct spectral map from coefficients to spectral data as a map between Hilbert spaces. To this end, we set

$$\mu_0(p) = \overline{p_1} = \int_0^1 p_1(x)\,dx$$

and

$$\mu_n(p) = \frac{\lambda_n(p) - \lambda_n(0) - n^2\pi^2\overline{p_1}}{n^2\pi^2}.$$

We will show that the sequence $\{\mu_n(p)\}_{n=0}^{\infty}$ belongs to the Hilbert space $F \equiv \ell^2(0 \cup \mathbb{N})$. The *direct spectral map* is the mapping $\mu : E \to F$ defined by $\mu(p) = \{\mu_n(p)\}$. The *isospectral set* $M(p)$ of a given $p \in E$ is the set of all $q \in E$ with $\mu(q) = \mu(p)$. We will say that $p \in E$ has *simple spectrum* if the sectorial operator $L(p)$ has only simple eigenvalues. First of all, we will prove the following theorem.

THEOREM 1.1. *The set of $p \in E$ with simple spectrum is open and dense in E.*

Denote this set by $\mathcal{E}$. There are physically relevant families of fourth-order problems, such as the Liouville–Green normal forms of the Euler–Bernoulli equation, which are known to have simple spectrum (see, e.g., [14]). Thus, restricting attention to $p \in \mathcal{E}$ is not unreasonable for many problems of physical interest. Our main result is as follows.

THEOREM 1.2. *For each $p \in \mathcal{E}$, $M(p) \cap \mathcal{E}$ is a real-analytic submanifold of E of infinite dimension and infinite codimension.*

We can quantify the "size" of $M(p)$ more precisely by introducing some auxiliary boundary value problems associated with the formal differential operator $L(p)$. To define these auxiliary boundary value problems, we introduce the closed sesquilinear forms q_1 and q_2 which are given by the expression (1.2) defined on the respective domains

$$\mathcal{Q}_1 = \{u \in H^2[0,1] : u(0) = 0, u'(1) = 0\}$$

and

$$\mathcal{Q}_2 = \{u \in H^2[0,1] : u(0) = 0, u(1) = u'(1) = 0\}.$$

We denote the associated sectorial operators by $L_1(p)$ and $L_2(p)$, and their corresponding eigenvalues by $\sigma_n(p)$ and $\tau_n(p)$, respectively. For $p \in C_0^\infty([0,1];\mathbb{C}^2)$, these operators carry the following boundary conditions:

$$L(p) : u(0) = u''(0) = u(1) = u''(1) = 0, \tag{1.3}$$

$$L_1(p) : u(0) = u''(0) = u'(1) = u'''(1) = 0, \tag{1.4}$$

$$L_2(p) : u(0) = u''(0) = u(1) = u'(1) = 0. \tag{1.5}$$

We conjecture that for $p \in \mathcal{E}$ and q in a dense and open subset of $M(p)$, the three sets of eigenvalues $\{\lambda_n(q)\}, \{\sigma_n(q)\}, \{\tau_n(q)\}$ give local coordinates for $M(p)$. We expect to prove this in a subsequent paper.

Theorem 1.2 involves a study of the differential of the direct spectral map μ. We will first study μ on a dense subset $\mathcal{D}$ of $\mathcal{E}$ consisting of functions $p \in C_0^\infty((0,1);\mathbb{R}^2)$ such that the spectra of each of the three boundary value problems is simple and the intersection of the sets $\{\lambda_n(p)\}$, $\{\sigma_n(p)\}$, and $\{\tau_n(p)\}$ is empty. We show that the set $\mathcal{D}$ is dense in $\mathcal{E}$ in Theorem 3.1. We will also show that eigenvalues and eigenfunctions associated with operators $L(q)$ with $q \in \mathcal{E}$ can be well approximated by those associated with operators $L(p)$ with $p \in \mathcal{D}$.

To show that the isospectral manifold is real-analytic, we wish to apply the real-analytic implicit function theorem (see, for example, [26, p. 154]). Theorem 1.2 follows from Theorem 1.3.

THEOREM 1.3. *The direct spectral map μ is a real-analytic mapping from $\mathcal{E}$ to F. For $p \in \mathcal{E}$ and each $q \in M(p)$, there is an orthogonal decomposition $T_q\mathcal{E} = \mathcal{E}_v(q) \oplus \mathcal{E}_h(q)$ such that $d\mu(p)$ is a linear isomorphism of $\mathcal{E}_v(q)$ onto F and $\mathcal{E}_h(q)$ has infinite dimension.*

We will prove Theorem 1.3 by showing that (1) the map μ is real-analytic as a map from $\mathcal{E}$ into F, (2) the differential $d\mu(q)$ for an arbitrary $q \in \mathcal{E}$ is well approximated by the differential $d\mu(p)$ of a "nearby" $p \in \mathcal{D}$, and (3) the differential $d\mu(p)$ has the required mapping properties for $p \in \mathcal{D}$.

To explain steps (2) and (3) more fully, let $z_n(\cdot; p)$ be the normalized eigenfunction corresponding to eigenvalue $\lambda_n(p)$. (Note that since $p \in \mathcal{E}$, this eigenfunction is unique up to a phase.) Let $\langle \cdot\ ,\ \cdot \rangle_E$ denote the inner product on E. A short calculation shows that for $p \in \mathcal{D}$, the differential $d\mu(p)$ is given by

$$d\mu(p)(v_1, v_2) = \{\langle g_n(\ \cdot\ ; p), v\rangle_E\}_{n=0}^{\infty}\,, \tag{1.6}$$

where the gradients g_n are given by

$$g_0(x; p) = (1, 0)$$

and

$$g_n(x; p) = \left(\frac{z_n'(x;p)^2}{n^2\pi^2} - 1, \frac{z_n(x;p)^2}{n^2\pi^2}\right), \quad n \geq 1\,. \tag{1.7}$$

We wish to take $\mathcal{E}_v$ to be the span of the g_n and $\mathcal{E}_h$ to be its orthogonal complement, the kernel of $d\mu$. If $\zeta = \sum_j c_j g_j$ and c denotes the sequence $\{c_j\}$, then $\|\zeta\|_E^2 = \langle c, A(q)c\rangle$, where A is the operator on F with matrix $\langle g_i, g_j\rangle_E$. If A is a bounded invertible operator, then the g_j form a *Riesz basis* [8] for $\mathcal{E}_v$, and the operator $T : \mathcal{E}_v \to F$ defined by $T\zeta = c$, is boundedly invertible. Moreover, $S(q) = d\mu(q) \circ T^{-1} \in \mathcal{B}(F, F)$ has matrix $A(q)$ and so is a linear isomorphism. In step (2), we show that for any $\epsilon > 0$ and each $q \in \mathcal{E}$, there is a $p \in \mathcal{D}$ such that $\|S(q) - S(p)\|_{\mathcal{B}(F,F)} < \epsilon$. In step (3) we show that $S(p)$ is boundedly invertible for each $p \in \mathcal{D}$ by proving that $A(p)$ has the same property. In order to do so we show that $A(0)$ is boundedly invertible, and, by perturbation estimates and linear independence of the g_n, that the same holds true for $A(p)$ if $p \in \mathcal{D}$. Since the boundedly invertible operators are open in $\mathcal{B}(F, F)$, this shows that $A(q)$, and hence $S(q)$, is boundedly invertible for any $q \in \mathcal{E}$.

The required perturbation estimates on the g_n show that

$$\sum_n \|g_n(\ \cdot\ ; p) - g_n(\ \cdot\ ; 0)\|_E^2$$

is finite. In order to obtain these estimates, we exploit the observation that the functions z_n^2 and $(z_n')^2$ can be recovered from the respective residues of the operators $(L(p)-z)^{-1}$ and $D(L(p)-z)^{-1}D$ at $z=\lambda_n(p)$. We use resolvent perturbation theory to estimate the differences $z_n(\ \cdot\ ;p)^2 - z_n(\ \cdot\ ;0)^2$ and $z_n'(\ \cdot\ ;p)^2 - z_n'(\ \cdot\ ;0)^2$.

To prove that the g_n are linearly independent for any $p \in \mathcal{D}$, we introduce an auxiliary fifth-order differential system, the *Borg system*, satisfied by the $g_n(p)$. An analogous third-order equation was used by Borg [9] in his study of eigenfunction-squares in the Sturm–Liouville problem. The Borg system for a fourth-order operator takes the form

$$\mathcal{M}(p)g = \lambda \mathcal{B}(p)g$$

for matrix-valued differential operators $\mathcal{M}(p)$ of fifth order and $\mathcal{B}(p)$ of third order. For $p \in \mathcal{D}$, the generalized resolvent

$$R(\lambda) = (\mathcal{M}(p) - \lambda \mathcal{B}(p))^{-1}$$

has simple poles, among which are the eigenvalues $\lambda_n(p)$, with corresponding generalized eigenfunctions

$$\widehat{g}_n(x;p) = \left(z_n(x;p)^2, z_n'(x;p)^2\right)$$

The remaining poles are associated with the two auxiliary boundary value problems; since $p \in \mathcal{D}$, these are distinct from the poles $\lambda_n(p)$, and, as we shall see, all of the poles of the generalized resolvent are simple. Using the simplicity of poles, we can then construct a biorthogonal set from the rank-one residues of the generalized resolvent $R(\lambda)$; this proves linear independence of the $\widehat{g}_n(p)$. The linear independence of the gradients $g_n(p)$ is an easy consequence. The residues of the Borg operator furnish tangent vectorfields to the isospectral manifold; we expect, but have not yet proved, that they are a basis for its tangent space.

We note that the eigenvalue equation

$$D^2\left(r(x)D^2y\right) = \mu\rho(x)y$$

for the Euler–Bernoulli beam can be transformed, by means of a Liouville transform, into Liouville–Green normal form for smooth coefficients (see, e.g., [5]). Thus our results apply to Euler–Bernoulli problems with suitable boundary conditions.

A number of results exist in the literature regarding the inverse spectral problem for fourth-order differential operators. Barcilon [1, 2, 3, 4, 5, 6, 7] proved that the density and bending stiffness of an Euler–Bernoulli beam can be recovered from three sets of spectra, showed that fewer than three spectra do not uniquely determine these coefficients, and also proved some general results on inverse spectral problems for differential equations of nth order in Liouville normal form. He also showed that three sequences of eigenvalues corresponding to certain distinct boundary conditions contain the same information as one sequence of eigenvalues together with two sets of norming constants [3]. McLaughlin developed a Gel'fand–Levitan-type reconstruction algorithm for smooth coefficients from one spectrum and two sequences of norming constants [21, 22, 23, 24]. In McLaughlin's papers [20, 21] it is shown that the isospectral set for the operator $L(0)$ with boundary conditions $u(0)=u'(0)=u(1)=u'(1)=0$ is infinite-dimensional with infinite codimension and that the isospectral set for the operator $L(p)$ with the same boundary conditions is also infinite dimensional, with

infinite codimension, provided that the eigenvalues satisfy certain asymptotic forms. Gladwell gave necessary and sufficient conditions on spectral data to produce an Euler–Bernoulli beam with strictly positive (i.e., physical) density and bending stiffness [13] and carried out numerical reconstructions of Euler–Bernoulli beams from finite spectral data [15, 16].

Our results appear to be the first systematic study of the isospectral manifold for fourth-order differential operators. It should be noted that an operator very similar to our "Borg operator" in the constant coefficient case appears in Barcilon's analysis [3] of the inverse spectral problem.

The plan of this paper is as follows. In section 2 we prove some basic results about the spectra of $L(p)$ and the two associated boundary value problems. In section 3 we prove Theorem 1.1. In section 4 we show that the sequence of functions $\{g_n(q)\}$ is stable, in $\ell^2(\mathbb{N}; E)$-sense, under small perturbations of $q \in \mathcal{E}$ and that the map μ has its range in F. In section 5, we prove that the map μ is an analytic mapping from $\mathcal{E}$ into F. In section 6, we introduce and analyze the Borg system and use it to prove linear independence of the vectors $g_n(p)$ for each fixed $p \in \mathcal{D}$. Finally, in section 7 we give the proofs of Theorems 1.2 and 1.3. In Appendix A, we collect some important estimates on the integral kernels of the resolvents, at $p = 0$, of each of the three boundary value problems considered. In Appendix B, we discuss the boundary conditions on the Borg system and prove some technical domain results needed for section 6.

The results in sections 2 and 4 are proved for a number of separated self-adjoint boundary conditions in the Ph.D. thesis of the third author [29].

2. Spectra. In this section we prove some basic results about the spectra of the operators $L(p)$, $L_1(p)$, and $L_2(p)$ for $p \in E$. The symbol $L_\#(p)$ will denote one of the operators $L(p)$, $L_1(p)$, or $L_2(p)$, and $\lambda_n^\#(p)$ will denote the nth eigenvalue of $L_\#(p)$. Similarly, $q_\#$ denotes one of the three sesquilinear forms q, q_1, or q_2.

The spectra of $L(0)$, $L_1(0)$, and $L_2(0)$ are given by explicit transcendental equations (see, for example, [29]). From these, we easily deduce that $\lambda_n(0) = n^4\pi^4$, $\sigma_n(0) = (n + \frac{1}{2})^4\pi^4$, and $|\tau_n(0)^{1/4} - (n + \frac{1}{4})\pi| \leq 4e^{-n\pi}$. We expect the eigenvalues of $L_\#(p)$ for $p \neq 0$ to approach these values asymptotically so that the three sets of spectra "separate" for n large. We will use resolvent perturbation theory to show this is the case.

The following technical lemma will enable us to prove certain resolvent estimates for coefficients $p \in C_0^\infty((0,1), \mathbb{C}^2)$ and extend them by continuity to $p \in E_\mathbb{C}$. Recall that a mapping f from an open subset of a Banach space E into a Banach space F is called *compact* if $f(p_n)$ converges strongly to $f(p)$ in F whenever p_n converges weakly to p in E.

LEMMA 2.1. *For any fixed z with $\Re(z)$ sufficiently negative, the mapping $p \mapsto (L(p) - z)^{-1}$ is a compact mapping from E into the bounded operators on $L^2[0,1]$.*

Proof. Suppose that $p_n \to p$ weakly in E. It is easy to verify that the sesquilinear forms $q_\#^n$ associated with p_n converge to the sesquilinear form $q_\#$ associated with p so that $L_\#(p_n)$ converges to $L_\#(p)$ in the strong resolvent sense (see Kato [17, Theorem VIII.3.6]). It is also easy to check that there is a fixed c, depending only on $\sup \|p_n\|_E$, such that $\Re q_\#^n(u,u) \geq -c + 1$ and that the operators $(L_\#(0) + 1)^{1/2}(L_\#(p_n) + c)^{-1}$ are bounded uniformly in n. Let $R_n = (L_\#(p_n) + c)^{-1} - (L_\#(p) + c)^{-1}$ and let P_N project onto the first N eigenvectors of $L_\#(0)$. We may estimate

$$\|R_n\| \leq \|P_N R_n\| + \|(I - P_N)R_n\|$$

$$\leq \|P_N R_n\| + \|(I - P_N)(L_\#(0) + c)^{-1/2}\| \, \|(L_\#(0) + c)^{1/2} R_n\|.$$

The second right-hand term goes to zero as $N \to \infty$ uniformly in n, and the first right-hand term goes to zero as $n \to \infty$ for each fixed N by the compactness of P_N and the fact that R_n converges strongly to zero. □

Note that the same proof works if z is only required to lie in the common resolvent set of the operators $L(p_n)$ and $L(p)$.

Let $\rho(L_\#(p))$ denote the resolvent set of the operator $L_\#(p)$. The remarks in the proof of Lemma 2.1 show that there is a fixed half-plane $\Re(z) < -c$ so that $(L_\#(p) - z)^{-1}$ exists for any z in this half-plane and any $p \in E_{\mathbb{C}}$ with $\|p\|_{E_{\mathbb{C}}} \leq M$. Thus the set

$$S_M = \cap \{\rho(L_\#(p)) : \|p\|_{E_{\mathbb{C}}} \leq M\}$$

has nonempty interior; we will shortly show that it includes the complement of a countable union of discs whose size depends on M and which are centered at the eigenvalues of $L_\#(0)$. In what follows, denote by $B_M(0)$ the set $\{p \in E : \|p\|_E < M\}$.

LEMMA 2.2. *Fix $M > 0$ and let U be the interior of the set S_M. The mapping $\Psi(z, p) = (L_\#(p) - z)^{-1}$ is a compact analytic mapping from $U \times B_M(0)$ to the bounded operators on $L^2[0, 1]$.*

Proof. Compactness is an immediate consequence of Lemma 2.1 and the first resolvent formula. The resolvent identity

$$(L_\#(p) - z)^{-1} - (L_\#(q) - z)^{-1}$$

$$= (L_\#(q) - z)^{-1}(D(q_1 - p_1)D + (q_2 - p_2))(L_\#(p) - z)^{-1}$$

holds, where $D(q_1 - p_1)D + (q_2 - p_2)$ is understood as a sesquilinear form on the form domain of $L_\#(0)$. This shows that Ψ is norm continuous. A short calculation with difference quotients shows that $(L_\#(p) - z)^{-1}$ is differentiable in the complex sense and that

$$d\Psi_{z,p}(w, h) = w(L_\#(p) - z)^{-2} + (L_\#(p) - z)^{-1}(Dh_1D + h_2)(L_\#(p) - z)^{-1}. \qquad \square$$

For numbers $R > 3$ and $\alpha \in (2, 3)$, we define a region $C^\#_{R,\alpha}$ of $\mathbb{C}$ as follows. Let N be an integer obeying the bounds

$$(8R)^{\frac{1}{3-\alpha}} < N < (16R)^{\frac{1}{3-\alpha}}, \tag{2.1}$$

let

$$D^\#_N = \{z \in \mathbb{C} : |z| < \lambda^\#_N(0) + RN^\alpha\}$$

be a disc containing the first N eigenvalues of $L_\#(0)$, and let

$$E^\#_n = \{z \in \mathbb{C} : |z - \lambda^\#_n(0)| < Rn^\alpha\},$$

a disc containing the nth eigenvalue of $L_\#(0)$. We set

$$C^\#_{R,\alpha} = D_N \cup \left(\cup_{n=N+1}^\infty E_n\right).$$

Thus, the set $C^\#_{R,\alpha}$ is the union of a large disc containing the first N eigenvalues of $L_\#(0)$ and infinitely many small discs each containing exactly one of the remaining eigenvalues (see Figure 2.1). We will show that this region still contains the spectrum of $L_\#(p)$ for R sufficiently large, depending on $\|p\|_E$.

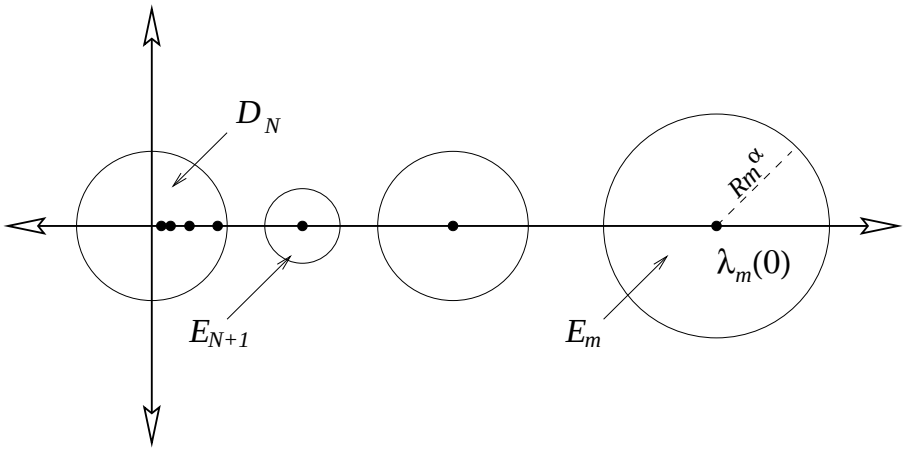

FIG. 2.1. *The set $C_{R,\alpha}$ (not drawn to scale).*

It is easy to check the following purely geometric properties of $C^{\#}_{R,\alpha}$.

LEMMA 2.3.

(i) *Fix one set of boundary conditions. For any $R > 3$, $\alpha \in (2,3)$, and $m > N$, the regions $D^{\#}_N$ and $E^{\#}_m$ are mutually disjoint.*

(ii) *Let $E^{(1)}_n$ and $E^{(2)}_n$ be the regions E_n associated with two distinct sets of boundary conditions. Then $E^{(1)}_n$ and $E^{(2)}_m$ are disjoint for $n \geq N+1$ and $m \geq N+1$.*

Proof. (i) The discs E_m have radii Rm^α, while $\lambda^{\#}_{m+1}(0) - \lambda^{\#}_m(0) \geq m^3$ if $m \geq 2$. Thus the discs will be separate if $2R(m+1)^\alpha < m^3$. This is true if $m > N$. The regions $D^{\#}_N$ and $E^{\#}_{N+1}$ will be disjoint so long as $\lambda^{\#}_{N+1}(0) - R(N+1)^\alpha - (\lambda^{\#}_N(0) + RN^\alpha) > 0$ or $N^3 > RN^\alpha + R(N+1)^\alpha$. This is guaranteed by the choice of N. (ii) Note that, by the mean value theorem, $(x+\frac{1}{4})^4 - x^4 \geq x^3$. Since the fourth roots of any two eigenvalues of the three operators are separated by a distance of at least $1/4$, it follows that the eigenvalue $\lambda^{\#}_m(0)$ associated with any one of the boundary conditions is separated from the closest eigenvalue associated with any of the three boundary conditions by at least $(m-1)^3$. Thus, it suffices to show that $(m-1)^3 > Rm^\alpha + R(m-1)^\alpha$. This will be true if $\left(\frac{m-1}{m}\right)^3 m^{3-\alpha} > R(1 + (\frac{m-1}{m})^\alpha)$. But $m > 1$ and $m^{3-\alpha} > N^{3-\alpha} > 8R$ by the choice of N. ∎

We can now state our rough bounds on the location of $\lambda^{\#}_n(p)$.

THEOREM 2.4. *Fix $M > 0$ and let $p \in E_{\mathbb{C}}$ with $\|p\|_{E_{\mathbb{C}}} < M$. There is a number $R > 3$ depending only on M so that:*

(i) *The spectrum of $L_{\#}(p)$ is contained in $C^{\#}_{R,\alpha}$.*

(ii) *The operators $L_{\#}(p)$ have exactly N eigenvalues in the region D_N.*

(iii) *The eigenvalues of $L_{\#}(p)$ with index $n \geq N+1$ are all simple.*

(iv) *The sets $\{\lambda_n(p)\}^\infty_{n=N+1}$, $\{\sigma_n(p)\}^\infty_{n=N+1}$, and $\{\tau_n(p)\}^\infty_{n=N+1}$ have empty intersection.*

Proof. The operators $L_{\#}(p)$ are sectorial with spectrum contained in a half-plane $\Re(\lambda) > -C(M)$, where $C(M)$ is a positive constant depending only on M [29]. We will construct the resolvents $(L_{\#}(p) - z)^{-1}$ perturbatively from $(L_{\#}(0) - z)^{-1}$ and estimate $\|(L_{\#}(p) - z)^{-1}\|$ uniformly in p with $\|p\|_E < M$ and $z \notin C^{\#}_{R,\alpha}$ for sufficiently large R. This will give (i); (iv) will then follow from Lemma 2.3(ii) and the following argument. Observe that for $p = 0$, the region D_N contains exactly N eigenvalues, and

the regions E_m each contain one eigenvalue. Analyticity of the resolvents as operator-valued analytic functions of $p \in E$ with $\|p\|_E < M$ will imply analyticity of the projections onto the eigenspaces of eigenvalues contained in $D_N^\#$ and $E_n^\#$; by standard perturbation theoretic arguments (see, for example, [28, section XII.2], and especially the lemma following Theorem XII.7), the corresponding spectral multiplicities must be stable under perturbation from 0 to p. This gives (ii) and (iii).

We now turn to the perturbative estimates that prove (i). We will use strong estimates on the integral kernel $G_0^\#(x,y;z)$ for the operator $(L_\#(0)-z)^{-1}$ in order to estimate $(L_\#(p)-z)^{-1}$ in operator norm. By Lemma 2.1, it suffices to prove these operator norm estimates for $p \in C_0^\infty((0,1),\mathbb{C}^2)$. This assumption allows us to bypass domain questions which might arise if the coefficients were more singular.

We begin by noting the resolvent equations, true for $\Re(z)$ sufficiently negative,

$$(L_\#(p)-z)^{-1} = (L_\#(0)-z)^{-1} - (L_\#(0)-z)^{-1}(Dp_1D+p_2)(L_\#(p)-z)^{-1}.$$

Since $(L_\#(p)-z)^{-1}$ maps into $H^3[0,1]$ and p_1 and p_2 are smooth, the composition of Dp_1D+p_2 with $(L_\#(p)-z)^{-1}$ is well defined. From this equation it is easy to derive the useful identity

$$(L_\#(p)-z)^{-1} = A(z) + B(z)(L_\#(p)-z)^{-1}\,, \tag{2.2}$$

where

$$\begin{aligned} A(z) &= (L_\#(0)-z)^{-1} \\ &\quad - (L_\#(0)-z)^{-1}Dp_1(I+C(z))^{-1}D(L_\#(0)-z)^{-1}, \end{aligned} \tag{2.3}$$

$$\begin{aligned} B(z) &= (L_\#(0)-z)^{-1}Dp_1(I+C(z)^{-1}D(L_\#(0)-z)^{-1}p_2 \\ &\quad - (L_\#(0)-z)^{-1}p_2, \end{aligned} \tag{2.4}$$

and

$$C(z) = D(L_\#(0)-z)^{-1}Dp_1. \tag{2.5}$$

These equations are valid whenever $\|C(z)\| < 1/2$. Using Lemma A.4(e), we see that this holds for $z \notin C_{R,\alpha}^\#$ so long as $CR^{-1/2}(\ln R)^{1/2}\|p_1\|_{L^2} < 1/2$, where C is a numerical constant; we can ensure this by choosing a sufficiently large R depending only on M. We wish to show that, by increasing R if necessary, we can make $\|B(z)\| < 1/2$ for $z \notin C_{R,\alpha}^\#$ and then show that $\|A(z)\| \le CR^{-1}$ for a constant C. We can then use standard analytic continuation arguments to conclude that $\|(L_\#(p)-z)^{-1}\|$ is bounded for $z \notin C_{R,\alpha}^\#$ for sufficiently large R depending on M.

First, we show how to choose R depending on M so that $\|B(z)\| < 1/2$ for $z \notin C_{R,\alpha}^\#$. From Lemma A.4(b), (d), and (e), we see that $\|B(z)\| \le CR^{-1}$ for a constant C depending on M so that $\|B(z)\| < 1$ for R sufficiently large. The estimates in Lemma A.4 also show that

$$\|A(z)\| \le \frac{C}{R} + \frac{C}{R^2}(1+\|p_1\|_{L^2}),$$

which gives an estimate of the desired form. □

3. Approximation. First of all, we give the proof of Theorem 1.1. It is not difficult to see that the set $\mathcal{E}$ is open, since all eigenvalues $\lambda_n(p)$ with $n > N$ are simple, and for each of the eigenvalues $\lambda_n(p)$ with $1 \leq n \leq N$, there is a neighborhood U_n in E of any $q \in \mathcal{E}$ such that $\lambda_n(p)$ is simple for all $p \in U_n$. Taking $U = \cap_{n=1}^N U_n$ we obtain an open neighborhood of q contained in $\mathcal{E}$.

To see that $\mathcal{E}$ is dense, we will exploit analytic perturbation theory. Let $p \in E$ with $\|p\| < M$, and suppose that one or more of the eigenvalues of $L(p)$ are degenerate. Consider the family of operators $M(t) = L(tp)$ where $|t| < 2$. By changing the values of R and N as defined in section 2 if necessary, we may assume that the conclusions of Theorem 2.4 hold for all tp with $|t| < 2$. Let

$$P(t) = \frac{1}{2\pi i} \int_{\partial D_N} (M(t) - z)^{-1}\, dz\,,$$

where D_N is as defined in the previous section. For t real, $P(t)$ is an orthogonal projection onto the first N eigenvalues of $M(t)$, counted with multiplicity. By Theorem XII.12 of [28], we can find an analytic family of holomorphically invertible operators $U(t)$ defined for $|t| < 2$ so that $U(t)$ is unitary for t real and $U(t)P(0)U(t)^{-1} = P(t)$. The operator $m(t) = U(t)^{-1}M(t)U(t)$ commutes with $P(0)$ and may be regarded, for t real, as a Hermitian matrix acting on $\mathbb{C}^N$; the first N eigenvalues of $L(tp)$ are simple if and only if the eigenvalues of $m(t)$ are simple. Observe that at $t = 0$, the first N eigenvalues of $L(0)$ are simple by explicit calculation, so the same holds for $|t|$ small. Moreover, the eigenvalues of $m(t)$ are analytic functions of t ([17, Theorem II.6.1]). Thus a given pair of eigenvalues of $m(t)$ can be degenerate for at most finitely many t between 0 and 1. Hence the same holds true of $L(tp)$, so for each $\epsilon > 0$ there is a $t \in (1-\epsilon, 1)$ so that $tp \in \mathcal{E}$. This shows that $\mathcal{E}$ is dense in E, and completes the proof of Theorem 1.1.

Next, we prove Theorem 3.1.

THEOREM 3.1. *Let $\mathcal{D}$ be the set of $p \in C_0^\infty((0,1);\mathbb{R}^2)$ such that $L_\#(p)$ has simple spectrum and the spectra of $L(p)$, $L_1(p)$, and $L_2(p)$ have empty intersection. Then $\mathcal{D}$ is dense in $\mathcal{E}$.*

Proof. First we show how small perturbations may be used to make the spectra of $L_1(p)$ and $L_2(p)$ simple, and the spectra of the three operators nonintersecting. By Theorem 2.4, we need only show that the first N eigenvalues of each operator are simple and that the union of the intersection of the three sets $\{\lambda_n\}_{n=1}^N$, $\{\sigma_n\}_{n=1}^N$, and $\{\tau_n\}_{n=1}^N$ is empty. Let $M(t) = L(tp)$, $M_1(t) = L_1(tp)$, and $M_2(t) = L_2(tp)$. By the technique used above we may associate with these operators analytic, $N \times N$ matrix-valued functions $m(t)$, $m_1(t)$, $m_2(t)$ whose eigenvalues depend holomorphically on t with $|t| < 2$. By explicit calculation, the matrices $m(0)$, $m_1(0)$, and $m_2(0)$ have simple spectra with empty intersection, so the same is true for $|t|$ small by analytic perturbation theory. Analyticity of the eigenvalues implies that the spectra of $m(t)$, $m_1(t)$, and $m_2(t)$ must be simple and have empty intersection for all but a countable set of t with no accumulation point in the region $\{t \in \mathbb{C} : |t| < 2\}$. Thus, given p and ϵ we can find a q with $\|p - q\| < \epsilon$ so that $L(q)$, $L_1(q)$, and $L_2(q)$ have simple spectrum and the three spectra have empty intersection. Since $C_0^\infty((0,1);\mathbb{R}^2)$ is norm dense in E and the simplicity and empty intersection properties involve only finitely many eigenvalues, there is an r with $\|r - q\| < \epsilon$ and $r \in \mathcal{E} \cap C_0^\infty((0,1);\mathbb{R}^2)$ so that $L(r)$, $L_1(r)$, and $L_2(r)$ have simple spectra and their spectra have empty intersection. It follows that $\mathcal{D}$ is dense in $\mathcal{E}$, as asserted. ∎

4. Stability estimates. For $m > N$, let $z_m(\,\cdot\,;p)$ denote the normalized eigenfunction of $L(p)$ corresponding to the eigenvalue $\lambda_m(p)$, and let $u_m(\cdot)$ denote the corresponding eigenfunction of $L(0)$. We wish to derive $C[0,1]$-norm estimates on the differences $z_m^2 - u_m^2$ and $(z_m')^2 - (u_m')^2$ and also on the differences $z_m^2(\,\cdot\,;p) - z_m^2(\,\cdot\,;q)$ and $(z_m')^2(\,\cdot\,;p) - (z_m')^2(\,\cdot\,;q)$. These estimates will be used to analyze the operator $A(p)$ discussed in the introduction.

Let $G(x,y;z)$ denote the integral kernel of the operator $(L(p)-z)^{-1}$. In order to estimate the above quantities, we observe that we can recover $z_m(x,q)^2$ from the diagonal of the residue of $G(x,y;z)$ at $z=\lambda_m(p)$, and $z_m'(x,q)^2$ from the diagonal of the residue of $G_{xy}(x,y;z)$. We will exploit resolvent perturbation theory to prove the following estimates.

THEOREM 4.1. *Let $M>0$ and let p and q belong to E with $\|p\|_E$, $\|q\|_E < M$. For $\alpha \in (2,3)$ choose R and N as in Theorem* 2.4. *Then there are constants C_1 and C_2 depending on M so that for any $m > N$,*

(a) $\sup_{x\in[0,1]} |z_m(x;p)^2 - z_m(x;q)^2| \le C_1 m^{2-\alpha}$ *and*

(b) $\sup_{x\in[0,1]} |z_m'(x;p)^2 - z_m'(x;q)^2| \le C_2 m^{4-\alpha}$

hold.

As an immediate corollary, setting $q=0$, we have the following theorem.

THEOREM 4.2. *Let $M>0$ and $p \in E$ with $\|p\|_E < M$. For $\alpha \in (2,3)$ choose R and N as in Theorem* 2.4. *Then there are constants C_1 and C_2 depending on M so that for any $m > N$, the estimates*

(a) $\sup_{x\in[0,1]} |z_m(x;p)^2 - z_m(x;0)^2| \le C_1 m^{2-\alpha}$ *and*

(b) $\sup_{x\in[0,1]} |z_m'(x;p)^2 - z_m'(x;0)^2| \le C_2 m^{4-\alpha}$ *hold.*

To prove these results, we first note the following lemma.

LEMMA 4.3. *Let $M>0$ and $p \in E$ with $\|p\|_E < M$, let $\alpha \in (2,3)$, and choose R and N as in Theorem* 2.4. *Then for any $m > N$, the maps $p \mapsto z_m(x;p)$ and $p \mapsto z_m'(x,p)$ are continuous as maps from E to $C[0,1]$ with the sup norm.*

We do not give the full proof of Lemma 4.3 here but refer the reader to [29, section 5.5]. One first shows the existence of fundamental solutions with the required norm continuity using a Volterra series construction. One then uses the continuity of the eigenvalue map $p \mapsto \lambda_n(p)$, together with explicit formulas for the eigenfunctions in terms of the fundamental solutions, to obtain the required continuity.

By the lemma, it is enough to prove the estimates in Theorem 4.1 for p and q belonging to $C_0^\infty((0,1);\mathbb{R}^2)$. This restriction facilitates calculations which we will carry out in what follows.

To prove Theorem 4.1 for such smooth coefficients, we exploit the fact that the difference of eigenfunction squares and derivatives can be recovered from the residues of the respective operators

$$\mathbb{A}(p,q;z) = (L(p)-z)^{-1} - (L(q)-z)^{-1}$$

and

$$\mathbb{B}(p,q;z) = D(\mathbb{A}(p,q;z))D,$$

at the appropriate eigenvalue. Here D denotes differentiation with respect to x.

We begin with the resolvent formula

$$(L(p)-z)^{-1} = (L(0)-z)^{-1} - (L(0)-z)^{-1}V_p(L(0)-z)^{-1}$$

$$+ (L(0)-z)^{-1}V_p(L(p)-z)^{-1}V_p(L(0)-z)^{-1}$$

where

$$V_p = -Dp_1D + p_2.$$

From this formula it follows that

$$\begin{aligned}
\mathbb{A}(p,q;z) &= (L(p)-z)^{-1} - (L(q)-z)^{-1} \\
&= (L(0)-z)^{-1}(-V_{p-q})(L(0)-z)^{-1} \\
&+ (L(0)-z)^{-1}V_{p-q}(L(p)-z)^{-1}V_p(L(0)-z)^{-1} \\
&+ (L(0)-z)^{-1}V_q(L(p)-z)^{-1}V_{p-q}(L(q)-z)^{-1}V_p(L(0)-z)^{-1} \\
&+ (L(0)-z)^{-1}V_q(L(q)-z)^{-1}V_{p-q}(L(0)-z)^{-1}
\end{aligned} \tag{4.1}$$

with an analogous identity for the operator $\mathbb{B}(p,q;z)$. The operator $\mathbb{B}(p,q;z)$ is initially defined on $C_0^\infty(0,1)$ and extended by density to a bounded operator from $L^2[0,1]$ to itself. Let $K_{\mathbb{A}}$ and $K_{\mathbb{B}}$ denote the respective integral kernels of $\mathbb{A}(p,q;z)$ and $\mathbb{B}(p,q;z)$. The kernels $K_{\mathbb{A}}$ and $K_{\mathbb{B}}$ can be expressed in terms of the integral kernels of $(L(p)-z)^{-1}$ and $(L(q)-z)^{-1}$, which are continuously differentiable in x and y; thus $\mathbb{A}(p,q;z)$ and $\mathbb{B}(p,q;z)$ have continuous kernels. Moreover, the formulas

$$z_m^2(x;p) - z_m^2(x;q) = \frac{1}{2\pi i}\int_{\gamma_m} K_{\mathbb{A}}(x,x;z)\,dz$$

and

$$z_m'(x;p)^2 - z_m'(x;q)^2 = \frac{1}{2\pi i}\int_{\gamma_m} K_{\mathbb{B}}(x,x;z)\,dz$$

hold, where γ_m is the contour $\{z : |z-\lambda_m(0)| = Rm^\alpha\}$.

Thus, Theorem 4.1 will follow if we can show that

$$\sup_{z\in\gamma_m}\sup_{(x,y)\in[0,1]} |K_{\mathbb{A}}(x,y;z)| \le C_1\|p-q\|_E m^{2-2\alpha} \tag{4.2}$$

and

$$\sup_{z\in\gamma_m}\sup_{(x,y)\in[0,1]} |K_{\mathbb{B}}(x,y;z)| \le C_2\|p-q\|_E m^{4-2\alpha}, \tag{4.3}$$

where C_1 and C_2 depend only on α and M. If T is an integral operator on $L^2[0,1]$ with continuous kernel $K(x,y)$, the sup norm of K is dominated by the $L^1[0,1]\to L^\infty[0,1]$ norm of the operator T. Thus it suffices to estimate the $L^1\to L^\infty$ operator norm of each of the terms in (4.1) and the corresponding identity for $\mathbb{B}(p,q;z)$. Note that each term in (4.1) contains at least one factor involving $p-q$.

Roughly speaking, each resolvent contributes a factor $m^{-\alpha}$, each derivative that occurs contributes a factor m, and each factor of p, q, or $p-q$ contributes a factor $\|p\|_E$, $\|q\|_E$, or $\|p-q\|_E$ to the estimates. This "naive power counting" gives estimates of the desired form. The power counting is justified by the following two results, which themselves depend on Lemma A.5 in Appendix A.

LEMMA 4.4. *Let $z \in \gamma_m$, let $0 \le i, j \le 1$, and let $M > 0$. Let $r \in C_0^\infty(0,1)$. Then for any p and q with $1 \le p < \infty$ and $1 \le q \le \infty$, the estimate*

$$\|D^i(L(0) - z)^{-1} D^j r\|_{p,q} \le C_{p,q} m^{i+j-\alpha} \|r\|_2$$

holds.

This lemma is a straightforward consequence of Lemma A.5; the following perturbative argument shows that an analogous result holds for the resolvent of $L(p)$ when $p \ne 0$.

LEMMA 4.5. *Let $z \in \gamma_m$, let $0 \le i, j \le 1$, and let $M > 0$. Let $r \in C_0^\infty(0,1)$. There is a positive integer $N_1 > N$ depending only on M so that for all $p \in E$ with $\|p\| < M$ and every $m > N_1$, the estimate*

$$\|D^i(L(p) - z)^{-1} D^j r\| \le C_{i+j} m^{i+j-\alpha} \|r\|_2$$

holds.

Proof. We will use equation (2.2). With R chosen sufficiently large, as in Theorem 2.4, so that (2.2) holds for $z \in \gamma_m$, we may estimate $\|A(z)\|$ and $\|B(z)\|$ for $z \in \gamma_m$ using Lemma A.5 and obtain

$$\|A(z)\| \le C m^{2-2\alpha} \|p_1\|_2$$

and

$$\|B(z)\| \le C m^{2-2\alpha} (1 + \|p_1\|_2) \|p_2\|_2.$$

Since $2 - 2\alpha < -\alpha$ for $\alpha > 2$, we recover the estimate with $i = j = 0$. If $i = 1$ and $j = 0$, we compute from the second resolvent identity that

$$\begin{aligned} &D(L(p) - z)^{-1} \\ &\quad = D(L(0) - z)^{-1} - D(L(0) - z)^{-1}(Dp_1 D + p_2)(L(p) - z)^{-1}. \end{aligned} \tag{4.4}$$

From Lemma A.5, we obtain

$$\|D(L(p) - z)^{-1}\| \le c_1 m^{1-\alpha} + c_3 \|p_1\|_2 m^{2-\alpha} \|D(L(p) - z)^{-1}\| + c_1 \|p_2\|_2 m^{1-\alpha}.$$

By choosing m so large that $c_3 \|p_1\|_2 m^{2-\alpha} < 1/2$, we can conclude that

$$\|D(L(p) - z)^{-1}\| \le C m^{1-\alpha}.$$

The proofs for $(i, j) = (0, 1)$ and $(i, j) = (1, 1)$ are similar. ∎

To finish the proof of Theorem 4.1, we use Lemmas 4.4 and 4.5 in conjunction with the identity (4.1) and the corresponding identity for the operator $D(L(p) - z)^{-1} D$ to estimate $\|\mathbb{A}(p, q; z)\|_{L^1 \to L^\infty}$ and $\|\mathbb{B}(p, q; z)\|_{L^1 \to L^\infty}$ and thereby show that (4.2) and (4.3) hold. For example, the norm of the second right-hand term in (4.1) is

$$\begin{aligned} &\|(L(0) - z)^{-1} V_{p-q} (L(p) - z)^{-1} V_p (L(0) - z)^{-1}\|_{L^1 \to L^\infty} \\ &\quad = \|(L(0) - z)^{-1} (D(p_1 - q_1)D + (p_2 - q_2)) \\ &\qquad \times (L(p) - z)^{-1} (Dp_1 D + p_2)(L(0) - z)^{-1}\|_{L^1 \to L^\infty}. \end{aligned}$$

The term of highest order in m for $z \in \gamma_m$ comes from the term involving p_1, because it involves the highest number of differentiations. In what follows, let C denote a generic constant depending on only M, a bound for $\|p\|_E$ and $\|q\|_E$, and let $\| \cdot \|_{p,q}$ denote the $\mathcal{B}(L^p[0,1], L^q[0,1])$-operator norm. We can estimate

$$\begin{aligned}
&\|(L(0)-z)^{-1}D(p_1-q_q)D(L(p)-z)^{-1}Dp_1D(L(0)-z)^{-1}\|_{L^1\to L^\infty} \\
&\quad \le \|(L(0)-z)^{-1}D(p_1-q_1)\|_{2,\infty}\ \|D(L(p)-z)^{-1}p_1\|_{2,2}\ \|D(L(0)-z)^1\|_{1,2} \\
&\quad \le C(m^{1-\alpha}\|p_1-q_1\|_{L^2[0,1]})(m^{1-\alpha}\|p_1\|_{L^2[0,1]})(m^{1-\alpha}) \\
&\quad \le Cm^{3-3\alpha}
\end{aligned}$$

using Lemma 4.4 for the first and third factors, and Lemma 4.5 for the second. Similar estimates on the remaining terms in (4.1) show that all terms can be bounded by $Cm^{2-2\alpha}\|p-q\|_E$ so that

$$\|\mathbb{A}(p,q;z)\|_{1,\infty} \le Cm^{2-2\alpha}\|p-q\|_E.$$

Analogous estimates show that

$$\|\mathbb{B}(p,q;z)\|_{1,\infty} \le Cm^{4-2\alpha}\|p-q\|_E.$$

Finally, we refine the crude eigenvalue asymptotics obtained in section 2. We let

$$p_{1,m} = \int_0^1 p_1(x)\cos(m\pi x)\,dx.$$

Note that the sequence $\{p_{1,m}\}$ belongs to $\ell^2(\mathbb{N})$.

THEOREM 4.6. *Let $p \in E$ with $\|p\|_E < M$, and $\alpha \in (2,3)$. There is a constant C depending only on α and M such that the estimate*

$$|\lambda_m(p) - \lambda_m(0) - m^2\pi^2\,(\overline{p_1} + p_{1,2m})\,| \le Cm^{4-\alpha}$$

holds for $n > N$. In particular, $m^{-2}(\lambda_m(p) - \lambda_m(0) - m^2\pi^2\overline{p_1})$ defines a sequence belonging to $\ell^2(\mathbb{N})$, and $\overline{p_1}$ may be recovered from the asymptotics of the $\lambda_m(p)$.

Proof. First suppose that $p \in C_0^\infty(0,1) \times C_0^\infty(0,1)$. It suffices to prove the estimate for such p since an arbitrary $q \in E$ can be approximated by such smooth p in norm and the eigenvalues are continuous functions of p. Let $\nu_m(t) = \lambda_m(tp)$ for $t \in [0,1]$. Then standard perturbative calculations show that

$$\begin{aligned}
&\nu_m(1) - \nu_m(0) \\
&\qquad = \int_0^1 \int_0^1 p_1(x)(z_m'(x;tp))^2\,dx\,dt \\
&\qquad + \int_0^1 \int_0^1 p_2(x)(z_m(x,tp))^2\,dx\,dt.
\end{aligned}$$

Using Theorem 4.2 together with the explicit formula

$$z_m(x;0) = \sqrt{2}\sin(m\pi x),$$

we readily obtain the claimed asymptotics. ∎

5. Analyticity. In this section, we prove the following theorem.

THEOREM 5.1. *The map μ is an analytic mapping from $\mathcal{E}$ into F.*

Proof. Theorem 4.6 already implies that the map μ has range in F. It remains to show that it has the required analyticity. It is not difficult to see that any particular μ_n is analytic in a small neighborhood of any $p \in \mathcal{E}$, where the size of the neighborhood may depend on n. To show analyticity of μ we must show, for any $p \in \mathcal{E}$, that the μ_n with $n > N$ are analytic in a fixed neighborhood of p independent of $n > N$.

To do this, we fix an $M > 0$ and choose N and R as in section 2. Let

$$P_n(p) = \frac{1}{2\pi i} \int_{\gamma_n} (L(p) - z)^{-1}\, dz\,,$$

where E_n is as defined in section 2. It follows from the analyticity of the resolvent that $P_n(p)$ is analytic in p. Moreover, for p and q with $\|p\| \le M$ and $\|q\| \le M$,

$$\begin{aligned} \|P_n(p) - P_n(q)\| &\le Rn^{\alpha} \sup_{z \in \gamma_n} \|(L(p) - z)^{-1} - (L(q) - z)^{-1}\| \\ &\le C\|p - q\|_E\, n^{2-\alpha} \end{aligned}$$

by the estimate in the proof Theorem 4.2. For $n > N$ and $\alpha > 2$ we may choose $\|p - q\| < (2CN^{2-\alpha})^{-1}$ and guarantee that $\|P_n(p) - P_n(q)\| \le 1/2$ for all $n > N$. From the formula

$$\lambda_n(q) = \frac{\langle z_n(\cdot, p), L(q)P(q)u_n(p)\rangle}{\langle z_n(\cdot, p), P_n(q)u_n(p)\rangle},$$

we see that $\lambda_n(q)$ is analytic for $\|p - q\| < (2CN^{2-\alpha})^{-1}$, which defines a fixed neighborhood of p independent of $n > N$. Thus, given $p \in \mathcal{E}$, there is a fixed neighborhood U of p so that all of the $\mu_n(q)$ are analytic for $q \in U$. This shows the required analyticity. □

6. Linear independence: The Borg system. We now consider linear independence of the functions $g_n(p)$ constructed from eigenfunctions of $L(p)$ via (1.7) when $p \in \mathcal{D}$. We shall accomplish this by displaying a set of functions which is biorthogonal to the $g_n(p)$ in E. The development of this biorthogonal set will involve the spectral theory of a non-self-adjoint fifth-order system, the *Borg system*, satisfied by the functions

$$\widehat{g}_n(x; p) = \begin{pmatrix} (z_n(x; p))^2 \\ (z_n'(x; p))^2 \end{pmatrix}, \tag{6.1}$$

where $z_n(x; p)$ is the nth eigenfunction of $L(p)$.

First, we will define the Borg system and construct a basis for its solution space from solutions of the underlying fourth-order problems. Then, we will show how one may specify boundary conditions for this system so that the spectrum of the resulting boundary value problem for the Borg system coincides with the spectra of the fourth-order operators $L(p)$, $L_1(p)$, and $L_2(p)$. Finally, we will show that the resolvent of the Borg system has simple poles and rank-one residues; this will enable us to construct the desired biorthogonal set.

6.1. The Borg system. Now, we define the Borg system and establish some of its properties.

LEMMA 6.1. *For $p \in C_0^{\infty}(0,1) \times C_0^{\infty}(0,1)$, there exist differential operators $\mathcal{M}(p)$ and $\mathcal{B}(p)$, mapping $C_0^{\infty}(0,1) \times C_0^{\infty}(0,1)$ into itself, such that*

(i)

$$\mathcal{M} = \begin{pmatrix} D^5 + M_{11}(x,D) & M_{12}(x,D) \\ M_{21}(x,D) & D^5 + M_{22}(x,D) \end{pmatrix},$$

where each M_{ij} is a linear differential operator of order not exceeding four with smooth coefficients depending on p, and

(ii)

$$\mathcal{B} = \begin{pmatrix} \frac{8}{3}D & 0 \\ \mathcal{B}_{21}(x,D) & -24D \end{pmatrix},$$

where $\mathcal{B}_{21}$ is a third-order linear differential operator with smooth coefficients depending on p.

(iii) *If u and v are solutions of $L(p)u = \lambda u$, then*

$$\mathcal{M}(p)\phi = \lambda \mathcal{B}(p)\phi, \tag{6.2}$$

where $\phi = (uv, u'v')^T$.

The proof is a direct calculation and is omitted. The explicit forms of $\mathcal{M}$ and $\mathcal{B}$ are given in Appendix B.

Next we note a purely algebraic lemma. It will be used to furnish bases of solutions from which Green's function for the fifth-order system

$$(\mathcal{M} - \lambda\mathcal{B})u = f, \tag{6.3}$$

with boundary conditions dictated by the chosen basis, can be calculated.

LEMMA 6.2. *Fix $\lambda \in \mathbb{C}$. Let $\{y_i\}_{i=1}^4$ be a fundamental set of solutions for the differential equation $L(p)u = \lambda u$. The ten products $\{y_i y_j : 1 \le i \le j \le 4\}$ have nonvanishing Wronskian.*

Lemma 6.2 is a consequence of the following abstract result about symmetric tensor products. Recall that if V is a real n-dimensional vector space with basis $\{e_i\}_{i=1}^n$, the *symmetric tensor product* $V \otimes_s V$ is the $n(n+1)/2$-dimensional real vector space spanned by the tensors $e_i \otimes_s e_j = e_i \otimes e_j + e_j \otimes e_i$. If $A : V \to V$ is a linear transformation, $A \otimes_s A$ is the linear transformation on $V \otimes_s V$ acting on basis vectors by $(A \otimes_s A)(e_i \otimes_s e_j) = (Ae_i) \otimes_s (Ae_j)$ and extended to $V \otimes_s V$ by linearity.

LEMMA 6.3. *Let $A : V \to V$ be a linear operator. Then,*

$$\det(A \otimes_s A) = 2^{\frac{n(n+1)}{2}} \det(A)^{n+1}.$$

Proof. Suppose first that A is diagonal with eigenvalues $\{\lambda_i\}_{i=1}^n$. The eigenvalues of $A \otimes_s A$ are $2\lambda_i\lambda_j$ for $1 \le i \le j \le n$. The product over these $n(n+1)/2$ numbers gives $2^{\frac{n(n+1)}{2}} \left(\prod_{i=1}^n \lambda_i\right)^{n+1}$. This proves the formula for the dense set of $n \times n$ matrices which are similar to a diagonal matrix. The general result follows by continuity of the determinant function. ∎

We denote the 10×10 matrix of products $y_i y_j$, $1 \le i \le j \le 4$, and their derivatives of up to ninth order by Y_S.

Proof of Lemma 6.2. Let Ψ be the 10×10 matrix consisting of the symmetric derivatives $D^{(k)}y_iD^{(l)}y_j + D^{(l)}y_iD^{(k)}y_j$ for $1 \le i \le j \le 4$ and $0 \le k \le l \le 3$. By Lemma 6.3,

$$\det(\Psi) = 2^{10}\left(W(y_1, y_2, y_3, y_4)\right)^5 \neq 0.$$

A direct calculation shows that there is a nonsingular constant matrix G_1 for which

$$Y_S = \Psi G_1^T, \tag{6.4}$$

which establishes the result. □

LEMMA 6.4. *Let y_i be as in Lemma* 6.2*, and let Φ be the 10×10 matrix consisting of the y_iy_j and their derivatives of up to fourth order, and the $y_i'y_j'$ and their derivatives of up to fourth order. There is a nonsingular constant matrix C such that $\Phi = Y_SC^T$.*

The proof is a direct calculation and is omitted. The nonsingular constant matrix C maps any row vector consisting of y_iy_j and its derivatives up to ninth order, where y_i and y_j are solutions of the fourth-order problem, to a corresponding row vector whose entries are y_iy_j and its first four derivatives, followed by $y_i'y_j'$ and its first four derivatives.

We conclude from Lemma 6.4 and relation (6.4) that

$$\left\{\left(y_iy_j,\, y_i'y_j'\right)^T \,:\, 1 \le i \le j \le 4\right\}$$

forms a basis for the ten-dimensional solution space of the fifth-order system (6.2).

6.2. Boundary conditions for the Borg system. We are now ready to prescribe boundary conditions on the Borg system. We do so implicitly, by specifying a basis for the desired ten-dimensional solution space. To this end, choose a basis y_j of solutions to $L(p)u = \lambda u$ to satisfy the initial conditions $D^{i-1}y_j(0) = \delta_{ij}$, $1 \le i, j \le 4$, and similarly choose a basis z_j of solutions to $L(p)u = \lambda u$ to satisfy $D^{i-1}z_j(1) = \delta_{ij}$, $1 \le i, j \le 4$. Denote by B the 4×4 matrix with

$$y_j(x,\lambda) = \sum_{i=1}^{4} B_{ij}z_i(x,\lambda), \quad 1 \le i, j \le 4;$$

the matrix B is a holomorphic function of λ with determinant 1. Bases of solutions for the fourth-order homogeneous problems $L(p)u = \lambda u$, $L_1(p)u = \lambda u$, and $L_2(p)u = \lambda u$ obeying the $x = 0$ and $x = 1$ boundary conditions are, respectively, $\{y_2, y_4, z_2, z_4\}$, $\{y_2, y_4, z_1, z_3\}$, and $\{y_2, y_4, z_3, z_4\}$. We denote the Wronskians of these sets, respectively, as $W_1(\lambda)$, $W_2(\lambda)$, and $W_3(\lambda)$; the respective zeros are exactly $\{\lambda_n(p)\}$, $\{\sigma_n(p)\}$, and $\{\tau_n(p)\}$. In terms of the matrix B,

$$\begin{aligned} W_1(\lambda) &= B_{1,4}B_{3,2} - B_{1,2}B_{3,4}, \\ W_2(\lambda) &= B_{2,4}B_{4,2} - B_{2,2}B_{4,4}, \\ W_3(\lambda) &= B_{1,2}B_{2,4} - B_{1,4}B_{2,2}. \end{aligned}$$

Let us denote, for each i and j,

$$\phi_{ij}^L = \begin{pmatrix} y_iy_j, \\ \\ y_i'y_j', \end{pmatrix} \tag{6.5}$$

and

$$\phi_{ij}^R = \begin{pmatrix} z_i z_j, \\ \\ z_i' z_j', \end{pmatrix}. \tag{6.6}$$

From Lemmas 6.2 and 6.4 it follows that either of the sets ϕ_{ij}^L or ϕ_{ij}^R form a basis for the solution space of (6.2).

In lieu of specifying explicit boundary conditions for the fifth-order system (6.2), we shall specify a ten-dimensional solution space for the Borg system by explicitly choosing a basis for the solution space. This basis, consisting of a subset $\mathcal{L}$ of the ϕ_{ij}^L and a subset $\mathcal{R}$ of the ϕ_{ij}^R, will be chosen so that the eigenfunctions of the three boundary value problems specified in section 2 will contribute to the eigenfunctions of (6.2) via (6.1). Explicitly, we choose

$$\mathcal{L} = (\phi_{22}^L, \phi_{44}^L, \phi_{24}^L)$$

and

$$\mathcal{R} = (\phi_{11}^R, \phi_{22}^R, \phi_{33}^R, \phi_{44}^R, \phi_{13}^R, \phi_{24}^R, \phi_{34}^R).$$

In what follows, we will also use the notation $\{\phi_i\}_{i=1}^{10}$ for these basis functions, where $1 \le i \le 3$ for the vectors in $\mathcal{L}$, and $4 \le i \le 10$ for the vectors in $\mathcal{R}$. We shall also designate the components of ϕ_i by

$$\phi_i(x;\lambda) = \begin{pmatrix} \zeta_i(x;\lambda), \\ \\ \eta_i(x;\lambda), \end{pmatrix}.$$

We need to verify that the ten functions in $\mathcal{L} \cup \mathcal{R}$ are linearly independent (and hence, a basis for the solution space). Computing an appropriate Wronskian determinant leads to an explicit eigenvalue condition. Recall that $\lambda_n(p)$, $\sigma_n(p)$, and $\tau_n(p)$ denote, respectively, the nth eigenvalues of $L(p)$, $L_1(p)$, and $L_2(p)$.

LEMMA 6.5. *Let $W(\lambda)$ be the Wronksian of the solution set $\mathcal{L} \cup \mathcal{R}$, and let $p \in \mathcal{D}$. Then $W(\lambda)$ is a constant multiple of $W_1(\lambda)W_2(\lambda)W_3(\lambda)$, and $W(\lambda)$ has simple zeros at the eigenvalues $\{\lambda_n(p)\}$, $\{\sigma_n(p)\}$, $\{\tau_n(p)\}$.*

Proof. By Lemma 6.4 and the remarks following it, it suffices to show that the assertion of Lemma 6.5 is true for the Wronskian determinant of the ten functions z_1^2, z_2^2, z_3^2, z_4^2, $z_1 z_3$, $z_2 z_4$, $z_3 z_4$, and y_2^2, y_4^2, $y_2 y_4$. Evaluating the determinant at $x = 1$ leads to the determinant of a block upper triangular matrix

$$A = \begin{pmatrix} I & A_{12} \\ \\ 0 & A_{22} \end{pmatrix}, \tag{6.7}$$

where I is the 7×7 identity matrix, A_{12} is a 7×3 matrix whose entries are polynomials in the $B_{i,j}$, and A_{22} is the 3×3 matrix

$$A_{22}(\lambda) = \begin{pmatrix} 2\,B_{1,2}\,B_{2,2} & B_{1,2}\,B_{2,4} + B_{2,2}\,B_{1,4} & 2\,B_{1,4}\,B_{2,4} \\ \\ 2\,B_{1,2}\,B_{4,2} & B_{1,2}\,B_{4,4} + B_{1,4}\,B_{4,2} & 2\,B_{1,4}\,B_{4,4} \\ \\ 2\,B_{2,2}\,B_{3,2} & B_{2,2}\,B_{3,4} + B_{2,4}\,B_{3,2} & 2\,B_{2,4}\,B_{3,4} \end{pmatrix}.$$

Explicit calculation gives the formula

$$\det(A_{22}(\lambda)) = W_1(\lambda)W_2(\lambda)W_3(\lambda).$$

The fact that $W(\lambda)$ has simple zeros follows from a result of Everitt (see [12]) and the fact that $p \in \mathcal{D}$. □

Thus, the spectrum of the boundary value problem for the Borg system coincides exactly with the spectra of $L(p)$, $L_1(p)$, and $L_2(p)$. With some additional calculation, we can show the following lemma.

LEMMA 6.6. *Let $p \in \mathcal{D}$. At each zero of $W(\lambda)$, the kernel of $\mathcal{M} - \lambda\mathcal{B}$ is one-dimensional.*

Proof. It is enough to show that the matrix A defined in (6.7) has a one-dimensional kernel at such points λ. To see this, note that a nonzero solution of the homogeneous equation $(\mathcal{M} - \lambda\mathcal{B})u = 0$, which satisfies the left and right boundary conditions, exists if and only if the spans of the vectors in $\mathcal{L}$ and $\mathcal{R}$ have nonempty intersection. Recalling the notation $\{\phi_i\}_{i=1}^{10}$ we see that the dimension of the kernel of $\mathcal{M} - \lambda\mathcal{B}$ is the dimension of solutions $\{\alpha_i\}$ of the equation

$$\sum_{i=1}^{10} \alpha_i \phi_i = 0\,, \tag{6.8}$$

since the sets $\{\phi_i\}_{i=1}^{3}$ and $\{\phi_j\}_{j=4}^{10}$ are linearly independent. Let $\mathbf{\Phi}$ denote the 10×10 matrix containing the components of ϕ_i and their derivatives of up to fourth order. This matrix is related by a nonsingular constant matrix to the 10×10 Wronskian matrix containing the corresponding products $y_i y_j$, $z_i z_j$ and their derivatives of up to ninth order. The solutions of (6.8) therefore correspond to the nullspace of the Wronskian matrix of the $y_i y_j$ and $z_i z_j$ so that the dimension of the space of solutions to (6.8) is exactly the dimension of the kernel of the matrix A in Lemma 6.5. Since A is upper triangular, $\dim\ker A = \dim\ker A_{22}$. The proof is completed by showing that $\dim\ker A_{22} = 1$ at each zero of $W(\lambda)$, which is the content of the next lemma. □

LEMMA 6.7. *If $W(\lambda) = 0$, then $\dim\ker(A_{22}) = 1$.*

Proof. By virtue of Lemma 6.5, $W(\lambda) = 0$ if and only if $W_j(\lambda) = 0$ for some j. Note that, since the spectra of the fourth-order problems do not overlap,

- $B_{1,2}$ and $B_{1,4}$ are never zero simultaneously (for otherwise, $W_1(\lambda) = W_3(\lambda) = 0$) and
- $B_{2,2}$ and $B_{2,4}$ are never zero simultaneously (for otherwise, $W_2(\lambda) = W_3(\lambda) = 0$).

Since the matrix A_{22} is symmetric (up to column-interchanges) with respect to the second index on the coefficients $B_{i,j}$, we may assume without loss of generality that $B_{2,2} \neq 0$ and express A_{22} equivalently as

$$A_{22} = \begin{pmatrix} 2B_{1,2} & B_{1,4} + B_{1,2}\alpha_2 & 2B_{1,4}\alpha_2 \\ 2B_{1,2}B_{4,2} & B_{1,2}B_{4,4} + B_{4,2}B_{1,4} & 2B_{1,4}B_{4,4} \\ 2B_{3,2} & B_{3,4} + B_{3,2}\alpha_2 & 2B_{3,4}\alpha_2 \end{pmatrix},$$

where

$$\alpha_2 \equiv \frac{B_{2,4}}{B_{2,2}}\,.$$

There are two possibilities: either $B_{1,2} \neq 0$ or $B_{1,4} \neq 0$. We consider the former only, the latter being essentially the same.

Assume $B_{1,2} \neq 0$. The matrix A_{22} can then be written equivalently as

$$A_{22} = \begin{pmatrix} 2 & \alpha_1 + \alpha_2 & 2\alpha_1\alpha_2 \\ 2B_{4,2} & B_{4,4} + B_{4,2}\alpha_1 & 2B_{4,4}\alpha_1 \\ 2B_{3,2} & B_{3,4} + B_{3,2}\alpha_2 & 2B_{3,4}\alpha_2 \end{pmatrix},$$

where

$$\alpha_1 \equiv \frac{B_{1,4}}{B_{1,2}}.$$

It is straightforward to show that there exist nonsingular matrices $\mathbf{C}$ and $\mathbf{E}$ for which

$$A_{22} = \mathbf{C}\mathbf{D}\mathbf{E}^T,$$

where

$$\mathbf{D} = \begin{pmatrix} 2 & \alpha_1 + \alpha_2 & 2\alpha_1\alpha_2 \\ 0 & B_{4,4} - B_{4,2}\alpha_2 & 2\alpha_1(B_{4,4} - B_{4,2}\alpha_2) \\ 0 & B_{3,4} - B_{3,2}\alpha_1 & 2\alpha_2(B_{3,4} - B_{3,2}\alpha_1) \end{pmatrix} = \begin{pmatrix} 2 & \alpha_1 + \alpha_2 & 2\alpha_1\alpha_2 \\ 0 & -\frac{W_2}{B_{2,2}} & -2\frac{\alpha_1 W_2}{B_{2,2}} \\ 0 & -\frac{W_1}{B_{1,2}} & -2\frac{\alpha_2 W_1}{B_{1,2}} \end{pmatrix}.$$

Noting that row 1 of $\mathbf{D}$ never vanishes (and is independent of the other rows) and rows 2 and 3 cannot vanish simultaneously, we see that $\dim\ker A_{22} = \dim\ker \mathbf{D} \leq 1$ and is determined by the dimension of the kernel of the 2×2 submatrix

$$AA \equiv \begin{pmatrix} -\frac{W_2}{B_{2,2}} & -2\frac{\alpha_1 W_2}{B_{2,2}} \\ -\frac{W_1}{B_{1,2}} & -2\frac{\alpha_2 W_1}{B_{1,2}} \end{pmatrix}.$$

We have

$$\det(AA) = \frac{2}{B_{1,2}B_{2,2}} W_1 W_2 (\alpha_2 - \alpha_1) = -\frac{2}{B_{1,2}^2 B_{2,2}^2} W_1 W_2 W_3,$$

and the result follows. □

As a consequence, we have not only that the eigenvalues $\{\nu_n\}$ of the boundary value problem (6.2) are precisely the eigenvalues of the three boundary value problems considered in section 2, but also that, for each such eigenvalue, the eigenfunction of (6.2) is $(z^2, (z')^2)^T$, where z is the eigenfunction of the corresponding fourth-order problem.

6.3. Biorthogonal set. We shall now construct the desired biorthogonal set from the residues of the resolvent $(\mathcal{M} - \lambda\mathcal{B})^{-1}$. It follows from explicit formulas for the Green's function in terms of the basis functions ϕ_{ij}^L, ϕ_{ij}^R and the Wronskian $W(\lambda)$ that the resolvent $(\mathcal{M} - \lambda\mathcal{B})^{-1}$ has simple poles with rank-one residues.

THEOREM 6.8. *Let $(\mathcal{M} - \lambda\mathcal{B})^{-1}$ be the resolvent of the non-self-adjoint boundary value problem* (6.2). *Then the poles of $(\mathcal{M} - \lambda\mathcal{B})^{-1}$ are simple and occur at the*

numbers ν_n. Their residue takes the form $(\chi_n, \cdot)\psi_n$, where $\psi_n \in \mathrm{Ker}(\mathcal{M} - \lambda\mathcal{B})$ and $\chi_n \in \mathrm{Ker}((\mathcal{M} - \lambda\mathcal{B})^*)$.

Proof. The integral kernel of $(\mathcal{M} - \lambda\mathcal{B})^{-1}$ is the matrix-valued function

$$\begin{pmatrix} G_{11}(x,t;\lambda) & G_{12}(x,t;\lambda) \\ G_{21}(x,t;\lambda) & G_{22}(x,t;\lambda) \end{pmatrix},$$

where the G_{ij} obey

- $G_{11}(x,t;\lambda)$ and $G_{22}(x,t;\lambda)$ are continuous in $(x,t) \in [0,1] \times [0,1]$ together with their derivatives of up to order three and have a unit jump at $x = t$ in their fourth derivative,
- $G_{12}(x,t;\lambda)$ and $G_{21}(x,t;\lambda)$ are continuous in $(x,t) \in [0,1] \times [0,1]$ together with their derivatives up to order four

and solve the differential equations

$$(\mathcal{M} - \lambda\mathcal{B})_x G_{ij}(x,t;\lambda) = 0$$

for $x \neq t$. We can find explicit expressions for the G_{ij} by setting

$$\begin{pmatrix} G_{11}, \\ G_{21}, \end{pmatrix} = \begin{cases} \sum_{i\in I} \alpha_i(t)\phi_i(x) & x < t, \\ -\sum_{j\in J} \alpha_j(t)\phi_j(x) & x > t \end{cases}$$

and

$$\begin{pmatrix} G_{12}, \\ G_{22}, \end{pmatrix} = \begin{cases} \sum_{i\in I} \beta_i(t)\phi_i(x) & x < t, \\ -\sum_{j\in J} \beta_j(t)\phi_j(x) & x > t \end{cases}$$

and solving the linear equations

$$\begin{aligned} \sum_{i=1}^{10} \alpha_i(x)\zeta_i^{(k)}(x) &= 0, \qquad 0 \le k \le 3, \\ \sum_{i=1}^{10} \alpha_i(x)\zeta_i^{(4)}(x) &= 1, \\ \sum_{i=1}^{10} \alpha_i(x)\eta_i^{(k)}(x) &= 0, \qquad 0 \le k \le 4, \end{aligned}$$

and

$$\begin{aligned} \sum_{i=1}^{10} \beta_i(x)\zeta_i^{(k)}(x) &= 0, \qquad 0 \le k \le 4, \\ \sum_{i=1}^{10} \beta_i(x)\eta_i^{(k)}(x) &= 0, \qquad 0 \le k \le 3, \\ \sum_{i=1}^{10} \beta_i(x)\eta_i^{(4)}(x) &= 1. \end{aligned}$$

Using Cramer's rule to solve for the functions α_i and β_i yields an expression for Green's function in terms of the holomorphic functions $\phi_i(x;\lambda)$ and the Wronskian $W(\lambda)$. Using the known properties of $W(\lambda)$ we conclude that Green's function has simple poles.

A simple argument shows that the residue of $(\mathcal{M}-\lambda\mathcal{B})^{-1}$ has range in $\mathrm{Ker}(\mathcal{M}-\lambda\mathcal{B})$ and is therefore rank-one by Lemma 6.6. Writing the residue at $\lambda=\nu_n$ in the form $(\chi_n,\cdot)\psi_n$, it follows from the identity

$$((\mathcal{M}-\lambda\mathcal{B})^*)^{-1}=((\mathcal{M}-\lambda\mathcal{B})^{-1})^*$$

that $\chi_n\in\mathrm{Ker}((\mathcal{M}-\lambda\mathcal{B})^*)$. □

Suppose that ν_i and ν_j are distinct eigenvalues of the Borg operator. It is not difficult to see that the resolvent identity

$$(\mathcal{M}-\lambda\mathcal{B})^{-1}-(\mathcal{M}-\mu\mathcal{B})^{-1}=(\mu-\lambda)(\mathcal{M}-\lambda\mathcal{B})^{-1}\mathcal{B}(\mathcal{M}-\mu\mathcal{B})^{-1}$$

holds. Let P_i and P_j be the rank-one residues corresponding to these distinct eigenvalues. From the resolvent identity above, it is easy to see that the relations $P_i\mathcal{B}P_i=P_i$ and $P_i\mathcal{B}P_j=0$ hold for $i\neq j$. Writing $P_i=(\chi_i,\cdot)\psi_i$, we obtain the following theorem.

THEOREM 6.9. *The biorthogonality relations*

$$(\chi_i,\mathcal{B}\psi_j)=\delta_{ij} \tag{6.9}$$

hold. Consequently, the eigenfunctions $\{\psi_j\}$ form a linearly independent set in E.

Proof. The conclusion that the set $\{\psi_j\}$ is linearly independent in E follows immediately from (6.9), once it is established that

$$\chi_i\in D(\mathcal{B}^*) \tag{6.10}$$

for each i. Appendix B gives explicitly the boundary conditions which determine $D((\mathcal{M}-\lambda\mathcal{B})^*)$ and $D(\mathcal{B}^*)$. Direct comparison shows that $D((\mathcal{M}-\lambda\mathcal{B})^*)\subset D(\mathcal{B}^*)$, so (6.10) holds. □

We now order the poles, ν_n, of the Borg operator so that $\nu_{3n}=\lambda_n$, $\nu_{3n+1}=\sigma_n$, $\nu_{3n+2}=\tau_n$. The vectors ψ_{3n} are, up to normalization, exactly the vectors $\widehat{g}_n$. Thus these vectors form a linearly independent set, and their orthogonal complement is an infinite-dimensional space spanned by the vectors

$$\{\mathcal{B}^*\chi_{3n+1},\mathcal{B}^*\chi_{3n+2}\}_{n=1}^{\infty}.$$

To conclude that the same is true of the gradients g_n for the direct spectral map, we need the following lemma.

LEMMA 6.10. *The kernel of $\mathcal{B}$ is the one-dimensional subspace of $L^2[0,1]\times L^2[0,1]$ spanned by the vector $\widehat{g}_0=(0,1)^T$.*

This is a direct computation using the formulas for $\mathcal{B}$ and its boundary conditions recorded in Appendix B.

Now consider the family of vectors $\{\tilde{g}_n\}_{n=0}^{\infty}$, where $\tilde{g}_0=(0,1)$ and $\tilde{g}_n=(n^2\pi^2)^{-1}\widehat{g}_n-\tilde{g}_0$. Since $\tilde{g}_0\in\ker(\mathcal{B})$, we have the biorthogonality relations

$$\langle\mathcal{B}^*\chi_n,\tilde{g}_m\rangle=c_n\delta_{nm}$$

for $n\in\mathbb{N}$, $c_n>0$, and $m\in 0\cup\mathbb{N}$. Thus the family $\{\tilde{g}_n\}_{n=0}^{\infty}$ is linearly independent. Since the gradients g_n are obtained from $\tilde{g}_n$ by permuting the first and second entries, we have proved the following theorem.

THEOREM 6.11. *For any $p\in\mathcal{D}$, the gradients $\{g_n(x;p)\}_{n=0}^{\infty}$ are linearly independent. Moreover, the complement of their span has infinite dimension in E.*

7. Proofs of the main theorems. We now prove Theorem 1.3, first proving that $d\mu(q)$ is a linear isomorphism from $\mathcal{E}_v(q)$ onto F, and then proving that the space $\mathcal{E}_h(q)$ is complementary. In light of the discussion following the statement of Theorem 1.3, and in view of Theorem 5.1 and the estimates of section 4, the first assertion will be proved once the following result is established.

LEMMA 7.1. *For each $p \in \mathcal{D}$, $d\mu(p)$ is a linear isomorphism from $\mathcal{E}_v(p)$ onto F.*

In proving this result, we will make use of some results on Riesz bases. Recall that if $\mathcal{H}$ is a Hilbert space with inner product $\langle \cdot, \cdot \rangle$, a basis $\{e_n\}$ is called a *Riesz basis* for $\mathcal{H}$ if there exist $a, b \in \mathbb{R}^+$ for which

$$a\|h\|^2 \leq \sum_n |\langle h, e_n \rangle|^2 \leq b\|h\|^2 \quad \forall\, h \in \mathcal{H}\,. \tag{7.1}$$

LEMMA 7.2. *Let $\mathcal{H}$ be a Hilbert space, and let $\{e_n\}$ be a Riesz basis for $\mathcal{H}$. Then, there is a unique set $\{\epsilon_m\} \subseteq \mathcal{H}$ for which*

(1) *$\langle e_n, \epsilon_m \rangle = \delta_{m,n}$ for all $m, n \in \mathbb{N}$,*

(2) *There exist $\alpha, \beta \in \mathbb{R}^+$ so that*

$$\alpha\|h\|^2 \leq \sum_m |\langle h, \epsilon_m \rangle|^2 \leq \beta\|h\|^2 \quad \forall h \in \mathcal{H}\,.$$

Proof. Let $Th = \sum_n \langle h, e_n \rangle e_n$. Then, T is self-adjoint, and

$$\langle h, Th \rangle = \left\langle h, \sum_n \langle h, e_n \rangle e_n \right\rangle = \sum_n |\langle h, e_n \rangle|^2.$$

It then follows from (7.1) that the spectrum of T is contained in the interval $[a, b]$ so that T^{-1} exists. By the spectral theorem, we have

$$b^{-2}\|h\|^2 \leq \|T^{-1}h\|^2 \leq a^{-2}\|h\|^2. \tag{7.2}$$

Let $\epsilon_n \equiv T^{-1}e_n$ for each $n \in \mathbb{N}$. Then

$$e_n = T\epsilon_n = \sum_m \langle \epsilon_n, e_m \rangle e_m,$$

so $\langle \epsilon_m, e_n \rangle = \delta_{nm}$ by the linear independence of the e_n; this establishes (1). Finally, it follows from relation (7.2) and the definition of ϵ_n that $\sum_n |\langle h, \epsilon_n \rangle|^2 = \sum_n |\langle T^{-1}h, e_n \rangle|^2$ obeys the inequality

$$ab^{-2}\|h\|^2 \leq \sum_n |\langle h, \epsilon_n \rangle|^2 \leq ba^{-2}\|h\|^2\,,$$

which establishes (2). □

LEMMA 7.3. *Let $\{d_n\}$ be a Riesz basis for $\mathcal{H}$. Then the linear map $\mathcal{A} : \mathcal{H} \mapsto \ell^2(\mathbb{N})$ defined by*

$$\mathcal{A}x = \{\langle x, d_n \rangle\}_{n \geq 1}\,,\ x \in \mathcal{H},$$

is an isomorphism.

Proof. We will show that $\mathcal{A}$ is a bounded bijection from $\mathcal{H}$ to ℓ^2. The conclusion of the lemma will then follow from the open mapping theorem. First, it is clear that

$\mathcal{A}x = 0$ only when $\langle x, d_n\rangle = 0$ for each n. Since $\{d_n\}$ is a basis for $\mathcal{H}$, we must have $x \equiv 0$ so that $\mathcal{A}$ is one-to-one. Further, for $x \in \mathcal{H}$ we have, from (7.1),

$$\|\mathcal{A}x\|^2 = \|\{\langle x, d_n\rangle\}\|_{\ell^2}^2 = \sum_n |\langle x, d_n\rangle|^2 \leq b\|x\|^2 ,$$

so $\mathcal{A}$ is bounded.

To show $\mathcal{A}$ is onto $\ell^2(\mathbb{N})$, we introduce $\{\delta_m\}$ as the Riesz basis biorthogonal to $\{d_n\}$, the existence of which is guaranteed by Lemma 7.2. Then, given $\{y_m\} \in \ell^2(\mathbb{N})$, set $y = \sum_m y_m \delta_m$. From (7.1),

$$\|y\|^2 \leq \frac{1}{a}\sum_n |\langle y, d_n\rangle|^2 = \frac{1}{a}\sum_n \left|\sum_m y_m \langle \delta_m, d_n\rangle\right|^2 = \frac{1}{a}\sum_n |y_n|^2 < \infty$$

so that $y \in \mathcal{H}$. Also,

$$\mathcal{A}y = \{\langle y, d_n\rangle\}_{n\geq 1} = \left\{\sum_m y_m \langle \delta_m, d_n\rangle\right\}_{n\geq 1} = \{y_n\}_{n\geq 1} ,$$

which shows that $\mathcal{A}$ maps onto $\ell^2(\mathbb{N})$. By the open mapping theorem, $\mathcal{A}$ is an isomorphism. □

For each $n \in \mathbb{N}$, let z_n and u_n denote, respectively, the nth eigenfunction of $L(p)$ and $L(0)$, and as before let

$$g_n(x,p) = \begin{pmatrix} \dfrac{z_n'(x,p)^2}{n^2\pi^2} - 1 \\ \\ \dfrac{z_n(x;p)^2}{n^2\pi^2} \end{pmatrix}.$$

By explicit computation

$$g_n(x,0) = \begin{pmatrix} \cos(2n\pi x) \\ \\ \dfrac{1-\cos(2n\pi x)}{n^2\pi^2} \end{pmatrix}. \tag{7.3}$$

Recalling the form (1.6) of $d\mu(p)$, it suffices, by virtue of Lemma 7.3, to show that $\{g_n(\,\cdot\,;p)\}$ is a Riesz basis for $\mathcal{E}_v(p) = \operatorname{span}\{g_n(\,\cdot\,;p)\}$. Using Fourier theory, one can show directly that $\{g_n(\,\cdot\,;0)\}$ is a Riesz basis for its span. To show that the same is true for $\{g_n(\,\cdot\,;p)\}$, we note that $\{g_n(\,\cdot\,;p)\}$ is linearly independent, by virtue of Theorem 6.11, and use the following stability result for Riesz bases.

LEMMA 7.4. *Let $\mathcal{H}$ be a Hilbert space, and let $\{e_n\} \subseteq \mathcal{H}$ be a Riesz basis for $\mathcal{H}_e \equiv \operatorname{span}\{e_n\}$. Let $\{d_n\} \subseteq \mathcal{H}$ be a linearly independent set for which*

$$\sum_n \|d_n - e_n\|^2 \equiv M < \infty.$$

Then, $\{d_n\}$ is a Riesz basis for $\mathcal{H}_d \equiv \operatorname{span}\{d_n\}$; i.e., there exist $\alpha, \beta \in \mathbb{R}^+$ so that, for each $h \in \mathcal{H}_d$,

$$\alpha\|h\|^2 \leq \sum_n |\langle h, d_n\rangle|^2 \leq \beta\|h\|^2. \tag{7.4}$$

Proof. Define a map $A : \mathcal{H}_e \longrightarrow \mathcal{H}_d$ by $Ae_n = d_n$ for each $n \in \mathbb{N}$, extended by linearity. Then, for $h \in \mathcal{H}_d$ and each n,

$$\langle h, d_n\rangle = \langle h, Ae_n\rangle = \langle A^*h, e_n\rangle. \tag{7.5}$$

Let a and b be the constants for which (7.1) holds for $\{e_n\}$ on $\mathcal{H}_e$. Then, from (7.4),

$$a\|A^*h\|^2 \le \sum_n |\langle A^*h, e_n\rangle|^2 = \sum_n |\langle h, d_n\rangle|^2 \le b\|A^*h\|^2. \tag{7.6}$$

We claim that A (and hence A^*) is boundedly invertible. If this is true, then (7.6) leads to

$$\frac{a}{\|(A^*)^{-1}\|^2}\|h\|^2 \le \sum_n |\langle h, d_n\rangle|^2 \le b\|A^*\|^2\|h\|^2,$$

which establishes (7.4).

To show A is invertible, we note that the linear independence of $\{d_n\}$ implies the injectivity of A. To see that the range of A is all of $\mathcal{H}_d$, note that any $h \in \mathcal{H}_d$ can be written as $h = \sum_n h_n d_n$, where $\{h_n\} \in \ell^2(\mathbb{N})$. Then, setting $x \equiv \sum_n h_n e_n$, one easily sees that $x \in \mathcal{H}_e$ and $Ax = h$. Hence, A maps $\mathcal{H}_e$ onto $\mathcal{H}_d$.

Finally, we show that A is bounded. Choose $x \in \mathcal{H}_e$, and write as

$$x = \sum_n x_n e_n = \sum_n \langle x, \epsilon_n\rangle e_n,$$

where $\{\epsilon_n\}$ is the Riesz basis for $\mathcal{H}_e$ which is biorthogonal to $\{e_n\}$. Then,

$$Ax = \sum_n x_n d_n = \sum_n x_n e_n + \sum_n x_n(d_n - e_n) = x + \sum_n x_n(d_n - e_n),$$

which yields

$$\begin{aligned} \|Ax\|^2 &\le \|x\|^2 + \left(\textstyle\sum_n |x_n|^2\right)\left(\textstyle\sum_n \|d_n - e_n\|^2\right) \\ &= \|x\|^2 + M\textstyle\sum_n |\langle x, \epsilon_n\rangle|^2 \\ &\le \|x\|^2 + M\beta\|x\|^2\,, \end{aligned}$$

where (7.4) was used in the last inequality. Thus,

$$\|A\|^2 \le 1 + M\beta < \infty\,,$$

and A is bounded. By the open mapping theorem, A has a bounded inverse, as asserted. □

Proof of Lemma 7.1. From the estimates of Theorem 4.1, one can show that

$$\sum_n \|g_n(\,\cdot\,;p) - g_n(\,\cdot\,;0)\|^2 < \infty\,, \tag{7.7}$$

so, by Lemma 7.4, $\{g_n\}$ is a Riesz basis for $\mathcal{E}_v(p)$. The result now follows from Lemma 7.3. □

Finally, we prove that for any $q \in \mathcal{E}$, the complementary space $\mathcal{E}_h(q)$ is infinite-dimensional. We first observe that, by the explicit formula (7.3) and Fourier analysis, the gradients $g_n(\cdot, 0)$ are orthogonal vectors, and the complementary space $\mathcal{E}_h(0)$ has infinite dimension. Since the gradients satisfy (7.7), the second part of Theorem 1.3 will follow from the next lemma.

LEMMA 7.5. *Let $\{v_n\}$ be an orthogonal set of vectors in a Hilbert space $\mathcal{H}$. Let $\{w_n\} \subset \mathcal{H}$ be a linearly independent set of vectors which satisfy $\sum_n \|v_n - w_n\|^2 < \infty$. Set $V \equiv \text{span}\{v_n\}$ and $W \equiv \text{span}\{w_n\}$. If $V^\perp$ has infinite dimension, then $W^\perp$ also has infinite dimension.*

Proof. Suppose not, and choose an infinite sequence of orthogonal unit vectors $\{e_n\}$ from $V^\perp$ so that $e_n \to 0$ weakly. Let $\epsilon > 0$ be given. Writing $e_n = P_W e_n + P_{W^\perp} e_n$ we see that $P_{W^\perp} e_n \to 0$ if $W^\perp$ has finite dimension. We will obtain a contradiction by showing that $\|P_W e_n\|$ is also small for large n. First observe that by hypothesis, for M sufficiently large and all n,

$$\sum_{m=M+1}^{\infty} |\langle e_n, w_m \rangle|^2 < \epsilon.$$

On the other hand, using the weak convergence again,

$$\sum_{m=1}^{M} |\langle e_n, w_m \rangle|^2 \to 0$$

as $n \to \infty$ for a fixed M. It follows that for any $\epsilon > 0$,

$$\limsup_{n \to \infty} \left(\sum_m |\langle e_n, w_m \rangle|^2 \right) \leq \epsilon.$$

Since $\{w_n\}$ is a Riesz basis, by virtue of Lemma 7.4, this means that $\limsup_{n\to\infty} \|P_W e_n\| \leq \epsilon$, a contradiction. ∎

Appendix A. The free Green's function and free resolvent operator. In this appendix, we prove some useful technical estimates on the Green's kernel for the differential operator $L_\#(0)$, where $L_\#(0)$ is one of the operators $L(0)$, $L_1(0)$, or $L_2(0)$ defined in (1.3)–(1.5). Let $G_0^\#(x, y; z)$ be the integral kernel of $(L_\#(0) - z)^{-1}$, and let $C^\#_{R,\alpha}$ be defined as in section 2.

In what follows, $\beta = (\beta_x, \beta_y)$, where β_x and β_y are nonnegative integers, and $\partial^\beta = \partial_x^{\beta_x} \partial_y^{\beta_y}$. We wish to derive estimates on $\partial^\beta G_0^\#(x, y; z)$. These estimates will involve series of the form

$$\sum_{n=1}^{\infty} \frac{D_x^{\beta_x} u_n^\#(x) D_y^{\beta_y} u_n^\#(y)}{\lambda_n^\#(0) - z}, \tag{A.1}$$

where $\lambda_n^\#(0)$ and $u_n^\#$ are the eigenvalues and eigenfunctions, respectively, of $L_\#(0)$. It can be verified directly that for each set of boundary conditions, the eigenfunctions obey

$$|D_x^j u_n^\#(x)| \leq C n^j, \quad 0 \leq j \leq 2,$$

for some constant C. Thus, to estimate series of the form (A.1), it suffices to majorize the numerical series

$$\sum_{n=1}^{\infty} \frac{n^{|\beta|}}{|\lambda_n^{\#}(0) - z|}.$$

In so doing, we will require the following technical result, which may be easily verified.

LEMMA A.1. *Let $R > 1$ and $\alpha \in (2,3)$. Then, for $m > (8R)^{\frac{1}{3-\alpha}}$,*

$$\int_1^{m-1} \frac{t^2}{m^4\pi^4 - t^4\pi^4}\, dt \le \frac{1}{m\pi^4} \ln m, \tag{A.2}$$

$$\int_{m+2}^{\infty} \frac{t^2}{t^4\pi^4 - [(m+1)^4\pi^4 + R(m+1)^{\alpha}]}\, dt \le \frac{C}{m}\, \ln m\,, \tag{A.3}$$

where the constant C depends only on α.

First of all, we have the following lemma.

LEMMA A.2. *Let $R > 0$, let $\alpha \in (2,3)$, and let N be an integer satisfying the bounds* (2.1). *Then for any $z \notin C_{R,\alpha}^{\#}$:*

(a) *for $|\beta| \le 1$,*

$$\sup_{x,y\in[0,1]} |\partial^{\beta} G_0^{\#}(x,y;z)| \le c_{|\beta|} R^{-1};$$

(b) *for $|\beta| = 2$,*

$$\sup_{x,y\in[0,1]} |\partial^{\beta} G_0^{\#}(x,y;z)| \le c_2 R^{-1} \ln(R),$$

where c_2 is a numerical constant depending only on α.

Proof. We consider the case $\lambda_n(0) = n^4\pi^4$, the computations for other boundary conditions being similar.

For $|\beta| \le 1$ we have the simple majorization

$$\sum_{n=1}^{\infty} \frac{n}{|n^4\pi^4 - z|} \le \sum_{n=1}^{\infty} \frac{n}{Rn^{\alpha}}\,,$$

which gives estimates of the desired form.

For $|\beta| = 2$, we seek to estimate the series

$$\sum_{n=1}^{\infty} \frac{n^2}{|n^4\pi^4 - z|}$$

for $z \notin C_{R,\alpha}$. We split the sum into

$$T_1 = \sum_{n=1}^{N} \frac{n^2}{|n^4\pi^4 - z|}$$

and

$$T_2 = \sum_{n=N+1}^{\infty} \frac{n^2}{|n^4\pi^4 - z|}\,,$$

where $N > (8R)^{\frac{1}{3-\alpha}}$.

To estimate T_1, we use the fact that for $1 \leq n \leq N$, $|z - n^4\pi^4| \geq |z_N - n^4\pi^4|$ where $z_N = N^4\pi^4 + RN^\alpha$. The integral test then yields the bound

$$\begin{aligned} T_1 &\leq \sum_{n=1}^{N-2} \frac{n^2}{|n^4\pi^4 - N^4\pi^4|} + \frac{(N-1)^2}{z_N - (N-1)^4\pi^4} \\ &\quad + \frac{N^2}{|N^4\pi^4 - z_N|} \\ &\leq \int_1^{N-1} \frac{t^2}{N^4\pi^4 - t^4\pi^4} + CR^{-1}\,. \end{aligned}$$

Using (A.2) and the fact that $N = O(R^{\frac{1}{3-\alpha}})$, we conclude that $T_1 \leq C(\alpha)R^{-1}\ln R$.

To estimate T_2, we consider the two cases $\Re(z) \leq z_N$ and $\Re(z) \geq z_N$ separately. If $\Re(z) \leq z_N$, then $|m^4\pi^4 - z| \geq |m^4\pi^4 - z_N|$, from which we obtain

$$T_2 \leq \sum_{n=N+1}^{\infty} \frac{n^2}{\pi^4 n^4 - [\pi^4 N^4 + RN^\alpha]}.$$

We may estimate this sum by

$$\frac{(N+1)^2}{\pi^4(N+1)^2 - z_N} + \int_{N+1}^{\infty} \frac{t^2}{t^4\pi^4 - [\pi^4 N^4 + CRN^\alpha]}\,dt\,,$$

which, in conjunction with (A.3), yields an estimate of the desired form.

If $\Re(z) > z_N$, we divide the half-plane $\Re(z) > z_N$ into strips

$$S_m = \{z \in \mathbb{C} : \Re(z) \in [m^4\pi^4 + Rm^\alpha, (m+1)^4\pi^4 + R(m+1)^\alpha)\}$$

and fix m so that $z \in S_m$. We can then estimate T_2 by letting $x = \Re(z)$ and splitting

$$\begin{aligned} \sum_{n=N+1}^{\infty} \frac{n^2}{|n^4\pi^4 - z|} &= \sum_{n=N+1}^{m-2} \frac{n^2}{|n^4\pi^4 - z|} \\ &\quad + \left(\frac{(m-1)^2}{z - (m-1)^4\pi^4} + \frac{m^2}{|z - m^4\pi^4|} \right. \\ &\quad \left. + \frac{(m+1)^2}{|z - (m+1)^4\pi^4|} + \frac{(m+2)^2}{|z - (m+2)^4\pi^4|} \right) \\ &\quad + \sum_{n=m+3}^{\infty} \frac{n^2}{n^4\pi^4 - x} \\ &= T_{21} + T_{22} + T_{23}\,. \end{aligned}$$

From the definition of $C_{R,\alpha}$, it is clear that

$$T_{22} \leq CR^{-1}\,,$$

which bounds T_{22}. Finally, using the fact that, for x in the interval $[m^4\pi^4+Rm^\alpha, (m+1)^4\pi^4 + R(m+1)^\alpha)$,

$$T_{21} \le \int_0^{m-1} \frac{t^2}{m^4\pi^4 - t^4\pi^4}\, dt,$$
$$T_{23} \le \int_{m+2}^{\infty} \frac{t^2}{t^4\pi^4 - [(m+1)^4\pi^4 + R(m+1)^\alpha]}\, dt\,,$$

we can use (A.2) and (A.3) to bound T_{21} and T_{23}, respectively. □

We will also need estimates on the free resolvent kernel on contours surrounding the sets $E_m^\#$.

LEMMA A.3. *Let $R > 0$, let $\alpha \in (2,3)$, let N be an integer satisfying the bounds (2.1), and let $E_m^\#$ be defined as in section 2. Let γ_m be the contour bounding $E_m^\#$. If $m > N$ and $|\beta| \le 2$, then the estimate*

$$\sup_{\substack{x,\,y\,\in\,[0,1]\\ z\,\in\,\gamma_m}} |\partial^\beta G_0^\#(x,y;z)| \le C_{|\beta|} m^{|\beta|-\alpha}$$

holds. Here $C_{|\beta|}$ is a numerical constant which diverges as $\alpha \uparrow 3$.

Proof. Here again we consider the case $\lambda_n(0) = n^4\pi^4$ and $|\beta| = 2$. We must majorize the numerical series

$$\sum_{n=1}^{\infty} \frac{n^2}{|z - n^4\pi^4|},$$

where $|z - m^4\pi^4| = Rm^\alpha$. We split the sum into

$$\sum\nolimits_{n=1}^{m-2} \frac{n^2}{|z - n^4\pi^4|}$$
$$+ \left[\frac{(m-1)^2}{|z-(m-1)^4\pi^4|} + \frac{m^2}{|z-m^4\pi^4|} + \frac{(m+1)^2}{|z-(m+1)^4\pi^4|}\right]$$
$$+ \sum\nolimits_{n=m+2}^{\infty} \frac{n^2}{|z - n^4\pi^4|}.$$

The three bracketed terms are easily estimated by $6Rm^{2-\alpha}$. We can estimate the first and last terms using (A.2) and (A.3). □

Now we derive estimates on operators involving compositions of the resolvent $(L_\#(0) - z)^{-1}$ with the operator of differentiation, D, and the operator of multiplication by a function $r \in C_0^\infty(0,1)$. These compositions are initially defined on $C_0^\infty(0,1)$ and extended by density to bounded operators. It follows from this definition and an integration by parts that the operator $D^{\beta_x}(L(0) - z)^{-1}D^{\beta_y}$ has integral kernel $(-1)^{\beta_y}(\partial^\beta G_0)(x,y;z)$. From the kernel estimates in Lemma A.2 and integration by parts, the following estimates are easily demonstrated.

LEMMA A.4. *Suppose that $r \in C_0^\infty(0,1)$. For $z \notin C_{R,\alpha}$, there exist $c_0, c_1, c_2 \in \mathbb{R}$ so that the following estimates hold:*

(a) $\|(L_\#(0) - z)^{-1}\| \le c_0 R^{-1}$.
(b) $\|(L_\#(0) - z)^{-1} r\| \le c_0 R^{-1} \|r\|_2$.
(c) $\|D(L_\#(0) - z)^{-1}\| \le c_1 R^{-1}$.

(d) $\|(L_\#(0)-z)^{-1}Dr\| \le c_1 R^{-1}\|r\|_2$.
(e) $\|D(L_\#(0)-z)^{-1}Dr\| \le c_2 R^{-1}\ln(R)\|r\|_2$.

The following bounds are used to estimate the resolvent $(L_\#(p)-z)^{-1}$ for $z \in \gamma_m$, the contour determined by the boundary of the set E_m defined in section 2. We denote by $\|A\|_{p,q}$ the norm of the linear operator A from $L^p[0,1]$ to $L^q[0,1]$, where $1 \le p,q \le \infty$. Using the strong pointwise estimates on the free resolvent and its partial derivatives from Lemma A.3, we easily obtain the following lemma.

LEMMA A.5. *Let $z \in \gamma_m$ and $r \in C_0^\infty(0,1)$, and let $0 \le i,j \le 1$. Then for any p,q with $1 \le p,q \le \infty$, the estimate*

$$\|D^i(L_\#(0)-z)^{-1}D^j\|_{p,q} \le C_{i+j} m^{i+j-\alpha}$$

holds, and for any p,q with $1 \le p \le 2$ and $1 \le q \le \infty$, the estimate

$$\|D^i(L_\#(0)-z)^{-1}D^j r\|_{p,q} \le C_{i+j} m^{i+j-\alpha}\|r\|_2$$

holds. Here C_{i+j} is the numerical constant defined in Lemma A.3.

Appendix B. Domains related to the Borg system. In this appendix, we collect some useful calculations regarding the Borg system $\mathcal{M}-\lambda\mathcal{B}$ of section 6. First of all, for $p=(p_1,p_2) \in \mathcal{D}$, the matrix-valued differential operators $\mathcal{M}$ and $\mathcal{B}$ which define the Borg system can be computed to be

$$\mathcal{M} = \begin{pmatrix} M_1 & M_2 \\ M_3 & M_4 \end{pmatrix} \quad \textit{and} \quad \mathcal{B} = \begin{pmatrix} B_1 & B_2 \\ B_3 & B_4 \end{pmatrix},$$

where

$$\begin{aligned}
M_1 &= D^5 - p_1 D^3 - 2p_1' D^2 + \left(\frac{8}{3}p_2 - p_1''\right) D + 2p_1', \\
M_2 &= -\frac{10}{3}D^3 + \frac{4}{3}p_1 D + \frac{2}{3}p_1', \\
M_3 &= -3p_1' D^4 + 10p_2 D^3 + (3p_1 p_1' + 5p_2')D^2 + \left(p_2'' - 4p_1 p_2 + 3(p_1')^2\right) D - 6p_1' p_2, \\
M_4 &= D^5 - 5p_1 D^3 - p_1' D^2 + (4p_1^2 - 8p_1'' - 24p_2)D + (2p_1 p_1' - 2p_1''' - 6p_2'), \\
B_1 &= \frac{8}{3}D, \\
B_2 &= 0, \\
B_3 &= 10D^3 + 4p_1 D - 6p_1', \\
B_4 &= -24D.
\end{aligned}$$

Boundary conditions are to be specified so that if w is an eigenfunction (with eigenvalue λ) of one of the three underlying fourth-order problems (1.3), (1.4), (1.5), then $z=[w^2,\,(w')^2]^T$ will be in the kernel of $\mathcal{M}-\lambda\mathcal{B}$. The three fourth-order operators $L(p)$, $L_1(p)$, and $L_2(p)$ underlying the Borg system carry the following boundary conditions (see section 1):

$$L(p): w(0) = w''(0) = w(1) = w''(1) = 0,$$

$$L_1(p): w(0) = w''(0) = w'(1) = w'''(1) = 0,$$

$$L_2(p): w(0) = w''(0) = w(1) = w'(1) = 0.$$

Setting $u \equiv w^2$ and $v \equiv (w')^2$, one can compute directly that the boundary conditions which determine the domain of $\mathcal{M}$ are:

- At $x = 0$: $\quad u = u' = u''' = v' = v''' = u'' - 2v = u^{(4)} - 4v'' = 0,$
- At $x = 1$: $\quad u' = u''' = v' = 0.$

The operator $\mathcal{B}$ is to be viewed as a perturbation of $\mathcal{M}$, so we take $D(\mathcal{B}) = D(\mathcal{M})$, from which it follows that $D(\mathcal{M} - \lambda\mathcal{B}) = D(\mathcal{M})$.

It will also be useful to determine the boundary conditions which define the domains of certain adjoint operators related to the Borg system. First, consider $D(\mathcal{M}^*)$, where $\mathcal{M}^*$ denotes the Hilbert space adjoint of the unbounded operator $\mathcal{M}$.

Let $z = [u,\, v]^T \in D(\mathcal{M})$. An element $\sigma = [\phi,\, \psi]^T \in D(\mathcal{M}^*)$ must satisfy

$$\langle \mathcal{M}z, \sigma\rangle - \langle z, \mathcal{M}^\dagger\sigma\rangle = 0\,,$$

where $\mathcal{M}^\dagger$ denotes the formal adjoint of $\mathcal{M}$. One can compute directly the following boundary conditions which define $D(\mathcal{M}^*)$:

- At $x = 0$: $\quad \psi = \psi'' + \frac{2}{3}\phi = \psi^{(4)} - \frac{4}{3}\phi'' + \frac{8}{3}p_1\phi = 0,$
- At $x = 1$: $\quad \phi = \phi'' = \phi^{(4)} = \psi = \psi' = \psi'' = \psi^{(4)} = 0.$

Similarly, one can compute the following boundary conditions which define $D(\mathcal{B}^*)$:

- At $x = 0$: $\quad \psi = 0,$
- At $x = 1$: $\quad \psi = 5\psi'' + \frac{4}{3}\phi = 0.$

One immediately observes the following containment:

$$D(\mathcal{M}^*) \subset D(\mathcal{B}^*)\,.$$

Finally, proceeding as above, one may compute the following set of boundary conditions which defines $D((\mathcal{M} - \lambda\mathcal{B})^*)$:

- At $x = 0$: $\quad \psi = \psi'' + \frac{2}{3}\phi = \psi^{(4)} - \frac{4}{3}\phi'' + \frac{8}{3}p_1\phi = 0,$
- At $x = 1$: $\quad \phi = \phi'' = \phi^{(4)} = \psi = \psi' = \psi'' = \psi^{(4)} = 0\,,$

which shows that $D((\mathcal{M} - \lambda\mathcal{B})^*) = D(\mathcal{M}^*)$.

Acknowledgments. The authors would like to acknowledge the hospitality of the Institute for Mathematics and its Applications during part of the time that this work was done, and to thank David Leep and Serge Ochanine for helpful conversations on the algebraic lemmas in section 6.

ASYMPTOTICS FOR THE SPECTRUM OF A FLUID/STRUCTURE HYBRID SYSTEM ARISING IN THE CONTROL OF NOISE*

SORIN MICU† AND ENRIQUE ZUAZUA‡

Abstract. We consider a simple model arising in the control of noise consisting of two coupled hyperbolic equations of dimensions two and one, respectively. The one-dimensional equation is assumed to be dissipative. We describe the asymptotic behavior of the eigenvalues and eigenfunctions of the system at high frequencies. Some other interesting features of the model, like the exponential decay of solutions or the compactness of the damping term, are also studied.

Key words. eigenvalues, eigenfunctions, high frequency asymptotics, hyperbolic system, aeromechanic structure interaction

1. Introduction.

Recently several works both in the mathematical and technical literature have dealt with the problem of the active control of noise generated in acoustic cavities by means of the vibrations of their flexible walls. Such studies were motivated, for instance, by the development of a new class of turboprop engines which are very fuel efficient but also very loud. In this context the low frequency high magnitude acoustic fields produced by these engines cause vibrations in the fuselage which in turn generate unwanted interior noise.

In this article we analyze the spectral properties of a linear two-dimensional hybrid system arising in the development of these new technologies for noise reduction in the interior of a cavity (plane, car, etc.) which was proposed in a series of works by Banks et al. (see [3]).

Let us describe the system we study. We consider the two-dimensional square $\Omega = (0,1) \times (0,1) \subset \mathbb{R}^2$. We assume that Ω is filled with an elastic, inviscid, compressible fluid whose velocity field $\vec{v}$ is given by the potential $\phi = \phi(x,y,t)$, ($\vec{v} = \nabla\phi$). By linearization we assume that the potential ϕ satisfies the linear wave equation in $\Omega \times (0,\infty)$ (see [8]).

The boundary $\Gamma = \partial\Omega$ of Ω is divided in two parts: $\Gamma_0 = \{(x,0) : x \in (0,1)\}$ and $\Gamma_1 = \Gamma \backslash \Gamma_0$. The subset Γ_1 is assumed to be rigid and we impose zero normal velocity of the fluid on it. The subset Γ_0 is supposed to be flexible and occupied by a flexible string that vibrates under the pressure of the fluid on the plane where Ω lies. The displacement of Γ_0, described by the scalar function $W = W(x,t)$, obeys the one-dimensional dissipative wave equation. On the other hand, on Γ_0 we impose the continuity of the normal velocities of the fluid and the string. The string is assumed to satisfy Neumann boundary conditions on its extremes.

All deformations are supposed to be small enough so that linear theory applies.

Under natural initial conditions for ϕ and W the linear motion of this system is described by means of the following coupled wave equations:

$$
\left\{
\begin{array}{lll}
\phi_{tt} - \Delta\phi = 0 & \text{in} & \Omega \times (0,\infty), \\
\frac{\partial \phi}{\partial \nu} = 0 & \text{on} & \Gamma_1 \times (0,\infty), \\
\frac{\partial \phi}{\partial y} = -W_t & \text{on} & \Gamma_0 \times (0,\infty), \\
W_{tt} - W_{xx} + W_t + \phi_t = 0 & \text{on} & \Gamma_0 \times (0,\infty), \\
W_x(0,t) = W_x(1,t) = 0 & \text{for} & t > 0, \\
\phi(0) = \phi^0, \phi_t(0) = \phi^1 & \text{in} & \Omega, \\
W(0) = W^0, W_t(0) = W^1 & \text{on} & \Gamma_0.
\end{array}
\right. \tag{1.1}
$$

By ν we denote the unit outward normal to Ω.

In (1.1) we have chosen to take the various parameters of the system to be equal to one. This restricts the generality of our analysis. The dependence of the most interesting features of the spectrum with respect to the various parameters of the system will be studied elsewhere.

We remark also that, in (1.1), two wave equations, of dimensions two and one, respectively, and representing vibrations of different nature, are coupled. Therefore we say that (1.1) is a two-dimensional hybrid system. For examples of hybrid systems of dimension one, such as those coupling strings or beams with rigid bodies, see [10], [7], and [18].

System (1.1) is a modified version of the one introduced by Banks et al. in [3] (see also [4]). In [3] the flexible part of the boundary Γ_0 is assumed to be occupied by a flexible beam, leading to a fourth-order one-dimensional equation on Γ_0. We have chosen to consider a one-dimensional wave equation instead to simplify the exposition. However, most of the relevant spectral properties remain unchanged considering a beam equation with appropriate boundary conditions.

We also remark that we choose Neumann boundary conditions for the string. This choice allows us to separate the variables and to obtain an explicit equation for the eigenvalues. In the case of Dirichlet boundary conditions, which are considered in [3], this is no longer possible. Nevertheless, using the information we get here about the eigenfunctions of system (1.1), it can be proved that the uniform decay fails and also that there exist solutions uniformly distributed in Ω with arbitrarily small decay (see [14]).

System (1.1) is well posed in the energy space

$$\mathcal{X} = H^1(\Omega) \times L^2(\Omega) \times H^1(\Gamma_0) \times L^2(\Gamma_0)$$

for the variables (ϕ, ϕ_t, W, W_t).

The energy

$$E(t) = \frac{1}{2}\int_\Omega \left[|\nabla\phi|^2 + |\phi_t|^2 \right] dxdy + \frac{1}{2}\int_{\Gamma_0} \left[|W_x|^2 + |W_t|^2 \right] dx \tag{1.2}$$

satisfies

$$\frac{dE}{dt}(t) = -\int_{\Gamma_0} |W_t|^2 \, dx. \tag{1.3}$$

Hence, the system (1.1) is dissipative, the damping term being localized in the subset Γ_0 of the boundary.

Some of the properties of this system like existence, uniqueness, asymptotic behavior, and existence of periodic solutions were studied in previous works (see [12] and [13]).

Our aim here is to characterize the asymptotic behavior of the eigenvalues and eigenfunctions of the differential operator corresponding to system (1.1) and to describe some interesting features of the model that are direct consequences of this analysis. The study is made by using separation of variables. In this way the system is reduced to an infinite number of one-dimensional systems depending on an integer parameter k which represents the frequency of vibration in the x-direction. This allows us to obtain explicit equations for eigenvalues and to use Rouché's theorem for their localization.

Let us describe briefly the most relevant results obtained in this paper:

(a) Whenever the frequency of vibration in the $x-$direction is fixed the corresponding one-dimensional system does not decay uniformly. Indeed, at high frequencies, the real part of the one-parameter family of eigenvalues converges to zero. This is a typical situation in one-dimensional hybrid systems (see [7], [10], and [18]).

(b) The effect of the damping term on the global dynamics of the system is almost negligible at high frequencies. Indeed, most of the eigenfunctions of the system (1.1) have their energy uniformly distributed in Ω while the real part of the eigenvalues converges to zero at high frequencies.

(c) Among the two-parameter family of eigenvalues of the two-dimensional system only a one-parameter family of them is effectively damped so that their real parts remain uniformly away from zero. The corresponding eigenfunctions have their energy exponentially concentrated on the string Γ_0.

(d) As a consequence of the previous property, the difference between the semigroup generated by the damped and undamped systems is not compact. This is in contrast with the results in [18] showing that the lack of uniform decay in damped one-dimensional hybrid systems is typically due to the compactness of the damping term. Thus, the noncompactness result is genuinely two-dimensional.

Let us remark that the case we have addressed is not generic. Even in the case of surfaces of revolution the cylindrical case is a degenerate one. This was exhibited in the thesis of Allibert in the frame of the classical wave equation with Dirichlet boundary conditions (see [1]). Nevertheless, in [11] we show that, in the case of a disk-shaped cavity surrounded by a circular dissipative string, the same phenomenon is present although all rays of geometric optics meet the boundary where the losses occur. This indicates that the same behavior can be expected for different kinds of geometries or boundary conditions (see also [14]).

The rest of the paper is organized as follows.

In section 2 we present in detail the main results of this paper and we discuss some of their consequences. In section 3 we localize the eigenvalues of the undamped system corresponding to (1.1) and describe its eigenfunctions. In section 4 we obtain asymptotic estimates for the eigenvalues and eigenmodes of the damped system (1.1). This section is divided in two parts. In section 4.1 we distinguish three types of eigenvalues which, at high frequencies, approach the imaginary axis. The corresponding eigenfunctions have the property that the energy concentrated in the string vanishes asymptotically. To complete the study, in section 4.2 we prove that there exists a sequence of eigenvalues, tending to infinity, with uniformly negative real parts. The

corresponding eigenfunctions have the property that the energy localized on the string does not vanish asymptotically. Moreover, as the frequency increases the whole energy is concentrated on the string at an exponential rate. These eigenfunctions span an infinite-dimensional subspace of the energy space in which the decay rate of solutions is exponential.

In the last section we prove that the difference between the semigroup generated by the differential operator associated with the undamped system and that associated with the damped one is not compact as a consequence of the existence of an infinite-dimensional subspace in which the damping term is effective; i.e., it produces an exponential decay. We end up with an appendix that contains some technical lemmas.

2. The main results: Statements and discussion. As we said in the introduction the aim of this paper is the study of the spectrum of (1.1). In this section we state the main results concerning the eigenvalues and eigenfunctions of the system and some of their consequences.

In order to analyze the spectrum of (1.1) we look for solutions in separated variables of the form $(\phi, W) = (\psi(y,t), V(t))\cos(k\pi x)$.

We deduce that $(\psi(y,t), V(t))$ verifies the following one-dimensional system:

$$\left\{\begin{array}{lll} \psi_{tt} - \psi_{yy} + k^2\pi^2\psi = 0 & \text{in} & (0,1)\times(0,\infty), \\ \psi_y(1) = 0 & \text{for} & t \in (0,\infty), \\ \psi_y(0) = -V_t & \text{for} & t \in (0,\infty), \\ V_{tt} + k^2\pi^2 V + V_t + \psi_t(0) = 0 & \text{for} & t \in (0,\infty). \end{array}\right. \tag{2.1}$$

Now if we look for solutions of (2.1) of the form $(\psi(y,t), V(t)) = e^{\lambda t}(\psi(y), V)$, with $V \in \mathbb{R}$, it follows that the eigenvalues λ of system (1.1) are the roots of the equation

$$e^{2\sqrt{\lambda^2+k^2\pi^2}} = -\frac{\lambda^2 - \sqrt{\lambda^2+k^2\pi^2}(\lambda^2+\lambda+k^2\pi^2)}{\lambda^2 + \sqrt{\lambda^2+k^2\pi^2}(\lambda^2+\lambda+k^2\pi^2)}. \tag{2.2}$$

The corresponding eigenfunctions are $\varphi_\lambda = \psi_\lambda \cos(k\pi x)$ where ψ_λ are the eigenfunctions of (2.1):

$$\psi_\lambda = \begin{pmatrix} \dfrac{1}{\lambda}\cosh\left(\sqrt{\lambda^2+k^2\pi^2}(y-1)\right) \\ \cosh\left(\sqrt{\lambda^2+k^2\pi^2}(y-1)\right) \\ \dfrac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\sinh\left(\sqrt{\lambda^2+k^2\pi^2}\right) \\ \dfrac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\sinh\left(\sqrt{\lambda^2+k^2\pi^2}\right) \end{pmatrix}. \tag{2.3}$$

We are interested in the asymptotic behavior of the eigenvalues λ when $|\lambda| \longrightarrow \infty$. For each $k \in \mathbb{N}$ we get a sequence of eigenvalues $(\lambda_{k,m})_{m\in\mathbb{Z}^*}$ for the system (2.1) of modulus greater than $k\pi$ (that will be analyzed in section 4.1) and two eigenvalues λ_k^* and λ_k^{**} with modulus less than $k\pi$ (that will be studied in section 4.2). All these are the eigenvalues of system (1.1). For each k, $(\lambda_{k,m})_{m\in\mathbb{N}^*}$ are ordered such that $|\lambda_{k,m}|$ increases as m does and $\lambda_{k,-m} = \bar{\lambda}_{k,m}$ if $m \in \mathbb{N}^*$. The general result on the existence of eigenvalues is given in the following theorem.

THEOREM 2.1. *Let $k \in \mathbb{N}$ be fixed. The spectrum of the differential operator corresponding to system* (2.1) *consists of a sequence of eigenvalues* $(\lambda_{k,m})_{m\in\mathbb{N}^*} \cup \{\lambda_k^*\}$

with positive imaginary part and another sequence of eigenvalues $(\lambda_{k,-m})_{m\in\mathbb{N}^*}\cup\{\lambda_k^{**}\}$ *with the property that* $\lambda_{k,-m}=\bar{\lambda}_{k,m}$ *if* $m>0$ *and* $\lambda_k^{**}=\bar{\lambda}_k^*$. *All these eigenvalues are zeros of the equation* (2.2). *If* $k=0$ *then* $\lambda_k^*=\lambda_k^{**}=0$.

Remark 1. We remark that the notation λ_k^* and λ_k^{**} are used for the eigenvalues with the smallest modulus of the system. We make this distinction since the properties of these wave numbers are different from the others, as we shall see in Theorem 2.9. Actually, these eigenvalues correspond to the eigenfunctions whose energy is concentrated on the string Γ_0 and decay uniformly as $t\to\infty$.

The asymptotic properties of the wave numbers and modes depend on the relation between k and m. Therefore we divide our analysis in four cases. First, in Theorems 2.2, 2.4, and 2.6, we characterize the eigenvalues that approach the imaginary axis as the wave number increases. These are the eigenvalues $(\lambda_{k,m})_{m\in\mathbb{Z}^*}$. Then, in Theorem 2.9, we study the eigenvalues λ_k^* and λ_k^{**} which have a uniformly negative real part.

THEOREM 2.2 (eigenvalues $\lambda_{k,m}$ with $|\lambda_{k,m}|\geq\sqrt{2}k\,\pi$). *Let* $k\in\mathbb{N}$ *be fixed. The eigenvalues* $\lambda_{k,m}$ *of* (2.1) *with* $\mid\lambda_{k,m}\mid>\sqrt{2}\pi\,k$ *approach the imaginary axis when* $\mid m\mid\to\infty$ *and satisfy the following:*

$$\begin{aligned}&\mid\lambda_{k,m}-\sqrt{k^2+m^2}\,\pi\,i\mid\leq\frac{24}{\sqrt{m^2+k^2}\,\pi}\quad\text{if }\mathcal{I}m\,\lambda_{k,m}>0\qquad(m>k>0),\\&\mid\lambda_{k,m}+\sqrt{k^2+m^2}\,\pi\,i\mid\leq\frac{24}{\sqrt{m^2+k^2}\,\pi}\quad\text{if }\mathcal{I}m\,\lambda_{k,m}<0\qquad(m<-k<0).\end{aligned}\tag{2.4}$$

Remark 2. Theorem 2.2 shows that when we fix the frequency of vibration in the x-direction (k fixed) and we consider large frequencies in the y-direction (m large), the system behaves like the wave equation in Ω with homogeneous Neumann boundary conditions in all $\partial\Omega$:

$$\begin{cases}\Phi_{tt}-\triangle\Phi=0 & \text{in}\quad\Omega\times(0,\infty),\\ \frac{\partial\Phi}{\partial\nu}=0 & \text{on}\quad\partial\Omega\times(0,\infty).\end{cases}\tag{2.5}$$

Therefore, the influence of the vibrating string on Γ_0 vanishes asymptotically.

Remark 3. Note that the existence of a sequence of eigenvalues $(\lambda_{k,m})_m$ which approach the imaginary axis when $\mid m\mid\to\infty$ implies that the decay rate of the energy of solutions of (1.1) is not exponential. It is known that, for linear problems, this is equivalent to a nonuniform decay rate of solutions (see [9]).

In fact we obtain that, for each $k\in\mathbb{N}$, the system (2.1) does not have an exponential decay. This is not the case in the classical wave equation with boundary dissipation:

$$\begin{cases}\Phi_{tt}-\triangle\Phi=0 & \text{in}\quad\Omega\times(0,\infty),\\ \frac{\partial\Phi}{\partial\nu}=0 & \text{on}\quad\Gamma_1\times(0,\infty),\\ \frac{\partial\Phi}{\partial\nu}+\Phi_t=0 & \text{on}\quad\Gamma_0\times(0,\infty).\end{cases}\tag{2.6}$$

In the context of (2.6), for k fixed, the corresponding one-dimensional systems have exponential decay, but the decay rate vanishes as $k\to\infty$. This is due to the fact that the region Γ_0 in which the damping is concentrated does not satisfy the necessary geometric control condition since there are rays of geometric optics that never intersect Γ_0 (see [5] and [17]). In our case the loss of uniform decay is even worse, and it is due to the hybrid structure of the system or, equivalently, to the type of boundary condition we have imposed on Γ_0 and not only to the support Γ_0 of the damping term.

Moreover, as we mention in Remark 6, we can find a sequence of solutions of (1.1) with the energy uniformly distributed in all Ω and with arbitrarily small exponential decay rate. This is not possible in the examples given in [5] and [17] where the energy of the solutions with nonuniform decay concentrates on rays of geometric optics.

Remark 4. The fact that the eigenvalues approach the imaginary axis is a consequence not only of the localization of the dissipative region but also of the hybrid structure of the system. In [11] we show that, in the case of a disk-shaped cavity surrounded by a circular dissipative string the same phenomenon is present although all rays of geometric optics meet the boundary where the losses occur.

This indicates that the same behavior can be expected for different kinds of geometries or boundary conditions (see also [14]).

We can now analyze the eigenfunctions corresponding to the wave numbers $\lambda_{k,m}$ of Theorem 2.2. Remark 2 indicates that one can expect the first two components of the eigenfunctions of (1.1) to behave like the eigenfunctions of (2.5). Therefore we define the function

$$\psi_{k,m} = \begin{pmatrix} \dfrac{(-1)^{m+1} i}{\sqrt{k^2+m^2}\pi} \cos m\pi y \cos k\pi x \\ (-1)^{m+1} \cos m\pi y \cos k\pi x \\ 0 \\ 0 \end{pmatrix}. \tag{2.7}$$

Observe that the eigenmodes of (2.5) are the first two components of $\psi_{k,m}$.

THEOREM 2.3. *The eigenfunctions φ_λ, corresponding to the eigenvalues $\lambda = \lambda_{k,m}$ satisfying* (2.4) *have the following property:*

$$\| \varphi_\lambda - \psi_{k,m} \|_{\mathcal{X}} \leq \frac{c}{m}, \tag{2.8}$$

where c is a constant which does not depend on m and k.

Remark 5. Theorem 2.5 indicates that the last two components of the eigenfunction φ_λ (which correspond to the string located in Γ_0) vanish asymptotically when the frequency increases. This implies that, at high frequencies (in the sense of (2.4)), the string does not play an important role in the dynamics of the system.

Remark 6. The solutions of (1.1) corresponding to the eigenfunctions given by Theorem 2.3 form a sequence of solutions with the energy uniformly distributed in all Ω and with arbitrarily small exponential decay rate. This proves that the lack of the uniform decay of our system is related not only to the support of the dissipative mechanism but also to the nature of the boundary conditions or of the coupling between the different components of the system.

The second range of frequencies is studied in the following theorem.

THEOREM 2.4. *[*eigenvalues $\lambda_{k,m}$ with $k\pi \leq |\lambda_{k,m}| \leq \sqrt{2}k\pi$, first part*] For $k \in \mathbb{N}$ sufficiently large and $m = \pm 1, \pm 2, ..., \pm[\sqrt[3]{k}]$, the eigenvalues $\lambda_{k,m}$ of* (1.1) *satisfy*

$$\begin{aligned} &\left| \lambda_{k,m} - \sqrt{k^2 + \left(\frac{2m-1}{2}\right)^2}\pi\, i \right| \leq \frac{2\pi}{\sqrt[3]{k}} \text{ if } \mathcal{I}m\,\lambda_{k,m} > 0 \quad (1 \leq m \leq [\sqrt[3]{k}]), \\ &\left| \lambda_{k,m} + \sqrt{k^2 + \left(\frac{2m+1}{2}\right)^2}\pi\, i \right| \leq \frac{2\pi}{\sqrt[3]{k}} \text{ if } \mathcal{I}m\,\lambda_{k,m} < 0 \quad (-[\sqrt[3]{k}] \leq m < 0). \end{aligned} \tag{2.9}$$

Remark 7. Consider the following conservative wave equation:

$$\begin{cases} \Phi_{tt} - \triangle\Phi = 0 & \text{in} \quad \Omega \times (0,\infty), \\ \frac{\partial\Phi}{\partial\nu} = 0 & \text{on} \quad \Gamma_1 \times (0,\infty), \\ \Phi = 0 & \text{on} \quad \Gamma_0 \times (0,\infty). \end{cases} \tag{2.10}$$

Its eigenvalues are exactly $\sqrt{k^2 + \left(\frac{2m+1}{2}\right)^2}\pi\, i$. Theorem 2.4 shows that when we fix the frequency of vibration in the y-direction (m is fixed) and we consider large frequencies in the x-direction (k large), the eigenvalues of (1.1) behave like those of (2.10). The influence of the vibrating string on Γ_0 vanishes asymptotically in this range of eigenvalues. However, when comparing the behavior of these eigenvalues with those of Theorem 2.2, we observe that the boundary conditions for Φ on Γ_0 change.

Let us analyze the eigenfunctions corresponding to the eigenvalues studied in Theorem 2.4. We consider first the function

$$\tilde{\psi}_{k,m} = \begin{pmatrix} \dfrac{(-1)^{m+1}\, i}{\sqrt{k^2 + \left(\dfrac{2m+1}{2}\right)^2}\,\pi}\ \sin\ \dfrac{2m+1}{2}\pi y\ \cos\ k\pi x \\ (-1)^{m+1}\ \sin\ \dfrac{2m+1}{2}\pi y\ \cos\ k\pi x \\ 0 \\ 0 \end{pmatrix} \tag{2.11}$$

and we remark that the first two components of it correspond to eigenfunctions of problem (2.10).

THEOREM 2.5. *The eigenfunctions φ_λ corresponding to the eigenvalues $\lambda = \lambda_{k,m}$ of Theorem* 2.4 *satisfy*

$$\| \varphi_\lambda - \tilde{\psi}_{k,m} \|_{\mathcal{X}} \leq \frac{c}{\sqrt[3]{k}}, \tag{2.12}$$

where c is a constant which does not depend on k and m.

Remark 8. Remark 5 applies in this case too.

The following theorem completes the study of the eigenvalues with real part tending to zero as the wave number increases.

THEOREM 2.6 (eigenvalues $\lambda_{k,m}$ with $k\,\pi \leq |\lambda_{k,m}| \leq \sqrt{2}k\,\pi$, second part). *For all $k \in \mathbb{N}$ sufficiently large the eigenvalues $\lambda_{k,m}$ of* (1.1) *with $[\sqrt[3]{k}] < |m| \leq k$ satisfy the following estimates:*

$$\begin{aligned} &\left|\lambda_{k,m} - \sqrt{\pi^2\, k^2 + k^2\, \zeta_{k,m}^2}\, i\right| \leq \frac{1}{\sqrt[5]{k}} \ \text{if } \mathcal{I}m\, \lambda_{k,m} > 0 \quad (k \geq m > [\sqrt[3]{k}]), \\ &\left|\lambda_{k,m} + \sqrt{\pi^2\, k^2 + k^2\, \zeta_{k,m}^2}\, i\right| \leq \frac{1}{\sqrt[5]{k}} \ \text{if } \mathcal{I}m\ \lambda_{k,m} < 0 \quad (-k \leq m < -[\sqrt[3]{k}]), \end{aligned} \tag{2.13}$$

where $\zeta_{k,m} \in \mathbb{R}_+$ is the positive root of the equation

$$\tan\ k\,\zeta\ = \frac{\pi^2}{k\,\zeta^3}, \tag{2.14}$$

which belongs to $\left(\frac{m}{k}\pi, \frac{2m+1}{2k}\pi\right)$.

Remark 9. When k remains bounded and m goes to infinity the roots $\zeta_{k,m}$ of the equation (2.14) behave like $\frac{m\pi}{k}$. This corresponds to the asymptotic behavior of the eigenvalues $\lambda_{k,m}$ studied in Theorem 2.2. On the other hand, when m remains bounded and k goes to infinity, the zeros $\zeta_{k,m}$ of (2.14) behave like $\frac{(2m+1)\pi}{2k}$. This agrees with the behavior of the eigenvalues $\lambda_{k,m}$ studied in Theorem 2.4.

The eigenvalues $\lambda_{k,m}$ of Theorem 2.6 make the transition from one zone to another and still approach the imaginary axis at high frequencies.

The eigenfunctions corresponding to these eigenvalues have the same property as those of Theorems 2.3 and 2.5; i.e., the last two components vanish asymptotically.

THEOREM 2.7. *The eigenfunctions* φ_λ *corresponding to the eigenvalues of Theorem* 2.6 *satisfy*

$$\lim_{|\lambda|\to\infty} \frac{||\varphi_\lambda^3||_{H^1(\Gamma_0)}}{||\varphi_\lambda||_{\mathcal{X}}} = 0, \quad \lim_{|\lambda|\to\infty} \frac{||\varphi_\lambda^4||_{L^2(\Gamma_0)}}{||\varphi_\lambda||_{\mathcal{X}}} = 0, \tag{2.15}$$

where φ_λ^3 *and* φ_λ^4 *are the third and the fourth components of* φ_λ.

Until now we have obtained eigenvalues of system (1.1) approaching the imaginary axis when their modulus tends to infinity. The following result exhibits a sequence of eigenvalues with uniformly bounded negative real parts.

THEOREM 2.8. *[*eigenvalues λ_k with $|\lambda_k| \le k\,\pi$*] The equation* (2.2) *has, for sufficiently large* k, *two eigenvalues* λ_k^* *and* λ_k^{**} *with* $\mathcal{I}m\,\lambda_k^* > 0$ *and*

$$\left| \lambda_k^* - \sqrt{k^2(\alpha_1)^2 - k^2\pi^2} \right| \le \frac{1}{k} \quad \textit{and} \quad \lambda_k^* = \bar{\lambda}_k^{**}, \tag{2.16}$$

where α_1 *is the root of*

$$z^2 - \pi^2 + kz^3 + z\sqrt{z^2 - \pi^2} = 0 \tag{2.17}$$

with the following asymptotic behavior:

$$\alpha_1 = \sqrt[3]{\frac{\pi^2}{k}} - \frac{1}{3}\sqrt[3]{\frac{\pi}{k^2}}\, i + o\left(\frac{1}{\sqrt[3]{k^2}}\right), \ \textit{as } k \to \infty. \tag{2.18}$$

Therefore, λ_k^* *satisfies*

$$\mathcal{R}e\,\lambda_k^* \longrightarrow -\frac{1}{3} \textit{ when } k \longrightarrow \infty. \tag{2.19}$$

Remark 10. In Theorem 2.8 we prove the existence of two eigenvalues λ_k^* and λ_k^{**} with modulus less than $k\pi$. These are, for k fixed, the eigenvalues with smallest modulus and are the only ones uniformly dissipated by the system at large frequencies.

The corresponding eigenfunctions λ_k^* can be written as

$$\varphi_{\lambda_k^*} = \begin{pmatrix} \dfrac{\cosh\left(\sqrt{(\lambda_k^*)^2 + k^2\pi^2}(y-1)\right)\cos k\pi x}{\sqrt{(\lambda_k^*)^2 + k^2\pi^2}\,\sinh\left(\sqrt{(\lambda_k^*)^2 + k^2\pi^2}\right)} \\ -\dfrac{\lambda_k^*\cosh\left(\sqrt{(\lambda_k^*)^2 + k^2\pi^2}(y-1)\right)\cos k\pi x}{\sqrt{(\lambda_k^*)^2 + k^2\pi^2}\,\sinh\left(\sqrt{(\lambda_k^*)^2 + k^2\pi^2}\right)} \\ -\dfrac{1}{\lambda_k^*}\cos k\pi x \\ \cos k\pi x \end{pmatrix},$$

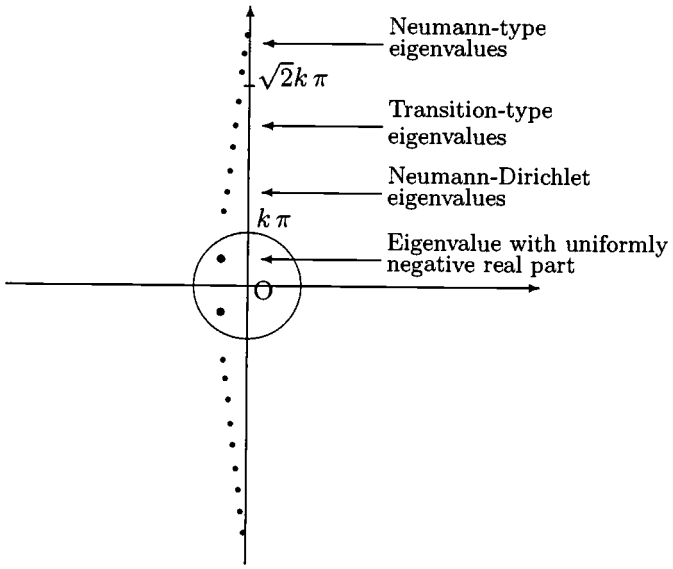

FIG. 2.1. *The sequence of eigenvalues for fixed* k.

and they have a different behavior.

THEOREM 2.9. (i) *The sequence of eigenfunctions* $\{\varphi_{\lambda_k^*}\}_k$ *converge weakly to zero in* $\mathcal{X}$ *when* k *tends to infinity.*

(ii) *The sequences* $\{\varphi^j_{\lambda_k^*}\}_k$ *do not converge strongly to zero for any* $j = 1, 2, 3, 4$ *in the corresponding norms.*

Remark 11. The eigenfunctions $\varphi_{\lambda_k^*}$ generate a subspace of the energy space of infinite dimension in which, in view of (2.19), the decay rate of the energy of the system is uniform. The energy of the solutions corresponding to the eigenfunctions of Theorem 2.9 is concentrated in the string. Indeed, the estimates of Theorem 2.9 allow us to prove that

$$\int_0^1 \int_\varepsilon^1 \left(||\varphi^1_{\lambda_k^*}||^2_{H^1(\Omega)} + ||\varphi^2_{\lambda_k^*}||^2_{L^2(\Omega)} \right) dx\, dy \leq Ce^{-2\sqrt[3]{k^2\pi^2}\varepsilon}.$$

This indicates that the energy of the acoustic wave decays exponentially fast from Γ_0 to the interior of the domain.

Figure 2.1 describes the behavior of the different families of eigenvalues for each k.

3. The conservative system. In this section we analyze the spectral properties of the conservative system corresponding to (1.1):

$$\left\{ \begin{array}{lll} \phi_{tt} - \Delta\phi = 0 & \text{in} & \Omega \times (0,\infty), \\ \frac{\partial\phi}{\partial\nu} = 0 & \text{on} & \Gamma_1 \times (0,\infty), \\ \frac{\partial\phi}{\partial y} = -W_t & \text{on} & \Gamma_0 \times (0,\infty), \\ W_{tt} - W_{xx} + \phi_t = 0 & \text{on} & \Gamma_0 \times (0,\infty), \\ W_x(0,t) = W_x(1,t) = 0 & \text{for} & t > 0. \end{array} \right. \tag{3.1}$$

In (3.1) the dissipative term W_t of the equation of displacement of the string has been dropped. The energy of this system is defined by (1.2) too, but in this case we have that $\frac{dE}{dt}(t) = 0$. This means that (3.1) is an undamped system.

The eigenvalues of (3.1) are characterized in the following theorem.

THEOREM 3.1. *System* (3.1) *has a two-parameter sequence of purely imaginary eigenvalues* $(\nu_{k,m})_{k\in\mathbb{N},\, m\in\mathbb{Z}^*}$ *given by*

$$\nu_{k,m} = \sqrt{z_{k,m}^2 + k^2\pi^2}\; i \quad \text{if } m > 0 \quad \text{and} \quad \nu_{k,m} = -\nu_{k,-m} \quad \text{if } m < 0\,, \tag{3.2}$$

where $(z_{k,m})_{m\in\mathbb{N}^*}$ *are the roots of the equation*

$$\tan z = \frac{z^2 + k^2\pi^2}{z^3}. \tag{3.3}$$

Moreover, there are another two eigenvalues of (3.1), ν_k^*, *and* ν_k^{**}, *with the modulus less than* $k\,\pi$, *given by*

$$\nu_k^* = \sqrt{k^2\pi^2 - (z_k^*)^2}\; i\,, \quad \nu_k^{**} = \bar{\nu}_k^*\,, \tag{3.4}$$

where z_k^* *is the unique positive root of the equation*

$$e^{2\,z} = \frac{z^3 - z^2 + k^2\pi^2}{z^3 + z^2 - k^2\pi^2}. \tag{3.5}$$

In the last case, $\nu_k^* = \nu_k^{**} = 0$ *when* $k = 0$.

Proof. In order to study the spectrum of (3.1) we look for solutions of this system in separated variables: $(\phi, W) = e^{\nu t}(\psi, V)\cos(n\pi x)$, where $\psi = \psi(y)$ and $V \in \mathbb{R}$. It follows that the eigenvalues ν satisfy the following transcendental equation:

$$e^{2\sqrt{\nu^2 + k^2\pi^2}} = -\frac{\nu^2 - \sqrt{\nu^2 + k^2\pi^2}(\nu^2 + k^2\pi^2)}{\nu^2 + \sqrt{\nu^2 + k^2\pi^2}(\nu^2 + k^2\pi^2)}. \tag{3.6}$$

Considering the change of variable $\nu = \sqrt{\zeta^2 - k^2\pi^2}$, equation (3.6) becomes

$$e^{2\zeta} = \frac{\zeta^3 - \zeta^2 + k^2\pi^2}{\zeta^3 + \zeta^2 - k^2\pi^2}. \tag{3.7}$$

Since the differential operator corresponding to (3.1) is conservative its eigenvalues will be all purely imaginary. Hence, we have to look only for those roots of (3.7) which are purely imaginary or real. It follows that the imaginary roots of (3.7) are the roots of the equation (3.3) and the real ones are roots of (3.5). □

We analyze now the eigenfunctions. By separation of variables, it is easy to see that the eigenfunctions have the following form:

$$\xi_\nu = \begin{pmatrix} \dfrac{-i}{\sqrt{z^2 + k^2\pi^2}}\cos\, z(y-1)\, \cos\, k\pi x \\ -\cos\, z(y-1)\, \cos\, k\pi x \\ -\dfrac{z}{z^2 + k^2\pi^2}\, \sin\, z\, \cos\, k\pi x \\ \dfrac{z\, i}{\sqrt{z^2 + k^2\pi^2}}\, \sin\, z\, \cos\, k\pi x \end{pmatrix}. \tag{3.8}$$

THEOREM 3.2. *The eigenfunctions* ξ_ν *defined by* (3.8) *corresponding to the eigenvalues* ν *given by* (3.3) *have the following property:*

$$\lim_{|\nu|\to\infty} \frac{||\xi_\nu^3||_{H^1(0,1)}}{||\xi_\nu||_{\mathcal{X}}} = 0, \quad \lim_{|\nu|\to\infty} \frac{||\xi_\nu^4||_{L^2(0,1)}}{||\xi_\nu||_{\mathcal{X}}} = 0,$$

where ξ_ν^j is the jth component of ξ_ν.

Proof. If ν is one of the eigenvalues of (3.1) with $|\nu| > k\,\pi$, it follows that $\zeta = \sqrt{\nu^2 + k^2\pi^2}$ is a purely imaginary number. Therefore $\zeta = z\,i$, where $z \in \mathbb{R}$ is a solution of the equation (3.3).

Taking into account that z satisfies (3.3), a simple calculation gives us that

$$||\xi_\nu^1||_{H^1}^2 + ||\xi_\nu^2||_{L^2}^2 = \frac{1}{2} + \frac{1}{4(z^2+k^2\pi^2)} + \frac{(1+2k^2\pi^2)\,\sin 2z}{8z(z^2+k^2\pi^2)}$$

$$= \frac{1}{2} + \frac{1}{4(z^2+k^2\pi^2)} + \frac{2z^3(z^2+k^2\pi^2)}{4(z^6+(z^2+k^2\pi^2)^2)},$$

$$||\xi_\nu^3||_{H^1}^2 = \frac{z^2(1+k^2\pi^2)\,\sin^2 z}{2(z^2+k^2\pi^2)^2} = \frac{z^2(1+k^2\pi^2)}{2(z^6+(z^2+k^2\pi^2)^2)},$$

$$||\xi_\nu^4||_{L^2}^2 = \frac{z^2\,\sin^2 z}{2(z^2+k^2\pi^2)} = \frac{z^2(z^2+k^2)}{2(z^6+(z^2+k^2\pi^2)^2)}.$$

We observe that if k remains bounded when $|\nu| \to \infty$ then, necessarily, $|z| \to \infty$. This remark allows us to conclude that

$$||\xi_\nu^1||_{H^1}^2 + ||\xi_\nu^2||_{L^2}^2 \longrightarrow \frac{1}{2} \text{ and } ||\xi_\nu^3||_{H^1}^2 + ||\xi_\nu^4||_{L^2}^2 \longrightarrow 0, \text{ when } \nu \longrightarrow \infty. \qquad \square$$

Remark 12. One can also see that ν_k^* does not have this property; i.e.,

$$\liminf_{|\nu_k^*|\to\infty} \frac{||\xi_{\nu_k^*}^3||_{H^1(0,1)}}{||\xi_{\nu_k^*}||_{\mathcal{X}}} \neq 0 \text{ and } \liminf_{|\nu|\to\infty} \frac{||\xi_{\nu_k^*}^4||_{L^2(0,1)}}{||\xi_{\nu_k^*}||_{\mathcal{X}}} \neq 0.$$

The proof of this fact is similar to that of Theorem 2.9.

4. The dissipative case. In this section we give the proofs of Theorems 2.1, 2.2, 2.3, 2.4, 2.5, 2.6, 2.7, 2.8, and 2.9 which characterize the asymptotic behavior of the eigenvalues and the eigenfunctions of (1.1).

We begin with the proof of Theorem 2.1.

Proof of Theorem 2.1. Suppose first that $k \neq 0$. It is easy to see that the differential operator corresponding to (2.1) has compact resolvent (see [11]). Therefore, the spectrum of (2.1) consists of a sequence of complex eigenvalues $(\lambda_{k,m})_{m\in\mathbb{N}} \cup (\bar{\lambda}_{k,m})_{m\in\mathbb{N}}$ with the property that $\lim_{m\to\infty} |\lambda_{k,m}| = \infty$ and $\lambda_{k,m} \neq 0$ for all $m \in \mathbb{Z}$.

If $k = 0$, the operator has the same properties but the first two eigenvalues $\lambda_{0,0}$ and $\bar{\lambda}_{0,0}$ are equal to zero.

Moreover, since all the elements of the spectrum are eigenvalues of the operator it follows that they are roots of equation (2.2). $\square$

With the change of variable $\sqrt{\left(\frac{\lambda}{k}\right)^2 + \pi^2} = z$ equation (2.2) is reduced to

$$e^{2k\,z} = -\frac{z^2 - \pi^2 - kz^3 - z\sqrt{z^2-\pi^2}}{z^2 - \pi^2 + kz^3 + z\sqrt{z^2-\pi^2}}. \tag{4.1}$$

We present now four technical lemmas which give us the information we need about the poles of the function in the right-hand side of (4.1). The proofs of these lemmas will be presented in an appendix at the end of this paper.

LEMMA 4.1. *If α is a root of the equation*

$$z^2 - \pi^2 + kz^3 + z\sqrt{z^2-\pi^2} = 0, \tag{4.2}$$

then, for k large enough, we have

$$\frac{\pi}{2\sqrt[3]{k}} <\mid \alpha \mid< \frac{2\pi}{\sqrt[3]{k}}. \tag{4.3}$$

LEMMA 4.2. *For k large enough, the equation (4.2) has three roots α_i, $i=1,2,3$, with the property that*

$$\left|\alpha_i - \sqrt[3]{\frac{\pi^2}{k}}\omega_i\right| \le \frac{10}{\sqrt[3]{k^2}}, \tag{4.4}$$

where ω_i, $i=1,2,3$, are the three cubic roots of unity.

LEMMA 4.3. *The root α_1 of (4.2) satisfies*

$$\alpha_1 = \sqrt[3]{\frac{\pi^2}{k}} - \frac{1}{3}\sqrt[3]{\frac{\pi}{k^2}}\,i + o\left(\frac{1}{\sqrt[3]{k^2}}\right) \quad \text{as } k\to\infty. \tag{4.5}$$

LEMMA 4.4. *For k large enough, the equation*

$$z^2 - \pi^2 - kz^3 - z\sqrt{z^2-\pi^2} = 0 \tag{4.6}$$

has three roots β_i, $i=1,2,3$, with the property that

$$\left|\beta_i - \sqrt[3]{\frac{\pi^2}{k}}\tilde{\omega}_i\right| \le \frac{10}{\sqrt[3]{k^2}}, \tag{4.7}$$

where $\tilde{\omega}_i = -\omega_i$, $i=1,2,3$.

We can pass now to prove Theorems 2.2, 2.3, 2.4, 2.5, 2.6, 2.7, 2.8, and 2.9. In section 4.1 we analyze the case of the eigenvalues with real parts tending to zero, as the frequency increases (Theorems 2.2, 2.3, 2.4, 2.5, 2.6, and 2.7). In section 4.2 we prove the existence of eigenvalues with uniformly negative real parts (Theorems 2.8 and 2.9).

4.1. Eigenvalues with real parts tending to zero.

Proof of Theorem 2.2. If we note $\sqrt{\lambda^2 + k^2\pi^2} = \mu$, we obtain that μ satisfies the following equation:

$$e^{2\mu} = -\frac{\mu^2 - k^2\pi^2 - \mu(\mu^2 + \sqrt{\mu^2 - k^2\pi^2})}{\mu^2 - k^2\pi^2 + \mu(\mu^2 + \sqrt{\mu^2 - k^2\pi^2})}. \tag{4.8}$$

We put the equation (4.8) in the form

$$e^{2\mu} - 1 = -\frac{2(\mu^2 - k^2\pi^2)}{\mu^2 - k^2\pi^2 + \mu(\mu^2 + \sqrt{\mu^2 - k^2\pi^2})}, \tag{4.9}$$

and we localize its roots applying Rouché's theorem.

In order to do this we consider the functions

$$f(z) = e^{2z} - 1 \text{ and } g(z) = -\frac{2(z^2 - k^2\pi^2)}{z^2 - k^2\pi^2 + z(z^2 + \sqrt{z^2 - k^2\pi^2})}.$$

We remark that the equation $f(z) = 0$ has the roots $(\alpha_m)_{m\in\mathbb{Z}}$ with $\alpha_m = m\pi\, i$.

For each $m \in \mathbb{Z} \setminus \{0\}$ we define the square γ_m^1 of center α_m and side $2\varepsilon_m$ and the rectangle γ_m^2 defined by the lines $\mathcal{R}e\, z = \pm\delta_m$ and $\mathcal{I}m\, z = m\pi \pm \frac{3\pi}{4}$. Moreover, we consider the square γ^0 of center 0 and side $2M_k$ (see Fig. 4.1).

The constants ε_m, δ_m, and M_k will be chosen in such a way that

$$| f(z) | > | g(z) | \quad \text{for all } z \in \gamma_m^1 \cup \gamma_m^2 \cup \gamma^0. \tag{4.10}$$

First of all we have that, for all $z \in \mathbb{C}$,

$$\begin{aligned} | f(z) |^2 = | e^{2z} - 1 |^2 &= (e^{2\mathcal{R}e\, z} - \cos 2\,\mathcal{I}m\, z)^2 + (\sin 2\,\mathcal{I}m\, z)^2 \\ &\geq \max\{| e^{2\mathcal{R}e\, z} - 1 |, | \sin 2\,\mathcal{I}m\, z |\}. \end{aligned} \tag{4.11}$$

In order to estimate g we consider the region G_1 of the complex plane defined by

$$G_1 = \{z \in \mathbb{C} : | z | > \max\{k\,\pi, 4\}\}, \tag{4.12}$$

where $g(z)$ is analytic in view of Lemma 4.2. We deduce that, for all $z \in G_1$,

$$\begin{aligned} | g(z) | &= \left| \frac{2(z^2 - k^2\pi^2)}{z^2 - k^2\pi^2 + z(z^2 + \sqrt{z^2 - k^2\pi^2})} \right| \leq \frac{2}{| z | \left| \frac{z^2 + \sqrt{z^2 - k^2\pi^2}}{z^2 - k^2\pi^2} \right| - 1} \\ &\leq \frac{2}{| z | \frac{|z|^2 - |\sqrt{z^2 - k^2\pi^2}|}{|z|^2 + k^2\pi^2} - 1} \leq \frac{2}{| z | \frac{|z|^2 - \sqrt{2}|z|}{|z|^2 + k^2\pi^2} - 1} \leq \frac{2}{\frac{|z|}{4} - 1} \leq \frac{8}{| z | - 4}. \end{aligned} \tag{4.13}$$

We are now in condition to determine the constants ε_m, δ_m, and M_k such that (4.10) is satisfied.

If $z \in \gamma_m^1 \cap G_1$, we obtain that $| f(z) | > \varepsilon_m > | g(z) |$ if $\frac{16}{2m\pi - 9} < \varepsilon_m < \frac{1}{2}$.

Applying Rouché's theorem, it turns out that there exists a unique root of the equation (4.8) in each square γ_m^1 if $m \geq k + 1$. We denote those roots by $\mu_{k,m}$.

If $z \in \gamma_m^2 \cap G_1$, we obtain that $| f(z) | > \frac{1}{2} > | g(z) |$ if $\delta_m > \frac{1}{2}$.

Since we did not impose any upper bound for δ_m we can apply again Rouché's theorem and we obtain that, for each $m \geq k+1$ in the regions $|\mathcal{I}m\, z - m\pi| \leq \frac{3\pi}{4}$, the equation (4.8) has the same number of roots as $f(z) = 0$ does. This implies that the only roots of (4.8) in G_1 are $\mu_{k,m}$ found above.

Finally, if we choose $M_k = k\,\pi + \frac{3\pi}{4}$ we obtain, like above, that if $z \in \gamma^0 \cap G_1$, then $| f(z) | > 1/2 > | g(z) |$.

Applying Rouché's theorem, we deduce that the number of roots of (4.8) in γ^0 is equal to $2k + 2$.

In order to obtain the roots of (2.2) we return to the variable λ.

First of all we remark that if λ solves (2.2) then $\bar{\lambda}$ is a solution too. Hence, it is sufficient to look for those λ with $\mathcal{I}m\, \lambda > 0$, the other eigenvalues being conjugates of these. On the other hand, when we pass from μ to λ we are interested in those values which have the property that $\mathcal{R}e\, \lambda < 0$, since the energy of the system decreases as t increases (see (1.2) and (1.3) above and [11] for a detailed discussion on this). Those

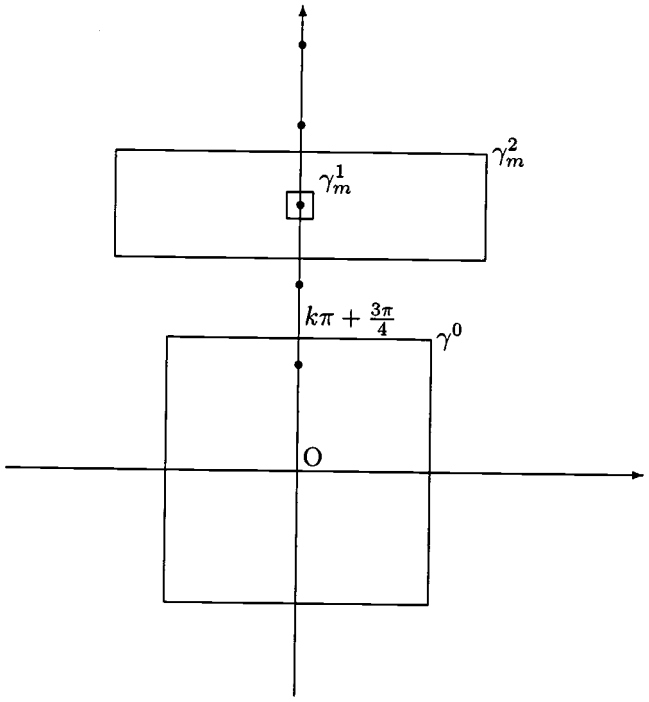

FIG. 4.1.

remarks indicate that we can establish a bijective correspondence between the zeros of the equation (4.8) and those of the equation (2.2).

Since the previous analysis gives us the roots μ of (4.8) with the property that $\mid \mu \mid > \max\{k\pi, 4\}$, we obtain all the roots $\lambda = \sqrt{\mu^2 - k^2\pi^2}$ of (2.2) with the property that $\mid \lambda \mid > \sqrt{2}k\pi$. For those eigenvalues λ with $\mathcal{I}m\,\lambda > 0$ we have

$$\mid \lambda - \sqrt{m^2+k^2}\,\pi\, i \mid = \mid \sqrt{\mu^2 - k^2\pi^2} - \sqrt{m^2+k^2}\,\pi\, i \mid$$

$$= \frac{\mid \mu - m\pi\, i \mid \mid \mu + m\pi\, i \mid}{\sqrt{\mid \mathcal{I}m\sqrt{\mu^2 - k^2\pi^2} + \sqrt{m^2+k^2}\pi \mid^2 + \mid \mathcal{R}e\sqrt{\mu^2 - k^2\pi^2} \mid^2}}$$

$$\leq \frac{\varepsilon_m \mid \mu + m\pi\, i \mid}{\mathcal{I}m\sqrt{\mu^2 - k^2\pi^2} + \sqrt{m^2+k^2}\pi} \leq \frac{\varepsilon_m(\varepsilon_m + 2m\pi)}{\sqrt{k^2+m^2}\pi} \leq \frac{3m}{\sqrt{k^2+m^2}}\varepsilon_m.$$

It turns out that, for $m > k+1$, the eigenvalues $\lambda_{k,m}$ with $\mathcal{I}m\,\lambda_{k,m} > 0$ satisfy (2.4). The corresponding result for the case $\lambda_{k,m}$ with $\mathcal{I}m\lambda_{k,m} < 0$ can be obtained in the same way. □

Remark 13. Theorem 2.2 tells us that, for each $k \in \mathbb{N}$ and for each eigenvalue $(\lambda_{k,m})_{m\in\mathbb{Z}^*}$ with $|m| \geq k+1$, the index m is given by the nearest value $\pm\sqrt{k^2+m^2}\,\pi\, i$. The other eigenvalues, which belong to the circle centered in 0 and of radius $\sqrt{2}\,k\,\pi$, are ordered in the increasing way with respect to the modulus: λ_k^*, λ_k^{**}, $\lambda_{k,\pm1}$, $\lambda_{k,\pm2}$,...,

$\lambda_{k,\pm k}$ (see Theorems 2.4, 2.6, and 2.8). Hence, for k fixed, λ_k^* and λ_k^{**} are the eigenvalues with the smallest modulus, while the modulus of $\lambda_{k,\pm k}$ approaches $\sqrt{2}k\pi$ when m increases.

We prove now Theorem 2.3.

Proof of Theorem 2.3. From (2.4) we deduce that $\sqrt{\lambda^2+k^2\pi^2}=\mu=m\pi\, i+\alpha(m)$ with $|\alpha(m)|\le\frac{1}{m}$.

The eigenfunction φ_λ can be decomposed as follows:

$$\varphi_\lambda=\begin{pmatrix} \frac{1}{\lambda}\cosh\sqrt{\lambda^2+k^2\pi^2}(y-1)\cos k\pi x \\ -\cosh\sqrt{\lambda^2+k^2\pi^2}(y-1)\cos k\pi x \\ -\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\sinh(\sqrt{\lambda^2+k^2\pi^2})\cos k\pi x \\ \frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\sinh(\sqrt{\lambda^2+k^2\pi^2})\cos k\pi x \end{pmatrix}$$

$$=\begin{pmatrix} (-1)^{m+1}\frac{i}{\lambda}\cosh\alpha(m)(y-1)\cos m\pi y\cos k\pi x \\ (-1)^m\, i\cosh\alpha(m)(y-1)\cos m\pi y\cos k\pi x \\ 0 \\ 0 \end{pmatrix}$$

$$+\begin{pmatrix} (-1)^m\frac{1}{\lambda}\sinh\alpha(m)(y-1)\sin m\pi y\cos k\pi x \\ (-1)^{m+1}\sinh\alpha(m)(y-1)\sin m\pi y\cos k\pi x \\ (-1)^{m+1}\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\sinh\alpha(m)\cos k\pi x \\ (-1)^m\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\sinh\alpha(m)\cos k\pi x \end{pmatrix}.$$

We denote by φ_1 and φ_2 the two vector-valued functions above.

We estimate first the norm of φ_2 in $\mathcal{X}$:

$$\|\varphi_2\|_{\mathcal{X}}^2=\int_0^1\int_0^1\left\{\left(\left|\frac{1}{\lambda}\cos k\pi x\right|^2+\left|\frac{k\pi}{\lambda}\sin k\pi x\right|^2\right)|\sinh\alpha(m)(y-1)\sin m\pi y|^2\right.$$

$$\left.+\left|\left(\frac{\alpha(m)}{\lambda}\cosh\alpha(m)(y-1)\sin m\pi y+\frac{m\pi}{\lambda}\sinh\alpha(m)(y-1)\cos m\pi y\right)\cos k\pi x\right|^2\right\}$$

$$+\int_0^1\int_0^1|\sinh\alpha(m)(y-1)\sin m\pi y\cos k\pi x|^2\,dx\,dy$$

$$+\int_0^1\left\{\left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\sinh\alpha(m)\cos k\pi x\right|^2+\left|\frac{k\pi\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\sinh\alpha(m)\sin k\pi x\right|^2\right\}dx$$

$$+\int_0^1 \left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\ \sinh\ \alpha(m)\ \cos\ k\pi x\right|^2\ dx\ \le \int_0^1 \left\{\left|\frac{1}{\lambda}\ \sinh\ \alpha(m)(y-1)\right|^2\right.$$

$$\left.+\left|\frac{\alpha(m)}{\lambda}\ \cosh\ \alpha(m)(y-1)\right|^2+\left(\frac{(k^2+m^2)\pi^2}{|\lambda|^2}+1\right)|\ \sinh\ \alpha(m)(y-1)|^2\right\}dy$$

$$+\left(\left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\right|^2+\left|\frac{k\pi\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\right|^2+\left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\right|^2\right)|\ \sinh\ \alpha(m)|^2$$

$$\le 4\frac{|\ \alpha(m)\ |^2}{|\lambda|^2}+4|\alpha(m)|^2+5\frac{|\ \alpha(m)\ |^2}{|\lambda|^2}+4\frac{(k^2+m^2)\pi^2\ |\ \alpha(m)\ |^2}{|\lambda|^2}$$

$$+4|\alpha(m)|^2\left|\frac{\lambda^2+k^2\pi^2}{\lambda^4}\right|^2\left|1+k^2\pi^2+\lambda^2\right|^2\le 33|\alpha(m)|^2\le\frac{c'}{m^2},$$

where we take into account that $|\sinh\ \alpha(m)|\le 2|\alpha(m)|$ and $|\cosh\ \alpha(m)|\le 2$.

In this way we obtain that

$$\|\varphi_2\|_{\mathcal{X}}\le\frac{c'}{m}. \tag{4.14}$$

We estimate now

$$\|\ \varphi_1-\psi_{k,m}\ \|_{\mathcal{X}}=\int_0^1\int_0^1\left\{\left|\frac{i}{\sqrt{m^2+k^2\pi}}+\frac{1}{\lambda}\cosh\alpha(m)(y-1)\right|^2|\cos m\pi y\cos k\pi x|^2\right.$$

$$+\left|\frac{i}{\sqrt{m^2+k^2\pi}}+\frac{1}{\lambda}\ \cosh\ \alpha(m)(y-1)\right|^2|k\pi\ \cos\ m\pi y\ \sin\ k\pi x|^2$$

$$+\left|\frac{i}{\sqrt{m^2+k^2\pi}}+\frac{1}{\lambda}\cosh\alpha(m)(y-1)\right|^2|m\pi\ \sin m\pi y\cos k\pi x|^2$$

$$\left.+\left(\left|\frac{\alpha(m)}{\lambda}\sinh\alpha(m)(y-1)\right|^2+|1-\cosh\alpha(m)(y-1)|^2\right)|\cos m\pi y\cos k\pi x|^2\right\}dxdy$$

$$\le\int_0^1\left\{\left|\frac{i}{\sqrt{m^2+k^2\pi}}+\frac{1}{\lambda}\ \cosh\ \alpha(m)(y-1)\right|^2\right.$$

$$+\left|\frac{i(k^2+m^2)\pi^2}{\sqrt{m^2+k^2}\pi}+\frac{(k^2+m^2)\pi^2}{\lambda}\cosh\,\alpha(m)(y-1)\right|^2$$

$$+\left|\frac{\alpha(m)}{\lambda}\sinh\,\alpha(m)(y-1)\right|^2+|1-\cosh\,\alpha(m)(y-1)|^2\Bigg\}\,dy$$

$$\leq\left|\frac{i}{\sqrt{m^2+k^2}\pi}+\frac{1}{\lambda}\right|^2+\int_0^1\left|\frac{1}{\lambda}(1-\cosh\,\alpha(m)(y-1))\right|^2\,dy$$

$$+(k^2+m^2)\pi^2\left|\frac{i}{\sqrt{m^2+k^2}\pi}+\frac{1}{\lambda}\right|^2+(m^2+k^2)\pi^2\int_0^1\left|\frac{1}{\lambda}(1-\cosh\,\alpha(m)(y-1))\right|^2\,dy$$

$$+\int_0^1\left|\frac{\alpha(m)}{\lambda}\sinh\,\alpha(m)(y-1)\right|^2\,dy+\int_0^1|1-\cosh\,\alpha(m)(y-1)|^2\,dy$$

$$\leq\frac{c''}{m^2}+4|\alpha(m)|^2+2\frac{c''}{m^2}+8|\alpha(m)|^2+4|\alpha(m)|^2+4|\alpha(m)|^2\leq\frac{c'''}{m^2},$$

where we take into account that $|1-\cosh\,\alpha(m)|\leq 2\mid\alpha(m)\mid$.

We obtain that

$$\|\varphi_1-\psi_{k,m}\|_{\mathcal{X}}\leq\frac{c'''}{m}. \tag{4.15}$$

From estimates (4.14) and (4.15) we deduce that (2.8) holds. □

Next we prove Theorem 2.4 which gives estimations for the eigenvalues $\lambda_{k,\pm 1}$, $\lambda_{k,\pm 2},\ldots,\lambda_{k,\pm q}$ for $q=q(k)\leq[\sqrt[3]{k}]$. By $[\,\cdot\,]$ we denote the integer part function.

Proof of Theorem 2.4. If we consider the change of variable $\lambda=\sqrt{k^2z^2-k^2\pi^2}$ the equation (2.2) is transformed in

$$e^{2k\,z}=-\frac{z^2-\pi^2-kz^3-z\sqrt{z^2-\pi^2}}{z^2-\pi^2+kz^3+z\sqrt{z^2-\pi^2}}. \tag{4.16}$$

Let $k\in\mathbb{N}$ be sufficiently large so that Lemma 4.1 holds. We define the functions

$$f(z)=e^{2kz}+1,\quad g(z)=\frac{2(kz^3+z\sqrt{z^2-\pi^2})}{z^2-\pi^2+kz^3+z\sqrt{z^2-\pi^2}}.$$

For each integer m with $0\leq|m|\leq[\sqrt[3]{k}]$ let $\gamma^1_{k,m}$ be the square of center $\frac{2m-1}{2k}\pi\,i$ and sides $\frac{3\pi}{2k\sqrt[3]{k}}$. For all $z\in\gamma^1_{k,m}$, we have

$$\mid f(z)\mid=\mid e^{2kz}+1\mid\geq\max\{\mid e^{2k\,\mathcal{R}e\,z}-1\mid,\mid\sin\,2k\,\mathcal{I}m\,z\mid\},$$

and since $|e^x-1|>\frac{|x|}{2}$ and $|\sin x|>\frac{|x|}{2}$ for small x, we deduce that

$$|f(z)|\geq \frac{3\pi}{4\sqrt[3]{k}} \quad \forall z\in\gamma_{k,m}. \tag{4.17}$$

We now estimate g in the region $G^2=\left\{z\in\mathbb{C}:|z|\leq \frac{\pi}{\sqrt[3]{k^2}}\right\}$.

Lemma 4.1 implies that g is analytic in G^2.

For all $z\in G^2$ we have $|z|\sqrt[3]{k}\leq\pi$. Therefore we obtain that

$$\lim_{k\to\infty} kz^2=\lim_{k\to\infty} z^2=\lim_{k\to\infty} kz^3=0.$$

Hence, for all $z\in G^2$,

$$\lim_{k\to\infty}\left|\frac{kz^2+\sqrt{z^2-\pi^2}}{z^2-\pi^2+kz^3+z\sqrt{z^2-\pi^2}}\right|=\frac{1}{\pi},$$

which implies that, for k sufficiently large,

$$\left|\frac{kz^2-\sqrt{z^2-\pi^2}}{z^2-\pi^2+kz^3-z\sqrt{z^2-\pi^2}}\right|\leq 1 \quad \forall z\in G^2.$$

This result allows us to estimate the function g in G^2:

$$|g(z)|=2\,|z|\left|\frac{kz^2+\sqrt{z^2-\pi^2}}{z^2-\pi^2+kz^3+z\sqrt{z^2-\pi^2}}\right|\leq 2|z|\leq\frac{2\pi}{\sqrt[3]{k^2}}.$$

Finally, we obtain that $|f(z)|>|g(z)|$ for all $z\in\gamma^1_{k,m}$ if k is sufficiently large and $\gamma^1_{k,m}\subset G^2$. Remark that $\gamma^1_{k,m}\subset G^2$ if $|m|\leq[\sqrt[3]{k}]$.

Applying Rouché's theorem we deduce that the equation (4.16) has a root $z_{k,m}$ in each square $\gamma^1_{k,m}$ if $|m|\leq[\sqrt[3]{k}]$. This root satisfies

$$\left|z_{k,m+1}-\frac{1}{2k}(2m+1)\pi\,i\right|\leq\frac{3\sqrt{2}\pi}{4k\sqrt[3]{k}}\leq\frac{2\pi}{k\sqrt[3]{k}} \quad \text{if } m\geq 0,$$

$$\left|z_{k,m}+\frac{1}{2k}(2m+1)\pi\,i\right|\leq\frac{3\sqrt{2}\pi}{4k\sqrt[3]{k}}\leq\frac{2\pi}{k\sqrt[3]{k}} \quad \text{if } m<0.$$

We deduce that the eigenvalues $\lambda_{k,m}=\sqrt{k^2z^2_{k,m}-k^2\pi^2}$ with $0<|m|\leq[\sqrt[3]{k}]$ satisfy (2.9). □

Proof of Theorem 2.5. Estimates (2.9) imply that

$$\sqrt{\lambda^2+k^2\pi^2}=\mu=\frac{2m+1}{2}\pi\,i+\alpha(k) \text{ with } |\alpha(k)|\leq\frac{2\pi}{\sqrt[3]{k}}.$$

We write the eigenfunction φ_λ in the following form:

$$\varphi_\lambda = \begin{pmatrix} \frac{1}{\lambda}\cosh\,(\sqrt{\lambda^2+k^2\pi^2}(y-1))\,\cos\,k\pi x \\ -\cosh\,(\sqrt{\lambda^2+k^2\pi^2}(y-1))\,\cos\,k\pi x \\ -\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\,\sinh\,(\sqrt{\lambda^2+k^2\pi^2})\,\cos\,k\pi x \\ \frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\,\sinh\,(\sqrt{\lambda^2+k^2\pi^2})\,\cos\,k\pi x \end{pmatrix}$$

$$= \begin{pmatrix} (-1)^m\frac{1}{\lambda}\cosh\,\alpha(k)(y-1)\,\sin\,\frac{2m+1}{2}\pi y\,\cos\,k\pi x \\ (-1)^{m+1}\cosh\,\alpha(k)(y-1)\,\sin\,\frac{2m+1}{2}\pi y\,\cos\,k\pi x \\ 0 \\ 0 \end{pmatrix}$$

$$+ \begin{pmatrix} (-1)^{m+1}\frac{i}{\lambda}\sinh\,\alpha(k)(y-1)\,\cos\,\frac{2m+1}{2}\pi y\,\cos\,k\pi x \\ (-1)^m i\,\sinh\,\alpha(k)(y-1)\,\cos\,\frac{2m+1}{2}\pi y\,\cos\,k\pi x \\ (-1)^{m+1}i\,\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\,\cosh\,\alpha(k)\,\cos\,k\pi x \\ (-1)^m i\,\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\,\cosh\,\alpha(k)\,\cos\,k\pi x \end{pmatrix}.$$

Let φ_1 and φ_2 be the vector-valued functions appearing in the decomposition of φ_λ above.

We evaluate first the norm of φ_2 in $\mathcal{X}$:

$$\|\varphi_2\|^2_{\mathcal{X}} = \int_0^1\int_0^1 \left|\frac{1}{\lambda}\,\cos\,k\pi x\right|^2\,\sinh\,\alpha(k)(y-1)\,\cos\,\frac{2m+1}{2}\pi y$$

$$+\int_0^1\int_0^1\left\{\left|\frac{k\pi}{\lambda}\,\sinh\,\alpha(k)(y-1)\,\cos\,\frac{2m+1}{2}\pi y\,\sin\,k\pi x\right|^2\right.$$

$$+\left|\frac{\alpha(k)}{\lambda}\,\cosh\,\alpha(k)(y-1)\,\cos\,\frac{2m+1}{2}\pi y\,\cos\,k\pi x + \frac{(2m+1)\pi}{2\lambda}\,\sinh\,\alpha(k)(y-1)\right.$$

$$\left.\left.\times\,\sin\,\frac{2m+1}{2}\pi y\,\cos\,k\pi x\right|^2\right\} + \int_0^1\int_0^1\left|\,\sinh\,\alpha(k)(y-1)\,\cos\,\frac{2m+1}{2}\pi y\,\cos\,k\pi x\right|^2$$

$$+\int_0^1\left\{\left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\cosh\alpha(k)\cos k\pi x\right|^2 + \left|\frac{k\pi\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\cosh\alpha(k)\sin k\pi x\right|^2\right\}$$

$$+\int_0^1 \left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\cosh\,\alpha(k)\,\cos\,k\pi x\right|^2 \leq \int_0^1 \left\{\left|\frac{1}{\lambda}\,\sinh\,\alpha(k)(y-1)\right|^2\right.$$

$$\left.+\left|\frac{\alpha(k)}{\lambda}\cosh\alpha(k)(y-1)\right|^2+\left(\left(k^2+\left(\frac{2m+1}{2}\right)^2\right)\frac{\pi^2}{|\lambda|^2}+1\right)|\sinh\alpha(k)(y-1)|^2\right\}$$

$$+\left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\cosh\alpha(k)\right|^2+\left|\frac{k\pi\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\cosh\alpha(k)\right|^2+\left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\cosh\alpha(k)\right|^2$$

$$\leq 4\frac{|\alpha(k)|^2}{|\lambda|^2}+5\frac{|\alpha(k)|^2}{|\lambda|^2}+\left(k^2+\left(\frac{2m+1}{2}\right)^2\right)\frac{|\alpha(k)|^2\pi^2}{|\lambda|^2}+4|\alpha(k)|^2$$

$$5(k^2\pi^2+1)\left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda^2}\right|^2+5\left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\right|^2\leq 14|\alpha(k)|^2+60|\alpha(k)|^2\leq\frac{c'}{\sqrt[3]{k}},$$

where we take into account that, for k large enough,

$$\left|\frac{\sqrt{\lambda^2+k^2\pi^2}}{\lambda}\right|\leq 2|\alpha(k)|,\ |\sinh\,\alpha(k)|\leq 2|\alpha(k)|\text{ and }|\cosh\,\alpha(k)|\leq 5.$$

We obtain that

$$\|\varphi_2\|_{\mathcal{X}}\leq\frac{c'}{\sqrt[3]{k}}. \tag{4.18}$$

We compute now

$$\|\,\varphi_1-\tilde{\psi}_{k,m}\,\|^2_{\mathcal{X}}$$

$$=\int_0^1\int_0^1\left|\frac{i}{\sqrt{\left(\frac{2m+1}{2}\right)^2+k^2\pi}}+\frac{1}{\lambda}\,\cosh\,\alpha(k)(y-1)\right|^2\left|\,\sin\,\frac{2m+1}{2}\pi y\,\cos\,k\pi x\right|^2$$

$$+\int_0^1\int_0^1\left\{\left|\frac{i}{\sqrt{\left(\frac{2m+1}{2}\right)^2+k^2\pi}}+\frac{1}{\lambda}\,\cosh\,\alpha(k)(y-1)\right|^2\left|k\pi\,\sin\,\frac{2m+1}{2}\pi y\,\sin\,k\pi x\right|^2\right.$$

$$\left.+\left|\frac{\alpha(k)}{\lambda}\,\sinh\,\alpha(k)(y-1)\,\sin\,\frac{2m+1}{2}\pi y\,\cos\,k\pi x\right|^2\right.$$

$$+\left|\left(\frac{i}{\sqrt{\left(\frac{2m+1}{2}\right)^2+k^2\pi}}+\frac{1}{\lambda}\cosh\alpha(k)(y-1)\right)\frac{2m+1}{2}\pi\,\cos\frac{2m+1}{2}\pi y\cos k\pi x\right|^2$$

$$+\left|(1-\ \cosh\ \alpha(k)(y-1))\,\sin\,\frac{2m+1}{2}\pi y\,\cos\,k\pi x\right|^2\Bigg\}\,dxdy$$

$$\leq\int_0^1\left(\left(\frac{(2m+1)\pi}{2}\right)^2+k^2\pi^2+1\right)\left|\frac{i}{\sqrt{\left(\frac{2m+1}{2}\right)^2+k^2\pi}}+\frac{1}{\lambda}\,\cosh\,\alpha(k)(y-1)\right|^2$$

$$+\int_0^1\left|\frac{\alpha(m)}{\lambda}\,\sinh\,\alpha(m)(y-1)\right|^2+|1-\ \cosh\,\alpha(k)(y-1)|^2$$

$$\leq\left(\left(\frac{(2m+1)\pi}{2}\right)^2+k^2\pi^2+1\right)\left|\frac{i}{\sqrt{\left(\frac{(2m+1)}{2}\right)^2+k^2\pi}}+\frac{1}{\lambda}\right|^2$$

$$+\left(\left(\frac{2m+1}{2}\right)^2\pi^2+k^2\pi^2+1\right)\int_0^1\left|\frac{1}{\lambda}(1-\ \cosh\,\alpha(k)(y-1))\right|^2$$

$$+\int_0^1\left|\frac{\alpha(k)}{\lambda}\,\sinh\,\alpha(k)(y-1)\right|^2+\int_0^1|1-\ \cosh\,\alpha(m)(y-1)|^2$$

$$\leq\frac{2\pi}{\sqrt[3]{k}}+4|\alpha(k)|^2+2\frac{2\pi}{\sqrt[3]{k}}+8|\alpha(m)|^2+4|\alpha(k)|^2+4|\alpha(k)|^2\leq\frac{c''}{\sqrt[3]{k}}$$

since, for k large enough ($k>(2\pi)^3$), $|1-\ \cosh\,\alpha(k)|\leq 2\mid\alpha(k)\mid$.

We obtain that

$$\|\,\varphi_1-\tilde{\psi}_{k,m}\,\|_{\mathcal{X}}\leq\frac{c'''}{\sqrt[3]{k}}. \tag{4.19}$$

The estimates (4.18) and (4.19) imply that (2.12) holds. □

We pass now to the analysis of the roots of (2.2) $\lambda_{k,\pm(q+1)}$, $\lambda_{k,\pm(q+2)},\ldots,\lambda_{k,\pm k}$, with $q=[\sqrt[3]{k}]$, which make the transition from the eigenvalues studied in Theorem 2.2 to those studied in Theorem 2.4. First we prove the following lemma.

LEMMA 4.5. *For each $k\in\mathbb{N}^*$, the equation*

$$e^{2k\,z}=\frac{\pi^2+kz^3}{-\pi^2+kz^3} \tag{4.20}$$

has a sequence of roots $\pm\zeta_{k,m}\, i$, $m \in \mathbb{N}^*$, *where* $\zeta_{k,m} \in \mathbb{R}_+$ *is the positive root of the equation* (2.14) *which belongs to* $\left(\frac{m}{k}\pi, \frac{2m+1}{2k}\pi\right)$.

Proof. We look for roots of (4.20) of the form $z = \zeta\, i$. Hence, ζ is a root of the equation

$$e^{2k\,\zeta\, i} = \frac{\pi^2 - k\,\zeta^3\, i}{-\pi^2 - k\,\zeta^3\, i}. \tag{4.21}$$

Consequently, z is a root of (4.20) if ζ satisfies

$$-\pi^2 \cos k\zeta + k\zeta^3 \sin k\zeta = 0, \tag{4.22}$$

which is equivalent to (2.14).

It is easy to see that (4.22) has a zero in each interval $\left(\frac{m}{k}\pi, \frac{2m+1}{2k}\pi\right)$ that we denote by $\zeta_{k,m}$ (see [15]). □

We pass now to study the eigenvalues $\lambda_{k,\pm([\sqrt[3]{k}]+1)}$, $\lambda_{k,\pm([\sqrt[3]{k}]+2)}, \dots, \lambda_{k,\pm k}$.

Proof of Theorem 2.6. We saw that the change of variables $\lambda = \sqrt{k^2z^2 - k^2\pi^2}$ transforms (2.2) in (4.16).

We define the region of the complex plane

$$G^3 = \left\{ z \in \mathbb{C}\colon \frac{\pi}{2\sqrt[3]{k^2}} \le |z| \le 2\pi, \quad |\mathcal{R}e\, z| \le \frac{1}{k}, \quad \mathcal{I}m\, z > 0 \right\}$$

and we prove that (4.16) has a set of zeros $z_{k,m}$ in G^3 satisfying the estimate

$$|z_{k,m} - \zeta_{k,m}\, i| \le \frac{1}{k\sqrt[5]{k}}, \quad m \in \{[\sqrt[3]{k}] + 1, \dots, k\}, \tag{4.23}$$

where $\zeta_{k,m}$ are the zeros of (2.14).

We remark that if $m \in \{[\sqrt[3]{k}] + 1, \dots, k\}$, then $\zeta_{k,m}$ belongs to G^3.

We write (4.16) in the following form:

$$e^{2k\,z} - \frac{\pi^2 + kz^3}{-\pi^2 + kz^3} = -\frac{2z(kz^4 + \pi^2\sqrt{z^2 - \pi^2})}{(-\pi^2 + kz^3)(z^2 - \pi^2 + kz^3 + z\sqrt{z^2 - \pi^2})},$$

and applying Rouché's theorem we prove that the zeros of (4.16) approach those of (4.20).

We consider first the function

$$g(z) = -\frac{2z(kz^4 + \pi^2\sqrt{z^2 - \pi^2})}{(-\pi^2 + kz^3)(z^2 - \pi^2 + kz^3 + z\sqrt{z^2 - \pi^2})},$$

and we obtain an upper bound for g in G^3.

To do this we evaluate first the denominator of g:

$$|2z(kz^4 + \pi^2\sqrt{z^2 - \pi^2})| \le 2k|z|^5 + 2\pi^2|z|^2 + 4\pi^3|z|.$$

We obtain that

$$|2z(kz^4 + \pi^2\sqrt{z^2 - \pi^2})| \le \begin{cases} 6k|z|^5 & \text{if } \dfrac{\pi}{2\sqrt[3]{k^2}} \le |z| \le \dfrac{\pi}{\sqrt[4]{k}}, \\ 6\pi^3|z| & \text{if } \dfrac{\pi}{\sqrt[4]{k}} \le |z| \le 2\pi. \end{cases}$$

We estimate now the numerator of g:

$$|(-\pi^2+kz^3)(z^2-\pi^2+kz^3+z\sqrt{z^2-\pi^2})|$$

$$\geq |-\pi^2+kz^3|\,(|-\pi^2+kz^3|-|z|(|z|+\sqrt{|z|^2+\pi^2}))$$

$$\geq |-\pi^2+kz^3|^2\ -\ 5\pi|z|\,|-\pi^2+kz^3|.$$

If $\frac{\pi}{2\sqrt[3]{k^2}}\leq|z|\leq\frac{\pi}{\sqrt[4]{k}}$ and $|\mathcal{R}e\,z|\leq\frac{1}{k}$ we have that, for k sufficiently large,

$$|-\pi^2+kz^3|\geq\mathcal{R}e\,(-\pi^2+kz^3)\geq\frac{\pi}{2}.$$

If $\frac{\pi}{\sqrt[4]{k}}\leq|z|\leq 2\pi$ we have that

$$|-\pi^2+kz^3|\,(|-\pi^2+kz^3|-|z|(|z|+\sqrt{|z|^2+\pi^2}))\geq\sqrt{k}k|z|^4\left(\sqrt{k}|z|^2-\frac{2\pi}{\sqrt{k}}\right).$$

From the last two inequalities, we deduce that, for k sufficiently large, the following estimate holds:

$$|(-\pi^2+kz^3)(z^2-\pi^2+kz^3+z\sqrt{z^2-\pi^2})|\geq\begin{cases}c_1 & \text{if } \frac{\pi}{2\sqrt[3]{k^2}}\leq|z|\leq\frac{\pi}{\sqrt[4]{k}},\\ c_2\sqrt{k}\,k\,|z|^4 & \text{if } \frac{\pi}{\sqrt[4]{k}}\leq|z|\leq 2\pi,\end{cases}$$

where c_1 and c_2 are two positive constants which do not depend on k.

Going back to the function g we obtain that, for k sufficiently large,

$$|g(z)|\leq\frac{c}{\sqrt[4]{k}}\quad\text{for all } z \text{ in } G^3,$$

where c is a positive constant which does not depend on k.

We study now the function

$$f(z)=e^{2k\,z}-\frac{\pi^2+kz^3}{-\pi^2+kz^3}.$$

For each $m\in\mathbb{N}^*$ we consider the circle $\gamma^2_{k,m}$ of center $\zeta_{k,m}\,i$ and radius $r_{k,m}=\frac{1}{k\sqrt[5]{k}}$ and the circle $\widehat{\gamma}^2_{k,m}$ with the same center but with radius $R_{k,m}=\frac{1}{k}$.

In G^3 the function f is analytic. Applying Taylor's formula at $\zeta_{k,m}\,i$ we obtain that

$$\begin{aligned}f(z)&=f(\zeta_{k,m}\,i)+(z-\zeta_{k,m}\,i)f'(\zeta_{k,m}\,i)\\&+\frac{(z-\zeta_{k,m}\,i)^2}{2\pi\,i}\int_{\widehat{\gamma}^2_{k,m}}\frac{f(\zeta)\,d\zeta}{(\zeta-\zeta_{k,m}\,i)^2(\zeta-z)}.\end{aligned}\tag{4.24}$$

We look for an upper bound for the error term on the circumference $\gamma^2_{k,m}$. We have

$$\left|\frac{(z-\zeta_{k,m}\,i)^2}{2\pi\,i}\int_{\widehat{\gamma}^2_{k,m}}\frac{f(\zeta)\,d\zeta}{(\zeta-\zeta_{k,m}\,i)^2(\zeta-z)}\right|\leq\frac{r^2_{k,m}}{2\pi}\frac{2\pi R_{k,m}M}{R^2_{k,m}(R_{k,m}-r_{k,m})}=\frac{M}{\sqrt[5]{k}(\sqrt[5]{k}-1)},$$

where M is an upper bound for f on the circumference $\widehat{\gamma}^2_{k,m}$.

On the other hand

$$|f(z)| = \left| e^{2k\,z} - \frac{\pi^2 + kz^3}{-\pi^2 + kz^3} \right| \leq |e^{2k\,z}| + \left| \frac{\pi^2 + kz^3}{-\pi^2 + kz^3} \right| \leq e^{2k\,|\mathcal{R}e\,z|} + 1 + \frac{2\pi^2}{|\pi^2 - k\,z^3|}.$$

Since $|\mathcal{R}e\,z| < \frac{1}{k}$ in G^3, we obtain that $|\pi^2 - k\,z^3| > 1$ and $|f(z)| < M = e^2 + 1 + 2\pi^2$. Therefore the error term in Taylor's formula on $\gamma^2_{k,m}$ satisfies

$$\left| \frac{(z - \zeta_{k,m}\,i)^2}{2\pi\,i} \int_{\widehat{\gamma}^2_{k,m}} \frac{f(\zeta)\,d\zeta}{(\zeta - \zeta_{k,m}\,i)^2(\zeta - z)} \right| \leq \frac{M}{\sqrt[5]{k}(\sqrt[5]{k} - 1)}.$$

On the other hand,

$$|(z - \zeta_{k,m}\,i)f'(\zeta_{k,m}\,i)| = r_{k,m} \left| 2k \frac{\pi^2 - k\zeta^3_{k,m}\,i}{-\pi^2 - k\,\zeta^3_{k,m}\,i} - \frac{6\pi^2 k\zeta^2_{k,m}}{(-\pi^2 - k\,\zeta^3_{k,m}\,i)^2} \right| \geq 2kr_{k,m}.$$

Going back to Taylor's formula (4.24), we deduce that if z belongs to the circumference $\gamma^2_{k,m}$, then

$$|f(z)| \geq |(z - \zeta_{k,m}\,i)f'(\zeta_{k,m}\,i)| - \left| \frac{(z - \zeta_{k,m}\,i)^2}{2\pi\,i} \int_{\widehat{\gamma}^2_{k,m}} \frac{f(\zeta)\,d\zeta}{(\zeta - \zeta_{k,m}\,i)^2(\zeta - z)} \right|$$

$$\geq 2kr_{k,m} - \frac{20}{\sqrt[5]{k}(\sqrt[5]{k} - 1)} \geq \frac{C}{\sqrt[5]{k}}.$$

Finally, we obtain that $|f(z)| > |g(z)|$ for all z in $\gamma^2_{k,m}$.

Applying Rouché's theorem we deduce that the equation (4.16) has a unique zero $z_{k,m}$ which satisfies (4.23) in each circle $\gamma^2_{k,m}$.

Taking into account that $\lambda = \sqrt{k^2\pi^2 + k^2 z^2}$ we deduce immediately the desired result. □

Proof of Theorem 2.7. The eigenvalues $\lambda_{k,m}$ studied in Theorem 2.6 approach $\sqrt{\pi^2\,k^2 + k^2\,\zeta^2_{k,m}}\,i$, where $\zeta_{k,m}$ are the roots of the equation

$$\tan k\,\zeta = \frac{\pi^2}{k\,\zeta^3}. \tag{4.25}$$

By a similar method one can prove that $\lambda_{k,m}$ satisfy the estimates

$$\begin{aligned} &\left| \lambda_{k,m} - \sqrt{\pi^2\,k^2 + k^2\,\varrho^2_{k,m}}\,i \right| \leq \frac{1}{\sqrt[5]{k}} \text{ if } \mathcal{I}m\,\lambda_{k,m} > 0 \quad (k \geq m > [\sqrt[3]{k}]), \\ &\left| \lambda_{k,m} + \sqrt{\pi^2\,k^2 + k^2\,\varrho^2_{k,m}}\,i \right| \leq \frac{1}{\sqrt[5]{k}} \text{ if } \mathcal{I}m\,\lambda_{k,m} < 0 \quad (-k \leq m < -[\sqrt[3]{k}]), \end{aligned} \tag{4.26}$$

where $\varrho_{k,m}$ is the root of the equation

$$\tan k\,\varrho = \frac{\pi^2 + \varrho^2}{k\varrho^3}, \tag{4.27}$$

which belongs to the interval $\left(\frac{m}{k}\pi, \frac{2m+1}{2k}\pi\right)$.

Taking into account the estimates of Theorem 3.1 for the eigenvalues $\nu_{k,m}$ of the conservative problem, we deduce that, for the eigenvalues $\lambda_{k,m}$ studied in Theorem 2.6, we have:

$$|\lambda_{k,m} - \nu_{k,m}| \leq \frac{1}{\sqrt[5]{k}} \text{ for } [\sqrt[3]{k}] < |m| \leq k. \tag{4.28}$$

Since the eigenfunctions $\varphi_{\lambda_{k,m}}$ and $\xi_{\nu_{k,m}}$ have the same form, we deduce that

$$||\varphi_{\lambda_{k,m}} - \xi_{\nu_{k,m}}||_{\mathcal{X}} \leq \frac{1}{\sqrt[5]{k}}.$$

The properties of the eigenfunctions $\varphi_{\lambda_{k,m}}$ are obtained from the corresponding properties of $\xi_{\nu_{k,m}}$ (see Theorem 3.2). □

4.2. Eigenvalues with uniform negative real parts. The eigenvalues obtained in Theorems 2.2, 2.4, and 2.6 have in common the fact that their real parts tend to zero when the modulus increases. On the other hand, the last two components of the corresponding eigenfunctions vanish asymptotically.

Next we prove that there exists a sequence of eigenvalues $(\lambda_k^*)_k$ of modulus less than $k\pi$ with completely different properties.

Proof of Theorem 2.8. We consider again equation (4.16) and we look for the roots with real part going to infinity.

In the circle δ_1 of center $\sqrt[3]{\frac{\pi^2}{k}}$ and radius $\frac{10}{\sqrt[3]{k^2}}$ the function $h(z) = z^2 - \pi^2 - kz^3 - z\sqrt{z^2-\pi^2}$ does not vanish (the three roots of this function are $\sqrt[3]{\frac{\pi^2}{k}}\tilde{\omega}_i$, where $\tilde{\omega}_i$ are the cubic roots of -1 as we saw in Lemma 4.3).

We write the equation (4.16) in the form

$$e^{-2k\,z} = -\frac{z^2 - \pi^2 + kz^3 + z\sqrt{z^2-\pi^2}}{z^2 - \pi^2 - kz^3 - z\sqrt{z^2-\pi^2}}. \tag{4.29}$$

If z belongs to the circle δ_1 we have that $\mathcal{R}e\, z > \frac{\pi}{2\sqrt[3]{k}}$ and hence

$$\left|e^{-2kz}\right| = e^{-2k\mathcal{R}e\, z} \leq e^{-2k\frac{\pi}{2\sqrt[3]{k}}} = e^{-\pi\sqrt[3]{k^2}}.$$

We consider now the circle $\mathcal{C}'$ centered in α_1 and of radius $\frac{1}{k^2}$ (see Fig. 4.2).

Since the circle $\mathcal{C}'$ is contained in δ_1 we have that

$$\left|e^{-2kz}\right| =\leq e^{-2k\frac{\pi}{2\sqrt[3]{k}}} = e^{-\pi\sqrt[3]{k^2}} \quad \forall z \in \mathcal{C}'. \tag{4.30}$$

In $\mathcal{C}'$ the function $u(z) = z^2 - \pi^2 + kz^3 + z\sqrt{z^2-\pi^2}$ is analytic and it has a unique zero α_1.

Since

$$|u'(\alpha_1)| \geq |3k\alpha_1^2| - \left(\left|\sqrt{\alpha_1^2-\pi^2}\right| + |\alpha_1|\left|2 + \frac{\alpha_1}{\sqrt{\alpha_1^2-\pi^2}}\right|\right)$$

$$> 3k\frac{\pi^2}{4\sqrt[3]{k^2}} - \left(|\alpha_1| + \pi + |\alpha_1|\left|2 + \frac{\alpha_1}{\sqrt{\alpha_1^2-\pi^2}}\right|\right) > \sqrt[4]{k}$$

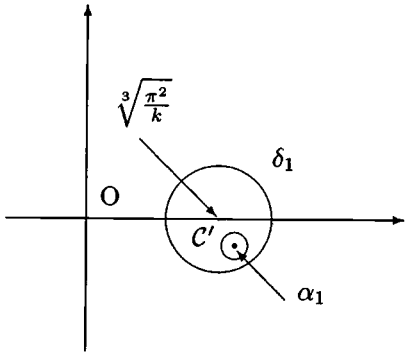

FIG. 4.2.

for k sufficiently large, by applying Taylor's theorem we obtain

$$|u(z) - u'(\alpha_1)(z-\alpha_1)| \leq a|z-\alpha_1|^2,$$

where a is a constant depending on k.

Nevertheless, we have that $|a| \leq \sup\{|u''(z)| : z \in \mathcal{C}'\} < k$.

We obtain that, if z belongs to the circumference of $\mathcal{C}'$,

$$|u(z)| \geq |u'(\alpha_1)||z-\alpha_1| - a|z-\alpha_1|^2 > \frac{1}{k^2}.$$

Hence

$$\left| -\frac{z^2-\pi^2+kz^3+z\sqrt{z^2-\pi^2}}{z^2-\pi^2-kz^3-z\sqrt{z^2-\pi^2}} \right| \geq \frac{|u(z)|}{|\,kz^3+\pi^2\,|+|z||z-\sqrt{z^2-\pi^2}|} \geq \frac{1}{k^3}.$$

Thus, for k sufficiently large and z on the circumference of $\mathcal{C}'$, we have

$$\left|e^{-2k\,z}\right| < \left| \frac{z^2-\pi^2+kz^3+z\sqrt{z^2-\pi^2}}{z^2-\pi^2-kz^3-z\sqrt{z^2-\pi^2}} \right|.$$

Applying Rouché's theorem we deduce that the equation (4.29) has a unique root z_k^* in $\mathcal{C}'$. Remark that if z_k^* is a root of (4.29), then $z_k^{**} = \bar{z}_k^*$, $-z_k^*$, and $-z_k^{**}$ are roots of this equation too.

Since $z_k^* \in \mathcal{C}'$ it follows that $z_k^* = \alpha_1 + \mathcal{O}\left(\frac{1}{k^2}\right)$. Hence, Lemma 4.3 ensures that

$$z_k^* = \sqrt[3]{\frac{\pi^2}{k}} - \frac{1}{3}\sqrt[3]{\frac{\pi}{k^2}}\,i + o\left(\frac{1}{\sqrt[3]{k^2}}\right). \tag{4.31}$$

We go back to the equation (2.2) and we obtain two roots λ_k^* and λ_k^{**} setting $\lambda_k^* = \sqrt{k^2(z_k^*)^2 - k^2\pi^2}$ and $\lambda_k^{**} = \sqrt{k^2(z_k^{**})^2 - k^2\pi^2}$.

We have

$$\left|\lambda_k^* - \sqrt{k^2(\alpha_1)^2 - k^2\pi^2}\right| = \frac{\left|(\lambda_k^*)^2 - (k^2(\alpha_1)^2 - k^2\pi^2)\right|}{\left|\lambda_k^* + \sqrt{k^2(\alpha_1)^2 - k^2\pi^2}\right|} = \frac{\left|k^2(z_k^*)^2 - k^2(\alpha_1)^2\right|}{\left|\lambda_k^* + \sqrt{k^2(\alpha_1)^2 - k^2\pi^2}\right|}$$

$$= \frac{k^2\,|(z_k^*-\alpha_1)(z_k^*+\alpha_1)|}{\left|\lambda_k^*+\sqrt{k^2(\alpha_1)^2-k^2\pi^2}\right|} \le \frac{|z_k^*+\alpha_1|}{k\left|\sqrt{(z_k^*)^2-\pi^2}+\sqrt{(\alpha_1)^2-\pi^2}\right|} \le \frac{1}{|k|}.$$

A similar result is obtained for λ_k^{**}.

We now prove (2.19). Remark first that if $\zeta = \sqrt{a+b\,i},\ a,b\in\mathbb{R}$ then $(\mathcal{R}e\,\zeta)^2 = \frac{1}{2}(a+\sqrt{a^2+b^2})$. We deduce that

$$\begin{aligned}(\mathcal{R}e\,\lambda_k^*)^2 = \frac{1}{2}\Big(&-k^2\pi^2 + k^2((\mathcal{R}e\,z_k^*)^2-(\mathcal{I}m\,z_k^*)^2)\\ &+\sqrt{(-k^2\pi^2+k^2((\mathcal{R}e\,z_k^*)^2-(\mathcal{I}m\,z_k^*)^2))^2+(2k^2\mathcal{R}e\ z_k^*\,\mathcal{I}m\,z_k^*)^2}\Big).\end{aligned} \tag{4.32}$$

Since z_k^* satisfies (4.31) we deduce from the relation (4.32) that

$$(\mathcal{R}e\,\lambda_k^*)^2 = \frac{1}{2}\Big(-k^2\pi^2 + k^2((\mathcal{R}e\,z_k^*)^2-(\mathcal{I}m\,z_k^*)^2)$$

$$+\sqrt{(-k^2\pi^2+k^2((\mathcal{R}e\,z_k^*)^2-(\mathcal{I}m\,z_k^*)^2))^2+(2k^2\mathcal{R}e\,z_k^*\,\mathcal{I}m\,z_k^*)^2}\Big)$$

$$= 2k^4(\mathcal{R}e\,z_k^*\,\mathcal{I}m\,z_k^*)^2\Big[k^2\pi^2 - k^2((\mathcal{R}e\,z_k^*)^2-(\mathcal{I}m\,z_k^*)^2)$$

$$+\sqrt{(-k^2\pi^2+k^2((\mathcal{R}e\,z_k^*)^2-(\mathcal{I}m\,z_k^*)^2))^2+(2k^2\mathcal{R}e\,z_k^*\,\mathcal{I}m\,z_k^*)^2}\ \Big]^{-1}.$$

Finally, taking into account the asymptotic expression for z_k^*, (4.31), we obtain that (2.19) holds. □

Proof of Theorem 2.9. (i) The weak convergence of $\{\varphi_{\lambda_k^*}\}_k$ is a direct consequence of the equation they satisfy.

(ii) We prove first that $\{\varphi^3_{\lambda_k^*}\}_k$ does not tend strongly to zero in $H^1(0,1)$. We have

$$||\varphi^3_{\lambda_k^*}||_{H^1(0,1)} = \frac{1}{|\lambda_k^*|^2}\left(\int_0^1 |\cos\ k\pi x|^2 + \int_0^1 |k\pi \sin\ k\pi x|^2\right) = \frac{1+k^2\pi^2}{2|\lambda_k^*|^2}.$$

Since $(\lambda_k^*)^2 = -k^2\pi^2 + k^2\alpha_1 + \mathcal{O}(k) = -k^2\pi^2 + \mathcal{O}(k)$ we obtain that $\varphi^3_{\lambda_k^*}$ does not tend to zero in $H^1(0,1)$. Evidently, $\varphi^4_{\lambda_k^*}$ does not tend to zero in $L^2(0,1)$.

We pass now to the study of $\varphi^1_{\lambda_k^*}$. We evaluate first the expression

$$|a_k|^2 = \left|\frac{1}{\sqrt{(\lambda_k^*)^2+k^2\pi^2}\,\sinh\,(\sqrt{(\lambda_k^*)^2+k^2\pi^2})}\right|^2$$

$$= \frac{1}{|(\lambda_k^*)^2+k^2\pi^2|\,\left(|\sinh\,\mathcal{R}e\,\sqrt{(\lambda_k^*)^2+k^2\pi^2}|^2 + |\sin\,\mathcal{I}m\,\sqrt{(\lambda_k^*)^2+k^2\pi^2}|^2\right)}.$$

Now,

$$\left|\left|\cosh\left(\sqrt{(\lambda_k^*)^2+k^2\pi^2}(y-1)\right)\cos k\pi x\right|\right|^2_{H^1(\Omega)}$$

$$=\frac{1}{2}\int_0^1\left(\left|\cosh\left(\sqrt{(\lambda_k^*)^2+k^2\pi^2}(y-1)\right)\right|^2+k^2\pi^2\left|\cosh\left(\sqrt{(\lambda_k^*)^2+k^2\pi^2}(y-1)\right)\right|^2\right.$$

$$\left.+((\lambda_k^*)^2+k^2\pi^2)\left|\sinh\left(\sqrt{(\lambda_k^*)^2+k^2\pi^2}(y-1)\right)\right|^2\right)$$

$$=\frac{1}{4}\int_0^1\left((-|(\lambda_k^*)^2+k^2\pi^2|+k^2\pi^2+1)\cos\left(\mathcal{I}m\sqrt{(\lambda_k^*)^2+k^2\pi^2}(y-1)\right)\right.$$

$$\left.+(|(\lambda_k^*)^2+k^2\pi^2|+k^2\pi^2+1)\sinh\left(2\mathcal{R}e\sqrt{(\lambda_k^*)^2+k^2\pi^2}(y-1)\right)\right)$$

$$=\frac{(-|(\lambda_k^*)^2+k^2\pi^2|+k^2\pi^2+1)\sin 2\mathcal{I}m\sqrt{(\lambda_k^*)^2+k^2\pi^2}}{8\mathcal{I}m\sqrt{(\lambda_k^*)^2+k^2\pi^2}}$$

$$+\frac{(|(\lambda_k^*)^2+k^2\pi^2|+k^2\pi^2+1)\sinh 2\mathcal{R}e\sqrt{(\lambda_k^*)^2+k^2\pi^2}}{8\mathcal{R}e\sqrt{(\lambda_k^*)^2+k^2\pi^2}}.$$

Taking into account that $\sqrt{(\lambda_k^*)^2+k^2\pi^2}=kz_k^*=\sqrt[3]{k^2\pi^2}-\frac{1}{3}\sqrt[3]{k\pi}\,i+o(\sqrt[3]{k})$, we obtain that

$$||\varphi^1_{\lambda_k^*}||^2_{H^1(\Omega)}\longrightarrow\frac{\sqrt[3]{\pi^2}}{4}.$$

Similarly it turns out that $||\varphi^2_{\lambda_k^*}||_{L^2(\Omega)}$ does not tend to zero. □

5. A noncompactness result. The following result is a direct application of the existence of a sequence of eigenvalues with modulus tending to infinity and uniformly negative real parts.

It is well known that, in the context of one-dimensional hybrid systems, the dissipative term is often a compact perturbation of the differential operator associated with the corresponding conservative system. This argument was used to prove that the decay rate of the energy of those systems is not uniform (see [18]). Nevertheless, in our case, this kind of argument cannot be used since the dissipative term $(0,0,0,W_t)$ is, at least apparently, a bounded but not compact perturbation of the conservative operator. It is natural to study whether this term produces a compact perturbation of the underlying conservative system.

A way to do this consists of analyzing whether the difference between the semigroup generated by the conservative operator and the semigroup generated by the dissipative one is compact or not. The existence of the sequence $(\lambda_k^*)_k$ of eigenvalues implies that the answer is negative.

THEOREM 5.1. *Let $\{S_D(t)\}_{t\geq 0}$ be the semigroup generated by the dissipative operator and let $\{S_C(t)\}_{t\geq 0}$ be the semigroup generated by the conservative system. Then, for all $t > 0$, the difference $(S_D - S_C)(t)$ is not a compact operator in $\mathcal{X}$.*

Proof. Suppose that there exists $t_0 > 0$ such that $(S_D - S_C)(t_0)$ is compact. Theorem 2.9 implies that there exists a sequence of eigenfunctions $\{\varphi_{\lambda_k^*}\}_k$, corresponding to the eigenvalues λ_k^*, which converges weakly to zero in $\mathcal{X}$. So,

$$||(S_C(t_0) - S_D(t_0))\varphi_{\lambda_k^*}||_{\mathcal{X}} \longrightarrow 0 \text{ when } k \longrightarrow \infty.$$

Since $\varphi_{\lambda_k^*}$ is an eigenfunction of the dissipative problem we have that

$$S_D(t_0)\varphi_{\lambda_k^*} = e^{\lambda_k^* t_0}\varphi_{\lambda_k^*}.$$

Hence,

$$||S_C(t_0)\varphi_{\lambda_k^*} - e^{\lambda_k^* t_0}\varphi_{\lambda_k^*}||_{\mathcal{X}} \longrightarrow 0 \text{ when } k \longrightarrow \infty. \tag{5.1}$$

Since the conservative operator generates a group of isometries (see [16]) we get that

$$||S_C(t_0)\varphi_{\lambda_k^*}||_{\mathcal{X}} = ||\varphi_{\lambda_k^*}||_{\mathcal{X}},$$

and therefore

$$||\varphi_{\lambda_k^*}||_{\mathcal{X}} = ||S_C(t_0)\varphi_{\lambda_k^*}||_{\mathcal{X}} \leq ||S_C(t_0)\varphi_{\lambda_k^*} - e^{\lambda_k^* t_0}\varphi_{\lambda_k^*}||_{\mathcal{X}} + \left|e^{\lambda_k^* t_0}\right| ||\varphi_{\lambda_k^*}||_{\mathcal{X}}. \tag{5.2}$$

In view of Theorem 2.8 we have that the sequence $(\lambda_k^*)_k$ has the property that $\mathcal{R}e\,\lambda_k^* \to -\frac{1}{3}$, when $k \to \infty$, and hence, there exists $k_1 \in \mathbb{N}$ such that $\mathcal{R}e\,\lambda_k^* < -\frac{1}{4}$ for all $k > k_1$.

We deduce that, for all $t > 0$, there exists a constant ε, depending on t but independent of k, such that

$$\left|e^{\lambda_k^* t}\right| = e^{\mathcal{R}e\,\lambda_k^* t} < 1 - \varepsilon.$$

Let us take $t = t_0$ in the last equality. Going back to (5.2), we obtain

$$\varepsilon||\varphi_{\lambda_k^*}||_{\mathcal{X}} \leq ||S_C(t_0)\varphi_{\lambda_k^*} - e^{\lambda_k^* t_0}\varphi_{\lambda_k^*}||_{\mathcal{X}}. \tag{5.3}$$

Remark that (5.1) and (5.3) imply that $||\varphi_{\lambda_k^*}||_{\mathcal{X}}$ goes to zero when $k \to \infty$ and this is a contradiction with the result of Theorem 2.9.

Finally, we obtain that $(S_D - S_C)(t)$ is not a compact operator for any $t > 0$. ∎

Remark 14. In order to compare the noncompactness result of Theorem 5.1 for our two-dimensional case with analogous one-dimensional models we consider the following problem (see [18]):

$$\begin{cases} u_{tt} - u_{xx} = 0, & x \in (0,1), \quad t > 0, \\ u(t,0) = 0, & t > 0, \\ u_{tt}(t,1) + u_t(t,1) = -u_x(t,1), & t > 0. \end{cases} \tag{5.4}$$

This is a "string-mass" model since it couples the vibrations of a string with a rigid body at the end $x = 1$ (see [9] and [18]).

The natural energy space corresponding to (5.4) is

$$\mathcal{Z} = V \times L^2(0,1) \times \mathbb{R},$$

where $V = \left\{ v \in H^1(0,1) : v(0) = 0 \right\}$.

Observe that if we define the energy of a solution u of (5.4) by

$$E(t) = \frac{1}{2} \int_0^1 \left(|u_t|^2 + |u_x|^2 \right) \, dx + \frac{1}{2} |u_t(t,1)|^2, \tag{5.5}$$

we obtain that

$$\frac{dE}{dt}(t) = -(u_t(t,1))^2 \leq 0. \tag{5.6}$$

Therefore we are dealing with a dissipative hybrid system, $u_t(t,1)$, in the last relation of (5.4), being the damping term.

Let us now consider the vector-valued unknown $U = (u, u_t, u(\cdot\,,1))$ and write equation (5.4) in the following abstract form:

$$\begin{cases} U_t + A_D(U) = 0, & t > 0, \\ U(0) = U_0. \end{cases} \tag{5.7}$$

The operator A_D in (5.7) is an unbounded operator in $\mathcal{Z}$ defined by

$$\begin{gathered} \mathcal{D} := \mathcal{D}(A_D) = \{ U \in \mathcal{Z} : A_D(U) \in \mathcal{Z} \} \\ = \left\{ U = (u,v,p) \in H^2(0,1) \cap V \times V \times \mathbb{R} : u(1) = p \right\}, \\ A_D(u,v,p) = (-v, -u_{xx}, v(1) + u_x(1)). \end{gathered}$$

It is easy to show that $(\mathcal{D}, A_D)$ is a maximal monotone operator in $\mathcal{Z}$.

Let us now consider the projection operator

$$B : \mathcal{Z} \to \mathcal{Z}, \quad B(u,v,p) = (0,0,p).$$

Observe that B is a compact operator in $\mathcal{Z}$ and $A_C = A_D - B$ is the conservative operator corresponding to (5.4).

Let $\{T_D(t)\}_{t \geq 0}$ be the strongly continuous semigroup generated by the dissipative operator A_D and let $\{T_C(t)\}_{t \geq 0}$ be the strongly continuous semigroup generated by the conservative operator A_C.

For (5.4) all the eigenvalues of the operator A_D approach the imaginary axis when the frequency increases. This is one of the consequences of the fact that A_D is obtained from A_C by a compact perturbation B. In the case of our system (1.1) this is not the case; the perturbation term is only bounded in the energy space. This is one of the major differences between one- and two-dimensional hybrid systems.

Moreover, since B is a compact operator, it can be shown that, for all $t \geq 0$, the difference $(T_D - T_C)(t)$ is a compact operator in $\mathcal{Z}$.

6. Comments. Our results indicate that the interaction between the fluid and structure in this type of model is very weak at high frequencies. As a consequence of this, if we try to change the dynamics of the system acting only on the string located on Γ_0, we have to impose very restrictive conditions on the data of the system. This

explains the results obtained in the context of the controllability of these systems and concerning the existence of periodic solutions (see [12] and [13]). The analysis of these problems was based on nonharmonic Fourier series (see [2]) and asymptotics for the spectrum.

The weak interaction of the string and the fluid is a consequence of both the hybrid structure of the system and of the localization of the string in a relatively small part of the boundary of Ω.

In [11] we analyze a slightly different model in which the domain Ω is a ball of $\mathbb{R}^2$ and the dissipation acts on the whole boundary. We prove that the energy does not decay uniformly. This clearly shows that the very weak interaction between fluid and structure at high frequencies is due to the hybrid structure of the system.

From our study the property of completeness of the eigenfunctions of the differential operator associated with (1.1) is easy to prove. The question of whether these eigenfunctions form a Riesz basis is open (for the notions of completeness and Riesz basis see [6]). For the one-dimensional systems, obtained by separation of variables fixing the number of oscillations in the x-variable, we can prove that the eigenfunctions do form a Riesz basis. However our estimates are not enough to give an answer to this question in the context of the two-dimensional problem.

We also remark that we have been able to obtain very precise information about the eigenvalues because we had the explicit equation they satisfy. We got this equation by separation of variables, which was possible since we considered Neumann boundary conditions for the string. The analysis in the case of Dirichlet boundary conditions for the string is much more difficult. Partial results, like the nonuniform decay of the energy of the system, were obtained in [11] (see also [14]).

The analysis of the rate of decay of low frequencies is a relevant problem for applications. Obviously, the techniques developed in this paper do not allow us to answer this question. This problem requires different approaches.

7. Appendix. We present here the proofs of Lemmas 4.1, 4.2, 4.3, and 4.4.

Proof of Lemma 4.1. If α is a root of (4.2), then

$$\mid k \mid\mid \alpha \mid^3 = \mid \alpha^2 - \pi^2 + \alpha\sqrt{\alpha^2 - \pi^2} \mid \leq 2 \mid \alpha \mid^2 + \pi \mid \alpha \mid + \pi^2 \leq \max\{4 \mid \alpha \mid^2, 4\pi^2\}.$$

We obtain that

$$\mid \alpha \mid \leq \max\left\{\frac{4}{k}, \sqrt[3]{\frac{4\pi^2}{k}}\right\} < \frac{2\pi}{\sqrt[3]{k}} \text{ for all } k \geq 1. \tag{7.1}$$

On the other hand we have

$$\mid k \mid\mid \alpha \mid^3 = \mid \alpha^2 - \pi^2 + \alpha\sqrt{\alpha^2 - \pi^2} \mid = \frac{\pi^2 \mid \alpha^2 - \pi^2 \mid}{\mid \alpha^2 - \pi^2 - \alpha\sqrt{\alpha^2 - \pi^2} \mid}$$

$$\geq \frac{\pi^2 \mid \alpha^2 - \pi^2 \mid}{\mid \alpha \mid^2 + \pi^2 + \mid \alpha \mid \sqrt{\mid \alpha \mid^2 + \pi^2}} \mid \geq \frac{\pi^2(\pi^2 - \mid \alpha \mid^2)}{\mid \alpha \mid^2 + \pi^2 + \mid \alpha \mid (\mid \alpha \mid + \pi)}.$$

In view of (7.1) we obtain that, if $k > 8\pi^3$, then

$$k \mid \alpha \mid^3 > \frac{\pi^2(\pi^2 - 1)}{2 + \pi^2 + \pi} > \frac{\pi^3}{8}. \qquad \square$$

Proof of Lemma 4.2. We study the relation between the roots of (4.2) and those of the equation

$$kz^3 - \pi^2 = 0. \tag{7.2}$$

The last equation has three roots $a_i = \sqrt[3]{\frac{\pi^2}{k}}\omega_i\,,\ i = 1, 2, 3$, where ω_i are the three cubic roots of unity.

We consider the functions $u(z) = kz^3 - \pi^2$ and $v(z) = z\sqrt{z^2 - \pi^2} + z^2$ defined in the circle δ_0 of center 0 and radius $\frac{2\pi}{\sqrt[3]{k}}$, where both are analytic.

In the circle δ_0 we have

$$\mid v(z) \mid = \mid z\sqrt{z^2 - \pi^2} + z^2 \mid \leq \mid z \mid (\sqrt{\mid z \mid^2 + \pi^2} + \mid z \mid) \leq \frac{10\pi^2}{\sqrt[3]{k}},$$

and hence

$$\mid v(z) \mid < \frac{10\pi^2}{\sqrt[3]{k}} \text{ if } \mid z \mid \leq \frac{2\pi}{\sqrt[3]{k}}. \tag{7.3}$$

On the other hand,

$$\mid u(z) \mid = \mid kz^3 - \pi^2 \Big| = k \mid z - \sqrt[3]{\frac{\pi^2}{k}}\omega_1 \Big| \Big| z - \sqrt[3]{\frac{\pi^2}{k}}\omega_2 \Big| \Big| z - \sqrt[3]{\frac{\pi^2}{k}}\omega_3 \Big|.$$

If z belongs to the circumference δ_0 we have that

$$\left| z - \sqrt[3]{\frac{\pi^2}{k}}\omega_i \right| \geq |z| - \left| \sqrt[3]{\frac{\pi^2}{k}}\omega_i \right| = \frac{2\pi}{\sqrt[3]{k}} - \sqrt[3]{\frac{\pi^2}{k}} > \sqrt[3]{\frac{\pi^3}{k}}, \quad i = 1, 2, 3.$$

Hence

$$\mid u(z) \mid > \pi^3 \text{ if } \mid z \mid = \frac{2\pi}{\sqrt[3]{k}}. \tag{7.4}$$

The inequalities (7.3) and (7.4) imply that $|u(z)| > |v(z)|$ for all z on the circumference δ_0.

Applying Rouché's theorem, we obtain that (4.2) has the same number of roots as (7.2) in the circle δ_0. It follows that (4.2) has three roots which satisfy (4.3). The inequality (7.3) is still valid in δ_i, $i = 1, 2, 3$. On the other hand, for all z on the circumference δ_i,

$$\mid u(z) \mid = \mid kz^3 - \pi^2 \mid = k \left| z - \sqrt[3]{\frac{\pi^2}{k}}\omega_1 \right| \left| z - \sqrt[3]{\frac{\pi^2}{k}}\omega_2 \right| \left| z - \sqrt[3]{\frac{\pi^2}{k}}\omega_3 \right|$$

$$> k\frac{10}{\sqrt[3]{k^2}} \left(\frac{\pi}{\sqrt[3]{k}} \right)^2 = \frac{10\pi^2}{\sqrt[3]{k}}.$$

Applying Rouché's theorem, we deduce that the roots of (4.2) are located in the circles δ_i and the estimate (4.5) holds. □

Proof of Lemma 4.3. Step 1: We prove first that the equation

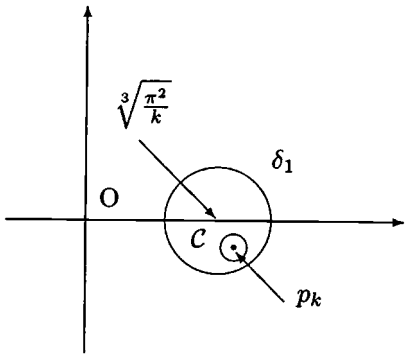

FIG. 7.1.

$$-\pi^2 + kz^3 + \pi z\, i = 0 \tag{7.5}$$

has a unique solution p_k in the circle δ_1 of center $\sqrt[3]{\frac{\pi^2}{k}}$ and radius $\frac{10}{\sqrt[3]{k^2}}$ and hence

$$p_k = \sqrt[3]{\frac{\pi^2}{k}} - \frac{1}{3}\sqrt[3]{\frac{\pi}{k^2}}\, i + o\left(\frac{1}{\sqrt[3]{k^2}}\right).$$

The existence of the root p_k in δ_1 follows by applying the estimates obtained in Lemma 4.2 to the functions $u(z) = -\pi^2 + kz^3$ and $v(z) = \pi z\, i$.

We define now $r_k = p_k - \sqrt[3]{\frac{\pi^2}{k}}$ and we deduce that r_k satisfies

$$kr_k^3 + 3kr_k^2\sqrt[3]{\frac{\pi^2}{k}} + 3kr_k\sqrt[3]{\frac{\pi^4}{k^2}} + \pi r_k\, i + \pi\sqrt[3]{\frac{\pi^2}{k}}\, i = 0.$$

Multiplying the last equation by $\sqrt[3]{k}$ we deduce that

$$\sqrt[3]{k}\left(3kr_k\sqrt[3]{\frac{\pi^4}{k^2}} + \pi\sqrt[3]{\frac{\pi^2}{k}}\, i\right) = \sqrt[3]{k}\left(-kr_k^3 - 3kr_k^2\sqrt[3]{\frac{\pi^2}{k}} - \pi r_k\, i\right).$$

Since $|r_k| = \left|p_k - \sqrt[3]{\frac{\pi^2}{k}}\right| \le \frac{10}{\sqrt[3]{k^2}}$ we have that $r_k = -\frac{1}{3}\sqrt[3]{\frac{\pi}{k^2}}\, i + o\left(\frac{1}{\sqrt[3]{k^2}}\right)$.

Hence, $p_k = \sqrt[3]{\frac{\pi^2}{k}} - \frac{1}{3}\sqrt[3]{\frac{\pi}{k^2}}\, i + o\left(\frac{1}{\sqrt[3]{k^2}}\right)$.

Step 2: We prove now that the root α_1 of (4.2) belongs to the circle $\mathcal{C}$ centered in p_k and of radius $s_k = \frac{1}{\sqrt[4]{k^3}}$ (see Fig. 7.1). This implies immediately that α_1 satisfies (4.5).

We use again Rouché's theorem considering the functions

$$u(z) = -\pi^2 + kz^3 + \pi z\, i, \quad v(z) = -z^2 - z\sqrt{z^2 - \pi^2} + \pi z\, i.$$

For z in δ_1 we have

$$|v(z)| = |z|^2\left|-1 - \frac{z}{\sqrt{z^2 - \pi^2} + \pi\, i}\right| \le 2|z|^2 \le \frac{100}{\sqrt[3]{k^2}}.$$

On the other hand, applying Taylor's formula in the point p_k, we get

$$u(z) = u'(p_k)(z-p_k) - \frac{(z-p_k)^2}{2\pi\, i}\int_{\widehat{\gamma}} \frac{u(\zeta)\, d\zeta}{(\zeta-p_k)^2(\zeta-z)},$$

where $\widehat{\gamma}$ is the circle of center p_k and radius $S_k = \frac{1}{\sqrt[3]{k}}$.

We estimate first the quantity

$$\left|\frac{(z-p_k)^2}{2\pi\, i}\int_{\widehat{\gamma}} \frac{u(\zeta) d\,\zeta}{(\zeta-p_k)^2(\zeta-z)}\right| \leq \frac{s_k^2}{2\pi}\, \frac{M}{S_k^2(S_k-s_k)}\, 2\pi S_k \leq 2M\, \sqrt[12]{\frac{1}{k^{10}}},$$

where M is an upper bound for u in $\widehat{\gamma}$.

On the other hand

$$|z-p_k|\,|u'(p_k)| = s_k|3kp_k^2 + \pi\, i| \geq s_k\,(3k|p_k|^2 - \pi) \geq \frac{1}{\sqrt[4]{k^3}}\left(3k\sqrt[3]{\frac{\pi^4}{k^2}} - \pi\right) \geq \frac{1}{2}\,\sqrt[12]{\frac{1}{k^5}}.$$

We obtain that for k sufficiently large and z on the circumference $\mathcal{C}$,

$$|u(z)| > |z-p_k|\,|u'(p_k)| - 2M\,\sqrt[12]{\frac{1}{k^{10}}} \geq \frac{1}{2}\,\sqrt[12]{\frac{1}{k^5}} - 2M\,\sqrt[12]{\frac{1}{k^{10}}} > \frac{1}{4\,\sqrt[12]{k^5}} > \frac{100}{\sqrt[3]{k^2}}.$$

We conclude that, for k sufficiently large, $|u(z)| > |v(z)|$ on the circumference of $\mathcal{C}$.

Applying Rouché's theorem, we deduce that α_1 satisfies (4.5). □

Proof of Lemma 4.4. We simply remark that, making $z = -s$, the equation (4.6) is transformed into (4.2). □

EVOLUTION OF MIXED-STATE REGIONS IN TYPE-II SUPERCONDUCTORS*

CHAOCHENG HUANG† AND THOMAS SVOBODNY†

Abstract. A mean-field model for dynamics of superconducting vortices is studied. The model, consisting of an elliptic equation coupled with a hyperbolic equation with discontinuous initial data, is formulated as a system of nonlocal integrodifferential equations. We show that there exists a unique classical solution in $C^{1+\alpha}\left(\bar{\Omega}_0\right)$ for all $t > 0$, where Ω_0 is the initial vortex region that is assumed to be in $C^{1+\alpha}$. Consequently, for any time t, the vortex region Ω_t is of $C^{1+\alpha}$, and the vorticity is in $C^{\alpha}\left(\bar{\Omega}_t\right)$.

Key words. high-temperature superconductor, nonequilibrium superconductivity, mixed-state region, vorticity, London equations

1. Introduction.

One of the phenomena that characterize a superconducting material is the Meissner effect. This refers to the exclusion from the material of time-independent as well as time-varying magnetic fields.

This state of exclusion, the Meissner phase, is independent of past history. Materials are superconducting, and thus exhibit a Meissner state, only below a certain critical temperature T_c. On the other hand, at any $0 < T < T_c$, the Meissner state is destroyed and the magnetic field penetrates the whole material (normal phase) when the magnetic field exceeds some critical value $H_c(T)$. A relation between magnetic field $\mathbf{H}$ and current $\mathbf{J}$ in the material was proposed to explain the Meissner effect:

$$\lambda^2 \nabla \times \mathbf{J} + \mathbf{H} = 0, \tag{1.1}$$

where λ is a characteristic length scale. With Ampére's law,

$$\mathbf{J} = \nabla \times \mathbf{H};$$

this leads to the London equation [11]

$$\lambda^2 \nabla \times \nabla \times \mathbf{H} + \mathbf{H} = 0.$$

It follows from this equation—and this has been corroborated by experiments—that λ gives the depth of penetration of the magnetic field.

The London equations follow from the Ginzburg–Landau equations, which couple the electrodynamics to the dynamics of an order parameter, in the limit as $\kappa = \lambda/\xi$ gets arbitrarily large, where ξ, the so-called coherence length, represents the length scale on which the order parameter (density of superconductivity) varies [6]. Thus, the London equations represent a superconductor with zero stiffness in the order parameter.

For high-κ (type-II) superconductors, the London relation (1.1) needs to be modified [11]. It was observed that the Meissner phase obtains for magnetic fields below a certain critical field H_{c_1}, that the normal phase obtains above a higher critical field H_{c_2}, and that a different phase, the so-called Abrikosov–Shubnikov, or mixed-state, phase obtains for intermediate values of the magnetic field between H_{c_1} and H_{c_2}. In this phase the magnetic field penetrates the material in the form of quantized vortices; each vortex carries a quantum of flux, ϕ_0, known as a fluxon. These vortices interact with each other and move under the influence of applied and induced currents. As $\kappa \to \infty$, the difference between H_{c_1} and H_{c_2} increases so that for high-κ materials, which include the high temperature superconductors, this mixed state is the phase of importance.

The London equations for a single vortex filament Γ are then

$$\lambda^2 \nabla \times \nabla \times \mathbf{H} + \mathbf{H} = -\phi_0 \delta_\Gamma.$$

A mean-field model for the mixed state was arrived at in [4] by averaging the above equations over the individual vortices

$$\lambda^2 \nabla \times \nabla \times \mathbf{H} + \mathbf{H} = -\boldsymbol{\omega}.$$

The variable $\boldsymbol{\omega}$ represents the density of quantum vortices and will be referred to as the vorticity. The vorticity is assumed to be convected at a velocity $\mathbf{u}$, which is the terminal speed in the presence of Lorentz forces due to the mean field (and is perpendicular to the current). In the case that the vorticity and the magnetic field remain in a fixed direction, say $x_3 - axis$, i.e., $\boldsymbol{\omega} = (0, 0, \omega)$, $\mathbf{H} = (0, 0, H)$, the complete system then reads (see [4])

$$\omega_t + \nabla \cdot (\omega u) = 0, \tag{1.2}$$

$$\Delta H - H = -\omega, \tag{1.3}$$

$$u = -sign\,(\omega)\, \nabla H. \tag{1.4}$$

In the region $\Omega_t = \{\omega(\cdot, t) \neq 0\}$, where vortices exist, the material is in the phase of the mixed state. The boundary then represents the interface between the mixed-state phase and the superconducting phase. The evolution of such a boundary is important since any such motion is manifested as electrical resistance [7]. An approach taken in [1] is to calculate the forces experienced by any vortex due to a magnetic field formed by integration over fluxons. Among other configurations, the authors studied, via numerical simulations, the evolution of the vortex lattice starting from a configuration where vortices are concentrated in a bounded region. In the mean-field setting (1.2)–(1.4), this configuration corresponds to the case of an initially isolated mixed-state domain $\bar{\Omega}_0$ evolving in the environment of a Meissner phase. In other words, the initial data should be taken as

$$\omega(x, 0) = \omega_0(x) = \varpi_0(x)\, \chi_{\bar{\Omega}_0}(x), \tag{1.5}$$

where $\chi_{\bar{\Omega}_0}$ is the characteristic function of Ω_0, which is the initial mixed-state or vortex region, and ϖ_0 is a continuous function in the whole space. In the present paper, we are mainly concerned with the problem (1.2)–(1.4) along with the initial condition (1.5).

Since the initial vorticity (1.5) is discontinuous only on $\partial\Omega_0$, one expects that the discontinuity will evolve with the velocity u. Hence, the motion equation (1.2)

is understood in the distribution sense. In order to define solutions in appropriate spaces, it has been proposed in [4] to treat the system as the following free boundary problem:

$$\omega_t = \nabla \cdot (|\omega| \nabla H) \quad \text{in } \Omega_t, \tag{1.6}$$

$$\Delta H - H = -\omega \quad \text{in } \Omega_t, \tag{1.7}$$

$$\Delta H - H = 0 \quad \text{in } R^2 \backslash \Omega_t, \tag{1.8}$$

$$[H] = \left[\frac{\partial H}{\partial n}\right] = 0 \quad \text{on } \Gamma_t = \partial\Omega_t, \tag{1.9}$$

$$V_n = -sign\,(w)\,\frac{\partial H}{\partial n} \quad \text{on } \Gamma_t, \tag{1.10}$$

where Ω_t is the moving domain initially at Ω_0, n is the outward normal, V_n is the normal velocity of the moving boundary Γ_t, and the bracket $[\cdot]$ denotes the jump across Γ_t.

In the present paper we propose a different approach to deal with the problem (1.2)–(1.5). The system will be formulated as the following integro-differential equation:

$$\begin{aligned} &\frac{d\Phi(x,t)}{dt} = -\int_{\Omega_t} \nabla K(\Phi(x,t) - y)\left(J(\Phi)^{-1}\varpi_0\right)\left(\Phi^{-1}(y,t)\right) dy, \\ &\Phi(x,0) = x \quad \text{for } x \in \bar{\Omega}_0, \end{aligned} \tag{1.11}$$

where $\Phi : \bar{\Omega}_0 \times [0,T) \mapsto R^2$, $K(x)$ is the Green's function for the elliptic equation (1.3), J is the Jacobian, and $\Phi^{-1}(\cdot,t)$ is the inverse mapping for any fixed t. One of the advantages of the above formulation is that we can work on the fixed domain.

The main intention is to investigate classical solutions Φ for the system (1.11). We shall study uniqueness, global existence, and regularity of solutions for system (1.11).

This approach is motivated by [8] in which the authors used a system analogue to (1.11) to study motion of charged particles. We shall modify the method developed in [8] to establish short-time existence and uniqueness of the solution for (1.11). The treatment for long-time existence is partially motivated by [3]. One observes that system (1.2)–(1.5) has a certain similarity to vorticity evolution for a two-dimensional incompressible Euler system. Roughly speaking, in a two-dimensional Euler system, instead of (1.3), the relationship between the vorticity and the fluid velocity is through the Biot–Savart law [10]. When $\varpi_0(x)$ is a constant (and consequently $\varpi(x,t)$ remains constant for all t), a global smooth solution for a two-dimensional Euler system was established in [3], [5]. In our system (1.2)–(1.5), the vorticity $\varpi(x,t)$ has a more complicated structure. The main idea introduced in this paper is to estimate—instead of a C^α norm as one usually did (see [3], [8], and [5])—a C^β norm of $\varpi(\cdot,t)$ for some $0 < \beta < \alpha$. We then use this norm to bound the velocity.

The paper is organized as follows. In section 2, some preliminaries, notations, and main results will be introduced. Uniqueness and short-time existence will be investigated in section 3. Section 4 will be devoted to the derivation of some a priori estimates for solutions. Global existence will be proved in section 5.

2. Preliminaries and main results. Throughout the paper, we assume that Ω_0 is a bounded domain and that

$$\partial\Omega_0 \in C^{1+\alpha}, \quad \varpi_0(x) > 0, \quad \varpi_0 \in C^\alpha. \tag{2.1}$$

Suppose that u and ω are smooth. Then the equation (1.2) can be rewritten as

$$\omega_t + (u \cdot \nabla)\,\omega = -\omega \nabla \cdot u. \tag{2.2}$$

Let $\Phi(x,t)$ be the solution of

$$\frac{d\Phi}{dt} = u(\Phi, t), \quad \Phi(x,0) = x \quad \text{for } x \in \bar{\Omega}_0. \tag{2.3}$$

By (2.2), $\omega(\Phi(x,t),t)$ solves

$$\frac{d\omega}{dt} = -\omega \nabla \cdot u. \tag{2.4}$$

Let $J(\Phi)$ be the Jacobian of Φ. It is known that $J(\Phi)$ solves

$$\frac{dJ(\Phi)}{dt} = J(\Phi)\,\nabla \cdot u \tag{2.5}$$

so that $J(\Phi)^{-1}$ is the solution of

$$\frac{dJ(\Phi)^{-1}}{dt} = -J(\Phi)^{-1}\,\nabla \cdot u. \tag{2.6}$$

Comparing (2.4) to (2.6), it follows from the uniqueness theory of ordinary differential equations (ODE) that

$$\omega(\Phi(x,t),t) = J(\Phi)^{-1}(x,t)\,\omega_0(x) \quad \text{for } x \in \bar{\Omega}_0. \tag{2.7}$$

Since at $t = 0$, $J(\Phi) = 1$, the expression (2.7) suggests that $\omega(\Phi(x,t),t) > 0$ for $x \in \bar{\Omega}_0$, provided $J(\Phi)(x,t)$ does not vanish for t. Set

$$\Omega_t = \Phi(\Omega_0, t).$$

Then Ω_t represents the mixed-state region at time t. We extend $\omega(x,t)$ by 0 for $x \notin \bar{\Omega}_t$.

Let $K(x)$ be the fundamental solution of the elliptic equation (1.3) that has the form [2]

$$K(x) = \frac{1}{2\pi} K_0(|x|) = \frac{1}{2\pi}\left(-\ln(|x|) + S(|x|)\right), \tag{2.8}$$

where K_0 is the 0th-order modified Bessel's function of the second kind (or Hankel function of imaginary part) and S is its regular part. Hence, assuming that $H(x,t) \to 0$ as $|x| \to \infty$, we have, from (1.3),

$$H(x,t) = \int_{\Omega_t} K(x-y)\,\omega(y,t)\,dy. \tag{2.9}$$

It is easy to check that

$$\nabla H(x,t) = \nabla \int_{R^2} K(x-y)\,\omega(y,t)\,dy = \int_{\Omega_t} \nabla_x K(x-y)\,\omega(y,t)\,dy. \tag{2.10}$$

Substituting this expression, (1.4), and (2.7) into (2.3), and noting that $\omega(x,t) > 0$ in $\bar{\Omega}_t$, we arrive at the following integro-differential equation for $\Phi(x,t)$ in $\bar{\Omega}_0 \times [0,T)$:

$$\frac{d\Phi(x,t)}{dt} = -\int_{\Omega_t} \nabla K(\Phi(x,t) - y) \left(J(\Phi)^{-1} \varpi_0\right) \left(\Phi^{-1}(y,t), t\right) dy, \tag{2.11}$$
$$\Phi(x,0) = x \quad \text{for } x \in \bar{\Omega}_0.$$

Before proceeding to state our main results, we need to introduce some function spaces and notations.

For any subset $G \subseteq R^2$, multi-index $\beta = (\beta_1, \beta_2)$, $m = |\beta|$, $0 < \alpha < 1$, and any function f in G, denote by $|f|_{m+\alpha}$ and $\|f\|_{m+\alpha}$, respectively, the Hölder seminorm and norm defined as

$$|f|_{m+\alpha} = \sup_{x,y \in G,\, |\beta| = m} \frac{\left|D^\beta f(x) - D^\beta f(y)\right|}{|x-y|^\alpha}$$

and

$$\|f\|_{m+\alpha} = \sup_{x \in G,\, |\beta| \le m} \left|D^\beta f(x)\right| + |f|_{m+\alpha}.$$

Denote by $C^{m+\alpha}(G)$ the set of all functions $f(x)$ defined in G such that $\|f\|_{m+\alpha}$ is finite. If $f(x,t)$ is defined in G_t for $t < T$, where $G_t \subseteq R^2$ depends on t, we sometimes use the notation $f \in C_x^{m+\alpha}(G_t)$ to specify that $f(\cdot,t) \in C^{m+\alpha}(G_t)$ for any fixed t. For clarity, sometimes we shall also use the notations $|f(t)|_{m+\alpha,G_t}$ and $\|f(t)\|_{m+\alpha,G_t}$ to specify the dependence on the domain G_t. We also introduce the following notation:

$$|f(t)|_{\inf,\partial G_t} = \inf_{x \in \partial G_t} |f(x,t)|.$$

Definition 2.1. *A function $\Phi(x,t)$, defined for $(x,t) \in \bar{\Omega}_0 \times [0,T)$ with values in R^2, is called a $C^{1+\alpha}\left(\bar{\Omega}_0\right)$ solution of (2.11) for $t < T$ if, for any fixed $t < T$, $\Phi(\cdot,t), D_t\Phi(\cdot,t) \in C^{1+\alpha}\left(\bar{\Omega}_0\right)$, $\Phi^{-1}(\cdot,t) \in C^{1+\alpha}\left(\bar{\Omega}_t\right)$, and $\Phi(x,t)$ solves (2.11) pointwise in $\bar{\Omega}_0 \times [0,T)$.*

We shall verify in the next section that in the class of $C^{1+\alpha}$, formulation (2.11) is equivalent to (1.2)–(1.5). We conclude this section with a statement of the main result of this paper.

Theorem 2.2. *Assume (2.1). Then there exists a unique $C^{1+\alpha}\left(\bar{\Omega}_0\right)$ solution $\Phi(x,t)$ for (2.11) for $t > 0$. Consequently, the mixed-state region $\bar{\Omega}_t$ is of $C^{1+\alpha}$ for all $t > 0$.*

3. Short-time existence. Let $\Phi(x,t)$ be a $C^{1+\alpha}(\Omega_0)$ function for fixed t, and $J(\Phi) \neq 0$. Introduce an operator A by

$$A(\Phi)(x,t) = x - \int_0^t \int_{\Omega_s} \nabla K(\Phi(x,s) - z) \left(J(\Phi)^{-1} \omega_0\right) \left(\Phi^{-1}(z,s), s\right) dz ds. \tag{3.1}$$

In this section, we shall show that under the assumption of (2.1), this operator has a unique fixed point in $C_x^{1+\alpha}$ for $0 < t < T$ for some $T > 0$. This fixed point is obviously a $C^{1+\alpha}\left(\bar{\Omega}_0\right)$ solution for (2.11).

Notice that at $r = 0$ the singular part of $\nabla K(x)$ (see (2.8)) is the Newtonian kernel $x/|x|$. We need the following modified version of [8, Lemma 3.1] that will be frequently used throughout the section.

LEMMA 3.1. *Let Ω be a bounded domain in R^2. Suppose that there exists a $\varphi \in C^{1+\alpha}\left(R^2\right)$ such that $\Omega = \{\varphi(x) < 0\}$ and that $\inf_{\partial\Omega} |\nabla\varphi(x)| > 0$. Define function $w(x)$ and $G(x)$, for any $g \in C^{\alpha}$, by*

$$w(x) = P_v \int_{\Omega} \nabla\left(\frac{x-z}{|x-z|^2}\right) dz,$$

$$G(x) = \int_{\Omega} \nabla\left(\frac{x-z}{|x-z|^2}\right) (g(x) - g(z))\, dz,$$

where P_v means the principal value. Then

$$|w|_{0,\Omega} \le c \ln(2 + \delta d(\Omega)), \tag{3.2}$$

$$|w|_{\alpha,\Omega} \le c\delta \ln(2 + \delta d(\Omega)), \tag{3.3}$$

$$|G|_{\alpha,\Omega} \le c\,|g|_{\alpha,\Omega} \ln(2 + \delta d(\Omega)), \tag{3.4}$$

where c is a constant depending only on α and Ω, $d(\Omega)$ is the diameter of Ω, and

$$\delta = \frac{|\nabla\varphi|_{\alpha,\partial\Omega}}{|\nabla\varphi|_{\inf,\partial\Omega}}. \tag{3.5}$$

Proof. By analyzing the proof of [3, Proposition 1], one found that $|w|_{0,\Omega} \le c$ if $\delta d(\Omega) < 1$. Assertion (3.2) then follows from [3, Proposition 1]. By carefully tracking various constants in the proof of [8, Lemma 3.1] and using (3.2), inequality (3.3) follows. Estimate (3.4) follows from (3.2) and [8, Lemma 3.2].

It follows that $\nabla A(\Phi)(x,t)$ exists for $x \in \Omega_0$ and that it has interior limit for $x \in \partial\Omega_0$. One can actually compute $\nabla A(\Phi)$ as

$$\nabla A(\Phi)(x,t) = I + A_1(\Phi)(x,t) + A_2(\Phi)(x,t), \tag{3.6}$$

for $x \in \bar{\Omega}_0$, where

$$A_1(\Phi)(x,t) = -\int_0^t P_v \int_{\Omega_s} \nabla^2 K(\Phi(x,s) - z) \cdot \left(J(\Phi)^{-1}\omega_0\right)\left(\Phi^{-1}(z,s), s\right) \nabla\Phi(x,s)\, dz ds, \tag{3.7}$$

$$A_2(\Phi)(x,t) = -\frac{1}{2\pi}\int_0^t \left(J(\Phi)^{-1}\omega_0\right)(x,s)\, \nabla\Phi(x,s)\, ds. \tag{3.8}$$

For convenience, in the following we will leave out the designation P_v; all singular integrals in the paper shall be understood as the principal values.

By (3.6)–(3.8), we can show that the $C^{1+\alpha}\left(\bar{\Omega}_0\right)$ solution is a weak solution in the following sense.

DEFINITION 3.2. *Assume* (2.1). *A pair of functions* $(\omega, H) \in L^2\left(R^2 \times (0,T)\right) \times L^2\left(W^{2,2}\left(R^2\right),(0,T)\right)$ *is called a weak solution of* (1.2)–(1.5) *for* $0 \le t < T$ *if*

$$\int_0^T \int_{R^2} \omega\,(x,t)\,\nabla H\,(x,t)\,\nabla \xi\,(x,t)\,dxdt$$

$$= \int_0^T \int_{R^2} \omega\,(x,t)\,\xi_t\,(x,t)\,dxdt + \int_{R^2} \omega_0\,(x)\,\xi\,(x,0)\,dx, \tag{3.9}$$

$$\Delta H\,(x,t) - H\,(x,t) = -\omega\,(x,t)\,, \qquad H\,(x,t) \longrightarrow 0 \quad \text{as } |x| \longrightarrow \infty, \tag{3.10}$$

for any $\xi\,(x,t) \in C_0^\infty\left(R^2 \times [0,T)\right)$.

PROPOSITION 3.3. *Assume* (2.1). *Let* Φ *be a* $C^{1+\alpha}\left(\bar{\Omega}_0\right)$ *solution of* (2.11) *for* $t < T$. *Define* $\omega\,(x,t)$ *by* (2.7) *for* $x \in \bar{\Omega}_t$ *and by* 0 *otherwise, and define* H *by* (2.9). *Then* (ω, H) *is a classical solution of* (1.2)–(1.5) *in the sense that the equations* (2.4), (1.3), *and* (1.5) *hold pointwise in* $\bar{\Omega}_t$, *with* $u = -\nabla H$ *and* $\nabla \cdot u\,(x,t)$ *being understood as the limit from the interior for* $x \in \partial\bar{\Omega}_t$, *and that* (1.3) *holds in* R^2. *The converse is also true. Consequently, any* $C^{1+\alpha}\left(\bar{\Omega}_0\right)$ *solution is a weak solution.*

Proof. We only sketch the proof. Suppose that Φ is a $C^{1+\alpha}\left(\bar{\Omega}_0\right)$ solution of (2.11). By (2.7), (2.11), and Lemma 3.1, it is clear that, for any $x \in \bar{\Omega}_0$, $\omega\,(\Phi\,(x,t)\,,t)$ is differentiable in t, and that $H\,(\cdot,t) \in C^{2+\alpha}\,(\Omega_t)$. From expression (3.6)–(3.8), one can easily verify (2.4) and (1.3)–(1.5). Obviously, $(\omega, H) \in L^2 \times W^{2,2}$, and (3.10) follows from (2.9). By (2.7), for any $\xi\,(x,t) \in C_0^\infty\left(R^2 \times [0,T)\right)$ and $x \in \Omega_0$,

$$\begin{aligned}
&\frac{d}{dt}\left(\omega\left(\Phi\,(x,t)\,,t\right) J\,(\Phi)\,(x,t)\,\xi\left(\Phi\,(x,t)\,,t\right)\right)\\
&\quad = \omega\left(\Phi\,(x,t)\,,t\right) J\,(\Phi)\,(x,t)\,\frac{d}{dt}\xi\left(\Phi\,(x,t)\,,t\right)\\
&\quad = \omega\left(\Phi\,(x,t)\,,t\right) J\,(\Phi)\,(x,t)\left(\nabla\xi\left(\Phi\,(x,t)\,,t\right)\cdot\frac{d\Phi\,(x,t)}{dt} + \xi_t\left(\Phi\,(x,t)\,,t\right)\right),
\end{aligned}$$

where $\xi_t\,(x,t) = \partial\xi/\partial t$. Hence, by integration in x and t, we obtain, by (2.3),

$$\begin{aligned}
-\int_{\Omega_0} \omega_0\,(x)\,\xi\,(x,0)\,dx = &-\int_0^T \int_{\Omega_0} \omega\left(\Phi\,(x,t)\,,t\right)\nabla H\cdot\nabla\xi\left(\Phi\,(x,t)\,,t\right) J\,(\Phi)\,(x,t)\,dxdt\\
&+\int_0^T \int_{\Omega_0} \omega\left(\Phi\,(x,t)\,,t\right)\xi_t\left(\Phi\,(x,t)\,,t\right) J\,(\Phi)\,(x,t)\,dxdt.
\end{aligned}$$

Assertion (3.9) follows by changes of variables $y = \Phi\,(x,t)$ and by the fact that $\omega\,(x,t) = 0$ outside $\bar{\Omega}_t$.

We next derive some $C^{1+\alpha}$ estimates for the operator A defined in (3.1) and use them to establish a fixed point. Notice that the function K_0 in (2.8) has the specific form

$$K_0\,(r) = -\ln r + S\,(r)\,, \qquad S\,(r) = -\left(\ln\frac{r}{2} + \gamma\right) I_0 - \ln\frac{\gamma}{2} + I_1,$$

where γ is the Euler constant (≈ 0.56), and

$$I_0 = \sum_{i=1}^{\infty} \frac{(r/2)^{2i}}{i!\Gamma(i+1)}, \quad I_1 = \sum_{i=1}^{\infty} \frac{(r/2)^{2i}}{(i!)^2} \left(\sum_{j=1}^{i} \frac{1}{j} \right).$$

The following properties can be verified through direct computations [2]:

(i) $S(r)$ is smooth for $r \geq 0$;

(ii) $K_0(r) = (e^{-r}/\sqrt{r})(1 + O((1/r)))$, as $r \to \infty$;

(iii) $K_0(r) = -\ln r + O(r)$, as $r \to 0$.

We need the following estimates for solutions of the equation (1.3).

LEMMA 3.4. *Suppose that* $\omega(x) = \varpi(x)\chi_\Omega$, *where* $\varpi \in C^\alpha$, $\Omega = \{\varphi(x) < 0\}$ *with* $\varphi \in C^{1+\alpha}$, $|\nabla\varphi|_{\inf,\partial\Omega} > 0$. *Let* H *be the solution of* (1.3) *that vanishes at infinity. Then*

$$0 \leq H \leq |\varpi|_{0,\Omega}, \tag{3.11}$$

$$\|H\|_{2,\Omega} \leq c\,|\varpi|_{0,\Omega} \ln\left[(2 + \delta d(\Omega))\left(2 + |\varpi|_{0,\Omega}^{-1} |\varpi|_{\alpha,\Omega}\, d(\Omega)\right)\right], \tag{3.12}$$

$$\|H\|_{2+\alpha,\Omega} \leq c\left(\|\varpi\|_{\alpha,\Omega} + \delta\,|\varpi|_{0,\Omega}\right) \ln(2 + \delta d(\Omega)), \tag{3.13}$$

where c *is a universal constant,* $d(\Omega)$ *is the diameter of* Ω, *and*

$$\delta = \frac{|\nabla\varphi|_{\alpha,\partial\Omega}}{|\nabla\varphi|_{\inf,\partial\Omega}}.$$

Proof. The inequalities (3.11) follow from the maximum principle for elliptic equations. By (2.10), for $x \in \bar{\Omega}$, we have the integral formula for $\nabla^2 H$ (analogous to (3.6)) as follows:

$$\begin{aligned}
\nabla^2 H(x,t) &= \int_\Omega \nabla^2 K(x-z)\,\omega(z)\,dz + \frac{1}{2\pi}\omega(x) \\
&= \frac{1}{2\pi}\int_\Omega \nabla\left(\frac{x-z}{|x-z|^2}\right) dz\omega(x) \\
&\quad + \frac{1}{2\pi}\int_\Omega \nabla\left(\frac{x-z}{|x-z|^2}\right)(\omega(z) - \omega(x))\,dz \\
&\quad + \frac{1}{2\pi}\omega(x) + \int_\Omega \nabla^2 S(|x-z|)\,\omega(z)\,dz = k_1 + k_2 + k_3 + k_4.
\end{aligned} \tag{3.14}$$

By Lemma 3.1, it is easy to see that

$$\|k_1\|_\alpha + \|k_3\|_\alpha \leq c\left(\|\varpi\|_{\alpha,\Omega} + \delta\,|\varpi|_{0,\Omega}\right) \ln(2 + \delta d(\Omega)). \tag{3.15}$$

To estimate k_2, we write

$$k_2 = \frac{1}{2\pi}\left(\int_{\Omega\setminus B_\varepsilon} + \int_{B_\varepsilon}\right) \nabla\left(\frac{x-z}{|x-z|^2}\right)(\omega(z) - \omega(x))\,dz = k_{21} + k_{22},$$

where B_ε is the ball centered at x with radius ε that will be chosen later on. By integration,

$$|k_{21}| \le c\,|\varpi|_{0,\Omega} \int\limits_{\Omega\setminus B_\varepsilon} \frac{1}{|x-z|^2}\,dz \le c\,|\varpi|_{0,\Omega} \ln\left(\frac{d(\Omega)}{\varepsilon}\right)$$

if $\varepsilon \le d(\Omega)$. Otherwise, $k_{21}=0$. Since $\varpi \in C^\alpha$, we find that

$$|k_{22}| \le c\,|\varpi|_{\alpha,\Omega} \int\limits_{B_\varepsilon} \frac{1}{|x-z|^{2-\alpha}}\,dz \le c\,|\varpi|_{\alpha,\Omega}\,\varepsilon^\alpha.$$

By choosing $\varepsilon^\alpha = |\varpi|_{0,\Omega}\left(|\varpi|_{\alpha,\Omega}\right)^{-1}$, we deduce that

$$|k_2| \le c\,|\varpi|_{0,\Omega}\left(1+\left|\ln\left(2+|\varpi|_{0,\Omega}^{-1}\,|\varpi|_{\alpha,\Omega}\,d(\Omega)\right)\right|\right). \tag{3.16}$$

By Lemma 3.1, we also have

$$|k_2|_\alpha \le c\,|\varpi|_{\alpha,\Omega} \ln\left(2+\delta d(\Omega)\right). \tag{3.17}$$

Combining (3.15)–(3.17), one sees that $|k_1+k_2+k_3|_0$ is bounded by the left-hand side of (3.12) and that $\|k_1+k_2+k_3\|_\alpha$ is bounded by the left-hand side of (3.13). The assertions thus follow from the fact that $\nabla^2 S$ is smooth in R^2 and that $\nabla^2 S$ decays at the rate r^{-2} as $r\to\infty$.

THEOREM 3.5. *Suppose that the initial data satisfy* (2.1). *Then there exists a unique* $C^{1+\alpha}(\Omega_0)$ *solution* $\Phi(x,t)$ *of* (2.11) *for* $t<T$ *for some* $T>0$.

Proof. For simplicity, we assume that there exists $\varphi_0 \in C^{1+\alpha}$ with $|\nabla\varphi_0|_{\inf,\partial\Omega_0} \neq 0$ such that $\Omega_0 = \{\varphi_0(x)<0\}$. For any $M,T>0$ to be chosen later on, we define a set $W(M,T)$ of vector value functions in $\bar\Omega_0\times[0,T)$ as follows:

$$\begin{aligned} W(M,T) = \{&\Phi(x,t)\in R^2 :\ \Phi(x,0)=x,\\ &\|\Phi(t)\|_{1+\alpha,\Omega_0}\le M,\ \|\Phi(x)\|_{\alpha,[0,T)}\le M,\ \ |\nabla\Phi - I|_0 \le 1/2\}. \end{aligned}$$

Since $|\nabla\Phi - I|\le 1/2$, $\Phi^{-1}(\cdot,t)$ exists and maps Ω_t onto Ω_0 so that the mapping A defined in (3.1) is well defined for any $\Phi\in W(M,T)$. By applying Lemma 3.4 to $A(\Phi)$ with

$$\varpi = \left(J(\Phi)^{-1}\,\omega_0\right)\left(\Phi^{-1}(x,s),s\right), \tag{3.18}$$

we find that

$$\begin{aligned} \|A(\Phi)\|_{1+\alpha,\Omega_0} \le c_0 + c\int\limits_0^t &\left(\|\Phi\|_{1+\alpha,\Omega_0}\right)^{1+\alpha}\left(1+\delta_s\,|\varpi|_{0,\Omega_s}+\|\varpi\|_{\alpha,\Omega_s}\right)\\ &\cdot\left(\ln\left(2+d(\Omega_s)\,\delta_s\right)+\ln\left(2+|\varpi|_{0,\Omega}^{-1}\,\|\varpi\|_{\alpha,\Omega_s}\,d(\Omega_s)\right)\right)ds, \end{aligned} \tag{3.19}$$

where c is a constant independent of Φ, $c_0=\sup_{x\in\Omega_0}|x|$, δ_t is defined in terms of Ω_t by

$$\delta_t = \frac{|\nabla\varphi(x,t)|_{\alpha,\partial\Omega_t}}{|\nabla\varphi(x,t)|_{\inf,\partial\Omega_t}} = \frac{\left|\nabla\varphi_0\left(\Phi^{-1}(x,t)\right)\nabla\Phi^{-1}(x,t)\right|_{\alpha,\partial\Omega_t}}{|\nabla\varphi_0\left(\Phi^{-1}(x,t)\right)\nabla\Phi^{-1}(x,t)|_{\inf,\partial\Omega_t}}, \tag{3.20}$$

since $\Omega_t = \{\varphi(x,t) < 0\}$, where $\varphi(x,t) = \varphi_0\left(\Phi^{-1}(x,t)\right)$. Notice that, by direct calculation,

$$\left|\nabla\Phi^{-1}\right|_{\alpha,\Omega_t} \le |\nabla\Phi|_{\alpha,\Omega_0}\left(\left|\nabla\Phi^{-1}\right|_{0,\Omega_t}\right)^{2+\alpha},$$
$$\left\|J(\Phi)^{-1}\right\|_{\alpha,\Omega_t} \le c_0\left(|\nabla\Phi|_{\alpha,\Omega_0}+1\right)\left(\left|\nabla\Phi^{-1}\right|_{0,\Omega_t}+1\right)^{3+\alpha},$$

where c_0 is a universal constant. Since $\Phi \in W(M,T)$, it is easy to see that

$$\delta_t \le c(M), \quad d(\Omega_t) \le 2|\Phi|_0 \le 2M, \quad \|\varpi\|_{\alpha,\Omega_t} \le c(M),$$

where the last inequality is due to (3.18), and the constant $c(M)$ is a polynomial of M with coefficients depending only on initial data. Hence (3.19) results in, for $t < T$,

$$\|A(\Phi)(t)\|_{1+\alpha,\Omega_0} \le c_0 + c(M)T.$$

It is easy to derive the following estimates:

$$\|A(\Phi)(x,\cdot)\|_{\alpha} \le c(M)T^{1-\alpha}$$

and

$$|\nabla(A(\Phi)) - I| \le c(M)T.$$

We now choose $M = 1+c_0$ and $T = \min\left((2C(M))^{-1}, (1+c_0)^{1/(1-\alpha)} C(M)^{-1/(1-\alpha)}\right)$. Then $A(\Phi) \in W(M,T)$. The mapping A maps $W(M,T)$ into itself.

For any $\Phi,\ \tilde{\Phi} \in W(M,T)$. Set $\Omega_t = \Phi(\Omega_0,t)$, $\tilde{\Omega}_t = \tilde{\Phi}(\Omega_0,t)$ and define

$$\rho(t) = \left|\Phi(t) - \tilde{\Phi}(t)\right|_{0,\Omega_0}.$$

By changing variables in the expressions for $A(\Phi)$ and $A\left(\tilde{\Phi}\right)$, we obtain, from (3.1),

$$A(\Phi)(x,t) = x + \int_0^t \int_{\Omega_0} \nabla K(\Phi(x,s) - \Phi(z,s))\,\omega_0(z)\,dzds,$$
$$A\left(\tilde{\Phi}\right)(x,t) = x + \int_0^t \int_{\Omega_0} \nabla K\left(\tilde{\Phi}(x,s) - \tilde{\Phi}(z,s)\right)\omega_0(z)\,dzds.$$

It follows that

$$\left|A(\Phi)(x,t) - A\left(\tilde{\Phi}\right)(x,t)\right|$$
$$\le c\int_0^t \int_{\Omega_0} \left|\nabla K(\Phi(x,s) - \Phi(z,s)) - \nabla K\left(\tilde{\Phi}(x,s) - \tilde{\Phi}(z,s)\right)\right| dzds. \tag{3.21}$$

For $\varepsilon > 0$ to be determined later, we decompose the right-hand side of (3.21) as

$$\int_{\Omega_0} \left|\nabla K(\Phi(x,s) - \Phi(z,s)) - \nabla K\left(\tilde{\Phi}(x,s) - \tilde{\Phi}(z,s)\right)\right| dz \tag{3.22}$$
$$= \int_{\Omega_0\setminus B_\varepsilon(x)} + \int_{\Omega_0\cap B_\varepsilon(x)} = k_1 + k_2.$$

From (2.8),

$$\nabla K(z) = -\frac{z}{2\pi |z|^2} + S'(|z|)\frac{z}{2\pi |z|}.$$

Since $\nabla\Phi^{-1}$ and $\nabla\tilde{\Phi}^{-1}$ are bounded, we have

$$|\Phi(x,s) - \Phi(z,s)|, \qquad \left|\tilde{\Phi}(x,s) - \tilde{\Phi}(z,s)\right| \geq c|x-z|.$$

Therefore,

$$\begin{aligned}&\left|\nabla K(\Phi(x,s) - \Phi(z,s)) - \nabla K\left(\tilde{\Phi}(x,s) - \tilde{\Phi}(z,s)\right)\right| \\ &\qquad \leq c\rho(s)\left(1 + \frac{1}{|x-z|} + \frac{1}{|x-z|^2}\right).\end{aligned}$$

Consequently, k_1 in (3.22) is bounded by

$$|k_1| \leq c\rho(s)\int_{\varepsilon}^{d(\Omega_0)}\left(r + 1 + \frac{1}{r}\right)dr = c\rho(s)(1 + |\ln\varepsilon|). \tag{3.23}$$

Since $|\Phi(x,s) - \Phi(z,s)| \leq c\varepsilon$ for $|x-z| \leq \varepsilon$, we know that

$$S'(|\Phi(x,s) - \Phi(z,s)|) \leq c\varepsilon \quad \text{for} \quad |x-z| \leq \varepsilon.$$

It follows from the obvious estimates

$$\begin{aligned}|\nabla K(\Phi(x,t) - \Phi(z,t))| &\leq |\Phi(x,t) - \Phi(z,t)|^{-1} + S'(|\Phi(x,s) - \Phi(z,s)|) \\ &\leq c\left(1 + |x-z|^{-1}\right)\end{aligned}$$

and

$$\begin{aligned}\left|\nabla K\left(\tilde{\Phi}(x,s) - \tilde{\Phi}(z,s)\right)\right| &\leq \left|\tilde{\Phi}(x,s) - \tilde{\Phi}(z,s)\right|^{-1} + S'(|\Phi(x,s) - \Phi(z,s)|) \\ &\leq c\left(1 + |x-z|^{-1}\right)\end{aligned}$$

that the term k_2 in (3.22) can be estimated as

$$|k_2| \leq c\int_0^{\varepsilon}\left(1 + \frac{1}{r}\right)r\,dr \leq c\left(\varepsilon + \varepsilon^2\right). \tag{3.24}$$

We now choose $\varepsilon = \min(\rho(t), 1)$. From (3.21)–(3.24), it follows that

$$\left|A(\Phi)(x,t) - A\left(\tilde{\Phi}\right)(x,t)\right| \leq c\int_0^t \rho(t)(1 + |\ln\rho(t)|)\,dt. \tag{3.25}$$

Define a sequence $\Phi_n(x,t)$ by

$$\Phi_0 = x, \qquad \Phi_{n+1}(x,t) = A(\Phi_n)(x,t).$$

Since $\Phi_n \in W(M,T)$, this sequence $\{\Phi_n\}$ is precompact under the $C_{x,t}^{1+\gamma,\gamma}$ norm for any $\gamma < \alpha$. Hence we can select a subsequence, still denoting it as $\{\Phi_n\}$, and a function $\Phi \in C_{x,t}^{1+\gamma,\gamma}(\Omega_0 \times [0,T))$ such that

$$\Phi_n \longrightarrow \Phi \text{ in } C_{x,t}^{1+\gamma,\gamma}\text{norm}.$$

This implies that $\Phi \in W(M,T)$ (by checking from the definitions) and by (3.25),

$$\begin{aligned}|\Phi_{n+1}(x,t) - A(\Phi)(x,t)| &= |A(\Phi_n)(x,t) - A(\Phi)(x,t)| \\ &\le cT \sup_{0\le t\le T}\left(|\Phi_n(t) - \Phi(t)|_{0,\Omega_0}\left|\ln|\Phi_n(t) - \Phi(t)|_{0,\Omega_0}\right|\right).\end{aligned}$$

Letting $n \to \infty$, we find that Φ is a fixed point for A, i.e., $A(\Phi) = \Phi$. Next, set

$$\rho_n(t) = \sup_x |\Phi_n(x,t) - \Phi(x,t)|.$$

It follows from (3.25) that

$$\rho_{n+1}(t) \le c\int_0^t \rho_n(t)\left(1 + |\ln\rho_n(t)|\right)\,dt.$$

By [9, section 9], it follows that

$$\rho_n(t) \le c\,|T\ln T|^n.$$

For small T, the above inequality implies uniqueness of the fixed point. The proof is complete.

Using exactly the same argument, we can extend the assertions of Theorem 3.5 to the equation (2.11) with more general initial data:

$$\frac{d\Phi(x,t)}{dt} = -\int_{\Phi\left(\bar\Omega_0,t\right)} \nabla K(\Phi(x,t) - y)\left(J(\Phi)^{-1}\varpi_0\right)\left(\Phi^{-1}(y,t)\right)\,dy, \tag{3.26}$$

$$\Phi(x,0) = \Phi_0(x) \quad \text{for } x \in \bar\Omega_0.$$

COROLLARY 3.6. *In addition to the assumptions in Theorem* 3.5*, suppose also that* $\Phi_0 \in C^{1+\alpha}(\Omega_0)$, $J(\Phi_0) \ne 0$. *Then there exists a unique* $C^{1+\alpha}(\Omega_0)$ *solution* $\Phi(x,t)$ *for* (3.26) *for* $t < T$ *for some* $T > 0$. *Moreover,* T *depends only on* $\|\Phi_0\|_{1+\alpha}$, $\left\|\Phi_0^{-1}\right\|_{1+\alpha}, d(\Omega_0)$ *and* δ_0.

Corollary 3.6 will be used in the next section to extend the solutions for large time.

4. A priori estimates. From Corollary 3.6, it appears that a priori estimates on the $C^{1+\alpha}$ norms of Φ and Φ^{-1} will be sufficient to establish existence of global solutions. We first show that, actually, a uniform bound on the vorticity ω will be enough to guarantee that the solution can be extended for all $t > 0$.

LEMMA 4.1. *Suppose that* $\Phi(x,t)$ *is the* $C^{1+\alpha}$ *solution. Then, for* $x \in \bar\Omega_0$,

$$\omega(\Phi(x,t),t) = \frac{\omega_0(x)\,e^{\sigma(x,t)}}{1 + \omega_0(x)\int_0^t e^{\sigma(x,s)}ds}, \tag{4.1}$$

where

$$\sigma(x,t) = \int_0^t H(\Phi(x,s),s)\, ds. \tag{4.2}$$

Proof. From (2.4), (1.3), (1.4), and the fact that $\omega(\Phi(x,t),t) > 0$ for $x \in \bar{\Omega}_0$, one sees that $\omega(\Phi(x,t),t)$ is the solution of the following ODE:

$$\frac{d\omega}{dt} = \omega H - \omega^2. \tag{4.3}$$

Let $p(t) = \omega(\Phi(x,t),t)^{-1}$. Then p solves

$$\frac{dp}{dt} = -pH + 1.$$

Integrating this ODE directly, we obtain (4.1).

LEMMA 4.2. *Let $\Phi(x,t)$ be the $C^{1+\alpha}$ solution for $t < T$. Suppose that*

$$\eta(T) \equiv \int_0^T \|\varpi(t)\|_{0,\Omega_t}\, dt < \infty. \tag{4.4}$$

Then there exists a $0 < \beta(T) \le \alpha$ depending only on $\eta(T)$ such that for $t < T$,

$$\|\varpi(t)\|_{\beta,\Omega_t} \le c(\eta(T)), \tag{4.5}$$

$c(\eta(T))$ being a constant depending only on $\eta(T)$ and T.

Proof. From Lemma 3.4, we know that $u = -\nabla H$ is Lipschitz in Ω_t. However, the Lipschitz constant may depend on the C^α characters of ω and the domain Ω_t. We claim that ∇H is quasi-Lipschitz, with the constant depending only on $\|\varpi(t)\|_{0,\Omega_t}$, i.e., for $x, y \in \bar{\Omega}_t, |x-y| \le 1/2$,

$$|\nabla H(x,t) - \nabla H(y,t)| \le c\|\varpi(t)\|_{0,\Omega_t} |x-y| (1 + |\ln|x-y||), \tag{4.6}$$

where c is a universal constant. We point out at this moment that c in general also depends on the $L^1(\bar{\Omega}_t)$ norm of $\varpi(\cdot,t)$. However, by (2.7), our previous claim remains true.

Indeed, from (2.8) and (2.9), we have

$$\begin{aligned}\nabla H(x,t) &= \frac{1}{2\pi}\int_{\Omega_t} \frac{x-z}{|x-z|^2}\varpi(z,t)\, dz + \int_{\Omega_t} \nabla_x S(|x-z|)\varpi(z,t)\, dz \\ &= \nabla H_1(x,t) + \nabla H_2(x,t).\end{aligned}$$

The results in [10] lead to

$$|\nabla H_1(x,t) - \nabla H_1(y,t)| \le c\|\varpi(t)\|_{0,\Omega_t} |x-y| (1 + |\ln|x-y||).$$

Since ∇S is smooth and $S'(r) \sim r^{-1}$ for large r, the inequality (4.6) thus follows immediately.

Now, since

$$\frac{d\Phi}{dt} = -\nabla H\left(\Phi, t\right),$$

it follows that the quantity $\rho\left(t\right) = \left|\Phi\left(x,t\right) - \Phi\left(y,t\right)\right|^2$, for $x \neq y \in \bar{\Omega}_t$, satisfies

$$\left|\frac{d\rho\left(t\right)}{dt}\right| \leq c\left\|\varpi\left(t\right)\right\|_{0,\Omega_t} \rho\left(t\right)\left(1 + \left|\ln \rho\left(t\right)\right|\right).$$

By the Gronwall lemma, we deduce that

$$c\left|x-y\right|^{1/\tilde{\beta}(t)} \leq \rho\left(t\right) = \left|\Phi\left(x,t\right) - \Phi\left(y,t\right)\right| \leq c\left|x-y\right|^{\tilde{\beta}(t)}, \tag{4.7}$$

where $\tilde{\beta}\left(t\right) = \exp\left(-c\eta\left(t\right)\right)$ is decreasing in t. The inequality (4.7) implies

$$\left|\Phi\left(t\right)\right|_{\tilde{\beta}(t),\Omega_0} + \left|\Phi^{-1}\left(t\right)\right|_{\tilde{\beta}(t),\Omega_t} \leq c.$$

By the regularity theory for elliptic partial differential equations (PDEs), we know that the solution H of (1.3) is of the class C^1 and

$$\left\|\nabla H\left(t\right)\right\|_0 \leq c\left\|\varpi\left(t\right)\right\|_{0,\Omega_t}. \tag{4.8}$$

Hence, the function $\sigma\left(x,t\right)$ defined in (4.2) is of the class C^{β} and

$$\left|\sigma\left(t\right)\right|_{\tilde{\beta}(t),\Omega_0} \leq \int_0^t \left\|\nabla H\left(s\right)\right\|_0 \left|\Phi\left(s\right)\right|_{\tilde{\beta}(s),\Omega_0} ds \leq c\eta\left(t\right),$$

for $t < T$. The bounds on $\left|\sigma\left(t\right)\right|_{0,\Omega_0}$ can be easily derived from (4.2). Choose $\beta\left(T\right) = \min(\tilde{\beta}\left(T\right)^2, \alpha)$. It then easy to see that the assertion (4.5) hence follows from (4.1).

LEMMA 4.3. *Under the assumptions of Lemma* 4.1*, we have*

$$\left|\nabla\left(\Phi\left(\Phi^{-1}\left(x,t\right),s\right)\right)\right| \leq \exp\left(\int_s^t \left|\nabla u\left(\tau\right)\right|_0 d\tau\right),$$

for $0 < s < t$*, and*

$$\left|\nabla\varphi\left(t\right)\right|_{\inf,\partial\Omega_t} \geq \left|\nabla\varphi\left(0\right)\right|_{\inf,\partial\Omega_0} \exp\left(-\int_0^t \left|\nabla u\left(\tau\right)\right|_0 d\tau\right).$$

Proof. The first inequality follows from the dynamical property of (2.3). Since $\varphi\left(\Phi\left(x,t\right),t\right) = \varphi_0\left(x\right)$, we have

$$\nabla\varphi\left(\Phi\left(x,t\right),t\right) = \left(\left(\nabla\Phi\left(x,t\right)\right)^T\right)^{-1} \nabla\varphi_0\left(x\right).$$

By (2.3), we have

$$\frac{d}{dt}\left(\nabla\Phi\left(x,t\right)\right)^{-1} = -\left(\nabla\Phi\left(x,t\right)\right)^{-1} \nabla u\left(\Phi\left(x,t\right),t\right) = \left(\nabla\Phi\left(x,t\right)\right)^{-1} \nabla^2 H\left(\Phi\left(x,t\right),t\right).$$

Hence,

$$\frac{d}{dt}\nabla\varphi\left(\Phi\left(x,t\right),t\right)=\left(\nabla^{2}H\right)^{T}\nabla\varphi\left(\Phi\left(x,t\right),t\right).$$

The second assertion of Lemma 4.3 follows from the Gronwall lemma.

LEMMA 4.4. *Under the assumptions of Lemma* 4.1*, we have*

$$\delta_{t,\beta}\leq c\left(\eta\left(T\right)\right),$$

where $\delta_{t,\beta}$ *is defined in* (3.20) *with* α *being replaced with* $\beta=\beta\left(T\right)$.

Proof. We recall that by definition, $\Omega_t=\{\varphi<0\}$ with $\varphi=\varphi_0\left(\Phi^{-1}\left(x,t\right)\right)$. Since Φ solves (2.3), we find that φ satisfies

$$\frac{\partial\varphi}{\partial t}+u\cdot\nabla\varphi=0,\qquad u=-\nabla H.$$

Hence $\nabla\varphi$ satisfies

$$\frac{\partial\nabla\varphi}{\partial t}+\left(u\cdot\nabla\right)\nabla\varphi=-\left(\nabla u\right)^{\top}\nabla\varphi. \tag{4.9}$$

Since $\nabla\cdot u=-\Delta H=H-\omega$, this equation can be rewritten as

$$\frac{\partial\nabla^{\perp}\varphi}{\partial t}+\left(u\cdot\nabla\right)\nabla^{\perp}\varphi=\nabla u\nabla^{\perp}\varphi+\left(\omega-H\right)\nabla^{\perp}\varphi, \tag{4.10}$$

where $\nabla^{\perp}\varphi=\left(-D_2\varphi,D_1\varphi\right)$ is divergence free and tangential to $\partial\Omega_t$. By (3.14), we have

$$\begin{aligned}\nabla u&=-\nabla^{2}H\left(x,t\right)\\&=-\frac{1}{2\pi}\int\limits_{\Omega_t}\nabla\left(\frac{x-z}{\left|x-z\right|^{2}}\right)dz\omega\left(x,t\right)\\&\quad-\frac{1}{2\pi}\int\limits_{\Omega_t}\nabla\left(\frac{x-z}{\left|x-z\right|^{2}}\right)\left(\omega\left(z,t\right)-\omega\left(x,t\right)\right)dz\\&\quad-\frac{1}{2\pi}\omega\left(x,t\right)-\int\limits_{\Omega_t}\nabla^{2}S\left(\left|x-z\right|\right)\omega\left(z,t\right)\,dz=k_1+k_2+k_3+k_4.\end{aligned}$$

Since $\nabla^{\perp}\varphi$ is divergence free and tangential to $\partial\Omega_t$, we find by direct computation that

$$k_1\nabla^{\perp}\varphi=\int\limits_{\Omega_t}\nabla\left(\frac{x-z}{\left|x-z\right|^{2}}\right)\left(\nabla^{\perp}\varphi\left(x,t\right)-\nabla^{\perp}\varphi\left(z,t\right)\right)dz\omega\left(x,t\right).$$

Consequently we deduce that, by Lemma 3.1, for $t\leq T$,

$$\begin{aligned}\left\|k_1\nabla^{\perp}\varphi\left(t\right)\right\|_{\beta}&\leq c\left(\left|\omega\left(t\right)\right|_{\beta}\left|\nabla^{\perp}\varphi\left(t\right)\right|_{0}+\left|\omega\right|_{0}\left|\nabla^{\perp}\varphi\left(t\right)\right|_{\beta}\right)\\&\quad\cdot\left(\ln\left(2+\left|\omega\right|_{0}^{-1}\left|\omega\left(t\right)\right|_{\beta}d\left(\Omega_t\right)\right)+\ln\left(2+d\left(\Omega_t\right)\delta_{t,\beta}\right)\right),\end{aligned}$$

where $\beta = \beta(T)$ obtained in Lemma 4.2. In a similar manner, we have

$$\begin{aligned}\left\|k_2\nabla^{\perp}\varphi(t)\right\|_{\beta} \le c\Big(&|\omega(t)|_{\beta}\left|\nabla^{\perp}\varphi(t)\right|_0 + |\omega|_0\left|\nabla^{\perp}\varphi(t)\right|_{\beta}\Big)\\ &\cdot\Big(\ln\Big(2+|\omega|_0^{-1}|\omega(t)|_{\beta}\,d(\Omega_t)\Big)+\ln\left(2+d(\Omega_t)\,\delta_{t,\beta}\right)\Big).\end{aligned}$$

Since $\nabla^2 S$ is smooth, it then follows that

$$\begin{aligned}\left\|\nabla u\nabla^{\perp}\varphi(t)\right\|_{\beta} \le{}& c(\eta(T))\left\|\nabla^{\perp}\varphi(t)\right\|_{\beta}\\ &\cdot\Big(\ln\Big(2+|\omega|_0^{-1}|\omega(t)|_{\beta}\,d(\Omega_t)\Big)+\ln\left(2+d(\Omega_t)\,\delta_{t,\beta}\right)\Big),\end{aligned}$$

where we have used the assertion of Lemma 4.2. Since $\partial\Phi/\partial t = -\nabla H(\Phi,t)$, from (4.5) and (4.8), it is clear that $d(\Omega_t) \le 2|\Phi|_0 \le c(\eta(T))$. Hence

$$\left\|\nabla u\nabla^{\perp}\varphi(t)\right\|_{\beta} \le c(\eta(T))\left\|\nabla^{\perp}\varphi(t)\right\|_{\beta}\ln\left(2+\delta_{t,\beta}\right). \tag{4.11}$$

Next, from (4.10), we have for $x \in \Omega_t$,

$$\begin{aligned}\nabla^{\perp}\varphi(x,t) = {}&\nabla^{\perp}\varphi_0\left(\Phi^{-1}(x,t)\right)+\int_0^t\left(\nabla u\nabla^{\perp}\varphi\right)\left(\Phi\left(\Phi^{-1}(x,t),s\right),s\right)ds\\ &+\int_0^t\left((\omega-H)\nabla^{\perp}\varphi\right)\left(\Phi\left(\Phi^{-1}(x,t),s\right),s\right)ds.\end{aligned}$$

Therefore, by using Lemma 4.3, we find

$$\begin{aligned}\left|\nabla^{\perp}\varphi(t)\right|_{\beta} \le{}&\left|\nabla^{\perp}\varphi_0\right|_{\beta}\exp\left(\int_0^t|\nabla u(\tau)|_0\,d\tau\right)\\ &+c\int_0^t\left(\left|\nabla u\nabla^{\perp}\varphi(s)\right|_{\beta}\right)\exp\left(\int_s^t|\nabla u(\tau)|_0\,d\tau\right)ds\\ &+c\int_0^t\left(\left|(\omega-H)\nabla^{\perp}\varphi(s)\right|_{\beta}\right)\exp\left(\int_s^t|\nabla u(\tau)|_0\,d\tau\right)ds.\end{aligned} \tag{4.12}$$

It follows from (4.11) and (4.8) that

$$\begin{aligned}\left\|\nabla^{\perp}\varphi(t)\right\|_{\beta}\exp\left(-\int_0^t|\nabla u(\tau)|_0\,d\tau\right) \le{}&\left\|\nabla^{\perp}\varphi_0(t)\right\|_{\beta}\\ &+c(\eta(T))\int_0^t\left\|\nabla\varphi(s)\right\|_{\beta}\cdot\ln\left(2+\delta_{t,\beta}\right)\exp\left(-\int_0^s|\nabla u(\tau)|_0\,d\tau\right).\end{aligned} \tag{4.13}$$

Set

$$f(t) = \left\|\varphi(t)\right\|_{1+\beta}\exp\left(-\int_0^t|\nabla u(\tau)|_0\,d\tau\right)+2.$$

Using the second assertion in Lemma 4.3, we obtain

$$\delta_{t,\beta} \leq \frac{|\nabla\varphi(t)|_\beta}{|\nabla\varphi(0)|_{\inf,\partial\Omega_0}} \exp\left(\int_0^t |\nabla u(\tau)|_0 \, d\tau\right).$$

Therefore

$$\ln(2+\delta_{t,\beta}) \leq c\ln f + \int_0^t |\nabla u(\tau)|_0 \, d\tau.$$

It follows from (4.13) that

$$f(t) \leq c + c(\eta(T)) \int_0^t f(s) \left(\ln f(s) + \int_0^s |\nabla u(\tau)|_0 \, d\tau\right) ds.$$

Denote by $h(t)$ the function on the right-hand side of the above inequality:

$$h(t) = c + c(\eta(T)) \int_0^t f(s) \left(\ln f(s) + \int_0^s |\nabla u(\tau)|_0 \, d\tau\right) ds.$$

Then

$$h'(t) \leq c(\eta(T)) h(t) \left(\ln h(t) + \int_0^t |\nabla u(\tau)|_0 \, d\tau\right).$$

It follows that

$$\frac{d}{dt}\ln h(t) \leq c(\eta(T)) \left(\ln h(t) + \int_0^t |\nabla u(\tau)|_0 \, d\tau\right).$$

By the standard Gronwall inequality, we obtain

$$\begin{aligned}
\ln f \leq \ln h(t) &\leq ce^{c(\eta(T))} \left(1 + \int_0^t c(\eta(T)) \int_0^s |\nabla u(\tau)|_0 \, d\tau \, ds\right) \\
&\leq ce^{c(\eta(T))} \left(1 + \int_0^t c(\eta(T)) \, ds \int_0^t |\nabla u(\tau)|_0 \, d\tau\right) \qquad (4.14) \\
&\leq c(\eta(T)) \left(1 + \int_0^t |\nabla u(\tau)|_0 \, d\tau\right),
\end{aligned}$$

where in the last inequality, $c(\eta(T))$ is a constant depending only on $\eta(T)$ and T. By Lemmas 3.4 and 4.2 and equation (4.13) we deduce

$$\int_0^t |\nabla u(s)|_{0,\Omega_s} \, ds = \int_0^t \left|\nabla^2 H(s)\right|_{0,\Omega_s} ds$$

$$\leq c\int_0^t \left(\ln f + \int_0^s |\nabla u(\tau)|_0 \, d\tau\right) ds \tag{4.15}$$

$$\leq c(\eta(T)) + c(\eta(T)) \int_0^t \left(\int_0^s |\nabla u(\tau)|_0 \, d\tau\right) ds.$$

It follows that

$$\int_0^t |\nabla u(\tau)|_0 \, d\tau \leq c(\eta(T)), \quad \text{for } t < T.$$

Substituting this into (4.14), we find $\|\nabla\varphi(t)\|_{\beta(T)}$ is bounded uniformly. Therefore, $\delta_{t,\beta}$ is bounded by a constant depending on $\eta(T)$ and T for $t \leq T$. The proof of Lemma 4.4 is complete.

THEOREM 4.5. *Suppose that the assumptions in Lemma* 4.2 *hold. Then there exists a unique* $C^{1+\alpha}(\Omega_0)$ *solution* $\Phi(x,t)$ *of* (2.11) *for* $t < T + T_0$ *for some* $T_0 > 0$ *depending only on* $\eta(T)$.

Proof. By Corollary 3.6, it suffices to show that $\|\nabla\Phi(t)\|_{\alpha,\Omega_0}$ and $\left\|\nabla\Phi^{-1}(t)\right\|_{\alpha,\Omega_t}$ are uniformly bounded by $c(\eta(T))$. Recall that by differentiating (2.3), $\nabla\Phi(x,t)$ satisfies

$$\frac{\partial\nabla\Phi(x,t)}{\partial t} = \nabla u(\Phi(x,t),t)\nabla\Phi(x,t) = -\nabla^2 H(\Phi(x,t),t)\nabla\Phi(x,t).$$

Applying Lemma 3.4 (estimate (3.12)) with $\alpha = \beta(T)$, and using Lemma 4.2 and 4.4, we deduce

$$\left|\nabla^2 H(\Phi(x,t),t)\right| \leq c(\eta(T)).$$

Therefore,

$$\left|\frac{\partial|\nabla\Phi(t)|_{0,\Omega_0}}{\partial t}\right| \leq c(\eta(T))|\nabla\Phi(t)|_{0,\Omega_0}.$$

It follows that

$$ce^{-c(\eta(T))} \leq |\nabla\Phi(t)|_{0,\Omega_0} \leq ce^{c(\eta(T))}. \tag{4.16}$$

Since, recalling definitions,

$$\omega(x,t) = \left(J(\Phi)^{-1}\omega_0\right)\left(\Phi^{-1}(x,t)\right), \qquad \varphi(x,t) = \varphi_0\left(\Phi^{-1}(x,t)\right),$$

it follows that

$$\delta_{t,\alpha} + \|\omega(t)\|_{\alpha,\Omega_t} + d(\Omega_t) \leq c(\eta(T))\|\Phi(t)\|_{1+\alpha,\Omega_0}.$$

By (3.19), since $A(\Phi) = \Phi$, we obtain

$$\|\Phi(t)\|_{1+\alpha,\Omega_0} \leq c + c(\eta(T))\int_0^t \|\omega(t)\|_{0,\Omega_t}\|\Phi(t)\|_{1+\alpha,\Omega_0}\left(1+\ln\left(1+\|\Phi\|_{1+\alpha,\Omega_0}\right)\right) dt.$$

By the Gronwall inequality, it follows that $\|\Phi(t)\|_{1+\alpha,\Omega_0} \leq c(\eta(t))$ for $t < T$. Combining this estimate and (4.16), we also obtain $\left\|\Phi^{-1}(t)\right\|_{1+\alpha,\Omega_0} \leq c(\eta(t))$ for $t < T$. The proof is now complete.

5. Proof of Theorem 2.2. From Theorem 4.5, it suffices to obtain an a priori estimate for $\eta(t)$ defined in (4.4). We shall use the expression (4.1) to estimate $\eta(t)$.

LEMMA 5.1. *Suppose that Φ is a $C^{1+\alpha}$ solution for $t<T$, and ω is the vorticity. Then, for $t<T$,*

$$|\omega(t)|_{0,\Omega_s} \leq \frac{|\varpi_0|_{0,\Omega_0} e^{\sigma_h(t)}}{1+|\varpi_0|_{0,\Omega_0} \int_0^t e^{\sigma_h(s)} ds}, \tag{5.1}$$

where

$$\sigma_h(t) = \int_0^t |\omega(s)|_{0,\Omega_s} \, ds.$$

Proof. By the maximum principle, we know that $H(x,t) \leq |\omega(t)|_{0,\Omega_s}$ for $t<T$. Since $\omega \geq 0$, by (4.3), we obtain that $\omega(\Phi(x,t),t)$ satisfies

$$\frac{d\omega}{dt} = \omega H - \omega^2 \leq \omega |\omega(s)|_{0,\Omega_s} - \omega^2.$$

Integrating this differential inequality as in Lemma 4.1, we derive

$$\omega(\Phi(x,t),t) \leq \frac{\varpi_0(x) e^{\sigma_h(t)}}{1+\varpi_0(x) \int_0^t e^{\sigma_h(s)} ds}.$$

Noticing that the function $x(1+cx)^{-1}$ is increasing in x (for $c>0$), the assertion follows.

Proof of Theorem 2.2. Let σ_h be the integral defined in Lemma 5.1 and

$$f(t) = \int_0^t e^{\sigma_h(s)} ds.$$

Then

$$f'(t) = e^{\sigma_h(t)}, \qquad f''(t) = e^{\sigma_h(t)} \sigma_h'(t) = |\omega(t)|_{0,\Omega_s} f'(t).$$

It follows from (5.1) that

$$f''(t) \leq \frac{|\varpi_0|_{0,\Omega_0} (f'(t))^2}{1+|\varpi_0|_{0,\Omega_0} f(t)}$$

or equivalently

$$\frac{f''(t)}{f'(t)} \leq \frac{|\varpi_0|_{0,\Omega_0} f'(t)}{1+|\varpi_0|_{0,\Omega_0} f(t)}.$$

By integration, noticing that $f(0)=0,\ f'(0)=1$, we deduce

$$f'(t) \leq 1+|\varpi_0|_{0,\Omega_0} f(t). \tag{5.2}$$

Applying the Gronwall inequality, it follows that

$$f(t) \leq \frac{\left(e^{t|\varpi_0|_{0,\Omega_0}} - 1\right)}{|\varpi_0|_{0,\Omega_0}}.$$

Combining this with (5.2), we find

$$\exp\left(\int_0^t |\omega(s)|_{0,\Omega_s}\, ds\right) = f'(t) \leq e^{t|\varpi_0|_{0,\Omega_0}}.$$

Consequently

$$\eta(t) \leq t\,|\varpi_0|_{0,\Omega_0}.$$

The assertion of Theorem 2.2 follows from Theorem 4.5.

By differentiating the equations (1.2) and (1.3) in x, we find that $\nabla\omega$ satisfies a similar system. Applying the same methods, we can also show the following regularity result.

THEOREM 5.2. *Suppose that* $\Omega_0 \in C^{m+1+\alpha}$, $\varpi_0 \in C^{m+\alpha}$. *Then the solution* Φ *of* (2.11) *is in* $C_x^{m+1+\alpha}(\Omega_0)$.

APPLICATIONS OF THE HOPF–LAX FORMULA FOR $u_t + H(u, Du) = 0$ *

E. N. BARRON†, R. JENSEN†, AND W. LIU‡

Abstract. The γ (sub)level set of the solution to $w_t + H(\gamma, D_x w) = 0$ is the same as the γ (sub)level set of the solution to $u_t + H(u, D_x u) = 0$, and the solution u may be built from w. This result is applied to determining upper and lower bounds for a solution of $u_t + H_1(u, Du) + H_2(u, Du) = 0$, with H_1 convex and H_2 concave, as well as $u_t + H(u, Du) = 0$, but with initial data $u(0, x) = g_1(x) \vee g_2(x)$ or $g_1(x) \wedge g_2(x)$, with g_1 quasi-convex and g_2 quasi-concave. A differential game in L^∞ is constructed giving a new proof of the Hopf formula.

1. Introduction.

Two papers have motivated the problems studied here. First, the paper by Bardi and Evans [1] used a representation theorem for the solution of a Hamilton–Jacobi equation as the value function of a differential game to prove the classical Hopf formula for $u_t + H(Du) = 0$ (see [17], [25]). Second, the paper by Bardi and Faggian [3] used the classical Hopf and Lax formulas to find sophisticated upper and lower bounds to some nonconvex and nonconcave problems. Specifically, they considered two problems. The first uses the Lax formula on the equation $u_t + H_1(Du) + H_2(Du) = 0$, but with arbitrary initial data, with H_1 convex and H_2 concave to get an upper and lower bound for u. The second uses the Hopf formula on the equation $u_t + H(Du) = 0$, with data $u(0, x) = g_1(x) + g_2(x)$ and g_1 convex, g_2 concave to also obtain upper and lower bounds for u. The objective of the present paper is to extend this result as much as possible to Hamiltonians which have u dependence and to quasi-convex–quasi-concave initial data.

We begin by looking at the connection between differential games in L^∞ and Hamilton–Jacobi equations (see [5]–[7]). In section 3, we use a representation due to Subbotin [26] for degree one homogeneous Hamiltonians to represent the solution of $u_t + H(u, Du) = 0$ with quasi-convex terminal data $u(T, x) = g(x)$ as the value function of a differential game in L^∞, see [6]. But we know that the solution of this problem is given by the Hopf formula from [10], [11]. Thus, it is the goal of this section to prove, using the differential game, that we recover the Hopf formula, i.e, that the value of the differential game is given by the Hopf formula. This is an extension of the idea of using optimal control in L^∞ to prove the Lax formula [9] as is done for the classical case in [1].

The following section contains the main result of this paper. For fixed $\gamma \in \mathbb{R}$, we consider the solution to $w_t + H(\gamma, Dw) = 0$ and let u be the solution of $u_t + H(u, Du) = 0$. We prove that

$$\{(t, x) : w(t, x) \leq \gamma\} = \{(t, x) : u(t, x) \leq \gamma\},$$

and $u(t,x) = \inf\{\gamma : w(t,x) \le \gamma\}$. This level set result is proved under a variety of hypotheses using the Hopf and Lax formulas of [9]–[11]. The referee has provided a proof (Theorem 4.2) under conditions which require only a comparison principle for the equation and $H(\gamma, p)$ nondecreasing in γ and homogeneous degree one in p. This level set result says that, in some sense, the equation with u in the hamiltonian is no more complicated than the equation without u—a remarkable fact.

Our level set result is of critical use in the proof of the upper and lower bound for solutions of $u_t + H_1(u, Du) + H_2(u, Du) = 0$, with $H_1(\cdot, p)$ convex and $H_2(\cdot, p)$ concave, and arbitrary initial data. The idea, which is due to Bardi and Faggian [3] and Bardi and Osher [2], is to double the variables, replace H_2 by a linear function in p, and apply the Lax formula to the resulting Hamiltonian, which is now convex again. The problem when one has u dependence is that the linear function will depend on u, creating a serious problem for carrying out the rest of the proof. But if we use the level set result, we may fix the u variable and the problem disappears. Then we use the construction of the actual solution from the level sets to obtain the upper and lower bounds in our case. The bounds are more complicated than those of Bardi and Faggian [3], but that is to be expected.

The final section seeks upper and lower bounds for solutions of $u_t + H(u, Du) = 0$, but with initial data for the upper bound $u(0,x) = g_1(x) \vee g_2(x)$, and $u(0,x) = g_1(x) \wedge g_2(x)$ for the lower bound, where g_1 is quasi-convex and g_2 is quasi-concave. In some ways this extends the result of [2] and [3] because, when $u(0,x) = g_1(x) + g_2(x)$, a lower bound can be found from the initial data $2(g_1 \wedge g_2)$ and an upper bound from $2(g_1 \vee g_2)$. The proof of this result is a straightforward adaptation of the doubling argument of [2], [3].

Of course the purpose of obtaining upper and lower bounds for equations is of obvious importance in numerical approximation of solutions.

One must take note that throughout this paper the Hamiltonians are assumed to be homogeneous degree one in the gradient variable. A device of Subbotin [26] allows one to dispense with this assumption in many cases, but as shown in [10], this will impose more severe convexity assumptions on the initial data to yield to our Hopf formula. The difficulty is that the sum of a quasi-convex function and a linear function is quasi-convex if and only if the quasi-convex function is convex. See [10] for a discussion of this.

2. Preliminary results. The following definitions are standard. See [18]-[20], [21], for the theory of quasi-convex duality.

DEFINITION 2.1. *A function $g : \mathbb{R}^n \to \mathbb{R}$ is quasi-convex if $\{x : g(x) \le \alpha\}$ is convex for all $\alpha \in R^1$. Equivalently, g is quasi-convex if $g(\lambda x + (1-\lambda)y) \le \max\{g(x), g(y)\}$ for all $x, y \in \mathbb{R}^n$, and $\lambda \in (0,1)$. g is quasi-concave if $-g$ is quasi-convex.*

The following quasi-convex and quasi-concave conjugates will be used in this paper.

Given a function $f : \mathbb{R}^n \to \mathbb{R} \cup \{\pm\infty\}$ satisfying the condition introduced in [19], $\forall \gamma < \sup_x f(x)$, there exists a continuous affine functional k, such that

$$k(x) \le f(x), \quad \forall\, x \in f^{-1}([-\infty, \gamma]). \tag{2.1}$$

Define

$$f^{\#}(\gamma, p) = \sup\{p \cdot x : x \in \mathbb{R}^n, f(x) \le \gamma\}, \qquad \gamma \in R^1,\ p \in \mathbb{R}^n, \tag{2.2}$$

$$f^{\#\#}(x) = \inf\{\gamma \in R^1 : \sup_{p \in \mathbb{R}^n} (p \cdot x - f^{\#}(\gamma, p)) \le 0\}. \tag{2.3}$$

The definition of $f^{\#}(\gamma,p)$ says that $f^{\#}$ is the support function of the γ (sub)level set of f. The function f is lower semicontinuous and quasi-convex if and only if $f=f^{\#\#}$. In general, $f^{\#\#}$ is the greatest quasi-convex minorant of f.

For quasi-concave conjugates, for $-f$ satisfying (2.1) define

$$f^{c\#}(\gamma,p)=\inf\{p\cdot x : x\in\mathbb{R}^n, f(x)\geq\gamma\}, \qquad \gamma\in R^1,\ p\in\mathbb{R}^n, \tag{2.4}$$

$$f^{c\#\#}(x)=\sup\{\gamma\in R^1 : \inf_{p\in\mathbb{R}^n}(p\cdot x-f^{c\#}(\gamma,p))\geq 0\}. \tag{2.5}$$

The function f is upper semicontinuous and quasi-concave if and only if $f=f^{c\#\#}$. In general, $f^{c\#\#}$ is the greatest quasi-concave majorant of f.

Viewing a quasi-convex function as the supremum of piecewise linear function of a particular type leads to the alternative definition of quasi-convex conjugates reminiscent of the usual Legendre–Fenchel conjugate.

$$f^{*}(\gamma,p)=\sup\{p\cdot x-f(x) : x\in\mathbb{R}^n, f(x)\leq\gamma\}, \qquad \gamma\in R^1,\ p\in\mathbb{R}^n,$$
$$f^{**}(x)=\sup\{(p\cdot x-f^{*}(\gamma,p))\wedge\gamma : \gamma\in\mathbb{R}, p\in\mathbb{R}^n\}.$$

and the quasi-concave conjugates

$$f^{c*}(\gamma,p)=\inf\{p\cdot x+f(x) : x\in\mathbb{R}^n, f(x)\geq\gamma\}, \qquad \gamma\in R^1,\ p\in\mathbb{R}^n,$$
$$f^{c**}(x)=\inf\{(p\cdot x+f^{c*}(\gamma,p))\vee\gamma : \gamma\in\mathbb{R}, p\in\mathbb{R}^n\}.$$

Again, f is lower (upper) semicontinuous and quasi-convex (quasi-concave), if and only if $f=f^{**}$ (respectively, $f=f^{c**}$).

Remark 2.1. The theory of quasi-convex duality and the conjugates defined here is due to Crouzeix, Martinez-Legaz, Penot, Volle, and others. See [14],[15],[18]–[21] and the references therein, especially [19]. Some of their results were rederived in [8] under stronger hypotheses on f, coercivity, for example. The condition (2.1) due to Martinez-Legaz [19] is the weakest possible assumption for duality, i.e., $f=f^{**}$.

In the next section we discuss the Hopf formula from [10], so in this section we record the Lax formula from [9] for the viscosity solution of $u_t+H(u,Du)=0$ on $(0,\infty)\times\mathbb{R}^n$ with initial condition $u(0,x)=g(x)$. The application of the Lax formula assumes that $\gamma\mapsto H(\gamma,p)$ is nondecreasing and upper semicontinuous, $p\mapsto H(\gamma,p)$ is convex and positively homogeneous degree one and continuous, and g is, say, Lipschitz and bounded. Then viewing $H(\gamma,p)$ as the first quasi-convex conjugate of a quasi-convex function $H^{\#}(x)$, we have

$$u(t,x)=\min_{y\in\mathbb{R}^n}\left(g(y)\vee H^{\#}\left(\frac{x-y}{t}\right)\right).$$

The formula is obviously valid for g which is merely continuous, since we may approximate by a sequence of Lipschitz and bounded functions.

3. The differential game in L^∞ and Hamilton–Jacobi equation. The problem we consider here is the *backward* Hamilton–Jacobi equation

$$u_t+H(u,Du)=0, \tag{3.1}$$

on $[0,T)\times\mathbb{R}^n$, with terminal condition

$$u(T,x)=g(x), \qquad x\in\mathbb{R}^n. \tag{3.2}$$

In this section, we study the backward problem due to the desired representation of u as the value function of a differential game for which terminal data is natural.

In [10] and [11] we proved the following theorem.

THEOREM 3.1. *Assume that*

(A) *The function $g : \mathbb{R}^n \to \mathbb{R}$ is continuous and quasi-convex and satisfies* (2.1).

(B) *The Hamiltonian function $H : R^1 \times \mathbb{R}^n \to R^1$ is continuous in both variables and*

(i) $H(\gamma, \lambda p) = \lambda H(\gamma, p)$ *for all* $\gamma \in R^1,\ \lambda \geq 0,\ p \in \mathbb{R}^n$;

(ii) $|H(\gamma, p) - H(\gamma, p')| \leq K_L|p - p'|$ *for all* $\gamma \in [-L, L],\ p, p' \in \mathbb{R}^n$;

(iii) $\gamma \mapsto H(\gamma, p)$ *is nonincreasing for* $\gamma \in R^1$.

Let

$$u(t,x) = \inf\{\gamma \in R^1 : \sup_{p\in\mathbb{R}^n} \inf_{\{y:g(y)\leq\gamma\}} (p \cdot (x-y) + (T-t)H(\gamma,p)) \leq 0\}. \tag{3.3}$$

Then u is a continuous viscosity solution of (3.1)–(3.2). *In other words, using the definition of the quasi-convex conjugates,*

$$u(t,x) = (g^{\#}(\gamma,p) - (T-t)H(\gamma,p))^{\#}(x), \tag{3.4}$$

where the # operation is performed only in x.

The fact that H is homogeneous in p allows us to assume that the solution is bounded, as the next proposition shows.

PROPOSITION 3.1. *Assume* (B) *and let g be continuous. Given $L > 0$ define*

$$\beta(r) = \begin{cases} L, & \text{if } r \geq L, \\ r, & \text{if } |r| \leq L, \\ -L, & \text{if } r \leq -L, \end{cases}$$

and set $w = \beta(u)$, where u is the viscosity solution of (3.1)–(3.2). *Then w is a bounded viscosity solution of*

$$w_t + H(w, D_x w) = 0, \quad (t,x) \in [0,T) \times \mathbb{R}^n, \quad w(T,x) = \beta(g(x)).$$

Proof. We will only prove that w is a subsolution since the proof that it is a supersolution is entirely similar.

Let $w - \varphi$ achieve a unique, zero maximum at $(t_0, x_0), t_0 < T$, with φ a smooth function. If $u(t_0, x_0) > L$, then $u > L$ in a neighborhood of (t_0, x_0) and so $w(t,x) = L$ in this neighborhood. Hence, φ achieves a minimum at (t_0, x_0) and so $\varphi_t(t_0, x_0) = |D_x\varphi(t_0, x_0)| = 0$. Since $H(\gamma, 0) = 0$, we have $\varphi_t(t_0, x_0) + H(w(t_0, x_0), D_x\varphi(t_0, x_0)) = 0$. If $u(t_0, x_0) \leq -L$, then $\varphi(t_0, x_0) \geq -L$, so again $\varphi_t(t_0, x_0) = |D_x\varphi(t_0, x_0)| = 0$. If $|u(t_0, x_0)| < L$, w is a subsolution immediately by definition of β. Finally, we are reduced to the case $u(t_0, x_0) = L$.

Suppose that β_ε is a smooth approximation to β, which is strictly monotone increasing and satisfies $\beta_\varepsilon(r) = r$ when $|r| < L$, and β_ε is linear when $|r| > L + \varepsilon$, and $\beta_\varepsilon \to \beta$ uniformly, as $\varepsilon \to 0$. Let $w_\varepsilon = \beta_\varepsilon(u)$. Then, $w_\varepsilon - \varphi_\varepsilon$ achieves a zero maximum at $(t_\varepsilon, x_\varepsilon)$, where φ_ε is at most a linear translation of φ, and $(t_\varepsilon, x_\varepsilon) \to (t_0, x_0)$ (since (t_0, x_0) is the unique maximum [4]). Also, $w_\varepsilon(t_\varepsilon, x_\varepsilon) \to w(t_0, x_0) = L$ as $\varepsilon \to 0$. But then $u - \beta_\varepsilon^{-1}(\varphi_\varepsilon)$ achieves a zero maximum at $(t_\varepsilon, x_\varepsilon)$. Since u is a subsolution, this implies

$$\frac{1}{\beta_\varepsilon'(\varphi_\varepsilon(t_\varepsilon, x_\varepsilon))}(\varphi_\varepsilon)_t(t_\varepsilon, x_\varepsilon) + H(u(t_\varepsilon, x_\varepsilon), \frac{1}{\beta_\varepsilon'(\varphi_\varepsilon(t_\varepsilon, x_\varepsilon))} D_x\varphi_\varepsilon(t_\varepsilon, x_\varepsilon)) \geq 0.$$

Now we use the homogeneity property of H and the fact that $\beta'_\varepsilon(\varphi_\varepsilon(t_\varepsilon, x_\varepsilon)) > 0$ to conclude that

$$(\varphi_\varepsilon)_t(t_\varepsilon, x_\varepsilon) + H(u(t_\varepsilon, x_\varepsilon), D_x\varphi_\varepsilon(t_\varepsilon, x_\varepsilon)) \geq 0.$$

Letting $\varepsilon \to 0$, we get

$$\varphi_t(t_0, x_0) + H(u(t_0, x_0), D_x\varphi(t_0, x_0)) = \varphi_t(t_0, x_0) + H(w(t_0, x_0), D_x\varphi(t_0, x_0)) \geq 0,$$

and so w is a subsolution of (3.1). Since $w(T, x) = \beta(g(x))$ is bounded, we are done. □

Note also that if g is quasi-convex, so is $\beta(g)$.

In this section, for the purpose of representing the solution of (3.1) as the value function of a differential game in L^∞, we will assume the following strengthened condition on g:

(C) g is uniformly Lipschitz continuous, and coercive, i.e., $\lim_{|x|\to\infty} g(x) = \infty$.

In view of the preceding proposition, without loss of generality, we may replace (B)(ii) by the following assumption:

(D) $|H(\gamma, p) - H(\gamma, p')| \leq K|p - p'|$ for all $\gamma \in R^1,\ p, p' \in \mathbb{R}^n$.

We use K to denote a generic constant greater than both of the Lipschitz constants of H and g.

Remark 3.1. Under the assumptions (A)–(D) there is a unique, bounded, Lipschitz continuous viscosity solution of (3.1)–(3.2) with Lipschitz constant no greater than K. Furthermore, (C) implies that (2.1) holds for g.

Using (A)–(D), we will represent the Hamiltonian H in a form suitable for use in a differential game in L^∞. This representation is introduced in [26].

LEMMA 3.1. *Let* (A)–(D) *hold. Then setting*

$$F(z, q) = \{f \in \mathbb{R}^n : |f| \leq K\sqrt{2} = K',\ f \cdot q \geq H(z, q)\}$$

we have

$$H(\gamma, p) = \max_{q\in B(0,K')} \min_{z\leq\gamma} \min_{f\in F(z,q)} p \cdot f, \qquad |p| \leq K'. \tag{3.5}$$

Here $B(0, K')$ is the closed ball centered at the origin with radius K'.

Proof. By (C) and (B)(iii),

$$\begin{aligned} H(\gamma, p) &\geq H(\gamma, q) - K'|p - q|, \qquad \forall q \in \mathbb{R}^n \\ &= \min_{f\in B(0,K')} H(\gamma, q) + f \cdot (p - q) \\ &= \min_{z\leq\gamma} \min_{f\in B(0,K')} H(z, q) + f \cdot (p - q). \end{aligned}$$

Hence, for $p \in B(0, K')$, we obtain

$$H(\gamma, p) = \max_{q\in B(0,K')} \min_{z\leq\gamma} \min_{f\in B(0,K')} H(z, q) + f \cdot (p - q).$$

Next, using (B)(i),

$$\begin{aligned} H(\gamma, p) = |p|H(\gamma, p/|p|) &= \max_{q\in B(0,K')} \min_{z\leq\gamma} \min_{f\in B(0,K')} H(z, q)|p| + |p|f \cdot (p/|p| - q) \\ &= \max_{q\in B(0,K')} \min_{z\leq\gamma} \min_{f\in B(0,K')} p \cdot f + |p|(H(z, q) - f \cdot q) \\ &\leq \max_{q\in B(0,K')} \min_{z\leq\gamma} \min_{f\in F(z,q)} p \cdot f. \end{aligned}$$

To prove the opposite inequality, Subbotin [26] proves that if one defines the vector

$$f_0 = \begin{cases} qH(z,q) + K'(p\cdot q\ q-p)\sqrt{1-(p\cdot q)^2}, & \text{if } 0 \le p\cdot q < 1,\\ \frac{q-p}{|q-p|}K', & \text{if } -1 \le p\cdot q < 0,\\ qH(z,q), & \text{if } p\cdot q = 1, \end{cases}$$

then f_0 satisfies $|f_0| \le K'$ and both conditions $f_0\cdot q \ge H(z,q)$, $f_0\cdot p \le H(z,p)$, $\forall p,q$. Here z is fixed and p and q may be assumed to be unit vectors by (B)(i). Hence,

$$H(\gamma,p) = \min_{z\le\gamma} H(z,p) \ge \min_{z\le\gamma}\min_{f\in F(z,q)} p\cdot f,$$

and since this is true for every $q \in B(0,K')$, we are done. □

We relabel K' as K in the following.

Remark 3.2. Evans and Souganidis [16] also have a way of representing H as a max-min. We chose this representation from [26] because it gives a particularly easy proof of Theorem 3.2 below.

Now we consider the lower differential game associated with the dynamical system

$$\frac{d\xi}{d\tau} = \varphi(\tau), \quad t < \tau \le T, \qquad \xi(t) = x \in \mathbb{R}^n \tag{3.6}$$

and payoff functional

$$P((\zeta,\varphi),\eta) = g(\xi(T)) \vee \operatorname*{ess\,sup}_{t\le s\le T} \zeta(s). \tag{3.7}$$

The minimizing controls of P are (ζ,φ), while η tries to maximize P. In the lower game, given a control choice η by the maximizing player, the minimizing player uses a nonanticipating strategy Δ, i.e.,

$$\Delta : L^\infty([t,T];B(0,K)) \to L^\infty[t,T]\times L^\infty([t,T];B(0,K)),$$

such that $\Delta[\eta](\tau) = (\zeta(\tau),\varphi(\tau))$ if and only if $\varphi(\tau)\in F(\zeta(\tau),\eta(\tau))$. We shall denote the class of all such strategies by D. Then the lower value of the differential game associated with (3.6) and payoff (3.7) is given by

$$V(t,x) = \inf_{\Delta\in D}\sup_{\eta\in B(0,K)} P((\zeta,\varphi),\eta), \quad t\in[0,T], \quad x\in\mathbb{R}^n, \quad 0\le t\le T.$$

PROPOSITION 3.2. *If* (A)–(D) *hold, then* V *is the unique uniformly Lipschitz continuous viscosity solution of* (3.1) *satisfying* (3.2).

Proof. Even though this is not quite a standard differential game due to the set valued map $F(z,q)$, and the fact that the ζ controls are not in a uniformly bounded set, the particular form of the problem allows us to apply the same argument as in [6], using dynamic programming, to prove that V is the unique viscosity solution of

$$\max\{V_t + \max_{q\in B(0,K)}\min_{z\le V}\min_{f\in F(z,q)} D_xV\cdot f, \max_q\min_{z,f} z - V\} = 0,$$

and $V(T,x) = \max_q \min_{z,f} g(x)\vee z$. Since $\min_z z = -\infty$ from (3.5) we get

$$V_t + H(V, D_xV) = 0 \quad \text{and} \quad V(T,x) = g(x).$$

See also [9] for similar details involving the optimal control problem and the Lax formula. □

THEOREM 3.2. *Assume* (A)–(D). *Then the value function* V *and the function* u *in* Theorem 3.1 *are identical.*

Proof. The function u in (3.3) is continuous on $[0,T]\times\mathbb{R}^n$ with $u(T,x) = \lim_{t\to T-0} u(t,x) = g(x)$. Furthermore, u is quasi-convex in both t and x.

We need to prove that $V(t,x) = u(t,x)$ for all $t\in[0,T]$ and $x\in\mathbb{R}^n$.

First we will show that $V\le u$. Let $t\in[0,T)$ and $x\in\mathbb{R}^n$. Fix γ such that

$$\sup_{p\in\mathbb{R}^n}\inf_{\{y:g(y)\le\gamma\}}(p\cdot(x-y)+(T-t)H(\gamma,p))\le 0. \tag{3.8}$$

We will show that $V\le\gamma$ and consequently $V\le u$.

From (3.8), we have for any control, $\gamma(\cdot)$,

$$\inf_{\{y:g(y)\le\gamma\}}(\eta(\tau)\cdot(x-y)+(T-t)H(\gamma,\eta(\tau)))\le 0,\qquad \tau\in[0,T). \tag{3.9}$$

Set $E_\gamma := \{y : g(y)\le\gamma\}$ and consider $\inf_{y\in E_\gamma}\eta(\tau)\cdot(x-y)$. Since E_γ is convex, the infimum of a linear function is either achieved (on the boundary) or $-\infty$. If the infimum is bounded from below we set $y = y(\tau)\in E_\gamma$ such that $\inf_{y\in E_\gamma}\eta(\tau)\cdot(x-y) = \eta(\tau)\cdot(x-y(\tau))$, and otherwise let $y(\tau)\in E_\gamma$ be any vector such that $\eta(\tau)\cdot(x-y(\tau))+(T-t)H(\gamma,\eta(\tau))\le 0$. Define $\varphi(\tau) = \frac{y(\tau)-x}{T-t}$. Finally, we define the strategy

$$\Delta[\eta](\tau) = (\zeta(\tau),\varphi(\tau)) \equiv (\gamma,\varphi(\tau)).$$

This strategy is obviously nonanticipating, but we must show it is admissible, i.e, we must show $H(\gamma,\eta(\tau))\le\eta(\tau)\cdot\varphi(\tau)$ for $\tau\in[0,T]$. By definition of φ we have from the definition of γ,

$$\eta(\tau)\cdot\varphi(\tau) = -\eta(\tau)\cdot\frac{x-y(\tau)}{T-t}\ge H(\gamma,\eta(\tau)),$$

and hence Δ is admissible. Then, letting $\xi(\cdot)$ denote the trajectory associated with Δ and η, we have $\xi(T) = x+\int_t^T\varphi(\tau)d\tau$, and

$$\begin{aligned}
V(t,x) &\le \sup_{\eta\in B(0,K)} g(\xi(T))\vee\gamma\\
&\le \sup_{\eta\in B(0,K)} g\left(x+\int_t^T\varphi(\tau)d\tau\right)\vee\gamma\\
&\le \sup_{\eta\in B(0,K)} g\left(\frac{1}{T-t}\int_t^T x+(T-t)\varphi(\tau)d\tau\right)\vee\gamma\\
&\le \sup_{\eta\in B(0,K)}\operatorname*{ess\,sup}_{t\le s\le T} g(x+(T-t)\varphi(s))\vee\gamma\\
&= \sup_{\eta\in B(0,K)}\operatorname*{ess\,sup}_{t\le s\le T} g(y(s))\vee\gamma\\
&= \gamma.
\end{aligned}$$

The last line follows from the fact that $g(y(s))\le\gamma$ for all $s\in[0,T]$. The next to last line follows from the extended Jensen inequality for quasi-convex functions [9],

which says that $g(\int h(s)d\mu(s)) \le \operatorname{ess\,sup}_s g(h(s))$, when g is quasi-convex and μ is a probability measure.

We conclude that $V(t,x) \le u(t,x)$.

To prove the opposite inequality we first claim that

$$V(t,x) \ge \max_{q\in B(0,K)} \min_{z} \min_{f\in F(z,q)} g(x+(T-t)f) \vee z. \tag{3.10}$$

To see that this is true, let $\varepsilon > 0$ and let $\Delta^* \in D$ be $\varepsilon-$near optimal. Then, letting $(\zeta^*, \varphi^*) = \Delta^*[\eta]$ and ξ^* the associated trajectory, we have from

$$V(t,x) = \inf_{\Delta\in D} \sup_{\eta\in B(0,K)} g(\xi(T)) \vee \operatorname*{ess\,sup}_{t\le s\le T} \zeta(s)$$

that

$$\begin{aligned} V(t,x)+\varepsilon &\ge \sup_{\eta\in B(0,K)} g(\xi^*(T)) \vee \operatorname*{ess\,sup}_{t\le s\le T} \zeta^*(s) \\ &\ge \max_{q\in B(0,K)} g(\xi(T)) \vee \operatorname*{ess\,sup}_{t\le s\le T} \zeta^*(s), \qquad \xi \text{ the outcome of } (\Delta[q],q) \\ &\ge \max_{q\in B(0,K)} \min_{z} \min_{f\in F(z,q)} g(x+(T-t)f)\vee z, \end{aligned}$$

and the claim follows. Observe that given the constant control $\eta(\tau) = q \in B(0,K)$, we have $d\xi/d\tau = \varphi(\tau)$ and $\varphi(\tau) \in F(\zeta(\tau), q)$. Using (3.10),

$$\begin{aligned} V(t,x) &= \inf_{\Delta\in D} \sup_{\eta\in B(0,K)} g(\xi(T)) \vee \operatorname*{ess\,sup}_{t\le s\le T} \zeta(s) \\ &\ge \max_{q\in B(0,K)} \min_{z} \min_{f\in F(z,q)} g(x+(T-t)f)\vee z \\ &\ge \max_{q\in B(0,K)} \min_{z} \min_{\{w: q\cdot \frac{w-x}{T-t} \ge H(z,q)\}} g(w)\vee z \\ &\ge \max_{q\in B(0,K)} \min_{z} \min_{\{w: q\cdot(x-w)+(T-t)H(z,q)\le 0\}} g(w)\vee z \\ &\equiv \alpha. \end{aligned}$$

Fix $q \in B(0,K)$ and $\varepsilon > 0$. Let z^* and w^* satisfy $\alpha+\varepsilon \ge g(w^*)\vee z^*$ and $q\cdot(x-w^*)+(T-t)H(z^*,q) \le 0$. Then $\alpha+\varepsilon \ge g(w^*)$ and $\alpha+\varepsilon \ge z^*$ imply that

$$\inf_{\{w: g(w)\le \alpha+\varepsilon\}} q\cdot(x-w)+(T-t)H(\alpha+\varepsilon,q) \le q\cdot(x-w^*)+(T-t)H(z^*,q) \le 0,$$

since $H(\gamma,p)$ is nonincreasing in γ. Since ε is arbitrary and the left side is continuous from the right in α (using the coercivity of g, [8]), by definition of $u(t,x)$ we conclude that $V(t,x) \ge \alpha \ge u(t,x)$. □

Remark 3.3. Differential games in L^∞ may also be used to gives a representation theorem for more general Hamilton–Jacobi equations, say, with t and x dependence in H, as in [16]. Once the solution of the equation is written as the value function of a differential game, one has the problem of evaluating the value function—not an easy task in general. Under the conditions assumed here, we are able to determine the value function as precisely the Hopf–Lax formula of [10]. We may view this as providing yet a new proof of the Hopf–Lax formula, but we note that the conditions assumed for the differential game are more stringent than necessary (see [11]).

4. Level sets. In the previous section it was natural to consider the terminal value problem because of the differential game formulation. In the rest of this paper we consider the forward problem on $(0,\infty)\times\mathbb{R}^n$.

The next theorem is the main result of this paper. It says that the solution of the problem $u_t + H(u,Du) = 0$ may be built by looking at solutions, say, w^γ of the problem with Hamiltonian $H^\gamma(Dw^\gamma) = H(\gamma, Dw^\gamma)$. It is remarkable that these problems have the same level sets and that the function u may be constructed from w^γ.

The theorem will apply to both hypotheses for the Hopf formula of [10] and the Lax formula of [9]. In fact, following the theorem we will see that the result holds under more general circumstances.

THEOREM 4.1. *Assume that $\gamma \mapsto H(\gamma,p)$ is nondecreasing in $\gamma \in R^1$ and $p \mapsto H(\gamma,p)$ is positively homogeneous degree one. Assume that g satisfies* (2.1).

For each $\gamma \in R^1$, let w^γ denote the viscosity solution of

$$w_t^\gamma(t,x) + H(\gamma, D_x w^\gamma(t,x)) = 0, w^\gamma(0,x) = g(x).$$

Let u denote the solution of

$$u_t(t,x) + H(u(t,x), D_x u(t,x)) = 0, \qquad u(0,x) = g(x).$$

Assume that either

(a) *g is quasi-convex and continuous and H is Lipschitz continuous; or*

(b) *g is continuous and $p \mapsto H(\gamma,p)$ is convex. Then,*

$$W^\gamma = \{(t,x) : w^\gamma(t,x) \le \gamma\} = \{(t,x) : u(t,x) \le \gamma\} = U^\gamma,$$

and hence w^γ and u have the same γ (sub)level sets. Furthermore,

$$u(t,x) = \inf\{\gamma : w^\gamma(t,x) \le \gamma\}. \tag{4.1}$$

Proof. Case (a). By the Hopf formula [10], [11] for quasi-convex data, we have

$$w^\gamma(t,x) = \inf\{\alpha : \sup_p p\cdot x - g^\#(\alpha,p) - tH(\gamma,p) \le 0\}, \tag{4.2}$$

and

$$u(t,x) = \inf\{\alpha : \sup_p p\cdot x - g^\#(\alpha,p) - tH(\alpha,p) \le 0\}. \tag{4.3}$$

Then, since $\alpha \mapsto \sup_p p\cdot x - g^\#(\alpha,p) - tH(\alpha,p)$ is nonincreasing,

$$\begin{aligned} W^\gamma &= \{(t,x) : w^\gamma(t,x) \le \gamma\} \\ &= \cup_{\alpha\le\gamma}\{(t,x) : \sup_p p\cdot x - g^\#(\alpha,p) - tH(\gamma,p) \le 0\} \\ &= \{(t,x) : \sup_p p\cdot x - g^\#(\gamma,p) - tH(\gamma,p) \le 0\} \\ &= \cup_{\alpha\le\gamma}\{(t,x) : \sup_p p\cdot x - g^\#(\alpha,p) - tH(\alpha,p) \le 0\} \\ &= \{(t,x) : u(t,x) \le \gamma\}. \end{aligned}$$

Observe that for fixed (t,x), the set $\{\gamma : w^\gamma(t,x) \le \gamma\}$ is nonempty. Indeed, if we fix $\gamma' \ge u(t,x)$, then by what we just proved $(t,x) \in U^{\gamma'} = W^{\gamma'}$, and thus $w^{\gamma'}(t,x) \le \gamma'$. So, fix (t,x) and let $\gamma \ge w^\gamma(t,x)$. Then, by (4.2), replacing α by γ, we get

$$\sup_p p \cdot x - g^{\#}(\gamma,p) - tH(\gamma,p) \le 0.$$

However, by (4.3) for u, γ is admissible and so $u(t,x) \le \gamma$. Since γ was arbitrary, $u(t,x) \le v(t,x) = \inf\{\gamma : w^\gamma(t,x) \le \gamma\}$.

Suppose that $u(t,x) \le v(t,x) - \epsilon$ for some $\epsilon > 0$. By definition of v as the smallest γ, we must have $w^{v-\epsilon} > v - \epsilon$ at (t,x). But $(t,x) \in U^{v-\epsilon} = W^{v-\epsilon}$, and this is a contradiction. Hence $u(t,x) = v(t,x)$.

Case (b). By the Lax formula [9] for convex H and continuous g, we have

$$w^\gamma(t,x) = \min_{y\in\mathbb{R}^n} g(x-ty) \vee H_\gamma^{\#}(y),$$

where

$$H_\gamma^{\#}(y) = \inf\{\alpha : \sup_p p \cdot y - H(\gamma,p) \le 0\},$$

and

$$u(t,x) = \min_{y\in\mathbb{R}^n} g(x-ty) \vee H^{\#}(y),$$

where

$$H^{\#}(y) = \inf\{\alpha : \sup_p p \cdot y - H(\alpha,p) \le 0\}.$$

However,

$$H_\gamma^{\#}(y) = \inf\{\alpha : \sup_p p \cdot y - H(\gamma,p) \le 0\} = \begin{cases} +\infty, & \text{if } \sup_p p \cdot y - H(\gamma,p) > 0, \\ -\infty, & \text{if } \sup_p p \cdot y - H(\gamma,p) \le 0. \end{cases}$$

Hence,

$$w^\gamma(t,x) = \min_{y\in\mathbb{R}^n} g(x-ty) \vee H_\gamma^{\#}(y) = \min_y \{g(x-ty) : \sup_p p \cdot y - H(\gamma,p) \le 0\}.$$

Let $(t_0,x_0) \in W^\gamma$. There is a y' such that $\sup_p p\cdot y' - H(\gamma,p) \le 0$ and $g(x_0 - t_0 y') \le \gamma$. However, $H^{\#}(y') \le \gamma$ as well, and so $g(x_0 - t_0 y') \vee H^{\#}(y') \le \gamma$. Consequently, $u(t_0,x_0) \le \gamma$ and so $(t_0,x_0) \in U^\gamma$.

Now let $(t_0,x_0) \in U^\gamma$. Then, there is a point $y' \in \mathbb{R}^n$ with $g(x_0 - t_0 y') \le \gamma$ and $H^{\#}(y') \le \gamma$. Since $H^{\#}(y') \le \gamma$, there is an $\alpha' \le \gamma$ so that $\sup_p p \cdot y' - H(\alpha', p) \le 0$. Since $\alpha \mapsto H(\alpha,p)$ is nondecreasing, we have $\sup_p p \cdot y' - H(\gamma,p) \le 0$. This implies that

$$\min_y \{g(x_0 - t_0 y) : \sup_p p \cdot y - H(\gamma,p) \le 0\} \le \gamma,$$

and therefore $(t_0,x_0) \in W^\gamma$. We have shown that $W^\gamma = U^\gamma$.

Since the proof that $u(t,x) = \inf\{\gamma : w^\gamma(t,x) \le \gamma\}$ is exactly the same as in case (a), we have completed the proof of the theorem. ∎

It was pointed out to us by the referee that the previous theorem will hold under much more general conditions than stated above. As long as a comparison principle holds for the equations, we may drop any convexity or quasi-convexity assumptions and retain only the homogenous degree one property of H. To be precise we state the following whose proof is due to the referee.

THEOREM 4.2. *Assume* (B) *and g continuous. Then the conclusions of* Theorem 4.1 *hold.*

Proof. Set $u^\gamma(t,x) = u(t,x) \vee \gamma$ and $\overline{w}^\gamma(t,x) = w^\gamma(t,x) \vee \gamma$. Using the same argument as in Proposition 3.1, by the fact that $H(\gamma,p)$ is nondecreasing in γ and homogeneous degree one in p, it is not hard to see that u^γ is a subsolution and $\overline{w}^\gamma$ is a solution of

$$\vartheta_t + H(\gamma, D_x\vartheta) = 0, \qquad \vartheta(0,x) = g(x) \vee \gamma.$$

By comparison (see [4], [12], [13]), we conclude that $u^\gamma(t,x) \le \overline{w}^\gamma(t,x)$ everywhere. Consequently, $\{\overline{w}^\gamma = \gamma\} \subset \{u^\gamma \le \gamma\}$. However,

$$\{w^\gamma \le \gamma\} = \{\overline{w}^\gamma = \gamma\} \subset \{u^\gamma \le \gamma\} = \{u \le \gamma\}.$$

For the opposite inclusion we now define $u^\gamma(t,x) = u(t,x) \wedge (\gamma + \varepsilon)$ and $\overline{w}^\gamma(t,x) = w^\gamma(t,x) \wedge (\gamma+\varepsilon)$, where $\varepsilon > 0$ is fixed. By the same argument, using the nondecreasing property in γ and homogeneous property in p of $H(\gamma,p)$, one shows that u^γ is a supersolution and $\overline{w}^\gamma$ is a solution of

$$\vartheta_t + H(\gamma, D_x\vartheta) = 0, \qquad \vartheta(0,x) = g(x) \wedge (\gamma + \varepsilon).$$

By comparison we may again conclude that $u^\gamma(t,x) \ge \overline{w}^\gamma(t,x)$ everywhere. Then, if $u(t,x) \le \gamma$ we have $u^\gamma(t,x) = u(t,x) \ge w^\gamma(t,x) \wedge (\gamma + \varepsilon)$, so $\gamma \ge u(t,x) \ge w^\gamma(t,x)$ and the opposite inclusion obtains. ∎

Observe that the comparison principle applied in the proof is for bounded functions, which is applicable by Proposition 3.1. Observe also that the proof of the theorem is much more succinct than Theorem 4.1 and in principle easier, but it was the explicit formulas of Hopf and Lax which led us to the conjecture.

Remark 4.1. Consider the equation (3.1) with $u(0,x) = g(x)$.

If $H(\gamma,p)$ is *concave* and positively homogeneous degree one in p, and nondecreasing in γ, we have for any continuous g,

$$u(t,x) = \max_{y\in\mathbb{R}^n} \left\{ g(y) \wedge H^{c\#}\left(\frac{x-y}{t}\right)\right\},$$

where

$$H^{c\#}(y) = \sup\{\alpha : \inf_{p\in\mathbb{R}^n} p\cdot y - H(\alpha,p) \ge 0\}.$$

In addition, $H(\gamma,p) = \inf\{p\cdot y : H^{c\#}(y) \ge \gamma\}$.

On the other hand, if g is continuous and *quasi-concave*, but now $H(\gamma,p)$ is only positively homogeneous degree one in p and nondecreasing in γ, then

$$u(t,x) = \sup\{\gamma : \inf_p p\cdot x - g^{c\#}(\gamma,p) - tH(\gamma,p) \ge 0\},$$

with $g^{c\#}(\gamma,p)=\inf\{p\cdot x : g(x)\geq\gamma\}$. In both cases, the analogous (super)level set result of the theorem remains true:

$$W^\gamma=\{(t,x):w^\gamma(t,x)\geq\gamma\}=\{(t,x):u(t,x)\geq\gamma\}=U^\gamma(t,x),\qquad\forall\gamma.$$

In addition, $u(t,x)=\sup\{\gamma : w^\gamma(t,x)\geq\gamma\}$.

5. The case $H(\gamma,p)=H_1(\gamma,p)+H_2(\gamma,p)$. The level set theorem is applied in this section to determine an upper and lower bound for equations with continuous data but Hamiltonians which are neither convex nor concave, but rather split into the sum of a convex and concave part. This extends the result of Bardi and Faggian [3] to Hamiltonians which depend on u, but we have the added assumption of homogeneity. Throughout the remainder of this paper we assume that initial conditions satisfy (2.1).

THEOREM 5.1. *Let $H(\gamma,p)=H_1(\gamma,p)+H_2(\gamma,p)$, where $H(\gamma,p)$ is assumed to be nondecreasing in γ, and $H_i(\gamma,p),\ i=1,2$ are assumed to be continuous and positively homogeneous degree one in $p\in R^n$. $H_1(\gamma,p)$ is convex in p and nondecreasing in γ. $H_2(\gamma,p)$ is concave in p and nondecreasing in γ.*

Then the viscosity solution of $u_t+H(u,Du)=0$ with $u(0,x)=g(x), x\in R^n$, and g assumed continuous, satisfies

$$\inf\left\{\gamma:\max_{\{z_2:H_2^{c\#}(z_2)\geq\gamma\}}\min_{y_1\in\mathbb{R}^n}\Big(g(x-t(y_1+z_2))\vee H_1^{\#}(y_1)\Big)\leq\gamma\right\}\leq u(t,x),$$

$$\sup\left\{\gamma:\min_{\{z_1:H_1^{\#}(y_1)\leq\gamma\}}\max_{y_2\in\mathbb{R}^n}\Big(g(x-t(z_1+y_2))\wedge H_2^{c\#}(y_2)\Big)\geq\gamma\right\}\geq u(t,x),$$

with $x\in\mathbb{R}^n,\ t\geq 0$.

Proof. We use the following representations for H_1 and H_2:

$$H_1(\gamma,p_1)=\sup_{\{z_1:H_1^{\#}(z_1)\leq\gamma\}}p_1\cdot z_1,\quad H_2(\gamma,p_2)=\inf_{\{z_2:H_2^{c\#}(z_2)\geq\gamma\}}p_2\cdot z_2,\ p_i\in\mathbb{R}^n,\ \ i=1,2,$$

where

$$H_1^{\#}(z_1)=\inf\{\gamma:\sup_{p_1\in\mathbb{R}^n}p_1\cdot z_1-H_1(\gamma,p_1)\leq 0\},$$
$$H_2^{c\#}(z_2)=\sup\{\gamma:\inf_{p_2\in\mathbb{R}^n}p_2\cdot z_2-H_2(\gamma,p_2)\geq 0\}.$$

The function $H_1^{\#}(z_1)$ is quasi-convex and $H_2^{c\#}(z_2)$ is quasi-concave (see [8], for example). Furthermore,

$$\inf_{z_1\in\mathbb{R}^n}H_1^{\#}(z_1)=-\infty\quad\text{and}\quad\lim_{|z_1|\to\infty}H_1^{\#}(z_1)=+\infty,\tag{5.1}$$

and

$$\sup_{z_2\in\mathbb{R}^n}H_2^{c\#}(z_2)=+\infty\quad\text{and}\quad\lim_{|z_2|\to\infty}H_2^{c\#}(z_1)=-\infty.\tag{5.2}$$

It follows that for any $\gamma\in R^1$,

$$E_{\gamma,H_2^{\#}}:=\{z\in\mathbb{R}^n:H_2^{c\#}(z_2)\geq\gamma\}\neq\emptyset.$$

Fix γ and $z_2 \in E_{\gamma,H_2^\#}$, noting that z_2 depends on γ. Then, writing $p = (p_1, p_2) \in R^{2n}$ with $p_1, p_2 \in \mathbb{R}^n$ we have

$$H(\gamma, p) = H_1(\gamma, p_1) + H_2(\gamma, p_2) \le H_1(\gamma, p_1) + p_2 \cdot z_2 =: \mathcal{H}(\gamma, p; z_2).$$

Now, $\mathcal{H}(\gamma, p; z_2)$ is nondecreasing in γ, convex in $p = (p_1, p_2)$, and positively homogeneous degree one in p. Hence, it is the conjugate of a quasi-convex function given as follows:

$$\begin{aligned}
\mathcal{H}^\#(x_1, x_2; z_2) &= \inf\{\gamma : \sup_{p_1,p_2} p_1 \cdot x_1 + p_2 \cdot x_2 - \mathcal{H}(\gamma, (p_1, p_2); z_2) \le 0\} \\
&= \inf\{\gamma : \sup_{p_1,p_2} p_1 \cdot x_1 + p_2 \cdot x_2 - H_1(\gamma, p_1) - p_2 \cdot z_2 \le 0\} \\
&= \inf\{\gamma : \sup_{p_1} p_1 \cdot x_1 - H_1(\gamma, p_1) + \sup_{p_2} p_2 \cdot (x_2 - z_2) \le 0\} \\
&= \begin{cases} +\infty, & \text{if } x_2 \ne z_2, \\ H_1^\#(x_1), & \text{if } x_2 = z_2. \end{cases}
\end{aligned}$$

Now, we shall use the doubled variables argument in [3]. We consider the function $U^\gamma : [0, T] \times \mathbb{R}^n \times \mathbb{R}^n \to R^1$ which is the solution of the problem (recall that γ is fixed)

$$U_t^\gamma + H_1(\gamma, D_{x_1} U^\gamma) + H_2(\gamma, D_{x_2} U^\gamma) = 0, \quad (t, x_1, x_2) \in (0, \infty) \times R^{2n}, \tag{5.3}$$

$$U(0, x_1, x_2) = g(x_1 + x_2), \qquad x_1, x_2 \in \mathbb{R}^n. \tag{5.4}$$

Then, as in [3], $w^\gamma(t, x)$ is a viscosity solution of

$$w_t^\gamma(t, x) + H(\gamma, D_x w^\gamma(t, x)) = 0, w^\gamma(0, x) = g(x), \quad x \in \mathbb{R}^n$$

if and only if $U^\gamma(t, x_1, x_2) = w^\gamma(t, x_1 + x_2)$ is the solution of (5.3).

With $z_2 \in E_{\gamma,H_2^\#} = \{z : H_2^{c\#}(z) \ge \gamma\}$ still fixed, consider next the Cauchy problem

$$\varphi_t(t, x) + \mathcal{H}(\gamma, D_x \varphi; z_2) = 0, \qquad (t, x) \in (0, \infty) \times R^{2n}, \qquad \varphi(0, x) = g(x_1 + x_2),$$

where $x = (x_1, x_2)$. This problem has the explicit solution given by the Hopf–Lax formula in [9]:

$$\begin{aligned}
\varphi^\gamma(t, x; z_2) &= \min_{y \in R^{2n}} \left(g(y_1 + y_2) \vee \mathcal{H}^\# \left(\frac{x - y}{t}; z_2 \right) \right) \\
&= \min_{y \in R^{2n}} \left(g(x_1 - t y_1 + x_2 - t y_2) \vee \mathcal{H}^\#(y; z_2) \right).
\end{aligned}$$

Using the calculation for $\mathcal{H}^\#$ and $y = (y_1, y_2)$ we get

$$\varphi^\gamma(t, (x_1, x_2); z_2) = \min_{y_1 \in R^n} \left(g(x_1 + x_2 - t(y_1 + z_2)) \vee H_1^\#(y_1) \right). \tag{5.5}$$

Since $H(\gamma, p) \le \mathcal{H}(\gamma, p; z_2)$ we have by comparison of viscosity solutions (see, for example, Barles [4]) that

$$\varphi^\gamma(t, x; z_2) \le U^\gamma(t, x_1, x_2), \qquad \forall z_2 \in E_{\gamma,H_2^{c\#}}.$$

Using (5.5) we see that

$$\max_{z_2 \in E_{\gamma, H_2^{c\#}}} \min_{y_1 \in \mathbb{R}^n} (g(x_1 + x_2 - t(y_1 + z_2)) \vee H_1^*(y_1)) \le U^\gamma(t, x_1, x_2).$$

By Theorem 4.1, we have that $U(t, x_1, x_2) := \inf\{\gamma : U^\gamma(t, x_1, x_2) \le \gamma\}$ is the solution of

$$U_t + H_1(U, D_{x_1}U) + H_2(U, D_{x_2}U) = 0, \quad (t, x) \in (0, \infty) \times R^{2n},$$

and initial condition $U(0, x_1, x_2) = g(x_1 + x_2)$. Given $x \in \mathbb{R}^n$ write it as $x = x_1 + x_2$ for some $x_1, x_2 \in \mathbb{R}^n$. Then the solution of our original problem

$$u_t + H_1(u, D_x u) + H_2(u, D_x u) = 0, \quad (t, x) \in (0, \infty) \times R^n, \quad u(0, x) = g(x)$$

is given by $u(t, x) = U(t, x_1, x_2)$. Combining these facts results in

$$\inf \left\{ \gamma : \max_{\{z_2 : H_2^{c\#}(z_2) \ge \gamma\}} \min_{y_1 \in \mathbb{R}^n} \Big(g(x - t(y_1 + z_2)) \vee H_1^{\#}(y_1) \Big) \le \gamma \right\} \le u(t, x).$$

For the upper bound inequality in the theorem, we use the quasi-concave conjugates. Thus, in a similar manner we prove that

$$\sup \left\{ \gamma : \min_{\{z_1 : H_1^{\#}(y_1) \le \gamma\}} \max_{y_2 \in \mathbb{R}^n} \Big(g(x - t(z_1 + y_2)) \wedge H_2^{c\#}(y_2) \Big) \ge \gamma \right\} \ge u(t, x). \qquad \square$$

6. The case $g(x) = g_1(x) \vee g_2(x)$ or $g(x) = g_1(x) \wedge g_2(x)$. We first consider the case when the data splits into the maximum of a quasi-convex function g_1 and a quasi-concave function g_2. Thus, we consider the Hamilton–Jacobi equation (3.1) with the initial data

$$u(0, x) = g_1(x) \vee g_2(x).$$

We assume that $H(\gamma, p)$ is nondecreasing in γ and homogeneous degree one in p. Again, we go through the problem with doubled variables

$$U_t + H(U, D_{x_1}U + D_{x_2}U) = 0, \qquad U(0, x_1, x_2) = g_1(x_1) \vee g_2(x_2).$$

Then (with the same proof as in [3]) $u(t, x) = U(t, x, x)$. Label the solution of the doubled problem $U_{g_1 \vee g_2}$.

Now, since g_2 is assumed to be quasi-concave, it is the infimum of piecewise linear functions lying above it. Precisely, using the alternate version of the quasi-concave conjugates (see section 2) from [11], [8], we have

$$g_2(x_2) = \inf_{p_2, \gamma_2} (p_2 \cdot x_2 + g_2^{c*}(\gamma_2, p_2)) \vee \gamma_2,$$

where

$$g_2^{c*}(\gamma_2, p_2) = \inf_{\{x_2 : g_2(x_2) \ge \gamma_2\}} p_2 \cdot x_2 + g_2(x_2)$$

is the first quasi-concave conjugate of g_2 (see [11]).

Fix $\overline{\gamma}_2 \in R^1$ and $\overline{p}_2 \in \mathbb{R}^n$ with $(\overline{\gamma}_2, \overline{p}_2) \in dom(g_2^{c*})$ and set

$$h(x_1, x_2; \overline{\gamma}_2, \overline{p}_2) = g_1(x_1) \vee (\overline{p}_2 \cdot x_2 + g_2^{c*}(\overline{\gamma}_2, \overline{p}_2)) \vee \overline{\gamma}_2.$$

Consider the following problem for U_h with initial data h:

$$\begin{aligned} &U_t + H(U, D_{x_1}U + D_{x_2}U) = 0, \\ &U(0, x_1, x_2) = h(x_1, x_2; \overline{\gamma}_2, \overline{p}_2). \end{aligned}$$

Since $(p_2 \cdot x_2 + g_2^{c*}(\gamma_2, p_2)) \vee \gamma_2$ is quasi-affine, i.e., both quasi-convex and quasi-concave, and the maximum of two quasi-convex functions is quasi-convex, we now have initial data h which is quasi-convex. Thus, we may apply the Hopf–Lax formula in [10] to obtain the solution

$$U_h(t, x_1, x_2) = \inf\{\gamma : \sup_{p_1, p_2} p_1 \cdot x_1 + p_2 \cdot x_2 - h^{\#}(\gamma, p_1, p_2; \overline{\gamma}_2, \overline{p}_2) - tH(\gamma, p_1 + p_2) \le 0\}.$$

We must calculate $h^{\#}(\gamma, p_1, p_2; \overline{\gamma}_2, \overline{p}_2)$. By definition, we have, for $\overline{\gamma}_2 \le \gamma$,

$$\begin{aligned} h^{\#}(\gamma, p_1, p_2; \overline{\gamma}_2, \overline{p}_2) &= \sup_{\{x_1, x_2 : h(x_1, x_2; \overline{\gamma}_2, \overline{p}_2) \le \gamma\}} p_1 \cdot x_1 + p_2 \cdot x_2 \\ &= \sup_{\{x_1 : g_1(x_1) \le \gamma\}} p_1 \cdot x_1 + \sup_{\{x_2 : \overline{p}_2 \cdot x_2 + g_2^{c*}(\overline{\gamma}_2, \overline{p}_2) \le \gamma\}} p_2 \cdot x_2 \\ &= g_1^{\#}(\gamma, p_1) + \sup_{\{x_2 : \overline{p}_2 \cdot x_2 + g_2^{c*}(\overline{\gamma}_2, \overline{p}_2) \le \gamma\}} p_2 \cdot x_2. \end{aligned}$$

If $\overline{\gamma}_2 > \gamma$, $h^{\#}(\gamma, p_1, p_2; \overline{\gamma}_2, \overline{p}_2) = -\infty$.

Now set $S = \{x_2 : \overline{p}_2 \cdot x_2 + g_2^{c*}(\overline{\gamma}_2, \overline{p}_2) \le \gamma\}$. This is a closed convex set, in fact a half space, and we seek the support function of S, which is the supremum on the preceding line.

If we consider the half space $C = \{x : \alpha \cdot x + \beta \le 0\}$, the Legendre–Fenchel conjugate of the affine function $f(x) = \alpha \cdot x + \beta$ is

$$f^*(p) = \begin{cases} +\infty, & \text{if } p \ne \alpha, \\ -\beta, & \text{if } p = \alpha. \end{cases}$$

From Theorem 13.5, page 118 in Rockafellar [22], the support function $\sigma_C(p)$ of C is then given by

$$\begin{aligned} \sigma_C(p) &= \inf_{\lambda > 0} \lambda f^*\left(\frac{p}{\lambda}\right) \\ &= \begin{cases} +\infty, & \text{if } p \ne \lambda\alpha, \quad \forall \lambda > 0, \\ -\beta\lambda, & \text{if } p = \lambda\alpha, \quad \exists \lambda > 0. \end{cases} \end{aligned}$$

Applying this result to S we get

$$\sigma_S(p_2) = \sup_{\{x_2 : \overline{p}_2 \cdot x_2 + g_2^{c*}(\overline{\gamma}_2, \overline{p}_2) \le \gamma\}} p_2 \cdot x_2 = \begin{cases} +\infty, & \text{if } p_2 \ne \lambda\overline{p}_2, \quad \forall \lambda > 0, \\ (\gamma - g_2^{\#}(\overline{\gamma}_2, \overline{p}_2))\lambda, & \text{if } p_2 = \lambda\overline{p}_2, \quad \exists \lambda > 0. \end{cases}$$

Summarizing, we have

$$h^{\#}(\gamma,p_1,p_2;\overline{\gamma}_2,\overline{p}_2)=\begin{cases}-\infty, & \text{if } \overline{\gamma}_2>\gamma\\ +\infty, & \text{if } p_2\neq\lambda\overline{p}_2, \quad \forall\lambda>0,\\ g_1^{\#}(\gamma,p_1)+\lambda(\gamma-g_2^{c*}(\overline{\gamma}_2,\overline{p}_2)), & \text{if } p_2=\lambda\overline{p}_2, \quad \exists\lambda>0.\end{cases}$$

Putting this into the formula for U_h, we get

$$\begin{aligned}U_h(t,x_1,x_2)=\inf\{\gamma\geq\overline{\gamma}_2:\ &\sup_{p_1\in\mathbb{R}^n,\lambda>0} p_1\cdot x_1+\lambda\overline{p}_2\cdot x_2-g_1^{\#}(\gamma,p_1)\\ &-\lambda(\gamma-g_2^{c*}(\overline{\gamma}_2,\overline{p}_2))-tH(\gamma,p_1+\lambda\overline{p}_2)\leq 0\}.\end{aligned}\tag{6.1}$$

Notice that the expression in the supremum is homogeneous degree one in (p_1,p_2) together, but not individually.

Since

$$U_h(0,x_1,x_2)=h(x_1,x_2;\overline{\gamma}_2,\overline{p}_2)\geq g(x_1)\vee g(x_2)=U_{g_1\vee g_2}(0,x_1,x_2),$$

comparison for (3.1) gives us $U_h(t,x_1,x_2)\geq U_{g_1\vee g_2}(t,x_1,x_2)$ for all $t\geq 0$, $x_1,x_2\in\mathbb{R}^n$. Using (6.1) and the fact that $(\overline{\gamma}_2,\overline{p}_2)$ in $dom(g_2^{c*})$ was arbitrary, results in

$$\begin{aligned}\inf_{\overline{\gamma}_2,\overline{p}_2\in dom(g_2^{c*})}\inf\{\gamma\geq\overline{\gamma}_2:\ &\sup_{p_1,\lambda>0} p_1\cdot x_1+\overline{p}_2\cdot x_2-g_1^{\#}(\gamma,p_1)\\ &-\lambda(\gamma-g_2^{c*}(\overline{\gamma}_2,\overline{p}_2))-tH(\gamma,p_1+\lambda\overline{p}_2)\leq 0\}\geq U_{g_1\vee g_2}(t,x_1,x_2).\end{aligned}$$

Finally, since $u(t,x)=U_{g_1\vee g_2}(t,x,x)$, we conclude

$$\begin{aligned}u(t,x)\leq\inf_{\overline{\gamma}_2,\overline{p}_2\in dom(g_2^{c*})}\inf\{\gamma\geq\overline{\gamma}_2:\ &\sup_{p_1,\lambda>0}(p_1+\lambda\overline{p}_2)\cdot x-g_1^{\#}(\gamma,p_1)\\ &-\lambda(\gamma-g_2^{c*}(\overline{\gamma}_2,\overline{p}_2))-tH(\gamma,p_1+\lambda\overline{p}_2)\leq 0\}.\end{aligned}\tag{6.2}$$

Similarly, if u satisfies the initial data $u(0,x)=g_1(x)\wedge g_2(x)$, we prove that

$$\begin{aligned}u(t,x)\geq\sup_{\overline{\gamma}_1,\overline{p}_1\in dom(g_1^{*})}\sup\{\gamma\leq\overline{\gamma}_1:\ &\inf_{p_2,\lambda>0}(\lambda\overline{p}_1+p_2)\cdot x\\ &-\lambda(\gamma+g_1^{*}(\overline{\gamma}_1,\overline{p}_1))+g_2^{c\#}(\gamma,p_2)-tH(\gamma,\lambda\overline{p}_1+p_2)\geq 0\}.\end{aligned}\tag{6.3}$$

We have proved the theorem.

THEOREM 6.1. *Let g_1 and g_2 be continuous functions with g_1 quasi-convex and g_2 quasi-concave. Let $H(\gamma,p)$ satisfy (B)*(i)–(ii)*, and $\gamma\mapsto H(\gamma,p)$ nondecreasing for any fixed $p\in\mathbb{R}^n$. Then the solution u of* (3.1) *with initial data $u(0,x)=g_1(x)\vee g_2(x)$ satisfies* (6.2)*, and with initial data $u(0,x)=g_1(x)\wedge g_2(x)$, satisfies* (6.3)*.*

Remark 6.1. It is very interesting that the upper and lower bounds in this theorem use both versions of the quasi-convex or quasi-concave conjugates, i.e., # and $*$ (see section 2), and this seems unavoidable. Of course, if we needed two ## or two $**$, this remark would not be true since they both lead to the greatest quasi-convex minorant. But the first conjugates are not the same.

Remark 6.2. If we have initial data $u(0,x)=g(x)$ which may be represented as $g_1\vee g_2$ and as $h_1\wedge h_2$ for some quasi-convex functions g_1,h_1 and quasi-concave function g_2,h_2, then we obtain an upper bound for u using the g's and a lower bound using

the h's. This raises the question as to what kind of functions may be represented as the max or min of quasi-convex, quasi-concave functions. More will be said in the following remark.

Remark 6.3. If we have initial data given by $u(0,x) = g_1(x) + g_2(x)$ where g_1 is convex and g_2 is concave, as in [3], a natural way to obtain an upper bound is to replace the initial data by $2(g_1 \vee g_2)$ and $2(g_1 \wedge g_2)$ for a lower bound. Using the results of this paper we may carry out this plan not just for convex and concave g's but also for quasi-convex, quasi-concave g's.

The class of functions representable as the sum of convex and concave is very wide. Indeed, any function with bounded second derivatives may be so represented. To see this, let K denote the bound on the second derivatives of a smooth function g and consider $g_2(x) = g(x) - K|x|^2$ and $g_1(x) = K|x|^2$. Then, g_2 is concave, g_1 is convex, and $g = g_1 + g_2$.

Acknowledgments. We would like to thank Professor Bardi for the preprint [3] which motivated this paper. We also thank the anonymous referee who provided a nice proof of Theorem 4.2 and who pointed out that Theorem 4.1 is true under under more general hypotheses.

ORTHONORMAL WAVELET BASES ADAPTED FOR PARTIAL DIFFERENTIAL EQUATIONS WITH BOUNDARY CONDITIONS*

PASCAL MONASSE† AND VALÉRIE PERRIER†

Abstract. We adapt ideas presented by Auscher to impose boundary conditions on the construction of multiresolution analyses on the interval, as introduced by Cohen, Daubechies, and Vial. We construct new orthonormal wavelet bases on the interval satisfying homogeneous boundary conditions. This construction can be extended to wavelet packets in the case of one boundary condition at each edge. We present in detail the numerical computation of the filters and the derivative operators associated with these bases. We derive quadrature formulae in order to study the approximation error at the edge of the interval. Several examples illustrate the present construction.

Key words. wavelet, multiresolution analysis, boundary conditions

1. Introduction.

Our ultimate goal is to solve numerically partial differential equations, for example, linear elliptic equations of the type

$$\left\{ \begin{array}{rcl} -\Delta u + \lambda u & = & f \text{ in } \Omega, \\ u & = & 0 \text{ on } \partial\Omega \end{array} \right. \tag{1}$$

where $\Omega = [0,1]^d$, $f \in L^2(\Omega)$, and $\lambda \geq 0$. The boundary conditions being taken by $u \in H_0^1(\Omega)$, the variational form of equation (1) is

$$\text{Find } u \in H_0^1(\Omega) \text{ such that } \forall v \in H_0^1(\Omega), \int_\Omega \nabla u \nabla v \, d\tau + \lambda \int_\Omega uv \, d\tau = \int_\Omega fv \, d\tau. \tag{2}$$

Riesz theorem proves the existence and the uniqueness of u satisfying (2). We want to find a function close to u according to the $H_0^1(\Omega)$ norm by using a Galerkin method. Thus, we have to construct finite dimensional subspaces V_j of $H_0^1(\Omega)$ such that $\forall j, V_j \subset V_{j+1}$ and $\overline{\bigcup V_j} = H_0^1(\Omega)$. Then an approximate solution u_j is given by solving a finite dimensional problem:

$$\text{Find } u_j \in V_j \text{ such that } \forall v \in V_j, \int_\Omega \nabla u_j \nabla v \, d\tau + \lambda \int_\Omega u_j v \, d\tau = \int_\Omega fv \, d\tau. \tag{3}$$

By introducing $\{v_{j,k}\}_k$, an orthonormal basis of V_j as test functions v, (3) is reduced to a linear system. Such embedded spaces V_j can be obtained from a multiresolution analysis (MRA). Test functions in (3) can be chosen among the *scaling functions* of the MRA, as in [BNR 94]; such a method then has convergence properties similar to those of spectral methods, the precision being limited by the regularity of the MRA. In order to derive adaptive schemes based on nonlinear approximation of the exact solution u (see [DVJP 92]), we prefer to consider as test functions v the *wavelet*

basis; this will reduce significantly the number of degrees of freedom, owing to the compression properties of the wavelet transform. These compression properties have been practically observed in numerical experiments computing the wavelet solution of linear PDEs with periodic boundary conditions ([MPR 91], [LPT 92], [ChPe 96]). Jaffard has already proven that, by using a diagonal preconditioner, the condition number of the linear system deduced from (3) is independent of the mesh size in the *wavelet* basis, which leads to a fast resolution of such a system (see [Jaff 92]). Our present objective is then to construct an MRA on the interval $[0,1]$ and the associated orthonormal wavelet basis satisfying the boundary conditions in (1) and finally to derive the expressions for the Galerkin derivative operators.

We want to construct an MRA, of $H_0^1([0,1])$. More generally, we want to characterize subspaces of $H^s(\Omega)$ defined by vanishing values of some derivatives at the boundaries 0 and 1. Even if we do not impose conditions at the boundaries, the construction of wavelets on the interval is not trivial. The simplest solution is to use periodic wavelets (defined in [Meye 90] and implemented in [PeBa 89]) adapted to nonperiodic conditions by the Chebyshev transform $x = 1/\pi \arccos y$, which leads to "Chebyshev" wavelets (see [PST 95]) and allows to use spectral schemes based on Tau methods [MaRa 92]. In 1989, Jaffard and Meyer proposed a construction of wavelet bases on open sets of $\mathbb{R}^n$ starting from spline functions [JM 89]. However, their construction was theoretical and has not yet been implemented numerically. More recently, other constructions of wavelet bases on the interval $[0,1]$ have been proposed; they are all based on Daubechies compactly supported wavelets in $L^2(\mathbb{R})$ [Daub 88]. The first construction was done by Meyer (see [Meye 92]). It was rather theoretical and had some drawbacks, the most important being its numerical instability. Another construction avoiding these problems was then proposed independently by [CDV 93] and [AHJP 93], and extended in dimension 2 in [CDDe 95]. Nevertheless, these wavelets take arbitrary values at the boundaries and are not well adapted to the resolution of boundary value problems. This problem was theoretically solved by Auscher (see [Ausc 93]) who adapted Meyer's construction when boundary conditions are imposed.

Our goal is to construct the wavelets of [CDV 93] in a practical way using Auscher's ideas. The construction presented here was already roughly described in [MoPe 95]. Since the submission of the present paper, an alternative construction was independently developed by Chiavassa and Liandrat [ChLi 97]. First, we want to construct embedded spaces V_j as introduced in (3). For that, we will construct MRAs on the interval $[0,1]$. Section 2 recalls the basic properties of MRAs on $\mathbb{R}$, then we describe the construction on $[0,+\infty[$ in section 3, on $[0,1]$ in section 4, and the computation of the numerical filters in section 5. The expressions of the first two derivative operators are computed in section 6, an interpolation procedure is derived in section 7, and finally we give some numerical results in section 8.

2. Orthonormal wavelet bases on $\mathbb{R}$. We briefly review wavelets and MRA of $L^2(\mathbb{R})$ (for further details, see [Daub 92, Mall 89, Meye 90]). An MRA is a set $(V_j)_{j\in\mathbb{Z}}$ of closed subspaces of $L^2(\mathbb{R})$ satisfying:

1. $\{0\} = \bigcap_{j\in\mathbb{Z}} V_j \subset \cdots \subset V_{-1} \subset V_0 \subset V_1 \subset \cdots \subset \overline{\bigcup_{j\in\mathbb{Z}} V_j} = L^2(\mathbb{R})$;
2. $f(x) \in V_0 \Longleftrightarrow f(2^j x) \in V_j$;
3. $\exists g \in V_0$ such that $g(.-k)_{k\in\mathbb{Z}}$ is a Riesz basis of V_0.

From g, it is possible to construct a function Φ (called the scaling function) of V_0 such that $\{\Phi(.-k)\}_{k\in\mathbb{Z}}$ is an orthonormal basis of V_0 and $\int_{-\infty}^{+\infty} \Phi(x)dx = 1$. Moreover,

because $V_0 \subset V_1$ and from point 2, there exist reals h_k such that

$$\Phi(x) = \sqrt{2} \sum_{k=-\infty}^{+\infty} h_k \Phi(2x-k). \tag{4}$$

Changing the scale, it follows that $\{2^{j/2}\Phi(2^j.-k)\}_{k\in\mathbb{Z}}$ is an orthonormal basis of V_j. Defining W_j as the orthogonal complement of V_j in V_{j+1}:

$$W_j = V_{j+1} \ominus V_j,$$

it is easy to verify that $L^2(\mathbb{R}) = \bigoplus_{j\in\mathbb{Z}} W_j$. Then it is possible to construct a function Ψ (called wavelet) of V_1 such that $\{\Psi(.-k)\}_{k\in\mathbb{Z}}$ is an orthonormal basis of W_0. Then $\{2^{j/2}\Psi(2^j.-k)\}_{j,k\in\mathbb{Z}}$ is an orthonormal basis of $L^2(\mathbb{R})$ and Ψ satisfies a two-scale equation:

$$\Psi(x) = \sqrt{2} \sum_{k=-\infty}^{+\infty} g_k \Phi(2x-k). \tag{5}$$

The number N of vanishing moments of the wavelet Ψ plays an important role in the approximation and in the compression of functions:

$$\int_{-\infty}^{+\infty} x^k \Psi(x)dx = 0 \quad \text{for } k = 0,\dots,N-1. \tag{6}$$

From (4) and (5) it follows that

$$\sqrt{2}\ \Phi(2x-n) = \sum_k \left(h_{n-2k}\Phi(x-k) + g_{n-2k}\Psi(x-k)\right). \tag{7}$$

Equations (4), (5), and (7) allow us to describe a fast algorithm to analyze and synthesize a given function in the wavelet basis (see [Mall 89]); it consists of a tree algorithm, each step of which is a filtering with the discrete filters h_k and g_k. In the case where only a finite number of these coefficients are nonzero, the wavelet and the scaling function are compactly supported. Daubechies was the first to construct such wavelets (see [Daub 88]) for every (finite) number of zero moments. For N vanishing moments, Φ and Ψ are supported on $[-N+1, N]$ (or whatever interval of integer boundaries and length $2N-1$) and the nonzero h_k and g_k are $(h_{-N+1},\dots,h_N)$ and $(g_{-N+1},\dots,g_N)$. Such wavelets have the minimal-length support between all the possible wavelets with N vanishing moments. Furthermore, the regularity of these functions increases asymptotically linearly with N:

$$\Phi, \Psi \in C^{\mu N} \tag{8}$$

for N sufficiently large, $\mu \simeq 0.2$.

3. Orthonormal wavelet bases on [0,+∞[. We will focus on the construction of an MRA on $[0,+\infty[$. Then, by a simple trick, it will be easy to construct an MRA on $[0,1]$.

3.1. MRA on [0,+∞[without boundary conditions. We follow first the construction of [CDV 93] by applying Auscher's ideas [Ausc 93]. We establish a few well-known properties based on Daubechies compactly supported wavelets, in order to define scaling functions at the edge 0.

3.1.1. Expression of monomials in V_0. We start from a usual MRA of $L^2(\mathbb{R})$ given by spaces V_j and a scaling function Φ. Although the monomials do not belong in the usual sense to V_0, we can write

$$\text{For } \ell = 0, \dots, N-1, \qquad \frac{x^\ell}{\ell!} = \sum_{k=-\infty}^{+\infty} P_\ell(k)\ \Phi(x-k) \tag{9}$$

with P_ℓ the polynomials defined by

$$P_\ell(X) = \sum_{n=0}^{\ell} \frac{C_{\ell-n}}{n!} X^n, \tag{10}$$

where

$$C_m = \int_{-\infty}^{+\infty} \frac{x^m}{m!} \Phi(x)dx = P_m(0). \tag{11}$$

The equality in (9) should be understood as a pointwise convergence on $\mathbb{R}$ or as a uniform or L^2 convergence on any compact set of $\mathbb{R}$. In fact, if we restrict to a compact set, the convergence is an equality since Φ is compactly supported, so that in the right-hand side of (9) only a finite number of terms participate in the sum. The proof of the existence of polynomial P_ℓ in (9) can be found, for example, in [CDV 93]. Remark that P_ℓ is a polynomial of degree ℓ and that $P_0(X) = 1$.

The coefficients C_ℓ can be computed recursively using (see [CDV 93]):

$$\begin{cases} C_0 &= 1 \\ C_\ell &= \dfrac{1}{2^\ell - 1} \displaystyle\sum_{r=1}^{\ell} M_r C_{\ell-r} \end{cases}$$

with

$$M_r = \frac{1}{\sqrt{2}} \sum_m h_m \frac{m^r}{r!}.$$

As in the case of the MRA on $\mathbb{R}$, we want the polynomials up to degree $N-1$ to remain in our new space $V_0^{[0,+\infty[}$. For that, following [Ausc 93], we define the edge scaling functions.

DEFINITION 3.1. *For $\ell = 0, \dots, N-1$, the edge scaling functions are defined by*

$$\tilde{\Phi}_\ell(x) = \sum_{k=-N+1}^{N-1-\alpha} P_\ell(k)\ \Phi(x-k)\ \chi_{[0,+\infty[}(x), \tag{12}$$

where α is a fixed parameter whose value is 0 or 1.

The interest of the parameter α will be clear later. It is linked to the (finite) dimension of the MRA spaces of $L^2([0,1])$. The functions $\tilde{\Phi}_\ell$ are such that for all x in $[0, +\infty[$

$$\frac{x^\ell}{\ell!} = \tilde{\Phi}_\ell(x) + P_\ell(N-\alpha)\ \Phi(x-(N-\alpha)) + \cdots.$$

Remark that the functions $\Phi(.-k)$ for $k \geq N-\alpha$ are all supported on $[0, +\infty[$. Moreover, according to (9), the functions $\tilde{\Phi}_\ell$ are purely polynomials on $[0,1]$ if $\alpha = 0$.

PROPOSITION 3.2. *The edge scaling functions $\tilde{\Phi}_\ell, \ell = 0, \dots, N-1$, are linearly independent and are orthogonal to the functions $\Phi_k = \Phi(. - k)$ for $k \geq N - \alpha$* (called the interior scaling functions on $[0, +\infty[$).

Proof. Knowing that the functions $\Phi_k \cdot \chi_{[0,+\infty[}$, for $k = -N+1, \dots, N-1-\alpha$ are linearly independent (see [Meye 92]) and that the degree of the polynomial P_ℓ is exactly ℓ, it is easy to see that by definition of the $\tilde{\Phi}_\ell$ these functions are independent. Moreover, for $\ell \in \{0, \dots, N-1\}$ and $k \geq N - \alpha$, we have

$$\begin{aligned}\left\langle \tilde{\Phi}_\ell \mid \Phi_k \right\rangle_{[0,+\infty[} &= \sum_{m=-N+1}^{N-1-\alpha} P_\ell(m) \int_0^{+\infty} \Phi(x-m)\Phi(x-k)dx \\ &= \sum_{m=-N+1}^{N-1-\alpha} P_\ell(m) \int_{-\infty}^{+\infty} \Phi(x-m)\Phi(x-k)dx \;=\; 0. \qquad \square\end{aligned}$$

We define now

$$V_0^{[0,+\infty[} = \overline{\operatorname{Span}\left\{(\tilde{\Phi}_\ell)_{\ell=0,\dots,N-1}, (\Phi_k)_{k\geq N-\alpha}\right\}},$$

and, more generally,

$$V_j^{[0,+\infty[} = \overline{\operatorname{Span}\left\{\left(\tilde{\Phi}_\ell(2^j.)\right)_{\ell=0,\dots,N-1}, (\Phi(2^j. - k))_{k\geq N-\alpha}\right\}}. \tag{13}$$

Then polynomials up to degree $N-1$ are in $V_j^{[0,+\infty[}$ in the same sense as in (9).

3.1.2. Two-scale equation. We will show that the set of spaces $V_j^{[0,+\infty[}$ is an MRA of $L^2([0,+\infty[)$ after establishing some preliminary results.

LEMMA 3.3. *For $\ell = 0, \dots, N-1$ and $k \in \mathbb{Z}$ we have*

$$\frac{P_\ell(k)}{2^\ell} = \sqrt{2} \sum_{m\in\mathbb{Z}} P_\ell(m)\; h_{k-2m}. \tag{14}$$

Proof. By definition of the polynomial P_ℓ

$$\frac{x^\ell}{\ell!} = \sum_m P_\ell(m)\; \Phi(x-m).$$

Changing the variable $(x \mapsto x/2)$ and using the two-scale equation (4)

$$\begin{aligned}\frac{1}{2^\ell}\frac{x^\ell}{\ell!} \;=\; \left(\frac{x}{2}\right)^\ell \frac{1}{\ell!} &= \sum_m P_\ell(m) \left(\sqrt{2}\sum_k h_{k-2m}\; \Phi(x-k)\right) \\ &= \sum_k \left(\sqrt{2}\sum_m P_\ell(m)\; h_{k-2m}\right) \Phi(x-k),\end{aligned}$$

which leads to (14), by unicity of the polynomial P_ℓ. $\square$

This lemma will be useful to prove the following two-scale equation.

PROPOSITION 3.4. *There exists a matrix b of size N x $(2N-1-\alpha)$ such that, writing $D = (d_{ij})_{1\leq i,j\leq N}$ the diagonal matrix $d_{ij} = \delta_{i-j}/2^{i-1}$,*

$$\begin{pmatrix} \tilde{\Phi}_0 \\ \vdots \\ \tilde{\Phi}_{N-1} \end{pmatrix} \left(\frac{x}{2}\right) = D \begin{pmatrix} \tilde{\Phi}_0 \\ \vdots \\ \tilde{\Phi}_{N-1} \end{pmatrix} (x) + b \begin{pmatrix} \Phi_{N-\alpha} \\ \vdots \\ \Phi_{3N-2-2\alpha} \end{pmatrix} (x). \tag{15}$$

Moreover, the general term of the matrix b is

$$b_{i+1,j-N+\alpha+1} = \frac{P_i(j)}{2^i} - \sqrt{2} \sum_{m=N-\alpha}^{\lfloor \frac{j+N-1}{2} \rfloor} P_i(m) h_{j-2m} \tag{16}$$

for $i = 0, \ldots, N-1$ and $j = N-\alpha, \ldots, 3N-2-2\alpha$, where $\lfloor x \rfloor$ is the integer part of x.

Notice that this formula has the advantage to use a *diagonal* matrix D, which is to be compared to the triangular matrix of [CDV 93]; this will be useful below. Although, contrary to [CDV 93], the supports of $\tilde{\Phi}_\ell$ are not staggered.

Proof. We know that for $x \geq 0$

$$\frac{x^i}{i!} = \tilde{\Phi}_i(x) + \sum_{k=N-\alpha}^{+\infty} P_i(k)\ \Phi(x-k).$$

Rewriting this at $x/2$ and using $2^i(x/2)^i = x^i$ leads to

$$2^i \left[\tilde{\Phi}_i(x/2) + \sqrt{2} \sum_{m=N-\alpha}^{+\infty} P_i(m) \sum_{k=2m-N+1}^{2m+N} h_{k-2m} \Phi(x-k) \right] = \tilde{\Phi}_i(x) + \sum_{k=N-\alpha}^{+\infty} P_i(k) \Phi(x-k)\ .$$

Inverting the sums in the left-hand side:

$$2^i \left[\tilde{\Phi}_i(x/2) + \sqrt{2} \sum_{k=N-2\alpha+1}^{+\infty} \left(\sum_{m=N-\alpha}^{\lfloor \frac{k+N-1}{2} \rfloor} P_i(m) h_{k-2m} \right) \Phi(x-k) \right] = \tilde{\Phi}_i(x) + \sum_{k=N-\alpha}^{+\infty} P_i(k) \Phi(x-k).$$

Thus

$$\tilde{\Phi}_i(x/2) = \frac{1}{2^i} \tilde{\Phi}_i(x) + \sum_{k=N-\alpha}^{+\infty} \left[\frac{P_i(k)}{2^i} - \sqrt{2} \sum_{m=N-\alpha}^{\lfloor \frac{k+N-1}{2} \rfloor} P_i(m) h_{k-2m} \right] \Phi(x-k)$$

with the convention $\sum_\emptyset = 0$. It just remains to show that

$$\frac{P_i(k)}{2^i} = \sqrt{2} \sum_{m=N-\alpha}^{\lfloor \frac{k+N-1}{2} \rfloor} P_i(m) h_{k-2m}$$

when $k \geq 3N-1-2\alpha$. But for such values of k, all the $h_{k-2m} = 0$ for $m < N-\alpha$ or $m > \lfloor k+N-1/2 \rfloor$, so that this is exactly (14). □

Using (14) we could also write

$$b_{i+1,j-N+\alpha+1} = \sqrt{2} \sum_{m=\lceil \frac{j-N}{2} \rceil}^{N-\alpha-1} P_i(m) h_{j-2m}.$$

The next proposition will be useful later.

PROPOSITION 3.5. *The rank of the matrix b defined in equations* (15–16) *is $N-\alpha$, and every submatrix b' obtained by extracting $N-\alpha$ rows of b and keeping one other two column, starting from the $(\alpha+1)$th is of full rank.*

Proof.

(i) For $\alpha = 0$. Note P the $N \times N$ matrix $P_{i,j} = P_{i-1}(j-1)$:

$$P = \begin{pmatrix} P_0(0) & \dots & P_0(N-1) \\ \vdots & \vdots & \vdots \\ P_{N-1}(0) & \dots & P_{N-1}(N-1) \end{pmatrix}.$$

Since *degree* $P_i = i$, the determinant of this matrix is the same as the one of a Vandermonde matrix; it is thus invertible. We can now write

$$b = \sqrt{2}\ P \begin{pmatrix} h_N & 0 & 0 & \dots & \dots & 0 \\ h_{N-2} & h_{N-1} & h_N & \ddots & & \vdots \\ \vdots & \vdots & \ddots & \ddots & \vdots & \vdots \\ h_{-N+4} & h_{-N+5} & & \ddots & 0 & 0 \\ h_{-N+2} & h_{-N+3} & \dots & \dots & h_{N-1} & h_N \end{pmatrix},$$

and thus the rank of b is the same as the one of the right matrix. But this $N \times (2N-1)$ matrix is of rank N: extracting the square matrix by taking one other two column (including thus the first and the last), we get a triangular matrix whose diagonal is only composed of $h_N \neq 0$. It is thus invertible.

(ii) For $\alpha = 1$. Note this time P the $N \times (N-1)$ matrix $P_{i,j} = P_{i-1}(j-1)$:

$$P = \begin{pmatrix} P_0(0) & \dots & P_0(N-2) \\ \vdots & \vdots & \vdots \\ P_{N-1}(0) & \dots & P_{N-1}(N-2) \end{pmatrix}.$$

Its rank is $N-1$ and getting out whatever line we get a square matrix of rank $N-1$. Moreover,

$$b = \sqrt{2}\ P \begin{pmatrix} h_{N-1} & h_N & 0 & \dots & \dots & \dots & 0 \\ h_{N-3} & h_{N-2} & h_{N-1} & h_N & \ddots & \ddots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \ddots & \ddots & \vdots \\ h_{-N+5} & h_{-N+6} & h_{-N+7} & \dots & \ddots & 0 & 0 \\ h_{-N+3} & h_{-N+4} & h_{-N+5} & \dots & \dots & h_{N-1} & h_N \end{pmatrix},$$

and the $(N-1) \times (2N-2)$ right matrix is of rank $N-1$ (extract one other two column, starting from the second column to see that). Then it becomes clear that b is of rank $N-1$ and that every extracted matrix b' taking any $N-1$ rows is also of rank $N-1$. □

Now, we can prove the main point of the section in the following.

THEOREM 3.6. *The set of spaces $\{V_j^{[0,+\infty[}\}_{j\in\mathbb{Z}}$ is an MRA of $L^2([0,+\infty[)$ in the sense:*

1. $\{0\} = \bigcap_{j\in\mathbb{Z}} V_j^{[0,+\infty[} \subset \cdots \subset V_{-1}^{[0,+\infty[} \subset V_0^{[0,+\infty[} \subset V_1^{[0,+\infty[} \subset \cdots \subset \overline{\bigcup_{j\in\mathbb{Z}} V_j^{[0,+\infty[}} = L^2([0,+\infty[)$.

2. $f(x) \in V_0^{[0,+\infty[} \Longleftrightarrow f(2^j x) \in V_j^{[0,+\infty[}$.

Proof.

(i) First verify that $V_{-1}^{[0,+\infty[} \subset V_0^{[0,+\infty[}$. Thanks to (15), we can see that $\tilde{\Phi}_\ell(x/2) \in V_0^{[0,+\infty[}$. Moreover, using (4), $\Phi_k(x/2) = \sqrt{2}\sum_{m=-N+1}^{N} h_m \Phi_{2k+m}(x)$, and for $k \geq N-\alpha$ and $m \geq -N+1$, we have $2k+m \geq N+1-2\alpha \geq N-\alpha$, so that $\Phi_k(x/2) \in V_0^{[0,+\infty[}$.

(ii) The density of $\bigcup_{j\in Z} V_j^{[0,+\infty[}$ in $L^2([0,+\infty[)$ is directly derived from the density of $\bigcup_{j\in Z} \mathrm{Span}\left\{\Phi(2^j.-k)\ ;\ k \geq N\right\}$ in $L^2([0,+\infty[)$ (see [Meye 92], [CDV 93]).

(iii) The property $\bigcap_{j\in Z} V_j^{[0,+\infty[} = \lim_{j\to-\infty} V_j^{[0,+\infty[} = 0$ results from the fact that all basis functions of $V_0^{[0,+\infty[}$ are in $L^\infty([0,+\infty[)$. □

3.2. Multiresolution analysis on [0,+∞[with boundary conditions. Let us introduce the notations for the homogeneous boundary conditions we impose to the functions.

DEFINITION 3.7. *Let $\Lambda \subset \{0,\ldots,N-1\}$ (it may be $\emptyset$). We define by $BC(\Lambda)$ the vector space of functions f in $L^2([0,+\infty[)$ that are at least $\max\Lambda$ times derivable at 0 and satisfy*

$$\forall \lambda \in \Lambda,\ f^{(\lambda)}(0) = 0.$$

We define now the spaces

$$V_j^{[0,+\infty[}(\Lambda) = V_j^{[0,+\infty[} \bigcap BC(\Lambda)\ . \tag{17}$$

Notice that in the case $\alpha = 0$, all edge functions are polynomial near 0, so there is no problem of derivability at 0. On the contrary, if $\alpha = 1$, the regularity of the edge scaling functions at 0 depends on N. In this case, we will suppose in the following that N is sufficiently large so that no problem of derivability would occur.

Remark that by definition of the edge scaling functions, we have

$$\tilde{\Phi}_\ell^{(\lambda)}(0) = \delta_{\ell-\lambda} \ \text{ for } \ell \in \{0,\ldots,N-1\}, \text{ and } \ \Phi_k^{(\lambda)}(0) = 0 \ \text{ for } k \geq N-\alpha,$$

whatever $\lambda \in \Lambda$. So that according to Proposition 3.2, a basis of $V_0^{[0,+\infty[}(\Lambda)$ is given by the family

$$\left\{\tilde{\Phi}_\ell\right\}_{\ell\notin\Lambda} \bigcup \{\Phi_k\}_{k\geq N-\alpha}\,.$$

To get an orthonormal basis of $V_0^{[0,+\infty[}(\Lambda)$, it is sufficient to orthonormalize the functions $\tilde{\Phi}_\ell$ for $\ell \notin \Lambda$. Let $\tilde{\tilde{\Phi}}_\ell, \ell \notin \Lambda$ the functions obtained by orthonormalization (the orthonormalization will be detailed in section 5). We will now construct the wavelets associated with this MRA.

3.3. Construction of the wavelets. In this section we construct the wavelet basis associated to the MRA $\{V_j^{[0,+\infty[}(\Lambda)\}$, with or without boundary conditions (this

latter case corresponds to $\Lambda = \emptyset$). We define the subspace of $L^2([0,+\infty[)$ orthogonal to $V_j^{[0,+\infty[}(\Lambda)$ in $V_{j+1}^{[0,+\infty[}(\Lambda)$:

$$W_j^{[0,+\infty[}(\Lambda) = V_{j+1}^{[0,+\infty[}(\Lambda) \ominus V_j^{[0,+\infty[}(\Lambda).$$

By scale invariance, the wavelet basis will be constructed from a basis of $W_0^{[0,+\infty[}(\Lambda)$. It is easy to see that the functions Ψ_k, for $k \geq N-\alpha$ belong to $W_0^{[0,+\infty[}(\Lambda)$. These are called interior wavelets. Let us now define the edge wavelets.

DEFINITION 3.8. *For $\ell \in \{0,\dots,N-1\}$ the edge wavelets $\tilde{\Psi}_\ell$ are defined by*

$$\text{For } x \geq 0,\ \tilde{\Psi}_\ell(x) = \sqrt{2}\left(I - P_{V_0^{[0,+\infty[}(\Lambda)}\right)\left(\tilde{\Phi}_\ell(2x) - 2^\ell \tilde{\Phi}_\ell(x)\right),$$

where I is the identity operator.

Notice that for $\ell \in \Lambda$ the equality simplifies because $\tilde{\Phi}_\ell \in V_0^{[0,+\infty[}(\Lambda)$ and therefore $\left(I - P_{V_0^{[0,+\infty[}(\Lambda)}\right)\left(\tilde{\Phi}_\ell\right) = 0$. Using (15) we can also write (using the notations of (15)):

$$\begin{pmatrix} \tilde{\Psi}_0 \\ \vdots \\ \tilde{\Psi}_{N-1} \end{pmatrix} = -\sqrt{2}\left(I - P_{V_0^{[0,+\infty[}(\Lambda)}\right) D^{-1} b \begin{pmatrix} \Phi_{N-\alpha}(2.) \\ \vdots \\ \Phi_{3N-2-2\alpha}(2.) \end{pmatrix}. \tag{18}$$

The main point of the section is the following.

THEOREM 3.9. *The edge wavelets $\tilde{\Psi}_\ell$ for $\ell = 0,\dots,N-1$ verify:*

1. *The functions $\tilde{\Psi}_\ell$ belong to $V_1^{[0,+\infty[}(\Lambda)$.*
2. *The functions $\tilde{\Psi}_\ell$ are orthogonal to $V_0^{[0,+\infty[}(\Lambda)$.*
3. *The functions $\tilde{\Psi}_\ell$ are orthogonal to the interior wavelets Ψ_k, $k \geq N-\alpha$.*
4. *The rank of the family $\left\{\tilde{\Psi}_0,\dots,\tilde{\Psi}_{N-1}\right\}$ is $N-\alpha$ and every subfamily of $N-\alpha$ functions is of full rank.*

Proof. By definition, the functions $\tilde{\Psi}_\ell$ verify the boundary conditions, and (18) leads to the point 1. The point 2 comes directly from Definition 3.8. For the point 3, let $\ell \in \{0,\dots,N-1\}$ and $k \geq N-\alpha$, then

$$\left\langle \tilde{\Psi}_\ell \mid \Psi_k \right\rangle = \left\langle \tilde{\Phi}_\ell(2.) \mid \Psi_k \right\rangle - 2^k \left\langle \tilde{\Phi}_\ell \mid \Psi_k \right\rangle - \left\langle P_{V_0^{[0,+\infty[}(\Lambda)}\left(\tilde{\Phi}_\ell(2x) - 2^\ell \tilde{\Phi}_\ell(x)\right) \mid \Psi_k \right\rangle.$$

Since Ψ_k is orthogonal to $V_0^{[0,+\infty[}(\Lambda)$, and using the two-scale equation (5), we get

$$\left\langle \tilde{\Psi}_\ell \mid \Psi_k \right\rangle = \left\langle \tilde{\Phi}_\ell(2.) \mid \Psi_k \right\rangle = \sum_m g_m \left\langle \tilde{\Phi}_\ell(2.) \mid \Phi(2.-m) \right\rangle = 0,$$

by the orthogonality between the edge scaling functions $\tilde{\Phi}_\ell$ and the interior scaling functions Φ_m.

The last point comes from a dimensional argument. By definition of the functions $\tilde{\Psi}_\ell$, and using (5), it is easy to verify that

$$\begin{aligned} &\operatorname{Span}\left\{\tilde{\Phi}_\ell\right\}_{\ell\notin\Lambda} \oplus \operatorname{Span}\left\{\tilde{\Psi}_\ell\right\}_{\ell=0,\dots,N-1} \\ &\quad = \operatorname{Span}\left\{\tilde{\Phi}_\ell(2.)\right\}_{\ell\notin\Lambda} \oplus \operatorname{Span}\left\{ b \begin{pmatrix} \Phi_{N-\alpha}(2.) \\ \vdots \\ \Phi_{3N-2-2\alpha}(2.) \end{pmatrix} \right\}; \end{aligned}$$

then

$$dim\ \mathrm{Span}\left\{\tilde{\Psi}_\ell\right\}_{\ell=0,\dots,N-1} = dim\ \mathrm{Span}\left\{ b \begin{pmatrix} \Phi_{N-\alpha}(2.) \\ \vdots \\ \Phi_{3N-2-2\alpha}(2.) \end{pmatrix} \right\} = N-\alpha,$$

since the rank of the matrix b is $N-\alpha$, and the result holds from Proposition 3.5. □

Then

$$W_0^{[0,+\infty[}(\Lambda) = \mathrm{span}\left\{ \{\tilde{\Psi}_\ell\}_{0\le\ell\le N-1}\ ;\ \{\Psi_k\}_{k\ge N-\alpha} \right\}.$$

To obtain a basis of $W_0^{[0,+\infty[}(\Lambda)$ it is sufficient to extract $N-\alpha$ functions of $\{\tilde{\Psi}_0,\dots,\tilde{\Psi}_{N-1}\}$ and to add the set of functions $\{\Psi_k\}_{k\ge N-\alpha}$. Then, orthonormalizing $N-\alpha$ of the functions $\tilde{\Psi}_\ell$ and adding the interior wavelets, we obtain an orthonormal basis of $W_0^{[0,+\infty[}(\Lambda)$.

4. Adaptation to the interval [0, 1]. The previous sections were devoted to the half line. Our goal is to construct an MRA on $[0,1]$. We will see how to adapt the above construction to this case. The boundary conditions at edge 0 are taken into account by constructing an MRA of $L^2([0,+\infty[)$ with boundary conditions $BC(\Lambda_0)$, and those at edge 1 by constructing an MRA of $L^2(]-\infty,1])$ with boundary conditions $BC(\Lambda_1)$. Then, merging the two MRAs will lead to the result.

4.1. MRA on]−∞, 1] with boundary conditions. The MRA on $]-\infty,1]$ will be constructed from an MRA on $[0,+\infty[$ by a change of variable given by the operator T:

$$\text{for } f\in L^2(\mathbb{R}),\quad Tf(x) = f(1-x). \tag{19}$$

Then Tf belongs to $L^2(\mathbb{R})$. We see that *support* $T\Phi = [-N+1, N]$, the same as Φ. $T\Phi$ satisfies a two-scale relation:

$$T\Phi(.) = \sqrt{2}\sum_{k=-N+1}^{N} \check{h}_k\ T\Phi(2.-k), \tag{20}$$

where $\check{h}_k = h_{1-k}$ for all k in $\mathbb{Z}$.

Notice that this operator is isometric from $L^2([0,+\infty[)$ to $L^2(]-\infty,1])$:

$$\int_{-\infty}^{1} Tf(x)\ Tg(x)dx = \int_0^{+\infty} f(x)g(x)dx,$$

and it is involutive on $L^2(\mathbb{R})$: $TT = I$.

Starting from the function $T\Phi$, instead of Φ, we can construct a new MRA of $L^2([0,+\infty[)$ satisfying boundary conditions defined by the set Λ_1. It provides us with the following:

(i) edge scaling functions $\tilde{\Phi}_\ell^\sharp$ for $\ell\notin\Lambda_1$,
(ii) interior scaling functions $T\Phi_k$ for $k\ge N-\alpha_1$,
(iii) edge wavelets $\tilde{\Psi}_\ell^\sharp$ for $\ell = 0,\dots,N-1-\alpha_1$,
(iv) interior wavelets $T\Psi_k$ for $k\ge N-\alpha_1$,

with a parameter α_1 which is either 0 or 1. Thus, to generate a basis of an MRA of $L^2(]-\infty,1])$ it is sufficient to consider the functions:

$$T(\tilde{\Phi}_\ell^\sharp), T(T\Phi_k), T(\tilde{\Psi}_\ell^\sharp), \text{ and } T(T\Psi_k).$$

Remark.

$$T\left(T\left[\Phi_k(2^j.)\right]\right)(x) = \Phi_{-1-k+2^j}(2^j x).$$

4.2. MRA on [0, 1] with boundary conditions. We merge the two MRAs of $L^2([0,+\infty[)$ and $L^2(]-\infty,1])$, in order to construct an MRA on $[0,1]$ verifying boundary conditions, $\{V_j^{[0,1]}(\Lambda_0,\Lambda_1)\}_{j\geq j_{min}}$. We will choose j_{min} so that edge functions at 0 and edge functions at 1 do not interact (i.e., their supports are disjoint). For a given scale j, the functions at edge 0 are supported on $[0,(2N-1-\alpha_0)/2^j]$ (we note α_0 instead of α not to confuse the parameters of both edges) and the functions at edge 1 are supported on $[1-(2N-1-\alpha_1)/2^j,1]$. Then j_{min} will be so that

$$2^{j_{min}} \geq 4N-\alpha_0-\alpha_1.$$

Since $\alpha_0,\alpha_1 \leq 1$, we get

$$j_{min} = \lceil \log_2 4N \rceil.$$

The vector space $V_j^{[0,1]}(\Lambda_0,\Lambda_1)$ for $j \geq j_{min}$ will be the span of the following functions:

(i) $\tilde{\Phi}_\ell(2^j.)$ for $\ell \notin \Lambda_0$ (edge functions at 0),
(ii) $\tilde{\Phi}_\ell^\sharp(2^j(1-.))$ for $\ell \notin \Lambda_1$ (edge functions at 1),
(iii) Φ_k for $\{k \geq N-\alpha_0; \exists \ell \geq N-\alpha_1, k=-1-\ell+2^j\}$ (interior scaling functions).

The interior scaling functions are those common in the MRA of $L^2([0,+\infty[)$ and $L^2(]-\infty,1])$. They correspond to

$$N-\alpha_0 \leq k \leq 2^j-N-1+\alpha_1.$$

We would like to renumber the scaling functions at edge 1. So we define

$$\tilde{\Phi}_{2^j-1-l} \stackrel{def}{=} \tilde{\Phi}_\ell^\sharp.$$

The indices cannot be confused with those at edge 0 when $j \geq j_{min}$.

The vector space $W_j^{[0,1]}(\Lambda_0,\Lambda_1)$ for $j \geq j_{min}$ is constructed similarly. Let us evaluate the dimensions of these spaces:

$$\begin{aligned} dim\ V_j^{[0,1]}(\Lambda_0,\Lambda_1) &= (N-\#\Lambda_0) + \big((2^j-N-1+\alpha_1)-(N-\alpha_0)+1\big) + (N-\#\Lambda_1) \\ &= 2^j - \#\Lambda_0 - \#\Lambda_1 + \alpha_0 + \alpha_1, \\ dim\ W_j^{[0,1]}(\Lambda_0,\Lambda_1) &= (N-\alpha_0) + \big((2^j-N-1+\alpha_1)-(N-\alpha_0)+1\big) + (N-\alpha_1) \\ &= 2^j. \end{aligned}$$

The interest of parameters α_0 and α_1 is now clear; when we need equal dimensions (for example, in order to construct wavelet packets), if there is at most one boundary condition at each edge, we can fix the parameters α_0 and α_1 so that $dim V_j^{[0,1]}(\Lambda_0,\Lambda_1) = 2^j$. Therefore, we will choose

$$\alpha_0 = \delta_{\#\Lambda_0-1} \text{ and } \alpha_1 = \delta_{\#\Lambda_1-1}.$$

5. Practical computations.

5.1. Orthonormalization of the scaling functions. It is often more interesting to have an orthonormal basis than a Riesz basis for the spaces $V_j^{[0,1]}(\Lambda_0,\Lambda_1)$ and $W_j^{[0,1]}(\Lambda_0,\Lambda_1)$. As we have seen before, orthonormalizing the edge functions would lead to orthonormal bases, since they are already orthogonal to interior functions. For that, we need their Gram matrix.

We use (15). Multiplying by the transpose of each term of this equality and integrating on $[0,+\infty[$ each member leads to the following proposition.

PROPOSITION 5.1. *The Gram matrix $G^{\tilde\Phi}$ of the edge scaling functions $\tilde\Phi_\ell$ for $\ell=0,\dots,N-1$ is given by*

$$2G^{\tilde\Phi} = DG^{\tilde\Phi}D + b\,{}^t\!b, \tag{21}$$

where the matrices D and b have been introduced in (15).

Actually the product $DG^{\tilde\Phi}D$ is the term-by-term multiplication of the matrix $G^{\tilde\Phi}$ by the matrix M of general term $M_{ij}=1/2^{i+j-2}$ for $1\le i,j\le N$. Denoting by M_1 the $N\times N$ matrix whose general term is 1, computing $G^{\tilde\Phi}$ is equivalent to divide term-by-term the matrix $b\,{}^t\!b$ by the matrix $2M_1-M$. Note that the computation of this matrix is easier than in [CDV 93].

To take into account the boundary conditions, we retain only the functions $\tilde\Phi_\ell$ for $\ell\notin\Lambda$. Their Gram matrix is obtained from $G^{\tilde\Phi}$ by keeping only the rows and the columns whose index is not in $1+\Lambda$. The 1 comes from the fact that we number the rows and columns of the matrix starting from 1 and not from 0: let $G_\Lambda^{\tilde\Phi}$ this matrix. The Gram procedure allows us to orthonormalize the edge scaling functions $(\tilde\Phi_\ell)_{\ell\notin\Lambda}$.

PROPOSITION 5.2. *Defining*

$$\begin{pmatrix} \tilde{\tilde\Phi}_0 \\ \vdots \\ \tilde{\tilde\Phi}_{N-1} \end{pmatrix}_{\ell\notin\Lambda} = (G_\Lambda^{\tilde\Phi})^{-\frac12} \begin{pmatrix} \tilde\Phi_0 \\ \vdots \\ \tilde\Phi_{N-1} \end{pmatrix}_{\ell\notin\Lambda} \tag{22}$$

the family of scaling functions $\{\tilde{\tilde\Phi}_\ell\}_{\ell\notin\Lambda}$ is orthonormal and satisfies the two-scale equation

$$\frac{1}{\sqrt2}\begin{pmatrix} \tilde{\tilde\Phi}_0 \\ \vdots \\ \tilde{\tilde\Phi}_{N-1} \end{pmatrix}_{\ell\notin\Lambda}\left(\frac{x}{2}\right) = H_0\begin{pmatrix} \tilde{\tilde\Phi}_0 \\ \vdots \\ \tilde{\tilde\Phi}_{N-1} \end{pmatrix}_{\ell\notin\Lambda}(x) + h_0\begin{pmatrix} \Phi_{N-\alpha} \\ \vdots \\ \Phi_{3N-2-2\alpha} \end{pmatrix}(x) \tag{23}$$

where H_0 and h_0 are the $(N-\#\Lambda)\times(N-\#\Lambda)$ and $(N-\#\Lambda)\times(2N-1-\alpha)$ matrices:

$$H_0 = \frac{1}{\sqrt2}\,(G_\Lambda^{\tilde\Phi})^{-1/2}\,D_\Lambda\,(G_\Lambda^{\tilde\Phi})^{1/2} \quad \textit{and} \quad h_0 = \frac{1}{\sqrt2}\,(G_\Lambda^{\tilde\Phi})^{-1/2}\,b_\Lambda.$$

The matrix D_Λ is extracted from D retaining only rows and columns of numbers not in $\Lambda+1$ and b_Λ from b retaining rows of numbers not in $\Lambda+1$.

Remark that $H_0\,{}^t\!H_0 + h_0\,{}^t\!h_0 = I$.

5.2. Orthonormalization of the wavelets. Similarly as for the scaling functions, orthonormalizing the wavelet basis amounts to orthonormalizing the edge wavelets $\tilde{\Psi}_\ell$. To compute the Gram matrix $G^{\tilde{\Psi}}$ of the $\tilde{\Psi}_\ell$, we need the following lemma.

LEMMA 5.3. *The edge wavelets $\tilde{\Psi}_\ell$ satisfy*

$$\frac{1}{\sqrt{2}}\begin{pmatrix}\tilde{\Psi}_0\\ \vdots\\ \tilde{\Psi}_{N-1}\end{pmatrix}\left(\frac{x}{2}\right) = g_1 \begin{pmatrix}\tilde{\tilde{\Phi}}_0\\ \vdots\\ \tilde{\tilde{\Phi}}_{N-1}\end{pmatrix}_{\ell\notin\Lambda}(x) + g_2 \begin{pmatrix}\Phi_{N-\alpha}\\ \vdots\\ \Phi_{3N-2-2\alpha}\end{pmatrix}(x) \tag{24}$$

with $g_1 = D^{-1}b\ {}^t h_0 H_0$ and $g_2 = D^{-1}b\ ({}^t h_0 h_0 - I)$.

Proof. By definition (18) of the $\tilde{\Psi}_\ell$:

$$\left(\frac{1}{\sqrt{2}}\tilde{\Psi}_\ell\left(\frac{x}{2}\right)\right)_{\ell=0,N-1} = -D^{-1}b \begin{pmatrix}\Phi_{N-\alpha}(x)\\ \vdots\\ \Phi_{3N-2-2\alpha}(x)\end{pmatrix} + D^{-1}b\ P_{V_0^{[0,+\infty[}(\Lambda)} \begin{pmatrix}\Phi_{N-\alpha}(2.)\\ \vdots\\ \Phi_{3N-2-2\alpha}(2.)\end{pmatrix}\left(\frac{x}{2}\right).$$

Let us compute, for $k = N-\alpha,\dots,3N-2-2\alpha$:

$$P_{V_0^{[0,+\infty[}(\Lambda)}\left(\Phi_k(2.)\right)\left(\frac{x}{2}\right) = \sum_{\ell\notin\Lambda}\langle\,\Phi_k(2.)\mid\tilde{\tilde{\Phi}}_\ell\rangle\,\tilde{\tilde{\Phi}}_\ell\left(\frac{x}{2}\right) + \sum_{n\geq N-\alpha}\langle\Phi_k(2.)\mid\Phi_n\rangle\,\Phi\left(\frac{x}{2}-n\right).$$

We have $\langle\Phi_k(2.)\mid\Phi_n\rangle = 0$ for $N-\alpha\leq k\leq 3N-2-2\alpha$ and $n\geq N-\alpha$.

Applying twice (23) and the orthonormality between the $\tilde{\tilde{\Phi}}_\ell$ leads to

$$\left(\langle\Phi_k(2.)\mid\tilde{\tilde{\Phi}}_\ell\rangle\right)_{\substack{N-\alpha\leq k\leq 3N-2-2\alpha\\ \ell\notin\Lambda}} = \frac{1}{\sqrt{2}}\ {}^t h_0,$$

and using (23) once more:

$$P_{V_0^{[0,+\infty[}(\Lambda)}\begin{pmatrix}\Phi_{N-\alpha}(2.)\\ \vdots\\ \Phi_{3N-2-2\alpha}(2.)\end{pmatrix}\left(\frac{x}{2}\right) = {}^t h_0\ H_0 \begin{pmatrix}\tilde{\tilde{\Phi}}_0(x)\\ \cdots\\ \tilde{\tilde{\Phi}}_{N-1}(x)\end{pmatrix}_{\ell\notin\Lambda} + {}^t h_0\ h_0 \begin{pmatrix}\Phi_{N-\alpha}(x)\\ \vdots\\ \Phi_{3N-2-2\alpha}(x)\end{pmatrix},$$

which gives the expected result. ∎

It is then easy to compute the Gram matrix $G^{\tilde{\Psi}}$of the edge wavelets:

$$G^{\tilde{\Psi}} = g_1\,{}^t g_1 + g_2\,{}^t g_2.$$

Remember that in the case $\alpha = 1$, we must skip one of the functions $\tilde{\Psi}_\ell$ then we skip the row and the corresponding column in $G^{\tilde{\Psi}}$. This matrix will be called $G^{\tilde{\Psi}}$ again. In order to simplify the notations, let us assume that the removed function is $\tilde{\Psi}_{N-1}$.

PROPOSITION 5.4. *Let* $G_0 = (G^{\tilde{\Psi}})^{-1/2}\ g_1$ *and* $g_0 = (G^{\tilde{\Psi}})^{-1/2}\ g_2$, *we can write*

$$\frac{1}{\sqrt{2}} \begin{pmatrix} \tilde{\tilde{\Psi}}_0 \\ \vdots \\ \tilde{\tilde{\Psi}}_{N-1-\alpha} \end{pmatrix} \left(\frac{x}{2}\right) = G_0 \begin{pmatrix} \tilde{\tilde{\Phi}}_0 \\ \vdots \\ \tilde{\tilde{\Phi}}_{N-1} \end{pmatrix}_{k \notin \Lambda} (x) + g_0 \begin{pmatrix} \Phi_{N-\alpha} \\ \vdots \\ \Phi_{3N-2-2\alpha} \end{pmatrix} (x). \tag{25}$$

As in [Ausc 93], the bases constructed here allow us to characterize some subspaces of $H^s([0,1])$ defined by vanishing derivatives at the edges. The characterizations provide, moreover, a diagonal preconditioner for the derivative operators, as in [Jaff 92].

Numerically, all the calculations have been done to obtain the two-scale relations (23) and (25) that give the matrices used in the fast algorithms.

5.3. Fast algorithms. As in the case of the real line, we can describe a fast algorithm for analyzing and synthesizing vectors in the spaces of the MRA. The algorithm is based on the elementary step

$$V_j^{[0,1]}(\Lambda_0, \Lambda_1) = V_{j-1}^{[0,1]}(\Lambda_0, \Lambda_1) \oplus W_{j-1}^{[0,1]}(\Lambda_0, \Lambda_1).$$

Suppose that we know the scalar products of a given function f in $V_j^{[0,1]}(\Lambda_0, \Lambda_1)$ with the corresponding scaling functions, and that we want to compute scalar products with the scaling functions of $V_{j-1}^{[0,1]}(\Lambda_0, \Lambda_1)$ and with the wavelets of $W_{j-1}^{[0,1]}(\Lambda_0, \Lambda_1)$.

We start then from a vector c^j composed of:

(i) $\langle\ f \mid 2^{j/2}\tilde{\tilde{\Phi}}_\ell(2^j .)\ \rangle$ for $\ell \in \{0, \ldots, N-1\} \backslash \Lambda_0$,

(ii) $\langle\ f \mid 2^{j/2}\Phi_k(2^j .)\ \rangle$ for $N - \alpha_0 \leq k \leq 2^j - 1 - N + \alpha_1$,

(iii) $\langle\ f \mid 2^{j/2}\tilde{\tilde{\Phi}}_\ell(2^j .)\ \rangle$ for $\ell \in \{2^j - 1, \ldots, 2^j - N\} \backslash \{2^j - 1 - \Lambda_1\}$.

To obtain the projection of the function f on $V_{j-1}^{[0,1]}(\Lambda_0, \Lambda_1)$, we have to multiply the vector c^j by the matrix

$$\begin{pmatrix} H_0 & h_0 & 0 \\ 0 & \mathcal{H}^j & 0 \\ 0 & h_1 & H_1 \end{pmatrix},$$

where:

(i) $\mathcal{H}^j$ is the square $(2^j - 2N + \alpha_0 + \alpha_1) \times (2^j - 2N + \alpha_0 + \alpha_1)$ matrix whose general term is $\mathcal{H}^j_{k,l} = h_{-N+1+\alpha_0+l-2k}$ (the classical filter h_k is defined in (4)),

(ii) h_0 (defined, as H_0, in (23) for the edge 0) is completed with columns of 0 at the right to fit the width of $\mathcal{H}^j$,

(iii) h_1 (defined, as H_1, in (23) for the edge 1) with columns of 0 at the left.

To obtain the projection on $W_{j-1}^{[0,1]}(\Lambda_0, \Lambda_1)$, we multiply c^j by the matrix

$$\begin{pmatrix} G_0 & g_0 & 0 \\ 0 & \mathcal{G}^j & 0 \\ 0 & g_1 & G_1 \end{pmatrix},$$

where

(i) $\mathcal{G}^j$ is the square $(2^j - 2N + \alpha_0 + \alpha_1) \times (2^j - 2N + \alpha_0 + \alpha_1)$ matrix whose general term is $\mathcal{G}^j_{k,l} = g_{-N+1+\alpha_0+l-2k}$ (the classical filter g_k is defined in (5)),

(ii) g_0 (defined, as G_0, in (25) for the edge 0) is completed with columns of 0 at the right to fit the width of $\mathcal{G}^j$,

(iii) g_1 (defined, as G_1, in (25) for the edge 1) with columns of 0 at the left.

The result lies in the vectors c^{j-1} and d^{j-1}.

To find c^j starting from c^{j-1} and d^{j-1}, we have to multiply the column vector

$$\begin{pmatrix} c^{j-1} \\ d^{j-1} \end{pmatrix}$$

by the matrix

$$\begin{pmatrix} {}^tH_0 & 0 & 0 & {}^tG_0 & 0 & 0 \\ {}^th_0 & \tilde{\mathcal{H}}^j & {}^th_1 & {}^tg_0 & \tilde{\mathcal{G}}^j & {}^tg_1 \\ 0 & 0 & {}^tH_1 & 0 & 0 & {}^tG_1 \end{pmatrix},$$

where the matrices $\tilde{\mathcal{H}}^j$ and $\tilde{\mathcal{G}}^j$ (which have the same size as $\mathcal{H}^j$ and $\mathcal{G}^j$) are built from the h_k and g_k and h_0, g_0, h_1, g_1 are completed with columns of zeros, as above. Notice that in practice, for this algorithm, matrix multiplication is used only for the edges; for interior points it is much faster to rely on discrete convolutions as on the real line.

5.4. Numerical filters and graphs. As an example we compute, for $N = 2$ vanishing moments, the discrete edge filters H_0, H_1, h_0, h_1, G_0, G_1, g_0, g_1 introduced in (23–25) (Tables 1, 2, and 3), for various boundary conditions and values of α. These filters are associated to the classical filters on $\mathbb{R}$ defined by [Daub 88]:

h_{-1}	=	0.48296291314453	g_{-1}	=	−0.12940952255126
h_0	=	0.83651630373781	g_0	=	−0.22414386804201
h_1	=	0.22414386804201	g_1	=	0.83651630373781
h_2	=	−0.12940952255126	g_2	=	−0.48296291314453.

In addition, we plot the graphs of the corresponding edge scaling functions and edge wavelets for Dirichlet boundary conditions and for the two possible values of the parameter α:

– for $\alpha = 0$: table 2 and Figure 1 (edge 0),

– for $\alpha = 1$: table 3 and Figure 2 (edge 0).

Note that for $\alpha = 0$ the edge functions are polynomials up to degree $N - 1$ near the boundary, this is no more true for $\alpha = 1$, but in this case $dim\ V_j^{[0,1]}(Dirichlet) = dim\ W_j^{[0,1]}(Dirichlet) = 2^j$.

6. Computation of operators. In the following, we will suppose that N is large enough so that the scaling functions and the wavelets are sufficiently differentiable, in order to compute the derivative operators.

6.1. First-order derivative operator. We focus first at edge 0. We want to compute the map:

$$P_{V_j^{[0,+\infty[}(\Lambda)} \left(\frac{d}{dx}\right) P_{V_j^{[0,+\infty[}(\Lambda)},$$

where $P_{V_j^{[0,+\infty[}(\Lambda)}$ is the orthogonal projection on $V_j^{[0,+\infty[}(\Lambda)$. Since we know an orthonormal basis of $V_j^{[0,+\infty[}(\Lambda)$, it is sufficient to estimate the operator on each

vector of the basis. Using the fact that we are working on an MRA of $L^2([0,+\infty[)$ which is scale invariant, we just have to compute

$$\partial_0 = P_{V_0^{[0,+\infty[}(\Lambda)} \left(\frac{d}{dx}\right) P_{V_0^{[0,+\infty[}(\Lambda)}.$$

We have thus to compute four types of inner products:

$$r_{k,\ell} = \left\langle \Phi_k | \frac{d\Phi_\ell}{dx} \right\rangle \quad \text{for } k, \ell \geq N - \alpha, \tag{26}$$

$$B_{k,\ell} = \left\langle \Phi_k | \frac{d\tilde{\tilde{\Phi}}_\ell}{dx} \right\rangle \quad \text{for } k \geq N - \alpha,\ \ell \notin \Lambda, \tag{27}$$

$$B'_{k,\ell} = \left\langle \tilde{\tilde{\Phi}}_k | \frac{d\Phi_\ell}{dx} \right\rangle \quad \text{for } k \notin \Lambda,\ \ell \geq N - \alpha, \tag{28}$$

$$A_{k,\ell} = \left\langle \tilde{\tilde{\Phi}}_k | \frac{d\tilde{\tilde{\Phi}}_\ell}{dx} \right\rangle \quad \text{for } k, \ell \notin \Lambda. \tag{29}$$

Notice that integrating by parts we have since $\Phi_\ell(0) = 0$, $B'_{k,\ell} = -B_{\ell,k}$. The calculation of the $r_{k,\ell}$ is as follows:

$$r_{k,\ell} = \int_0^{+\infty} \Phi(x-k)\ \frac{d\Phi}{dx}(x-\ell)\ dx = \int_{\mathbb{R}} \Phi(x-(k-\ell))\ \frac{d\Phi}{dx}(x)\ dx \overset{def}{=} r_{k-\ell}.$$

As explained in [Beyl 92], the r_i can be computed by an eigenvalue problem.

It remains to obtain the matrices A and B corresponding to the terms $A_{k,\ell}$ and $B_{k,\ell}$. According to the supports of the scaling functions, A is a square matrix of size $(N - \#\Lambda)^2$ and B a rectangular matrix, of size $(N - \#\Lambda)$ x $(2N - 2)$.

PROPOSITION 6.1. *The matrices A and B in* (29) and (27) *can be expressed:*

(i) *The matrix B of size $(N - \#\Lambda) \times (2N - 2 - \alpha)$ is given by*

$$B = (G_\Lambda^{\tilde\Phi})^{-1/2}\ B^{\tilde\Phi}$$

where

$$\begin{aligned} B^{\tilde\Phi}_{i+1,j-N+\alpha+1} &\overset{def}{=} \left\langle \tilde\Phi_i \mid \frac{d\Phi_j}{dx} \right\rangle \\ &= \sum_{k=-N+1}^{N-1-\alpha} P_i(k)\ r_{k-j}, \end{aligned} \tag{30}$$

for $i = 0, \dots, N-1, i \notin \Lambda$, and $N - \alpha \le j \le 3N - 3 - 2\alpha$.

(ii) *The matrix A of size $(N - \#\Lambda) \times (N - \#\Lambda)$ is given by*

$$A = (G_\Lambda^{\tilde\Phi})^{-1/2}\ A^{\tilde\Phi}\ {}^t(G_\Lambda^{\tilde\Phi})^{-1/2}$$

where $A^{\tilde\Phi}$ satisfies

$$A^{\tilde\Phi} = D_\Lambda\ A^{\tilde\Phi}\ D_\Lambda - b_\Lambda\ {}^tB^{\tilde\Phi}\ D_\Lambda + D_\Lambda\ B^{\tilde\Phi}\ {}^tb_\Lambda + b_\Lambda\ r\ {}^tb_\Lambda \tag{31}$$

(*r is the square matrix of size $2N - 1 - \alpha$ whose general term is r_{i-j}, D_Λ is the submatrix of D in* (15) *containing only the rows and columns of numbers not in $1 + \Lambda$, b_Λ the submatrix of b in* (15) *containing only the rows of numbers not in $1 + \Lambda$, and $G_\Lambda^{\tilde\Phi}$ is defined in* (21)).

Actually in the case $\alpha = 0$, the above equation has no meaning because of the size of $B^{\tilde\Phi}$: we must add a new column of 0 at the right corresponding to the zero value of the scalar products $\langle \tilde\Phi_k | d\Phi_{3N-2}/dx \rangle$ (the intersection of the supports of these functions is reduced to one point).

Proof. Equation (30) comes directly from Definition 3.1 of the edge functions $\tilde\Phi_i$. Equation (31) is derived from (15) by taking the derivative of each member, transposing, multiplying at right with (15), and integrating. $A^{\tilde\Phi}$ is the matrix of the scalar products $\langle \tilde\Phi_k | d\tilde\Phi_\ell/dx \rangle$. □

As for the Gram matrix in (21), $A^{\tilde\Phi}$ can be computed by a term by term division of matrices. Nevertheless, we can see that here, if $0 \notin \Lambda$, this does not determine the

upper left term of $A^{\tilde{\Phi}}$. Fortunately, we can compute it directly:

$$A^{\tilde{\Phi}}_{1,1} = \int_0^{+\infty} \tilde{\Phi}_0(x) \frac{d\tilde{\Phi}_0}{dx}(x)dx = -\frac{1}{2}\tilde{\Phi}_0(0)^2 = -\frac{1}{2}.$$

As for the construction of the MRA on $[0,1]$, the adaptation to the interval is given through the operator T (given in (19)) and

$$T\frac{df}{dx}(x) \stackrel{def}{=} \frac{df}{dx}(1-x) = -\frac{d\ Tf}{dx}(x),$$

which leads to the following shape for the matrix of the first-order derivative operator in $V_j^{[0,1]}(\Lambda_0, \Lambda_1)$:

$$\delta_j = \left(\begin{array}{c|c|c} A_0 & B_0 & 0 \\ \hline -{}^tB_0 & r^j & -{}^tB_1 \\ \hline 0 & B_1 & A_1 \end{array}\right)$$

where the matrices B_0 (edge 0) and B_1 (edge 1) are completed with columns of zeros, and r^j is built from the r_k. Notice that as usual, the multiplication of a column vector by r^j can be computed by a discrete convolution, which is more efficient.

It is often more interesting to know the derivative operator expressed in the basis of scaling functions at the largest scale and wavelets at intermediate scales. Actually we know the matrix of the derivative operator in the basis of $V_J^{[0,1]}(\Lambda_0, \Lambda_1)$. We use the decomposition

$$V_J^{[0,1]}(\Lambda_0, \Lambda_1) = W_{J-1}^{[0,1]}(\Lambda_0, \Lambda_1) \oplus \cdots \oplus W_{j_{min}}^{[0,1]}(\Lambda_0, \Lambda_1) \oplus V_{j_{min}}^{[0,1]}(\Lambda_0, \Lambda_1).$$

Let $\mathcal{B}$ the basis $V_J^{[0,1]}(\Lambda_0, \Lambda_1)$ composed of scaling functions at the coarsest scale and wavelets at intermediate scales (called the "wavelet" basis). To compute the derivative matrix in this "wavelet" basis, since all the bases are orthonormal, the matrix of the change of basis P from the scaling function basis of $V_J^{[0,1]}(\Lambda_0, \Lambda_1)$ to $\mathcal{B}$ satisfies $P^{-1} = {}^tP$, so that the matrix of the derivative operator in $\mathcal{B}$ is ${}^tP\delta_J P$. Figure 3 gives the shape of the first-order derivative operator and the number of nonzero coefficients, in the two bases.

6.2. Second-order derivative operator. In this section we want to compute the Galerkin operator:

$$P_{V_j^{[0,+\infty[}(\Lambda)} \left(\frac{d^2}{dx^2}\right) P_{V_j^{[0,+\infty[}(\Lambda)}.$$

Knowing this time the scalar products among the scaling functions

$${}_2r_k = \left\langle\ \Phi_k \mid \frac{d^2\Phi}{dx^2}\ \right\rangle,$$

we want to compute the matrices ${}_2A$ and ${}_2B$ of the scalar products:

$$ {}_2A_{i,j} = \left\langle\ \tilde{\tilde{\Phi}}_i \mid \frac{d^2\tilde{\tilde{\Phi}}_j}{dx^2}\ \right\rangle, \tag{32}$$

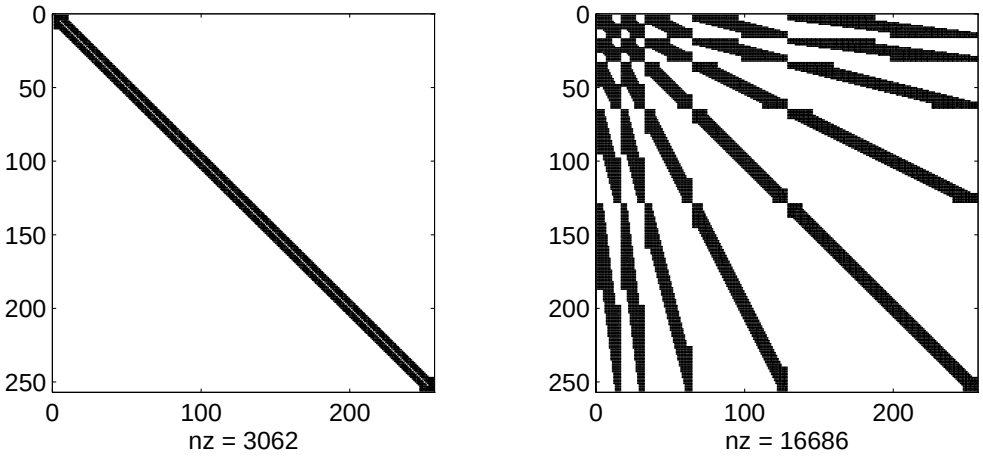

FIG. 3. *Shape of the first-order derivative operator in the basis of scaling functions (left) and in the wavelet basis (right) ($N = 4, j = 8, \Lambda = \emptyset$). We give the number (nz) of nonzero coefficients in each case.*

$$ {}_2B_{i,j} = \left\langle \tilde{\tilde{\Phi}}_i \mid \frac{d^2\Phi_j}{dx^2} \right\rangle. \tag{33} $$

Remark that integrating twice by parts we get ${}_2B_{i,j} = \langle\, \Phi_j \mid d^2\tilde{\tilde{\Phi}}_i/dx^2 \,\rangle$. Similarly, as for Proposition 6.1, we derive the following proposition.

PROPOSITION 6.2. *The matrices ${}_2A$ and ${}_2B$ in* (32–33) *can be expressed:*

(i) *The matrix ${}_2B$ of size $(N - \#\Lambda) \times (2N - 2 - \alpha)$ is given by*

$$ {}_2B = (G_\Lambda^{\tilde{\Phi}})^{-1/2}\ {}_2B^{\tilde{\Phi}} $$

where

$$ \begin{aligned} {}_2B^{\tilde{\Phi}}_{i+1,j-N+\alpha+1} &\overset{def}{=} \left\langle \tilde{\Phi}_i \mid \frac{d^2\Phi_j}{dx^2} \right\rangle \\ &= \sum_{k=-N+1}^{N-1-\alpha} P_i(k)\ {}_2r_{k-j}, \end{aligned} \tag{34} $$

for $i = 0, \ldots, N-1, i \notin \Lambda$, and $N - \alpha \le j \le 3N - 3 - 2\alpha$.

(ii) *The matrix ${}_2A$ of size $(N - \#\Lambda) \times (N - \#\Lambda)$ is given by*

$$ {}_2A = (G_\Lambda^{\tilde{\Phi}})^{-1/2}\ {}_2A^{\tilde{\Phi}}\ {}^t(G_\Lambda^{\tilde{\Phi}})^{-1/2} $$

where $A^{\tilde{\Phi}}$ satisfies

$$ \frac{1}{2}\ ({}_2A^{\tilde{\Phi}}) = D_\Lambda\ ({}_2A^{\tilde{\Phi}})\ D_\Lambda - b_\Lambda\ ({}^t{}_2B^{\tilde{\Phi}})\ D_\Lambda + D_\Lambda\ ({}_2B^{\tilde{\Phi}})\ {}^t b_\Lambda + b_\Lambda\ {}_2r\ {}^t b_\Lambda \tag{35} $$

(${}_2r$ is the square matrix of size $2N - 1 - \alpha$ whose general term is ${}_2r_{i-j}$, D_Λ is the submatrix of D in (15) *containing only the rows and columns of numbers not in $1 + \Lambda$, b_Λ the submatrix of b in* (15) *containing only the rows of numbers not in $1 + \Lambda$, and $G_\Lambda^{\tilde{\Phi}}$ is defined in* (21)).

If $0 \notin \Lambda$ and $1 \notin \Lambda$, (35) allows us to compute all the coefficients of the matrix ${}_2A^{\tilde{\Phi}}$ except the terms ${}_2A^{\tilde{\Phi}}_{1,2}$ and ${}_2A^{\tilde{\Phi}}_{2,1}$. We must compute them directly by

$$\begin{aligned}
{}_2A^{\tilde{\Phi}}_{1,2} &\stackrel{def}{=} \int_0^{+\infty} \tilde{\Phi}_0(x)\ \frac{d^2\tilde{\Phi}_1}{dx^2}(x)\ dx \\
&= \int_0^{+\infty} (1 - \sum_{k=N-\alpha}^{+\infty} \Phi(x-k)) \frac{d^2\tilde{\Phi}_1}{dx^2}(x) dx \\
&= \left[\tilde{\Phi}'_1(x)\right]_0^{+\infty} - \sum_{k=N-\alpha}^{+\infty} \left({}_2B^{\tilde{\Phi}}_{\Lambda}\right)_{2,k-N+\alpha+1} \\
&= -1 - \sum_{k=N-\alpha}^{3N-3-\alpha} \left({}_2B^{\tilde{\Phi}}_{\Lambda}\right)_{2,k-N+\alpha+1},
\end{aligned}$$

and integrating by parts,

$$\begin{aligned}
{}_2A^{\tilde{\Phi}}_{2,1} &= \left[\tilde{\Phi}'_0(x)\tilde{\Phi}_1(x)\right]_0^{+\infty} - \int_0^{+\infty} \tilde{\Phi}'_0(x)\tilde{\Phi}'_1(x) dx \\
&= -\left[\tilde{\Phi}_0(x)\tilde{\Phi}'_1(x)\right]_0^{+\infty} + \int_0^{+\infty} \tilde{\Phi}_0(x) \frac{d^2\tilde{\Phi}_1}{dx^2}(x) dx \\
&= 1 + {}_2A^{\tilde{\Phi}}_{1,2}.
\end{aligned}$$

For the edge 1, things happen in the same way since

$$\left\langle\ Tf \mid \frac{d^2Tg}{dx^2}\ \right\rangle_{L^2([0,+\infty[)} = \left\langle\ f \mid \frac{d^2g}{dx^2}\ \right\rangle_{L^2(]-\infty,1])}.$$

7. Quadrature formulae. The problem discussed here is: Given a continuous function f on $[0,1]$, how to compute its projection on the space $V_j^{[0,1]}(\Lambda_0,\Lambda_1)$? Numerically, the problem is formulated slightly differently.

1. Given the collocation values $\{f(k/2^j)\}_{0\le k\le 2^j}$, how to approximate the inner products:

$$\begin{gathered}
\{\ \langle\ f \mid 2^{j/2}\tilde{\tilde{\Phi}}_\ell(2^j.)\ \rangle\ \}_{\ell\notin\Lambda_0}, \\
\{\ \langle\ f \mid 2^{j/2}\Phi_k(2^j.)\ \rangle\ \}_{N-\alpha_0\le k\le 2^j-1-N+\alpha_1}, \\
\{\ \langle\ f \mid 2^{j/2}\tilde{\tilde{\Phi}}_\ell(2^j(1-.))\ \rangle\ \}_{\ell\notin 2^j-1-\Lambda_1}?
\end{gathered}$$

This point addresses the problem of quadrature formulae, as presented by Sweldens and Piessens in [SwPi 94]; in the case of the real line, they estimate the accuracy of the approximation obtained by the quadrature formulae presented below. We will adapt their method to the interval for our construction of scaling functions (with and without boundary condition).

2. Given a function f in $V_j^{[0,+\infty[}(\Lambda_0,\Lambda_1)$ by its scalar products on the related basis, how to compute the grid values $\{f(k/2^j)\}_{0\le k\le 2^j}$? This point is concerned with the values of scaling functions at points $k/2^j$. We will see how to compute these values in our case.

Note that these two problems are not unisolvant since we have $(2^j - \#\Lambda_0 - \#\Lambda_1 + \alpha_0 + \alpha_1)$ scalar products whereas $2^j + 1$ values of f.

Thus, to go through to solve the point 1, we introduce an integer $q \geq N$, and, as explained in [SwPi 94] and also by Masson in [Mass 96], we consider the nodes for $0 \leq p \leq q$:

$$\begin{aligned} x_p &= -\lfloor q/2 \rfloor + p, \\ y_p &= p. \end{aligned} \tag{36}$$

From the grid values of f at these points, we deduce an approximation of:

- the scalar product $\langle\ f \mid 2^{j/2}\Phi_k(2^j.)\ \rangle$ thanks to the values of f at nodes $(k + x_p)/2^j$,
- the edge scalar product $\langle\ f \mid 2^{j/2}\tilde{\tilde{\Phi}}_\ell(2^j.)\ \rangle$ thanks to the values of f at nodes $y_p/2^j$ (for the edge 0) or $(1 - y_p)/2^j$ (for the edge 1).

The weight coefficients w_p are introduced such that

$$\int_{\mathbb{R}} P(x)\ \Phi(x)\ dx = \sum_{p=0}^{q} w_p\ P(x_p) \tag{37}$$

for all polynomial function P of degree $\leq q$. To find the weights w_p, it is sufficient to solve the linear system

$$\begin{pmatrix} \frac{x_0^0}{0!} & \cdots & \frac{x_q^0}{0!} \\ \vdots & & \vdots \\ \frac{x_0^q}{q!} & \cdots & \frac{x_q^q}{q!} \end{pmatrix} \begin{pmatrix} w_0 \\ \vdots \\ w_q \end{pmatrix} = \begin{pmatrix} C_0 \\ \vdots \\ C_q \end{pmatrix}$$

(the C_k are recursively defined in (11)). Then the inner product is approximated by

$$\langle\ f \mid 2^{j/2}\Phi_k(2^j.)\ \rangle \approx \sum_{p=0}^{q} w_p\ f((k + x_p)/2^j).$$

Remarks. 1. Since the quadrature formula is exact for polynomials up to degree q, the accuracy of the previous interpolation is of order $q+1$; that is, the error between f and its interpolation in V_j is of order $2^{-j(q+1)s}$ in L^2-norm for a s-regular function. To be consistent with the accuracy order of the wavelet projection in V_j, that is 2^{jNs} for Daubechies wavelets (see [Daub 92]), it is sufficient to take $q = N - 1$. But as experimented by Sweldens and Piessens in [SwPi 94], the choice $q = N - 1$ can ruin the approximation properties of the wavelet expansion. Therefore, it is preferable to choose $q \geq N$.

2. As the nodes x_p are equally spaced, we derive no more than a Lagrangian interpolation to compute each coefficient, and for high values of q, the system is ill conditioned. As stated in [SwPi 94], it is then advisable in this case to use Chebyshev nodes.

To take into account these two remarks, we will take q close to N in numerical experiments (see section 8.1).

For the edge 0, we proceed similarly to define the weights w_p^ℓ for $\ell \notin \Lambda_0$ by

$$\int_0^{+\infty} P(x)\tilde{\tilde{\Phi}}_\ell(x)dx = \sum_{p=0}^{q} w_p^\ell\ P(y_p),$$

for all polynomial function P of degree $\leq q$. The remarks stated above concerning the choice of q are also valid for the quadrature formula at the edges, since the approximation properties of wavelets on the interval are similar (see [CDV 93] and [Ausc 93]).

As above, we have to compute the moments of the edge scaling functions. For $0 \leq p \leq q$, define the column vector X_p (vector of edge moments) by

$$X_p = \int_0^{+\infty} \begin{pmatrix} \tilde{\tilde{\Phi}}_0(x) \\ \vdots \\ \tilde{\tilde{\Phi}}_{N-1}(x) \end{pmatrix}_{\ell \notin \Lambda_0} \frac{x^p}{p!} dx.$$

Then using (23) we get

$$X_p = \frac{1}{2^{p+1/2}} \left(H_0 X_p + h_0 \int_0^{+\infty} \begin{pmatrix} \Phi(x - N + \alpha_0) \\ \vdots \\ \Phi(x - (3N - 2 - 2\alpha_0)) \end{pmatrix} \frac{x^p}{p!} dx \right),$$

so that changing of variable in the integrals and using the binomial formula:

$$(2^{p+1/2} I - H_0) X_p = h_0 \begin{pmatrix} \frac{(N-\alpha_0)^p}{p!} & \cdots & \frac{(N-\alpha_0)^0}{0!} \\ \vdots & & \vdots \\ \frac{(3N-2-2\alpha_0)^p}{p!} & \cdots & \frac{(3N-2-2\alpha_0)^0}{0!} \end{pmatrix} \begin{pmatrix} C_0 \\ \vdots \\ C_p \end{pmatrix},$$

which determines exactly X_p since H_0 is similar to $1/\sqrt{2} D_{\Lambda_0}$, so that $2^{p+1/2}$ cannot be an eigenvalue of H_0. Then the w_p^ℓ are determined by the linear systems

$$\begin{pmatrix} w_0^0 & \cdots & w_q^0 \\ \vdots & & \vdots \\ w_0^{N-1} & \cdots & w_q^{N-1} \end{pmatrix}_{\ell \notin \Lambda_0} \begin{pmatrix} \frac{x_0^0}{0!} & \cdots & \frac{x_0^q}{q!} \\ \vdots & & \vdots \\ \frac{x_q^0}{0!} & \cdots & \frac{x_q^q}{q!} \end{pmatrix} = (\, X_0 \mid \cdots \mid X_q \,),$$

and the inner product is approximated by

$$\langle \, f \mid 2^{j/2} \tilde{\tilde{\Phi}}_\ell(2^j .) \, \rangle \;\approx\; \sum_{p=0}^{q} w_p^\ell \, f(p/2^j).$$

The same procedure should be done for the edge 1.

Let us now see how to deal with problem 2. It is clear that it is sufficient to know the values of the scaling functions at integer points. To compute this for interior scaling functions, see [DaMi 93]; using the two-scale equation, we have to solve an eigenvalue problem. For edge scaling functions, we proceed as follows: The nonzero integer values of the $\tilde{\Phi}_\ell$ are at points $0, 1, \ldots, 2N - 2 - \alpha_0$. We use Definition 3.1 to obtain the values $\tilde{\Phi}_\ell(k)$ for $\ell \notin \Lambda_0$ and $0 \leq k \leq 2N - 2 - \alpha_0$, then (22) for the values $\tilde{\tilde{\Phi}}_\ell(k)$.

Notice that all these values could have been approximately obtained via the *cascade algorithm* (see [Daub 92]).

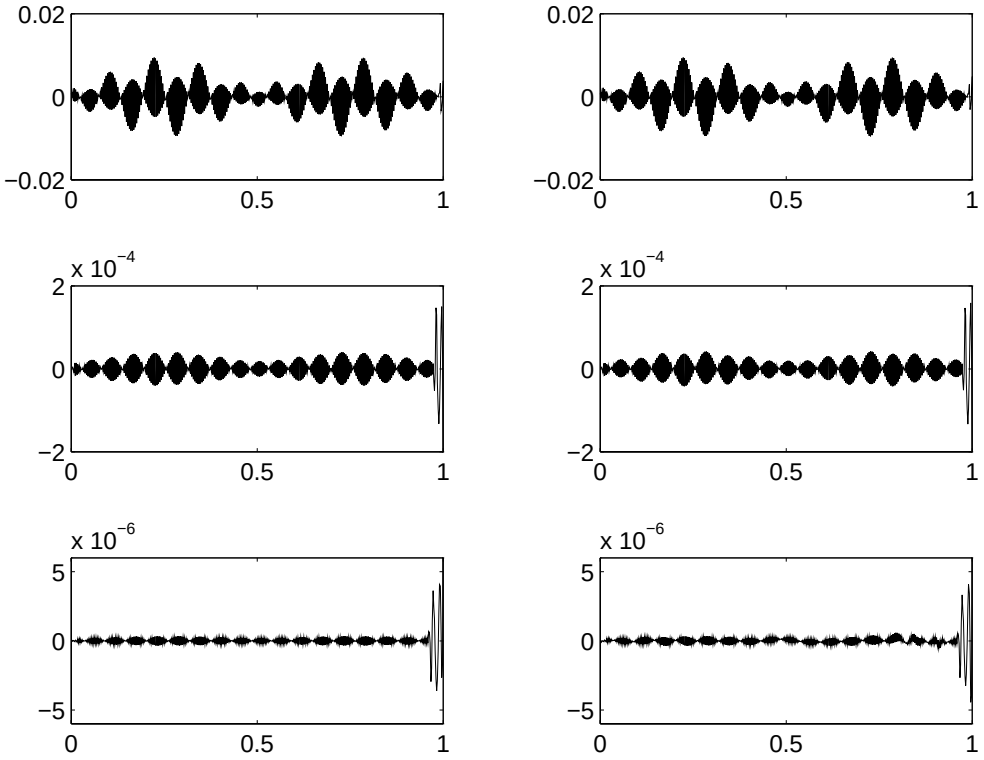

FIG. 4. *Interpolation error (left column) and projection error (right column) in space* V_8 *for* $f(x) = sin(2\pi x)sin(50x)$*, for* $N = q = 2$ *(first row),* $N = 4, q = 5$ *(second row), and* $N = 6, q = 8$ *(last row).*

8. Numerical results.

8.1. Interpolation and projection error. It becomes possible then to compute numerically the projection on $V_j^{[0,1]}(\Lambda_0, \Lambda_1)$ of a given function f.

To compare the interpolation error at the edges and in the interior, we draw the points:

$$\left(\frac{k}{2^p} \ , \ \left(f - \tilde{f}_j\right)\left(\frac{k}{2^p}\right) \right)_{0 \le k \le 2^p}$$

where $\tilde{f}_j$ is the interpolating function of f in $V_j^{[0,1]}(\Lambda_0, \Lambda_1)$, computed by the procedure described in section 7, from the values of f at node points $k/2^j$.

To compare this interpolation error to the projection error $\left(f - P_{V_j^{[0,1]}(\Lambda_0,\Lambda_1)} f\right)$, we also draw the points

$$\left(\frac{k}{2^p} \ , \ \left(f - P_{V_j^{[0,1]}(\Lambda_0,\Lambda_1)} \tilde{f}_{j+4}\right)\left(\frac{k}{2^p}\right) \right)_{0 \le k \le 2^p}.$$

In this case, the interpolation error to compute $\tilde{f}_{j+4}$ will be negligible with regard to the projection in $V_j^{[0,1]}(\Lambda_0, \Lambda_1)$.

Figure 4 represents these curves plotted for $(N = 2, q = 2)$, $(N = 4, q = 5)$, and $(N = 6, q = 8)$ ($q + 1$ is the number of nodes defined in (36) for the quadrature formulae), and $j = 8, p = 9$ and without boundary conditions, analyzing the projection of $f(x) = sin(2\pi x)sin(50x)$.

Experiments show that the interpolation procedure has the same order of accuracy as the projection error. In both cases, we can see that the error is not satisfactory at edge 1, comparatively with the interior. This difference between the error in the interior and the error at the edges grows rapidly with the order N of vanishing moments. However, numerical experiments show that the global error decreases as expected, both in the interior and at the edges, when j is growing. This (relatively) bad result at edge 1 can be interpreted in two manners.

The interpolation error at edge 1 comes from the fact that in the quadrature formula, the $N + 1$ equidistant nodes are localized near the edge. Recalling that the length of the support of the edge basis functions is $2^{-j}(2N - 1)$ at scale j, the nodes cover only half the support of the integrated function! Since usual Daubechies compactly supported wavelets present a strong asymmetry, they are more localized at the left of their support. If we had chosen the least asymmetric ones, the interpolation error would be shared by the two edges.

The projection error at the edges is due to the fact that we keep only N functions at each edge, whereas there are $2N - 1$ scaling functions of $\mathbb{R}$ that contain 0 in their support. The consequence is that there is a loss at the edges of the superconvergence phenomenon observed for the wavelet approximation on $\mathbb{R}$ [Go 95]. The fact that this problem is not visible at the edge 0 comes from the strong asymmetry of the chosen wavelets.

Note that the curves plotted in Figure 4 are very close to those obtained by Masson in [Mass 96], studying the projection error with biorthogonal wavelet bases on the interval.

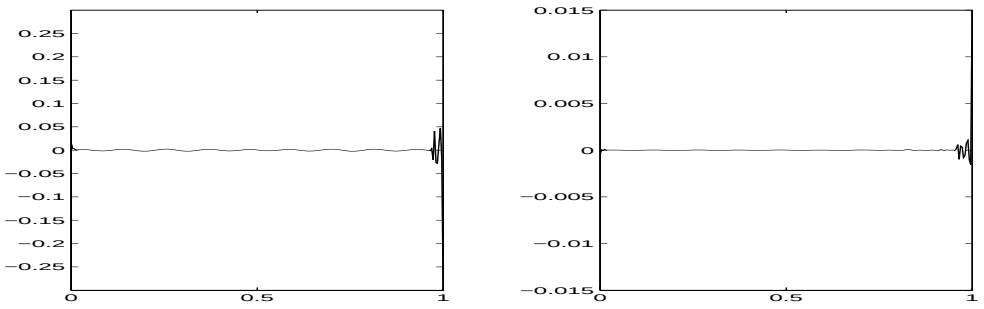

FIG. 5. *Derivative error for $N = 4$ (left column) and $N = 6$ (right column) of $f(x) = sin(2\pi x)sin(50x)$ ($j = 8$ scales).*

8.2. Derivative error. We draw on Figure 5 the derivative error for $N = 4$ and $N = 6$ vanishing moments, without boundary conditions for $f(x) = sin(2\pi x)sin(50x)$, between the exact derivative and the derivative obtained by the Galerkin procedure, as explained in section 6, for $j = 8$ scales. As previously, this derivative error being linked to the projection error, the accuracy is lost at the right edge.

HOPF-TYPE ESTIMATES AND FORMULAS FOR NONCONVEX NONCONCAVE HAMILTON–JACOBI EQUATIONS*

MARTINO BARDI† AND SILVIA FAGGIAN‡

Abstract. Simple explicit estimates are presented for the viscosity solution of the Cauchy problem for the Hamilton–Jacobi equation where either the Hamiltonian or the initial data are the sum of a convex and a concave function. The estimates become equalities whenever a "minmax" equals a "maxmin" and thus a representation formula for the solution is obtained, generalizing the classical Hopf formulas as well as some formulas of Kružkov [*Functional Anal. Appl.*, 2 (1969), pp. 128–136].

Key words. Hamilton–Jacobi equations, viscosity solutions, Hopf's representation formulas, Lax–Oleinik formula, nonconvex Hamiltonians

AMS subject classifications. 35F25, 49L25, 35C99, 35L99

1. Introduction.

We consider the initial value problem for the Hamilton–Jacobi equation

$$\begin{cases} (HJ) \quad u_t + H(D_x u) = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ (IC) \quad u(x,0) = u_0(x) & \text{in } \mathbb{R}^N \times \{0\}, \end{cases}$$

where $H \in C(\mathbb{R}^N)$ is continuous and $u_0 : \mathbb{R}^N \to \mathbb{R}$ is uniformly continuous. This problem has a unique viscosity solution u in the space $UC_x(\mathbb{R}^N \times [0,T])$ of the continuous functions which are uniformly continuous in x uniformly in t, see [23] or [15] (for the general theory of viscosity solutions we refer to [12, 14, 5, 34, 2]).

We are interested in giving explicit pointwise upper and lower bounds for the solution, yielding in some cases a representation formula for u, and involving only a finite number of max-min operations over finite dimensional sets of parameters. The prototypes of this sort of results are the first Hopf formula (sometimes called Lax formula)

$$\begin{aligned} u(x,t) :&= \inf_{z\in\mathbb{R}^N} \sup_{y\in\mathbb{R}^N} \{u_0(z) + y\cdot(x-z) - tH(y)\} \\ &= \min_{z\in\mathbb{R}^N} \left\{u_0(z) + tH^*\left(\tfrac{x-z}{t}\right)\right\} \\ &= \min_{k\in\mathbb{R}^N} \{u_0(x-tk) + tH^*(k)\} \end{aligned} \tag{1.1}$$

holding for convex (or concave) Hamiltonian and Lipschitz initial data [22, 30, 19, 3, 18], or for Lipschitz and convex H and continuous u_0 [34, section 10.1], or also for strictly convex Hamiltonian and *lower semicontinuous (l.s.c.)* u_0 [26, 27], and the second Hopf formula

$$\begin{aligned} u(x,t) :&= \sup_{y\in\mathbb{R}^N} \inf_{z\in\mathbb{R}^N} \{u_0(z) + y\cdot(x-z) - tH(y)\} \\ &= \max_{y\in\mathbb{R}^N} \{x\cdot y - u_0^*(y) - tH(y)\} \end{aligned} \tag{1.2}$$

in the case of Lipschitz and convex (or concave) initial data and merely continuous Hamiltonian [22, 3, 31], or for convex u_0 and Lipschitz H [34, section 10.1]. Here H^* and u_0^* denote, respectively, the Legendre transforms (convex conjugates) of H and u_0, and in the following we denote with F^* also the Legendre transform of a concave function F, namely,

$$F^*(y) = -(-F)^*(y) = \inf_{x\in\mathbb{R}^N}\{-x\cdot y - F(x)\}.$$

Let us mention that both formulas were recently extended to the case of quasiconvex data by means of a suitable notion of quasiconvex conjugate function [8, 9, 10].

Our main results are the following extensions of the Hopf formulas.

THEOREM A. *If $H(p) = H_1(p) + H_2(p)$ with H_1 convex, H_2 concave, and u_0 is uniformly continuous, then the unique viscosity solution $u \in UC_x(\mathbb{R}^N \times [0,T])$ of $(HJ)(IC)$ satisfies*

$$\max_{w\in\mathbb{R}^N}\min_{k\in\mathbb{R}^N} g(k,w,x,t) \le u(x,t) \le \min_{k\in\mathbb{R}^N}\max_{w\in\mathbb{R}^N} g(k,w,x,t),$$

where $g(k,w,x,t) := u_0(x - t(k-w)) + tH_1^*(k) + tH_2^*(w)$.

THEOREM B. *If $u_0 = u_1 + u_2$, with u_1 convex and Lipschitz continuous, u_2 concave and Lipschitz continuous, and $H \in C(\mathbb{R}^N)$, then the unique viscosity solution $u \in UC_x(\mathbb{R}^N \times [0,T])$ of $(HJ)(IC)$ satisfies*

$$\max_{k\in\mathbb{R}^N}\min_{w\in\mathbb{R}^N} f(k,w,x,t) \le u(x,t) \le \min_{w\in\mathbb{R}^N}\max_{k\in\mathbb{R}^N} f(k,w,x,t),$$

where $f(k,w,x,t) := x\cdot(k+w) - u_1^*(k) - u_2^*(-w) - tH(k+w)$.

The main features of the estimates of both theorems are that

(i) all the inequalities are equalities at the initial time $t = 0$,

(ii) the lower and upper bound on u are, respectively, the max-min and the min-max of the same family of explicit functions, so they might be shown to coincide in many cases.

These properties suggest that one should be able to derive a representation formula for u at least for short times, by applying some min-max theorem. Indeed, we give results of this kind under some additional assumptions on the data.

Also note that the assumption that H be the sum of a convex and a concave function, is a rather mild regularity property which is satisfied, for instance, by semiconcave or semiconvex functions, e.g., by functions with second derivatives bounded either from above or below.

Theorem A contains as a special case the extension of the first Hopf formula (1.1) to the case of uniformly continuous initial data. Moreover, the representation formula we obtain for short times coincides with a formula of Kružkov [28] for the short time classical solution of $(HJ)(IC)$ in the case of smooth data.

On the other hand, Theorem B contains the second Hopf formula (1.2), as well as the estimates of Bardi and Osher [4] for the case of initial data sum of a convex function in a group of variables and a concave function in the remaining variables. Indeed we use their result to prove Theorem B. A similar pair of inequalities for some special Hamiltonians is the intermediate step in the proof of Theorem A. We borrow from Kružkov [28] an idea of "doubling the variables" to complete the proofs once this first step is established.

If the Hamiltonian depends explicitly on the variable x, i.e., $H = H(x, D_x u)$, then the solution u of $(HJ)(IC)$ can be represented as the value function of a differential

game, that is, as an inf-sup over infinite dimensional sets of controls and strategies, see [20, 25]. Here we show that for some Hamiltonians depending on x in a rather special way one can derive a much simpler representation formula by using Theorem A or B after a change of variables.

The classical Hopf formulas are important tools for the study of several properties of solutions of Hamilton–Jacobi equations, such as the asymptotic behavior as time goes to infinity [30, 6], the connection with geometric solutions in the sense of symplectic mechanics [11], uniqueness [7], and they have been used for numerical schemes [4, 33, 16, 17]. Moreover, from any formula for a viscosity solution of (HJ) one derives a representation formula for the entropy weak solution of a scalar conservation law, such as the Lax–Oleinik formula if one starts from the first Hopf formula, see, e.g., [13, 32, 18]. The results of this paper have similar applications that will be studied elsewhere.

The paper is organized as follows. In section 2 we extend the first Hopf formula to the case of uniformly continuous initial data. In section 3 we prove Theorem A and some related results. Section 4 is devoted to the proof of Theorem B. In section 5 we describe some cases where Theorems A and B give representation formulas for the solution, as well as some examples where the inequalities are strict. Finally, in section 6 we give an extension to equations with Hamiltonian depending on x.

2. First Hopf formula for uniformly continuous initial data. In this section, we revisit the first Hopf formula (1.1) for convex Hamiltonian H under the relaxed assumption $u_0 \in UC(\mathbb{R}^N)$ on the initial data. The main result of the section is in the following.

THEOREM 2.1. *If $H : \mathbb{R}^N \to \mathbb{R}$ is convex and $u_0 : \mathbb{R}^N \to \mathbb{R}$ uniformly continuous, then*

$$u(x,t) := \begin{cases} \min\limits_{z\in\mathbb{R}^N} \left\{ u_0(z) + tH^*\left(\dfrac{x-z}{t}\right)\right\} & \text{in } \mathbb{R}^N \times (0,+\infty), \\ u_0(x) & \text{in } \mathbb{R}^N \times \{0\} \end{cases} \tag{2.1}$$

gives the unique viscosity solution of $(HJ)(IC)$ in the space $UC_x(\mathbb{R}^N \times [0,+\infty))$ of continuous functions of (x,t), uniformly continuous in x, uniformly in t.

The proof of Theorem 2.1 is only slightly different from its previous editions, such as in [30, 3, 18], so we omit it. We check only that (2.1) defines a function of $UC_x(\mathbb{R}^N \times [0,+\infty))$, in particular, that $u(x,t)$ is continuous in t because the proof of this part is different. Note that in [18, 3] the authors proved that u_0 Lipschitzean implies that u defined by (2.1) is itself Lipschitzean in both x and t, which is not necessarily true in our case.

Let us observe that the min in (2.1) is attained because H^* is *l.s.c.* and superlinear, i.e., $\lim_{|p|\to+\infty} H^*(p)/|p| = +\infty$.

As done in [18], it can be shown that for any fixed $x \in \mathbb{R}^N$, and $t > 0$

$$u(x,t) = \min_{y\in\mathbb{R}^N} \left\{ u(y,s) + (t-s)H^*\left(\frac{x-y}{t-s}\right)\right\} \tag{2.2}$$

for any fixed $s \in [0,t]$, and this crucial relation is used throughout the proof of the theorem. We need the following lemma.

LEMMA 2.2. *Let $x \in \mathbb{R}^N,\ t \geq 0$. If $z^* := z^*(x,t) \in \mathbb{R}^N$ is such that*

$$u(x,t) = u_0(z^*) + tH^*\left(\frac{x-z^*}{t}\right),$$

then

$$\lim_{t\to 0+} z^*(x,t) = x. \tag{2.3}$$

Moreover, for any fixed $h \in [0,t]$, *let* $y^* := y^*(x,t,h)$ *be such that*

$$u(x,t) = u(y^*, t-h) + hH^*\left(\frac{x-y}{h}\right).$$

Then,

$$\lim_{h\to 0+} y^*(x,t,h) = x. \tag{2.4}$$

Proof. Fix any $\delta > 0, 0 < t < \delta$, and $b \in dom(H^*)$. Since $u(x,t) \le tH^*(b) + u_0(x-tb)$, we have

$$tH^*\left(\frac{x-z^*}{t}\right) \le u_0(x-tb) - u_0(z^*) + tH^*(b).$$

It is easy to check that H^* is superlinear, that is, $|v| = H^*(v)o(1)$, as $|v| \to +\infty$. Then

$$|x-z^*| \le o(1)(u_0(x-tb) - u_0(z^*) + tH^*(b)),$$

for $|x-z^*|/t \to +\infty$. Now observe that $u_0 \in UC(\mathbb{R}^N)$ implies that for all $z \in \mathbb{R}^N$, $|u(z)| \le C(1+|z|)$ for some constant $C > 0$. Hence, $\exists C_1 > 0$ such that

$$|x-z^*| \le o(1)(C|z^*| + C_1), \tag{2.5}$$

and then $\exists C_2 > 0$ such that

$$|z^*|(1 + Co(1)) \le C_2 + o(1) \tag{2.6}$$

for $|x-z^*|/t \to +\infty$. Let t_n be any sequence such that $t_n \to 0+$, as $n \to \infty$. We claim that $z_n^* := z_n^*(x,t_n)$ is bounded. In fact, if this is false, then we can find a subsequence t_{n_k} such that $|z_{n_k}^*| \to +\infty$, as $k \to \infty$. In this case $|x - z_{n_k}^*|/t_{n_k} \to +\infty$, as $k \to \infty$, then plugging $z_{n_k}^*$ into (2.6) and passing to limits as $k \to \infty$, we derive a contradiction.

In order to prove that (2.3) holds, we assume by contradiction that t_n is a sequence such that $t_n \to 0+$, as $n \to \infty$, and $|z_n^* - x| \ge \alpha > 0$ for all $n \in \mathbb{N}$ and for some $\alpha > 0$. Again, $|x - z_n^*|/t_n \to +\infty$, as $n \to \infty$, and by passing to limits in (2.5) we get a contradiction.

The second assertion can be proved in a similar way using (2.2). ∎

PROPOSITION 2.3. *In the hypotheses of Theorem* 2.1, $u(x,t)$, *defined by* (2.1), *is a continuous function of* (x,t); *it is also uniformly continuous in* x, *uniformly in* t.

Proof. It can be easily shown that $|u(x,t) - u(\bar{x},t)| \le \omega_0(|x-\bar{x}|)$ for any x, $\bar{x} \in \mathbb{R}^N$, $t > 0$, where ω_0 is a modulus of continuity for u_0 (see [18, 3]).

Then, we observe that

$$|u(y,t) - u_0(x)| \le \omega_0(|x-y|) + |u(x,t) - u_0(x)|$$

so it's enough to show that $|u(x,t) - u_0(x)| \to 0$, as $t \to 0+$. Pick $z^* = z^*(x,t)$ as in (2.2), and note that $H^*(v) \geq -H(0),\ \forall v \in \mathbb{R}^N$. Hence,

$$u_0(x) - u(x,t) \leq \omega_0(|x - z^*|) + |H(0)|t,$$

and the right-hand side tends to 0 as t tends to $0+$. Also, for any fixed $b \in dom(H^*)$, we have

$$\begin{aligned} u(x,t) - u_0(x) &\leq u_0(x - tb) + tH^*(b) - u_0(x) \\ &\leq \omega_0(|b|t) + |H^*(b)|t \end{aligned}$$

and again the right-hand side goes to 0, as $t \to 0+$.

We see last that $t \mapsto u(x,t)$ is continuous, for any fixed $x \in \mathbb{R}^N$. Suppose $\bar{t} < t$. From (2.2) we derive

$$u(x,t) \leq (t - \bar{t})H^*\left(\frac{x-y}{t-\bar{t}}\right) + u(y,t),$$

where y can be chosen in such a way that $q := x - y/(t - \bar{t}) \in dom(H^*)$. Then,

$$u(x,t) - u(x,\bar{t}) \leq \omega_0(|q||t - \bar{t}|) + |H^*(q)||t - \bar{t}|.$$

Now we choose $y^* = y^*(x,t,t-\bar{t})$ as in (2.4). Then,

$$u(x,\bar{t}) - u(x,t) \leq \omega_0(|y^* - x|) + |H(0)||t - \bar{t}|,$$

and the proof is complete by Lemma 2.2. □

Remark. It was shown by other authors that the first Hopf formula (2.1) gives the viscosity solution of $(HJ)(IC)$ under weaker assumptions on the initial data and stronger hypotheses on the Hamiltonian. Subbotin [34, Proposition 10.3] proved that if H is Lipschitz continuous and u_0 is merely continuous, then (2.1) gives the unique minimax solution, and therefore viscosity solution, of the problem. Kružkov [26, 27] proved that in the case of *l.s.c.* u_0 with at most linear growth at infinity and H of class C^2 with positive least eigenvalue of the Hessian matrix, (2.1) gives the unique generalized solution of $(HJ)(IC)$ in his sense, which is equivalent to the viscosity sense.

3. Estimates for the solution for Hamiltonians sum of a convex and a concave function. Now we relax the convexity hypothesis on H, replace it with

$$(H1) \qquad \begin{cases} H_1 : \mathbb{R}^N \to \mathbb{R} & \text{convex,} \\ H_2 : \mathbb{R}^N \to \mathbb{R} & \text{concave,} \\ H(p) = H_1(p) + H_2(p), \end{cases}$$

still assume $u_0 : \mathbb{R}^N \to \mathbb{R}$ uniformly continuous, and under these assumptions we prove sharp estimates for the solution of $(HJ)(IC)$. To this end, set $g : \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}^N \times [0,+\infty) \to \mathbb{R}$

$$g(k,w,x,t) := u_0(x - t(k-w)) + tH_1^*(k) + tH_2^*(w), \tag{3.1}$$

where H_1^*, H_2^* are, respectively, the Legendre transforms of H_1, H_2. Set also

$$u_-(x,t) := \sup_{w \in \mathbb{R}^N} \inf_{k \in \mathbb{R}^N} g(k,w,x,t), \tag{3.2}$$

$$u_+(x,t) := \inf_{k\in\mathbb{R}^N} \sup_{w\in\mathbb{R}^N} g(k,w,x,t). \tag{3.3}$$

THEOROM A. *Assume $u_0 : \mathbb{R}^N \to \mathbb{R}$ uniformly continuous and $(H1)$. Then the unique viscosity solution $u \in UC_x(\mathbb{R}^N \times [0,T])$ of $(HJ)(IC)$ satisfies*

$$u_-(x,t) \le u(x,t) \le u_+(x,t) \tag{3.4}$$

for all $(x,t) \in \mathbb{R}^N \times [0,T]$.

Remark. Note that for $t = 0$ the inequalities in (3.4) are equalities and $u_-(x,0) = u(x,0) = u_+(x,0) = u_0(x)$. Note further that if $H_2 = 0$, then

$$H_2^*(p) = \begin{cases} -\infty & \text{if } p \neq 0, \\ 0 & \text{if } p = 0, \end{cases}$$

and a simple computation shows that u_-, u_+ (and then u itself) are both given by the Hopf formula for convex Hamiltonian. Similarly, if $H_1 = 0$ we get the Hopf formula for concave Hamiltonian.

The proof of Theorem A consists essentially of two steps. First, we follow an idea of Kružkov [28], and show in Lemma 3.1 that the solution u of $(HJ)(IC)$ can be related to the solution of the following Cauchy problem in doubled state variables

$$\begin{cases} U_t + H_1(D_yU) + H_2(D_zU) = 0 & \text{in } \mathbb{R}^{2N} \times (0,T) \quad (HJ'), \\ U(y,z,0) = u_0(y+z) & \text{in } \mathbb{R}^{2N} \times \{0\} \quad (IC'), \end{cases}$$

where U is the unknown, and D_yU (respectively, D_zU) denotes the gradient of U with respect to the first (resp., the last) N space variables. Next, we prove an estimate like (3.4) in the case of H_1 depending only on the first j variables and H_2 depending only on the last $N-j$ (forthcoming Proposition 3.2). Finally, we apply this result to (HJ') (IC') and derive (3.4) from the related estimate on U.

LEMMA 3.1. *The function $u(x,t)$ is a viscosity solution of $(HJ)(IC)$ if and only if $U(y,z,t) := u(y+z,t)$ is a viscosity solution of $(HJ')(IC')$.*

Proof. Let (x_0,t_0) be fixed in $\mathbb{R}^N \times (0,T)$, and $y_0, z_0 \in \mathbb{R}^N$ such that $y_0 + z_0 = x_0$. Trivially, u satisfies (IC) if and only if U satisfies (IC'). First we show that if $U(y,z,t) = u(y+z,t)$ is a viscosity solution of (HJ') then $u(x,t)$ is a viscosity solution of (HJ). Consider a test function $\psi \in C^1(\mathbb{R}^N \times (0,T))$ such that $u - \psi$ has a local maximum at (x_0,t_0), and set $\varphi(y,z,t) := \psi(y+z,t)$. Then,

$$(U-\varphi)(y,z,t) \le (U-\varphi)(y_0,z_0,t_0)$$

for every (y,z,t) sufficiently close to (y_0,z_0,t_0). Hence, since U is a subsolution of (HJ'), we have

$$\varphi_t + H_1(D_y\varphi) + H_2(D_z\varphi) \le 0 \quad \text{at} \quad (y_0,z_0,t_0),$$

and by replacing φ_t, $D_y\varphi$, $D_z\varphi$ with the corresponding expressions involving ψ, we deduce

$$\psi_t + H(D_x\psi) \le 0 \quad \text{at} \quad (x_0,t_0).$$

Since (x_0,t_0) was arbitrary, we have proved that u is a subsolution of (HJ). By similar reasoning, we also obtain that u is a supersolution of (HJ).

Next we show that if u is a viscosity solution of (HJ), then $U(y,z,t) = u(y+z,t)$ is a viscosity solution of (HJ'). Let $(y_0,z_0,t_0) \in \mathbb{R}^N \times \mathbb{R}^N \times (0,T)$ and $\varphi \in C^1(\mathbb{R}^N \times \mathbb{R}^N \times (0,T))$ such that $U-\varphi$ has a local maximum at (y_0,z_0,t_0). Adding if necessary a constant to φ, we may assume

$$(U-\varphi)(y,z,t) \le (U-\varphi)(y_0,z_0,t_0) = 0 \tag{3.5}$$

for all (y,z,t) near (y_0,z_0,t_0). Thus, by fixing $z = z_0$ and using the definition of U, we get

$$u(y+z_0,t) - \varphi(y,z_0,t) \le u(y_0+z_0,t_0) - \varphi(y_0,z_0,t_0) \tag{3.6}$$

for all (y,t) close to (y_0,t_0). Since $\varphi(\cdot,z_0,\cdot) \in C^1(\mathbb{R}^N \times (0,T))$ and $(y,t) \mapsto u(y+z_0,t)$ is itself a viscosity solution of (HJ) (easy proof), (3.6) establishes

$$\varphi_t + H_1(D_y\varphi) + H_2(D_z\varphi) \le 0 \quad \text{at} \quad (y_0,z_0,t_0).$$

To demonstrate that U is a subsolution of (HJ') at (y_0,z_0,t_0) it is enough to show that

$$D_y\varphi(y_0,z_0,t_0) = D_z\varphi(y_0,z_0,t_0).$$

Set $z := z_0 - se_i$ and $y := y_0 + se_i$, where $s \in \mathbb{R}$, note that (3.5) holds for $|s|$ small enough and gives

$$\varphi(y_0,z_0,t_0) - \varphi(y_0+se_i, z_0-se_i, t_0) \le 0.$$

We divide both sides by $s > 0$ ($s < 0$), and by passing to limits as $s \to 0+$ (resp., as $s \to 0-$) we obtain $\partial\varphi/\partial y_i \le \partial\varphi/\partial z_i$ (resp., $\partial\varphi/\partial y_i \ge \partial\varphi/\partial z_i$) at (y_0,z_0,t_0), and then $D_y\varphi = D_z\varphi$ at (y_0,z_0,t_0).

In a similar way we can show that U is a supersolution of (HJ') at an arbitrarily fixed (y_0,z_0,t_0), and thus the proof is complete. □

From now on, we write $p = (p_A, p_B)$ and mean $p_A \in \mathbb{R}^j,\ p_B \in \mathbb{R}^{N-j}$.

PROPOSITION 3.2. *Assume $u_0 \in UC(\mathbb{R}^N)$, $H_1 : \mathbb{R}^N \to \mathbb{R}$ convex, $H_2 : \mathbb{R}^N \to \mathbb{R}$ concave, and $H(p) = H_1(p_A) + H_2(p_B)$. Then the unique viscosity solution $u \in UC_x(\mathbb{R}^N \times [0,T])$ satisfies for all $(x,t) \in \mathbb{R}^N \times [0,T]$*

$$\sup_{z_B \in \mathbb{R}^{N-j}} \inf_{z_A \in \mathbb{R}^j} G(z,x,t) \le u(x,t) \le \inf_{z_A \in \mathbb{R}^j} \sup_{z_B \in \mathbb{R}^{N-j}} G(z,x,t), \tag{3.7}$$

where $G : \mathbb{R}^N \times \mathbb{R}^N \times [0,+\infty) \to \mathbb{R}$ is either defined by

$$G(z,x,t) = u_0(x_A - tz_A, x_B + tz_B) + tH_1^*(z_A) + tH_2^*(z_B) \tag{3.8}$$

or, for $t \ne 0$, by

$$G(z,x,t) = u_0(z) + tH_1^*\left(\frac{x_A - z_A}{t}\right) + tH_2^*\left(\frac{z_B - x_B}{t}\right). \tag{3.9}$$

Proof. We prove (3.7) for G given by (3.8): the other case can be immediately derived from the change of variables $w = x - tz$. Since H_2 can be written as the Legendre transform of H_2^*, we have

$$H(p) \le H_1(p_A) - z_B \cdot p_B - H_2^*(z_B) =: \mathcal{H}(z_B,p)$$

$\forall z_B \in \mathbb{R}^{N-j}$. Let $z_B \in dom(H_2^*)$ be fixed; then $H_2^*(z_B) > -\infty$. The Legendre transform of the convex function $p \mapsto \mathcal{H}(z_B, p)$ is then given by

$$\mathcal{H}^*(z_B, p) = \begin{cases} H_2^*(z_B) + H_1^*(p_A), & \text{if } p_B = -z_B, \\ +\infty, & \text{if } p_B \neq -z_B. \end{cases}$$

Let's now consider the following Cauchy problem:

$$\begin{cases} \psi_t + \mathcal{H}(z_B, D_x\psi) = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ \psi(z_B, x, 0) = u_0(x) & \text{in } \mathbb{R}^N \times \{0\}. \end{cases}$$

Its unique viscosity solution is given by the first Hopf formula that is

$$\begin{aligned} \psi(z_B, x, t) &= \min_{z_A \in \mathbb{R}^j} \{u_0(x_A - tz_A, x_B + tz_B) + tH_2^*(z_B) + tH_1^*(z_A)\} \\ &= \min_{z_A \in \mathbb{R}^j} G(z, x, t) \\ &= \min_{z_A \in dom(H_1^*)} G(z, x, t). \end{aligned} \tag{3.10}$$

Furthermore, $\psi(z_B, x, t)$ is a subsolution of $(HJ)(IC)$, since

$$\varphi_t + H(D_x\varphi) \leq \varphi_t + \mathcal{H}(z_B, D_x\varphi) \leq 0, \quad \text{at } (x,t)$$

for any $x \in \mathbb{R}^N$ and $t > 0$, provided that $\varphi \in C^1(\mathbb{R}^N \times (0,T))$ is a test function such that $\psi(z_B, \cdot, \cdot) - \varphi(\cdot, \cdot)$ has a local maximum at (x,t). Hence, a standard comparison theorem for unbounded viscosity solutions (see, e.g., [15]) gives

$$\psi(z_B, x, t) \leq u(x,t) \quad \forall z_B \in dom(H_2^*).$$

By taking the supremum for $z_B \in dom(H_2^*)$ we deduce

$$\sup_{z_B \in dom(H_2^*)} \psi(z_B, x, t) = \sup_{z_B \in dom(H_2^*)} \min_{z_A \in dom(H_1^*)} G(z, x, t) \leq u(x,t)$$

that is the first inequality in (3.7), for we note that

$$\sup_{z_B \in dom(H_2^*)} \min_{z_A \in dom(H_1^*)} G(z, x, t) = \sup_{z_B \in \mathbb{R}^{N-j}} \min_{z_A \in \mathbb{R}^j} G(z, x, t).$$

The second inequality in (3.7) can be derived by similar reasoning. We apply the first Hopf formula to compute the unique viscosity solution of

$$\begin{cases} \xi_t + \tilde{\mathcal{H}}(z_A, D_x\xi) = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ \xi(z_A, x, 0) = u_0(x) & \text{in } \mathbb{R}^N \times \{0\}, \end{cases}$$

where

$$\tilde{\mathcal{H}}(z_A, p) := z_A \cdot p_A - H_1^*(z_A) + H_2(p_B) \leq H(p)$$

is a concave function of p, $\tilde{\mathcal{H}} \not\equiv -\infty$, for all fixed $z_A \in dom(H_1^*)$. Similarly, we get

$$\max_{z_B \in \mathbb{R}^{N-j}} G(z, x, t) = \xi(z_A, x, t) \geq u(x,t)$$

by means of the same comparison theorem, and draw the conclusion by taking the infimum for $z_A \in dom(H_1^*)$. □

Proof of Theorem A. We observe that the initial data $U_0(y,z) = u_0(y+z)$ and the Hamiltonian $h(p,q) = H_1(p) + H_2(q)$ of the problem $(HJ')(IC')$ satisfy the assumptions of Proposition 3.2, and then the unique viscosity solution $U(y,z,t)$ of $(HJ')(IC')$ in $UC_{y,z}(\mathbb{R}^N \times \mathbb{R}^N \times \times[0,T])$ verifies

$$U_-(y,z,t) \le U(y,z,t) \le U_+(y,z,t), \tag{3.11}$$

where

$$\begin{aligned} U_-(y,z,t) &= \sup_{w\in\mathbb{R}^N} \inf_{k\in\mathbb{R}^N} \{u_0(y+z+t(w-k)) + tH_1^*(k) + tH_2^*(w)\}, \\ U_+(y,z,t) &= \inf_{k\in\mathbb{R}^N} \sup_{w\in\mathbb{R}^N} \{u_0(y+z+t(w-k)) + tH_1^*(k) + tH_2^*(w)\}. \end{aligned}$$

Since, by Lemma 3.1, $u(y+z,t)$ is a solution of $(HJ')(IC')$, then it coincides with $U(y,z,t)$. Now we fix $z_0 \in \mathbb{R}^N$. Then, for every $x \in \mathbb{R}^N$, (3.11) holds, in particular, for $z = z_0$ and $y = x - z_0$, which gives exactly (3.4). □

Remark 1. Theorem A has an interpretation within the theory of differential games. Consider the controlled dynamical system

$$y'(s) = b(s) - a(s), \quad y(0) = x,$$

where the controls a and b belong to $\mathcal{L} = L^1([0,t],\mathbb{R}^N)$ and the cost functional

$$J(a,b,x,t) := \int_0^t \left(H_1^*\left(a(s)\right) + H_2^*\left(b(s)\right)\right) ds + u_0(y(t)),$$

which the controller of a seeks to minimize while that of b wants to maximize. Consider the set of nonanticipating strategies $\mathcal{S}$, i.e., the maps $\alpha : \mathcal{L} \to \mathcal{L}$ such that, for all $\tau > 0$, $b(s) = \tilde{b}(s)$ for all $s \le \tau$ implies $\alpha[b](s) = \alpha[\tilde{b}](s)$ for all $s \le \tau$. The value of this differential game is

$$v(x,t) := \inf_{\alpha\in\mathcal{S}} \sup_{b\in\mathcal{L}} J(\alpha[b],b,x,t) = \sup_{\beta\in\mathcal{S}} \inf_{a\in\mathcal{L}} J(a,\beta[a],x,t),$$

provided the last equality holds, and the PDE

$$u_t + H_1(Du) + H_2(Du) = 0 \ \text{ on } \ \mathbb{R}^N \times (0,\infty) \tag{3.12}$$

is the Isaacs equation associated to the game by the dynamic programming method. By the results of [20, 25] the value function v exists and it is the unique solution of (3.12) such that $u(x,0) = u_0(x)$. On the other hand, if the choice of both controllers is restricted to *constant* controls $a(\cdot) \equiv k$, $b(\cdot) \equiv w$, we have the so–called *game with simple motions*, a static game where the decision variables k and w are chosen in $\mathbb{R}^N$. In this case

$$J(a,b,x,t) = g(k,w,x,t),$$

so $u_-(x,t)$ and $u_+(x,t)$ are, respectively, the lower and the upper value of this game. Therefore, Theorem A states that the value $v(x,t)$ of the differential game is between the lower and the upper value of the game with simple motions.

In the case of a single controller, i.e., either H_1 or H_2 is null, the first Hopf formula states that constant controls generate the same value function as integrable controls (see [3]). In general, this is no longer true for two controllers, as we will see on some examples in section 5.

Remark 2. Observe that all 'inf' and 'sup' in (3.2), (3.3), (3.7) can be computed, respectively, on $dom(H_1^*)$, $dom(H_2^*)$ (see proof of Proposition 3.2), and that they are actually attained. For instance,

$$\sup_{z_B} \inf_{z_A} G(z,x,t) = \max_{z_B} \min_{z_A} G(z,x,t). \tag{3.13}$$

In fact, directly from the first Hopf formula we get that 'inf'='min,' and since the inf-envelope in (3.13) defines an *upper semicontinuous (u.s.c.)* function of z_B, and $\lim_{|p|\to+\infty} H_2^*(p)/|p| = -\infty$, we have also 'sup'='max.'

Remark 3. A simple computation shows that if H_1 (resp., H_2) depends only on the first j variables (resp., the last $N-j$ variables) then $dom(H_1) \subset \{(p_A,0) \in \mathbb{R}^N : p_A \in \mathbb{R}^j\}$ (resp., $dom(H_2) \subset \{(0,p_B) \in \mathbb{R}^N : p_B \in \mathbb{R}^{N-j}\}$). Thus the inequalities in (3.7), which we use indeed to demonstrate Theorem A, are special cases of (3.4).

Remark 4. The functions u_-, u_+ defined in Theorem A are, respectively, a sub and a supersolution of $(HJ)(IC)$ in the generalized sense of Ishii [24].

Proof. Since u_- is *l.s.c.*, we have to prove that the upper semicontinuous envelope u_- is a viscosity subsolution of (HJ) in the usual sense. By a result of Ishii [24], this is true if u_- is a (finite) sup of subsolutions. In the assertion and proof of Proposition 3.2, replace N, j, x_A, x_B, z_A, z_B with, respectively, $2N, N, y, z, k, w$, and consider for any fixed $w \in dom(H_2^*)$, the function $\psi(w,(y,z),t)$ defined by (3.10) with such substitutions. Then ψ is the solution of

$$\begin{cases} \psi_t + \mathcal{H}(w, D_y\psi, D_z\psi) = 0 & \text{in } \mathbb{R}^{2N} \times (0,T), \\ \psi(w,y,z,0) = u_0(y+z) & \text{in } \mathbb{R}^{2N} \times \{0\}, \end{cases}$$

where, for $p, q \in \mathbb{R}^N$

$$\mathcal{H}(w,p,q) := H_1(p) - w \cdot q - H_2^*(w) \geq H_1(p) + H_2(q). \tag{3.14}$$

Since the data of this problem satisfy the assumptions of Lemma 3.1, the unique viscosity solution of

$$\begin{cases} \tilde{\psi}_t + \mathcal{H}(w, D_x\tilde{\psi}, D_x\tilde{\psi}) = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ \tilde{\psi}(w,x,0) = u_0(x) & \text{in } \mathbb{R}^N \times \{0\} \end{cases}$$

is given by $\tilde{\psi}(w,x,t) := \psi(w,(x_0, x-x_0),t)$, for any fixed $x_0 \in \mathbb{R}^N$. Since (3.14) holds, we observe that $\tilde{\psi}(w,\cdot,\cdot)$ is a (continuous) subsolution of $(HJ)(IC)$ for all $w \in dom(H_2^*)$, and we reach the conclusion by noting that the proof of Proposition 3.2 gives

$$u_-(x,t) = \max_{w \in \mathbb{R}^N} \psi(w,(x_0,x-x_0),t).$$

A similar argument shows that u_+ is a generalized supersolution of $(HJ)(IC)$, i.e., its lower semicontinuous envelope is a viscosity supersolution. □

Remark 5. In a special case, Kružkov proved that U_+ is Lipschitz and satisfies (HJ) almost everywhere, see Theorem 4 in [28] for the precise assumptions.

Remark 6. It can be shown that if u_0 is Lipschitz continuous, then 'inf' and 'sup' in formulas (3.2), (3.3) can be computed on particular compact subsets of $\mathbb{R}^N$, i.e.,

$$\max_{|w| \leq L_2} \min_{|k| \leq L_1} g(k,w,x,t) \leq u(x,t) \leq \min_{|k| \leq L_1} \max_{|w| \leq L_2} g(k,w,x,t),$$

where L_1 (resp., L_2) is the Lipschitz constant of H_1 (resp., H_2) on $\bar{B}(0, Lip(u_0))$. This result follows from the lemma below.

LEMMA 3.3. *Let the hypotheses of Proposition* 3.2 *be satisfied, assume* u_0 *Lipschitz continuous, and let* $L_1 > 0$ *(respectively,* $L_2 > 0$*) be such that* $|H_1(p_A) - H_1(q_A)| \le L_1|p_A - q_A|$*, for all* $|p_A|, |q_A| \le Lip(u_0)$*, (resp.,* $|H_2(p_B) - H_2(q_B)| \le L_2|p_B - q_B|$*, for all* $|p_B|, |q_B| \le Lip(u_0)$*,). Then, for any compact* $K_1 \subset \mathbb{R}^j$*, (resp.,* $K_2 \subset \mathbb{R}^{N-j}$*), such that* $K_1 \supset B(x_A, L_1 t)$ *(resp.,* $K_2 \supset B(x_B, L_2 t)$*), we have*

$$\max_{z_B \in K_2} \min_{z_A \in K_1} G(z, x, t) \le u(x, t) \le \min_{z_A \in K_1} \max_{z_B \in K_2} G(z, x, t),$$

if G *is given by* (3.9)*, and*

$$\max_{|z_B| \le L_2} \min_{|z_A| \le L_1} G(z, x, t) \le u(x, t) \le \min_{|z_A| \le L_1} \max_{|z_B| \le L_2} G(z, x, t),$$

if G *is defined by* (3.8).

Proof. Observe that, for any fixed $z_B \in \mathbb{R}^{N-j}$, the solution $w(z_B, x_A, t)$ of

$$\begin{cases} w_t + H_1(D_{x_A} w) = 0, & \text{in } \mathbb{R}^j \times (0, T), \\ w(x_A, 0) = u_0(x_A, z_B), & \text{in } \mathbb{R}^j \times \{0\} \end{cases}$$

is given by

$$\begin{aligned} w(z_B, x_A, t) &= \min_{z_A \in \mathbb{R}^j} \left\{ u_0(z_A, z_B) + tH_1^* \left(\frac{x_A - z_A}{t} \right) \right\} + tH_2^* \left(\frac{z_B - x_B}{t} \right) \\ &= \min_{z_A \in B(x_A, L_1 t)} \left\{ u_0(z_A, z_B) + tH_1^* \left(\frac{x_A - z_A}{t} \right) \right\} + tH_2^* \left(\frac{z_B - x_B}{t} \right) \end{aligned}$$

by the property of the cone of dependence. Now we take the max for $z_B \in B(x_B, L_2 t)$ and use (3.7), (3.9) to get

$$\max_{z_B \in K_2} w(z_B, x_A, t) \le \sup_{z_B \in \mathbb{R}^{N-j}} \inf_{z_A \in \mathbb{R}^j} G(z, x, t) \le u(x, t).$$

By similar reasoning we get the second inequality. The inequalities with G given by (3.8) follow from the change of variables $w = (x - z)/t$. ∎

4. Estimates for the solution with initial data sum of a convex and a concave function. In this section we give a result similar to that of Theorem A for the following type of data:

$$(H2) \qquad \begin{cases} u_1 : \mathbb{R}^N \to \mathbb{R} & \text{convex and Lipschitzean,} \\ u_2 : \mathbb{R}^N \to \mathbb{R} & \text{concave and Lipschitzean,} \\ u_0(x) = u_1(x) + u_2(x) \end{cases}$$

and $H : \mathbb{R}^N \to \mathbb{R}$ merely continuous. We set $f : \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}^N \times [0, \infty) \to \mathbb{R}$

$$f(k, w, x, t) := x \cdot (k + w) - u_1^*(k) - u_2^*(-w) - tH(k + w), \tag{4.1}$$

where u_1^*, u_2^* are, respectively, the Legendre transforms of u_1, u_2; we set also

$$v_-(x, t) := \sup_{k \in \mathbb{R}^N} \inf_{w \in \mathbb{R}^N} f(k, w, x, t), \tag{4.2}$$

$$v_+(x,t) := \inf_{w\in\mathbb{R}^N} \sup_{k\in\mathbb{R}^N} f(k,w,x,t). \tag{4.3}$$

THEOREM B. *Assume (H2) and H continuous. The unique viscosity solution $u \in UC_x(\mathbb{R}^N \times [0,T])$ of (HJ)(IC) satisfies*

$$v_-(x,t) \le u(x,t) \le v_+(x,t) \tag{4.4}$$

for all $(x,t) \in \mathbb{R}^N \times [0,T]$.

Remark. Note that for $t = 0$ the inequalities in (4.4) are equalities, and that for $u_2 = 0$ (resp., $u_1 = 0$), both u_-, u_+ are given by the second Hopf formula for convex (resp., concave) initial data.

The idea of the proof of Theorem B is similar to that of Theorem A. We study the Cauchy problem in doubled state variables

$$\begin{array}{lll} V_t + H(D_yV + D_zV) = 0 & \text{in } \mathbb{R}^{2N}\times(0,T) & (HJ''),\\ V(y,z,0) = u_1(y) + u_2(z) & \text{in } \mathbb{R}^{2N}\times\{0\} & (IC''). \end{array}$$

Let $V = V(y,z,t)$ be the unique viscosity solution of (HJ'') (IC'') in $UC_{y,z}(\mathbb{R}^{2N} \times (0,T))$. The initial data of this problem is the sum of a convex function of the first N variables and a concave function of the last N variables, so the analogue of Proposition 3.2 for this problem is known from [4] and gives the following estimate:

$$\sup_{k\in\mathbb{R}^N} \inf_{w\in\mathbb{R}^N} F(k,w,y,z,t) \le V(y,z,t) \le \inf_{w\in\mathbb{R}^N} \sup_{k\in\mathbb{R}^N} F(k,w,y,z,t), \tag{4.5}$$

where $F : \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}^N \times \mathbb{R}^N \times [0,\infty) \to \mathbb{R}$ is defined by

$$F(k,w,x,t) := y\cdot k + z\cdot w - u_1^*(k) - u_2^*(-w) - tH(k+w). \tag{4.6}$$

The next step is the connection between V and u, which is given by the following statement.

LEMMA 4.1. *Let u_0 satisfy (H2), H be continuous, and $V(y,z,t)$ be a continuous viscosity solution of $(HJ'')(IC'')$. Then, $u(x,t) := V(x,x,t)$ is a viscosity solution of (HJ)(IC).*

Proof. The initial condition (IC) is trivially satisfied by $u(x,t) = V(x,x,t)$. We claim now that u is a subsolution of (HJ). Let $\varphi \in C^1(\mathbb{R}^N \times [0,T])$ and suppose $u - \varphi$ has a local strict maximum at (x_0,t_0), that is $\exists \delta > 0$ such that

$$V(x,x,t) - \varphi(x,t) < V(x_0,x_0,t_0) - \varphi(x_0,t_0) \tag{4.7}$$

for all $(x,t) \in K := \bar{B}(x_0,\delta) \times [t_0-\delta, t_0+\delta] \setminus \{(x_0,t_0)\}$. Define the sequence of test functions

$$\Phi_n(y,z,t) := \varphi(y,t) + n|y-z|^2,\ n \in \mathbb{N},$$

and let (y_n,z_n,t_n) be the point at which $V - \Phi_n$ attains its maximum in K. Then,

$$(V-\Phi_n)(y_n,z_n,t_n) \ge (V-\Phi_n)(x_0,x_0,t_0) = V(x_0,x_0,t_0) - \varphi(x_0,t_0), \tag{4.8}$$

and by adding and subtracting $V(y_n,y_n,t_n) - \varphi(y_n,t_n)$ to the left-hand side of (4.8) and employing (4.7), we see also that

$$\begin{aligned}(V-\Phi_n)(y_n,z_n,t_n) \le\ & V(y_n,z_n,t_n) - V(y_n,y_n,t_n)\\ & + V(x_0,x_0,t_0) - \varphi(x_0,t_0) - n|y_n-z_n|^2.\end{aligned}$$

Now we combine this last inequality with (4.8) and deduce by the continuity of V that $n|y_n - z_n|^2$ is bounded on K. Thus we may assume, upon passing to subsequences and reindexing if necessary, that

$$\begin{aligned} &(y_n, z_n, t_n) \to (\bar{y}, \bar{z}, \bar{t}) \in K, \\ &n|y_n - z_n|^2 \to \alpha \in \mathbb{R}, \\ &n \to +\infty. \end{aligned}$$

In particular, $|y_n - z_n| \to 0$, $n \to +\infty$, that implies $\bar{y} = \bar{z}$. Now, by passing to limits as $n \to +\infty$ in (4.8), we derive

$$V(\bar{y}, \bar{y}, \bar{t}) - \varphi(\bar{y}, \bar{t}) - \alpha \geq V(x_0, x_0, t_0) - \varphi(x_0, t_0).$$

Then from (4.7) we get $\alpha = 0$, $(\bar{y}, \bar{t}) = (x_0, t_0)$. Provided V is a subsolution of (HJ''), we have

$$\frac{\partial \Phi_n}{\partial t} + H(D_y \Phi_n + D_z \Phi_n) \leq 0 \quad \text{at } (y_n, z_n, t_n)$$

and then, letting $n \to \infty$,

$$\frac{\partial \varphi}{\partial t} + H(D_x \varphi) \leq 0 \quad \text{at } (x_0, t_0),$$

i.e., $u(x,t)$ is a subsolution of (HJ) at (x_0, t_0). Similarly, it can be shown that u is a supersolution of (HJ) at any point (x_0, t_0), by using in this case the sequence of test functions

$$\Psi_n(y, z, t) = \xi(y, t) - n|y - z|^2,$$

where $\xi \in C^1(\mathbb{R}^N \times (0, T))$ is such that $u - \xi$ has a local strict minimum at (x_0, t_0). □

Proof of Theorem B. Just put $y = z = x$ in (4.5). □

Remark 1. The result of Bardi and Osher (4.5) is a special case of Theorem B. It can be obtained from (4.4) by assuming $u_1(x) = u_2(x_A)$ and $u_2(x) = u_2(x_B)$ and by simple calculations. A similar computation shows that (4.4) implies the second Hopf formula (1.2), provided $u_2 \equiv 0$.

Remark 2. Also in this case 'inf' and 'sup' in (4.2), (4.3) are actually attained, for they can be computed, respectively, on the bounded sets $dom(u_2^*)$, $dom(u_1^*)$.

Remark 3. The function v_-, v_+ defined in Theorem B, are, respectively, a sub and a supersolution of $(HJ)(IC)$ in the generalized sense of Ishii [24].

Proof. As proved by Bardi and Osher in their paper [4], for any fixed $k \in dom(u_1^*)$, the function

$$(y, z, t) \to \xi(k, y, z, t) := \min_{w \in \mathbb{R}^N} F(k, w, y, z, t),$$

where F is defined by (4.6), is the viscosity solution of (HJ''), with the initial condition

$$\xi(k, y, z, 0) = k \cdot y - u_1^*(k) + u_2(z) \leq u_1(y) + u_2(z) \tag{4.9}$$

(see [4], proof of Theorem 1, for details). Hence, Lemma 4.1 shows $(x,t) \to \xi(k, x, x, t)$ solves (HJ), and since (4.9) holds, this function is also a (continuous) subsolution of $(HJ)(IC)$. Finally,

$$v_-(x, t) = \max_{k \in \mathbb{R}^N} \xi(k, x, x, t)$$

yields the thesis. The proof for v_+ is symmetric. □

Remark 4. Van, Than, and Hoang [35] have recently proved that v_+, defined by (4.3), is Lipschitz continuous in $\mathbb{R}^N \times [0, T]$ and satisfies (HJ) almost everywhere.

5. Representation formulas. In this section, we study sufficient conditions for (3.4) and (4.4) to hold as equalities, and hence derive representation formulas for the solution of $(HJ)(IC)$ in both sets of assumptions: $(H1)$ and general u_0, $(H2)$ and general H.

Consider $f : \mathbb{R}^N \to \mathbb{R}$ and define the *index of nonconvexity* as

$$\mu(f) = \inf\{\alpha \in \mathbb{R} \ : \ f(x) + \alpha|x|^2 \text{ convex}\} \leq +\infty.$$

It is easy to check that if the 'inf' is finite it is actually attained, that f is convex iff $\mu(f) \leq 0$ and semiconvex iff $\mu(f)$ is finite. It is also easy to show that if $f \in C^2(\mathbb{R}^N)$ and semiconvex and λ is the infimum of the eigenvalues of $D^2 f(x)$ for $x \in \mathbb{R}^N$, then $\lambda = -2\mu(f)$.

Hereafter, we show that a representation formula can be obtained at least for small times, i.e., for $t \in [0, T]$, where T can be estimated in terms of the index of nonconvexity of the data.

We can assume with no loss of generality that $0 < \mu(u_0), \mu(-u_0)$, (if u_0 is convex or concave the second Hopf formula applies) and we will also assume $\mu(u_0), \mu(-u_0) < +\infty$, which are equivalent, respectively, to the semiconvexity and semiconcavity of u_0.

PROPOSITION 5.1. *Under the hypotheses of Theorem* A*, assume*

$$T \leq \min\left\{ \frac{|\mu(H_1^*)|}{\mu(u_0)}, \frac{|\mu(-H_2^*)|}{\mu(-u_0)} \right\},$$

and $0 < \mu(u_0), \mu(-u_0) < +\infty$. *Then the unique viscosity solution of* $(HJ)(IC)$ *in* $UC_x(\mathbb{R}^N \times [0, T])$ *is given by*

$$u(x, t) = u_-(x, t) = u_+(x, t),$$

where the functions u_-, u_+ *are defined in* (3.2), (3.3).

The proof of this proposition is based on the following theorem, which is a simplified version of the classical minimax results in [1, chapter 6, section 2].

MINIMAX THEOREM. *Let* $A \subset \mathbb{R}^n$ *and* $B \subset \mathbb{R}^m$ *be convex sets. Let also* $L : A \times B \to \mathbb{R}$ *be such that the following assumptions are satisfied:*

(i) $\forall b \in B, a \mapsto L(a, b)$ *is* l.s.c. *and convex, and* $\forall a \in A, b \mapsto L(a, b)$ *is* u.s.c. *and concave;*

(ii) $\exists b_0 \in B$ *and* $\exists a_0 \in A$ *such that* $\forall \lambda \in \mathbb{R}$ *the sets* $\{a \in A \ : \ L(a, b_0) \leq \lambda\}$ *and* $\{b \in B \ : \ L(a_0, b) \geq \lambda\}$ *are bounded.*

Then there exists a saddle point*, that is,* $(a^*, b^*) \in A \times B$ *such that*

$$L(a^*, b^*) = \min_{a \in A} \max_{b \in B} L(a, b) = \max_{b \in B} \min_{a \in A} L(a, b).$$

Proof of Proposition 5.1. We first observe that $k \mapsto g(k, w, x, t)$ is *l.s.c.* and that it is convex since it can be written as the sum of four convex functions of k as follows:

$$\begin{aligned} g(k, w, x, t) = &\{u_0(x - t(k - w)) + \mu(u_0)|x - t(k - w)|^2\} \\ &+ \ \{-\mu(u_0)\left(|x|^2 + t|w|^2 + 2tx \cdot w - 2t(x + tw) \cdot k\right) + tH_2^*(w)\} \\ &+ \ \{t(H_1^*(k) + \mu(H_1^*)|k|^2) \ \} \ + \ \{ \ - t(\mu(H_1^*) + t\mu(u_0))|k|^2\}. \end{aligned}$$

For any fixed x, t, $w \in dom(H_2^*)$ and $\lambda \in \mathbb{R}$, set

$$A_\lambda := \{k \in dom(H_1^*) \mid g(k, w, x, t) \leq \lambda\}.$$

Since H_1^* is superlinear, we have $H_1^*(k) = |k|h(k)$ with $h{:}\mathbb{R}^N \to \mathbb{R}$ such that $\lim_{|k|\to\infty} h(k) = +\infty$; moreover, let $C > 0$ be such that $u_0(x) \geq -C(|x| + 1)$. Then,

$$\begin{aligned} g(k,w,x,t) - tH_2^*(w) &= u_0(x - t(k-w)) + tH_1^*(k) \\ &\geq t|k|(h(k) - C) + K \end{aligned} \tag{5.1}$$

for a suitable $K > 0$, dependent only from x, t, C, w. Note that the right-hand side of (5.1) tends to $+\infty$ as $|k| \to \infty$, thus $\lim_{|k|\to\infty} g(k,w,x,t) = +\infty$. Then there exists $R > 0$ such that $|x| > R$ implies $g(k,w,x,t) > \lambda$, and so $A_\lambda \subset \bar{B}(0,R)$.

Similarly, it can be shown that $w \mapsto g(k,w,x,y)$ is concave and *u.s.c.*, and that for all fixed x, t, $k \in dom(H_1^*)$ and $\lambda \in \mathbb{R}$, the set

$$B_\lambda := \{w \in dom(H_2^*) \mid g(k,w,x,t) \geq \lambda\}$$

is a bounded subset of $\mathbb{R}^N$. □

Remark. In the case of smooth H and u_0, Kružkov [28, Theorem 1] proved an analogue of Proposition 5.1 for smooth solutions, where the index of nonconvexity of the data is replaced by a bound on the eigenvalues of the Hessian matrix.

While Proposition 5.1 applies to the general case, a stronger assertion can be proved in the case $H(p) = H_1(p_A) + H_2(p_B)$, where T can be arbitrarily large in some special cases. Set

$$\mu_A(u_0) = \sup_{v_B \in \mathbb{R}^{N-j}} \mu(u_0(\cdot, v_B)), \quad \mu_B(-u_0) = \sup_{v_A \in \mathbb{R}^j} \mu(-u_0(v_A, \cdot))$$

and consider the properties

$$\text{for any fixed } v_B \in \mathbb{R}^{N-j}, \quad v_A \mapsto u_0(v_A, v_B) \text{ convex}, \tag{5.2}$$

$$\text{for any fixed } v_A \in \mathbb{R}^j, \quad v_B \mapsto u_0(v_A, v_B) \text{ concave}. \tag{5.3}$$

Next, define

$$T_1 := \begin{cases} +\infty & \text{if (5.2) holds,} \\ \dfrac{|\mu(H_1^*)|}{\mu_A(u_0)} & \text{otherwise,} \end{cases}$$

$$T_2 := \begin{cases} +\infty & \text{if (5.3) holds,} \\ \dfrac{|\mu(-H_2^*)|}{\mu_B(-u_0)} & \text{otherwise,} \end{cases}$$

where $\mu(H_1^*)$ (resp., $\mu(-H_2^*)$) is the index of nonconvexity of H_1 (resp., H_2) as a function defined on $\mathbb{R}^j$ (resp., $\mathbb{R}^{N-j}$). Observe that if (5.2) (resp., (5.3)) does not hold, we have $\mu_A(u_0) > 0$ (resp., $\mu_B(-u_0) > 0$).

PROPOSITION 5.2. *Under the hypotheses of Proposition* 3.2, *for* $T < \min\{T_1, T_2\}$, *the unique viscosity solution in* $UC_x(\mathbb{R}^N \times [0,T])$ *of* $(HJ)(IC)$ *is given by*

$$u(x,t) = \sup_{z_B \in \mathbb{R}^{N-j}} \inf_{z_A \in \mathbb{R}^j} G(z,x,t) = \inf_{z_A \in \mathbb{R}^j} \sup_{z_B \in \mathbb{R}^{N-j}} G(z,x,t),$$

where G *is the function defined either by* (3.8) *or* (3.9).

Proof. Apply the minimax theorem. □

Remark 1. Note that if (5.2) and (5.3) hold, then $T_1 = T_2 = +\infty$, so we have a representation formula for all times. This result extends Theorem 2 in [28].

Remark 2. For times larger than the bounds indicated in Proposition 5.1 and 5.2, it may happen that $u_- < u_+$. We show this on some examples. The first two are taken from [29] and we report them for the reader's convenience.

Example 5.1. Consider the equation

$$u_t + u_{x_1}^2 - \frac{1}{2}u_{x_2}^2 = 0 \quad \text{in } \mathbb{R}^2 \times (0,\infty),$$

and the initial data

$$u_0(x) = -|x_1 + x_2|.$$

Here u_0 is concave, but $\mu_A(u_0) = +\infty$, so $T_1 = 0$. We use G given by (3.8), set $z = (k, w)$, and compute

$$g(k,w,x,t) = -|x_1 + x_2 - tk + tw| + \frac{tk^2}{4} - \frac{tw^2}{2}.$$

By remark (6) in section 3 (see Lemma 3.3), we can restrict the minmax procedure to compact sets and more precisely, since $\mathrm{Lip}(u_0) = 1$,

$$u_-(x,t) = \max_{|w|\le 1} \min_{|k|\le 2} g(k,w,x,t),$$

$$u_+(x,t) = \min_{|k|\le 2} \max_{|w|\le 1} g(k,w,x,t).$$

A straightforward but tedious computation gives

$$u_+(x,t) = -|x_1 + x_2| - \frac{t}{2}, \tag{5.4}$$

$$u_-(x,t) = \begin{cases} u_+(x,t) & \text{for } |x_1 + x_2| \ge t, \\ -t - (x_1 + x_2)^2/(2t) & \text{otherwise.} \end{cases} \tag{5.5}$$

Example 5.2. For the equation of Example 5.1, and for fixed $t > 0$, a smooth initial function u_0 such that $u_-(x,t) < u_+(x,t)$ can be constructed as follows. Take the initial data of the previous example, $\tilde{u}_0(x) = -|x_1 + x_2|$, and rename $\tilde{u}_+$, $\tilde{u}_-$ the corresponding super and subsolution given by (5.4), (5.5). It is easy to check that

$$|\tilde{u}_+(0,t) - u_+(0,t)| \le \sup_{[-2t,2t]\times[-t,t]} |\tilde{u}_0 - u_0|$$

and the same inequality holds for $|\tilde{u}_-(0,t) - u_-(0,t)|$. Since $\tilde{u}_+(0,t) - \tilde{u}_-(0,t) = t/2$ by (5.4), (5.5), we can take a smooth function u_0 approximating $\tilde{u}_0$ uniformly on a compact set so that $u_+(0,t) - u_-(0,t) \ge t/4$.

Example 5.3. Consider the equation

$$u_t + |u_{x_1}| - |u_{x_2}| = 0 \quad \text{in } \mathbb{R}^2 \times (0,\infty),$$

and observe that $\mu(H_1^*) = 0$, so that $T_1 = 0$. It is easy to compute

$$u_-(x,t) = \max_{|w|\le 1} \min_{|k|\le 1} u_0(x_1 + kt, x_2 + wt),$$

$$u_+(x,t) = \min_{|k|\le 1} \max_{|w|\le 1} u_0(x_1 + kt, x_2 + wt).$$

Now we choose any u_0 such that

$$\max_{|y_2|\le t} \min_{|y_1|\le t} u_0(y_1, y_2) < \min_{|y_1|\le t} \max_{|y_2|\le t} u_0(y_1, y_2).$$

Then $u_-(0,t) < u_+(0,t)$.

In the case of general Hamiltonian and u_0 satisfying (H2), we have similar results.

PROPOSITION 5.3. *Under the hypotheses of Theorem* B*, assume that* T *satisfies*

$$T \le \min\left\{ \frac{|\mu(u_1^*)|}{\mu(H)}, \frac{|\mu(-u_2^*)|}{\mu(-H)} \right\}$$

and $0 < \mu(H), \mu(-H) < +\infty$. *Then the unique viscosity solution of* $(HJ)(IC)$ *in* $UC_x(\mathbb{R}^N \times [0,T])$ *is given by*

$$u(x,t) = v_-(x,t) = v_+(x,t)$$

where the functions v_-, v_+ *are defined in* (4.2), (4.3).

Proof. Apply the minimax theorem. □

As we noted before for the dual case, we have a better result for initial data satisfying (H2) and such that $u_1(x) = u_1(x_A)$ and $u_2(x) = u_2(x_B)$. Similarly, we set

$$\mu_A(H) = \sup_{v_B \in \mathbb{R}^{N-j}} \mu(H(\cdot, v_B)), \quad \mu_B(-H) = \sup_{v_A \in \mathbb{R}^j} \mu(-H(v_A, \cdot)),$$

and

(5.6) for any fixed $v_B \in \mathbb{R}^{N-j}$, $v_A \mapsto H(v_A, v_B)$ convex,

(5.7) for any fixed $v_A \in \mathbb{R}^j$, $v_B \mapsto H(v_A, v_B)$ concave,

and then

$$T_1 := \begin{cases} +\infty & \text{if (5.6) holds,} \\ \dfrac{|\mu(u_1^*)|}{\mu_A(H)} & \text{otherwise,} \end{cases}$$

$$T_2 := \begin{cases} +\infty & \text{if (5.7) holds,} \\ \dfrac{|\mu(-u_2^*)|}{\mu_B(H)} & \text{otherwise,} \end{cases}$$

where $\mu(u_1^*)$ (resp., $\mu(-u_2^*)$) is the index of nonconvexity of u_1 (resp., u_2) as a function defined on $\mathbb{R}^j$ (resp., on $\mathbb{R}^{N-j}$).

PROPOSITION 5.4. *Assume* $H \in C(\mathbb{R}^N)$ *and* u_0 *satisfying* $(H2)$ *and such that* $u_1(x) = u_1(x_A)$ *and* $u_2(x) = u_2(x_B)$. *Then for* $T < \min\{T_1, T_2\}$, *the unique viscosity solution in* $UC_x(\mathbb{R}^N \times [0,T])$ *of* $(HJ)(IC)$ *is given by*

$$u(x,t) = \sup_{z_B \in \mathbb{R}^{N-j}} \inf_{z_A \in \mathbb{R}^j} F(z,x,t) = \inf_{z_A \in \mathbb{R}^j} \sup_{z_B \in \mathbb{R}^{N-j}} F(z,x,t),$$

where $F : \mathbb{R}^N \times \mathbb{R}^N \times [0,+\infty) \to \mathbb{R}$ *is defined by*

$$F(v,x,t) = x \cdot v - u_1^*(v_A) - u_2^*(-v_B) - tH(v).$$

Proof. Combine [4] Theorem 1 and the minimax theorem. □

6. Hamiltonians with dependence on the state variable. Hopf's formula can be extended to Cauchy problems for Hamiltonians with a particular dependence on the state variable x, i.e.,

$$\begin{cases} (HJ)_x \quad u_t + H(B(x)D_x u) = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ (IC) \quad u(x,0) = u_0(x) & \text{in } \mathbb{R}^N \times \{0\}, \end{cases}$$

where $\psi : \mathbb{R}^N \to \mathbb{R}$ is a C^1-diffeomorphism and $B(x) = [D\psi(x)]^{-1}$. To this purpose, we are going to study the following associated problem:

$$\begin{cases} (HJ) \quad v_t + H(D_x v) = 0 & \text{in } \mathbb{R}^N \times (0,T), \\ (IC)_\psi \quad v(x,0) = u_0(\psi^{-1}(x)) & \text{in } \mathbb{R}^N \times \{0\}. \end{cases}$$

If H is convex and $u_0 \cdot \psi^{-1} \in UC(\mathbb{R}^N)$, its unique viscosity solution in $UC_x(\mathbb{R}^N \times [0,T])$ is, of course,

$$\begin{aligned} v(y,t) &= \min_{z \in \mathbb{R}^N} \left\{ u_0(\psi^{-1}(z)) + tH^* \left(\frac{y-x}{t} \right) \right\} \\ &= \min_{w \in \mathbb{R}^N} \{ u_0(\psi^{-1}(y - tw)) + tH^*(w) \}. \end{aligned}$$

LEMMA 6.1. *Let $\psi : \mathbb{R}^N \to \mathbb{R}$ be a C^1-diffeomorphism, $u, v \in C(\mathbb{R}^N \times [0,T])$ be such that $u(x,t) = v(\psi(x),t)$. Then v is a viscosity solution of $(HJ)(IC)_\psi$ if and only if u is a viscosity solution of $(HJ)_x(IC)$.*

Proof. Apply a change of variables for viscosity solutions [2]. □

A direct consequence of the preceding lemma is the following proposition.

PROPOSITION 6.2. *If H is convex, $u_0 \in C(\mathbb{R}^N)$, and $u_0 \cdot \psi^{-1} \in UC(\mathbb{R}^N)$, then the unique viscosity solution $u \in C(\mathbb{R}^N \times [0,T])$ of $(HJ)_x(IC)$ is given by*

$$\begin{aligned} u(x,t) &= \min_{z \in \mathbb{R}^N} \left\{ u_0(z) + tH^* \left(\frac{\psi(x) - \psi(z)}{t} \right) \right\} \\ &= \min_{w \in \mathbb{R}^N} \{ u_0(\psi^{-1}(\psi(x) - tw)) + tH^*(w) \}. \end{aligned} \tag{6.1}$$

Observe that uniqueness follows from Lemma 6.1 and the uniqueness of v as a solution of $(HJ)(IC)_\psi$ in $UC(\mathbb{R}^N \times [0,T])$.

Example. Formula (6.1) applies to the following case: consider the Hamiltonian $H = H(g_1(x_1)u_{x_1}, \dots, g_N(x_N)u_{x_N})$, where $g_i \in C(\mathbb{R}^N)$, $g_i > 0$, $g_i \in L^\infty(\mathbb{R})$. Then $\psi : \mathbb{R}^N \to \mathbb{R}^N$ defined by

$$\psi(x) = \left(\int_0^{x_1} \frac{1}{g_1(t)} dt, \dots, \int_0^{x_N} \frac{1}{g_N(t)} dt \right)$$

is the required isomorphism, and its inverse $\varphi = (\varphi_1, \dots, \varphi_N)$ is Lipschitz since it satisfies

$$\varphi_(y_i) = \int_0^{y_i} g_i(\varphi_i(t)) dt,$$

(see [21] for some physical examples).

Now we extend Theorem A to problems with Hamiltonians dependent on x. Applying Proposition 3.2, Theorem A, and Lemma 6.1 to $(HJ)(IC)_\psi$, we easily obtain the next result.

THEOREM 6.3. *Assume $u_0 \in C(\mathbb{R}^N)$, $u_0 \cdot \psi^{-1} \in UC(\mathbb{R}^N)$, $H \in C(\mathbb{R}^N)$, $H(p) = H_1(p) + H_2(p)$, with H_1 convex and H_2 concave. Then the unique (continuous) viscosity solution of $(HJ)_x(IC)$, satisfies*

$$\max_{w\in\mathbb{R}^N} \min_{k\in\mathbb{R}^N} g_\psi(k,w,x,t) \le u(x,t) \le \min_{k\in\mathbb{R}^N} \max_{w\in\mathbb{R}^N} g_\psi(k,w,x,t),$$

where $g_\psi(k,w,x,t) := u_0(\psi^{-1}(\psi(x) - t(k-w))) + tH_1^*(k) + tH_2^*(w)$.

Remark. It is clear that one can proceed similarly to extend Theorem B to $(HJ)_x(IC)$ under the assumption of section 4 and, for example, the additional condition that ψ^{-1} is Lipschitz continuous.

NONEXISTENCE OF HIGHER DIMENSIONAL STABLE TURING PATTERNS IN THE SINGULAR LIMIT*

YASUMASA NISHIURA† AND HIROMASA SUZUKI‡

Abstract. When the thickness of the interface (denoted by ε) tends to zero, any *stable* stationary internal layered solutions to a class of reaction–diffusion systems cannot have a smooth limiting interfacial configuration. This means that if the limiting configuration of the interface has a smooth limit, it must become unstable for small ε, which makes a sharp contrast with the one-dimensional case. This suggests that stable layered patterns must become very fine and complicated in this singular limit. In fact we can formally derive that the rate of shrinking of stable patterns is of order $\varepsilon^{1/3}$. Using this scaling, the resulting rescaled reduced equation determines the morphology of magnified patterns. A variational characterization of the critical eigenvalue combined with the matched asymptotic expansion method is a key ingredient for the proof, although the original linearized system is not of self-adjoint type.

Key words. reaction–diffusion system, interfacial pattern, singular perturbation, matched asymptotic expansion

1. Introduction.

Dynamics of interfacial patterns attracts much interest in many fields such as population dynamics, combustion, chemical reaction, solidification, and so on. One of the pioneering works in the pattern formation problem can be traced back to Turing [9], who found that spatially inhomogeneous patterns can be formed by diffusion-driven instability if the inhibitor diffuses faster than the activator. A typical model system is of the form

$$\begin{cases} u_t = \varepsilon^2 \Delta u + f(u,v), & \\ & (x,t) \in \Omega \times (0,\infty), \\ v_t = D\Delta v + g(u,v), & \\ \dfrac{\partial u}{\partial n} = 0 = \dfrac{\partial v}{\partial n}, & (x,t) \in \partial\Omega \times (0,\infty), \end{cases} \tag{1.1}$$

where u is the activator, v is the inhibitor, Ω is a smooth bounded domain in $\mathbf{R}^N$ ($N \geq 2$), and ε is a small positive parameter. The nonlinearity f has at least two stable branches for a fixed v, and the signs of g are different on these branches, typically $(f,g) = (u(1-u)(u-a) - v, u - \gamma v)$, where $0 < a < 1$, $\gamma > 0$. More precise assumptions for (f,g) are displayed at the end of this section. Although (1.1) exhibits a variety of patterns depending on diffusion and/or reaction rates, we focus on the stationary ones in higher space dimensions; we are especially interested in layered solutions which have internal transition layers from one stable branch of the nullcline $f = 0$ to the other one (see (A.4)). The basic issue asks, *Does* (1.1) *have nonconstant stable stationary solutions up to* $\varepsilon = 0$*? And, if it does, what are the*

*Received by the editors December 9, 1996; accepted for publication (in revised form) September 15, 1997; published electronically April 14, 1998.

asymptotic configurations of them as $\varepsilon \downarrow 0$*?* As we shall see, this is closely related to finding the location of free boundary called the *interface* separating two different states. Numerically as well as experimentally, for a *fixed* $\varepsilon > 0$, a variety of stationary patterns have been observed such as spots, stripes, and labyrinthine patterns for (1.1) (see, for instance, [1] and the references therein). Hence naively one can expect that (1.1) has a lot of stable stationary solutions for small ε up to $\varepsilon = 0$.

In fact, for the one-dimensional case, it is proved rigorously (see [5]) that many stable layered solutions coexist up to $\varepsilon = 0$. It should be noted that each layer position has a definite limit and the distance between layer positions remains finite as $\varepsilon \downarrow 0$.

On the other hand, for the higher dimensional case, we know very little about the limiting configuration of *stable* stationary solutions to (1.1) when ε tends to zero. For instance, the planar front does not persist as a stable one (see [7]), and more complicated patterns take it over for small ε. We rephrase our basic question in the following way: *Does* (1.1) *have an* ε*-family of stable stationary layered solutions* $(U^\varepsilon, V^\varepsilon)$ *with smooth interface* Γ^ε *up to* $\varepsilon = 0$*?* Here Γ^ε is defined by

$$\Gamma^\varepsilon \equiv \{x \in \Omega \mid U^\varepsilon(x) = \alpha^*\},$$

where α^* is an intermediate value between two stable branches of $f = 0$ and, for instance, is equal to $1/2$ for the above specific example. Note that "smooth up to $\varepsilon = 0$" means that there exists an $(N-1)$-dimensional smooth compact connected manifold Γ^0 without boundary embedded in $\mathbf{R}^N$ such that Γ^ε converges to Γ^0 smoothly as $\varepsilon \downarrow 0$.

The goal in this paper is to give a *negative* answer to this question under the assumption that it has a matched asymptotic expansion of order 1 (see section 2 for details). Namely, we have the following theorem.

THEOREM 1.1 (main theorem). *Suppose that* (1.1) *has an* ε*-family of stationary matched asymptotic solutions of order* 1 *whose interface is smooth up to* $\varepsilon = 0$*. Then it must become unstable for small* ε*.*

We prove this in section 3 by converting the linearized eigenvalue problem around $(U^\varepsilon, V^\varepsilon)$ to a variational one (see (3.5)) which consists of a scalar elliptic part and a nonlocal term coming from the coupling of the two equations. A key idea is that in the variational characterization of the maximal eigenvalue of the system, the term associated with the (local) elliptic boundary problem is positive and it dominates the contribution from the nonlocal term for a highly oscillating admissible function in azimuthal direction. This instability result leads to the natural question, how about the fate of stable ones when $\varepsilon \downarrow 0$? The above theorem strongly suggests that stable patterns somehow must become very fine and/or complicated when $\varepsilon \downarrow 0$, and if it happens, can we characterize the domain size of those patterns and their morphologies? We shall discuss these issues in section 4; in fact we can formally derive that the rate of shrinking of stable patterns is of order $\varepsilon^{1/3}$. Using this scaling, the resulting rescaled reduced equation determines the morphology of magnified patterns (see also [5], [6], and [8]).

We prove the above theorem under the following assumptions.

(A.0) Γ^ε is an $(N-1)$-dimensional smooth compact connected manifold without boundary inside of Ω, and the domain surrounded by Γ^ε is simply connected.

(A.1) f and g are smooth functions of u and v defined on some open set $\mathcal{O}$ in $\mathbf{R}^2$ and the partial derivative f_v(resp., g_u) is a negative (resp., positive) constant function.

(A.2) (a) The nullcline of f is sigmoidal and consists of three smooth curves $u = h_-(v)$, $h_0(v)$, and $h_+(v)$ defined on the intervals I_-, I_0, and I_+, respectively. Let

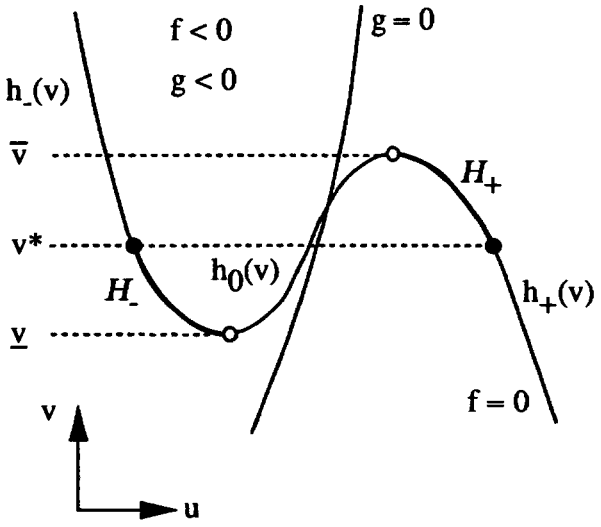

FIG. 1.1. *Functional forms of* $f = 0$ *and* $g = 0$.

$\min I_- = \underline{v}$ and $\max I_+ = \overline{v}$; then the inequality $h_-(v) < h_0(v) < h_+(v)$ holds for $v \in I^* \equiv (\underline{v}, \overline{v})$, and $h_+(v)$ (resp., $h_-(v)$) coincides with $h_0(v)$ at only one point $v = \overline{v}$ (resp., $\underline{v}$), respectively.

(b) The nullcline of g intersects with that of f at one or three points transversally as in Figure 1.1. The critical point on $u = h_-(v)$ (resp., $h_+(v)$ or $h_0(v)$), if it exists, is denoted by $P = (u_-, v_-) = (h_-(v_-), v_-)$ (resp., $Q = (u_+, v_+) = (h_+(v_+), v_+)$ or $R = (u_0, v_0) = (h_0(v_0), v_0)$).

(A.3) $J(v)$ has an isolated zero at $v = v^* \in I^*$ such that $dJ/dv < 0$ at $v = v^*$, where $J(v) = \int_{h_-(v)}^{h_+(v)} f(s, v)ds$. Moreover, we assume that $v_- < v^* < v_+$.

(A.4) $f_u < 0$ on $H_+ \cup H_-$, where H_- (resp., H_+) denotes the part of the curve $u = h_-(v)$ (resp., $h_+(v)$) defined by H_- (resp., H_+) $= \{(u, v) | u = h_-(v)$(resp., $h_+(v))$ for $v_- \le v < v^* (v^* < v \le v_+)\}$, respectively. Note that $v_- \le$ (resp., $\le v_+$) is replaced by $\underline{v} <$ (resp., $< \overline{v}$) when there are no critical points on the branch $u = h_-(v)$ (resp., $h_+(v)$). H_+ and H_- are called the stable branches of $f = 0$. See the thick solid part of $f = 0$ in Figure 1.1.

(A.5) (a)
$$g|_{H_-} < 0 < g|_{H_+},$$

(b)
$$\det\left(\frac{\partial(f, g)}{\partial(u, v)}\right)\Big|_{H_+ \cup H_-} > 0.$$

(A.6)
$$g_v|_{H_+ \cup H_-} < 0.$$

Remark 1.1. The assumption for the partial derivatives in (A.1) is necessary to make the problem (3.4) self-adjoint; however, it is plausible that our result holds true for the general case.

Remark 1.2. It is not known rigorously that, under the above assumptions, any smooth layered solution with a smooth limiting interface has a matched asymptotic

expansion of order 1; however, it is conjectured to be true at least for a large class of such layered solutions.

Remark 1.3. (A.4) and (A.5) (b) imply that

$$\frac{d}{dv}g(h_{\pm}(v),v) = \left.\frac{f_u g_v - f_v g_u}{f_u}\right|_{H_+\cup H_-} < 0. \tag{1.2}$$

We use the following notation throughout the paper: let $\sigma = (\sigma_1, \sigma_2, \ldots, \sigma_N)$ denote the usual multi-index of order $|\sigma| = \sigma_1 + \sigma_2 + \cdots + \sigma_N$ with nonnegative integers σ_i, and write $\partial_i = \partial/\partial x_i$ $(1 \le i \le N)$.

(i) Let k be a nonnegative integer and $\alpha \in (0,1)$. By $C^{k+\alpha}(\overline{\Omega})$ we mean the Banach space of all real-valued functions $u \in C^k(\overline{\Omega})$ for which the derivatives $\partial^\sigma u$ with $|\sigma| = k$ are Hölder continuous on $\overline{\Omega}$ with exponent α. The norm is

$$\|u\|_{C^{k+\alpha}(\overline{\Omega})} = \sum_{j=0}^{k} |u|_{j,\overline{\Omega}} + |u|_{k+\alpha,\overline{\Omega}},$$

where

$$|u|_{j,\overline{\Omega}} = \max_{|\sigma|=k} \sup_{x\in\overline{\Omega}} |\partial^\sigma u(x)|,$$

and

$$|u|_{k+\alpha,\overline{\Omega}} = \max_{|\sigma|=k} \sup_{x,y\in\overline{\Omega}} \frac{|\partial^\sigma u(x) - \partial^\sigma u(y)|}{|x-y|^\alpha}.$$

(ii) $C_0^{k+\alpha}(\overline{\Omega})$ is the subspace of $C^{k+\alpha}(\overline{\Omega})$ whose elements are functions vanishing on $\partial\Omega$.

(iii) $C_\varepsilon^{k+\alpha}(\overline{\Omega})$ is the Banach space of all real-valued functions in $C^{k+\alpha}(\overline{\Omega})$ but with the special norm depending on ε:

$$\|u\|_{C_\varepsilon^{k+\alpha}(\overline{\Omega})} = \sum_{j=0}^{k} \varepsilon^j |u|_{j,\overline{\Omega}} + \varepsilon^{k+\alpha} |u|_{k+\alpha,\overline{\Omega}}.$$

(iv) $C_{\varepsilon,0}^{k+\alpha}(\overline{\Omega})$ is the subspace of $C_\varepsilon^{k+\alpha}(\overline{\Omega})$ whose elements are functions vanishing on $\partial\Omega$.

2. Matched asymptotic expansion of singularly perturbed stationary solutions. In this section, we summarize the necessary conditions for the existence of the ε-family of matched asymptotic solutions with internal transition layers of the following stationary problem:

$$\begin{cases} 0 = \varepsilon^2 \Delta u + f(u,v) \\ \\ 0 = D\Delta v + g(u,v) \end{cases} \qquad \text{in } \Omega, \tag{2.1}$$

$$\frac{\partial u}{\partial n} = 0 = \frac{\partial v}{\partial n} \qquad \text{on } \partial\Omega. \tag{2.2}$$

Before presenting the precise form of matched asymptotic expansion, we need to do a change of variables near the interface. Let us assume that there exists an ε-family

of smooth solutions $(U^\varepsilon(x), V^\varepsilon(x))$ to (2.1) and (2.2) with interior transition layers such that the interface defined by

$$\Gamma^\varepsilon \equiv \{x \in \Omega \mid U^\varepsilon(x) = \alpha^*\} \tag{2.3}$$

is a compact smooth manifold of dimension $N-1$ embedded in $\mathbf{R}^N$ and has a definite limit Γ^0 with the same properties as $\varepsilon \downarrow 0$. Let (X_ϕ, ϕ) be a local chart on Γ^0, with $\phi(X_\phi)$ an open subset of $\mathbf{R}^{N-1}$. For $x_0 \in X_\phi$, $\phi(x_0) = s = (s^1, \dots, s^{N-1})$ and we denote the inverse of ϕ by

$$x_0 = (x_0^1(s), \dots, x_0^N(s)).$$

In some tubular neighborhood $U_d(\Gamma^0) = \{x \in \mathbf{R}^N \mid |y(x)| \le d\}$ of Γ^0, the local coordinate system $(s, y) = (s^1, \dots, s^{N-1}, y)$ is defined and for $x \in U_d(\Gamma^0)$,

$$x = X(s, y) \equiv x_0(s^1, \dots, s^{N-1}) + y\nu(s^1, \dots, s^{N-1}) \tag{2.4}$$

holds, where $\nu(s^1, \dots, s^{N-1})$ is the outward unit normal vector at $s = (s^1, \dots, s^{N-1})$ to Γ^0. Then, X becomes a diffeomorphism from $[-d, d] \times \Gamma^0$ to $U_d(\Gamma^0)$ if d is strictly smaller than the infimum of the radii of curvature of Γ^0. Its inverse is denoted by $(S(x), Y(x))$. Then Γ^ε can be represented by

$$\Gamma^\varepsilon = \{x_0(s) + \gamma(s, \varepsilon)\nu(s) \mid s \in \Gamma^0\},$$

where

$$\gamma(s, \varepsilon) = \sum_{k=1}^{m} \varepsilon^k \gamma_k(s) + \varepsilon^m \hat{\gamma}_{m+1}(s, \varepsilon).$$

Here we introduce the local shift variable τ by the following relation:

$$y = \tau + \omega\left(\frac{\tau}{d}\right)\gamma(s, \varepsilon), \tag{2.5}$$

where $\omega(\tau) \in C^\infty(\mathbf{R})$ is a cut-off function such that

$$\omega(\tau) = 1 \quad \text{for} \quad |\tau| \le \frac{1}{2}, \quad \omega(\tau) = 0 \quad \text{for} \quad |\tau| \ge 1,$$

$$0 \le \omega(\tau) \le 1, \quad |\omega'| \le 3.$$

Then, by the implicit function theorem, $\tau = \tau(s, y, \varepsilon)$ satisfying (2.5) is defined for sufficiently small ε. In place of x, we use a new independent variable $\hat{x}$, defined by

$$\hat{x} = \hat{X}(x, \varepsilon) = \begin{cases} x, & x \in \Omega \backslash U_d(\Gamma^0), \\ X(S(x), \tau(S(x), Y(x), \varepsilon)), & x \in U_d(\Gamma^0). \end{cases}$$

Let Ω_ε^+ (resp., Ω_0^+) be the region surrounded by Γ^ε (resp., Γ^0) and $\Omega_\varepsilon^- \equiv \Omega \backslash \overline{\Omega}_\varepsilon^+$ (resp., $\Omega_0^- \equiv \Omega \backslash \overline{\Omega}_0^+$). Then, note that $\hat{x} = \hat{X}(x, \varepsilon)$ maps Γ^ε to Γ^0, and $\Omega_\varepsilon^\pm$ to $\Omega_0^\pm$, respectively; namely, the free boundary Γ^ε becomes a fixed boundary Γ^0 in the new coordinate. Throughout the paper, we shall use the following notation:

$$u(x) = u(s, y), \quad \hat{u}(\hat{x}) = \hat{u}(s, \tau).$$

Using the above transformation, the stationary problem (2.1) with (2.2) can be rewritten as

$$\begin{cases} \varepsilon^2 M^\varepsilon \hat{u} + f(\hat{u}, \hat{v}) = 0 \\ \\ D M^\varepsilon \hat{v} + g(\hat{u}, \hat{v}) = 0 \end{cases} \qquad \text{in } \Omega, \tag{2.6}$$

$$\frac{\partial \hat{u}}{\partial n} = 0 = \frac{\partial \hat{v}}{\partial n} \qquad \text{on } \partial\Omega, \tag{2.7}$$

where $\hat{u} = \hat{u}(\hat{x})$, $\hat{v} = \hat{v}(\hat{x})$, and M^ε is the representation of the Laplacian Δ_x in $\hat{x}$. In $\Omega \backslash U_d(\Gamma^0)$, M^ε is equal to $\Delta_{\hat{x}}$. On the other hand, in the neighborhood $U_d(\Gamma^0)$, M^ε is defined in the following way: for the local coordinate system (s, y) defined by (2.4) in $\mathbf{R}^N$, let g^{ij} be the contravariant metric tensor and $g = \det(g^{ij})$. Then for $u(x) = u(s, y)$, Laplacian Δ_x is expressed by

$$\begin{aligned} (\Delta_x u)(x) &= (\Delta_{(s,y)} u)(s, y) \\ &\equiv \frac{\partial^2}{\partial y^2} u(s, y) + (N-1) H(s, y) \frac{\partial}{\partial y} u(s, y) \\ &\quad + \frac{1}{\sqrt{g}} \sum_{i=1}^{N-1} \frac{\partial}{\partial s^i} \left(\sqrt{g} \sum_{j=1}^{N-1} g^{ij} \frac{\partial}{\partial s^j} u(s, y) \right), \end{aligned} \tag{2.8}$$

where $H = H(s, y)$ is the mean curvature of the hypersurface $\Gamma(y) = \{x_0(s) + y\nu(s) \mid s \in \Gamma^0\}$ at (s, y). Using this representation, for $\hat{u}(\hat{x}) = \hat{u}(s, \tau)$, M^ε is defined by

$$(M^\varepsilon \hat{u})(\hat{x}) \equiv \Delta_{(s,y)} \hat{u}(s, \tau(s, y, \varepsilon)).$$

It follows from this definition that M^ε can be expanded as $M^\varepsilon = \sum_{k \geq 0} \varepsilon^k M_k$, where

$$M_0 \equiv \Delta_{\hat{x}}, \qquad \hat{x} \in \Omega,$$

and for $k \geq 1$,

$$M_k = \begin{cases} 0, & \hat{x} \in \Omega \backslash U_d(\Gamma^0), \\ \\ \text{at most the second order differential operator in} \\ s^i \ \ (i = 1, \ldots, N-1) \ \text{ and } \ \tau, & \hat{x} \in U_d(\Gamma^0). \end{cases}$$

In the following, we consider only (2.6) and (2.7), so we omit the hat symbol ($\hat{}$). A family of solutions $(U^\varepsilon, V^\varepsilon) \in X_\varepsilon \equiv C_\varepsilon^{2+\alpha}(\overline{\Omega}) \times C^{2+\alpha}(\overline{\Omega})$ of (2.6) and (2.7) is called an *ε-family of matched asymptotic solutions of order m* when it has the following expansions (2.9)–(2.12). Roughly speaking, $(U^\varepsilon, V^\varepsilon)$ is expanded separately in two regions $\Omega_0^\pm$ divided by the interface Γ^0, and they are matched smoothly at Γ^0. It should be recalled that the boundary condition (2.3) is always satisfied at Γ^0 for small ε owing to the change of variables (2.5). More precisely, for any positive integer m, we have

$$U^\varepsilon(x) = \begin{cases} U_+^\varepsilon(x) \equiv U_m^+(x, \varepsilon) + \Phi_m^+(x, \varepsilon) + o(\varepsilon^m), & x \in \Omega_0^+, \\ \\ U_-^\varepsilon(x) \equiv U_m^-(x, \varepsilon) + \Phi_m^-(x, \varepsilon) + o(\varepsilon^m), & x \in \Omega_0^-, \end{cases}$$

(2.9)
$$V^\varepsilon(x) = \begin{cases} V_+^\varepsilon(x) \equiv V_m^+(x,\varepsilon) + \varepsilon^2 \Psi_m^+(x,\varepsilon) + o(\varepsilon^m), & x \in \Omega_0^+, \\ V_-^\varepsilon(x) \equiv V_m^-(x,\varepsilon) + \varepsilon^2 \Psi_m^-(x,\varepsilon) + o(\varepsilon^m), & x \in \Omega_0^-, \end{cases}$$

where

$$U_m^\pm(x,\varepsilon) = \sum_{k=0}^m u_k^\pm(x)\varepsilon^k, \quad V_m^\pm(x,\varepsilon) = \sum_{k=0}^m v_k^\pm(x)\varepsilon^k, \tag{2.10}$$

$$\Phi_m^\pm(x,\varepsilon) = \begin{cases} \omega(\frac{Y(x)}{d}) \displaystyle\sum_{k=0}^m \phi_k^\pm\left(S(x), \frac{Y(x)}{\varepsilon}\right)\varepsilon^k, & x \in U_d(\Gamma^0) \cap \Omega_0^\pm, \\ 0, & x \in \Omega_0^\pm \backslash U_d(\Gamma^0), \end{cases} \tag{2.11}$$

$$\Psi_m^\pm(x,\varepsilon) = \begin{cases} \omega(\frac{Y(x)}{d}) \displaystyle\sum_{k=0}^m \psi_k^\pm\left(S(x), \frac{Y(x)}{\varepsilon}\right)\varepsilon^k, & x \in U_d(\Gamma^0) \cap \Omega_0^\pm, \\ 0, & x \in \Omega_0^\pm \backslash U_d(\Gamma^0), \end{cases} \tag{2.12}$$

$\phi_k^\pm$ and $\psi_k^\pm$ are functions of s and ξ, and ξ is the *stretched variable* $\xi \equiv \tau/\varepsilon$ (recall that $Y(\hat{x}) = \tau$). Here the topology of Landau's o is X_ε. The coefficients $u_k^\pm$, $v_k^\pm$, $\phi_k^\pm$, and $\psi_k^\pm$ satisfy the equations listed below in appropriate function spaces, which can be obtained by making *outer* and *inner* expansions and equating like powers of ε^k. The inner and outer solutions are not independent in the sense that they must satisfy the boundary conditions as well as the C^1-*matching conditions* between $(U_+^\varepsilon, V_+^\varepsilon)$ and $(U_-^\varepsilon, V_-^\varepsilon)$ on Γ^0. Let $\beta^\varepsilon(s) = v^* + \sum_{k=1}^m \beta_k(s)\varepsilon^k + \varepsilon^m \beta_{m+1}(s,\varepsilon)$ be the expansion of the value of V^ε on Γ^0. Note that the 0th order should be v^* from (A.3), since $(U^\varepsilon, V^\varepsilon)$ is a stationary solution.

We briefly explain the algorithm of the matched asymptotic expansion method and display the equations and relations up to order $O(\varepsilon^m)$. For more detailed arguments, see [2] and [6].

First we divide (2.6) into two problems as follows:

$$\begin{cases} \varepsilon^2 M^\varepsilon u^+ + f(u^+, v^+) = 0 & \\ & \text{in } \Omega_0^+, \\ DM^\varepsilon v^+ + g(u^+, v^+) = 0 & \\ u^+ = \alpha^*, \quad v^+ = \beta^\varepsilon & \text{on } \Gamma^0, \end{cases} \tag{2.13}_+$$

$$\begin{cases} \varepsilon^2 M^\varepsilon u^- + f(u^-, v^-) = 0 & \\ & \text{in } \Omega_0^-, \\ DM^\varepsilon v^- + g(u^-, v^-) = 0 & \\ u^- = \alpha^*, \quad v^- = \beta^\varepsilon & \text{on } \Gamma^0, \\ \dfrac{\partial u^-}{\partial n} = 0 = \dfrac{\partial v^-}{\partial n} & \text{on } \partial\Omega. \end{cases} \tag{2.13}_-$$

Then the interface is regarded as the boundary layer at Γ^0.

Outer expansion. Let

$$u^{\pm} = \sum_{k=0}^{m} u_k^{\pm}(x)\varepsilon^k, \quad v^{\pm} = \sum_{k=0}^{m} v_k^{\pm}(x)\varepsilon^k, \tag{2.14}$$

where both $u_k^{\pm}(x)$ and $v_k^{\pm}(x)$ belong to $C^{\infty}(\overline{\Omega}_0^{\pm})$. Substituting (2.14) into $(2.13)_{\pm}$ and equating like powers of ε, then $(u_k^{\pm}(x), v_k^{\pm}(x))$ satisfy the following equations:

$k = 0$

$$\begin{cases} f(u_0^{\pm}, v_0^{\pm}) = 0 & \\ & \text{in } \Omega_0^{\pm}, \\ DM_0 v_0^{\pm} + g(u_0^{\pm}, v_0^{\pm}) = 0 & \\ & \\ \dfrac{\partial v_0^{-}}{\partial n} = 0 & \text{on } \partial\Omega, \end{cases} \tag{2.15}$$

$k \geq 1$

$$\begin{cases} f_u^{0\pm} u_k^{\pm} + f_v^{0\pm} v_k^{\pm} = -\displaystyle\sum_{i+j=k-2} M_i u_j^{\pm} + P_{k-1}^{\pm} & \\ & \\ DM_0 v_k^{\pm} + g_u^{0\pm} u_k^{\pm} + g_v^{0\pm} v_k^{\pm} = -D \displaystyle\sum_{i+j=k, i\geq 1} M_i v_j^{\pm} + Q_{k-1}^{\pm} \text{ in } \Omega_0^{\pm}, & \\ & \\ \dfrac{\partial v_k^{-}}{\partial n} = 0 \qquad \text{on } \partial\Omega, & \end{cases} \tag{2.16}$$

where $f_u^{0\pm} \equiv \frac{\partial}{\partial u} f(u_0^{\pm}, v_0^{\pm})$, $f_v^{0\pm} \equiv \frac{\partial}{\partial v} f(u_0^{\pm}, v_0^{\pm})$, and so on. $P_{k-1}^{\pm}$ and $Q_{k-1}^{\pm}$ are functions determined only by $u_0^{\pm}, v_0^{\pm}, \ldots, u_{k-1}^{\pm}, v_{k-1}^{\pm}$. For $k = 1$, we define the right-hand side of (2.16) as equal to zero. Since $(U^{\varepsilon}, V^{\varepsilon})$ is a layered solution connecting two stable branches of the kinetics (f, g), it follows from (A.4) and the first equation of (2.15) that $(u_0^{\pm}, v_0^{\pm})$ lies on either H_+ or H_-. For definiteness, we assume that $u_0^{\pm} = h_{\pm}(v_0^{\pm})$. Then (2.16) can be uniquely solved recursively owing to the assumptions (A.4) and (A.5). This expansion is, however, insufficient because the layer part is not taken into account; in fact, u_0^{+} and u_0^{-} are discontinuous on Γ^0. To cope with this defect, we introduce a new variable $\xi = \tau/\varepsilon$ that rescales a neighborhood of the interface. Also note that the boundary conditions for $v_k^{\pm}$ are determined by the C^1-matching conditions discussed later.

Inner expansion. We introduce the stretched variable $\xi = \tau/\varepsilon$ and let

$$\begin{aligned} u^{\pm} &= U_m^{\pm}(x,\varepsilon) + \sum_{k=0}^{m} \phi_k^{\pm}\left(S(x), \frac{Y(x)}{\varepsilon}\right)\varepsilon^k, \\ v^{\pm} &= V_m^{\pm}(x,\varepsilon) + \varepsilon^2 \sum_{k=0}^{m} \psi_k^{\pm}\left(S(x), \frac{Y(x)}{\varepsilon}\right)\varepsilon^k, \end{aligned} \tag{2.17}$$

where $\phi_k^{\pm} = \phi_k^{\pm}(s,\xi)$ and $\psi_k^{\pm} = \psi_k^{\pm}(s,\xi)$. Since the definition domains of $\phi_k^{\pm}$ and $\psi_k^{\pm}$ are semi-infinite, these functions and the inhomogeneous terms of their equations listed below must have some decaying property for solvability. An appropriate function space for this purpose is the following.

DEFINITION 2.1. *Let $\mathcal{E}^{\pm}$ be the set of functions $E^{\pm}(s,\xi,\varepsilon)$ defined on $\Gamma_0 \times I^{\mp} \times [0,\varepsilon_0)$ with the property that for each C^{∞} linear differential operator D of any order in the variables s and ξ, there exist positive constants $C_{\pm}$ and K (possibly depending on D and $E^{\pm}$, but not on s, ξ, and ε) with $|DE^{\pm}| \le Ke^{-C_{\pm}|\xi|}$. Here $I^{-} \equiv (-\infty, 0)$ and $I^{+} \equiv (0,\infty)$.*

Substituting (2.17) into $(2.13)_{\pm}$ and equating like powers of ε, we obtain the following equations:

$k = 0$

$$\begin{cases} \ddot{\phi}_0^{\pm} + f(h_{\pm}(v^*) + \phi_0^{\pm}, v^*) = 0, \\ D\ddot{\psi}_0^{\pm} = g(h_{\pm}(v^*), v^*) - g(h_{\pm}(v^*) + \phi_0^{\pm}, v^*), \\ \phi_0^{\pm}(s, \mp\infty) = 0, \quad \psi_0^{\pm}(s, \mp\infty) = 0 = \dot{\psi}_0^{\pm}(s, \mp\infty), \end{cases}$$

$k = 1$

$$\begin{cases} \ddot{\phi}_1^{\pm} + \tilde{f}_u^{0\pm}\phi_1^{\pm} = -\tilde{M}_1\phi_0^{\pm} - \tilde{f}_u^{0\pm}\{u_1^{\pm}(s,0) + (u_0^{\pm})_{\tau}(s,0)\xi\} \\ \qquad\qquad\qquad\qquad -\tilde{f}_v^{0\pm}\{v_1^{\pm}(s,0) + (v_0^{\pm})_{\tau}(s,0)\xi\}, \\ D\ddot{\psi}_1^{\pm} = -D\tilde{M}_1\psi_0^{\pm} + \tilde{Q}_0^{\pm}, \\ \phi_1^{\pm}(s, \mp\infty) = 0, \quad \psi_1^{\pm}(s, \mp\infty) = 0 = \dot{\psi}_1^{\pm}(s, \mp\infty), \end{cases}$$

$k \ge 2$

$$\begin{cases} \ddot{\phi}_k^{\pm} + \tilde{f}_u^{0\pm}\phi_k^{\pm} = -\displaystyle\sum_{i+j=k, i\ge 1} \tilde{M}_i\phi_j^{\pm} + \tilde{P}_{k-1}^{\pm}, \\ D\ddot{\psi}_k^{\pm} = -D\displaystyle\sum_{i+j=k, i\ge 1} \tilde{M}_i\psi_j^{\pm} + \tilde{Q}_{k-1}^{\pm}, \\ \phi_k^{\pm}(s, \mp\infty) = 0, \quad \psi_k^{\pm}(s, \mp\infty) = 0 = \dot{\psi}_k^{\pm}(s, \mp\infty) \end{cases}$$

for $\xi \in I^{\mp}$ and $s \in \Gamma^0$, where $\cdot = \frac{\partial}{\partial\xi}$, $\tilde{f}_u^{0\pm} \equiv \frac{\partial}{\partial u} f(h_{\pm}(v^*) + \phi_0^{\pm}, v^*)$, $(u_0^{\pm})_{\tau}(s,0) = \frac{\partial}{\partial\tau}u_0^{\pm}(s,0)$, and so on. $\tilde{P}_{k-1}^{\pm}$ depends on $u_0^{\pm}, v_0^{\pm}, \ldots, u_k^{\pm}, v_k^{\pm}, \phi_0^{\pm}, \psi_0^{\pm}, \ldots, \phi_{k-1}^{\pm}, \psi_{k-2}^{\pm}$, and $\tilde{Q}_{k-1}^{\pm}$ does, moreover, depend on $\psi_{k-1}^{\pm}$. The solvability of the above equations in the space $\mathcal{E}^{\pm}$ can be shown in a similar way to [2], so we leave the details to the reader. $\tilde{M}^{\varepsilon}$ is the representation of M^{ε} in variables s and ξ and is expanded as

$$\tilde{M}^{\varepsilon} \equiv \frac{1}{\varepsilon^2}\sum_{k\ge 0}\varepsilon^k\tilde{M}_k.$$

Here $\tilde{M}_k$ $(k \ge 0)$ are at most second-order differential operators in s and ξ. The precise forms of $\tilde{M}_k$ are presented at the end of this section.

Boundary conditions and C^1-matching conditions. Now we describe the boundary conditions of $v_k^{\pm}$ and $\phi_k^{\pm}$ on Γ^0. Then $u_k^{\pm}$, $v_k^{\pm}$, $\phi_k^{\pm}$, and $\psi_k^{\pm}$ are determined

recursively. These conditions are given by

$$\alpha^* = \sum_{k=0}^{m} u_k^{\pm}(s,0)\varepsilon^k + \sum_{k=0}^{m} \phi_k^{\pm}(s,0)\varepsilon^k,$$

$$v^* + \sum_{k=1}^{m} \beta_k(s)\varepsilon^k = \sum_{k=0}^{m} v_k^{\pm}(s,0)\varepsilon^k + \varepsilon^2 \sum_{k=0}^{m-2} \psi_k^{\pm}(s,0)\varepsilon^k.$$

Equating like powers of ε, we have the following boundary conditions:

$k = 0$

$$\phi_0^{\pm}(s,0) = \alpha^* - u_0^{\pm}(s,0), \quad v_0^{\pm} = v^* \qquad s \in \Gamma^0, \tag{2.18}$$

$k \geq 1$

$$\phi_k^{\pm}(s,0) = -u_k^{\pm}(s,0), \quad v_k^{\pm}(s,0) = \beta_k(s) - \psi_{k-2}^{\pm}(s,0) \qquad s \in \Gamma^0.$$

In this way, we obtain the formal asymptotic solution of $(2.13)_{\pm}$. Since $(U^\varepsilon, V^\varepsilon)$ is a stationary solution of (2.6), $(U_\pm^\varepsilon, V_\pm^\varepsilon)$ must satisfy the C^1-matching conditions; that is,

$$\varepsilon \frac{\partial U_+^\varepsilon}{\partial \nu} = \varepsilon \frac{\partial U_-^\varepsilon}{\partial \nu}, \quad \varepsilon \frac{\partial V_+^\varepsilon}{\partial \nu} = \varepsilon \frac{\partial V_-^\varepsilon}{\partial \nu} \quad \text{on} \quad \Gamma^0.$$

After some computation, we have

$k = 0$

$$(v_0^+)_\tau(s,0) = (v_0^-)_\tau(s,0), \quad \dot{\phi}_0^+(s,0) = \dot{\phi}_0^-(s,0), \qquad s \in \Gamma^0. \tag{2.19}$$

$k \geq 1$

$$\begin{aligned} &(v_k^+)_\tau(s,0) + \dot{\psi}_{k-1}^+(s,0) = (v_k^-)_\tau(s,0) + \dot{\psi}_{k-1}^-(s,0), \\ &\dot{\phi}_k^+(s,0) + (u_{k-1}^+)_\tau(s,0) = \dot{\phi}_k^-(s,0) + (u_{k-1}^-)_\tau(s,0). \end{aligned} \qquad s \in \Gamma^0 \tag{2.20}$$

The second equation of (2.15) with the boundary and C^1-matching conditions (see (2.18) and (2.19)) is called the *reduced problem*; namely,

$$\begin{cases} D\Delta v_0^{\pm} + g(h_{\pm}(v_0^{\pm}), v_0^{\pm}) = 0 & \text{in} \quad \Omega_0^{\pm}, \\ v_0^{\pm} = v^*, \quad \dfrac{\partial v_0^+}{\partial \nu} = \dfrac{\partial v_0^-}{\partial \nu} & \text{on} \quad \Gamma^0, \\ \dfrac{\partial v_0^-}{\partial n} = 0 & \text{on} \quad \partial\Omega. \end{cases} \tag{2.21}$$

This is a free boundary problem for Γ^0 which determines the asymptotic configuration of stationary interfacial patterns. We define $v_0(x) \in C^1(\overline{\Omega})$ by

$$v_0(x) = \begin{cases} v_0^+(x), & x \in \Omega_0^+, \\ v_0^-(x), & x \in \Omega_0^-. \end{cases}$$

We close this section by presenting a lemma on the representations of $\tilde{M}_k$, which will become useful in the next section. The proof is delegated to [6].

LEMMA 2.2. *$\tilde{M}_0$, $\tilde{M}_1$, and $\tilde{M}_2$ have the following forms:*

$$\tilde{M}_0 \equiv \frac{\partial^2}{\partial \xi^2}, \quad \tilde{M}_1 \equiv (N-1)H_0(s)\frac{\partial}{\partial \xi},$$

$$\tilde{M}_2 \equiv \Delta^{\Gamma^0} - (P_1(s)+P_2(s))\frac{\partial}{\partial \xi} + P_3(s)\frac{\partial^2}{\partial \xi^2}$$

$$-D_s\frac{\partial}{\partial \xi} - H_1(s)(\xi+\gamma_1(s))\frac{\partial}{\partial \xi},$$

where

$$P_1(s) = \frac{1}{2G}\sum_{i=1}^{N-1} G_{s^i}\sum_{j=1}^{N-1} G^{ij}\partial_{s^j}\gamma_1,\ P_2(s) = \sum_{i=1}^{N-1}\sum_{j=1}^{N-1}[G^{ij}_{s^i}\partial_{s^j}\gamma_1 + G^{ij}\partial_{s^i s^j}\gamma_1],$$

$$P_3(s) = \sum_{i=1}^{N-1}\sum_{j=1}^{N-1} G^{ij}\partial_{s^i}\gamma_1\partial_{s^j}\gamma_1 > 0,\ D_s = \sum_{i=1}^{N-1}\sum_{j=1}^{N-1} G^{ij}\left(\partial_{s^i}\gamma_1\frac{\partial}{\partial s^j} + \partial_{s^j}\gamma_1\frac{\partial}{\partial s^i}\right),$$

$$H_1(s) \equiv \sum_{i=1}^{N-1}\kappa_i(s)^2.$$

$H_0(s)$ (resp., $\kappa_i(s)$) are the mean (resp., principal) curvature of Γ^0 at $s \in \Gamma^0$, G^{ij} is the contravariant metric tensor for the manifold Γ^0 of dimension $N-1$, $G = \det(G^{ij})$, and Δ^{Γ^0} is Laplace–Beltrami's operator defined on Γ^0. In particular, the coefficients of $\frac{\partial}{\partial s^j}$ in D_s are independent of ξ.

3. Instability result for stationary patterns as $\varepsilon \downarrow 0$. In this section we prove that the internal layered solutions in the previous section must become unstable when ε tends to zero. For this purpose, we show that the linearized eigenvalue problem around $(U^\varepsilon, V^\varepsilon)$,

$$\begin{cases} \lambda w = \varepsilon^2 M^\varepsilon w + f^\varepsilon_u w + f^\varepsilon_v z, \\ \lambda z = DM^\varepsilon z + g^\varepsilon_u w + g^\varepsilon_v z, \end{cases} \tag{3.1}$$

has an unstable eigenvalue where λ is the eigenvalue parameter, where $f^\varepsilon_u = \frac{\partial}{\partial u} f(U^\varepsilon, V^\varepsilon)$ and so on. The main result is the following.

THEOREM 3.1. *Suppose that* (1.1) *has an ε-family of stationary matched asymptotic solutions of order* 1 *(i.e., $m = 1$) whose interface is smooth up to $\varepsilon = 0$. Then,* (3.1) *has a positive (i.e., unstable) eigenvalue of $O(\varepsilon)$ for small ε.*

Proof. We divide the proof into three steps. In the first two steps we assume that the ε-family of stationary solutions has an asymptotic expansion up to order 2 (i.e., $m = 2$), which makes the proof readable, especially to understand how to handle the Laplacian part. Then it is easy to modify the proof to be valid for the order 1 case (see Step 3 below). Apparently (3.1) is not a self-adjoint problem, since $f^\varepsilon_v \neq g^\varepsilon_u$. In order to reduce the problem to a self-adjoint one, we first introduce the following

auxiliary problem:

$$\begin{cases} \lambda w = \varepsilon^2 M^\varepsilon w + f_u^\varepsilon w + f_v^\varepsilon z, \\ \eta z = DM^\varepsilon z + g_u^\varepsilon w + g_v^\varepsilon z, \end{cases} \tag{3.2}$$

where η is an auxiliary parameter. The following Step 1 deals with the case $\eta = 0$, where, by solving the second equation with respect to z (see (A.6)) and substituting it into the first equation, we have a self-adjoint problem of w. Then the existence of the unstable eigenvalue for (3.2) with $\eta = 0$ is shown via the variational method. This result can be extended to case $\eta > 0$ in Step 2, where it is proved that a positive eigenvalue of $O(\varepsilon)$ of (3.2) exists for each $\eta \neq 0$. The proof of Theorem 3.1 for $m = 2$ is an immediate consequence of these two steps. Finally in Step 3 we show that the expansion up to order 1 is sufficient for the proof of instability. Note that the linearized instability implies a nonlinear one for the class of evolutional systems like (1.1).

Step 1 ($\eta = 0$ case). Solving the second equation of (3.2) with $\eta = 0$ with respect to z as

$$z = (N^\varepsilon)^{-1} g_u^\varepsilon w, \tag{3.3}$$

where $(N^\varepsilon)^{-1} \equiv (-DM^\varepsilon - g_v^\varepsilon)^{-1}$, which is well defined from (A.6), and then substituting (3.3) into the first equation of (3.2), we obtain a scalar problem for w:

$$\lambda w = \varepsilon^2 M^\varepsilon w + f_u^\varepsilon w + f_v^\varepsilon (N^\varepsilon)^{-1} g_u^\varepsilon w. \tag{3.4}$$

From (A.1), (3.4) becomes a self-adjoint problem.

LEMMA 3.2. (3.4) *has a positive* (*i.e., unstable*) *eigenvalue of* $O(\varepsilon)$ *for small* ε.

Proof. In what follows, for simplicity of notation, we can assume that $f_v \equiv -1$ and $g_u \equiv 1$ without loss of generality. Since the linearized operator (3.4) is self-adjoint, we shall prove that the largest eigenvalue λ_0^ε of (3.4) becomes positive for small ε, which is characterized by

$$\lambda_0^\varepsilon = \sup_{w \in H^1(\Omega)} \frac{\displaystyle\int_\Omega \{-\varepsilon^2 |\nabla_{M^\varepsilon} w|^2 + f_u^\varepsilon w^2 - |(N^\varepsilon)^{-1/2} w|^2\} dx}{\displaystyle\int_\Omega w^2 dx}, \tag{3.5}$$

where ∇_{M^ε} is the representation of ∇ with respect to the coordinate $\hat{x}$ (see section 2). Recall that we write x instead of $\hat{x}$ and hence $Y(x) = \tau$ and $\xi \equiv \tau/\varepsilon$. Now we construct a suitable test function for our purpose. Let

$$Q(\xi) = \begin{cases} \omega\left(\dfrac{\varepsilon\xi}{d}\right) \dot{U}(\xi) & \text{for} \quad |\xi| \le \dfrac{d}{\varepsilon}, \\ 0 & \text{for} \quad |\xi| \ge \dfrac{d}{\varepsilon}, \end{cases}$$

where U is a solution of

$$\begin{cases} \ddot{U} + f(U, v^*) = 0, \\ U(\pm\infty) = h_\mp(v^*), \quad U(0) = \alpha^*. \end{cases} \tag{3.6}$$

We define $w(x)$ by the following product with $\Theta \in L^2(\Gamma^0)$ and $\|\Theta\|_{L^2(\Gamma^0)} = 1$:

$$w(x) = \begin{cases} Q\left(\dfrac{Y(x)}{\varepsilon}\right)\Theta(S(x)), & x \in U_d(\Gamma^0), \\ 0, & x \in \Omega \backslash U_d(\Gamma^0). \end{cases}$$

For this $w(x)$, $\varepsilon^2|\nabla_{M^\varepsilon} w|^2$ is computed as

$$\begin{aligned} \varepsilon^2|\nabla_{M^\varepsilon} w|^2 = \varepsilon^2(\dot{U}^2|\nabla^{\Gamma^0}\Theta|^2 - 2\ddot{U}^2\dot{U}^2\nabla^{\Gamma^0}\Theta \cdot \nabla^{\Gamma^0}\gamma_1 + \ddot{U}^2|\nabla^{\Gamma^0}\gamma_1|^2) \\ +\dddot{U}^2\Theta^2 + O(\varepsilon^3) \end{aligned} \tag{3.7}$$

in $U_d(\Gamma^0)$, where

$$\nabla^{\Gamma^0}\Theta_1 \cdot \nabla^{\Gamma^0}\Theta_2 \equiv \sum_{i,j=1}^{N-1} G^{ij}\frac{\partial\Theta_1}{\partial s^i}\frac{\partial\Theta_2}{\partial s^j}, \quad |\nabla^{\Gamma^0}\Theta_3|^2 \equiv \nabla^{\Gamma^0}\Theta_3 \cdot \nabla^{\Gamma^0}\Theta_3$$

for $\Theta_i \in L^2(\Gamma^0)(i = 1, 2, 3)$, and G^{ij} is the contravariant metric tensor for Γ^0. Here we used the fact that

$$|\nabla_{M^\varepsilon}\hat{u}|^2 = |\nabla_{(s,y)}u|^2 \equiv \sum_{i,j=1}^{N-1} g^{ij}\frac{\partial u}{\partial s^i}\frac{\partial u}{\partial s^j} + \left(\frac{\partial u}{\partial y}\right)^2$$

for $\hat{u}(s, \tau) = u(s, y)$. Hence, for a function $\varphi = \varphi(s, \tau(s, y, \varepsilon)/\varepsilon)$, we note that $\frac{\partial\varphi}{\partial s^i} = \varphi_{s^i} + \frac{1}{\varepsilon}\varphi_\xi\tau_{s^i}$, $\frac{\partial\varphi}{\partial y} = \frac{1}{\varepsilon}\varphi_\xi\tau_y$, $\tau_{s^i} = -\varepsilon\partial_{s^i}\gamma_1 + O(\varepsilon^2)$, and $\tau_y \equiv 1$ in a neighborhood of $\tau = 0$ (see (2.5)). Integrating (3.7) over Ω, the first term of numerator of (3.5) becomes

$$\begin{aligned} &\int_\Omega \varepsilon^2|\nabla_{M^\varepsilon} w|^2 dx \\ &= \varepsilon\int_{\Gamma^0}\int_{|\xi|\le\frac{d}{\varepsilon}} \{\varepsilon^2\dot{U}^2|\nabla^{\Gamma^0}\Theta|^2 + \varepsilon^2\ddot{U}^2\hat{P}_1(s)\Theta^2 + \dddot{U}^2\Theta^2\} d\xi dS + O(\varepsilon^4), \end{aligned} \tag{3.8}$$

where $\hat{P}_1(s) = |\nabla^{\Gamma^0}\gamma_1|^2$. The remainder term $O(\varepsilon^4)$ depends only on Γ^0 and the L^2-norm of Θ. In order to compute the second term of the numerator of (3.5), first note that

$$f_u^\varepsilon = \begin{cases} \tilde{F}_u^{0+} + \varepsilon\tilde{F}_u^{1+} + \varepsilon^2\tilde{F}_u^{2+} + O(\varepsilon^3) \ \text{ in } \ \Omega_0^+ \cap U_d(\Gamma^0), \\ \tilde{F}_u^{0-} + \varepsilon\tilde{F}_u^{1-} + \varepsilon^2\tilde{F}_u^{2-} + O(\varepsilon^3) \ \text{ in } \ \Omega_0^- \cap U_d(\Gamma^0), \end{cases} \tag{3.9}$$

where

$$\begin{aligned} \tilde{F}_u^{0\pm} &\equiv f_u(h_\pm(v^*) + \phi_0^\pm, v^*), \\ \tilde{F}_u^{1\pm} &\equiv f_{uu}(h_\pm(v^*) + \phi_0^\pm, v^*)\{\xi(u_0^\pm)_\tau(s, 0) + u_1^\pm(s, 0) + \phi_1^\pm\} \\ &\quad + f_{uv}(h_\pm(v^*) + \phi_0^\pm, v^*)\{\xi(v_0)_\tau(s, 0) + v_1^\pm(s, 0)\}, \end{aligned}$$

and the remainder term $O(\varepsilon^3)$ depends only on the stationary pattern $(U^\varepsilon, V^\varepsilon)$. The $O(1)$ term of (3.9) multiplied by w^2 combined with the third term of (3.8) vanishes, which is easily seen by differentiating (3.6) with respect to ξ. Hence we only focus on the contribution of (3.9) coming from the $O(\varepsilon)$-term and higher. The next equality is a key ingredient for the proof

$$\int_{-\infty}^{0} \tilde{F}_u^{1+}\dot{U}^2 d\xi + \int_{0}^{\infty} \tilde{F}_u^{1-}\dot{U}^2 d\xi = (v_0)_\tau(s,0)\frac{d}{dv}J(v^*) > 0. \tag{3.10}$$

In order to show (3.10), we note that $\dot{U} = \dot{\phi}_0^{\pm}$, $\ddot{U} = \ddot{\phi}_0^{\pm}$ for $\xi \in I^{\mp}$ (so we omit the superscript $\pm$ of $\dot{\phi}_0$ and $\ddot{\phi}_0$), and $p^{\pm} \equiv \dot{\phi}_1^{\pm}$ satisfy the next equation (see section 2):

$$\ddot{p}^{\pm} + \tilde{F}_u^{0\pm} p^{\pm} = \Omega^{\pm}, \tag{3.11}$$

where

$$\Omega^{\pm}(s,\xi) \equiv H^{\pm}(s,\xi) - \{(u_0^{\pm})_\tau(s,0)\tilde{f}_u^{0\pm} + (v_0)_\tau(s,0)\tilde{f}_v^{0\pm}\}$$

and

$$H^{\pm} \equiv -(N-1)H_0\ddot{\phi}_0 - \tilde{F}_u^{1\pm}\dot{\phi}_0. \tag{3.12}$$

Multiplying $\dot{\phi}_0$ on both sides of (3.11) and using the relations

$$\int_{\mp\infty}^{0} \tilde{f}_u^{0\pm}\dot{\phi}_0(z)dz = -\ddot{\phi}_0(0), \qquad \int_{\mp\infty}^{0} \tilde{f}_v^{0\pm}\dot{\phi}_0(z)dz = \int_{h_\pm(v^*)}^{\alpha^*} f_v(u,v^*)du,$$

we obtain, by integration by parts,

$$\begin{aligned}\int_{\mp\infty}^{0} H^{\pm}(s,z)\dot{\phi}_0(z)dz &= \ddot{\phi}_1^{\pm}(s,0)\dot{\phi}_0(0) - \ddot{\phi}_0(0)\{\dot{\phi}_1^{\pm}(s,0) + (u_0^{\pm})_\tau(s,0)\} \\ &\quad + (v_0)_\tau(s,0)\int_{h_\pm(v^*)}^{\alpha^*} f_v(u,v^*)du.\end{aligned} \tag{3.13}$$

On the other hand, multiplying $\dot{\phi}_0$ on both sides of (3.12) and using (3.13), we have

$$\begin{aligned}&\int_{-\infty}^{0} \tilde{F}_u^{1+}\dot{U}^2 d\xi + \int_{0}^{\infty} \tilde{F}_u^{1-}\dot{U}^2 d\xi = \int_{-\infty}^{0} \tilde{F}_u^{1+}\dot{\phi}_0^2 d\xi + \int_{0}^{\infty} \tilde{F}_u^{1-}\dot{\phi}_0^2 d\xi \\ &= -(N-1)H_0\int_{-\infty}^{0} \ddot{\phi}_0\dot{\phi}_0 d\xi - (N-1)H_0\int_{0}^{\infty} \ddot{\phi}_0\dot{\phi}_0 d\xi \\ &\quad -\ddot{\phi}_1^{+}(s,0)\dot{\phi}_0(0) + \ddot{\phi}_0\{\dot{\phi}_1^{+}(s,0) + (u_0^{+})_\tau(s,0)\} - (v_0)_\tau(s,0)\int_{h_+(v^*)}^{\alpha^*} f_v(u,v^*)du \\ &\quad +\ddot{\phi}_1^{-}(s,0)\dot{\phi}_0(0) - \ddot{\phi}_0\{\dot{\phi}_1^{-}(s,0) + (u_0^{-})_\tau(s,0)\} + (v_0)_\tau(s,0)\int_{h_-(v^*)}^{\alpha^*} f_v(u,v^*)du \\ &= (v_0)_\tau(s,0)\int_{h_-(v^*)}^{h_+(v^*)} f_v(u,v^*)du,\end{aligned}$$

which is the required result (3.10). Here we used the fact that $\ddot{\phi}_1^+(s,0) = \ddot{\phi}_1^-(s,0)$ and the C^1-matching condition of $\phi_1^\pm$ (see (2.20)). Using (3.8), (3.9), (3.10), and the Hopf boundary Lemma for v^0 on Γ^0 (see (1.2) and (2.21)), we obtain

$$\begin{aligned}\lambda_0^\varepsilon \geq C \Bigg[& \varepsilon \frac{m_*}{K_1} \frac{d}{dv} J(v^*) \\ & + \int_\Gamma \varepsilon^2 \left\{ -|\nabla^{\Gamma^0} \Theta|^2 - \frac{1}{K_1}(K_2 \hat{P}_1(s) - \hat{P}_2(s))\Theta^2 \right\} dS \\ & - \frac{1}{K_1 \varepsilon} \int_\Omega |(N^\varepsilon)^{-1/2} w|^2 dx \Bigg] + O(\varepsilon^3),\end{aligned} \tag{3.14}$$

where

$$m_* \equiv \min_{s \in \Gamma^0} (v_0)_\tau(s,0) < 0, \qquad K_1 \equiv \int_{-\infty}^{\infty} \dot{U}^2 d\xi, \qquad K_2 \equiv \int_{-\infty}^{\infty} \ddot{U}^2 d\xi,$$

$$\hat{P}_2(s) \equiv \int_{-\infty}^{0} \tilde{F}_u^{2+} \dot{U}^2 d\xi + \int_0^{\infty} \tilde{F}_u^{2-} \dot{U}^2 d\xi,$$

and C is a positive constant. The objective is to choose an appropriate test function in order to make the first term of $[\,\cdot\,]$ in (3.14) dominant, which is positive and $O(\varepsilon)$. First we choose Θ as the kth eigenfunction Θ_k of the following eigenvalue problem:

$$\Delta^\Gamma \Theta_k - \frac{1}{K_1}(K_2 \hat{P}_1(s) - \hat{P}_2(s))\Theta_k = \mu_k \Theta_k \qquad \text{on } \Gamma^0.$$

Then the second term of (3.14) is equal to $\varepsilon^2 \mu_k$. Note also that Θ_k converges to 0 as $k \to \infty$ in weak $L^2(\Gamma^0)$-sense. As for the third term of (3.14), which comes from the nonlocal part, we first note that when ε tends to zero,

$$\frac{1}{\varepsilon} Q\left(\frac{\tau}{\varepsilon}\right) = \frac{1}{\varepsilon} \dot{U}\left(\frac{\tau}{\varepsilon}\right) \omega\left(\frac{\tau}{d}\right) \longrightarrow c_0 \delta(\tau) \qquad \text{in } H^{-1}((-d,d))\text{-sense}, \tag{3.15}$$

where $\delta(\tau)$ is a Dirac's δ-function at 0 and c_0 is a positive constant. Let K_k^ε be

$$K_k^\varepsilon \equiv \int_\Omega \left| (N^\varepsilon)^{-1/2} \left(\frac{w_k}{\varepsilon}\right) \right|^2 dx = \int_\Omega \left[(N^\varepsilon)^{-1} \left(\frac{w_k}{\varepsilon}\right) \right] \left(\frac{w_k}{\varepsilon}\right) dx.$$

In view of (3.15) and considering that $(N^\varepsilon)^{-1}$ is a uniformly bounded operator mapping from $H^{-1}(\Omega)$ to $H^1(\Omega)$ with respect to ε, we see that K_k^ε is uniformly bounded with respect to ε and k and that $\int_{-d}^{d} (Q(\tau/\varepsilon)/\varepsilon) \cdot d\tau$ converges to the trace operator on Γ^0 from $H^1(\Omega)$ to $H^{1/2}(\Gamma^0)$ in operator norm sense. Therefore, by using the fact that Θ_k converges weakly to 0 as $k \to \infty$, we see that for any given small $c^* > 0$, there exists an ε_0 and k_0 such that

$$K_k^\varepsilon < c^* \quad \text{for} \quad 0 < \varepsilon \leq \varepsilon_0, \ k \geq k_0. \tag{3.16}$$

Substituting $\Theta = \Theta_k$ and $w = w_k$ into (3.14), we have

$$\lambda_0^\varepsilon \geq C\varepsilon \left[\frac{m_*}{K_1} \frac{d}{dv} J(v^*) - \frac{1}{K_1} K_k^\varepsilon + \varepsilon \mu_k \right] + O(\varepsilon^3),$$

where C is a positive constant. Using (3.16) and taking ε smaller, if necessary, we see that

$$\frac{m_*}{K_1}\frac{d}{dv}J(v^*) - \frac{1}{K_1}K_k^\varepsilon > 0. \tag{3.17}$$

Therefore the right-hand side of (3.5) becomes positive for sufficiently small $\varepsilon > 0$, which is greater or equal to the $O(\varepsilon)$ quantity. In the rest of the proof, we show that the upper bound of (3.5) is also of $O(\varepsilon)$. Since the first and the third terms of the numerator of (3.5) are nonpositive, it holds obviously that

$$\lambda_0^\varepsilon \le \sup_{w\in H^1(\Omega)} \frac{\displaystyle\int_\Omega f_u^\varepsilon w^2 dx}{\displaystyle\int_\Omega w^2 dx}.$$

In view of the expansion (3.9) and the assumptions (A.2) and (A.4), f_u^ε has a positive sign only in the ε-neighborhood along the normal direction of Γ^0. Therefore we have the estimate

$$\lambda_0^\varepsilon \le C\varepsilon|\Gamma^0|,$$

where C is a positive constant and $|\cdot|$ denotes the area, which completes the proof of Lemma 3.2. □

Step 2 ($\eta \neq 0$ case). Rewriting (3.2) as

$$\begin{cases} \lambda w = \varepsilon^2 M^\varepsilon w + f_u^\varepsilon w + f_v^\varepsilon z, \\ \\ 0 = DM^\varepsilon z + g_u^\varepsilon w + (g_v^\varepsilon - \eta)z \end{cases} \tag{3.18}$$

and noting that $g_v^\varepsilon - \eta < 0$ for $\eta \ge 0$ from (A.6), we see that all the computation in Step 1 is also valid for (3.18) with $\eta \ge 0$. Therefore we have the following lemma.

LEMMA 3.3. (3.18) *has a positive eigenvalue* $\lambda = \lambda^\varepsilon(\eta)$ *for* $\eta \ge 0$. *Moreover, there exist positive constants* C_0 *and* C_1 ($C_0 < C_1$) *which are independent of* η *and* ε *such that*

$$C_0\varepsilon < \lambda^\varepsilon(\eta) < C_1\varepsilon \tag{3.19}$$

holds for $\eta \ge 0$.

Proof of Theorem 3.1 ($m = 2$ case). It follows from Lemma 3.3 that $\lambda^\varepsilon(\eta)$ is a continuous function of η for $\eta \ge 0$. Since $\lambda^\varepsilon(\eta)$ has lower and upper bounds like (3.19), we see that $\eta = \lambda^\varepsilon(\eta)$ holds at least at one point $\eta = \eta^*$ (> 0) by the intermediate value theorem. This η^* is the required unstable eigenvalue for (3.1).

Step 3 (extension to $m = 1$ case). It suffices to show how Step 1 should be changed under the weaker assumption. When the asymptotic expansion has only terms up to $m = 1$, we see from Lemma 2.2 that we lose the precise expression for the gradient part $|\nabla_{M^\varepsilon} w|^2$, and the right-hand side of (3.7) becomes $\ddot{U}^2\Theta^2 + O(\varepsilon^2)$; namely, the gradient part is part of the remainder term $O(\varepsilon^2)$. Similarly, the first two terms of the integrand of the right-hand side of (3.8) move to the remainder term $O(\varepsilon^3)$. On the other hand, (3.10) remains valid. Hence (3.14) becomes the following:

$$\lambda_0^\varepsilon \ge C\left[\varepsilon\frac{m_*}{K_1}\frac{d}{dv}J(v^*) - \frac{1}{K_1\varepsilon}\int_\Omega |(N^\varepsilon)^{-1/2}w|^2 dx\right] + O(\varepsilon^2). \tag{3.20}$$

Note that the remainder term $O(\varepsilon^2)$ depends on Θ. In order to get the estimate (3.16), we select the function Θ in Step 1 as an eigenfunction of the elliptic operator of second order. However it is not necessary to take such an eigenfunction; in fact it suffices to employ any weakly convergent sequence to zero. Once we fix an appropriate Θ and then take ε to be sufficiently small, we have a similar estimate to (3.17). It is easy to see that Lemma 3.3 and the proof after it hold true for this case. This completes the proof of Theorem 3.1. □

4. Concluding remarks. As was mentioned in section 1, Theorem 1.1 strongly suggests that stable patterns of (1.1) become very fine and/or complicated in the limit of $\varepsilon \downarrow 0$ in higher dimensional spaces. What we discuss here seeks to find an appropriate scaling in space and time by which the resulting singular limit dynamics could have stable patterns of *finite* size. Such patterns are usually maintained by the balance of two competing forces as described below. In the course of the following formal analysis, it is intuitive why the stable patterns of (1.1) must become fine in the original scale.

Suppose there is a sharp transition layer (interface) Γ connecting two stable bulk states. There are two forces that drive the interface: one is the bulk force causing the translation of interface with certain speed $W(v|_\Gamma)$ which depends on the value of v at Γ; the other is a geometric force, i.e., mean-curvature effect.

In one word, the characteristic size of stable patterns is determined by the *balance between the above two forces* and turns out to be proportional to $\varepsilon^{1/3}$. It should be noted that the scale $\varepsilon^{1/3}$ coincides with the fastest growing wavelength of the planar front of (1.1) (see [7]). In what follows we consider a smooth subdomain $\tilde{\Omega}_\varepsilon$ ($\subset \Omega$) and assume that both u and v satisfy the Neumann boundary conditions on $\partial\tilde{\Omega}_\varepsilon$ and the diameter of $\tilde{\Omega}_\varepsilon$ shrinks to zero as $\varepsilon \downarrow 0$ with order ε^α. Here α $(0 < \alpha < 1)$ is an unknown exponent. Typically $\tilde{\Omega}_\varepsilon$ is a unit cell of some periodic structure in $\mathbf{R}^N$.

Applying a change of variable with unknown exponent α

$$\mathbf{y} = \frac{\mathbf{x}}{\varepsilon^\alpha} \qquad (0 < \alpha < 1)$$

to (1.1) ($D = 1$ for simplicity), we have

$$\text{(4.1)} \qquad \begin{cases} u_t = \varepsilon^{2(1-\alpha)}\Delta_{\mathbf{y}} u + f(u,v) \\ \\ v_t = \varepsilon^{-2\alpha}\Delta_{\mathbf{y}} v + g(u,v) \end{cases} \qquad \text{in } \hat{\Omega}_\varepsilon,$$

where $\Delta_{\mathbf{y}}$ stands for the Laplacian in $\mathbf{y}$-variable and $\hat{\Omega}_\varepsilon$ is the stretched domain of $\tilde{\Omega}_\varepsilon$. It is more convenient to rewrite (4.1) in the following form:

$$\text{(4.2)} \qquad \begin{cases} \varepsilon^{-(1-\alpha)} u_t = \varepsilon^{1-\alpha}\Delta_{\mathbf{y}} u + \varepsilon^{-(1-\alpha)} f(u,v), \\ \\ \varepsilon^{2\alpha} v_t = \Delta_{\mathbf{y}} v + \varepsilon^{2\alpha} g(u,v). \end{cases}$$

Suppose $\hat{\Omega}_\varepsilon$ has a smooth limit $\hat{\Omega}$ as $\varepsilon \downarrow 0$. Taking a limiting procedure similar to [3], we obtain the following interfacial dynamics:

$$\text{(4.3)} \qquad \begin{cases} \varepsilon^{-(1-\alpha)}\Gamma_t = \{W(v|_\Gamma) - \varepsilon^{1-\alpha}\kappa\}\mathbf{N} & \text{on } \Gamma(t), \\ \\ \varepsilon^{2\alpha} v_t^{\pm} = \Delta_{\mathbf{y}} v^{\pm} + \varepsilon^{2\alpha} g(h^{\pm}(v^{\pm}), v^{\pm}) & \text{in } \hat{\Omega}^{\pm}(t), \end{cases}$$

where $\Gamma(t)$ stands for the limiting configuration of the interface, κ denotes the mean curvature of $\Gamma(t)$, $\mathbf{N}$ is the unit normal vector at Γ pointing from $\hat{\Omega}^+$ to $\hat{\Omega}^-$, $W(\cdot)$ is the travelling velocity of the first equation of (1.1) with $\varepsilon = 1$ for a fixed v and is typically a monotone decreasing function of v, the domain $\hat{\Omega}$ is divided into two parts $\bar{\Omega}^{\pm}(t)$ by $\Gamma(t)$ where $u = h^{\pm}(v)$ on each subdomain, respectively, and v is matched in C^1-sense at $\Gamma(t)$. In view of the second equation of (4.3), $v^{\pm}$ may be expanded as

$$v^{\pm} = v_0^{\pm}(\mathbf{y}, t) + \varepsilon^{2\alpha} v_1^{\pm}(\mathbf{y}, t) + O(\varepsilon^{4\alpha}). \tag{4.4}$$

Substituting (4.4) into (4.3) and equating like powers of ε, we easily see that $v_0^{\pm} \equiv v^*$, where v^* is the equal area level of $f(u, v)$ (see (A.3)) with $W(v^*) = 0$. Expanding $W(v|_\Gamma)$ into the Taylor series, the principal part of the next order of (4.3) becomes

$$\begin{cases} \varepsilon^{-(1-\alpha)} \Gamma_t = \{\varepsilon^{2\alpha} W'(v^*) v_1|_\Gamma - \varepsilon^{1-\alpha} \kappa\} \mathbf{N} & \text{on } \Gamma(t), \\ 0 = \Delta_{\mathbf{y}} v_1^{\pm} + g(h^{\pm}(v^*), v^*) & \text{in } \hat{\Omega}^{\pm}(t). \end{cases} \tag{4.5}$$

The first term of the right-hand side of (4.5) is the bulk force and the second one is the mean-curvature effect. In order to make these two terms comparable, namely, in order that the bulk force is balanced with the curvature effect, the exponent α must be taken as $\alpha = \frac{1}{3}$. Suppose $\alpha \neq \frac{1}{3}$. Then either the bulk force or the curvature effect becomes dominant as $\varepsilon \downarrow 0$; hence there is no chance to have nontrivial stationary patterns of finite size in such an ε^{α}-rescaled domain. Employing this exponent $\alpha = \frac{1}{3}$ and introducing a new time scale $\tau \equiv \varepsilon^{4/3} t$, the rescaled interfacial dynamics is given by

$$\begin{cases} \Gamma_\tau = \{W'(v^*) v_1|_\Gamma - \kappa\} \mathbf{N} & \text{on } \Gamma(t), \\ 0 = \Delta_{\mathbf{y}} v_1^{\pm} + g(h^{\pm}(v^*), v^*) & \text{in } \bar{\Omega}^{\pm}(t). \end{cases} \tag{4.6}$$

Suppose $\tilde{\Omega}_\varepsilon$ is the unit cell of a periodic structure such as hexagonal lattice and that $\tilde{\Omega}_\varepsilon / \varepsilon^{1/3}$ has a definite limit $\hat{\Omega}$ as $\varepsilon \downarrow 0$; then the stationary problem of (4.6)

$$\begin{cases} 0 = \{W'(v^*) v_1|_\Gamma - \kappa\} \mathbf{N} & \text{on } \Gamma, \\ 0 = \Delta_{\mathbf{y}} v_1^{\pm} + g(h^{\pm}(v^*), v^*) & \text{in } \hat{\Omega}^{\pm}, \\ v_1^{\pm} \quad \text{are matched in} \quad C^1 \text{ -sense at} \quad \Gamma \end{cases} \tag{4.7}$$

is expected to give a stable morphology of the unit cell. We call (4.7) the *morphology equations* of (1.1). Note that (4.7) is exactly the same as (2.19) in [6] where Suzuki used the matched asymptotic method to obtain it. However very little is known about the existence problem for (4.7) as well as their geometric profiles.

There is another observation due to [4] for a related system to (1.1) from a different point of view, that claims that the global minimizer of the following functional must oscillate rapidly with frequency being proportional to $\varepsilon^{1/3}$. The functional is given by

$$\int_\Omega \left\{ \varepsilon |\nabla u|^2 + \frac{1}{\varepsilon} W(u) + \frac{1}{\varepsilon} |(-\Delta + \gamma I)^{-1/2} u|^2 \right\} dx, \tag{4.8}$$

where $W(u)$ is a double-well potential like $u^4/4-u^2/2$. This is related to our problem in the following sense. Suppose the relaxation time of v is much shorter than u (i.e., the quasi-static assumption for v is valid); then (1.1) can be replaced by

$$\text{(4.9)}\qquad \begin{cases} u_t = \varepsilon\Delta u + \dfrac{1}{\varepsilon} f_0(u) - \dfrac{1}{\varepsilon} v & \\ & (x,t) \in \Omega \times (0,\infty), \\ 0 = D\Delta v + u - \gamma v & \\ & \\ \dfrac{\partial u}{\partial n} = 0 = \dfrac{\partial v}{\partial n} & (x,t) \in \partial\Omega \times (0,\infty), \end{cases}$$

where $f_0(u) = u - u^3$. Solving the second equation with respect to v and substituting it to the first equation, we have a scalar equation for u with nonlocal term

$$u_t = \varepsilon\Delta u + \frac{1}{\varepsilon} f_0(u) - \frac{1}{\varepsilon}(-\Delta + \gamma I)^{-1} u,$$

which is the L^2-gradient equation of the functional (4.8). Suppose that $\Omega = Q = (0,1)^N$ (N-dimensional cube) with periodic boundary conditions. We see by employing the arguments of [4] that the global minimizer u_ε of (4.8) has to satisfy the following inequality:

$$\text{(4.10)}\qquad C_1\varepsilon^{-1/3} \le \frac{\displaystyle\int_Q |\nabla H(u_\varepsilon)| dx}{\displaystyle\int_Q |u_\varepsilon| dx} \le C_2\varepsilon^{-1/3},$$

where $H(z) = \int_0^z W^{1/2}(s)ds$ and C_1,C_2 are positive constants independent of ε. Roughly speaking, the middle term of (4.10) counts the number of interface, and hence, (4.10) means that the global minimizer has to take a fine structure, although we do not know whether u_ε is spatially periodic or not. Finally, it should be noted that the estimate (4.10) is valid only for the global minimizer and not for the local minimizers.

ON MOTHER BODIES OF CONVEX POLYHEDRA*

BJÖRN GUSTAFSSON†

Abstract. If Ω is a bounded domain in $\mathbb{R}^N$ provided with a mass distribution ρ_Ω (e.g., Lebesgue measure restricted to Ω), another mass distribution μ sitting in Ω and producing the same external Newtonian potential as ρ_Ω is sometimes called a mother body of Ω, provided it is maximally concentrated in some sense. We first discuss the meaning of this and formulate five desirable properties ("axioms") of mother bodies. Then we show that convex polyhedra do have unique mother bodies in that sense made precise in the case that ρ_Ω is either Lebesgue measure on Ω, hypersurface measure on $\partial\Omega$, or any mixture of these two.

Key words. convex polyhedron, ridge, mother body, skeleton, balayage

1. Introduction.

A mother body (or maternal or materic body) in the terminology of the Bulgarian school of geophysics [Zi], [Ko1], [Ko2] is a more concentrated mass distribution sitting in a given body and producing the same external gravitational field as the latter. For example, one good mother body for a ball with constant mass density is a point mass (of appropriate strength) at the center of the ball. The meaning of a mother body being "more concentrated" is quite vague and there is no general agreement of its exact meaning.

Mother bodies are an important computational tool in geophysics (see, e.g., [Zi], [Ko2]). For solid polyhedra with constant mass density there are natural candidates of mother bodies with support on systems of hyperplanes reaching the boundary of the polyhedron at edges and corners. There is a beautiful example of D. Zidarov [Zi, Sect. III.6] (see also section 4 in the present paper) showing that mother bodies of this sort are not unique in general. One purpose of the present paper is to show that for *convex* polyhedra we do have uniqueness. (Zidarov's counterexample is a square in two dimensions with a smaller square at one corner cut away; hence, it is nonconvex.) The same result holds if, instead of constant volume density, the mass of the polyhedron is sitting on its boundary and has constant density there with respect to surface measure and even for any mixture of these two measures.

This paper however starts with a long discussion of what one should reasonably require of a mother body. This results in five "axioms" ((1)–(5) below), which we feel are fairly well motivated. In practice it is usually not possible to satisfy them all, but they could at least be looked upon as guide lines. The formulation of such a system of axioms is a secondary purpose of this paper.

SOME GENERAL NOTATION. If $A \subset \mathbb{R}^N$ we set
$A^c = \mathbb{R}^N \backslash A$,
$A^e = \mathbb{R}^N \backslash \bar{A}$ ($\bar{A}$ = closure of A),
int A = the interior of A,
$B(x,r) = \{y \in \mathbb{R}^N : |y-x| < r\}$,
$\mathcal{L}^N = N$-dimensional Lebesgue measure,

$\mathcal{H}^{N-1}$ = $(N-1)$-dimensional Hausdorff measure,
$\mathcal{L}^N \lfloor \Omega$, $\mathcal{H}^{N-1} \lfloor \partial\Omega$: the above measures restricted to Ω and $\partial\Omega$, respectively,
supp μ = the closed support of a distribution μ.
$E(x) = \begin{cases} -c_2 \log|x| & (N=2), \\ c_N |x|^{2-N} & (N \geq 3) \end{cases}$
is the Newtonian kernel so that $-\Delta E = \delta$, the Dirac measure at the origin.
$U^\mu = E * \mu$ = the Newtonian potential of μ, if μ is a distribution with compact support in $\mathbb{R}^N$. Thus $-\Delta U^\mu = \mu$.

2. Discussion of mother bodies. By a "body" we shall mean a bounded domain $\Omega \subset \mathbb{R}^N$ satisfying $\Omega = \operatorname{int}(\overline{\Omega})$, $\mathcal{H}^{N-1}(\partial\Omega) < \infty$, and provided with an associated mass distribution $\rho = \rho_\Omega$. Primarily we think of the mass distribution with density one in the domain and density zero outside; i.e., $\rho = \mathcal{L}^N \lfloor \Omega$. However, the results in this paper work equally well for the case of hypersurface measure on the boundary, i.e., $\rho = \mathcal{H}^{N-1} \lfloor \partial\Omega$, or for any mixture of these two.

Thus given any two constants $a, b \geq 0$ with $a + b > 0$ we associate with any Ω as above the mass distribution

$$\rho_\Omega = a\mathcal{H}^{N-1} \lfloor \partial\Omega + b\mathcal{L}^N \lfloor \Omega.$$

Then ρ_Ω is a positive Radon measure, and we denote by U^Ω its Newtonian potential

$$U^\Omega = U^{\rho_\Omega} = E * \rho_\Omega$$

(a and b will be kept fixed throughout the discussion).

Given a body $\Omega \subset \mathbb{R}^N$, a mother body for it should be a signed measure μ having certain properties. The basic requirement is that

$$U^\mu = U^\Omega \qquad \text{in } \Omega^e. \tag{1}$$

Clearly this implies that supp $\mu \subset \bar{\Omega}$.

One possible additional requirement is that

$$U^\mu \geq U^\Omega \qquad \text{in all } \mathbb{R}^N. \tag{2}$$

Such a condition is natural if one wishes to think of ρ_Ω as being the result of applying some kind of (partial) balayage process to μ (cf. [Zi], [Sa1], [Ko1], [Ko2], [Gu-Sa1], [Gu-Sg], [Gu2]). Indeed, any balayage (or "sweeping") process we know of can be thought of as being composed of elementary steps in which point masses are swept to measures of the kind ρ_B for balls B centered at the support of the point masses, and for each such elementary step the potential of the measure decreases.

Thus in order to have a μ which is as "primitive" as possible with respect to balayage one should ask U^μ to be as large as possible. For this to be sensible one has to have a lower bound on μ because otherwise one can always increase a given U^μ. For example, as is natural, one may ask μ to be positive:

$$\mu \geq 0. \tag{3}$$

Since $\mu = \rho_\Omega$ itself satisfies (1)–(3) and the supremum of any increasing sequence of superharmonic functions is superharmonic (or $\equiv +\infty$), it follows that for any given Ω there exist (plenty of) measures μ satisfying (1)–(3) with U^μ maximal among potentials of such measures. A mother body for Ω should be one of these (cf. Proposition 2.1 at the end of this section).

In order for μ to be a good mother body it should be concentrated or minimal in some sense, such as having small support sitting deeply inside Ω. Although this is to some degree implicit in the desire that U^μ should be as large as possible, we also want to formulate such conditions in direct geometric terms. One way to be concentrated is simply to be singular with respect to Lebesgue measure. We shall find the slightly stronger requirement

$$\mathcal{L}^N(\text{supp } \mu) = 0 \tag{4}$$

convenient to work with.

It is easy to see, however, that (4) does not guarantee a good mother body. For any Ω there are an abundance of measures μ satisfying all of (1)–(4). It is just to fill Ω with (infinitely many) disjoint balls so that the remaining set has measure zero, and then replace the volume part of ρ_Ω by the sum of the appropriate point masses sitting in the centers of these balls. In other words, one writes $\Omega = \bigcup_{j=1}^\infty B(x_j, r_j) \cup (\text{null set})$, where the $B(x_j, r_j)$ are disjoint, and then takes $\mu = a\mathcal{H}^{N-1}\lfloor\partial\Omega + b\sum_{j=1}^\infty \mathcal{L}^N(B(x_j, r_j))\delta_{x_j}$, δ_x denoting the unit point mass at $x \in \mathbb{R}^N$.

One way in which a mother body μ constructed as above, by ball-packing, is not good is that supp μ typically (even if $a = 0$) contains all of $\partial\Omega$, and therefore cuts off the exterior of Ω from the interior. This must necessarily be so in general because when supp μ does not reach $\partial\Omega$ then (1) gives a harmonic continuation of U^Ω across $\partial\Omega$ into Ω, which is not possible unless $\partial\Omega$ is real analytic (roughly speaking). Nevertheless, whenever possible we desire something like the following to hold.

$$\text{Each component of } \mathbb{R}^N\backslash\text{supp } \mu \text{ intersects } \Omega^e. \tag{5}$$

This simply means that for each $x \in \Omega\backslash\text{supp } \mu$ there is a curve in $\mathbb{R}^N\backslash\text{supp } \mu$ joining x with some point in Ω^e.

The requirements (1)–(5) are the "axioms" for a mother body which we propose. As indicated earlier there is neither existence nor uniqueness of mother bodies satisfying (1)–(5) in general (Zidarov's counterexample fulfills all of (1)–(5)). Indeed, the problem of finding a mother body of a given body exhibits all features of an ill-posed problem: existence and uniqueness of solutions only under special conditions and sensitive dependence on given data when solutions do exist. Nevertheless, for certain particular classes of bodies, e.g., various kinds of polyhedra (see sections 3 and 4 below and [Gu-Sa2]) and certain types of algebraic domains [Sav-St-Sv], there are constructive algorithms for computing (candidates of) mother bodies.

For the rest of this section, we discuss in more detail the roles of the axioms (1)–(5) and various ways of relaxing or strengthening them. The axioms naturally fall into three groups: (1); (2) and (3); (4) and (5).

Axiom (1) is the most indispensable one. In the case that Ω^e has more than one component, a possible way to relax it is to require only

$$\nabla U^\mu = \nabla U^\Omega \text{ in } \Omega^e$$

(equality of the corresponding fields), which is actually more physical. An even weaker requirement is to ask (1) to hold only in the unbounded component of Ω^e.

The role of the conditions (2) and (partly) (3) is to guarantee that ρ_Ω is the result of a natural balayage operator applied to μ. When $a = 0$, $b > 0$, such an operator $\mu \mapsto \text{Bal}(\mu; b)$ can be defined by declaring that $\text{Bal}(\mu; b)$ shall be the measure which is closest to μ in the energy norm among all measures ν which satisfy $\nu \le b\mathcal{L}^N$. This

makes plain sense and defines $\mathrm{Bal}(\mu; b)$ uniquely whenever $\mu \geq 0$ has finite energy. The definition can then easily be extended to the case of infinite energy. One can show that if Ω is a body, then $\mathrm{Bal}(\mu; b) = \rho_\Omega$ holds if and only if both (1) and (2) are satisfied. In particular, it is possible to reconstruct Ω from μ when (1) and (2) hold, and both conditions are really necessary for this (there are examples of two different Ω satisfying (1), (3)–(5) for the same μ).

Thus the perhaps abstract-looking condition (2) plays a significant role in the context of balayage. It is probably more important than (3) because it is possible, to a certain extent, to allow nonpositive measures μ in $\mathrm{Bal}(\mu; b)$. We refer to [Sa1], [Gu-Sa1], [Gu2] for details on the above balayage operators.

For a general measure μ, $\mathrm{Bal}(\mu; b)$ will not necessarily be of the form ρ_Ω for some open set Ω, but if μ satisfies (3) and (4), it will. This allows for doing "continuous balayage," as follows. Suppose (1)–(4) hold for the pair (Ω, μ), and define for any $t \in \mathbb{R}$ the open set $\Omega(t)$ by $\mathrm{Bal}(e^t\mu; b) = \rho_{\Omega(t)}$. (This defines $\Omega(t)$ only up to a null set, but one naturally takes the largest possible $\Omega(t)$.) Then $\Omega(s) \subset \Omega(t)$ for $s < t$, $\Omega(0) = \Omega$, and $\Omega(t)$ shrinks down to $\mathrm{supp}\, \mu$ as $t \to -\infty$. Moreover, the pair $(\Omega(t), e^t\mu)$ satisfies (1)–(4) for each $t \in \mathbb{R}^N$.

One important point with this family $\Omega(t)$ is that its evolution can be described without reference to μ. Indeed, under some smoothness assumptions the evolution can be described by a nonlocal, but μ-independent, differential equation for the motion of $\partial\Omega(t)$: the normal velocity of the boundary $\partial\Omega(t)$ at any particular point is to be equal to the normal derivative at that point of the function $p = p_{\Omega(t)}$ which solves the Dirichlet problem $\Delta p = 1$ in $\Omega(t)$, $p = 0$ on $\partial\Omega(t)$. This is a Hele–Shaw type moving boundary problem, and by solving it (backwards) for $-\infty < t \leq 0$ with $\Omega(0) = \Omega$ as initial domain one should, in principle, get a canonical candidate of a mother body, namely by taking $\mu = \lim_{t\to-\infty} e^{-t}\rho_{\Omega(t)}$. Unfortunately, however, this moving boundary problem is badly ill-posed and existence of global solutions is not to be expected in general. Local in time solutions exist if, and basically only if, the initial domain has a real analytic boundary (see, e.g., [Re-Wo], [Ti]).

It is possible to introduce balayage operators as above and to do continuous balayage also when $a > 0$, but everything is more complicated in that case: the balayage operators are less well behaved and the evolution families are less continuous (cf. [He], [Gu-Sg]). It is not even true that μ determines Ω uniquely via (1)–(5) [He, Prop. 6.2]. Axiom (2) does not quite suffice for this, as it does in the case $a = 0$, and should therefore ideally be replaced by something stronger.

Returning now to the general case $(a, b \geq 0)$, another advantage with conditions (2), (3) is that they guarantee a certain coupling between the geometry of Ω and of $\mathrm{supp}\, \mu$. One may therefore prove [Gu-Sa1], [Sg], [Gu-Sg] that for any Ω and any point $x \in \partial\Omega$, the inward normal ray of $\partial\Omega$ at x intersects the closed convex hull of the support of any μ satisfying (1)–(3). Without (2), (3) there will be no geometric coupling whatsoever between Ω and $\mathrm{supp}\, \mu$. For any domain D and any (small) ball $B \subset D$ one can find a domain Ω approximating D arbitrarily well and a signed measure μ with $\mathrm{supp}\, \mu \subset B$ such that (1), (4), (5) hold for Ω, μ. See [Gu1], [Sa2] for the case $a = 0$.

From what has been said above it should be clear that conditions (2) and (3) have strong potential theoretic significance. There are however other points of view for which they seem less urgent. In certain complex variable and PDE approaches, see, e.g., [Eb], [Kh-Sh], [Sh], [St-Sv], one considers the search for mother bodies mainly as a problem of analytic continuation (of U^Ω), and one is happy if one can find

a distribution (or even analytic functional) μ which satisfies (1) and some (usually stronger) form of (4), (5). If supp μ is then sufficiently small there will simply be no other good candidate for a mother body.

Also for questions of uniqueness of mother bodies conditions (2) and (3) appear often to be dispensable.

The last group of axioms, (4) and (5), are requirements only on the set supp μ. They imply that supp μ is minimal as a set (see Proposition 2.1 below), and they are necessary to guarantee any reasonable degree of uniqueness of mother bodies, e.g., to exclude occurrence of continuous families of them. A sharper form of (5), which together with (1) and (4) definitely guarantees uniqueness (see Proposition 2.1), is

(6) supp μ does not disconnect any open set

(i.e., $D \setminus \text{supp } \mu$ is connected whenever D is an open connected set). Clearly (6) implies (5). However, with requirement (6) in place of (5), mother bodies will exist more rarely (polyhedra will not admit mother bodies, for example). On the other hand, in cases when one allows distributional mother bodies (5) becomes too weak to even exclude continuous families of mother bodies and therefore has to be replaced by something stronger, like (6).

The strongest reasonable requirement in the direction of (4), (5), (6) is to require supp μ to consist of only finitely many points. This is what one (classically) requires of a "quadrature domain," namely that there exists a measure or distribution μ with finite support and satisfying some form of (1). The word quadrature domain is however also used in wider senses. See [Sh] for an overview.

In two dimensions, quadrature domains in the above (classical) sense can be produced as conformal images of the unit disc under rational mapping functions. (This is for the case $a = 0$, to which we stick for a moment.) Taking for example $\Omega = f(B(0,1))$, where $f(z) = z + c_2 z^2 + \cdots + c_n z^n$ is a univalent polynomial of degree $n \geq 2$ ($z = x_1 + ix_2$), (1) will hold with μ a distribution of order $n-1$ supported at the origin. Clearly also (4)–(6) will hold then, but (2) and (3) will fail. By an argument similar to the proof of Proposition 2.1 (iii), one realizes that there cannot simultaneously exist measures satisfying (1), (4), and (5).

Thus such a simple and smooth domain as the conformal image of the unit disc under a quadratic (or higher degree) polynomial does not admit a mother body in our sense. This is of course disappointing, but one has to keep in mind that the problem of finding a mother body is ill-posed and that the requirements (1)–(5) taken all together combine several different aspects of it (balayage, analytic continuation, minimality, etc.).

Indeed, as the following proposition shows, our axioms for a mother body seem to be fairly complete in the sense that they contain or imply many of the criteria for concentration and minimality which have been used previously for similar purposes. Examples of such criteria are minimality of supp μ as a set, largeness of U^μ (e.g., Kounchev [Ko2] maximizes integrallike $\int_\Omega U^\mu dx$ among all μ satisfying (1), (3)), and μ being an extremal point in a suitable convex set [An1],[An2], [Ka-Pi]. Proposition 2.1 shows (in particular) that if (1), (3), (4), (5) hold for a measure μ then, within the class of measures satisfying (1) and (3), supp μ is minimal, U^μ is maximal, and μ is an extremal point.

PROPOSITION 2.1. *Let μ be a measure satisfying* (1), (4), (5) *with respect to a given body Ω, and let ν, μ_1, μ_2 be (possibly) other measures.*

(i) *If ν satisfies* (1) *and supp $\nu \subset$ supp μ, then $\nu = \mu$.*

(ii) *If ν satisfies* (1), (3) *and $U^\nu \geq U^\mu$ in all $\mathbb{R}^N$, then $\nu = \mu$.*

(iii) *If ν satisfies* (1), (4), (6), *then $\nu = \mu$.*

(iv) *If μ_1, μ_2 satisfy* (1), (3) *and $\mu = \frac{1}{2}(\mu_1 + \mu_2)$, then $\mu_1 = \mu_2 = \mu$.*

Proof. We first consider statements (i)–(iii). Since $U^\nu, U^\mu \in L^1_{loc}(\mathbb{R}^N)$ it is enough to prove that $U^\nu = U^\mu$ holds almost everywhere (a.e.), or by (4) a.e. in $\mathbb{R}^N \backslash \text{supp } \mu$. So let D be a component of $\mathbb{R}^N \backslash \text{supp } \mu$, set $u = U^\nu - U^\mu$, and we shall prove that $u = 0$ a.e. in D. Note that D meets Ω^e by (5) and that $u = 0$ in $D \cap \Omega^e$.

In case (i) u is harmonic in D; hence, it follows by harmonic continuation that $u = 0$ in all D. In case (ii) u is superharmonic and nonnegative in D; hence, it is either strictly positive in all D or vanishes identically in D. But the first alternative has already been excluded, and we again get $u = 0$ in D. In case (iii) u is harmonic in $D \backslash \text{supp } \nu$. Using (6) it follows that $u = 0$ in $D \backslash \text{supp } \nu$, hence, a.e. in D.

Proof of (iv): Since $\mu_1, \mu_2 \geq 0$ we have supp $\frac{1}{2}(\mu_1 + \mu_2) =$ supp $\mu_1 \cup$ supp μ_2. Thus supp $\mu_j \subset$ supp μ, and the conclusion follows immediately from (i). ∎

Note. If, in (i)–(iii) of the proposition, one allows μ and ν to be general distributions (instead of measures), then one still gets the conclusion that $U^\nu = U^\mu$ outside a compact set K of measure zero ($K =$ supp μ in cases (i) and (ii), $K =$ supp $\mu \cup$ supp ν in case (iii)). This means that $\mu - \nu$ annihilates all functions which are harmonic in some neighborhood of K, which is about as close to the conclusion $\nu = \mu$ as one may come in the case of distributions. Note that there are distributions with support at a single point, e.g., the Laplacian of the Dirac measure, whose potential vanishes identically outside that point.

3. Mother bodies for convex polyhedra. Having formulated precise requirements for mother bodies ((1)–(5) above) one naturally wonders which bodies admit mother bodies in that precise sense and when they are unique. This is a question which is largely open, but in this section we at least start answering it by proving that convex polyhedra always have unique mother bodies.

THEOREM 3.1. *Let $\Omega \subset \mathbb{R}^N$ be a convex bounded open polyhedron provided with a mass distribution ρ_Ω as in section* 2. *Then there exists a measure μ satisfying* (1)–(5). *Its support is contained in a finite union of hyperplanes and reaches $\partial\Omega$ only at corners and edges (not at faces), it has no mass on $\partial\Omega$, and U^μ is a Lipschitz continuous function. Moreover, μ is unique among all signed measures satisfying* (1), (4), (5).

Note. The support of μ coincides with what is sometimes called the "ridge" of Ω [Ev-Ha], [Ja]. For convex polyhedra this is the set of points in Ω which have at least two closest neighbors on $\partial\Omega$. See Figure 1 for an example in two dimensions.

Proof. Write $\Omega = \bigcap_{j=1}^m H_j$, where H_j are open half spaces and m is minimal. For any j, set

$$\delta_j(x) = \text{dist}\left(x, H_j^c\right),$$
$$u_j(x) = a\delta_j(x) + \frac{b}{2}\,\delta_j(x)^2.$$

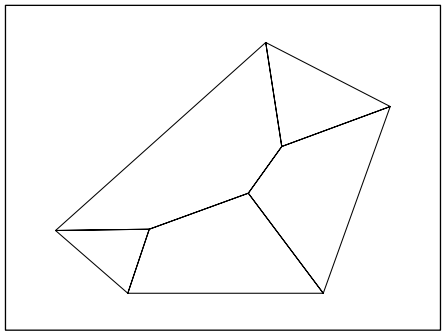

FIG. 1. *The mother body of a convex polyhedron.*

Then $u_j > 0$ in H_j, $u_j = 0$ on H_j^c, and $\Delta u_j = a\mathcal{H}^{N-1}\lfloor\partial H_j + b\mathcal{L}^N\lfloor H_j$. Set also

$$\begin{aligned}
\delta(x) &= \operatorname{dist}(x, \Omega^c) \\
&= \inf\{\delta_1(x), \dots, \delta_m(x)\}, \\
u(x) &= a\delta(x) + \frac{b}{2}\,\delta(x)^2 \\
&= \inf\{u_1(x), \dots, u_m(x)\}, \\
R &= \{x \in \Omega : \delta(x) = \delta_j(x) \text{ for at least two different } j\}, \\
D_j &= \{x \in \Omega \backslash R : \delta(x) = \delta_j(x)\} \\
&= \{x \in \Omega : \delta_j(x) < \delta_k(x) \text{ for all } k \neq j\}.
\end{aligned}$$

Note that u and u_j are strictly monotone functions of δ and δ_j, respectively (on the range $[0, +\infty)$).

We note that R (the "ridge") is contained in a finite union of hyperplanes, $\Omega = R \cup D_1 \cup \cdots \cup D_m$, u is Lipschitz continuous, $u > 0$ in Ω, $u = 0$ on Ω^c. Within Ω we have $\Delta u_j = b$ for all j, hence, $\Delta u \le b$ in Ω, using the principle that the infimum of a finite family of superharmonic functions (e.g., $u_j(x) - (b/2N)|x|^2$) is superharmonic. The same principle actually gives that $\Delta u \le b + \sum_{j=1}^m a\mathcal{H}^{N-1}\lfloor\partial H_j$ in all $\mathbb{R}^N$ and hence (since $u = 0$ on Ω^c) that $\Delta u \le b\mathcal{L}^N\lfloor\Omega + a\mathcal{H}^N\lfloor\partial\Omega = \rho_\Omega$. Outside $\overline{R}$ we have equality in this formula, as is easily seen. Thus $\Delta u = \rho_\Omega - \mu$ where μ is a positive measure with $\operatorname{supp}\mu \subset \overline{R}$. Since u vanishes at infinity and $\Delta u = \Delta\left(U^\mu - U^\Omega\right)$ we have $u = U^\mu - U^\Omega$. It now follows that μ satisfies (1)–(4) and that U^μ is Lipschitz continuous.

The latter property implies that μ is absolutely continuous with respect to $\mathcal{H}^{N-1}$. Since $\mathcal{H}^{N-1}\left(\overline{R} \cap \partial\Omega\right) = 0$ it follows that $\mu(\partial\Omega) = 0$.

To see finally that μ satisfies (5), take any $x \in \Omega$ and let $y \in \partial\Omega$ be a closest point on the boundary. Then $y \in \partial H_j$ for a unique j, and it is easy to see that the whole segment (x, y) is in D_j and that $y \notin \bar{R}$. Thus, if $x \notin \operatorname{supp}\mu$, the closed segment $[x, y + \varepsilon(y - x)]$ $(\varepsilon > 0)$ connects x with Ω^e without meeting $\operatorname{supp}\mu$, proving (5).

It remains to prove the uniqueness part of the theorem. Let μ, u, and u_j be as above, and let ν be any signed measure satisfying (1), (4), (5) (when stated for ν). Set $v = U^\nu - U^\Omega$. Then $v = 0 = u_j$ in H_j^e and $\Delta(v - u_j) = 0$ in $\operatorname{int}(H_j^c \cup \Omega) \setminus \operatorname{supp}\nu$. Set

$$\omega_j = \text{ the unbounded component of } \operatorname{int}(H_j^c \cup \Omega) \setminus \operatorname{supp}\nu.$$

It follows that

$$v = u_j \qquad \text{in} \qquad \omega_j \tag{7}$$

and also, since ω_j is open, that

$$\nabla v = \nabla u_j \qquad \text{in} \qquad \omega_j. \tag{8}$$

Assumption (5) for ν implies that

$$\omega_1 \cup \cdots \cup \omega_m = \mathbb{R}^N \setminus \operatorname{supp} \nu.$$

Since $\mathcal{L}^N(\operatorname{supp} \nu) = 0$ by (4) it follows that $\bigcup_{j=1}^m \omega_j$ is an open subset of $\mathbb{R}^N$ satisfying

$$\mathcal{L}^N \left(\mathbb{R}^N \setminus \bigcup_{j=1}^m \omega_j \right) = 0, \tag{9}$$

$$\bigcup_{j=1}^m \bar{\omega}_j = \mathbb{R}^N. \tag{10}$$

By (7), (8) v is continuously differentiable in $\bigcup_{j=1}^m \omega_j$ with

$$|\nabla v(x)| \le C < \infty \qquad \left(x \in \bigcup_{j=1}^m \omega_j \right). \tag{11}$$

Next we claim that the distributional gradient of v is a locally integrable function. To see this, note that $v = U^\nu - U^\Omega = E * (\nu - \rho_\Omega)$; hence,

$$\nabla v = (\nabla E) * (\nu - \rho_\Omega). \tag{12}$$

Here everything is to be interpreted in the sense of distributions. Now, ∇E is a locally integrable (vector) function and $\nu - \rho_\Omega$ is a signed Radon measure with compact support. It then follows (cf. [Do, Sect. 26]) from (12) that ∇v is also a locally integrable (vector) function.

Combining this information with (9), (11) we conclude that the distributional gradient ∇v is in $L^\infty\left(\mathbb{R}^N\right)$ and hence that v is a Lipschitz continuous function (i.e., has such a representative).

By continuity, for the Lipschitz continuous version of v, the relation (7) on ω_j extends to hold on all $\bar{\omega}_j$. Thus it follows from (10) that for each $x \in \mathbb{R}^N$ we have $v(x) = u_j(x)$ for some j.

Now let $x \in D_j$, and let y be the closest point on ∂H_j. Then $u_j(\xi) < u_k(\xi)$ for every $\xi \in [x, y]$ and for every $k \neq j$. On H_j^e, $v = u_j = 0$, so by continuity $v(y) = u_j(y)$. Since v is continuous and coincides everywhere with some u_k it follows that $v(\xi) = u_j(\xi)$ for all $\xi \in [x, y]$, in particular $v(x) = u_j(x)$. Thus $v = u_j = u$ in D_j. Since j was arbitrary we conclude that $v = u$ and $\nu = \mu$, completing the proof of the theorem. □

Example. Let Ω be a regular polygon in $\mathbb{R}^2$, say centered at the origin and with $n \ge 3$ corners uniformly distributed on the unit circle. Clearly Ω is convex. Let us compute its mother body μ.

The support of μ, i.e., the ridge R of Ω, consists of the n radii from the origin to the corners of Ω. The density of μ with respect to arclength on R equals the jump of the normal derivative of U^μ across R, or, what is the same, the jump of the normal derivative of $u = U^\mu - U^\Omega$. Since, in the notations of the proof above, $\nabla u = (a+b\delta)\nabla\delta$ and $\nabla\delta$ is a constant unit vector in each component of $\Omega\setminus R$, it follows that the density of μ is proportional to $a + b(1-r)$ on R, where $r = |x|$. Indeed, evaluation of the constant of proportionality gives that

$$d\mu = \frac{2\pi}{n}(a + b(1-r))dr \quad \text{on } R. \tag{13}$$

As n increases, Ω approaches the unit disc $B(0,1)$. One might hope then that μ should approach the unique mother body of the disc, namely $2\pi(a+\frac{b}{2})$ times the Dirac measure at the origin. However, one sees from (13) that, as $n \to \infty$, the μ converge towards that measure on $B(0,1)$ which has density $\frac{a}{r} + b(\frac{1}{r} - 1)$ with respect to area measure. This certainly is more concentrated than the original mass distribution $\rho_{B(0,1)}$, but less concentrated than the Dirac measure. In particular, the mother bodies of the regular polyhedra do not converge towards the mother body of the limiting disc.

This failure of convergence should not be surprising since, as was discussed in section 2, the search for mother bodies is an ill-posed problem with no continuous dependence on initial data, even when unique solutions do exist. The mother bodies for the approximating polyhedra may actually be more useful and more realistic in practical problems than the mother body for the disc itself. Consider, e.g., the case $a = 0$, $b = 1$ and think of the ill-posed Hele–Shaw model briefly discussed in section 2. In experiments with Hele–Shaw flows one never sees an initially circular blob shrinking down to a point. The predominant phenomenon always is that shrinking occurs by development of fingers of the exterior domain penetrating into the fluid (see, e.g., [Ho]). What eventually remains of the fluid domain is not a pointlike blob, but rather a kind of skeleton, which is somewhat reminiscent of the mother body of the approximating polygon Ω for a suitable n.

Thus there is a possibility that mother bodies of polyhedra could be a useful tool for handling ill-posed Hele–Shaw problems: one approximates a given initial fluid domain by a polygon, computes its mother body (uniquely determined and easily computed in the convex case), and then the whole evolution in time is obtained by balayage (section 2). The initial approximation with a polygon of course contains a degree of arbitrariness, but it is also known, for real Hele–Shaw flows, that the onset of the finger development contains a stochastic element.

4. General polyhedra and Zidarov's counterexample. By a (general) polyhedron we mean a domain which is the interior of a finite union of compact convex polyhedra. Mother bodies for general polyhedra will be treated in subsequent papers, e.g., [Gu-Sa2]. The situation in higher dimensions is not completely clear at present, but let us summarize what is known in the two-dimensional case.

When hypersurface measure is present in ρ_Ω, i.e., when $a > 0$, $b \geq 0$, nonconvex polyhedra do not admit mother bodies satisfying all of (1)–(5). Indeed, if Ω is a nonconvex polyhedron in $\mathbb{R}^2$, then Ω must have a nonconvex corner and it is well known that classical balayage of any positive measure μ in Ω onto $\partial\Omega$ will then be a measure on $\partial\Omega$ whose density with respect to $\mathcal{H}^1$ tends to infinity at the corner. When $b = 0$, requirement (1) means that ρ_Ω will have to coincide with this balayage measure; hence, a mother body μ cannot exist in this case. This argument extends

to the case $a > 0$, $b > 0$.

On the other hand, extending previous work of G. Choquet and I. Deny [Ch-De] concerning regular polyhedra, D. Siegel [Si] has constructed, in the pure hypersurface case ($a > 0$, $b = 0$), mother bodies (or skeletons, as he calls them) for general polyhedra which satisfy (1)–(2), (4)–(5). The construction actually works for general a, $b \geq 0$. Moreover the construction is canonical (involves no choices) and the shape of the mother body reflects that of the original body. Hence we feel that it is a satisfactory mother body, although the positivity requirement (3) is violated in the nonconvex case.

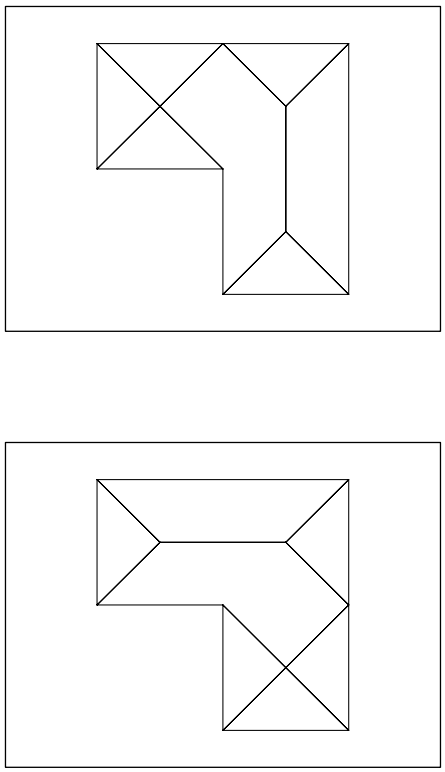

FIG. 2. *Two mother bodies for a nonconvex polyhedron in the case* $a = 0$ *(Zidarov's example).*

In the case of pure volume measure ($a = 0$, $b > 0$) the function $\Omega \mapsto \rho_\Omega$ is additive under disjoint unions (even after "removal of slits," i.e., after taking the interior of the closure). Therefore a possible way to construct a mother body for a polyhedron Ω is to decompose it into finitely many subpolyhedra, e.g., convex ones, each of which has a mother body satisfying (1)–(5). By adding these up one gets a measure μ which automatically satisfies (1)–(4) for Ω. Requirement (5) is more troublesome, but at least in the two-dimensional case it can be met by choosing the decomposition properly [Gu-Sa2].

In conclusion, mother bodies satisfying all of (1)–(5) do exist for arbitrary polyhedra when $N = 2$ and $a = 0$. However, as Zidarov discovered, there is no uniqueness of mother bodies for nonconvex polyhedra. Zidarov's example is a square in $\mathbb{R}^2$ with a smaller square at one corner removed, say $\Omega = (-1, 1)^2 \backslash (-1, 0]^2$. This can be de-

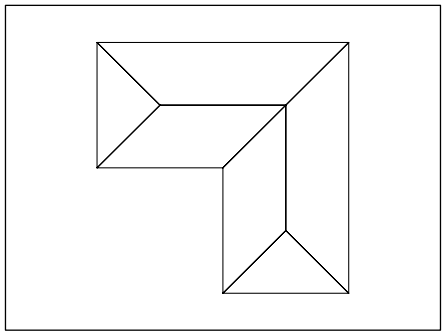

FIG. 3. *Siegel's mother body (with* (3) *violated) for the same nonconvex polyhedron* ($a, b \geq 0$).

composed into three squares (with side length one) in a natural way. Adding up the mother bodies for these, one gets a measure not satisfying (5). But, if Ω is instead decomposed into a rectangle (with side lengths one and two) and a square, the sum of the mother bodies for these will satisfy all of (1)–(5). This decomposition can be made in two different ways, and the result will be two different mother bodies.

These are depicted in Figure 2. Figure 3 shows the mother body obtained by Siegel's procedure for the same Ω. The latter does not satisfy (3), but it has other advantages, namely that supp μ meets $\partial\Omega$ only at corners not at smooth points of $\partial\Omega$, that it shares the symmetry properties of Ω, and that it is indecomposable in a certain sense.

Acknowledgments. I would like to dedicate this paper to the memory of Dimiter Zidarov, who died in 1993. His work in geophysical potential theory has for several years been one of my main sources of inspiration. I also want to thank Ognyan Kounchev and Harold S. Shapiro for many interesting discussions concerning mother bodies and Siv Sandvik for typing my manuscript.

A UNIQUENESS THEOREM FOR AN INVERSE SCATTERING PROBLEM IN AN EXTERIOR DOMAIN*

PETER HÄHNER†

Abstract. The scattering of time-harmonic acoustic waves by a simply connected, sound-soft obstacle in an inhomogeneous medium in $\mathbb{R}^2$ is considered. We prove that the Cauchy data of the scattered waves on a large circle for all incident waves and for an interval of wave numbers κ uniquely determine the obstacle and the inhomogeneity. To this end we show that products of harmonic functions satisfying a Dirichlet condition on the interior boundary of an annular plane domain are complete. Then, we use the limit $\kappa \to 0$ and obtain uniqueness of the obstacle from Schiffer's uniqueness result. Uniqueness of the inhomogeneity also follows from $\kappa \to 0$ together with the denseness result for the linear span of products of harmonic functions.

Key words. inverse obstacle scattering, inhomogeneous medium, complete set, products of harmonic functions

1. Introduction.

We consider the scattering of time-harmonic waves by a simply connected obstacle in a two-dimensional inhomogeneous medium assuming a Dirichlet boundary condition. Problems of this type occur when a three-dimensional acoustic scattering problem at an infinitely long cylinder is reduced to two dimensions by assuming that the fields and the refractive index are constant along each line parallel to the cylinder. Similarly, the scattering of time-harmonic electromagnetic waves by an infinitely long cylindrical conductor leads to this problem assuming a constant magnetic permeability, the invariance of the electric permittivity in the direction of the cylinder axis and the electric field polarized in that direction.

We suppose that on a large circle, surrounding the obstacle, the Cauchy data of the scattered fields are known for an interval of wave numbers and for all possible incident waves. Our aim is to prove that these data uniquely determine the obstacle and the inhomogeneity.

Although there are many papers dealing with similar problems in the absence of an obstacle or investigating an inverse obstacle problem in a homogeneous medium to the author's knowledge there is only one paper which examines an inverse obstacle problem in an inhomogeneous medium. However, in [7] the authors assume that the inhomogeneity in the exterior domain is known and then prove uniqueness of the obstacle with techniques used in [6].

For the full space problem, i.e., without any obstacle, in three or more dimensions, Sylvester and Uhlmann and others even obtained uniqueness of the inhomogeneity assuming only the knowledge of the Cauchy data at a fixed wave number for all incident fields (see the review of results in [10]). In two dimensions there are only partial results of this type [10, 5] and no general uniqueness result using only one fixed wave number is known. Therefore, we use an interval of wave numbers κ. This means that we use more data than expected from a count of degrees of freedom. It

*Received by the editors March 24, 1997; accepted for publication (in revised form) August 27, 1997; published electronically April 14, 1998.

†Institut für Numerische und Angewandte Mathematik, Lotzestraße 16–18, D-37083 Göttingen, Germany (haehner@math.uni-goettingen.de).

is then possible to use the limit $\kappa \to 0$ to reduce the problem to two questions about harmonic functions.

First, do the Cauchy data of a suitable harmonic function satisfying a Dirichlet boundary condition uniquely determine the obstacle? The answer attributed to Schiffer is yes and can be found in [3, Theorem 5.1] in a slightly different setting.

Second, are linear combinations of products of harmonic functions, satisfying a Dirichlet condition on the interior boundary of an annular plane domain, dense in certain function spaces? Although we use it as an auxiliary result to prove uniqueness of the inverse scattering problem we think that this question is interesting in itself. A positive answer for this question without imposing the Dirichlet boundary condition was given by Calderón in [2]. We shall give a positive answer for our case in the next section. We first assume the obstacle to be a disk and use separation of variables for the density result. For the general case we use a conformal mapping.

In the third section we state existence and uniqueness of the direct scattering problem and examine the behavior of the solutions as $\kappa \to 0$. There are some difficulties due to the fact that in $\mathbb{R}^2$ the fundamental solutions for the Helmholtz equation do not converge as $\kappa \to 0$.

Finally, in the fourth section we combine the results of the previous sections to prove the uniqueness result for the inverse scattering problem.

2. Completeness of products of harmonic functions. Let $D_0 \subset \mathbb{R}^2$ be a nonempty, open, connected, and bounded set. We assume the exterior domain $D := \mathbb{R}^2 \setminus \overline{D_0}$ to be connected and to have a C^2-smooth boundary $\partial D = \partial D_0$. For $R > 0$ we define the disk $B_R := \{x \in \mathbb{R}^2 : |x| < R\}$. In the sequel we suppose that R is sufficiently large to ensure $\overline{D_0} \subset B_R$. For a bounded domain, n denotes the normal vector at the boundary directed into the exterior of the domain.

The main result of this section is the following theorem.

THEOREM 2.1. *Let $q \in L^2(D)$ satisfy $q(x) = 0$ for all $|x| \geq R$. Furthermore, assume that*

$$\int_{D \cap B_{2R}} q(x)u(x)v(x)dx = 0 \tag{2.1}$$

for all functions u, $v \in C^2(D \cap B_{2R}) \cap C^1(\overline{D} \cap B_{2R})$ satisfying $\Delta u = 0$, $\Delta v = 0$ in $D \cap B_{2R}$, $u|_{\partial D} = v|_{\partial D} = 0$, and $\int_{\partial D} \frac{\partial u}{\partial n} ds = \int_{\partial D} \frac{\partial v}{\partial n} ds = 0$. Then $q(x) = 0$ almost everywhere in D.

We shall reduce this theorem to the special case $D = \mathbb{R}^2 \setminus \overline{B_1}$ with the help of a conformal mapping. Hence, we first examine the special case $D_0 = B_1$. Using polar coordinates $x = (x_1, x_2) = (r\cos\theta, r\sin\theta)$ for $x \in \mathbb{R}^2$ it is easily seen that the functions

$$u_l(x) = (x_1 + ix_2)^l - (x_1 - ix_2)^{-l} = (r^l - r^{-l})e^{il\theta} \ , \ l \in \mathbb{N} \ , \ x \in \mathbb{R}^2 \setminus B_1 \ ,$$

$$u_l(x) = (x_1 - ix_2)^{|l|} - (x_1 + ix_2)^{-|l|} = (r^{|l|} - r^{-|l|})e^{il\theta} \ , \ -l \in \mathbb{N} \ , \ x \in \mathbb{R}^2 \setminus B_1 \ ,$$

satisfy $\Delta u_l = 0$ in $\mathbb{R}^2 \setminus \overline{B_1}$, $u_l|_{\partial B_1} = 0$, and $\int_{\partial B_1} \frac{\partial u_l}{\partial n} ds = 0$.

Equation (2.1) reads for $u = u_l$, $v = u_m$,

$$\int_1^{2R} r \int_0^{2\pi} q(r\cos\theta, r\sin\theta)e^{i(l+m)\theta} d\theta (r^{|l|} - r^{-|l|})(r^{|m|} - r^{-|m|})dr = 0 \ .$$

For a fixed $k \in \mathbb{N}_0$ we choose $l = k + j$ and $m = -j$, $j \in \mathbb{N}$, and obtain

$$\int_1^{2R} r \int_0^{2\pi} q(r\cos\theta, r\sin\theta) e^{ik\theta} d\theta (r^{|k|+j} - r^{-(|k|+j)})(r^j - r^{-j}) dr = 0 \ , \ j \in \mathbb{N} \ . \tag{2.2}$$

Choosing $l = k - j$, $m = j$, $j \in \mathbb{N}$, in the case $-k \in \mathbb{N}$ we find that the equations (2.2) hold for all $k \in \mathbb{Z}$, $j \in \mathbb{N}$. Therefore, we first examine whether a function $f \in L^2(1, \rho)$ satisfying

$$\int_1^{\rho} f(r)(r^{k+j} - r^{-(k+j)})(r^j - r^{-j}) dr = 0 \ , \ j \in \mathbb{N} \ ,$$

for a fixed $k \in \mathbb{N}_0$ must vanish almost everywhere in $(1, \rho)$.

To this end we define for $j \in \mathbb{N}$, $k \in \mathbb{N}_0$, $r \geq 1$ the functions

$$\begin{aligned} e_{j,k}(r) &:= (r^{k+j} - r^{-(k+j)})(r^j - r^{-j}) \ , \\ f_j(r) &:= (r + r^{-1})(r - r^{-1})^{2j} \ , \\ g_j(r) &:= (r - r^{-1})^{2j} \ . \end{aligned}$$

The $e_{j,k}$ appear in the above equation but they are difficult to work with. However, it turns out that the f_j, g_j are contained in $\operatorname{span}\{e_{j,1} : j \in \mathbb{N}\}$, $\operatorname{span}\{e_{j,0} : j \in \mathbb{N}\}$, respectively. Since the f_j, g_j are essentially even polynomials in the variable $(r - 1/r)$ they are more suitable for our purposes than the $e_{j,k}$. Hence, we start with the following lemma.

LEMMA 2.2. $\operatorname{span}\{g_j : j \in \mathbb{N}\} \subset \operatorname{span}\{e_{j,0} : j \in \mathbb{N}\}$ *and* $\operatorname{span}\{f_j : j \in \mathbb{N}\} \subset \operatorname{span}\{e_{j,1} : j \in \mathbb{N}\}$.

Proof. We observe with the help of

$$(r + r^{-1})(r^j - r^{-j}) = (r^{j+1} - r^{-(j+1)}) + (r^{j-1} - r^{-(j-1)}) \ , \ j \in \mathbb{N} \ ,$$

that

$$(r + r^{-1})^2 e_{1,0}(r) = e_{2,0}(r) \ , \tag{2.3}$$

$$(r + r^{-1})^2 e_{j,0}(r) = e_{j+1,0}(r) + 2e_{j,0}(r) + e_{j-1,0}(r) - 2e_{1,0}(r) \ , \ j \geq 2 \ , \tag{2.4}$$

$$(r + r^{-1})^2 e_{1,1}(r) = e_{2,1}(r) + e_{1,1}(r) \ , \tag{2.5}$$

$$(r + r^{-1})^2 e_{j,1}(r) = e_{j+1,1}(r) + 2e_{j,1}(r) + e_{j-1,1}(r) - e_{1,1}(r) \ , \ j \geq 2 \ . \tag{2.6}$$

Starting with

$$g_1(r) = e_{1,0}(r) \ , \ f_1(r) = (r + r^{-1})(r - r^{-1})^2 = e_{1,1}(r)$$

we now use induction to prove $f_N \in \operatorname{span}\{e_{j,1} : j = 1, \ldots, N\}$ and $g_N \in \operatorname{span}\{e_{j,0} : j = 1, \ldots, N\}$ for all $N \in \mathbb{N}$. From $f_{N-1} = \sum_{j=1}^{N-1} \alpha_j e_{j,1}$ for a fixed $N \geq 2$ we conclude

$$\begin{aligned} f_N(r) &= (r - r^{-1})^2 f_{N-1}(r) \\ &= ((r + r^{-1})^2 - 4) f_{N-1}(r) \\ &= \sum_{j=1}^{N-1} \alpha_j (r + r^{-1})^2 e_{j,1}(r) - 4 \sum_{j=1}^{N-1} \alpha_j e_{j,1}(r) \ , \end{aligned}$$

i.e., $f_N = \sum_{j=1}^{N} \beta_j e_{j,1}$ by (2.5) and (2.6). Using (2.3) and (2.4), a similar reasoning yields the assertion for g_N and we have proved the lemma. □

Now, we prove the density result for $\operatorname{span}\{e_{j,k}: j \in \mathbb{N}\}$ with respect to the L^2-norm. $C_0(1,\rho)$ denotes the space of continuous functions having compact support in $(1,\rho)$.

LEMMA 2.3. *Assume $k \in \mathbb{N}_0$ and $\rho > 1$. Then, $\operatorname{span}\{e_{j,k}: j \in \mathbb{N}\}$ is dense in $L^2(1,\rho)$; i.e., if $f \in L^2(1,\rho)$ satisfies*

$$\int_1^\rho f(r) e_{j,k}(r)\,dr = 0 \quad \text{for all } j \in \mathbb{N},$$

then $f = 0$.

Proof. We start with the case $k = 0$ and show that for any $f \in C_0(1,\rho)$ there is a sequence $q_N \in \operatorname{span}\{e_{j,0}: j \in \mathbb{N}\}$, $N \in \mathbb{N}$, with $\|q_N - f\|_{L^2} \to 0$, $N \to \infty$. Then, the assertion for $k = 0$ follows from the density of $C_0(1,\rho)$ in $L^2(1,\rho)$.

The transformation $t = r - 1/r$, $r > 1$, maps $(1,\infty)$ bijectively onto $(0,\infty)$. The inverse map is given by $r = z(t)$ with $z(t) := t/2 + \sqrt{1 + t^2/4}$, $t > 0$. We use this transformation to reduce the problem to an approximation problem with even polynomials. Defining $g(t) := t^{-2} f(z(|t|))$ for $0 < |t| \le \rho - 1/\rho$ and $g(0) := 0$, we have that $g \in C[-\rho + 1/\rho, \rho - 1/\rho]$ is an even function. Hence, by the Weierstrass approximation theorem there is a sequence $\tilde{q}_N$, $N \in \mathbb{N}$, of even polynomials which converge uniformly to g,

$$\max\{|\tilde{q}_N(t) - g(t)|: t \in [-\rho + 1/\rho, \rho - 1/\rho]\} \to 0\ ,\ N \to \infty\ .$$

With $q_N(r) := (r - 1/r)^2 \tilde{q}_N(r - 1/r)$, $1 \le r \le \rho$, $N \in \mathbb{N}$, we have $q_N \in \operatorname{span}\{g_j: j \in \mathbb{N}\}$ and thus $q_N \in \operatorname{span}\{e_{j,0}: j \in \mathbb{N}\}$ by Lemma 2.2. Furthermore, using the transformation $r = z(t)$ we can estimate

$$\int_1^\rho |q_N(r) - f(r)|^2\,dr = \int_0^{\rho - 1/\rho} |\tilde{q}_N(t) - g(t)|^2 t^4 z'(t)\,dt$$

$$\le c \max\{|\tilde{q}_N(t) - g(t)|^2: t \in [0, \rho - 1/\rho]\} \to 0\ ,\ N \to \infty\ ,$$

with a suitable positive constant c and we have proved the lemma for $k = 0$.

Now, we consider the case $k \in \mathbb{N}$. For $f \in C_0(1,\rho)$ we define

$$g(t) := t^{-2}\Big(z(|t|) + z(|t|)^{-1}\Big)^{-1} f((z(|t|))^{1/k})$$

for $0 < |t| \le \rho^k - 1/\rho^k$ and $g(0) := 0$. We have again that $g \in C[-\rho^k + 1/\rho^k, \rho^k - 1/\rho^k]$ is an even function which can be approximated uniformly by a sequence $\tilde{q}_N$, $N \in \mathbb{N}$, of even polynomials,

$$\max\{|\tilde{q}_N(t) - g(t)|: t \in [-\rho^k + 1/\rho^k, \rho^k - 1/\rho^k]\} \to 0\ ,\ N \to \infty\ .$$

Defining $q_N(s) := (s + 1/s)(s - 1/s)^2 \tilde{q}_N(s - 1/s)$, $1 \le s \le \rho^k$, $N \in \mathbb{N}$, we have $q_N \in \operatorname{span}\{f_j: j \in \mathbb{N}\}$ and $q_N \in \operatorname{span}\{e_{j,1}: j \in \mathbb{N}\}$ by Lemma 2.2. Hence, $p_N(r) := q_N(r^k)$, $1 \le r \le \rho$, can be represented as

$$p_N(r) = \sum_{j=1}^{M} a_j e_{j,1}(r^k) = \sum_{j=1}^{M} a_j (r^{k+jk} - r^{-(k+jk)})(r^{jk} - r^{-jk})\ ,$$

i.e., $p_N \in \operatorname{span}\{e_{j,k}: j \in \mathbb{N}\}$.

With the help of the transformations $r = s^{1/k}$ and $s = z(t)$ we can estimate

$$\int_1^\rho |p_N(r) - f(r)|^2 dr = \int_1^{\rho^k} |q_N(s) - f(s^{1/k})|^2 (1/k) s^{1/k-1} ds$$

$$= \int_1^{\rho^k} \Big| \tilde{q}_N\Big(s - \frac{1}{s}\Big) - \Big(s + \frac{1}{s}\Big)^{-1} \Big(s - \frac{1}{s}\Big)^{-2} f(s^{1/k}) \Big|^2 \Big(s + \frac{1}{s}\Big)^2 \Big(s - \frac{1}{s}\Big)^4 \frac{1}{k} s^{1/k-1} ds$$

$$= \int_0^{\rho^k - 1/\rho^k} |\tilde{q}_N(t) - g(t)|^2 w(t) dt$$

$$\le c \max\{|\tilde{q}_N(t) - g(t)|^2 : t \in [0, \rho^k - 1/\rho^k]\} \to 0 \ , \ N \to \infty \ ,$$

with a bounded function w and a positive constant c. This ends the proof of the lemma. □

Since we shall map $B_{2R} \cap D$ conformally on an annulus during the proof of Theorem 2.1 we state the needed results about the conformal mapping and its inverse in the following lemma and briefly sketch its proof.

LEMMA 2.4. *Let $G := D \cap B_{2R}$, D, and R as in Theorem 2.1. Then there exist a constant $\rho > 1$ and a conformal mapping*

$$\varphi: \{z \in \mathbb{C}: (\Re z, \Im z) \in G\} \to \{w \in \mathbb{C}: 1 < |w| < \rho\} \ .$$

Furthermore, $\varphi \in C^1(\overline{G})$ and, denoting by ψ the inverse function to φ , $|\psi'|^2$ is bounded in $\{w \in \mathbb{C}: 1 < |w| < \rho\}$, where ψ' is the complex derivative of ψ.

Proof. Let $u \in C^2(G) \cap C^1(\overline{G})$ be the unique solution of the Dirichlet problem $\Delta u = 0$ in G, $u|_{\partial D} = 0$, $u|_{\partial B_{2R}} = 1$. Uniqueness of the solution can be inferred from the maximum principle. Existence and $C^1(\overline{G})$-regularity of the solution can be obtained with the help of a single-layer ansatz [9, Theorems 7.29, 7.27]. Defining $k := \int_{\partial B_{2R}} \frac{\partial u}{\partial n} ds$, we conclude from Green's theorem

$$k = \int_{\partial G} \frac{\partial u}{\partial n} \overline{u} ds = \int_G |\nabla u|^2 dx > 0 \ .$$

Let v be a real-valued conjugate harmonic function to u, i.e., u and v satisfy the Cauchy–Riemann equations, and define

$$\varphi(x_1 + ix_2) := \exp((2\pi/k)(u(x_1, x_2) + iv(x_1, x_2))) \ \text{ for } (x_1, x_2) \in G \ .$$

Note that v is not single-valued. However, φ is a single-valued holomorphic function in $\{z \in \mathbb{C}: (\Re z, \Im z) \in G\}$ and $\varphi \in C^1(\overline{G})$. Then φ is the searched-for conformal mapping with $\rho := e^{2\pi/k} > 1$ (see the proof of [1, Theorem 10, Chapter 6, p. 247]).

If ψ is the inverse function to φ we have $\varphi'(\psi(w))\psi'(w) = 1$ for $1 < |w| < \rho$, hence $|\varphi'(z)|^2 > 0$ for $z \in G$. The boundary point lemma states $\frac{\partial u}{\partial n}(z) \neq 0$ for $z \in \partial G$ (see

[4, Lemma 3.4]). Therefore we compute $|\varphi'(z)|^2 = ((2\pi/k)e^{(2\pi/k)u(z)})^2|\nabla u(z)|^2 > 0$ for $z \in \partial G$. Then, $|\varphi'(z)|^2 \geq \delta > 0$ for all $z \in \overline{G}$ and $|\psi'(w)|^2 \leq \delta^{-1}$ for $1 < |w| < \rho$. This ends the proof of the lemma. □

We are now in a position to prove Theorem 2.1.

Proof of Theorem 2.1. Let us first consider the case $D_0 = B_1$ and assume equation (2.1) holds for all harmonic functions u, v in $\mathbb{R}^2 \setminus \overline{B_1}$ which vanish on ∂B_1 and satisfy $\int_{\partial B_1} \frac{\partial u}{\partial n} ds = \int_{\partial B_1} \frac{\partial v}{\partial n} ds = 0$. By the reasoning immediately after Theorem 2.1 we arrive at equation (2.2), which reads

$$\int_1^{2R} \left(r \int_0^{2\pi} q(r\cos\theta, r\sin\theta) e^{ik\theta} d\theta \right) e_{j,|k|}(r) dr = 0 \ , \ j \in \mathbb{N} \ , \ k \in \mathbb{Z} \ .$$

We define, for $k \in \mathbb{Z}$,

$$f_k(r) := r \int_0^{2\pi} q(r\cos\theta, r\sin\theta) e^{ik\theta} d\theta \ , \ 1 < r < 2R \ ,$$

and obtain from Lemma 2.3 for all $k \in \mathbb{Z}$: $f_k(r) = 0$ almost everywhere in $(1, 2R)$. Since the trigonometric polynomials are a complete orthogonal system in $L^2(0, 2\pi)$ we can conclude $q(r\cos\theta, r\sin\theta) = 0$ for almost all $1 < r < 2R$, $0 \leq \theta \leq 2\pi$, i.e., $q = 0$.

In the general case we use the conformal mapping φ with inverse ψ from Lemma 2.4. For any function $\tilde{u} \in C^2(\mathbb{R}^2 \setminus \overline{B_1}) \cap C^1(\mathbb{R}^2 \setminus B_1)$ with $\tilde{u}|_{\partial B_1} = 0$, $\Delta\tilde{u} = 0$ in $\mathbb{R}^2 \setminus \overline{B_1}$ and $\int_{\partial B_1} \frac{\partial \tilde{u}}{\partial n} ds = 0$, the function

$$u(x) := \tilde{u}(\Re\varphi(x_1 + ix_2), \Im\varphi(x_1 + ix_2)) \ , \ x = (x_1, x_2) \in \overline{D} \cap B_{2R} \ ,$$

satisfies $u \in C^2(D \cap B_{2R}) \cap C^1(\overline{D} \cap B_{2R})$, $u(x) = 0$, $x \in \partial D$, and

$$\Delta u(x) = (\Delta\tilde{u})(\Re\varphi(x_1 + ix_2), \Im\varphi(x_1 + ix_2))|\varphi'(x_1 + ix_2)|^2 = 0 \ \text{ in } D \cap B_{2R} \ .$$

Due to $\int_{\partial B_1} \frac{\partial \tilde{u}}{\partial n} ds = 0$ there is a single-valued conjugate harmonic function $\tilde{w} \in C^2(\mathbb{R}^2 \setminus \overline{B_1}) \cap C^1(\mathbb{R}^2 \setminus B_1)$ to $\tilde{u}$. Hence, defining

$$f(x_1 + ix_2) := \tilde{u}(\Re\varphi(x_1 + ix_2), \Im\varphi(x_1 + ix_2)) + i\tilde{w}(\Re\varphi(x_1 + ix_2), \Im\varphi(x_1 + ix_2))$$

for $x = (x_1, x_2) \in \overline{D} \cap B_{2R}$, f is a single-valued holomorphic function and we can compute

$$\int_{\partial D} \frac{\partial u}{\partial n} ds = \int_{\partial D} \frac{\partial(\Re(f))}{\partial n} ds = \int_{\partial D} \frac{d(\Im(f))}{ds} ds = 0;$$

i.e., the condition for the normal derivative is also satisfied.

Analogously, we can define v from $\tilde{v} \in C^2(\mathbb{R}^2 \setminus \overline{B_1}) \cap C(\mathbb{R}^2 \setminus B_1)$ with $\tilde{v}|_{\partial B_1} = 0$, $\int_{\partial B_1} \frac{\partial \tilde{v}}{\partial n} ds = 0$, and $\Delta\tilde{v} = 0$ in $\mathbb{R}^2 \setminus \overline{B_1}$. Using the change of variables formula and the fact that $|\psi'(y_1 + iy_2)|^2$ is the Jacobian of the transformation in $\mathbb{R}^2$ which is given by ψ, we obtain

$$0 = \int_{D \cap B_{2R}} q(x)u(x)v(x)dx$$

$$= \int\limits_{1<|y|<\rho} q((\Re\psi(y_1+iy_2),\Im\psi(y_1+iy_2)))\tilde{u}(y)\tilde{v}(y)|\psi'(y_1+iy_2)|^2 dy$$

for all harmonic functions $\tilde{u}$, $\tilde{v}$ in $\mathbb{R}^2\setminus\overline{B_1}$ which vanish on ∂B_1 and whose integral over ∂B_1 of the normal derivative is zero. Therefore, from the considerations for $D_0 = B_1$ we can conclude $q((\Re\psi(y_1+iy_2),\Im\psi(y_1+iy_2)))|\psi'(y_1+iy_2)|^2 = 0$, almost everywhere in $1 < |y| < \rho$, hence $q = 0$, and we have proved Theorem 2.1. □

3. The direct scattering problem. With D and B_R as in the previous section we shall examine the following scattering problems (P_κ): given $\kappa > 0$, a uniformly Hölder continuous function $q \in C^{0,\alpha}(\overline{D})$, $0 < \alpha < 1$, satisfying $\operatorname{supp}(1-q) \subset B_R$ and $\Im(q) \geq 0$ in D, and an incident field $u^i \in C^2(B_R)$ with $\Delta u^i + \kappa^2 u^i = 0$ in B_R, find the scattered field $u^s \in C^2(D) \cap C(\overline{D})$ satisfying $\Delta u^s + \kappa^2 q u^s = \kappa^2(1-q)u^i$ in D; the Sommerfeld radiation condition $|\hat{x}\cdot\nabla u^s(x) - i\kappa u^s(x)|^2 = o(|x|^{-1/2})$, $|x| \to \infty$, uniformly for all directions $\hat{x} := |x|^{-1}x$; and the boundary condition $u^s|_{\partial D} = -u^i|_{\partial D}$.

We are interested in the unique solvability of (P_κ) and in the behavior of the solutions as $\kappa \to 0$. Therefore, we also state (P_0): given an incident field $u^i \in C^2(B_R)$ with $\Delta u^i = 0$ in B_R, find the scattered field $u^s \in C^2(D) \cap C(\overline{D})$ satisfying $\Delta u^s = 0$ in D; $|u^s(x)| = O(1)$, $|x| \to \infty$, uniformly for all directions $\hat{x} := |x|^{-1}x$; and the boundary condition $u^s|_{\partial D} = -u^i|_{\partial D}$.

We denote by

$$\Phi_\kappa(x,y) := \frac{i}{4} H_0^{(1)}(\kappa|x-y|)\ ,\ x,y \in \mathbb{R}^2\ ,\ x \neq y\ ,\ \kappa > 0,$$

and

$$\Phi_0(x,y) := \frac{1}{2\pi}\ln\frac{1}{|x-y|}\ ,\ x,y \in \mathbb{R}^2\ ,\ x \neq y,$$

the fundamental solutions to the Helmholtz equation and Laplace equation, respectively.

THEOREM 3.1. *(P_κ) has a unique solution for all $\kappa \geq 0$.*

Let $u_0^i \in C^2(B_R)$ be a harmonic function in B_R. If for $0 < \kappa < 1$ the incident fields u_κ^i satisfy $\|u_\kappa^i - u_0^i\|_{\infty,B_R} \to 0$, $\kappa \to 0$, then the solutions u_κ^s of (P_κ) converge uniformly in $\overline{D\cap B_R}$ to the solution of (P_0) for the incident field u_0^i.

Proof. The existence and uniqueness results can be found in the literature. The case $\kappa = 0$ is treated in [9, Theorem 6.20]. Since the uniqueness proofs given for the three-dimensional case in [11, Satz 2] or in [3, Theorem 3.7] can be carried over to our case (P_κ) has at most one solution if $\kappa > 0$. Moreover, analogously to [11, Satz 10], the existence of a solution to (P_κ), $\kappa > 0$, can be established by an ansatz of a combined volume and double-layer potential. However, we are also interested in the behavior of the solutions for $\kappa \to 0$, and the second assertion of the theorem cannot be inferred from the ansatz in [11] (see [12, 8] for the case $q = 1$). Therefore, we choose a more complicated ansatz along the lines suggested in [8] which yields the desired convergence.

For $0 < \kappa < 1$, $a \in C(\overline{D\cap B_R})$, and $\varphi \in C(\partial D)$ we define

$$u^s(x) := \int\limits_{\partial D} \Big\{\frac{\partial\Phi_\kappa}{\partial n(y)}(x,y) + \Big(1 - \frac{2\pi}{\ln\kappa}\Big)\Phi_\kappa(x,y)\Big\}\varphi(y)ds(y)$$
$$-\frac{1}{|\partial D|}\int\limits_{\partial D}\Phi_\kappa(x,z)ds(z)\int\limits_{\partial D}\varphi(y)ds(y)$$

$$+\kappa \int_{D\cap B_R} \Phi_\kappa(x,y)a(y)dy \ , \ x \in D \ . \tag{3.1}$$

The normal vector n is directed into D and by $|\partial D|$ we denote the arclength of ∂D.

From the mapping properties and jump relations of potentials we can conclude that if a and φ are a solution of the integral equations

$$\begin{aligned} -a(x) + \kappa(q(x)-1)\Bigg\{ & \int_{\partial D} \Big\{ \frac{\partial \Phi_\kappa}{\partial n(y)}(x,y) + \Big(1 - \frac{2\pi}{\ln \kappa}\Big)\Phi_\kappa(x,y)\Big\}\varphi(y)ds(y) \\ & - \frac{1}{|\partial D|}\int_{\partial D} \Phi_\kappa(x,z)ds(z) \int_{\partial D} \varphi(y)ds(y) \\ & + \kappa \int_{D\cap B_R} \Phi_\kappa(x,y)a(y)dy \Bigg\} = \kappa(1-q(x))u^i(x) \ , \ x \in D \cap B_R, \end{aligned} \tag{3.2}$$

$$\begin{aligned} \varphi(x) + 2\Bigg\{ & \int_{\partial D} \Big\{ \frac{\partial \Phi_\kappa}{\partial n(y)}(x,y) + \Big(1 - \frac{2\pi}{\ln \kappa}\Big)\Phi_\kappa(x,y)\Big\}\varphi(y)ds(y) \\ & - \frac{1}{|\partial D|}\int_{\partial D} \Phi_\kappa(x,z)ds(z) \int_{\partial D} \varphi(y)ds(y) \\ & + \kappa \int_{D\cap B_R} \Phi_\kappa(x,y)a(y)dy \Bigg\} = -2u^i(x) \ , \ x \in \partial D, \end{aligned} \tag{3.3}$$

then u^s as in (3.1) is a solution to (P_κ).

Using the asymptotic behavior of $H_0^{(1)}(z)$ for $|z| \to 0$ (see [8]), for $\kappa \to 0$ we obtain the operator

$$\begin{pmatrix} -I & 0 \\ 0 & I + L_0 \end{pmatrix} : C(\overline{D\cap B_R}) \times C(\partial D) \to C(\overline{D\cap B_R}) \times C(\partial D)$$

as the uniform limit of the integral operators in equations (3.2) and (3.3). Here, I denotes the identity map on $C(\overline{D\cap B_R})$ and $C(\partial D)$, respectively, and $L_0 : C(\partial D) \to C(\partial D)$ is defined by

$$\begin{aligned} (L_0\varphi)(x) := 2 & \int_{\partial D} \Big\{ \frac{\partial \Phi_0}{\partial n(y)}(x,y) + \Phi_0(x,y) + 1\Big\}\varphi(y)ds(y) \\ & - \frac{2}{|\partial D|}\int_{\partial D} \Phi_0(x,z)ds(z) \int_{\partial D} \varphi(y)ds(y) \ , \ x \in \partial D. \end{aligned}$$

Since $I + L_0$ has a bounded inverse [8, Theorem 2.1] we know by a Neumann series argument that for sufficiently small κ the integral equations (3.2), (3.3) have a unique solution and that these solutions $(a_\kappa, \varphi_\kappa)$ converge to $(0, \varphi_0)$, φ_0 being the unique solution to $(I + L_0)\varphi_0 = -2u_0^i|_{\partial D}$. Therefore, inserting $(a_\kappa, \varphi_\kappa)$ into the potential in (3.1) and using once more the behavior of $H_0^{(1)}(z)$ for $|z| \to 0$ we see that the solutions

u_κ^s converge uniformly in $D \cap B_R$ to the function

$$u_0^s(x) := \int_{\partial D} \Big\{ \frac{\partial \Phi_0}{\partial n(y)}(x,y) + \Phi_0(x,y) + 1 \Big\} \varphi_0(y) ds(y) \\ - \frac{1}{|\partial D|} \int_{\partial D} \Phi_0(x,z) ds(z) \int_{\partial D} \varphi_0(y) ds(y) \ , \ x \in D,$$

(see [8, Theorem 2.2]). u_0^s is harmonic and bounded in D and satisfies $u_0^s|_{\partial D} = (1/2)(I + L_0)\varphi_0 = -u_0^i|_{\partial D}$ due to the jump relations. Hence, it is the solution of (P_0) for the incident field u_0^i. This ends the proof of the theorem. □

Now, we know the behavior of the scattered fields as $\kappa \to 0$. In the next section we also need some knowledge concerning the approximation of a harmonic function by incident fields or by the sum of incident and scattered fields as $\kappa \to 0$. We establish these results in the last theorem of this section.

THEOREM 3.2.

(a) *Let $u_0^i \in C^2(\overline{B_{3R/2}})$ be harmonic. Then, there are incident fields $u_\kappa^i \in C^2(B_{3R/2})$, $0 < \kappa < 1$, such that $\|u_\kappa^i - u_0^i\|_{\infty, B_R} \to 0$, $\kappa \to 0$.*

(b) *Let $u_0 \in C^2(D \cap B_{2R}) \cap C^1(\overline{D} \cap B_{2R})$ be harmonic in $D \cap B_{2R}$, $u_0|_{\partial D} = 0$, and $\int_{\partial D} \frac{\partial u_0}{\partial n} ds = 0$. Then, there are incident fields $u_\kappa^i \in C^2(B_{3R/2})$, $0 < \kappa < 1$, such that the solutions u_κ^s to (P_κ) satisfy $\|u_\kappa^i + u_\kappa^s - u_0\|_{\infty, D \cap B_R} \to 0$, $\kappa \to 0$.*

Proof. For part (a) we define $\varphi \in C(\partial B_{3R/2})$ to be the unique solution to

$$\varphi(x) - 2 \int_{\partial B_{3R/2}} \frac{\partial \Phi_0}{\partial n(y)}(x,y) \varphi(y) ds(y) = -2u_0^i(x) \ , \ x \in \partial B_{3R/2}.$$

It is well known that this integral equation has a unique solution [9, Theorem 6.16] and that

$$u_0^i(x) = \int_{\partial B_{3R/2}} \frac{\partial \Phi_0}{\partial n(y)}(x,y) \varphi(y) ds(y) \ , \ x \in B_{3R/2}.$$

Now, we set

$$u_\kappa^i(x) = \int_{\partial B_{3R/2}} \frac{\partial \Phi_\kappa}{\partial n(y)}(x,y) \varphi(y) ds(y) \ , \ x \in B_{3R/2},$$

and use the convergence of the double-layer potentials as in Theorem 3.1 to obtain $\|u_\kappa^i - u_0^i\|_{\infty, B_R} \to 0$, $\kappa \to 0$. This proves part (a).

For part (b) we choose R' with $3R/2 < R' < 2R$. Adding

$$u_0^i(x) := \int_{\partial B_{R'}} \Big\{ \frac{\partial u_0}{\partial n}(y) \Phi_0(x,y) - \frac{\partial \Phi_0}{\partial n(y)}(x,y) u_0(y) \Big\} ds(y) \ , \ x \in B_{R'},$$

and

$$u_0^s(x) := - \int_{\partial D} \frac{\partial u_0}{\partial n}(y) \Phi_0(x,y) ds(y) \ , \ x \in D,$$

and using $u_0|_{\partial D} = 0$ and Green's formula, we obtain $u_0^i(x) + u_0^s(x) = u_0(x)$, $x \in D \cap B_{R'}$. u_0^i is harmonic in $B_{R'}$. u_0^s is harmonic and bounded in D because of $\int_{\partial D} \frac{\partial u_0}{\partial n} ds = 0$. Hence, u_0^s is the solution of (P_0) for the incident field u_0^i. According to part (a) u_0^i can be approximated by u_κ^i in B_R. Because Theorem 3.1 implies that the solutions u_κ^s to (P_κ) with incident fields u_κ^i converge to u_0^s we have proved the theorem. □

4. A uniqueness theorem for the inverse scattering problem. Let B_R, D_0, D, and q satisfy the assumptions of the previous sections. Moreover, we assume that $\tilde{D}_0 \subset B_R$, $\tilde{D} := \mathbb{R}^2 \setminus \overline{\tilde{D}_0}$, and $\tilde{q} \in C^{0,\alpha}(\overline{\tilde{D}})$ satisfy the analogous assumptions. (P_κ) denotes the scattering problem with data D, q, and u_κ^i, u_κ^s is its solution. $(\tilde{P}_\kappa)$ denotes the scattering problem with data $\tilde{D}$, $\tilde{q}$, and u_κ^i, $\tilde{u}_\kappa^s$ its solution. Our final theorem states that, if for $(\tilde{P}_\kappa)$ and (P_κ) the Cauchy data of the scattered fields coincide on ∂B_R for all possible incident fields u_κ^i and for all $0 < \kappa < 1$, then $\partial D = \partial \tilde{D}$ and $q = \tilde{q}$; i.e., the Cauchy data for an interval of frequencies and all possible incident fields uniquely determine the obstacle D_0 and the inhomogeneity q.

Let us add two remarks before we prove the theorem.

The incident fields are very often chosen to be plane waves $u_\kappa^i(x) = \exp(i\kappa d \cdot x)$, $x \in \mathbb{R}^2$, propagating in the direction $d \in \mathbb{R}^2$, $|d| = 1$. In any closed subset of B_R any solution to $\Delta u + \kappa^2 u = 0$ in B_R can be uniformly approximated by elements from the span of the plane waves [6, Lemma 3.2]. Therefore we could also work with plane waves instead of the larger set of incident fields.

Furthermore, in scattering theory one usually works with the far field pattern of the scattered fields. But since the far field pattern uniquely determines the Cauchy data of the scattered field [3, Theorem 2.13] and vice versa [3, Theorem 2.5], coincidence of the far field patterns and coincidence of the Cauchy data are equivalent.

THEOREM 4.1. *If for all $0 < \kappa < 1$ and for all solutions $u_\kappa^i \in C^2(B_{3R/2})$ of $\Delta u_\kappa^i + \kappa^2 u_\kappa^i = 0$ in $B_{3R/2}$ the Cauchy data of the scattered fields for (P_κ) and $(\tilde{P}_\kappa)$ coincide, i.e., $u_\kappa^s|_{\partial B_R} = \tilde{u}_\kappa^s|_{\partial B_R}$ and $\frac{\partial u_\kappa^s}{\partial n}|_{\partial B_R} = \frac{\partial \tilde{u}_\kappa^s}{\partial n}|_{\partial B_R}$, then $\partial D = \partial \tilde{D}$ and $q = \tilde{q}$.*

Proof. We first prove $\partial D = \partial \tilde{D}$ by reducing everything to the case $\kappa = 0$ and using Schiffer's idea. We choose $u_0^i(x_1, x_2) := x_1 + ix_2$, $(x_1, x_2) \in \mathbb{R}^2$, and according to Theorem 3.2 (a) incident fields $u_\kappa^i \in C^2(B_{3R/2})$, $0 < \kappa < 1$, with $\|u_\kappa^i - u_0^i\|_{\infty, B_R} \to 0$, $\kappa \to 0$. From $u_\kappa^s|_{\partial B_R} = \tilde{u}_\kappa^s|_{\partial B_R}$, $0 < \kappa < 1$, and Theorem 3.1 we obtain $u_0^s|_{\partial B_R} = \tilde{u}_0^s|_{\partial B_R}$. Denoting by G the unbounded component of $D \cap \tilde{D}$ we have $u_0^s(x) = \tilde{u}_0^s(x)$ for all $x \in G$ because of the uniqueness for the Dirichlet problem in the exterior of B_R and because harmonic functions are analytic.

If we assume $D_0 \neq \tilde{D}_0$, without loss of generality, we can assume that $D_1 := (\mathbb{R}^2 \setminus \overline{G}) \setminus \overline{D_0}$ is nonempty. D_1 is an open subset of D and $\partial D_1 \subset \partial G \cup \partial D = (\partial G \setminus \partial D) \cup \partial D$. Since u_0^s coincides with $-u_0^i$ on ∂D and with $\tilde{u}_0^s = -u_0^i$ on $\partial G \setminus \partial D$ the maximum principle implies $u_0^s = -u_0^i$ in D_1 and hence in D by analyticity. This is a contradiction because u_0^i is unbounded in D whereas u_0^s is bounded. Then, we must have $D_0 = \tilde{D}_0$, i.e., $\partial D = \partial \tilde{D}$.

Now, we prove $q = \tilde{q}$. We first establish the relation (2.1) in Theorem 2.1 with $q - \tilde{q}$. To this end we choose harmonic functions u, $v \in C^2(D \cap B_{2R}) \cap C^1(\overline{D} \cap B_{2R})$ satisfying $u|_{\partial D} = v|_{\partial D} = 0$ and $\int_{\partial D} \frac{\partial u}{\partial n} ds = \int_{\partial D} \frac{\partial v}{\partial n} ds = 0$. According to Theorem 3.2 (b) there are incident fields $u_\kappa^i \in C^2(B_{3R/2})$, $0 < \kappa < 1$, such that the solutions u_κ^s to (P_κ) satisfy $\|u_\kappa^i + u_\kappa^s - u\|_{\infty, D \cap B_R} \to 0$, $\kappa \to 0$, and similarly for the solutions $\tilde{u}_\kappa^s$ to $(\tilde{P}_\kappa)$ with incident field u_κ^i. To shorten notation we define $u_\kappa := u_\kappa^i + u_\kappa^s$ and $\tilde{u}_\kappa := u_\kappa^i + \tilde{u}_\kappa^s$ in $\overline{D \cap B_R}$. From $u_\kappa^s|_{\partial B_R} = \tilde{u}_\kappa^s|_{\partial B_R}$ and $\frac{\partial u_\kappa^s}{\partial n}|_{\partial B_R} = \frac{\partial \tilde{u}_\kappa^s}{\partial n}|_{\partial B_R}$ we infer

the same equations for u_κ and $\tilde{u}_\kappa$ for $0 < \kappa < 1$. This yields, together with Green's theorem,

$$\begin{aligned}
0 &= \int\limits_{\partial(D\cap B_R)} \Big(v\frac{\partial}{\partial n}(u_\kappa - \tilde{u}_\kappa) - (u_\kappa - \tilde{u}_\kappa)\frac{\partial v}{\partial n}\Big) ds \\
&= \int\limits_{D\cap B_R} (\Delta u_\kappa - \Delta \tilde{u}_\kappa) v dx \\
&= \kappa^2 \int\limits_{D\cap B_R} (\tilde{q}\tilde{u}_\kappa - q u_\kappa) v dx \\
&= \kappa^2 \int\limits_{D\cap B_R} (\tilde{q} - q) u_\kappa v dx + \kappa^2 \int\limits_{D\cap B_R} \tilde{q}(\tilde{u}_\kappa - u_\kappa) v dx.
\end{aligned}$$

Using $q(x) - \tilde{q}(x) = 0$ for $|x| \geq R$, dividing by κ^2, and taking $\kappa \to 0$ we obtain

$$\int\limits_{D\cap B_{2R}} (\tilde{q} - q) u v dx = 0$$

because $\tilde{u}_\kappa$ and u_κ converge uniformly to u according to Theorem 3.2 (b). Then, from Theorem 2.1 we can conclude $q = \tilde{q}$ and we have proved the uniqueness result. ∎

CONVERGENCE AND DIVERGENCE OF DECREASING REARRANGED FOURIER SERIES*

ANTONIO CÓRDOBA† AND PABLO FERNÁNDEZ†

Abstract. In a number of useful applications, e.g., data compression, the appropriate partial sums of the Fourier series are formed by taking into consideration the size of the coefficients rather than the size of the frequencies involved. The purpose of this paper is to show the limitations of that method of summation. We use several results from the number theory to construct counterexamples to L^p-convergence for $p < 2$. We also show how to obtain positive results if we combine the two points of view, i.e., cutting on frequencies and the size of coefficients at the same time. This can be considered as a kind of uncertainty principle for Fourier sums.

Key words. partial Fourier sums, L_p-convergence, Gaussian sums

1. Introduction.

For any function, $f \in L^1(\mathbf{T})$, we can construct its Fourier series

$$f(x) \sim \sum_{k=-\infty}^{\infty} \hat{f}(k) e^{2\pi i k x}.$$

The traditional way of reconstructing the function from its Fourier coefficients is to consider the partial sums

$$S_N f(x) = \sum_{|k| \le N} \hat{f}(k) e^{2\pi i k x}.$$

It is well known that there is convergence in norm. If $f \in L^p(\mathbf{T})$, for $1 < p < \infty$, then

$$S_N f \to f \text{ in } L^p(\mathbf{T}) \text{ as } N \to \infty;$$

and since Carleson [1], it is also known that we have almost everywhere convergence.

However, taking into account the interpretation of the Fourier coefficients as, for example, the x-ray diffraction pattern of a periodic electron density, it seems to be more natural to pay attention to the coefficients that give us more information, that is, those of bigger magnitude, and to reconstruct the function ordering the Fourier coefficients in decreasing order. The same comments also apply if we are interested in the application of the Fourier series to signal processing algorithms. The mathematical expression of this fact leads us to consider, for each $\lambda > 0$, partial sums

$$\tilde{S}_\lambda f(x) = \sum_{|\hat{f}(k)| > \lambda} \hat{f}(k) e^{2\pi i k x}$$

and their limit when $\lambda \to 0^+$.

In a recent paper [2], Körner answered in the negative a question asked by Carleson and Coifman, proving the existence of a function $f \in L^2(\mathbf{T})$ such that

$$\limsup_{\lambda \to 0^+} \left| \sum_{|\hat{f}(k)| \geq \lambda} \hat{f}(k) e^{2\pi i k\, x} \right| = \infty \text{ for almost every } x \in \mathbf{T}.$$

Körner's proof is based on an ingenious modification of a construction due to Olevskii for the Haar system, and it also uses a probabilistic lemma of Salem and Zygmund.

Using a different method, we show in this paper that L^p-convergence, for $p < 2$, also fails for the partial sums $\tilde{S}_\lambda$. More concretely, we have the following theorem.

THEOREM 1.

a) *If we define a maximal operator*

$$\tilde{S}^* f(x) = \sup_{\lambda > 0} \left| \tilde{S}_\lambda f(x) \right|,$$

then, for all $1 \leq p < 2$, *there is a function* $f \in L^p(\mathbf{T})$ *(explicitly constructed) such that*

$$\|\tilde{S}^* f\|_p = \infty.$$

b) *For each* $p < 2$, *there exists a function* $f \in L^p$ *such that* $\limsup_{\lambda \to 0^+} \|\tilde{S}_\lambda f\|_p = \infty$.

Our arguments are of a number theory nature, and we use the Farey dissection of the interval $[0, 1)$ and the prime number theorem in the proof.

This divergence phenomenon suggests that $\tilde{S}_\lambda f$ is not the proper sum to be taken. One may argue that one reason for the failure of $\tilde{S}_\lambda f$ to converge is because we have not taken into account the uncertainty principle in the following way: it does not make sense to impose restrictions upon the size of $|\hat{f}(k)|$ and not upon $|k|$ itself.

Let us consider the modified partial sums

$$S_N^\delta f(x) = \sum_{\substack{|k| \leq N \\ |\hat{f}(k)| \geq N^{-\delta}}} \hat{f}(k) e^{2\pi i k x}, \delta > 0.$$

Then we have the following theorem.

THEOREM 2.

a) *If* $\delta < \frac{1}{2}$, *then for every* $p < 2$ *there is a function* $f \in L^p(\mathbf{T})$ *such that*

$$\| \limsup_{N \to \infty} S_N^\delta f \|_p = \infty.$$

b) *If* $\delta \geq \frac{1}{2}$, *then*

$$\sup_N \|S_N^\delta f\|_p < \infty \text{ for every } f \in L^p(\mathbf{T}), 1 < p \leq 2.$$

c) *If* $\delta > \frac{1}{2}$, *then we have*

$$\lim_{N \to \infty} \|S_N^\delta f - f\|_p = 0 \quad \text{for every } f \in L^p(\mathbf{T}), 1 < p \leq 2.$$

d) *If* $\delta = \frac{1}{2}$, *then for every* $p < 2$ *there exists* $f \in L^p(\mathbf{T})$ *such that*

$$\limsup_{N \to \infty} \|S_N^\delta f - f\|_p > 0.$$

More generally, given a decreasing function ϕ, one can consider partial sums

$$S_N^{\phi} f(x) = \sum_{\substack{|k| \le N \\ |\hat{f}(k)| \ge \phi(N)}} \hat{f}(k) e^{2\pi i k x}.$$

Our construction shows that the behavior of S_N^{ϕ} depends upon the condition

$$N \cdot \phi^2(N) = o(1).$$

Finally, we would like to say that we believe more important than the actual results presented in this paper, are the methods of construction of the examples. They illustrate, yet again, the connection between Fourier series and number theory.

2. A trigonometrical sum estimate. Take N large enough and consider

$$P_N^*(x) = \max_{1 \le j \le N} \left| P_N^j(x) \right| = \max_{1 \le j \le N} \left| \sum_{\substack{p \text{ prime} \\ N < p \le N + j}} e^{2\pi i p x} \right|.$$

LEMMA 1.

$$\|P_N^*\|_r \ge C\, N^{3/4 - 1/2r} \log^{-1-1/r}(N), \text{ for any } 1 < r < 2.$$

Proof. First, we take the primes q, $\sqrt{N} \le q < \sqrt{2\,N}$. For each a, $(a, q) = 1$, we have the Farey intervals

$$I_{a/q} = \left(\frac{a}{q} - \frac{1}{8\,q^2}\,,\, \frac{a}{q} + \frac{1}{8\,q^2} \right).$$

It is easy to see that these intervals are disjoint. Let us consider the set

$$E_N = \bigcup_{\substack{q \text{ prime} \\ \sqrt{N} \le q < \sqrt{2N}}} \bigcup_{a=1}^{q-1} I_{a/q}.$$

Then,

$$\begin{aligned} \|P_N^*\|_r^r &= \int_0^1 \left(P_N^*(x)\right)^r \, dx \ge \int_{E_N} \left(P_N^*(x)\right)^r \, dx \\ &= \sum_{\substack{q \text{ prime} \\ \sqrt{N} \le q < \sqrt{2N}}} \sum_{a=1}^{q-1} \int_{I_{a/q}} \left(P_N^*(x)\right)^r \, dx. \end{aligned}$$

We have the following fact.

FACT 1. *If* $|x - y| \le \frac{1}{8q^2}$, *with* $q \ge \sqrt{N}$, *then* $P_N^*(x) \ge C P_N^*(y)$. (The proof follows by summation in parts.)

Using this fact, we obtain

$$\begin{aligned}
\|P_N^*\|_r^r &\geq C \sum_{\substack{q \text{ prime} \\ \sqrt{N} \leq q < \sqrt{2N}}} \sum_{a=1}^{q-1} \int_{I_{a/q}} dx \, (P_N^*(a/q))^r \\
&\geq C \sum_{\substack{q \text{ prime} \\ \sqrt{N} \leq q < \sqrt{2N}}} \frac{1}{q^2} \sum_{a=1}^{q-1} \left| \sum_{\substack{p \text{ prime} \\ N < p < 2N}} e^{2\pi i p\, a/q} \right|^r \\
&= C \sum_{\substack{q \text{ prime} \\ \sqrt{N} \leq q < \sqrt{2N}}} \frac{1}{q^2} \sum_{a=1}^{q-1} \left| \sum_{r=1}^{q-1} \sum_{\substack{p \text{ prime} \\ N < p < 2N \\ p \equiv r(q)}} e^{2\pi i p\, a/q} \right|^r \\
&= C \sum_{\substack{q \text{ prime} \\ \sqrt{N} \leq q < \sqrt{2N}}} \frac{1}{q^2} \sum_{a=1}^{q-1} \left| \sum_{r=1}^{q-1} e^{2\pi i r\, a/q} \left[\pi(2N, q, r) - \pi(N, q, r) \right] \right|^r,
\end{aligned}$$

where $\pi(x, a, b)$, with $(a, b) = 1$, counts the number of primes less than or equal to x in the arithmetic progression $b, b + a, b + 2a, b + 3a, \ldots$. Let us rename the difference of π's in our expression as a coefficient $b_{N,q,r}$, such that $b_{N,q,r} \geq 0$. Then, using the inequality

$$\left(\sum |a_j|^r \right)^{1/r} \geq \left(\sum |a_j|^2 \right)^{1/2}, \text{if } r \leq 2,$$

we can write

$$\begin{aligned}
\|P_N^*\|_r^r \geq\ & C \sum_{\substack{q \text{ prime} \\ \sqrt{N} \leq q < \sqrt{2N}}} \frac{1}{q^2} \left\{ \sum_{a=1}^{q-1} \left| \sum_{r=1}^{q-1} e^{2\pi i r\, a/q} b_{N,r,q} \right|^2 \right\}^{r/2} \\
&= C \sum_{\substack{q \text{ prime} \\ \sqrt{N} \leq q < \sqrt{2N}}} \frac{1}{q^2} \left\{ (q-1) \sum_{r=1}^{q-1} b_{N,r,q}^2 + \sum_{r \neq s} b_{N,q,r}\, b_{N,q,s} \sum_{a=1}^{q-1} e^{2\pi i\, a\, (r-s)/q} \right\}^{r/2} \\
&= C \sum_{\substack{q \text{ prime} \\ \sqrt{N} \leq q < \sqrt{2N}}} \frac{1}{q^2} \left\{ (q-1) \sum_{r=1}^{q-1} b_{N,q,r}^2 - \sum_{r \neq s} b_{N,q,r}\, b_{N,q,s} \right\}^{r/2}.
\end{aligned}$$

Since the inequality

$$N \sum_{j=1}^{N} a_j^2 - \sum_{j \neq k} a_j\, a_k \geq \sum_{j=1}^{N} a_j^2$$

holds for $a_k \geq 0$, we have

$$\|P_N^*\|_r^r \geq C \sum_{\substack{q \text{ prime} \\ \sqrt{N} \leq q < \sqrt{2N}}} \frac{1}{q^2} \left\{ \sum_{r=1}^{q-1} b_{N,q,r}^2 \right\}^{r/2} \geq \frac{C}{N} \sum_{\substack{q \text{ prime} \\ \sqrt{N} \leq q < \sqrt{2N}}} \left\{ \sum_{r=1}^{q-1} b_{N,q,r}^2 \right\}^{r/2}.$$

Now we want to estimate the size of the interior sum, $\sum_{r=1}^{q-1} b_{N,q,r}^2$. In general, it is quite difficult to obtain lower bounds for the size of the $b_{N,q,r}$'s, even assuming the generalized Riemann hypothesis, especially if we want to make these estimates uniform in q and r (in the considered range). Fortunately, we are dealing with the sum of the squares and this makes things easier. By Cauchy's inequality and Chebyshev's theorem, we have

$$(q-1)\sum_{r=1}^{q-1} b_{N,q,r}^2 \geq \left(\sum_{r=1}^{q-1} b_{N,q,r}\right)^2 > C\frac{N^2}{\log^2(N)}.$$

Therefore,

$$\begin{aligned}\|P_N^*\|_r^r &\geq \frac{C}{N} \sum_{\substack{q \text{ prime} \\ \sqrt{N} \leq q < \sqrt{2N}}} \left(\frac{N^2}{(q-1)\log^2(N)}\right)^{r/2} \\ &\geq \frac{C}{N}\,\frac{N^r}{N^{r/4}\log^r(N)}\,\#\{\text{primes } q\ /\sqrt{N} \leq q < \sqrt{2N}\} \\ &\geq C\,N^{3r/4-1/2}\log^{-r-1}(N) \qquad \square\end{aligned}$$

3. Basic construction. Take $\alpha > 0$ (to be determined) and consider the functions

$$f_1(x) = 1 + 2\sum_{k=0}^{\infty} \underbrace{\frac{1}{2^{k\alpha}} \sum_{n=2^k}^{2^{k+1}-1} \cos(2\pi\, n\, x)}_{f_{2^k}^1(x)},$$

$$f(x) = 1 + 2\sum_{k=0}^{\infty} \underbrace{\frac{1}{2^{k\alpha}} \sum_{n=2^k}^{2^{k+1}-1} a_n\, \cos(2\pi\, n\, x)}_{f_{2^k}(x)},$$

$$\text{where } a_n = \begin{cases} 1 + \frac{1}{n} & \text{if } n \text{ prime,} \\ 1 - \frac{1}{2^k} & \text{if not.} \end{cases}$$

We can evaluate the L^p norm, for $p > 1$, of the functions f_{2^k} using the well-known estimates for the L^p-norm of the *Dirichlet kernel*,

$$\|f_{2^k}\|_p \leq \left\|f_{2^k} - f_{2^k}^1\right\|_p + \left\|f_{2^k}^1\right\|_p \leq C\,2^{k\,(1-1/p-\alpha)}.$$

Therefore,

$$\|f\|_p \leq 1 + 2\sum_{k=0}^{\infty} \|f_{2^k}\|_p \leq 1 + C\sum_{k=0}^{\infty} 2^{k(1-1/p-\alpha)}.$$

As a result, $f \in L^p(\mathbf{T})$ whenever $\alpha > 1 - \frac{1}{p}$.

For each $k = 0, 1, 2 \dots$ and for some j, $2^k < j < 2^{k+1}$ (we will see later how to choose j), we construct the sequence

$$a_{k,j} = \frac{1}{2^{k\alpha}} \left(1 + \frac{1}{j}\right) \searrow 0 \ \text{ as } k \to \infty.$$

The operator $\tilde{S}_{a_{k,j}}$ keeps all the frequencies up to 2^k; and from the next dyadic block, it keeps only some prime frequencies (those less than j):

$$|\tilde{S}_{a_{k,j}} f(x)| \geq \frac{1}{2^{k\alpha}} \left| \sum_{\substack{\nu \text{ prime} \\ 2^k \leq \nu \leq j}} e^{2\pi i \nu x} \right| - \left| \underbrace{\sum_{|\nu| \leq 2^k} \hat{f}(\nu) e^{2\pi i \nu x}}_{I} + \underbrace{\sum_{\substack{\nu \text{ prime} \\ 2^k \leq \nu \leq j}} \frac{e^{2\pi i \nu x}}{\nu}}_{II} \right|.$$

Now, for each $x \in \mathbf{T}$, we can choose $j = j(x)$ in such a way that the first term equals $2^{-k\alpha} P^*_{2^k}(x)$ (see the previous section for the definition of P^*_N). On the other hand, both terms I and II are $O(1)$ as $k \to \infty$, so for every $x \in \mathbf{T}$, we have

$$\sup_{\lambda > 0} \left| \tilde{S}_\lambda f(x) \right| \geq \frac{1}{2^{k\alpha}} P^*_{2^k}(x) - O(1).$$

It follows that

$$\|\tilde{S}^* f\|_p \geq \frac{1}{2^{k\alpha}} \|P^*_{2^k}\|_p - O(1).$$

Recalling our basic lemma, with $N = 2^k$, we obtain

$$\|\tilde{S}^* f\|_p \geq C_p \ 2^{k(3/4 - 1/2p - \alpha)} k^{-1-1/p} - O(1).$$

So the L^p norm diverges when $\alpha < \frac{3}{4} - \frac{1}{2p}$. Therefore, for each $1 \leq p < 2$, we can find an α with

$$1 - \frac{1}{p} < \alpha < \frac{3}{4} - \frac{1}{2p}$$

such that the function f constructed above satisfies

$$\|f\|_p < \infty \text{ and } \left\| \tilde{S}^* f \right\|_p = \infty.$$

This completes the proof of Theorem 1a).

In order to prove part b), we need an extra argument. Let us begin with the well-known estimate (see [3], Khintchin inequality)

$$\left[\int_0^1 \int_0^1 \left| \sum_{k=2^n}^{2^{n+1}-1} r_k(t) e^{2\pi i k x} \right|^p dx\, dt \right]^{1/p} \sim 2^{n/2},$$

where $\{r_k(t)\}$ denotes the Rademacher system of orthonormal functions. We use it to "construct," for each $p < 2$, a polynomial

$$P_n(x) = \sum_{k=2^n}^{2^{n+1}-1} a_k \, e^{2\pi i k x}, \text{ where } a_k \text{ is either 0 or 1,}$$

with $\|P_n\|_p \geq C_p\, 2^{n/2}$, for some $C_p > 0$. Next, we consider, for some $\alpha > 0$ to be determined, the function

$$Q_n(x) = \sum_{k=2^n}^{2^{n+1}-1} b_k\, e^{2\pi i k x}, \text{ where } b_k = \begin{cases} 2^{-n\alpha} & \text{if } a_k = 1, \\ 2^{-n\alpha} - 2^{-n} & \text{if } a_k = 0. \end{cases}$$

Then,

$$\|Q_n\|_p \leq C_p\ 2^{n(1-1/p-\alpha)} +\ C'_p\ 2^{-n/p} +\ C''_p\ 2^{-n/2},$$

thus the function

$$f(x) = \sum_{n=1}^{\infty} Q_n(x)$$

satisfies

$$\|f\|_p < \infty \text{ if } \alpha > 1 - \frac{1}{p}.$$

On the other hand,

$$\sum_{|\hat{f}(k)| \geq 2^{-n\alpha}} \hat{f}(k) e^{2\pi i\, k\, x} = \sum_{|k| \leq 2^n} \hat{f}(k) e^{2\pi i\, k\, x} + 2^{-n\alpha} P_n(x),$$

and so

$$\begin{aligned} \left\| \sum_{|\hat{f}(k)| \geq 2^{-n\alpha}} \hat{f}(k) e^{2\pi i\, k\, x} \right\|_p &\geq 2^{-n\alpha}\, \|P_n\|_p - O(1) \\ &\geq C_p 2^{n(1/2-\alpha)} - O(1). \end{aligned}$$

Consequently, for each $p < 2$, we can find an α, $1 - 1/p < \alpha < 1/2$, such that

$$\|f\|_p < \infty \text{ and } \limsup_{\lambda \to 0^+} \|\tilde{S}_\lambda f\|_p = \infty.$$

This proves part b) of Theorem 1.

4. The modified partial sums. Now we consider, for each $\delta > 0$, the modified partial sums

$$S_N^\delta f(x) = \sum_{\substack{|k|\ \leq\ N \\ |\hat{f}(k)|\ \geq\ N^{-\delta}}} \hat{f}(k) e^{2\pi i k x}.$$

Case $\delta \geq \frac{1}{2}$. For $r \leq 2$, let us compare these operators with the following partial sums:

$$\begin{aligned} \|S_N^\delta f - S_N f\|_r &= \left(\int_0^1 |S_N^\delta f(x) - S_N f(x)|^r dx \right)^{1/r} \\ &= \left(\int_0^1 \left| \sum_{\substack{|k|\ \leq\ N \\ |\hat{f}(k)|\ <\ N^{-\delta}}} \hat{f}(k) e^{2\pi i\, k\, x} \right|^r dx \right)^{1/r} \end{aligned}$$

$$\leq \left(\int_0^1 \left| \sum_{\substack{|k| \leq N \\ |\hat{f}(k)| < N^{-\delta}}} \hat{f}(k) e^{2\pi i\, k\, x} \right|^2 dx \right)^{1/2}$$

$$= \left(\sum_{\substack{|k| \leq N \\ |\hat{f}(k)| < N^{-\delta}}} |\hat{f}(k)|^2 \right)^{1/2} \leq C \left(N\, N^{-2\delta} \right)^{1/2} \leq C\, N^{1/2-\delta}.$$

Therefore,

$$\|S_N^\delta f - S_N f\|_r = O(1) \text{ as } N \to \infty.$$

If $f \in L^r$, the partial sums $S_N f$ tend to f in the L^r-norm. Therefore, applying the triangular inequality, we obtain

$$\left\| S_N^\delta f - f \right\|_r = O(1) \qquad \text{as } N \to \infty.$$

This proves part b) of Theorem 2. Part c) is quite easy now, because if $\delta > \frac{1}{2}$, we get an $o(1)$ as $N \to \infty$, that is, the function is recovered, in norm, when we sum its Fourier series in this way.

Case $\delta < \frac{1}{2}$. We have to make a slight modification of the function f defined in section 3. Let us begin with

$$f_k(x) = \frac{1}{2^{k/2}} \sum_{n=2^k}^{2^{k+1}-1} a_n e^{2\pi i n x},$$

$$\text{with } a_n = \begin{cases} 1 - \frac{1}{\lfloor 2^{k/2\delta} \rfloor} + \frac{1}{n^{1/2\delta}} & \text{if } n \text{ is prime,} \\ 1 - \frac{1}{\lfloor 2^{k/2\delta} \rfloor} & \text{if not.} \end{cases}$$

Thus,

$$f(x) = \sum_k f_k(x) \quad \text{is in } L^p \text{ for any } p < 2.$$

Next, we translate these frequencies to the right:

$$g_k(x) = e^{2\pi i x \left\{ \lfloor 2^{k/2\delta} \rfloor - 2^k \right\}} f_k(x)$$

$$= \frac{1}{2^{k/2}} \sum_{l=\lfloor 2^{k/2\delta} \rfloor}^{\lfloor 2^{k/2\delta} \rfloor + 2^k} a_{l+2^k-\lfloor 2^{k/2\delta} \rfloor} e^{2\pi i l x}.$$

The function $g(x) = \sum_k g_k(x)$ is, of course, in all L^p, $p < 2$. Now, take the sequence

$$a_{k,j} = \frac{1}{\lfloor 2^{k/2\delta} \rfloor^\delta} \left(1 - \frac{1}{\lfloor 2^{k/2\delta} \rfloor} + \frac{1}{\left(j + 2^k - \lfloor 2^{k/2\delta} \rfloor \right)^{1/2\delta}} \right).$$

If we estimate the sums

$$\sum_{\substack{|\nu| \leq a_{k,j}^{-\delta} \\ |\hat{g}(\nu)| \geq a_{k,j}}} \hat{g}(\nu) e^{2\pi i \nu x},$$

it is easy to see that we are just summing

$$\sum_{|\hat{g}(\nu)|\geq a_{k,j}} \hat{g}(\nu)e^{2\pi i\nu x},$$

and we have seen that these sums diverge in norm as $k\to\infty$ with the adequate choice of j.

Case $\delta=\frac{1}{2}$. We can use the same arguments with the Rademacher functions used in the proof of part b) of Theorem 1 to construct, for each $p<2$, a polynomial P_n, with coefficients 0 or 1, such that $\|P_n\|_p \geq C_p\, 2^{\frac{n}{2}}$ for some $C_p>0$; and a polynomial Q_n (putting $\alpha=1/2$ in the definition of its coefficients) in such a way that

$$\|Q_n\|_p \leq C'_p\ 2^{-n/2}\cdot 2^{n(1-1/p)}.$$

Therefore,

$$f(x)=\sum_{n=1}^{\infty} Q_n(x) \text{ satisfies } \|f\|_p \leq C'_p \sum_{n=1}^{\infty} 2^{-n(1/p-1/2)} <\infty.$$

On the other hand,

$$\sum_{\substack{|k|\ \leq\ 2^n\\ |\hat{f}(k)|\ \geq\ 2^{-n/2}}} \hat{f}(k)e^{2\pi i\,k\,x} = \sum_{|k|\leq 2^{n-1}} \hat{f}(k)e^{2\pi i\,k\,x} + 2^{-n/2}P_n(x),$$

and so

$$\begin{aligned}\left\| \sum_{\substack{|k|\ \leq\ 2^n\\ |\hat{f}(k)|\ \geq\ 2^{-n/2}}} \hat{f}(k)e^{2\pi i\,k\,x} - f\right\|_p &\geq 2^{-n/2}\,\|P_n\|_p - \left\|\sum_{k=n}^{\infty} Q_k\right\|_p\\ &\geq \frac{C_p}{\sqrt{2}} - o(1) \qquad \text{as } n\to\infty.\end{aligned}$$

5. Final remarks. With the use of Gaussian sums, one may produce explicit examples of functions $f\in L^p(\mathbf{T})$, $p<\frac{4}{3}$, such that

$$\limsup_{\lambda\to 0^+}\left|\sum_{|\hat{f}(k)|\geq\lambda} \hat{f}(k)e^{2\pi ik\,x}\right| =\infty \quad \text{ for almost every } x\in\mathbf{T}.$$

The construction is as follows. Take

$$f_k(x)=\sum_{2^{2k}}^{2^{2k+2}-1} a_n\,\cos(2\pi nx)$$

$$\text{with } a_n=\begin{cases} 2^{-k/2+k\epsilon}-2^{-3k}, & \text{if} \quad n\neq s^2,\\ 2^{-k/2+k\epsilon}-2^{-3k}(2^{2k+2}-|n|)^{-1/2}, & \text{if} \quad n=s^2.\end{cases}$$

Clearly,

$$\|f_k\|_p \sim 2^{k(\epsilon+3/2-2/p)}.$$

For each $p < 4/3$, taking ϵ small enough, we have that

$$f(x) = \sum_{k=1}^{\infty} f_k(x) \quad \in L^p.$$

Next, we will use the following facts.

FACT 2. *If $(P,Q) = 1$, with $\frac{M}{2} \le Q \le M$ and $Q \not\equiv 2 \bmod 4$, then*

$$\sup_{1\le k\le M} \left| \sum_{j=M}^{M+k} e^{2\pi i j^2 P/Q} \right| \ge C\sqrt{Q}.$$

FACT 3. *If $|x-y| \le \frac{1}{M^2}$, then*

$$\sup_{1\le k\le M} \left| \sum_{j=M}^{M+k} e^{2\pi i j^2 x} \right| \ge C \sup_{1\le k\le M} \left| \sum_{j=M}^{M+k} e^{2\pi i j^2 y} \right|.$$

FACT 4. *For each $x \in [0,1)$, let us consider the sequence of convergents $\{P_n/Q_n\}$ of its continuous fraction expansion. Then, for all irrational x, there are infinite Q_n, which are not congruent with 2 mod 4.* Consider the function f defined by

$$f(x) = \sum_k f_k(x) = \sum_\nu \hat{f}(\nu)\, e^{2\pi i \nu x}.$$

Take an irrational x and its sequence $\{Q_n\}$ of denominators not congruent with 2 mod 4. It determines dyadic blocks,

$$2^{n-1} \le Q_n \le 2^n.$$

We introduce the coefficients

$$a_{n,j} = \frac{1}{2^{n/2-n\epsilon}} - \frac{1}{2^{3n}\sqrt{2^{2n+2}-|j|}},$$

where n identifies the dyadic block previously selected and j, $2^{2n} < j < 2^{2n+2}$, is chosen so that

$$\left| \sum_{\nu=2^n}^{k(j)} e^{2\pi i \nu^2 P_n/Q_n} \right| \ge C\sqrt{Q_n},$$

where $k(j)$ is the first integer less or equal $\sqrt{j}$. Then,

$$\begin{aligned} \left| \sum_{|\hat{f}(\nu)|\ge a_{n,j}} \hat{f}(\nu) e^{2\pi i \nu x} \right| &\ge \frac{1}{2^{n/2-n\epsilon}} \left| \sum_{s=2^n}^{k(j)} e^{2\pi i s^2 x} \right| + O(1) \\ &\ge \frac{C}{2^{n/2-n\epsilon}} \sqrt{Q_n} + O(1) \ge C\, 2^{n\epsilon} + O(1). \end{aligned}$$

Hence,

$$\sup_{\lambda\to 0^+} \left| \sum_{|\hat{f}(\nu)|\ge\lambda} \hat{f}(\nu) e^{2\pi i \nu x} \right| = \infty \quad \text{for almost all } x \in [0,1).$$

As we stated in the introduction, Körner [2] obtained almost everywhere divergence for functions f in the class $L^2(\mathbf{T})$.

STABILITY AND LINEAR INDEPENDENCE ASSOCIATED WITH SCALING VECTORS*

JIANZHONG WANG†

Abstract. In this paper, we discuss stability and linear independence of the integer translates of a scaling vector $\Phi = (\phi_1, \ldots, \phi_r)^T$, which satisfies a matrix refinement equation

$$\Phi(x) = \sum_{k=0}^{n} P_k \Phi(2x - k),$$

where (P_k) is a finite matrix sequence. We call $P(z) = \frac{1}{2}\sum P_k z^k$ the symbol of Φ. Stable scaling vectors often serve as generators of multiresolution analyses (MRAs) and therefore play an important role in the study of multiwavelets. Most useful MRA generators are also linearly independent.

The purpose of this paper is to characterize stability and linear independence of the integer translates of a scaling vector via its symbol. A polynomial matrix $P(z)$ is said to be two-scale similar to a polynomial matrix $Q(z)$ if there is a polynomial matrix $T(z)$ such that $P(z) = T(z^2)Q(z)T^{-1}(z)$. This kind of factorization of $P(z)$ is called two-scale factorization. We give a necessary and sufficient condition, in terms of two-scale factorization of the symbol, for stability and linear independence of the integer translates of a scaling vector.

Key words. stability, linear independence, scaling vectors, multiwavelets, multiresolution analysis, two-scale similarity

1. Introduction.

In this paper, we discuss stability and linear independence of the integer translates of a scaling vector. A distribution vector

$$\Phi(x) = (\phi_1(x), \phi_2(x), \ldots, \phi_r(x))^T, \quad x \in \mathbb{R},$$

is said to be a scaling vector if it is compactly supported and satisfies a matrix refinement equation

$$\Phi(x) = \sum_{k\in\mathbb{Z}} P_k \Phi(2x - k), \tag{1.1}$$

where the matrix sequence $(P_k)_{k\in\mathbb{Z}}$ is called a *mask* of Φ. Taking the Fourier transform of both sides of (1.1), we obtain

$$\hat{\Phi}(\omega) = P(z)\hat{\Phi}(\omega/2), \qquad z = e^{-i\omega/2}, \tag{1.2}$$

where $P(z) := \frac{1}{2}\sum P_k z^k$ is a *symbol* of Φ. We call $\hat{\Phi}(0)$ the *moment* (of order 0) of Φ since $\hat{\Phi}(0) = \int_{\mathbb{R}} \Phi(x)dx$. When $\hat{\Phi}(0) = 0$, we call Φ a zero-moment scaling vector. We will characterize stability and linear independence of the integer translates of a scaling vector via a special factorization of its symbol. Our study of scaling vectors is based on shift-invariant spaces. Hence, we first introduce some notions and results in the theory of shift-invariant spaces.

Let S be a linear space of distributions on $\mathbb{R}$. We say that S is *shift-invariant* if

$$f \in S \quad \Longrightarrow \quad f(\cdot - j) \in S \quad \forall j \in \mathbb{Z}.$$

We are interested in shift-invariant spaces generated by entries of a scaling vector [4]. In this paper, since only scaling vectors are considered, any distribution vector is assumed to be compactly supported. Let l denote the space containing all sequences of complex numbers and l_0 denote the space of all compactly supported sequences in l. For a distribution vector Φ, the semiconvolution of Φ with a vector sequence $\mathbf{a} := (\mathbf{a}_k) \in (l)^r$, denoted by $\Phi * \mathbf{a}$, is defined by

$$\Phi * \mathbf{a} = \sum_{j=1}^{r} \sum_{k \in \mathbb{Z}} a_{j,k} \phi_j(x - k).$$

We define

$$S_0(\Phi) := \{\Phi * \mathbf{a}; \quad \mathbf{a} \in (l_0)^r\},$$

$$S(\Phi) := \{\Phi * \mathbf{a}; \quad \mathbf{a} \in (l)^r\},$$

and, if $\Phi \in (L^p)^r$, $1 \le p \le \infty$,

$$S_p(\Phi) := \mathrm{clos}_{L^p}(S_0(\Phi)).$$

It is obvious that these sets are shift-invariant spaces of functions and distributions. The vector Φ is called the generator of $S(\Phi)$ ($S_0(\Phi)$, $S_p(\Phi)$).

For $\Phi \in (L^p)^r, 1 \le p \le \infty$, its L^p norm is defined by $\|\Phi\|_p = (\sum_{i=1}^r \|\phi_i\|_p^p)^{1/p}$. Similarly, for a vector sequence $\mathbf{a} \in (l^p)^r$, its l^p norm is $\|\mathbf{a}\|_p = (\sum_{j=1}^r \sum_{k \in \mathbb{Z}} |a_{j,k}|^p)^{1/p}$. The integer translates of a distribution vector $\Phi \in (L^p)^r$ are said to be *l^p-stable* ($1 \le p \le \infty$) if there exist two positive constants C_1 and C_2 such that, for any $\mathbf{a} \in (l^p)^r$,

$$C_1 \|\mathbf{a}\|_p \le \|\Phi * \mathbf{a}\|_p \le C_2 \|\mathbf{a}\|_p. \tag{1.3}$$

It is known that (1.3) holds if and only if the r sequences

$$(\hat{\phi}_l(\omega + 2k\pi))_{k \in \mathbb{Z}}, \quad l = 1, 2, \ldots, r, \tag{1.4}$$

are linearly independent for all $\omega \in \mathbb{R}$ (see [12]), where $\hat{f}$ denotes the Fourier transform of function f:

$$\hat{f}(\omega) := \int_{x \in \mathbb{R}} f(x) \exp(-ix\omega)\, dx.$$

Note that the linear independence of sequences (1.4) does not depend on p and that it does make sense even for the distribution vectors not in $(L^p)^r$. (Recall that distribution vectors in this paper are assumed to be compactly supported. Hence, their Fourier transforms are entire function vectors.) Therefore, we give the following definition.

A distribution vector Φ is said to have *stable* integer translates if the sequences in (1.4) are linearly independent for all $\omega \in \mathbb{R}$ [12].

Another important notion for distribution vectors is linear independence.

A distribution vector Φ is said to have *linearly independent* integer translates if for any $\mathbf{a} \in (l)^r$, $\Phi * \mathbf{a} = \mathbf{0} \Longrightarrow \mathbf{a} = \mathbf{0}$.

Jia and Micchelli in [12] proved the following result. The integer translates of Φ are linearly independent if and only if the sequences in (1.4) are linearly independent for all $\omega \in \mathbb{C}$. Hence, the linear independence of the integer translates of Φ implies the stability of the integer translates of Φ.

For a distribution vector, we also introduce the notion of finitely linear independence.

A distribution vector Φ is said to have *finitely linearly independent* integer translates if for any $\mathbf{a} \in (l_0)^r$, $\Phi * \mathbf{a} = \mathbf{0} \Longrightarrow \mathbf{a} = \mathbf{0}$.

It is clear that if the integer translates of Φ are stable (or linearly independent), then they also are finitely linearly independent. But the converse is not true.

For convenience, in the rest of the paper, we will simply say that Φ is *stable* (*linearly independent, finitely linearly independent*) instead of that Φ has *stable* (*linearly independent, finitely linearly independent*) integer translates.

Stability and linear independence are important properties of distribution vectors. Bases of shift-invariant spaces are often required to be stable so that the duality principle can be applied efficiently (see [1], [2]). In wavelet theory, generators of MRAs are stable. Moreover, most useful generators of MRAs also are linearly independent. Hence, it is desirable to give a criterion for stability and linear independence of scaling vectors in terms of their symbols.

Scaling vectors are discussed in several papers for different purposes. Goodman and Lee [6] and Goodman, Lee, and Tang [7] discussed scaling vectors in generality and constructed multiwavelets using MRAs generated by scaling vectors. In [8], Heil and Colella discussed the existence and uniqueness of the solution of a matrix refinement equation, and the regularity of the solution as well. Discussions of the supports of scaling vectors can be found in Massopust, Ruch, and Van Fleet [15]; Ruch, So, and Wang [19]; and So and Wang [20]. Approximation order provided by scaling vectors was studied by Heil, Strang, and Strela [9]; Jia, Riemenschneider, and Zhou [13]; and Plonka [16]. In [16], Plonka introduced two-scale similarity for the symbol of a scaling vector to characterize its approximation order. This method also was successfully applied in the construction of the scaling vectors with required regularity (see [3]) and with symmetry (see [17], [21]).

In this paper, we use two-scale similarity to characterize stability, linear independence, and finitely linear independence of scaling vectors. In section 2, we discuss stability and linear independence of a distribution vector. A result of [11] shows that any generator of a shift-invariant space can be obtained as a finitely transformed linearly independent generator in the same space. Using this result, we obtain necessary and sufficient conditions for stability (linear independence) of a scaling vector in terms of properties of the corresponding transform. In section 3, we discuss two-scale similarity of the symbol of a scaling vector. Based on the results in section 2, we derive necessary and sufficient conditions for stability (linear independence) of a scaling vector in terms of two-scale similarity. Some examples are given in section 4.

2. Transform of generators of a shift-invariant space. In this section, we discuss stability and linear independence of a distribution vector. We denote by $\dim \Phi$ the dimension (i.e., the number of the components) of a distribution vector Φ. We start with the following result in [11].

THEOREM 2.1 (Jia). *Let Φ be a distribution vector. Then there exists a linearly independent distribution vector $\Psi \in S(\Phi)$ such that $\dim \Psi \leq \dim \Phi$, $\Phi \subset S_0(\Psi)$, and*

$S(\Psi) = S(\Phi)$.

We will call $\dim \Psi$ the *index* of Φ and denote it by $\Phi^\#$. It is obvious that $\Phi^\# \le \dim \Phi$, and $\Phi^\# < \dim \Phi$ if and only if Φ is finitely linearly dependent.

Let Ψ and Φ be two generators of a shift-invariant space S. Then there is a rational function matrix $T(z)$ such that $\hat{\Phi}(\omega) = T(e^{-i\omega})\hat{\Psi}(\omega)$, where $T(z)$ is called the *transform* (matrix) from Ψ to Φ. By Theorem 2.1, if $\Psi \in S(\Phi)$ is linearly independent, then the transform $T(z)$ is a Laurent polynomial matrix. We now introduce some notations for transform matrices. In the rest of this paper, a polynomial always means a Laurent polynomial. We denote the polynomial ring over $\mathbb{C}$ by $\mathcal{P}$ and denote the field of rational functions over $\mathbb{C}$ by $\mathcal{R}$. We shall simply call a polynomial matrix a *P-matrix* and call a matrix with rational function entries an *R-matrix*. The set of all $r \times s$ P-matrices is denoted by $\mathcal{P}^{r\times s}$, and the set of all $r \times s$ R-matrices is denoted by $\mathcal{R}^{r\times s}$. When $r = s$, we use $\mathcal{P}^r$ ($\mathcal{R}^r$) instead of $\mathcal{P}^{r\times r}$ ($\mathcal{R}^{r\times r}$). A matrix $P(z) \in \mathcal{P}^r$ is said to be invertible if there is an R-matrix $R(z)(:= P^{-1}(z)) \in \mathcal{R}^r$ such that $R(z)P(z) = I$, where I is the identity matrix, and $P(z)$ is said to be *invertible everywhere* if $P(z)$ is invertible for any $z \in \mathbb{C} \setminus \{0\}$. Hence, an invertible polynomial matrix may not be invertible everywhere. If $P(z)$ is invertible everywhere, then $\det P(z) = cz^k$ with $c \neq 0$, which implies that its inverse $P^{-1}(z)$ is also a polynomial matrix. For a nonsquare P-matrix, its rank and its everywhere rank can be defined in the same way. For an arbitrary P-matrix, the following three types of operations are called *elementary row (column) operations*:

1. multiplying the ith row (column) by cz^k, where c is a nonzero constant and k is an integer;
2. interchanging the ith and the jth row (column);
3. adding the product of $p(z) \in \mathcal{P}$ and the jth row(column) to the ith row (column), where $i \neq j$.

A matrix that performs an elementary operation is said to be an *elementary P-matrix*, and a finite product of elementary matrices is said to be a *fundamental P-matrix*. It is clear that a P-matrix is fundamental if and only if it is invertible everywhere. Recall that a (nonsquare) everywhere full rank P-matrix can always be extended to a (square) fundamental P-matrix. Hence, for convenience, we also call a (nonsquare) everywhere full rank matrix a fundamental P-matrix.

Fundamental P-matrices play an important role in the study of transforms between the generators of a shift-invariant space. The first observation is that if $\dim \Phi = \dim \Psi$ and the transform from Ψ to Φ is a fundamental matrix, then $S(\Phi) = S(\Psi)$ and Φ is linearly independent (finitely linearly independent, stable) if and only if Ψ is linearly independent (finitely linearly independent, stable).

Generally, let Φ and Ψ be two generators of a shift-invariant space S. The transform T from Ψ to Φ is not necessarily fundamental. However, since both Φ and Ψ are compactly supported, T is at least an R-matrix, and T reduces to a P-matrix if $\Phi \in S_0(\Psi)$.

Now we begin to discuss finitely linear dependence with the following lemma.

LEMMA 2.2. *If Φ is finitely linearly dependent, then there is a finitely linearly independent distribution vector $\Psi \subset S_0(\Phi)$ such that $\dim \Psi = \Phi^\#$, $S_0(\Psi) = S_0(\Phi)$, and therefore the transform matrix from Ψ to Φ is fundamental.*

Proof. Set $r = \dim \Phi$ and $s = \Phi^\#$. By Theorem 2.1, there is a linearly independent generator $\Phi_I \subset S(\Phi)$ such that $\dim \Phi_I = s$ and $\Phi \subset S_0(\Phi_I)$. Therefore, there is a full rank matrix $T(z) \in \mathcal{P}^{r\times s}$ such that $\hat{\Phi}(\omega) = T(e^{-i\omega})\hat{\Phi}_I(\omega)$. Let $D(z)$ be the canonical Smith's form of $T(z)$. Since $T(z)$ has full rank, we have $D(z) = \binom{D_s}{O}$,

where $D_s(z) = \mathrm{diag}\{d_1(z), d_2(z), \ldots, d_s(z)\}$ with $d_i(z) \neq 0, 1 \leq i \leq s$, and O is the $(r-s) \times s$ zero matrix. Furthermore, there are two fundamental matrices $L(z) \in \mathcal{P}^r$ and $R(z) \in \mathcal{P}^s$ such that

$$T(z) = L(z)D(z)R(z). \tag{2.1}$$

Defining Ψ_I by

$$\hat{\Psi}_I(\omega) = D(e^{-i\omega})R(e^{-i\omega})\hat{\Phi}_I(\omega),$$

we obtain $\Psi_I = (\psi_1, \psi_2, \ldots, \psi_s, 0, \ldots, 0)^T$. Let $\Psi = (\psi_1, \psi_2, \ldots, \psi_s)^T$ and $L_s(z)$ be the $r \times s$ matrix containing the first s columns of $L(z)$. Then Ψ is finitely linearly independent and $\hat{\Phi}(\omega) = L_s(z)\hat{\Psi}(\omega)$, which implies that $\Phi \subset S_0(\Psi)$. On the other hand, we also have $\hat{\Psi}(z) = L\hat{}_s(e^{-i\omega})\hat{\Phi}(\omega)$, where $L\hat{}_s(z)$ is the $s \times r$ matrix containing the first s rows of $L^{-1}(z)$. Since $L(z)$ is fundamental, so are $L^{-1}(z)$, $L_s(z)$, and $L\hat{}_s(z)$. Hence, $\Psi \subset S_0(\Phi)$. The proof is completed. □

The following theorem characterizes finitely linear dependence of distribution vectors.

THEOREM 2.3. *A distribution vector Φ ($\dim \Phi = r$) is finitely linearly dependent if and only if there exists a nonidentity matrix $T(z) \in \mathcal{P}^r$ such that $\hat{\Phi}(\omega) = T(e^{-i\omega})\hat{\Phi}(\omega)$.*

Proof. "$\Longrightarrow$". Set $\Phi^{\#} = s$. Since Φ is finitely linearly dependent, $s < r$. Let Ψ_I, Ψ, $L(z)$, $L_s(z)$, and $L\hat{}_s(z)$ be defined as in the proof of the above lemma. Then we have $\hat{\Phi}(\omega) = L_s(e^{-i\omega})L_s\hat{}(e^{-i\omega})\hat{\Phi}(\omega)$ and $L\hat{}_s(e^{-i\omega})L_s(e^{-i\omega}) \neq I$.

"$\Longleftarrow$". Suppose that there is a P-matrix $T(z) \neq I$ such that

$$\hat{\Phi}(\omega) = T(e^{-i\omega})\hat{\Phi}(\omega).$$

Then we have

$$0 = (I - T(e^{-i\omega}))\hat{\Phi}(\omega),$$

which implies that Φ is finitely linearly dependent. □

Now we characterize linear independence of a distribution vector.

THEOREM 2.4. *Φ is linearly dependent if and only if there is a distribution vector $\Psi \subset S(\Phi)$ and a nonfundamental P-matrix $P(z)$ such that*

$$\hat{\Phi}(\omega) = P(e^{-i\omega})\hat{\Psi}(\omega). \tag{2.2}$$

Proof. "$\Longrightarrow$". If Φ is linearly dependent, then, by [12], there is a nonzero vector (a_i) such that the distribution $\phi = \sum_{i=1}^{r} a_i\phi_i$ is linearly dependent. Without loss of generality, we may assume $a_1 = 1$. By [18], there is a polynomial $p(z)$ with at least one zero in $\mathbb{C} \setminus \{0\}$ and a distribution g in $S(\phi)$ such that $\hat{\phi}(\omega) = p(e^{-i\omega})\hat{g}(\omega)$. Therefore, we have

$$\begin{pmatrix} \hat{\phi}_1(\omega) \\ \hat{\phi}_2(\omega) \\ \vdots \\ \hat{\phi}_r(\omega) \end{pmatrix} = \begin{pmatrix} p(e^{-i\omega}) & -a_2 & \cdots & -a_r \\ & 1 & & \\ & & \ddots & \\ & & & 1 \end{pmatrix} \begin{pmatrix} \hat{g}(\omega) \\ \hat{\phi}_2(\omega) \\ \vdots \\ \hat{\phi}_r(\omega) \end{pmatrix},$$

where $p(z)$ has at least one zero in $\mathbb{C} \setminus \{0\}$. Hence, the transform matrix is not fundamental.

"$\Longleftarrow$". Assume there exists a distribution vector $\Psi \subset S(\Phi)$ and a nonfundamental P-matrix $P(z)$ such that (2.2) holds. Write $\dim \Phi = r$ and $\dim \Psi = s$. If $r > s$, then Φ is finitely linearly dependent. We now assume $r \leq s$. Choose two square fundamental matrices $L(z)$ and $R(z)$ so that $P(z) = L(z)D(z)R(z)$, where $D(z)$ is the canonical Smith's form of $P(z)$. Setting $\hat{\Phi}_l(\omega) = L^{-1}(e^{-i\omega})\hat{\Phi}(\omega)$ and $\hat{\Psi}_r(\omega) = R(e^{-i\omega})\hat{\Psi}(\omega)$, respectively, we have $\hat{\Phi}_l(\omega) = D(e^{-i\omega})\hat{\Psi}_r(\omega)$. Let $D = \begin{pmatrix} D_r & O \end{pmatrix}$, where $D_r(e^{-i\omega}) = \operatorname{diag}\{d_1(e^{-i\omega}), \ldots, d_r(e^{-i\omega})\}$ and O is the $r \times (s-r)$ zero matrix. Since $P(z)$ is nonfundamental, at least one of $d_1(e^{-i\omega}), \ldots, d_r(e^{-i\omega})$ vanishes at an $\omega_0 \in \mathbb{C}$. Hence, one of the components of Φ_l is linearly dependent. It follows that Φ is also linearly dependent. ∎

COROLLARY 2.5. *The transform between two linearly independent generators (of a shift-invariant space) must be a fundamental matrix.*

We have similar results for stability of a distribution vector.

THEOREM 2.6. *Let* $\Gamma = \{z \in \mathbb{C}; \quad |z| = 1\}$. Φ *is unstable if and only if there is a distribution vector* $\Psi \subset S(\Phi)$ *such that the transform from* Ψ *to* Φ *is a P-matrix which is singular at a value* $z \in \Gamma$.

COROLLARY 2.7. *The transform between two stable generators (of a shift-invariant space) is an R-matrix invertible over* Γ.

3. Stability and linear independence of a scaling vector. We now characterize the linear independence (finitely linear independence, stability) of a scaling vector in terms of its symbol. We are interested in the scaling vector Φ with a P-matrix symbol. It is clear that if a scaling vector Φ has symbol $P(z)$, then its moment $\hat{\Phi}(0)$ satisfies $\hat{\Phi}(0) = P(1)\hat{\Phi}(0)$, which implies that $\hat{\Phi}(0)$ is either a zero vector or a 1-eigenvector of $P(1)$. If $P(1)$ has more than one 1-eigenvectors, then different scaling vectors may share one symbol.

We now assume that Φ is a solution of (1.1) with a nonvanished moment $\mathbf{v}$, which is a 1-eigenvector of $P(1)$. If (1.1) also has a nontrivial zero-moment solution Φ_0, then all functions $\Phi + c\Phi_0$, $c \in \mathbb{C}$, have the same symbol $P(z)$ and the same moment $\mathbf{v}$. On the other hand, if two scaling vectors Φ_1 and Φ_2 have the same symbol and the same moment, then $\Phi_1 - \Phi_2$ is a zero-moment scaling vector. Hence, we have the following conclusion. Let $\mathbf{v} \neq 0$ be a 1-eigenvector of $P(1)$. The solution of (1.1) with a given moment $\mathbf{v}$ is unique if and only if (1.1) has no nontrivial zero-moment solution.

As mentioned in [8], if (1.1) has nontrivial zero-moment solutions, then $P(1)$ must have eigenvalue 2^β, $(\beta \geq 1, \beta \in \mathbb{Z})$. We now denote by $E(M)$ the set of all eigenvalues of matrix M, and let

$$\mathcal{O}P^r = \left\{A \in \mathcal{P}^r; \quad 2^\beta \notin E(A(1)),\ \beta \in \mathbb{Z},\ \beta \geq 1\right\}$$

and

$$\mathcal{S}P^r = \left\{A \in \mathcal{O}P^r; \quad 1 \in E(A(1))\right\}.$$

Therefore, if $P \in \mathcal{S}P^r$ and $\mathbf{v}$ is a 1-eigenvector of $P(1)$, then (1.1) has a unique solution Φ with the moment $\mathbf{v}$.

In contrast with the fact that several scaling vectors may share a symbol, a scaling vector may have more than one symbol. However, the following lemma confirms the uniqueness of the symbol of a finitely linearly independent scaling vector.

LEMMA 3.1. *The symbol of a scaling vector* Φ *(with* $\dim \Phi = r$*) is unique in* $\mathcal{P}^r$ *if and only if* Φ *is finitely linearly independent.*

Proof. Assume Φ is finitely linearly independent. Then $\dim \Phi = \Phi^{\#}$. If Φ satisfies the two scaling equations

$$\Phi(x) = \sum_{k\in\mathbb{Z}} C_k \Phi\left(2x-k\right)$$

and

$$\Phi(x) = \sum_{k\in\mathbb{Z}} D_k \Phi\left(2x-k\right),$$

then

$$0 = \sum_{k\in\mathbb{Z}} (C_k - D_k)\Phi\left(2x-k\right). \tag{3.1}$$

Since $\Phi(\cdot)$ is finitely linearly independent, so is $\Phi(2\cdot)$. By $(C_k - D_k) \in (l_0)^{r\times r}$, we have $C_k - D_k = 0$. The converse is trivial. □

Since the relation between a scaling function and its symbols has been cleared, we are ready to characterize scaling vectors via their symbols. The notion of two-scale similarity plays an important role in characterizing scaling vectors [17]. A matrix $P \in \mathcal{P}^r$ is said to be *two-scale similar* to $Q \in \mathcal{P}^r$ if there exists an invertible matrix $T \in \mathcal{P}^r$ such that

$$P(z) = T(z^2)Q(z)T^{-1}(z). \tag{3.2}$$

The matrix $T(z)$ in (3.2) is called *two-scale similar transform.* Since the matrix $T^{-1}(z)$ need not necessarily be a polynomial matrix, $T(z)$ may be singular at some points in $\mathbb{C}\setminus\{0\}$. Hence, P being two-scale similar to Q does not imply Q being two-scale similar to P. However, if P is two-scale similar to Q with a fundamental transform, then Q also is two-scale similar to P. In this case, we say that P and Q are *fundamentally two-scale similar*. As shown in section 2, Ψ and Φ with $S(\Phi) = S(\Psi)$ have the same linear independence (finitely linear independence, stability) if and only if their symbols P and Q are fundamentally two-scale similar.

The following fact is often used in the rest. If P is fundamentally two-scale similar to Q with the two-scale transform T, and Φ satisfies the two-scaling equation

$$\hat{\Phi}(\omega) = P(e^{-i\omega/2})\hat{\Phi}(\omega/2),$$

then the scaling vector Ψ_I determined by

$$\hat{\Psi}_I(\omega) = T^{-1}(e^{-i\omega})\hat{\Phi}(\omega) \tag{3.3}$$

satisfies

$$\hat{\Psi}_I(\omega) = Q(e^{-i\omega/2})\hat{\Psi}_I(\omega/2). \tag{3.4}$$

The following theorem characterizes a finitely linearly dependent scaling vector.

THEOREM 3.2. *Let $P \in \mathcal{S}P^r$ be a symbol of Φ ($\dim\Phi = r$). Then Φ is finitely linearly dependent if and only if the following two conditions are satisfied.*

(1) *$P(z)$ is fundamentally two-scale similar to a matrix*

$$Q(z) = \begin{pmatrix} Q_s(z) & Y(z) \\ 0 & X(z) \end{pmatrix}, \tag{3.5}$$

where $Q_s \in \mathcal{S}P^s, X \in \mathcal{O}P^{r-s}$, *and* $s < r$.

(2) *Let* T *be the two-scale similar transform:* $P(z) = T(z^2)Q(z)T^{-1}(z)$. *Then the last* $r - s$ *components of* $T^{-1}(1)\hat{\Phi}(0)$ *vanish; that is*

$$T^{-1}(1)\hat{\Phi}(0) = (u_1, \ldots, u_s, 0, \ldots, 0)^T. \tag{3.6}$$

Furthermore, if $P(1)$ *has only a single* 1*-eigenvector, then the solution* Φ *of* (1.1) *with* $\hat{\Phi}(0) \neq 0$ *is unique, and therefore* Φ *is finitely linearly dependent if and only if* (1) *holds.*

Proof. " $\Longrightarrow$ ". Assume Φ is finitely linearly dependent with a symbol $P \in \mathcal{S}P^r$. By Lemma 2.2, there is a finitely linearly independent scaling vector Ψ such that $\hat{\Phi}(\omega) = \overline{T}(e^{-i\omega})\hat{\Psi}(\omega)$, where $\overline{T}(z)$ is an $r \times s$ fundamental matrix. Let $\Psi_I = (\psi_1, \ldots, \psi_s, 0, \ldots, 0)^T$ and $T(z)$ be an $r \times r$ fundamental matrix extended from $\overline{T}(z)$. Then $\hat{\Phi}(\omega) = T(e^{-i\omega})\hat{\Psi}_I(\omega)$. Let $Q(z) = T^{-1}(z^2)P(z)T(z)$. Then, setting $z = e^{-i\omega/2}$, we obtain

$$\begin{aligned}\hat{\Psi}(\omega) &= T^{-1}(z^2)\hat{\Phi}(\omega) = T^{-1}(z^2)P(z)\hat{\Phi}(\omega/2)\\ &= T^{-1}(z^2)P(z)T(z)\hat{\Psi}(\omega/2) = Q(z)\hat{\Psi}(\omega/2),\end{aligned}$$

which implies that $Q(z)$ is a symbol of Ψ_I. Writing

$$Q(z) = \begin{pmatrix} Q_s(z) & Y(z) \\ W(z) & X(z) \end{pmatrix},$$

we have

$$\begin{pmatrix} \hat{\Psi}(\omega) \\ 0 \end{pmatrix} = \begin{pmatrix} Q_s(z) & Y(z) \\ W(z) & X(z) \end{pmatrix} \begin{pmatrix} \hat{\Psi}(\omega/2) \\ 0 \end{pmatrix}, \qquad z = e^{-i\omega/2}. \tag{3.7}$$

From (3.7), we obtain $W(z)\hat{\Psi}(\omega/2) = 0$. Since Ψ is finitely linearly independent, by Lemma 3.1, $W(z) = 0$.

We now prove $Q_s \in \mathcal{S}P^s$. From (3.7), we have

$$\hat{\Psi}(\omega) = Q_s(e^{-i\omega/2})\hat{\Psi}(\omega/2), \tag{3.8}$$

which derives $\hat{\Psi}(0) = Q_s(1)\hat{\Psi}(0)$, and therefore 1 is an eigenvalue of $Q_s(1)$. Note that matrix $P(1)$ is similar to matrix $Q(1)$. Hence, they have the same set of eigenvalues. However, all eigenvalues of both $Q_s(1)$ a nd $X(1)$ are also eigenvalues of $Q(1)$. Therefore, we have the following:

$$P \in \mathcal{S}P^r \Longleftrightarrow Q \in \mathcal{S}P^r \Longleftrightarrow Q_s \in \mathcal{S}P^s \text{ and } \ X \in \mathcal{O}P^{r-s},$$

which implies (1).

Choosing $\omega = 0$ in $\hat{\Phi}(\omega) = T(e^{-i\omega})\hat{\Psi}_I(\omega)$, we obtain

$$T^{-1}(1)\hat{\Phi}(0) = (\hat{\psi}_1(0), \ldots, \hat{\psi}_s(0), 0, \ldots, 0)^T,$$

which is (3.6).

" $\Longleftarrow$ ". Let Φ be a scaling vector whose symbol P is fundamentally two-scale similar to a $Q(z)$:

$$P(z) = T(z^2)Q(z)T^{-1}(z),$$

where

$$Q(z) = \begin{pmatrix} Q_s(z) & Y(z) \\ 0 & X(z) \end{pmatrix}, \qquad s < r,$$

with $Q_s \in \mathcal{S}P^s$ and $X \in \mathcal{O}P^{r-s}$, and

$$T^{-1}(1)\hat{\Phi}(0) = (u_1, \ldots, u_s, 0, \ldots, 0)^T := \mathbf{u}_I.$$

We prove that Φ is finitely linearly dependent. Note that

$$Q_s \in \mathcal{S}P^s \text{ and } X \in \mathcal{O}P^{r-s} \Longrightarrow Q \in \mathcal{S}P^r.$$

Besides,

$$Q(1)\mathbf{u}_I = T^{-1}(1)P(1)T(1)\mathbf{u}_I = \mathbf{u}_I.$$

Hence, there is a unique distribution $\Psi_I = (\psi_{I,1}, \ldots, \psi_{I,r})^T$ satisfying (3.4) with the moment $\mathbf{u}_I$. Write $\mathbf{u} = (u_1, \ldots, u_s)^T$. By (3.2) and (3.5), we have $Q_s(1)\mathbf{u} = \mathbf{u}$. Let $\Psi = (\psi_1, \ldots, \psi_s)^T$ be the unique solution of (3.8) with the moment $\mathbf{u}$. Then the scaling vector $(\psi_1, \ldots, \psi_s, 0, \ldots, 0)^T$ is a solution of (3.4) with the moment $\mathbf{u}_I$. Since the solution of (3.4) with the moment $\mathbf{u}_I$ is unique, we have $\Psi_I = (\psi_1, \ldots, \psi_s, 0, \ldots, 0)^T$. By $\hat{\Phi}(\omega) = T(e^{-i\omega})\hat{\Psi}_I(\omega)$, Φ is finitely linearly dependent.

Finally, we prove that if $P(1)$ has only a single 1-eigenvector, then (2) will be unconditionally satisfied. In fact, if $P(1)$ has only a single 1-eigenvector, so do Q and $Q_s(z)$. Let $\mathbf{u} = (u_1, \ldots, u_s)^T$ be the 1-eigenvector of Q_s. Then $\mathbf{u}_I = (u_1, \ldots, u_s, 0, \ldots, 0)^T$ is the only 1-eigenvector (without counting the scalar multiples) of $Q(1)$. Recalling that $\hat{\Phi}(0)$ is the only 1-eigenvector (without counting the scalar multiples) of $P(1)$, we have $T^{-1}(1)\hat{\Phi}(0) = c\mathbf{u}_I = (cu_1, \ldots, cu_s, 0, \ldots, 0)^T$, which implies that (2) is true. □

Remark 1. If $P(1)$ has more than one (linearly independent) 1-eigenvector, then the solutions of (1.1) corresponding to different moments (without counting the scalar multiples) may have differently linearly independent properties. We illustrate this phenomenon in the following example.

Example 1. Let

$$P(z) = \begin{pmatrix} (\frac{1+z}{2})^2 & 0 \\ 0 & (\frac{1+z}{2})^4 \end{pmatrix}.$$

It is clear that $P(z) \in \mathcal{S}P^2$ and vector $(0, 1)$ and $(1, 1)$ are two linearly independent 1-eigenvectors of $P(1)$. Obviously, $P(z)$ is two-scale fundamentally similar to itself with transform $T(z) = I$. Denote by $N_m(x)$ the mth order cardinal B-spline [2]. The scaling vectors $\Phi_1 = (N_2(x), 0)^T$ and $\Phi_2 = (N_2(x), N_4(x))^T$ are solutions of (1.1) with the moments $\hat{\Phi}_1(0) = (1, 0)^T$ and $\hat{\Phi}_2(0) = (1, 1)^T$, respectively. Note that Φ_1 is finitely linearly dependent but Φ_2 is not. Note also that the vector $(1, 0)^T$ satisfies (3.6) while $(1, 1)^T$ does not.

Remark 2. If, in Theorem 3.2, $P(z)$ is merely assumed to be in $\mathcal{P}^r$, then the solution of (1.1) with a certain moment is not necessarily unique. In this case, if a solution of (1.1) Φ with $\hat{\Phi}(0) \neq 0$ is finitely linearly dependent, then its symbol P is still fundamentally two-scale similar to a matrix Q in the form (3.5), but Q_s is no longer necessarily in $\mathcal{S}P^r$ and X is no longer necessarily in $\mathcal{O}P^{r-s}$. On the other hand, if one of Φ's symbols is fundamentally two-scale similar to Q in the form (3.5)

with a matrix X such that the refinement equation $\hat{F}(\omega) = X(e^{-i\omega/2})\hat{F}(\omega/2)$ has only the trivial solution $F = 0$ with $\hat{F}(0) = 0$, and if $\hat{\Phi}(0)$ satisfies the condition (2) in 3.2, then Φ is finitely linearly dependent. The proof of this remark is similar to that for Theorem 3.2.

According to Theorem 3.2, from the set of symbols of a finitely linearly dependent scaling vector, we can select a relatively simple symbol for it.

COROLLARY 3.3. *If Φ ($\dim \Phi = r$) is finitely linearly dependent and $\Phi^{\#} = s$ and one of its symbols is in $\mathcal{S}P^r$, then Φ has a symbol fundamentally two-scale similar to a matrix*

$$\begin{pmatrix} Q_s(z) & 0 \\ 0 & 0 \end{pmatrix}. \tag{3.9}$$

Proof. Let P be a symbol of Φ. By Theorem 3.2, P is fundamentally two-scale similar to a matrix Q in the form (3.5) with a two-scale transform matrix T, and $T^{-1}(1)\hat{\Phi}(0) = (u_1, \ldots, u_s, 0, \ldots, 0)^T$. Let Ψ_I be defined by $\hat{\Phi}(\omega) = T(e^{-i\omega})\hat{\Psi}_I(\omega)$. Since $X \in \mathcal{O}P^r$ and

$$\hat{\Psi}_I(0) = (u_1, \ldots, u_s, 0, \ldots, 0)^T,$$

we have

$$\Psi_I = (\psi_1, \ldots, \psi_s, 0, \ldots, 0)^T,$$

which satisfies

$$\begin{pmatrix} Q_s(e^{-i\omega/2}) & 0 \\ 0 & 0 \end{pmatrix} \hat{\Psi}(\omega/2) = \hat{\Psi}(\omega).$$

Setting

$$\bar{P}(z) = T^2(z) \begin{pmatrix} Q_s(z) & 0 \\ 0 & 0 \end{pmatrix} T^{-1}(z),$$

we have

$$\hat{\Phi}(\omega) = \bar{P}(e^{-i\omega/2})\hat{\Phi}(\omega/2),$$

where $\bar{P}(z)$ is a symbol of Φ. □

We now characterize linear independence of a scaling vector. First, we prove the following lemma.

LEMMA 3.4. *The symbol of a linearly independent scaling vector is a P-matrix.*

Proof. Assume the scaling vector Φ is linearly independent, as is $\Phi(2\cdot)$. By [22], a compactly supported function in $S(\Phi(2\cdot))$ is also in $S_0(\Phi(2\cdot))$. Hence, $\Phi \in S_0(\Phi(2\cdot))$, and therefore its symbol is a P-matrix. □

The following theorem characterizes linear independence of a scaling vector.

THEOREM 3.5. *Assume the scaling vector Φ with nonzero moment is finitely linearly independent and its symbol is a P-matrix $P \in \mathcal{P}^r(\mathcal{S}P^r)$. Then Φ is linearly dependent if and only if P is two-scale similar to a matrix $Q \in \mathcal{P}^r(\mathcal{S}P^r)$ with a nonfundamental two-scale similar transform T such that*

$$\operatorname{rank} T(1) = \operatorname{rank}\left(T(1), \hat{\Phi}(0)\right). \tag{3.10}$$

Remark 3. If the matrix $T(1)$ is nonsingular, then the condition (3.10) is always true. Hence, the condition (3.10) is effective whenever $T(1)$ is singular. Note that the condition (3.10) is equivalent to "there is a $\mathbf{u} \in \mathbb{C}^r$ such that $T(1)\mathbf{u} = \hat{\Phi}(0)$."

To prove this theorem, we need some notations. Let $m > 1$ be an odd integer, and let h_m be the smallest positive integer such that $2^{h_m} \equiv 1 (\mathrm{mod}\, m)$. For a primitive mth root of unit z_0, we call

$$p_m(z) = (z_0 - z)(z_0^2 - z) \cdots (z_0^{2^{h_m-1}} - z)$$

an *m-cycle polynomial*. Since $z_0^{2^{h_m}} = z_0$, it can be verified that $p_m(z_0^{2^l}) = 0$ for any integer $l \geq 0$, and therefore $p_m(z^2) = p_m(z)p_m(-z)$. We say that $p(z)$ has *m-cycle zeros* if $p_m(-z)$ (NOT $p_m(z)$!) is a factor of $p(z)$. When we will not stress the index m, m-cycle zeros and m-cycle polynomials are simply called cycle zeros and cycle polynomials, respectively. A polynomial $p(z)$ is said to have *symmetric zeros* if there is an $\alpha \in \mathbb{C}, \alpha \neq 0$, such that $p(\alpha) = p(-\alpha) = 0$.

Note that any polynomial $p(z)$ has a unique factorization

$$p(z) = cz^k \prod_{j=1}^{l} p_{m_j}(z) \prod_{l=1}^{t} (z - z_i), \tag{3.11}$$

where $p_{m_j}, j = 1, \ldots, l$, are all cycle polynomials, and $z_i \neq 0$, $i = 1, \ldots, t$.

LEMMA 3.6. *Assume the scaling vector Φ's symbol $P \in \mathcal{P}^r$ is two-scale similar to a P-matrix Q,*

$$P(z) = T_c(z^2)Q(z)T_c^{-1}(z), \tag{3.12}$$

with the two-scale transform matrix

$$T_c(z) = \mathrm{diag}(\underbrace{1, 1, \ldots,}_{j-1} c(z), \ldots, 1), \tag{3.13}$$

where $c(z)$ is either $(z - c)$, $c \neq 0$, or an m-cycle polynomial $p_m(z)$. Also assume $\hat{\phi}_j(0) = 0$ whenever $c(z) = z - 1$. Then there is a compactly supported function $\psi \in S(\Phi)$ such that $\hat{\phi}_j(\omega) = c(e^{-i\omega})\hat{\psi}(\omega)$, and therefore Φ is linearly dependent. Furthermore, if $P \in \mathcal{S}P^r$, then $Q \in \mathcal{S}P^r$.

Proof. Without loss of generality, we assume $j = 1$. By (3.12) and (3.13), we have

$$\hat{\phi}_1(\omega) = p_{11}(e^{-i\omega/2})\hat{\phi}_1(\omega/2) + \sum_{i=2}^{r} c(e^{-i\omega})q_{i1}(e^{-i\omega/2})\hat{\phi}_i(\omega/2), \tag{3.14}$$

where $p_{11}(z) = q_{11}(z)\frac{c(z^2)}{c(z)}$.

If $c(z) = z - c$, $c \neq 0$ and 1, then $c(z)$ cannot be a factor of $c(z^2)$. It follows that $c(z^2)$ is a factor of $p_{11}(z)$. Let ω_0 satisfy $e^{-i\omega_0} - c = 0$. We have, for an integer k,

$$\begin{aligned}
\hat{\phi}_1(\omega_0 + 2k\pi) &= p_{11}((-1)^k e^{-i\frac{\omega_0}{2}})\hat{\phi}_1\left(\frac{\omega_0}{2} + k\pi\right) \\
&\quad + \sum_{i=2}^{r} c(e^{-i\omega_0})q_{i1}((-1)^k e^{-i\frac{\omega_0}{2}})\hat{\phi}_i\left(\frac{\omega_0}{2} + \pi\right) \\
&= q_{11}((-1)^k e^{-i\omega_0/2})\frac{c(e^{-i\omega_0})}{c((-1)^k e^{-i\omega_0/2})}\hat{\phi}_1\left(\frac{\omega_0}{2} + k\pi\right) \\
&= 0.
\end{aligned}$$

In the case $c(z) = z - 1$, by the assumption, $\hat{\phi}_1(0) = 0$. For $k \neq 0$, writing $k = 2^l j$ with odd j, we have, by (3.14),

$$\begin{aligned}\hat{\phi}_1(2k\pi) &= p_{11}(e^{-ik\pi})\hat{\phi}_1(k\pi) = (e^{-i2^l j\pi} + 1)q_{11}(e^{-i2^l j\pi})\hat{\phi}_1(2^l j\pi) \\ &= (2q_{11}(1))^l\,(e^{-ij\pi} + 1)q_{11}(-1)\hat{\phi}_1(j\pi) = 0.\end{aligned}$$

We now prove $\hat{\phi}_1(\omega_0 + 2k\pi) = 0, k \in \mathbb{Z}$, for some $\omega_0 \in \mathbb{R}$ in the case $c(z) = p_m(z)$. The proof is similar to that one of Theorem 1 in [14]. For reader's convenience, we include it here. Let z_0 be a primitive mth root. Then z_0 has the form $e^{-i2n\pi/m}$, where n is an integer relatively prime to m, and $p_m(e^{-i2^{d+1}n\pi/m}) = 0$, for all integers $d \geq 0$. We claim that for all integers k,

$$\hat{\phi}_1(2n\pi/m + 2k\pi) = 0. \tag{3.15}$$

To prove (3.15), we write $n + km$ in the form $2^l j$, where l is a nonnegative integer and j is an odd integer. Recalling that $p_m(-z) = p_m(z^2)/p_m(z)$, we have

$$\begin{aligned}&\hat{\phi}_1\left(\frac{2n\pi}{m} + 2k\pi\right) = \hat{\phi}_1(2^{l+1}j\pi/m) \\ &= p_{11}(e^{-i2^l j\pi/m})\hat{\phi}_1\left(\frac{2^l j\pi}{m}\right) + \sum_{i=2}^{r} p_m(e^{-i2^{l+1}j\pi/m})q_{i1}(e^{-i2^l j\pi/m})\hat{\phi}_i\left(\frac{2^l j\pi}{m}\right) \\ &= q_{11}(e^{-i2^l j\pi/m})\frac{p_m(e^{-i2^{l+1}j\pi/m})}{p_m(e^{-i2^l j\pi/m})}\hat{\phi}_1\left(\frac{2^l j\pi}{m}\right) \\ &= p_{m(-}e^{-i2^l j\pi/m})q_{11}(e^{-i2^l j\pi/m})\hat{\phi}_1\left(\frac{2^l j\pi}{m}\right) \\ &= \left(\prod_{t=0}^{l} p_m(-e^{-i2^t j\pi/m})\prod_{t=0}^{l} q_{11}(-e^{-i2^t j\pi/m})\right)\hat{\phi}_1\left(\frac{j\pi}{m}\right).\end{aligned}$$

Hence, in order to prove (3.15) it suffices to show that $p_m(-e^{-ij\pi/m}) = 0$. For this purpose, we invoke Euler's theorem to find an integer $s > l$ such that $2^s \equiv 1 (\mathrm{mod}\, m)$. It follows that

$$j \equiv 2^s j \equiv 2^{s-l}(2^l j) \equiv 2^{s-l}n \pmod{m}. \tag{3.16}$$

Since j is odd, by (3.16), $j - 2^{s-l}n = (2t+1)m$ for some integer t. From this we see that

$$p_m(-e^{-ij\pi/m}) = p_m(e^{-i2^{s-l}n\pi/m}) = 0.$$

In all cases, ϕ_1 is linearly dependent, as is Φ. It is also clear that the function ψ defined by $\hat{\phi}_1(\omega) = c(e^{-i\omega})\hat{\psi}(\omega)$ is compactly supported and in the space $S(\Phi)$.

Finally, we prove $P \in \mathcal{S}P^r \Longrightarrow Q \in \mathcal{S}P^r$. When $c(z) \neq z - 1$, $Q(1)$ is similar to $P(1)$, and therefore $P \in \mathcal{S}P^r \Longleftrightarrow Q \in \mathcal{S}P^r$. When $c(z) = z - 1$, (3.12) implies

$$P(1) = \begin{pmatrix} p_{11}(1) & 0 \\ & P_{r-1}(1) \end{pmatrix}, \qquad Q(1) = \begin{pmatrix} p_{11}(1)/2 & * \\ 0 & P_{r-1}(1) \end{pmatrix}.$$

Therefore, $Q(1)$ preserves all eigenvalues of $P(1)$ except $p_{11}(1)$, which changes to $p_{11}(1)/2$. Note that $P \in \mathcal{S}P^r$. Hence, there is no positive integer β such that $p_{11}(1) =$

2^β. It follows that $p_{11}(1)/2 \notin \{2^\beta; \quad \beta \geq 0\}$ and, therefore, $Q \in \mathcal{O}P^r$. We now prove $1 \in E(Q(1))$ so that $Q \in \mathcal{S}P^r$. Let $\Phi_1 = (\phi_2, \ldots, \phi_r)^T$. Then $P(1)\hat{\Phi}(0) = \hat{\Phi}(0)$ and $\hat{\phi}_1(0) = 0$ imply that $\hat{\Phi}_1(0) \neq 0$ and $P_{r-1}(1)\hat{\Phi}_1(0) = \hat{\Phi}_1(0)$. It follows that $1 \in E(P_{r-1}(1))$ and $1 \in E(Q(1))$. □

The following is the proof of Theorem 3.5.

Proof. "$\Longrightarrow$". If Φ is linearly dependent, then, by Theorem 2.1, there exists a linearly independent scaling vector $\Psi \in S(\Phi)$ such that $\Phi \subset S_0(\Psi)$ and $S(\Psi) = S(\Phi)$. Since Φ is finitely linearly independent, $\dim \Phi = \dim \Psi$. By Lemma 3.4, Ψ's symbol Q is a P-matrix. Let T be the polynomial matrix determined by $\hat{\Phi}(\omega) = T(e^{-i\omega})\hat{\Psi}(\omega)$. Then $P(z)$ is two-scale similar to $Q(z)$ with the transform $T(z)$. By Corollary 2.5, T is nonfundamental. Besides, we have $T(1)\hat{\Psi}(0) = \hat{\Phi}(0)$. Thus, (3.10) is true.

"$\Longleftarrow$ ". We assume $P(z)$ is the symbol of Φ, and $P \in \mathcal{P}^r(\mathcal{S}P^r)$ is two-scale similar to $Q \in \mathcal{P}^r(\mathcal{S}P^r)$ with a nonfundamental two-scale transform matrix $T \in \mathcal{P}^r$. We now factor T into the form $T(z) = L(z)D(z)R(z)$, where L and R both are fundamental and D is the canonical Smith's form of T. It is clear that D is a nonfundamental diagonal matrix. We define Φ_E by $\hat{\Phi}_E(\omega) = L^{-1}(e^{-i\omega})\hat{\Phi}(\omega)$. Then Φ is linearly independent if and only if Φ_E is linearly independent. The symbol of Φ_E is $\tilde{P}(z) = L^{-1}(z^2)P(z)L(z)$. It is obvious that $\operatorname{rank} T(1) = \operatorname{rank}(T(1), \hat{\Phi}(0))$ if and only if $\operatorname{rank} D(1) = \operatorname{rank}(D(1), \hat{\Phi}_E(0))$. Let $\tilde{Q}(z) = R(z^2)Q(z)R^{-1}(z)$. Then $\tilde{P}(z) = D(z^2)\tilde{Q}(z)D^{-1}(z)$. We now factor $D(z)$ into $D(z) = \prod_s T_s(z) \prod_j U_j(z)$, where T_s is the diagonal matrix of the form (3.13) with $\det(T_s(1)) \neq 0$, while $U_j(z)$ is the diagonal matrix of the form (3.13) with $\det(U_j(1)) = 0$. If the product $\prod_s T_s(z)$ has at least one factor, by Lemma 3.6, Φ_E and hence Φ are linearly dependent. Now if $\prod_s T_s(z) = I$, then the product $\prod_j U_j(z)$ has at least one factor. Without loss of generality, we can assume $U_1(z) = \operatorname{diag}(z-1, 1, \ldots, 1)$. It follows that the first row of $D(1)$ is zero. Since there is a $\mathbf{v} \in \mathbb{C}^r$ such that $D(1)\mathbf{v} = \hat{\Phi}_E(0)$, $\hat{\phi}_{E,1}(0) = 0$. By Lemma 3.6, Φ_E and hence Φ are linearly dependent.

The proof of $P \in \mathcal{P}S^r \Longrightarrow Q \in \mathcal{S}P^r$ is similar to that one in Lemma 3.6. □

From Theorem 3.5, we derive a sufficient condition for linear independence of a scaling vector.

COROLLARY 3.7. *Assume the scaling vector Φ is finitely linearly independent and its symbol is a P-matrix $P \in \mathcal{P}^r$. Then Φ is linearly independent if* (i) *the matrix $(P(-1), \hat{\Phi}(0))$ has the full rank, and* (ii) $\det P(z)$ *has neither symmetric zeros nor cycle zeros.*

Proof. Assume that conditions (i) and (ii) hold and Φ is linearly dependent. By Theorem 3.5, there is a P-matrix Q and a nonfundamental P-matrix T such that $P(z) = T(z^2)Q(z)T^{-1}(z)$ and

$$\operatorname{rank} T(1) = \operatorname{rank}(T(1), \hat{\Phi}(0)).$$

Note that

$$\det P(z) = \det Q(z) \det T(z^2) / \det T(z). \tag{3.17}$$

Write $t(z) = \det T(z)$, $p(z) = \det P(z)$, and $q(z) = \det Q(z)$. Then (3.17) becomes $p(z) = q(z)t(z^2)/t(z)$, where t, p, and q are polynomials with $\deg(t) \geq 1$. We factor the polynomial $t(z)$ into $t(z) = (1-z)^s d(z)$ with $d(1) \neq 0$. If $\deg(d) \geq 1$, then $p(z)$ has either symmetric zeros or cycle zeros. This contradicts the condition (ii). Now if $\deg(d) = 0$, then $t(z) = c(1-z)^s$, $s \geq 1$. In this case, $T(1)$ is singular, and therefore $(T(1), \hat{\Phi}(0))$ does not have full rank. Since $P(-1) = T(1)Q(-1)T^{-1}(-1)$, the matrix $(P(-1), \hat{\Phi}(0))$ does not have full rank. This contradicts condition (i). □

Similarly, we have the following result for the stability of a scaling vector.

THEOREM 3.8. *Assume the scaling vector Φ is finitely linearly independent and its symbol is a P-matrix $P \in \mathcal{P}^r(\mathcal{S}P^r)$. Then Φ is unstable if and only if P is two-scale similar to a P-matrix $Q \in \mathcal{P}^r(\mathcal{S}P^r)$ with a nonfundamental two-scale transform matrix T such that* $\det T(z)$ *has zeros on* $|z| = 1$ *and* $\operatorname{rank} T(1) = \operatorname{rank}(T(1), \hat{\Phi}(0))$.

COROLLARY 3.9. *Assume the scaling vector Φ is finitely linearly independent and its symbol is a P-matrix $P \in \mathcal{P}^r$. Then Φ is stable if* (i) *the matrix* $(P(-1), \hat{\Phi}(0))$ *has full rank and* (ii) $\det P(z)$ *has neither symmetric zeros on* $|z| = 1$ *nor cycle zeros.*

Remark 3. When $r = 1$, the scaling vector Φ reduces to a single function. A sufficient and necessary condition for linear independence (stability) of a scaling function has been obtained by Jia and Wang [14]. Besides, Hogan [10] also obtained the same results as Corollary 3.7 and 3.9 in a different way.

4. Examples. In this section we give more examples.

Example 2. Consider the following scaling equation:

$$\Phi(x) = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \Phi(2x) + \begin{bmatrix} 1 & -1 \\ 1 & 0 \end{bmatrix} \Phi(2x-1) + \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \Phi(2x-2). \tag{4.1}$$

Its symbol is

$$P(z) = \frac{1}{2} \begin{pmatrix} 1+z+z^2 & -z \\ z+z^2 & -1+z^2 \end{pmatrix},$$

where matrix $P(1) = \left(\begin{smallmatrix} 3/2 & -1/2 \\ 1 & 0 \end{smallmatrix}\right)$ has eigenvalues 1 and 1/2. A right 1-eigenvector is $\mathbf{v}_0 = \begin{pmatrix} 1 & 1 \end{pmatrix}^T$. $P(1)\mathbf{v}_0 = \mathbf{v}_0$. It is easy to check that

$$\frac{1}{2} \begin{pmatrix} 1+z+z^2 & -z \\ z+z^2 & -1+z^2 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ z^2 & -1 \end{pmatrix} \begin{pmatrix} (1+z)/2 & z/2 \\ 0 & (-1+z^2+z^3)/2 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ z & -1 \end{pmatrix},$$

and the equation $x(\cdot) = -x(2\cdot) + x(2\cdot -2) + x(2\cdot -3)$ has only the trivial compactly supported solution $x(\cdot) = 0$. Hence, by Theorem 3.2, the solution of (4.1) with the mean value $\begin{pmatrix} \hat{\phi}_1(0) & \hat{\phi}_2(0) \end{pmatrix}^T = \begin{pmatrix} 1 & 1 \end{pmatrix}^T$ is finitely linearly dependent. In fact, this solution is $\Phi(x) = \begin{pmatrix} \chi(0,1] & \chi(1,2] \end{pmatrix}^T$. By Corollary 3.3, one of Φ's symbols is

$$\begin{pmatrix} (1+z)/2 & 0 \\ z^2(1+z)/2 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ z^2 & -1 \end{pmatrix} \begin{pmatrix} (1+z)/2 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ z & -1 \end{pmatrix}.$$

We can verify that $\Phi(x)$ satisfies the following equation:

$$\Phi(x) = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \Phi(2x) + \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} \Phi(2x-1) + \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \Phi(2x-2) + \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \Phi(2x-3).$$

By Theorem 3.2, $\Phi(x)$ will satisfy any equation with a symbol having the form of

$$\begin{pmatrix} 1 & 0 \\ z^2 & -1 \end{pmatrix} \begin{pmatrix} (1+z)/2 & Y(z) \\ 0 & X(z) \end{pmatrix} \begin{pmatrix} 1 & 0 \\ z & -1 \end{pmatrix},$$

where $Y(z)$ and $X(z)$ are arbitrary polynomials such that $X(1) \neq 2^{\beta}(\beta \geq 1, \beta \in \mathbb{Z})$. For example, if we set $Y(z) = -1/2$, $X(z) = z/2$, then, by Theorem 3.2, the matrix

$$\begin{pmatrix} 1/2 & 1/2 \\ 0 & (z+z^2)/2 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ z^2 & -1 \end{pmatrix} \begin{pmatrix} (1+z)/2 & -1/2 \\ 0 & z/2 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ z & -1 \end{pmatrix}$$

should be a new symbol of Φ. It can be verified that $\Phi(x)$ satisfies the following equation:

$$\Phi(x) = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} \Phi(2x) + \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} \Phi(2x-1) + \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix} \Phi(2x-2).$$

Example 3. Now we analyze the scaling vector in Example 4.6 in [15] (for the case of $L = r = 2$). The symbol of the scaling vector $\Phi = (\phi_1, \phi_2)^T$ is

$$P(z) = \left(\frac{1+z}{2}\right)^2 \begin{pmatrix} 1/2 & 1/2 \\ z/2 & 1/2 \end{pmatrix}.$$

Using the formula of Theorem 2.3 in [20], we obtain $\operatorname{supp}\phi_1 \subset [0, 2\frac{1}{3}]$ and $\operatorname{supp}\phi_2 \subset [0, 2\frac{2}{3}]$. The graphs of $(\phi_1, \phi_2)^T$, which can be found in Figure 4.1 of [15], show that $\operatorname{supp}\phi_1 = [0, 2\frac{1}{3}]$ and $\operatorname{supp}\phi_2 = [0, 2\frac{2}{3}]$. Since the right end-point of the support of any finitely linear combination of the integer translates of ϕ_1 is $k+1/3$ while the right end-point of the support of any finitely linear combination of the integer translates of ϕ_2 is $k + 2/3$, scaling vector $(\phi_1, \phi_2)^T$ is finitely linearly independent. Matrix $P(1) = \left(\begin{smallmatrix} 1/2 & 1/2 \\ 1/2 & 1/2 \end{smallmatrix}\right)$ has eigenvalues 1 and 0, and $\begin{pmatrix} \hat{\phi}_1(0) & \hat{\phi}_2(0) \end{pmatrix}^T = \begin{pmatrix} 1 & 1 \end{pmatrix}^T$ is a 1-eigenvector. $P(z)$ has the following two-scale similarity:

$$P(z) = T(z^2)Q(z)T^{-1}(z),$$

where

$$T(z) = \begin{pmatrix} 1 & 0 \\ 1 & z-1 \end{pmatrix}, \quad Q(z) = \begin{pmatrix} (\frac{1+z}{2})^2 & (\frac{z-1}{2})(\frac{z+1}{2})^2 \\ \frac{1+z}{8} & 0 \end{pmatrix}.$$

Note that $T(z)$ is nonfundamental and the equation $T(1)\mathbf{u} = (1 \quad 1)^T$ has a solution $\mathbf{u} = (1, 0)^T$. By Theorem 3.5, $(\phi_1, \phi_2)^T$ is linearly dependent. Indeed, we have $\sum_{k\in\mathbb{Z}}(\phi_1(x-k) - \phi_2(x-k)) = 0$.

Example 4. Finally, we consider the orthonormal fractal scaling vector in [5]. Its symbol is

$$P(z) = \frac{\sqrt{2}}{20} \begin{pmatrix} 6\sqrt{2}(1+z) & 16 \\ -(1+z)(1-10z+z^2) & -\sqrt{2}(3-10z+3z^2) \end{pmatrix},$$

and the initial vector is $\hat{\Phi}(0) = \begin{pmatrix} \sqrt{2} & 1 \end{pmatrix}^T$. Using the formula of Theorem 2.3 in [20], we obtain that $\operatorname{supp}\phi_1 \subset [0, 1]$ and $\operatorname{supp}\phi_2 \subset [0, 2]$. We first point out that Φ is finitely linearly independent. Indeed, since $\operatorname{supp}\phi_1 \subset [0, 1]$, the integer translates of ϕ_1 are linearly independent. It follows that the entire function $\hat{\phi}_1$ has no 2π-periodic zero in $\mathbb{C}$. Assuming Φ is finitely linearly dependent, then there are two polynomials $a(z)$ and $b(z)$ such that $a(z)\hat{\phi}_1(\omega) - b(z)\hat{\phi}_2(\omega) = 0$, $z = e^{-i\omega}$. Hence, $\hat{\phi}_2(\omega) = \frac{a(z)}{b(z)}\hat{\phi}_1(\omega)$. Since $\hat{\phi}_2$ is also an entire function and $\hat{\phi}_1$ has no 2π-periodic zero in $\mathbb{C}$, $s(z) := \frac{a(z)}{b(z)}$ must be a polynomial. Furthermore, since $\operatorname{supp}\phi_1 \subset [0, 1]$ and $\operatorname{supp}\phi_2 \subset [0, 2]$, $s(z)$ must be a

linear polynomial. Assuming that $s(z) = (c + dz)$, we have $\hat{\phi}_2(\omega) = (c + de^{-i\omega})\hat{\phi}_1(\omega)$. Therefore, $T(e^{-i\omega})\hat{\Phi}(\omega) = (\hat{\phi}_1(\omega), 0)^T$, where $T(z) = \left(\begin{smallmatrix} 1 & 0 \\ c+dz & -1 \end{smallmatrix}\right)$. By Theorem 3.2, we also have $T^{-1}(z^2)P(z)T(z) = \left(\begin{smallmatrix} * & * \\ 0 & * \end{smallmatrix}\right)$; thus

$$(c + dz^2)\left(6\sqrt{2}(1 + z) + 16(c + dz)\right) + (1 + z)(1 - 10z + z^2)$$
$$+\sqrt{2}(c + dz)(3 - 10z + 3z^2) = 0.$$

However, this equation has no solution for c and d. Hence, Φ is finitely linearly independent. Finally, we confirm the linear independence of Φ from the fact that $\det P(z) = -\frac{1}{40}(z + 1)^3$ and $(P(-1), \hat{\Phi}(0)) = \left(\begin{smallmatrix} 0 & 4\sqrt{5} & \sqrt{2} \\ 0 & -8/5 & 1 \end{smallmatrix}\right)$ has full rank.

Acknowledgment. The author would like to thank the referees for their helpful comments.

ON THE REGULARITY OF MATRIX REFINABLE FUNCTIONS*

QINGTANG JIANG†

Abstract. It is shown that the transition operator $\mathbf{T_P}$ associated with the matrix refinement mask $\mathbf{P}(\omega) = 2^{-d}\Sigma_{\alpha\in[0,N]^d}\mathbf{P}_\alpha\exp(-i\alpha\omega)$ is equivalent to the matrix $(2^{-d}\mathcal{A}_{2i-j})_{i,j}$ with $\mathcal{A}_j = \Sigma_{\kappa\in[0,N]^d}\mathbf{P}_{\kappa-j}\otimes\mathbf{P}_\kappa$ and $\mathbf{P}_{\kappa-j}\otimes\mathbf{P}_\kappa$ denoting the Kronecker product of matrices $\mathbf{P}_{\kappa-j}$, $\mathbf{P}_\kappa$. Some spectral properties of $\mathbf{T_P}$ are studied and a complete characterization of the matrix refinable functions in the Sobolev space $W^n(\mathbf{R}^d)$ for nonnegative integers n is provided. The Sobolev regularity estimate of the matrix refinable function is given in terms of the spectral radius of a restricted transition operator. These estimates are analyzed in some examples.

Key words. matrix refinable function, transition operator, regularity

1. Introduction. Let $\{\mathbf{P}_\alpha\}$ be a real $r\times r$ matrix sequence with finite elements nonzero. The vectors Φ, r-dimensional column functions, used in this paper are solutions to functional equations of the type

$$\Phi = \sum_{\alpha\in\mathbf{Z}^d}\mathbf{P}_\alpha\Phi(2\cdot-\alpha). \tag{1.1}$$

Define

$$\mathbf{P}(\omega) := 2^{-d}\sum_{\alpha\in\mathbf{Z}^d}\mathbf{P}_\alpha\exp(-i\alpha\omega);$$

then, in the Fourier domain, functional equations (1.1) can be written as

$$\widehat{\Phi}(\omega) = \mathbf{P}(\omega/2)\widehat{\Phi}(\omega/2). \tag{1.2}$$

Equations of the type (1.1) or (1.2) are called *matrix* (*vector*) *refinement equations*; $\mathbf{P}$ ($\{\mathbf{P}_\alpha\}$) is called the (*matrix*) *refinement mask*, and any solution Φ of (1.1) is called a *matrix refinable function* (or *refinable vector*). Equations (1.1) are considered in the area of wavelets for the construction of multiwavelets, and there are many papers on the existence of the solutions of equations (1.1), the constructions of multiwavelets, and related topics; see, e.g., [1], [3], [7], [8], [11]–[16], [21]–[23], [25]–[27], and [29]–[31]. The present paper considers the Sobolev regularity of the matrix refinable functions.

For the case $r = 1, d = 1$, compactly supported refinable functions are solutions of the two-scale equation

$$\phi(x) = \sum_{j=0}^{J} h_j\phi(2x-j).$$

Over the years, several techniques have been developed to determine the regularity of refinable functions; see [5], [9], [32], [6], [10], [17], and [2] (in [17] and [2], the refinement mask $\{h_j\}$ is not necessarily finitely supported). One of the main results is the following (see [32], [9]): assume that the refinement mask

$$m_0(\omega) = \frac{1}{2}\sum_{j=0}^{J} h_j e^{-ij\omega} \tag{1.3}$$

can be factorized as

$$m_0(\omega) = \left(\frac{1+e^{-i\omega}}{2}\right)^K q(\omega), \tag{1.4}$$

where $q(\omega)$ is a trigonometric polynomial. Then the Sobolev exponent $s(\phi) := \sup\{s \geq 0 : \int(1+|\omega|^2)^s|\widehat{\phi}(\omega)|^2 d\omega < +\infty\}$ satisfies

$$s(\phi) \geq K - \log_4 \rho(\mathbf{T}_q),$$

where $\mathbf{T}_q$ is the transition operator associated with q and $\rho(\mathbf{T}_q)$ is the spectral radius of $\mathbf{T}_q$. For a trigonometric polynomial $p(\omega) = \sum_{l=0}^{L} p_l e^{-il\omega}$, the transition operator associated with p is defined by

$$\mathbf{T}_p f(\omega) := \left|p\Big(\frac{\omega}{2}\Big)\right|^2 f\Big(\frac{\omega}{2}\Big) + \left|p\Big(\frac{\omega}{2}+\pi\Big)\right|^2 f\Big(\frac{\omega}{2}+\pi\Big), \quad f \in V_L,$$

where V_L denotes the vector space of trigonometric polynomials defined by

$$V_L := \left\{ \sum_{l=-L}^{L} f_l e^{-il\omega} : \quad f_l \in \mathbf{C} \right\}.$$

Further, if refinable function ϕ is stable and $q(\pi) \neq 0$, then above regularity estimate is optimal; i.e.,

$$s(\phi) = K - \log_4 \rho(\mathbf{T}_q).$$

There is another method to give regularity estimates of refinable functions. Let ϕ be a compactly supported refinable function with corresponding mask $m_0(\omega)$ given by (1.3) for some positive integer J. Assume that $m_0(\omega)$ satisfies the vanishing moment conditions of order $K+1$; i.e., $\frac{d^\alpha}{d\omega^\alpha} m_0(\omega)|_{\omega=\pi} = 0, 0 \leq \alpha \leq K$. Equivalently, $m_0(\omega)$ can be written in the form of (1.4). Let V_J^0 denote the subspace of V_J defined by

$$V_J^0 := \left\{ f \in V_J : \quad \sum_{j=-J}^{J} j^n f_j = 0, \quad n = 0, \ldots, 2K-1 \right\}. \tag{1.5}$$

Then V_J^0 is invariant under $\mathbf{T}_{m_0}$. Let $\mathbf{T}_{m_0}|_{V_J^0}$ denote the restriction of $\mathbf{T}_{m_0}$ to V_J^0. If $\rho(\mathbf{T}_{m_0}|_{V_J^0}) < 1$, then

$$s(\phi) \geq -\log_4 \rho(\mathbf{T}_{m_0}|_{V_J^0}).$$

In fact the above two methods are completely equivalent; see [6]. The first method relies upon the factorization of the refinement mask $m_0(\omega)$. However in the higher

dimension case, the refinement mask is often irreducible. The second method was successfully used by Riemenschneider and Shen to estimate the regularities of two dimension refinable functions constructed in [28]. Further studies on the problem of the regularity in higher dimensions with dilation matrices were carried out in [20] and [4].

The regularity of the matrix refinable function Φ (for the case $d = 1$) was first studied by Cohen, Daubechies, and Plonka [3] based on the factorization of the matrix refinement mask $\mathbf{P}(\omega)$. However such estimates of regularity are usually hard to compute. There is another approach (essentially the second method for the scalar case) to the regularity estimate of the refinable vector Φ carried out by Shen in [29], and such estimates are provided in terms of the spectral radius of a restricted transition operator. More precisely, letting $\mathbf{P}(\omega) = 2^{-d}\sum_{\alpha\in[0,N]^d}\mathbf{P}_\alpha e^{-i\alpha\omega}$ be the corresponding matrix refinement mask, the *transition operator* $\mathbf{T_P}$ associated with $\mathbf{P}$ is defined by

$$\mathbf{T_P}H(\omega) := \sum_{\nu\in\mathbf{Z}^d/2\mathbf{Z}^d}\mathbf{P}\Big(\frac{\omega}{2}+\pi\nu\Big)H\Big(\frac{\omega}{2}+\pi\nu\Big)\mathbf{P}^*\Big(\frac{\omega}{2}+\pi\nu\Big), \quad H\in\mathbf{H}_N. \tag{1.6}$$

Throughout this paper $\mathbf{H}_N$ denotes the space of all $r\times r$ matrices with each entry a trigonometric polynomial whose Fourier coefficients are supported in $[-N,N]^d$; M^* and M^T denote the Hermitian adjoint and the transpose of a matrix M, respectively. The transition operator $\mathbf{T_P}$ leaves $\mathbf{H}_N$ invariant. In [29], the regularity of Φ was given in terms of the spectral radius of $\mathbf{T_P}|_{\mathbf{H}_N^0}$, the restricted operator of $\mathbf{T_P}$ to an invariant subspace $\mathbf{H}_N^0$ of $\mathbf{H}_N$ under $\mathbf{T_P}$. The smaller the invariant subspace $\mathbf{H}_N^0$, the smaller $\rho(\mathbf{T_P}|_{\mathbf{H}_N^0})$ will be and hence the better the estimate on the regularity of Φ. Thus a small $\mathbf{T_P}$ invariant subspace of $\mathbf{H}_N$ is required.

For the case $r = 1, d = 1$, let m_0 be a given refinement mask defined by (1.3) for some positive integer J; then the transition operator $\mathbf{T}_{m_0}$ is equivalent under the basis $\{e^{-ij\omega}\}_{j=-J}^{J}$ of V_J to the matrix

$$\mathcal{T}_{m_0} = (2^{-1}a_{2i-j})_{-N\le i,j\le N},$$

where a_j is the autocorrelation of $\{c_\kappa\}$ defined by $a_j := \sum_\kappa c_{\kappa-j}\overline{c_\kappa}$; see [24], [6]. We note that the invariant subspace V_J^0 defined by (1.5) can be written as

$$V_J^0 = \{f\in V_J: \quad v_n(f_{-J},\dots,f_J)^T = 0, \quad n = 0,\dots,2K-1\},$$

where

$$v_n := ((-J)^n,\dots,J^n), \quad n = 0,\dots,2K-1. \tag{1.7}$$

The row vector v_n is a generalized left 2^{-n}-eigenvector of the matrix $\mathcal{T}_{m_0}$ (see [6]). Thus to give the regularity estimates of refinable vectors, we at first change equivalently the transition operator $\mathbf{T_P}$ into its representing matrix $\mathcal{T}_\mathbf{P}$, then find left 2^{-n}-eigenvectors of the matrix $\mathcal{T}_\mathbf{P}$. Using these left eigenvectors, we construct the invariant subspace $\mathbf{H}_N^0$ and then provide the regularity estimates in terms of the spectral radius of the restricted transition operator $\mathbf{T_P}|_{\mathbf{H}_N^0}$.

This paper is organized as follows. In section 2 we show that the transition operator $\mathbf{T_P}$ is equivalent to the matrix $\mathcal{T}_\mathbf{P} = (2^{-d}\mathcal{A}_{2i-j})_{i,j\in[-N,N]^d}$, where $\mathcal{A}_j$ is the $r^2\times r^2$ matrix given by

$$\mathcal{A}_j = \sum_{\kappa\in[0,N]^d}\mathbf{P}_{\kappa-j}\otimes\mathbf{P}_\kappa$$

and $\mathbf{P}_{\kappa-j}\otimes\mathbf{P}_\kappa$ is the Kronecker product of $\mathbf{P}_{\kappa-j}$ and $\mathbf{P}_\kappa$. In section 2, we also find left eigenvectors of $\mathcal{T}_\mathbf{P}$ which will be used for the regularity estimate of refinable vectors. In the first part of section 3, we will give a characterization of refinable vectors in the Sobolev space $W^n(\mathbf{R}^d), n \in \mathbf{Z}_+$. In the second part of section 3, we provide a $\mathbf{T_P}$-invariant subspace $\mathbf{H}_N^0$ of $\mathbf{H}_N$ and give the regularity estimate of refinable vectors in terms of the spectral radius of the restricted transition operator $\mathbf{T_P}|_{\mathbf{H}_N^0}$. In the last part of this paper, section 4, we will give the estimates on the smoothness of some matrix refinable functions. About the B-splines defined by knots $0, 0, 1, 1$ and $0, 1, 1, 2$ and the GHM-orthogonal scaling functions, our estimates on their regularities are optimal.

Before going to the next section, we introduce some notation used in this paper. Let $\mathbf{Z}_+$ denote the set of all nonnegative integers and $\mathbf{Z}_+^d$ denote the set of all d-tuples of nonnegative integers. We shall adopt the multi-index notation

$$\omega^\beta := \omega^{\beta_1}\cdots\omega_d^{\beta_d}, \quad \beta! := \beta_1!\cdots\beta_d!, \quad |\beta| := \beta_1+\cdots+\beta_d$$

for $\omega = (\omega_1,\ldots,\omega_d)^T \in \mathbf{R}^d$, $\beta = (\beta_1,\ldots,\beta_d)^T \in \mathbf{Z}_+^d$. If $\alpha, \beta \in \mathbf{Z}^d$ satisfy $\beta-\alpha \in \mathbf{Z}_+^d$, we shall write $\alpha \le \beta$ and denote

$$\binom{\beta}{\alpha} := \frac{\beta!}{\alpha!(\beta-\alpha)!}.$$

For $\beta = (\beta_1,\ldots,\beta_d)^T \in \mathbf{Z}_+^d$, denote

$$D^\beta := \frac{\partial^{\beta_1}}{\partial x_1^{\beta_1}}\cdots\frac{\partial^{\beta_d}}{\partial x_d^{\beta_d}},$$

where $\partial_j = \frac{\partial}{\partial x_j}$ is the partial derivative operator with respect to the jth coordinate, $1 \le j \le d$. For $\omega, \zeta \in \mathbf{R}^d$, we use $\zeta\omega$ to denote their scalar product.

For $j = 1,\ldots,r$, let $\mathbf{e}_j := (\delta_j(k))_{k=1}^r$ denote the standard unit vectors in $\mathbf{R}^r$. In this paper, for an $r\times 1$ vector function $f = (f_1,\ldots,f_r)^T$, *f is in a space on* $\mathbf{R}^d$ means that every component f_i of f is in this space, and we will use the notation $|f| := (\sum_{i=1}^r |f_i|^2)^{\frac{1}{2}}$.

For a matrix or an operator A, we say$A$ satisfies *Condition E* if the spectral radius of $A \le 1$, 1 is the unique eigenvalue of A on the unit circle and 1 is simple. For two matrices A, B, $A \le B$ should be understood as stating that $B-A$ is positive semidefinite.

For a finitely supported sequence s on $\mathbf{Z}^d$, its support is defined by $\mathrm{supp}s := \{\beta \in \mathbf{Z}^d : s(\beta) \ne 0\}$, and for a finitely supported $r\times r$ matrix sequence S on $\mathbf{Z}^d$, its support is defined by $\mathrm{supp}S := \cup\mathrm{supp}s_{ij}$, where s_{ij} is the (i,j)-entry of S. Throughout this paper, we assume that the matrix refinement mask $\mathbf{P}$ satisfies $\mathrm{supp}\{\mathbf{P}_\alpha\} \subset [0,N]^d$ for some positive integer N, and we use c to denote the universal constant which may be different at different occurrences.

2. Transition operator. In this section, we first show that the transition operator $\mathbf{T_P}$ defined by (1.6) is equivalent to a matrix, then we study some spectral properties of $\mathbf{T_P}$.

For any $H = \sum_{j\in[-N,N]^d} H_j e^{-ij\omega} \in \mathbf{H}_N$,

$$\mathbf{P}(\omega)H(\omega)\mathbf{P}(\omega)^* = 2^{-2d}\sum_{\ell\in[0,N]^d}\sum_{\kappa\in[0,N]^d}\mathbf{P}_\kappa e^{-i\omega\kappa}H(\omega)\mathbf{P}_\ell^T e^{i\omega\ell}$$

$$= 2^{-2d} \sum_{\ell\in[0,N]^d} \sum_{\kappa\in[0,N]^d} \mathbf{P}_\kappa H(\omega)\mathbf{P}_\ell^T e^{-i\omega(\kappa-\ell)}$$
$$= 2^{-2d} \sum_{\kappa\in[0,N]^d} \sum_{n\in[-N,N]^d} \mathbf{P}_\kappa H(\omega)\mathbf{P}_{\kappa-n}^T e^{-i\omega n}$$
$$= 2^{-2d} \sum_{j\in[-N,N]^d} \sum_{\kappa\in[0,N]^d} \sum_{n\in[-N,N]^d} \mathbf{P}_\kappa H_j \mathbf{P}_{\kappa-n}^T e^{-i\omega(n+j)}.$$

Thus

$$\mathbf{T_P} H(\omega) = 2^{-2d} \sum_{\nu\in\mathbf{Z}^d/2\mathbf{Z}^d} \sum_{j\in[-N,N]^d} \sum_{n\in[-N,N]^d} \sum_{\kappa\in[0,N]^d} \mathbf{P}_\kappa H_j \mathbf{P}_{\kappa-n}^T (-1)^{\nu(n+j)} e^{-i\frac{\omega}{2}(n+j)}.$$

For any $n \in [-N,N]^d, j \in [-N,N]^d$, write $n+j = 2\ell+\mu$ for some $\ell \in [-N,N]^d$ and $\mu \in \mathbf{Z}^d/2\mathbf{Z}^d$. By the fact that $\sum_{\nu\in\mathbf{Z}^d/2\mathbf{Z}^d}(-1)^{\nu\mu} = 2^d\delta_\mu$,

$$\sum_{\nu\in\mathbf{Z}^d/2\mathbf{Z}^d} (-1)^{\nu(n+j)} = 2^d\delta_\mu.$$

Hence

$$\mathbf{T_P} H(\omega) = 2^{-d} \sum_{j\in[-N,N]^d} \sum_{\ell\in[-N,N]^d} \sum_{\kappa\in[0,N]^d} \mathbf{P}_\kappa H_j \mathbf{P}_{\kappa-(2\ell-j)}^T e^{-i\omega\ell} \tag{2.1}$$
$$= \sum_{\ell\in[-N,N]^d} \left(2^{-d} \sum_{j\in[-N,N]^d} \sum_{\kappa\in[0,N]^d} \mathbf{P}_\kappa H_j \mathbf{P}_{\kappa-(2\ell-j)}^T \right) e^{-i\omega\ell}.$$

That is, $\mathbf{T_P}$ changes sequence $\{H_j\}_{j\in[-N,N]^d}$ into another sequence:

$$\left\{ 2^{-d} \sum_{j\in[-N,N]^d} \sum_{\kappa\in[0,N]^d} \mathbf{P}_\kappa H_j \mathbf{P}_{\kappa-(2\ell-j)}^T \right\}_{\ell\in[-N,N]^d}.$$

Let M be an $r\times r$ matrix with $M(j)$ the jth column of M. Define the $r^2\times 1$ vector $\mathrm{vec}(M)$ by

$$\mathrm{vec}(M) := (M(1)^T, \dots, M(r)^T)^T.$$

For $H = \sum_{j\in[-N,N]^d} H_j e^{-i\omega j} \in \mathbf{H}_N$, let $\mathrm{vec}(H)$ be the $(r^2(2N+1)^d)\times 1$ vectors defined by

$$\mathrm{vec}(H) := \left((\mathrm{vec}(H_j))^T|_{j=(-N,\dots,-N)}, \dots, (\mathrm{vec}(H_j))^T|_{j=(N,\dots,N)} \right)^T. \tag{2.2}$$

For the matrices of the form $\mathbf{P}_\ell H_j \mathbf{P}_\kappa^T$, we have (see [19])

$$\mathrm{vec}(\mathbf{P}_\ell H_j \mathbf{P}_\kappa^T) = (\mathbf{P}_\kappa \otimes \mathbf{P}_\ell)\mathrm{vec}(H_j), \tag{2.3}$$

where $\mathbf{P}_\kappa \otimes \mathbf{P}_\ell$ denotes the Kronecker product of matrices $\mathbf{P}_\kappa$ and $\mathbf{P}_\ell$:

$$\mathbf{P}_\kappa \otimes \mathbf{P}_\ell = (p_\kappa(\tau,i)\mathbf{P}_\ell)_{1\le\tau,i\le r}, \quad \mathbf{P}_\kappa = (p_\kappa(\tau,i))_{1\le\tau,i\le r}.$$

For $j\in\mathbf{Z}^d$, define the $r^2\times r^2$ matrices

$$\mathcal{A}_j := \sum_{\ell\in[0,N]^d} \mathbf{P}_{\ell-j} \otimes \mathbf{P}_\ell$$

and define the $(r^2(2N+1)^d) \times (r^2(2N+1)^d)$ matrix

$$\mathcal{T}_{\mathbf{P}} := \left(2^{-d}\mathcal{A}_{2i-j}\right)_{i,j\in[-N,N]^d}. \tag{2.4}$$

Then from (2.1) and (2.3) and for any $\kappa \in [-N,N]^d$,

$$\begin{aligned}\mathrm{vec}((\mathbf{T}_{\mathbf{P}}H)_\kappa) &= 2^{-d}\sum_{j\in[-N,N]^d}\sum_{\ell\in[0,N]^d}\mathrm{vec}(\mathbf{P}_\ell H_j \mathbf{P}^T_{\ell-(2\kappa-j)})\\ &= 2^{-d}\sum_{j\in[-N,N]^d}\sum_{\ell\in[0,N]^d}(\mathbf{P}_{\ell-(2\kappa-j)}\otimes\mathbf{P}_\ell)\mathrm{vec}(H_j)\\ &= \sum_{j\in[-N,N]^d} 2^{-d}\mathcal{A}_{2\kappa-j}\mathrm{vec}(H_j) = (\mathcal{T}_{\mathbf{P}}\mathrm{vec}(H))(\kappa).\end{aligned}$$

Hence we have the following theorem.

THEOREM 2.1. *The transition operator $\mathbf{T}_{\mathbf{P}}$ is equivalent to the matrix $\mathcal{T}_{\mathbf{P}}$ defined by* (2.4) *under the basis $\{e^{-i\omega\ell}\}_{\ell\in[-N,N]^d}$ of $\mathbf{H}_N$, and for any $H \in \mathbf{H}_N$,*

$$\mathrm{vec}(\mathbf{T}_{\mathbf{P}}H) = \mathcal{T}_{\mathbf{P}}\mathrm{vec}(H), \tag{2.5}$$

where $\mathrm{vec}(H)$ *is the vector defined by* (2.2).

In the rest of this section, we will find some left eigenvectors of $\mathcal{T}_{\mathbf{P}}$. These eigenvectors are associated with the vanishing moment conditions of the matrix refinement mask $\mathbf{P}$. We say that mask $\mathbf{P}(\omega)$ satisfies the *vanishing moment conditions* of order $m \in \mathbf{Z}_+$ if there exist $1\times r$ real vectors $\mathbf{l}_0^\beta$ with $\mathbf{l}_0^0 \neq 0$, $\beta \in \mathbf{Z}_+^d, |\beta| \le m-1$ such that

$$\sum_{0\le\alpha\le\beta}\binom{\beta}{\alpha}(2i)^{|\alpha-\beta|}\mathbf{l}_0^\alpha(D^{\beta-\alpha}\mathbf{P})(\nu\pi) = \delta_\nu 2^{-|\beta|}\mathbf{l}_0^\beta, \quad \nu \in \mathbf{Z}^d/2\mathbf{Z}^d. \tag{2.6}$$

Assume that $\Phi = (\phi_l)_{l=1}^r \in L^2(\mathbf{R}^d)$ is a compactly supported matrix refinable function with corresponding mask $\mathbf{P}$. Under the assumption that $\phi_l(x-j)$, $1\le l\le r$, $j\in\mathbf{Z}^d$, are linearly independent, that there exist vectors $\mathbf{l}_0^\beta, |\beta| \le m-1$ satisfying (2.6) is equivalent to that ϕ_l, $1\le l\le r$, provide approximation of order m, see [15], [27] for $d=1$. For $d=1$, (2.6) implies a matrix factorization of $\mathbf{P}(\omega)$ under the assumption that Φ is stable (see [27], [3]). It is shown in [23] that if $\det G_\Phi(\nu\pi) \neq 0, \nu \in \mathbf{Z}^d/2\mathbf{Z}^d$, then $\mathbf{P}(0)$ satisfies Condition E and $\mathbf{P}$ satisfies the vanishing moment conditions of order at least 1, where

$$G_\Phi(\omega) := \sum_{\kappa\in\mathbf{Z}^d}\widehat{\Phi}(\omega+2\pi\kappa)\widehat{\Phi}^*(\omega+2\pi\kappa).$$

Thus in what follows we will assume that $\mathbf{P}(0)$ satisfies Condition E and $m \ge 1$ in (2.6). In this case, if Φ is a compactly supported nontrivial refinable vector, then $\widehat{\Phi}(0) = c\mathbf{r}$ for some nonzero constant c, where $\mathbf{r}$ is the normalized right 1-eigenvector of $\mathbf{P}(0)$.

Let $m_0 \in \mathbf{Z}_+, m_0 \le m$ be the largest integer such that there exist row vectors $\mathbf{l}_0^\beta \in \mathbf{R}^r$, $\beta \in \mathbf{Z}_+^d, m \le |\beta| \le m+m_0-1$ satisfying

$$\sum_{0\le\alpha\le\beta}\binom{\beta}{\alpha}(2i)^{|\alpha-\beta|}\mathbf{l}_0^\alpha(D^{\beta-\alpha}\mathbf{P})(0) = 2^{-|\beta|}\mathbf{l}_0^\beta. \tag{2.7}$$

Equations (2.7) can be written as

$$\mathbf{l}_0^\beta \left(2^{-|\beta|}\mathbf{I}_r - \mathbf{P}(0)\right) = \sum_{0\le\alpha<\beta} \binom{\beta}{\alpha} (2i)^{|\alpha-\beta|} \mathbf{l}_0^\alpha (D^{\beta-\alpha}\mathbf{P})(0), \tag{2.8}$$

where $\mathbf{I}_r$ is the $r\times r$ identity matrix. Thus if each of the numbers of $2^{-m}, 2^{-m-1}, \dots, 2^{-m-m_0}$ is not an eigenvalue of $\mathbf{P}(0)$ for some $m_0 \in \mathbf{Z}_+$, then vectors $\mathbf{l}_0^\beta \in \mathbf{R}^r$, $\beta \in \mathbf{Z}_+^d, m \le |\beta| \le m+m_0-1$ can be chosen iteratively by (2.8). Since in the examples which are analyzed below $m_0 = m$, in the following we will assume that $m_0 = m$. For the case $r = 1$, since $\mathbf{P}(0) = 1$, such assumption is not needed.

Let $B(\omega) = \sum_{\kappa\in\mathbf{Z}_+^d, |\kappa|\le 2m-1} B_\kappa e^{i\kappa\omega}$ be the vector trigonometric polynomial satisfying

$$D^\beta B(0) = i^{|\beta|}\mathbf{l}_0^\beta, \quad \beta \in \mathbf{Z}_+^d, |\beta| \le 2m-1. \tag{2.9}$$

The coefficients B_κ, $1\times r$ vectors, can be found by the following equations:

$$\sum_{|\kappa|\le 2m-1} \kappa^\beta B_\kappa = \mathbf{l}_0^\beta, \quad \beta \in \mathbf{Z}_+^d, |\beta| \le 2m-1.$$

One can check that the vanishing moment conditions (2.6) and (2.7) can be written equivalently in the form

$$D^\beta (B(2\omega)\mathbf{P}(\omega))|_{\omega=0} = D^\beta B(0) \quad \forall \beta \in \mathbf{Z}_+^d, |\beta| \le 2m-1, \tag{2.10}$$

and

$$D^\beta \left(B(2\omega)\,\mathbf{P}(\omega)\right)|_{\omega=\nu\pi} = 0 \quad \forall \beta \in \mathbf{Z}_+^d, |\beta| \le m-1, \nu \in \mathbf{Z}^d/2\mathbf{Z}^d\backslash\{0\}. \tag{2.11}$$

Let $\mathbf{l}_0^\beta$, $\beta \in \mathbf{Z}_+^d, |\beta| \le 2m-1$ be the row vectors satisfying (2.6) and (2.7). For $\kappa \in \mathbf{Z}^d$, define row vectors $\mathbf{l}_\kappa^\beta$ by

$$\mathbf{l}_\kappa^\beta := \sum_{0\le\alpha\le\beta} \binom{\beta}{\alpha} \kappa^{\beta-\alpha}\mathbf{l}_0^\alpha \quad \text{for } \beta \in \mathbf{Z}_+^d, |\beta| \le 2m-1, \tag{2.12}$$

and then define the $1\times(r^2(2N+1)^d)$ vectors $\mathbf{L}_N^\beta$ by

$$\mathbf{L}_N^\beta := (\mathbf{l}^\beta(\kappa)|_{\kappa=(-N,\dots,-N)}, \dots, \mathbf{l}^\beta(\kappa)|_{\kappa=(N,\dots,N)}) \tag{2.13}$$

with

$$\mathbf{l}^\beta(\kappa) := \sum_{0\le\alpha\le\beta} (-1)^\alpha \binom{\beta}{\alpha} \mathbf{l}_\kappa^\alpha \otimes \mathbf{l}_0^{\beta-\alpha}, \quad \kappa \in \mathbf{Z}^d.$$

For the case $d = 1$, $\mathbf{l}_\kappa^\beta, \kappa \in \mathbf{Z}^d$, are the coefficients for the reproduction of polynomials by the integer translates of Φ; see [15].

For two $1\times r$ vectors $\mathbf{v}, \mathbf{u}$ and the $r\times r$ matrix M, we have (see [19])

$$(\mathbf{v}\otimes\mathbf{u})\mathrm{vec}(M) = \mathbf{u}M\mathbf{v}^T. \tag{2.14}$$

LEMMA 2.1. *Assume that the refinement mask* $\mathbf{P}$ *satisfies* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}_0^\beta$, $|\beta| \le 2m-1$, *and* B *is the vector trigonometric polynomial satisfying* (2.9). *Let* $\mathbf{L}_N^\beta$ *be the vectors defined by* (2.13)*; then for any* $H \in \mathbf{H}_N$

$$\mathbf{L}_N^\beta \mathrm{vec}(H) = (-i)^{|\beta|} D^\beta \left(B(\omega)H(\omega)B^*(\omega)\right)|_{\omega=0}, \quad \beta \in \mathbf{Z}_+^d, |\beta| \le 2m-1,$$

where $\mathrm{vec}(H)$ *is the vector defined by* (2.2).

Proof. By (2.14), for any $\beta \in \mathbf{Z}_+^d, |\beta| \le 2m-1$, and any $H \in \mathbf{H}_N$,

$$\begin{aligned}
\mathbf{L}_N^\beta \mathrm{vec}(H) &= \sum_\kappa \mathbf{L}_N^\beta(\kappa)\mathrm{vec}(H_\kappa) = \sum_\kappa \sum_{0\le\alpha\le\beta} (-1)^{|\alpha|}\binom{\beta}{\alpha}\mathbf{l}_0^{\beta-\alpha} H(\kappa)(\mathbf{l}_\kappa^\alpha)^T \\
&= \sum_\kappa \sum_{0\le\alpha\le\beta} (-1)^{|\alpha|}\binom{\beta}{\alpha}\mathbf{l}_0^{\beta-\alpha} H(\kappa) \sum_{0\le\gamma\le\alpha} \kappa^\gamma \binom{\alpha}{\gamma}(\mathbf{l}_0^{\alpha-\gamma})^T \\
&= \sum_\kappa \sum_{0\le\alpha\le\beta} \sum_{0\le\gamma\le\alpha} (-1)^{|\alpha|}\binom{\beta}{\alpha}\kappa^\gamma\binom{\alpha}{\gamma}(-i)^{|\beta-\alpha|} D^{\beta-\alpha}B(0)H(\kappa) i^{|\alpha-\gamma|} D^{\alpha-\gamma}B^*(0) \\
&= (-i)^{|\beta|} \sum_{0\le\alpha\le\beta} \sum_{0\le\gamma\le\alpha} \binom{\beta}{\alpha}\binom{\alpha}{\gamma} D^{\beta-\alpha}B(0) \sum_\kappa (-i\kappa)^\gamma H(\kappa) D^{\alpha-\gamma}B^*(0) \\
&= (-i)^{|\beta|} \sum_{0\le\alpha\le\beta} \sum_{0\le\gamma\le\alpha} \binom{\beta}{\alpha}\binom{\alpha}{\gamma} D^{\beta-\alpha}B(0) D^\gamma H(0) D^{\alpha-\gamma}B^*(0) \\
&= (-i)^{|\beta|} D^\beta \left(B(\omega)H(\omega)B^*(\omega)\right)|_{\omega=0}. \qquad \square
\end{aligned}$$

THEOREM 2.2. *Assume that the refinement mask* $\mathbf{P}$ *satisfies* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}_0^\beta$, $|\beta| \le 2m-1$, *and* B *is the vector trigonometric polynomial satisfying* (2.9). *Let* $\mathbf{L}_N^\beta$ *be the vectors defined by* (2.13); *then*

$$\mathbf{L}_N^\beta \mathcal{T}_\mathbf{P} = 2^{-|\beta|}\mathbf{L}_N^\beta, \quad \beta \in \mathbf{Z}_+^d, |\beta| \le 2m-1.$$

Proof. We need only to show that for any $H \in \mathbf{H}_N$, $\mathbf{L}_N^\beta \mathcal{T}_\mathbf{P}\mathrm{vec}(H) = 2^{-|\beta|}\mathbf{L}_N^\beta \mathrm{vec}(H)$. In fact, by (2.5) and Lemma 2.1,

$$\begin{aligned}
(2i)^{|\beta|}\mathbf{L}_N^\beta \mathcal{T}_\mathbf{P}\mathrm{vec}(H) &= (2i)^{|\beta|}\mathbf{L}_N^\beta \mathrm{vec}(\mathbf{T}_\mathbf{P} H) = D^\beta\left(B(2\omega)\mathbf{T}_\mathbf{P} H(2\omega)B^*(2\omega)\right)|_{\omega=0} \\
&= \sum_{\nu\in\mathbf{Z}^d/2\mathbf{Z}^d} D^\beta(B(2\omega)\mathbf{P}(\omega+\nu\pi)H(\omega+\nu\pi)\mathbf{P}(\omega+\nu\pi)^* B^*(2\omega))|_{\omega=0} \\
&= \sum_{\nu\in\mathbf{Z}^d/2\mathbf{Z}^d} \sum_{0\le\alpha\le\beta} \sum_{0\le\gamma\le\alpha} \binom{\beta}{\alpha}\binom{\alpha}{\gamma} D^\alpha\left(B(2\omega)\mathbf{P}(\omega)\right)|_{\omega=\nu\pi} \\
&\qquad \cdot D^\gamma H(\omega)|_{\omega=\nu\pi} D^{\beta-\alpha-\gamma}\left(B(2\omega)\mathbf{P}(\omega)\right)^*|_{\omega=\nu\pi}.
\end{aligned}$$

Since for any $\beta,\alpha,\gamma \in \mathbf{Z}_+^d$ with $|\beta| \le 2m-1$ and $\gamma \le \alpha \le \beta$, $\min(|\alpha|, |\beta-\alpha-\gamma|) \le m-1$, then by (2.10) and (2.11)

$$\begin{aligned}
&(2i)^{|\beta|}\mathbf{L}_N^\beta \mathcal{T}_\mathbf{P}\mathrm{vec}(H) \\
&= \sum_{0\le\alpha\le\beta} \sum_{0\le\gamma\le\alpha} \binom{\beta}{\alpha}\binom{\alpha}{\gamma} D^\alpha(B(2\omega)\mathbf{P}(\omega))|_{\omega=0} D^\gamma H(\omega)|_{\omega=0} D^{\beta-\alpha-\gamma}\left(B(2\omega)\mathbf{P}(\omega)\right)^*|_{\omega=0} \\
&= \sum_{0\le\alpha\le\beta} \sum_{0\le\gamma\le\alpha} \binom{\beta}{\alpha}\binom{\alpha}{\gamma} D^\alpha B(0) D^\gamma H(0) D^{\beta-\alpha-\gamma}B^*(0) \\
&= D^\beta\left(B(\omega)H(\omega)B^*(\omega)\right)|_{\omega=0} = i^{|\beta|}\mathbf{L}_N^\beta \mathrm{vec}(H).
\end{aligned}$$

Therefore $\mathbf{L}_N^\beta \mathcal{T}_\mathbf{P}\mathrm{vec}(H) = 2^{-|\beta|}\mathbf{L}_N^\beta \mathrm{vec}(H)$; the proof of Theorem 2.2 is completed. $\square$

Since $\mathbf{L}_N^0 = (\mathbf{l}_0^0 \otimes \mathbf{l}_0^0, \dots, \mathbf{l}_0^0 \otimes \mathbf{l}_0^0) \neq 0$, 1 is an eigenvalue of $\mathbf{T_P}$. In the case $r = 1, d = 1$, for any $n \in \mathbf{Z}_+$, $n \leq 2m-1$, the vector v_n defined by (1.7) is a generalized left eigenvector of eigenvalue 2^{-n} of $\mathcal{T}_\mathbf{P}$ (see p. 228 in [6]), and hence $2^{-n}, 0 \leq n \leq 2m-1$ are eigenvalues of $\mathbf{T_P}$. Theorem 2.2 says that for $n \in \mathbf{Z}_+, n \leq 2m-1$, if there exists $\beta \in \mathbf{Z}_+^d, |\beta| = n$, and $\mathbf{L}_N^\beta \neq 0$, then 2^{-n} is an eigenvalue of $\mathcal{T}_\mathbf{P}$ (also $\mathbf{T_P}$) with $\mathbf{L}_N^\beta$ being a corresponding left eigenvector. As the vectors v_n do for the case $r = 1, d = 1$, vectors $\mathbf{L}_N^\beta$ also play an important role in the estimate of the Sobolev regularity of refinable vector Φ, which will be shown in the next section.

3. Sobolev regularity estimates. In this section we will consider the Sobolev regularity of the matrix refinable function Φ of (1.1). For $s \geq 0$, we say $f \in W^s(\mathbf{R}^d)$ if $(1 + |\omega|^2)^{\frac{s}{2}} \widehat{f}(\omega) \in L^2(\mathbf{R}^d)$. In the first part of this section, we will provide a characterization of Φ in $W^n(\mathbf{R}^d)$ for $n \in \mathbf{Z}_+$. We need a lemma.

LEMMA 3.1. *Assume that* $\mathbf{P}(\omega)$ *satisfies* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}_0^\beta$, $|\beta| \leq 2m-1$, *and* B *is the vector trigonometric polynomial satisfying* (2.9)*; then for any compactly supported solution* Φ *of* (1.1),

$$D^\beta \Big(B(\omega)\widehat{\Phi}(\omega) \Big) |_{\omega = 2\pi\ell} = 0 \quad \textit{for any } \ell \in \mathbf{Z}^d \backslash \{0\}, \beta \in \mathbf{Z}_+^d, |\beta| \leq m-1.$$

Proof. Since Φ is compactly supported, $\widehat{\Phi}(\omega)$ is analytic. For any $\ell \in \mathbf{Z}^d \backslash \{0\}$, write ℓ in the form of $\ell = 2^n\nu + 2^{n+1}\kappa$ for some $n \in \mathbf{Z}_+, \nu \in \mathbf{Z}^d/2\mathbf{Z}^d \backslash \{0\}, \kappa \in \mathbf{Z}^d$. Then

$$\begin{aligned}\widehat{\Phi}(2\pi\ell + \omega) &= \mathbf{P}\Big(\frac{2\pi\ell+\omega}{2}\Big) \cdots \mathbf{P}\Big(\frac{2\pi\ell+\omega}{2^n}\Big)\mathbf{P}\Big(\frac{2\pi\ell+\omega}{2^{n+1}}\Big)\widehat{\Phi}\Big(\frac{2\pi\ell+\omega}{2^{n+1}}\Big) \\ &= \mathbf{P}\Big(\frac{\omega}{2}\Big) \cdots \mathbf{P}\Big(\frac{\omega}{2^n}\Big)\mathbf{P}\Big(\frac{\omega}{2^{n+1}} + \nu\pi\Big)\widehat{\Phi}\Big(\frac{2\pi\ell+\omega}{2^{n+1}}\Big).\end{aligned}$$

Thus by (2.6) and (2.7), or by its equivalent forms (2.10) and (2.11),

$$\begin{aligned}&D^\beta \Big(B(\omega)\widehat{\Phi}(\omega) \Big) |_{\omega=2\pi\ell} = D^\beta \Big(B(\omega)\widehat{\Phi}(2\pi\ell+\omega) \Big) |_{\omega=0} \\ &= \sum_{0 \leq \alpha \leq \beta} \binom{\beta}{\alpha} D^\alpha \Big(B(\omega)\mathbf{P}\Big(\frac{\omega}{2}\Big) \Big) |_{\omega=0} \\ &\quad \cdot D^{\beta-\alpha} \Big(\mathbf{P}\Big(\frac{\omega}{2^2}\Big) \cdots \mathbf{P}\Big(\frac{\omega}{2^n}\Big)\mathbf{P}\Big(\frac{\omega}{2^{n+1}} + \nu\pi\Big)\widehat{\Phi}\Big(\frac{2\pi\ell+\omega}{2^{n+1}}\Big) \Big) |_{\omega=0} \\ &= \sum_{0 \leq \alpha \leq \beta} \binom{\beta}{\alpha} D^\alpha B\Big(\frac{\omega}{2}\Big) |_{\omega=0} \\ &\quad \cdot D^{\beta-\alpha} \Big(\mathbf{P}\Big(\frac{\omega}{2^2}\Big) \cdots \mathbf{P}\Big(\frac{\omega}{2^n}\Big)\mathbf{P}\Big(\frac{\omega}{2^{n+1}} + \nu\pi\Big)\widehat{\Phi}\Big(\frac{2\pi\ell+\omega}{2^{n+1}}\Big) \Big) |_{\omega=0} \\ &= D^\beta \Big(B\Big(\frac{\omega}{2}\Big)\mathbf{P}\Big(\frac{\omega}{2^2}\Big) \cdots \mathbf{P}\Big(\frac{\omega}{2^n}\Big)\mathbf{P}\Big(\frac{\omega}{2^{n+1}} + \nu\pi\Big)\widehat{\Phi}\Big(\frac{2\pi\ell+\omega}{2^{n+1}}\Big) \Big) |_{\omega=0} = \cdots \\ &= D^\beta \Big(B\Big(\frac{\omega}{2^n}\Big)\mathbf{P}\Big(\frac{\omega}{2^{n+1}} + \nu\pi\Big)\widehat{\Phi}\Big(\frac{2\pi\ell+\omega}{2^{n+1}}\Big) \Big) |_{\omega=0} = 0\end{aligned}$$

since $D^\alpha \big(B(\frac{\omega}{2^n})\mathbf{P}(\frac{\omega}{2^{n+1}} + \nu\pi) \big) |_{\omega=0} = 0$ for any $\alpha \leq \beta$. ∎

If a refinable vector Φ is contained in $W^{\frac{n}{2}}(\mathbf{R}^d)$ for some $n \in \mathbf{Z}_+$, then

$$\int_{\mathbf{R}^d} |\omega|^n |\widehat{\Phi}(\omega)|^2 d\omega < \infty. \tag{3.1}$$

For any $\beta_0 \in \mathbf{Z}_+^d$, $|\beta_0| = n$, define

$$H_{\beta_0}(\kappa) := \frac{1}{(2\pi)^d} \int_{\mathbf{R}^d} (i\omega)^{\beta_0} \widehat{\Phi}(\omega)\widehat{\Phi}^*(\omega) e^{i\kappa\omega} d\omega, \quad \kappa \in \mathbf{Z}_+^d.$$

Let F be the matrix function defined by

$$\widehat{F}(\omega) := (i\omega)^{\beta_0} \widehat{\Phi}(\omega)\widehat{\Phi}^*(\omega).$$

The finiteness of the integral in (3.1) implies that every entry of F is continuous and hence $H_{\beta_0}(\kappa) = F(\kappa)$. (3.1) also implies the existence of $D^{\beta_0}(\text{auto}(\Phi))(= F)$, where

$$\text{auto}(\Phi)(y) := \int_{\mathbf{R}^d} \Phi(x)\Phi^*(x-y)dx.$$

Since Φ is compactly supported on $[0, N]^d$, the support of F is contained in $[-N, N]^d$. Therefore $H_{\beta_0}(\kappa) = 0$ for $\kappa \notin [-N, N]^d$. Define

$$G^{(\beta_0)}(\omega) := \sum_{\kappa} H_{\beta_0}(\kappa) e^{-i\kappa\omega};$$

then $G^{(\beta_0)}(\omega) \in \mathbf{H}_N$ for any $|\beta_0| = n$.

PROPOSITION 3.1. *Assume that the refinement mask* $\mathbf{P}$ *satisfies* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}_0^\beta$, $|\beta| \le 2m-1$. *Suppose there exists a refinable vector* Φ *contained in* $W^{\frac{n}{2}}(\mathbf{R}^d)$ *for some* $n \in \mathbf{Z}_+$ *with* $n \le 2m-1$; *then for any* $\beta_0 \in \mathbf{Z}_+^d$, $|\beta_0| = n$,

$$\mathcal{T}_{\mathbf{P}} \text{vec}(G^{(\beta_0)}) = 2^{-n} \text{vec}(G^{(\beta_0)})$$

and for any $\beta \in \mathbf{Z}_+^d, \beta \le \beta_0$,

$$\mathbf{L}_N^\beta \text{vec}(G^{(\beta_0)}) = \beta_0! \delta_{\beta_0}(\beta) |\mathbf{l}_0^0 \widehat{\Phi}(0)|^2 = \begin{cases} 0, & \beta < \beta_0, \\ \beta_0! |\mathbf{l}_0^0 \widehat{\Phi}(0)|^2, & \beta = \beta_0. \end{cases}$$

Proof. By the Poisson summation formula,

$$G^{(\beta_0)}(\omega) = \sum_{\ell \in \mathbf{Z}^d} (i\omega + i2\pi\ell)^{\beta_0} \widehat{\Phi}(\omega + 2\pi\ell)\widehat{\Phi}^*(\omega + 2\pi\ell).$$

By the definition of $\mathbf{T}_{\mathbf{P}}$,

$$\begin{aligned} \mathbf{T}_{\mathbf{P}} G^{(\beta_0)}(\omega) &= \sum_{\nu \in \mathbf{Z}^d/2\mathbf{Z}^d} \sum_{\ell \in \mathbf{Z}^d} (i\omega/2 + 2\ell\pi i + \nu\pi i)^{\beta_0} \mathbf{P}(\omega/2 + \nu\pi) \\ &\quad \cdot \widehat{\Phi}(\omega/2 + 2\ell\pi + \nu\pi)\widehat{\Phi}^*(\omega/2 + 2\ell\pi + \nu\pi)\mathbf{P}^*(\omega/2 + \nu\pi) \\ &= \frac{1}{2^n} \sum_{\nu \in \mathbf{Z}^d/2\mathbf{Z}^d} \sum_{\ell \in \mathbf{Z}^d} (i\omega + 4\ell\pi i + 2\nu\pi i)^{\beta_0} \widehat{\Phi}(\omega + 4\ell\pi + 2\nu\pi)\widehat{\Phi}^*(\omega + 4\ell\pi + 2\nu\pi) \\ &= \frac{1}{2^n} G^{(\beta_0)}(\omega), \end{aligned}$$

and hence $\mathcal{T}_{\mathbf{P}} \text{vec}(G^{(\beta_0)}) = 2^{-n} \text{vec}(G^{(\beta_0)})$ by (2.5).

By Lemma 3.1, for any $\alpha \in \mathbf{Z}_+^d, |\alpha| < 2m-1$, and $\ell \in \mathbf{Z}^d \backslash \{0\}$,

$$D^\alpha \left(B(\omega)\widehat{\Phi}(\omega + 2\ell\pi)\widehat{\Phi}^*(\omega + 2\ell\pi)B^*(\omega)\right)|_{\omega=0} = 0.$$

Therefore, by Lemma 2.1,

$$\begin{aligned}
&\mathbf{L}_N^\beta \mathrm{vec}(G^{(\beta_0)}) = (-i)^{|\beta|} D^\beta (B(\omega)G^{(\beta_0)}(\omega)B^*(\omega))|_{\omega=0} \\
&= (-i)^{|\beta|} D^\beta ((i\omega)^{\beta_0} B(\omega)\widehat{\Phi}(\omega)\widehat{\Phi}^*(\omega)B^*(\omega))|_{\omega=0} \\
&\quad + (-i)^{|\beta|} D^\beta \left(\sum_{\ell \in \mathbf{Z}^d \backslash \{0\}} (i\omega + i2\ell\pi)^{\beta_0} B(\omega)\widehat{\Phi}(\omega + 2\ell\pi)\widehat{\Phi}^*(\omega + 2\ell\pi)B^*(\omega) \right)|_{\omega=0} \\
&= \beta_0! \delta_{\beta_0}(\beta) |\mathbf{l}_0^0 \widehat{\Phi}(0)|^2. \qquad \square
\end{aligned}$$

We note that if λ is a simple eigenvalue of a matrix, then the product of the corresponding left row eigenvector and right column eigenvector is not zero (see Lemma 6.3.10 in [18]). Thus $\mathbf{l}_0^0 \widehat{\Phi}(0) \neq 0$ since $\mathbf{P}(0)$ satisfies Condition E and $\widehat{\Phi}(0)$ is a right 1-eigenvector of $\mathbf{P}(0)$. By the fact that $\Phi \in W^{s_1}(\mathbf{R}^d)$ if $\Phi \in W^s(\mathbf{R}^d)$ and $s_1 < s$, Proposition 3.1 leads to the following corollary.

COROLLARY 3.1. *Assume that the refinement mask* $\mathbf{P}$ *satisfies* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}_0^\beta$, $|\beta| \leq 2m-1$. *Suppose there exists a nontrivial refinable vector* Φ *contained in* $W^{\frac{n}{2}}(\mathbf{R}^d)$ *for some* $n \in \mathbf{Z}_+$ *with* $n \leq 2m-1$; *then for any* $\beta \in \mathbf{Z}_+^d, |\beta| \leq n$, $\mathbf{L}_N^\beta \neq 0$, *and* $1, 2^{-1}, \ldots, 2^{-n}$ *are eigenvalues of* $\mathbf{T}_\mathbf{P}$.

The next theorem will give a characterization of the refinable vector Φ in the Sobolev space $W^n(\mathbf{R}^d)$, $n \in \mathbf{Z}_+$. But first, we need another lemma. For $j \in \mathbf{Z}_+$, denote

$$\Pi_j(\omega) := \chi_{2^j \mathbf{T}^d}(\omega) \Pi_{i=1}^j \mathbf{P}(2^{-i}\omega).$$

LEMMA 3.2. *For any* $H_1(\omega), H_2(\omega) \in \mathbf{H}_N$,

$$\int_{\mathbf{T}^d} H_1(\omega)(\mathbf{T}_\mathbf{P}^j H_2)(\omega)d\omega = \int_{\mathbf{R}^d} H_1(\omega)\Pi_j(\omega)H_2(2^{-j}\omega)\Pi_j(\omega)^* d\omega. \tag{3.2}$$

Proof. The proof of (3.2) can be found in [26]. In fact for $j = 1$,

$$\begin{aligned}
&\int_{\mathbf{R}^d} H_1(\omega)\Pi_1(\omega)H_2\left(\frac{\omega}{2}\right)\Pi_1(\omega)^* d\omega \\
&= \sum_{\beta \in \mathbf{Z}^d} \int_{\mathbf{T}^d} H_1(\omega)\mathbf{P}\left(\frac{\omega}{2} + \beta\pi\right)H_2\left(\frac{\omega}{2} + \beta\pi\right)\mathbf{P}^*\left(\frac{\omega}{2} + \beta\pi\right)\chi_{\mathbf{T}^d}\left(\frac{\omega}{2} + \beta\pi\right)d\omega \\
&= \sum_{\alpha \in \mathbf{Z}^d} \sum_{\nu \in \mathbf{Z}^d/2\mathbf{Z}^d} \int_{\mathbf{T}^d} H_1(\omega)\mathbf{P}\left(\frac{\omega}{2} + \nu\pi\right)H_2\left(\frac{\omega}{2} + \nu\pi\right)\mathbf{P}^*\left(\frac{\omega}{2} + \nu\pi\right)\chi_{\mathbf{T}^d}\left(\frac{\omega}{2} + 2\alpha\pi + \nu\pi\right)d\omega \\
&= \sum_{\nu \in \mathbf{Z}^d/2\mathbf{Z}^d} \int_{\mathbf{T}^d} H_1(\omega)\mathbf{P}\left(\frac{\omega}{2} + \nu\pi\right)H_2\left(\frac{\omega}{2} + \nu\pi\right)\mathbf{P}^*\left(\frac{\omega}{2} + \nu\pi\right)d\omega \\
&= \int_{\mathbf{T}^d} H_1(\omega)\mathbf{T}_\mathbf{P}H_2(\omega)d\omega.
\end{aligned}$$

For general j, this formula can be found by induction. $\square$

THEOREM 3.1. *Assume that the refinement mask* $\mathbf{P}$ *satisfies* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}_0^\beta$, $|\beta| \le 2m-1$; *then a refinable vector* Φ *is contained in* $W^n(\mathbf{R}^d)$ *for some* $n \in \mathbf{Z}_+$ *with* $n \le m-1$ *if and only if there exists a positive semidefinite* $H \in \mathbf{H}_N$ *satisfying the following conditions:*

(i) $\mathbf{T_P} H = 4^{-n} H$;

(ii) *there exist constants* $c_0, \delta > 0$ *such that*

$$H(\omega) \ge c_0 |\omega|^{2n} \mathbf{r}\mathbf{r}^T \quad \text{for } \omega \in [-\delta, \delta]^d,$$

where $\mathbf{r}$ *is the normalized right* 1*-eigenvector of* $\mathbf{P}(0)$.

Proof. "$\Longrightarrow$" If $\Phi \in W^n(\mathbf{R}^d)$, let

$$H(\omega) = (-1)^n \sum_{|\beta_0|=n} G^{(2\beta_0)}(\omega) \ge 0. \tag{3.3}$$

Then Proposition 3.1 leads to $\mathbf{T_P} H = 4^{-n} H$.

Since $\mathbf{P}(0)$ satisfies Condition E, $\widehat{\Phi}(\omega) \to c\mathbf{r}$ with $c \ne 0$ as $\omega \to 0$ (see [14], [23], and [26]). Thus there exists a constant $\delta > 0$ such that

$$\widehat{\Phi}(\omega)\widehat{\Phi}^*(\omega) \ge \frac{c^2}{2} \mathbf{r}\mathbf{r}^T \quad \text{for } \omega \in [-\delta, \delta]^d.$$

Therefore

$$\begin{aligned} H(\omega) &= (-1)^n \sum_{|\beta_0|=n} \sum_{\ell \in \mathbf{Z}^d} (i\omega + i2\ell\pi)^{2\beta_0} \widehat{\Phi}(\omega + 2\ell\pi)\widehat{\Phi}^*(\omega + 2\ell\pi) \\ &\ge \sum_{|\beta_0|=n} \omega^{2\beta_0} \widehat{\Phi}(\omega)\widehat{\Phi}^*(\omega) \ge \frac{c^2}{2} \mathbf{r}\mathbf{r}^T \sum_{|\beta_0|=n} \omega^{2\beta_0} = \frac{c^2 |\omega|^{2n}}{2} \mathbf{r}\mathbf{r}^T. \end{aligned}$$

"$\Longleftarrow$" Denote $g_j(\omega) := 4^{nj} \Pi_j(\omega) H(2^{-j}\omega) \Pi_j(\omega)^*$. Then

$$\begin{aligned} g_j(\omega) &\ge c_0 4^{nj} \chi_{[-\delta,\delta]^d}\left(\frac{\omega}{2^j}\right) \Pi_j(\omega) \left(\frac{|\omega|}{2^j}\right)^{2n} \mathbf{r}\mathbf{r}^T \Pi_j(\omega)^* \\ &= c_0 |\omega|^{2n} \chi_{[-\delta,\delta]^d}\left(\frac{\omega}{2^j}\right) \Pi_j(\omega)\mathbf{r}(\Pi_j(\omega)\mathbf{r})^*. \end{aligned}$$

Thus by the Fatou lemma and the fact that $\widehat{\Phi}(\omega) = \lim_{j\to\infty} \chi_{[-\delta,\delta]^d}(\frac{\omega}{2^j}) \Pi_j(\omega)\mathbf{r}$,

$$\begin{aligned} \int_{\mathbf{R}^d} |\omega|^{2n} |\widehat{\Phi}(\omega)|^2 d\omega &= c \int_{\mathbf{R}^d} \sum_{i=1}^r \mathbf{e}_i^T \liminf_{j\to\infty} |\omega|^{2n} \chi_{[-\delta,\delta]^d}\left(\frac{\omega}{2^j}\right) \Pi_j(\omega)\mathbf{r}(\Pi_j(\omega)\mathbf{r})^* \mathbf{e}_i d\omega \\ &\le c \sum_{i=1}^r \mathbf{e}_i^T \liminf_{j\to\infty} \int_{\mathbf{R}^d} |\omega|^{2n} \chi_{[-\delta,\delta]^d}\left(\frac{\omega}{2^j}\right) \Pi_j(\omega)\mathbf{r}(\Pi_j(\omega)\mathbf{r})^* d\omega \mathbf{e}_i \\ &\le c \sum_{i=1}^r \mathbf{e}_i^T \liminf_{j\to\infty} \int_{\mathbf{R}^d} g_j(\omega) d\omega \mathbf{e}_i < \infty, \end{aligned}$$

where the last inequality follows from

$$\int_{\mathbf{R}^d} g_j(\omega) d\omega = 4^{jn} \int_{\mathbf{T}^d} \mathbf{T}_\mathbf{P}^j H(\omega) d\omega = \int_{\mathbf{T}^d} H(\omega) d\omega < \infty.$$

By the continuity of $\widehat{\Phi}$, this leads to $\Phi \in W^n(\mathbf{R}^d)$. □

For $n = 0$, $W^0(\mathbf{R}^d) = L^2(\mathbf{R}^d)$. In fact the characterization of $\Phi \in L^2(\mathbf{R}^d)$ can be given in a more easy checking way. In [23], it was shown that under the assumption that $\mathbf{P}(0)$ satisfies Condition E, $\Phi \in L^2(\mathbf{R}^d)$ if and only if there exists a positive semidefinite $H \in \mathbf{H}_N$ satisfying $\mathbf{T}_{\mathbf{P}}H = H$ and $\mathbf{l}_0^0 H(0)(\mathbf{l}_0^0)^T > 0$.

If $\Phi \in W^n(\mathbf{R}^d)$, $n \le m-1$, where $H \in \mathbf{H}_N$ is defined by (3.3), then Proposition 3.1 implies that there exists a positive semidefinite H satisfying $\mathbf{T}_{\mathbf{P}}H = 4^{-n}H$ and

$$\mathbf{L}_N^{\beta}\mathrm{vec}(H) = c\beta! \sum_{|\beta_0|=n} \delta_{2\beta_0}(\beta) \tag{3.4}$$

for any $\beta \in \mathbf{Z}_+^d, |\beta| \le 2n$, where c is a nonzero constant independent of β. In the case $r = 1$, the existence of such positive semidefinite H is also sufficient for $\Phi \in W^n(\mathbf{R}^d)$. In fact by Lemma 2.1, (3.4) is equivalent to that for any $\beta \in \mathbf{Z}_+^d, |\beta| \le 2n$,

$$D^{\beta}\left(|B(\omega)|^2 H(\omega)\right)|_{\omega=0} = c \sum_{|\beta_0|=n} \delta_{2\beta_0}(\beta), \tag{3.5}$$

which implies that $D^{\beta}H(0) = c(\mathbf{l}_0^0)^{-2}\sum_{|\beta_0|=n}\delta_{2\beta_0}(\beta)$ (in this case $\mathbf{l}_0^0$ is a nonzero real number). Thus $H(\omega) = c|\omega|^{2n} + \mathrm{o}(|\omega|^{2n})$ (as $\omega \to 0$) and hence $H(\omega)$ satisfies condition (ii) of Theorem 3.1. For $r = 1, d = 1$, such results were given in [32].

Theorem 3.1 gives the characterization of refinable vectors $\Phi \in W^s(\mathbf{R}^d)$ with s being nonnegative integers. In the following, we will give an estimate of the Sobolev regularity of Φ in terms of the spectral radius of $\mathbf{T}_{\mathbf{P}}|_{\mathbf{H}_N^0}$, the restricted operator of $\mathbf{T}_{\mathbf{P}}$ to an invariant subspace $\mathbf{H}_N^0$ of $\mathbf{H}_N$.

For $j \in \mathbf{Z}_+, 1 \le j \le r$ and $\alpha \in \mathbf{Z}_+^d, |\alpha| \le m-1$, let ${}_j\mathbf{l}_N^{\alpha}$, ${}_j\mathbf{r}_N^{\alpha}$ be the $1 \times (r^2(2N+1)^d)$ vectors defined by

$$\begin{aligned} {}_j\mathbf{l}_N^{\alpha} &:= ({}_j\mathbf{l}^{\alpha}(\kappa)|_{\kappa=(-N,\dots,-N)}, \dots, {}_j\mathbf{l}^{\alpha}(\kappa)|_{\kappa=(N,\dots,N)}), \\ {}_j\mathbf{r}_N^{\alpha} &:= ({}_j\mathbf{r}^{\alpha}(\kappa)|_{\kappa=(-N,\dots,-N)}, \dots, {}_j\mathbf{r}^{\alpha}(\kappa)|_{\kappa=(N,\dots,N)}), \end{aligned} \tag{3.6}$$

with

$${}_j\mathbf{l}^{\alpha}(\kappa) := \mathbf{e}_j^T \otimes \mathbf{l}_{-\kappa}^{\alpha}, \quad {}_j\mathbf{r}^{\alpha}(\kappa) := \mathbf{l}_{\kappa}^{\alpha} \otimes \mathbf{e}_j^T, \quad \kappa \in \mathbf{Z}^d,$$

where $\mathbf{l}_{\kappa}^{\alpha}$ are the vectors defined by (2.12).

LEMMA 3.3. *Assume that the refinement mask* $\mathbf{P}$ *satisfies* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}_0^{\beta}$, $|\beta| \le 2m-1$, *and* B *is the vector trigonometric polynomial satisfying* (2.9). *For* $1 \le j \le r$ *and* $\alpha \in \mathbf{Z}_+^d, |\alpha| \le m-1$, *let* ${}_j\mathbf{l}_N^{\alpha}$ *and* ${}_j\mathbf{r}_N^{\alpha}$ *be the row vectors defined by* (3.6); *then for any* $H \in \mathbf{H}_N$,

$${}_j\mathbf{l}_N^{\alpha}\mathrm{vec}(H) = i^{\alpha}D^{\alpha}\left(B(\omega)H(\omega)\mathbf{e}_j\right)|_{\omega=0}, {}_j\mathbf{r}_N^{\alpha}\mathrm{vec}(H) = (-i)^{\alpha}D_V^{\alpha}\left(\mathbf{e}_j^T H(\omega)B^*(\omega)\right)|_{\omega=0},$$

where $\mathrm{vec}(H)$ *is the vector defined by* (2.2).

Proof. For any $H \in \mathbf{H}_N$, $H(\omega) = \sum_{\kappa\in[-N,N]^d} H_{\kappa}e^{-i\kappa\omega}$,

$$\begin{aligned} D^{\alpha}\left(B(\omega)H(\omega)\mathbf{e}_j\right)|_{\omega=0} &= \sum_{0\le\gamma\le\alpha}\binom{\alpha}{\gamma}D^{\gamma}B(0)D^{\alpha-\gamma}H(0)\mathbf{e}_j \\ &= i^{\alpha}\sum_{\kappa}\sum_{0\le\gamma\le\alpha}\binom{\alpha}{\gamma}(-\kappa)^{\alpha-\gamma}\mathbf{l}_0^{\gamma}H_{\kappa}\mathbf{e}_j = i^{\alpha}\sum_{\kappa}\mathbf{l}_{-\kappa}^{\alpha}H_{\kappa}\mathbf{e}_j \\ &= i^{\alpha}\sum_{\kappa}(\mathbf{e}_j^T \otimes \mathbf{l}_{-\kappa}^{\alpha})\mathrm{vec}(H_{\kappa}) = i^{\alpha}{}_j\mathbf{l}_N^{\alpha}\mathrm{vec}(H). \end{aligned}$$

The proof of the second formula is similar and details are omitted here. ∎

Let $\mathbf{H}_N^0$ be the subspace of $\mathbf{H}_N$ defined by

$$\begin{aligned}(3.7)\quad \mathbf{H}_N^0 := \{H \in \mathbf{H}_N : \quad & \mathbf{L}_N^\beta \mathrm{vec}(H) = 0, \quad {}_j\mathbf{l}_N^\alpha \mathrm{vec}(H) = 0, \text{ and} \\ & {}_j\mathbf{r}_N^\alpha \mathrm{vec}(H) = 0 \ \forall \beta, \alpha \in \mathbf{Z}_+^d, |\beta| \le 2m-1, |\alpha| \le m-1, 1 \le j \le r\}.\end{aligned}$$

PROPOSITION 3.2. *Assume that the refinement mask* $\mathbf{P}$ *satisfies* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}_0^\beta$, $|\beta| \le 2m-1$. *Let* $\mathbf{H}_N^0$ *be the subspace of* $\mathbf{H}_N$ *defined by* (3.7)*; then* $\mathbf{H}_N^0$ *is invariant under* $\mathbf{T}_\mathbf{P}$.

Proof. By Theorem 2.2, for any $H \in \mathbf{H}_N^0$ and $\beta \in \mathbf{Z}_+^d, |\beta| \le 2m-1$,

$$\mathbf{L}_N^\beta \mathrm{vec}(\mathbf{T}_\mathbf{P} H) = \mathbf{L}_N^\beta \mathcal{T}_\mathbf{P} \mathrm{vec}(H) = 2^{-|\beta|} \mathbf{L}_N^\beta \mathrm{vec}(H) = 0.$$

Let B be the vector trigonometric polynomial satisfying (2.9). By Lemma 3.3, for any $\alpha \in \mathbf{Z}_+^d, |\alpha| < m$, ${}_j\mathbf{l}_N^\alpha \mathrm{vec}(H) = 0$, and ${}_j\mathbf{r}_N^\alpha \mathrm{vec}(H) = 0$ for all $j, 1 \le j \le r$, are equivalent to $D^\alpha \left(B(\omega)H(\omega)\right)|_{\omega=0} = 0$ and $D^\alpha \left(H(\omega)B^*(\omega)\right)|_{\omega=0} = 0$, respectively. One can check by (2.10) and (2.11), $D^\alpha \left(B(\omega)\mathbf{T}_\mathbf{P} H(\omega)\right)|_{\omega=0} = 0$ ($D_V^\alpha \left(\mathbf{T}_\mathbf{P} H(\omega)B^*(\omega)\right)|_{\omega=0} = 0$, respectively) for all $\alpha \in \mathbf{Z}_+^d, |\alpha| < m$ if $D^\alpha \left(B(\omega)H(\omega)\right)|_{\omega=0} = 0$ ($D_V^\alpha \left(H(\omega)B^*(\omega)\right)|_{\omega=0} = 0$, respectively) for any $\alpha \in \mathbf{Z}_+^d, |\alpha| < m$. Thus $\mathbf{H}_N^0$ is invariant under $\mathbf{T}_\mathbf{P}$. ∎

Let $\mathbf{T}_\mathbf{P}|_{\mathbf{H}_N^0}$ denote the restriction of $\mathbf{T}_\mathbf{P}$ to $\mathbf{H}_N^0$. By the fact that the product of the left and right eigenvectors of a simple eigenvalue of a matrix is not zero again, Theorem 2.2 leads to the following corollary.

COROLLARY 3.2. *If* 2^{-n}, $0 \le n \le 2m-1$, *is a simple eigenvalue of* $\mathbf{T}_\mathbf{P}$ *and there exists* $\beta \in \mathbf{Z}_+^d$ *such that* $|\beta| = n$, $\mathbf{L}_N^\beta \ne 0$, *then* 2^{-n} *is not an eigenvalue of* $\mathbf{T}_\mathbf{P}|_{\mathbf{H}_N^0}$.

For the next proposition, we need to consider the transition operators on other spaces. Let $\mathbf{P}$ ($\{\mathbf{P}_\kappa\}$) be a given matrix mask satisfying (2.6) and (2.7) for some row vectors $\mathbf{l}_0^\beta$, $|\beta| \le 2m-1$, and $\mathrm{supp}\{\mathbf{P}_\kappa\} \subset [0, N]^d$. Denote $\mathcal{N} := \max(N, 2m)$. Let $\mathbf{H}_\mathcal{N}$ denote the space of all $r \times r$ matrices with each entry a trigonometric polynomial whose Fourier coefficients are supported in $[-\mathcal{N}, \mathcal{N}]^d$, and let $\mathbf{T}_{\mathbf{P},\mathcal{N}}$ denote the transition operator on $\mathbf{H}_\mathcal{N}$ defined by

$$\mathbf{T}_{\mathbf{P},\mathcal{N}} H(\omega) := \sum_{\nu \in \mathbf{Z}^d/2\mathbf{Z}^d} \mathbf{P}\left(\frac{\omega}{2} + \pi\nu\right) H\left(\frac{\omega}{2} + \pi\nu\right) \mathbf{P}^*\left(\frac{\omega}{2} + \pi\nu\right), \quad H \in \mathbf{H}_\mathcal{N}.$$

Then $\mathbf{T}_{\mathbf{P},\mathcal{N}}$ is a linear operator on $\mathbf{H}_\mathcal{N}$ leaving $\mathbf{H}_\mathcal{N}$ and $\mathbf{H}_N$ invariant, and $\mathbf{T}_{\mathbf{P},\mathcal{N}}$ is equivalent to the matrix

$$\mathcal{T}_{\mathbf{P},\mathcal{N}} := (2^{-d} \mathcal{A}_{2i-j})_{i,j \in [-\mathcal{N},\mathcal{N}]^d},$$

where $\mathcal{A}_j = \sum_{\ell \in [0,N]^d} \mathbf{P}_{\ell-j} \otimes \mathbf{P}_\ell$.

Let $\mathbf{H}_\mathcal{N}^0$ be the subspace of $\mathbf{H}_\mathcal{N}$ defined as follows: $H \in \mathbf{H}_\mathcal{N}^0$ if and only if $\mathbf{L}_\mathcal{N}^\beta \mathrm{vec}(H) = 0$, ${}_j\mathbf{l}_\mathcal{N}^\alpha \mathrm{vec}(H) = 0$, and ${}_j\mathbf{r}_\mathcal{N}^\alpha \mathrm{vec}(H) = 0$ for all $\beta, \alpha \in \mathbf{Z}_+^d, |\beta| \le 2m-1, |\alpha| \le m-1, 1 \le j \le r$. In this case $\mathbf{L}_\mathcal{N}^\beta$, ${}_j\mathbf{l}_\mathcal{N}^\alpha$, and ${}_j\mathbf{r}_\mathcal{N}^\alpha$ are $1 \times (r^2(2\mathcal{N}+1)^d)$ vectors defined by (2.12) and (3.6), respectively, with $\mathcal{N}$ instead of N. It can be shown similarly that $\mathbf{H}_\mathcal{N}^0$ is invariant under $\mathbf{T}_{\mathbf{P},\mathcal{N}}$. Let $\mathbf{T}_{\mathbf{P},\mathcal{N}}|_{\mathbf{H}_\mathcal{N}^0}$ denote the restriction of $\mathbf{T}_{\mathbf{P},\mathcal{N}}$ to $\mathbf{H}_\mathcal{N}^0$, and let $H_0 \in \mathbf{H}_\mathcal{N}$ defined by

$$(3.8)\qquad H_0(\omega) := \sum_{i=1}^d (1 - \cos\omega_i)^{2m} \mathbf{I}_r, \quad \omega = (\omega_1, \ldots, \omega_d)^T \in \mathbf{T}^d;$$

then $H_0(\omega) \in \mathbf{H}^0_{\mathcal{N}}$.

We note that the transition operator $\mathbf{T_P}$ defined by (1.6) is the restriction of $\mathbf{T}_{\mathbf{P},\mathcal{N}}$ to the subspace $\mathbf{H}_N$ of $\mathbf{H}_{\mathcal{N}}$, and $\mathcal{T}_{\mathbf{P}}$ defined by (2.4) is a submatrix of $\mathcal{T}_{\mathbf{P},\mathcal{N}}$. In fact, if $\mathcal{N} > N$, then $\mathcal{T}_{\mathbf{P},\mathcal{N}}$ can be written as

$$\mathcal{T}_{\mathbf{P},\mathcal{N}} = \begin{bmatrix} M_1 & \mathbf{0} & \mathbf{0} \\ * & \mathcal{T}_{\mathbf{P}} & * \\ \mathbf{0} & \mathbf{0} & M_2 \end{bmatrix},$$

where M_1 (M_2, respectively) is a strictly lower (upper, respectively) triangular matrix. Thus $\mathbf{T}_{\mathbf{P},\mathcal{N}}$ ($\mathbf{T}_{\mathbf{P},\mathcal{N}}|_{\mathbf{H}^0_{\mathcal{N}}}$, respectively) and $\mathbf{T_P}$ ($\mathbf{T_P}|_{\mathbf{H}^0_N}$, respectively) have the same nonzero eigenvalues and the eigenvectors of $\mathbf{T}_{\mathbf{P},\mathcal{N}}$ are in $\mathbf{H}_N$. Hence $\rho(\mathbf{T_P}|_{\mathbf{H}^0_N}) = \rho(\mathbf{T}_{\mathbf{P},\mathcal{N}}|_{\mathbf{H}^0_{\mathcal{N}}})$, where $\rho(\mathbf{T_P}|_{\mathbf{H}^0_N})$ and $\rho(\mathbf{T}_{\mathbf{P},\mathcal{N}}|_{\mathbf{H}^0_{\mathcal{N}}})$ denote the spectral radii of $\mathbf{T_P}|_{\mathbf{H}^0_N}$ and $\mathbf{T}_{\mathbf{P},\mathcal{N}}|_{\mathbf{H}^0_{\mathcal{N}}}$, respectively.

Choose a vector norm on space $\mathbf{H}^0_{\mathcal{N}}$ and define the operator (matrix) norm $\|\mathbf{T}_{\mathbf{P},\mathcal{N}}|_{\mathbf{H}^0_{\mathcal{N}}}\|$ with respect to this vector norm. Then

$$\lim_{n\to\infty} \|(\mathbf{T}_{\mathbf{P},\mathcal{N}}|_{\mathbf{H}^0_{\mathcal{N}}})^n\|^{1/n} = \rho(\mathbf{T}_{\mathbf{P},\mathcal{N}}|_{\mathbf{H}^0_{\mathcal{N}}}) = \rho(\mathbf{T_P}|_{\mathbf{H}^0_N}).$$

PROPOSITION 3.3. *Assume that* $\mathbf{P}$ *satisfies conditions* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}^\beta_0, |\beta| \le 2m-1$. *Let* $\mathbf{H}^0_N$ *be the subspace of* $\mathbf{H}_N$ *defined by* (3.7) *and* $\rho(\mathbf{T_P}|_{\mathbf{H}^0_N})$ *the spectral radius of* $\mathbf{T_P}|_{\mathbf{H}^0_N}$. *Then for any* $\epsilon > 0$, *for the corresponding refinable function* Φ, *there exists a constant* c *independent of* n *such that*

$$\int_{\mathbf{\Omega}_n} \left|\widehat{\Phi}(w)\right|^2 dw \le c\left(\rho(\mathbf{T_P}|_{\mathbf{H}^0_N}) + \epsilon\right)^n,$$

where $\mathbf{\Omega}_n := 2^n\mathbf{T}^d \backslash 2^{n-1}\mathbf{T}^d$, $n \in \mathbf{Z}_+$.

This proposition together with the usual Littlewood–Paley technique leads to the following Sobolev estimate of refinable vector Φ.

THEOREM 3.2. *Assume that* $\mathbf{P}$ *satisfies conditions* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}^\beta_0, |\beta| \le 2m-1$. *Let* $\mathbf{H}^0_N$ *be the subspace of* $\mathbf{H}_N$ *defined by* (3.7) *and* $\rho(\mathbf{T_P}|_{\mathbf{H}^0_N})$ *the spectral radius of* $\mathbf{T_P}|_{\mathbf{H}^0_N}$. *Then the matrix refinable function* Φ *is in* $W^s(\mathbf{R}^d)$ *for any* $s < s_0 := -\log_4 \rho(\mathbf{T_P}|_{\mathbf{H}^0_N})$.

The proofs of Proposition 3.3 and Theorem 3.2 can be carried out by modifying the proofs of Proposition 4.4 and Theorem 4.5 in [29]. For completeness, we give them here.

Proof of Proposition 3.3. Let $H_0(\omega) \in \mathbf{H}^0_{\mathcal{N}}$ defined by (3.8). Note that $H_0(\omega) \ge \mathbf{I}_r$ for $\omega \in \mathbf{T}^d \backslash (\frac{1}{2}\mathbf{T}^d)$, and $\widehat{\Phi}$ is continuous on $\mathbf{T}^d$; thus for any positive integer n,

$$\begin{aligned}\int_{\mathbf{\Omega}_n} \widehat{\Phi}(\omega)\widehat{\Phi}^*(\omega)d\omega &= \int_{\mathbf{\Omega}_n} \Pi_n(\omega)\widehat{\Phi}(2^{-n}\omega)\widehat{\Phi}^*(2^{-n}\omega)\Pi_n^*(\omega)d\omega \\ &\le c\int_{\mathbf{\Omega}_n} \Pi_n(\omega)\Pi_n^*(\omega)d\omega \le c\int_{\mathbf{\Omega}_n} \Pi_n(\omega)H_0(2^{-n}\omega)\Pi_n^*(\omega)d\omega \\ &= c\int_{\mathbf{T}^d} (\mathbf{T}^n_{\mathbf{P},\mathcal{N}}H_0)(\omega)d\omega,\end{aligned}$$

where the last equation can be shown similar to (3.2). Since the Hilbert–Schmidt norm $\|M\|_2 = \sqrt{\mathrm{Tr}(MM^*)}$ is an equivalent norm for finite matrices, by applying the

trace operation, we obtain

$$\int_{\mathbf{\Omega}_n} |\widehat{\Phi}(\omega)|^2 d\omega = \int_{\mathbf{\Omega}_n} \mathrm{Tr}\Big(\widehat{\Phi}(\omega)\widehat{\Phi}^*(\omega)\Big)\, d\omega \\ \le c_\epsilon \left(\rho(\mathbf{T}_{\mathbf{P},\mathcal{N}}|_{\mathbf{H}^0_{\mathcal{N}}}) + \epsilon\right)^n = c_\epsilon \left(\rho(\mathbf{T}_{\mathbf{P}}|_{\mathbf{H}^0_N}) + \epsilon\right)^n$$

with c_ϵ independent of n. ∎

Proof of Theorem 3.2. For $s < s_0$, let $\epsilon > 0$ be a constant satisfying $s < -\log_4(\rho(\mathbf{T}_{\mathbf{P}}|_{\mathbf{H}^0_N}) + \epsilon)$.

$$\int_{\mathbf{\Omega}_n} |\widehat{\Phi}(w)|^2 d\omega \le c(\epsilon + \rho(\mathbf{T}_{\mathbf{P}}|_{\mathbf{H}^0_N}))^n$$

for some constant c independent of n and $\widehat{\Phi}$ is continuous on $\mathbf{T}^d$; thus

$$\int_{\mathbf{R}^d} (1+|\omega|^2)^s |\widehat{\Phi}(\omega)|^2 d\omega = \int_{\mathbf{T}^d} (1+|\omega|^2)^s |\widehat{\Phi}(\omega)|^2 d\omega + \sum_{n=1}^{\infty} \int_{\mathbf{\Omega}_n} (1+|\omega|^2)^s |\widehat{\Phi}(\omega)|^2 d\omega \\ \le c + c\sum_{n=1}^{\infty} 2^{2ns} \left(\epsilon + \rho(\mathbf{T}_{\mathbf{P}}|_{\mathbf{H}^0_N})\right)^n < \infty.$$

Therefore $\Phi \in W^s(\mathbf{R}^d)$. ∎

Let $C^\gamma(\mathbf{R}^d)$ denote the space defined in the following way: if $\gamma = n + \gamma_1$ with $n \in \mathbf{Z}_+$ and $0 \le \gamma_1 < 1$, then $f \in C^\gamma(\mathbf{R}^d)$ if and only if $f \in C^{(n)}(\mathbf{R}^d)$ and $f^{(n)}$ is uniformly Hölder continuous with exponent γ_1; i.e.,

$$|D^\beta f(x+y) - D^\beta f(x)| \le c|y|^{\gamma_1} \text{ for any } \beta \in \mathbf{Z}^d_+, |\beta| = n,$$

for some constant c independent of $x, y \in \mathbf{R}^d$. With the well-known inclusion

$$W^s(\mathbf{R}^d) \subset C^\gamma(\mathbf{R}^d) \quad \text{for } s > \gamma + \frac{d}{2},$$

Theorem 3.2 leads to the following corollary.

Corollary 3.3. *Suppose* $\mathbf{P}$ *satisfies conditions* (2.6) *and* (2.7) *for some row vectors* $\mathbf{l}_0^\beta, |\beta| \le 2m-1$. *Let* $\mathbf{H}^0_N$ *be the subspace of* $\mathbf{H}_N$ *defined by* (3.7) *and* $\rho(\mathbf{T}_{\mathbf{P}}|_{\mathbf{H}^0_N})$ *the spectral radius of* $\mathbf{T}_{\mathbf{P}}|_{\mathbf{H}^0_N}$; *then refinable vector* $\Phi \in C^\gamma(\mathbf{R}^d)$ *for any* $\gamma < -\log_4 \rho(\mathbf{T}_{\mathbf{P}}|_{\mathbf{H}^0_N}) - \frac{d}{2}$.

4. Examples. In this section, we will give the Sobolev regularity estimates of some refinable vectors Φ. Before doing this, we shall decide if $\Phi = (\phi_l)_{l=1}^r$ is stable or orthogonal. It was shown (see [7], [13], [21], and [26]) that Φ is stable if and only if there exists a positive constant c such that $G_\Phi(\omega) \ge c\mathbf{I}_r$ for all $\omega \in \mathbf{T}^d$ and that Φ is orthogonal if and only if $G_\Phi(\omega) = \mathbf{I}_r$ for all $\omega \in \mathbf{T}^d$ and the matrix mask $\mathbf{P}$ is a *CQF* (*conjugate quadrature filter*), i.e., $\mathbf{P}$ satisfies

$$\sum_{\nu \in \mathbf{Z}^d/2\mathbf{Z}^d} \mathbf{P}(\omega + \nu\pi)\mathbf{P}^*(\omega + \nu\pi) = \mathbf{I}_r.$$

Assume that $\mathbf{P}$ satisfies the vanishing moment conditions of order at least one, and $\mathbf{P}(0)$ satisfies Condition E. By Theorem 2.2, 1 is an eigenvalue of $\mathbf{T}_{\mathbf{P}}$. If the 1-eigenmatrix of $\mathbf{T}_{\mathbf{P}}$ is positive (or negative) definite on $\mathbf{T}^d$, then there exists a nontrivial

refinable vector Φ in $L^2(\mathbf{R}^d)$ by Theorem 3.1, and $G_\Phi(\omega)$ is also a 1-eigenmatrix of $\mathbf{T_P}$. Therefore if eigenvalue 1 is simple, then $G_\Phi(\omega)$ is the unique (up to a constant) 1-eigenmatrix of $\mathbf{T_P}$ and hence Φ is stable. If $\mathbf{P}$ is a CQF, then $\mathbf{I}_r$ is a 1-eigenmatrix of $\mathbf{T_P}$. Thus if 1 is a simple eigenvalue of $\mathbf{T_P}$, then $\Phi \in L^2(\mathbf{R}^d)$ and $G_\Phi(\omega) = c\mathbf{I}_r$ for some nonzero constant c. Hence Φ is orthogonal; i.e., the integer shifts of ϕ_l, $1 \le l \le r$, form an orthogonal basis of their closed linear span in $L^2(\mathbf{R}^d)$. Therefore to decide if the refinable vector Φ is stable (or orthogonal), we need only to check that if 1 is a simple eigenvalue of $\mathbf{T_P}$ and the corresponding eigenmatrix is positive (or negative) definite on $\mathbf{T}^d$. In fact the stability of Φ implies that $\mathbf{T_P}$ satisfies Condition E and the 1-eigenmatrix of $\mathbf{T_P}$ is positive (or negative) definite on $\mathbf{T}^d$; see [29].

Assume that Φ is a compactly supported refinable vector with refinement mask $\mathbf{P}$ satisfying (2.6) and (2.7) for some row vectors $\mathbf{l}_0^\beta$, $|\beta| \le 2m-1$. To estimate the regularity of Φ by Theorem 3.2, we need to find $\rho(\mathbf{T_P}|_{\mathbf{H}_N^0})$. We note that λ is an eigenvalue of $\mathbf{T_P}|_{\mathbf{H}_N^0}$ if and only if there exists a right eigenvector $\mathbf{v}$ of eigenvalue λ of $\mathcal{T}_\mathbf{P}$ satisfying that for any $\beta, \alpha \in \mathbf{Z}_+^d, |\beta| \le 2m-1, |\alpha| \le m-1, 1 \le j \le r$,

$$\mathbf{L}_N^\beta \mathbf{v} = 0, \quad {}_j\mathbf{l}_N^\alpha \mathbf{v} = 0, \text{ and } {}_j\mathbf{r}_N^\alpha \mathbf{v} = 0, \tag{4.1}$$

where $\mathbf{L}_N^\beta$, ${}_j\mathbf{l}_N^\alpha$, and ${}_j\mathbf{r}_N^\alpha$ are the vectors defined by (2.13) and (3.6), respectively. Let $H_0 \in \mathbf{H}_N$ be the unique matrix function such that $\mathrm{vec}(H_0) = \mathbf{v}$; then H_0 is a λ-eigenmatrix of $\mathbf{T_P}|_{\mathbf{H}_N^0}$. Thus $\rho(\mathbf{T_P}|_{\mathbf{H}_N^0})$ is the largest modulus of all such eigenvalues of $\mathcal{T}_\mathbf{P}$ that have corresponding right eigenvectors satisfying (4.1).

We say that the Sobolev regularity estimate s_0 is optimal if $\Phi \in W^s(\mathbf{R}^d)$ if and only if $s < s_0$.

Example 4.1. Let ϕ_1 and ϕ_2 be the B-splines defined by the knots $0,0,1,1$ and $0,1,1,2$, respectively; i.e., $\phi_1(x) = 2x(1-x)\chi_{[0,1]}(x)$ and $\phi_2(x) = x^2\chi_{[0,1)}(x) + (2-x)^2\chi_{[1,2]}(x)$. Then $\Phi = (\phi_1, \phi_2)^T$ satisfies the matrix refinement equation (1.1) with mask

$$\mathbf{P}(\omega) := \frac{1}{4}\begin{bmatrix} 1+e^{-i\omega} & 1 \\ e^{-i\omega}+e^{-2i\omega} & \frac{1}{2}+2e^{-i\omega}+\frac{1}{2}e^{-2i\omega} \end{bmatrix}.$$

Mask $\mathbf{P}$ satisfies the vanishing moment conditions of order 3 with $\mathbf{l}_0^0 = (1,1)$, $\mathbf{l}_0^1 = (\frac{1}{2}, 1)$ and $\mathbf{l}_0^2 = (0,1)$; see [27]. The eigenvalues of $\mathbf{P}(0)$ are $1, \frac{1}{4}$. We can find vectors $\mathbf{l}_0^3 = (-\frac{1}{4}, 1)$, $\mathbf{l}_0^4 = (-\frac{1}{10}, \frac{9}{10})$ and $\mathbf{l}_0^5 = (\frac{1}{4}, \frac{1}{2})$ satisfying (2.7). In this case, $\mathcal{T}_\mathbf{P}$ is a 20×20 matrix. For $0 \le \beta \le 5$, $\mathbf{L}_2^\beta \ne 0$. Thus $2^{-\beta}$, $0 \le \beta \le 5$, are eigenvalues of $\mathcal{T}_\mathbf{P}$. In fact the eigenvalues of $\mathcal{T}_\mathbf{P}$ or $\mathbf{T_P}$ are $1, \frac{1}{2}, \frac{1}{4}(3), \frac{1}{8}(4), \frac{1}{16}(3), \frac{1}{32}(2), 0(4)$. Here, for an eigenvalue λ, the notation $\lambda(\ell)$ means that the algebraic multiplicity of λ is ℓ. Thus $\mathbf{T_P}$ satisfies Condition E. We can find a right 1-eigenvector $\mathbf{v}$ of $\mathcal{T}_\mathbf{P}$:

$$\mathbf{v} = (0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 0 \quad 3 \quad 1 \quad 4 \quad 3 \quad 3 \quad 12 \quad 0 \quad 3 \quad 0 \quad 1 \quad 0 \quad 0 \quad 0 \quad 0)^T.$$

That is,

$$H(\omega) = \begin{bmatrix} 4 & 3+3e^{i\omega} \\ 3+3e^{-i\omega} & 12+e^{i\omega}+e^{-i\omega} \end{bmatrix}$$

is a 1-eigenmatrix of $\mathbf{T_P}$. Checking directly, $H(\omega) \ge 2\mathbf{I}_2$ for all $\omega \in \mathbf{T}^d$; thus Φ is stable since $\mathbf{T_P}$ satisfies Condition E.

To estimate the regularity by our method, we need to find the largest eigenvalue module of $\mathbf{T_P}|_{\mathbf{H}_N^0}$. By Corollary 3.2, 1, $\frac{1}{2}$ are not eigenvalues of $\mathbf{T_P}|_{\mathbf{H}_N^0}$. We find $\frac{1}{8}$

is the largest eigenvalue module of $\mathbf{T_P}|_{\mathbf{H}_N^0}$ with a corresponding eigenmatrix

$$\begin{bmatrix} (e^{-i\omega}+e^{i\omega})/2 & -1-e^{i\omega} \\ -1-e^{-i\omega} & 2 \end{bmatrix}.$$

Therefore $\Phi \in W^{\frac{3}{2}-\epsilon}(\mathbf{R})$ or $\Phi \in C^{1-\epsilon}(\mathbf{R})$ for any $\epsilon > 0$, and our estimate is optimal from the definition of Φ.

Example 4.2. Let $\Phi = (\phi_1, \phi_2)^T$ be the refinable vectors treated in [11]. The mask of Φ is given by

$$\mathbf{P}(\omega) := \frac{1}{20}\begin{bmatrix} 6+6e^{-i\omega} & 8\sqrt{2} \\ (-1+9e^{-i\omega}+9e^{-2i\omega}-e^{-3i\omega})/\sqrt{2} & -3+10e^{-i\omega}-3e^{-2i\omega} \end{bmatrix}.$$

Mask $\mathbf{P}$ is a CQF and satisfies the vanishing moment conditions of order 2 with $\mathbf{l}_0^0 = (1.4142, 1)$ and $\mathbf{l}_0^1 = (.7071, 1)$; see [27]. The eigenvalues of $\mathbf{P}(0)$ are $1, -.2$ and we can find vectors $\mathbf{l}_0^2 = (.4714, .8333)$ and $\mathbf{l}_0^3 = (.3536, .5)$ satisfying (2.7). For $0 \le \beta \le 3$, vectors $\mathbf{L}_3^\beta \neq 0$; thus $2^{-\beta}$ are eigenvalues of $\mathcal{T}_\mathbf{P}$. The eigenvalues of $\mathcal{T}_\mathbf{P}$ or $\mathbf{T_P}$ are $1, \frac{1}{2}, \frac{1}{4}, \frac{1}{8}(2), -.2(2), .2(2), -.1(2), -.05(4), .04$, and $0(12)$. Thus $\mathbf{T_P}$ satisfies Condition E and hence Φ is orthogonal.

By Corollary 3.2, $1, \frac{1}{2}$, and $\frac{1}{4}$ are not eigenvalues of $\mathbf{T_P}|_{\mathbf{H}_N^0}$. We find that the largest eigenvalue module of $\mathbf{T_P}|_{\mathbf{H}_N^0}$ is $\frac{1}{8}$ with a corresponding eigenmatrix $H(\omega) = \sum_{k=-3}^{3} H_k e^{-ik\omega}$ given by

$$H_0 = \begin{bmatrix} -.0875 & .0674 \\ .0674 & -.1085 \end{bmatrix}, \quad H_1 = H_{-1}^T = \begin{bmatrix} -.0042 & .0004 \\ .0674 & -.0417 \end{bmatrix}$$

and

$$H_2 = H_{-2}^T = \begin{bmatrix} 0 & 0 \\ .0004 & 0 \end{bmatrix}, \quad H_3 = H_{-3} = \mathbf{0}.$$

Thus $\Phi \in W^{\frac{3}{2}-\epsilon}(\mathbf{R})$ or $\Phi \in C^{1-\epsilon}(\mathbf{R})$ for any $\epsilon > 0$. It was shown in [11] that Φ is in the Lip space, i.e., $|\Phi(x) - \Phi(y)| \le c|x-y|$ for some constant c independent of $x, y \in \mathbf{R}$. However $\Phi \notin C^1(\mathbf{R})$ since $\frac{1}{\sqrt{2}}(\phi_1(x)+\phi_1(x-1))+\phi_2(x)$ is the hat function $x\chi_{[0,1]}(x) + (2-x)\chi_{(1,2]}(x)$ (see [31]); thus our estimate is optimal.

At last we will analyze two refinable vectors from [1].

Example 4.3. Let $\Phi = (\phi_1, \phi_2)^T$ be the refinable vector treated in [1]. The mask of Φ is given by

$$\mathbf{P}(\omega) := \frac{1}{8}\begin{bmatrix} 2+4e^{-i\omega}+2e^{-2i\omega} & 2-2e^{-2i\omega} \\ -\sqrt{7}+\sqrt{7}e^{-2i\omega} & -\sqrt{7}+2e^{-i\omega}-\sqrt{7}e^{-2i\omega} \end{bmatrix}.$$

Mask $\mathbf{P}$ is a CQF and satisfies the vanishing moment conditions of order 2 with $\mathbf{l}_0^0 = (1, 0)$ and $\mathbf{l}_0^1 = (1, .2743)$, see [1]. The eigenvalues of $\mathbf{P}(0)$ are $1, -.4114$, and we can find vectors $\mathbf{l}_0^2 = (1.0752, .5486)$ and $\mathbf{l}_0^3 = (1.2257, .7909)$ satisfying (2.7). For $0 \le \beta \le 3$, vectors $\mathbf{L}_2^\beta \neq 0$; thus $2^{-\beta}$, $0 \le \beta \le 3$ are eigenvalues of $\mathcal{T}_\mathbf{P}$. The eigenvalues of $\mathbf{T_P}$ or $\mathcal{T}_\mathbf{P}$ are $1, \frac{1}{2}, \frac{1}{4}, \frac{1}{8}, -.4114(2), .2318, -.2057(3), .0130(2)$, and $0(8)$. Thus $\mathbf{T_P}$ satisfies Condition E and Φ is orthogonal.

By Corollary 3.2, $1, \frac{1}{2}$, $\frac{1}{4}$, and $\frac{1}{8}$ are not eigenvalues of $\mathbf{T_P}|_{\mathbf{H}_N^0}$. We find the largest eigenvalue module of $\mathbf{T_P}|_{\mathbf{H}_N^0}$ is .2318 with a corresponding eigenmatrix $H(\omega) =$

$\sum_{k=-2}^{2} H_k e^{-ik\omega}$ given by

$$H_0 = \begin{bmatrix} .2117 & 0 \\ 0 & .7564 \end{bmatrix}, \quad H_1 = H_{-1}^T = \begin{bmatrix} -.1059 & .1930 \\ -.1930 & .3253 \end{bmatrix}$$

and $H_2 = H_{-2} = \mathbf{0}$. Thus $\Phi \in W^{1.0545-\epsilon}(\mathbf{R})$ or $\Phi \in C^{.5545-\epsilon}(\mathbf{R})$ for any $\epsilon > 0$.

Example 4.4. Let $\Phi = (\phi_1, \phi_2)^T$ be another refinable vector treated in [1]. The mask $\mathbf{P}(\omega) := \frac{1}{2}\sum_{k=0}^{3} \mathbf{P}_k e^{-ik\omega}$ of Φ is given by

$$\mathbf{P}_0 = \frac{1}{40}\begin{bmatrix} 10-3\sqrt{10} & 5\sqrt{6}-2\sqrt{15} \\ 5\sqrt{6}-3\sqrt{15} & 5-3\sqrt{10} \end{bmatrix}, \mathbf{P}_1 = \frac{1}{40}\begin{bmatrix} 30+3\sqrt{10} & 5\sqrt{6}-2\sqrt{15} \\ -5\sqrt{6}-7\sqrt{15} & 5-3\sqrt{10} \end{bmatrix},$$

and $\mathbf{P}_2 = S_0\mathbf{P}_1 S_0, \mathbf{P}_3 = S_0\mathbf{P}_0 S_0$, where $S_0 = \mathrm{diag}(1,-1)$. Mask $\mathbf{P}$ is a CQF and satisfies the vanishing moment conditions of order 3 with $\mathbf{l}_0^0 = (1,0)$, $\mathbf{l}_0^1 = (1.5, .2372)$, and $\mathbf{l}_0^2 = (2.3063, .7117)$; see [1]. The eigenvalues of $\mathbf{P}(0)$ are $1, .0257$ and we can find vectors $\mathbf{l}_0^3 = (3.6283, 1.8980)$, $\mathbf{l}_0^4 = (6.0943, 4.9822)$, and $\mathbf{l}_0^5 = (11.5329, 13.4836)$ satisfying (2.7). Vectors $\mathbf{L}_3^\beta \neq 0$, thus $2^{-\beta}$, $0 \leq \beta \leq 5$, are eigenvalues of $\mathbf{T_P}$. The eigenvalues of $\mathbf{T_P}$ or $\mathcal{T}_\mathbf{P}$ are $1, \frac{1}{2}, \frac{1}{4}, \frac{1}{8}, \frac{1}{16}, \frac{1}{32}, .1357, -.0625, -.0576, .0257(2)$, $.0128(2), .0078(2), .0064(4), -.0016(4), .0032(2), .0007$, and $.0003(2)$. Thus $\mathbf{T_P}$ satisfies Condition E and Φ is orthogonal.

By Corollary 3.2, $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, and $\frac{1}{32}$ are not eigenvalues of $\mathbf{T_P}|_{\mathbf{H}_N^0}$. We find the largest eigenvalue module of $\mathbf{T_P}|_{\mathbf{H}_N^0}$ is .1357 with a corresponding eigenmatrix $H(\omega) = \sum_{k=-3}^{3} H_k e^{-ik\omega}$ given by

$$H_0 = \begin{bmatrix} .1180 & 0 \\ 0 & .8072 \end{bmatrix}, \quad H_1 = H_{-1}^T = \begin{bmatrix} -.0506 & .1602 \\ -.1602 & .3362 \end{bmatrix}$$

and

$$H_2 = H_{-2}^T = \begin{bmatrix} -.0084 & .0087 \\ -.0087 & .0086 \end{bmatrix}, \quad H_3 = H_{-3} = \mathbf{0}.$$

Thus $\Phi \in W^{1.4408-\epsilon}(\mathbf{R})$ or $\Phi \in C^{.9408-\epsilon}(\mathbf{R})$ for any $\epsilon > 0$.

Acknowledgments. The author would like to express his thanks to two anonymous referees for many helpful suggestions to this paper.

MULTIVARIATE REFINEMENT EQUATIONS AND CONVERGENCE OF SUBDIVISION SCHEMES*

BIN HAN† AND RONG-QING JIA†

Abstract. Refinement equations play an important role in computer graphics and wavelet analysis. In this paper we investigate multivariate refinement equations associated with a dilation matrix and a finitely supported refinement mask. We characterize the L_p-convergence of a subdivision scheme in terms of the p-norm joint spectral radius of a collection of matrices associated with the refinement mask. In particular, the 2-norm joint spectral radius can be easily computed by calculating the eigenvalues of a certain linear operator on a finite dimensional linear space. Examples are provided to illustrate the general theory.

Key words. refinement equations, subdivision schemes, joint spectral radii, wavelets

1. Introduction. The purpose of this paper is to investigate functional equations of the form

$$f = \sum_{\alpha \in \mathbb{Z}^s} a(\alpha) f(M\cdot - \alpha), \tag{1.1}$$

where f is the unknown function defined on the s-dimensional Euclidean space $\mathbb{R}^s$, a is a finitely supported sequence on $\mathbb{Z}^s$, and M is an $s \times s$ integer matrix such that $\lim_{n\to\infty} M^{-n} = 0$. Equation (1.1) is called a *refinement equation*, and the matrix M is called a *dilation matrix*. Correspondingly, the sequence a is called the *refinement mask*. Any function satisfying a refinement equation is called a *refinable function*. Refinement equations play an important role in computer graphics and wavelet analysis. See Jia and Micchelli [9] for some discussion of multiresolution and wavelet decompositions related to general dilation matrices.

If a satisfies

$$\sum_{\alpha \in \mathbb{Z}^s} a(\alpha) = m := |\det M|, \tag{1.2}$$

then it is known that there exists a unique compactly supported distribution f satisfying the refinement equation (1.1) subject to the condition $\hat{f}(0) = 1$. This distribution is said to be *the normalized solution* to the refinement equation with mask a. This fact was essentially proved by Cavaretta, Dahmen, and Micchelli in [1, Chap. 5] for the case in which the dilation matrix is two times the $s \times s$ identity matrix I. The same proof applies to the general refinement equation (1.1).

For $1 \le p \le \infty$, by $L_p(\mathbb{R}^s)$ we denote the Banach space of all (complex-valued) measurable functions f on $\mathbb{R}^s$ such that $\|f\|_p < \infty$, where

$$\|f\|_p := \left(\int_{\mathbb{R}^s} |f(x)|^p \, dx \right)^{1/p} \qquad \text{for } 1 \le p < \infty$$

and $\|f\|_\infty$ is the essential supremum of f on $\mathbb{R}^s$. The Fourier transform of a function $f \in L_1(\mathbb{R}^s)$ is defined to be

$$\hat{f}(\xi) := \int_{\mathbb{R}^s} f(x) e^{-ix\cdot\xi} \, dx, \qquad \xi \in \mathbb{R}^s,$$

where $x \cdot \xi$ denotes the inner product of two vectors x and ξ in $\mathbb{R}^s$.

Let f be the normalized solution to the refinement equation (1.1). Taking the Fourier transform of the functions on both sides of (1.1), we obtain

$$\hat{f}(\xi) = H\big((M^T)^{-1}\xi\big)\hat{f}\big((M^T)^{-1}\xi\big), \qquad \xi \in \mathbb{R}^s, \tag{1.3}$$

where M^T denotes the transpose of M, and

$$H(\xi) := \sum_{\alpha\in\mathbb{Z}^s} a(\alpha) e^{-i\alpha\cdot\xi}/m, \qquad \xi \in \mathbb{R}^s. \tag{1.4}$$

Obviously, (1.2) implies $H(2\beta\pi) = 1$ for all $\beta \in \mathbb{Z}^s$. Thus, it follows from (1.3) that, for all positive integers k and all $\beta \in \mathbb{Z}^s$,

$$\hat{f}\big(2\pi(M^T)^k\beta\big) = \hat{f}(2\pi\beta).$$

If, in addition, f lies in $L_1(\mathbb{R}^s)$, then by the Riemann–Lebesgue lemma we have

$$\hat{f}(2\pi\beta) = \lim_{k\to\infty} \hat{f}\big(2\pi(M^T)^k\beta\big) = 0 \qquad \forall\, \beta \in \mathbb{Z}^s \setminus \{0\}.$$

A function f is said to satisfy the *moment conditions* of order 1 if $\hat{f}(0) = 1$ and $\hat{f}(2\pi\beta) = 0$ for all $\beta \in \mathbb{Z}^s \setminus \{0\}$. Thus, if the normalized solution f of the refinement equation (1.1) lies in $L_1(\mathbb{R}^s)$, then f satisfies the moment conditions of order 1.

In order to solve the refinement equation (1.1), we start with a compactly supported function $\phi \in L_p(\mathbb{R}^s)$ $(1 \le p \le \infty)$ and use the iteration scheme $f_n := T_a^n\phi$, $n = 0, 1, 2, \ldots$, where T_a is the bounded linear operator on $L_p(\mathbb{R}^s)$ given by

$$T_a\phi := \sum_{\alpha\in\mathbb{Z}^s} a(\alpha)\phi(M\cdot - \alpha), \qquad \phi \in L_p(\mathbb{R}^s). \tag{1.5}$$

This iteration scheme is called a *subdivision scheme* (see [1]). In the literature a subdivision scheme is also referred to as a *cascade algorithm*.

Let $\ell(\mathbb{Z}^s)$ denote the linear space of all sequences on $\mathbb{Z}^s$, and let $\ell_0(\mathbb{Z}^s)$ denote the linear space of all finitely supported sequences on $\mathbb{Z}^s$. For $\beta \in \mathbb{Z}^s$ we use δ_β to denote the sequence on $\mathbb{Z}^s$ given by

$$\delta_\beta(\alpha) = \begin{cases} 1 & \text{if } \alpha = \beta, \\ 0 & \text{if } \alpha \in \mathbb{Z}^s \setminus \{\beta\}. \end{cases}$$

In particular, we write δ for δ_0. For a vector $y \in \mathbb{Z}^s$ we use ∇_y to denote the difference operator on $\ell(\mathbb{Z}^s)$ given by

$$\nabla_y u = u - u(\cdot - y), \qquad u \in \ell(\mathbb{Z}^s).$$

Let $e_1, \dots, e_s$ denote the unit coordinate vectors in $\mathbb{R}^s$. For simplicity, we write ∇_j for ∇_{e_j}, $j = 1, \dots, s$.

The *subdivision operator* S_a associated with a (see [1]) is the linear operator on $\ell(\mathbb{Z}^s)$ given by

$$S_a u(\alpha) := \sum_{\beta \in \mathbb{Z}^s} a(\alpha - M\beta) u(\beta), \qquad \alpha \in \mathbb{Z}^s, \tag{1.6}$$

where $u \in \ell(\mathbb{Z}^s)$. Then for $\phi \in L_p(\mathbb{R}^s)$ $(1 \le p \le \infty)$ we have

$$T_a \phi = \sum_{\alpha \in \mathbb{Z}^s} S_a \delta(\alpha) \phi(M\cdot - \alpha).$$

By induction on n, it is easily verified that

$$T_a^n \phi = \sum_{\alpha \in \mathbb{Z}^s} S_a^n \delta(\alpha) \phi(M^n \cdot - \alpha). \tag{1.7}$$

Taking the Fourier transform of both sides of (1.5), we obtain

$$\widehat{T_a \phi}(\xi) = H\big((M^T)^{-1}\xi\big)\, \hat{\phi}\big((M^T)^{-1}\xi\big), \qquad \xi \in \mathbb{R}^s, \tag{1.8}$$

where H is given by (1.4). It follows from (1.8) that

$$\hat{f}_n(\xi) = \prod_{k=1}^{n} H\big((M^T)^{-k}\xi\big) \hat{\phi}\big((M^T)^{-n}\xi\big), \qquad \xi \in \mathbb{R}^s.$$

Since $H(2\pi\beta) = 1$ for all $\beta \in \mathbb{Z}^s$, we have $\hat{\phi}(2\pi\beta) = \hat{f}_n(2\pi(M^T)^n\beta)$. Suppose f_n converges to the normalized solution f of (1.1) in the L_p-norm for some p $(1 \le p \le \infty)$. Then

$$\hat{\phi}(2\pi\beta) = \lim_{n\to\infty} \hat{f}_n(2\pi(M^T)^n\beta) = \delta(\beta) \qquad \forall\, \beta \in \mathbb{Z}^s.$$

In other words, ϕ must satisfy the moment conditions of order 1.

By using the Poisson summation formula, it is easily seen that a compactly supported integrable function ϕ satisfies the moment conditions of order 1 if and only if its shifts form a partition of unity; i.e.,

$$\sum_{\alpha \in \mathbb{Z}^s} \phi(\cdot - \alpha) = 1. \tag{1.9}$$

Let ϕ_0 be the function given by

$$\phi_0(x) := \prod_{j=1}^{s} \chi(x_j) \qquad \text{for } x = (x_1, \dots, x_s) \in \mathbb{R}^s, \tag{1.10}$$

where

$$\chi(t) = \begin{cases} 1+t & \text{for } t \in [-1,0), \\ 1-t & \text{for } t \in [0,1], \\ 0 & \text{for } t \in \mathbb{R} \setminus [-1,1]. \end{cases}$$

Evidently, ϕ_0 satisfies (1.9).

We say that the subdivision scheme associated with mask a *converges in the* L_p*-norm* if there is a function $f \in L_p(\mathbb{R}^s)$ such that

$$\lim_{n\to\infty} \|T_a^n \phi_0 - f\|_p = 0,$$

where ϕ_0 is the function given in (1.10). If the subdivision scheme converges in the L_∞-norm, then the limit function is continuous.

When the dilation matrix is two times the $s \times s$ identity matrix I, the uniform convergence of a subdivision scheme was studied by Cavaretta, Dahmen, and Micchelli [1]. In particular, they proved that the subdivision scheme associated with a mask a converges uniformly, provided the normalized solution of the corresponding refinement equation is continuous and has stable shifts. Dyn [4] also considered the uniform convergence of multivariate subdivision schemes and related her study to matrix subdivision schemes. Concerning general dilation matrices, Deslauriers, Dubois, and Dubuc [3] found a necessary and sufficient condition for the uniform convergence of interpolatory subdivision schemes.

In their study of nonseparable multidimensional wavelet bases, Kovaĉević and Vetterli [10] assumed the L_2-convergence of the subdivision scheme, but did not give any detail about possible characterization of the L_2-convergence. In [2], Cohen and Daubechies built orthonormal and biorthogonal wavelet bases of $L_2(\mathbb{R}^2)$ with dilation matrices of determinant 2 and established a sufficient condition for the uniform convergence of the corresponding subdivision scheme. In [13] Villemoes investigated continuity of nonseparable quincunx wavelets and the uniform convergence of related subdivision schemes.

In this paper we give a systematic and comprehensive study of multivariate refinement equations and subdivision schemes. Our main result characterizes the L_p-convergence of a subdivision scheme associated with a general dilation matrix M and a mask a. All the relevant results mentioned above are special cases of the general setting considered in this paper.

To describe our main result, we introduce the linear operators A_ε ($\varepsilon \in \mathbb{Z}^s$) on $\ell_0(\mathbb{Z}^s)$ as follows:

$$A_\varepsilon v(\alpha) = \sum_{\beta\in\mathbb{Z}^s} a(\varepsilon + M\alpha - \beta) v(\beta), \qquad v \in \ell_0(\mathbb{Z}^s),\ \alpha \in \mathbb{Z}^s. \tag{1.11}$$

We observe that the set $\mathbb{Z}^s$ is an abelian group under addition, and $M\mathbb{Z}^s$ is a subgroup of $\mathbb{Z}^s$. Let E be a complete set of representatives of the distinct cosets of the quotient group $\mathbb{Z}^s/M\mathbb{Z}^s$. For a finite subset K of $\mathbb{Z}^s$, we denote by $\ell(K)$ the linear subspace of $\ell_0(\mathbb{Z}^s)$ consisting of all sequences supported on K. It will be proved in section 2 that there exists a finite subset K of $\mathbb{Z}^s$ such that $\ell(K)$ contains $\nabla_j \delta$ for $j = 1, \ldots, s$ and is invariant under every A_ε ($\varepsilon \in E$). Let

$$V := \Big\{ v \in \ell(K) : \sum_{\alpha\in\mathbb{Z}^s} v(\alpha) = 0 \Big\}.$$

It is easily seen that V is a common invariant subspace of A_ε ($\varepsilon \in E$) if and only if $\sum_{\beta\in\mathbb{Z}^s} a(\alpha - M\beta) = 1$ for all $\alpha \in \mathbb{Z}^s$.

Let M be a dilation matrix with $m := |\det M|$ and let a be an element in $\ell_0(\mathbb{Z}^s)$ such that $\sum_{\alpha\in\mathbb{Z}^s} a(\alpha) = m$. Our main result states that the subdivision scheme associated with the mask a and the dilation matrix M converges in the L_p-norm ($1 \le p \le \infty$) if and only if the following two conditions are satisfied:

(a) $\sum_{\beta\in\mathbb{Z}^s} a(\alpha - M\beta) = 1$ for all $\alpha \in \mathbb{Z}^s$;

(b) $\rho_p(\{A_\varepsilon|_V : \varepsilon \in E\}) < m^{1/p}$, where $\rho_p(\{A_\varepsilon|_V : \varepsilon \in E\})$ denotes the joint p-norm spectral radius of the linear operators $A_\varepsilon|_V$, $\varepsilon \in E$.

This result will be proved in section 3 after a discussion of the joint spectral radius in section 2. In section 4, we demonstrate that the 2-norm joint spectral radius can be easily computed by calculating the eigenvalues of a certain linear operator on a finite dimensional linear space. Throughout the paper, examples are provided to illustrate the general theory.

2. Joint spectral radius. This section is devoted to a study of joint spectral radii of a finite collection of linear operators associated to a refinement equation.

Let $\mathcal{A}$ be a finite collection of linear operators on a *finite dimensional* vector space V. A vector norm $\|\cdot\|$ on V induces a norm on the linear operators on V as follows. For a linear operator A on V, define

$$\|A\| := \max_{\|v\|=1} \big\{\|Av\|\big\}.$$

For a positive integer n we denote by $\mathcal{A}^n$ the Cartesian power of $\mathcal{A}$:

$$\mathcal{A}^n = \big\{(A_1, \dots, A_n) : A_1, \dots, A_n \in \mathcal{A}\big\}.$$

When $n = 0$, we interpret $\mathcal{A}^0$ as the set $\{I\}$, where I is the identity mapping on V. Let

$$\|\mathcal{A}^n\|_\infty := \max\big\{\|A_1 \cdots A_n\| : (A_1, \dots, A_n) \in \mathcal{A}^n\big\}.$$

Then the uniform joint spectral radius of $\mathcal{A}$ is defined to be

$$\rho_\infty(\mathcal{A}) := \lim_{n\to\infty} \|\mathcal{A}^n\|_\infty^{1/n}.$$

The uniform joint spectral radius was introduced by Rota and Strang in [12].

The p-norm joint spectral radius of a finite collection of linear operators was introduced by Jia in [6]. We define, for $1 \le p < \infty$,

$$\|\mathcal{A}^n\|_p := \left(\sum_{(A_1,\dots,A_n)\in\mathcal{A}^n} \|A_1 \cdots A_n\|^p\right)^{1/p}.$$

For $1 \le p \le \infty$, the *p-norm joint spectral radius* of $\mathcal{A}$ is defined to be

$$\rho_p(\mathcal{A}) := \lim_{n\to\infty} \|\mathcal{A}^n\|_p^{1/n}.$$

It is easily seen that this limit indeed exists, and

$$\lim_{n\to\infty} \|\mathcal{A}^n\|_p^{1/n} = \inf_{n\ge1} \|\mathcal{A}^n\|_p^{1/n}.$$

Clearly, $\rho_p(\mathcal{A})$ is independent of the choice of the vector norm on V.

If $\mathcal{A}$ consists of a single linear operator A, then

$$\rho_p(\mathcal{A}) = \rho(A),$$

where $\rho(A)$ denotes the spectral radius of A, which is independent of p. If $\mathcal{A}$ consists of more than one element, then $\rho_p(\mathcal{A})$ depends on p in general. By some basic properties of ℓ_p spaces, we have that, for $1 \le p \le r \le \infty$,

$$(\#\mathcal{A})^{1/r-1/p}\rho_p(\mathcal{A}) \le \rho_r(\mathcal{A}) \le \rho_p(\mathcal{A}),$$

where $\#\mathcal{A}$ denotes the number of elements in $\mathcal{A}$. Furthermore, it is easily seen from the definition of the joint spectral radius that $\rho(A) \le \rho_\infty(\mathcal{A})$ for any element A in $\mathcal{A}$.

Recall that S_a is the subdivision operator given in (1.6). From (1.7) we see that, in order to study convergence of the subdivision scheme, we need to analyze the sequences $S_a^n\delta$, $n = 1, 2, \ldots$. For this purpose, we introduce the biinfinite matrices A_ε ($\varepsilon \in \mathbb{Z}^s$) as follows:

$$A_\varepsilon(\alpha, \beta) := a(\varepsilon + M\alpha - \beta), \qquad \alpha, \beta \in \mathbb{Z}^s. \tag{2.1}$$

LEMMA 2.1. *Suppose $\alpha = \varepsilon_1 + M\varepsilon_2 + \cdots + M^{n-1}\varepsilon_n + M^n\gamma$, where $\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n$, $\gamma \in \mathbb{Z}^s$. Then for any $\beta \in \mathbb{Z}^s$,*

$$S_a^n\delta(\alpha - \beta) = A_{\varepsilon_n} \cdots A_{\varepsilon_1}(\gamma, \beta).$$

Proof. The proof proceeds by induction on n. For $n = 1$ and $\alpha = \varepsilon_1 + M\gamma$, we have

$$S_a\delta(\alpha - \beta) = a(\varepsilon_1 + M\gamma - \beta) = A_{\varepsilon_1}(\gamma, \beta).$$

Suppose $n > 1$ and the lemma has been verified for $n - 1$. For $\alpha = \varepsilon_1 + M\alpha_1$, where $\alpha_1, \varepsilon \in \mathbb{Z}^s$, we have

$$S_a^n\delta(\alpha - \beta) = \sum_{\eta\in\mathbb{Z}^s} a(\alpha - \beta - M\eta)S_a^{n-1}\delta(\eta) = \sum_{\eta\in\mathbb{Z}^s} a(\varepsilon_1 + M\eta - \beta)S_a^{n-1}\delta(\alpha_1 - \eta). \tag{2.2}$$

Suppose $\alpha_1 = \varepsilon_2 + \cdots + M^{n-2}\varepsilon_n + M^{n-1}\gamma$. Then by the induction hypothesis we have

$$S_a^{n-1}\delta(\alpha_1 - \eta) = A_{\varepsilon_n} \cdots A_{\varepsilon_2}(\gamma, \eta).$$

This, in connection with (2.2), gives

$$S_a^n\delta(\alpha - \beta) = \sum_{\eta\in\mathbb{Z}^s} A_{\varepsilon_n} \cdots A_{\varepsilon_2}(\gamma, \eta)A_{\varepsilon_1}(\eta, \beta) = A_{\varepsilon_n} \cdots A_{\varepsilon_2}A_{\varepsilon_1}(\gamma, \beta),$$

thereby completing the induction procedure. ∎

The biinfinite matrices A_ε ($\varepsilon \in \mathbb{Z}^s$) defined in (2.1) may be viewed as the linear operators given in (1.11).

Now let $\mathcal{A}$ be a finite collection of linear operators on a vector space V, which is not necessarily finite dimensional. A subspace W of V is said to be $\mathcal{A}$-invariant if it is invariant under every operator A in $\mathcal{A}$. Let U be a subset of V. The intersection of all $\mathcal{A}$-invariant subspaces of V containing U is $\mathcal{A}$-invariant, and we call it the *minimal*

$\mathcal{A}$-*invariant subspace* generated by U, or the *minimal common invariant subspace* of the operators A in $\mathcal{A}$ generated by U. This subspace is spanned by the set

$$\{A_1 \cdots A_j u : u \in U,\, (A_1, \dots, A_j) \in \mathcal{A}^j,\, j = 0, 1, \dots\}.$$

If, in addition, V is finite dimensional, then there exists a positive integer k such that the set

$$\{A_1 \cdots A_j u : u \in U,\, (A_1, \dots, A_j) \in \mathcal{A}^j,\, j = 0, 1, \dots, k\}$$

already spans the minimal $\mathcal{A}$-invariant subspace generated by U.

We define, for $1 \le p < \infty$,

$$\|\mathcal{A}^n v\|_p := \left(\sum_{(A_1, \dots, A_n) \in \mathcal{A}^n} \|A_1 \cdots A_n v\|^p \right)^{1/p}$$

and, for $p = \infty$,

$$\|\mathcal{A}^n v\|_\infty := \max\bigl\{ \|A_1 \cdots A_n v\| : (A_1, \dots, A_n) \in \mathcal{A}^n \bigr\}.$$

The *symbol* of a sequence $a \in \ell_0(\mathbb{Z}^s)$ is the Laurent polynomial $\tilde{a}(z)$ given by

$$\tilde{a}(z) := \sum_{\alpha \in \mathbb{Z}^s} a(\alpha) z^\alpha, \qquad z \in (\mathbb{C} \setminus \{0\})^s,$$

where $z^\alpha := z_1^{\alpha_1} \cdots z_s^{\alpha_s}$ for $z = (z_1, \dots, z_s) \in (\mathbb{C} \setminus \{0\})^s$ and $\alpha = (\alpha_1, \dots, \alpha_s) \in \mathbb{Z}^s$.

For $\beta \in \mathbb{Z}^s$ we denote by τ^β the shift operator on $\ell_0(\mathbb{Z}^s)$ given by

$$\tau^\beta \lambda := \lambda(\cdot - \beta) \qquad \text{for } \lambda \in \ell_0(\mathbb{Z}^s).$$

Let ν be an element of $\ell_0(\mathbb{Z}^s)$. Then its symbol $\tilde{\nu}(z)$ is a Laurent polynomial, which induces the difference operator $\tilde{\nu}(\tau) := \sum_{\beta \in \mathbb{Z}^s} \nu(\beta) \tau^\beta$.

Let E be a complete set of representatives of the distinct cosets of the quotient group $\mathbb{Z}^s / M\mathbb{Z}^s$. We assume that E contains 0. Thus, each element $\alpha \in \mathbb{Z}^s$ can be uniquely represented as $\varepsilon + M\gamma$, where $\varepsilon \in E$ and $\gamma \in \mathbb{Z}^s$.

As usual, for $1 \le p \le \infty$, $\ell_p(\mathbb{Z}^s)$ denotes the Banach space of all sequences on $\mathbb{Z}^s$ such that $\|a\|_p < \infty$, where

$$\|a\|_p := \Bigl(\sum_{\alpha \in \mathbb{Z}^s} |a(\alpha)|^p \Bigr)^{1/p} \qquad \text{for } 1 \le p < \infty,$$

and $\|a\|_\infty$ is the supremum of a on $\mathbb{Z}^s$. In the following lemma, the underlying vector norm on $\ell_0(\mathbb{Z}^s)$ is chosen to be the ℓ_p-norm.

LEMMA 2.2. *Let S_a be the subdivision operator associated with a dilation matrix M and a mask a. Let $\mathcal{A} := \{A_\varepsilon : \varepsilon \in E\}$, where A_ε are the linear operators on $\ell_0(\mathbb{Z}^s)$ given by* (1.11). *Then for $1 \le p \le \infty$ and $\nu \in \ell_0(\mathbb{Z}^s)$,*

$$\|\tilde{\nu}(\tau) S_a^n \delta\|_p = \|\mathcal{A}^n \nu\|_p, \qquad n = 1, 2, \dots. \tag{2.3}$$

Proof. Suppose $\alpha = \varepsilon_1 + M\varepsilon_2 + \cdots + M^{n-1}\varepsilon_n + M^n\gamma$, where $\varepsilon_1, \varepsilon_2, \dots, \varepsilon_n \in E$ and $\gamma \in \mathbb{Z}^s$. Then by Lemma 2.1 we have

$$\begin{aligned} \tilde{\nu}(\tau) S_a^n \delta(\alpha) &= \sum_{\beta \in \mathbb{Z}^s} \nu(\beta) S_a^n \delta(\alpha - \beta) \\ &= \sum_{\beta \in \mathbb{Z}^s} A_{\varepsilon_n} \cdots A_{\varepsilon_1}(\gamma, \beta) \nu(\beta) = A_{\varepsilon_n} \cdots A_{\varepsilon_1} \nu(\gamma). \end{aligned}$$

Hence, (2.3) is true for $p = \infty$. When $1 \le p < \infty$ we have

$$\sum_{\alpha\in\mathbb{Z}^s} \left|\tilde{\nu}(\tau) S_a^n \delta(\alpha)\right|^p = \sum_{(\varepsilon_1,\dots,\varepsilon_n)\in E^n} \sum_{\gamma\in\mathbb{Z}^s} \left|A_{\varepsilon_n}\cdots A_{\varepsilon_1}\nu(\gamma)\right|^p.$$

This verifies (2.3) for $1 \le p < \infty$. □

Let $\mathcal{A} := \{A_\varepsilon : \varepsilon \in E\}$. We claim that, for each $\nu \in \ell_0(\mathbb{Z}^s)$, the minimal $\mathcal{A}$-invariant subspace generated by ν is finite dimensional. To establish this result, we shall introduce the concept of admissible sets. For a finite subset K of $\mathbb{Z}^s$, recall that $\ell(K)$ is the linear subspace of $\ell_0(\mathbb{Z}^s)$ consisting of all sequences supported on K. Let A be a linear operator on $\ell_0(\mathbb{Z}^s)$. A finite subset K of $\mathbb{Z}^s$ is said to be *admissible* for A if $\ell(K)$ is invariant under A. See [5] for the related notion of *good* sets. The following lemma shows that there exists a finite subset K of $\mathbb{Z}^s$ such that K contains the support of ν and is admissible for all A_ε, $\varepsilon \in E$.

LEMMA 2.3. *Suppose M is an $s \times s$ dilation matrix and a is a sequence on $\mathbb{Z}^s$ with its support $\Omega := \{\alpha \in \mathbb{Z}^s : a(\alpha) \ne 0\}$ being finite. Let A_ε ($\varepsilon \in E$) be the linear operators on $\ell_0(\mathbb{Z}^s)$ given by* (1.11). *Then a finite subset K of $\mathbb{Z}^s$ is admissible for $A := A_0$ if and only if*

$$M^{-1}(\Omega + K) \cap \mathbb{Z}^s \subseteq K. \tag{2.4}$$

Consequently, for any finite subset G of $\mathbb{Z}^s$, there exists a finite subset K of $\mathbb{Z}^s$ such that K contains G and K is admissible for all A_ε, $\varepsilon \in E$.

Proof. Suppose K is admissible for A. Let $\alpha \in M^{-1}(\Omega + K) \cap \mathbb{Z}^s$. Then we have $M\alpha = \gamma + \beta$ for some $\gamma \in \Omega$ and $\beta \in K$. It follows that

$$A\delta_\beta(\alpha) = a(M\alpha - \beta) = a(\gamma) \ne 0.$$

Since K is admissible for A, we have $A\delta_\beta \in \ell(K)$, and therefore $\alpha \in K$. This shows that (2.4) is true.

Conversely, suppose (2.4) is true. Let $v \in \ell(K)$ and $\alpha \in \mathbb{Z}^s$. Then

$$Av(\alpha) = \sum_{\beta\in\mathbb{Z}^s} a(M\alpha - \beta)v(\beta) \ne 0$$

implies that $M\alpha - \beta \in \Omega$ for some $\beta \in K$. It follows that $M\alpha \in \Omega + K$. Therefore, $\alpha \in M^{-1}(\Omega+K)\cap\mathbb{Z}^s$, and so $\alpha \in K$ by (2.4). This shows that A maps $\ell(K)$ to $\ell(K)$. In other words, K is admissible for A.

From the above proof we see that a finite subset K of $\mathbb{Z}^s$ is admissible for A_ε if and only if

$$M^{-1}(\Omega - \varepsilon + K) \cap \mathbb{Z}^s \subseteq K. \tag{2.5}$$

The set $\Omega - E$ consists of all the points $\omega - \varepsilon$, where $\omega \in \Omega$ and $\varepsilon \in E$.

Now suppose G is a finite subset of $\mathbb{Z}^s$. Let $H := MG \cup (\Omega - E) \cup \{0\}$, and let

$$K := \left(\sum_{n=1}^{\infty} M^{-n}H\right) \cap \mathbb{Z}^s.$$

In other words, an element $\alpha \in \mathbb{Z}^s$ belongs to K if and only if $\alpha = \sum_{n=1}^{\infty} M^{-n}h_n$ for some sequence of elements $h_n \in H$. Since $0 \in H$ and $M^{-1}H \supseteq G$, we have

$$K \supseteq \mathbb{Z}^s \cap M^{-1}H \supseteq \mathbb{Z}^s \cap G = G.$$

Moreover,

$$\begin{aligned} M^{-1}(\Omega - \varepsilon + K) \cap \mathbb{Z}^s &\subseteq M^{-1}(H + K) \cap \mathbb{Z}^s \\ &= (M^{-1}H + M^{-1}K) \cap \mathbb{Z}^s \\ &\subseteq (M^{-1}H + M^{-2}H + \cdots) \cap \mathbb{Z}^s = K. \end{aligned}$$

Thus, K satisfies (2.5). Hence, K is admissible for all A_ε, $\varepsilon \in E$. □

LEMMA 2.4. *Let $\mathcal{A}$ be a finite collection of linear operators on a vector space V. Let ν be a vector in V, and let $V(\nu)$ be the minimal $\mathcal{A}$-invariant subspace generated by ν. If $V(\nu)$ is finite dimensional, then*

$$\lim_{n\to\infty} \|\mathcal{A}^n \nu\|_p^{1/n} = \rho_p\big(\mathcal{A}|_{V(\nu)}\big). \tag{2.6}$$

Proof. Let $\|\cdot\|$ be a vector norm on $V(\nu)$. Since $V(\nu)$ is finite dimensional, there exists a positive integer k such that $V(\nu)$ is spanned by the set

$$Y := \{A_1 \cdots A_j \nu : (A_1, \ldots, A_j) \in \mathcal{A}^j,\ j = 0, 1, \ldots, k\}.$$

Thus, there exists a constant $C_1 > 0$ such that $\|\mathcal{A}^n y\|_p \le C_1 \|\mathcal{A}^n \nu\|_p$ for all $y \in Y$ and all $n = 1, 2, \ldots$. Moreover, there exists a positive constant C_2 such that

$$\|\mathcal{A}^n|_{V(\nu)}\|_p \le C_2 \max_{y\in Y} \|\mathcal{A}^n y\|_p, \qquad n = 1, 2, \ldots .$$

Therefore, there exists a positive constant C such that for all $n = 1, 2, \ldots$,

$$\|\mathcal{A}^n|_{V(\nu)}\|_p \le C \|\mathcal{A}^n \nu\|_p .$$

But $\|\mathcal{A}^n \nu\|_p \le \|\mathcal{A}^n|_{V(\nu)}\|_p \|\nu\|$. This proves the desired relation (2.6). □

THEOREM 2.5. *Let S_a be the subdivision operator associated with a dilation matrix M and a mask a. Let $\mathcal{A} := \{A_\varepsilon : \varepsilon \in E\}$, where E is a complete set of representatives of the distinct cosets of the quotient group $\mathbb{Z}^s/M\mathbb{Z}^s$ and A_ε are the linear operators on $\ell_0(\mathbb{Z}^s)$ given by* (1.11). *Then for $\nu \in \ell_0(\mathbb{Z}^s)$,*

$$\lim_{n\to\infty} \|\tilde{\nu}(\tau) S_a^n \delta\|_p^{1/n} = \rho_p\big(\{A_\varepsilon|_{V(\nu)} : \varepsilon \in E\}\big), \tag{2.7}$$

where $V(\nu)$ is the minimal $\mathcal{A}$-invariant subspace generated by ν. Moreover, if W is the minimal $\mathcal{A}$-invariant subspace generated by a finite set Y, then

$$\rho_p\big(\{A_\varepsilon|_W : \varepsilon \in E\}\big) = \max_{\nu\in Y} \big\{ \lim_{n\to\infty} \|\tilde{\nu}(\tau) S_a^n \delta\|_p^{1/n} \big\}. \tag{2.8}$$

Proof. By Lemma 2.3, $V(\nu)$ is finite dimensional, and so the relevant joint spectral radius in (2.7) is well defined. By Lemma 2.2 we have

$$\|\tilde{\nu}(\tau) S_a^n \delta\|_p = \|\mathcal{A}^n \nu\|_p, \qquad 1 \le p \le \infty,\ n = 1, 2, \ldots .$$

Applying Lemma 2.4 to the present situation, we obtain (2.7).

For the second part of the theorem, we let W be the minimal $\mathcal{A}$-invariant subspace generated by a finite set Y, and observe that W is a finite sum of the linear subspaces $V(\nu)$, $\nu \in Y$. Hence

$$\rho_p\big(\{A_\varepsilon|_W : \varepsilon \in E\}\big) = \max_{\nu\in Y} \big\{ \rho_p\big(\{A_\varepsilon|_{V(\nu)} : \varepsilon \in E\}\big) \big\}.$$

This, together with (2.7), verifies (2.8). □

3. Convergence of subdivision schemes. In this section we characterize the L_p-convergence ($1 \le p \le \infty$) of a subdivision scheme in terms of the corresponding refinement mask.

In our study of convergence, the concept of stability plays an important role. The shifts of a function ϕ in $L_p(\mathbb{R}^s)$ are said to be *stable* if there are two positive constants C_1 and C_2 such that

$$C_1\|\lambda\|_p \le \Big\|\sum_{\alpha\in\mathbb{Z}^s} \lambda(\alpha)\phi(\cdot-\alpha)\Big\|_p \le C_2\|\lambda\|_p \qquad \forall\, \lambda \in \ell_0(\mathbb{Z}^s). \tag{3.1}$$

It was proved by Jia and Micchelli [8] that a compactly supported function $\phi \in L_p(\mathbb{R}^s)$ satisfies the L_p-stability condition in (3.1) if and only if, for any $\xi \in \mathbb{R}^s$, there exists an element $\beta \in \mathbb{Z}^s$ such that

$$\hat{\phi}(\xi + 2\pi\beta) \ne 0.$$

It is easily seen that the shifts of the function ϕ_0 given in (1.10) are stable.

First, we give a necessary condition for the subdivision scheme to converge.

THEOREM 3.1. *Let M be a dilation matrix with $m := |\det M|$, a an element in $\ell_0(\mathbb{Z}^s)$ with $\sum_{\alpha\in\mathbb{Z}^s} a(\alpha) = m$, and S_a the subdivision operator associated with M and a. If the subdivision scheme associated with M and a converges in the L_p-norm ($1 \le p \le \infty$), then for any vector $y \in \mathbb{Z}^s$,*

$$\lim_{n\to\infty} m^{-n/p}\|\nabla_y S_a^n \delta\|_p = 0. \tag{3.2}$$

Consequently, if the subdivision scheme associated with a converges in the L_p-norm, then

$$\sum_{\beta\in\mathbb{Z}^s} a(\alpha - M\beta) = 1 \qquad \forall\, \alpha \in \mathbb{Z}^s. \tag{3.3}$$

Proof. Suppose ϕ is a compactly supported function in $L_p(\mathbb{R}^s)$, ϕ satisfies the moment conditions of order 1, and the shifts of ϕ are stable. For $n = 0, 1, 2, \ldots$, let $a_n := S_a^n\delta$ and $f_n := T_a^n\phi$, where T_a is the operator given in (1.5). Then by (1.7) we have

$$f_n = \sum_{\alpha\in\mathbb{Z}^s} a_n(\alpha)\phi(M^n\cdot - \alpha).$$

Hence, for $y \in \mathbb{Z}^s$ we have

$$\begin{aligned} f_n - f_n(\cdot - M^{-n}y) &= \sum_{\alpha\in\mathbb{Z}^s} \big[a_n(\alpha) - a_n(\alpha - y)\big]\phi(M^n\cdot - \alpha) \\ &= \sum_{\alpha\in\mathbb{Z}^s} \nabla_y a_n(\alpha)\phi(M^n\cdot - \alpha). \end{aligned}$$

Since the shifts of ϕ are stable, there exists a constant $C > 0$ such that

$$m^{-n/p}\|\nabla_y a_n\|_p \le C\|f_n - f_n(\cdot - M^{-n}y)\|_p. \tag{3.4}$$

In particular, the above estimate is valid for $f_n = T_a^n\phi_0$, where ϕ_0 is the function given in (1.10). If the subdivision scheme converges in the L_p-norm, then there exists

a compactly supported function f in $L_p(\mathbb{R}^s)$ ($f \in C(\mathbb{R}^s)$ in the case $p = \infty$) such that $\|f_n - f\|_p \to 0$ as $n \to \infty$. Moreover, by the triangle inequality, we have

$$\|f_n - f_n(\cdot - M^{-n}y)\|_p \le \|f - f(\cdot - M^{-n}y)\|_p + 2\|f - f_n\|_p.$$

Hence, $\|f_n - f_n(\cdot - M^{-n}y)\|_p \to 0$ as $n \to \infty$. This, together with (3.4), verifies (3.2).

For the second part of the theorem, we observe that if the subdivision scheme converges in the L_p-norm for some p with $1 \le p \le \infty$, then it also converges in the L_1-norm. Thus, we only have to deal with the case $p = 1$.

Let E be a complete set of representatives of the distinct cosets of $\mathbb{Z}^s/M\mathbb{Z}^s$. Then $\#E = m$, and $\mathbb{Z}^s$ is the disjoint union of $\alpha + M\mathbb{Z}^s$, $\alpha \in E$. Since $\sum_{\alpha\in\mathbb{Z}^s} a(\alpha) = m$, we have

$$\sum_{\alpha\in E}\sum_{\beta\in\mathbb{Z}^s} a(\alpha - M\beta) = m.$$

Thus, (3.3) will be proved if we can show

$$\sum_{\beta\in\mathbb{Z}^s} a(\alpha - M\beta) = \sum_{\beta\in\mathbb{Z}^s} a(-M\beta) \qquad \forall\, \alpha \in E. \tag{3.5}$$

To this end, we deduce from $a_n = S_a a_{n-1}$ that

$$\sum_{\alpha\in\mathbb{Z}^s} a_n(\alpha) = \sum_{\alpha\in\mathbb{Z}^s}\sum_{\beta\in\mathbb{Z}^s} a(\alpha - M\beta)a_{n-1}(\beta) = m\sum_{\beta\in\mathbb{Z}^s} a_{n-1}(\beta).$$

An induction argument gives $\sum_{\alpha\in\mathbb{Z}^s} a_n(\alpha) = m^n$. Moreover,

$$\begin{aligned}\sum_{\beta\in\mathbb{Z}^s} a_n(\alpha - M\beta) &= \sum_{\beta\in\mathbb{Z}^s}\sum_{\gamma\in\mathbb{Z}^s} a(\alpha - M\beta - M\gamma)a_{n-1}(\gamma)\\ &= \sum_{\beta\in\mathbb{Z}^s} a(\alpha - M\beta)\sum_{\gamma\in\mathbb{Z}^s} a_{n-1}(\gamma - \beta) = m^{n-1}\sum_{\beta\in\mathbb{Z}^s} a(\alpha - M\beta).\end{aligned}$$

Thus, we have

$$\sum_{\beta\in\mathbb{Z}^s}\big[a(\alpha - M\beta) - a(-M\beta)\big] = m^{-(n-1)}\sum_{\beta\in\mathbb{Z}^s}\big[a_n(\alpha - M\beta) - a_n(-M\beta)\big].$$

It follows that

$$\left|\sum_{\beta\in\mathbb{Z}^s}\big[a(\alpha - M\beta) - a(-M\beta)\big]\right| \le m^{-(n-1)}\|\nabla_\alpha a_n\|_1. \tag{3.6}$$

If the subdivision scheme is L_1-convergent, then by the first part of the theorem we have $m^{-(n-1)}\|\nabla_\alpha a_n\|_1 \to 0$ as $n \to \infty$. This, together with (3.6), implies (3.5), as desired. □

For the case $M = 2I$, it was proved by Cavaretta, Dahmen, and Micchelli [1] that the condition in (3.3) is necessary for the subdivision scheme to converge in the L_∞-norm.

The next theorem gives a characterization of convergence of the subdivision scheme.

THEOREM 3.2. *Let M be a dilation matrix with $m := |\det M|$, a an element in $\ell_0(\mathbb{Z}^s)$ such that $\sum_{\alpha\in\mathbb{Z}^s} a(\alpha) = m$, and S_a the corresponding subdivision operator. Then the subdivision scheme associated with M and a converges in the L_p-norm $(1 \le p \le \infty)$ if and only if*

$$\lim_{n\to\infty} \|\nabla_j S_a^n \delta\|_p^{1/n} < m^{1/p} \qquad \text{for } j = 1, \dots, s. \tag{3.7}$$

Proof. Let A_ε be the linear operators on $\ell_0(\mathbb{Z}^s)$ given by (2.1), and let V be the minimal common invariant subspace of A_ε $(\varepsilon \in E)$ generated by $\nabla_j\delta$, $j = 1, \dots, s$. Then V is finite dimensional, and by Theorem 2.5 we have

$$\rho_p := \rho_p\big(\{A_\varepsilon|_V : \varepsilon \in E\}\big) = \max_{1\le j\le s} \big\{ \lim_{n\to\infty} \|\nabla_j S_a^n \delta\|_p^{1/n} \big\}.$$

Thus, (3.7) is equivalent to $\rho_p\big(\{A_\varepsilon|_V : \varepsilon \in E\}\big) < m^{1/p}$.

Let $\mathcal{A} := \{A_\varepsilon|_V : \varepsilon \in E\}$. If $\rho_p(\{A_\varepsilon|_V : \varepsilon \in E\}) \ge m^{1/p}$, then we have

$$\inf_{n\ge1} \|\mathcal{A}^n\|_p^{1/n} = \lim_{n\to\infty} \|\mathcal{A}^n\|_p^{1/n} \ge m^{1/p}.$$

It follows that

$$m^{-n/p}\|\mathcal{A}^n\|_p \ge 1 \qquad \forall\, n.$$

From the proof of Lemma 2.4 we see that there exists a positive constant C such that $\|\mathcal{A}^n\|_p \le C \max_{1\le j\le s} \|\mathcal{A}^n \nabla_j \delta\|_p$ for all n. Moreover, by Lemma 2.2, we have $\|\mathcal{A}^n\nabla_j\delta\|_p = \|\nabla_j S_a^n\delta\|_p$. Hence,

$$\rho_p \ge m^{1/p} \quad \Longrightarrow \quad \max_{1\le j\le s} \big\{ m^{-n/p} \|\nabla_j S_a^n \delta\|_p \big\} \ge 1/C.$$

Thus, the subdivision scheme associated with a is not L_p-convergent, by Theorem 3.1. This shows that (3.7) is necessary for the subdivision scheme to converge in the L_p-norm.

In order to prove the sufficiency part of the theorem, we pick a compactly supported function ϕ in $L_p(\mathbb{R}^s)$ such that ϕ satisfies the moment conditions of order 1. (In the case $p = \infty$, we assume that ϕ is continuous.) Let $f_n := T_a^n\phi_0$ and $g_n := T_a^n\phi$ for $n = 1, 2, \dots$, where T_a is the operator given in (1.5) and ϕ_0 is the hat function given in (1.10). Moreover, let b_n be the sequence given by

$$b_n(\alpha) = \max_{1\le j\le s} |\nabla_j a_n(\alpha)|, \qquad \alpha \in \mathbb{Z}^s.$$

We claim that there exists a positive constant C independent of n such that

$$\|f_{n+1} - g_n\|_p \le C\, m^{-n/p} \|b_n\|_p, \qquad 1 \le p \le \infty. \tag{3.8}$$

If $\rho_p < m^{1/p}$, then we can find r, $0 < r < 1$, such that $\rho_p < r m^{1/p}$. By the definition of ρ_p and Theorem 2.5, we see that $\|b_n\|_p^{1/n} < r m^{1/p}$ is valid for sufficiently large n. Hence, there exists a positive constant C_0 such that $\|b_n\|_p \le C_0 (r m^{1/p})^n$ for all $n \ge 1$. If we choose ϕ to be ϕ_0, then it follows from (3.8) that

$$\|f_{n+1} - f_n\|_p \le C C_0 r^n, \qquad n = 1, 2, \dots.$$

This shows that the sequence f_n converges to a function f in the L_p-norm. Furthermore, (3.8) tells us that $\|f_{n+1} - g_n\|_p \to 0$ as $n \to \infty$. However,

$$\|g_n - f\|_p \le \|g_n - f_{n+1}\|_p + \|f_{n+1} - f\|_p$$

by the triangle inequality. Therefore, $\|g_n - f\|_p \to 0$ as $n \to \infty$. Thus, it suffices to prove (3.8). For this purpose, we shall follow the lines of Jia and Lei [7].

In what follows, by $\operatorname{supp}\phi$ we denote the support of ϕ, and by $\operatorname{supp} a$ we denote the set $\{\alpha \in \mathbb{Z}^s : a(\alpha) \neq 0\}$. For a sequence $\lambda \in \ell_\infty(\mathbb{Z}^s)$ and a subset G of $\mathbb{R}^s$, we use $\|\lambda\|_\infty(G)$ to denote the supremum of λ on the set $\mathbb{Z}^s \cap G$. Moreover, for $n = 1, 2, \ldots$, let

$$X_n(\gamma) := M^{-n}\big([0,1)^s + \gamma\big), \qquad \gamma \in \mathbb{Z}^s.$$

Let x be a point in $\mathbb{R}^s$. By (1.7) we have

$$f_{n+1}(x) = \sum_{\beta\in\mathbb{Z}^s} a_{n+1}(\beta)\phi_0(M^{n+1}x - \beta) \qquad \text{and} \qquad g_n(x) = \sum_{\alpha\in\mathbb{Z}^s} a_n(\alpha)\phi(M^n x - \alpha).$$

Since $\sum_{\beta\in\mathbb{Z}^s} \phi_0(\cdot - \beta) = 1$ and $\sum_{\alpha\in\mathbb{Z}^s} \phi(\cdot - \alpha) = 1$, it follows that

$$f_{n+1}(x) - g_n(x) = \sum_{\alpha\in\mathbb{Z}^s}\sum_{\beta\in\mathbb{Z}^s} \big[a_{n+1}(\beta) - a_n(\alpha)\big]\phi(M^n x - \alpha)\phi_0(M^{n+1}x - \beta). \tag{3.9}$$

In the above sum we only have to consider those terms for which $\phi(M^n x - \alpha) \neq 0$ and $\phi_0(M^{n+1}x - \beta) \neq 0$.

Let $x \in X_n(\gamma)$, where $\gamma \in \mathbb{Z}^s$ is fixed for the time being. Suppose $\phi(M^n x - \alpha) \neq 0$. Then we have $M^n x - \gamma \in [0,1)^s$ and $M^n x - \alpha \in \operatorname{supp}\phi$. It follows that

$$\alpha = \gamma + (M^n x - \gamma) - (M^n x - \alpha) \in \gamma + [0,1)^s - \operatorname{supp}\phi. \tag{3.10}$$

Suppose $\phi_0(M^{n+1}x - \beta) \neq 0$. Then $M^{n+1}x - \beta \in \operatorname{supp}\phi_0$. This, in connection with $M^n x - \alpha \in \operatorname{supp}\phi$, yields

$$M\alpha - \beta = (M^{n+1}x - \beta) - M(M^n x - \alpha) \in \operatorname{supp}\phi_0 - M\operatorname{supp}\phi. \tag{3.11}$$

Moreover, Theorem 3.1 tells us that (3.7) implies $\sum_{\eta\in\mathbb{Z}^s} a(\beta - M\eta) = 1$ for all $\beta \in \mathbb{Z}^s$; hence, we have

$$a_{n+1}(\beta) - a_n(\alpha) = \sum_{\eta\in\mathbb{Z}^s} a(\beta - M\eta)[a_n(\eta) - a_n(\alpha)]. \tag{3.12}$$

We observe that $a(\beta - M\eta) \neq 0$ implies $\beta - M\eta \in \operatorname{supp} a$. This, together with (3.11), gives

$$M(\alpha - \eta) = (M\alpha - \beta) + (\beta - M\eta) \in \operatorname{supp}\phi_0 - M\operatorname{supp}\phi + \operatorname{supp} a. \tag{3.13}$$

In light of (3.10) and (3.13), there exists a positive integer N such that both α and η belong to $\gamma + [-N, N]^s$, provided $\phi(M^n x - \alpha) \neq 0$, $\phi_0(M^{n+1}x - \beta) \neq 0$, and $a(\beta - M\eta) \neq 0$. However, $a_n(\eta) - a_n(\alpha)$ can be written as a sum of finitely many terms of the form $\nabla_j a_n(\nu)$, where $\nu \in \gamma + [-N, N]^s \cap \mathbb{Z}^s$ and $j = 1, \ldots, s$. Therefore, (3.12) tells us that there exists a positive constant C independent of n such that

$$|a_{n+1}(\beta) - a_n(\alpha)| \le C\|b_n\|_\infty(\gamma + [-N, N]^s), \tag{3.14}$$

provided $\phi(M^n x - \alpha)\phi_0(M^{n+1}x - \beta) \neq 0$ for some $x \in X_n(\gamma)$.

We observe that $\sum_{\beta\in\mathbb{Z}^s}|\phi_0(M^{n+1}x-\beta)|=1$. Consequently, by (3.9) and (3.14) we obtain

$$|f_{n+1}(x)-g_n(x)|\le C|\phi|^\circ(M^nx)\|b_n\|_\infty(\gamma+[-N,N]^s)\qquad\text{for } x\in X_n(\gamma), \tag{3.15}$$

where $|\phi|^\circ$ denotes the 1-periodization of $|\phi|$:

$$|\phi|^\circ(x):=\sum\nolimits_{\alpha\in\mathbb{Z}^s}|\phi(x-\alpha)|,\qquad x\in\mathbb{R}^s.$$

In the case $p=\infty$, ϕ is a continuous function with compact support; hence, there exists a constant $C_1>0$ such that $|\phi|^\circ(x)\le C_1$ for all $x\in\mathbb{R}^s$. It follows from (3.15) that $\|f_{n+1}-g_n\|_\infty\le CC_1\|b_n\|_\infty$. This proves (3.8) for the case $p=\infty$.

For $1\le p<\infty$, we deduce from (3.15) that

$$\int_{X_n(\gamma)}|f_{n+1}(x)-g_n(x)|^p\,dx\le C^p\biggl(\int_{X_n(\gamma)}\bigl[|\phi|^\circ(M^nx)\bigr]^p\,dx\biggr)\sum_{\alpha\in\gamma+[-N,N]^s}|b_n(\alpha)|^p.$$

Since $\phi\in L_p(\mathbb{R}^s)$ is compactly supported, we have

$$|\phi|^\circ(x)=\sum_{\alpha\in\mathbb{Z}^s\cap([0,1)^s-\operatorname{supp}\phi)}|\phi(x-\alpha)|,\qquad x\in[0,1)^s.$$

Hence, $C_2:=\int_{[0,1)^s}|\phi|^\circ(x)^p\,dx<\infty$. Consequently,

$$\int_{X_n(\gamma)}\bigl[|\phi|^\circ(M^nx)\bigr]^p\,dx=m^{-n}\int_{\gamma+[0,1)^s}\bigl[|\phi|^\circ(x)\bigr]^p\,dx=C_2m^{-n}.$$

Finally, we obtain

$$\begin{aligned}\|f_{n+1}-g_n\|_p^p&=\sum_{\gamma\in\mathbb{Z}^s}\int_{X_n(\gamma)}|f_{n+1}(x)-g_n(x)|^p\,dx\\&\le C^pC_2m^{-n}\sum_{\gamma\in\mathbb{Z}^s}\sum_{\alpha\in\gamma+[-N,N]^s}|b_n(\alpha)|^p.\end{aligned}$$

However,

$$\sum_{\gamma\in\mathbb{Z}^s}\sum_{\alpha\in\gamma+[-N,N]^s}|b_n(\alpha)|^p=\sum_{\alpha\in\mathbb{Z}^s}|b_n(\alpha)|^p\sum_{\gamma\in\alpha+[-N,N]^s}1=(2N+1)^s\sum_{\alpha\in\mathbb{Z}^s}|b_n(\alpha)|^p.$$

The preceding discussion tells us that

$$\|f_{n+1}-g_n\|_p\le C_3m^{-n/p}\|b_n\|_p$$

for some constant $C_3>0$. The proof is complete. □

Suppose K is an admissible set for every A_ε, $\varepsilon\in E$, and $\ell(K)$ contains $\nabla_j\delta$ for $j=1,\dots,s$. Let

$$V:=\Bigl\{v\in\ell(K):\sum_{\alpha\in\mathbb{Z}^s}v(\alpha)=0\Bigr\}.$$

If $\sum_{\beta\in\mathbb{Z}^s}a(\alpha-M\beta)=1$, then V is invariant under every A_ε, $\varepsilon\in E$. Thus, we may restate Theorem 3.2 as follows.

THEOREM 3.3. *Under the conditions of Theorem* 3.2*, the subdivision scheme associated with* a *converges in the* L_p*-norm* $(1 \le p \le \infty)$ *if and only if the following two conditions are satisfied:*

(a) $\sum_{\beta\in\mathbb{Z}^s} a(\alpha - M\beta) = 1$ *for all* $\alpha \in \mathbb{Z}^s$*;*

(b) $\rho_p(\{A_\varepsilon|_V : \varepsilon \in E\}) < m^{1/p}$.

Proof. For $j = 1, \dots, s$, $\nabla_j\delta \in V$. Conversely, V is spanned by vectors of the form $\tau^\beta\nabla_j\delta$, where $\beta \in \mathbb{Z}^s$, $j = 1, \dots, s$. Let $\mathcal{A} := \{A_\varepsilon|_V : \varepsilon \in E\}$. By Lemma 2.2 we have

$$\|\mathcal{A}^n\tau^\beta\nabla_j\delta\|_p = \|\tau^\beta\nabla_j S_a^n\delta\|_p = \|\nabla_j S_a^n\delta\|_p.$$

This shows that

$$\rho_p(\{A_\varepsilon|_V : \varepsilon \in E\}) = \max_{1\le j\le s}\big\{\lim_{n\to\infty}\|\nabla_j S_a^n\delta\|_p^{1/n}\big\}.$$

Thus, Theorem 3.3 follows from Theorem 3.2 at once. □

After a closer examination of the proof of Theorems 3.1 and 3.2, we obtain the following result.

THEOREM 3.4. *Let* a *be a finitely supported sequence on* $\mathbb{Z}^s$ *satisfying* (1.2) *and let* $T = T_a$ *be the linear operator given by* (1.5)*. Suppose* u *is a compactly supported function in* $L_p(\mathbb{R}^s)$ $(1 \le p \le \infty)$*,* u *satisfies the moment conditions of order* 1*, and the shifts of* u *are stable. If there exists a function* $f \in L_p(\mathbb{R}^s)$ (*a continuous function* f *in the case* $p = \infty$) *such that*

$$\lim_{n\to\infty}\|T^n u - f\|_p = 0, \tag{3.16}$$

then for any compactly supported function $v \in L_p(\mathbb{R}^s)$ *satisfying the moment conditions of order* 1 *we also have*

$$\lim_{n\to\infty}\|T^n v - f\|_p = 0. \tag{3.17}$$

Consequently, if the normalized solution f *of* (1.1) *lies in* $L_p(\mathbb{R}^s)$ (f *is a continuous function in the case* $p = \infty$)*, and if the shifts of* f *are stable, then the subdivision scheme associated with mask* a *converges to* f *in the* L_p*-norm.*

Proof. Suppose (3.16) is true for a function u that satisfies the moment conditions of order 1 and has stable shifts. Then the proof of Theorem 3.1 tells us that (3.2) is valid for every vector $y \in \mathbb{Z}^s$. Therefore, from the proof of Theorem 3.2 we see that (3.17) holds true for any compactly supported function $v \in L_p(\mathbb{R}^s)$ satisfying the moment conditions of order 1. In particular, if f itself has stable shifts, then we may choose u to be f in (3.16). Thus, in such a case, the subdivision scheme converges in the L_p-norm. □

We end this section by two examples which illustrate the general theory developed so far.

Example 3.5. Let $M = 2I$, where I is the 2×2 identity matrix. Consider the refinement equation

$$f = \sum_{\alpha\in\mathbb{Z}^2} a(\alpha) f(2\cdot - \alpha), \tag{3.18}$$

where the mask a is given by its symbol

$$\tilde{a}(z) = \frac{1}{4}\,z_1^{-1} + 1 + \frac{3}{4}\,z_1 + \frac{3}{4}\,z_1^{-1}z_2 + z_2 + \frac{1}{4}\,z_1 z_2, \qquad z = (z_1, z_2) \in \mathbb{T}^2.$$

We claim that the subdivision scheme associated with a is convergent in the L_p-norm for $1 \le p < \infty$, but it is not L_∞-convergent.

For $\varepsilon \in E := \{(0,0),(1,0),(0,1),(1,1)\}$, let A_ε be the operator on $\ell_0(\mathbb{Z}^2)$ given by

$$A_\varepsilon v(\alpha) = \sum_{\beta\in\mathbb{Z}^2} a(\varepsilon + 2\alpha - \beta)v(\beta), \qquad \alpha \in \mathbb{Z}^2,\ v \in \ell_0(\mathbb{Z}^2).$$

Let K be the set consisting of the points $(-1,0),(0,0),(1,0),(-1,1),(0,1),(1,1)$. Then K is admissible for A_ε, $\varepsilon \in E$. Let V be the linear space

$$\Big\{v \in \ell(K) : \sum_{\alpha\in\mathbb{Z}^2} v(\alpha) = 0\Big\}.$$

Then V is the minimal common invariant space of A_ε ($\varepsilon \in E$) generated by $\nabla_j\delta$, $j = 1, 2$. The dimension of V is 5. We choose a basis for V as follows:

$$v_1 = \delta - \delta_{(1,0)},\ v_2 = \delta - \delta_{(-1,0)},\ v_3 = \delta_{(0,1)} - \delta_{(1,1)},$$
$$v_4 = \delta_{(0,1)} - \delta_{(-1,1)}, \quad \text{and} \quad v_5 = r(\delta - \delta_{(0,1)}),$$

where $v = 1$ for $p = \infty$, and r is a number such that $0 < r < (3/2)^{1/p} - 1$ for $1 \le p < \infty$.

By computation, the matrix representations of $A_\varepsilon|_V$ ($\varepsilon \in E$) under this basis are given by

$$A_{(0,0)}|_V = \begin{bmatrix} 3/4 & 0 & 0 & 0 & 0 \\ 0 & 1/4 & 0 & 0 & 0 \\ 0 & 0 & 1/4 & 0 & 0 \\ 0 & 0 & 0 & 3/4 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}, \quad A_{(1,0)}|_V = \begin{bmatrix} 0 & -1/4 & 0 & 0 & 0 \\ 0 & 3/4 & 0 & 0 & 0 \\ 0 & 0 & 0 & -3/4 & 0 \\ 0 & 0 & 0 & 1/4 & 0 \\ 0 & -r/4 & 0 & 3r/4 & 1 \end{bmatrix},$$

and

$$A_{(0,1)}|_V = \begin{bmatrix} 1/4 & 0 & 0 & 0 & 0 \\ 0 & 3/4 & 0 & 0 & 0 \\ 3/4 & 0 & 0 & 0 & 0 \\ 0 & 1/4 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \qquad A_{(1,1)}|_V = \begin{bmatrix} 0 & -3/4 & 0 & 0 & 0 \\ 0 & 1/4 & 0 & 0 & 0 \\ 0 & -1/4 & 0 & 0 & 0 \\ 0 & 3/4 & 0 & 0 & 0 \\ 0 & -r/2 & 0 & 0 & 0 \end{bmatrix}.$$

Since $A_{(0,0)}|_V$ has an eigenvalue 1, we have

$$\rho_\infty\big(\{A_\varepsilon|_V : \varepsilon \in E\}\big) \ge 1.$$

Therefore, the subdivision scheme is not L_∞-convergent.

For the case $1 \le p < \infty$, we choose the maximum row sum norm as the matrix norm. Since $0 < r < (3/2)^{1/p} - 1$, we have

$$\sum_{\varepsilon\in E} \|A_\varepsilon|_V\|^p \le 1 + (1+r)^p + (3/4)^p + (3/4)^p < 4.$$

This shows that

$$\rho_p\big(\{A_\varepsilon|_V : \varepsilon \in E\}\big) < 4^{1/p}.$$

By Theorem 3.3, the subdivision scheme is L_p-convergent for $1 \le p < \infty$.

Example 3.6. Let

$$M = \begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}.$$

Then M is a dilation matrix with $\det M = 2$. Let a be the sequence on $\mathbb{Z}^2$ given by its symbol

$$\tilde{a}(z) = 1 + tz_1 + (1-t)z_2, \qquad z = (z_1, z_2) \in \mathbb{T}^2,$$

where t is a real number. We claim that the subdivision scheme associated with a and M is L_∞-convergent if and only if $0 < t < 1$.

Let A_0 and A_1 be the linear operators on $\ell_0(\mathbb{Z}^2)$ given by

$$A_0 v(\alpha) = \sum_{\beta \in \mathbb{Z}^2} a(M\alpha - \beta) v(\beta) \quad \text{and} \quad A_1 v(\alpha) = \sum_{\beta \in \mathbb{Z}^2} a((1,0) + M\alpha - \beta) v(\beta),$$

where $\alpha \in \mathbb{Z}^2$ and $v \in \ell_0(\mathbb{Z}^2)$. Let K be the set

$$[-1,2] \times [-2,2] \cap \mathbb{Z}^2 \setminus \{(-1,-2), (2,-2), (2,2), (-1,2)\}.$$

Then K is admissible for both A_0 and A_1. Let V be the linear space

$$\Big\{ v \in \ell(K) : \sum_{\alpha \in \mathbb{Z}^2} v(\alpha) = 0 \Big\}.$$

Then V is the minimal common invariant subspace of A_0 and A_1 generated by $\nabla_j \delta$, $j = 1, 2$. The dimension of V is 15. By Theorem 3.3, the subdivision scheme associated with a and M is L_∞-convergent if and only if $\rho_\infty(A_0|_V, A_1|_V) < 1$.

We observe that

$$A_0(\delta - \delta_{(0,-1)}) = t(\delta - \delta_{(0,-1)}) \quad \text{and} \quad A_0(\delta_{(0,1)} - \delta_{(1,1)}) = -(1-t)(\delta_{(0,1)} - \delta_{(1,1)}).$$

Hence, both t and $-(1-t)$ are eigenvalues of A_0. Consequently,

$$\rho_\infty(A_0|_V, A_1|_V) \geq \max\{|t|, |1-t|\}.$$

Therefore, for $t \leq 0$ or $t \geq 1$, the subdivision scheme associated with a and M is *not* convergent in the L_∞-norm.

Now assume that $0 < t < 1$. We wish to show $\rho_\infty(A_0|_V, A_1|_V) < 1$ in this case. Let

$$W := \big\{ \delta_\alpha - \delta_\beta : \alpha, \beta \in K,\ |\alpha - \beta| \leq 1 \big\},$$

where $|\alpha| := \max\{|\alpha_1|, |\alpha_2|\}$ for $\alpha = (\alpha_1, \alpha_2) \in \mathbb{Z}^2$. Then W is a spanning set for V. Any vector $v \in V$ can be represented as $\sum_{w \in W} c_w w$, where the coefficients c_w ($w \in W$) are not uniquely determined. Define

$$\|v\| := \min\Big\{ \sum_{w \in W} |c_w| : v = \sum_{w \in W} c_w w. \Big\}$$

Clearly, $\|\cdot\|$ is a norm on V.

We observe that

$$A_0(\delta-\delta_{(-1,0)})=(1-t)(\delta-\delta_{(0,1)}),\qquad A_0(\delta-\delta_{(0,-1)})=t(\delta-\delta_{(0,-1)})$$

and

$$A_1(\delta-\delta_{(1,0)})=-(1-t)(\delta-\delta_{(0,1)}),\qquad A_1(\delta-\delta_{(0,1)})=t(\delta-\delta_{(0,1)}).$$

With the help of these relations, we can verify through a simple but tedious computation that

$$\big\|A_{\varepsilon_1}A_{\varepsilon_2}A_{\varepsilon_3}A_{\varepsilon_4}A_{\varepsilon_5}w\big\|<1$$

for all $w\in W$ and all $\varepsilon_j\in\{0,1\}$, $j=1,\dots,5$. Thus, there exists a positive number $\sigma<1$ such that

$$\big\|A_{\varepsilon_1}A_{\varepsilon_2}A_{\varepsilon_3}A_{\varepsilon_4}A_{\varepsilon_5}w\big\|\le\sigma$$

for all $w\in W$ and all $\varepsilon_j\in\{0,1\}$, $j=1,\dots,5$. Let v be a unit vector in V. Choose a representation $\sum_{w\in W}c_ww$ for v such that $\sum_{w\in W}|c_w|=\|v\|=1$. Then

$$\big\|A_{\varepsilon_1}A_{\varepsilon_2}A_{\varepsilon_3}A_{\varepsilon_4}A_{\varepsilon_5}v\big\|\le\sum_{w\in W}|c_w|\big\|A_{\varepsilon_1}A_{\varepsilon_2}A_{\varepsilon_3}A_{\varepsilon_4}A_{\varepsilon_5}w\big\|\le\sigma<1.$$

This shows that $\|A_{\varepsilon_1}A_{\varepsilon_2}A_{\varepsilon_3}A_{\varepsilon_4}A_{\varepsilon_5}\|\le\sigma<1$ for all $\varepsilon_j\in\{0,1\}$, $j=1,\dots,5$. Therefore, $\rho_\infty(A_0|_V,A_1|_V)<1$ and the subdivision scheme associated with a and M is L_∞-convergent if $0<t<1$.

4. L_2-convergence. In general, the p-norm joint spectral radius is difficult to compute. However, the 2-norm joint spectral radius can be easily computed by calculating the spectral radius of a certain finite matrix.

Given $a\in\ell_0(\mathbb{Z}^s)$, the symbol $\tilde a(z)$ is well defined on the s-torus

$$\mathbb{T}^s:=\{(z_1,\dots,z_s)\in\mathbb{C}^s:|z_1|=\cdots=|z_s|=1\}.$$

For $a,b\in\ell_0(\mathbb{Z}^s)$, the discrete convolution of a and b, denoted $a*b$, is given by

$$a*b(\alpha):=\sum_{\beta\in\mathbb{Z}^s}a(\alpha-\beta)b(\beta),\qquad\beta\in\mathbb{Z}^s.$$

It is easily seen that

$$\widetilde{a*b}(z)=\tilde a(z)\tilde b(z),\qquad z\in(\mathbb{C}\setminus\{0\})^s.$$

For $z\in\mathbb{C}$, we use $\overline{z}$ to denote the complex conjugate of z. Note that for $z\in\mathbb{T}^s$ and $\alpha\in\mathbb{Z}^s$, we have $\overline{z^\alpha}=z^{-\alpha}$. For $a\in\ell_0(\mathbb{Z}^s)$, we denote by a^* the sequence given by $a^*(\alpha):=\overline{a(-\alpha)}$, $\alpha\in\mathbb{Z}^s$. Then for $z\in\mathbb{T}^s$ we have

$$\widetilde{a^*}(z)=\sum_{\alpha\in\mathbb{Z}^s}\overline{a(-\alpha)}z^\alpha=\sum_{\alpha\in\mathbb{Z}^s}\overline{a(-\alpha)z^{-\alpha}}=\overline{\tilde a(z)}.$$

If $b=a*a^*$, then we have

$$\tilde b(z)=\tilde a(z)\widetilde{a^*}(z)=|\tilde a(z)|^2\qquad\text{for }z\in\mathbb{T}^s.$$

THEOREM 4.1. *Let M be an $s \times s$ dilation matrix. For $a \in \ell_0(\mathbb{Z}^s)$, let $b := a*a^*$ and denote by S_a and S_b the subdivision operators associated with a and b, respectively. Then for $\nu \in \ell_0(\mathbb{Z}^s)$,*

$$\lim_{n\to\infty} \|\tilde{\nu}(\tau) S_a^n \delta\|_2^{1/n} = \sqrt{\rho(B|_W)}$$

and

$$\lim_{n\to\infty} \|\tilde{\mu}(\tau) S_b^n \delta\|_\infty^{1/n} = \rho(B|_W),$$

where $\mu := \nu*\nu^*$, B is the linear operator on $\ell_0(\mathbb{Z}^s)$ given by

$$Bw(\alpha) = \sum_{\beta\in\mathbb{Z}^s} b(M\alpha - \beta) w(\beta), \qquad \alpha \in \mathbb{Z}^s,\ w \in \ell_0(\mathbb{Z}^s), \tag{4.1}$$

and W is the minimal B-invariant subspace generated by μ.

Proof. For $n = 1, 2, \ldots$, write a_n for $S_a^n \delta$ and b_n for $S_b^n \delta$. Note that the symbol of $\tilde{\nu}(\tau) a_n$ is $\tilde{\nu}(z)\tilde{a}_n(z)$, and the symbol of $\tilde{\mu}(\tau) b_n$ is $\tilde{\mu}(z)\tilde{b}_n(z)$. By the Parseval identity we have

$$\begin{aligned} \|\tilde{\nu}(\tau) a_n\|_2^2 &= \sum_{\alpha\in\mathbb{Z}^s} \left|\tilde{\nu}(\tau) a_n(\alpha)\right|^2 \\ &= \frac{1}{(2\pi)^s} \int_{[0,2\pi)^s} \left|\tilde{\nu}(e^{i\xi})\tilde{a}_n(e^{i\xi})\right|^2 d\xi = \frac{1}{(2\pi)^s} \int_{[0,2\pi)^s} \tilde{\mu}(e^{i\xi})\tilde{b}_n(e^{i\xi})\, d\xi. \end{aligned}$$

Since $\tilde{\mu}(e^{i\xi})\tilde{b}_n(e^{i\xi}) \ge 0$ for all $\xi \in \mathbb{R}^s$, it follows that

$$\begin{aligned} \tilde{\mu}(\tau) b_n(0) \le \|\tilde{\mu}(\tau) b_n\|_\infty &\le \frac{1}{(2\pi)^s} \int_{[0,2\pi)^s} \left|\tilde{\mu}(e^{i\xi})\tilde{b}_n(e^{i\xi})\right| d\xi \\ &= \frac{1}{(2\pi)^s} \int_{[0,2\pi)^s} \tilde{\mu}(e^{i\xi})\tilde{b}_n(e^{i\xi})\, d\xi = \tilde{\mu}(\tau) b_n(0). \end{aligned}$$

From the proof of Lemma 2.2 we see that $\tilde{\mu}(\tau) b_n(0) = B^n \mu(0)$. Hence,

$$\|\tilde{\nu}(\tau) S_a^n \delta\|_2^2 = \|\tilde{\mu}(\tau) S_b^n \delta\|_\infty = B^n \mu(0).$$

It follows that

$$\lim_{n\to\infty} \|\tilde{\mu}(\tau) S_b^n \delta\|_\infty^{1/n} \le \lim_{n\to\infty} |B^n \mu(0)|^{1/n} \le \rho(B|_W).$$

Moreover, since W is the minimal B-invariant subspace generated by μ, Theorem 2.5 tells us that

$$\rho(B|_W) \le \lim_{n\to\infty} \|\tilde{\mu}(\tau) S_b^n \delta\|_\infty^{1/n}.$$

This completes the proof. □

We remark that Goodman, Micchelli, and Ward in [5] established a result similar to Theorem 4.1 for the special case $\nu = \delta$.

The following theorem discusses the relationship among the spectra of B when it is restricted to different invariant subspaces.

THEOREM 4.2. *Let M be an $s \times s$ dilation matrix. For an element $b \in \ell_0(\mathbb{Z}^s)$, let B be the linear operator on $\ell_0(\mathbb{Z}^s)$ given by (4.1). Suppose Ω is the support of b. Then the set K_0 given by*

$$K_0 := \Big(\sum_{n=1}^{\infty} M^{-n}\Omega\Big) \cap \mathbb{Z}^s \tag{4.2}$$

is admissible for B. Moreover, if W is a finite dimensional B-invariant subspace, then the eigenvalues of $B|_{W\cap\ell(K_0)}$ are also eigenvalues of $B|_W$, and all the other eigenvalues of $B|_W$ are 0.

Proof. Let K_0 be the set given in (4.2). Then

$$M^{-1}(\Omega + K_0) \subseteq \sum_{n=1}^{\infty} M^{-n}\Omega.$$

This shows that K_0 satisfies (2.4). Hence, K_0 is an admissible set for B, by Lemma 2.3. Since $\ell(K_0)$ is an invariant subspace of B, the eigenvalues of $B|_{W\cap\ell(K_0)}$ also are eigenvalues of $B|_W$.

Let K be an admissible set for B such that $\ell(K) \supseteq W$. In order to prove that all the other eigenvalues of $B|_W$ are 0, it suffices to show that there exists a positive integer N such that

$$B^N\lambda \in \ell(K_0) \qquad \forall\, \lambda \in \ell(K). \tag{4.3}$$

To see this, suppose (4.3) is valid and σ is an eigenvalue of $B|_W$ with an eigenvector $\lambda \in W \setminus \ell(K_0)$. Then by (4.3) we have $\sigma^N\lambda = B^N\lambda \in \ell(K_0)$. However, $\lambda \notin \ell(K_0)$. Hence, this happens only if $\sigma = 0$. Thus, it remains to prove (4.3). For this purpose, it suffices to prove that for each $\beta \in K \setminus K_0$, there exists a positive integer N such that $B^N\delta_\beta \in \ell(K_0)$.

Let j be a positive integer. For $\lambda \in \ell(K)$, we have

$$B^j\lambda(\alpha) = \sum_{\gamma\in\mathbb{Z}^s} b(M\alpha - \gamma)B^{j-1}\lambda(\gamma).$$

Hence, $B^j\lambda(\alpha) \neq 0$ only if $M\alpha - \gamma \in \Omega$ for some $\gamma \in \mathbb{Z}^s$ with $B^{j-1}\lambda(\gamma) \neq 0$. Let n be a positive integer and let $\alpha, \beta \in \mathbb{Z}^s$. Then $B^n\delta_\beta(\alpha) \neq 0$ holds true only if there exist $\alpha_0, \alpha_1, \dots, \alpha_n \in \mathbb{Z}^s$ such that $\alpha_0 = \beta$, $\alpha_n = \alpha$, and

$$M\alpha_j - \alpha_{j-1} \in \Omega \qquad \text{for } j = 1, \dots, n.$$

Hence, $B^n\delta_\beta(\alpha) \neq 0$ implies

$$\alpha \in M^{-1}\Omega + M^{-2}\Omega + \cdots + M^{-n}\Omega + M^{-n}K =: \Gamma_n.$$

Let $\Gamma := \sum_{n=1}^{\infty} M^{-n}\Omega$. Then $K_0 = \mathbb{Z}^s \cap \Gamma$ and $(\mathbb{Z}^s \setminus K_0) \cap \Gamma = \emptyset$. We shall show that Γ is a compact set. Let H be an infinite subset of Γ. Note that Ω is a finite set. By induction on n we can find a sequence of elements $\omega_n \in \Omega$ $(n = 1, 2, \dots)$ such that

$$(M^{-1}\omega_1 + \cdots + M^{-n}\omega_n + M^{-n-1}\Omega) \cap H$$

is an infinite set. Then the element $\gamma := \sum_{n=1}^{\infty} M^{-n}\omega_n$ is a limit point of H. Since $\mathbb{Z}^s \setminus K_0$ is closed and Γ is compact, $\eta := \operatorname{dist}(\mathbb{Z}^s \setminus K_0, \Gamma)$, the distance between two

sets $\mathbb{Z}^s \setminus K_0$ and Γ, is positive. Note that $M^{-n} \to 0$ as $n \to \infty$. Thus, there exists a positive integer N such that

$$B^N \delta_\beta(\alpha) \neq 0 \quad \Longrightarrow \quad \operatorname{dist}(\alpha, \Gamma) < \eta.$$

From $\operatorname{dist}(\alpha, \Gamma) < \eta$ and $\alpha \in \mathbb{Z}^s$ we deduce that $\alpha \in K_0$. This shows $B^N \delta_\beta \in \ell(K_0)$, as desired. □

The L_2-convergence of a subdivision scheme can be determined by using Theorems 3.2 and 4.1. The following theorem gives another form of characterization for the L_2-convergence.

THEOREM 4.3. *Let M be an $s \times s$ dilation matrix with $m := |\det M|$. For $a \in \ell_0(\mathbb{Z}^s)$, let $b := a*a^*/m$ and let B be the linear operator on $\ell_0(\mathbb{Z}^s)$ given by*

$$Bw(\alpha) = \sum_{\beta \in \mathbb{Z}^s} b(M\alpha - \beta) w(\beta), \qquad \alpha \in \mathbb{Z}^s,\ w \in \ell_0(\mathbb{Z}^s).$$

Denote by K_0 the set $\mathbb{Z}^s \cap \sum_{n=1}^\infty M^{-n}\Omega$, where Ω is the support of b. Let V be the linear space

$$\Big\{ w \in \ell(K_0) : \sum_{\alpha \in \mathbb{Z}^s} w(\alpha) = 0 \Big\}.$$

Then the subdivision scheme associated with a converges in the L_2-norm if and only if the following two conditions are satisfied:

(a) $\sum_{\beta \in \mathbb{Z}^s} a(\alpha - M\beta) = 1$ *for all* $\alpha \in \mathbb{Z}^s$;

(b) $\rho(B|_V) < 1$.

Proof. First, assuming that conditions (a) and (b) are satisfied, we shall prove that the subdivision scheme associated with a converges in the L_2-norm. Let W be the minimal B-invariant subspace generated by $-\delta_{e_j} + 2\delta - \delta_{e_j}$, $j = 1, \ldots, s$. By Theorem 4.2,

$$\rho(B|_W) = \rho(B|_{W \cap \ell(K_0)}).$$

It follows from condition (a) that $\sum_{\beta \in \mathbb{Z}^s} b(\alpha - M\beta) = 1$ for all $\alpha \in \mathbb{Z}^s$. Consequently, if w is an element in $\ell_0(\mathbb{Z}^s)$ such that $\sum_{\alpha \in \mathbb{Z}^s} w(\alpha) = 0$, then $\sum_{\alpha \in \mathbb{Z}^s} Bw(\alpha) = 0$. This shows $W \cap \ell(K_0) \subseteq V$. Hence, $\rho(B|_W) \le \rho(B|_V)$. By Theorem 4.1 we have that, for $j = 1, \ldots, s$,

$$\lim_{n \to \infty} \|\nabla_j S_a^n \delta\|_2^{1/n} \le \sqrt{m\rho(B|_W)} \le \sqrt{m\rho(B|_V)} < \sqrt{m}.$$

By Theorem 3.2 we conclude that the subdivision scheme associated with a converges in the L_2-norm.

Next, suppose that the subdivision scheme associated with a converges in the L_2-norm. By Theorem 3.1, condition (a) is satisfied. It remains to prove $\rho(B|_V) < 1$. Let ϕ_0 be the function given in (1.10) and let $f_n := T_a^n \phi_0$, where T_a is the operator given in (1.5). Then there exists a function $f \in L_2(\mathbb{R}^s)$ such that $\|f_n - f\|_2 \to 0$ as $n \to \infty$. For a function f defined on $\mathbb{R}^s$, let f^* be the function given by $f^*(x) = \overline{f(-x)}$ for $x \in \mathbb{R}^s$. Let $\phi := \phi_0 * \phi_0^*$ be the convolution of ϕ_0 and ϕ_0^*. Similarly, let $g_n := f_n * f_n^*$ and $g = f * f^*$. It is easily seen that $g_n = T_b^n \phi$, where T_b is the operator given by $T_b\phi = \sum_{\alpha \in \mathbb{Z}^s} b(\alpha)\phi(M \cdot - \alpha)$. Then we have

$$\begin{aligned} \|g_n - g\|_\infty &= \|f_n * f_n^* - f * f^*\|_\infty \\ &\le \|f_n * (f_n^* - f^*)\|_\infty + \|(f_n - f) * f^*\|_\infty \\ &\le (\|f_n\|_2 + \|f\|_2)\|f_n - f\|_2. \end{aligned}$$

Note that ϕ is a continuous function, ϕ satisfies the moment conditions of order 1, and the shifts of ϕ are stable. Thus, by Theorem 3.4, the subdivision scheme associated with b converges in the L_∞-norm. By Theorem 3.3, we conclude that $\rho(B|_V) < 1$. This finishes the proof of the theorem. □

In the case $s = 1$ and $M = (2)$, Theorem 4.3 was established by Jia [6]. In the multivariate case, Theorem 4.3 was also obtained independently by Lawton, Lee, and Shen [11].

We finish this paper by an example about the L_2-convergence of a subdivision scheme.

Example 4.4. Let $M = 2I$, where I is the 2×2 identity matrix. Consider the refinement equation (3.18), where the mask a is given by its symbol

$$\tilde{a}(z) = 1 + (1/2 + t)(z_1 + z_2 + z_1 z_2) + (1/2 - t)(z_1^{-1} + z_2^{-1} + z_1^{-1} z_2^{-1}),$$

with t being a real number. The normalized solution of the refinement equation is the standard linear element if $t = 0$, and is the characteristic function of the unit square $[0, 1)^2$ if $t = 1/2$. Let $b := a * a^*$. By computation we find that

$$\begin{aligned}\tilde{b}(z) = |\tilde{a}(z)|^2 = {} & (5/2 + 6t^2) + (3/2 + 2t^2)(z_1 + z_2 + z_1^{-1} + z_2^{-1}) \\ & + (3/2 - 2t^2)(z_1 z_2 + z_1^{-1} z_2^{-1}) + (1/2 + 2t^2)(z_1 z_2^{-1} + z_1^{-1} z_2) \\ & + (1/4 - t^2)(z_1^2 + z_1^2 z_2^2 + z_2^2 + z_1^{-2} + z_1^{-2} z_2^{-2} + z_2^{-2}) \\ & + (1/2 - 2t^2)(z_1^2 z_2 + z_1 z_2^2 + z_1^{-2} z_2^{-1} + z_1^{-1} z_2^{-2}).\end{aligned}$$

With this b, the operator B is given by

$$Bw(\alpha) = \sum_{\beta \in \mathbb{Z}^2} b(2\alpha - \beta) w(\beta), \qquad w \in \ell_0(\mathbb{Z}^2),\ \alpha \in \mathbb{Z}^2.$$

For $j = 1, 2$, let $\nu_j = \delta - \delta_{e_j}$ and $\mu_j = \nu_j * \nu_j^* = -\delta_{e_j} + 2\delta - \delta_{-e_j}$. Then

$$B\mu_j = B(-\delta_{e_j} + 2\delta - \delta_{-e_j}) = (1 + 4t^2)(-\delta_{e_j} + 2\delta - \delta_{-e_j}) = (1 + 4t^2)\mu_j.$$

Thus, the minimal B-invariant subspace W_j generated by μ_j is the one-dimensional subspace spanned by μ_j. By Theorem 4.1 we conclude that

$$\lim_{n \to \infty} \|\nabla_j S_a^n \delta\|_2^{1/n} = \sqrt{\rho(B|_{W_j})} = \sqrt{1 + 4t^2}\,.$$

By Theorem 3.2, the subdivision scheme associated with a converges in the L_2-norm if and only if $\sqrt{1 + 4t^2} < \sqrt{4}$; that is, $|t| < \sqrt{3}/2$.

CONVERGENCE RESULTS FOR SOME CONSERVATION LAWS WITH A REFLUX BOUNDARY CONDITION AND A RELAXATION TERM ARISING IN CHEMICAL ENGINEERING*

FRANÇOIS JAMES†

Abstract. This paper deals with a system of $2N$ semilinear transport equations with a boundary condition of imposed flux. The right-hand side models some kinetic exchange between two phases. It is thus a stiff term involving a small parameter which will tend to 0. Using compensated compactness, one proves, under some assumptions on the flux, that the solution to this system converges to a solution to a system of N quasilinear equations, a solution which satisfies a set of entropy inequalities. Thus the reflux boundary condition for the quasi-linear system is given a meaning.

Key words. hyperbolic systems, boundary conditions, relaxation, entropy, compensated compactness, chromatography, distillation

1. Introduction. We are interested in the following system of $2N$ equations, $N \geq 1$,

$$\begin{cases} \partial_t \mathbf{c}_\varepsilon^1 + \partial_x u \mathbf{c}_\varepsilon^1 = \frac{1}{\varepsilon}\big(\mathbf{c}_\varepsilon^2 - \mathbf{h}(\mathbf{c}_\varepsilon^1)\big), \\ \partial_t \mathbf{c}_\varepsilon^2 + \partial_x v \mathbf{c}_\varepsilon^2 = -\frac{1}{\varepsilon}\big(\mathbf{c}_\varepsilon^2 - \mathbf{h}(\mathbf{c}_\varepsilon^1)\big), \end{cases} \tag{1.1}$$

which is a simplified model of diphasic propagation arising in chemical engineering. In this kind of problem, two phases labelled 1 and 2 are in motion with respective velocities $u > 0$ and $v \leq 0$, which are assumed here to be constant. The case $v = 0$ corresponds to a model of chromatography (a mobile phase and a stationary one), and the case $v < 0$ corresponds to distillation (two phases moving countercurrent).

In equations (1.1), $\mathbf{c}_\varepsilon^1$ and $\mathbf{c}_\varepsilon^2$ are related to the concentrations in phase 1 and 2, respectively, and therefore should be nonnegative. The right-hand side rules the matter exchanges between the two phases. Without motion, the two phases would reach a state of thermodynamical equilibrium: the concentration in phase 2 is therefore related to the concentration in phase 1 by the function $\mathbf{h}$, which enjoys several properties coming from the thermodynamics.

In the case we are considering, the equilibrium cannot be reached because of the motion. The time needed to reach the equilibrium is not negligible with respect to the characteristic times induced by the velocities u and v. This phenomenon is known as a finite exchange kinetic: the actual concentration $\mathbf{c}_\varepsilon^2$ in phase 2 differs from $\mathbf{h}(\mathbf{c}_\varepsilon^1)$. The right-hand side of the equations quantifies the attraction of the system to the equilibrium state: it is a pulling-back force, and the constant parameter $1/\varepsilon$ is the "velocity" of exchange between the two phases.

A natural question arises here: how do the solutions of (1.1) behave when ε tends to 0, that is, when the exchange kinetic becomes instantaneous (the process is then quasi-static)? The limit system is obtained in a natural way by summing the $2N$

equations in (1.1) and by putting $\mathbf{c}_\varepsilon^1 = \mathbf{c}$, $\mathbf{c}_\varepsilon^2 = \mathbf{h}(\mathbf{c})$, which means indeed that the concentration in phase 2 is actually the equilibrium concentration. We are led to the following nonlinear hyperbolic system, which expresses the conservation of matter:

$$\partial_t \left(\mathbf{c} + \mathbf{h}(\mathbf{c})\right) + \partial_x \left(u\mathbf{c} + v\mathbf{h}(\mathbf{c})\right) = 0. \tag{1.2}$$

The aim of this paper is to analyze the behavior of the solutions of (1.1) when ε tends to 0, when it is provided with boundary conditions

$$\mathbf{c}_\varepsilon^1(0,t) = \mathbf{a}(t) \in L^\infty(]0,+\infty[)^N, \quad u\mathbf{c}_\varepsilon^1(1,t) + v\mathbf{c}_\varepsilon^2(1,t) = \mathbf{b}(t) \in L^\infty(]0,+\infty[)^N, \tag{1.3}$$

together with Cauchy data in $L^\infty(]0,1[)^N$. To avoid any initial layer, we shall assume that the initial data are at equilibrium, that is, $\mathbf{c}_\varepsilon^1(\cdot,0) = \mathbf{c}^0 \in L^\infty(]0,1[)^N$ and $\mathbf{c}_\varepsilon^2(\cdot,0) = \mathbf{h}(\mathbf{c}^0)$. From the point of view of distillation, the boundary conditions are natural: the first one is a Dirichlet-like "injection" at one end of a column and acts only on the incoming variable ($u > 0$); the second one looks like a Neumann condition on the other end and imposes $v < 0$ (it is a simplified model of the "reflux" in a distillation column).

Concerning the standard Cauchy problem in the scalar case, i.e., $c(0,x) = c^0(x)$, $x \in \mathbb{R}$, $c^0 \in L^\infty$, the analysis is straightforward, and the solution of (1.1) tends to the entropy solution of (1.2), thus providing an alternative to the artificial viscosity method. Such results were obtained, for instance, by Tveito and Winther in [29], where the rate of convergence is estimated, and by Natalini [22]. Let us mention also the work by Katsoulakis and Tzavaras [19], where they give contraction properties for the solution of the system with relaxation. For systems of conservation laws, we refer to Chen, Levermore, and Liu [7], where a convergence result is proved for a 2×2 genuinely nonlinear system. This point of view can be successfully used for numerical purpose, see Jin and Xin [16] for a general setting for systems and Aregba-Driollet and Natalini [2] for convergence results in the scalar case.

On the other hand, the problem with boundary conditions is not as well behaved when ε tends to 0: it is well known that the setting of a Dirichlet boundary condition for a nonlinear hyperbolic scalar equation is difficult. Bardos, Leroux, and Nédélec [3] gave such a setting in the Kružkov sense, using the artificial viscosity method in the context of BV functions. We shall not recover this formulation here, since the Dirichlet data act only on incoming variables. For systems, the first existence result was given by Benabdallah and Serre [4] for systems of two equations. We refer also to works by Dubois and LeFloch [8], where the Dirichlet boundary condition appears as a Riemann problem on a half-plane, Gisclon [10], and Gisclon and Serre [11]. We mention also Goodman's work [12], where global existence is proved for strictly hyperbolic systems of conservation laws with initial and boundary data of small BV norm. The solutions also have small total variation and therefore have strong traces on the boundary. On the other hand, in [18] Kan, Santos, and Xin consider a general system of conservation laws and compare various notions of boundary conditions (vanishing viscosity, half-space Riemann problem). Their solution is built by a Godunov method. In the same spirit, we also mention the paper by Joseph and LeFloch [17], who also compare different approximations and the resulting boundary layers.

The reflux boundary condition at $x = 1$ seems to have been very little studied. For the scalar Burgers equation with the boundary condition $u^2(.,t) = 0$, Gisclon proved in [9] that the solution satisfies $u(.,t) \leq 0$ on the boundary (which coincides with the solution in the sense of [3]).

Finally, let us mention one work which is concerned with both relaxation and boundary conditions. Wang and Xin [30] consider a 2×2 system with relaxation. The boundary condition is chosen so that uniform BV estimates hold, and they prove convergence to a scalar conservation law satisfying a boundary-entropy condition, for which uniqueness holds.

We are going to prove that, under suitable conditions on the flux $u\mathbf{c} + v\mathbf{h}(\mathbf{c})$ with respect to $\mathbf{b}$, there exists a subsequence of solutions of (1.1) which converges to a weak solution of (1.2). This solution is characterized by a set of entropy inequalities. Since we have no BV estimates for the solution with $\varepsilon > 0$, we are led to work with bounded measurable functions, and use the compensated compactness method. This can be done in two cases: first for scalar equations with any smooth function $\mathbf{h}$ and then for a system of N equations, for a specific $\mathbf{h}$, the so-called Langmuir isotherm. Notice that the Langmuir system is not hyperbolic on the whole physical domain of interest. However, we use a specific set of entropies, namely the so-called kinetic entropies, which were introduced in [14], that allows us to achieve compactness.

Finally, we prove that the weak solutions are indeed solutions in the sense of distributions and that they satisfy in a strong sense the initial condition as well as the reflux boundary condition at $x = 1$. The incoming boundary condition seems to be lost in the limiting system. This is not very surprising, since we fall from a $2N$ equations system to N equations. Some boundary layer phenomena probably occur at $x = 0$, which we do not investigate here. This may indicate that the system of conservation laws with the reflux boundary condition is well-posed, but the precise study of this is left for future research.

The paper is organized as follows. In section 2 we state a few results and notations which hold for both the scalar equation and the system. Section 3 and 4 are devoted to the proof of a priori estimates and compactness, respectively, for the scalar equation and the system. Section 5 deals with boundary conditions.

2. Preliminary results.

We state here a few results and remarks that are common to both the scalar equation and the Langmuir model. Namely, we prove that equation (1.1) is well-posed for $\varepsilon > 0$, and we also define a particular set of entropies, which appears to be natural from the structure of the equations. In the following, we shall set $\Omega \stackrel{\text{def}}{=}]0,1[\times]0,T[$.

2.1. Existence for $\varepsilon > 0$.

THEOREM 2.1. *For a given $T > 0$, assume that $\mathbf{a}$ and $\mathbf{b}$ are in $L^\infty(]0,T[)^N$, $\mathbf{c}^0 \in L^\infty \cap L^1(]0,1[)^N$, and that the function $\mathbf{h}$ is of class C^1. Then there exists a unique solution to* (1.1), *which lies in $L^\infty(]0,T[; L^1(]0,1[))$.*

Proof. We first rewrite (1.1) in an equivalent integral form by using Duhamel's principle; then we prove a contraction estimate to apply a fixed point theorem. This is rather tedious, because of the initial and boundary conditions. The set $[0,1]\times[0,+\infty[$ is indeed divided into four zones, namely, $Z_1 = \{(x,t) \quad | \quad x \geq ut, x \leq 1 + vt\}$, $Z_2 = \{(x,t) \quad | \quad x \geq ut, x \geq 1 + vt\}$, $Z_3 = \{(x,t) \quad | \quad x \leq ut, x \leq 1 + vt\}$, $Z_4 = \{(x,t) \quad | \quad x \leq ut, x \geq 1 + vt\}$, depending upon whether the characteristics encounter $\{t = 0\}$, $\{x = 0\}$, or $\{x = 1\}$.

We shall fully write the contraction estimate for t large enough so that $(x,t) \in Z_4$ for every $x \in [0,1]$. We omit in this proof the dependence in ε. Taking into account the reflux boundary condition on $x = 1$, Duhamel's principle writes, for almost every

$(x,t) \in Z_4$,

(2.1)
$$\begin{cases} \mathbf{c}^1(x,t) = \mathbf{a}\left(t - \frac{x}{u}\right) + \frac{1}{\varepsilon}\int_{t-\frac{x}{u}}^{t} \left[\mathbf{c}^2(x+u(s-t),s) - \mathbf{h}(\mathbf{c}^1(x+u(s-t),s))\right] ds, \\ \mathbf{c}^2(x,t) = \frac{1}{v}\mathbf{b}\left(t + \frac{1-x}{v}\right) - \frac{u}{v}\mathbf{a}\left(t + \frac{1-x}{v} - \frac{1}{u}\right) \\ -\frac{u}{v}\frac{1}{\varepsilon}\int_{t+\frac{1-x}{v}-\frac{1}{u}}^{t+\frac{1-x}{v}} \left[\mathbf{c}^2(1+u(s-t-\frac{1-x}{v}),s) - \mathbf{h}(\mathbf{c}^1(1+u(s-t-\frac{1-x}{v}),s))\right] ds \\ \qquad -\frac{1}{\varepsilon}\int_{t+\frac{1-x}{v}}^{t} \left[\mathbf{c}^2(x+v(s-t),s) - \mathbf{h}(\mathbf{c}^1(x+v(s-t),s))\right] ds. \end{cases}$$

Denote by $\mathcal{T}$ the application from $X = L^\infty(]0,T[;L^1_x)^{2N}$ into itself which associates the right-hand side of the equations in (2.1) with a pair $C = (\mathbf{c}^1, \mathbf{c}^2) \in X$. For two elements C and $\hat{C}$ in X, with the same initial and boundary data, the terms involving $\mathbf{a}$ and $\mathbf{b}$ in (2.1) disappear when computing $\mathcal{T}(C) - \mathcal{T}(\hat{C})$, so, for a given (x,t), we have

$$|\mathcal{T}(C)(x,t) - \mathcal{T}(\hat{C})(x,t)| \le \frac{1}{\varepsilon}\max(|T_1(x,t)|, |T_2(x,t)|),$$

where T_i follows from the difference of the integral terms and $|\cdot|$ is a norm on $\mathbb{R}^{2N}$. One has easily

$$\begin{aligned} |T_1(x,t)| &\le \int_{t-\frac{x}{u}}^{t} \left|\mathbf{c}^2(x+u(s-t),s) - \hat{\mathbf{c}}^2(x+u(s-t),s)\right| ds \\ &+ \int_{t-\frac{x}{u}}^{t} \left|\mathbf{h}(\mathbf{c}^1(x+u(s-t),s)) - \mathbf{h}(\hat{\mathbf{c}}^1(x+u(s-t),s))\right| ds \\ &\le \int_{t-\frac{x}{u}}^{t} \left|\mathbf{c}^2(x+u(s-t),s) - \hat{\mathbf{c}}^2(x+u(s-t),s)\right| ds \\ &+ K\int_{t-\frac{x}{u}}^{t} \left|\mathbf{c}^1(x+u(s-t),s) - \hat{\mathbf{c}}^1(x+u(s-t),s)\right| ds \end{aligned}$$

if K is the Lipschitz constant of $\mathbf{h}$. We can estimate $\|T_1(.,t)\|_{L^1_x}$ by Fubini's theorem, which gives

$$\begin{aligned} \|T_1(.,t)\|_{L^1_x} &\le \int_{t-1/u}^{t} \|\mathbf{c}^2(.,s) - \hat{\mathbf{c}}^2(.,s)\|_{L^1_x} ds + K\int_{t-1/u}^{t} \|\mathbf{c}^1(.,s) - \hat{\mathbf{c}}^1(.,s)\|_{L^1_x} ds \\ &\le t\left(\max_{s\in[0,t]} \|\mathbf{c}^2(.,s) - \hat{\mathbf{c}}^2(.,s)\|_{L^1_x} + K\max_{s\in[0,t]} \|\mathbf{c}^1(.,s) - \hat{\mathbf{c}}^1(.,s)\|_{L^1_x}\right). \end{aligned}$$

A similar formula can be obtained for T_2, involving the quantity $u/|v|$.

Now, if (x,t) changes zone with x, we proceed in the same way in each zone and separate the integral for the L^1_x norm. We do not write these straightforward computations, which lead to the existence of a constant $M > 0$, which depends on K and $u/|v|$, such that

$$\|\mathcal{T}(C) - \mathcal{T}(\hat{C})\|_{L^\infty(]0,t[;L^1_x)^{2N}} \le \frac{tM}{\varepsilon}\|C - \hat{C}\|_{L^\infty(]0,t[;L^1_x)^{2N}}.$$

Now, choose T_0 such that $T_0 M/\varepsilon < 1$, and apply the fixed point theorem on $L^\infty(]0,T_0[;L^1_x)^{2N}$. This gives existence and uniqueness of the solution on $[0,T_0]$.

Since the contraction estimate does not depend on the initial data, we can perform again the same argument on $[T_0, 2T_0]$, and so on, to finally reach any prescribed $T > 0$. Thus the theorem is proved. □

2.2. Diphasic entropies. We introduce here a set of entropies which is quite natural in view of the structure of the equations. They are actually a discrete version (with two velocities only) of the kinetic entropies introduced by Perthame and Tadmor in [23].

DEFINITION 2.1. *We shall say that a function $\eta : \mathbb{R}^N \longrightarrow \mathbb{R}$ is a "diphasic entropy" for* (1.2) *if there exist two convex functions $\eta_1, \eta_2 : \mathbb{R}^N \longrightarrow \mathbb{R}$ satisfying*

$$\nabla_{\mathbf{c}}\eta_1(\mathbf{c}) = \nabla_{\mathbf{c}}\eta_2\big(\mathbf{h}(\mathbf{c})\big) \qquad \forall \mathbf{c} \in \mathbb{R}^N, \tag{2.2}$$

such that $\eta(\mathbf{c}) = \eta_1(\mathbf{c}) + \eta_2\big(\mathbf{h}(\mathbf{c})\big)$.

Remark 2.1. The function $\mathbf{h}$ itself is, in general, defined by such a pair of functions, which are given, for instance, by statistical thermodynamics models (see [15] and the quoted references therein for examples and more information). Actually, the pair $(\mathbf{c}, \mathbf{h}(\mathbf{c}))$ is a stable state of equilibrium for the diphasic system. Thus it achieves the infimum of $\eta_1(\mathbf{c}_1) + \eta_2(\mathbf{c}_2)$ under the constraint that the total amount of matter $\mathbf{c}_1 + \mathbf{c}_2$ is constant. The relation (2.2) is nothing but the characterization of the minimum and is a generalized version of the well-known "chemical potential equalities" in thermodynamics. Consequently, $\mathbf{h}'(\mathbf{c})$ is positive in the scalar case and is diagonable with positive eigenvalues for a system. This leads also to the existence of a natural "physical" entropy for such systems.

Our main concern in the following is to obtain a priori estimates on the solution $(\mathbf{c}_\varepsilon^1, \mathbf{c}_\varepsilon^2)$ to (1.1) which are uniform in ε. The classical method here is to prove that the entropy production associated with (1.1) is nonpositive for several well-chosen entropies. Consider any pair (η_1, η_2) satisfying (2.2); multiply the two equations in (1.1), respectively, by $\nabla_{\mathbf{c}}\eta_1(\mathbf{c}_\varepsilon^1)$ and $\nabla_{\mathbf{c}}\eta_2(\mathbf{c}_\varepsilon^2)$; sum; then use (2.2). We formally obtain the following law for the entropy production:

$$\begin{aligned} &\partial_t \left(\eta_1(\mathbf{c}_\varepsilon^1) + \eta_2(\mathbf{c}_\varepsilon^2)\right) + \partial_x \left(u\eta_1(\mathbf{c}_\varepsilon^1) + v\eta_2(\mathbf{c}_\varepsilon^2)\right) \\ &\qquad = \frac{1}{\varepsilon}\left[\left(\nabla_{\mathbf{c}}\eta_2\big(h(\mathbf{c}_\varepsilon^1)\big) - \nabla_{\mathbf{c}}\eta_2(\mathbf{c}_\varepsilon^2)\right) \cdot \big(\mathbf{c}_\varepsilon^2 - \mathbf{h}(\mathbf{c}_\varepsilon^1)\big)\right]. \end{aligned} \tag{2.3}$$

It remains to notice that the right-hand side is always nonpositive, since η_2 is convex. Integrating on $[0,1]$ therefore gives, at least formally,

$$\frac{d}{dt}\int_0^1 \big[\eta_1(\mathbf{c}_\varepsilon^1(x,t)) + \eta_2(\mathbf{c}_\varepsilon^2(x,t))\big]dx \leq -\big[u\eta_1(\mathbf{c}_\varepsilon^1(.,t)) + v\eta_2(\mathbf{c}_\varepsilon^2(.,t))\big]\big|_0^1, \tag{2.4}$$

and all the technical work is now to estimate the boundary terms. To give a precise meaning to this differential inequality, we have to rewrite it in a weak form by multiplying by a test function $\varphi \geq 0$ and integrating by parts.

Provided we have enough entropies, (2.4) will give a priori estimates as well as compactness of a subsequence of solutions to (1.1). We can exhibit such entropies in the scalar case on the one hand and for the system of chromatography with the Langmuir isotherm on the other hand. In both cases, the local solution of Theorem 2.1 is therefore global for fixed ε.

2.3. Subcharacteristic condition. Before proceeding to estimates, we would like to relate system (1.1) with the usual form of systems with relaxation. This is done easily in the particular case $v = -u$ by setting $\mathbf{U}^\varepsilon = \mathbf{c}^1_\varepsilon + \mathbf{c}^2_\varepsilon \in \mathbb{R}^N$ and $\mathbf{V}^\varepsilon = u\mathbf{c}^1_\varepsilon - u\mathbf{c}^2_\varepsilon \in \mathbb{R}^N$. System (1.1) is therefore rewritten as

$$\partial_t \mathbf{U}^\varepsilon + \partial_x \mathbf{V}^\varepsilon = 0, \qquad \partial_t \mathbf{V}^\varepsilon + u^2 \partial_x \mathbf{U}^\varepsilon = \frac{2}{\varepsilon}\left(\mathbf{V}^\varepsilon - u(\mathbf{c}^1_\varepsilon - \mathbf{h}(\mathbf{c}^1_\varepsilon))\right). \tag{2.5}$$

Now, we notice that, since by Remark 2.1 $\mathbf{h}'(\mathbf{c})$ has positive eigenvalues, the function $\mathbf{c} + \mathbf{h}(\mathbf{c})$ is one-to-one. Let us denote $\mathbf{U} = \mathbf{c} + \mathbf{h}(\mathbf{c})$, its inverse by $\mathbf{c} = \mathbf{g}(\mathbf{U})$, and $\mathbf{F}(\mathbf{U}) \overset{\text{def}}{=} u[\mathbf{g}(\mathbf{U}) - \mathbf{h}(\mathbf{g}(\mathbf{U}))]$. The usual form of this kind of system should involve $\mathbf{F}(\mathbf{U})$ instead of $u(\mathbf{c}^1_\varepsilon - \mathbf{h}(\mathbf{c}^1_\varepsilon))$ in (2.5). This discrepancy appears because the right-hand side of system (1.1) is not symmetric with respect to $\mathbf{c}^1$ and $\mathbf{c}^2$. Another possible writing would make use of the "Maxwellians" $\mathbf{M}_1(\mathbf{U}) = \mathbf{g}(\mathbf{U})$ and $\mathbf{M}_2(\mathbf{U}) = \mathbf{h}(\mathbf{g}(\mathbf{U}))$. The convergence results would not be affected by this change.

In [21], Liu introduced a necessary condition on $\mathbf{F}'(\mathbf{U})$ to ensure the convergence of a subsequence of solutions of (1.1) to a solution of (1.2). This condition is known as the subcharacteristic condition, and we would like to point out that it is satisfied here because the function $\mathbf{h}$ is, in some sense, monotone (see Remark 2.1). Indeed, we have

$$\mathbf{F}'(\mathbf{U}) = [I_N + \mathbf{h}'(\mathbf{g}(\mathbf{U}))]\,\mathbf{g}'(\mathbf{U}),$$

where I_N stands for the identity matrix in $\mathbb{R}^N$. However, $\mathbf{g}'(\mathbf{U}) = (I_N + \mathbf{h}'(\mathbf{g}(\mathbf{U})))^{-1}$, so $\mathbf{F}'(\mathbf{U})$ is diagonable, and its eigenvalues are given for general values of u and v by

$$\lambda_i(\mathbf{U}) = \frac{u + v\mu_i(\mathbf{U})}{1 + \mu_i(\mathbf{U})},$$

where $\mu_i > 0$ are the eigenvalues of $\mathbf{h}'$, $1 \le i \le N$. It is readily seen that $v < \lambda_i(\mathbf{U}) < u$, which is the specific version of Liu's condition in this context.

3. Scalar equation. This section is devoted to the proof of the strong convergence of a subsequence of solutions to (1.1) in the scalar case. The function h is therefore a scalar function, which satisfies

$$h(0) = 0 \qquad \text{and} \quad h'(c) > 0 \quad \forall c. \tag{3.1}$$

Also, for any given convex η_2, we can define η_1 by $\eta_1(c) = \int_0^c \eta_2'\big(h(\sigma)\big)\,d\sigma$. We have, obviously, $\eta_1'(c) = \eta_2'\big(h(c)\big)$ and $\eta_1''(c) = \eta_2''\big(h(c)\big)h'(c) > 0$. Two particular cases are interesting. These are nonsmooth entropies, but a classical regularization argument, omitted in the following, allows us to deal with them.

- "Kružkov-like" entropies. For $k \in \mathbb{R}$, we set

$$\varphi_1^k(c^1) = |c^1 - k|, \qquad \varphi_2^k(c^2) = |c^2 - h(k)|.$$

It is easily checked that φ_1^k and φ_2^k satisfy (2.2), since h is increasing.

- L^∞ entropies. For $k \in \mathbb{R}$, we define

$$\psi_1^k(c^1) = (c^1 - k)^+, \qquad \psi_2^k(c^2) = \big(c^2 - h(k)\big)^+.$$

With these last entropies, the entropy estimates on c^i_ε become L^∞ estimates.

We begin in a classical way with some entropy and a priori estimates and first notice that, to prove entropy estimates for a given pair (η_1, η_2) giving a diphasic entropy, we need the condition

$$f(c) \overset{\text{def}}{=} uc + vh(c) \leq \min_{t>0} b(t) \qquad \text{for } c \geq M. \tag{3.2}$$

This is not a very satisfactory condition to impose, since it is not satisfied by such an usual isotherm as the Langmuir one,

$$h(c) = Kc/(1+c), \qquad K > 0. \tag{3.3}$$

Condition (3.2) actually implies some restrictions on the initial and boundary data, which lead to uniform L^∞ estimates for the solution to (1.1), for a broader class of fluxes.

THEOREM 3.1. *Assume $a \geq 0$, $b \leq 0$, $c^0 \geq 0$, and*

$$c^\star \overset{\text{def}}{=} \sup\{c \geq 0; \exists c' \leq c, f(c') \leq \min b(t)\} \geq \max[\|a\|_\infty, \|c^0\|_\infty]. \tag{3.4}$$

Then there exists a constant C depending only on c_1^0, a, and b such that $0 \leq c_\varepsilon^i(t,.) \leq C$, $i = 1, 2$.

Remark 3.1. Of course the result is meaningful only if $c^\star > 0$. This occurs only if $f(c)$ becomes nonpositive for some c. For instance, consider again the case of the Langmuir isotherm (3.3). It is easily seen that for $b = 0$, $c^\star > 0$ only if $u/|v| < K$. More generally, f achieves its minimum for $c_{\min} = \sqrt{K|v|/u} - 1$, which is positive if $u/|v| < K$, and $c^\star > 0$ if we have $f(c_{\min}) \leq b$, that is, $(\sqrt{K|v|} - \sqrt{u})^2 \geq -b$.

Remark 3.2. The choice $k = \max(\|a\|, \|c^0\|)$ is possible only if $f(a(t)) - b(t) \geq 0$ and $f(c^0(x)) - b(x) \geq 0$ for all $t > 0$ and a.e. $x \in]0,1[$. Otherwise, the L^∞ norm of the solution may not be bounded by the initial and Dirichlet boundary data.

From the above L^∞ estimate, we can easily obtain a weak convergence result by considering the weak form of the first equation in (1.1). Since c_ε^1 is L^∞ bounded uniformly in ε, and ε tends to 0, then $c_\varepsilon^2 - h(c_\varepsilon^1)$ tends to 0 in the sense of distributions on Ω when ε tends to 0. But we actually have the following stronger result.

LEMMA 3.2. *Under the assumptions of Theorem* 3.1, *ensuring the L^∞ bounds on the solution, $c_\varepsilon^2 - h(c_\varepsilon^1)$ tends to 0 in $L^2_{\text{loc}}(\Omega)$.*

From this result we can deduce, using the compensated compactness method, the following main result of this section.

THEOREM 3.3. *Consider $a, b \in L^\infty(]0,T[)$, and $c^0 \in L^1 \cap L^\infty(]0,1[)$. Under the assumptions of Theorem* 3.1, *that is,*

$$a \geq 0, \quad b \leq 0, \quad c^0 \geq 0, \quad c^\star \geq \max[\|a\|_\infty, \|c^0\|_\infty],$$

there then exists a subsequence of solutions to (1.1), *still denoted by c_ε^1, which converges a.e. and strongly in $]0,1[\times]0,T[$ to $c \in L^\infty(]0,T[; L^1(]0,1[))$. Moreover, c satisfies, for any $\varphi \in \mathcal{D}(\overline{\Omega})$, $\varphi \geq 0$, $k \in \mathbb{R}$,*

$$\begin{aligned} -\int_0^T \int_0^1 \Big[\big(|c-k| + |h(c)-h(k)|\big)\partial_t\varphi + \big(u|c-k| + v|h(c)-h(k)|\big)\partial_x\varphi \Big] dxdt \\ \leq \int_0^T u|a(t)-k|\varphi(0,t)dt + \int_0^T |b(t)-f(k)|\varphi(1,t)dt \\ - \int_0^1 \big(|c^0(x)-k| + |h(c^0(x))-h(k)|\big)\,\varphi(x,0)dx. \end{aligned} \tag{3.5}$$

Section 3.1 contains the entropy estimates and the proof of Theorem 3.1, while section 3.2 is devoted to the convergence results. Finally, we give a few remarks on viscous regularization is section 3.3.

3.1. A priori estimates. First we briefly show how condition (3.2) gives general entropy estimates. Consider a pair (η_1, η_2) which satisfies (2.2), and assume for simplicity that η_2 is bounded from below by 0. We start from equation (2.4) and estimate the boundary terms.

At $x = 0$, we have $c_\varepsilon^1(0, \cdot) = a(\cdot)$. We have, since $v < 0$, $\big[u\eta_1(c_\varepsilon^1) + v\eta_2(c_\varepsilon^2)\big]\big|_0 \le u\eta_1(a) \le C$ if $a \in L^\infty$. Next at $x = 1$, we rewrite the boundary condition in the form

$$c_\varepsilon^2 = \frac{u}{|v|} c_\varepsilon^1 - \frac{b}{|v|}.$$

We want to make $-[u\eta_1(c_\varepsilon^1) + v\eta_2(\frac{u}{|v|}c_\varepsilon^1 - \frac{b}{|v|})] \le K$, K being a constant. A sufficient condition to ensure this is

$$\zeta(c) \stackrel{\text{def}}{=} -\left[u\eta_1(c) + v\eta_2\left(\frac{u}{|v|}c - \frac{b}{|v|}\right)\right] \le K,$$

or $\zeta'(c) \le 0$, for c large. Differentiating ζ and using (2.2) shows that this occurs if $\eta_1'(c) = \eta_2'(h(c)) \le \eta_2'(\frac{u}{|v|}c - \frac{b}{|v|})$. Now, the fact that η_2' is nondecreasing and condition (3.2) lead to

$$\frac{d}{dt}\int_0^1 \big[\eta_1(c_\varepsilon^1(x,t)) + \eta_2(c_\varepsilon^2(x,t))\big]dx \le C(a, b, \eta_1, \eta_2, M, K),$$

where $K = \sup_{0 \le c \le M} \zeta(c)$. By integration, this leads to

$$\int_0^1 \big[\eta_1(c_\varepsilon^1(x,t)) + \eta_2(c_\varepsilon^2(x,t))\big]dx \le \int_0^1 \big[\eta_1(c^0(x)) + \eta_2(h(c^0)(x))\big]dx + C(a, b, \eta, M, K)t.$$

We point out again the fact that condition (3.2) is not to be used as it stands, since it depends on the flux. We prefer to put restrictions on the initial and boundary data, as in Theorem 3.1, which we are going to prove now. Actually, we perform the same computations as above, with two particular choices for η_i.

Proof of Theorem 3.1. (i) We first take $\eta_j(c^j) = [c^j]^-$, which happens to be a diphasic entropy since h is increasing. With this choice, the right-hand side of (2.4) is clearly bounded by $ua(t)^- - [uc_\varepsilon^1(1,t) + vc_\varepsilon^2(1,t)]^- = ua(t)^- + [-b(t)]^-$ (by using the boundary condition at $x = 1$). This becomes nonnegative provided $a \ge 0$ and $b \le 0$. Integrating in time now gives

$$\int_0^1 \big[\eta_1(c_\varepsilon^1(x,t)) + \eta_2(c_\varepsilon^2(x,t))\big]dx \le \int_0^1 \big[(c_1^0(x))^- + (c_2^0(x))^-\big]dx \le 0$$

if the initial data are nonnegative. Thus (1.1) preserves the positivity.

(ii) We now choose $\eta_i = \psi_i^k$, for an adequate k, which will give the upper bound. Indeed, the ψ_i^k are bounded from below (by 0!), and for $k \ge \|a\|_\infty$, the term on $x = 0$ becomes nonpositive. Now, for $x = 1$, we have with our choice for η_i,

$$\zeta(c) = -u(c-k)^+ - v\left[\frac{u}{v}c + \frac{b}{v} - h(k)\right]^+ \le [f(k) - b]^+$$

by a triangle inequality. To make the right-hand side nonpositive, we must find k such that $f(k) \le b$. This implies $k \le c^\star$ and is compatible with the constraint at $x = 0$ only if $\|a\|_\infty$ is less than $c^\star$.

Finally, by integration, provided k satisfies $c^\star \ge k \ge \|a\|_\infty$, we have

$$\int_0^1 \left[(c_\varepsilon^1(x,t)-k)^+ + \big(c_\varepsilon^2(x,t)-h(k)\big)^+\right] dx \\ \le C(b,k)t + \int_0^1 \left[(c^0(x)-k)^+ + \big(h(c^0(x))-h(k)\big)^+\right] dx.$$

Now, provided $c^\star \ge \max[\|a\|_\infty, \|c^0\|_\infty]$, we can choose k such that the right-hand side is nonpositive. ∎

3.2. Strong convergence. We turn to the proof of the convergence results.

Proof of Lemma 3.1. We begin from (2.3) with the diphasic entropy given by $\eta_2(c_2) = (1/2)c_2^2$, $\eta_1(c_1) = \int_0^{c_1} h(\sigma)\,d\sigma$, then multiply by φ with compact support in $]0,1[\times]0,T[$, and integrate by parts:

$$-\int_0^T\int_0^1 \big([\eta_1(c_\varepsilon^1)+\eta_2(c_\varepsilon^2)]\partial_t\varphi + [u\eta_1(c_\varepsilon^1)+v\eta_2(c_\varepsilon^2)]\partial_x\varphi\big)\,dx\,dt \\ = -\frac{1}{\varepsilon}\int_0^T\int_0^1 \big(c_\varepsilon^2 - h(c_\varepsilon^1)\big)^2\,\varphi dx\,dt.$$

Since c_ε^1 and c_ε^2 are L^∞-bounded uniformly in ε, multiplying this relation by ε gives the result. ∎

We now wish to prove a strong convergence property on c_ε^i by using Murat–Tartar's compensated compactness argument [27].

Proof of Theorem 3.2. *Step* 1. First we prove that, up to a subsequence, c_ε^1 converges strongly. Since c_ε^1 is L^∞ bounded uniformly in ε, and the functions h and η_i are smooth, the sequences c_ε^1, $h(c_\varepsilon^1)$, and $\eta_i(c_\varepsilon^i)$ converge in $L^\infty - w*$, respectively, to $\bar c$, $\bar h$, and $\bar\eta_i$, $i = 1, 2$. Now consider the following two quantities:

$$S^\varepsilon \stackrel{\text{def}}{=} \partial_t\left(c_\varepsilon^1 + h(c_\varepsilon^1)\right) + \partial_x\left(uc_\varepsilon^1 + vh(c_\varepsilon^1)\right),$$
$$T^\varepsilon \stackrel{\text{def}}{=} \partial_t\left(\eta_1\big(c_\varepsilon^1\big) + \eta_2\big(h(c_\varepsilon^1)\big)\right) + \partial_x\left(u\eta_1\big(c_\varepsilon^1\big) + v\eta_2\big(h(c_\varepsilon^1)\big)\right).$$

We want to apply the classical div-curl lemma, which asserts that the quantity

$$(c_\varepsilon^1 + h(c_\varepsilon^1))[u\eta_1\big(c_\varepsilon^1\big) + v\eta_2\big(h(c_\varepsilon^1)\big)] - [\eta_1\big(c_\varepsilon^1\big) + \eta_2\big(h(c_\varepsilon^1)\big)](uc_\varepsilon^1 + vh(c_\varepsilon^1))$$

passes to the L^∞ weak-$*$ limit (see [27]), provided S^ε and T^ε are compact in $H^{-1}_{\text{loc}}(\Omega)$. But, for any pair (η_1,η_2) of diphasic entropies (in particular for the trivial entropies $(c_\varepsilon^1, c_\varepsilon^2)$ which give back S^ε), $T^\varepsilon = \mu^\varepsilon + g^\varepsilon$, where

$$\mu^\varepsilon \stackrel{\text{def}}{=} \partial_t\left(\eta_1(c_\varepsilon^1) + \eta_2(c_\varepsilon^2)\right) + \partial_x\left(u\eta_1(c_\varepsilon^1) + v\eta_2(c_\varepsilon^2)\right),$$
$$g^\varepsilon \stackrel{\text{def}}{=} \partial_t\left(\eta_2(h(c_\varepsilon^1)) - \eta_2(c_\varepsilon^2)\right) + \partial_x v\left(\eta_2(h(c_\varepsilon^1)) - \eta_2(c_\varepsilon^2)\right).$$

Now, T^ε is bounded in $W^{-1,\infty}$ since c_ε^1 is bounded in L^∞, and μ^ε is a nonpositive measure (it is actually 0 for the trivial entropies). By Lemma 3.1, we have that

$c_\varepsilon^2 - h(c_\varepsilon^1)$ tends to 0 in $L^2_{\rm loc}(\Omega)$; hence $\eta_2(c_\varepsilon^2) - \eta_2(h(c_\varepsilon^1))$ also tends to 0 in $L^2_{\rm loc}(\Omega)$. Since the operators ∂_t and ∂_x are continuous from $L^2_{\rm loc}(\Omega)$ to $H^{-1}_{\rm loc}(\Omega)$, g^ε tends to 0, and hence is compact, in $H^{-1}_{\rm loc}(\Omega)$. Thus, by Murat's lemma, T^ε is compact in $H^{-1}_{\rm loc}(\Omega)$.

With the obvious notation denoting the weak-$*$ limit with an overline, we obtain, after trivial simplifications,

$$\overline{h(c_1)\eta_1(c_1)} - \overline{h}\;\overline{\eta_1} = \overline{c_1\eta_2\big(h(c_1)\big)} - \bar{c}_1\overline{\eta_2}. \tag{3.6}$$

We now proceed classically by introducing the Young measure $\nu = \nu_{x,t}$ associated with the sequence c_ε^1: for every function α,

$$\alpha(c_\varepsilon^1) \rightharpoonup \overline{\alpha} = \int_{\mathbb{R}} \alpha(\xi)\, d\nu(\xi) = \langle \alpha(\xi), \nu\rangle \qquad \text{in } L^\infty - w*.$$

Equation (3.6) therefore becomes

$$\Big\langle (\xi - \bar{c})\eta_2\big(h(\xi)\big) - \Big(h(\xi) - \overline{h(c)}\Big)\,\eta_1(\xi), \nu\Big\rangle = 0.$$

If we now introduce the aforementioned Kružkov-like entropies $\eta_1(c_1) = |\xi - c_1|$, $\eta_2(c_2) = |h(\xi) - c_2|$, the preceding equality becomes

$$\Big\langle (\xi - \bar{c})|h(\xi) - h(\bar{c})| - \big(h(\xi) - \overline{h(c)}\big)|\xi - \bar{c}|, \nu\Big\rangle = 0.$$

But the fact that h is increasing implies easily that $(\xi - \bar{c})|h(\xi) - h(\bar{c})| = |\xi - \bar{c}|\big(h(\xi) - h(\bar{c})\big)$, so we finally obtain

$$\big(\overline{h(c)} - h(\bar{c})\big)\,\langle |\xi - \bar{c}|, \nu\rangle = 0.$$

The conclusion now follows exactly in the same way as in [27]: ν is a Dirac mass, except where h is affine.

Proof of Theorem 3.2. *Step* 2. First notice that any solution $(c_\varepsilon^1, c_\varepsilon^2)$ to (1.1) with the boundary conditions (1.3) satisfies

$$\begin{aligned} -\int_0^T \int_0^1 \Big[\big(|c_\varepsilon^1 - k| + |c_\varepsilon^2 - h(k)|\big)\partial_t\varphi + \big(u|c_\varepsilon^1 - k| + v|c_\varepsilon^2 - h(k)|\big)\partial_x\varphi\Big]dxdt \\ \le \int_0^T u|a(t) - k|\varphi(0,t)dt + \int_0^T |b(t) - f(k)|\varphi(1,t)dt \\ - \int_0^1 \big(|c^0(x) - k| + |h(c^0(x)) - h(k)|\big)\,\varphi(x,0)dx. \end{aligned} \tag{3.7}$$

Indeed, rewrite (2.3) with $\eta_1(c^1) = |c^1 - k|$ and $\eta_2(c^2) = |c^2 - h(k)|$, multiply by $\varphi(x,t) \ge 0$, and integrate by parts with respect to x and t. We obtain, using the

boundary condition on $x = 0$ and the fact that $v < 0$,

$$
\begin{aligned}
-\int_0^T \int_0^1 \Big[\big(|c_\varepsilon^1 - k| + |c_\varepsilon^2 - h(k)|\big)\partial_t\varphi + \big(u|c_\varepsilon^1 - k| + v|c_\varepsilon^2 - h(k)|\big)\partial_x\varphi \Big] dxdt \\
\leq \int_0^T u|a(t) - k|\varphi(0,t)dt \\
- \int_0^T \big(u|c_\varepsilon^1(1,t) - k| + v|c_\varepsilon^2(1,t) - h(k)|\big)\,\varphi(1,t)dt \\
- \int_0^1 \big(|c^0(x) - k| + |h(c^0)(x) - h(k)|\big)\,\varphi(x,0)dx.
\end{aligned}
$$

For $x = 1$, we use the boundary condition to get

$$
\begin{aligned}
&\int_0^T (u|c_\varepsilon^1(1,t) - k| + v|c_\varepsilon^2(1,t) - h(k)|)\varphi(1,t)dt \\
&\qquad = \int_0^T \left(u|c_\varepsilon^1(1,t) - k| + v\frac{1}{|v|}|b(t) - uc_\varepsilon^1(1,t) - vh(k)| \right) \varphi(1,t)dt.
\end{aligned}
$$

Again since $v < 0$, $v/|v| = -1$, we add and subtract uk in the second term of the right-hand side, and we use the triangle inequality to conclude. Finally, the first step of this proof allows us to pass to the limit in the left-hand side of (3.7). □

3.3. Remarks on viscous regularization. We consider here another possible perturbation of the hyperbolic equation, by means of a viscous regularization. We go back to the classical form of conservation law,

$$
\partial_t w + \partial_x f(w) = \varepsilon\partial_{xx} w, \qquad x < 1, \tag{3.8}
$$

provided with a perturbed Neumann condition on $x = 1$:

$$
-\varepsilon\partial_x w(t,1) + f\big(w(t,1)\big) = b(t).
$$

This is exactly the context considered by Gisclon in [9] for the Burgers equation.

We drop the Dirichlet condition on $x = 0$: it has been fully considered by Bardos, Leroux, and Nédélec in [3] and cannot be treated without a priori BV estimates, since the entropy condition on the boundary involves the trace of the solution. Notice that our boundary condition differs from the one in [3], since we do not impose the equilibrium at the boundary.

We are going to formally recover the L^∞ estimate from this perturbation, under the same assumptions as in Theorem 3.1, that is, $b \leq 0$ and condition (3.4). After that, classical compactness arguments can be performed in order to obtain strong convergence of the sequence w^ε to a weak solution.

Indeed, multiply (3.8) by $\eta'(w)$, where (η, q) is any pair entropy-flux; then integrate in x. We obtain

$$
\begin{aligned}
\frac{d}{dt}\int_{-\infty}^1 \eta(w(x,t))\,dx + q(w(1,t)) = (\varepsilon\eta'(w(1,t))\partial_x w(1,t)) \\
-\varepsilon\int_{-\infty}^1 \eta''(w(x,t))(\partial_x w(x,t))^2\,dx
\end{aligned} \tag{3.9}
$$

Now, the term involving η'' is nonnegative since η is convex, and we wish to control the quantity $q(w) - \varepsilon\eta'(w)\partial_x w$ on the boundary. Using the boundary condition, we have $q(w) - \varepsilon\eta'(w)\partial_x w = q(w) + \eta'(w)\,(b - f(w))$. But, assuming $f(0) = 0$, we can write

$$q(w) = \int_0^w \eta'(v)f'(v)\,dv = -\int_0^w \eta''(v)f(v)\,dv + \eta'(w)f(w),$$

so that

$$\frac{d}{dt}\int_{-\infty}^1 \eta(w(x,t))\,dx \le \int_0^{w(1,t)} \eta''(v)\,[f(v) - b]\,dv. \tag{3.10}$$

Now, for a general η, if we assume that

$$f(w) \le \min_{t>0} b(t) \qquad \text{if} \quad |w| \ge M, \tag{3.11}$$

for some $M > 0$ then, since $\eta'' \ge 0$, the right-hand side in (3.10) is bounded by

$$\inf_{w\le M}\int_0^w \eta''(v)\,(f(v) - b)\,dv \stackrel{\text{def}}{=} C.$$

This proves an entropy estimate for any entropy η, provided (3.11) is satisfied. Notice that, in the particular case $f(w) = ug(w)+vh\big(g(w)\big)$, condition (3.11) is exactly (3.2). Notice also that such a flux condition on a Burgers-like equation does not satisfy the assumption, since the function $w \mapsto w^2$ is not bounded.

To recover the L^∞ estimates, we first consider $\eta(w) = w^-$. Then we have $\eta''(w) = -\delta_0(w)$, so that (3.10) becomes

$$\frac{d}{dt}\int_{-\infty}^1 w(x,t)^-\,dx \le b(t) \le 0.$$

Hence $w(x,t) \ge 0$ if $w(x,0) \ge 0$. For the upper bound, we choose $\eta(w) = (w-k)^+$, for a given $k \in \mathbb{R}$, which gives $\eta''(w) = \delta_k(w)$. Thus

$$\frac{d}{dt}\int_{-\infty}^1 [w(x,t) - k]^+\,dx \le \begin{cases} 0 & \text{if } k \notin [0, w(1,t)], \\ f(k) - b(t) & \text{if } k \in [0, w(1,t)]. \end{cases}$$

If one can choose k such that $f(k) - b(t) \le 0$, then we are done. This can be done precisely if condition (3.4) is satisfied.

4. The Langmuir model. We now consider an $N \times N$ system which appears in chemical engineering both in chromatography and distillation. The unknowns are N functions $c_i(x,t)$ solutions of

$$\begin{gathered}\partial_t\big(c_i + h_i(\mathbf{c})\big) + \partial_x\big(uc_i + vh_i(\mathbf{c})\big) = 0, \quad t \ge 0,\ x \in]0,1[,\ 1 \le i \le N, \\ c_i(x,0) = c_i^\circ(x) \ge 0,\end{gathered} \tag{4.1}$$

where the vector-valued function $\mathbf{h}$ is the so-called Langmuir isotherm (see [20]),

$$h_i(\mathbf{c}) = \frac{k_i c_i}{D}. \tag{4.2}$$

The k_i's given here are numbers $0 < k_1 < k_2 < \cdots < k_N$ and $D = 1+c_1+c_2+\cdots+c_N$. Function $\mathbf{h}$ is defined for $D > 0$, which contains the "physical domain" $\{c_i \geq 0, 1 \leq i \leq N\}$. We set in the following $\mathbf{c}(x,t) = (c_1(x,t), \ldots, c_N(x,t))$.

System (4.1) of partial differential equations has been treated by Rhee, Aris, and Admundson in [24] for chromatography, which corresponds to $v = 0$, and in [25] for a countercurrent model of chromatography, which is very close to the system we deal with. Canon and James also studied both systems [5], [6], respectively, for distillation and chromatography. Serre [26] studied a variant of this system, which emphasizes the structure of the function $\mathbf{h}$. On the same variant, a kinetic formulation was obtained in [14], which led to L^∞ estimates and strong convergence properties for bounded sequences of solutions, even though system (4.1) is not hyperbolic on the whole physical domain. The entropies we are about to use are very similar to those in [14], and before defining them, we recall without proof some fundamental algebraic properties of $\mathbf{h}$ (see [5], [24], [26]).

LEMMA 4.1. (i) *If $c_i \geq 0$ for $1 \leq i \leq N$, then $A(\mathbf{c}) = \nabla_{\mathbf{c}}\mathbf{h}(\mathbf{c})$ has N real eigenvalues $\mu_i(\mathbf{c})$, and $w_i \overset{\text{def}}{=} D\mu_i$ satisfies*

$$0 < w_1 \leq k_1 \leq w_2 \leq k_2 \leq \cdots \leq k_{N-1} \leq w_N \leq k_N;$$

(ii) *w_i is a strong i-Riemann invariant, in the sense that $\nabla_{\mathbf{c}} w_i$ is a left eigenvector of $A(\mathbf{c})$;*

(iii)
$$D = \prod_{i=1}^{N} \frac{k_i}{w_i};$$

(iv)
$$c_i \prod_{j \neq i} \left(1 - \frac{k_i}{k_j}\right) = -\prod_{j=1}^{N} \left(1 - \frac{k_i}{w_j}\right);$$

(v)
$$\sigma_0 \overset{\text{def}}{=} \prod_{i=1}^{N} k_i, \qquad \sigma_j(\mathbf{c}) \overset{\text{def}}{=} \sum_{1 \leq i_1, \ldots, i_j \leq N} \frac{1}{w_{i_1} \ldots w_{i_j}} \quad \text{for } 1 \leq j \leq N,$$

are $N+1$ independent affine functions of $(c_1, \ldots, c_N)$.

These properties are very strong. (i) and (ii) give the so-called richness (Serre [26]): system (4.1) admits a diagonal form for smooth solutions, namely,

$$(1 + \mu_i)\partial_t w_i + (u + v\mu_i)\partial_x w_i = 0. \tag{4.3}$$

Moreover, this system also belongs to the Temple class [28] for which some existence and uniqueness results are known in BV when they are strictly hyperbolic (see [26], [13]).

Remark 4.1. Let us point out an important point (see [6] for further details). Property (i) allows a degeneracy of the system (two equal eigenvalues). This can happen only for $w_i = w_{i+1} = k_i$, then $\mu_i = \mu_{i+1}$, and $c_i = 0$. It requires that, initially, $w_i^0(x) = w_{i+1}^0(x) = k_i$ for some $x \in \mathbb{R}$.

Section 4.1 is devoted to some technical devices to generalize the kinetic entropies of [14] for system (4.1). Next, we establish some invariants regions in section 4.2. In

particular, we prove that the domain $\{c_i \geq 0\}$ is invariant. Finally, we prove strong convergence results in section 4.3. In the following, we shall say that a vector $\mathbf{z}$ is nonnegative, $\mathbf{z} \in \mathbb{R}^N_+$ (respectively, nonpositive, $\mathbf{z} \in \mathbb{R}^N_-$), if all its components are nonnegative (respectively, nonpositive). We denote by w_1 (respectively, $w_i^{\mathbf{a}}$, w_i^0) the i-Riemann invariant associated by Lemma 4.1(ii) with $\mathbf{c}^1_\varepsilon$ (respectively, with the data on $x = 0$, with the initial data).

4.1. Some specific entropies. Now, we define a first trivial (i.e., affine) diphasic entropy for system (4.1), from which we shall build a specific family of nontrivial (i.e., convex) diphasic entropies. This set of entropies was already mentioned by Serre [26]. For $\xi \in \mathbb{R}_+$ and $\mathbf{c}^1 \in \mathbb{R}^N_+$, we set

$$E_0(\xi; \mathbf{c}^1) = \prod_{i=1}^N \left(1 - \frac{\xi}{w_i^1}\right), \qquad \gamma(\xi) = E_0(\xi; 0) = \prod_{i=1}^N \left(1 - \frac{\xi}{k_i}\right),$$

where w_i^1 are the Riemann invariants corresponding to $\mathbf{c}^1$.

LEMMA 4.2. *The function E_0 is affine with respect to $\mathbf{c}^1$. Let $\nabla_{\mathbf{c}} E_0(\xi)$ denote its gradient. We now define, for $\xi \in \mathbb{R}^+$ and $\mathbf{c}^2 \in \mathbb{R}^N$,*

$$F_0(\xi; \mathbf{c}^2) = \nabla_{\mathbf{c}} E_0(\xi) \cdot \mathbf{c}^2 + \xi \gamma(\xi). \tag{4.4}$$

Then the pair of functions (E_0, F_0) defines a diphasic entropy for (4.1)*, and we have*

$$F_0(\xi; \mathbf{h}(\mathbf{c}^1)) = \frac{\xi E_0(\xi; \mathbf{c}^1)}{D}. \tag{4.5}$$

Proof. First notice that, if E_0 is affine and F_0 is given by (4.4), then obviously the pair (E_0, F_0) defines a diphasic entropy, since $\nabla_{\mathbf{c}^2} F_0(\xi; \mathbf{h}(\mathbf{c}^1)) = \nabla_{\mathbf{c}} E_0(\xi)$.

We are going to prove that E_0 satisfies

$$\left\{ \begin{array}{ll} E_0(k_i; \mathbf{c}^1) & = \beta_i c_i^1, \qquad \text{where} \quad \beta_i = \prod_{j \neq i} (1 - k_i/k_j), \\ E_0(\xi; \mathbf{c}^1) & = -\gamma(\xi) \left[\sum_{i=1}^N \frac{k_i c_i^1}{k_i - \xi} - D \right] \\ & = -\gamma(\xi) \left[\xi \sum_{i=1}^N \frac{c_i^1}{k_i - \xi} - 1 \right] \quad \text{for } \xi \neq k_i, \end{array} \right. \tag{4.6}$$

so that for $\xi \neq k_i$, $\nabla_{\mathbf{c}} E_0(\xi) = -\xi \gamma(\xi) (\frac{1}{k_i - \xi})_{1 \leq i \leq N}$. To prove (4.6), recall that the Riemann invariants w_i^1 are the roots of the algebraic equation $\varphi(\xi) = 0$, where

$$\varphi(\xi) = \sum_{i=1}^N \frac{k_i c_i}{k_i - \xi} - D = \xi \sum_{i=1}^N \frac{c_i}{k_i - \xi} - 1. \tag{4.7}$$

But φ is also a rational fraction with poles k_i and roots w_i^1; thus an easy computation gives

$$\varphi(\xi) = -D \prod_{i=1}^N \frac{\xi - w_i^1}{\xi - k_i} = -\prod_{i=1}^N \frac{\frac{\xi}{w_i^1} - 1}{\frac{\xi}{k_i} - 1} = -\frac{E_0}{\gamma(\xi)} \tag{4.8}$$

by Lemma 4.1(iii) and the definitions of E_0 and $\gamma(\xi)$. Putting together (4.7) and (4.8) gives (4.6). Finally, (4.5) is obtained by playing with the two definitions of E_0, since

$$\nabla_{\mathbf{c}} E_0(\xi) \cdot \mathbf{h}(\mathbf{c}^1) = -\xi \gamma(\xi) \sum_{i=1}^N \frac{k_i c_i^1}{D} \frac{1}{k_i - \xi} = \frac{\xi}{D} E_0(\xi; \mathbf{c}^1) - \xi \gamma(\xi),$$

and this completes the proof. ∎

Remark 4.2. We state here a few useful properties of F_0. First, it is a polynomial of degree $N+1$ in ξ, very similar to E_0: if $c_i^2 \in \mathbb{R}_+^N$, it has roots $0, w_1^2, \dots, w_N^2$, with $0 < w_1^2 \le k_1 \le \cdots \le w_N^2 \le k_N$. We easily obtain also that, for any $\mathbf{z} \in \mathbb{R}^N$,

$$F_0(k_i; \mathbf{z}) = \nabla_{\mathbf{c}} E_0(k_i) \cdot \mathbf{z} = \beta_i z_i, \qquad 1 \le i \le N. \tag{4.9}$$

A crucial point now is to remark that $E_0(\xi; \mathbf{c})$ and $F_0(\xi; \mathbf{h}(\mathbf{c}))$ vanish simultaneously for $\xi = w_i^1 = w_i^2$, $1 \le i \le N$. Thus, taking the convention $w_0^j = 0$ and $w_{N+1}^j = +\infty$, we easily deduce the following.

COROLLARY 4.3. *For $0 \le i \le N$, $\mathbf{c}^1 \in \mathbb{R}_+^N$, $\mathbf{c}^2 \in \mathbb{R}_+^N$, let w_i^1 (respectively, w_i^2) be the roots of E_0 (respectively, the nonzero roots of F_0). Define*

$$\begin{aligned} \chi_i^1(\xi; \mathbf{c}^1) &= |E_0(\xi; \mathbf{c})| \mathbb{1}_{\{\xi \in]w_i^1, w_{i+1}^1[\}}, \\ \chi_i^2(\xi; \mathbf{c}^2) &= |F_0(\xi; \mathbf{c}^2)| \mathbb{1}_{\{\xi \in]w_i^2, w_{i+1}^2[\}}. \end{aligned} \tag{4.10}$$

Then the pair (χ_i^1, χ_i^2) defines a diphasic entropy for (4.1).

Notice that χ_i^1 (respectively, χ_i^2) is actually convex with respect to $\mathbf{c}^1$ (respectively, to $\mathbf{c}^2$), as the absolute value of an affine function. Thus the function $\eta_i(\xi; \mathbf{c}) \overset{\text{def}}{=} \chi_i^1(\xi; \mathbf{c}) + \chi_i^2(\xi; \mathbf{h}(\mathbf{c}))$ is indeed a nontrivial convex diphasic entropy for (4.1).

The class of entropies we consider now is defined as follows. Set, for $j = 1, 2$, $\mathbf{c}^j \in \mathbb{R}_+^N$, and a fixed $0 \le i \le N$,

$$S^j(\mathbf{c}^j) = \int_{\mathbb{R}_+} g(\xi) \chi_i^j(\xi; \mathbf{c}^j)\, d\xi, \qquad j = 1, 2.$$

The functions $S(\mathbf{c}) = S^1(\mathbf{c}) + S^2(\mathbf{h}(\mathbf{c}))$ are diphasic entropies for (1.2), for any nonnegative function g such that $g\chi_i^j$ is integrable at $+\infty$ in ξ (recall that χ_i^j is a polynomial in ξ). The corresponding entropy flux is $Q(\mathbf{c}) = uS^1(\mathbf{c}) + vS^2(\mathbf{h}(\mathbf{c}))$. We have to complement these functions by using for g a Dirac mass, $g(\xi) = \delta_{\xi^*}(\xi)$. To justify this, consider a sequence of nonnegative g's which converge to such a Dirac mass. These entropies will appear in the proof of the maximum principle below. Let us denote by $\mathcal{E}$ the set of all these entropies for $0 \le i \le N$.

Remark 4.3. The entropies in $\mathcal{E}$ are defined only on $\mathbb{R}_+^N$ and therefore cannot be used to prove the invariance of $\mathbb{R}_+^N$. But it is easily checked that the pairs $([c_i^1]^-, [c_i^2]^-)$, where r^- is the negative part of $r \in \mathbb{R}$, define diphasic entropies on the domain $D > 0$.

4.2. Invariant regions. In this subsection, we shall prove that the solution $(\mathbf{c}_\varepsilon^1, \mathbf{c}_\varepsilon^2)$ to (4.1) is bounded in L^∞ uniformly in ε, thus giving rise to a weakly convergence subsequence. In the next subsection, we prove that this subsequence actually converges almost everywhere to a solution in the sense of (4.14) below.

THEOREM 4.4. *Assume $\mathbf{c}^0 \in L^1 \cap L^\infty(]0,1[)^N$, $\mathbf{a} \in L^\infty(\mathbb{R}_+)^N$, $\mathbf{b} \in L^\infty(\mathbb{R}_+)^N$, $\mathbf{c}^0, \mathbf{a}$ nonnegative, and $\mathbf{b}$ nonpositive. Let $0 < w^- \le k_1$ satisfy $w^- \le w_1^{\mathbf{a}}(t), w_1^0(x) \le k_1$ for all (t, x). Define*

$$\psi(\xi) \overset{\text{def}}{=} \nabla_{\mathbf{c}} E_0(\xi) \cdot \mathbf{b} + (u + v\xi)\gamma(\xi),$$

and assume that

$$\xi^\star \overset{\text{def}}{=} \inf\{\xi \le k_1; \exists \xi' \le \xi, \psi(\xi') \le 0\} > w^-. \tag{4.11}$$

Let $(\mathbf{c}^1_\varepsilon, \mathbf{c}^2_\varepsilon)$ *be a solution of* (1.1). *Then there exists a constant* C *independent of* ε *such that* $0 \le \mathbf{c}^i_\varepsilon(x,t) \le C$, $1 \le i \le N$, $\forall (t,x) \in [0,T] \times [0,1]$.

Remark 4.4. Once again, one can choose $\xi_0 = w^-$ only if w^- satisfies $\psi(w^-) \le 0$.

Remark 4.5. The existence of ξ^* relies on the nonpositivity of the polynomial ψ on $[0,k_1]$ (one has $\psi(0) = u > 0$ and $\psi(k_1) = -k_1 b_1 \prod_{i>1}(k_i - k_1) \ge 0$, so this is not trivially satisfied). This leads to a condition on $u, v, \mathbf{b}$, and k_1, which is actually not very explicit, except for $N = 1$ (see Remark 3.1). However, one can rewrite things as follows. For $0 < \xi < k_1$, define $\mathbf{c}(\xi) \in \mathbb{R}^N_+$ by

$$c_i(\xi) = \frac{k_i - \xi}{N\xi}, \qquad 1 \le i \le N.$$

Then a few easy algebraic computations prove

$$\nabla_{\mathbf{c}} E_0(\xi) \cdot \mathbf{c}(\xi) = -\gamma(\xi), \quad \nabla_{\mathbf{c}} E_0(\xi) \cdot \mathbf{h}(\mathbf{c}(\xi)) = -\xi\gamma(\xi),$$

so that $\psi(\xi) \le 0$ rewrites $\nabla_{\mathbf{c}} E_0(\xi) \cdot [\mathbf{b} - (u\mathbf{c}(\xi) + \xi\gamma(\xi))] \le 0$. Thus condition (4.11) can be compared to (3.4) in a more consistent way. Notice that this can also be read as an entropy inequality, since $\nabla_{\mathbf{c}} E_0(\xi) \cdot [\mathbf{b} - (u\mathbf{c}(\xi) + \xi\mathbf{h}(\mathbf{c}(\xi)))] = E_0(\xi; \mathbf{b}) - E_0(\xi; u\mathbf{c}(\xi) + \xi\mathbf{h}(\mathbf{c}((\xi))) = F_0(\xi; \mathbf{b}) - F_0(\xi; u\mathbf{c}(\xi) + \xi\mathbf{h}(\mathbf{c}((\xi)))$.

Proof of Theorem 4.1. To lighten the notations a bit, we omit the index ε in this proof. First notice that w^- exists since $\mathbf{a}$ and $\mathbf{c}^0$ are nonnegative and uniformly bounded.

Let us prove first that for a given index i, if $a_i \ge 0$, $b_i \le 0$, and $c_i^0 \ge 0$, then $c_i^j \ge 0$ for $j = 1, 2$. For this purpose we make use of the entropy introduced in Remark 4.3. Inequality (2.4) can be rewritten here as

$$\frac{d}{dt}\int_0^1 \left([c_i^1(x,t)]^- + [c_i^2(x,t)]^-\right) dx \le [c_i^1(0,t)]^- + v[c_i^2(0,t)]^- - u[c_i^1(1,t)]^- - v[c_i^2(1,t)]^-.$$

Now, as in the scalar case, we notice that $v < 0$ and $(c_i^j)^- \ge 0$, so $u[c^1(0,t)]^- + v[c^2(0,t)]^- \le u[a_i(t)]^-$ by the boundary condition at $x = 0$. Since $a_i(t) \ge 0$ for $1 \le i \le N$, $[a_i(t)]^- = 0$, and the same occurs for the initial data.

For $x = 1$, we have to prove that $F \overset{\text{def}}{=} -u[c^1(1,t)]^- - v[c^2(1,t)]^- \le 0$. This clearly occurs if $(b_i - uc_i^1(1,t))/v \ge 0$. If this is not the case, we have $0 \ge b_i(t) \ge uc_i(t)$ since $v < 0$ so that $F = b_i(t)|\beta_i| \le 0$. Hence the following differential inequality holds:

$$\frac{d}{dt}\int_0^1 \left([c^1(x,t)]^- + [c^2(x,t)]^-\right) dx \le 0.$$

The conclusion now follows easily: the components of $\mathbf{c}^1_\varepsilon$ and $\mathbf{c}^2_\varepsilon$ remain nonnegative for any $t > 0$.

We turn now to the proof of the upper bound. For simplicity, we assume the nonnegativity. In view of formula (iv) in Lemma 4.1, we have to prove that there exists $\xi_0 > 0$ such that $w_1^j \ge \xi_0$ for all (t,x). We consider the diphasic entropy (S^1, S^2),

$$S^1(\mathbf{c}^1) = \int_{w_1^1}^{w_2^1} |E_0(\xi; \mathbf{c}^1)| g(\xi) d\xi, \quad S^2(\mathbf{c}^2) = \int_{w_1^2}^{w_2^2} |F_0(\xi; \mathbf{c}^2)| g(\xi) d\xi.$$

The usual trick of convexity of S^1 and S^2 leads to

$$\frac{d}{dt}\int_0^1 [S^1(\mathbf{c}^1(x,t))+S^2(\mathbf{c}^2(x,t))]\,dx \leq -[uS^1(\mathbf{c}^1(x,t))+vS^2(\mathbf{c}^2(x,t))]\Big|_{x=0}^{x=1}. \tag{4.12}$$

Set $H_0 = uS^1(\mathbf{c}^1(0,t))+vS^2(\mathbf{c}^2(0,t))$ and $H_1 = -[uS^1(\mathbf{c}^1(1,t))+vS^2(\mathbf{c}^2(1,t))]$. We have

$$H_0 = \int_{w_1^1}^{w_2^1} u|E_0(\xi;\mathbf{c}^1)|g(\xi)d\xi + \int_{w_1^2}^{w_2^2} v|F_0(\xi;\mathbf{c}^2)|g(\xi)d\xi \leq \int_{w_1^{\mathbf{a}}}^{w_2^{\mathbf{a}}} u|E_0(\xi;\mathbf{a})|g(\xi)d\xi,$$

since $v<0$. For any $\xi_0 \leq w^-$, choosing $g=\delta_{\xi_0}$ cancels the right-hand side of the preceding inequality.

Concerning H_1, we want to take $g=\delta_{\xi_0}$ for a carefully chosen $\xi_0 \leq w^-$ such that

$$H_1 = -\int_{w_1^1}^{w_2^1} u|E_0(\xi;\mathbf{c}^1)|\delta_{\xi_0}(\xi)d\xi - \int_{w_1^2}^{w_2^2} v\left|F_0\left(\xi;\frac{1}{v}[\mathbf{b}-u\mathbf{c}^1]\right)\right|\delta_{\xi_0}(\xi)d\xi \leq 0. \tag{4.13}$$

We know, since everything is nonnegative, that $0<w_1^1,w_1^2\leq k_1\leq w_2^1,w_2^2$, so that necessarily $\xi_0\leq w_2^1,w_2^2$. Now, if $\xi_0<w_1^2$, then $H_1\leq 0$ by (4.13). If $\xi_0\geq w_1^2$, we have by construction $F_0(\xi_0;(\mathbf{b}-u\mathbf{c}^1)/v)\leq 0$ (indeed one can check that $F_0(\xi=0)=0$ and $\partial_\xi F_0(\xi=0)\geq 0$). On the other hand, an easy computation shows

$$vF_0\left(\xi;\frac{1}{v}[\mathbf{b}-u\mathbf{c}^1]\right) = \psi(\xi_0) - uE_0(\xi_0;\mathbf{c}^1).$$

Since $w^-\geq\xi^\star$, one can choose any $\xi^\star\leq\xi_0\leq w^-$ such that $\psi(\xi_0)\leq 0$. The preceding equality therefore gives $E_0(\xi_0;\mathbf{c})\leq 0$, so that $\xi_0\in[w_{2p+1}^1,w_{2p+2}^1]$ for some $p\geq 1$, by assertion (iv) in Lemma 4.1. Since $\xi_0\leq k_1\leq w_2^1$, necessarily $\xi_0\in[w_1^1,w_2^1]$ so that finally, H_1 can be rewritten, by simple consideration of sign on E_0 and F_0,

$$H_1 = uE_0(\xi_0;\mathbf{c}^1) + vF_0\left(\xi_0;\frac{1}{v}[\mathbf{b}-u\mathbf{c}^1]\right) = \psi(\xi_0)\leq 0.$$

The preceding choice of ξ_0 cancels the right-hand side of (4.12). When integrating in t, we introduce the initial data, but the choice of $g=\delta_{\xi_0}$ for $\xi_0\leq w^-$ gives also $S^1(\mathbf{c}^0(x)) = S^2(\mathbf{h}(\mathbf{c}^0(x))=0$, so finally (4.12) gives

$$\int_0^1 [S^1(\mathbf{c}^1(x,t))+S^2(\mathbf{c}^2(x,t))]\,dx \leq 0,$$

which leads to $S^1(\mathbf{c}^1(x,t))=S^2(\mathbf{c}^2(x,t))=0$, $\forall t>0$. A simple contradiction argument then gives $w_1^1(x,t)\geq\xi_0$ and $w_1^2(x,t)\geq\xi_0$ for a.e. x, $\forall t>0$. □

4.3. Strong convergence. The L^∞ estimate leads obviously to the following weak convergence result: $\mathbf{c}_\varepsilon^2 - h(\mathbf{c}_\varepsilon^1)$ tends to 0 in $\mathcal{D}'(\Omega)^N$ when ε tends to 0. We actually have a stronger convergence result.

LEMMA 4.5. *Under the above assumptions ensuring the L^∞ bounds on the solution, $\mathbf{c}_\varepsilon^2 - h(\mathbf{c}_\varepsilon^1)$ tends to 0 in $L^2_{\mathrm{loc}}(\Omega)^N$.*

From (1.1), we can obtain the following inequality for the entropies (χ_i^1,χ_i^2):

$$\partial_t\left(\chi_i^1(\xi;\mathbf{c}_\varepsilon^1)+\chi_i^2(\xi;\mathbf{c}_\varepsilon^2)\right) + \partial_x\left(u\chi_i^1(\xi;\mathbf{c}_\varepsilon^1)+v\chi_i^2(\xi;\mathbf{c}_\varepsilon^2)\right)\leq 0.$$

The negative sign holds since $\nabla_{\mathbf{c}}\chi_i^2(\xi;\cdot)$ is a monotone operator, as before. Now, multiply this inequality by any nonnegative $\varphi \in \mathcal{D}(\overline{\Omega})$, integrate by parts, and treat the boundary conditions as in the above proof. One obtains

$$\begin{aligned}
&-\int_0^T\int_0^1 \left[\partial_t\varphi\left(\chi_i^1(\xi;\mathbf{c}_\varepsilon^1(x,t))+\chi_i^2(\xi;\mathbf{c}_\varepsilon^2(x,t))\right)\right.\\
&\left.+\partial_x\varphi\left(u\chi_i^1(\xi;\mathbf{c}_\varepsilon^1(x,t))+v\chi_i^2(\xi;\mathbf{c}_\varepsilon^2(x,t))\right)\right]\,dx\,dt\\
&\le \int_0^T \varphi(0,t)u\chi_i^1(\xi;\mathbf{a}(t))\,dt-\int_0^1\varphi(x,0)S(\mathbf{c}^0(x))\,dx\\
&\quad-\int_0^T\left[u\chi_i^1(\xi;\mathbf{c}_\varepsilon^1(1,t))+v\chi_i^2(\xi;\mathbf{c}_\varepsilon^2(1,t))\right]\varphi(1,t)\,dt.
\end{aligned}$$

Once again, some considerations of sign allow us to prove that for the boundary term on $x=1$, we have for any ξ, since $\mathbf{c}_\varepsilon^2(1,t)=(\mathbf{b}(t)-u\mathbf{c}_\varepsilon^1(1,t))/v$,

$$u\chi_i^1(\xi;\mathbf{c}_\varepsilon^1(1,t))+v\chi_i^2(\xi;\mathbf{c}_\varepsilon^2(1,t))\le|\nabla_{\mathbf{c}}E_0(\xi)\cdot\mathbf{b}(t)-(u+v\xi)\gamma(\xi)|\stackrel{\text{def}}{=}B(t).$$

The resulting entropy estimate is analogous to (3.7). Now, following the lines of [14], we can apply compensated compactness to obtain the following result of strong convergence.

THEOREM 4.6. *We make the same assumptions as in Theorem* 4.1. *Then there exists a subsequence of solutions to* (1.1), *still denoted by* $\mathbf{c}_\varepsilon^1$, *which converges almost everywhere and strongly in* $]0,1[\times]0,T[$ *to* $\mathbf{c}\in L^\infty(]0,T[;L^1(]0,1[))^N$. *Moreover,* $\mathbf{c}$ *satisfies, for any* $\varphi\in\mathcal{D}(\overline{\Omega})$, $\varphi\ge0$, $\xi>0$,

(4.14)
$$\begin{aligned}
&-\int_0^T\int_0^1\left[S(\mathbf{c})\partial_t\varphi+Q(\mathbf{c})\partial_x\varphi\right]\,dx\,dt\\
&\quad\le\int_0^T u\chi_i^1(\mathbf{a}(t))\varphi(0,t)\,dt-\int_0^T B(t)\varphi(1,t)\,dt-\int_0^1 S(\mathbf{c}^0(x))\varphi(x,0)\,dx,
\end{aligned}$$

with $B(t)=|\nabla_{\mathbf{c}}E_0(\xi)\cdot\mathbf{b}(t)-(u+v\xi)\gamma(\xi)|$, *for* $S(\mathbf{c})=\chi_i^1(\mathbf{c})+\chi_i^2(\mathbf{h}(\mathbf{c}))$, $Q(\mathbf{c})=u\chi_i^1(\mathbf{c})+v\chi_i^2(\mathbf{h}(\mathbf{c}))$, *and* χ_i^j *being defined by* (4.10).

Proof of Lemma 4.3. Consider the pair of entropies (η_1,η_2) obtained by choosing, for a given i, $g=\mathbb{1}_{[0,k_i]}$. Their gradients are given by

$$\begin{aligned}
\nabla_{\mathbf{c}}\eta_1(\mathbf{c}^1)&=\int_{w_i^1}^{k_i}\operatorname{sign}(E_0(\xi;\mathbf{c}^1))\nabla_{\mathbf{c}}E_0(\xi)d\xi,\\
\nabla_{\mathbf{c}}\eta_2(\mathbf{c}^2)&=\int_{w_i^2}^{k_i}\operatorname{sign}(F_0(\xi;\mathbf{c}^2))\nabla_{\mathbf{c}}E_0(\xi)d\xi.
\end{aligned}$$

Omitting here the dependence in ε, we take the scalar product of the two equations in (1.1), respectively, by $\nabla_{\mathbf{c}}\eta_1(\mathbf{c}^1)$ and $\nabla_{\mathbf{c}}\eta_2(\mathbf{c}^2)$, sum the two equations, and integrate $dx\,dt$ with a nonnegative test function $\varphi\in\mathcal{D}(\overline{\Omega})$. We obtain, after integration by

parts and multiplication by ε,

$$A^\varepsilon \stackrel{\text{def}}{=} \varepsilon \int_0^T \int_0^1 \left(\partial_t \varphi(x,t)\left[\mathbf{c}^1(x,t)+\mathbf{c}^2(x,t)\right] + \partial_x \varphi(x,t)\left[u\mathbf{c}^1(x,t)+v\mathbf{c}^2(x,t)\right]\right) dx\,dt$$
$$= -\int_0^T \int_0^1 \left[\int_{w_i^1}^{k_i} \operatorname{sign}(E_0(\xi;\mathbf{c}^1))\nabla_{\mathbf{c}} E_0(\xi) d\xi - \int_{w_i^2}^{k_i} \operatorname{sign}(F_0(\xi;\mathbf{c}^2))\nabla_{\mathbf{c}} E_0(\xi) d\xi\right] \cdot (\mathbf{c}^2 - \mathbf{h}(\mathbf{c}^1)) dx\,dt.$$

Notice that $A^\varepsilon \geq 0$ by the second equality and the convexity of η_i. Obviously, since $\mathbf{c}^1$ and $\mathbf{c}^2$ are bounded in L^∞, A^ε tends to 0 when ε goes to zero. We have to work from now on with

$$P(x,t) \stackrel{\text{def}}{=} -\left[\int_{w_i^1}^{k_i} \operatorname{sign}(E_0(\xi;\mathbf{c}^1))\nabla_{\mathbf{c}} E_0(\xi) d\xi - \int_{w_i^2}^{k_i} \operatorname{sign}(F_0(\xi;\mathbf{c}^2))\nabla_{\mathbf{c}} E_0(\xi) d\xi\right] \cdot (\mathbf{c}^2 - \mathbf{h}(\mathbf{c}^1)).$$

It is easy to check that $\operatorname{sign} E_0(\xi;\mathbf{c}^1) = \operatorname{sign} F_0(\xi,\mathbf{h}(\mathbf{c}^1)) = \operatorname{sign} F_0(\xi;\mathbf{c}^2)$ for $\xi \in [w_i^1,k_i] \cap [w_i^2,k_i]$. We are thus left with an integral over $[\min(w_i^1,w_i^2),\max(w_i^1,w_i^2)]$. Let us assume that $w_i^1 \leq w_i^2$; the computations are the same if the converse holds. We have, by considerations of sign on F_0,

$$P(x,t) = 2\int_{w_i^1}^{w_i^2} \left[|F_0(\xi;\mathbf{c}^2)| + |F_0(\xi;\mathbf{h}(\mathbf{c}^1))|\right] d\xi.$$

Now, we write for $N \geq 4$,

$$|F_0(\xi;\mathbf{c}^2)| = (\xi - w_{i-1}^2)(\xi - w_i^2)(w_{i+1}^2 - \xi)\frac{\prod_{j\notin\{i-1,i,i+1\}} |w_j^2 - \xi|}{\prod_{i=1}^N w_j^2}.$$

The fourth term is greater than some $K > 0$ (K depending on $k_1,\dots,k_N$ and ξ_0), since either $w_j^2 \leq k_{i-2}$ or $w_j^2 \geq k_{i+1}$, and $k_{i-1} \leq \xi \leq k_i$. For the first three terms, we simply write $(\xi - w_{i-1}^2)(\xi - w_i^2)(w_{i+1}^2 - \xi) \geq (\xi - w_i^2)^2(w_{i+1}^2 - w_i^2)$, which leads by integration to

$$\int_{w_i^1}^{w_i^2} |F_0(\xi;\mathbf{c}^2)| d\xi \geq \frac{K}{3}(w_i^1 - w_i^2)^3(w_{i+1}^2 - w_i^2) \geq \frac{K}{3}(w_i^1 - w_i^2)^4.$$

For $N = 3$, we have a similar estimate, since the fourth term reduces to $K/(w_1^2 w_2^2 w_3^2)$. Because the same holds for $|F_0(\xi;\mathbf{h}(\mathbf{c}^1))|$, we have finally that for some $C > 0$, depending only on $k_1,\dots,k_N$,

$$\int_0^T \int_0^1 |w_i^1(x,t) - w_i^2(x,t)|^4 \varphi(x,t) dx\,dt \leq C\int_0^T \int_0^1 P(x,t)\varphi(x,t) dx\,dt = A^\varepsilon$$

tends to zero. Thus $|w_i^1 - w_i^2|$ tends to 0 in $L^4_{\text{loc}}(\Omega)$ and therefore in $L^2_{\text{loc}}(\Omega)$. For $N = 2$, the same computations lead to convergence in $L^3_{\text{loc}}(\Omega)$ and hence in $L^2_{\text{loc}}(\Omega)$. Finally, if $N = 1$, we directly obtain $L^2_{\text{loc}}(\Omega)$. Since the function $(w_1,\dots,w_N) \mapsto (c_1,\dots,c_N)$ is Lipschitz continuous, we are done. ∎

Proof of Theorem 4.2. We merely give the sketch of the proof, referring to [14] for the detailed computations, which are identical. Summing the equations for $0 \le i \le N$, we obtain, with the same notations as in the scalar case,

(4.15)
$$T^\varepsilon(\xi) = \partial_t[G_0(\xi, \mathbf{c}^1) + H_0(\xi, \mathbf{h}(\mathbf{c}^1))] + \partial_x[uG_0(\xi, \mathbf{c}^1) + vH_0(\xi, \mathbf{h}(\mathbf{c}^1))] = \mu^\varepsilon(\xi) + g^\varepsilon(\xi),$$

with $G_0 = |E_0|$ and $H_0 = |F_0|$. Since η_1 and η_2 are convex, the usual computation proves that $\mu^\varepsilon(\xi)$ is a nonpositive measure. By Lemma 4.3, $g^\varepsilon(\xi)$ is compact in $H^{-1}_{\mathrm{loc}}(\Omega)$; thus, again applying Murat's lemma, we can apply the compensated compactness lemma to (4.15), for two different values ξ and ξ'. We obtain, after some easy simplifications,

$$\overline{G_0(\xi)}\ \overline{\xi' G_0(\xi')/D} - \overline{G_0(\xi')}\ \overline{\xi G_0(\xi)/D} \ = \ (\xi' - \xi)\overline{G_0(\xi)G_0(\xi')/D}.$$

Dividing by $\overline{G_0(\xi)}\ \overline{G_0(\xi')}\ (\xi' - \xi)$ and letting ξ' go to ξ, we get

$$\partial_\xi \frac{\xi\overline{G_0(\xi)/D}}{\overline{G_0(\xi)}} = \frac{\overline{G_0(\xi)^2/D}}{\overline{G_0(\xi)}^2}. \tag{4.16}$$

Of course (4.16) has to be justified at points where $\overline{G_0(\xi)} = 0$. This occurs when $G_0(\xi_0, w) = 0$ for all w in the support of ν, that is, $w_j = \xi_0$ for some j. If w_j is a simple eigenvalue, the formula is justified by applying l'Hospital's rule in a neighborhood of ξ_0 to G_0', which is not zero since the root is simple. When we have a double root, that is, $\xi_0 = k_j$, the same technique can be used with G_0'', which in no case can be zero, since the root cannot be triple.

Equation (4.16) is not completely satisfactory because its right-hand side does not vanish when $d\nu$ is a Dirac mass. Therefore, we again apply compensated compactness to (4.15) for a given ξ and

$$\partial_t\left(D + \frac{\alpha}{D}\right) + \partial_x\left(uD + v\frac{\alpha}{D}\right) = 0, \qquad \alpha = k_1u_1 + \cdots + k_Nu_N.$$

This yields $\overline{G_0(\xi)}\ \overline{\alpha/D} - \xi\overline{G_0(\xi)/D}\ \overline{D} = \overline{G_0(\xi)\alpha/D} - \xi\overline{G_0(\xi)}$. After dividing it by $\overline{D}\,\overline{G_0(\xi)}$, we can combine it with the left-hand side of (4.15) to get

$$-\partial_\xi \frac{\overline{G_0(\xi)\alpha/D}}{\overline{G_0(\xi)}} = \frac{\overline{G_0(\xi)^2/D}}{\overline{G_0(\xi)}^2} - \frac{1}{\overline{D}} \ \ge 0, \tag{4.17}$$

this last inequality being just Cauchy–Schwarz. Inequality (4.17) is the keystone to proving that $d\nu$ is in fact a Dirac mass.

Indeed, if in (4.17) the inequality is strict at some point, we obtain a contradiction by comparing the values of the nonincreasing function

$$\frac{\overline{G_0(\xi)\alpha/D}}{\overline{G_0(\xi)}}$$

at the points $\xi = 0$ and $\xi = +\infty$, then $\xi = k_i$ and $\xi = \infty$. This means that the inequality in (4.17) is just an equality for all $\xi \ge 0$, so that the equality case in Cauchy–Schwarz applies. We obtain the existence of a function $\lambda(\xi)$ such that, for all $\xi \ge 0$, $G_0(\xi, \mathbf{c}^1) = \lambda(\xi)D(\mathbf{c}^1)$ a.e. in the support of $d\nu(\mathbf{c}^1)$. From this we deduce

that, for two possible elements $\mathbf{c}^1$, $\mathbf{c}^{'1}$ of the support of $d\nu(\mathbf{c}^1)$, we have necessarily $G_0(\xi, \mathbf{c}^1) = G_0(\xi, \mathbf{c}^{'1})$. Thus $\sigma_j(\mathbf{c}^1) = \sigma_j(\mathbf{c}^{'1})$, and by Lemma 4.1 (v) this proves that $\mathbf{c}^1 = \mathbf{c}^{'1}$ and the support of ν is a single point. ∎

Remark 4.6. Notice that formula (4.14) is exactly the kinetic formulation obtained in [14], but the boundary terms forbid us to write it in the usual way, with some nonnegative measure on the right-hand side.

5. Boundary conditions. So far, we have defined in Theorems 3.2 and 4.2 kinds of weak solutions. The aim of this section is to prove that these solutions are actually solutions to (1.2) in the sense of distributions, and to give a meaning to the reflux boundary condition at $x = 1$. It seems that we lose the Dirichlet-like boundary condition at $x = 0$ when passing to the limit. This is not really surprising, since we pass from $2N$ equations to N equations: the system becomes overdetermined.

Before precisely stating our results, we need to introduce some material. Indeed, we want to precisely state the meaning of the boundary conditions. But we deal with L^∞ functions, which usually do not have any trace on the boundary. The following result, which we state as a lemma, follows easily by choosing the test functions $\varphi \in \mathcal{D}(\Omega)$ in (3.5) or (4.14).

LEMMA 5.1. *Let (η_1, η_2) be any pair of convex functions defining a diphasic entropy. Let $\mathbf{c} \in L^\infty(\Omega)$ be a weak solution as in Theorems* 3.2 *or* 4.2. *Then the vector-valued function $\psi = (\psi_1, \psi_2) \overset{\text{def}}{=} (\eta_1(\mathbf{c}) + \eta_2(\mathbf{h}(\mathbf{c})), u\eta_1(\mathbf{c}) + v\eta_2(\mathbf{h}(\mathbf{c})))$ is in $L^\infty(\Omega)$, and $\operatorname{div}\psi = \partial_t\psi_1 + \partial_x\psi_2$ is a nonnegative measure in Ω.*

We are thus in a position to apply a result by Anzellotti [1, Theorems 1.2 and 1.9], which essentially states that ψ has a trace on $\partial\Omega$, in some sense. We recall this result here without proof.

THEOREM 5.2. *Let $\Omega \subset \mathbb{R}^n$ be a bounded domain with locally Lipschitz boundary $\partial\Omega$. Set $X(\omega) = \{\psi \in L^\infty(\Omega; \mathbb{R}^n); \operatorname{div}\psi$ is a bounded measure in $\Omega\}$. Then there exists a trace operator*

$$\gamma : X(\Omega) \to L^\infty(\partial\Omega),$$

such that, for any $\varphi \in BV(\Omega) \cap L^\infty(\Omega) \cap C^0(\Omega)$,

$$\int_\Omega \varphi \operatorname{div}\psi \, dx + \int_\Omega (\psi, \varphi) \, dx = \int_{\partial\Omega} \gamma\psi \, \varphi \, d\sigma, \tag{5.1}$$

where σ is the superficial measure on $\partial\Omega$.

In this result, (ψ, φ) has to be defined as a measure (Definition 1.4 in [1]). We denote by γ^0 the trace on $]0,1[\times\{0\}$, by γ_0 and γ_1 the traces, respectively, on $\{0\}\times]0,T[$ and $\{1\}\times]0,T[$. Since $\gamma\psi$ is, by construction, a weak trace on $\partial\Omega$ of the normal component of ψ, we have

at $t = 0$, $\quad \gamma\psi = \gamma^0[\eta_1(\mathbf{c}) + \eta_2(\mathbf{h}(\mathbf{c}))]$,

at $x = 0, 1$, $\quad \gamma\psi = \gamma_{0,1}[u\eta_1(\mathbf{c}) + v\eta_2(\mathbf{h}(\mathbf{c}))]$.

In particular, for the trivial entropies, we recover the conservative variables so that, for $1 \le i \le N$, $c_i + h_i(\mathbf{c})$ has a trace on $t = 0$, and $uc_i + vh_i(\mathbf{c})$ has traces on $x = 0$ and $x = 1$. Notice that this trace is attained in a weak sense (see [18]), in contrast with the traces of BV functions, which are attained in L^1.

THEOREM 5.3. (i) *Let $\mathbf{c}$ be a solution as in Lemma* 5.1. *Then it is a solution to* (1.2) *in $\mathcal{D}'(\Omega)$, and we have, for $1 \le i \le N$,*

$$\begin{cases} \gamma_1[uc_i + vh_i(\mathbf{c})] & = b_i, \quad \text{a.e. } t \in]0,T[; \\ \gamma^0[c_i + h_i(\mathbf{c})] & = c_i^0 + h_i(\mathbf{c}^0), \quad \text{a.e. } x \in]0,1[. \end{cases} \tag{5.2}$$

(ii) *For any pair* (η_1, η_2) *denoting the Kružkov entropies in the scalar case, the kinetic entropies for the Langmuir system, define* ψ *as in Lemma* 5.1. *Then the following entropy inequalities hold for a.e.* $t \in]0,T[$:

$$\left\{ \begin{array}{ll} \gamma_0[u\eta_1(\mathbf{c}) + v\eta_2(\mathbf{h}(\mathbf{c}))] & \leq u\eta_1(\mathbf{a}), \\ \gamma_1[u\eta_1(\mathbf{c}) + v\eta_2(\mathbf{h}(\mathbf{c}))] & \leq B(t), \end{array} \right. \tag{5.3}$$

where $B(t) = |b(t) - f(k)|$ *in the scalar case and is defined in Theorem* 4.2 *for the Langmuir system.*

Remark 5.1. This theorem shows that the initial condition and the reflux boundary condition are satisfied in a strong sense (in $L^\infty(\partial\Omega)$, actually). We have no information about the input boundary condition at $x = 0$, except for the entropy inequalities (5.3). Notice that, even for the conservative variables themselves, we loose some information. Indeed, we know that there is a trace for $u\mathbf{c} + v\mathbf{h}(\mathbf{c})$ at $x = 0$, but this function is not one-to-one, so we cannot compare $\mathbf{c}$ to $\mathbf{a}$. Moreover, even if $u\mathbf{c} + v\mathbf{h}(\mathbf{c})$ is one-to-one, a boundary layer phenomenon will very likely occur here, as the following easy computation shows.

Consider a stationary solution to (1.1) in the scalar case, for a linear function $f(c) = (u + vk)c$, with $k > u/|v|$. The system boils down to the single ordinary differential equation

$$\frac{dc}{dx} = \frac{1}{\varepsilon uv}[b - f(c)], \qquad c(0) = a.$$

There exists a unique equilibrium point c^* such that $f(c^*) = b$, and it is attractive. The solution c_ε is computed explicitly:

$$c_\varepsilon(x) = \frac{b}{u+kv} + \left(a - \frac{b}{u+kv}\right) \exp\left(-\frac{u+kv}{\varepsilon uv}x\right) = c^* + (a - c^*) \exp\left(-\frac{u+kv}{\varepsilon uv}x\right).$$

Obviously, the trace of the limit solution is c^*, which has no reason to coincide with a. We do not wish to investigate this boundary layer now, and leave it for future work.

Proof of Theorem 5.2. To prove part (i) of the theorem, we sum the two equations in (1.1), which gives the conservation of matter, and proceed exactly as in the proof of the convergence theorems. Provided we choose a test function $\varphi \in \mathcal{D}(]0,1] \times [0,T[)$, that is, if the test function does not see the boundary condition at $x = 0$, we obtain a weak formulation with an equality sign:

$$\begin{aligned} -\int_0^1 \int_0^T [(\mathbf{c} + \mathbf{h}(\mathbf{c}))\partial_t\varphi + (u\mathbf{c} + v\mathbf{h}(\mathbf{c}))\partial_x\varphi]dx\,dt \\ = \int_0^1 [\mathbf{c}^0 + \mathbf{h}(\mathbf{c}^0)]\varphi(x,0)dx - \int_0^T \mathbf{b}(t)\varphi(1,t)dt, \end{aligned} \tag{5.4}$$

since the boundary condition at $x = 1$ is satisfied exactly.

As a first consequence, we obtain, by taking $\varphi \in \mathcal{D}(\Omega)$, that $\mathbf{c}$ is actually a solution to (1.2) in $\mathcal{D}'(\Omega)$. Therefore we can apply (5.1) with $\psi = (c_i + h_i(\mathbf{c}), uc_i + vh_i(\mathbf{c}))$, $1 \leq i \leq N$, and $\varphi \in \mathcal{D}(]0,1] \times [0,T[)$. The left-hand side of (5.4) is exactly $\int_\Omega (\psi, \varphi)$, and $\operatorname{div} \psi = 0$, so we are left with

$$\begin{aligned} \int_0^1 \gamma^0[c_i + h_i(\mathbf{c})]\varphi(x,0)dx - \int_0^T \gamma_1[uc_i + vh_i(\mathbf{c})]\varphi(1,t)dt \\ = \int_0^1 [c_i^0 + h_i(\mathbf{c}^0)]\varphi(x,0)dx - \int_0^T b_i(t)dt. \end{aligned}$$

Since this holds for any φ, we obtain (5.2).

Now, (5.3) follows from (3.5) or (4.14). By Lemma 5.1, for any pair (η_1, η_2), $\psi = (\eta_1(\mathbf{c})+\eta_2(\mathbf{h}(\mathbf{c})), u\eta_1(\mathbf{c})+v\eta_2(\mathbf{h}(\mathbf{c})))$ satisfies that div ψ is a nonnegative measure. Thus we can apply (5.1) in both formulae, with $\varphi \in \mathcal{D}([0,1] \times [0,T[)$, and obtain

$$\int_0^1 \gamma^0[\eta_1(\mathbf{c}) + \eta_2(\mathbf{h}(\mathbf{c}))]\varphi(x,0)dx - \int_0^T \gamma_1[u\eta_1(\mathbf{c}) + v\eta_2(\mathbf{h}(\mathbf{c}))]\varphi(1,t)dt \leq \int_0^1 [\eta_1(\mathbf{c}^0) + \eta_2(\mathbf{h}(\mathbf{c}^0))]\varphi(x,0)dx - \int_0^T B(t)dt.$$

Since this holds for any φ, we obtain (5.3). □

SOME INEQUALITIES FOR THE GROWTH OF ELLIPTIC INTEGRALS*

S.-L. QIU†, M. K. VAMANAMURTHY‡, AND M. VUORINEN§

Abstract. Growth of the complete elliptic integral $\mathcal{K}(r)$ near the singularity $r = 1$ is studied and new bounds in terms of elementary functions are obtained. In particular, two recent conjectures are solved and various convexity properties of $\mathcal{K}(r)$ are given.

Key words. concave, convex, elliptic integrals, modulus, ring

AMS subject classifications. Primary, 33E05; Secondary, 30C62

PII. S0036141096310491

1. Introduction.

For $r \in [0, 1]$, Legendre's complete elliptic integrals of the first and second kind are defined by

$$\mathcal{K} = \mathcal{K}(r) = \int_0^{\pi/2} (1 - r^2 \sin^2 t)^{-1/2} dt,\ \mathcal{K}' = \mathcal{K}'(r) = \mathcal{K}(r'), \tag{1.1}$$

$$\mathcal{E} = \mathcal{E}(r) = \int_0^{\pi/2} (1 - r^2 \sin^2 t)^{1/2} dt,\ \mathcal{E}' = \mathcal{E}'(r) = \mathcal{E}(r'), \tag{1.2}$$

respectively, where $r' = \sqrt{1 - r^2}$. Note that $\mathcal{K}(0) = \mathcal{E}(0) = \pi/2$ and $\mathcal{K}(1) = \infty$, $\mathcal{E}(1) = 1$.

These integrals have been studied extensively by several authors from different points of view. Asymptotic approximation of symmetric normal forms of these integrals appears in [C, CG]. Behavior of $\mathcal{K}(r)$ near the singularity $r = 1$ has been studied in [K]. Monotonicity properties of certain combinations of $\mathcal{E}(r)$ and $\mathcal{K}(r)$, with applications to Robin capacity, appear in [DP, ADV]. Relationships among these elliptic integrals, the Gauss arithmetic-geometric mean, and other mean values have been studied in [BB2, G, VV].

The present study is motivated by the theory of quasi-conformal maps, where elliptic integrals occur in the formulas for the moduli of plane ring domains (cf. (1.3)). In this context, the following two conjectures were stated in [AVV2, Conjectures 3.1].

Conjecture 1.1. For $r \in (0, 1)$,

$$r'^2 < \frac{r' \exp(\mathcal{K}(r)) - 4}{\exp(\pi/2) - 4} < 2\frac{\sqrt{1 - r}}{2 - r}.$$

Conjecture 1.2. For $r \in (0,1)$,

$$\mathcal{K}(r) < \log(1 + (4/r')) - (\log 5 - \pi/2)(1 - r).$$

These conjectures are proved in Theorem 1.7. We shall also establish monotonicity and concavity properties of certain combinations of complete elliptic integrals, from which sharp functional inequalities for these integrals follow. As a by-product, we shall provide affirmative answers to the following two questions.

Question 1.3. Is the function $\mathcal{E}'(r)[\mathcal{K}(r) - \mathcal{E}(r)]/\{r^2[2\log(4/r') - 1]\}$ increasing from (0, 1) onto $(\pi/[4(\log 16 - 1)], \pi/4)$?

Question 1.4. Is the function $[\mathcal{E}(r)\,\mathcal{E}'(r) - \mathcal{K}(r)\,\mathcal{E}'(r) + r^2\,\mathcal{K}(r)\,\mathcal{K}'(r)]/[r^2\,\mathcal{K}'(r)]$ decreasing from $(0,1)$ onto $(1, \pi/2)$?

As an application, sharp lower and upper bounds are obtained for the modulus of the Grötzsch ring $B\backslash[0,r]$ defined by

$$\mu(r) = \frac{\pi\,\mathcal{K}'(r)}{2\,\mathcal{K}(r)}, \quad 0 < r < 1, \tag{1.3}$$

where B is the unit disk in the plane (cf. [LV]).

Throughout this paper, r' denotes $\sqrt{1-r^2}$ for all $r \in [0,1]$, and c denotes the constant $e^{\pi/2} - 4 = 0.81047\ldots$.

We now state some of our main results.

THEOREM 1.5. *There exists a unique $r_0 \in (0,1)$ such that the function $f(r) \equiv \mathcal{K}'(r)/\log((4/r) + cr)$ is strictly increasing on $(0, r_0]$ and decreasing on $[r_0, 1)$, with $f(0^+) = f(1^-) = 1$. In particular, for $r \in (0,1)$,*

$$\mathcal{K}(r) > \log(cr' + (4/r')). \tag{1.4}$$

This inequality is sharp as r tends to 0 or 1.

THEOREM 1.6. *For $a \in (0,\infty)$, define the function f on $[0,1]$ by*

$$f(r) = \log(1 + (a/r')) - \mathcal{K}(r)$$

for $r \in [0,1)$, and $f(1) = \lim_{r\to 1^-} f(r) = \log(a/4)$. Then

(1) For $0 < a \le \pi/(4-\pi)$, f is strictly decreasing from $[0,1]$ onto $[c_1, c_2]$, where $c_1 = \log(a/4)$ and $c_2 = \log(1+a) - \pi/2$. In particular, for $r \in (0,1)$,

$$\log\left(\frac{4}{a} + \frac{4}{r'}\right) - b_1 < \mathcal{K}(r) < \log\left(\frac{4}{a} + \frac{4}{r'}\right),$$

where $b_1 = \log 4 - (\pi/2) + \log(1 + (1/a)) \ge \log(16/\pi) - \pi/2 = 0.05706\ldots$.

(2) For $a > \pi/(4-\pi)$, there exists a unique $r_0 = r_0(a) \in (0,1)$ such that f is strictly increasing on $(0, r_0]$ and decreasing on $[r_0, 1)$. In particular, for $r \in (0,1)$,

$$\mathcal{K}(r) < \log\left(\frac{4}{a} + \frac{4}{r'}\right) + b_2, \tag{1.5}$$

where

$$b_2 = \begin{cases} 0 \text{ if } a \le 4/c, \\ \pi/2 - \log(4 + (4/a)) \text{ if } a > 4/c. \end{cases}$$

The next theorem settles Conjectures 1.1 and 1.2.

THEOREM 1.7. *For $r \in (0,1)$,*

$$r'^2 < \frac{r' \exp(\mathcal{K}(r)) - 4}{\exp(\pi/2) - 4} < r' < 2\frac{\sqrt{1-r}}{2-r}, \tag{1}$$

$$\mathcal{K}(r) < \log(1 + (4/r')) - (\log 5 - \pi/2)(1-r), \tag{2}$$

$$\frac{\pi \log((4/r) + cr)}{2\log((4/r') + c)} < \mu(r) < \frac{\pi \log((4/r) + c)}{2\log((4/r') + cr')}. \tag{3}$$

The inequalities in (1) *are sharp as r tends to* 0, *while those in* (2) *and* (3) *are sharp as r tends to* 0 *or* 1.

The next result answers the Question 1.3 in the affirmative.

THEOREM 1.8. *The function $f(r) \equiv \mathcal{E}'(r)[\mathcal{K}(r) - \mathcal{E}(r)]/\{r^2[2\log(4/r') - 1]\}$ is strictly increasing from* (0, 1) *onto* $(\pi/(4a), \pi/4)$, *where $a = 4\log 2 - 1$.*

Our next result shows that the answer to the Question 1.4 is also affirmative.

THEOREM 1.9. *The function*

$$f(r) \equiv \frac{[\mathcal{E}(r)\,\mathcal{E}'(r) - \mathcal{K}(r)\,\mathcal{E}'(r) + r^2\,\mathcal{K}(r)\,\mathcal{K}'(r)]}{[r^2\,\mathcal{K}'(r)]}$$

is strictly decreasing on $(0,1)$, *with $f(0^+) = \pi/2$ and $f(1^-) = 1$.*

2. Preliminary results. In this section, we prove monotonicity properties for certain combinations of $\mathcal{K}(r)$ and $\mathcal{E}(r)$. These are needed for the proofs of the theorems stated in section 1.

LEMMA 2.1. *The function*

$$f_1(r) \equiv [16 + 32c - (144c + 16c^2)r^2 - 25c^2r^4]\,\mathcal{K}'(r) + (48c + 40c^2r^2)\,\mathcal{E}'(r)$$

is strictly decreasing from $(0,1)$ *onto* (a_1, ∞), *where* $a_1 = \pi(16 - 64c - c^2)/2 = -57.377146\ldots$, *so that f_1 has a unique zero $r_1 \in (0,1)$ such that $f_1(r) > 0$ for $r \in (0, r_1)$ and $f_1(r) < 0$ for $r \in (r_1, 1)$.*

Proof. By [AVV2, Theorem 1.2], $f_1(0^+) = \infty$ and $f_1(1) = a_1$. Next, rearranging the terms, we have

$$f_1(r) = 48c(\mathcal{K}' + \mathcal{E}') + 16(1-c)\,\mathcal{K}' - 40c^2r^2(2\,\mathcal{K}' - \mathcal{E}') - 16c(9-4c)r^2\,\mathcal{K}' - 25c^2r^4\,\mathcal{K}'. \tag{2.1}$$

Since

$$\frac{d}{dr}[r'^2(2\,\mathcal{K} - \mathcal{E})] = -\frac{1+3r^2}{r}(\mathcal{K} - \mathcal{E}),$$

which is clearly negative for all $r \in (0,1)$, the function $r^2(2\,\mathcal{K}' - \mathcal{E}')$ is strictly increasing on $(0,1)$. Hence, from [AVV2, Theorems 2.1(3) and 1.2] we see that the right side of (2.1) is a sum of strictly decreasing functions, so that the result follows. □

LEMMA 2.2. *Let r_1 be as in Lemma* 2.1. *Then the function*

$$f_2(r) \equiv [16(1+c) - 4c(12+c)r^2 - 5c^2r^4]r^2\,\mathcal{K}'(r) - (16 - 32cr^2 - 9c^2r^4)\,\mathcal{E}'(r)$$

is strictly increasing on $(0, r_1]$ and decreasing on $[r_1, 1)$, so that, on $(0,1)$, f_2 has a unique zero r_2 such that $f_2(r) < 0$ for $r \in (0, r_2)$ and $f_2(r) > 0$ for $r \in (r_2, 1)$.

Proof. Since

$$f'_2(r) = r f_1(r),$$

where f_1 is as in Lemma 2.1, the piecewise monotonicity of f_2 follows from Lemma 2.1.

Clearly, $f_2(0^+) = -16$ and $f_2(1) = 0$. Hence, the assertion for the zero of f_2 follows from the first conclusion. □

LEMMA 2.3. *Let r_2 be as in Lemma 2.2. Then the function*

$$f_3(r) \equiv [16 + 16(1+c)r^2 - c(16+c)r^4 - c^2r^6]\,\mathcal{K}'(r) - [16(2+c) - 16cr^2 - 2c^2r^4]\,\mathcal{E}'(r)$$

is strictly decreasing on $(0, r_2]$ and increasing on $[r_2, 1)$, so that, on $(0,1)$, f_3 has a unique zero r_3 such that $f_3(r) > 0$ for $r \in (0, r_3)$ and $f_3(r) < 0$ for $r \in (r_3, 1)$.

Proof. The piecewise monotonicity of f_3 follows from the derivative

$$f'_3(r) = f_2(r)/r,$$

where f_2 is as in Lemma 2.2.

Since $f_3(0^+) = \infty$ and $f_3(1) = 0$, the assertion for the zero of f_3 follows from the first conclusion. □

LEMMA 2.4. *Let r_3 be as in Lemma 2.3. Then the function*

$$f_4(r) \equiv \frac{4 - cr^2}{4 + cr^2}\,\frac{r'^2\,\mathcal{K}'(r)}{\mathcal{E}'(r) - r^2\,\mathcal{K}'(r)} - \log\left(\frac{4}{r} + cr\right)$$

is strictly increasing on $(0, r_3]$ and decreasing on $[r_3, 1)$, with $f_4(0^+) = 0$ and $f_4(1) = 16e^{-\pi/2} - 2 - \pi/2 = -0.24472\ldots$, so that, on $(0,1)$, f_4 has a unique zero r_4 such that $f_4(r) > 0$ for $r \in (0, r_4)$ and $f_4(r) < 0$ for $r \in (r_4, 1)$.

Proof. By differentiation,

$$(4 + cr^2)^2(\,\mathcal{E}' - r^2\,\mathcal{K}')^2 f'_4(r) = r\,\mathcal{K}' f_3(r),$$

where f_3 is as in Lemma 2.3. Hence, the piecewise monotonicity of f_4 follows from Lemma 2.3.

Hence, $f_4(1) = 16e^{-\pi/2} - 2 - \pi/2$. By l'Hôpital's rule and [AVV2, Theorem 1.2], we have

$$\lim_{r\to 0}\left\{r'^2 - \left(\,\mathcal{E}' - r^2\,\mathcal{K}'\right)\right\}/r = 0,$$

and hence, by [AVV2, Theorem 1.2] and $\lim_{r\to 0}(\,\mathcal{K}'(r) - \log(4/r)) = 0$ [WW, p. 521],

$$f_4(0^+) = \lim_{r\to 0}\left\{\left(\,\mathcal{K}' - \log\frac{4}{r}\right) - \log\left(1 + \frac{c}{4}r^2\right) + \frac{r\,\mathcal{K}'}{\mathcal{E}' - r^2\,\mathcal{K}'}\left[\frac{r'^2 - (\,\mathcal{E}' - r^2\,\mathcal{K}')}{r} - \frac{2crr'^2}{4 + cr^2}\right]\right\} = 0.$$

The assertion for the zero of f_4 is clear. □

LEMMA 2.5. *The function $f(r) \equiv \sqrt{r'}\,\frac{(2-r^2)\,\mathcal{K}(r) - 2\,\mathcal{E}(r)}{(1-r')^2}$ is strictly decreasing and concave from $(0,1)$ onto $(0, \pi/4)$. In particular, for $r \in (0,1)$,*

$$\pi(1-r)/4 < f(r) < \pi/4.$$

Proof. Put $r = 2\sqrt{x}/(1+x)$. Then $r' = (1-x)/(1+x), x = (1-r')/(1+r')$, and by the Landen transformation [BB1, Theorem 1.2],

$$f(r) = x'[\,\mathcal{K}(x) - \mathcal{E}(x)]/x^2,$$

which, as a function of x, is strictly decreasing and concave from $(0,1)$ onto $(0,\pi/4)$ [QV1, Theorem 1.8(1)]. Since x is a convex function of r, the result follows from [AQV, Lemma 2.1(2)]. □

THEOREM 2.6. *For $a \in (-\infty,\infty)$, define the function f on $[0,1]$ by*

$$f(r) = (a+r')[\,\mathcal{E}(r) - r'^2\,\mathcal{K}(r)]/r^2$$

for $r \in (0,1), f(0) = \pi(a+1)/4$, and $f(1) = a$. Then

(1) *f is strictly decreasing on $[0,1]$ iff $a \le 3$. Moreover, for $a \in [1,3]$, f is concave on $(0,1)$.*

(2) *For $a > 3$, there exists an $r_0 = r_0(a) \in (0,1)$ such that f is strictly increasing on $(0,r_0]$ and decreasing on $[r_0,1)$.*

Proof. Since $f(r) = (a-1)(\,\mathcal{E} - r'^2\,\mathcal{K})/r^2 + (\,\mathcal{E} - r'^2\,\mathcal{K})/(1-r')$,

$$\begin{aligned}\frac{r'(1-r')^2}{r(\,\mathcal{E} - r'\,\mathcal{K})} f'(r) &= g_1(r)\\ &\equiv (a-1)\frac{\sqrt{r'}}{1+r'}\cdot\sqrt{r'}\frac{(2-r^2)\,\mathcal{K} - 2\,\mathcal{E}}{(1-r')^2}\cdot\frac{(1-r')^3}{r^2(\,\mathcal{E} - r'\,\mathcal{K})} - 1\\ &\equiv (a-1)g_2(r) - 1,\end{aligned} \tag{2.2}$$

with $g_1(0) = (a-3)/2$ and $g_1(1^-) = -1$. Clearly, $\sqrt{r'}/(1+r')$ is strictly decreasing on (0, 1). Hence, g_2 is a product of three positive and strictly decreasing functions on $(0,1)$, by Lemma 2.5 and [QV1, Theorem 1.7(1)].

(1) If $a \le 1$, then g_1 is negative on $(0,1)$, and hence f is strictly decreasing on $(0,1)$.

If $1 < a \le 3$, then g_1 is strictly decreasing from (0, 1) onto $(-1,(a-3)/2)$. Hence, it follows from (2.8) that f is strictly decreasing on (0, 1).

Conversely, if f is strictly decreasing on (0, 1), then $g_1(0) = (a-3)/2 \le 0$, and hence $a \le 3$.

For $a \in [1,3]$, g_1 is negative and decreasing on (0, 1). Since

$$-f'(r) = (-g_1(r))\cdot\frac{r}{r'(1+r')}\cdot r^2\frac{\mathcal{E} - r'\,\mathcal{K}}{(1-r')^3},$$

and since $r^2(\,\mathcal{E} - r'\,\mathcal{K})(1-r')^{-3}$ is a positive and increasing function on (0, 1) [QV1, Theorem 1.7 (1)], we see that f' is decreasing on (0, 1). This yields the concavity of f on (0, 1) for $a \in [1,3]$.

(2) If $a > 3$, then g_1 is strictly decreasing on (0, 1) with $g_1(0^+) = (a-3)/2 > 0$ and $g_1(1^-) = -1 < 0$, and hence, part (2) follows. □

COROLLARY 2.7. *For $a \in [1,3]$, let $a_1 = (\pi(1+a)/4) - a$. Then*

$$(\pi(1+a)/4) - a_1 r < (a+r')[\,\mathcal{E}(r) - r'^2\,\mathcal{K}(r)]/r^2 < \pi(a+1)/4$$

for $r \in (0,1)$.

Proof. The result follows from Theorem 2.6(1). □

The next theorem complements the well-known result that the function $\mathcal{K}(r) + \log r'$ is decreasing and concave from $(0,1)$ onto $(\log 4, \pi/2)$ [AVV1, Theorem 2.2(2)].

THEOREM 2.8. (1) *The function* $f(r) \equiv \mathcal{K}'(r) + \log(r/(1+r))$ *is strictly decreasing and convex from* $(0,1)$ *onto* $(\pi/2 - \log 2, \log 4)$. *In particular,*

$$\frac{\pi}{2} - \log 2 + \log(1 + 1/r) < \mathcal{K}'(r) < \frac{\pi}{2} - \log 2 + \left(\log 8 - \frac{\pi}{2}\right)(1-r) + \log(1+1/r)$$

for $r \in (0,1)$.

(2) *The function* $g(r) \equiv \mathcal{K}(r) + \log(r'/(1+r'))$ *is strictly increasing and convex from* $(0,1)$ *onto* $(\pi/2 - \log 2, \log 4)$.

Proof. For part (1), let $F_1(r) = [1 - r - (\mathcal{E}' - r^2\mathcal{K}')]/r$, $F_2(r) = r'^2$, $F_3(r) = \mathcal{E}' - 1$ and $F_4(r) = r^3$. Then $F_1(1) = F_2(1) = F_3(0) = F_4(0) = 0$, and

$$f'(r) = F_1(r)/F_2(r), 2F_1'(r)/F_2'(r) = -F_3(r)/F_4(r).$$

Since $3F_3'(r)/F_4'(r) = (\mathcal{K}' - \mathcal{E}')/(rr'^2)$ is strictly decreasing on (0, 1) [AVV2, Theorem 2.1(6)], f' is negative and strictly increasing on (0, 1) by [VV, Lemma 1.1]. The value $f(1)$ is clear, and the limit $f(0^+)$ follows from $\lim_{r\to 0}(\mathcal{K}'(r) - \log(4/r)) = 0$ [WW, p. 521].

Part (2) follows from part (1) and [AQV, Lemma 2.1(2)]. □

Remark 2.9. It is natural to ask if the function $f(r) \equiv \mathcal{K}'(r) + \log r$ is convex on $(0,1)$. By differentiation we get

$$f'(r) = \frac{1}{r}\left(1 - \frac{\mathcal{E}' - r^2\mathcal{K}'}{r'^2}\right), \quad f''(r) = \frac{(1+r^2)\mathcal{K}' - 2\mathcal{E}'}{r'^4} + \frac{1}{r^2}\left(\frac{\mathcal{E}' - r^2\mathcal{K}'}{r'^2} - 1\right).$$

Thus by l'Hôpital's rule, $f''(0)^+ = \infty$ and $f''(1^-) = (5\pi/16) - 1 < 0$, so that f is neither convex nor concave.

LEMMA 2.10. (1) *The function* $f(r) \equiv 2\mathcal{E}(r) - r'^2\mathcal{K}(r)$ *is strictly increasing and convex from* $(0,1)$ *onto* $(\pi/2, 2)$.

(2) *There exists a unique* $r_1 \in (0.251, 0.252)$ *such that the function* $g(r) \equiv [1 - 2r^2\log(4/r)]/[2\log(4/r) - 1]^2$ *is strictly increasing on* $(0, r_1]$ *and decreasing on* $[r_1, 1]$ *with* $g(1) = -1/(\log 16 - 1) = -0.56414\ldots$, *so that* g *has a unique zero* $r_2 \in (0.487, 0.488)$ *such that* $g(r) > 0$ *for* $r \in (0, r_2)$ *and* $g(r) < 0$ *for* $r \in (r_2, 1]$.

(3) *The function* $h(r) \equiv \{[2\mathcal{E}(r) - r'^2\mathcal{K}(r)]/\mathcal{E}(r)\} + \{2r'^2/[2\log(4/r) - 1]\}$ *is strictly increasing from* $(0,1)$ *onto* $(1,2)$.

Proof. The value $f(0) = 2$ is clear, while the limit $f(1^-) = \pi/2$ follows from [AVV2, Theorem 1.2]. Then part (1) follows since

$$f'(r) = (\mathcal{E} - r'^2\mathcal{K})/r$$

is positive and strictly increasing from (0,1) onto (0,1) by [AVV1, Theorem 2.2(7)].

For part (2), we have $rg'(r)(2\log(4/r) - 1)^3 = 2g_1(r)$, where $g_1(r) = 2 - r^2 - 4[r\log(4/r)]^2$. Then g_1 is strictly decreasing from (0, 1) onto $(1 - 16(\log 2)^2, 2)$. Since $g_1(0.251) = 0.0053\ldots > 0$, while $g_1(0.252) = -0.0049\ldots < 0$, g_1 has a unique zero $r_1 \in (0.251, 0.252)$ such that $g_1(r) > 0$ for $r \in (0, r_1)$ and $g_1(r) < 0$ for $r \in (r_1, 1)$. Hence, the piecewise monotonicity of g follows, and g has a unique zero $r_2 \in (0,1)$ such that $g(r) > 0$ for $r \in (0, r_2)$ and $g(r) < 0$ for $r \in (r_2, 1)$.

Let $g_2(r) = 1 - 2r^2\log(4/r)$. Then $g_2(0.487) = 0.00114\ldots$ and $g_2(0.488) = -0.00198\ldots$. Hence, $0.487 < r_2 < 0.488$.

For part (3), let $h_1(r) = \mathcal{K}(2\,\mathcal{E} - r'^2\,\mathcal{K})/\,\mathcal{E}^2 + 4g(r) - 1$. Then

$$rh'(r) = h_1(r). \tag{2.3}$$

By part (1), $\mathcal{K}(2\,\mathcal{E} - r'^2\,\mathcal{K})/\,\mathcal{E}^2$ is strictly increasing from $(0,1)$ onto $(1,\infty)$. Hence, it follows from part (2) that $h_1(r) > 0$ for $r \in (0, r_2]$, and for $r \in [a,b) \subset (0.487, 1)$,

$$h_1(r) \geq h_2(a,b) \equiv \frac{\mathcal{K}(a)[2\,\mathcal{E}(a) - a'^2\,\mathcal{K}(a)]}{\mathcal{E}(a)^2} + 4g(b) - 1.$$

Computation gives

$$h_2(0.487, 0.64) = 0.006\ldots, \quad h_2(0.64, 0.73) = 0.028\ldots,$$

$$h_2(0.73, 0.8) = 0.031\ldots, \quad h_2(0.8, 0.87) = 0.001\ldots,$$

$$h_2(0.87, 0.94) = 0.075\ldots, \quad h_2(0.94, 1) = 0.642\ldots.$$

Hence, $h_1(r) > 0$ also for $r \in [0.487, 1)$. Consequently, the monotonicity of h follows from (2.3).

The limiting values of h are clear. □

LEMMA 2.11. (1) *The function* $f(r) \equiv [(4 - 3r^2)\,\mathcal{K}(r) - 4\,\mathcal{E}(r)]/r^2$ *is strictly increasing and convex from* $(0,1)$ *onto* $(-\pi/2, \infty)$.

(2) *The function* $g(r) \equiv [(8-7r^2)\,\mathcal{E}(r) - (8-3r^2)(r')^2\,\mathcal{K}(r)]/r^6$ *is strictly increasing and convex from* $(0,1)$ *onto* $(3\pi/32, 1)$.

Proof. The limiting values are clear. Next, the power series expansions for $\mathcal{K}$ and $\mathcal{E}$ [BF, eqs. 900.00 and 900.07] give

$$f(r) = \frac{\pi}{2}\left\{-1 + \sum_{n=1}^{\infty} \frac{n-1}{n+1}\left[\frac{1.3\cdots(2n-1)}{2.4\cdots(2n)}\right]^2 r^{2n}\right\}$$

and

$$g(r) = \frac{9\pi}{16}\sum_{n=1}^{\infty}\left[\frac{1.3\cdots(2n+1)}{2^n}\right]^2 \frac{1}{n!(n+3)!}r^{2n},$$

so that the assertions follow. □

THEOREM 2.12 (cf. [Q2, Lemma 7]). (1) *The function* $f(r) \equiv [(2 - r^2)\,\mathcal{K} - 2\,\mathcal{E}]/[2\log(1/r') - r^2]$, *is increasing from* $(0,1)$ *onto* $(\pi/8, 1/2)$.

(2) *The function* $g(r) \equiv [(3-r^2)\,\mathcal{K} - 3\,\mathcal{E}]/\log(1/r')$ *is increasing from* $(0,1)$ *onto* $(\pi/2, 1)$.

(3) *The function* $h(r) \equiv [(4-r^2)\,\mathcal{K} - 4\,\mathcal{E}]/\log(1/r')$ *is decreasing from* $(0,1)$ *onto* $(3,\pi)$.

(4) *The function* $F(r) \equiv [(8-7r^2)\,\mathcal{E} - (8-3r^2)(r'^2)\,\mathcal{K}]/[(r^2)(1+r'^2) - 4(r'^2)\log(1/r')]$ *is increasing from* $(0,1)$ *onto* $(9\pi/32, 1)$.

Proof. (1) Denote the numerator and denominator of $f(r)$ by $f_1(r)$ and $f_2(r)$, respectively. Then $f_1(0) = f_2(0) = 0$, and $f_1'(r)/f_2'(r) = [\,\mathcal{E} - (r'^2)\,\mathcal{K}]/(2r^2)$. By (1.1), (1.2), this is increasing from $(0,1)$ onto $(\pi/8, 1/2)$. Hence, the assertion follows from [VV, Lemma 1.1].

(2) $g(r) = g_1(r)/g_2(r)$, with $g_1(0) = g_2(0) = 0$. Then $g_1'(r)/g_2'(r) = 2\,\mathcal{E} - (r'^2)\,\mathcal{K}$, which is easily seen to be increasing from (0,1) onto $(\pi/2, 2)$. Hence, the assertion follows from [VV, Lemma 1.1].

(3) $h(r) = h_1(r)/h_2(r)$, with $h_1(0) = h_2(0) = 0$. Then $h_1'(r)/h_2'(r) = 3\,\mathcal{E} - (r'^2)\,\mathcal{K}$, which is easily seen to be decreasing from (0,1) onto $(3, \pi)$. Hence, the assertion follows from [VV, Lemma 1.1].

(4) $F(r) = F_1(r)/F_2(r)$, with $F_1(0) = F_2(0) = 0$. Then $F_1'(r)/F_2'(r) = (9/4)f(r)$. Hence, the assertion follows from (1) and [VV, Lemma 1.1]. □

3. Proofs of the main theorems. In this section, we prove the main theorems stated in section 1.

3.1. Proof of Theorem 1.5. Differentiation gives

$$r[r' \log(cr + (4/r))]^2 f'(r) = (\,\mathcal{E}' - r^2\,\mathcal{K}')f_4(r), \tag{3.1}$$

where f_4 is as in Lemma 2.4.

Take $r_0 = r_4$, the zero of f_4 on (0, 1). Then the piecewise monotonicity of f follows from (3.1) and Lemma 2.4.

Next, the limiting values $f(0^+) = f(1) = 1$ are clear. Hence, the inequality (1.4) and its sharpness follow. □

3.2. Proof of Theorem 1.6. By differentiation,

$$\begin{aligned} r'^2(a + r')f'(r)/r &= g(r) \\ &\equiv a - (a + r')(\,\mathcal{E} - r'^2\,\mathcal{K})/r^2, \end{aligned} \tag{3.2}$$

with $g(0^+) = a - \pi(a + 1)/4$ and $g(1^-) = 0$.

For (1), we investigate two cases.

Case 1. $0 < a \le 3$.

In this case, it follows from Theorem 2.6(1) that g is strictly increasing on (0, 1), and hence $g(r) < 0$ for $r \in (0, 1)$, so that f is strictly decreasing on (0, 1) by (3.2).

Case 2. $3 < a \le \pi/(4 - \pi) = 3.65979\ldots$.

In this case, by Theorem 2.6(2) there exists an $r_0 = r_0(a) \in (0, 1)$ such that g is strictly decreasing on $(0, r_0]$ and increasing on $[r_0, 1)$. Since $g(0^+) = a(4-\pi)/4-\pi/4 \le 0$ and $g(1^-) = 0$, it follows that $g(r) < 0$ for all $r \in (0, 1)$. Hence, f is strictly decreasing on $(0, 1)$ by (3.2).

For part (2), we note that $g(0) > 0$ when $a > \pi/(4 - \pi)$. Hence, the piecewise monotonicity of f follows from (3.2) and Theorem 2.6(2), and

$$f(r) > \min\{f(0), f(1^-)\} = \begin{cases} \log(a/4) & \text{if } a \le 4/c, \\ \log(1 + a) - \pi/2 & \text{if } a > 4/c \end{cases}$$

for $r \in (0, 1)$, so that the inequality (1.5) holds. □

COROLLARY 3.5. (1) *For* $r \in (0, 1)$,

$$\log((4/r') + cr') < \mathcal{K}(r) < \log((4/r') + c). \tag{3.3}$$

These inequalities are sharp as r *tends to* 0 *or* 1.

(2) *There exists a unique* $r_1 \in (0, 1)$ *such that the inequality*

$$\mathcal{K}(r) \le \log(1 + (4/r')) - (\log 5 - \pi/2) \tag{3.4}$$

holds for $r \in (0, r_1]$, with equality iff $r = r_1$. The inequality is reversed if $r \in [r_1, 1)$.

Proof. The first inequality in (3.3) and its sharpness were obtained in Theorem 1.5. Taking $a = 4/c$ in (1.5), we get the second inequality in (3.3), with

$$\lim_{r\to 0} \mathcal{K}/\log(c + (4/r')) = \lim_{r\to 1} \mathcal{K}/\log(c + (4/r')) = 1.$$

Part (2) follows from the piecewise monotonicity of f in Theorem 1.6(2) with $a = 4$. □

COROLLARY 3.2. *There exists a unique $r_2 \in (\sin 70^\circ, \sin 71^\circ)$ such that the function $F(r) \equiv \log((4/r') + c) - \mathcal{K}(r)$ is strictly increasing on $(0, r_2]$ and decreasing on $[r_2, 1)$ with $F((0,1)) = (0, c_1]$, where $c_1 = F(r_2) < 0.067809628$. In particular, for $r \in (0, 1)$,*

$$\log\left(\frac{4}{r'} + c\right) - 0.067809628 < \log\left(\frac{4}{r'} + c\right) - c_1 < \mathcal{K}(r) < \log\left(\frac{4}{r'} + c\right). \tag{3.5}$$

Proof. Put $a = 4/c$. Then $F(r) = \log c + \log(1 + (a/r')) - \mathcal{K}$, and the piecewise monotonicity of F follows from Theorem 1.6(2).

Let $F_1(r) = cg(r)$, where g is as in (3.2). Then

$$r'^2(4 + cr')F'(r) = rF_1(r) = r\left\{4 - (4 + cr')(\mathcal{E} - r'^2\mathcal{K})/r^2\right\}.$$

Since $F_1(\sin 70^\circ) = 0.001\ldots$ and $F_1(\sin 71^\circ) = -0.002\ldots$, $r_2 \in (\sin 70^\circ, \sin 71^\circ)$ by Theorem 2.6(2), and

$$\begin{aligned} c_1 = F(r_2) &< \log((4/\cos 71^\circ) + c) - \mathcal{K}(\sin 70^\circ) \\ &< \log((4/\cos 71^\circ) + c) - 2.50455 = 0.067809627\ldots < 0.067809628. \end{aligned}$$

The inequalities in (3.5) are clear. □

3.3. Proof of Theorem 1.7. The first and second inequalities in part (1) follow from Corollary 3.5(1). Since $\sqrt{1+r}(2-r)$ is strictly decreasing from (0, 1) onto $(\sqrt{2}, 2)$,

$$r' = \sqrt{1+r}(2-r) \cdot \frac{\sqrt{1-r}}{2-r} < 2\frac{\sqrt{1-r}}{2-r}.$$

Clearly, the inequalities in (1) are all sharp as r tends to 0.

For part (2), by Corollary 3.5(1), we need only to prove that

$$\log((4/r') + c) \le \log((4/r') + 1) - (\log 5 - (\pi/2))(1 - r)$$

or, equivalently,

$$\log(1 + (cr'/4)) \le \log(1 + (r'/4)) - (\log 5 - (\pi/2))(1 - r) \tag{3.6}$$

for $r \in (0, 1)$. For this purpose, we investigate the minimum of the function

$$H(r) \equiv \log(1 + (r'/4)) - \log(1 + (cr'/4)) - (\log 5 - (\pi/2))(1 - r)$$

for $r \in [0, 1]$. It is obvious that $H(0) = H(1) = 0$.

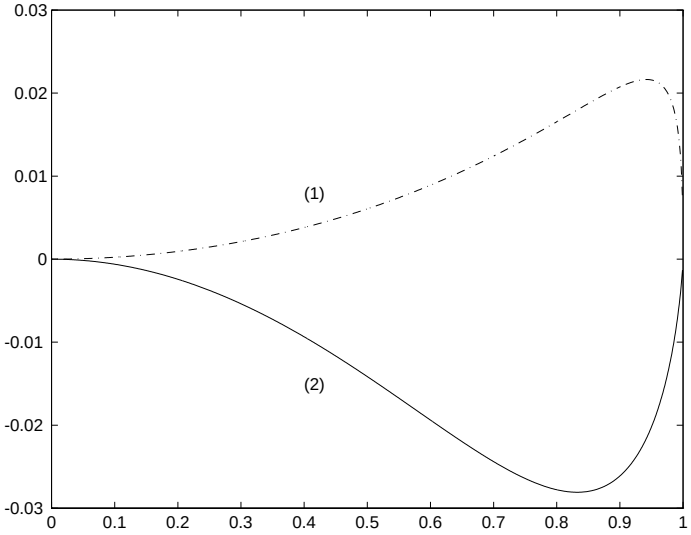

FIG. 1.

By differentiation, we get

$$H'(r) = \log 5 - \frac{\pi}{2} - \frac{4(1-c)r}{r'(4+r')(4+cr')},$$

which is clearly strictly decreasing from (0, 1) onto $(-\infty, \log 5 - \pi/2)$. Since $\log 5 - \pi/2 > 0$, there exists a unique $r_0 \in (0,1)$ such that H is strictly increasing on $(0, r_0]$ and decreasing on $[r_0, 1)$. This yields

$$\min\{H(r); 0 \le r \le 1\} = \min\{H(0), H(1)\} = 0,$$

from which inequality (3.6) follows.

Next, the inequality (2) is sharp as r tends to 0 or 1, since

$$\begin{aligned} &\lim_{r\to 0} \mathcal{K}/\{\log(1+(4/r')) - (\log 5 - (\pi/2))(1-r)\} \\ =&\lim_{r\to 1} \mathcal{K}/\{\log(1+(4/r')) - (\log 5 - (\pi/2))(1-r)\} = 1. \end{aligned}$$

Finally, part (3) follows from Corollary 3.5(1). □

Remark 3.3. (1) From the proof of Theorem 1.7(2), one can see that the upper bound of $\mathcal{K}(r)$ given in Corollary 3.5(1) is better than that in Theorem 1.7(2). Thus, Conjecture 1.2 is proved.

(2) In order to illuminate Corollary 3.5(1) we have graphed in Figure 1 the functions $\log((4/r') + c) - \mathcal{K}(r)$ and $\log((4/r') + cr') - \mathcal{K}(r)$ labeled by (1) and (2), respectively.

In order to illuminate Theorem 1.7(2) we have graphed in Figure 2 the function $\log(1 + (4/r')) - (\log 5 - (\pi/2))(1-r) - \mathcal{K}(r)$.

3.4. Proof of Theorem 1.8. By differentiation,

$$\{r'[2\log(4/r') - 1]\}^2 f'(r) = r(2\,\mathcal{E}' - r^2\,\mathcal{K}')F_1(r')F(r), \tag{3.7}$$

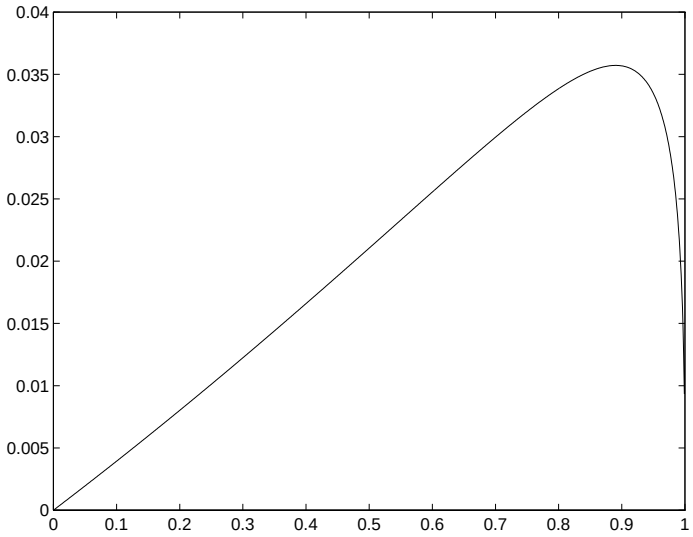

FIG. 2.

where

$$\begin{aligned} F_1(r) &\equiv 2\log(4/r) + 2r'^2\,\mathcal{E}/(2\,\mathcal{E} - r'^2\,\mathcal{K}) - 1,\\ F(r) &\equiv \mathcal{K}\,\mathcal{K}'/[2\,\mathcal{E}'F_2(r')] - \mathcal{K}\,\mathcal{E}'/[(2\,\mathcal{E}' - r^2\,\mathcal{K}')F_1(r')]\\ &\quad - [(2-r^2)\,\mathcal{K} - 2\,\mathcal{E}]/(2r^4),\\ F_2(r) &\equiv (2\,\mathcal{E} - r'^2\,\mathcal{K})/\,\mathcal{E} + 2r'^2/[2\log(4/r) - 1]. \end{aligned}$$

By Lemma 2.10(1) and (3), F_1 and F_2 are positive, and decreasing and increasing on $(0,\,1)$, respectively. Hence, for $r \in (a, b] \subset (0, 1)$,

$$F(r) > \frac{\mathcal{K}'(r)\,\mathcal{K}(a)}{2\,\mathcal{E}'(r)F_2(a')} - \frac{\mathcal{K}(r)\,\mathcal{E}'(r)}{[2\,\mathcal{E}'(r) - r^2\,\mathcal{K}'(r)]F_1(a')} \tag{3.8}$$

$$-[(2-r^2)\,\mathcal{K}(r) - 2\,\mathcal{E}(r)]/(2r^4).$$

By [QV1, Corollary 3.12] and [AVV2, Theorem 2.1(7)], the last term is strictly decreasing on $(0, 1)$, while the second term is decreasing by Lemma 2.10(1), so the right side of (3.8) is decreasing on $(0, 1)$. Therefore, it follows from (3.8) that

$$F(r) > F_3(a,b) \equiv \frac{\mathcal{K}(a)\,\mathcal{K}'(b)}{2F_2(a')\,\mathcal{E}'(b)} \tag{3.9}$$

$$-\frac{\mathcal{K}(b)\,\mathcal{E}'(b)}{[2\,\mathcal{E}'(b) - b^2\,\mathcal{K}'(b)]F_1(a')} - \frac{(2-b^2)\,\mathcal{K}(b) - 2\,\mathcal{E}(b)}{2b^4}$$

for $r \in (a, b] \subset (0, 1)$. Computation gives

$$\begin{aligned} F_3(0, \sin 28^\circ) &= 0.019\ldots, \quad F_3(\sin 28^\circ, \sin 37^\circ) = 0.053\ldots,\\ F_3(\sin 37^\circ, \sin 45^\circ) &= 0.005\ldots, \quad F_3(\sin 45^\circ, \sin 51^\circ) = 0.007\ldots,\\ F_3(\sin 51^\circ, \sin 56^\circ) &= 0.005\ldots, \quad F_3(\sin 56^\circ, \sin 60^\circ) = 0.012\ldots. \end{aligned}$$

Hence, it follows from (3.7) and (3.9) that

$$f'(r) > 0 \quad \text{for } r \in (0, \sqrt{3}/2]. \tag{3.10}$$

Next, making use of Legendre's relation [BB, p. 24], [WW, p. 52], we can write (3.7) as

$$r\{r'[2\log(4/r') - 1]\}^2 f'(r) = F_4(r)F_5(r), \tag{3.11}$$

where

$$F_4(r) \equiv 2\log(4/r') - 2\,\mathcal{E}'(\mathcal{K} - \mathcal{E})/F_5(r) - 1, \quad F_5(r) \equiv 2\,\mathcal{E}'(\mathcal{E} - r'^2\,\mathcal{K})/r^2 - (\pi/2).$$

This is seen as follows.

By differentiation and Legendre's relation [BB, p. 24]

$$\begin{aligned}\left[r^2\left(2\log\left(\frac{4}{r'}\right) - 1\right)\right]^2 f'(r) &= \left(\frac{r}{r'^2}\right)\left[r^2\left(2\log\left(\frac{4}{r'}\right) - 1\right)((\mathcal{K} - \mathcal{E})(\mathcal{K}' - \mathcal{E}') + \mathcal{E}\,\mathcal{E}')\right.\\ &\qquad \left. - 2\;\mathcal{E}'(\mathcal{K} - \mathcal{E})\left(r^2 + \left(2\log\left(\frac{4}{r'}\right) - 1\right)r'^2\right)\right]\\ &= \left(\frac{r}{r'^2}\right)\left[r^2\left(2\log\left(\frac{4}{r'}\right) - 1\right)\left(2\,\mathcal{E}\,\mathcal{E}' - \left(\frac{\pi}{2}\right)\right)\right.\\ &\qquad \left. - 2\,\mathcal{E}'(\mathcal{K} - \mathcal{E})\left(r^2 + \left(2\log\left(\frac{4}{r'}\right) - 1\right)r'^2\right)\right]\\ &= \left(\frac{r}{r'^2}\right)\left[\left(2\log\left(\frac{4}{r'}\right) - 1\right)\left\{2\,\mathcal{E}'(\mathcal{E} - r'^2\,\mathcal{K}) - \left(\frac{\pi}{2}\right)r^2\right\} - 2\,\mathcal{E}'(\mathcal{K} - \mathcal{E})r^2\right].\end{aligned}$$

Hence,

$$\begin{aligned}r^3 r'^2\left(2\log\left(\frac{4}{r'}\right) - 1\right)^2 f'(r) &= r^2 F_5(r)\left[2\log\left(\frac{4}{r'}\right) - 1 - 2\,\mathcal{E}'(\mathcal{K} - \mathcal{E})/F_5(r)\right]\\ &= r^2 F_5(r)F_4(r),\end{aligned}$$

which proves (3.11).

Clearly, F_5 is strictly increasing from $(0,\,1)$ onto $(0, \pi/2)$ [AVV2, Theorem 2.1(7)].

By differentiation,

$$r^3 r'^2 F_5'(r) = 2\left\{r^2(\mathcal{K}' - \mathcal{E}')(\mathcal{E} - r'^2\,\mathcal{K}) + r'^2\,\mathcal{E}'[(2 - r^2)\,\mathcal{K} - 2\,\mathcal{E}]\right\},$$

and hence, by Legendre's relation [BB, p. 24],

$$\begin{aligned}F_4'(r) = \frac{2r}{r'^2} - \frac{2}{F_5(r)^2}\left\{\frac{r}{r'^2}F_5(r)\,[2\,\mathcal{E}\,\mathcal{E}' + \mathcal{K}\,\mathcal{K}' - \mathcal{E}\,\mathcal{K}' - \mathcal{K}'\,\mathcal{E} + F_5(r) - F_5(r)]\right.\\ \left. - \mathcal{E}'(\mathcal{K} - \mathcal{E})F_5'(r)\right\}\\ = \frac{4}{rF_5(r)^2}\,\mathcal{E}'(\mathcal{K} - \mathcal{E})\left[\frac{r}{2}F_5'(r) - F_5(r)\right]\end{aligned}$$

so that

$$rF_5(r)^2 F_4'(r) = 4\,\mathcal{E}'(\mathcal{K} - \mathcal{E})F_6(r), \tag{3.12}$$

where

$$\begin{aligned} F_6(r) &\equiv \frac{r}{2}F_5'(r) - F_5(r) \\ &= [(\mathcal{K}' - \mathcal{E}')(\mathcal{E} - r'^2\mathcal{K})/r'^2] + \mathcal{E}'F_7(r) + \pi/2, \\ F_7(r) &\equiv [(4-3r^2)\mathcal{K} - 4\mathcal{E}]/r^2. \end{aligned}$$

Next, let $F_8(r) \equiv \mathcal{E}'F_7(r)$. Then

$$F_7'(r) = \left[(8-7r^2)\mathcal{E} - (8-3r^2)r'^2\mathcal{K}\right]/(r^3r'^2)$$

and hence,

$$\frac{r'^2F_8'(r)}{r(\mathcal{K}' - \mathcal{E}')} = F_9(r) \equiv F_7(r) + \frac{\mathcal{E}'}{\mathcal{K}' - \mathcal{E}'} \cdot \frac{(8-7r^2)\mathcal{E} - (8-3r^2)r'^2\mathcal{K}}{r^4}. \tag{3.13}$$

By Lemma 2.11(2), F_9 is strictly increasing from (0, 1) onto $(-\pi/2, \infty)$. Since $F_9(\sqrt{3}/2) = 1.32\ldots > 0$, it follows from (3.13) that F_8 is strictly increasing on $[\sqrt{3}/2, 1)$, and hence, by [QV2, Theorem 2.1(6)], F_6 is strictly increasing on $[\sqrt{3}/2, 1)$. Since $F_6(\sqrt{3}/2) = 0.06\ldots > 0$, it follows from (3.12) that F_4 is strictly increasing on $[\sqrt{3}/2, 1)$. Since $F_4(\sqrt{3}/2) = 0.53\ldots > 0$, it follows from (3.11) that

$$f'(r) > 0, \quad \text{for } r \in [\sqrt{3}/2, 1). \tag{3.14}$$

The monotonicity of f now follows from (3.10) and (3.14).

The remaining conclusions are clear. □

3.5. Proof of Theorem 1.9. The limit $f(0^+)$ is clear, while $f(1^-) = 1$ follows from [AVV2, Theorems 1.2, 2.1(7)]. Next, $f(r) = g(r)/h(r)$, where $g(r) = \mathcal{E}(r)\mathcal{E}'(r) - \mathcal{K}(r)\mathcal{E}'(r) + r^2\mathcal{K}(r)\mathcal{K}'(r), h(r) = r^2\mathcal{K}'(r)$. Hence, by [AVV2, Theorem 1.2], $g(0^+) = h(0^+) = 0$. By differentiation and simplification,

$$\frac{g'(r)}{h'(r)} = \frac{2\mathcal{E}(r)}{1 + (G(r')/H(r'))}, \tag{3.15}$$

where $G(r) = r^2\mathcal{K}(r), H(r) = \mathcal{K}(r) - \mathcal{E}(r)$. Again $G(0) = H(0) = 0$, and

$$\frac{G'(r)}{H'(r)} = 1 + \frac{r'^2\mathcal{K}(r)}{\mathcal{E}(r)}.$$

Hence, the result follows from [AVV2, Theorems 1.2, 1.3] and [VV, Lemma 1.1]. □

Some of the above results (e.g., Theorem 1.7), together with those in [Q1, Q2, QV2] solve all the conjectures raised in [AVV2, Conjecture 3.1].

Acknowledgments. The authors are grateful to the referee for many helpful suggestions.

ON THE EQUATIONS DESCRIBING A RELAXATION TOWARD A STATISTICAL EQUILIBRIUM STATE IN THE TWO-DIMENSIONAL PERFECT FLUID DYNAMICS*

ANDRO MIKELIĆ† AND RAOUL ROBERT†

Abstract. The large scale evolution of a two-dimensional (2D) incompressible ideal fluid can be modeled by introducing eddy-viscosity terms. This procedure introduces a new convection-diffusion equation for vorticity. Such relaxation equations have a structural similarity with the 2D Navier–Stokes equations in the "stream function-vorticity" formulation but also contain an additional degenerate transport term being essential for conserving the kinetic energy. Using the negative entropy as the Lyapunov functional and after performing the precise estimates for the degenerate transport, we prove existence and uniqueness of solutions to the relaxation equation for a large class of initial data. Furthermore, we study the long time dynamics of the solution, making a link with the statistical equilibrium theory.

Key words. relaxation equations, two-dimensional incompressible perfect fluid, statistical equilibrium, small scale turbulence

1. Introduction.

We are concerned here with the behavior of a 2D incompressible perfect fluid in a periodic domain $\mathcal{Y} = (\mathbb{R}/\mathbb{Z})^2$. The motion of the fluid is described by Euler equations, which we write in the classical stream function-vorticity formulation:

$$(E) \quad \begin{cases} \dfrac{\partial \omega}{\partial t} + \operatorname{div}\,(\omega \nabla \times \psi) \;= 0 \quad \text{in } \mathcal{Y}, \\ -\Delta \psi = \omega \quad \text{in } \mathcal{Y}, \quad \displaystyle\int_{\mathcal{Y}} \psi \, dy = 0, \quad \psi \text{ is periodic,} \end{cases}$$

where ω is the scalar vorticity of the flow (satisfying of course $\int_{\mathcal{Y}} \omega \, dy = 0$) and ψ is the corresponding stream function.

The global existence and uniqueness of the solution for a given initial datum $\omega_0 \in L^\infty(\mathcal{Y})$ are well known (it is the famous Youdovitch's theorem [18]).

A further step is to describe the long-time dynamics of the flow: how does $\omega(t)$ behave when $t \to +\infty$? We know that, in general, the function $\omega(t)$ develops oscillations at smaller and smaller scales so that, from a practical point of view, an exhaustive deterministic description soon fails. On the other hand, when observed at a large scale (taking local averages of $\omega(t)$), the flow displays the formations of large structures (the so-called coherent structures in meteorology). In previous works [9], [11], [12], [14], [15] we gave a description of this phenomenon in terms of statistical mechanics, showing that the formation of these structures corresponds to the tendency of the system to reach its statistical equilibrium (see also [5]).

To briefly summarize these works let us say that to each initial datum ω_0 we can associate an equilibrium state ω^* (or more generally, an equilibrium set) that the system is likely to reach (in the weak sense) when $t \to +\infty$.

†C.N.R.S. U.M.R. 5585, Analyse Numérique, Bât. 101, Université Lyon 1, 43, Bd. du onze novembre, 69622 Villeurbanne Cedex, France (andro@iris.univ-lyon1.fr, robert@iris.univ-lyon1.fr).

In this paper we shall consider the simplest case, where the initial vorticity ω_0 can take only the two values $+1, -1$. In this case we have the following simple description of ω^*. It is obtained by solving the variational problem $(\mathcal{V}.\mathcal{P}.)$:

Find the minimum value of the (negative) entropy functional

$$\mathcal{J}(\omega) = \int_{\mathcal{Y}} \Big(\frac{1+\omega}{2} \ln(1+\omega) + \frac{1-\omega}{2} \ln(1-\omega) \Big)\, dy$$

under the constraints

$$(\mathcal{V}.\mathcal{P}.1) \qquad \int_{\mathcal{Y}} \omega \, dy = 0,$$

$$(\mathcal{V}.\mathcal{P}.2) \qquad \frac{1}{2} \int_{\mathcal{Y}} \psi\omega \, dy = \frac{1}{2} \int_{\mathcal{Y}} \psi_0\omega_0 \, dy \quad \text{(the energy corresponding to } \omega_0\text{)}.$$

It is easily seen that this problem always has a solution (not necessarily unique).

Once a statistical equilibrium state (or set) is defined, we can study the relaxation process of the system toward the equilibrium. This issue was addressed in [13] and [17], where we have proposed a simple model of convection–diffusion equation to describe this relaxation process. In this model $\omega(t, y)$ denotes the local mean value of the "microscopic" vorticity which oscillates at small scale between $+1$ and -1.

Then we get for ω the equation

$$\frac{\partial \omega}{\partial t} + \text{div } (\omega \nabla \times \psi) - A \text{ div } \big(\nabla\omega + \beta(\omega)\, (1-\omega^2) \nabla\psi \big) = 0, \tag{1.1}$$

with

$$\beta(\omega) = -\frac{\int_{\mathcal{Y}} \omega^2 \, dy}{\int_{\mathcal{Y}} (1-\omega^2)\, |\nabla\psi|^2 \, dy},$$

where $A > 0$ is a viscosity-type coefficient.

Equation (1.1) looks like Navier–Stokes equations, with the only difference being in the supplementary term $\beta(\omega)(1-\omega^2)\nabla\psi$, which ensures the conservation of the energy.

Our approach raises a natural question: Is (1.1) physically realistic?

The derivation of (1.1) is based upon the two following strong physical assumptions:

First, the adequacy of the entropy functional given by the statistical equilibrium theory of the perfect fluid. Some experiments and results of numerical simulations indicate that it is a rather reasonable hypothesis [10], [16], [17].

Second, the validity of the empirical principle of nonequilibrium thermodynamics used to derive (1.1). This issue, which is out of the scope of this paper, is discussed in [17]. It is known from [17] that the case $A =$ constant, which is considered here, is only a rough approximation; a detailed study of the vorticity diffusion mechanism yields a function $A(\omega)$.

Let us emphasize that the interest of this approach is to obtain relaxation equations like (1.1) with an eddy-viscosity term which is explicitly calculated on the basis of a clear physical hypothesis. Moreover such equations are found to be efficient in performing numerical simulations (see [17]).

One may wonder why (1.1) is not Galilean invariant. This follows naturally from the fact that the statistical equilibrium states for the Euler equation are defined

globally on the whole domain and not locally. Let us note here a close similarity with the Vlasov–Fokker–Planck equation introduced by Chandrasekhar [2] to describe the relaxation of stellar systems (see also [3]).

We give here a first mathematical study of (1.1). In our opinion the interest of the study goes beyond this particular case, and our approach is extendible to other equations of the same kind, modeling relaxation processes.

The reader acquainted with the classical techniques of nonlinear parabolic problems readily sees that for a given fixed β the compacity method works straightforwardly and gives a solution of (1.1) for all time. But β is not fixed and the specific difficulty of the problem is to get some estimate on β. We will show in this paper that such an estimate can be obtained by introducing some restriction on the initial datum ω_0; then the solution exists for all time. Moreover we prove a uniform (in time) H^1 estimate on a solution. As a consequence, we can apply the method from Dafermos [4] to get some information on the asymptotic behavior of the solution: under some condition on the initial datum ω_0 we can prove that the Ω-limit set associated with ω_0 is included in the set of the critical points of the variational problem $(\mathcal{V}.\mathcal{P}.)$.

2. Some auxiliary results. In this section we define the operators connecting velocity and vorticity (stream function and vorticity, resp.) and prove some auxiliary inequalities.

Our flow domain is the unit periodic cell $\mathcal{Y} =]-\frac{1}{2}, \frac{1}{2}[^2$. Let $L^2_0(\mathcal{Y}) = \{\varphi \in L^2(\mathcal{Y}) : \int_{\mathcal{Y}} \varphi = 0\}$ and $\tilde{H}^\alpha_{per}(\mathcal{Y}) = H^\alpha_{per}(\mathcal{Y}) \cap L^2_0(\mathcal{Y}), 0 \le \alpha \le 2$, where $H^\alpha_{per}(\mathcal{Y})$ is the usual Sobolev space of periodic functions.

Let $\mathcal{A}u = -\Delta u$ for $u \in C^2_{per}(\mathcal{Y}) \cap L^2_0(\mathcal{Y})$.

Using Friedrichs theorem we extend $\mathcal{A}$ to a self-adjoint densely defined linear operator in $L^2_0(\mathcal{Y})$. In this case $\mathcal{D}(\mathcal{A}) = \{\varphi \in L^2_0(\mathcal{Y}) \ | \mathcal{A}\varphi \in L^2_0(\mathcal{Y})\} = \tilde{H}^2_{per}(\mathcal{Y})$ and the spectrum $\sigma(\mathcal{A})$ consists of the eigenvalues $\lambda_{k,l} = 4(k^2 + l^2)\pi^2$, $\lambda_{k,l} \neq 0$. Since its resolvent set meets the right half-plane, $\mathcal{A}$ is sectorial (in the sense of Henry [7]).

In the next step we introduce the system

$$\left\{ \begin{array}{rrrrr} & & \text{curl} & u = \omega & \text{in} \quad \mathcal{Y}, \\ & & \text{div} & u = 0 & \text{in} \quad \mathcal{Y}, \\ u & \text{is} & 1-\text{periodic}, & \displaystyle\int_{\mathcal{Y}} u dx = 0. & \end{array} \right. \tag{2.1}$$

Then we set $u = G\omega$. Obviously G is continuous as a linear operator $G : L^2_0(\mathcal{Y}) \to \tilde{H}^1_{per}(\mathcal{Y})^2$ and $G : \tilde{H}^\alpha_{per}(\mathcal{Y}) \to \tilde{H}^{1+\alpha}_{per}(\mathcal{Y})^2$, $0 \le \alpha \le 2$.

Throughout the paper the stream function ψ is defined by

$$\left\{ \begin{array}{rrrr} & & -\Delta\psi = \omega & \text{in} \quad \mathcal{Y}, \\ \psi & \text{is} & 1-\text{periodic}, & \displaystyle\int_{\mathcal{Y}} \psi dx = 0. \end{array} \right. \tag{2.2}$$

Obviously, $\psi = \mathcal{A}^{-1}\omega$ and $\mathcal{A}^{-1}$ is continuous as an operator $\mathcal{A}^{-1} : L^2_0(\mathcal{Y}) \to \tilde{H}^2_{per}(\mathcal{Y})$.

In our considerations an important role is played by the function (negative entropy)

$$S(x) = \frac{1+x}{2}\ln(1+x) + \frac{1-x}{2}\ln(1-x), \qquad x \in]-1, 1[. \tag{2.3}$$

Obviously

$$S'(x) = \frac{1}{2}\ln\frac{1+x}{1-x}, \quad S''(x) = \frac{1}{1-x^2}, \quad S(x) = S(-x),$$

and $S \in C^\infty(]-1,1[)$. It is convex on $]-1,1[$ and monotone and increasing on $]0,1[$.

It is of some importance to compare $S(x)$ with $|x|^p, p \geq 2$, on $]-1,1[$. We have the following.

LEMMA 2.1. *Let $p \geq 2$ and $x \in]-1,1[$. Then*

$$S(x) \geq \frac{1}{2(p-1)}\left(\frac{p}{p-2}\right)^{\frac{p-2}{2}}|x|^p. \tag{2.4}$$

Furthermore for $0 < \delta << 1$ we have

$$S(\delta x) = \frac{1}{2}\delta^2 x^2 + \mathcal{O}(\delta^3). \tag{2.5}$$

We continue by obtaining explicit constants in various embedding and interpolation inequalities.

LEMMA 2.2. *Let $\varphi \in \tilde{H}^1_{per}(\mathcal{Y})$. Then we have $|\varphi(x)| \leq \int_{\mathcal{Y}} |x-y|^{-1}|\nabla\varphi(y)|\,dy$ and*

$$\|\varphi\|_{L^{2q}(\mathcal{Y})} \leq \big(q+1\big)^{\frac{q+1}{2q}}\sqrt{\pi}\|\nabla\varphi\|_{L^2(\mathcal{Y})^2} \qquad \forall q \in]1,+\infty[. \tag{2.6}$$

Proof. The first inequality is classical (see, e.g., Chapter 7 in Gilbarg and Trudinger [6]). Inequality (2.6) is a consequence of the theory of the Riesz potentials V_μ, $(V_\mu f)(x) \equiv \int_{\mathcal{Y}} |x-y|^{2(\mu-1)} f(y)\,dy$, $f \in L^1(\mathcal{Y})$, applied to the case $\mu = \frac{1}{2}$. We refer to Gilbarg and Trudinger [6] for more details. □

LEMMA 2.3. *Let $\varphi \in \tilde{H}^1_{per}(\mathcal{Y})$. Then we have*

$$\|\varphi\|_{L^2(\mathcal{Y})} \leq \frac{1}{2\pi}\|\nabla\varphi\|_{L^2(\mathcal{Y})^2} \tag{2.7}$$

and

$$\|\varphi\|_{\tilde{H}^{-1}_{per}(\mathcal{Y})} \leq \frac{1}{2\pi}\|\varphi\|_{L^2(\mathcal{Y})}. \tag{2.8}$$

Proof. $4\pi^2$ is the first eigenvalue of the operator $\mathcal{A}$. Hence the second Poincaré's inequality and the condition $\int_{\mathcal{Y}} \varphi = 0$ imply (2.7). Estimate (2.8) is proved using the definition of the norm in $\tilde{H}^{-1}_{per}(\mathcal{Y}) = (\tilde{H}^1_{per}(\mathcal{Y}))'$ and (2.7):

$$\|\varphi\|_{\tilde{H}^{-1}_{per}(\mathcal{Y})} = \sup_{\zeta \in \tilde{H}^1_{per}(\mathcal{Y})} \frac{\int_{\mathcal{Y}} \varphi\zeta\,dy}{\|\nabla\zeta\|_{L^2(\mathcal{Y})^2}} \leq \frac{1}{2\pi}\|\varphi\|_{L^2(\mathcal{Y})}.$$

Note that

$$\|\varphi\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})} = \int_{\mathcal{Y}} |\nabla\theta|^2\,dy$$

for any periodic function θ such that $\mathcal{A}\theta = \varphi$. □

LEMMA 2.4. *Let $\varphi \in \tilde{H}^1_{per}(\mathcal{Y})$. Then we have*

$$\|\varphi\|_{L^{2+2\delta}(\mathcal{Y})} \leq \frac{\sqrt{1+\delta}}{\sqrt[4]{\pi}} \left(2\pi^{\frac{3}{2}}\right)^{\frac{\delta}{2(1+\delta)}} \|\nabla\varphi\|_{L^2(\mathcal{Y})^2}, \qquad 0 < \delta. \tag{2.9}$$

Proof. An estimate for the $L^{2+2\delta}$-norm is obtained by interpolation between $L^2(\mathcal{Y})$ and $L^{2+4\delta}(\mathcal{Y})$. Then inequalities (2.6) and (2.7) imply (2.9). ∎

We will need a particular form of Gronwall's inequality.

LEMMA 2.5. *Assume a, b, α, β are nonnegative constants with $\alpha < 1, \beta < 1$, and $0 < T < +\infty$. Then there exists a constant $M = M(b, \alpha, \beta, T) < +\infty$ such that for any integrable function $h : [0, T] \to \mathbb{R}$ satisfying*

$$0 \leq h(t) \leq at^{-\alpha} + b\int_0^t (t-s)^{-\beta} h(s)ds \quad \textit{for almost every} \quad t \in [0, T]$$

we have

$$0 \leq h(t) \leq aMt^{-\alpha} \quad \textit{a.e. on} \quad]0, T].$$

Proof. See, e.g., Henry [7, pp. 188–190]. ∎

Finally, for the comfort of the reader we recall the classic existence of the unique local mild solution from Henry [7]:

Let us consider the nonlinear Cauchy problem

$$\begin{cases} \dfrac{dx}{dt} + Bx = f(t, x), \quad t > t_0, \\ x(t_0) = x_0, \end{cases} \tag{2.10}$$

where it is assumed that B is a sectorial operator in the Banach space X and that f maps some open set $\mathcal{U}$ in $\mathbb{R} \times X^\alpha$ into X for some $\alpha \in [0, 1[$ and X^α being the domain of definition for $(B + \lambda I)^\alpha$, for some $\lambda > 0$. Suppose that f is locally Hölder continuous in t and locally Lipschitz in x on $\mathcal{U}$.

Then for any $(t_0, x_0) \in \mathcal{U}$ there exists $T = T(t_0, x_0) > 0$ such that the problem (2.10) has a unique mild solution x on $]t_0, t_0 + T[$ with initial value $x(t_0) = x_0$. More precisely, there exists a unique continuous function $x : [t_0, t_0 + T[\to X$ such that $x(t_0) = x_0$, and on $]t_0, t_0 + T[$ we have that $(t, x(t)) \in \mathcal{U}, x(t) \in D(B)$, $\frac{dx}{dt}(t)$ exists, $t \to f(t, x(t))$ is locally Hölder continuous, and $\int_{t_0}^{t_0+\rho} \|f(t, x(t))\|_X dt < +\infty$ for some $\rho > 0$, and the differential equation (2.10) is satisfied on $]t_0, t_0 + T[$.

3. Existence and uniqueness of a mild solution. We start with the position of the problem. Because of the singular nature of the parameter β we introduce the set $\mathcal{V}_\gamma, \gamma > 1$, by

$$\mathcal{V}_\gamma = \{z \in \tilde{H}^\gamma_{per}(\mathcal{Y}) : \int_{\mathcal{Y}} (1 - z^2(y))|\nabla \mathcal{A}^{-1} z|^2 dy \neq 0\}. \tag{3.1}$$

Obviously $\mathcal{V}_\gamma$ is an open set in $\tilde{H}^\gamma_{per}(\mathcal{Y})$.

Then we have the following.

DEFINITION 3.1. *Let $\omega_0 \in \mathcal{V}_\gamma$. Then a mild solution of the problem (1.1) on $[0, T[$ is a function $\omega \in C([0, T[; \mathcal{V}_\gamma)$ such that $\omega(0) = \omega_0$, $\omega \in C(]0, T[; \tilde{H}^2_{per}(\mathcal{Y}))$, $\frac{d\omega}{dt} \in C(]0, T[; L^2_0(\mathcal{Y}))$, and*

(3.2)

$$\frac{d\omega}{dt} + A\mathcal{A}\omega = -\operatorname{div}\{\omega G(\omega)\} + A\beta(\omega)\operatorname{div}\{(1-\omega^2)\nabla(\mathcal{A}^{-1}\omega)\} \equiv F(\omega) \quad on \quad]0,T[,$$

where

(3.3)

$$\beta(\xi) = \begin{cases} -\dfrac{\displaystyle\int_{\mathcal{Y}} \xi^2(y)dy}{\displaystyle\int_{\mathcal{Y}} (1-\xi^2(y))|\nabla\mathcal{A}^{-1}\xi|^2 dy} \text{ for } \xi \in L_0^2(\mathcal{Y}), \quad \text{such that} \\ \displaystyle\int_{\mathcal{Y}} (1-\xi^2)|\nabla\mathcal{A}^{-1}\xi|^2 \neq 0, \\ \\ -\infty \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{otherwise.} \end{cases}$$

Remark 3.2. For $z \in L_0^{2+\delta}(\mathcal{Y}), \delta > 0$, we have $\nabla\mathcal{A}^{-1}z \in L^\infty(\mathcal{Y})^2$, and

$$\int_{\mathcal{Y}} (1-z^2(y))|\nabla\mathcal{A}^{-1}z|^2\, dy$$

is finite. □

Our first goal is to establish a local existence of a mild solution for (3.2). After that initial step we will prove the global existence.

In order to apply the abstract local existence theorem we have to establish the properties of F. We write the nonlinear mapping F from (3.2) in the form

$$F(\xi) = -\nabla\xi \cdot G(\xi) - A\beta(\xi)\xi(1-\xi^2) - 2A\beta(\xi)\xi\nabla\xi \cdot \nabla(\mathcal{A}^{-1}\xi), \tag{3.4}$$

and straightforward estimates give the following.

PROPOSITION 3.3. *$F : \mathcal{V}_\gamma \to L_0^2(\mathcal{Y})$ is locally Lipschitzian.*

Since we know that $\mathcal{A}$ is a sectorial operator and $F : \mathcal{V}_\gamma \to L_0^2(\mathcal{Y})$ is locally Lipschitz continuous, we are in the situation to use the general local existence result for nonlinear parabolic equations and obtain the following.

THEOREM 3.4. *Let A be a positive constant, and let $\omega_0 \in \mathcal{V}_\gamma, \gamma > 1$. Then there exists $T = T(\omega_0, \gamma) > 0$ such that* (3.2) *has a unique mild solution $\omega \in C([0,T[;\mathcal{V}_\gamma) \cap C^1(]0,T[;L_0^2(\mathcal{Y}))$ on $]0,T[$, with initial value $\omega(0) = \omega_0$.*

Remark 3.5. Using Theorem 3.3.4. from Henry [7] we have that either $T = +\infty$ or else there exists a sequence $t_n \to T$ as $n \to +\infty$ such that $\int_{\mathcal{Y}}(1-\omega^2(t_n))|\nabla\mathcal{A}^{-1}\omega(t_n)|^2 \to 0$ as $n \to +\infty$ or $\|\omega(t_n)\|_{\tilde{H}^\gamma_{per}(\mathcal{Y})} \to +\infty$. □

Now it is important to extend the existence to any time interval.

The usual approach is to get some a priori estimates for some norms, which stay bounded. Here the essential difficulty will be controlling the singular parameter $\beta(\omega)$.

Let us use the physical structure of our problem and obtain a uniform $L^\infty-$ bound on ω.

First we introduce an appropriate weak formulation for (3.2):

$$\int_0^t \int_{\mathcal{Y}} \frac{\partial\omega}{\partial\tau}\varphi\, dyd\tau + A\int_0^t \int_{\mathcal{Y}} \nabla\omega \cdot \nabla\varphi\, dyd\tau = \int_0^t \int_{\mathcal{Y}} \omega G(\omega) \cdot \nabla\varphi\, dyd\tau$$
$$- \int_0^t \int_{\mathcal{Y}} A\beta(\omega)(1-\omega^2)\nabla(\mathcal{A}^{-1}\omega) \cdot \nabla\varphi\, dyd\tau \quad \forall\varphi \in L^2(0,T;H^1_{per}(\mathcal{Y})). \tag{3.5}$$

We use (3.5) in proving the following result.

PROPOSITION 3.6. *Let $\omega_0 \in \mathcal{V}_\gamma$ and $-1 \le \omega_0 \le 1$ in $\mathcal{Y}$. Then $-1 \le \omega(t) \le 1$ in $\mathcal{Y}$ $\forall t \in [0,T[$.*

Proof. We use the truncation method (see, for example, Artola [1]). Let $w_\eta^+ = \sup\{(\omega-1)^+ - \eta, 0\} \equiv (\omega - \eta - 1)^+, \eta > 0$.

Then we insert $\varphi = \frac{1}{\eta} - \frac{1}{\eta + w_\eta^+}$ as a test function for (3.5). It follows that

$$\int_{\mathcal{Y}} \left\{ \frac{w_\eta^+(t)}{\eta} - \ln\left(1 + \frac{w_\eta^+(t)}{\eta}\right)\right\} dy + A\int_0^t \int_{\mathcal{Y}} \left| \frac{\nabla w_\eta^+}{\eta + w_\eta^+}\right|^2 dy d\tau$$
$$- A\int_0^t \beta(\omega) \int_{\mathcal{Y}} \{1 + \eta + w_\eta^+\} \left\{ w_\eta^+ + 2\ln\left(1 + \frac{w_\eta^+(t)}{\eta}\right)\right\} dy d\tau = 0.$$

Since $\beta(\omega) \le 0$, we get

$$\int_{\mathcal{Y}} \left\{ \frac{w_\eta^+(t)}{\eta} - \ln\left(1 + \frac{w_\eta^+(t)}{\eta}\right)\right\} dy \le 0 \quad \forall t.$$

Finally, $w_\eta^+(t) = 0$, implying $(\omega(t) - 1)^+ \le \eta$ $\forall \eta > 0$. Therefore $\omega(t) \le 1$ in $\mathcal{Y}$ $\forall t \in [0,T[$.

Inequality $\omega(t) \ge -1$ is proved analogously. ∎

We continue by proving that energy is conserved.

PROPOSITION 3.7. *Let ω be a mild solution for* (3.2), *corresponding to the initial datum $\omega_0 \in \mathcal{V}_\gamma$.*

Then we have

$$\|\omega(t)\|_{\tilde{H}^{-1}_{per}(\mathcal{Y})} = \|\omega_0\|_{\tilde{H}^{-1}_{per}(\mathcal{Y})} \quad \forall t \in [0,T[, \tag{3.6}$$

where we recall that

$$\|\zeta\|_{\tilde{H}^{-1}_{per}(\mathcal{Y})} \overset{def}{=} \|\nabla(\mathcal{A}^{-1}\zeta)\|_{L^2(\mathcal{Y})^2} \quad \forall \zeta \in L^2_0(\mathcal{Y}).$$

Proof. Using the regularity of $\psi = \mathcal{A}^{-1}\omega$, we have

$$-\Delta \frac{\partial \psi}{\partial t} = \frac{\partial \omega}{\partial t} \qquad \text{in} \quad \mathcal{Y},$$

which implies $\displaystyle\int_{\mathcal{Y}} \nabla \frac{\partial \psi}{\partial t} \cdot \nabla \psi \, dy = \int_{\mathcal{Y}} \frac{\partial \omega}{\partial t} \psi \, dy$. Finally,

$$\frac{1}{2}\int_{\mathcal{Y}} |\nabla(\mathcal{A}^{-1}\omega(t))|^2 \, dy = \frac{1}{2}\int_{\mathcal{Y}} |\nabla(\mathcal{A}^{-1}\omega_0)|^2 \, dy + \int_0^t \int_{\mathcal{Y}} \frac{\partial \omega}{\partial t} \psi \, dy d\tau. \tag{3.7}$$

Now using $\psi = \mathcal{A}^{-1}\omega$ as a test function in (3.5) and the definition of $\beta(\omega)$, we obtain

$$\int_0^t \int_{\mathcal{Y}} \frac{\partial \omega}{\partial t} \psi \, dy d\tau + A\int_0^t \int_{\mathcal{Y}} \nabla\omega \cdot \nabla\psi \, dy d\tau - A\int_0^t \int_{\mathcal{Y}} \omega^2 \, dy d\tau = 0. \tag{3.8}$$

Obviously, $\int_0^t \int_{\mathcal{Y}} \nabla\omega \cdot \nabla\psi \, dy d\tau = \int_0^t \int_{\mathcal{Y}} \omega^2 \, dy d\tau$ and (3.7) and (3.8) imply (3.6). ∎

In the next step we would like to use the fact that negative entropy should be decreasing during the evolution in time. We have the following.

PROPOSITION 3.8. *Let ω be a mild solution for* (3.2), *corresponding to the initial datum $\omega_0 \in \mathcal{V}_\gamma$, and $-1 \le \omega_0 \le 1$ in $\mathcal{Y}$. Then we have*

$$\int_{\mathcal{Y}} S(\omega(t))\,dy \le \int_{\mathcal{Y}} S(\omega_0)\,dy \quad \forall t \in [0,T[\tag{3.9}$$

with the entropy function S given by (2.3).

Proof. The idea is to use $S'(\omega)$ as a test function in (3.5). However, this is not possible since we do not know whether $S'(\omega) \in L^2(0,T;H^1_{per}(\mathcal{Y}))$ or not.

We introduce "regularized entropy functions" S_δ, $\delta > 0$, by

$$S_\delta(\xi) = \frac{1+\delta+\xi}{2}\ln(1+\delta+\xi) + \frac{1+\delta-\xi}{2}\ln(1+\delta-\xi) \tag{3.10}$$

$\forall \xi \in L^2_0(\mathcal{Y})$, $-1 \le \xi \le 1$. Obviously, $S_\delta \in C^\infty[-1,1]$ $\forall \delta > 0$. Now we choose $\varphi = S'_\delta(\omega)$ as a test function for (3.5). It gives

$$\begin{aligned}\int_{\mathcal{Y}} S_\delta(\omega(t))\,dy - \int_{\mathcal{Y}} S_\delta(\omega_0)\,dy + A(1+\delta)\int_0^t\int_{\mathcal{Y}} \frac{|\nabla\omega|^2}{(1+\delta)^2-\omega^2}\,dyd\tau \\ = A(1+\delta)\int_0^t(-\beta(\omega))\int_{\mathcal{Y}}\left\{\omega^2 - \frac{\delta(2+\delta)}{2(1+\delta)}\omega\ln\frac{1+\delta+\omega}{1+\delta-\omega}\right\}dyd\tau.\end{aligned} \tag{3.11}$$

It should be noticed that $-\beta(\omega) \ge 0$ and $x\ \ln\frac{1+\delta+x}{1+\delta-x} \ge 0$ on $[-1,1]$. Therefore, we only have to estimate $\int_0^t(-\beta(\omega))\int_{\mathcal{Y}}\omega^2\,dyd\tau$.

Before estimating $(-\beta)$ we remark that passing to the limit $\delta \to 0$ in (3.11) and using the theorem of B. Levi imply

$$A\int_0^t\int_{\mathcal{Y}}\frac{|\nabla\omega|^2}{1-\omega^2}\,dyd\tau = \int_{\mathcal{Y}} S(\omega_0)\,dy - \int_{\mathcal{Y}} S(\omega(t))\,dy + A\int_0^t(-\beta(\omega))\int_{\mathcal{Y}}\omega^2\,dyd\tau,$$

and, consequently, $\frac{|\nabla\omega|}{\sqrt{1-\omega^2}} \in L^2(]0,t[\times\mathcal{Y})$.

Let us now estimate $-\beta(\omega)$. We start with an obvious inequality:

$$\frac{1}{\int_{\mathcal{Y}}(1-\omega^2)|\nabla(\mathcal{A}^{-1}\omega)|^2} \le \frac{\int_{\mathcal{Y}}(1-\omega^2)|\mathcal{B}'(\omega)|^2|\nabla\omega|^2}{\{\int_{\mathcal{Y}}(1-\omega^2)\nabla(\mathcal{A}^{-1}\omega)\cdot\nabla\mathcal{B}(\omega)\}^2}$$

$$= \frac{\int_{\mathcal{Y}}(1-\omega^2)|\mathcal{B}'(\omega)|^2|\nabla\omega|^2}{\{\int_{\mathcal{Y}}\omega\int_{-1}^{\omega}(1-\xi^2)\mathcal{B}'(\xi)d\xi\}^2} \quad \forall\mathcal{B}\in C^1[-1,1].$$

We take $\mathcal{B}(\xi) = S'_\delta(\xi)$ and obtain

$$\int_{\mathcal{Y}}\omega\int_{-1}^{\omega}(1-\xi^2)S''_\delta(\xi)d\xi\,dy = (1+\delta)\int_{\mathcal{Y}}\left\{\omega^2 - \frac{\delta(2+\delta)}{2(1+\delta)}\omega\ \ln\frac{1+\delta+\omega}{1+\delta-\omega}\right\}dy.$$

Consequently,

$$0 \le -\beta(\omega) \le \frac{\int_{\mathcal{Y}}\omega^2\,dy\cdot\int_{\mathcal{Y}}\frac{|\nabla\omega|^2}{(1+\delta)^2-\omega^2}\,dy}{\left\{\int_{\mathcal{Y}}\left[\omega^2 - \frac{\delta(2+\delta)}{2(1+\delta)}\omega\ \ln\frac{1+\delta+\omega}{1+\delta-\omega}\right]dy\right\}^2}.$$

After inserting this inequality in (3.11) and passing to the limit $\delta \to 0$, we get the result. ∎

COROLLARY 3.9. *Let ω be a mild solution for* (3.2), *corresponding to the initial datum $\omega_0 \in \mathcal{V}_\gamma, \gamma > 1$, and $-1 \le \omega_0 \le 1$ in $\mathcal{Y}$. Then we have*

$$\int_{\mathcal{Y}} S(\omega(t_2))\,dy \le \int_{\mathcal{Y}} S(\omega(t_1))\,dy \quad \forall t_1, t_2 \in [0, T[, \quad t_1 < t_2. \tag{3.12}$$

Up to now, we have obtained an estimate on the L^∞-norm of the vorticity but no information on the derivatives. We come now to prove that it is equivalent to get an estimate on $\|\nabla\omega\|^2_{L^2(]0,t[\times\mathcal{Y})^2}$ or on $\|\beta(\omega)\|_{L^1(0,t)}$. We have the following result.

PROPOSITION 3.10. *Let ω be a mild solution for* (3.2) *with $\omega_0 \in \mathcal{V}_\gamma$, and $-1 \le \omega_0 \le 1$ in $\mathcal{Y}$. Then we have*

$$\|\nabla\omega\|^2_{L^2(]0,t[\times\mathcal{Y})^2} \le \frac{1}{2A}\|\omega_0\|^2_{L^2(\mathcal{Y})} + \frac{2}{3}\|\beta(\omega)\|_{L^1(0,t)} \tag{3.13}$$

and

$$4\pi^2 \le \frac{\int_{\mathcal{Y}} \omega^2(t)\,dy}{\|\omega_0\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})}} \le -\beta(\omega) \le \left(\frac{4}{\pi}\right)^2 \frac{\int_{\mathcal{Y}} |\nabla\omega(t)|^2\,dy}{\int_{\mathcal{Y}} \omega^2(t)\,dy} \le \frac{4}{\pi^4}\frac{\int_{\mathcal{Y}} |\nabla\omega(t)|^2\,dy}{\|\omega_0\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})}} \tag{3.14}$$

for (a.e.) t belonging to the interval of existence.

This result indicates that it is crucial to estimate β. Also, due to the inequalities (3.13) and (3.14), it is unlikely that some estimate for $\nabla\omega$ could be obtained by some clever choice of the test function. Finally, differentiating (3.2) does not seem to be promising either.

We try another approach. Now, in order to get the crucial estimate on β, we construct an invariant set of initial values.

Let $+\infty > p > 2$, and let $1 > \epsilon > 0$. We introduce the set $\mathcal{U}(p,\varepsilon)$ by

$$\begin{aligned}\mathcal{U}(p,\varepsilon) = \Big\{ & z \in L^2_0(\mathcal{Y}) : -1 \le z \le 1 \text{ a.e. in } \mathcal{Y}, \quad \|z\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})} \\ & \ge \frac{\mathcal{C}(p)}{(1-\varepsilon)} \left\{ \int_{\mathcal{Y}} S(z)\,dy \right\}^{1+2/p} \Big\},\end{aligned} \tag{3.15}$$

where $\mathcal{C}(p) > 0$ is a constant which will be prescribed later. Of course, since the energy is conserved and the (negative) entropy $\int_{\mathcal{Y}} S(z)\,dy$ is decreasing in time, the set $\mathcal{U}(p,\varepsilon)$ is conserved by the flow of (1.1).

The significance of $\mathcal{U}(p,\varepsilon)$ will appear in the following results.

PROPOSITION 3.11. *$\mathcal{U}(p,\varepsilon) \setminus \{0\}$ and $\mathcal{U}(p,\varepsilon) \cap \tilde{H}^\gamma_{per}(\mathcal{Y}) \setminus \{0\}$ are nonempty.*

Proof. Let $z_0 \in \tilde{H}^\gamma_{per}(\mathcal{Y}), -1 \le z_0 \le 1, z_0 \ne 0$, and let $\delta > 0$. We would like to prove $\delta z_0 \in \mathcal{U}(p,\varepsilon)$ for $\delta \le \delta_0$. Using (2.5) we get

$$\left| S(\delta z_0) - \frac{1}{2}\delta^2 z_0^2 \right| \le C\delta^3.$$

As $\frac{2p}{p+2} \in]1,2[$ we conclude that

$$\int_{\mathcal{Y}} S(\delta z_0)\,dy \le \frac{\delta^2}{2}\int_{\mathcal{Y}} z_0^2\,dy + C\delta^3 \le \delta^{\frac{2p}{p+2}} \|z_0\|^{2p/(p+2)}_{\tilde{H}^{-1}_{per}(\mathcal{Y})} \left\{ \frac{1-\varepsilon}{\mathcal{C}(p)} \right\}^{p/(p+2)}$$

for $\delta \le \delta_0$. □

For the function $z \in \mathcal{U}(p,\varepsilon)$ we have a natural estimate on $\beta(\omega)$. More precisely we have the following.

PROPOSITION 3.12. *Let $z \in \mathcal{U}(p,\varepsilon)$ for some $p > 2$ and $1 > \varepsilon > 0$, and let us take*

$$\mathcal{C}(p) = \frac{2}{\sqrt{\pi}} \left\{ \frac{4p(p-1)\pi^{3/2}}{p-2} \right\}^{2/p}. \tag{3.16}$$

Then we have

$$\int_{\mathcal{Y}} (1-z^2)|\nabla \mathcal{A}^{-1} z|^2 \, dy \ge \varepsilon \|z\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})}. \tag{3.17}$$

Proof. Let us estimate from below the term $\int_{\mathcal{Y}} (1-z^2)|\nabla \mathcal{A}^{-1} z|^2 \, dy$. We have

$$\begin{aligned} \int_{\mathcal{Y}} (1-z^2)|\nabla \mathcal{A}^{-1} z|^2 \, dy &= \int_{\mathcal{Y}} |\nabla \mathcal{A}^{-1} z|^2 \, dy - \int_{\mathcal{Y}} z^2(y)|\nabla \mathcal{A}^{-1} z|^2 \, dy \\ &= \|z\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})} - \int_{\mathcal{Y}} z^2(y)|\nabla \mathcal{A}^{-1} z|^2 \, dy \\ &\ge \|z\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})} - \|z\|^2_{L^p(\mathcal{Y})} \| |\nabla \mathcal{A}^{-1} z| \|^2_{L^{2p/(p-2)}(\mathcal{Y})}. \end{aligned} \tag{3.18}$$

Now (2.4) implies

$$\|z\|_{L^p(\mathcal{Y})} \le \{2(p-1)\}^{1/p} \left(\frac{p-2}{p} \right)^{(p-2)/2p} \left\{ \int_{\mathcal{Y}} S(z) \, dy \right\}^{1/p},$$

and for $p > 2$ (see Lemma 2.4)

$$\| |\nabla \mathcal{A}^{-1} z| \|^2_{L^{2p/(p-2)}(\mathcal{Y})} \le \frac{1}{\sqrt{\pi}} \frac{p}{p-2} \left(2\pi^{3/2}\right)^{2/p} \sum_{i=1}^{2} \int_{\mathcal{Y}} \left| \frac{\partial}{\partial y_i} \nabla \mathcal{A}^{-1} z \right|^2 dy$$

so that

$$\begin{aligned} \int_{\mathcal{Y}} (1-z^2)|\nabla \mathcal{A}^{-1} z|^2 \, dy &\ge \|z[\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})} \\ &- \frac{1}{\sqrt{\pi}} \left(\frac{4\pi^{3/2} p(p-1)}{p-2} \right)^{2/p} \left\{ \int_{\mathcal{Y}} S(z) \, dy \right\}^{2/p} \sum_{i=1}^{2} \int_{\mathcal{Y}} \left| \frac{\partial}{\partial y_i} \nabla \mathcal{A}^{-1} z \right|^2 dy. \end{aligned} \tag{3.19}$$

Using regularity we have

$$-\triangle \frac{\partial \psi}{\partial y_i} = \frac{\partial z}{\partial y_i}, \quad i = 1, 2 \text{ (where } \psi = \mathcal{A}^{-1} z),$$

which implies

$$\sum_i \int_{\mathcal{Y}} \left| \nabla \frac{\partial \psi}{\partial y_i} \right|^2 dy = \sum_i \int_{\mathcal{Y}} \frac{\partial z}{\partial y_i} \frac{\partial \psi}{\partial y_i} \, dy = -\sum_i \int_{\mathcal{Y}} z \frac{\partial^2 \psi}{\partial y_i^2} \, dy = \int_{\mathcal{Y}} z^2 \, dy.$$

Hence we have

$$\sum_i \int_{\mathcal{Y}} \left| \frac{\partial}{\partial y_i} \nabla \mathcal{A}^{-1} z \right|^2 dy = \int_{\mathcal{Y}} z^2 \, dy. \tag{3.20}$$

Now (2.4) implies $\|z\|^2_{L^2(\mathcal{Y})} \le 2\int_{\mathcal{Y}} S(z)\,dy$ so that $z \in \mathcal{U}(p,\varepsilon)$ gives

$$\int_{\mathcal{Y}} (1-z^2)|\nabla \mathcal{A}^{-1} z|^2\,dy \ge \|z\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})} - \frac{2}{\sqrt{\pi}}\left(\frac{4\pi^{3/2}p(p-1)}{p-2}\right)^{2/p}\left\{\int_{\mathcal{Y}} S(z)\right\}^{1+2/p} \ge \varepsilon\|z\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})},$$

and the proposition is proved. ∎

Now we are in a situation to state a global existence result.

THEOREM 3.13. *Let $\omega_0 \in \mathcal{U}(p,\varepsilon) \cap \tilde{H}^{\gamma}_{per}(\mathcal{Y}) \setminus \{0\}$ for some $p > 2, 1 > \varepsilon > 0$, and $\gamma > 1$. Then the unique mild solution for (3.2) exists for all $T > 0$.*

Proof. Using Propositions 3.12 and 3.7 we immediately find that the theorem can fail only if there exists a sequence $t_n \to T_{max} < +\infty$ such that $\|\omega(t_n)\|_{\tilde{H}^{\gamma}_{per}(\mathcal{Y})} \to +\infty$.

Let us use the classical expression for the solution

$$\omega(t) = e^{-t\mathcal{A}}\omega_0 + \int_0^t e^{-(t-s)\mathcal{A}} F(\omega(s))\,ds,$$

and take the norm

$$\|\omega\|_{\tilde{H}^{\gamma}_{per}(\mathcal{Y})} = \|\mathcal{A}^{\gamma/2}\omega\|_{L^2(\mathcal{Y})},$$

which gives

$$\|\omega(t)\|_{\tilde{H}^{\gamma}_{per}(\mathcal{Y})} \le \|e^{-\mathcal{A}t}\omega_0\|_{\tilde{H}^{\gamma}_{per}(\mathcal{Y})} + \int_0^t \|\mathcal{A}^{\gamma/2}e^{-\mathcal{A}(t-s)}\|_{op}\|F(\omega(s))\|_{L^2(\mathcal{Y})}\,ds,$$

where $\|\cdot\|_{op}$ denotes the operator norm on $\mathcal{L}\big(L^2(\mathcal{Y}), L^2(\mathcal{Y})\big)$.

Straightforward estimates give

$$\|F(\omega(s))\|_{L^2(\mathcal{Y})} \le C(1+|\beta(s)|)(1+\|\nabla\omega(s)\|_{L^2(\mathcal{Y})^2}).$$

But from Proposition 3.12 we know that $|\beta(s)|$ remains bounded so that we finally get

$$\|\omega(t)\|_{\tilde{H}^{\gamma}_{per}(\mathcal{Y})} \le \frac{C_1}{t^{\gamma/2}} + C_2\int_0^t \frac{1+\|\omega(s)\|_{\tilde{H}^{\gamma}_{per}(\mathcal{Y})}}{(t-s)^{\gamma/2}}\,ds. \tag{3.21}$$

After applying the generalization of Gronwall's inequality from Lemma 2.5 to (3.21), we conclude that $\|\omega(t)\|_{\tilde{H}^{\gamma}_{per}(\mathcal{Y})}$ remains bounded as $T \to T_{max}$.

Now Theorem 3.3.4. from Henry [7] implies global existence. ∎

Finally, we will discuss the case of nonsmooth ω_0. We have the following result.

THEOREM 3.14. *Let $\omega_0 \in \mathcal{U}(p,\varepsilon) \setminus \{0\}$ for some $p > 2$ and $1 > \varepsilon > 0$. Then for all $T > 0$ there exists a unique $\omega \in C([0,T]; L^2_0(\mathcal{Y})) \cap L^2(0,T;\tilde{H}^1_{per}(\mathcal{Y}))$, $\frac{d\omega}{dt} \in L^2(0,T;\tilde{H}^{-1}_{per}(\mathcal{Y}))$ such that*

$$\begin{cases} -1 \le \omega(t,x) \le 1 \quad \text{a.e. on} \quad]0,T[\times\mathcal{Y}, \\ \omega(0) = \omega_0, \quad \beta(\omega) \in L^\infty(0,T), \end{cases} \tag{3.22}$$

and it satisfies

(3.23)
$$\begin{cases} \displaystyle\int_0^T \left\langle \frac{d\omega}{dt}, \varphi \right\rangle_{\tilde{H}^{-1}_{per}(\mathcal{Y}), \tilde{H}^{1}_{per}(\mathcal{Y})} dt + A \int_0^T \int_{\mathcal{Y}} \nabla\omega \cdot \nabla\varphi \, dydt \\ \displaystyle - \int_0^T \int_{\mathcal{Y}} \omega G(\omega) \cdot \nabla\varphi \, dydt + A \int_0^T \beta(\omega) \int_{\mathcal{Y}} (1-\omega^2) \nabla \mathcal{A}^{-1} \omega \cdot \nabla\varphi \, dydt = 0 \\ \forall \varphi \in L^2(0,T; \tilde{H}^1_{per}(\mathcal{Y})). \end{cases}$$

Furthermore, the energy is conserved, i.e.,

$$\|\omega(t)\|_{\tilde{H}^{-1}_{per}(\mathcal{Y})} = \|\omega_0\|_{\tilde{H}^{-1}_{per}(\mathcal{Y})} \qquad \forall t \in [0,T], \tag{3.24}$$

and the (negative) entropy is decreasing, i.e.,

$$\int_{\mathcal{Y}} S(\omega(t_1)) \leq \int_{\mathcal{Y}} S(\omega(t_2)) \quad \textit{for} \quad t_1 \geq t_2. \tag{3.25}$$

Proof. We consider problem (3.2) with initial condition $\omega_0^\delta = \omega_0 * \rho_\delta$, where ρ_δ is a regularizing sequence such that

$$\begin{cases} \rho_\delta \in \mathcal{D}(\mathbb{R}^2), \quad \displaystyle\int_{\mathbb{R}^2} \rho_\delta(x)\, dx = 1, \quad \rho_\delta(x) \geq 0, \\ \text{supp } \rho_\delta \subset B(0, r_\delta), \qquad r_\delta \to 0 \quad \text{as} \quad \delta \to 0. \end{cases}$$

Since we have $\|\omega_0^\delta - \omega_0\|_{L^2(\mathcal{Y})} \to 0$ when $\delta \to 0$, we deduce easily that $\omega_0^\delta \in \mathcal{U}(p, \varepsilon/2) \cap \mathcal{V}_\gamma$, for $\delta \leq \delta_0$, δ_0 small enough.

Consequently, for δ small enough, we can apply Theorem 3.4 and get a unique mild solution ω^δ for all $T > 0$.

Now we take $\varphi = \omega^\delta$ in the variational equation (3.23) and obtain the standard a priori estimates

$$\begin{aligned} &\|\omega^\delta\|_{L^\infty(0,T;L^2_0(\mathcal{Y}))} \leq C\{1 + \|\omega_0^\delta\|_{L^2_0(\mathcal{Y})}\}, \\ &\|\nabla\omega^\delta\|_{L^2(0,T;L^2_0(\mathcal{Y}))} \leq C\{1 + \|\omega_0^\delta\|_{L^2_0(\mathcal{Y})}\}, \\ &\left\| \frac{\partial \omega^\delta}{\partial t} \right\|_{L^2(0,T;\tilde{H}^{-1}_{per}(\mathcal{Y}))} \leq C\{1 + \|\omega_0^\delta\|_{L^2_0(\mathcal{Y})}\}. \end{aligned}$$

Using the above a priori estimate we subtract a subsequence converging weakly star in the above functional spaces. The application of Aubin's lemma and passing once again to the subsequence gives, in addition, strong convergence in $L^2(]0,T[\times\mathcal{Y})$. Now the standard variational argument completes the proof of existence. Identity (3.24) and estimate (3.25) follow straightforwardly.

Uniqueness easily follows from Proposition 3.3 and the estimates (3.22), (3.24), and (3.25). ∎

Remark 3.15. The condition $\omega_0 \in \mathcal{U}(p, \varepsilon)$ gives a relation between the initial energy and the initial entropy which represents a sufficient condition for solvability for problem (3.2). It is an open problem to determine if it is the necessary condition for existence of a solution global in time. ∎

4. Asymptotic behavior. In this section we study the asymptotic behavior of the solutions of problem (1.1) given by Theorem 3.14.

The entropy functional $\int_{\mathcal{Y}} S(\omega)$ defines a natural Lyapunov functional for our evolution problem. However, we have uniform time estimates only for $\|\omega(t)\|_{\tilde{H}^{-1}_{per}(\mathcal{Y})}$, $\|\omega(t)\|_{L^\infty(\mathcal{Y})}$, and $\int_{\mathcal{Y}} S(\omega(t))$. Since the functional $\omega_0 \longmapsto \int_{\mathcal{Y}} S(\omega_0)\,dy - \int_{\mathcal{Y}} S(\omega(t))\,dy$ is not weakly lower semicontinuous on $\mathcal{U}(p,\varepsilon)$, we need L^2-compactness to apply classical results on the asymptotic behavior; we are going to prove a new H^1- estimate uniform in time.

We start with the corresponding regularity result.

PROPOSITION 4.1. *Let $\omega_0 \in \mathcal{U}(p,\varepsilon) \cap \tilde{H}^1_{per}(\mathcal{Y})$, $\omega_0 \neq 0$. Then the unique solution given by Theorem* 3.14 *satisfies*

$$\omega \in L^2(0,T;\tilde{H}^2_{per}(\mathcal{Y})), \quad \frac{d\omega}{dt} \in L^2(0,T;L^2_0(\mathcal{Y}))$$

so that $\omega \in C([0,T];\tilde{H}^1_{per}(\mathcal{Y}))$.

Proof. We need only to go back to the proof of Theorem 3.14. In addition to the choice $\varphi = \omega^\delta$, we also take $\varphi = \frac{d\omega^\delta}{dt}$. Then

$$\int_0^T dt \int_{\mathcal{Y}} \left|\frac{d\omega^\delta}{dt}\right|^2 dy + \frac{A}{2}\int_{\mathcal{Y}} |\nabla\omega^\delta(T)|^2\,dy - \frac{A}{2}\int_{\mathcal{Y}} |\nabla\omega_0^\delta|^2\,dy = \int_0^T dt \int_{\mathcal{Y}} F(\omega^\delta(t))\frac{d\omega^\delta}{dt}\,dy.$$

Now, since $\displaystyle\int_{\mathcal{Y}} |\nabla\omega_0^\delta|^2\,dy$ is bounded, from the inequalities

$$\|F(\omega^\delta(s))\|_{L^2(\mathcal{Y})} \le C\big(1 + \|\nabla\omega^\delta(s)\|_{L^2(\mathcal{Y})^2}\big),$$
$$\int_0^T dt \int_{\mathcal{Y}} |\nabla\omega^\delta|^2\,dy \le C$$

we get

$$\left\|\frac{d\omega^\delta}{dt}\right\|^2_{L^2(]0,T[\times\mathcal{Y})} \le C_1 + C_2\left\|\frac{d\omega^\delta}{dt}\right\|_{L^2(]0,T[\times\mathcal{Y})}.$$

Thus, $\frac{d\omega^\delta}{dt}$ is bounded in $L^2(0,T;L^2_0(\mathcal{Y}))$, which implies $\frac{d\omega}{dt} \in L^2(0,T;L^2_0(\mathcal{Y}))$. Finally from $\frac{\partial\omega}{\partial t} - A\triangle\omega = F(\omega)$ we deduce $\omega \in L^2(0,T;\tilde{H}^2_{per}(\mathcal{Y}))$. ∎

Our next step is obtaining an $H^1(\mathcal{Y})-$estimate which is uniform in time.

We have the following result.

PROPOSITION 4.2. *Let $\omega_0 \in \mathcal{U}(p,\varepsilon) \cap \tilde{H}^1_{per}(\mathcal{Y}) \setminus \{0\}$. Then we have the estimate*

$$\|\nabla\omega(t)\|_{L^2(\mathcal{Y})^2} \le R. \tag{4.1}$$

Proof. Let ω be the solution given by Proposition 4.1. We have

$$\begin{aligned}\frac{\partial\omega}{\partial t} - A\triangle\omega = F(\omega) \equiv -\nabla\omega\cdot G(\omega) - A\beta(\omega)\omega(1-\omega^2)\\ - 2A\beta(\omega)\omega\nabla\omega\cdot\nabla(\mathcal{A}^{-1}\omega) \quad \text{a.e. on} \quad]0,T[\times\mathcal{Y}.\end{aligned} \tag{4.2}$$

Let us choose $-\triangle\omega$ as a test function. Then we get

$$\frac{d}{dt}\frac{1}{2}\|\nabla\omega(t)\|^2_{L^2(\mathcal{Y})^2} + A\|\triangle\omega(t)\|^2_{L^2(\mathcal{Y})} \leq \|F(\omega)(t)\|_{L^2(\mathcal{Y})}\|\triangle\omega\|_{L^2(\mathcal{Y})^2} \tag{4.3}$$

a.e. on $]0,T[$.

We need an estimate on $\|F(\omega)(t)\|_{L^2(\mathcal{Y})}$:

$$\begin{aligned}\|F(\omega)\|_{L^2(\mathcal{Y})} &\leq \|\nabla\omega\cdot G(\omega)\|_{L^2(\mathcal{Y})}\\ &+ A|\beta(\omega)|\||\omega(1-\omega^2)\|_{L^2(\mathcal{Y})} + 2A|\beta(\omega)|\|\omega\nabla\omega\cdot\nabla(\mathcal{A}^{-1}\omega)\|_{L^2(\mathcal{Y})}.\end{aligned} \tag{4.4}$$

Since $\|\omega\|_{L^\infty(\mathcal{Y})} \leq 1$, we have $\||\nabla(\mathcal{A}^{-1}\omega)|\|_{L^\infty(\mathcal{Y})} = \||G(\omega)|\|_{L^\infty(\mathcal{Y})} \leq C$, and from the interpolation inequality

$$\|\nabla\omega\|_{L^2(\mathcal{Y})} \leq C\|\omega\|^{1/2}_{L^2(\mathcal{Y})}\|\triangle\omega\|^{1/2}_{L^2(\mathcal{Y})}$$

we get

$$\|\nabla\omega\|_{L^2(\mathcal{Y})} \leq C\|\triangle\omega\|^{1/2}_{L^2(\mathcal{Y})}. \tag{4.5}$$

(For sake of simplicity we will denote by the same letter C the different constants that we will encounter.)

Then we have

$$\|\nabla\omega\cdot G(\omega)\|_{L^2(\mathcal{Y})} \leq C\|\triangle\omega\|^{1/2}_{L^2(\mathcal{Y})}, \tag{4.6}$$

$$|\beta(\omega)| \leq \frac{\int_{\mathcal{Y}}\omega^2(t)\,dy}{\varepsilon\|\omega_0\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})}} \leq \frac{1}{\varepsilon\|\omega_0\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})}} \leq C, \tag{4.7}$$

$$2A|\beta(\omega)|\|\omega\nabla\omega\nabla(\mathcal{A}^{-1}\omega)\|_{L^2(\mathcal{Y})} \leq C\|\triangle\omega\|^{1/2}_{L^2(\mathcal{Y})}, \tag{4.8}$$

and thus

$$\|F(\omega)(t)\|_{L^2(\mathcal{Y})} \leq C\big(1+\|\triangle\omega\|^{1/2}_{L^2(\mathcal{Y})}\big). \tag{4.9}$$

Now setting $v(t) = \|\nabla\omega\|^2_{L^2(\mathcal{Y})^2}$, (4.3) becomes

$$\frac{1}{2}\frac{d}{dt}v(t) + A\|\triangle\omega(t)\|^2_{L^2(\mathcal{Y})} \leq C\big(\|\triangle\omega\|^{3/2}_{L^2(\mathcal{Y})} + \|\triangle\omega\|_{L^2(\mathcal{Y})}\big).$$

A straightforward application of Young's inequality then gives

$$\frac{1}{2}\frac{d}{dt}v(t) + \frac{A}{2}\|\triangle\omega(t)\|^2_{L^2(\mathcal{Y})} \leq C,$$

but we have $\|\triangle\omega\|^2_{L^2(\mathcal{Y})^2} \geq \|\nabla\omega\|^2_{L^2(\mathcal{Y})^2}$ so that

$$\frac{d}{dt}v(t) + Av(t) \leq C, \tag{4.10}$$

which yields the bound (4.1). □

Our next step is to construct a continuous nonlinear semigroup connected with our evolution problem.

Let us consider the complete metric space $X = \mathcal{U}(p,\varepsilon), p \in]2,+\infty[$, endowed with the $L^2_0(\mathcal{Y})-$metric (it is not a linear space) and $X^* = X \setminus \{0\}$. It should be noticed that $\omega_0 \in X^*$ implies $\omega(t) \in X^*\ \forall t \geq 0$.

Let us define a family of maps $\{\mathcal{T}(t) : X^* \to X^*, \quad t \geq 0\}$ by setting

$$\mathcal{T}(t)\omega_0 = \omega(t,x) \quad \forall \omega_0 \in X^*, \tag{4.11}$$

where $\omega \in C\big([0,+\infty[,\, L^2_0(\mathcal{Y})\big)$ is the unique solution given by Theorem 3.14.

LEMMA 4.3. *The family of maps* $\{\mathcal{T}(t) : X^* \to X^*, \quad t \geq 0\}$ *is a continuous nonlinear semigroup.*

Proof. It is straightforward, and we leave it to the reader. □

Remark 4.4. It is easy to see that if $\omega_0^n \to 0$ in X, then $\mathcal{T}(t)(\omega_0^n) \to 0\ \forall t > 0$. Hence the semigroup $\mathcal{T}$ is extended continuously to X by defining $\mathcal{T}(t)0 = 0$. □

Let us consider the functional

$$\mathcal{J}(\varphi) = \int_{\mathcal{Y}} S(\varphi)\, dy.$$

Obviously, $\mathcal{J}$ is continuous on X, and we have seen that $\mathcal{J}\big(\mathcal{T}(t)(\omega_0)\big)$ is a decreasing function of t so that it is a Lyapunov functional for $\mathcal{T}$.

We define the $\Omega-$limit set for ω_0 by

$$\Omega(\omega_0) = \{z \in X : \exists t_n \to +\infty \quad \text{such that} \quad \mathcal{T}(t_n)\omega_0 \to z\} \equiv \bigcap_{s\geq 0} \overline{\bigcup_{t\geq s} \mathcal{T}(t)}\omega_0. \tag{4.12}$$

PROPOSITION 4.5. *For every* $\omega_0 \in X \cap \tilde{H}^1_{per}(\mathcal{Y})$, $\Omega(\omega_0)$ *is a compact connected and nonempty subset of* X. *Furthermore,* $\Omega(\omega_0)$ *is* $\mathcal{T}$*-invariant and* $\mathcal{J}$ *has a constant value on it.*

Proof. First, because of Proposition 4.2, the orbit of ω_0 defined by $\gamma(\omega_0) \equiv \big\{\mathcal{T}(t)\omega_0 : \quad t \geq 0\big\}$ is relatively compact in X. Consequently, Proposition 4.5 is a direct consequence of Propositions 2.1 and 2.2 from Dafermos [4]. □

Our next goal is to describe $\Omega(\omega_0)$ in terms of statistical equilibrium. We will prove that any $\overline{\omega} \in \Omega(\omega_0)$ is a Gibbs state (as described in [11], [12]).

THEOREM 4.6. *Let us consider* $\omega_0 \in X \cap \tilde{H}^1_{per}(\mathcal{Y})$, *and let* $\overline{\omega}$ *be any element of* $\Omega(\omega_0)$. *Then there exist constants* $\lambda > 0$ *and* $C \in \mathbb{R}$ *such that*

$$\overline{\omega} = \tanh\big(\lambda\overline{\psi} + C\big) \quad \text{on} \quad \mathcal{Y}, \tag{4.13}$$

where $\overline{\psi}$ *is the stream function associated with* $\overline{\omega}$.

Furthermore, taking any sequence $\{t_n\}, t_n \to +\infty$ *such that* $\omega(t_n) \rightharpoonup \overline{\omega}$ *weakly in* $\tilde{H}^1_{per}(\mathcal{Y})$, *we have* $\beta(\omega(t_n)) \to \beta_\infty = -\lambda$.

Proof. From Proposition 4.2 we deduce that $\overline{\omega} \in X \cap \tilde{H}^1_{per}(\mathcal{Y})$. Let us now take $\overline{\omega}$ as initial datum and consider $\omega(t) = \mathcal{T}(t)\overline{\omega}$; we have $\omega \in C\big([0,+\infty[,\, \tilde{H}^1_{per}(\mathcal{Y})\big)$.

Let us now consider the function

$$F_\delta(t,y) = \frac{\nabla\omega(t,y)}{\sqrt{(1+\delta^2) - \omega^2}}, \quad \delta > 0.$$

As $\delta \to 0$, $|F_\delta|$ is obviously increasing, and we know from the proof of Proposition 3.8 that

$$\int_0^t \int_{\mathcal{Y}} |F_\delta(t,y)|^2 \, dydt \le C \quad (\text{when } \delta \to 0).$$

We deduce that there exists a function $\zeta(t,y) \in L^2(]0,T[\times\mathcal{Y})$ such that $F_\delta \to \zeta$ a.e. on $]0,T[\times\mathcal{Y}$ and strongly in $L^2(]0,T[\times\mathcal{Y})$.

Moreover ζ satisfies

$$\sqrt{1-\omega^2}\zeta = \nabla\omega \qquad \text{a.e. on }]0,T[\times\mathcal{Y}.$$

Now taking the limit $\delta \to 0$, we get from (3.11)

$$A\int_0^t \int_{\mathcal{Y}} \zeta^2 \, dyd\tau = \int_{\mathcal{Y}} S(\overline{\omega})\, dy - \int_{\mathcal{Y}} S(\omega(t))\, dy - A\int_0^t \int_{\mathcal{Y}} \beta(\omega)\omega^2 \, dyd\tau \quad \forall t \ge 0.$$

Since $\mathcal{J}$ is constant on $\Omega(\omega_0)$, we have for all t

$$\int_0^t \int_{\mathcal{Y}} \zeta^2 \, dyd\tau = -\int_0^t \int_{\mathcal{Y}} \beta(\omega)\omega^2 \, dyd\tau.$$

Taking the derivative with respect to t, we get

$$\int_{\mathcal{Y}} \zeta^2 \, dy = -\int_{\mathcal{Y}} \beta(\omega)\omega^2 \, dy \quad \text{for almost all } t \ge 0.$$

Since

$$\int_{\mathcal{Y}} \omega^2 \, dy = \int_{\mathcal{Y}} \nabla\omega \cdot \nabla\psi \, dy = \int_{\mathcal{Y}} \zeta\sqrt{1-\omega^2}\nabla\psi \, dy$$

and

$$-\beta(\omega) = \frac{\int_{\mathcal{Y}} \omega^2 \, dy}{\int_{\mathcal{Y}} (1-\omega^2)|\nabla\psi|^2 \, dy},$$

we get

$$\left(\int_{\mathcal{Y}} \zeta^2 \, dy\right)^{1/2} \left(\int_{\mathcal{Y}} (1-\omega^2)|\nabla\psi|^2 \, dy\right)^{1/2} = \int_{\mathcal{Y}} \sqrt{1-\omega^2}\zeta\cdot\nabla\psi \, dy \quad \text{for almost all } t \ge 0.$$

Due to the Cauchy–Schwarz inequality, this is possible if and only if ζ and $\sqrt{1-\omega^2}\nabla\psi$ are (positively) colinear for almost all $t \ge 0$, which implies that $\nabla\omega$ and $(1-\omega^2)\nabla\psi$ are (positively) colinear a.e. on $\mathcal{Y}$ for almost all $t \ge 0$. But $\omega \in C\big([0,+\infty[, \tilde{H}^1_{per}(\mathcal{Y})\big)$, and we deduce that $\nabla\overline{\omega}$ and $(1-\overline{\omega}^2)\nabla\overline{\psi}$ are (positively) colinear. Now, since $\nabla\overline{\omega} \not\equiv 0$ and $(1-\overline{\omega}^2)\nabla\psi \not\equiv 0$, we have

$$\nabla\overline{\omega} = \lambda(1-\overline{\omega}^2)\nabla\overline{\psi} \quad \text{a.e. on } \mathcal{Y}, \text{ with } \lambda > 0.$$

This implies that $\nabla\overline{\omega} \in L^\infty(\mathcal{Y})^2$ so that $\overline{\omega}$ is Lipschitz continuous.

Let us now prove that $-1 < \overline{\omega} < 1$ on $\mathcal{Y}$. We define $\mathcal{Y}^* = \{y \in \mathcal{Y} : -1 < \overline{\omega}(y) < 1\}$, $\mathcal{Y}^*$ is an open set of $\mathcal{Y}$. Let us assume that $\mathcal{Y}^* \ne \mathcal{Y}$ and take $y^* \in \partial\mathcal{Y}^*$. We denote by $\mathcal{Y}^*_1$ a connected component of $\mathcal{Y}^*$ such that $y^* \in \partial\mathcal{Y}^*_1$.

On $\mathcal{Y}_1^*$ we have

$$\lambda\nabla\overline{\psi} = \frac{\nabla\overline{\omega}}{1-\overline{\omega}^2},$$

i.e.,

$$\nabla\left(\lambda\overline{\psi} - \frac{1}{2}\ln\frac{1+\overline{\omega}}{1-\overline{\omega}}\right) = 0 \quad \text{on} \quad \mathcal{Y}_1^*;$$

that is,

$$\overline{\omega} = \tanh\bigl(\lambda\overline{\psi} + C\bigr),$$

but $\overline{\psi}$ is bounded so that $\overline{\omega}(y)$ cannot converge to 1 or -1 when $y \to y^*$. Thus $\mathcal{Y}^* = \mathcal{Y}$, and the above relationship holds on all $\mathcal{Y}$.

The proof of the last assertion is straightforward. ∎

As a straightforward consequence of Theorem 4.6, we have the following.

COROLLARY 4.7. *Any $\overline{\omega} \in \Omega(\omega_0)$ is a critical point of the variational problem $(\mathcal{V}.\mathcal{P}.)$.*

Remark 4.8. The variational problem $(\mathcal{V}.\mathcal{P}.)$ always has solutions. Indeed, let us take $\omega_0 \in L^2_0(\mathcal{Y})$ such that $-1 \le \omega_0 \le 1$ a.e. We define the set

$$\mathcal{E} = \bigl\{\omega \in L^2_0(\mathcal{Y}) : \quad -1 \le \omega_0 \le 1 \quad \text{a.e. and } \|\omega\|_{\tilde{H}^{-1}_{per}(\mathcal{Y})} = \|\omega_0\|_{\tilde{H}^{-1}_{per}(\mathcal{Y})}\bigr\}.$$

$\mathcal{E}$ is a compact subset of $L^2_0(\mathcal{Y})$ for the weak L^2-topology. Thus, the convex, positive, and weakly lower semicontinuous functional $\mathcal{J}(\omega)$ reaches its infimum on $\mathcal{E}$.

Theorem 4.7 shows that for $\omega_0 \in X \cap \tilde{H}^1_{per}(\mathcal{Y})$, $(\mathcal{V}.\mathcal{P}.)$ has critical points such that $\|\omega\|_{L^\infty(\mathcal{Y})} < 1$. This consequence is not trivial since nothing ensures a priori that the solution ω^* of $(\mathcal{V}.\mathcal{P}.)$ does not reach the values ± 1. ∎

Remark 4.9. Let us consider any critical point $\overline{\omega} \neq 0$ such that

$$\overline{\omega} = \tanh\bigl(\lambda\overline{\psi} + C\bigr), \quad \lambda > 0.$$

Then, we have $\nabla\overline{\omega} = \lambda(1-\overline{\omega}^2)\nabla\overline{\psi}$ on $\mathcal{Y}$ so that

$$\int_{\mathcal{Y}} \nabla\overline{\omega}\cdot\nabla\overline{\psi}\,dy = \lambda\int_{\mathcal{Y}}(1-\overline{\omega}^2)|\nabla\overline{\psi}|^2\,dy < \lambda\int_{\mathcal{Y}}|\nabla\overline{\psi}|^2\,dy,$$

and integrating by parts yields

$$\lambda > \frac{\int_{\mathcal{Y}}\overline{\omega}^2\,dy}{\int_{\mathcal{Y}}\overline{\omega}\overline{\psi}\,dy} \ge 4\pi^2 = \lambda_1,$$

where λ_1 is the first eigenvalue of the operator $\mathcal{A}$.

Since $\overline{\omega}$ is a function of $\overline{\psi}$, we know that it is a stationary solution of incompressible Euler equations. But due to the above inequality we are in a situation where Arnold's stability criterion (see, e.g., chapter 3 in Marchioro and Pulvirenti [8]) does not apply.

Another related consequence is that the classical appeal to the free energy functional for studying $(\mathcal{V}.\mathcal{P}.)$ fails.

Indeed, let us consider the free energy functional

$$\mathcal{F}(\xi) \equiv \mathcal{J}(\xi) - \frac{\lambda}{2}\|\xi\|^2_{\tilde{H}^{-1}_{per}(\mathcal{Y})},$$

defined on $\{\omega \in L^2_0(\mathcal{Y}) : \quad -1 \leq \omega \leq 1 \quad \text{a.e.}\}$.

It is easy to see that for $\lambda > \lambda_1$, $\mathcal{F}(\omega)$ need not be convex.

This situation is a special feature of the periodic geometry which, on one hand, simplifies the study of (1.1), getting rid of some intricacies connected with the boundary conditions. On the other hand it introduces a great complexity in the study of $(\mathcal{V}.\mathcal{P}.)$, describing the statistical equilibrium: we *never* have a case where a simple criterion ensures existence of a unique critical point. The case of a bounded domain with boundary is quite different (see [11], [12], [17]). □

SCATTERING THEORY FOR THE HARTREE EQUATION*

NAKAO HAYASHI†, PAVEL I. NAUMKIN‡, AND TOHRU OZAWA§

Abstract. We study the scattering problem for the Hartree equation

$$i\partial_t u = -\frac{1}{2}\Delta u + f(|u|^2)u, \quad (t,x) \in \mathbf{R}\times\mathbf{R}^n,$$

with initial data $u(0,x) = u_0(x), x \in \mathbf{R}^n$, where $f(|u|^2) = V * |u|^2, V(x) = \lambda|x|^{-1}, \lambda \in \mathbf{R}, n \geq 2$. We prove that for any $u_0 \in H^{0,\gamma} \cap H^{\gamma,0}$, with $\frac{1}{2} < \gamma < \frac{n}{2}$, such that the value $\epsilon = \|u_0\|_{0,\gamma} + \|u_0\|_{\gamma,0}$ is sufficiently small, there exist unique $u_\pm \in H^{\sigma,0} \cap H^{0,\sigma}$ with $\frac{1}{2} < \sigma < \gamma$ such that for all $|t| \geq 1$

$$\left\| u(t) - \exp\left(\mp i f(|\hat{u}_\pm|^2)\left(\frac{x}{t}\right)\log|t|\right) U(t)u_\pm \right\|_{L^2} \leq C\epsilon|t|^{-\mu+7\nu},$$

where $\mu = \min(1, \frac{\gamma}{2})$, $0 < \nu < \min(1, \frac{\gamma-\sigma}{12})$, $\hat{\varphi}$ denotes the Fourier transform of φ, $U(t)$ is the free Schrödinger evolution group, and $H^{m,s}$ is the weighted Sobolev space defined by

$$H^{m,s} = \{\varphi \in \mathcal{S}'; \|\varphi\|_{m,s} = \|(1+|x|^2)^{s/2}(1-\Delta)^{m/2}\varphi\|_{L^2} < \infty\}.$$

1. Introduction.

This paper is devoted to the study of the asymptotic behavior for large time of solutions to the Cauchy problem for the Hartree equation

$$\begin{cases} i\partial_t u = -\frac{1}{2}\Delta u + f(|u|^2)u, \quad (t,x) \in \mathbf{R}\times\mathbf{R}^n, \\ u(0,x) = u_0(x), \quad x \in \mathbf{R}^n, \end{cases} \tag{1.1}$$

where

$$f(|u|^2) = V * |u|^2 = \int V(x-y)|u|^2(y)dy, \quad V(x) = \lambda|x|^{-1}, \quad \lambda \in \mathbf{R}, \quad \text{and} \quad n \geq 2.$$

There is a large amount of literature on the Cauchy problem (1.1) and the asymptotic behavior in time of solutions for (1.1) with $\lambda > 0$ (see [2, 3, 4, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 18, 19, 20, 22]). The nonlinearity in equation (1.1) is critical from the point of view of large time asymptotic behavior of solutions since the L^2 norm of the nonlinear term is not integrable in time at infinity. The scattering problem for (1.1) has been studied in the framework of the nonexistence of scattering states [14] and of the existence of modified wave operators [6]. If the initial data is $u_0, xu_0 \in L^2$. Some time decay estimates of the nonlinearity $f(|u|^2)$ in L^p norms were obtained in [3] by using the pseudoconformal conservation law, and it was proved in papers [18, 19] that for large time the potential $tf(|u(t,tx)|^2)$ behaves as the Coulomb potential $\frac{1}{|x|}$. It

seems that the decay rates of solutions to (1.1) obtained in [3, 4, 8, 9, 11, 13] through the pseudoconformal conservation law are not sufficient to obtain the existence and uniqueness of the modified scattering states (see [16] for a study in this direction). The only exception is [10], where the existence of solutions with the same decay rate as in the free case is proved and the asymptotic profile of the solutions is obtained. In the present paper we propose a new setting for the study of large time behavior of solutions to (1.1) to make clear the connection with the theory of long range scattering for (1.1). Although the method of the present paper follows [10], the argument here is different from the previous one in some respects and requires a number of sharp estimates. Our approach here is based on the sharp L^p estimates of the time decay rate of the solutions to the Cauchy problem (1.1). As far as we know there are no other results concerning the sharp L^p time decay estimates of solutions to the Cauchy problem (1.1) for the critical case in higher space dimensions under consideration. To derive the desired L^p estimates of the solutions we have to introduce a certain phase function since the previous methods [4, 11, 12] based solely on the a priori estimates of the L^2 norm of $(x + it\nabla)u(t)$ without specifying any phase function do not work for the critical case. Also we extensively use an explicit representation of the free Schrödinger evolution group (see formula (1.4) below). We note that the method presented here is general enough since it is also applicable to a wide class of nonlinear Schrödinger equations with derivatives in the nonlinear term.

We denote by $\mathcal{F}\varphi$ or $\hat{\varphi}$ the Fourier transform of φ defined by

$$\mathcal{F}\varphi(\xi) = \frac{1}{(2\pi)^{\frac{n}{2}}} \int e^{-ix\xi}\varphi(x)dx$$

and let $\mathcal{F}^{-1}\varphi(x)$ be the inverse Fourier transform of φ:

$$\mathcal{F}^{-1}\varphi(x) = \frac{1}{(2\pi)^{\frac{n}{2}}} \int e^{ix\xi}\varphi(\xi)d\xi.$$

The free Schrödinger evolution group $U(t) = e^{\frac{it}{2}\Delta}$ is given by

$$U(t)\varphi = \frac{1}{(2\pi it)^{\frac{n}{2}}} \int e^{\frac{i(x-y)^2}{2t}}\varphi(y)dy = \mathcal{F}^{-1}e^{-\frac{it}{2}\xi^2}\mathcal{F}\varphi.$$

We define the weighted Sobolev space $H^{m,s}$ by $H^{m,s} = \{\varphi \in \mathcal{S}'; \|\varphi\|_{m,s} = \|(1 + |x|^2)^{s/2}(1-\Delta)^{m/2}\varphi\| < \infty\}$, where $m, s \in \mathbf{R}$ and $\|\cdot\|$ denotes the usual L^2 norm.

We now state our results in this paper.

THEOREM 1.1. *We assume that $u_0 \in H^{\gamma,0} \cap H^{0,\gamma}$ and $\epsilon = \|u_0\|_{\gamma,0} + \|u_0\|_{0,\gamma}$ is sufficiently small, where $\frac{1}{2} < \gamma < \frac{n}{2}$, $n \geq 2$.*

Then there exists a unique global solution u of the Hartree equation (1.1) *such that $u \in C(\mathbf{R}; H^{\gamma,0} \cap H^{0,\gamma})$ and*

$$\sup_{\alpha\in[\frac{1}{2},\sigma]} \sup_{t\in\mathbf{R}} (1 + |t|)^{\alpha}\|u(t)\|_{p(\alpha)} \leq C\epsilon,$$

where $\frac{1}{2} < \sigma < \gamma$, $p(\alpha) = \frac{2n}{n-2\alpha}$.

THEOREM 1.2. *Let u be the solution of* (1.1) *obtained in Theorem* 1.1.

Then for any initial data u_0 satisfying the conditions of Theorem 1.1, *there exist unique functions $u_\pm \in H^{\sigma,0} \cap H^{0,\sigma}$, $\frac{1}{2} < \sigma < \gamma$, such that for all $|t| \geq 1$*

$$\|u(t) - \exp\left(\mp if(|\hat{u}_\pm|^2)\left(\frac{x}{t}\right)\log|t|\right)U(t)u_\pm\| \leq C\epsilon|t|^{-\mu+7\nu}, \tag{1.2}$$

where $\mu = \min(1, \frac{\gamma}{2})$, $0 < \nu < \min\left(1, \frac{\gamma-\sigma}{12}\right)$.

In the previous paper [10] the following results were shown. When the initial data $u_0 \in H^{\gamma,0} \cap H^{0,\gamma}$, where $\gamma > \frac{n}{2}$, are such that the norm $\epsilon = \|u_0\|_{\gamma,0} + \|u_0\|_{0,\gamma}$ is sufficiently small, then there exists a unique global solution u of the Hartree equation (1.1) such that $u \in C(\mathbf{R}; H^{\gamma,0} \cap H^{0,\gamma})$ and $\|u(t)\|_\infty \le C\epsilon(1+|t|)^{-n/2}$. Moreover there exist unique functions $\Phi \in L^\infty$ and $\hat{u}_+ \in L^\infty \cap L^2$ such that $\| \int_1^t f(|\hat{u}(\tau)|^2)\frac{d\tau}{\tau} - f(|\hat{u}_+|^2)\log t - \Phi\|_\infty \le C\epsilon t^{-\xi\eta}$ and $\|\mathcal{F}(U(-t)u)(t)\exp\left(i\int_1^t f(|\hat{u}(\tau)|^2)\frac{d\tau}{\tau}\right) - \hat{u}_+ e^{i\Phi}\|_k \le C\epsilon t^{-\xi}$ for $t \ge 1$, where $k = 2$ or ∞, $0 < \eta < \frac{2}{n}$, $2\xi + \frac{n}{2} < \gamma$, and $0 < \xi < 1$. Furthermore the following asymptotic formula is valid for large time t uniformly with respect to $x \in \mathbf{R}^n$:

$$u(t,x) = \frac{1}{(2\pi i t)^{\frac{n}{2}}}\hat{u}_+\left(\frac{x}{t}\right)\exp\left(i\frac{x^2}{2t} - if(|\hat{u}_+|^2)\left(\frac{x}{t}\right)\log t\right) + O\left(\epsilon t^{-\frac{n}{2}-\xi\eta}\right) \tag{1.3}$$

with the estimate $\|\mathcal{F}\left(U(-t)u\right)(t) - \hat{u}_+\exp\left(-if\left(|\hat{u}_+|^2\right)\log t\right)\|_k \le C\epsilon t^{-\xi\eta}$, where $k = 2$ or ∞. If we write formula (1.3) in the form

$$u(t,x) = \exp\left(-if(|\hat{u}_+|^2)\left(\frac{x}{t}\right)\log t\right)U(t)u_+ + O\left(\epsilon t^{-\frac{n}{2}-\xi\eta}\right),$$

then we get the inequality

$$\|u(t) - \exp\left(-if(|\hat{u}_+|^2)\left(\frac{x}{t}\right)\log t\right)U(t)u_+\|_\infty \le C\epsilon t^{-\frac{n}{2}-\xi\eta},$$

which is similar to (1.2) but gives the estimate in the uniform norm. The setting in Theorem 1.2 fits more closely to the theory of long-range scattering developed in [6], where the existence of modified wave operators for (1.1) has been proved. Roughly speaking, the result of Theorem 1.2 implies the asymptotic completeness of the modified wave operators. Another advantage of the setting in Theorem 1.2 over the previous one in [10] is that for the L^2 theory of scattering one needs only the requirement $\gamma > \frac{1}{2}$ for the index of the weighted Sobolev spaces as compared to the previous assumption, namely $\gamma > \frac{n}{2}$.

We organize our paper as follows. Below we explain the necessary notations and then in section 2 we give some preliminary results. In Lemma 2.1 we formulate well-known embedding results for the Sobolev spaces. Lemma 2.2 gives the sharp time decay estimate of the L^p norm of the function in terms of the free evolution group $U(t)$. In Lemma 2.3 we prove the estimates of the nonlinearity of equation (1.1) in the weighted Sobolev spaces. In section 3 we prove Theorems 1.1 and 1.2 by using a priori estimates of the solutions obtained in Lemma 3.2 in a space X_T. The function space X_T is the following:

$$X_T = X_T^\nu = \Bigg\{\varphi \in C([-T,T];\mathcal{S}'); |||\varphi|||_{X_T} = \sup_{t\in[-T,T]}(1+|t|)^{-\nu}\|\varphi(t)\|_{\gamma,0}$$
$$+ \sup_{t\in[-T,T]}(1+|t|)^{-\nu}\|U(-t)\varphi(t)\|_{0,\gamma} + \sup_{\alpha\in[\frac{1}{2},\sigma]}\sup_{t\in[-T,T]}(1+|t|)^{\alpha}\|\varphi(t)\|_{p(\alpha)} < \infty\Bigg\},$$

where $p(\alpha) = \frac{2n}{n-2\alpha}$, $\frac{1}{2} < \sigma < \gamma < \frac{n}{2}$, $0 < \nu < \min(1, \frac{\gamma-\sigma}{12})$.

We consider below the case $t > 0$ since the opposite case is treated analogously.

Notation and function spaces. We let $\partial_j = \partial/\partial x_j, \partial^l = \partial_1^{l_1}\cdots\partial_n^{l_n}$, $l \in (\mathbf{N}\cup\{0\})^n$, $M = M(t) = \exp(ix^2/2t)$, $J_j = J_j(t) = (x_j + it\partial_j) = U(t)x_jU(-t)$, $J =$

$(J_1,\dots,J_n)=U(t)xU(-t)$, and $|J|^\zeta=U(t)|x|^\zeta U(-t)$, $\zeta\in[0,\infty)$. We introduce some function spaces. As usual, $L^p=\{\varphi\in\mathcal{S}';\|\varphi\|_p<\infty\}$, where $\|\varphi\|_p=(\int|\varphi(x)|^p dx)^{\frac{1}{p}}$ if $1\le p<\infty$ and $\|\varphi\|_\infty=\mathrm{ess.sup}\{|\varphi(x)|;x\in\mathbf{R}^n\}$ if $p=\infty$. For simplicity we let $\|\varphi\|=\|\varphi\|_2$. The weighted Sobolev space $H_p^{m,s}$ is defined by $H_p^{m,s}=\{\varphi\in\mathcal{S}';\|\varphi\|_{m,s,p}=\|(1+|x|^2)^{s/2}(1-\Delta)^{m/2}\varphi\|_p<\infty\}$, $m,s\in\mathbf{R}$, $1\le p\le\infty$; also for simplicity we denote $H^{m,s}=H_2^{m,s}$, $\|\cdot\|_{m,s}=\|\cdot\|_{m,s,2}$. We let $(\psi,\varphi)=\int\psi\cdot\overline{\varphi}dx$. Denote by $\dot{B}^s_{p,q}$ the homogeneous Besov space with the seminorm

$$\|\psi\|_{\dot{B}^s_{p,q}}=\Big(\int_0^\infty y^{-1-\xi q}\sup_{|z|\le y}\sum_{|k|\le[s]}\|\partial^k(\psi_{(z)}-\psi)\|_p^q dy\Big)^{\frac{1}{q}},$$

where $s=[s]+\xi$, $0<\xi<1$, $\psi_{(z)}(x)=\psi(x+z)$, and $[s]$ is the largest integer less than s. We note that the seminorm of $\dot{B}^\gamma_{2,2}$ is equivalent to that of the homogeneous Sobolev space $\dot{H}^{\gamma,0}$, where $\dot{H}^{s,m}=\{\varphi\in\mathcal{S}';\|\varphi\|_{\dot{H}^{s,m}}=\||x|^s(-\Delta)^{m/2}\varphi\|<\infty\}$ (see [1]). We let $C(I;E)$ be the space of continuous functions from an interval I to a Banach space E. Different positive constants might be denoted by the same letter C.

Note that the free Schrödinger evolution group can be represented as $U(t)=M(t)D(t)\mathcal{F}M(t)$, where $D(t)$ is the dilation operator defined by $(D(t)\psi)(x)=(it)^{-\frac{n}{2}}\psi(\frac{x}{t})$ and

$$U(-t)=M(-t)\mathcal{F}^{-1}D(t)^{-1}M(-t)=M(-t)i^n\mathcal{F}^{-1}D\left(\frac{1}{t}\right)M(-t), \tag{1.4}$$

since $D(t)^{-1}=i^nD(\frac{1}{t})$. By using the above identities we easily get

$$\begin{aligned}J_j(t)&=U(t)x_jU(-t)=M(t)D(t)\mathcal{F}M(t)x_jM(-t)\mathcal{F}^{-\infty}\rangle\backslash\mathcal{D}\left(\frac{\infty}{\sqcup}\right)\mathcal{M}(-\sqcup)\\&=M(t)D(t)i^n(i\partial_j)D\left(\frac{1}{t}\right)M(-t)=M(t)D(t)i^nD\left(\frac{1}{t}\right)(it\partial_j)M(-t)\\&=M(t)(it\partial_j)M(-t)\text{ and }|J|^\zeta(t)=M(t)(-t^2\Delta)^{\frac{\zeta}{2}}M(-t),\zeta\in[0,\infty).\end{aligned}$$

2. Preliminaries.

LEMMA 2.1. *Let q,r be any numbers satisfying $1\le q,r\le\infty$, and let j,m be any real numbers satisfying $0\le j<m$. If $u\in H_r^{m,0}(\mathbf{R}^n)\cap L^q(\mathbf{R}^n)$, then the following inequality is valid:*

$$\|(-\Delta)^{j/2}u\|_p\le C\|(-\Delta)^{m/2}u\|_r^a\|u\|_q^{1-a}, \tag{2.1}$$

where C is a constant depending only on n,m,j,q,r,a. Here $p\ge1$ is such that $\frac{1}{p}=\frac{j}{n}+a(\frac{1}{r}-\frac{m}{n})+\frac{1-a}{q}$ and the parameter a is any from the interval $\frac{j}{m}\le a\le1$, with the following exception: if the value $m-j-\frac{n}{r}$ is a nonnegative integer, then the parameter a is any from the interval $\frac{j}{m}\le a<1$.

For proof of Lemma 2.1, see, e.g., [5, 21].

LEMMA 2.2. *We let $u(t,x)$ be a smooth function. Then we have the estimate*

$$\|u(t)\|_{p(\alpha)}\le C|t|^{-\alpha}\|\mathcal{F}U(-t)u(t)\|_{p(\alpha)}+C|t|^{-\alpha-\varrho}\|U(-t)u(t)\|_{0,\gamma}\text{for}|t|\ge1,$$

where $p(\alpha)=\frac{2n}{n-2\alpha}$, $\alpha\in[\frac{1}{2},\frac{n}{2})$, $n\ge2$, $\varrho\in[0,1]$, $\gamma=\alpha+2\varrho$.

Remark. We will show (see Lemma 3.2 below) that the norm $\|\mathcal{F}U(-t)u(t)\|_{p(\alpha)}$ does not grow with time and the norm $\|U(-t)u(t)\|_{0,\gamma}$ grows a little with time; i.e., it obeys the estimate $\|U(-t)u(t)\|_{0,\gamma} \le C(1+|t|)^{\nu}$, where $0 < \nu < \min(1, \frac{\gamma-\alpha}{12})$. Therefore Lemma 2.2 gives us the estimate of the decay rate of the solution u of the Cauchy problem (1.1).

Proof. We have the identity, with $v(t) = U(-t)u(t)$ and $w(t,x) = (e^{\frac{ix^2}{2t}} - 1)v(t,x)$,

$$\begin{aligned} u(t) = U(t)v(t) &= M(t)D(t)\mathcal{F}v(t) + M(t)D(t)\mathcal{F}\left(M(t)-1\right)v(t) \\ &= \frac{e^{\frac{ix^2}{2t}}}{(2\pi it)^{\frac{n}{2}}} \int e^{-iy\frac{x}{t}} v(t,y) \left(1 + \left(e^{\frac{iy^2}{2t}} - 1\right)\right) dy \\ &= \frac{e^{\frac{ix^2}{2t}}}{(it)^{\frac{n}{2}}} \left(\hat{v}\left(t, \frac{x}{t}\right) + \hat{w}\left(t, \frac{x}{t}\right)\right). \end{aligned} \tag{2.2}$$

We get the estimate

$$\left|e^{\frac{iy^2}{2t}} - 1\right| = 2\left|\sin\frac{y^2}{4t}\right| \le \min\left(2, \frac{|y|^2}{2|t|}\right) \le 2^{1-2\varrho}\frac{|y|^{2\varrho}}{|t|^{\varrho}} \tag{2.3}$$

for any ϱ satisfying $0 \le \varrho \le 1$, and by a direct calculation we see that

$$|f\left(\frac{\cdot}{t}\right)\|_p = |t|^{n/p}\|f\|_p. \tag{2.4}$$

Applying equality (2.4) and estimate (2.3) to identity (2.2) and using Lemma 2.1 with $p = p(\alpha), a = 1, r = 2, j = 0, m = \alpha$, we get

$$\begin{aligned} \|u(t)\|_p &\le C|t|^{-\alpha}(\|\hat{v}(t)\|_p + \|\hat{w}(t)\|_p) \le C|t|^{-\alpha}(\|\hat{v}(t)\|_p + \|\hat{w}(t)\|_{\alpha,0}) \\ &\le C|t|^{-\alpha}(\|\hat{v}(t)\|_p + \|w(t)\|_{0,\alpha}) \le C|t|^{-\alpha}(\|\hat{v}(t)\|_p + |t|^{-\varrho}\|v(t)\|_{0,\gamma}). \end{aligned}$$

This implies the lemma. □

LEMMA 2.3. *We let $u(t,x)$ be a smooth function and $0 < \gamma < \frac{n}{2}$. Then the following estimates are valid*:

$$\left|Im\left(|x|^{\gamma}U(-t)f(|u|^2)u(t), |x|^{\gamma}U(-t)u(t)\right)\right| \le C\|u\|^2_{2n/(n-1)}\|U(-t)u\|^2_{\dot{H}^{0,\gamma}}$$

and

$$\left|Im\left((-\Delta)^{\gamma/2}f(|u|^2)u(t), (-\Delta)^{\gamma/2}U(-t)u(t)\right)\right| \le C\|u\|^2_{2n/(n-1)}\|u\|^2_{\dot{H}^{\gamma,0}}.$$

Proof. Let us only consider the case $0 < \gamma < 1$ since the other cases are treated analogously. By the relation $M(t)(-t^2\Delta)^{\gamma/2}M(-t) = U(t)|x|^{\gamma}U(-t)$, we have, with $g = M(-t)u$ and $f = f(|u|^2) = f(|g|^2)$,

$$\begin{aligned} &|\ \mathrm{Im}\left(|x|^{\gamma}U(-t)f(|u|^2)u, |x|^{\gamma}U(-t)u\right)\ | = \left|\mathrm{Im}\left((-t^2\Delta)^{\gamma/2}fg, (-t^2\Delta)^{\gamma/2}g\right)\right| \\ &= \left|\mathrm{Im}\left((-t^2\Delta)^{\gamma/2}fg - f(-t^2\Delta)^{\gamma/2}g, (-t^2\Delta)^{\gamma/2}g\right)\right| \\ &\le C\|g\|_{2n/(n-2\gamma)}\|(-t^2\Delta)^{\gamma/2}f\|_{n/\gamma}\|(-t^2\Delta)^{\gamma/2}g\|, \end{aligned}$$

where we have used the fractional Leibniz rule which is proved in [17]. Since $f = V * |u|^2 = C(-\Delta)^{-(n-1)/2}|g|^2$ with a certain constant C (see [21]) we obtain by

Lemma 2.1, with $j=0$, $m=n-1-\gamma$, $p=\frac{n}{\gamma}$, $r=\frac{n}{n-1}$, $a=1$,

$$\begin{aligned}&\left|\mathrm{Im}\left(|x|^\gamma U(-t)(V*|u|^2)u, |x|^\gamma U(-t)u\right)\right|\\&\le C|t|^\gamma\|g\|_{2n/(n-2\gamma)}\|(-\Delta)^{-(n-1-\gamma)/2}|g|^2\|_{n/\gamma}\||x|^\gamma U(-t)u\|\\&\le C|t|^\gamma\|g\|_{2n/(n-2\gamma)}\|u\|^2_{2n/(n-1)}\||x|^\gamma U(-t)u\|\\&\le C\|u\|^2_{2n/(n-1)}\|U(-t)u\|^2_{H^{0,\gamma}}.\end{aligned}$$

The second estimate of the lemma follows from the same argument as in the proof of the first one, so we omit it. □

3. Proofs of Theorems 1.1 and 1.2. Below we follow the notation in the statement of Theorems 1.1 and 1.2 without further comments. To clarify the idea of the proof of the theorems we only show a priori estimates of local solutions to (1.1). For that purpose we use the following local existence theorem.

THEOREM 3.1. *We assume that the initial data $u_0\in H^{\gamma,0}\cap H^{0,\gamma}$, where $\frac{1}{2}<\gamma<\frac{n}{2}$, are such that the norm $\epsilon=\|u_0\|_{\gamma,0}+\|u_0\|_{0,\gamma}$ is sufficiently small. Then there exists a finite time interval $[-T,T]$ with $T>1$ such that there exists a unique solution $u\in C([-T,T];H^{\gamma,0}\cap H^{0,\gamma})$ of the Cauchy problem* (1.1).

For the proof of Theorem 3.1, see, e.g., [3, 8, 15].

LEMMA 3.2. *Let u be the local solutions to* (1.1) *stated in Theorem* 3.1. *Then for all $t\in[-T,T]$ we have the following estimates*:

$$(1+|t|)^{-\nu}(\|u(t)\|_{\gamma,0}+\|U(-t)u(t)\|_{0,\gamma})<2\epsilon \tag{3.1}$$

and

$$\sup_{\alpha\in[\frac{1}{2},\sigma]}(1+|t|)^{\alpha}\|u(t)\|_{p(\alpha)}<\sqrt{\epsilon}, \tag{3.2}$$

where $\frac{1}{2}<\sigma<\gamma$, $p(\alpha)=\frac{2n}{n-2\alpha}$.

Proof. On the contrary, let at least one of the estimates (3.1) or (3.2) be violated in the whole time interval $[-T,T]$. Via the continuity of the norms in the left-hand sides of (3.1) and (3.2), we can find a maximal-time interval $[-T_0,T_0]$ such that

$$\begin{aligned}&(1+|t|)^{-\nu}(\|u(t)\|_{\gamma,0}+\|U(-t)u(t)\|_{0,\gamma})\le 2\epsilon \text{ and}\\&\qquad\sup_{\alpha\in[\frac{1}{2},\sigma]}(1+|t|)^{\alpha}\|u(t)\|_{p(\alpha)}\le\sqrt{\epsilon}\end{aligned} \tag{3.3}$$

for all $t\in[-T_0,T_0]$. By using the commutation relation $[L,|J|^\gamma]=0$, where $L=i\partial_t+\frac{1}{2}\Delta$, we get from the Hartree equation (1.1) $L|J|^\gamma u=|J|^\gamma f(|u|^2)u$. Multiplying both sides of this equation by $\overline{|J|^\gamma u}$ and using Lemma 2.3, we obtain

$$\||J|^\gamma u(t)\|^2\le\||x|^\gamma u_0\|^2+C\int_0^t\|u(s)\|^2_{2n/(n-1)}\||J|^\gamma u(s)\|^2ds.$$

We use the estimate $\|u(t)\|_{p(\frac{1}{2})}\le 2\sqrt{\epsilon}(1+|t|)^{-\frac{1}{2}}$, which follows from (3.3), to get

$$\||J|^\gamma u(t)\|^2\le\||x|^\gamma u_0\|^2+C\epsilon\int_0^t(1+s)^{-1}\||J|^\gamma u(s)\|^2ds,$$

whence via Gronwall's inequality we find the estimate $\||J|^\gamma u(t)\| \le \||x|^\gamma u_0\|(1+t)^\nu$, which implies

$$(1+t)^{-\nu}\||x|^\gamma U(-t)u(t)\| \le \||x|^\gamma u_0\|. \tag{3.4}$$

Here ν is given explicitly by $\nu = C\epsilon$, where C is the same as above and therefore dependent only on n and γ. We may therefore take ν as small as we like by taking ϵ sufficiently small. In particular, we may always take ν in the range as in the statement of the theorem at the cost of taking ϵ accordingly small. In the same way as in the proof of (3.4), we have $(1+t)^{-\nu}\|u(t)\|_{\gamma,0} \le \|u_0\|_{\gamma,0}$, whence the first estimate (3.1) of the lemma follows on the time interval$[-T_0, T_0]$. By Lemma 2.1 and estimate (3.3) we have

$$\sup_{\alpha\in[\frac12,\sigma]}\sup_{t\in[-1,1]}(1+|t|)^\alpha\|u(t)\|_{p(\alpha)} \le C\epsilon < \sqrt{\epsilon}. \tag{3.5}$$

Now let us consider $t \ge 1$. From Lemma 2.2 and estimate (3.3) it follows that

$$\|u(t)\|_{p(\alpha)} \le C\epsilon t^{-\alpha-\beta+\nu} + Ct^{-\alpha}\|\mathcal{F}U(-t)u(t)\|_{p(\alpha)} \tag{3.6}$$

for any $\alpha \in [\frac12, \sigma]$, where $\beta = \min(1, \frac{\gamma-\sigma}{2})$, $0 < \nu < \beta/6$. Multiplying both sides of (1.1) by $U(-t)$, we obtain $i(U(-t)u(t))_t + U(-t)f(|u|^2)u = 0$, whence in view of identity (1.4) we have

$$i\hat v_t - t^{-1}f(|\hat v|^2)\hat v = t^{-1}\left(I_1(t) + I_2(t)\right), \tag{3.7}$$

where

$$I_1(t) = \mathcal{F}\left(M(-t) - 1\right)\mathcal{F}^{-1}f\left(|\mathcal{F}M(t)v|^2\right)\mathcal{F}M(t)v,$$

$$I_2(t) = f\left(|\mathcal{F}M(t)v|^2\right)\mathcal{F}M(t)v - f(|\hat v|^2)\hat v.$$

Introducing a new dependent variable $\hat w = \hat v B(t)$, where $B(t) = \exp(i\int_1^t f(|\hat v|^2)\frac{d\tau}{\tau})$, we write (3.7) in the form $i\hat w_t = B(t)t^{-1}\left(I_1(t) + I_2(t)\right)$, whence, integrating with respect to t from 1 to t, we get

$$\hat w(t) = \hat w(1) - i\int_1^t B(\tau)\left(I_1(\tau) + I_2(\tau)\right)\frac{d\tau}{\tau}. \tag{3.8}$$

In the same way as in the proof of Lemma 2.3, we have, with $\frac12 < \theta \le \gamma$ (we now let $\gamma < 1$ since the case $1 \le \gamma < \frac{n}{2}$ is treated analogously),

$$\begin{aligned}
\|f(h_1h_2)h_3\|_{\theta,0} &\le C(\|f\|_\infty\|h_3\| + \|(-\Delta)^{\theta/2}(fh_3)\|)\\
&\le C(\|f\|_\infty\|h_3\| + \|(-\Delta)^{\theta/2}(fh_3) - f(-\Delta)^{\theta/2}h_3\| + \|f(-\Delta)^{\theta/2}h_3\|)\\
&\le C(\|f\|_\infty\|h_3\|_{\theta,0} + \|h_3\|_{p(\theta)}\|(-\Delta)^{\theta/2}f\|_{n/\theta})\\
&\le C(\|f\|_\infty\|h_3\|_{\theta,0} + \|h_3\|_{p(\theta)}\|(-\Delta)^{-(n-1-\theta)/2}h_1h_2\|_{n/\theta})\\
&\le C\|h_3\|_{\theta,0}(\|f\|_\infty + \|h_1\|_{p(\frac12)}\|h_2\|_{p(\frac12)})\\
&\le C\|h_3\|_{\theta,0}(\|h_1\|_q\|h_2\|_q + \|h_1\|_r\|h_2\|_r + \|h_1\|_{\frac12,0}\|h_2\|_{\frac12,0}) \le C\prod_{j=1}^3\|h_j\|_{\theta,0},
\end{aligned} \tag{3.9}$$

where $q < p(\frac{1}{2}) < r < p(\theta)$. We use (3.9) and (2.3) to obtain, with $h = M(t)v$ and $0 \le \theta \le \sigma$,

$$\begin{aligned}\|I_1(t)\|_{\theta,0} &\le C\|\mathcal{F}\left(M(-t)-1\right)\mathcal{F}^{-1}f(|\hat{h}|^2)\hat{h}\|_{\theta,0} \le Ct^{-\omega}\|\mathcal{F}^{-1}f(|\hat{h}|^2)\hat{h}\|_{0,\gamma}\\ &\le Ct^{-\omega}\|f(|\hat{h}|^2)\hat{h}\|_{\gamma,0} \le Ct^{-\omega}\|\hat{h}\|_{\gamma,0}^3 \le Ct^{-\omega}\|v\|_{0,\gamma}^3, \qquad (3.10)\end{aligned}$$

where $\omega = \min(1, \frac{\gamma-\theta}{2})$. We easily see that

$$f(|\hat{h}|^2)\hat{h} - f(|\hat{v}|^2)\hat{v} = f(|\hat{h}|^2)(\hat{h}-\hat{v}) + f\left((\hat{h}-\hat{v})\overline{\hat{h}}\right)\hat{v} + f\left((\overline{\hat{h}}-\overline{\hat{v}})\hat{v}\right)\hat{v},$$

whence, by virtue of (3.10) and using (2.3) and Lemma 2.1, we obtain

$$\begin{aligned}\|I_2(t)\|_{\sigma,0} &= \|f(|\hat{h}|^2)\hat{h} - f(|\hat{v}|^2)\hat{v}\|_{\sigma,0} \le C\|\hat{h}-\hat{v}\|_{\sigma,0}\left(\|\hat{h}\|_{\sigma,0}^2 + \|\hat{v}\|_{\sigma,0}^2\right)\\ &\le C\|\left(M(t)-1\right)v\|_{0,\sigma}\|v\|_{0,\sigma}^2 \le Ct^{-\beta}\|v\|_{0,\gamma}^3, \qquad (3.11)\end{aligned}$$

where $\frac{1}{2} < \sigma < \gamma < \frac{n}{2}$, $\beta = \min(1, \frac{\gamma-\sigma}{2})$. By (3.8), (3.10), (3.11), and estimate (3.3) we have

$$\begin{aligned}\|\mathcal{F}U(-t)u\|_{p(\alpha)} &= \|\hat{v}\|_{p(\alpha)} = \|\hat{w}\|_{p(\alpha)} \le C\epsilon + C\int_1^t \left(\|I_1(\tau)\|_{p(\alpha)} + \|I_2(\tau)\|_{p(\alpha)}\right)\frac{d\tau}{\tau}\\ &\le C\epsilon + C\int_1^t \left(\|I_1(\tau)\|_{\alpha,0} + \|I_2(\tau)\|_{\alpha,0}\right)\frac{d\tau}{\tau} \le C\epsilon\int_1^t \tau^{-1-\beta+3\nu}d\tau \le C\epsilon. \qquad (3.12)\end{aligned}$$

We apply (3.12) to (3.6) to get the estimate (3.2) on the interval $[-T_0, T_0]$. The contradiction obtained proves the estimates (3.1) and (3.2) on the whole-time interval $[-T, T]$ of the existence of solutions u to the Cauchy problem (1.1). Lemma 3.2 is proved. □

We are now in a position to prove Theorems 1.1 and 1.2.

Proof of Theorem 1.1. We have by Lemma 3.2

$$|||u|||_{X_T} \le 2\epsilon + \sqrt{\epsilon}.$$

Then the standard continuation argument yields the result. □

Proof of Theorem 1.2. By (3.8), (3.10), (3.11), and Theorem 1.1 we have

$$\|\hat{w}(t) - \hat{w}(s)\|_{\sigma,0} \le C\epsilon s^{-\beta+3\nu} \qquad (3.13)$$

for $t > s \ge 1$, where $\frac{1}{2} < \sigma < \gamma$, $\beta = \min(1, \frac{\gamma-\sigma}{2})$, $0 < \nu < \beta/6$. Therefore we find that there exists a unique function $\hat{w}_+ \in H^{\sigma,0}$ such that

$$\|\hat{w}(t) - \hat{w}_+\|_{\sigma,0} \le C\epsilon t^{-\beta+3\nu}. \qquad (3.14)$$

In the same way as in the proof of (3.9) and (3.11) we have

$$\|I_1(t)\|_{0,\sigma} + \|I_2(t)\|_{0,\sigma} \le Ct^{-\beta}(\|v\|_{0,\gamma} + \|v\|_{\gamma,0})^3 \le C\epsilon t^{-\beta+3\nu}. \qquad (3.15)$$

Hence from (3.8) we see that $\hat{w}_+ \in H^{0,\sigma}$ and

$$\|\hat{w}(t) - \hat{w}_+\|_{0,\sigma} \le C\epsilon t^{-\beta+3\nu}. \qquad (3.16)$$

By Lemma 2.1, with $p = 2n$, $j = 0$, $a = 1$, $m = n-1$, $r = \frac{2n}{2n-1}$, we find that

$$\begin{aligned} \|f(h_1h_2)\|_{2n} &= C\|(-\Delta)^{-(n-1)/2}(h_1h_2)\|_{2n} \\ &\le C\|h_1\|\|h_2\|_{p(\frac12)} \le C\|h_1\|\|h_2\|_{\frac12,0}. \end{aligned} \tag{3.17}$$

Let us now consider the case $\frac12 < \sigma < 1$. The other cases can be treated analogously. We use estimate (3.17) to get the following estimate with $\frac12 < \sigma < \gamma$:

$$\begin{aligned} \|f(h_1h_2)\|_{\dot B^\sigma_{2n,2}} &= \bigg(\int_0^\infty y^{-1-2\sigma} \sup_{|z|\le y} \|(f_{(z)} - f)\|_{2n}^2 dy\bigg)^{1/2} \\ &\le C\|h_2\|_{\frac12,0}\bigg(\int_0^\infty y^{-1-2\sigma} \sup_{|z|\le y} \|(h_{1(z)} - h_1)\|^2 dy\bigg)^{1/2} \\ &\quad + C\|h_1\|_{\frac12,0}\bigg(\int_0^\infty y^{-1-2\sigma} \sup_{|z|\le y} \|(h_{2(z)} - h_2)\|^2 dy\bigg)^{1/2} \\ &\le C\|h_1\|_{\sigma,0}\|h_2\|_{\sigma,0}, \end{aligned} \tag{3.18}$$

whence we obtain

$$\begin{aligned} &\|f(|\hat w(t)|^2) - f(|\hat w(s)|^2)\|_{\dot B^\sigma_{2n,2}} = \Big\| f\left((\hat w(t) - \hat w(s))\,\overline{\hat w(t)}\right) \\ &\quad + f\left((\overline{\hat w(t)} - \overline{\hat w(s)})\hat w(s)\right)\Big\|_{\dot B^\sigma_{2n,2}} \le C\|\hat w(t) - \hat w(s)\|_{\sigma,0}(\|\hat w(t)\|_{\sigma,0} + \|\hat w(s)\|_{\sigma,0}) \\ &\le Cs^{-\beta+6\nu}(\|u_0\|_{0,\gamma} + \|u_0\|_{\gamma,0}) \end{aligned} \tag{3.19}$$

for all $1 < s < t$, where $\beta = \min(1, \frac{\gamma-\sigma}{2})$, $0 < \nu < \beta/6$.

We now let $\Psi(t) = \int_1^t \left(f(|\hat w(\tau)|^2) - f(|\hat w(t)|^2)\right)\frac{d\tau}{\tau}$. Then

$$\begin{aligned} \Psi(t) - \Psi(s) &= \int_s^t \left(f(|\hat w(\tau)|^2) - f(|\hat w(t)|^2)\right)\frac{d\tau}{\tau} \\ &\quad - \left(f(|\hat w(t)|^2) - f(|\hat w(s)|^2)\right)\log s, \end{aligned} \tag{3.20}$$

where $1 < s < \tau < t$. We apply (3.19) to (3.20) to get, for all $1 < s < t$,

$$\|\Psi(t) - \Psi(s)\|_{\dot B^\sigma_{2n,2}} \le C\epsilon s^{-\beta+6\nu}. \tag{3.21}$$

This implies that there exists a unique real-valued function $\Phi \in \dot B^\sigma_{2n,2}$ such that $\lim_{t\to\infty}\Psi(t) = \Phi$ in $\dot B^\sigma_{2n,2}$. We let $t \to \infty$ in (3.21). Then

$$\|\Phi - \Psi(t)\|_{\dot B^\sigma_{2n,2}} \le C\epsilon t^{-\beta+6\nu}. \tag{3.22}$$

We note that $\hat u_+ = \hat w_+ \exp(-i\Phi)$. (For the function $\hat u_-$, analogously we have $\hat u_- = \overline{\hat w_+}\exp(i\Phi)$.) By the facts that $\Phi \in \dot B^\sigma_{2n,2}$, $\hat w_+ \in H^{\sigma,0}\cap H^{0,\sigma}$, and Lemma 2.1, we see that $\hat u_+ \in H^{\sigma,0}\cap H^{0,\sigma}$, and we also have the following by Theorem 1.1, (3.14), (3.21), and (3.22):

$$\begin{aligned} \|u_+\|_{0,\sigma} &= \|\hat u_+\|_{\sigma,0} = \|\exp(i\Phi)\hat w_+\|_{\sigma,0} \le C(\|w_+\| + \|\hat w_+\exp(i\Phi)\|_{\dot B^\sigma_{2,2}}) \\ &\le C\epsilon + C\bigg(\int_0^\infty y^{-1-2\sigma}\sup_{|z|\le y}\|(\hat w_{+(z)} - \hat w_+)\exp(i\Phi_{(z)})\|^2 dy\bigg)^{\frac12} \\ &\quad + C\|\hat w_+\|_{p(\frac12)}\bigg(\int_0^\infty y^{-1-2\sigma}\sup_{|z|\le y}\|\Phi_{(z)} - \Phi\|_{2n}^2 dy\bigg)^{\frac12} \\ &\le C\epsilon + C\|\hat w_+\|_{\sigma,0} + C\|\hat w_+\|_{\frac12,0}\|\Phi\|_{\dot B^\sigma_{2n,2}} \le C\epsilon. \end{aligned} \tag{3.23}$$

We easily find that the following identity holds:

$$\int_1^t f(|\hat{w}(\tau)|^2)\frac{d\tau}{\tau} = f(|\hat{w}_+|^2)\log t + \Phi + (\Psi(t)-\Phi) + \left(f(|\hat{w}(t)|^2) - f(|\hat{w}_+|^2)\right)\log t. \tag{3.24}$$

In the same way as in the proof of (3.11), (3.17), we have

$$\begin{aligned}\|I_2(t)\| &= \|f(|\hat{h}|^2)\hat{h} - f(|\hat{v}|^2)\hat{v}\| \le \|\hat{h}-\hat{v}\|\|f(|\hat{h}|^2)\|_\infty \\ &\quad + \|\hat{v}\|_{p(\frac{1}{2})}\left(\|f\left((\hat{h}-\hat{v})\overline{\hat{h}}\right)\|_{2n} + \|f\left((\overline{\hat{h}}-\overline{\hat{v}})\hat{v}\right)\|_{2n}\right) \\ &\le C\|\hat{h}-\hat{v}\|\left(\|\hat{h}\|_{\sigma,0}^2 + \|\hat{v}\|_{\sigma,0}^2\right) \le C\|\left(M(t)-1\right)v\|\|v\|_{0,\sigma}^2 \\ &\le Ct^{-\mu}\|v\|_{0,\gamma}^3 \le Ct^{-\mu+3\nu}\left(\|v\|_{0,\gamma}+\|v\|_{\gamma,0}\right)^3 \le C\epsilon t^{-\mu+3\nu}, \end{aligned} \tag{3.25}$$

where $\mu = \min(1, \frac{\gamma}{2})$. Hence by virtue of (3.10) with $\theta = 0$ and (3.25) we see from (3.8) that

$$\|\hat{w}(t) - \hat{w}_+\| \le C\epsilon t^{-\mu+3\nu}. \tag{3.26}$$

Using (3.17) and (3.26), analogously to (3.19) we get

$$\begin{aligned}\|f(|\hat{w}(t)|^2) - f(|\hat{w}(s)|^2)\|_{2n} &= \|f\left((\hat{w}(t)-\hat{w}(s))\overline{\hat{w}(t)}\right) + f\left((\overline{\hat{w}(t)}-\overline{\hat{w}(s)})\hat{w}(s)\right)\|_{2n} \\ &\le C\|\hat{w}(t)-\hat{w}(s)\|\left(\|\hat{w}(t)\|_{p(\frac{1}{2})} + \|\hat{w}(s)\|_{p(\frac{1}{2})}\right) \\ &\le Cs^{-\mu+6\nu}\left(\|u_0\|_{0,\gamma} + \|u_0\|_{\gamma,0}\right), \end{aligned} \tag{3.27}$$

and therefore we obtain

$$\|\Phi - \Psi(t)\|_{2n} \le C\epsilon t^{-\mu+6\nu}. \tag{3.28}$$

By (3.24), (3.27), and (3.28) we have

$$\left\|\int_1^t f(|\hat{w}(\tau)|^2)\frac{d\tau}{\tau} - f(|\hat{w}_+|^2)\log t - \Phi\right\|_{2n} \le C\epsilon t^{-\mu+7\nu}. \tag{3.29}$$

Since $\hat{w}(t) = B(t)\mathcal{F}U(-t)u(t) = \exp(i\int_1^t f(|\hat{w}(\tau)|^2)\frac{d\tau}{\tau})\mathcal{F}U(-t)u(t)$, we have, in view of (3.14), (3.26), and (3.29),

$$\begin{aligned}&\|\mathcal{F}U(-t)u(t) - \hat{u}_+\exp\left(-if(|\hat{u}_+|^2)\log t\right)\| \\ &= \left\|\hat{w}(t)\exp\left(-i\int_1^t f(|\hat{w}(\tau)|^2)\frac{d\tau}{\tau}\right) - \hat{u}_+\exp\left(-if(|\hat{u}_+|^2)\log t\right)\right\| \\ &\le \left\|\hat{w}(t)-\hat{w}_+\| + C\|\left(\int_1^t f(|\hat{w}(\tau)|^2)\frac{d\tau}{\tau} - f(|\hat{u}_+|^2)\log t - \Phi\right)\hat{w}_+\right\| \\ &\le C\epsilon t^{3\nu-\mu} + C\left\|\hat{w}_+\|_{p(\frac{1}{2})}\|\int_1^t f(|\hat{w}(\tau)|^2)\frac{d\tau}{\tau} - f(|\hat{w}_+|^2)\log t - \Phi\right\|_{2n} \\ &\le C\epsilon t^{7\nu-\mu}. \end{aligned} \tag{3.30}$$

By (2.3) and Theorem 1.1 we get

$$\begin{aligned}\|u(t) - M(t)D(t)\mathcal{F}U(-t)u(t)\| &= \|M(t)D(t)\mathcal{F}\left(M(t)-1\right)U(-t)u(t)\| \\ &= \|\left(M(t)-1\right)U(-t)u(t)\| \le Ct^{-\mu}\|U(-t)u(t)\|_{0,\gamma} \le C\epsilon t^{-\mu+\nu}. \end{aligned} \tag{3.31}$$

Via (3.23), (3.30), and (3.31) it follows that

$$\begin{aligned}
&\|u(t) - \exp\left(-if\left(|\hat{u}_+|^2\right)\left(\frac{x}{t}\right)\log t\right)U(t)u_+\| \\
&\quad = \|u(t) - M(t)D(t)\exp\left(-if(|\hat{u}_+|^2)\log t\right)\mathcal{F}M(t)u_+\| \\
&\quad \le \|u(t) - M(t)D(t)\mathcal{F}U(-t)u(t)\| \\
&\quad + \|M(t)D(t)\left(\mathcal{F}U(-t)u(t) - \hat{u}_+\exp\left(-if(|\hat{u}_+|^2)\log t\right)\right)\| \\
&\quad + \|M(t)D(t)\exp\left(-if(|\hat{u}_+|^2)\log t\right)\mathcal{F}\left(M(t)-1\right)u_+\| \\
&\quad \le C\epsilon t^{7\nu-\mu} + Ct^{7\nu-\mu}\|u_+\|_{0,\sigma} \le C\epsilon t^{7\nu-\mu}. \qquad (3.32)
\end{aligned}$$

From (3.32), Theorem 1.2 follows. □

Acknowledgments. The authors would like to thank the referee for letting us know of some recent works on the asymptotic behavior of solutions of Schrödinger–Poisson equation [3, 18, 19] and for useful comments. P. Naumkin is grateful to Instituto de Física y Matemáticas de Universidad Michoacana for kind hospitality.

POROUS MEDIUM EQUATION WITH ABSORPTION*

CATHERINE BANDLE†, TOKUMORI NANBU‡, AND IVAR STAKGOLD§

Abstract. We study the approach to the steady state for the porous medium equation with absorption under positive, time-independent, Dirichlet boundary conditions. Special attention is given to the case where the solution of the steady-state problem vanishes in an interior region (known as a dead core.) The results are compared to those for the heat equation with absorption.

Key words. reaction-diffusion, porous medium, dead core

1. Introduction.

We shall study the asymptotic behavior of the solution of the initial-boundary value problem for a generalization of the porous medium equation with absorption. The porous medium occupies a bounded domain Ω and the solution obeys Dirichlet boundary conditions independent of time. Our goal is to describe how the solution $u(x,t)$ of the evolution problem tends to its steady state $\phi(x)$. In applications, u is either a concentration or a temperature required to be nonnegative; either physical interpretation will be used as is convenient.

Although we are mainly interested in the case of positive Dirichlet conditions, let us begin with some remarks for the case of zero boundary conditions. The steady state then vanishes identically and the possibility of *extinction in finite time* arises: is there a time T such that $u(x,t) \equiv 0$ for all x and $t \geq T$? It is known (see [13] and [16]; for the heat equation, see [11] and [15]) that extinction in finite time occurs when the absorption is strong or the diffusion is fast (see below for the definition of these terms).

By contrast, when the boundary values are positive, the steady state does not vanish identically and one can no longer expect $u(x,t)$ to coincide with $\phi(x)$ beyond some finite time. If, however, $\phi(x)$ vanishes in an interior region D, known as a *dead core*, then $u(x,t)$ may also vanish in a time-dependent dead core $D(t)$ whose relationship to D is one of the objects of our study. For the heat equation with absorption, we showed in [3] that a dead core for the stationary problem can occur only if the absorption is strong, and then the corresponding evolution problem for large t always has a dead core $D(t)$ which, for typical initial and boundary conditions, expands to D as $t \to \infty$; whether or not there is a steady core, Ricci [18] proved that the supnorm $\|u(x,t) - \phi(x)\|$ decays exponentially in time when the absorption is of power-law type. For the porous medium equation with absorption, we shall show that the existence of a nonempty D no longer guarantees that $D(t)$ is nonempty for large t, but if $D(t)$ is nonempty, then again $D(t) \to D$ as $t \to \infty$.

In the next section we formulate the problem more precisely and introduce the familiar model problem with power-law diffusion and absorption. We briefly discuss existence and uniqueness and define the notions of sub- and supersolution. In section 3 we state some monotonicity theorems and use the nondiffusive (lumped-parameter) problem and the steady-state problem to obtain the bounds needed in section 4, where we prove the principal theorem relating the evolutionary and stationary dead cores. In section 5 we establish decay estimates and find that there are cases when $\|u(x,t) - \phi(x)\|$ does not decay exponentially in time, in contrast with the one-dimensional treatment given by Ricci and Tarzia [19], where the assumptions made always led to exponential decay.

2. Formulation and model problem. We consider the following initial-boundary value problem for $u(x,t)$:

$$u_t - \Delta(A(u)) = -\lambda f(u) \qquad \text{in } Q = \Omega \times R^+ \tag{2.1}$$

subject to the boundary condition

$$u(x,t) = \chi(x) \geq 0 \qquad \text{on } \Gamma = \partial\Omega \times R^+ \tag{2.2}$$

and the initial condition

$$u(x,0) = u_0(x) \text{ in } \Omega, \qquad \text{with } 0 \leq u_0(x) \leq 1. \tag{2.3}$$

Here $\chi(x)$ is continuous on Γ and $u_0(x)$ can be extended to a continuous function on $\bar{\Omega}$, satisfying the compatibility condition

$$u_0(x) = \chi(x), \ x \in \partial\Omega.$$

The physical domain Ω is either an open interval in R^1 or a bounded, arcwise connected domain in $R^N (N > 1)$ whose boundary is of class C^3; $\lambda \in R^+$; Δ denotes the N-dimensional Laplace operator.

The function $A \geq 0$ characterizes the diffusion and $f \geq 0$ characterizes the absorption. Writing

$$\Delta(A(u)) = \text{ div } (A'(u)\text{grad}u),$$

we recognize the diffusion coefficient (or thermal conductivity) as $A'(u)$. We shall choose A and f to generalize the *model* equation

$$u_t - \Delta(u^m) = -\lambda u^p, \quad m > 0, \quad p > 0. \tag{2.4}$$

The following terminology for (2.4) is now fairly standard and stems from the behavior of the diffusion and absorption near $u = 0$:

$m < 1$	fast-diffusion equation,
$m = 1$	heat equation,
$m > 1$	porous-medium equation,
$p < 1$	strong absorption,
$p \geq 1$	weak absorption.

Note that if $p < 1$, the absorption is non-Lipschitz at $u = 0$; if $m < 1$, the diffusion coefficient mu^{m-1} is infinite at $u = 0$. For (2.1) we make the following definitions

consistent with the model problem:

$$\int_0^\epsilon \frac{1}{A(s)} ds < \infty \quad \Longleftrightarrow \text{fast diffusion}, \tag{2.5}$$

$$\int_0^\epsilon \frac{1}{f(s)} ds < \infty \quad \Longleftrightarrow \text{strong absorption}. \tag{2.6}$$

If the integrals are infinite, we speak, respectively, of slow diffusion and weak absorption. Thus, the heat equation would fall in the category of slow diffusion.

When $\chi(x) \equiv 0$ in (2.2), the steady state vanishes and $u(x,t)$ tends to zero as $t \to \infty$. Fast diffusion *or* strong absorption yields extinction in finite time (see [13] for a survey; the best necessary condition can be found in [16]). We can perhaps understand this phenomenon by the following qualitative argument. For small u, the absorption is still relatively large in the case of strong absorption and will tend to drive the solution more quickly to zero than in the case of weak absorption. Fast diffusion has the same effect: for small u, the diffusion is large and creates a large flux of concentration directed toward the lower concentration (= zero) on the boundary. If $\chi(x)$ is not identically zero in (2.2), the corresponding steady state $\phi(x)$ does not vanish identically, but it is still true that $u(x,t)$ tends to $\phi(x)$ as t approaches infinity. We see that fast diffusion no longer tends to lower the interior concentration. Indeed, suppose $\chi(x) \equiv 1$; then diffusion will generate a flux from the boundary to the smaller interior concentration and fast diffusion will serve to counteract absorption rather than to reinforce it, as was the case when $\chi(x) \equiv 0$. We shall therefore be more interested in slow diffusion and we shall impose the following conditions on $A(u)$ that generalize the case $m \geq 1$ for the model problem:

$$(P_A) \qquad \begin{cases} A(u) \in C^1[0,\infty) \cap C^2(0,\infty); \\ A'(u) > 0, \quad A''(u) \geq 0 \quad (u > 0); \\ A(0) = 0, \quad A'(0) \geq 0, \quad A(1) = 1. \end{cases}$$

Note that $A'(0)$ is finite so that the integral in (2.5) is indeed infinite.

For the absorption f, we impose the following conditions, which generalize the model problem:

$$(P_f) \qquad \begin{cases} f \in C[0,\infty) \cap C^2(0,\infty), \\ f(0) = 0, \quad f(1) = 1, \quad f'(s) > 0 \quad (s > 0). \end{cases}$$

The function

$$g(s) = f(A^{-1}(s)) \tag{2.7}$$

plays a role in the analysis of the steady-state problem

$$-\Delta(A(\phi)) = -\lambda f(\phi) \text{ in } \Omega, \quad \phi(x) = \chi(x) \text{ on } \partial\Omega. \tag{2.8}$$

Setting $\Phi = A(\phi)$, (2.8) reduces to

$$-\Delta\Phi = -\lambda g(\Phi) \text{ in } \Omega, \quad \Phi = A^{-1}(\chi(x)) \text{ on } \partial\Omega, \tag{2.9}$$

where g is defined in (2.7). Thus, the steady-state problem depends only on the single combined function g rather than on the individual functions f and A. In the model

problem $g(\Phi) = \Phi^{p/m}$. In any event, (2.9) is the same type of steady-state problem that arises for the heat equation with absorption. This problem was analyzed in [2], [9], [12], and [21]. In [2], we found that (2.9) can have a dead core—for sufficiently large λ—only if

$$(*) \qquad \int_0^1 \frac{ds}{\sqrt{G(s)}} < \infty, \text{ where } G(s) = \int_0^s g(\xi)d\xi.$$

For the model problem this reduces to $\frac{p}{m} < 1$, which is then also sufficient (see [2]). The sufficiency of $(*)$ for more general g satisfying

$$(P_g) \qquad \begin{cases} g \in C^2(0,1),\ g(0) = 0,\ g(1) = 1,\ g'(s) \geq 0 \text{ on } (0,1), \\ \quad \text{either } g''(s) \geq 0 \text{ on } (0,1) \text{ or } g''(s) \leq 0 \text{ on } (0,1), \end{cases}$$

will be shown in section 3. Most of our results can be proved under the less restrictive assumption of g being concave or convex only in some neighborhood of the origin, but for simplicity we have taken g to be either convex or concave in (0,1). The function g can easily be extended to $[0,2]$ without sacrificing smoothness, convexity, or concavity. Such an extension is needed in some proofs and will be used without further discussion.

Proofs of existence and uniqueness for problem (2.1)–(2.3) are based on a suitable notion of weak solution (see [5], and also [1], [6], [14]), which we include here for the sake of completeness.

Definition. Let $Q_T = \Omega \times (0,T)$ and let n denote the outward unit normal to Ω. A function $u \in C([0,T] : L^1(\Omega)) \cap L^\infty(Q_T)$ is called a weak solution of the problem (1.1)–(1.3) if it satisfies

$$(2.10) \quad \int_\Omega u(x,T)\sigma(x,T)dx - \int_{Q_T} [u\sigma_t + A(u)\triangle\sigma]dxdt + \int_0^T \int_{\partial\Omega} A(\chi)\frac{\partial\sigma}{\partial n}ds = \int_\Omega u_0\sigma(x,0)dx + \int_{Q_T} -f(u)\sigma dxdt$$

for all $\sigma \in C^2(\bar{Q}_T)$ with $\sigma = 0$ on $\partial\Omega \times (0,T)$. Equation (2.10) is obtained easily by multiplying (2.1) by σ, integrating over Q_T, and using the divergence theorem. The proof of existence and uniqueness of a weak solution to (2.1)–(2.3) now follows the lines of Bertsch [5].

A weak supersolution of (2.1)–(2.3) is defined by replacing the equal sign in (2.10) by $\geq$ and restricting σ to be nonnegative. Similarly, one can define a weak subsolution. For our purposes, it suffices to consider the usual super- and subsolutions (easily seen to be weak super- and subsolutions) defined as follows.

We say that $\bar{u} \geq 0$ is a supersolution of (2.1)–(2.3) if

$$(2.11) \qquad \bar{u}_t - \Delta A(\bar{u}) + \lambda f(\bar{u}) \geq 0\ , \quad \bar{u}(x,0) \geq u_0(x), \quad \bar{u}|_{\partial\Omega} \geq \chi(x).$$

Similarly, $u \geq 0$ is a subsolution if all the inequalities in (2.11) are reversed. If $\underline{u} \leq \bar{u}$, then the unique weak solution u of (2.1)–(2.3) satisfies (see [5])

$$\underline{u} \leq u \leq \bar{u}, \text{ almost everywhere (a.e.) in } Q_T.$$

Note that in general u is not continuous in Q_T. However, if χ is smooth, say differentiable, then a bounded weak solution is also continuous. This follows from

the arguments of [17], together with the very general result of [7]. We, henceforth, assume that u is continuous so that we shall write $\underline{u} \leq u$ or $u \leq \bar{u}$, dropping the a.e. qualification. Similar definitions apply to the steady-state problem (2.8) if g satisfies (P_g).

It follows from the maximum principle that the solutions of (2.1)–(2.3) and of (2.8) satisfy $u(x,t) \leq 1$ in $Q, \phi(x) \leq 1$ in Ω.

To show monotonicity of $u(x,t)$ in time, we need to impose a natural condition on the initial value $u_0(x)$:

$$\Delta(A(u_0)) - \lambda f(u_0) \leq a < 0, \quad x \in \Omega. \tag{2.12}$$

This condition holds automatically if $u_0(x)$ is a positive constant. If $u_0(x)$ satisfies (2.12), it is an upper solution to (2.1)–(2.3) so that $u(x,t) \leq u_0(x)$ for any t. Now let $v(x,t) = u(x,t+\tau)$; then $v(x,t)$ satisfies

$$v_t - \Delta(A(v)) = -\lambda f(v), \quad v(x,0) = u(x,\tau), \;\; v(\partial\Omega, t) = \chi(x).$$

Since $u(x,\tau) \leq u_0(x)$, v is a subsolution of (2.1)–(2.3), and hence $u(x,t+\tau) \leq u(x,t)$. Hence, $u(\cdot,t)$ is monotonically decreasing. Standard theorems can be used to show that $u(x,t)$ tends to the steady state $\phi(x)$ as $t \to \infty$.

3. Monotonicity and other comparison theorems. Consider problem (2.1)–(2.3) when only one part of the data is changed. We then have the following monotonicity properties:

(a) Let u_1 and u_2 be the solutions corresponding to λ_1, λ_2, respectively, with $\lambda_1 \leq \lambda_2$; then $u_2 \leq u_1$ in Q.

(b)If $f_1 \leq f_2$ on [0, 1], then $u_2 \leq u_1$ in Q.

(c) If the initial or the boundary value is decreased so is the solution.

(d) Let $u_0(x) \equiv 1, \chi(x) \equiv 1$ and consider two domains $\Omega_1 \subset \Omega_2$. Then $u_2 \leq u_1$ on Q_1.

These all are easy to prove using super- and subsolution techniques. Let us prove (d), for instance. Since u_2 satisfies the differential equation on Ω_2, it also satisfies it on Ω_1. Moreover, by the maximum principle, $u_2 \leq 1$ in Q_2 and hence on $\partial\Omega_1$. Clearly $u_2(x,0) = 1$ on Ω_1. Therefore $u_2(x,t)$ is a subsolution of (2.1)–(2.3) on Q_1 and $u_2 \leq u_1$ on Q_1 as required.

Remarks.

1. There is no straightforward comparison theorem with respect to $A(u)$ or $A'(u)$. (See, however, [4] for some partial results when $f = 0$.)
2. Similar results to (a)–(d) hold for the steady-state problem (see [2]).

Next we look at the "lumped-parameter" problem and the steady-state problem with a view to using them as comparison problems for (2.1)–(2.3). The lumped parameter problem has no diffusion term. It can be obtained as a special case of (2.1) with initial value $u_0(x) \equiv 1$ and boundary condition of vanishing *normal derivative*. We can then seek a solution $z(t)$ independent of x:

$$z_t = -\lambda f(z), \quad t > 0; \quad z(0) = 1. \tag{3.1}$$

As long as $z(t) > 0$, we integrate (3.1) to obtain

$$\lambda t = \int_{z(t)}^{1} \frac{ds}{f(s)}. \tag{3.2}$$

Thus, if $\int_0^1 \frac{ds}{f(s)} = \infty$ (weak absorption), (3.2) provides a solution $z(t) > 0$ for all t, with z tending to zero as $t \to \infty$. If, however,

$$\int_0^1 \frac{ds}{f(s)} = I < \infty \text{ (strong absorption)}, \tag{3.3}$$

then $z(t) > 0$ for $\lambda t < I$ and $z(t) \equiv 0$ for $\lambda t \geq I$. Strong absorption therefore leads to extinction in finite time. Note that the phenomenon is independent of λ, although the *time* of extinction does depend on λ. Similar results hold if the initial value for z is any positive number.

In the model problem, the solution of (3.1) is given explicitly by

$$z(t) = \begin{cases} [1 + \lambda\,(p-1)t]^{-\frac{1}{p-1}}, & p > 1; \\ e^{-\lambda t}, & p = 1; \\ [1 - \lambda\,(1-p)t]_+^{\frac{1}{1-p}}, & p < 1. \end{cases} \tag{3.4}$$

Therefore, extinction occurs in finite time if and only if $p < 1$. Then, $I = \frac{1}{1-p}$.

Comparison with (3.1) leads immediately to two results for (2.1)–(2.3).

THEOREM 3.1. (a) *If $\chi(x) = 0$, then $z(t)$ is a supersolution of* (2.1)–(2.3) *so that $u(x,t) \leq z(t)$ and, if the absorption is strong, there is extinction in finite time for $u(x,t)$.*

(b) *If $\min_{\overline{\Omega}} u_0(x) = \theta > 0$, then the solution $z(t,\theta)$ of* (3.1) *with initial value θ is a subsolution of* (2.1)–(2.3) *so that $u(x,t) \geq z(t,\theta)$. If the absorption is weak, then $z(t,\theta) > 0$ for all t, and hence $u(x,t) > 0$ in Q.*

We also need information on the steady-state problem.

The following theorem shows that $(*)$ is necessary and sufficient for the existence of a dead core for sufficiently large λ. We are grateful to J. Ildefonso Diaz for pointing out the sufficiency (see also [8]).

THEOREM 3.2 (see [2]). *Let g satisfy (P_g) and let $\chi(x) > 0$. If $(*)$ is not satisfied, there is no dead core for any λ; if $(*)$ is satisfied, then a dead core exists for sufficiently large λ.*

Proof. (a) Suppose $\int_0^1 \frac{ds}{\sqrt{G(s)}} = \infty$. Then $w(x)$ defined implicitly by

$$\int_{w(x)}^a \frac{ds}{\sqrt{G(s)}} = \sqrt{2\lambda}\, x \tag{3.5}$$

is positive for all $x > 0$, is a decreasing function of x, and satisfies the ordinary differential equation

$$w'' = \lambda g(w),\ x > 0;\ w(0) = a.$$

Now let Ω be a bounded domain and consider problem (2.9) with $\Phi(\partial\Omega) = A^{-1}(\chi) \geq a$. Then choosing the coordinate system so that Ω lies in the half-space $x > 0$, we see that $w(x)$ is a lower solution and, since $w > 0, \Phi > 0$ and so is ϕ. Thus, no dead core is possible for any λ.

(b) If $\int_0^1 \frac{ds}{\sqrt{G(s)}} < \infty$, then $g'(0) = \infty$ and hypothesis (P_g) implies g is concave. Hence, $g(v) \geq vg(1), 0 \leq v \leq 1$, and

$$G(v) = \int_0^v g(s)ds \leq vg(v) \leq \frac{1}{g(1)}\, g^2(v), \quad 0 \leq v \leq 1. \tag{3.6}$$

We shall construct, for λ sufficiently large, an upper solution $v(r)$ to (2.9) for a ball B_R, with $v \equiv 0, 0 < r < R/2$. We begin by observing that on the positive real line, the function $w(x)$ defined implicitly by

$$\int_0^{w(x)} \frac{ds}{\sqrt{G(s)}} = \sqrt{2\mu}\ x \tag{3.7}$$

satisfies $w'' = \mu g(w)$, $x > 0; w(0) = w'(0) = 0$. We note that w is an increasing function of x and μ. Now *choose* μ so that $w\left(\frac{R}{2}\right) = 1$ and consider the function

$$v = w\left(r - \frac{R}{2}\right)$$

in the ball $r \le R$ in R^N (having extended v to be zero for $r < R/2$). We then obtain

$$\begin{aligned} \triangle v = v'' + \frac{N-1}{r}\, v' &= \mu g(v) + \frac{N-1}{r}\sqrt{2\mu G(v)} \quad \text{in } \left(\frac{R}{2}, R\right) \\ &\le \mu g(v) + \frac{2(N-1)}{R}\sqrt{2\mu}\ \sqrt{G(v)} \\ &\le \left[\mu + \frac{2(N-1)}{R}\sqrt{\frac{2\mu}{g(1)}}\right] g(v) \doteq \nu g(v) \qquad \text{(by (3.6))}. \end{aligned}$$

Since $v\left(\frac{R}{2}\right) = 0, v'\left(\frac{R}{2}\right) = 0$, and $g(0) = 0$, the last inequality can be extended to $(0, R)$. Furthermore, $v(R) = 1$ so that $v(r)$ is an upper solution of the elliptic problem (2.9) for $\lambda \ge \nu$. Since v vanishes for $r < \frac{R}{2}$, so do Φ and ϕ. Now consider (2.9) on an arbitrary domain Ω with $\Phi(\partial\Omega) = A^{-1}(\chi) \le 1$. Then Ω contains a ball B_R on whose boundary $\Phi \le 1$. Therefore, $\Phi \le v$ and Ω contains a dead core for $\lambda \ge \nu$. □

For any $x_0 \in \Omega$, we can take $R = r_0 =$ the distance from x_0 to the boundary; part (b) of Theorem 3.2 then shows that for λ large enough, x_0 belongs to the dead core. This suggests making the following definition.

DEFINITION 3.3. *Let $x_0 \in \Omega$ and let g satisfy $(*)$ and (P_g). Define*

$$\lambda_0 = \inf_{\lambda} \{\Phi(x_0, \lambda) = 0\}\,;\ \lambda^* = \inf_{x_0} \lambda_0. \tag{3.8}$$

Remarks.

(a) Of course $\Phi(x_0, \lambda)$ and $\phi(x_0, \lambda)$ either both vanish or are both positive.

(b) Particularly simple estimates for λ_0 and $\lambda^\star$ are available in the model problem (see [13], [20]). In that case we are considering (2.9) with $g(s) = s^\alpha$, $\alpha < 1$. We claim that

$$\lambda_0 \le \frac{P_{n,\alpha}}{r_0^2}, \quad \lambda^\star \le \frac{P_{n,\alpha}}{\rho^2}, \tag{3.9}$$

where $P_{n,\alpha} = \frac{4+2(n-2)(1-\alpha)}{(1-\alpha)^2}, r_0 = \text{dist } (x_0, \partial\Omega); \rho =$ inradius of Ω. The proof consists in noting that the function $w = (\frac{|x-x_0|}{r_0})^{2/1-\alpha}$ satisfies $-\Delta w + \frac{P_{n,\alpha}}{r_0^2} w^\alpha = 0$ in Ω and $w(\partial\Omega) \ge 1$. Thus, w is a supersolution of (2.9) for any $\lambda \ge \frac{P_{n,\alpha}}{r_0^2}$. Since w vanishes at x_0, so does Φ, and hence ϕ. This proves the first part of (3.9) and the second follows at once.

4. The evolution problem whose steady state has a dead core. Suppose $(*)$ is satisfied with λ large enough for the steady state to have a dead core. Does the corresponding evolution problem have a dead core and, if so, how does it behave for large t? The answer is given by the following theorem.

THEOREM 4.1. *Let $u(x,t)$ be the solution of* (2.1)–(2.3) *under properties* $(P_A), (P_f), (*)$, *and* (P_g). *For fixed $x_0 \in \Omega$, choose $\lambda > \lambda_0$, where λ_0 is defined in* (3.8). *Then*

(a) *if f satisfies* (3.3), $u(x_0,t) = 0$ *for*

$$t \geq t_0 \doteq \frac{I}{\lambda - \lambda_0};$$

(b) *if the integral in* (3.3) *is infinite and* $\min_{\overline{\Omega}} u_0(x) > 0$, *then* $u(x_0,t) > 0$ *for all t.*

Proof. Part (b) is equivalent to Theorem 3.1(b). To prove part (a), it suffices to exhibit a supersolution $w(x,t)$ such that $w(x_0,t) = 0$ for $t \geq t_0$. Modifying the idea in [3] (see also [10]), we are led to try a function w of the form

$$w = A^{-1}(Az + A\phi) \qquad \text{(i.e., } Aw = Az + A\phi\text{)},$$

where $z(t,\gamma)$ is the solution of (3.1) with a parameter γ to be chosen and ϕ is the solution of (2.8) with $\lambda = \lambda_0$. Note that w vanishes at x_0 for $\gamma t \geq I$. Since $w \geq z$ and $w \geq \phi$, it is clear that $w(x,0) \geq u_0(x)$ and $w(\partial\Omega,t) \geq \chi(x)$; it remains only to choose γ to satisfy the differential inequality for a supersolution. From the definition of w, we have

$$(Aw)_t = A'(w)w_t = A'(z)z_t$$

so that

$$w_t = \frac{A'(z)}{A'(w)} z_t \geq z_t = -\gamma f(z),$$

where we have used the fact that $A'' \geq 0$ and $z_t \leq 0$. It follows that

$$\begin{aligned} w_t - \Delta(A(w)) + \lambda f(w) &\geq -\gamma f(z) - \Delta(A(\phi)) + \lambda f(w) \\ &= -\gamma f(z) - \lambda_0 f(\phi) + \lambda f(w) \\ &\geq (\lambda - \lambda_0 - \gamma) f(w). \end{aligned}$$

By choosing $\gamma = \lambda - \lambda_0$ we obtain the desired result. □

Remarks.

1. If f satisfies (3.3) we may be interested in the time of onset of the dead core. Then, if $\lambda > \lambda^*$ (see (3.8)), a nonempty dead core $D(t)$ will exist for $t \geq I/(\lambda - \lambda^*)$.
2. In the model problem, condition $(*)$ means $p/m < 1$, and then the steady state has a dead core for $\lambda > \lambda^*$. Suppose $\lambda > \lambda^*$. Then Theorem (4.1) states that if $p < 1$ (so that (3.3) is satisfied), the evolution problem for large times contains a dead core which ultimately covers any interior point of the steady dead core; if, however, $p \geq 1$ (so that the integral in (3.3) is infinite), then $u(x,t)$ is positive for all $x \in \Omega, t > 0$.

3. Often only an upper bound $\overline{\lambda}_0$ to λ_0 is known explicitly (see, for instance, (3.9)). Then, if $\lambda > \overline{\lambda}_0$ and f satisfies (3.3), we have $u(x_0, t) = 0$ for $t \geq I/(\lambda - \overline{\lambda}_0)$.
4. Note that our proof does not go through if $A'' < 0$, which corresponds to $m < 1$ in the model problem.

5. Decay estimates. We consider (2.1)–(2.3) with $u_0(x) \geq \phi(x)$, where $\phi(x)$ is the solution of the corresponding steady-state problem (2.8). It then follows, since ϕ is a lower solution, that $u(x,t) \geq \phi(x)$. If we assume in addition that $u_0 \in L^\infty(\Omega)$, then u is bounded a.e. in Q_∞. From a result of [17] it then follows that $A(u(\cdot,t)) \to A(\phi)$ in $L^2(\Omega)$ as $t \to \infty$. Hence, $\lim_{t\to\infty} |u(x,t) - \phi(x)|_\infty = 0$.

Our estimates hold for almost all $x \in \Omega$. If the data are smooth (cf. section 2), the solution is continuous and the estimates hold pointwise. We seek decay estimates for $\delta(x,t) \doteq u(x,t) - \phi(x)$ when conditions $(P_A), (P_f)$, and (P_g) are satisfied. For the model problem (2.4) this would mean $m \geq 1, p > 0$. Our principal results are contained in the following theorem.

THEOREM 5.1.

(a) *if g is convex, then*

$$0 \leq \delta(x,t) \leq z(t),$$

where $z(t)$ is the solution of (3.1).

(b) *if g is concave, then*

$$0 \leq \delta(x,t) \leq \zeta(t),$$

where $\zeta(t)$ is the solution of

$$\zeta_t = -\gamma A(\zeta),\ \zeta(0) = 1,\ \gamma = \lambda g'(1). \tag{5.1}$$

Proof. (a) As candidate for a supersolution to (2.1)–(2.3), choose $w(x,t)$ defined by

$$Aw = Az + A\phi \qquad (w = A^{-1}(Az + A\phi)),$$

where $z(t)$ satisfies (3.1) and ϕ satisfies (2.8). Then, as in the preceding section, we find

$$(Aw)_t = A'(w)w_t = A'(z)z_t, \quad w_t \geq z_t = -\lambda f(z).$$

Thus,

$$\begin{aligned} w_t - \triangle(A(w)) + \lambda f(w) \quad &\geq \lambda\left[f(w) - f(z) - f(\phi)\right] \\ &= \lambda\left[g(Aw) - g(Az) - g(A\phi)\right], \end{aligned}$$

and, since $Aw = Az + A\phi$ and g is convex, the right side is nonnegative. Because we also have $w \geq z$ and $w \geq \phi$, we see that w is a supersolution to (2.1)–(2.3). The convexity of A implies the concavity of A^{-1} so that

$$\delta = u - \phi \leq w - \phi = A^{-1}Aw - A^{-1}A\phi \leq A^{-1}Az = z.$$

(b) As candidate for an upper solution we now choose

$$v = A^{-1}(A\zeta + A\phi) \text{ or } Av = A\zeta + A\phi,$$

where ζ satisfies (5.1) and ϕ satisfies (2.8). By a similar calculation, as in part (a) we find $v_t \geq \zeta_t$ so that

$$v_t - \triangle(A(v)) + \lambda f(v) \geq \lambda\,[g(Av) - g(A\phi)] - \gamma A\zeta. \tag{5.2}$$

The concavity of g yields

$$g(Av) - g(A\phi) \geq g'(Av)\,[Av - A\phi] = g'(Av)\,[A\zeta]\,.$$

Since $A(1) = 1$, we have $Av \leq 2$ and $g(Av) - g(A\phi) \geq g'(2)A\zeta$. The values of g in [1,2] being at our disposal (subject to preserving smoothness and concavity), we can take $g'(2)$ as close to $g'(1)$ as we please so that the last inequality is also valid with $g'(1)$ replacing $g'(2)$. Thus, if $\gamma = \lambda g'(1)$, the right side of (5.2) is nonnegative, and, since the boundary and initial inequalities in (2.11) are clearly satisfied, $v(x,t)$ is an upper solution to (2.1)–(2.3). We therefore find, using the concavity of A^{-1},

$$\delta = u - \phi \leq v - \phi \leq A^{-1}Av - A^{-1}A\phi \leq A^{-1}A\zeta = \zeta,$$

thereby proving part (b) of our theorem. □

Remarks.

1. These results can be generalized to the case where g is only convex or concave in a neighborhood of the origin.

2. For the model problem, $p \geq m$ corresponds to convex g and $p \leq m$ corresponds to concave g. Thus, using the explicit form (3.4), our results take the form

$$0 \leq u - \phi \leq \begin{cases} [1 + \lambda(p-1)t]^{-\frac{1}{p-1}}\,, & p \geq m \geq 1 \text{ with } p > 1, \\ e^{-\lambda t}, & p \geq m = 1. \end{cases} \tag{5.3}$$

$$0 \leq u - \phi \leq \begin{cases} [1 + \gamma(m-1)t]^{-\frac{1}{m-1}}\,, & p \leq m \text{ with } m > 1, \\ e^{-\gamma t}, & p \leq m = 1. \end{cases} \tag{5.4}$$

Here $\gamma = \lambda g'(1) = \frac{\lambda p}{m}$. Note that for $p = m = 1$, the two estimates agree. For the heat operator ($m = 1$) and arbitrary p, Ricci [18] showed that $u(x,t)$ decays exponentially to $\phi(x)$, whereas our method gives this result only if $p \leq 1$. Of course if $m \neq 1$, we have new results for the porous medium equation with absorption. Even though our estimates are not optimal, they suggest the possibility of nonexponential decay to the steady state. We now exhibit such a case. Suppose $u_0(x) \equiv 1, 1 < p < m$, and $\lambda > \lambda^*$ (see (3.8)); then the stationary problem has a dead core D and, by combining (5.4) with Theorem 3.1(b), we find for $x \in D$

$$[1 + \lambda(p-1)t]^{-\frac{1}{p-1}} \leq u(x,t) \leq [1 + \gamma(m-1)t]^{-\frac{1}{m-1}}\,.$$

These two estimates are compatible and show that $u(x,t)$ does not decay exponentially to zero in the dead core.

SHARP ESTIMATES FOR THE EIGENVALUES OF SOME DIFFERENTIAL EQUATIONS*

SAMIR KARAA†

Abstract. We present optimal upper and lower bounds for the eigenvalues of the differential equations $y'' - q(x)y + \lambda\rho(x)y = 0$ and $(q(x)y')' + \lambda\rho(x)y = 0$ on a finite interval with Dirichlet boundary conditions when the coefficient functions $q(x)$ and $\rho(x)$ are nonnegative and are subjected to some kind of additional constraints. One of the basic ideas used in our work consists in reducing the problem of maximizing $\lambda(q,\rho)$ to an elementary problem of calculus of variations. This allows us to establish sufficient optimality conditions for our problems. We establish in the last part of this paper some comparison results for eigenvalues via symmetrization.

Key words. eigenvalue, Lagrange multiplier, rearrangement, isoperimetric inequalities

1. Introduction. Let $\lambda(q,\rho)$ denote the first eigenvalue of the boundary-value problem

$$y'' - q(x)y + \lambda\rho(x)y = 0, \tag{1.1}$$

$$y(0) = y(l) = 0, \tag{1.2}$$

with l being a positive real number. Let also H, A, and B be positive numbers such that $Hl > B$ and define the sets

$$U = \left\{ q \in L^1(0,l) \,/\, q(x) \geq 0,\ \int_0^l q(x)\,dx = A \right\}$$

and

$$V = \left\{ \rho \in L^\infty(0,l) \,/\, 0 \leq \rho(x) \leq H,\ \int_0^l \rho(x)\,dx = B \right\}.$$

The first aim of this paper is to study the extremal eigenvalue problem

$$\text{maximize } \lambda(q,\rho) \quad \text{subject to} \quad (q,\rho) \in U \times V. \tag{1.3}$$

If the function q is identically zero, then the eigenvalues of the new system

$$y'' + \lambda\rho(x)y = 0, \quad y(0) = y(l) = 0,$$

which will be denoted by $\lambda_n^0(\rho)$, characterize the frequencies of a string of density $\rho(x)$, fixed at its endpoints $x = 0$ and $x = l$ and having a unit tension. Krein [16] determined the densities which maximize $\lambda_n^0(\rho)\,(n = 1, 2, ...)$ among all measurable

functions $\rho(x)$ from V. He has shown that the extremal functions are step periodic functions, having the period l/n and taking only the values h and H. The minimum (resp., maximum) of λ_n^0 occurs for the periodic step function which in each interval $[(k-1)l/n, kl/n]$, $k = 1, ..., n$, is symmetrically decreasing (resp., increasing) i.e., symmetric with respect to (w.r.t.) $(2k-1)l/(2n)$ and increasing (resp., decreasing) in $[(k-1)l/n, (2k-1)l/(2n)]$. He has also shown that unlike the minimal function, the maximal function is not unique in the case $n \geq 2$. We recall his sharp estimates

$$\frac{4n^2H}{B^2}\, X\left(\frac{B}{Hl}\right) \leq \lambda_n^0(\rho) \leq \frac{n^2\pi^2 H}{B^2}, \tag{1.4}$$

where $X(t)$ is the smallest positive root of the equation $X^{1/2}\, tg\, X^{1/2} = t(1-t)^{-1}$. However, Banks [3] has determined upper and lower bounds for the eigenvalues of the fourth-order differential equation

$$y^{(4)} + \lambda\rho(x)y = 0,$$

$$y(0) = y''(0) = y(l) = y''(l) = 0$$

under the condition that $\rho \in V$.

The problem when q is not zero and $\rho(x) = 1$ has been solved in [20] and [12] by different methods. Later, the authors of [9] studied the same problem when $q(x)$ satisfies the condition $\int_0^1 q(x)^\alpha\, dx = 1$, α being a nonzero real. In [14] and [15], sharp estimates for the first eigenvalue of problem (1.1)–(1.2) are obtained when the coefficients $q(x)$ and $\rho(x)$ are subjected to a general kind of constraints. For other extremal problems concerning eigenvalues see [4], [5], [6], [7], [8], [11], [18], [19], and the references quoted there.

To solve our problem (1.3), we are led to study the following problem:

$$\text{maximize} \quad \mu(\rho) \quad \text{subject to} \quad \rho \in V,$$

where $\mu(\rho) = \inf_y G[\rho, y]$ and

$$G[\rho, y] = \frac{\int_0^l y'^2\, dx + A \max|y|^2}{\int_0^l \rho y^2\, dx}.$$

The inf above is taken in the class of nonzero functions from $H_0^1(0, l)$. Thus, the major purpose of the first part of this work is to provide answers to the following problems.
Problem I. Find a function $\rho_0 \in V$ for which $\mu(\rho) \leq \mu(\rho_0) \quad \forall \rho \in V$.
Problem II. Find a pair of functions $(q_0, \rho_0) \in U \times V$ for which

$$\lambda(q, \rho) \leq \lambda(q_0, \rho_0) \qquad \forall (q, \rho) \in U \times V.$$

It is clear that standard compactness arguments do not enable us to establish the existence of solutions for Problem II. Before presenting our analysis, we give the following propositions

PROPOSITION 1.1. (i) *If $H = \infty$, then $\lambda(q, \rho)$ cannot be estimated from above.*
(ii) *If H is finite, then $\lambda(q, \rho) \leq (1 + Al)\pi^2 HB^{-2}$ for all $(q, \rho) \in U \times V$.*
(iii) *If $q \in U$ and if ρ is subjected to the constraints*

$$\int_0^l \rho(x)\, dx = B, \qquad \rho(x) \geq h,$$

where h is a positive number satisfying $hl < B$, then

$$\lambda(q,\rho) \le (1+Al)l^{-2}\pi^2/h^3.$$

Proof. Suppose that $H = \infty$ and put $q(x) \equiv Al^{-1}$ and $\rho(x) = \varepsilon^{-1}B.\chi_{[0,\varepsilon]}(x)$. (Here and throughout the paper $\chi_I(x)$ denotes the characteristic function of the set $I \subset R$.) Then we have $q \in U$, $\rho \in V$, and

$$\int_0^l \rho(x)y(x)^2\,dx = \varepsilon^{-1}B\int_0^\varepsilon y(x)^2\,dx \le \varepsilon B\int_0^\varepsilon y'(x)^2\,dx$$

for all $y \in H_0^1(0,l)$. It follows that $\lambda(q,\rho) \ge \varepsilon^{-1}B^{-1}$, and therefore $\lambda(q,\rho)$ can be arbitrarily big. The second part of the proposition follows from (1.4) and from the fact that for every function $q \in U$,

$$\int_0^l q(x)y(x)^2\,dx \le Al\int_0^l y'(x)^2\,dx$$

for all $y \in H_0^1(0,l)$. Finally we establish (iii) by using the last inequalities and the fact that $\int_0^l \rho(x)y(x)^2\,dx \ge h\int_0^l y(x)^2\,dx$ for all $y \in H_0^1(0,l)$ since $\rho(x) \ge h$. □

PROPOSITION 1.2. *Let (q,ρ) be in $U \times V$. Then there exist two functions $\bar q \in U$ and $\bar\rho \in V$, even w.r.t. $x = l/2$, such that $\lambda(q,\rho) \le \lambda(\bar q,\bar\rho)$.*

Proof. For given admissible functions q and ρ, let us define the functions $\bar q$ and $\bar\rho$ by

$$\bar q(x) = \frac{1}{2}\left[q(x)+q(l-x)\right] \quad \text{and} \quad \bar\rho(x) = \frac{1}{2}\left[\rho(x)+\rho(l-x)\right].$$

It is clear that $\bar q \in U$ and $\bar\rho \in V$. Let $\bar y$ denote the even first eigenfunction corresponding to $\lambda(\bar q,\bar\rho)$. Then we have

$$\int_0^l q(x)\bar y(x)^2\,dx = \int_0^l q(l-x)\bar y(x)^2\,dx = \int_0^l \bar q(x)\bar y(x)^2\,dx$$

and, similarly, $\int_0^l \rho(x)\bar y(x)^2\,dx = \int_0^l \bar\rho(x)\bar y(x)^2\,dx$. Now suppose that $\int_0^l \rho(x)\bar y(x)^2\,dx = 1$. Then we have

$$\begin{aligned}\lambda(q,\rho) &\le \int_0^l \bar y'(x)^2\,dx + \int_0^l q(x)\bar y(x)^2\,dx\\ &= \int_0^l \bar y'(x)^2\,dx + \int_0^l \bar q(x)\bar y(x)^2\,dx \le \lambda(\bar q,\bar\rho).\end{aligned}$$ □

2. Sufficient optimality conditions. The book of Hestenes [13, p. 215], provides a theorem used for solving problems of the following type.

Problem III. Minimize $\int_0^l F_0(x,\rho(x))\,dx$ subject to the constraints $h \le \rho \le H, 0 \le h < H$, and

$$\int_0^l F_i(x,\rho(x))\,dx = M_i, \quad i = 1,...,N,$$

where $F_0, F_1, ..., F_N$ are given functions, each continuous on $[0,l]\times[h,H]$, and $M_1, ..., M_N$ are given constants. There is a dual theorem used for maximizing the functional $\int_0^l F_0(x,\rho(x))\,dx$, which we do not state here.

THEOREM 2.1. *If $\rho_0(x)$ is a solution of Problem* III, *then there exist constants (Lagrange multipliers) $\nu_0 \geq 0, \nu_1, \nu_2, ..., \nu_N$, not all zero such that for every $x \in [0, l]$*

$$\min_{h \leq \rho \leq H} [\nu_0 F_0(x,\rho) + \nu_1 F_1(x,\rho) + \cdots + \nu_N F_N(x,\rho)] \tag{2.1}$$

$$= \nu_0 F_0(x,\rho_0(x)) + \nu_1 F_1(x,\rho_0(x)) + \cdots + \nu_N F_N(x,\rho_0(x)).$$

Conversely, if a function $\rho_0(x)$ and constants $\nu_0 > 0, \nu_1, ..., \nu_N$ exist which satisfy (2.1) *and if the conditions*

$$\int_0^l F_i(x,\rho_0(x))\,dx = M_i$$

hold for $i = 1, ..., N$, then $\rho_0(x)$ solves Problem III.

Owing to the sufficiency part of the theorem, once we have determined a function $\rho_0(x)$ satisfying the conditions of the theorem, we can affirm that this function is optimal. Our Problems I and II are clearly not of the form III. To see how Theorem 2.1 applies to them we need Propositions 2.2 and 2.3 below. These propositions give sufficient conditions for a function $\rho_0(x)$ (a couple of functions $(\tilde{q}(x), \tilde{\rho}(x))$) to be a solution of Problem I (II). Having these propositions and Theorem 2.1 at hand we can solve Problem I (II) by constructing a function (a couple of functions) satisfying the conditions of the propositions.

PROPOSITION 2.2. *Let $\rho_0(x)$ be a function of V and $y_0(x)$ be a minimizer of functional $G[\rho_0, y]$ over $H_0^1(0,l)$. If*

$$\int_0^l \rho_0(x) y_0(x)^2\,dx \leq \int_0^l \rho(x) y_0(x)^2\,dx$$

for every function $\rho(x) \in V$, then $\rho_0(x)$ is a solution of Problem I.

Proof. Let $\rho(x)$ be an arbitrary member in V. Then we have

$$\begin{aligned}
\mu(\rho) &= \inf_{y \in H_0^1} \left[\int_0^l y'^2\,dx + A \max |y|^2\right] \Big/ \int_0^l \rho y^2\,dx \\
&\leq \left[\int_0^l y_0'^2\,dx + A \max |y_0|^2\right] \Big/ \int_0^l \rho y_0^2\,dx \\
&\leq \left[\int_0^l y_0'^2\,dx + A \max |y_0|^2\right] \Big/ \int_0^l \rho_0 y_0^2\,dx \\
&= \mu(\rho_0).
\end{aligned}$$

Therefore ρ_0 is a solution of Problem I. □

PROPOSITION 2.3. *Let $(\tilde{q}, \tilde{\rho})$ be in $U \times V$ and $\tilde{y}$ be any first eigenfunction of the problem $y'' - \tilde{q}(x)y + \lambda \tilde{\rho}(x) y = 0$, $y(0) = y(l) = 0$. If*

$$\int_0^l \tilde{\rho}(x) \tilde{y}(x)^2\,dx \leq \int_0^l \rho(x) \tilde{y}(x)^2\,dx, \tag{2.2}$$

$$\int_0^l q(x) \tilde{y}(x)^2\,dx \leq \int_0^l \tilde{q}(x) \tilde{y}(x)^2\,dx \tag{2.3}$$

for every couple $(q, \rho) \in U \times V$, then $(\tilde{q}, \tilde{\rho})$ solves Problem II.

Another way of stating Proposition 2.2 is to say that a sufficient condition for a function $\rho_0(x) \in V$ to be a solution of Problem I is that there exist constants $\nu_0 > 0$ and ν_1 such that for every $x \in [0, l]$

$$\min_{0 \le \rho \le H} [\nu_0 y_0^2(x)\rho + \nu_1 \rho] = \nu_0 y_0^2(x)\rho_0(x) + \nu_1 \rho_0(x),$$

where y_0 is a minimizer of functional $G[\rho_0, y]$ over $H_0^1(0, l)$. This is in fact the reason for choosing the trial function given by (3.1) below. Of course, this remark may be applied to Proposition 2.3 and the couple $(\tilde{q}, \tilde{\rho})$.

A similar approach was used by Barnes [6] to solve other kinds of extremal eigenvalue problems. For example, he studied the problem of determining the shape of the strongest column in the class of all columns of length l, volume V and having similar cross-sectional areas $A(x)$ satisfying $a \le A(x) \le b$, where a and b are prescribed positive bounds.

Remark 2.4. Conditions (2.2) and (2.3) are necessary for any extremal couple. In fact, suppose that $(\tilde{q}, \tilde{\rho})$ is a solution of Problem II. Then $\tilde{q}$ maximizes the first eigenvalue of the problem $y'' - q(x)y + \lambda\tilde{\rho}(x)y = 0$, $y(0) = y(1) = 0$ in the set U. Since U is convex, a standard argument of calculus of variations yields

$$\int_0^l [q(x) - \tilde{q}(x)]\, \tilde{y}(x)^2\, dx \le 0$$

for all functions q in U. Similarly, since $\tilde{\rho}$ maximizes the first eigenvalue of the problem $y'' - \tilde{q}(x)y + \lambda\rho(x)y = 0$, $y(0) = y(1) = 0$ in the convex set V, we deduce as above that

$$\int_0^l [\rho(x) - \tilde{\rho}(x)]\, \tilde{y}(x)^2\, dx \ge 0$$

for all functions ρ in V.

3. Optimal solutions. As shown above, Problem I (II) will be solved by finding a function ρ_0 (a couple of functions $(\tilde{q}, \tilde{\rho})$) and y_0 $[\tilde{y}]$ satisfying the conditions of Proposition 2.2 (2.3). Let ρ_0 be the function defined by

$$\rho_0(x) = \begin{cases} H & \text{if } 0 \le x \le a_0, \\ 0 & \text{if } a_0 < x < l - a_0, \\ H & \text{if } l - a_0 \le x \le l. \end{cases} \tag{3.1}$$

The number a_0 is chosen so that $\rho_0(x) \in V$. This means that

$$a_0 = (2H)^{-1}B. \tag{3.2}$$

LEMMA 3.1. *Let* $m_0 = \inf_{y \in H_0^1} G[y]$, *where*

$$G[y] = \frac{\int_0^l y'^2\, dx + A \max |y|^2}{\int_0^l \rho_0 y^2\, dx}. \tag{3.3}$$

Then m_0 *is attained on a nonnegative function* $y_0 \in H_0^1(0, l)$ *and*

$$m_0 = \frac{\pi^2 H}{B^2} \left[\frac{1}{2} + \sqrt{\frac{1}{4} + \frac{AB}{H\pi^2}} \right]^2. \tag{3.4}$$

Proof. A similar result when $\rho_0 \equiv 1$ has been obtained by Talenti. Our proof will use some arguments of his paper [20].

Step 1. First, it is easily seen that G has a nonnegative minimizer y_0 in $H_0^1(0,l)$, which is symmetric with respect to $l/2$. Suppose now that y_0 is convex in an interval (x_1,x_2), where $0 \le x_1 < x_2 \le l$. If z is given by

$$z(x) = y_0(x_1) + \delta(x - x_1), \quad \text{where} \quad \delta = [y_0(x_2) - y_0(x_1)]/(x_2 - x_1)$$

for $x \in (x_1,x_2)$ and coincides with y_0 out of (x_1,x_2), then the value of $G[y_0]$ is greater than $G[z]$. Indeed we have $y_0(x_1) = z(x_1)$, $y_0(x_2) = z(x_2)$, and

$$\int_{x_1}^{x_2} \rho_0(x) y_0^2(x)\,dx \le \int_{x_1}^{x_2} \rho_0(x) z^2(x)\,dx.$$

On the other hand, by Hölder's inequality

$$\int_{x_1}^{x_2} y_0'\,dx \le \left(\int_{x_1}^{x_2} {y_0}'^2\,dx\right)^{1/2} \left(\int_{x_1}^{x_2} dx\right)^{1/2};$$

$$[y_0(x_2) - y_0(x_1)]^2 \le \left(\int_{x_1}^{x_2} {y_0}'^2\,dx\right)(x_2 - x_1);$$

$$\int_{x_1}^{x_2} z'^2\,dx \le \int_{x_1}^{x_2} {y_0}'^2\,dx.$$

Since we can do the same for all other intervals where y_0 is convex, one deduces that the function y_0 is concave in the interval $[0,l]$. Now put

$$z_0(x) = \begin{cases} y_0(a_0) & \text{if } x \in [a_0, l - a_0], \\ y_0(x) & \text{otherwise.} \end{cases}$$

Therefore, $z_0 \in H_0^1(0,l)$, $\max|z_0| \le \max|y_0|$, $\int_0^l z_0'^2\,dx \le \int_0^l y_0'^2\,dx$, and $\int_0^l \rho_0 z_0^2\,dx = \int_0^l \rho_0 y_0^2\,dx$, which implies that $G[z_0] \le G[y_0]$. Hence y_0 must be constant in the interval $[a_0, l - a_0]$.

Step 2. Now we shall show that y_0' is everywhere continuous in $]0,l[$.

Let E denote the set of all $x \in [0,l]$ such that $y_0(x) = \max|y_0|$. Since y_0 is concave and symmetric about $x = l/2$, E is exactly an interval of the form $[b_0, l - b_0]$, where $0 < b_0 \le a_0$. Besides, the concavity of y_0 implies also that $y_0'(\xi^-)$ and $y_0'(\xi^+)$ exist and are finite at every point ξ from $]0,l[$ and

$$y_0'(\xi^+) \le y_0'(\xi^-). \tag{3.5}$$

Let z be a function of $H_0^1(0,l)$, achieving its maximum at $x = l/2$. Then we have

$$\max_x |y_0(x) + tz(x)| = y_0(l/2) + tz(l/2)$$

for all $t > 0$ small enough. Since y_0 minimizes G over $H_0^1(0,l)$, the directional derivative $G'[y_0,z]$ must be nonnegative. $G'[y_0,z]$ is by definition the limit of

$$\frac{1}{t}(G[y_0 + tz] - G[y_0])$$

as t approaches zero through positive values. Now pick $\xi \in]0, b_0]$ and choose

$$z(x) = \begin{cases} 1 - n|x - \xi| & \text{for } x \in I_n, \\ 0 & \text{otherwise,} \end{cases}$$

where $n > \xi^{-1}$ and $I_n = \{x \in [0, l],\, |x - \xi| < 1/n\}$. As mentioned above, we have $G'[y_0, z] \geq 0$ for all $n > \xi^{-1}$, which yields

$$-n \int_{\xi - 1/n}^{\xi} y_0' \, dx + n \int_{\xi}^{\xi + 1/n} y_0' \, dx \geq -HG[y_0] \int_{I_n} y_0 \, dx$$

for all $n > \xi^{-1}$. Letting $n \to \infty$ gives $y_0'(\xi^+) \geq y_0'(\xi^-)$. From (3.5) we deduce that $y_0'(\xi^+) = y_0'(\xi^-)$ for all $\xi \in]0, b_0]$ and therefore y_0' is everywhere continuous in $]0, l[$. Thus we have in particular $y_0'(b_0) = y_0'(l - b_0) = 0$.

Step 3. Let

$$\mathcal{O} = \{x \in]0, l[,\, y_0(x) < \max |y_0|\}.$$

Then as is shown in [20], G is Gâteaux differentiable at y_0 and

$$G'[y_0][z] = 2 \left(\int_0^l \rho_0 y_0^2 \, dx \right)^{-1} \left(\int_0^l y_0' z' \, dx - G[y_0] \int_0^l \rho_0 y_0 z \, dx \right)$$

for all test functions $z \in H_0^1(0, l)$ such that

$$\textit{support of } z \ \subset \ \mathcal{O}.$$

Hence it follows that y_0 satisfies the differential equation

$$y_0''(x) + HG[y_0] y_0(x) = 0 \ \ \textit{in } \ \mathcal{O}.$$

Integrating this equation, we arrive at the following representation:

$$y_0(x) = \begin{cases} C \sin \sqrt{m_0 H} x & \text{for } x \in [0, b_0], \\ y_0(b_0) & \text{for } x \in]b_0, l - b_0[, \\ C \sin \sqrt{m_0 H} (l - x) & \text{for } x \in [l - b_0, l], \end{cases}$$

where $m_0 = G[y_0]$. Since y_0 is concave and $y_0'(b_0) = 0$, we must have $\sqrt{m_0 H} b_0 = \pi/2$ and hence

$$b_0 = \frac{\pi}{2} (m_0 H)^{-1/2}. \tag{3.6}$$

Now the constant C is known. In fact, $C = y_0(b_0)$. On the other hand, plugging y_0 into (3.3) gives

$$m_0 = \frac{m_0 b_0 H + A}{(2a_0 - b_0) H}, \tag{3.7}$$

which yields

$$B m_0 - \pi H^{1/2} m_0^{1/2} - A = 0.$$

The unique solution of this equation is given by (3.4). □

THEOREM 3.2. *The function ρ_0 defined by* (3.1) *is a solution of Problem* I.

Proof. Let ν_0 and ν_1 be two numbers such that $\nu_0 = 1$ and $\nu_1 = -y_0^2(b_0)$, where the function y_0 and the number b_0 are as above. Then ρ_0 satisfies condition (2.1) of Theorem 2.1. Indeed, for all $x \in [0, l]$,

$$\min_{0\le\rho\le H}[y_0^2(x)\rho - y_0^2(b_0)\rho] = \min_{0\le\rho\le H}[y_0^2(x) - y_0^2(b_0)]\rho_0(x),$$

which implies that $\int_0^l \rho_0(x)y_0(x)^2\,dx \le \int_0^l \rho(x)y_0(x)^2\,dx$ for all $\rho \in V$. By Proposition 2.2, ρ_0 is a solution of Problem I. □

THEOREM 3.3. *Put $q_0(x) = \frac{1}{2}A(a_0 - b_0)^{-1}\chi_I(x)$, where a_0 and b_0 are given by* (3.2) *and* (3.6)*, respectively, and $I = [b_0, a_0] \cup [l - a_0, l - b_0]$. Then the pair (q_0, ρ_0) is a solution of Problem* II.

Proof. It is clear that $q_0 \in U$. Moreover we have for all $q \in U$

$$\int_0^l q(x)y_0^2(x)\,dx \le A\max_x |y_0^2(x)| = \int_0^l q_0(x)y_0^2(x)\,dx,$$

since $y_0(x) = \max|y_0|$ for $x \in [b_0, l - b_0]$. In order to apply Proposition 2.3, it remains to show that y_0 satisfies

$$y'' - \frac{1}{2}A(a_0 - b_0)^{-1}\chi_I\, y + m_0 H\chi_J\, y = 0 \tag{3.8}$$

everywhere in $]0, l[$, where $J = [0, a_0] \cup [l - a_0, l]$. From (3.7), we get

$$2m_0 H = A(a_0 - b_0)^{-1}. \tag{3.9}$$

On the other hand, since the differential equation

$$y_0''(x) + m_0 H y_0(x) = 0$$

holds everywhere in $\mathcal{O} = \,]0, b_0[\, \cup \,]l - b_0, l[$, relation (3.9) implies that y_0 is a solution of (3.8). Hence (q_0, ρ_0) satisfies the conditions of Proposition 2.3 and therefore is a solution of Problem II. □

Remark 3.4. For a given function $f(x)$ defined on the interval $[0, l]$, we shall use the notation $f^+(x)$ and $f^-(x)$ to denote the symmetrically increasing rearrangement and the symmetrically decreasing rearrangement of f, respectively. We recall that the function f^+ is characterized by the condition that f^+ is symmetric about $x = l/2$, decreasing on the interval $[0, l/2]$ and equimeasurable to $f(x)$ on $[0, l]$; that is,

$$\text{meas}\{x/\, f^+(x) \ge t\} = \text{meas}\{x/\, f(x) \ge t\}$$

for all $t \ge 0$. The function f^- is symmetric about $x = l/2$ and satisfies $f^-(x) = f^+(l/2 + x)$ for all x in $[0, l/2]$. Theorem 3.3 shows that an estimate from above of $\lambda(q, \rho)$ of either the form

$$\lambda(q, \rho) \le \lambda(q^-, \rho^+)$$

or the form

$$\lambda(q, \rho) \le \lambda(q^+, \rho^+)$$

is in general impossible. In fact, suppose for instance that $\lambda(q_0, \rho_0) \le \lambda(q_0^-, \rho_0)$; i.e., the couple (q_0^-, ρ_0) is also a solution of Problem II. Then Remark 2.4 tells us

that $\int_0^l q_0^-(x)\bar{y}(x)^2\,dx \geq \int_0^l q(x)\bar{y}(x)^2\,dx$ for all functions q in U, where $\bar{y}$ is the first eigenfunction of the problem $y'' - q_0^-(x)y + \lambda\rho_0(x)y = 0$, $y(0) = y(l) = 0$. Since q_0^- is symmetrically decreasing and takes only the values 0 and $m_0.H$, the function $\bar{y}$ is concave in a neighborhood of $l/2$. Consequently, one can construct a function q belonging to U, taking only the values 0 and $m_0.H$ and such that $\int_0^l q(x)\bar{y}(x)^2\,dx > \int_0^l q_0^-(x)\bar{y}(x)^2\,dx$. This, however, implies that $\lambda(q_0^-, \rho_0) < \lambda(q_0, \rho_0)$. Besides, one can easily check that $\lambda(q_0^+, \rho_0) < \lambda(q_0, \rho_0)$.

Remark 3.5. We have

$$\inf_{U\times V} \lambda(q,\rho) = 4HB^{-2}\,X\left(\frac{B}{Hl}\right), \tag{3.10}$$

where $X(t)$ is the smallest positive root of the equation $X^{1/2}\,tg\,X^{1/2} = t(1-t)^{-1}$. Moreover the inf in (3.10) is not attained. In fact, from [16] we deduce that for every $(q,\rho) \in U \times V$

$$4HB^{-2}\,X\left(\frac{B}{Hl}\right) = \mu(\bar{\rho}) \leq \mu(\rho) \leq \lambda(q,\rho),$$

where $\bar{\rho} = H.\chi_{[a,l-a]}$, $a = (H-B)/(2H)$, and $\mu(\rho)$ is the first eigenvalue of

$$\begin{cases} y'' + \mu\rho(x)y = 0, \\ y(0) = y(1) = 0. \end{cases}$$

Let y_0 be a first eigenfunction of this problem when $\rho = \bar{\rho}$. Let $\{y_n\}$ be a sequence of $C_0^\infty[0,l]$ converging to y_0. Then it is possible to find a sequence of nonnegative functions $\{q_n\}$ such that

$$\int_0^l q_n\,dx = 1, \quad \int_0^1 q_n\,y_n^2\,dx = 0.$$

Hence equality (3.10) follows since $\lambda(q_n,\bar{\rho}) \to \mu(\bar{\rho})$ as $n \to \infty$. On the other hand, if there exists a couple $(\tilde{q},\tilde{\rho})$ in $U \times V$ such that $\mu(\bar{\rho}) = \lambda(\tilde{q},\tilde{\rho})$, then we must have $\tilde{q} \equiv 0$. This function is of course not admissible. Therefore the infimum in (3.10) is not achieved in $U \times V$.

4. Generalization of the preceding results. Results analogous to the preceding ones may be obtained in the more general situation in which the function ρ is subjected to the constraints

$$\int_0^l \rho(x)\,dx = B, \qquad 0 < h \leq \rho(x) \leq H, \tag{4.1}$$

where $hl < B < Hl$. Suppose now that H is a given positive constant and consider the function ρ_h defined by

$$\rho_h(x) = \begin{cases} H & \text{if } 0 \leq x \leq a, \\ h & \text{if } a < x < l-a, \\ H & \text{if } l-a \leq x \leq l, \end{cases}$$

where $a = \frac{1}{2}(B-lh)/(H-h)$. Then we have the following lemma.

LEMMA 4.1. *Let* $\delta = (B\sqrt{m_0 H} - \pi H)/(hl\sqrt{m_0 H} - \pi)$, $0 \le \delta < H$, *and* $m_h = \inf_{y \in H_0^1} G_h[y]$, *where*

$$G_h[y] = \frac{\int_0^l y'^2\,dx + A \max |y|^2}{\int_0^l \rho_h y^2\,dx}.$$

Then m_h *is attained on a nonnegative function* $y_h \in C_0^1[0,l]$ *and there exists a positive constant* $b < l/2$ *depending on* h *such that* $y_h(x) = \max |y_h|$ *for* $x \in [b, l-b]$. *Moreover if* $h \le \delta$, *then* $m_h = m_0$, *and if* $h > \delta$, *then* m_h *is strictly less than* m_0 *and equals the least positive root of the equation*

$$\frac{\cot(\sqrt{mh}a) + \sqrt{h/H}\tan(\sqrt{mH}a)}{\sqrt{h/H}\cot(\sqrt{mh}a)\tan(\sqrt{mH}a) - 1} = \tan\frac{1}{2}\left(\sqrt{mh} - \frac{A}{\sqrt{mh}}\right).$$

The proof of this lemma is similar to that of Lemma 3.1. First of all it is easily verified that for each positive $h < H$, y_h is symmetrically decreasing and concave and belongs to $C_0^1[0,l]$. On the other hand, the set $E_h = \{x \in [0,l],\ y_h(x) = \max |y_h|\}$ must have a nonzero measure; otherwise y_h will satisfy the Euler–Lagrange equation $y_h'' + m_h \rho_h y_h = 0$ on the whole interval $(0,l)$ and minimize the functional $y \longrightarrow \int_0^l y'^2\,dx / \int_0^l \rho_h y^2\,dx$ over $H_0^1(0,l)$, which is impossible. The remainder of the lemma is proved by exploiting the differential equation above, which holds outside E_h, and by taking into account the relation $m_h = G_h[y_h]$.

THEOREM 4.2. *For all* $q \in U$ *and for all* ρ *satisfying* (4.1),

$$\lambda(q,\rho) \le m_h. \tag{4.2}$$

If $h < \delta$, *then the equality is attained if* $\rho = \rho_h$ *and if* q *is defined by*

$$q(x) = \begin{cases} m_0 H & \text{if } b_0 \le x \le a \text{ or} \\ & l - a \le x \le l - b_0, \\ m_0 h & \text{if } a < x < l - a, \\ 0 & \text{otherwise.} \end{cases}$$

If $h = \delta$, *then* (4.2) *becomes equality if* $\rho = \rho_h$ *and if* $q(x) = m_0 h \chi_{[b_0, l-b_0]}$. *If* $h > \delta$, *then* (4.2) *becomes equality if* $\rho = \rho_h$ *and if* $q(x) = m_h h \chi_{[b, l-b]}$. *Here* δ *is as in Lemma* 4.1, b_0 *is given by* (3.6),

$$a = \frac{B - lh}{2(H-h)}, \qquad b = \frac{1}{2}\left(l - \frac{A}{h m_h}\right).$$

To prove this theorem it is sufficient to verify that for each h such that $0 < h < H$, the pair (q,ρ) constructed above and the function y_h found in Lemma 4.1 satisfy the conditions of Proposition 2.3. Notice that Theorem 4.2 implies that for $h < \delta$ (in particular for $h = 0$) Problem II possesses infinitely many solutions.

It should also be mentioned that our method applies to the case when the function ρ satisfies the conditions

$$\left(\int_0^l \rho(x)^s\,dx\right)^{1/s} = B, \qquad 0 \le \rho(x) \le H, \tag{4.3}$$

where s is a number > 1. In this case the upper bound for the first eigenvalue $\lambda(q,\rho)$ is

$$\Lambda_s = \frac{\pi^2 H^{2s-1}}{B^{2s}} \left[\frac{1}{2} + \sqrt{\frac{1}{4} + \frac{AB^s}{H^s\pi^2}}\right]^2,$$

which is achieved when

$$\rho(x) = \begin{cases} H & \text{if } 0 \le x \le a_s, \\ 0 & \text{if } a_s < x < l - a_s, \\ H & \text{if } l - a_s \le x \le l, \end{cases}$$

$a_s = B^s(2H^s)^{-1}$, and when $q(x) = \Lambda_s H \chi_{I_s}$, where $I_s = [b_s, a_s] \cup [l - a_s, b - b_s]$ and $b_s = (\Lambda_s H)^{-1/2}\pi/2$.

5. Another eigenvalue problem. Now we shall be concerned with an eigenvalue problem of the form

$$(q(x)y')' + \lambda\rho(x)y = 0, \tag{5.1}$$

$$y(0) = y(l) = 0. \tag{5.2}$$

As before we would like to find sharp upper bound for the first eigenvalue $\lambda(q,\rho)$ of problem (5.1)–(5.2) under the conditions that $\rho \in V$ and $q \in U_\alpha$, where

$$U_\alpha = \left\{ q \in L^\alpha(0,l) \,/\, q \ge 0, \int_0^l q^\alpha(x)\,dx = A^\alpha \right\}$$

and $\alpha \ge 1$. Estimates of $\lambda(q,\rho)$ are obtained in [10] when $q(x)$ and $\rho(x)$ are nonnegative and are subjected to the constraints

$$\int_0^l q^\alpha(x)\,dx = 1, \qquad \int_0^l \rho^\beta(x)\,dx = 1,$$

where α and β are nonzero real numbers. It has been shown that $\lambda(q,\rho)$ cannot be estimated from above in the case $\alpha \ge 1$ and $\beta \ge 1$. Another problem has been considered by Bandle [2], who has given upper bounds for the eigenvalues of the problem

$$(q(x)y')' + \lambda y = 0, \qquad (qy')(0) = (qy')(l) = 0,$$

when $q \in U_\alpha$ and $0 < q(x) < \sigma$ for $x \in (0,l)$. σ is a given positive constant. In [11], Egorov and Kondratiev have studied the problem of determining the shape of the column clamped at both of its extremities and having the largest buckling load among all columns of length l and volume V. This problem is equivalent to that of finding a nonnegative function (*cross-sectional area*) $q(x)$ which maximizes the first eigenvalue of the following problem:

$$(q(x)y'')'' + \lambda y'' = 0,$$

$$y(0) = y'(0) = 0, \quad y(l) = y'(l) = 0,$$

under the condition that

$$\int_0^l q^\beta(x)\,dx = V,$$

where $\beta > -1/2$ and $V > 0$. Now let us consider the following problem.

Problem IV. Find a pair of functions $(\tilde{q}, \tilde{\rho}) \in U_\alpha \times V$ for which

$$\lambda(q,\rho) \le \lambda(\tilde{q},\tilde{\rho}) \qquad \forall (q,\rho) \in U_\alpha \times V.$$

The variational principle holds, which says

$$\lambda(q,\rho) = \inf_y R[q,\rho,y],$$

where

$$R[q,\rho,y] = \frac{\int_0^l qy'^2\,dx}{\int_0^l \rho y^2\,dx},$$

and the inf is taken over all nonzero functions y from $C_0^1[0,l]$. Put now

$$M_\alpha = \sup_{q,\rho} \lambda(q,\rho),$$

where the supremum is taken in the class of all pairs $(q,\rho) \in U_\alpha \times V$.

PROPOSITION 5.1. *For any couple (q,ρ) in $U_\alpha \times V$, there exist two functions $\hat{q} \in U$ and $\hat{\rho} \in V$, both symmetric w.r.t. $l/2$ such that $\lambda(q,\rho) \le \lambda(\hat{q},\hat{\rho})$.*

Proof. For given admissible functions q and ρ, consider the functions

$$\bar{q}(x) = \frac{1}{2}\left[q(x) + q(l-x)\right] \quad \text{and} \quad \bar{\rho}(x) = \frac{1}{2}\left[\rho(x) + \rho(l-x)\right].$$

Arguing as in the proof of Proposition 1.2 gives $\lambda(q,\rho) \le \lambda(\bar{q},\bar{\rho})$. Besides,

$$\begin{aligned}\int_0^l \bar{q}^\alpha(x)\,dx &= \int_0^l \left[\frac{q(x)+q(l-x)}{2}\right]^\alpha dx \\ &\le \frac{1}{2}\left[\int_0^l q^\alpha(x)\,dx + \int_0^l q^\alpha(l-x)\,dx\right] = A^\alpha,\end{aligned}$$

since $\alpha \ge 1$. Therefore one can choose $\hat{q}(x) = A\left(\int_0^l \bar{q}^\alpha(x)\,dx\right)^{-1/\alpha} \bar{q}(x)$ and $\hat{\rho}(x) = \bar{\rho}(x)$. □

The main result of this section is the following theorem.

THEOREM 5.2. *Let $\alpha > 1$ and $p = 2\alpha/(\alpha-1)$. Let $\tilde{y}$ be the first eigenfunction of the nonlinear problem*

$$(A||y'||_p^{2-p}|y'|^{p-2}y')' + \lambda\tilde{\rho}y = 0, \quad y(0) = y(l) = 0,$$

where $\tilde{\rho}\,(= \rho_0)$ is given by (3.1). Put $\tilde{q} = A||y'||_p^{2-p}|y'|^{p-2}$. Then the couple $(\tilde{q},\tilde{\rho})$ is a solution of Problem IV. *Moreover we have*

$$M_\alpha = 2A\frac{H^{1+1/\alpha}}{B^{2+1/\alpha}}\left(\frac{\alpha+1}{\alpha}\right)^{1/\alpha-1}\left(\frac{5\alpha+1}{4\alpha}\right)^{1/\alpha}\mathcal{B}^2\left(\frac{1}{2},\frac{1}{2}+\frac{1}{2\alpha}\right), \tag{5.3}$$

where $\mathcal{B}$ is Euler's beta function.

To prove this theorem, we will use three lemmas. The first one is analogous to Proposition 2.3.

LEMMA 5.3. *Let $(\tilde{q},\tilde{\rho})$ be a couple from $U_\alpha \times V$ and $\tilde{y}$ be any first eigenfunction of the problem*

$$(\tilde{q}(x)y')' + \lambda\tilde{\rho}(x)y = 0,\ \ y(0) = y(l) = 0.$$

If

$$\int_0^l \tilde{\rho}(x)\tilde{y}(x)^2\,dx \le \int_0^l \rho(x)\tilde{y}(x)^2\,dx,$$

$$\int_0^l q(x)\tilde{y}'(x)^2\,dx \le \int_0^l \tilde{q}(x)\tilde{y}'(x)^2\,dx$$

for every couple $(q,\rho) \in U_\alpha \times V$, then $(\tilde{q},\tilde{\rho})$ is a solution of Problem IV.

LEMMA 5.4. *Let p be a number > 1. Let $m = \inf_y G[y]$, where*

$$G[y] = \frac{(\int_0^l |y'|^p\,dx)^{2/p}}{\int_0^l \tilde{\rho}y^2\,dx}$$

and $\tilde{\rho}$ is given by (3.1). *The infimum above is taken in the class of all nonzero functions y from $W_0^{1,p}(0,l)$. Then G has a nonnegative minimizer $\tilde{y}$ in $W_0^{1,p}(0,l)$ with the following properties:*

(i) *$\tilde{y}$ is concave and symmetric about $x = l/2$.*

(ii) *$I = \{x \in [0,l], \tilde{y}(x) = \max|\tilde{y}|\}$ is exactly the interval $[a, l-a]$; $a = (2H)^{-1}B$.*

(iii) *$\tilde{y}'$ is everywhere continuous and $\tilde{y}$ satisfies the equation*

$$(||y'||_p^{2-p}|y'|^{p-2}y')' + m\tilde{\rho}y = 0$$

at every point of the interval $]0,l[$.

(iv)

$$m = 2\frac{H^{2-2/p}}{B^{3-2/p}}\left(\frac{p-1}{p}\right)^{-2/p}\left(\frac{3p-1}{2p}\right)^{1-2/p}\mathcal{B}^2\left(\frac{1}{2}, 1-\frac{1}{p}\right).$$

(v) *We have*

$$\tilde{y}(x) = \tilde{y}(a) + c_1(a-x)^{p/(p-1)}[1+o(1)] \ \ as\ \ x \to a^-,$$

$$\tilde{y}'(x) = c_2(a-x)^{1/(p-1)}[1+o(1)] \ \ as\ \ x \to a^-,$$

$$\tilde{y}(x) = c_3 x[1+o(1)] \ \ as\ \ x \to 0^+,$$

where c_1, c_2, and c_3 are nonzero numbers.

The proof of this lemma is similar to that of Lemma 3.1 and will therefore be omitted.

LEMMA 5.5. *Let $p > 2$ and let the functions $\tilde{\rho}$ and $\tilde{y}$ be as in Lemma* 5.4. *Put $\tilde{q}(x) = ||\tilde{y}'||_p^{2-p}|\tilde{y}'(x)|^{p-2}$. Let*

$$\mu = \inf_{y \in H_0^1(0,l)} \frac{\int_0^l \tilde{q}y'^2\,dx}{\int_0^l \tilde{\rho}y^2\,dx}.$$

Then μ is attained at $\tilde{y}$ and $\mu = m$.

Proof. Let $\{y_k\} \subset H_0^1(0,l)$ be a minimizing sequence normalized so that $\int_0^l \tilde{\rho} y_k^2\,dx = 1$. Then the integrals $\int_0^{a-\varepsilon} y_k'^2\,dx$ and $\int_{l-a+\varepsilon}^l y_k'^2\,dx$ are bounded and so there exists a subsequence converging uniformly in $[0,a-\varepsilon]$ and in $[l-a+\varepsilon,l]$ and weakly in $H^1(0,a-\varepsilon)$ and in $H^1(l-a+\varepsilon,l)$. Using a diagonalization one can find a subsequence converging almost everywhere in $(0,a)$ and in $(l-a,l)$ to a function $\bar{y}(x)$. We shall reason only in the interval $(0,a)$. We shall show that $\int_{a-\varepsilon}^a y_k^2\,dx \le C_0\varepsilon^\beta$, where C_0 and β are positive numbers independent of k. Taking into account the fact that

$$\tilde{q}(x) = c(a-x)^\gamma[1+o(1)] \ \ as\ x \to a^-,$$

where $\gamma = (p-2)/(p-1)$, $0<\gamma<1$, we deduce from the equality $y_k(a-\varepsilon) = \int_0^{a-\varepsilon} y_k'(t)\,dt$ that

$$y_k^2(a-\varepsilon) \le \int_0^{a-\varepsilon} \tilde{q}(x) y_k'^2(x)\,dx \int_0^{a-\varepsilon} \tilde{q}^{-1}(x)\,dx \le C\varepsilon^{1-\gamma}.$$

Similarly, for every x in $(a-\varepsilon,a)$, we have $y_k(x) = y_k(a-\varepsilon) + \int_{a-\varepsilon}^x y_k'(t)\,dt$ and therefore

$$\begin{aligned} y_k^2(x) &\le 2y_k^2(a-\varepsilon) + 2\left(\int_{a-\varepsilon}^x y_k'(t)\,dt\right)^2 \\ &\le 2C\varepsilon^{1-\gamma} + \frac{2C}{1-\gamma}\varepsilon^{1-\gamma} \le 4C\varepsilon^{1-\gamma} \end{aligned}$$

for ε small enough. It follows that $\int_{a-\varepsilon}^a y_k^2\,dx \le 4C\varepsilon^{2-\gamma}$. Repeating the same argument in the interval $(l-a,a)$ we obtain that $\int_{l-a}^{l-a+\varepsilon} y_k^2(x)\,dx \le 4C\varepsilon^{2-\gamma}$. If we extend the function $\bar{y}$ to the whole interval $(0,l)$ by a smooth function (the obtained function will also be denoted by $\bar{y}$), we obtain

$$\int_0^l \tilde{\rho}(x)\bar{y}^2(x)\,dx = 1 \ \text{ and } \ \int_0^l \tilde{q}(x)\bar{y}'^2(x)\,dx \le \mu.$$

This implies that $\int_0^l \tilde{q}(x)\bar{y}'^2(x)\,dx = \mu$. Since $\bar{y}$ is a minimizer in $H_0^1(0,l)$, it satisfies the equation

$$(\tilde{q}(x)\bar{y}')' + \mu\tilde{\rho}\bar{y} = 0 \tag{5.4}$$

and the boundary conditions $\bar{y}(0) = \bar{y}(l) = 0$. Similarly, $\tilde{y}$ satisfies

$$(\tilde{q}(x)\tilde{y}')' + m\tilde{\rho}\tilde{y} = 0 \tag{5.5}$$

and $\tilde{y}(0) = \tilde{y}(l) = 0$. Multiplying (5.4) (resp., (5.5)) by $\tilde{y}$ (resp., $\bar{y}$), integrating, and taking the difference, we obtain that

$$(m-\mu)\int_0^l \tilde{y}(x)\bar{y}(x)\,dx = \tilde{q}(x)\tilde{y}(x)\bar{y}'(x) - \tilde{q}(x)\tilde{y}'(x)\bar{y}(x)|_{x=0}^{x=l} = 0.$$

Since we can assume that $\tilde{y}$ and $\bar{y}$ take positive values in $(0,l)$, we deduce that $m=\mu$ and that $\tilde{y} = c\bar{y}$ in $(0,a)\cup(l-a,l)$. □

Note that the spectrum of (5.4) subject to Dirichlet boundary conditions is equal to that of the problem

$$(\bar{q}(x)y')' + \lambda H y = 0, \ \ y(0) = y(a) = 0, \tag{5.6}$$

where the function $\bar{q}$ is the restriction of $\tilde{q}$ to the interval $(0, a)$. But unlike (5.6), the eigenvalues of (5.4) all have multiplicity of infinite order.

Proof of Theorem 5.2. Let $\alpha > 1$ and $p = 2\alpha/(\alpha-1)$. Put $\tilde{q}(x) = A||\tilde{y}'||_p^{2-p}|\tilde{y}'(x)|^{p-2}$, where $\tilde{y}$ is given in Lemma 5.4. We have $\int_0^l \tilde{q}(x)^\alpha\,dx = A^\alpha$, which implies that $\tilde{q} \in U_\alpha$. Hölder's inequality implies

$$\int_0^l q(x)\tilde{y}'(x)^2\,dx \le \left(\int_0^l |\tilde{y}'(x)|^p\,dx\right)^{2/p}\left(\int_0^l q(x)^\alpha\,dx\right)^{1/\alpha}$$
$$= A\left(\int_0^l |\tilde{y}'(x)|^p\,dx\right)^{2/p} = \int_0^l \tilde{q}(x)\tilde{y}'(x)^2\,dx$$

for all $q \in U_\alpha$. On the other hand, since for each $x \in [0, l]$

$$\min_{0\le\rho\le H}[\tilde{y}^2(x)\rho - \tilde{y}^2(a_0)\rho] = \tilde{y}^2(x)\tilde{\rho}(x) - \tilde{y}^2(a_0)\tilde{\rho}(x),$$

Theorem 2.1 shows that $\int_0^l \tilde{\rho}(x)\tilde{y}(x)^2\,dx \le \int_0^l \rho(x)\tilde{y}(x)^2\,dx$ for every function $\rho \in V$. Furthermore, since the differential equation $(||\tilde{y}'||_p^{2-p}|\tilde{y}'|^{p-2}\tilde{y}')' + m\tilde{\rho}\tilde{y} = 0$ holds everywhere in $(0, l)$, Lemma 5.3 and Lemma 5.5 imply that $(\tilde{q}, \tilde{\rho})$ is a solution of Problem IV, and hence Theorem 5.2 is proved. □

COROLLARY 5.6. *Let q and ρ be two functions not identically zero such that $q \in L^\alpha(0, l)$ and $\rho \in L^\infty(0, l)$, where $\alpha > 1$. Then*

$$\lambda(q, \rho) \le C(\alpha)\,\frac{||q||_\alpha||\rho||_\infty^{1+1/\alpha}}{||\rho||_1^{2+1/\alpha}}, \tag{5.7}$$

where $C(\alpha)$ is a constant depending only on α.

Proof. To prove (5.7), it is sufficient to take

$$A = ||q||_\alpha, \qquad B = ||\rho||_1, \qquad H = ||\rho||_\infty$$

and use (5.3). Thus one obtains that

$$C(\alpha) = 2\left(\frac{\alpha+1}{\alpha}\right)^{1/\alpha-1}\left(\frac{5\alpha+1}{4\alpha}\right)^{1/\alpha}\mathcal{B}^2\left(\frac{1}{2}, \frac{1}{2}+\frac{1}{2\alpha}\right). \tag{5.8}$$

□

THEOREM 5.7. *If $\alpha = 1$, then for all $(q, \rho) \in U_1 \times V$*

$$\lambda(q, \rho) \le 12AH^2B^{-3}.$$

The equality is attained if ρ equals the function $\tilde{\rho}$ defined by (3.1) *and*

$$\tilde{q}(x) = \begin{cases} M_1H(a^2 - x^2)/2 & \text{if } 0 \le x \le a, \\ 0 & \text{if } a < x \le l/2, \\ \tilde{q}(l-x) & \text{if } l/2 \le x \le l, \end{cases}$$

where $M_1 = 12AH^2B^{-3}$ and $a = (2H)^{-1}B$.

Proof. The key to the proof is choosing a test function $\tilde{y}$ defined by

$$\tilde{y}(x) = \begin{cases} ax & \text{if } 0 \le x \le a, \\ a^2 & \text{if } a < x \le l/2, \\ \tilde{y}(l-x) & \text{if } l/2 \le x \le l, \end{cases}$$

for which we have for all $(q,\rho)\in U_1\times V$

$$\lambda(q,\rho)\le \frac{\int_0^l q\tilde{y}'^2\,dx}{\int_0^l \rho\tilde{y}^2\,dx}\le \frac{a^2A}{\int_0^l \rho\tilde{y}^2\,dx}. \tag{5.9}$$

By using the same argument as in the proof of Theorem 5.2, we obtain that

$$\int_0^l \tilde{\rho}(x)\tilde{y}(x)^2\,dx\le\int_0^l \rho(x)\tilde{y}(x)^2\,dx$$

for all $\rho\in V$. Hence from (5.9) we get

$$\lambda(q,\rho)\le a^2A\left(\int_0^l \tilde{\rho}(x)\tilde{y}(x)^2\,dx\right)^{-1}=M_1.$$

Now we shall construct a function $\tilde{q}$ such that $\tilde{y}$ satisfies the equation

$$(\tilde{q}\tilde{y}')'+M_1\tilde{\rho}\tilde{y}=0. \tag{5.10}$$

To do this we solve at first the differential equation

$$q'+M_1Hx=0,\qquad 0\le x\le a,$$

with the boundary condition $q(a)=0$. This gives

$$q(x)=M_1H(a^2-x^2)/2,\qquad 0\le x\le a.$$

Then we construct the function $\tilde{q}$ on the whole interval $[0,l]$ in the following way: $\tilde{q}(x)=q(x)$ for $0\le x\le a$, $\tilde{q}(x)=0$ for $a\le x\le l/2$, and $\tilde{q}(x)=\tilde{q}(l-x)$ for $l/2\le x\le l$. Thus $\tilde{q}\in U_1$ and the differential equation (5.10) holds everywhere in $]0,l[$, which implies that $\lambda(\tilde{q},\tilde{\rho})=M_1$ (by means of a result analogous to Lemma 5.5). Therefore the couple $(\tilde{q},\tilde{\rho})$ is extremal. □

Observe that Theorem 5.7 can be seen as a limiting case of Theorem 5.2 as $\alpha\to 1$. In fact, we have

$$M_1=\lim_{\alpha\to 1}M_\alpha.$$

Above we have not discussed the uniqueness of the obtained solutions. However, it can be proved that for each $\alpha\ge 1$ the extremal couple $(\tilde{q},\tilde{\rho})$, solution of Problem IV, is unique. Finally, we mention that, as for Problems I and II, our method applies to Problem IV when ρ satisfies conditions (4.1) or (4.3).

6. Estimates of all the eigenvalues. We now give an upper bound for the nth eigenvalue of problem (5.1)–(5.2) considered in the last section. The main result presented here is the following theorem.

THEOREM 6.1. *Let $\lambda_n(q,\rho)$ be the nth eigenvalue of problem* (5.1)–(5.2). *Suppose that the coefficients q and ρ are not identically zero and satisfy $q\in L^\alpha(0,l)$ and $\rho\in L^\infty(0,l)$, where α is a number ≥ 1. Then*

$$\lambda_n(q,\rho)\le n^2\bar{C}(\alpha)\,||q||_\alpha||\rho||_\infty^{1+1/\alpha}||\rho||_1^{-(2+1/\alpha)},$$

where $\bar{C}(\alpha)$ is given by (5.8) *if $\alpha>1$ and $\bar{C}(1)=12$. Moreover the equality is attained by two periodic functions q and ρ with period l/n and such that $q(x)=$*

$\tilde{q}(nx)$, $\rho(x) = \tilde{\rho}(nx)$ *for all* $x \in (0, l/n)$, *where* $\tilde{q}$ *and* $\tilde{\rho}$ *are the optimal functions indicated in Theorems* 5.1 *and* 5.2.

To prove this theorem, we shall use the following lemma.

LEMMA 6.2. *Let* r, s *be two real numbers such that* $rs < 0$ *and* $r + s \geq 1$. *Denote by* E *the set of all vectors* $X = (x_1, x_2, ..., x_n) \in (]0, 1[)^n$ *satisfying* $\sum_{i=1}^n x_i < 1$ *and define the function* $F : E \times E \longrightarrow R$ *by*

$$F(X, Y) = x_1^r y_1^s + x_2^r y_2^s + \cdots + x_n^r y_n^s$$

$$+ (1 - x_1 - x_2 - \cdots - x_n)^r (1 - y_1 - y_2 - \cdots - y_n)^s.$$

Then the function F *attains its minimum value* $F_{min} = (n+1)^{1-(r+s)}$ *when* $X = Y = (n+1)^{-1}(1, 1, ..., 1)$. *Moreover the minimum point is unique in the case* $r + s > 1$.

This lemma generalizes a result in [11], regarding the minimal value of the function

$$G(x, y) = x^{2/p} y^{3-2/p} + (1 - x)^{2/p} (1 - y)^{3-2/p}$$

defined on the square $0 < x < 1$, $0 < y < 1$, where p is a real number satisfying $p < 2/3$ and $p \neq 0$. We refer to [11] for the proof. We note that the minimum point in Lemma 6.2 is not unique in general. Indeed, for the case $r + s = 1$, one can easily verify that the function F achieves its minimum $F_{min} = 1$ at every couple $(X, Y) \in E \times E$ satisfying $x_i = y_i$ for $i = 1, ..., n$. If $rs < 0$ and $r + s < 1$, then the function F can take arbitrary small positive values.

Proof of Theorem 6.1. We begin with the case $n = 2$. The general case follows from similar arguments. Let q and ρ be two measurable functions such that $||q||_\alpha = 1$, $\alpha \geq 1$, $||\rho||_1 = 1$ and $0 \leq \rho(x) \leq H$ for all $x \in [0, l]$. Let y_2 (resp., $\lambda_2(q, \rho)$) be the second eigenfunction (resp., eigenvalue) of the problem

$$(q(x)y')' + \lambda \rho(x) y = 0, \quad y(0) = y(l) = 0.$$

As is well known, the function y_2 admits precisely one zero (call it x_1) in the interval $(0, l)$. The number $\lambda_2(q, \rho)$ is the first eigenvalue of the two problems

$$(q(x)y')' + \lambda \rho(x) y = 0, \quad y(0) = y(x_1) = 0,$$

$$(q(x)y')' + \lambda \rho(x) y = 0, \quad y(x_1) = y(l) = 0.$$

According to Corollary 5.6 and Theorem 5.7, we have

$$\lambda_2(q, \rho) \leq \bar{C}(\alpha) H^{1+1/\alpha} \left(\int_0^{x_1} q(x)^\alpha \, dx \right)^{1/\alpha} \left(\int_0^{x_1} \rho(x) \, dx \right)^{-(2+1/\alpha)}, \tag{6.1}$$

where $\bar{C}(\alpha)$ is given by (5.8) if $\alpha > 1$ and $\bar{C}(1) = 12$. Inequality (6.1) can be written as

$$\left(\int_0^{x_1} q(x)^\alpha \, dx \right)^{-1/\alpha} \left(\int_0^{x_1} \rho(x) \, dx \right)^{2+1/\alpha} \leq \bar{C}(\alpha) \, H^{1+1/\alpha} \, [\lambda_2(q, \rho)]^{-1}. \tag{6.2}$$

Similarly, we have

$$\left(\int_{x_1}^{l} q(x)^\alpha \, dx \right)^{-1/\alpha} \left(\int_{x_1}^{l} \rho(x) \, dx \right)^{2+1/\alpha} \leq \bar{C}(\alpha) \, H^{1+1/\alpha} \, [\lambda_2(q, \rho)]^{-1}. \tag{6.3}$$

Put $a = \int_0^{x_1} q(x)^\alpha\,dx$ and $b = \int_0^{x_1} \rho(x)\,dx$. By summing (6.2) and (6.3), we obtain

$$a^{-1/\alpha}b^{2+1/\alpha} + (1-a)^{-1/\alpha}(1-b)^{2+1/\alpha} \le \bar{C}(\alpha)H^{1+1/\alpha}\,[\lambda_2(q,\rho)]^{-1}. \tag{6.4}$$

By Lemma 6.2 (applied for $n = 1$), the left side of (6.4) is not less than 2^{-1} since a and b are both in the interval $(0,1)$. Therefore

$$1/2 \le 2\,\bar{C}(\alpha)\,H^{1+1/\alpha}\,[\lambda_2(q,\rho)]^{-1},$$

which shows that $\lambda_2(q,\rho) \le 4\,\bar{C}(\alpha)\,H^{1+1/\alpha}$. If $||q||_\alpha = A$ and $||\rho||_1 = B$, we obtain

$$\lambda_2(q,\rho) \le 4\,\bar{C}(\alpha)\,H^{1+1/\alpha}\,A\,B^{-(2+1/\alpha)}.$$

To prove the general case $n \ge 2$, we argue as above and take into account the fact that the nth eigenfunction of (5.1)–(5.2) has exactly $(n-1)$ zeros between 0 and l. □

7. Some isoperimetric inequalities. For a given function f defined on the interval $[0,l]$, we denote by f_n^+ (resp., f_n^-) the symmetrically increasing (resp., decreasing) rearrangement of f of degree n. We recall that the function f_n^+ is uniquely defined by the following conditions (see [17]):

(i) f_n^+ and f are equimeasurable on $[0,l]$. That is, for all $t \ge 0$

$$\text{meas}\{x/f_n^+(x) \ge t\} = \text{meas}\{x/f(x) \ge t\}.$$

(ii) f_n^+ is periodic on $[0,l]$ with a period equal to l/n.

(iii) f_n^+ is symmetric in $[0,l/n]$ about $x = l/(2n)$.

(iv) f_n^+ is decreasing in the interval $[0,l/(2n)]$.

Similarly, f_n^- is (uniquely) defined by (i)–(iii) and (iv)′: f_n^- is increasing in the interval $[0,l/(2n)]$. We will use throughout the notation f^+ and f^- to denote f_1^+ and f_1^-, respectively. For more information on rearrangements see [1] and [17].

We now return to problem (1.1)–(1.2). Let q and ρ be arbitrary measurable and nonnegative functions. We have already seen in Remark 3.4 that in general we cannot have an estimate for the first eigenvalue $\lambda(q,\rho)$ of problem (1.1)–(1.2) of the form $\lambda(q,\rho) \le \lambda(q^-,\rho^+)$, neither of the form $\lambda(q,\rho) \le \lambda(q^+,\rho^+)$. In this section we shall derive some conditions on q and on ρ so that the inequality $\lambda(q,\rho) \le \lambda(q^-,\rho^+)$ holds. For rearrangements of higher degree we shall prove the inequality $\lambda_n(q,\rho) \ge \lambda_n(q_n^+,\rho_n^-)$ for all integers n, where here and throughout $\lambda_n(q,\rho)$ is the nth eigenvalue of problem (1.1)–(1.2); $[\lambda_1(q,\rho) = \lambda(q,\rho)]$.

Some results concerning other differential equations have been obtained by Barnes [5]. He determined lower bounds for the first eigenvalues of the equations $(p(x)y')' + q(x)y + \lambda\rho(x)y = 0$ and $(p(x)y'')''q(x)y\mu\rho(x)y = 0$, subject to Dirichlet boundary conditions. He found that if $\lambda_1(p,q,\rho)$ (resp., $\mu_1(p,q,\rho)$) is positive, then

$$\lambda_n(p,q,\rho) \ge \lambda_n(p_n^-,q_n^-,\rho_n^-), \quad \text{resp.,} \quad \mu_n(p,q,\rho) \ge \mu_n(p_n^+,q_n^-,\rho_n^-).$$

These inequalities do not require additional conditions aside from some regularity assumptions on the coefficients p, q, and ρ and the positivity of the eigenvalues $\lambda_1(p,q,\rho)$ and $\mu_1(p,q,\rho)$. In what follows we suppose that the function ρ satisfies $h \le \rho(x) \le H$ for all $x \in [0,l]$, where h and H are two positive numbers.

LEMMA 7.1. *Let $I(\rho)$ denote the Lebesgue integral of $\rho(x)$ over $[0,l]$. If*

$$H\max_x q(x) - h\min_x q(x) \le \max\left\{h\pi^2 l^{-2},\, 4hHl^{-1}I(\rho)^{-1}\right\}, \tag{7.1}$$

then $q(x) - \lambda_1(q,\rho)\rho(x) \le 0$ for all $x \in [0,l]$. Consequently, if $y_1(x)$ is a positive

first eigenfunction of problem (1.1)–(1.2) *and if condition* (7.1) *holds, then* $y_1(x)$ *is concave.*

Proof. A variational principle implies that

$$\lambda(q,\rho)=\inf_y \frac{\int_0^l y'^2\,dx+\int_0^l qy^2\,dx}{\int_0^l \rho y^2\,dx},$$

where the infimum is taken in the class of all nonzero functions y from $C_0^1[0,l]$. By taking into account the inequality (see, for example, [11])

$$\max_{x\in[0,l]}|y(x)|^2\le\frac{l}{4}\int_0^l y'^2\,dx$$

valid for all $y\in H_0^1(0,l)$, we obtain

$$\begin{aligned}\lambda(q,\rho)&\ge\inf_y\left[\int_0^l y'^2\,dx\Big/\int_0^l\rho y^2\,dx\right]+\min_x q(x)/H\\&\ge\max\left\{H^{-1}(\pi/l)^2,\,4l^{-1}I(\rho)^{-1}\right\}+\min_x q(x)/H.\end{aligned}$$

If (7.1) holds, from the last inequality we get $\lambda(q,\rho)\ge\max_x q(x)/h$, which implies that $\lambda(q,\rho)\rho(x)-q(x)\ge 0$ for all x in $[0,l]$. If $y_1(x)$ is a positive first eigenfunction of problem (1.1)–(1.2) corresponding to $\lambda(q,\rho)$, then $y_1''(x)=[q(x)-\lambda_1(q,\rho)\rho(x)]y_1(x)\le 0$ in $[0,l]$. This means that $y_1(x)$ is a concave function. □

The following result generalizes a theorem of Schwarz [17].

THEOREM 7.2. *If condition* (7.1) *holds, then*

$$\lambda(q,\rho)\le\lambda(q^-,\rho^+).\tag{7.2}$$

Moreover if $q=q^-$ *(resp.,* $\rho=\rho^+$*) and equality holds in* (7.2)*, then* $\rho=\rho^+$ *(resp.,* $q=q^-$*).*

Proof. Suppose that (7.1) is fulfilled, and let $y_1(x)$ be a positive first eigenfunction of problem (1.1)–(1.2) corresponding to q^- and ρ^+. Since q^- and ρ^+ satisfies condition (7.1), Lemma 7.1 shows that $y_1(x)$ is a concave function. In view of the symmetry of q^- and ρ^+, $y_1(x)$ is also symmetric and symmetrically decreasing. Thus using the inequality

$$\int_0^l f^-\,g^+\,dx\le\int_0^l f\,g\,dx\le\int_0^l f^-\,g^-\,dx,$$

where f and g are two measurable nonnegative functions defined on $[0,l]$, we see that

$$\int_0^l qy_1^2\,dx\le\int_0^l q^-y_1^2\,dx\quad\text{and}\quad\int_0^l\rho^+y_1^2\,dx\le\int_0^l\rho y_1^2\,dx.$$

Hence it follows that

$$\begin{aligned}\lambda(q^-,\rho^+)&\ge\frac{\int_0^l y_1'^2\,dx+\int_0^l qy_1^2\,dx}{\int_0^l\rho y_1^2\,dx}\\&\ge\lambda(q,\rho).\end{aligned}$$

Suppose now that equality holds in (7.2) for a couple (q,ρ) satisfying (7.1) and such that $q = q^-$. Then $\lambda(q,\rho^+) = \lambda(q,\rho)$ and the reasoning above implies that $\lambda(q,\rho^+)$ and $\lambda(q,\rho)$ have the same first eigenfunction. This means that $\rho = \rho^+$. □

Remark. Suppose that ρ vanishes at some $x \in [0,l]$. To simplify this remark we suppose that q and ρ are both continuous and not identically zero. Then $q^-(l/2) > 0$ and ρ^+ vanishes at the point $x = l/2$. Let y_1 be a positive first eigenfunction of problem (1.1)–(1.2) corresponding to q^- and ρ^+. Since y_1'' is continuous and $y_1''(l/2) > 0$, y_1'' takes positive values in a neighborhood of $l/2$. Therefore y_1 is not a concave function. Thus in the case where ρ has zeros in $[0,l]$ there are no conditions assuring the concavity of the first eigenfunction. This interpretation leads us to the question of whether the concavity of the first eigenfunction corresponding to q^- and ρ^+ is necessary for estimate (7.2) to hold.

COROLLARY 7.3. *Let $\lambda(q)$ denote the first eigenvalue of the problem*

$$y'' - q(x)y + \lambda y = 0, \quad y(0) = y(l) = 0.$$

If $\max_x q(x) - \min_x q(x) \le \pi^2/l^2$, then

$$\lambda(q) \le \lambda(q^-).$$

Moreover equality holds only if $q = q^-$.

THEOREM 7.4. *For any nonzero integer n, we have*

$$\lambda_n(q,\rho) \ge \lambda_n(q_n^+, \rho_n^-). \tag{7.3}$$

Proof. Unlike (7.2), inequality (7.3) does not require condition (7.1). In fact, for $n = 1$ we have

$$\begin{aligned}\lambda(q,\rho) &\ge \frac{\int_0^l (y_1^-)'^2\,dx + \int_0^l q^+(y_1^-)^2\,dx}{\int_0^l \rho^-(y_1^-)^2\,dx}\\ &\ge \lambda(q^+,\rho^-),\end{aligned}$$

where $y_1(x)$ is a first eigenfunction of (1.1) and (1.2) corresponding to $\lambda(q,\rho)$. Let us prove the case $n = 2$. For this we shall need some concepts from [17]. The general case may be obtained via similar arguments. Let a be the zero in $(0,l)$ of the second eigenfunction of problem (1.1)–(1.2) (it is well known that a is unique for such a eigenfunction). Put $I_1 = [0,a]$ and $I_2 = [a,l]$. We consider the restriction of $\rho(x)$ and $q(x)$ in each of those intervals and we denote by $\rho^{-(i)}$ (resp., $q^{+(i)}$) the symmetrically decreasing (resp., increasing) rearrangement of first degree of the restriction of $\rho(x)$ (resp., $q(x)$) to I_i, $i = 1,2$. Let $\lambda^{(1)}$ and $\lambda^{(2)}$ be the first eigenvalues to the problems

$$y'' - q^{+(1)}(x)y + \lambda\rho^{-(1)}(x)y = 0, \quad y(0) = y(a) = 0, \tag{7.4}$$

and

$$y'' - q^{+(2)}(x)y + \lambda\rho^{-(2)}(x)y = 0, \quad y(a) = y(l) = 0, \tag{7.5}$$

respectively. By the first part of the proof we obtain

$$\lambda_2(q,\rho) \ge \max\left\{\lambda^{(1)}, \lambda^{(2)}\right\}.$$

Without loss of generality we assume that $\lambda^{(1)} \geq \lambda^{(2)}$ and define two functions P and Q as follows:

$$P(x) = \rho^{-(1)}(x) \text{ in } I_1, \quad P(x) = \rho^{-(2)}(x) \text{ in } I_2,$$

and

$$Q(x) = \begin{cases} q^{+(1)}(x) & \text{for } x \in I_1, \\ q^{+(2)}(x) + (\lambda^{(1)} - \lambda^{(2)})\rho^{-(2)}(x) & \text{for } x \in I_2. \end{cases}$$

Let $y_{(1)}(x)$ (resp., $y_{(2)}(x)$) be the first eigenfunction of problem (7.4) (resp., (7.5)). Define the function $Y(x)$ by $Y(x) = y_{(1)}(x)$ in I_1 and $Y(x) = \xi y_{(2)}(x)$ in I_2. The real ξ is chosen such that $Y'(x)$ is continuous at $x = a$. Thus $\lambda^{(1)}$ (resp., $Y(x)$) is the second eigenvalue (resp., eigenfunction) of the eigenvalue problem

$$Y'' - QY + \lambda PY = 0, \quad Y(0) = Y(l) = 0.$$

Let α be the midpoint of I_1. We may assume that $Y(x) > 0$ in the interior of I_1, and we define the new functions $\tilde{P}$, $\tilde{Q}$, and $\tilde{Y}$ in the interval $[0, l/2]$ as follows:

$$\tilde{P}(x) = \begin{cases} P(x) & \text{for } x \in [0, \alpha], \\ P(x + l/2) & \text{for } x \in [\alpha, l/2], \end{cases}$$

$$\tilde{Q}(x) = \begin{cases} Q(x) & \text{for } x \in [0, \alpha], \\ Q(x + l/2) & \text{for } x \in [\alpha, l/2], \end{cases}$$

and

$$\tilde{Y}(x) = \begin{cases} Y(x) & \text{for } x \in [0, \alpha], \\ \zeta Y(x + l/2) & \text{for } x \in [\alpha, l/2]. \end{cases}$$

The nonpositive real ζ is chosen such that $\tilde{Y}$ is continuous at $x = \alpha$. Thus $\tilde{Y}$ is the first eigenfunction of the problem

$$Y'' - \tilde{Q}Y + \lambda \tilde{P}Y = 0, \quad Y(0) = Y(l/2) = 0, \tag{7.6}$$

and $\lambda^{(1)}$ is the first eigenvalue of (7.6). Now denote by $\tilde{P}^-$ (resp., $\tilde{Q}^+$) the symmetrically decreasing (resp., increasing) rearrangement of $\tilde{P}$ (resp., $\tilde{Q}$) of first degree in $[0, l/2]$. Then, the beginning of the proof shows that

$$\lambda^{(1)} \geq \lambda_1(\tilde{Q}^+, \tilde{P}^-). \tag{7.7}$$

On the other hand, it is easy to see that the extension of $\tilde{P}^-$ (resp., $\tilde{Q}^+$) to the whole interval $[0, l]$ with a period equal to $l/2$ is exactly the symmetrically decreasing (resp., increasing) rearrangement of second degree of P (resp., Q) in $[0, l]$. Hence (7.7) and the equality $\lambda_1(\tilde{Q}^+, \tilde{P}^-) = \lambda_2(Q_2^+, P_2^-)$ yield

$$\lambda^{(1)} \geq \lambda_2(Q_2^+, P_2^-).$$

On the other hand, as $Q_2^+(x) \geq q_2^+(x)$ and $P_2^-(x) = \rho_2^-(x)$ in $[0, l]$, Sturm comparison theorem implies that

$$\lambda_2(Q_2^+, P_2^-) \geq \lambda_2(q_2^+, \rho_2^-).$$

Hence inequality (7.3) holds for $n = 2$ since $\lambda_2(q, \rho) \geq \lambda^{(1)}$. □

We finally mention that, unlike (7.3), it is not clear whether the inequality $\lambda_n(q,\rho) \le \lambda_n(q_n^-, \rho_n^+)$ holds for $n > 1$, even when q and ρ satisfy condition (7.1). However, by modifying the proof of Theorem 7.2, we can prove the inequality

$$\lambda_n(q,\rho) \le \frac{n^2\pi^2 H}{B^2}\left[\frac{1}{2} + \sqrt{\frac{1}{4} + \frac{AB}{n^2 H\pi^2}}\right]^2$$

for all $(q,\rho) \in U \times V$, where the sets U and V are as in section 1. The equality is reached by two periodic functions q and ρ having period l/n and such that $q(x) = q_0(nx)$, $\rho(x) = \rho_0(nx)$ for all $x \in (0, l/n)$, where q_0 and ρ_0 are the optimal functions found in Theorem 3.3.

BLOW-UP IN NONLOCAL REACTION-DIFFUSION EQUATIONS*

PHILIPPE SOUPLET†

Abstract. We present new blow-up results for reaction-diffusion equations with nonlocal nonlinearities. The nonlocal source terms we consider are of several types, and are relevant to various models in physics and engineering. They may involve an integral of the unknown function, either in space, in time, or both in space and time, or they may depend on localized values of the solution. For each type of problems, we give finite time blow-up results which significantly improve or extend previous results of several authors. In some cases, when the nonlocal source term is in competition with a local dissipative or convective term, optimal conditions on the parameters for finite time blow-up or global existence are obtained.

Our proofs rely on comparison techniques and on a variant of the eigenfunction method combined with new properties on systems of differential inequalities. Moreover, a unified local existence theory for general nonlocal semilinear parabolic equations is developed.

Key words. nonlinear parabolic equations, nonlocal source, partial integrodifferential equations, finite-time blow-up, global existence

1. Introduction and examples.

The purpose of this paper is to study the blow-up behavior of nonnegative solutions for some classes of reaction-diffusion equations, where the reaction term may have a nonlocal, functional dependence either in space or in time (or possibly in both space and time). Given a (smoothly) bounded domain Ω in $\mathbb{R}^N$, such an equation may be written in the following general form:

$$u_t - \Delta u = F^t\big(R^t u\big)(x), \quad t > 0, \quad x \in \Omega, \tag{NLRD}$$

where, for each $t > 0$, $F^t : C([0,t] \times \overline{\Omega}) \to C(\overline{\Omega})$, and the past time restriction operator R^t is defined by $R^t u = u_{|[0,t]\times\overline{\Omega}}$. We here consider the initial-boundary value problem associated with (NLRD), with homogeneous Dirichlet boundary conditions. The structure of the right hand of equation (NLRD) means that the "heat source" at a point (t,x) may possibly depend on the whole past history of the temperature in the whole domain Ω.

A very large literature has been devoted to the study of more "classical" diffusion equations with local reaction terms:

$$u_t - \Delta u = f\big(t,x,u(t,x)\big), \quad t > 0, \quad x \in \Omega,$$

subject to appropriate initial and boundary conditions. However, numerous problems, which fall into the form of (NLRD), have been studied, and many of them arise in applications. (Note that nonlocal partial integrodifferential equations not of parabolic type are also widely encountered in applications; see, e.g., [G], [MR].)

To motivate our study, we first give a short review of examples of such parabolic equations studied in the literature, for which existence of nonglobal solutions may

*Received by the editors March 26, 1997; accepted for publication (in revised form) October 13, 1997; published electronically June 22, 1998.

†Laboratoire Analyse Géométrie et Applications, UMR CNRS 7539, Institut Galilée, Université Paris-Nord, 93430 Villetaneuse, France (souplet@math.univ-paris13.fr).

occur. (For other properties of nonlocal equations, see the references in the appendix and in the cited works.) One can distinguish, at least, four types of problems of the form (NLRD).

1.1. Problems with nonlocal reaction terms in space. They take the form

$$u_t - \Delta u = F\big((t,x,u(t,.)\big), \quad t>0, \quad x\in\Omega. \tag{NLS}$$

We distinguish two types within this category. In the first one, the functional F involves an integral of some function of $u(t,.)$ over Ω.

1.1.1. Nonlocal terms induced by an integral over Ω. For instance, Bebernes and Bressan [BB] (see also [BE], [P2]) consider the equation

$$u_t - \Delta u = f\big(t,u(t,x)\big) + \int_\Omega g\big(t,u(t,y)\big)\,dy, \quad t>0, \quad x\in\Omega. \tag{1.1}$$

These authors pay special attention to the case $f(t,u)=e^u$, $g(t,u)=ke^u$ $(k>0)$, for which (1.1) represents an ignition model for a compressible reactive gas, and prove that solutions blow up in the whole domain. Wang and Wang [WW] study the blow up behavior of solutions of the equation

$$u_t - \Delta u = \int_\Omega u^p(t,y)\,dy - ku^q(t,x), \quad t>0, \quad x\in\Omega, \tag{1.2}$$

with $p,\ q>1$, while Budd, Dold, and Stuart [BDS] and Hu and Yin [HY] consider the symmetric of problem (1.2) in the case $q=p$,

$$u_t - \Delta u = u^p - \frac{1}{|\Omega|}\int_\Omega u^p(t,y)\,dy, \quad t>0, \quad x\in\Omega,$$

for which the L^1 energy of the solutions is conserved (under Neumann boundary conditions).

A nonlocal problem where the nonlinearity also involves spatial derivatives of u has been considered by Deng, Kwang, and Levine [DKL]. They investigate the blow-up/global existence properties of the following one-dimensional convection-reaction-diffusion equation:

$$u_t - \Delta u = f\big(u(t,x),\|u(t,.)\|_k\big) + uu_x, \quad t>0, \quad x\in\Omega, \tag{1.3}$$

where

$$\|u(t,.)\|_k = \left(\int_\Omega |u|^k(t,y)\,dy\right)^{1/k} \quad \text{and} \quad f(u,\|u\|_k) = \Big(a\|u\|_k^{p-1}+b\Big)\,u,$$

with $p>1$, $1\le k<\infty$, $a>0$, and $b\in\mathbb{R}$. This problem is related to a turbulence model proposed by Burgers (see the references in [DKL]). On the other hand, Deng [D] and Y. Yin [Yi] recently studied related equations with singular nonlocal nonlinearities, typically

$$u_t - \Delta u = \frac{1}{1-\|u(t,.)\|_k}, \quad t>0, \quad x\in\Omega,$$

with zero initial and boundary conditions. For this problem, the quenching of the solution is proved [Yi]; i.e., $\|u(t,.)\|_k$ reaches 1 and u_t blows up in finite time.

Problems of the form

$$u_t - \Delta u = \frac{f(u(t,x))}{\left(\int_\Omega g(u(t,y))\,dy\right)^p}, \quad t>0, \quad x\in\Omega,$$

with $p>0$, and, e.g., $f(u)=g(u)=e^u$, arise in the modelization of shear banding in metals (see [BT], [F], and the references therein). Similar problems arise in a simplified model for Ohmic heating in a thermistor (see [L]; the full model is a coupled system of a parabolic and an elliptic equation — see [AC1], [AC2], and the references therein).

1.1.2. Localized reaction terms. Another kind of nonlocal problems in space occurs when the intensity of the source at the point x depends on the value of u at a single point x_0, different from x. Physical phenomena where the reaction is driven by the temperature at a single site can be described by equations of the type

$$u_t - \Delta u = f\big(u(t,x_0(t))\big), \quad t>0, \quad x\in\Omega. \tag{LRT}$$

Cannon and Yin [CaY] study the local solvability of (LRT), and Chadam, Peirce, and Yin [CPY] investigate the blow-up property for equation (LRT) with superlinear convex nonlinearities f, in the case when $x_0(t)$ is a constant point x_0.

Problem (LRT) is also related to some local equations with a singular source term, of the form

$$u_t - \Delta u = \delta(x-x_0(t))f(u(t,x)), \quad t>0, \quad x\in\Omega,$$

where δ is the Dirac delta distribution, studied by Olmstead and Roberts (see, e.g., [OR], [O]).

1.2. Problems with nonlocal reaction terms in time. The source term here involves an integral over $[0,t]$ of some function of the solution and of the independent variables:

$$u_t - \Delta u = f\left(u(t,x), \int_0^t g\big(t,x,s,u(s,x)\big)\,ds\right), \quad t>0, \quad x\in\Omega. \tag{NLT}$$

Such equations model diffusion phenomena with memory effects. A special case widely encountered in population dynamics are Volterra diffusion equations, where the nonlocal "hereditary" term takes the form of a convolution with a kernel:

$$g\big(t,x,s,u(s,x)\big) = k(t-s)h(u(s,x)).$$

See [Y1], [Y2], and the references therein for the study of global solutions and their stability properties in the case

$$f \equiv \big(a-bu(t,x)\big)u(t,x) - \int_0^t k(t-s)u(s,x)\,ds,$$

$a, b>0$, $k(t-s)\geq 0$. See also [BG] for some examples relevant to the thermodynamics of phase transition.

Some blow-up results were obtained for equations of the type (NLT) with "explosive" nonlinearities, of the form

$$u_t - \Delta u = \int_0^t k(t,x,s)g(u(s,x))\,ds - f(u(t,x)), \quad t>0, \quad x\in\Omega,$$

in the case $g(u)\sim u^p$ $(p>1)$, $f(u)=\lambda u$ and, e.g., $k(t,s,u)\geq k>0$ (see [Be], [Ko], and [So]).

1.3. Problems with nonlocal reaction terms in space and time. They usually take the form

(NLST)

$$u_t - \Delta u = f\left(t, x, u(t,x), \int_0^t \int_\Omega k(t,x,s,y) g(u(s,y))\, dy\, ds\right), \quad t > 0, \quad x \in \Omega.$$

Let us mention the special example

$$u_t - \Delta u = \mu(x)\left\{p \exp\left[\int_0^t \int_\Omega \beta(y) u(s,y)\, dy\, ds\right] - 1\right\}, \quad t > 0, \quad x \in \Omega, \tag{1.4}$$

which plays an important role in the theory of nuclear reactor dynamics (see the numerous references in [P1] for physical motivation). The blow up behavior was studied by Pao [P1], who proved the finite-time blow-up for large positive initial data when $\mu \equiv \text{Const.} > 0$, $\beta \geq 0$, $\beta \not\equiv 0$, and $p > 1$. His result was later improved by Guo and Su [GS], who proved the blow-up of all nonnegative solutions when $\mu \geq 0$, $\mu \not\equiv 0$, $\beta \geq 0$, $\beta \not\equiv 0$, and $p > 1$.

2. Main results. The purpose of this paper is to present new blow-up results, which, for each type of problems, significantly improve and/or generalize several of the above cited results on blow-up for nonlocal parabolic equations. In many of the equations under consideration, the nonlinearity involves both local and nonlocal terms. In particular, the competition between nonlocal source terms and local dissipative or convective terms will be rather extensively investigated, and we will determine some sharp critical exponents for blow-up or global existence. Let us illustrate our results by some typical examples of each type. (Further results will be stated in the following sections. Local existence-uniqueness and comparison theorems are given in the appendix.)

First consider the following class of nonlocal problems with integral term in space.

$$u_t - \Delta u = u^m(t,x) \|u(t,.)\|_k^p - a u^q(t,x) - b.\nabla u^r(t,x), \quad t > 0, \quad x \in \Omega, \tag{2.1}$$

$$u(t,x) = 0, \quad t > 0, \quad x \in \partial\Omega, \tag{2.2}$$

$$u(0,x) = u_0(x), \quad x \in \Omega. \tag{2.3}$$

We have the following theorem.

THEOREM A. *Assume that p, q, $r \geq 1$, $m = 0$ or $m \geq 1$, $1 \leq k \leq \infty$, $a \in \mathbb{R}$, and $b \in \mathbb{R}^N$. Let $\phi \in C(\overline{\Omega})$, with $\phi \geq 0$, $\phi \not\equiv 0$, $\phi_{|\partial\Omega} = 0$, $u_0 = \lambda\phi$, $\lambda > 0$, and let u (≥ 0) be the solution of* (2.1)–(2.3).

(i) *If $m + p > \max(q, r)$, then there exists $\Lambda(\phi) > 0$, such that u blows up in finite time in L^∞ norm if $\lambda > \Lambda(\phi)$.*

(ii) *If $m + p \leq q$ and $a > 0$ (with a large enough in case of equality), or if $m + p \leq r$ and $b \neq 0$ (with $|b|$ large enough in case of equality), then u is global and bounded.*

Theorem A extends the results of Deng, Kwang, and Levine [DKL] and Wang and Wang [WW], who proved the possibility of blow up, in the cases $m = q = 1$, $r = 2$, and $m = 0$, $b = 0$, $p = k$, respectively. The authors of [DKL] also proved that $p = 1$ is the critical blow-up exponent in the case $m = 1$, $r = 2$ (if $q = 1$). Theorem A shows that, more generally, the critical blow-up exponents are given by $r = m + p$ and $q = m + p$. Let us point out that the methods used in [DKL] and [WW] do not seem applicable to the present case. The argument in [DKL] is a comparison with a subsolution of separated form, $z(t)w(x)$, with $z(t)$ growing unbounded in finite time,

and one easily checks that $m \le 1$ is a necessary condition for a function of this form to be a subsolution. The authors of [WW] use an eigenfunction argument which does not apply for a more complicated nonlocal term such as in (2.1).

Next, we turn to nonlocal problems with moving localized source:

$$u_t - \Delta u = f\big(u(t, x_0(t))\big), \quad t > 0, \quad x \in \Omega. \tag{LST}$$

THEOREM B. *Assume that $x_0 : \mathbb{R}^+ \to \Omega$ is Hölder continuous, and let $f : \mathbb{R} \to \mathbb{R}$, locally Lipschitz, be such that*

$$\lim_{s\to\infty} f(s)/s = \infty, \quad f \text{ nondecreasing}, \quad \int^{\infty} \frac{ds}{f(s)} < \infty, \quad \text{and} \quad f(0) \ge 0. \tag{2.4}$$

Let $\phi \in C(\overline{\Omega})$, with $\phi \ge 0$, $\phi \not\equiv 0$, $\phi_{|\partial\Omega} = 0$, $u_0 = \lambda\phi$, $\lambda > 0$, and let u (≥ 0) be the solution of (LST), (2.2), (2.3). *Then there exists $\Lambda(\phi) > 0$, such that u blows up in finite time in L^∞ norm if $\lambda > \Lambda(\phi)$.*

Theorem B improves the result of Chadam, Peirce, and Yin [CPY] by allowing the localization point $x_0(t)$ to describe an arbitrary curve in the domain Ω, instead of being fixed. Moreover, the authors of [CPY] need the additional assumptions that f is convex, and that the initial data is large in the neighborhood of x_0, which we do not require. Here again, the previous argument—a comparison with the solution of the corresponding local, radially symmetric problem—does not seem to apply under the weakened assumptions of Theorem B, and some different approach is necessary.

We then consider the following nonlocal equations in time and in space and time:

$$u_t - \Delta u = \mu(x) \int_0^t u^p(s, x)\, ds - a u^q(t, x) \quad t > 0, \quad x \in \Omega, \tag{2.5}$$

and

$$u_t - \Delta u = \mu(x) \int_0^t \int_\Omega \beta(y) u^p(s, y)\, dy\, ds - a u^q(t, x), \quad t > 0, \quad x \in \Omega, \tag{2.6}$$

where $p, q \ge 1$, $a > 0$, μ is Hölder continuous in $\overline{\Omega}$, $\mu \ge 0$, $\mu \not\equiv 0$ and (in case of (2.6)) $\beta \in C(\overline{\Omega})$, $\beta \ge 0$, $\beta \not\equiv 0$. We obtain the following theorem.

THEOREM C. *Let $u_0 \in C^1(\overline{\Omega})$, with $u_0 \ge 0$, $u_0 \not\equiv 0$, $u_{0|\partial\Omega} = 0$, and let u (≥ 0) be the solution of* (2.5) *or* (2.6), *with conditions* (2.2), (2.3). *In case of* (2.6), *also assume that $\mu\beta \not\equiv 0$.*

(i) *If $p > q$, then u blows up in finite time in L^∞ norm.*

(ii) *If $p \le q$, then u is global and unbounded, that is,* $\limsup_{t\to\infty} |u(t)|_\infty = \infty$.

Theorem C improves the results of Bellout [Be], Kozhanov [Ko], and Souplet [So]. In these papers (which were concerned only with the case of (2.5)), blow-up was obtained only for sufficiently large initial data u_0 and under the strong restriction that the local dissipative term grow at most linearly. Here we prove that blow up occurs whenever $p > q$ and *for all nonnegative nontrivial* u_0. Moreover, $p = q$ is proved to be the critical blow up exponent, so that the result is optimal. Interestingly, no matter how large q is, the problems (2.5) (or (2.6)), (2.2), (2.3) admit no bounded positive solutions at all.

Concerning the nonlocal equation in space and time (1.4), with μ and β as above, we also obtain the following result.

THEOREM D. *Let $p \ge 1$ and assume that $\mu\beta \not\equiv 0$. Let $u_0 \in C^1(\overline{\Omega})$, with $u_0 \ge 0$, $u_0 \not\equiv 0$, $u_{0|\partial\Omega} = 0$, and let u (≥ 0) be the solution of* (1.4), (2.2), (2.3). *Then u blows up in finite time in L^∞ norm.*

Theorem D partially improves the results of Pao [P1] and Guo and Su [GS], who obtained the same conclusion for $p > 1$ (without assuming $\mu\beta \not\equiv 0$ in the case of [GS]). The case $p = 1$ is more difficult, in particular because the nonlinearity vanishes for $u = 0$, so that the equation admits the trivial solution. Moreover, the comparison arguments with a subsolution of separated form in [P1] and [GS] do not apply when $p = 1$.

Our results rely on three different methods. The first one is an extension of the method of self-similar subsolutions, used extensively in a recent work of Souplet and Weissler [SW1], in order to handle general parabolic equations with local, gradient-dependent nonlinearity. Since this is a comparison method, it applies under the restriction that the functional in the nonlocal reaction term be monotonically nondecreasing with respect to the unknown function, so that the comparison principle apply (see the appendix). Although this method can work also for nonlocal problems in time (see Theorem 5.4), the best results are obtained for nonlocal problems in space, either of integral type (Theorems A and 3.1) or of localized type (Theorem 4.1), yielding the optimal critical exponents.

For Theorem B, we use a comparison with a subsolution of separated form, along with some strong maximum principle arguments.

The third method is a variant of the eigenfunction method, introduced by Kaplan [Ka], combined with some new properties on systems of differential inequalities. This approach turns out to be especially powerful for nonlocal problems in time or in space and time (Theorems C, D, 5.1, and 5.2), also leading to critical exponents and to the proof of blow up of all nonnegative nontrivial solutions. Let us recall that the usual eigenfunction method introduces a single auxiliary function (namely, the first generalized Fourier coefficient of $u(t,.)$) and reduces the problem to proving global nonexistence for a differential inequality. The main difference in our approach is that we introduce *two* independent auxiliary functions (see formula (5.5)), leading to a system of two coupled differential inequalities, whose analysis is more delicate (Lemma 5.3). The classical approach with a single function, which was used in [Be, Kh, So], seems to enable one to obtain blow up only for large initial data.

Sections 3 and 4 treat nonlocal problems in space, respectively of integral and localized types. Section 5 is concerned with nonlocal problems in time or in space and time. The necessary local existence-uniqueness and comparison theorems are given in the appendix, where we construct in some detail a unified local theory for the general equation (NLRD).

3. Nonlocal reaction in space: Integral source terms. The blow up part of Theorem A is a consequence of the following more general result, concerning equations of the form

$$u_t - \Delta u = u^m(t,x)\|u(t,.)\|_k^p - F\big(u(t,x), \nabla u(t,x)\big), \quad t > 0, \quad x \in \Omega. \tag{3.1}$$

THEOREM 3.1. *Let p, $q \geq 1$, $m = 0$ or $m \geq 1$, $1 \leq k \leq \infty$, $a > 0$. Assume that $F : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ is locally Lipschitz continuous, with $F(0,0) \leq 0$, and satisfies*

$$F\big(u,U\big) \leq a\big(|u|^q + |u| + |U|^q + |U|\big), \quad u \in \mathbb{R}, \quad U \in \mathbb{R}^N, \tag{3.2}$$

and that

$$m + p > q.$$

Let $\phi \in C^1(\overline{\Omega})$, $\phi \geq 0$, $\phi \not\equiv 0$, $\phi_{|\partial\Omega} = 0$, and let u (≥ 0) be the solution of (3.1), (2.2), (2.3). *Then there exists $\Lambda(\phi) > 0$, such that u blows up in finite time in C^1 norm if $\lambda > \Lambda(\phi)$.*

Our arguments rely on a comparison with a *self-similar subsolution* which blows up in finite time. This method was used in a previous work [SW1] in order to solve the general problem of the critical blow up exponent for nonlinear parabolic equations with local gradient-dependent nonlinearity, of the form

$$u_t - \Delta u = F(u, \nabla u).$$

One of the main results of [SW1] was, in rough terms, that blow up is possible whenever F grows positively with respect to u faster than its negative growth with respect to ∇u. This principle can be illustrated on the simple model equation

$$u_t - \Delta u = u^p - \mu|\nabla u|^q$$

(with $\mu > 0$, in a bounded domain) for which (i) blow-up occurs for large initial data if $p > q$; (ii) all solutions are global and bounded if $p \leq q$. (See also [SW2], [STW], and the references therein, for related results.)

The method of self-similar subsolutions here confirms its ability to handle a wide variety of blow up problems (see also the case of spatially localized or time-integral source terms in the next sections). Let us point out that this method can be extended to handle degenerate parabolic problems (replacing the Laplacian in equation (2.1) with any nonnegative, semidefinite, possibly nonlinear, elliptic operator, e.g., the porous medium operator; see [SW1]). However, for simplicity, we have here restricted ourselves to the semilinear case.

Proof of Theorem 3.1. Since (3.1) does not a priori make sense for negative values of u, we actually consider the equation

$$Pu(t,x) \equiv u_t - \Delta u - u_+^m(t,x)\|u_+(t,.)\|_k^p + F\big(u(t,x), \nabla u(t,x)\big) = 0. \tag{3.3}$$

Existence-uniqueness of a maximal in time solution, with blow-up alternative in C^1 norm, and the validity of the comparison principle, then follow from Theorem A.12. In particular, since $F(0,0) \leq 0$, $u \geq 0$ as long as it exists.

By translation, one may assume without loss of generality that $0 \in \Omega$ and $\phi(0) > 0$. We seek a blowing up subsolution in the self-similar form

$$v(t,x) = \frac{1}{(T-t)^\gamma}\, V\left[\frac{|x|}{(T-t)^\sigma}\right],$$

with

$$V(y) = 1 + \frac{A}{2} - \frac{y^2}{2A}, \quad y \geq 0, \tag{3.4}$$

where γ, $\sigma > 0$, $A > 1$, and $0 < T < 1$ are to be determined. First note that, for T small enough,

$$\mathrm{Supp}(v_+(t,.)) = \overline{B}(0, R(T-t)^\sigma) \subset \overline{B}(0, RT^\sigma) \subset \Omega, \quad 0 \leq t < T, \tag{3.5}$$

with $R = \big(A(2+A)\big)^{1/2}$.

Next, we estimate the different terms from $Pv(t,x)$. We have

$$-\Delta v(t,x) = \frac{N/A}{(T-t)^{\gamma+2\sigma}}.$$

For all $(t,x)\in(0,T)\times\Omega$, we find

$$|v|(t,x)\le\frac{1+A+\mathrm{diam}^2(\Omega)}{(T-t)^{\gamma+2\sigma}}$$

and

$$|\nabla v|(t,x)\le\frac{\mathrm{diam}(\Omega)}{(T-t)^{\gamma+2\sigma}}.$$

The remaining terms are estimated in two different ways according to the size of $y=|x|/(T-t)^\sigma$. If $0\le y\le A$, we have $1\le V(y)\le 1+A/2$ and $V'(y)\le 0$, hence

$$v_t(t,x)=\frac{(\gamma V(y)+\sigma yV'(y))}{(T-t)^{\gamma+1}}\le\frac{\gamma(1+A)}{(T-t)^{\gamma+1}}.$$

In the case $k<\infty$, setting $M=\int_{B(0,R)}V^p(|\xi|)\,d\xi>0$ and $\alpha=p/k$, we have, after a change of variable and using (3.5),

$$\begin{aligned}v_+^m(t,x)\|v_+(t,.)\|_k^p&=\frac{V_+^m(y)}{(T-t)^{\gamma(m+p)}}\left(\int_{B(0,R(T-t)^\sigma)}V^k\left[\frac{|z|}{(T-t)^\sigma}\right]dz\right)^\alpha\\&=\frac{M^\alpha V_+^m(y)}{(T-t)^{\gamma(m+p)-N\sigma\alpha}}\\&\ge\frac{M^\alpha}{(T-t)^{\gamma(m+p)-N\sigma\alpha}}.\end{aligned}$$

(This formula remains valid for $k=\infty$ with $\alpha=0$.) Combining these estimates and using (3.2) yield, for all $(t,x)\in(0,T)\times\Omega$ such that $0\le y\le A$,

$$\begin{aligned}Pv(t,x)\le{}&\frac{\gamma(1+A)}{(T-t)^{\gamma+1}}+\frac{N}{(T-t)^{\gamma+2\sigma}}-\frac{M^\alpha}{(T-t)^{\gamma(m+p)-N\sigma\alpha}}\\&+a\frac{2\big[1+A+\mathrm{diam}^2(\Omega)\big]^q+2\,\mathrm{diam}^q(\Omega)+1}{(T-t)^{(\gamma+2\sigma)q}}.\end{aligned}\tag{3.6}$$

On the other hand, if $y\ge A$, we have $V(y)\le 1$ and $V'(y)\le -1$, so that

$$v_t(t,x)\le\frac{\gamma-\sigma A}{(T-t)^{\gamma+1}}.$$

Therefore, for all $(t,x)\in[0,T)\times\Omega$ such that $y\ge A$, we obtain

$$Pv(t,x)\le\frac{\gamma-\sigma A}{(T-t)^{\gamma+1}}+\frac{N}{(T-t)^{\gamma+2\sigma}}+a\frac{2\big[1+A+\mathrm{diam}^2(\Omega)\big]^q+2\,\mathrm{diam}^q(\Omega)+1}{(T-t)^{(\gamma+2\sigma)q}}.\tag{3.7}$$

Now the assumptions allow one to choose

$$\frac{1}{m+p-1}<\gamma<\frac{1}{q-1}\quad\big(\infty\text{ if }q=1\big).$$

Next, we may choose $\sigma>0$ so small that

$$\gamma(m+p)-N\sigma\alpha>\gamma+1>(\gamma+2\sigma)q,$$

and last we take

$$A > \max(1, \gamma/\sigma).$$

Then, for $T > 0$ sufficiently small, (3.6), (3.7) imply that $Pv \le 0$ in $(0,T) \times \Omega$.

Since $\phi(0) > 0$ and ϕ is continuous, there exist two real numbers ρ and $\epsilon > 0$, such that $\phi(x) \ge \epsilon$ for all $x \in B(0,\rho) \subset \Omega$. Taking smaller T if necessary, we have $B(0, RT^\sigma) \subset B(0,\rho) \subset \Omega$ and hence $v \le 0$ on $(0,T) \times \partial\Omega$, and from (3.5) it follows that $v(0,x) \le \lambda\phi(x)$ in $\overline{\Omega}$ for all sufficiently large λ. The comparison principle then implies that the solution u can exist no later than $t = T$, and the proof is complete. □

Remark 3.1. A careful reading of the above proof yields the following upper estimate on the blow up time:

$$T^*(\lambda\phi) \le C_\epsilon [\lambda |\phi|_\infty]^{-(m+p-1)+\epsilon} \quad \text{as } \lambda \to \infty \quad \text{for all } \epsilon > 0.$$

On the other hand, by comparing with a homogeneous supersolution obtained as a solution of the ODE $u' = u^{m+p}$, one obtains the lower bound

$$T^*(\lambda\phi) \ge C' \big(\lambda |\phi|_\infty\big)^{-(m+p-1)}, \quad \lambda > 0.$$

Proof of Theorem A. (i) The nonlinearity $f(u, \nabla u) = (b.\nabla u) r u^{r-1} = b.\nabla(u^r)$ is not locally Lipschitz continuous if $1 < r < 2$, so that the uniqueness theorem A.4 does not apply immediately. However, using the special conservative form of the gradient term, local existence and uniqueness of classical, nonnegative solutions of (2.1)–(2.3), with blow-up alternative in L^∞ norm, is proved in [DKL, p. 195] for all $\phi \in C(\overline{\Omega})$, $\phi \ge 0$, $\phi_{|\partial\Omega} = 0$, in dimension $N = 1$, and the arguments there extend without difficulty to any dimension $N \ge 1$. On the other hand, since $|(b.\nabla u) r u^{r-1}| \le C(|u|^r + |\nabla u|^r)$, finite-time blow-up for large $\lambda > 0$ is a consequence of Theorem 3.1 and of the maximum principle.

(ii) Let e_1 be the first unit vector and x_1 be the first coordinate. If $m + p \le r$, by rotation, we may assume without loss of generality that $a = |a| e_1$. A straightforward calculation then shows that $v(x) = Ce^{x_1}$ is a (bounded, stationary) supersolution for all sufficiently large $C > 0$ if $m + p \le q$ (with k large in case of equality), or if $m + p \le r$ (with $|a|$ large in case of equality). □

Remark 3.2. Under the assumptions of Theorem A, with $m + p > 1$ and $r > 1$, the solution of (2.1)–(2.3) is global and bounded if the initial data is small in L^∞ norm. Indeed, the function $v(x) = \epsilon(K - |x|^2)$ is a bounded stationary supersolution for $K = 1 + \sup_\Omega |x|^2$ and $\epsilon > 0$ sufficiently small.

4. Nonlocal reaction in space: Localized source terms. Before proving Theorem B, we state another result for a different equation, which is a localized analogue of equations (1.3) and (3.1) (studied in [DKL] and in Theorem A). The nonlocal (localized) term is involved in a product with a local one, and the source term may in addition be in competition with a local damping term. Namely, we consider the equation

$$u_t - \Delta u = u^m(t,x) u^p\big(t, x_0(t)\big) - \mu u^q(t,x), \quad t > 0, \quad x \in \Omega. \tag{4.1}$$

For this equation, we obtain a sharp critical blow-up exponent.

THEOREM 4.1. *Let p, $q \ge 1$, $m = 0$ or $m \ge 1$, $\mu > 0$, and assume that $x_0 : \mathbb{R}^+ \to \Omega$ is a function of class C^1. Let $\phi \in C(\overline{\Omega})$, $\phi \ge 0$, $\phi \not\equiv 0$, $\phi_{|\partial\Omega} = 0$, $u_0 = \lambda\phi$, $\lambda > 0$, and let u (≥ 0) be the solution of* (4.1), (2.2), (2.3).

(i) *If $m+p>q$ or $m+p=q>1$ and $\mu<1$, then there exists $\Lambda(\phi)>0$, such that u blows up in finite time in L^∞ norm if $\lambda>\Lambda(\phi)$.*

(ii) *If $m+p<q$ or $m+p=q$ and $\mu\geq 1$, then u is global and bounded.*

As in (1.3) and (3.1), a convective or dissipative gradient term may be added, which, for simplicity, we have not considered in the above statement (see Remark 4.3).

Proof of Theorem B. The existence and uniqueness of a maximal in time solution, with blow-up alternative in L^∞ norm, and the validity of the comparison principle follow from Example A.2 in section A.5 of the appendix. In particular, since $f(0)\geq 0$, $u\geq 0$ as long as it exists.

Let $T>1$, ϕ as in the hypotheses, $\lambda>1$, and assume that $T^*(\lambda\phi)>T$. Denote by v the solution of the linear heat equation

$$\begin{aligned} &v_t-\Delta v=0, \quad t>0, \quad x\in\Omega\\ &v(t,x)=0, \quad t>0, \quad x\in\partial\Omega\\ &v(0,x)=\phi(x), \quad x\in\overline{\Omega}. \end{aligned}$$

By the strong maximum principle, we have $V(x)=v(1,x)>0$ in Ω. Since x_0 is continuous into Ω, we have

$$d=\operatorname{dist}\big(x_0\langle[0,T]\rangle,\Omega^C\big)>0.$$

Since $K=\{x\in\Omega;\ \operatorname{dist}(x,\Omega^C)\geq d\}$ is compact, there exists a constant $\epsilon>0$, such that

$$V(x)\geq\epsilon, \quad x\in K. \tag{4.2}$$

On the other hand, since $f\geq 0$ on $\mathbb{R}^+$, the maximum principle implies that

$$u(1,x)\geq\lambda V(x), \quad x\in\Omega.$$

We now seek an unbounded subsolution of the form

$$w(t,x)=\lambda z(t)V(x), \quad 1\leq t<T_1<T, \quad x\in\Omega,$$

with $z\in C^1([1,T_1);\mathbb{R}^+)$ to be determined, such that $z(1)=1$ and z is nondecreasing. We have

$$\begin{aligned} Pw(t,x)&=w_t-\Delta w-f(w(t,x_0(t)))\\ &=\lambda z'(t)V(x)-\lambda z(t)\Delta V(x)-f\big[\lambda z(t)V(x_0(t))\big]. \end{aligned}$$

Using (4.2) and the fact that f is nondecreasing, we get $f\big[\lambda z(t)V(x_0(t))\big]\geq f(\lambda\epsilon z(t))$ on $[1,T_1)$. Let $A=\max(|V|_\infty,|\Delta V|_\infty)>0$. Using $(2.4)_1$, since $z(t)\geq 1$, we obtain

$$\begin{aligned} Pw(t,x)&\leq\lambda A\big(z'(t)+z(t)\big)-f\big[\lambda\epsilon z(t)\big]\\ &\leq\lambda Az'(t)-\frac{1}{2}f\big[\lambda\epsilon z(t)\big] \end{aligned}$$

if one takes λ sufficiently large. Now choose z to be the solution of the ODE

$$z'(t)=\frac{1}{2\lambda A}f\big[\lambda\epsilon z(t)\big], \quad t>1, \quad \text{with } z(1)=1.$$

Using $(2.4)_3$, we find that $\lim_{t\to T_1} z(t) = +\infty$, with

$$\begin{aligned} T_1 &= 1 + 2\lambda A \int_1^\infty \frac{z'(t)}{f\big[\lambda\epsilon z(t)\big]}\, dt \\ &= 1 + \frac{2A}{\epsilon}\int_{\lambda\epsilon}^\infty \frac{ds}{f(s)}, \end{aligned}$$

and $T_1 < T$ if λ is large enough. But clearly, w is a subsolution of (LRT), (2.2), (2.3), and the comparison principle implies that $u(t,x) \geq w(t,x)$ as long as u and w exist. Therefore u can exist no later than $t = T_1 < T$, which is a contradiction. The result follows. □

The method of proof of Theorem 4.1 is different from that of Theorem B. The blow up part relies on a method of self-similar subsolutions with moving center.

Proof of Theorem 4.1. Similarly as in the proof of Theorem 3.1, instead of (4.1), we actually consider the equation

$$Pu \equiv u_t - \Delta u - u_+^m(t,x)u_+^p(t,x_0(t)) + \mu u_+^q(t,x) = 0. \tag{4.3}$$

The properties of local solutions are then the same as in the proof of Theorem B.

(i) We construct a blowing up self-similar subsolution, whose support is centered at the point $x_0(t)$. Namely, we set

$$v(t,x) = \frac{C}{(T-t)^\gamma}\, V\left[\frac{|x - x_0(t)|}{(T-t)^\sigma}\right], \tag{4.4}$$

where V is given by (3.4), and $C > 0$, $A > 1$, and $0 < T < 1$ are to be determined. We set

$$d = \operatorname{dist}\big(x_0\langle[0,1]\rangle, \Omega^C\big) > 0$$

and

$$K = \sup_{t\in[0,1]} |x_0'(t)| < \infty.$$

We now set $y = |x - x_0(t)|/(T-t)^\sigma$, and we compute

$$\begin{aligned} Pv(t,x) =& \frac{C(\gamma V(y) + \sigma y V'(y))}{(T-t)^{\gamma+1}} + \frac{C(x - x_0(t)).x_0'(t)V'(y)}{(T-t)^{\gamma+\sigma}} \\ &+ \frac{NC}{(T-t)^{\gamma+2\sigma}} - \frac{C^{p+m}V_+^m(y)V_+^p(0)}{(T-t)^{\gamma(m+p)}} + \mu\frac{C^qV_+^q(y)}{(T-t)^{\gamma q}}. \end{aligned} \tag{4.5}$$

This time, we choose

$$\gamma = \frac{1}{m+p-1} < \frac{1}{q-1},$$

so that $\gamma + 1 = \gamma(m+p)$, and we take $0 < \sigma < 1/2$ and $A > \max(1, \gamma/\sigma)$.

First consider the case $m + p > q$; hence $\gamma q < \gamma + 1$. By taking C so large that $C^{p+m} > \gamma C(1+A)$, and then $T > 0$ suitably small, we get

$$Pv(t,x) \leq \frac{\gamma C(1+A)}{(T-t)^{\gamma+1}} + \frac{KC\,\mathrm{diam}^2(\Omega)}{(T-t)^{\gamma+\sigma}} + \frac{NC}{(T-t)^{\gamma+2\sigma}} - \frac{C^{p+m}}{(T-t)^{\gamma+1}} + \mu\frac{C^q(1+A)^q}{(T-t)^{\gamma q}} \leq 0$$

if $0 \le y \le A$ and

$$Pv(t,x) \le \frac{C(\gamma-\sigma A)}{(T-t)^{\gamma+1}} + \frac{KC\,\mathrm{diam}^2(\Omega)}{(T-t)^{\gamma+\sigma}} + \frac{NC}{(T-t)^{\gamma+2\sigma}} + \mu\frac{C^q(1+A)^q}{(T-t)^{\gamma q}} \le 0$$

if $y \ge A$.

Now suppose that $m+p=q$ and $\mu<1$. We rewrite the last two terms in (4.5) as

$$-\frac{C^{m+p}V_+^m(y)V_+^p(0)}{(T-t)^{\gamma(m+p)}} + \mu\frac{C^qV_+^q(y)}{(T-t)^{\gamma q}} = -\frac{C^{m+p}V_+^m(y)\big(1-\mu V_+^p(y)\big)}{(T-t)^{\gamma+1}},$$

so that

$$-\frac{C^{m+p}V_+^m(y)V_+^p(0)}{(T-t)^{\gamma(m+p)}} + \mu\frac{C^qV_+^q(y)}{(T-t)^{\gamma q}} \le \begin{cases} \dfrac{-(1-\mu)C^{m+p}}{(T-t)^{\gamma+1}}, & 0 \le y \le A, \\ 0, \quad y \ge A. \end{cases}$$

We then easily find again that

$$Pv(t,x) \le 0, \quad 0<t<T, \quad x \in \Omega.$$

On the other hand, thanks to the strong maximum principle ($q \ge 1$), by starting from some $t=t_0>0$, we may reduce to the case when $\phi(x)>0$ in Ω. In particular, we may assume that $\phi(x) \ge \epsilon > 0$ in some neighborhood of $x(0)$. The end of the proof is then identical to that of Theorem 3.1.

(ii) It suffices to notice that $v \equiv C > 0$ is a supersolution (with C large in the case $m+p<q$). □

Remark 4.1. Similarly as in Remark 3.1, one can derive the following estimate on the blow-up time:

$$c_1\big(\lambda|\phi|_\infty\big)^{-(p-1)} \le T^*(\lambda\phi) \le c_2\big(\lambda|\phi|_\infty\big)^{-(p-1)} \quad \text{as } \lambda \to \infty.$$

Remark 4.2. As for (2.1) (see Remark 3.2), the solution of (4.1), (2.2), (2.3) is global and bounded if the initial data is small and $m+p>1$.

Remark 4.3. The result of Theorem 4.1 (i) remains valid if a local term $-F(u,\nabla u)$ is added to the right-hand side of equation (4.1), where F satisfies the assumptions of Theorem 3.1 (the exponent r in (3.2) being replaced with some $q \in [1, m+p)$).

5. Nonlocal reaction terms in time and in space and time. The blow-up part in Theorem C will be a special case of the following results. Consider the parabolic inequalities

$$u_t - \Delta u \ge \mu(x)\left(\int_0^t u^p(s,x)\,ds\right)^\alpha - au^q(t,x), \quad t>0, \quad x \in \Omega, \tag{5.1}$$

and

$$u_t - \Delta u \ge \mu(x)\left(\int_0^t \int_\Omega \beta(y)u^p(s,y)\,dy\,ds\right)^\alpha - au^q(t,x), \quad t>0, \quad x \in \Omega, \tag{5.2}$$

where $p, \alpha \ge 1$, $q>0$, $a \ge 0$, $\mu \in C^\gamma(\overline{\Omega})$ for some $\gamma>0$, $\mu \ge 0$, $\mu \not\equiv 0$ and (in case of (5.2)) $\beta \in C(\overline{\Omega})$, $\beta \ge 0$, $\beta \not\equiv 0$.

THEOREM 5.1. *Assume that either*

$$\alpha = 1, \quad p > \max(q, 1) \tag{5.3}$$

or

$$\alpha > 1, \quad p \geq \max(q, 1). \tag{5.4}$$

Let $u \in C([0,T) \times \overline{\Omega}) \cap C^{1,2}((0,T) \times \overline{\Omega})$, $u \geq 0$, *satisfy* (5.1), *with* $u(0,x) \not\equiv 0$. *If* $0 < q < 1$, *also assume that either* $u(0,x) > 0$ *in* Ω *or* $\mu(x) \geq \mu_0 > 0$ *in* $\overline{\Omega}$. *Then* $T < \infty$.

THEOREM 5.2. *Assume that* $\mu\beta \not\equiv 0$ *and that either* (5.3) *or* (5.4) *holds. Let* $u \in C([0,T) \times \overline{\Omega}) \cap C^{1,2}((0,T) \times \overline{\Omega})$, $u \geq 0$, *satisfy* (5.2), *with* $u(0,x) \not\equiv 0$. *If* $0 < q < 1$, *also assume that either* $u(0,x) > 0$ *in* Ω *or* $\beta(x) \geq \beta_0 > 0$ *in* $\overline{\Omega}$. *Then* $T < \infty$.

Our argument is a variant of the eigenfunction technique, combined with some new properties on systems of differential inequalities. (Note that we do not require $q \geq 1$: since we do not rely on a comparison argument, no Lipschitz assumption is necessary. Theorems 5.1 and 5.2 give an a priori information on any solution, which does not suppose uniqueness of local solutions.)

Proof of Theorem 5.1. There exists some $\delta > 0$, such that $\mu(x) \geq \delta$ in some open subset $\omega \subset\subset \Omega$ (for instance a ball). Let $\lambda > 0$ be the first eigenvalue of $-\Delta$ in ω with Dirichlet boundary conditions, and ψ be the corresponding normalized positive eigenfunction, that is: $-\Delta\psi = \lambda\psi$ and $\psi > 0$ in ω, $\int_\omega \psi(x)\,dx = 1$, and $\psi = 0$ on $\partial\omega$. We also have $\partial\psi/\partial\nu \leq 0$ on $\partial\omega$ (with ν the outward normal of $\partial\omega$). Define the functions

(5.5)
$$y(t) = \int_\omega u(t,x)\psi(x)\,dx \quad \text{and} \quad z(t) = \int_0^t \int_\omega u^p(s,x)\psi(x)\,dx\,ds, \quad 0 \leq t < T.$$

Multiplying (5.1) by ψ, integrating over ω, and applying Green's formula, we get the following (denoting $' = d/dt$):

$$y' = \int_\omega u\Delta\psi\,dx + \int_{\partial\omega} \left(\psi\frac{\partial u}{\partial\nu} - \nu\frac{\partial\psi}{\partial\nu}\right) d\sigma + \int_\omega \left(\int_0^t u^p(s,x)\,ds\right)^\alpha \mu(x)\psi(x)\,dx - a\int_\omega u^q(t,x)\psi(x)\,dx$$

for all $0 < t < T$. Hence, by the properties of ψ,

$$y' + \lambda y \geq \delta \int_\omega \left(\int_0^t u^p(s,x)\,ds\right)^\alpha \psi(x)\,dx - a\int_\omega u^q(t,x)\psi(x)\,dx.$$

By Jensen's inequality ($\alpha \geq 1$) and Fubini's theorem, it follows that

$$y' + \lambda y \geq \delta z^\alpha - a\int_\omega u^q(t,x)\psi(x)\,dx.$$

Since $p \geq q$, letting $r = q/p \leq 1$, another application of Jensen's inequality yields the differential inequality

$$y' + \lambda y + az'^r \geq z^\alpha, \tag{5.6}$$

where the parameter $\delta > 0$ has been scaled out.

If $q \geq 1$, the strong maximum principle implies that $u(t,x) > 0$ for all $t \in (0,T)$, $x \in \Omega$, so that

$$z(t) > 0, \quad 0 < t < T. \tag{5.7}$$

If $0 < q < 1$ and $u_0(x) > 0$ in Ω, then (5.7) is obviously also valid. If $0 < q < 1$ and $\mu(x) \geq \mu_0$ in $\overline{\Omega}$, we replace ω with Ω and δ with μ_0 in the above argument, which yields inequality (5.6) again, and we also have (5.7) since $u(0,x) \not\equiv 0$.

Let us first handle the easier case $p = 1$ (hence $\alpha > 1$ and $q \leq 1$). We have $z' = y$, and z satisfies

$$z'' + \lambda z' + a z'^r \geq z^\alpha, \quad 0 < t < T.$$

Pick $t_0 \in (0,T)$. Since $r \leq 1$, there exists a constant $C > 0$, such that $a z'^r \leq C z' + (1/2) z^\alpha(t_0)$, so that

$$z'' + (C + \lambda) z' \geq (1/2) z^\alpha, \quad t_0 \leq t < T,$$

and [So, Theorem 1.1] enables one to conclude that $T < \infty$.

To treat the case $p > 1$, we first note that, by Jensen's inequality again,

$$z' \geq y^p.$$

The result then follows from the following lemma on systems of differential inequalities, which is of independent interest.

LEMMA 5.3. *Assume $p > 1$, $r > 0$, $a \in \mathbb{R}$, and*

$$\alpha = 1 > r \quad \text{or} \quad \alpha > 1 \geq r. \tag{5.8}$$

Let y, z be some functions in $C^1(0,T)$, with $y \geq 0$ and $z > 0$ on $(0,T)$, such that

$$\begin{cases} z' \geq y^p, \\ y' + \lambda y + a z'^r \geq z^\alpha, \end{cases} \quad 0 < t < T. \tag{5.9}$$

Then $T < \infty$.

Proof of Lemma 5.3. By translating the origin of time, we may assume that actually y, $z \in C^1([0,T))$ and $z(0) > 0$. Choose $\gamma = 1$ if $r = 1$, and $\max(r, 1/p) < \gamma < 1$ if $0 < r < 1$. It follows from (5.9) that, for all $\epsilon > 0$, there exists a constant $C_\epsilon > 0$, such that

$$C_\epsilon z'^\gamma \geq y^{p\gamma} + (3\lambda + 1) y - \epsilon \quad \text{and} \quad C_\epsilon z'^\gamma \geq 3 a z'^r - \epsilon;$$

hence

$$2 C_\epsilon z'^\gamma + 3 y' \geq 3 \Big[\lambda y + a z'^r + y' \Big] + y^{p\gamma} + y - 2\epsilon,$$

so that

$$2 C_\epsilon z'^\gamma + 3 y' \geq 3 z^\alpha + y^{p\gamma} + y - 2\epsilon. \tag{5.10}$$

We then consider two cases.

Case 1. $r = 1$ (hence $\gamma = 1$ and $\alpha > 1$). Choosing $\epsilon < z^\alpha(0)$ and setting $\nu = \min(\alpha, p) > 1$, it follows that

$$(2C_\epsilon + 3)\big[z + y\big]' \geq z^\alpha + y^p + y \geq \big[z(0)\big]^{\alpha-\nu} z^\nu + y^\nu, \quad 0 \leq t < T,$$

where we have used the fact that z is nondecreasing. Using the inequality

$$a^\nu + b^\nu \geq C(\nu)(a+b)^\nu, \quad a, b \geq 0, \tag{5.11}$$

it then follows that

$$\big[z + y\big]' \geq C[z + y]^\nu, \quad 0 \leq t < T,$$

for some $C > 0$, so that $T < \infty$.

Case 2. $r < 1$ (hence $0 < \gamma < 1$ and $\alpha \geq 1$). Picking $m \in (0, \gamma)$, by Young's inequality, we have, for some large constant $C''_\epsilon > 3$,

$$2C_\epsilon z'^\gamma = 2C_\epsilon \frac{z'^\gamma}{z^m} z^m \leq \epsilon z^{m/(1-\gamma)} + C'_\epsilon \frac{z'}{z^{m/\gamma}} = \epsilon z^{m/(1-\gamma)} + C''_\epsilon \big[z^{1-(m/\gamma)}\big]'.$$

One may assume m to be so small that $m/(1-\gamma) < 1$ and put $\theta = 1 - m/\gamma \in (0,1)$. By substituting into (5.10), with $\epsilon < 1$, we get

$$C''_\epsilon \big[z^\theta + y\big]' \geq 3z^\alpha + y^{p\gamma} + y - 2\epsilon - \epsilon z^{m/(1-\gamma)} \geq 2z^\alpha + y^{p\gamma} + y - 3\epsilon, \quad 0 \leq t < T.$$

Choosing $\epsilon < z^\alpha(0)/3$ and setting $\nu = \min(p\gamma, 1/\theta) > 1$, it follows that

$$C''_\epsilon \big[z^\theta + y\big]' \geq z^\alpha + y^{p\gamma} + y \geq \big[z(0)\big]^{\alpha-\theta\nu} z^{\theta\nu} + y^\nu, \quad 0 \leq t < T,$$

where we have used the fact that z is nondecreasing. Using (5.11), it then follows that

$$\big[z^\theta + y\big]' \geq C[z^\theta + y]^\nu, \quad 0 \leq t < T,$$

for some $C > 0$, so that $T < \infty$. □

Remark 5.1. The assumption (5.8) in Lemma 5.3 is essential (at least if $a > 0$). Indeed, if $\alpha = r > 0$, then $z(t) = Ce^t$, $y(t) = C^p e^{pt}$ is a global positive solution of (5.9) if $C > 0$ is large.

Proof of Theorem 5.2. The proof is almost identical to that of Theorem 5.1, up to the following changes. Since $\mu\beta \not\equiv 0$, we may assume $\beta(x) \geq \delta$ in ω. Proceeding as before, it follows that

$$y' + \lambda y \geq \int_\omega \mu(x)\psi(x)\,dx \left(\int_0^t \int_\Omega \beta(y) u^p(s,y)\,dy\,ds\right)^\alpha - a\int_\omega u^q(t,x)\psi(x)\,dx.$$

We then obtain the differential inequality (5.6), where δ is replaced with

$$\delta' = \big(\delta/|\psi|_\infty\big)^\alpha \int_\omega \mu(x)\psi(x)\,dx > 0,$$

and the hypotheses again imply that $z(t) > 0$ for $t \in (0,T)$. The rest then is unchanged. □

Proof of Theorem C. By replacing u with u_+ in the right-hand side of equations (5.1) and (5.2), the existence and uniqueness of a maximal in time solution, with

blow-up alternative in L^∞ norm, and the validity of the comparison principle, follow from Theorem A.13. In particular, $u \geq 0$ as long as it exists.

(i) This is a special case of Theorems 5.1 and 5.2.

(ii) If $p < q$, a simple calculation shows that $v(t,x) = C(1+t)^{1/(q-p)}$ is a supersolution for all large $C > 0$. If $p = q$, the same holds with $v(t,x) = Ce^{Ct}$. Taking $C > |u_0|_\infty$, it follows from the comparison principle that u must exist globally.

Last, if $q \geq p \geq 1$, assume for contradiction that u is globally bounded by a constant $M > 0$. Then u satisfies

$$u_t - \Delta u \geq \mu(x) \int_0^t u^p(s,x)\, ds - aM^{q-1}u(t,x), \quad t > 0, \quad x \in \Omega$$

(in the case of (5.1), and an analogous inequality in the case of (5.2)). If $p > 1$, this immediately implies finite-time blow-up by Theorems 5.1 and 5.2: a contradiction. In the case $p = 1$, by arguing as in the beginning of the proof of Theorem 5.1, one is reduced to the differential inequality

$$z'' + 2kz' \geq z, \quad t > 0, \quad \text{with } z(0) = 0 \text{ and } z' > 0,$$

for some $k > 0$. By setting $w(t) = z(t)\exp(kt)$, we see that

$$w'' \geq (1+k^2)w, \quad t > 0, \quad \text{with } w(0) = 0 \text{ and } w' > 0,$$

so that $w' \geq (1+k^2)^{1/2}w$. It follows that $z(t) \geq C\exp[((1+k^2)^{1/2} - k)t]$, for all $t \geq 1$ and some $C > 0$, and we obtain again a contradiction. We conclude that u must be global and unbounded if $q \geq p \geq 1$. □

Proof of Theorem D. Since $e^z - 1 \geq z^2/2$, $z \geq 0$, the result follows from Theorem 5.2 (with $p = 1$, $\alpha = 2$, $a = 0$ in (5.2)), in view of the maximum principle. □

Some blow up results can also be stated for the nonlocal in time analogue of (3.1) (or (1.3)) and (4.1):

$$u_t - \Delta u = u^m(t,x)\|u(.,x)\|^p_{L^k(0,t)} - F\big(u(t,x), \nabla u(t,x)\big), \quad t > 0, \quad x \in \Omega, \tag{5.12}$$

where $\|u(.,x)\|_{L^k(0,t)} = \big(\int_0^t |u|^k(s,x)\, ds\big)^{1/k}$.

The structure of the nonlocal term now does not allow the application of the previous eigenfunction technique. However, the method of self-similar subsolutions, suitably adapted, can still be used. Although the result is probably not optimal, we give it also as an illustration of this method, which seems to be the only applicable one here (if $m > 1$). We mention that similar results can be obtained along the same lines for analogous nonlocal nonlinearities in space and time.

THEOREM 5.4. *Let p, $q \geq 1$, $m = 0$ or $m \geq 1$, $1 \leq k \leq \infty$, $a > 0$. Assume that $F : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}$ is locally Lipschitz continuous, with $F(0,0) \leq 0$, and satisfies*

$$F\big(u,U\big) \leq a\big(|u|^q + |u| + |U|^q + |U|\big) \tag{5.13}$$

and that

$$m + p > q + \frac{p}{k}(q-1). \tag{5.14}$$

Assume that $\phi \in C^{2+\alpha}(\overline{\Omega})$, $\phi \geq 0$, $\phi \not\equiv 0$ satisfies $\phi_{|\partial\Omega} = 0$ and $\Delta\phi + F(0, \nabla\phi) = 0$ on $\partial\Omega$. Let $u_0 = \lambda\phi$, $\lambda > 0$, and let u (≥ 0) be the solution of (5.12), (2.2), (2.3). *Then there exists $\Lambda(\phi) > 0$, such that u blows up in finite time in C^1 norm if $\lambda > \Lambda(\phi)$.*

Proof of Theorem 5.4. Again, we modify (5.12) into

$$Pu(t,x) \equiv u_t - \Delta u - u_+^m(t,x)\|u_+(.,x)\|_{L^k(0,t)}^p + F\big(u(t,x), \nabla u(t,x)\big) = 0.$$

The existence and uniqueness of a maximal in time solution, with blow-up alternative in C^1 norm, and the validity of the comparison principle follow from Theorems A.1, A.2, A.3, and A.13 (ii).

Assume, without loss of generality, that $B(0,\rho) \subset \Omega$, and that $\phi(x) \geq \epsilon > 0$ in $B(0,\rho)$. The blowing up subsolution is sought under the form

$$v(t,x) = \frac{1}{(T-t)^\gamma}\, V\left[\frac{|x|}{(T-t)^\sigma}\right] + w(t,x), \tag{5.15}$$

with

$$w(t,x) = \frac{M}{T^\gamma}\left(3 - \frac{3|x|^2}{\rho^2} - 2\frac{t}{T}\right),$$

where V is given by (3.4), and A, $M > 1$, γ, $\sigma > 0$, and $0 < T < 1$ are to be fixed later.

Since the source term involves an integral over $[0,t]$, its effect for small t is not strong enough to compensate the action of the dissipative terms at the early stage of the time evolution. This is the reason for the adjunction of the polynomial part $w(t,x)$, in addition to the self-similar one. This additional term is designed to provide a negative contribution under the action of the linear part of the parabolic operator P. Namely, assuming $T < \rho^2/6N$, we have

$$w_t - \Delta w = \frac{M}{T^{\gamma+1}}(-2 + 6NT/\rho^2) \leq -\frac{M}{T^{\gamma+1}}.$$

On the other hand, to estimate the gradient term, we compute, for $0 < t < T$,

$$\nabla v(t,x) = \frac{-x}{A(T-t)^{\gamma+2\sigma}} - \frac{6Mx}{\rho^2 T^\gamma},$$

hence, since $T < 1$ and A, $M > 1$,

$$|\nabla v|(t,x) \leq \frac{\mathrm{diam}(\Omega)(1 + 6M/\rho^2)}{(T-t)^{\gamma+2\sigma}} \leq \frac{CM}{(T-t)^{\gamma+2\sigma}}.$$

(Here and in the rest of the proof, C denotes a generic constant which depends only on Ω and ρ.)

Setting $y = |x|/(T-t)^\sigma$, we have to distinguish three cases.

• First case: $0 \leq t \leq T/2$. We find

$$|v|(t,x) \leq \frac{C + A}{(T-t)^{\gamma+2\sigma}} + \frac{CM}{T^\gamma} \quad \text{and} \quad v_t(t,x) \leq \frac{\gamma(1+A)}{(T-t)^{\gamma+1}}.$$

Assuming that

$$\sigma < 1/2 \quad \text{and} \quad \gamma + 1 > (\gamma + 2\sigma)q, \tag{5.16}$$

letting

$$\delta = \gamma + 1 - (\gamma + 2\sigma)q > 0,$$

and using (5.13), we obtain, after some computations similar to those in the proof of Theorem 3.1, that

$$Pv(t,x) \le \frac{-M + 2^{\gamma+1}\big[\gamma(1+A) + N + 4a(CM+A)^q T^\delta\big]}{T^{\gamma+1}}. \tag{5.17}$$

• Second case: $T/2 \le t < T$ and $y \ge A$. We have

$$|v|(t,x) \le \frac{C}{(T-t)^{\gamma+2\sigma}} + \frac{CM}{T^\gamma} \quad \text{and} \quad v_t(t,x) \le \frac{\gamma - \sigma A}{(T-t)^{\gamma+1}}.$$

Thus we find

$$Pv(t,x) \le \frac{\gamma - \sigma A + N + 4a(CM)^q T^\delta}{(T-t)^{\gamma+1}}. \tag{5.18}$$

(Note that in cases 1 and 2, we did not use the growth of the nonlocal term, only its nonnegativeness.)

• Third case: $T/2 \le t < T$ and $0 \le y \le A$. Assuming that $T^\sigma A < \rho/2$, hence $|x| \le (T-t)^\sigma A \le \rho/2$, it follows that

$$\frac{1}{(T-s)^\gamma} \le v(s,x) \le \frac{3M}{T^\gamma} + \frac{1+A}{(T-s)^\gamma}, \quad 0 \le s \le t.$$

Denote by Bv the nonlocal term in Pv. In the case $k < \infty$, assuming that $\gamma k \ne 1$, and setting $\alpha = p/k$, we then have

$$\begin{aligned} Bv(t,x) &\ge \frac{1}{(T-t)^{\gamma m}} \left(\int_0^t \frac{ds}{(T-s)^{\gamma k}} \right)^\alpha = \frac{1}{(T-t)^{\gamma m}} \left(\frac{(T-t)^{1-\gamma k} - T^{1-\gamma k}}{\gamma k - 1} \right)^\alpha \\ &\ge (T-t)^{(1-\gamma k)\alpha} \left(\frac{1 - 2^{1-\gamma k}}{\gamma k - 1} \right)^\alpha \frac{1}{(T-t)^{\gamma m}} \\ &\ge \frac{C(\gamma,p,k)}{(T-t)^{\gamma(m+p)-\alpha}} \end{aligned}$$

for some $C(\gamma,p,k) > 0$, where we have used the fact that $T > 2(T-t)$ (consider separately the cases $\gamma k > 1$ and $\gamma k < 1$). This formula remains valid for $k = \infty$ with $\alpha = 0$. It follows that

$$Pv(t,x) \le \frac{\gamma(1+A) + N + 4a(CM+A)^q}{(T-t)^{\gamma+1}} - \frac{C(\gamma,p,k)}{(T-t)^{\gamma(m+p)-\alpha}}. \tag{5.19}$$

By the hypothesis (5.14), it is possible to choose $\gamma \ne 1/k$, such that

$$\frac{\alpha+1}{m+p-1} < \gamma < \frac{1}{q-1},$$

so that in particular

$$\gamma(m+p) - \alpha > \gamma + 1,$$

and next to take $\sigma > 0$ so small that (5.16) holds. Now, by choosing

$$A > (\gamma + N)/\sigma,$$

$$M > 2^{\gamma+1}\big(\gamma(1+A)+N\big),$$

and then T sufficiently close to 0, it follows from formulas (5.17), (5.18), and (5.19), that $Pv(t,x) \le 0$ in the three cases, that is, for all $t \in [0,T)$, $x \in \Omega$.

Taking still smaller T if necessary, we have $v(t,x) \le 0$ for x outside of $B(0,\rho)$, hence on $[0,T) \times \partial\Omega$, and $\lambda\phi(x) \ge \lambda\epsilon \ge v(0,x)$ in Ω for all sufficiently large λ. The comparison principle then implies that the solution u can exist no later than $t = T$, and the Theorem is proved. □

Appendix A. Local theory for general nonlocal semilinear parabolic equations. The local solvability for various classes of functional parabolic equations has been studied in many articles. See, e.g., [A], [BB], [CaY] for nonlocal problems in space. For nonlocal problems in time, see, e.g., [Y1], [Y2], and the references therein. Also, fully nonlinear equations with integral terms have been investigated (see, e.g., [LS], [CP], [Sf] for time-integrals and [CY] for space-integrals), and semilinear parabolic equations with constant delay have been treated in [TW], both subject matters which are out of the scope of the present article.

However, as far as we know, there does not seem to be in the literature a local theory that would apply to the nonlocal semilinear parabolic equation (NLRD) in general form. We wish to construct such a local theory. In the same time, since many (though not all) of the proofs of our blow up and global existence results rely on comparison arguments, we need a version of the comparison principle adapted to the case of nonlocal problems. Such results are proved in many of the cited works, for the specific types of nonlocal equations they consider. We here prove a general comparison principle for the equation (NLRD) in abstract form, which recovers most of these specific results. (Since we consider nonlocal problems, some care is needed. In addition to the usual Lipschitz condition, we have to require a certain assumption of nondecreasing monotonicity on the nonlocal term; see section A.4 and Example A.5 in section A.5.)

Our results enable one to handle in a same formalism all of the four types of problems described in the introduction (and actually much more general ones). On the other hand, we want to allow the nonlinearity to depend on u and ∇u as well. For these reasons, the formalism developed in this Appendix needs to be a bit abstract, although the arguments of the proofs will be rather standard, relying on Schauder a priori estimates and fixed point theorem. Let us point out that what is going to be said remains valid, as usual, if the Laplacian in (NLRD) is replaced with a strongly elliptic operator with sufficiently smooth coefficients. Moreover, other kinds of (linear) boundary conditions may be treated similarly, under suitable assumptions.

The outline of the appendix is as follows. Section A.1 contains some preliminaries and notations for the precise formulation of general nonlocal problems. The abstract existence, uniqueness, and continuation results are stated in section A.2 and proved in section A.3. Section A.4 is devoted to the comparison principle. Finally, in section A.5, the abstract results are illustrated by examples which include, in particular, the specific cases considered in the main text of the article.

A.1. Preliminaries and notations. Let Ω be a bounded domain in $\mathbb{R}^N$. In what follows, we fix some $\alpha \in (0,1)$. We will assume that

(A1) $\partial\Omega$ is of class $C^{2+\alpha}$

or, in some cases, that

(A1)′ $\partial\Omega$ is of class $C^{3+\alpha}$.

We set $Q_T = (0,T]\times\Omega$, $S_T = (0,T]\times\partial\Omega$, and $Q_{t_0,T} = (t_0,T]\times\Omega$, $0 \le t_0 < T < \infty$.

Let us set some notations concerning the needed function spaces. By $C(\overline{\Omega})$ (resp., $C^1(\overline{\Omega})$), we denote the space of real valued continuous (resp., continuously differentiable) functions on $\overline{\Omega}$, endowed with the norm

$$|\phi|_{L^\infty(\Omega)} = \sup_{x\in\overline{\Omega}} |\phi(x)| \quad \left(\text{resp.,} \quad |\phi|_{C^1(\overline{\Omega})} = |\phi|_{L^\infty(\Omega)} + \sum_{i=1}^N |\partial_{x_i}\phi|_{L^\infty(\Omega)}\right).$$

For each $T > 0$, $C\big(\overline{Q_T}\big)$ is the space of real valued continuous functions on $\overline{Q_T}$, endowed with the norm

$$|u|_{L^\infty(Q_T)} = \sup_{(t,x)\in\overline{Q_T}} |u(t,x)|.$$

$C^{0,1}\big(\overline{Q_T}\big)$ is the space of functions u of $\overline{Q_T}$, such that $\partial_{x_i}u$, $i = 1,\dots,N$, belong to $C(\overline{Q_T})$, endowed with the norm

$$|u|_{C^{0,1}\left(\overline{Q_T}\right)} = |u|_{L^\infty(Q_T)} + \sum_{i=1}^N |\partial_{x_i}u|_{L^\infty(Q_T)}.$$

$C^{1,2}\big(Q_T\big)$ is the space of functions u on Q_T, such that u, $\partial_t u$, $\partial_{x_i}u$, $\partial^2_{x_ix_j}u$, $i,j = 1,\dots,N$, are continuous in Q_T.

In addition, we will use some Hölder spaces of functions of t and x, whose definition we recall for convenience. $C^\alpha(\overline{Q_{t_0,T}})$ is the space of functions u which are uniformly Hölder continuous on $\overline{Q_{t_0,T}}$, with exponents $\alpha/2$ in t and α in x, endowed with the norm

$$|u|_{C^\alpha(\overline{Q_{t_0,T}})} = |u|_{L^\infty(Q_{t_0,T})} + \sup_{(t,x)\ne(s,y)\in Q_{t_0,T}} \frac{|u(t,x)-u(s,y)|}{(|t-s|+|x-y|^2)^{\alpha/2}}.$$

$C^{1+\alpha}(\overline{Q_{t_0,T}})$ (resp., $C^{2+\alpha}(\overline{Q_{t_0,T}})$) is the space of those u such that u, $\partial_{x_i}u$, $i = 1,\dots,N$ (resp., u, $\partial_t u$, $\partial_{x_i}u$, $\partial^2_{x_ix_j}u$, $i,j = 1,\dots,N$) belong to $C^\alpha(\overline{Q_{t_0,T}})$, the norms being defined by the sum of the C^α norms of u and of the corresponding derivatives.

Next we define the nonlocal operators making up the equation. For all $t \ge 0$, we define the past time restriction operator R^t by setting, for all $T \ge t$ and $u \in C(\overline{Q_T})$,

$$R^t u = u_{\big|[0,t]\times\overline{\Omega}} \in C(\overline{Q_t}).$$

We take a collection of functionals $\{F^t\}_{t\ge0}$, with $F^t : C(\overline{Q_t}) \to C(\overline{\Omega})$, or $F^t : C^{0,1}(\overline{Q_t}) \to C(\overline{\Omega})$. (By convention, we identify $C(\overline{Q_0})$ with $C(\overline{\Omega})$ and $C^{0,1}(\overline{Q_0})$ with $C^1(\overline{\Omega})$.) We then consider a general nonlocal problem in the form

$$\text{(A2)} \qquad \begin{cases} u_t - \Delta u = F^t\big(R^t u\big)(x), & (t,x)\in Q_T,\\ u(t,x) = 0, & (t,x)\in S_T,\\ u(0,x) = u_0(x), & x\in\overline{\Omega}. \end{cases}$$

For convenience, when T is implicitly understood, we will use the operator $F : u \mapsto Fu$, where

$$Fu(t,x) = F^t(R^t u)(x).$$

A.2. Local existence, uniqueness, and continuation results. We first give a result of local existence of classical solutions up to $t = 0$ for smooth initial data (with first order compatibility conditions). Let $\gamma > 0$ be fixed. We will assume that, for all $T > 0$, F possesses the following properties:

(A3) $$\forall u \in C^{1+\gamma}(\overline{Q_T}), Fu \in C^{\alpha}(\overline{Q_T});$$

(A4) $$F \text{ is continuous from } C^{1+\gamma}(\overline{Q_T}) \text{ to } C(\overline{Q_T}).$$

THEOREM A.1. *Assume* (A1), (A3), (A4), *and let* $u_0 \in C^{2+\alpha}(\overline{\Omega})$ *satisfy the compatiblity conditions*

(A5) $$u_0|_{\partial\Omega} = 0 \quad \textit{and} \quad \Delta u_0 + F^0 u_0 = 0 \textit{ on } \partial\Omega.$$

Then there exists a (nonnecessarily unique) maximal in time function u, *defined on* $[0, T^*) \times \overline{\Omega}$ *for some* $T^* \in (0, \infty]$, *such that for all* $T \in (0, T^*)$, $u \in C^{2+\alpha}(\overline{Q_T})$ *and* u *is a (classical) solution of* (A2).

We next give a continuation result, which states that any nonglobal solution must blow up in finite time in C^1 norm. Instead of (A3), we will assume the stronger condition that, for all $T > 0$,

(A6) $$F \text{ is bounded on bounded sets from } C^{1+\gamma}(\overline{Q_T}) \text{ to } C^{\alpha}(\overline{Q_T}),$$

and in addition to (A4), we will suppose that, for all $T > 0$,

(A7) $$F \text{ is bounded on bounded sets from } C^{0,1}(\overline{Q_T}) \text{ to } C(\overline{Q_T}).$$

On the other hand, as in classical problems with local nonlinearities, if one is concerned with nonlocal problems where the nonlinearity "does not depend on the (spatial) gradient of u," it is possible to prove blow up in L^∞ norm instead of C^1 norm. To express the fact that the nonlocal functionals F^t do not depend on the gradient of u, we consider, instead of (A7), the stronger assumption

(A7)′ $$F \text{ is bounded on bounded sets from } C(\overline{Q_T}) \text{ to } C(\overline{Q_T})$$

for all $T > 0$.

THEOREM A.2. *Assume* (A1), (A4), (A6), *and* (A7) (*resp.*, (A7)′), *and let* u *be any solution of* (A2) *as in Theorem* A.1. *If* $T^* < \infty$, *then* u *blows up in finite time in* C^1 *norm* (*resp., in* L^∞ *norm*) *in the sense that*

(A8) $$\limsup_{t \to T^*} |u(t)|_{C^1(\overline{\Omega})} = \infty \quad (\textit{resp.}, \limsup_{t \to T^*} |u(t)|_{L^\infty(\Omega)} = \infty).$$

Now, assume one of the following Lipschitz conditions, for all $T > 0$:

(A9) $$F \text{ is Lipschitz continuous on bounded sets from } C^{0,1}(\overline{Q_T}) \text{ to } C(\overline{Q_T})$$

or, alternatively,

(A9)′ $$F \text{ is Lipschitz continuous on bounded sets from } C(\overline{Q_T}) \text{ to } C(\overline{Q_T}).$$

Then one obtains a local uniqueness result.

THEOREM A.3. *Assume* (A1), *and* (A9) (*resp.*, (A9)′). *Then, for all* $T > 0$, *there exists at most one (classical) solution of* (A2) *in the class* $C^{0,1}(\overline{Q_T}) \cap C^{1,2}(Q_T)$ (*resp., in the class* $C(\overline{Q_T}) \cap C^{1,2}(Q_T)$).

Next, we wish to prove the local solvability of (A2) for less smooth initial data. For this purpose, we need reinforced assumptions on F. Namely, we may consider C^1 data (with zero order compatibility conditions) if we assume that, for all $T > 0$,

(A10) F is continuous from $C^{0,1}(\overline{Q_T})$ to $C(\overline{Q_T})$ and bounded on bounded sets,

(A11) for all sequence $(u_n) \in C^{0,1}(\overline{Q_T})$ such that the sequence $|u_n|_{C^{1+\gamma}(\overline{Q_{\epsilon,T}})}$ is bounded for all $\epsilon \in (0,T)$, then the sequence $|Fu_n|_{C^{\alpha}(\overline{Q_{\epsilon,T}})}$ is bounded for all $\epsilon \in (0,T)$.

In the same way, we may consider merely continuous data, under the analogous "gradient-independent" assumptions, i.e.,

(A10)′ F is continuous from $C(\overline{Q_T})$ to $C(\overline{Q_T})$ and bounded on bounded sets,

(A11)′ for all sequence $(u_n) \in C(\overline{Q_T})$ such that the sequence $|u_n|_{C^{\gamma}(\overline{Q_{\epsilon,T}})}$ is bounded for all $\epsilon \in (0,T)$, then the sequence $|Fu_n|_{C^{\alpha}(\overline{Q_{\epsilon,T}})}$ is bounded for all $\epsilon \in (0,T)$.

THEOREM A.4. *Assume* (A1)′, (A10), (A11), *and let*

$$u_0 \in C^1(\overline{\Omega}), \qquad \text{with } u_0{}_{|\partial\Omega} = 0.$$

(i) *Then there exists a (nonnecessarily unique) maximal in time function* u, *defined on* $[0,T^*) \times \overline{\Omega}$ *for some* $T^* \in (0,\infty]$, *such that for all* $0 < \epsilon < T < T^*$, $u \in C^{0,1}(\overline{Q_T}) \cap C^{2+\alpha}(\overline{Q_{\epsilon,T}})$, *and* u *is a (classical) solution of* (A2). (ii) *If* $T^* < \infty$, *then* u *blows up in finite time in* C^1 *norm in the sense of* (A8).

THEOREM A.4′. *Assume* (A1), (A10)′, (A11)′, *and let*

$$u_0 \in C(\overline{\Omega}), \qquad \text{with } u_0{}_{|\partial\Omega} = 0.$$

(i) *Then there exists a (nonnecessarily unique) maximal in time function* u, *defined on* $[0,T^*) \times \overline{\Omega}$ *for some* $T^* \in (0,\infty]$, *such that for all* $0 < \epsilon < T < T^*$, $u \in C(\overline{Q_T}) \cap C^{2+\alpha}(\overline{Q_{\epsilon,T}})$, *and* u *is a (classical) solution of* (A2).

(ii) *If* $T^* < \infty$, *then* u *blows up in finite time in* L^∞ *norm in the sense of* (A8).

The assumptions (A11) or (A11)′ hold if the nonlinearity does not depend on the past (nonlocal problems in space) or, more generally, if it does not involve the past up to $t = 0$, e.g., for $F^t(R^t u)(x) = \int_{t/2}^t f(u(s,x))\,ds$. On the contrary, if the nonlinearity involves the whole past, for instance for $F^t(R^t u)(x) = \int_0^t f(u(s,x))\,ds$, then these assumptions will not be satisfied a priori. However, thanks to the regularizing effect of the time integral, for this type of nonlocal terms, with no dependence on the gradient, it is still possible to prove local existence for C^1 data and to get a blow up alternative in L^∞ norm. The kind of general assumption satisfied by such F is the following:

(A12) F is continuous from $C^{0,1}(\overline{Q_T})$ to $C^{\alpha}(\overline{Q_T})$ and bounded on bounded sets

for all $T > 0$. We then have the following theorem.

THEOREM A.5. *Assume* (A1)′, (A12), *and let*

$$u_0 \in C^1(\overline{\Omega}), \quad \text{with } u_0|_{\partial\Omega} = 0.$$

(i) *Then there exists a (nonnecessarily unique) maximal in time function* u, *defined on* $[0, T^*) \times \overline{\Omega}$ *for some* $T^* \in (0, \infty]$, *such that for all* $0 < \epsilon < T < T^*$, $u \in C^{0,1}(\overline{Q_T}) \cap C^{2+\alpha}(\overline{Q_{\epsilon,T}})$, *and* u *is a (classical) solution of* (A2).

(ii) *If* $T^* < \infty$, *then* u *blows up in finite time in* C^1 *norm in the sense of* (A8). *If, in addition* (A10)′ *holds, then the blow up occurs in* L^∞ *norm.*

In the special case when the nonlocal operator F does not depend on the past, that is, if F^t is of the form

$$F^t(R^t u) \equiv f(t, u(t, .)), \quad \text{with } f : \mathbb{R}^+ \times C(\overline{\Omega}) \to C(\overline{\Omega}), \tag{A13}$$

and under a Lipschitz condition, then the blow up alternative can be made more precise, with the "lim sup" becoming a limit. (See Remark A.1 at the end of section A.3 for a variant without Lipschitz condition.)

PROPOSITION A.6. *Let* $\{F^t\}_{t\geq 0}$ *be of the form* (A13), *and assume* (A1), (A3), *and* (A9) (*resp.,* (A9)′). *Assume that* $u \in C^{0,1}(\overline{Q_T}) \cap C^{2+\alpha}(\overline{Q_{\epsilon,T}})$ (*resp.,* $u \in C(\overline{Q_T}) \cap C^{2+\alpha}(\overline{Q_{\epsilon,T}})$), $0 < \epsilon < T < T^*$, *is a maximal, classical solution of* (A2) (*which is necessarily unique by Theorem* A.3). *If* $T^* < \infty$, *then*

$$\lim_{t\to T^*} |u(t)|_{C^1(\overline{\Omega})} = \infty \quad (\textit{resp.,} \lim_{t\to T^*} |u(t)|_{L^\infty(\Omega)} = \infty). \tag{A14}$$

A.3. Proofs of the local results. We first state two preliminary results on the heat equation that we will use repeatedly. The first one is the $C^{1+\delta}$ estimate for the heat equation (see [Fr, Theorem 4, p. 191, and formula (3.23), p. 200]).

LEMMA A.7. *Assume* (A1) *and let* $W \in C(\overline{Q_T}) \cap C^{1,2}(Q_T)$. *Let* $g \in C(\overline{Q_T})$ *satisfy* $g(0, x) = 0$ *on* $\partial\Omega$, *and assume that*

$$\begin{aligned} W_t - \Delta W &= g(t, x), \quad (t, x) \in Q_T, \\ W(t, x) &= 0, \quad (t, x) \in S_T, \\ W(0, x) &= 0, \quad x \in \overline{\Omega}. \end{aligned}$$

Then

$$|W|_{C^{1+\delta}(\overline{Q_T})} \leq K T^\sigma |g|_{L^\infty(Q_T)}$$

for all $0 < \delta < 1$, *where* $\sigma > 0$ *depends only on* δ, *and* K *depends only on* Ω *and* δ *for bounded* T.

The second one gives an estimate on the heat semigroup in C^1 spaces and requires higher ($C^{3+\alpha}$) regularity on $\partial\Omega$ (see [M, Theorem 2.3, p. 39, and formula (2.39), p. 40] and also [Bel]).

LEMMA A.8. *Assume* (A1)′ *and denote by* $e^{t\Delta}$ *the heat semigroup on* $C_0(\overline{\Omega})$. *Then, for all functions* ϕ *in* $C^1(\overline{\Omega})$ *which vanish on* $\partial\Omega$, *we have*

$$|e^{t\Delta}\phi|_{C^{0,1}(\overline{Q_T})} \leq C_1 |\phi|_{C^1(\overline{\Omega})},$$

where C_1 *depends only on* Ω *for bounded* T.

Proof of Theorem A.1. It can be proved in much the same way as in [Fr, Theorem 8, p. 204 and Theorem 10, p. 206]. However, the result there is proved for local nonlinearities. Therefore, we give the proof for sake of completeness. Let $0 < T < 1$ and $M > 0$ (to be fixed later), and consider the set C_M of functions $v \in C^{1+\gamma}(\overline{Q_T})$, satisfying

$$|v|_{C^{1+\gamma}(\overline{Q_T})} \le M, \quad v(0,.) = u_0, \quad v_{|(0,T]\times\partial\Omega} = 0.$$

We define a transformation Z on C_M as follows. $w = Zv$ is the unique solution of the linear problem

$$\begin{aligned} w_t - \Delta w &= Fv, \quad (t,x) \in Q_T, \\ w(t,x) &= 0, \quad (t,x) \in S_T, \\ w(0,x) &= u_0(x), \quad x \in \overline{\Omega}. \end{aligned}$$

(Using (A3), the existence and uniqueness of w follows from [Fr, Theorem 7, p. 65], and $w \in C^{2+\alpha}(\overline{Q_T})$.) We prove that Z admits a fixed point, if $T < 1$ is sufficiently small, by employing the Schauder fixed point theorem (see, e.g., [Fr, Theorem 2, p. 189]).

We first claim that Z maps C_M into itself if T is small. Thanks to (A5), we may take $W(t,x) \equiv w(t,x) - u_0(x)$, hence $g = Fv + \Delta u_0$, in Lemma A.7, which yields

$$|w|_{C^{1+\delta}(\overline{Q_T})} \le |u_0|_{C^{1+\delta}(\overline{\Omega})} + KT^\sigma\big(k_M + |\Delta u_0|_{L^\infty(Q_T)}\big), \tag{A15}$$

where $k_M = \sup\big\{|Fv|_{L^\infty(Q_1)};\ |v|_{C^{1+\gamma}(\overline{Q_1})} \le M\big\}$, which is finite by (A4). Now, choosing

$$M = 1 + |u_0|_{C^{1+\gamma}(\overline{\Omega})}, \quad T < \max\big[1, \big[K\big(k_M + |\Delta u_0|_{L^\infty(Q_T)}\big)\big]^{-1/\sigma}\big],$$

with $\delta = \gamma$ in formula (A15), it follows that $w \in C_M$.

Applying formula (A15) for some $\delta \in (\gamma, 1)$, by the compactness of the injection $C^{1+\delta}(\overline{Q_T}) \subset C^{1+\gamma}(\overline{Q_T})$, it follows that $Z(C_M)$ is a compact subset of C_M.

To check the continuity of Z, assume that v, $v_m \in C_M$ are such that $v_m \to v$ in $C^{1+\gamma}(\overline{Q_T})$, as m goes to ∞. Then $z_m = Zv_m - Zv$ satisfies

$$z_{mt} - \Delta z_m = Fv_m - Fv, \quad (t,x) \in Q_T,$$

with null initial and boundary conditions. Thus, by Lemma A.7 and assumption (A4), we obtain

$$|z_m|_{C^{1+\gamma}(\overline{Q_T})} \le KT^\sigma |Fv_m - Fv|_{L^\infty(Q_T)} \to 0, \text{ as } m \to \infty,$$

that is, $Zv_m \to Zv$ in $C^{1+\gamma}(\overline{Q_T})$.

Since C_M is a closed convex set of the Banach space $C^{1+\gamma}(\overline{Q_T})$, by the previous properties and Schauder's fixed point theorem, there exists a fixed point u of the map Z, which is a solution of the problem (A2).

Finally, by Zorn's lemma, follows as usual the existence of a solution (still denoted by u), which extends u and is maximal in time (i.e., which cannot be extended to a solution on a larger time interval). ∎

Proof of Theorem A.2. (i) Under hypothesis (A7), assume that, for some $T_0 \in (0,\infty)$ and all $T \in (0,T_0)$, $u \in C^{2+\alpha}(\overline{Q_T})$, u is a solution of (A2), and u is such that

$$\sup_{0\le t<T_0} |u(t)|_{C^1(\overline{\Omega})} < \infty.$$

(A7) then implies

$$|Fu|_{L^\infty(Q_T)} \le M_1, \quad 0 < T < T_0.$$

By Lemma A.7, with $W(t,x) = u(t,x) - u_0(x)$ and $g = Fu + \Delta u_0$, it follows that

$$|u|_{C^{1+\gamma}(\overline{Q_T})} \le |u_0|_{C^{1+\gamma}(\overline{\Omega})} + KT^\sigma\big(M_1 + |\Delta u_0|_{L^\infty(\Omega)}\big) = M_2, \quad 0 < T < T_0.$$

From (A6), we infer that

$$|Fu|_{C^\alpha(\overline{Q_T})} \le M_3, \quad 0 < T < T_0.$$

By the $C^{2+\alpha}$ parabolic estimate [Fr, Theorem 6 p. 65], we get

$$|u|_{C^{2+\alpha}(\overline{Q_T})} \le K'\big(M_3 + |u_0|_{C^{2+\alpha}(\overline{\Omega})}\big) = M_4, \quad 0 < T < T_0.$$

(The constant K' depends only on Ω and α for bounded T; see [Fr, p. 123].) From this estimate, it is easily seen that u can be (uniquely) extended to a function $\tilde{u} \in C^{2+\alpha}(\overline{Q_{T_0}})$. To prove that u may be extended to a solution of (A2) for some $T > T_0$, it then suffices to show the existence for small τ of a solution w of the problem

$$\begin{aligned} w_t - \Delta w = G^t\big(R^t w\big)(x), &\quad (t,x) \in Q_\tau, \\ w(t,x) = 0, &\quad (t,x) \in S_\tau, \\ w(0,x) = \tilde{u}(T_0,x), &\quad x \in \overline{\Omega}, \end{aligned}$$

where G^t is defined as

$$\forall z \in C^{0,1}(\overline{Q_t}),\ G^t(z) = F^{T_0+t}(z_1), \quad \text{with } z_1(s,.) = \begin{cases} u(s,.),\ 0 \le s < T_0, \\ z(s-T_0,.),\ T_0 \le s \le T_0 + t. \end{cases}$$

The existence of such w follows from Theorem A.1, since, as is readily verified, the functionals G^t satisfy the assumptions (A3) and (A4) for all z such that $z(0,.) = \tilde{u}(T_0)$, and since $\tilde{u}(T_0)$ satisfies the corresponding compatibility conditions. From the above, we deduce that $(\mathrm{A8})_1$ holds whenever $T^*(u) < \infty$.

(ii) Under assumption (A7)′, the proof of $(\mathrm{A8})_2$ is exactly similar. □

Proof of Theorem A.3. We just need to prove the result under assumption (A9), the other case being similar. Let $T > 0$ and assume that u and v are two solutions of (A2), with $u,\ v \in C^{0,1}(\overline{Q_T}) \cap C^{1,2}(Q_T)$. Set $h = T/p$ with p a positive integer to be chosen, and $D_n = \overline{Q_{nh,(n+1)h}}$ for $n = 0, \cdots, p-1$. By Lemma A.7 with $W = u - v$ (noting that $g(0,.) = F^0u(0,.) - F^0v(0,.) = 0$), and using (A9), we obtain

$$\begin{aligned} |W|_{C^{0,1}(D_n)} &\le Kh^\sigma\big(|Fu - Fv|_{L^\infty(D_n)} + |\Delta W(nh,.)|_{L^\infty(\Omega)}\big) \\ &\le Kh^\sigma\big(L_{M,T}|W|_{C^{0,1}(\overline{Q_{(n+1)h}})} + |\Delta W(nh,.)|_{L^\infty(\Omega)}\big). \end{aligned}$$

Choosing p so large that $Kh^\sigma L_{M,T} < 1$, since $W(0,.) = 0$, it follows easily by induction that $|W|_{C^{0,1}(D_{p-1})} = 0$, that is $u = v$ on $\overline{Q_T}$. □

Proof of Theorem A.4. (i) Assume $u_0 \in C^1(\overline{\Omega})$, $u_0{}_{|\partial\Omega} = 0$. From [M, Theorem 3.1, p. 49], $\partial\Omega$ being of class $C^{3+\alpha}$, we know that there exists a sequence $u_0^n \in C^{2+\alpha}(\overline{\Omega})$, with $u_0{}_{|\partial\Omega} = 0$ and $\Delta u_0{}_{|\partial\Omega} = 0$, such that $u_0^n \to u_0$ in $C^1(\overline{\Omega})$, as $n \to \infty$. Let $\xi \in C^\infty(\mathbb{R})$, with $\xi(t) = 0$, $t \le 1/2$, $\xi(t) = 1$, $t \ge 1$, and $0 \le \xi \le 1$. Let $\xi_n(t) = \xi(nt)$, and consider the approximating problems

$$\text{(A16)} \qquad \begin{cases} u_t^n - \Delta u^n = \xi_n(t) F^t\big(R^t u^n\big)(x) \equiv F_n u^n, \quad (t,x) \in Q_T, \\ u^n(t,x) = 0, \quad (t,x) \in S_T, \\ u^n(0,x) = u_0^n(x), \quad x \in \overline{\Omega}. \end{cases}$$

The assumptions (A10) and (A11) imply that the map $u^n \mapsto F_n u^n$ satisfies (A3) and (A4). Since the compatibility conditions (A5) are verified by u_0^n, that is,

$$u_0^n{}_{|\partial\Omega} = 0 \quad \text{ and } \quad -\Delta u_0^n(x) + F_n u^n(0,x) = 0 \quad \text{ on } \partial\Omega,$$

by Theorem A.1, there exists a (maximal) solution u^n of (A16), of existence time $T_n^* \in (0,\infty]$, with $u^n \in C^{2+\alpha}(\overline{Q_T})$ for all $0 < T < T_n^*$. We then have the following lemma.

LEMMA A.9. *With the notation above, there exists $T_0 \in (0,1]$ and $C_0 > 0$ such that*

$$T_n^* > T_0 \quad \text{ and } \quad |u^n|_{C^{0,1}(\overline{Q_{T_0}})} \le C_0$$

for all n.

Proof of Lemma A.9. Let $M = \sup_{n\ge1} |u_0^n|_{C^1(\overline{\Omega})} < \infty$. For each n and for each $T \in (0, T_n^*)$, $T \le 1$, we may write u^n under the form $u^n = e^{t\Delta} u_0^n + w^n$, where $w^n \in C^{2+\alpha}(\overline{Q_T})$ is the solution of the linear problem

$$\text{(A17)} \qquad w_t^n - \Delta w^n = F_n u^n, \quad (t,x) \in Q_T,$$

with null initial and boundary conditions. Since $\partial\Omega$ is of class $C^{3+\alpha}$, from Lemma A.8 it follows that

$$\text{(A18)} \qquad |e^{t\Delta} u_0^n|_{C^{0,1}(\overline{Q_T})} \le C_1 |u_0^n|_{C^1(\overline{\Omega})} \le C_1 M.$$

Set

$$k'_M = \sup\big\{ |Fv|_{L^\infty(Q_1)};\ |v|_{C^{0,1}(\overline{Q_1})} \le (1+C_1)M \big\},$$

which is finite by (A10). (By an easy extension argument, it can be seen that k'_M stands also for an upper bound of the sets $\big\{ |Fv|_{L^\infty(Q_\tau)};\ |v|_{C^{0,1}(\overline{Q_\tau})} \le (1+C_1)M \big\}$, for all $\tau \in (0,1)$.) Suppose that $T_n^* \le 1$, or that $T_n^* > 1$ and $|u^n|_{C^{0,1}(\overline{Q_1})} > (1+C_1)M$. Then one can set $T'_n = \min\big\{ t \in (0, T_n^*);\ |u^n(t,.)|_{C^1(\overline{\Omega})} \ge (1+C_1)M \big\}$, and we have $0 < T'_n < T_n^*$, $T'_n < 1$. On the other hand, by Lemma A.7, we get

$$|w^n|_{C^{0,1}(\overline{Q_{T'_n}})} \le |w^n|_{C^{1+\gamma}(\overline{Q_{T'_n}})} \le K {T'_n}^{\sigma} k'_M;$$

hence, by (A18),

$$(1+C_1)M = |v^n|_{C^{0,1}(\overline{Q_{T'_n}})} \le C_1 M + K {T'_n}^{\sigma} k'_M,$$

so that

$$T_n' \geq \big(M/(Kk_M')\big)^{1/\sigma}.$$

The lemma follows, with $T_0 = \min\big[1, \big(M/(Kk_M')\big)^{1/\sigma}\big]$ and $C_0 = (1+C_1)M$. □

Proof of Theorem A.4 (i) (continued). From Lemma A.9 and (A10), we deduce the uniform bound

$$|F_n u^n|_{L^\infty(\overline{Q_{T_0}})} \leq M_1. \tag{A19}$$

But (A17) and Lemma A.7 then imply that $|w^n|_{C^{1+\delta}(\overline{Q_{T_0}})} \leq KM_1T_0^\sigma$ so that, by Ascoli–Arzelà's theorem, (some subsequence of) w^n converges in $C^{0,1}(\overline{Q_{T_0}})$ to some $w \in C^{0,1}(\overline{Q_{T_0}})$. Moreover, by Lemma A.8 applied to $u_0^n - u_0$, it follows that $e^{t\Delta}u_0^n$ converges to $e^{t\Delta}u_0$ in $C^{0,1}(\overline{Q_{T_0}})$; hence

$$u^n \to u = e^{t\Delta}u_0 + w \quad \text{ in } C^{0,1}(\overline{Q_{T_0}}) \quad \text{as } n \to \infty.$$

By assumption (A10), this implies that $Fu^n \to Fu$ in $C(\overline{Q_{T_0}})$, and in particular

$$F_n u^n \to Fu \quad \text{everywhere in } (0,T_0] \times \overline{\Omega}. \tag{A20}$$

On the other hand, picking $\epsilon \in (0,T_0)$, the function $z^n = \xi(t/\epsilon)u^n$ now solves

$$z_t^n - \Delta z^n = \xi(t/\epsilon)F_n u^n + (1/\epsilon)\xi'(t/\epsilon)u^n \equiv h_n, \quad (t,x) \in Q_{T_0},$$

with null initial and boundary conditions, so that, applying Lemma A.9, (A19), and Lemma A.7 again, one obtains

$$|u^n|_{C^{1+\delta}(\overline{Q_{\epsilon,T_0}})} \leq |z^n|_{C^{1+\delta}(\overline{Q_{T_0}})} \leq C(\epsilon).$$

By assumption (A11), we deduce the bound

$$|F_n u^n|_{C^\alpha(\overline{Q_{\epsilon,T_0}})} \leq C_1(\epsilon), \quad 0 < \epsilon < T_0,$$

and then, by the $C^{2+\alpha}$–parabolic estimate (see [Fr, Theorem 6, p. 65]) and the definition of ξ,

$$\begin{aligned} |u^n|_{C^{2+\alpha}(\overline{Q_{\epsilon,T_0}})} &\leq |z^n|_{C^{2+\alpha}(\overline{Q_{T_0}})} \leq C|h_n|_{C^\alpha(\overline{Q_{T_0}})} \\ &\leq C|F_n u^n|_{C^\alpha(\overline{Q_{\epsilon/2,T_0}})} + C_2(\epsilon)|u^n|_{C^\alpha(\overline{Q_{\epsilon/2,T_0}})} \leq C_3(\epsilon). \end{aligned} \tag{A21}$$

By Ascoli–Arzelà's theorem and a diagonal procedure, (some subsequence of) u^n must converge to v in $C^{1,2}(\overline{Q_{\epsilon,T_0}})$ for all $0 < \epsilon < T_0$, which, along with (A20), implies that

$$u_t - \Delta u = Fu, \quad (t,x) \in Q_{T_0}.$$

Moreover, from the bound (A21), it follows that $u \in C^{2+\alpha}(\overline{Q_{\epsilon,T_0}})$ for all $0 < \epsilon < T_0$. The existence of a maximal solution follows as in Theorem A.1.

(ii) Assume that, for some $T_0 \in (0,\infty)$ and all $0 < \epsilon < T < T_0$, $u \in C^{2+\alpha}(\overline{Q_{\epsilon,T}})$, $u \in C^{0,1}(\overline{Q_T})$, u is a solution of (A2), and u is such that

$$\sup_{0 \leq t < T_0} |u(t)|_{C^1(\overline{\Omega})} < \infty.$$

(A10) then implies

$$|Fu|_{L^\infty(Q_T)} \le M_1, \quad 0 < T < T_0.$$

By Lemma A.7, with $W(t,x) = u(t,x) - u(\epsilon,x)$ and $g = Fu + \Delta u(\epsilon,.)$, it follows that

$$|u|_{C^{1+\gamma}(\overline{Q_{\epsilon,T}})} \le |u(\epsilon,.)|_{C^{1+\gamma}(\overline{\Omega})} + KT^\sigma\big(M_1 + |\Delta u(\epsilon,.)|_{L^\infty(\Omega)}\big) = M_2(\epsilon), \quad 0 < \epsilon < T < T_0.$$

From (A11), we infer that

$$|Fu|_{C^\alpha(\overline{Q_{T_0/2,T}})} \le M_2, \quad T_0/2 < T < T_0.$$

By the $C^{2+\alpha}$ parabolic estimate, we get

$$|u|_{C^{2+\alpha}(\overline{Q_{T_0/2,T}})} \le K'\big(M_3 + |u(T_0/2,.)|_{C^{2+\alpha}(\overline{\Omega})}\big) = M_4, \quad T_0/2 < T < T_0,$$

so that u can be (uniquely) extended to a function $\tilde{u} \in C^{2+\alpha}(\overline{Q_{T_0/2,T_0}})$. The end of the proof is then identical to that of Theorem A.2 (i) (the fact that the functionals G^t satisfy the assumptions (A3) and (A4) for all z such that $z(0,.) = \tilde{u}(T_0)$ being now a consequence of (A10) and (A11)). □

Proof of Theorem A.4′. (i) The result can be proved along the lines of Theorem A.4, up to some natural changes. In particular, we need only approximate u_0 by a sequence $u_0^n \in C^{2+\alpha}(\overline{\Omega})$ in L^∞ norm. From [M, Theorem 3.1 p. 49], this can be done, assuming only $\partial\Omega$ of class $C^{2+\alpha}$. On the other hand, instead of Lemma A.8, we simply use the estimate

$$|e^{t\Delta}u_0^n|_{C(\overline{Q_T})} \le |u_0^n|_{C(\overline{\Omega})},$$

which is a consequence of the maximum principle (and hence does not require the $C^{3+\alpha}$ regularity).

(ii) The proof is exactly similar to that of Theorem A.4 (ii). □

Proof of Theorem A.5. The proof is similar to that of Theorem A.4. The main difference is that (A12) implies that $F_n u^n \to Fu$ in $C^\alpha(\overline{Q_T})$, instead of (A20). One can then obtain (A21) directly. □

Proof of Proposition A.6. We just need to prove the result under assumption (A9), the other case being similar. Suppose that (A14) is false. Then there exists $M > 0$ such that for all $\epsilon > 0$, $|u(t_1,.)|_{C^1(\overline{\Omega})} \le M$, for some $t_1 \in (T^* - \epsilon, T^*)$. Taking t_1 as a new origin of time, since $u(t_1,.) \in C^{2+\alpha}(\overline{\Omega})$ and satisfies the compatiblity conditions (A5), there exists a local solution v with initial data $u(t_1,.)$ by Theorem A.1. But since F^t is independent of the past (that is, of the form (A13)), it is easily seen from the proof of Lemma A.9 that the existence time of v is bounded from below by a positive constant which depends only on M. Moreover, the solution obtained by extending u by v after $t = t_1$ has the same regularity as u. This contradicts the maximality of u and the local uniqueness property of Theorem A.3, if one chooses ϵ small enough. □

Remark A.1. In the "gradient-independent" case, Proposition A.6 remains valid without Lipschitz assumption, supposing only (A4), (A7)′ instead of (A9)′. This can be proved in a similar way as in [B, Theorem 3.1, p. 477, and Remark, p. 478], by estimating $|u(t+\epsilon,.)|_{L^\infty(\Omega)}$ from $|u(t,.)|_{L^\infty(\Omega)}$ for small $\epsilon > 0$. In particular, $(A14)_2$ holds even if local uniqueness is not assured.

However, we do not know whether the analogue is true in the gradient-dependent case (replacing (A9) by (A4), (A7)). Indeed, $|u(t+\epsilon,.)|_{C^1(\overline{\Omega})}$ can be estimated from $|u(t,.)|_{C^1(\overline{\Omega})}$ via the C_0–C^1 estimates of the heat semigroup (see [M]), but this requires that the nonlocal nonlinear term $f(t,u(t,.))$ vanish on $\partial\Omega$, which has no reason to be satisfied, especially if f is nonlocal in space and depends on the gradient of u.

A.4. Comparison principle. We present a general version of the comparison principle, which is valid for a large class of problems of the form (A2). The nonlinearity may depend on the (local) values of $u(t,x)$ and $\nabla u(t,x)$ in any (locally Lipschitz) way, and may functionally depend on $R^t u = u(s,y)$, $0 \le s \le t$, $y \in \overline{\Omega}$, in a "Lipschitz-monotone" way, with respect to the L^∞ norm. To be more precise, we consider the operator

$$Pu \equiv Pu(t,x) = u_t - \Delta u - F^t\big(R^t u\big)(x), \quad (t,x) \in \overline{Q_T}, \tag{A22}$$

where F^t is of the form

$$F^t\big(R^t u\big)(x) = G^t\big(u(t,x), \nabla u(t,x), R^t u\big)(x), \quad G^t : \mathbb{R} \times \mathbb{R}^N \times C(\overline{Q_t}) \to C(\overline{\Omega}), \quad t \ge 0,$$

and we assume that, for all $M, T > 0$, there exists $L_{M,T} > 0$ such that for all p, $\overline{p} \in \mathbb{R}$, q, $\overline{q} \in \mathbb{R}^N$, $u \in C(\overline{Q_T})$, with $|p|$, $|\overline{p}|$, $|q|$, $|\overline{q}|$, $|u|_{L^\infty(Q_T)} \le M$,

$$\big|G^t(p,q,R^t u) - G^t\big(\overline{p},\overline{q},R^t u\big)\big|_{L^\infty(\Omega)} \le L_{M,T}\big(|p-\overline{p}| + |q-\overline{q}|\big), \tag{A23}$$

and for all $p \in \mathbb{R}$, $q \in \mathbb{R}^N$, u, $\overline{u} \in C(\overline{Q_T})$, with $|p|$, $|q|$, $|u|_{L^\infty(Q_T)}$, $|\overline{u}|_{L^\infty(Q_T)} \le M$,

$$\big|\big(G^t\big(p,q,R^t u\big) - G^t\big(p,q,R^t \overline{u}\big)\big)_+\big|_{L^\infty(\Omega)} \le L_{M,T}|(u-\overline{u})_+|_{L^\infty(Q_T)}, \quad 0 \le t \le T. \tag{A24}$$

THEOREM A.10. *Let P be defined by* (A22) *and assume that* (A23)–(A24) *are fulfilled. Let u, $v \in C(\overline{Q_T}) \cap C^{1,2}(Q_T)$ satisfy*

$$\begin{aligned} Pu(t,x) &\le Pv(t,x), \quad (t,x) \in Q_T, \\ u(t,x) &\le v(t,x), \quad (t,x) \in S_T \cup \big(\{0\} \times \overline{\Omega}\big). \end{aligned}$$

Then $u \le v$ in $\overline{Q_T}$.

Proof. Let $M = \max(|u|_{L^\infty(Q_T)}, |v|_{L^\infty(Q_T)})$. By (A23)–(A24), the function $w = u - v$ satisfies

$$\begin{aligned} w_t - \Delta w &= F^t\big(u(t,x), \nabla u(t,x), R^t u\big)(x) - F^t\big(v(t,x), \nabla v(t,x), R^t v\big)(x) \\ &= \Big(F^t\big(u(t,x), \nabla u(t,x), R^t u\big)(x) - F^t\big(v(t,x), \nabla v(t,x), R^t u\big)(x)\Big) \\ &\qquad + \Big(F^t\big(v(t,x), \nabla v(t,x), R^t u\big)(x) - F^t\big(v(t,x), \nabla v(t,x), R^t (v)\big)(x)\Big) \\ &\le L_{M,T}\Big(|w(t,x)| + |\nabla w(t,x)| + \sup_{\overline{Q_T}} w\Big). \end{aligned}$$

Take $\alpha > 2L_{M,T}$. The function $z(t,x) = w(t,x)e^{-\alpha t}$ satisfies

$$z_t - \Delta z \le L_{M,T}\Big(|z(t,x)| + |\nabla z(t,x)| + \sup_{\overline{Q_T}} z\Big) - \alpha z(t,x).$$

It follows that z cannot attain a positive maximum at a point $(\tau, c) \in Q_T$, since otherwise

$$0 \le z_t(\tau,c) - \Delta z(\tau,c) \le (2L_{M,T} - \alpha) z(\tau,c) < 0,$$

which is a contradiction. The result follows. □

We will see in section A.5 that the assumption (A24) is verified for many nonlocal nonlinearities induced by integral norms, in space, time or space-time as well. This will be essentially a consequence of the following lemma.

LEMMA A.11. *Let Ω be a bounded open set of $\mathbb{R}^N$, $1 \le k \le \infty$, and ϕ, $\psi \in L^\infty(\Omega)$. Then*

$$|\phi_+|_k - |\psi_+|_k \le C(k, |\Omega|)\ |(\phi - \psi)_+|_\infty. \tag{A25}$$

Proof of Lemma A.11. Since $\phi_+ - \psi_+ \le (\phi - \psi)_+$, we may assume ϕ and $\psi \ge 0$ a.e., without loss of generality. We may also restrict ourselves to $1 < k < \infty$, the other cases being trivial. We start from the elementary inequality

$$x^\alpha - y^\alpha \le C(\alpha)(x+y)^{\alpha-1}(x-y), \quad x,\ y > 0, \quad \alpha > 0. \tag{A26}$$

(By homogeneity, one may assume $y = 1$, and (A26) then follows from the fact that the function $x \mapsto (x^\alpha - 1)[(x+1)^{\alpha-1}(x-1)]^{-1}$ is continuous positive on $[0,\infty) \setminus \{1\}$ and has finite, positive limits at $x = 1$ and ∞.) Thus, applying (A26) for $\alpha = 1/k$ and $\alpha = k$ and Hölder's inequality yields

$$\begin{aligned}
|\phi|_k - |\psi|_k &\le C(1/k) \left(\int \phi^k(x)\,dx + \int \psi^k(x)\,dx \right)^{(1/k)-1} \int [\phi^k - \psi^k](x)\,dx \\
&\le C(1/k)C(k) \left(\int \phi^k(x)\,dx + \int \psi^k(x)\,dx \right)^{(1/k)-1} \\
&\qquad \times \int (\phi+\psi)^{k-1}(x)\,dx\ |(\phi-\psi)_+|_\infty \\
&\le C(1/k)C(k) \left(\int \phi^k(x)\,dx + \int \psi^k(x)\,dx \right)^{-\frac{k-1}{k}} |\Omega|^{1/k} \\
&\qquad \times \left(\int (\phi+\psi)^k(x)\,dx \right)^{\frac{k-1}{k}} |(\phi-\psi)_+|_\infty.
\end{aligned}$$

Then, by the inequality $(x+y)^k \le 2^{k-1}(x^k + y^k)$, $x,\ y \ge 0$, we finally conclude that

$$|\phi|_k - |\psi|_k \le C(1/k)C(k)\, 2^{(k-1)^2/k}\, |\Omega|^{1/k} |(\phi-\psi)_+|_\infty. \qquad \square$$

A.5. Examples and applications. We illustrate the previous abstract results by examples which include the specific cases under consideration in the main text of the article.

Example A.1. Consider spatially nonlocal problems of integral type, defined by

$$F^t\big(R^t u\big)(x) = f\big(t, x, u(t,x), \nabla u(t,x), |u_+(t,.)|_k\big), \tag{A27}$$

where $|.|_k = \|.\|_{L^k(\Omega)}$, $1 \le k \le \infty$, and $f : \mathbb{R}^+ \times \overline{\Omega} \times \mathbb{R} \times \mathbb{R}^N \times \mathbb{R}^+ \to \mathbb{R}$. We have the following theorem.

THEOREM A.12. *Assume* (A1)′ *and let* F^t *be defined by* (A27)*, where* f *is locally Lipschitz continuous.*

(i) *Let*

$$u_0 \in C^1(\overline{\Omega}), \qquad \text{with } u_{0|\partial\Omega} = 0.$$

Then there exists a unique, maximal in time function u*, defined on* $[0,T^*)\times\overline{\Omega}$ *for some* $T^* = T^*(u_0) \in (0,\infty]$*, such that for all* $0 < \epsilon < T < T^*$*,* $u \in C^{0,1}(\overline{Q_T}) \cap C^{2+\alpha}(\overline{Q_{\epsilon,T}})$*, is a (classical) solution of* (A2)*. Moreover, if* $T^* < \infty$*, then*

$$\lim_{t\to T^*} |u(t,.)|_{C^1(\overline{\Omega})} = \infty.$$

(ii) *If* f *is nondecreasing with respect to its last argument, then the comparison principle* (*Theorem* A.10) *is valid.*

Remark A.2. If f does not depend on $\nabla u(t,x)$, the previous result holds (under the weaker assumption (A1)), for all $u_0 \in C(\overline{\Omega})$, $u_{0|\partial\Omega} = 0$, with blow up alternative in L^∞ norm (but $u \in C(\overline{Q_T})$ instead of $C^{0,1}(\overline{Q_T})$).

Part (i) of Theorem A.12 is a corollary of Theorems A.4 (i) and A.3 and Proposition A.6. To prove part (ii), we just need to check the validity of property (A24). To do this, we note that

$$f\big(t,x,p,q,|\phi_+|_k\big) - f\big(t,x,p,q,|\psi_+|_k\big) \le \begin{cases} 0 & \text{if } |\phi_+|_k \le |\psi_+|_k, \\ L_{M,T}\big(|\phi_+|_k - |\psi_+|_k\big) & \text{otherwise,} \end{cases}$$

where $L_{M,T}$ stands for a local Lipschitz constant of f. Property (A24) then follows from Lemma A.11.

Example A.2. The results of Theorem A.12 and of Remark A.2 remain valid without change for spatially nonlocal problems of localized type, defined by

$$F^t\big(R^t u\big)(x) = f\big(t,x,u(t,x),\nabla u(t,x),u(t,x_0(t))\big),$$

where $f : \mathbb{R}^+\times\overline{\Omega}\times\mathbb{R}\times\mathbb{R}^N\times\mathbb{R} \to \mathbb{R}$ is locally Lipschitz continuous and $x_0 : [0,\infty) \to \overline{\Omega}$ is locally Hölder continuous.

Example A.3. Consider time nonlocal problems defined by

$$F^t\big(R^t u\big)(x) = f\big(t,x,u(t,x),|u_+(.,x)|_{L^k(0,t)}\big), \tag{A28}$$

where $1 \le k \le \infty$ and $f : \mathbb{R}^+\times\overline{\Omega}\times\mathbb{R}\times\mathbb{R}^N\times\mathbb{R}^+ \to \mathbb{R}$ is locally Lipschitz continuous. We may also consider space-time nonlocal problems defined by

$$F^t\big(R^t u\big)(x) = f\big(t,x,u(t,x),I(t,u)\big), \tag{A29}$$

where

$$I(t,u) = \left(\int_0^t \int_\Omega \beta(y) u_+^k(s,y)\,dy\,ds\right)^{1/k}, \quad 1 \le k < \infty, \quad \beta \in C(\overline{\Omega}),$$

or

$$I(t,u) = |u_+|_{L^\infty((0,t)\times\Omega)}.$$

We have the following theorem.

THEOREM A.13. *Assume* (A1)′ *and let* F^t *be defined by* (A28) *or* (A29), *with* f *as above.*

(i) *Let*

$$u_0 \in C^1(\overline{\Omega}), \qquad \text{with } u_0{}_{|\partial\Omega} = 0.$$

Then there exists a unique, maximal in time function u, *defined on* $[0,T^*)\times\overline{\Omega}$ *for some* $T^* = T^*(u_0) \in (0,\infty]$, *such that for all* $0<\epsilon<T<T^*$, $u \in C^{0,1}(\overline{Q_T})\cap C^{2+\alpha}(\overline{Q_{\epsilon,T}})$, *and* u *is a (classical) solution of* (A2). *Moreover, if* $T^*<\infty$, *then* $\limsup_{t\to T^*}|u(t,.)|_{L^\infty(\Omega)}=\infty$.

(ii) *If* f *is nondecreasing with respect to its last argument, then the comparison principle* (*Theorem* A.10) *is valid.* (*This is still true if* f *depends also on* $\nabla u(t,x)$.)

Part (i) is a corollary of Theorems A.5 and A.3. Part (ii) follows from Lemma A.11 with $(0,T)$ or $(0,T)\times\Omega$ instead of Ω.

Of course, if F^t is a more general, gradient-dependent, time or space-time nonlocal operator, then local existence of solutions is valid for smoother ($C^{2+\alpha}$) initial data by Theorem A.1. (Observe that, even for (1.4), which falls within the range of Theorem A.13, local existence is proved in [P1] and [GS] only for $C^{2+\alpha}$ data.)

On the other hand, Theorem A.13 remains valid for problems with localization in time, defined by

$$F^t(R^t)(x) = f\big(t,x,u(t_0(t,x),x)\big),$$

with t_0 locally Hölder continuous $[0,\infty)\times\overline{\Omega}\to[0,\infty)$, and $0\le t_0(t,x)\le t$. Still further, there would be no obstruction to localizing both in space and time.

Remark A.3. In the case of equation (1.4), it is proved in [GS] that the blowing up solutions actually satisfy $\lim_{t\to T^*}|u(t,.)|_{L^\infty(\Omega)}=\infty$, and an estimate on the blow-up rate is also given.

Example A.4. In Examples A.1 and A.3, it is also possible to replace the L^k-norm with an expression of the form $[\int_\Omega K(t,x,y)u_+^k(t,y)\,dx]^{1/k}$ or $\int_0^t K(t,x,s)u_+^k(s,x)\,ds$ under suitable assumptions on the weight function $K\ge 0$. Nonlocal terms of the form $\int_{t/2}^t u_+^k(s,x)\,ds$, for instance, can be treated in this way.

Example A.5. To see that an assumption of nondecreasing monotonicity on the nonlocal term cannot be avoided for the comparison principle to hold, let us recall the following counterexample [WW, p. 1143]: $N=1$, $\Omega=(-1,1)$, $F^t(R^tu) = -18\int_{-1}^1 u(t,y)\,dy$, and $w(t,x)=x^2-t$, which satisfies

$$\begin{aligned} w_t-\Delta w = -3 \ge -18\textstyle\int_{-1}^1 w(t,y)\,dy, \quad 0<t<1/4, \quad -1<x<1,\\ w(t,\pm1) = 1-t>0, \quad 0<t<1/4,\\ w(0,x)=x^2\ge 0, \quad -1<x<1, \end{aligned}$$

but $w(t,0)=-t<0$. In the same direction, see the example from [CaY, p. 287], which shows that the maximum principle can be false if the gradient of u is involved in a nonlocal way in the equation.

ADIABATIC INVARIANT OF THE HARMONIC OSCILLATOR, COMPLEX MATCHING AND RESURGENCE *

CARLES BONET†, DAVID SAUZIN‡, TERE SEARA†, AND MARTA VALÈNCIA†

Abstract. The linear oscillator equation with a frequency slowly dependent on time is used to test a method to compute exponentially small quantities. This work presents the matching method in the complex plane as a tool to obtain rigorously the asymptotic variation of the action of the associated Hamiltonian *beyond all orders*.

The solution in the complex plane is approximated by a series in which all terms present a singularity at the same point. Following matching techniques near this singularity one is led to an equation which does not depend on any parameter, the so-called inner equation, of a Riccati-type. This equation is studied by resurgence methods.

Key words. Adiabatic invariants, exponentially small, matching theory, resurgence theory

1. Introduction.

We consider one degree of freedom Hamiltonian system depending on a parameter that changes slowly with time modelled by a Hamiltonian of the form (see [1])

$$H(I,\varphi,\varepsilon t) = H_0(I,\lambda(\varepsilon t)) + \varepsilon\lambda'(\varepsilon t)H_1(I,\varphi,\varepsilon t)\,,$$

where $\lambda(\varepsilon t)$ is a function with definite limits at $\pm\infty$ and such that $\lambda^{k)}(\tilde{t}) \to 0$ when $\tilde{t} \to \pm\infty$, for all $k \in \mathbf{N}$. The equations of the motion are given by

$$\left\{\begin{array}{rcl} \dot{I} &=& -\varepsilon\lambda'\dfrac{\partial H_1}{\partial\varphi}, \\ \dot{\varphi} &=& \dfrac{\partial H_0}{\partial I} + \varepsilon\lambda'\dfrac{\partial H_1}{\partial I}\,. \end{array}\right. \tag{1.1}$$

This is a quasi-integrable system in the sense that we can apply the classical averaging procedure looking for a change of variables, close to the identity in powers of ε,

$$\left\{\begin{array}{rcl} I &=& J + \varepsilon u_1(J,\psi,t) + \varepsilon^2 u_2(J,\psi,t) + \cdots, \\ \varphi &=& \psi + \varepsilon v_1(J,\psi,t) + \varepsilon^2 v_2(J,\psi,t) + \cdots, \end{array}\right. \tag{1.2}$$

in order to eliminate the angle variables of the Hamiltonian.

If we truncate the formal series (1.2) at order n, the system obtained is of the form

$$\left\{\begin{array}{rcl} \dot{J} &=& \varepsilon^n\lambda'(\varepsilon t)\ldots, \\ \dot{\psi} &=& \dfrac{\partial\mathcal{H}}{\partial I}(I,\varepsilon) + \varepsilon^n\ldots. \end{array}\right. \tag{1.3}$$

Poincaré proved that even though the series (1.2) are divergent they are asymptotic. In our case that means that the actions of systems (1.1) and (1.3) satisfy

$$|I(t) - J(t) - \varepsilon u_1(J(t), \psi(t), t) - \cdots - \varepsilon^{n-1} u_{n-1}(J(t), \psi(t), t)| \leq K\varepsilon^n,$$

for all $t \in \mathbf{R}$. As a consequence, $I(t)$ is an adiabatic invariant for system (1.1), in the sense that its variation is small for a long time interval. Moreover, due to the asymptotic properties of λ it happens that $u_n(J, \psi, t) \to 0$ and $v_n(J, \psi, t) \to 0$, as $t \to \pm\infty$. Then, one can see that I and J have limits at $\pm\infty$ verifying $I(\pm\infty, \varepsilon) = J(\pm\infty, \varepsilon) + O(\varepsilon^n)$, for all $n \in \mathbf{N}$. Moreover, from (1.3) and taking into account that $\lambda(\varepsilon t)$ is bounded, one has that $J(+\infty, \varepsilon) = J(-\infty, \varepsilon) + O(\varepsilon^n)$, $\forall n \in \mathbf{N}$. Hence, it follows that

$$\Delta I(\varepsilon) := I(+\infty, \varepsilon) - I(-\infty, \varepsilon) = O(\varepsilon^n), \quad \forall n \in \mathbf{N}. \tag{1.4}$$

That is, $I(t, \varepsilon)$ is a perpetual adiabatic invariant at all orders.

Nevertheless, this discrepancy is nonzero (otherwise, system (1.1) would be integrable) but it cannot be viewed directly from the asymptotic series (1.2). The goal of this paper is to present a method to compute the asymptotic expansion of the adiabatic invariant "beyond all orders."

1.1. Matching and resurgence. In fact, we have an asymptotic development of I uniformly valid for all $t \in \mathbf{R}$ and the problem is to catch the part of I invisible in the series (1.2). Matching theory principle says that in order to see the *hidden* properties of a function defined by an asymptotic series we must go to the regions, called *boundary layers*, where these series are no longer asymptotic. Boundary layers can be found by two fundamental methods: the first one is an a priori knowledge of its location provided by heuristic arguments and the second one is to look for the singularities of the series terms.

If we follow the second method for (1.2), we see that the terms of these series do not have singularities in $\mathbf{R}$ (due to the asymptotic properties of λ) and therefore, we are led to look for the boundary layers in $\mathbf{C}$. This is the principal reason why these problems are formulated using complex numbers and why the equation requires analyticity properties. Furthermore, working with analytic functions and complex asymptotic theory gives us more chances to obtain refined results.

Among others, we use as a basic tool in this paper resurgence theory for understanding the nature of the divergence of the series. But instead of analyzing the outer expansion (1.2), we apply resurgence theory to the *inner expansion* (the series near the boundary layer) to compute $\Delta I(\varepsilon)$ given in (1.4). These techniques have been used by V. Hakim and K. Mallick in [7] to compute formally the separatrix splitting of the standard map.

In the present paper we use their aproach to compute the behavior of the adiabatic invariant for a simple oscillator

$$\ddot{x} + \phi^2(\varepsilon\tau)x = 0, \tag{1.5}$$

obtaining rigorously an asymptotic expression for the adiabatic invariant $\Delta I(\varepsilon)$ *beyond all orders*. This problem is quite well understood [3] but we think useful and clarifying to treat it joining matching techniques and the resurgence theory. We have followed closely Wasow [18] and Meyer [12] formulation reducing (1.5) to a Riccati equation.

1.2. Wasow formulation and reduction to a Riccati equation. Following [18] and taking $t = \varepsilon\tau$ in (1.5), let us consider the equation

$$\varepsilon^2\ddot{u} + \phi^2(t)u = 0, \quad t \in \mathbf{R} \tag{1.6}$$

where $\phi(t)$ satisfies
H1 $\phi(t) > 0$, $\forall t \in \mathbf{R}$,
H2 $\lim_{t\to\pm\infty} \phi(t) = \phi_\pm > 0$,
H3 $\phi \in \mathcal{C}^\infty(\mathbf{R})$ and $\phi^{k)} \in L_1((-\infty, +\infty))$, $k \in \mathbf{N}$, (i.e., $\dot{\phi}$ is a gentle function).
Now, given any solution $u(t,\varepsilon)$ of (1.6), let us denote by $I(t,\varepsilon)$ the function

$$I^2(t,\varepsilon) := \phi(t)u^2(t,\varepsilon) + \varepsilon^2\frac{\dot{u}^2(t,\varepsilon)}{\phi(t)}$$

(when ϕ is a constant, $I(t,\varepsilon)$ is the action variable of the integrable Hamiltonian system associated to (1.6)). Littlewood proved in [9] that for any solution $u(t,\varepsilon)$ the limits $I(\pm\infty,\varepsilon)$ exist, and

$$\Delta I^2(\varepsilon) = I^2(+\infty,\varepsilon) - I^2(-\infty,\varepsilon) = O(\varepsilon^n), \quad \forall n \in \mathbf{N}.$$

Moreover, Wasow proved that ΔI^2 satisfies

$$\Delta I^2(\varepsilon) = 2\varepsilon\mathrm{Re}\left[\left(\sqrt{\phi(0)}u_0 + i\frac{\varepsilon}{\sqrt{\phi(0)}}\dot{u}_0\right)^2 \hat{p}(+\infty,\varepsilon)\right](1 + O(\varepsilon)), \tag{1.7}$$

where $(u_0, \dot{u}_0)$ are the initial conditions of $u(t,\varepsilon)$, and $\hat{p}(t,\varepsilon) = e^{-(2i/\varepsilon)\int_0^t \phi(s)ds}p(t,\varepsilon)$, with $p(t,\varepsilon)$ being the solution of the Riccati equation

$$\begin{cases} \varepsilon\dot{p} = 2i\phi(t)p + \dfrac{\dot{\phi}(t)}{2\phi(t)}(1 - \varepsilon p^2), \\ p(-\infty,\varepsilon) = 0 \end{cases} \tag{1.8}$$

for all $\varepsilon > 0$. Looking for the solution as a power series in ε, one can prove Littlewood's results, but in order to obtain more acurate estimates for $\Delta I^2(\varepsilon)$ we will need to extend our problem to the complex domain for the variable t.

By the change of variable $x = \int_0^t \phi(s)ds$ (1.8) becomes

$$\varepsilon w' = 2iw + f(x)(1 - \varepsilon^2 w^2), \tag{1.9}$$

where $f(x) = \frac{\dot{\phi}(t)}{2\phi^2(t)}$. Now, due to hypotheses **H1**, **H2**, **H3**, on ϕ, it is clear that $f(x)$ is a real function with gentle properties. But in order to study the problem on **C**, let us make the following extra hypotheses on f:

H4 f is real analytic in $\bar{\Gamma} - \{x_0\}$, where $x_0 \in \mathbf{C}$, such that Im $(x_0) < 0$ and $\Gamma = \{x \in \mathbf{C} : \text{Im } (x_0) < \text{Im } (x) \le 0\}$, and for $|x - x_0| \le 1$ one has

$$f(x) = \frac{1}{6(x - x_0)}\left[1 + \tilde{f}((x - x_0)^{2/3})\right]$$

with $\tilde{f}(u)$ being an holomorphic function such that $\tilde{f}(0) = 0$.

H5 f is **C**-gentle in the sense that for all $x \in \bar{\Gamma} - \{x_0\}$ one has

$$\lim_{\mathrm{Re}\, x\to\pm\infty} \int_{C_\pm(x)} \left|f^{k)}(s)\right| ds = 0, \quad k \in \mathbf{N},$$

uniformly on x, where

$$C_+(x) = \{t \in \mathbf{C} : \text{Im } (t) = \text{Im } (x), \quad \text{Re } (t) \geq \text{Re } (x) \}$$

and

$$C_-(x) = \{t \in \mathbf{C} : \text{Im } (t) = \text{Im } (x), \quad \text{Re } (t) \leq \text{Re } (x) \}.$$

Although our hypotheses **H4** and **H5** of f can seem capricious, they are deduced from the more natural hypotheses on ϕ made by Wasow in [19], namely, ϕ^2 has an analytic continuation to the complex domain and has a simple zero in $\mathbf{C}$ noted t_0, with Im $(t_0) < 0$, such that $x_0 = \int_0^{t_0} \phi(s)ds$ (the case Im $(t_0) > 0$ can be studied in an analogous way).

The aim of this paper is to compute $w(+\infty, \varepsilon)$, where $w(x, \varepsilon)$ is the solution of the Riccati equation (1.9) such that $w(-\infty, \varepsilon) = 0$. The rest of this paper is structured as follows: First of all, in section 2 we seek for $w(x, \varepsilon)$ as a power series in ε, for complex values of x. We will study its asymptotic validity until some neighborhood of the singularity x_0 which is called the *inner region*. As is usual in matching methods, in the inner region a change of variables will be needed in order to enlarge the validity of the solution. This is done in section 3, obtaining as a first approximation in this region the solution of the so-called *inner equation*. This inner equation is studied by the help of resurgence theory in a self-contained way in section 5. In the inner region we can catch some terms of our solution hidden in the power series, and in section 4 we prove that they are going to be exponentially small on ε (but not zero!) at $+\infty$. Finally, in section 6 we make some remarks for more general nonlinear inner equations. We defer for another paper the general study of (1.1) in a Hamiltonian form (see [16]). Recently, Ramis and Schäfke [14] have obtained upper bounds for $\Delta I(\varepsilon)$ showing the Gevrey-1 character (see footnote 1 in section 5) of the series (1.2) in the general case.

All of this is summarized in the following theorem.

THEOREM 1.1 (main theorem). *Let $w(x, \varepsilon)$ be the solution of the Riccati equation* (1.9) *such that* $\lim w(x, \varepsilon) = 0$ *when* $x \to -\infty$. *Then, if hypotheses* **H1**,...,**H5** *are satisfied one has*

$$\lim_{x \to +\infty} \hat{w}(x, \varepsilon) = -\frac{i}{\varepsilon} e^{-2ix_0/\varepsilon}(1 + O(\varepsilon^{2\gamma/3}))$$

where $\hat{w}(x, \varepsilon) := e^{-2ix/\varepsilon} w(x, \varepsilon)$ and γ is any number verifying $0 < \gamma < 1/2$. Moreover, the variation of the action of the Hamiltonian system associated to (1.6) *is given by*

$$\Delta I^2(\varepsilon) = -2\phi(0)u_0^2 e^{\frac{2\text{Im } (x_0)}{\varepsilon}} \sin\left(\frac{2\text{Re } (x_0)}{\varepsilon}\right)(1 + O(\varepsilon^{2\gamma/3}));$$

therefore, it is a quantity exponentially small in ε.

2. The solution in the outer left domain. In this section we prove the existence of the solution $w(x, \varepsilon)$ of the Riccati equation (1.9),

$$\varepsilon w' = 2iw + f(x)(1 - \varepsilon^2 w^2),$$

such that $\lim w(x, \varepsilon) = 0$, for Re $(x) \to -\infty$ and $x \in \Gamma$ (where Γ is defined in hypothesis **H4**), and we give an asymptotic expression of the solution in a suitable subdomain of Γ.

First of all, we look for a formal solution of (1.9) in the following proposition.

PROPOSITION 2.1. *There exists a series* $\sum_{n\geq 0}\varepsilon^n w_n(x)$ *that formally satisfies the Riccati equation* (1.9). *The functions* $w_n(x)$,

i. *verify the recurrence*

$$\text{(2.1)}\qquad \begin{cases} w_0(x) &= \dfrac{-f(x)}{2i} \\ w_1(x) &= \dfrac{w_0'(x)}{2i} \\ w_n(x) &= \dfrac{w_{n-1}'(x)}{2i} + \dfrac{f(x)}{2i}\sum_{i+j=n-2} w_i(x)w_j(x), \quad n>1; \end{cases}$$

ii. *are* **C**-*gentle functions (see hypothesis* **H5**);

iii. *are analytic functions in* $\bar{\Gamma}-\{x_0\}$ *with a singularity at* $x=x_0$ *such that*

$$\text{(2.2)}\qquad |w_n^{k)}(x)| \leq C_{n,k}\ |x-x_0|^{-(n+k+1)}\ , \quad \text{if } |x-x_0|\leq 1,\ k\in\mathbf{N}.$$

Remark. Due to the fact that $w_n(x)$ are **C**-gentle functions uniformly bounded for $|x-x_0|\geq 1$, we can choose the constants $C_{n,k}$ such that

$$\text{(2.3)}\qquad |w_n^{k)}(x)| \leq C_{n,k}\ , \quad \text{if } |x-x_0|\geq 1,\ k\in\mathbf{N}\,.$$

Proof. The recurrence is obtained directly by the substitution of the series into (1.9) and the properties of $w_n(x)$ follow from hypotheses **H4** and **H5** on $f(x)$. □

Now we will prove that if we are not close to the singularity x_0, the formal series of Proposition 2.1 is asymptotic to a **C**-gentle function $\hat{w}(x,\varepsilon)$. Unfortunately, $\hat{w}(x,\varepsilon)$ will not be a solution of (1.9) but, nevertheless, it will help us to prove the existence of the solution of (1.9) and its asymptoticity to the formal series.

Let $\Gamma_{\varepsilon^\gamma}$ be the following subdomain of Γ for a suitable $\gamma>0$.

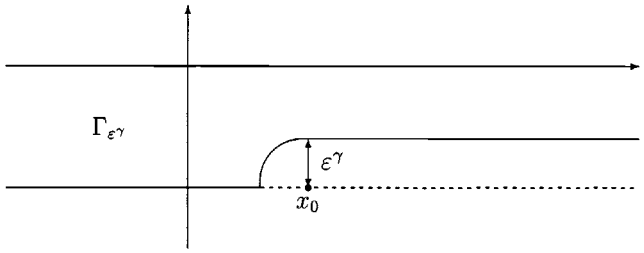

FIG. 1.

PROPOSITION 2.2. *Let* $w_n(x)$, $n\geq 0$, *be functions defined in* Γ *verifying* ii) *and* iii) *of Proposition* 2.1. *Then, for* $0\leq\gamma<1$ *and* $\varepsilon>0$ *sufficiently small, there exists an analytic function* $\hat{w}(x,\varepsilon)$ *defined for* $x\in\Gamma_{\varepsilon^\gamma}$, *such that*

i. *for any* $\delta>0$ *and* $k\in\mathbf{N}$,

$$|\hat{w}^{k)}(x,\varepsilon) - \sum_{n=0}^{N}\varepsilon^n w_n^{k)}(x)| \leq \hat{C}_{N,k}\varepsilon^{-(\gamma+\delta)}\varepsilon^{(N+1)(1-\gamma)-\gamma k}\,,$$

for all $x\in\Gamma_{\varepsilon^\gamma}$, *where* $\hat{C}_{N,k}$ *are constants independent of* ε *and* δ,

ii. $\hat{w}(x,\varepsilon)$ *is a* $\mathbf{C}$*-gentle function for* $\mathrm{Im}\,(x) \geq \mathrm{Im}\,(x_0) - \varepsilon^\gamma$.

Remark. Let us note that if $\gamma = 0$ (this means that we are far away from the singularity) this proposition says that the series $\sum_{n\geq 0} \varepsilon^n w_n(x)$ is asymptotic to the function $\hat{w}(x,\varepsilon)$ on Γ_1. In this sense we can look at i) as a weak form of asymptotic expansion near the singularity.

Proof. First of all, let us define

$$K_n(\varepsilon) := \max_{0\leq k\leq n} \left\{ \sup_{\Gamma_{\varepsilon^\gamma}} |w_n^{k)}(x)|, \sup_{\Gamma_{\varepsilon^\gamma}} \int_{C_\pm(x)} |w_n^{k)}(s)ds| \right\}.$$

From bounds (2.2) and (2.3), as $x \in \Gamma_{\varepsilon^\gamma}$ it follows that

$$K_n(\varepsilon) \leq C_n \varepsilon^{-\gamma(2n+1)},$$

where $C_n := \max\{C_{n,k} \,:\, 0 \leq k \leq n\}$ are independent of ε. Secondly, let us define, for any $\delta > 0$,

$$\alpha_n(\varepsilon) := 1 - e^{-1/(\varepsilon^\delta C_n)},$$

and note that $\alpha_n(\varepsilon) < \frac{1}{\varepsilon^\delta C_n}$.

Then, let us consider

$$\hat{\omega}^{k)}(x,\varepsilon) = \sum_{n\geq 0} \alpha_n(\varepsilon) w_n^{k)}(x) \varepsilon^n,$$

and let us define

$$L_k := \max\left\{1; \frac{C_{0,k}}{C_0}; \ldots; \frac{C_{k-1,k}}{C_{k-1}}; C_0; \ldots; C_k; C_{0,k}; \ldots; C_{k,k}\right\}.$$

Using bounds (2.2) and (2.3) it follows that

$$|\alpha_n(\varepsilon) w_n^{k)}(x)| \leq \frac{C_{n,k}}{C_n} \varepsilon^{-(\delta+\gamma)} \varepsilon^{-\gamma(n+k)}.$$

Thus, for any $k \geq 0$ and $n \geq 0$, we have that

$$|\alpha_n(\varepsilon) w_n^{k)}(x)| \leq L_k \varepsilon^{-(\gamma+\delta)} \varepsilon^{-\gamma(n+k)}. \tag{2.4}$$

So, from (2.4) and taking ε small enough, we obtain that

$$|\hat{w}^{k)}(x,\varepsilon)| \leq \sum_{n=0}^{\infty} |\alpha_n(\varepsilon) w_n^{k)}(x) \varepsilon^n| \leq 2L_k \varepsilon^{-\gamma-\delta} \varepsilon^{-k\gamma}, \tag{2.5}$$

and thus, that $\hat{w}^{k)}(x,\varepsilon)$ converges uniformly in $\Gamma_{\varepsilon^\gamma}$, for $0 \leq \gamma < 1$, $k \in \mathbf{N}$, and ε sufficiently small. Furthermore, if we define $\hat{w}(x,\varepsilon) := \hat{w}^{0)}(x,\varepsilon)$, we have that $\hat{w}^{k)}(x,\varepsilon)$ are the k-derivatives of $\hat{w}(x,\varepsilon)$.

Now, in order to see i) let us take $N > 0$ and let us again use the bounds (2.2), (2.3), and (2.4). It follows

$$|\hat{w}^{k)}(x,\varepsilon) - \sum_{n=0}^{N} w_n^{k)}(x)\varepsilon^n| = |\hat{w}^{k)}(x,\varepsilon) - \sum_{n=0}^{N} \alpha_n(\varepsilon) w_n^{k)}(x)\varepsilon^n + \sum_{n=0}^{N} (\alpha_n(\varepsilon) - 1) w_n^{k)}(x)\varepsilon^n|$$

$$\leq \sum_{n=N+1}^{\infty} |\alpha_n(\varepsilon) w_n^{k)}(x)\varepsilon^n| + \sum_{n=0}^{N} |(\alpha_n(\varepsilon)-1) w_n^{k)}(x)\varepsilon^n|$$
$$\leq L_k \sum_{n=N+1}^{\infty} \varepsilon^{n-\gamma(n+k+1)-\delta} + e^{-1/(L_N\varepsilon^\delta)} L_N \sum_{n=0}^{N} \varepsilon^{n-\gamma(n+k+1)}$$
$$\leq \hat{C}_{N,k}\varepsilon^{-(\delta+\gamma)}\varepsilon^{(N+1)(1-\gamma)-\gamma k}.$$

(we have used that $e^{-1/(L_N\varepsilon^\delta)}$ is exponentially small in ε).

By an analogous argument, using the integrals of $\hat{w}(x,\varepsilon)$ on $C_{\pm}(x)$, we can prove ii). □

Finally, the following theorem proves the existence of the solution $w(x,\varepsilon)$ and give us estimates on its domain of definition. In this domain we will also prove that the series of Proposition 2.1 is weakly asymptotic to $w(x,\varepsilon)$.

THEOREM 2.3. *Let us take* $0<\delta<1$ *and* $0\leq\gamma<1-\delta$. *Then, if* $\varepsilon>0$ *is small enough, the Riccati equation* (1.9) *defined for* $x\in\Gamma_{\varepsilon^\gamma}$, *has a unique solution* $w(x,\varepsilon)$ *such that* $\lim w(x,\varepsilon)=0$, *when* $\mathrm{Re}\,(x)\to-\infty$. *Furthermore, the solution* $w(x,\varepsilon)$ *satisfies that*

$$|w^{k)}(x,\varepsilon) - \sum_{n=0}^{N}\varepsilon^n w_n^{k)}(x)| \leq K_{N,k}\ \varepsilon^{-(\gamma+\delta)}\varepsilon^{(N+1)(1-\gamma)-\gamma k}, \tag{2.6}$$

for all $x\in\Gamma_{\varepsilon^\gamma}$ *and* $k,N\in\mathbf{N}$, *where the* $K_{N,k}$ *are constants independent of* ε *and* δ.

Proof. Let us take $w(x,\varepsilon)=\hat{w}(x,\varepsilon)+Q(x,\varepsilon)$, where $\hat{w}(x,\varepsilon)$ is the gentle function obtained in Proposition 2.2. Then, $w(x,\varepsilon)$ will be the solution of (1.9) if $Q(x,\varepsilon)$ is the solution of the equation

$$\varepsilon Q' = 2iQ - f(x)\varepsilon^2(\hat{w}Q - Q^2) + q(x,\varepsilon)\,, \tag{2.7}$$

where $q(x,\varepsilon):=2i\hat{w}+f(x)(1-\varepsilon^2\hat{w}^2)-\varepsilon\hat{w}'$ is an analytic $\mathbf{C}$-gentle function in $\Gamma_{\varepsilon^\gamma}$ such that $q(x,\varepsilon)=O(\varepsilon^n)$, for all $n\in\mathbf{N}$ and for all $x\in\Gamma_{\varepsilon^\gamma}$. Let us note that this implies that q verifies that, for any $n\in\mathbf{N}$

$$\int_{C_-(x)}\left|\frac{q(s,\varepsilon)}{\varepsilon}\right| \leq K_n\varepsilon^n \tag{2.8}$$

for some constant K_n.

Let us now consider the operator

$$T(Q)=\int_{C_-(x)} e^{2i(x-s)/\varepsilon}\left(\frac{q(s,\varepsilon)}{\varepsilon} - f(s)\varepsilon\left[\hat{w}(s,\varepsilon)Q(s,\varepsilon)-Q^2(s,\varepsilon)\right]\right)ds$$

defined in the Banach space of continuous bounded functions, with the supremum norm. Then, using bounds (2.5) and (2.8), and hypothesis **H4** we have, for ε small enough, that

1) if $||Q||\leq 1$,

$$||T(Q)||\leq K_n\varepsilon^n + \varepsilon\ln\varepsilon^\gamma(2L_0\varepsilon^{-(\gamma+\delta)}+1)\leq 1,$$

2) if $||Q_i|| \leq 1$, for $i = 1, 2$,

$$||T(Q_1) - T(Q_2)|| \leq ||Q_1 - Q_2||\varepsilon(||\hat{w}|| + 2) \int_{C_-(x)} |f(s)|ds$$
$$\leq ||Q_1 - Q_2||\varepsilon(2L_0\varepsilon^{-(\gamma+\delta)} + 2)|\ln \varepsilon^\gamma| \leq \frac{1}{2}||Q_1 - Q_2||.$$

So, by the fixed-point theorem the integral equation $T(Q) = Q$, and thus the differential equation (2.7) have a unique solution Q. Moreover, using again (2.8), one has, for any $n \in \mathbf{N}$

$$||Q|| = ||T(Q)|| \leq 2||T(0)|| \leq 2 \int_{C_-(x)} \left| \frac{q(s,\varepsilon)}{\varepsilon} \right| ds \leq 2K_n\varepsilon^n .$$

Finally, using that $Q(x,\varepsilon) = w(x,\varepsilon) - \hat{w}(x,\varepsilon)$ and the bound of $\hat{w}(x,\varepsilon)$ given in Proposition 2.2 we obtain the desired result. To obtain the bounds for the derivatives $w^{k)}(x,\varepsilon)$ we only have to use (2.7) to see that all the derivatives of Q are asymptotic to zero. □

Unfortunately, with Theorem 2.3 we have proved that $\lim w(x,\varepsilon) = O(\varepsilon^n)$ when Re $(x) \to +\infty$, for all $n \in \mathbf{N}$, but we cannot obtain a more refined description of it at infinity. So, if we want to obtain an asymptotic expression for this limit, we will need to study the solution near the singularity $x = x_0$ of $w_n(x)$. In order to simplify the exposition, we will assume from now on $0 < \gamma < 1/2$.

3. The solution in the inner domain. The goal of this section is to obtain an asymptotic representation of $w(x,\varepsilon)$ near the singularity $x = x_0$ of $w_n(x)$. Of course, we cannot obtain it at $x = x_0$ but as we will see in section 4 it will be sufficient to work at a distance of order ε of this singularity. So, we will extend $w(x,\varepsilon)$ of Theorem 2.3 from a point x^* such that $|x - x^*| = \varepsilon^\gamma$, Im $(x^*) \geq$ Im $(x_0) + \varepsilon$, and Re $(x^*) \leq$ Re (x_0) (i.e., x^* belongs to the boundary of the left domain) up to the point $\tilde{x}^*$ symmetric of x^* with respect to the line $\{\text{Re } (x) = \text{Re } (x_0)\}$. From $\tilde{x}^*$ we will continue the solution in the next section.

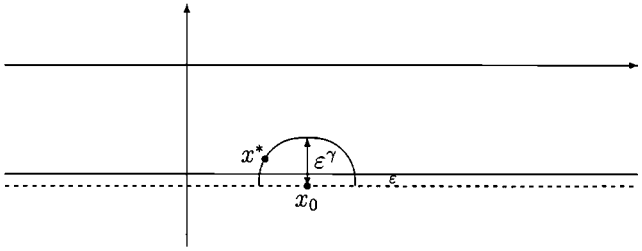

FIG. 2.

Note that, taking into account the bound (2.6), for $N = 0$, the asymptotic expression of f given by hypothesis **H4** and that $0 < \gamma < 1/2$, the initial condition of $w(x,\varepsilon)$ in the inner domain verifies

$$|w(x^*,\varepsilon) - \frac{1}{12i(x^* - x_0)}| \leq \bar{K}\varepsilon^{-\gamma}(\varepsilon^{2/3\gamma} + \varepsilon^{1-\gamma-\delta}) \leq K^*\varepsilon^{-\gamma/3},$$

where $\bar{K}$ and K^* are constants independent of ε.

Then, if we consider the change of variable and function

$$\tau = \frac{x - x_0}{\varepsilon} \qquad p(\tau, \varepsilon) = \varepsilon w(x_0 + \varepsilon\tau, \varepsilon)$$

(1.9) is transformed into

$$p' = 2ip + \varepsilon f(x_0 + \varepsilon\tau)(1 - p^2) \tag{3.1}$$

and defining $\tau^* = \frac{x^* - x_0}{\varepsilon}$, the initial condition for $p(\tau, \varepsilon)$ in the inner domain must verify

$$\left| p(\tau^*, \varepsilon) - \frac{1}{12i\tau^*} \right| \leq K^* \varepsilon^{1-\gamma/3}. \tag{3.2}$$

So, we have to study the solution of (3.1) verifying (3.2) for $\tau \in \mathbf{C}$ such that Im $\tau \geq 1$ and Re $(\tau^*) <$ Re $(\tau) <$ Re $(\tilde{\tau}^*)$, where $\tilde{\tau}^* = \frac{\tilde{x}^* - x_0}{\varepsilon}$ (we will establish in Theorem 3.2 the unicity of such a solution). In order to do this, we will compare $p(\tau, \varepsilon)$ with the solution of

$$p_0' = 2ip_0 + \frac{1}{6\tau}(1 - p_0^2) \tag{3.3}$$

such that $\lim p_0(\tau) = 0$ when Re $(\tau) \to -\infty$. This equation is obtained from (3.1) when ε tends to 0 where the initial condition is obtained "matching" the inner solution with the outer solution at τ^*.

It is easy to see, as in Proposition 2.1, that there exists a formal solution $\sum_{n\geq 0} a_n \tau^{-n-1}$ of (3.3). Moreover, looking at (2.1) and the behavior of f assumed in hypothesis **H4** one can see that the a_n are the principal parts of the terms of the outer series near the singularity, that is

$$w_n(x) = \frac{a_n}{(x - x_0)^{n+1}}(1 + O((x - x_0)^{2/3})).$$

In the next theorem existence, analytic properties, and asymptoticity of $p_0(\tau)$ are described. The proof, done with resurgence theory methods, is given in section 5.

THEOREM 3.1. i. *Equation* (3.3) *admits a unique solution* $p_0(\tau)$ *analytic in a sectorial neighborhood of* $-\infty$ *such that*

$$\lim_{\text{Re } \tau \to -\infty} p_0(\tau) = 0.$$

Moreover, this function is analytic in $\mathbf{C} - \mathbf{R}^+$*, and is asymptotic to the formal solution of* (3.3) *in every proper subsector of this set.*

ii. *Equation* (3.3) *admits a unique solution* $\tilde{p}_0(\tau)$ *analytic in a sectorial neighborhood of* $+\infty$ *such that*

$$\lim_{\text{Re } \tau \to +\infty} \tilde{p}_0(\tau) = 0.$$

Moreover, this function is analytic in $\mathbf{C} - \mathbf{R}^-$*, and is asymptotic to the formal solution of* (3.3) *in every proper subsector of this set.*

iii. *If* Re $\tau > 0$ *and* Im $\tau > 0$*,*

$$p_0(\tau) - \tilde{p}_0(\tau) = -ie^{2i\tau}(1 + O(\tau^{-1}))\,. \tag{3.4}$$

Now, if we compare $p(\tau,\varepsilon)$ with $p_0(\tau)$ we have the following theorem.

THEOREM 3.2. *The problem* (3.1), (3.2) *has a unique solution* $p(\tau,\varepsilon)$ *defined for* $D_{\tau^*} = \{\tau \in \mathbf{C} : \mathrm{Re}\,(\tau^*) \le \mathrm{Re}\,(\tau) \le \mathrm{Re}\,(\tilde{\tau}^*)\,, \mathrm{Im}\,\tau \ge 1\}$. *Moreover,* $p(\tau,\varepsilon)$ *satisfies that*

$$|p(\tau,\varepsilon) - p_0(\tau)| \le L\varepsilon^{(2/3)\gamma}$$

for all $\tau \in D_{\tau^*}$, *where* L *is independent of* ε.

For the proof of this theorem we will need the following lemma.

LEMMA 3.3. *There exists a constant* B, *independent of* ε, *such that for* τ, τ_1, *and* $\tau_2 \in D_{\tau^*}$:

i. $|p_0(\tau)| \le B$,

ii. $|\int_{\tau_1}^{\tau_2} \frac{p_0(s)}{s} ds| \le B$,

iii. $\int_{\tau_1}^{\tau_2} |\frac{\tilde{f}((\varepsilon s)^{2/3})}{s}| ds \le B\varepsilon^{(2/3)\gamma}$, *where* $\tilde{f}$ *is defined in hypothesis* **H4**.

Proof. Let us take $p_0(\tau)$ the unique solution of Theorem 3.1, and $0 < \alpha < \pi/2$ some fixed angle. Then there exists some constant C_α such that for $\tau \in \mathbf{C}$,

a. if $|\arg(\tau)| > \alpha$,

$$\left| p_0(\tau) + \frac{1}{12i\tau} \right| \le C_\alpha \frac{1}{\tau^2} \tag{3.5}$$

(use that $p_0(\tau)$ is asymptotic to the series $\sum_{n\ge 0} a_n \tau^{-n-1}$, where $a_0 = -\frac{1}{12i}$);

b. if $-\pi + \alpha \le \arg(\tau) \le \pi - \alpha$,

$$\left| \tilde{p}_0(\tau) + \frac{1}{12i\tau} \right| \le C_\alpha \frac{1}{\tau^2}$$

(use the same argument as before for $\tilde{p}_0(\tau)$);

c. if $|\arg(\tau)| < \alpha$,

$$|p_0(\tau) + ie^{2i\tau} - \tilde{p}_0(\tau)| \le C_\alpha \frac{1}{\tau}$$

(use (3.4)).

From these inequalities i) follows inmediately. In order to prove ii) we only need to integrate by parts and show that $\int_{\tau_1}^{\tau_2} \frac{e^{2is} ds}{s}$ is bounded for any τ_1, τ_2 in D_{τ^*}. Finally, iii) follows from hypothesis **H4** taking into account that $|\tau_i| \le \varepsilon^{\gamma-1}$. ∎

Proof (of Theorem 3.2). If we consider $v := p - p_0$, the problem that we have to study is

$$\begin{cases} v' &= \left[2i - \dfrac{p_0(\tau)}{3\tau}(1 + \tilde{f}((\varepsilon\tau)^{2/3}))\right] v - \dfrac{1}{6\tau}[1 + \tilde{f}((\varepsilon\tau)^{2/3}))]v^2 \\ & \quad -\dfrac{1}{6\tau}\tilde{f}((\varepsilon\tau)^{2/3})(1 - p_0^2), \\ v(\tau^*,\varepsilon) &= p(\tau^*,\varepsilon) - p_0(\tau^*). \end{cases} \tag{3.6}$$

Taking into account (3.2) and (3.5) (note that $|\arg\tau^*| > \alpha$) we have that

$$|v(\tau^*,\varepsilon)| \le K^*\varepsilon^{1-\gamma/3} + C_\alpha\varepsilon^{2(1-\gamma)} \le 2K^*\varepsilon^{1-\gamma/3}\,. \tag{3.7}$$

Now, let us consider the operator

$$\begin{aligned} T(v) = {} & e^{2i(\tau-\tau^*)} e^{-\int_{\tau^*}^{\tau} (p_0(r)/3r)(1+\tilde{f})dr} v(\tau^*, \varepsilon) \\ & - \int_{\tau^*}^{\tau} e^{2i(\tau-s)} e^{-\int_{s}^{\tau} (p_0(r)/3r)(1+\tilde{f})dr} \frac{1}{6s} v^2(s,\varepsilon) ds \\ & + \int_{\tau^*}^{\tau} e^{2i(\tau-s)} e^{-\int_{s}^{\tau} (p_0(r)/3r)(1+\tilde{f})dr} \frac{1}{6s} \tilde{f}(1-p_0^2(s)) ds, \end{aligned}$$

defined in the Banach space of continuous functions on D_{τ^*} with the supremum norm, such that $\|v\| \le L\varepsilon^{2/3\gamma}$ with $L = \frac{1}{2} e^{2B/3} B(1+B^2)$. Taking into account the bounds (3.7), (3.3), (3.3), and (3.3) of Lemma 3.3, for ε small enough, we have that

1) if $\|v\| \le L\varepsilon^{2/3\gamma}$,

$$\|T(v)\| \le \frac{1}{6} e^{2B/3} \left(12K^* \varepsilon^{1-\gamma} + 2L^2 \varepsilon^{(2/3)\gamma} \ln \varepsilon^{\gamma-1} + B(1+B^2) \right) \varepsilon^{(2/3)\gamma} \le L\varepsilon^{(2/3)\gamma};$$

2) if $\|v_i\| \le L\varepsilon^{(2/3)\gamma}$, for $i = 1, 2$,

$$\|T(v_1) - T(v_2)\| \le 2e^{2B/3} L\varepsilon^{(1/3)\gamma} \ln \varepsilon^{\gamma-1} \|v_1 - v_2\| \le \frac{1}{2} \|v_1 - v_2\|.$$

So, by the fixed-point theorem, the integral equation $T(v) = v$ and thus the differential equation (3.6) has a unique solution. Moreover, this solution can be bounded by

$$|v(\tau, \varepsilon)| \le L\varepsilon^{(2/3)\gamma},$$

for $\tau \in D_{\tau^*}$.

Finally, using that $v = p - p_0$ we finish the proof of the theorem. □

As we have seen, Theorem 3.2 gives us a bound of the function $w(x, \varepsilon)$ on the right side of the inner domain. In fact, at the point $\tilde{x}^*$ symmetric of x^*, we have

$$\left| w(\tilde{x}^*, \varepsilon) - \frac{1}{\varepsilon} p_0 \left(\frac{\tilde{x}^* - x_0}{\varepsilon} \right) \right| \le L\varepsilon^{(2/3)\gamma - 1}, \tag{3.8}$$

which will be used in the next section.

4. The solution in the outer right domain. In this section, we will extend the solution $w(x, \varepsilon)$ from the end point $\tilde{x}^*$ of the inner domain up to $+\infty$. We will do this comparing $w(x, \varepsilon)$ with the solution $\tilde{w}(x, \varepsilon)$ of (1.9) such that $\lim \tilde{w}(x, \varepsilon) = 0$, for Re $(x) \to +\infty$. The existence and the properties of $\tilde{w}(x, \varepsilon)$ are analogous to $w(x, \varepsilon)$ now considering x belonging to the outer right domain $\tilde{\Gamma}_{\varepsilon^\gamma}$.

All of this is summarized in the following theorem.

THEOREM 4.1. *Let us take $\delta > 0$. The Riccati equation* (1.9) *defined for $x \in \tilde{\Gamma}_{\varepsilon^\gamma}$, $0 < \gamma < 1 - \delta$, and $\varepsilon > 0$ sufficiently small has a unique solution $\tilde{w}(x, \varepsilon)$ such that $\lim \tilde{w}(x, \varepsilon) = 0$ when* Re $(x) \to +\infty$. *Furthermore, the solution $\tilde{w}(x, \varepsilon)$ satisfies that*

$$\left| \tilde{w}^{k)}(x, \varepsilon) - \sum_{n=0}^{N} \varepsilon^n w_n^{k)}(x) \right| \le K_{N,k}\ \varepsilon^{-(\gamma+\delta)} \varepsilon^{(N+1)(1-\gamma)-\gamma k}, \quad k \in \mathbf{N},$$

for all $x \in \tilde{\Gamma}_{\varepsilon^\gamma}$, where $K_{N,k}$ are constants independent of ε and of δ, and $w_n(x)$ are the functions given in Proposition 2.1.

Proof. It is analogous to the proof of Theorem 2.3. □

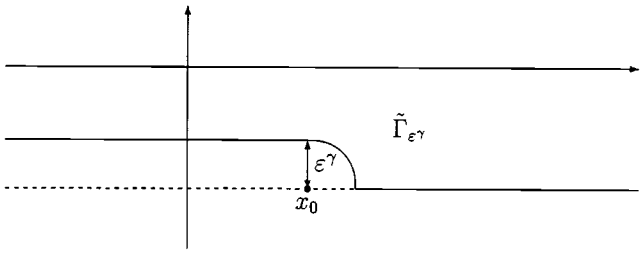

FIG. 3.

Remark. As in the previous section, in order to simplify the exposition, we will take from now on $0 < \gamma < 1/2$.

Now, let us take again $\tilde{x}^* = x_0 + \varepsilon\tilde{\tau}^*$. We want to have an estimate of $w(\tilde{x}^*, \varepsilon)$ in order to consider it as an initial condition to extend $w(x, \varepsilon)$. As we have seen in (3.8),

$$\left| w(\tilde{x}^*, \varepsilon) - \frac{1}{\varepsilon} p_0 \left(\frac{\tilde{x}^* - x_0}{\varepsilon} \right) \right| \leq L\varepsilon^{(2/3)\gamma - 1},$$

and from (3.4) with $\tau = \tilde{\tau}^*$ it follows that

$$\left| p_0 \left(\frac{\tilde{x}^* - x_0}{\varepsilon} \right) + ie^{2i(\tilde{x}^* - x_0)/\varepsilon} - \tilde{p}_0 \left(\frac{\tilde{x}^* - x_0}{\varepsilon} \right) \right| \leq C_\alpha \varepsilon^{1-\gamma}.$$

On the other hand, using Theorem 3.1 and 4.1, the asymptotic expression of f, and that $0 < \gamma < 1/2$ we obtain an analogous formula to (3.7), i.e.,

$$|\tilde{w}(\tilde{x}^*, \varepsilon) - \frac{1}{\varepsilon} \tilde{p}_0 \left(\frac{\tilde{x}^* - x_0}{\varepsilon} \right)| \leq 2\tilde{K}^* \varepsilon^{-\gamma/3}.$$

Considering this altogether, one can obtain that

$$\left| w(\tilde{x}^*, \varepsilon) - \tilde{w}(\tilde{x}^*, \varepsilon) + \frac{i}{\varepsilon} e^{2i(\tilde{x}^* - x_0)/\varepsilon} \right| \leq 3L\varepsilon^{(2/3)\gamma - 1}. \tag{4.1}$$

Now we are willing to prove the following theorem.

THEOREM 4.2. *The solution $w(x, \varepsilon)$ of (1.9) exists for $x \in \mathbf{C}$ such that* Re $(\tilde{x}^*) \leq$ Re (x) *and* Im $(x_0) + \varepsilon \leq$ Im $(x) \leq 0$ *and verifies*

$$|w(x, \varepsilon) - \tilde{w}(x, \varepsilon) + \frac{i}{\varepsilon} e^{(2i/\varepsilon)(x - x_0)}| \leq Ce^{-2/\varepsilon \text{Im } (x - x_0)} \varepsilon^{(2/3)\gamma - 1}. \tag{4.2}$$

In order to prove this theorem we need the following lemma.

LEMMA 4.3. *For $x \in \mathbf{C}$ such that* Re $(x) \geq$ Re $(\tilde{x}^*)$ *and* Im $(x) \geq$ Im $(x_0 + \varepsilon)$ *the following bounds hold:*

i. $|\int_{\tilde{x}^*}^{x} \varepsilon f(t)\tilde{w}(t, \varepsilon)dt| \leq C\varepsilon^{1-\gamma}$,

ii. $\left| \int_{\tilde{x}^*}^{x} e^{-(2i/\varepsilon)(\tilde{x}^* - s) + \int_s^{\tilde{x}^*} 2\varepsilon f(t)\tilde{w}(t, \varepsilon)dt} \varepsilon f(s)ds \right| \leq \varepsilon^{2-\gamma}$,

where C is a constant independent of ε.

Proof. The first bound follows inmediately from hypothesis **H4** and the asymptoticity of $\tilde{w}$ given in Theorem 4.1. For the second one it is sufficient to integrate by parts. □

Proof (of Theorem 4.2). Let us define $z(x,\varepsilon) := w(x,\varepsilon) - \tilde{w}(x,\varepsilon)$. From (1.9) and (4.1), $z(x,\varepsilon)$ verifies

$$\varepsilon z'(x,\varepsilon) = (2i - 2\varepsilon^2 f(x)\tilde{w}(x,\varepsilon))z(x,\varepsilon) - \varepsilon^2 f(x) z^2$$

and

$$\left| z(\tilde{x}^*,\varepsilon) + \frac{i}{\varepsilon} e^{2i(\tilde{x}^* - x_0)/\varepsilon} \right| \leq 3L\varepsilon^{2/3\gamma - 1}.$$

Thus, noting that z is the solution of a Bernoulli equation one can obtain the following integral expression for z:

$$z(x,\varepsilon) = \frac{e^{(2i/\varepsilon)(x-\tilde{x}^*) - \int_{\tilde{x}^*}^{x} 2\varepsilon f(t)\tilde{w}(t,\varepsilon)dt} z(\tilde{x}^*,\varepsilon)}{1 + z(\tilde{x}^*) \displaystyle\int_{\tilde{x}^*}^{x} e^{-(2i/\varepsilon)(\tilde{x}^* - s) + \int_{s}^{\tilde{x}^*} 2\varepsilon f(t)\tilde{w}(t,\varepsilon)dt} \varepsilon f(s) ds}. \tag{4.3}$$

Now, using the bounds given by Lemma 4.3 and (4.3), there exist some constants $\tilde{C}_i$, $i = 1, 2, 3$, independent of ε such that

$$|z(x,\varepsilon) - e^{(2i/\varepsilon)(x-\tilde{x}^*)} z(\tilde{x}^*,\varepsilon)| \leq \tilde{C}_1 \varepsilon^{-\gamma} |e^{(2i/\varepsilon)(x-\tilde{x}^*)}|$$

and then

$$\left| z(x,\varepsilon) + \frac{i}{\varepsilon} e^{(2i/\varepsilon)(x-x_0)} \right| \leq \tilde{C}_2 \varepsilon^{2/3\gamma - 1} |e^{(2i/\varepsilon)(x-\tilde{x}^*)}|.$$

Now, using that $\text{Im}\ (\tilde{x}^*) = \text{Im}\ (x_0) + \varepsilon$, we obtain

$$\left| z(x,\varepsilon) + \frac{i}{\varepsilon} e^{(2i/\varepsilon)(x-x_0)} \right| \leq \tilde{C}_3 \varepsilon^{2/3\gamma - 1} |e^{(2i/\varepsilon)(x-x_0)}| = \tilde{C}_3 \varepsilon^{2/3\gamma - 1} e^{-2/\varepsilon \text{Im}\ (x-x_0)}.$$

Finally, taking into account that $z(x,\varepsilon) = w(x,\varepsilon) - \tilde{w}(x,\varepsilon)$ we obtain the theorem. ∎

Now we are in a position to prove the main Theorem 1.1 by taking the limit as $\text{Re}\ (x) \to +\infty$ in inequality (4.2):

$$\left| \lim_{\text{Re}\ (x) \to +\infty} e^{-(2i/\varepsilon)x} w(x,\varepsilon) + \frac{i}{\varepsilon} e^{-(2i/\varepsilon)x_0} \right| \leq e^{2\text{Im}\ (x_0)/\varepsilon} \varepsilon^{(2/3)\gamma - 1}.$$

5. Resurgence of the solutions of the inner equation – Proof of Theorem 3.1.

5.1. Introduction. In this part of the article we provide a self-contained introduction to Écalle's theory of resurgent functions, and we show how our inner problem (3.3) fits within this framework.

We already know a formal solution to it:

$$\sum_{n \geq 0} a_n \tau^{-n-1},$$

and it is easy to see that there is no other formal solution. Our goal is to prove Theorem 3.1.

After the change of variable

$$z = 2i\tau,$$

(3.3) may be viewed as a particular case of singular Riccati equation of the type

$$\frac{dY}{dz} = Y + H^-(z) + H^+(z)Y^2 \tag{5.1}$$

where $H^\pm \in z^{-1}\mathbf{C}\{z^{-1}\}$ (analytic germs at infinity, vanishing at infinity); in our case, $H^-(z) = -H^+(z) = 1/6z$.

Now, resurgence is a good tool for analyzing all the equations of this kind; in fact, Écalle's theory allows the analytic classification of local equations in far more general contexts [4, 5, 2] (Of course, resurgence is not the only possible approach; see [10, 11] for another method of classifying singular local equations.), but the study of (5.1) provides a nice elementary introduction to some aspects of Écalle's work, even if many simplifications arise in the case of Riccati equations.

5.2. Singular Riccati equations and resurgence.

5.2.1. Resurgence of the formal solution. In the sequel, H^+ and H^- are two fixed analytic germs, vanishing at infinity. As (3.3), (5.1) admits a unique solution among formal expansions in negative powers of the variable; let's denote $Y_- \in z^{-1}\mathbf{C}[[z^{-1}]]$ this unique formal solution. We shall show that it is generically divergent using formal Borel transform $\mathcal{B}$.

The linear mapping $\mathcal{B}$ is defined by

$$\begin{cases} z^{-1}\mathbf{C}[[z^{-1}]] & \to & \mathbf{C}[[\zeta]], \\ z^{-n-1} & \mapsto & \zeta^n/n! \end{cases}$$

and it induces an isomorphism between the multiplicative algebra of Gevrey-1[1] formal series (without constant term) and the convolutive algebra of analytic germs at the origin $\mathbf{C}\{\zeta\}$, that is,

$$\begin{aligned} \varphi_1(z) &\mapsto \hat{\varphi}_1(\zeta), \\ \varphi_2(z) &\mapsto \hat{\varphi}_2(\zeta), \\ \varphi_1(z)\varphi_2(z) &\mapsto \hat{\varphi}_1 * \hat{\varphi}_2(\zeta) = \int_0^\zeta \varphi_1(\zeta_1)\varphi_2(\zeta-\zeta_1)d\zeta_1. \end{aligned}$$

Moreover, a formal series $\varphi(z)$ converges for $|z| > \rho$ if and only if its Borel transform is an entire function of exponential type at most ρ : $|\hat{\varphi}(\zeta)| \leq \text{const } e^{\rho|\zeta|}$. Hence, finite radius of convergence for $\hat{\varphi}$ (i.e., existence of singularities in ζ-plane) means divergence for φ.

We shall call *resurgent function* a Gevrey-1 formal series φ whose Borel transform has the following property: on any broken line issuing from the origin, there is a finite set of points such that $\hat{\varphi}$ may be continued analytically along any path that closely follows the broken line in the forward direction, while circumventing (to the right or to the left) those singular points. A nontrivial fact is the stability under convolution of this property. Indeed, resurgent functions form an algebra which can be considered either as a subalgebra of $\mathbf{C}[[z^{-1}]]$ (*formal model*) or, via $\mathcal{B}$, as a subalgebra of $\mathbf{C}\{\zeta\}$

[1]Let us recall that a formal power series $\sum_{n\geq 0} a_n\tau^{-n-1}$ is said to be Gevrey-1 if there exist two positive constants M, K such that $|a_n| \leq Mn!K^n$.

(*convolutive model*). The Borel transform of a given resurgent function is often called its *minor*.

PROPOSITION 5.1. *The formal solution of* (5.1) *is a resurgent function, with singularities in the convolutive model over the negative integers only.*

Proof. We start by performing Borel transform on (5.1) itself; differentiation with respect to z yields multiplication by $-\zeta$ and we obtain an equation for $\hat{Y}_-$:

$$-(\zeta+1)\hat{Y}(\zeta) = \hat{H}^- + \hat{H}^+ * \hat{Y}^{*2}, \tag{5.2}$$

where $\hat{H}^+$ and $\hat{H}^-$ are some entire series with infinite radius of convergence.

Let's define inductively a sequence of $\mathbf{C}[[\zeta]]$ by

- $\hat{Y}_0(\zeta) = -\hat{H}^-(\zeta)/(\zeta+1)$,
- $\forall n \geq 1$,

$$\hat{Y}_n(\zeta) = \frac{-1}{\zeta+1}\left(\hat{H}^+ * \sum_{n_1+n_2=n-1} \hat{Y}_{n_1} * \hat{Y}_{n_2}\right).$$

The valuation of $\hat{Y}_n$ being at least $2n$, the series $\sum_{n\geq 0}\hat{Y}_n$ converges formally in $\mathbf{C}[[\zeta]]$ towards the unique solution $\hat{Y}_-$ of (5.2). Now we observe that $\hat{H}^+$ and $\hat{H}^-$ define entire functions of at most exponential growth in any direction; $\hat{Y}_0$ defines thus a meromorphic function with a simple pole at -1, and, by successive convolutions, we only get for the $\hat{Y}_n$'s other simple poles at the negative integers together with ramification (logarithmic singularities).

In particular, for each integer n, $\hat{Y}_n$ is analytic in the universal covering of $\mathbf{C}\setminus(-\mathbf{N}^*)$; with some technical but easy work, one can prove that the series of holomorphic functions $\sum\hat{Y}_n$ is uniformly convergent in every compact subset of this universal covering. Therefore, $\hat{Y}_-$ is convergent at the origin and satisfies the required property of Borel transforms of resurgent functions. □

Remark 1. The definition of a general resurgent function doesn't impose anything on the nature of singularities one may encounter in following the analytic continuation of its minor and visiting the various leaves of its Riemann surface. We shall call *simple resurgent function* a resurgent function $\varphi(z)$ whose minor $\hat{\varphi}(\zeta)$ has only singularities of the form

$$\hat{\varphi}(\omega+\zeta) = \frac{c}{2\pi i\zeta} + \hat{\psi}(\zeta)\frac{\log\zeta}{2\pi i} + \hat{R}(\zeta)$$

with $c\in\mathbf{C}$ and $\hat{\psi},\hat{R}\in\mathbf{C}\{\zeta\}$. Simple resurgent functions form a subalgebra, which contains Y_- and all the other resurgent functions that appear in the sequel.

Remark 2. When writing in details the proof of Proposition 5.1, one obtains, in fact, exponential bounds in any sector $S_\alpha^+ = \{\zeta\in\mathbf{C}^*/-\pi+\alpha\leq\arg\zeta\leq\pi-\alpha\}$ (α being a small positive angle):

$$\forall\zeta\in S_\alpha^+,\ |\hat{Y}_-(\zeta)|\leq \text{const}\ e^{\rho|\zeta|},$$

where the positive number ρ depends on the radii of convergence of H^+ and H^- and on α. This allows us to apply *Laplace transform* in any direction different from the direction of $\mathbf{R}^-$.

Laplace transform in a direction θ is defined by

$$\mathcal{L}^\theta :\ \hat{\varphi}(\zeta)\mapsto\varphi^\theta(z) = \int_0^{e^{i\theta}\infty}\hat{\varphi}(\zeta)e^{-z\zeta}d\zeta.$$

When applied to an analytic function of exponential type at most ρ in direction θ, it yields a function φ^θ analytic in a half-plane bisected by the conjugate direction: Re $(ze^{i\theta}) > \rho$. If $\hat{\varphi}$ has at most exponential growth and no singularity in a sector of aperture α (in ζ-plane), by moving the direction of integration and using Cauchy theorem, we get a function analytic in a sectorial neighborhood of infinity of aperture $\pi+\alpha$ (in z-plane)[2]; moreover, in this neighborhood, $\varphi^\theta(z)$ is asymptotic in Gevrey-1 sense[3] to the formal series $\varphi = \mathcal{B}^{-1}\hat{\varphi}$ (a series which is the result of termwise application of Laplace transform to the Taylor series of $\hat{\varphi}$: $\mathcal{B}^{-1}$ is, in fact, the *formal Laplace transform*).

So, by choosing different values for θ, it is possible to associate to the formal series $\varphi(z)$ a family of sectorial germs $\{\varphi^\theta(z)\}$. When the series φ is convergent, the different φ^θ's yield the same analytic germ at infinity: the sum of φ. In general, the passage from φ to φ^θ through $\mathcal{L}^\theta \circ \mathcal{B}$ may be considered as a *resummation* process, since multiplication of formal series is taken to multiplication of sectorial germs, and differentiation w.r.t. z is respected too. We sum up this Borel–Laplace process in the following diagram.

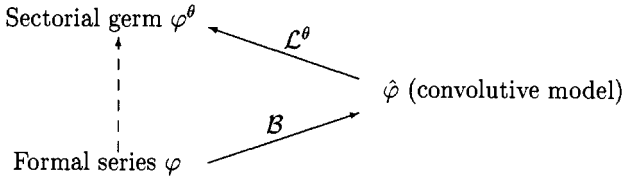

FIG. 4.

Applying Laplace transform $\mathcal{L}^\theta$ to $\hat{Y}_-$ with $\theta \in]-\pi, \pi[$, we get an analytic function defined in a sectorial neighborhood of infinity of aperture 3π in z-plane, which is a solution of (5.1). In particular, we have two possible summations of the formal solution Y_- in the half-plane $\{\text{Re } z < 0\}$ near infinity: Y_-^θ with θ close to π, and $Y_-^{\theta'}$ with θ' close to $-\pi$. These functions correspond respectively to the solutions $p_0(\tau)$ and $\tilde{p}_0(\tau)$ Theorem 3.1 refers to.

The question now is to compute the difference $Y_-^{\theta'} - Y_-^\theta$; we shall do it by analyzing the singularities of the minor $\hat{Y}_-$.

5.2.2. Formal integral. Before that, we will study a formal object, more general than the formal solution Y_-, which solves (5.1) too: the *formal integral*. We shall see that Y_- is the first term of a sequence $(\phi_n(z))$ of simple resurgent functions such that

$$Y(z,u) = \sum_{n\geq 0} u^n e^{nz} \phi_n(z) \in \mathbf{C}[[z^{-1}, ue^z]]$$

[2]This is a subset of $\mathbf{C}$ which contains, for all $\delta \in]0, \pi+\alpha[$, a sector $\{z \in \mathbf{C} / |\arg(ze^{i\theta})| < \delta/2\,,\ |z| > \rho\}$ for some positive ρ.

[3] If $\varphi(z) = \sum \varphi_n z^{-n-1}$, this means that in every closed subsector $\bar{S}$ of the domain, there exist $C, K > 0$ such that:

$$\forall N \geq 1, \forall z \in \bar{S},\ |z|^{N+1} |\varphi^\theta(z) - \sum_{n=0}^{N-1} \varphi_n z^{-n-1}| \leq CK^N N!.$$

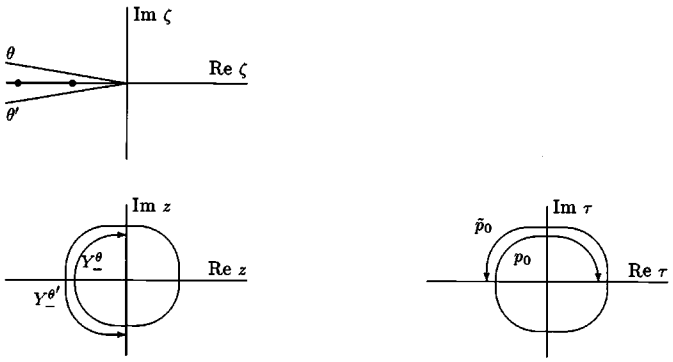

FIG. 5.

formally satisfies the equation. This means that (5.1) is formally conjugated to

$$\frac{dX}{dz} = X \tag{5.3}$$

through the formal diffeomorphism

$$Y = \Phi(z, X) = \sum_{n \geq 0} X^n \phi_n(z) \in \mathbf{C}[[z^{-1}, X]] \,.$$

Due to the fact that we deal with a Riccati equation, the formal integral admits a simple expression.

PROPOSITION 5.2. *There are formal series* $Y_+ \in z^{-1}\mathbf{C}[[z^{-1}]]$ *and* $Y_0(z) \in 1 + z^{-1}\mathbf{C}[[z^{-1}]]$ *such that*

$$Y(z,u) = \frac{ue^z Y_0(z) + Y_-(z)}{ue^z Y_0(z) Y_+(z) + 1}$$

formally solves (5.1). *Like* Y_-, *these formal series are simple resurgent functions;* [4] *their Borel transforms have singularities over* $\mathbf{Z}$ *only, and at most exponential growth at infinity.*

Proof. First we observe that our equation is equivalent to

$$-\frac{d}{dz}(1/Y) = 1/Y + H^+(z) + H^-(z)(1/Y)^2 \,. \tag{5.4}$$

Thus, using the same arguments that we used for proving Proposition 5.1, we see that there is a unique formal series $Y_+ \in z^{-1}\mathbf{C}[[z^{-1}]]$ whose inverse solves (5.1), and that it is a simple resurgent function whose Borel transform has singularities over the positive integers only and at most exponential growth.

Expecting a linear fractional dependence on the free parameter, we perform the change of unknown function

$$Y = \frac{a + Y_-(z)}{aY_+(z) + 1}.$$

[4] The definition of resurgent functions can be extended to allow them to have a constant term. Being the unity of the convolution, the Borel transform of 1 may be considered as the Dirac distribution δ at $\zeta = 0$. If $\varphi = c + \psi$ is a resurgent function of constant term c, its Borel transform is $\mathcal{B}\varphi = c\delta + \mathcal{B}\psi$, but we still call minor the germ $\hat{\varphi} = \mathcal{B}\psi$. See section 5.3 for one further generalization.

It yields the equation $da/dz = a(1 + H^+Y_- + H^-Y_+)$: the general solution is $a = ue^{z+\alpha(z)}$, where α is the unique formal series without constant term of derivative $H^+Y_- + H^-Y_+$. The series α is a simple resurgent function; its Borel transform

$$\hat{\alpha}(\zeta) = -\frac{1}{\zeta}(\hat{H}^+ * \hat{Y}_- + \hat{H}^- * \hat{Y}_+)$$

has singularities over $\mathbf{Z}^*$ only and at most exponential growth. Its exponential $Y_0 = e^\alpha$ inherits this property, by general properties of exponentiation of resurgent functions ([4, 2] : Y_0 has constant term 1 and its minor $\hat{Y}_0(\zeta) = \sum_{n\geq 1} \hat{\alpha}^{*n}/n!$ is analytic in the universal covering of $\mathbf{C} \setminus \mathbf{Z}$, with no singularity at the origin on the main sheet). □

So, we have $Y(z,u) = \sum_{n\geq 0} u^n e^{nz}\phi_n(z)$ with $\phi_0 = Y_-$, and for positive n,

$$\phi_n = (-1)^{n-1}Y_0^n Y_+^{n-1}(1 - Y_-Y_+)\,.$$

If we apply Laplace transform in a nonsingular direction θ, we obtain a one-parameter family of analytic solutions of (5.1):

$$Y^\theta(z,u) = \sum_{n\geq 0} u^n e^{nz}\mathcal{L}^\theta\hat{\phi}_n = \frac{ue^z Y_0^\theta(z) + Y_-^\theta(z)}{ue^z Y_0^\theta(z)Y_+^\theta(z) + 1},$$

defined for $\mathrm{Re}\,(ze^{i\theta}) - \rho > \text{const.}|ue^z|$ (a condition meant to ensure that the Laplace transforms of $\hat{Y}_0$, $\hat{Y}_-$, $\hat{Y}_+$ are defined and that the denominator in $Y^\theta(z,u)$ does not vanish).

In the convolutive model, we can apply Cauchy theorem and move the direction of integration in the upper or lower half-plane (depending on the value of θ). This provides an analytic continuation of $Y^\theta(z,u)$ allowing z to vary in a sectorial neighborhood of infinity of aperture 2π, that we call $Y^+(z,u)$ or $Y^-(z,u)$ as illustrated in the following diagram.

FIG. 6.

Thus, we essentially have two one-parameter families of analytic solutions of (5.1), characterized by their asymptotic behavior in the above-mentioned domains in z-plane. There must be some connection between them: a member $Y^+(.\,,u)$ of the first family has to coincide with some member $Y^-(.\,,u')$ of the other family for values of z with negative real part, and with some solution $Y^-(.\,,u'')$ for values of z with positive real part. These connection formulae will be computed in the following sections.

We are especially concerned with the functions $Y^+(z,0)$ and $Y^-(z,0)$ which correspond respectively to $p_0(\tau)$ and $\tilde{p}_0(\tau)$. At this stage, the first two statements of Theorem 3.1 are proved; the unicity assertion for the second one, for instance, is a consequence of the following easy lemma.

LEMMA 5.3. *If $u \in \mathbf{C}^*$, $Y^-(z,u)$ is defined for* $\mathrm{Re}\ z \leq 0$, $\mathrm{Im}\ z \geq 0$, *and $|z|$ big enough, and*

$$Y^-(z,u) - Y^-(z,0) = ue^z(1 + O(z^{-1})).$$

Indeed any solution of (5.1) analytic in a neighborhood of $i.\infty$ on the imaginary axis has to coincide with some function $Y^-(z,u)$; only one tends to 0 as Im z tends to infinity, and it corresponds to $u=0$.

And now we see that in order to prove the last statement of the theorem, we simply need to compute the value u_0 of the parameter such that $Y^+(z,0)=Y^-(z,u_0)$ for Re $z<0$ and to apply the lemma.

5.2.3. Alien calculus. It is essential to be able to analyze the singularities that appear in the convolutive model, for they are responsible for the divergence in the formal model. This is done by means of *alien calculus*, one of the main features of Écalle's theory, which relies on a new family of derivations: the *alien derivations*. Let's introduce them in the case of simple resurgent functions.

Let ω be in $\mathbf{C}^*$. We define an operator Δ_ω in the following way: given a simple resurgent function $\varphi(z)$, let's try to follow the analytic continuation of its minor $\hat\varphi(\zeta)$ along the half-line issuing from the origin and passing by ω (the minor is defined by the Borel transform of φ without taking into account the constant term if there is any); on this line, there is an ordered sequence $(\omega_1,\omega_2,\ldots)$ of singular points to be circumvented. If $r\geq 1$, we obtain in this way 2^{r-1} determinations of the minor in the segment $]\omega_{r-1},\omega_r[$ (with the convention $\omega_0=0$ if $r=1$ — in this case, there is only one determination), and we denote them by

$$\hat\varphi^{\varepsilon_1,\ldots,\varepsilon_{r-1}}_{\omega_1,\ldots,\omega_{r-1}},$$

each ε_i being a plus or minus sign indicating whether ω_i is circumvented to the right or to the left:

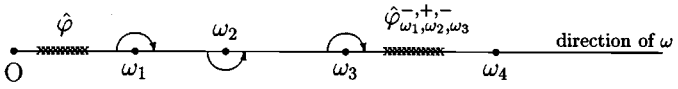

FIG. 7.

- If $\omega\notin\{\omega_1,\omega_2,\ldots\}$, we set

$$\Delta_\omega\varphi=0.$$

- If $\omega=\omega_r$ for $r\geq 1$, each of the above-mentioned determinations may have a singularity at ω:

$$\hat\varphi^{\varepsilon_1,\ldots,\varepsilon_{r-1}}_{\omega_1,\ldots,\omega_{r-1}}(\omega+\zeta)=\frac{c^{\varepsilon_1,\ldots,\varepsilon_{r-1}}_{\omega_1,\ldots,\omega_{r-1}}}{2\pi i\zeta}+\hat\psi^{\varepsilon_1,\ldots,\varepsilon_{r-1}}_{\omega_1,\ldots,\omega_{r-1}}(\zeta)\frac{\log\zeta}{2\pi i}+\text{ regular function},$$

and we set

$$\Delta_{\omega_r}\varphi=\sum_{\varepsilon_1,\ldots,\varepsilon_{r-1}}\frac{p(\varepsilon)!q(\varepsilon)!}{r!}\left(c^{\varepsilon_1,\ldots,\varepsilon_{r-1}}_{\omega_1,\ldots,\omega_{r-1}}+\mathcal{B}^{-1}\hat\psi^{\varepsilon_1,\ldots,\varepsilon_{r-1}}_{\omega_1,\ldots,\omega_{r-1}}\right),\tag{5.5}$$

where the integers p and $q=r-1-p$ are the numbers of plus signs and of minus signs in the sequence $(\varepsilon_1,\ldots,\varepsilon_{r-1})$.

It is easy to check the consistency of this definition. In some sense, $\Delta_\omega\varphi$ is a well-balanced average of the singularities of the determinations of the minor over ω; adding or removing false singularities in the list $(\omega_1,\omega_2,\ldots)$ would not affect the result, which

is a simple resurgent function (the definitions of section 5.2.1 were formulated exactly for this purpose).

The definition of operators Δ_ω for more general algebras of resurgence is given in [4, 5, 6]. In fact, these operators encode the whole singular behavior of the minor; given a sequence of points $(\omega_1, \dots, \omega_n)$ in $\mathbf{C}^*$, not necessarily on the same line, the composed operator $\Delta_{\omega_n} \cdots \Delta_{\omega_1}$ measures singularities over the point $\omega_1 + \cdots + \omega_n$.

The main property that makes these operators very useful in practice is the following: *the Δ_ω are derivations of the algebra of resurgent functions, i.e.,*

$$\forall \omega \in \mathbf{C}^*, \forall \varphi_1, \varphi_2 \text{ resurgent functions}, \ \Delta_\omega(\varphi_1\varphi_2) = (\Delta_\omega\varphi_1)\varphi_2 + \varphi_1(\Delta_\omega\varphi_2)\,.$$

By contrast with the natural derivation $\frac{d}{dz}$, they are called *alien derivations*.

Alien derivations interact with natural derivations according to the rule

$$\frac{d}{dz}\Delta_\omega\varphi = \Delta_\omega\frac{d\varphi}{dz} + \omega\Delta_\omega\varphi,$$

which reads

$$\frac{d}{dz}\dot{\Delta}_\omega\varphi = \dot{\Delta}_\omega\frac{d\varphi}{dz} \tag{5.6}$$

when one introduces the symbol $\dot{\Delta}_\omega = e^{-\omega z}\Delta_\omega$ (*pointed alien derivation*). But the $(\Delta_\omega)_{\omega\in\mathbf{C}^*}$ generate a free Lie algebra.

Finally, let's state the other property that we shall use: suppose that all the singularities of the minor of φ in a sector $\{\theta < \arg\zeta < \theta'\}$ form an ordered sequence $(\omega_1, \omega_2, \dots)$ on a half-line inside the sector

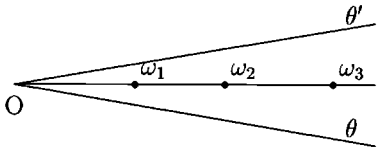

FIG. 8.

and that we can apply Borel–Laplace summation process, then

(5.7)

$$\varphi^\theta = \varphi^{\theta'} + \sum_{r\geq 1;\, i_1,\dots,i_r\geq 1} \frac{1}{r!} e^{-(\omega_{i_1}+\dots+\omega_{i_r})z}(\Delta_{\omega_{i_1}}\cdots\Delta_{\omega_{i_r}}\varphi)^{\theta'} = \left[\left(\exp\sum_{i\geq 1}\dot{\Delta}_{\omega_i}\right).\varphi\right]^{\theta'}$$

if we systematically use the notation ψ^θ for $\mathcal{L}^\theta\mathcal{B}\psi$, and $(e^{-\omega z}\psi)^\theta$ for $e^{-\omega z}\psi^\theta$.

5.2.4. Bridge equation. Coming back to our Riccati equation (5.1), let's try to compute the alien derivatives of the various simple resurgent functions that appear in the formal integral of Proposition 5.2. We shall use the generating series

$$Y(z,u) = \sum_{n\geq 0} u^n e^{nz}\phi_n(z)\,,\ \Delta_\omega Y = \sum_{n\geq 0} u^n e^{nz}\Delta_\omega\phi_n,$$

and we shall assume $\omega \in \mathbf{Z}^*$, since we already know that $\Delta_\omega Y$ vanishes if it is not the case.

Of course, it is equivalent to look for $\dot{\Delta}_\omega Y$, and it turns out that one can easily derive from (5.1) a deep relation, simply by applying $\dot{\Delta}_\omega$ to the equation itself. One obtains a linear equation for $\dot{\Delta}_\omega Y$

$$\frac{d}{dz}(\dot{\Delta}_\omega Y) = (1 + 2H^+ Y)\dot{\Delta}_\omega Y$$

(because pointed alien derivations commute with natural derivation, vanish on convergent series like $H^\pm$, and satisfy Leibniz rule), which admits $\partial Y/\partial u$ as a nontrivial solution, so that there must be some proportionality relationship

$$\dot{\Delta}_\omega Y = A_\omega(u)\frac{\partial Y}{\partial u}.$$

Simple arguments show that the coefficient $A_\omega(u)$ must be zero if $\omega \leq -2$ (because $\phi_1 \neq 0$, so the valuation of $\partial Y/\partial u$ w.r.t. e^z is exactly 1), that it is of the form $A_\omega(u) = A_\omega u^{\omega+1}$ (for homogeneity reasons), and finally that it is zero if $\omega \geq 2$ (Because one can repeat everything with (5.4); it's only here that we use the fact that (5.1) is a Riccati equation and not a more general nonlinear equation). We end up with the following proposition.

PROPOSITION 5.4. *There exist* $A^-, A^+ \in \mathbf{C}$ *such that*

$$\begin{aligned}
\dot{\Delta}_{-1} Y &= A^- \partial \frac{Y}{\partial u}, \\
\dot{\Delta}_{+1} Y &= -A^+ u^2 \partial \frac{Y}{\partial u}, \\
\dot{\Delta}_\omega Y &= 0 \text{ if } \omega \notin \{-1, +1\}.
\end{aligned}$$

So, the action of alien derivations on the formal integral is equivalent to the action of some differential operator: this important and very general result was called *bridge equation* by Écalle, since it throws a bridge between alien and ordinary calculus. When interpreted in the convolutive model, it expresses a strong link between an analytic germ at the origin and its singularities: in some ways, the germ reproduces itself at singular points, and this was the reason for naming "resurgent" such an object. Of course, with our definitions, not all resurgent functions have this property, but Écalle observed that it holds for all resurgent functions that arise "naturally" (as solutions of some analytic problem).

For instance, bridge equation holds for more general nonlinear equations, but in contrast with Riccati case, there can then be an infinity of numbers A_ω, $\omega \in \{-1, 1, 2, \ldots\}$; they are called *analytic invariants* of the equation, because it can be proven that two such equations are analytically (not only formally) conjugated if and only if they have the same set of A_ω's.

Thus, in our problem, inside the class of formally conjugated equations (5.1) (they are all conjugated to (5.3)), analytic classes are parametrized by a pair of two numbers.

Alien derivatives can be computed explicitly in terms of the two analytic invariants A^- and A^+:

$$\begin{aligned}
\Delta_{-1} Y_- &= A^- Y_0 (1 - Y_- Y_+), & \Delta_{+1} Y_- &= 0, \\
\Delta_{-1} Y_+ &= 0, & \Delta_{+1} Y_+ &= A^+ Y_0^{-1} (1 - Y_- Y_+), \\
\Delta_{-1} Y_0 &= -A^- Y_0^2 Y_+, & \Delta_{+1} Y_0 &= A^+ Y_-.
\end{aligned}$$

In particular, $\Delta_{\pm 1} Y_\pm = A^\pm + O(z^{-1})$, which means that $A^\pm$ is the residuum of $\hat{Y}_\pm(\zeta)$ at the point ± 1. These two numbers are transcendent functions of the convergent germs H^+ and H^-; we shall see later how to compute them in special cases. The vanishing of alien derivatives at integer points other than ± 1 does not mean that there is no singularity at those points: these other singularities can be detected by iterating bridge equation.

Bridge equation may be used for other purposes than analytic classification: formula (5.7) can be justified with $\varphi = Y(.\,, u)$, and we are now in a position to compare $Y^-(z,u)$ and $Y^+(z,u)$, the two families of solutions of (5.1) we obtained by resummation at the end of section 5.2.2. In the sequel, we shall take various values of z with big enough modulus and appropriated values of u in order to have $Y^\pm(z,u)$ defined.

If Re $z < 0$, applying formula (5.7) with $\theta < \pi < \theta'$ (and these angles both close to π) yields

$$Y^\theta(z,u) = [\exp \dot{\Delta}_{-1}]^{\theta'}(z,u) = \left[\exp\left(A^- \frac{\partial}{\partial u}\right)\right]^{\theta'}(z,u) = Y^{\theta'}(z, u + A^-)\,,$$

that is

$$Y^+(z,u) = Y^-(z, u + A^-)\,; \tag{5.8}$$

and similarly, if Re $z > 0$, choosing $\theta < 0 < \theta'$,

$$Y^-(z,u) = Y^+\left(z, \frac{u}{1 + A^+ u}\right). \tag{5.9}$$

Let's take $u = 0$: we already knew that $Y^+(z,0)$ and $Y^-(z,0)$ coincide for Re $z > 0$ (as was noticed at the end of section 5.2.1), but now, formula (5.8) and Lemma 5.3 show that, for Re $z < 0$ and Im $z > 0$,

$$Y^+(z,0) - Y^-(z,0) = A^- e^z (1 + O(z^{-1}))\,.$$

Finally, when the original variable $\tau = -iz/2$ has positive real and imaginary parts,

$$p_0(\tau) - \tilde{p}_0(\tau) = A^- e^{2i\tau}(1 + O(\tau^{-1}))\,. \tag{5.10}$$

5.3. Computation of analytic invariants. To complete the proof of Theorem 3.1, we only need to compute the coefficient A^- associated with an equation

$$\frac{dY}{dz} = Y + \frac{1}{6z}(1 - Y^2) \tag{5.11}$$

deduced from (3.3) by the change of variable $z = 2i\tau$, and to put it inside formula (5.10).

We shall, in fact, compute the pair of analytic invariants for all equations

$$\frac{dY}{dz} = Y - \frac{1}{2\pi i z}(B^- + B^+ Y^2), \tag{5.12}$$

where $B^\pm \in \mathbf{C}$. The result is proved in the second volume of [4], but we present here an alternative method.

PROPOSITION 5.5. *The analytic invariants of* (5.12) *are given by*

$$A^- = B^- \sigma(B^- B^+)\,,\ A^+ = -B^+ \sigma(B^- B^+),$$

where $\sigma(b) = \frac{2}{b^{1/2}} \sin \frac{b^{1/2}}{2}$. Note that this implies $A^- = -i$ in the case of (5.11), as required for ending the proof of the theorem.

Proof. Let's begin with a few simple remarks. The coefficient $A^{\pm}$ is the residuum at ± 1 of the Borel transform of $Y_{\pm}$, where $Y_-(z)$ is the unique formal solution of (5.12) and $Y_+(z)$ the unique formal solution of the equation corresponding to (5.4). It is easy to see that

$$Y_-(z) = B^- y(z)\,,\ Y_+(z) = -B^+ y(-z)\,,$$

where y is the unique formal solution of an equation depending only on $b = B^- B^+$:

$$\frac{dy}{dz} = y - \frac{1}{2\pi i z}(1 + by^2).$$

If we solve the Borel transform of this equation like we did in the proof of Proposition 5.1 (by expanding everything in powers of b), we find for the residuum of $\hat{y}(\zeta)$ at -1 an analytic function $\sigma(b)$ such that $\sigma(0) = 1$, and we obtain $A^- = B^- \sigma(b)$ and $A^+ = -B^+ \sigma(b)$.

Rather than studying the power expansion of $\sigma(b)$ (this is more or less what is done in [4, Vol. 2, pp. 476–480], but in a very efficient manner through the theory of *moulds*), we prefer to perform the change of unknown function

$$y(z) = \frac{2\pi i}{b} \cdot \frac{z q'(z)}{q(z)}\,,$$

which leads us to a second-order linear equation

$$z^2 q'' + (z - z^2) q' - \beta^2 q = 0$$

where $\beta^2 = \frac{b}{4\pi^2}$. We assume in the the sequel that $\operatorname{Re} \beta > 0$ (excluding real nonpositive values of b is innocuous since the function σ is analytic).

We exploit the peculiar form of this new equation, and write its unique formal solution with constant term 1 as the product of a monomial and expansion in fractional powers of z:

$$q(z) = z^{\beta} r(z) = 1 + O(z^{-1})\,,\ \ r(z) \in z^{-\beta}\mathbf{C}[[z^{-1}]]. \tag{5.13}$$

The series $r(z)$ may be called resurgent if we extend the definition of Borel transform by

$$z^{-\nu} \mapsto \zeta^{\nu-1}/\Gamma(\nu)\ ,\ \text{if}\ \ \nu \in \mathbf{C}\ \ \text{and}\ \ \operatorname{Re} \nu > 0,$$

and admit among resurgent functions all formal series (with possibly fractional powers) whose Borel transform, which may now be ramified at the origin and has endless analytic continuation. The convolution of minors is defined as before and we are still dealing with an algebra.

The point is that alien derivatives of r are easy to compute, for the equation it satisfies

$$r'' + (-1 + (2\beta + 1)z^{-1}) r' - \beta z^{-1} r = 0 \tag{5.14}$$

can be solved explicitly in the convolutive model.

LEMMA 5.6. *The Borel transform $\hat{r} = \mathcal{B}r$ is given by*

$$\hat{r}(\zeta) = \frac{\zeta^{\beta-1}}{\Gamma(\beta)}(1+\zeta)^{\beta}.$$

Proof. The Borel transform of (5.14)

$$(\zeta^2+\zeta)\hat{r} - (2\beta+1)1 * (\zeta\hat{r}) - \beta(1*\hat{r}) = 0$$

is equivalent to a first-order linear equation obtained by differentiation with respect to ζ (this was the only purpose of the change of unknown function (5.13)),

$$\zeta(\zeta+1)\frac{d\hat{r}}{d\zeta} = [(2\beta-1)\zeta+\beta-1]\hat{r}. \qquad \square$$

Alien calculus applies in this slightly generalized context. We only need to be careful about the determination of ζ^β we use (let's say it is the principal one) and about the sheet of the Riemann surface of the logarithm we look at. In particular, alien derivations are now indexed by points in this Riemann surface rather than by points in $\mathbf{C}^*$, and in order to compute $\Delta_{e^{i\pi}} r$ we perform a translation,

$$\hat{r}(e^{i\pi}+\zeta) = e^{i\pi(\beta-1)}\frac{\zeta^\beta}{\Gamma(\beta)}(1-\zeta)^{\beta-1},$$

and take the variation of the resulting singular germ (just as we were asked to retain the coefficient of $\log\zeta/2\pi i$ in the case of pure logarithmic singularities, according to formula (5.5)),

$$\mathcal{B}\,\Delta_{e^{i\pi}} r = -e^{i\pi\beta}(1-e^{2i\pi\beta})\frac{\zeta^\beta}{\Gamma(\beta)}(1-\zeta)^{\beta-1}.$$

We deduce that

$$\Delta_{e^{i\pi}} r = -e^{i\pi\beta}(1-e^{2i\pi\beta})\beta z^{-\beta-1}(1+O(z^{-1}))$$

and

$$\Delta_{-1}\, q = z^\beta \Delta_{e^{i\pi}} r = -2i\beta\sin(\pi\beta)z^{-1}(1+O(z^{-1})).$$

Finally we use Leibniz rule and formula (5.6):

$$\Delta_{-1}\, y = \frac{2\pi i}{b}\, z\, \Delta_{-1}(q'/q) = \frac{2}{b^{1/2}}\sin\frac{b^{1/2}}{2} + O(z^{-1}).$$

The constant term of the alien derivative is the residuum $\sigma(b)$. $\square$

6. Remarks on general nonlinear inner equations: The Kruskal–Segur strategy. Formula $p_0(\tau) - \tilde{p}_0(\tau) = -ie^{2i\tau}(1+O(\tau^{-1}))$ obtained in Theorem 3.1 for the inner equation (3.3) has been crucial for determining $w(+\infty,\varepsilon)$ and thus $\Delta I^2(\varepsilon)$, and this was the aim of the previous section. There (3.3) is studied by the resurgence theory obtaining the formula (5.10): $p_0(\tau)-\tilde{p}_0(\tau) = A^- e^{2i\tau}(1+O(\tau^{-1}))$. In order to compute exactly the coefficient $A^-(=-i)$ in the subsection 5.3, it is essential to be assured that (3.3) can be transformed into a second-order linear equation. However, in most applications (for example, for standard maps, see [7]) the inner equation is

not a Riccati equation and the method outlined in section 5 does not give quantitative results. Nevertheless, in the general case we can join the resurgence method with the Kruskal and Segur strategy [8]. This strategy adapted to our case would have the following form.

The main idea is that A^- can be computed looking at the coefficients of the formal solution of (3.3). Following the Kruskal–Segur strategy one can see that the growth of a_n is controlled comparing them with the coefficients b_n of the associated linear problem.

In this sense let $\sum_{n\geq 0} a_n \tau^{-n-1}$ be the formal solution of (3.3), which vanish at $-\infty$ (and, in fact, at $+\infty$), and let $\sum_{n\geq 0} b_n \tau^{-n-1}$ be the associated formal solution of the linear part of (3.3) $q_0' = 2iq_0 + (1)/6\tau$. We obtain that $b_n = (-1)^{n+1}(1)/12i(n!)/(2i)^n$ and as a first step in this method we would have to prove the following.

PROPOSITION 6.1. *$a_n = k_n b_n$, where $k_n = 3/\pi + O(\frac{1}{n})$, as $n \to \infty$.*

In our case we have numerical evidences of this result, and probably using the special form of our equation it could be proved analytically (see [17]). In this paper, we have not adopted this strategy because of the special form of our equation where this result is a consequence of the computation of $\Delta_{-1} Y_-$ in section 5.

Proposition 6.1 would be essential to control the behavior of the Borel transform of our solution. Let $\varphi(\xi) := \sum_{n\geq 0} (a_n \xi^n)/n!$ be the Borel transformation of $\sum_{n\geq 0} a_n \tau^{-n-1}$ and $\varphi_0(\xi) := 3/\pi \sum_{n\geq 0} (b_n \xi^n)/n! = -(1/2\pi)(1/2i + \xi)$ the Borel transformation of $3/\pi \sum_{n\geq 0} b_n \tau^{-n-1}$, and let us call $\varphi_1 := \varphi - \varphi_0$. Finally, let $f(\tau)$ be the Borel resummation of $\varphi(\xi)$, that is, its Laplace transform in some direction of the upper plane $Im\xi > 0$. As we know exactly $\varphi_0(\xi)$ in all the complex plane, this method allows us to compute its contribution to the resummation $f(\tau)$. Nevertheless, it would remain to prove that $\varphi_1(\xi)$ contributes to $f(\tau)$ only with higher-order terms. In order to prove this, it would be necessary to know the behavior of $\varphi_1(\xi)$, and, for our case, this is done in Proposition 6.2.

PROPOSITION 6.2.

i. *φ_0 has a unique singularity at $-2i$, which is a pole with residue $-\frac{1}{2\pi}$,*
ii. *φ_1 has logarithmic singularities at $-2i, -4i, -6i, \ldots$,*
iii. *Moreover, $f(\tau)$ is Gevrey-1 asymptotic to the formal solution $\sum_{n\geq 0} a_n \tau^{-n-1}$ in the sector $-3\pi/2 + \alpha \leq \arg \tau \leq \pi/2 - \alpha$, when $|\tau| \to \infty \ldots$*

An analogous proposition is studied in section 5 with the help of resurgent theory for our equation, and it seems that this can be generalized to other equations, as in [15]. Resurgent theory gives us the location of the singularities of φ_1, as well as their type and, consequently, their contribution to the "resummation" $f(\tau)$.

Finally, as a last step of this method, putting together Propositions 6.1 and 6.2 we would have the following.

PROPOSITION 6.3.

i. $f(\tau) = p_0(\tau)$ *if* $\pi/2 < \arg \tau < 2\pi$,
ii. $f(\tau) = \tilde{p}_0(\tau)$ *if* $-\pi < \arg \tau < \pi/2$.

Then, for τ such that $0 \leq \arg \tau < \pi/2$, one can use the analytic continuation of $f(\tau)$, and using these propositions and the Cauchy theorem, one can see that in our equation:

$$p_0(\tau) - \tilde{p}_0(\tau) = \int_{-\infty}^{+\infty} e^{-\tau s} \varphi(s) ds$$

$$= \int_{-\infty}^{+\infty} e^{-\tau s}\varphi_0(s)ds + \int_{-\infty}^{+\infty} e^{-\tau s}\varphi_1(s)ds$$
$$= e^{2i\tau}(-i + O(\tau^{-1})).$$

Observe that following the Kruskal–Segur strategy we can compute the coefficient $A^-/(2\pi i)$ as the residue of the Borel transform φ_0 at its pole $-2i$. We are convinced that the link between the resurgence approach and Kruskal–Segur strategy rests on the fact that, in general, all the successive approximations of the corresponding (5.2) have a pole at $-2i$. Then φ_0 would be the summation of all the polar parts at $-2i$ of those approximations, and its residue the sum of their residues (which corresponds to the coefficient A^- computed in Proposition 5.5).

LOCALIZED SPATIAL HOMOGENIZATION AND LARGE DIFFUSION*

ANÍBAL RODRÍGUEZ-BERNAL†

Abstract. We analyze singular perturbations in elliptic equations, subjected to various boundary conditions, in which the diffusion is going to infinity in localized regions inside the domain and therefore solutions undergo a localized spatial homogenization. The limiting elliptic operator is analyzed as well as convergence of solutions, eigenvalues, and eigenvectors.

Key words. singular perturbation, eigenvalue problems, large diffusion

1. Introduction.

When dealing with the modeling of some physical problem it is often the case that there are some physical properties that differ very strongly from one part of the physical system to the other. As a consequence the constituting laws, although obeying a general formulation, have some significant differences depending on what part of the system one is looking at. This, in turn, implies that the differential equations describing the behavior of the system may also have different properties all along the system. In some cases this leads to the existence of some singularities in the equations and/or in the solutions. It is also often the case that one must study some singular limit problem because some parameter of the problem is varied.

For example, in past years numerous results have been given concerning the behavior of semilinear parabolic equations (or systems)

$$u_t - D\Delta u + f(u, \nabla u) = 0$$

with Neumann boundary conditions, where $u = (u_1, \dots, u_m)^T$ and $D = \mathrm{diag}(D_1 \dots, D_m)$ are the (constant) diffusion coefficients, [4, 9, 11, 12, 15]. In these cases the singular limit problem is obtained when one considers the case in which the diffusivity of the component species is very large, i.e., when $D_0 = \inf_i\{D_i\}$ is very large. Then one tries to understand the properties and behavior of the solutions as $D_0 \to \infty$. The results in those papers assert the physically clear fact that large diffusivity implies a very rapid redistribution of the spatial inhomogeneities of u and, therefore, u approaches, as time increases, a function constant in space. The dynamics of the "asymptotic set of states," i.e., constant functions, is given explicitly by the kinetic equation

$$\dot{u} + f(u, 0) = 0,$$

which is a system of ordinary differential equations (ODEs) in $\mathbb{R}^m$ that reflects the dynamics of the full reaction-diffusion system as D_0 increases. Therefore, the ODE is the true limiting problem for the singular limit $D_0 \to \infty$.

The same problem was studied in [13], when only some of the diffusion coefficients are sufficiently large. Thus in this case there are strong differences in the physical properties of the species (the diffusivities). Now the equations describing the behavior of the solutions, as some of the diffusion coefficients go to infinity, consist of a system of partial differential equations (PDEs) coupled with a system of ODEs for the components that tend to be constant in space functions. Those equations are called "shadow systems." Similar situations have been considered in [6] for the case of delayed semilinear parabolic equations or in [10, 5], where they described the large time dynamics of parabolic equations in one-dimensional domains with the diffusion coefficient being large except in a neighborhood of a finite number of points where it becomes small. The asymptotic dynamics of the parabolic problem are again described by a system of ODEs.

For the case of semilinear wave equations describing, for example, the vibrations of an elastic body [1, 8] when the wave speed is large everywhere, one also expects that the solutions will converge to constant in space functions, reflecting the property that the body tends to behave as a rigid body and then all points oscillate in phase with the same amplitude and frequency. In fact the trend to spatial homogeneity has also been established [18, 3] provided that the damping is large enough. In this case the result states that if vibrations propagate very rapidly, then in the limit an elastic body behaves as a rigid structure.

An indication of this property of spatial homogenization, when the diffusion is very large, can be obtained from the linear elliptic problem

$$\begin{cases} -\frac{1}{\epsilon}\Delta u^\epsilon + \lambda u^\epsilon = f, \\ \frac{\partial u^\epsilon}{\partial \vec{n}} = 0, \end{cases}$$

where after multiplying by ϵ one gets that u^ϵ must converge to the solution of

$$\begin{cases} -\Delta u = 0, \\ \frac{\partial u}{\partial \vec{n}} = 0. \end{cases}$$

Hence u must be constant. But integrating we get $\lambda \int_\Omega u^\epsilon = \int_\Omega f$, and in the limit $u = \frac{1}{\lambda} \fint_\Omega f$, where $\fint_\Omega = \frac{1}{|\Omega|}\int_\Omega$. Also, by looking at the eigenvalue problem

$$\begin{cases} -\frac{1}{\epsilon}\Delta u^\epsilon + \lambda u^\epsilon = \mu u^\epsilon, \\ \frac{\partial u^\epsilon}{\partial \vec{n}} = 0, \end{cases}$$

the first eigenvalue is $\mu_1^\epsilon = \lambda$ and the first eigenfunction is $\phi_1^\epsilon = |\Omega|^{-1/2}$. But the second eigenvalue is

$$\mu_2^\epsilon = \inf_{\substack{u \in H^1(\Omega) \\ \int u = 0 \\ \|u\| = 1}} \frac{1}{\epsilon}\int_\Omega |\nabla u|^2 + \lambda \int_\Omega |u|^2 \geq \frac{1}{\epsilon} c(\Omega) + \lambda \to \infty,$$

where we have used the Poincaré inequality for zero mean functions. These computations prove that only the first mode, i.e., the average of the solution, matters as ϵ goes to zero. Note that the previous arguments, applied to the case with Dirichlet boundary conditions, imply the solution converges to zero and all the eigenvalues converge to infinity. Therefore, boundary conditions also play a role in the determination of the limiting problem.

On the other hand, in this paper we are concerned with the case in which the diffusion coefficient becomes large in a localized region inside the physical domain of the differential equation, while it remains bounded away from zero in the rest. That situation can be found, for example, in composite materials, where the heat diffusion properties differ very strongly from one part to another of the material, or in population dynamics in which one species diffuses much faster than the others in some determined regions. Also, one can consider the vibrations of an elastic membrane and assume that some part of the membrane is made of a more rigid material than the rest. In the limit, one obtains a multistructure vibrating system composed of a rigid plate bound from its boundary to a membrane. In all these cases, passing to the singular limit can be regarded as a process describing a transition phenomena of rigidization or solidification in a composite material. In this situation one expects that in the "large diffusion" region, Ω_0, the solution tends to be space homogeneous and satisfies an ODE, while in the other part it must satisfy a PDE. There must be also some coupling between the two equations. Our goal is then to obtain the equations that describe the limiting problem and to study the properties and relationships between the approximating problems and the limit one.

We will be concerned with linear elliptic problems, under suitable boundary conditions, and we will analyze the behavior of solutions as $\epsilon \to 0$. We will also consider the corresponding eigenvalue problems. In this way we will obtain a description of the asymptotic behavior, as $\epsilon \to 0$, of the eigenmodes and eigenfrequencies of the system. To be more precise, we will consider the family of elliptic problems

$$(P_\epsilon)\quad \begin{cases} -Div(d_\epsilon(x)\nabla u^\epsilon) + (\lambda + V_\epsilon(x))u^\epsilon = f^\epsilon & \text{on } \Omega, \\ \frac{\partial u^\epsilon}{\partial \vec{n}_\epsilon} + b_\epsilon(x)u^\epsilon = g^\epsilon & \text{on } \Gamma, \end{cases} \tag{1.1}$$

where $0 < \epsilon \le \epsilon_0$, $\Omega \subset \mathbb{R}^N$ is a bounded regular open connected set, and Γ is the boundary of Ω. Note that $\frac{\partial u}{\partial \vec{n}_\epsilon}$ denotes the conormal derivative relative to the diffusion operator $-Div(d_\epsilon(x)\nabla u)$, i.e., $\frac{\partial u}{\partial \vec{n}_\epsilon} = d_\epsilon(x)\langle \nabla u, \vec{n}\rangle$. Also, $\lambda \in \mathbb{R}$ and the potentials $V_\epsilon(x)$ and $b_\epsilon(x)$ are given functions on Ω and Γ, respectively. Let $\Omega_0 = \cup_{i=1}^m \Omega_{0,i}$ be an open subset of Ω with boundary $\Gamma_0 = \cup_{i=1}^m \Gamma_{0,i}$ such that $\Omega_{0,i}$ is connected with boundary $\Gamma_{0,i}$, $\Gamma \cap \Gamma_0 = \emptyset$, and $\Gamma_{0,i} \cap \Gamma_{0,j} = \emptyset$ for $i \neq j$. We denote $\Omega_1 = \Omega \setminus \overline{\Omega_0}$. Note that the boundary of Ω_1 is $\Gamma \cup \Gamma_0$. The diffusion coefficients $d_\epsilon(x)$, $0 \le \epsilon \le \epsilon_0$, are assumed to be smooth, strictly positive functions on Ω, such that

$$0 < m_0 \le d_\epsilon(x) \le M_\epsilon \tag{1.2}$$

for every $x \in \Omega$ and $0 \le \epsilon \le \epsilon_0$. We also assume that the diffusion is very large on Ω_0 as ϵ approaches zero. More precisely, we assume

$$d_\epsilon(x) \longrightarrow \begin{cases} \infty & \text{uniformly on compact subsets of } \Omega_0, \\ d_0(x) & \text{uniformly on } \Omega_1 \end{cases} \tag{1.3}$$

as $\epsilon \to 0$. Finally, the potentials verify

$$V_\epsilon \to V \in L^{q_0}(\Omega) \quad \text{with } q_0 \begin{cases} > N/2 & \text{if } N \ge 3, \\ > 1 & \text{if } N = 2, \\ \ge 1 & \text{if } N = 1, \end{cases} \tag{1.4}$$

$$b_\epsilon \to b \in L^{q_1}(\Gamma) \quad \text{with } q_1 \begin{cases} > N-1 & \text{if } N \ge 3, \\ > 1 & \text{if } N = 2, \\ \ge 1 & \text{if } N = 1. \end{cases} \tag{1.5}$$

We will show that the family of solutions to these problems, $\{u^\epsilon\}_\epsilon$, converges, in some sense, to a function u that is constant in Ω_0 and that verifies a "limiting elliptic problem," the shadow system for the elliptic problem, which is of nonlocal nature. We will show that in the process of convergence there is a loss of regularity for the limiting solution by showing that typically the normal derivative of u jumps across Γ_0. Concerning the eigenvalue problem, we will show that the spectral properties of the approximate and limiting problem are close by showing that the eigenvalues and eigenfunctions converge.

The form of the shadow system is formally guessed in section 2. After introducing some notations in section 3, in section 4 we prove the convergence of solutions and in section 5 we prove convergence of eigenvalues and eigenfunctions. Finally, in section 6, we will consider the case of mixed or Dirichlet boundary conditions and different types of diffusion coefficients for which the same results hold true.

It is important to note here that the assumption

$$\Gamma \cap \Gamma_0 = \emptyset \tag{1.6}$$

that is, the diffusion is large in the interior of Ω, is crucial in the development of our analysis. The case $\Gamma \cap \Gamma_0 \neq \emptyset$ requires a different analysis that will be pursued somewhere else. In that case the interaction between diffusion and boundary conditions becomes more subtle.

In [7] the problem of convergence of solutions is analyzed for the corresponding parabolic equations.

2. The formal limiting problem. We will show some heuristic argument showing what the limiting, or "shadow" problem, should be. In doing this we will interpret (P_ϵ) in terms of a heat distribution equilibrium. Hence, $(\lambda + V_\epsilon(x))u$ accounts for the heat absorption in Ω, while f^ϵ accounts for the heat sources and $b_\epsilon(x)u - g^\epsilon(x)$ for the heat flow across the boundary.

Assume Ω_0 is connected, i.e., $m = 1$, f, g and V, b are fixed regular functions, i.e., they do not depend on ϵ. And assume that one has already obtained that the family of solutions to these problems, $\{u^\epsilon\}_\epsilon$, converges, in some sense, to a function u which is constant in Ω_0. Assume all functions live in the Sobolev space $H^1(\Omega)$. Note that if the limit function u is also in $H^1(\Omega)$, then its constant value on Ω_0, denoted u_{Ω_0}, cannot be arbitrary.

Since on Ω_1 we have $-Div(d_\epsilon(x)\nabla u^\epsilon) + (\lambda + V(x))u^\epsilon = f$ from the convergence properties of $d_\epsilon(x)$ in Ω_1, it seems reasonable to have in the limit

$$-Div(d_0(x)\nabla u) + (\lambda + V(x))u = f \quad \text{on } \Omega_1.$$

Analogously, on Γ, $\frac{\partial u^\epsilon}{\partial \vec{n}_\epsilon} + b(x)u^\epsilon = d_\epsilon(x)\langle \nabla u^\epsilon, \vec{n}\rangle + b(x)u^\epsilon = g(x)$ and then we expect to have in the limit

$$\frac{\partial u}{\partial \vec{n}_0} + b(x)u = d_0(x)\langle \nabla u, \vec{n}\rangle + b(x)u = g(x) \quad \text{on } \Gamma.$$

Also on Γ_0 we must have $u_{|\Gamma_0} = u_{\Omega_0}$.

On the other hand, integrating on Ω_0 we have $\int_{\Gamma_0} \frac{\partial u^\epsilon}{\partial \vec{n}_\epsilon} + \int_{\Omega_0} (\lambda + V(x))u^\epsilon = \int_{\Omega_0} f$, where we use the direction of the inward unit normal to Ω_0 in the surface integral. Therefore, passing to the limit we have

$$\int_{\Gamma_0} \frac{\partial u}{\partial \vec{n}_0} + u_{\Omega_0} \int_{\Omega_0} (\lambda + V(x)) = \int_{\Omega_0} f,$$

which is an equation relating the total heat flow from Ω_1 to Ω_0 through Γ_0 with the total heat absorbed in Ω_0 and the total heat input in Ω_0. It also relates the value of u_{Ω_0} with the values of u in Ω_1 through the integral term along Γ_0.

With this heuristic consideration and assuming that in the limit we will work with a space of functions constant on Ω_0, we can write the previous equalities as an "elliptic equation" for the function $u = u\mathcal{X}_{\Omega_1} + u_{\Omega_0}\mathcal{X}_{\Omega_0}$,

$$B_0(u) = (-Div(d_0(x)\nabla u) + (\lambda + V(x))u)\,\mathcal{X}_{\Omega_1} + \left(\frac{1}{|\Omega_0|}\int_{\Gamma_0}\frac{\partial u}{\partial \vec{n}_0} + \left(\fint_{\Omega_0}\lambda + V\right)u_{\Omega_0}\right)\mathcal{X}_{\Omega_0} = \hat{f}, \tag{2.1}$$

where $\fint_{\Omega_0} = \frac{1}{|\Omega_0|}\int_{\Omega_0}$ and $\hat{f} = f\mathcal{X}_{\Omega_1} + (\fint_{\Omega_0} f)\mathcal{X}_{\Omega_0}$, and boundary condition $\frac{\partial u}{\partial \vec{n}_0} + bu = g$. Note that f has been substituted in the limit by a "projection" $\hat{f}$. Also note the nonlocal coupling between the equation for $u\mathcal{X}_{\Omega_1}$ and u_{Ω_0}, given by the term $\frac{1}{|\Omega_0|}\int_{\Gamma_0}\frac{\partial u}{\partial \vec{n}_0}$, that represents the total heat flow from Ω_1 to Ω_0.

In the next sections we will show that all these formal computations can be justified, and, moreover, we will prove that the limiting "elliptic operator" has good functional properties.

3. Functional setting. Now we will introduce notation and several function spaces that will be used henceforth. Concerning functional spaces, we will use the standard Sobolev spaces $H^1(\Omega)$ and $H^{1/2}(\Gamma)$. Also, we will denote by H^{-s} the dual space of H^s, either on Ω or Γ. Note that this symbol is usually reserved to denote the dual space of H_0^s. However, this notation should produce no confusion. The duality pairing between the spaces above will be denoted $\langle\cdot,\cdot\rangle_{-s,s}$. In particular, the scalar product in L^2 will be denoted by $\langle\cdot,\cdot\rangle$. If there is no possible confusion, we will not indicate if the spaces or duality products are referred to as functions on Ω or Γ. When required, we will write $\langle\cdot,\cdot\rangle_\Omega$ and $\langle\cdot,\cdot\rangle_\Gamma$ to differentiate both cases.

We will denote by γ the trace operator defined on $H^1(\Omega)$, with values in $H^{1/2}(\Gamma)$. Analogously, we will also denote by γ_0 the trace operator defined in $H^1(\Omega)$ that restricts functions to Γ_0, i.e., $\gamma_0 : H^1(\Omega) \to H^{1/2}(\Gamma_0)$. Similarly, $\gamma_{0,i}$ will denote the trace operator on $\Gamma_{0,i}$. Moreover, for a given function $f \in H^1(\Omega)$, we will identify its trace, $\gamma(f) \in H^{1/2}(\Gamma)$, with the linear form $\gamma(f) \in H^{-1/2}(\Gamma) \subset H^{-1}(\Omega)$ such that for every $\phi \in H^1(\Omega)$,

$$\langle\gamma(f),\phi\rangle_{-1,1} \stackrel{def}{=} \langle f,\phi\rangle_\Gamma \stackrel{def}{=} \int_\Gamma f\phi;$$

that is, we use the embedding $H^{1/2}(\Gamma) \subset L^2(\Gamma) \subset H^{-1/2}(\Gamma) \subset H^{-1}(\Omega)$. The same holds for γ_0, i.e., $\gamma_0(f) \in H^{-1/2}(\Gamma_0) \subset H^{-1}(\Omega)$.

We will also consider the normal derivative operator, relative to the diffusion operator $-Div(d_\epsilon(x)\nabla u)$, defined as follows: let 2^* be the critical Sobolev exponent for the inclusion $H^1(\Omega) \subset L^p(\Omega)$; i.e.,

$$2^* = \begin{cases} \frac{2N}{N-2} & \text{if } N \geq 3, \\ \text{any positive number} & \text{if } N = 2, \\ \infty & \text{if } N = 1. \end{cases} \tag{3.1}$$

Hence $H^1(\Omega) \subset L^p(\Omega)$ with continuous inclusion if $p \leq 2^*$ and compact inclusion if $p < 2^*$. For any $p \leq 2^*$ denote $Y_{\epsilon,p} \stackrel{def}{=} \{z \in H^1(\Omega),\ -Div(d_\epsilon(x)\nabla z) \in L^{p'}(\Omega)\}$, with

$1/p + 1/p' = 1$. Then for $u \in Y_{\epsilon,p}$, $\frac{\partial u}{\partial \vec{n}_\epsilon} \in H^{-1/2}(\Gamma)$ is defined as

$$\left\langle \frac{\partial u}{\partial \vec{n}_\epsilon}, \gamma(v) \right\rangle_{-1/2,1/2} = \int_\Omega Div(d_\epsilon(x)\nabla u)v + \int_\Omega d_\epsilon(x)\nabla u \nabla v \tag{3.2}$$

for every $v \in H^1(\Omega)$. Observe that $Y_{\epsilon,p}$ is a Banach space for the norm

$$\|z\|_{Y_{\epsilon,p}} = \|z\|_{H^1(\Omega)} + \|Div(d_\epsilon \nabla z)\|_{L^{p'}(\Omega)},$$

which is, moreover, a Hilbert space if $p = 2$, and the mapping $z \mapsto \frac{\partial z}{\partial \vec{n}_\epsilon}$ is continuous between $Y_{\epsilon,p}$ and $H^{-1/2}(\Gamma)$. In the sequel we will often find the normal derivative operator on Γ_0 for functions defined either on Ω or Ω_1. When doing this, we will always take the direction of the *inner* normal to Ω_0; that is, whenever an expression of the form $\int_{\Gamma_0} \frac{\partial u}{\partial \vec{n}_\epsilon}$ appears we will assume the direction of the outward normal to Ω_1.

We now introduce a linear positive operator, L_ϵ, between $H^1(\Omega)$ and its dual, $H^{-1}(\Omega)$, such that for every $u, \phi \in H^1(\Omega)$,

$$a_\epsilon(u,\phi) = \langle L_\epsilon(u), \phi \rangle_{-1,1} = \int_\Omega d_\epsilon(x)\nabla u \nabla \phi. \tag{3.3}$$

Note that we can then write (3.2) as

$$\langle L_\epsilon(u), v \rangle_{-1,1} = \langle -Div(d_\epsilon(x)\nabla u), v \rangle + \left\langle \frac{\partial u}{\partial \vec{n}_\epsilon}, \gamma(v) \right\rangle_{-1/2,1/2} \tag{3.4}$$

for $u \in Y_{\epsilon,p}$ and $v \in H^1(\Omega)$. Also, for any $\lambda > 0$ we consider in $H^1(\Omega)$ the scalar product

$$\langle u, v \rangle_\epsilon = a_\epsilon(u,v) + \lambda \int_\Omega uv = \int_\Omega d_\epsilon \nabla u \nabla v + \lambda \int_\Omega uv = \langle L_\epsilon u + \lambda u, v \rangle_{-1,1}, \tag{3.5}$$

which, for fixed $0 < \epsilon \le \epsilon_0$, gives a norm, $\|\cdot\|_\epsilon$, equivalent to the usual one and defines the isomorphism between $H^1(\Omega)$ and its dual, $H^{-1}(\Omega)$, $L_\epsilon + \lambda I$. Note, however, that if we take the norm $\|u\|^2_{H^1(\Omega)} = \int_\Omega |\nabla u|^2 + \lambda \int_\Omega |u|^2$, then for $0 < \epsilon \le \epsilon_0$ we have from (1.2)

$$m_0 \|u\|^2_{H^1(\Omega)} \le \|u\|^2_\epsilon \le M_\epsilon \|u\|^2_{H^1(\Omega)}, \tag{3.6}$$

but $M_\epsilon \to \infty$ as $\epsilon \to 0$. Throughout the paper we will find a special class of elements $h \in H^{-1}(\Omega)$ defined as

$$\langle h, \phi \rangle_{-1,1} = \langle f, \phi \rangle_\Omega + \langle g, \gamma(\phi) \rangle_\Gamma$$

for every $\phi \in H^1(\Omega)$, where $f \in L^{p'}(\Omega)$, for some $p \le 2^*$, and $g \in H^{-1/2}(\Gamma)$. So, in brief, $h \overset{def}{=} f_\Omega + g_\Gamma$. The space $L^{p'}(\Omega) + H^{-1/2}(\Gamma)$ is endowed with the natural norm $\|f\|_{L^{p'}(\Omega)} + \|g\|_{H^{-1/2}(\Gamma)}$, and for this norm the inclusion $L^{p'}(\Omega) + H^{-1/2}(\Gamma) \subset H^{-1}(\Omega)$ is continuous.

Denote by q_0^* the number in the right-hand side of (1.4); i.e.,

$$q_0^* = \begin{cases} N/2 & \text{if } N \ge 3, \\ 1 & \text{if } N = 1, 2. \end{cases} \tag{3.7}$$

Then for any $q_0 \geq q_0^*$ if $N = 1$ or $N \geq 3$ or $q_0 > q_0^*$ if $N = 2$, let $p_0 \leq 2^*$ be such that $2/p_0 + 1/q_0 = 1$. Then the mapping $(V, u) \mapsto Vu$ is continuous from $L^{q_0}(\Omega) \times H^1(\Omega)$ into $L^{p_0'}(\Omega)$. Moreover, for every $\eta > 0$ there exists C_η such that for every $u, \phi \in H^1(\Omega)$,

$$\left| \int_\Omega Vu\phi \right| \leq \eta \|u\|_{H^1(\Omega)} \|\phi\|_{H^1(\Omega)} + C_\eta \|u\|_{L^2(\Omega)} \|\phi\|_{L^2(\Omega)}; \tag{3.8}$$

see [2].

Analogously, for the terms on the boundary, denote by 2_Γ^* the critical Sobolev exponent for the inclusion $H^{1/2}(\Gamma) \subset L^p(\Gamma)$; i.e.,

$$2_\Gamma^* = \begin{cases} \frac{2(N-1)}{N-2} & \text{if } N \geq 3, \\ \text{any positive number} & \text{if } N = 2, \\ \infty & \text{if } N = 1. \end{cases} \tag{3.9}$$

Hence $H^{1/2}(\Gamma) \subset L^p(\Gamma)$ with continuous inclusion if $p \leq 2_\Gamma^*$ and compact inclusion if $p < 2_\Gamma^*$. Also, denote by q_1^* the number in the right-hand side of (1.5); i.e.,

$$q_1^* = \begin{cases} N - 1 & \text{if } N \geq 3, \\ 1 & \text{if } N = 1, 2. \end{cases} \tag{3.10}$$

Then for any $q_1 \geq q_1^*$, if $N = 1$ or $N \geq 3$, or $q_1 > q_1^*$ if $N = 2$, let $p_1 \leq 2_\Gamma^*$ be such that $2/p_1 + 1/q_1 = 1$. Then $(b, u) \mapsto b\gamma(u)$ is continuous from $L^{q_1}(\Gamma) \times H^1(\Omega)$ into $L^{p_1'}(\Gamma)$ and for every $\eta > 0$ there exists some C_η such that for every $u, \phi \in H^1(\Omega)$,

$$\left| \int_\Gamma bu\phi \right| \leq \eta \|u\|_{H^1(\Omega)} \|\phi\|_{H^1(\Omega)} + C_\eta \|u\|_{L^2(\Gamma)} \|\phi\|_{L^2(\Gamma)}. \tag{3.11}$$

Also, for every $\eta > 0$,

$$\|u\|_{L^2(\Gamma)}^2 \leq \eta \|u\|_{H^1(\Omega)}^2 + C_\eta \|u\|_{L^2(\Omega)}^2. \tag{3.12}$$

Finally, we consider the Hilbert space

$$L^2_{\Omega_0}(\Omega) = \{u \in L^2(\Omega),\ u \text{ is constant on } \Omega_{0,i},\ i = 1, \ldots, m\}$$

and denote $H^1_{\Omega_0}(\Omega) = L^2_{\Omega_0}(\Omega) \cap H^1(\Omega)$. As a general notation, for $u \in L^2_{\Omega_0}(\Omega)$, we denote by $u_{\Omega_{0,i}}$ the constant value of u on $\Omega_{0,i}$ for $i = 1, \ldots, m$. Therefore, $u \in L^2_{\Omega_0}(\Omega)$ can be written as $u = u\mathcal{X}_{\Omega_1} + \sum_{i=1}^m u_{\Omega_{0,i}} \mathcal{X}_{\Omega_{0,i}}$.

For $\lambda \in \mathbb{R}$ we define the symmetric bilinear form

$$a_0(u, \phi) + \lambda \int_\Omega u\phi = \int_{\Omega_1} d_0(x) \nabla u \nabla \phi + \lambda \int_\Omega u\phi, \tag{3.13}$$

which is continuous and coercive on $H^1_{\Omega_0}(\Omega)$ if $\lambda > 0$. Hence (3.13) induces an operator $L_0 + \lambda I$ between $H^1_{\Omega_0}(\Omega)$ and its dual $H^{-1}_{\Omega_0}(\Omega)$, which for $\lambda > 0$ is an isomorphism.

4. The elliptic problem. In this section we analyze the solvability of problem (1.1) and the limiting one, and we make precise in what sense the solutions converge. In doing this, we will make rigorous all the formal manipulations leading to (2.1). First we study the solvability of the Neumann problem

$$\begin{cases} -Div(d_\epsilon(x)\nabla u) + (\lambda + V(x))u = f & \text{on } \Omega, \\ \frac{\partial u}{\partial \vec{n}_\epsilon} + b(x)u = g & \text{on } \Gamma \end{cases} \tag{4.1}$$

that we treat in a variational way in $H^{-1}(\Omega)$. Note that if we take test functions $\phi \in H^1(\Omega)$ and multiply in (4.1) and formally integrate by parts, we get

$$\int_\Omega d_\epsilon(x)\nabla u\nabla\phi + \int_\Omega (\lambda + V)u\phi + \int_\Gamma b(x)u\phi = \int_\Omega f\phi + \int_\Gamma g\phi;$$

see [2] for the case of Dirichlet boundary conditions.

Assume $V \in L^{q_0}(\Omega)$ and $b \in L^{q_1}(\Gamma)$ with $q_0 \geq q_0^*$, $q_1 \geq q_1^*$ as defined in the previous section. Then denoting by V_- and b_- the negative parts of V and b, respectively, we have the following theorem.

THEOREM 4.1. (i) *There exists a constant $c = c(\|V_-\|_{L^{q_0}}, \|b_-\|_{L^{q_1}})$ such that $c(0,0) = 0$ and for $\lambda > c$ the operator $T_\epsilon = L_\epsilon + (\lambda I + V)_\Omega + (b\gamma)_\Gamma$, defined by the bilinear form*

$$\tau_\epsilon(u,v) = \langle T_\epsilon u, v\rangle_{-1,1} = \int_\Omega d_\epsilon(x)\nabla u\nabla v + \int_\Omega (\lambda + V(x))uv + \int_\Gamma b(x)uv, \tag{4.2}$$

is an isomorphism between $H^1(\Omega)$ and its dual and between Y_{ϵ,p_0} and $L^{p_0'}(\Omega) + H^{-1/2}(\Gamma)$. Moreover, between the latter spaces T_ϵ is given by

$$T_\epsilon = (-Div(d_\epsilon(x)\nabla\cdot) + (\lambda + V(x))\cdot)_\Omega + \left(\frac{\partial\cdot}{\partial\vec{n}_\epsilon} + b(x)\gamma(\cdot)\right)_\Gamma.$$

By restriction to $L^2(\Omega)$, T_ϵ induces an unbounded self-adjoint positive operator with compact resolvent, B_ϵ, with domain $D(B_\epsilon) = \{u \in H^1(\Omega),\ -Div(d_\epsilon\nabla u) + Vu \in L^2(\Omega),\ \frac{\partial u}{\partial\vec{n}_\epsilon} + b(x)u = 0 \text{ on } \Gamma\}$ and for $u \in D(B_\epsilon)$,

$$B_\epsilon u = -Div(d_\epsilon(x)\nabla u) + (\lambda + V(x))u. \tag{4.3}$$

(ii) *If $\lambda \in \mathbb{R}$ and if $u \in H^1(\Omega)$ is a solution of*

$$T_\epsilon u = h = f_\Omega + g_\Gamma \tag{4.4}$$

with $f \in L^{p_0'}(\Omega)$ and $g \in H^{-1/2}(\Gamma)$, then $u \in Y_{\epsilon,p_0}$ and

$$-Div(d_\epsilon(x)\nabla u) + (\lambda + V(x))u = f \text{ in } L^{p_0'}(\Omega) \quad \text{and} \quad \frac{\partial u}{\partial\vec{n}_\epsilon} + b(x)u = g \text{ in } H^{-1/2}(\Gamma).$$

Proof. The proof is rather standard but is given for completeness. We first show that the bilinear form τ_ϵ in (4.2) is coercive on $H^1(\Omega)$ for λ large. Since $\tau_\epsilon(u,u) \geq m_0\int_\Omega|\nabla u|^2 + \int_\Omega(\lambda - V_-)|u|^2 - \int_\Gamma b_-|u|^2$ and $V_- \in L^{q_0}(\Omega)$, $b_- \in L^{q_1}(\Gamma)$, from (3.8), (3.11), and (3.12), we get coerciveness for λ large. Also, if $V \geq 0$ and $b \geq 0$, then τ_ϵ is coercive for $\lambda > 0$ and this gives $c(0,0) = 0$. Now if $h = f_\Omega + g_\Gamma \in L^{p_0'}(\Omega) + H^{-1/2}(\Gamma) \subset H^{-1}(\Omega)$ and $u \in H^1(\Omega)$ verifies $T_\epsilon u = h$, then for every $\phi \in H^1(\Omega)$,

$$\int_\Omega d_\epsilon\nabla u\nabla\phi + \int_\Omega (\lambda + V)u\phi + \int_\Gamma bu\phi = \int_\Omega f\phi + \langle g, \gamma(\phi)\rangle_\Gamma.$$

If $\phi \in \mathcal{D}(\Omega)$, then we get $-Div(d_\epsilon(x)\nabla u) + (\lambda + V)u = f$ a.e. on Ω and in particular $u \in Y_{\epsilon,p_0}$. Using this and $\phi \in H^1(\Omega)$, from (3.4), we get $\frac{\partial u}{\partial\vec{n}_\epsilon} + b(x)u = g$ on Γ.

Conversely, from (3.4) we have that T_ϵ maps Y_{ϵ,p_0} into $L^{p_0'}(\Omega) + H^{-1/2}(\Gamma)$ and on this space $T_\epsilon = (-Div(d_\epsilon(x)\nabla\cdot) + (\lambda + V(x))\cdot)_\Omega + (\frac{\partial\cdot}{\partial\vec{n}_\epsilon} + b(x)\gamma(\cdot))_\Gamma$. From this the continuity of T_ϵ and its inverse follows easily and the rest is obvious. ∎

Observe that if V, b, and Ω are smooth enough, then $D(B_\epsilon) = \{u \in H^2(\Omega),\ \frac{\partial u}{\partial \vec{n}_\epsilon} + b(x)u = 0 \text{ on } \Gamma\}$ and the graph norm in $D(B_\epsilon)$ is equivalent to that of $H^2(\Omega)$. For this a sufficient regularity condition is that $Vu \in L^2(\Omega)$ for $u \in H^1(\Omega)$, i.e., $V \in L^{q_0}$ for $q_0 \geq N$ if $N \geq 3$, or $q_0 > 2$ if $N = 2$ or $q_0 \geq 2$ if $N = 1$, and b is the restriction to Γ of a function $b \in C^1(\overline{\Omega})$ since in this case, for $u \in H^1(\Omega)$, $bu \in H^{1/2}(\Gamma)$ and elliptic regularity results give the $H^2(\Omega)$ regularity. The same situation holds for the solution of (4.1) if $g \in H^{1/2}(\Gamma)$. In other words, under suitable regularity assumptions, solutions of (4.1) are smooth in Ω and depend smoothly on f and g.

Now we analyze the solvability of the "limiting problem" described in terms of the operator L_0 defined in (3.13).

THEOREM 4.2. (i) *Assume $V \in L^{q_0}(\Omega)$ and $b \in L^{q_1}(\Gamma)$, with q_0, q_1 as above; then there exists a constant $c = c(\|V_-\|_{L^{q_0}}, \|b_-\|_{L^{q_1}})$ such that $c(0,0) = 0$ such that, for $\lambda > c$, the bilinear form*

$$\tau_0(u,\phi) = \int_{\Omega_1} d_0 \nabla u \nabla \phi + \int_\Omega (\lambda + V) u\phi + \int_\Gamma bu\phi \tag{4.5}$$

with $u, \phi \in H^1_{\Omega_0}(\Omega)$, defines an isomorphism, T_0, from $H^1_{\Omega_0}(\Omega)$ into its dual $H^{-1}_{\Omega_0}(\Omega)$. The restriction

$$\begin{aligned} T_0 : Y_{\Omega_0,p_0} &= \{z \in H^1_{\Omega_0}(\Omega),\ Div(d_0(x)\nabla z) \in L^{p_0'}(\Omega_1)\} \\ &\longrightarrow L^{p_0'}_{\Omega_0}(\Omega) + H^{-1/2}(\Gamma) \subset H^{-1}_{\Omega_0}(\Omega) \end{aligned}$$

is also an isomorphism, and on this space

$$\begin{aligned} T_0(u) = \Bigg[&(-Div(d_0(x)\nabla u) + (\lambda + V)u)\mathcal{X}_{\Omega_1} \\ &+ \sum_{i=1}^m \left(\frac{1}{|\Omega_{0,i}|} \int_{\Gamma_{0,i}} \frac{\partial u}{\partial \vec{n}_0} + \left(\fint_{\Omega_{0,i}} \lambda + V \right) u_{\Omega_{0,i}} \right) \mathcal{X}_{\Omega_{0,i}} \Bigg]_\Omega + \left(\frac{\partial u}{\partial \vec{n}_0} + bu \right)_\Gamma , \end{aligned}$$

where $u_{\Omega_{0,i}}$ denotes the constant value of u on $\Omega_{0,i}$ for $i = 1, \ldots, m$.

By restriction, the operator T_0 induces an unbounded, positive, self-adjoint operator with compact resolvent, B_0, in $H = L^2_{\Omega_0}(\Omega)$ with domain $D(B_0) = \{u \in H^1_{\Omega_0}(\Omega),\ -Div(d_0(x)\nabla u) + Vu \in L^2(\Omega_1),\ \frac{\partial u}{\partial \vec{n}_0} + bu = 0 \text{ on } \Gamma\}$ and for $u \in D(B_0)$,

$$\begin{aligned} B_0(u) = &(-Div(d_0(x)\nabla u) + (\lambda + V)u)\,\mathcal{X}_{\Omega_1} \\ &+ \sum_{i=1}^m \left(\frac{1}{|\Omega_{0,i}|} \int_{\Gamma_{0,i}} \frac{\partial u}{\partial \vec{n}_0} + \left(\fint_{\Omega_{0,i}} \lambda + V \right) u_{\Omega_{0,i}} \right) \mathcal{X}_{\Omega_{0,i}}. \end{aligned} \tag{4.6}$$

(ii) *If $\lambda \in \mathbb{R}$ and $u \in H^1_{\Omega_0}(\Omega)$ is a solution of*

$$T_0(u) = h = f_\Omega + g_\Gamma \tag{4.7}$$

with $f \in L^{p_0'}_{\Omega_0}(\Omega)$ and $g \in H^{-1/2}(\Gamma)$, then $u \in Y_{\Omega_0,p_0}$ and then (4.7) is equivalent to

$$\begin{aligned} &-Div(d_0(x)\nabla u) + (\lambda + V(x))u = f && \text{on } \Omega_1, \\ &\frac{\partial u}{\partial \vec{n}_0} + b(x)u = g && \text{on } \Gamma, \\ &\gamma_{0,i}(u) = u_{\Omega_{0,i}} && \text{on } \Gamma_{0,i}, \quad i = 1, \ldots, m, \\ &\frac{1}{|\Omega_{0,i}|} \int_{\Gamma_{0,i}} \frac{\partial u}{\partial \vec{n}_0} + \left(\fint_{\Omega_{0,i}} \lambda + V \right) u_{\Omega_{0,i}} = f_{\Omega_{0,i}}, && i = 1, \ldots, m, \end{aligned} \tag{4.8}$$

where $u_{\Omega_{0,i}}$ and $f_{\Omega_{0,i}}$ denote, respectively, the constant values of u and f on $\Omega_{0,i}$ for $i = 1, \dots, m$.

Proof. First note that the assumptions on V and b, (3.8), (3.11), and (3.12), imply that the bilinear form $\tau_0(\cdot,\cdot)$ is coercive on $H^1_{\Omega_0}(\Omega)$ for λ large enough. Hence T_0 is an isomorphism. From here one easily gets that B_0 is self-adjoint and positive in $L^2_{\Omega_0}(\Omega)$, and the compactness of the resolvent follows from the compactness of the inclusion $H^1_{\Omega_0}(\Omega) \subset L^2_{\Omega_0}(\Omega)$, since Ω is bounded.

Now assume $h = f_\Omega + g_\Gamma \in L^{p_0'}_{\Omega_0}(\Omega) + H^{-1/2}(\Gamma)$ and $u \in H^1_{\Omega_0}(\Omega)$ such that $T_0 u = h$; then taking in (4.5) first $\phi \in \mathcal{D}(\Omega_1)$ and then $\phi \in H^1_{\Omega_0}(\Omega)$ such that it vanishes on Ω_0, we get $-Div(d_0(x)\nabla u) + (\lambda + V)u = f$ on Ω_1, which implies $u \in Y_{\Omega_0,p_0}$, and $\frac{\partial u}{\partial \vec{n}_0} + bu = g$ on Γ. Using this information on Ω_1 and integrating by parts, again using (3.4), for an arbitrary $\phi \in H^1_{\Omega_0}(\Omega)$ we get

$$\sum_{i=1}^m \phi_{\Omega_{0,i}} \left(\int_{\Gamma_{0,i}} \frac{\partial u}{\partial \vec{n}_0} + \left(\int_{\Omega_{0,i}} \lambda + V \right) u_{\Omega_{0,i}} |\Omega_{0,i}| \right) = \sum_{i=1}^m \phi_{\Omega_{0,i}} |\Omega_{0,i}| f_{\Omega_{0,i}},$$

and we get the expression for T_0 on Y_{Ω_0,p_0}. From this one easily gets that T_0 is an isomorphism between Y_{Ω_0,p_0} and $L^{p_0'}_{\Omega_0}(\Omega) + H^{-1/2}(\Gamma)$. The rest is obvious. ∎

Remark. (i) Observe that if $V \in L^{q_0}(\Omega)$ and $b \in L^{q_1}(\Gamma)$, with q_0, q_1 as above, then for $u, \phi \in H^1_{\Omega_0}(\Omega)$ we have

$$\int_\Omega Vu\phi = \int_{\Omega_1} Vu\phi + \sum_{i=1}^m \left(\int_{\Omega_{0,i}} V \right) u_{\Omega_{0,i}} \phi_{\Omega_{0,i}} = \int_\Omega \hat{V} u\phi,$$

where $\hat{V} = V\mathcal{X}_{\Omega_1} + \sum_{i=1}^m (⨍_{\Omega_{0,i}} V)\mathcal{X}_{\Omega_{0,i}} \in L^{q_0}_{\Omega_0}(\Omega)$. Consequently, on $H^1_{\Omega_0}(\Omega)$, T_0 coincides with the operator $L_0 + (\lambda + \hat{V})_\Omega + (b\gamma)_\Gamma$.

Also note that since $H^1_{\Omega_0}(\Omega) \subset H^1(\Omega)$, if $h \in H^{-1}(\Omega)$ then we have $h_{|H^1_{\Omega_0}(\Omega)} \in H^{-1}_{\Omega_0}(\Omega)$. In particular, if $h = f_\Omega + g_\Gamma$, with $f \in L^{p_0'}(\Omega)$ and $g \in H^{-1/2}(\Gamma)$, we have for every $\phi \in H^1_{\Omega_0}(\Omega)$,

$$\int_\Omega f\phi + \langle g, \gamma(\phi)\rangle_\Gamma = \sum_{i=1}^m \phi_{\Omega_{0,i}} \int_{\Omega_{0,i}} f + \int_{\Omega_1} f\phi + \langle g, \gamma(\phi)\rangle_\Gamma = \int_\Omega \hat{f}\phi + \langle g, \gamma(\phi)\rangle_\Gamma,$$

where $\hat{f} = f\mathcal{X}_{\Omega_1} + \sum_{i=1}^m (⨍_{\Omega_{0,i}} f)\mathcal{X}_{\Omega_{0,i}} \in L^{p_0'}_{\Omega_0}(\Omega)$. That is, $h_{|H^1_{\Omega_0}(\Omega)} = \hat{f}_\Omega + g_\Gamma$.

(ii) Note that if Ω, Ω_1, V, and b are smooth enough, say, V bounded and $b \in C^1(\Omega_1)$, then $D(B_0) = H^1_{\Omega_0}(\Omega) \cap H^2(\Omega_1)$ both algebraically and topologically, since for $u \in D(B_0)$ the part in Ω_1 satisfies $-Div(d_0(x)\nabla u) \in L^2(\Omega_1)$, $\frac{\partial u}{\partial \vec{n}_0} + bu = 0$ on Γ and $\gamma_{0,i}(u) = u_{\Omega_{0,i}}$ on $\Gamma_{0,i}$, $i = 1, \dots, m$ and elliptic regularity results give the $H^2(\Omega_1)$ regularity. Also, since u is constant on Ω_0 it is in $H^2(\Omega_0)$. The same applies to the solution of (4.8) if $g \in H^{1/2}(\Gamma)$ and then $u \in H^1_{\Omega_0}(\Omega) \cap H^2(\Omega_1)$.

However, $D(B_0)$ is not included with continuous inclusion in $H^2(\Omega)$, since typically there is a jump on the normal derivative $\frac{\partial u}{\partial \vec{n}_0}$ across Γ_0 for $u \in D(B_0)$.

To see this, we will show that the mapping $L^2_{\Omega_0}(\Omega) \ni f \to u = B_0^{-1}(f) \in D(B_0)$ is not continuous with the topology of $H^2(\Omega)$. In fact, assume that for some $f \in L^2_{\Omega_0}(\Omega)$

we have $u = B_0^{-1}(f) \in H^2(\Omega)$. Then $\frac{\partial u}{\partial \vec{n}_0} = 0$ on Γ_0 and the restriction to Ω_1 satisfies

$$\begin{aligned} &-Div(d_0(x)\nabla u) + (\lambda + V(x))u = f \quad \text{on } \Omega_1, \\ &\frac{\partial u}{\partial \vec{n}_0} + b(x)u = 0 \quad \text{on } \Gamma, \\ &\frac{\partial u}{\partial \vec{n}_0} = 0 \quad \text{on } \Gamma_0. \end{aligned}$$

Hence, on Ω_1, u is uniquely determined by the restriction of f to Ω_1 and so are the traces $\gamma_{0,i}(u)$, $i = 1, \dots, m$. On the other hand, on $\Omega_{0,i}$ we have $\fint_{\Omega_{0,i}} \lambda + V) u_{\Omega_{0,i}} = f_{\Omega_{0,i}}$ and therefore $u_{\Omega_{0,i}}$ can be changed at will by changing $f_{\Omega_{0,i}}$. As a consequence, the matching conditions $\gamma_{0,i}(u) = u_{\Omega_{0,i}}$ on $\Gamma_{0,i}$, $i = 1, \dots, m$, cannot be verified and this is a contradiction. In fact, the same argument gives that $D(B_0)$ is not included with continuous inclusion in $H^{3/2+\delta}(\Omega)$ for any $\delta > 0$. The same argument applies to the solution of (4.8) when $g \neq 0$, and hence u does not depend continuously on f and g in the topology of $H^{3/2+\delta}(\Omega)$.

In other words, under suitable regularity assumptions, solutions of (4.8) are smooth on Ω_1, and obviously on Ω_0, and depend smoothly on f and g, but they are not smooth or do not depend smoothly on f and g on the entire Ω. The problem of course comes from the normal derivative across Γ_0.

The next theorem, which is the main result of this section, in particular states rigorously that, as $\epsilon \to 0$, the family of solutions of (1.1) converges to a solution of (4.8). Note that from the previous results we cannot expect convergence in a very strong topology on the entire Ω. However, we will show that convergence in $H^1(\Omega)$ always holds true. We start with the following lemma.

LEMMA 4.3. *Assume as* $\epsilon \to 0$,

$$d_\epsilon(x) \to d_0(x), \text{ uniformly on } \Omega_1 \quad \text{and} \quad u^\epsilon \to u, \text{ weakly in } H^1(\Omega_1).$$

Then

$$\int_{\Omega_1} d_0 |\nabla u|^2 \leq \liminf_\epsilon \int_{\Omega_1} d_\epsilon |\nabla u^\epsilon|^2.$$

If, moreover, $u^\epsilon \to u$ *in* $L^2(\Omega_1)$, *then* $u^\epsilon \to u$ *in* $H^1(\Omega_1)$ *if and only if*

$$\int_{\Omega_1} d_0 |\nabla u|^2 = \lim_\epsilon \int_{\Omega_1} d_\epsilon |\nabla u^\epsilon|^2.$$

Proof. From lower semicontinuity, we have $\int_{\Omega_1} d_0 |\nabla u|^2 \leq \liminf_\epsilon \int_{\Omega_1} d_0 |\nabla u^\epsilon|^2$ and then

$$\int_{\Omega_1} d_\epsilon |\nabla u^\epsilon|^2 - \int_{\Omega_1} d_0 |\nabla u|^2 = \int_{\Omega_1} (d_\epsilon - d_0) |\nabla u^\epsilon|^2 + \int_{\Omega_1} d_0 |\nabla u^\epsilon|^2 - \int_{\Omega_1} d_0 |\nabla u|^2.$$

But $| \int_{\Omega_1} (d_\epsilon - d_0) |\nabla u^\epsilon|^2 | \leq \|d_\epsilon - d_0\|_{L^\infty(\Omega_1)} \int_{\Omega_1} |\nabla u^\epsilon|^2 \to 0$ and we get the first statement. If, moreover, $u^\epsilon \to u$ in $L^2(\Omega_1)$, we have that the strong convergence in $H^1(\Omega_1)$ is equivalent to $\int_{\Omega_1} d_0 |\nabla u|^2 = \lim_\epsilon \int_{\Omega_1} d_0 |\nabla u^\epsilon|^2$ and the lemma is proved □

THEOREM 4.4. (i) *Assume that for* $0 < \epsilon \leq \epsilon_0$, $\{u^\epsilon\}_\epsilon \subset H^1(\Omega)$ *are given such that they are bounded in* $L^2(\Omega)$ *and* $0 \leq \int_\Omega d_\epsilon |\nabla u^\epsilon|^2 \leq M$ *for some constant independent*

of ϵ. Then, by taking subsequences if necessary, u^ϵ converges to $u \in H^1_{\Omega_0}(\Omega)$ weakly in $H^1(\Omega)$ and strongly in $L^2(\Omega)$.

Even more,

$$\lim_\epsilon \int_\Omega d_\epsilon |\nabla u^\epsilon|^2 = \int_\Omega d_0 |\nabla u|^2 = \int_{\Omega_1} d_0 |\nabla u|^2$$

if and only if u^ϵ converges strongly in $H^1(\Omega)$ to u and $\lim_\epsilon \int_{\Omega_0} d_\epsilon |\nabla u^\epsilon|^2 = 0$.

(ii) *Assume that for $0 < \epsilon \le \epsilon_0$, V_ϵ and b_ϵ verify (1.4), (1.5), respectively, $\lambda \in \mathbb{R}$ and $\{h^\epsilon\}_\epsilon \subset H^{-1}(\Omega)$ is bounded and weakly convergent to $h \in H^{-1}(\Omega)$. Assume $\{u^\epsilon\}_\epsilon$ are bounded in $L^2(\Omega)$ and verify*

$$T_\epsilon u^\epsilon = (L_\epsilon + (\lambda I + V_\epsilon)_\Omega + (b_\epsilon \gamma)_\Gamma) u^\epsilon = h^\epsilon.$$

Then $0 \le \int_\Omega d_\epsilon |\nabla u^\epsilon|^2 \le M$ for some constant independent of ϵ and by taking subsequences if necessary, u^ϵ converges to $u \in H^1_{\Omega_0}(\Omega)$ weakly in $H^1(\Omega)$ and $V_\epsilon u^\epsilon$ and $b_\epsilon u^\epsilon$ converge strongly in $L^{p_0'}(\Omega)$ and $L^{p_1'}(\Gamma)$, respectively, to Vu and bu. Moreover, $u \in H^1_{\Omega_0}(\Omega)$ verifies

$$T_0 u = (L_0 + (\lambda I + V)_\Omega + (b\gamma)_\Gamma) u = h_{|H^1_{\Omega_0}(\Omega)} \quad \text{in } H^{-1}_{\Omega_0}(\Omega). \tag{4.9}$$

If the function u above is unique, for example, when λ is sufficiently large, then the full family u^ϵ converges to u.

Finally, u^ϵ converges strongly in $H^1(\Omega)$ to u if and only if $\langle h^\epsilon, u^\epsilon \rangle_{-1,1} \to \langle h, u \rangle_{-1,1}$, and this happens, for example, if $h^\epsilon \to h$ in $H^{-1}(\Omega)$. In such a case, we also have

$$\lim_\epsilon \tau_\epsilon(u^\epsilon, u^\epsilon) = \tau_0(u, u) \tag{4.10}$$

and in particular $\lim_\epsilon \int_{\Omega_0} d_\epsilon |\nabla u^\epsilon|^2 = 0$.

Proof. (i) From (1.2), we have $m_0 \int_\Omega |\nabla u^\epsilon|^2 \le \int_\Omega d_\epsilon |\nabla u^\epsilon|^2 \le M$ and then, from the boundedness in $L^2(\Omega)$, u^ϵ is bounded in $H^1(\Omega)$ and, taking subsequences if necessary, it converges weakly to u in $H^1(\Omega)$ and strongly in $L^2(\Omega)$. Using lower semicontinuity, we get $\int_K |\nabla u|^2 \le \liminf_\epsilon \int_K |\nabla u^\epsilon|^2$ for any compact set $K \subset \Omega_0$. On the other hand,

$$\inf_{x \in K} \{d_\epsilon(x)\} \int_K |\nabla u^\epsilon|^2 \le \int_K d_\epsilon |\nabla u^\epsilon|^2 \le M$$

and therefore from (1.3), we obtain $\lim_\epsilon \int_K |\nabla u^\epsilon|^2 = 0$ and $u \in H^1_{\Omega_0}(\Omega)$. From Lemma 4.3, we have

$$\liminf_\epsilon \int_\Omega d_\epsilon |\nabla u^\epsilon|^2 \ge \liminf_\epsilon \int_{\Omega_1} d_\epsilon |\nabla u^\epsilon|^2 \ge \int_{\Omega_1} d_0 |\nabla u|^2 = \int_\Omega d_0 |\nabla u|^2$$

and, in fact, $\lim_\epsilon \int_\Omega d_\epsilon |\nabla u^\epsilon|^2 = \int_\Omega d_0 |\nabla u|^2$ if and only if $\lim_\epsilon \int_{\Omega_0} d_\epsilon |\nabla u^\epsilon|^2 = 0$ and $\lim_\epsilon \int_{\Omega_1} d_\epsilon |\nabla u^\epsilon|^2 = \int_{\Omega_1} d_0 |\nabla u|^2$. Again, Lemma 4.3 gives the result.

(ii) Since $T_\epsilon u^\epsilon = (L_\epsilon + (\lambda I + V_\epsilon)_\Omega + (b_\epsilon \gamma)_\Gamma) u^\epsilon = h^\epsilon$, we have

$$\int_\Omega d_\epsilon |\nabla u^\epsilon|^2 + \int_\Omega (\lambda + V_\epsilon) |u^\epsilon|^2 + \int_\Gamma b_\epsilon |u^\epsilon|^2 = \langle h^\epsilon, u^\epsilon \rangle_{-1,1}. \tag{4.11}$$

From (3.8), (3.11), and (3.12) we get $\int_\Omega d_\epsilon |\nabla u^\epsilon|^2 \le M$ and the above applies. Also, since the inclusion $H^1(\Omega) \subset L^{p_0}(\Omega)$ is compact, taking subsequences if necessary, we

can assume $V_\epsilon u^\epsilon$ converges strongly in $L^{p_0'}(\Omega)$. The same holds for $b_\epsilon u^\epsilon$ in $L^{p_1'}(\Gamma)$, since $H^{1/2}(\Gamma) \subset L^{q_1}(\Gamma)$ is also compact. Moreover, for every $\phi \in H^1_{\Omega_0}(\Omega)$ it holds that

$$\tau_\epsilon(u^\epsilon, \phi) = \int_{\Omega_1} d_\epsilon \nabla u^\epsilon \nabla \phi + \int_\Omega (\lambda + V_\epsilon) u^\epsilon \phi + \int_\Gamma b_\epsilon u^\epsilon \phi = \langle h^\epsilon, \phi \rangle_{-1,1},$$

and we can pass to the limit to get

$$\tau_0(u, \phi) = \int_{\Omega_1} d_0 \nabla u \nabla \phi + \int_\Omega (\lambda + V) u \phi + \int_\Gamma b u \phi = \langle h, \phi \rangle_{-1,1},$$

i.e., $T_0 u = h_{|H^1_{\Omega_0}(\Omega)}$. In particular, with $\phi = u$,

$$\int_{\Omega_1} d_0 |\nabla u|^2 + \int_\Omega (\lambda + V)|u|^2 + \int_\Gamma b|u|^2 = \langle h, u \rangle_{-1,1}. \tag{4.12}$$

Furthermore, from (4.11) and (4.12), $\lim_\epsilon \int_\Omega d_\epsilon |\nabla u^\epsilon|^2 = \int_{\Omega_1} d_0 |\nabla u|^2$ if and only if $\langle h^\epsilon, u^\epsilon \rangle_{-1,1} \to \langle h, u \rangle_{-1,1}$, which holds true if u^ϵ or h^ϵ converges strongly. The rest follows easily. □

From this theorem we get the following consequence.

COROLLARY 4.5. *Assume that in Theorem* 4.4, $h^\epsilon = f^\epsilon_\Omega + g^\epsilon_\Gamma$ *and* $f^\epsilon \to f$ *weakly in* $L^{p_0'}(\Omega)$ *and* $g^\epsilon \to g$ *weakly in* $H^{-1/2}(\Gamma)$. *Then* (i) *From inside* Ω_1

$$Div(d_\epsilon \nabla u^\epsilon) \to Div(d_0 \nabla u) \text{ weakly in } L^{p_0'}(\Omega_1),$$

$$\frac{\partial u^\epsilon}{\partial \vec{n}_\epsilon} \to \frac{\partial u}{\partial \vec{n}_0} \text{ weakly in } H^{-1/2}(\Gamma \cup \Gamma_0).$$

(ii) *From inside* Ω_0,

$$Div(d_\epsilon \nabla u^\epsilon) \to f - (\lambda + V) \sum_{i=1}^m u_{\Omega_{0,i}} \mathcal{X}_{\Omega_{0,i}} \text{ weakly in } L^{p_0'}(\Omega_0),$$

$$\fint_{\Omega_{0,i}} -Div(d_\epsilon \nabla u^\epsilon) \to \frac{1}{|\Omega_{0,i}|} \int_{\Gamma_{0,i}} \frac{\partial u}{\partial \vec{n}_0}.$$

Also, if $f^\epsilon \to f_{\Omega_{0,i}}$, *weakly in* $L^{p_0'}(\Omega_{0,i})$ *and* $V_\epsilon \to V_{\Omega_{0,i}}$ *strongly in* $L^{q_0}(\Omega_{0,i})$, *then*

$$-Div(d_\epsilon \nabla u^\epsilon) \to \frac{1}{|\Omega_{0,i}|} \int_{\Gamma_{0,i}} \frac{\partial u}{\partial \vec{n}_0} \text{ weakly in } L^{p_0'}(\Omega_{0,i}).$$

If f^ϵ *and* g^ϵ *converge strongly, then all the convergences above are strong.*

Furthermore, u^ϵ *converges strongly to* u *in* $H^1(\Omega)$ *if and only if* $\langle g^\epsilon, u^\epsilon \rangle_\Gamma$ *converges to* $\langle g, u \rangle_\Gamma$, *and this happens, for example, if* $g^\epsilon \to g$ *strongly in* $H^{-1/2}(\Gamma)$. *In such a case we have* $\lim_\epsilon \int_{\Omega_0} d_\epsilon |\nabla u^\epsilon|^2 = 0$.

Proof. The convergence on Ω_1 and Ω_0 follows easily, since u^ϵ verifies

$$\begin{cases} -Div(d_\epsilon(x) \nabla u^\epsilon) + (\lambda + V_\epsilon(x)) u^\epsilon = f^\epsilon & \text{on } \Omega, \\ \frac{\partial u^\epsilon}{\partial \vec{n}_\epsilon} + b_\epsilon(x) u = g^\epsilon & \text{on } \Gamma, \end{cases}$$

and the convergence of $V_\epsilon u^\epsilon$ and $b_\epsilon u^\epsilon$ are obtained in the theorem. The convergence of the normal derivative on Γ_0 follows from the above and (3.2) applied to Ω_1. Integrating on $\Omega_{0,i}$ we get the convergence of the average of $-Div(d_\epsilon \nabla u^\epsilon)$ and the rest is obvious.

Since, from the theorem, u^ϵ converges strongly in $L^2(\Omega)$ then the strong convergence in $H^1(\Omega)$ is equivalent to the convergence $\langle g^\epsilon, u^\epsilon \rangle_\Gamma \to \langle g, u \rangle_\Gamma$. □

5. The eigenvalue problem. Consider the operators B_ϵ and B_0 of the previous section. Since they have compact resolvent their spectrum consists solely of eigenvalues of finite multiplicity, i.e., $\sigma(B_\epsilon)=\{\mu_n^\epsilon\}_n$ and $\sigma(B_0)=\{\mu_n\}_n$, which form increasing sequences converging to ∞. Note that the eigenvalue problem for B_ϵ is given by

$$\left\{\begin{array}{ll} -Div(d_\epsilon(x)\nabla u)+(\lambda+V_\epsilon)u=\mu u & \text{on } \Omega,\\ \frac{\partial u}{\partial \vec{n}_\epsilon}+b_\epsilon u=0 & \text{on } \Gamma \end{array}\right. \tag{5.1}$$

in $H^1(\Omega)$, while for B_0 the eigenvalue problem is given by

$$\begin{array}{ll} -Div(d_0(x)\nabla u)+(\lambda+V)u=\mu u & \text{on } \Omega_1,\\ \dfrac{\partial u}{\partial \vec{n}_0}+bu=0 & \text{on } \Gamma,\\ \gamma_{0,i}(u)=u_{\Omega_{0,i}} & \text{on } \Gamma_{0,i},\quad i=1,\dots,m,\\ \dfrac{1}{|\Omega_{0,i}|}\displaystyle\int_{\Gamma_{0,i}}\frac{\partial u}{\partial \vec{n}_0}+\left(\fint_{\Omega_{0,i}}\lambda+V\right)u_{\Omega_{0,i}}=\mu u_{\Omega_{0,i}}, & i=1,\dots,m, \end{array} \tag{5.2}$$

in $H^1_{\Omega_0}(\Omega)$, where $u_{\Omega_{0,i}}$ denotes the constant value of u on $\Omega_{0,i}$ for $i=1,\dots,m$.

The next result, which is the main result in this section, asserts that the spectral properties of B_ϵ and B_0 are close. Note that since B_ϵ and B_0 and their inverses are not defined on the same space, then one cannot use classical results, e.g., [14, Theorem VIII.1.14] or [16, Theorems V.9.10 and V.11.1], to analyze the behavior of eigenfunctions and eigenvalues.

THEOREM 5.1. *Assume that V_ϵ, b_ϵ verify* (1.4), (1.5) *and assume the spectrum of B_ϵ is given by*

$$\mu_1^\epsilon\le\cdots\le\mu_n^\epsilon\le\mu_{n+1}^\epsilon\cdots$$

counting multiplicities and, for each n, let ϕ_n^ϵ be an eigenfunction of μ_n^ϵ such that $\|\phi_n^\epsilon\|_{L^2(\Omega)}=1$ and such that $\{\phi_n^\epsilon\}_n$ is a Hilbert basis of $L^2(\Omega)$. Also, assume that the spectrum of B_0 is given by

$$\mu_1\le\cdots\le\mu_n\le\mu_{n+1}\cdots$$

counting multiplicities. Then the following conditions hold.

(i) *For each $n\in\mathbb{N}$,*

$$\mu_n^\epsilon\to\mu_n \text{ as } \epsilon\to 0.$$

(ii) *For each $n\in\mathbb{N}$, and for any sequence converging to zero that we still denote $\epsilon\to 0$, there exists a subsequence ϵ_j such that*

$$\phi_n^{\epsilon_j}\to\phi_n\in H^1_{\Omega_0}(\Omega) \text{ as } j\to\infty$$

strongly in $H^1(\Omega)$ and $\lim_{j\to\infty}\int_{\Omega_0}d_{\epsilon_j}|\nabla\phi_n^{\epsilon_j}|^2=0$, where ϕ_n is an eigenfunction of B_0 corresponding to μ_n and $\{\phi_n\}_n$ is a Hilbert basis of $L^2_{\Omega_0}(\Omega)$.

Proof. Note that it is sufficient to prove the result for λ large enough such that B_ϵ is an isomorphism, i.e., such that τ_ϵ in (4.2) is coercive. Then we proceed by induction in n. From the min-max characterization of the eigenvalues, we first have

$$\mu_1^\epsilon=\inf_{\substack{u\in H^1(\Omega)\\ \|u\|=1}}\int_\Omega d_\epsilon|\nabla u|^2+\int_\Omega(\lambda+V_\epsilon)|u|^2+\int_\Gamma b_\epsilon|u|^2=\inf_{\substack{u\in H^1(\Omega)\\ \|u\|=1}}\tau_\epsilon(u,u)>0$$

and

$$\mu_1 = \inf_{\substack{u\in H^1_{\Omega_0}(\Omega)\\ \|u\|=1}} \int_{\Omega_1} d_0|\nabla u|^2 + \int_\Omega (\lambda+V)|u|^2 + \int_\Gamma b|u|^2 = \inf_{\substack{u\in H^1_{\Omega_0}(\Omega)\\ \|u\|=1}} \tau_0(u,u) > 0,$$

where $\|\cdot\|$ represents the $L^2(\Omega)$ norm. Observe that for the Neumann boundary condition, $V_\epsilon = 0$, $b_\epsilon = 0$, $\mu_1^\epsilon = \mu_1 = \lambda$, and the first eigenfunction is constant on Ω. Also note that in any case the inf is attained.

On the one hand, if we restrict u to be in $H^1_{\Omega_0}(\Omega)$ with $\|u\| = 1$, we get, since u is constant on Ω_0 and from the convergence of d_ϵ, V_ϵ, b_ϵ,

$$\mu_1^\epsilon \le \tau_\epsilon(u,u) \to \tau_0(u,u)$$

and in particular $\limsup_\epsilon \mu_1^\epsilon \le \mu_1$.

On the other hand, by taking the family of first eigenfunctions, $\{\phi_1^\epsilon\}_\epsilon$, we have

$$\tau_\epsilon(\phi_1^\epsilon,\phi_1^\epsilon) = \int_\Omega d_\epsilon|\nabla\phi_1^\epsilon|^2 + \int_\Omega(\lambda+V_\epsilon)|\phi_1^\epsilon|^2 + \int_\Gamma b_\epsilon|\phi_1^\epsilon|^2 = \mu_1^\epsilon \le M$$

for some constant independent of ϵ. Therefore, by Theorem 4.4, and by taking subsequences if necessary, we have $\mu_1^\epsilon \to \mu^0$ and $\phi_1^\epsilon \to \phi \in H^1_{\Omega_0}(\Omega)$, where $\|\phi\| = 1$ and the latter convergence is weak in $H^1(\Omega)$ and strong in $L^2(\Omega)$. Even more, we can also assume $V_\epsilon\phi_1^\epsilon \to V\phi$ in $L^{p_0'}(\Omega)$ and $b_\epsilon\phi_1^\epsilon \to b\phi$ in $L^{p_1'}(\Gamma)$. But $B_\epsilon(\phi_1^\epsilon) = \mu_1^\epsilon\phi_1^\epsilon$ and then, since $\mu_1^\epsilon\phi_1^\epsilon$ converges in $H^{-1}(\Omega)$ to $\mu^0\phi$, by Theorem 4.4, ϕ satisfies $B_0(\phi) = \mu^0\phi$ and we have $\phi_1^\epsilon \to \phi \in H^1_{\Omega_0}(\Omega)$ strongly in $H^1(\Omega)$ and, even more, $\lim_\epsilon \int_{\Omega_0} d_\epsilon|\nabla\phi_1^\epsilon|^2 = 0$.

Consequently, $\mu^0 = \tau_0(\phi,\phi) \ge \mu_1$. Since the argument is independent of the subsequence we take, we really have proven $\liminf_\epsilon \mu_1^\epsilon \ge \mu_1$ and the function ϕ above, which may depend on the subsequence, is a normalized eigenfunction of μ_1. Therefore, the theorem is proved for $n = 1$.

Assume the result is proved for the first n eigenvalues. Then from the min-max characterization we have

$$\mu_{n+1}^\epsilon = \inf_{\substack{u\in H^1(\Omega)\\ u\perp\phi_1^\epsilon,\dots,\phi_n^\epsilon\\ \|u\|=1}} \tau_\epsilon(u,u).$$

Then take any sequence converging to zero that we still denote $\epsilon \to 0$, and, therefore, there exists a subsequence ϵ_j such that for every $i = 1,\dots,n$,

$$\phi_i^{\epsilon_j} \to \phi_i \in H^1_{\Omega_0}(\Omega) \text{ as } j\to\infty$$

strongly in $H^1(\Omega)$ and $\lim_{j\to\infty}\int_{\Omega_0} d_{\epsilon_j}|\nabla\phi_i^{\epsilon_j}|^2 = 0$, and ϕ_i is an eigenfunction of μ_i and the ϕ_i are mutually orthogonal and have $L^2(\Omega)$ norm equal to 1. With this we have

$$\mu_{n+1} = \inf_{\substack{u\in H^1_{\Omega_0}(\Omega)\\ u\perp\phi_1,\dots,\phi_n\\ \|u\|=1}} \tau_0(u,u).$$

We define in $L^2(\Omega)$ and $H^1(\Omega)$ the projections $P_n^{\epsilon_j} = \sum_{i=1}^n \langle\phi_i^{\epsilon_j},\cdot\rangle_\Omega\phi_i^{\epsilon_j}$, $Q_n^{\epsilon_j} = I - P_n^{\epsilon_j}$, and $P_n = \sum_{i=1}^n\langle\phi_i,\cdot\rangle_\Omega\phi_i$, $Q_n = I - P_n$. Hence from the strong convergence of $\phi_i^{\epsilon_j}$ in $H^1(\Omega)$ we have

$$P_n^{\epsilon_j} \to P_n, \qquad Q_n^{\epsilon_j} \to Q_n$$

strongly in $\mathcal{L}(L^2(\Omega), H^1(\Omega))$.

Therefore, for a given $u \in H^1_{\Omega_0}(\Omega)$, we take $u^{\epsilon_j} = Q_n^{\epsilon_j}(u)$ which is orthogonal in $L^2(\Omega)$ to $\phi_1^{\epsilon_j}, \dots, \phi_n^{\epsilon_j}$ and converges strongly in $H^1(\Omega)$ to $u^0 = Q_n(u)$, and then we claim that

$$\mu_{n+1}^{\epsilon_j} \le \frac{\tau_{\epsilon_j}(u^{\epsilon_j}, u^{\epsilon_j})}{\|u^{\epsilon_j}\|^2} \to \frac{\tau_0(u^0, u^0)}{\|u^0\|^2} \text{ as } j \to \infty.$$

Since $u^0 \perp \{\phi_1, \dots, \phi_n\}$ is arbitrary, we obtain $\limsup_j \mu_{n+1}^{\epsilon_j} \le \mu_{n+1}$. Also, since this upper bound is independent of the sequence ϵ and the subsequence ϵ_j, we have $\limsup_\epsilon \mu_{n+1}^{\epsilon} \le \mu_{n+1}$.

Now we prove our claim. The first inequality is obvious and then $\mu_{n+1}^{\epsilon_j} \le \frac{\tau_{\epsilon_j}(u^{\epsilon_j}, u^{\epsilon_j})}{\|u^{\epsilon_j}\|^2}$. But since $u^{\epsilon_j} = Q_n^{\epsilon_j}(u) = u - P_n^{\epsilon_j}(u)$, we have $\tau_{\epsilon_j}(u^{\epsilon_j}, u^{\epsilon_j}) = \tau_{\epsilon_j}(u, u) + \tau_{\epsilon_j}(P_n^{\epsilon_j}(u), P_n^{\epsilon_j}(u)) - 2\tau_{\epsilon_j}(u, P_n^{\epsilon_j}(u))$. Now, since u is constant on Ω_0, we get $\tau_{\epsilon_j}(u, u) \to \tau_0(u, u)$ and

$$\tau_{\epsilon_j}(u, P_n^{\epsilon_j}(u)) = \int_{\Omega_1} d_{\epsilon_j} \nabla u \nabla P_n^{\epsilon_j}(u) + \int_\Omega (\lambda + V_{\epsilon_j}) u P_n^{\epsilon_j}(u) + \int_\Gamma b_{\epsilon_j} u P_n^{\epsilon_j}(u)$$

$$\to \int_{\Omega_1} d_0 \nabla u \nabla P_n(u) + \int_\Omega (\lambda + V) u P_n(u) + \int_\Gamma b u P_n(u) = \tau_0(u, P_n(u)).$$

Finally,

$$\tau_{\epsilon_j}(P_n^{\epsilon_j}(u), P_n^{\epsilon_j}(u)) = \sum_{i=1}^n |\langle \phi_i^{\epsilon_j}, u\rangle|^2 \tau_{\epsilon_j}(\phi_i^{\epsilon_j}, \phi_i^{\epsilon_j})$$

$$\to \sum_{i=1}^n |\langle \phi_i, u\rangle|^2 \tau_0(\phi_i, \phi_i) = \tau_0(P_n(u), P_n(u)),$$

where we have used (4.10). Consequently, since $u^0 = Q_n(u) = u - P_n(u)$, then $\tau_\epsilon(u^\epsilon, u^\epsilon) \to \tau_0(u^0, u^0)$, and the claim is proved.

As a consequence of the above, by taking the family of $(n+1)$th eigenfunctions, $\{\phi_{n+1}^\epsilon\}_\epsilon$, we have

$$\tau_\epsilon(\phi_{n+1}^\epsilon, \phi_{n+1}^\epsilon) = \mu_{n+1}^\epsilon \le M$$

for some constant independent of ϵ. Therefore, $\int_\Omega d_\epsilon |\nabla \phi_{n+1}^\epsilon|^2$ is bounded and then by Theorem 4.4, and by taking subsequences if necessary, we have $\mu_i^\epsilon \to \mu_i$, for $i = 1, \dots, n$, $\mu_{n+1}^\epsilon \to \mu^0$, and $\phi_i^\epsilon \to \phi_i \in H^1_{\Omega_0}(\Omega)$, $i = 1, \dots, n$, and $\phi_{n+1}^\epsilon \to \phi \in H^1_{\Omega_0}(\Omega)$, where $\|\phi_i\| = \|\phi\| = 1$, ϕ_i are eigenfunctions of μ_i, and the latter convergence is weak in $H^1(\Omega)$ and strong in $L^2(\Omega)$. In addition, we can assume $V_\epsilon \phi_{n+1}^\epsilon \to V\phi$ in $L^{p_0'}(\Omega)$ and $b_\epsilon \phi_{n+1}^\epsilon \to b\phi$ in $L^{p_1'}(\Gamma)$. But since $B_\epsilon(\phi_{n+1}^\epsilon) = \mu_{n+1}^\epsilon \phi_{n+1}^\epsilon$ and since $\mu_{n+1}^\epsilon \phi_{n+1}^\epsilon$ converges in $H^{-1}(\Omega)$ to $\mu^0 \phi$, then by Theorem 4.4 ϕ satisfies $B_0(\phi) = \mu^0 \phi$ and we have $\phi_{n+1}^\epsilon \to \phi \in H^1_{\Omega_0}(\Omega)$ strongly in $H^1(\Omega)$ and, furthermore, $\lim_\epsilon \int_{\Omega_0} d_\epsilon |\nabla \phi_{n+1}^\epsilon|^2 = 0$.

Since we also have $\langle \phi_{n+1}^\epsilon, \phi_j^\epsilon\rangle_\Omega = 0$, for $j = 1, \dots, n$, then in the limit, $\langle \phi, \phi_j\rangle_\Omega = 0$. Consequently, $\mu^0 = \tau_0(\phi, \phi) \ge \mu_{n+1}$. Since the argument is independent of the subsequence we take, we really have proved $\liminf_\epsilon \mu_{n+1}^\epsilon \ge \mu_{n+1}$. Hence $\lim_\epsilon \mu_{n+1}^\epsilon = \mu_{n+1}$ and the function ϕ above, which may depend on the subsequence, is a normalized eigenfunction of μ_{n+1}. Therefore, the theorem is proved for $n+1$. ∎

COROLLARY 5.2. *Under the above conditions* (i) *If* $\mu \in \rho(B_0)$ *then for sufficiently small* ϵ, $\mu \in \rho(B_\epsilon)$. (ii) *If* $(a,b) \subset \mathbb{R}$ *is a bounded interval and* $K_\epsilon = \#\{\mu_n^\epsilon \in \sigma(B_\epsilon),\ \mu_n^\epsilon \in (a,b)\}$ *(counting multiplicities), then for sufficiently small* ϵ, K_ϵ *is independent of* ϵ. (iii) *If* $\mu \in \mathbb{R}$ *is such that* $\mu \in \rho(B_0)$, *and for* $0 \leq \epsilon$ *we take* $M_\epsilon = \{\mu_n^\epsilon \in \sigma(B_\epsilon),\ \mu_n^\epsilon < \mu\}$ *and we define* P_μ^ϵ *as the orthogonal projection onto the subspace* $\bigoplus_{\lambda \in M_\epsilon} E(\lambda, \epsilon)$, *then*

$$P_\mu^\epsilon \to P_\mu^0, \ \text{as } \epsilon \to 0$$

in the norm of $\mathcal{L}(H^1(\Omega))$, *where* $E(\lambda,\epsilon)$ *denotes the eigenspace of the eigenvalue* λ *of* B_ϵ.

Proof. Parts i and ii follow from the pointwise convergence of the eigenvalues. Now, for part iii note that the dimension of $\bigoplus_{\lambda \in M_\epsilon} E(\lambda,\epsilon)$ is finite and independent of ϵ. Therefore, after suitable choice of eigenfunctions we have for $\epsilon > 0$, $P_\mu^\epsilon = \sum_{i=1}^M \langle \phi_i^\epsilon, \cdot \rangle_\Omega \phi_i^\epsilon$ for some fixed $M \in \mathbb{N}$. From the theorem we get that for any sequence that we still denote $\epsilon \to 0$ there exists a subsequence ϵ_j such that $P_\mu^{\epsilon_j}$ converges to P_μ^0 strongly in $\mathcal{L}(L^2(\Omega), H^1(\Omega))$. Since the limit is independent of the subsequence we get that the full family converges. Finally, note that we are in a position to apply [16, Lemma V.9.12], and hence we get the convergence in the operator norm. ∎

6. Further comments and remarks. Now we discuss some different situations that can be handled similarly. Therefore, we just give the main arguments.

Concerning other boundary conditions, assume now $\Gamma = \Gamma_1 \cup \Gamma_2$ is a partition of the boundary, where $\Gamma_2 \neq \emptyset$ and Γ_1 could be empty, and consider the mixed problem with respect to this partition; that is, we impose the Neumann condition on Γ_1 and the Dirichlet condition on Γ_2. Note that when $\Gamma_1 = \emptyset$ we are solving the Dirichlet case. Therefore, we consider

$$\begin{cases} -Div(d_\epsilon(x)\nabla u^\epsilon) + (\lambda + V_\epsilon)u^\epsilon = f^\epsilon & \text{on } \Omega, \\ \frac{\partial u^\epsilon}{\partial \vec{n}_\epsilon} + b_\epsilon u^\epsilon = g^\epsilon & \text{on } \Gamma_1, \\ u^\epsilon = j^\epsilon & \text{on } \Gamma_2 \end{cases} \tag{6.1}$$

for which a weak formulation, using the bilinear form τ_ϵ defined in (4.2), is given as follows. Consider the Sobolev space

$$H^1_{\Gamma_2}(\Omega) = \{u \in H^1(\Omega),\ u = 0 \text{ on } \Gamma_2\}$$

whose dual space is denoted $H^{-1}_{\Gamma_2}(\Omega)$. Note that when $\Gamma_1 = \emptyset$, then $H^1_{\Gamma_2}(\Omega) = H^1_0(\Omega)$. Assume V_ϵ as in (1.4) and $b_\epsilon \in L^{q_1}(\Gamma_1)$ and converges to b. Then, for $h^\epsilon \in H^{-1}_{\Gamma_2}(\Omega)$ and $j^\epsilon \in H^{1/2}(\Gamma_2)$, a solution of the mixed problem is $u^\epsilon \in H^1(\Omega)$ such that

$$\begin{cases} \tau_\epsilon(u^\epsilon, \phi) = \displaystyle\int_\Omega d_\epsilon \nabla u^\epsilon \nabla \phi + \int_\Omega (\lambda + V_\epsilon) u^\epsilon \phi + \int_{\Gamma_1} b_\epsilon u^\epsilon \phi = \langle h^\epsilon, \phi \rangle_{-1,1}, \\ \gamma_2(u^\epsilon) = j^\epsilon \text{ on } \Gamma_2, \end{cases} \tag{6.2}$$

where the first equation holds for every $\phi \in H^1_{\Gamma_2}(\Omega)$.

For the homogeneous case, i.e., when $j^\epsilon = 0$, all the results of the previous sections apply by working on spaces with subscripts Γ_2 indicating that all functions have traces that vanish on Γ_2. Now, for the full problem (6.1) when $j^\epsilon \neq 0$, we construct a function J^ϵ in Ω with trace j^ϵ on Γ_2, and we write an equation for $v^\epsilon = u^\epsilon - J^\epsilon$ thus reducing

the problem to the homogeneous case. For this we have to control J^ϵ on Ω_0 and the way it depends on j^ϵ. For this assume that j^ϵ is such that

$$\hat{j}^\epsilon = \begin{cases} j^\epsilon & \text{on } \Gamma_2 \\ 0 & \text{on } \Gamma_1 \end{cases} \in H^{1/2}(\Gamma).$$

This condition holds true if $j^\epsilon \in H^{1/2}(\Gamma_2)$ and if $\bar{\Gamma}_1 \cap \bar{\Gamma}_2 = \emptyset$.

LEMMA 6.1. *With the above assumption, assume $\lambda > 0$ and let J^ϵ be defined as the unique solution of*

$$\begin{cases} -Div(d_\epsilon(x)\nabla J^\epsilon) + \lambda J^\epsilon = 0 & \text{on } \Omega_1, \\ \gamma(J^\epsilon) = 0 & \text{on } \Gamma_0 \cup \Gamma_1, \\ \gamma(J^\epsilon) = j^\epsilon & \text{on } \Gamma_2, \end{cases}$$

and we extend J^ϵ by zero to Ω_0; hence, $J^\epsilon \in H^1_{\Omega_0}(\Omega)$. Then the following conditions hold.

(i) *If $\{\hat{j}^\epsilon\}_\epsilon$ is bounded in $H^{1/2}(\Gamma)$, then $\{J^\epsilon\}_\epsilon$ is bounded in $H^1(\Omega)$. Moreover, if $\hat{j}^\epsilon \to j$ weakly in $H^{1/2}(\Gamma)$, then $J^\epsilon \to J$ weakly in $H^1(\Omega)$.*

(ii) *If $\hat{j}^\epsilon \to j$ strongly in $H^{1/2}(\Gamma)$, then $J^\epsilon \to J$ strongly in $H^1(\Omega)$.*

With this special choice for J^ϵ we have the following theorem.

THEOREM 6.2. *Assume V_ϵ, b_ϵ verify* (1.4) *and* (1.5)*, respectively, $h^\epsilon \to h$ weakly in $H^{-1}_{\Gamma_2}(\Omega)$, $\hat{j}^\epsilon \to j$ weakly in $H^{1/2}(\Gamma)$, λ is large enough, and u^ϵ is the unique solution of* (6.2)*. Then*

$$u^\epsilon \to u \in H^1_{\Omega_0}(\Omega)$$

weakly in $H^1(\Omega)$, where u verifies

$$\begin{cases} \tau_0(u,\phi) = \displaystyle\int_{\Omega_1} d_0 \nabla u \nabla \phi + \int_\Omega (\lambda + V) u\phi + \int_{\Gamma_1} bu\phi = \langle h, \phi\rangle_{-1,1}, \\ \gamma_2(u) = j \ \text{ on } \Gamma_2 \end{cases} \tag{6.3}$$

for every $\phi \in H^1_{\Gamma_2,\Omega_0}(\Omega) = H^1_{\Omega_0}(\Omega) \cap H^1_{\Gamma_2}(\Omega)$. Moreover, if the convergence for h^ϵ and $\hat{j}^\epsilon$ is strong, then u^ϵ converges strongly. Furthermore, $\lim_\epsilon \int_{\Omega_0} d_\epsilon |\nabla u^\epsilon|^2 = 0$.

In particular, if $h = f_\Omega + g_{\Gamma_1}$ with $f \in L^{p_0'}(\Omega)$ and $g \in H^{-1/2}(\Gamma_1)$, then u verifies

$$\begin{array}{ll} -Div(d_0(x)\nabla u) + (\lambda + V(x))u = f & \text{on } \Omega_1, \\ \frac{\partial u}{\partial \vec{n}_0} + bu = g & \text{on } \Gamma_1, \\ \gamma_2(u) = j & \text{on } \Gamma_2, \\ \gamma_{0,i}(u) = u_{\Omega_{0,i}} & \text{on } \Gamma_{0,i}, \quad i = 1, \dots, m, \\ \displaystyle\frac{1}{|\Omega_{0,i}|} \int_{\Gamma_{0,i}} \frac{\partial u}{\partial \vec{n}_0} + \left(\fint_{\Omega_{0,1}} \lambda + V \right) u_{\Omega_{0,i}} = \fint_{\Omega_{0,i}} f, & i = 1, \dots, m, \end{array} \tag{6.4}$$

where $u_{\Omega_{0,i}}$ denotes the constant value of u on $\Omega_{0,i}$ for $i = 1, \dots, m$.

Proof. If u^ϵ is a solution of (6.2), then the function $v^\epsilon = u^\epsilon - J^\epsilon \in H^1_{\Gamma_2}(\Omega)$ verifies

$$\tau_\epsilon(v^\epsilon, \phi) = \langle h^\epsilon, \phi\rangle_{-1,1} - \int_{\Omega_1} d_\epsilon \nabla J^\epsilon \nabla \phi - \int_{\Omega_1} (\lambda + V_\epsilon) J^\epsilon \phi - \int_{\Gamma_1} b_\epsilon J^\epsilon \phi \overset{def}{=} \langle H^\epsilon, \phi\rangle_{-1,1}$$

for every $\phi \in H^1_{\Gamma_2}(\Omega)$. From the lemma, we get that if $h^\epsilon \to h$ weakly (strongly) in $H^{-1}_{\Gamma_2}(\Omega)$ and $\hat{j}^\epsilon \to j$ weakly (strongly) in $H^{1/2}(\Gamma)$, then $H^\epsilon \to H$ weakly (strongly)

in $H^{-1}_{\Gamma_2}(\Omega)$, where H is defined by $\langle H,\phi\rangle_{-1,1} = \langle h,\phi\rangle_{-1,1} - \int_{\Omega_1} d_0 \nabla J \nabla\phi - \int_{\Omega_1}(\lambda + V)J\phi - \int_{\Gamma_1} bJ\phi$.

From the result for the homogeneous case above, we get $v^\epsilon \to v \in H^1_{\Gamma_2,\Omega_0}(\Omega)$ weakly in $H^1_{\Gamma_2}(\Omega)$ (strongly and $\lim_\epsilon \int_{\Omega_0} d_\epsilon |\nabla v^\epsilon|^2 = 0$). Also, v satisfies $T_0(v) = H_{|H^1_{\Gamma_2,\Omega_0}(\Omega)}$ in $H^{-1}_{\Gamma_2,\Omega_0}(\Omega)$. Therefore, $u^\epsilon \to u = v + J \in H^1_{\Omega_0}(\Omega)$ weakly in $H^1(\Omega)$ (strongly and $\lim_\epsilon \int_{\Omega_0} d_\epsilon |\nabla u^\epsilon|^2 = 0$). The rest is obvious. □

We can also consider, without any change in the analysis, the same problem for diffusion operators of the form

$$-Div(D_\epsilon(x)\nabla u),$$

where $D_\epsilon(x)$ is a positive definite symmetric matrix for each $x \in \Omega$ with smooth coefficients and such that if $\lambda^\epsilon_1(x)$ denotes the first eigenvalue of $D_\epsilon(x)$, then $0 < m_0 \le \lambda^\epsilon_1(x)$ for every $x \in \Omega$ and $0 \le \epsilon \le \epsilon_0$, and $\lambda^\epsilon_1(x) \longrightarrow \infty$ uniformly on compact subsets of Ω_0, as $\epsilon \to 0$, and $D_\epsilon(x) \longrightarrow D_0(x)$ uniformly on Ω_1, as $\epsilon \to 0$. In this case, the conormal derivative is given by $\frac{\partial u}{\partial \vec{n}_\epsilon} = \langle D_\epsilon(x)\nabla u, \vec{n}\rangle = \langle \nabla u, D^*_\epsilon(x)\vec{n}\rangle$. Also, the case of discontinuous diffusion coefficients d_ϵ can be dealt with no change, since no elliptic regularity results are needed in most of our analysis; see [17].

FINITE SPEED OF PROPAGATION FOR THE POROUS MEDIA EQUATION*

S. BONAFEDE†, G. R. CIRMI†, AND A. F. TEDEEV‡

Abstract. We consider the Cauchy–Dirichlet problem for the equation

$$u_t = \Delta u^m, \quad m > 1, \quad \text{on } D = \Re_k^N \times (t > 0),$$

where $\Re_k^N = \Re^N \cap \{x_1, ..., x_k > 0\}$, $1 \le k \le N$, $N \ge 1$. Sharp bounds of the interface (or free boundary) are obtained. We use a weighted energy method, which allows us to consider more general equations.

Key words. porous media equation, energy solution, free boundary

AMS subject classifications. 35K60, 35B05, 35K65

1. Introduction. This paper is concerned with the qualitative properties of the solution of the following initial-boundary value problem:

$$\begin{cases} \frac{\partial u}{\partial t} = \Delta u^m & \text{in } D = \Re_k^N \times (0, \infty), \\ u(x,t) = 0 & \text{on } \partial\Re_k^N \times (0, \infty), \\ u(x,0) = u_o(x) & \text{on } \Re_k^N, \end{cases} \tag{1}$$

where $\Re_k^N = \Re^N \cap \{x_1, ..., x_k > 0\}$, $1 \le k \le N$, $N \ge 1$, $m > 1$. In [5], [7], [11], [13] (see also the references therein) the authors investigated the qualitative properties of the solution of the Cauchy problem for more general parabolic equations, including the porous media equation. Moreover, it is well known that the energy solutions of the initial-boundary value problem for the porous media equation in any unbounded open set of $\Re^N$ have the property of so-called finite speed of propagation of perturbations, provided that the initial data have compact support.

In [7], estimates on the growth of the free boundary defined by support $u(., t)$ are found. As a matter of fact, assuming u_o compactly supported and setting

$$\zeta(T) = \text{supremum}\,\{|x| : x \in \text{support } u(., T)\},$$

Corollary 6.1 of [7] guarantees that $\zeta(T) = O(T^\beta)$, where $\beta = \frac{1}{N(m-1)+2}$ is the Barenblatt exponent.

Of course, this result still holds in our case.

Our aim is to find new bounds on $\zeta(T)$. Indeed, we shall prove that if the support of the initial datum is bounded, then for the solution of problem (1) we have the following:

$$\gamma_1 \mu_k(0)^{\frac{\sigma(m-1)}{N+k}} T^{\frac{\sigma}{N+k}} \le \zeta(T) \le \gamma_2 \mu_k(0)^{\frac{\sigma(m-1)}{N+k}} T^{\frac{\sigma}{N+k}} \quad \forall T > T_o, \tag{2}$$

where γ_1, γ_2 are positive constants, $\mu_k(0)$ is the moment defined by

$$\mu_k(0) = \int_{\Re_k^N} x_1 \cdots x_k u_o(x) dx,$$

σ is the number defined by

$$\sigma = \frac{N+k}{(N+k)(m-1)+2},$$

and T_o is a sufficiently large constant.

A result of this type has been obtained in [11], but in the case $k = 1$. The method used in [11] is different from ours since it is based on the construction of the so-called dipole solutions and doesn't permit consideration of more general situations, as problem (1).

In order to get the above result, we use a weighted energy method, adapted from [5], [7], combined with the moment technique of [15], [16]. The main tools are some technical inequalities together with an estimate on the $\|u(.,t)\|_{L^\infty(\Re_k^N)}$.

The second result of our paper deals with the finite speed of propagation of the solution of the following initial-boundary value problem:

$$\begin{cases} \frac{\partial}{\partial t}(|u|^{r-1}u) + (-1)^l u^{(2l)} = 0 & \text{in } Q = \Re_+ \times (t > 0), \\ u^{(j)} = 0,\ j = 0, 1, ..., l-1, & \text{on } \{0\} \times (t > 0), \\ u(x, 0) = u_o(x) & \text{on } \Re_+, \end{cases} \tag{3}$$

where $0 < r < 1$, $u^{(j)} = \frac{\partial^j u}{\partial x^j}$, $l > 1$ is an integer. In section 4, we shall prove that if the support of u_o is bounded, then for any $T > 0$, sufficiently large, the following estimate holds:

$$\zeta(T) \le \gamma_3 T^{\frac{r+1}{2(l-1)(r+1)+4}}, \tag{4}$$

with γ_3 positive constant.

If, in addition,

$$\sup_{0<t<\infty} \int_{\Re_+} x|u|^r dx = \mu_o < \infty, \tag{5}$$

then

$$\zeta(T) \le \gamma_4 T^{\frac{r}{2(1+(l-1)r)}}, \tag{6}$$

where γ_4 is a positive constant. We point out that estimates (4) and (6) improve the results of [7, Corollaries 2.2 and 6.1]. Moreover, our results can be extended to the case of equations with lower order terms in multidimensional half-space (see [3]).

2. Statement of main results. Throughout the paper we will assume that in problem (1), $u_o \ge 0$ on $\Re_k^N$,

$$u_o \in L_1(\Re_k^N) \cap L_\infty(\Re_k^N),$$

and in problem (3),

$$u_o \in L_{r+1}(\Re_+).$$

Let us denote by W the closure of $C_o^\infty(\Re_k^N)$ with respect to the seminorm

$$\left(\int_{\Re_k^N} |Dv|^2 dx\right)^{\frac{1}{2}}.$$

Let us set $q = \frac{1}{m}$.

DEFINITION 1. *Given u_o in* (1)*, we say that u is an energy solution to* (1) *if $u \geq 0$ in D,*

$$u^m \in C([0,\infty); L_{q+1}(\Re_k^N)) \cap L_2(0,T;W) \cap L_\infty(0,T; L_\infty(\Re_k^N)),$$

$\forall$ finite $T > 0$, and u satisfies the equation of problem (1) *in $\mathcal{D}'(D)$, together with the initial-boundary conditions.*

Let us denote by V the closure of $C_o^\infty(\Re_+)$ with respect to the seminorm

$$\left(\int_{\Re_+} \|u^{(l)}\|^2 dx\right)^{\frac{1}{2}}.$$

DEFINITION 2. *Given u_o in* (3)*, we say that u is an energy solution to* (3) *if*

$$u \in C([0,\infty); L_{r+1}(\Re_+)) \cap L_2(0,T;V)$$

$\forall$ finite $T > 0$, and u satisfies the equation of (3) *in $\mathcal{D}'(\Re_+)$, together with the initial-boundary conditions.*

The existence of an energy solution to problems (1) and (3) follows from the results of [6]. Related existence results can be found in [9], [1], and [12].

Our main goal is to prove the following.

THEOREM 1. *Let $u(x,t)$ be an energy solution of problem* (1)*. Assume that*

$$\textit{support } u_o \subset B_{R_o}^k,$$

where

$$B_{R_o}^k = \left\{x \in \Re_k^N, |x| < R_o\right\}.$$

Then the estimates (2) *hold.*

Remark 1. We recall that, due to Corollary 6.1 of [7], $\zeta(T) = O(T^\beta)$, where $\beta = \frac{1}{N(m-1)+2}$ is the Barenblatt exponent, while estimate (2) states that $\zeta(T) = O(T^{\frac{\sigma}{N+k}})$. As we have remarked in the introduction, Theorem 1 improves Corollary 6.1 of [7], since $\frac{\sigma}{N+k} < \beta$.

In section 4 we shall prove the following.

THEOREM 2. *Let $u(x,t)$ be an energy solution of problem* (3)*. Assume that*

$$\textit{support } u_o \in (0, R_o).$$

Then estimate (4) *holds. If, in addition, $u(x,t)$ satisfies condition* (5)*, then estimate* (6) *is also true.*

Remark 2. As a consequence of Corollary 2.1 of [7], for $T > 0$ sufficiently large,

$$\zeta(T) \leq c_o T^{\beta_o}, \tag{7}$$

where $\beta_o = \frac{r+1}{(2l-1)(r+1)+2}$, so the upper bound (4) improves (7). Furthermore, if $u \in L^\infty(0,T;L^r(\Omega))$, due to Corollary 6.1 of [7], we deduce

$$\zeta(T) \le c_1 T^{\beta_1} \quad \text{for } T>0 \text{ sufficiently large,} \tag{8}$$

with $\beta_1 = \frac{r}{(2l-1)(r+1)+1}$. Since $r \in (0,1)$, estimate (6) is better than (8).

However, we must remark that assumption (5) is stronger than assumption $u \in L^\infty(0,T;L^r(\Omega))$ and also, that we don't know under which conditions the energy solutions of problem (3) satisfy assumption (5).

3. Some technical lemmas. We recall here some technical inequalities which we shall employ in the proof of our theorems.

LEMMA 1 (Hardy's inequality). *Let $\theta>0$, $R>0$, and*

$$\int_R^\infty y(y-R)^{\theta+1}u_y^2 dy < \infty.$$

Then

$$\int_R^\infty y(y-R)^{\theta-1}u^2 dy \le \frac{4}{\theta^2}\int_R^\infty y(y-R)^{\theta+1}u_y^2 dy. \tag{9}$$

For the proof, see [10, Theorem 330]. Let us set

$$X_k = x_1 \cdots x_2 \cdots x_k.$$

LEMMA 2 (weighted Nirenberg–Gagliardo inequality). *Let $\omega \in W_2^1(\Re_k^N)\cap L_\beta(\Re_k^N)$ and $0<\beta<1<\lambda\le 2$. Then,*

$$\int_{\Omega_R^+} X_k|\omega|^\lambda dx$$

$$\le (\gamma(N,k,\beta))^\lambda \left(\int_{\Omega_R^+} X_k|\nabla\omega|^2 dx\right)^{\theta_1}\left(\int_{\Omega_R^+} X_k|\omega|^\beta dx\right)^{\theta_2}, \tag{10}$$

where

$$\theta_1 = \frac{(\lambda-\beta)(N+k)}{(N+k)(2-\beta)+2\beta}$$

and

$$\theta_2 = \frac{(2-\lambda)(N+k)+2\lambda}{(N+k)(2-\beta)+2\beta}.$$

Proof. Let

$$\Omega_{N+k} = \Re_k^N \times \{(z_1,...,z_k) : 0<z_i<x_i, \quad i=1,...,k\}$$

and $\overline{\omega} \in W_2^1(\Omega_{N+k}) \cap L_\beta(\Omega_{N+k})$. Let us put

$$\nabla_{x,z}\overline{\omega} = \left(\frac{\partial\overline{\omega}}{\partial x_1},...,\frac{\partial\overline{\omega}}{\partial x_N},\frac{\partial\overline{\omega}}{\partial z_1},...,\frac{\partial\overline{\omega}}{\partial z_N}\right),$$

$$\overline{E}_q(\overline{\omega}) = \int_{\Omega_{N+k}} |\overline{\omega}|^q dxdz,$$

$$\overline{J}(\overline{\omega}) = \int_{\Omega_{N+k}} |\nabla_{x,z}\overline{\omega}|^2 dxdz,$$

$$E_{k,q}(\omega) = \int_{\Re_k^N} X_k |\omega|^q dx,$$

$$J(\omega) = \int_{\Re_k^N} X_k |\nabla\omega|^2 dx.$$

By virtue of the Nirenberg–Gagliardo inequality (see Theorem 58.XII of [14]), there exists a constant γ, which depends only on $N+k, \beta$ such that

$$\overline{E}_\lambda(\overline{\omega}) \le \gamma^\lambda (\overline{J}(\overline{\omega}))^{\theta_1} (\overline{E}_\beta(\overline{\omega}))^{\theta_2}. \tag{11}$$

If we take $\overline{\omega}(x,z) = \omega(x)$, we have

$$\overline{E}_q(\omega) = E_{k,q}(\omega), \qquad \overline{J}(\omega) = J(\omega),$$

and so, from (11) we complete the proof.

LEMMA 3. *Assume u is an energy solution of problem* (1) *and $\rho(x) \in W^1_\infty(\Re_k^N)$, $\rho \ge 0$ on $\Re_k^N$. Then, for all T_1, T_2, $0 \le T_1 < T_2$ the following inequality is true:*

$$\frac{q}{q+1}\int_{\Re_k^N} \rho(x) v^{q+1}(x,T_2)dx + \int_{T_1}^{T_2}\int_{\Re_k^N} DvD(\rho v)dxdt$$

$$= \frac{q}{q+1}\int_{\Re_k^N} \rho(x) v^{q+1}(x,T_1)dx, \tag{12}$$

where $v = u^m$.

For the proof, we refer to Proposition 3.3 of [7].

LEMMA 4. *Let u be a solution of problem* (1) *and*

$$\zeta_1(T) = \textit{supremum}\,\{x_1 : x \in \textit{support}\ u(.,T)\}.$$

Then, for all $T_1, T_2 > 0$, $T_1 < T_2 < T$ we have

$$\zeta_1(T_2) - \zeta_1(T_1) \le \gamma (T_2 - T_1)^{\beta_o} \left(\int_{\Re_k^N} X_k u^{m+1}(x,T_1)dx \right)^{\lambda_0}, \tag{13}$$

where

$$\beta_o = \frac{m+1}{(N+k)(m-1)+2(m+1)},$$

$$\lambda_o = \frac{m-1}{m+1}\beta_o,$$

and γ is a positive constant which depends on N, k, m.

Proof. In view of the known results for the Cauchy–Dirichlet problem for the porous media equation in any unbounded domain (see [7, Corollary 6.1]), we deduce

$$\text{support } u(x,t) \subset B_{R(T)},$$

where

$$R(T) \le R_o + \gamma T^{\frac{1}{N(m-1)+2}}.$$

Let us denote

$$(x_1 - R)_+^s = \begin{cases} (x_1 - R)^s & \text{for} \quad x_1 > R, \\ 0 & \text{for} \quad x_1 \le R. \end{cases}$$

Then, choosing in (12),

$$\rho(x) = X_k (x_1 - R)_+^s, \quad T_1 = 0, \quad T_2 = T > 0, \quad R > R_o,$$

with s a sufficiently large positive number, we infer

$$\operatorname*{ess\,sup}_{0 \le t \le T} \int_{\Omega_R^+} X_k (x_1 - R)^s v^{q+1} dx + \int_0^T \int_{\Omega_R^+} X_k (x_1 - R)^s |\nabla v|^2 dx dt$$

$$\le \gamma \int_0^T \int_{\Omega_R^+} X_k (x_1 - R)^{s-1} |\nabla v| v dx dt$$

$$+ \int_0^T \int_{\Omega_R^+} \sum_{i=1}^k X_k^i v_{x_i} v (x_1 - R)^s dx dt = I_1 + I_2, \tag{14}$$

where

$$X_k^i = x_1 \cdots x_{i-1} x_{i+1} \cdots x_k$$

and

$$\Omega_R^+ = \Re_k^N \setminus \{x_1 \le R\}.$$

Let us estimate I_1, I_2. Integrating by parts, we obtain

$$I_2 = -\frac{s}{2} \int_0^T \int_{\Omega_R^+} x_2 \cdots x_k v^2 (x_1 - R)^{s-1} dx dt$$

$$\le \frac{s}{2} \int_0^T \int_{\Omega_R^+} X_k (x_1 - R)^{s-2} v^2 dx dt. \tag{15}$$

Moreover, the application of Young's inequality yields

$$I_1 \le \frac{\epsilon}{2} \int_0^T \int_{\Omega_R^+} X_k (x_1 - R)^s |\nabla v|^2 dx dt$$

$$+\frac{1}{2\epsilon}\int_0^T\int_{\Omega_R^+} X_k(x_1-R)^{s-2}v^2dxdt. \tag{16}$$

Thus, from (14)–(16) and for a sufficiently small ϵ, it follows that

$$\operatorname*{ess\,sup}_{0\le t\le T}\int_{\Omega_R^+} X_k(x_1-R)^s v^{q+1}dx+\int_0^T\int_{\Omega_R^+} X_k(x_1-R)^s|\nabla v|^2dxdt$$

$$\le \gamma\int_0^T\int_{\Omega_R^+} X_k(x_1-R)^{s-2}v^2dxdt. \tag{17}$$

Now, we would like to estimate the right-hand side of the last inequality. First, by virtue of Hardy's inequality (9), we can establish the following estimate:

$$\int_0^T\int_{\Omega_R^+} X_k(x_1-R)^{s-2}v^2dxdt\le\gamma\int_0^T\int_{\Omega_R^+} X_k(x_1-R)^s|\nabla v|^2dxdt.$$

So, if we set

$$\mathcal{F}_s=\mathcal{F}_s(T,R)=\operatorname*{ess\,sup}_{0\le t\le T}\int_{\Omega_R^+} X_k(x_1-R)^s v^{q+1}dx,$$

$$\mathcal{I}_s=\mathcal{I}_s(T,R)=\int_0^T\int_{\Omega_R^+} X_k(x_1-R)^s|\nabla v|^2dxdt,$$

from (17) we can deduce

$$\mathcal{F}_s\le\gamma\mathcal{I}_s. \tag{18}$$

Now, we can use the following weighted Nirenberg–Gagliardo inequality (see Lemma 2):

$$\int_{\Omega_R^+} X_k^1|\omega|^2dx$$

$$\le\gamma\left(\int_{\Omega_R^+} X_k^1|\nabla\omega|^2dx\right)^a\left(\int_{\Omega_R^+} X_k^1|\omega|^{q+1}dx\right)^{\frac{2(1-a)}{1+q}}, \tag{19}$$

where

$$X_k^1=x_2\cdots x_k$$

and

$$a=\frac{(N+k-1)(1-q)}{(N+k-1)(1-q)+2(q+1)}.$$

Setting in this inequality

$$\omega=(x_1(x_1-R)^{s-2})^{\frac{1}{2}}v,$$

we have

$$\int_{\Omega_R^+} X_k(x_1-R)^{s-2}v^2dx \le \gamma\left(\int_{\Omega_R^+} X_k(x_1-R)^{s-2}|\nabla v|^2dx\right.$$

$$\left.+\int_{\Omega_R^+} X_k(x_1-R)^{s-4}v^2dx\right)^a\left(\int_{\Omega_R^+} X_k^1(x_1(x_1-R)^{s-2})^{\frac{q+1}{2}}v^{q+1}dx\right)^{\frac{2(1-a)}{q+1}},$$

from which, using also Hardy and Young's inequalities, we obtain

$$\int_{\Omega_R^+} X_k(x_1-R)^{s-2}v^2dx$$

$$\le \gamma\left(\int_{\Omega_R^+} X_k(x_1-R)^{s-2}|\nabla v|^2dx\right)^a\left(\int_{\Omega_R^+} X_k v^{q+1}dx\right)^{\frac{\theta 2(1-a)}{q+1}}$$

$$\cdot\left(\int_{\Omega_R^+} X_k(x_1-R)^s v^{q+1}dx\right)^{\frac{2(1-\theta)(1-a)}{q+1}}, \tag{20}$$

where

$$\theta=\frac{s(1-q)+2(q+1)-q+1}{2s}.$$

Let us denote

$$\mathcal{E}_s=\mathcal{E}_s(t,R)=\int_{\Omega_R^+} X_k(x_1-R)^s v^{q+1}dx,$$

$$\mathcal{J}_s=\mathcal{J}_s(t,R)=\int_{\Omega_R^+} X_k(x_1-R)^s|\nabla v|^2dx.$$

Then, with the help of (20), inequality (17) may be rewritten as follows:

$$\mathcal{I}_s\le\gamma\int_0^T \mathcal{J}_{s-2}^a(t).\mathcal{E}_o^{\frac{2\theta(1-a)}{q+1}}.\mathcal{E}_s^{\frac{2(1-\theta)(1-a)}{q+1}}dt.$$

Estimating the right-hand side of the last inequality by Holder's inequality and also using (18), we can obtain

$$\mathcal{I}_s\le\gamma\mathcal{I}_{s-2}^a\mathcal{F}_o^{\frac{2\theta(1-a)}{q+1}}\mathcal{F}_s^{\frac{2(1-\theta)(1-a)}{q+1}}T^{1-a},$$

$$\le\gamma\mathcal{I}_{s-2}^a\mathcal{I}_o^{\frac{2\theta(1-a)}{q+1}}\mathcal{I}_s^{\frac{2(1-\theta)(1-a)}{q+1}}T^{1-a}. \tag{21}$$

Again, by virtue of Holder's inequality, it easily follows that

$$\begin{aligned}&\mathcal{I}_{s-2}\le\mathcal{I}_s^{\frac{s-2}{s}}\mathcal{I}_o^{\frac{2}{s}},\\ &\mathcal{I}_1\le\mathcal{I}_s^{\frac{1}{s}}\mathcal{I}_o^{\frac{s-1}{s}}.\end{aligned} \tag{22}$$

Estimating in (21) $\mathcal{I}_{s-2}$ from above and $\mathcal{I}_s$ from below, after easy manipulations we get

$$\mathcal{I}_1^{\lambda_1}(R,T) \le \gamma \mathcal{I}_o T^{\beta_1}, \tag{23}$$

where

$$\lambda_1 = \frac{(N+k)(1-q)+2(q+1)}{(N+k)(1-q)+2(q+1)+1-q}$$

and

$$\beta_1 = \frac{q+1}{(N+k)(1-q)+2(q+1)+1-q}.$$

Noticing that

$$\mathcal{I}_o(R,T) = -\frac{d\mathcal{I}_1}{dR},$$

from (23) we deduce

$$T^{-\beta_1}\mathcal{I}_1^{\lambda_1} \le -\gamma \frac{d\mathcal{I}_1}{dR}.$$

Hence

$$\mathcal{I}_1^{1-\lambda_1}(R,T)$$

$$\le \mathcal{I}_1^{1-\lambda_1}(R_o,T) - \gamma(R-R_o)T^{-\beta_1}$$

$$\le \gamma \mathcal{I}_o^{\frac{1-\lambda_1}{\lambda_1}}(R_o,T)T^{\frac{(1-\lambda_1)\beta_1}{\lambda_1}} - \gamma(R-R_o)T^{-\beta_1},$$

and therefore

$$\zeta_1(T) \le R_o + \gamma \mathcal{I}_o^{\lambda_o} T^{\beta_o}, \tag{24}$$

where λ_o, β_o are defined in Lemma 5.

By a slight modification of the proof, we can also obtain that for any T_1, T_2, with $0 \le T_1 < T_2$,

$$\zeta_1(T_2) - \zeta_1(T_1) \le \gamma(T_2-T_1)^{\beta_o} \left(\int_{T_1}^{T_2} \int_{\Re_k^N} X_k |\nabla u^m|^2 dx dt \right)^{\lambda_o}. \tag{25}$$

Finally, taking in (12) $\rho(x) = X_k$, it follows that

$$\int_{T_1}^{T_2} \int_{\Re_k^N} X_k |\nabla u^m|^2 dx \le \frac{q+1}{q} \int_{\Re_k^N} X_k u^{m+1}(x,T_1) dx, \tag{26}$$

and so from (25) and (26) we get (13).

In order to improve inequality (13), we need an estimate on the $\|u(.,t)\|_{\infty,\Re_k^N}$-norm; for this aim, we follow the method used in [15], combined with the iterative technique of [2].

LEMMA 5. *Let u be an energy solution of problem* (1). *Then, for any $t > 0$, the following estimate holds:*

$$\|u(.,t)\|_{L^\infty(\Re_k^N)} \leq \gamma \mu_k(0)^{\frac{2\sigma}{N+k}} t^{-\sigma}, \tag{27}$$

where

$$\mu_k(0) = \int_{\Re_k^N} X_k u_o(x) dx$$

and

$$\sigma = \frac{N+k}{(N+k)(m-1)+2}.$$

Proof. Using a standard method, from the weak formulation of (1), for any $p \geq m$ we obtain

$$\frac{d}{dt} \int_{\Re_k^N} X_k u^{p+1} dx$$

$$= -\frac{4mp(p+1)}{(m+p)^2} \int_{\Re_k^N} X_k |\nabla u^{\frac{p+m}{2}}|^2 dx - (p+1) \int_{\Re_k^N} \sum_{i=1}^{k} (u^m)_{x_i} X_k^i u^p dx dt.$$

By virtue of Green's formula and taking into account the boundary condition, the second term on the right-hand side is zero. Therefore, for a.e. $t > 0$, we have

$$\frac{d}{dt} \int_{\Re_k^N} X_k u^{p+1} dx = -\frac{4mp(p+1)}{(m+p)^2} \int_{\Re_k^N} X_k |\nabla u^{\frac{p+m}{2}}|^2 dx. \tag{28}$$

Moreover, since support $u(x,t)$ is bounded, for any $t > 0$ we obtain

$$\mu_k(t) = \int_{\Re_k^N} X_k u(x,t) dx = \int_{\Re_k^N} X_k u_o dx = \mu_k(0). \tag{29}$$

For any n, positive integer, let us denote by

$$p_n = m + 2^n - 2,$$

$$E_n(t) = \int_{\Re_k^N} X_k u(x,t)^{p_n+1} dx.$$

We shall obtain estimate (27) by proving that, for any $t > 0$, there exist two constants θ_1, θ_2, independent of n, such that

$$E_n(t) \leq A_n \mu_k(0)^{\sigma \frac{(N+k)(m-1)+2(p_n+1)}{N+k}} t^{-\sigma p_n}, \tag{30}$$

where

$$A_n = \left(\prod_{i=1}^{n} (\theta_1 p_i)^{\frac{\theta_2}{p_i+1}} \right)^{p_n+1}.$$

We shall prove (30) by induction on n. For $n = 1$, it follows from (28) and the weighted Nirenberg–Gagliardo inequality (10), provided $\theta_1 \geq \max(1, \sigma, \gamma(N, k, \frac{1}{m}))$ and $\theta_2 \geq 3(m+1)\sigma$, where $\gamma(N, k, \frac{1}{m})$ is the constant which appears in the inequality (10). Assume that (30) holds for n and let us prove it for $n+1$. From (28), with $p = p_{n+1} + 1$ we deduce

$$\frac{d}{dt} \int_{\Re_k^N} X_k u^{p_{n+1}+1} dx \leq - \int_{\Re_k^N} X_k |\nabla u^{p_n+1}|^2 dx; \tag{31}$$

moreover, from inequality (10), we have

$$\int_{\Re_k^N} X_k |\nabla u^{p_n+1}|^2 dx \geq \frac{[E_{n+1}(t)]^{\alpha_n}}{[E_n(t)]^{\beta_n} [\gamma(N, k, 1)]^{\delta_n}}, \tag{32}$$

where

$$\alpha_n = \frac{(N+k+2)(p_n+1)}{(p_{n+1} - p_n)(N+k)},$$

$$\beta_n = \frac{(N+k)(m-1) + 2(p_{n+1}+1)}{(p_{n+1} - p_n)(N+k)},$$

$$\delta_n = \alpha_n \frac{p_{n+1}+1}{p_n+1}.$$

Thus, from (31) and (32) we obtain

$$\frac{d}{dt} E_{n+1}(t) \leq - \frac{[E_{n+1}(t)]^{\alpha_n}}{[E_n(t)]^{\beta_n} [\gamma(N, k, 1)]^{\delta_n}}.$$

Integrating this inequality and using (30), we get

$$E_{n+1}(t) \leq [\gamma(N, k, 1)]^{\frac{\delta_n}{\alpha_n - 1}} [\sigma p_{n+1}]^{\frac{1}{\alpha_n - 1}} A_n^{\frac{\beta_n}{\alpha_n - 1}} \mu_k(0)^{\sigma \frac{(N+k)(m-1)+2(p_{n+1}+1)}{N+k}} t^{-\sigma p_{n+1}}.$$

Thus, after easy manipulations, we obtain

$$E_{n+1}(t)$$

$$\leq [\max(1, \gamma(N, k, 1), \sigma) p_{n+1}]^{2(N+k+2)} \cdot \left[\prod_{i=1}^{n} (\theta_1 p_i)^{\frac{2\theta_2}{p_i+1}} \right]^{p_{n+1}+1}$$

$$\cdot \mu_k(0)^{\sigma \frac{(N+k)(m-1)+2(p_{n+1}+1)}{N+k}} \cdot t^{-\sigma p_{n+1}}.$$

Finally, we get the proof of (30), taking

$$\theta_1 \geq \max\left(1, \sigma, \gamma(N,k,1), \gamma\left(N,k,\frac{1}{m}\right)\right)$$

and

$$\theta_2 \geq \max\left(3(m+1)\sigma, \frac{N+k+2}{4}\right).$$

Letting $n \to \infty$ in

$$[E_n(t)]^{\frac{1}{p_n+1}} \leq \left[\prod_{i=1}^{n}(\theta_1 p_i)^{\frac{\theta_2}{p_i+1}}\right] \mu_k(0)^{\sigma\frac{(N+k)(m-1)+2(p_n+1)}{(N+k)(p_n+1)}} t^{-\sigma\frac{p_n}{p_n+1}},$$

we complete the proof of Lemma 5, choosing $\gamma = \exp\left(\sum_{i=1}^{+\infty}\frac{\theta_2}{p_i+1}\log\theta_1 p_i\right)$.

The following lemma, due to F. Bernis (see [7, Lemma 6.1]), allows us to prove Theorem 1.

LEMMA 6. *Let $f : \Re \to \Re$ be a function such that*

$$f(t) - f(s) \leq C(t-s)^a s^{-b} \quad \forall t > s \geq t_o > 0,$$

where $a > b > 0$.

Then $\forall T \geq t_o$,

$$f(T) - f(t_o) \leq C(1-2^{b-a})^{-1} T^{a-b}.$$

Now we are able to prove Theorem 1.

Proof of Theorem 1. From (13) and (27) we get

$$\zeta_1(T_2) - \zeta_1(T_1) \leq \gamma\mu_k(0)^{(\frac{2\sigma}{N+k}m+1)\lambda_o}(T_2-T_1)^{\beta_o} T_1^{-\lambda_o m\sigma}.$$

Thanks to the last inequality, we can apply Lemma 6.1 of [7], which gives

$$\zeta_1(T) \leq \gamma\mu_k(0)^{\frac{\sigma}{N+k}(m-1)} T^{\frac{\sigma}{N+k}}$$

for a sufficiently large $T > 0$. In the same way, we can obtain the previous estimate for $\zeta_j(T)$, $j = 2, ..., N$, and hence,

$$\zeta(T) \leq \gamma\mu_k(0)^{\frac{\sigma}{N+k}(m-1)} T^{\frac{\sigma}{N+k}}$$

for a sufficiently large $T > 0$. Now we are able to estimate $\zeta(T)$ from below. Using (29) and the last inequality, we get

$$\mu_k(0) = \mu_k(t) = \int_{\Re_k^N} X_k u(x,t)dx$$

$$\leq \gamma\zeta(t)^{N+k}\|u(.,t)\|_{\infty,\Re_k^N}$$

$$\leq \gamma\zeta(t)^{N+k}\mu_k(0)^{\frac{2\sigma}{N+k}} t^{-\sigma},$$

or

$$\zeta(t) \geq \gamma\mu_k(0)^{\frac{\sigma(m-1)}{N+k}} t^{\frac{\sigma}{N+k}},$$

for a sufficiently large $t > 0$. The proof of Theorem 1 is complete.

4. The higher order case for $N = 1$. In order to prove Theorem 2, we need the following lemma.

LEMMA 7 (Nirenberg–Gagliardo inequality). *Given $l \geq 2$, $s \geq 2$, $0 < q < 1$, the following inequality holds:*

$$\int_R^\infty x(x-R)^{s-2}(u^{(l-1)})^2 dx \tag{33}$$
$$\leq \gamma \left(\int_R^\infty x(x-R)^{s-2}(u^{(l)})^2 dx \right)^{\beta_1} \left(\int_R^\infty x|u|^{q+1} dx \right)^{\beta_2} \left(\int_R^\infty x(x-R)^s |u|^{q+1} dx \right)^{\beta_3},$$

where

$$\beta_1 = \frac{l-1}{l} + \frac{\theta_1}{l(l-(l-1)\theta_1)},$$

$$\beta_2 = \frac{2\theta_2(1-\theta_1)}{(q+1)(l-(l-1)\theta_1)},$$

$$\beta_3 = \frac{2(1-\theta_2)(1-\theta_1)}{(q+1)(l-(l-1)\theta_1)},$$

$$\theta_1 = \frac{1-q}{1-q+2(q+1)},$$

$$\theta_2 = \frac{s(1-q)+2(q+1)+q-1}{2s}.$$

Proof. First of all, we will prove the following inequalities:

$$\int_R^\infty x(x-R)^{s-2}(u^{(l-1)})^2 dx$$

$$\leq \gamma \left(\int_R^\infty x(x-R)^{s-2}(u^{(l)})^2 dx \right)^{\frac{l-1}{l}} \left(\int_R^\infty x(x-R)^{s-2}u^2 dx \right)^{\frac{1}{l}}, \tag{34}$$

$$\int_R^\infty x(x-R)^{s-2}u_x^2 dx$$

$$\leq \gamma \left(\int_R^\infty x(x-R)^{s-2}(u^{(l)})^2 dx \right)^{\frac{1}{l}} \left(\int_R^\infty x(x-R)^{s-2}u^2 dx \right)^{\frac{l-1}{l}}. \tag{35}$$

Let us prove (34). Using [7], we can write

$$\int_R^\infty x(x-R)^{s-2}(u^{(l-1)})^2 dx$$

$$= \int_R^\infty (x-R)^{s-1}(u^{(l-1)})^2 dx + R\int_R^\infty (x-R)^{s-2}(u^{(l-1)})^2 dx$$

$$\leq \gamma \left(\int_R^\infty (x-R)^{s-1}(u^{(l)})^2 dx\right)^{\frac{1}{l}} \left(\int_R^\infty (x-R)^{s-1}u^2 dx\right)^{\frac{l-1}{l}}$$

$$+\gamma R \left(\int_R^\infty (x-R)^{s-2}(u^{(l)})^2 dx\right)^{\frac{1}{l}} \left(\int_R^\infty (x-R)^{s-2}u^2 dx\right)^{\frac{l-1}{l}}$$

$$\leq \gamma \left(\int_R^\infty x(x-R)^{s-2}(u^{(l)})^2 dx\right)^{\frac{1}{l}} \left(\int_R^\infty x(x-R)^{s-2}u^2 dx\right)^{\frac{l-1}{l}}.$$

Inequality (35) may be proved in the same way. Now, from (19) with $k = 1$, it follows that

$$\int_R^\infty x(x-R)^{s-2}u^2 dx$$

$$\leq \gamma \left(\int_R^\infty x(x-R)^{s-2}u_x^2 dx\right)^{\theta_1} \left(\int_R^\infty x|u|^{q+1} dx\right)^{\frac{2(1-\theta_1)}{q+1}\theta_2},$$

$$\left(\int_R^\infty x(x-R)^s |u|^{q+1} dx\right)^{\frac{2(1-\theta_1)}{q+1}(1-\theta_2)}$$

$$\leq \gamma \left(\left(\int_R^\infty x(x-R)^{s-2}(u^{(l)})^2 dx\right)^{\frac{1}{l}} \left(\int_R^\infty x(x-R)^s u^2 dx\right)^{\frac{l-1}{l}}\right)^{\theta_1},$$

$$\left(\int_R^\infty x|u|^{q+1}\right)^{\frac{2(1-\theta_1)\theta_2}{q+1}} \left(\int_R^\infty x(x-R)^s |u|^{q+1} dx\right)^{\frac{2(1-\theta_1)(1-\theta_2)}{q+1}}.$$

From this inequality, we can estimate

$$\int_R^\infty x(x-R)^{s-2}u^2 dx,$$

and substituting this bound into (35) we get (33). Thus, the lemma is proved.

LEMMA 8. *Let u be an energy solution of problem* (3) *and $\rho(x) \in W_\infty^l(0,\infty)$, $\rho(x) \geq 0$. Then, for any $T_1, T_2 : 0 \leq T_1 < T_2$, the following equality is true:*

$$\frac{1}{r+1}\int_0^\infty \rho(x)|u(x,T_2)|^{r+1} dx - \frac{1}{r+1}\int_0^\infty \rho(x)|u(x,T_1)|^{r+1} dx$$

$$+\int_{T_1}^{T_2}\int_0^\infty u^{(l)}(\rho(x)u)^{(l)} dx dt = 0. \tag{36}$$

For the proof, see [7].

LEMMA 9. *Assume that u is an energy solution of problem* (3). *Then, for any $T_1, T_2 : 0 \le T_1 < T_2$, we have*

$$\zeta(T_2) - \zeta(T_1)$$

$$\le \gamma (T_2 - T_1)^{\frac{r+1}{2(l-1)(r+1)+4}} \left(\int_{T_1}^{T_2} \int_0^\infty x (u^{(l)})^2 dx dt \right)^{\frac{1-r}{2(l-1)(r+1)+4}}. \tag{37}$$

Proof. Substituting $T_1 = 0$, $T_2 = T$, $\rho(x) = x(x-R)_+^s$ with $R > R_o$ and s sufficiently large positive number, and taking into account that

$$(x(x-R)^s u)^{(l)} = x((x-R)^s u)^{(l)} + l((x-R)^s u)^{(l-1)}$$

and

$$\left| \int_0^T \int_R^\infty u^{(l)} ((x-R)^s u)^{(l-1)} dx \right|$$

$$= \left| \sum_{j=0}^{l-1} C_j \int_0^T \int_R^\infty (u^{(l-j-1)})^2 (x-R)^{s-2j-1} dx dt \right|$$

$$\le \gamma \sum_{j=0}^{l-1} \int_0^T \int_R^\infty x (x-R)^{s-2j-2} (u^{(l-j-1)})^2 dx dt$$

from (36), it follows that

$$\operatorname*{ess\,sup}_{0<t\le T} \int_R^\infty x(x-R)^s |u|^{r+1} dx + \int_0^T \int_R^\infty |u^{(l)}|^2 x (x-R)^s dx dt$$

$$\le \gamma \int_0^T \int_R^\infty x \sum_{j=0}^{l-1} (x-R)^{s-2j-2} (u^{(l-j-1)})^2 dx dt$$

$$+\gamma \int_0^T \int_R^\infty \left| x \sum_{j=0}^{l-1} (x-R)^{s-j-1} u^{(l-j-1)} u^{(l)} \right| dx dt. \tag{38}$$

Using Young's inequality, the second term on the right-hand side may be estimated by

$$\frac{\epsilon}{2} \int_0^T \int_R^\infty x (x-R)^s (u^{(l)})^2 dx dt$$

$$+\frac{1}{2\epsilon} \int_0^T \int_R^\infty x \sum_{j=0}^{l-1} (x-R)^{s-2j-2} (u^{(l-j-1)})^2 dx dt.$$

So, choosing a sufficiently small $\epsilon > 0$, from (38) we have

$$\operatorname*{ess\,sup}_{0<t\le T} \int_R^\infty x(x-R)^s |u|^{r+1} dx + \int_0^T \int_R^\infty (u^{(l)})^2 x(x-R)^s dxdt$$

$$\le \gamma \int_0^T \int_R^\infty x \sum_{j=0}^{l-1} (x-R)^{s-2j-2} (u^{(l-j-1)})^2 dxdt.$$

The use of Hardy's inequality yields

$$\mathcal{F}_s + \mathcal{I}_s \le \gamma \int_0^T \int_R^\infty x(x-R)^{s-2} (u^{(l-1)})^2 dxdt, \tag{39}$$

where

$$\mathcal{F}_s = \operatorname*{ess\,sup}_{0<t\le T} \int_R^\infty x(x-R)^s |u|^{r+1} dx,$$

$$\mathcal{I}_s = \int_0^T \int_R^\infty x(x-R)^s (u^{(l)})^2 dxdt.$$

Again applying Hardy's inequality, we obtain

$$\mathcal{F}_s \le \gamma \mathcal{I}_s. \tag{40}$$

Moreover, estimating the right-hand side of (39) by the Nirenberg–Gagliardo inequality (33) and using (40), we deduce

$$\mathcal{I}_s \le \gamma \int_0^T \mathcal{J}_{s-2}^{\beta_1} \mathcal{E}_o^{\beta_2} \mathcal{E}_s^{\beta_3} dt \le \gamma \mathcal{I}_{s-2}^{\beta_1} \mathcal{I}_o^{\beta_2} \mathcal{I}_s^{\beta_3} T^{1-\beta_1}, \tag{41}$$

where

$$\mathcal{J}_{s-2} = \int_R^\infty x(x-R)^{s-2} (u^{(l)})^2 dx,$$

$$\mathcal{E}_s = \int_R^\infty x(x-R)^{s-2} |u|^{r+1} dx,$$

$$\mathcal{E}_0 = \int_R^\infty x|u|^{r+1} dx.$$

From (41), it follows that

$$\mathcal{I}_1^{\beta_4} \le -\frac{d\mathcal{I}_1}{dR} T^{\beta_5},$$

with

$$\beta_4 = \frac{2(l-1)(r+1)+4}{2(l-1)(r+1)+4+(1-r)}, \qquad \beta_5 = \frac{r+1}{2(l-1)(r+1)+4+(1-r)}.$$

From the last inequality, we derive, in the usual way, estimate (37).

Proof of Theorem 2. Let us substitute in (36) $\rho(x) = x$. Since the support of u is bounded, and taking into account the identity

$$xu^{(l)} + lu^{(l-1)} = (xu)^{(l)},$$

we obtain

$$\int_{T_1}^{T_2} \int_0^\infty x(u^{(l)})^2 dxdt \le \gamma \int_0^\infty x|u(x,T_1)|^{r+1} dx. \tag{42}$$

Thus, using (42) in (37) easily follows (4).

In order to prove inequality (6), let us note that

$$\frac{1}{r+1}\frac{d}{dt}\int_0^\infty x|u(x,t)|^{r+1}dx = -\int_0^\infty x(u^{(l)})^2 dx. \tag{43}$$

Now, we remember that the following weighted Nirenberg–Gagliardo inequality holds (see [7]):

$$\left(\int_0^\infty x|u|^{r+1}dx\right)^{\frac{1}{r+1}} \le \gamma \left(\int_0^\infty x(u^{(l)})^2 dx\right)^{\frac{\theta}{2}} \left(\int_0^\infty x|u|^q dx\right)^{\frac{1-\theta}{r}},$$

where

$$\theta = \frac{2}{(r+1)(2+(l-1)r)}.$$

Thus, using this inequality and assumption (5) from (43), we derive

$$\frac{d}{dt}\int_0^\infty x|u|^{r+1}dx \le -\gamma\mu_o^{l+1}\left(\int_0^\infty x|u|^{r+1}dx\right)^{\chi},$$

where $\chi = 2 + (l-1)r$. The last inequality yields

$$\int_0^\infty x|u|^{r+1}dx \le \gamma\mu_o^{\frac{l-1}{1+(l-1)r}} t^{\frac{-1}{1+(l-1)r}}. \tag{44}$$

From (37), (42), and (44) we get

$$\zeta(T_2) - \zeta(T_1) \le \gamma(T_2 - T_1)^{\frac{r+1}{2(l-1)(r+1)+4}} T_1^{-\frac{1-r}{(1+(l-1)r)(2(l-1)(r+1)+4)}}.$$

Therefore, Lemma 1.6 of [7] gives estimate (6). The proof of Theorem 2 is complete.

Acknowledgment. The authors thank Professor F. Nicolosi for helpful suggestions.

BIFURCATION TO SPIRAL WAVES IN REACTION-DIFFUSION SYSTEMS*

ARND SCHEEL†

Abstract. For a large class of reaction-diffusion systems on the plane, we show rigorously that m-armed spiral waves bifurcate from a homogeneous equilibrium when the latter undergoes a Hopf bifurcation. In particular, we construct a finite-dimensional manifold which contains the set of small rotating waves close to the homogeneous equilibrium. Examining the flow on this center-manifold in a very general example, we find different types of spiral waves, distinguished by their speed of rotation and their asymptotic shape at large distances of the tip. The relation to the special class of λ-ω systems and the validity of these systems as an approximation is discussed.

Key words. spiral waves, center-manifolds, Ginzburg–Landau equations, λ-ω systems

1. Introduction.

We study reaction-diffusion systems

$$U_t = D\triangle U + F(\lambda, U), \qquad U(x,t) \in \mathbb{R}^N, \quad \lambda \in \mathbb{R}^p, \tag{1.1}$$

on the plane $x \in \mathbb{R}^2$. The N-dimensional vector U typically describes a set of chemical concentrations and temperature, depending on time $t \in \mathbb{R}$ and the space variable x. The parameter λ is a p-dimensional control parameter which shall allow us to create instabilities of spatially homogeneous equilibria. We shall be interested in rotating wave solutions $U(t,x) = U(0, R_{ct}x)$, $c \neq 0$, where R_φ is the rotation in $\mathbb{R}^2$ around the origin by the angle $\varphi \in \mathbb{R}/2\pi\mathbb{Z}$. Our analysis shows that this class of solutions appears naturally via some type of Hopf bifurcation. Moreover the spatial structure resembles n-armed spiral waves.

Experimentally this type of spatiotemporal pattern has been observed frequently in chemical, biological, physiological, and physical experiments (e.g., the Belousov–Zhabotinsky reaction, the catalysis on platinum surfaces, electrochemical waves in the cortex of the brain, signaling patterns of the slime mold, and the Rayleigh–Bénard convection). Nevertheless a rigorous treatment of existence and creation is still not available—for various reasons.

Spiral waves are typically observed in spatially extended oscillatory processes. Near Hopf bifurcation points the dynamics of these processes are approximated by Ginzburg–Landau equations or λ-ω-systems [1, 10]. This has been shown using formal asymptotic methods; see [1] for example. Recently a rigorous proof of the approximation property of Ginzburg–Landau equations has been given by Schneider; see [21]. The important property of the approximating equations is a decoupling of Fourier modes, which was exploited by several authors in order to construct spiral wave solutions [1, 5, 6, 7, 11], although the methods are still formal or do not cover the typical nonlinearities appearing close to bifurcation points.

Of course a treatment of Hopf bifurcation using classical bifurcation methods with symmetry is not possible because either center-manifolds do not exist or Lyapunov–Schmidt reduction cannot be applied, due to presence of continuous spectrum. Another explanation is provided by the fact that the symmetry of the reaction-diffusion equation, the Euclidean symmetry, does not have bounded finite-dimensional representations; see [12] for an approach to Ginzburg–Landau equations exploiting symmetry.

In spatially extended systems including only one unbounded spatial variable, typically cylindrical domains, the continuous spectrum can be avoided by restricting to steady state solutions and considering the unbounded spatial variable as a new time direction. This approach was introduced by Kirchgässner [9] and applied to various interesting problems in mechanics, fluid dynamics, and physics; see, for example, [13, 19]. Unfortunately, considering systems with several unbounded directions, this method becomes less successful; see, however, [14].

We adopt the idea of spatial dynamics, now considering the radial direction in polar coordinates as a new time variable, in order to describe the spatial structure of rotating waves by a surprisingly finite-dimensional, nonautonomous ordinary differential equation (ODE) on a center-manifold. In particular any small bounded solution to this ODE corresponds to a rotating wave of the original reaction-diffusion system. This approach allows us to describe systematically the creation of rotating waves from homogeneous equilibria of reaction-diffusion systems.

The paper is organized as follows. In the next section we fix the abstract functional analytic setting in which we formulate a center-manifold reduction theorem. This theorem, our main result, is stated in section 3 and proved in the two subsequent sections. The key to the proof are exponential dichotomies which are proved to exist in our functional analytic framework in section 4. In section 6 we comment on a localization of our main theorem using cutoff procedures and we briefly discuss regularity of solutions in section 7. The last important abstract result is stated in section 8, where we formulate and prove the existence of a larger manifold, containing solutions which might be singular at the origin. This manifold is tangent to a subspace which is independent of time τ (alias the distance to the origin in $\mathbb{R}^2$) and therefore allows us to derive explicit bifurcation equations. We conclude by applying our results to a model problem in the remaining sections.

2. The abstract setting. Introducing polar coordinates $x = (r\cos\varphi, r\sin\varphi)$, the equation for rotating wave solutions of (1.1) becomes

$$D\left(U'' + \frac{1}{r}U' + \frac{1}{r^2}U_{\varphi\varphi}\right) + F(\lambda, U) = cU_\varphi, \tag{2.1}$$

where $' = \frac{\partial}{\partial r}$, $\varphi \in S^1 = \mathbb{R}/2\pi\mathbb{Z}$, $r \in (0,\infty)$, and c is again the speed of rotation.

We suppose that for an initial parameter value λ_0 we are given a spatially homogeneous equilibrium $U_0(\lambda_0)$ which solves $F(\lambda_0, U_0(\lambda_0)) = 0$. As we are merely interested in Hopf bifurcation, we suppose that this solution can be continued in λ to a branch $U_0(\lambda)$, which we can assume without loss of generality to be the zero solution.

To sum up we suppose that $F(\lambda, 0) = 0$ and $D = D^* > 0$.

Note, however, that the first assumption is merely a simplification for clarity of the statements and the second assumption might be generalized slightly.

As a most elementary example, which is discussed in section 9, the reader might think of $D = \mathrm{id}$ and $F(\lambda, U) = iU + \mathrm{O}(|U|^2), U \in \mathbb{R}^2 \simeq \mathbb{C}$.

Next we multiply (2.1) by D^{-1},

$$U'' + \frac{1}{r}U' + \frac{1}{r^2}U_{\varphi\varphi} = -D^{-1}F(\lambda, U) + cD^{-1}U_\varphi, \tag{2.2}$$

and linearize around $U = 0$

$$U'' + \frac{1}{r}U' + \frac{1}{r^2}U_{\varphi\varphi} = -D^{-1}F_U(\lambda, 0)U + cD^{-1}U_\varphi. \tag{2.3}$$

We work in the function spaces $H^l(S^1, \mathbb{R}^N), l \geq 0$. Functions $u \in H^l$ may be represented by their Fourier series

$$u(\varphi) = \sum_{k\in\mathbb{Z}} u_k e^{ik\varphi},$$

with $u_{-k} = \bar{u}_k$ and $\|u\|^2_{H^l} = \sum_{k\in\mathbb{Z}} |u_k|^2 k^{2l} < \infty$.

The operator $A = -\partial_{\varphi\varphi}$ is self-adjoint and positive in H^l with spectrum $\{k^2;\ k \in \mathbb{Z}\}$ and domain of definition H^{l+2}. The spectral information on our bifurcation problem is contained in the operator

$$\begin{aligned} B_{\lambda,c} : H^{l+1} \subset H^l &\to H^l, \\ u(\cdot) &\mapsto -D^{-1}F_U(\lambda, 0)u(\cdot) + cD^{-1}u_\varphi(\cdot). \end{aligned}$$

As $c \neq 0$, the operator $B_{\lambda,c}$ can be considered as a bounded perturbation of the closed, antisymmetric, unbounded operator $C_c = cD^{-1}\partial_\varphi$ on H^l. Therefore $B_{\lambda,c}$ has point spectrum, and any strip $\{z \in \mathbb{C};\ |\operatorname{Im} z| < M\}$ contains only a finite number of eigenvalues, each of finite multiplicity.

We denote by $\tilde{P}^c_+(\lambda, c)$ the spectral projection to the operator $B_{\lambda,c}$ on $(-\infty, 0] \subset \mathbb{C}$. Of course $\tilde{P}^c_+(\lambda, c)$ can be constructed via Dunford's integral.

We rewrite (2.2) as an equation in function space,

$$u'' + \frac{1}{r}u' - \frac{1}{r^2}Au = -\tilde{F}(\lambda, u) + C_c u, \tag{2.4}$$

and linearize around $u = 0$,

$$u'' + \frac{1}{r}u' - \frac{1}{r^2}Au = B_{\lambda,c}u. \tag{2.5}$$

We suppose that $\tilde{F} \in C^K(\mathbb{R}^p \times H^{l+1/2}, H^l)$, $K \geq 1$, which can be achieved assuming $F \in C^K$ and either $l > 0$ such that $H^{l+1/2} \hookrightarrow C^0$ or suitable growth conditions on F.

We say that u is a solution of (2.4) (or (2.5)) on an interval $I \subset (0, \infty)$ if

$$u \in C^0(\operatorname{clos} I, H^{l+1}) \cap C^1(\operatorname{clos} I, H^l) \cap C^2(\operatorname{int} I, H^l) \cap C^1(\operatorname{int} I, H^{l+1}) \cap C^0(\operatorname{int} I, H^{l+2})$$

and if (2.4) (or (2.5), respectively) is satisfied in H^l.

Furthermore we introduce a new time

$$\tau(r) = \begin{cases} \log r & \text{if } r \leq \bar{r}, \\ r & \text{if } r \geq 2\bar{r}, \end{cases}$$

defined by smooth, monotone interpolation on $(\bar{r}, 2\bar{r})$ such that $\tau \in C^\infty(\mathbb{R}^+, \mathbb{R})$. The exact value of the positive constant $\bar{r}$ is of no importance for the statement of the results.

For $r < \bar r$ the differential equation (2.4) becomes

$$u_{\tau\tau} - Au = -e^{2\tau}(\tilde F(\lambda, u) - C_c u).$$

Of course (2.4) remains unchanged for $r \geq 2\bar r$.

We conclude this section emphasizing the symmetry of (2.4). The rotation $\varphi \to \varphi + \bar\varphi$ on $S^1 \simeq \mathcal{SO}(2)$ acts on $H^l(S^1, \mathbb{R}^N)$ by shifting functions on the circle: $u(\varphi) \to u(\varphi - \bar\varphi)$. Of course this symmetry is inherited from the Euclidean symmetry of the original problem. Note that translations are ruled out by the ansatz for equilibria in a fixed rotating coordinate system. Translations of any solution found with this ansatz would be periodic solutions in our coordinate system.

3. Main results. We write (2.4) as a first-order differential equation,

$$\frac{d}{d\tau}\underline{u}(\tau) = \mathcal{A}(\tau)\underline{u}(\tau) + \mathcal{G}(\underline{u}(\tau)), \qquad \underline{u} = \left(u, \frac{d}{d\tau}u(\tau)\right), \tag{3.1}$$

on the space $\underline{u} \in X = H^{l+1}(S^1, \mathbb{R}^N) \times H^l(S^1, \mathbb{R}^N)$. Here

$$\mathcal{A}(\tau) = \begin{pmatrix} 0 & 1 \\ A + e^{2\tau}B_{\lambda,c} & 0 \end{pmatrix}, \qquad \mathcal{G}(\underline{u}) = -e^{2\tau}\begin{pmatrix} 0 \\ \tilde F(\lambda, u) + B_{\lambda,c}u - C_c u \end{pmatrix}$$

if $\tau \leq \log \bar r$ and

$$\mathcal{A}(\tau) = \begin{pmatrix} 0 & 1 \\ \tau^{-2}A + B_{\lambda,c} & -\tau^{-1} \end{pmatrix}, \qquad \mathcal{G}(\underline{u}) = -\begin{pmatrix} 0 \\ \tilde F(\lambda, u) + B_{\lambda,c}u - C_c u \end{pmatrix}$$

if $\tau \geq 2\bar r$. For $\tau \in (\log \bar r, 2\bar r)$, the exact form of the equation is not important, as solutions arise from solutions of (2.4) by a bounded diffeomorphic rescaling of time. The linearization of (3.1) along $\underline{u} = 0$ is

$$\frac{d}{d\tau}\underline{u}(\tau) = \mathcal{A}(\tau)\underline{u}(\tau). \tag{3.2}$$

We let

$$Y_\delta = \{\underline{u} \in C^0(\mathbb{R}, X);\ \|u\|_{Y_\delta} < \infty\}, \quad \text{where } \|u\|_{Y_\delta} := \sup_{\tau\in\mathbb{R}} e^{-\delta|\tau|}|\underline{u}(\tau)|_{X_\tau},$$

and, similarly,

$$Y_\delta^\pm = \{\underline{u} \in C^0(\overline{\mathbb{R}}^\pm, X);\ \|u\|_{Y_\delta} < \infty\}, \quad \text{where } \|u\|_{Y_\delta^\pm} := \sup_{\tau\in\mathbb{R}^\pm} e^{-\delta|\tau|}|\underline{u}(\tau)|_{X_\tau}.$$

The norm in X_τ of $\underline{u}(\tau) = (u(\tau), v(\tau))$ is defined as

$$|\underline{u}(\tau)|_{X_\tau} := \begin{cases} \tau^{-1}|u|_{H^{l+1}} + |u|_{H^{l+1/2}} + |v|_{H^l} & \text{if } \tau \geq 2\bar r, \\ |u(\tau)|_{H^{l+1}} + |v(\tau)|_{H^l} & \text{if } \tau < 2\bar r. \end{cases}$$

Let us denote by $E^c(\tau)$ the (possibly empty) linear subspace of initial values of the linear equation (3.2) at time τ, which give rise to Y_δ-bounded solutions. Of course E^c depends also on δ.

THEOREM 1. *Suppose the superposition operator $\tilde F$ to the nonlinearity F belongs to the class $C^K(\mathbb{R}^p \times H^{l+1/2}(S^1, \mathbb{R}^N), H^l(S^1, \mathbb{R}^N))$, $1 \leq K < \infty$. Suppose, furthermore, that for $\lambda = \lambda_0$ and $c = c_0$ we have $\tilde P_+^c(\lambda, c) \neq 0$.*

Then there are $\epsilon, \delta > 0$ such that, if

$$\mathrm{Lip}_u[\tilde{F} - \tilde{F}_u(\lambda, 0)] + |\lambda - \lambda_0| + |c - c_0| < \epsilon,$$

there exists a unique finite-dimensional C^K-center-manifold $\mathcal{M} \subset X \times \mathbb{R}$ which contains all solutions of (3.1) *which are bounded in Y_δ. The manifold $\mathcal{M}$ is given as a graph over $\{E^c(\tau);\ \tau \in \mathbb{R}\}$ and depends smoothly on λ, c. In any section $\tau = \tau_0$, it is tangent to $E^c(\tau)$ at $\lambda = \lambda_0, c = c_0$.*

Moreover we have

(i) flow property: *for any $\underline{u}_0 = \underline{u}(\tau_0, c, \lambda) \in \mathcal{M}$, there is a unique Y_δ-bounded solution $\underline{u}(\tau), \tau \in \mathbb{R}$, to* (3.1) *with $\underline{u}(\tau_0) = \underline{u}_0$;*

(ii) invariance: *this unique solution $\underline{u}(\tau)$ lies on $\mathcal{M}$ for all times τ and depends C^K on $\underline{u}_0, \tau, \lambda$, and c;*

(iii) dimension: *the dimension of $E^c(\tau)$ is* $\dim R(\tilde{P}^c_+(\lambda_0, c_0)) + \dim \tilde{P}^c_+(\lambda_0, 0)\mathbb{R}^N$, *where the second summand is the dimension of the range when restricted on the homogeneous N-dimensional subspace of H^l;*

(iv) symmetry: *the manifold $\mathcal{M}$ is invariant and the flow on $\mathcal{M}$ is equivariant under the diagonal action of $\mathcal{SO}(2)$ on $X = H^{l+1} \times H^l$.*

Remarks.

(i) Let us emphasize that the operator $D\triangle + \partial_\varphi$ has continuous spectrum close to the imaginary axis, which makes a standard, finite-dimensional bifurcation approach to the dynamical reaction-diffusion problem impossible.

(ii) We will later give expansions for the spaces $E^c(\tau)$ at $\tau = \infty$ and describe how to obtain expansions for $\mathcal{M}$.

(iii) It is possible to treat the case of F depending on ∇u with the same methods. Indeed, both components of the gradient, u_r and $\frac{1}{r}u_\varphi$, are bounded with respect to $|(u, u_r)|_{X_\tau}$.

(iv) A slight generalization could be obtained by the use of interpolation spaces between X_τ and $D(\mathcal{A}(\tau))$. We avoided these additional technical difficulties for the sake of clarity.

(v) Making δ larger it is possible to allow singularities of the rotating waves at the origin, a phenomenon which is frequently attributed in the literature to spiral waves. The manifold will be larger if we allow for this type of solution but will still be finite-dimensional. However, the point in this work is that even spiral wave-like solutions without singularities at the tip are created via Hopf bifurcation.

4. The linearized equation. The key to a center-manifold theorem is the construction of exponential dichotomies for the linear equation. Background information on exponential dichotomies might be found in the textbooks [2], [8], in [15], or in a non-evolutionary, elliptic context in [16].

4.1. Bounded solutions for $\tau \to -\infty$. We construct a family of projections $P^{cu}_-(\tau)$ which project on the initial values of bounded solutions to (3.2) on $(-\infty, \tau]$. In a more general context this problem has been studied in [16]. The main theorems there (Theorem 1 and Theorem 3), applied to our setting, state the following lemma.

LEMMA 2. *Under the conditions of Theorem* 1, *suppose $\tau_0, \tau_1, \tau \le 2\bar{r}$. Then there are families of evolution operators, smoothly depending on λ and c,*

$$\Phi^u_-(\tau, \tau_0): \quad X \to X, \quad \tau \le \tau_0,$$
$$\Phi^s_-(\tau, \tau_0): \quad X \to X, \quad \tau \ge \tau_0,$$

and constants $C > 0$, $\eta^u_- > \eta^s_- > 0$ such that

(i) $\Phi_-^{u/s}(\cdot,\tau_0)\underline{u}$ *is a solution of* (3.2) *for any* $\underline{u}\in X$,
(ii) $\Phi_-^{u/s}(\cdot,\cdot)\underline{u}$ *is continuous in* X,
(iii) $\Phi_-^{u}(\tau_0,\tau_0)+\Phi_-^{s}(\tau_0,\tau_0)=\mathrm{id}$,
(iv) $\Phi_-^{u/s}(\tau,\tau_1)\Phi_-^{u/s}(\tau_1,\tau_0)=\Phi_-^{u/s}(\tau,\tau_0)$, $\Phi_-^{u/s}(\tau,\tau_1)\Phi_-^{s/u}(\tau_1,\tau_0)=0$, *and*
(v) $|\Phi_-^{u}(\tau,\tau_0)|_{L(X,X)}\le Ce^{-\eta_-^u(\tau-\tau_0)}$, $|\Phi_-^{s}(\tau,\tau_0)|_{L(X,X)}\le Ce^{-\eta_-^s(\tau-\tau_0)}$,
and we can choose any $\eta_-^u>0$. *We define* $P_-^{cu}(\tau):=\Phi_-^u(\tau,\tau)$.

We will later see how we can give a more explicit representation of the evolution operators Φ in terms of Bessel functions. This also will show why the uniqueness assumption from [16] is automatically satisfied in our context because the linear equation splits into an infinite product of ODEs, which are all uniquely solvable in forward and in backward time.

4.2. Bounded solutions for $\tau\to+\infty$. The situation at $\tau=+\infty$ is considerably more difficult as $B_{\lambda,c}$ is no more τ-uniformly bounded with respect to $\tau^{-2}A$. It is due to our careful choice of norms in X_τ that we still have an analogous result to Lemma 2.

LEMMA 3. *Under the conditions of Theorem* 1, *suppose* $\tau_0,\tau_1,\tau\ge 2\bar r$. *Then there are families of evolution operators, smoothly depending on* λ,c,

$$\begin{aligned}\Phi_+^u(\tau,\tau_0):&\quad X_{\tau_0}\to X_\tau,\quad \tau\le\tau_0,\\ \Phi_+^s(\tau,\tau_0):&\quad X_{\tau_0}\to X_\tau,\quad \tau\ge\tau_0,\end{aligned}$$

and constants $C>0$, $\eta_+^u>\eta_+^s>0$ *such that*
(i) $\Phi_+^{u/s}(\cdot,\tau_0)\underline{u}$ *is a solution of* (3.2) *for any* $\underline{u}\in X$,
(ii) $\Phi_+^{u/s}(\cdot,\cdot)\underline{u}$ *is continuous in* X,
(iii) $\Phi_+^{u}(\tau_0,\tau_0)+\Phi_+^{s}(\tau_0,\tau_0)=\mathrm{id}$,
(iv) $\Phi_+^{u/s}(\tau,\tau_1)\Phi_+^{u/s}(\tau_1,\tau_0)=\Phi_+^{u/s}(\tau,\tau_0)$, $\Phi_+^{u/s}(\tau,\tau_1)\Phi_+^{s/u}(\tau_1,\tau_0)=0$, *and*
(v) $|\Phi_+^{u}(\tau,\tau_0)|_{L(X_{\tau_0},X_\tau)}\le Ce^{\eta_+^u(\tau-\tau_0)}$, $|\Phi_+^{s}(\tau,\tau_0)|_{L(X_{\tau_0},X_\tau)}\le Ce^{\eta_+^s(\tau-\tau_0)}$,
and we can choose any $\eta_+^s>0$. *We define* $P_+^{cs}(\tau):=\Phi_+^s(\tau,\tau)$.

Proof.

Step 1. *Fourier ansatz.* The proof of this lemma is the central part of our analysis. Complexifying X, the subspaces

$$E^k=\{(ue^{ik\varphi},ve^{ik\varphi})\in X;\ \underline{u}=(u,v)\in(\mathbb{C}^N)^2\}\le X_\tau$$

are invariant under (3.2). Of course, we are primarily interested in the real subspace, where we have a relation between the vectors in E^k and E^{-k}. In E^k the differential equation reads

$$u''+\frac{1}{\tau}u'-\frac{k^2}{\tau^2}u=-D^{-1}(F_u(\lambda,0)+cik)u=:B_{\lambda,c}^k u.$$

If we expand $\underline{u}(\tau)=\sum_{k\in\mathbb{Z}}\underline{u}^k(\tau)e^{ik\varphi}$, then $|\underline{u}(\tau)|_{X_\tau}$ is equivalent to $(\sum_{k\in\mathbb{Z}}|\underline{u}^k|_{E_\tau^k}^2)^{1/2}$, where

$$|\underline{u}^k|_{E_\tau^k}=k^l\left(\frac{1}{\tau}|ku^k|_{\mathbb{C}^N}+|k^{1/2}u^k|_{\mathbb{C}^N}+|v|_{\mathbb{C}^N}\right)$$

if $k\ne0$ and $|\underline{u}^0|_{E_\tau^k}=|\underline{u}^0|_{(\mathbb{C}^N)^2}$.

By the above considerations we see that it is sufficient to construct the evolution operators on E_τ^k, and uniform exponential bounds on the norms in E_τ^k will carry over to X_τ.

Step 2. *Projections.* According to the remarks in section 2, we decompose E^k into $E^k_{c,+} = P^c_+ E^k$ and $E^k_{h,+} = (1 - P^c_+)E^k$, where $P^c_+ = \mathrm{diag}\,(\tilde{P}^c_+(\lambda_0, c_0), \tilde{P}^c_+(\lambda_0, c_0))$ and $\tilde{P}^c_+(\lambda_0, c_0)$ projects on the negative part of the spectrum of B_{λ_0,c_0}.

Step 3. *Stable projections, estimates.* We show that all solutions in $E^k_{c,+}$ are exponentially bounded in E^k_τ with an arbitrarily small exponent δ, keeping λ, c sufficiently close to λ_0, c_0.

As the range of $\tilde{P}^c_+(\lambda_0, c_0)$ is finite-dimensional, only finitely many modes k are involved in the computation. We therefore use the equivalent, standard, k- and τ-independent norm on $(\mathbb{C}^N)^2$. Furthermore decomposing $B^k_{\lambda,c}$ into Jordan blocks, it is sufficient to consider

$$u'' + \frac{1}{\tau}u' - \frac{k^2}{\tau^2}u + \Lambda(k, \lambda, c)u = 0,$$

where $\Lambda(k, \lambda_0, c_0)$ is a Jordan block. The eigenvalue of $\Lambda(k, \lambda_0, c_0)$ belongs to $\overline{\mathbb{R}}_+$ as $u \in R(\tilde{P}^c_+(\lambda_0, c_0))$. If we add $\alpha' = -\alpha^2$, then $\tau = 1/\alpha$ and we see that at $\lambda = \lambda_0$, $c = c_0$, the origin $u = 0, u' = 0$, and $\alpha = 0$ (alias $\tau = \infty$) is an equilibrium with all eigenvalues of the linearization being situated on the imaginary axis. Exponential growth with rate $\eta^s_+ > 0$ arbitrarily small now follows from standard Gronwall estimates for bounded α, that is, choosing $\bar{r}$ bounded away from zero, and λ, c sufficiently close to λ_0, c_0. This proves the second inequality in (v).

Step 4. *Unstable projections, estimates.* Now let $\underline{u} \in E^k_{h,+}$. Our aim is to decompose $E^k_{h,+}$ in subspaces of exponentially decaying and exponentially growing solutions. We set

$$\tilde{u}(\tau) = \left(\frac{k^2}{\tau^2} + B^k_{\lambda_0,c_0}\right)^{1/2} u(\tau).$$

As here $B^k_{\lambda,c}$ does not have eigenvalues on $\overline{\mathbb{R}}_-$, we can use the standard square root cut along $\mathbb{R}_-$. Moreover the norm $|\underline{u}|_{E^k_\tau}$ is equivalent to $|\tilde{u}|_{\mathbb{C}^N} + |v|_{\mathbb{C}^N}$. Note that here we omitted the factor k^l, as it is independent of time and does not change the equations to be considered below. We write $\alpha = 1/\tau$ and $L(\alpha) = (k^2\alpha^2 + B^k_{\lambda_0,c_0})^{1/2}$. In the new variables, the differential equation on $E^k_{h,+}$ reads

$$\begin{aligned} \tilde{u}' &= L(\alpha)v + \partial_\alpha L(\alpha)\alpha' u \\ &= L(\alpha)v - \alpha^3 k^2 L^{-2}(\alpha)\tilde{u}, \\ v' &= -\alpha v + L(\alpha)\tilde{u}, \\ \alpha' &= -\alpha^2. \end{aligned} \tag{4.1}$$

Next, we set $|L^{-1}(\alpha)|\frac{d}{d\tau} = \frac{d}{ds}$ and obtain

$$\begin{aligned} \frac{d\tilde{u}}{ds} &= L|L^{-1}|v - \alpha^3 k^2 L^{-2}|L^{-1}|\tilde{u}, \\ \frac{dv}{ds} &= -\alpha|L^{-1}|v + L|L^{-1}|\tilde{u}, \\ \frac{d\alpha}{ds} &= -\alpha^2|L^{-1}|, \end{aligned} \tag{4.2}$$

with $L = L(\alpha)$. The linearization at $\tilde u = v = 0$, $\alpha = 0$,

$$\begin{aligned} \frac{d\tilde u}{ds} &= L|L^{-1}|v, \\ \frac{dv}{ds} &= L|L^{-1}|\tilde u, \\ \frac{d\alpha}{ds} &= 0, \end{aligned} \tag{4.3}$$

admits a projection $P(\tilde u, v) = \frac{1}{2}(\tilde u + v, \tilde u + v)$, which is independent of k and α. Therefore the flow $\tilde\Phi_0$ of (4.3) possesses uniform exponential dichotomies at $\tilde u = v = 0$. To see this, we first observe that for $s \le s_0$,

$$|\tilde\Phi_0(s, s_0)P|_{L(\mathbb{C}^{2N})} \le |e^{L|L^{-1}|(s-s_0)}|_{L(\mathbb{C}^{2N})}.$$

Now remember that by definition of the square root, the spectrum of L lies in the right half plane and is, for $|k| \to \infty, \alpha = 0$, asymptotic to $k^{1/2}e^{\pm i\pi/4}$. For finitely many k, we therefore obtain

$$\left|e^{-L|L^{-1}|t}\right|_{L(\mathbb{C}^{2N})} \le C_1 e^{-\eta_1 t}, \quad t > 0,$$

with some constants $C_1, \eta_1 > 0$, independent of k, α. As $k \to \infty$, we consider first $\tilde L = k^{-1/2}L$. Of course $\tilde L|\tilde L^{-1}| = L|L^{-1}|$. For k large, the operator $\tilde L_0 = (k\alpha^2 + D^{-1}ci)^{1/2}$ is a small (uniformly in α, k) perturbation of $\tilde L$. As $D > 0$, the spectrum of $D^{-1}i$ lies on $i\mathbb{R}^+$. Therefore the spectrum of $\tilde L_0$ lies in the right half plane, uniformly bounded away from the imaginary axis, and we can diagonalize $\tilde L_0$ by a transformation which is independent of α and k to obtain

$$\left|e^{-\tilde L_0|\tilde L_0^{-1}|t}\right|_{L(\mathbb{C}^{2N})} \le C_2 e^{-\eta_2 t}, \quad t > 0,$$

for some constants $C_2, \eta_2 > 0$, independent of α, k. By perturbation arguments, the same estimate holds true for $\tilde L$ and L, and we conclude

$$|\tilde\Phi_0(s; s_0)P|_{L(\mathbb{C}^{2N})} \le Ce^{\eta(s-s_0)}, \quad s \le s_0,$$

for some $C, \eta > 0$, independent of α and k. The calculation on $R(1-P)$ is the same and we obtain

$$|\tilde\Phi_0(s; s_0)(1-P)|_{L(\mathbb{C}^{2N})} \le \left|e^{-L|L^{-1}|(s-s_0)}\right|_{L(\mathbb{C}^{2N})} \le Ce^{-\eta(s-s_0)}, \quad s \ge s_0.$$

These two estimates together guarantee an exponential dichotomy for (4.3). Equation (4.2) is a perturbation of (4.3). We show that the perturbation of the vector field is $\mathrm{O}(\alpha)$, uniformly in k. By standard perturbation results on exponential dichotomies [2, 8], this then proves that (4.2) possesses an exponential dichotomy with projection $\tilde P(k, \alpha)$ and constants $\tilde C, \tilde\eta > 0$, independent of k, α as long as α is bounded.

The error terms we have to deal with are $\alpha^3k^2L^{-2}|L^{-1}|$ and $\alpha|L^{-1}|$. Of course for finite k these terms are $\mathrm{O}(\alpha)$. Consider now the first expression for large k:

$$\begin{aligned} \alpha^3k^2|L^{-3}| &= \alpha^3k^2|[\alpha^2k^2 + B^k_{\lambda_0,c_0}]^{-3/2}| \\ &\le \alpha^3k^2|[\alpha^2k^2 + D^{-1}cik + \mathrm{O}(1)]^{-1}| \cdot |D^{-1}cik + \mathrm{O}(1)|^{-1/2} \\ &= \left|\left[1 + D^{-1}ci\frac{1}{\alpha^2k}(1 + \mathrm{O}(1/k))\right]^{-1}\right| \cdot \mathrm{O}(\alpha k^{-1/2}). \end{aligned}$$

As $|[1 + D^{-1}ci\frac{1}{\alpha^2 k}]^{-1}| \le C_3$ uniformly in α, k, the above expression is $\mathrm{O}(\alpha k^{-1/2})$, uniformly in k. Next we consider the second error term $\alpha|L^{-1}|$:

$$\begin{aligned}\alpha|L^{-1}| &= \alpha|[\alpha^2k^2 + D^{-1}cik + \mathrm{O}(1)]^{-1/2}| \\ &= \alpha k^{-1/2}|\tilde{L}_0^{-1}(1 + \mathrm{O}(1/k))| \\ &= \mathrm{O}(\alpha k^{-1/2}).\end{aligned}$$

This proves uniform smallness of the perturbation. It remains to translate the exponential dichotomy rate $\tilde{\eta}$ into the correct time $\tau = \tau(s)$.

As $\frac{ds}{d\tau} = |L^{-1}(\alpha)|^{-1}$, it is sufficient to get α, k-uniform bounds $|L^{-1}(\alpha)|^{-1} \ge \eta_0 > 0$. This is precisely the type of estimate we developed above for $\alpha|L^{-1}|$. Indeed we showed that

$$|L^{-1}| = k^{-1/2}|\tilde{L}_0^{-1}|(1 + \mathrm{O}(1/k));$$

therefore η_0 can be chosen $\mathrm{O}(k^{1/2})$ as $k \to \infty$. This proves the lemma with $\eta_+^u = \eta_0\eta$ and η_+^s from step 3. □

4.3. Matching at $\bar{\tau} = 2\bar{r}$, the center space $E^c(\tau)$. We define $E^c(\tau) = \Phi_+^s(\tau,\tau)\Phi_-^u(\tau,\tau)X$, which, by the previous two lemmata, coincides with the definition of $E^c(\tau)$ as the initial values for Y_δ-bounded solutions if we only choose δ small enough. In order to prove the claim on the dimension of $E^c(\tau)$, we need a transversality result from the theory of Bessel functions. Suppose first that $\underline{u}(\bar{\tau}) \in E^0$, the subspace of radially homogeneous functions. For $\tau \to -\infty$ the linear equation in E^0 is $u_{\tau\tau} = e^{2\tau}\Lambda u$ with some matrix Λ, and clearly any solution is Y_δ-bounded as exponential rates of solutions coincide with the rates of the autonomous part $u_{\tau\tau} = 0$. So the negative orbit of $\underline{u}(\bar{\tau})$ is Y_δ-bounded. The positive orbit is bounded in Y_δ if and only if $\underline{u}(\bar{\tau}) \in P_+^c(\lambda_0, 0)E^0$; therefore $\dim E^c \cap E^0 = 2\dim \tilde{P}_+^c(\lambda_0,0)\mathbb{R}^N$. For the rest of this section we restrict to $(E^0)^\perp$, the nonhomogeneous Fourier modes. Recall that $P_+^c = \mathrm{diag}\,(\tilde{P}_+^c(\lambda_0,c_0), \tilde{P}_+^c(\lambda_0,c_0))$ and $P_+^h = 1 - P_+^c$ projects on the hyperbolic part of (3.2) at $r = \infty$. We claim that

$$\Phi_+^s(\bar{\tau},\bar{\tau})\Phi_-^u(\bar{\tau},\bar{\tau})P_+^h\underline{u} = 0 \tag{4.4}$$

for $\underline{u} \in (E^0)^\perp$. We decompose into Fourier modes $e^{ik\varphi}$ and minimal Jordan blocks Λ, and we consider

$$u'' + \frac{1}{\tau}u' - \frac{k^2}{\tau^2}u + \Lambda(k,\lambda_0,c_0)u = 0.$$

If Λ is semisimple, that is, $\Lambda \in \mathbb{C} \setminus \overline{\mathbb{R}}_+$, then the solutions of this scalar ODE are the Bessel functions. Indeed, we can write this equation as

$$r^2u'' + ru' + (-k^2 + (r\sqrt{\Lambda})^2)u = 0;$$

therefore

$$u(r) = u_0J_k(r\sqrt{\Lambda}) + u_1Y_k(r\sqrt{\Lambda}).$$

As $J_k(r) = r^k(1 + \mathrm{O}(r))$ and $Y_k(r) = r^{-k}(1 + \mathrm{O}(r))$ for $r \to 0$, if $k \ne 0$, solutions bounded close to $r = 0$ satisfy $u_1 = 0$. At infinity the J_k behave like

$$J_k(r) = \sqrt{\frac{2}{\pi r}}\left[\cos\left(r - \frac{k\pi}{2} - \frac{\pi}{4}\right) + \mathrm{O}(1/r)\right].$$

Solutions $u(r) = u_0 J_k(r\sqrt{\Lambda})$ can stay exponentially bounded by $e^{\delta r}$ as $r \to \infty$, for a small fixed δ, only if $\sqrt{\Lambda}$ is real. But then Λ is real and positive, that is, $u \in \tilde{P}^c_+ X$. This proves the required transversality result (4.4) for semisimple eigenvalues.

If Λ is a Jordan block we can rescale the principal vectors—without changing the angle between stable and unstable subspaces—to make it a small perturbation of its semisimple part. The transverse intersection persists for the nonsemisimple Jordan block.

Now suppose $u \in \tilde{P}^c_+ X$. Then the above reasoning showed that for any such u there is exactly one Y_δ-bounded solution. This implies $\dim (E^c(\tau) \cap (E^0)^\perp) = \dim R(\tilde{P}^c_+(\lambda_0, c_0)(E^0)^\perp)$ and proves the claim (iii) in Theorem 1 on the dimension of the invariant manifold, once it is constructed as a graph over $\{E^c(\tau);\ \tau \in \mathbb{R}\}$.

5. Nonlinear equations, proof of Theorem 1. With the estimates on the linearized equation at hand, it is fairly standard to construct invariant manifolds for the nonlinear equation. We consider (3.1).

PROPOSITION 4. *Under the conditions of Theorem* 1*, any Y^-_δ-bounded (or Y^+_δ-bounded) solution $\underline{u}(\tau, \tau_0)$ on $(-\infty, \tau_0]$ (or $[\tau_0, +\infty)$, respectively) satisfies*

$$\underline{u}(\tau, \tau_0) = \Phi^u_-(\tau, \tau_0)\underline{u}(\tau_0, \tau_0) + \int_{\tau_0}^{\tau} \Phi^u_-(\tau, \sigma)\mathcal{G}(\underline{u}(\sigma, \tau_0))d\sigma + \int_{-\infty}^{\tau} \Phi^s_-(\tau, \sigma)\mathcal{G}(\underline{u}(\sigma, \tau_0))d\sigma,$$

or

$$\underline{u}(\tau, \tau_0) = \Phi^s_+(\tau, \tau_0)\underline{u}(\tau_0, \tau_0) + \int_{\tau_0}^{\tau} \Phi^s_+(\tau, \sigma)\mathcal{G}(\underline{u}(\sigma, \tau_0))d\sigma + \int_{+\infty}^{\tau} \Phi^u_+(\tau, \sigma)\mathcal{G}(\underline{u}(\sigma, \tau_0))d\sigma,$$

respectively. On the other hand, the above integral equations possess for any $\underline{u}(\tau_0, \tau_0)$ a unique solution $\underline{u}(\tau, \tau_0)$ in $Y^\pm_\delta$ which depends C^K on $\underline{u}(\tau_0, \tau_0), \lambda, c, \tau$ and τ_0.

Proof. The integral operators are bounded operators on $Y^\pm_\delta$ and the Lipschitz constant of the nonlinearity $\mathcal{G}$ is small. Indeed

$$\mathrm{Lip}_{X_\tau} \mathcal{G} \le \mathrm{Lip}_{H^{l+1/2} \to H^l}[\tilde{F} - \tilde{F}_u],$$

which was supposed to be sufficiently small. Regularity of the unique fixed point can be proved as usually for center-manifolds; see [24] for example. □

We call the set

$$\left\{ \Phi^u_-(\tau, \tau)\underline{u} + \int_{-\infty}^{\tau} \Phi^s_-(\tau, \sigma)\mathcal{G}(\underline{u}(\sigma, \tau))d\sigma =: \Psi_-(\Phi^u_-(\tau, \tau)\underline{u});\ \underline{u} \in X \right\}$$

the center-unstable manifold $\mathcal{M}^{cu}_-(\tau)$ at $-\infty$ and the set

$$\left\{ \Phi^s_+(\tau, \tau)\underline{u} + \int_{\infty}^{\tau} \Phi^u_+(\tau, \sigma)\mathcal{G}(\underline{u}(\sigma, \tau))d\sigma =: \Psi_+(\Phi^s_+(\tau, \tau)\underline{u});\ \underline{u} \in X \right\}$$

the center-stable manifold $\mathcal{M}^{cs}_+(\tau)$ at $+\infty$, and we define

$$\mathcal{M}(\tau) = \mathcal{M}^{cu}_-(\tau) \cap \mathcal{M}^{cs}_+(\tau).$$

By definition, $\mathcal{M}(\tau) = \{\text{initial values at time } \tau \text{ of } Y_\delta\text{-bounded solutions}\}$. We have to show that $\mathcal{M}(\tau)$ is a smooth manifold, parameterized over $E^c(\tau)$.

Therefore, we have to solve $\Psi_+ - \Psi_- = 0$. The linearization is given by $\Phi^u_- - \Phi^s_+ = 0$. We already know that the kernel of this equation is exactly E^c, thus finite-dimensional. In order to apply the implicit function theorem we have to show that $\Phi^u_- - \Phi^s_+$ is surjective. We have to decompose $\underline{u} \in E^k$ into two vectors belonging to the range of Φ^s_+ and Φ^u_-, respectively, with estimates on the norms uniform with respect to k. The fact that we can decompose follows simply from the linear independence of the Bessel functions of the first and second kind J_k and Y_k (actually, we merely refer to purely imaginary arguments, the hyperbolic case, where the notation is I_k for the Bessel function bounded at $r = 0$ and K_k for the solution bounded at $r = \infty$). Estimates on the norms—for a fixed time τ—follow from uniform estimates on the Wronski determinant

$$\det \begin{pmatrix} I_k(\tau) & K_k(\tau) \\ I_k'(\tau) & K_k'(\tau) \end{pmatrix},$$

which in turn are an immediate consequence of the Taylor expansions at $r = 0$ of the Bessel functions; see for example [25]. As in section 4.3, Jordan blocks can be considered as a small perturbation. By Lyapunov–Schmidt reduction we can now solve $\Psi_+ - \Psi_- = 0$, parameterizing the set of solutions over the kernel of the linearization $E^c(\tau)$. This proves Theorem 1.

6. Local center-manifolds. If the nonlinearity $\tilde{F}$ does not have a small Lipschitz constant, which is usually the case in applications, we have to modify $\tilde{F}$.

We cut off $\tilde{F}$ outside a small neighborhood B_{ϵ_0} of zero with a smooth cutoff function in $H^{l+1/2}$, for example, the norm, which is invariant under the action of $\mathcal{SO}(2)$. Therefore let $\chi \in C^\infty([0,\infty), \mathbb{R})$ with $\chi(t) = 1$ if $t \le 1$ and $\chi(t) = 0$ if $t \ge 2$. Then define

$$\tilde{F}_{mod}(\lambda, u) = \chi(|u|^2_{H^{l+1/2}}/\epsilon_0)(\tilde{F}(\lambda, u) - \tilde{F}_u(\lambda, 0)u) + \tilde{F}_u(\lambda, 0)u.$$

The nonlinear part of $\tilde{F}_{mod}$ has an arbitrarily small Lipschitz constant if we make ϵ_0 sufficiently small, and thereby satisfies the conditions of Theorem 1. Any solution on the center-manifold to the modified nonlinearity $\tilde{F}_{mod}$, which has norm $\sup_\tau |\underline{u}(\tau)|_{X_\tau}$ small enough, will have $\sup_\tau |u(\tau)|_{H^{l+1/2}}$ small such that the modified nonlinearity coincides with the original nonlinearity on the solution $u(\tau)$, which is in consequence a solution to the original equation. Note that bounds on the norm in X_τ are by construction of $\mathcal{M}$ equivalent to bounds on the norms of the projection of the solution on $\{E^c(\tau);\ \tau \in \mathbb{R}\}$.

7. Regularity of solutions. The solutions $u(r, \varphi)$ we obtain are bounded in X_τ. By the smoothing property of the equation (which can be considered for any l, without changing $\mathcal{M}$), any solution is actually of class C^∞ with respect to $r > 0$ and φ, if F is—although $\mathcal{M}$ is not C^∞ in general! As $r \to \infty$, the angular derivatives $\partial^m_\varphi u(r, \varphi)$ are bounded for any m, which implies that the derivatives along curves $r \equiv$ const with respect to arclength $r d\varphi$ are of order $1/r^m$: patterns are slowly varying in the angular direction far away from the origin.

At $r = 0$ we have to be careful about smoothness of the solution. Suppose first that $E^c(\tau)$ does not contain solutions in the angular homogeneous subspace E^0. Then solutions in $E^c(\tau)$ are $\mathrm{O}(r) = \mathrm{O}(e^\tau)$ as $r \to 0$ and smooth in a neighborhood of the origin by interior elliptic regularity.

The homogeneous subspace can be—and has been—treated separately studying the ODE on $\mathrm{Fix}(\mathcal{SO}(2))$. Indeed there is a subspace of dimension N with solutions which actually stay bounded, whereas solutions outside this subspace have singularities of order $\log r$.

On the other hand, considering again τ-dynamics in $\mathcal{M}$, this subspace of homogeneous functions is fibered by strongly unstable fibers such that any solution in $\mathcal{M}$ converges with rate $\mathrm{O}(e^\tau)$ to a solution in the homogeneous subspace and inherits its regularity.

8. Center-manifolds at infinity. We construct a finite-dimensional invariant manifold which contains all solutions which are bounded at $\tau = +\infty$ but do not decay too rapidly. Recall that $P^c_+ = \mathrm{diag}\,(\tilde P^c_+, \tilde P^c_+)$ projects on the center part of (3.2) at $\alpha = 1/r = 1/\tau = 0$.

PROPOSITION 5. *Under the conditions of Theorem* 1*, consider equation* (3.1) *close to* $\underline{u} = 0$*. Fix* $\delta > 0$ *sufficiently small and* $K < \infty$*.*

Then there is an invariant C^K*-manifold* $\mathcal{M}^c_+$*, contained in* $\mathcal{M}^{cs}_+$ *and containing* $\mathcal{M}$*, given as a graph over* $\{R(P^c_+);\ \tau \in \mathbb{R}\}$*, smoothly depending on* λ, c*.*

Moreover there is a C^K*-flow on* $\mathcal{M}^c_+$ *such that any orbit is a solution of* (3.1) *and any solution* $\underline{u}(\tau)$ *of* (3.1) *with*

$$\sup_{\tau_0 \geq \tau > 2\bar r} e^{-\delta|\tau-\tau_0|} \frac{|\underline{u}(\tau)|_{X_\tau}}{|\underline{u}(\tau_0)|_{X_{\tau_0}}} < \infty$$

is contained in $\mathcal{M}^c_+$*.*

Proof. We start by constructing $\mathcal{M}^c_+$ for $0 < \alpha = 1/r \leq 1/2\bar r$ bounded. The manifold $\mathcal{M}^c_+$ is the union of center-unstable fibers of the zero-solution in the center-stable manifold $\mathcal{M}^{cs}_+$. These fibers can easily be shown to exist, using graph transformation (we have a smooth semiflow on $\mathcal{M}^{cs}_+$) or a Lyapunov–Perron approach as in [16]. The dependence on time $\alpha = 1/\tau$ is smooth as fibers are mapped into each other by the flow.

We have to ensure that we can arrange to have $\mathcal{M}$ included in $\mathcal{M}^c_+$. This can be achieved by either starting the graph transformation with graphs that contain $\mathcal{M}$ (and "feeding in" such graphs appropriately) or, referring to the Lyapunov–Perron approach of [16], including the manifold $\mathcal{M}$ in the fixed initial unstable fiber at $\tau = 2\bar r$ (see, for example, [16, at the end of section 3]).

We next have to continue this manifold for $\alpha > 1/2\bar r$ or, equivalently, for $\tau \to -\infty$. This will again be done using the methods from [16]. If we had an evolution-type equation we would propagate the manifold $\mathcal{M}^c_+$ with the flow. Here we do not have a flow! By [16], the equation possesses an exponential dichotomy which permits us to prove the existence of the center-unstable manifold $\mathcal{M}^{cu}_-$ (the union of unstable fibers over time τ), as pointed out in Lemma 2, and, furthermore, the existence of stable fibrations to any solution in $\mathcal{M}^{cu}_-$ for any fixed initial fiber at $\tau = 2\bar r$ (which is transversely intersecting $\mathcal{M}^{cu}_- \cap \{\tau = 2\bar r\}$). We are interested in the stable fibration induced by the manifold $\mathcal{M}^c_+$, which is of course not complementary to $\mathcal{M}^{cu}_-$. However, the methods from [16] can be adapted in order to guarantee precisely the existence of such a manifold. In the following we indicate how to make the necessary changes.

We solve the integral equation for stable and unstable fibrations with the restriction that the fiber at the initial time $\tau = 2\bar r$ belongs to a fixed manifold transverse to $\mathcal{M}^{cu}_-$ which we can choose to contain $\mathcal{M}^c_+ \cap \{\tau = 2\bar r\}$. On this smaller subspace the fixed-point equation for stable and unstable fibers still defines a contraction mapping and the solution is the desired global continuation of $\mathcal{M}^c_+$. The smoothness of the

union of the fibers as a manifold follows, because we can differentiate the fixed-point equation with respect to the base solution in the center-unstable manifold $\mathcal{M}^{cu}_{-}$. The exponential properties of the new fixed-point equation allow for a setting in the usual scale of exponentially weighted spaces [23], because the equation for the stable fiber at a fixed time τ involves only the finite time interval $[\tau, 1/2\bar{r}]$. We do not carry out the details, which include only straightforward modifications of smoothness proofs for fibrations (note, however, that we do not care about the limit $\tau = -\infty$—alias $r = 0$—of the fibration, which would lead to limitation in regularity of the fibration).

Of course the projected vector field is also smooth and thereby defines a smooth flow on the finite-dimensional manifold $\mathcal{M}^{c}_{+}$. □

The hypothesis $\tilde{F}(\lambda, 0) = 0$ was only needed in order to fix a reference solution in $\mathcal{M}^{cs}_{+}$, notably the zero solution. In general we could construct smooth fibrations along any solution in $\mathcal{M}^{cs}_{+}$.

The manifold $\mathcal{M}^{c}_{+}$ we constructed is very useful in order to describe bounded solutions near infinity, although most solutions on $\mathcal{M}^{c}_{+}$ are not bounded at the origin $r = 0$.

9. Hopf bifurcation and (λ, ω)-systems. We give the most simple nontrivial application of our main theorem. Suppose $D = \mathrm{id}$, $\tilde{F}(\lambda, 0) = 0$, $\lambda \in \mathbb{R}$, and $N = 2$; that is, $U \in \mathbb{R}^2$, which we identify with $\mathbb{C}$. Suppose that the homogeneous zero state undergoes a nondegenerate Hopf bifurcation in the space of homogeneous solutions:

$$\frac{d}{dU}\tilde{F}(\lambda, 0) = i\omega + \lambda, \quad \omega \neq 0.$$

We write U as a complex Fourier series $U(r, \varphi) = \sum_{k \in \mathbb{Z}} U^k(r) e^{ik\varphi}$. The spaces E^k are just the complex two-dimensional spans $\langle (e^{ik\varphi}, 0), (0, e^{ik\varphi}) \rangle$. The operator $B_{\lambda,c}$ acts on E^k as multiplication $B^k(\lambda, c) : U^k \to (cik - i\omega - \lambda)U^k$. Thereby $E^c(r) \leq E^{k_0}$ if $c_0 k_0 = \omega$. In other words, for any k(-armed spiral) there is a rotation speed $c = \omega/k$ such that rotating waves with this speed may bifurcate. Our analysis has shown that for other wave speeds, the homogeneous state is isolated as a rotating wave.

Let us comment on the symmetry. The flow on $\mathcal{M}$ projected on $E^c(r) \leq E^k$ is equivariant with respect to the action of $\mathcal{SO}(2)$:

$$(U, U') \to (Ue^{i\psi}, U'e^{i\psi}), \qquad \psi \in \mathbb{R}/2\pi\mathbb{Z} \simeq \mathcal{SO}(2).$$

This is exactly the same symmetry that authors usually *assumed* to be present in bifurcation equations, the so-called (λ, ω)-systems, modeling the creation of spiral waves; see [1]. We showed *rigorously* that the symmetry of (λ, ω)-systems, without any error term, is present in this type of bifurcation.

The actual solutions $U = U^k(r)e^{ik\varphi}$ of the linearized system in $E^c(\tau)$ are easily calculated: they solve $(U^k)'' + \frac{1}{r}(U^k)' = (k^2/r^2)U^k$ and are given as $U(r, \varphi) = U^c r^k e^{ik\varphi}, U^c \in \mathbb{C}$. Note that the invariant complement in E^k, spanned by $\tilde{U}(r, \varphi) = \tilde{U}^c r^{-k} e^{ik\varphi}, \tilde{U}^c \in \mathbb{C}$, converges as $E^c(r)$ to the same limit $\{(U, U');\ U' = 0\}$ as $\varphi \to \infty$. This is the reason why we constructed $\mathcal{M}^{c}_{+}$ tangent to E^k in section 8. The equation on $\mathcal{M}^{c}_{+}$ is a nonautonomous, $\mathcal{SO}(2)$-equivariant ODE in $\mathbb{C}^2$ with the linear part given by Bessel's differential equation. It can be smoothly extended to time $\tau = \infty (\alpha = 0)$, where the equation becomes autonomous. In order to determine existence and shape of rotating waves at $r = \infty$, we have to calculate expansions of the vector field on $\mathcal{M}^{c}_{+}$ and determine the ω-limit set of the two-dimensional slice $\mathcal{M}(\tau)$ in $\mathcal{M}^{c}_{+}$. We examine a simple model problem in the next sections.

10. An example. As an example we study the following reaction-diffusion system:

$$\begin{aligned} u_t &= d_1 \triangle u + \kappa u - v - a u^3, \\ v_t &= d_2 \triangle v + b u - \gamma v \end{aligned}$$

in the plane $x \in \mathbb{R}^2$. When $\kappa = \gamma$ and $b - \gamma\kappa > 0$, the pure reaction system undergoes a Hopf bifurcation in the origin $u = v = 0$. Rescaling u, v, t, and x, we may assume the system to be in the particular form

$$\begin{aligned} u_t &= \triangle u + \alpha u - \beta v - a u^3, \\ v_t &= \nu \triangle v + \beta u - \alpha v + \lambda v, \end{aligned}$$

with $\beta^2 - \alpha^2 = 1$ and $\alpha, \beta > 0$. We assume in the following that λ is close to zero; that is, we are close to a Hopf bifurcation with eigenvalues $\pm i$ of the linearized reaction system. The rotating wave ansatz yields

$$\begin{aligned} c u_\varphi &= \triangle_{r,\varphi} u + \alpha u - \beta v - a u^3, \\ c u_\varphi &= \nu \triangle_{r,\varphi} v + \beta u - \alpha v + \lambda v, \end{aligned} \tag{10.1}$$

where $\triangle_{r,\varphi} = \partial_{rr} + \frac{1}{r}\partial_r + \frac{1}{r^2}\partial_{\varphi\varphi}$. The linearization at $\lambda = 0, u = v = 0$ is

$$\begin{aligned} c u_\varphi &= \triangle_{r,\varphi} u + \alpha u - \beta v, \\ c v_\varphi &= \nu \triangle_{r,\varphi} v + \beta u - \alpha v. \end{aligned} \tag{10.2}$$

We now expand the solutions in Fourier series with respect to φ

$$(u, v) = \sum_{k \in \mathbb{Z}} (u^k, v^k) e^{ik\varphi}, \quad (u^{-k}, v^{-k}) = (\overline{u^k}, \overline{v^k}).$$

The linearization (10.2) then becomes an uncoupled system of ODEs for the Fourier coefficients

$$\begin{aligned} \triangle_{r,k} u^k &= (cik - \alpha) u^k + \beta v^k, \\ \nu \triangle_{r,k} v^k &= -\beta u^k + (cik + \alpha) v^k, \end{aligned}$$

where $\triangle_{r,k} = \partial_{rr} + \frac{1}{r}\partial_r - \frac{k^2}{r^2}$. The right side has a kernel as a linear operator on $\mathbb{C}^2$ whenever $ck = 1$. We therefore set $c = 1/k_0 + \mu$ with μ close to zero, having fixed $k_0 \in \mathbb{N}$ for the sequel.

Remember that together with the above equations we should write the equations for the complex conjugates, which are just the conjugate equations.

The eigenvector in the kernel is easily calculated as

$$w_0 = \beta u^k + \nu(i - \alpha) v^k, \quad \triangle_{r,k} w_0 = 0,$$

and

$$w_1 = -\beta u^k + (i + \alpha) v^k, \quad \triangle_{r,k} w_1 = \left(i - \alpha + \frac{i + \alpha}{\nu} \right) w_1$$

is the complementary eigenvector to the eigenvalue $i - \alpha + (i + \alpha)/\nu$.

Proposition 5 implies the existence of a center-manifold $\mathcal{M}^c_+$ with a smooth vector field, tangent to the span of $w_0 e^{ik_0\varphi}$ and $\partial_r w_0 e^{ik_0\varphi}$ at any "time" r. The vector field is obtained up to third order using the following strategy:

(i) Write the linear equation for w_0, depending on parameters λ, μ; this gives the linear part of the vector field on $\mathcal{M}_+^c$.

(ii) Calculate the quadratic (in w_0) expansion of $\mathcal{M}_+^c$ depending on time; this is zero, due to the absence of quadratic terms in the reaction.

(iii) Evaluate the nonlinearity au^3 on $w_0 e^{ik_0\varphi}$.

(iv) Project away noncritical Fourier modes.

(v) Project on $\langle w_0 e^{ik_0\varphi}\rangle$ along $\langle w_1 e^{ik_0\varphi}\rangle$.

Carrying out the necessary calculations gives first, by projecting away the noncritical Fourier modes,

$$\begin{aligned}\triangle_{r,k}u^k &= (i-\alpha)u^k + \beta v^k + i\mu u^k + au^k|u^k|^2,\\ \nu\triangle_{r,k}v &= -\beta u^k + (i+\alpha v^k) + i\mu v^k - \lambda v^k,\end{aligned}$$

and therefore

$$\triangle_{r,k}w_0 = i\mu\beta u^k + \beta a u^k|u^k|^2 - (i-\alpha)\lambda v^k + (i-\alpha)i\mu v^k.$$

Transforming back

$$\begin{aligned}u^k &= \frac{i+\alpha}{\beta(i+\alpha+\nu(i-\alpha))}w_0 + O(w_1),\\ v^k &= \frac{1}{i+\alpha+\nu(i-\alpha)}w_0 + O(w_1)\end{aligned}$$

gives, on $\mathcal{M}_+^c$, up to third order, the second-order-in-time ODE

$$\triangle_{r,k}w_0 = \frac{-2\mu-(i-\alpha)\lambda}{i+\alpha+\nu(i-\alpha)}w_0 + \frac{a}{\beta^2}\frac{1}{1+\nu\frac{i-\alpha}{i+\alpha}}\left|\frac{1}{1+\nu\frac{i-\alpha}{i+\alpha}}\right|^2 w_0|w_0|^2.$$

The fifth-order terms might of course destroy the second-order structure of this equation, although keeping the structure of a local nonautonomous differential equation in $\mathbb{C}^2$.

We write new parameters $\lambda', a' \in \mathbb{C}$ such that the truncated equation takes the form

$$(w_0)_{rr} + \frac{1}{r}(w_0)_r - \frac{k^2}{r^2}w_0 = \lambda' w_0 + a' w_0|w_0|^2. \tag{10.3}$$

Disregarding all of our efforts in reducing and simplifying the problem, this equation is in general still hard to solve analytically. In the following section we study this problem, obtaining existence of bounded solutions $w(r)$ (and thereby solutions $(u(r,\varphi), v(r,\varphi))$ to (10.1)), when a' is almost real. This is actually the approach taken by [7, 11], who deal with a similar system.

By our explicit calculations, the imaginary part of a' will be small if the diffusion rate ν or the parameter α is close to zero.

The first condition has an interesting interpretation as the limit $d_2 \to 0$ is exactly the interesting limit in excitable media, although we admit that our equation is different from the typical models for excitable media (the null-clines of $\alpha u - au^3 - v$ are symmetric to the origin whereas this is not the usual assumption for excitable media, modeled for example by the FitzHugh–Nagumo equation). We refer the reader to the interesting, although formal, work on spiral waves in excitable media reviewed in [22].

The second, alternative condition is merely an assumption on the location of equilibria in the pure reaction system, which are situated approximately at $u \sim \pm\sqrt{b/(a\alpha)}$ and zero.

The important point to notice at this stage is that the full equation on $\mathcal{M}_+^c$ is a small perturbation of the truncated equation close to the bifurcation point; that is, close to $\operatorname{Re}\lambda' = 0$. Indeed, scaling $|\operatorname{Re}\lambda'|r^2 = \tilde{r}^2$ and $w_0^2 = |\operatorname{Re}\lambda'|\tilde{w_0}^2$ makes the higher-order terms $\mathrm{O}(|\operatorname{Re}\lambda'|)$. Structurally stable dynamics of the truncated equation persist for the full system on $\mathcal{M}_+^c$ for sufficiently small $|\operatorname{Re}\lambda'|$.

In this sense, we have established a rigorous proof of the validity of approximations of reaction-diffusion systems by λ-ω systems, at least when we restrict to the question of existence of rotating wave solutions. This was proved up to now only using formal multiscale methods. The advantage of our approach is that it gives rigorous proofs and information on the domain of validity in parameter space of such kinds of approximations.

Furthermore, we should comment on the symmetry. The equation possesses, as announced, an $\mathcal{SO}(2)$-symmetry $w_0 \to w_0 e^{i\theta}$, $\theta \in S^1$. The additional reflection $(u, v) \to (-u, -v)$ in the original reaction-diffusion system does not yield any more symmetry in the bifurcation equation.

At $\operatorname{Im} a' = \operatorname{Im}\lambda' = 0$, there is the additional reflectional symmetry $w_0 \to \overline{w_0}$, fixing the real subspace. Note also that $\operatorname{Im}\lambda' = 0$ can be achieved by adjusting the wave speed c.

11. The bifurcation equations. During this section we omit the primes of λ and a. We begin with a study of possible asymptotic states of (10.3) at $r = \infty$. The limit equation

$$w'' = \lambda w + aw|w|^2, \quad {}' = \frac{d}{dr},$$

can be simplified by dividing out the symmetry with the new coordinates $z = z_R + iz_I = w'/w \in \bar{\mathbb{C}}$ and $R = |w| \in \mathbb{R}_+$:

$$\begin{aligned} R' &= z_R R, \\ z' &= -z^2 + \lambda + aR^2. \end{aligned} \tag{11.1}$$

Reversibility of the w-equation ($r \to -r$) is translated into reversibility with respect to the reflection $z \to -z$ (and, of course, $r \to -r$). Any equilibrium of (11.1) corresponds to a periodic orbit of the w-equation, which we call a rotating wave, as it is a relative equilibrium, for the dynamics in r, with respect to rotational symmetry $\mathcal{SO}(2)$. The asymptotic shape of a spiral wave behaving like such a rotating wave for large r is just a one-dimensional periodic wave-train, translation invariant in one space-direction. There are two types of equilibria. Type I has $R = 0$ and corresponds to the origin of the w-equation, and $z = \pm\sqrt{\lambda}$ are the blown up invariant manifolds of the equilibrium $w = w' = 0$. Type II has necessarily $z_R = 0$ and

$$R^2 = -\frac{\lambda_I}{a_I}, \quad z_I^2 = -\lambda_R + a_R\frac{\lambda_I}{a_I}.$$

A linear stability analysis gives that the type I equilibrium with $\operatorname{Re}\sqrt{\lambda} > 0$ is stable in $\{R = 0, z \in \bar{\mathbb{C}}\}$ and unstable in the direction of R. The equilibrium with $\operatorname{Re}\sqrt{\lambda} < 0$ is unstable in $\{R = 0, z \in \bar{\mathbb{C}}\}$ but stable in the direction of R. Along the type II

equilibria the linearization is

$$L = \begin{pmatrix} 0 & R & 0 \\ 2a_R R & 0 & 2z_I \\ 2a_I R & -2z_I & 0 \end{pmatrix}, \qquad \det L = -4\lambda_I z_I, \quad \operatorname{trace} L = 0,$$

such that one equilibrium is two-dimensional unstable and the other is two-dimensional stable.

Bifurcations occur at $\operatorname{Re}\sqrt{\lambda} = 0$, where type I equilibria coalesce, the origin becomes a center, and when $a\bar{\lambda} \in \mathbb{R}$, where a reversible saddle-node bifurcation of the type II equilibria occurs.

For the nonautonomous system, we can interpret the manifold $\mathcal{M}$ as a shooting manifold, which is two-dimensional in (w, w')-space at any fixed time r, invariant under the symmetry and therefore yields a one-dimensional shooting curve in the reduced phase space (z, R). We focus here on asymptotically stationary behavior, where the shooting curve intersects the stable manifold of an equilibrium of (11.1). These are possibly not the only asymptotic shapes at large distances from the center of rotation, but they seem to be of sufficient physical relevance, making such a restriction reasonable.

In the following, we distinguish two different cases which we refer to as the subcritical case, when $a_R > 0$, and the supercritical case, when $a_R < 0$. These terms are justified by the branching of equilibria of (11.1) at $\lambda_I = a_I = 0$. In our model problem of the preceding section, these two cases are distinguished by the sign of $a(1 - \nu(\alpha^2 - 1)/\beta^2)$.

We now study the real subsystem in the nonautonomous setting.

LEMMA 6 (supercritical [5, 11]). *Suppose $a_R < 0$ and $\lambda_R > 0$. Then for any wave number $k_0 \in \mathbb{N}$, there exists a heteroclinic orbit $w(r) > 0$, with $\lim_{r\to 0} w(r) = 0$ and $\lim_{r\to\infty} w(r) = \sqrt{-\lambda_R/a_R}$. Moreover the heteroclinic orbit is transverse in the real subsystem: the center-manifold $\mathcal{M}$ intersects transversely the stable manifold of $\sqrt{-\lambda_R/a_R}$.*

Proof. The proof of this lemma can be found in [11], where the necessary modifications to the proof of a similar statement in [5] are indicated. □

LEMMA 7 (subcritical). *Suppose $a_R > 0$ and $\lambda_R < 0$. Then for any $k_0 \in \mathbb{N}$, there exists a heteroclinic orbit $w(r)$, with $\lim_{r\to 0} w(r) = \lim_{r\to\infty} w(r) = 0$. Moreover the heteroclinic orbit is transverse in the real subsystem: the manifold $\mathcal{M}$ intersects transversely the stable manifold of the origin at $r = \infty$.*

Proof. The proof, together with a more detailed description of such solutions, can be found in [20]. □

We next examine the nondegenerate system with $a_I \neq 0$.

PROPOSITION 8 (supercritical, $a_I \neq 0$). *Suppose $a_R < 0$ and $\lambda_R > 0$ and fix any wave number $k_0 \in \mathbb{N}$. Then for any a_I, λ_I sufficiently small and $\lambda_I/a_I - 1 \gg a_I^2$ there exists a heteroclinic orbit $w(r)$, with $\lim_{r\to 0} w(r) = 0$ and tending to a type* II *equilibrium as $r \to \infty$. The heteroclinic orbit is transverse. Moreover there exists a unique value $\lambda_I^0 = \mathrm{O}(a_I)$ such that the heteroclinic orbit tends to the other type* II *equilibrium as $r \to \infty$. This heteroclinic orbit is transversely unfolded by the parameter λ_I.*

Proof. We suppose $a_R = -1$ and $\lambda_R = 1$. We use singular perturbation methods in order to establish the existence of heteroclinic orbits for the perturbed system. At $a_I = \lambda_I = 0$, there is a curve of type II equilibria for the asymptotic equations at $r = \infty$, given by $z_I^2 = 1 - R^2$, which intersects transversely the real subspace at the

equilibrium $z = 0, R = 1$. Therefore the center-stable manifold of this line of equilibria intersects transversely the shooting manifold $\mathcal{M}$ in (z, R, τ)-space. In the perturbed system, the line of equilibria persists as a normally hyperbolic slow manifold (see [3]). The heteroclinic as a transverse intersection persists as the intersection with a strong stable fiber of the slow manifold for a_I, λ_I small enough. On the slow manifold there are two equilibria $z_I^2 = -1 - \lambda_I/a_I$, which are close to the real subspace $\{z_I = 0\}$ if $-\lambda_I/a_I$ is close to but bigger than one. By the above stability analysis, the equilibrium which is stable within the slow manifold has $\det L > 0$ and thereby $\lambda_I z_I < 0$. We now have to examine the perturbation of the shooting manifold $\mathcal{M}$ by the complex perturbation terms involving λ_I and a_I. The derivative along the real heteroclinic at $\lambda_I = a_I = 0$ of the nonautonomous equation for z_I with respect to λ_I and a_I gives

$$z_I' = \lambda_I + a_I R^2 = a_I(\lambda_I/a_I + R^2).$$

Thereby the Melnikov integral along the heteroclinic gives a contribution $\mathrm{O}(a_I)$, which shows that the shooting manifold $\mathcal{M}$ intersects transversely a stable fiber of a point on the slow manifold with $z_I^0 = \mathrm{O}(a_I)$.

With these ingredients we can establish the existence of the desired connections. First choosing λ_I as a parameter, the shooting manifold $\mathcal{M}$ crosses transversely the strong stable fibers of the slow manifold. The type II equilibria on the slow manifold are located at $\mathrm{O}(\sqrt{|\lambda_I/a_I + 1|})$. If $|z_I^0| < \sqrt{|\lambda_I/a_I - 1|}$, there is a heteroclinic trajectory connecting to the type II equilibrium, which is stable within the slow manifold. If $(z_I^0)^2 = -\lambda_I/a_I - 1$, the heteroclinic trajectory connects to the type II equilibrium, which is unstable on the slow manifold. This proves the proposition. □

PROPOSITION 9 (subcritical, $a_I \neq 0$). *Suppose $a_R > 0$ and $\lambda_R < 0$ and fix any wave number $k_0 \in \mathbb{N}$. Then for any a_I sufficiently small, there exists a smooth function $\lambda_I = \lambda_I(a_I)$ such that there exists a heteroclinic orbit $w(r)$, with $\lim_{r\to 0} w(r) = \lim_{r\to\infty} w(r) = 0$. The heteroclinic orbit is transversely unfolded by the parameter λ_I.*

Proof. We suppose $a_R = 1$ and $\lambda_R = -1$. In the real subspace at $\lambda_I = a_I = 0$, the heteroclinic orbit joining the origin at $r = 0$ to the origin at $r = \infty$ is transverse by Lemma 7. Transverse to the real subspace, the origin is unstable at both $r = 0$ and $r = \infty$: the heteroclinic is nontransverse in full-space. We now need the parameter λ_I (alias the speed of rotation) in order to obtain connections for specific values of the parameter $\lambda_I = \lambda_I(a_I)$. For this it is sufficient to show that the Melnikov integral with respect to the parameter λ_I along the heteroclinic does not vanish. The adjoint variational equation along the heteroclinic has a unique (up to scalar multiples) bounded solution which lies strictly in the half space $z_I > 0$, because $z_I = 0$ is invariant. The derivative of the vector field with respect to λ_I in the direction of this half space is just 1, which proves that the Melnikov integral is nonzero. In other words we can push through the stable and unstable manifolds with the help of λ_I with nonzero speed. This proofs the proposition. □

12. Conclusions. For a large class of reaction-diffusion systems we have shown the existence of spiral wave solutions. In contrast to the previous results on λ-ω systems, our reduction to a nonautonomous ODE is not based on the *assumption* that Fourier modes decouple. We merely show that, close to the threshold of instability of a homogeneous equilibrium, there is some kind of decoupling. The interaction between critical modes is in a smooth sense of higher order than the projection on the critical modes. Compared to similar reduction methods, technical complications arise here

because the problem is nonautonomous, even in the principal part (from a regularity point of view).

As another advantage of our method, we are able to determine explicitly coefficients in our bifurcation equations. These are in general still hard to analyze analytically—we considered a simple but interesting model problem in the last section—but can easily be studied numerically.

The reduction procedure can be applied to other problems, possibly involving higher-dimensional center-manifolds. A systematic treatise of such equations (as known for elliptic problems in infinite cylinders, exploiting reversibility, integrability, and normal forms of the reduced bifurcation equations) would be interesting.

The rotating waves we discover are of various shape, depending on the nature of the bifurcation. In supercritical bifurcations, they are approximately archimedian spirals at large distances from the tip. Indeed, the derivative of the phase of u is given by z_I and approaches for large values of the radius r a constant but nonzero value. As a subtle difference we noticed that in the supercritical case there are two different types of asymptotic states, given by the two different types of equilibria $z_I = \pm\sqrt{-\lambda_I/a_I - 1}$ (see the preceding section). For the first type, z_I approaches its limit value exponentially at a uniform rate with respect to λ_I, whereas for the other type the exponential rate is close to zero. The sign of z_I has another important interpretation. If z_I is positive, then the arms turn in the sense of the rotation of the spiral; at a fixed ray, under time evolution of the reaction-diffusion system, the arms move toward the center of rotation. Similarly, $z_I < 0$ corresponds to an outwards movement of the arms. Therefore the waves, appearing for discrete wave speeds, move outward if $a_I < 0$ and inward if $a_I > 0$.

The rotating waves bifurcating subcritically are isolated as rotating waves and appear for distinguished speeds of rotation. Their shape at large distances from the center of rotation is determined by the phase varying according to $\varphi \sim e^{-\mathrm{const}\cdot r}$ and their amplitude decaying to zero exponentially.

Although we do not carry out here a stability analysis, we comment on the difference between sub- and supercritical bifurcation. Linearizing the reaction-diffusion system along the subcritical waves in, say, $L^2(\mathbb{R}^2, \mathbb{R}^2)$ gives us a linearized operator for the period map whose continuous spectrum is strictly contained in the left half plane, bounded away from the imaginary axis. Zero is (at least) a triple eigenvalue due to the Euclidean symmetry, generated by rotation and translations. An analysis of secondary bifurcations from this type of spiral wave, including meandering and drifting waves, has been carried out in [17, 18] and [4].

The linearized period map along supercritical waves has zero in the essential spectrum and rigorous stability proofs seem to be hard. Hagan [7] showed that one-armed spiral waves might be stable whereas multiarmed waves ($k_0 \neq 1$) should be unstable.

THE SURFACE DIFFUSION FLOW FOR IMMERSED HYPERSURFACES*

JOACHIM ESCHER†, UWE F. MAYER‡, AND GIERI SIMONETT‡

Abstract. We show existence and uniqueness of classical solutions for the motion of immersed hypersurfaces driven by surface diffusion. If the initial surface is embedded and close to a sphere, we prove that the solution exists globally and converges exponentially fast to a sphere. Furthermore, we provide numerical simulations showing the creation of singularities for immersed curves.

Key words. surface diffusion, mean curvature, free boundary problem, immersed hypersurfaces, center manifolds, maximal regularity, numerical simulations

1. Introduction.

In this paper we study the motion of a family of immersed hypersurfaces whose normal velocity is equal to its surface diffusion. More precisely, let Γ_0 be a compact closed immersed orientable hypersurface in $\mathbb{R}^n$ of class $C^{2+\beta}$. We are looking for a family $\Gamma = \{\Gamma(t); t \geq 0\}$ of smooth immersed orientable hypersurfaces satisfying the following evolution equation:

$$V(t) = \Delta_{\Gamma(t)} H_{\Gamma(t)}\,, \qquad \Gamma(0) = \Gamma_0\,. \tag{1.1}$$

Here $V(t)$ denotes the velocity in the normal direction of Γ at time t, while $\Delta_{\Gamma(t)}$ and $H_{\Gamma(t)}$ stand for the Laplace–Beltrami operator and the mean curvature of $\Gamma(t)$, respectively. Both the normal velocity and the curvature depend on the local choice of the orientation; however, (1.1) does not, and so we are free to choose whichever one we like. In particular, if $\Gamma(t)$ is embedded and encloses a region $\Omega(t)$, we always choose the *outer* normal, so that V is positive if $\Omega(t)$ grows and so that $H_{\Gamma(t)}$ is positive if $\Gamma(t)$ is convex with respect to $\Omega(t)$. Due to the local nature of the evolution, we may assume the hypersurface Γ_0 to be connected.

In order to give precise results, let us introduce the following notation. Given an open set $U \subset \mathbb{R}^n$, let $h^s(U)$ denote the little Hölder spaces of order $s > 0$, that is, the closure of $BUC^\infty(U)$ in $BUC^s(U)$, the latter space being the Banach space of all bounded and uniformly Hölder continuous functions of order s. If Σ is a (sufficiently) smooth submanifold of $\mathbb{R}^n$ then the spaces $h^s(\Sigma)$ are defined by means of a smooth atlas for Σ.

THEOREM 1.1. *Assume that $0 < \beta < 1$, and let Γ_0 be a compact closed immersed orientable hypersurface in $\mathbb{R}^n$ belonging to the class $h^{2+\beta}$.*

(a) *The surface diffusion flow* (1.1) *has a unique local classical solution $\Gamma = \{\Gamma(t); t \in [0,T)\}$ for some $T > 0$. Each hypersurface $\Gamma(t)$ is of class C^∞ for $t \in (0,T)$. Moreover, the mapping $[t \mapsto \Gamma(t)]$ is continuous on $[0,T)$ with respect to the $h^{2+\beta}$-topology and smooth on $(0,T)$ with respect to the C^∞-topology.*

*Received by the editors April 23, 1997; accepted for publication (in revised form) December 8, 1997; published electronically August 3, 1998.

(b) *Suppose that the initial hypersurface* Γ_0 *is a* $h^{2+\beta}$*-graph in normal direction over some smooth immersed hypersurface* Σ*. Then the mapping* $\varphi := [(t, \Gamma_0) \mapsto \Gamma(t)]$ *induces a smooth local semiflow on an open subset of* $h^{2+\beta}(\Sigma)$*.*

Remark. The assumption that the initial surface be orientable is not necessary for Theorem 1.1(a) to hold true.

This follows by evolving the double cover in case the initial hypersurface is not orientable. The double cover remains a double cover by uniqueness of smooth solutions, and (1.1) is invariant with respect to the local orientation, as noted before. Hence, one can go back to the quotient space which therefore also evolves according to the surface diffusion flow. □

The motion given by (1.1) has some interesting geometrical features. Assume that Γ is a smooth orientable solution to (1.1) and let $\mathcal{A}(t)$ denote the area of $\Gamma(t)$. Then the function $\mathcal{A}$ is smooth and we find for its derivative (e.g., see [22, Theorem 4] or [15, p. 70])

$$\begin{aligned} \frac{1}{n-1}\frac{d}{dt}\mathcal{A}(t) &= \int_{\Gamma(t)} V(t) H_{\Gamma(t)}\, d\sigma = \int_{\Gamma(t)} [\Delta_{\Gamma(t)} H_{\Gamma(t)}] H_{\Gamma(t)}\, d\sigma \\ &= -\int_{\Gamma(t)} |\mathrm{grad}_{\Gamma(t)} H_{\Gamma(t)}|^2_{\Gamma(t)} d\sigma \le 0\,. \end{aligned} \tag{1.2}$$

Hence the motion driven by surface diffusion is area decreasing.

It is also possible to identify the surface diffusion flow as an H^{-1}-gradient flow for the area functional; see [10, 25]. The notion of such gradient flows was proposed by Fife [19, 20].

Assume that Γ is a smooth solution to (1.1) consisting of embedded hypersurfaces which enclose a region $\Omega(t)$, and let $\mathrm{Vol}(t)$ denote the volume of $\Omega(t)$. The derivative of the smooth function Vol is then given by

$$\frac{d}{dt}\mathrm{Vol}(t) = \int_{\Gamma(t)} V(t)\, d\sigma = \int_{\Gamma(t)} \Delta_{\Gamma(t)} H_{\Gamma(t)}\, d\sigma = 0\,,$$

thus the motion driven by surface diffusion is also volume preserving in the embedded case. Every Euclidean sphere is an equilibrium for (1.1), and it follows from Alexandrov's characterization [1] of embedded constant mean curvature surfaces that spheres are the only equilibria. However, none of these equilibria is isolated, since in every neighborhood of a fixed sphere there is a continuum of further spheres. Thus the dynamics of the flow generated by (1.1) is even locally quite copious.

THEOREM 1.2. *Let* S *be a fixed Euclidean sphere and let* $\mathcal{M}$ *denote the set of all spheres which are sufficiently close to* S*. Then* $\mathcal{M}$ *attracts all embedded solutions which are* $h^{2+\beta}(S)$*-close to* $\mathcal{M}$ *at an exponential rate. In particular, if* Γ_0 *is sufficiently close to* S *in* $h^{2+\beta}(S)$*, then* Γ *exists globally and converges exponentially fast to some sphere in* $\mathcal{M}$ *enclosing the same volume as* Γ_0*. The convergence is in the* C^k*-topology for every initial hypersurface* Γ_0 *which is in a sufficiently small* $h^{2+\beta}(S)$*-neighborhood* $W = W(k)$ *of* S*, where* $k \in \mathbb{N}$ *is a fixed number.*

The surface diffusion flow (1.1) was first proposed by Mullins [26] to model surface dynamics for phase interfaces when the evolution is only governed by mass diffusion in the interface. It has also been examined in a more general mathematical and physical context by Davì and Gurtin [13], and by Cahn and Taylor [9]. More recently, Cahn, Elliott, and Novick-Cohen [8] showed by formal asymptotics that the surface diffusion flow is the singular limit of the zero level set of the solution to the Cahn–Hilliard

equation with a concentration-dependent mobility. In the case of constant mobility in the Cahn–Hilliard equation, Alikakos, Bates, and Chen [2] proved that the motion of the singular limit is governed by the Mullins–Sekerka model (also called the Hele–Shaw model with surface tension), rigorously establishing a result that was formally derived by Pego [27]. The Mullins–Sekerka model shares many properties with the surface diffusion flow (1.1). They both preserve the enclosed volume and decrease the area of the interface, and for both the invariant manifold $\mathcal{M}$ of spheres is exponentially attracting; see [16, 17, 18].

In two dimensions and for strip-like domains, the surface diffusion flow was investigated by Baras, Duchon, and Robert [7]. They prove global existence of weak solutions. Also in two dimensions, the surface diffusion flow for closed embedded curves was analytically investigated by Elliott and Garcke [14]. They show local existence and regularization for C^4-initial curves, and global existence for small perturbations of circles. Furthermore, assuming global existence, they show that any closed curve will become circular under this evolution. They do not obtain uniqueness of solutions. Recently, Giga and Ito [21] established the existence of unique (local) solutions for immersed H^4-initial curves. Moreover, they prove that the surface diffusion flow can drive an initially embedded curve to a self intersection. The techniques in [14, 21] seem to be restricted to two dimensions.

Our methods work in any dimension, and we obtain existence and uniqueness for immersed hypersurfaces. This is of particular interest since embedded hypersurfaces can become immersed under the surface diffusion flow, which is in clear contrast to the mean curvature flow where smooth solutions remain embedded if their initial surface is embedded. Our numerical simulations show that an immersed curve can develop singularities under the surface diffusion flow. Our example consists of a curve with a loop within a loop where the inner loop tightens and then contracts to a point. This situation has been analyzed in great detail by Angenent [6] for the mean curvature flow. In case of surface diffusion we do not have an analytical proof for the occurrence of singularities. We also give an example showing that an immersed curve evolves towards a stable limiting configuration which is not an embedded circle, but a multiply covered immersed circle. Finally, we provide evidence that the surface diffusion flow shrinks a figure eight to a point in finite time. Our approach for proving existence and uniqueness of solutions can be used to set up the numerical scheme for our simulations.

In case the initial hypersurface has several components, it is clear that some components may collide under the surface diffusion flow. This is most easily seen by choosing any nonstationary initial hypersurface, and then placing a stationary sphere in its path.

Theorem 1.1 constitutes a precise local existence and uniqueness result for classical solutions to (1.1) starting out as immersed hypersurfaces. In particular, the results disclose a parabolic regularization of the flow φ since we are allowed to choose initial surfaces Γ_0 of class $h^{2+\beta}$, although $\Delta_{\Gamma_0} H_{\Gamma_0}$ is for such Γ_0 in general not a classical function. This parabolic structure also provides the foundation for the study of the qualitative behavior of the semiflow φ. Our approach for proving existence, uniqueness, and regularity of solutions is based on the general theory of Amann [3, 4] for quasi-linear parabolic evolution equations.

The proof of Theorem 1.2 consists of two steps. We first show that the semiflow φ admits a stable $(n+1)$-dimensional local center manifold $\mathcal{M}^c$. This means, in particular, that $\mathcal{M}^c$ is a locally invariant manifold and that $\mathcal{M}^c$ contains all small global

solutions of φ. In a second step we then prove that $\mathcal{M}^c$ coincides with the manifold $\mathcal{M}$ of the theorem. It is well-known that local center manifolds are generally not unique. However, since each local center manifold of the surface diffusion flow consists only of equilibria, this forces uniqueness. Under suitable spectral assumptions for the linearization, the existence of center manifolds is well known for finite-dimensional dynamical systems. The corresponding construction for quasi-linear infinite-dimensional semiflows (e.g., for φ) is considerably more involved. The basic technical tool here is the theory of maximal regularity, due to Da Prato and Grisvard [11]; see also [4, 5, 23]. In particular, these results allow to treat (1.1) as a fully nonlinear perturbed linear evolution equation; see [12, 23, 29].

2. Existence and uniqueness. In this section we introduce the mathematical setting in order to reformulate (1.1) as a quasi-linear parabolic evolution equation. Let Σ be a smooth compact closed immersed oriented hypersurface in $\mathbb{R}^n$, and assume that Γ_0 is close to this fixed reference manifold Σ. Let ν be the unit normal field on Σ commensurable with the chosen orientation. Choose $a > 0$ and an open covering $\{U_l\,;\, l = 1, \dots, m\}$ of Σ such that

$$X_l : U_l \times (-a, a) \to \mathbb{R}^n\,, \qquad X_l(s, r) := s + r\nu(s)$$

is a smooth diffeomorphism onto its image $\mathcal{R}_l := \mathrm{im}(X_l)$, that is,

$$X_l \in \mathit{Diff}^\infty(U_l \times (-a, a), \mathcal{R}_l)\,, \qquad 1 \le l \le m\,.$$

This can be done by choosing the open sets $U_l \subset \Sigma$ in such a way that they are embedded in $\mathbb{R}^n$ instead of only immersed, and then taking $a > 0$ sufficiently small so that each of the U_l has a tubular neighborhood of radius a. It is convenient to decompose the inverse of X_l into $X_l^{-1} = (S_l, \Lambda_l)$, where

$$S_l \in C^\infty(\mathcal{R}_l, U_l) \qquad \text{and} \qquad \Lambda_l \in C^\infty(\mathcal{R}_l, (-a, a))\,.$$

Note that $S_l(x)$ is the nearest point on U_l to $x \in \mathcal{R}_l$, and that $\Lambda_l(x)$ is the signed distance from x to U_l (that is, to $S_l(x)$). Moreover, the union of the sets $\mathcal{R}_l$, $1 \le l \le m$, consists exactly of those points in $\mathbb{R}^n$ with distance less than a to Σ.

Let $T > 0$ be a fixed number. We assume that $\Gamma := \{\Gamma(t),\, t \in [0, T)\}$ is a family of immersed graphs in normal direction over Σ. To be precise, we ask that there is a globally defined function

$$\rho : \Sigma \times [0, T) \to (-a, a)$$

such that for fixed $t \in [0, T)$, a manifold $\Gamma(t)$ is locally given by the images of the maps $[s \mapsto X_l(s, \rho(s, t))]$, $1 \le l \le m$.

Conversely, given any (sufficiently) smooth function $\rho : \Sigma \times [0, T) \to (-a, a)$, let

$$\Phi_{l,\rho} : \mathcal{R}_l \times [0, T) \to \mathbb{R}\,, \qquad \Phi_{l,\rho}(x, t) := \Lambda_l(x) - \rho(S_l(x), t)\,, \quad 1 \le l \le m\,. \tag{2.1}$$

Then for each $t \in [0, T)$, the zero-level set $\Phi_{l,\rho}^{-1}(0, t) \subset \mathcal{R}_l$ defines a smooth hypersurface, and the hypersurfaces $\Phi_{l,\rho}^{-1}(0, t)$ can be glued together to constitute a compact closed immersed orientable hypersurface $\Gamma_{\rho(t)}$. It is then easy to see that

$$\Gamma_{\rho(t)} = \Gamma(t) = \bigcup_{l=1}^{m} \mathrm{Im}\left(X_l : U_l \to \mathbb{R}^n\,,\ [s \mapsto X_l(s, \rho(s, t))]\right).$$

In addition, the normal velocity V of $\Gamma := \{\Gamma_{\rho(t)} \,;\, t \in [0,T)\}$ at time t and at the point $x = X_l(s,\rho(s,t))$, expressed as a function over U_l, is given by

$$V(s,t) = -\left.\frac{\partial_t \Phi_{l,\rho}(x,t)}{|\nabla_x \Phi_{l,\rho}(x,t)|}\right|_{x=X_l(s,\rho(s,t))} = \left.\frac{\partial_t \rho(s,t)}{|\nabla_x \Phi_{l,\rho}(x,t)|}\right|_{x=X_l(s,\rho(s,t))}$$

for $(s,t) \in U_l \times (0,T)$. In the following, we fix $t \in [0,T)$ and drop it in our notation. Moreover, we fix $0 < \alpha < \beta < 1$ and define

$$\mathfrak{A} := \{\rho \in h^{2+\alpha}(\Sigma) \,;\, \|\rho\|_{C(\Sigma)} < a\}\,.$$

Then for any $\rho \in \mathfrak{A}$,

$$\theta_\rho \,:\, \Sigma \to \Gamma_\rho, \qquad \theta_\rho(s) := X_l(s,\rho(s)) \text{ for } s \in U_l\,,$$

is a well-defined global $(2+\alpha)$-diffeomorphism. We write Δ_{Γ_ρ} for the Laplace–Beltrami operator of Γ_ρ and H_{Γ_ρ} for the mean curvature of Γ_ρ. Finally, let

$$G(\rho) := -L_\rho \theta_\rho^*(\Delta_{\Gamma_\rho} H_{\Gamma_\rho}) \quad \text{for} \quad \rho \in h^{4+\alpha}(\Sigma) \cap \mathfrak{A}\,,$$

where $L_\rho(s) := \theta_\rho^* |\nabla_x \Phi_{l,\rho}|(s)$ for $s \in U_l$, $1 \le l \le m$. On the phase space

$$\mathcal{V} := h^{2+\beta}(\Sigma) \cap \mathfrak{A},$$

we are now considering the following evolution equation for the distance function ρ:

$$\partial_t \rho + G(\rho) = 0\,, \qquad \rho(0) = \rho_0\,, \tag{2.2}$$

where ρ_0 is a function on Σ determined by Γ_0. More precisely, given $\rho \in \mathcal{V}$, we call a family $\rho \,:\, [0,T) \to \mathcal{V}$ a classical solution of (2.2) if

$$\rho \in C([0,T),\mathcal{V}) \cap C^\infty((0,T),C^\infty(\Gamma))$$

and if ρ satisfies (2.2) pointwise for $t \in (0,T)$. It is not difficult to see that the surface diffusion flow (1.1) and the evolution equation (2.2) are equivalent on $\mathcal{R} := \cup_{l=1}^m \mathcal{R}_l$. That is, if $\Gamma := \{\Gamma(t) \,;\, t \in [0,T)\}$ is a classical solution of (1.1) such that $\Gamma(t) \subset \mathcal{R}$ for $t \in [0,T)$, then the above construction yields a classical solution of (2.2) and vice-versa; if $\rho \,:\, [0,T) \to \mathcal{V}$ is a classical solution of (2.2), then $\Gamma := \{\Gamma_{\rho(t)} \,;\, t \in [0,T)\}$ is a classical solution of (1.1).

In order to state our next result, let E_1 and E_0 be Banach spaces with $E_1 \hookrightarrow E_0$, and let $\mathcal{H}(E_1,E_0)$ be the set of all $A \in \mathcal{L}(E_1,E_0)$ such that $-A$, considered as an unbounded operator in E_0, generates a strongly continuous analytic semigroup on E_0. It can be shown that $\mathcal{H}(E_1,E_0)$ is open in $\mathcal{L}(E_1,E_0)$; cf. [4, Theorem 1.3.1]. We always assume that $\mathcal{H}(E_1,E_0)$ carries the corresponding relative topology. Recall that we already fixed $0 < \alpha < \beta < 1$. Now, in addition, pick $\beta_0 \in (\alpha,\beta)$ and let

$$\mathcal{U} := h^{2+\beta_0}(\Sigma) \cap \mathfrak{A}\,.$$

LEMMA 2.1. *There exist*

$$P \in C^\infty(\mathcal{U},\mathcal{H}(h^{4+\alpha}(\Sigma),h^\alpha(\Sigma)))\,, \quad F \in C^\infty(\mathcal{U},h^{\beta_0}(\Sigma))\,,$$

such that

$$G(\rho) = P(\rho)\rho + F(\rho), \qquad \rho \in h^{4+\alpha}(\Sigma) \cap \mathfrak{A}\,.$$

Proof. (a) The first step is to define a metric on Σ that lends itself well for computations in local coordinates. We choose a system of local coordinates on Σ, where we can assume that the sets U_l, $1 \le l \le m$, are exactly the domains of the charts. We fix some index $l \in \{1, \dots, m\}$ and we let η be the restriction of the Euclidean metric on $\mathcal{R}_l \subset \mathbb{R}^n$. Now define the pull-back metric

$$g_l := X_l^* \eta \quad \text{on} \quad T(U_l \times (-a,a)) \,.$$

The mapping X_l is exactly translation into the normal direction of U_l, and hence it is easily seen that the metric g_l splits along the fibers of $U_l \times (-a,a)$, i.e., $g_l = w_l(r) + dr \otimes dr$. Here r denotes the coordinate in the normal direction of U_l, and $w_l(r)$ is a metric on the tangent space to $U_l \times \{r\} \equiv U_l$. Given $\rho \in \mathcal{U}$, we set

$$g(\rho) := w(\rho) + dr \otimes dr := g_l|_{(s,\rho(s))} \quad \text{on} \quad T_{(s,\rho(s))}(U_l \times (-a,a)) \,.$$

In particular $w(\rho)$ constitutes a metric on $T(U_l)$ with components $w_{jk}(\rho)$. Furthermore, let $w^*(\rho)$ be the induced metric on the cotangent bundle $T^*(U_l)$, that is, $w^*(\rho)(\xi,\zeta) := w^{jk}(\rho)\xi_j\zeta_k$ for $\xi, \zeta \in T^*(U_l)$, where $w^{jk}(\rho)$ are the entries of the inverse matrix of $[w_{jk}(\rho)]$. Note that the metric $w(\rho)$ is not the same as $\theta_\rho^*\eta$. In particular, $w(\rho)$ does not involve any derivatives of ρ, whereas $\theta_\rho^*\eta$ does. We define $U_{l,\rho} := (U_l, w(\rho))$ and $\Xi_l := (U_l \times (-a,a), g_l)$. As a consequence of the special form (2.1) of $\Phi_{l,\rho}$, we have $\widehat{\Phi}_{l,\rho}(s,r) := \Phi_{l,\rho}(X_l(s,r)) = r - \rho(s)$ on $\mathcal{R}_l$, and hence

$$\nabla_{\Xi_l} \widehat{\Phi}_{l,\rho}(s,r) = \tfrac{\partial}{\partial r} - \nabla_{U_{l,\rho}} \rho(s) \,, \qquad (s,r) \in U_l \times (-a,a) \,.$$

Therefore we get for $s \in U_l$

$$\begin{aligned} L_\rho^2(s) = \; & |\nabla_{\mathbb{R}^n} \Phi_{l,\rho}|^2 \Big|_{x = X_l(s,\rho(s))} = g_l(\nabla_{\Xi_l} \widehat{\Phi}_{l,\rho}, \nabla_{\Xi_l} \widehat{\Phi}_{l,\rho}) \Big|_{(s,\rho(s))} \\ = \; & 1 + w(\rho)(\nabla_{U_{l,\rho}} \rho, \nabla_{U_{l,\rho}} \rho) \Big|_s = 1 + w^*(\rho)(d\rho, d\rho) \Big|_s \,, \end{aligned} \tag{2.3}$$

where $d\rho := \partial_j \rho dx^j \in T^*(\Sigma)$ denotes the exterior differential of any $\rho \in C^1(\Sigma)$. We did not label the metrics $g(\rho)$ and $w(\rho)$ with an index l as they can be defined globally on Σ.

To simplify the notation we set $H_\rho := \theta_\rho^* H_{\Gamma_\rho}$. It is known that the mean curvature operator H_ρ is a second order quasi-linear elliptic operator acting on functions defined on Σ; see, for instance, [18, Lemma 3.1]. Moreover, it follows from the proof of that lemma presented in [18] that

$$H_\rho = P_1(\rho)\rho + F_1(\rho), \qquad \rho \in \mathcal{U} \,.$$

$P_1(\rho)$ and $F_1(\rho)$ are represented in local coordinates by

$$\begin{aligned} P_1(\rho) = \tfrac{1}{(n-1)L_\rho^3} \Big[\; & \big(- L_\rho^2 w^{jk}(\rho) + w^{jl}(\rho) w^{km}(\rho) \partial_l \rho \partial_m \rho \big) \partial_j \partial_k \\ & + \big(L_\rho^2 w^{jk}(\rho) \Gamma_{jk}^i(\rho) + w^{jl}(\rho) w^{ki}(\rho) \Gamma_{jk}^n(\rho) \partial_l \rho \\ & \quad + 2 w^{km}(\rho) \Gamma_{nk}^i(\rho) \partial_m \rho - w^{jl}(\rho) w^{km}(\rho) \Gamma_{jk}^i(\rho) \partial_l \rho \partial_m \rho \big) \partial_i \Big], \\ F_1(\rho) = -\frac{1}{(n-1)L_\rho} & w^{jk}(\rho) \Gamma_{jk}^n(\rho). \end{aligned}$$

Here the summation runs from 1 to $(n-1)$ for all repeated indices. Moreover, Γ_{jk}^i are the Christoffel symbols of the metric g_l and

$$\Gamma_{jk}^i(\rho) := \Gamma_{jk}^i \Big|_{(s,\rho(s))} \quad \text{on} \quad T_{(s,\rho(s))}(\Xi_l) \,.$$

An important observation here is that $w^{jk}(\rho)$ and $\Gamma^i_{jk}(\rho)$ are all independent of the derivatives of ρ, and hence the above equations together with (2.3) give complete information on how derivatives of ρ go into the operators $P_1(\rho)$ and $F_1(\rho)$.

Given $\xi \in T^*(\Sigma)$, let $p_1^\pi(\rho)(\xi)$ denote the symbol of the principal part of $P_1(\rho)$. Then (2.3) and the Cauchy–Schwarz inequality yield

$$\begin{aligned} p_1^\pi(\rho)(\xi) &= \frac{1}{(n-1)L_\rho^3}\big[w^*(\rho)(\xi,\xi) + w^*(\rho)(d\rho,d\rho)w^*(\rho)(\xi,\xi) - (w^*(\rho)(d\rho,\xi))^2\big] \\ &\geq \frac{w^*(\rho)(\xi,\xi)}{(n-1)L_\rho^3} \end{aligned}$$

for any $\xi \in T^*(\Sigma)$.

(b) Let us now turn to the operator $\theta_\rho^*\Delta_{\Gamma_\rho}$. Since θ_ρ is a diffeomorphism between Σ and Γ_ρ, we obtain that

$$\theta_\rho^*\Delta_{\Gamma_\rho} = \Delta_\rho\theta_\rho^*\,, \quad \rho \in \mathcal{U}\,,$$

where Δ_ρ is the Laplace–Beltrami operator on $(\Sigma, \theta_\rho^*\eta)$. Here η is the Euclidean metric on the immersed manifold Γ_ρ and $\theta_\rho^*\eta$ denotes the Riemannian metric that is induced by θ_ρ on the manifold Σ. To simplify the notation we set $\sigma(\rho) := \theta_\rho^*\eta$. Let $\sigma_{jk}(\rho)$ be the components of $\sigma(\rho)$ in local coordinates and let $\sigma^*(\rho)$ be the induced metric on $T^*(\Sigma)$, that is, $\sigma^*(\rho)(\xi,\zeta) := \sigma^{jk}(\rho)\xi_j\zeta_k$ for $\xi,\zeta \in T^*(\Sigma)$. As usual, $\sigma^{jk}(\rho)$ are the entries of the inverse matrix of $[\sigma_{jk}(\rho)]$. Finally, $\gamma^i_{jk}(\rho)$ denote the Christoffel symbols of $\sigma(\rho)$. Using local coordinates, we find

$$\Delta_\rho = \sigma^{jk}(\rho)\big(\partial_j\partial_k - \gamma^i_{jk}(\rho)\partial_i\big)\,, \qquad \rho \in \mathcal{U}\,.$$

(c) Let $\rho \in \mathcal{U}$ be given. Then we define $P^\pi(\rho) \in \mathcal{L}(h^{4+\alpha}(\Sigma), h^\alpha(\Sigma))$ by

$$P^\pi(\rho) := -\frac{1}{(n-1)L_\rho^2}\,\sigma^{rs}(\rho)\big[-L_\rho^2 w^{jk}(\rho) + w^{jl}(\rho)w^{km}(\rho)\partial_l\rho\partial_m\rho\big]\partial_r\partial_s\partial_j\partial_k\,.$$

We show that there exists a mapping $Q(\rho) \in \mathcal{L}(h^{3+\alpha}(\Sigma), h^\alpha(\Sigma))$ such that

$$-L_\rho\Delta_\rho P_1(\rho)\rho - P^\pi(\rho)\rho = Q(\rho)\rho, \quad \rho \in \mathcal{U} \cap h^{4+\alpha}(\Sigma)\,.$$

Using the representations of Δ_ρ and $P_1(\rho)\rho$ in local coordinates we see that fourth order derivatives of ρ can only occur when $\partial_r\partial_s$ falls on $\partial_j\partial_k\rho$, and these terms are collected exactly in the operator $P^\pi(\rho)$. Third order derivatives of ρ can only enter in a linear way. For this recall that $w^{jk}(\rho)$ and $\Gamma^i_{jk}(\rho)$ do depend on ρ, but not on its derivatives. So $\partial_r\partial_s$ applied to these functions will only generate second order derivatives of ρ. Hence

$$\partial_r\partial_s(w^{jl}(\rho)w^{km}(\rho)\partial_l\rho\partial_m\rho)$$

will, for instance, produce a third order derivative of ρ exactly when $\partial_r\partial_s$ falls on $\partial_l\rho$ or on $\partial_m\rho$. The result is clearly linear in the third order derivatives. Next observe that L_ρ is represented in local coordinates by

$$L_\rho = \sqrt{1 + w^{jk}(\rho)\partial_j\rho\partial_k\rho}\,,$$

see (2.3). It is then easily seen that $\partial_r\partial_s L_\rho^{-1}$ generates, once again, third order derivatives which enter linearly. Similar arguments apply to all of the remaining

terms. Finally, in case that an expression does not contain third order derivatives we can always split off a linear term $\partial_j\partial_k\rho$ or $\partial_i\rho$. By similar arguments we also conclude that there exists a mapping $R(\rho) \in \mathcal{L}(h^{3+\alpha}(\Sigma), h^\alpha(\Sigma))$ such that

$$-L_\rho \left(\Delta_\rho \frac{1}{L_\rho}\right) L_\rho F_1(\rho) = R(\rho)\rho\,, \quad \rho \in \mathcal{U} \cap h^{3+\alpha}(\Sigma)\,.$$

We set

$$\begin{aligned} P(\rho) &:= P^\pi(\rho) + Q(\rho) + R(\rho), \quad \rho \in \mathcal{U}\,, \\ F(\rho) &:= -L_\rho\Delta_\rho F_1(\rho) - R(\rho)\rho, \quad \rho \in \mathcal{U} \cap h^{3+\alpha}(\Sigma)\,. \end{aligned}$$

It follows from the above considerations and from the representation of $F_1(\rho)$ in local coordinates that

$$P \in C^\infty(\mathcal{U}, \mathcal{L}(h^{4+\alpha}(\Sigma), h^\alpha(\Sigma)))\,, \quad F \in C^\infty(\mathcal{U}, h^{\beta_0}(\Sigma))$$

and that $G(\rho) = P(\rho)\rho + F(\rho)$ for $\rho \in h^{4+\alpha}(\Sigma) \cap \mathfrak{A}$.

(d) It remains to show that $P(\rho) \in \mathcal{H}(h^{4+\alpha}(\Sigma), h^\alpha(\Sigma))$ for $\rho \in \mathcal{U}$. Given $\rho \in \mathcal{U}$, let $p^\pi(\rho)$ denote the symbol of $P^\pi(\rho)$. Then the results in steps (a)–(c) yield

$$p^\pi(\rho)(\xi) = L_\rho\, \sigma^*(\rho)(\xi,\xi)\, p_1^\pi(\rho)(\xi) \geq \frac{1}{(n-1)L_\rho^2}\sigma^*(\rho)(\xi,\xi)\, w^*(\rho)(\xi,\xi)$$

for all $\xi \in T^*(\Sigma)$. Hence, for any fixed $\rho \in \mathcal{U}$, the operator $P^\pi(\rho)$ is a uniformly elliptic fourth order operator acting on functions over the compact manifold Σ. Consequently, $-P^\pi(\rho)$ generates a strongly continuous analytic semigroup on $h^\alpha(\Sigma)$, that is, we have that

$$P^\pi(\rho) \in \mathcal{H}(h^{4+\alpha}(\Sigma), h^\alpha(\Sigma)), \quad \rho \in \mathcal{U}\,.$$

Since $Q(\rho)$ and $R(\rho)$ are lower order perturbations, we can now conclude that $-P(\rho)$ generates an analytic semigroup on $h^\alpha(\Sigma)$ as well. □

Now we are in a position to apply the general theory of quasi-linear evolution equations developed by H. Amann providing a unique classical solution of problem (2.2). More precisely, we have the following theorem.

THEOREM 2.2. *Given any $\rho \in \mathcal{V}$, there exists a unique classical solution*

$$\rho \in C([0,t^+), \mathcal{V}) \cap C^\infty((0,t^+), C^\infty(\Sigma))$$

of problem (2.2). *Here, $t^+ := t^+(\rho_0) > 0$ stands for the maximal time of existence. The map $[(t,\rho_0) \mapsto \rho(t,\rho_0)]$ defines a smooth local semiflow on $\mathcal{V}$.*

Proof. Set $E_0 := h^\alpha(\Sigma)$ and $E_1 := h^{4+\alpha}(\Sigma)$ and let

$$E_\theta := (E_0, E_1)^0_{\theta,\infty}, \qquad \theta \in (0,1)\,,$$

denote the continuous interpolation spaces between E_1 and E_0; see [23] or [4]. Next we fix

$$\theta_1 := \frac{2+\beta-\alpha}{4}\,, \quad \theta_0 := \frac{2+\beta_0-\alpha}{4}\,, \quad \theta := \frac{\beta_0-\alpha}{4}\,.$$

Since the little Hölder spaces are stable under continuous interpolation, we get the following identities

$$E_{\theta_1} = h^{2+\beta}(\Sigma)\,, \quad E_{\theta_0} = h^{2+\beta_0}(\Sigma)\,, \quad E_\theta = h^{\beta_0}(\Sigma)\,.$$

Hence Lemma 2.1 and [3, Theorem 12.1] imply that there exists a unique solution in the class

$$C([0,t^+),\mathcal{V})\cap C((0,t^+),h^{4+\alpha}(\Sigma))\cap C^1((0,t^+),h^{\alpha}(\Sigma))\,.$$

The additional regularity in the assertion follows from a bootstrapping argument in the scale of Banach spaces $h^s(\Sigma)$, cf. the proof of [17, Theorem 1]. Moreover, the results in [3, section 12] also show that the map $[(t,\rho_0)\mapsto\rho(t,\rho_0)]$ defines a smooth local semiflow on $\mathcal{V}$. □

3. Global existence. To prove Theorem 1.2, we fix a Euclidean sphere S and set $\Sigma=S$ in the construction of section 2. Without loss of generality we may assume that S is the unit sphere centered at 0. Observe that Lemma 2.1 implies that

$$G\ :\ \mathcal{U}\cap h^{4+\alpha}(S)\to h^{\alpha}(S)\,,\qquad \rho\mapsto G(\rho)$$

is smooth. Let $A:=\partial G(0)$ be the Fréchet derivative of G at 0. Then we have the following representation of A.

LEMMA 3.1.

$$A=\frac{1}{n-1}\Delta_S^2+\Delta_S\,,$$

where Δ_S denotes the Laplace–Beltrami operator on S.

Proof. Recall that $G(\rho)=-L_\rho\Delta_\rho H_\rho$ for $\rho\in\mathcal{U}\cap h^{4+\alpha}(S)$. Thus we get

$$Ah=\partial G(0)h=-\partial\big(L_\rho\Delta_\rho\big)\big|_{\rho=0}[h,H_0]-L_0\Delta_0\partial H_\rho\big|_{\rho=0}h \tag{3.1}$$

for $h\in h^{4+\alpha}(S)$. Furthermore, observe that

$$L_0\equiv 1,\qquad \Delta_0=\Delta_S,\qquad H_0\equiv 1\,. \tag{3.2}$$

In particular, given $\rho\in\mathcal{U}$, we have that $L_\rho\Delta_\rho H_0=0$. Hence

$$\partial\big(L_\rho\Delta_\rho\big)\big|_{\rho=0}[h,H_0]=\frac{d}{d\varepsilon}\big(L_{\varepsilon h}\Delta_{\varepsilon h}\big)\big|_{\varepsilon=0}H_0=0\,. \tag{3.3}$$

Finally, it was shown in [18, Lemma 3.1] that

$$\partial H_\rho\big|_{\rho=0}h=-\frac{1}{n-1}\big(n-1+\Delta_S\big)h, \tag{3.4}$$

and the assertion follows from (3.1)–(3.4). □

LEMMA 3.2. *The spectrum of $-A$ consists of a sequence of real eigenvalues*

$$\cdots<\mu_{k+1}<\mu_k<\mu_{k-1}<\cdots<\mu_1<\mu_0=0\,.$$

In addition, μ_0 is an eigenvalue of geometric multiplicity $(n+1)$.

Proof. (a) Due to the compact embedding of $h^{4+\alpha}(S)$ in $h^{\alpha}(S)$ it is clear that the spectrum of $-A$ consists only of eigenvalues.

(b) Assume that

$$Ah = \frac{1}{n-1}\Delta_S(n-1+\Delta_S)h = 0$$

for some $h \in h^{4+\alpha}(S)$. Then

$$(n-1+\Delta_S)h = c \tag{3.5}$$

for some constant c. Observe that $g_0 = c/(n-1)$ is a solution of (3.5). Consequently, we find that

$$(n-1+\Delta_S)(h-g_0) = 0\,.$$

On the other hand it is well known that $(n-1)$ is an eigenvalue of $-\Delta_S$ of multiplicity n and that the spherical harmonics $\{Y_k; 1 \le k \le n\}$ of degree 1 span the corresponding eigenspace. Let $Y_0 = 1$ and set $N := \operatorname{span}\{Y_k\,;\, 0 \le k \le n\}$. We have shown that 0 is an eigenvalue of A of geometric multiplicity $(n+1)$ with eigenspace N.

(c) Suppose that $\lambda \in \mathbb{C} \setminus \{0\}$ and $h \in h^{4+\alpha}(S)$ satisfy the equation $(\lambda + A)h = 0$. Then h belongs to $N^\perp$, where the orthogonal complement has to be taken in $L_2(S)$. Indeed, given $k \in \{0, \dots, n\}$, we have that

$$0 = \big((\lambda + A)h|Y_k\big) = \lambda\,(h|Y_k)\,,$$

showing that $h \in N^\perp$. Next observe that there are positive constants c_1 and c_2 such that

$$\big((\Delta_S)^{-1}g|g\big) \le -c_1\big(g|g\big), \qquad \big((n-1+\Delta_S)g|g\big) \le -c_2\big(g|g\big)$$

for all $g \in h^{2+\alpha}(S) \cap N^\perp$, where $(\,\cdot\,|\,\cdot\,)$ denotes the inner product in $L_2(S)$. Now, multiplying the equation $(\lambda + A)h = 0$ in $L_2(S)$ with $(\Delta_S)^{-1}h$, we get

$$\lambda\,(h|(\Delta_S)^{-1}h) + \frac{1}{n-1}\big((n-1+\Delta_S)h|h\big) = 0\,.$$

It follows that $\lambda < 0$ and this completes the proof. □

We are now ready to prove our Theorem 1.2. Here we follow [18].

(i) In a first step we sketch the construction of a center manifold $\mathcal{M}^c$ over N. For $g \in h^r(S)$, $r > 0$, let $Pg := \sum_{k=0}^n (g|Y_k)Y_k$. Then it is easily verified that P is a continuous projection of $h^r(S)$ onto $N = \{Y_k\,;\, 0 \le k \le n\}$, the kernel of the operator A. Moreover, P commutes with A, that is, $PAg = APg = 0$ for all $g \in h^{4+\alpha}(S)$. Therefore, N and $h_s^{4+\alpha}(S) := \ker(P)$ provide topologically complementary subspaces of $h^{4+\alpha}(S)$, which reduce the operator A. We conclude that $\sigma(-\pi^c A) = \{0\}$ and $\sigma(-\pi^s A) \subset (-\infty, \mu_1]$ with $\mu_1 < 0$, where $\pi^c = P$ and $\pi^s = id - P$ denote the projections onto N and $h_s^{4+\alpha}(S)$, respectively, the center subspace and the stable subspace of $-A$. It is now clear that the eigenvalue 0 also has algebraic multiplicity $(n+1)$. We can now apply [29, Theorem 4.1]; see also [23, Theorem 9.2.2]. These results imply that, given $m \in \mathbb{N}^*$, there exists an open neighborhood U of 0 in N and a mapping

$$\gamma \in C^m(U, h_s^{4+\alpha}(S)) \quad \text{with} \quad \gamma(0) = 0,\ \ \partial\gamma(0) = 0$$

such that $\mathcal{M}^c := \operatorname{graph}(\gamma)$ is a locally invariant manifold for the semiflow generated by the solutions of (2.2). $\mathcal{M}^c$ is an $(n+1)$-dimensional submanifold of $h^{4+\alpha}(S)$

with $T_0(\mathcal{M}^c) = N$. In addition, the manifold $\mathcal{M}^c$ is exponentially attractive. More precisely, it follows from [29, Theorem 5.8] that given $\omega \in (0, -\mu_1)$, there exist a positive constant c and a neighborhood W of 0 in $h^{2+\beta}(S)$ such that

$$\|\pi^s\rho(t,\rho_0) - \gamma(\pi^c\rho(t,\rho_0))\|_{h^{4+\alpha}(S)} \le \frac{c}{t^{1-\theta}} e^{-\omega t}\|\pi^s\rho_0 - \gamma(\pi^c\rho_0)\|_{h^{2+\beta}(S)} \tag{3.6}$$

for each ρ_0 in W. Estimate (3.6) is valid for all $t \in (0, t^+(\rho_0))$ with $\pi^c\rho(t,\rho_0) \in U$. Moreover, $\theta := (2+\beta-\alpha)/4$.

(ii) Step (i) implies that $\mathcal{M}^c$ contains all small equilibria of (2.2). We show that $\mathcal{M}^c$ and $\mathcal{M}$ coincide near 0. Suppose that S' is a sphere which is sufficiently close to S. Let $(z_1, \dots, z_n)$ be the coordinates of its center and r be its radius. Recall that S is the unit sphere in $\mathbb{R}^n$ and let $z_0 := 1 - r$. If ρ measures the distance from S to S' in normal direction with respect to S, we get the identity

$$(1+z_0)^2 = \sum_{k=1}^n \big((1+\rho)Y_k - z_k\big)^2. \tag{3.7}$$

Here we used that the spherical harmonics Y_k, $k = 1, \dots, n$, are just the restrictions of the harmonic polynomials $[x \mapsto x_k]$. Solving (3.7) for ρ we obtain that S' can be parameterized over S by the distance function

$$\rho(z) = \sum_{k=1}^n z_k Y_k - 1 + \sqrt{\left(\sum_{k=1}^n z_k Y_k\right)^2 + (1+z_0)^2 - \sum_{k=1}^n z_k^2}\,, \tag{3.8}$$

where $z := (z_0, \dots, z_n) \in \mathbb{R}^{n+1}$. If O is a sufficiently small neighborhood of 0 in $\mathbb{R}^{n+1}$, then it is clear that any sphere S' which is close to S can be characterized by (3.8) with $z \in O$. Furthermore, the mapping $[z \mapsto \rho(z)] : O \to h^{4+\alpha}(S)$ is smooth and its derivative at 0 is given by

$$\partial\rho(0)h = \sum_{k=0}^n h_k Y_k, \qquad h \in \mathbb{R}^{n+1}\,. \tag{3.9}$$

Now, let $\{F_0(z), \dots, F_n(z)\}$ be the coordinates of $\pi^c\rho(z)$ with respect to the basis $\{Y_0, \dots, Y_n\}$ of N. Then (3.9) yields that $\partial F(0) = \mathrm{id}_{\mathbb{R}^{n+1}}$. Consequently, the inverse function theorem implies that F is a smooth diffeomorphism from O onto its image $V := \mathrm{im}(F)$, provided O is small enough. Let $\mathcal{M} := \{\rho(z)\,;\, z \in O\}$. Then it follows that $\pi^c\mathcal{M}$ is an open neighborhood of 0 in N which can be assumed to coincide with the open neighborhood U of 0 in N obtained in step (i). Hence we conclude that $\mathcal{M} = \mathcal{M}^c$.

(iii) It follows from step (ii) that the reduced flow of (2.2) on $\mathcal{M}^c$ consists of equilibria. Therefore, 0 is a stable equilibrium for the reduced flow and we conclude that 0 is also stable for the evolution equation (2.2); see [28, Theorem 3.3]. In particular, there exists a neighborhood W of 0 in $h^{2+\beta}(S)$ such that solutions of (2.2) exist globally for every initial value $\rho_0 \in W$ and such that estimate (3.6) is satisfied for all $t > 0$.

(iv) As in [18, Theorems 6.5 and 6.6] one can show the following result. Given $k \in \mathbb{N}$ and $\omega \in (0, -\mu_1)$, there exists a neighborhood $W = W(k,\omega)$ of 0 in $h^{2+\beta}(S)$

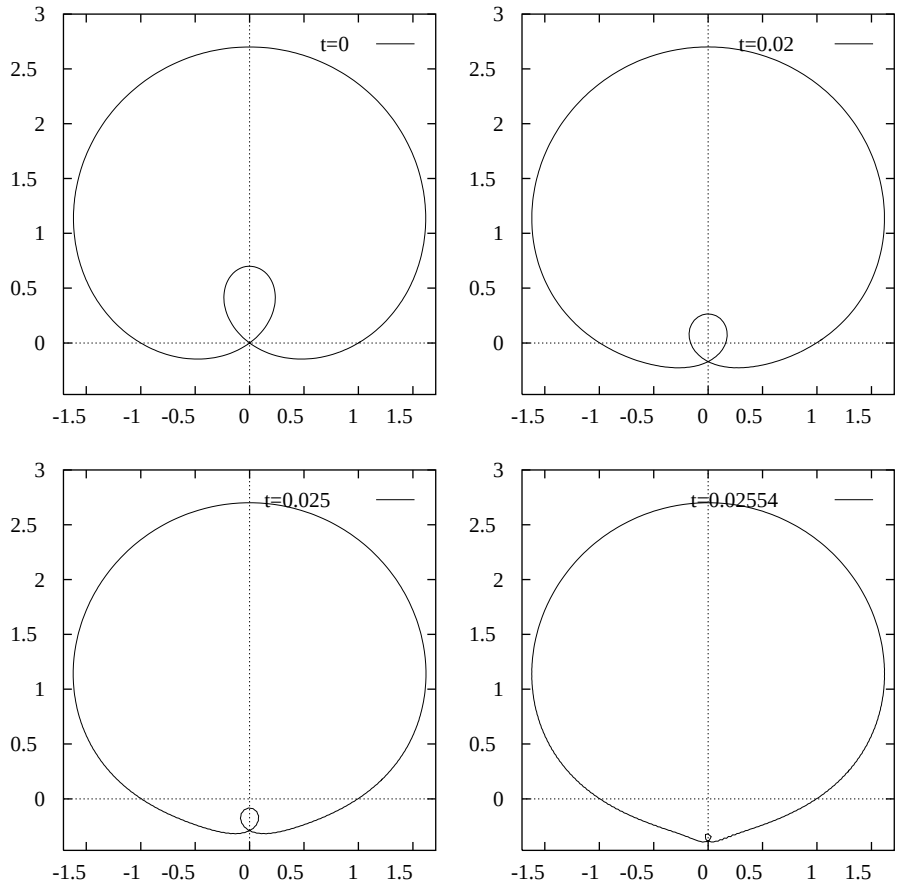

FIG. 1. *The limaçon* $r(\theta) = 1 + 1.7\sin(\theta)$.

with the following property. Given $\rho_0 \in W$, the solution $\rho(\cdot, \rho_0)$ of (2.2) exists globally and there exist $c = c(k, \omega) > 0$ and a unique $z_0 = z_0(\rho_0) \in U$ such that

$$\|\big(\pi^c\rho(t,\rho_0), \pi^s\rho(t,\rho_0)\big) - \big(z_0, \gamma(z_0)\big)\|_{C^k(S)} \le ce^{-\omega t}\|\pi^s\rho_0 - \gamma(\pi^c\rho_0)\|_{h^{2+\beta}(S)}$$

for $t \ge 1$. According to step (ii), $(z_0, \gamma(z_0)) \in \mathcal{M}^c$ is a sphere. Hence we have proved that given $\rho_0 \in W$ the solution $\rho(t, \rho_0)$ of (2.2) exists globally and converges to the sphere $(z_0, \gamma(z_0))$ exponentially fast in the C^k-topology as $t \to \infty$. And so, the proof of Theorem 1.2 is now completed.

4. Numerical simulations. The general theory from the previous sections can be used to set up a numerical scheme as well. The idea is to discretize in time and to use an implicit scheme for stability reasons. Linearization of the dependence on the next time step leads to a semi-implicit scheme. Discretization of the interface leads then to a front-tracking method. We implement this here for two space dimensions; for three space dimensions, and for further details see [24, 25].

4.1. A limaçon. The example of a limaçon shows that the surface diffusion flow can produce singularities. This is not unlike the mean curvature flow, for which Angenent [6] has investigated the singularities arising from the evolution of this shape.

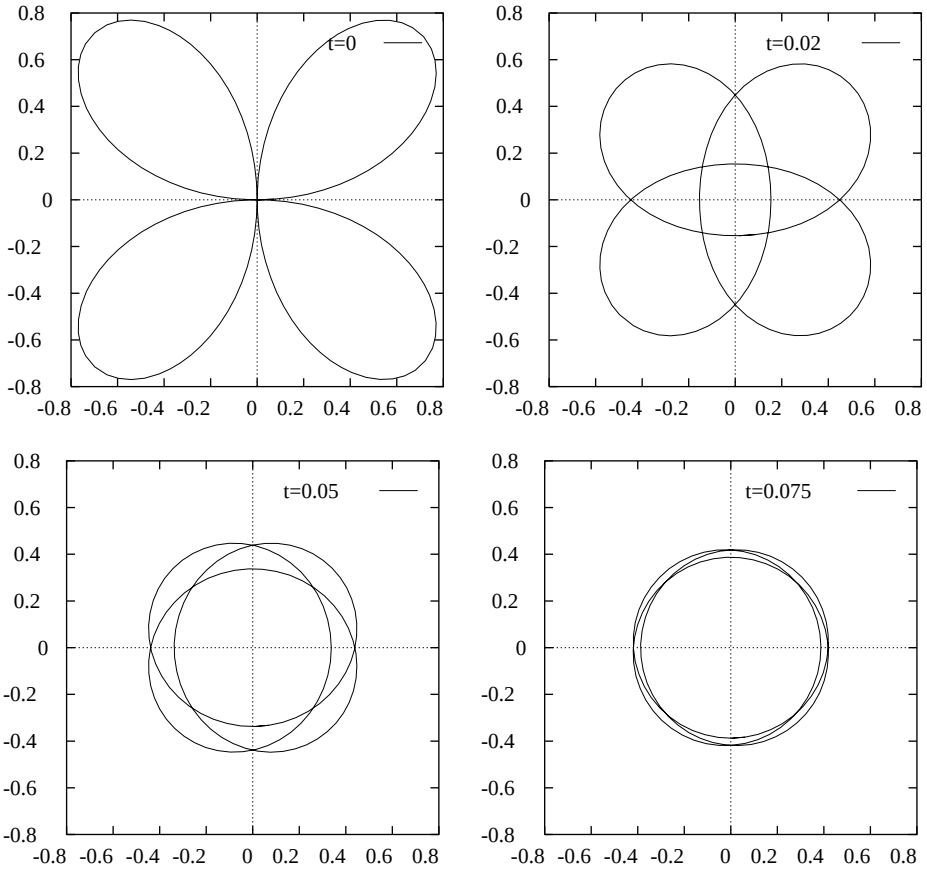

FIG. 2. *The rose* $r(\theta) = \sin(2\theta)$.

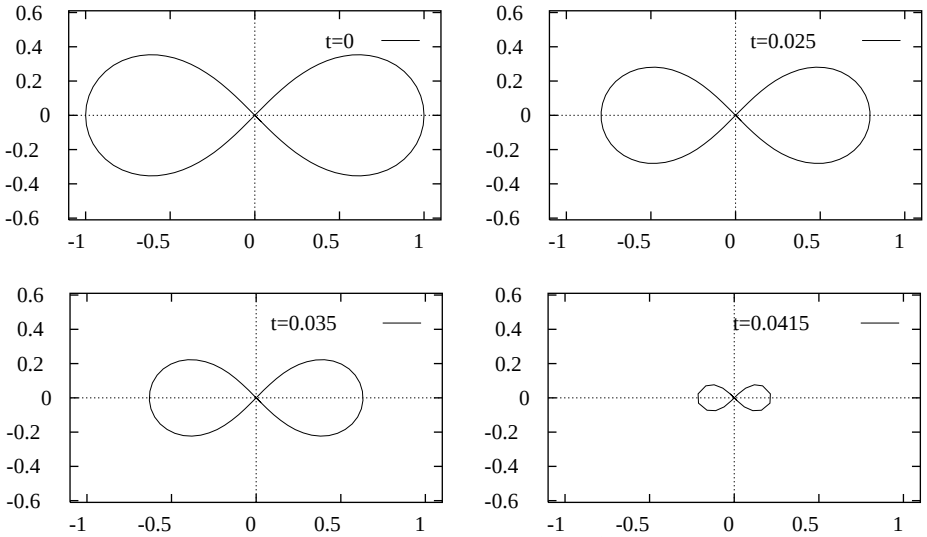

FIG. 3. *The figure eight* $r(\theta) = \sqrt{\cos(\theta)}$.

The smaller loop tightens, having a maximum for the curvature. Therefore the curvature increases for the smaller loop. This leads to a blow-up of the curvature in finite time (Figure 1.)

4.2. A four-leafed rose. The rose exhibits the phenomenon that the stable limiting configuration need not necessarily be an embedded circle, it can also be a multiply covered immersed circle. For positive time the winding number of the curve with respect to the origin does not change, and hence the limiting curve is a triply covered circle (Figure 2.)

4.3. A figure eight. One can make perfect sense of the enclosed signed area of a figure eight, which is for a symmetric figure eight equal to zero. As the evolution decreases the length of the curve and preserves the enclosed area, it can be expected that the limiting figure has zero area and zero length. This is exactly what happens, the figure eight shrinks in finite time to a point. As the curve shortens it is necessary to remove vertices from the numerical simulation to maintain the ratio of temporal versus spatial resolution. In other words, as the length of the curve decreases one needs to remove vertices to maintain a given lower bound on the distance between any two consecutive points of the discretized curve. This is somewhat visible in the last picture where the curve has shrunk so much that because of the increased curvature one can discern faint corners (Figure 3.)

BLOWUP AND LIFE SPAN OF SOLUTIONS FOR A SEMILINEAR PARABOLIC EQUATION*

NORIKO MIZOGUCHI† AND EIJI YANAGIDA‡

Abstract. This paper is concerned with the Cauchy problem

$$\begin{cases} u_t = \Delta u + |u|^{p-1}u & \text{in } \mathbf{R}^N \times (0,\infty), \\ u(x,0) = u_0(x) & \text{in } \mathbf{R}^N, \end{cases}$$

where $p > 1$. Let Ω be a set in $\mathbf{R}^N$ given by

$$\Omega \equiv \left\{ (r,\omega) \in \mathbf{R}^+ \times S^{N-1} \ : \ r > R, \ d(\omega,\omega_0) < cr^{-\mu} \right\}$$

for some $R > 0$, $c > 0$, $\omega_0 \in S^{N-1}$, and $0 \le \mu < 1$, where $d(\cdot,\cdot)$ denotes the standard distance on S^{N-1}. It is shown that if u_0 decays like $|x|^{-\alpha}$ as $|x| \to \infty$ in Ω with $0 < \alpha < 2(1-\mu)/(p-1)$, then the solution blows up in finite time regardless of the behavior of u_0 outside Ω. Moreover the life span of such a solution with $u_0 = \lambda\varphi$ is estimated from above for small $\lambda > 0$ in terms of p, α, and μ. The optimality of these results is also studied.

Key words. blowup, life span, semilinear parabolic equations

1. Introduction.

In this paper, we consider the Cauchy problem for the semilinear parabolic equation

$$\begin{cases} u_t = \Delta u + |u|^{p-1}u & \text{in } \mathbf{R}^N \times (0,\infty), \\ u(x,0) = u_0(x) & \text{in } \mathbf{R}^N, \end{cases} \tag{1.1}$$

where $p > 1$. Since the pioneering work of Fujita [1] on the critical exponent for global existence and blowup, many results concerning the blowup of solutions have been obtained by many authors. Among them, Lee and Ni [7] proved that any nonnegative solution of (1.1) blows up in finite time if the nonnegative initial data u_0 decays more slowly than $|x|^{-2/(p-1)}$ as $|x| \to \infty$. Later, Gui and Wang [5] obtained some related results. See the survey paper by Levine [8] and the book by Samarskii et al. [12] for detailed information on this subject.

On the other hand, it seems that little is known about the blowup of sign-changing solutions. In fact, the methods of the above authors cannot be applied to such solutions. Recently, the result of Fujita was extended in [9, 10] for a one-dimensional problem when the number of sign changes of initial data is prescribed. It was also shown in [10] that any (sign-changing) solution of (1.1) in one-dimensional space blows up in finite time provided that u_0 decays more slowly than $|x|^{-2/(p-1)}$ as $x \to +\infty$ or $-\infty$. This implies that in this case, the number of sign changes of initial data are irrelevant to the blowup or global existence of solutions of (1.1). Since the existence

of forward self-similar solutions of (1.1) in $\mathbf{R}^N$ decaying like $|x|^{-2/(p-1)}$ is shown in [6, 11, 13], $|x|^{-2/(p-1)}$ is the critical decay order of initial data for the blowup in the one-dimensional case.

Our first purpose in this paper is to generalize the results of Lee and Ni [7] and obtain a sufficient condition on the decay order of initial data, which may change sign, such that the solution of (1.1) blows up in finite time. Let (r, ω) be the polar coordinate in $\mathbf{R}^N$ with $r > 0$ and $\omega \in S^{N-1}$, and $d(\cdot, \cdot)$ denotes the usual distance on S^{N-1}. We denote by $\Omega = \Omega(R, c, \omega_0, \mu)$ a set in $\mathbf{R}^N$ defined by

$$\Omega \equiv \left\{(r, \omega) \in \mathbf{R}^+ \times S^{N-1} \ : \ r > R, \ d(\omega, \omega_0) < cr^{-\mu}\right\}$$

for some $R > 0$, $c > 0$, $\omega_0 \in S^{N-1}$, and $0 \le \mu < 1$. We note that if $\mu > 0$, Ω can be regarded as a small set in the sense that the Lebesgue measure of the set

$$\{\omega \in S^{N-1} \ : \ (r, \omega) \in \Omega\}$$

tends to zero as $r \to \infty$. We also note that if $\mu = 0$, then Ω is a cone. Let φ be any bounded function on $\mathbf{R}^N$ that decays like $|x|^{-\alpha}$ as $|x| \to \infty$ in Ω with $0 < \alpha < 2(1-\mu)/(p-1)$. We will show that the solution with initial data φ blows up in finite time, regardless of the value of $p > 1$ and the behavior of φ outside Ω. Moreover we will show that the condition on α is sharp if $p \ge (N+1)/(N-1)$.

Our second purpose is to estimate the life span of solutions. We call the maximal existence time of a solution u in the classical sense the life span (or blowup time) of u. We denote by $T(\lambda)$ for $\lambda > 0$ the life span of the solution u of (1.1) with initial data $u_0 = \lambda\varphi$. Under the same assumption on φ as above, we will give an upper estimate of $T(\lambda)$ in terms of α, μ, and p, and study the best possibility of this estimate.

The difficulty in studying the blowup when solutions are allowed to change sign lies in the fact that the standard comparison theorem is not useful, because sign-changing solutions have two directions of blowup, that is, $+\infty$ and $-\infty$. In order to overcome it, the nonincrease (in time) of intersection number of two solutions was essentially used in [10] in one-dimensional problems. However, this tool cannot be applied to higher-dimensional problems. In this paper, we make use of the transformed equation and the corresponding energy which were effectively used by Giga and Kohn [2, 3, 4] to study the backward self-similarity of solutions of (1.1) near a blowup point. We also modify the method of Lee and Ni [7] to study the best possibility.

This paper is organized as follows. In the next section, we introduce precise assumptions on initial data and state our main results. In section 3, we derive a sufficient condition on initial data for the blowup of solutions and obtain an upper estimate of the life span. In section 4, we study the optimality of these results.

2. Main results. We begin this section by introducing precise assumptions. We will impose the following conditions on initial data:

(A1) $\varphi \ge K_1 r^{-\alpha}$ in Ω for some $\alpha > 0$ and $K_1 > 0$.

(A2) $|\nabla\varphi| \le K_2 r^{-\alpha-1+\mu}$ in Ω for some $\alpha > 0$ and $K_2 > 0$.

It should be noted that these conditions impose no restriction on the behavior of φ outside Ω.

In our first result, we show that if the initial data decay slowly only in Ω, then the solution blows up in finite time.

THEOREM 2.1. *Suppose that* $\varphi \in W^{1,\infty}(\mathbf{R}^N)$ *satisfies* (A1) *and* (A2) *with*

$$0 < \alpha < \frac{2(1-\mu)}{p-1}.$$

Then the solution of (1.1) *with initial data* $u_0 = \varphi$ *blows up in finite time.*

For nonnegative initial data, the condition above can be weakened somewhat. In fact, by using the comparison theorem, we can obtain the same result under the assumption that $\varphi \in L^\infty(\mathbf{R}^N)$ is nonnegative in $\mathbf{R}^N$ and satisfies (A1) with $0 < \alpha < 2(1-\mu)/(p-1)$.

It is shown in [6, 11, 13] that there exists a global self-similar solution with radial symmetry that decays like $|x|^{-2/(p-1)}$ as $|x| \to \infty$. Therefore the condition on α in Theorem 2.1 is sharp in case $\mu = 0$.

In the next theorem, we show that if α is large, then there exists a global solution of (1.1) with initial data satisfying (A1) and (A2).

THEOREM 2.2. *Let*

$$\alpha > \begin{cases} \dfrac{2(1-\mu)}{p-1} & \text{if } \ p \geq \dfrac{N+1}{N-1}, \\ \dfrac{2}{p-1} - (N-1)\mu & \text{if } \ 1 < p < \dfrac{N+1}{N-1}. \end{cases}$$

Then there exists $\varphi \in W^{1,\infty}(\mathbf{R}^N)$ *satisfying* (A1) *and* (A2) *such that the solution of* (1.1) *with initial data* $u_0 = \varphi$ *exists globally in time.*

We note that the above theorem implies that if $p \geq (N+1)/(N-1)$, then the condition on α in Theorem 2.1 is sharp. However, since

$$\frac{2(1-\mu)}{p-1} < \frac{2}{p-1} - (N-1)\mu$$

if $1 < p < (N+1)/(N-1)$, there is a gap between the ranges of α in Theorems 2.1 and 2.2. It seems that this gap comes from a technical reason (see Remark 4.1).

Next we consider the life span of solutions of (1.1) with initial data $u_0 = \lambda\varphi$.

THEOREM 2.3. *Suppose that* $\varphi \in W^{1,\infty}(\mathbf{R}^N)$ *satisfies* (A1) *and* (A2) *with*

$$0 < \alpha < \frac{2(1-\mu)}{p-1}.$$

Then for any $\varepsilon > 0$, *there exists* $\lambda_\varepsilon > 0$ *such that*

$$T(\lambda) \leq \lambda^{-\left(\frac{1}{p-1} - \frac{\alpha}{2(1-\mu)}\right)^{-1} - \varepsilon} \tag{2.1}$$

for $0 < \lambda \leq \lambda_\varepsilon$.

As noted above, the condition can be weakened somewhat for nonnegative initial data.

In the next result, we provide some lower bounds that complement (2.1) in Theorem 2.3.

THEOREM 2.4. *Let*

$$0 < \alpha < \frac{2(1-\mu)}{p-1}.$$

Then there exists $\varphi \in W^{1,\infty}(\mathbf{R}^N)$ *satisfying* (A1) *and* (A2) *such that for any* $\varepsilon > 0$, $T(\lambda)$ *satisfies*

$$T(\lambda) \geq \begin{cases} \lambda^{-\left(\frac{1}{p-1} - \frac{\alpha}{2(1-\mu)}\right)^{-1} + \varepsilon} & \text{if } \ \alpha \leq (1-\mu)(N-1), \\ \lambda^{-\left(\frac{1}{p-1} - \frac{\alpha+(N-1)\mu}{2}\right)^{-1} + \varepsilon} & \text{if } \ \alpha > (1-\mu)(N-1) \end{cases}$$

for $0 < \lambda \le \lambda_\varepsilon$ *with some* $\lambda_\varepsilon > 0$.

We note that if $p \ge (N+1)/(N-1)$ and $0 < \alpha < 2(1-\mu)/(p-1)$, then

$$\alpha < \frac{2(1-\mu)}{p-1} \le (1-\mu)(N-1).$$

This implies that if $p \ge (N+1)/(N-1)$, then the estimate of $T(\lambda)$ in Theorem 2.3 is sharp. However, if $1 < p < (N+1)/(N-1)$ and $\alpha > (1-\mu)(N-1)$, there is a gap between the exponents in Theorems 2.3 and 2.4. Again the authors conjecture that the gap comes from a technical reason, and the estimate of $T(\lambda)$ in Theorem 2.3 is optimal (see Remark 4.1).

Finally we remark that a sharp estimate from below for positive solutions was obtained in [7], but one cannot expect a similar one in our situation. Indeed, the solution can blow up independently of the assumption in Ω, because no restriction is imposed on the behavior of initial data outside Ω.

3. Blowup and life span. Let $\tau > 0$ and $a \in \mathbf{R}^N$ be fixed. For a solution u of (1.1), we set

$$w(y,s) = (\tau - t)^{1/(p-1)} u(x,t)$$

with

$$y = (\tau - t)^{-1/2}(x - a), \quad s = -\log(\tau - t).$$

Then (1.1) is written as

$$\text{(3.1)} \qquad \begin{cases} w_s = \Delta w - \dfrac{y}{2}\nabla w - \dfrac{1}{p-1} w + |w|^{p-1} w & \text{in } \mathbf{R}^N \times (s_0, \infty), \\ w(y, s_0) = \tau^{1/(p-1)} u_0(\tau^{1/2} y + a) & \text{in } \mathbf{R}^N, \end{cases}$$

where $s_0 = -\log \tau$. We define

$$I_{a,\tau}(u_0) \equiv \int_{\mathbf{R}^N} \left\{ \frac{1}{2}|\nabla u_0|^2 - \frac{1}{p+1}|u_0|^{p+1} \right\} \cdot \exp\left(-\frac{|x-a|^2}{4\tau} \right) dx + \tau^{-1} \int_{\mathbf{R}^N} \frac{1}{2(p-1)} u_0^2 \cdot \exp\left(-\frac{|x-a|^2}{4\tau} \right) dx.$$

The following lemma is obtained by a minor modification of the argument in [3].

LEMMA 3.1. *If* $I_{a,\tau}(u_0) < 0$ *for some* $a \in \mathbf{R}^N$ *and* $\tau > 0$, *then the solution of* (1.1) *blows up at some* $t < \tau$.

Proof. We define the energy associated with (3.1) by

$$E(w) \equiv \int_{\mathbf{R}^N} \left\{ \frac{1}{2}|\nabla w|^2 + \frac{1}{2(p-1)} w^2 - \frac{1}{p+1}|w|^{p+1} \right\} \rho dy,$$

where

$$\rho(y) = \exp\left(-\frac{|y|^2}{4} \right).$$

Multiplying (3.1) by $w_s \rho$ and integrating it by parts, we obtain

$$\frac{d}{ds} E(w(y,s)) = -\int_{\mathbf{R}^N} w_s^2 \rho dy \le 0.$$

Hence $E(w(y,s))$ is nonincreasing in s. Multiplying (3.1) by $w\rho$ and integrating it by parts, we get

$$\begin{aligned}\frac{1}{2}\frac{d}{ds}\int_{\mathbf{R}^N} w(y,s)^2\rho dy &= -2E(w(y,s)) + \frac{p-1}{p+1}\int_{\mathbf{R}^N} |w(y,s)|^{p+1}\rho dy \\ &\geq -2E(w(y,s_0)) + \frac{p-1}{p+1}\int_{\mathbf{R}^N} |w(y,s)|^{p+1}\rho dy.\end{aligned}$$

Assume here $E(w(y,s_0)) < 0$. Then, by Jensen's inequality, there is $C_1 > 0$ such that

$$\frac{1}{2}\frac{d}{ds}\int_{\mathbf{R}^N} w(y,s)^2\rho dy \geq C_1\left(\int_{\mathbf{R}^N} w(y,s)^2\rho dy\right)^{(p+1)/2}.$$

Hence $\int_{\mathbf{R}^N} w(y,s)^2\rho dy$ diverges to ∞ at some finite s, which implies the blowup of $w(y,s)$. Thus, if $E(w(y,s_0)) < 0$, the corresponding solution u of (1.1) blows up at some $t < \tau$. Since

$$E(w(y,s_0)) = \tau^{\frac{2}{p-1}-\frac{N}{2}+1} I_{a,\tau}(u_0),$$

the proof is complete. □

We set

$$\begin{aligned}I_1(u_0) &= \int_{\mathbf{R}^N} |\nabla u_0|^2 \cdot \exp\left(-\frac{|x-a|^2}{4\tau}\right) dx, \\ I_2(u_0) &= \int_{\mathbf{R}^N} |u_0|^{p+1} \cdot \exp\left(-\frac{|x-a|^2}{4\tau}\right) dx, \\ I_3(u_0) &= \int_{\mathbf{R}^N} u_0^2 \cdot \exp\left(-\frac{|x-a|^2}{4\tau}\right) dx.\end{aligned}$$

LEMMA 3.2. *Suppose that $\varphi \in W^{1,\infty}(\mathbf{R}^N)$ satisfies* (A1) *and* (A2) *with $0 < \alpha < 2(1-\mu)/(p-1)$. If $a = (\tau^{\frac{\beta}{1-\mu}}, \omega_0) \in \Omega$ with some $\beta > 1/2$, then the following hold:*

(a) $\lim_{\tau\to\infty} I_1(\varphi)/I_2(\varphi) = 0$.

(b) $\lim_{\tau\to\infty} I_1(\varphi)/\tau^{-1} I_3(\varphi) = 0$.

(c) $\limsup_{\tau\to\infty} \tau^{-\frac{\alpha\beta(p-1)}{1-\mu}} I_3(\varphi)/I_2(\varphi) < \infty$.

Proof. We define

$$\Omega_\beta = \left\{ (r,\omega) \in \mathbf{R}^N \ : \ |r - \tau^{\frac{\beta}{1-\mu}}| \leq \frac{1}{2}\tau^\beta, \ d(\omega,\omega_0) \leq \frac{c}{2}\tau^{\frac{-\mu\beta}{1-\mu}} \right\}.$$

Then $\Omega_\beta \subset \Omega$ for sufficiently large $\tau > 0$. Since

$$\exp\left(-\frac{|x-a|^2}{4\tau}\right) = O\left(\exp\left(-\frac{\tau^{2\beta-1}}{4}\right)\right) \quad \text{in } \mathbf{R}^N\backslash\Omega_\beta$$

as $\tau \to \infty$, the contribution from $\mathbf{R}^N\backslash\Omega_\beta$ is smaller than any power of τ.

By (A1) and (A2), we have

$$\frac{|\nabla\varphi|^2}{|\varphi|^{p+1}} \leq \frac{K_2^2 r^{2(-\alpha-1+\mu)}}{K_1^{p+1} r^{-(p+1)\alpha}} \quad \text{in } \Omega_\beta.$$

Since

$$2(-\alpha-1+\mu) < -(p+1)\alpha$$

by assumption on α, we obtain (a). Similarly we have

$$\frac{\tau|\nabla\varphi|^2}{\varphi^2} \le \frac{\tau K_2^2 r^{2(-\alpha-1+\mu)}}{K_1^2 r^{-2\alpha}} = \frac{\tau K_2^2 r^{2(-1+\mu)}}{K_1^2} \le C_1\tau^{-2\beta+1} \quad \text{in } \Omega_\beta$$

for some $C_1 > 0$ and large $\tau > 0$. Since $\beta > 1/2$, (b) is proved. Finally, we have

$$\frac{\tau^{-\frac{\alpha\beta(p-1)}{1-\mu}}\varphi^2}{|\varphi|^{p+1}} \le \frac{\tau^{-\frac{\alpha\beta(p-1)}{1-\mu}}}{K_1^{p+1} r^{-\alpha(p-1)}} \le C_2 \quad \text{in } \Omega_\beta$$

for some $C_2 > 0$ and large $\tau > 0$. Thus (c) holds. □

We are now in a position to prove Theorems 2.1 and 2.3.

Proof of Theorem 2.1. By assumption on α, we can take β satisfying

$$\frac{1}{2} < \beta < \frac{1-\mu}{\alpha(p-1)}. \tag{3.2}$$

Let $a = (\tau^{\frac{\beta}{1-\mu}}, \omega_0) \in \Omega$. Then, by Lemma 3.2 and the above inequality, $I_1(\varphi)$ and $\tau^{-1}I_3(\varphi)$ are negligible compared with $I_2(\varphi)$. Hence

$$I_{a,\tau}(\varphi) = \frac{1}{2}I_1(\varphi) - \frac{1}{p+1}I_2(\varphi) + \frac{1}{2(p-1)}\tau^{-1}I_3(\varphi) < 0$$

if $\tau > 0$ is sufficiently large. Thus, by virtue of Lemma 3.1, the solution of (1.1) with initial data $u_0 = \varphi$ must blow up in finite time. □

Proof of Theorem 2.3. Let $\overline{u}(t)$ be a spatially homogeneous solution of (1.1) with initial data $\overline{u}(0) = \lambda|\varphi|_{L^\infty}$. Then $\overline{u}(t)$ is explicitly obtained as

$$\overline{u}(t) = \left\{\lambda^{1-p}|\varphi|_{L^\infty}^{1-p} - (p-1)t\right\}^{-1/(p-1)},$$

which blows up at $t = \lambda^{1-p}|\varphi|_{L^\infty}^{1-p}/(p-1)$. By the comparison theorem, the solution of (1.1) with initial data $u_0 = \lambda\varphi$ satisfies

$$-\overline{u}(t) \le u(x,t) \le \overline{u}(t)$$

for $0 \le t < \lambda^{1-p}|\varphi|_{L^\infty}^{1-p}/(p-1)$. Hence we obtain

$$T(\lambda) \ge \frac{\lambda^{1-p}|\varphi|_{L^\infty}^{1-p}}{p-1}$$

for all λ, which implies that $T(\lambda) \to \infty$ as $\lambda \to 0$.

By Lemma 3.1, we have

$$I_{a,T(\lambda)}(\lambda\varphi) = \frac{1}{2}\lambda^2 I_1(\varphi) - \frac{1}{p+1}\lambda^{p+1}I_2(\varphi) + \frac{1}{2(p-1)}\lambda^2 T(\lambda)^{-1}I_3(\varphi) \ge 0$$

for any $a \in \mathbf{R}^N$. (Otherwise the solution must blow up at some $t < T(\lambda)$, contradicting the definition of $T(\lambda)$.) Let $a = (T(\lambda)^{\frac{\beta}{1-\mu}}, \omega_0) \in \Omega$ with β as in (3.2). Since

$T(\lambda) \to \infty$ as $\lambda \to 0$, it follows from Lemma 3.2 (b) that $I_1(\varphi)$ is negligible compared with $T(\lambda)^{-1} I_3(\varphi)$. Hence, by Lemma 3.2 (c), we obtain

$$\begin{aligned} T(\lambda) &\le \frac{C_1 \lambda^2 I_3(\varphi)}{\lambda^{p+1} I_2(\varphi)} \\ &= \frac{C_1}{\lambda^{p-1} T(\lambda)^{-\frac{\alpha\beta(p-1)}{1-\mu}}} \cdot \frac{T(\lambda)^{-\frac{\alpha\beta(p-1)}{1-\mu}} I_3(\varphi)}{I_2(\varphi)} \\ &\le \frac{C_2}{\lambda^{p-1} T(\lambda)^{-\frac{\alpha\beta(p-1)}{1-\mu}}} \end{aligned}$$

for some positive constants C_1 and C_2. Namely, we have

$$T(\lambda) \le C_3 \lambda^{-\left(\frac{1}{p-1} - \frac{\alpha\beta}{1-\mu}\right)^{-1}}$$

for some $C_3 > 0$ and small $\lambda > 0$. Since $\beta > 1/2$ can be chosen arbitrarily close to $1/2$, the proof is complete. □

4. Optimality of blowup results. This section is devoted to proofs of Theorems 2.2 and 2.4. To do that, we employ the technique of Lee and Ni [7], who constructed and effectively used positive supersolutions with radial symmetry. Since we are concerned with solutions that are not necessarily positive, we need to modify their method.

We rewrite $x = (x_1, x_2, \dots, x_N) \in \mathbf{R}^N$ and $y = (y_1, y_2, \dots, y_N) \in \mathbf{R}^N$ as

$$x = (\xi \cos\theta, \xi \sin\theta, x'), \quad y = (\eta \cos\kappa, \eta \sin\kappa, y'),$$

where x', $y' \in \mathbf{R}^{N-2}$. We put

$$\theta_0 = \pi/m$$

for some positive integer m, and define a domain D by

$$D = \left\{ x = (\xi \cos\theta, \xi \sin\theta, x') \ : \ \xi > 0, \ -\frac{\theta_0}{2} < \theta < \frac{\theta_0}{2} \right\}.$$

Let $G(x, y, t)$ be a fundamental solution of the heat equation on D with Dirichlet condition on ∂D. It is known that $G(x, y, t) = G(y, x, t) > 0$ on D. Set

$$g(x, y, t) = \frac{1}{(4\pi t)^{N/2}} \exp\left(-\frac{|x - y|^2}{4t} \right).$$

Since $g(x, y, t)$ is a fundamental solution of the heat equation on $\mathbf{R}^N$, it follows from the comparison theorem that

$$G(x, y, t) < \frac{1}{(4\pi t)^{N/2}} \exp\left(-\frac{|x - y|^2}{4t} \right) \tag{4.1}$$

for $(x, y, t) \in D \times D \times (0, \infty)$. Moreover the following estimate is obtained.

LEMMA 4.1. *For any positive integer m, there exists a constant $C > 0$ such that*

$$0 < G(x, y, t) \le C t^{-\frac{N}{2} - m} |x|^m |y|^m$$

for $(x, y, t) \in D \times D \times (0, \infty)$.

Proof. For $y = (\eta \cos\kappa, \eta \sin\kappa, y') \in \mathbf{R}^N$, we put

$$\kappa_j^+ = \kappa + 2(j-1)\theta_0, \quad \kappa_j^- = -\kappa + (2j-1)\theta_0, \quad j = 1, 2, \ldots, m,$$

and define $2m$ points in $\mathbf{R}^N$ by

$$y_j^+ = (\eta \cos\kappa_j^+, \eta \sin\kappa_j^+, y'), \quad y_j^- = (\eta \cos\kappa_j^-, \eta \sin\kappa_j^-, y').$$

Then $G(x, y, t)$ is explicitly written by the superposition of g as

$$G(x, y, t) = \sum_{j=1}^{m} g(x, y_j^+, t) - \sum_{j=1}^{m} g(x, y_j^-, t).$$

Set

$$\begin{aligned} h(x, y, t) &\equiv \frac{1}{g(x, y, t)} \cdot \left\{ \sum_{j=1}^{m} g(x, y_j^+, t) - \sum_{j=1}^{m} g(x, y_j^-, t) \right\} \\ &= \sum_{j=1}^{m} \exp\left(\frac{\langle\, x, y_j^+ \,\rangle - \langle\, x, y \,\rangle}{2t} \right) - \sum_{j=1}^{m} \exp\left(\frac{\langle\, x, y_j^- \,\rangle - \langle\, x, y \,\rangle}{2t} \right), \end{aligned}$$

where $\langle\, \cdot, \cdot \,\rangle$ denotes the usual inner product of two vectors in $\mathbf{R}^N$. It is easy to see that

$$h(t^{-1/2}x, t^{-1/2}y, 1) \equiv h(x, y, t).$$

Hence, if there exists a constant $C_1 > 0$ such that

$$h(x, y, 1) \le C_1 |x|^m |y|^m \tag{4.2}$$

for $(x, y) \in \mathbf{R}^N \times \mathbf{R}^N$, then

$$\begin{aligned} G(x, y, t) &= g(x, y, t) h(x, y, t) \\ &= g(x, y, t) h(t^{-1/2}x, t^{-1/2}y, 1) \\ &\le \frac{1}{(4\pi t)^{N/2}} \cdot C_1 |t^{-1/2}x|^m |t^{-1/2}y|^m \quad \text{in } D, \end{aligned}$$

which proves the lemma.

Let us prove (4.2). Since $h(\gamma x, \gamma^{-1} y, t) \equiv h(x, y, t)$ for any $\gamma \neq 0$, it suffices to show that (4.2) holds for any $|x| > 1$ and $|y| = 1$. By the location of the points y_j^+ and y_j^-, we have $h(x, y, t) = 0$ if x is on the plane $\theta = (j - 1/2)\theta_0$ for some j. Namely, $h(x, y, t) = 0$ if $a_j x_1 + b_j x_2 = 0$, where

$$a_j = \sin\left(j - \frac{1}{2}\right)\theta_0, \quad b_j = -\cos\left(j - \frac{1}{2}\right)\theta_0, \quad j = 1, 2, \ldots, m.$$

Since $h(x, y, t)$ is analytic in x and y and $h(x, y, t) \equiv h(y, x, t)$, we can write $h(x, y, 1)$ as

$$h(x, y, 1) = \left\{ \prod_{j=1}^{m} (a_j x_1 + b_j x_2) \right\} \left\{ \prod_{j=1}^{m} (a_j y_1 + b_j y_2) \right\} h_0(x, y),$$

where $h_0(x,y)$ is analytic in $(x,y) \in \mathbf{R} \times \mathbf{R}$. Thus, if we take

$$C_1 > \sup \{ \, |h_0(x,y)| \ : \ |x| \le 1, \ |y| = 1\},$$

then (4.2) holds for $|x| \le 1$ and $|y| = 1$, because $|a_j x_1 + b_j x_2| \le |x|$ and $|a_j y_1 + b_j y_2| \le |y|$.

It remains to show (4.2) in the case where $|x| > 1$ and $|y| = 1$. Since

$$\begin{aligned} \langle \, x, y_j^+ \, \rangle - \langle \, x, y \, \rangle &= \xi \cos\theta \cdot \eta \cos\kappa_j^+ + \xi \sin\theta \cdot \eta \sin\kappa_j^+ \\ &\quad -\xi \cos\theta \cdot \eta \cos\kappa - \xi \sin\theta \cdot \eta \sin\kappa \\ &= \xi\eta \, \{ \cos(\theta - \kappa_j^+) - \cos(\theta - \kappa) \, \} \\ &= -2\xi\eta \sin(\theta - \kappa - (j-1)\theta_0) \sin(-(j-1)\theta_0) \\ &\le 0, \end{aligned}$$

we have

$$h(x,y,1) = \sum_{j=1}^m \exp\left(\frac{\langle \, x, y_j^+ \, \rangle - \langle \, x, y \, \rangle}{2} \right) - \sum_{j=1}^m \exp\left(\frac{\langle \, x, y_j^- \, \rangle - \langle \, x, y \, \rangle}{2} \right) \le m.$$

Hence, if we take $C_1 \ge m$, then (4.2) holds for $|x| > 1$ and $|y| = 1$. Thus the proof is complete. □

We assume $\omega_0 = (1, 0, \dots, 0)$ and choose a nonnegative function $\psi \in W_0^{1,\infty}(D)$ such that

(i) $\psi(r,\omega)$ satisfies (A1), (A2) and $\psi(r,\omega) \le K_3 r^{-\alpha}$ in Ω for some K_3;
(ii) $\psi(r,\omega)$ is rotationally symmetric with respect to ω_0;
(iii) $\psi(r,\omega)$ is nonincreasing in $d(\omega,\omega_0) \in [0, 2cr^{-\mu}]$ for each $r > R/2$;
(iv) $\psi(r,\omega) \equiv 0$ if $r \le R/2$ or $d(\omega,\omega_0) \ge 2cr^{-\mu}$.

It is easy to verify that such a function $\psi(r,\omega)$ exists.

Now we consider the following auxiliary problems:

$$\text{(4.3)} \qquad \begin{cases} w_t = \Delta w + |w|^{p-1} w & \text{in } D \times (0,\infty), \\ w(x,t) = 0 & \text{on } \partial D \times (0,\infty), \\ w(x,0) = \lambda\psi(x) & \text{in } D \end{cases}$$

and

$$\text{(4.4)} \qquad \begin{cases} U_t = \Delta U & \text{in } D \times (0,\infty), \\ U(x,t) = 0 & \text{on } \partial D \times (0,\infty), \\ U(x,0) = \psi(x) & \text{in } D. \end{cases}$$

LEMMA 4.2. *Let $\overline{w}(x,t) = h(t)U(x,t)$, where $U(x,t)$ is the solution of* (4.4) *and*

$$h(t) = \left\{ \lambda^{1-p} - (p-1) \int_0^t |U(x,t)|_{L^\infty(D)}^{p-1} dt \right\}^{1/(1-p)}.$$

Then $\overline{w}(x,t)$ is a supersolution of (4.3) *with initial data $u_0 = \lambda\psi$ as long as $h(t)$ is positive.*

Proof. If $h(t) > 0$, then we have

$$\begin{aligned} &\overline{w}_t(x,t) - \Delta w_t(x,t) - w^p \\ &= h_t(t)U(x,t) + h(t)U_t(x,t) - h(t)\Delta U(x,t) - \{h(t)U(x,t)\}^p \\ &= h(t)^p |U(x,t)|_{L^\infty(D)}^{p-1} U(x,t) - \{h(t)U(x,t)\}^p \\ &\ge 0. \end{aligned}$$

Since $\overline{w}(x,t) = 0$ on ∂D, $\overline{w}(x,t)$ is a supersolution. The equality $\overline{w}(x,0) = \lambda\psi(x)$ is obvious. □

In order to apply Lemma 4.2 to our problem, we need an upper estimate of $|U(x,t)|_{L^\infty(D)}$. The next lemma is crucial for the proofs of Theorems 2.2 and 2.4.

LEMMA 4.3. *Let m be a positive integer satisfying*

$$m - \alpha + (1-\mu)(N-1) > 0,$$

and let $U(x,t)$ be the solution of (4.4). Then for any $\varepsilon > 0$, there exists t_0 such that

$$|U(x,t)|_{L^\infty(D)} \le t^{-\frac{N}{2}+\frac{\nu}{2}+\varepsilon}$$

for $t \ge t_0$, where

$$\nu = \max\left\{1 - \alpha + (1-\mu)(N-1),\ -\frac{\alpha}{1-\mu} + N\right\}.$$

Proof. We first note that $U(x,t)$ is given by

$$U(x,t) = \int_D G(x,y,t)\psi(y)dy.$$

We see from (ii) and (iii) that

$$|U(x,t)|_{L^\infty(D)} = \sup_{x\in\Gamma} U(x,t)$$

for $t > 0$, where $\Gamma = \{(r,\omega_0) : r > 0\}$. Therefore it suffices to estimate $U(x,t)$ for $x \in \Gamma$ and $t > 0$.

We take a constant $\beta > 1/2$ arbitrarily, and set

$$D_\beta = \{x \in D \ :\ |x| \le 3t^\beta\}.$$

Let $x \in \Gamma$ with $|x| \le 2t^\beta$. Then, by (4.1), Lemma 4.1, and the assumption on m, we have

$$\begin{aligned}
U(x,t) &\le C\int_{D_\beta} G(x,y,t)\psi(y)dy \\
&\le Ct^{-\frac{N}{2}-m}\int_{D_\beta} |x|^m|y|^m\psi(y)dy \\
&\le Ct^{-\frac{N}{2}-m+m\beta}\int_0^{3t^\beta} r^m(1+r)^{-\alpha}r^{(1-\mu)(N-1)}dr \\
&\le Ct^{-\frac{N}{2}-m+m\beta}\int_0^{3t^\beta} r^{m-\alpha+(1-\mu)(N-1)}dr \\
&= Ct^{-\frac{N}{2}+\beta\{1-\alpha+(1-\mu)(N-1)\}+m(2\beta-1)}
\end{aligned}$$

for sufficiently large $t > 0$. (Here and hereafter, C denotes a generic positive constant which may vary from line to line.)

Next, let $x \in \Gamma$ with $2t^\beta < |x| \le t^{\beta/(1-\mu)}$. Then

$$\frac{1}{2}|x| \le |x| - t^\beta \le |x| + t^\beta \le 2|x|.$$

Hence we have

$$\begin{aligned} U(x,t) &\le Ct^{-\frac{N}{2}} \int_{|x|-t^\beta}^{|x|+t^\beta} (1+r)^{-\alpha} r^{(1-\mu)(N-1)} dr \\ &\le Ct^{-\frac{N}{2}} \int_{|x|-t^\beta}^{|x|+t^\beta} r^{-\alpha+(1-\mu)(N-1)} dr \\ &\le Ct^{-\frac{N}{2}+\beta} |x|^{-\alpha+(1-\mu)(N-1)} \end{aligned}$$

for sufficiently large $t > 0$. Putting $|x| = 2t^\beta$ or $|x| = t^{\beta/(1-\mu)}$ in the right-hand side of the last inequality, $U(x,t)$ is estimated as

$$U(x,t) \le Ct^{-\frac{N}{2}+\beta\nu}.$$

Finally, for $x \in \Gamma$ with $|x| > t^{\beta/(1-\mu)}$ (or $|x|^{1-\mu} > t^\beta$), we have

$$\begin{aligned} U(x,t) &\le Ct^{-\frac{N}{2}} \int_{|x|-t^\beta}^{|x|+t^\beta} r^{-\alpha} t^{\beta(N-1)} dr \\ &\le Ct^{-\frac{N}{2}} |x|^{-\alpha} t^{\beta(N-1)} t^\beta \\ &\le Ct^{-\frac{N}{2}+\beta\left\{-\frac{\alpha}{(1-\mu)}+N\right\}} \end{aligned}$$

for sufficiently large $t > 0$.

Thus $U(x,t)$ is estimated as

$$U(x,t) \le Ct^{-\frac{N}{2}+\beta\nu+m(2\beta-1)}$$

for sufficiently large $t > 0$. Since $\beta > 1/2$ can be arbitrarily close to $1/2$, the proof is complete. □

Now we are in a position to prove Theorems 2.2 and 2.4.

Proof of Theorem 2.2. Without loss of generality, we may assume $\omega_0 = (1, 0, \ldots)$. For $x = (\xi\cos\theta, \xi\sin\theta, x')$ with $\theta \in [-\theta_0/2, \theta_0/2)$, we put

$$\theta_j^+ = \theta + 2(j-1)\theta_0, \quad \theta_j^- = -\theta + (2j-1)\theta_0, \quad j = 1, 2, \ldots, m,$$

and

$$x_j^+ = (\xi\cos\theta_j^+, \xi\sin\theta_j^+, x'), \quad x_j^- = (\xi\cos\theta_j^-, \xi\sin\theta_j^-, x').$$

We define a function $\varphi \in W^{1,\infty}(\mathbf{R}^N)$ by

$$\varphi(x_j^+) = \psi(x), \quad \varphi(x_j^-) = -\psi(x), \quad j = 1, 2, \ldots, m. \tag{4.5}$$

It is clear that $\lambda\varphi$ satisfies (A1) and (A2) for any $\lambda > 0$. Then the solution of (1.1) with initial data $u_0 = \lambda\varphi$ satisfies

$$u(x_j^+, t) = w(x,t), \quad u(x_j^-, t) = -w(x,t), \quad j = 1, 2, \ldots, m,$$

for all $x \in D$ and $t > 0$. Hence u exists globally in time if and only if w exists globally in time.

Let $\overline{w}$ be a supersolution of (4.3) given as in Lemma 4.2. Suppose that

$$\int_0^\infty |U(x,t)|_{L^\infty(D)}^{p-1} dt < \infty.$$

Then, by taking

$$0 < \lambda < \left\{ (p-1) \int_0^\infty |U(x,t)|^{p-1}_{L^\infty(D)} dt \right\}^{1/(1-p)},$$

$h(t)$ is positive for all $t \geq 0$ so that $\overline{w}$ exists globally in time. Then, by the comparison theorem, the solution w of (1.1) with initial data $u_0 = \lambda\varphi$ exists globally.

Therefore, by Lemma 4.3, it suffices to show that

$$\left(-\frac{N}{2} + \frac{\nu}{2} \right) (p-1) < -1.$$

By definition of ν, this inequality holds if and only if

$$\alpha > \frac{2}{p-1} - (N-1)\mu \quad \text{and} \quad \alpha > \frac{2(1-\mu)}{p-1}.$$

Since

$$\frac{2}{p-1} - (N-1)\mu > \frac{2(1-\mu)}{p-1}$$

is equivalent to $p < (N+1)/(N-1)$, the proof is complete. □

Proof of Theorem 2.4. Let φ be given as in (4.5). By Theorem 2.1, the solution u of (1.1) blows up in finite time. Let $\overline{T}(\lambda)$ be the life span of $\overline{w}$ given in Lemma 4.2. Then it follows from the comparison theorem that $\overline{T}(\lambda) \leq T(\lambda) < \infty$. On the other hand, we have

$$(p-1)^{-1}\lambda^{1-p} = \int_0^{\overline{T}(\lambda)} |U(x,t)|^{p-1}_{L^\infty(D)} dt.$$

Thus, making use of Lemma 4.3, we obtain

$$\begin{aligned}
(p-1)^{-1}\lambda^{1-p} &\leq \int_0^{T(\lambda)} |U(x,t)|^{p-1}_{L^\infty(D)} dt \\
&\leq \int_0^{t_0} |U(x,t)|^{p-1}_{L^\infty(D)} dt + \int_{t_0}^{T(\lambda)} t^{\left(-\frac{N}{2}+\frac{\nu}{2}+\varepsilon\right)(p-1)} dt \\
&\leq C_0 + \int_{t_0}^{T(\lambda)} t^{\left(-\frac{N}{2}+\frac{\nu}{2}+\varepsilon\right)(p-1)} dt
\end{aligned}$$

for some positive constants t_0 and C_0. Since

$$\left(-\frac{N}{2} + \frac{\nu}{2} \right) (p-1) > -1$$

by our assumption on α, $T(\lambda)$ satisfies

$$\lambda^{1-p} \leq T(\lambda)^{\left(-\frac{N}{2}+\frac{\nu}{2}+2\varepsilon\right)(p-1)+1}$$

for sufficiently small $\lambda > 0$, or equivalently,

$$T(\lambda) \geq \lambda^{-\left(-\frac{N}{2}+\frac{\nu}{2}+\frac{1}{p-1}\right)^{-1}+\varepsilon}.$$

Since the inequality

$$1-\alpha+(1-\mu)(N-1) \le -\frac{\alpha}{1-\mu}+N$$

is equivalent to

$$\alpha \le (1-\mu)(N-1),$$

the proof is complete. □

Remark 4.1. As we noted in section 2, there is a gap between the ranges of α in Theorems 2.1 and 2.2 if $1 < p < (N+1)/(N-1)$. Also, there is a gap between the exponents of λ in Theorems 2.3 and 2.4 if $1 < p < (N+1)/(N-1)$ and $\alpha > (1-\mu)(N-1)$. We notice that $p = (N+1)/(N-1)$ is Fujita's exponent [1] for the blowup of positive solutions in $\mathbf{R}^{N-1}$. We suspect that the gaps arise from the assumption that ψ is nonnegative in D.

INTERIOR BLOWUP IN A CONVECTION-DIFFUSION EQUATION*

CHRISTOPHER P. GRANT†

Abstract. This paper addresses the qualitative behavior of a nonlinear convection-diffusion equation on a smooth bounded domain in $\mathbf{R}^n$, in which the strength of the convection grows superlinearly as the density increases. While the initial-boundary value problem is guaranteed to have a local-in-time solution for smooth initial data, it is possible for this solution to be extinguished in finite time. We demonstrate that the way this may occur is through finite-time "blow up," i.e., the unboundedness of the solution in arbitrarily small neighborhoods of one or more points in the closure of the spatial domain. In special circumstances, such as the presence of radial symmetry, the set of blowup points can be identified; these points may be either on the boundary or on the interior of the domain. Furthermore, criteria can be established that guarantee that blowup occurs. In this paper, such criteria are presented, involving the dimension of the space, the growth rate of the nonlinearity, the strength of the imposed convection field, the diameter of the domain, and the mass of the initial data. Furthermore, the temporal rate of blowup is estimated.

1. Introduction.

Let $\Omega \subset \mathbf{R}^n$ be a bounded domain with smooth boundary, and consider the initial-boundary value problem

$$\begin{cases} u_t = \operatorname{div}(\nabla u - u^q \vec{a}), & (x,t) \in \Omega \times (0,T), \\ u_\nu = u^q \vec{a} \cdot \vec{\nu}, & (x,t) \in \partial\Omega \times (0,T), \\ u(x,0) = u_0(x), & x \in \Omega, \end{cases} \tag{1.1}$$

where $\vec{\nu}$ is the unit outward normal on $\partial\Omega$ and u_ν is the corresponding directional derivative, and (for simplicity) the initial data u_0 are assumed to be extendable to a smooth, positive function on $\overline{\Omega}$ that satisfies the boundary conditions.

The unknown quantity $u = u(x,t)$ represents the local density of some material that is evolving in response to diffusion and the effects of an imposed convection field $\vec{a} : \overline{\Omega} \to \mathbf{R}^n$. The exponent q (which we shall call the *exponent of the nonlinearity*) is assumed to be greater than 1, so the magnitude of the convection term is superlinear in u.

Although (1.1) is similar in many respects to equations appearing in the scientific literature (see, e.g., [6] and [10]), the motivation for studying it has less to do with its applicability to any specific physical problem than with its role as an archetype for interacting diffusion and nonlinear convection. In this sense, it plays a role similar to the one that the nonlinear heat equation of Fujita [5],

$$u_t = \Delta u + u^p, \tag{1.2}$$

has come to play for the study of the interaction between diffusion and nonlinear reaction. (For a survey of (1.2) and related equations, see [8].)

†Department of Mathematics, Brigham Young University, Provo, UT 84602 (grant@math.byu.edu).

The Cauchy problem corresponding to (1.1) in the special case that the convection field is constant has been studied in a series of papers [3], [4], [12]. In that context, solutions decay to zero as $t \to \infty$, with the asymptotic profile of the decaying solution depending on the particular value of the exponent q.

The one-dimensional version of (1.1) with constant convection

$$\begin{cases} u_t = (u_x + u^q)_x, & (x,t) \in (0,1) \times (0,T), \\ u_x + u^q = 0, & (x,t) \in \{0,1\} \times (0,T), \\ u(x,0) = u_0(x), & x \in (0,1), \end{cases} \tag{1.3}$$

was studied in [1] and [2]. While solutions to (1.3) stabilize as $t \to \infty$ if $q < 2$, if $q > 2$ the convection is strong enough that its concentrating force, in combination with the obstacle posed by the boundary, can overwhelm the diffusion's homogenizing force on the boundary, and solutions can *blow up* in finite time. By this it is meant that there is a time T such that (1.3) has a classical solution for $t \in (0,T)$, but

$$\limsup_{t \to T} \|u(\cdot,t)\|_\infty = +\infty. \tag{1.4}$$

(Here and throughout this paper $\|\psi\|_p$ will represent the L^p norm on the domain of ψ.) The value of T for which (1.4) holds, if it exists, is called the *blowup time* of the solution.

The purpose of this paper is to address questions about the qualitative behavior of solutions to (1.1): Do solutions exist globally (i.e., for $T = +\infty$)? Can solutions blow up in finite time? At what points in $\overline{\Omega}$ does blowup occur? What can be said about the asymptotic form of u as the blowup time is approached?

Throughout the remainder of this paper, we will confine our attention to the case that $\vec{a}$ is conservative. More precisely, we shall assume the existence of a continuous function $f : \overline{\Omega} \to \mathbf{R}$ such that $\nabla f = \vec{a}$. Note that this case includes the case of constant convection.

The first thing that we will show is that the only way solutions to (1.1) can cease to exist is by blowing up.

THEOREM 1.1. *Given u_0 and sufficiently smooth $\vec{a}$,* (1.1) *has a (unique) positive classical solution for some $T > 0$. Furthermore, if T^* is the supremum of all $T > 0$ for which* (1.1) *has a solution and $T^* < +\infty$, then* $\limsup_{t \to T^*} \|u(\cdot,t)\|_\infty = +\infty$.

In order to obtain more detailed information about the way that blowup can occur, we will focus on the special case of radial symmetry. Consider the following conditions:

(R1) $\Omega = B(0,R) := \{x \in \mathbf{R}^n : |x| < R\}$.

(R2) $\vec{a}(x) = -g(r)x/r$ for some function $g : [0,R] \to [0,\infty)$. (Here and throughout this paper, $r := |x|$.)

(R3) $\vec{a}(x) = g(r)x/r$ for some function $g : [0,R] \to [0,\infty)$.

(R4) $u_0(x) = U_0(r)$.

The following theorem limits the set of possible blowup points for (1.1). (We will call a point $x \in \overline{\Omega}$ a blowup point if there is not a neighborhood N of x in $\overline{\Omega}$ such that u remains bounded on $N \cap \Omega$.)

THEOREM 1.2. *Under conditions* (R1), (R2), *and* (R4), *the only possible blowup point for* (1.1) *is the origin. Under conditions* (R1), (R3), *and* (R4), *all blowup points lie on the sphere $\partial\Omega$.*

In keeping with our interpretation of u as a density, we define the *mass* M of u by

$$M = M(u) = \int_\Omega u\,dx.$$

Note that (1.1) conserves mass, since

$$\begin{aligned} M_t &= \left(\int_\Omega u\,dx\right)_t = \int_\Omega u_t\,dx = \int_\Omega \operatorname{div}(\nabla u - u^q\vec{a})\,dx \\ &= \int_{\partial\Omega} (\nabla u - u^q\vec{a})\cdot\vec{\nu}\,d\sigma = 0. \end{aligned}$$

If, in addition to assuming that the convection is unidirectional and radially oriented, we assume that the convection is inward at the origin and not too weak and that the mass is not too small, we can show that finite-time blowup does occur. More precisely, we have the following result.

THEOREM 1.3. *Suppose* $q > 2$, (R1) *and* (R2) *hold, and there exist constants* $C > 0$ *and* $p < n(q-1)-1$ *such that* $g(r) \geq Cr^p$ *for all* $r \in [0, R]$. *Then there exists a constant* $M_0 = M_0(C, p, q, n, R)$ *such that if the mass* $M(u_0) > M_0$, *then the solution* u *of* (1.1) *blows up in finite time.*

Note that Theorem 1.3 makes no assumption about the radial symmetry of the initial data (and, therefore, of the solution). If this assumption is added, then Theorem 1.2 identifies the point where the blowup takes place.

In situations where finite-time blowup does occur and the strength of the convection field can be appropriately bounded, the rate at which blowup occurs can be estimated.

THEOREM 1.4. *Suppose hypotheses* (R1) *and* (R2) *hold and the solution* u *of* (1.1) *blows up at the origin at time* $T \in (0, \infty)$. *If* $g(r) \leq Cr^p$ *for some constants* $C > 0$ *and* $p < n(q-1) - 1$ *and all* $r \in [0, R]$, *then there exists a constant* K *such that, for all* $t < T$,

$$\|u(\cdot, t)\|_\infty \geq \frac{K}{(T-t)^\beta}, \tag{1.5}$$

where

$$\beta = \frac{p+1}{(n+p+1)(q-1)}. \tag{1.6}$$

If, in addition, hypothesis (R4) *holds, then* (1.5) *holds for*

$$\beta = \frac{p+1}{n(q-1)-(p+1)}. \tag{1.7}$$

We will proceed as follows. In section 2 we will prove that a unique solution of (1.1) exists locally for smooth initial data and that the only way this solution can fail to be global is for it to blow up. In section 3 we will prove the specific results about radially symmetric systems.

2. Existence until blowup. For the proof of Theorem 1.1, as well as for other reasons, it will be helpful to understand the set $\mathcal{E}$ of positive equilibrium solutions, i.e., functions $u_0 : \overline{\Omega} \to (0, \infty)$ for which $u(x,t) \equiv u_0(x)$ solves (1.1).

Suppose $u = u(x)$ is a positive equilibrium solution, and let $w = u^{(1-q)}/(1-q) - f$. A calculation shows that

$$\operatorname{div}(u^q \nabla w) = 0 \tag{2.1}$$

in Ω and

$$u^q \frac{\partial w}{\partial \nu} = 0 \tag{2.2}$$

on $\partial\Omega$. Multiplying (2.1) by w and using the generalized divergence theorem and the boundary condition (2.2) yields

$$\int_\Omega u^q |\nabla w|^2 dx = 0.$$

Thus, $\nabla w \equiv 0$, which implies that

$$u(x) = \frac{1}{[(q-1)(C - f(x))]^{1/(q-1)}} \tag{2.3}$$

for some constant C. It is easy to check that (2.3) defines an equilibrium solution of (1.1) for every $C > \|f\|_\infty$.

Among the facts about $\mathcal{E}$ that follow immediately from this explicit formula is the one that we state without proof in the following lemma.

LEMMA 2.1. *If $\mathcal{E}$ is the set of positive equilibrium solutions of* (1.1) *and $k \in (0, \infty)$, then*

$$\#\{u \in \mathcal{E} : \|u\|_\infty = k\} = 1.$$

We now proceed to prove that the only way that solutions can fail to be global is for them to blow up in finite time.

Proof of Theorem 1.1. Let positive initial data u_0 be given. Pick $b, c > 0$ such that $u_0(x) \in (b, c)$ for every $x \in \overline{\Omega}$, and pick $b' \in (0, b)$ and $c' \in (c, \infty)$. Now, choose $h : \mathbf{R} \to \mathbf{R}$ to be a C^∞ function, such that $h(\sigma) = \sigma^q$ for $\sigma \in (b', c')$ and $h(\sigma) = 0$ if $\sigma < b'/2$ or if $\sigma > 2c'$. Let (1.1′) be the initial-boundary value problem that results when u^q in (1.1) is replaced by $h(u)$. From Theorem 7.4 in [7], we know (1.1′) has a unique solution $\tilde{u}$ and it exists globally. (In fact, for given $\theta > 0$, existence of a solution in $C^{2+\theta, 1+\theta/2}$ is guaranteed if $\vec{a} \in C^{1+\theta}$ and $\partial\Omega \in C^{2+\theta}$.) Note that for some $T > 0$, $u = \tilde{u}$ is also a solution of (1.1) for $t < T$. This proves the first half of the theorem.

Let T^* be as defined in the statement of the theorem, and suppose

$$\limsup_{t \to T^*} \|u(\cdot, t)\|_\infty < +\infty.$$

Let b and c be as above. By Lemma 2.1, we can choose $u_1 \in \mathcal{E}$ with $\|u_1\|_\infty < b$. Pick $b' > 0$ small enough that $u_1(x) > b'$ for every $x \in \overline{\Omega}$. Pick the value $c' > c$ large enough that $u(x,t) < c' - 1$ for all $t < T^*$. Now, consider the solution $\tilde{u}$ to (1.1′). Note that u_1 is an equilibrium solution for the modified equation as well, so by the

strong maximum principle $\tilde{u} > u_1$. Thus, $\tilde{u}$ never leaves the interval (b', c') where the cutoff function h agrees with $u \mapsto u^q$. Hence, $u = \tilde{u}$ is a global solution to (1.1), which implies that $T^* = +\infty$. This proves the second half of the theorem. □

Throughout the remainder of this paper we shall assume that $\vec{a} \in C^{1+\theta}$ for some $\theta > 0$.

3. Radially symmetric systems. The proof of Theorem 1.2 hinges on the existence of quantities which remain bounded and which tie u to u_r. Such quantities are described in the following lemma.

LEMMA 3.1. *Suppose hypotheses* (R1) *and* (R4) *are satisfied. Suppose also that initial data* u_0 *are given and* u *is the corresponding solution to* (1.1). *Then*

1. *if hypothesis* (R2) *is satisfied, then* u *is radially symmetric and the quantity* $Q(x,t) := r^{n-1}(u_r + u^q g(r))$ *is bounded on* $\Omega \times (0,T)$*;*
2. *if hypothesis* (R3) *is satisfied, then* u *is radially symmetric and the quantity* $Q(x,t) := r^{n-1}(u_r - u^q g(r))$ *is bounded on* $\Omega \times (0,T)$.

Proof. The radial symmetry of u in either case is a consequence of the uniqueness of solutions to (1.1) (which was established in Theorem 1.1).

Suppose hypotheses (R1), (R2), and (R4) are satisfied, and let

$$Q(x,t) = r^{n-1}(u_r + u^q g(r)).$$

A calculation shows that Q satisfies the initial-boundary problem

$$\begin{cases} Q_t = \Delta Q + q u^{q-1} g(r) Q_r, & (x,t) \in \Omega \times (0,T), \\ Q = 0, & (x,t) \in \partial\Omega \times (0,T), \\ Q(x,0) = Q_0(x,t) := r^{n-1}(u_{0r} + u_0^q g(r)), & x \in \Omega. \end{cases}$$

By the weak maximum principle for parabolic equations (see [9]),

$$-\|Q_0\|_\infty \le Q(x,t) \le \|Q_0\|_\infty \tag{3.1}$$

for all $x \in \Omega$ and all $t > 0$. This completes the proof of part 1.

Now, suppose hypotheses (R1), (R3), and (R4) are satisfied, and let $Q(x,t) = r^{n-1}(u_r - u^q g(r))$. By an argument similar to the one before, we find, once again, that (3.1) holds for all $x \in \Omega$ and all $t > 0$, where, now, $Q_0(x) = r^{n-1}(u_{0r} - u_0^q g(r))$. This completes the proof of part 2. □

Proof of Theorem 1.2. Under hypotheses (R1), (R2), and (R4), part 1 of Lemma 3.1 states that the quantity $Q := r^{n-1}(u_r + u^q g(r))$ is bounded, say, by C. Thus,

$$u_r \le \frac{C}{r^{n-1}} - u^q g(r) \tag{3.2}$$

for all nonzero $x \in \Omega$ and all $t > 0$.

If u had a blowup point $x_0 \neq 0$, then (3.2) would imply the existence of $\varepsilon > 0$ and a sequence of times $t_1, t_2, t_3, \ldots$ such that $u(x, t_n) > n$ for every $x \in B(0, |x_0|) \setminus B(0, |x_0| - \varepsilon)$. Because of the nonnegativity of u, this would contradict the conservation of mass. Hence, 0 is the only possible blowup point.

If hypothesis (R2) is replaced by (R3), part 2 of Lemma 3.1 states that the quantity $Q := r^{n-1}(u_r - u^q g(r))$ is bounded, say, by C. Thus,

$$-\frac{C}{r^{n-1}} + u^q g(r) \le u_r \tag{3.3}$$

for all nonzero $x \in \Omega$ and all $t > 0$.

If u had a blowup point x_0 with $0 < |x_0| < R$, then (3.2) would imply the existence of $\varepsilon > 0$ and a sequence of times $t_1, t_2, t_3, \ldots$ such that $u(x, t_n) > n$ for every $x \in B(0, |x_0| + \varepsilon) \setminus B(0, |x_0|)$. Because of the nonnegativity of u, this would again contradict the conservation of mass.

Now, note that, from the definition of blowup point, if $x_0 \in \overline{\Omega}$ is not a blowup point, then there exists $\delta > 0$ such that if $x_1 \in \overline{\Omega}$ and $|x_1 - x_0| < \delta$, then x_1 is not a blowup point either. Hence, the complement of the set of blowup points is open (relative to $\overline{\Omega}$) and the set of blowup points is closed (relative to $\overline{\Omega}$). In combination with the result of the previous paragraph, this implies that 0 is not a blowup point. Thus, any blowup points must lie on $\partial\Omega$. □

The crucial idea in proving Theorem 1.3 is focusing on the amount of mass that has accumulated in a neighborhood of a potential blowup point rather than focusing on the density itself.

Proof of Theorem 1.3. Suppose hypotheses (R1) and (R2) hold and that p, q, and C satisfy the conditions in the statement of the theorem. To prove blowup, we measure the concentration of mass near the origin with the variable $w : [0, R^n] \times (0, T)$ defined by

$$w(\rho, t) = \int_{B(0,\rho^{1/n})} u(x, t)\, dx.$$

Straightforward computations reveal that

$$w_t = \int_{S(0,\rho^{1/n})} (u_r + u^q g(\rho^{1/n}))\, d\sigma(x), \tag{3.4}$$

$$w_\rho = \frac{\rho^{(1-n)/n}}{n} \int_{S(0,\rho^{1/n})} u\, d\sigma(x), \tag{3.5}$$

and

$$w_{\rho\rho} = \frac{\rho^{(2-2n)/n}}{n^2} \int_{S(0,\rho^{1/n})} u_r\, d\sigma(x). \tag{3.6}$$

Since $\xi \mapsto \xi^q$ is convex on $(0, \infty)$, applying Jensen's inequality [11] to (3.5) (after scaling $d\sigma(x)$ so that it is a probability measure) and combining it with (3.4) and (3.6) yield

$$w_t \geq n^2 \rho^{2\gamma} w_{\rho\rho} + n^q \omega_n^{1-q} \rho^\gamma g(\rho^{1/n}) w_\rho^q \tag{3.7}$$

for all $\rho \in (0, R^n)$, where ω_n is the area of the unit sphere in $\mathbf{R}^n$ and $\gamma = (n-1)/n$.

Let $p' = \max\{p, n-1\}$. Since, by hypothesis, $g(r) \geq Cr^p$, we have

$$g(r) \geq C' r^{p'}, \tag{3.8}$$

for all $r \in [0, R]$, where $C' = CR^{p-p'} > 0$. Using (3.8) and the fact that, by definition, w_ρ is nonnegative, (3.7) implies that

$$w_t \geq n^2 \rho^{2\gamma} w_{\rho\rho} + C' n^q \omega_n^{1-q} \rho^{\gamma + p'/n} w_\rho^q. \tag{3.9}$$

Now, define

$$M_0 = \omega_n \left(\frac{p'+1}{C'(q-1)} \right)^{1/(q-1)} \frac{R^{n-(p'+1)/(q-1)}}{n - \frac{p'+1}{q-1}}.$$

By hypothesis, $p < n(q-1)-1$ and $q > 2$. The first implies that $n-(p+1)/(q-1) > 0$ and the second implies that $n - ((n-1)+1)/(q-1) > 0$. Since either $p' = p$ or $p' = n-1$, we can conclude that $n - (p'+1)/(q-1) > 0$, so M_0 is well defined, positive, and finite.

Suppose that $M = M(u_0) > M_0$, and set

$$z(\rho, t) = \begin{cases} 0 & \text{if } \rho \in [0, \alpha(t)), \\ M \left(\dfrac{\rho - \alpha(t)}{R^n} \right)^{\lambda} & \text{if } \rho \in [\alpha(t), R^n], \end{cases}$$

where

$$\lambda = 1 - \frac{p'+1}{n(q-1)}$$

and $\alpha(t)$ is a continuous, decreasing function of t yet to be determined. Note that, from the discussion in the previous paragraph, $\lambda \in (0,1)$. Thus, in particular, z is continuous.

If possible, we want to choose α so that z can serve as a comparison function with which we can estimate w and, thereby, u. In particular, we want z to satisfy the opposite inequality to (3.9); i.e., we want z to satisfy

$$z_t \le n^2 \rho^{2\gamma} z_{\rho\rho} + C' n^q \omega_n^{1-q} \rho^{\gamma + p'/n} z_\rho^q \tag{3.10}$$

whenever $\rho \neq \alpha(t)$. Clearly, (3.10) is satisfied whenever $\rho < \alpha(t)$. A straightforward calculation reveals that (3.10) is satisfied for $\rho > \alpha(t)$ if and only if

$$-\alpha'(t) \le (\rho - \alpha(t))^{-\mu} \rho^{2\gamma} (A\rho^{\mu-1} - B(\rho - \alpha(t))^{\mu-1}), \tag{3.11}$$

where $\mu = (p'+1)/n$,

$$A = C' \left(\frac{M\lambda}{\omega_n} \right)^{q-1} n^q R^{n(\mu - q + 1)},$$

and $B = n^2(1-\lambda)$. Another calculation reveals that, because $M > M_0$, $A > B$. Since $\rho > \alpha(t)$, $\rho > \rho - \alpha(t)$, and $\mu - 1 \ge 0$, this means that (3.11) will be satisfied if

$$-\alpha'(t) \le (A-B)(\alpha(t))^{1-2/n}. \tag{3.12}$$

If we take $\alpha(t)$ to be the solution of the initial value problem

$$\begin{cases} \alpha'(t) = -(A-B)(\alpha(t))^{1-2/n}, \\ \alpha(0) = R^n, \end{cases}$$

then (3.12) will be satisfied, and furthermore, there will be some finite T^* such that $\alpha(t) \to 0$ as $t \to T^*$.

Now, suppose that the solution u to (1.1) does not blow up by time T^*. Then, by Theorem 1.1, u is defined for $t \in [0, T^*]$. Consider the function $y : [0, R^n] \times [0, T^*] \to \mathbf{R}$

defined by $y(\rho,t) = e^{-t}(z(\rho,t) - w(\rho,t))$. We claim that $y \le 0$ on its domain D. If it is not, then since y is continuous, it must achieve a positive maximum on D.

Note that

$$y(\rho,0) = z(\rho,0) - w(\rho,0) = -\int_{B(0,\rho^{1/n})} u_0(x)\,dx \le 0,$$

$y(0,t) = e^{-t}(z(0,t) - w(0,t)) = 0$, and

$$y(R^n,t) = e^{-t}(z(R^n,t) - w(R^n,t)) = e^{-t}\left(M\left(\frac{R^n - \alpha(t)}{R^n}\right)^{\lambda} - M\right) \le 0,$$

so y does not achieve a positive maximum on

$$\{(\rho,0) : \rho \in [0,R^n]\} \cup \{(0,t) : t \in [0,T^*]\} \cup \{(R^n,t) : t \in [0,T^*]\}.$$

Also, because $\lambda < 1$,

$$\lim_{\rho \to \alpha(t)^+} z_\rho(\rho,t) = -\infty,$$

so y cannot achieve a positive maximum at a point where $\rho = \alpha(t)$. This implies that at a positive maximum, y must satisfy $y_\rho = 0$, $y_{\rho\rho} \le 0$, and $y_t \ge 0$. But, using (3.9) and (3.10), that would mean that at such a point

$$\begin{aligned} y_t &= -y + e^{-t}(z_t - w_t) \\ &\le -y + e^{-t}(n^2\rho^{2\gamma}(z-w)_{\rho\rho} + C'n^q\omega_n^{1-q}\rho^{\gamma+p'/n}(z_\rho^q - w_\rho^q)) \\ &= -y + n^2\rho^{2\gamma}y_{\rho\rho} < 0, \end{aligned}$$

which is a contradiction.

This contradiction verifies the nonnegativity of y, which means that $w \ge z$ on all of D. But it is not hard to see that $\sup\{z(\rho,t)/\rho : \rho \in (0,R^n)\}$ becomes unbounded as $t \to T^*$, so $\sup\{w(\rho,t)/\rho : \rho \in (0,R^n)\}$ must also become unbounded. From the definition of w and the mean value theorem for integrals, this, in turn, implies that $\|u(\cdot,t)\|_\infty$ becomes unbounded as $t \to T^*$, contradicting the assumption that u does not blow up by time T^*. This completes the proof. □

In order to prove the estimates on the temporal blowup rate, it will be helpful to have the following technical lemma, which estimates the degree to which equilibrium solutions concentrate mass near the origin.

LEMMA 3.2. *Suppose that* (R1) *and* (R2) *hold and that* $g(r) \le Cr^p$ *for some* $p < n(q-1) - 1$ *and all* $r \in [0,R]$, *and let*

$$w_c(\rho) = \int_{B(0,\rho^{1/n})} u_c(x)\,dx,$$

where

$$u_c(x) = \sup\{u(x) : u \in \mathcal{E}\}.$$

Then

$$\rho \mapsto -\int_{B(0,\rho^{1/n})} u(x)\,dx$$

is convex for any $u \in \mathcal{E}$, and so is $-w_c$. Furthermore, there exists a positive constant K' such that

$$\sup\{w_c(\rho) - \lambda\rho : \rho \in [0, R^n]\} \geq K'\lambda^\mu \tag{3.13}$$

for every λ sufficiently large, where

$$\mu = 1 - \frac{n(q-1)}{p+1}. \tag{3.14}$$

Proof. It is not hard to see (e.g., by examining (2.3)) that u_c is radially symmetric and satisfies the same equation as the members of $\mathcal{E}$ but has a singularity at the origin. Furthermore, its radial symmetry implies that equality holds in (3.7) for $w = w_c$ (because Jensen's inequality is an equality in that case). Hence,

$$w_c'' = -K'\rho^{-(n-1)/n} g(\rho^{1/n})(w_c')^q \tag{3.15}$$

for some positive constant K'. (Throughout this proof, K' will represent a positive constant whose value may change from line to line.) Note that (3.15) implies the convexity of $-w_c$, and since

$$\rho \mapsto -\int_{B(0,\rho^{1/n})} u(x)\,dx$$

satisfies a similar equation for any $u \in \mathcal{E}$, it is convex also.

Integrating (3.15) and using the fact that $w_c'(\rho) \to +\infty$ as ρ approaches zero from the right yield

$$w_c'(\rho) = K' \left(\int_0^\rho \sigma^{(1-n)/n} g(\sigma^{1/n})\,d\sigma \right)^{-1/(q-1)}. \tag{3.16}$$

Applying the fact that $w_c(0) = 0$ and the assumption that $g(r) \leq Cr^p$ in (3.16) yields

$$w_c(\rho) \geq K'\rho^\mu, \tag{3.17}$$

where μ is as in (3.14). Using (3.17), it is a straightforward calculus exercise to verify that (3.13) holds for all λ sufficiently large. ∎

Lemma 3.2 provides a crucial estimate for constructing a type of supersolution that will provide an estimate of the blowup rate.

Proof of Theorem 1.4. Assume that the hypotheses (R1) and (R2) hold and that $g(r) \leq Cr^p$ for some constants $C > 0$ and $p < n(q-1) - 1$ and for all $r \in [0, R]$. Assume also that the solution u of (1.1) blows up at the origin at time $T \in (0, \infty)$. Fix $t_0 \in (0, T)$, and let $\lambda = (\omega_n/n)\|u(\cdot, t_0)\|_\infty$.

Pick $\tilde{u} \in \mathcal{E}$ such that $\|\tilde{u}\|_\infty > \|u(\cdot, t_0)\|_\infty$, and let

$$\tilde{w}(\rho) = \int_{B(0,\rho^{1/n})} \tilde{u}(x)\,dx.$$

For y between 0 and

$$G[\tilde{w}] := \sup\{\tilde{w}(\rho) - \lambda\rho : \rho \in [0, R^n]\},$$

let $\varrho(y)$ be the leftmost zero of $\tilde{w}(\rho) - \lambda\rho - y$. For $t \geq t_0$ consider the function

$$z(\rho,t) = \begin{cases} \tilde{w}(\rho) & \text{if } \rho \in [0, \varrho(v(t-t_0))], \\ \lambda\rho + v(t-t_0) & \text{if } \rho \in [\varrho(v(t-t_0)), R^n], \end{cases}$$

where v is a positive constant to be specified later. The intention is that by picking v appropriately, $z(\rho,t)$ will serve as an upper bound for

$$w(\rho,t) := \int_{B(0,\rho^{1/n})} u(x,t)\,dx, \tag{3.18}$$

and therefore, $\|\tilde{u}\|_\infty$ will bound u in a neighborhood of the origin.

Under the assumptions made above, let $v = CR^p n^q \omega_n^{1-q} \lambda^q$. We claim that $w \leq z$ as long as z is well defined (i.e., until $\tilde{w}(\rho) - \lambda\rho - v(t-t_0)$ has no zeros). By the strong maximum principle, it suffices to prove that $W \leq z$, where

$$W(\rho,t) := \int_{B(0,\rho^{1/n})} U(x,t)\,dx,$$

and U is a radially symmetric solution of (1.1) for $t \geq t_0$ that satisfies $u(x,t_0) \leq U(x,t_0) \leq \|u(\cdot,t_0)\|_\infty$.

Suppose that $W(\rho,t) > z(\rho,t)$ for some $\rho \in [0,R^n]$ and some $t \geq t_0$. Note that by the choice of λ, $W(\rho,t_0) \leq z(\rho,t_0)$. Also, $W(0,t) = z(0,t) = 0$ and $W(R^n,t) = W(R^n,t_0) \leq z(R^n,t_0) \leq z(R^n,t)$ for every $t \geq t_0$. Thus, there must be some $t_1 > t_0$ and $\rho_1 \in (0,R^n)$ for which $\zeta := (W-z)e^{-t}$ satisfies $\zeta(\rho_1,t_1) > 0$ and $\zeta(\rho_1,t_1) \geq \zeta(\rho,t)$ for every $t \in [t_0,t_1]$ and every $\rho \in [0,R^n]$. Note that (ρ_1,t_1) cannot be a point $(\varrho(v(t_1-t_0)),t_1)$ at which ζ is not smooth because W is continuously differentiable and the limit of $z_\rho(\rho,t_1)$ as ρ approaches $\varrho(v(t_1-t_0))$ from the left is higher than the corresponding right-hand limit. Hence, it must be the case that

$$\zeta_\rho(\rho_1,t_1) = 0, \tag{3.19}$$

$$\zeta_{\rho\rho}(\rho_1,t_1) \leq 0, \tag{3.20}$$

and

$$\zeta_t(\rho_1,t_1) \geq 0. \tag{3.21}$$

Equation (3.19) implies that

$$W_\rho(\rho_1,t_1) = z_\rho(\rho_1,t_1), \tag{3.22}$$

and (3.20) implies that

$$W_{\rho\rho}(\rho_1,t_1) \leq z_{\rho\rho}(\rho_1,t_1). \tag{3.23}$$

But, because $z = \tilde{w}$ for $\rho < \varrho(v(t_1-t_0))$, and because of the choice of v,

$$z_t \geq n^2\rho^{2\gamma} z_{\rho\rho} + n^q \omega_n^{1-q} \rho^\gamma g(\rho^{1/n}) z_\rho^q \tag{3.24}$$

at (ρ_1,t_1). Also, the radial symmetry of W implies that

$$W_t = n^2\rho^{2\gamma} W_{\rho\rho} + n^q \omega_n^{1-q} \rho^\gamma g(\rho^{1/n}) W_\rho^q. \tag{3.25}$$

Using (3.22)−(3.25) we find that at (ρ_1, t_1)

$$\zeta_t = -\zeta + (W_t - z_t)e^{-t} \leq -\zeta < 0,$$

which contradicts (3.21), so $w(\rho, t) \leq z(\rho, t)$ for all $\rho \in [0, R^n]$ and all $t \geq t_0$ for which z is defined. As was mentioned above, this implies that u does not blow up in this time interval.

Note that the length of this time interval past t_0 on which u is guaranteed not to blow up is proportional to $G[\tilde{w}]$ (because of the convexity of $-\tilde{w}$) and inversely proportional to v. Letting $\tilde{u} \to u_c$ (and, therefore, $\tilde{w} \to w_c$) and using Lemma 3.2 (which estimates $G[w_c]$), we find that

$$T - t_0 \geq \tilde{C}\|u(\cdot, t_0)\|_\infty^{\mu - q}, \tag{3.26}$$

for some constant $\tilde{C}$ (independent of t_0), if $\|u(\cdot, t_0)\|_\infty$ is sufficiently large. It is not hard to see that (by possibly decreasing $\tilde{C}$) we can get (3.26) to hold for t_0 bounded away from T as well, so (3.26) holds for all $t_0 \geq 0$. Replacing t_0 by t and rewriting (3.26) we get (1.5) and (1.6).

Now, suppose that the hypothesis of radial symmetry for u is added. Let w be defined as in (3.18). By part 1 of Lemma 3.1, $Q := r^{n-1}(u_r + u^q g(r))$ is bounded by a constant v, and a calculation shows that $w_t = Q$. Using this fact, an improved lower bound on the size of the remaining interval existence until blowup can be obtained in much the same way as the previous bound. In particular, we can define z as previously but pick v in the definition of z to be equal to the constant that bounds Q. An argument similar to the one used before implies that $w \leq z$ as long as z is defined; the only difference is that for $\rho > \varrho(v(t_1 - t_0))$, the inequality (3.24) no longer holds, so we use the fact that the constant v bounds w_t in place of the combination of (3.24) and (3.25) to conclude directly that $z_t \geq w_t$ for such ρ. Since v is now independent of λ, we obtain

$$T - t_0 \geq \tilde{C}\|u(\cdot, t_0)\|_\infty^{\mu}$$

in place of (3.26). The estimate (1.5) with (1.7) is an immediate consequence. □

INEQUALITIES FOR THE POLYGAMMA FUNCTIONS*

HORST ALZER† AND JIM WELLS‡

Abstract. Let

$$F_n(x;c) = (\Psi^{(n)}(x))^2 - c\Psi^{(n-1)}(x)\Psi^{(n+1)}(x) \quad (x>0),$$

where Ψ denotes the logarithmic derivative of the gamma function, $n \geq 2$ is an integer, and c is a real number. The authors prove that the function $x \mapsto F_n(x;\alpha)$ is strictly completely monotonic on $(0,\infty)$ if and only if $\alpha \leq (n-1)/n$, while $x \mapsto -F_n(x;\beta)$ is strictly completely monotonic on $(0,\infty)$ if and only if $\beta \geq n/(n+1)$.

Key words. polygamma functions, complete monotonicity, convexity, concavity, superadditivity, inequalities

1. Introduction. The psi (or digamma) function Ψ is defined for all positive real numbers x by

$$\Psi(x) = \Gamma'(x)/\Gamma(x) = -C + \sum_{i=0}^{\infty}\left(\frac{1}{1+i} - \frac{1}{x+i}\right),$$

where Γ denotes Euler's gamma function and $C = 0.5772\ldots$ is Euler's constant. Ψ and its derivatives are called polygamma functions.

Polygamma functions arise naturally in the study of beta distributions-probability models for random variables restricted to $[0,1]$. There, geometric properties, such as concavity, assist in determining the uniqueness of maximum likelihood estimates.

Several important inequalities involving the polygamma functions have been obtained in the recent past (cf. [2], [3], [4], [5], [10], [11], [12], [13], [14], [15]). The following inequality was given by S.Y. Trimble, J. Wells, and F.T. Wright [17] in 1989:

$$\frac{1}{2}\Psi'(x)\Psi'''(x) \leq (\Psi''(x))^2 \qquad (x>0). \tag{1.1}$$

The authors, however, did not give a proof for (1.1). They only remarked that "a rather tedious argument" [17, p. 1257] is necessary to establish this inequality. Recently, B.J. English and G. Rousseau [7, Prop. 1] presented a short proof for (1.1) (with "$<$" instead of "$\leq$") and used this result to establish monotonicity properties of certain harmonic sums.

It is natural to look for an extension of (1.1) involving $\Psi^{(n)}$. The direction of our investigation is suggested by the inequality

$$(\Psi^{(n)}(x))^2 \leq \Psi^{(n-1)}(x)\Psi^{(n+1)}(x) \quad (x>0; n=2,3,\ldots), \tag{1.2}$$

which follows from a result of A.M. Fink [9, Thm. 1]. For $n = 2$, this provides a converse version of inequality (1.1).

In this paper we establish sharp upper and lower bounds, depending only on n, for the ratio

$$\frac{(\Psi^{(n)}(x))^2}{\Psi^{(n-1)}(x)\Psi^{(n+1)}(x)} \qquad (x > 0; n = 2, 3, \ldots).$$

In particular, we obtain a generalization of (1.1) and a refinement of (1.2).

Our approach is based on the observation that many inequalities involving $\Psi^{(n)}$ flow from monotonicity properties of functions connected with the psi function. Indeed, in many cases it is shown that these functions are not only monotonic but actually completely monotonic (cf. [2], [3], [5], [12], [16]).

A function f is said to be completely monotonic on an interval I, if $f \in C^\infty(I)$ and

$$(-1)^k f^{(k)}(x) \geq 0 \tag{1.3}$$

for all $x \in I$ and for all integers $k \geq 0$. If inequality (1.3) is strict for all $x \in I$ and for all $k \geq 0$, then f is said to be strictly completely monotonic on I.

Completely monotonic functions play an important role in physics, numerical analysis, probability theory, and in other fields (cf. [6], [8], [16], [19]). An exposition of the most interesting properties on completely monotonic functions can be found in [18].

The main purpose of this paper is to present new completely monotonic functions which involve the polygamma functions. More precisely, we consider the function

$$F_n(x; c) = (\Psi^{(n)}(x))^2 - c\Psi^{(n-1)}(x)\Psi^{(n+1)}(x) \quad (x > 0),$$

where $n \geq 2$ is an integer and c is a real number, and we determine all real numbers α and β such that $x \mapsto F_n(x; \alpha)$ and $x \mapsto -F_n(x; \beta)$ are strictly completely monotonic on $(0, \infty)$.

2. Main result. Our main result is the following theorem.

THEOREM 2.1. *Let $n \geq 2$ be an integer, and let α and β be real numbers. The function*

$$x \mapsto F_n(x; \alpha)$$

is strictly completely monotonic on $(0, \infty)$ if and only if

$$\alpha \leq (n-1)/n,$$

and

$$x \mapsto -F_n(x; \beta)$$

is strictly completely monotonic on $(0, \infty)$ if and only if

$$\beta \geq n/(n+1).$$

The proof of this theorem needs the following technical lemma.

LEMMA 2.2. *For any fixed integer $n \geq 2$, let*

$$I_n(a) = \int_0^1 [(2n-1)x^2 - 1] f_n(a(1-x)) f_n(a(1+x)) dx,$$

where

$$f_n(t) = t^{n-1}/(1 - e^{-t}).$$

Then $I_n(a) < 0$ for all $a > 0$.

Proof. Let

$$h_n(x) = [(2n-1)x^2 - 1](1-x^2)^{n-2}$$

and

$$u(x;a) = \frac{a(1-x)}{1 - e^{-a(1-x)}} \; \frac{a(1+x)}{1 - e^{-a(1+x)}}.$$

Then

$$I_n(a) = a^{2(n-2)} \int_0^1 h_n(x) u(x;a) dx. \tag{2.1}$$

Now, we show that $x \mapsto u(x;a)$ is strictly decreasing on $(0,1)$. In order to prove that

$$\frac{\partial}{\partial x} u(x;a) < 0 \qquad (0 < x < 1; a > 0),$$

we define

$$v(x;a) = \log u(x;a).$$

Then we have

$$\frac{\partial}{\partial x} v(x;a) = a[w(a(1+x)) - w(a(1-x))],$$

where

$$w(z) = \frac{1}{z} - \frac{1}{e^z - 1}.$$

Since

$$\frac{d}{dz} w(z) = \left[\left(\frac{z}{2}\right)^2 - \left(\sinh \frac{z}{2}\right)^2 \right] \Big/ \left(z \sinh \frac{z}{2}\right)^2 < 0 \qquad \text{for } z > 0,$$

and since $0 < a(1-x) < a(1+x)$ we have

$$w(a(1+x)) < w(a(1-x)),$$

so that

$$\frac{\partial}{\partial x} u(x;a) = u(x,a) \frac{\partial}{\partial x} v(x;a) < 0,$$

and, hence,

$$h_n(x)u(x;a) < h_n(x)u((2n-1)^{-1/2};a) \tag{2.2}$$

for $0 < x < 1$, $x \neq (2n-1)^{-1/2}$, $a > 0$. From (2.1), (2.2), and

$$\int_0^1 h_n(x)dx = \left[-x(1-x^2)^{n-1}\right]_0^1 = 0,$$

it follows that

$$I_n(a) < a^{2(n-2)}u((2n-1)^{-1/2};a)\int_0^1 h_n(x)dx = 0. \qquad \square$$

Proof of Theorem 2.1. First we show that

$$x \mapsto F_n(x;(n-1)/n)$$

is strictly completely monotonic on $(0,\infty)$. From the series representation

$$(-1)^{m+1}\Psi^{(m)}(x) = m!\sum_{i=0}^{\infty}\frac{1}{(x+i)^{m+1}} \qquad (x>0; m=1,2,\ldots) \tag{2.3}$$

we obtain for $x > 0$ and $n \geq 2$:

$$(-1)^n\Psi^{(n-1)}(x) = \int_0^{\infty} e^{-xt}f_n(t)dt, \tag{2.4}$$

where f_n is as in Lemma 2.2 (cf. [1, p. 260]). Differentiation leads to

$$(-1)^{n+1}\Psi^{(n)}(x) = \int_0^{\infty} e^{-xt}tf_n(t)dt, \tag{2.5}$$

and

$$(-1)^{n+2}\Psi^{(n+1)}(x) = \int_0^{\infty} e^{-xt}t^2f_n(t)dt. \tag{2.6}$$

It follows from (2.4), (2.5), and (2.6) that

$$\begin{aligned} F_n(x;(n-1)/n) &= [(-1)^{n+1}\Psi^{(n)}(x)]^2 \\ &\quad - \frac{n-1}{n}[(-1)^n\Psi^{(n-1)}(x)(-1)^{n+2}\Psi^{(n+1)}(x)] \\ &= \int_0^{\infty} e^{-xt}g_n(t)dt, \end{aligned} \tag{2.7}$$

where

$$g_n(t) = (tf_n(t) * tf_n(t)) - \frac{n-1}{n}(f_n(t) * t^2f_n(t))$$

and $*$ denotes the Laplace convolution. We have

$$g_n(t) = \int_0^t \left(t - \frac{2n-1}{n}s\right)sf_n(t-s)f_n(s)ds.$$

Let $s = \frac{t}{2}(1+x)$. Then

$$g_n(t) = \frac{t^3}{8n}\int_{-1}^{1}[1-2(n-1)x-(2n-1)x^2]f_n\left(\frac{t}{2}(1-x)\right)f_n\left(\frac{t}{2}(1+x)\right)dx.$$

Since $x \mapsto xf_n(\frac{t}{2}(1-x))f_n(\frac{t}{2}(1+x))$ is an odd function, we obtain

$$\begin{aligned} g_n(t) &= \frac{t^3}{8n}\int_{-1}^{1}[1-(2n-1)x^2]f_n\left(\frac{t}{2}(1-x)\right)f_n\left(\frac{t}{2}(1+x)\right)dx \\ &= -\frac{t^3}{4n}I_n\left(\frac{t}{2}\right), \end{aligned}$$

where I_n is as in Lemma 2.2. Hence, it follows from Lemma 2.2 and (2.7) that

$$(-1)^k\frac{d^k}{dx^k}F_n(x;(n-1)/n) = \int_0^\infty e^{-xt}t^k g_n(t)dt > 0 \quad (x>0; k=0,1\ldots).$$

This proves that $x \mapsto F_n(x;(n-1)/n)$ is strictly completely monotonic on $(0,\infty)$.

The series representation (2.3) implies that $(-1)^{m+1}\Psi^{(m)}(m \geq 1)$ is strictly completely monotonic on $(0,\infty)$. Since the sum and the product of two strictly completely monotonic functions are also strictly completely monotonic, we get from

$$\begin{aligned} F_n(x;\alpha) &= F_n(x;(n-1)/n) \\ &\quad + ((n-1)/n-\alpha)(-1)^n\Psi^{(n-1)}(x)(-1)^{n+2}\Psi^{(n+1)}(x) \end{aligned}$$

that $x \mapsto F_n(x;\alpha)$ is strictly completely monotonic on $(0,\infty)$ if $\alpha \leq (n-1)/n$.

Conversely, if $x \mapsto F_n(x;\alpha)$ is strictly completely monotonic on $(0,\infty)$, then we obtain

$$\alpha < (\Psi^{(n)}(x))^2/[\Psi^{(n-1)}(x)\Psi^{(n+1)}(x)] \quad (x>0). \tag{2.8}$$

From the asymptotic expansion

$$\Psi^{(m)}(x) \sim (-1)^{m-1}\left[\frac{(m-1)!}{x^m}+\frac{m!}{2x^{m+1}}+\sum_{k=1}^{\infty}B_{2k}\frac{(2k+m-1)!}{(2k)!x^{2k+m}}\right]$$
$$(x\to\infty; m=1,2,\ldots)$$

(cf. [1, p. 260]), we conclude

$$\lim_{x\to\infty}x^m\Psi^{(m)}(x) = (-1)^{m-1}(m-1)!,$$

and, hence,

$$\lim_{x\to\infty}\frac{(\Psi^{(n)}(x))^2}{\Psi^{(n-1)}(x)\Psi^{(n+1)}(x)} = \frac{n-1}{n}, \tag{2.9}$$

so that (2.8) and (2.9) imply $\alpha \leq (n-1)/n$.

Next, we prove that

$$x \mapsto -F_n(x;n/(n+1))$$

is strictly completely monotonic on $(0,\infty)$. From (2.3) and Lagrange's identity (cf. [15, p. 41]), we obtain

$$\begin{aligned}-F_n(x;n/(n+1)) &= (n/(n+1))\Psi^{(n-1)}(x)\Psi^{(n+1)}(x) - (\Psi^{(n)}(x))^2\\ &= (n!)^2\left[\sum_{i=0}^{\infty}(x+i)^{-n}\sum_{i=0}^{\infty}(x+i)^{-n-2}\right.\\ &\qquad\left.-\left(\sum_{i=0}^{\infty}(x+i)^{-n-1}\right)^2\right]\\ &= (n!)^2\sum_{i=0}^{\infty}\sum_{j=i+1}^{\infty}(j-i)^2[(x+i)(x+j)]^{-n-2}.\end{aligned}$$

Hence, for all integers $k \geq 0$,

$$\begin{aligned}&(-1)^k\frac{d^k}{dx^k}(-F_n(x;n/(n+1)))\\ &\quad= (n!)^2\sum_{i=0}^{\infty}\sum_{j=i+1}^{\infty}(j-i)^2\sum_{r=0}^{k}\binom{k}{r}(x+i)^{-n-2-r}(x+j)^{-n-2-k+r}\\ &\qquad\times\prod_{s=0}^{r-1}(n+2+s)\prod_{s=0}^{k-r-1}(n+2+s) > 0 \quad (x>0).\end{aligned}$$

The representation

$$\begin{aligned}-F_n(x;\beta) &= -F_n(x;n/(n+1))\\ &\quad+(\beta-n/(n+1))(-1)^n\Psi^{(n-1)}(x)(-1)^{n+2}\Psi^{(n+1)}(x)\end{aligned}$$

implies that $x \mapsto -F_n(x;\beta)$ is strictly completely monotonic on $(0,\infty)$ if $\beta \geq n/(n+1)$.

Finally, we assume that $x \mapsto -F_n(x;\beta)$ is strictly completely monotonic on $(0,\infty)$. Then we obtain

$$(\Psi^{(n)}(x))^2/[\Psi^{(n-1)}(x)\Psi^{(n+1)}(x)] < \beta \quad (x>0). \tag{2.10}$$

Using the identity

$$\Psi^{(m)}(x) = \Psi^{(m)}(x+1) + (-1)^{m+1}m!x^{-m-1} \quad (x>0; m=0,1,\ldots), \tag{2.11}$$

we conclude

$$\lim_{x\to 0}\frac{(\Psi^{(n)}(x))^2}{\Psi^{(n-1)}(x)\Psi^{(n+1)}(x)} = \frac{n}{n+1}. \tag{2.12}$$

From (2.10) and (2.12) we obtain $\beta \geq n/(n+1)$. This completes the proof of the theorem. □

As an immediate consequence of the theorem and the limit relations (2.9) and (2.12) we get sharp bounds for the ratio

$$(\Psi^{(n)}(x))^2/[\Psi^{(n-1)}(x)\Psi^{(n+1)}(x)].$$

COROLLARY 2.3. *Let $n \geq 2$ be an integer. Then for all positive real numbers x,*

$$\frac{n-1}{n} < \frac{(\Psi^{(n)}(x))^2}{\Psi^{(n-1)}(x)\Psi^{(n+1)}(x)} < \frac{n}{n+1}. \tag{2.13}$$

Both bounds are best possible.

Remark 2.4. The series representation (2.3) and the left-hand inequality of (2.13) lead to an inequality for infinite series, which can be considered as a converse of the Cauchy–Schwarz inequality:

$$\frac{n^2-1}{n^2}\sum_{i=0}^{\infty}(x+i)^{-n}\sum_{i=0}^{\infty}(x+i)^{-n-2} < \left(\sum_{i=0}^{\infty}(x+i)^{-n-1}\right)^2 \tag{2.14}$$
$$(x>0; n=2,3,\ldots).$$

From (2.9) we conclude that the constant factor $(n^2-1)/n^2$ is best possible. The special case $n=2$ (with "$\leq$" instead of "$<$") was given in [17] without a proof. We note that slight modifications in the proof of Theorem 2.1 reveal that inequality (2.14) holds for all real numbers $n>1$.

It was mentioned in [17] that inequality (1.1) implies the convexity of $1/\Psi'$ on $(0,\infty)$. This result can be generalized.

COROLLARY 2.5. *Let*

$$f_n(x;c) = ((-1)^{n+1}\Psi^{(n)}(x))^c \quad (x>0),$$

where $n \geq 1$ is an integer and c is a real number. The function $x \mapsto f_n(x;\alpha)$ is strictly convex on $(0,\infty)$ if and only if $\alpha \leq -1/n$ or $\alpha > 0$, while $x \mapsto f_n(x;\beta)$ is strictly concave on $(0,\infty)$ if and only if $-1/(n+1) \leq \beta < 0$.

Proof. Let $\alpha \neq 0$ and $x>0$; we have

$$\begin{aligned}&\frac{1}{\alpha}(\Psi^{(n+1)}(x))^{-2}(f_n(x;\alpha))^{-1+2/\alpha}\frac{\partial^2}{\partial x^2}f_n(x;\alpha)\\ &= \alpha - 1 + \Psi^{(n)}(x)\Psi^{(n+2)}(x)(\Psi^{(n+1)}(x))^{-2}.\end{aligned} \tag{2.15}$$

If $\alpha \leq -1/n$, then we conclude from the first inequality of (2.13) that the expression on the right-hand side of (2.15) is negative. And, if $\alpha > 0$, then the second inequality of (2.13) implies that the right-hand side of (2.15) is positive. In both cases we obtain

$$\frac{\partial^2}{\partial x^2}f_n(x;\alpha) > 0.$$

Now, let $x \mapsto f_n(x;\alpha)$ be strictly convex on $(0,\infty)$. Then we have

$$f_n(\delta x + (1-\delta)y;\alpha) < \delta f_n(x;\alpha) + (1-\delta)f_n(y;\alpha) \tag{2.16}$$
$$(x,y>0, x\neq y; 0<\delta<1).$$

We assume (for a contradiction) that $\alpha \in (-1/n, 0)$. If we multiply both sides of (2.16) by $x^{n\alpha}$ and let x tend to ∞, then we get $\delta^{-n\alpha}((n-1)!)^\alpha \leq \delta((n-1)!)^\alpha$, which implies $\alpha \leq -1/n$.

Similarly, we can prove that $x \mapsto f_n(x;\beta)$ is strictly concave on $(0,\infty)$ if and only if $-1/(n+1) \leq \beta < 0$. We omit the details. □

Remark 2.6. If a function f is strictly convex on $(0,\infty)$ and satisfies $\lim_{x\to 0} f(x) = 0$, then f is strictly superadditive, that is, we have

$$f(x) + f(y) < f(x+y) \quad (x, y > 0)$$

(cf. [17]). From (2.11) we obtain $\lim_{x\to 0}(-1)^{m+1}\Psi^{(m)}(x) = \infty (m \geq 0)$. This implies that the functions $((-1)^{n+1}\Psi^{(n)})^{\alpha} (n \geq 1; \alpha \leq -1/n)$ and $-((-1)^{n+1}\Psi^{(n)})^{\beta} (n \geq 1; -1/(n+1) \leq \beta < 0)$ are strictly superadditive on $(0,\infty)$. Hence, we get the following bounds for $(-1)^{n+1}\Psi^{(n)}(x+y)$:

$$\begin{aligned}
&[((-1)^{n+1}\Psi^{(n)}(x))^{\beta} + ((-1)^{n+1}\Psi^{(n)}(y))^{\beta}]^{1/\beta} \\
&\quad < \ (-1)^{n+1}\Psi^{(n)}(x+y) \\
&\quad < \ [((-1)^{n+1}\Psi^{(n)}(x))^{\alpha} + ((-1)^{n+1}\Psi^{(n)}(y))^{\alpha}]^{1/\alpha} \\
&(x, y > 0; n = 1, 2, \ldots; \alpha \leq -1/n, -1/(n+1) \leq \beta < 0).
\end{aligned}$$

Acknowledgments. The authors thank the referees for helpful comments which improved the presentation of the paper.

A METHOD OF CHARACTERISTICS FOR SOME SYSTEMS OF CONSERVATION LAWS*

ARNAUD HEIBIG† AND AMINA SAHEL†

Abstract. We study systems of conservation laws which belong to the Temple class. Some algebraic formulas are derived and used to integrate the Cauchy problem. In particular, the method of characteristics is extended to the case of a system of two coupled equations.

Key words. conservation laws, systems of the Temple class, characteristics

AMS subject classifications. 35L65, 35L99

PII. S0036141096310351

Introduction. This paper deals with $n \times n$ systems of conservation law,

$$u_t + f(u)_x = 0, \qquad t > 0,$$
$$u(x,0) = u_0(x),$$

which belong to the Temple class [19]. A system of the Temple class is defined by the following algebraic requirements:

- It is strictly hyperbolic and diagonalizable.
- Its characteristic hypersurfaces are included in hyperplanes.

Examples of such systems arise in the study of nonlinear motion in elastic strings, or multicomponent chromatography. From a mathematical point of view, the main interest of Temple systems is that no secondary waves can be generated by interaction.

The Temple class has been studied by numerous authors (see [17] for a survey), and most of the scalar theory has been generalized to that frame. The reader may refer to [2], [3], [4], [5], [6], [11], [14], and [15] for existence and uniqueness results. However, unlike the scalar case, no system ($n \geq 2$) has been integrated explicitly. The aim of this paper is to give integration formulas. Our main result can be stated as follows.

for a "general" 2×2 system of the Temple class (we mainly exclude uncoupled equations), if two characteristics issued from two given points of the real axis happen to intersect, then the location of the intersection can be computed by a quadrature of the initial data and the inversion of a linear system.

Our method is valid for piecewise smooth solutions and can therefore be used after the formation of shocks.

This paper is divided into seven parts. The second part is introductory. The third contains the algebraic part of our study (Theorem 2.4). We give some properties related to functions $f(u) - \lambda_i(u)u$ and, in particular, establish by a new proof that systems of the Temple class are semi-Hamiltonian. Various consequences of Theorem 2.4 are presented in part four, including a statement on the generic smoothness of admissible solutions. Next, we give an explicit formula for the infinitesimal displacement of characteristics. The sixth part is devoted to our explicit integration formula

for the 2×2 systems. Last, we discuss a generalized Lax formula (introduced in [2]) in term of saddle points.

1. Definitions and notations. First results. Let D be a domain of $\mathbb{R}^n$, and let $f : D \to \mathbb{R}^n$ be a smooth function. For $u \in D$, we denote by $A(u)$ the Jacobian matrix of $f(u)$. Throughout this paper, we assume that the system of conservation laws with initial data $u_0 : D \to \mathbb{R}^n$,

$$u_t + f(u)_x = 0, \quad x \in \mathbb{R}, \quad t > 0, \tag{1.1}$$

$$u(x,0) = u_0(x), \qquad x \in \mathbb{R}, \tag{1.2}$$

is strictly hyperbolic (i.e., the eigenvalues of $A(u)$ are real and simple). The eigenvalues of $A(u)$ are indexed in a natural fashion: $\lambda_1(u) < \cdots < \lambda_n(u)$. We denote by $r_i(u)$ (resp., $l_i(u)$) $(1 \le i \le n)$ a right eigenvector (resp., a left eigenvector) of $A(u)$ associated with $\lambda_i(u)$. Without loss of generality, we can assume that $(l_1(u), \cdots, l_n(u))$ is the dual basis of $(r_1(u), \cdots, r_n(u))$, i.e., the basis of (co)vectors satisfying $< l_i(u), r_j(u) >= \delta_{ij}$. Last, recall that a function $w_i : D \to \mathbb{R}\,(1 \le i \le n)$ is a (strict) i-Riemann invariant of system 1.1 if

$$\begin{array}{ll} \text{(a)} & \forall u \in D, \qquad dw_i(u) \wedge l_i(u) = 0, \\ \text{(b)} & \forall u \in D, \qquad dw_i(u) \neq 0. \end{array}$$

We now give a definition of the Temple class.

DEFINITION 1.1. (1) *Let $i \in \{1, \ldots, n\}$. We say that the ith characteristic field of system* 1.1 *is a Temple field if*

(*i*) *there exists a (strict) i-Riemann invariant.*

(*ii*) *for any $s \in \mathbb{R}$, the level sets $H_i(s) = \{u \in D / w_i(u) = s\}$ are (linear) affine submanifolds in the u-space D.*

(2) *We say that system* 1.1 *belongs to the Temple class if any of its characteristic fields is a Temple field.*

Example 1. (a) Any conservation law ($n = 1$) belongs to the Temple class.

(b) The system of isotachophoresis can be written as (see [2])

$$\partial_t u_i + \partial_x \left(\frac{a_i u_i}{m} \right) = 0, \qquad m = \sum_{i=1}^{n} u_i,$$

where a_i are positive constants. We assume that $a_1 < a_2 < \cdots < a_n$ and set $D = (\mathbb{R}_+^*)^n$. The linear function $w_1(u) = \sum_{i=1}^n (u_i/a_i)$ is a Riemann invariant associated with the eigenvalue $\lambda_1 = 0$. For any $i \in \{2, \cdots, n\}$, there exists a smooth function w_i with values in $]a_{i-1}, a_i[$ such that

$$\forall u \in D, \qquad \sum_{j=1}^{n} \frac{u_j}{a_j - w_i(u)} = 0.$$

Function w_i is a Riemann invariant associated with the eigenvalue $\lambda_i = w_i/m$. Moreover, $m = w_1(a_1 \ldots a_n)/(w_2 \ldots w_n)$. The characteristic hypersurfaces are given by $H_i(s) = \{u \in D / \sum_{j=1}^n (u_j)/(a_j - s) = 0\}$, with $s \in]a_{i-1}, a_i[$ $(i \in \{2, \ldots, n\})$. Therefore, the general system of isotachophoresis belongs to the Temple class. Last, choosing $l_i(u) = \left((w_i(u) - a_1)^{-1}, ..., (w_i(u) - a_n)^{-1}\right)$ as a left eigenvector $(i \in \{2, \ldots, n\})$, we notice that for any $u \in D$, $l_i(u) \cdot u = 0$ and $l_i(u) \cdot f(u) = -1$ $(i \in \{2, \ldots, n\})$. Hence,

the previous quantities are independent of the w_j ($j \in \{1,\dots,n\}$). See Proposition 2.2 below.

(c) Let $n = 2, \mathcal{U} =]0,+\infty[\times\mathbb{R}$, $\phi \in C^1(\mathcal{U},\mathbb{R})$, and $D = \{u \in \mathcal{U}, \sum_{j=1}^{2}(\partial\Phi/\partial u_j)(u)u_j \neq 0\}$. The Keyfitz–Kranzer system

$$u_t + (\phi(u)u)_x = 0$$

has one Temple field. In fact, the speed $\lambda = \phi$ is associated with the Riemann invariant $\theta = \arctan(u_2/u_1)$. Hence, the characteristic sets $\theta = cte$ are included in straight lines.

From now on, in order to simplify the statements, we assume that system 1.1 belongs to the Temple class. Nevertheless (except in Theorem 3.1 and Proposition 5.2) we may assume that one single field is Temple and state our results "field by field."

2. Systems of the Temple class are semi-Hamiltonian. Systems of the Temple class are conservative and endowed with a complete set of (strict) Riemann invariants, i.e., they are semi-Hamiltonian (see [16] or [20]). Hence, there exist functions $N_i : D \to \mathbb{R}_+^*$ ($i \in \{1,\dots,n\}$) with the following properties:

$$\forall u \in D, \quad \forall j \in \{1,\dots,n\} \setminus \{i\}, \quad \left(N_i \frac{\partial \lambda_i}{\partial w_j}\right)(u) = \left((\lambda_j - \lambda_i)\left(\frac{\partial N_i}{\partial w_j}\right)\right)(u).$$

Expressions of functions N_i are given in [15]. We shall derived these formulae by different means. First, we recall some formal consequences of Definition 1.1.

2.1. Definition of functions m_i and q_i ($i \in \{1,\dots,n\}$). Results of this section are classical (see, for example, [5] or [15]). We fix $i \in \{1,\dots,n\}$ and notice that function l_i (up to a scalar multiplicative function) is constant along each characteristic hyperplane $H_i(a) = \{u \in D / w_i(u) = a\}, a \in \mathbb{R}$ (cf. Definition 1.1). Hence, we may write $l_i(w_i(u))$ instead of $l_i(u)$.

LEMMA 2.1. *Assume that system* 1.1 *belongs to the Temple class. The following assertion holds* ($i \in \{1,\dots,n\}$):

$$\forall (u,v) \in D^2, \qquad l_i(w_i(u)) \cdot (u - v) = 0 \Longrightarrow l_i(w_i(u)) \cdot (f(u) - f(v)) = 0.$$

Proof. Equality $l_i(w_i(v)) \cdot (u - v) = 0$ is nothing but $v \in H_i(w_i(u))$. We also have $u \in H_i(w_i(u))$. Therefore, for any $s \in [0,1], v + s(u - v) \in H_i(w_i(u))$ and

$$\begin{aligned} l_i(w_i(u)) \cdot [f(u) - f(v)] &= \int_0^1 l_i(w_i(u)) \cdot A(v + s(u - v)) \cdot (u - v) ds \\ &= \int_0^1 \lambda_i(v + s(u - v))\, l_i(w_i(u)) \cdot (u - v) ds = 0. \end{aligned}$$ ∎

We deduce from Lemma 2.1 the following proposition.

PROPOSITION 2.2. *Assume that system* 1.1 *belongs to the Temple class. Then, for any* $i \in \{1,\dots,n\}$, *there exist smooth functions* $m_i : w_i(D) \to \mathbb{R}$ *and* $q_i : w_i(D) \to \mathbb{R}$ *such that*

$$\forall u \in D, \quad m_i(w_i(u)) = l_i(w_i(u)) \cdot u \quad \textit{and} \quad q_i(w_i(u)) = l_i(w_i(u)) \cdot f(u).$$

Proof. Due to Definition 1.1, for any $u \in D$ and $v \in H_i(w_i(u))$, $l_i(u)$ is orthogonal to $v - u$, i.e.,

$$w_i(u) = w_i(v) \Longrightarrow l_i(w_i(u)) \cdot u = l_i(w_i(v)) \cdot v,$$

and it follows that $l_i(w_i(u)) \cdot u$ is a function of $w_i(u)$ alone. We set $m_i(w_i(u)) = l_i(w_i(u)) \cdot u$. Similarly, due to Lemma 2.1, $l_i(w_i(u)) \cdot f(u)$ is a function of $w_i(u)$ alone. We set $q_i(w_i(u)) = l_i(w_i(u)) \cdot f(u)$. Functions m_i and q_i are smooth. ∎

From now on, we note $m_i(w_i)$, instead of $m_i(w_i(u))$, $q_i(w_i)$ instead of $q_i(w_i(u))$, etc.

2.2. Functions N_i. Expressions of functions N_i are given in Theorem 2.4. First we need a lemma.

LEMMA 2.3. $\forall u \in D,\ \forall i \in \{1, \dots, n\},\ l_i'(w_i) \cdot u - m_i'(w_i) \neq 0.$

Proof. Assume that $l_i'(w_i(u_0)) \cdot u_0 = m_i'(w_i(u_0))$ for some point $u_0 \in D$ and some index $i \in \{1, \dots, n\}$. Differentiating the expression of m_i, with respect to w_i, we find that

$$\forall u \in D, \qquad l_i'(w_i) \cdot u - m_i'(w_i) + l_i(w_i) \frac{\partial u}{\partial w_i} = 0.$$

Therefore $(l_i(w_i) \cdot (\partial u/\partial w_i))(u_0) = 0$. Next, equality $dw_j(u) \wedge l_j(u) = 0$ implies that $(l_j(w_j) \cdot (\partial u/\partial w_i))(u) = 0$ for any $j \neq i$ and $u \in D$. Finally, $(\partial u/\partial w_i)(u_0) = 0$, which is impossible since $u \mapsto (w_1(u), w_2(u), \cdots, w_n(u))$ is a local diffeomorphism. ∎

From now on, we assume (changing function l_i into $-l_i$ if necessary) that

$$\forall u \in D, \quad \forall i \in \{1, \dots, n\}, \quad m_i'(w_i) - l_i'(w_i) \cdot u > 0.$$

The following theorem is the first step in our method of characteristics.

THEOREM 2.4. (a) $\forall u \in D, \forall i \in \{1, \dots, n\}$,

$$\begin{cases} l_i(w_i)(f(u) - \lambda_i(u)u) &= q_i(w_i) - \lambda_i(u) m_i(w_i), \\ l_i'(w_i)(f(u) - \lambda_i(u)u) &= q_i'(w_i) - \lambda_i(u) m_i'(w_i), \end{cases}$$

(b) $\forall i \in \{1, \dots, n\}, \exists N_i : D \to \mathbb{R}_+^*, \forall j \in \{1, \dots, n\} \setminus \{i\},\ \forall u \in D,$

$$\left(N_i \frac{\partial \lambda_i}{\partial w_j} \right)(u) = \left((\lambda_j - \lambda_i) \left(\frac{\partial N_i}{\partial w_j} \right) \right)(u).$$

Moreover, we can choose $N_i(u) = m_i'(w_i) - l_i'(w_i) \cdot u$.

(c) $\forall u \in D, \forall i \in \{1, \dots, n\}$,

$$\left(N_i \frac{\partial \lambda_i}{\partial w_i} \right)(u) = q_i''(w_i) - \lambda_i(u) m_i''(w_i) - l_i''(w_i) \cdot (f(u) - \lambda_i(u)u),$$

(with $N_i(u) = m_i'(w_i) - l_i'(w_i) \cdot u$).

Proof. (a) The first equality is a consequence of the definition of the functions m_i and the functions q_i. Next, we differentiate this equality with respect to w_i,

$$\begin{aligned} &l_i'(w_i)(f(u) - \lambda_i(u)u) + l_i(w_i) \cdot (A(u) - \lambda_i(u)) \cdot (\partial u/\partial w_i) - (\partial \lambda_i/\partial w_i)(u) \\ &(l_i(w_i) \cdot u) = q'(w_i) - \lambda_i(u) m_i'(w_i) - (\partial \lambda_i/\partial w_i)(u) m_i(w_i). \end{aligned}$$

Therefore, the second formula follows from the definition of m_i and the identity $l_i(w_i) \cdot (A(u) - \lambda_i(u)) = 0$.

(b) We differentiate the second identity of (a) with respect to $w_j, j \neq i$. We get

$$\begin{aligned} & l_i'(w_i) \cdot (\partial f/\partial w_j)(u) - \lambda_i(u) \cdot (\partial u/\partial w_j)(u) - (\partial \lambda_i/\partial w_j)(u)(l_i'(w_i) \cdot u) \\ = \quad & -(\partial \lambda_i/\partial w_j)(u) \cdot m_i'(w_i). \end{aligned}$$

We use the identity $(\partial f/\partial w_j) - \lambda_j(\partial u/\partial w_j) = 0$ and find that

$$(m_i'(w_i) - l_i'(w_i) \cdot u)(\partial \lambda_i/\partial w_j)(u) = (\lambda_j - \lambda_i)(\partial/\partial w_j)(m_i'(w_i) - l_i'(w_i) \cdot u).$$

Now, Lemma 2.3 asserts that $m_i'(w_i) - l_i'(w_i) \cdot u$ doesn't vanish.

(c) Differentiate the second identity of (a) with respect to w_i and use identity $(\partial f/\partial w_i) - \lambda_i(\partial u/\partial w_i) = 0$. □

Remark 1. (a) A proof of Theorem 2.4 (b) is given in [15].

(b) For a general hyperbolic system of conservation laws, the existence of a complete set of (strict) Riemann invariants $(w_1, \ldots, w_n)$ implies the integrability conditions of Theorem 2.4 (b). See [16] and [18].

(c) Functions N_i and $N_i(\partial \lambda_i/\partial w_i)$ were introduced by Lax (cf. [9]) in the 2×2 case. Recall that for a general semi-Hamiltonian system of conservation laws, the following Riccati equation holds (here, the function u is a smooth solutions of (1.1, 1.2)):

$$\forall i \in \{1, \ldots, n\}, \qquad (\partial_t + \lambda_i \partial_x)\left(\frac{\partial_x w_i}{N_i}\right) = -N_i \frac{\partial \lambda_i}{\partial w_i}\left(\frac{\partial_x w_i}{N_i}\right)^2.$$

Example 2. Theorem 2.4 (a) is a generalization of Dafermos–Geng's results. Following [4], we consider the 2×2 system (which can be derived from the 3×3 isotachophoresis system),

$$\begin{cases} \partial_t u_1 - \partial_x(u_2/u_1) & = 0, \\ \partial_t u_2 - \partial_x(1/u_1) & = 0. \end{cases}$$

The domain of strict hyperbolicity is

$$D = \{(u_1, u_2) \in \mathbb{R}^2 / u_1 \neq 0 \text{ and } u_2^2 - 4u_1 > 0\}.$$

We set $\triangle = u_2^2 - 4u_1$. The eigenvalues of $f'(u)$ are $\lambda_i(u) = (u_2 + \varepsilon_i \sqrt{\triangle})/(2u_1^2)$ ($\varepsilon_2 = -\varepsilon_1 = 1$). Corresponding Riemann invariants are given by $w_i(u) = -(u_1 \lambda_i(u))^{-1}$. Corresponding left and right eigenvectors are given by $l_i(w_i) = (1, w_i)$ and $r_i(w_i) = {}^t(-w_j, 1)$ $(j \neq i)$. Hence, the system belongs to the Temple class. One checks that $u_1 = w_1 w_2, u_2 = -(w_1 + w_2), m_i(w_i) = -w_i^2$, and $q_i(w_i) = 1/w_i$. Therefore, for any $u \in D, N_i(u) = \mid w_2(u) - w_1(u) \mid$.

3. A few consequences of Theorem 2.4.

3.1. Generic smoothness of admissible solutions. We assume that $n = 2$, $l_i(w_i) = (1, w_i), i \in \{1, 2\}$, and that $\overline{D}$ is a compact convex subset of $\mathbb{R}^n$. Moreover assume that system (1.1) is strictly hyperbolic on $\overline{D}$. Under the hypothesis of genuine nonlinearity,

$$\forall i \in \{1, 2\}, \quad \forall u \in D, \quad \frac{\partial \lambda_i}{\partial w_i}(u) > 0,$$

the following statement still holds (cf. [4]).

THEOREM 3.1. *Solutions of the Cauchy problem* (1.1, 1.2) *(with bounded variation, constructed as limits in* $L^1_{loc}(\mathbb{R}\times\mathbb{R}_+)$ *of Glimm's approximate solutions) and with initial data in* C^k $(k \geq 4)$*, are generically piecewise* C^k *smooth and do not contain centered compression waves. Solutions of* (1.1, 1.2) *(with bounded variation, constructed as limits in* $L^1_{loc}(\mathbb{R}\times\mathbb{R}_+)$ *of Glimm's approximate solutions) and with real analytic initial data are always piecewise smooth.*

In the previous statement, the expression "solutions of the Cauchy problem (1.1, 1.2) are generically piecewise C^k smooth" means that the set of initial data which does not lead to piecewise C^k smooth solutions of (1.1, 1.2) is a set of the first category.

The proof of Theorem 3.1 is similar to the original proof of [4] in the case of the 2×2 isotachophoresis system. It makes use of Theorem 2.4 and of a one-sided inequality on Riemann invariants (analogous to the Oleinik E-inequality; see [12]) proved in [6] and [13] by means of the Glimm scheme (see also [1]). The restriction $n = 2$ comes from the term $l_i''(w_i)\cdot(f(u)-\lambda_i(u)u)$ in Theorem 2.4 (c). Indeed the function $l_i''(w_i)\cdot(f(u)-\lambda_i(u)u)$ is not identically equal to zero in the general case $n > 2$ and cannot be written nicely as a function of w_i and $\lambda_i(u)$ (see Proposition 3.3 (b)). In our case $(n = 2)$, following Dafermos and Geng, we make use of functions Z_i $(i \in \{1, 2\})$ defined by

$$\begin{aligned}&\forall\ (y,x,t)\in\mathbb{R}^2\times\mathbb{R}_+,\\ &\quad Z_i(y,x,t) = N_i(u_0(y)) + [tq''(w_i(y,0)) - (x-y)m''(w_i(y,0))]w_i'(y,0).\end{aligned}$$

See details in [4] and [13]. See also Proposition 4.2 below.

3.2. The case of a linearly degenerate field. In the case of a linearly degenerate field, we can generalize Theorem 2.4 (a) as follows (Proposition 3.2(b)).

PROPOSITION 3.2. (a) *Let* $n \geq 3$*. Then, for any pair of functions* Q *and* M : $w_i(D)\to\mathbb{R}$*, we have*

$$\forall i\in\{1,...,n\},\quad \exists u\in D,\quad f(u)-\lambda_i(u)u \neq Q(w_i)-\lambda_i(u)M(w_i).$$

(b) *Let* $n \in \mathbb{N}^*$*. Assume that the* i*th characteristic field is linearly degenerate* $(i \in \{1,\dots,n\}$ *is a fixed index). Then*

$$\forall k\in\mathbb{N},\quad \forall u\in D,\quad l_i^{(k)}(w_i)\cdot(f(u)-\lambda_i(u)u) = q_i^{(k)}(w_i)-\lambda_i(u)\cdot m_i^{(k)}(w_i).$$

Moreover, assume that $n \geq 3$*. Then, for any* $u \in D$*, the family* $(l_i(w_i),...,l_i^{(n-1)}(w_i))$ *is not a basis of* $(\mathbb{R}^n)^*$.

Proof. (a) Assume that, for some index $i \in \{1,...,n\}$,

$$\forall u\in D,\qquad f(u)-\lambda_i(u)u = Q(w_i)-\lambda_i(u)M(w_i).$$

Differentiate this expression with respect to w_j $(j \neq i)$ and use identity $(\partial f/\partial w_j)-\lambda_j(\partial u/\partial w_j) = 0$. We get

$$\forall u\in D,\qquad (\partial u/\partial w_j)(u) = (\lambda_j(u)-\lambda_i(u))^{-1}(\partial\lambda_i/\partial w_j)(u)(u-M(w_i)),$$

(strict hyperbolicity ensures that $\lambda_j(u)-\lambda_i(u)\neq 0$). Therefore, for $j \neq k$ and $j \neq i \neq k$,

$$\forall u\in D,\qquad r_j(u)\wedge r_k(u) = 0,$$

contradicting the assumption that $(r_1(u), r_2(u),\dots, r_n(u))$ is a basis.

(b) In the case $k = 0$, or 1, it is just Theorem 2.4 (a). In the case $k = 2$, we use $(\partial\lambda_i/\partial w_i) = 0$ and Theorem 2.4 (c). The general case $k \geq 2$ is similar. Finally, assume that $n \geq 3$. If $(l_i(w_i), \dots, l_i^{(n-1)}(w_i))$ were a basis of $(\mathbb{R}^n)^*$, we could find functions $Q_i : w_i(D) \to \mathbb{R}^n$ and $M_i : w_i(D) \to \mathbb{R}^n$ such that

$$\forall u \in D, \qquad f(u) - \lambda_i(u)u = Q_i(w_i) - \lambda_i(u)M_i(w_i),$$

contradicting (a). □

3.3. The general case. We return to the general case, i.e., we do not assume any longer that system (1.1) is linearly degenerate. The aim of this section is to discuss formula (c) of Theorem 2.4.

PROPOSITION 3.3. (a) *Assume $n = 2$ and $l_i(w_i) = (1, w_i)$ for any $i \in \{1, 2\}$ and $u \in D$. Then,*

$$\left(N_i \frac{\partial \lambda_i}{\partial w_i}\right)(u) = q_i''(w_i) - \lambda_i(u) m_i''(w_i). \tag{3.1}$$

(b) *Let $n = 3$, and let $i \in \{1, 2, 3\}$ be a fixed index. Assume that, for all $u \in D, det(l_i(u), l_i'(u), l_i''(u)) \neq 0$. Then, for any pair of functions g and h: $w_i(D) \to \mathbb{R}$, we have*

$$\exists u \in D, \qquad \left(N_i \frac{\partial \lambda_i}{\partial w_i}\right)(u) \neq h(w_i) - \lambda_i(u) g(w_i).$$

Proof. (a) The proof follows from Theorem 2.4 (c).

(b) Assume that, for all $u \in D, N_i(\partial\lambda_i/\partial w_i)(u) = h(w_i) - \lambda_i(u)g(w_i)$. Theorem 2.4 (c) asserts that

$$\forall u \in D, \qquad l_i''(w_i) \cdot (f(u) - \lambda_i(u)u) = \overline{h}(w_i) - \lambda_i(u)\ \overline{g}(w_i),$$

with $\overline{h} = q_i'' - h$ and $\overline{g} = m_i'' - g$. We now use Theorem 2.4 (a), hypothesis $\det(l_i(u), l_i'(u), l_i''(u)) \neq 0$ and Proposition 3.2 (a) to get a contradiction. □

It is a straightforward computation to check that the isotachophoresis system (Example 1 (b)) satisfies the assumption of Proposition 3.3 (b) $(n = 3, i = 2, 3)$.

Remark 2. Set $n = 2$. For any $i \in \{1, 2\}$, $l_i(w_i) = (\phi_i(w_i), \gamma_i(w_i))$ with $\phi_i : w_i(D) \to \mathbb{R}$ and $\gamma_i : w_i(D) \to \mathbb{R}$. Let $v \in D$, and assume that $\phi_i \neq 0$ in a neighborhood Ω of v. Then the covector $L_i(w_i) = (1, (\gamma_i/\phi_i)(w_i))$ is a left eigenvector of $f'(u)$ in Ω, and function (γ_i/ϕ_i) forms a Riemann invariant. Of course (see Theorem 3.1 and Proposition 3.3), it is easier to assume directly that $l_i(w_i) = (1, w_i)$ in D.

4. The method of characteristics. We now give two formulas which can be viewed as a generalization of the method of characteristics. Following [9], we introduce a function v defined by

$$v(x, t) = \int_\alpha^x u(\xi, t) d\xi - \int_0^t f(u(\alpha, \tau))\, d\tau. \tag{4.1}$$

Here, $\alpha \in \mathbb{R}$ is a fixed number. We set $v_0 = v(., 0)$.

Recall that a function u is piecewise smooth solution if, for any compact $K \subset \mathbb{R} \times \mathbb{R}_+$, the restriction of u on K is smooth on domains D_j $(1 \leq j \leq M_K, M_K \in \mathbb{N})$ separated by smooth (shock) curves $t \mapsto \gamma_j(t)$, with left and right C^1 limits along

γ_j $(1 \leq j \leq M_K)$. If u is a piecewise smooth solution of (1.1, 1.2) on the strip $\mathbb{R} \times [0,T]$, and y is a C^1 regularity point of u_0, we denote by $t \mapsto \xi_i(y,t)$ the ith characteristic with foot $y \in \mathbb{R}$, i.e., the maximal solution of the ordinary differential equation (O.D.E.)

$$\partial_t \xi_i(y,t) = \lambda_i(u(\xi_i(y,t),t)), \tag{4.2}$$

$$\xi_i(y,0) = y. \tag{4.3}$$

In the above system, we admit Lipschitz "solutions" ξ_i such that equation (4.2) may fail across the j-shock curves of u $(j \neq i)$.

We write w_i instead of $w_i(u)$. Obviously, $t \mapsto w_j(\xi_i(y,t),t)$ may not be equal to a constant for $j \neq i$. Hence, the i-characteristics of system (1) may not be straight lines. Nevertheless, we can (in some sense) integrate system (4.2, 4.3).

First we claim that, for any entropy, piecewise smooth solution u of $(1.1, 1.2)$, $w_i(\xi_i(y,t),t) = w_i(y,0)$ along an i-characteristic curve (see [15]). Indeed, any j-wave curve $O_j(v_0)$ $(j \neq i, v_0 \in D)$ is included in the intersection of the $(n-1)$ characteristic hyperplanes $\cap_{k \neq j} H_k(v_0) = \cap_{k \neq j} w_k^{-1}(v_0)$. Hence, $t \mapsto w_i(\xi_i(y,t),t)$ $(i \neq j)$ is constant through a j $(j \neq i)$ shock curve. Of course, an i-characteristic curve never crosses an i-shock curve, due to the Lax shock conditions. This proves the claims.

Finally, for $(x,t) \in \mathbb{R} \times \mathbb{R}_+$, notice that any backward characteristic through (x,t) is defined on the whole interval $[0,t]$ (see [17]).

We are now in a position to prove Proposition 4.1. Earlier statements are given in [15] and [17].

PROPOSITION 4.1. *Let u be an entropy, piecewise smooth solution of* (1.1, 1.2) *and let $(x,t) \in \mathbb{R} \times \mathbb{R}_+$ be a point of continuity of u. Let y be the foot of the ith characteristic $(1 \leq i \leq n)$ through (x,t). Then,*

$$\begin{cases} l_i(w_i(y,0)) \cdot (v(y,0) - v(x,t)) + (x-y) m_i(w_i(y,0)) - t q_i(w_i(y,0)) = 0, \\ l_i'(w_i(y,0)) \cdot (v(y,0) - v(x,t)) + (x-y) m_i'(w_i(y,0)) - t q_i'(w_i(y,0)) = 0. \end{cases}$$

Here, w_i is the i-Riemann invariant associated with the function u, i.e., $w_i = w_i(u)$.

Proof. We integrate equations (1.1, 1.2) over the domain delimited by the x-axis, the vertical axis $\{(z,s) \in \mathbb{R} \times \mathbb{R}_+ / z = x\}$, and the ith characteristic $s \mapsto \xi_i(y,s)$. Using Green's formula (for functions with bounded variation), we have

$$-\int_y^x u_0(\xi) d\xi + \int_0^t f(u(x,s)) ds - \int_0^t (f(u) - \lambda_i(u)u)(\xi_i(y,s),s) ds = 0.$$

Notice that

$$v_0(y) - v(x,t) \quad = \quad -\int_y^x u_0(\xi) d\xi + \int_0^t f(u(x,s)) ds.$$

Hence,

$$v_0(y) - v(x,t) - \int_0^t (f(u) - \lambda_i(u)u)(\xi_i(y,s),s) ds = 0.$$

We multiply this equality by $l_i(w_i(\xi_i(y,s),s)) = l_i(w_i(y,0))$, and we use Theorem 2.4 to get the first equality. Using $l_i'(w_i(\xi_i(y,s),s))$ instead of $l_i(w_i(y,s),s)$, we get the second equality. ∎

From the previous proposition we deduce a formula for $\partial_y \xi_i(y,t)$, which generalizes the classical formula in the scalar case (see Example 3(a) below).

PROPOSITION 4.2. *Let $u \in C^1(\mathbb{R}\times[0,T[)\,(T>0)$ be a solution of system* (1.1). *Then, for any $(y,t)\in\mathbb{R}\times[0,T[$, we have,*

$$N_i(u(\xi_i(y,t),t))\;\partial_y\xi_i(y,t) = [tq''(w_i(y,0)) - l_i''(w_i(y,0))\cdot(v(y,0)-v(\xi_i(y,t),t)) \\ -(\xi_i(y,t)-y)m_i''(w_i(y,0))]w_i'(y,0) + N_i(u_0(y)).$$

Proof. Let $\xi_i : [0,T_1]\to\mathbb{R}, t\mapsto \xi_i(y,t)$ be the ith characteristic curve with foot $y\in\mathbb{R}$. We first prove that the function $y\to\xi_i(y,t)$ $(1\le i\le n, t\in[0,T_1])$ is differentiable. Set

$$H(x,y) = l_i'(w_i(y,0))\cdot(v(y,0)-v(x,t)) + (x-y)m_i'(w_i(y,0)) - tq_i'(w_i(y,0)),$$

and notice that $H(\xi_i(y,t),y)=0$, due to Proposition 4.1. A straightforward computation gives us

$$\begin{aligned}\frac{\partial H}{\partial x}(\xi_i(y,t),y) &= -l_i'(w_i(y,0))\cdot u(\xi_i(y,t),t) + m_i'(w_i(y,0)) \\ &= N_i(u(\xi_i(y,t),t)) \neq 0.\end{aligned}$$

Hence, function $y\mapsto\xi_i(y,t)$ is differentiable. Moreover, if we differentiate equality $H(\xi_i(y,t),y)=0$ with respect to y, we get our formula. ∎

Remark 3. The ith characteristics may not be straight lines. Nevertheless, in the previous formula, intermediate values of ξ_i (say, $\xi_i(y,s)$ with $0<s<t$) are not required.

Example 3. (a) In the scalar case ($n=1$), one may choose $l_1(u)=1$ and $N_1(u)=1$. Proposition 4.2 reads as follows: $\partial_y\xi_1(y,t) = 1+tf''(u_0(y))u_0'(y)$. Since $\xi_1(y,0)=y$, we get $\xi_1(y,t) = y+tf'(u_0(y))$.

(b) For the case of the 3×3 isotachophoresis system, see [4].

5. The case $n=2$. In the case $n=2$, we can derive from Theorem 2.4 (a) an explicit integration formula. We assume that system (1.1) is coupled, in the sense that

$$\forall i\in\{1,2\},\quad \forall u\in D,\quad l_i(w_i(u))\wedge l_i'(w_i(u))\neq 0, \tag{5.1}$$

i.e., the system cannot be reduced to two scalar equations. To be precise, if $l_i\wedge l_i'$ were (identically) equal to zero for some index $i\in\{1,2\}$, we could, up to affine transformation in the u-plane, assume that $l_i(v) = (\delta_{ij})_{j=1,2}$ and $f_i(v) = f_i(v_i)$ identically. Therefore, in order to solve the Cauchy problem (1.1, 1.2), we would have to solve two scalar Cauchy problems (i.e., $\partial_t u_i + \partial_x f_i(u_i)=0$ and $u_i(x,0)=u_{0,i}(x,0)$, and the other equation).

Recall now that (see the proof of Proposition 3.2) the following holds.

LEMMA 5.1. *Assume that system* (1.1) *belongs to the 2×2 Temple class and that property* (5.1) *is satisfied. Then, for any $i\in\{1,2\}$, we can find two smooth functions $Q_i : w_i(D)\to\mathbb{R}^2$ and $M_i : w_i(D)\to\mathbb{R}^2$, such that*

$$\forall u\in D,\qquad f(u)-\lambda_i(u)u = Q_i(w_i) - \lambda_i(u)\cdot M_i(w_i).$$

Proof. It is a consequence of Theorem 2.4 (a) and hypothesis (5.1). ∎

In the following statement, function v is still given by formula (4.1).

PROPOSITION 5.2. *Assume that system* (1.1) *belongs to the* 2×2 *Temple class and that property* (5.1) *is satisfied. Let* $u \in C^1_{ps}(\mathbb{R}\times[0,T[)$ $(T>0)$ *be a piecewise smooth solution of the Cauchy problem* (1.1, 1.2), *and let* $(y_1,y_2)\in\mathbb{R}^2, y_2<y_1$. *Assume that the* i_1th *characteristic with foot* y_1 *intersects the* i_2th *characteristic with foot* y_2 $((i_1,i_2)\in\{1,2\}^2)$, *at a point* (X,T_0) *in* $\mathbb{R}\times[0,T[$. *Then* (X,T_0) *is a solution of the following linear system*

$$[M_{i_1}(w_{i_1}(y_1,0))-M_{i_2}(w_{i_2}(y_2,0))]X+[Q_{i_2}(w_{i_2}(y_2,0))-Q_{i_1}(w_{i_1}(y_1,0))]T_0$$
$$=v_0(y_2)-v_0(y_1)+y_1M_{i_1}(w_{i_1}(y_1,0))-y_2M_{i_2}(w_{i_2}(y_2,0)).$$

Proof. We denote by Ω the domain delimited by the i_1th characteristic with foot y_1, the i_2th characteristic with foot y_2, and the axis $\{(x,t)\in\mathbb{R}\times\mathbb{R}_+, t=0, y_2\le x\le y_1\}$. We integrate equations (1.1, 1.2) over Ω,

$$\int_{y_2}^{y_1}u_0(\xi)d\xi-\int_0^{T_0}(f(u)-\lambda_{i_1}(u)u)(\xi_{i_1}(y,s),s)ds$$
$$+\int_0^{T_0}(f(u)-\lambda_{i_2}(u)u)(\xi_{i_2}(y,s),s)ds=0.$$

On the other hand (see Lemma 5.1),

$$\forall i\in\{1,2\},\qquad f(u)-\lambda_i(u)u=Q_i(w_i)-\lambda_i(u)M_i(w_i).$$

Notice also that $(i\in\{1,2\})$,

$$X-y_j=\int_0^{T_0}\lambda_{i_j}(u)(\xi_{i_j}(y,s),s)ds.$$

Hence,

$$v_0(y_1)-v_0(y_2)+[Q_{i_2}(w_{i_2}(y_2,0))-Q_{i_1}(w_{i_1}(y_1,0))]T_0$$
$$-(X-y_2)M_{i_2}(w_{i_2}(y_2,0))+(X-y_1)M_{i_1}(w_{i_1}(y_1,0))=0.\qquad\square$$

Under the hypothesis $\det\,[M_{i_2}(w_{i_2}(y_2,0))\ -M_{i_1}(w_{i_1}(y_1,0)),\ Q_{i_2}(w_{i_2}(y_2,0))-Q_{i_1}(w_{i_1}(y_1,0))]\neq 0$, one can solve (uniquely) the previous system. Take now $i_1=1$ and $i_2=2$. We get, for any $i\in\{1,2\}$, $w_i(X,T_0)=w_i(y_i,0)$, which are the formulae we were looking for. In the case $i_1=i_2$, the point (X,T_0) lies on a shock curve.

Example 4. The following system (cf. [10]) belongs to the Temple class:

$$\begin{cases}\partial_t u_1+\partial_x(u_1u_2)=0,\\ \partial_t u_2+\partial_x(u_2^2+u_1)=0.\end{cases}$$

Set $\Delta=\{(u_1,u_2)\in\mathbb{R}^2/u_2^2+4u_1>0\}$. One checks that $\lambda_1(u)=w_2+2w_1$ and $\lambda_2(u)=w_1+2w_2$, with $w_1+w_2=u_2$ and $w_1w_2=-u_1$, for $u\in\Delta$. Define D by $D=\{(w_1,w_2)\in\mathbb{R}^2/\alpha_1\le w_1\le\beta_1<\alpha_2\le w_2\le\beta_2\}$ (we assume that the constants α_i and β_i satisfy $\alpha_1\le\beta_1<\alpha_2\le\beta_2$ and $D\subset\subset\Delta$). For $i=1,2$, we choose $l_i(u)=(1,w_i)$, and we check that $m_i(w_i)=w_i^2$, $q_i(w_i)=w_i^3$, $Q_i(w_i)={}^t(-2w_i^3,3w_i^2)$ and $M_i(w_i)={}^t(-w_i^2,2w_i)$. Let $i_1=1, i_2=2$, $y_2<y_1$, and set $\overline{w}_1=w_1(y_1,0)$, $\overline{w}_2=w_2(y_2,0)$. Set also $u_0=(u_{0,1},u_{0,2})$ and let $(\overline{u}_1,\overline{u}_2)\in D$ be the point with Riemann invariants $(\overline{w}_1,\overline{w}_2)$. We have $\det(M_2(\overline{w}_2)-M_1(\overline{w}_1),Q_1(\overline{w}_1)-Q_2(\overline{w}_2))=-(\overline{w}_2-\overline{w}_1)^4\le-(\alpha_2-\beta_1)^4<0$. Assume now that $u_0\in C^\infty(\mathbb{R},D)$ and that functions $(w_i\circ u_0)$ are bounded and

nondecreasing ($i \in \{1,2\}$). Since $(\partial\lambda_i/\partial w_i) > 0$, system (1.1, 1.2) admits a smooth solution. Characteristics are defined globally in time. Moreover, the 2-characteristic with foot y_2 intersects the 1-characteristic with foot $y_1 > y_2$. The intersection point (X,T) is given by $X = y_1 + \Lambda(y_1 - y_2)/(\overline{w}_2 - \overline{w}_1)$ and $T = C(y_1 - y_2)/(\overline{w}_2 - \overline{w}_1)$ with

$$\Lambda = \int_{y_2}^{y_1} \frac{3u_{0,1}\overline{u}_2 + 2(\overline{u}_2^2 + \overline{u}_1)u_{0,2} - \overline{w}_2(4\overline{w}_1^2 + \overline{w}_1\overline{w}_2 + \overline{w}_2^2)}{(\overline{w}_2 - \overline{w}_1)^2}(\xi)\frac{d\xi}{y_1 - y_2},$$

$$C = \int_{y_2}^{y_1} \frac{u_{0,1}\overline{u}_1 + 2(u_{0,1} + \overline{u}_1)}{\overline{u}_2^2 + 4\overline{u}_1}(\xi)\frac{d\xi}{y_1 - y_2}.$$

These formulas can be used in a numerical scheme (see [6]). Finally, notice that, in the case of constant initial data u_0, the previous equalities reduce to $\Lambda = \lambda_1(u_0)$ and $C = 1$, as expected.

6. Lax formula. The smooth case. The aim of this section is to discuss an inf sup formula introduced in [2]. This formula, similar to the well-known Lax formula in the scalar case [9], is recalled below. But first, we need a few notations.

Let $n \in \mathbb{N}^*$ and $i \in \{1,\dots,n\}$ be a fixed index. We assume that $\overline{D}$ is compact, and that system 1.1 is strictly hyperbolic on $\overline{D}$. Moreover, we assume that the ith characteristic field is genuinely nonlinear, i.e.,

$$\forall v \in D, \quad (\partial\lambda_i/\partial w_i)(v) > 0.$$

Throughout this section, we denote by $u \in C^\infty(\mathbb{R} \times [0,T[)$ a smooth solution of the Cauchy problem (1.1, 1.2). In order to simplify our statements, we assume that u is equal to a constant $u_\infty \in D$ outside a compact $K \subset \mathbb{R} \times [0,T]$ $(T > 0)$ and takes values in D. Function v is defined by equality (4.1). We set $D_i = w_i(D)$ and define the function $\mathcal{L}_i$ by

$$\forall\ (y,a,x,t) \in \mathbb{R} \times D_i \times \mathbb{R} \times \mathbb{R}_+,$$

$$\mathcal{L}_i(y,a,x,t) = l_i(a) \cdot [v(y,0) - v(x,t)] + (x-y)m_i(a) - tq_i(a).$$

Following [2], the conjectured representation formula reads as follows:

$$\forall (x,t) \in \mathbb{R} \times \mathbb{R}_+, \qquad \inf_{y\in\mathbb{R}} \sup_{a\in D_i} \mathcal{L}_i(y,a,x,t) = 0. \tag{6.1}$$

As noticed in [2], this formula reduces to the Lax formula in the convex scalar case. Then indeed, equation (6.1) just means that $\inf_{y\in\mathbb{R}} \sup_{a\in\mathbb{R}} \{v_0(y) - v(x,t) + (x-y)a - tf(a)\} = 0$. Which is, for $t > 0$,

$$v(x,t) = \inf_{y\in\mathbb{R}} \left\{ v_0(y) + tf^* \left(\frac{x-y}{t} \right) \right\}.$$

Here, function f^* denotes the Legendre transform of the scalar function f.

Coming back to the general case $n \geq 1$, we now define T^* by

$$T^* = \sup\{t \in [0,T[,\ \text{such that } \partial_y \xi_i(.,t) > 0\}.$$

Inequality $T^* > 0$ is a consequence of $\partial_y \xi_i(.,0) = 1$. We now fix a time $t \in]0,T^*[$ and $\overline{x} \in \mathbb{R}$. Let $\overline{y}$ be the foot of the ith characteristic defined by $\overline{x} = \xi_i(\overline{y},t)$. Our goal is

to prove that $(\overline{y}, w_i(\overline{y},0))$ is a (critical) hyperbolic point of $\mathcal{L}_i(.,.,\overline{x},t)$ (see Theorem 6.2 below). Set $P=(\overline{y}, w_i(\overline{y},0),\overline{x},t)$. We will need the following lemma.

LEMMA 6.1. *Let $u \in C^\infty(\mathbb{R}\times[0,T[)(T>0)$ be a smooth solution of the system (1.1, 1.2). Assume that u is equal to a constant $u_\infty \in D$ outside a compact $K \subset \mathbb{R}\times[0,T]$. Then, for $\overline{y}\in\mathbb{R}$ and $i\in\{1,\dots,n\}$, we have*

(1) $\forall t\in[0,T[$,

$$\int_0^t \left(N_i \frac{\partial \lambda_i}{\partial w_i}\right)(\xi_i(\overline{y},s),s)ds = tq_i''(w_i(\overline{y},0)) - (\xi_i(\overline{y},t)-\overline{y})m_i''(w_i(\overline{y},0)) - l_i''(w_i(\overline{y},0))[v_0(\overline{y}) - v(\xi_i(\overline{y},t),t)].$$

(2) $\forall t\in[0,T[$,

$$\partial_y \xi_i(\overline{y},t) = \left[1+\left(\int_0^t \left(N_i\frac{\partial\lambda_i}{\partial w_i}\right)(\xi_i(\overline{y},s),s)ds\right)\frac{w_i'(\overline{y},0)}{N_i(u_0(\overline{y}))}\right]\frac{N_i(u_0(\overline{y}))}{N_i(u(\xi_i(\overline{y},t),t))}.$$

Proof. (1) Let $\overline{y}\in\mathbb{R}$. We now choose $z\in\mathbb{R}^-$, $|z|$ large enough, and set $\overline{x}=\xi_i(\overline{y},t)$ and $\overline{z}=\xi_i(z,t)$. We want to prove that $\int_0^t (f(u)-\lambda_i(u)u)(\xi_i(\overline{y},s),s)ds = v_0(\overline{y}) - v(\overline{x},t)$. Indeed, integrate equations (1.1, 1.2) over the domain Ω delimited by the two ith characteristics with feet $\overline{y}$ and z, and the lines $\{(\xi,0)\in\mathbb{R}\times\mathbb{R}^+, z\le\xi\le\overline{y}\}$ and $\{(\xi,s)\in\mathbb{R}\times[0,t],\ \xi_i(z,s)\le\xi\le\xi_i(\overline{y},s)\}$. We find

$$\int_z^{\overline{y}} u_0(\xi)d\xi - \int_{\overline{z}}^{\overline{x}} u(\xi,t)d\xi - \int_0^t (f(u)-\lambda_i(u)u)(\xi_i(\overline{y},s),s)ds + \int_0^t (f(u)-\lambda_i(u)u)(\xi_i(z,s),s)ds = 0.$$

A straightforward computation shows that, for $|z|$ large enough,

$$v_0(\overline{y}) - v(\overline{x},t) - f(u_\infty)t + \lambda_i(u_\infty)\,u_\infty\,t - \int_0^t (f(u)-\lambda_i(u)u)(\xi_i(\overline{y},s),s)ds + [f(u_\infty)-\lambda_i(u_\infty)\,u_\infty]t = 0.$$

Hence,

$$\int_0^t (f(u)-\lambda_i(u)u)(\xi_i(\overline{y},s),s)ds = v_0(\overline{y}) - v(\overline{x},t).$$

We now integrate identity (c) of Theorem 2.4, along the ith characteristic with foot $y\in\mathbb{R}$. We use $w_i(\xi_i(\overline{y},s),s)=w_i(\overline{y},0)$ and $\int_0^t \lambda_i(\xi(\overline{y},s),s)ds = \xi_i(\overline{y},t)-\overline{y}$ to obtain our formula.

(2) This follows from equations (1.1, 1.2) and Proposition 4.2. ∎

We deduce the following from Lemma 6.1.

THEOREM 6.2. *Assume $0<t<T^*$. Then, $(\overline{y}, w_i(\overline{y},0))$ is a (critical) hyperbolic point of function $(y,a)\mapsto\mathcal{L}_i(y,a,x,t)$. Moreover, $(\partial^2\mathcal{L}_i/\partial^2 a)(P)<0$ (here, $P=(\overline{y}, w_i(\overline{y},0),\overline{x},t)$).*

Proof. From Proposition 4.1, we have $\mathcal{L}_i(P)=0$. Let $(y,a,x,t)\in\mathbb{R}\times D_i\times\mathbb{R}\times\mathbb{R}_+$. We differentiate function $\mathcal{L}_i$, with respect to the a variable,

$$(\partial\mathcal{L}_i/\partial a)(y,a,x,t) = l_i'(a)[v(y,0)-v(x,t)] + (x-y)m_i'(a) - tq_i'(a).$$

Proposition 4.1 gives us $(\partial\mathcal{L}_i/\partial a)(P)=0$. Next, we differentiate $\mathcal{L}_i$ with respect to the y variable,

$$(\partial\mathcal{L}_i/\partial y)(y,a,x,t) = l_i(a)\cdot u(y,0) - m_i(a).$$

Hence, from definition of m_i, we get $(\partial\mathcal{L}_i/\partial y)(P) = 0$. Now, $(\partial^2\mathcal{L}_i/\partial^2 y)(y,a,x,t) = l_i(a)\cdot u_0'(y)$. Therefore $(\partial^2\mathcal{L}_i/\partial^2 y)(P) = l_i(w_i(\overline{y},0))\cdot u_0'(\overline{y})$. We use identities $m_i(w_i(y,0))\ -(l_i(w_i)\cdot u(y,0)) = 0$ and $N_i(u(y,0)) = m_i'(w_i(y,0)) - l_i'(w_i(y,0))\cdot u$ to conclude that $l_i(w_i(y,0))\cdot u_0'(y) = N_i(u(y,0))\cdot w_i'(y,0)$. Hence,

$$(\partial^2\mathcal{L}_i/\partial^2 y)(P) = N_i(u(\overline{y},0))\cdot w_i'(\overline{y},0).$$

We also have $(\partial^2\mathcal{L}_i/\partial y\partial a)(y,a,x,t) = l_i'(a)\cdot u_0(y) - m_i'(a)$. It follows that

$$(\partial^2\mathcal{L}_i/\partial y\partial a)(P) = -N_i(u(\overline{y},0)).$$

Next, $(\partial^2\mathcal{L}_i/\partial^2 a)(y,a,x,t) = l_i''(a)\cdot[v(y,0)-v(x,t)]+(x-y)m_i''(a)-tq_i''(a)$. Therefore,

$$\begin{aligned}(\partial^2\mathcal{L}_i/\partial^2 a)(P) &= l_i''(w_i(\overline{y},0))\cdot[v(\overline{y},0)-v(\overline{x},t)] + (\overline{x}-\overline{y})m_i''(w_i(\overline{y},0)) - tq_i''(w_i(\overline{y},0))\\ &= -\int_0^t\left(N_i\frac{\partial\lambda_i}{\partial w_i}\right)(\xi_i(\overline{y},s),s)ds,\end{aligned}$$

(cf. Lemma 6.1). In particular, genuine nonlinearity and $N_i > 0$ implies $(\partial^2\mathcal{L}_i/\partial^2 a)(P) < 0$. Lastly,

$$\begin{aligned}\det(\mathcal{L}_i'')(P) &= -N_i(u(\overline{y},0))w_i'(\overline{y},0)\left(\int_0^t N_i\frac{\partial\lambda_i}{\partial w_i}(\xi_i(y,s),s)ds\right) - (N_i(u(\overline{y},0)))^2\\ &= -(N_i(u(\overline{y},0)))^2\left[1+\left(\int_0^t N_i\frac{\partial\lambda_i}{\partial w_i}(\xi_i(y,s),s)ds\right)\left(\frac{w_i'(\overline{y},0)}{N_i(u(\overline{y},0))}\right)\right]\\ &= -N_i(u(\overline{y},0))N_i(u(\overline{x},t))\,\partial_y\xi_i(\overline{y},t),\end{aligned}$$

(cf. Lemma 6.1). But, $t\in]0,T^*[$ implies that $\partial_y\xi_i(\overline{y},t) > 0$. Since N_i is a positive function, we get $\det(\mathcal{L}_i''(P)) < 0$. □

For $y\in\mathbb{R}$, we set $\phi(y) = \sup_{a\in D_i}\mathcal{L}_i(y,a,\overline{x},t)$. Function ϕ has finite values (the set $\overline{D}$ is compact) and is continuous on $\mathbb{R}$. Moreover, we have the following.

COROLLARY 6.3. *Under the assumption (and with the notations) of Theorem* 6.2*, there exists a neighborhood $V(\overline{y})$ of $\overline{y}$ and a bounded interval J (which may depend on $(\overline{x},t)$) such that*

(1)$\forall y\in V(\overline{y}),\ \phi(y)\geq 0$.

(2) $\inf_{y\in V(\overline{y})}\sup_{a\in D_i}\mathcal{L}_i(y,a,\overline{x},t) = 0$.

(3) $\inf_{y\in\mathbb{R}}\sup_{a\in D_i}\mathcal{L}_i(y,a,\overline{x},t) = \inf_{y\in J}\sup_{a\in D_i}\mathcal{L}_i(y,a,\overline{x},t)$.

Proof. (1) This follows from Theorem 6.2 and the Morse lemma.

(2) Inequality $\inf_{y\in V(\overline{y})}\sup_{a\in D_i}\mathcal{L}_i(y,a,\overline{x},t)\geq 0$ follows from (1). The opposite inequality is proved in [2].

(3) Let $A_0\in D$ and set $a_0 = w_i(A_0)$. Obviously $a_0\in D_i$. Since D is an open set and $u_\infty\in D$, we can choose $A_0\in D$ in such a way that $l_i(a_0)\cdot(u_\infty - A_0) > 0$. Next, notice that

$$\mathcal{L}_i(y,a_0,\overline{x},t) = l_i(a_0)\cdot\left[\int_{\overline{x}}^y(u_0(\xi)-A_0)d\xi + \int_0^t(f(u(\overline{x},\tau))-f(A_0))d\tau\right],$$

and assume, for instance, that $y\in\mathbb{R}_+$. We fix $\beta\in\mathbb{R}_+$, β large enough. We have, as $y > \beta$,

$$\begin{aligned}\mathcal{L}_i(y,a_0,\overline{x},t) &= l_i(a_0)\cdot\int_\beta^y(u_\infty - A_0)d\xi + l_i(a_0)\cdot\left[\int_{\overline{x}}^\beta(u_0(\xi)-A_0)d\xi\right.\\ &\qquad\left.\int_0^t(f(u(\overline{x},\tau))-f(A_0))\,d\tau\right].\end{aligned}$$

Hence, $\mathcal{L}_i(y, a_0, \overline{x}, t) \to +\infty$ when $y \to +\infty$. In the case $y \to -\infty$, we argue in the same way. It follows that $\sup_{a\in D_i} \mathcal{L}_i(y, a_0, \overline{x}, t) > 0$ for $|y|$ large enough. □

See [9] for an inf sup equality in the scalar case and [2] for the Temple case for the inequality $\inf_{y\in\mathbb{R}} \sup_{a\in D_i} \mathcal{L}_i(y, a, \overline{x}, t) \leq 0$. In the case of a general solution u (with bounded variations), equality $\inf_{y\in\mathbb{R}} \sup_{a\in D_i} \mathcal{L}_i(y, a, \overline{x}, t) = 0$ is still an open problem.

Acknowledgments. The authors are indebted to the referee for various improvements to the text.

ON THE DIRICHLET PROBLEM FOR VECTORIAL HAMILTON–JACOBI EQUATIONS*

SANDRO ZAGATTI†

Abstract. We give sufficient conditions for the existence of solutions to the Hamilton–Jacobi equations with Dirichlet boundary condition:

$$\begin{cases} g(x, \det Du(x)) = 0, & \text{for a.e. } x \in \Omega, \\ u(x) = \varphi(x), & \text{for } x \in \partial\Omega, \end{cases}$$

obtaining, in addition, an application to the theory of existence of minimizers for a class of nonconvex variational problems.

Key words. Hamilton–Jacobi equations, minimum problem, Jacobian determinant, Baire category method

AMS subject classification. 49A50

PII. S0036141097321279

1. Introduction.

The purpose of this paper is to contribute to the theory of existence of solutions for the Dirichlet problem for Hamilton–Jacobi equations and to give applications of such a theory to the minimum problem in the vectorial case of the calculus of variations.

Consider the problem of minimizing the energy functional (see, for example, [D], [CZ2])

$$G(u) = \int_\Omega g(x, \det Du(x))dx,$$

on the space of maps $u \in W^{1,p}(\Omega, \mathbb{R}^n)$ $(p \geq 1)$ satisfying the boundary condition $u = \varphi$ on $\partial\Omega$, where $g = g(x, \xi)$ is a map from $\Omega(\subseteq \mathbb{R}^n) \times \mathbb{R}$ to $\overline{\mathbb{R}}$. The existence of minimum points for G cannot be deduced by the direct method of the calculus of variations since, in general, the minimizing sequences of G are not weakly compact in $W^{1,p}(\Omega, \mathbb{R}^n)$ and, moreover, if no convexity assumption is made on g (with respect to its second variable), the functional G fails to be weakly lower semicontinuous.

Suppose then $g(x, \xi) \geq 0$ for any $(x, \xi) \in \Omega \times \mathbb{R}$; clearly a solution of the problem

$$(\mathcal{P}) \qquad \begin{cases} g(x, \det Du(x)) = 0, & \text{for a.e. } x \in \Omega, \\ u(x) = \varphi(x), & \text{for } x \in \partial\Omega, \end{cases}$$

which is the vectorial Hamilton–Jacobi equation with Dirichlet boundary condition studied in this paper, is a minimum point for G.

To solve problem $\mathcal{P}$ we follow the idea, contained in a recent paper of Dacorogna and Marcellini ([DMa]), of making use of the Baire category argument. To overcome the difficulties due to the x-dependence of g we impose, instead of global condition on g, suitable compatibility conditions between the set $Z(x)$ in which the map $g(x, \cdot)$ vanishes and the boundary datum φ. More precisely we take φ in $W^{1,\infty}(\Omega, \mathbb{R}^n)$ and

†Scuola Internazionale Superiore di Studi Avanzati (SISSA), via Beirut 2–4, I–34014 Trieste, Italy (zagatti@sissa.it).

assume that for any $x \in \Omega$ there exist real positive numbers $\alpha(x)$ and $\beta(x)$ such that $g(x, \alpha(x)) = g(x, \beta(x)) = 0$ and $\alpha(x) \leq \det D\varphi(x) \leq \beta(x)$ almost everywhere. Hence, problem $\mathcal{P}$ reduces to the differential inclusion:

$$(\mathcal{E}) \qquad \begin{cases} \det Du(x) \in \{\alpha(x), \beta(x)\}, & \text{for a. e. } x \in \Omega, \\ u(x) = \varphi(x), & \text{for } x \in \partial\Omega. \end{cases}$$

By this way no convexity, continuity, or growth condition assumption on g are needed, and the only difficulty consists in finding a suitable complete metric space in which to apply Baire's method. In our main result (Theorem 3.1) we will show that if α and β are (essentially) strictly positive elements of $L^\infty(\Omega, \mathbb{R})$, which can be approximated in $L^1(\Omega, \mathbb{R})$ from above and below, respectively, by continuous functions, then the differential inclusion $\mathcal{E}$ admits solutions in $W^{1,\infty}(\Omega, \mathbb{R}^n)$.

2. Preliminaries and notations. In this paper Ω is an open subset of $\mathbb{R}^n$ ($n \geq 1$), $|\cdot|$ and $\langle \cdot, \cdot \rangle$ denote, respectively, the Euclidean norm and the scalar product in $\mathbb{R}^n$; μ denotes the Lebesgue measure. Given that $E \subseteq \mathbb{R}^n$, $\mathrm{co}(E)$, $\mathrm{extr}(E)$, $\mathrm{int}(E)$, $\mathrm{diam}(E)$, and $\mathrm{Ls}(E)$ are, respectively, the convex hull, the set of extreme points, the interior, the diameter, and the linear span of E, $\mathrm{relint}(E)$ is the interior of E relative to $\mathrm{Ls}(E)$.

Given a set of vectors $V = \{y^i \in \mathbb{R}^n : i = 1, \ldots, m\}$ ($m \leq n+1$), $\mathrm{co}(V)$ is said to be an $(m-1)$-simplex (of $\mathbb{R}^n$) if the dimension of $\mathrm{Ls}(\mathrm{co}(V))$ is $m-1$. Moreover, for $y \in \mathbb{R}^n$ we call $(y)^\perp$ the orthogonal complement of $\mathrm{Ls}(\{y\})$, i.e., $(y)^\perp := \{z \in \mathbb{R}^n : \langle z, y \rangle = 0\}$.

A real $n \times n$ matrix A is written as

$$A = \left(A^i_j\right)_{\substack{i=1,\ldots,n \\ j=1,\ldots,n}} = \begin{pmatrix} A^1_1 & \ldots & A^1_n \\ \vdots & \ddots & \vdots \\ A^n_1 & \cdots & A^n_n \end{pmatrix} = \begin{pmatrix} A^1 \\ \vdots \\ A^n \end{pmatrix} = (A_1, \ldots, A_n)$$

and the space $\mathcal{M}_n$ of real $n \times n$ matrices is endowed with the norm

$$\|A\|_{\mathcal{M}_n} := \max\{|A^i|, i = 1, \ldots, n\}.$$

Following [D] (p. 186 ff.), we introduce the vectors of $\mathbb{R}^n$ $(\mathrm{adj}_{n-1}A)^i$, $\quad i = 1, \ldots n$, defined by $(\mathrm{adj}_{n-1}A)^i_j = (-1)^{(i+j)} (\mathrm{cof}A)^i_j$ where

$$\left((\mathrm{cof}A)^i_j\right)_{\substack{i=1,\ldots,n \\ j=1,\ldots,n}}$$

is the adjoint matrix of A and recall that

$$\det A = \langle A^i, (\mathrm{adj}_{n-1}A)^i \rangle \tag{2.1}$$

for any $i = 1, \ldots, n$.

A map $u : \Omega \to \mathbb{R}^n$ is written as

$$u = \begin{pmatrix} u^1 \\ \vdots \\ u^n \end{pmatrix}$$

and its Jacobian matrix will be

$$Du = \begin{pmatrix} Du^1 \\ \vdots \\ Du^n \end{pmatrix}.$$

We shall use the spaces $C^0(\Omega,\mathbb{R})$, $L^\infty(\Omega,\mathbb{R})$, $L^\infty(\Omega,\mathbb{R}^n)$, $L^\infty(\Omega,\mathcal{M}_n)$, $W^{1,\infty}(\Omega,\mathbb{R})$, $W^{1,\infty}(\Omega,\mathbb{R}^n)$, $W_0^{1,\infty}(\Omega,\mathbb{R})$, $W_0^{1,\infty}(\Omega,\mathbb{R}^n)$ endowed with their usual norms.

An element $u \in W^{1,\infty}(\Omega,\mathbb{R}^m)$ ($m = 1$ or $m = n$) is said to be *countably piecewise affine* (CPA) if there exists a countable collection $\{\Omega_j, j \in \mathbb{N}\}$ of open, pairwise disjoint subsets of Ω with Lipschitz boundary, such that $\Omega = (\bigcup_{j\in\mathbb{N}} \Omega_j) \bigcup N$ (where N is a null set) and the restriction of u to Ω_j is affine.

We shall make use of tools and results obtained by Baire category methods in the study of differential inclusions (see, for example, [B], [C1], [DP]). To do this let $\mathcal{I}$ be the set of compact intervals of $\mathbb{R}$ endowed with the Hausdorff topology, following Bressan ([B]), we define the map $h : \mathbb{R} \times \mathcal{I} \to \mathbb{R} \cup \{-\infty\}$ by setting

(2.2)
$$h(\xi, I) = \begin{cases} \sup\left\{ \left(\int_0^1 |\xi - \phi(t)|^2 dt \right)^{\frac{1}{2}}, \phi : [0,1] \to I : \int_0^1 \phi(t)dt = \xi, \right\} & \text{if } \xi \in I, \\ -\infty & \text{if } \xi \notin I. \end{cases}$$

By the properties of the map h listed in [B], we have that, if $I = [a, b]$, then

$$h(\xi, I) = [\xi(a + b) - ab - \xi^2]^{\frac{1}{2}};$$

hence, the following properties are trivial.

PROPOSITION 2.1.

(i) *The map* $\mathbb{R} \times \mathcal{I} \ni (\xi, I) \mapsto h(\xi, I)$ *is upper semicontinuous;*

(ii) *the map* $I \ni \xi \mapsto h(\xi, I)$ *is strictly concave for every* $I \in \mathcal{I}$*;*

(iii) *if* $I = [a, b]$ *then* $h(\xi, I) = 0$ *if and only if* $\xi \in \{a, b\}$ *and, moreover,* $h(\xi, I) \leq \min\{|\xi - a|, |\xi - b|\}$ *for every* $\xi \in I$.

In the proof of our main result we will make use of the *likelihood* functional:

$$L(u) := \int_\Omega h(\det Du(x), J(x))dx,$$

where $u \in W^{1,\infty}(\Omega,\mathbb{R})$ and $J : \Omega \to \mathcal{I}$.

We will need the following tool (see [C2], [CZ1]).

PROPOSITION 2.2. *Let* Ω *be an open subset of* $\mathbb{R}^n$, $\epsilon > 0$ *and let* S *be an* n*-simplex with* $0 \in \operatorname{int}(S)$. *Then there exists a CPA* $u \in W_0^{1,\infty}(\Omega,\mathbb{R})$ *such that*

(i) $Du(x) \in extr(S)S$ *for almost every* $x \in \Omega$*;*

(ii) $\|u\|_{L^\infty(\Omega,\mathbb{R})} \leq \epsilon$.

Proof. Let $S = \operatorname{co}\left(\{s^i, i = 0, 1, \ldots, n\}\right)$ (i.e. $\{s^i, i = 0, 1, \ldots, n\}$ is the set of vertices of S coinciding with the set of extreme points of S) and define the polar set of S, $S^* := \bigcap_{i=0}^n \{x \in \mathbb{R}^n : \langle s^i, x\rangle \leq 1\}$. Applying Lemma 1 of [C2] we construct $v \in W_0^{1,\infty}(S^*,\mathbb{R})$ such that $Dv \in \operatorname{extr}(S)S$ almost everywhere. Then consider the following collection of subsets of Ω:

$$\mathcal{U} := \left\{ z + \rho S^* \subseteq \Omega, z \in \Omega, 0 < \rho < \epsilon(\operatorname{diam}(S))^{-1} \quad \text{subject to} \quad \operatorname{diam}(z + \rho S^*) \leq 1 \right\}.$$

By Vitali covering lemma we may select a countable subfamily of disjoint elements of $\mathcal{U}$, say $\mathcal{V} = \{V_j = z_j + \rho_j S^*, z_j \in \Omega, 0 < \rho_j < \epsilon(\operatorname{diam}(S))^{-1}, j \in \mathbb{N}\}$ and define maps $w_j \in W_0^{1,\infty}(V_j,\mathbb{R})$ by setting

$$w_j(x) := \rho_j v\left(\frac{x - z_j}{\rho_j}\right).$$

Clearly, $Dw_j \in \mathrm{extr}(S)$ almost everywhere and $|w_j(x)| \leq \rho_j(\sup_{V_j}|Dw_j|)\mathrm{diam}(V_j) \leq \epsilon$ almost everywhere.

Setting $u := \lim \sum_{j\in\mathbb{N}} w_j$, (the limit is intended in $W^{1,1}$) we have the thesis. □

We also need the following simple geometric argument.

PROPOSITION 2.3. *Let $a, b \in \mathbb{R}^n$ such that $\langle a, b\rangle \neq 0$. Let $\Sigma = \mathrm{co}(\{\sigma^i, i = 1, \ldots, n\})$ be an $(n-1)$-simplex contained in $(b)^\perp$ such that $0 \in \mathrm{relint}(\Sigma)$. Let $\lambda^-, \lambda^+, \rho \in \mathbb{R}$ such that $\rho > 0$ and $\lambda^- < 0 < \lambda^+$. Set $s^0 = \lambda^+ a$, $s^i = \lambda^- a + \rho\sigma^i$, $i = 1, \ldots, n$, and $S := \mathrm{co}(\{s^i, i = 0, \ldots, n\})$. Then S is an n-simplex and $0 \in \mathrm{int}(S)$.*

Proof. First of all remark that the dimension of $W := \mathrm{Ls}(\{\lambda^- a + \rho\sigma^i, i = 1, \ldots, n\}) = \lambda^- a + (b)^\perp$, is $n-1$. Since $\lambda^+ a \notin W$ it follows that the dimension of $\mathrm{Ls}(S)$ is n. Since $0 \in \mathrm{relint}(\Sigma)$ there exist $\mu_1, \ldots, \mu_n \in]0, 1[$ such that $\sum_{i=1}^n \mu_i = 1$ and $\sum_{i=1}^n \mu_i\sigma^i = 0$ Then

$$\begin{aligned} 0 &= \left(\frac{-\lambda^-}{\lambda^+ - \lambda^-}\right)(\lambda^+ a) + \left(\frac{\lambda^+}{\lambda^+ - \lambda^-}\right)(\lambda^- a) + \sum_{i=1}^n \mu_i\sigma^i \\ &= \left(\frac{-\lambda^-}{\lambda^+ - \lambda^-}\right)(\lambda^+ a) + \left(\frac{\lambda^+}{\lambda^+ - \lambda^-}\right)\left(\sum_{i=1}^n \mu_i\right)(\lambda^- a) + \sum_{i=1}^n \left(\frac{\lambda^+}{\lambda^+ - \lambda^-}\rho\right)\mu_i\sigma^i \\ &= \sum_{i=0}^n \nu_i s^i, \end{aligned}$$

where

$$\nu_0 = \frac{-\lambda^-}{\lambda^+ - \lambda^-}, \quad \nu_i = \frac{\lambda^+}{\lambda^+ - \lambda^-}\mu_i, \quad i = 1, \ldots, n.$$

Since $\nu_0, \ldots, \nu_n \in]0, 1[$ and $\sum_{i=1}^n \nu_i = 1$, this means $0 \in \mathrm{int}(S)$. □

3. Main result. We are interested in the following problem:

$$(\mathcal{P}) \qquad \begin{cases} g(x, \det Du(x)) = 0, & \text{for a. e. } x \in \Omega, \\ u(x) = \varphi(x), & \text{for } x \in \partial\Omega, \end{cases}$$

where $g = g(x, \xi)$ is a map from $\Omega \times \mathbb{R}$ to $\overline{\mathbb{R}}$, and we assume that for every $x \in \Omega$ there exist $\alpha(x), \beta(x) \in \mathbb{R}$ such that $0 < \alpha(x) < \beta(x)$ for every $x \in \Omega$, and $g(x, \alpha(x)) = g(x, \beta(x)) = 0$.

Hence, problem $(\mathcal{P})$ reduces to the solution of the differential inclusion:

$$\begin{cases} \det Du(x) \in \{\alpha(x), \beta(x)\}, & \text{for a. e. } x \in \Omega, \\ u(x) = \varphi(x), & \text{for } x \in \partial\Omega. \end{cases}$$

Before stating our main result we specify the assumption on the map α and β. No more assumptions on g are needed.

DEFINITION 3.1. *Let $\alpha, \beta \in L^\infty(\Omega, \mathbb{R})$. We say that α and β satisfy condition* (A) *if there exist two numbers $\overline{\alpha}, \overline{\beta} \in \mathbb{R}^+$ and two sequences $\{\alpha_l\}_{l\in\mathbb{N}}$, $\{\beta_l\}_{l\in\mathbb{N}}$ in $C^0(\Omega, \mathbb{R})$ such that*

$$0 < \overline{\alpha} \leq \alpha(x) < \beta(x) \leq \overline{\beta} \quad \text{a.e. in } \Omega;$$

$$\alpha_l(x) \geq \alpha(x) \quad \text{and} \quad \beta_l(x) \leq \beta(x) \quad \text{a.e. in } \Omega, \ \forall l \in \mathbb{N};$$

$$\alpha_l \overset{l\to\infty}{\longrightarrow} \alpha, \quad \beta_l \overset{l\to\infty}{\longrightarrow} \beta \quad \text{in } L^1(\Omega, \mathbb{R}).$$

We have the following result.

THEOREM 3.1. *Let Ω be a bounded open subset of $\mathbb{R}^n$ and $\alpha, \beta \in L^\infty(\Omega, \mathbb{R})$ satisfy* (A). *Let $\varphi \in W^{1,\infty}(\Omega, \mathbb{R}^n)$ be a countably piecewise affine map such that $\det D\varphi(x) \in [\alpha(x), \beta(x)]$ for almost every $x \in \Omega$. Then there exists $\overline{u} \in \varphi + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$ such that $\det D\overline{u}(x) \in \{\alpha(x), \beta(x)\}$ for almost every $x \in \Omega$.*

Moreover,

$$\|D\overline{u}\|_{L^\infty(\Omega,\mathcal{M}_n)} \le \max\left\{ \|D\varphi\|_{L^\infty(\Omega,\mathcal{M}_n)}, 2\frac{\overline{\beta}\|D\varphi\|^n_{L^\infty(\Omega,\mathcal{M}_n)}}{\overline{\alpha}^{\frac{2n-1}{n}}} \right\}.$$

Proof. Set

$$\gamma = \frac{1}{2}\mathrm{essinf}_{x\in\Omega}\left\{ \min \frac{\det D\varphi(x)}{|D\varphi^i(x)||(\mathrm{adj}_{n-1}D\varphi(x))^i|}, \quad i = 1, \dots, n \right\}.$$

Since, for every $A \in \mathcal{M}_n$, we have that

$$\left((\mathrm{adj}_{n-1}A)^i_j\right)^2 \le \prod_{\substack{k=1\\k\neq i}}^{n} \sum_{\substack{l=1\\l\neq j}}^{n} (A^k_l)^2,$$

it follows that

$$|(\mathrm{adj}_{n-1}A)^i|^2 \le \sum_{j=1}^{n} \prod_{\substack{k=1\\k\neq i}}^{n} \sum_{\substack{l=1\\l\neq j}}^{n} (A^k_l)^2 \le \prod_{\substack{k=1\\l\neq i}}^{n} \sum_{l=1}^{n} (A^k_l)^2 = \prod_{\substack{k=1\\k\neq i}}^{n} |A^k|^2.$$

Hence, recalling that $\det D\varphi \ge \overline{\alpha}$ almost everywhere, we have that

$$\gamma \ge \frac{1}{2}\frac{\overline{\alpha}}{\|D\varphi\|^n_{L^\infty(\Omega,\mathcal{M}_n)}}. \tag{3.1}$$

We set

$$M := \max\left\{ \|D\varphi\|_{L^\infty(\Omega,\mathcal{M}_n)}, \frac{\overline{\beta}}{\overline{\alpha}^{\frac{n-1}{n}}\gamma} \right\} \tag{3.2}$$

and consider the elements u of $W^{1,\infty}(\Omega, \mathbb{R}^n)$ such that

$$\|Du(x)\|_{\mathcal{M}_n} \le M \quad \text{a.e.}, \tag{3.3}$$

$$\det Du(x) \in [\alpha(x), \beta(x)] \quad \text{a.e.}, \tag{3.4}$$

$$\frac{\det Du(x)}{|Du^i(x)||(\mathrm{adj}_{n-1}Du(x))^i|} > \gamma \quad \forall i = 1, \dots, n, \quad \text{a.e.} \tag{3.5}$$

More precisely, we introduce the set

$$V_{M,\gamma} := \left\{ u \in \varphi + W_0^{1,\infty}(\Omega, \mathbb{R}^n) \text{ such that } u \text{ is CPA and satisfies (3.3), (3.4), (3.5)} \right\},$$

remarking that $V_{M,\gamma}$ is nonempty since it contains φ.

Now we call V the completion of $V_{M,\gamma}$ with respect to the $L^\infty(\Omega, \mathbb{R}^n)$ topology and observe that

$$V \subseteq \left\{ u \in \varphi + W_0^{1,\infty}(\Omega, \mathbb{R}^n) : (3.3), (3.4) \text{ hold} \right\}.$$

To prove the last assertion take a sequence $(u_k)_{k\in\mathbb{N}}$ in $V_{M,\gamma}$ converging to some u in $L^\infty(\Omega,\mathbb{R}^n)$. Since $\|Du_k(x)\|_{\mathcal{M}_n} \le M$ a.e. we may extract a subsequence, that we still call (u_k), converging to u in the weak* topology of $W^{1,\infty}$. Hence, clearly, $\|Du(x)\|_{\mathcal{M}_n} \le M$ a.e. Moreover, for every $p > n$, $(u_k) \rightharpoonup u$ in (the weak topology of) $W^{1,p}(\Omega,\mathbb{R}^n)$; hence, (see, for example, [E, p. 31]) $\det Du_k \rightharpoonup \det Du$ in (the weak topology of) $L^{p/n}(\Omega,\mathbb{R})$ consequently, recalling that (3.4) holds for any element of the sequence $(u_k)_{k\in\mathbb{N}}$ we have that $\det Du(x) \in [\alpha(x),\beta(x)]$ for almost every $x \in \Omega$.

Consider now the multifunction $J : \Omega \to \mathcal{I}$, $J(x) = [\alpha(x),\beta(x)]$ and the *likelihood* functional $L : V \to \mathbb{R}$:

$$L(u) := \int_\Omega h(\det Du(x), J(x))dx,$$

where the map h is defined in (2.2). We define the sets

$$V_s := \left\{ u \in V : L(u) < \frac{1}{s} \right\}, \qquad s \in \mathbb{N}.$$

Our aim is now to show that $(V_s)_{s\in\mathbb{N}}$ is a collection of open and dense subsets of V.

Step 1. The sets V_s are open in V.

First of all remark that the map J is continuous with respect to Hausdorff topology; moreover, by the properties of h listed in Proposition 2.1, the map $\mathcal{M}_n \ni A \mapsto h(\det A, J(x))$ is *quasi-concave* for every $x \in \Omega$ (i.e., $\mathcal{M}_n \ni A \mapsto -h(\det A, J(x))$ is quasi-convex in Morrey sense), then L turns out to be upper semicontinuous on V with respect to weak* topology of $W^{1,\infty}$.

Fix $s \in \mathbb{N}$ and take now a sequence $(u_k)_{k\in\mathbb{N}}$ in $V - V_s$ (so that, in particular, $L(u_k) \ge 1/s$) converging in $L^\infty(\Omega,\mathcal{M}_n)$ to some $u \in V$. By the previous argument we may suppose that $(u_k) \overset{*}{\rightharpoonup} u$ in $W^{1,\infty}$; hence,

$$L(u) \ge \limsup_{k\to\infty} L(u_k) \ge \frac{1}{s}.$$

This proves that $V - V_s$ is closed in V and then V_s is open.

Step 2. The sets V_s are dense in V.

Fix $s \in \mathbb{N}$, $u \in V_{M,\gamma}$ and $\epsilon > 0$. We shall construct $v \in V_{M,\gamma}$ such that $L(v) < \frac{1}{s}$ and $\|u - v\|_{L^\infty(\Omega,\mathcal{M}_n)} \le \epsilon$. It will follow that V_s is dense in $V_{M,\gamma}$ and then in V too.

Consider the sequences $\{\alpha_l\}_{l\in\mathbb{N}}$ and $\{\beta_l\}_{l\in\mathbb{N}}$ of Definition 3.1 and take an integer l such that

$$\begin{cases} l \ge \dfrac{1}{10s\mu(\Omega)}, \\ \|\alpha_l - \alpha\|_{L^1(\Omega,\mathbb{R})} \le \dfrac{1}{5s}, \\ \|\beta_l - \beta\|_{L^1(\Omega,\mathbb{R})} \le \dfrac{1}{5s} \end{cases} \tag{3.6}$$

and an open set Λ such that $\overline{\Lambda} \subseteq \Omega$ and

$$\mu(\Omega - \Lambda) \le \frac{1}{5s(\overline{\beta} - \overline{\alpha})}. \tag{3.7}$$

Recall that u is CPA i.e., there exists a collection $\{\Omega_j, j \in \mathbb{N}\}$ of open, pairwise disjoint subsets of Ω such that $\Omega = (\bigcup \Omega_j) \bigcup N$ (N null set) and

$$u = \sum_{j=1}^{\infty} u_j \chi_{\Omega_j},$$

where u_j is affine.

Now set $\Lambda_j := \Omega_j \bigcap \Lambda$ and, for any $j \in \mathbb{N}$, consider the open set

$$\Lambda_j^* := \left\{ x \in \Lambda_j : \det Du_j(x) \in \left(\alpha_l(x) + \frac{1}{l}, \beta_l(x) - \frac{1}{l} \right) \right\}.$$

We call

$$\Lambda^* := \bigcup_{j=1}^{\infty} \Lambda_j^*,$$

set

$$v|_{\Omega - \Lambda^*} := u|_{\Omega - \Lambda^*}, \tag{3.8}$$

and now proceed to define v on each Λ_j^*.

By the uniform continuity of α_l and β_l on Λ^* we may infer the existence of a positive δ such that for any $E \subseteq \Lambda^*$ with $\operatorname{diam}(E) \leq \delta$, each one of the multifunctions

$$E \ni x \mapsto \left[\alpha_l(x), \alpha_l(x) + \frac{1}{l} \right], \qquad E \ni x \mapsto \left[\beta_l(x) - \frac{1}{l}, \beta_l(x) \right]$$

admits at least one constant selection, and by Vitali covering lemma, we may assume that each Λ_j^* has diameter less than δ.

Fix then $j \in \mathbb{N}$ such that $\Lambda_j^* \neq \emptyset$. Let d_j^-, d_j^+ be real numbers such that

$$d_j^- \in \left[\alpha_l(x), \alpha_l(x) + \frac{1}{l} \right], \qquad d_j^+ \in \left[\beta_l(x) - \frac{1}{l}, \beta_l(x) \right] \qquad \forall x \in \Lambda_j^*, \tag{3.9}$$

and, in order to simplify the notations, set

$$Du_j = A = \begin{pmatrix} A^1 \\ \vdots \\ A^n \end{pmatrix},$$

remarking that, by the definition of Λ_j^*,

$$d_j^- < \det A < d_j^+. \tag{3.10}$$

Let $i_0 \in \{1, \ldots, n\}$ be the index such that $|(\operatorname{adj}_{n-1} A)^{i_0}| \geq |(\operatorname{adj}_{n-1} A)^i|$ for $i = 1, \ldots, n$, and assume, to fix the ideas, $i_0 = 1$. We then have

(3.11)

$$\begin{aligned} |(\operatorname{adj}_{n-1} A)^1|^n \geq \prod_{i=1}^{n} |(\operatorname{adj}_{n-1} A)^i| &\geq \det \left(\left((\operatorname{adj}_{n-1} A)_j^i \right)_{\substack{i=1,\ldots,n \\ j=1,\ldots,n}} \right) \\ &= \det \left(\left((\operatorname{cof} A)_j^i \right)_{\substack{i=1,\ldots,n \\ j=1,\ldots,n}} \right) = (\det A)^{n-1}. \end{aligned}$$

Now consider the $(n-1)$-dimensional linear subspace of $\mathbb{R}^n$:

$$\left((\mathrm{adj}_{n-1}A)^1\right)^\perp = \{y \in \mathbb{R}^n : \langle y, (\mathrm{adj}_{n-1}A)^1\rangle = 0\}$$

and take an $(n-1)$-simplex $\Sigma = \mathrm{co}(\{\sigma^k, k = 1, \ldots, n\})$ in $\left((\mathrm{adj}_{n-1}A)^1\right)^\perp$ such that zero (of $\mathbb{R}^n$) belongs to its relative interior and $|\sigma^k| = 1$ for every k. Then, for $\rho \in \mathbb{R}$ such that

$$0 < \rho \leq |A^1| \left(1 - \frac{d_j^-}{\det A}\right), \tag{3.12}$$

we define the vectors of $\mathbb{R}^n$:

$$s_\rho^0 := \frac{d_j^+ - \det A}{\det A} A^1, \quad s_\rho^k := \frac{d_j^- - \det A}{\det A} A^1 + \rho\sigma^k, \ k = 1, \ldots, n,$$

and the matrices

$$A(k,\rho) = \begin{pmatrix} A^1 + s_\rho^k \\ A^2 \\ \vdots \\ A^n \end{pmatrix}, k = 0, \ldots, n.$$

Remark that for any $i = 1, \ldots, n$ and $k = 0, 1, \ldots, n$ the map

$$\rho \mapsto g_{k,i}(\rho) := \frac{\det A(k,\rho)}{|A(k,\rho)^i|(\mathrm{adj}_{n-1}A(k,\rho))^i|}$$

is continuous in a neighborhood of $\rho = 0$, and that

$$g_{k,i}(0) = \frac{\det A}{|A^i|(\mathrm{adj}_{n-1}A)^i|} > \gamma.$$

Hence, we can choose a $\overline{\rho}$ sufficiently small so that

$$g_{k,i}(\overline{\rho}) > \gamma \tag{3.13}$$

for any k and i.

Then set $s^k := s_{\overline{\rho}}^k$ for $k = 1, \ldots, n$ and $S := \mathrm{co}\left(\{s^k, k = 0, 1, \ldots, n\}\right)$. By (3.10) and Proposition 2.3, S is an n-simplex and $0 \in \mathrm{int}(S)$. Applying Proposition 2.2 we define a CPA map $w_j \in W_0^{1,\infty}(\Lambda_j^*, \mathbb{R})$ such that $\|w_j\|_{L^\infty(\Lambda_j^*,\mathbb{R})} \leq \epsilon$ and $Dw_j \in \{s^k, k = 0, 1, \ldots, n\}$ a.e. in Λ_j^*. Now define, on Λ_j^*,

$$v_j = \begin{pmatrix} v_j^1 \\ v_j^2 \\ \vdots \\ v_j^n \end{pmatrix} = \begin{pmatrix} u_j^1 + w_j \\ u_j^2 \\ \vdots \\ u_j^n \end{pmatrix}.$$

Clearly, v_j is a CPA element of $u_j + W_0^{1,\infty}(\Lambda_j^*, \mathbb{R}^n)$, $\|u_j - v_j\|_{L^\infty(\Lambda_j^*,\mathbb{R}^n)} \leq \epsilon$, and

$$Dv_j \in \left\{ A(k) = \begin{pmatrix} A^1 + s^k \\ A^2 \\ \vdots \\ A^n \end{pmatrix}, k = 0, \ldots, n \right\}$$

almost everywhere in Λ_j^*. We now show that v_j satisfies (3.3), (3.4), and (3.5).

First of all remark that, by the choice of $\overline{\rho}$ ((3.13)), v_j satisfies (3.5).

Recalling (2.1), we have, by elementary computations,

$$\det A(k) = \langle A^1 + s^k, (\mathrm{adj}_{n-1}A)^1\rangle = \det A + \frac{d_j^{\pm} - \det A}{\det A}\langle A^1, (\mathrm{adj}_{n-1}A)^1\rangle = d_j^{\pm}.$$

Hence,

$$\det Dv_j \in \{d_j^-, d_j^+\} \tag{3.14}$$

almost everywhere in Λ_j^*. Hence, by (3.9), (3.4) holds.

We are left to prove that v_j satisfy (3.3), i.e., that $\|A(k)\|_{\mathcal{M}_n} \le M$ for any k. This means $|A^1 + s^k| \le M$ for $k = 0, 1, \dots, n$. By (3.12) this is trivial for $k = 1, \dots, n$; hence, we estimate $|A^1 + s^0|$. By (3.2), (3.5), (3.11), recalling that u belongs to $V_{M,\gamma}$ and remarking that $d_j^+ \le \overline{\beta}$, we have

$$|A^1 + s^0| = |A^1|\frac{d_j^+}{\det A} = \frac{d_j^+}{|(\mathrm{adj}_{n-1}A)^1|\frac{\det A}{|A^1||(\mathrm{adj}_{n-1}A)^1|}} \le \frac{\overline{\beta}}{(\det A)^{\frac{n-1}{n}}\gamma} \le \frac{\overline{\beta}}{(\overline{\alpha})^{\frac{n-1}{n}}\gamma} \le M.$$

Now we set

$$v|_{\Lambda^*} = \sum_{j=1}^{\infty} v_j|_{\Lambda_j^*}. \tag{3.15}$$

Equations (3.8) and (3.15) define v on the whole Ω. Clearly, v turns out to be a CPA element of $u + W_0^{1,\infty}(\Omega, \mathbb{R}^n) = \varphi + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$; moreover, by construction, conditions (3.3), (3.4), and (3.5) are satisfied locally, and then hold on the whole Ω. Hence v belongs to $V_{M,\gamma}$. Moreover, by construction, $\|u - v\|_{L^\infty} \le \epsilon$ and to end the proof of Step 2 we are left to show that v belongs to V_s.

Let us estimate $L(v)$. By (3.9), (3.14) and by the definition of Λ^*, we have that

$$\det Dv(x) \in \left[\alpha(x), \alpha_l(x) + \frac{1}{l}\right] \bigcup \left[\beta_l(x) - \frac{1}{l}, \beta(x)\right]$$

almost everywhere in Λ. Hence, recalling point (iii) of Proposition 2.1, (3.6) and (3.7) we have

$$\begin{aligned} L(v) &= \int_{\Omega-\Lambda} h(\det Du(x), J(x))dx + \int_{\Lambda} h(\det Dv(x), J(x))dx \\ &\le \mu(\Omega - \Lambda)(\overline{\beta} - \overline{\alpha}) + \int_{\Lambda}\left(\left|\beta(x) - \beta_l(x) - \frac{1}{l}\right| + \left|\alpha(x) - \alpha_l(x) - \frac{1}{l}\right|\right)dx \\ &\le \mu(\Omega - \Lambda)(\overline{\beta} - \overline{\alpha}) + \|\beta - \beta_l\|_{L^1} + \|\alpha - \alpha_l\|_{L^1} + \frac{2}{l}\mu(\Omega) \le \frac{4}{5s} < \frac{1}{s}. \end{aligned}$$

By this way Step 2 is proved.

Now we apply the Baire theorem to conclude that $U := \bigcap_{s\in\mathbb{N}} V_s$ is nonempty. Take any element in $\overline{u} \in U$. Clearly, $\det D\overline{u}(x) \in [\alpha(x), \beta(x)]$ and $\|D\overline{u}(x)\|_{\mathcal{M}_n} \le M$ almost everywhere in Ω; moreover, $L(\overline{u}) = 0$. Hence, $h(x, \det D\overline{u}(x)) = 0$ (a.e.) and this implies, by point (iii) of Proposition 2.1, that $\det D\overline{u}(x) \in \{\alpha(x), \beta(x)\}$ almost everywhere in Ω.

Recalling (3.1), this ends the proof. □

Remarks. 1. In the proof of the theorem we have supposed that Ω is bounded; clearly, such a condition can be removed, considering arbitrary open subsets of $\mathbb{R}^n$ and solving the problem on a countable family of open, bounded, disjoint subsets of Ω.

2. In Theorem 3.1 we impose a condition on the behavior of the boundary value φ in the interior of Ω. This fact is in some sense unnatural. In Corollary 3.1 below we show that under some additional hypothesis such conditions can be removed.

COROLLARY 3.1. *Let Ω be an open bounded connected subset of $\mathbb{R}^n$ with C^∞ boundary $\partial\Omega$. Let $\alpha, \beta : \overline{\Omega} \to \mathbb{R}$ be elements of $L^\infty(\Omega, \mathbb{R})$ satisfying assumption* (A) *and such that $\alpha(x) < \beta(x)$ for almost every $x \in \overline{\Omega}$. Let φ be a C^∞–diffeomorphism of $\overline{\Omega}$ onto $\varphi(\overline{\Omega})$ such that*

$$\int_\Omega \alpha(x)dx < \int_\Omega \det D\varphi(x)dx = \mu(\varphi(\Omega)) < \int_\Omega \beta(x)dx.$$

Then there exists $\overline{u} \in \varphi + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$ such that $\det D\overline{u}(x) \in \{\alpha(x), \beta(x)\}$ almost everywhere in Ω.

Proof. Let $f \in C^\infty(\overline{\Omega}, \mathbb{R})$ be such that

$$\alpha(x) < f(x) < \beta(x) \quad \forall x \in \overline{\Omega}$$

and

$$\int_\Omega f(x)dx = \mu(\varphi(\Omega)).$$

By Theorem 5 in [DMo] there exists a C^∞-diffeomorphism ψ of $\overline{\Omega}$ onto itself such that

$$\begin{cases} \det D\varphi(\psi(x)) \det D\psi(x) = f(x), & x \in \Omega, \\ \psi(x) = x, & x \in \partial\Omega. \end{cases}$$

Since $\Phi := \varphi \circ \psi$ is C^∞, by standard approximation arguments (see [ET, Prop 2.1 p. 309]) we may find a sequence $(\Phi_k)_{k\in\mathbb{N}}$ of CPA elements of $\Phi + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$ such that $\Phi_k \to \Phi$ in $W^{1,\infty}(\Omega, \mathbb{R}^n)$ as $k \to \infty$. Consequently, we may choose an element $\overline{\Phi}$ of such sequence such that

$$\det\overline{\Phi}(x) \in (\alpha(x), \beta(x)),$$

almost everywhere in Ω. Then, applying Theorem 3.1, we can find $\overline{u} \in \overline{\Phi} + W_0^{1,\infty}(\Omega, \mathbb{R}^n) = \varphi + W_0^{1,\infty}(\Omega, \mathbb{R}^n)$ such that $\det D\overline{u}(x) \in \{\alpha(x), \beta(x)\}$. ∎

Acknowledgment. I would like to thank Professor Alberto Bressan for a useful suggestion about the final form of this work.

ON THE STATIONARY CAHN–HILLIARD EQUATION: BUBBLE SOLUTIONS*

JUNCHENG WEI† AND MATTHIAS WINTER‡

Abstract. We study stationary solutions of the Cahn–Hilliard equation in a bounded smooth domain that have an interior spherical interface (bubbles). We show that a large class of interior points (the "nondegenerate peak" points) have the following property: there exists such a solution whose bubble center lies close to a given nondegenerate peak point. Our construction uses, among others, the Liapunov–Schmidt reduction method and exponential asymptotics.

Key words. bubbles, exponential asymptotics, phase transition

1. Introduction.

In this paper, we continue our investigation of stationary solutions of the Cahn–Hilliard equation.

The Cahn–Hilliard equation is the simplest model for the separation of a binary mixture in the presence of a mass constraint (see [7]). It can be derived from a Helmholtz-free energy

$$E(u) = \int_\Omega \left[F\big(u(x)\big) + \frac{1}{2}\epsilon^2 |\nabla u(x)|^2 \right] dx \tag{1.1}$$

subject to the constraint $\frac{1}{|\Omega|}\int_\Omega u\,dx = m$. Here Ω is a bounded smooth domain corresponding to the region occupied by the body, $u(x)$ is a conserved order parameter representing, for example, the concentration, ϵ is the range of intermolecular forces, the gradient term is a contribution to the free energy coming from spatial fluctuations of the order parameter, and $F(u)$ is the free energy density which has a double-well structure at low temperatures. The simplest one is $F(u) = \frac{1}{4}(1-u^2)^2$. Hence, $f(u) := F'(u) = u^3 - u$. For the rest of the paper we often write $u^3 - u$ instead of $f(u)$. However, since we are looking for solutions of (1.2) with $\|u\|_{L^\infty(\Omega)} \le C$, we can modify the nonlinearity $f(u) = u^3 - u$ for u large so that the mapping $u \mapsto u^3$, $H^2(\Omega) \to L^2(\Omega)$ is compact regardless of the dimension N. See [32] and [34] for more general nonlinearities.

A stationary solution of $E(u)$ satisfies the following Euler–Lagrange equation:

$$\begin{cases} \epsilon^2 \triangle u - f(u) = \sigma_\epsilon & \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu} = 0 & \text{on } \partial\Omega, \\ \dfrac{1}{\Omega}\displaystyle\int_\Omega u\,dx = m, \end{cases} \tag{1.2}$$

where $f(u) = F'(u)$, σ_ϵ is a constant, and $\nu(x)$ is the unit outer normal at $x \in \partial\Omega$.

Equation (1.2) has been studied extensively by many authors. It was first observed by Modica in [19] that global minimizers u_ϵ of $E(u)$ under $m = \frac{1}{|\Omega|}\int_\Omega u\,dx$ have a transition layer. Namely, there exists an open set $\Gamma \subset \Omega$ such that if a sequence u_ϵ converges, then $u_\epsilon \longrightarrow 1$ on $\Omega\backslash\bar{\Gamma}, u_\epsilon \longrightarrow -1$ on Γ as $\epsilon \longrightarrow 0$, and $\partial\Gamma \cap \bar{\Omega}$ is a minimal surface having constant mean curvature. Kohn and Sternberg in [16] studied local minimizers of the functional without mass conservation by using Γ-convergence. Chen and Kowalczyk [9] proved the existence of local minimizers using a geometric approach. The dynamics of the transition layer solution have been studied by many authors, e.g., Chen [8], Alikakos, Bates, and Fusco [3], Alikakos, Bates, and Chen [2], Alikakos, Fusco, and Kowalczyk [4], Pego [25], etc.

The study of the solution set of (1.2) is the key to understanding the global dynamics, as this has been illustrated by Bates and Fife in one dimension [6], Alikakos, Fusco, and Kowalczyk [4], and Grinfeld and Novick-Cohen [13], [14].

In the one-dimensional case, Grinfeld and Novick-Cohen [13], [14] completely determined all stationary solutions and proved some properties of their connecting orbits. In the higher-dimensional case ($N \geqslant 2$), little is known about stationary solutions except for the transition layer solution. In [32], we first established the existence of boundary spike layer solutions, namely, solutions that are "almost" constant and have a spike on the boundary. More precisely, suppose that $\sqrt{\frac{1}{3}} < m < 1$ and $P_0 \in \partial\Omega$ such that $\nabla_{\tau_{P_0}} H(P_0) = 0$, $(\nabla^2_{\tau_{P_0}} H(P_0)) := G_B(P_0)$ is nondegenerate, where $H(P_0)$ is the mean curvature function at P_0 and $\nabla_{\tau_{P_0}}$ is the tangential derivative at P_0. Then for ϵ sufficiently small there exists a solution u_ϵ of (1.2) such that $u_\epsilon(x) \to m$ for $x \in \bar{\Omega}\backslash\{P_0\}$. Moreover, u_ϵ has only one local minimum P_ϵ, where $P_\epsilon \in \partial\Omega, P_\epsilon \longrightarrow P_0$ and $u_\epsilon(P_\epsilon) \longrightarrow \beta < m$. Multiple boundary spikes are also constructed in [33].

In [34], we established the existence of interior spike layer solutions under some geometric conditions on the domain.

We first introduced the following set: For each $P \in \Omega$, we define

$$\Lambda_P := \left\{ d\mu_P(z) \in M(\partial\Omega) \;\middle|\; \begin{array}{l} \exists \epsilon_k \longrightarrow 0 \text{ such that} \\ d\mu_P(z) = \lim\limits_{\epsilon_k \to 0} \dfrac{e^{-(|z-P|/\epsilon_k)}dz}{\int_{\partial\Omega} e^{(-|z-P|/\epsilon_k)}dz} \end{array} \right\}, \tag{1.3}$$

where $M(\partial\Omega)$ are the bounded Borel measures on $\partial\Omega$, and the convergence is the weak convergence of measures.

A point $P_0 \in \Omega$ is called a *nondegenerate peak* point if it satisfies the following conditions:

(1) $\Lambda_{P_0} = \{d\mu_{P_0}(z)\}$.

(2) There exists $a \in R^N$ such that $\int_{\partial\Omega} e^{\langle z-P_0,a\rangle}(z-P_0)d\mu_{P_0}(z) = 0$ and

$$\int_{\partial\Omega} \left\{ \frac{e^{(-|z-P_0|/\epsilon)} e^{\langle z-P_0,a\rangle}}{\int_{\partial\Omega} e^{(-|z-P_0|/\epsilon)}dz} \right\} (z-P_0)\,dz = O(\epsilon^{\alpha_0})$$

for some $\alpha_0 > 0$. Here and throughout the paper $\langle A, B\rangle$ means the inner product of $A \in R^N$ and $B \in R^N$.

(3) The matrix $G(P) := \left(\int_{\partial\Omega} e^{\langle z-P_0,a\rangle}(z-P_0)_i(z-P_0)_j\,d\mu_{P_0}(z)\right)$ is nondegenerate, where a is given in (2).

Remark. The vector $a \in R^N$ in (2) and (3) is unique. A more geometric characterization of a nondegenerate peak point is the following fact: P_0 is a nondegenerate peak point if and only if $P_0 \in$ int (conv(supp $(d\mu_{P_0})$)) where int (conv(supp $(d\mu_{P_0})$)) is the interior of the convex hull of the support of $d\mu_{P_0}$. Moreover, when Ω is strictly

convex, the maximum point of the distance function, $d(x, \partial\Omega)$, is a nondegenerate peak point. See [29]. This is much in line with the formal analysis done in [27] (but here we don't need $N = 2$).

Under conditions (1)–(3), we proved in [34] that if $\sqrt{\frac{1}{3}} < m < 1$, then for ϵ sufficiently small, there exist solutions u_ϵ of (1.2) with the property that u_ϵ has only one local minimum P_ϵ and $u_\epsilon \to m$ for $x \in \overline{\Omega} \setminus \{P_0\}$, $u_\epsilon(P_\epsilon) \to \beta < m$, $P_\epsilon \to P_0$.

In this paper, we shall construct another kind of solution: bubbles. A bubble solution is a transition layer solution with a spherical interface. More precisely, u_ϵ is a bubble solution if there exists an open ball (with center x_0 and radius r_b) $B_{r_b}(x_0) \subset \Omega$ such that $u_\epsilon \to +1$ in $B_{r_b}(x_0)$ and $u_\epsilon \to -1$ in $\overline{\Omega} \setminus \overline{B_{r_b}(x_0)}$.

Bubble-like solutions have been studied recently by some authors. Alikakos and Fusco [5] and Ward [27] studied the dynamics of bubbles. It was proved that bubble solutions are metastable, and the bubble drifts across the domain with exponentially small velocity without changing shape while maintaining a constant radius (to principal order) to conserve mass. In [27], Ward used matched asymptotics expansions to give a careful but formal (*nonrigorous*) analysis on stationary bubbles for equation (1.2) in a strictly convex domain in R^2 and some special domains in R^3. More precisely, it was shown in [27] that for a strictly convex domain Ω in R^2, the center of a bubble is at an $O(\epsilon)$ distance from the center of the largest inscribed circle in Ω. Some special results for R^3 were also contained in [27]. As far as we know, a rigorous proof of the existence of stationary bubbles in general domains has not been given.

The goal of this paper is to give an *explicit* and *rigorous* construction of bubble-like solutions in general domains. Our analysis is based on the Liapunov–Schmidt reduction method which was used in a similar context by Floer and Weinstein [11] and extended by Oh [23], [24] in the study of semiclassical states of the following nonlinear Schrödinger equation

$$\epsilon^2 \Delta u - V(x)u + u^p = 0, \qquad x \in R^N.$$

There they studied the role of the potential $V(x)$ for the existence of concentrated solutions, and the order of the error is algebraic (i.e., $O(\epsilon)$). Here we have to overcome two additional difficulties. First, the error term is exponentially small, and we use the method of viscosity solutions as introduced in [18] and used in [22] to estimate exponentially small terms. Second, the linearized operator, modulo its approximate kernel, is not uniformly invertible with respect to ϵ (it is uniformly invertible in [11], [23], [24], and [34]). We have to estimate the order of small eigenvalues of the linearized operator (modulo its kernel).

The following is the main result of this paper.

THEOREM 1.1. *Let $P_0 \in \Omega$ and $m \in (-1, \frac{2|B_{d(P_0,\partial\Omega)}(P_0)|}{|\Omega|} - 1)$. Suppose P_0 is a "nondegenerate peak" point. Then for ϵ sufficiently small there exists a solution u_ϵ of (1.2) such that $u_\epsilon \to 1$ in $B_{r_b}(P_0)$ and $u_\epsilon \to -1$ in $\overline{\Omega} \setminus \overline{B_{r_b}(P_0)}$, where r_b is such that*

$$|B_{r_b}(P_0)| = \frac{m+1}{2}|\Omega|. \tag{1.4}$$

Examples. (1) A bubble in a dumbbell domain (see Fig. 1.1).

By explicit computation, we know that P_1 and P_2 are nondegenerate peak points. There are two bubble solutions for (1.2).

(2) Let $\Omega \subset R^2$. If the support of $d\mu_{P_0}(z)$ contains more than two points, then P_0 is a nondegenerate peak point (see Fig. 1.2).

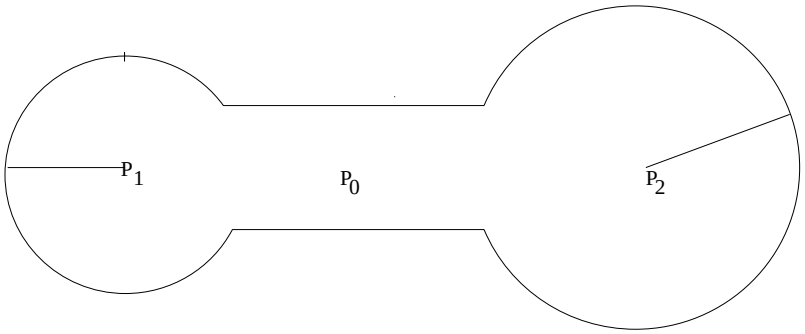

FIG. 1.1. *Dumbbell domain.*

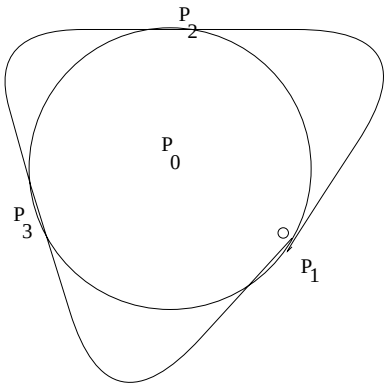

FIG. 1.2. *Support of* $d\mu_{P_0}$ *contains exactly* 3 *points.*

To lay down the proof of Theorem 1.1, we first transform equation (1.2). It is easy to see that equation (1.2) is equivalent to the following:

$$\begin{cases} \epsilon^2 \triangle u + u - u^3 = m - \dfrac{1}{|\Omega|}\displaystyle\int_\Omega u(x)^3\,dx & \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu} = 0 & \text{on } \partial\Omega, \\ \dfrac{1}{|\Omega|}\displaystyle\int_\Omega u\,dx = m. \end{cases} \tag{1.5}$$

We prove Theorem 1.1 in the following steps.

We first study a problem in R^N, namely, the following:

$$\begin{cases} \triangle v + v - v^3 = \sigma & \text{in } R^N, \\ v(0) = \max_{y\in R^N} v(y), v \geqslant \tau_\sigma, v(y) \longrightarrow \tau_\sigma & \text{as } |y| \to +\infty, \end{cases} \tag{1.6}$$

where τ_σ is such that

$$v - v^3 - \sigma = (v - \tau_\sigma)(v - a_\sigma)(b_\sigma - v), \qquad \tau_\sigma < a_\sigma < b_\sigma.$$

Note that as $\sigma \to 0$, $\tau_\sigma \to -1$, $a_\sigma \to 0$, $b_\sigma \to 1$. Moreover, if $\sigma > 0$, we have

$$\int_{\tau_\sigma}^{b_\sigma} [v - v^3 - \sigma]dv > 0.$$

It is well known (see [10] and [26]) that the equation

$$\begin{cases} \triangle w + w(w-a)(b-w) = 0 & \text{in } R^N, \\ w(0) = \max_{z\in R^N} w(z), w(z) > 0, w(z) \to 0 & \text{as } |z| \to \infty \end{cases} \tag{1.7}$$

has a unique solution which is radial if

$$0 < a < b$$

and

$$\int_0^b w(w-a)(b-w)dw > 0.$$

Hence, $\sigma > 0$ fixed and small (1.6) has a unique solution v_σ which is radial.

In section 2, we study the asymptotic behavior of v_σ as $\sigma \to 0$. By a special choice of σ (namely, $\sigma = O(\epsilon)$), we have

$$v_\sigma\left(\frac{|x-P_0|}{\epsilon}\right) \to +1 \text{ in } B_{r_b}(P_0), \qquad v_\sigma\left(\frac{|x-P_0|}{\epsilon}\right) \to -1 \text{ in } \overline{\Omega} \setminus \overline{B_{r_b}(P_0)}$$

for some $r_b > 0$. Hence, v_σ is a bubble solution to (1.6). However, v_σ does not satisfy the boundary condition (which is why we need to introduce the geometric conditions (1)–(3)).

Set

$$\Omega_\epsilon = \{y | \epsilon y \in \Omega\}, \qquad \Omega_{\epsilon,P} = \{y | \epsilon y + P \in \Omega\}.$$

In section 3, we study a function $P_{\Omega_{\epsilon,P}} v_\sigma$ which is a modification of v_σ. It satisfies the Neumann boundary condition on $\partial\Omega_{\epsilon,P}$.

In section 4, we choose σ such that

$$\sigma = m - \frac{1}{|\Omega|}\int_\Omega (P_{\Omega_{\epsilon,P_0}} v_\sigma)^3\, dx. \tag{1.8}$$

We set $P_{\Omega_{\epsilon,P}} v_\sigma = w_{\epsilon,P}$. We use $w_{\epsilon,P}$ as our approximate solution.

In section 5, we set

$$u_\epsilon = w_{\epsilon,P_0+z} + \Phi_{\epsilon,z}, \tag{1.9}$$

where

$$z = \epsilon\left(\frac{1}{2\sqrt{2}} d(P_0, \partial\Omega) a + \tilde{z}\right),$$

and substitute into equation (1.2). We linearize equation (1.2) around w_{ϵ,P_0+z}. The linearized operator is

$$L_\epsilon \Phi = \triangle\Phi + (1 - 3w^2_{\epsilon,P_0+z})\Phi + 3\frac{1}{|\Omega|}\int_\Omega w^2_{\epsilon,P_0+z}\Phi\, dx.$$

The error term $\Phi_{\epsilon,z}$ is exponentially small. We need to obtain the precise exponential asymptotics. This is done in section 5.

In section 6, we use the classical Liapunov–Schmidt reduction procedure. We first define the approximate kernel

$$K_{\epsilon,z} = \text{span}\left\{ \frac{\partial w_{\epsilon,P_0+z}}{\partial z_i} \middle| i = 1, \dots, N \right\} \subset H^2(\Omega_\epsilon)$$

and approximate cokernel

$$C_{\epsilon,z} = \text{span}\left\{ \frac{\partial w_{\epsilon,P_0+z}}{\partial z_i} | i = 1, \dots, N \right\} \subset L^2(\Omega_\epsilon).$$

We solve $\Phi_{\epsilon,z}$ in the approximate kernel. To this end, we need to analyze the small eigenvalues of L_ϵ (modulo $K_{\epsilon,z}$). We will show that these small eigenvalues are of order $O(\epsilon^2)$. Thus $\Phi_{\epsilon,z}$ can be solved. Equation (1.2) is reduced to finite dimensions.

In section 7 we apply a degree-theoretic argument to solve the reduced finite-dimensional problem (in which the nondegeneracy of the peak point P_0 is essential) and complete the proof of Theorem 1.1.

We note that Ward in [27] obtained identities similar to condition (2) about bubbles. In [28], he also derived a similar identity for the location of peaks of localized solutions for a semilinear elliptic equations with Robin boundary conditions. Such kind of identities have also appeared in the analysis of interior spike solutions for the stationary reaction-diffusion equation

$$\begin{cases} \epsilon^2 \triangle u + f(u) = 0 & \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu} = 0 \text{ or } u = 0 & \text{on } \partial\Omega. \end{cases} \tag{1.10}$$

See [22], [29], [30], [31], [34], etc.

Throughout this paper, we use C, C_0, C_N, c, etc. to denote various generic constants. The symbols $O(A), o(A)$ mean that $|O(A)| \le C|A|, o(A)/|A| \to 0$, respectively. $A \sim B$ means $A/B \to C$ in some limit. The numbers μ, δ are small positive numbers.

2. Equation in R^N. In this section, we study a parametrized semilinear elliptic equation in R^N.

Let v_σ be the unique solution of the problem

$$\begin{cases} \triangle v + v - v^3 = \sigma & \text{in } R^N, \\ v(0) = \max_{y \in R^N} v(y), v \geqslant \tau_\sigma, v(y) \longrightarrow \tau_\sigma & \text{as } |y| \to +\infty. \end{cases} \tag{2.11}$$

For σ small, let $v - v^3 - \sigma = (v - \tau_\sigma)(v - a_\sigma)(b_\sigma - v)$, where $\tau_\sigma < a_\sigma < b_\sigma$. Then

$$\tau_\sigma = -1 + c_0\sigma + O(\sigma^2), \quad a_\sigma = 0 + c_1\sigma + O(\sigma^2), \quad b_\sigma = 1 + c_2\sigma + O(\sigma^2), \tag{2.12}$$

where c_0, c_1, c_2 are constants.

Let R_σ be the radius such that

$$v_\sigma(R_\sigma) = 0. \tag{2.13}$$

We have the following.

LEMMA 2.1.

$$\sigma R_\sigma = c_b + O(\sigma) \tag{2.14}$$

as $\sigma \to 0$ where $c_b > 0$ is a positive constant.

Proof. We divide the proof into the following steps.

STEP 1. *$R_\sigma \to \infty$ as $\sigma \to 0$.*

We have $v_\sigma \to v_0$ uniformly in any compact set, where v_0 satisfies

$$\begin{cases} \triangle v_0 + v_0 - v_0^3 = 0, \\ v_0(0) = 1, \qquad v_0'(0) = 0. \end{cases} \tag{2.15}$$

This implies $v_0 \equiv 1$ (since v_0 is radial). Therefore, $R_\sigma \to \infty$ as $\sigma \to 0$ and Step 1 is proved.

STEP 2. *$v_\sigma(R_\sigma + s) \to U_0(s)$ in $C^2_{loc}(R)$ as $\sigma \to 0$, where $U_0(s)$ is the unique solution of the ODE*

$$\begin{cases} u'' + u - u^3 = 0, \qquad -\infty < r < +\infty, \\ u(0) = 0, \quad \lim_{r\to-\infty} u(r) = -1, \quad \lim_{r\to+\infty} u(r) = +1. \end{cases} \tag{2.16}$$

Set $\hat{v}_\sigma(|x|) := v_\sigma(x)$ and $\tilde{v}_\sigma(s) := \hat{v}_\sigma(R_\sigma + s)$. Note that $\tilde{v}_\sigma$ satisfies

$$\tilde{v}_\sigma'' + \frac{N-1}{R_\sigma + s}\tilde{v}_\sigma' + \tilde{v}_\sigma - \tilde{v}_\sigma^3 = \sigma. \tag{2.17}$$

Now

$$\frac{1}{R_\sigma + s} \to 0 \tag{2.18}$$

uniformly with respect to s in any compact subset of the real line R since $R_\sigma \to \infty$.

This implies that $\tilde{v}_\sigma \to U_0$ in $C^2_{loc}(R)$, where U_0 satisfies (2.16). Step 2 is thus proved.

STEP 3. *$\sigma R_\sigma = c_b + O(\sigma)$ as $\sigma \to 0$.*

Set $\Phi_\sigma(s) = \tilde{v}_\sigma(s) - U_0(s)$. Then Φ_σ satisfies

$$\Phi_\sigma'' + (1 - 3U_0^2)\Phi_\sigma + O(|\Phi_\sigma|)\Phi_\sigma = \sigma - \frac{N-1}{R_\sigma + s}\tilde{v}_\sigma' \tag{2.19}$$

uniformly in any compact subset of R. This implies

$$\|\Phi_\sigma\|_{C^2_{loc}[-R_\sigma,\infty)} \le C\mathrm{Max}(\sigma, R_\sigma^{-1}). \tag{2.20}$$

Furthermore, U_0' satisfies

$$(U_0')'' + (1 - 3U_0^2)U_0' = 0. \tag{2.21}$$

Multiplying (2.19) by U_0' and (2.21) by Φ_σ, integrating, and taking the difference, we get

$$\begin{aligned}&\Phi_\sigma' U_0' - \Phi_\sigma U_0''|_{-R_\sigma}^{\infty} + \int_{-R_\sigma}^{\infty} O(|\Phi_\sigma|^2) U_0'\, ds \\ &= \sigma \int_{-R_\sigma}^{\infty} U_0'\, ds - \int_{-R_\sigma}^{\infty} \frac{N-1}{R_\sigma + s} \tilde{v}_\sigma' U_0'\, ds. \end{aligned} \tag{2.22}$$

This implies

$$\sigma R_\sigma = \frac{N-1}{2} \int_{-\infty}^{\infty} (U_0')^2\, ds + O(R_\sigma \mathrm{Max}(\sigma^2, R_\sigma^{-2})) \tag{2.23}$$

as $\sigma \to 0$. Therefore, Step 3 is proved and Lemma 2.1 follows. □

Let $U_0(r)$ be the solution of (2.16). We then have the following.

LEMMA 2.2.

$$v_\sigma(r) = U_0(r - R_\sigma) + O(\sigma). \tag{2.24}$$

Proof. Lemma 2.2 follows by Lemma 2.1 and (2.20). □

Next we shall study the eigenvalues associated with the linearized operator

$$L_\sigma \Phi := \triangle \Phi + (1 - 3v_\sigma^2)\Phi,$$

$$L_\sigma : H_N^2(\Omega_{\epsilon,P}) \to L^2(\Omega_{\epsilon,P}),$$

where

$$\Omega_{\epsilon,P} = \{y | \epsilon y + P \in \Omega\}$$

and

$$H_N^2(\Omega_{\epsilon,P}) = \left\{ u \in H^2(\Omega_{\epsilon,P}) \middle| \frac{\partial u}{\partial \nu} = 0 \text{ on } \partial\Omega_{\epsilon,P} \right\}.$$

We first consider the operator on R^N:

$$L\Phi := \triangle \Phi + (1 - 3v_\sigma^2)\Phi,$$

$$L : H^2(R^N) \to L^2(R^N).$$

LEMMA 2.3. *For $\sigma > 0$ sufficiently small*

$$\mathrm{Kernel}(L) := X = \mathrm{span} \left\{ \frac{\partial v_\sigma}{\partial y_j} \middle| j = 1, 2, \ldots, N \right\} \subset H^2(R^N).$$

Proof. By [26], L_σ is invertible in the space $H_r^2(R^N) = \{u = u(|y|) \in H^2(R^N)\}$. Similar to the proof of Lemma B.2 in [21], we have Lemma 2.3. □

We now use a perturbation analysis to extend Lemma 2.3 to the operator defined on $\Omega_{\epsilon,P}$. Similar to [32], we introduce a notion of "distance" between two closed subspaces E, F of a Hilbert space $H := L^2(\Omega_\epsilon)$. Following [15], we set

$$\vec{d}\,(E, F) = \sup\{d(x, F) | x \in E, \|x\|_H = 1\}.$$

It is easy to see that $\vec{d}$ is nonsymmetric, $\vec{d}\,(E,F) \leqslant 1$, and that

$$\vec{d}(E,F) = 1 \quad \text{if and only if } E \perp F. \tag{2.25}$$

Moreover, it is not hard to show that

$$\vec{d}\,(E,F) = \vec{d}\,(F^{\perp}, E^{\perp}).$$

Then the following two lemmata are proved in [15].

LEMMA 2.4. *Let A be a self-adjoint operator on a Hilbert space H, I a compact interval in R, and $\{\Psi_1, \dots, \Psi_N\}$ linearly independent normalized elements in $D(A)$. Assume that the following conditions are true:*

(i)

$$\begin{cases} A\Psi_j = \mu_j \Psi_j + r_j, & \|r_j\| < \epsilon', \\ \mu_j \in I, \ j = 1, \dots, N. \end{cases}$$

(ii) *There is a number $a > 0$ such that I is a-isolated in the spectrum of A:*

$$(\sigma(A) \setminus I) \cap (I + (-a, a)) = \emptyset.$$

Then

$$\vec{d}\,(E,F) = \sup\{d(x,F) | x \in E, \|x\|_H = 1\} \leq \frac{N^{1/2}\epsilon'}{a(\lambda_{\min})^{1/2}},$$

where

$$E = \operatorname{span}\{\Psi_1, \dots, \Psi_N\},$$

$$F = \text{closed subspace associated to } \sigma(A) \cap I,$$

$$\lambda_{\min} = \text{the smallest eigenvalue of the matrix } (\langle \Psi_i, \Psi_j \rangle).$$

LEMMA 2.5. *Let $K > 0$, and consider that part of the spectra of two linear operators L and M which lie in $I(\epsilon) = (-\infty, K\epsilon^2)$. Let E and F be the corresponding spectral subspaces. Assume, moreover, that $I(\epsilon)$ is ϵ^2-isolated in $\sigma(L)$ for $\epsilon < \epsilon_0$:*

$$\sigma(L) \cap \left(K\epsilon^2, (K + \overline{a})\epsilon^2\right) = \emptyset$$

for some $\overline{a} > 0$. Then there is a bijection

$$b : \sigma(L) \cap I(\epsilon) \to \sigma(M) \cap I(\epsilon)$$

(counting multiplicities) such that for $\epsilon < \epsilon_0$ the following estimates hold:

$$b(\lambda) - \lambda = O(e^{-C/\epsilon}), \tag{2.26}$$

$$\vec{d}\,(E,F) = O(e^{-C/\epsilon}), \tag{2.27}$$

$$\vec{d}\,(F,E) = O(e^{-C/\epsilon}), \tag{2.28}$$

for some $C > 0$.

The following result gives an approximation of the kernel of the linear operator L_σ defined on $\Omega_{\epsilon,P}$.

LEMMA 2.6. *Suppose that $\sigma = c\epsilon + O(\epsilon^2)$, where $c > 0$ is constant. For $\epsilon > 0$ sufficiently small there exists $C > 0$ such that*

$$\vec{d}(Kernel(L), X_\sigma) = O(e^{-C/\epsilon})$$

and

$$\vec{d}(X_\sigma, Kernel(L)) = O(e^{-C/\epsilon}),$$

where

$$X_\sigma = span\left\{ \frac{\partial v_\sigma}{\partial y_j} \in L^2(\Omega_{\epsilon,P}) \middle| \, j = 1, 2, \ldots, N \right\}$$

is the kernel of L_σ defined on $\Omega_{\epsilon,P}$.

Proof. The lemma is an immediate consequence of Lemma 2.5. □

Now we estimate the eigenvalues of the operator defined on $\Omega_{\epsilon,P}$.

LEMMA 2.7. *Let (τ, Φ_τ) with $\Phi_\tau \in H^2(\Omega_{\epsilon,P})$ be a solution of the following eigenvalue problem*

$$\begin{cases} \Delta\Phi + (1 - 3v_\sigma^2)\Phi = \tau\Phi & \text{in } \Omega_{\epsilon,P}, \\ \dfrac{\partial\Phi}{\partial\nu} = 0 & \text{on } \partial\Omega_{\epsilon,P}. \end{cases} \tag{2.29}$$

Suppose that $\sigma = c\epsilon + O(\epsilon^2)$ and $\Phi_\tau \perp X_\sigma$, where $c > 0$ and

$$X_\sigma := span\left\{ \frac{\partial v_\sigma}{\partial y_j} \in L^2(\Omega_{\epsilon,P}) \middle| \, j = 1, 2, \ldots, N \right\}.$$

Then $|\tau| \geq C\sigma^2$, where C is independent of $\sigma \ll 1$.

Proof. Suppose Lemma 2.7 is not true. Then there exist sequences τ_k and σ_k, $k = 1, 2, \ldots$ such that $\frac{\tau_k}{\sigma_k^2} \to 0$ as $k \to \infty$. Here τ_k is an eigenvalue of L_{σ_k} and $\tau_k \neq 0$, i.e.,

$$L_{\sigma_k}\Phi_k = \tau_k\Phi_k, \qquad \Phi_k \perp X_{\sigma_k},$$

where

$$X_{\sigma_k} = \left\{ \frac{\partial v_{\sigma_k}}{\partial y_j}, \, j = 1, 2, \ldots, N \right\} \subset L^2(\Omega_{\epsilon,P}).$$

Φ_k satisfies

$$\Phi_k'' + \frac{N-1}{r}\Phi_k' + \frac{1}{r^2}\triangle_{S^{N-1}}\Phi_k + (1 - 3v_{\sigma_k}^2)\Phi_k = \tau_k\Phi_k. \tag{2.30}$$

Assume that

$$\|\Phi_k\|_{H^2(\Omega_{\epsilon,P})} = 1. \tag{2.31}$$

Extend Φ_k from $\Omega_{\epsilon,P}$ to a function in R^N such that $\Phi_k = O(e^{-C|y|})$ for $y \in R^N \setminus \Omega_{\epsilon,P}$ and such that the same result holds for the first and second derivatives of Φ_k.

We make the following decomposition:

$$\Phi_k(r) = \sum_{m=1}^{\infty} \Phi_{k,m}(r - R_{\sigma_k}) e_m(\theta), \tag{2.32}$$

where $r = |y|$. Here $e_m(\theta)$ are the eigenfunctions of $\Delta_{S^{N-1}}$, i.e.,

$$\triangle_{S^{N-1}} e_m + \mu_m e_m = 0.$$

Note that $\Phi_k(r) = O(e^{-\delta R_\sigma})$ for $|r - R_\sigma| \geq \beta\delta_0 > 0$. Hence, there exists $\delta > 0$ such that

$$\Phi_{k,m}(r) = \int_{|\theta|=1} \Phi_k(r) e_m(\theta)\, d\theta = O(e^{-\delta R_\sigma}) \quad \text{for } |r - R_\sigma| \geq \beta\delta_0 > 0.$$

It is well known that

$$\mu_0 = 0, \quad \mu_1 = \cdots = \mu_N = N - 1, \quad \mu_{N+1} > N - 1, \quad \mu_m \sim m^2 \text{ as } m \to \infty.$$

Furthermore, $\Phi_{k,m}$ satisfies

$$\Phi''_{k,m} + \frac{N-1}{R_{\sigma_k} + s}\Phi'_{k,m} - \frac{\mu_m}{(R_{\sigma_k} + s)^2}\Phi_{k,m} + (1 - 3\tilde{v}^2_{\sigma_k})\Phi_{k,m} = \tau_k \Phi_{k,m} \tag{2.33}$$

in $[-R_\sigma, \infty)$. Note that $\tilde{v}'_{\sigma_k}$ satisfies

$$(\tilde{v}'_{\sigma_k})'' + \frac{N-1}{R_{\sigma_k} + s}(\tilde{v}'_{\sigma_k})' + (1 - 3\tilde{v}^2_{\sigma_k})\tilde{v}'_{\sigma_k} = \frac{N-1}{(R_{\sigma_k} + s)^2}\tilde{v}'_{\sigma_k} \quad \text{in } [-R_\sigma, \infty). \tag{2.34}$$

We next decompose $\Phi_{k,m}$ into

$$\Phi_{k,m} = C_{k,m}\tilde{v}'_{\sigma_k} + \Phi^2_{k,m},$$

where

$$\Phi^2_{k,m} \perp \tilde{v}'_{\sigma_k}.$$

Multiplying (2.33) by $\tilde{v}'_{\sigma_k}$, multiplying (2.34) by $\Phi_{k,m}$, taking the difference, and integrating we obtain

$$\int_{-R_\sigma}^{\infty} \left(\tau_k + \frac{\mu_m - (N-1)}{(R_{\sigma_k} + s)^2}\right) \Phi_{k,m}\tilde{v}'_{\sigma_k}\, ds = O(e^{-\delta R_\sigma}). \tag{2.35}$$

Since $\tau_k = o(1)\sigma_k^2$, we have

$$C_{k,m} = O\left(\frac{R_\sigma^2 e^{-\delta R_\sigma}}{\mu_m}\right). \tag{2.36}$$

Note that $\Phi^2_{k,m}$ satisfies

$$(\Phi^2_{k,m})'' + \frac{N-1}{R_{\sigma_k} + s}(\Phi^2_{k,m})' + (1 - 3\tilde{v}^2_{\sigma_k})(\Phi^2_{k,m}) = \frac{\mu_m}{(R_{\sigma_k} + s)^2}\Phi^2_{k,m}$$

$$+ \tau_k \Phi^2_{k,m} + \frac{\mu_m - (N-1)}{(R_{\sigma_k} + s)^2} C_{k,m}\tilde{v}'_{\sigma_k} + \tau_k C_{k,m}\tilde{v}'_{\sigma_k} \quad \text{in } [-R_\sigma, \infty). \tag{2.37}$$

Multiplying (2.37) by $\Phi_{k,m}^2$ and integrating by parts, we have

$$\int_{-R_\sigma}^{\infty}\left[((\Phi_{k,m}^2)')^2-(1-3\tilde{v}_{\sigma_k}^2)(\Phi_{k,m}^2)^2+\left(\frac{\mu_m}{(R_{\sigma_k}+s)^2}+\tau_k\right)(\Phi_{k,m}^2)^2\right.$$

$$\left.-\frac{N-1}{R_{\sigma_k}+s}(\Phi_{k,m}^2)'\Phi_{k,m}^2\right]ds=O(e^{-\delta R_\sigma}). \tag{2.38}$$

Since $\Phi_{k,m}^2\perp\tilde{v}_{\sigma_k}'$, we have that

$$\int_{-R_\sigma}^{\infty}\left[((\Phi_{k,m}^2)')^2-(1-3\tilde{v}_{\sigma_k}^2)(\Phi_{k,m}^2)^2+\left(\frac{\mu_m}{(R_{\sigma_k}+s)^2}+\tau_k\right)(\Phi_{k,m}^2)^2\right.$$

$$\left.-\frac{N-1}{R_{\sigma_k}+s}(\Phi_{k,m}^2)'\Phi_{k,m}^2\right]ds\geq\int_{-R_\sigma}^{\infty}\sigma_0[((\Phi_{k,m}^2)')^2+(\Phi_{k,m}^2)^2]\,ds. \tag{2.39}$$

(Suppose not. Then there exists a subsequence, again denoted by $\Phi_{k,m}^2$, such that $\Phi_{k,m}^2\to\Phi_0$ in $H^1(-\infty,\infty)$, where $\int_{-\infty}^{\infty}((\Phi_0)')^2+(\Phi_0)^2=1$ and $\Phi_0\perp U_0'$. Furthermore, Φ_0 satisfies

$$\int_{-\infty}^{\infty}[((\Phi_0)')^2-(1-3(U_0)^2)(\Phi_0)^2]\,ds=0.$$

This is a contradiction since the operator $-\Delta+(1-3U_0^2)$ is positive and has the kernel $\operatorname{span}(U_0')$.)

Hence, combining (2.38) and (2.39),

$$\int_{-R_\sigma}^{\infty}[((\Phi_{k,m}^2)')^2+(\Phi_{k,m}^2)^2]\,ds=O\left(\frac{e^{-\delta R_\sigma}}{R_\sigma^2+\mu_m}\right)=O\left(\frac{e^{-\delta R_\sigma}}{\mu_m}\right),$$

or, in other words,

$$\|\Phi_{k,m}^2\|_{H^1([-R_\sigma,\infty))}^2=O(e^{-\delta R_\sigma}/\mu_m).$$

By elliptic regularity theory we also know that

$$\|\Phi_{k,m}^2\|_{H^2([-R_\sigma,\infty))}=O(e^{-\delta R_\sigma}/\mu_m).$$

Hence,

$$\|\Phi_{k,m}^2\|_{H^2(R^N)}^2=O(R_\sigma^{N-1}e^{-\delta R_\sigma}/\mu_m). \tag{2.40}$$

By (2.36) and (2.40),

$$\|\Phi_k\|_{H^2(\Omega_{\epsilon,P})}^2\leq\sum_{m=N+1}^{\infty}\|\Phi_{k,m}\|_{H^2(R^N)}^2=O(R_\sigma^{N+1}e^{-\delta R_\sigma})\sum_{m=N+1}^{\infty}\frac{1}{\mu_m}=o(1).$$

This is a contradiction! The proof is finished. ∎

COROLLARY 2.1. *For all $\Phi\in H_N^2(\Omega_{\epsilon,P})$, where Φ is orthogonal to the kernel of L_σ, we have*

$$\|L_\sigma\Phi\|_{L^2(\Omega_{\epsilon,P})}\geq C\sigma^2\|\Phi\|_{H^2(\Omega_{\epsilon,P})}, \tag{2.41}$$

where $C>0$ is independent of $\sigma\ll 1$.

Proof. Let $L_\sigma \Phi = \sigma^2 f$. Then by Lemma 2.4, we have

$$\|\sigma^2 f\|_{L^2(\Omega_{\epsilon,P})} \geq C\sigma^2 \|\Phi\|_{L^2(\Omega_{\epsilon,P})}.$$

On the other hand, Φ satisfies

$$\Delta\Phi - 2\Phi = (3v_\sigma^2 - 3)\Phi + \sigma^2 f.$$

Hence, by elliptic regularity estimates, we have

$$\|\Phi\|_{H^2(\Omega_{\epsilon,P})} \leq C(\|\Phi\|_{L^2(\Omega_{\epsilon,P})} + \sigma^2 \|f\|_{L^2(\Omega_{\epsilon,P})})$$

$$\leq C\|f\|_{L^2(\Omega_{\epsilon,P})} \leq C\sigma^{-2}\|L_\sigma \Phi\|_{L^2(\Omega_{\epsilon,P})}.$$

The corollary is thus proved. □

Finally, we study the asymptotic behavior of v_σ.

LEMMA 2.8. *For σ sufficiently small, we have*

$$v_\sigma - \tau_\sigma = C\left(\frac{r}{R_\sigma}\right)^{-\frac{N-1}{2}} e^{\bar\nu_\sigma(R_\sigma - r)}(1 + O(\sigma)) \quad \text{for } r \geq R_\sigma, \tag{2.42}$$

where τ_σ is defined in section 2 (note that $\tau_\sigma \to -1$ as $\sigma \to 0$), $C \neq 0$ is a generic constant, and

$$\bar\nu_\sigma = \sqrt{3\tau_\sigma^2 - 1}.$$

Proof. We use matched asymptotics as in [27], although the proof can be made rigorous by ODE arguments and the maximum principle.

Let $\hat v_\sigma = v_\sigma - \tau_\sigma$. Linearizing (2.1) around τ_σ, we have that $\hat v_\sigma$ satisfies

$$\hat v_\sigma'' + \frac{N-1}{r}\hat v_\sigma' - \bar\nu_\sigma^2 \hat v_\sigma + O(\hat v_\sigma^2) = 0.$$

Note that $\bar\nu_\sigma = \sqrt{2} + O(\sigma)$, and the exact solution of the following problem

$$u'' + \frac{N-1}{r}u' - \bar\nu_\sigma^2 u = 0, \quad u(R_\sigma) = -\tau_\sigma, \quad r \geq R_\sigma, \quad u(r) \to 0 \text{ as } r \to \infty$$

is $(-\tau_\sigma)(\frac{r}{R_\sigma})^{1-N/2} K_m(\bar\nu_\sigma r)(K_m(\bar\nu_\sigma R_\sigma))^{-1}$, where $m = (N-2)/2$ and $K_m(z)$ is the modified Bessel function of the second kind of order m.

Since

$$K_m(z) = \left(1 + O\left(\frac{1}{z}\right)\right)(\pi/(2z))^{1/2} e^{-z}$$

as $z \to \infty$, we have

$$\hat v_\sigma = C_\sigma \left(\frac{r}{R_\sigma}\right)^{1-\frac{N}{2}} \left(\frac{\pi}{2r}\right)^{\frac{1}{2}} e^{-\bar\nu_\sigma r}(1 + O(\sigma)) \quad \text{as } r \to \infty, \tag{2.43}$$

where C_σ may depend on σ. On the other hand, let $r = R_\sigma + s$; then

$$\hat v_\sigma = C_0 e^{-\bar\nu_\sigma s}(1 + O(\sigma)) \tag{2.44}$$

for s large, where $C_0 \neq 0$ is a generic constant. Combining (2.43) and (2.44), we have

$$C_\sigma = C_0 \pi^{-1/2} (2\bar{\nu}_\sigma R_\sigma)^{1/2} e^{\bar{\nu}_\sigma R_\sigma}.$$

Hence Lemma 2.8 is proved. □

In the following, it will be more convenient to rewrite (2.42) as follows:

$$v_\sigma - \tau_\sigma = C\sigma^l r^{-\frac{N-1}{2}} e^{\bar{\nu}_\sigma (R_\sigma - r)}(1 + O(\sigma)) \quad \text{for } r \geq R_\sigma, \tag{2.45}$$

where $l = -(N-1)/2$.

3. The projection of v_σ. In this section, we construct a modified function $P_{\Omega_{\epsilon,P}} v_\sigma$. It is close to v_σ and satisfies the Neumann boundary condition. Furthermore, we provide an error estimate for $\Psi_{\epsilon,P} = v_\sigma - P_{\Omega_{\epsilon,P}} v_\sigma$.

Let $\Psi_{\epsilon,P}$ be the unique solution of

$$\begin{cases} \epsilon^2 \triangle u - \bar{\nu}_\sigma^2 u = 0 & \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu} = \dfrac{\partial v_\sigma((x-P)/\epsilon)}{\partial \nu} & \text{on } \partial\Omega. \end{cases} \tag{3.46}$$

Define $P_{\Omega_{\epsilon,P}} v_\sigma := v_\sigma - \Psi_{\epsilon,P}$. Later, in section 4, we will show that for every small $\epsilon > 0$ there exists exactly one $\sigma = \sigma(\epsilon)$ satisfying a certain nonlinear equation, and, furthermore, we have $\sigma(\epsilon) = \gamma_0 \epsilon + O(\epsilon^2)$ as $\epsilon \to 0$, where γ_0 is some positive constant. In this section we will write σ and ϵ with the understanding that this relation holds. We set

$$\nu_\epsilon = \bar{\nu}_{\sigma(\epsilon)}.$$

Note that by (2.45) on the boundary of $\partial\Omega$,

$$v_\sigma\left(\frac{x-P}{\epsilon}\right) = \tau_\sigma + C\sigma^l \left(\frac{|x-P|}{\epsilon}\right)^{-\frac{N-1}{2}} e^{-\nu_\epsilon(|x-P|/\epsilon - R_\sigma)}(1 + O(\sigma)).$$

In particular, we have the following asymptotic expansion of $\Psi_{\epsilon,P}$. A proof can be found in [34].

LEMMA 3.1. *For ϵ sufficiently small, we have*

$$\begin{aligned} \Psi_{\epsilon,P}(x) &= (C_N + O(\epsilon))\epsilon^{l_1} e^{\nu_\epsilon R_\sigma} \\ &\quad \times \int_{\partial\Omega} \left\{ e^{-\nu_\epsilon \frac{|t-P|+|t-x|}{\epsilon}} |t-P|^{-\frac{N-1}{2}} |t-x|^{-\frac{N-1}{2}} \frac{\langle t-x, \nu\rangle}{|t-x|} \right\} dt, \end{aligned} \tag{3.47}$$

where l_1 is a rational number.

Let us introduce the following notation:

$$\tilde{\varphi}_{\epsilon,P}(P) := \left[\int_0^\infty (\tau_\sigma^2 - v_\sigma^2(r)) v_\sigma'(r) u_\sigma'(r) r^{N-1}\, dr \right] \Psi_{\epsilon,P}(P), \tag{3.48}$$

where u_σ is the unique solution of

$$\Delta u - \nu_\epsilon^2 u = 0,\ u(0) = 1,\ u > 0,\ u = u(r) \quad \text{for } r \in [0, \infty). \tag{3.49}$$

We have the following key computations.

LEMMA 3.2. *Let P_0 be a nondegenerate peak point of Ω, and $\alpha_0 > 0$ is given by condition (2) in section 1. Suppose $P_\epsilon = P_0 + \epsilon(\frac{a}{2\sqrt{2}} d(P_0, \partial\Omega) + \tilde{z})$ with $|\tilde{z}| = O(\epsilon^\alpha), 0 < \alpha < \alpha_0$. Then*

$$\begin{aligned} L_j(\epsilon, \tilde{z}) &:= \int_{\Omega_{\epsilon,P_\epsilon}} (\tau_\sigma^2 - v_\sigma^2)\Psi_{\epsilon,P_\epsilon} \frac{\partial v_\sigma}{\partial y_j} \\ &= L_j(\tilde{z})\tilde{\varphi}_{\epsilon,P_\epsilon}(P_\epsilon) + O\big(\tilde{\varphi}_{\epsilon,P_\epsilon}(P_\epsilon)\epsilon^{\min(1,2\alpha,\alpha_0)}\big), \end{aligned} \tag{3.50}$$

where $L(\tilde{z}) := (L_1(\tilde{z}), \dots, L_N(\tilde{z}))$ is a matrix which satisfies

$$L_j(\tilde{z}) = \gamma \frac{\int_{\partial\Omega} e^{\langle t-P_0, a\rangle} \langle t - P_0, \tilde{z}\rangle \big(t_j - P_{0,j}\big)\, d\mu_{P_0}(t)}{\int_{\partial\Omega} e^{\rangle t-P_0, a\langle}\, d\mu_{P_0}(t)},$$

where $\gamma \neq 0$ is a constant depending on N and $d(P_0, \partial\Omega)$ only.

Proof. Since the proof is quite similar to the proof of Lemma 3.4 in [34], we will merely sketch it. Note that

$$L_j(\epsilon, \tilde{z}) = \int_{\Omega_{\epsilon,P_\epsilon}} (\tau_\sigma^2 - v_\sigma^2)\Psi_{\epsilon,P_\epsilon} \frac{\partial v_\sigma}{\partial y_j}$$

$$= \int_0^\infty (\tau_\sigma^2 - v_\sigma^2) v_\sigma' r^{N-1}\, dr \int_{|\theta|=1} \theta_j \Psi_{\epsilon,P_\epsilon}(\epsilon y + P_\epsilon)\, d\theta + O(\tilde{\varphi}^{1+\mu}_{\epsilon,P_\epsilon}(P_\epsilon)).$$

However (let $x = \epsilon y + P_\epsilon$),

$$\begin{aligned} &\Psi_{\epsilon,P_\epsilon}(\epsilon y + P_\epsilon) \\ &= \Psi_{\epsilon,P_\epsilon}(P_\epsilon) \frac{\int_{\partial\Omega} \Big\{ e^{-\nu_\epsilon \frac{|t-P_\epsilon|+|t-x|}{\epsilon}} |t-P_\epsilon|^{-\frac{N-1}{2}} |t-x|^{-\frac{N-1}{2}} (\langle t-x, \nu\rangle/|t-x|) \Big\}\, dt}{\int_{\partial\Omega} \Big\{ e^{-\nu_\epsilon \frac{2|t-P_\epsilon|}{\epsilon}} |t-P_\epsilon|^{-\frac{N-1}{2}} |t-x|^{-\frac{N-1}{2}} (\langle t-x, \nu\rangle/|t-x|) \Big\}\, dt} \\ &= \Psi_{\epsilon,P_\epsilon}(P_\epsilon) \\ &\quad \times \frac{\int_{\partial\Omega} \Big\{ e^{-\nu_\epsilon \frac{2|t-P_\epsilon|}{\epsilon}} e^{\nu_\epsilon \langle \frac{t-P_\epsilon}{|t-P_\epsilon|}, y\rangle} |t-P_\epsilon|^{-\frac{N-1}{2}} |t-x|^{-\frac{N-1}{2}} (\langle t-x, \nu\rangle/|t-x|) \Big\}\, dt}{\int_{\partial\Omega} \Big\{ e^{-\nu_\epsilon \frac{2|t-P_\epsilon|}{\epsilon}} |t-P_\epsilon|^{-\frac{N-1}{2}} |t-x|^{-\frac{N-1}{2}} (\langle t-x, \nu\rangle/|t-x|) \Big\}\, dt} \\ &= \Psi_{\epsilon,P_\epsilon}(P_\epsilon) \int_{\partial\Omega} e^{\langle t-P_0, a\rangle} e^{\nu_\epsilon \langle \frac{t-P_0}{|t-P_0|}, y\rangle}\, d\mu^a_{P_0}(t)(1 + O(\epsilon^{\alpha_0})) \end{aligned}$$

by condition (2) in section 1, where

$$d\mu^a_P(t) = \lim_{\epsilon\to 0} \frac{e^{-2\nu_\epsilon |t-P_\epsilon|/\epsilon}\, dt}{\int_{\partial\Omega} e^{-2\nu_\epsilon |t-P_\epsilon|/\epsilon}\, dt}.$$

Hence,

$$\begin{aligned} L_j(\epsilon, \tilde{z}) &= \left[\int_0^\infty (\tau_\sigma^2 - v_\sigma^2(r)) v_\sigma'(r) u_\sigma'(r) r^{N-1}\, dr \right] \Psi_{\epsilon,P_\epsilon}(P_\epsilon) L_j(\tilde{z}) \\ &\quad + O(\tilde{\varphi}_{\epsilon,P_\epsilon}(P_\epsilon)\epsilon^{\min(1,2\alpha,\alpha_0)}) \\ &= L_j(\tilde{z})\tilde{\varphi}_{\epsilon,P_\epsilon}(P_\epsilon) + O\big(\tilde{\varphi}_{\epsilon,P_\epsilon}(P_\epsilon)\epsilon^{\min(1,2\alpha,\alpha_0)}\big). \qquad \square \end{aligned}$$

4. Choosing σ. In this section we choose σ and give an asymptotic expansion including error estimate for its behavior as $\epsilon \to 0$.

Let $P_{\Omega_{\epsilon,P}} v_\sigma$ be defined as in section 3. Set

$$\sigma = m - \frac{1}{|\Omega|} \int_\Omega P_{\Omega_{\epsilon,P}} v_\sigma \, dx. \tag{4.51}$$

We show that this equation has a unique solution σ if ϵ is small enough.

Note that

$$\int_\Omega (P_{\Omega_{\epsilon,P}} v_\sigma)^3 \, dx = \int_\Omega v_\sigma^3 \, dx + \int_\Omega [(P_{\Omega_{\epsilon,P}} v_\sigma)^3 - v_\sigma^3] \, dx.$$

Now choose R_σ such that, for $r_b = \epsilon R_\sigma$,

$$\frac{|B_{r_b}| - |\Omega \setminus B_{r_b}|}{|\Omega|} = m + O(\sigma) + O(\epsilon) \tag{4.52}$$

as $\sigma, \epsilon \to 0$. This implies

$$\frac{1}{|\Omega|} \int_\Omega v_\sigma^3 \, dx = m + c\sigma + O(\sigma^2)$$

for some constant $c > 0$. Furthermore, there exists $C > 0$ such that

$$\int_\Omega \left[(P_{\Omega_{\epsilon,P}} v_\sigma)^3 - v_\sigma^3 \right] dx \le C \int_\Omega |\Psi_{\epsilon,P}| = O(e^{-C/\epsilon}).$$

Therefore, by the implicit function theorem, if ϵ is small enough, there exists exactly one solution σ of (4.51). Furthermore, this σ satisfies

$$\sigma = \gamma_0 \epsilon + O(\epsilon^2) \tag{4.53}$$

as $\epsilon \to 0$, where $\gamma_0 = c_b / r_b$.

5. Technical framework. In this section, we set up the technical framework to solve equation (1.2). As we mentioned in section 1, this framework was originated by Floer and Weinstein [11] and later used by Oh [23], [24]. We modified their approach to the Cahn–Hilliard equation in [32], [33], and [34]. We shall follow [34].

Without loss of generality, we assume that $P_0 = 0 \in \Omega$ is a nondegenerate peak point, i.e.,

(1) $\Lambda_0 = \{d\mu_0(t)\}$,

(2) $\exists a \in R^N$ such that

$$\int_{\partial\Omega} e^{\langle t,a \rangle} t \, d\mu_0(t) = 0$$

and

$$\int_{\partial\Omega} \left\{ \frac{e^{-\frac{|t|}{\epsilon}} e^{\langle t,a \rangle}}{\int_{\partial\Omega} e^{-\frac{|t|}{\epsilon}} \, dt} \right\} t \, dt = O(\epsilon^{\alpha_0})$$

for some $\alpha_0 > 0$,

(3) the matrix $G(0) := \left(\int_{\partial\Omega} e^{\langle t,a \rangle} (t_i t_j) \, d\mu_0(t) \right)$ is nondegenerate.

Let $z = \epsilon(\frac{a}{2\sqrt{2}} d(0, \partial\Omega) + \tilde{z})$, where $|\tilde{z}| < \epsilon^\alpha$, with $0 < \alpha < 1$ to be chosen later.
We assume that $\sigma = \sigma(\epsilon)$, where $\sigma(\epsilon)$ is defined in section 4.
Define $H_\epsilon : H^2_N(\Omega_\epsilon) \to L^2(\Omega_\epsilon)$ by

$$H_\epsilon(u) := \triangle u + u - u^3 - m + \frac{1}{|\Omega_\epsilon|} \int_{\Omega_\epsilon} u^3 \, dy, \tag{5.54}$$

where

$$H^2_N(\Omega_\epsilon) := \left\{ u \in H^2(\Omega_\epsilon) : \frac{\partial u}{\partial \nu} = 0 \text{ on } \partial\Omega_\epsilon \right\}.$$

We are looking for a nontrivial zero of (5.1). We make the ansatz

$$u = P_{\Omega_{\epsilon,z}} v_\sigma + \Phi_\epsilon,$$

where Φ_ϵ is now the unknown. Recall that we set $w_{\epsilon,z} = P_{\Omega_{\epsilon,z}} v_\sigma$. We assume that $\epsilon > 0$ is small and Φ_ϵ is small in $C^2_{loc}(\Omega_\epsilon)$. We shall see that solutions of this particular form correspond to bubble solutions of (1.2), where the center of the bubble is located near zero. Inserting this into the equation gives

$$\triangle\Phi_\epsilon + \Phi_\epsilon + \triangle(P_{\Omega_{\epsilon,z}} v_\sigma) + P_{\Omega_{\epsilon,z}} v_\sigma - (P_{\Omega_{\epsilon,z}} v_\sigma + \Phi_\epsilon)^3$$

$$= m - \frac{1}{|\Omega_\epsilon|} \int_{\Omega_\epsilon} (P_{\Omega_{\epsilon,z}} v_\sigma + \Phi_\epsilon)^3 \, dy.$$

Recall that

$$\triangle(P_{\Omega_{\epsilon,z}} v_\sigma) + P_{\Omega_{\epsilon,z}} v_\sigma = \Delta v_\sigma - \triangle\Psi_{\epsilon,z} + v_\sigma - \Psi_{\epsilon,z}$$

$$= v_\sigma^3 + \sigma - 3\tau_\sigma^2 \Psi_{\epsilon,z}.$$

This implies

$$\triangle\Phi_\epsilon + \Phi_\epsilon + v_\sigma^3 + \sigma - 3\tau_\sigma^2 \Psi_{\epsilon,z} - (P_{\Omega_{\epsilon,z}} v_\sigma + \Phi_\epsilon)^3$$

$$= m - \frac{1}{|\Omega_\epsilon|} \int_{\Omega_\epsilon} (P_{\Omega_{\epsilon,z}} v_\sigma + \Phi_\epsilon)^3 \, dy.$$

By the choice of σ,

$$L_\epsilon \Phi_\epsilon + v_\sigma^3 - 3\tau_\sigma^2 \Psi_{\epsilon,z} - (v_\sigma - \Psi_{\epsilon,z})^3 + N_{\epsilon,z}(\Phi_\epsilon) = 0,$$

where

$$L_\epsilon \Phi_\epsilon := \triangle\Phi_\epsilon + \Phi_\epsilon - 3(P_{\Omega_{\epsilon,z}} v_\sigma)^2 \Phi_\epsilon + 3 \frac{1}{|\Omega_\epsilon|} \int_{\Omega_\epsilon} (P_{\Omega_{\epsilon,z}} v_\sigma)^2 \Phi_\epsilon \, dy$$

and

$$N_{\epsilon,z}(\Phi_\epsilon) = -3 P_{\Omega_{\epsilon,z}} v_\sigma \Phi_\epsilon^2 - \Phi_\epsilon^3 + \frac{1}{|\Omega_\epsilon|} \int_{\Omega_\epsilon} [3 P_{\Omega_{\epsilon,z}} v_\sigma \Phi_\epsilon^2 + \Phi_\epsilon^3] \, dy.$$

Recalling that $\Phi_\epsilon \to 0$ as $\epsilon \to 0$ in $C^2_{loc}(\Omega_\epsilon)$, we finally arrive at

$$L_\epsilon \Phi_\epsilon + 3(v_\sigma^2 - \tau_\sigma^2)\Psi_{\epsilon,z} + N_{\epsilon,z}(\Phi_\epsilon) + M_{\epsilon,z}(\Psi_{\epsilon,z}) = 0,$$

where

$$M_{\epsilon,z}(\Psi_{\epsilon,z}) = -3v_\sigma \Psi^2_{\epsilon,z} + \Psi^3_{\epsilon,z}.$$

It is easy to see the following.

LEMMA 5.1. *For ϵ sufficiently small,*

$$\|N_{\epsilon,z}(\Phi_\epsilon)\|_{L^2(\Omega_{\epsilon,z})} \leqslant c\|\Phi_\epsilon\|^2_{H^2(\Omega_{\epsilon,z})},$$
$$\|M_{\epsilon,z}(\Psi_{\epsilon,z})\|_{L^2(\Omega_{\epsilon,z})} \leqslant c\|\Psi_{\epsilon,z}\|^2_{L^2(\Omega_{\epsilon,z})} \leq c|\tilde{\varphi}_{\epsilon,z}(z)|.$$

Furthermore,

$$\|N_{\epsilon,z}(\Phi^{(1)}_\epsilon) - N_{\epsilon,z}(\Phi^{(2)}_\epsilon)\|_{L^2(\Omega_{\epsilon,z})} \leq c\|\Phi^{(1)}_\epsilon - \Phi^{(2)}_\epsilon\|^2_{H^2(\Omega_{\epsilon,z})}.$$

It remains then to estimate the term $3(v_\sigma^2 - \tau_\sigma^2)\Psi_{\epsilon,z}$. We have the following.

LEMMA 5.2. *For ϵ sufficiently small, we have*

$$\|(v_\sigma^2 - \tau_\sigma^2)\Psi_{\epsilon,z}\|^2_{L^2(\Omega_\epsilon,z)} \leq C|\tilde{\varphi}_{\epsilon,z}(z)|^{1.5}. \tag{5.55}$$

Proof. In fact,

$$(v_\sigma^2 - \tau_\sigma^2)\Psi_{\epsilon,z} = e^{\nu_\epsilon R_\sigma} u_\sigma (v_\sigma^2 - \tau_\sigma^2) u_\sigma^{-1} e^{-\nu_\epsilon R_\sigma}\Psi_{\epsilon,z},$$

where u_σ is the unique radial solution of $\Delta u - \nu_\epsilon^2 u = 0, u(0) = 1, u > 0$.

Now

$$|u_\sigma(v_\sigma^2 - \tau_\sigma)| \leq e^{(\nu_\epsilon+\delta)R_\sigma}, \tag{5.56}$$

where $\delta > 0$ is small. Furthermore, by Lemma 3.1, (note that $\epsilon y + z = x$),

$$e^{-\nu_\epsilon R_\sigma}\Psi_{\epsilon,z}$$

$$= (C_N + O(\epsilon)) \int_{\partial\Omega} \left\{ e^{-\nu_\epsilon \frac{|t-z|+|t-x|}{\epsilon}} |t-z|^{-\frac{N-1}{2}} |t-x|^{-\frac{N-1}{2}} \frac{\langle t-x, \nu\rangle}{|t-x|} \right\} dt$$

$$\leq e^{\nu_\epsilon R_\sigma} e^{-2\nu_\epsilon d(z,\partial\Omega)/\epsilon} e^{(\nu_\epsilon+\delta)|y|}.$$

Therefore,

$$|u_\sigma^{-1} e^{-\nu_\epsilon R_\sigma}\Psi_{\epsilon,z}| \leq Ce^{-2\nu_\epsilon\, d(z,\partial\Omega)/\epsilon} e^{(\nu_\epsilon+\delta)R_\sigma}. \tag{5.57}$$

Combining (5.56) and (5.57), we obtain

$$|(v_\sigma^2 - \tau_\sigma^2)\Psi_{\epsilon,z}| \leq Ce^{-2\nu_\epsilon(d(z,\partial\Omega)-\epsilon R_\sigma)+2(\delta+\nu_\epsilon)R_\sigma}$$

$$\leq C(\tilde{\varphi}_{\epsilon,z}(z))^{0.8}.$$

This implies

$$\|(v_\sigma^2 - \tau_\sigma^2)\Psi_{\epsilon,z}\|^2_{L^2(\Omega_{\epsilon,z})} \leq \tilde{\varphi}_{\epsilon,z}(z)^{1.5}.$$

The lemma is thus proved. □

6. Reduction to finite dimensions: Fredholm inverses. In this section, we show that $H'_\epsilon(w_{\epsilon,z})$, modulo its approximate kernel, is an invertible linear operator if ϵ is small enough. Moreover, we show that the operator norm of the inverse operator is bounded by $C\epsilon^{-2}$. (Note that in [11], [23], [24], and [34] the operator norm of the inverse operator is uniformly bounded.)

Set

$$K_{\epsilon,z} = \text{ span}\left\{ \frac{\partial w_{\epsilon,z}}{\partial z_i} | i = 1, \dots, N \right\} \subset H^2_N(\Omega_\epsilon) \tag{6.58}$$

and

$$C_{\epsilon,z} = \text{ span } \left\{ \frac{\partial w_{\epsilon,z}}{\partial z_i} | i = 1, \dots, N \right\} \subset L^2(\Omega_\epsilon). \tag{6.59}$$

$K_{\epsilon,z}$ is called the approximate kernel, while $C_{\epsilon,z}$ is called the approximate cokernel. Note that a function $\Phi \in$ cokernel of $H'_\epsilon(w_{\epsilon,z})$ if and only if for all $\psi \in H^2_N(\Omega_\epsilon)$ we have

$$\int_{\Omega_\epsilon} \Phi H'_\epsilon(w_{\epsilon,z})\psi \, dy = 0.$$

Integrating by parts, we have

$$\begin{aligned} &\int_{\partial\Omega_\epsilon} \psi \frac{\partial \Phi}{\partial \nu} \, do + \int_{\Omega_\epsilon} [(\Delta\Phi + (1 - 3w^2_{\epsilon,z})\Phi)\psi] \, dy \\ &\quad + 3\frac{1}{|\Omega_\epsilon|} \int_{\Omega_\epsilon} \Phi \, dy \int_{\Omega_\epsilon} w^2_{\epsilon,z}\psi \, dy = 0, \quad \text{for all } \psi \in H^2_N(\Omega_\epsilon). \end{aligned}$$

Hence, $\Phi \in$ cokernel of $H'_\epsilon(w_{\epsilon,z})$ if and only if

$$\begin{cases} \Delta\Phi + (1 - 3w^2_{\epsilon,z})\Phi + 3w^2_{\epsilon,z}\dfrac{1}{|\Omega_\epsilon|}\displaystyle\int_{\Omega_\epsilon} \Phi \, dy = 0 & \text{in } \Omega_\epsilon, \\ \dfrac{\partial \Phi}{\partial \nu} = 0 & \text{in } \partial\Omega_\epsilon. \end{cases}$$

Observe also that $\text{span}\{(\partial v_\sigma/\partial y_i) | i = 1, \dots, N\}$ is the kernel of L, where L is the linear operator defined as

$$L\Phi := \Delta\Phi + \Phi - 3v^2_\sigma\Phi, \qquad \Phi \in H^2(R^N).$$

Our main result in this section can be stated as follows.

PROPOSITION 6.1. *There exist positive constants ϵ_1, λ such that, for all $\epsilon \in (0, \epsilon_1)$,*

$$\|L_{\epsilon,z}\Phi\|_{L^2(\Omega_\epsilon)} \geqslant \lambda\sigma^2\|\Phi\|_{H^2(\Omega_\epsilon)} \tag{6.60}$$

for all $|z| \leq C\epsilon$ and for all $\Phi \in K^\perp_{\epsilon,z}$, where

$$L_{\epsilon,z} = \pi_{\epsilon,z} \circ H'_\epsilon(w_{\epsilon,z}), \tag{6.61}$$

and $\pi_{\epsilon,z}$ is the L^2-orthogonal projection from $L^2(\Omega_\epsilon)$ to $C^\perp_{\epsilon,z}$.

The next proposition gives the surjectivity of $L_{\epsilon,z}$.

PROPOSITION 6.2. *There exists a positive constant ϵ_2 such that, for all $\epsilon \in (0, \epsilon_2)$ and $|z| \leq C\epsilon$, the map*

$$L_{\epsilon,z} = \pi_{\epsilon,z} \circ H'_\epsilon(w_{\epsilon,z}) : K^\perp_{\epsilon,z} \longrightarrow C^\perp_{\epsilon,z}$$

is surjective.

Combining Propositions 6.1 and 6.2 gives us the invertibility of $L_{\epsilon,z}$.

PROPOSITION 6.3.

$$L_{\epsilon,z} : K^{\perp}_{\epsilon,z} \longrightarrow C^{\perp}_{\epsilon,z}$$

is invertible, namely,

$$L^{-1}_{\epsilon,z} : C^{\perp}_{\epsilon,z} \longrightarrow K^{\perp}_{\epsilon,z}$$

exists. Furthermore, $L^{-1}_{\epsilon,z}$ *is bounded in the operator norm by* $C\epsilon^{-2}$.

We now begin to prove Proposition 6.1.

Proof of Proposition 6.1. We use a different strategy than in [32].

Suppose (6.60) is false. Then there exist sequences $\{\epsilon_k\}, \{z_k\}$, and $\{\Phi_k\}$, with $|z_k| \leqslant C\epsilon_k$ and $\epsilon_k \to 0$ as $k \to \infty$ such that

$$\Phi_k \in K^{\perp}_{\epsilon_k, z_k}$$

and

$$\|L_{\epsilon_k,z_k}(\Phi_k)\|_{L^2(\Omega_{\epsilon_k})} = o(1)\epsilon_k^2, \qquad \|\Phi_k\|_{H^2(\Omega_{\epsilon_k})} = 1. \tag{6.62}$$

We denote, for $i = 1, \ldots, N$,

$$e_{k,i} = \frac{(\partial w_{\epsilon_k,z_k}/\partial z_i)}{\|(\partial w_{\epsilon_k,\epsilon_k}/\partial z_i)\|_{L^2(\Omega_{\epsilon_k})}}, \quad e^*_{k,i} = \frac{(\partial v_{\sigma_k}/\partial y_i)}{\|(\partial v_{\sigma_k}/\partial y_i)\|_{L^2(\Omega_{\epsilon_k})}}. \tag{6.63}$$

Note that the difference between $e_{k,i}$ and $e^*_{k,i}$ is exponentially small. Hence, after applying the Gram–Schmidt process to $\{e_{k,i} | i = 1, \ldots, N\}$, we obtain a family of orthonormal functions $\{\tilde{e}_{k,i} | i = 1, \ldots, N\}$ with

$$\tilde{e}_{k,i} = e_{k,i} + \delta_{k,i}, \quad i = 1, \ldots, N,$$

where $\delta_{k,i} = O(e^{-\delta/\epsilon})$ in $L^2(\Omega_{\epsilon_k})$ as $k \to \infty$ for each $i = 1, \ldots, N$.

Hence,

$$L_{\epsilon_k,z_k}\Phi_k = H'_{\epsilon_k}(w_{\epsilon_k,z_k})\Phi_k - \sum_{i=1}^{N-1}\left(\int_{\Omega_{\epsilon_k}} [H'_{\epsilon_k}(w_{\epsilon_k,z_k})\Phi_k]e_{k,i}\,dy\right)e_{k,i} + E_k, \tag{6.64}$$

where E_k is defined by (6.64), and it is easy to see that $\|E_k\|_{L^2(\Omega_{\epsilon_k})} = O(e^{-\delta/\epsilon_k})$ as $k \to \infty$.

Note that

$$\begin{aligned} \|L_{\epsilon_k,z_k}\Phi_k\|^2_{L^2(\Omega_{\epsilon_k})} = \; & \|H'_{\epsilon_k}(w_{\epsilon_k,z_k})\Phi_k\|^2_{L^2(\Omega_{\epsilon_k})} \\ & - \sum_{i=1}^{n}\left(\int_{\Omega_{\epsilon_k}} [H'_{\epsilon_k}(w_{\epsilon_k,z_k})\Phi_k]e_{k,i}\,dy\right)^2 + O(e^{-\delta/\epsilon_k}) \end{aligned} \tag{6.65}$$

as $k \to \infty$.

Let us denote

$$\Delta\Phi_k + (1 - 3w^2_{\epsilon_k,z_k})\Phi_k + 3\frac{1}{|\Omega_{\epsilon_k}|}\int_{\Omega_{\epsilon_k}} w^2_{\epsilon_k,z_k}\Phi_k\,dy = \sigma_k^2 f_k.$$

By Corollary 2.1, we have

$$\left\| f_k - 3\frac{1}{|\Omega_{\epsilon_k}|\sigma_k^2}\int_{\Omega_{\epsilon_k}} w_{\epsilon_k,z_k}^2\Phi_k\,dy\right\|_{L^2(\Omega_{\epsilon_k})} \geq C\|\Phi_k\|_{H^2(\Omega_{\epsilon_k})}. \tag{6.66}$$

Note that since Φ_k satisfies the Neumann boundary condition, we have

$$\left|\int_{\Omega_{\epsilon_k}}\Phi_k\right| = \left|\sigma_k^2\int_{\Omega_{\epsilon_k}} f_k\,dy\right| \leq C\epsilon_k^{2-\frac{N}{2}}\|f_k\|_{L^2(\Omega_{\epsilon_k})}.$$

Hence,

$$3\frac{1}{|\Omega_{\epsilon_k}|\sigma_k^2}\int_{\Omega_{\epsilon_k}} w_{\epsilon_k,z_k}^2\Phi_k\,dy \leq C\epsilon_k^{\frac{N}{2}}\|f_k\|_{L^2(\Omega_{\epsilon_k})}.$$

Thus,

$$\left\|3\frac{1}{|\Omega_{\epsilon_k}|\sigma_k^2}\int_{\Omega_{\epsilon_k}} w_{\epsilon_k,z_k}^2\Phi_k\,dy\right\|_{L^2(\Omega_{\epsilon_k})} \leq C\|f_k\|_{L^2(\Omega_{\epsilon_k})}.$$

The last inequality and (6.66) imply that

$$\|f_k\|_{L^2(\Omega_{\epsilon_k})} \geq C\|\Phi_k\|_{H^2(\Omega_{\epsilon_k})} \geq C.$$

Therefore,

$$\|H'_{\epsilon_k}(w_{\epsilon_k,z_k})\Phi_k\|^2_{L^2(\Omega_{\epsilon_k})} \geq C\sigma_k^2. \tag{6.67}$$

Now we estimate

$$\begin{aligned}
&\int_{\Omega_{\epsilon_k}}[H'_{\epsilon_k}(w_{\epsilon_k,z_k})\Phi_k]e_{k,i}\,dy\\
&\quad= \int_{\Omega_{\epsilon_k}}[H'_{\epsilon_k}(w_{\epsilon_k,z_k})\Phi_k]\frac{\partial w_{\epsilon_k,z_k}}{\partial z_i}\,dy + O(e^{-\delta/\epsilon_k})\\
&\quad= \int_{\Omega_{\epsilon_k}}\left[\Delta\Phi_k + (1-3v_{\sigma_k}^2)\Phi_k + 3\frac{1}{|\Omega_{\epsilon_k}|}\int_{\Omega_{\epsilon_k}} v_{\sigma_k}^2\Phi_k\,dy\right]\frac{\partial v_{\sigma_k}}{\partial y_i}\,dy + O(e^{-\delta/\epsilon_k})\\
&\quad= \int_{\partial\Omega_{\epsilon_k}}\left[\frac{\partial v_{\sigma_k}}{\partial y_i}\frac{\partial\Phi_k}{\partial\nu} - \Phi_k\frac{\partial}{\partial\nu}\left(\frac{\partial v_{\sigma_k}}{\partial y_i}\right)\right]do\\
&\qquad+ 3\frac{1}{|\Omega_{\epsilon_k}|}\int_{\Omega_{\epsilon_k}} v_{\sigma_k}^2\Phi_k\,dy\int_{\Omega_{\epsilon_k}}\frac{\partial v_{\sigma_k}}{\partial y_i}\,dy\\
&\qquad+ O(e^{-\delta/\epsilon_k}) = O(e^{-\delta/\epsilon_k}).
\end{aligned}$$

Therefore, (6.65) implies that

$$o(1)\epsilon_k^2 \geq C\sigma_k^2 - o(e^{-\delta/\epsilon_k}). \tag{6.68}$$

This is a contradiction! Proposition 6.1 is thus proved. □

The following lemma, which can be found in [15], will be needed in the proof of Proposition 6.2.

LEMMA 6.1 (see [15, Lemma 1.3]). *If* $\vec{d}\ (E,F) := \sup\{d(x,F)|x \in E, \|x\|_H = 1\} < 1$, *then* $\pi_{F|E} : E \to F$ *is injective and* $\pi_{E|F} : F \to E$ *has a bounded right inverse, where* π_E (π_F, *respectively*) *is the orthogonal projection from* H *to* E (F, *respectively*). *In particular,* $\pi_{E|F} : F \to E$ *is surjective.*

We are now ready to prove Proposition 6.2.

Proof of Proposition 6.2. Let $CK_{\epsilon,z}$ = cokernel of $H'_\epsilon(w_{\epsilon,z})$. We first claim that

$$\vec{d}(CK_{\epsilon,z}, C_{\epsilon,z}) < 1 \tag{6.69}$$

for all $\epsilon > 0$ sufficiently small.

In fact, suppose (6.69) is not true. Then there exist $\epsilon_k \to 0$ and $\Phi_k \in CK_{\epsilon_k,z_k}$ such that

$$\Delta\Phi_k + (1 - 3w^2_{\epsilon_k,z_k})\Phi_k + 3w^2_{\epsilon_k,z_k}\frac{1}{|\Omega_{\epsilon_k}|}\int_{\Omega_{\epsilon_k}} \Phi_k\, dy = 0 \quad \text{in } \Omega_{\epsilon_k}, \tag{6.70}$$

$$\frac{\partial\Phi_k}{\partial\nu} = 0 \quad \text{on } \partial\Omega_{\epsilon_k}, \tag{6.71}$$

$$\|\Phi_k\|_{L^2(\Omega_{\epsilon_k})} = 1, \tag{6.72}$$

$$\int_{\Omega_{\epsilon_k}} \Phi_k \frac{\partial(w_{\epsilon_k,z_k})}{\partial z_i}\, dy = 0, \qquad i = 1,\dots,N. \tag{6.73}$$

By (6.70) and (6.71), we have

$$\int_{\Omega_{\epsilon_k}} (1 - 3w^2_{\epsilon_k,z_k})\Phi_k\, dy + 3\int_{\Omega_{\epsilon_k}} w^2_{\epsilon_k,z_k}\, dy \frac{1}{|\Omega_{\epsilon_k}|}\int_{\Omega_{\epsilon_k}} \Phi_k\, dy = 0.$$

Note that

$$\int_{\Omega_{\epsilon_k}} w^2_{\epsilon_k,z_k}\, dy = |\Omega_{\epsilon_k}|(1 + O(\epsilon_k)).$$

Hence, we have

$$\int_{\Omega_{\epsilon_k}} \Phi_k\, dy = \int_{\Omega_{\epsilon_k}} (1/3 - w^2_{\epsilon_k,z_k})\Phi_k\, dy(1 + O(\epsilon_k)) \le O(\epsilon_k^{\frac{N+1}{2}})\|\Phi_k\|_{L^2(\Omega_{\epsilon_k})}.$$

Similar to the proof of Proposition 6.1, we conclude that

$$\|\Phi_k\|_{H^2(\Omega_{\epsilon_k})} = o(1). \tag{6.74}$$

This is a contradiction! Hence, (6.69) is true.

Now by the fact that $\vec{d}(E,F) = \vec{d}(F^\perp, E^\perp)$, we have

$$\vec{d}(\overline{C}^\perp_{\epsilon,z}, \overline{CK}^\perp_{\epsilon,z}) < 1,$$

where $\overline{C}^\perp_{\epsilon,z}$ ($\overline{CK}^\perp_{\epsilon,z}$, respectively) is the orthogonal complement of $C_{\epsilon,z}$ ($CK_{\epsilon,z}$, respectively) in $L^2(\Omega_\epsilon)$. Thus, the map

$$\pi_{\overline{C}^\perp_{\epsilon,z}}\big|_{\overline{CK}^\perp_{\epsilon,z}} : \overline{CK}^\perp_{\epsilon,z} \to \overline{C}^\perp_{\epsilon,z} \tag{6.75}$$

is surjective by Lemma 6.1.

Since $\overline{CK}^{\perp}_{\epsilon,z}$ is the range of L_ϵ, it suffices to show that the map in (6.75), when restricted to $CK^{\perp}_{\epsilon,z}$, which is just $\pi_{\epsilon,z}$, is onto $C^{\perp}_{\epsilon,z}$. However, this follows easily from the expression

$$\pi_{\overline{C}^{\perp}_{\epsilon,z}}(\Phi) = \Phi - \pi_{C_{\epsilon,z}}\Phi. \qquad \square$$

Finally, in this section we solve the following equation for $\Phi_\epsilon \in K^{\perp}_{\epsilon,z}$:

$$\pi_{\epsilon,z} \circ H_\epsilon(w_{\epsilon,z})(w_{\epsilon,z} + \Phi_\epsilon) = 0. \tag{6.76}$$

Since $L_{\epsilon,z}\big|_{K^{\perp}_{\epsilon,z}}$ is invertible (and we shall denote its inverse just by $L^{-1}_{\epsilon,z}$) by Proposition 6.3, this is equivalent to solving

$$\Phi_\epsilon = L^{-1}_{\epsilon,z} \circ \pi_{\epsilon,z}(L_\epsilon(\Phi_\epsilon)) = -L^{-1}_{\epsilon,z} \circ \pi_{\epsilon,z}(3(v_\sigma^2 - \tau_\sigma^2)\Psi_{\epsilon,z} + N_{\epsilon,z}(\Phi_\epsilon) + M_{\epsilon,z}(\Psi_{\epsilon,z}))$$

$$:\equiv Q_{\epsilon,z}(\Phi_\epsilon),$$

where $Q_{\epsilon,z}$ is defined in the last equality for every $\Phi_\epsilon \in H^2_N(\Omega_\epsilon)$.

By Proposition 6.3, we have

$$\|L^{-1}_{\epsilon,z}\| \le C\epsilon^{-2}.$$

Hence,

$$\begin{aligned}\|Q_{\epsilon,z}(\Phi_\epsilon)\|_{H^2(\Omega_\epsilon)} &\leqslant C\epsilon^{-2}(\|(v_\sigma^2 - \tau_\sigma^2)\Psi_{\epsilon,z}\|_{L^2(\Omega_\epsilon)} + \|N_{z,\epsilon}(\Phi_\epsilon)\|_{L^2(\Omega_\epsilon)} \\ &\quad + \|M_{z,\epsilon}(\Psi_{\epsilon,z})\|_{L^2(\Omega_\epsilon)}) \\ &\leqslant c\epsilon^{-2}(\tilde{\varphi}_{\epsilon,z}^{\frac{1}{2}+\tilde{\eta}} + \ \delta\|\Phi_\epsilon\|_{H^2(\Omega_\epsilon)})\end{aligned}$$

for some $\tilde{\eta} > 0$ (in fact, we can take $\tilde{\eta} = \frac{1}{4}$ by Lemma 5.1).

Take $\delta = |\tilde{\varphi}_{\epsilon,z}(z)|^{\frac{1+\eta}{2}}$ for $0 < \eta < 2\tilde{\eta}$. Then we have (since $\delta\epsilon^{-2} = o(1)$)

$$\|Q_{\epsilon,z}(\Phi_\epsilon)\|_{H^2(\Omega_\epsilon)} \leqslant C(\tilde{\varphi}_{\epsilon,z}^{\frac{1+\eta}{2}}(z)). \tag{6.77}$$

Equation (6.77) says that $Q_{\epsilon,z}(\Phi)$ is a continuous map:

$$B_\delta(0) \cap H^2_N(\Omega_\epsilon) \longrightarrow B_\delta(0) \cap H^2_N(\Omega_\epsilon).$$

Furthermore, $Q_{\epsilon,z}(\Phi)$ is a contracting map if ϵ is small by Lemma 5.1. Hence, by the contraction mapping principle we have the following proposition.

PROPOSITION 6.4. *There exists $\epsilon_0 > 0$ such that, for $\epsilon < \epsilon_0, |z| \le C\epsilon$ there is a unique $\Phi_{\epsilon,z} \in K^{\perp}_{\epsilon,z}$ such that*

$$H_\epsilon(w_{\epsilon,z} + \Phi_{\epsilon,z}) \in C_{\epsilon,z}. \tag{6.78}$$

Furthermore,

$$\|\Phi_{\epsilon,z}\|_{H^2(\Omega_\epsilon)} \le C\tilde{\varphi}_{\epsilon,z}^{\frac{1+\mu}{2}}(z). \tag{6.79}$$

7. The reduced problem. In this section, we shall prove our main result, Theorem 1.1.

By Proposition 6.4, for $\epsilon \leqslant \epsilon_0$ and $|z| \leq C\epsilon$, there exists a unique $\Phi_{\epsilon,z}$ such that

$$H_\epsilon(w_{\epsilon,z} + \Phi_{\epsilon,z}) \in C_{\epsilon,z}. \tag{7.80}$$

Therefore, it is enough to show that for some $|z| \leq C\epsilon$, we have

$$H_\epsilon(w_{\epsilon,z} + \Phi_{\epsilon,z}) \perp C_{\epsilon,z}.$$

To this end, we now define a vector field

$$V_{\epsilon,j}(\tilde{z}) := \frac{1}{\epsilon^{\alpha-1}\tilde{\varphi}_{\epsilon,z}(z)}\left[\int_{\Omega_\epsilon} H_\epsilon(w_{\epsilon,z} + \Phi_{\epsilon,z})\frac{\partial w_{\epsilon,z}}{\partial z_j}\,dy\right], \tag{7.81}$$

where $z = \epsilon\frac{a}{2\sqrt{2}}\,d(0,\partial\Omega) + \epsilon^{\alpha+1}\tilde{z}, |\tilde{z}| \leqslant 1$, and $\vec{a}$ is given by conditions (2) and (3) in section 1.

The main estimate of this section is the following.

LEMMA 7.1. *For every $0 < \alpha < \alpha_0$, the vector field V_ϵ converges uniformly to V_0 in $B_1(0)$ as $\epsilon \to 0$, where*

$$V_0 = (V_{0,1}, \ldots, V_{0,N}),$$

$$V_{0,j} = \frac{\gamma}{\int_{\partial\Omega} e^{\langle t - P_0, a\rangle}\,d\mu_{P_0}(t)}\sum_{i=1}^{N}\left(\int_{\partial\Omega} e^{\langle x-P_0,a\rangle}x_i x_j\,d\mu_{P_0}(x)\tilde{z}_i\right), \qquad j = 1,\ldots,N,$$

and γ is given by Lemma 3.2.

Once Lemma 7.1 is proved, then Theorem 1.1 follows easily. In fact, since 0 is a nondegenerate peak point, V_0 has a nondegenerate zero at 0 (with degree different from 0). Then Lemma 7.1 and a simple degree theoretic argument imply that V_ϵ has a zero $\tilde{z}(\epsilon) \in B_{\frac{1}{2}}(0)$ for every ϵ sufficiently small. This solves the equation $H_\epsilon(w_{\epsilon,z}+\Phi_{\epsilon,z}) = 0$ for every ϵ sufficiently small. Setting $z(\epsilon) = \epsilon\frac{a}{2\sqrt{2}}d(0,\partial\Omega) + \epsilon^{\alpha+1}\tilde{z}(\epsilon)$ and

$$v_\epsilon = w_{\epsilon,z(\epsilon)} + \Phi_{\epsilon,z(\epsilon)}$$

for $x \in \Omega$ and ϵ sufficiently small, it then follows that

$$v_\epsilon \not\equiv 0 \quad \text{since } \Phi_{\epsilon,z(\epsilon)} \to 0 \quad \text{in } H^2(\Omega_\epsilon) \quad \text{as } \epsilon \to 0,$$

while $w_{\epsilon,z(\epsilon)}$ remains bounded away from 0 in $H^2(\Omega_\epsilon)$ as $\epsilon \to 0$.

In other words, v_ϵ is a nontrivial solution of (1.2). By the structure of v_ϵ, v_ϵ has all the properties of Theorem 1.1.

It remains to prove Lemma 7.1. To this end, we have

$$\begin{aligned}
&\int_{\Omega_{\epsilon,z}} H_\epsilon(w_{\epsilon,z} + \Phi_{\epsilon,z})\frac{\partial w_{\epsilon,z}}{\partial z_j}\\
&\quad= \int_{\Omega_{\epsilon,z}} [H_\epsilon'(w_{\epsilon,z})\Phi_{\epsilon,z}]\frac{\partial w_{\epsilon,z}}{\partial z_j}\\
&\qquad+ \int_{\Omega_{\epsilon,z}} [N_{\epsilon,z}(\Phi_{\epsilon,z})]\frac{\partial w_{\epsilon,z}}{\partial z_j}\\
&\qquad+ \int_{\Omega_{\epsilon,z}} M_{\epsilon,z}(\Psi_{\epsilon,z})\frac{\partial w_{z,\epsilon}}{\partial z_j}\\
&\qquad+ \int_{\Omega_{\epsilon,z}} 3[v_\sigma^2 - \tau_\sigma^2]\Psi_{\epsilon,z}\frac{\partial w_{\epsilon,z}}{\partial z_j}\\
&\quad= I_1 + I_2 + I_3 + I_4,
\end{aligned}$$

where $I_i, i = 1,2,3,4$ are defined by the last equality.

Note that

$$\begin{aligned}
I_1 &= 3\int_{\Omega_{\epsilon,z}} \big[(P_{\Omega_{\epsilon,z}} v_\sigma)^2 - v_\sigma^2\big]\Phi_{\epsilon,z}\frac{\partial w_{\epsilon,z}}{\partial z_j}\,dy \\
&\quad + 3\int_{\Omega_{\epsilon,z}} \frac{\partial w_{\epsilon,z}}{\partial z_j}\,dy \int_{\Omega_{\epsilon,z}} (P_{\Omega_{\epsilon,z}} v_\sigma)^2\Phi_{\epsilon,z}\,dy \\
&\le C\left\|(P_{\Omega_{\epsilon,z}} v_\sigma - v_\sigma)\frac{\partial w_{\epsilon,z}}{\partial z_j}\right\|_{L^2(\Omega_{\epsilon,z})} \|\Phi_{\epsilon,z}\|_{L^2(\Omega_{\epsilon,z})} \\
&\quad + 3\int_{\Omega_{\epsilon,z}} \frac{\partial w_{\epsilon,z}}{\partial z_j}\,dy \epsilon^{-N/2}\|\Phi_{\epsilon,z}\|_{L^2(\Omega_{\epsilon,z})} \\
&\le C\tilde{\varphi}_{\epsilon,z}(z)^{\frac{1+\mu}{2}}\tilde{\varphi}_{\epsilon,z}(z)^{\frac{1+\mu}{2}} \\
&= O(\tilde{\varphi}_{\epsilon,z}^{1+\mu}(z)),
\end{aligned}$$

where $\mu > 0$ is some small number. By Lemma 5.1 and Proposition 6.4, we have

$$|I_2| \le C|\tilde{\varphi}_{\epsilon,z}(z)|^{1+\mu}$$

and

$$|I_3| \le C|\tilde{\varphi}_{\epsilon,z}(z)|^{1+\mu},$$

since $N_{\epsilon,z}(\cdot)$ and $M_{\epsilon,z}(\cdot)$ depend on their arguments only in the second or higher powers. So we just need to compute I_4. In fact,

$$\begin{aligned}
I_4 &= -\int_{\Omega_{\epsilon,z}} 3\big[\tau_\sigma^2 - v_\sigma^2\big]\Psi_{\epsilon,z}\frac{\partial P_{\Omega_{\epsilon,z}} v_\sigma}{\partial z_j} \\
&= -\epsilon\int_{\Omega_{\epsilon,z}} 3[\tau_\sigma^2 - v_\sigma^2]\Psi_{\epsilon,z}\frac{\partial v_\sigma}{\partial y_j} \\
&\quad + O\big(e^{-\sqrt{\nu_\epsilon}\frac{(2+\mu)d(z,\partial\Omega)}{\epsilon}}\big).
\end{aligned}$$

By Lemma 3.2, we conclude the proof of Lemma 7.1.

Acknowledgment. The first author wishes to thank Professor Wei-Ming Ni for his constant encouragement.

Note Added in Proof. After the paper was accepted for publication we were informed by Professor Alikakos that in [35] an implicit proof of the existence of stationary bubbles in a general domain is given. However, the exact location of stationary bubbles is left open.

SINGULAR PERTURBATION APPROACH TO A 3-COMPONENT REACTION-DIFFUSION SYSTEM ARISING IN POPULATION DYNAMICS*

YUKIO KAN-ON† AND MASAYASU MIMURA‡

Abstract. In order to understand theoretically predation-mediated coexistence of competing species which is often observed in ecological systems, we consider a 3-component reaction-diffusion system describing the interaction of one predator and two competing prey species which move by diffusion. It is shown that there exist stable spatially inhomogeneous positive equilibrium solutions of the one-dimensional system under the Neumann boundary condition. This implies ecologically that in the presence of the predator, two competing species coexist with spatially segregating structures. The main tools we use are the singular perturbation technique and the associated singular limit spectral analysis.

Key words. prey-predator model, singular perturbation, stability

1. Introduction.

It is often observed that predation may have a tendency to increase species diversity in competitive communities. This is called *predation-mediated coexistence*. There have been a number of theoretical studies on the possibility of temporal coexistence of competing species under predation pressure by using ODE models with Lotka–Volterra prey-predator interaction (for example, see Takeuchi and Adachi [18]). In this paper, we consider the situation where all species can move by diffusion and study the spatial structure of competing species that may coexist in the presence of predators.

In order to study this situation, we propose here the following 3-component reaction-diffusion system for two prey and one predator species:

$$\text{(1.1a)}\qquad \begin{cases} u_{1t} = d_1\,\Delta u_1 + u_1\,(a_1 - b_1\,u_1 - c_1\,u_2 - k_1\,v), \\ u_{2t} = d_2\,\Delta u_2 + u_2\,(a_2 - c_2\,u_1 - b_2\,u_2 - k_2\,v), \\ v_t = d_v\,\Delta v + v\,(-r + \alpha_1\,k_1\,u_1 + \alpha_2\,k_2\,u_2), \quad x \in \Omega, \quad t > 0, \end{cases}$$

where u_1 and u_2 are the population densities of two competing prey species, and v is that of their predator. d_1, d_2, and d_v are the diffusion rates, r is the death rate for the predator, a_i is the intrinsic growth rate, b_i and c_i are the intraspecific and interspecific competition rates, respectively, k_i is the predation rate, and α_i is the transformation rate of predation ($i = 1, 2$). All of the coefficients are positive constants. Ω is a bounded domain with smooth boundary $\partial\Omega$. We assume that u_1, u_2, and v satisfy the Neumann boundary conditions on the boundary $\partial\Omega$, given by

$$\text{(1.1b)}\qquad \frac{\partial}{\partial\nu}u_1 = 0, \quad \frac{\partial}{\partial\nu}u_2 = 0, \quad \frac{\partial}{\partial\nu}v = 0, \quad x \in \partial\Omega, \quad t > 0,$$

where ν is the outward normal unit vector on $\partial\Omega$.

Let us begin by reviewing the qualitative behaviors of solutions of two 2-species systems deriving from (1.1). The first system is a two-competing-species model for (u_1, u_2) in the absence of the predator ($v = 0$):

$$\begin{cases} u_{1t} = d_1\,\Delta u_1 + u_1\,(a_1 - b_1\,u_1 - c_1\,u_2), \\ u_{2t} = d_2\,\Delta u_2 + u_2\,(a_2 - c_2\,u_1 - b_2\,u_2), \quad x \in \Omega, \quad t > 0, \\ \frac{\partial}{\partial\nu} u_1 = 0, \quad \frac{\partial}{\partial\nu} u_2 = 0, \quad x \in \partial\Omega, \quad t > 0. \end{cases} \tag{1.2}$$

Suppose

$$\frac{b_1}{c_2} < \frac{a_1}{a_2} < \frac{c_1}{b_2}, \tag{1.3}$$

which indicates that the interspecific competition is stronger than the intraspecific one for the competing species. For an arbitrary convex domain Ω, Kishimoto and Weinberger [11] proved that any spatially inhomogeneous positive (SIP) equilibrium solution of (1.2) is unstable even if it exists, that is, any stable positive equilibrium solution of (1.2) has to be spatially homogeneous. The condition (1.3) means that any positive solution (u_1, u_2) of (1.2) generically tends to either $(0, a_2/b_2)$ or $(a_1/b_1, 0)$ as $t \to +\infty$, which ecologically implies that competitive exclusion occurs between two species. On the other hand, Matano and Mimura [13] showed that when the domain Ω is of suitable dumbbell shape, there are stable SIP equilibrium solutions which exhibit regionally segregating coexistence of two competing species. These results indicate that the stability as well as the existence of SIP equilibrium solutions of the competition-diffusion system (1.2) depends on the shapes of the domain Ω.

The second system is a one prey–one predator model in the absence of one of the competing species (either $u_1 = 0$ or $u_2 = 0$), under which (1.1) becomes

$$\begin{cases} u_t = d\,\Delta u + u\,(a - b\,u - k\,v), \\ v_t = d_v\,\Delta v + v\,(-r + \alpha\,k\,u), \quad x \in \Omega, \quad t > 0, \\ \frac{\partial}{\partial\nu} u = 0, \quad \frac{\partial}{\partial\nu} v = 0, \quad x \in \partial\Omega, \quad t > 0, \end{cases} \tag{1.4}$$

where d, a, b, k, and α are positive constants which have the same meanings as d_i, a_i, b_i, k_i, and α_i, respectively, in (1.1). For any domain Ω, it is shown in Rothe [17] that any positive solution of (1.4) tends to a homogeneous equilibrium solution

$$\left(\frac{r}{\alpha\,k},\ \max\left\{ 0, \frac{a\,\alpha\,k - b\,r}{\alpha\,k^2} \right\} \right)$$

as $t \to +\infty$.

Integrating the above results, we address the following questions: (i) Does the system (1.1) possess stable SIP equilibrium solutions when Ω is convex? (ii) If such solutions exist, what is the spatial profile of the two competing species (u_1, u_2)? In a previous paper [15], we numerically answered that solutions stably exist such that u_1 and u_2 exhibit spatially segregating structures for values of parameters in a suitable region. Figure 1 demonstrates that in the absence of the predator ($t < t_0$), the u_1-species occupies almost the whole interval and the u_2-species is extinct due to competition, but when the predator is present ($t \geq t_0$), the spatial segregating coexistence occurs for two competing species. This clearly shows the occurrence of predation-mediated coexistence of two competing species which move by diffusion.

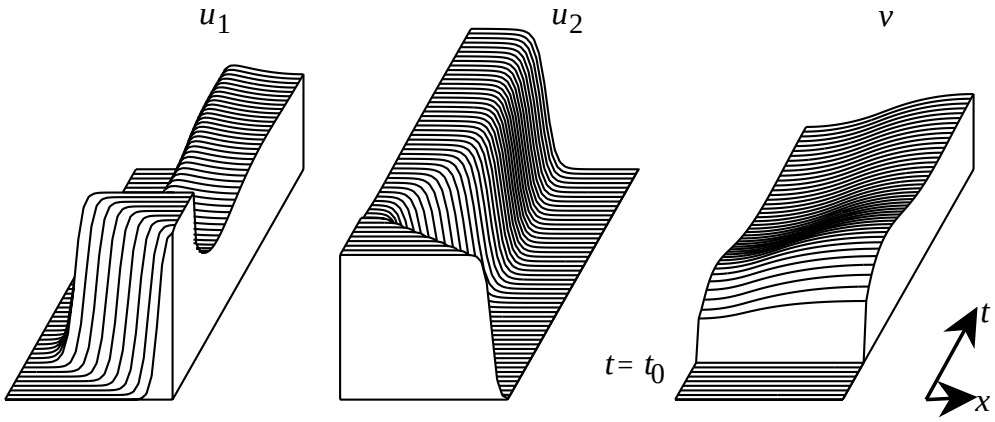

FIG. 1. *Spatially segregating coexistence of u_1 and u_2 in the presence of v. The predator is absent for $0 < t < t_0$ and is present for $t > t_0$.*

In this paper, we restrict our discussion to the one-dimensional problem of (1.1) in the interval $(0, 1)$ and show the existence of stable SIP equilibrium solutions when the diffusion rates of u_1 and u_2 are sufficiently smaller than that of v. To express (1.1) in nondimensional variables, we set

$$\bar{t} = a_1\, t, \quad \bar{u}_1 = b_1\, u_1/a_1, \quad \bar{u}_2 = c_2\, u_2/a_1, \quad \bar{v} = k_1\, v/a_1, \quad \bar{r} = r\, b_1/(a_1\, \alpha_1\, k_1),$$

$$a = a_2/a_1, \quad b = b_2/b_1, \quad c = c_1/c_2, \quad d = d_2/d_1, \quad k = k_2/k_1,$$

$$\varepsilon^2 = d_1/a_1, \quad \sigma = a_1/d_v, \quad \alpha = \alpha_1\, k_1/b_1, \quad \beta = \alpha_2\, b_1/(\alpha_1\, c_2).$$

Dropping the overbar of $\bar{t}$, $\bar{u}_1$, $\bar{u}_2$, $\bar{v}$, and $\bar{r}$, we can rewrite (1.1) as

$$\begin{cases} \boldsymbol{u}_t = \varepsilon^2\, D\, \boldsymbol{u}_{xx} + \boldsymbol{f}(\boldsymbol{u}, v), \\ \sigma\, v_t = v_{xx} + \sigma\, g(\boldsymbol{u}, v), \quad x \in (0,1), \quad t > 0, \\ \boldsymbol{u}_x = 0, \quad v_x = 0, \quad x = 0, 1, \quad t > 0, \end{cases} \tag{1.5}$$

where $\boldsymbol{u} = (u_1, u_2)$, $D = \mathrm{diag}(1, d)$, $\boldsymbol{f}(\boldsymbol{u}, v) = (f_1, f_2)(\boldsymbol{u}, v)$ with

$$\begin{aligned} f_1(\boldsymbol{u}, v) &= u_1\,(1 - u_1 - c\, u_2 - v), \\ f_2(\boldsymbol{u}, v) &= u_2\,(a - b\, u_1 - u_2 - k\, v), \\ g(\boldsymbol{u}, v) &= \alpha\, v\,(-r + u_1 + \beta\, k\, u_2), \end{aligned}$$

and all of the coefficients in the system are positive constants.

For the kinetics $(\boldsymbol{f}, g)$ in (1.5), we first assume

$$k < a < 1/c < b, \tag{H.1}$$

which is ecologically interpreted as follows: Suppose that the predator v is always constant. Then (1.5) is reduced to a two-competing-species model with a parameter v:

$$\begin{cases} \boldsymbol{u}_t = \varepsilon^2\, D\, \boldsymbol{u}_{xx} + \boldsymbol{f}(\boldsymbol{u}, v), \quad x \in (0,1), \quad t > 0, \\ \boldsymbol{u}_x = 0, \quad x = 0, 1, \quad t > 0. \end{cases} \tag{1.6}$$

Let $v_\pm$ and $\boldsymbol{h}_\pm(v)$ be

$$v_- = \frac{1-a\,c}{1-c\,k}, \quad v_+ = \frac{b-a}{b-k}, \quad \boldsymbol{h}_-(v) = (0, a-k\,v), \quad \boldsymbol{h}_+(v) = (1-v, 0)$$

($0 < v_- < v_+$ by (H.1)). If the initial condition $\boldsymbol{u}(x,0)$ is nonnegative but not identically zero on $[0,1]$, then the asymptotic behavior of the solution $\boldsymbol{u}(x,t)$ of (1.6) can be classified into the following three cases (see de Mottoni [3], for instance):

(a) If $v \le v_-$, then $\lim_{t\to+\infty} \boldsymbol{u}(x,t) = \boldsymbol{h}_+(v)$.

(b) If $v \in (v_-, v_+)$, then almost every solution converges to either $\boldsymbol{h}_-(v)$ or $\boldsymbol{h}_+(v)$ as $t \to +\infty$, depending on the initial condition.

(c) If $v \ge v_+$, then $\lim_{t\to+\infty} \boldsymbol{u}(x,t) = \boldsymbol{h}_-(v)$.

Inequalities $k < a < 1/c$ in (H.1) mean that the predator prefers to eat the u_1-species over the u_2-species. Therefore, cases (a), (b), and (c) can be easily interpreted as the following: Suppose that v is constant. Then only the u_1-species always survives and the u_2-species is extinct for smaller $v > 0$, while the situation is the reverse for larger $v > 0$.

First of all, we consider the situation where all of the diffusion rates are very large (that is, $\varepsilon > 0$ and $\sigma^{-1} > 0$ are both very large) in (1.5). Under this situation, it turns out that any solution of (1.5) becomes spatially homogeneous asymptotically so that the asymptotic state of solutions of (1.5) is described by the diffusionless system of (1.5):

$$\boldsymbol{u}_t = \boldsymbol{f}(\boldsymbol{u}, v), \quad v_t = g(\boldsymbol{u}, v), \quad t > 0 \tag{1.7}$$

(see Conway, Hoff, and Smoller [1]). The existence and stability of positive solutions of the ODEs (1.7) have been intensively studied, from viewpoints on the possibility of temporally segregating coexistence of two competing species (see Fujii [5], Hsu [6], and Takeuchi and Adachi [18], for instance). Let E_{+++} be an equilibrium point of (1.7) in the positive quadrant, which indicates the coexistence of two competing species. When r and k are taken as free parameters and the others appropriately fixed, the existence region of E_{+++} is shown in Figure 2. The region consists of two subregions A and B which are surrounded by the curves $r = r_c^-(k)$ and $r = r_c^+(k)$, where

$$r_c^-(k) = \beta\,k\,\frac{a-k}{1-c\,k}, \quad r_c^+(k) = \frac{a-k}{b-k}.$$

In region A, the stability of E_{+++} depends on the values of the parameters a, b, c, α, and β. If E_{+++} is not stable, there exist not only periodic solutions but also chaotic ones (for more information, we refer to [15]). On the other hand, in the region B, E_{+++} is always unstable. In the region not including A, numerical calculations suggest that neither stable positive equilibria nor stable positive periodic solutions exist. In view of these results, we may conclude that there occurs no predation-mediated coexistence for arbitrarily fixed (r,k) in the region not including A, if all of the diffusion rates are very large.

We now propose the following problem: Under the situation where (r,k) is arbitrarily fixed in the region not including A (that is, there occurs no predation-mediated coexistence under spatially homogeneous situations), is it possible for two competing species to coexist in the presence of a predator when one of the diffusion rates is not necessarily large?

In order to study this problem, we assume that

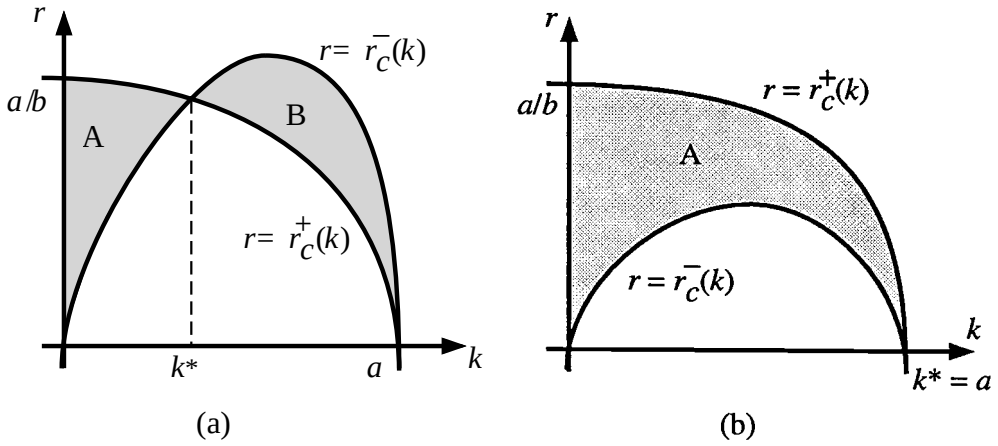

FIG. 2. *Existence region of* E_{+++}.

(H.2) $\varepsilon > 0$ is sufficiently small compared with other parameters,
which indicates that the prey species diffuse very slowly compared to the predator.

(H.3) r and k satisfy

$$(r_t^-(k) \equiv)\, a_0\, \beta\, k\, \frac{a-k}{a_0-k} < r < \frac{a-k}{a_0-k}\, (\equiv r_t^+(k)),$$

where a_0 is given by Lemma 2.1 in the next section. If $k > 0$ is sufficiently small, the inequalities $1/c < a_0 < b$ give the inequalities $r_t^-(k) < r_c^-(k) < r_c^+(k) < r_t^+(k)$. Hence it turns out that (r, k) does not lie in the region A shown in Figure 2 if (r, k) satisfies either

$$r_t^-(k) < r < r_c^-(k) \quad \text{or} \quad r_c^+(k) < r < r_t^+(k).$$

Our main theorem is stated as follows.

THEOREM 1.1. *Under the assumptions* (H.1), (H.2), *and* (H.3), *there exist* $\varepsilon_0 > 0$, $\sigma_0 > 0$, *and* $k_0 > 0$ *such that* (1.5) *has a stable SIP equilibrium solution* $(\boldsymbol{u}^{\varepsilon,\sigma}, v^{\varepsilon,\sigma})(x)$ *for any* $(\varepsilon, \sigma, k) \in (0, \varepsilon_0] \times (0, \sigma_0] \times (0, k_0]$. *Furthermore* $(\boldsymbol{u}^{\varepsilon,\sigma}, v^{\varepsilon,\sigma})(x)$ *satisfies the following properties:*

(i) $(\boldsymbol{u}^{\varepsilon,\sigma}, v^{\varepsilon,\sigma})$ *is bounded in* $\mathcal{Z}_\varepsilon \times C^2([0,1])$,

(ii) $\lim_{(\varepsilon,\sigma)\to(0,0)} \boldsymbol{u}^{\varepsilon,\sigma}(x) = \boldsymbol{h}(x, v_0, x_0)$ *uniformly on* $[0, x_0 - \kappa) \cup (x_0 + \kappa, 1]$ *for any* $\kappa > 0$,

(iii) $\lim_{(\varepsilon,\sigma)\to(0,0)} v^{\varepsilon,\sigma}(x) = v_0$ *uniformly on* $[0,1]$
(*see Figure* 3), *where* v_0 *is given in Lemma* 2.1 *and satisfies*

$$g(\boldsymbol{h}_-(v_0), v_0) < 0 < g(\boldsymbol{h}_+(v_0), v_0),$$

and $\mathcal{Z}_\varepsilon$, x_0, *and* $\boldsymbol{h}(x, v, \tau)$ *are defined by*

$$\mathcal{Z}_\varepsilon = \{\, \boldsymbol{u} \in C^0([0,1], \mathbf{R}^2) \,|\, \|\, \boldsymbol{u} \,\|_{\mathcal{Z}_\varepsilon} < +\infty \,\},$$

$$\|\, \boldsymbol{u} \,\|_{\mathcal{Z}_\varepsilon} = \textstyle\sum_{j=0}^{2} \|\, (\varepsilon\, \frac{d}{dx})^j \boldsymbol{u} \,\|_{C^0([0,x_0)\cup(x_0,1],\mathbf{R}^2)},$$

$$x_0 = \frac{g(\boldsymbol{h}_+(v_0), v_0)}{g(\boldsymbol{h}_+(v_0), v_0) - g(\boldsymbol{h}_-(v_0), v_0)} \quad \textit{and} \quad \boldsymbol{h}(x, v, \tau) = \begin{cases} \boldsymbol{h}_-(v) & \textit{for } x < \tau, \\ \boldsymbol{h}_+(v) & \textit{for } x > \tau, \end{cases}$$

respectively.

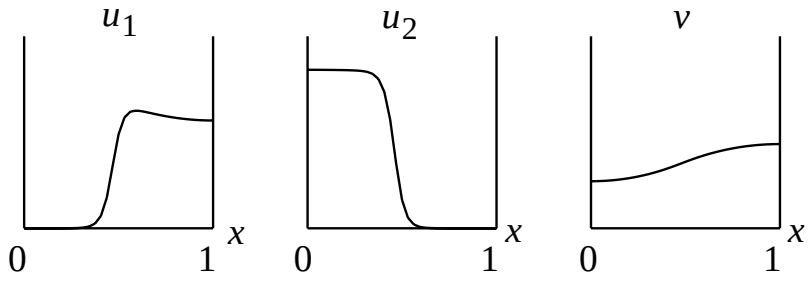

FIG. 3. *Spatial profiles of SIP equilibrium solution* $(u_1, u_2, v)(x)$ *of* (1.5).

The proof is achieved by the singular perturbation technique and the associated singular limit eigenvalue problem (SLEP) method. It is stated in sections 2 and 3.

Figure 3 demonstrates the spatial profiles of the SIP equilibrium solution $(\boldsymbol{u}, v)(x)$, where the solution $\boldsymbol{u}(x)$ clearly exhibits spatial segregation of two competing species, which are separated by an internal layer, while $v(x)$ is distributed smoothly in $(0, 1)$.

2. Construction of equilibrium solutions. In order to obtain SIP equilibrium solutions shown in Figure 3, we use singular perturbation methods for sufficiently small $\varepsilon > 0$. Since the case of multi-internal layers can be treated similarly, we restrict our discussion to the case of a single internal layer.

Let us consider the situation where such an internal layer exists in the vicinity of $x = \tau$, where τ is not known a priori. The resulting problem is the following stationary problem of (1.5):

$$\text{(2.1L)} \qquad \begin{cases} 0 = \varepsilon^2 D\, \boldsymbol{u}_{xx} + \boldsymbol{f}(\boldsymbol{u}, v), \\ 0 = v_{xx} + \sigma\, g(\boldsymbol{u}, v), \quad x \in (0, \tau), \\ \boldsymbol{u}_x(0) = 0, \quad v_x(0) = 0, \\ \boldsymbol{u}(\tau) = \hat{\boldsymbol{u}}, \quad v(\tau) = \hat{v}, \end{cases}$$

$$\text{(2.1R)} \qquad \begin{cases} 0 = \varepsilon^2 D\, \boldsymbol{u}_{xx} + \boldsymbol{f}(\boldsymbol{u}, v), \\ 0 = v_{xx} + \sigma\, g(\boldsymbol{u}, v), \quad x \in (\tau, 1), \\ \boldsymbol{u}(\tau) = \hat{\boldsymbol{u}}, \quad v(\tau) = \hat{v}, \\ \boldsymbol{u}_x(1) = 0, \quad v_x(1) = 0, \end{cases}$$

$$\text{(2.1B)} \qquad \boldsymbol{u}_x(\tau-) = \boldsymbol{u}_x(\tau+), \quad v_x(\tau-) = v_x(\tau+),$$

where $\hat{\boldsymbol{u}}$, $\hat{v}$, and τ are constants to be determined appropriately, and $u(x-)$ and $u(x+)$ are denoted by

$$u(x-) = \lim_{\delta \uparrow 0} u(x + \delta), \quad u(x+) = \lim_{\delta \downarrow 0} u(x + \delta),$$

respectively. Our strategy to construct SIP equilibrium solutions is stated as follows:

(i) Construct an inner (respectively, outer) approximated solution of (2.1L), (2.1R) in a neighborhood of (respectively, outside of) $x = \tau$ which is of C^1-class in $(\varepsilon, \hat{\boldsymbol{u}}, \hat{v})$ (respectively, $(\sigma, \hat{v}, \tau)$).

(ii) Assume $\varepsilon > 0$ and $\sigma > 0$ to be sufficiently small, and seek a solution of (2.1L), (2.1R) by using the inner and outer approximated solutions constructed in (i).

(iii) Determine $\hat{\boldsymbol{u}}$, $\hat{v}$, and τ as C^1-class functions of (ε, σ) such that the solution given in (ii) satisfies the boundary condition (2.1B).
This is a modified version of the usual singular perturbation method (for instance, see Fife [4]).

2.1. Inner approximation. In this subsection, we obtain an approximated solution of (2.1) in a neighborhood of $x = \tau$. To do this, we use the stretched variable $\xi = (x - \tau)/\varepsilon$ to rewrite (2.1) as

$$0 = D\,\boldsymbol{u}_{\xi\xi} + \boldsymbol{f}(\boldsymbol{u}, v), \quad 0 = v_{\xi\xi} + \varepsilon^2\,\sigma\,g(\boldsymbol{u}, v).$$

When $\varepsilon \to 0$, the second equation formally becomes $v_{\xi\xi} = 0$, so that v becomes constant because of the Neumann boundary condition, which implies $v(.) \to \hat{v}$ as $\varepsilon \to 0$. Hence as $\varepsilon \to 0$, the above equation can be approximated by

$$\begin{cases} 0 = D\,\boldsymbol{u}_{\xi\xi} + \boldsymbol{f}(\boldsymbol{u}, \hat{v}), \quad \xi \in R_- \cup R_+, \\ \boldsymbol{u}(0) = \hat{\boldsymbol{u}}, \end{cases} \tag{2.2a}$$

where $R_- = (-\infty, 0)$ and $R_+ = (0, +\infty)$. For the boundary conditions of $\boldsymbol{u}$ at $\xi = \pm\infty$, we may take

$$\boldsymbol{u}(-\infty) = \boldsymbol{h}_-(\hat{v}), \quad \boldsymbol{u}(+\infty) = \boldsymbol{h}_+(\hat{v}). \tag{2.2b}$$

Let us define the order relations $\preceq_s$ and $\preceq_o$ in the following manner:

$$(u_1, u_2) \preceq_s (\bar{u}_1, \bar{u}_2) \iff u_1 \le \bar{u}_1,\ u_2 \le \bar{u}_2,$$
$$(u_1, u_2) \preceq_o (\bar{u}_1, \bar{u}_2) \iff u_1 \le \bar{u}_1,\ u_2 \ge \bar{u}_2.$$

Similarly to the above definition, $\prec_s$ and $\prec_o$ are also defined by replacing $\le$ with $<$. We shall say that $\boldsymbol{u}(\xi)$ is *monotone* if $\boldsymbol{u}_\xi(\xi) \succ_o (0, 0)$ holds for any $\xi \in \mathbf{R}$.

LEMMA 2.1 (Theorem A2 in [14]). *Under the assumption* (H.1)*, there exists* $a_0 = a_0(b, c) \in (1/c, b)$ *such that* (2.2) *with*

$$\hat{v} = \frac{a_0 - a}{a_0 - k}\,(\equiv v_0 \in (v_-, v_+))$$

has a monotone solution $\boldsymbol{u}_0(\xi) = (u_{01}, u_{02})(\xi) \in C^2(\mathbf{R}, \mathbf{R}^2)$.

Let us define the linear operators $\mathcal{L}_0$ and $\mathcal{L}_0^*$ by $\mathcal{L}_0\,\boldsymbol{u} = D\,\boldsymbol{u}_{\xi\xi} + \boldsymbol{f}_{\boldsymbol{u}}(\boldsymbol{u}_0(\xi), v_0)\,\boldsymbol{u}$ and its formal adjoint operator, respectively. Setting

$$\gamma_1^\pm = \sqrt{-f_{1u_1}(\boldsymbol{h}_\pm(v_0), v_0)}, \quad \gamma_2^\pm = \sqrt{-f_{2u_2}(\boldsymbol{h}_\pm(v_0), v_0)/d},$$
$$\Gamma_1^\pm = \min\{\,\gamma_1^\pm, \gamma_2^\pm\,\}, \quad \Gamma_2^\pm = \max\{\,\gamma_1^\pm, \gamma_2^\pm\,\}, \quad m_\pm = 2 - {}^{\#}\{\,\gamma_1^\pm, \gamma_2^\pm\,\},$$

where ${}^{\#}A$ is the number of elements of the set A, we obtain the following lemmas.

LEMMA 2.2 (section 3.2 in [7]). *There exists a fundamental set* $\{\,\boldsymbol{U}_j(\xi)\,\}_{j=1}^4$ *of solutions of* $\mathcal{L}_0\,\boldsymbol{u} = 0$ *such that the limits as* $\xi \to \pm\infty$ *given by*

$$\lim_{\xi\to-\infty} \left| \boldsymbol{U}_1(\xi)\,\xi^{-m_-}\,e^{\Gamma_2^-\,\xi} \right|, \qquad \lim_{\xi\to+\infty} \left| \boldsymbol{U}_1(\xi)\,e^{\Gamma_2^+\,\xi} \right|,$$
$$\lim_{\xi\to-\infty} \left| \boldsymbol{U}_2(\xi)\,e^{\Gamma_1^-\,\xi} \right|, \qquad \lim_{\xi\to+\infty} \left| \boldsymbol{U}_2(\xi)\,e^{-\Gamma_1^+\,\xi} \right|,$$
$$\lim_{\xi\to-\infty} \left| \boldsymbol{U}_3(\xi)\,\xi^{-m_-}\,e^{-\Gamma_1^-\,\xi} \right|, \quad \lim_{\xi\to+\infty} \left| \boldsymbol{U}_3(\xi)\,\xi^{-m_+}\,e^{\Gamma_1^+\,\xi} \right|,$$
$$\lim_{\xi\to-\infty} \left| \boldsymbol{U}_4(\xi)\,e^{-\Gamma_2^-\,\xi} \right|, \qquad \lim_{\xi\to+\infty} \left| \boldsymbol{U}_4(\xi)\,\xi^{-m_+}\,e^{-\Gamma_2^+\,\xi} \right|$$

exist and all of the limits are positive. Furthermore, $\boldsymbol{U}_1(\xi)$*,* $\boldsymbol{U}_3(\xi)$*, and* $\boldsymbol{U}_4(\xi)$ *can be chosen to satisfy*

$$\boldsymbol{U}_1(\xi) \succ_s (0,0), \quad \boldsymbol{U}_3(\xi) = \boldsymbol{u}_{0\xi}(\xi), \quad \boldsymbol{U}_4(\xi) \succ_s (0,0)$$

for any $\xi \in \mathbf{R}$.

LEMMA 2.3 (Theorem A.2 in [10]). *Any nontrivial solution* $(u_1^*, u_2^*)(\xi)$ *of* $\mathcal{L}_0^* \boldsymbol{u} = 0$ *satisfies* $u_1^*(\xi)\, u_2^*(\xi) < 0$ *for any* $\xi \in \mathbf{R}$.

LEMMA 2.4 (Theorem 3.6 in [9]). *There exists* $\mu_0 > 0$ *such that*

$$\sigma(\mathcal{L}_0) \subset \{\, 0 \,\} \cup \{\, \lambda \in \mathbf{C} \,|\, \mathrm{Re}\ \lambda \le -\mu_0 \,\}$$

holds, where $\sigma(\mathcal{L}_0)$ *is the set of spectra of* $\mathcal{L}_0$ *relative to the space of bounded uniformly continuous functions from* $\mathbf{R}$ *to* $\mathbf{R}^2$ *with the supremum norm. Furthermore* $0 \in \sigma(\mathcal{L}_0)$ *is a simple eigenvalue.*

Putting $\hat{v} = v_0 + \omega$, we show that (2.2) has a positive solution for any ω in a neighborhood of $\omega = 0$. To do this, we use the new variable $\boldsymbol{y}$ with the form $\boldsymbol{y}\,(\equiv (y_1, y_2, y_3, y_4)) = (\boldsymbol{u}, \boldsymbol{u}_\xi)$ so that

$$\begin{cases} \frac{d}{d\xi}\boldsymbol{y} = \boldsymbol{F}(\boldsymbol{y}, \omega), \quad \xi \in R_- \cup R_+, \\ \boldsymbol{y}(\pm\infty) = \boldsymbol{H}_\pm(\omega), \quad (y_1, y_2)(0) = \hat{\boldsymbol{u}}, \end{cases} \tag{2.3}$$

where $\boldsymbol{F}(\boldsymbol{y}, \omega) = (\boldsymbol{u}_\xi, -D^{-1}\, \boldsymbol{f}(\boldsymbol{u}, v_0 + \omega))$ and $\boldsymbol{H}_\pm(\omega) = (\boldsymbol{h}_\pm(v_0 + \omega), 0, 0)$. Without loss of generality, we may assume $\hat{\boldsymbol{u}} = \boldsymbol{u}_0(0) + (0, \eta)$, where η will be determined later. Setting

$$\boldsymbol{y} = \boldsymbol{y}_0(\xi) + \boldsymbol{H}_\pm(\omega) - \boldsymbol{H}_\pm(0) + \boldsymbol{z} \quad \text{ on } R_\pm,$$

we rewrite (2.3) as

$$\begin{cases} \frac{d}{d\xi}\boldsymbol{z} = A(\xi)\, \boldsymbol{z} + \boldsymbol{N}(\xi, \boldsymbol{z}, \omega), \quad \xi \in R_- \cup R_+, \\ \boldsymbol{z}(\pm\infty) = 0, \quad \boldsymbol{z}(0\pm) = \boldsymbol{H}_\pm(0) - \boldsymbol{H}_\pm(\omega) + (0, \eta, \boldsymbol{q}_\pm), \end{cases} \tag{2.4}$$

where

$$A(\xi) = \boldsymbol{F}_{\boldsymbol{y}}(\boldsymbol{y}_0(\xi), 0), \quad \boldsymbol{N}(\xi, \boldsymbol{z}, \omega) = \boldsymbol{F}(\boldsymbol{y}, \omega) - \boldsymbol{F}(\boldsymbol{y}_0(\xi), 0) - A(\xi)\, \boldsymbol{z}$$

for $\boldsymbol{y}_0(\xi) = (\boldsymbol{u}_0, \boldsymbol{u}_{0\xi})(\xi)$, and η, ω, and $\boldsymbol{q} = (\boldsymbol{q}_-, \boldsymbol{q}_+)$ will be determined later.

We define $X(\xi)$ by

$$X(\xi) = \begin{pmatrix} \boldsymbol{U}_3 & \boldsymbol{U}_4 & \boldsymbol{U}_1 & \boldsymbol{U}_2 \\ \boldsymbol{U}_{3\xi} & \boldsymbol{U}_{4\xi} & \boldsymbol{U}_{1\xi} & \boldsymbol{U}_{2\xi} \end{pmatrix}(\xi),$$

where $\{\, \boldsymbol{U}_j(\xi) \,\}_{j=1}^4$ is a fundamental set of solutions of $\mathcal{L}_0\, \boldsymbol{u} = 0$ given in Lemma 2.2. We easily see that $X(\xi)$ is a fundamental matrix of $\frac{d}{d\xi}\boldsymbol{x} = A(\xi)\, \boldsymbol{x}$. It follows from Lemma 2.2 and the definition of Coppel [2] that $\frac{d}{d\xi}\boldsymbol{x} = A(\xi)\, \boldsymbol{x}$ has an exponential dichotomy on R_- (respectively, R_+) with the projection matrix $P_- = \mathrm{diag}(0, 0, 1, 1)$ (respectively, $P_+ = \mathrm{diag}(1, 0, 1, 0)$). Let $\boldsymbol{x}_i^*(\xi)$ and $x_{ij}^*(\xi)$ be the ith row vector and the (i, j)th element, respectively, of $X(\xi)^{-1}$. Using the estimates in Lemma 2.2, we can calculate $X(\xi)^{-1}$ directly, and then obtain

$$\boldsymbol{x}_4^*(\xi) = \begin{cases} O(\xi^{m_-}\, e^{\Gamma_1^-\, \xi}) & \text{as } \xi \to -\infty, \\ O(\xi^{m_+}\, e^{-\Gamma_1^+\, \xi}) & \text{as } \xi \to +\infty, \end{cases}$$

which means that $(u_{01}^*, u_{02}^*)(\xi) \equiv (x_{43}^*, x_{44}^*/d)(\xi)$ is a bounded solution of $\mathcal{L}_0^* \boldsymbol{u} = 0$. By Lemma 2.3, we have $u_{01}^*(\xi)\, u_{02}^*(\xi) < 0$ for any $\xi \in \mathbf{R}$.

LEMMA 2.5 (Lemma 3.2 in Kokubu [12]). *$\boldsymbol{z}(\xi, \boldsymbol{q}, \eta, \omega)$ is a solution of (2.4) if and only if $\boldsymbol{z}(\xi, \boldsymbol{q}, \eta, \omega)$ satisfies*

$$E(\boldsymbol{q}, \eta, \omega) \equiv \begin{pmatrix} \boldsymbol{x}_3^*(0)\, \boldsymbol{z}(0-, \boldsymbol{q}, \eta, \omega) - \int_{R_-} \boldsymbol{x}_3^*(\xi)\, \boldsymbol{N}(\xi, \boldsymbol{z}(\xi, \boldsymbol{q}, \eta, \omega), \omega)\, d\xi \\ \boldsymbol{x}_4^*(0)\, \boldsymbol{z}(0-, \boldsymbol{q}, \eta, \omega) - \int_{R_-} \boldsymbol{x}_4^*(\xi)\, \boldsymbol{N}(\xi, \boldsymbol{z}(\xi, \boldsymbol{q}, \eta, \omega), \omega)\, d\xi \\ \boldsymbol{x}_2^*(0)\, \boldsymbol{z}(0+, \boldsymbol{q}, \eta, \omega) + \int_{R_+} \boldsymbol{x}_2^*(\xi)\, \boldsymbol{N}(\xi, \boldsymbol{z}(\xi, \boldsymbol{q}, \eta, \omega), \omega)\, d\xi \\ \boldsymbol{x}_4^*(0)\, \boldsymbol{z}(0+, \boldsymbol{q}, \eta, \omega) + \int_{R_+} \boldsymbol{x}_4^*(\xi)\, \boldsymbol{N}(\xi, \boldsymbol{z}(\xi, \boldsymbol{q}, \eta, \omega), \omega)\, d\xi \end{pmatrix} = 0.$$

Let $B = (b_{ij})$ be an arbitrary $n \times n$ matrix. We denote by $\Delta_{j_1, \dots, j_\ell}^{i_1, \dots, i_\ell}(B)$ the determinant of the $(n-\ell) \times (n-\ell)$-matrix obtained by eliminating the i_1th, …, i_ℓth rows and j_1th, …, j_ℓth columns in B. By definition, we have $b_{ij} = (-1)^{i+j}\, \Delta_i^j(B^{-1})\, \det B$ for each i and j, if the inverse matrix B^{-1} exists. We know the following formula (for example, see [19, p. 379]):

$$\Delta_{j_1, j_2}^{i_1, i_2}(B)\, \det B = \Delta_{j_1}^{i_1}(B)\, \Delta_{j_2}^{i_2}(B) - \Delta_{j_2}^{i_1}(B)\, \Delta_{j_1}^{i_2}(B) \tag{2.5}$$

holds for any $i_1 < i_2$ and $j_1 < j_2$.

Clearly we know that $E(0,0,0) = 0$ because $\boldsymbol{z}(\xi, 0, 0, 0) = 0$ for any $\xi \in \mathbf{R}$. Since $\boldsymbol{N}_{\boldsymbol{z}}(\xi, 0, 0) = 0$ on $\mathbf{R}$ and $\boldsymbol{N}_\omega(\xi, 0, 0) = A(\xi)\, \boldsymbol{H}_\pm'(0) + \boldsymbol{F}_\omega(\boldsymbol{y}_0(\xi), 0)$ on $R_\pm$ are satisfied, we obtain

$$\begin{aligned} &\frac{\partial}{\partial \boldsymbol{q}} \int_0^\xi \boldsymbol{x}_j^*(\zeta)\, \boldsymbol{N}(\zeta, \boldsymbol{z}(\zeta, \boldsymbol{q}, 0, 0), 0)\, d\zeta \bigg|_{\boldsymbol{q}=0} = 0, \\ &\frac{\partial}{\partial \eta} \int_0^\xi \boldsymbol{x}_j^*(\zeta)\, \boldsymbol{N}(\zeta, \boldsymbol{z}(\zeta, 0, \eta, 0), 0)\, d\zeta \bigg|_{\eta=0} = 0, \\ &\frac{\partial}{\partial \omega} \int_0^\xi \boldsymbol{x}_j^*(\zeta)\, \boldsymbol{N}(\zeta, \boldsymbol{z}(\zeta, 0, 0, \omega), \omega)\, d\zeta \bigg|_{\omega=0} \\ &\qquad = (\boldsymbol{x}_j^*(0) - \boldsymbol{x}_j^*(\xi))\, \boldsymbol{H}_\pm'(0) + \int_0^\xi \boldsymbol{x}_j^*(\zeta)\, \boldsymbol{F}_\omega(\boldsymbol{y}_0(\zeta), 0)\, d\zeta, \end{aligned}$$

and then we have

$$E_{\boldsymbol{q}}(0,0,0) = \begin{pmatrix} \hat{x}_{33}^* & \hat{x}_{34}^* & 0 & 0 \\ \hat{x}_{43}^* & \hat{x}_{44}^* & 0 & 0 \\ 0 & 0 & \hat{x}_{23}^* & \hat{x}_{24}^* \\ 0 & 0 & \hat{x}_{43}^* & \hat{x}_{44}^* \end{pmatrix}, \quad \frac{\partial E}{\partial(\eta, \omega)}(0,0,0) = \begin{pmatrix} \hat{x}_{32}^* & -F_3^- \\ \hat{x}_{42}^* & -F_4^- \\ \hat{x}_{22}^* & F_2^+ \\ \hat{x}_{42}^* & F_4^+ \end{pmatrix},$$

where $\hat{x}_{ij}^* = x_{ij}^*(0)$ and

$$F_j^\pm = \int_{R_\pm} \boldsymbol{x}_j^*(\xi)\, \boldsymbol{F}_\omega(\boldsymbol{y}_0(\xi), 0)\, d\xi = \int_{R_\pm} (x_{j3}^*(\xi)\, u_{01}(\xi) + k\, x_{j4}^*(\xi)\, u_{02}(\xi)/d)\, d\xi.$$

By (2.5) and Lemma 2.2, we have

$$\det E_{\boldsymbol{q}}(0,0,0) = -\frac{\det(\boldsymbol{U}_3, \boldsymbol{U}_4)(0)\, \det(\boldsymbol{U}_3, \boldsymbol{U}_1)(0)}{(\det X(0))^2} \neq 0.$$

Consequently it follows from the implicit function theorem that there exists a C^1-class function $\boldsymbol{q}(\eta,\omega)=(\boldsymbol{q}_-,\boldsymbol{q}_+)(\eta,\omega)$ defined in a neighborhood of $(\eta,\omega)=(0,0)$ such that $E(\boldsymbol{q}(\eta,\omega),\eta,\omega)=0$ is satisfied for each (η,ω). Since

$$\begin{aligned}\frac{\partial(\boldsymbol{q}_+-\boldsymbol{q}_-)}{\partial\eta}(0,0)=&\begin{pmatrix}\hat{x}^*_{33}&\hat{x}^*_{34}\\ \hat{x}^*_{43}&\hat{x}^*_{44}\end{pmatrix}^{-1}\begin{pmatrix}\hat{x}^*_{32}\\ \hat{x}^*_{42}\end{pmatrix}-\begin{pmatrix}\hat{x}^*_{23}&\hat{x}^*_{24}\\ \hat{x}^*_{43}&\hat{x}^*_{44}\end{pmatrix}^{-1}\begin{pmatrix}\hat{x}^*_{22}\\ \hat{x}^*_{42}\end{pmatrix}\\ =&\frac{u_{01\xi}(0)}{\det X(0)\,\det E_{\boldsymbol{q}}(0,0,0)}\begin{pmatrix}-\hat{x}^*_{44}\\ \hat{x}^*_{43}\end{pmatrix}\end{aligned}$$

and

$$\begin{aligned}\frac{\partial(\boldsymbol{q}_+-\boldsymbol{q}_-)}{\partial\omega}(0,0)=&-\begin{pmatrix}\hat{x}^*_{23}&\hat{x}^*_{24}\\ \hat{x}^*_{43}&\hat{x}^*_{44}\end{pmatrix}^{-1}\begin{pmatrix}F^+_2\\ F^+_4\end{pmatrix}-\begin{pmatrix}\hat{x}^*_{33}&\hat{x}^*_{34}\\ \hat{x}^*_{43}&\hat{x}^*_{44}\end{pmatrix}^{-1}\begin{pmatrix}F^-_3\\ F^-_4\end{pmatrix}\\ =&\left(\frac{F^+_2}{\Delta^{1,3}_{1,2}(X(0)^{-1})}+\frac{F^-_3}{\Delta^{1,2}_{1,2}(X(0)^{-1})}\right)\begin{pmatrix}-\hat{x}^*_{44}\\ \hat{x}^*_{43}\end{pmatrix}\\ &+\frac{F^+_4}{\Delta^{1,3}_{1,2}(X(0)^{-1})}\begin{pmatrix}\hat{x}^*_{24}\\ -\hat{x}^*_{23}\end{pmatrix}+\frac{F^-_4}{\Delta^{1,2}_{1,2}(X(0)^{-1})}\begin{pmatrix}\hat{x}^*_{34}\\ -\hat{x}^*_{33}\end{pmatrix}\end{aligned}$$

hold by virtue of (2.5), we have

$$\begin{aligned}\det\frac{\partial(\boldsymbol{q}_+-\boldsymbol{q}_-)}{\partial(\eta,\omega)}(0,0)=&\frac{u_{01\xi}(0)}{\det X(0)\,\det E_{\boldsymbol{q}}(0,0,0)}\\ &\times\int_{\mathbf{R}}(u_{01}(\xi)\,u^*_{01}(\xi)+k\,u_{02}(\xi)\,u^*_{02}(\xi))\,d\xi\,(\equiv J_1(k)).\end{aligned}$$

By combining the above argument with the comparison principle, we obtain the following lemma.

LEMMA 2.6. *There exists a C^1-class function $\boldsymbol{u}^I(.,\eta,\omega)$ defined on a neighborhood of $(\eta,\omega)=(0,0)$ such that (2.2) has a positive solution $\boldsymbol{u}^I(\xi,\eta,\omega)$ for each (η,ω), which satisfies $\boldsymbol{u}^I(.,\eta,\omega)\to\boldsymbol{u}_0$ in the C^2-sense as $(\eta,\omega)\to(0,0)$, and furthermore*

$$\det\left.\frac{\partial(\boldsymbol{u}^I_\xi(0+,\eta,\omega)-\boldsymbol{u}^I_\xi(0-,\eta,\omega))}{\partial(\eta,\omega)}\right|_{(\eta,\omega)=(0,0)}=J_1(k).$$

2.2. Outer approximation. In this subsection, we shall construct an approximate solution of (2.1) outside of $x=\tau$. As $\varepsilon\to0$, (2.1) is formally reduced to

$$\begin{cases}0=\boldsymbol{f}(\boldsymbol{u},v),\\ 0=v_{xx}+\sigma\,g(\boldsymbol{u},v),\quad x\in(0,\tau)\cup(\tau,1),\\ v_x(0)=0,\quad v(\tau)=v_0+\omega,\quad v_x(1)=0.\end{cases}\tag{2.6}$$

By the definition of $\boldsymbol{h}(x,v,\tau)$, we easily have $\boldsymbol{f}(\boldsymbol{h}(x,v,\tau),v)=0$ for any $x\in[0,\tau)\cup(\tau,1]$. Substituting $\boldsymbol{u}=\boldsymbol{h}(x,v,\tau)$ into the second equation of (2.6), we obtain the following equation for v only:

$$\begin{cases}0=v_{xx}+\sigma\,g(\boldsymbol{h}(x,v,\tau),v),\quad x\in(0,\tau)\cup(\tau,1),\\ v_x(0)=0,\quad v(\tau)=v_0+\omega,\quad v_x(1)=0.\end{cases}\tag{2.7}$$

Setting $J_2(v,\tau)=\int_0^1 g(\boldsymbol{h}(x,v,\tau),v)\,dx$, we find $J_2(v_0,x_0)=0$ and

$$J_{2\tau}(v_0,x_0)=g(\boldsymbol{h}_-(v_0),v_0)-g(\boldsymbol{h}_+(v_0),v_0)<0.$$

LEMMA 2.7. *Under the assumptions* (H.1) *and* (H.3)*, there exist* $\sigma_1>0$*,* $\delta_1>0$*, and* $\omega_1>0$ *such that* (2.7) *with* $\tau=x_0+\delta$ *has a unique solution* $v^O(x,\sigma,\delta,\omega)$ *for any* $\sigma\in[0,\sigma_1]$*,* $|\,\delta\,|\le\delta_1$*, and* $|\,\omega\,|\le\omega_1$ *which satisfies the following properties:*

(i) $v^O(x,\sigma,\delta,\omega)$ *is of* C^1*-class with respect to* (σ,δ,ω)*;*

(ii) $\frac{\partial}{\partial\delta}[v_x^O(x_0+\delta-,\sigma,\delta,\omega)-v_x^O(x_0+\delta+,\sigma,\delta,\omega)]/\sigma\to-J_{2\tau}(v_0,x_0)$ *as* $(\sigma,\delta,\omega)\to(0,0,0)$.

Proof. Setting $v=v_0+\omega+\sigma V$, we see that $V(x)$ satisfies

$$\begin{cases}0=V_{xx}+g(\boldsymbol{h}(x,v,x_0+\delta),v), & x\in(0,x_0+\delta)\cup(x_0+\delta,1),\\ V_x(0)=0, \quad V(x_0+\delta)=0, \quad V_x(1)=0.\end{cases}\tag{2.8}$$

Since $J_2(v_0,x_0)=0$ holds and the variational problem of (2.8) with respect to V at $(\sigma,\delta,\omega)=0$ is represented as

$$\begin{cases}0=V_{xx}, & x\in(0,x_0)\cup(x_0,1),\\ V_x(0)=0, \quad V(x_0)=0, \quad V_x(1)=0,\end{cases}$$

property (i) can be shown by virtue of the implicit function theorem. Furthermore by (2.7), we obtain

$$\begin{aligned}&\frac{1}{\sigma}\,\frac{\partial}{\partial\delta}[v_x^O(x_0+\delta-,\sigma,\delta,\omega)-v_x^O(x_0+\delta+,\sigma,\delta,\omega)]\\ &\qquad=-\frac{\partial}{\partial\delta}\int_0^1 g(\boldsymbol{h}(x,v^O(x,\sigma,\delta,\omega),x_0+\delta),v^O(x,\sigma,\delta,\omega))\,dx\to-J_{2\tau}(v_0,x_0)\end{aligned}$$

as $(\sigma,\delta,\omega)\to(0,0,0)$, which proves property (ii). ∎

2.3. Construction of solutions. In this subsection, we shall prove the existence of a C^2-class solution $(\boldsymbol{u},v)(x)$ of (2.1) on the whole interval $[0,1]$ by matching the inner and outer approximated solutions which were constructed in the previous subsections. In order to do this, we define $\boldsymbol{u}^a(x,\rho)$ and $v^a(x,\rho)$ with $\rho=(\varepsilon,\sigma,\delta,\eta,\omega)$ by

$$\begin{aligned}\boldsymbol{u}^a(x,\rho)&=\boldsymbol{h}(x,v^O(x,\sigma,\delta,\omega),x_0+\delta)\\ &\qquad+\theta(x)\,(\boldsymbol{u}^I((x-x_0-\delta)/\varepsilon,\eta,\omega)-\boldsymbol{h}(x,v_0+\omega,x_0+\delta)),\\ v^a(x,\rho)&=v^O(x,\sigma,\delta,\omega),\end{aligned}$$

where

$$\theta(x)=\begin{cases}\theta_0(x/(x_0+\delta)) & \text{for } x\le x_0+\delta,\\ \theta_0((1-x)/(1-x_0-\delta)) & \text{for } x>x_0+\delta\end{cases}$$

with a C^∞-cutoff function $\theta_0(x)$ which satisfies $0\le\theta_0(x)\le1$ for any $x\ge0$ and

$$\theta_0(x)=\begin{cases}0 & \text{for } 0\le x\le1/4,\\ 1 & \text{for } x\ge3/4.\end{cases}$$

We shall find a solution $(\boldsymbol{u}, v)$ of (2.1) in the following form:

$$(\boldsymbol{u}, v) = (\boldsymbol{u}^a, v^a)(x, \rho) + t, \quad t = (\boldsymbol{r}, s).$$

Here we define $\mathcal{T} : \mathcal{X} \to \mathcal{Y}$ by

$$\mathcal{T}(t, \rho) = \begin{pmatrix} \varepsilon^2 D\, \boldsymbol{u}_{yy} + \chi(., \delta)\, \boldsymbol{f}(\boldsymbol{u}, v) \\ v_{yy} + \sigma\, \chi(., \delta)\, g(\boldsymbol{u}, v) \end{pmatrix},$$

where

$$y = \begin{cases} \dfrac{x_0\, x}{x_0 + \delta} & \text{for } x < x_0 + \delta, \\ x_0 + \dfrac{(1 - x_0)\,(x - x_0 - \delta)}{1 - x_0 - \delta} & \text{for } x > x_0 + \delta, \end{cases}$$

$$\chi(y, \delta) = \begin{cases} \dfrac{(x_0 + \delta)^2}{x_0^2} & \text{for } y < x_0, \\ \dfrac{(1 - x_0 - \delta)^2}{(1 - x_0)^2} & \text{for } y > x_0, \end{cases}$$

$$\mathcal{X} = \mathcal{X}_u \times (H^2(0,1) \cap \mathcal{Z}_0([0,1], \mathbf{R})), \quad \mathcal{X}_u = \mathcal{Z}_\varepsilon \cap \mathcal{Z}_0([0,1], \mathbf{R}^2),$$

$$\mathcal{Y} = \mathcal{Y}_u \times L^2(0,1), \quad \mathcal{Y}_u = C^0([0,1], \mathbf{R}^2),$$

$$\mathcal{Z}_0([0,1], \mathbf{R}^\ell) = \{\, u \in C^1([0,1], \mathbf{R}^\ell) \,|\, u_y(0) = 0,\ u(x_0) = 0,\ u_y(1) = 0 \,\}.$$

LEMMA 2.8. *The following properties are satisfied in a neighborhood of $\rho = 0$:*
(i) *$\mathcal{T}$ is of C^1-class with respect to t, and there exists $C_1 > 0$ such that*

$$\| \mathcal{T}_t(t_1, \rho) - \mathcal{T}_t(t_2, \rho) \|_{\mathcal{L}(\mathcal{X}, \mathcal{Y})} \le C_1 \| t_1 - t_2 \|_{\mathcal{X}}$$

for any t_1, $t_2 \in \mathcal{X}$.
(ii) *$\mathcal{T}_t(0, \rho)$ has an inverse.*
(iii) *$\| \mathcal{T}(0, \rho) \|_{\mathcal{Y}} \to 0$ as $\varepsilon \to 0$ uniformly in $(\sigma, \delta, \eta, \omega)$.*

Proof. Using the arguments in Fife [4], we may only show that there exist $C_2 > 0$, $\varepsilon_1 > 0$, and $\sigma_2 > 0$ such that $\| (\hat{\mathcal{L}}^{\varepsilon,\sigma})^{-1} \|_{\mathcal{L}(\mathcal{X}_u, \mathcal{Y}_u)} \le C_2$ holds for any $(\varepsilon, \sigma) \in (0, \varepsilon_1] \times (0, \sigma_2]$, where $\boldsymbol{f}^a_{\boldsymbol{u}}(y, \varepsilon, \sigma) = \boldsymbol{f}_{\boldsymbol{u}}((\boldsymbol{u}^a, v^a)(y, \varepsilon, \sigma, 0, 0, 0))$ and $\hat{\mathcal{L}}^{\varepsilon,\sigma}\, \boldsymbol{u} = \varepsilon^2 D\, \boldsymbol{u}_{yy} + \boldsymbol{f}^a_{\boldsymbol{u}}(y, \varepsilon, \sigma)\, \boldsymbol{u}$.

Contrary to the conclusion, suppose that there exists $\{\, (\hat{\boldsymbol{u}}_n(y), \hat{\varepsilon}_n, \hat{\sigma}_n) \,\}_{n=1}^\infty$ such that $\lim_{n\to\infty}(\hat{\varepsilon}_n, \hat{\sigma}_n) = (0, 0)$ and $1 = \| \hat{\boldsymbol{u}}_n \|_{\mathcal{X}_u} \ge n \| \mathcal{L}^{\hat{\varepsilon}_n, \hat{\sigma}_n}\, \hat{\boldsymbol{u}}_n \|_{\mathcal{Y}_u}$ for any $n \in \mathbf{N}$. Since

$$\boldsymbol{f}^a_{\boldsymbol{u}}(x_0 + \varepsilon\, \xi, \varepsilon, \sigma) \to \boldsymbol{f}_{\boldsymbol{u}}(\boldsymbol{u}_0(\xi), v_0) \quad \text{as } (\varepsilon, \sigma) \to (0, 0)$$

uniformly on any compact set of $\mathbf{R}$ in the C^0-sense, it follows from the Ascoli–Arzelà theorem that there exists $\hat{\boldsymbol{u}}_0(\xi)$ such that $\hat{\boldsymbol{u}}_0(\xi)$ is a solution of $\mathcal{L}_0\, \boldsymbol{u} = 0$ on $R_- \cup R_+$ and satisfies $\hat{\boldsymbol{u}}_0(0) = 0$ and $\| \hat{\boldsymbol{u}}_0 \|_{C^2(R_- \cup R_+, \mathbf{R}^2)} = 1$. By Lemma 2.2, we have $\hat{\boldsymbol{u}}_0(\xi) = 0$ for any $\xi \in \mathbf{R}$. This contradiction implies that the desired result holds. ∎

By the above lemma and the implicit function theorem [4, Theorem 3.4], we see that there exists a solution family $(\boldsymbol{u}, v)(x, \rho)$ of (2.1L) and (2.1R) in a neighborhood of $\rho = 0$ such that

$$\| \boldsymbol{u}(., \rho) - \boldsymbol{u}^a(., \rho) \|_{Z_\varepsilon} + \| v(., \rho) - v^a(., \rho) \|_{H^2(0,1)} \to 0 \tag{2.9}$$

as $\varepsilon \to 0$.

We now define $(\Phi, \Psi)(\rho)$ by

$$(\Phi, \Psi)(\rho) = (\varepsilon\, \boldsymbol{u}_x, v_x/\sigma)(x_0 + \delta+, \rho) - (\varepsilon\, \boldsymbol{u}_x, v_x/\sigma)(x_0 + \delta-, \rho).$$

By Lemma 2.7 and (2.9), it is obvious that $(\Phi, \Psi)(0) = 0$,

$$\frac{\partial \Phi}{\partial \delta}(0) = 0, \quad \text{and} \quad \frac{\partial \Psi}{\partial \delta}(0) = J_{2\tau}(v_0, x_0)\, (< 0)$$

hold. Lemma 2.3 implies that there exists $k_0 > 0$ such that

$$\int_{\mathbf{R}} (u_{01}(\xi)\, u_{01}^*(\xi) + k\, u_{02}(\xi)\, u_{02}^*(\xi))\, d\xi \neq 0$$

holds for any $k \in [0, k_0]$. Thus we find

$$\det \frac{\partial(\Phi, \Psi)}{\partial(\delta, \eta, \omega)}(0) = -J_1(k)\, J_{2\tau}(v_0, x_0) \neq 0$$

for $k \in [0, k_0]$. By using the implicit function theorem, we find that there exist $\varepsilon_2 > 0$ and $\sigma_3 > 0$ such that (2.1) has a solution $(\boldsymbol{u}^{\varepsilon,\sigma}, v^{\varepsilon,\sigma})(x)$ for any $(\varepsilon, \sigma) \in (0, \varepsilon_2] \times (0, \sigma_3]$.

We thus find that the spatial profile of $\boldsymbol{u}^{\varepsilon,\sigma}(x)$ indicates that two competing species exhibit spatial segregation with a small overlapping zone in $[0, 1]$, as was shown in Figure 3.

3. Stability. In this section, we shall discuss the stability of the equilibrium solution $(\boldsymbol{u}^{\varepsilon,\sigma}, v^{\varepsilon,\sigma})(x)$ of (1.5) which was given in the previous section. To do this, it is enough to study the distribution of eigenvalues of the following linearized eigenvalue problem of (1.5) around $(\boldsymbol{u}^{\varepsilon,\sigma}, v^{\varepsilon,\sigma})(x)$ for $(\varepsilon, \sigma) \in (0, \varepsilon_2] \times (0, \sigma_3]$:

$$\begin{cases} \lambda\, \boldsymbol{w} = \varepsilon^2\, D\, \boldsymbol{w}_{xx} + \boldsymbol{f}_{\boldsymbol{u}}^{\varepsilon,\sigma}(x)\, \boldsymbol{w} + \boldsymbol{f}_{v}^{\varepsilon,\sigma}(x)\, z, \\ \lambda\, \sigma\, z = z_{xx} + \sigma\, g_{\boldsymbol{u}}^{\varepsilon,\sigma}(x)\, \boldsymbol{w} + \sigma\, g_{v}^{\varepsilon,\sigma}(x)\, z, \quad x \in (0, 1), \\ \boldsymbol{w}_x = 0, \quad z_x = 0, \quad x = 0, 1, \end{cases} \tag{3.1}$$

where $\boldsymbol{f}_{\boldsymbol{u}}^{\varepsilon,\sigma}(x) = \boldsymbol{f}_{\boldsymbol{u}}((\boldsymbol{u}^{\varepsilon,\sigma}, v^{\varepsilon,\sigma})(x))$, and the other functions $\boldsymbol{f}_{v}^{\varepsilon,\sigma}(x)$, $g_{\boldsymbol{u}}^{\varepsilon,\sigma}(x)$, and $g_{v}^{\varepsilon,\sigma}(x)$ are similarly defined.

We define the operators $\mathcal{L}^{\varepsilon,\sigma}$ and $\mathcal{L}^{*\,\varepsilon,\sigma}$ by

$$\mathcal{L}^{\varepsilon,\sigma}\, \boldsymbol{w} = \varepsilon^2\, D\, \boldsymbol{w}_{xx} + \boldsymbol{f}_{\boldsymbol{u}}^{\varepsilon,\sigma}(x)\, \boldsymbol{w} \quad \text{and} \quad \mathcal{L}^{*\,\varepsilon,\sigma}\, \boldsymbol{w} = \varepsilon^2\, D\, \boldsymbol{w}_{xx} + {}^t\boldsymbol{f}_{\boldsymbol{u}}^{\varepsilon,\sigma}(x)\, \boldsymbol{w},$$

respectively. Let $\{\, \zeta_n^{\varepsilon,\sigma} \,\}_{n=0}^{\infty}$ be the set of eigenvalues of $\mathcal{L}^{\varepsilon,\sigma}$ with the Neumann boundary condition, and let $\phi_n^{\varepsilon,\sigma}$ (respectively, $\phi_n^{*\,\varepsilon,\sigma}$) be an eigenfunction of $\mathcal{L}^{\varepsilon,\sigma}$ (respectively, $\mathcal{L}^{*\,\varepsilon,\sigma}$) corresponding to the eigenvalue $\zeta_n^{\varepsilon,\sigma}$ (respectively, $\overline{\zeta_n^{\varepsilon,\sigma}}$) for each n. Here we normalize $\phi_n^{\varepsilon,\sigma}$ and $\phi_n^{*\,\varepsilon,\sigma}$ as $\| \phi_n^{\varepsilon,\sigma} \|_{L^2(0,1)} = 1$ and $\langle\, \phi_n^{\varepsilon,\sigma}, \phi_n^{*\,\varepsilon,\sigma} \,\rangle = 1$ for each $n \geq 0$, where $\langle ., . \rangle$ is the inner product in $L^2(0, 1)$. Without loss of generality, we may assume that $\zeta_n^{\varepsilon,\sigma}$ satisfies $\operatorname{Re} \zeta_n^{\varepsilon,\sigma} \leq \operatorname{Re} \zeta_0^{\varepsilon,\sigma}$ for any $n \geq 1$. In a similar manner to the proof of Lemma 1.4 in Nishiura and Fujii [16], the following lemma can be proved by using Lemma 2.4.

LEMMA 3.1. *$\{\, \zeta_n^{\varepsilon,\sigma} \,\}_{n=0}^{\infty}$ satisfies the following properties:*

(i) $\operatorname{Re} \zeta_0^{\varepsilon,\sigma} = o(\varepsilon)$ *as* $(\varepsilon, \sigma) \to (0, 0)$.

(ii) *There exist* $\varepsilon_3 > 0$, $\sigma_4 > 0$, *and* $\mu_1 > 0$ *such that* $\operatorname{Re}\, \zeta_n^{\varepsilon,\sigma} \leq -\mu_1$ *for any* $(\varepsilon, \sigma) \in (0, \varepsilon_3] \times (0, \sigma_4]$ *and* $n \geq 1$.

We denote by $\Sigma^{\varepsilon,\sigma}$ the set of eigenvalues of (3.1) for (ε,σ). Let the projection $P_{\varepsilon,\sigma}$ be $P_{\varepsilon,\sigma}\,\boldsymbol{u} = \boldsymbol{u} - \langle\, \boldsymbol{u}, \phi_0^{*\,\varepsilon,\sigma}\,\rangle\,\phi_0^{\varepsilon,\sigma}$. By setting $\mu_2 = \mu_1/2$ and $\Lambda(\mu) = \{\,\lambda \in \mathbf{C} \,|\, \mathrm{Re}\ \lambda \geq -\mu\,\}$, Lemma 3.1 shows that $(\mathcal{L}^{\varepsilon,\sigma} - \lambda)\,P_{\varepsilon,\sigma}$ has a uniformly L^2-bounded inverse for any $(\varepsilon,\sigma) \in (0,\varepsilon_3] \times (0,\sigma_4]$ and $\lambda \in \Lambda(\mu_2)$, i.e.,

$$\| \,[(\mathcal{L}^{\varepsilon,\sigma} - \lambda)\,P_{\varepsilon,\sigma}]^{-1}\, \| \leq \frac{C_3}{|\,\mu_2 + \lambda\,|}$$

for some $C_3 > 0$. Hence we see that the solution $\boldsymbol{w}$ of $(\mathcal{L}^{\varepsilon,\sigma} - \lambda)\,\boldsymbol{w} = -\boldsymbol{f}_v^{\varepsilon,\sigma}\,z$ is represented as

$$\boldsymbol{w} = -\frac{\langle\, \boldsymbol{f}_v^{\varepsilon,\sigma}\,z, \phi_0^{*\,\varepsilon,\sigma}\,\rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda}\,\phi_0^{\varepsilon,\sigma} - [(\mathcal{L}^{\varepsilon,\sigma} - \lambda)\,P_{\varepsilon,\sigma}]^{-1}\,P_{\varepsilon,\sigma}\,[\boldsymbol{f}_v^{\varepsilon,\sigma}\,z].$$

Substituting the above formula into the second equation of (3.1), we obtain the following eigenvalue problem:

$$\text{(3.2)}\qquad \begin{cases} 0 = \dfrac{1}{\sigma}\,z_{xx} - \dfrac{\langle\, \boldsymbol{f}_v^{\varepsilon,\sigma}\,z, \phi_0^{*\,\varepsilon,\sigma}\,\rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda}\,g_{\boldsymbol{u}}^{\varepsilon,\sigma}\,\phi_0^{\varepsilon,\sigma} \\ \qquad\qquad -g_{\boldsymbol{u}}^{\varepsilon,\sigma}\,[(\mathcal{L}^{\varepsilon,\sigma} - \lambda)\,P_{\varepsilon,\sigma}]^{-1}\,P_{\varepsilon,\sigma}\,[\boldsymbol{f}_v^{\varepsilon,\sigma}\,z] \\ \qquad\qquad +g_v^{\varepsilon,\sigma}\,z - \lambda\,z, \quad x \in (0,1), \\ z_x = 0, \quad x = 0,1, \end{cases}$$

so that

$$\begin{aligned} 0 =& K^{\varepsilon,\sigma}(z,\lambda) \equiv \frac{\langle\, \boldsymbol{f}_v^{\varepsilon,\sigma}\,z, \phi_0^{*\,\varepsilon,\sigma}\,\rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda}\,\langle\, g_{\boldsymbol{u}}^{\varepsilon,\sigma}\,\phi_0^{\varepsilon,\sigma}, 1\,\rangle \\ &+ \langle\, g_{\boldsymbol{u}}^{\varepsilon,\sigma}\,[(\mathcal{L}^{\varepsilon,\sigma} - \lambda)\,P_{\varepsilon,\sigma}]^{-1}\,P_{\varepsilon,\sigma}\,[\boldsymbol{f}_v^{\varepsilon,\sigma}\,z], 1\,\rangle - \langle\, g_v^{\varepsilon,\sigma}\,z, 1\,\rangle + \lambda\,\langle\, z, 1\,\rangle \end{aligned}$$

is satisfied for any eigenvalue $\lambda \in \Sigma^{\varepsilon,\sigma}$ and its eigenfunction $z(x)$.

Let B_δ be a closed ball with center at the origin and radius δ in the complex plane $\mathbf{C}$. We set $\Lambda_\delta(\mu) = \Lambda(\mu) \setminus B_\delta$ for an arbitrarily fixed small constant $\delta > 0$. For a given (ε,σ)-dependent function $u^{\varepsilon,\sigma}$, we define $u^{0,0}$ by $u^{0,0} = \lim_{(\varepsilon,\sigma)\to(0,0)} u^{\varepsilon,\sigma}$. We obtain the following lemma.

LEMMA 3.2 (Sublemma 2.1 and Corollary 2.1 in [16]). *There exists $C_4 > 0$ such that for each $(\varepsilon,\sigma) \in (0,\varepsilon_3] \times (0,\sigma_4]$, $|\,\lambda\,| \leq C_4$ and $1 \leq \|\,z\,\|_{H^1(0,1)} \leq \sqrt{1 + \sigma\,C_4}$ hold for any eigenvalue $\lambda \in \Lambda_\delta(\mu_2)$ and its eigenfunction $z(x)$ with $\|\,z\,\|_{L^2(0,1)} = 1$.*

LEMMA 3.3 (Lemmas 2.2 and 2.3 in [16]). *As $(\varepsilon,\sigma) \to (0,0)$, the following assertion holds: For $z \in L^2(0,1) \cap L^\infty(0,1)$,*

(i) $[(\mathcal{L}^{\varepsilon,\sigma} - \lambda)\,P_{\varepsilon,\sigma}]^{-1}\,P_{\varepsilon,\sigma}\,[\boldsymbol{f}_v^{\varepsilon,\sigma}\,z] \to (\boldsymbol{f}_{\boldsymbol{u}}^{0,0} - \lambda)^{-1}\,[\boldsymbol{f}_v^{0,0}\,z]$ *strongly in the $L^2(0,1)$-sense;*

(ii) $\langle\, \boldsymbol{f}_v^{\varepsilon,\sigma}\,z, \phi_0^{*\,\varepsilon,\sigma}\,\rangle\,\langle\, g_{\boldsymbol{u}}^{\varepsilon,\sigma}\,\phi_0^{\varepsilon,\sigma}, 1\,\rangle/\varepsilon \to C_0\,z(x_0)$,

where

$$\begin{aligned} C_0 =& (g(\boldsymbol{h}_-(v_0), v_0) - g(\boldsymbol{h}_+(v_0), v_0)) \\ &\times \frac{\int_{\mathbf{R}} (u_{01}(\xi)\,u_{01}^*(\xi) + k\,u_{02}(\xi)\,u_{02}^*(\xi))\,d\xi}{\int_{\mathbf{R}} (u_{01\xi}(\xi)\,u_{01}^*(\xi) + u_{02\xi}(\xi)\,u_{02}^*(\xi))\,d\xi}. \end{aligned}$$

The convergence in (i) *and* (ii) *is uniform for $\lambda \in \Lambda(\mu_2)$. Furthermore if $z \in H^1(0,1)$, then the convergence in* (i) *is also uniform on a bounded set in $H^1(0,1)$.*

By (H.3) and Lemma 2.3, we easily find $C_0 < 0$ for $k \in (0,k_0]$.

We set

$$\Sigma_1 = \cap_{(p,q)\in(0,\varepsilon_3]\times(0,\sigma_4]}\overline{\cup_{(\varepsilon,\sigma)\in(0,p]\times(0,q]}\Sigma^{\varepsilon,\sigma}},$$

$$Q_1(x) = \begin{cases} f_{2u_2}(\boldsymbol{h}_-(v_0), v_0)\,(<0) & \text{for } x < x_0, \\ f_{1u_1}(\boldsymbol{h}_+(v_0), v_0)\,(<0) & \text{for } x > x_0, \end{cases}$$

$$Q_2(x) = \begin{cases} f_{2v}(\boldsymbol{h}_-(v_0), v_0)\, g_{u_2}(\boldsymbol{h}_-(v_0), v_0)\,(<0) & \text{for } x < x_0, \\ f_{1v}(\boldsymbol{h}_+(v_0), v_0)\, g_{u_1}(\boldsymbol{h}_+(v_0), v_0)\,(<0) & \text{for } x > x_0, \end{cases}$$

$$\mu_3 = \min\left\{ \mu_2,\, \langle\, Q_2/(2\,Q_1), 1\,\rangle,\, \inf_{x\in[0,x_0)\cup(x_0,1]} |\, Q_1(x)/4\,| \right\}\ (>0),$$

and assume that λ satisfies $\lambda \in (\Sigma_1 \cap \Lambda(\mu_3)) \setminus \{\,0\,\}$. By the definition of Σ_1, we see that there exists $\{\,(\hat\varepsilon_n, \hat\sigma_n, \hat\lambda_n)\,\}_{n=1}^{\infty}$ such that $\lim_{n\to\infty}(\hat\varepsilon_n, \hat\sigma_n, \hat\lambda_n) = (0,0,\lambda)$ and $\hat\lambda_n \in \Sigma^{\hat\varepsilon_n,\hat\sigma_n}$ for each n. Let $\hat z_n(x)$, which is normalized as $\|\,\hat z_n\,\|_{L^2(0,1)} = 1$, be an eigenfunction of (3.2) corresponding to $\hat\lambda_n$. We know $\langle\, g_v^{0,0}, 1\,\rangle = 0$ by construction. Since $\hat z_n(x) \to 1$ as $n \to \infty$ by virtue of Lemma 3.2, we obtain

$$0 = K^{\hat\varepsilon_n,\hat\sigma_n}(\hat z_n, \hat\lambda_n) \to K_0(\lambda) \equiv \left\langle \frac{Q_2}{Q_1 - \lambda} + \lambda, 1 \right\rangle \quad \text{as } n \to \infty.$$

Since $Q_1(x) \le Q_1(x) - \lambda < 0$ holds for any $x \in [0, x_0) \cup (x_0, 1]$ and $\lambda \in (-\mu_3, 0]$, we have

$$0 = K_0(\lambda) \begin{cases} > 0 & \text{if } \lambda > 0, \\ \ge \langle\, Q_2/Q_1, 1\,\rangle + \lambda > 0 & \text{if } \lambda \in (-\mu_3, 0], \end{cases}$$

$$0 = \text{Re } K_0(\lambda) - \frac{\text{Re }\lambda}{\text{Im }\lambda}\,\text{Im } K_0(\lambda)$$
$$= \int_0^1 \frac{Q_2(x)\,(Q_1(x) - 2\,\text{Re }\lambda)}{|\,Q_1(x) - \lambda|^2}\,dx > 0 \quad \text{if } \lambda \in \Lambda(\mu_3) \setminus \mathbf{R}.$$

This is a contradiction, which leads to $\Sigma_1 \cap \Lambda(\mu_3) \subset \{\,0\,\}$.

We define $\mathcal{K}^{\varepsilon,\sigma,\lambda}$ by

$$\mathcal{K}^{\varepsilon,\sigma,\lambda}\, z = \frac{1}{\sigma}\, z_{xx} - g_{\boldsymbol{u}}^{\varepsilon,\sigma}\,[(\mathcal{L}^{\varepsilon,\sigma} - \lambda)\, P_{\varepsilon,\sigma}]^{-1}\, P_{\varepsilon,\sigma}\,[\boldsymbol{f}_v^{\varepsilon,\sigma}\, z] + g_v^{\varepsilon,\sigma}\, z - \lambda\, z.$$

Then we have the following lemma.

LEMMA 3.4 (Lemma 3.1 in [16]). *There exist $\varepsilon_4 > 0$, $\sigma_5 > 0$, and $\mu_4 > 0$ such that $\mathcal{K}^{\varepsilon,\sigma,\lambda}$ has a uniformly bounded inverse $(\mathcal{K}^{\varepsilon,\sigma,\lambda})^{-1} : H^{-1}(0,1) \to H_N^1(0,1)$ for any $(\varepsilon,\sigma) \in (0,\varepsilon_4] \times (0,\sigma_5]$ and $\lambda \in \Lambda(\mu_4)$, which is continuous on (ε,σ) and analytical on λ in the operator norm sense, where $H_N^1(0,1) = \{\, z \in H^1(0,1) \,|\, z_x(0) = 0 = z_x(1)\,\}$. Furthermore, $(\mathcal{K}^{\varepsilon,\sigma,\lambda})^{-1}\, z \to -\langle\, z, 1\,\rangle / K_0(\lambda)$ as $(\varepsilon,\sigma) \to (0,0)$ holds for any $\lambda \in \Lambda(\mu_4)$.*

Let $\lambda^{\varepsilon,\sigma}$ be an eigenvalue of (3.1) for (ε,σ) which satisfies $\lambda^{\varepsilon,\sigma} \to 0$ as $(\varepsilon,\sigma) \to (0,0)$, and let $(\boldsymbol{w}^{\varepsilon,\sigma}, z^{\varepsilon,\sigma})(x)$ be an eigenfunction of (3.1) corresponding to $\lambda^{\varepsilon,\sigma}$. Since $z^{\varepsilon,\sigma}(x)$ is represented as

$$z^{\varepsilon,\sigma} = \frac{\langle\, \boldsymbol{f}_v^{\varepsilon,\sigma}\, z^{\varepsilon,\sigma}, \phi_0^{*\,\varepsilon,\sigma}\,\rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda^{\varepsilon,\sigma}} \left(\mathcal{K}^{\varepsilon,\sigma,\lambda^{\varepsilon,\sigma}}\right)^{-1} [g_{\boldsymbol{u}}^{\varepsilon,\sigma}\, \phi_0^{\varepsilon,\sigma}],$$

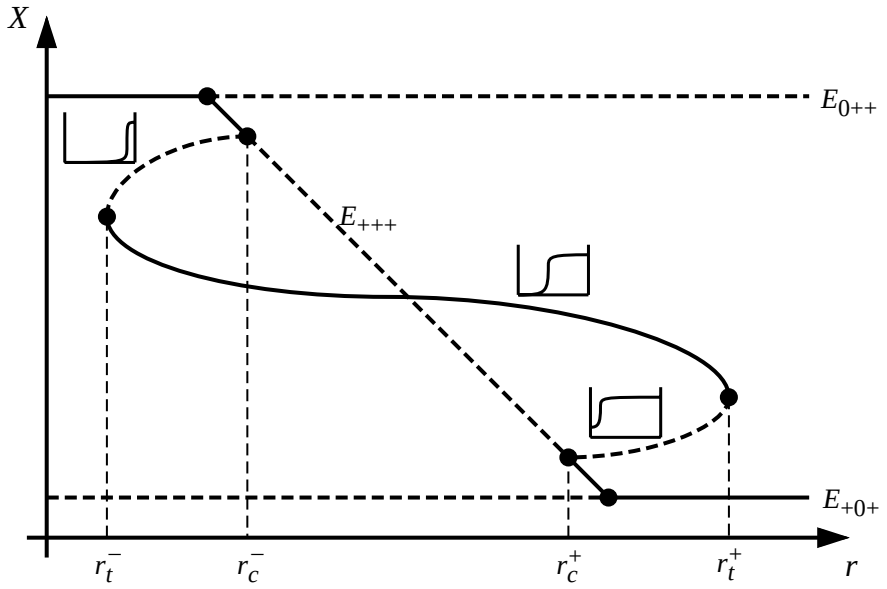

FIG. 4. *Bifurcation picture of positive equilibrium solutions. Solid curves indicate the stable branch, and broken ones the unstable branch. The profile of the u_1-component on the branch is shown. E_{0++} and E_{+0+} indicate the equilibrium points $(0, r/(\beta k), (a\beta k - r)/(\beta k^2))$ and $(r, 0, 1-r)$, respectively.*

we find

$$\langle \boldsymbol{f}_v^{\varepsilon,\sigma}\, z^{\varepsilon,\sigma}, \phi_0^{*\,\varepsilon,\sigma} \rangle \left\{ 1 - \frac{\langle \boldsymbol{f}_v^{\varepsilon,\sigma}\, \left(\mathcal{K}^{\varepsilon,\sigma,\lambda^{\varepsilon,\sigma}}\right)^{-1} [g_{\boldsymbol{u}}^{\varepsilon,\sigma}\, \phi_0^{\varepsilon,\sigma}], \phi_0^{*\,\varepsilon,\sigma} \rangle}{\zeta_0^{\varepsilon,\sigma} - \lambda^{\varepsilon,\sigma}} \right\} = 0.$$

If $\langle \boldsymbol{f}_v^{\varepsilon,\sigma}\, z^{\varepsilon,\sigma}, \phi_0^{*\,\varepsilon,\sigma} \rangle = 0$ holds, then $(\boldsymbol{w}^{\varepsilon,\sigma}, z^{\varepsilon,\sigma})(x) = 0$ is satisfied for any $x \in [0,1]$. Therefore we obtain $\langle \boldsymbol{f}_v^{\varepsilon,\sigma}\, z^{\varepsilon,\sigma}, \phi_0^{*\,\varepsilon,\sigma} \rangle \neq 0$. From $K_0(0) > 0$ and Lemmas 3.1, 3.3, and 3.4, we have

$$\frac{\lambda^{\varepsilon,\sigma}}{\varepsilon} = \frac{1}{\varepsilon} \left\{ \zeta_0^{\varepsilon,\sigma} - \left\langle \boldsymbol{f}_v^{\varepsilon,\sigma} \left(\mathcal{K}^{\varepsilon,\sigma,\lambda^{\varepsilon,\sigma}}\right)^{-1} [g_{\boldsymbol{u}}^{\varepsilon,\sigma}\, \phi_0^{\varepsilon,\sigma}], \phi_0^{*\,\varepsilon,\sigma} \right\rangle \right\} \to C_0/K_0(0) < 0$$

as $(\varepsilon, \sigma) \to (0,0)$ for any $k \in (0, k_0]$.

By summarizing the above results, we arrive at the fact that $(\boldsymbol{u}^{\varepsilon,\sigma}, v^{\varepsilon,\sigma})(x)$ is stable for sufficiently small $\varepsilon > 0$ and $\sigma > 0$.

4. Concluding remarks. In this paper, we have proved that there are stable SIP equilibrium solutions of the 3-component reaction-diffusion system which describes the interaction of one predator and two competing prey species. This result is ecologically stated in the following: Consider the situation where coexistence of two competing species never occurs even in the presence of a predator if the diffusion rates of the three species are very large. Then, if the diffusion rates of two competing species are much smaller than that of the predator ($\varepsilon > 0$ and $\sigma > 0$ are sufficiently small), predator-mediated coexistence possibly occurs so that two competing species coexist with spatial segregation.

For the existence of stable SIP equilibrium solutions, we assumed r satisfied the inequality (H.3) for fixed $k > 0$. It would be interesting to consider the case when (H.3) is violated. In Figure 4, the global structure of positive equilibrium solutions is

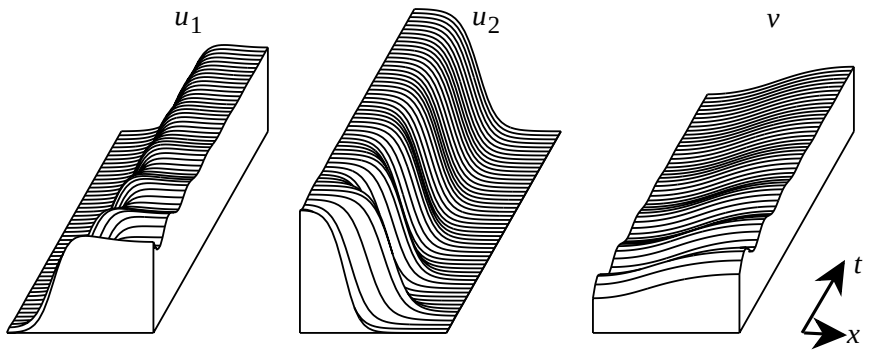

Figure 5a. $a = 0.85$, $\alpha = 0.1$ and $\sigma = 100$.

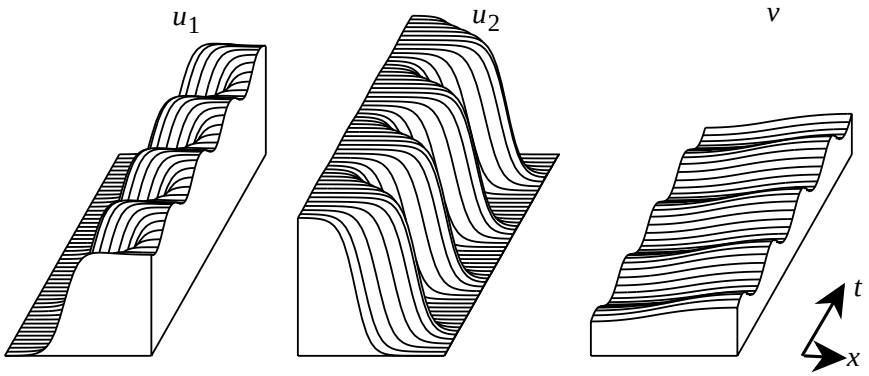

Figure 5b. $a = 0.95$, $\alpha = 0.05$ and $\sigma = 100$.

FIG. 5. *Numerical simulations of equilibrium solutions* (a) *and periodic solutions* (b), *where* $\varepsilon = 0.02$, $d = 1$, $b = 1.5$, $c = 1$, $k = 0.1$, $r = 0.4$, *and* $\beta = 1$.

numerically shown when r is globally varied. The branch of SIP equilibrium solutions with a single layer bifurcates from E_{+++} at $r = r_c^-$ and $r = r_c^+$ and consists of three parts: (i) an upper branch ($r_t^- < r < r_c^-$), (ii) a middle branch ($r_t^- < t < r_t^+$), and (iii) a lower branch ($r_c^+ < r < r_t^+$). The stable solutions which we discussed in the previous section correspond to the middle branch. On the other hand, there are SIP equilibrium solutions with a boundary layer in a neighborhood of $x = 1$ or $x = 0$ which correspond to the upper and lower branches, respectively. Quite recently the existence and instability of such solutions have been proved in [8].

In this paper, we restricted our discussion to the case when $\sigma > 0$ is small. When $\sigma > 0$ is not so small, the situation is changed and our equilibrium solutions might be destabilized through Hopf bifurcation so that there are periodic solutions as shown in Figure 5. These periodic solutions demonstrate spatially oscillating segregation of two competing species. This will be discussed elsewhere.
