THEOREM 2.1. *Let $\phi(\mathbf{x})$ satisfy the dilation equation (2.1) with dilation $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ and coefficient mask $C(z, w) = A(z) + wB(z)$, where $A(1) \neq 0$ and $B(0) \neq 0$. Let $r \in \mathbb{N}$ and let ν be an odd integer with $\nu \geq \deg A$. If the scaling function $\phi(\mathbf{x})$ is orthogonal and has accuracy $r+1$, then the polynomials $A(z)$ and $B(z)$ have the form*

$$z^\nu A(z^{-1}) = H^r(z)L(z)S(z^2), \tag{2.6}$$

$$B(z) = H^r(z)L(-z)Q(z^2)H^{2r}(-z), \tag{2.7}$$

where $L(z)$, $S(z)$, and $Q(z)$ are any polynomials that satisfy

$$\mathcal{P}_S(z^2) = 1 - \left(\frac{1-z^2}{4}\right)^r \left(\frac{1-z^{-2}}{4}\right)^r \mathcal{P}_Q(z^2), \tag{2.8}$$

$$\mathcal{P}_L(z) = \sum_{j=0}^{r-1} \binom{r+j-1}{j} \left(\frac{1-u}{2}\right)^j + (1-u)^r u\, R(u^2), \quad u := \frac{1}{2}(z + z^{-1}), \tag{2.9}$$

$$S(1) = L(1) = 1, Q(1) = (-1)^r L(-1), \quad \text{and} \quad L(0)Q(0) \neq 0 \tag{2.10}$$

and $R(z)$ is an arbitrary polynomial.

Remark. The converse of Theorem 2.1 holds if, in addition to (2.6)–(2.10), the mask $C(z, w)$ satisfies Cohen's criterion (2.2).

Theorem 2.1 suggests the following procedure for obtaining the coefficients of $C(z, w)$:

(i) Choose polynomials Q and R so that the right-hand sides of (2.8)–(2.9) are nonnegative along the unit circle $|z| = 1$ (thus ensuring that the next step can be performed).

(ii) Using some spectral factorization method, make a list of all polynomials S and L that satisfy (2.8)–(2.10). Choose a specific pair. (Observe that if $R = 0$, then the polynomial L is one of the univariate orthogonal coefficients masks with accuracy r constructed by Daubechies [7].)

(iii) Substitute L, S, and Q in (2.6)–(2.7) and expand. Choose an odd $\nu \geq \deg A$.

Note that the choices in step (ii) are not unique. Unlike the univariate case, there is no obvious way to single out a "minimal phase" coefficient mask $C(z, w)$.

The minimal degree of $A(z)$ and $B(z)$ in Theorem 2.1 is $4r - 1$ and is achieved if

$$Q(z) = \text{const} = (-1)^r L(-1), \quad R(z) = \text{const} = 0, \quad \text{and} \quad \nu = 4r - 1. \tag{2.11}$$

There are $2^{1+2\lfloor r/2 \rfloor}$ coefficient masks $C(z, w)$ that satisfy the conditions (2.11) and $A(0) \neq 0$ in addition to the conditions in Theorem 2.1. Denote the set of those masks by $\mathcal{C}_{r+1}$. Every $C(z, w)$ in $\mathcal{C}_{r+1}$ produces a scaling function $\phi(\mathbf{x})$ with accuracy $r + 1$. Denote the set of those scaling functions by Φ_{r+1}.

Our second theorem states that all functions in Φ_{r+1} are compactly supported orthogonal nonseparable scaling functions that can be made arbitrarily smooth by choosing the accuracy $r + 1$ large enough. The proof is in section 4.

THEOREM 2.2. *Let* $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ *and let* $\phi \in \Phi_{r+1}$. *Then*

(i) ϕ *is an orthogonal scaling function with accuracy* $r + 1$;

(ii) $\operatorname{supp} \phi \subseteq [0, 4r + 1] \times [0, 4r]$;

(iii) ϕ *is nonseparable;*

(iv) *if* $r \geq 5$, *then* $\phi \in C^{r - \mu_r - 2}$, *where*

$$\mu_r := \frac{1}{2} \log_2 \left(\sum_{j=0}^{r-1} \binom{r + j - 1}{j} \left(\frac{3}{4}\right)^j \right).$$

Furthermore,

$$r - \mu_r > \left(1 - \frac{1}{2} \log_2 3\right) r + \frac{1}{2} \log_2 3 \tag{2.12}$$

and

$$\lim_{r \to \infty} \frac{r - \mu_r - 2}{r} = 1 - \frac{1}{2} \log_2 3 \approx 0.2075. \tag{2.13}$$

Remark. As in the univariate case, the statements (2.12)–(2.13) guarantee the existence of orthogonal wavelets of any desired smoothness. In particular, $\Phi_{5+1} \subset C^0$, $\Phi_{9+1} \subset C^1$, and $\Phi_{13+1} \subset C^2$. The smoothness estimate $\phi \in C^{r - \mu_r - 2}$ applies to all ϕ in Φ_{r+1} uniformly and is not sharp. Lemma 5.1 provides sharper smoothness estimates for individual functions in Φ_{r+1}, involving numerical computations.

If $\phi(\mathbf{x})$ is an orthogonal scaling function, then its associated *wavelet* $\psi(\mathbf{x})$ has the form

$$\psi(\mathbf{x}) = 2 \sum_{\mathbf{n} \in \mathbb{Z}^2} d_{\mathbf{n}} \phi(M\mathbf{x} - \mathbf{n}).$$

FIG. 2.1. *The quincunx and the column sublattice.*

Obviously, the wavelet ϕ has the same smoothness as the scaling function ϕ. It is known that if the *wavelet coefficients* (*high-pass filter coefficients*) $d_{\mathbf{n}}$ are given by

$$d_{\mathbf{n}} = (-1)^{n_1} c_{\mathbf{e}-\mathbf{n}}, \quad \text{where } \mathbf{n} = (n_1, n_2) \text{ and } \mathbf{e} = (1, 0),$$

then the wavelet $\psi(\mathbf{x})$ is orthogonal to $\{\phi(\mathbf{x} - \mathbf{k}) : \mathbf{k} \in \mathbb{Z}^2\}$, and its lattice translates and dilates form an orthogonal basis of $L^2(\mathbb{R}^2)$ [13, 14].

Although Theorems 2.1 and 2.2 are formulated for $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$, they can be generalized [2] to other expanding matrices with integer entries and $|\det(M)| = 2$. Each such matrix transforms the lattice $\mathbb{Z}^2$ into three types of sublattices: the *quincunx*, the *column* sublattice (see Figure 2.1), and the *row* sublattice (the row sublattice is merely a transpose of the column sublattice).

The accuracy and the orthogonality conditions depend only on the sublattice type and not on the dilation matrix, as we shall see in section 3. Therefore, Theorem 2.1 still holds if $\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ is replaced by any other expanding integral matrix M that generates the column sublattice $2\mathbb{Z} \times \mathbb{Z}$, such as $\left(\begin{smallmatrix} 0 & -2 \\ 1 & 0 \end{smallmatrix}\right)$. If $\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ is replaced by the quincunx matrix $\left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$, or any other matrix that generates the quincunx lattice, such as $\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$, then $A(z) + wB(z)$ must be replaced by $A(z) + wzB(z)$, as we shall see at the end of section 5.

In contrast, the smoothness of the scaling function does depend on the dilation matrix. Theorem 2.2 can be extended to any dilation M with the properties $M^2 = \pm 2I$, such as $\left(\begin{smallmatrix} 0 & -2 \\ 1 & 0 \end{smallmatrix}\right)$ or $\left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$. Although the quincunx matrix $\left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ has often been used in nonseparable constructions, the authors know of no scaling functions that are both differentiable and orthogonal with respect to the quincunx matrix; it is quite possible that $\left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ admits no such scaling functions at all.

3. Accuracy and orthogonality conditions. In this section we prove Theorem 2.1. First, we study how the accuracy and the orthogonality of the scaling function restrict the scaling coefficients. Then, we derive the formulas (2.6)–(2.10). Recall that $H(z) = \frac{1}{2}(1 + z)$.

Accuracy. The accuracy of the scaling function ϕ has many equivalent formulations, such as the vanishing moments condition for the wavelet ($\int \mathbf{x}^\alpha \psi(\mathbf{x})\, d\mathbf{x} = 0$, $|\alpha| < r$) or the "sum rules" on the coefficients $c_{\mathbf{n}}$ [4]. Here, we prefer to work with the sum rules. Applied to our dilation matrix $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$, a general result by Cabrelli, Heil, and Molter [4] states that an orthogonal scaling function ϕ has accuracy r if and only if its coefficient mask $C(z, w)$ satisfies the following *accuracy condition*:

$$\frac{\partial^{p+q}}{\partial z^p \partial w^q} C(-1, 1) = 0 \quad \text{for all } p, q \geq 0 \text{ with } p + q < r. \tag{3.1}$$

Observe that the analogous condition for a univariate polynomial $C(z)$ implies the factorization $C(z) = (1+z)^r Q(z)$ for some $Q(z)$. Unfortunately, bivariate polynomials $C(z, w)$ cannot be described in such a simple way. (This fact is one of the main

obstacles in studying nonseparable bivariate wavelets.) Nevertheless, the accuracy condition (3.1) takes on a simple form for our special two-row mask $C(z,w)$.

LEMMA 3.1. *Let* $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$. *The dilation equation* (2.1) *with coefficient mask* $C(z,w) = A(z) + wB(z)$ *has accuracy* $r+1$ *if and only if*

$$A(z) = H^r(z)A_0(z), \quad B(z) = H^r(z)B_0(z), \tag{3.2}$$

$$A_0(-1) + B_0(-1) = 0. \tag{3.3}$$

Proof. It is easy to check that (3.2)–(3.3) imply (3.1). We now prove the converse. By taking $q = 0$ in (3.1), we obtain $A^{(p)}(-1) + B^{(p)}(-1) = 0$ for all $0 \le p \le r$. By taking $q = 1$, we obtain $B^{(p)}(-1) = 0$ for all $0 \le p \le r-1$. These conditions imply $A^{(p)}(-1) = 0$ for all $0 \le p \le r-1$. Hence $A(z) = H^r(z)A_0(z)$ and $B(z) = H^r(z)B_0(z)$. Finally, $A^{(r)}(-1) + B^{(r)}(-1) = 0$ yields $A_0(-1) + B_0(-1) = 0$. ∎

Note that, unlike the univariate case, here accuracy $r+1$ corresponds to r Haar factors plus one extra condition (3.3).

Orthogonality. If $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$, the orthogonality condition (2.3) is equivalent to

$$\mathcal{P}_C(z,w) + \mathcal{P}_C(-z,w) = 1.$$

For the special two-row coefficient mask (2.4), this condition splits further into the following two conditions imposed on the polynomials A and B:

$$\mathcal{P}_A(z) + \mathcal{P}_A(-z) + \mathcal{P}_B(z) + \mathcal{P}_B(-z) = 1, \tag{3.4}$$

$$A(z^{-1})B(z) + A(-z^{-1})B(-z) = 0. \tag{3.5}$$

Remark. The second condition means that $A(z^{-1})B(z)$ contains no even powers of z. Therefore, $\deg A$ must be odd if $B(0) \neq 0$.

The main task in the remainder of this section is to solve (3.2)–(3.5) for the unknown polynomials A and B. Observe that (3.2)–(3.3) are linear and that (3.4)–(3.5) are quadratic.

First, we investigate (3.5).

LEMMA 3.2. *For every polynomial* $p(z) = z^{2n}p_1(z)$ *with* $p_1(0) \neq 0$ *and* $n \ge 0$, *there exist polynomials* q *and* ℓ *such that* $p(z) = q(z^2)\ell(z)$ *and* $\gcd(\ell(z), \ell(-z)) = 1$.

Proof. Consider $t(z) := \gcd(p(z), p(-z))$. Clearly, $t(z) = t(-z) = q(z^2)$ for some polynomial $q(z)$. Let $\ell(z) := p(z)/q(z^2)$, and observe that $\gcd(\ell(z), \ell(-z)) = 1$. ∎

LEMMA 3.3. *The following are equivalent:*

(i) *The polynomials* A *and* B *satisfy condition* (3.5) *and* $B(0) \neq 0$.

(ii) *There exist an odd integer* $\nu \ge \deg A$ *and real polynomials* s, q, *and* ℓ *such that* $z^\nu A(z^{-1}) = s(z^2)\ell(z)$, $B(z) = q(z^2)\ell(-z)$, *and* $\gcd(\ell(z), \ell(-z)) = 1$.

Proof. The implication (ii) ⇒ (i) follows from

$$z^\nu s(z^2)\ell(z)q(z^2)\ell(-z) + (-z)^\nu s(z^2)\ell(-z)q(z^2)\ell(z) = 0.$$

Assume that (i) holds, and fix an odd $\nu \ge \deg A$. Lemma 3.2 allows us to write $z^\nu A(z^{-1}) = s(z^2)\ell(z)$ and $B(z) = q(z^2)m(z)$ for some polynomials s, q, ℓ, and m. Substituting $A(z^{-1})$ and $B(z)$ in (3.5) yields

$$m(z)\ell(z) = m(-z)\ell(-z).$$

Since $\gcd(m(z), m(-z)) = \gcd(\ell(z), \ell(-z)) = 1$, it follows that $m(z) = \ell(-z)$. ∎

Next, we take into account the accuracy of $C(z,w)$.

LEMMA 3.4. *Let A and B be polynomials with $A(1) \neq 0$ and $B(0) \neq 0$. Then the following are equivalent:*

(i) *The two-row coefficient mask $C(z,w) = A(z) + wB(z)$ satisfies* (3.5) *and has accuracy $r+1$.*

(ii) *There exists an odd integer $\nu \geq \deg A$ and real polynomials S, Q, and L with $L(0)Q(0) \neq 0$, $S(1) = L(1) = 1$, and $Q(1) = (-1)^r L(-1)$ such that*

$$z^\nu A(z^{-1}) = H^r(z)L(z)S(z^2),$$
$$B(z) = H^r(z)L(-z)Q(z^2)H^{2r}(-z).$$

Proof. The implication (ii)⇒(i) follows from Lemmas 3.1 and 3.3 by letting $s(z^2) = S(z^2)$, $q(z^2) = Q(z^2)\big(\frac{1-z^2}{2}\big)^r$, and $\ell(z) = H^r(z)L(z)$. We now prove that (i)⇒(ii). By Lemma 3.1, $H^r(z)$ divides both $A(z)$ and $B(z)$. Therefore, $z = -1$ is a root of multiplicity $2r$ of $P(z) := z^\nu A(z^{-1})B(z)$. On the other hand, $P(z) = P(-z)$ by (3.5); hence $z = 1$ is another root of multiplicity $2r$ of $P(z)$. Since $A(1) \neq 0$ by assumption, $H^{2r}(-z)$ must divide $B(z)$. Define

$$A_1(z) := A(z)z^r/H^r(z), \quad \text{and} \quad B_1(z) := B(z)/\big(H^r(z)H^{2r}(-z)\big).$$

Noting that $H(z^{-1}) = z^{-1}H(z)$, we rewrite

$$A(z^{-1})B(z) = H(z)^{2r}H(-z)^{2r}A_1(z^{-1})B_1(z)$$

and substitute in (3.5). Factoring out $H(z)^{2r}H(-z)^{2r}$ yields the equation

$$A_1(z^{-1})B_1(z) + A_1(-z^{-1})B_1(-z) = 0.$$

Therefore, Lemma 3.2 applies to A_1 and B_1, and we obtain the desired factorization in (ii). Since $B(1) = 0$, and therefore $A(1) = 1$, we can normalize L and S so that $L(1) = S(1) = 1$. The only restriction on Q, that $Q(1) = (-1)^r L(-1)$, then follows directly from the extra accuracy condition (3.3). ∎

Finally, to prove Theorem 2.1 we need to solve the remaining equation, (3.4).

Proof of Theorem 2.1. We need only show that the polynomials S, Q and L in Lemma 3.4 have the autocorrelations given by (2.8) and (2.9). By Lemma 3.4,

$$\mathcal{P}_A(z) = \mathcal{P}_H^r(z)\mathcal{P}_S(z^2)\mathcal{P}_L(z), \quad \text{and} \quad \mathcal{P}_B(z) = \mathcal{P}_H^r(z)\mathcal{P}_H^{2r}(-z)\mathcal{P}_L(-z)\mathcal{P}_Q(z^2).$$

Hence $\mathcal{P}_A(z) + \mathcal{P}_B(-z) = \mathcal{P}_H^r(z)\mathcal{P}_L(z)U(z^2)$, where

$$U(z^2) := \mathcal{P}_S(z^2) + \mathcal{P}_H^r(-z)\mathcal{P}_H^r(z)\mathcal{P}_Q(z^2).$$

Therefore, the orthogonality condition (3.4) can be factored as follows:

$$\big(\mathcal{P}_H^r(z)\mathcal{P}_L(z) + \mathcal{P}_H^r(-z)\mathcal{P}_L(-z)\big)U(z^2) = 1.$$

It follows that $U(z^2)$ must be a constant. In particular, $U(z^2) = U(1) = \mathcal{P}_S(1) = 1$, which immediately yields (2.8). Finally, the equation

$$\mathcal{P}_H^r(z)\mathcal{P}_L(z) + \mathcal{P}_H^r(-z)\mathcal{P}_L(-z) = 1 \tag{3.6}$$

characterizes all univariate orthogonal masks with accuracy r and was solved by Daubechies [7]. The solution to (3.6) is given by (2.9). ∎

Remark. Although the results in this section are formulated for $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$, the accuracy and orthogonality conditions (2.3) and (3.1) depend only on the sublattice $M\mathbb{Z}^2$ (in our case, the column sublattice), not on the particular dilation matrix. Therefore, Theorem 2.1 and all results in this section apply to any other integer expanding matrix M that satisfies $M\mathbb{Z}^2 = 2\mathbb{Z} \times \mathbb{Z}$. Corollary 5.3 and Lemma 5.4 explain how to apply Theorem 2.1 to other dilation matrices, such as $\left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ or $\left(\begin{smallmatrix} 2 & 0 \\ 0 & 2 \end{smallmatrix}\right)$.

The statement of Theorem 2.1 contains two assumptions: $B(0) \neq 0$ and $A(1) \neq 0$. Now we explain why these assumptions impose no loss of generality.

First, by shifting the variables in the dilation equation (2.1), one can check that a shift of the coefficient mask by a vector $\mathbf{s}$ results in a shift of the scaling function by $(M - I)\mathbf{s}$. Therefore, without loss of generality, the coefficients of any mask $C(z, w)$ can always be shifted so that $C(z, w)$ contains no negative powers of w, and so that the smallest power of z in $B(z)$ is zero. (The Laurent polynomial $A(z)$ may contain negative powers of z; nevertheless, Theorem 2.1 holds.)

Second, suppose that $A(1) = 0$ and $B(1) \neq 0$ (recall that $A(1) + B(1) = 1$). Change the variables $\mathbf{x} \mapsto -\mathbf{x}$ and $\mathbf{n} \mapsto -\mathbf{n}$ in (2.1), and note (cf. Lemma 5.2) that if $\phi(\mathbf{x})$ solves (2.1) with the coefficient mask $C(z, w)$, then $\phi(-\mathbf{x})$ solves (2.1) with the coefficient mask $\tilde{C}(z, w) = C(z^{-1}, w^{-1})$. Shift the coefficients of $\tilde{C}(z, w)$ to the first quadrant (that is, multiply by $z^N w$, where $N = \max(\deg A, \deg B)$) and observe that $z^N w\, \tilde{C}(z, w) = \tilde{A}(z) + w\tilde{B}(z)$, where $\tilde{A}(1) = B(1) \neq 0$. The shift of $\phi(-\mathbf{x})$ is orthogonal and has accuracy r if and only if $\phi(\mathbf{x})$ is orthogonal and has accuracy r. So the assumption $A(1) \neq 0$ causes no loss of generality in Theorem 2.1.

4. Smoothness. In this section we prove Theorem 2.2. To prove the orthogonality of a scaling function $\phi \in \Phi_{r+1}$, we check Cohen's criterion (4.6). We establish the smoothness of ϕ by estimating the decay of its Fourier transform $\widehat{\phi}$ in a series of lemmas. In this section, $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ and $W = M^{\mathrm{T}}$.

The *symbol* of the dilation equation (2.1) with coefficient mask $C(z, w)$ is the trigonometric polynomial $m(\omega_1, \omega_2) := C(e^{i\omega_1}, e^{i\omega_2})$. Taking the Fourier transform of (2.1) and iterating, we obtain

$$\widehat{\phi}(\omega) = \widehat{\phi}(0) \cdot \prod_{j=1}^{\infty} m(W^{-j}\omega). \tag{4.1}$$

Since $W^{-2} = \frac{1}{2}I$, the infinite product (4.1) breaks into two parts:

$$\prod_{j=1}^{\infty} m(W^{-j}\omega) = \left(\prod_{j=1}^{\infty} m(2^{-j}\omega)\right)\left(\prod_{j=1}^{\infty} m(2^{-j}W\omega)\right). \tag{4.2}$$

Our goal is to derive an estimate for $\prod_{j=1}^{\infty} m(2^{-j}\omega)$ when $C(z, w) \in \mathcal{C}_{r+1}$ by using only the first frequency ω_1.

First, let $C(z, w) = H(z) = \frac{1}{2}(1 + z)$ in (2.1). It can be checked that (2.1) is solved by the Haar scaling function $\chi_{[0,1)^2}$ and that

$$\prod_{j=1}^{\infty} m_H(W^{-j}\omega) = \widehat{\chi_{[0,1)}}(\omega_1) \cdot \widehat{\chi_{[0,1)}}(\omega_2) = \frac{(e^{i\omega_1} - 1)}{i\omega_1} \cdot \frac{(e^{i\omega_2} - 1)}{i\omega_2},$$

where $m_H(\omega_1, \omega_2) := H(e^{i\omega_1})$. Therefore, there is a constant $c > 0$ such that

$$\left|\prod_{j=1}^{\infty} m_H(W^{-j}\omega)\right| \leq c \cdot \big(1 + |\omega_1|\big)^{-1}\big(1 + |\omega_2|\big)^{-1}. \tag{4.3}$$

Next, fix $r \in \mathbb{N}$, and consider any coefficient mask $C(z,w) \in \mathcal{C}_{r+1}$, as described in Theorem 2.1 and (2.11). The corresponding symbol has the form

$$m(\omega_1,\omega_2) = C(e^{i\omega_1}, e^{i\omega_2}) = H^r(e^{i\omega_1})\big(A_0(e^{i\omega_1}) + e^{i\omega_2}B_0(e^{i\omega_1})\big).$$

Define

$$q(\omega_1,\omega_2) := A_0(e^{i\omega_1}) + e^{i\omega_2}B_0(e^{i\omega_1}) \quad \text{and} \quad \ell(\omega_1) := |A_0(e^{i\omega_1})| + |B_0(e^{i\omega_1})|. \tag{4.4}$$

Clearly, $|q(\omega_1,\omega_2)| \le \ell(\omega_1)$. We estimate $\ell(\omega_1)$ in a series of lemmas. Define

$$T_r(y) := \sum_{j=0}^{r-1} \binom{r+j-1}{j} y^j. \tag{4.5}$$

LEMMA 4.1. *Let $L(z)$ satisfy* (2.9). *Assume $r \ge 1$. Then*

$$\mathcal{P}_H^r(-e^{i\omega_1})L^2(-1) \le T_r\left(\sin^2\frac{\omega_1}{2}\right),$$

and equality holds only if $\omega_1 \equiv \pi \pmod{2\pi}$.

Proof. From (2.9) we obtain $L^2(-1) = \mathcal{P}_L(-1) = T_r(1) = \sum_{j=0}^{r-1}\binom{r+j-1}{j}$. By the definition of H in (2.5),

$$\mathcal{P}_H^r(-e^{i\omega_1}) = \left(\frac{1-\cos\omega_1}{2}\right)^r = \left(\sin\frac{\omega_1}{2}\right)^{2r} \le \left(\sin\frac{\omega_1}{2}\right)^{2j} \quad \text{for all } j \le r.$$

Hence

$$\begin{aligned} L^2(-1)\mathcal{P}_H^r(-e^{i\omega_1}) &= \sum_{j=0}^{r-1}\binom{r+j-1}{j}\left(\sin\frac{\omega_1}{2}\right)^{2r} \\ &\le \sum_{j=0}^{r-1}\binom{r+j-1}{j}\left(\sin\frac{\omega_1}{2}\right)^{2j} = T_r\left(\sin^2\frac{\omega_1}{2}\right). \end{aligned}$$

Because the coefficients of T_r are positive, equality holds only when $\sin^2\frac{\omega_1}{2} = 1$, that is, when $\omega_1 \equiv \pi \pmod{2\pi}$. ∎

COROLLARY 4.2. *There exist real polynomials S and L that satisfy* (2.8)–(2.11).

Proof. We need only show that (2.8) defines a valid autocorrelation; that is,

$$1 - \mathcal{P}_H^r(z)\mathcal{P}_H^r(-z)L^2(-1) \ge 0 \quad \text{for all} \quad |z| = 1.$$

Let $|z| = 1$. From Lemma 4.1 and (3.6) we obtain

$$\mathcal{P}_H^r(z)\mathcal{P}_H^r(-z)L^2(-1) \le \mathcal{P}_H^r(z)\mathcal{P}_L(z) = 1 - \mathcal{P}_H^r(-z)\mathcal{P}_L(-z) \le 1.$$

The last inequality holds because $\mathcal{P}_H(z) \ge 0$ and $\mathcal{P}_L(z) \ge 0$ for $|z| = 1$. ∎

LEMMA 4.3. $|A_0(e^{i\omega_1})|^2 \le T_r(\sin^2\frac{\omega_1}{2})$ *and* $|B_0(e^{i\omega_1})|^2 \le T_r(\sin^2\frac{\omega_1}{2})$. *Each equality holds only if $\omega_1 \equiv \pi \pmod{2\pi}$.*

Proof. By the construction in Theorem 2.1 and (2.11) we have

$$\begin{aligned} \mathcal{P}_{A_0}(z) &= \mathcal{P}_L(z)\mathcal{P}_S(z^2) = \mathcal{P}_L(z)\big(1 - \mathcal{P}_H^r(z)\mathcal{P}_H^r(-z)L^2(-1)\big), \\ \mathcal{P}_{B_0}(z) &= \mathcal{P}_H^r(-z)\mathcal{P}_H^r(-z)\mathcal{P}_L(-z)L^2(-1). \end{aligned}$$

Since $\mathcal{P}_H^r(e^{i\omega}) \geq 0$ for all ω,

$$|A_0(e^{i\omega_1})|^2 = \mathcal{P}_{A_0}(e^{i\omega_1}) \leq \mathcal{P}_L(e^{i\omega_1}) \cdot 1 = T_r(\sin^2 \tfrac{\omega_1}{2}).$$

Observe that (3.6) yields $0 \leq \mathcal{P}_H^r(-z)\mathcal{P}_L(-z) \leq 1$ for $z = e^{i\omega_1}$. Therefore,

$$|B_0(e^{i\omega_1})|^2 = \mathcal{P}_{B_0}(e^{i\omega_1}) \leq \mathcal{P}_H^r(-e^{i\omega_1}) \cdot 1 \cdot L^2(-1).$$

Lemma 4.1 completes the inequality for B_0. □

Before we proceed with the estimate of the infinite product (4.2), we recall the following lemma (without proof) from Daubechies [8, pp. 220–226]:

LEMMA 4.4 (Cohen and Conze [5]). *Let* $\mu_r := \frac{1}{2}\log_2 T_r(\frac{3}{4})$. *Then*

$$T_r\big(\sin^2 \tfrac{\omega_1}{2}\big) \leq T_r\big(\tfrac{3}{4}\big) \quad \text{if } |\omega_1| \leq \tfrac{2\pi}{3},$$
$$T_r(\sin^2 \omega_1) T_r\big(\sin^2 \tfrac{\omega_1}{2}\big) \leq T_r^2\big(\tfrac{3}{4}\big) \quad \text{if } \tfrac{2\pi}{3} < |\omega_1| \leq \pi.$$

Furthermore,

$$r - \mu_r > \left(1 - \frac{1}{2}\log_2 3\right) r + \frac{1}{2}\log_2 3,$$
$$\lim_{r\to\infty} \frac{r - \mu_r - 2}{r} = 1 - \frac{1}{2}\log_2 3 \approx 0.2075. \quad \square$$

LEMMA 4.5. *There exist constants* $c > 0$ *and* $\epsilon > 0$ *such that*

$$\prod_{j=1}^{\infty} \ell(2^{-j}\omega_1) \leq c \cdot |\omega_1|^{\mu_r + 1 - \epsilon}, \quad \text{where } \mu_r := \tfrac{1}{2}\log_2 T_r(\tfrac{3}{4}).$$

Proof. Lemma 4.3 implies that $\ell^2(\omega_1) = \big(|A_0(e^{i\omega_1})| + |B_0(e^{i\omega_1})|\big)^2 \leq 4\, T_r(\sin^2 \frac{\omega_1}{2})$ and that equality holds only when $\omega_1 \equiv \pi \pmod{2\pi}$. By combining these statements with Lemma 4.4, we obtain the following strict inequalities:

$$\ell^2(\omega_1) < 4\, T_r\big(\tfrac{3}{4}\big) \quad \text{if } |\omega_1| \leq \tfrac{2\pi}{3},$$
$$\ell^2(\omega_1)\ell^2(2\omega_1) < 4^2\, T_r^2\big(\tfrac{3}{4}\big) \quad \text{if } \tfrac{2\pi}{3} < |\omega_1| \leq \pi.$$

Since ℓ and T_r are continuous, we can preserve these inequalities even after we replace 4 by $(4-\delta)$ for some small $\delta > 0$. By Theorem 2.3 of Cohen and Daubechies [6, p. 69], there exists a constant $c > 0$ such that

$$\prod_{j=1}^{\infty} \ell(2^{-j}\omega_1) \leq c \cdot |\omega_1|^b,$$

where $b := \frac{1}{2}\log_2\big((4-\delta)T_r(\frac{3}{4})\big)$. Observe that $b = 1 - \epsilon + \mu_r$ for some $\epsilon > 0$. □

COROLLARY 4.6. *Let* $W = M^{\mathrm{T}}$. *There exist constants* $c > 0$ *and* $\epsilon > 0$ *such that*

$$\left|\prod_{j=1}^{\infty} q(W^{-j}\omega)\right| \leq c \cdot |\omega_1|^{\mu_r + 1 - \epsilon}\, |\omega_2|^{\mu_r + 1 - \epsilon},$$

where $\mu_r := \frac{1}{2}\log_2 T_r(\frac{3}{4})$, *and* $q(\omega)$ *is defined in* (4.4).

Proof. Note that $W(\omega_1, \omega_2) = (\omega_2, 2\omega_1)$. Therefore, (4.2) and (4.4) yield

$$\begin{aligned}\left|\prod_{j=1}^{\infty} q(W^{-j}\omega)\right| &= \prod_{j=1}^{\infty} \left|q(2^{-j}\omega)\right| \prod_{j=1}^{\infty} \left|q(2^{-j}W\omega)\right| \\ &\le \prod_{j=1}^{\infty} \ell(2^{-j}\omega_1) \prod_{j=1}^{\infty} \ell(2^{-j}\omega_2) \\ &\le c \cdot |\omega_1|^{\mu_r+1-\epsilon} |\omega_2|^{\mu_r+1-\epsilon}. \qquad \square\end{aligned}$$

The following lemma establishes a simple fact about the zeros of $m(\omega_1, \omega_2)$:

LEMMA 4.7. *Suppose that* $m(\omega_1, \omega_2) = 0$. *Then* $\omega_1 \equiv \pi \pmod{2\pi}$.

Proof. If $m(\omega_1, \omega_2) = 0$, then $|A(e^{i\omega_1})| = |B(e^{i\omega_1})|$, and therefore $\mathcal{P}_A(z) = \mathcal{P}_B(z)$ for some $z = e^{i\omega_1}$. Thus, either $H(z) = 0$, and therefore $z = -1$, or $\mathcal{P}_{A_0}(z) = \mathcal{P}_{B_0}(z)$; that is,

$$\left(1 - \mathcal{P}_H^r(-z)\mathcal{P}_H^r(z)L^2(-1)\right)\mathcal{P}_L(z) = \mathcal{P}_H^{2r}(-z)\mathcal{P}_L(-z)L^2(-1),$$

and therefore

$$\mathcal{P}_L(z) = \mathcal{P}_H^r(-z)\mathcal{P}_H^r(z)\mathcal{P}_L(z)L^2(-1) + \mathcal{P}_H^r(-z)\mathcal{P}_H^r(-z)\mathcal{P}_L(-z)L^2(-1).$$

Due to (3.6),

$$\mathcal{P}_L(z) = \mathcal{P}_H^r(-z)L^2(-1).$$

By Lemma 4.1, this can happen only when $\omega_1 \equiv \pi \pmod{2\pi}$. $\square$

Proof of Theorem 2.2.

(i) Since the conditions for accuracy (3.2)–(3.3) and orthogonality (2.3) hold by Theorem 2.1, to ensure that ϕ is an orthogonal scaling function, we need only verify Cohen's criterion by finding a compact fundamental domain Ω of the lattice $2\pi\mathbb{Z}^2$ with the property

$$m(W^{-j}\omega) \neq 0 \quad \text{for all } j \ge 1 \text{ and for all } \omega \in \Omega. \tag{4.6}$$

Let $\Omega = [-\pi, \pi]^2$. Clearly, Ω is a compact fundamental domain of $2\pi\mathbb{Z}^2$. Observe that $W^{-1}\Omega = [-\frac{\pi}{2}, \frac{\pi}{2}] \times [-\pi, \pi]$. Therefore, Lemma 4.7 guarantees that $m(\omega) \neq 0$ for $\omega \in W^{-1}\Omega$. Finally, $W^{-j-1}\Omega \subset W^{-j}\Omega$ for all $j \ge 1$, which proves (4.6).

(ii) Berger and Wang [3] showed that the support of the solution to the dilation equation (2.1) is the attractor of the iterated function system (IFS)

$$\left\{ f_{\mathbf{n}}(\mathbf{x}) := M^{-1}(\mathbf{x} + \mathbf{n}) \ : \ c_{\mathbf{n}} \neq 0 \right\}.$$

If $\operatorname{supp} c = [0, N_x] \times [0, N_y]$, it can be checked that $\operatorname{supp} \phi \subseteq [0, N_x + 2N_y] \times [0, N_x + N_y]$. For all ϕ in Φ_{r+1}, we have $N_x = 4r - 1$ and $N_y = 1$, which proves part (ii).

(iii) Define $m_1(\omega) := m(\omega)\, m(W^{-1}\omega)$. By (4.1), we have $\widehat{\phi}(\omega) = m_1(\omega/2)\, \widehat{\phi}(\omega/2)$. Assume that $\phi(\mathbf{x})$ is separable. Then $\widehat{\phi}(\omega)$ and $m_1(\omega/2)$ are separable. This is impossible, because the coefficient mask $C(z, w)$ is nonseparable by (2.6)–(2.7).

(iv) Let $\mu_r := \frac{1}{2} \log_2 T_r(\frac{3}{4})$. Combining (4.1)–(4.3) with Corollary 4.6, we obtain the following estimate for the decay of the Fourier transform of any ϕ in Φ_{r+1}:

$$|\widehat{\phi}(\omega)| \le c \cdot (1 + |\omega_1|)^{\mu_r+1-r-\epsilon} (1 + |\omega_2|)^{\mu_r+1-r-\epsilon}$$

for some constants $c > 0$ and $\epsilon > 0$. As a result, $\phi \in C^{r-\mu_r-2}(\mathbb{R}^2)$. Lemma 4.4 provides the asymptotics for $r - \mu_r$. ∎

Remark. Observe that, aside from the claim on the size of $\operatorname{supp}\phi$ in part (ii), in the proof of Theorem 2.2 and Corollary 4.6 we used only the following properties of the dilation matrix $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$:

$$M^2 = \pm 2I \quad \text{and} \quad M\mathbb{Z}^2 = 2\mathbb{Z} \times \mathbb{Z}. \tag{4.7}$$

Therefore, aside from part (ii), Theorem 2.2 holds for any dilation matrix M satisfying (4.7), such as $M = \left(\begin{smallmatrix} 0 & -2 \\ 1 & 0 \end{smallmatrix}\right)$. Lemma 5.2 and a result by Lagarias and Wang [11] extend Theorem 2.2 to all dilation matrices with $M^2 = \pm 2I$ [2].

5. Examples. In this section we consider a few of the coefficient masks in Theorem 2.1 for $r = 1$, 2, and 6. We plot the corresponding scaling functions and study their smoothness. Finally, we discuss how to modify these masks for other dilation matrices. Additional coefficient values can be found in the appendix of [2].

Devil's Tower. The simplest case of Theorem 2.1 is when $r = 1$ and (2.11) holds. In this case $L(z) = 1$, and the autocorrelation

$$\mathcal{P}_S(z^2) = 1 - \Big(\frac{1 - z^2}{4}\Big)\Big(\frac{1 - z^{-2}}{4}\Big)$$

has only two spectral factors, which can be computed explicitly:

$$S^{(1)}(z^2) = \frac{2 - \sqrt{3}}{4} + \frac{2 + \sqrt{3}}{4} z^2 \quad \text{and} \quad S^{(2)}(z^2) = \frac{2 + \sqrt{3}}{4} + \frac{2 - \sqrt{3}}{4} z^2.$$

The corresponding coefficient masks are given below. For brevity we omit the powers of z and w; the constant term c_{00} is anchored at the lower-left corner:

$$c^{(1)} = \frac{1}{8} \begin{bmatrix} -1 & 1 & 1 & -1 \\ 2 - \sqrt{3} & 2 - \sqrt{3} & 2 + \sqrt{3} & 2 + \sqrt{3} \end{bmatrix},$$

$$c^{(2)} = \frac{1}{8} \begin{bmatrix} -1 & 1 & 1 & -1 \\ 2 + \sqrt{3} & 2 + \sqrt{3} & 2 - \sqrt{3} & 2 - \sqrt{3} \end{bmatrix}.$$

The corresponding scaling functions $\phi^{(1)}$ and $\phi^{(2)}$ are supported on $[0, 5] \times [0, 4]$, have accuracy 2, and are discontinuous. The mesh plot of $\phi^{(1)}$ resembles the famous Wyoming mountain, as depicted in Figure 5.1.

Continuous scaling function. In the case $r = 2$, four spectral factors of $\mathcal{P}_S$ are combined with two spectral factors of $\mathcal{P}_L$ to produce eight coefficient masks in $\mathcal{C}_{2+1}$ (see Table A.1 in the Appendix). The second mask has the following coefficients:

$$c = \begin{bmatrix} 0.03697 & -0.06403 & -0.05678 & 0.13797 & 0.00265 & -0.08384 & 0.01716 & 0.00991 \\ 0.00790 & -0.01369 & -0.13808 & 0.12118 & 0.54993 & 0.34617 & 0.08025 & 0.04633 \end{bmatrix}. \tag{5.1}$$

The corresponding scaling function (Figure 5.2) has accuracy $2 + 1 = 3$ and is continuous. The continuity does not follow from Theorem 2.2, because $2 - \mu_2 - 2 \approx 1.339 - 2 < 0$. Instead, the continuity of the scaling function in Figure 5.2 follows from Lemma 5.1, which is a straightforward modification of Lemma 7.1.2 by Daubechies [8, p. 217]; the proof is essentially the same and is therefore omitted here.

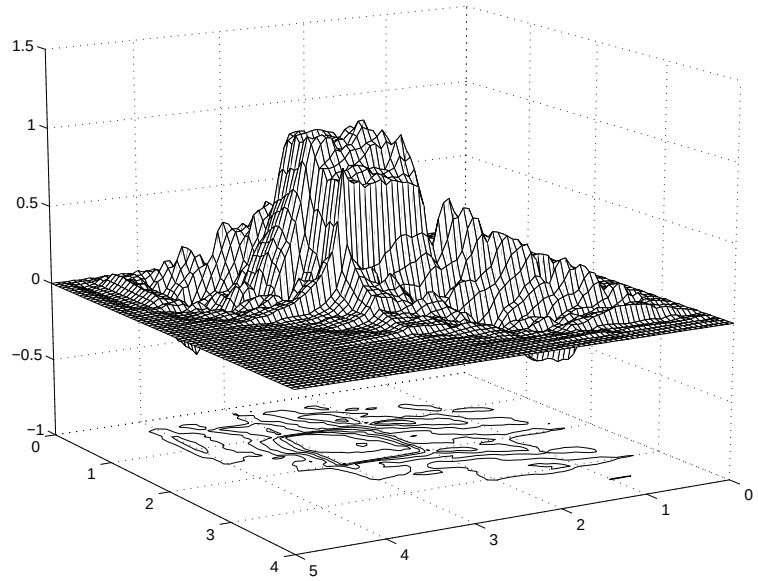

FIG. 5.1. *"Devil's Tower": a discontinuous scaling function with accuracy* $1+1=2$ *and support* $[0,5]\times[0,4]$.

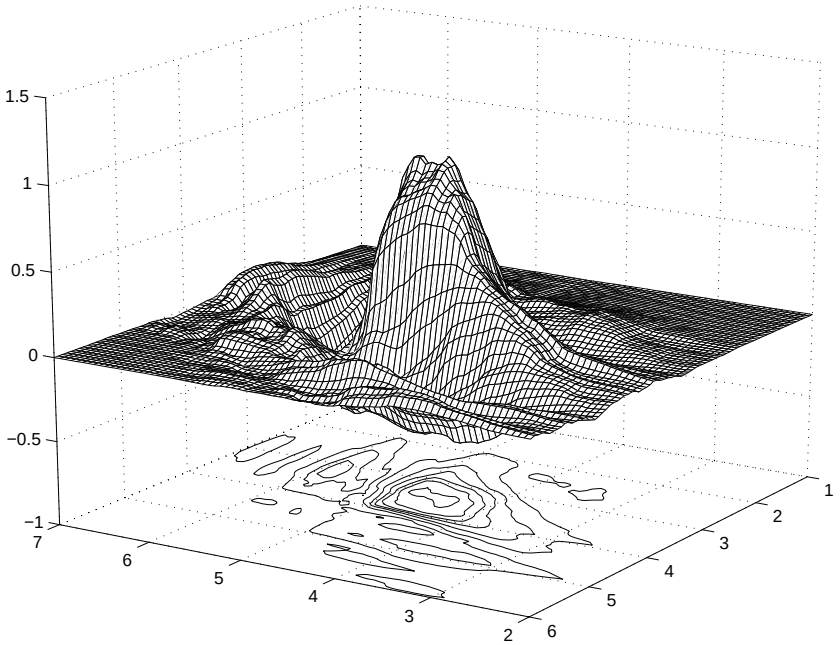

FIG. 5.2. *"Resting Dog": a continuous nonseparable scaling function with accuracy* $2+1=3$ *and support* $[0,9]\times[0,8]$.

LEMMA 5.1. *Let $W = M^{\mathrm{T}}$. Suppose that there exist $p \in \mathbb{N}$ and $\lambda > 0$ such that*

$$\sup_{\omega} \prod_{j=0}^{p-1} \left|q(2^{-j}\omega)\, q(2^{-j}W^{-1}\omega)\right| < 2^{\lambda p}, \tag{5.2}$$

where $q(\omega)$ is defined in (4.4). *Then there exist constants c' and c'' such that*

$$\prod_{j=1}^{\infty} \left|q(W^{-j}\omega)\right| < c' \cdot (1+|\omega|)^{\lambda} < c'' \cdot (1+|\omega_1|)^{\lambda}(1+|\omega_2|)^{\lambda}.$$

Hence $\phi \in C^{r-1-\lambda}$. ∎

The authors evaluated the trigonometric polynomial in (5.2) numerically for 120 values of ω within a single period and verified that the coefficient mask (**??**) satisfies (5.2) for $p = 4$ and $\lambda = 1$. Therefore, the scaling function in Figure 5.2 is continuous.

While Theorem 2.2 claims only that $\Phi_{5+1} \subset C^0$, it can be verified numerically that all masks in $\mathcal{C}_{3+1}$ (see Table A.3 in the Appendix) satisfy (5.2) for $p = 4$ and $\lambda = 2$; hence $\Phi_{3+1} \subset C^0$.

Differentiable scaling functions. About half of the 128 coefficient masks in $\mathcal{C}_{6+1}$ satisfy (5.2) for $p = 4$ and $\lambda = 4$ and therefore produce differentiable scaling functions. To the best of the authors' knowledge, these are the first nonseparable orthogonal scaling functions (for a dilation matrix with $|\det(M)| = 2$) that are differentiable. The 2×24 scaling coefficients of the differentiable scaling function in Figure 5.3 are displayed in Table A.2 in the Appendix. Numerical computations confirm also that $\Phi_{7+1} \subset C^1$.

Other dilations. The following lemma explains what happens when we manipulate the coefficient mask in the dilation equation (2.1). Let J be any lattice-preserving matrix, that is, any matrix J such that both J and J^{-1} have integer entries. An example is $J = \left(\begin{smallmatrix} 1 & 1 \\ 0 & 1 \end{smallmatrix}\right)$. For any function $f : \mathbb{R}^2 \to \mathbb{R}$ define its "upsampling by J" as $(J \uparrow f)(\mathbf{x}) := f(J^{-1}\mathbf{x})$. Similarly, define the "upsampled by J" scaling coefficients as $(J \uparrow c)_{\mathbf{n}} := c_{J^{-1}\mathbf{n}}$.

LEMMA 5.2. *Let ϕ be a solution to the dilation equation* (2.1) *with coefficients c and dilation matrix M. Then $J \uparrow \phi$ is a solution to the dilation equation* (2.1) *with coefficients $J \uparrow c$ and dilation matrix JMJ^{-1}.*

Proof. Make the substitution $\mathbf{x} \mapsto J^{-1}\mathbf{y}$ in the dilation equation. ∎

A surprising example is $J = \left(\begin{smallmatrix} -1 & 0 \\ 0 & 1 \end{smallmatrix}\right)$, the matrix of the reflection about the y-axis. Let $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$. Then $JMJ^{-1} = -M$. Therefore, the scaling function with coefficient mask $w^{-1}(B(z) + wA(z))$ and dilation M is a reflection of the scaling function with coefficient mask $A(z) + wB(z)$ and dilation $-M$, but it is *not* a reflection of the scaling function with coefficient mask $A(z) + wB(z)$ and dilation M. The difference is obvious in Figure 5.4, which shows the contour plots of two scaling functions with the same dilation matrix $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ and x-reflected coefficients. (The one on the left was plotted in Figure 5.2.)

The plots exhibit a peculiar feature: all scaling functions appear so far to be "almost symmetric" with respect to the bisectrix $x = y$. This is not surprising, since the dilation matrix $\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ swaps the axes and stretches along x by a factor of two. Unfortunately, the case $|\det(M)| = 2$ is similar to the univariate case $M = 2$—the only symmetric orthogonal scaling function is the Haar function.

Lemma 5.2 allows us to adapt the coefficient masks described in Theorem 2.1 to dilation matrices that generate the quincunx sublattice in the following way.

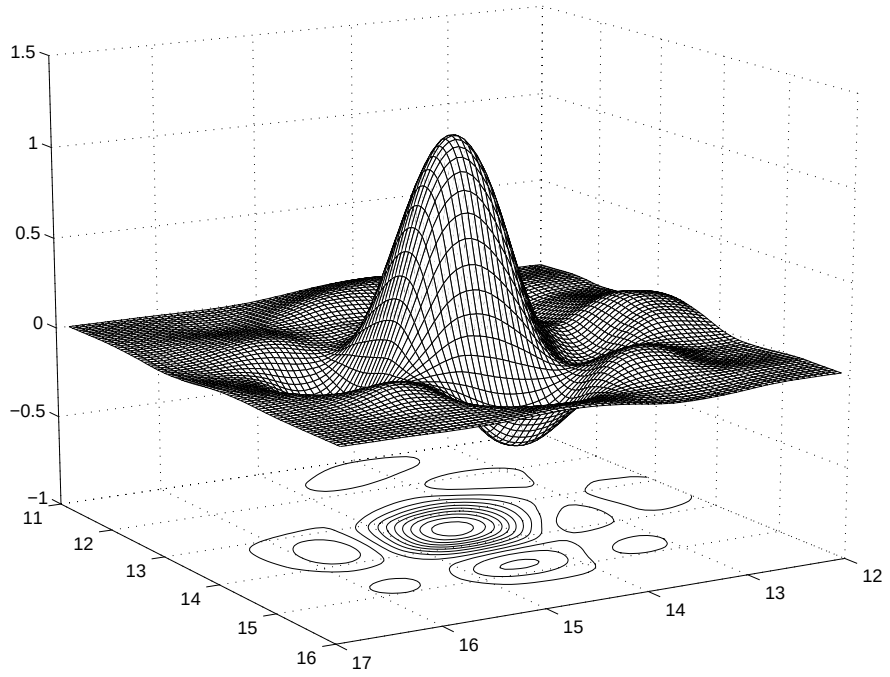

FIG. 5.3. *A differentiable nonseparable scaling function with accuracy* $6 + 1 = 7$.

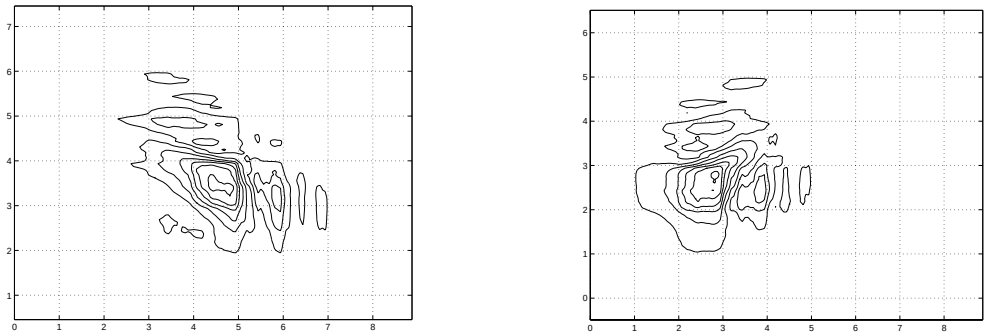

FIG. 5.4. *Level sets of scaling functions with x-reflected scaling coefficients: the functions are not similar.*

COROLLARY 5.3. *Let* ν *be odd. If* $A(z) + wB(z)$ *is a two-row orthogonal coefficient mask with accuracy r for the column lattice, then* $A(z) + z^\nu wB(z)$ *is a two-row orthogonal coefficient mask with accuracy r for the quincunx lattice.*

Proof. Set $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ and $J = \left(\begin{smallmatrix} 1 & \nu \\ 0 & 1 \end{smallmatrix}\right)$ in Lemma 5.2. Observe that the J-upsampling of $A(z) + wB(z)$ is $A(z) + z^\nu wB(z)$ and that the matrix $J\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)J^{-1}$ generates the quincunx sublattice. □

If we shift the top row of coefficients in (**??**) one position to the left and use the dilation matrix $\left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ in (2.1), then we obtain an orthogonal nonseparable quincunx scaling function with accuracy $2 + 1 = 3$, plotted in Figure 5.5 (cf. Kovačević and Vetterli's scaling function with accuracy 2 [12]).

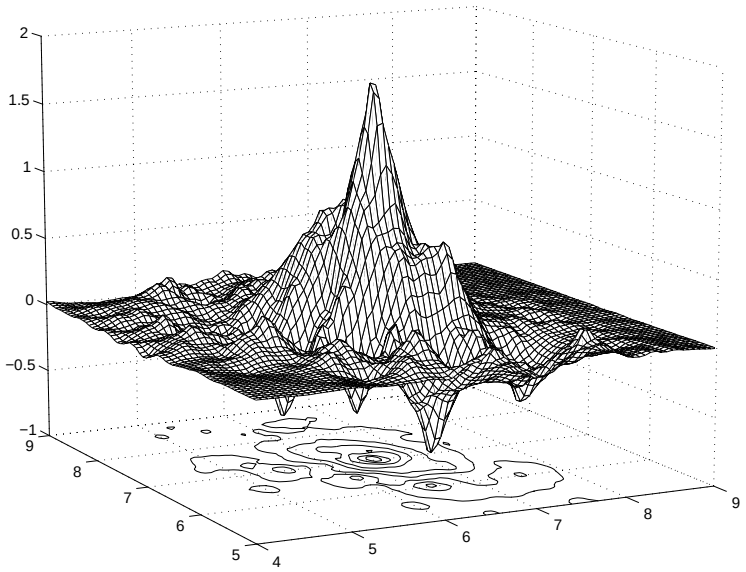

FIG. 5.5. *An orthogonal nonseparable scaling function with accuracy* $2+1=3$ *for the quincunx dilation matrix.*

Every 2×2 dilation matrix M with $M^2 = 2I$ can be factored in the form $J\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)J^{-1}$ [11]. Therefore, Lemma 5.2 and Theorem 2.2 provide arbitrarily smooth nonseparable wavelet bases for such dilation matrices.

The convolution of two sets of scaling coefficients $a_{\mathbf{n}}$ and $b_{\mathbf{n}}$ is defined by $(a*b)_{\mathbf{n}} := \sum_{\mathbf{k}\in\mathbb{Z}^2} a_{\mathbf{k}}\, b_{\mathbf{n}-\mathbf{k}}$. The following statement combines two levels of the MRA into one.

LEMMA 5.4. *Let* ϕ *be a solution to the dilation equation* (2.1) *with coefficients* c *and dilation matrix* M*. Then* ϕ *is also a solution to the dilation equation* (2.1) *with coefficients* $c * (M \uparrow c)$ *and dilation matrix* M^2*.*

Proof. Iterate the dilation equation (2.1); that is, replace each ϕ on the right by the sum of its dilates. □

Since $\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)^2 = 2I$, by Theorem 2.2 and Lemma 5.4, we obtain the following.

COROLLARY 5.5. *Aside from the separable Daubechies MRA, there exists a bivariate nonseparable orthogonal MRA of any given smoothness for the dilation* $\left(\begin{smallmatrix} 2 & 0 \\ 0 & 2 \end{smallmatrix}\right)$.

Ayache [1] obtained this result independently by perturbing the separable Daubechies basis.

6. Summary. We showed how to obtain orthogonal two-row coefficient masks (low-pass filter coefficients) with arbitrarily high accuracy for dilation matrices M with $|\det(M)| = 2$, such as $\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ or $\left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$. We proved that if $M^2 = \pm 2I$, then the smoothness of the scaling functions corresponding to those coefficient masks increases asymptotically with the accuracy and can be made arbitrarily high.

Appendix. Scaling coefficients. The following tables contain the coefficients of $A(z)$ and $B(z)$ that satisfy the conditions (2.6)–(2.11) in Theorem 2.1, that is, the coefficients of $C(z,w)$ in $\mathcal{C}_{r+1}$ for some values of r. Generally speaking, the scaling coefficients in the beginning of each table correspond to the "least symmetric" scaling functions; the scaling coefficients towards the end of the table correspond to the "most symmetric" scaling functions.

TABLE A.1
Scaling coefficients (first half of $\mathcal{C}_{2+1}$) of accuracy $2+1$.

Note. To save space, we displayed only the *first half* of $\mathcal{C}_{r+1}$. To obtain the other half, simply take the coefficients (both a_n and b_n) in reverse order. Recall that the scaling functions with scaling coefficients in the second half of the family $\mathcal{C}_{r+1}$ are different than, and are not mere flips of, the scaling functions with scaling coefficients in the first (tabulated) half (see the discussion after Lemma 5.2).

Acknowledgments. The authors thank the referees for their useful suggestions, and Albert Cohen for the helpful discussions and for communicating Ayache's work. Special thanks go to Chris Heil, for providing the preprint [4] of the accuracy condition and for carefully revising the early drafts, and to Tim Flaherty for his meticulous work in discovering several inaccuracies in the manuscript. Thanks to Huibin Zhou for his comments. Wang acknowledges the support of the Mathematics Department at Cornell University, where he was a visitor during the completion of this paper. The fruitful blend of theoretical mathematics and computer numerics was essential to our work; the plots and the numerical computations were aided by Mathematica and MATLAB.

INVERSE CONDUCTIVITY PROBLEM WITH ONE MEASUREMENT: ERROR ESTIMATES AND APPROXIMATE IDENTIFICATION FOR PERTURBED DISKS*

EUGENE FABES†, HYEONBAE KANG‡, AND JIN KEUN SEO§

Abstract. This paper studies the global uniqueness and stability questions of the inverse conductivity problem to determine the unknown object D entering $\mathrm{div}((1+(k-1)\chi_D)\nabla u)=0$ in Ω and $\frac{\partial u}{\partial \nu}=g$ on $\partial\Omega$ from the boundary measurement $\Lambda_D(g)=u|_{\partial\Omega}$. The results of this paper are fourfold. We first obtain a Hölder stability estimate for disks. Second, a uniform stability estimate for the direct problem is obtained. Third, we obtain the stability estimates $|D_1 \setminus \tilde{D}_2| + |D_2 \setminus \tilde{D}_1| \le C(\|\Lambda_{D_1}(g)-\Lambda_{D_2}(g)\|^{\alpha}_{L^\infty(\partial\Omega)}+\epsilon)$ for some $\alpha>0$ when g satisfies some condition if D_1 and D_2 are ϵ-perturbations of two disks. We then drop the condition on g and show that if $\Lambda_{D_1}(g)=\Lambda_{D_2}(g)$ on $\partial\Omega$, then the two domains must be very close.

1. Introduction.

This paper studies the inverse problem to determine the unknown object D entering the Neumann problem

$$P[D,g]\begin{cases} \mathrm{div}((1+(k-1)\chi_D)\nabla u)=0 \quad \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu}=g \quad \text{on } \partial\Omega, \quad \displaystyle\int_{\partial\Omega} u=0, \quad \int_{\partial\Omega} g=0, \quad g\in L^2(\partial\Omega), \end{cases}$$

from the single Cauchy data $(u|_{\partial\Omega}, g)$. By the uniqueness of the Neumann problem $P[D,g]$, we can define the Neumann-to-Dirichlet map Λ_D by

$$\Lambda_D(g) := u|_{\partial\Omega}, \quad g\in L^2_0(\partial\Omega) := \left\{ \psi\in L^2(\partial\Omega) : \int_{\partial\Omega}\psi=0 \right\},$$

where u is the solution of the Neumann problem $P[D,g]$. We are interested in the uniqueness and stability questions, which we state roughly as follows:

Uniqueness: Does $\Lambda_{D_1}(g)=\Lambda_{D_2}(g)$ imply $D_1=D_2$? $\quad(\overline{D_j}\subset\Omega)$

Stability: If $\|\Lambda_{D_1}(g)-\Lambda_{D_2}(g)\|_{L^\infty(\partial\Omega)}$ is small, is $|D_1\Delta D_2|$ small?

Here $|D_1\Delta D_2| = |D_1\setminus D_2| + |D_2\setminus D_1|$ and $|E|$ denotes the Lebesgue measure of the set E.

This paper is concerned primarily with global uniqueness and stability within the class of small perturbation of disks. To explain our result, let us fix the notion of ϵ-perturbations of disks. Let ϵ be a positive number and let Ω_0 be an open subset of

Ω at some distance, say, $2\delta_0$, from $\partial\Omega$. A C^2-domain D being an ϵ-perturbation of a disk B means that there is $\omega \in C^1(\partial B)$ with $\|\omega\|_{C^1(\partial B)} \le 1$ such that

$$\partial D : x + \epsilon\omega(x)\nu(x), \quad x \in \partial B, \tag{1.1}$$

where $\nu(x)$ is the outward unit normal to ∂B at x. Let $\mathcal{C}[\epsilon]$ denote the class of ϵ-perturbations of all disks contained in Ω_0 with the radius larger than a fixed number d_0.

The results of this paper are fourfold. The first two results are of preparatory nature for the last two results. However, they have their own interest.

The first result is the Hölder stability estimate within the class of disks. We prove that if the Neumann data g satisfy the conditions

(N1) there exists a positive number M such that $|g'(P)| > M$ if $|g(P)| < M$, $P \in \partial\Omega$ (here, g' means the tangential derivative on $\partial\Omega$); and

(N2) $\{P \in \partial\Omega : g(P) > 0\}$ and $\{P \in \partial\Omega : g(P) < 0\}$ are nonempty connected subsets of $\partial\Omega$,

then

$$|D_1 \Delta D_2| \le C\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|^{\alpha}_{L^\infty(\partial\Omega)} \tag{1.2}$$

for every disk D_1, D_2 contained in Ω_0 and $0 < \alpha < 1$. (See Theorem 3.1.) The conditions on the Neumann data g guarantee the existence of the lower bound of $|\nabla u|$, which depends only on M when $D \in \mathcal{C}[\epsilon]$ and u is the weak solution to $P[D, g]$. (See [KSS1].) This result is an improvement upon the previous logarithmic estimate in [KSS1].

The second result is a uniform stability for the direct problem; namely, if D_ϵ is an ϵ-perturbation of C^2-domain D (D is not necessarily a disk) and u, u_ϵ are solutions of $P[D, g]$, $P[D_\epsilon, g]$, respectively, then

$$\|u - u_\epsilon\|_{L^\infty(\Omega)} \le C\epsilon\|g\|_{L^2(\partial\Omega)}.$$

(See Theorem 4.1.) This result improves upon the L^2-estimate of [BFI].

The third main result of this paper deals with global stability within the class $\mathcal{C}[\epsilon]$. We prove that if the Neumann data g satisfy the conditions (N1) and (N2), then

$$|D_1 \Delta D_2| \le C\left(\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|^{\alpha}_{L^\infty(\partial\Omega)} + \epsilon\right) \tag{1.3}$$

for every $D_1, D_2 \in \mathcal{C}[\epsilon]$ and for some constants C and $0 < \alpha < 1$ independent of ϵ. (See Theorem 5.2.)

The last main result of this paper is concerned with the global uniqueness without any restriction on the Neumann data g. Let $D_0 \in \mathcal{C}[\epsilon]$ and let $\Lambda_{D_0}(g) = f$. If $D \in \mathcal{C}[\epsilon]$ and $\Lambda_D(g) = \Lambda_{D_0}(g)$, we show that

$$|D_0 \Delta D| \le C\epsilon, \tag{1.4}$$

where the constant C depends on (f, g) not on D or ϵ. The estimate (1.4) means that if the boundary measurements are the same, then the two domains must be very close. For this reason we call this result an approximate identification. It seems that this approximate identification of a domain is quite meaningful in a practical sense. This result together with the local uniqueness result of Alessandrini, Isakov, and Powell [AIP] gives the global uniqueness within $\mathcal{C}[\epsilon]$ provided that ϵ is sufficiently small and g satisfies a certain condition.

The classes of domains for which the global uniqueness is proved so far are only polygons, cylinders, and disks in the plane, convex polyhedra, and balls in three dimensions. (See [BFS, FI, IP, KS1, KS2, S].) The log-type global stability is obtained in [KSS1] within the class of the disks. There are local uniqueness and local stability results in two dimensions (see [AIP] and [BFI]).

The organization of this paper is as follows; in section 2 we review the representation formula in [KS1], and some other preliminary results are reviewed or obtained. In section 3 we prove the Hölder stability for the disks. In section 4 we obtain the uniform stability of the solutions to the direct problem $P[D, g]$ under perturbation of domains. The third main result (1.3) is proved in section 5 and the last one (1.4) in section 6.

2. Notation and preliminary definitions. Let us define the Lipschitz character.

Definition of the Lipschitz character. A bounded open connected domain $D \subset \mathbb{R}^2$ is called a Lipschitz domain with Lipschitz character (r_0, L) if for each $P \in \partial D$ there is an open rectangle $Z(P, r_0)$ centered at P, with the bottom length equal to r_0, whose bottom and top sides are at a positive distance l, $r_0 < l < 2r_0$ from ∂D, such that there is a coordinate system $(t, s) \in \mathbb{R} \times \mathbb{R}$, with the s-axis containing the axis of Z and a Lipschitz function $\phi : \mathbb{R} \to \mathbb{R}$ such that $Z \cap D = \{(t, s) \in \mathbb{R} \times \mathbb{R} : s > \phi(t)\} \cap Z$, $Z \cap \partial D = \{(t, s) \in \mathbb{R} \times \mathbb{R} : s = \phi(t)\} \cap Z$, and $\|\phi'\|_{L^\infty(\mathbb{R})} \leq L$.

Throughout this paper, we assume that Ω and D are simply connected bounded Lipschitz domains in $\mathbb{R}^2$ with Lipschitz character (r_0, L) and

$$D \subset \Omega_0 := \{x \in \Omega : \operatorname{dist}(x, \partial\Omega) > 2\delta_0\},$$

where δ_0 is a fixed positive number. We denote by $B_d(a)$ the disk centered at a with radius d.

Let

$$\begin{aligned}
\mathcal{S}_\Omega \phi(x) &= \frac{1}{2\pi} \int_{\partial\Omega} \log|x - y| \phi(y) d\sigma_y, \quad x \in \mathbb{R}^2, \\
\mathcal{D}_\Omega \phi(x) &= \frac{1}{2\pi} \int_{\partial\Omega} \frac{\langle x - y, \nu_y \rangle}{|x - y|^2} \phi(y) d\sigma_y, \quad x \in \mathbb{R}^2 \setminus \partial\Omega, \\
\mathcal{K}_D \phi(x) &= \frac{1}{2\pi} \int_{\partial D} \frac{\langle x - y, \nu_y \rangle}{|x - y|^2} \phi(y) d\sigma_y, \quad x \in \partial D,
\end{aligned}$$

and let $\mathcal{K}_D^*$ be the dual of $\mathcal{K}_D$. Recall the classical trace formula (see [F] or [V])

$$\lim_{t \to 0^+} \langle \nu_P, \nabla S_D \phi(P \pm t\nu_P) \rangle = \left(\pm \frac{1}{2} I + \mathcal{K}_D^* \right) \phi(P) \quad \text{almost all } P \in \partial D. \tag{2.1}$$

From [KS1] and [KSS2], the weak solution u to the Neumann problem $P[D, g]$ can be uniquely expressed as

$$u(x) = H(x) + \mathcal{S}_D \varphi_D(x) \quad \text{for } x \in \Omega, \tag{2.2}$$

where

$$H(x) = -\mathcal{S}_\Omega g(x) + \mathcal{D}_\Omega f(x), \quad f = u|_{\partial\Omega}, \quad x \in \mathbb{R}^2 \setminus \partial\Omega, \tag{2.3}$$

$$(\lambda I - \mathcal{K}_D^*) \varphi_D = \frac{\partial H}{\partial \nu}|_{\partial D} \quad \text{on } \partial D, \tag{2.4}$$

where $\lambda = \frac{k+1}{2(k-1)}$. Moreover, we have

$$\int_{\partial D} \varphi_D = 0, \tag{2.5}$$

$$H(x) + \mathcal{S}_D \varphi_D(x) = 0, \quad x \in \mathbb{R}^2 \setminus \overline{\Omega}. \tag{2.6}$$

Let $u^i := u|_D$ and $u^e := u|_{\Omega \setminus \overline{D}}$. Then

$$\varphi_D = (k-1)\frac{\partial u^i}{\partial \nu} = \frac{k-1}{k}\frac{\partial u^e}{\partial \nu} \quad \text{on } \partial D$$

and hence

$$\varphi_D = \frac{\partial u^e}{\partial \nu} - \frac{\partial u^i}{\partial \nu} \quad \text{on } \partial D. \tag{2.7}$$

(See [KS1] and [KSS2] for proofs.)

In [EFV], it was shown that there is a positive constant C depending only on the Lipschitz character (r_0, L) of D and δ_0 so that

$$\|(\nabla u)^{**}\|_{L^2(\partial D)} \le C \|\nabla u\|_{L(\Omega)}, \tag{2.8}$$

where $(\nabla u)^{**}(x)$ is the interior and exterior nontangential maximal function of ∇u at $x \in \partial D$:

$$(\nabla u)^{**}(x) = \sup\{|\nabla u(y)| : |x-y| \le (2L+1)\mathrm{dist}(y, \partial D),\ y \in \Omega_0\}.$$

Because of the above regularity estimate (2.8), the following transmission condition holds in the $L^2(\partial D)$-sense:

$$\frac{\partial u^e}{\partial \nu} = k \frac{\partial u^i}{\partial \nu} \quad \text{on } \partial D. \tag{2.9}$$

LEMMA 2.1. *Let u be the solution of the Neumann problem $P[D, g]$ and H be as in* (2.3). *Then there is a positive constant C depending on the Lipschitz character of Ω and δ_0 (independent of D) so that*

$$\int_{\partial\Omega} |\nabla u|^2 + \int_\Omega |\nabla u|^2 + |\nabla H|^2 \le C \int_{\partial\Omega} |g|^2. \tag{2.10}$$

Proof. The proof of this lemma is based on the Rellich identity. Let $\vec{\alpha}$ be the smooth vector field such that the support of $\vec{\alpha}$ lies in $\mathbb{R}^2 \setminus \Omega_0$ and $\langle \vec{\alpha}, \nu \rangle > c_1 > 0$ on $\partial\Omega$ (here, c_1 depend on the Lipschitz character of $\partial\Omega$). If $v \in C^2(\overline{\Omega})$, we have

$$\mathrm{div}(\vec{\alpha}|\nabla v|^2) = 2\mathrm{div}(\nabla v \langle \vec{\alpha}, \nabla v\rangle) + \mathrm{div}\vec{\alpha}|\nabla v|^2 - 2\langle \nabla\vec{\alpha}\nabla v, \nabla v\rangle - 2\langle \vec{\alpha}, \nabla v\rangle \Delta v$$

and by integrating both sides of the above identity over Ω we obtain the Rellich identity

$$\int_{\partial\Omega} \langle \vec{\alpha}, \nu\rangle \left|\frac{\partial v}{\partial \nu}\right|^2 = \int_{\partial\Omega} \langle \vec{\alpha}, \nu\rangle \left|\frac{\partial v}{\partial T}\right|^2 - 2\int_{\partial\Omega} \langle \vec{\alpha}, T\rangle \frac{\partial v}{\partial T}\frac{\partial v}{\partial \nu} + \mathcal{R}, \tag{2.11}$$

where

$$\mathcal{R} = \int_\Omega 2\langle \nabla\vec{\alpha}\nabla v, \nabla v\rangle - \mathrm{div}\vec{\alpha}|\nabla v|^2 + 2\langle \vec{\alpha}, \nabla v\rangle \Delta v.$$

Here $T(P)$ is the tangent vector to $\partial\Omega$ at a point P. If we substitute $v = u$ in the above identity (2.11), then we obtain

$$\int_{\partial\Omega} \left|\frac{\partial u}{\partial T}\right|^2 \le C\left(\int_{\partial\Omega} |g|^2 + \int_{\Omega} |\nabla u|^2\right), \tag{2.12}$$

where C is depending only on $\|\vec{\alpha}\|_{C^1(\mathbb{R}^2)}$ and c_1. Since

$$\int_{\Omega} (1 + (k-1)\chi_D)|\nabla u|^2 = \int_{\partial\Omega} gu \le \left(\int_{\partial\Omega} |g|^2\right)^{1/2} \left(\int_{\partial\Omega} |u|^2\right)^{1/2}, \tag{2.13}$$

it follows from (2.12) and the Poincaré inequality on $\partial\Omega$ that

$$\int_{\Omega} |\nabla u|^2 \le C \int_{\partial\Omega} |g|^2 \tag{2.14}$$

and therefore

$$\int_{\partial\Omega} \left|\frac{\partial u}{\partial T}\right|^2 \le C \int_{\partial\Omega} |g|^2. \tag{2.15}$$

Hence (2.10) follows from (2.3), (2.14), and (2.15). This completes the proof. □

The following theorem will be used in section 6 (for the proof, see [FJR] or [V]).

THEOREM 2.2. *Let u be the solution to the Neumann problem:*

$$\begin{cases} \Delta u = 0 & \text{in } D, \\ \dfrac{\partial u}{\partial \nu} = g & \text{on } \partial D, \quad \displaystyle\int_{\partial D} u = 0. \end{cases}$$

Then there is a positive constant C depending only on the Lipschitz character (r_0, L) of D so that

$$\|(\nabla u)^*\|_{L^2(\partial D)} \le C\|g\|_{L^2(\partial D)}, \tag{2.16}$$

where

$$(\nabla u)^*(x) := \sup\{|\nabla u(y)| : |y - x| \le (2L+1)\mathrm{dist}(y, \partial D),\ y \in D\}. \tag{2.17}$$

3. Stability of disks. Recall that $\mathcal{C}[0]$ denotes the family of all disks contained in Ω_0 with radii larger than d_0. In this section we improve the logarithmic stability obtained in [KSS1] to get a Hölder stability of the disk, which we state as follows.

THEOREM 3.1. *Let g be a Neumann data with the condition (N). There exist $\alpha > 0$ and C depending only on δ_0 and d_0 such that*

$$|D_1 \Delta D_2| \le C\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|^{\alpha}_{L^\infty(\partial\Omega)} \tag{3.1}$$

for every disk $D_1, D_2 \in \mathcal{C}[0]$.

To prove (3.1), we need to study the harmonic extension property of the solution u of the Neumann problem $P[D, g]$.

LEMMA 3.2. *Let $D = B_d(a) \in \mathcal{C}[0]$. Then the general solution to $P[D, g]$ is given by*

$$\begin{cases} u^i(x) = H(x) - \dfrac{1}{2\lambda}\left(H(x) - H(a)\right), \quad x \in D, \\ u^e(x) = H(x) - \dfrac{1}{2\lambda}\left(H\left(a + \dfrac{d^2(x-a)}{|x-a|^2}\right) - H(a)\right), \quad x \in \Omega \setminus D, \end{cases} \tag{3.2}$$

where H is a harmonic function in Ω given in (2.2).

Proof. Let $u = H(x) + \mathcal{S}_D\varphi_D$ as in (2.1). Since D is a disk, $\mathcal{K}_D^*\varphi_D = 0$ on ∂D and

$$\frac{\partial u^i}{\partial \nu} = \frac{\partial H}{\partial \nu} - \frac{1}{2}\varphi = \left(1 - \frac{1}{2\lambda}\right)\frac{\partial H}{\partial \nu}$$

(see [KS1]). Note that $\int_{\partial D} \mathcal{S}_D\phi_D = \int_{\partial D} \phi_D \mathcal{S}_D 1 = 0$ because $\mathcal{S}_D 1$ is constant on ∂D. From the uniqueness of the Neumann problem in D, u^i must be as in (3.2). Now it is straightforward to check that the function u in (3.2) satisfies the transmission condition (2.9) and continuity across ∂D. This completes the proof. ∎

Using Lemma 3.2, we can derive the following lemma.

LEMMA 3.3. *Let $D = B_d(a) \in \mathcal{C}[0]$. Let u be the solution of $P[D, g]$. Then u^e extends harmonically to $\Omega \setminus \overline{B_{d-2s}(a)}$ where $s = \frac{d\delta_0}{d+2\delta_0}$; that is, there is a harmonic function $\tilde{u}^e$ in $\Omega \setminus \overline{B_{d-2s}(a)}$ so that $\tilde{u}^e = u^e$ in $\Omega \setminus \overline{D}$. Moreover, there is a positive constant C depending only on d_0 and δ_0 so that*

$$\sup_{\Omega_0 \setminus \overline{B_{d-s}(a)}} |\nabla \tilde{u}^e(x)| \le C\|g\|_{L^2(\partial\Omega)}. \tag{3.3}$$

Proof. It follows from (3.2) that

$$u^e(x) = H(x) - \frac{1}{2\lambda}\left(H\left(a + \frac{d^2(x-a)}{|x-a|^2}\right) - H(a)\right), \quad x \in \Omega \setminus D.$$

Since H is harmonic in $B_{d+2\delta_0}(a) \subset \Omega$, the first statement of Lemma 3.3 is easy. Using the previous identity and Lemma 2.1, we have

$$\sup_{\Omega_0 \setminus \overline{B_{d-s}(a)}} |\nabla \tilde{u}^e(x)| \le C \sup_{\Omega_0} |\nabla H| \le C\left(\int_\Omega |\nabla H|^2\right)^{1/2} \le C\|g\|_{L^2(\partial\Omega)}.$$

This completes the proof. ∎

PROPOSITION 3.4. *Let $D_j \in \mathcal{C}[0]$ and u_j be the solution to $P[D_j, g], j = 1, 2$. There exist constants C and α depending only on δ_0 and d_0 such that if $\|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^\infty(\partial\Omega)} \le \epsilon$, then*

$$\sup_{\Omega_0} |u_1 - u_2| \le C\epsilon^\alpha, \tag{3.4}$$

$$\sup_{\Omega_0 \setminus (D_1 \cup D_2)} |\nabla(u_1^e - u_2^e)| \le C\epsilon^\alpha, \tag{3.5}$$

$$\sup_{D_1 \cap D_2} |\nabla(u_1^i - u_2^i)| \le C\epsilon. \tag{3.6}$$

Proof. Let $D_j = B_{d_j}(a_j)$. Then $d_j > d_0$ and $\operatorname{dist}(a_j, \partial\Omega) > d_j + 2\delta_0$ because $D_j \in \mathcal{C}[0]$ $(j = 1, 2)$. By Lemma 3.3, u_j^e can be harmonically extended to $\Omega \setminus B_{d_j - 2s_j}(a_j)$, where $s_j = \frac{d_j \delta_0}{d_j + 2\delta_0}$. We also denote the extended function by u_j^e. Let v_j^e be a harmonic conjugate of u_j^e with $v_1^e = v_2^e$ on $\partial\Omega$. (Such harmonic conjugates $v_j^e (j = 1, 2)$ exist since u_j is the solution of $P[D_j, g]$ with the same Neumann data g. See [AIP].) The function $h := u_1^e + iv_1^e - (u_2^e + iv_2^e)$ is holomorphic in $\Omega \setminus \overline{B_{d_j - s_1}(a_1) \cup B_{d_j - s_2}(a_2)}$ and satisfies

$$M := \sup\{|\nabla h(x)| : x \in \Omega_0 \setminus \overline{B_{d_j - s_1}(a_1) \cup B_{d_j - s_2}(a_2)}\} \le C\|g\|_{L^2(\partial\Omega)},$$
$$|h| \le \epsilon \quad \text{on } \partial\Omega.$$

Hence M depends only on $\|g\|_{L^2(\partial\Omega)}$, δ_0, and d_0. Let ω be the solution to the Dirichlet problem:

$$\begin{cases} \Delta\omega &= 0 \quad \text{in } \Omega \setminus \overline{B_{d_1 - s_1}(a_1) \cup B_{d_2 - s_2}(a_2)}, \\ \omega &= 1 \quad \text{on } \partial\Omega, \\ \omega &= 0 \quad \text{on } \partial(B_{d_1 - s_1}(a_1) \cup B_{d_2 - s_2}(a_2)). \end{cases}$$

Then by the maximum principle, for all $x \in \Omega \setminus (D_1 \cup D_2)$,

$$\log|h(x)| \le \omega(x) \log\epsilon + (1 - \omega(x)) \log M. \tag{3.7}$$

From a standard argument, one can see that there is a positive constant α depending only on δ_0, d_0, and Ω so that

$$\inf_{\Omega \setminus (D_1 \cup D_2)} \omega \ge \alpha.$$

Therefore, we obtain

$$\sup_{\Omega \setminus (D_1 \cup D_2)} |u_1 - u_2| \le C\epsilon^\alpha.$$

The rest of the proof is the same as the proof of Proposition 5.2 of [KSS1]. This completes the proof. □

Considering Proposition 3.4, Theorem 3.1 can also be proved in the exact same way as the proof of Theorem 5.1 of [KSS1].

4. Uniform stability for the direct problem. Let Ω and Ω_0 be as before. Let D be a simply connected subdomain (not necessarily a disk) of Ω_0 with C^2-boundary. Let D_ϵ be an ϵ-perturbation of D; i.e., ∂D_ϵ is C^2 and

$$\partial D_\epsilon : P + \epsilon\omega_\epsilon(P)\nu(P), \quad P \in \partial D, \tag{4.1}$$

where $\|\omega_\epsilon\|_{C^1(\partial D)} \le 1$ and $\nu(P)$ is the outward unit normal to ∂D at P. Let u and u_ϵ be solutions of $P[D, g]$ and $P[D_\epsilon, g]$, respectively.

The main result of this section is the following uniform stability of solutions to the direct problem.

THEOREM 4.1. *Let D_ϵ be an ϵ-perturbation of the C^2-domain D. There is a positive constant C depending only on the C^2-character of D, Ω and δ_0 such that*

$$\|u - u_\epsilon\|_{L^\infty(\Omega)} < C\epsilon\|g\|_{L^2(\partial\Omega)}. \tag{4.2}$$

To prove Theorem 4.1, we need L^2-stability. The L^2-stability $\|u-u_\epsilon\|_{L^2(\Omega)} < C\epsilon$ was proven in [BF] and [BFI]. However, we will give the proof to clarify the dependency of the constant C. The following theorem states the L^2-stability.

THEOREM 4.2. *There is a positive constant C depending only on the Lipschitz characters of D, D_ϵ and δ_0 such that*

$$\|u-u_\epsilon\|_{L^2(\Omega)} < C\epsilon\|g\|_{L^2(\partial\Omega)}. \tag{4.3}$$

Indeed, the above estimate is true for general Lipschitz domains D, D_ϵ with the Hausdorff distance $\operatorname{dist}(D, D_\epsilon) < \epsilon$.

Proof. Put

$$U_\epsilon = \frac{u-u_\epsilon}{\epsilon}.$$

Let $c_\epsilon = \frac{1}{|\Omega|}\int_\Omega U_\epsilon$. We first show that

$$\|U_\epsilon - c_\epsilon\|_{L^2(\Omega)} < C\|g\|_{L^2(\partial\Omega)}. \tag{4.3$'$}$$

By integrating by parts, we have

$$\int_\Omega (1+(k-1)\chi_{D_\epsilon})\nabla U_\epsilon \nabla\xi = \frac{k-1}{\epsilon}\int_\Omega (\chi_{D_\epsilon}-\chi_D)\nabla u\nabla\xi \tag{4.4}$$

for all $\xi \in W^{1,2}(\Omega)$. Let w_ϵ be the solution to the problem:

$$\begin{cases} \nabla\cdot((1+(k-1)\chi_{D_\epsilon})\nabla w_\epsilon) = U_\epsilon - c_\epsilon \quad \text{in } \Omega, \\ \dfrac{\partial w_\epsilon}{\partial\nu} = 0 \quad \text{on } \partial\Omega, \qquad \displaystyle\int_\Omega w_\epsilon = 0. \end{cases}$$

By substituting $\eta = w_\epsilon$ in (4.4) as in [BFI], one obtains the following identity:

$$\int_\Omega |U_\epsilon - c_\epsilon|^2 = \frac{k-1}{\epsilon}\int_\Omega (\chi_{D_\epsilon}-\chi_D)\nabla u\nabla w_\epsilon.$$

Hence,

$$\int_\Omega |U_\epsilon - c_\epsilon|^2 \le \frac{|k-1|}{\epsilon}\left(\int_\Omega |\chi_{D_\epsilon}-\chi_D||\nabla u|^2\right)^{1/2}\left(\int_\Omega |\chi_{D_\epsilon}-\chi_D||\nabla w_\epsilon|^2\right)^{1/2}. \tag{4.5}$$

From (2.8) and Lemma 2.1, we obtain

$$\int_\Omega |\chi_{D_\epsilon}-\chi_D||\nabla u|^2 \le C\epsilon\|(\nabla u)^{**}\|^2_{L^2(\partial D)} \le C\epsilon\|\nabla u\|^2_{L^2(\Omega)} \le C\epsilon\|g\|^2_{L^2(\partial\Omega)}.$$

Thus, to prove (4.3$'$) it suffices to prove that

$$\int_\Omega |\chi_{D_\epsilon}-\chi_D||\nabla w_\epsilon|^2 \le C\epsilon\|U_\epsilon - c_\epsilon\|^2_{L^2(\Omega)}. \tag{4.6}$$

Let

$$V(x) := w_\epsilon(x) - \Gamma(x) + \mathcal{S}_{D_\epsilon}\eta(x), \quad x\in\Omega,$$

where

$$\Gamma(x) := \frac{1}{2\pi}\int_\Omega \log|x-y|\left(\chi_{\Omega\setminus\overline{D_\epsilon}}(y)+\frac{1}{k}\chi_{D_\epsilon}(y)\right)(U_\epsilon(y)-c_\epsilon)dy,$$

$$(\lambda I - \mathcal{K}_{D_\epsilon}^*)\eta = -\frac{\partial\Gamma}{\partial\nu} \quad \text{on } \partial D_\epsilon. \tag{4.7}$$

Then one can check that V satisfies the transmission condition (2.9) as well as $\Delta V = 0$ in $\Omega\setminus\partial D_\epsilon$. Therefore, V is the solution to the Neumann problem $P[D_\epsilon,\tilde{g}]$, where

$$\tilde{g} := \frac{\partial V}{\partial\nu} = -\frac{\partial\Gamma}{\partial\nu} + \frac{\partial}{\partial\nu}\mathcal{S}_{D_\epsilon}\eta \quad \text{on } \partial\Omega.$$

By (2.8) and Lemma 2.1, we have

$$\|(\nabla V)^{**}\|_{L^2(\partial D_\epsilon)} \le C\|\nabla V\|_{L^2(\Omega)} \le C\|\tilde{g}\|_{L^2(\partial\Omega)}. \tag{4.8}$$

From the Calderón and Zygmund estimate, we have

$$\|\Gamma\|_{W^{2,2}(\Omega)} \le C\|U_\epsilon - c_\epsilon\|_{L^2(\Omega)}. \tag{4.9}$$

It also follows from the singular integral estimate and (4.7) (see [V]) that

positive constant C depending only on the Lipschitz character of D_ϵ so that

$$\|(\nabla\mathcal{S}_{D_\epsilon}\eta)^{**}\|_{L^2(\partial D_\epsilon)} \le C\|\eta\|_{L^2(\partial D_\epsilon)} \le C\|\nabla\Gamma\|_{L^2(\partial D_\epsilon)}. \tag{4.10}$$

By (4.9), (4.10), and the trace theorem,

$$\begin{aligned}\int_{\partial\Omega}|\tilde{g}|^2 &\le C\int_{\partial\Omega}\left|\frac{\partial\Gamma}{\partial\nu}\right|^2 + \left|\frac{\partial}{\partial\nu}\mathcal{S}_{D_\epsilon}\eta\right|^2 \\ &\le C\left(\int_{\partial\Omega}|\nabla\Gamma|^2 + \int_{\partial D_\epsilon}|\nabla\Gamma|^2\right) \\ &\le C\|\Gamma\|^2_{W^{2,2}(\Omega)} \le C\|U_\epsilon - c_\epsilon\|^2_{L^2(\Omega)}.\end{aligned} \tag{4.11}$$

By (4.8) and (4.11), we obtain

$$\int_\Omega |\chi_{D_\epsilon}-\chi_D||\nabla V|^2 \le C\epsilon\|(\nabla V)^{**}\|^2_{L^2(\partial D_\epsilon)} \le C\epsilon\|\tilde{g}\|^2_{L^2(\partial\Omega)} \le C\epsilon\|U_\epsilon - c_\epsilon\|^2_{L^2(\Omega)}. \tag{4.12}$$

It then follows from (4.10) and (4.12) that

$$\begin{aligned}\int_\Omega |\chi_{D_\epsilon}-\chi_D||\nabla w_\epsilon|^2 &\le C\int_\Omega |\chi_{D_\epsilon}-\chi_D|(|\nabla V|^2 + |\nabla\Gamma|^2 + |\nabla\mathcal{S}_{D_\epsilon}\eta|^2) \\ &\le C\epsilon\|U_\epsilon - c_\epsilon\|^2_{L^2(\Omega)}.\end{aligned}$$

This proves (4.6) and (4.3′).

Now we prove (4.3). Let $\eta := \operatorname{sign}(u-u_\epsilon)$ on $\partial\Omega$ and v_η be the solution to $P[D_\epsilon, \eta - \int_{\partial\Omega}\eta]$. Then by substituting $\xi = v_\eta$ in (4.4) we obtain

$$\begin{aligned}\int_{\partial\Omega}|U_\epsilon| &= \frac{k-1}{\epsilon}\int_\Omega(\chi_{D_\epsilon}-\chi_D)\nabla u\nabla v_\eta \\ &\le C|k-1|\|(\nabla u)^{**}\|_{L^2(\partial D)}\|(\nabla v_\eta)^{**}\|_{L^2(\partial D_\epsilon)}.\end{aligned}$$

By Lemma 2.1, $\int_{\partial D_\epsilon} |(\nabla v_\eta)^{**}|^2 \le \int_{\partial D_\epsilon} |\eta - \int_{\partial\Omega} \eta|^2 \le C$ and hence we have

$$\int_{\partial\Omega} |U_\epsilon| \le C|k-1| \|\nabla u\|_{L^2(\Omega)} \le C|k-1| \|g\|_{L^2(\partial\Omega)}. \tag{4.13}$$

Let

$$\tilde{\Gamma}(x) := \frac{1}{2\pi} \int_\Omega \log|x-y| \left(\chi_{\Omega\setminus\overline{D}_\epsilon}(y) + \frac{1}{k}\chi_{D_\epsilon}(y) \right) dy$$

as in (4.6). Then, as before,

$$\tilde{V}(x) := \tilde{\Gamma}(x) + \mathcal{S}_{D_\epsilon}(\lambda I - \mathcal{K}^*_{D_\epsilon})^{-1} \left(\frac{\partial \tilde{\Gamma}}{\partial \nu}|_{\partial D_\epsilon} \right)(x)$$

satisfies $\nabla \cdot ((1+(k-1)\chi_{D_\epsilon})\nabla \tilde{V}) = 1$ in Ω and $\|\nabla \tilde{V}\|_{L^\infty(\partial\Omega)} \le C$. By substituting $\eta = \tilde{V}$ in (4.4) again, we obtain

$$\int_\Omega U_\epsilon \le \int_{\partial\Omega} |U_\epsilon| \left| \frac{\partial \tilde{V}}{\partial \nu} \right| + C\frac{1}{\epsilon} \int_\Omega |\chi_{D_\epsilon} - \chi_D| |\nabla u| |\nabla \tilde{V}|.$$

Hence (4.3) follows from the above estimate, (4.13), and (4.3′). This completes the proof. □

LEMMA 4.3. *Let* $\Omega_1 = \{X \in \Omega : \operatorname{dist}(X, \partial\Omega) < \delta_0\}$. *Then*

$$\sup_{X\in\Omega_1} |U_\epsilon(X)| + \sup_{X\in\Omega_1} |\nabla U_\epsilon(X)| \le C\|g\|_{L^2(\partial\Omega)}, \tag{4.14}$$

where the constant C *depends on* δ_0, *the Lipschitz characters of* D, D_ϵ, *and the* C^2*-character of* Ω.

Proof. Since $\Delta U_\epsilon = 0$ in Ω_1, U_ϵ and $|\nabla U_\epsilon|$ cannot assume an interior maximum in Ω_1. Suppose $X_0 \in \partial\Omega_1 \cap \Omega$. By the mean value theorem and the standard interior estimates of derivatives, we obtain

$$|U_\epsilon(X_0)| + |\nabla U_\epsilon(X_0)| \le C \left(\frac{1}{|B_{\delta_0(X_0)}|} \int_{B_{\delta_0}(X_0)} |U_\epsilon|^2 + |\nabla U_\epsilon|^2 \right)^{1/2}.$$

By Theorem 4.2 and the standard interior estimate, we obtain

$$|U_\epsilon(X_0)| + |\nabla U_\epsilon(X_0)| < C\|g\|_{L^2(\partial\Omega)}. \tag{4.15}$$

Now suppose $X_0 \in \partial\Omega$. Then we first straighten a boundary portion near X_0, and using the condition $\frac{\partial U_\epsilon}{\partial \nu} = 0$ on $\partial\Omega$ and the Schauder estimate we obtain the estimate (4.14) (see [GT, p. 126]). This completes the proof. □

By (2.1), the solutions u and u_ϵ can be expressed uniquely as

$$u = H + \mathcal{S}_D(\varphi_D) \quad \text{and} \quad u_\epsilon = H_\epsilon + \mathcal{S}_{D_\epsilon}(\varphi_{D_\epsilon}) \quad \text{in } \Omega, \tag{4.16}$$

where H, φ_D, H_ϵ, and φ_{D_ϵ} satisfy the relations (2.3) and (2.4). For notational simplicity, we will write

$$\varphi = \varphi_D,\ \mathcal{S} = \mathcal{S}_D,\ \mathcal{K}^* = \mathcal{K}^*_D,\ \varphi_\epsilon = \varphi_{D_\epsilon},\ \mathcal{S}_\epsilon = \mathcal{S}_{D_\epsilon},\ \mathcal{K}^*_\epsilon = \mathcal{K}^*_{D_\epsilon}.$$

We first prove the stability of the harmonic part of the solution in Lemma 4.4.

LEMMA 4.4. *We have that*

$$\|H - H_\epsilon\|_{L^\infty(\Omega)} + \|\nabla(H - H_\epsilon)\|_{L^\infty(\Omega)} < C\epsilon\|g\|_{L^2(\partial\Omega)}, \tag{4.17}$$

where the constant C depends on δ_0, the Lipschitz characters of D, D_ϵ, and the C^2-character of Ω.

Proof. From (2.3), we have

$$\frac{H - H_\epsilon}{\epsilon} = \mathcal{D}_\Omega(U_\epsilon|_{\partial\Omega}).$$

Since $\partial\Omega \in C^2$, $|\frac{\langle P-Q,\nu(Q)\rangle}{|P-Q|^2}| \le C$ for $P, Q \in \partial\Omega$ where C depends on the C^2-character of $\partial\Omega$. Hence for $P \in \partial\Omega$,

$$\begin{aligned}\left|\frac{H(P) - H_\epsilon(P)}{\epsilon}\right| &\le \int_{\partial\Omega}\left|\frac{\partial}{\partial\nu}\Gamma(P-Q)\right||U_\epsilon(Q)|d\sigma(Q)\\ &\le C\|U_\epsilon\|_{L^1(\partial\Omega)} \le C\|g\|_{L^2(\partial\Omega)}\end{aligned}$$

by Lemma 4.3. Thus by the maximum principle we have

$$\left\|\frac{H - H_\epsilon}{\epsilon}\right\|_{L^\infty(\Omega)} \le C\|g\|_{L^2(\partial\Omega)}.$$

By the relation (4.16) and Lemma 4.3, we have

$$\left\|\frac{\mathcal{S}\varphi - \mathcal{S}_\epsilon\varphi_\epsilon}{\epsilon}\right\|_{L^\infty(\partial\Omega)} \le \left\|\frac{H - H_\epsilon}{\epsilon}\right\|_{L^\infty(\partial\Omega)} + \|U_\epsilon\|_{L^\infty(\partial\Omega)} \le C\|g\|_{L^2(\partial\Omega)}.$$

Since $\Delta(\mathcal{S}\varphi - \mathcal{S}_\epsilon\varphi_\epsilon) = 0$ in $\mathbb{R}^2 \setminus (\partial D \cup \partial D_\epsilon)$ and $|\mathcal{S}\varphi(X)| = O(|X|^{-1})$ for $|X|$ large (recall $\int_{\partial D}\varphi = 0$),

$$\left\|\frac{\mathcal{S}\varphi - \mathcal{S}\varphi_\epsilon}{\epsilon}\right\|_{L^\infty(\mathbb{R}^2\setminus\Omega)} = \left\|\frac{\mathcal{S}\varphi - \mathcal{S}_\epsilon\varphi_\epsilon}{\epsilon}\right\|_{L^\infty(\partial\Omega)} \le C\|g\|_{L^2(\partial\Omega)}. \tag{4.18}$$

Then, for $P \in \partial\Omega$,

$$\begin{aligned}&\left|\nabla\left(\frac{\mathcal{S}\varphi - S_\epsilon\varphi_\epsilon}{\epsilon}\right)(P)\right|\\ &\le C\left\|\frac{\mathcal{S}\varphi - \mathcal{S}_\epsilon\varphi_\epsilon}{\epsilon}\right\|_{L^1(B_{\delta_0}(P))} \qquad \text{(by the interior estimate)}\\ &\le C\left\|\frac{\mathcal{S}\varphi - \mathcal{S}_\epsilon\varphi_\epsilon}{\epsilon}\right\|_{L^1(B_{\delta_0}(P)\cap\Omega)} + C\|g\|_{L^2(\partial\Omega)} \qquad \text{(by (4.18))}\\ &\le C\left\|\frac{H - H_\epsilon}{\epsilon}\right\|_{L^1(B_{\delta_0}(P)\cap\Omega)} + \|U_\epsilon\|_{L^1(B_{\delta_0}(P)\cap\Omega)} + C\|g\|_{L^2(\partial\Omega)} \qquad \text{(by (4.16))}\\ &\le C\|g\|_{L^2(\partial\Omega)}.\end{aligned}$$

From Lemma 4.3 and (4.16), we obtain

$$\begin{aligned}\left\|\nabla\left(\frac{H - H_\epsilon}{\epsilon}\right)\right\|_{L^\infty(\Omega)} &\le \left\|\nabla\left(\frac{H - H_\epsilon}{\epsilon}\right)\right\|_{L^\infty(\partial\Omega)}\\ &\le \|\nabla U_\epsilon\|_{L^\infty(\partial\Omega)} + \left\|\nabla\left(\frac{\mathcal{S}\varphi - \mathcal{S}_\epsilon\varphi_\epsilon}{\epsilon}\right)\right\|_{L^\infty(\partial\Omega)}\\ &\le C\|g\|_{L^2(\partial\Omega)}.\end{aligned}$$

This completes the proof. □

We now prove the uniform stability of the single layer potential which, combined with Lemma 4.4, proves Theorem 4.1.

We first compare $\mathcal{K}_\epsilon^*$ with $\mathcal{K}^*$ in the uniform norm. Let Φ_ϵ be the diffeomorphism from ∂D onto ∂D_ϵ given by $\Phi_\epsilon(P) = P + \epsilon\omega_\epsilon(P)\nu(P)$.

LEMMA 4.5. *There exists C depending only on the C^2-character of ∂D such that for any function $f \in L^2(\partial D_\epsilon)$,*

$$\|(\mathcal{K}_\epsilon^* f)\circ\Phi_\epsilon - \mathcal{K}^*(f\circ\Phi_\epsilon)\|_{L^2(\partial D)} \le C\epsilon\|f\|_{L^2(\partial D_\epsilon)}. \tag{4.19}$$

Proof. Fix $P \in \partial D$. Let

$$k(P,Q) = \frac{\langle P-Q, \nu(P)\rangle}{|P-Q|^2} \quad \text{and} \quad k_\epsilon(P,Q) = \frac{\langle \Phi_\epsilon(P)-\Phi_\epsilon(Q), \nu(\Phi_\epsilon(P))\rangle}{|\Phi_\epsilon(P)-\Phi_\epsilon(Q)|^2},$$

which are integral kernels for $\mathcal{K}$ and $\mathcal{K}_\epsilon$. Then

$$\begin{aligned}&(\mathcal{K}_\epsilon^* f)\circ\Phi_\epsilon(P) - \mathcal{K}^*(f\circ\Phi_\epsilon)(P)\\ &\quad = \int_{\partial D}[k_\epsilon(P,Q)j_\epsilon(Q) - k(P,Q)]f\circ\Phi_\epsilon(Q)d\sigma(Q),\end{aligned}$$

where j_ϵ is the Jacobian of Φ_ϵ. To estimate $k_\epsilon(P,Q) - k(P,Q)$, we observe that

$$\nu(\Phi_\epsilon(P)) = (1+O(\epsilon))\nu(P) + O(\epsilon)T(P), \tag{4.20}$$

where $T(P)$ is the unit tangent to ∂D at P. Note that above $O(\epsilon)$ depends only on the C^2-norm of ∂D. Since $\partial D \in C^2$, we have

$$k_\epsilon(P,Q) - k(P,Q) = O(\epsilon) + O(\epsilon)\frac{\langle P-Q, T(P)\rangle}{|P-Q|^2}$$

and hence

$$\begin{aligned}&|(\mathcal{K}_\epsilon^* f)\circ\Phi_\epsilon(P) - \mathcal{K}^*(f\circ\Phi_\epsilon)(P)|\\ &\quad \le O(\epsilon)\int_{\partial D}|f\circ\Phi_\epsilon(Q)|d\sigma(Q) + O(\epsilon)|\mathcal{T}(f\circ\Phi_\epsilon)(P)|,\end{aligned}$$

where

$$\mathcal{T}f\circ\Phi_\epsilon(P) = \int_{\partial D}\frac{\langle P-Q, T(P)\rangle}{|P-Q|^2}f\circ\Phi_\epsilon(Q)d\sigma(Q).$$

It is now standard to show that

$$\|\mathcal{T}f\|_{L^2(\partial D)} \le C\|f\|_{L^2(\partial D)}.$$

This completes the proof. □

LEMMA 4.6. *We have that*

$$\|\varphi_\epsilon\circ\Phi_\epsilon - \varphi\|_{L^2(\partial D)} \le C\epsilon\|g\|_{L^2(\partial\Omega)}, \tag{4.21}$$

where the constant C depends on C^2-characters of $\partial D, \partial\Omega$, and δ_0.

Proof. Let $\lambda = \frac{k+1}{2(k-1)}$. Since $(\lambda I - \mathcal{K}^*)$ is invertible on $L^2(\partial D)$ (see [F]), we have from Lemmas 4.4 and 4.5 that

$$\begin{aligned}
&\|\varphi_\epsilon \circ \Phi_\epsilon - \varphi\|_{L^2(\partial D)} \\
&\quad \le C\|(\lambda I - \mathcal{K}^*)(\varphi_\epsilon \circ \Phi_\epsilon - \varphi)\|_{L^2(\partial D)} \\
&\quad \le C\|((\lambda I - \mathcal{K}_\epsilon^*)\varphi_\epsilon) \circ \Phi_\epsilon - (\lambda I - \mathcal{K}^*)\varphi\|_{L^2(\partial D)} \\
&\qquad\quad + C\|(\mathcal{K}_\epsilon^*\varphi_\epsilon) \circ \Phi_\epsilon - \mathcal{K}^*(\varphi_\epsilon \circ \Phi_\epsilon)\|_{L^2(\partial D)} \\
&\quad \le C\left\|\frac{\partial H_\epsilon}{\partial \nu} \circ \Phi_\epsilon - \frac{\partial H}{\partial \nu}\right\|_{L^2(\partial D)} + C\epsilon\|\varphi_\epsilon\|_{L^2(\partial D_\epsilon)} \\
&\quad \le C\left\|\frac{\partial H_\epsilon}{\partial \nu} \circ \Phi_\epsilon - \frac{\partial H}{\partial \nu} \circ \Phi_\epsilon\right\|_{L^2(\partial D)} + C\left\|\frac{\partial H}{\partial \nu} \circ \Phi_\epsilon - \frac{\partial H}{\partial \nu}\right\|_{L^2(\partial D)} \\
&\qquad\quad + C\epsilon\left\|(\lambda I - \mathcal{K}_\epsilon^*)^{-1}\frac{\partial H_\epsilon}{\partial \nu}\right\|_{L^2(\partial D_\epsilon)} \\
&\quad \le C\epsilon(\|H\|_{W^{2,\infty}(\Omega_0)} + \|H\|_{W^{2,\infty}(\Omega_0)}) \\
&\quad \le C\epsilon\left(\|H\|_{L^2(\Omega)} + \|H_\epsilon\|_{L^2(\Omega)}\right) \\
&\quad \le C\epsilon\|g\|_{L^2(\partial\Omega)}.
\end{aligned}$$

The last inequality follows from Lemma 2.1. This completes the proof. ∎

LEMMA 4.7. *We have that*

$$\|\mathcal{S}\varphi - \mathcal{S}_\epsilon\varphi_\epsilon\|_{L^\infty(\Omega)} \le C\epsilon\|g\|_{L^2(\partial\Omega)},$$

where the constant C depends on C^2-characters of $\partial D, \partial\Omega$, and δ_0.

Proof. Since $\mathcal{S}\varphi(X) = \mathcal{S}_\epsilon\varphi_\epsilon(X) = O(|X|^{-1})$ as $|X| \to \infty$, by the maximum principle, there is a $P \in \partial D \cup \partial D_\epsilon$ such that

$$|\mathcal{S}\varphi(P) - \mathcal{S}_\epsilon\varphi_\epsilon(P)| = \sup_{X\in\Omega} |\mathcal{S}\varphi(X) - \mathcal{S}_\epsilon\varphi_\epsilon(X)|.$$

Suppose that $P \in \partial D$. (The case when $P \in \partial D_\epsilon$ can be treated in the exact same way by interchanging the role of ∂D and ∂D_ϵ.) Then

$$\begin{aligned}
&\mathcal{S}\varphi(P) - \mathcal{S}_\epsilon\varphi_\epsilon(P) \\
&= \frac{1}{2\pi}\int_{\partial D} [\log|P - Q|\varphi(Q) - \log|P - \Phi_\epsilon(Q)|]\, j_\epsilon(Q)\varphi_\epsilon \circ \Phi_\epsilon(Q)d\sigma(Q) \\
&= \frac{1}{2\pi}\int_{\partial D} [\log|P - Q| - \log|P - \Phi_\epsilon(Q)|]\, \varphi(Q)d\sigma(Q) \\
&\quad + \frac{1}{2\pi}\int_{\partial D} \log|P - \Phi_\epsilon(Q)|\, [1 - j_\epsilon(Q)]\, \varphi_\epsilon \circ \Phi_\epsilon(Q)d\sigma(Q) \\
&\quad + \frac{1}{2\pi}\int_{\partial D} \log|P - \Phi_\epsilon(Q)|\, [\varphi(Q) - \varphi_\epsilon \circ \Phi_\epsilon(Q)]\, d\sigma(Q) \\
&:= I_1 + I_2 + I_3.
\end{aligned}$$

It follows from Lemma 4.6 that

$$|I_3| \le C\epsilon\|g\|_{L^2(\partial\Omega)}.$$

It is easy to see that

$$|I_2| \le C\epsilon\|g\|_{L^2(\partial\Omega)}.$$

Since

$$\left| \int_{\partial D} \log|P-Q| - \log|P-\Phi_\epsilon(Q)| d\sigma(Q) \right| \le C\epsilon,$$

it follows from the standard argument of singular integral that

$$|I_1| \le C\epsilon \|\varphi\|_{C^{1/2}(\partial D)} \le C\epsilon \|g\|_{L^2(\partial\Omega)}.$$

The last inequality follows from Lemma 2.1 and the invertibility of $\lambda I - \mathcal{K}^*$ on $C^\alpha(\partial D)$, $0 < \alpha < 1$. This completes the proof. □

5. Perturbation of disk-error estimates. In this section, we apply the results from sections 3 and 4 to the class of perturbation of disks. From Theorem 4.1, we have the following theorem.

THEOREM 5.1. *Let $D \in \mathcal{C}[\epsilon]$ and D be an ϵ-perturbation of a disk B. There is a constant C depending on δ_0 and d_0, not on D or B, such that if u_D and u_B are solutions to $P[D,g]$ and $P[B,g]$, respectively, then*

$$\|u_D - u_B\|_{L^\infty(\Omega)} \le C\epsilon. \tag{5.1}$$

Theorems 5.1 and 4.1 give the following stability for $\mathcal{C}[\epsilon]$.

THEOREM 5.2. *Suppose that $D_1, D_2 \in \mathcal{C}[\epsilon]$. Let g satisfy the condition (N). Then there is a positive constant C independent of D_j so that*

$$|D_1 \Delta D_2| \le C\left(\epsilon + \|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^\infty(\partial\Omega)}\right)^\alpha. \tag{5.2}$$

Proof. By the definition, there are two balls B_1 and B_2 such that D_j is an ϵ-perturbation of B_j. Let v_j and u_j be the solutions of the Neumann problems $P[B_j, g]$ and $P[D_j, g]$, respectively. By Theorem 5.1, we have

$$\sup_{x\in\Omega} |v_j(x) - u_j(x)| \le C\epsilon.$$

Hence

$$\|v_1 - v_2\|_{L^\infty(\partial\Omega)} \le C\left(\epsilon + \|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^\infty(\partial\Omega)}\right).$$

It then follows from Theorem 3.1 that

$$d(B_1, B_2) \le C\left(\epsilon + \|\Lambda_{D_1}(g) - \Lambda_{D_2}(g)\|_{L^\infty(\partial\Omega)}\right)^\alpha$$

and hence (5.2) follows. This completes the proof. □

6. Approximate identification (without restriction on g). In this section, we consider the uniqueness question without imposing any restriction on the Neumann data g. Let g be any given nonzero function on $\partial\Omega$. Let $D_0 \in \mathcal{C}[\epsilon]$ and let $\Lambda_{D_0}(g) = f$. We obtain that if $D \in \mathcal{C}[\epsilon]$ satisfies $\Lambda_D(g) = f$, then D must be close to D_0. Indeed, we obtain the following result.

THEOREM 6.1. *There is a positive constant C such that if $D \in \mathcal{C}[\epsilon]$ and $\Lambda_D(g) = f$ on $\partial\Omega$, then*

$$|D \Delta D_0| \le C\epsilon.$$

Remark. Theorem 6.1 together with the result in [AIP] gives the global uniqueness within $\mathcal{C}[\epsilon]$ for sufficiently small ϵ if g satisfies the following condition: $\partial\Omega$ is the union of two disjoint arcs Γ_1 and Γ_2, and

$$g \geq 0 \quad \text{on } \Gamma_1 \qquad \text{and} \qquad g \leq 0 \quad \text{on } \Gamma_2.$$

Here $\partial\Omega$ is smooth.

Without loss of generality, we assume D_0 is an ϵ-perturbation of a disk $B_0 = B_{r_0}(0)$ and D is an ϵ-perturbation of a disk $B = B_r(a)$. For notational simplicity, we will write

$$\varphi_0 = \varphi_{D_0},\ \varphi = \varphi_D;\ \mathcal{S}_0 = \mathcal{S}_{D_0},\ \mathcal{S} = \mathcal{S}_D;\ \mathcal{K}_0^* = \mathcal{K}_{D_0}^*,\ \mathcal{K}^* = \mathcal{K}_D^*.$$

By (2.2), the solution $u = u_D$ can be expressed uniquely as

$$u = H + \mathcal{S}\varphi \quad \text{in } \Omega, \tag{6.1}$$

where H and φ are given in the formulas (2.3) and (2.4); that is,

$$\varphi = (\lambda I - \mathcal{K}^*)^{-1}\left(\frac{\partial H}{\partial \nu}\right) \qquad \text{on } \partial D. \tag{6.2}$$

From (6.2), $\int_{\partial D} \varphi = 0 = \int_{\partial D} \mathcal{K}^*\varphi$.

LEMMA 6.2. *We have that*

$$\mathcal{S}\varphi = -\frac{1}{2\lambda}H + w + c \quad \text{in } D, \tag{6.3}$$

where c is a constant and w is the solution to the Neumann problem:

$$\begin{cases} \Delta w = 0 & \text{in } D, \\ \dfrac{\partial w}{\partial \nu}|_{\partial D} = \left(1 - \dfrac{1}{2\lambda}\right)\mathcal{K}^*\varphi, \quad \displaystyle\int_{\partial D} w = 0. \end{cases} \tag{6.4}$$

Proof. Since

$$\begin{aligned} \frac{\partial}{\partial \nu^-}\mathcal{S}\varphi|_{\partial D} &= \left(-\frac{1}{2}I + \mathcal{K}^*\right)\varphi \\ &= -\frac{1}{2\lambda}(\lambda I - \mathcal{K}^*)\varphi + \left(1 - \frac{1}{2\lambda}\right)\mathcal{K}^*\varphi \\ &= -\frac{1}{2\lambda}\frac{\partial H}{\partial \nu}\Big|\partial D + \left(1 - \frac{1}{2\lambda}\right)\mathcal{K}^*\varphi, \end{aligned} \tag{6.5}$$

(6.3) follows from the uniqueness of the Neumann problem. □

Observe that if D is a disk, then $\mathcal{K}^*\varphi = 0$ and hence $w = 0$ in D (see [KS1]).

LEMMA 6.3. *There exists C depending only on δ_0 and d_0 such that*

$$\|\mathcal{K}^*\varphi\|_{L^2(\partial D)} \leq C\epsilon\|\varphi\|_{L^2(\partial D)}.$$

Proof. Let φ_B be the density function in (6.2) with D replaced by B. Then $\mathcal{K}_B^*\varphi_B = 0$. Therefore, Lemma 6.3 follows from Lemma 4.5. □

Set

$$U = u_0 - u = \mathcal{S}_0\varphi_0 - \mathcal{S}\varphi. \tag{6.6}$$

It follows from the basic regularity theory that $u \in C^1(\overline{D}) \cap C^1(\Omega \setminus D)$ and $u_0 \in C^1(\overline{D_0}) \cap C^1(\Omega \setminus D_0)$. We will denote by $\frac{\partial U^\#}{\partial \nu}$ the outer normal derivative of U on the boundary from the region $(D \setminus \overline{D_0}) \cup (D_0 \setminus \overline{D})$.

LEMMA 6.4. *Assume that $\Omega \setminus \overline{D \cup D_0}$ is connected. Then*

(1) $U = 0$ *in* $\Omega \setminus \overline{D \cup D_0}$,

(2) $$\frac{\partial U^\#}{\partial \nu} = -\varphi \quad \text{on } \partial D \setminus \overline{D_0} \quad \text{and} \quad \frac{\partial U^\#}{\partial \nu} = -\varphi_0 \quad \text{on } \partial D_0 \setminus \overline{D},$$

(3) $$\frac{\partial U^\#}{\partial \nu} = \varphi + \frac{\partial}{\partial \nu}(w_0 - w) \quad \text{on } \partial D \cap D_0,$$
$$\frac{\partial U^\#}{\partial \nu} = \varphi_0 + \frac{\partial}{\partial \nu}(w_0 - w) \quad \text{on } \partial D_0 \cap D.$$

Here w_0 is the function in Lemma 6.2 for D_0; i.e., $\mathcal{S}_0\varphi_0 = -\frac{1}{2\lambda}H + w_0 + c_0$ in D_0.

Proof. Since $U = \frac{\partial U}{\partial \nu} = 0$ on $\partial\Omega$, (1) follows from the unique continuation of the harmonic function. From (1) and the jump relation (2.1), for $x \in \partial D_0 \setminus \overline{D}$,

$$\begin{aligned}\frac{\partial U^\#}{\partial \nu}(x) &= \frac{\partial u_0^i}{\partial \nu}(x) - \frac{\partial u^e}{\partial \nu}(x) = \frac{\partial u_0^i}{\partial \nu}(x) - \frac{\partial u^e}{\partial \nu}(x) - \left(\frac{\partial u_0^e}{\partial \nu}(x) - \frac{\partial u^e}{\partial \nu}(x)\right) \\ &= \frac{\partial u_0^i}{\partial \nu}(x) - \frac{\partial u_0^e}{\partial \nu}(x) = -\varphi_0(x),\end{aligned}$$

which proves the second part of (2). The first part of (2) can be proved in the same way. From Lemma 6.2 and the trace formula (2.1), we have for $x \in \partial D \cap D_0$,

$$\begin{aligned}\frac{\partial U^\#}{\partial \nu}(x) &= \frac{\partial u_0^i}{\partial \nu}(x) - \frac{\partial u^e}{\partial \nu}(x) \\ &= \frac{\partial u_0^i}{\partial \nu}(x) - \frac{\partial u^e}{\partial \nu}(x) - \left(\frac{\partial u_0^i}{\partial \nu}(x) - \frac{\partial u^i}{\partial \nu}(x)\right) + \left(\frac{\partial u_0^i}{\partial \nu}(x) - \frac{\partial u^i}{\partial \nu}(x)\right) \\ &= \varphi(x) + \frac{\partial}{\partial \nu}(w_0 - w)(x).\end{aligned}$$

This completes the proof. ∎

LEMMA 6.5. *Assume that $\Omega \setminus \overline{D \cup D_0}$ is connected. Then there exists a positive constant C depending only on the radii of B_0 and B so that*

$$\begin{aligned}&\frac{1}{2}\left(\|\varphi_0\|^2_{L^2(\partial D_0 \setminus E)} + \|\varphi\|^2_{L^2(\partial D \setminus E)}\right) - C\epsilon^2\left(\|\varphi_0\|^2_{L^2(\partial D_0)} + \|\varphi\|^2_{L^2(\partial D)}\right) \\ &\le \int_{\partial(D \setminus \overline{D_0})} \left|\frac{\partial U^\#}{\partial \nu}\right|^2 + \int_{\partial(D_0 \setminus \overline{D})} \left|\frac{\partial U^\#}{\partial \nu}\right|^2 \\ &\le C\left(\|\varphi_0\|^2_{L^2(\partial D_0)} + \|\varphi\|^2_{L^2(\partial D)}\right),\end{aligned} \tag{6.7}$$

where $E = \partial D_0 \cap \partial D$.

Proof. From Lemma 6.4, we have

$$\int_{\partial D_0\setminus\overline{D}}\left|\frac{\partial U^{\#}}{\partial\nu}\right|^2=\int_{\partial D_0\setminus\overline{D}}|\varphi_0|^2.$$

We also obtain

$$\int_{\partial D\cap D_0}\left|\frac{\partial U^{\#}}{\partial\nu}\right|^2\geq\frac{1}{2}\int_{\partial D\cap D_0}|\varphi|^2-\int_{\partial D\cap D_0}\left|\frac{\partial w_0}{\partial\nu}-\frac{\partial w}{\partial\nu}\right|^2.$$

Thus by Theorem 2.2 and Lemmas 6.2 and 6.3, we have

$$\begin{aligned}\int_{\partial D\cap D_0}\left|\frac{\partial w_0}{\partial\nu}-\frac{\partial w}{\partial\nu}\right|^2&\leq 2\int_{\partial D_0}|(\nabla w_0)^*|^2+2\int_{\partial D}|(\nabla w)^*|^2\\&\leq C\left(\int_{\partial D_0}\left|\frac{\partial w_0}{\partial\nu}\right|^2+\int_{\partial D}\left|\frac{\partial w}{\partial\nu}\right|^2\right)\\&=C\left(\int_{\partial D_0}|\mathcal{K}_0^*\varphi_0|^2+\int_{\partial D}|\mathcal{K}^*\varphi|^2\right)\\&\leq C\epsilon^2\left(\|\varphi_0\|^2_{L^2(\partial D_0)}+\|\varphi\|^2_{L^2(\partial D)}\right).\end{aligned}$$

The other inequalities can be obtained in the same way. Thus we have the first inequality in (6.7).

The second inequality in (6.7) follows from the singular integral estimates

$$\|(\nabla\mathcal{S}\varphi)^{**}\|_{L^2(\partial D)}\leq C\|\varphi\|_{L^2(\partial D)}\quad\text{and}\quad\|(\nabla\mathcal{S}_0\varphi_0)^{**}\|_{L^2(\partial D)}\leq C\|\varphi_0\|_{L^2(\partial D)},$$

where C is a positive constant depending only on the Lipschitz characters of D and D_0. This completes the proof. □

We are now ready to prove Theorem 6.1.

Proof of Theorem 6.1. If $\Lambda_{D_0}(g)=\Lambda_D(g)$ on $\partial\Omega$, it is known that $\overline{D}\cap\overline{D_0}\neq\emptyset$ and one domain cannot be contained in the other (see [FI].) Hence it must be

$$\partial D\cap\partial D_0\neq\emptyset.$$

Assume first that $\Omega\setminus\overline{D\cup D_0}$ is connected. Let M be a fixed number to be chosen later. Take a function $\eta\in C^2(\mathbb{R}^2)$ so that $\eta=1$ in $\mathbb{R}^2\setminus B_{r+2M\epsilon}(a)$, $\eta=0$ in $B_{r+\epsilon}(a)$, and $\|\nabla\eta\|_{L^\infty}\leq\frac{1}{M\epsilon}$. Let $\vec{\alpha}(x)=x\eta(x)$. If we apply the Rellich identity as in (2.11) with $U=u_0-u$ over the region $D_0\setminus\overline{D}$, then

(6.8)
$$\int_{\partial(D_0\setminus\overline{D})}\langle\vec{\alpha},\nu\rangle\left|\frac{\partial U^{\#}}{\partial\nu}\right|^2=\int_{\partial(D_0\setminus\overline{D})}\langle\vec{\alpha},\nu\rangle\left|\frac{\partial U}{\partial T}\right|^2-2\int_{\partial(D_0\setminus\overline{D})}\langle\vec{\alpha},T\rangle\frac{\partial U}{\partial T}\frac{\partial U^{\#}}{\partial\nu}+\mathcal{R},$$

where

$$\mathcal{R}=\int_{D_0\setminus\overline{D}}2\langle\nabla\vec{\alpha}\nabla U,\nabla U\rangle-\mathrm{div}\vec{\alpha}|\nabla U|^2.$$

Here $\frac{\partial U}{\partial T}$ denotes the tangential derivative on the boundary. Since $U=0$ in $\Omega\setminus\overline{D_0\cup D}$, $\frac{\partial U}{\partial T}=0$ along $\partial D_0\setminus\overline{D}$ and $\partial D\setminus\overline{D_0}$. And $\vec{\alpha}=0$ on $\partial D\cap\overline{D_0}$. Therefore, the first and

second terms of the right side of the equality in (6.8) vanish. Moreover, we have

$$
\begin{aligned}
|\mathcal{R}| &\le C\|\nabla\vec{\alpha}\|_{L^\infty(\mathbb{R}^2)}\int_{D_0\setminus\overline{D}}|\nabla U|^2 \\
&\le C\left(\frac{1}{M\epsilon}+1\right)\int_{\partial(D_0\setminus\overline{D})}\frac{\partial U^\#}{\partial\nu}U \\
&\le C\left(\frac{1}{M\epsilon}+1\right)\left(\int_{\partial(D_0\setminus\overline{D})}\left|\frac{\partial U^\#}{\partial\nu}\right|^2\right)^{1/2}\left(\int_{\partial(D_0\setminus\overline{D})}|U|^2\right)^{1/2}.
\end{aligned}
\tag{6.9}
$$

From Lemma 6.5, we obtain

$$
|\mathcal{R}| \le C\left(\frac{1}{M\epsilon}+1\right)\left(\|\varphi_0\|^2_{L^2(\partial D_0)}+\|\varphi\|^2_{L^2(\partial D)}\right)^{1/2}\left(\int_{\partial(D_0\setminus\overline{D})}|U|^2\right)^{1/2}. \tag{6.10}
$$

It follows from Lemma 6.2 that

$$
\begin{aligned}
\int_{\partial(D_0\setminus\overline{D})}|U|^2 &= \int_{\overline{D_0}\cap\partial D}|U|^2 \\
&= \int_{\overline{D_0}\cap\partial D}|w_0-c_0-(w-c)|^2 \\
&\le C(\|w\|^2_{L^\infty(D)}+\|w\|^2_{L^\infty(D)}+|c-c_0|^2).
\end{aligned}
$$

We now show that

$$
\|w\|^2_{L^\infty(D)}+\|w\|^2_{L^\infty(D)}+|c-c_0|^2 \le C\epsilon^2\left(\|\varphi_0\|^2_{L^2(\partial D_0)}+\|\varphi\|^2_{L^2(\partial D)}\right). \tag{6.11}
$$

There exists $\psi\in L^2(\partial D)$ with $\int_{\partial D}\psi=0$ so that $(-\frac{1}{2}I+\mathcal{K}^*)\psi=(1-\frac{1}{2\lambda})\mathcal{K}^*\varphi$ on ∂D (see [F]). Thus

$$
\begin{aligned}
&w(x)=\frac{1}{2\pi}\int_{\partial D}\log|x-y|\psi(y)d\sigma(y)\quad\text{for } x\in D,\\
&\|\psi\|_{L^2(\partial D)}\le C\left\|\left(1-\frac{1}{2\lambda}\right)\mathcal{K}^*\varphi\right\|_{L^2(\partial D)}\le C\epsilon\|\varphi\|_{L^2(\partial D)}.
\end{aligned}
$$

From the Schwartz inequality, we obtain

$$
\|w\|_{L^\infty(D)}\le\left(\int_{\partial D}|\log|x-y||^2\right)^{1/2}\left(\int_{\partial D}|\psi|^2\right)^{1/2}\le C\epsilon\|\varphi\|_{L^2(\partial D)}.
$$

Suppose that $\partial(\overline{D_0\cup D})\cap\partial(D_0\cap D)\neq\emptyset$. At a point $P\in\partial(\overline{D_0\cup D})\cap\partial(D_0\cap D)$, $U(P)=0=\mathcal{S}_0\varphi_0(P)-\mathcal{S}\varphi(P)$. It follows from the above estimate that

$$
\begin{aligned}
|c_0-c| &= |w_0(P)-w(P)| \\
&\le \|w_0\|_{L^\infty(D_0)}+\|w\|_{L^\infty(D)} \\
&\le C\epsilon\left(\|\varphi_0\|_{L^2(\partial D_0)}+\|\varphi\|_{L^2(\partial D)}\right).
\end{aligned}
$$

This proves the estimate (6.11).

It then follows from (6.8)–(6.11) that

$$\int_{\partial(D_0\setminus\overline{D})}\langle\vec{\alpha},\nu\rangle\left|\frac{\partial U^{\#}}{\partial\nu}\right|^2\le C\left(\frac{1}{M}+\epsilon\right)\left(\|\varphi_0\|^2_{L^2(\partial D_0)}+\|\varphi\|^2_{L^2(\partial D)}\right). \tag{6.12}$$

As before, we apply the Rellich identity (6.8) with the vector field $\vec{\beta}(x)=(\eta(x)-1)(x-a)$ over the domain $D_0\setminus\overline{D}$ and obtain

$$\int_{\partial(D_0\setminus\overline{D})}\langle\vec{\beta},\nu\rangle\left|\frac{\partial U^{\#}}{\partial\nu}\right|^2\le C\left(\frac{1}{M}+\epsilon\right)\left(\|\varphi_0\|^2_{L^2(\partial D_0)}+\|\varphi\|^2_{L^2(\partial D)}\right)+|\mathcal{J}|, \tag{6.13}$$

where

$$\mathcal{J}=\int_{\partial(D\setminus\overline{D_0})}\langle\vec{\beta},\nu\rangle\left|\frac{\partial U}{\partial T}\right|^2-2\int_{\partial(D\setminus\overline{D_0})}\langle\vec{\beta},T\rangle\frac{\partial U}{\partial T}\frac{\partial U^{\#}}{\partial\nu}.$$

Since $\frac{\partial U}{\partial T}=0$ on $\partial D\setminus\overline{D_0}$,

$$|\mathcal{J}|\le C\int_{\partial D_0\cap\overline{D}}\left|\frac{\partial U}{\partial T}\right|^2+\left|\frac{\partial U}{\partial T}\right|\left|\frac{\partial U^{\#}}{\partial\nu}\right|. \tag{6.14}$$

Note that

$$\frac{\partial U}{\partial T}=\frac{\partial}{\partial T}(w_0-w)\quad\text{ on }\partial D_0\cap D.$$

By Lemmas 6.3 and 6.5 and (6.14), we obtain

$$|\mathcal{J}|\le C\epsilon\left(\|\varphi_0\|^2_{L^2(\partial D_0)}+\|\varphi\|^2_{L^2(\partial D)}\right).$$

It then follows from (6.13) that

$$\int_{\partial(D_0\setminus\overline{D})}\langle\vec{\beta},\nu\rangle\left|\frac{\partial U^{\#}}{\partial\nu}\right|^2\le C\left(\frac{1}{M}+\epsilon\right)\left(\|\varphi_0\|^2_{L^2(\partial D_0)}+\|\varphi\|^2_{L^2(\partial D)}\right). \tag{6.15}$$

Let $\gamma_0^\epsilon=(\partial D_0\setminus\overline{D})\cap B_{r+2M\epsilon}(a)$. Observe that $\langle\vec{\alpha},\nu\rangle\ge r_0-\epsilon$ on $(\partial D_0\setminus\overline{D})\setminus\gamma_0^\epsilon$ and $\langle\vec{\beta},\nu\rangle\ge r-\epsilon$ on $\partial D\cap\overline{D_0}$. It follows from (6.12) and (6.15) that

$$\int_{\partial(D_0\setminus\overline{D})}\left|\frac{\partial U^{\#}}{\partial\nu}\right|^2-C\int_{\gamma_0^\epsilon}\left|\frac{\partial U^{\#}}{\partial\nu}\right|^2\le C\left(\frac{1}{M}+\epsilon\right)\left(\|\varphi_0\|^2_{L^2(\partial D_0)}+\|\varphi\|^2_{L^2(\partial D)}\right). \tag{6.16}$$

If we put $\gamma^\epsilon=(\partial D\setminus\overline{D_0})\cap B_{r+2M\epsilon}(0)$, we have in the same way that

$$\int_{\partial(D\setminus\overline{D_0})}\left|\frac{\partial U^{\#}}{\partial\nu}\right|^2-C\int_{\gamma^\epsilon}\left|\frac{\partial U^{\#}}{\partial\nu}\right|^2\le C\left(\frac{1}{M}+\epsilon\right)\left(\|\varphi_0\|^2_{L^2(\partial D_0)}+\|\varphi\|^2_{L^2(\partial D)}\right). \tag{6.17}$$

In (6.16) and (6.17), the constant C depends only on the radii of B_0 and B. Recall that $\frac{\partial U^{\#}}{\partial\nu}=\varphi$ on γ^ϵ and $\frac{\partial U^{\#}}{\partial\nu}=\varphi_0$ on γ_0^ϵ (see Lemma 6.4). From (6.7), (6.16), and (6.17), we obtain that

$$\begin{aligned}\|\varphi_0\|^2_{L^2(\partial D_0\setminus E)}+\|\varphi\|^2_{L^2(\partial D\setminus E)}\le{}&\left(C\epsilon+\frac{C}{M}\right)\left(\|\varphi_0\|^2_{L^2(\partial D_0)}+\|\varphi\|^2_{L^2(\partial D)}\right)\\&+C\left(\|\varphi_0\|^2_{L^2(\gamma_0^\epsilon)}+\|\varphi\|^2_{L^2(\gamma^\epsilon)}\right).\end{aligned} \tag{6.18}$$

Now let us choose M so that $\frac{C}{M} < \frac{1}{4}$. It then follows from (6.18) that

$$\|\varphi_0\|^2_{L^2(\partial D_0)} + \|\varphi\|^2_{L^2(\partial D)} \le C\left(\|\varphi_0\|^2_{L^2(\gamma_0^\epsilon \cup E)} + \|\varphi\|^2_{L^2(\gamma^\epsilon \cup E)}\right) \tag{6.19}$$

provided that ϵ is small enough so that $C\epsilon \le \frac{1}{4}$. By (6.2) and Lemma 6.3, we have

$$\begin{aligned}|\lambda|\|\varphi\|_{L^2(\gamma^\epsilon \cup E)} &\le \|\mathcal{K}^*\varphi\|_{L^2(\gamma^\epsilon \cup E)} + \|(\lambda I - \mathcal{K}^*)\varphi\|_{L^2(\gamma^\epsilon \cup E)} \\ &\le C\epsilon\|\varphi\|_{L^2(\partial D)} + \left\|\frac{\partial H}{\partial \nu}\right\|_{L^2(\gamma^\epsilon \cup E)}.\end{aligned}$$

Therefore we have from (6.2) and (6.19) that

$$\left\|\frac{\partial H}{\partial \nu}\right\|^2_{L^2(\partial D_0)} + \left\|\frac{\partial H}{\partial \nu}\right\|^2_{L^2(\partial D)} \le C\left(\left\|\frac{\partial H}{\partial \nu}\right\|^2_{L^2(\gamma_0^\epsilon \cup E)} + \left\|\frac{\partial H}{\partial \nu}\right\|^2_{L^2(\gamma^\epsilon \cup E)}\right). \tag{6.20}$$

By the interior estimate of harmonic functions, one can easily see that

$$\left\|\frac{\partial H}{\partial \nu}\right\|^2_{L^2(\gamma^\epsilon \cup E)} + \left\|\frac{\partial H}{\partial \nu}\right\|^2_{L^2(\gamma_0^\epsilon \cup E)} \le C(l(\gamma_0^\epsilon \cup E) + l(\gamma^\epsilon \cup E)) \int_\Omega |\nabla H|^2,$$

and hence we have from (6.20) that

$$\left\|\frac{\partial H}{\partial \nu}\right\|^2_{L^2(\partial D_0)} + \left\|\frac{\partial H}{\partial \nu}\right\|^2_{L^2(\partial D)} \le C(l(\gamma_0^\epsilon \cup E) + l(\gamma^\epsilon \cup E)) \int_\Omega |\nabla H|^2, \tag{6.21}$$

where $l(\gamma_0^\epsilon)$ and $l(\gamma^\epsilon)$ denote the length of γ_0^ϵ and γ^ϵ.

Let $\Omega_1 = \{x \in \Omega | \text{dist}(x, \partial\Omega) > \delta_0\}$. Since ∇H is harmonic, one can apply the same argument of the harmonic measure used in the proof of Proposition 3.4 and the standard interior estimate to see that there exist $C > 0$ and $0 < \alpha < 1$ such that for every $x \in \Omega_0$,

$$\begin{aligned}|\nabla H(x)|^2 &\le C \sup_{y \in B_{r_0/2}(0)} |\nabla H(y)|^{2\alpha} \sup_{y \in \Omega_1} |\nabla H(y)|^{2(1-\alpha)} \\ &\le C\left(\int_{D_0} |\nabla H(y)|^2\right)^\alpha \left(\int_\Omega |\nabla H(y)|^2\right)^{1-\alpha}.\end{aligned}$$

By integrating the left-hand side of the above inequality over Ω_0, we obtain

$$C\frac{\left(\int_{\Omega_0} |\nabla H(y)|^2\right)^{1/\alpha}}{\left(\int_\Omega |\nabla H(y)|^2\right)^{1/\alpha - 1}} \le \int_{D_0} |\nabla H(y)|^2 \le C\left\|\frac{\partial H}{\partial \nu}\right\|^2_{L^2(\partial D_0)}.$$

It then follows from (6.21) that

$$l(\gamma_0^\epsilon \cup E) + l(\gamma^\epsilon \cup E) \ge CA, \qquad A := \left(\frac{\int_{\Omega_0} |\nabla H(y)|^2}{\int_\Omega |\nabla H(y)|^2}\right)^{1/\alpha}. \tag{6.22}$$

By the definition of the ϵ-perturbation of a disk, there is a positive constant C so that

$$\begin{aligned}&l(\{x \in \partial B_r(a) : x \in B_{r_0+\epsilon}(0) \setminus B_{r_0-\epsilon}(0)\}) \\ &\qquad + l(\{x \in \partial B_{r_0}(0) : x \in B_{r+\epsilon}(a) \setminus B_{r-\epsilon}(a)\}) \ge CA.\end{aligned}$$

From the elementary geometry of two circles, there is a positive constant C depending only on r, r_0, A so that

$$|B_{r_0}(0) \setminus B_r(a)| + |B_r(a) \setminus B_{r_0}(0)| \leq C\epsilon.$$

It follows from the definition of the ϵ-perturbation of a disk that

$$|D_0 \setminus \overline{D}| + |D \setminus \overline{D_0}| \leq C\epsilon.$$

Now let us consider the remaining two cases:

(1) $\Omega \setminus \overline{D_0 \cup D}$ is connected and $\partial(\overline{D_0 \cup D}) \cap \partial(D_0 \cap D) = \emptyset$;

(2) $\Omega \setminus \overline{D_0 \cup D}$ is not connected.

From elementary geometry, it is not difficult to see that the above two cases occur when

$$|a| = r_0 + r + O(\epsilon). \tag{6.23}$$

Indeed, in case (1) there is a point $P \in \partial D \cap \partial D_0$ so that the outer normal vector of ∂D at P is in the opposite direction of the normal vector of ∂D_0 at P. Then (6.23) follows from the property of two circles and the ϵ-perturbation of a disk. In case (2), there is a point $Q = (Q_1, Q_2)$ which lies in a bounded component of $\mathbb{R}^2 \setminus \overline{D \cup D_0}$. Assume $Q_2 \geq 0$. The upper half vertical line $L := \{(x_1, x_2) : x_1 = Q_1 \text{ and } x_2 > Q_2\}$ starting from Q cuts or intersects one of the domains D and D_0. Assume that the vertical line L cuts D. It follows from Rolle's theorem that there is a point $P \in \partial D$ with $Q_2 \leq P_2$ such that the normal vector $\nu(P)$ at ∂D is parallel to the x_1-axis. Then $0 \leq Q_2 < P_2 = O(\epsilon)$, because ∂D is an ϵ-perturbation of a disk. This gives (6.23) because $|Q| > r_0 - \epsilon$ and $|Q - a| > r - \epsilon$.

Let $I_0 := \partial D_0 \cap B_{r+\epsilon}(a)$ and $I := \partial D \cap B_{r_0+\epsilon}(0)$. Then it is easy to see that

$$l(I_0 \cup I) \leq C\sqrt{\epsilon}. \tag{6.24}$$

As in (6.8), we apply the Rellich identity with vector field x and we obtain

$$\int_{\partial(D_0 \setminus \overline{D})} \langle x, \nu \rangle \left| \frac{\partial U^\#}{\partial \nu} \right|^2 = \int_{\partial(D_0 \setminus \overline{D})} \langle x, \nu \rangle \left| \frac{\partial U}{\partial T} \right|^2 - 2 \int_{\partial(D_0 \setminus \overline{D})} \langle x, T \rangle \frac{\partial U}{\partial T} \frac{\partial U^\#}{\partial \nu}. \tag{6.25}$$

(Note that $\mathcal{R} = 0$ with the vector field x.) Similarly, we obtain

(6.26)

$$\int_{\partial(D \setminus \overline{D_0})} \langle x - a, \nu \rangle \left| \frac{\partial U^\#}{\partial \nu} \right|^2 = \int_{\partial(D \setminus \overline{D_0})} \langle x - a, \nu \rangle \left| \frac{\partial U}{\partial T} \right|^2 - 2 \int_{\partial(D \setminus \overline{D_0})} \langle x - a, T \rangle \frac{\partial U}{\partial T} \frac{\partial U^\#}{\partial \nu}.$$

Since $\frac{\partial U}{\partial T} = 0$ on $(\partial D \cup \partial D_0) \setminus (I \cup I_0)$, it follows from (6.25) and (6.26) that

$$\int_{(\partial D \cup \partial D_0) \setminus (I_0 \cup I)} \left| \frac{\partial U^\#}{\partial \nu} \right|^2 \leq C \int_{I_0 \cup I} \left| \nabla U^\# \right|^2.$$

From Lemma 6.4 and the above estimate, we obtain as before that

$$\|\varphi_0\|_{L^2(\partial D_0)} + \|\varphi\|_{L^2(\partial D)} \leq C \left(\|\varphi_0\|_{L^2(I_0)} + \|\varphi\|_{L^2(I)} \right),$$

which is similar to (6.19). We repeat the argument as before and obtain $l(I \cup I_0) > C$ as in (6.22). This is not possible for small ϵ because of (6.24). This completes the proof. □

Acknowledgments. This work was completed before professor E. Fabes passed away. We will remember him as a man of humanism and as a great teacher in our life. We would like to thank the referee for several helpful comments.

LOWER BOUNDS FOR GENERALIZED GINZBURG–LANDAU FUNCTIONALS*

ROBERT L. JERRARD†

Abstract. We study properties of Ginzburg–Landau functionals $I_U^\epsilon(\cdot)$, defined for functions $u \in W^{1,n}(U;\mathcal{R}^n)$, where $U \subset \mathcal{R}^n$. In particular, we establish lower bounds relating the energy $I_U^\epsilon(u)$ to the Brouwer degree of u, and we prove under additional hypotheses that the energy concentrates on a small number of small sets. As a consequence we deduce some compactness theorems. Such estimates are useful in studying Ginzburg–Landau-type PDEs associated with the functional I_U^ϵ.

Key words. Ginzburg–Landau functional, lower bounds, energy concentration, compactness

1. Introduction.

We study Ginzburg–Landau functionals of the form

$$I^\epsilon(u) := \int_U \mathcal{E}^\epsilon[u]dx,$$

where U is a bounded open subset of $\mathcal{R}^n$, $u \in W^{1,n}(U;\mathcal{R}^n)$, and

$$\mathcal{E}^\epsilon[u] := \frac{1}{n}|\nabla u|^n + \frac{1}{4\epsilon^2}(1-|u|^2)^2.$$

Our results apply also to the functional with magnetic potential,

$$I^\epsilon_{\rm mag}(u,A) := \int_U \mathcal{E}^\epsilon_{\rm mag}[u,A]dx,$$

where U is a bounded open subset of $\mathcal{R}^2$ and

$$\mathcal{E}^\epsilon_{\rm mag}[u,A] := \frac{1}{2}|\nabla_A u|^2 + \frac{1}{2}|\nabla \times A|^2 + \frac{1}{4\epsilon^2}(1-|u|^2)^2.$$

The notation is explained below.

When there is no possibility of confusion, we will typically write $\mathcal{E}^\epsilon$ and $\mathcal{E}^\epsilon_{\rm mag}$, suppressing the dependence on u and A.

It is known that if the trace of u on ∂U is a fixed function of nonzero Brouwer degree, then $I^\epsilon(u) > C\ln(\frac{1}{\epsilon})$, for ϵ small, and similarly for $I^\epsilon_{\rm mag}(u,A)$. We give a new proof of lower bounds of this form, and we show that under additional hypotheses the unbounded part of the energy is concentrated on a small number of small sets. As a consequence we establish new results on the weak compactness of functions with nonzero degree.

In the magnetic case, we further show that if the energy of a pair (u,A) is within $O(1)$ of the appropriate lower bound, then the term $\int |\nabla \times A|^2$ is bounded independent of ϵ.

The first results of this character were proven by Bethuel, Brezis, and Hélein [2], using lower bounds established by Brezis, Merle, and Rivière [4]. Other important contributions include papers of Struwe [11], Bethuel and Rivière [3], Han and Li [6], and Hong [7]. Most of these results deal only with sequences of energy-minimizers, and provide detailed information about their asymptotic behavior. A paper of Lin [8] establishes compactness results under weaker assumptions which are naturally satisfied by solutions of parabolic equations.

Our techniques are substantially new, and for many purposes they are more precise and flexible than earlier arguments. In particular, they require no a priori control on the modulus of continuity of a function u. We thus do not need to use any regularity theory—we instead rely entirely on elementary arguments.

In particular, our results show that the compactness of energy-minimizing sequences does not in any way depend on the fact that they solve some PDE; instead, it is merely an outcome of the real variable structure of the Ginzburg–Landau functional.

After completing this paper, we have become aware of several related works, including a recent paper of Almeida and Bethuel [1] and preprints of Lin [9] and Sandier [10]. These papers deal mainly with the case $n = 2$; as far as we know, our compactness results are the only ones valid in higher dimensions. The main focus of [1] is on topological methods, but their work can be used to deduce the compactness of nonminimizing, though appropriately bounded, sequences. Lin [9] and Sandier [10] both establish results similar to ours. Sandier uses estimates on annuli, rather similar to ours, together with an elegant application of the coarea formula. Lin's arguments are different; he uses a regularization to reduce the general case (with no control on the modulus of continuity) to a situation he studied earlier in [8]. Lin further applies this result to the study of asymptotic vortex dynamics in solutions of a Ginzburg–Landau wave equation.

In general, results of the sort we establish are very useful in studying vortex dynamics for evolutionary equations of Ginzburg–Landau-type, especially in situations where there is only weak control over the modulus of continuity.

Ginzburg–Landau-type functionals in n-dimensions. Suppose that ∂U is smooth, and let $g : \partial U \to S^{n-1}$ be smooth, with

$$|\deg(g; \partial U)| = d.$$

We are interested in the case $d \neq 0$, and given this, we assume for convenience that $\deg(g; \partial U) > 0$.

Let

$$W^{1,n}_g(U; \mathcal{R}^n) := \{u \in W^{1,n}(U; \mathcal{R}^n) \,|\, u = g \text{ on } \partial U\}. \tag{1.1}$$

We define a constant

$$\kappa_n = \frac{1}{n}(n-1)^{n/2}|\partial B_1|. \tag{1.2}$$

The following result is proven in Han and Li [6] and Hong [7], who obtain it by analyzing energy-minimizing sequences. These authors obtain also much more detailed information about the limiting behavior of minimizers.

THEOREM 1.1. *If $u \in W^{1,n}_g(U; \mathcal{R}^n)$, then*

$$\int_U \mathcal{E}^\epsilon dx \geq d\kappa_n \ln\left(\frac{1}{\epsilon}\right) - C. \tag{1.3}$$

The constant here depends on the domain U and the data g.

We will show that a matching upper bound implies energy concentration. In fact, the following result states that energy concentrates around at most d points.

THEOREM 1.2. *Suppose that $u \in W_g^{1,n}(U;\mathcal{R}^n)$. There exists a number $\sigma_0 > 0$ (depending only on the domain U) such that, for any $\sigma \in (0,\sigma_0]$, if*

$$\int_U \mathcal{E}^\epsilon dx \le d\kappa_n \ln\left(\frac{1}{\epsilon}\right) + C \tag{1.4}$$

and ϵ is sufficiently small, i.e., $\epsilon \le \epsilon_0(C,\sigma)$, then there are points $\{x_1,\dots,x_m\}$ and positive integers $\{d_1,\dots,d_m\}$ such that

$$\sum_i d_i = d,$$

and

$$\int_{\cup_i B_{d_i\sigma}(x_i)\cap U} \mathcal{E}^\epsilon dx \ge d\kappa_n \ln\left(\frac{\sigma}{\epsilon}\right) - C.$$

Note that Theorem 1.2 implies Theorem 1.1. Indeed, if $u \in W_g^{1,n}(U;\mathcal{R}^n)$ satisfies (1.4), then (1.3) follows by Theorem 1.2, and if (1.4) does not hold, then (1.3) follows trivially.

A compactness result follows as an easy consequence of Theorem 1.2

THEOREM 1.3. *Suppose u^ϵ is a collection of functions in $W_g^{1,n}(U;\mathcal{R}^n)$ and that u^ϵ satisfies*

$$\int_U \mathcal{E}^\epsilon dx \le d\kappa_n \ln\left(\frac{1}{\epsilon}\right) + C$$

for every $\epsilon > 0$. Then there exist points $x_1,\dots,x_m \in \bar{U}$, with $m \le d$, a subsequence $\epsilon_k \to 0$, and a function $u \in W^{1,n}_{loc}(U \setminus \{x_1,\dots,x_m\}; S^{n-1})$ such that

$$u^{\epsilon_k} \rightharpoonup u \qquad \text{weakly in } W^{1,n}_{loc}(U \setminus \{x_1,\dots,x_m\};\mathcal{R}^n).$$

Also, there are integers $d_i > 0$ for $i = 1,\dots,m$ such that $\sum d_i = d$ and

$$\mu^\epsilon := |\ln\epsilon|^{-1}\mathcal{E}^\epsilon\, dx \to \kappa_n \sum_{i=1}^m d_i \delta_{x_i}$$

weakly as measures.

Remarks. 1. It is straightforward to construct examples of functions satisfying the hypotheses of Theorem 1.3, so the theorem is not vacuous. Such constructions are standard and may be found in [2] and [7], for example. In particular, Theorem 1.3 implies the compactness of a sequence of energy-minimizers.

2. In Lin [9] it is shown that $m = d$ and that all points x_i lie in the interior of U. These results are almost certainly true in higher dimensions as well, but we do not prove them here.

3. Although we do not assume continuity in the statements of the above theorems, in many of our proofs we work with continuous functions. The general results as stated here will follow from regularization arguments.

The gauge-invariant Ginzburg–Landau functional. Consider the gauge-invariant functional

$$I^{\epsilon}_{\mathrm{mag}}(u;A) := \int_U \frac{1}{2}|\nabla_A u|^2 + \frac{1}{2}|\nabla \times A|^2 + \frac{1}{4\epsilon^2}(1-|u|^2)^2 dx.$$

Here $U \subset \mathcal{R}^2$ is assumed open and bounded, with smooth boundary. We now think of u as taking values in the complex plane $\mathcal{C}$, and $A = A_1 dx_1 + A_2 dx_2$ is a 1-form with coefficients $A_i \in H^1(U)$. We will identify A with the function $(A_1, A_2) \in H^1(U;\mathcal{R}^2)$. We define $\nabla \times A := A_{2,x_1} - A_{1,x_2}$ and $\nabla_A u := (\nabla - iA)u$, where $i = \sqrt{-1}$.

A thorough description of asymptotic behavior of minimizers, subject to gauge-invariant Dirichlet conditions, has been carried out by Bethuel and Rivière [3], who in particular determine a renormalized energy which governs the location of limiting singular points.

We will prove the following.

THEOREM 1.4. *Suppose that $u \in H^1_g(U;\mathcal{C})$ and $A \in H^1(U;\mathcal{R}^2)$. There exists a number $\sigma_0 > 0$ (depending only on the domain U) such that, for any $\sigma \in (0,\sigma_0]$, if*

$$\int_U \mathcal{E}^{\epsilon}_{mag} dx \le d\pi \ln\left(\frac{1}{\epsilon}\right) + C$$

and $\epsilon \le \epsilon_0(C,\sigma)$, then

$$\int_U |\nabla \times A|^2 dx \le C, \tag{1.5}$$

and there are points $\{x_1,\dots,x_m\}$ and positive integers $\{d_1,\dots,d_m\}$ such that

$$\sum_i d_i = d,$$

and

$$\int_{\cup_i B_{d_i\sigma}(x_i)\cap U} \mathcal{E}^{\epsilon}_{mag} dx \ge d\kappa_n \ln\left(\frac{\sigma}{\epsilon}\right) - C.$$

Note in particular the *upper* bound (1.5).

This immediately yields a lower bound, analogous to Theorem 1.1. We obtain also a compactness result along the lines of Theorem 1.3.

Notation, and preliminary remarks about degree. We let $B_r(x)$ denote the *closed* ball $\{y \in \mathcal{R}^n \mid |x-y| \le r\}$.

Let ω_n be the volume of the unit ball in $\mathcal{R}^n$.

We recall some facts about degree. A good general reference for this and related material is Brezis and Nirenberg [5].

When we refer to degree $\deg(u;\partial V)$, we always mean the degree of u around the origin. Informally, this counts the number of points in $u^{-1}(0)\cap V$, with multiplicity. In two dimensions, $\deg(u;\partial V)$ is just the winding number of ∂V around the origin.

More precisely, let $u \in W^{1,n}(U;\mathcal{R}^n)$, and suppose that $V \subset U$ and that V is bounded, with smooth boundary. If ess $\inf_{\partial V}|u| > 0$, then the Brouwer degree of u is defined by

$$\deg(u;\partial V) = \int_V \eta(u) \det Du \, dx, \tag{1.6}$$

where $\eta \in C^\infty(\mathcal{R}^n)$ satisfies

$$\int \eta = 1, \qquad \eta \geq 0, \qquad \text{spt } \eta \subset \{y \in \mathcal{R}^n : |y| < \text{ess inf}_{\partial V} |u|\}.$$

The degree is an integer, and it is independent of the specific choice of η and thus well defined. It can also be defined by the formula

$$\deg(u; \partial V) = \frac{1}{|\partial B_1|} \int_{\partial V} \det \nabla_\tau v \, dH^{n-1}. \tag{1.7}$$

Here $v := \frac{u}{|u|}|_{\partial V}$ is a map $\partial V \to \partial B_1$. The differential of v is a linear map $T_x \partial V \to T_{v(x)} \partial B_1$, and as such it can be expressed as an $(n-1) \times (n-1)$ matrix, in terms of orthonormal bases for $T_x \partial V$ and $T_{v(x)} \partial B_1$, which inherit natural orientations from the ambient spaces. This matrix is denoted $\nabla_\tau v$. The right-hand side of (1.7) is well defined, since $\det \nabla_\tau v$ is independent of the specific choice of bases. Also, it follows from the trace theorem that, under the stated assumptions, $v \in W^{1,n-1}(\partial V; \partial B_1)$, so the integration makes sense.

We will use the fact that

$$\det \nabla_\tau v \leq (n-1)^{-\frac{n-1}{2}} |\nabla_\tau v|^{n-1}, \tag{1.8}$$

which follows immediately from the inequality of arithmetic and geometric means.

It will be convenient for our purposes to use an approximation to the degree, which will enable us to ignore "inessential" components of the zero set of u. We will define this approximation only for $u \in C \cap W^{1,n}(U; \mathcal{R}^n)$. Before giving the definition, we introduce some notation.

We let S denote the set on which $|u|$ is small,

$$S := \{x \in U | \ |u(x)| \leq 1/2\}. \tag{1.9}$$

If we assume that u is continuous, then the connected components of S are closed, and each component S_i of S has a well-defined degree, given by the definition (1.6). This degree is an integer even when ∂S_i is not smooth, as may be seen by approximating S_i by smooth sets.

For $u \in C \cap W^{1,n}(U; \mathcal{R}^n)$ we may thus define the *essential* part of S,

$$S_E := \cup\{\text{components } S_i \text{ of } S | \deg(u; \partial S_i) \neq 0\} \tag{1.10}$$

and the *negligible* part of S,

$$\begin{aligned} S_N &:= \cup\{\text{components } S_i \text{ of } S | \deg(u; \partial S_i) = 0\} \\ &= S \setminus S_E. \end{aligned} \tag{1.11}$$

For any subset $V \subset U$ such that $\partial V \cap S_E \neq \emptyset$, we define the approximate degree

$$\text{dg}(u; \partial V) := \sum \{\deg(u; \partial S_i) \mid \text{components } S_i \text{ of } S_E \text{ such that } S_i \subset\subset V\}. \tag{1.12}$$

The advantage of using the approximate degree dg is that it allows us to conduct our analysis as if every component of S has nonzero degree, which is useful in one or two places. Note that dg agrees with the ordinary degree on sets for which both are defined. Indeed, for many purposes the distinction between the two can be ignored with very little loss of understanding.

2. An estimate on spheres. In this section we establish an estimate on spheres. A similar estimate is proven by Han and Li [6] and Hong [7], who establish a lower bound for $||Du||_{L^n}$ on an annulus, under the assumption that $\int(1-|u|^2)^2dx$ is small. Both of these proofs use a good deal of machinery from elliptic regularity theory.

We use the following.

Notation. Recall that we have defined the constant $\kappa_n = \frac{1}{n}(n-1)^{n/2}|\partial B_1|$. We also define

$$\lambda^\epsilon(r;d) = \min_{m\in[0,1]}\left[m^n\frac{\kappa_n|d|^{\frac{n}{n-1}}}{r} + \frac{1}{C\epsilon}(1-m)^N\right], \tag{2.1}$$

where $C, N > 0$ will be specified below and will depend only on the dimension n.

The main result of this section is the following theorem.

THEOREM 2.1. *λ^ϵ has the following properties: First,*

$$\lambda^\epsilon(r;d) \geq \kappa_n|d|^{\frac{n}{n-1}}\frac{1}{r}\left(1 - C(d)\frac{\epsilon^\alpha}{r^\alpha}\right) \tag{2.2}$$

for $\alpha = \frac{1}{N-1} > 0$.

Second, if $r > \epsilon$, $u \in W^{1,n}(\partial B_r; B_1)$, and $|\deg(u;\partial B_r)| = d > 0$, then

$$\int_{\partial B_r}\mathcal{E}^\epsilon\, dH^{n-1} \quad \geq \quad \lambda^\epsilon(r;d). \tag{2.3}$$

We assume several lemmas, and use them to prove the following theorem.

Proof. 1. We first prove (2.3). Given u as stated, we define

$$\rho := |u|, \qquad v := u/\rho, \qquad m := 1 \wedge \min_{x\in\partial B_r}\rho(x). \tag{2.4}$$

Since $n \geq 2$, we see that

$$\begin{aligned}|\nabla_\tau u|^n &\geq |\nabla_\tau\rho|^n + \rho^n|\nabla_\tau v|^n\\ &\geq |\nabla_\tau\rho|^n + m^n|\nabla_\tau v|^n.\end{aligned}$$

Thus

$$\begin{aligned}\int_{\partial B_r}\mathcal{E}^\epsilon &\geq \int_{\partial B_r}\frac{m^n}{n}|\nabla_\tau v|^n + \frac{1}{n}|\nabla_\tau\rho|^n + \frac{1}{\epsilon^n}(1-\rho^2)^2\\ &\geq m^n\frac{\kappa_n|d|^{\frac{n}{n-1}}}{r} + \frac{1}{C\epsilon}|1-m|^N\end{aligned}$$

by Lemmas 2.3 and 2.4 below. This last inequality and the definition of λ^ϵ directly imply (2.3).

2. Next, for n, N as above, $m \in [0,1]$, and any fixed constant $K > 0$, we estimate

$$\begin{aligned}1 - m^n &\leq n(1-m)\\ &= \left((KN)^{1/N}(1-m)\right)\frac{n}{(KN)^{1/N}}\\ &\leq K(1-m)^N + \frac{N-1}{N}\left(\frac{n}{(KN)^{1/N}}\right)^{N/(N-1)}\\ &= K(1-m)^N + CK^{-1/(N-1)}\end{aligned}$$

using Young's inequality. Thus

$$\max_{m\in[0,1]}\left[(1-m^n)-K(1-m)^N\right]\le CK^{-1/(N-1)} \tag{2.5}$$

for any $K>0$.

It follows that for any $A,B>0$

$$\begin{aligned}\min_{m\in[0,1]}\left[m^nA+(1-m)^NB\right] &= A-A\max_{m\in[0,1]}\left[(1-m^n)-\frac{B}{A}(1-m)^N\right]\\ &\ge A\left(1-C\left(\frac{A}{B}\right)^{1/(1-N)}\right).\end{aligned}$$

This immediately gives (2.2). □

We now fill in the proofs of the lemmas used above. We continue to assume the hypotheses of Theorem 2.1, so that, for example, $u\in W^{1,n}(\partial B_r;\partial B_1)$. We first recall the following estimate of Morrey.

LEMMA 2.2. *ρ is Hölder continuous on ∂B_r, and in fact*

$$|\rho(x)-\rho(y)|\le C||\nabla_\tau\rho||_{L^n}|x-y|^{1/n}$$

for some constant C independent of r.

Proof. The stated estimate is invariant under rescalings, so it suffices to prove it on the unit sphere. This, however, follows easily from the standard Morrey inequality on $\mathcal{R}^{n-1}$. □

LEMMA 2.3. *If $r\ge\epsilon$, then*

$$\int_{\partial B_r}\frac{1}{n}|\nabla_\tau\rho|^n+\frac{1}{\epsilon^n}(1-\rho^2)^2dH^{n-1}\ge\frac{1}{C\epsilon}|1-m|^N$$

for some $C,N>0$.

Remark. It is clear from the proof that this lemma does not depend on the exact form of $W(\rho):=(1-\rho^2)^2$.

Proof. Let

$$\gamma:=\int_{\partial B_r}\frac{1}{n}|\nabla_\tau\rho|^ndH^{n-1},$$

and let $x_{\min}\in\partial B_r$ be a point at which $\rho(x_{\min})=m$.

Lemma 2.2 implies that

$$\begin{aligned}\rho(x)&\le m+C\gamma^{1/n}|x_{\min}-x|^{1/n}\\ &\le\frac{1+m}{2}\qquad\text{whenever } |x-x_{\min}|\le\frac{|1-m|^n}{C\gamma}.\end{aligned} \tag{2.6}$$

Since $r\ge\epsilon$ and $x_{\min}\in\partial B_r$,

$$H^{n-1}\left(\partial B_r\cap B_\sigma(x_{\min})\right)\ge C^{-1}(\sigma^{n-1}\wedge\epsilon^{n-1}) \tag{2.7}$$

for any $\sigma>0$. Since $(1-\rho^2)^2\ge C^{-1}|1-m|^2$ whenever $\rho\le(1+m)/2$, we deduce from (2.6) and (2.7) that

$$\int_{\partial B_r}(1-\rho^2)^2dH^{n-1}\ \ge\ C^{-1}|1-m|^2\left(\epsilon^{n-1}\wedge\frac{|1-m|^{n(n-1)}}{\gamma^{n-1}}\right).$$

It follows that

$$\int_{\partial B_r} \frac{1}{n}|\nabla_\tau \rho|^n + \frac{1}{\epsilon^n}(1-\rho^2)^2 dH^{n-1} \;\geq\; \gamma + \frac{1}{C\epsilon^n}|1-m|^2\left(\epsilon^{n-1} \wedge \frac{|1-m|^{n(n-1)}}{\gamma^{n-1}}\right).$$

The conclusion of the lemma is obvious if $\epsilon^{n-1} \leq |1-m|^{n(n-1)}\gamma^{1-n}$. If the other inequality holds, the desired estimate follows by using calculus to minimize over $\gamma > 0$. □

Our next assertion seems to be quite well known; it appears without proof in Han and Li [6], who remark that it is elementary. Nevertheless, we provide a proof for the reader's convenience.

LEMMA 2.4. *Suppose that $v \in W^{1,n}(\partial B_r, \partial B_1)$ for some $r > 0$ and that*

$$\deg(v; \partial B_r) = d.$$

Then

$$\int_{\partial B_r} \frac{1}{n}|\nabla_\tau v|^n dH^{n-1} \geq \frac{\kappa_n}{r}|d|^{\frac{n}{n-1}}.$$

Proof. We compute, using (1.8) in the second line below,

$$\begin{aligned}
\deg(v; \partial B_r) &= \frac{1}{|\partial B_1|}\int_{\partial B_r} \det \nabla_\tau v \; dH^{n-1} \\
&\leq \frac{1}{|\partial B_1|}(n-1)^{-\frac{n-1}{2}} \int_{\partial B_r} |\nabla_\tau v|^{n-1} dH^{n-1} \\
&\leq \frac{(n-1)^{-\frac{n-1}{2}}}{|\partial B_1|}\left(\int_{|\partial B_r|} |\nabla_\tau v|^n dH^{n-1}\right)^{\frac{n-1}{n}} |\partial B_r|^{\frac{1}{n}}.
\end{aligned}$$

After some rearranging, this becomes the conclusion of the lemma. □

Finally, we record a technical refinement of Lemma 2.3 which will be needed later.

LEMMA 2.5. *Suppose that $U \subset \mathcal{R}^n$ is a bounded open subset with a smooth boundary. Then there exists $\hat{r} > 0$ such that for every $r \in [\epsilon, \hat{r})$ and every $y \in U$ we have*

$$\int_{\partial B_r(y)\cap U} |\nabla_\tau \rho|^n + \frac{1}{\epsilon^n}(1-\rho^2)^2 dH^{n-1} \geq \frac{1}{C\epsilon}|1-m|^N,$$

where C depends on the smoothness of the boundary and on the dimension n.

Proof. The proof follows that of Lemma 2.3, except that in place of (2.7) we substitute

$$H^{n-1}\left(\partial B_r(y) \cap U \cap B_\sigma(x_{\min})\right) \geq C^{-1}(\sigma^{n-1} \wedge r^{n-1}) \tag{2.8}$$

for $y \in U, x_{\min} \in \partial B_r(y) \cap U$. Since $r > \epsilon$ by hypothesis, this is enough to extend the earlier argument to the present case.

We deduce (2.8) as a consequence of the smoothness of ∂U. Indeed, (2.8) is clear if U is the half-space $\{x \in \mathcal{R}^n : x_n > 0\}$. The general case follows by flattening out the boundary. □

3. Properties of Λ^ϵ. In this section we define a function Λ^ϵ, which provides a convenient way of keeping track of lower bounds on balls, and we record several properties of Λ^ϵ.

We define

$$\Lambda^\epsilon(s) := \int_0^s \lambda^\epsilon(r;1) \wedge \frac{c_0}{\epsilon} dr, \tag{3.1}$$

where c_0 is a constant to be selected below, depending only on the dimension n.

We first note some elementary properties of Λ^ϵ.

PROPOSITION 3.1. *$\Lambda^\epsilon(\cdot)$ is increasing, and moreover,*

$$\Lambda^\epsilon(r+s) \le \Lambda^\epsilon(r) + \Lambda^\epsilon(s) \qquad \forall\, r, s \ge 0, \tag{3.2}$$

$$s \mapsto \frac{1}{s}\Lambda^\epsilon(s) \qquad \textit{is nonincreasing,} \qquad \textit{and} \tag{3.3}$$

$$\Lambda^\epsilon(r) \ge \kappa_n \ln\left(\frac{r}{\epsilon}\right) - C(n) \qquad \forall\, r \ge 0. \tag{3.4}$$

Proof. From the definition (2.1) of λ^ϵ, it is clear that $\lambda^\epsilon > 0$ and that $r \mapsto \lambda^\epsilon(r;1)$ is nonincreasing. The first of these facts implies that Λ^ϵ is increasing; from the two facts together it is easy to see that (3.2) holds.

Next, (3.3) is clear, since $\frac{1}{s}\Lambda^\epsilon(s)$ is just the average over the interval $[0,s]$ of the nonincreasing function $r \mapsto \lambda^\epsilon(r;1) \wedge \frac{c_0}{\epsilon}$.

To prove the lower bound (3.4), recall first from Theorem 2.1 that

$$\lambda^\epsilon(r,1) \ge \kappa_n \left(\frac{1}{r} - \frac{C\epsilon^\alpha}{r^{1+\alpha}}\right).$$

As a result, $\lambda^\epsilon \wedge \frac{c_0}{\epsilon} \ge \kappa_n(\frac{1}{r} - \frac{C\epsilon^\alpha}{r^{1+\alpha}})$ whenever $r \ge c_1\epsilon$ for some $c_1 > 0$. Thus

$$\begin{aligned}
\Lambda^\epsilon(r) &\ge \int_{c_1\epsilon}^r \kappa_n \left(\frac{1}{s} - \frac{C\epsilon^\alpha}{s^{1+\alpha}}\right) ds \\
&\ge \kappa_n \ln\left(\frac{r}{c_1\epsilon}\right) - C\epsilon^\alpha \int_{c_1\epsilon}^\infty s^{-1-\alpha}\, ds \\
&\ge \kappa_n \ln\left(\frac{r}{\epsilon}\right) - C. \qquad \square
\end{aligned}$$

We next restate the lower bounds of the previous sections in terms of Λ^ϵ.

PROPOSITION 3.2. *Let $u \in C \cap W^{1,n}(U;\mathcal{R}^n)$, $\epsilon \le r_0 \le r_1$, and suppose that $|\mathrm{dg}\,(u;\partial B_\rho)| = d > 0$ $\forall$ $\rho \in [r_0, r_1]$, then*

$$\int_{B_{r_1}\setminus B_{r_0}} \mathcal{E}^\epsilon dx \ge d\left[\Lambda^\epsilon\left(\frac{r_1}{d}\right) - \Lambda^\epsilon\left(\frac{r_0}{d}\right)\right]. \tag{3.5}$$

Remark. Recall that dg is defined in (1.12). Stating this estimate in terms of dg allows us to ignore the "negligible" set S_N in our later arguments.

Proof

1. We first claim that if $|\mathrm{dg}(u;\partial B_r)| = d > 0$, then

$$\int_{\partial B_r} \mathcal{E}^\epsilon \, dH^{n-1} \quad \geq \quad \lambda^\epsilon(r;d) \wedge \frac{c_0}{\epsilon}$$

for some $c_0(n)$.

To see this, observe that the definition of dg implies that either $\deg(u;\partial B_r) = d$, in which case the claim follows immediately from (2.3), or $\partial B_r \cap S_N \neq \emptyset$, which implies that $m \leq \frac{1}{2}$, in the notation (2.4). Lemma 2.3 then implies that

$$\int_{\partial B_r} \mathcal{E}^\epsilon dH^{n-1} \geq \frac{c_0}{\epsilon}$$

if c_0 is small enough.

2. From the definition (2.1) of λ^ϵ it is clear that $\lambda^\epsilon(r;d) \geq \lambda^\epsilon(\frac{r}{d};1)\ \forall\ r > 0, d \geq 1$. We use this fact and step 1 to compute

$$\begin{aligned}
\int_{B_{r_1}\setminus B_{r_0}} \mathcal{E}^\epsilon dx &= \int_{r_0}^{r_1} \int_{\partial B_r} \mathcal{E}^\epsilon dH^{n-1} dr \\
&\geq \int_{r_0}^{r_1} \lambda^\epsilon\left(\frac{r}{d};1\right) \wedge \frac{c_0}{\epsilon} dr \\
&= d\int_{\frac{r_0}{d}}^{\frac{r_1}{d}} \lambda^\epsilon(r;1) \wedge \frac{c_0}{\epsilon} dr \quad = \quad d\left[\Lambda^\epsilon\left(\frac{r_1}{d}\right) - \Lambda^\epsilon\left(\frac{r_0}{d}\right)\right]. \qquad \square
\end{aligned}$$

The final property of Λ that we will need is the following.

PROPOSITION 3.3. *Suppose that $u \in W^{1,n}(U;\mathcal{R}^n)$ and that u is continuous. If $S_E \subset\subset U$, then there is a collection of closed, pairwise disjoint balls $\{B_i\}_{i=1}^k$ with radii r_i such that*

$$S_E \subset \cup_{i=1}^k B_i, \tag{3.6}$$

$$r_i \geq \epsilon \qquad \forall\, i; \tag{3.7}$$

$$B_i \cap S_E \neq \emptyset \qquad \text{for each } i, \tag{3.8}$$

$$\int_{B_i \cap U} \mathcal{E}^\epsilon dx \ \geq\ \frac{c_0}{\epsilon} r_i \ \geq\ \Lambda^\epsilon(r_i). \tag{3.9}$$

Remarks. 1. It is not true in general that the entire zero set of u can be covered by balls satisfying a lower bound of the form (3.9). This is the reason we need to decompose the set S into S_E and S_N (see (1.10) and (1.11)) and to introduce the approximate degree dg.

2. The technical assumption $S_E \subset\subset U$ is satisfied if $|u| > 1/2$ on ∂U.

We start by proving several lemmas. The first is a trivial observation which we will use repeatedly.

LEMMA 3.1. *Given any finite collection of closed balls in* $\mathbf{R}^k$, *say* $\{B_i\}_{i=1}^N$, *we can find a collection* $\{\tilde{B}_i\}_{i=1}^{\tilde{N}}$ *of pairwise disjoint balls such that*

$$\bigcup_{i=1}^{N} B_i \subset \bigcup_{i=1}^{\tilde{N}} \tilde{B}_i,$$

$$\sum_{B_j \subset \tilde{B}_i} \operatorname{diam} B_j = \operatorname{diam} \tilde{B}_i, \tag{3.10}$$

$$\tilde{N} \leq N, \quad \textit{with strict inequality unless } \{B_i\}_{i=1}^N \textit{ is pairwise disjoint.}$$

Proof. Replace pairs of intersecting balls B_i, B_j by larger single balls $\tilde{B}$ such that $B_i \cup B_j \subset \tilde{B}$ and diam $\tilde{B}$ = diam B_i + diam B_j, continuing until a pairwise disjoint collection is reached. This collection has the stated properties. □

LEMMA 3.2. *Let* S_i *be a connected component of* S_E, *and assume that* $S_i \subset\subset U$. *Then*

$$\int_{S_i} |Du|^n dx \geq C^{-1} |\deg(u; \partial S_i)|. \tag{3.11}$$

Proof. Fix a nonnegative function $\eta \in C^\infty(\mathcal{R}^n)$ such that $\int \eta = 1$ and spt $\eta \subset B_{1/4}$. Then, by the definition (1.6) of degree,

$$\begin{aligned} |\deg(u; \partial S_i)| &= \left| \int_{S_i} \eta(u) \det Du \, dx \right| \\ &\leq C \int_{S_i} |\det Du| \, dx \\ &\leq C \int_{S_i} |Du|^n dx. \end{aligned}$$

In the last line we have used the inequality of arithmetic and geometric means. □

LEMMA 3.3. *Suppose that* $u \in W^{1,n}(U; \mathcal{R}^n)$ *and that* u *is continuous. If* $S_E \subset\subset U$, *then there is a collection of closed, pairwise disjoint sets* $\{C_i\}_{i=1}^k$ *such that*

$$S_E \subset \cup_{i=1}^k C_i, \tag{3.12}$$

$$\int_{C_i \cap U} \mathcal{E}^\epsilon dx \geq \frac{c_0}{\epsilon} \, (\operatorname{diam} C_i \vee \epsilon). \tag{3.13}$$

Proof. 1. First note that Lemma 3.2 implies that S_E has a finite number of components, and clearly each component has nonempty interior.

For each component $S_i \subset S_E$, select a point $x_i \in S_i$ and define

$$\rho_i := \sup\{r > 0 | \partial B_s(x_i) \cap S_E \neq \emptyset \quad \forall \, s \in (0, r)\}. \tag{3.14}$$

Clearly $S_i \subset B_{\rho_i}(x_i)$, so $S_E \subset \cup_i B_{\rho_i}(x_i)$. We assert also that if $c_1 = c_1(n, U)$ is sufficiently small, then

$$\int_{B_{\rho_i}(x_i) \cap U} \mathcal{E}^\epsilon dx \geq \frac{1}{\epsilon} c_1 \rho_i. \tag{3.15}$$

This follows from Lemma 3.2 if $\rho_i \le 2\epsilon$. If $\rho_i > 2\epsilon$, then Lemma 2.5 implies that

$$\begin{aligned}\int_{B_{\rho_i}(x_i)\cap U} \mathcal{E}^\epsilon dx &\ge \int_\epsilon^{\rho_i\wedge\hat r}\int_{\partial B_r\cap U} \mathcal{E}^\epsilon dH^{n-1}dr\\ &\ge \frac{1}{C\epsilon}((\rho_i\wedge\hat r)-\epsilon).\end{aligned}$$

Recall that $\hat r$ is some constant depending only on the geometry of U. If $2\epsilon \le \rho_i \le \hat r$, then $\rho_i - \epsilon \ge \frac{1}{2}\rho_i$ and (3.15) follows. If $2\epsilon \le \hat r < \rho_i$, then $((\rho_i\wedge\hat r)-\epsilon) \ge \frac{\hat r}{2}$. Moreover, $\rho_i \le \operatorname{diam} U \le C\hat r$, for some C depending on the geometry of U; thus (3.15) holds for appropriately small c_1.

2. Next, if $x_1 \in B_{\rho_j}(x_j)$ for some $j \ne 1$, the choice of ρ_j implies that $S_1 \subset B_{\rho_j}(x_j)$. If this holds, we may drop the ball $B_{\rho_1}(x_1)$ from the collection, and the remaining balls will still cover S_E. Proceeding in this fashion and relabelling as necessary, we obtain a collection $\{B_{\rho_i}(x_i)\}_{i=1}^k$ covering S_E, each satisfying (3.15) and such that

$$x_i \notin B_{\rho_j}(x_j) \qquad \text{whenever } i \ne j. \tag{3.16}$$

3. Let $C_i, i = 1,\dots,\tilde k$ be the connected components of $\cup_{i=1}^k B_{\rho_i}(x_i)$. We will complete the proof by showing that these sets satisfy (3.13).

Fix some i and define

$$\mathcal{B} := \{B_{\rho_j}(x_j) \mid B_{\rho_j}(x_j) \subset C_i\}.$$

According to the Besicovitch covering lemma, we may find subcollections $\mathcal{B}_1,\dots,\mathcal{B}_N$ such that the balls within each subcollection are pairwise disjoint, and the set of centers of balls in the original collection $\mathcal{B}$ is contained in the union of all the balls in all the subcollections. The latter fact, together with (3.16), implies that

$$\mathcal{B} = \cup_{l=1}^N \mathcal{B}_l.$$

Here N is an absolute constant depending only on the dimension n. So

$$\begin{aligned}N\int_{C_i\cap U}\mathcal{E}^e dx &\ge \sum_{l=1}^N \int_{(\cup_{\mathcal{B}_l} B_{\rho_j}(x_j))\cap U}\mathcal{E}^\epsilon dx\\ &= \sum_{\mathcal{B}}\int_{B_{\rho_j}(x_j)\cap U}\mathcal{E}^\epsilon dx\\ &\ge \sum_{\mathcal{B}}\frac{1}{\epsilon}c_1\rho_j\\ &\ge \frac{c_1}{\epsilon}\operatorname{diam} C_i.\end{aligned}$$

Also, each set C_i contains at least one component S_i of S_E by construction, so it is clear from Lemma 3.2 that

$$\int_{C_i\cap U}\mathcal{E}^e dx \ge C^{-1}$$

for each i. The proof of (3.13) is concluded by selecting c_0 sufficiently small. □

We can now easily complete the proof of Proposition 3.3.

Proof. 1. For each of the sets C_i found above, fix $x_i \in C_i$ and let

$$\rho_i := \sup\{r > 0 | \partial B_s(x_i) \cap C_i \neq \emptyset \quad \forall\, s \in (0,r)\} \;\leq\; \operatorname{diam} C_i;$$

$$\sigma_i := \epsilon \vee \rho_i \;\leq\; \epsilon \vee \operatorname{diam} C_i.$$

Let $\{B_i^{\text{new}}\}_{i=1}^k$ be the collection of pairwise disjoint balls formed by combining the balls $\{B_{\sigma_i}(x_i)\}$ following the algorithm of Lemma 3.1, and let r_i^{new} be the radius of B_i^{new}. Clearly this collection of balls satisfies (3.6), (3.7), and (3.8). Moreover, since the sets C_j from Lemma 3.3 are pairwise disjoint,

$$\begin{aligned}
\int_{B_i^{\text{new}} \cap U} \mathcal{E}^\epsilon dx &\geq \sum_{\{j : B_{\sigma_j}(x_j) \subset B_i^{\text{new}}\}} \int_{C_j \cap U} \mathcal{E}^\epsilon dx \\
&\geq \sum_{\{j : B_{\sigma_j}(x_j) \subset B_i^{\text{new}}\}} \frac{c_0}{\epsilon}(\epsilon \vee \operatorname{diam} C_j) \\
&\geq \frac{c_0}{\epsilon} \sum_{\{j : B_{\sigma_j}(x_j) \subset B_i^{\text{new}}\}} \sigma_j \\
&= \frac{c_0 r_i^{\text{new}}}{\epsilon}.
\end{aligned}$$

We have used (3.13) and (3.10) in the above estimates.

Finally, it is immediate from the definition (3.1) of Λ^ϵ that $\frac{c_0 r}{\epsilon} \geq \Lambda^\epsilon(r)$. ∎

4. Lower bounds and concentration. In this section we prove Theorem 1.2.

We assume that U is a bounded, open subset of $\mathcal{R}^n$. We will in fact establish that the conclusion of Theorem 1.2 is valid under somewhat more general boundary conditions than are stated in the introduction. Throughout this section we will assume that $u \in W^{1,n}(U)$ satisfies

$$|u(x)| \geq \frac{1}{2} \qquad \text{in } \{x \in U | \operatorname{dist}(x, \partial U) \leq r\}, \tag{4.1}$$

$$|\deg(u; \partial U)| = d > 0, \tag{4.2}$$

and

$$\int_U \mathcal{E}^\epsilon[u] dx \leq d\kappa_n \ln\left(\frac{1}{\epsilon}\right) + C \tag{4.3}$$

for some $\epsilon > 0$.

Our first lemma shows that (4.1)–(4.2) are in fact more general than the boundary conditions stated in the introduction. This construction is standard.

LEMMA 4.1. *Let $u \in W_g^{1,n}(U; \mathcal{R}^n)$, where g is a smooth function of nonzero degree and $W_g^{1,n}$ is as defined in* (1.1). *Then u can be extended to a function $\tilde{u}$, defined on a set $\tilde{U} \supset U$ and satisfying* (4.1)–(4.2) *above. Also, if u satisfies* (4.3), *then so does its extension $\tilde{u}$.*

Proof. To see this, let $\tilde{U} := \{x \in \mathcal{R}^n | \operatorname{dist}(x; U) \leq r\}$ for some $r > 0$. We assume that r is small enough that each point in $\tilde{U} \setminus U$ has a unique closest point in ∂U and that U and $\tilde{U}$ have the same topology. We define $\tilde{u}(x) = u(x)$ for $x \in U$, and

$$\tilde{u}(x) = g(y) \qquad \text{for the unique } y \in \partial U \text{ such that } \operatorname{dist}(x, \partial U) = |x - y|$$

if $x \in \tilde{U} \setminus U$. One then immediately sees that $\tilde{u}$ satsifies (4.1) and (4.2) on $\tilde{U}$. Also,

$$\int_{\tilde{U}\setminus U} \mathcal{E}^\epsilon(\tilde{u})\, dx \le C,$$

which yields the final assertion of the lemma. □

Theorem 1.2 will follow directly from the next proposition and the above lemma.

PROPOSITION 4.1. *Assume that u is continuous and satisfies* (4.1)–(4.3). *Then, given any $\sigma \in (0, \frac{r}{4d})$, there exists some $\epsilon_0(\sigma) > 0$ such that, for each $\epsilon \in (0, \epsilon_0)$, we can find a collection of closed balls $\{B_i\}_{i=1}^m$ of radius r_i and degree d_i such that*

(4.4) *the interiors of the balls are pairwise disjoint,*

$$\int_{B_i\cap U} \mathcal{E}^\epsilon[u]dx \ge \frac{r_i}{s}\Lambda^\epsilon(s), \qquad \text{for every } i, \text{ where } s := \min_j r_j/|d_j|, \tag{4.5}$$

$$S_E \subset\subset \bigcup_{i=1}^m B_i, \qquad \text{and } B_i \cap S_E \neq \emptyset \text{ for every } i. \tag{4.6}$$

Moreover,

$$s \in \left[\frac{\sigma}{2}, \sigma\right] \tag{4.7}$$

$$d_i \ge 0 \qquad \forall\, i. \tag{4.8}$$

Proof. 1. We first claim that if ϵ is sufficiently small and $\{B_i\}$ is a collection of balls satisfying (4.4)–(4.7), then (4.8) holds.

Noting that

$$\frac{r_i}{s} \ge |d_i| \qquad \forall\, i, \tag{4.9}$$

we use (4.4), (4.5), and (3.4) to compute

$$\begin{aligned}
\int_U \mathcal{E}^\epsilon dx &\ge \sum_i \int_{B_i\cap U} \mathcal{E}^\epsilon dx \\
&\ge \sum_i \frac{r_i}{s}\Lambda^\epsilon(s) \\
&\ge \sum_i |d_i|\Lambda^\epsilon(s) \\
&\ge \left[\kappa_n \ln\left(\frac{s}{\epsilon}\right) - C\right] \sum_i |d_i|. \qquad (4.10)
\end{aligned}$$

If $d_i < 0$ for some i, then $\sum |d_i| \ge d + 2$, in which case (4.3) and (4.7) yield

$$\kappa_n d \ln\left(\frac{1}{\epsilon}\right) + C \;\ge\; (d+2)\left[\kappa_n \ln\left(\frac{\sigma}{2\epsilon}\right) - C\right].$$

This is impossible for ϵ sufficiently small.

It therefore suffices to find a collection satisfying (4.4)–(4.7).

2. Next, if $\{B_i\}$ is a collection of balls satisfying (4.4), (4.5), (4.6), and if

$$s := \min_i \frac{r_i}{|d_i|} \leq \sigma,$$

then $B_i \cap \partial U = \emptyset$ for each i.

Suppose, toward a contradiction, that $B_i \cap \partial U \neq \emptyset$ for some i. From (4.6) we deduce that B_i contains a zero of u. With (4.1) this implies that B_i has radius $r_i \geq r/2 \geq 2d\sigma$. Then

$$\begin{aligned} \int_{B_i \cap U} \mathcal{E}^\epsilon dx &\geq \frac{r_i}{s}\Lambda^\epsilon(s) \\ &\geq \frac{r_i}{\sigma}\Lambda^\epsilon(\sigma) \\ &\geq 2d\left[\kappa_n \ln\left(\frac{\sigma}{\epsilon}\right) - C\right] \end{aligned} \tag{4.11}$$

by (4.5), (3.3), and (3.4). If ϵ is sufficiently small, this contradicts (4.3).

3. Let $\{B_i\}$ be the collection of balls found in Proposition 3.3. This collection satisfies (4.4), (4.5), and (4.6) by construction.

We now claim that, for this particular collection of balls, $s \leq \sigma/2$ if ϵ is sufficiently small. To see this, use (4.3), (3.9), and (4.9) to estimate

$$\begin{aligned} d\kappa_n \ln\left(\frac{1}{\epsilon}\right) + C &\geq \sum_i \int_{B_i \cap U} \mathcal{E}^\epsilon dx \\ &\geq \frac{1}{\epsilon} c_0 \sum_i r_i \\ &\geq \frac{1}{\epsilon} c_0 s \sum_i |d_i|. \end{aligned}$$

Thus in fact $s = O(\epsilon |ln\epsilon|)$, which certainly implies our claim.

We now successively modify these balls in such a way that (4.4), (4.5), and (4.6) remain true, and eventually (4.7) is satisfied.

At each step some balls are changed. We use the notation B_i^{old} and B_i^{new} to distinguish the ith ball, before and after it is modified, and similarly $r_i^{\text{old}}, r_i^{\text{new}}$, etc. When there is no possibility of confusion, we omit the superscripts.

4. *Expansion:* Note that the collection of balls obtained above is disjoint by construction. We modify these balls as follows.

(i) Identify the subcollection of balls B_i satisfying

$$\frac{r_i}{|d_i|} = \min_j \frac{r_j}{|d_j|} = s.$$

We refer to these as minimizing balls. The other balls are called nonminimizing balls.

(ii) Expand the minimizing balls uniformly by leaving the centers fixed and letting the radii grow. This is done in such a way that the ratio $s = r_i/|d_i|$ is always uniform for the minimizing balls. Thus one may think of the expansion as simply increasing the parameter s. Leave the nonminimizing balls unchanged.

More precisely, for $s \geq s^{\text{old}}$ define

$$B_i^s := \begin{cases} B_i^{\text{old}} & \text{if } B_i^{\text{old}} \text{ is nonminimizing,} \\ B_{s|d_i^{\text{old}}|}(x_i^{\text{old}}) & \text{if } B_i^{\text{old}} \text{ is minimizing.} \end{cases}$$

(iii) Define

$$s^{\text{new}} := \sup\{s \geq s^{\text{old}} | \text{ conditions (4.12)–(4.14) below are all satisfied.}\}$$

The conditions alluded to are

$$s < \frac{\sigma}{2}, \tag{4.12}$$

$$s < \frac{r_j^{\text{old}}}{|d_j^{\text{old}}|} \qquad \text{for all nonminimizing balls } B_j^{\text{old}}, \tag{4.13}$$

$$B_i^s \cap B_j^s = \emptyset \qquad \text{whenever } i \neq j, \tag{4.14}$$

where B_i^s, B_j^s are the expanded balls.

(iv) Let $B_i^{\text{new}} := B_i^{s^{\text{new}}}$.

(v) Note that, by step 2, $B_i^{\text{new}} \cap \partial U = \emptyset \ \forall\ i$, because $s^{\text{new}} \leq \sigma$, by (4.12).

(vi) We will verify in step 5 below that (4.4)–(4.6) hold for this new collection.

(vii) It must be the case that s^{new} violates one of (4.12), (4.13), or (4.14).

(viii) If (4.12) does not hold, then $s^{\text{new}} = \sigma/2$ and we are finished.

(ix) If (4.13) does not hold, then $s^{\text{new}} = r_j^{\text{old}}/|d_j^{\text{old}}|$ for some j such that B_j^{old} was nonminimizing. In this case we add all such balls B_j to the collection of minimizing balls and then start another expansion step.

(x) If (4.14) does not hold, we proceed with an "amalgamation step," as described in step 6 below.

Note that each time an expansion step terminates with (4.13) being satisfied, the number of nonminimizing balls decreases. As the total number of balls is finite, this can happen only finitely many times in succession. Thus a series of expansion steps must lead always to either (4.12) or (4.14) being satisfied.

5. It is clear that the collection of balls produced by the above expansion algorithm satisfies (4.6). Moreover, (4.4) holds as a consequence of the stopping criterion (4.14). So we need only to verify (4.5).

First, consider some i such that B_i^{old} was nonminimizing, which implies that $B_i^{\text{new}} = B_i^{\text{old}}$. Then

$$\int_{B_i^{\text{new}}} \mathcal{E}^\epsilon dx = \int_{B_i^{\text{old}}} \mathcal{E}^\epsilon dx \geq \frac{r_i}{s^{\text{old}}} \Lambda^\epsilon(s^{\text{old}}) \geq \frac{r_i}{s^{\text{new}}} \Lambda^\epsilon(s^{\text{new}}).$$

We have used (3.3) and the fact that $s^{\text{new}} \geq s^{\text{old}}$, which is clear from the expansion procedure.

Next, suppose that B_i^{old} was minimizing. We temporarily drop the subscripts i. The expansion procedure is carried out in such a way that $B^{\text{new}} \setminus B^{\text{old}}$ is an annulus with center x, inner radius r^{old}, and outer radius r^{new}; moreover

$$[B_{r^{\text{new}}}(x) \setminus B_{r^{\text{old}}}(x)] \cap S_E = \emptyset.$$

This last fact follows from (4.6) and the stopping criterion (4.14). This implies that $d^{\text{old}} = d^{\text{new}} = \deg(u; \partial B_r)\ \forall\ r \in [r^{\text{old}}, r^{\text{new}}]$. Proposition 3.2 thus allows us to estimate

$$\begin{aligned}\int_{B^{\text{new}}} \mathcal{E}^\epsilon dx &= \int_{B^{\text{new}} \setminus B^{\text{old}}} \mathcal{E}^\epsilon dx + \int_{B^{\text{old}}} \mathcal{E}^\epsilon dx \\ &\geq |d^{\text{new}}| \left[\Lambda^\epsilon\left(\frac{r^{\text{new}}}{|d^{\text{new}}|}\right) - \Lambda^\epsilon\left(\frac{r^{\text{old}}}{|d^{\text{old}}|}\right)\right] + \frac{r^{\text{old}}}{s^{\text{old}}}\Lambda^\epsilon(s^{\text{old}}) \\ &= |d^{\text{new}}|\Lambda^\epsilon\left(\frac{r^{\text{new}}}{|d^{\text{new}}|}\right) \\ &= \frac{r^{\text{new}}}{s^{\text{new}}}\Lambda^\epsilon(s^{\text{new}}).\end{aligned}$$

In the above computation, we have repeatedly used the fact that $s = r/|d|$ for minimizing balls.

6. *Amalgamation:* Suppose now that we have a collection of balls $\{B_i\}_i$ satisfying (4.4)–(4.6), such that (4.7) does not hold and that $B_i \cap B_j \neq \emptyset$ for some $i \neq j$. Combine the balls following the procedure of Lemma 3.1 to obtain a new collection of pairwise disjoint balls $\{B_j^{\text{new}}\}_j$. It is clear that this collection satisfies (4.4) and (4.6). We now verify that (4.5) also holds.

First, for any B_j^{new}, we have

$$r_j^{\text{new}} = \sum_{B_i^{\text{old}} \subset B_j^{\text{new}}} r_i^{\text{old}}, \qquad d_j^{\text{new}} = \sum_{B_i^{\text{old}} \subset B_j^{\text{new}}} d_i^{\text{old}}.$$

It is thus clear that

$$s^{\text{new}} = \min_j \frac{r_j^{\text{new}}}{|d_j^{\text{new}}|} \geq s^{\text{old}}. \tag{4.15}$$

Also, for each j,

$$\begin{aligned}\int_{B_j^{\text{new}}} \mathcal{E}^\epsilon dx &\geq \sum_{B_i^{\text{old}} \subset B_j^{\text{new}}} \int_{B_i^{\text{old}}} \mathcal{E}^\epsilon dx \\ &\geq \frac{1}{s^{\text{old}}}\Lambda^\epsilon(s^{\text{old}}) \sum_{B_i^{\text{old}} \subset B_j^{\text{new}}} r_i^{\text{old}} \\ &\geq \frac{r_j^{\text{new}}}{s^{\text{new}}}\Lambda^\epsilon(s^{\text{new}})\end{aligned}$$

by (3.10), (3.3), and (4.15).

7. We next show that $s^{\text{new}} \leq \sigma$. Recall that we have assumed that $s^{\text{old}} \leq \sigma/2$. This implies that

$$\begin{aligned}\sum_i \int_{B_i^{\text{old}}} \mathcal{E}^\epsilon dx &\geq \sum_i \frac{r_i^{\text{old}}}{s^{\text{old}}}\Lambda^\epsilon(s^{\text{old}}) \\ &\geq \sum_i \frac{r_i^{\text{old}}}{\sigma/2}\Lambda^\epsilon\left(\frac{\sigma}{2}\right) \\ &\geq \frac{2}{\sigma}\left(\kappa_n \ln\left(\frac{\sigma}{2\epsilon}\right) - C\right)\sum_i r_i^{\text{old}}.\end{aligned}$$

With (4.3) this shows that

$$\sum_i r_i^{\text{old}} \leq d\sigma$$

if ϵ is sufficiently small. Note also from the construction of Lemma 3.1 that

$$\begin{aligned} d\sigma &\geq \sum_i r_i^{\text{old}} \\ &= \sum_j r_j^{\text{new}} \\ &\geq \sum_j |d_j^{\text{new}}| s^{\text{new}} \\ &\geq d s^{\text{new}}. \end{aligned}$$

8. Thus an amalgamation step yields a collection of balls which satisfy (4.4)–(4.6), with $s \leq \sigma$. If $s \in [\sigma/2, \sigma]$, then we are finished. If not, because the balls are pairwise disjoint, we modify them again using the expansion procedure of steps 4 and 5 above. We continue in this fashion, expanding and combining balls, until (4.7) is satisfied.

This must happen eventually, for the following reasons: each amalgamation step decreases the number of balls, and each expansion step leaves the total number of balls unchanged. Thus there can be only finitely many amalgamations. Also, as remarked above, there can only be finitely many expansions. It is therefore clear that the process must eventually terminate. By construction this can happen only when $s \in [\sigma/2, \sigma]$. □

We now complete the proof of Theorem 1.2:

Proof. We may assume that (4.1)–(4.3) hold, if necessary by extending u in a neighborhood of ∂U, as in Lemma 4.1.

By a standard approximation argument, we may assume that u is continuous.

We may thus construct balls as in Proposition 4.1. By an obvious modification of Proposition 4.1, we may prescribe that $s := \min r_i/|d_i| \in [\sigma/4, \sigma/2]$.

Let $\{x_1, \ldots, x_m\}$ be the centers of the balls which have nonzero degree, and let $\{d_1, \ldots, d_m\}$ be the corresponding degrees. In view of (4.8) it is clear that $d_i > 0$ for all i. From (4.6), (4.2), and the definition of S_E, we deduce that $\sum d_i = d$.

Finally, from (4.3), (4.4), (4.5), and (3.4) we deduce that $\sum_i (r_i/s) \leq d + 1$ for ϵ small. Since $d_i \leq r_i/s$, this implies that $r_i \leq 2d_i s \leq d_i \sigma \ \forall\ i$. Thus

$$B_i \subset B_{d_i \sigma}, \tag{4.16}$$

and so we can use familiar properties of Λ^ϵ to estimate

$$\begin{aligned} \int_{\cup_i B_{d_i\sigma}(x) \cap U} \mathcal{E}^\epsilon \, dx &\geq \int_{\cup_i B_i \cap U} \mathcal{E}^\epsilon \, dx \\ &\geq \sum_i \frac{r_i}{s} \Lambda^\epsilon(s) \\ &\geq \sum_i d_i \Lambda^\epsilon(s) \\ &\geq d\Lambda^\epsilon\left(\frac{\sigma}{4}\right) \\ &\geq d\kappa_n \ln\left(\frac{\sigma}{\epsilon}\right) - C. \end{aligned}$$

□

5. Compactness. Theorem 1.2 implies a compactness result in a straightforward way. The point is that, given a sequence of functions, we can find a subsequence along which the energy is uniformly bounded away from a collection of at most d limiting singular points.

In this section we will prove the following proposition.

PROPOSITION 5.1. *Suppose u^ϵ is a collection of functions and that for each ϵ, u^ϵ satisfies* (4.1), (4.2), *and*

$$\int_U \mathcal{E}^\epsilon dx \le d\kappa_n \ln\left(\frac{1}{\epsilon}\right) + C.$$

Then there exist points $x_1, \dots, x_m \in \bar{U}$, with $m \le d$, a subsequence $\epsilon_k \to 0$, and a function $u \in W^{1,n}_{loc}(U \setminus \{x_1, \dots, x_m\}; S^{n-1})$ such that

$$u^{\epsilon_k} \rightharpoonup u \qquad \text{weakly in } W^{1,n}_{loc}(U \setminus \{x_1, \dots, x_m\}; \mathcal{R}^n).$$

Finally, there are integers $d_i > 0$ for $i = 1, \dots, m$ such that $\sum d_i = d$ and

$$\mu^{\epsilon_k} := |\ln \epsilon_k|^{-1} \mathcal{E}^{\epsilon_k} dx \to \kappa_n \sum_{i=1}^m d_i \delta_{x_i}$$

weakly as measures.

Remark. Theorem 1.3 follows immediately from this proposition and Lemma 4.1.

Proof. 1. Fix $\sigma_1 \in (0, r/4d)$, and for every $\epsilon < \epsilon_0(\sigma)$, apply Proposition 4.1 to the function u^ϵ. This yields a collection of balls $\{B_i^\epsilon\}_{i=1}^M$. Let B_i^ϵ have center x_i^ϵ, and let $d_i^\epsilon := \deg(u^\epsilon; \partial B_i^\epsilon)$. Discard all balls for which $d_i^\epsilon = 0$. Then at most d balls remain, the balls are disjoint, and each ball satisfies

$$\int_{B_i^\epsilon} \mathcal{E}^\epsilon dx \ge d_i^\epsilon \Lambda^\epsilon \left(\frac{\sigma_1}{2}\right) \ge d_i^\epsilon \left[\kappa_n \ln\left(\frac{\sigma_1}{\epsilon}\right) - C\right] \tag{5.1}$$

by construction. Arguing as in (4.16), we see that

$$B_i^\epsilon \subset B_{2d_i^\epsilon \sigma_1}(x_i^\epsilon). \tag{5.2}$$

We may easily find positive integers d_i^1, points x_i^1, and a subsequence $\epsilon_j \to 0$ such that

$$d_i^{\epsilon_j} \to d_i^1, \qquad \sum_i d_i^1 = d,$$

and for each i,

$$x_i^{\epsilon_j} \to x_i^1$$

as $j \to \infty$.

Define $B_i^1 := B_{4d_i^1 \sigma_1}(x_i^1)$, and

$$U^1 := U \setminus (\cup_i B_i^1).$$

From (5.2) we see that $B_i^{\epsilon_j} \subset B_i^1$ for all sufficiently large j. Thus (4.3) and (5.1) imply that

$$\liminf_j \int_{B_i^1} \mathcal{E}^{\epsilon_j} dx - d_i^1 \kappa_n \ln\left(\frac{\sigma_1}{\epsilon}\right) \ge -C, \tag{5.3}$$

$$\limsup_j \int_{U^1} \mathcal{E}^{\epsilon_j}\,dx \le d\kappa_n \ln\left(\frac{1}{\sigma_1}\right) + C. \tag{5.4}$$

2. Now repeat the above process for $\sigma_2 = \frac{1}{2}\sigma_1$ to find positive integers d_i^2, points x_i^2, and a further subsequence, which we still write as ϵ_j, such that (5.3) and (5.4) hold with σ_1 replaced with σ_2, where B_i^2 and U^2 are defined as before.

Note that for any j,

$$B_j^1 \cap (\cup_i B_i^2) \neq \emptyset \qquad \text{and} \qquad B_j^2 \cap (\cup_i B_i^1) \neq \emptyset.$$

If this is not the case, then, for example,

$$B_j^2 \subset U^1,$$

which would lead to a contradiction between (5.4) and (5.1).

It follows that

$$\operatorname{dist}\left(\{x_i^1\}_i\,,\,\{x_i^2\}_i\right) \le \sigma_1 + \sigma_2, \tag{5.5}$$

where dist here denotes the Hausdorff distance between two sets,

$$\operatorname{dist}(A,B) = \max\{\max_{x\in A}\min_{y\in B}|x-y|\,,\,\max_{y\in B}\min_{x\in A}|x-y|\}.$$

3. We now repeat the same procedure for each k, with $\sigma_k = 2^{-k+1}\sigma_1$, each time passing to subsequences and finding points x_i^k and positive integers d_i^k such that $\sum_i d_i^k = d$,

$$\liminf_j \int_{B_i^k} \mathcal{E}^{\epsilon_j}\,dx - d_i^k\kappa_n \ln\left(\frac{\sigma_k}{\epsilon}\right) \ge\ -C, \tag{5.6}$$

and

$$\limsup_j \int_{U^k} \mathcal{E}^{\epsilon_j}\,dx \le d\kappa_n \ln\left(\frac{1}{\sigma_k}\right) + C \tag{5.7}$$

for balls B_i^k and U^k defined as in step 1.

By a diagonal argument we may extract a subsequence, still denoted ϵ_j, such that (5.6) and (5.7) hold for every k. Moreover it is clear from (5.5) that the sets $\{x_i^k\}_i$ must converge in the Hausdorff metric to some limiting set $\{x_1,\dots,x_m\}$ as $k\to\infty$. Any compact subset of $U\setminus\{x_1,\dots,x_m\}$ is contained in some U_k for k sufficiently large. Thus $\{u^{\epsilon_j}\}$ is weakly precompact in $W^{1,n}_{\text{loc}}(U\setminus\{x_1,\dots,x_m\};\mathcal{R}^n)$.

The other conclusion of the theorem follows similarly from (5.6) and (5.7). ∎

6. The gauge-invariant functional. The above framework can be modified to give estimates for the gauge-invariant functional $I^\epsilon_{\text{mag}}(u,A)$.

Let $\gamma := ||\nabla\times A||_{L^2(U)}$ and

$$\mathcal{F}^\epsilon_{\text{mag}}[u,A] := \frac{1}{2}|\nabla_A u|^2 + \frac{1}{4\epsilon^2}(1-|u|^2)^2,$$

so that $I^\epsilon_{\text{mag}}(u,A) = \frac{1}{2}\gamma^2 + \int_U \mathcal{F}^\epsilon_{\text{mag}}[u,A]\,dx$.

We also define

$$\lambda^\epsilon_\gamma(r;d) := \min_{m\in[0,1]}\left\{\frac{1}{C\epsilon}|1-m|^N + \frac{m^2}{r}\left[\left(\sqrt{\pi}d - \frac{r\gamma}{2}\right)^+\right]^2\right\}. \tag{6.1}$$

We will regard γ as fixed and establish lower bounds for $\mathcal{F}^\epsilon_{\text{mag}}$ in which γ appears as a parameter. These bounds have exactly the same structure as our earlier bounds, so that the covering arguments from earlier sections may by employed almost without change to find global lower bounds for $\mathcal{F}^\epsilon_{\text{mag}}$ which depend on the parameter γ. We then obtain estimates for the full energy I^ϵ_{mag} by minimizing over $\gamma > 0$.

LEMMA 6.1. *λ^ϵ_γ has the following properties. First,*

$$\lambda^\epsilon_\gamma(r;d) \geq \frac{\pi}{r}\left[\left(d - \frac{r\gamma}{2\sqrt{\pi}}\right)^+\right]^2 \left[1 - C\frac{\epsilon^\alpha}{r^\alpha}\right]. \tag{6.2}$$

Second, if $r \geq \epsilon$, $B_r \subset U$, $u \in H^1(\partial B_r, \mathcal{C})$, and $|\deg(u;\partial B_r)| = d$, then

$$\int_{\partial B_r} \mathcal{F}^\epsilon_{mag}[u,A]\, dH^1 \;\geq\; \lambda^\epsilon_\gamma(r;d). \tag{6.3}$$

Proof. 1. We omit the proof of (6.2), as it is exactly like the proof of (2.2).

2. We may assume without loss that $d > 0$. We write $u = \rho e^{i\phi}$, where ϕ is multivalued. A calculation shows that

$$|\nabla_A u|^2 = |D\rho|^2 + \rho^2|D\phi - A|^2.$$

Thus

$$\int_{\partial B_r} \mathcal{F}^\epsilon_{\text{mag}}\, dH^1 = I_1 + I_2,$$

for

$$I_1 := \int_{\partial B_r} \frac{1}{2}|D\rho|^2 + \frac{1}{4\epsilon^2}(1-\rho^2)^2,$$

$$I_2 := \int_{\partial B_r} \frac{1}{2}\rho^2|D\phi - A|^2.$$

Define $m := \inf_{\partial B_r} \rho$. Exactly as in Lemma 2.3 we see that

$$I_1 \geq \frac{1}{C\epsilon}|1-m|^N$$

for some $C, N > 0$. It is at this stage that we use the assumption $r \geq \epsilon$.

3. For $x := (x_1, x_2) \in \partial B_r$, let $\tau(x) := \frac{1}{|x|}(-x_2, x_1)$ denote the oriented tangent at x.

Because u has degree d,

$$\int_{\partial B_r} D\phi \cdot \tau\, dH^1 = 2\pi d.$$

Also, by Stokes' theorem,

$$\begin{aligned}\int_{\partial B_r} A \cdot \tau\, dH^1 &= \int_{B_r} \nabla \times A \\ &\leq (\pi r^2)^{1/2}\left(\int_{B_r} |\nabla \times A|^2\right)^{1/2} \\ &\leq \sqrt{\pi} r\gamma.\end{aligned}$$

Thus

$$2\pi d - \sqrt{\pi} r\gamma \;\le\; \int_{\partial B_r} (D\phi - A)\cdot\tau,$$

and therefore

$$(2\pi d - \sqrt{\pi} r\gamma)^+ \le \sqrt{2\pi} r \left(\int_{\partial B_r} |D\phi - A|^2 \right)^{1/2}.$$

Here $s^+ := \max\{s, 0\}$ for $s \in \mathcal{R}$, as usual. Rearranging and using the definition of m, we obtain

$$I_2 \ge \frac{m^2}{r} \left[\left(\sqrt{\pi} d - \frac{r\gamma}{2} \right)^+ \right]^2$$

With step 2 this immediately gives the conclusion of the lemma. □

Next we define

$$\Lambda^\epsilon_\gamma(r) := \int_0^r \lambda^\epsilon_\gamma(s;1) \wedge \frac{c_0}{\epsilon} ds \tag{6.4}$$

for some appropriately small c_0. We continue to assume that $\gamma = ||\nabla \times A||_{L^2}$ is some known, finite number.

Λ^ϵ_γ has the following properties.

PROPOSITION 6.1. *$\Lambda^\epsilon_\gamma(\cdot)$ is increasing; moreover,*

$$\Lambda^\epsilon_\gamma(r+s) \le \Lambda^\epsilon_\gamma(r) + \Lambda^\epsilon_\gamma(s) \qquad \forall\, r, s \ge 0; \tag{6.5}$$

$$s \mapsto \frac{1}{s}\Lambda^\epsilon_\gamma(s) \qquad \textit{is nonincreasing}; \qquad \textit{and} \tag{6.6}$$

$$\Lambda^\epsilon_\gamma(r) \;\ge\; \pi \log\left(\frac{1}{\epsilon}\right) + \log(r \wedge \gamma^{-1}) - C. \tag{6.7}$$

Proof. The lower estimate (6.7) follows by integrating the lower bound (6.2) for λ^ϵ_γ. The other claims are proven by exactly the arguments used in the proof of Proposition 3.1. □

The next proposition follows from (6.3) by exactly the arguments of Proposition 3.2.

PROPOSITION 6.2. *Let $u \in H^1(U;\mathcal{C})$ be continuous. If $|\mathrm{dg}\,(u;\partial B_\rho)| = d > 0$ for all $\rho \in [r_0, r_1]$ and $\epsilon \le r_0 \le r_1$, then*

$$\int_{B_{r_1}\setminus B_{r_0}} \mathcal{F}^\epsilon_{mag}[u,A]\,dx \ge d\left[\Lambda^\epsilon_\gamma\left(\frac{r_1}{d}\right) - \Lambda^\epsilon_\gamma\left(\frac{r_0}{d}\right)\right]. \tag{6.8}$$

Also,

$$\int_{B_{r_1}\setminus B_{r_0}} \mathcal{F}^\epsilon{}_{mag}\,[u,A]\,dx \ge \Lambda^\epsilon_\gamma(r_1) - \Lambda^\epsilon_\gamma(r_0). \tag{6.9}$$

□

The final property of Λ that we will need is the following. For this we assume that $u \in C \cap H^1(U;\mathcal{C})$, and we define S_E as in (1.10).

PROPOSITION 6.3. *Suppose that $u \in C \cap H^{1,2}(U;\mathcal{C})$ and that $A \in H^1(U;\mathcal{R}^2)$, with $\gamma := ||\nabla \times A||_{L^2} \leq C\epsilon^{-1/2}$. If $S_E \subset\subset U$, then there is a collection of closed, pairwise disjoint balls $\{B_i\}_{i=1}^k$ such that*

$$S_E \subset \cup_{i=1}^k B_i,$$

$$\int_{B_i \cap U} \mathcal{F}^\epsilon_{mag} dx \geq \Lambda^\epsilon_\gamma(r_i),$$

$$r_i \geq \epsilon \qquad \forall\, i,$$

$$B_i \cap S_E \neq \emptyset \qquad \text{for each } i.$$

Proof. The proof follows exactly that of Proposition 3.3, which uses only Lemmas 2.5, 3.1, and 3.2. In this context, the first two of these are still valid, and in place of Lemma 3.2, we have Lemma 6.2 below, so the desired result is a consequence of our earlier arguments. □

LEMMA 6.2. *Let S_i be a connected component of S_E, and assume that $S_i \subset\subset U$. Assume also that $\gamma \leq C\epsilon^{-1/2}$. Then there exists some constant C such that, for all sufficiently small ϵ,*

$$\int_{S_i} \mathcal{F}^\epsilon[u,A]dx \geq C^{-1}.$$

Proof. 1. We may assume by an approximation argument that u is C^∞. As above we write $u := \rho e^{i\phi}$.

Let $f := \frac{1}{2}\rho^2$. We will use the coarea formula,

$$\int_{S_i} g\, Jf\, dx = \int_0^\infty \left(\int_{S_i \cap f^{-1}(s)} g dH^{n-1} \right) ds, \tag{6.10}$$

where Jf is the Jacobian of f, which in this case is given by

$$Jf = |Df| = \rho |D\rho|.$$

Thus

$$\begin{aligned} |\nabla_A u|^2 &= |D\rho|^2 + \rho^2 |D\phi - A|^2 \\ &= Jf \left(\frac{|D\rho|}{\rho} + \frac{\rho}{|D\rho|} |D\phi - A|^2 \right) \\ &\geq Jf |D\phi - A|. \end{aligned}$$

The coarea formula thus gives

$$\begin{aligned} \int_{S_i} |\nabla_A u|^2 &\geq \int_0^\infty \left(\int_{f^{-1}(s)\cap S_i} |D\phi - A| dH^1 \right) ds \\ &\geq \int_0^\infty \left| \int_{f^{-1}(s)\cap S_i} (D\phi - A)\cdot \tau dH^1 \right| ds. \end{aligned}$$

2. For $s \in [0,1]$, $f^{-1}(s) \cap S_i$ is nonempty, since u is continuous and must have a zero in each component of S_E. Moreover, for Lebesgue (almost everywhere) such s, $f^{-1}(s) \cap S_i$ is a smooth compact manifold, by Sard's theorem. Fix some s for which this is the case. The definition of degree (1.6) easily implies that

$$\deg(u^\epsilon; f^{-1}(s) \cap S_i) = \deg(u^\epsilon; \partial S_i) := d.$$

It follows that

$$\int_{f^{-1}(s)\cap S_i} D\phi \cdot \tau = d.$$

Also,

$$\begin{aligned}\int_{f^{-1}(s)\cap S_i} A \cdot \tau \, dH^1 &= \int_{\{\frac{1}{2}\rho^2 \le s\}\cap S_i} \nabla \times A \, dx \\ &\le |S_i|^{1/2} \left(\int_{S_i} |\nabla \times A|^2 \, dx \right)^{1/2} \\ &\le |S_i|^{1/2} \gamma.\end{aligned}$$

Putting these together, we find that

$$\int_{f^{-1}(s)\cap S_i} (D\phi - A) \cdot \tau dH^1 \ge d - |S_i|^{1/2}\gamma.$$

3. Combining steps 1 and 2 and using the fact that $(1-|u|^2)^2 \ge C^{-1}$ on S_i, we obtain

$$\int_{S_i} \mathcal{F}_{\text{mag}} dx \ge d - |S_i|^{1/2}\gamma + |S_i| \frac{1}{C\epsilon^2}.$$

Since we have assumed that $\gamma \le C\epsilon^{-1/2}$, the conclusion follows by calculus. □

Using Propositions 6.1, 6.2, and 6.3, we can repeat the proofs of Proposition 4.1 and Theorem 1.2 with only minor modifications. We indicate how this is done.

PROPOSITION 6.4. *Assume that u is continuous and satisfies* (4.1)–(4.2) *and that*

$$\int \mathcal{E}^\epsilon_{mag}[u, A] \, dx \le \pi d \ln\left(\frac{1}{\epsilon}\right) + C. \tag{6.11}$$

Then

$$\int_U |\nabla \times A|^2 \, dx \le C. \tag{6.12}$$

Moreover, given any $\sigma \in (0, \frac{r}{4d})$, there exists some $\epsilon_0(\sigma) > 0$ such that, for each $\epsilon \in (0, \epsilon_0)$, we can find a collection of closed balls $\{B_i\}_{i=1}^M$ of radius r_i and degree d_i such that

the interiors of the balls are pairwise disjoint, (6.13)

$$\int_{B_i \cap U} \mathcal{F}^\epsilon_{mag}[u, A] \, dx \ge \frac{r_i}{s} \Lambda^\epsilon(s), \qquad \text{for } s := \min_j r_j/|d_j|, \tag{6.14}$$

$$S_E \subset\subset \bigcup_{i=1}^{M} B_i, \qquad \text{and } B_i \cap S_E \neq \emptyset \text{ for every } i. \tag{6.15}$$

Moreover,

$$s \in \left[\frac{\sigma}{2}, \sigma\right], \tag{6.16}$$

$$d_i \geq 0 \qquad \forall i. \tag{6.17}$$

Proof. 1. Fix some $\sigma \in (0, \frac{r}{4d})$. Following step 1 of the proof of Proposition 4.1, we show that it suffices to find a collection of balls satisfying (6.13)–(6.16).

Suppose that we have found such a collection; we need to show that (6.12) and (6.17) necessarily hold. Following (4.10),

$$\begin{aligned}\int_U \mathcal{E}^\epsilon_{\text{mag}}\, dx &\geq \frac{1}{2}\gamma^2 + \sum_i \int_{B_i} \mathcal{F}^\epsilon_{\text{mag}}\, dx \\ &\geq \frac{1}{2}\gamma^2 + \Lambda^\epsilon_\gamma\left(\frac{\sigma}{2}\right)\sum |d_i| \\ &\geq \frac{1}{2}\gamma^2 + \pi\left[\ln\left(\frac{1}{\epsilon}\right) + \ln\left(\frac{\sigma}{2}\wedge\frac{1}{\gamma}\right)\right]\sum |d_i|. \qquad (6.18)\end{aligned}$$

If $d_i < 0$ for some i, then $\sum |d_i| \geq d+2$. If this holds, then (6.18) and (6.11) yield

$$\pi d \ln\left(\frac{1}{\epsilon}\right) + C \;\geq\; \frac{1}{2}\gamma^2 + (d+2)\pi\left[\ln\left(\frac{1}{\epsilon}\right) + \ln\left(\frac{\sigma}{2}\wedge\frac{1}{\gamma}\right)\right].$$

By minimizing the right-hand side over $\gamma > 0$, we obtain a contradiction if ϵ is sufficiently small. This proves that $d_i \geq 0\ \forall\ i$.

Once we know that $\sum |d_i| = d$, by comparing (6.18) and (6.11) we obtain

$$\frac{1}{2}\gamma^2 + d\pi \ln\left(\frac{\sigma}{2}\wedge\frac{1}{\gamma}\right) \;\leq\; C.$$

This clearly implies that $\gamma \leq C$, which is (6.12).

2. As in step 2 of the proof of Proposition 4.1, we next show that if a collection of balls satisfies (6.13)–(6.15), and if $s \leq \sigma$, then $B_i \cap \partial U = \emptyset$ for every ball in the collection.

Suppose, toward a contradiction, that $B_i \cap \partial U \neq \emptyset$ for some i. By following exactly the argument that leads to (4.11), we see that

$$\begin{aligned}\int_U \mathcal{E}^\epsilon_{\text{mag}}\, dx &\geq \frac{1}{2}\gamma^2 + \int_{B_i} \mathcal{F}^\epsilon_{\text{mag}}\, dx \\ &\geq \frac{1}{2}\gamma^2 + \frac{r_i}{\sigma}\Lambda^\epsilon_\gamma(\sigma) \\ &\geq \frac{1}{2}\gamma^2 + 2d\pi\left[\ln\left(\frac{1}{\epsilon}\right) + \ln\left(\frac{\sigma}{2}\wedge\frac{1}{\gamma}\right)\right].\end{aligned}$$

This leads to a contradiction with (6.11) for sufficiently small ϵ, again by minimizing over $\gamma \geq 0$.

3. Steps 3 through 6 and step 8 of the proof of Proposition 4.1 may be repeated without change. Step 7 requires some small modifications, which can be carried out along the lines already indicated above. ∎

Acknowledgment. I am indebted to Mete Soner for pointing out the result of Lemma 2.3.

STRUCTURAL STABILITY FOR THE EULER METHOD*

MING-CHIA LI†

Abstract. In this paper, we show that if a flow φ^t has a hyperbolic chain recurrent set either without fixed points or with only fixed points, and satisfies the strong transversality condition, then φ^t is structurally stable with respect to numerical methods, including the Euler method, which was not done in [B. M. Garay, *Numer. Math.*, 72 (1996), pp. 449–479], [M.-C. Li, *J. Differential Equations*, 141 (1997), pp. 1–12], and [M.-C. Li, *SIAM J. Math. Anal.*, 28 (1997), pp. 381–388]. The proof is an application of the invariant manifold techniques developed by Hirsch, Pugh, and Shub [M. Hirsh, C. Pugh, and M. Shub, Invariant Manifolds, *Lecture Notes in Math.* 583, *Springer-Verlag, New York,* 1977] and Robinson [C. Robinson, *J. Differential Equations*, 22 (1976), pp. 28–73]. The result is an extension of our previous work [M.-C. Li, *Proc. Amer. Math. Soc.*, 127 (1999), pp. 289–295].

1. Introduction.

How much confidence can we have in computer simulation? For example, suppose we use a numerical method to approximate the general solution of a differential equation. Does the numerical approximation exhibit the same global geometry and dynamics as the exact solution? There have been theorems showing that the answer to this question is yes for several cases. Before going into these theorems, we give an introduction on how the global qualitative theory in dynamical systems applies to numerical analysis.

Numerical methods and dynamical systems are deeply connected. As is well known, general solutions of differential equations are considered continuous-time dynamical systems. On the other hand, numerical methods frequently involve iterative processes, and so they are discrete-time dynamical systems. Suppose we use a numerical method to approximate the general solution of a differential equation. The numerical method can be interpreted as a small perturbation of the solution flow. The natural question is whether the numerical approximation accurately reflects the dynamics of the original flow. In the terminology of global stabilities, this is the same as asking whether certain flows are structurally stable with respect to numerical methods.

There are many classical stability theorems in dynamical systems. Local stability results include the Hartman–Grobman theorem, the stable manifold theorem, and the normally hyperbolic stability theorem. For global results, we have the Ω-stability theorem and the structural stability theorem. The structural stability theorem states that a continuous/discrete-time dynamical system preserves its global geometric structure under small C^1 perturbations. Here, we have to point out that results about structural stability cannot be applied directly to our situation: a flow is approximated by a numerical method which is a discrete-time system, not a continuous system. In order to show structural stability of flows for numerical methods, we need to make

explicit estimations by going through the mathematical techniques in the proof of the structural stability theorem.

Historically, the structural stability theorem was attacked for several special cases before the general proof was given. First, the case of Anosov systems when the whole manifold has a hyperbolic structure was proved by Anosov [1] and Moser [21]. Next, the case of Morse–Smale systems when the nonwandering set is a finite number of hyperbolic closed orbits was proved by Palis and Smale [22]. Finally, the case of Axiom A systems when the nonwandering set is the union of finitely many basic sets was proved by Robbin [25] for C^2 diffeomorphisms, by Robinson [26] for C^2 vector fields, and again by Robinson for C^1 diffeomorphisms [28] and C^1 flows [27].

Suppose that we have a flow φ^t on a compact manifold M which is approximated by a numerical method N in the following sense: the numerical method of stepsize h and order p, N^h, is $O(h^{p+1})$-close to the time-h map of the flow, φ^h. Under certain differentiability conditions on φ and N, one can show that N^h is $O(h^p)$-close to φ^h in the C^1 topology (see Lemma 1). We want to match the trajectories of φ^t with the orbits of N^h by constructing a homeomorphism H_h, depending on h, to conjugate N^h to φ. In terms of dynamical systems, H_h is usually called a *topological conjugacy*, if there is no reparametrization on φ^t, or a *topological equivalence* otherwise. If such a homeomorphism H_h exists, we say that the flow φ^t is *structurally stable* with respect to the numerical method N.

Global stability under numerical approximation is analogous to the structural stability theorem. Two analytic approaches were used by Robinson in [28] to prove the structural stability theorem. One involves solving a functional equation by means of the implicit function theorem. The other involves using compatible families of stable and unstable disks by the method of graph transforms.

Certain flows are structurally stable with respect to numerical methods. The case of Morse–Smale gradient-like flows, i.e., Morse–Smale flows without closed orbits, was proved by Garay [12]. See also [18] for a slightly better result. The case of Axiom A flows with the strong transversality condition was shown in [17]. The proof of these theorems is essentially based on the first approach in [28]: solve a functional equation to construct a conjugacy H_h and use the d_φ-Lipschitz metric, due to Robbin [25], to prove H_h is one to one. These theorems work well for numerical methods of order $p \geq 2$. If we consider the Euler method of order $p = 1$, then we get that H_h is a semiconjugacy but cannot prove it is one to one.

The challenge for the Euler method led us to consider the second approach in [28] using the graph transforms. In [19], we assumed φ^t has a hyperbolic attractor $\mathcal{A}_\varphi$. Relying on the abstract invariant manifold theorems in [28] and the idea of laminations given by Hirsch, Pugh, and Shub [16], we showed that the restriction of the flow φ^t to the basin of attraction, $B(\mathcal{A}_\varphi)$, is structurally stable with respect to numerical methods of order $p \geq 1$. Earlier, Garay [13] showed that the restriction of φ^t to $B(\mathcal{A}_\varphi)\backslash\mathcal{A}_\varphi$, $\varphi^t|B(\mathcal{A}_\varphi)\backslash\mathcal{A}_\varphi$, is structurally stable under discretizations.

In this paper, we extend our previous result [19] to the case when the flow φ^t has a hyperbolic chain recurrent set but no fixed points. By using compatible families of stable and unstable disks due to Robinson [28], we are able to construct a topological equivalence and prove that φ^t is structurally stable with respect to numerical methods, including the Euler method. The proof is even simpler for the case when the chain recurrent set has only fixed points.

It is not clear whether we can use this method to prove that φ^t with hyperbolic fixed and periodic points simultaneously is structurally stable with respect to the Eu-

ler method. Proving the structural stability theorem for flows, Robinson [28] put a reparametrization on the perturbed flow and successfully made a transition from no reparametrization near fixed points to a reparametrization away from fixed points. Here, we cannot parametrize the numerical method since it is discrete. Recently, Pilyugin [23] showed a shadowing result for structurally stable flows by dealing with different hyperbolic structures near fixed points and near periodic points.

Although not emphasized here, the persistence of local properties under approximation has been widely studied. See [4], [10] for hyperbolic equilibria, [3], [6], [8], [9], [24] for hyperbolic closed orbits, and [7], [11], [14], [20], [24] for normally hyperbolic invariant manifolds. Most of such results are discussed in a survey by Stuart [36] (see also [37]).

2. Statement of theorems. First, we introduce notations and basic definitions.

Let M be a smooth complete Riemannian manifold with a distance d arising from the Riemannian metric and $\mathrm{Diff}(M)$ be the set of diffeomorphisms on M with the strong topology and distance d_{C^1}. A *flow* is a map $\varphi : \mathbb{R} \times M \to M$ that satisfies the group property $\varphi(s, \varphi(t, x)) = \varphi(s + t, x)$. We write $\varphi(t, x) = \varphi^t(x)$.

A compact invariant set Λ for a C^1 flow φ^t on M is *hyperbolic* if the restriction of the tangent bundle TM of M to Λ splits into three continuous subbundles, $TM|\Lambda = \mathbb{E}^u \oplus \mathbb{E}^s \oplus Span(X)$, invariant under the derivative of φ^t, $D\varphi^t$, such that $D\varphi^t$ expands $\mathbb{E}^u$ and $D\varphi^t$ contracts $\mathbb{E}^s$ for all $t \geq t_0$, where X is the vector field induced by the flow φ^t. The *stable manifold* of $x \in M$ is the set of all points in M whose forward orbits under φ^t tend to x. The *unstable manifold* of $x \in M$ is the set of all points in M whose backward orbits under φ^t tend to x. The flow φ^t satisfies the *strong transversality condition* if all the stable manifolds of orbits of φ^t transversally intersect the unstable manifolds of orbits of φ^t. See [30] for a more complete explanation of these definitions.

Chain recurrent sets for flows are defined as follows.

Definition 1. *A pair of sets $(\mathcal{A}, \mathcal{A}^*)$ is called the* attractor-repeller pair *for the flow φ^t if there exists a neighborhood U of $\mathcal{A}$ such that $\varphi^T(\mathrm{cl}(U)) \subset \mathrm{int}(U)$ for some $T > 0$, $\mathcal{A} = \cap_{t \geq 0} \varphi^t(U)$, and $\mathcal{A}^* = \bigcap_{t \leq 0} \varphi^t(M \backslash U)$. The* chain recurrent set $\Re_\varphi$ *for φ^t is the set $\Re_\varphi = \cap_{i \in I}(\mathcal{A}_i \cup \mathcal{A}^*{}_i)$, the intersection of all attractor-repeller pairs.*

One can define the chain recurrent set to be the points x such that there is a periodic ϵ-chain through x for all $\epsilon > 0$. These two definitions are equivalent; see [30] for the proof. In our previous results on structural stability for numerical methods, we assumed hyperbolicity on the nonwandering set Ω_φ in [17] and on an attractor $\mathcal{A}_\varphi$ in [19]. In the present paper, the hyperbolicity will be assumed on the chain recurrent set $\Re_\varphi \supset \Omega_\varphi \supset \mathcal{A}_\varphi$.

We use a general definition of numerical methods on manifolds.

Definition 2. *Let φ^t be a flow on M. For $p \geq 1$, a C^{p+1} function $N : \mathbb{R} \times M \to M$ is called a* numerical method of order p *for φ^t if there are positive constants K and h_0 such that $d(\varphi^h(x), N^h(x)) \leq Kh^{p+1}$, for all $h \in [0, h_0]$ and $x \in M$. Here h stands for a* stepsize *of N. We denote the ith iterate of $N^h(x)$ by $(N^h)^i(x)$.*

The definition is related to standard numerical analysis. For example, the explicit Euler method in Euclidean spaces corresponds to $N^h(x) = x + h\varphi^h(x)$ and is of order $p = 1$. Both the improved Euler method and the three term Taylor series method are of order 2. The usual Runge–Kutta methods are of order $p \geq 4$. See [2] and [5]. The pth-order multiderivative method is another example satisfying the above conditions (see [15]).

The distance between φ^h and N^h in the C^1-topology is estimated in the following lemma.

LEMMA 1 (see [11]). *Let N be a numerical method of order p for a C^{p+1} flow φ^t on a compact manifold M. Then there is a positive constant K_1 such that $d_{C^1}(\varphi^h, N^h) \le K_1 h^p$ for all sufficiently small h. Moreover, given $T > 0$, there is a positive constant K_2 such that $d_{C^1}(\varphi^T, (N^{\frac{T}{n}})^n) \le K_2 n^{1-p}$ for all large $n \in \mathbb{N}$.*

For convenience, we give the theorem for the general numerical methods first and state those for the Euler method later. The proof of the following theorem is postponed until section 4.

THEOREM 1. *Let M be a compact manifold and φ^t be a C^1 flow on M such that* (i) *φ^t has no fixed point,* (ii) *the chain recurrent set $\Re_\varphi$ is hyperbolic, and* (iii) *φ^t satisfies the strong transversality condition. Let $p \ge 1$, $T > 0$, and N be a numerical method of order p for φ^t satisfying $d_{C^1}(\varphi^T, (N^{\frac{T}{n}})^n) \le K n^{-1}$ for all large $n \in \mathbb{N}$, where K is a positive constant. Then for all sufficiently large n, there is a homeomorphism H_n on M and a continuous function $\tau_n : M \to \mathbb{R}$ such that for all $x \in M$, $H_n \circ \varphi^{\tau_n(x)}(x) = (N^{\frac{T}{n}})^n \circ H_n(x)$ and $d(H_n(x), x) \to 0$ as $n \to \infty$.*

The applicability of Theorem 1 to the Euler method follows from the following result of Shub [31].

LEMMA 2. *Let X be a C^2 bounded vector field on M, φ^t be the flow of the differential equation $\dot{x} = X(x)$, and E be the Euler method for φ^t. Then for all sufficiently small h, there is a positive constant K_1 such that $d_{C^1}(\varphi^h, E^h) \le K_1 h^2$. Moreover, given $T > 0$, there is a positive constant K_2 such that $d_{C^1}(\varphi^T, (E^{\frac{T}{n}})^n) \le K_2 n^{-1}$ for all large $n \in \mathbb{N}$.*

Now we can use Theorem 1 to get the following result for the Euler method.

THEOREM 2. *Let X be a C^2 vector field on a compact manifold M without zeros such that the differential equation $\dot{x} = X(x)$ induces a flow φ^t such that* (i) *the chain recurrent set $\Re_\varphi$ is hyperbolic and* (ii) *φ^t satisfies the strong transversality condition. Let E^h be the Euler method of stepsize h for φ^t and let $T > 0$ be given. Then for all sufficiently large n, there is a homeomorphism H_n on M and a continuous function $\tau_n : M \to \mathbb{R}$ such that for all $x \in M$, $H_n \circ \varphi^{\tau_n(x)}(x) = (E^{\frac{T}{n}})^n \circ H_n(x)$ and $d(H_n(x), x) \to 0$ as $n \to \infty$.*

We can also consider Morse–Smale gradient-like systems for the Euler method which was not done in [12] and [18].

THEOREM 3. *Let X be a C^2 vector field on a compact manifold M such that the differential equation $\dot{x} = X(x)$ induces a flow φ^t satisfying* (i) *the chain recurrent set $\Re_\varphi$ is the union of a finite number of hyperbolic fixed points and* (ii) *the stable and unstable manifolds of fixed points meet transversally. Let E^h be the Euler method of stepsize h for φ^t and $T > 0$ be given. Then for all sufficiently large n, there is a homeomorphism H_n on M and a continuous function $\tau_n : M \to \mathbb{R}$ such that for all $x \in M$, $H_n \circ \varphi^T(x) = (E^{\frac{T}{n}})^n \circ H_n(x)$ and $d(H_n(x), x) \to 0$ as $n \to \infty$.*

Note that there is no reparametrization needed for the Morse-Smale gradient-like flows. This fits well with the result in [18]. For the proof of Theorem 3, see the remark at the end of section 4.

All theorems above are still true for the case when M has boundary under the additional assumption that φ^t flows into M along the boundary. These can be done by making an adaptation of the proof in [29] (see also [18]).

3. Application. This application to the zero-finding problem is due to Shub [31].

Given a nonconstant complex polynomial $p : \mathbb{C} \to \mathbb{C}$, we then can ask to find the zeros of p, i.e., those z in $\mathbb{C}$ for which $p(z) = 0$. There are two usual approaches to turn this problem into an algorithm. One is to define the Newton differential equation

$\dot{z} = -\frac{p(z)}{p'(z)}$, where p' is the (complex) derivative of p. Then consider the Euler approximation to the solution of the Newton differential equation, that is, for h a positive real, $E_N^h(z) = z - h\frac{p(z)}{p'(z)}$. When $h = 1$, this is the Newton method. The other is to consider the Euler approximation to the gradient differential equation $\dot{z} = -\frac{1}{2}\text{grad}|p|^2$.

There is an intimately close relationship between the Newton differential equation $\dot{z} = -\frac{p(z)}{p'(z)}$ and the gradient differential equation $\dot{z} = -\frac{1}{2}\text{grad}|p|^2$. It was explained by Smale [35].

LEMMA 3. *$-\frac{1}{2}\text{grad}|p|^2 = \rho(z)(-\frac{p(z)}{p'(z)})$, where $\rho : \mathbb{C} \to \mathbb{R}$ is the positive scalar function $\rho(z) = p'(z)\overline{p'(z)}$ and $\overline{p'(z)}$ denotes the complex conjugate of $p'(z)$.*

Proof. Let $p = u + iv$ on $\mathbb{C}$. Then $|p|^2 = u^2 + v^2$. Represent $\text{grad}f = f_x + if_y$, where f_x and f_y are the partial derivatives of $f(x, y)$ with respect to x and y. We have that $\text{grad}|p|^2 = (2uu_x + 2vv_x) + i(2uu_y + 2vv_y)$. On the other hand, differentiating along the real axis, we get $p' = u_x + iv_x$ and so $\overline{p'}p = (u_x - iv_x)(u + iv) = (uu_x + vv_x) + i(-uv_x + vu_x)$.

Because p is a polynomial, it satisfies the Cauchy–Riemann equations, $u_x = v_x$ and $u_y = -v_y$. Therefore, $-\frac{1}{2}\text{grad}|p|^2 = -\overline{p'}p$ and we are done. □

This lemma says that the Newton and gradient differential equations have the same solution curves. Therefore, up to changes of the stepsize ρ, the Euler schemes of the Newton and gradient differential equations are the same.

Let r be large enough so that the disk $D_r = \{z \in \mathbb{C}; |z| \le r\}$ contains all the zeros of p. The following proposition is given by Shub and Smale [32].

PROPOSITION 1. *The trajectories of the gradient differential equation point inward transversally to the boundary of D_r.*

If all zeros of p and p' are simple, then $|p(z)|^2$ is a Morse function and $-\frac{1}{2}\text{grad}|p|^2$ is transversal to the boundary of the disk. Therefore, there is a C^1 approximation Y with $Y = -\frac{1}{2}\text{grad}|p|^2$ in a neighbor of the zeros; see [33]. We say $-\frac{1}{2}\text{grad}|p|^2$ is *generically* a Morse–Smale vector field. This fact, together with Theorem 3 for $M = D_r$, which is a manifold with a boundary, gives us an explanation of why the Newton method is convergent near the zeros of the polynomial p.

4. Proof of Theorem 1. We divide the proof into several steps.

Step 1 (preliminary setup). Because $\Re_\varphi$ is hyperbolic, the tangent bundle of M along $\Re_\varphi$ splits as the sum of three bundles $TM|\Re_\varphi = \mathbb{E}^u \oplus \mathbb{E}^s \oplus Span(X)$, where $X(x) = \frac{d\varphi^t}{dt}(x)|_{t=0}$ is the tangent vector field for φ^t. Let V_0 be a small neighborhood of $\Re_\varphi$. We want the normal bundle η of φ^t to be smooth. It is no loss of generality to make a convenient choice of η : Let η^u and η^s be smooth subbundles of $TM|V_0$ approximating $\mathbb{E}^u$ and $\mathbb{E}^s$ so that $TM|V_0 = \eta^u \oplus \eta^s \oplus Span(X)$, and choose $\eta = \eta^u \oplus \eta^s$. For $\delta = u, s$, let $\eta^\delta(r) = \{v \in \eta^\delta : |v| \le r\}$ be the r disk bundles and $\eta(r) = \eta^u(r) \oplus \eta^s(r)$.

To get an idea of the space of sections, we need to define a section's slope. If $\sigma : \eta^u(r) \to \eta$ is a section, then the *slope* of σ at $v_x \in \eta^u(r)$ is

$$\limsup_{v_y \to v_x} \frac{|s(v_x) - s(v_y)|_s}{d_u(v_x, v_y)},$$

where $\sigma(v_x) = (v_x, s(v_x)) \in \eta^u \times \eta^s$, $|\cdot|_s$ is the norm on η^s, and d_u is the metric on η^u. Let $\Sigma(1, r) = \{\text{section } \sigma : \eta^u(r) \to \eta(r) \text{ such that } slope(\sigma) \le 1\}$. Putting the C^0 sup norm on $\Sigma(1, r)$ makes it a complete metric space as usual. Let $\pi^u : \eta \to \eta^u$ be a projection along η^s and $\pi^s : \eta \to \eta^s$ be a projection along η^u.

In order to prove the conjugacy is one to one, we will need the d_φ metrics on M and TM, due to Robbin [25]. First we define the d_φ topology on M by $d_\varphi(x,y) = \sup\{d(\varphi^t(x),\varphi^t(y)) : t \in \mathbb{R}\}$. Then we isometrically embed M in $\mathbb{R}^m$ for some Euclidean space. The embedding trivializes $\eta^u \subset TM \subset M \times \mathbb{R}^m$ and $\eta^s \subset TM \subset M \times \mathbb{R}^m$. Put the d_φ metric on TM by $d_\varphi(v_x, w_y) = \max\{d_\varphi(x,y), |\pi^u v - \pi^u w|, |\pi^s v - \pi^s w|\}$, where we can subtract $\pi^\sigma v$ and $\pi^\sigma w$ since they both are in $\mathbb{R}^m$.

Step 2 (definition of bundle map). We use the concept of laminations in [16] to define a bundle map F on η. For f near φ^T in the C^1 topology, let $\Theta(\tau, v_x, f) = \exp_y^{-1} \circ f \circ \exp v_x$ where $y = \varphi^\tau(x)$. There is a neighborhood $V_1 \subset V_0$ of $\Re_\varphi$, a constant $r_1 > 0$, a neighborhood $\mathcal{U}$ of φ^T in $\mathrm{Diff}(M)$, and a continuous function $\tau : \eta(r_1)|_{V_1} \times \mathcal{U} \to \mathbb{R}$ such that for all $x \in V_1$, $v_x \in \eta_x(r_1)$, and $f \in \mathcal{U}$,

$$\Theta(\tau(v_x, f), v_x, f) \in \eta_{\varphi^{\tau(v_x,f)}(x)}(r_1).$$

Here τ stands for a reparametrization of φ^t. See [27] and also page 95 of [16]. Define a bundle map F by

$$F(v_x) \equiv \Theta(\tau(v_x, \varphi^T), v_x, \varphi^T) = \exp^{-1}_{\varphi^\tau(x)} \circ \varphi^T \circ \exp v_x.$$

Then F is a C^1 bundle map on $\eta(r_1)$.

Step 3 (existence of compatible families of unstable disks). As in [34] (see also [30]), the chain recurrent set $\Re_\varphi$ satisfying the hyperbolicity condition has a *spectral decomposition* $\Re_\varphi = \Lambda_1 \cup \cdots \cup \Lambda_m$, where the Λ_i's are pairwise disjoint and each Λ_i is closed, invariant, and topologically transitive. Since φ^t satisfies the strong transversality condition, there is a partial ordering among these sets defined by $\Lambda_i \le \Lambda_j$ if and only if $W^u(\Lambda_i) \cap W^s(\Lambda_j) \neq \emptyset$. We can extend this partial ordering to a total ordering and reindex the sets such that if $W^u(\Lambda_i) \cap W^s(\Lambda_j) \neq \emptyset$, then $i \le j$.

Now, we use the method of Robinson [28] to construct compatible families of unstable disks.

LEMMA 4. *There are neighborhoods U_i of Λ_i and families $\{Z^{u\varphi}_{ix} : x \in O(U_i)\}$, where each $Z^{u\varphi}_{ix}$ is a C^1 disk in η of dimension equal dimension $\eta^u|\Lambda_i$ such that*

1. *$F(Z^{u\varphi}_i) \supset Z^{u\varphi}_i$.*
2. *If $x \in W^u(\Lambda_i, \varphi^T)$, then $\exp Z^{u\varphi}_{ix}$ is a local unstable manifold of x.*
3. *$\{Z^{u\varphi}_{ix} : x \in U_i\}$ can be written as the image of $\sigma^{u\varphi} : \eta^u(r_2) \to \eta$ and the slope of $\sigma^{u\varphi}$ is uniformly bounded, where $r_2 > 0$ is a constant.*
4. *If $i \le j$ and $x \in O(U_i) \cap O(U_j)$, then $Z^{u\varphi}_i \supset Z^{u\varphi}_j$.*
5. *Given the d_φ metrics on M and TM, $\sigma^{u\varphi}$ is Lipschitz with a uniform Lipschitz constant as a map from $\eta^u(r_2)$ to η and the Lipschitz jet on the whole bundle varies uniformly continuously along fibers as explained in* [28].

Proof. We construct the families of unstable disks for F as in section 5 of [28] (see also [27]). By induction, assume that they are constructed for $i = 1, \ldots, k-1$ and then construct them for a neighborhood of Λ_k. Let $U \subset V_1$ be a small neighborhood of Λ_k. Let $B^s_k \subset W^s(\Lambda_k)$ be a fundamental domain of φ^T. Take the sets P_{iq} so that $P^{iq} = \bigcup_{p=i}^{k-1} P_{pq}$ is a closed neighborhood of $B^s_k \cap \bigcup_{p=i}^{k-1} W^u(\Lambda_p)$. The section $\sigma_0 : \eta^u(r)|P^{11} \to \eta$ is constructed to be compatible with $\{Z^{u\varphi}_i(x) : x \in O(U_i)\}$ for $1 \le i \le k-1$ and to be d_φ-Lipschitz. Let $U_k = (W^u(\Lambda_k) \cap U) \cup O^+(P^{11}, U)$, where $O^+(P^{11}, U) = \{\varphi^s(x) : x \in P^{11}$ and $\varphi^s(x) \in U$ for $0 \le s \le t\}$. We extend σ_0 to U_k using F as follows. Let $\Sigma(1, r, \sigma_0) = \{$section $\sigma : \eta^u(r)|U_k \to \eta(r)$ such that $\sigma = \sigma_0$ on the domain of σ_0 and *slope*$(\sigma_x) \le 1$ for $x \in U_k\}$. Define $F_\#(\sigma)$ to be the graph

transform of σ by F extended back over P^{11} using σ_0,

$$\begin{cases} F(image(\sigma_{\varphi^{-T}(x)})) \supset image(F_{\#}(\sigma)_x) & \text{if} \quad \varphi^{-T}(x), \qquad x \in U_k, \\ F_{\#}(\sigma_x) = \sigma_{0x} & \text{if} \quad x \in P^{11}. \end{cases}$$

Using Theorems 3.1 and 3.2 of [28], we get that $F_{\#}$ is a contraction on the space of sections $\Sigma(1, r_2, \sigma_0)$ for some sufficiently small constant $r_2 > 0$ and so has a unique fixed point $\sigma^{u\varphi}$ which is d_φ-Lipschitz. Let $Z_{ix}^{u\varphi} = image(\sigma_x^{u\varphi})$ for $x \in U_i$. In this way, we complete the induction step to construct compatible families of unstable disks. □

Step 4 (construction of conjugacy and reparametrization). In order to prove structural stability, we do the same construction for $(N^{\frac{T}{n}})^n$. Because $(N^{\frac{T}{n}})^n \to \varphi^T$ in the C^1 topology as $n \to \infty$, we can take n sufficiently large so that $(N^{\frac{T}{n}})^n \in \mathcal{U}$, the neighborhood of φ^T in $\mathrm{Diff}(M)$ where Θ is defined. Let

$$G_n(v_x) \equiv \Theta(\tau(v_x, (N^{\frac{T}{n}})^n), v_x, (N^{\frac{T}{n}})^n) = \exp^{-1}_{\varphi^\tau(x)} \circ (N^{\frac{T}{n}})^n \circ \exp v_x.$$

Then G_n is a C^1 bundle map on $\eta(r_1)$ and C^1 close to F. By the permanence results in Theorem 3.1 of [28] and Theorem 6.1 of [16], we can construct compatible families of unstable disks for G_n over the $O(U_i)$, $\{Z_{ix}^{uN} : x \in O(U_i)\}$. Since G_n^{-1} is a fiber contraction on the bundle $\{Z_{ix}^{uN} : x \in O(U_i)\}$, by induction on i ($i = m, m-1, \ldots, 1$), we can construct a section $v_n : M \to \eta(r_2)$ such that $G_n \circ v_n(x) = v_n \circ \varphi^\tau(x)$. Also v_n is continuous and uniformly d_φ-Lipschitz. Moreover, as n tends to infinity, v_n converges to the zero section in the C^0 and d_φ-Lipschitz senses.

We now define the conjugacy and the reparametrization. Let $H_n(x) = \exp v_n(x)$ and $\tau_n(x) = \tau(v_n(x), (N^{\frac{T}{n}})^n)$ for all $x \in M$. Then both $H_n : M \to M$ and $\tau_n : M \to \mathbb{R}$ are continuous, and H_n converges to the identity in the C^0 sense as $n \to \infty$. Since v_n is invariant by $G_{n\#}$, we get that $v_n \circ \varphi^{\tau_n(x)}(x) = \exp^{-1}_{\varphi^{\tau_n(x)}(x)} \circ (N^{\frac{T}{n}})^n \circ \exp v_n(x)$ and so $H_n \circ \varphi^{\tau_n(x)}(x) = (N^{\frac{T}{n}})^n \circ H_n(x)$. Because H_n is homotopic to the identity, H_n is onto on M. Last, we prove that H_n is one to one in the following lemma and hence complete the proof of Theorem 1.

LEMMA 5. *For all n sufficiently large, H_n is one to one.*

Proof. Let $\tau_n(1, x) = \tau_n(x)$ and $\tau_n(i+1, x) = \tau_n(1, \varphi^{\tau_n(i,x)}(x))$ for $i \geq 1$. If $H_n(x) = H_n(y)$, then $d(x, y) \leq d(x, H_n(x)) + d(H_n(y), y) \leq 2r_2$ and $H_n(\varphi^{\tau_n(i,x)}(x)) = ((N^{\frac{T}{n}})^n)^i(H_n(x)) = ((N^{\frac{T}{n}})^n)^i(H_n(y)) = H_n(\varphi^{\tau_n(i,y)}(y))$ for all $i \in \mathbb{N}$. As Robinson pointed out in the proof of Theorem 2.3 of [27], there exist i_0 and $B > 0$ such that $d_\varphi(p, q) \leq 2Bd(p, q)$, where $p = \varphi^{\tau_n(i_0,x)}(x)$ and $q = \varphi^{\tau_n(i_0,y)}(y)$. By Lemma 2.3 of [25], there is a constant $\alpha > 0$ such that

$$\alpha d(p, q) - |v_n(p) - v_n(q)| \leq d(\exp(v_n(p)), \exp(v_n(q))).$$

Thus

$$\begin{aligned} 0 &= d(H_n(p), H_n(q)) \\ &\geq \alpha d(p, q) - |v_n(p) - v_n(q)| \\ &\geq \alpha d(p, q) - \Lambda(v_n) d_\varphi(p, q) \\ &\geq \alpha d(p, q) - \Lambda(v_n) 2Bd(p, q) \\ &\geq (\alpha - \Lambda(v_n) 2B) d(p, q). \end{aligned}$$

Because $\Lambda(v_n) \to 0$ as $n \to \infty$, we can take n large enough so that $\alpha - \Lambda(v_n)2B > 0$. Then $d(p,q) = 0$ and $p = q$. Therefore x and y are on the same orbit of φ^t. Exponentiating $\eta(r_2)|_{O(x)}$ forms transversal disks along the orbit $O(x)$. But transversal disks are disjoint for two nearby points on the same orbit. Thus $x = y$. This shows that H_n is one to one. □

Remark. It is not difficult to use the above argument to prove Theorem 3. Note that, in this case, the space of the vector field restricted to the chain recurrent set is the zero space, i.e., $Span(X)|\mathcal{R}_\varphi = \{0\}$, and so reparametrization is not necessary. We can simply define our bundle maps F and G_n by $F(v_x) = \exp^{-1}_{\varphi^T(x)} \circ \varphi^T \circ \exp v_x$ and $G_n(v_x) = \exp^{-1}_{\varphi^T(x)} \circ (N^{\frac{T}{n}})^n \circ \exp v_x$, then go through the same argument.

Acknowledgments. The author thanks Professor Clark Robinson of Northwestern University for helpful conversation and unknown referees for valuable suggestions.

THE CRYSTALLINE VERSION OF THE MODIFIED STEFAN PROBLEM IN THE PLANE AND ITS PROPERTIES*

PIOTR RYBKA†

Abstract. We study the modified Stefan problem in the plane for polygonal interfacial curves. Uniqueness of local in time solutions is shown while existence of local in time solutions has been proved in an earlier work of the author [P. Rybka, *Advances in Differential Equations*, 3 (1998), pp. 687–713]. Geometric properties of the flow are studied if the Wulff shape is a regular N-sided polygon and the initial interface has sufficiently small perimeter. Namely, if the isoperimetric quotient of the initial interface does not differ much from the isoperimetric quotient of the Wulff shape, then the interface shrinks to a point in finite time and the isoperimetric quotient decreases.

Key words. free boundary, Stefan problem, Gibbs–Thomson law, crystalline anisotropy

1. Introduction. We study a version of the modified Stefan problem in the plane. The special feature of our approach is that we assume that the interfacial curve is a polygon. We stress that admitting nonsmooth interfaces is natural from the viewpoint of modelling crystal evolution. We shall pursue this direction.

Describing the process of melting or growing a crystal requires setting the problem in the framework of two-phase thermodynamics. This is done in the book of Gurtin [Gu]. The author of the book pays special attention to the evolution of nonsmooth interfaces (see Section 12 in [Gu]). Developing this theory Gurtin and Matias proposed in their paper [GM] the particular problem we study here. The setting is the following: a crystal $\Omega_1(t)$ is in a bounded container Ω filled with melt $\Omega_2(t)$, i.e., $\Omega_2(t) = \Omega \backslash \overline{\Omega_1}(t)$ (the notation shall be explained in detail in the next section). The heat transport is described by the equation

$$e_i u_t = -\operatorname{div} \mathbf{q} \quad \text{in} \bigcup_{0<t<T} \Omega_i(t), \quad i = 1, 2, \tag{1.1}$$

which is complemented by the Fourier law

$$\mathbf{q} = -k_i \nabla u, \quad i = 1, 2. \tag{1.2}$$

The temperature u is continuous across the interface $s = \partial\Omega_1 \cap \partial\Omega_2$ being a polygon with facets s_i, $s = \bigcup_{i=1}^{N} s_i$. We assume the number of facets is constant. We are fully aware that this assumption can be the subject of discussion. (We will make some comments on this issue in section 5.) We claim, however, that in the case of small perimeter of $s(t)$ the stabilizing forces of surface tension prevail over destabilizing bulk forces and as a consequence $s(t)$ shrinks to a point. We will prove this in the last section.

Continuing the description of our problem we denote by V_i the velocity of s_i in the direction of the outer normal ν_i. This velocity satisfies the equation

$$[\![\mathbf{q}]\!]\nu_j = V_j, \quad j = 1, \dots, N. \tag{1.3}$$

Finally, we need a condition that the temperature u must satisfy on the interface. The approximation to the balance of capillary forces yields

$$\int_{s_j(t)} u = \Gamma_j - \beta_j L_j(t) V_j(t), \quad j = 1, \dots, N. \tag{1.4}$$

We remark here that the above problem was formulated by Herring in the metallurgical literature in the 1950s; see [Hr]. Later, it was independently rediscovered by Ben Amar–Pomeau [BP] and Gurtin–Matias [GMl].

One might expect here a version of Gibbs–Thomson law (with or without kinetic undercooling). This law states that the temperature on the interface is proportional to the curvature of the interface. In our consideration u is a normalized temperature, so u is zero at melting temperature on a flat interface. Indeed, (1.4) is a version of the Gibbs–Thomson law, where because of lack of smoothness the definition of curvature is adjusted so that it is well defined for polygons. As a matter of fact Γ_i/L_i is the "weighted crystalline curvature" of the edge s_i, $i = 1, \dots, N$ (Γ_i is an appropriate constant).

We note here that the modified Stefan problem for smooth interfaces (without kinetic undercooling) has already been studied. The first paper is by Luckhaus [L], who considered weak solutions and C^1-interfaces. Almgren and Wang [AW] studied this problem in a more general setting allowing for anisotropic surface energy densities.

The presence of nonzero kinetic undercooling makes the analysis somewhat simpler. The modified Stefan problem with kinetic undercooling was studied in particular by Chen and Reitich (see [CR]). They showed local in time existence and uniqueness of smooth temperature u (away from the interface) as well as smooth interface. Independently, Radkevich [Ra] studied the same problem. The advantage of [Ra] is that the author allows a slightly more general form of the heat equation. These results were extended by Soner [So]. He showed global in time existence of weak solutions (his interface is just $(n-1)$-rectifiable). He constructs them as limits of solutions to a phase field model.

For the sake of simplicity we work assuming that the bulk specific heats e_i are equal $e_1 = e_2 = \epsilon > 0$, and similarly we set the coefficients of conductivity k_i, $i = 1, 2$, to be 1. Existence of weak solutions to (1.1)–(1.4) with these simplifications and augmented with initial and boundary conditions has already been established by the author in [Ry2]. However, the method of proof does not yield uniqueness. On the other hand uniqueness holds for the smooth counterpart of our problem. We show that it is also true here. We do this in a way similar to that employed in [Ry1] to show uniqueness for the quasi-steady approximation of (1.1)–(1.4), i.e., for $e_1 = e_2 = 0$. Namely, we derive more or less explicit representation of solutions enabling us to reduce the problem to a uniqueness question for an integral equation. We also point out that unlike the case $e_1 = e_2 = 0$ we crucially depend on all β's being positive, not just nonnegative.

Thus, we touched the question of how (1.1)–(1.4) is related to its quasi-steady approximation. In particular, the problem of convergence of solutions u^ϵ of (1.1)–(1.4) as ϵ goes to zero is open. We leave this for further investigations.

For convenience of the reader we recall in the next section the weak formulation of the problem (1.1)–(1.4) augmented with initial and boundary conditions. In section 3 we derive the representation of solutions which permits us to reduce the problem to a simpler question regarding integral equations. We subsequently prove uniqueness of solutions constructed in [Ry2]. We stress that in any case we have no ground to claim that solutions are global in time. To the contrary, we anticipate that geometry may change during the evolution. In particular for small s_0 we expect finite extinction time.

Apart from showing uniqueness we will present some properties of the flow. The aim of section 4 is to prepare some geometric background needed in the last section. We show in particular that if the isoperimetric ratio L^2/A is only slightly bigger than that of the Wulff shape then the quotient

$$\frac{\max_{i=1,\dots,N} L_i}{\min_{i=1,\dots,N} L_i}$$

remains bounded. Thus, we can improve the qualitative results of [Ry1] for the quasi-steady flow; see section 5.

In order to derive properties of the flow (1.1)–(1.4) we compare it to the system of motion by crystalline curvature

$$\Gamma_i = \beta_i L_i V_i, \tag{1.5}$$

which may be seen as the "zero-temperature-limit" of (1.1)–(1.4). Interestingly, both flows behave similarly if the initial interface has small perimeter.

The system (1.5) was first studied by J. Taylor [T]. Estimates for solutions are particularly easy if the initial polygon is the Wulff shape. But our indispensable tool is a comparison principle of [GG] for solutions of (1.5). We will also use the results of Stancu [St], who derived properties of (1.5) analogous to that for the smooth motion by curvature.

In section 5 we investigate properties of solutions if an initial interface has small perimeter and isoperimetric ratio not much bigger than for the Wulff shape. If the initial temperature distribution is negative and small in an appropriate sense, then the interface shrinks to a point in finite time. We have proved a weaker version of this result in [Ry2, Theorem 4.1], where we assumed that the initial interface is a scaled Wulff shape. Finally, we prove an a priori bound for temperature in the $L^\infty(\Omega)$ norm. This means that no matter how small $s(t)$ is, nor how fast its facets move, the temperature may not drop too much.

2. Weak formulation. Before stating the problem (1.1)–(1.4) in the weak form let us explain the setting and our basic assumptions. We shall consider only *admissible* polygonal interfaces, where the edges s_i and vertices v_i are numbered counterclockwise. Admissibility means here that the outer normals ν_i to the facets s_i belong to the set $\mathcal{S}$ of normals of a given Wulff shape W (cf. Sections 7 and 12 in [Gu]). Moreover, we require that normals to successive facets in s must be neighboring normals to W. For the sake of present analysis we may think of W as being a given, convex polygon with M edges numbered counterclockwise. Let us note that $N \geq M$ and the equality holds if s is convex.

The length of facet s_i determined by its vertices v_i, v_{i+1} is denoted by L_i, $L_i = |v_i - v_{i+1}|$. The perimeter L of s is equal to $\sum_{i=1}^N L_i$. The velocity of V_i of the edge

s_i in the direction of the outer normal ν_i is defined by

$$V_i(t) = \frac{d}{dt} z_i(t),$$

where

$$z_i(t) = \begin{cases} \operatorname{dist}(l_i(t), l_i(0)) & \text{if } (v_i(t) - v_i(0)) \cdot \nu_i > 0, \\ -\operatorname{dist}(l_i(t), l_i(0)) & \text{if } (v_i(t) - v_i(0)) \cdot \nu_i < 0, \end{cases} \tag{2.1}$$

and $l_i(t)$ is the line containing $s_i(t)$. The definition of V_i in (1.3) involves the jump $[\![\cdot]\!]$ across $s(t)$. This quantity is given by

$$[\![\phi]\!](x_0) = \lim_{\Omega_2(t) \ni x \to x_0} \phi(x) - \lim_{\Omega_1(t) \ni x \to x_0} \phi(x), \quad x_0 \in s(t) = \partial\Omega_1(t) \cap \partial\Omega_2(t).$$

We assume that the sets Ω, $\Omega_1(t)$, $\Omega_2(t)$ are regions in $\mathbb{R}^2$, where $\Omega_1(t) \subset\subset \Omega$ and $\Omega = \Omega_1(t) \cup s(t) \cup \Omega_2(t)$. At last we assume that the boundary $\partial\Omega$ of Ω is smooth and Ω is bounded.

The kinetic coefficients $\beta_j > 0$ are constants, so are Γ_j, $j = 1, \dots, N$, and they are defined depending on s as follows (see Section 12.5 in [Gu]):

$$\Gamma_j = \begin{cases} -\ell_j & \text{if } s \text{ is locally convex near both vertices } v_i,\ v_{i+1}, \\ \ell_j & \text{if } s \text{ is locally concave near both vertices } v_i,\ v_{i+1}, \\ 0 & \text{otherwise,} \end{cases}$$

where ℓ_j is the length of the edge of the Wulff shape with normal ν_j.

Interestingly, Γ_j / L_j is weighted crystalline curvature of s_j. The relevant definition, which does not need any differential structure of s is given in [T]. We will recall it in a simple setting. But let us first remark that Γ_j is closely related to the underlying interface energy density f (which is basically defined on the unit circle). This is due to the fact that f enters the definition of the Wulff shape W (see Section 7 of [Gu] and especially Section 7.5). It follows from this definition that if d_i is the distance from the origin to the ith edge of W, then

$$d_i = f(\nu_i),$$

where ν_i is the outer normal to the ith edge of W. These relations have no implication for existence theory as well as for the uniqueness result presented here in section 3. On the other hand they are quite important for our geometrical considerations. For the sake of simplicity of exposition we carry out our analysis in sections 4 and 5 assuming that W is a regular polygon, i.e., $d_i = d$, $i = 1, \dots, M$; hence $f(\nu)$ has the same value for all $\nu \in \mathcal{S}$. Of course f must not be constant on $\{|\nu| = 1\}$.

Let us now recall the definition of crystalline curvature (see [T, p. 423]). If z_i is as defined above and $\mathbf{z} = (z_1, \dots, z_N)$, i.e., $s(\mathbf{z})$ is a polygon resulting from s by moving entire facet s_i by z_i in the direction of the normal ν_i, $A(\mathbf{z})$ is the area surrounded by $s(\mathbf{z})$, and $L(\mathbf{z})$ is the perimeter of $s(\mathbf{z})$, then the *crystalline curvature* $\mathcal{K}_i$ *of* s_i is

$$\mathcal{K}_i = -\lim_{\Delta z_i \to 0} \frac{L(\mathbf{z} + \mathbf{e}_i \Delta z_i) - L(\mathbf{z})}{A(\mathbf{z} + \mathbf{e}_i \Delta z_i) - A(\mathbf{z})},$$

where $\mathbf{e}_i$, $i = 1, \dots, N$, are the standard unit vectors of the coordinate axis in $\mathbb{R}^N$. This limit may be evaluated with the aid of the lemma below whose proof we leave to the reader (cf. also [Ry1]).

LEMMA 2.1. *Let us suppose we are given a polygon s with its edges s_i numbered counterclockwise, $i = 1, \dots, N$. If L_i is the length of edge s_i and θ_i is the (oriented) angle between normals ν_{i-1} and ν_i to s_{i-1} and s_i, respectively, then*

$$\begin{aligned} \Delta L_i &:= L_i(\mathbf{z} + \Delta\mathbf{z}) - L_i(\mathbf{z}) \\ &= -\Delta z_i(\operatorname{ctan}\theta_i + \operatorname{ctan}\theta_{i+1}) + \frac{\Delta z_{i-1}}{\sin\theta_i} + \frac{\Delta z_{i+1}}{\sin\theta_{i+1}}, \end{aligned} \tag{2.2}$$

where $\Delta\mathbf{z} = (\Delta z_1, \dots, \Delta z_N)$. If we further assume that s is a convex polygon, the origin belongs to the region bounded by s and d_i is the distance from the origin to s_i, then

$$L_i = -d_i(\operatorname{ctan}\theta_i + \operatorname{ctan}\theta_{i+1}) + \frac{d_{i-1}}{\sin\theta_i} + \frac{d_{i+1}}{\sin\theta_{i+1}}.$$

Here, by convention $s_{N+1} = s_1$, etc. □

We note that for convex polygons Lemma 2.1 implies that

$$\mathcal{K}_i = \frac{\kappa_i}{L_i} < 0, \quad i = 1, \dots, N = M,$$

where

$$\kappa_i = -(\operatorname{ctan}\theta_i + \operatorname{ctan}\theta_{i+1}) + \frac{1}{\sin\theta_i} + \frac{1}{\sin\theta_{i+1}} < 0. \tag{2.3}$$

In the case of convex, admissible polygon s and the Wulff shape W being a regular N-gon formula (2.3) reduces to

$$\kappa_i = \kappa = 2\operatorname{ctan}\theta - \frac{2}{\sin\theta} = -2\tan\frac{\pi}{N}, \tag{2.4}$$

because $\theta_i = \theta = \frac{2\pi}{N}$, $i = 1, \dots, N$. In the special case of s being the Wulff shape we have

$$\ell_i = |\kappa| d, \quad i = 1, \dots, N. \tag{2.5}$$

In order to obtain a closed system we augment (1.1)–(1.4) with initial and boundary data. We consider here only homogeneous Dirichlet boundary data:

$$u(0, x) = u_0(x), \quad s(0) = s_0, \quad u|_{\partial\Omega} = 0 \qquad \text{for } t \geq 0. \tag{2.6}$$

This choice gives us some technical advantages. We shall not consider the Neumann condition, which is physically relevant, because our tools do not apply directly to it.

The process of multiplication (1.1) by a test function, then integration by parts using (1.3) leads to the following definition: a pair $(\mathbf{z}, u)$, where $\mathbf{z}$ is as in (2.1), is called a *weak solution* to (1.1)–(1.4) *and* (2.6) *on* $[0, T)$; if $\mathbf{z} \in C^1([0, T); \mathbb{R}^N)$, $\mathbf{z}(0) = 0$, $u \in C^\alpha([0, T), H_0^1(\Omega))$ with $u(0) = u_0$, $u_t \in L^\infty_{loc}([0, T), H^{-1}(\Omega))$, where $H^{-1}(\Omega)$ is the dual of $H_0^1(\Omega)$, and the identities

(2.7a)

$$\epsilon\langle u_t, h\rangle = -\int_\Omega \nabla u(t, x) \cdot \nabla h(x) dx + \sum_{j=1}^N \int_{s_j(t)} V_j(t) h(x) dl \qquad \text{for all} \quad h \in H_0^1(\Omega),$$

$$\int_{s_j(t)} u\,dl = \Gamma_j - \beta_j L_j(t) V_j(t), \quad j = 1, \dots, N, \tag{2.7b}$$

hold, where $\langle \cdot, \cdot \rangle$ is the pairing between $H^{-1}(\Omega)$ and $H_0^1(\Omega)$.

Existence of a weak solution $(\mathbf{z}, u)$ on a maximal interval of existence $[0, T_max)$ has been shown in [Ry2]. Here, in section 3 we show uniqueness. We stress that a global existence result cannot be expected, especially if we fix the number of edges, because topological catastrophes like self-intersection, collapsing of a facet to a point, bumping into the boundary are imminent. In the last section we study some qualitative properties of solutions in the case where the Wulff shape is a regular polygon.

Notation. Throughout the paper vector quantities are set in bold, e.g., $\mathbf{z} = (z_1, \dots, z_N)$, the inner product in $\mathbb{R}^k$ is denoted by dot: $\mathbf{a} \cdot \mathbf{b} = \sum_{i=1}^k a_i b_i$, $|\mathbf{a}|$ is the Euclidean norm $|\mathbf{a}|^2 = \mathbf{a} \cdot \mathbf{a}$, and finally (f, g) is the inner product in $H_0^1(\Omega)$, i.e., $(f, g) = \int_\Omega \nabla f(x) \cdot \nabla g(x)\,dx$ and $\|f\|^2 = (f, f)$. Occasionally, in order to avoid confusion we will write $(f, g)_{H_0^1(\Omega)}$ for (f, g).

3. Uniqueness of solutions. In this section we show that solutions to (2.7), which we constructed in [Ry2], are unique. We apply a method similar to that used in [Ry1] for the quasi-steady approximation. Namely, we derive a representation of solutions in terms of a Green function (here for the heat operator). Historically, the construction of an appropriate Green function led to existence theorems; see [LSU]. However, we use here results of [LSU] to prove properties of the Green function. We recall that if u is a sufficiently smooth solution of

$$\begin{aligned} &u_t = \Delta u, \qquad u|_{\partial\Omega} = 0, \\ &u(0, x) = u_0(x), \end{aligned}$$

then u may be represented as

$$u(t, x) = \int_\Omega G(x, y, t) u_0(y)\,dy,$$

where G satisfies $(\partial_t - \Delta_x) G(x, y, t) = \delta_y$, i.e., G is the Green function. Some expressions become more handy if we use the above formula for solutions to the heat equations. In particular, we will need the representation in case u_0 is a measure.

We need to introduce some background for transforming (2.7a) into a more appropriate form. We first rewrite (2.7a) in a unified form. Let us recall that if $g \in H^{-1}(\Omega) (= (H_0^1(\Omega))')$, then there exists $g_i \in L^2(\Omega)$, $i = 1, 2$ such that $g = \sum_{i=1}^2 \frac{\partial g_i}{\partial x_i}$, i.e., the pairing $\langle g, h \rangle$ is given by

$$\langle g, h \rangle = -\int_\Omega \sum_{i=1}^2 g_i \frac{\partial h}{\partial x_i}. \tag{3.1}$$

Let us also recall that the mapping

$$H_0^1(\Omega) \ni f \mapsto -\Delta f \in H^{-1}(\Omega)$$

is an isomorphism of Hilbert spaces. If we now set for any $g \in H^{-1}(\Omega)$

$$F = -\Delta^{-1} g,$$

then we can rewrite (3.1) as

$$\langle g, h\rangle = \langle -\Delta F, h\rangle = \langle -\mathrm{div}\nabla F, h\rangle = \int_\Omega \nabla F(x)\cdot\nabla h(x)\,dx = (F, h).$$

Let us now look at the right-hand side of (2.7a). We note that the mapping

$$H_0^1(\Omega) \ni h \mapsto \int_{s_i} h\,dl =: \delta_{s_i}(h) \in \mathbb{R}$$

is a continuous functional over $H_0^1(\Omega)$. Thus we can now define elements f_i, $i = 1, \dots, N$, as follows:

$$f_i = -\Delta^{-1}\delta_{s_i}. \tag{3.2}$$

Thus, by (3.2) we obtain

$$\int_{s_i} h\,dl = -\langle \Delta f_i, h\rangle = (f_i, h).$$

In the following, since s is defined by $\mathbf{z}$ we will write $s(\mathbf{z})$ as well as $f(\mathbf{z})$ in order to stress this dependence.

Thus, after taking into account the above remarks and after setting

$$U = -\Delta^{-1}u,$$

we obtain that $U \in H^3(\Omega)\cap H_0^1(\Omega)$, $U_t \in H_0^1(\Omega)$. We can rewrite (2.7a) as

$$\epsilon(U_t, h) = (\Delta U, h) + \sum_{j=1}^N V_j\,(f_j(\mathbf{z}), h) \quad \text{for all} \quad h \in H_0^1(\Omega).$$

Therefore, (2.7a) is equivalent to

$$\epsilon U_t = \Delta U + \sum_{j=1}^N V_j f_j(\mathbf{z}), \quad U(0) = U_0 \tag{3.3a}$$

and (2.7b) becomes

$$\frac{dz_i}{dt} = \frac{\Gamma_i + (\Delta U, f_i(\mathbf{z}))}{\beta_i L_i}, \quad z_i(0) = 0, \quad i = 1, \dots, N. \tag{3.3 b}$$

We may now recall the following proposition.

Proposition 3.1 (see [Ry2, Theorem 3.1]). *Let us suppose that $\beta_i > 0$, Γ_i, $i = 1, \dots, N$ are as in section 2, $f_i(\mathbf{z})$ is defined by (3.2), and $\epsilon > 0$. We also assume that s_0 is an admissible polygon, $U_0 = -\Delta^{-1}u_0$ is compatible with the problem (3.3), i.e., $u_0 \in H_0^1(\Omega)$ and*

$$u_0 - \sum_{j=1}^N f_j(0)V_j(0) \in H^2(\Omega)\cap H_0^1(\Omega), \tag{3.4}$$

where $V_i(0)$ is given by (3.3 b),

$$V_i(0) = \frac{\Gamma_i - \int_{s_i(0)} u_0\,dl}{\beta_i L_i(0)}.$$

Then, there exists $T_{\max} > 0$ *and* $\mathbf{z}$, U *solutions of* (3.3) *such that*

$$U \in C^\alpha([0, T_{\max}), H^3(\Omega)), \quad U_t \in C^\alpha([0, T_{\max}), H_0^1(\Omega)),$$
$$z_i \in C^{1,\alpha}([0, T_{\max})), \quad i = 1, \dots, N,$$

for any $\frac{1}{2} > \alpha > 0$.

This proposition immediately yields the following corollary.

COROLLARY 3.2 (see [Ry2, Proposition 3.2]). *If* Γ_i, β_i, ϵ, u_0, *and* s_0 *are as in the previous proposition, then the pair* $(u, \mathbf{z})$, *where* $u = -\Delta U$ *is a weak solution to* (2.7) *on the interval* $[0, T_{\max})$ *and*

$$u \in C^\alpha([0, T_{\max}), H_0^1(\Omega)), \qquad z_i \in C^{1,\alpha}([0, T_{\max})), \quad i = 1, \dots, N. \qquad \square$$

Remark. The condition (3.4) is necessary to obtain claimed smoothness of solutions in time.

It is apparent that the transformed system (3.3) is a parabolic equation coupled to an ODE. We will look at (3.3a) not only from the viewpoint of [LSU] but also from the abstract standpoint of semigroup theory. For this matter our basic reference is [Hn] with the changes made in the Russian translation of the book. Having this in mind we define an operator $\mathcal{A} : D(\mathcal{A}) \subset L^2(\Omega) \to L^2(\Omega)$, by

$$\mathcal{A}u = -\Delta u,$$

where $D(\mathcal{A}) = H^2(\Omega) \cap H_0^1(\Omega)$. Then we have the following result whose proof may be found in [Hn, Section 1.6].

LEMMA 3.3. $\mathcal{A}$ *is self-adjoint; moreover* $\mathcal{A}$ *is positive definite and hence it is a sectorial operator.* $\square$

It follows that the fractional powers X^α of $X = L^2(\Omega)$ are well defined. In particular, it is a well-known fact (see Theorems 1.15.3 and 4.3.3 in [Tr]) that

$$X^{1/2} = H_0^1(\Omega). \tag{3.5}$$

We want to apply to (3.3a) the variation of constant formula [Hn, Theorem 3.2.2]. In order to apply this theorem we need to know that the source term is Hölder continuous in time into $L^2(\Omega)$. We showed in [Ry2] (see Lemmas 3.3, 3.4, and 3.5) that $\mathbf{z} \to f_i(\mathbf{z})$ is Hölder continuous with exponent $\alpha \in (0, \frac{1}{2})$ into X^σ, where $\sigma + \frac{1}{2}\alpha < 3/4$. Proposition 3.1 yields $\mathbf{z} \in C^{1,\alpha}(\Omega, \mathbb{R}^N)$ so that we can write

$$U(t) = e^{\Delta t/\epsilon} U_0 + \frac{1}{\epsilon} \int_0^t e^{\Delta(t-\tau)/\epsilon} \sum_{i=1}^N f_i(\tau) V_i(\tau)\, d\tau. \tag{3.6}$$

We can insert this into (3.3b) to obtain

$$\frac{dz_i}{dt}(t) = \frac{\Gamma_i}{\beta_i L_i} - \frac{1}{\beta_i L_i} \left(e^{\Delta t/\epsilon} u_0 + \frac{1}{\epsilon} \int_0^t \Delta e^{\Delta(t-\tau)/\epsilon} \sum_{j=1}^N V_j(\tau) f_j(\tau)\, d\tau, f_i(t) \right)_{H_0^1(\Omega)}$$
$$= \frac{\Gamma_i}{\beta_i L_i} - \frac{1}{\beta_i L_i} \left(\int_{s_i} e^{\Delta t/\epsilon} u_0 + \frac{1}{\epsilon} \int_{s_i} \int_0^t \Delta e^{\Delta(t-\tau)/\epsilon} \sum_{j=1}^N V_j(\tau) f_j(\tau)\, d\tau \right). \tag{3.7}$$

The integral on the right-hand side is well defined but it is not quite convenient to deal with if we want to prove that it is Lipschitz continuous in $\mathbf{z}$. We cannot simply

interchange the order of operations in the last integrand because $-\Delta f_j = \delta_{s_j}$ is a measure. We find it is more convenient to work with Green functions.

Existence of the Green function and parts (a) and (b) of the lemma below are well established (see [LSU]). Essentially, part (c) is also a well-known fact. It is apparent from the eigenfunction representation of G as in [TS, Chapter VI, Sections 1, 2]. However, we present an independent and more general proof, which does not refer to eigenfunctions of Laplace operator.

LEMMA 3.4. *Let us suppose that $\partial\Omega$ is smooth, $g \in L^p(\Omega)$, $p \in [2, \infty)$. Then, there exists a function $G(x, y, t)$ such that $LG(x, y, t) := (\partial_t - \Delta_x)G(x, y, t) = \delta_y$ and for $t \geq 0$, and*

$$e^{\Delta t} g(x) = \int_\Omega G(x, y, t) g(y)\, dy.$$

Moreover, $G(x, y, t) = K_t(x - y) + H(x, y, t)$, where

(a) $K_t(\xi) = 4^{-1}\pi^{-1}t^{-1}\exp(-|\xi|^2/4t)$ *for* $t > 0$; $K_0(\xi) = 0$;

(b) $H \in C^\infty(\bar{\Omega} \times \Omega \times \mathbb{R}_+)$ *and*

$$\begin{aligned} &\frac{\partial H}{\partial t} - \Delta_x H = 0 \quad \text{in } \Omega; \\ &H(x, y, t) = -K_t(x - y) \quad \text{for } x \in \partial\Omega, \quad y \in \Omega; \\ &H(x, y, 0) = 0 \quad \text{for } x \in \bar{\Omega}, \quad y \in \Omega; \end{aligned}$$

(c) $H(x, y, t) = H(y, x, t)$ *for* $(x, y) \in \Omega \times \Omega$, $t > 0$.

Proof. Existence and smoothness of H will follow from the classical theory of parabolic equation after we check that the compatibility conditions hold. It is the case since

$$\frac{\partial^k}{\partial t^k} K_t(x - y) = 0, \quad k = 0, 1, 2, \ldots,$$

for $t > 0$, and $x \in \partial\Omega$, $y \in \Omega$. We may now invoke Theorem 5.2 of [LSU, Chapter IV] to finish the proof of (b).

Let us now set

$$w(x, t) = \int_\Omega [K_t(x - y) + H(x, y, t)] g(y)\, dy.$$

It is not difficult to check that $Lw = 0$, $w(x, 0) = g(x)$, $w|_{\partial\Omega} = 0$, so by uniqueness of solutions to the heat equations we have

$$e^{\Delta t} g(x) = \int_\Omega G(x, y, t) g(y)\, dy.$$

We still need to prove (c). It is well known that if $\mathcal{A}$ is a self-adjoint positive operator then $e^{-\mathcal{A}t}$ is self-adjoint too (e.g., this follows from the representation for $e^{-\mathcal{A}t}$ given in [Hn, Theorem 1.3.4]). Now, if $T : L^2(\Omega) \to L^2(\Omega)$ is given by

$$(Tf)(x) = \int_\Omega G(x, y) f(y)\, dy,$$

where $G \in L^2(\Omega \times \Omega)$ then it is also well known that

$$(Tf)^*(x) = \int_\Omega \bar{G}(y, x) f(y)\, dy.$$

Thus it follows that

$$\int_\Omega [K_t(x-y)+H(x,y,t)]g(y)\,dy = e^{\Delta t}g(x)$$
$$= ((e^{\Delta t})^* g)(x) = \int_\Omega [\bar{K}_t(y-x) + \bar{H}(y,x,t)]g(y)\,dy.$$

Since $K_t(\xi)$ and $H(x,y,t)$ are real and $K_t(-\xi) = K_t(\xi)$ it follows that

$$\int_\Omega H(x,y,t)g(y)\,dy = \int_\Omega H(y,x,t)g(y)\,dy$$

and finally

$$H(x,y,t) = H(y,x,t),$$

as desired. □

The above lemma much simplifies the form of the RHS of (3.7). We have the following lemma.

LEMMA 3.5. *We assume that f_i is as before, $t > 0$, $s_i \subset\subset \Omega$, then*

$$\Delta e^{\Delta t} f_i(x) = -\int_{s_i} [K_t(x-y) + H(x,y,t)]\,dy.$$

Proof. Let us take the inner product of the LHS with an arbitrary $g \in C(\Omega)$. Because $e^{\Delta t}$ is smoothing for $t > 0$ and self-adjoint we see that

$$\begin{aligned}\int_\Omega \Delta e^{\Delta t} f_i(x)g(x)\,dx &= \int_\Omega \Delta e^{\Delta t/2} e^{\Delta t/2} f_i(x)g(x)\,dx \\ &= \int_\Omega \Delta e^{\Delta t/2} f_i(x) e^{\Delta t/2} g(x)\,dx = \int_\Omega e^{\Delta t/2} f_i(x) \Delta e^{\Delta t/2} g(x)\,dx \\ &= \int_\Omega f_i(x)\Delta e^{\Delta t} g(x)\,dx = -\int_{s_i} e^{\Delta t} g(x)\,dl(x) \\ &= -\int_{s_i}\int_\Omega [K_t(x-y) + H(x,y,t)]g(y)\,dy dl(x),\end{aligned}$$

where we used also the definition of f_i. By part (c) of the previous lemma we have

$$\int_\Omega \Delta e^{\Delta t} f_i(x)g(x)\,dx = -\int_\Omega \int_{s_i} [K_t(x-y) + H(x,y,t)]\,dl(y)g(x)\,dx$$

for all $g \in C(\Omega)$. The lemma follows. □

We immediately apply this result to transform (3.7) further

$$\frac{dz_i}{dt}(t) = \frac{\Gamma_i}{\beta_i L_i} - \frac{1}{\beta_i L_i}\int_{s_i(t)}\int_\Omega G(x,y,t/\epsilon)u_0(y)\,dy dl(x)$$
$$+ \frac{1}{\epsilon\beta_i L_i}\sum_{j=1}^N \int_0^t \int_{s_i(t)}\int_{s_j(\tau)} G(x,y,(t-\tau)/\epsilon)V_j(\tau)\,dl(x)\,dl(y)d\tau.$$

We note that the last integrand is well defined for $\tau \neq t$ and

$$\|H\|_{L^\infty(\Omega_\eta \times \Omega_\eta)} \leq C(\eta),$$

where

$$\Omega_\eta = \{x \in \Omega : \operatorname{dist}(x, \partial\Omega) \geq \eta > 0\}.$$

Let us now state our main theorem of the section.

THEOREM 3.6. *There exists exactly one weak solution of* (2.7).

We recall that we have already shown existence of at least one solution [Ry2, Theorem 3.1]. We will prove here that there is no more than one solution and the above representation suggests the idea of proof. We will show that the difference of velocities $\mathbf{V}$ and $\mathbf{V}'$ corresponding to two solutions satisfies an integral equation. We will be able to conclude our result if we know that the function

$$M_{ij}(\mathbf{z}_1, \mathbf{z}_2, t) := \int_{s_i(\mathbf{z}_1)} \int_{s_j(\mathbf{z}_2)} G(x, y, t)\, dl(y) dl(x)$$

is Lipschitz continuous. It turns out that the Lipschitz constant blows up, but at an integrable (in time) rate. Therefore, we have the following lemma.

LEMMA 3.7. *If $\zeta > 0$, $dist(s(\mathbf{z}_k), \partial\Omega) > \eta > 0$, $k = 1, 2$, then there exists a neighborhood of $(\mathbf{z}_1, \mathbf{z}_2) \in \mathbb{R}^N \times \mathbb{R}^N$ such that for all $(\mathbf{z}_1', \mathbf{z}_2')$ in this neighborhood we have*

$$|M_{ij}(\mathbf{z}_1, \mathbf{z}_2, \zeta) - M_{ij}(\mathbf{z}_1', \mathbf{z}_2', \zeta)| \leq \frac{C}{\sqrt{\zeta}}(|z_1 - z_1'| + |z_2 - z_2'|),$$

where the constant $C = C(\eta, \mathbf{z}_1, \mathbf{z}_2)$ is independent of ζ.

Proof. We will proceed in a few steps. Since $G(x, y, \zeta) = K_\zeta(x - y) + H(x, y, \zeta)$, where $K_\zeta(x-y)$ is singular and away from $\partial\Omega$ the function $H(x, y, \zeta)$ is bounded with its derivative, then we will first look at

$$M_{ij}'(\mathbf{z}_1, \mathbf{z}_2, \zeta) = \int_{s_i(\mathbf{z}_1)} \int_{s_j(\mathbf{z}_2)} K_\zeta(x - y)\, dl(y) dl(x).$$

(a) $s_i(\mathbf{z}_1)$ and $s_j(\mathbf{z}_2)$ are not parallel. If it is so, then the lines containing $s_i(\mathbf{z}_1)$ and $s_j(\mathbf{z}_2)$ intersect at point p. Hence, we can choose a neighborhood of $(\mathbf{z}_1, \mathbf{z}_2)$ in $\mathbb{R}^N \times \mathbb{R}^N$ such that the lines containing $s_i(\mathbf{z}_1')$ and $s_j(\mathbf{z}_2')$ intersect at point p' which is close to p. We will describe these segments precisely in order to facilitate our analysis. According to the notation convention of section 2 v_i and v_{i+1} are vertices of s_i. We define $\mathbf{w}_i = (v_{i+1} - v_i)/|v_{i+1} - v_i|$ and analogously $\mathbf{w}_j = (v_{j+1} - v_j)/|v_{j+1} - v_j|$, furthermore we set

$$a_i = \begin{cases} |v_i - p| & \text{if } \mathbf{w}_i \cdot (v_i - p) \geq 0, \\ -|v_i - p| & \text{if } \mathbf{w}_i \cdot (v_i - p) < 0. \end{cases}$$

We adopt the analogous definitions for a_j, a_i', and a_j'. Hence, we have

$$s_i(\mathbf{z}_1) = \{p + t_i\mathbf{w}_i :\ t_i \in [a_i, a_i + L_i]\}, \quad s_j(\mathbf{z}_2) = \{p + t_j\mathbf{w}_j :\ t_j \in [a_j, a_j + L_j]\},$$
$$s_i(\mathbf{z}_1') = \{p' + t_i\mathbf{w}_i :\ t_i \in [a_i', a_i' + L_i']\}, \quad s_j(\mathbf{z}_2') = \{p' + t_j\mathbf{w}_j :\ t_j \in [a_j', a_j' + L_j']\}.$$

Having this in mind, if $x \in s_i(\mathbf{z}_1')$, $y \in s_j(\mathbf{z}_2')$ (possibly $\mathbf{z}_1' = \mathbf{z}_1$, $\mathbf{z}_2' = \mathbf{z}_2$), then we calculate

$$|x - y|^2 = |t_i\mathbf{w}_i - t_j\mathbf{w}_j|^2 = t_i^2 + t_j^2 - 2\mathbf{w}_i \cdot \mathbf{w}_j t_i t_j \geq (t_i^2 + t_j^2)(1 - \cos\theta) > 0, \tag{3.8}$$

because the angle between $\mathbf{w}_i$ and $\mathbf{w}_j$ is no less than θ. We may now estimate the difference $|M'_{ij}(\mathbf{z}_1,\mathbf{z}_2,\zeta) - M'_{ij}(\mathbf{z}'_1,\mathbf{z}'_2,\zeta)| =: I$ using the definition of $K_\zeta(x-y)$

$$I \le \frac{1}{\pi\zeta}\left|\int_{a_i}^{a_i+L_i}\int_{a_j}^{a_j+L_j} e^{-\frac{|t_i\mathbf{w}_i - t_j\mathbf{w}_j|^2}{4\zeta}}\,dt_i dt_j - \int_{a'_i}^{a'_i+L'_i}\int_{a'_j}^{a'_j+L'_j} e^{-\frac{|t_i\mathbf{w}_i - t_j\mathbf{w}_j|^2}{4\zeta}}\,dt_i dt_j\right|.$$

Let us set

$$Q = [a_i, a_i+L_i]\times[a_j, a_j+L_j], \qquad Q' = [a'_i, a'_i+L'_i]\times[a'_j, a'_j+L'_j].$$

It is now clear that there is no contribution from the integrals over $Q\cap Q'$ to the difference. Therefore we have to estimate the contribution from the symmetric difference $Q\triangle Q' = \bigcup_{k=1}^4 R_k$; see Figure 1. Lemma 2.1 provides us with the estimates for the lengths of edges of R_k, $k=1,2,3,4$. The list of estimates goes as follows:

$$\begin{aligned}
R_1:&\quad |a_j - a'_j| \text{ and } L_i + C|\mathbf{z}_1 - \mathbf{z}'_1|;\\
R_2:&\quad |a_i - a'_i| \text{ and } L_j + C|\mathbf{z}_2 - \mathbf{z}'_2|;\\
R_3:&\quad |a_i - a'_i| + C|\mathbf{z}_1 - \mathbf{z}'_1| \text{ and } L_j + C|\mathbf{z}_2 - \mathbf{z}'_2|;\\
R_4:&\quad |a_j - a'_j| + C|\mathbf{z}_2 - \mathbf{z}'_2| \text{ and } L_i + C|\mathbf{z}_1 - \mathbf{z}'_1|;
\end{aligned}$$

for some constant C if $(\mathbf{z}'_1,\mathbf{z}'_2)$ is sufficiently close to $(\mathbf{z}_1,\mathbf{z}_2)$. We now estimate $|a_j - a'_j|$ as well as $|a_j - a'_j|$. Restricting if necessary the neighborhood of $(\mathbf{z}_1,\mathbf{z}_2)$ we are working in we may assume that

$$a_i a'_i \ge 0 \qquad \text{and} \qquad a_j a'_j \ge 0.$$

Let us set

$$\mathbf{p} = p' - p, \quad \mathbf{u}_i = v'_i - v_i, \quad \mathbf{u}_j = v'_j - v_j,$$

then we see

$$\begin{aligned}
\mathbf{p} &= \nu_i(z'_{1i} - z_{1i}) + \nu_j(z'_{2j} - z_{2j}),\\
\mathbf{u}_i &= \nu_i(z'_{1i} - z_{1i}) + \nu_{i-1}(z'_{1(i-1)} - z_{1(i-1)}),\\
\mathbf{u}_j &= \nu_j(z'_{2j} - z_{2j}) + \nu_{j-1}(z'_{2(j-1)} - z_{2(j-1)}),
\end{aligned} \tag{3.9}$$

where ν_k is the outer normal to s_k, $k=i,j$ (see section 2).

It is easy to observe that if a, b are real and $ab\ge 0$, then $|a-b| = ||a|-|b||$. This observation and the triangle inequality yield

$$|a_i - a'_i| = ||v_i - p| - |v'_i - p'|| \le |\mathbf{u}_i - \mathbf{p}|.$$

By (3.9) we arrive at

$$|a_i - a'_i| \le c(N)|\mathbf{z}_1 - \mathbf{z}'_1| + |\mathbf{z}_2 - \mathbf{z}'_2|),$$

where $c(N)$ depends only on N.

Combining these estimates with (3.8) we may estimate the integral over R_1

$$\begin{aligned}
\frac{1}{\pi\zeta}\int_{R_1} e^{-|t_i\mathbf{w}_i - t_j\mathbf{w}_j|^2/4\zeta}\,dt_i dt_j &\le \frac{1}{\pi\zeta}\int_{R_1} e^{-\frac{1-\cos\theta}{4\zeta}(t_i^2+t_j^2)}\,dt_i dt_j\\
&\le C\frac{|a_i - a'_i|}{\pi\zeta}\int_{-\infty}^{+\infty} e^{-\frac{(1-\cos\theta)}{4\zeta}t_j^2}\,dt_j = \frac{C|a_i - a'_i|}{\sqrt{\pi\zeta}\sqrt{1-\cos\theta}}\\
&\le \frac{C}{\sqrt{\zeta}}(|\mathbf{z}_1 - \mathbf{z}'_1| + |\mathbf{z}_2 - \mathbf{z}'_2|).
\end{aligned}$$

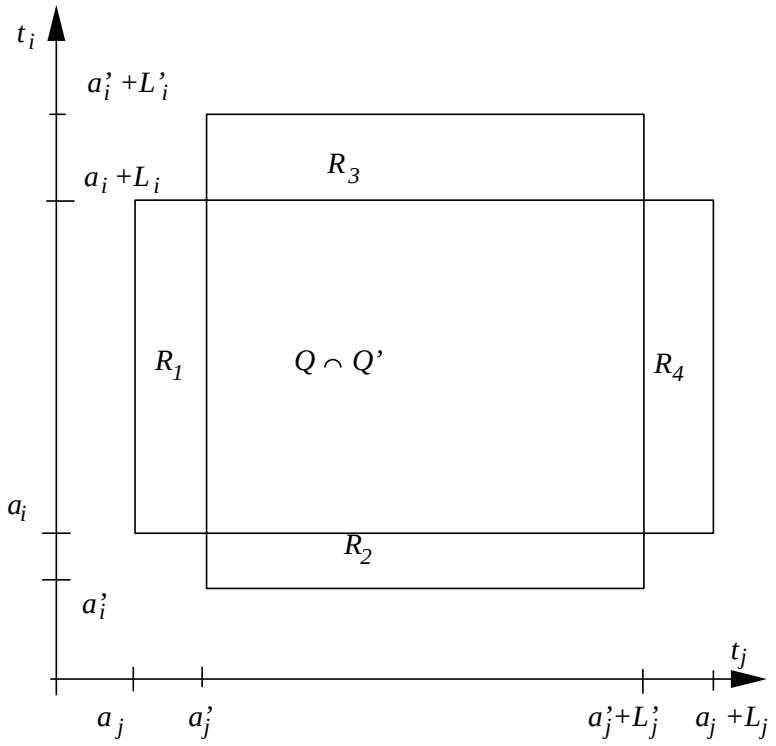

FIG. 1.

Similar calculations lead us to

$$\frac{1}{\pi\zeta}\int_{R_k} e^{-|t_i\mathbf{w}_i - t_j\mathbf{w}_j|^2/4\zeta}\, dt_i dt_j \le \frac{C}{\sqrt{\zeta}}(|\mathbf{z}_1 - \mathbf{z}_1'| + |\mathbf{z}_2 - \mathbf{z}_2'|)$$

for $k = 2, 3, 4$. It follows that

$$|M_{ij}'(\mathbf{z}_1, \mathbf{z}_2, \zeta) - M_{ij}'(\mathbf{z}_1', \mathbf{z}_2', \zeta)| \le C\frac{1}{\sqrt{(1-\cos\theta)\pi\zeta}}(|\mathbf{z}_1 - \mathbf{z}_1'| + |\mathbf{z}_2 - \mathbf{z}_2'|).$$

(b) $s_i(\mathbf{z}_1)$ and $s_j(\mathbf{z}_2)$ are parallel, possibly on the same line. Thus we may write

$$s_i(\mathbf{z}_1) = \{x:\ x = \mathbf{w}t_i + \bar{v}_i, t_i \in [0, L_i]\}, \qquad s_j(\mathbf{z}_2) = \{y:\ y = -\mathbf{w}t_j + \bar{v}_j, t_j \in [0, L_j]\},$$

where $\mathbf{w} = \pm(v_{i+1} - v_i)/|v_{i+1} - v_i|$ and $\bar{v}_k \in \{v_{k+1}, v_k\}$, $k = i, j$. We can choose $\mathbf{w}$, $\bar{v}_i$, and $\bar{v}_j$ in a such a way that

$$\mathbf{w} \cdot (\bar{v}_i - \bar{v}_j) > 0. \tag{3.10}$$

We leave to the reader a proof of this simple geometric fact. We note that after replacing $\bar{v}_k$ with $\bar{v}_k'$, $k = i, j$ inequality (3.10) holds for $(\mathbf{z}_1', \mathbf{z}_2')$ sufficiently close to $(\mathbf{z}_1, \mathbf{z}_2)$. Taking (3.10) into account we obtain for $x \in s_i(\mathbf{z}_1')$, $y \in s_j(\mathbf{z}_2')$ (possibly $\mathbf{z}_1' = \mathbf{z}_1$, $\mathbf{z}_2' = \mathbf{z}_2$)

$$\begin{aligned} |x - y|^2 &= |t_i\mathbf{w} + \bar{v}_i' + t_j\mathbf{w} - \bar{v}_j'|^2 = |(t_i + t_j)\mathbf{w} + (\bar{v}_i' - \bar{v}_j')|^2 \\ &= (t_i + t_j)^2 + |\bar{v}_i' - \bar{v}_j'|^2 + 2(t_i + t_j)\mathbf{w} \cdot (\bar{v}_i' - \bar{v}_j') \ge (t_i^2 + t_j^2). \end{aligned} \tag{3.11}$$

We may now argue as in step (a) using (3.11) in place of (3.8) that

$$|M'_{ij}(\mathbf{z}_1,\mathbf{z}_2,\zeta)-M'_{ij}(\mathbf{z}'_1,\mathbf{z}'_2,\zeta)|\le C\frac{1}{\sqrt{(1-\cos\theta)\pi\zeta}}(|\mathbf{z}_1-\mathbf{z}'_1|+|\mathbf{z}_2-\mathbf{z}'_2|).$$

(c) It remains to show that

$$\left|\int_{s_i(\mathbf{z}_1)}\int_{s_j(\mathbf{z}_2)}H(x,y,\zeta)\,dl(y)dl(x)-\int_{s_i(\mathbf{z}'_1)}\int_{s_j(\mathbf{z}'_2)}H(x,y,\zeta)\,dl(y)dl(x)\right| \le C(|\mathbf{z}_1-\mathbf{z}'_1|+|\mathbf{z}_2-\mathbf{z}'_2|).$$

This part is now easy and we leave it to the reader. □

There is one more term in the integral equation for $\mathbf{V}$ whose Lipschitz continuity has to be investigated.

LEMMA 3.8. *Let us suppose that $\zeta>0$, $u_0\in H^1_0(\Omega)$, and dist$(s_i(z),\partial\Omega)>\eta>0$ then the map*

$$\mathbf{z}\mapsto\int_{s_i(\mathbf{z})}e^{\Delta\zeta}u_0\,dl(y)$$

is locally Lipschitz continuous with the Lipschitz constant independent of ζ.

Proof. We note

$$\begin{aligned}\int_{s_i(\mathbf{z})}e^{\Delta\zeta}u_0\,dl(x)&-\int_{s_i(\mathbf{z}')}e^{\Delta\zeta}u_0\,dl(y)\\ &=\int_{s_i(\mathbf{z})}\int_\Omega K_\zeta(x-y)u_0(y)\,dydl(x)-\int_{s_i(\mathbf{z}')}\int_\Omega K_\zeta(x-y)u_0(y)\,dydl(x)\\ &\quad+\int_{s_i(\mathbf{z})}\int_\Omega H(x,y,\zeta)u_0(y)\,dydl(x)-\int_{s_i(\mathbf{z}')}\int_\Omega H(x,y,\zeta)u_0(y)\,dydl(x)\\ &=I_1+I_2.\end{aligned}$$

We now estimate I_1. We may extend u_0 by zero to the entire plane, so $u_0\in H^1(\mathbb{R}^2)$. We also set $\mathbf{v}=(z'_i-z_i)\nu_i$

$$\begin{aligned}I_1&=\int_{s_i(\mathbf{z})}\int_{\mathbb{R}^2}K_\zeta(x-y)u_0(y)\,dydl(x)-\int_{s_i(\mathbf{z}')}\int_{\mathbb{R}^2}K_\zeta(x-y)u_0(y)\,dydl(x)\\ &=\int_{s_i(\mathbf{z})}\int_{\mathbb{R}^2}K_\zeta(x-y)u_0(y)\,dydl(x)-\int_{s_i(\mathbf{z}')-\mathbf{v}}\int_{\mathbb{R}^2}K_\zeta(x+\mathbf{v}-y)u_0(y)\,dydl(x)\\ &=\int_{s_i(\mathbf{z})\cap(s_i(\mathbf{z}')-\mathbf{v})}\int_{\mathbb{R}^2}K_\zeta(x-y)(u_0(y)-u_0(y-\mathbf{v}))\,dydl(x)\\ &\quad+\int_{s_i(\mathbf{z})\triangle(s_i(\mathbf{z}')-\mathbf{v})}\int_{\mathbb{R}^2}(\chi(x)K_\zeta(x-y)-(1-\chi(x))K_\zeta(x+\mathbf{v}-y))u_0(y)\,dydl(x)\\ &=I_3+I_4,\end{aligned}$$

where

$$\chi(x)=\begin{cases}1 & \text{if } x\in s_i(\mathbf{z})\setminus(s_i(\mathbf{z}')-\mathbf{v});\\ 0 & \text{if } x\in(s_i(\mathbf{z}')-\mathbf{v})\setminus s_i(\mathbf{z}).\end{cases}$$

Schwarz inequality and $\int_{\mathbb{R}^2} K_\zeta^2(x)\,dx = 1$ lead us to

$$\begin{aligned}|I_3| &\le \int_{s_i(\mathbf{z})\cap(s_i(\mathbf{z}')-\mathbf{v})} \|K_\zeta(x-\cdot)\|_{L^2(\Omega)}\|\nabla u_0\|_{L^2(\Omega)}\,dl(x)|\mathbf{v}| \\ &\le |\mathbf{z}-\mathbf{z}'||s_i(\mathbf{z})|\|\nabla u_0\|_{L^2(\Omega)}.\end{aligned}$$

Similar calculations and $|s_i(\mathbf{z})\triangle(s_i(\mathbf{z}')-\mathbf{v})| \le C|\mathbf{z}-\mathbf{z}'|$ imply that

$$|I_4| \le C|\mathbf{z}-\mathbf{z}'|\|u_0\|_{L^2(\Omega)}.$$

Combining estimates for I_3, I_4 we obtain

$$|I_1| \le C|\mathbf{z}-\mathbf{z}'|(\|\nabla u_0\|_{L^2(\Omega)} + \|u_0\|_{L^2(\Omega)}),$$

where the constant C is independent of $\zeta > 0$.

We now estimate I_2. We note

$$\begin{aligned}|I_2| \le &\int_{s_i(\mathbf{z})\cap(s_i(\mathbf{z}')-\mathbf{v})}\int_{\mathbb{R}^2} |H(x,y,\zeta)-H(x+\mathbf{v},y,\zeta)||u_0(y)|\,dydl(x) \\ &+\int_{s_i(\mathbf{z})\triangle(s_i(\mathbf{z}')-\mathbf{v})}\int_{\mathbb{R}^2} |H(x,y,\zeta)-H(x+\mathbf{v},y,\zeta)||u_0(y)|\,dydl(x) = I_5+I_6.\end{aligned}$$

Since $\operatorname{dist}(s_i(\mathbf{z}),\partial\Omega)$, $\operatorname{dist}(s_i(\mathbf{z}'),\partial\Omega) > \eta$, then

$$|H(x,y,\zeta)-H(x+\mathbf{v},y,\zeta)| \le \|D_xH\|_{L^\infty(\Omega_\eta\times\Omega\times[0,\zeta])}|\mathbf{v}|.$$

We claim that $\|D_xH\|_{L^\infty(\Omega_\eta\times\Omega\times[0,\zeta])}$ is independent of ζ. In order to see this we consider the equation defining H (see Lemma 3.4(b)) when $x\in\bar\Omega$ and $y\in\Omega_\eta$. We may differentiate this equation as well as the boundary conditions with respect to y_k, $k=1,2$. We apply the maximum principle to the resulting heat equation. This yields

$$\begin{aligned}\max_{(x,t)\in\Omega\times[0,\zeta]}|D_{y_k}H(x,y,t)| &\le \max_{(x,t)\in\partial\Omega\times[0,\zeta]}\left|\frac{x_k-y_k}{2t}K_t(x-y)\right| \\ &\le \max_{(x,t)\in\partial\Omega\times[0,\zeta]} Ct^{-3/2}e^{-\frac{|x-y|^2}{8t}}\end{aligned}$$

for some C independent of ζ. Since $y\in\Omega_\eta$ we infer that

$$\max_{(x,t)\in\Omega\times[0,\zeta]}|D_{y_k}H(x,y,t)| \le C\max_{t\in[0,\zeta]} t^{-3/2}e^{-\eta^2/8t} \le A < \infty.$$

Hence by Lemma 3.4(c)

$$\|D_xH\|_{L^\infty(\Omega_\eta\times\Omega\times[0,\zeta])} = \|D_yH\|_{L^\infty(\Omega\times\Omega_\eta\times[0,\zeta])} \le A.$$

Let us also note that this argument shows that

$$\|H\|_{L^\infty(\Omega_\eta\times\Omega\times[0,\zeta])} = \|H\|_{L^\infty(\Omega\times\Omega_\eta\times[0,\zeta])} \le A. \tag{3.12}$$

Thus, we easily see that

$$I_5 \le A|v||\Omega|^{1/2}\|u_0\|_{L^2(\Omega)} \le C|\mathbf{z}-\mathbf{z}'|\|u_0\|_{L^2(\Omega)}.$$

The estimate for I_6 is even simpler:

$$\begin{aligned} I_6 &\le |s_i(\mathbf{z}) \triangle (s_i(\mathbf{z}') - \mathbf{v})| \max_x \int_{\mathbb{R}^2} |H(x,y,\zeta) - H(x+\mathbf{v},y,\zeta)||u_0(y)|\, dydl(x) \\ &\le 2C|\mathbf{z}-\mathbf{z}'| \|H\|_{L^\infty(\Omega_\eta \times \Omega \times [0,\zeta])} |\Omega|^{1/2} \|u_0\|_{L^2(\Omega)} \le C'|\mathbf{z}-\mathbf{z}'| \|u_0\|_{L^2(\Omega)}, \end{aligned}$$

where C' is independent from ζ. The lemma follows after we combine the estimates for I_1 and I_2. ∎

We remark that it is important to assume that $\zeta > 0$; without this assumption the lemma is false.

We are now in a position to complete the proof of Theorem 3.6. We have

$$\begin{aligned} V_i = {} & \frac{\Gamma_i}{\beta_i L_i} - \frac{1}{\beta_i L_i} \int_{s_i(t)} \int_\Omega G(x,y,t) u_0(y)\, dydl(x) d\tau \\ & + \frac{1}{\epsilon \beta_i L_i} \sum_{j=1}^N \int_0^t M_{ij}(\mathbf{z}(t), \mathbf{z}(\tau), (t-\tau)/\epsilon) V_j(\tau)\, d\tau \end{aligned} \tag{3.13}$$

for $i = 1, \dots, N$. This identity is valid for any weak solution. Suppose now we have two of them, $(\mathbf{z}', u')$ and $(\mathbf{z}, u)$. We take the difference $V_i - V_i'$. By (3.13), for $t > 0$ we have

$$\begin{aligned} V_i - V_i' = {} & \left(\frac{1}{\beta_i L_i} - \frac{1}{\beta_i L_i'} \right) \left(\Gamma_i + \int_{s_i(t)} \int_\Omega G(x,y,t) u_0(y)\, dydl(x) \right) \\ & + \left(\frac{1}{\epsilon \beta_i L_i} - \frac{1}{\epsilon \beta_i L_i'} \right) \sum_{j=1}^N \int_0^t M_{ij} \left(\mathbf{z}(t), \mathbf{z}(\tau), \frac{t-\tau}{\epsilon} \right) V_j(\tau)\, d\tau \\ & + \frac{1}{\beta_i L_i'} \left(\int_{s_i'(t)} \int_\Omega G(x,y,t) u_0(y)\, dydl(x) - \int_{s_i(t)} \int_\Omega G(x,y,t) u_0(y)\, dydl(x) \right) \\ & + \frac{1}{\epsilon \beta_i L_i'} \sum_{j=1}^N \int_0^t M_{ij} \left(\mathbf{z}(t), \mathbf{z}(\tau), \frac{t-\tau}{\epsilon} \right) (V_j(\tau) - V_j'(\tau))\, dt \\ & + \frac{1}{\epsilon \beta_i L_i'} \sum_{j=1}^N \int_0^t \left(M_{ij} \left(\mathbf{z}(t), \mathbf{z}(\tau), \frac{t-\tau}{\epsilon} \right) - M_{ij} \left(\mathbf{z}'(t), \mathbf{z}'(\tau), \frac{t-\tau}{\epsilon} \right) \right) V_j'(\tau)\, d\tau. \end{aligned}$$

We may now apply Lemmas 3.7 and 3.8 for sufficiently small $t > 0$. We thus obtain

$$\begin{aligned} |V_i - V_i'|(t) \le {} & C|\mathbf{z} - \mathbf{z}'|(t) \\ & + C \left(\int_0^t |V_i - V_i'|(\tau)\, d\tau + \int_0^t (t-\tau)^{-1/2} (|\mathbf{z}-\mathbf{z}'|(t) + |\mathbf{z}-\mathbf{z}'|(\tau))\, d\tau \right). \end{aligned}$$

But $|z_i - z_i'|(t) = |\int_0^t (V_i - V_i')(\tau)\, d\tau|$, so having this in mind we arrive at

$$|\mathbf{V} - \mathbf{V}'|(t) \le C \left(2(1+\sqrt{t}) \int_0^t |\mathbf{V} - \mathbf{V}'|(\tau)\, d\tau + \int_0^t (t-\tau)^{-1/2} \int_0^\tau |\mathbf{V} - \mathbf{V}'|(\sigma)\, d\sigma \right).$$

Changing the order of integration in the double integral yields

$$|\mathbf{V} - \mathbf{V}'|(t) \le C' \int_0^t |\mathbf{V} - \mathbf{V}'|(\tau)\, d\tau.$$

Now, by Grönwall's inequality we obtain that

$$\mathbf{V}(\tau) = \mathbf{V}'(\tau)$$

for all $\tau \in [0, t]$, as desired. □

We remark that the above representation of $\mathbf{V}$ does not yield an improved regularity solution.

4. Geometric estimates. We gather here some estimates which are necessary for the next section but they may be of independent interest. We first state the underlying assumption for the rest of the paper, namely,

(W) the Wulff shape W is a regular polygon with N sides, and the distance from the center of symmetry to its facets is $d > 0$.

It is clear that if we fix the inner angle of a polygon, then if the quantity

$$\frac{\max_{i=1,\dots,N} L_i}{\min_{i=1,\dots,N} L_i} \tag{4.1}$$

is bounded, then the isoperimetric ratio L^2/A is finite. But in general the converse is not true. One can devise a sequence of polygons $\{\gamma_n\}_{n=1}^{\infty}$ for which the quotients $(L^n)^2/A^n$ remain bounded but (4.1) explodes. On the other hand we depend on boundedness of (4.1); see the next section or [Ry1, Theorem 10]. Here we prove that the needed estimate holds but only for polygons with L^2/A only slightly bigger than for the regular polygon.

We also recall the estimates for the extinction time for regular polygons moving by crystalline curvature

$$V_i = \frac{\Gamma_i}{\beta_i L_i}. \tag{4.2}$$

Such a bound combined with the comparison principle of Giga and Gurtin [GG] will provide estimates for maximal existence times of solution to (4.2) for any initial polygon.

We now introduce some simplifying notation. We also recall that $\mathcal{S}$ is the set of outer normals to W. Let us suppose that γ is a convex polygon. We denote by D_γ the region bounded by γ, $|D_\gamma|$ is its Lebesgue measure, $n(\gamma)$ is the number of (nonzero) facets, and $|\gamma|$ is the perimeter of γ; $\theta = 2\pi/N$. We set $Q(\gamma)$ to be the isoperimetric quotient of γ, i.e.,

$$Q(\gamma) = \frac{|\gamma|^2}{|D_\gamma|}.$$

We restrict our attention to polygons which may be obtained from W by moving its sides in normal directions, where we do not exclude the possibility that some of the facets get lost. By definition, $\mathcal{P}$ is the set of all planar polygons γ such that

(a) D_γ is convex;

(b) $n(\gamma) \le N$;

(c) the outer normals to the edges to γ belong to $\mathcal{S}$.

We will show this in the following theorem.

THEOREM 4.1. *There exist positive numbers $\lambda_1 > Q(W)$ and Λ_1 such that if $\gamma \in \mathcal{P}$ and $Q(\gamma) \le \lambda_1$, then*

$$\frac{\max_{i=1,\dots,N} L_i(\gamma)}{\min_{i=1,\dots,N} L_i(\gamma)} \le \Lambda_1.$$

Remark. This theorem is trivial for $N = 4$; we leave to the reader to work out the formula expressing $\max\{a, b\}/\min\{a, b\}$ in terms of the isoperimetric quotient of rectangle with sides a and b. We will consider only $N \geq 5$. In this case the bound on λ_1 is constructive while that for Λ_1 is not.

The proof of this theorem requires a lemma.

LEMMA 4.2. *There exists $\alpha > 0$ such that for any $\gamma \in \mathcal{P}$ having less than N sides the following inequality holds:*

$$Q(\gamma) \geq \omega_N + \alpha,$$

where $\omega_N := \frac{1}{4}Q(W) = N \tan \frac{\pi}{N}$.

Proof. In what follows we use the notation convention of section 2. Let us set $s_0 = W$. Thus, by the very definition of $\mathcal{P}$, if $\gamma \in \mathcal{P}$, then $\gamma = s(\mathbf{z})$, where $\mathbf{z} \in \mathbb{R}^N$ is defined as in (2.1) (to be precise we have to substitute the line l_i containing the ith facet of γ for $l_i(t)$). We recall that Lemma 2.1 guarantees that the mapping $\mathcal{P} \ni \gamma \mapsto Q(\gamma)$ is continuous, because $\gamma = s(\mathbf{z})$.

Our argument is organized in several steps. We claim that the general case may be reduced to $n(\gamma) = N - 1$.

(a) We will first show that if $n(\gamma) < N$, then there exists nearby $\gamma' \in \mathcal{P}$ such that $n(\gamma') = n(\gamma) + 1$ and $Q(\gamma') < Q(\gamma)$. Let us suppose that $n(\gamma) = N - m$, $m \geq 1$, and at vertex v_i the edges $s_{i+1}, \ldots, s_{i+j-1}$ are missing, i.e., $\{v_{i+1}\} = s_i \cap s_{i+j}$, $j > 1$, and $m \geq j - 1$. The angle between the normal to s_i and the normal to s_{i+j} is $j\theta$. We will construct a new polygon γ' by moving facet s_{i+1} of zero length by h into the direction of ν_{i+1} (hence, $\Delta\mathbf{z} = h\mathbf{e}_i$), where $h < 0$, i.e., we move it inward. We also assume that $|h|$ and $|h|/L$ are small, where $L = |\gamma|$ is the perimeter of γ. We note that by the definition of $\mathcal{P}$ the angle between ν_i and ν_{i+1} is θ and the angle between ν_{i+1} and ν_{i+j} is $k\theta$, where $k = j - 1 > 0$. By Lemma 2.1 we have

$$\begin{aligned} \Delta L_i &= h/\sin\theta, \\ \Delta L_{i+1} &= -h(\operatorname{ctan}\theta + \operatorname{ctan}k\theta), \\ \Delta L_{i+j} &= h/\sin k\theta; \end{aligned}$$

then

$$\Delta L = \left(\tan\frac{\theta}{2} + \tan k\frac{\theta}{2}\right) h < 0.$$

The change in the area ΔA is also negative and

$$\Delta A = \frac{1}{2}h|\Delta L_i| = -\frac{1}{2}h^2(\operatorname{ctan}\theta + \operatorname{ctan}k\theta) =: -h^2 c(\theta).$$

Now,

$$Q(\gamma') = \frac{(L + \Delta L)^2}{A + \Delta A}.$$

We note that Taylor's expansion yields

$$\begin{aligned} \frac{1}{A + \Delta A} &= \frac{1}{A} \cdot \frac{1}{1 + \Delta A/A} = \frac{1}{A}\left(1 - \frac{\Delta A}{A} + \left(\frac{\Delta A}{A}\right)^2 \int_0^1 \frac{2(1-s)}{(1 + s\Delta A/A)^3}\, ds\right) \\ &\leq \frac{1}{A}\left(1 - \frac{\Delta A}{A} + 8\left(\frac{\Delta A}{A}\right)^2\right), \end{aligned}$$

provided that

$$\left|\frac{h}{L}\right| \le \sqrt{\frac{2A}{L^2 c(\theta)}}. \tag{4.3}$$

By simple algebra we arrive at

$$Q(\gamma') \le \frac{L^2}{A}\left(1+\frac{4h}{L}\left(\tan\frac{\theta}{2}+\tan k\frac{\theta}{2}\right)+\left(\frac{h}{L}\right)^2\left(4\left(\tan\frac{\theta}{2}+\tan k\frac{\theta}{2}\right)^2+c(\theta)\frac{L^2}{A}\right)\right),$$

provided that

$$\left|\frac{h}{L}\right| \le \frac{\tan\frac{\theta}{2}+\tan k\frac{\theta}{2}}{(\tan\frac{\theta}{2}+\tan k\frac{\theta}{2})^2+2c(\theta)Q(\gamma)} \tag{4.4}$$

and

$$\left|\frac{h}{L}\right| \le \frac{1}{\tan\frac{\theta}{2}+\tan k\frac{\theta}{2}}. \tag{4.5}$$

We note that (4.4) is more restrictive than (4.3) and (4.5). But neither of them takes into account the length of neighboring facets s_i, s_{i+j}. We have to restrict the size of $|h|$ again in order to guarantee that $n(\gamma') = n(\gamma)+1$. Finally,

$$Q(\gamma') \le Q(\gamma)\left(1+\frac{2h}{L}\left(\tan\frac{\theta}{2}+\tan k\frac{\theta}{2}\right)\right) < Q(\gamma),$$

provided that h/L is sufficiently small.

(b) If $n(\gamma) = N-m$, $m>1$, then by step (a) we may construct polygons γ_k, $k=1,\dots,m-1$, which are all close to γ and

$$n(\gamma_k) = N-m+k, \quad Q(\gamma_{k-1}) > Q(\gamma_k), \qquad k=1,\dots,m-1,$$

where $\gamma_0 := \gamma$. It follows that

$$Q(\gamma) > Q(\gamma_{m-1}), \qquad n(\gamma_{m-1}) = N-1.$$

(c) The general case has been now reduced to $n(\gamma) = N-1$. Obviously we have

$$Q(\gamma) \ge \min\{Q(\gamma_1):\ \gamma_1\in\mathcal{P},\ n(\gamma_1)=N-1\}.$$

We claim that this minimum is attained. As a matter of fact this follows from the Hausdorff selection theorem but we prefer to prove it directly. Let us suppose that $\{\gamma^n\}_{n=1}^\infty \subset \mathcal{P}$ is a minimizing sequence. After rescaling we may assume that $|D_{\gamma^n}| = 1$. Then,

$$|s(\mathbf{z}^n)|^2 \le 1+\min\{Q(\gamma_1):\ \gamma_1\in\mathcal{P},\ n(\gamma_1)=N-1\} =: A$$

for sufficiently large n. After shifting the polygons we may assume that they all lay in a ball $B(0,A^{1/2})$. Hence the sequence $\{\mathbf{z}^n\}_{n=1}^\infty \subset \mathbb{R}^N$ defining them (i.e., $\gamma^n = s(\mathbf{z}^n)$) is bounded. We may extract a convergent subsequence, still denoted $\{\mathbf{z}^n\}_{n=1}^\infty$, and $\mathbf{z}^n \to \mathbf{z}^\infty$. It follows from Lemma 2.1 that

$$Q(\gamma^n) \to Q(s(\mathbf{z}^\infty)) = \min\{Q(\gamma_1):\ \gamma_1\in\mathcal{P},\ n(\gamma_1)=N-1\}.$$

(d) By the argument in (a) there exists a polygon $\gamma' \in \mathcal{P}$, which is close to $s(\mathbf{z}^\infty)$, $n(\gamma') = N$ and which satisfies

$$Q(\gamma') < Q(s(\mathbf{z}^\infty)) \le Q(\gamma).$$

Of course,

$$Q(\gamma') \ge \min\{Q(\gamma_1) :\ \gamma_1 \in \mathcal{P},\ n(\gamma_1) = N\} = Q(W).$$

The compactness argument in (c) shows that the minimum is attained. For the sake of completeness we should show that indeed the minimum is equal to $Q(W)$. As a matter of fact a more general result is true. Stancu proved (see [St, Theorem 4.2]) that for any $\gamma \in \mathcal{P}$ with N sides the following inequality holds:

$$B_W(\rho) := \rho|\gamma| - |D_\gamma| - \omega_N \rho^2 \ge 0 \tag{4.6}$$

for all $\rho \in [\rho_{in}, \rho_{out}]$. For the moment the specific definitions of $0 < \rho_{in} < \rho_{out}$ are not important. We will present them later. We note that (4.6) is equivalent to

$$\left(\omega_N \rho - \frac{|\gamma|}{2\sqrt{\omega_N}}\right)^2 \le \frac{|\gamma|^2 - 4\omega_N |D_\gamma|}{4\omega_N},$$

hence

$$Q(\gamma) = \frac{|\gamma|^2}{|D_\gamma|} \ge 4\omega_N = Q(W).$$

Combining these estimates we conclude that

$$Q(\gamma) \ge \min_{\{\gamma_1 \in \mathcal{P}: n(\gamma_1) = N-1\}} Q(\gamma_1) = Q(W) + \alpha,$$

where

$$\alpha = \min_{\{\gamma \in \mathcal{P}: n(\gamma) = N-1\}} Q(\gamma) - \min_{\{\gamma \in \mathcal{P}: n(\gamma) = N\}} Q(\gamma) > 0. \qquad \square$$

We are now ready for the proof.

Proof of Theorem 4.1. We take $\lambda_1 = \omega_N + \alpha/2$, but let us suppose that the desired number Λ_1 does not exist, i.e., there is a sequence of polygons $\{\gamma^n\}_{n=1}^\infty \subset \mathcal{P}$ such that

$$\frac{\max L_i^n}{\min L_i^n} \to \infty \quad \text{as } n \to \infty, \tag{4.7}$$

and

$$Q(\gamma^n) \le \lambda_1.$$

All the polygons γ^n, $n = 1, 2, \ldots$, have N sides, so there exists at least one pair of indices (l, j) such that $\max_k L_k^n = L_l^n$ and $\min_k L_k^n = L_j^n$ for infinitely many n's. After choosing an appropriate subsequence of $\{\gamma^n\}_{n=1}^\infty$, which is denoted again by $\{\gamma^n\}_{n=1}^\infty$ condition (4.7) implies that

$$L_l^n / L_j^n \to \infty$$

as n goes to infinity.

Possibly after scaling the polygons, we may assume that $|D_{\gamma^n}| = 1$. Subsequently, we apply the compactness argument as in step (c) in the proof of Lemma 4.2. Hence, we may assume $\mathbf{z}^n \to \mathbf{z}^\infty$, where $\gamma^n = s(\mathbf{z}^n)$. In particular we have $L_i^n \to L_i^\infty$, $i = 1, \dots, N$.

By (4.7) for any $\delta > 0$ there exists n_0 such that

$$L_l^n / L_j^n > 1/\delta$$

for $n \geq n_0$, or

$$\frac{1}{2}\delta\sqrt{\lambda_1} \geq \delta L_l^n > L_j^n.$$

This implies that L_j^n converges to zero. But, γ^∞ is not a point since the area of D_{γ^∞} is one. Hence, $n(\gamma^\infty) < N$ and this implies that

$$\lambda_1 \geq Q(\gamma^n) \to Q(\gamma^\infty) \geq \omega_N + \alpha > \lambda_1.$$

We reached a contradiction, and our theorem follows. □

We now gather estimates for solutions of (4.2). We start with a definition

$$\rho_{out} = \inf\{\mu : \exists p \in \mathbb{R}^2,\ \mu W + p \supset D_\gamma\},$$
$$\rho_{in} = \sup\{\mu : \exists p \in \mathbb{R}^2,\ \mu W + p \subset D_\gamma\}.$$

The next lemma applies to admissible polygons. Let us recall that admissibility was defined at the beginning of section 2.

LEMMA 4.3. *Suppose γ is an admissible convex polygon, then*

(a) $$\rho_{out} \leq L + \frac{\sqrt{L^2 - 4\omega_N A}}{2\omega_N},$$

(b) $$2A/L \geq \rho_{in} \geq A/L.$$

Proof. (a) Stancu proved (see [St, Theorem 4.2]) that

$$B_W(\rho) := \rho L - A - \omega_N \rho^2 \geq 0$$

for all $\rho \in [\rho_{in}, \rho_{out}]$. Thus solving the equation $B_W(\rho) = 0$ provides an upper bound for ρ_{out}.

(b) We note

$$A = \frac{1}{2}\sum_{i=1}^{N} d_i L_i \geq \frac{1}{2}\sum_{i=1}^{N} \rho_{in} L_i = \frac{1}{2}\rho_{in} L.$$

On the other hand $B_W(\rho_{in}) \geq 0$ implies that

$$\rho_{in} L \geq A + \omega_N \rho_{in}^2 \geq A.$$

Part (b) follows. □

This lemma tells us how much we have to scale the Wulff shape so that it contains (or is contained) after scaling and translation a given (respectively, in a given) admissible convex polygon. We find it useful for the estimating of the times of extinction for solutions of (4.2). We recall the lemma below.

LEMMA 4.4 (see [Ry2, Lemma 4.3]). *Let us assume that* $s_0 = \sigma W + p$ *and it evolves according to* (4.2)*; then*

$$L(t) = c_w(T_{\max} - t)^{1/2},$$

where

$$c_w = N\left(\frac{2\kappa\Gamma}{\beta}\right)^{1/2}, \qquad T_{\max} = \left(\frac{L(0)}{c_w}\right)^2 = \frac{L^2(0)\beta}{2N^2\kappa\Gamma}. \qquad \square$$

This lemma gives also the estimates for extinction time of the flow (4.2) for arbitrary convex initial polygon s_0. If s_0 is given then Lemma 4.3 yields $\bar{\gamma}$, $\underline{\gamma}$ such that

$$D_{\bar{\gamma}} \supset D_{s_0} \supset D_{\underline{\gamma}},$$

where $\bar{\gamma} = \rho_{out}W + p_1$, $\underline{\gamma} = \rho_{in}W + p_2$. The first comparison principle of Giga and Gurtin [GG, Section 4] implies that

$$D_{\bar{\gamma}(t)} \supset D_{s(t)} \supset D_{\underline{\gamma}(t)} \tag{4.8}$$

if all polygons evolve according to (4.2), for as long as the solutions exist. Let us denote by $T(s_0)$ the maximal time of existence of solution to (4.2) for a given s_0. We are now in a position to estimate $T(s_0)$ in terms of s_0. The starting point is inclusion (4.8), which shows that

$$T(\underline{\gamma}) \le T(s_0) \le T(\bar{\gamma}).$$

Lemma 4.4 permits us to estimate $T(\bar{\gamma})$ as well as $T(\underline{\gamma})$. We carry out the calculations for $T(\bar{\gamma})$. It is easy to find out $|\bar{\gamma}|$ knowing ρ_{out}; hence by definition of Γ_i's, (2.4) and (2.5) we come to

$$T(\bar{\gamma}) \le \frac{4\beta N^2 \tan^2\frac{\theta}{2}\rho_{out}^2}{2N^2\kappa\Gamma} = \frac{\beta}{2d}\rho_{out}^2.$$

Lemma 4.3 now yields

$$T(\bar{\gamma}) \le \frac{\beta|s_0|^2}{2d}\left(\frac{1+\sqrt{1-Q(W)/Q(s_0)}}{\omega_N}\right)^2. \tag{4.9}$$

Similar calculations lead us to

$$T(\underline{\gamma}) = \frac{\beta}{2d}\rho_{in}^2 \ge \frac{\beta|s_0|^2}{2dQ^2(s_0)}. \tag{4.10}$$

We finally recall the following lemma.

LEMMA 4.5. *If* $V_i < 0$, κ *is defined by* (2.4)*, then*

$$L' = -\sum_{i=1}^{N} V_i\kappa < 0.$$

This follows immediately from Lemma 2.1. $\square$

5. Properties of solutions if the perimeter of s_0 is small. We would like to exhibit in this section some geometric properties of weak solutions in case of convex s_0. We keep the basic assumption (W) of the previous section. Thus, it follows immediately that $\Gamma_i = \Gamma < 0$, $i = 1, \dots, N$. We also assume that all β_i are equal to $\beta > 0$.

We first show that if perimeter L_0 is sufficiently small, and $Q(s_0)$ is close to $Q(W)$ and $u_0 \leq 0$ then the interface $s(t)$ shrinks to a point and $Q(s(t))$ is a decreasing function of time, moreover the temperature remains negative. Of course L_0 must be in some balance with the size of initial distribution of temperature u_0. We may say that for small s_0 the surface tension prevails over the destabilizing bulk forces.

Let us point out a possible interpretation of our result. Since during the evolution the isoperimetric quotient decreases, it seems there is no need for creating new facets during the evolution provided L_0 is already small, as this would increase the isoperimetric quotient. A similar point of view on the problem of whether or not to split a facet is provided by M.-H. Giga and Y. Giga in [Gi]. Their setting, however, is different from ours; they consider curve moving by crystalline curvature under the driving force. Their results are not directly applicable. Nonetheless, we would like to point to [Gi, Lemma 5]. This lemma states that small facets of polygons evolving by crystalline curvature do not split. Obviously, this does not settle the matter here. More work should be done.

After making these remarks let us return to the topic of this section. The main method we use here is based on a priori estimates for

$$\sum_{i=1}^{N} \left| \int_{s_i} u \, dl \right|,$$

and it aims at showing that the time derivative of $Q(s(t))$ is nonpositive. This is the place where the estimates of section 4 come into play. We compare $s(t)$ to evolution of s_0 under the flow of

$$V_i = \frac{\Gamma}{\beta' L_i}, \tag{5.1}$$

where $\beta' > 0$ is chosen appropriately. Here we exploit the comparison principle of Giga and Gurtin [GG].

The last result of this section is concerned with behavior of temperature u as $t \to T_max$. Because at that instance facets move very fast it is not clear whether or not u blows up. It turns out that we are able to show a bound in the $L^\infty(\Omega)$ norm for u in terms of initial data.

We also note a by-product of Theorem 4.1. Namely, we are able to improve Theorem 10 of [Ry1]; we can now show the corollary.

COROLLARY 5.1. *If $(\mathbf{z}, u)$ is a unique weak solution of the quasi-steady approximation of* (2.7)*, i.e., $(\mathbf{z}, u)$ is a solution of*

$$0 = -\int_\Omega \nabla u(x) \cdot \nabla h(x) dx + \sum_{j=1}^{N} \int_{s_j(t)} V_j(t) h(x) dl \qquad \text{for all} \quad h \in H_0^1(\Omega),$$

$$\int_{s_j(t)} u \, dl = \Gamma_j - \beta_j L_j(t) V_j(t), \quad j = 1, \dots, N, \tag{5.2}$$

where s_0 is convex and such that

(a) L_0 *is sufficiently small* (*see Theorem* 10 *in* [Ry1]*)*,
(b) $Q(s_0) \le \lambda_1$,
then

$$\frac{d}{dt} Q(s(t)) \le 0.$$

Proof. We proved in [Ry1, Theorem 10] that $Q(s(t))' \le 0$ provided that

$$\max L_i / \min L_i \le \Lambda_1$$

remains bounded independent of time. Theorem 4.1 provides such a bound if $Q(s_0) \le \lambda_1$. Thus the set $\mathcal{P} \cap \{\gamma : \ |\gamma| \text{ is small, } Q(\gamma) \le \lambda_1\}$ is invariant under the flow of (5.2) and the corollary follows. □

Suppose now we are given an arbitrary convex, an admissible polygon s_0, and a number δ, $\delta \in (0,1)$. Let us now define $\bar{s}(t)$ (respectively, $\underline{s}(t)$) as unique solutions to (5.1) with $\beta' = \beta/(1-\delta)$, (respectively, $\beta' = \beta/(1+\delta)$) and $\underline{s}(0) = s_0$ (respectively, $\bar{s}(0) = s_0$). By (4.9) we have the estimates for T_U the extinction time of $\bar{s}(t)$

$$T_U = T(\bar{\gamma}) \le \frac{\beta |s_0|^2}{2(1-\delta)d} \left(\frac{1 + \sqrt{1 - Q(W)/Q(s_0)}}{\omega_N} \right)^2. \tag{5.3a}$$

Similarly, we have a bound on T_L the extinction time of $\underline{s}(t)$. The formula (4.10) yields

$$T_L = T(\underline{\gamma}) \ge \frac{\beta |s_0|^2}{2(1+\delta) d Q^2(s_0)}. \tag{5.3b}$$

We will compare the flows generated by (5.1) and (2.7), and from the properties of solutions to (5.1) we will infer the behavior of solutions to (2.7). For instance T_U and T_L defined by (5.3) provide upper and lower estimates for T_max.

Here is our main result. It is a strengthened version of [Ry2, Theorem 4.1] which was established only for s_0 being a scaled Wulff shape.

THEOREM 5.2. *Let us suppose that* $0 < \delta < 1$ *is fixed,* s_0 *is a given convex, admissible polygon, and* u_0 *satisfies the condition* (3.4). *The numbers* λ_1 *and* Λ_1 *are given by Theorem* 4.1. *We assume that* $(\mathbf{z}, u)$ *is the unique weak solution with initial conditions* s_0 *and* u_0. *Let us finally suppose that the data fulfill*

(i) $u_0 \le 0$;
(ii) $Q(s_0) \le \lambda_1$;
(iii) $\sum_{i=1}^N |\int_{s_{0i}} u_0 \, dl| \le \exp(C_1 T_U)(C_R L_0^{1/2} \|u_0\|_{H_0^1(\Omega)} + C_2 T_U) \le \delta |\Gamma|$,
where C_R *is defined in* (5.9) *below,*

$$C_1 = N^{3/2} \Lambda_1^{1/2} \beta^{-1} C_0, \quad C_2 = N^{5/2} \Lambda_1^{1/2} |\Gamma| \beta^{-1} C_0,$$

T_L *and* T_U *are given by* (5.3), *and* C_0 *is defined in* (5.7) *below. Then the solution* $(\mathbf{z}, u)$ *satisfies*

(a) $\sum_{i=1}^N |\int_{s_i(t)} u \, dl| \le \exp(C_1 t)(C_R L_0^{1/2} \|u_0\|_{H_0^1(\Omega)} + C_2 t)$, $t \in [0, T_{\max})$;
(b) $V_i(t) < 0$, $i = 1, \dots, N$ *for all* $t \in (0, T_{\max})$, $T_L \le T_{\max} \le T_U$;
(c) $u(t,x) < 0$ *for all* $t \in (0, T_{\max})$, $x \in \Omega$;
(d) $Q(s(t))$ *is a decreasing function of time*;

(e) $s(t)$ *shrinks to a point as* $t \to T_{\max}$.

Proof. We first show that if (a) holds for $t \in [0,\tau]$, where $\tau \in (0, T_max)$, then (b)–(d) are satisfied on this interval.

We begin with proving (b). If (a) holds, then

$$\left| \int_{s_i(t)} u\, dl \right| \le \sum_{i=1}^{N} \left| \int_{s_i(t)} u\, dl \right| \le \delta |\Gamma|$$

and

$$\frac{(1+\delta)\Gamma}{\beta_i L_i} < V_i < \frac{(1-\delta)\Gamma}{\beta_i L_i} < 0, \quad i = 1, \dots, N. \tag{5.4}$$

We have already defined $\bar{s}(t)$ and $\underline{s}(t)$. We immediately obtain from the second comparison theorem of Giga and Gurtin [GG, Section 4] that $D_{\underline{s}(t)} \subset D_{\bar{s}(t)}$ for all t such that $\underline{s}(t)$ is defined. We would be able to estimate T_max above and below only after establishing that

$$\begin{aligned} &D_{\underline{s}(t)} \subset D_{s(t)} \qquad \text{for } t \le \min\{\tau, T_L\}, \\ &D_{s(t)} \subset D_{\bar{s}(t)} \qquad \text{for } t \le \min\{\tau, T_U\}. \end{aligned} \tag{5.5}$$

We cannot use the comparison principles of [GG] because they apply only to solutions of an ODE generalizing (5.1). We will show (5.5) directly.

Let us set

$$E = \{t \in [0,\tau] :\ D_{s(\zeta)} \subset D_{\bar{s}(\zeta)} \text{ for all } \zeta \in [0,t]\};$$

of course $E \neq \emptyset$ since $0 \in E$. We now set $t_1 = \sup E$. We claim that $t_1 = \tau$. Let us suppose the contrary, i.e., $t_1 < \tau$. Hence, by the very definition of t_1 as well as continuity of motion of $s(\zeta)$ and $\bar{s}(\zeta)$ we infer that $s(t_1)$ must touch $\bar{s}(t_1)$. It follows that for some $i \in \{1, \dots, N\}$

$$s_i(t_1) \cap \bar{s}_i(t_1) \neq \emptyset.$$

Let us denote by $\mathcal{I}$ the set of i with the above property, and $\mathcal{I}' = \{1, \dots, N\} \setminus \mathcal{I}$. If $i \in \mathcal{I}$, then because of $D_{s(t_1)} \subset D_{\bar{s}(t_1)}$ we have $|s_i(t_1)| \le |\bar{s}_i(t_1)|$. Inequality (5.4) now yields

$$V_i(t_1) < \frac{(1-\delta)\Gamma}{\beta L_i(t_1)} = \frac{(1-\delta)\Gamma}{|s_i(t_1)|} \le \frac{(1-\delta)\Gamma}{|\bar{s}_i(t_1)|} < 0.$$

We thus conclude that for $i \in \mathcal{I}$ $s_i(t)$ moves inward faster than $\bar{s}_i(t)$ for $t \in [t_1, t_1+\eta)$, η. On the other hand, if $i \in \mathcal{I}'$, then $s_i(t_1) \cap \bar{s}_i(t_1) = \emptyset$. Hence by the continuity of motion, $s_i(t)$ and $\bar{s}_i(t)$ will be separated for $t \in [t_1, t_1+\eta_1)$, $\eta_1 > 0$. We now conclude that $D_{s(\zeta)} \subset D_{\bar{s}(\zeta)}$ for $\zeta \in [t_1, t_1 + \min\{\eta, \eta_1\})$. This contradicts the definition of t_1; hence the second inclusion of (5.5) follows and

$$\tau \le T_U.$$

A similar argument proves the first inclusion of (5.5).

In order to prove that (a) implies (c) we use the variation of constants formula (3.6) and $u = -\Delta U$, and we obtain

$$u(t) = e^{\Delta t/\epsilon} u_0 - \frac{1}{\epsilon} \sum_{i=1}^{N} \int_0^t \Delta e^{\Delta(t-\sigma)/\epsilon} f_i(\mathbf{z}(\sigma)) V_i(\sigma)\, d\sigma.$$

We showed in [Ry2, Lemma 4.5] that $\Delta e^{\Delta t/\epsilon} f_i \le 0$ for $t > 0$, so since $V_i < 0$ we infer that the above integral is nonpositive. By the maximum principle $e^{\Delta t/\epsilon} u_0 < 0$, and (c) follows.

(d) We may now calculate the derivative of the isoperimetric quotient $Q(s(t))$. Since $u(t) < 0$ for $t \in (0, \tau)$ we apply the reasoning as in the proof of Theorem 10 in [Ry1], and we come to

$$\frac{d}{dt} Q(s(t)) \le -\frac{L}{A\beta} \left(\sum_{j=1}^{N} \frac{\kappa^2}{L_j} + \frac{1}{2} \frac{L}{A} N\kappa \right) \left(d - \frac{1}{\kappa N} \sum_{j=1}^{N} \int_{s_j} u \, dl \right),$$

where $d = |\Gamma/\kappa|$ (see the definition of Γ_i's and (2.5)). By Lemmas 11 and 12 of [Ry1] it follows that

$$\sum_{j=1}^{N} \frac{\kappa^2}{L_j} + \frac{1}{2} \frac{L}{A} N\kappa \ge 0.$$

On the other hand since (a) and (b) hold, then

$$d - \frac{1}{N\kappa} \int_{s(t)} u \, dl = \frac{1}{N\kappa} \sum_{i=1}^{N} \left(\Gamma - \int_{s_i(t)} u \, dl \right) \ge 0.$$

Thus,

$$\frac{d}{dt} Q(s(t)) \le 0 \quad \text{on } [0, \tau)$$

(see also proof of Theorem 4.1 in [Ry2]).

We will prove now that (a) holds for $t \in [0, T_max)$. Let us set

$$E = \left\{ t \in [0, T_{\max}) : \sum_{i=1}^{N} \left| \int_{s_i(\tau)} u \, dl \right| \le \exp(C_1 \tau)(C_R L_0^{1/2} \|u_0\|_{H_0^1(\Omega)} + C_2 \tau) \forall \tau \in [0, t) \right\}.$$

Of course $E \ne \emptyset$ because our assumptions imply that $0 \in E$. Let us set $\omega = \sup E$. We shall show that $\omega = T_max$. Let us suppose that $\omega < T_max$; then by definition of ω and (iii)

$$\sum_{i=1}^{N} \left| \int_{s_i(\omega)} u \, dl \right| \le \exp(C_1 \omega)(C_R L_0^{1/2} \|u_0\|_{H_0^1(\Omega)} + C_2 \omega) < \delta |\Gamma|.$$

Thus, there exists $\eta > 0$ such that for $\tau \in [\omega, \omega + \eta)$ we have

$$\sum_{i=1}^{N} \left| \int_{s_i(\tau)} u \, dl \right| < \delta |\Gamma|.$$

Let us note that by (2.7b) and Lemma 3.5, (5.6) takes the form

$$u(t) = e^{\Delta t/\epsilon} u_0 - \frac{1}{\epsilon} \sum_{i=1}^{N} \int_0^t e^{\Delta(t-\tau)/\epsilon} \int_{s_i(\tau)} G(x, y, (t-\tau)/\epsilon) \, dy \frac{\Gamma - \int_{s_i(\tau)} u \, dl}{\beta L_i(\tau)} \, d\tau.$$

Hence,

$$\left|\int_{s_j(t)} u\,dl\right| \le \left|\int_{s_j(t)} e^{\Delta t/\epsilon}u_0\,dl\right| + \sum_{i=1}^{N}\left|\int_0^t\int_{s_j(t)}\int_{s_i(\tau)} \frac{1}{\epsilon}G(x,y,(t-\tau)/\epsilon)\,dydl(x)\frac{\Gamma-\int_{s_i(\tau)}u\,dl}{\beta L_i(\tau)}\,d\tau\right|.$$

We note that since all V_i are negative, then $s(t)$ for $t\in[0,\omega)$ are contained in $D_{s_0}$and

$$\int_{s_i(t)}\int_{s_j(\tau)} G^2(x,y,(t-\tau)/\epsilon)\,dydx \le C_0 < \infty, \tag{5.7}$$

where C_0 is independent of time. Hence, the Schwarz inequality implies

$$\begin{aligned}\left|\int_{s_j(t)} u\,dl\right| &\le \left|\int_{s_j(t)} e^{\Delta t/\epsilon}u_0\,dl\right| + C_0\beta^{-1}\sum_{i=1}^{N}\int_0^t L_j^{1/2}(t)L_i^{-1/2}(\tau)\left(|\Gamma|+\left|\int_{s_i(\tau)}u\,dl\right|\right)d\tau\\ &\le \left|\int_{s_j(t)} e^{\Delta t/\epsilon}u_0\,dl\right| + C_0\beta^{-1}\sum_{i=1}^{N}\int_0^t \frac{L^{1/2}(t)}{\min L_k^{-1/2}(\tau)}\left(|\Gamma|+\left|\int_{s_i(\tau)}u\,dl\right|\right)d\tau.\end{aligned}$$

In order to estimate it further we recall that by Theorem 4.1 $\min L_i \ge \Lambda_1^{-1}\max L_i$ and $N\max L_i \ge L$. Thus, we arrive at

$$\left|\int_{s_j(t)} u\,dl\right| \le \left|\int_{s_j(t)} e^{\Delta t/\epsilon}u_0\,dl\right| + C_0\beta^{-1}\Lambda_1^{1/2}N^{1/2}\int_0^t L^{1/2}(t)L^{-1/2}(\tau)\left(N|\Gamma|+\sum_{i=1}^{N}\left|\int_{s_i(\tau)}u\,dl\right|\right)d\tau.$$

By Corollary 4.5 $L(t) < L(\tau)$ if $\tau < t$. Therefore, the summing up of the estimates for $|\int_{s_j(t)} u\,dl|$ yields

$$\begin{aligned}\sum_{j=1}^{N}\left|\int_{s_j(t)} u\,dl\right| &\le \sum_{j=1}^{N}\left|\int_{s_j(t)} e^{\Delta t/\epsilon}u_0\,dl\right|\\ &\quad + C_0\beta^{-1}\Lambda_1^{1/2}N^{3/2}\int_0^t\left(N|\Gamma|+\sum_{j=1}^{N}\left|\int_{s_j(\tau)}u\,dl\right|\right)d\tau.\end{aligned} \tag{5.8}$$

We are almost in a position to apply Grönwall's inequality, but before doing so we note that

$$\begin{aligned}\sum_{j=1}^{N}\left|\int_{s_j(t)} e^{\Delta t/\epsilon}u_0\,dl\right| &\le \sum_{j=1}^{N} L_j^{1/2}(t)\left\|\int_{s_j(t)} e^{\Delta t/\epsilon}u_0\right\|_{L^2(s_j(t))}\\ &\le L^{1/2}(t)N^{1/2}c_r\|e^{\Delta t/\epsilon}u_0\|_{H_0^1(\Omega)}\\ &\le L^{1/2}(0)N^{1/2}c_r\|e^{\Delta t/\epsilon}u_0\|_{H_0^1(\Omega)}\end{aligned}$$

and c_r is the constant in the inequality

$$\|u\|_{L^2(l\cap\Omega)} \le c_r \|u\|_{H_0^1(\Omega)};$$

l is any line in $\mathbb{R}^2$.

We now need to estimate $\|e^{\Delta t/\epsilon}u_0\|_{H_0^1(\Omega)}$. This can be done with the help of (3.5) and the properties of fractional powers of $-\Delta$ (see [He, Sections 1.3 and 1.4]). One can see that

$$\|e^{\Delta t/\epsilon}u_0\|_{H_0^1(\Omega)} \le B\|(-\Delta)^{1/2}e^{\Delta t/\epsilon}u_0\|_{L^2(\Omega)} \le BM\|u_0\|_{X^{1/2}} \le B^2M\|u_0\|_{H_0^1(\Omega)}.$$

Combining these estimates we come to

$$\sum_{j=1}^{N}\left|\int_{s_j(t)} e^{\Delta t/\epsilon}u_0\,dl\right| \le C_R L^{1/2}(0)\|u_0\|_{H_0^1(\Omega)},$$

where

$$C_R = c_r N^{1/2}B^2M. \tag{5.9}$$

By Grönwall's inequality applied to (5.8) we obtain

$$\sum_{j=1}^{N}\left|\int_{s_j(t)} u\,dl\right| \le e^{C_1 t}(C_2 t + C_R L_0^{1/2}\|u_0\|_{L^2(\Omega)}),$$

so (a) holds on $[0, \omega+\eta]$ too, contrary to the maximality of ω.

Now, after we established that (a) holds for all $t < T_max$, the first inclusion of (5.5) implies the lower bound on T_max, and the second inclusion of (5.5) implies the upper bound, i.e.,

$$T_U \ge T_{\max} \ge T_L.$$

(e) Since all the velocities V_i's are negative and $Q(s(t))$ decreases in time, then the only possibility of extinction is that $s(t)$ shrinks to a point. □

We showed that integrals of u over $s(t)$ remain bounded throughout the evolution. We shall prove a stronger result, namely that u itself remains bounded.

THEOREM 5.3. *Under the assumptions of the previous theorem, we have*

$$\|u(t)\|_{L^\infty(\Omega)} \le \|u_0\|_{L^\infty(\Omega)} + C(L_0).$$

Proof. We claim that the compatibility condition (3.4) implies that $\|u_0\|_{L^\infty(\Omega)}$ is finite for

$$u_0 - \sum_{j=1}^{N} f_j(0)V_j(0) = h \in H^2(\Omega)\cap H_0^1(\Omega).$$

On the other hand by [Ry2, Lemma 3.3], $f_i(0)$ may be decomposed in the following way:

$$f_i(0) = \varphi g_i + r_i,$$

where $\varphi \in C_0^\infty(\Omega)$, $g_i \in H^\sigma(\mathbb{R}^2)$ ($\sigma \in (1, 3/2)$ is arbitrary), and $r_i \in H^2(\Omega) \cap H_0^1(\Omega)$. Our claim now follows from the Sobolev embedding theorem.

We use the variation of constants formula (3.6). Next, we apply $-\Delta$ to both sides. After setting $u = -\Delta U$ we obtain

$$u(t) = e^{\Delta t/\epsilon} u_0 - \frac{1}{\epsilon} \int_0^t \Delta e^{\Delta(t-\tau)/\epsilon} \sum_{i=1}^N f_i(\tau) V_i(\tau)\, d\tau.$$

By the maximum principle $\|e^{\Delta t/\epsilon} u_0\|_{L^\infty(\Omega)} \le \|u_0\|_{L^\infty(\Omega)}$. Let us pick $\alpha \in (\frac{1}{2}, 1)$, then by the embedding theorem (see [Hn, Theorem 1.6.1]) $X^\alpha \subset C^{0,\mu}(\Omega)$, where $0 \le \mu < 2\alpha - 1$. Hence we have

$$\begin{aligned}
\|u(t)\|_{L^\infty(\Omega)} &\le \|u_0\|_{L^\infty(\Omega)} + \frac{1}{\epsilon} \left\| \int_0^t \Delta e^{\Delta(t-\tau)/\epsilon} \sum_{i=1}^N f_i(\tau) V_i(\tau)\, d\tau \right\|_{X^\alpha} \\
&\le \|u_0\|_{L^\infty(\Omega)} + \frac{1}{\epsilon} \lim_{\eta \to 0^+} \int_0^{t-\eta} \left\| (-\Delta)^{1+\alpha} e^{\Delta(t-\tau)/\epsilon} \sum_{i=1}^N f_i(\tau) V_i(\tau) \right\|_{L^2(\Omega)} d\tau \\
&\le \|u_0\|_{L^\infty(\Omega)} \\
&+ \frac{1}{\epsilon} \lim_{\eta \to 0^+} \int_0^{t-\eta} \left\| (-\Delta)^{\alpha} e^{\Delta \frac{(t-\tau)}{2\epsilon}} \Delta e^{\Delta \frac{(t-\tau)}{2\epsilon}} \sum_{i=1}^N f_i(\tau) V_i(\tau) \right\|_{L^2(\Omega)} d\tau \\
&= \|u_0\|_{L^\infty(\Omega)} + J.
\end{aligned}$$

We estimate J using Lemma 3.5 and [He, Theorem 1.4.3]. This yields

$$J \le C_\alpha \lim_{\eta \to 0^+} \int_0^{t-\eta} \frac{(2\epsilon)^\alpha}{(t-\tau)^\alpha} \sum_{i=1}^N \left\| \int_{s_i(\tau)} G(x, y, \frac{t-\tau}{2\epsilon})\, dl(y) \right\|_{L^2(\Omega)} |V_i(\tau)|\, d\tau.$$

The problem now is to bound the integral involving the Green function. It is a simple task using the Schwarz inequality, (3.12), and an inequality $t^{-2} \exp(-|\xi|^2/t) \le At^{-1} \exp(-|\xi|^2/(2t))$,

$$\begin{aligned}
\int_\Omega \left(\int_{s_i(\tau)} G(x, y, \zeta)\, dl(y) \right)^2 dx &\le \int_\Omega |s_i(\tau)| \int_{s_i(\tau)} G^2(x, y, \zeta)\, dl(y) dx \\
&\le 2L_i(\tau) \int_{s_i(\tau)} \int_\Omega (K_\zeta^2(x-y) + H^2(x, y, \zeta))\, dx dl(y) \\
&\le 2L_i(\tau) \int_{s_i(\tau)} (A + \|H\|^2_{L^\infty(\Omega \times \Omega_h \times [0, T_{\max}])})\, dl(y) \\
&\le A' L_i^2(\tau),
\end{aligned}$$

where $h = \operatorname{dist}(s_0, \partial\Omega)$, $\zeta = (t-\tau)/(2\epsilon)$, and A' is independent of T_max. Combining the above inequality with (5.4) yields

$$J \le C_\alpha \epsilon^\alpha \int_0^t (t-\tau)^{-\alpha} \sum_{i=1}^N \frac{L_i(\tau)(1+\delta)}{\beta L_i(\tau)}\, d\tau.$$

Finally,

$$\|u(t)\|_{L^\infty(\Omega)} \le \|u_0\|_{L^\infty(\Omega)} + J \le \|u_0\|_{L^\infty(\Omega)} + C' T_U^{(1-\alpha)}.$$

Since T_U can be bounded in terms of $L(0)$ our theorem follows. □

We close by stating a simple estimate for perimeter of $s(t)$.

COROLLARY 5.4. *Under the assumptions of Theorem* 5.2*, we have*

$$L(t) \geq C(T_{\max} - t)^{1/2}.$$

Proof. To see this we differentiate $L(t)$

$$L'(t) = -\sum_{i=1}^{N} V_i \kappa = -\kappa\beta^{-1} \sum_{i=1}^{N} \left(\Gamma - \int_{s_i} u \, dl \right) L_i^{-1}(t) \leq -\Gamma(1-\delta)\kappa\beta^{-1} \sum_{i=1}^{N} L_i^{-1}(t).$$

Since $L_i \geq \min L_i \geq \Lambda_1^{-1} \max L_i \geq \Lambda_1^{-1} N^{-1} L$ we obtain for $C_u = \Gamma(1-\delta)\kappa\Lambda_1 N\beta^{-1}$

$$L'(t) \leq -C_u L^{-1}.$$

Our result follows immediately from this differential inequality. □

ASYMPTOTICS OF SOLUTIONS TO THE MODIFIED NONLINEAR SCHRÖDINGER EQUATION: SOLITONS ON A NONVANISHING CONTINUOUS BACKGROUND*

A. V. KITAEV† AND A. H. VARTANIAN†

Abstract. Using the matrix Riemann–Hilbert factorization approach for nonlinear evolution systems which take the form of Lax-pair isospectral deformations and whose corresponding Lax operators contain both discrete and continuous spectra, we obtain the leading-order asymptotics as $t\to\pm\infty$ of the solution to the Cauchy problem for the modified nonlinear Schrödinger equation, $i\partial_t u+\frac{1}{2}\partial_x^2 u+|u|^2u+is\partial_x(|u|^2u)=0$, $s\in\mathbb{R}_{>0}$, which is a model for nonlinear pulse propagation in optical fibers in the subpicosecond time scale. Also derived are analogous results for two gauge-equivalent nonlinear evolution equations—in particular, the derivative nonlinear Schrödinger equation $i\partial_t q+\partial_x^2 q-i\partial_x(|q|^2q)=0$. As an application of these asymptotic results, explicit expressions for position and phase shifts of solitons in the presence of the continuous spectrum are calculated.

Key words. asymptotics, Riemann–Hilbert problem, solitons, optical fibers

1. Introduction.

With the current emphasis on the utilization of optical fibers, capable of supporting solitons, as the communication channel in the practical realization and implementation of all-optical (lightwave), ultrahigh-bit-rate, long-distance communication systems using the return-to-zero (RZ) format for generating the optical bit stream, design issues requiring the consideration of several factors, e.g., soliton widths and intersoliton spacings, are intimately related to the study of the fundamental dynamical processes associated with the propagation of high-power ultrashort pulses in optical fibers (at the present stage of technology, these systems can at best still only be called near-soliton(ic)-based) [1, 2, 3]. The standard, classical mathematical model for nonlinear pulse propagation in the picosecond time scale in the anomalous dispersion regime in an isotropic, homogeneous, lossless, nonamplifying, polarization-preserving single-mode optical fiber is the nonlinear Schrödinger equation (NLSE) [1, 2, 3, 4]. However, experiments and theories on the propagation of high-power ultrashort pulses in the subpicosecond-femtosecond time scale in monomode optical fibers have shown that the NLSE is no longer a valid model and that additional nonlinear terms (dispersive and dissipative) and higher-order linear dispersion must be taken into account: in this case, pulse-like propagation is described (in dimensionless and normalized form) by the following nonlinear evolution equation (NLEE) [1, 2, 3]:

$$i\partial_z u+\frac{1}{2}\partial_\tau^2 u+|u|^2u+is\partial_\tau(|u|^2u)=-i\widetilde{\Gamma}u+i\breve{\delta}\partial_\tau^3 u+\frac{\widetilde{\tau}_n}{\widetilde{\tau}_0}u\partial_\tau(|u|^2), \tag{1}$$

where u is the slowly varying amplitude of the complex field envelope, z is the propagation distance along the fiber length, τ is the time measured in a frame of reference

moving with the pulse at the group velocity, $s \in \mathbb{R}_{>0}$ governs the effects due to the intensity dependence of the group velocity (self-steepening), $\widetilde{\Gamma}$ is the intrinsic fiber loss, $\breve{\delta}$ governs the effects of the third-order linear dispersion, and $\widetilde{\tau}_n/\widetilde{\tau}_0$ governs the soliton self-frequency shift effect.

Since, under typical operating conditions, $\widetilde{\Gamma}$, $\breve{\delta}$, and $\widetilde{\tau}_n/\widetilde{\tau}_0$ are small parameters [1, 2, 3], a strategy to study the solutions of (1), for which the nonlinear effects dominate the higher-order linear dispersive effect, is to set the right-hand side equal to zero, thus obtaining the following NLEE (integrable in the sense of the inverse scattering method (ISM) [5, 6, 7]):

$$i\partial_t u + \frac{1}{2}\partial_x^2 u + |u|^2 u + is\partial_x(|u|^2 u) = 0, \tag{2}$$

which hereafter is called the modified nonlinear Schrödinger equation (MNLSE) (the physical variables z and τ have been mapped isomorphically onto the mathematical t and x variables, which are standard in the ISM context) and to treat (1) as a nonintegrable perturbation of the MNLSE. From the above discussion, it is clear that perturbations of multisoliton solutions of the MNLSE can be very important in the physical context, related to optical fibers [1, 2, 3]. Since practical lasers excite not only the soliton(ic) mode(s) but also an entire continuum of linear-like dispersive (radiative) waves, to have physically meaningful and practically representative results, it is necessary to investigate solutions of the MNLSE under general initial (launching, in the optical fiber literature [1, 2, 3]) conditions, without any artificial restrictions and/or constraints, which have both soliton(ic) and nonsoliton(ic) (continuum) components: it is towards such a solution that the initial pulse launched into an optical fiber is evolving asymptotically [8]. In physical terms, the pulse adjusts its width as it propagates along the optical fiber to evolve into a (multi)soliton, and a part of the pulse energy is shed in the form of dispersive waves in the process: normally, these dispersive waves form a low-level broadband background radiation that accompanies the (multi)soliton [1, 2, 3, 8]. From the physical point of view, therefore, it is important to understand how the continuum and the (near)soliton(s) interact and to be able to derive an explicit functional form for this process. Since (2) is integrable via the ISM, we can use one of the techniques developed in the framework of this approach to solve the aforementioned problem; in particular, in this paper the matrix Riemann–Hilbert (RH) factorization method is applied.

For several soliton-bearing equations, e.g., KdV, Landau–Lifshitz, NLS, sine-Gordon and MKdV, it is known that the dominant ($\mathcal{O}(1)$) asymptotic ($t \to \pm\infty$) effect of the continuous spectra on the multisoliton solutions is a shift in phase and position of their constituent solitons [9, 10, 11, 12]: as will be shown in this paper, an analogous, though analytically more complicated, situation takes place for the MNLSE (the additional complexification occurs due to the nonstandard normalization of the associated RH problem). While the abovementioned works deal only with the leading-order ($\mathcal{O}(1)$) asymptotic term, in this paper, for the MNLSE, not only the leading-order, but the next-to-leading-order ($\mathcal{O}(t^{-1/2})$) term as well is derived; in particular, besides inducing an $\mathcal{O}(1)$ position and phase shift on the multisoliton solution, this $\mathcal{O}(t^{-1/2})$ term represents the evolution of the continuum component (dispersive wavetrain [1, 2, 3]) as well as the nontrivial interaction (overlap) of the soliton and continuum components of the solution. It is worth mentioning that, even though there have been several papers [13, 14] devoted to studying the soliton solutions of the MNLSE, to the best of our knowledge, very little, if anything, was known about its solution(s) for the class of nonreflectionless initial data until very recently [15]. In

the framework of the ISM, an asymptotic analysis of the aforementioned solution for the MNLSE can be divided into two stages: (1) the investigation of the continuum (solitonless) component of the solution [16, 17, 18, 19, 20, 21]; and (2) the inclusion of the (multi)soliton component via the application of a "dressing" procedure [22, 23] to the continuum background. In this paper, the abovementioned asymptotic paradigm is carried out systematically for the MNLSE: the results obtained in this paper are formulated as Theorems 2.1–2.3.

This paper is organized as follows. In section 2, a matrix RH problem for the solution of an NLEE gauge-equivalent to equation (2) is stated, and the results of this paper are summarized as Theorems 2.1–2.3. In section 3, an extended RH problem is formulated and shown to be equivalent to the original one stated in section 2, and as $t \to +\infty$, it is shown that the solution of the extended RH problem converges, modulo exponentially decreasing terms, to the solution of a model RH problem. In section 4, the Beals–Coifman [24, 25] formulation for the solution of an RH problem on an oriented contour is succinctly recapitulated, and the model RH problem is solved asymptotically as $t \to +\infty$ for the Schwartz class of nonreflectionless generic potentials. In section 5, a phase integral which is associated with the nonstandard normalization of the abovementioned RH problem is evaluated asymptotically as $t \to +\infty$. Finally, in section 6 the asymptotic analysis as $t \to -\infty$ is presented.

2. The RH problem and summary of results. In this section, the matrix RH problem is stated, and the main results of the paper are formulated as Theorems 2.1–2.3. Before doing so, however, it is necessary to introduce some notation and definitions which are used throughout the paper.

In this paper, as in [15], along with the MNLSE, the following NLEEs are studied:

$$i\partial_t Q + \partial_x^2 Q + iQ^2\partial_x \overline{Q} + \frac{1}{2}Q|Q|^4 = 0, \tag{3}$$

with initial condition $Q(x,0) \in \mathcal{S}(\mathbb{R};\mathbb{C})$, and the derivative nonlinear Schrödinger equation (DNLSE),

$$i\partial_t q + \partial_x^2 q - i\partial_x(|q|^2 q) = 0, \tag{4}$$

with initial condition $q(x,0)\in\mathcal{S}(\mathbb{R};\mathbb{C})$. To recall the relations between the solutions of these NLEEs, the following propositions are formulated.

PROPOSITION 2.1 (see [26]). *The necessary and sufficient condition for the compatibility of the following system of linear ODEs (the Lax pair) for arbitrary $\lambda\in\mathbb{C}$:*

$$\partial_x\Psi(x,t;\lambda)=U(x,t;\lambda)\Psi(x,t;\lambda),\qquad \partial_t\Psi(x,t;\lambda)=V(x,t;\lambda)\Psi(x,t;\lambda), \tag{5}$$

where

$$U(x,t;\lambda)=-i\lambda^2\sigma_3+\lambda(\overline{Q}\sigma_-+Q\sigma_+)-\frac{i}{2}|Q|^2\sigma_3,$$
$$V(x,t;\lambda)=2\lambda^2U(x,t;\lambda)-i\lambda((\partial_x\overline{Q})\sigma_--(\partial_xQ)\sigma_+)+\left(\frac{i}{4}|Q|^4+\frac{1}{2}(\overline{Q}\partial_xQ-Q\partial_x\overline{Q})\right)\sigma_3,$$

is that $Q(x,t)$ satisfies (3).

Proof. Equation (3) is the Frobenius compatibility condition for system (5). □

PROPOSITION 2.2. *Let $Q(x,t)$ be a solution of* (3). *Then there exists a corresponding solution of system* (5) *such that $\Psi(x,t;0)$ is a diagonal matrix.*

Proof. For given $Q(x,t)$, let $\widehat{\Psi}(x,t;\lambda)$ be a solution of system (5) which exists in accordance with Proposition 2.1. Setting $\lambda=0$ in system (5), one gets that $\widehat{\Psi}(x,t;0)=\exp\{-\frac{i\sigma_3}{2}\int_{x_0}^x|Q(\varrho,t)|^2d\varrho\}\widehat{\mathcal{K}}(\lambda)$, for some $x_0\in\mathbb{R}$ and nondegenerate matrix $\widehat{\mathcal{K}}(\lambda)$ which is independent of x and t. The function $\Psi(x,t;\lambda):=\widehat{\Psi}(x,t;\lambda)(\widehat{\mathcal{K}}(\lambda))^{-1}$ is the solution of system (5) which is diagonal at $\lambda=0$. □

PROPOSITION 2.3 (see [27]). *Let $Q(x,t)$ be a solution of* (3) *and $\Psi(x,t;\lambda)$ the corresponding solution of system* (5) *given in Proposition* 2.2. *Set $\Psi_q(x,t;\lambda):=\Psi^{-1}(x,t;0)\Psi(x,t;\lambda)$. Then*

$$\partial_x\Psi_q(x,t;\lambda)=\mathcal{U}_q(x,t;\lambda)\Psi_q(x,t;\lambda),\qquad \partial_t\Psi_q(x,t;\lambda)=\mathcal{V}_q(x,t;\lambda)\Psi_q(x,t;\lambda), \tag{6}$$

where

$$\mathcal{U}_q(x,t;\lambda)=-i\lambda^2\sigma_3+\lambda(\overline{q}\sigma_-+q\sigma_+), \tag{7}$$

$$\mathcal{V}_q(x,t;\lambda)=\begin{pmatrix}-2i\lambda^4-i\lambda^2|q|^2 & 2\lambda^3q+i\lambda\partial_xq+\lambda|q|^2q\\ 2\lambda^3\overline{q}-i\lambda\partial_x\overline{q}+\lambda|q|^2\overline{q} & 2i\lambda^4+i\lambda^2|q|^2\end{pmatrix}, \tag{8}$$

with $q(x,t)$ defined by

$$q(x,t):=Q(x,t)((\Psi^{-1}(x,t;0))_{11})^2 \tag{9}$$

being the "Kaup–Newell" [28] Lax pair for the DNLSE.

Proof. Differentiating $\Psi_q(x,t;\lambda):=\Psi^{-1}(x,t;0)\Psi(x,t;\lambda)$ with respect to x and t and using the fact that $\Psi(x,t;0)=\exp\{-\frac{i\sigma_3}{2}\int_{x_0}^x|Q(\varrho,t)|^2d\varrho\}$, for some $x_0\in\mathbb{R}$, and $\Psi(x,t;\lambda)$ satisfy system (5) for $\lambda=0$ and $\lambda\in\mathbb{C}\setminus\{0\}$, resp., defining $q(x,t)$ as in (9), one gets that $\Psi_q(x,t;\lambda)$ satisfies system (6), where $\mathcal{U}_q(x,t;\lambda)$ and $\mathcal{V}_q(x,t;\lambda)$ are given by (7) and (8): (4) is the Frobenius compatibility condition for system (6). □

PROPOSITION 2.4. *If $q(x,t)$ is a solution of the DNLSE such that $q(x,0)\in\mathcal{S}(\mathbb{R};\mathbb{C})$, then*

$$u(x,t):=\frac{1}{\sqrt{2s}}\exp\left\{\frac{i}{s}\left(x-\frac{t}{2s}\right)\right\}q\left(\frac{t}{s}-x,\frac{t}{2}\right) \tag{10}$$

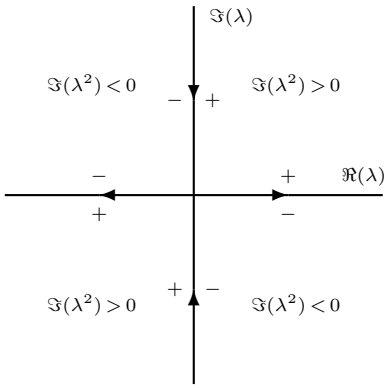

FIG. 1. *Continuous spectrum* $\widehat{\Gamma}$.

satisfies the MNLSE with initial condition $u(x,0)\in\mathcal{S}(\mathbb{R};\mathbb{C})$.

Proof. The proof is by direct substitution. □

Remark 2.1. A convention is now adopted which is adhered to *strictly* throughout the paper: for each segment of an oriented contour, according to the given orientation, the "+" side is to the left and the "−" side is to the right as one traverses the contour in the direction of the orientation; hence, $(\bullet)_+$ and $(\bullet)_-$ denote, resp., the nontangential limits (boundary values) of $(\bullet)$ on an oriented contour from the "+" (left) and "−" (right) sides.

Before stating the matrix RH problem which is investigated asymptotically (as $t\to\pm\infty$) in this paper (see Lemma 2.1), it will be convenient to introduce the following notation: *let* $\mathcal{Z}_d:=\cup_{i=1}^N(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\})$ *and* $\widehat{\Gamma}:=\{\lambda;\,\Im(\lambda^2)=0\}$ (*oriented as in Figure* 1) *denote, resp., the discrete and continuous spectra of the operator* $\partial_x-U(x,t;\lambda)$, *and* $\sigma_{\mathcal{L}}:=\mathrm{Spec}(\partial_x-U)=\mathcal{Z}_d\cup\widehat{\Gamma}$ $(\mathcal{Z}_d\cap\widehat{\Gamma}=\emptyset)$.

LEMMA 2.1. *Let* $Q(x,t)$, *as a function of* $x,\in\mathcal{S}(\mathbb{R};\mathbb{C})$. *Set*

$$m(x,t;\lambda):=\Psi(x,t;\lambda)\exp\{i(\lambda^2x+2\lambda^4t)\sigma_3\}.$$

Then (1) *the bounded discrete set* $\mathcal{Z}_d$ *is finite* $(\mathrm{card}(\mathcal{Z}_d)<\infty)$; (2) *the poles of* $m(x,t;\lambda)$ *are simple*; (3) *the first* (*resp., second*) *column of* $m(x,t;\lambda)$ *has poles at* $\{\pm\lambda_i\}_{i=1}^N$ (*resp.,* $\{\pm\overline{\lambda_i}\}_{i=1}^N$); *and* (4) *for all* $t\in\mathbb{R}$ *the function* $m(x,t;\lambda):\mathbb{C}\setminus(\mathcal{Z}_d\cup\widehat{\Gamma})\to\mathrm{SL}(2,\mathbb{C})$ *solves the following RH problem:*

a. $m(x,t;\lambda)$ *is meromorphic for all* $\lambda\in\mathbb{C}\setminus\widehat{\Gamma}$;

b. $m(x,t;\lambda)$ *satisfies the following jump conditions:*

$$m_+(x,t;\lambda)=m_-(x,t;\lambda)v(x,t;\lambda),\qquad\lambda\in\widehat{\Gamma},$$

where

$$v(x,t;\lambda):=\exp\{-i(\lambda^2x+2\lambda^4t)\mathrm{ad}(\sigma_3)\}\begin{pmatrix}1-r(\lambda)\overline{r(\overline{\lambda})} & r(\lambda)\\ -\overline{r(\overline{\lambda})} & 1\end{pmatrix},$$

$r(\lambda)$, *the reflection coefficient associated with the direct scattering problem for the operator* $\partial_x-U(x,t;\lambda)$, *satisfies* $r(-\lambda)=-r(\lambda)$, *and* $r(\lambda)\in\mathcal{S}(\widehat{\Gamma};\mathbb{C})$;

c. *for the simple poles of* $m(x,t;\lambda)$ *at* $\{\pm\lambda_j\}_{j=1}^N$ *and* $\{\pm\overline{\lambda_j}\}_{j=1}^N$, *there exist nilpotent matrices* $\{v_j(x,t)\sigma_-\}_{j=1}^N$ *and* $\{\overline{v_j(x,t)}\sigma_+\}_{j=1}^N$, *resp., such that the residues, for* $1\le j\le N$, *satisfy the* (*Beals–Coifman* [24, 25]) *polar conditions*

$$\begin{aligned}
\operatorname{res}(m(x,t;\lambda);\lambda_j) &= \lim_{\lambda\to\lambda_j} m(x,t;\lambda)v_j(x,t)\sigma_-,\\
\operatorname{res}(m(x,t;\lambda);-\lambda_j) &= -\sigma_3\operatorname{res}(m(x,t;\lambda);\lambda_j)\sigma_3,\\
\operatorname{res}(m(x,t;\lambda);\overline{\lambda_j}) &= \lim_{\lambda\to\overline{\lambda_j}} m(x,t;\lambda)\overline{v_j(x,t)}\sigma_+,\\
\operatorname{res}(m(x,t;\lambda);-\overline{\lambda_j}) &= -\sigma_3\operatorname{res}(m(x,t;\lambda);\overline{\lambda_j})\sigma_3,
\end{aligned}$$

where $v_j(x,t):=C_j\exp\{2i(\lambda_j^2x+2\lambda_j^4t)\}$, *and* C_j *are complex constants associated with the direct scattering problem for the operator* $\partial_x-U(x,t;\lambda)$;

d. *as* $\lambda\to\infty$, $\lambda\in\mathbb{C}\setminus(\mathcal{Z}_d\cup\widehat{\Gamma})$,

$$m(x,t;\lambda)=\mathrm{I}+\mathcal{O}(\lambda^{-1}).$$

Proof. Conditions (1)–(4) follow from the results given in [15, 24, 29, 30]. □

LEMMA 2.2. *Let* $||r||_{\mathcal{L}^\infty(\mathbb{R};\mathbb{C})}:=\sup_{\lambda\in\mathbb{R}}|r(\lambda)|<1$. *Then* (1) *the RH problem formulated in Lemma* 2.1 *is uniquely solvable*; (2) $\Psi(x,t;\lambda)=m(x,t;\lambda)\exp\{-i(\lambda^2x+2\lambda^4t)\sigma_3\}$ *is the solution of system* (5) *with*

$$Q(x,t):=2i\lim_{\lambda\to\infty}(\lambda m(x,t;\lambda))_{12}; \tag{11}$$

(3) *the function* $Q(x,t)$ *defined by* (11) *satisfies equation* (3), *and*

$$q(x,t):=Q(x,t)((m^{-1}(x,t;0))_{11})^2 \tag{12}$$

satisfies the DNLSE; *and* (4) $m(x,t;\lambda)$ *possesses the following symmetry reductions:* $m(x,t;\lambda)=\sigma_3m(x,t;-\lambda)\sigma_3$ *and* $m(x,t;\lambda)=\sigma_1\overline{m(x,t;\overline{\lambda})}\sigma_1$.

If $r(\lambda)\in\mathcal{S}(\widehat{\Gamma};\mathbb{C})$, *then, for any* $t\in\mathbb{R}$, $Q(x,t)$ (*resp.*, $q(x,t)$), *as a function of* x, $\in\mathcal{S}(\mathbb{R};\mathbb{C})$.

Proof. The solvability of the RH problem (formulated in Lemma 2.1) is a consequence of Theorem 9.3 in [31] and the vanishing winding number of $1-r(\lambda)\overline{r(\overline{\lambda})}$, $\int_{\widehat{\Gamma}}d(\arg(1-r(\lambda)\overline{r(\overline{\lambda})}))=\sum_{l\in\{\substack{>\\<}\}}\mathrm{s}(l)\mathrm{n}(l)=0$, where $\mathrm{s}(>)=-\mathrm{s}(<)=1$, and $\mathrm{n}(\substack{>\\<}):=\operatorname{card}(\{\lambda_j;\ \Im(\lambda_j^2)\substack{>\\<}0\})$; items (2) and (4) can be verified through straightforward calculations, and the fact that $q(x,t)$ (equation (12)) satisfies the DNLSE follows from Proposition 2.3 and the definition of $m(x,t;\lambda)$. □

Remark 2.2. In fact, in this paper, the solvability of the RH problem for $||r||_{\mathcal{L}^\infty(\mathbb{R};\mathbb{C})}<1$ is proved for all sufficiently large $|t|$: the solvability of the RH problem for $||r||_{\mathcal{L}^\infty(\widehat{\Gamma})}<1$ in the solitonless sector, $\mathcal{Z}_d\equiv\emptyset$, for all sufficiently large $|t|$ was proved in [15]. *Note:* the condition $||r||_{\mathcal{L}^\infty(\widehat{\Gamma})}<1$, which appears in [15], is restrictive and can be replaced by the weaker condition $||r||_{\mathcal{L}^\infty(\mathbb{R};\mathbb{C})}<1$.

Before summarizing the main results of this paper, namely, Theorems 2.1–2.3, some further preamble is required: (1) *the Kaup–Newell parametrization* [28] *is adopted for the discrete eigenvalues,* $\lambda_j:=\Delta_j\exp\{\frac{i}{2}(\pi-\gamma_j)\}$, $\Delta_j>0$, $\gamma_j\in(0,\pi)$, $1\le j\le N$, *and* $\lambda_j^2:=\xi_j+i\eta_j$, *where* $\xi_j=-\Delta_j^2\cos\gamma_j$ *and* $\eta_j=\Delta_j^2\sin\gamma_j$ (*note that, with this parametrization,* $\{\pm\lambda_i\}_{i=1}^N$ (*resp.*, $\{\pm\overline{\lambda_i}\}_{i=1}^N$) *lie in the* 1*st and* 3*rd quadrants* (*resp.*, 2*nd and* 4*th quadrants*) *of the complex plane of the auxiliary spectral parameter,* λ); *and* (2) *it is*

supposed throughout that $\xi_i \neq \xi_j$, $1 \leq i \neq j \leq N$, *so that it is convenient to choose the following enumeration for the points of the discrete spectrum (ordering of the solitons),* $\xi_1 > \cdots > \xi_n > \cdots > \xi_N$.

Remark 2.3. Even though the "symbol" ("notation") $C(z)$ appearing in the various *final* error estimations is *not* the same and should be properly denoted as $C_1(z)$, $C_2(z)$, etc., the simplified "notation" $C(z)$ is retained throughout since the principal concern here is not its explicit functional z-dependence but rather the functional class(es) to which it belongs. Throughout the paper, $M \in \mathbb{R}_{>0}$ is a fixed constant.

Remark 2.4. In Theorems 2.1–2.3 (see below), one should keep the upper signs as $t \to +\infty$ and the lower signs as $t \to -\infty$ everywhere.

THEOREM 2.1. *Let* $m(x,t;\lambda)$ *be the solution of the RH problem formulated in Lemma* 2.1 *with the condition* $||r||_{\mathcal{L}^\infty(\mathbb{R};\mathbb{C})} < 1$ *and* $Q(x,t)$ *be defined by* (11). *Then as* $t \to \pm\infty$ *and* $x \to \mp\infty$ *such that* $\lambda_0 := \frac{1}{2}\sqrt{-\frac{x}{t}} > M$ *and* $(x,t) \in \Omega_n := \{(x,t);\, x - 4t\Delta_n^2 \cos\gamma_n := l_n(t) = \mathcal{O}(1)\}$, *for those* $\gamma_n \in (\frac{\pi}{2}, \pi)$,

and $C(\widehat{\mu}_0) \in \mathcal{S}(\mathbb{R}_{>M};\mathbb{C})$.

One possible application of the asymptotic results obtained in Theorems 2.1–2.3 is associated with the so-called "soliton scattering," namely, the calculation of the position and phase shifts of the nth soliton ($1 \le n \le N$) for $Q(x,t)$, $q(x,t)$, and $u(x,t)$ in the presence of the continuous spectrum: other physical applications of these asymptotic results include, for example, the calculation of the temporal and spectral intensities for the solutions of the DNLSE and MNLSE.

Corollary 2.1.

(A) $Q(x,t)$:

$$\begin{aligned} \Delta x_n^{Q^{\mathcal{S}}} &:= (2\eta_n)^{-1}(\widehat{x}_n^+ - \widehat{x}_n^-) \\ &= \eta_n^{-1} \left\{ \sum_{\substack{l=1 \\ \neq n}}^{N} \operatorname{sgn}(l-n) \ln\left(\frac{|\lambda_n - \lambda_l||\lambda_n + \lambda_l|}{|\lambda_n - \overline{\lambda_l}||\lambda_n + \overline{\lambda_l}|} \right) - \ln\left(\frac{|\delta^+(\lambda_n;\lambda_0)|}{|\delta^-(\lambda_n;\lambda_0)|} \right) \right\}, \end{aligned}$$

$$\begin{aligned} \Delta\phi_n^{Q^{\mathcal{S}}} &:= 2(\widehat{\phi}_n^+ - \widehat{\phi}_n^-) \\ &= 2 \left\{ \sum_{\substack{l=1 \\ \neq n}}^{N} \operatorname{sgn}(l-n) \arg\left(\frac{(\lambda_n - \overline{\lambda_l})(\lambda_n + \overline{\lambda_l})}{(\lambda_n - \lambda_l)(\lambda_n + \lambda_l)} \right) + \arg\left(\frac{\delta^+(\lambda_n;\lambda_0)}{\delta^-(\lambda_n;\lambda_0)} \right) \right\}, \end{aligned}$$

$$\begin{aligned} \Delta x_n^{Q^{\mathcal{S}\prime}} &:= (2\eta_n)^{-1}(\widehat{x}_n^{+\prime} - \widehat{x}_n^{-\prime}) \\ &= \eta_n^{-1} \left\{ \sum_{\substack{l=1 \\ \neq n}}^{N} \operatorname{sgn}(l-n) \ln\left(\frac{|\lambda_n - \lambda_l||\lambda_n + \lambda_l|}{|\lambda_n - \overline{\lambda_l}||\lambda_n + \overline{\lambda_l}|} \right) - \ln\left(\frac{|\delta_\flat^+(\overline{\lambda_n};\mu_0)|}{|\delta_\flat^-(\overline{\lambda_n};\mu_0)|} \right) \right\}, \end{aligned}$$

$$\begin{aligned} \Delta\phi_n^{Q^{\mathcal{S}\prime}} &:= 2(\widehat{\phi}_n^{+\prime} - \widehat{\phi}_n^{-\prime}) \\ &= -2 \left\{ \sum_{\substack{l=1 \\ \neq n}}^{N} \operatorname{sgn}(l-n) \arg\left(\frac{(\lambda_n - \overline{\lambda_l})(\lambda_n + \overline{\lambda_l})}{(\lambda_n - \lambda_l)(\lambda_n + \lambda_l)} \right) - \arg\left(\frac{\delta_\flat^+(\overline{\lambda_n};\mu_0)}{\delta_\flat^-(\overline{\lambda_n};\mu_0)} \right) \right\}; \end{aligned}$$

(B) $q(x,t)$ (DNLSE):

$$\begin{aligned}
\Delta x_n^{q^{\mathcal{S}}} &= \Delta x_n^{Q^{\mathcal{S}}},\\
\Delta\phi_n^{q^{\mathcal{S}}} &= \Delta\phi_n^{Q^{\mathcal{S}}} - 4\sum_{\substack{l=1\\ \neq n}}^{N}\operatorname{sgn}(l-n)\gamma_l + \mathcal{Y}_+(\lambda_0) - \mathcal{Y}_-(\lambda_0),\\
\Delta x_n^{q^{\mathcal{S}\prime}} &= \Delta x_n^{Q^{\mathcal{S}\prime}},\\
\Delta\phi_n^{q^{\mathcal{S}\prime}} &= \Delta\phi_n^{Q^{\mathcal{S}\prime}} + 4\sum_{\substack{l=1\\ \neq n}}^{N}\operatorname{sgn}(l-n)\gamma_l + \mathcal{Y}'_+(\mu_0) - \mathcal{Y}'_-(\mu_0);
\end{aligned}$$

(C) $u(x,t)$ (MNLSE):

$$\begin{aligned}
\Delta x_n^{u^{\mathcal{S}}} &= \Delta x_n^{Q^{\mathcal{S}}}\big|_{\lambda_0\to\widehat{\lambda}_0},\\
\Delta\phi_n^{u^{\mathcal{S}}} &= \Delta\phi_n^{q^{\mathcal{S}}}\big|_{\lambda_0\to\widehat{\lambda}_0},\\
\Delta x_n^{u^{\mathcal{S}\prime}} &= \Delta x_n^{Q^{\mathcal{S}\prime}}\big|_{\mu_0\to\widehat{\mu}_0},\\
\Delta\phi_n^{u^{\mathcal{S}\prime}} &= \Delta\phi_n^{q^{\mathcal{S}\prime}}\big|_{\mu_0\to\widehat{\mu}_0}.
\end{aligned}$$

Proof. The proof follows from the definition of soliton position and phase shifts given in [4] and Theorems 2.1–2.3, equations (16), (17), (33), (34), (48), (53), (60), (61), (69), (74), (75), and (83). □

Remark 2.5. The expressions for the soliton phase shifts given in Corollary 2.1, namely, $\Delta\phi_n^{Q^{\mathcal{S}}}$, $\Delta\phi_n^{Q^{\mathcal{S}\prime}}$, $\Delta\phi_n^{q^{\mathcal{S}}}$, $\Delta\phi_n^{q^{\mathcal{S}\prime}}$, $\Delta\phi_n^{u^{\mathcal{S}}}$, and $\Delta\phi_n^{u^{\mathcal{S}\prime}}$, $1\le n\le N$, are to be understood $\operatorname{mod}(2\pi)$.

Remark 2.6. For the asymptotics of the $\mathbb{C}$-valued functions $Q(x,t)$, $q(x,t)$, and $u(x,t)$, one must actually consider four different cases, depending, resp., on the quadrant of the (x,t)-plane. In this paper, the proof of the asymptotic expansions for $Q(x,t)$ and $q(x,t)$ (resp., $u(x,t)$) is presented for the cases $(x,t)\to(\mp\infty,\pm\infty)$ (resp., $(x,t)\to(\pm\infty,\pm\infty)$) such that $\lambda_0 > M$ and $(x,t)\in\Omega_n$ (resp., $\widehat{\lambda}_0 > M$ and $(x,t)\in\widetilde{\Omega}_n$) for those $\gamma_n\in(\frac{\pi}{2},\pi)$: the results for the remaining domains of the (x,t)-plane are obtained analogously. If the conditions on γ_n stated in Theorems 2.1–2.3 are violated, then $(x,t)\in\{\mathbb{R}^2\setminus\Omega_n, \mathbb{R}^2\setminus\widetilde{\Omega}_n, \mathbb{R}^2\setminus\mho_n, \mathbb{R}^2\setminus\widetilde{\mho}_n\}$, but the asymptotic results stated still remain valid although the second terms on the right-hand sides of the asymptotic expansions become the leading-order terms of the corresponding asymptotic expansions, while the remaining terms are exponentially small and negligible with respect to the given error estimations.

3. The model RH problem. In order to simplify the asymptotic analysis of the original RH problem formulated in Lemma 2.1, a simpler, model RH problem (see Lemma 3.3) is derived in this section. As an intermediate step towards the formulation of the model RH problem, it will be convenient to derive an "extended" RH problem (see Lemma 3.2): the general idea pertaining to the transformations from the original RH problem to the model one is elucidated in the paragraph following Lemma 3.1 (see below).

PROPOSITION 3.1 (see [15]). *In the solitonless sector* ($\mathcal{Z}_d \equiv \emptyset$), *as* $t \to +\infty$ *and* $x \to -\infty$ *such that* $\lambda_0 := \frac{1}{2}\sqrt{-\frac{x}{t}} > M$,

$$m(x,t;\lambda) = \Delta(\lambda) + \mathcal{O}\left(\frac{C(\lambda_0)}{\sqrt{t}}\right),$$

where $\Delta(\lambda) := (\delta^+(\lambda;\lambda_0))^{\sigma_3}$,

$$\delta^+(\lambda;\lambda_0) = \left(\left(\frac{\lambda-\lambda_0}{\lambda}\right)\left(\frac{\lambda+\lambda_0}{\lambda}\right)\right)^{i\nu} \exp\left\{\sum_{l\in\{\pm\}} (\rho_l(\lambda) + \widehat{\rho}_l(\lambda))\right\},$$

$$\rho_\pm(\lambda) = \frac{1}{2\pi i}\int_0^{\pm\lambda_0} \ln\left(\frac{1-|r(\varsigma)|^2}{1-|r(\lambda_0)|^2}\right)\frac{d\varsigma}{(\varsigma-\lambda)}, \qquad \widehat{\rho}_\pm(\lambda) = \int_{\pm i\infty}^{i0} \frac{\ln(1-r(\varsigma)\overline{r(\bar{\varsigma})})}{(\varsigma-\lambda)}\frac{d\varsigma}{2\pi i},$$

$\nu := \nu(\lambda_0)$ *is given by* (21), $||(\delta^+(\cdot;\lambda_0))^{\pm 1}||_{\mathcal{L}^\infty(\mathbb{C};\mathbb{C})} := \sup_{\lambda\in\mathbb{C}} |(\delta^+(\lambda;\lambda_0))^{\pm 1}| < \infty$, $\overline{(\delta^+(\pm\overline{\lambda};\lambda_0))^{-1}} = \delta^+(\lambda;\lambda_0)$, *the principal branch of the logarithmic function is taken*, $\ln(\mu-\lambda) := \ln|\mu-\lambda| + i\arg(\mu-\lambda)$, $\arg(\mu-\lambda) \in (-\pi,\pi)$, *and* $C(\lambda_0) \in \mathcal{S}(\mathbb{R}_{>M}; M_2(\mathbb{C}))$.

Remark 3.1. For notational convenience, until the end of section 5, all explicit x,t dependencies are suppressed, except where absolutely necessary, and $\delta^+(\lambda;\lambda_0) := \delta(\lambda)$.

LEMMA 3.1. *There exists a unique solution* $m^\Delta(\lambda): \mathbb{C}\setminus(\mathcal{Z}_d \cup \widehat{\Gamma}) \to \mathrm{SL}(2,\mathbb{C})$ *of the following RH problem:*

1. $m^\Delta(\lambda)$ *is meromorphic for all* $\lambda \in \mathbb{C}\setminus\widehat{\Gamma}$,
2. $$m_+^\Delta(\lambda) = m_-^\Delta(\lambda) v^\Delta(\lambda), \quad \lambda \in \widehat{\Gamma},$$
   where
   $$v^\Delta(\lambda) = e^{-i\theta(\lambda)\mathrm{ad}(\sigma_3)} \begin{pmatrix} (1-r(\lambda)\overline{r(\overline{\lambda})})\delta_-(\lambda)(\delta_+(\lambda))^{-1} & r(\lambda)\delta_-(\lambda)\delta_+(\lambda) \\ -\overline{r(\overline{\lambda})}(\delta_-(\lambda))^{-1}(\delta_+(\lambda))^{-1} & (\delta_-(\lambda))^{-1}\delta_+(\lambda) \end{pmatrix},$$
   and $\theta(\lambda) := \lambda^2 x + 2\lambda^4 t$,
3. $m^\Delta(\lambda)$ *has simple poles at* $\{\pm\lambda_i, \pm\overline{\lambda_i}\}_{i=1}^N$ *with* $(1 \le i \le N)$,
   $$\begin{aligned} \mathrm{res}(m^\Delta(\lambda);\lambda_i) &= \lim_{\lambda\to\lambda_i} m^\Delta(\lambda) v_i (\delta(\lambda_i))^{-2}\sigma_-, \\ \mathrm{res}(m^\Delta(\lambda);-\lambda_i) &= -\sigma_3 \mathrm{res}(m^\Delta(\lambda);\lambda_i)\sigma_3, \\ \mathrm{res}(m^\Delta(\lambda);\overline{\lambda_i}) &= \lim_{\lambda\to\overline{\lambda_i}} m^\Delta(\lambda)\overline{v_i}(\delta(\overline{\lambda_i}))^2\sigma_+, \\ \mathrm{res}(m^\Delta(\lambda);-\overline{\lambda_i}) &= -\sigma_3 \mathrm{res}(m^\Delta(\lambda);\overline{\lambda_i})\sigma_3, \end{aligned}$$
4. *as* $\lambda \to \infty$, $\lambda \in \mathbb{C}\setminus(\mathcal{Z}_d \cup \widehat{\Gamma})$,
   $$m^\Delta(\lambda) = \mathrm{I} + \mathcal{O}(\lambda^{-1});$$

moreover, $Q(x,t) = 2i\lim_{\lambda\to\infty}(\lambda m^\Delta(x,t;\lambda))_{12}$ *is equal to* $Q(x,t)$ *in Lemma* 2.2, (11).

Proof. Let $m(\lambda)$ be the solution of the RH problem formulated in Lemma 2.1. Define $m^\Delta(\lambda) := m(\lambda)(\Delta(\lambda))^{-1}$. □

In order to motivate Proposition 3.2 and Lemma 3.2 (see below), consider the trajectory of the nth soliton with $\gamma_n \in (\frac{\pi}{2},\pi)$ in the (x,t)-plane which belongs to

the set $\Omega_n := \{(x,t);\, x - 4t\Delta_n^2 \cos\gamma_n = \mathcal{O}(1)\}$, and note from Lemma 2.1 and the soliton ordering in section 2 that, as $t \to +\infty$ and $x \to -\infty$ such that $\lambda_0 > M$ and $(x,t) \in \Omega_n$: (1) $\Re(v_i|_{\Omega_n}) \sim \mathcal{O}(\exp\{-8t\eta_i(\xi_i - \xi_n)\}) \to 0 \,\forall\, i < n$ $(i \in \{1,2,\dots,n-1\})$; (2) $\Re(v_i|_{\Omega_n}) \to \infty \,\forall\, i > n$ $(i \in \{n+1, n+2, \dots, N\})$; and (3) $\Re(v_i|_{\Omega_n}) \sim \mathcal{O}(1)$ for $i = n$. Thus, along the trajectory of the arbitrarily fixed nth soliton, there are exponentially growing polar conditions for solitons i with $n+1 \le i \le N$. One must effectively deal with such growing polar conditions in a self-consistent manner. In a recent paper [33] devoted to the asymptotics of the Toda rarefaction problem, Deift et al. showed how this could be done: they noticed that it is possible to replace the poles with the exponentially growing polar conditions by jump matrices on small, mutually disjoint (*and* disjoint with respect to $\widehat{\Gamma}$) circles such that these jump matrices behave like I + exponentially decreasing terms as $t \to +\infty$. Thus, instead of the original RH problem, one gets a new, "extended" RH problem with $4(N-n)$ fewer poles, and $4(N-n)$ additional circles with jump conditions stated on them. Finally, by removing the added circles from the specification of the extended RH problem, one arrives at the model RH problem: the estimation of the "difference" between the extended and model RH problems shows that the solution of the model RH problem approximates the solution of the original one modulo terms which are decaying exponentially as $t \to +\infty$.

PROPOSITION 3.2. *Introduce arbitrarily small, clockwise and counterclockwise-oriented, mutually disjoint (and disjoint with respect to $\widehat{\Gamma}$) circles $K_j^{\pm}$ and $L_j^{\pm}$, $n+1 \le j \le N$, around the eigenvalues $\{\pm\lambda_j\}_{j=n+1}^N$ and $\{\pm\overline{\lambda_j}\}_{j=n+1}^N$, resp., and define*

$$m^{\flat}(\lambda) := \begin{cases} m^{\Delta}(\lambda), \quad \lambda \in \mathbb{C} \setminus \left(\widehat{\Gamma} \cup \left(\bigcup_{i=n+1}^{N} (K_i^{\pm} \cup L_i^{\pm}) \right) \right), \\ m^{\Delta}(\lambda)\Big(\mathrm{I} - \frac{v_i(\delta(\pm\lambda_i))^{-2}}{(\lambda \mp \lambda_i)} \sigma_- \Big), \quad \lambda \in \mathrm{int} K_i^{\pm}, \quad n+1 \le i \le N, \\ m^{\Delta}(\lambda)\Big(\mathrm{I} + \frac{\overline{v_i}(\delta(\pm\overline{\lambda_i}))^{2}}{(\lambda \mp \overline{\lambda_i})} \sigma_+ \Big), \quad \lambda \in \mathrm{int} L_i^{\pm}, \quad n+1 \le i \le N. \end{cases} \tag{85}$$

Then $m^{\flat}(\lambda)$ solves a RH problem on $(\sigma_{\mathcal{L}} \setminus \cup_{i=n+1}^N (\{\pm\lambda_i\} \cup \{\pm\overline{\lambda_i}\})) \cup (\cup_{i=n+1}^N (K_i^{\pm} \cup L_i^{\pm}))$ with the same jumps as $m^{\Delta}(\lambda)$ on $\widehat{\Gamma}$, $m_+^{\flat}(\lambda) = m_-^{\flat}(\lambda) v^{\Delta}(\lambda)$, and

$$m_+^{\flat}(\lambda) = \begin{cases} m_-^{\flat}(\lambda)\Big(\mathrm{I} + \frac{v_i(\delta(\pm\lambda_i))^{-2}}{(\lambda \mp \lambda_i)} \sigma_- \Big), \quad \lambda \in K_i^{\pm}, \quad n+1 \le i \le N, \\ m_-^{\flat}(\lambda)\Big(\mathrm{I} + \frac{\overline{v_i}(\delta(\pm\overline{\lambda_i}))^{2}}{(\lambda \mp \overline{\lambda_i})} \sigma_+ \Big), \quad \lambda \in L_i^{\pm}, \quad n+1 \le i \le N. \end{cases}$$

Proof. The proof follows from Lemma 3.1 and the definition of $m^{\flat}(\lambda)$. ∎

Remark 3.2. The superscripts $\pm$ on $\{K_i^{\pm}\}_{i=n+1}^N$ and $\{L_i^{\pm}\}_{i=n+1}^N$, which are related to $\{\pm\lambda_i\}_{i=n+1}^N$ and $\{\pm\overline{\lambda_i}\}_{i=n+1}^N$, resp., should *not* be confused with the subscripts $\pm$ appearing in the various RH problems in sections 3–5, namely, $m_{\pm}(\lambda)$, $m_{\pm}^{\Delta}(\lambda)$, $m_{\pm}^{\flat}(\lambda)$, $m_{\pm}^{\sharp}(\lambda)$, $\chi_{\pm}(\lambda)$, $E_{\pm}(\lambda)$, and $\chi_{\pm}^{c}(\lambda)$.

Remark 3.3. Even though the exponentially growing polar (residue) conditions have been replaced by jump matrices, it should be noted that, along the trajectory of soliton n, these jump matrices are also exponentially growing as $t \to +\infty$. These lower/upper diagonal, exponentially growing jump matrices are now replaced, through a sequence of $N-n$ similar transformations, by upper/lower diagonal jump matrices which converge, along the trajectory of soliton n, to I as $t \to +\infty$.

LEMMA 3.2. *Set*

(86)
$$m^\sharp(\lambda):=\begin{cases} m^\flat(\lambda)\prod\limits_{l=n+1}^{N}(d_{l_+}(\lambda))^{-\sigma_3}, & \lambda\in\mathbb{C}\setminus\left(\widehat{\Gamma}\cup\left(\bigcup\limits_{i=n+1}^{N}(K_i^\pm\cup L_i^\pm)\right)\right),\\ m^\flat(\lambda)(J_{K_i^\pm}(\lambda))^{-1}\prod\limits_{l=n+1}^{N}(d_{l_-}(\lambda))^{-\sigma_3}, & \lambda\in\operatorname{int}K_i^\pm,\quad n+1\le i\le N,\\ m^\flat(\lambda)(J_{L_i^\pm}(\lambda))^{-1}\prod\limits_{l=n+1}^{N}(d_{l_-}(\lambda))^{-\sigma_3}, & \lambda\in\operatorname{int}L_i^\pm,\quad n+1\le i\le N,\end{cases}$$

where

(87)
$$d_{l_+}(\lambda):=\tfrac{(\lambda-\overline{\lambda_l})(\lambda+\overline{\lambda_l})}{(\lambda-\lambda_l)(\lambda+\lambda_l)},\quad \lambda\in\mathbb{C}\setminus\left(\bigcup_{i=n+1}^{N}(K_i^\pm\cup L_i^\pm)\right),\quad n+1\le l\le N,$$
$$d_{l_-}(\lambda):=\begin{cases}\frac{(\lambda-\overline{\lambda_l})(\lambda+\overline{\lambda_l})}{(\lambda\pm\lambda_l)}, & \lambda\in\bigcup\limits_{i=n+1}^{N}\operatorname{int}K_i^\pm,\quad n+1\le l\le N,\\ \frac{(\lambda\pm\overline{\lambda_l})}{(\lambda-\lambda_l)(\lambda+\lambda_l)}, & \lambda\in\bigcup\limits_{i=n+1}^{N}\operatorname{int}L_i^\pm,\quad n+1\le l\le N,\end{cases}$$

and the SL(2,$\mathbb{C}$)*-valued, holomorphic in* $\operatorname{int}K_i^\pm$ *and* $\operatorname{int}L_i^\pm$, *resp., functions* $J_{K_i^\pm}(\lambda)$ *and* $J_{L_i^\pm}(\lambda)$, $n{+}1\le i\le N$, *are given by*

$$J_{K_i^\pm}(\lambda)=\begin{pmatrix}\dfrac{\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}^{-1}(\lambda)}-\frac{v_i(\delta(\pm\lambda_i))^{-2}C_i^\sharp}{(d_{i_-}(\lambda))^2}\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}(\lambda)}}{(\lambda\mp\lambda_i)}, & \dfrac{C_i^\sharp}{(d_{i_-}(\lambda))^2}\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}(\lambda)}\\ -v_i(\delta(\pm\lambda_i))^{-2}\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}(\lambda)}{d_{l_+}(\lambda)}, & (\lambda\mp\lambda_i)\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}(\lambda)}{d_{l_+}(\lambda)}\end{pmatrix},$$
$$J_{L_i^\pm}(\lambda)=\begin{pmatrix}(\lambda\mp\overline{\lambda_i})\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}^{-1}(\lambda)}, & \overline{v_i}(\delta(\pm\overline{\lambda_i}))^2\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}^{-1}(\lambda)}\\ -\frac{\overline{C_i^\sharp}}{(d_{i_-}(\overline{\lambda}))^{-2}}\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}(\lambda)}{d_{l_+}^{-1}(\lambda)}, & \dfrac{\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}(\lambda)}{d_{l_+}(\lambda)}-\frac{\overline{v_i}(\delta(\pm\overline{\lambda_i}))^2\overline{C_i^\sharp}}{(d_{i_-}(\lambda))^{-2}}\prod\limits_{l=n+1}^{N}\frac{d_{l_-}(\lambda)}{d_{l_+}^{-1}(\lambda)}}{(\lambda\mp\overline{\lambda_i})}\end{pmatrix},$$

with

(88)
$$C_i^\sharp=(v_i)^{-1}(\delta(\pm\lambda_i))^2(d_{i_-}(\pm\lambda_i))^2\prod_{\substack{l=n+1\\ \neq i}}^{N}(d_{l_+}(\pm\lambda_i))^2,\qquad n+1\le i\le N.$$

Then $m^\sharp(\lambda)\colon\mathbb{C}\setminus((\mathcal{Z}_d\setminus\cup_{i=n+1}^{N}(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\}))\cup(\widehat{\Gamma}\cup(\cup_{i=n+1}^{N}(K_i^\pm\cup L_i^\pm))))\to\mathrm{SL}(2,\mathbb{C})$ *solves the following, extended RH problem on* $(\sigma_{\mathcal{L}}\setminus\cup_{i=n+1}^{N}(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\}))\cup(\cup_{i=n+1}^{N}(K_i^\pm\cup L_i^\pm))$:

$$m_+^\sharp(\lambda)=m_-^\sharp(\lambda)e^{-i\theta(\lambda)\mathrm{ad}(\sigma_3)}v^\sharp(\lambda),$$

where

$$v^{\sharp}(\lambda)|_{\widehat{\Gamma}}=\begin{pmatrix} (1-r(\lambda)\overline{r(\overline{\lambda})})\frac{\delta_-(\lambda)}{\delta_+(\lambda)}, & \frac{r(\lambda)}{(\delta_-(\lambda)\delta_+(\lambda))^{-1}}\prod_{l=n+1}^{N}\left(\frac{(\lambda-\overline{\lambda_l})(\lambda+\overline{\lambda_l})}{(\lambda-\lambda_l)(\lambda+\lambda_l)}\right)^2 \\ -\frac{\overline{r(\overline{\lambda})}}{\delta_-(\lambda)\delta_+(\lambda)}\prod_{l=n+1}^{N}\left(\frac{(\lambda-\overline{\lambda_l})(\lambda+\overline{\lambda_l})}{(\lambda-\lambda_l)(\lambda+\lambda_l)}\right)^{-2}, & \frac{\delta_+(\lambda)}{\delta_-(\lambda)} \end{pmatrix},$$

$$v^{\sharp}(\lambda)=\begin{cases} \mathrm{I}+\frac{(v_i)^{-1}(\delta(\pm\lambda_i))^2}{(\lambda\mp\lambda_i)}\left(\frac{\lambda_i^2-\overline{\lambda_i}^2}{2\lambda_i}\right)^2\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\left(\frac{\overline{\lambda_l}^2-\lambda_i^2}{\lambda_l^2-\lambda_i^2}\right)^2\sigma_+, & \lambda\in\bigcup\limits_{i=n+1}^{N}K_i^{\pm}, \\ \mathrm{I}+\frac{(\overline{v_i})^{-1}(\delta(\pm\overline{\lambda_i}))^{-2}}{(\lambda\mp\overline{\lambda_i})}\left(\frac{\lambda_i^2-\overline{\lambda_i}^2}{2\overline{\lambda_i}}\right)^2\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\left(\frac{\lambda_l^2-\overline{\lambda_i}^2}{\overline{\lambda_l}^2-\overline{\lambda_i}^2}\right)^2\sigma_-, & \lambda\in\bigcup\limits_{i=n+1}^{N}L_i^{\pm}, \end{cases} \tag{89}$$

with polar (*residue*) *conditions*,

$$\mathrm{res}(m^{\sharp}(\lambda);\lambda_i)=\lim_{\lambda\to\lambda_i}m^{\sharp}(\lambda)v_i(\delta(\lambda_i))^{-2}\prod_{l=n+1}^{N}\left(\frac{(\lambda_i-\lambda_l)(\lambda_i+\lambda_l)}{(\lambda_i-\overline{\lambda_l})(\lambda_i+\overline{\lambda_l})}\right)^2\sigma_-,\quad 1\le i\le n,$$

$$\mathrm{res}(m^{\sharp}(\lambda);-\lambda_i)=-\sigma_3\mathrm{res}(m^{\sharp}(\lambda);\lambda_i)\sigma_3,\quad 1\le i\le n,$$

$$\mathrm{res}(m^{\sharp}(\lambda);\overline{\lambda_i})=\lim_{\lambda\to\overline{\lambda_i}}m^{\sharp}(\lambda)\overline{v_i}(\delta(\overline{\lambda_i}))^2\prod_{l=n+1}^{N}\left(\frac{(\overline{\lambda_i}-\overline{\lambda_l})(\overline{\lambda_i}+\overline{\lambda_l})}{(\overline{\lambda_i}-\lambda_l)(\overline{\lambda_i}+\lambda_l)}\right)^2\sigma_+,\quad 1\le i\le n,$$

$$\mathrm{res}(m^{\sharp}(\lambda);-\overline{\lambda_i})=-\sigma_3\mathrm{res}(m^{\sharp}(\lambda);\overline{\lambda_i})\sigma_3,\quad 1\le i\le n,$$

and, as $\lambda\to\infty$, $\lambda\in\mathbb{C}\backslash((\mathcal{Z}_d\backslash\cup_{i=n+1}^{N}(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\}))\cup(\widehat{\Gamma}\cup(\cup_{i=n+1}^{N}(K_i^{\pm}\cup L_i^{\pm}))))$,

$$m^{\sharp}(\lambda)=\mathrm{I}+\mathcal{O}(\lambda^{-1});$$

moreover, $Q(x,t)=2i\lim_{\lambda\to\infty}(\lambda m^{\sharp}(x,t;\lambda))_{12}$ *is equal to* $Q(x,t)$ *in Lemma* 2.2, (11).

Proof. The proof is presented for the eigenvalues $\{\lambda_i\}_{i=n+1}^{N}$, around which are defined the small, clockwise-oriented, mutually disjoint circles $\{K_i^{+}\}_{i=n+1}^{N}$: the proof for the eigenvalues $\{-\lambda_i\}_{i=n+1}^{N}$ and $\{\pm\overline{\lambda_i}\}_{i=n+1}^{N}$ follows in an analogous manner. From the definition of $m^{\sharp}(\lambda)$ and Proposition 3.2, one sees that, on $\{K_i^{+}\}_{i=n+1}^{N}$, $m^{\sharp}(\lambda)$ solves the following RH problem ($\lambda\in\cup_{i=n+1}^{N}K_i^{+}$):

$$m_+^{\sharp}(\lambda)=m_-^{\sharp}(\lambda)\underbrace{\prod_{l=n+1}^{N}(d_{l_-}(\lambda))^{\sigma_3}J_{K_i^{+}}(\lambda)\left(\mathrm{I}+\frac{v_i(\delta(\lambda_i))^{-2}}{(\lambda-\lambda_i)}\sigma_-\right)\prod_{l=n+1}^{N}(d_{l_+}(\lambda))^{-\sigma_3}}_{\text{jump matrix}}.$$

Demanding that the above "jump matrix" be equal to the following upper triangular form, $\mathrm{I}+\frac{C_i^{\sharp}}{(\lambda-\lambda_i)}\sigma_+$, $n+1\le i\le N$, one shows that

$$J_{K_i^{+}}(\lambda)=\begin{pmatrix} \frac{d_{i_+}(\lambda)}{d_{i_-}(\lambda)}\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_+}(\lambda)}{d_{l_-}(\lambda)}-\frac{v_i(\delta(\lambda_i))^{-2}C_i^{\sharp}\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}(\lambda)}}{(\lambda-\lambda_i)^2d_{i_-}(\lambda)d_{i_+}(\lambda)}, & \frac{C_i^{\sharp}}{(\lambda-\lambda_i)}\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}(\lambda)}\frac{}{d_{i_-}(\lambda)d_{i_+}(\lambda)} \\ -\frac{v_i(\delta(\lambda_i))^{-2}}{(\lambda-\lambda_i),}\frac{d_{i_-}(\lambda)}{d_{i_+}(\lambda)}\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}(\lambda)}{d_{l_+}(\lambda)}, & \frac{d_{i_-}(\lambda)}{d_{i_+}(\lambda)}\prod\limits_{\substack{l=n+1\\ \neq i}}^{N}\frac{d_{l_-}(\lambda)}{d_{l_+}(\lambda)} \end{pmatrix}.$$

Note that $\det(J_{K_i^+}(\lambda))=1$ $(n+1\le i\le N)$. Defining, for $n+1\le l\le N$, $d_{l_+}(\lambda)$ and $d_{l_-}(\lambda)$ as in (87), and choosing $C_i^\sharp$, $n+1\le i\le N$, as in (88) (with $+\lambda_i$), one gets the expression for $J_{K_i^+}(\lambda)$ (which is holomorphic for all $\lambda\in\cup_{i=n+1}^N \mathrm{int}K_i^+$) given in the lemma; also, because of the symmetry properties of $\delta(\lambda)$ (Proposition 3.1), $\overline{C_i^\sharp}=(\overline{v_i})^{-1}(\delta(\pm\overline{\lambda_i}))^{-2}\cdot(d_{i_-}(\pm\overline{\lambda_i}))^{-2}\prod_{\substack{l=n+1\\ \neq i}}^N(d_{l_+}(\pm\overline{\lambda_i}))^{-2}$. The remainder of the proof is a consequence of Lemma 3.1, Proposition 3.2, and the definition of $m^\sharp(\lambda)$. □

Remark 3.4. Even though, along the trajectory of soliton n, all the initial, exponentially growing nilpotent residue matrices have been replaced by jump matrices which tend to I as $t\to+\infty$, i.e., $\exists\,\varepsilon\in\mathbb{R}_{>0}$ such that $\forall\, i\in\{n+1,n+2,\dots,N\}$ $|(v_i|_{\Omega_n})^{-1}|\sim\mathcal{O}(\exp\{-\varepsilon t\})$, it does not necessarily follow that elements in the solution of the extended RH problem for $m^\sharp(\lambda)$ cannot grow exponentially; for example, note that the $(2\,1)$-elements of $J_{K_i^\pm}(\lambda)$ and the $(1\,2)$-elements of $J_{L_i^\pm}(\lambda)$, $n+1\le i\le N$, grow exponentially.

By estimating the error, along the trajectory of soliton n $(1\le n\le N)$, when the jump matrices on $\{K_i^\pm,L_i^\pm\}_{i=n+1}^N$ are removed from the specification of the RH problem for $m^\sharp(\lambda)$, one gets the following—asymptotically solvable—model RH problem.

LEMMA 3.3. *Let* $\chi(\lambda)$ *solve the following RH problem on* $\sigma_{\mathcal{L}}\setminus\cup_{i=n+1}^N(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\})$:

$$\chi_+(\lambda)=\chi_-(\lambda)e^{-i\theta(\lambda)\mathrm{ad}(\sigma_3)}v^\sharp(\lambda)|_{\widehat{\Gamma}},\qquad \lambda\in\widehat{\Gamma},$$

with polar (*residue*) *conditions*

$$\begin{aligned}
\mathrm{res}(\chi(\lambda);\lambda_i)&=\lim_{\lambda\to\lambda_i}\chi(\lambda)v_i(\delta(\lambda_i))^{-2}\prod_{l=n+1}^N\left(\frac{(\lambda_i-\lambda_l)(\lambda_i+\lambda_l)}{(\lambda_i-\overline{\lambda_l})(\lambda_i+\overline{\lambda_l})}\right)^2\sigma_-,\qquad 1\le i\le n,\\
\mathrm{res}(\chi(\lambda);-\lambda_i)&=-\sigma_3\mathrm{res}(\chi(\lambda);\lambda_i)\sigma_3,\qquad 1\le i\le n,\\
\mathrm{res}(\chi(\lambda);\overline{\lambda_i})&=\lim_{\lambda\to\overline{\lambda_i}}\chi(\lambda)\overline{v_i}(\delta(\overline{\lambda_i}))^{2}\prod_{l=n+1}^N\left(\frac{(\overline{\lambda_i}-\overline{\lambda_l})(\overline{\lambda_i}+\overline{\lambda_l})}{(\overline{\lambda_i}-\lambda_l)(\overline{\lambda_i}+\lambda_l)}\right)^2\sigma_+,\qquad 1\le i\le n,\\
\mathrm{res}(\chi(\lambda);-\overline{\lambda_i})&=-\sigma_3\mathrm{res}(\chi(\lambda);\overline{\lambda_i})\sigma_3,\qquad 1\le i\le n,
\end{aligned}$$

and, as $\lambda\to\infty$, $\lambda\in\mathbb{C}\setminus(\cup_{i=1}^n(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\})\cup\widehat{\Gamma})$,

$$\chi(\lambda)=\mathrm{I}+\mathcal{O}(\lambda^{-1}).$$

Then as $t\to+\infty$ *and* $x\to-\infty$ *such that* $\lambda_0>M$, *and* $(x,t)\in\Omega_n$, *the function* $E(\lambda):=m^\sharp(\lambda)(\chi(\lambda))^{-1}$ *has the following asymptotics:*

$$E(\lambda)=\mathrm{I}+\mathcal{O}(F(\lambda;\lambda_0)\exp\{-abt\}),\tag{90}$$

where $||F(\cdot;\lambda_0)||_{\mathcal{L}^\infty(\mathbb{C};M_2(\mathbb{C}))}<\infty$, $||F(\lambda;\cdot)||_{\mathcal{L}^\infty(\mathbb{R}_{>M};M_2(\mathbb{C}))}<\infty$, $F(\lambda;\lambda_0)\sim\mathcal{O}\left(\frac{C(\lambda_0)}{\lambda}\right)$ *as* $\lambda\to\infty$ *with* $C(\lambda_0)\in\mathcal{L}^\infty(\mathbb{R}_{>M};M_2(\mathbb{C}))$, $a:=8\min\{\eta_i\}_{i=n+1}^N\,(>0)$, *and* $b:=\min\{|\xi_n-\xi_i|\}_{i=n+1}^N$.

Proof. Writing, for $n+1\le i\le N$, (89) in the following form:

$$v^\sharp(\lambda):=\begin{cases}\mathrm{I}+(v_i)^{-1}\widetilde{\mathcal{W}}_{K_i^\pm}(\lambda)\sigma_+, & \lambda\in\bigcup_{i=n+1}^N K_i^\pm,\\ \mathrm{I}+(\overline{v_i})^{-1}\widetilde{\mathcal{W}}_{L_i^\pm}(\lambda)\sigma_-, & \lambda\in\bigcup_{i=n+1}^N L_i^\pm,\end{cases}$$

consider the "error function" $E(\lambda)$ defined in the lemma. One notes that (1) $\det(E(\lambda)) = 1$; (2) $E(\lambda)$ has no poles; and (3) $E(\lambda)$ solves the following RH problem on the oriented contour $\Sigma_E := \cup_{i=n+1}^{N}(K_i^+ \cup K_i^- \cup L_i^+ \cup L_i^-)$:

$$E_+(\lambda) = E_-(\lambda)\left(\mathrm{I} + (v_i)^{-1}\widetilde{\mathcal{W}}_{K_i^{\pm}}(\lambda)\begin{pmatrix} -\chi_{11}(\lambda)\chi_{21}(\lambda) & (\chi_{11}(\lambda))^2 \\ -(\chi_{21}(\lambda))^2 & \chi_{11}(\lambda)\chi_{21}(\lambda) \end{pmatrix}\right), \quad \lambda \in K_i^{\pm},$$

$$E_+(\lambda) = E_-(\lambda)\left(\mathrm{I} + (\overline{v_i})^{-1}\widetilde{\mathcal{W}}_{L_i^{\pm}}(\lambda)\begin{pmatrix} \chi_{12}(\lambda)\chi_{22}(\lambda) & -(\chi_{12}(\lambda))^2 \\ (\chi_{22}(\lambda))^2 & -\chi_{12}(\lambda)\chi_{22}(\lambda) \end{pmatrix}\right), \quad \lambda \in L_i^{\pm},$$

$n+1 \le i \le N$, and, as $\lambda \to \infty$, $\lambda \in \mathbb{C} \setminus \Sigma_E$, $E(\lambda) = \mathrm{I} + \mathcal{O}(\lambda^{-1})$. Now, writing the RH problem for $E(\lambda)$ on the oriented contour Σ_E in terms of an equivalent system of linear singular integral equations, using the explicit asymptotic solution of the model RH problem for $\chi(\lambda)$ given in section 4, recalling that, as $t \to +\infty$ and $x \to -\infty$ such that $\lambda_0 > M$ and $(x,t) \in \Omega_n$, $(v_i|_{\Omega_n})^{-1} \sim \mathcal{O}(\exp\{-8t\eta_i|\xi_n - \xi_i|\})$, $n+1 \le i \le N$, and proceeding as in the proof of Lemma 3.3 in [33], one deduces the estimate in (90). □

4. Asymptotic solution of the model RH problem. In this section, the asymptotic (as $t \to +\infty$ and $x/t \sim \mathcal{O}(1)$) solution of the model RH problem (Lemma 3.3) for the Schwartz class of nonreflectionless generic potentials ($r(\lambda) \in \mathcal{S}(\widehat{\Gamma};\mathbb{C})$) is presented. Before doing so, however, recall the following well-known fact from the matrix RH theory [22, 24].

PROPOSITION 4.1. *The solution of the model RH problem* (*Lemma* 3.3), $\chi(\lambda)\colon \mathbb{C} \setminus (\widehat{\Gamma} \cup (\cup_{i=1}^{n}(\{\pm\lambda_i\} \cup \{\pm\overline{\lambda_i}\}))) \to \mathrm{SL}(2,\mathbb{C})$, *has the following representation:*

$$\chi(\lambda) = \chi_d(\lambda) + \int_{\widehat{\Gamma}} \frac{\chi_-(\varrho)(v^{\sharp}(\varrho)|_{\widehat{\Gamma}} - \mathrm{I})}{(\varrho - \lambda)} \frac{d\varrho}{2\pi i}, \tag{91}$$

where

$$\chi_d(\lambda) = \mathrm{I} + \sum_{i=1}^{n}\left(\frac{\mathrm{res}(\chi(\lambda);\lambda_i)}{(\lambda - \lambda_i)} - \frac{\sigma_3 \mathrm{res}(\chi(\lambda);\lambda_i)\sigma_3}{(\lambda + \lambda_i)} + \frac{\mathrm{res}(\chi(\lambda);\overline{\lambda_i})}{(\lambda - \overline{\lambda_i})} - \frac{\sigma_3 \mathrm{res}(\chi(\lambda);\overline{\lambda_i})\sigma_3}{(\lambda + \overline{\lambda_i})}\right). \tag{92}$$

The solution of (91) *can be written as the following ordered product:*

$$\chi(\lambda) = \chi_d(\lambda)\chi^c(\lambda), \tag{93}$$

where $\chi_d(\lambda)$ *is given by* (92), *and* $\chi^c(\lambda)$ *solves the following RH problem:* (1) $\chi^c(\lambda)$ *is piecewise holomorphic for all* $\lambda \in \mathbb{C} \setminus \widehat{\Gamma}$; (2) $\chi_+^c(\lambda) = \chi_-^c(\lambda)\exp\{-i\theta(\lambda)\mathrm{ad}(\sigma_3)\}(v^{\sharp}(\lambda)|_{\widehat{\Gamma}})$, $\lambda \in \widehat{\Gamma}$; *and* (3) *as* $\lambda \to \infty$, $\lambda \in \mathbb{C} \setminus \widehat{\Gamma}$, $\chi^c(\lambda) = \mathrm{I} + \mathcal{O}(\lambda^{-1})$.

Remark 4.1. From Proposition 4.1, (93), it is seen that, in order to solve the model RH problem, explicit knowledge of $\chi_d(\lambda)$ and $\chi^c(\lambda)$ is necessary. The determination of $\chi^c(\lambda)$ is technically the more complicated of the two: actually, the determination of $\chi_d(\lambda)$ depends on the explicit knowledge of $\chi^c(\lambda)$ (see Proposition 4.2); hence, the asymptotic solution of $\chi^c(\lambda)$ is presented first (see Lemma 4.1).

In order to more fully comprehend certain elements of the proof of Lemma 4.1 given below, the Beals–Coifman [24, 25] formulation for the solution of a (matrix) RH problem on an oriented contour is requisite: a self-contained synopsis of this

formulation as it applies to the solution of the RH problem for $\chi^c(\lambda)$ stated in Proposition 4.1 now follows. Writing the jump matrix in the following factorized form: $v^\sharp(\lambda)|_{\widehat{\Gamma}} := (\mathrm{I}-w^-_{x,t}(\lambda))^{-1}(\mathrm{I}+w^+_{x,t}(\lambda))$, $\lambda\in\widehat{\Gamma}$, where $w^\pm_{x,t}(\lambda)\in\cap_{k\in\{2,\infty\}}\mathcal{L}^k(\widehat{\Gamma};M_2(\mathbb{C}))$ (with $||w^\pm_{x,t}(\cdot)||_{\cap_{k\in\{2,\infty\}}\mathcal{L}^k(\widehat{\Gamma};M_2(\mathbb{C}))} := \sum_{k\in\{2,\infty\}}||w^\pm_{x,t}(\cdot)||_{\mathcal{L}^k(\widehat{\Gamma};M_2(\mathbb{C}))}$), resp., are nilpotent off-diagonal upper/lower triangular matrices, define $w_{x,t}(\lambda) := w^-_{x,t}(\lambda) + w^+_{x,t}(\lambda)$, and introduce the operator $C_{w_{x,t}}$ on $\mathcal{L}^2(\widehat{\Gamma};M_2(\mathbb{C}))$ as $C_{w_{x,t}}f := C_+(f\,w^-_{x,t}) + C_-(f\,w^+_{x,t})$, where $f\in\mathcal{L}^2(\widehat{\Gamma};M_2(\mathbb{C}))$, and $C_\pm\colon\mathcal{L}^2(\widehat{\Gamma};M_2(\mathbb{C}))\to\mathcal{L}^2(\widehat{\Gamma};M_2(\mathbb{C}))$ denote the Cauchy operators

$$(C_\pm f)(\lambda) := \lim_{\substack{\lambda'\to\lambda\\ \lambda'\in\pm\text{ side of }\widehat{\Gamma}}}\int_{\widehat{\Gamma}}\frac{f(\varrho)}{(\varrho-\lambda')}\frac{d\varrho}{2\pi i}.$$

THEOREM 4.1 (see [24]). *If $\mu^c(\lambda)\in\mathrm{I}\oplus\mathcal{L}^2(\widehat{\Gamma};M_2(\mathbb{C}))$ solves the following linear singular integral equation:*

$$(\underline{\mathbf{Id}} - C_{w_{x,t}})\mu^c = \mathrm{I},$$

where $\underline{\mathbf{Id}}$ is the identity operator on $\mathrm{I}\oplus\mathcal{L}^2(\widehat{\Gamma};M_2(\mathbb{C}))$, then the solution of the RH problem for $\chi^c(\lambda)$ is

$$\chi^c(\lambda) = \mathrm{I} + \int_{\widehat{\Gamma}}\frac{\mu^c(\varrho)w_{x,t}(\varrho)}{(\varrho-\lambda)}\frac{d\varrho}{2\pi i},\qquad \lambda\in\mathbb{C}\backslash\widehat{\Gamma},$$

where $\mu^c(\lambda) = \chi^c_+(\lambda)(\mathrm{I}+w^+_{x,t}(\lambda))^{-1} = \chi^c_-(\lambda)(\mathrm{I}-w^-_{x,t}(\lambda))^{-1}$.

LEMMA 4.1. *Let ϵ_0 denote an arbitrarily fixed, sufficiently small positive real number. For $\aleph\in\{0,\pm\lambda_0\}$, set $\mathcal{N}(\aleph;\epsilon_0) := \{\lambda;\,|\lambda-\aleph|\le\epsilon_0\}$. Then as $t\to+\infty$ and $x\to-\infty$ such that $\lambda_0 > M$ and $\lambda\in\mathbb{C}\backslash\cup_{\aleph\in\{0,\pm\lambda_0\}}\mathcal{N}(\aleph;\epsilon_0)$, $\chi^c(\lambda)$ has the following asymptotic expansion:*

$$\chi^c(\lambda) = \mathrm{I} + \frac{1}{4}\sqrt{\frac{\nu(\lambda_0)}{2\lambda_0^2 t}}\left(\frac{1}{\lambda-\lambda_0}+\frac{1}{\lambda+\lambda_0}\right)\Big(\exp\{-i(\phi^+(\lambda_0)+\widehat{\Phi}^+(\lambda_0;t))\}\sigma_- + \exp\{i(\phi^+(\lambda_0)+\widehat{\Phi}^+(\lambda_0;t))\}\sigma_+\Big) + \mathcal{O}\left(\frac{G(\lambda;\lambda_0)\ln t}{t}\right),$$

where $\nu(\lambda_0)$, $\phi^+(\lambda_0)$, and $\widehat{\Phi}^+(\lambda_0;t)$ are given in Theorem 2.1, equations (21), (22), and (24), $||G(\cdot;\lambda_0)||_{\mathcal{L}^\infty(\mathbb{C}\backslash\cup_{\aleph\in\{0,\pm\lambda_0\}}\mathcal{N}(\aleph;\epsilon_0);M_2(\mathbb{C}))}<\infty$, $G(\lambda;\cdot)\in\mathcal{S}(\mathbb{R}_{>M};M_2(\mathbb{C}))$, $G(\lambda;\lambda_0)\sim\mathcal{O}(\frac{C(\lambda_0)}{\lambda})$ as $\lambda\to\infty$ with $C(\lambda_0)\in\mathcal{S}(\mathbb{R}_{>M};M_2(\mathbb{C}))$, and satisfies the following involutions: $\chi^c(-\lambda) = \sigma_3\chi^c(\lambda)\sigma_3$ and $\chi^c(\lambda) = \sigma_1\overline{\chi^c(\overline{\lambda})}\sigma_1$.

Proof. In sections 5 and 6 of [15], it was shown that, for $\lambda\in\mathbb{C}\backslash\cup_{\aleph\in\{0,\pm\lambda_0\}}\mathcal{N}(\aleph;\epsilon_0)$, as $t\to+\infty$ and $x\to-\infty$ such that $\lambda_0 > M$, for arbitrary $l'\in\mathbb{Z}_{\ge1}$,

$$\chi^c(\lambda) = \mathrm{I} + \sum_{\vec{m}_3\in\mathbb{M}_3}\int_{a_l(\vec{m}_3)}^{a_u(\vec{m}_3)}\frac{m_3\mu^c(\varsigma)|_{\mathrm{sgn}(m_3)}(\delta(\varsigma))^{2m_3}e^{-2im_3t\theta(\varsigma)}\mathcal{R}^{\vec{m}_3}(\varsigma)\sigma_{\mathrm{sgn}(m_3)}}{(\varsigma-\lambda)}\frac{d\varsigma}{2\pi i} + \sum_{\vec{m}_2\in\mathbb{M}_2}\int_0^{b(\vec{m}_2)}\frac{m_2\mu^c(\varsigma)|_{\mathrm{sgn}(m_2)}(\delta(\varsigma))^{2m_2}e^{-2im_2t\theta(\varsigma)}\mathcal{R}^{\vec{m}_2}(\varsigma)\sigma_{\mathrm{sgn}(m_2)}}{(\varsigma-\lambda)}\frac{d\varsigma}{2\pi i} + \mathcal{O}\left(\frac{\underline{c}(\lambda_0)}{(\lambda_0^2t)^{l'}}\right),$$

where (1) $\vec{m}_k \in \mathbb{M}_k$ denotes the set of vectors with k components, each of which take the values ± 1 ($\text{card}(\mathbb{M}_k) = 2^k$); (2) $a_l(\vec{m}_3) = m_1\lambda_0 + m_2\varepsilon \exp\{-\frac{i\pi m_3}{4}\}$, $a_u(\vec{m}_3) = m_1\lambda_0$, and $b(\vec{m}_2) = m_1\varepsilon \exp\{\frac{i\pi m_2}{4}\}$, where ε is an arbitrarily fixed, sufficiently small positive real number; (3) $\mu^c(\varsigma)|_+ := \mu^c(\varsigma)|_{L'}$, $\mu^c(\varsigma)|_- := \mu^c(\varsigma)|_{\overline{L'}}$, with $L' = \{\lambda;\ \lambda = \widehat{u}\exp\{\frac{i\pi}{4}\},\ \widehat{u} \in (-\varepsilon, \varepsilon)\} \cup (\cup_{l\in\{\pm 1\}}\{\lambda;\ \lambda = l\lambda_0 + \widehat{u}\exp\{-\frac{i\pi}{4}\},\ \widehat{u} \in (-\varepsilon, \varepsilon)\})$, and where $\mu^c(\cdot)$ is the solution of the Beals–Coifman [24] linear singular integral equation (Theorem 4.1); (4) $\theta(\varsigma) = 2\varsigma^2(\varsigma^2 - 2\lambda_0^2)$; (5) $\delta(\varsigma) = ((\frac{\varsigma-\lambda_0}{\varsigma})(\frac{\varsigma+\lambda_0}{\varsigma}))^{i\nu} \exp\{\sum_{l\in\{\pm\}}(\rho_l(\varsigma) + \widehat{\rho}_l(\varsigma))\}$, $\nu := \nu(\lambda_0)$, $\rho_\pm(\varsigma) = \frac{1}{2\pi i}\int_0^{\pm\lambda_0} \ln\left(\frac{1-|r(\varrho)|^2}{1-|r(\lambda_0)|^2}\right)\frac{d\varrho}{(\varrho-\varsigma)}$, and $\widehat{\rho}_\pm(\varsigma) = \int_{\pm i\infty}^{i0} \frac{\ln(1-r(\varrho)\overline{r(\overline{\varrho})})}{(\varrho-\varsigma)}\frac{d\varrho}{2\pi i}$; (6) $\mathcal{R}^{-1,-1,1}(\varsigma) = \mathcal{R}^{1,1,1}(\varsigma) = -r(\varsigma)\mathcal{P}(\varsigma)$, $\mathcal{R}^{-1,1,1}(\varsigma) = \mathcal{R}^{1,-1,1}(\varsigma) = \frac{r(\varsigma)\mathcal{P}(\varsigma)}{(1-r(\varsigma)\overline{r(\overline{\varsigma})})}$, $\mathcal{R}^{-1,-1,-1}(\varsigma) = \mathcal{R}^{1,1,-1}(\varsigma) = (\mathcal{R}^{1,1,1}(\varsigma))^*$, and $\mathcal{R}^{-1,1,-1}(\varsigma) = \mathcal{R}^{1,-1,-1}(\varsigma) = (\mathcal{R}^{1,-1,1}(\varsigma))^*$, where $\mathcal{P}(z) := \prod_{l=n+1}^{N}\left(\frac{(z-\overline{\lambda_l})(z+\overline{\lambda_l})}{(z-\lambda_l)(z+\lambda_l)}\right)^2$, and $\alpha(\cdot) = (\beta(\cdot))^*$ means that $\alpha(\cdot)$ is the same piecewise-rational function as $\beta(\cdot)$ except with the complex conjugated coefficients; (7) $\mathcal{R}^{1,1}(\varsigma) = \mathcal{R}^{-1,1}(\varsigma) = \frac{r(\varsigma)\mathcal{P}(\varsigma)}{(1-|r(\varsigma)|^2)} - \frac{r(i\varsigma)\mathcal{P}(i\varsigma)}{(1+|r(i\varsigma)|^2)}$ and $\mathcal{R}^{1,-1}(\varsigma) = \mathcal{R}^{-1,-1}(\varsigma) = -(\mathcal{R}^{1,1}(\varsigma))^*$; and (8) $\underline{c}(\lambda_0) \in \mathcal{L}^\infty(\mathbb{R}_{>M}; M_2(\mathbb{C}))$. Since, in the above expression for $\chi^c(\lambda)$, the estimation of all the integrals is analogous, without loss of generality, the following integral is considered:

$$I_0 := \int_{\lambda_0 + \varepsilon e^{-\frac{i\pi}{4}}}^{\lambda_0} \mathcal{A}_0(\varsigma)\mathcal{B}_0(\varsigma)\frac{d\varsigma}{2\pi i},$$

where $\mathcal{A}_0(\varsigma) := \mu^c(\varsigma)|_{L'}$, and $\mathcal{B}_0(\varsigma) := -\frac{\delta^2(\varsigma)\exp\{-2it\theta(\varsigma)\}r(\varsigma)\mathcal{P}(\varsigma)}{(\varsigma-\lambda)}\sigma_+$. Begin by estimating $\mathcal{B}_0(\varsigma)\frac{d\varsigma}{2\pi i}$: (1) expand $\mathcal{B}_0(\varsigma)$ in a Taylor series about λ_0; (2) make the following change of variable [15]: $\varsigma := \varsigma(\widetilde{w}) = \lambda_0 + \widetilde{w}(16\lambda_0^2 t)^{-1/2}$, and express the expansion obtained in (1) above in terms of $\widetilde{w}$; and (3) use the following identity: $ab = (a-1)(b-1) + (a-1) + (b-1) + 1$. Carrying out steps (1)–(3), one gets that

$$\begin{aligned}
\mathcal{B}_0(\varsigma)\frac{d\varsigma}{2\pi i}|_{\varsigma(\widetilde{w})} = &-\frac{(\widetilde{w})^{2i\nu}\lambda_0^{-4i\nu}t^{-i\nu}2^{-2i\nu}e^{2s(\lambda_0)}e^{4i\lambda_0^4 t}e^{-i\widetilde{w}^2}d\widetilde{w}\sigma_+}{(\lambda-\lambda_0)(2\pi i)\sqrt{16\lambda_0^2 t}}\left\{\mathcal{R}(\lambda_0)\right.\\
&\left.+\left(\mathcal{R}'(\lambda_0) - \frac{3i\nu\mathcal{R}(\lambda_0)}{\lambda_0}\right)\frac{\widetilde{w}}{\sqrt{16\lambda_0^2 t}}\right\}\sum_{\vec{l}_4\in\mathbb{L}_4}\prod_{k=1}^{4}(p_k(\widetilde{w}))^{l_k}\\
&-\frac{(\widetilde{w})^{2i\nu+1}\lambda_0^{-4i\nu}t^{-i\nu}2^{-2i\nu}e^{2s(\lambda_0)}e^{4i\lambda_0^4 t}e^{-i\widetilde{w}^2}d\widetilde{w}\sigma_+}{(\lambda-\lambda_0)^2(2\pi i)(16\lambda_0^2 t)}\\
\times\mathcal{R}(\lambda_0)\sum_{\vec{l}_4\in\mathbb{L}_4}\prod_{k=1}^{4}(p_k(\widetilde{w}))^{l_k} &+ \mathcal{O}\left(\left\{\frac{C_1^\flat(\lambda_0)}{(\lambda-\lambda_0)} + \frac{C_2^\flat(\lambda_0)}{(\lambda-\lambda_0)^2}\right\}\frac{e^{4i\lambda_0^4 t}\widetilde{w}^{2i\nu+2}e^{-i\widetilde{w}^2}d\widetilde{w}\sigma_+}{t^{3/2+i\nu}}\right),
\end{aligned}$$

where $\vec{l}_k \in \mathbb{L}_k$ denotes the set of vectors with k components, each of which take the values 0 and 1 ($\text{card}(\mathbb{L}_k) = 2^k$), $s(\lambda_0) := \sum_{l\in\{\pm\}}(\rho_l(\lambda_0) + \widehat{\rho}_l(\lambda_0))$, $\mathcal{R}(\lambda_0) := -r(\lambda_0)\mathcal{P}(\lambda_0)$, $\mathcal{R}'(\lambda_0) = -r'(\lambda_0)\mathcal{P}(\lambda_0) - r(\lambda_0)\mathcal{P}(\lambda_0)\sum_{k=n+1}^{N}\{\frac{4i\sin(\arg(\lambda_0-\lambda_k))}{|\lambda_0-\lambda_k|} + \frac{4i\sin(\arg(\lambda_0+\lambda_k))}{|\lambda_0+\lambda_k|}\}$, $(\bullet)'(\lambda_0) := \frac{d(\bullet)(z)}{dz}|_{z=\lambda_0}$,

$$p_k(\widetilde{w}) := \exp\left\{2\widetilde{\Delta}_k\left(\lambda_0 + \frac{\widetilde{w}}{\sqrt{16\lambda_0^2 t}}\right)\right\} - 1, \qquad k \in \{1, 2\},$$

$$p_3(\widetilde{w}) := \exp\left\{-\frac{i\widetilde{w}^3}{\lambda_0\sqrt{16\lambda_0^2 t}}\right\} - 1, \quad p_4(\widetilde{w}) := \exp\left\{-\frac{i\widetilde{w}^4}{4^3\lambda_0^4 t}\right\} - 1,$$

$$\widetilde{\Delta}_1\left(\lambda_0 + \frac{\widetilde{w}}{\sqrt{16\lambda_0^2 t}}\right) = \sum_{l\in\{\pm\}}\left(\rho_l\left(\lambda_0 + \frac{\widetilde{w}}{\sqrt{16\lambda_0^2 t}}\right) - \rho_l(\lambda_0)\right),$$

$$\widetilde{\Delta}_2\left(\lambda_0 + \frac{\widetilde{w}}{\sqrt{16\lambda_0^2 t}}\right) = \sum_{l\in\{\pm\}}\left(\widehat{\rho}_l\left(\lambda_0 + \frac{\widetilde{w}}{\sqrt{16\lambda_0^2 t}}\right) - \widehat{\rho}_l(\lambda_0)\right),$$

and $C_i^{\flat}(\lambda_0) \in \mathcal{S}(\mathbb{R}_{>M};\mathbb{C})$, $i \in \{1,2\}$. Now, proceed to estimate $\mu^c(\varsigma)|_{L'}$ for $\varsigma \in (\lambda_0, \lambda_0 + \varepsilon\exp\{-\frac{i\pi}{4}\})$: for this, the Beals–Coifman [24] formulation for the solution of a RH problem on an oriented contour is necessary (Theorem 4.1 and the paragraph preceding it for discussion and notation); in particular, one has to estimate the functions $w_{x,t}^{\pm}(\varsigma)$ on $L' \cup \overline{L'}$. In section 5 of [15], it was shown that, on $(\lambda_0, \lambda_0 + \varepsilon\exp\{-\frac{i\pi}{4}\})$, $w_{x,t}^{+}(\varsigma) = -(\delta(\varsigma))^{\mathrm{ad}(\sigma_3)}\exp\{-it\theta(\varsigma)\mathrm{ad}(\sigma_3)\}r(\varsigma)\mathcal{P}(\varsigma)\sigma_+$ and $w_{x,t}^{-}(\varsigma) = 0$; hence, from the Beals–Coifman [24] formulation, for any $f \in \mathcal{L}^2(L';M_2(\mathbb{C}))$, $C_{w_{x,t}}f = C_-(f\, w_{x,t}^{+})$. To estimate $w_{x,t}^{+}(\varsigma)$, one proceeds as follows: (1) recalling that $r(\varsigma) \in \mathcal{S}(\widehat{\Gamma};\mathbb{C})$ and $||r||_{\mathcal{L}^\infty(\mathbb{R};\mathbb{C})} < 1$, expand $(\delta(\varsigma))^{\mathrm{ad}(\sigma_3)}$, for $\varsigma \in (\lambda_0, \lambda_0 + \varepsilon\exp\{-\frac{i\pi}{4}\})$, via an integration by parts argument; (2) expand $\exp\{-it\theta(\varsigma)\mathrm{ad}(\sigma_3)\}r(\varsigma)\mathcal{P}(\varsigma)$ in a Taylor series about λ_0; and (3) change variables [15], $\varsigma := \varsigma(\widetilde{w})$. Carrying out steps (1)–(3), one shows that

$$w_{x,t}^{+}(\varsigma)\big|_{\varsigma(\widetilde{w})} = e^{i\{4\lambda_0^4 t - \widetilde{w}^2 + 2\nu\ln(\widetilde{w}/2) - \nu\ln t + 2\phi(\lambda_0)\}}\left(v_{00}(\widetilde{w};\lambda_0) + \frac{v_{10}(\widetilde{w};\lambda_0) + v_{11}(\widetilde{w};\lambda_0)\ln t}{\sqrt{t}}\right) + \mathcal{O}\left(\frac{v_{22}(\widetilde{w};\lambda_0)(\ln t)^2}{t}\right),$$

where $\phi(\lambda_0) = 2\nu\ln\lambda_0 + \frac{1}{2\pi}\int_0^{\lambda_0}\ln|z^2 - \lambda_0^2|d\ln(1-|r(z)|^2) - \frac{1}{2\pi}\int_0^{\infty}\ln|z^2 + \lambda_0^2|d\ln(1 + |r(iz)|^2)$, $v_{00}(\widetilde{w};\lambda_0) := \mathcal{R}(\lambda_0)$, $v_{10}(\widetilde{w};\lambda_0), v_{11}(\widetilde{w};\lambda_0)$, and $v_{22}(\widetilde{w};\lambda_0)$ are nilpotent matrix polynomials whose elements are sums of products of terms of the type $\widetilde{w}^j$ and $(\ln\widetilde{w})^k$, $j \in \mathbb{Z}_{\geq 1}$, $k \in \mathbb{Z}_{\geq 0}$, with λ_0-dependent coefficients, and, for $0 \leq j \leq 2$, $0 \leq k \leq j$,

$$||\exp\{-i(\cdot)^2\}\exp\{2i\nu\ln(\cdot)\}v_{jk}(\cdot;\lambda_0)||_{\cap_{l\in\{1,2,\infty\}}\mathcal{L}^l(L_s'\setminus\{0\};\mathbb{C})} < \infty,$$

with $||(\cdot)||_{\cap_{l\in\{1,2,\infty\}}\mathcal{L}^l(L_s'\setminus\{0\};\mathbb{C})} := \sum_{l\in\{1,2,\infty\}}||(\cdot)||_{\mathcal{L}^l(L_s'\setminus\{0\};\mathbb{C})}$, where $L_s'\setminus\{0\}$ denotes the scaled and shifted version of $L'\setminus\{\lambda_0\}$. Hence, for any $f \in \mathcal{L}^l(L_s';M_2(\mathbb{C}))$, $l \in \{2,\infty\}$,

$$(C_{w_{x,t}}f)(\widetilde{w};\lambda_0) = \sum_{j=0}^{1}\sum_{k=0}^{j}\frac{(\ln t)^k}{t^{j/2}}(C_{jk}^{\natural}f)(\widetilde{w};\lambda_0) + \mathcal{O}\left(\frac{(\ln t)^2}{t}(C_{22}^{\natural}f)(\widetilde{w};\lambda_0)\right),$$

where

$$\frac{\exp\{2i\nu\ln 2\}}{\exp\{2i\phi(\lambda_0)\}}(C_{jk}^{\natural}f)(\widetilde{w};\lambda_0) := \lim_{\substack{\lambda'\to\widetilde{w}\\ \lambda'\in-\text{ side of }L_s'}}\int_{L_s'}\frac{f(z)\exp\{-iz^2\}z^{2i\nu}v_{jk}(z;\lambda_0)}{(z-\lambda')}\frac{dz}{2\pi i},$$

$$0 \leq j \leq 2, 0 \leq k \leq j,$$

and $||C_{jk}^{\natural}(\cdot;\lambda_0)||_{\mathcal{M}(L_s'\setminus\{0\};M_2(\mathbb{C}))} \leq \mathcal{K}_1^{\natural}(\lambda_0) < \infty$, with $\mathcal{M}(\bullet;M_2(\mathbb{C}))$ denoting the space of bounded linear operators acting from $\mathcal{L}^l(\bullet;M_2(\mathbb{C}))$ into $\mathcal{L}^2(\bullet;M_2(\mathbb{C}))$, $l \in \{2,\infty\}$.

According to Theorem 4.1, $\mu^c(\cdot)$ satisfies the following linear singular integral equation on $L' \cup \overline{L'}$, $(\underline{\mathbf{Id}} - C_{w_{x,t}})\mu^c = \mathrm{I}$; hence, $\mu^c = (\underline{\mathbf{Id}} - C_{w_{x,t}})^{-1}\mathrm{I}$. It was shown in [15] that, as $t \to +\infty$ and $x \to -\infty$ such that $\lambda_0 > M$, $\ker(\underline{\mathbf{Id}} - C_{w_{x,t}}) = \emptyset$ and $||(\underline{\mathbf{Id}} - C^{\natural}_{00}(\cdot;\lambda_0))^{-1}||_{\mathcal{M}(L'_s\setminus\{0\};M_2(\mathbb{C}))} \le \mathcal{K}^{\natural}_2(\lambda_0) < \infty$. Using the method of successive approximations, one shows that, as $t \to +\infty$ and $x \to -\infty$ such that $\lambda_0 > M$, $\mu^c(\cdot)$ can be expanded in the following Neumann-type series (see also Part II of [23], and [34]):

$$\mathcal{A}_0(\varsigma)|_{\varsigma(\widetilde{w})} = \mu^c(\widetilde{w})|_{L'_s\setminus\{0\}} = \mu^c_{00}(\widetilde{w};\lambda_0) + \frac{\mu^c_{10}(\widetilde{w};\lambda_0) + \mu^c_{11}(\widetilde{w};\lambda_0)\ln t}{\sqrt{t}} + \mathcal{O}\left(\frac{\mu^c_{22}(\widetilde{w};\lambda_0)(\ln t)^2}{t}\right),$$

where $\mu^c_{00}(\widetilde{w};\lambda_0) := (\underline{\mathbf{Id}} - C^{\natural}_{00}(\widetilde{w};\lambda_0))^{-1}\mathrm{I}$, $||(\underline{\mathbf{Id}} - C^{\natural}_{00}(\cdot;\lambda_0))^{-1}\mathrm{I}||_{\mathcal{L}^2(L'_s\setminus\{0\};M_2(\mathbb{C}))} < \infty$, and $||\mu^c_{jk}(\cdot;\lambda_0)||_{\mathcal{L}^2(L'_s\setminus\{0\};M_2(\mathbb{C}))} < \infty$, $1 \le j \le 2$, $0 \le k \le j$: an explicit expression for $(\underline{\mathbf{Id}} - C^{\natural}_{00}(\widetilde{w};\lambda_0))^{-1}\mathrm{I}$ in terms of parabolic-cylinder functions was given in section 7 of [15] (see below). Making one more change of variable, $\varrho = \sqrt{2}\widetilde{w}\exp\{\frac{i\pi}{4}\}$, and recalling the definition of I_0, one shows that

$$I_0 - I_{1/2} = I_{0,a} + I_{0,b} + I_{0,c} + I_{0,d} + \mathcal{E}_r,$$

where

$$I_{1/2} := Y_a(\lambda,\lambda_0;t)\int_0^{\widehat{\alpha}} \mu^c_{00}\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right)\varrho^{2i\nu}e^{-\varrho^2/2}\sigma_+ d\varrho,$$

$$I_{0,a} := Y_a(\lambda,\lambda_0;t)\sum_{\vec{l}_4\in\mathbb{L}_4}{}' \int_0^{\widehat{\alpha}} \mu^c_{00}\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right)\prod_{k=1}^4\left(p_k\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}}\right)\right)^{l_k}\varrho^{2i\nu}e^{-\varrho^2/2}\sigma_+ d\varrho,$$

$$I_{0,b} := Y_b(\lambda,\lambda_0;t)\sum_{\vec{l}_4\in\mathbb{L}_4} \int_0^{\widehat{\alpha}} \mu^c_{00}\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right)\prod_{k=1}^4\left(p_k\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}}\right)\right)^{l_k}\varrho^{2i\nu+1}e^{-\varrho^2/2}\sigma_+ d\varrho,$$

$$I_{0,c} := Y_c(\lambda,\lambda_0;t)\sum_{\vec{l}_4\in\mathbb{L}_4} \int_0^{\widehat{\alpha}} \left\{\mu^c_{10}\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right) + \mu^c_{11}\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right)\ln t\right\} \times \prod_{k=1}^4\left(p_k\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}}\right)\right)^{l_k}\varrho^{2i\nu}e^{-\varrho^2/2}\sigma_+ d\varrho,$$

$$I_{0,d} := Y_d(\lambda,\lambda_0;t)\sum_{\vec{l}_4\in\mathbb{L}_4} \int_0^{\widehat{\alpha}} \mu^c_{00}\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right)\prod_{k=1}^4\left(p_k\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}}\right)\right)^{l_k}\varrho^{2i\nu+1}e^{-\varrho^2/2}\sigma_+ d\varrho,$$

$$\mathcal{E}_r := \mathcal{O}\left(\frac{y(\lambda_0;t)}{\lambda_0^3 t^{3/2}}\left\{\sum_{k=1}^2 \frac{C^{\sharp}_k(\lambda_0)}{(\lambda-\lambda_0)^k}\right\}\int_0^{\widehat{\alpha}} \mu^c_{00}\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right)\varrho^{2i\nu+2}e^{-\varrho^2/2}\sigma_+ d\varrho\right)$$
$$+ \mathcal{O}\left(\frac{y(\lambda_0;t)}{\lambda_0^2 t^{3/2}}\left\{\sum_{k=1}^2 \frac{C^{\sharp}_{k+2}(\lambda_0)}{(\lambda-\lambda_0)^k}\right\}\int_0^{\widehat{\alpha}} \left\{\mu^c_{10}\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right) + \mu^c_{11}\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right)\ln t\right\}\varrho^{2i\nu+1}e^{-\varrho^2/2}\sigma_+ d\varrho\right),$$

$\widehat{\alpha}:=(32\varepsilon^2\lambda_0^2 t)^{1/2}$, the prime on the summation in the expression for $I_{0,a}$ means that the term corresponding to $(l_1,l_2,l_3,l_4)=(0,0,0,0)$ is omitted from the sum,

$$Y_a(\lambda,\lambda_0;t)=\frac{y(\lambda_0;t)e^{-\frac{i\pi}{4}}\mathcal{R}(\lambda_0)}{(\lambda-\lambda_0)\sqrt{32\lambda_0^2 t}},\qquad Y_b(\lambda,\lambda_0;t)=\frac{iy(\lambda_0;t)\{3i\nu\mathcal{R}(\lambda_0)-\lambda_0\mathcal{R}'(\lambda_0)\}}{(\lambda-\lambda_0)(32\lambda_0^3 t)},$$

$$Y_c(\lambda,\lambda_0;t)=\frac{y(\lambda_0;t)e^{-\frac{i\pi}{4}}\mathcal{R}(\lambda_0)}{(\lambda-\lambda_0)\sqrt{32\lambda_0^2 t}},\qquad Y_d(\lambda,\lambda_0;t)=-\frac{iy(\lambda_0;t)\mathcal{R}(\lambda_0)}{(\lambda-\lambda_0)^2(32\lambda_0^2 t)},$$

$y(\lambda_0;t):=\frac{e^{\frac{\pi\nu}{2}}e^{2s(\lambda_0)}e^{4i\lambda_0^4 t}}{(2\pi i)\lambda_0^{4i\nu}2^{3i\nu}t^{i\nu}}$, and $C_i^\sharp(\lambda_0)\in\mathcal{S}(\mathbb{R}_{>M};\mathbb{C})$, $1\le i\le 4$. As will be shown below, $I_{1/2}$ gives rise to the leading-order ($\mathcal{O}(t^{-1/2})$) term: towards the proof of this statement, one proceeds by estimating the difference, $I_0-I_{1/2}$. Recall first the following inequality: $|\exp\{(\cdot)\}-1|\le|(\cdot)|\sup_{s\in[0,1]}|\exp\{s(\cdot)\}|$; hence, $|\exp\{\widetilde{\Delta}_i^\flat\}-1|\le|\widetilde{\Delta}_i^\flat|\sup_{s\in[0,1]}|\exp\{s\widetilde{\Delta}_i^\flat\}|$, where

$$\widetilde{\Delta}_i^\flat:=2\widetilde{\Delta}_i\left(\lambda_0+\frac{\varrho\exp\{-\frac{i\pi}{4}\}}{\sqrt{32\lambda_0^2 t}}\right),\qquad i\in\{1,2\}.$$

Since, as shown in [15], $||(\delta(\cdot))^{\pm1}||_{\mathcal{L}^\infty(\mathbb{C};\mathbb{C})}<\infty$, from the definitions of $\rho_\pm(\lambda_0)$, $\widehat{\rho}_\pm(\lambda_0)$, and $\widetilde{\Delta}_i^\flat$, $i\in\{1,2\}$, it follows that $\sup_{s\in[0,1]}|\exp\{s\widetilde{\Delta}_i^\flat\}|<\infty$; furthermore, using the Lipschitz property of $\ln\left(\frac{1-|r(\lambda)|^2}{1-|r(\lambda_0)|^2}\right)$, $|\lambda|<\lambda_0$, and the fact that $r(\lambda)\in\mathcal{S}(\widehat{\Gamma};\mathbb{C})$ and $||r||_{\mathcal{L}^\infty(\mathbb{R};\mathbb{C})}<1$, via an integration by parts argument, one deduces that

$$|\widetilde{\Delta}_1^\flat|\le\frac{K_1^\flat(\lambda_0)\varrho+K_2^\flat(\lambda_0)\varrho\ln\varrho+K_3^\flat(\lambda_0)\varrho\ln t}{\sqrt{\lambda_0^2 t}},\qquad |\widetilde{\Delta}_2^\flat|\le\frac{K_4^\flat(\lambda_0)\varrho}{\sqrt{\lambda_0^2 t}},$$

with $K_i^\flat(\lambda_0)\in\mathcal{L}^\infty(\mathbb{R}_{>M};\mathbb{R}_{>0})$, $i\in\{1,4\}$. Similarly, one gets that

$$\left|\exp\left\{-\frac{i\varrho^3\exp(-\frac{3\pi i}{4})}{8\sqrt{2}\lambda_0^2\sqrt{t}}\right\}-1\right|\le\frac{\varrho^3}{8\sqrt{2}\lambda_0^2\sqrt{t}}\underbrace{\sup_{s\in[0,1]}\left|\exp\left\{\frac{-s(1-i)\varrho^3}{16\lambda_0^2\sqrt{t}}\right\}\right|}_{<\infty}:=\frac{\widetilde{K}_1(\lambda_0)\varrho^3}{\sqrt{\lambda_0^2 t}},$$

$$\left|\exp\left\{\frac{i\varrho^4}{4^4\lambda_0^4 t}\right\}-1\right|\le\frac{\varrho^4}{4^4\lambda_0^4 t}\underbrace{\sup_{s\in[0,1]}\left|\exp\left\{\frac{is\varrho^4}{4^4\lambda_0^4 t}\right\}\right|}_{<\infty}:=\frac{\widetilde{K}_2(\lambda_0)\varrho^4}{\lambda_0^2 t},$$

with $\widetilde{K}_i(\lambda_0)\in\mathcal{L}^\infty(\mathbb{R}_{>M};\mathbb{R}_{>0})$, $i\in\{1,2\}$. Although the expression for the difference, $I_0-I_{1/2}$, contains many terms, estimations for the respective terms are analogous. Consider, say, the bound for the term corresponding to $(l_1,l_2,l_3,l_4)=(1,0,0,0)$ in $I_{0,a}$, which is denoted by $I_{0,a}^1$:

$$I_{0,a}^1:=Y_a(\lambda,\lambda_0;t)\int_0^{\widehat{\alpha}}\mu_{00}^c\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right)p_1\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}}\right)\varrho^{2i\nu}e^{-\varrho^2/2}\sigma_+ d\varrho.$$

Using the fact that $0<\nu\le\nu_{\max}:=-\frac{1}{2\pi}\ln(1-\sup_{\lambda\in\mathbb{R}}|r(\lambda)|^2)<\infty$, and recalling the definitions of $s(\lambda_0)$ and $\mathcal{R}(\lambda_0)$, one gets that, for $\lambda\in\mathbb{C}\setminus\mathcal{N}(\lambda_0;\epsilon_0)$, $|Y_a(\lambda,\lambda_0;t)|\le$

$\frac{\exp\{\frac{\pi\nu_{\max}}{2}\}|r(\lambda_0)|}{2\pi|\lambda-\lambda_0|\sqrt{32\lambda_0^2 t}}$; hence, letting the upper limit of integration tend to $+\infty$ (for brevity, the following notation is used: for *matrices* A and B, the inequality $|A|\leq|B|$ means that $|A_{ij}|\leq|B_{ij}|\ \forall\, i,j$),

$$|I_{0,a}^1|\leq\frac{\exp\{\frac{\pi\nu_{\max}}{2}\}|r(\lambda_0)|}{2\pi|\lambda-\lambda_0|\sqrt{32\lambda_0^2 t}}\int_0^\infty\left|\mu_{00}^c\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right)\right|\left|p_1\left(\frac{\varrho e^{-\frac{i\pi}{4}}}{\sqrt{2}}\right)\right|e^{-\varrho^2/2}\sigma_+ d\varrho.$$

In [15], it was shown that

$$\mathcal{U}_{00}^c:=\left\|\mu_{00}^c\left(\frac{(\cdot)e^{-\frac{i\pi}{4}}}{\sqrt{2}};\lambda_0\right)\right\|_{\mathcal{L}^2(\mathbb{R}_{\geq 0};M_2(\mathbb{C}))}<\infty;$$

hence, from this estimate and the Cauchy–Schwarz inequality for integrals,

$$|I_{0,a}^1|\leq\frac{\exp\{\frac{\pi\nu_{\max}}{2}\}|r(\lambda_0)|\,\mathcal{U}_{00}^c\sigma_+}{2\pi|\lambda-\lambda_0|\sqrt{32\lambda_0^2 t}}\left\|p_1\left(\frac{(\cdot)e^{-\frac{i\pi}{4}}}{\sqrt{2}}\right)\exp\{-(\cdot)^2/2\}\right\|_{\mathcal{L}^2(\mathbb{R}_{\geq 0};\mathbb{C})}.$$

Recalling the estimate for $|\exp\{\widetilde{\Delta}_1^\flat\}-1|$, one shows that

$$\left\|p_1\left(\frac{(\cdot)e^{-\frac{i\pi}{4}}}{\sqrt{2}}\right)\exp\{-(\cdot)^2/2\}\right\|_{\mathcal{L}^2(\mathbb{R}_{\geq 0};\mathbb{C})}\leq\frac{\widetilde{K}^\flat(\lambda_0)\ln t}{\sqrt{\lambda_0^2 t}},$$

where $\widetilde{K}^\flat(\lambda_0)\in\mathcal{L}^\infty(\mathbb{R}_{>M};\mathbb{R}_{>0})$; hence, uniformly for $\lambda\in\mathbb{C}\backslash\mathcal{N}(\lambda_0;\epsilon_0)$,

$$|I_{0,a}^1|\leq\frac{\widetilde{K}_1^\sharp(\lambda_0)\ln t}{|\lambda-\lambda_0|\lambda_0^2 t},$$

with $\widetilde{K}_1^\sharp(\lambda_0)\in\mathcal{S}(\mathbb{R}_{>M};M_2(\mathbb{R}_{>0}))$. Similarly, recalling the estimates for

$$\left|\exp\left\{-\frac{i\varrho^3\exp(-\frac{3\pi i}{4})}{8\sqrt{2}\lambda_0^2\sqrt{t}}\right\}-1\right|,\qquad\left|\exp\left\{\frac{i\varrho^4}{4^4\lambda_0^4 t}\right\}-1\right|,\quad\text{and}\quad|\exp\{\widetilde{\Delta}_2^\flat\}-1|,$$

and using the triangle inequality for $\mathcal{L}^2$-norms, one shows that the remaining terms for $I_{0,a}$ are of the type $\mathcal{O}(t^{-\frac{m}{2}})$ and $\mathcal{O}(t^{-\frac{n}{2}}\ln t)$, $2\leq m\leq 5$, $3\leq n\leq 6$. Estimating the remaining terms of $I_0-I_{1/2}$ analogously, one shows that, as $t\to+\infty$ and $x\to-\infty$ such that $\lambda_0>M$, uniformly for $\lambda\in\mathbb{C}\backslash\mathcal{N}(\lambda_0;\epsilon_0)$,

$$|I_0-I_{1/2}|\leq\frac{\widetilde{K}_2^\sharp(\lambda;\lambda_0)\ln t}{\lambda_0^2 t},$$

where $||\widetilde{K}_2^\sharp(\cdot;\lambda_0)||_{\mathcal{L}^\infty(\mathbb{C}\backslash\mathcal{N}(\lambda_0;\epsilon_0);M_2(\mathbb{R}_{>0}))}<\infty$, $\widetilde{K}_2^\sharp(\lambda;\cdot)\in\mathcal{S}(\mathbb{R}_{>M};M_2(\mathbb{R}_{>0}))$, and, as $\lambda\to\infty$, $\widetilde{K}_2^\sharp(\lambda;\lambda_0)\sim\mathcal{O}(\widetilde{k}_2^\sharp(\lambda_0)|\lambda|^{-1})$, with $\widetilde{k}_2^\sharp(\lambda_0)\in\mathcal{S}(\mathbb{R}_{>M};M_2(\mathbb{R}_{>0}))$.

Repeating the whole of the above analysis mutatis mutandis for each term on the right-hand side of the original integral expression for $\chi^c(\lambda)$ which appears at the very beginning of the proof, one shows that, as $t\to+\infty$ and $x\to-\infty$ such that $\lambda_0>M$, uniformly for $\lambda\in\mathbb{C}\backslash\cup_{\aleph\in\{0,\pm\lambda_0\}}\mathcal{N}(\aleph;\epsilon_0)$,

$$|\chi^c(\lambda)-\chi_{1/2}^c(\lambda)|\leq\frac{(h_1^+(\lambda;\lambda_0)+h_2^+(\lambda;\lambda_0))\ln t}{\lambda_0^2 t},$$

where $h_1^+(\lambda;\lambda_0):=\sum_{l'\in\{0,i0\}}e_{l'}^+(\lambda;\lambda_0)|r(l')|$, $h_2^+(\lambda;\lambda_0):=\sum_{l\in\{\pm\lambda_0\}}e_l^+(\lambda;\lambda_0)$, and the functions $e_{l'}^+(\lambda;\lambda_0)$ and $e_l^+(\lambda;\lambda_0)$ have the following property as $\lambda\to\infty$:

$$h_1^+(\lambda;\lambda_0)+h_2^+(\lambda;\lambda_0)\sim\mathcal{O}\left(\left\{\sum_{l'\in\{0,i0\}}e_{l'}^\sharp(\lambda_0)|r(l')|+\sum_{l\in\{\pm\lambda_0\}}e_l^\sharp(\lambda_0)\right\}|\lambda|^{-1}\right),$$
$$e_{l'}^\sharp(\lambda_0)\in\mathcal{L}^\infty(\mathbb{R}_{>M};M_2(\mathbb{R}_{>0})),$$

$l'\in\{0,i0\}$, and $e_l^\sharp(\lambda_0)\in\mathcal{S}(\mathbb{R}_{>M};M_2(\mathbb{R}_{>0}))$, $l\in\{\pm\lambda_0\}$; moreover,

$$||h_1^+(\cdot;\lambda_0)||_{\mathcal{L}^\infty(\mathbb{C}\setminus\mathcal{N}(0;\epsilon_0);M_2(\mathbb{R}_{>0}))}<\infty,$$
$$||h_2^+(\cdot;\lambda_0)||_{\mathcal{L}^\infty(\mathbb{C}\setminus\cup_{\aleph\in\{\pm\lambda_0\}}\mathcal{N}(\aleph;\epsilon_0);M_2(\mathbb{R}_{>0}))}<\infty, h_1^+(\lambda;\cdot)\in\mathcal{L}^\infty(\mathbb{R}_{>M};M_2(\mathbb{R}_{>0})),$$
$$h_2^+(\lambda;\cdot)\in\mathcal{S}(\mathbb{R}_{>M};M_2(\mathbb{R}_{>0})),$$

and $\chi_{1/2}^c(\lambda)$ represents the sum over all $I_{1/2}$-like terms in which the upper limits of integration tend to $+\infty$. One can write $\chi_{1/2}^c(\lambda)$ in the following form,

$$\chi_{1/2}^c(\lambda)=\mathrm{I}+\frac{(\widetilde{\Lambda}^0)^{\mathrm{ad}(\sigma_3)}}{\sqrt{16\lambda_0^2t}}\mathcal{X}^{\Sigma_r}(\lambda)+\frac{(\widehat{\Lambda}_{\mathcal{C}}^0)^{\mathrm{ad}(\sigma_3)}}{\sqrt{8\lambda_0^2t}}\mathcal{X}^{\Sigma_{\mathcal{C}}}(\lambda),$$

where

$$\widetilde{\Lambda}^0 = \frac{\exp\{2i\lambda_0^4t\}}{(16\lambda_0^4t)^{\frac{i\nu}{2}}}\exp\left\{\sum_{l\in\{\pm\}}(\rho_l(\lambda_0)+\widehat{\rho}_l(\lambda_0))\right\},$$
$$\rho_\pm(\lambda_0) = \frac{1}{2\pi i}\int_0^{\pm\lambda_0}\ln\left(\frac{1-|r(\varsigma)|^2}{1-|r(\lambda_0)|^2}\right)\frac{d\varsigma}{(\varsigma-\lambda_0)},\qquad \widehat{\rho}_\pm(\lambda_0)=\int_{\pm i\infty}^{i0}\frac{\ln(1-r(\varsigma)\overline{r(\overline{\varsigma})})}{(\varsigma-\lambda_0)}\frac{d\varsigma}{2\pi i},$$
$$\mathcal{X}_{11}^{\Sigma_r}(\lambda) = \frac{\overline{r_{\mathcal{B}}(\lambda_0)}}{2^{2i\nu}}\int_0^{\varepsilon_1}\frac{\mathcal{X}_{+,12}^{\Sigma_{B,r}}(\varsigma)\varsigma^{-2i\nu}e^{i\varsigma^2}}{(\lambda-\lambda_0)}\frac{d\varsigma}{2\pi i}-\frac{\overline{r_{\mathcal{B}}(\lambda_0)}e^{2\pi\nu}}{2^{2i\nu}}\int_0^{\varepsilon_2}\frac{\mathcal{X}_{-,12}^{\Sigma_{B,r}}(\varsigma)\varsigma^{-2i\nu}e^{i\varsigma^2}}{(\lambda-\lambda_0)}\frac{d\varsigma}{2\pi i}$$
$$+\frac{\overline{r_{\mathcal{B}}(\lambda_0)}}{2^{2i\nu}}\int_0^{\varepsilon_1}\frac{\mathcal{X}_{+,12}^{\Sigma_{A,r}}(\varsigma)\varsigma^{-2i\nu}e^{i\varsigma^2}}{(\lambda+\lambda_0)}\frac{d\varsigma}{2\pi i}-\frac{\overline{r_{\mathcal{B}}(\lambda_0)}e^{2\pi\nu}}{2^{2i\nu}}\int_0^{\varepsilon_2}\frac{\mathcal{X}_{-,12}^{\Sigma_{A,r}}(\varsigma)\varsigma^{-2i\nu}e^{i\varsigma^2}}{(\lambda+\lambda_0)}\frac{d\varsigma}{2\pi i},$$
$$\mathcal{X}_{12}^{\Sigma_r}(\lambda) = -\frac{r_{\mathcal{B}}(\lambda_0)}{2^{-2i\nu}}\int_0^{\overline{\varepsilon_1}}\frac{\mathcal{X}_{-,11}^{\Sigma_{B,r}}(\varsigma)\varsigma^{2i\nu}e^{-i\varsigma^2}}{(\lambda-\lambda_0)}\frac{d\varsigma}{2\pi i}+\frac{r_{\mathcal{B}}(\lambda_0)e^{2\pi\nu}}{2^{-2i\nu}}\int_0^{\overline{\varepsilon_2}}\frac{\mathcal{X}_{+,11}^{\Sigma_{B,r}}(\varsigma)\varsigma^{2i\nu}e^{-i\varsigma^2}}{(\lambda-\lambda_0)}\frac{d\varsigma}{2\pi i}$$
$$-\frac{r_{\mathcal{B}}(\lambda_0)}{2^{-2i\nu}}\int_0^{\overline{\varepsilon_1}}\frac{\mathcal{X}_{-,11}^{\Sigma_{A,r}}(\varsigma)\varsigma^{2i\nu}e^{-i\varsigma^2}}{(\lambda+\lambda_0)}\frac{d\varsigma}{2\pi i}+\frac{r_{\mathcal{B}}(\lambda_0)e^{2\pi\nu}}{2^{-2i\nu}}\int_0^{\overline{\varepsilon_2}}\frac{\mathcal{X}_{+,11}^{\Sigma_{A,r}}(\varsigma)\varsigma^{2i\nu}e^{-i\varsigma^2}}{(\lambda+\lambda_0)}\frac{d\varsigma}{2\pi i},$$
$$\mathcal{X}_{21}^{\Sigma_r}(\lambda) = \frac{\overline{r_{\mathcal{B}}(\lambda_0)}}{2^{2i\nu}}\int_0^{\varepsilon_1}\frac{\mathcal{X}_{+,22}^{\Sigma_{B,r}}(\varsigma)\varsigma^{-2i\nu}e^{i\varsigma^2}}{(\lambda-\lambda_0)}\frac{d\varsigma}{2\pi i}-\frac{\overline{r_{\mathcal{B}}(\lambda_0)}e^{2\pi\nu}}{2^{2i\nu}}\int_0^{\varepsilon_2}\frac{\mathcal{X}_{-,22}^{\Sigma_{B,r}}(\varsigma)\varsigma^{-2i\nu}e^{i\varsigma^2}}{(\lambda-\lambda_0)}\frac{d\varsigma}{2\pi i}$$
$$+\frac{\overline{r_{\mathcal{B}}(\lambda_0)}}{2^{2i\nu}}\int_0^{\varepsilon_1}\frac{\mathcal{X}_{+,22}^{\Sigma_{A,r}}(\varsigma)\varsigma^{-2i\nu}e^{i\varsigma^2}}{(\lambda+\lambda_0)}\frac{d\varsigma}{2\pi i}-\frac{\overline{r_{\mathcal{B}}(\lambda_0)}e^{2\pi\nu}}{2^{2i\nu}}\int_0^{\varepsilon_2}\frac{\mathcal{X}_{-,22}^{\Sigma_{A,r}}(\varsigma)\varsigma^{-2i\nu}e^{i\varsigma^2}}{(\lambda+\lambda_0)}\frac{d\varsigma}{2\pi i},$$
$$\mathcal{X}_{22}^{\Sigma_r}(\lambda) = -\frac{r_{\mathcal{B}}(\lambda_0)}{2^{-2i\nu}}\int_0^{\overline{\varepsilon_1}}\frac{\mathcal{X}_{-,21}^{\Sigma_{B,r}}(\varsigma)\varsigma^{2i\nu}e^{-i\varsigma^2}}{(\lambda-\lambda_0)}\frac{d\varsigma}{2\pi i}+\frac{r_{\mathcal{B}}(\lambda_0)e^{2\pi\nu}}{2^{-2i\nu}}\int_0^{\overline{\varepsilon_2}}\frac{\mathcal{X}_{+,21}^{\Sigma_{B,r}}(\varsigma)\varsigma^{2i\nu}e^{-i\varsigma^2}}{(\lambda-\lambda_0)}\frac{d\varsigma}{2\pi i}$$

$$r_{\mathcal{B}}(\lambda_0):=r(\lambda_0)\prod_{l=n+1}^{N}\left(\frac{(\lambda_0-\overline{\lambda_l})(\lambda_0+\overline{\lambda_l})}{(\lambda_0-\lambda_l)(\lambda_0+\lambda_l)}\right)^2,$$

$$\mathcal{X}^{\Sigma_{B,r}}_{-,11}(\varsigma)=\frac{\varsigma^{-i\nu}e^{\frac{i\varsigma^2}{2}}}{2^{\frac{i\nu}{2}}e^{-\frac{\pi\nu}{4}}}D_{i\nu}(\sqrt{2}\varsigma e^{\frac{i\pi}{4}}),\qquad \mathcal{X}^{\Sigma_{B,r}}_{+,11}(\varsigma)=\frac{\varsigma^{-i\nu}e^{\frac{i\varsigma^2}{2}}}{2^{\frac{i\nu}{2}}e^{\frac{3\pi\nu}{4}}}D_{i\nu}(\sqrt{2}\varsigma e^{-\frac{3\pi i}{4}}),$$

$$\mathcal{X}^{\Sigma_{B,r}}_{+,12}(\varsigma)=\frac{2^{\frac{i\nu}{2}}\varsigma^{i\nu}e^{-\frac{i\varsigma^2}{2}}e^{\frac{\pi\nu}{4}}}{\beta_{21}}\{\partial_\varsigma D_{-i\nu}(\sqrt{2}\varsigma e^{-\frac{i\pi}{4}})-i\varsigma D_{-i\nu}(\sqrt{2}\varsigma e^{-\frac{i\pi}{4}})\},$$

$$\mathcal{X}^{\Sigma_{B,r}}_{-,12}(\varsigma)=\frac{2^{\frac{i\nu}{2}}\varsigma^{i\nu}e^{-\frac{i\varsigma^2}{2}}e^{-\frac{3\pi\nu}{4}}}{\beta_{21}}\{\partial_\varsigma D_{-i\nu}(\sqrt{2}\varsigma e^{\frac{3\pi i}{4}})-i\varsigma D_{-i\nu}(\sqrt{2}\varsigma e^{\frac{3\pi i}{4}})\},$$

$$\mathcal{X}^{\Sigma_{B,r}}_{-,21}(\varsigma)=\frac{2^{-\frac{i\nu}{2}}\varsigma^{-i\nu}e^{\frac{i\varsigma^2}{2}}e^{\frac{\pi\nu}{4}}}{\beta_{12}}\{\partial_\varsigma D_{i\nu}(\sqrt{2}\varsigma e^{\frac{i\pi}{4}})+i\varsigma D_{i\nu}(\sqrt{2}\varsigma e^{\frac{i\pi}{4}})\},$$

$$\mathcal{X}^{\Sigma_{B,r}}_{+,21}(\varsigma)=\frac{2^{-\frac{i\nu}{2}}\varsigma^{-i\nu}e^{\frac{i\varsigma^2}{2}}e^{-\frac{3\pi\nu}{4}}}{\beta_{12}}\{\partial_\varsigma D_{i\nu}(\sqrt{2}\varsigma e^{-\frac{3\pi i}{4}})+i\varsigma D_{i\nu}(\sqrt{2}\varsigma e^{-\frac{3\pi i}{4}})\},$$

$$\mathcal{X}^{\Sigma_{B,r}}_{+,22}(\varsigma)=\frac{\varsigma^{i\nu}e^{-\frac{i\varsigma^2}{2}}}{2^{-\frac{i\nu}{2}}e^{-\frac{\pi\nu}{4}}}D_{-i\nu}(\sqrt{2}\varsigma e^{-\frac{i\pi}{4}}),\qquad \mathcal{X}^{\Sigma_{B,r}}_{-,22}(\varsigma)=\frac{\varsigma^{i\nu}e^{-\frac{i\varsigma^2}{2}}}{2^{-\frac{i\nu}{2}}e^{\frac{3\pi\nu}{4}}}D_{-i\nu}(\sqrt{2}\varsigma e^{\frac{3\pi i}{4}}),$$

$$\mathcal{X}^{\Sigma_{A,r}}_{\pm,11}(\varsigma)=\mathcal{X}^{\Sigma_{B,r}}_{\pm,11}(\varsigma),\qquad \mathcal{X}^{\Sigma_{A,r}}_{\pm,12}(\varsigma)=-\mathcal{X}^{\Sigma_{B,r}}_{\pm,12}(\varsigma),$$

$$\mathcal{X}^{\Sigma_{A,r}}_{\pm,21}(\varsigma)=-\mathcal{X}^{\Sigma_{B,r}}_{\pm,21}(\varsigma),\qquad \mathcal{X}^{\Sigma_{A,r}}_{\pm,22}(\varsigma)=\mathcal{X}^{\Sigma_{B,r}}_{\pm,22}(\varsigma),$$

$$\beta_{12}=-\frac{2^{1+i\nu}\sqrt{\pi}e^{-\frac{\pi\nu}{2}}e^{\frac{i\pi}{4}}}{\overline{r_{\mathcal{B}}(\lambda_0)}\,\Gamma(-i\nu)},\qquad \beta_{21}=\overline{\beta_{12}},$$

the integrals are evaluated along the rays $(0,\varepsilon_k)$ (and their complex conjugates), $\varepsilon_1:=\infty\exp\{\frac{i\pi}{4}\}$, $\varepsilon_2:=\infty\exp\{-\frac{3\pi i}{4}\}$, $D_{\pm i\nu}(\cdot)$ is the parabolic-cylinder function [32], and

$$\widehat{\Lambda}^0_{\mathcal{C}}\;=\;\exp\Big\{\sum_{l\in\{\pm\}}(\rho^{\mathcal{C}}_l(0)+\widehat{\rho}^{\mathcal{C}}_l(0))\Big\},$$

$$\rho^{\mathcal{C}}_{\pm}(0)=-\frac{1}{2\pi i}\int_0^{\pm\lambda_0}\ln|\varsigma|\,d\ln(1-|r(\varsigma)|^2),\qquad \widehat{\rho}^{\mathcal{C}}_{\pm}(0)=\int_{\pm\infty}^0\frac{\ln(1+|r(i\varsigma)|^2)}{\varsigma}\,\frac{d\varsigma}{2\pi i},$$

$$\mathcal{X}^{\Sigma_{\mathcal{C}}}_{11}(\lambda)\;=\;\widehat{\mathcal{R}}^{(-)}_{\mathcal{C}}(0)\int_0^{\overline{\varepsilon_1}}\frac{\mathcal{X}^{\Sigma^2_{\mathcal{C},r}}_{-,12}(\varsigma)e^{-i\varsigma^2}}{\lambda}\,\frac{d\varsigma}{2\pi i}-\widehat{\mathcal{R}}^{(-)}_{\mathcal{C}}(0)\int_0^{\overline{\varepsilon_2}}\frac{\mathcal{X}^{\Sigma^4_{\mathcal{C},r}}_{-,12}(\varsigma)e^{-i\varsigma^2}}{\lambda}\,\frac{d\varsigma}{2\pi i},$$

$$\mathcal{X}^{\Sigma_{\mathcal{C}}}_{12}(\lambda)\;=\;-\widehat{\mathcal{R}}^{(+)}_{\mathcal{C}}(0)\int_0^{\varepsilon_1}\frac{\mathcal{X}^{\Sigma^1_{\mathcal{C},r}}_{-,11}(\varsigma)e^{i\varsigma^2}}{\lambda}\,\frac{d\varsigma}{2\pi i}+\widehat{\mathcal{R}}^{(+)}_{\mathcal{C}}(0)\int_0^{\varepsilon_2}\frac{\mathcal{X}^{\Sigma^3_{\mathcal{C},r}}_{-,11}(\varsigma)e^{i\varsigma^2}}{\lambda}\,\frac{d\varsigma}{2\pi i},$$

$$\mathcal{X}^{\Sigma_{\mathcal{C}}}_{21}(\lambda)\;=\;\widehat{\mathcal{R}}^{(-)}_{\mathcal{C}}(0)\int_0^{\overline{\varepsilon_1}}\frac{\mathcal{X}^{\Sigma^2_{\mathcal{C},r}}_{-,22}(\varsigma)e^{-i\varsigma^2}}{\lambda}\,\frac{d\varsigma}{2\pi i}-\widehat{\mathcal{R}}^{(-)}_{\mathcal{C}}(0)\int_0^{\overline{\varepsilon_2}}\frac{\mathcal{X}^{\Sigma^4_{\mathcal{C},r}}_{-,22}(\varsigma)e^{-i\varsigma^2}}{\lambda}\,\frac{d\varsigma}{2\pi i},$$

$$\mathcal{X}^{\Sigma_{\mathcal{C}}}_{22}(\lambda)\;=\;-\widehat{\mathcal{R}}^{(+)}_{\mathcal{C}}(0)\int_0^{\varepsilon_1}\frac{\mathcal{X}^{\Sigma^1_{\mathcal{C},r}}_{-,21}(\varsigma)e^{i\varsigma^2}}{\lambda}\,\frac{d\varsigma}{2\pi i}+\widehat{\mathcal{R}}^{(+)}_{\mathcal{C}}(0)\int_0^{\varepsilon_2}\frac{\mathcal{X}^{\Sigma^3_{\mathcal{C},r}}_{-,21}(\varsigma)e^{i\varsigma^2}}{\lambda}\,\frac{d\varsigma}{2\pi i},$$

$$\widehat{\mathcal{R}}^{(+)}_{\mathcal{C}}(0)\;=\;(-1)^{2i\nu}\lambda_0^{4i\nu}\left\{\frac{r_{\mathcal{C}}(0)}{(1-|r(0)|^2)}-\frac{r_{\mathcal{C}}(i0)}{(1+|r(i0)|^2)}\right\},\qquad \widehat{\mathcal{R}}^{(-)}_{\mathcal{C}}(0)=\overline{\widehat{\mathcal{R}}^{(+)}_{\mathcal{C}}(0)},$$

$$r_{\mathcal{C}}(0):=r(0)\exp\left\{4i\sum_{l=n+1}^{N}\gamma_l\right\},\qquad r_{\mathcal{C}}(i0):=r(i0)\exp\left\{4i\sum_{l=n+1}^{N}\gamma_l\right\},$$

where $r(0):=(r(\lambda)|_{\lambda\in\mathbb{R}})|_{\lambda=0}$ and $r(i0):=(r(\lambda)|_{\lambda\in i\mathbb{R}})|_{\lambda=0}$: the explicit expressions for $\mathcal{X}^{\Sigma^i_{\mathcal{C},r}}_{-,jk}(\varsigma)$, $i\in\{1,2,3,4\}$, $j,k\in\{1,2\}$, are not written down here since they will

not actually be needed. Since [15] $(r(\lambda)|_{\lambda\in\mathbb{R}})|_{\lambda=0}=(r(\lambda)|_{\lambda\in i\mathbb{R}})|_{\lambda=0}=0$, $\widehat{\mathcal{R}}_{\mathcal{C}}^{(+)}(0)=\widehat{\mathcal{R}}_{\mathcal{C}}^{(-)}(0)=h_1^+(\lambda;\lambda_0)=0$, hence, $\mathcal{X}_{ij}^{\Sigma_C}(\lambda)=0$, $i,j\in\{1,2\}$. To obtain the expression for $\mathcal{X}_{ij}^{\Sigma_r}(\lambda)$, $i,j\in\{1,2\}$, given above, use was made of the explicit representation for $\mu_{00}^c(\cdot;\lambda_0):=(\underline{\mathbf{Id}}-C_{00}^\natural(\cdot;\lambda_0))^{-1}\mathrm{I}$ on $L'\cup\overline{L'}$ (recall the definition of $I_{1/2}$) in terms of parabolic-cylinder functions given in section 7 of [15]. Now, substituting the expressions given above for $\mathcal{X}_{\pm,ij}^{\Sigma_{B,r}}(\varsigma)$ and $\mathcal{X}_{\pm,ij}^{\Sigma_{A,r}}(\varsigma)$, $i,j\in\{1,2\}$, into the corresponding integrals for $\mathcal{X}_{ij}^{\Sigma_r}(\lambda)$, $i,j\in\{1,2\}$, and using the following identities [32], $\partial_\varsigma D_a(\varsigma)=\frac{1}{2}(aD_{a-1}(\varsigma)-D_{a+1}(\varsigma))$, $\varsigma D_a(\varsigma)=D_{a+1}(\varsigma)+aD_{a-1}(\varsigma)$, and $|\Gamma(i\nu)|^2=\pi/(\nu\sinh\pi\nu)$, as well as the following integral [32]:

$$\int_0^\infty \exp\left(-\frac{x^2}{4}\right)x^{a-1}D_{-b}(x)dx=\frac{\sqrt{\pi}\exp\{-\frac{1}{2}(a+b)\ln 2\}\Gamma(a)}{\Gamma(\frac{1}{2}(a+b)+\frac{1}{2})},\qquad \Re(a)>0,$$

one obtains the result stated in the lemma. □

PROPOSITION 4.2. *As $\lambda\to\infty$, $\lambda\in\mathbb{C}\setminus(\widehat{\Gamma}\cup(\cup_{i=1}^n(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\})))$, $\chi(\lambda)$ has the following asymptotic expansion:*

$$\begin{aligned}\chi(\lambda)=\mathrm{I}+\frac{1}{2\lambda}\Bigg(&\left\{\overline{Q^\chi(x,t)}+4\sum_{i=1}^n\left(\beta_i-\frac{\chi_{21}^c(\overline{\lambda_i})}{\chi_{11}^c(\overline{\lambda_i})}\widehat{\delta}_i\right)\right\}\sigma_-\\ &+\left\{Q^\chi(x,t)+4\sum_{i=1}^n\left(\omega_i-\frac{\chi_{12}^c(\lambda_i)}{\chi_{22}^c(\lambda_i)}\alpha_i\right)\right\}\sigma_+\Bigg)+\mathcal{O}(\lambda^{-2}),\end{aligned}\tag{94}$$

where $\lim_{\lambda\to\infty}(\chi^c(x,t;\lambda))_{12}:=Q^\chi(x,t)/2\lambda$, $\{\alpha_i,\omega_i\}_{i=1}^n$ satisfy the following nondegenerate system of $2n$ linear inhomogeneous algebraic equations:

$$\begin{bmatrix}\widehat{\mathcal{A}}^+ & \widehat{\mathcal{B}}^+\\ \widehat{\mathcal{C}}^+ & \widehat{\mathcal{D}}^+\end{bmatrix}\begin{bmatrix}\alpha_1\\ \alpha_2\\ \vdots\\ \alpha_n\\ \omega_1\\ \omega_2\\ \vdots\\ \omega_n\end{bmatrix}=\begin{bmatrix}g_1^+\chi_{12}^c(\lambda_1)\\ g_2^+\chi_{12}^c(\lambda_2)\\ \vdots\\ g_n^+\chi_{12}^c(\lambda_n)\\ \overline{g_1^+}\chi_{11}^c(\overline{\lambda_1})\\ \overline{g_2^+}\chi_{11}^c(\overline{\lambda_2})\\ \vdots\\ \overline{g_n^+}\chi_{11}^c(\overline{\lambda_n})\end{bmatrix},\tag{95}$$

where, for $i,j\in\{1,2,\dots,n\}$, the $n\times n$ matrix blocks $\widehat{\mathcal{A}}^+$, $\widehat{\mathcal{B}}^+$, $\widehat{\mathcal{C}}^+$, and $\widehat{\mathcal{D}}^+$ are defined as follows,

$$\widehat{\mathcal{A}}_{ij}^+:=\begin{cases}\frac{\lambda_i+g_i^+\chi_{12}^c(\lambda_i)\chi_{22}^c(\lambda_i)+\lambda_i g_i^+\mathrm{W}(\chi_{12}^c(\lambda_i),\chi_{22}^c(\lambda_i))}{\lambda_i\chi_{22}^c(\lambda_i)}, & i=j,\\ -\frac{2g_i^+(-\lambda_i\chi_{22}^c(\lambda_i)\chi_{12}^c(\lambda_j)+\lambda_j\chi_{22}^c(\lambda_j)\chi_{12}^c(\lambda_i))}{\chi_{22}^c(\lambda_j)(\lambda_i^2-\lambda_j^2)}, & i\neq j,\end{cases}$$

$$\widehat{\mathcal{B}}_{ij}^+:=\begin{cases}-\frac{2g_i^+(\lambda_i\chi_{22}^c(\lambda_i)\chi_{11}^c(\overline{\lambda_i})-\overline{\lambda_i}\chi_{21}^c(\overline{\lambda_i})\chi_{12}^c(\lambda_i))}{\chi_{11}^c(\overline{\lambda_i})(\lambda_i^2-\overline{\lambda_i}^2)}, & i=j,\\ -\frac{2g_i^+(\lambda_i\chi_{22}^c(\lambda_i)\chi_{11}^c(\overline{\lambda_j})-\overline{\lambda_j}\chi_{21}^c(\overline{\lambda_j})\chi_{12}^c(\lambda_i))}{\chi_{11}^c(\overline{\lambda_j})(\lambda_i^2-\overline{\lambda_j}^2)}, & i\neq j,\end{cases}$$

$$\widehat{\mathcal{D}}^+_{ij} := \begin{cases} \frac{\overline{\lambda_i}-\overline{g_i^+}\chi^c_{21}(\overline{\lambda_i})\chi^c_{11}(\overline{\lambda_i})+\overline{\lambda_i}\,\overline{g_i^+}\mathrm{W}(\chi^c_{21}(\overline{\lambda_i}),\chi^c_{11}(\overline{\lambda_i}))}{\overline{\lambda_i}\chi^c_{11}(\overline{\lambda_i})}, & i=j,\\ -\frac{2\overline{g_i^+}(\overline{\lambda_i}\chi^c_{21}(\overline{\lambda_i})\chi^c_{11}(\overline{\lambda_j})-\overline{\lambda_j}\chi^c_{21}(\overline{\lambda_j})\chi^c_{11}(\overline{\lambda_i}))}{\chi^c_{11}(\overline{\lambda_j})(\overline{\lambda_i}^2-\overline{\lambda_j}^2)}, & i\neq j, \end{cases}$$

$\{\beta_i,\widehat{\delta}_i\}_{i=1}^n$ satisfy the following nondegenerate system of $2n$ linear inhomogeneous algebraic equations,

$$\begin{bmatrix} \boxed{\widehat{\mathcal{E}}^+} & \boxed{\widehat{\mathcal{F}}^+} \\ \boxed{\widehat{\mathcal{G}}^+} & \boxed{\widehat{\mathcal{H}}^+} \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_n \\ \widehat{\delta}_1 \\ \widehat{\delta}_2 \\ \vdots \\ \widehat{\delta}_n \end{bmatrix} = \begin{bmatrix} g_1^+\chi^c_{22}(\lambda_1) \\ g_2^+\chi^c_{22}(\lambda_2) \\ \vdots \\ g_n^+\chi^c_{22}(\lambda_n) \\ \overline{g_1^+}\chi^c_{21}(\overline{\lambda_1}) \\ \overline{g_2^+}\chi^c_{21}(\overline{\lambda_2}) \\ \vdots \\ \overline{g_n^+}\chi^c_{21}(\overline{\lambda_n}) \end{bmatrix}, \tag{96}$$

where, for $i,j\in\{1,2,\dots,n\}$, the $n\times n$ matrix blocks $\widehat{\mathcal{E}}^+$, $\widehat{\mathcal{F}}^+$, $\widehat{\mathcal{G}}^+$, and $\widehat{\mathcal{H}}^+$ are defined as follows,

$$\widehat{\mathcal{E}}^+_{ij} := \begin{cases} \frac{\lambda_i-g_i^+\chi^c_{12}(\lambda_i)\chi^c_{22}(\lambda_i)+\lambda_i g_i^+\mathrm{W}(\chi^c_{12}(\lambda_i),\chi^c_{22}(\lambda_i))}{\lambda_i\chi^c_{22}(\lambda_i)}, & i=j,\\ \frac{2g_i^+(\lambda_j\chi^c_{12}(\lambda_j)\chi^c_{22}(\lambda_i)-\lambda_i\chi^c_{12}(\lambda_i)\chi^c_{22}(\lambda_j))}{\chi^c_{22}(\lambda_j)(\lambda_i^2-\lambda_j^2)}, & i\neq j, \end{cases}$$

$$\widehat{\mathcal{F}}^+_{ij} := \begin{cases} \frac{2g_i^+(\lambda_i\chi^c_{12}(\lambda_i)\chi^c_{21}(\overline{\lambda_i})-\overline{\lambda_i}\chi^c_{11}(\overline{\lambda_i})\chi^c_{22}(\lambda_i))}{\chi^c_{11}(\overline{\lambda_i})(\lambda_i^2-\overline{\lambda_i}^2)}, & i=j,\\ \frac{2g_i^+(\lambda_i\chi^c_{12}(\lambda_i)\chi^c_{21}(\overline{\lambda_j})-\overline{\lambda_j}\chi^c_{11}(\overline{\lambda_j})\chi^c_{22}(\lambda_i))}{\chi^c_{11}(\overline{\lambda_j})(\lambda_i^2-\overline{\lambda_j}^2)}, & i\neq j, \end{cases}$$

$$\widehat{\mathcal{G}}^+_{ij} := \begin{cases} \frac{2\overline{g_i^+}(\lambda_i\chi^c_{12}(\lambda_i)\chi^c_{21}(\overline{\lambda_i})-\overline{\lambda_i}\chi^c_{11}(\overline{\lambda_i})\chi^c_{22}(\lambda_i))}{\chi^c_{22}(\lambda_i)(\overline{\lambda_i}^2-\lambda_i^2)}, & i=j,\\ \frac{2\overline{g_i^+}(\lambda_j\chi^c_{12}(\lambda_j)\chi^c_{21}(\overline{\lambda_i})-\overline{\lambda_i}\chi^c_{11}(\overline{\lambda_i})\chi^c_{22}(\lambda_j))}{\chi^c_{22}(\lambda_j)(\overline{\lambda_i}^2-\lambda_j^2)}, & i\neq j, \end{cases}$$

$$\widehat{\mathcal{H}}^+_{ij} := \begin{cases} \frac{\overline{\lambda_i}+\overline{g_i^+}\chi^c_{11}(\overline{\lambda_i})\chi^c_{21}(\overline{\lambda_i})-\overline{\lambda_i}\,\overline{g_i^+}\mathrm{W}(\chi^c_{11}(\overline{\lambda_i}),\chi^c_{21}(\overline{\lambda_i}))}{\overline{\lambda_i}\chi^c_{11}(\overline{\lambda_i})}, & i=j,\\ \frac{2\overline{g_i^+}(\overline{\lambda_i}\chi^c_{11}(\overline{\lambda_i})\chi^c_{21}(\overline{\lambda_j})-\overline{\lambda_j}\chi^c_{11}(\overline{\lambda_j})\chi^c_{21}(\overline{\lambda_i}))}{\chi^c_{11}(\overline{\lambda_j})(\overline{\lambda_i}^2-\overline{\lambda_j}^2)}, & i\neq j, \end{cases}$$

with

$$g_j^+ := C_j e^{2i\lambda_j^2x+4i\lambda_j^4t}(\delta^+(\lambda_j;\lambda_0))^{-2}\prod_{l=n+1}^{N}\left(\frac{(\lambda_j-\lambda_l)(\lambda_j+\lambda_l)}{(\lambda_j-\overline{\lambda_l})(\lambda_j+\overline{\lambda_l})}\right)^2, \qquad 1\le j\le n,$$

$\delta^+(\lambda_k;\lambda_0)$, $k\in\{1,2,\dots,n\}$, given in Theorem 2.1, (18), *and $\mathrm{W}(\chi^c_{ij}(z),\chi^c_{i'j'}(z))$ is the Wronskian of $\chi^c_{ij}(\lambda)$ and $\chi^c_{i'j'}(\lambda)$ $(i,j,i',j'\in\{1,2\})$ evaluated at z: $\mathrm{W}(\chi^c_{ij}(z),\chi^c_{i'j'}(z)) := (\chi^c_{ij}(\lambda)\partial_\lambda\chi^c_{i'j'}(\lambda)-\chi^c_{i'j'}(\lambda)\partial_\lambda\chi^c_{ij}(\lambda))|_{\lambda=z}$.*

Proof. For $1\le i\le n$, set

$$\mathrm{res}(\chi(\lambda);\lambda_i) = \begin{pmatrix} \alpha_i & a_i \\ \beta_i & b_i \end{pmatrix}, \qquad \mathrm{res}(\chi(\lambda);\overline{\lambda_i}) = \begin{pmatrix} c_i & \omega_i \\ d_i & \widehat{\delta}_i \end{pmatrix}. \tag{97}$$

From (92), (93), (97), and the polar (residue) conditions in Lemma 3.3, one gets a system of linear algebraic equations for $\{\alpha_i,\beta_i,a_i,b_i,c_i,d_i,\omega_i,\widehat{\delta}_i\}_{i=1}^n$: from this system, one shows that, for $1\le i\le n$,

$$\left.\begin{aligned}
(\chi_{12}^c(\lambda_i)\alpha_i+\chi_{22}^c(\lambda_i)a_i)g_i^+=0 &\Rightarrow a_i=-\tfrac{\chi_{12}^c(\lambda_i)}{\chi_{22}^c(\lambda_i)}\alpha_i,\\
(\chi_{12}^c(\lambda_i)\beta_i+\chi_{22}^c(\lambda_i)b_i)g_i^+=0 &\Rightarrow b_i=-\tfrac{\chi_{12}^c(\lambda_i)}{\chi_{22}^c(\lambda_i)}\beta_i,\\
(\chi_{11}^c(\overline{\lambda_i})c_i+\chi_{21}^c(\overline{\lambda_i})\omega_i)\overline{g_i^+}=0 &\Rightarrow c_i=-\tfrac{\chi_{21}^c(\overline{\lambda_i})}{\chi_{11}^c(\overline{\lambda_i})}\omega_i,\\
(\chi_{11}^c(\overline{\lambda_i})d_i+\chi_{21}^c(\overline{\lambda_i})\widehat{\delta}_i)\overline{g_i^+}=0 &\Rightarrow d_i=-\tfrac{\chi_{21}^c(\overline{\lambda_i})}{\chi_{11}^c(\overline{\lambda_i})}\widehat{\delta}_i;
\end{aligned}\right\}. \tag{98}$$

Using (98), which show that the matrices $\{\mathrm{res}(\chi(\lambda);\lambda_i)\}_{i=1}^n$ and $\{\mathrm{res}(\chi(\lambda);\overline{\lambda_i})\}_{i=1}^n$, resp., are degenerate, one simplifies the resulting system of linear algebraic equations for $\{\alpha_i,\beta_i,a_i,b_i,c_i,d_i,\omega_i,\widehat{\delta}_i\}_{i=1}^n$ and obtains (95) and (96): the nondegeneracy of systems (95) and (96) is a consequence of the unique solvability of the original RH problem (Lemma 2.2). By substituting (97) into (92) and defining $Q^\chi(x,t)$ as in the proposition, one obtains, using (93), the result given in Lemma 4.1, and (98), the result given by (94). □

COROLLARY 4.1. *As $t\to+\infty$ and $x\to-\infty$ such that $\lambda_0>M$ and $(x,t)\in\Omega_n$,*

$$Q(x,t)=\underset{-}{Q}{}_+^{\mathcal{C}}(x,t)+4i\sum_{j=1}^n\left(\omega_j-\frac{\chi_{12}^c(\lambda_j)}{\chi_{22}^c(\lambda_j)}\alpha_j\right)+\mathcal{O}(C(\lambda_0)\exp\{-abt\}),$$

where $\underset{-}{Q}{}_+^{\mathcal{C}}(x,t):=iQ^\chi(x,t)$, a and b are given in Lemma 3.3, and $C(\lambda_0)\in\mathcal{L}^\infty(\mathbb{R}_{>M};\mathbb{C})$.

Proof. Since, from Lemma 3.2, $Q(x,t)=2i\lim_{\lambda\to\infty}(\lambda m^\sharp(x,t;\lambda))_{12}$, the result follows from Lemma 3.3 and Proposition 4.2. □

PROPOSITION 4.3. *As $t\to+\infty$ and $x\to-\infty$ such that $\lambda_0>M$ and $(x,t)\in\Omega_n$,*

$$\begin{aligned}
Q(x,t)=Q_+^{\mathcal{C}}(x,t)&+4i\left(\omega_n-\frac{\chi_{12}^c(\lambda_n)}{\chi_{22}^c(\lambda_n)}\alpha_n\right)\\
&+\mathcal{O}\left(\frac{C_1(\lambda_0)\ln t}{t}\right)+\mathcal{O}(C_2(\lambda_0)e^{-a_0b_0t}),
\end{aligned} \tag{99}$$

where

$$\alpha_n=\frac{\widehat{a}_{12}\overline{g_n^+}\chi_{11}^c(\overline{\lambda_n})+\widehat{a}_{22}g_n^+\chi_{12}^c(\lambda_n)}{(\widehat{a}_{11}\widehat{a}_{22}-\widehat{a}_{12}\widehat{a}_{21})}, \tag{100}$$

$$\omega_n=\frac{\widehat{a}_{11}\overline{g_n^+}\chi_{11}^c(\overline{\lambda_n})+\widehat{a}_{21}g_n^+\chi_{12}^c(\lambda_n)}{(\widehat{a}_{11}\widehat{a}_{22}-\widehat{a}_{12}\widehat{a}_{21})}, \tag{101}$$

$$\widehat{a}_{11}:=\frac{\lambda_n+g_n^+\chi_{12}^c(\lambda_n)\chi_{22}^c(\lambda_n)+\lambda_ng_n^+\mathrm{W}(\chi_{12}^c(\lambda_n),\chi_{22}^c(\lambda_n))}{\lambda_n\chi_{22}^c(\lambda_n)}, \tag{102}$$

$$\widehat{a}_{12}:=\frac{2g_n^+(\lambda_n\chi_{22}^c(\lambda_n)\chi_{11}^c(\overline{\lambda_n})-\overline{\lambda_n}\chi_{21}^c(\overline{\lambda_n})\chi_{12}^c(\lambda_n))}{\chi_{11}^c(\overline{\lambda_n})(\lambda_n^2-\overline{\lambda_n}^2)}, \tag{103}$$

$$\widehat{a}_{21}:=\frac{2\overline{g_n^+}(\lambda_n\chi_{22}^c(\lambda_n)\chi_{11}^c(\overline{\lambda_n})-\overline{\lambda_n}\chi_{21}^c(\overline{\lambda_n})\chi_{12}^c(\lambda_n))}{\chi_{22}^c(\lambda_n)(\overline{\lambda_n}^2-\lambda_n^2)}, \tag{104}$$

$$\widehat{a}_{22}:=\frac{\overline{\lambda_n}-\overline{g_n^+}\chi_{21}^c(\overline{\lambda_n})\chi_{11}^c(\overline{\lambda_n})+\overline{\lambda_n}\,\overline{g_n^+}\mathrm{W}(\chi_{21}^c(\overline{\lambda_n}),\chi_{11}^c(\overline{\lambda_n}))}{\overline{\lambda_n}\chi_{11}^c(\overline{\lambda_n})}, \tag{105}$$

$Q_+^{\mathcal{C}}(x,t)$ *is given in Theorem* 2.1, (20)–(22) *and* (24), $a_0 := \min(a, 8\min\{\eta_l\}_{l=1}^{n-1})$ (>0), $b_0 := \min(b, \min\{|\xi_n - \xi_l|\}_{l=1}^{n-1})$, $C_1(\lambda_0) \in \mathcal{S}(\mathbb{R}_{>M};\mathbb{C})$, *and* $C_2(\lambda_0) \in \mathcal{L}^\infty(\mathbb{R}_{>M};\mathbb{C})$.

Proof. Solving (95) as $t \to +\infty$ and $x \to -\infty$ such that $\lambda_0 > M$ and $(x,t) \in \Omega_n$ for $\{\alpha_i\}_{i=1}^n$ and $\{\omega_i\}_{i=1}^n$ via Cramer's rule, one shows that

$$\alpha_i,\ \omega_i \sim \mathcal{O}\left(\exp\left\{-a^\flat \min_{1\le l\le n-1} |\xi_n - \xi_l| t\right\}\right), \qquad 1 \le i \le n-1, \tag{106}$$

where $a^\flat := 8\min\{\eta_l\}_{l=1}^{n-1}$ (>0), and α_n and ω_n are given by (100) and (101): the result now follows from Corollary 4.1 and the estimates in (106). ∎

PROPOSITION 4.4. *As* $t \to +\infty$ *and* $x \to -\infty$ *such that* $\lambda_0 > M$ *and* $(x,t) \in \Omega_n$,

$$Q(x,t) = Q_{\text{as}}^+(x,t) + \mathcal{O}\left(\frac{C(\lambda_0)\ln t}{t}\right),$$

where $Q_{\text{as}}^+(x,t)$ *is given in Theorem* 2.1, (14)–(29), *and* $C(\lambda_0) \in \mathcal{S}(\mathbb{R}_{>M};\mathbb{C})$.

Proof. For the proof substitute $\chi_{ij}^c(\cdot)$, $i,j \in \{1,2\}$, from Lemma 4.1 into (99)–(105) and neglect exponentially small terms. ∎

5. Asymptotic evaluation of $((\Psi^{-1}(x,t;0))_{11})^2$. In this section, the phase integral, $((\Psi^{-1}(x,t;0))_{11})^2$, which appears in the gauge transformation (Proposition 2.3, (9)) is evaluated asymptotically as $t \to +\infty$ $(x/t \sim \mathcal{O}(1))$.

LEMMA 5.1. *As* $t \to +\infty$ *and* $x \to -\infty$ *such that* $\lambda_0 > M$ *and* $(x,t) \in \Omega_n$,

$$\begin{aligned}((\Psi^{-1}(x,t;0))_{11})^2 = {}& \exp\{2\ln(\chi_{22}^c(0))\} \\ & \times \exp\left\{\frac{2i}{\pi}\left(\int_0^{\lambda_0} \frac{\ln(1-|r(\varrho)|^2)}{\varrho} d\varrho - \int_0^\infty \frac{\ln(1+|r(i\varrho)|^2)}{\varrho} d\varrho\right)\right\} \\ & \times \exp\left\{-4i\sum_{l=n+1}^N \gamma_l\right\} \exp\left\{2\ln\left(1 - \sum_{i=1}^n \left(\frac{2b_i}{\lambda_i} + \frac{2\widehat{\delta}_i}{\overline{\lambda_i}}\right)\right)\right\} \\ & + \mathcal{O}(C(\lambda_0)e^{-abt}),\end{aligned}$$

where $b_i = -\frac{\chi_{12}^c(\lambda_i)}{\chi_{22}^c(\lambda_i)}\beta_i$, $1 \le i \le n$, $\{\beta_i, \widehat{\delta}_i\}_{i=1}^n$ *satisfy* (96), a *and* b *are given in Lemma* 3.3, *and* $C(\lambda_0) \in \mathcal{L}^\infty(\mathbb{R}_{>M};\mathbb{C})$.

Proof. From Lemma 2.1, the proof of Lemma 3.1, Proposition 3.2, (85), Lemma 3.2, (86), and Lemma 3.3, one gets that

$$\Psi(x,t;0) = \chi(0)(\delta(0))^{\sigma_3} \prod_{l=n+1}^N (d_{l_+}(0))^{\sigma_3} + \mathcal{O}(C_1(\lambda_0)\exp\{-abt\}),$$

where $C_1(\lambda_0) \in \mathcal{L}^\infty(\mathbb{R}_{>M};M_2(\mathbb{C}))$. From Propositions 2.1–2.3, the parametrization for the discrete eigenvalues (section 2), Lemma 3.2 (equation (87)), Proposition 4.1 (equations (92) and (93)), the proof of Proposition 4.2 (equations (97) and (98)), and the σ_1 and σ_3 symmetry reductions for $\chi(\lambda)$, one shows that,

$$\Psi^{-1}(x,t;0) = (\widehat{h}(0))^{\sigma_3} \begin{pmatrix} 1 - \sum_{i=1}^n \left(\frac{2b_i}{\lambda_i} + \frac{2\widehat{\delta}_i}{\overline{\lambda_i}}\right) & 0 \\ 0 & 1 - \sum_{i=1}^n \left(\frac{2\alpha_i}{\lambda_i} + \frac{2c_i}{\overline{\lambda_i}}\right) \end{pmatrix} + \mathcal{O}(C_2(\lambda_0)e^{-abt}),$$

where $\widehat{h}(0) := \chi^c_{22}(0)(\delta(0))^{-1}\exp\{-2i\sum_{l=n+1}^{N}\gamma_l\}$, b_i, $1\le i\le n$, and $\{\beta_i,\widehat{\delta}_i\}_{i=1}^n$ are as given in the lemma, $c_i = -\frac{\chi^c_{21}(\overline{\lambda_i})}{\chi^c_{11}(\lambda_i)}\omega_i$, $1\le i\le n$, $\{\alpha_i,\omega_i\}_{i=1}^n$ are defined by system (95), and $C_2(\lambda_0)\in\mathcal{L}^\infty(\mathbb{R}_{>M};M_2(\mathbb{C}))$: using the expression for $\delta^+(\lambda;\lambda_0)$ given in Proposition 3.1 (and Remark 3.1), one obtains the result stated in the lemma. ∎

In order to estimate $(\chi^c_{22}(0))^2$, the following proposition and lemma are necessary.

PROPOSITION 5.1. *Define* $Q^\sharp(x,t) := 2i\lim_{\lambda\to\infty}(\lambda\chi^c(x,t;\lambda))_{12}$. *Then*

$$(||Q^\sharp(\cdot,t)||_{\mathcal{L}^2(\mathbb{R};\mathbb{C})})^2 = \frac{2}{\pi}\left(\int_0^\infty \frac{\ln(1+|r(i\varrho)|^2)}{\varrho}d\varrho - \int_0^\infty \frac{\ln(1-|r(\varrho)|^2)}{\varrho}d\varrho\right),$$
$$(\chi^c_{22}(0))^2 = (\delta^+(0;\lambda_0))^2\exp\left\{i\int_{+\infty}^x |Q^\sharp(\varrho,t)|^2 d\varrho\right\}.$$

Proof. The proof follows from the definition of $\chi^c(\lambda)$ given in Proposition 4.1, Proposition 2.2, and Proposition 8.1 in [15]. ∎

LEMMA 5.2 (see [35]). *As* $t\to+\infty$ *and* $x\to-\infty$ *such that* $\lambda_0>M$,

$$Q^\sharp(x,t) = \frac{u^+_{1,1,0}(\lambda_0)e^{i(4\lambda_0^4 t-\nu(\lambda_0)\ln t)}}{\sqrt{t}} + \frac{u^+_{-1,2,0}(\lambda_0)}{t} + \mathcal{O}\left(\frac{C(\lambda_0)(\ln t)^2}{t^{3/2}}\right),$$

where

$$u^+_{1,1,0}(\lambda_0) = \sqrt{\frac{\nu(\lambda_0)}{2\lambda_0^2}}\exp\{i\theta^+(\lambda_0)\},$$
$$\theta^+(\lambda_0) = \phi^+(\lambda_0) - \frac{3\pi}{4} + \arg\Gamma(i\nu(\lambda_0)) + \arg r(\lambda_0) - 3\nu(\lambda_0)\ln 2 + 2\sum_{l=n+1}^{N}\arg\left(\frac{(\lambda_0-\overline{\lambda_l})(\lambda_0+\overline{\lambda_l})}{(\lambda_0-\lambda_l)(\lambda_0+\lambda_l)}\right),$$
$$u^+_{-1,2,0}(\lambda_0) = -\frac{i}{8\pi\lambda_0^2}\left(\left.\frac{d(r(\varrho)|_{\varrho\in\mathbb{R}})}{d\varrho}\right|_{\varrho=0} - \left.\frac{d(r(\varrho)|_{\varrho\in i\mathbb{R}})}{d\varrho}\right|_{\varrho=0}\right) \times\exp\left\{i\left(4\sum_{l=n+1}^{N}\gamma_l + 2\vartheta^+(\lambda_0)\right)\right\},$$
$$\vartheta^+(\lambda_0) = -\int_0^{\lambda_0}\frac{\ln(1-|r(\varrho)|^2)}{\varrho}\frac{d\varrho}{\pi} + \int_0^\infty \frac{\ln(1+|r(i\varrho)|^2)}{\varrho}\frac{d\varrho}{\pi},$$

$\phi^+(\cdot)$ *is given in Theorem* 2.1, (22), *and* $C(\lambda_0)\in\mathcal{S}(\mathbb{R}_{>M};\mathbb{C})$.

Comment to proof. Up to the leading ($\mathcal{O}(t^{-1})$) term, the asymptotic expansion was proved in [15]. The $\mathcal{O}(t^{-1})$ term constitutes the leading-order contribution from the first-order stationary phase point at $\lambda=0$: the complete proof of this asymptotic expansion can be found in [35].

PROPOSITION 5.2. *As* $t\to+\infty$ *and* $x\to-\infty$ *such that* $\lambda_0>M$,

$$(\chi^c_{22}(0))^2 = \exp\left\{i\left(\sqrt{\frac{2}{t}}\int_{\lambda_0}^\infty \frac{\sqrt{\nu(\mu)}}{\mu^2}\left(R_i^+(0)\cos(\kappa^+(\mu;t)) - R_r^+(0)\sin(\kappa^+(\mu;t))\right)\frac{d\mu}{\pi}\right)\right\} + \mathcal{O}\left(\frac{C(\lambda_0)(\ln t)^2}{\lambda_0^2 t}\right),$$

where

$$R_i^+(0) = \Im\{R^+(0)\}, \qquad R_r^+(0) = \Re\{R^+(0)\}$$

$$:= \left(\frac{d(r(\varrho)|_{\varrho\in\mathbb{R}})}{d\varrho}\bigg|_{\varrho=0} - \frac{d(r(\varrho)|_{\varrho\in i\mathbb{R}})}{d\varrho}\bigg|_{\varrho=0} \right) \exp\left\{ 4i \sum_{l=n+1}^{N} \gamma_l \right\},$$

$$\kappa^+(\lambda_0;t) := 4\lambda_0^4 t - \nu(\lambda_0)\ln t + \theta^+(\lambda_0) - 2\vartheta^+(\lambda_0),$$

and $C(\lambda_0)\in\mathcal{S}(\mathbb{R}_{>M};\mathbb{C})$.

Proof. Writing $\int_{+\infty}^{x}|Q^\sharp(\varrho,t)|^2 d\varrho = -(||Q^\sharp(\cdot,t)||_{\mathcal{L}^2(\mathbb{R};\mathbb{C})})^2 + \int_{-\infty}^{x}|Q^\sharp(\varrho,t)|^2 d\varrho$, using the expressions for $(||Q^\sharp(\cdot,t)||_{\mathcal{L}^2(\mathbb{R};\mathbb{C})})^2$ and $(\chi_{22}^c(0))^2$ given in Proposition 5.1, the asymptotic expansion for $Q^\sharp(x,t)$ given in Lemma 5.2, the following inequalities: $|\exp\{(\cdot)\}-1| \le |(\cdot)|\sup_{s\in[0,1]}|\exp\{s(\cdot)\}|$ and $0<\nu(\lambda_0)\le\nu_{\max} := -\frac{1}{2\pi}\ln(1-\sup_{\lambda\in\mathbb{R}}|r(\lambda)|^2)<\infty$, and the fact that $r(\lambda)\in\mathcal{S}(\widehat{\Gamma};\mathbb{C})$, one obtains the result stated in the proposition. ∎

LEMMA 5.3. *As* $t\to+\infty$ *and* $x\to-\infty$ *such that* $\lambda_0>M$ *and* $(x,t)\in\Omega_n$,

$$((\Psi^{-1}(x,t;0))_{11})^2 = \exp\{i\arg q_{\text{as}}^+(x,t)\} + \mathcal{O}\left(\frac{C(\lambda_0)(\ln t)^2}{t}\right),$$

where $\arg q_{\text{as}}^+(x,t)$ *is given in Theorem* 2.2, (48)–(51), *and* $C(\lambda_0)\in\mathcal{S}(\mathbb{R}_{>M};\mathbb{C})$.

Proof. According to Lemma 5.1, in order to evaluate $((\Psi^{-1}(x,t;0))_{11})^2$, estimates for $\exp\{2\ln(\chi_{22}^c(0))\}$ and $\{b_i,\widehat{\delta}_i\}_{i=1}^n$ are required: the estimation for $\exp\{2\ln(\chi_{22}^c(0))\}$ is given in Proposition 5.2; hence, it remains to estimate $\{b_i,\widehat{\delta}_i\}_{i=1}^n$. Solving system (96) as $t\to+\infty$ and $x\to-\infty$ such that $\lambda_0>M$ and $(x,t)\in\Omega_n$ for $\{\beta_i\}_{i=1}^n$ and $\{\widehat{\delta}_i\}_{i=1}^n$ via Cramer's rule, one shows that β_i, $\widehat{\delta}_i\sim\mathcal{O}(\exp\{-a^\flat\min_{1\le i\le n-1}|\xi_n-\xi_i|t\})$, $1\le i\le n-1$, and

$$\beta_n = \frac{\beta_n^+}{(\widehat{\mathcal{E}}_{nn}^+\widehat{\mathcal{H}}_{nn}^+ - \widehat{\mathcal{F}}_{nn}^+\widehat{\mathcal{G}}_{nn}^+)}, \qquad \widehat{\delta}_n = \frac{\widehat{\delta}_n^+}{(\widehat{\mathcal{E}}_{nn}^+\widehat{\mathcal{H}}_{nn}^+ - \widehat{\mathcal{F}}_{nn}^+\widehat{\mathcal{G}}_{nn}^+)},$$

where

$$\begin{aligned}
\beta_n^+ :=\ & \frac{g_n^+\chi_{22}^c(\lambda_n)}{\chi_{11}^c(\overline{\lambda_n})} + \frac{|g_n^+|^2\chi_{21}^c(\overline{\lambda_n})\chi_{22}^c(\lambda_n)}{\overline{\lambda_n}} - \frac{|g_n^+|^2\chi_{22}^c(\lambda_n)W(\chi_{11}^c(\overline{\lambda_n}),\chi_{21}^c(\overline{\lambda_n}))}{\chi_{11}^c(\overline{\lambda_n})} \\
& + \frac{2\overline{\lambda_n}|g_n^+|^2\chi_{22}^c(\lambda_n)\chi_{21}^c(\overline{\lambda_n})}{(\lambda_n^2-\overline{\lambda_n}^2)}, \\
\widehat{\mathcal{E}}_{nn}^+\widehat{\mathcal{H}}_{nn}^+ - \widehat{\mathcal{F}}_{nn}^+\widehat{\mathcal{G}}_{nn}^+ :=\ & \frac{1}{\chi_{22}^c(\lambda_n)\chi_{11}^c(\overline{\lambda_n})} + \frac{\overline{g_n^+}W(\chi_{21}^c(\overline{\lambda_n}),\chi_{11}^c(\overline{\lambda_n}))}{\chi_{22}^c(\lambda_n)\chi_{11}^c(\overline{\lambda_n})} \\
& + \frac{g_n^+W(\chi_{12}^c(\lambda_n),\chi_{22}^c(\lambda_n))}{\chi_{11}^c(\overline{\lambda_n})\chi_{22}^c(\lambda_n)} + \frac{\overline{g_n^+}\chi_{21}^c(\overline{\lambda_n})}{\overline{\lambda_n}\chi_{22}^c(\lambda_n)} - \frac{g_n^+\chi_{12}^c(\lambda_n)}{\lambda_n\chi_{11}^c(\overline{\lambda_n})} \\
& + \frac{(2\overline{\lambda_n})^2|g_n^+|^2\chi_{22}^c(\lambda_n)\chi_{11}^c(\overline{\lambda_n})}{(\lambda_n^2-\overline{\lambda_n}^2)^2}, \widehat{\delta}_n^+ \\
:=\ & \frac{\overline{g_n^+}\chi_{21}^c(\overline{\lambda_n})}{\chi_{22}^c(\lambda_n)} - \frac{2\overline{\lambda_n}|g_n^+|^2\chi_{11}^c(\overline{\lambda_n})\chi_{22}^c(\lambda_n)}{(\lambda_n^2-\overline{\lambda_n}^2)}.
\end{aligned}$$

Substituting the expressions for $\chi^c_{ij}(\cdot)$, $i,j\in\{1,2\}$, given in Lemma 4.1 into the above equations for β_n^+, $\widehat{\delta}_n^+$, and $\widehat{\mathcal{E}}^+_{nn}\widehat{\mathcal{H}}^+_{nn}-\widehat{\mathcal{F}}^+_{nn}\widehat{\mathcal{G}}^+_{nn}$, and recalling that (see (98)) $b_i=-\frac{\chi^c_{12}(\lambda_i)}{\chi^c_{22}(\lambda_i)}\beta_i$, $1\le i\le n$, one obtains, as a result of Lemma 5.1, keeping only $\mathcal{O}(1)$ and $\mathcal{O}(t^{-1/2})$ terms, the result stated in the lemma. □

COROLLARY 5.1. *As $t\to+\infty$ and $x\to-\infty$ such that $\lambda_0>M$ and $(x,t)\in\Omega_n$,*

$$q(x,t)=Q^+_{\rm as}(x,t)\exp\{i\arg q^+_{\rm as}(x,t)\}+\mathcal{O}\bigg(\frac{C(\lambda_0)(\ln t)^2}{t}\bigg),$$

where $Q^+_{\rm as}(x,t)$ is given in Theorem 2.1, (14)–(29), *$\arg q^+_{\rm as}(x,t)$ is given in Theorem* 2.2, (48)–(51), *and $C(\lambda_0)\in\mathcal{S}(\mathbb{R}_{>M};\mathbb{C})$.*

Proof. The proof is a consequence of Proposition 2.3 and Lemma 5.3. □

COROLLARY 5.2. *As $t\to+\infty$ and $x\to+\infty$ such that $\widehat{\lambda}_0:=\sqrt{\frac{1}{2}(\frac{x}{t}-\frac{1}{s})}>M$, $\frac{x}{t}>\frac{1}{s}$, $s\in\mathbb{R}_{>0}$, and $(x,t)\in\widetilde{\Omega}_n$,*

$$u(x,t)=v^+_{\rm as}(x,t)w^+_{\rm as}(x,t)+\mathcal{O}\bigg(\frac{C(\widehat{\lambda}_0)(\ln t)^2}{t}\bigg),$$

where $v^+_{\rm as}(x,t)$ and $w^+_{\rm as}(x,t)$ are given in Theorem 2.3, (58)–(70), *and $C(\widehat{\lambda}_0)\in\mathcal{S}(\mathbb{R}_{>M};\mathbb{C})$.*

Proof. The proof is a consequence of Proposition 2.4 and Corollary 5.1. □

6. Asymptotics as $t\to-\infty$. In this section, the asymptotic paradigm presented in sections 3–5 is reworked for the case when $t\to-\infty$: since the proofs of all obtained results are analogous, they will be omitted. This section is divided into three parts: (1) in subsection 6.1, extended and model RH problems are formulated as $t\to-\infty$; (2) in subsection 6.2, the model RH problem formulated in (1) above is solved asymptotically as $t\to-\infty$ for the Schwartz class of nonreflectionless generic potentials; and (3) in subsection 6.3, the phase integral, $((\Psi^{-1}(x,t;0))_{11})^2$, is evaluated asymptotically as $t\to-\infty$.

6.1. Extended and model RH problems.

PROPOSITION 6.1.1. *In the solitonless sector ($\mathcal{Z}_d\equiv\emptyset$), as $t\to-\infty$ and $x\to+\infty$ such that $\lambda_0>M$,*

$$m(x,t;\lambda)=\widetilde{\Delta}(\lambda)+\mathcal{O}\bigg(\frac{C(\lambda_0)}{\sqrt{-t}}\bigg),$$

where $\widetilde{\Delta}(\lambda):=(\delta^-(\lambda;\lambda_0))^{\sigma_3}$,

$$\delta^-(\lambda;\lambda_0)=((\lambda-\lambda_0)(\lambda+\lambda_0))^{-i\nu}\exp\bigg\{\sum_{l\in\{\pm\}}\widetilde{\rho}_l(\lambda)\bigg\},$$

$$\widetilde{\rho}_\pm(\lambda)=-\frac{1}{2\pi i}\int_{\pm\lambda_0}^{\pm\infty}\ln(\varsigma-\lambda)d\ln(1-|r(\varsigma)|^2),$$

$\nu:=\nu(\lambda_0)$ is given by (21), *$||(\delta^-(\cdot;\lambda_0))^{\pm1}||_{\mathcal{L}^\infty(\mathbb{C};\mathbb{C})}:=\sup_{\lambda\in\mathbb{C}}|(\delta^-(\lambda;\lambda_0))^{\pm1}|<\infty$, $\overline{(\delta^-(\pm\overline{\lambda};\lambda_0))^{-1}}=\delta^-(\lambda;\lambda_0)$, the principal branch of the logarithmic function is taken, $\ln(\mu-\lambda):=\ln|\mu-\lambda|+i\arg(\mu-\lambda)$, $\arg(\mu-\lambda)\in(-\pi,\pi)$, and $C(\lambda_0)\in\mathcal{S}(\mathbb{R}_{>M};M_2(\mathbb{C}))$.*

Remark 6.1.1. Hereafter, all explicit x, t dependencies are suppressed, except where absolutely necessary, and $\delta^-(\lambda;\lambda_0) := \widetilde{\delta}(\lambda)$.

LEMMA 6.1.1. *There exists a unique solution* $\widetilde{m}^{\widetilde{\Delta}}(\lambda) := m(\lambda)(\widetilde{\Delta}(\lambda))^{-1}: \mathbb{C}\setminus(\mathcal{Z}_d \cup \widehat{\Gamma}) \to \mathrm{SL}(2,\mathbb{C})$ *of the following RH problem:*

1. $\widetilde{m}^{\widetilde{\Delta}}(\lambda)$ *is meromorphic for all* $\lambda \in \mathbb{C}\setminus\widehat{\Gamma}$,
2. $$\widetilde{m}^{\widetilde{\Delta}}_+(\lambda) = \widetilde{m}^{\widetilde{\Delta}}_-(\lambda)\widetilde{v}^{\widetilde{\Delta}}(\lambda), \quad \lambda \in \widehat{\Gamma},$$
where
$$\widetilde{v}^{\widetilde{\Delta}}(\lambda) = e^{-i\theta(\lambda)\mathrm{ad}(\sigma_3)} \begin{pmatrix} (1 - r(\lambda)\overline{r(\overline{\lambda})})\widetilde{\delta}_-(\lambda)(\widetilde{\delta}_+(\lambda))^{-1} & r(\lambda)\widetilde{\delta}_-(\lambda)\widetilde{\delta}_+(\lambda) \\ -\overline{r(\overline{\lambda})}(\widetilde{\delta}_-(\lambda))^{-1}(\widetilde{\delta}_+(\lambda))^{-1} & (\widetilde{\delta}_-(\lambda))^{-1}\widetilde{\delta}_+(\lambda) \end{pmatrix},$$
3. $\widetilde{m}^{\widetilde{\Delta}}(\lambda)$ *has simple poles at* $\{\pm\lambda_i, \pm\overline{\lambda_i}\}_{i=1}^N$ *with* $(1 \le i \le N)$
$$\begin{aligned} \mathrm{res}(\widetilde{m}^{\widetilde{\Delta}}(\lambda);\lambda_i) &= \lim_{\lambda\to\lambda_i} \widetilde{m}^{\widetilde{\Delta}}(\lambda) v_i (\widetilde{\delta}(\lambda_i))^{-2}\sigma_-, \\ \mathrm{res}(\widetilde{m}^{\widetilde{\Delta}}(\lambda);-\lambda_i) &= -\sigma_3 \mathrm{res}(\widetilde{m}^{\widetilde{\Delta}}(\lambda);\lambda_i)\sigma_3, \\ \mathrm{res}(\widetilde{m}^{\widetilde{\Delta}}(\lambda);\overline{\lambda_i}) &= \lim_{\lambda\to\overline{\lambda_i}} \widetilde{m}^{\widetilde{\Delta}}(\lambda) \overline{v_i} (\widetilde{\delta}(\overline{\lambda_i}))^{2}\sigma_+, \\ \mathrm{res}(\widetilde{m}^{\widetilde{\Delta}}(\lambda);-\overline{\lambda_i}) &= -\sigma_3 \mathrm{res}(\widetilde{m}^{\widetilde{\Delta}}(\lambda);\overline{\lambda_i})\sigma_3, \end{aligned}$$
4. *as* $\lambda \to \infty$, $\lambda \in \mathbb{C}\setminus(\mathcal{Z}_d \cup \widehat{\Gamma})$,
$$\widetilde{m}^{\widetilde{\Delta}}(\lambda) = \mathrm{I} + \mathcal{O}(\lambda^{-1});$$

moreover, $Q(x,t) = 2i\lim_{\lambda\to\infty}(\lambda \widetilde{m}^{\widetilde{\Delta}}(x,t;\lambda))_{12}$ *is equal to* $Q(x,t)$ *in Lemma* 2.2, (11).

PROPOSITION 6.1.2. *Introduce arbitrarily small, clockwise- and counterclockwise-oriented, mutually disjoint (and disjoint with respect to* $\widehat{\Gamma}$*) circles* $\widetilde{K}_j^{\pm}$ *and* $\widetilde{L}_j^{\pm}$, $1 \le j \le n-1$, *around the eigenvalues* $\{\pm\lambda_j\}_{j=1}^{n-1}$ *and* $\{\pm\overline{\lambda_j}\}_{j=1}^{n-1}$, *resp., and define*

$$\widetilde{m}^{\flat}(\lambda) := \begin{cases} \widetilde{m}^{\widetilde{\Delta}}(\lambda), \quad \lambda \in \mathbb{C}\Big\backslash \left(\widehat{\Gamma} \cup \left(\bigcup_{i=1}^{n-1} (\widetilde{K}_i^{\pm} \cup \widetilde{L}_i^{\pm})\right)\right), \\ \widetilde{m}^{\widetilde{\Delta}}(\lambda)\left(\mathrm{I} - \frac{v_i(\widetilde{\delta}(\pm\lambda_i))^{-2}}{(\lambda \mp \lambda_i)}\sigma_-\right), \quad \lambda \in \mathrm{int}\widetilde{K}_i^{\pm}, \quad 1 \le i \le n-1, \\ \widetilde{m}^{\widetilde{\Delta}}(\lambda)\left(\mathrm{I} + \frac{\overline{v_i}(\widetilde{\delta}(\pm\overline{\lambda_i}))^{2}}{(\lambda \mp \overline{\lambda_i})}\sigma_+\right), \quad \lambda \in \mathrm{int}\widetilde{L}_i^{\pm}, \quad 1 \le i \le n-1. \end{cases}$$

Then $\widetilde{m}^{\flat}(\lambda)$ *solves an RH problem on* $(\sigma_{\mathcal{L}}\setminus\cup_{i=1}^{n-1}(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\}))\cup(\cup_{i=1}^{n-1}(\widetilde{K}_i^{\pm}\cup\widetilde{L}_i^{\pm}))$ *with the same jumps as* $\widetilde{m}^{\widetilde{\Delta}}(\lambda)$ *on* $\widehat{\Gamma}$, $\widetilde{m}^{\flat}_+(\lambda) = \widetilde{m}^{\flat}_-(\lambda)\widetilde{v}^{\widetilde{\Delta}}(\lambda)$, *and*

$$\widetilde{m}^{\flat}_+(\lambda) = \begin{cases} \widetilde{m}^{\flat}_-(\lambda)\left(\mathrm{I} + \frac{v_i(\widetilde{\delta}(\pm\lambda_i))^{-2}}{(\lambda \mp \lambda_i)}\sigma_-\right), \quad \lambda \in \widetilde{K}_i^{\pm}, \quad 1 \le i \le n-1, \\ \widetilde{m}^{\flat}_-(\lambda)\left(\mathrm{I} + \frac{\overline{v_i}(\widetilde{\delta}(\pm\overline{\lambda_i}))^{2}}{(\lambda \mp \overline{\lambda_i})}\sigma_+\right), \quad \lambda \in \widetilde{L}_i^{\pm}, \quad 1 \le i \le n-1. \end{cases}$$

Remark 6.1.2. The superscripts $\pm$ on $\{\widetilde{K}_i^{\pm}\}_{i=1}^{n-1}$ and $\{\widetilde{L}_i^{\pm}\}_{i=1}^{n-1}$, which are related with $\{\pm\lambda_i\}_{i=1}^{n-1}$ and $\{\pm\overline{\lambda_i}\}_{i=1}^{n-1}$, resp., should *not* be confused with the subscripts $\pm$

appearing in the various RH problems in this and the next subsection, namely, $m_\pm(\lambda)$, $\widetilde{m}^{\widetilde{\Delta}}_\pm(\lambda)$, $\widetilde{m}^\flat_\pm(\lambda)$, $\widetilde{m}^\sharp_\pm(\lambda)$, $\widetilde{\chi}_\pm(\lambda)$, $\widetilde{E}_\pm(\lambda)$, and $\widetilde{\chi}^c_\pm(\lambda)$.

LEMMA 6.1.2. *Set*

$$\widetilde{m}^\sharp(\lambda):=\begin{cases}\widetilde{m}^\flat(\lambda)\prod\limits_{l=1}^{n-1}(d_{l_+}(\lambda))^{-\sigma_3}, & \lambda\in\mathbb{C}\setminus\left(\widehat{\Gamma}\cup\left(\bigcup\limits_{i=1}^{n-1}(\widetilde{K}_i^\pm\cup\widetilde{L}_i^\pm)\right)\right),\\ \widetilde{m}^\flat(\lambda)(\widetilde{J}_{\widetilde{K}_i^\pm}(\lambda))^{-1}\prod\limits_{l=1}^{n-1}(d_{l_-}(\lambda))^{-\sigma_3}, & \lambda\in\mathrm{int}\widetilde{K}_i^\pm,\quad 1\le i\le n-1,\\ \widetilde{m}^\flat(\lambda)(\widetilde{J}_{\widetilde{L}_i^\pm}(\lambda))^{-1}\prod\limits_{l=1}^{n-1}(d_{l_-}(\lambda))^{-\sigma_3}, & \lambda\in\mathrm{int}\widetilde{L}_i^\pm,\quad 1\le i\le n-1,\end{cases}$$

where

$$d_{l_+}(\lambda):=\tfrac{(\lambda-\overline{\lambda_l})(\lambda+\overline{\lambda_l})}{(\lambda-\lambda_l)(\lambda+\lambda_l)},\quad \lambda\in\mathbb{C}\setminus\left(\bigcup_{i=1}^{n-1}(\widetilde{K}_i^\pm\cup\widetilde{L}_i^\pm)\right),\quad 1\le l\le n-1,$$

$$d_{l_-}(\lambda):=\begin{cases}\frac{(\lambda-\overline{\lambda_l})(\lambda+\overline{\lambda_l})}{(\lambda\pm\lambda_l)}, & \lambda\in\bigcup\limits_{i=1}^{n-1}\mathrm{int}\widetilde{K}_i^\pm,\quad 1\le l\le n-1,\\ \frac{(\lambda\pm\overline{\lambda_l})}{(\lambda-\lambda_l)(\lambda+\lambda_l)}, & \lambda\in\bigcup\limits_{i=1}^{n-1}\mathrm{int}\widetilde{L}_i^\pm,\quad 1\le l\le n-1,\end{cases}$$

and the $\mathrm{SL}(2,\mathbb{C})$*-valued, holomorphic in* $\mathrm{int}\widetilde{K}_i^\pm$ *and* $\mathrm{int}\widetilde{L}_i^\pm$*, resp., functions* $\widetilde{J}_{\widetilde{K}_i^\pm}(\lambda)$ *and* $\widetilde{J}_{\widetilde{L}_i^\pm}(\lambda)$, $1\le i\le n-1$, *are given by*

$$\widetilde{J}_{\widetilde{K}_i^\pm}(\lambda)=\begin{pmatrix}\dfrac{\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}^{-1}(\lambda)}-\frac{v_i(\widetilde{\delta}(\pm\lambda_i))^{-2}\widetilde{C}_i^\sharp}{(d_{i_-}(\lambda))^2}\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}(\lambda)}}{(\lambda\mp\lambda_i)} & \frac{\widetilde{C}_i^\sharp}{(d_{i_-}(\lambda))^2}\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}(\lambda)}\\ -v_i(\widetilde{\delta}(\pm\lambda_i))^{-2}\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\frac{d_{l_-}(\lambda)}{d_{l_+}(\lambda)} & (\lambda\mp\lambda_i)\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\frac{d_{l_-}(\lambda)}{d_{l_+}(\lambda)}\end{pmatrix},$$

$$\widetilde{J}_{\widetilde{L}_i^\pm}(\lambda)=\begin{pmatrix}(\lambda\mp\overline{\lambda_i})\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}^{-1}(\lambda)} & \overline{v_i}(\widetilde{\delta}(\pm\overline{\lambda_i}))^2\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\frac{d_{l_-}^{-1}(\lambda)}{d_{l_+}^{-1}(\lambda)}\\ -\frac{\overline{\widetilde{C}_i^\sharp}}{(d_{i_-}(\lambda))^{-2}}\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\frac{d_{l_-}(\lambda)}{d_{l_+}^{-1}(\lambda)} & \dfrac{\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\frac{d_{l_-}(\lambda)}{d_{l_+}(\lambda)}-\frac{\overline{v_i}(\widetilde{\delta}(\pm\overline{\lambda_i}))^2\overline{\widetilde{C}_i^\sharp}}{(d_{i_-}(\lambda))^{-2}}\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\frac{d_{l_-}(\lambda)}{d_{l_+}^{-1}(\lambda)}}{(\lambda\mp\overline{\lambda_i})}\end{pmatrix},$$

with

$$\widetilde{C}_i^\sharp=(v_i)^{-1}(\widetilde{\delta}(\pm\lambda_i))^2(d_{i_-}(\pm\lambda_i))^2\prod_{\substack{l=1\\ \neq i}}^{n-1}(d_{l_+}(\pm\lambda_i))^2,\quad 1\le i\le n-1.$$

Then $\widetilde{m}^\sharp(\lambda)\colon\mathbb{C}\setminus((\mathcal{Z}_d\setminus\cup_{i=1}^{n-1}(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\}))\cup(\widehat{\Gamma}\cup(\cup_{i=1}^{n-1}(\widetilde{K}_i^\pm\cup\widetilde{L}_i^\pm))))\to\mathrm{SL}(2,\mathbb{C})$ *solves the following, extended RH problem on* $(\sigma_{\mathcal{L}}\setminus\cup_{i=1}^{n-1}(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\}))\cup(\cup_{i=1}^{n-1}(\widetilde{K}_i^\pm\cup\widetilde{L}_i^\pm))$*:*

$$\widetilde{m}^\sharp_+(\lambda)=\widetilde{m}^\sharp_-(\lambda)e^{-i\theta(\lambda)\mathrm{ad}(\sigma_3)}\widetilde{v}^\sharp(\lambda),$$

where

$$\widetilde{v}^\sharp(\lambda)|_{\widehat{\Gamma}}=\begin{pmatrix}(1-r(\lambda)\overline{r(\overline{\lambda})})\frac{\widetilde{\delta}_-(\lambda)}{\widetilde{\delta}_+(\lambda)} & \frac{r(\lambda)}{(\widetilde{\delta}_-(\lambda)\widetilde{\delta}_+(\lambda))^{-1}}\prod\limits_{l=1}^{n-1}\left(\frac{(\lambda-\overline{\lambda_l})(\lambda+\overline{\lambda_l})}{(\lambda-\lambda_l)(\lambda+\lambda_l)}\right)^2\\ -\frac{\overline{r(\overline{\lambda})}}{\widetilde{\delta}_-(\lambda)\widetilde{\delta}_+(\lambda)}\prod\limits_{l=1}^{n-1}\left(\frac{(\lambda-\overline{\lambda_l})(\lambda+\overline{\lambda_l})}{(\lambda-\lambda_l)(\lambda+\lambda_l)}\right)^{-2} & \frac{\widetilde{\delta}_+(\lambda)}{\widetilde{\delta}_-(\lambda)}\end{pmatrix},$$

$$\widetilde{v}^{\sharp}(\lambda)=\begin{cases}\mathrm{I}+\frac{(v_i)^{-1}(\widetilde{\delta}(\pm\lambda_i))^2}{(\lambda\mp\lambda_i)}\left(\frac{\lambda_i^2-\overline{\lambda_i}^2}{2\lambda_i}\right)^2\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\left(\frac{\overline{\lambda_l}^2-\lambda_i^2}{\lambda_l^2-\lambda_i^2}\right)^2\sigma_+, & \lambda\in\bigcup\limits_{i=1}^{n-1}\widetilde{K}_i^{\pm},\\ \mathrm{I}+\frac{(\overline{v_i})^{-1}(\widetilde{\delta}(\pm\overline{\lambda_i}))^{-2}}{(\lambda\mp\overline{\lambda_i})}\left(\frac{\lambda_i^2-\overline{\lambda_i}^2}{2\overline{\lambda_i}}\right)^2\prod\limits_{\substack{l=1\\ \neq i}}^{n-1}\left(\frac{\lambda_l^2-\overline{\lambda_i}^2}{\overline{\lambda_l}^2-\overline{\lambda_i}^2}\right)^2\sigma_-, & \lambda\in\bigcup\limits_{i=1}^{n-1}\widetilde{L}_i^{\pm},\end{cases}$$

with polar (residue) conditions

$$\begin{aligned}\mathrm{res}(\widetilde{m}^{\sharp}(\lambda);\lambda_i)&=\lim_{\lambda\to\lambda_i}\widetilde{m}^{\sharp}(\lambda)v_i(\widetilde{\delta}(\lambda_i))^{-2}\prod_{l=1}^{n-1}\left(\frac{(\lambda_i-\lambda_l)(\lambda_i+\lambda_l)}{(\lambda_i-\overline{\lambda_l})(\lambda_i+\overline{\lambda_l})}\right)^2\sigma_-,\quad n\le i\le N,\\ \mathrm{res}(\widetilde{m}^{\sharp}(\lambda);-\lambda_i)&=-\sigma_3\mathrm{res}(\widetilde{m}^{\sharp}(\lambda);\lambda_i)\sigma_3,\quad n\le i\le N,\\ \mathrm{res}(\widetilde{m}^{\sharp}(\lambda);\overline{\lambda_i})&=\lim_{\lambda\to\overline{\lambda_i}}\widetilde{m}^{\sharp}(\lambda)\overline{v_i}(\widetilde{\delta}(\overline{\lambda_i}))^2\prod_{l=1}^{n-1}\left(\frac{(\overline{\lambda_i}-\overline{\lambda_l})(\overline{\lambda_i}+\overline{\lambda_l})}{(\overline{\lambda_i}-\lambda_l)(\overline{\lambda_i}+\lambda_l)}\right)^2\sigma_+,\quad n\le i\le N,\\ \mathrm{res}(\widetilde{m}^{\sharp}(\lambda);-\overline{\lambda_i})&=-\sigma_3\mathrm{res}(\widetilde{m}^{\sharp}(\lambda);\overline{\lambda_i})\sigma_3,\quad n\le i\le N,\end{aligned}$$

and, as $\lambda\to\infty$, $\lambda\in\mathbb{C}\backslash((\mathcal{Z}_d\backslash\cup_{i=1}^{n-1}(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\}))\cup(\widehat{\Gamma}\cup(\cup_{i=1}^{n-1}(\widetilde{K}_i^{\pm}\cup\widetilde{L}_i^{\pm}))))$,

$$\widetilde{m}^{\sharp}(\lambda)=\mathrm{I}+\mathcal{O}(\lambda^{-1});$$

moreover, $Q(x,t)=2i\lim_{\lambda\to\infty}(\lambda\widetilde{m}^{\sharp}(x,t;\lambda))_{12}$ *is equal to* $Q(x,t)$ *in Lemma* 2.2, (11).

LEMMA 6.1.3. *Let* $\widetilde{\chi}(\lambda)$ *solve the following RH problem on* $\sigma_{\mathcal{L}}\backslash\cup_{i=1}^{n-1}(\{\pm\lambda_i\}\cup\{\pm\overline{\lambda_i}\})$:

EXISTENCE AND BEHAVIOR OF SOLUTIONS TO THE LANDAU–LIFSHITZ EQUATION*

JIAN ZHAI†

Abstract. We prove the existence of nontrivial stable solutions to the Landau–Lifshitz equation with a Neumann boundary condition. The Landau–Lifshitz equation is a phenomenological model for ferromagnets.

Key words. Landau–Lifshitz equation, harmonic map, stable nontrivial solution

1. Introduction.

Let Ω be an nonsimply connected bounded domain in $\mathbb{R}^3$ with C^3 boundary. We seek for a solution $u = (u_1, u_2, u_3) : \Omega \to S^2 \subset \mathbb{R}^3$ of the Landau–Lifshitz equation

$$\begin{cases} \Delta u + |\nabla u|^2 u - \lambda(W_u(u) - (W_u(u) \cdot u)u) = 0 \quad \text{in} \quad \Omega, \\ \partial u/\partial \nu = 0 \quad \text{on} \quad \partial\Omega, \end{cases} \tag{1.1}$$

where $\lambda > 0$ is a parameter and ν is the unit outer normal vector of $\partial\Omega$. In this paper, we assume $W(u) = u_3^2$ and denote $W_u(u) = (0, 0, 2u_3)^t$.

Equation (1.1) is the Euler–Lagrange equation of the Landau–Lifshitz energy functional

$$E_\lambda(u) = \int_\Omega \frac{1}{2}|\nabla u|^2 + \lambda W(u) dx \tag{1.2}$$

on $H^1(\Omega, S^2)$.

Functional (1.2) was first derived for ferromagnetic problems by Landau and Lifshitz [LL] in 1935. The ferromagnetic theory states that below a critical temperature, a sufficiently large ferromagnetic body breaks up into small uniformly magnetized regions separated by thin transition layers. Equation (1.1) is the static equivalent of the time-dependent Landau–Lifshitz equation

$$\begin{aligned} \frac{\partial u}{\partial t} &= -u \times (u \times (\Delta u - \lambda W_u(u))) \\ &\quad + \gamma u \times (\Delta u - \lambda W_u(u)). \end{aligned} \tag{1.3}$$

Here $\gamma \geqq 0$ is called Gilbert damping constant.

It is clear that (1.1) is related to harmonic maps from Ω to S^2. The solutions to (1.1) have similar properties as those of the Ginzburg–Landau equation: there are vortices motions and so on (c.f. [PZ]). Similar properties for the Ginzburg–Landau equation have been discussed recently in a large number of papers (see [BBH], [JMZ],

*Received by the editors September 29, 1997; accepted for publication (in revised form) August 3, 1998; published electronically May 13, 1999. This research was partly supported by the Japan Society for the Promotion of Science.

†Department of Mathematics, Hokkaido University, Sapporo, Japan (zhai@math.sci.hokudai.ac.jp).

etc. and references therein). These results motivate us to conjecture similar conclusions for the Landau–Lifshitz equation.

In this paper, we study the static Landau–Lifshitz equation (1.1) in an nonsimply connected bounded domain of $\mathbb{R}^3$. The existence of nontrivial solutions and their stability are obtained. We shall use the methods developed for the Ginzburg–Landau equation. But the Landau–Lifshitz equation is more complicated: we have to deal carefully with the constraint condition $u \in S^2$, to analyze the spectrum of the linearized operator in a detailed way by using Kato's perturbation theory (c.f. [K]) since the linearized operator is not self-adjoint, and to use some new techniques developed recently for fully nonlinear parabolic equations (c.f. [L]).

Here, we assume $W(u) = u_3^2$, which corresponds to the presence of a continuum of directions of easy magnetization in $S^2 \cap \{u_3 = 0\}$. Our results assert that in each homotopy class from a nonsimply connected bounded domain Ω to $S^2 \cap \{u_3 = 0\}$, there exists a stable distribution of directions of easy magnetization.

This paper consists of five sections and an appendix. In section 2, we state the main theorems of this paper which are proved in sections 3–5. In the Appendix, we modify a stability result given in [H, chapter 5, exercise 6] by the theory of fully nonlinear parabolic equations (see [L], chapter 9) such that it can be applied to the Landau–Lifshitz equation.

2. Main theorems.

THEOREM 1. *Assume that Ω is not simply connected. Then there is $\lambda_0 > 0$ such that for $\lambda > \lambda_0$, there exists a solution,*

$$u_\lambda(x) = (\cos\xi_\lambda(x)\cos\theta_\lambda(x), \cos\xi_\lambda(x)\sin\theta_\lambda(x), \sin\xi_\lambda(x)) \in C^{2+\alpha}(\overline{\Omega}),$$

$0 < \alpha < 1$ to (1.1) corresponding to each homotopy class $[\theta_0]$ of continuous maps from Ω to $S^2 \cap \{u_3 = 0\}$. Moreover, θ_λ is homotopic to θ_0 and

$$\|\xi_\lambda\|_{C^\alpha(\overline{\Omega})} \leqq \frac{C}{\lambda}, \tag{2.1}$$

where the constant C is independent of λ and θ_λ is S^1-valued.

THEOREM 2. *Assume that Ω is not simply connected. Then there exists a $\bar{\lambda} > 0$, and for $\lambda \geqq \bar{\lambda}$, there exists a $\bar{\gamma} = \bar{\gamma}(\lambda) > 0$ such that, for $\lambda \geqq \bar{\lambda}$ and $\gamma \in [0, \bar{\gamma}]$, the solutions $u_\lambda(x)$ obtained in Theorem 1 are stable steady state solutions of the time-dependent Landau–Lifshitz equation*

$$\begin{cases} \dfrac{\partial u}{\partial t} = -u \times (u \times (\Delta u - \lambda W_u(u))) \\ \qquad\qquad + \gamma u \times (\Delta u - \lambda W_u(u)) \quad \textit{in} \quad \Omega \times (0, \infty), \\ \dfrac{\partial u}{\partial \nu} = 0 \quad \textit{on} \quad \partial\Omega \times (0, \infty), \\ u \in S^2 \quad \textit{in} \quad \Omega \times (0, \infty). \end{cases} \tag{2.2}$$

Remark 3. Here stability means Liapunov stability.

Remark 4. The solutions obtained in Theorem 1 take their values inside a neighborhood of the equator of S^2, and thus they can be viewed as maps into a set which is homotopically equivalent to the equatorial S^1. In this sense, we say that the solutions are nontrivial.

3. Proof of Theorem 1. Let $u = (\cos\xi\cos\theta, \cos\xi\sin\theta, \sin\xi)$ $(-\frac{\pi}{2} \leqq \xi \leqq \frac{\pi}{2},\ \theta \in S^1 = \mathbb{R}/2\pi\mathbb{Z})$ in (1.2). The energy functional E_λ is translated into

$$E_\lambda(\theta,\xi) = \int_\Omega \left(\frac{1}{2}|\nabla\xi|^2 + \frac{\cos^2\xi}{2}|\nabla\theta|^2 + \lambda\sin^2\xi\right) dx. \tag{3.1}$$

For any given smooth map $\theta_0 : \overline{\Omega} \to S^1$, $(\theta - \theta_0, \xi)$ can be regarded as a $\mathbb{R}^2$-valued function for any $\theta \in [\theta_0]$ and the Euler–Lagrange equation of (3.1) can be written as

$$\begin{cases} \Delta\xi - \left(\lambda - \dfrac{|\nabla\theta|^2}{2}\right)\sin 2\xi = 0 \quad \text{in} \quad \Omega, \\ \dfrac{\partial\xi}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega \end{cases} \tag{3.2}$$

and

$$\begin{cases} \operatorname{div}(\cos^2\xi\nabla\theta) = 0 \quad \text{in} \quad \Omega, \\ \dfrac{\partial\theta}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega. \end{cases} \tag{3.3}$$

We first consider the limit functional of (3.1) as $\lambda \to \infty$,

$$E_\infty(\theta) = \int_\Omega \frac{1}{2}|\nabla\theta|^2 dx.$$

Its critical points are well-known harmonic maps to S^1 which satisfy

$$\begin{cases} \Delta\theta = 0 \quad \text{in} \quad \Omega, \\ \dfrac{\partial\theta}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega. \end{cases} \tag{3.4}$$

The following lemma is standard (the proof can been found, for example, in [JMZ]).

LEMMA 3.1. *Assume that Ω is not simply connected. Then there exists a solution $\theta_* \in C^{2+\alpha}(\overline{\Omega}, S^1)$ to (3.4) in each homotopy class of continuous mappings from $\overline{\Omega}$ into S^1. Moreover, the solution is unique up to an additive constant.*

Hereafter, for technical reasons we fix a point $p \in \Omega$ and let $q = \theta_*(p)$.

DEFINITION 3.2. *Let $\alpha_0 \in (0,1)$ and define*

$$E(\theta_*) = \{\theta | \theta - \theta_* \in C^{1+\alpha_0}(\overline{\Omega}, \mathbb{R}),\ \theta(p) = q,\ \theta \quad \text{is homotopic to} \quad \theta_*, \\ \|\theta - \theta_*\|_{C^{1+\alpha_0}(\overline{\Omega})} \leqq 1\}.$$

LEMMA 3.3. *For any given $\theta \in E(\theta_*)$, there exists a solution ξ_λ^θ to (3.2) which satisfies*

$$\|\xi_\lambda^\theta\|_{C^{2+\alpha_0}(\overline{\Omega})} \leqq C_1, \tag{3.5}$$

$$\lim_{\lambda\to\infty} \sup_{\theta\in E(\theta_*)} \|\xi_\lambda^\theta\|_{C^2(\overline{\Omega})} = 0, \tag{3.6}$$

and

$$\|\xi_\lambda^\theta\|_{C^{\alpha_0}(\overline{\Omega})} \leqq \frac{C_2}{\lambda}, \tag{3.7}$$

provided λ is large enough. Here the constants $C_i = C_i(\|\theta\|_{C^{1+\alpha_0}(\overline{\Omega})})$ $(i = 1, 2)$ are independent of λ.

Proof. Let $\eta := \xi + \frac{C}{\lambda}$, where C is a constant, to be determined in the proof. The equation for η is written as

$$\begin{cases} \Delta\eta - \Big(\lambda - \dfrac{|\nabla\theta|^2}{2}\Big)\sin 2\Big(\eta - \dfrac{C}{\lambda}\Big) = 0 \quad \text{in} \quad \Omega, \\ \dfrac{\partial\eta}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega. \end{cases} \tag{3.8}$$

Let

$$F(\eta) = -\left(\lambda - \frac{|\nabla\theta|^2}{2}\right)\sin 2\left(\eta - \frac{C}{\lambda}\right).$$

It is easy to check that there exists a constant $C = C(\|\theta\|_{C^{1+\alpha_0}(\overline{\Omega})})$ and $\lambda_0(> 0)$ such that

$$F(0) \geqq 0, \qquad F\Big(\frac{2C}{\lambda}\Big) \leqq 0$$

for $\lambda \geqq \lambda_0$. From [A], there exists a nonnegative solution η_λ^θ to (3.8) which satisfies

$$0 \leqq \eta_\lambda^\theta \leqq \frac{2C}{\lambda},$$

provided $\lambda \geqq \lambda_0$. Let $\xi_\lambda^\theta = \eta_\lambda^\theta - \frac{C}{\lambda}$. Thus ξ_λ^θ is a solution of (3.2) and

$$-\frac{C}{\lambda} \leqq \xi_\lambda^\theta \leqq \frac{C}{\lambda}, \tag{3.9}$$

provided $\lambda \geqq \lambda_0$.

Rewrite (3.2) as

$$-\Delta\xi + 2\lambda\xi = \lambda(2\xi - \sin 2\xi) + \frac{|\nabla\theta|^2}{2}\sin 2\xi,$$

and use the Campanato inequality [C2] to obtain

$$\|\xi\|_{C^{\alpha_0}(\overline{\Omega})} \leqq \frac{C}{\lambda}(\lambda\|2\xi - \sin 2\xi\|_{C^{\alpha_0}(\overline{\Omega})} + \|\xi\|_{C^{\alpha_0}(\overline{\Omega})} + \|\theta\|^2_{C^{1+\alpha_0}(\overline{\Omega})}) \tag{3.10}$$

for a solution $\xi \in C^{\alpha_0}(\overline{\Omega})$ to (3.2).

Claim 1. For $\delta > 0$, there exists $\lambda(\delta) > 0$ such that

$$\|2\xi_\lambda^\theta - \sin 2\xi_\lambda^\theta\|_{C^{\alpha_0}(\overline{\Omega})} \leqq \delta\|\xi_\lambda^\theta\|_{C^{\alpha_0}(\overline{\Omega})},$$

provided $\lambda \geqq \lambda(\delta)$.

Using (3.10) and Claim 1, we get (3.7).

From (3.7) and standard linear elliptic equation theory, we can prove (3.5). Equation (3.6) is a simple corollary of (3.5) and (3.7). □

Proof of Claim 1. For simplicity, we denote $2\xi_\lambda^\theta$ by ξ. Since

$$\sin\xi = \xi - \frac{\xi^3}{3!} + \frac{\xi^5}{5!} - \cdots$$

for small $|\xi|$, from the definition of Hölder seminorm, we have

$$\|\xi - \sin\xi\|_{C^{\alpha_0}(\overline{\Omega})} = \sup_{x,y\in\overline{\Omega},\ x\neq y} \frac{|\xi(x) - \sin\xi(x) - \xi(y) + \sin\xi(y)|}{|x-y|^{\alpha_0}}$$
$$\leqq \|\xi\|_{C^{\alpha_0}(\overline{\Omega})} \sum_{\frac{m-1}{2}=1}^{\infty} \frac{(m-1)(\frac{C}{\lambda})^{m-1}}{m!}.$$

Claim 1 is proved. □

LEMMA 3.4. *For ξ_λ^θ obtained in Lemma* 3.3, *there exists a solution $\theta(\xi_\lambda^\theta)$ to* (3.3) *which satisfies*

$$\|\theta(\xi_\lambda^\theta) - \theta_*\|_{C^{2+\alpha_0}(\overline{\Omega})} \to 0 \quad as \quad \lambda\to\infty \tag{3.11}$$

uniformly for $\theta \in E(\theta_*)$.

Proof. The proof of existence part is similar to Lemma 3.1. So we need only to prove (3.11). For simplicity, we denote ξ_λ^θ and $\theta(\xi_\lambda^\theta)$ by ξ and $\bar\theta$, respectively. From (3.3)–(3.4), we obtain equations for $\bar\theta - \theta_*$:

$$\begin{cases} \operatorname{div}(\cos^2\xi\nabla(\bar\theta-\theta_*)) = -\nabla\cos^2\xi\cdot\nabla\theta_* + (1-\cos^2\xi)\Delta\theta_* \quad \text{in} \quad \Omega, \\ \dfrac{\partial(\bar\theta-\theta_*)}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega. \end{cases} \tag{3.12}$$

By standard elliptic regularity theory and Lemma 3.3, we have

$$\|\bar\theta - \theta_*\|_{C^{2+\alpha_0}(\overline{\Omega})} \to 0 \quad \text{as} \quad \lambda\to\infty$$

uniformly for $\theta \in E(\theta_*)$. □

PROPOSITION 3.5. *Let $T_\lambda(\theta) = \theta(\xi_\lambda^\theta)$ for $\theta \in E(\theta_*)$. Then $T_\lambda(E(\theta_*))$ is precompact in $E(\theta_*)$ and T_λ is continuous provided λ is large enough.*

Proof. From Lemmas 3.3–3.4, we obtain that $T_\lambda(E(\theta_*))$ is precompact. Let θ_1 and θ_2 be two elements in $E(\theta_*)$. Assume that $\xi_1 = \xi_\lambda^{\theta_1}$, $\xi_2 = \xi_\lambda^{\theta_2}$, and $\bar\theta_1 = \theta(\xi_\lambda^{\theta_1})$, $\bar\theta_2 = \theta(\xi_\lambda^{\theta_2})$ are the solutions of (3.2) and (3.3), respectively. We consider the equations

$$\Delta(\xi_1-\xi_2) - \lambda(\sin 2\xi_1 - \sin 2\xi_2) + \frac{|\nabla\theta_1|^2}{2}\sin 2\xi_1 - \frac{|\nabla\theta_2|^2}{2}\sin 2\xi_2 = 0,$$
$$\operatorname{div}(\cos^2\xi_1\nabla\bar\theta_1) - \operatorname{div}(\cos^2\xi_2\nabla\bar\theta_2) = 0.$$

As in the proof of Lemmas 3.3–3.4, we can prove the continuity of T_λ. □

Proof of Theorem 1. From Proposition 3.5 and the Schauder fixed point theorem, T_λ has a fixed point θ_λ in $E(\theta_*)$ for large λ. Then we obtain a solution $(\theta_\lambda, \xi_\lambda)$ to (3.2)–(3.3) which has the properties stated in Theorem 1. □

4. Proof of Theorem 2 for $\gamma = 0$. By the change of coordinates $u = (\cos\xi\cos\theta, \cos\xi\sin\theta, \sin\xi)$, (2.2) is rewritten as

$$\begin{cases} \partial_t\theta = \left(\dfrac{1}{\cos^2\xi}\right)\operatorname{div}(\cos^2\xi\nabla\theta) \quad \text{in} \quad \Omega\times(0,\infty), \\ \partial_t\xi = \Delta\xi + \left(\dfrac{|\nabla\theta|^2}{2} - \lambda\right)\sin 2\xi \quad \text{in} \quad \Omega\times(0,\infty), \\ \dfrac{\partial\theta}{\partial\nu} = 0, \quad \dfrac{\partial\xi}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega\times(0,\infty). \end{cases} \tag{4.1}$$

For the solution $(\theta_\lambda, \xi_\lambda)$ obtained in Theorem 1, the linearized operator A_λ of the terms in the right-hand side of (4.1) at $(\theta_\lambda, \xi_\lambda)$ can be written as

$$\begin{pmatrix} \Delta + (\frac{1}{\cos^2 \xi_\lambda})\nabla \cos^2 \xi_\lambda \cdot \nabla & -\frac{2}{\cos^2 \xi_\lambda}\nabla\xi_\lambda \cdot \nabla\theta_\lambda - \frac{2\sin \xi_\lambda}{\cos \xi_\lambda}\nabla\theta_\lambda \cdot \nabla \\ (\sin 2\xi_\lambda)\nabla\theta_\lambda \cdot \nabla & \Delta + (|\nabla\theta_\lambda|^2 - 2\lambda)\cos 2\xi_\lambda \end{pmatrix}.$$

Noting that A_λ is not self-adjoint, we decompose A_λ into two parts: $A_\lambda = \bar{A}_\lambda + G$, where

$$\bar{A}_\lambda = \begin{pmatrix} \Delta & -\frac{2}{\cos^2 \xi_\lambda}\nabla\xi_\lambda \cdot \nabla\theta_\lambda \\ 0 & \Delta + (|\nabla\theta_\lambda|^2 - 2\lambda)\cos 2\xi_\lambda \end{pmatrix},$$

and

$$G = \begin{pmatrix} \frac{1}{cos^2\xi_\lambda}\nabla \cos^2 \xi_\lambda \cdot \nabla & -\frac{\sin 2\xi_\lambda}{\cos^2 \xi_\lambda}\nabla\theta_\lambda \cdot \nabla \\ \sin 2\xi_\lambda \nabla\theta_\lambda \cdot \nabla & 0 \end{pmatrix}.$$

Denote $H = L^2(\Omega) \times L^2(\Omega)$ with the standard inner product. It is easy to see that $\bar{A}_\lambda$ can be extended to a self-adjoint operator in H.

We consider the eigenvalue problem for $\bar{A}_\lambda$

$$-\bar{A}_\lambda \begin{pmatrix} \phi \\ \psi \end{pmatrix} = \bar{\mu} \begin{pmatrix} \phi \\ \psi \end{pmatrix}, \tag{4.2}$$

where ϕ and ψ belong to $H^1(\Omega)$ and $\frac{\partial \phi}{\partial \nu} = 0$, $\frac{\partial \psi}{\partial \nu} = 0$ on $\partial\Omega$.

The eigenvalues and eigenfunctions of (4.2) are denoted by

$$\bar{\mu}_1(\lambda) \leqq \bar{\mu}_2(\lambda) \leqq \cdots \leqq \bar{\mu}_k(\lambda) \leqq \cdots$$

and $\{(\phi_k^\lambda, \psi_k^\lambda)\}$, respectively, where $\|\phi_k^\lambda\|^2_{L^2(\Omega)} + \|\psi_k^\lambda\|^2_{L^2(\Omega)} = 1$.

LEMMA 4.1. *For $k \geqq 1$, there exists a constant C_k which is independent of λ such that*

$$\limsup_{\lambda \to \infty} |\bar{\mu}_k(\lambda)| \leqq C_k.$$

Proof. Note that

$$-\int_\Omega (\phi_k^\lambda, \psi_k^\lambda)\bar{A}_\lambda(\phi_k^\lambda, \psi_k^\lambda)^t dx \geqq C(\xi_\lambda, \theta_\lambda) + 2\lambda \int_\Omega (\cos 2\xi_\lambda)(\psi_k^\lambda)^2 dx.$$

Let $\phi_k \in H^1(\Omega)$ ($\|\phi_k\|_{L^2(\Omega)} = 1$) be the kth eigenfunction of Laplace operator $-\Delta$ with the Neumann boundary condition. Then

$$C(\xi_\lambda, \theta_\lambda) \leqq \bar{\mu}_k(\lambda) \leqq -\int_\Omega (\phi_k, 0)\bar{A}_\lambda(\phi_k, 0)^t dx \leqq C(\|\phi_k\|_{H^1(\Omega)}).$$

We get the conclusion of Lemma 4.1. □

From the proof of Lemma 4.1 and (2.1), we also obtain the following lemma.

LEMMA 4.2. *There exists a constant $\bar{C}_k$ such that for large λ,*

$$\left|\lambda \int_\Omega (\psi_k^\lambda)^2 dx\right| \leqq \bar{C}_k.$$

Rewrite the eigenvalue problem (4.2) in the form

$$\begin{cases} \Delta\phi - \dfrac{2}{\cos^2\xi_\lambda}(\nabla\xi_\lambda\cdot\nabla\theta_\lambda)\psi = -\bar{\mu}\phi, \\ \Delta\psi + (|\nabla\theta_\lambda|^2 - 2\lambda)(\cos 2\xi_\lambda)\psi = -\bar{\mu}\psi, \end{cases} \tag{4.3}$$

where ϕ and ψ belong to $H^1(\Omega)$, and $\frac{\partial\phi}{\partial\nu} = 0$, $\frac{\partial\psi}{\partial\nu} = 0$ on $\partial\Omega$.

LEMMA 4.3. *There exists a constant C which is independent of λ such that for large λ,*

$$\|\psi_k^\lambda\|_{C^\alpha(\overline{\Omega})} \leqq \frac{C}{\lambda}, \tag{4.4}$$

$$\|\psi_k^\lambda\|_{C^{2+\alpha}(\overline{\Omega})} \leqq C, \tag{4.5}$$

and

$$\|\phi_k^\lambda\|_{C^{2+\alpha}(\overline{\Omega})} \leqq C. \tag{4.6}$$

Proof. Applying the Campanato inequality to the second equation of (4.3), we obtain

$$\|\psi_k^\lambda\|_{C^\alpha(\overline{\Omega})} \leqq \frac{C}{\lambda}. \tag{4.7}$$

Applying the linear elliptic regularity theory to the second equation again, we get

$$\|\psi_k^\lambda\|_{C^{2+\alpha}(\overline{\Omega})} \leqq C. \tag{4.8}$$

Using (4.8) and the linear elliptic regularity theory for the first equation of (4.3), we obtain that if λ is large enough, then

$$\|\phi_k^\lambda\|_{C^{2+\alpha}(\overline{\Omega})} \leqq C. \tag{4.9}$$

Thus, we proved the lemma. □

By direct calculation, we can prove the following.

LEMMA 4.4. *0 is always the eigenvalue of* (4.3) *and* (4.10). *The corresponding eigenfunction is* $(\frac{1}{\sqrt{|\Omega|}}, 0)$.

$$\begin{cases} -A_\lambda\Phi = \mu\Phi & \text{in} \quad \Omega, \\ \dfrac{\partial\Phi}{\partial\nu} = 0 & \text{on} \quad \partial\Omega. \end{cases} \tag{4.10}$$

Next, we consider the spectrum of operator A_λ and analyze its behavior by the perturbation theory (c.f. [K]).

LEMMA 4.5. *Let $T = \rho I - \bar{A}_\lambda$. For $\delta > 0$, there exist $\rho > 0$ and $\lambda_0 = \lambda_0(\delta)$, such that G is T-bounded with T-bound b: $b \leqq \delta^{1/2}$ for $\lambda \geqq \lambda_0$.*

Proof. It is clear that T can be extended to a self-adjoint operator in Hilbert space H and $D(G) \supset D(T)$. For $\Phi = (\phi, \psi)^t \in D(T)$, and for $\delta > 0$, there exists $\lambda_0 = \lambda_0(\delta)$

such that for $\lambda \geqq \lambda_0$ we have

$$\begin{aligned}\|G\Phi\|_H^2 &= \int_\Omega \left(\frac{1}{\cos^2\xi_\lambda}\nabla\cos\xi_\lambda\cdot\nabla\phi - \frac{\sin 2\xi_\lambda}{\cos^2\xi_\lambda}\nabla\theta_\lambda\cdot\nabla\psi\right)^2 + \int_\Omega (\sin 2\xi_\lambda\nabla\theta_\lambda\cdot\nabla\phi)^2\\ &\leqq \max_\Omega\left(2\frac{|\nabla\cos^2\xi_\lambda|^2}{\cos^4\xi_\lambda} + |\sin 2\xi_\lambda\nabla\theta_\lambda|^2\right)\int_\Omega|\nabla\phi|^2\\ &\quad + 2\max_\Omega\left(\frac{|\sin 2\xi_\lambda\nabla\theta_\lambda|}{\cos^2\xi_\lambda}\right)^2\int_\Omega|\nabla\psi|^2\\ &\leqq \delta\langle T\Phi,\Phi\rangle_H\\ &\leqq \delta\|T\Phi\|_H^2\|\Phi\|_H^2,\end{aligned}$$

for some $\rho > 0$. Thus

$$\|G\Phi\|_H \leqq \delta^{1/2}(\|\Phi\|_H + \|T\Phi\|_H). \qquad \square$$

Let $\sigma(T)$ denote the spectral set of T and $\rho(T) = \mathbb{C}\setminus\sigma(T)$. For $\mu\in\sigma(T)$, let

$$d = \operatorname{dist}(\mu, \sigma(T)\setminus\{\mu\})$$

and $\Gamma_r = \{\zeta\in\mathbb{C} : |\zeta-\mu| = r\}$ for $0 < r \leqq d/2$. From [K, Chapter IV, Theorem 3.17], we have following lemma.

LEMMA 4.6. *If* $1+2r+|\mu| < r\delta^{-1/2}$, *then* $\Gamma_r\subset\rho(T-G)$ *and* Γ_r *encloses exactly Multiple*(μ) *eigenvalues of* $T-G$ *and no other points of* $\sigma(T-G)$.

Proof of Theorem 2 *when* $\gamma = 0$. Applying Lemmas 4.1–4.3 to the formula

$$\bar\mu_k(\lambda) = -\int_\Omega(\phi_k^\lambda,\psi_k^\lambda)\bar A_\lambda(\phi_k^\lambda,\psi_k^\lambda)^t dx,$$

we find that as $\lambda\to\infty$,

$$\bar\mu_k(\lambda)\to\mu_k,$$

where μ_k is the kth eigenvalue of the Laplace operator Δ with the Neumann boundary condition. Since

$$0 = \mu_1 < \mu_2 \leqq \mu_3 \leqq \cdots \leqq \mu_k \leqq \cdots,$$

by Lemmas 4.4–4.6, we have

$$0 \equiv \mu_1(\lambda) < \operatorname{Re}(\mu_2(\lambda)),$$

for large λ, where $\mu_k(\lambda)$ denote the kth eigenvalue of the eigenvalue problem (4.10) for A_λ. By [L, chapter 9], we can prove a modification of [H, chapter 5, exercise 6], which is applied to quasi-linear parabolic equations including our case (see the Appendix). From this modification, we get that the solution $(\theta_\lambda,\xi_\lambda)$ is stable provided λ is large enough. Thus we proved Theorem 2 in the case of $\gamma = 0$. $\square$

5. Proof of Theorem 2 when $\gamma \neq 0$. For simplicity, we denote the solution $(\theta_\lambda,\xi_\lambda)$ obtained in section 3 by (θ,ξ). The linearized operator A_λ is written as

$$A_\lambda = \begin{pmatrix} a_{11} & a_{12}\\ a_{21} & a_{22}\end{pmatrix},$$

where

$$a_{11} = \Delta + \frac{\nabla \cos^2 \xi \cdot \nabla}{\cos^2 \xi} - \frac{\gamma \sin 2\xi}{\cos \xi} \nabla\theta \cdot \nabla,$$

$$a_{12} = \begin{pmatrix} -\dfrac{2}{\cos^2 \xi_\lambda} \nabla\xi \cdot \nabla\theta - \dfrac{2 \sin \xi}{\cos \xi} \nabla\theta \cdot \nabla \\ -\dfrac{\gamma}{\cos \xi} (\Delta + (|\nabla\theta|^2 - 2\lambda) \cos 2\xi) \\ -\left(\dfrac{\gamma \sin \xi}{\cos^2 \xi}\right) \left(\Delta\xi + \left(\dfrac{|\nabla\theta|^2}{2} - \lambda\right) \sin 2\xi\right) \end{pmatrix},$$

$$a_{21} = \sin 2\xi \nabla\theta \cdot \nabla + \left(\frac{\gamma}{\cos \xi}\right) (\cos^2 \xi \Delta + \nabla \cos^2 \xi \cdot \nabla),$$

$$a_{22} = \begin{pmatrix} \Delta + (|\nabla\theta|^2 - 2\lambda) \cos 2\xi + \left(\dfrac{\gamma}{\cos \xi}\right) (-\sin 2\xi \Delta\theta \\ -2 \cos 2\xi \nabla\xi \cdot \nabla\theta - \sin 2\xi \nabla\theta \cdot \nabla) + \left(\dfrac{\gamma \sin \xi}{\cos^2 \xi}\right) \operatorname{div}(\cos^2 \xi \nabla\theta) \end{pmatrix}.$$

Decompose the operator A_λ into $\bar{A}_\lambda$ and the perturbation G:

$$\begin{aligned} G &= A_\lambda - \bar{A}_\lambda \\ &= \begin{pmatrix} \frac{\nabla \cos^2 \xi \cdot \nabla}{\cos^2 \xi} - \frac{\gamma \sin 2\xi \nabla\theta \cdot \nabla}{\cos \xi} & \left\{ \begin{array}{c} -\dfrac{\sin 2\xi \nabla\theta \cdot \nabla}{\cos^2 \xi} - \dfrac{\gamma \Delta}{\cos \xi} \\ +\dfrac{2\gamma\lambda}{\cos \xi} (\cos 2\xi + \sin^2 \xi) \end{array} \right\} \\ a_{21} & -\dfrac{\gamma \sin 2\xi \nabla\theta \cdot \nabla}{\cos \xi} \end{pmatrix}. \end{aligned} \tag{5.1}$$

Let $\bar{\mu}_1(\lambda) \leqq \bar{\mu}_2(\lambda) \leqq \cdots \leqq \bar{\mu}_k(\lambda) \leqq \cdots$ and

$$(\bar{\phi}_k^\lambda, \bar{\psi}_k^\lambda), \qquad \|\bar{\phi}_k^\lambda\|^2_{L^2(\Omega)} + \|\bar{\psi}_k^\lambda\|^2_{L^2(\Omega)} = 1, \qquad k = 1, 2, \ldots$$

denote the eigenvalues and eigenfunctions of $\bar{A}_\lambda$, respectively. Then, there exists a constant C which is independent of $\lambda \geqq \bar{\lambda}$ and $\gamma \in [0, \bar{\gamma}]$ for some $\bar{\gamma} > 0$ and $\bar{\lambda} > 0$, such that

$$\begin{aligned} -C + 2\lambda \int_\Omega \cos 2\xi (\bar{\psi}_k^\lambda)^2 dx &\leqq \bar{\mu}_k(\lambda) \\ &= -\int_\Omega (\bar{\phi}_k^\lambda, \bar{\psi}_k^\lambda) \bar{A}_\lambda (\bar{\phi}_k^\lambda, \bar{\psi}_k^\lambda)^t dx \\ &\leqq C, \end{aligned}$$

uniformly for $\lambda \geqq \bar{\lambda}$ and $\gamma \in [0, \bar{\gamma}]$. That is, we have the following lemma.

LEMMA 5.1. *There exist $\bar{\lambda} > 0$, $\bar{\gamma} > 0$, and $C_k > 0$ such that $|\bar{\mu}_k(\lambda)| \leqq C_k$ and*

$$\lambda \int_\Omega (\bar{\psi}_k^\lambda)^2 dx \leqq C_k$$

for $\lambda \geqq \bar{\lambda}$ and $\gamma \in [0, \bar{\gamma}]$, where C_k is independent of λ and γ.

Proof. First we have the estimates

$$\begin{aligned}\bar{\mu}_k(\lambda) &= -\int_\Omega (\bar{\phi}_k^\lambda, \bar{\psi}_k^\lambda)\bar{A}_\lambda(\bar{\phi}_k^\lambda, \bar{\psi}_k^\lambda)^t dx \\ &\geqq \int_\Omega (|\nabla\bar{\phi}_k^\lambda|^2 + |\nabla\bar{\psi}_k^\lambda|^2)dx - C\int_\Omega \gamma(|\nabla\bar{\phi}_k^\lambda \cdot \nabla\bar{\psi}_k^\lambda|)dx - C\int_\Omega (|\nabla\xi\cdot\nabla\bar{\phi}_k^\lambda| \\ &\quad + |\nabla\theta\cdot\nabla\bar{\phi}_k^\lambda| + |\nabla\xi\cdot\nabla\bar{\phi}_k^\lambda| + |\nabla\theta\cdot\nabla\bar{\psi}_k^\lambda|)(|\bar{\phi}_k^\lambda| + |\bar{\psi}_k^\lambda|)dx - C \\ &\quad + 2\lambda\int_\Omega \cos 2\xi(\bar{\psi}_k^\lambda)^2 dx \\ &\geqq \frac{1}{2}\int_\Omega (|\nabla\bar{\phi}_k^\lambda|^2 + |\nabla\bar{\psi}_k^\lambda|^2)dx + 2\lambda\int_\Omega \cos 2\xi(\bar{\psi}_k^\lambda)^2 dx - C \\ &\geqq -C,\end{aligned}$$

provided γ is small enough and λ is large enough, where C only depends on $\|\xi\|_{C^2(\overline{\Omega})}$ and $\|\theta\|_{C^2(\overline{\Omega})}$.

For $\phi \in H^1(\Omega)$ ($\|\phi\|_{L^2(\Omega)} = 1$), we have

$$-\int_\Omega (\phi, 0)\bar{A}_\lambda(\phi, 0)^t dx \leqq C(\|\phi\|^2_{H^1(\Omega)} + 1).$$

Thus we proved the lemma. □

Next the lemma is obtained by direct calculation.

LEMMA 5.2. *0 is always a eigenvalue of operator $\bar{A}_\lambda$ and A_λ. The corresponding eigenfunction is* $(\frac{1}{\sqrt{|\Omega|}}, 0)$.

The eigenvalue problem for $\bar{A}_\lambda$ can be written as

$$\begin{cases} \Delta\phi - \dfrac{2}{\cos^2\xi}(\nabla\xi\cdot\nabla\theta)\psi \\ \qquad -(\dfrac{\gamma}{\cos\xi})(|\nabla\theta|^2(\cos 2\xi)\psi) - \left(\dfrac{\gamma\sin\xi}{\cos^2\xi}\right)\left(\Delta\xi + \dfrac{|\nabla\theta|^2}{2}\sin 2\xi\right)\psi \\ \qquad = -\bar{\mu}\phi \quad \text{in} \quad \Omega, \\ \dfrac{\partial\phi}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega, \end{cases} \tag{5.2}$$

and

$$\begin{cases} \Delta\psi + (|\nabla\theta|^2 - 2\lambda)(\cos 2\xi)\psi + \left(\dfrac{\gamma}{\cos\xi}\right)(-\sin 2\xi\Delta\theta - 2\cos 2\xi\nabla\xi\cdot\nabla\theta)\psi \\ \qquad + \left(\dfrac{\gamma\sin\xi}{\cos^2\xi}\right)\operatorname{div}(\cos^2\xi\nabla\theta)\psi = -\bar{\mu}\psi \quad \text{in} \quad \Omega, \\ \dfrac{\partial\psi}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega. \end{cases} \tag{5.3}$$

LEMMA 5.3. *There exist $\bar{\lambda} > 0$ and $\bar{\gamma} > 0$ such that*

$$\|\bar{\psi}_k^\lambda\|_{C^\alpha(\overline{\Omega})} \leqq \frac{C}{\lambda}, \tag{5.4}$$

$$\|\bar{\psi}_k^\lambda\|_{C^{2+\alpha}(\overline{\Omega})} \leqq C, \tag{5.5}$$

and

$$\|\bar{\phi}_k^{\lambda}\|_{C^{2+\alpha}(\overline{\Omega})} \leqq C, \tag{5.6}$$

provided $\lambda \geqq \bar{\lambda}$ *and* $\gamma \in [0, \bar{\gamma}]$, *where constant* C *only depends on* k *and the* $C^{2+\alpha}(\overline{\Omega})$ *norm of* $(\xi_\lambda, \theta_\lambda)$.

Proof. For simplicity, we denote $(\bar{\phi}_k^{\lambda}, \bar{\psi}_k^{\lambda})$ by (ϕ, ψ).

Step 1. Using the Campanato inequality in (5.3), we find that there exist $\bar{\gamma} > 0$ and $\bar{\lambda} > 0$ such that for $\gamma \in [0, \bar{\gamma}]$ and $\lambda \geqq \bar{\lambda}$,

$$\|\psi\|_{C^{\alpha}(\overline{\Omega})} \leqq \frac{C}{\lambda}, \tag{5.7}$$

where constant C is independent of λ, γ and $\|\phi\|_{C^{2+\alpha}(\overline{\Omega})}$.

By the elliptic regularity theory, there exist $\bar{\gamma} > 0$ and $\bar{\lambda} > 0$ such that for $\gamma \in [0, \bar{\gamma}]$ and $\lambda \geqq \bar{\lambda}$,

$$\|\psi\|_{C^{2+\alpha}(\overline{\Omega})} \leqq C, \tag{5.8}$$

with constant $C < \infty$.

Step 2. Using the boundary extending method, we may extend the Neumann boundary problem (5.2) in Ω to an interior elliptic problem in a larger domain $\tilde{\Omega}$ ($\Omega \subset \tilde{\Omega}$). From the interior boundedness estimate (see, for example, Theorem 8.17 in [GT]) we obtain

$$\sup_{\Omega} |\phi| \leqq C(\|\phi\|_{L^2(\Omega)} + \|\psi\|_{C^{2+\alpha}(\overline{\Omega})} + 1). \tag{5.9}$$

Applying the elliptic regularity theory to (5.2), we have

$$\|\phi\|_{C^{2+\alpha}(\overline{\Omega})} \leqq C(\|\phi\|_{C^{0}(\overline{\Omega})} + \|\psi\|_{C^{2+\alpha}(\overline{\Omega})} + 1). \tag{5.10}$$

By (5.8), (5.9), and (5.10), (5.6) is obtained. □

LEMMA 5.4. *There exist* $\bar{\lambda} > 0$ *and* $d > 0$ *such that for* $\lambda \geqq \bar{\lambda}$,

$$\bar{\mu}_1(\lambda) = 0 \quad \textit{is a simple eigenvalue of} \quad \bar{A}_\lambda,$$

and

$$\bar{\mu}_2(\lambda) \geqq d$$

uniformly for $\gamma \in [0, \bar{\gamma}]$, *where* d *is independent of* λ *and* γ, *and* $\bar{\gamma}$ *is the same as in Lemma* 5.3.

Proof. From Lemma 5.3, (5.2) and (5.3) converge to the eigenvalue problem

$$\begin{cases} \Delta\phi = -\mu\phi & \text{in} \quad \Omega, \\ \dfrac{\partial\phi}{\partial\nu} = 0 & \text{on} \quad \partial\Omega. \end{cases} \tag{5.11}$$

The first eigenvalue of (5.11) is simple and $\mu_1 = 0$. We get the conclusion of this lemma. □

Next, we consider the spectrum of the operator A_λ by a similar method as in section 4. Precisely, we have the following.

LEMMA 5.5. *Let $T = \rho I - \bar{A}_\lambda$. For $\delta > 0$, there exist $\rho > 0$, $\lambda_0 = \lambda_0(\delta)$, and for $\lambda \geqq \lambda_0$ there exists $\gamma_0(\lambda) > 0$ such that for $\lambda \geqq \lambda_0$ and $\gamma \in (0, \gamma_0)$, we have*

$$\|G\Phi\|_H \leqq \delta^{1/2}((\rho+1)\|\Phi\|_H + \|T\Phi\|_H) \quad \textit{for} \quad \Phi \in D(T).$$

That is, G is T-bounded with T-bound $b : b \leqq \delta^{1/2}$.

Proof of Theorem 2. For fixed $\lambda \geqq \bar{\lambda}$, we can choose $\gamma \in (0, \bar{\gamma})$ such that $\gamma\lambda$ is small enough. By a perturbating argument (c.f. [K]), we have that for fixed $\lambda \geqq \bar{\lambda}$, there exists $\bar{\gamma}(\lambda) > 0$ such that for $\gamma \in [0, \bar{\gamma}(\lambda)]$, the eigenvalues $\{\mu_k(\lambda)\}_k$ of operator A_λ have a similar behavior to that of $\bar{A}_\lambda$. Note that 0 is always a eigenvalue of A_λ. Then $\mu_1(\lambda) = 0$ is simple and

$$\mathrm{Re}(\mu_2(\lambda)) \geqq \frac{d}{2}.$$

As in section 4, by Lemma A.1, we proved Theorem 2. □

Appendix. In this appendix, we extend a stability result for a semilinear parabolic equation given in [H, exercise 6, pp. 108] to quasi-linear equations, including the time-dependent Landau–Lifshitz equation. To overcome some technical difficulties, we use the theory for nonlinear parabolic equations (c.f. [L]).

Using spherical coordinates, the time-dependent Landau–Lifshitz equation with the Neumann boundary condition is written as

$$\begin{cases} \eta_t = \dfrac{1}{\cos^2\xi}(\mathrm{div}(\cos^2\xi\nabla(\eta+\theta_0)) + \cos\xi(h_2\cos(\eta+\theta_0) \\ \qquad - h_1\sin(\eta+\theta_0))) - \dfrac{\gamma}{\cos\xi}\left(\Delta\xi + \left(\dfrac{|\nabla(\eta+\theta_0)|^2}{2} - \lambda\right)\sin 2\xi\right. \\ \qquad \left. + H\cdot(-\sin\xi\cos(\eta+\theta_0), -\sin\xi\sin(\eta+\theta_0), \cos\xi)\right) \\ \xi_t = \Delta\xi + \left(\dfrac{|\nabla(\eta+\theta_0)|^2}{2} - \lambda\right)\sin 2\xi \\ \qquad + H\cdot(-\sin\xi\cos(\eta+\theta_0), -\sin\xi\sin(\eta+\theta_0), \cos\xi) \\ \qquad + \dfrac{\gamma}{\cos\xi}(\mathrm{div}(\cos^2\xi\nabla(\eta+\theta_0)) \\ \qquad + \cos\xi(h_2\cos(\eta+\theta_0) - h_1\sin(\eta+\theta_0))) \end{cases} \tag{A.1}$$

in $\Omega \times (0, \infty)$ with the Neumann boundary condition

$$\frac{\partial\eta}{\partial\nu} = 0, \qquad \frac{\partial\xi}{\partial\nu} = 0 \quad \text{on} \quad \partial\Omega \times (0, \infty).$$

Here, $\eta := \theta - \theta_0$, θ_0 is a given map from Ω to $S^2 \cap \{u_3 = 0\}$ with $\partial\theta_0/\partial\nu = 0$ on $\partial\Omega$, and $\theta \in [\theta_0]$. We only need to consider the case of $H \equiv 0$. Denote the right terms by $F(\eta, \xi)$ and (A.1) by

$$y_t = A_\lambda y + \tilde{F}(y); \tag{A.2}$$

here, $y = (\eta, \xi)^T$, A_λ is the linearized operator of F at the steady state solution $(\eta_\lambda, \xi_\lambda) = (\theta_\lambda - \theta_0, \xi_\lambda)$ and

$$\tilde{F}(y) := F(y + (\eta_\lambda, \xi_\lambda)) - A_\lambda y.$$

Let $X = L^2(\Omega, \mathbb{R}^2)$. It is clear that A_λ is a closed sectorial operator from

$$D(A_\lambda) := \{y \in W^{2,2}(\Omega, \mathbb{R}^2) : \partial y/\partial \nu = 0 \text{ on } \partial\Omega\}$$

to X (c.f. [L, pp. 72]). By a direct calculation, we have that $\bar{y}(\tau) = (\tau, 0)^T$ for $\tau \in \mathbb{R}$ satisfies

$$A_\lambda \bar{y}(\tau) + \tilde{F}(\bar{y}(\tau)) = 0.$$

Let $N = \text{span} - \{\bar{y}'(0)\}$ and $X_2 = \overline{R(A_\lambda)}$. Then

$$X = N + X_2.$$

For y given in a neighborhood of 0 in X, we can decompose it into

$$y = \bar{y}(\tau) + z,$$

where z belongs to X_2. Let

$$v \in X : A_\lambda^* v = 0, \langle v, \bar{y}'(0)\rangle_X = 1.$$

Since 0 is a simple eigenvalue of A_λ, (A.2) is equivalent to

$$\text{(A.3)} \qquad \begin{cases} \dfrac{d\tau}{dt} = \phi(\tau, z), \\ \dfrac{dz}{dt} = E_2 A_\lambda z + g(\tau, z), \end{cases}$$

where

$$\phi(\tau, z) = \frac{\langle v, \tilde{F}(\bar{y}(\tau) + z) - \tilde{F}(\bar{y}(\tau))\rangle_X}{\langle v, \bar{y}'(\tau)\rangle_X},$$

E_2 is the projector from X to X_2, and

$$g(\tau, z) = E_2(\tilde{F}(\bar{y}(\tau) + z) - \tilde{F}(\bar{y}(\tau)) - \bar{y}'(\tau)\phi(\tau, z)).$$

LEMMA A.1. *There exists a neighborhood O of 0 in $D := X_2 \cap W^{2,2}(\Omega, \mathbb{R}^2)$ such that $\phi(\tau, \cdot)$ and $g(\tau, \cdot)$ are C^1 functions from O to $\mathbb{R}$ and from O to X, respectively, with a locally Lipschitz continuous derivative, uniformly for $|\tau| \leqq 1$.*

Proof. We have to prove that there exists a neighborhood O of 0 in D, and for $z_0 \in O$ there exist $\delta > 0$ and $C = C(O, \delta) > 0$ such that for $z_1 : \|z_1 - z_0\|_D \leqq \delta$,

$$\|D_z g(\tau, z_0)y - D_z g(\tau, z_1)y\|_X \leqq C\|z_1 - z_0\|_D,$$

$$|D_z \phi(\tau, z_0)y - D_z \phi(\tau, z_1)y| \leqq C\|z_1 - z_0\|_D,$$

uniformly for $y \in D : \|y\|_D = 1$ and $\tau : |\tau| \leqq 1$. Here,

$$\|\cdot\|_D = \|\cdot\|_{W^{2,2}(\Omega)}.$$

By a direct calculation, we find that we only need to prove following estimate:

$$\|(A_\lambda(\bar{y}(\tau) + (\eta_\lambda, \xi_\lambda) + z_0) - A_\lambda(\bar{y}(\tau) + (\eta_\lambda, \xi_\lambda) + z_1))y\|_X \leqq C\|z_0 - z_1\|_D.$$

To obtain the last estimate, we use the Sobolev imbedding inequality. Let $(\eta_i, \xi_i) = \bar{y}(\tau) + (\eta_\lambda, \xi_\lambda) + z_i$ $(i = 0, 1)$. For example, the following inequalities can be proved:

$$\begin{aligned}\int_\Omega \left(\frac{\sin 2\xi_1}{\cos^2 \xi_1}\Delta\eta_1 - \frac{\sin 2\xi_0}{\cos^2 \xi_0}\Delta\eta_0\right)^2 &\leqq C(\xi_1)\int_\Omega (\Delta\eta_1 - \Delta\eta_0)^2 \\ &\quad + \int_\Omega \left(\frac{\sin 2\xi_1}{\cos^2 \xi_1} - \frac{\sin 2\xi_0}{\cos^2 \xi_0}\right)^2 (\Delta\eta_0)^2 \\ &\leqq C(\xi_1)\|\eta_1 - \eta_0\|_D^2 + \left(\int_\Omega (\Delta\eta_0)^2\right)\left\|\frac{\sin 2\xi_1}{\cos^2 \xi_1} - \frac{\sin 2\xi_0}{\cos^2 \xi_0}\right\|_{L^\infty(\Omega)}^2 \\ &\leqq C(\xi_1, \xi_0, \eta_0)(\|\eta_1 - \eta_0\|_D^2 + \|\xi_1 - \xi_0\|_D^2),\end{aligned}$$

and

$$\begin{aligned}\int_\Omega |\nabla(\xi_1 - \xi_0)|^2 |\nabla\eta_0|^2 &\leqq C(\eta_0)\left(\int_\Omega |\nabla(\xi_1 - \xi_0)|^4\right)^{1/2} \\ &\leqq C_1(\eta_0)\|\xi_1 - \xi_0\|_D^2,\end{aligned}$$

etc. Thus, we proved this lemma. □

Next, we apply the theory of [L, chapter 9] to the second equation of (A.3); here we assume that τ satisfies $|\tau| \leqq 1$. It is clear that the graph norm of $E_2 A_\lambda : D(A_\lambda) \cap X_2 \to X_2$ is equivalent to the norm of D. From section 5, we know that 0 is a simple eigenvalue of A_λ for large λ and small γ, and the eigenvalues of $E_2 A_\lambda$ lie in the half plane $\{\omega \in \mathbb{C} : \mathrm{Re}(\omega) \geqq d\}$ for some $d > 0$. Thus we can apply [L, Theorem 9.1.2] to the second equation of (A.3) and obtain that there exists $M > 0$, if $\|z(0)\|_D$ is small; then the solution $z(t)$ satisfies

$$\|z(t)\|_D \leqq Me^{-dt}\|z(0)\|_D \quad \text{for} \quad t \geqq 0. \tag{A.4}$$

Thus, there exists $M' > 0$ such that if $|\tau(0)| + \|z(0)\|_D$ is small, then

$$|\tau(t)| + \|z(t)\|_D \leqq M'e^{-dt}|\tau(0)| + \|z(0)\|_D \quad \text{for} \quad t \geqq 0.$$

That is, the solutions which satisfy the conditions in Theorem 2 are stable in Liapunov meaning.

Acknowledgments. The author is grateful to Prof. Y. Giga and Prof. S. Jimbo for introducing their attention to the Landau–Lifshitz equation and the Ginzburg–Landau equation and for many helpful conversations. The author is also grateful to the referees for many helpful suggestions.

GENERALIZATION OF THE SCHWARZ REFLECTION PRINCIPLE IN SCATTERING THEORY FOR DISSIPATIVE SYSTEMS: APPLICATION TO PURELY IMAGINARY RESONANT FREQUENCIES*

CHRISTOPHE LABREUCHE†

Abstract. The purpose of this paper is to give an asymptotic estimate of the counting function of the number of resonant frequencies on the purely imaginary axis in the case of the impedance boundary condition. We extend the work of P. Lax, R. Phillips, and J. Beale who studied the Dirichlet, Neumann, and Robin boundary conditions associated with the Helmholtz equation. The method they developed hinges on a special link between the poles of the scattering matrix (i.e., the resonant frequencies) and the zeros of the scattering matrix. This relation holds for conservative boundary conditions but not for absorbing boundary conditions. The first part of this paper consists in finding a relation of this form for the impedance boundary condition. Then we follow the work of P. Lax, R. Phillips, and J. Beale in order to get the final estimate.

Key words. wave equations, scattering theory, integral operators, eigenvalue problem

1. Introduction.

In a lot of physical problems, such as radar identification, the analysis of physical measurements is done through the transient response. The behavior of this latter is explained by the existence of complex frequencies called the *"resonant frequencies"* (see the Singularity Expansion Method [1]). In the view of inverse problems, one can wonder what can be deduced of the obstacle from a knowledge of its resonant frequencies. We wish to infer from these numbers an estimate of the size of the obstacle. This is of great practical interest. This is also mathematically very important since this piece of information can remove the ill-posedness of the inverse problem [8].

Let Ω^{int} be an open bounded domain and Ω its complement in $\mathbb{R}^N$. The outward normal to $\Gamma = \partial\Omega^{\text{int}}$ is denoted by $\mathbf{n}$. We assume that Γ is twice differentiable. The resonant frequencies are defined as the poles of the scattering matrix or equivalently the singularities of the *"outgoing"* Green's function for the Helmholtz equation outside an obstacle [9]. A lot of work has been done on the location of the resonant frequencies (see [16] for an overview). There are in fact two classes of results on poles: counting functions of the number of poles and pole-free regions. We focus in this paper only on the first class. Several results dealing with pole-free regions can be found in [11, 13, 18]. It is known that the set of all resonant frequencies has no cluster point, except at infinity. Hence in any compact set of $\mathbb{C}$, there is only a finite number of poles. Let us denote by $N_{\text{G}}(\sigma)$ the number of poles within the circle $|z| < \sigma$. R. Melrose has shown in [15] the following sharp polynomial bound in the case of the Dirichlet boundary condition

$$N_{\text{G}}(\sigma) \leq C_{\text{G}} + C_{\text{G}}\,\sigma^N, \tag{1}$$

*Received by the editors October 27, 1997; accepted for publication July 22, 1998; published elctronically May 13, 1999. This work was carried out while the author was visiting the University of Delaware, Newark, DE.

where N is the dimension of space. For this result as well as for most results on poles, the dimension of space is assumed to be odd. Inequality (1) has no application to the inverse problem, since no lower bound of $N_{\mathrm{G}}(\sigma)$ is known and no information about C_{G} is at our disposal.

The second result concerns the counting function on the purely imaginary axis for odd space dimensions:

$$N_{\mathrm{I}}(\sigma) = \#\{k \text{ pole }, \ k \in \mathbb{R} \text{ and } |k| < \sigma\}\,.$$

In odd space dimensions, we know that there are infinitely many poles on the purely imaginary axis. More precisely, we have

$$\frac{1}{(N-1)!}\left(\frac{R_1}{\gamma_0}\right)^{N-1} \leq \lim_{\sigma\to\infty} \frac{N_{\mathrm{I}}(\sigma)}{\sigma^{N-1}} \leq \frac{1}{(N-1)!}\left(\frac{R_2}{\gamma_0}\right)^{N-1}, \tag{2}$$

where R_1 is the radius of the largest sphere contained in Ω^{int}, R_2 is the radius of the smallest sphere containing Ω^{int}, and γ_0 is a known constant. This result has been shown by P. Lax and R. Phillips in [10] for the Dirichlet and the Neumann boundary conditions, and by J. Beale in [2] for the Robin boundary condition. The aim of this work is to show (2) in the case of the impedance boundary condition.

Let us now give the idea of the proof of (2) in the case of the Dirichlet, Neumann, and Robin boundary conditions. These three boundary conditions are very close to one another since they share a very important property: the energy of the acoustic waves in the whole exterior domain is conserved. The conservative nature of the boundary condition means that the scattering matrix $\mathcal{S}(k)$ is unitary for $k \in \mathbb{R}$. When k is not real, there is a more general relation (namely the Schwarz reflection principle):

$$\mathcal{S}(\overline{k}) = [\mathcal{S}^*(k)]^{-1}\,. \tag{3}$$

It follows that $\overline{k}$ is a zero of $\mathcal{S}$ if and only if k is a pole of $\mathcal{S}^*$. On the other hand, the poles of $\mathcal{S}$ are exactly the poles of $\mathcal{S}^*$ (see Lemma 23). Therefore the location of the zeros of $\mathcal{S}$ is linked to the location of the poles of $\mathcal{S}$, as stated in the following rule: k is a pole of $\mathcal{S}$ if and only if $\overline{k}$ is a zero of $\mathcal{S}$. Consequently, the repartitioning of the resonant frequencies on the purely imaginary axis is symmetric to the repartitioning of the zeros of $\mathcal{S}$ on the purely imaginary axis. This property is at the root of (2), since it is easier to study the zeros of an operator than it is to study its poles. A special analysis of the zeros of the scattering matrix can be carried out on a purely imaginary axis since the study of the zeros of $\mathcal{S}(k)$ for $k \in i\mathbb{R}^+$ turns into a real symmetric eigenvalue problem for an elliptic operator. As a matter of fact, the scattering matrix reads

$$\mathcal{S}(k) = (-1)^{\frac{N+1}{2}}\,[\mathrm{I} + Q(k)W]\,, \tag{4}$$

where $Q(k)$ is a compact operator and W is a unitary operator. Moreover, $Q(k)$ is also self-adjoint on the purely imaginary axis. Hence, $N_{\mathrm{I}}(\sigma)$ is the number of times -1 is an eigenvalue of $Q(i\mu)W$ (where $Q(i\mu)$ is compact and self-adjoint) when μ runs in the slab $[0, \sigma]$.

The general theory of the Lax–Phillips group for dissipative systems can be found

in [12], the following problem is studied

$$\left\{\begin{array}{ll} \dfrac{\partial^2 w(t,\mathbf{x})}{\partial t^2} - \Delta w(t,\mathbf{x}) = 0\ , & \text{in} \quad \mathbb{R}^+\times\Omega \\ \dfrac{\partial w(t,\mathbf{x})}{\partial \mathbf{n}} - \lambda(\mathbf{x})\dfrac{\partial w(t,\mathbf{x})}{\partial t} = 0, & \text{on} \quad \mathbb{R}^+\times\Gamma \\ w(0,\mathbf{x}) = f_0(\mathbf{x}) \quad \text{in} \quad \Omega & \\ \dfrac{\partial w(0,\mathbf{x})}{\partial t} = f_1(\mathbf{x}) \quad \text{in} \quad \Omega. & \end{array}\right. \tag{5}$$

The impedance λ is assumed to satisfy the physical hypotheses

$$0 \leq \lambda(\mathbf{x}) < 1, \qquad \forall \mathbf{x} \in \Gamma. \tag{6}$$

The time translation operator $U(t)$ is defined by

$$U(t)\ :\ \left(\begin{array}{c} f_0 \\ f_1 \end{array}\right) \mapsto \left(\begin{array}{c} w(t,.) \\ \frac{\partial w(t,.)}{\partial t} \end{array}\right).$$

The scattering theory developed by P. Lax and R. Phillips in [9] consists of studying the properties of the one-parameter semigroup $\{U(t)\}_{t\in\mathbb{R}}$ acting on $L^2(\Omega)\times L^2(\Omega)$. P. Lax and R. Phillips showed that $U(t)$ has some eigenvalues

$$U(t)g = e^{-ikt}g$$

for some $g \in L^2_{loc}(\Omega)\times L^2_{loc}(\Omega)$ and some discrete values $k \in \mathbb{C}$. The factors k are the resonant frequencies . The first component u of g is a nontrivial solution to

$$\left\{\begin{array}{ll} \Delta u + k^2 u = 0 & \text{in} \quad \Omega, \\ \frac{\partial u}{\partial \mathbf{n}} + ik\lambda u = 0 & \text{on} \quad \Gamma, \\ u \quad \text{outgoing.} & \end{array}\right. \tag{7}$$

In section 2, we will explain what is meant by *"outgoing."*

We wish to extend (2) to the impedance problem described above. Problem (5) corresponds to the fact that the obstacle is absorbing some energy. The main difficulty due to this boundary condition is that the scattering matrix is no longer unitary for real frequencies. Moreover (3) does not hold, which implies that there does not seem to be any link between the zeros and the poles of $\mathcal{S}$. For this reason, as noticed in [2], the proof of (2) seems to be nonachievable.

To generalize the Schwarz reflection principle, we find it more convenient to focus on the problem in frequency (i.e., (7)) rather than the problem in time (i.e., (5)). This enables us to introduce a more general impedance boundary condition, $\frac{\partial u}{\partial \mathbf{n}} + i\zeta(k)u = g$, where $\zeta(k)$ is the impedance function (which depends on $k \in \mathbb{C}$ and on $\mathbf{x} \in \Gamma$). $\zeta(k)$ is supposed to be analytic in k and to satisfy the following physical assumption:

$$\Re\big(\zeta(k)\,\overline{k}\big) \geq 0 \quad \forall k \in \mathbb{C}. \tag{8}$$

The positive sign means that the obstacle is absorbing some energy. Obviously, this condition is satisfied with the impedance function $\zeta(k) = \lambda k$.

By studying more deeply the form of the scattering matrix, a relation quite similar to (3) can be derived. To allow this, the impedance $\zeta(k)$ must be put as an argument of the scattering matrix: we denote by $\mathcal{S}(k,\zeta(k))$ the scattering matrix at the frequency k with the impedance function $\zeta(k)$. With this notation, we will show that

$$\mathcal{S}\Big(\overline{k}, -\overline{\zeta(k)}\Big) = [\mathcal{S}^*(k,\zeta(k))]^{-1}. \tag{9}$$

In other words, k is a pole of $\mathcal{S}$ with the impedance function $\zeta(k)$ if and only if $\overline{k}$ is a zero of $\mathcal{S}$ with the impedance function $-\overline{\zeta(k)}$. The application of (3) to this case would lead to this equivalence: k is a pole of $\mathcal{S}$ with the impedance function $\zeta(k)$ if and only if $\overline{k}$ is a zero of $\mathcal{S}$ with the impedance function $\zeta(\overline{k})$. Consequently, the use of (9) implies a modification of the impedance function considered when studying the zeros of $\mathcal{S}$. If $(k, \zeta(k))$ satisfies (8), then $\left(\overline{k}, -\overline{\zeta(k)}\right)$ does not satisfy condition (8) since

$$\Re\left(-\overline{\zeta(k)}\,\overline{\overline{k}}\right) = -\Re\big(\zeta(k)\,\overline{k}\big) \leq 0 \quad \forall k \in \mathbb{C}.$$

Therefore, we shall need to define and study the scattering matrix for nonphysical impedances. However, we assume that the nonphysical impedances satisfy the following growth condition

$$\left|\Re\big(\zeta(k,\mathbf{x})\overline{k}\big)\right| \leq \lambda_m |k|^2 \quad \forall k \in \mathbb{C} \text{ with } |k| \geq K \text{ and } \forall \mathbf{x} \in \Gamma, \tag{10}$$

for some $K \geq 0$ and $0 < \lambda_m < 1$. At this point, we are ready to apply the work of P. Lax, R. Phillips, and J. Beale in order to give an estimate of the number $N_{\mathrm{I}}(\sigma)$ of purely imaginary resonant frequencies for the impedance boundary condition $\frac{\partial w}{\partial \mathbf{n}} - \lambda \frac{\partial w}{\partial t} = 0$ whose modulus is lower than σ. From (9), it suffices to count the number of zeros of $\mathcal{S}(i\mu, -i\lambda\mu)$ when μ runs in $[0, \sigma]$.

One can hint at formula (2) from a completely different method than that developed in the rest of this paper.

THEOREM 1. *There exists a constant C such that for σ large enough, we have*

$$N_{\mathrm{I}}(\sigma) \leq C\sigma^{N-1} \ .$$

Proof. The scattering matrix reads (see (45))

$$\mathcal{S}(i\sigma, -i\sigma\lambda) = (-1)^{\frac{N+1}{2}} \left[\mathrm{I} - \left(\frac{-\sigma}{2\pi}\right)^{\frac{N-1}{2}} s(\sigma) W\right],$$

where $s(\sigma)$ is the so-called *transmission coefficient*. We will show in Lemma 27 that for σ large enough, $s(\sigma)$ is a negative and self-adjoint operator. Consequently, the singular values [6] $s_j(s(\sigma))$ of $s(\sigma)$ are identical to the eigenvalues $\pm\lambda_j(s(\sigma)W)$ of $\pm s(\sigma)W$ (the $\pm$ sign comes from W). From Theorem 34, the number of poles in the slab $[-i\sigma, 0]$ is asymptotically (as $\sigma \to \infty$) equal to the number of eigenvalues of $\left(\frac{-\sigma}{2\pi}\right)^{\frac{N-1}{2}} s(\sigma)W$ that are greater than 1. Up to a factor 2, this is also asymptotically equal to the number of singular values of $\left(\frac{-\sigma}{2\pi}\right)^{\frac{N-1}{2}} s(\sigma)$ that are greater than 1. From (32) and (33), the kernel of $s(\sigma)$ is

$$-\frac{\sigma^{\frac{N-3}{2}}}{2(2\pi)^{\frac{N-1}{2}}} \int_\Gamma \left(\frac{\partial e^{\sigma \hat{\mathbf{y}}\cdot\mathbf{z}}}{\partial \mathbf{n}_\mathbf{z}} + \lambda\sigma e^{\sigma\hat{\mathbf{y}}\cdot\mathbf{z}}\right) S^+(i\sigma, -i\lambda\sigma) \left(\frac{\partial e^{\sigma\hat{\mathbf{x}}\cdot\mathbf{z}}}{\partial \mathbf{n}_\mathbf{z}} + \lambda\sigma e^{\sigma\hat{\mathbf{x}}\cdot\mathbf{z}}\right) d\gamma(\mathbf{z}),$$

where the jump operator $S^+(i\sigma, -i\lambda\sigma)$ is defined in section 2. Let us denote by Δ_S the Laplace–Beltrami operator on the unit sphere S_1. Using the classical estimate $\left|(\Delta_S + 1)^{m/2} e^{\sigma\hat{\mathbf{x}}\cdot\mathbf{z}}\right| \leq C m^m e^{C\sigma}$ for $\mathbf{z} \in \Gamma$, we get for an arbitrary integer m:

$$\left\| \left(\frac{-\sigma}{2\pi}\right)^{\frac{N-1}{2}} (\Delta_S + 1)^{m/2}\, s(\sigma) \right\|_{L^2(S_1)\to L^2(S_1)} \leq C m^m e^{C\sigma} \ .$$

Writing $s(\sigma) = (\Delta_S + 1)^{-m/2} (\Delta_S + 1)^{m/2} s(\sigma)$, we have [6]

$$s_j\left(\left(\frac{-\sigma}{2\pi}\right)^{\frac{N-1}{2}} s(\sigma)\right)$$
$$\leq s_j\left((\Delta_S+1)^{-m/2}\right)\left\|\left(\frac{-\sigma}{2\pi}\right)^{\frac{N-1}{2}} (\Delta_S+1)^{m/2} s(\sigma)\right\|_{L^2(S_1)\to L^2(S_1)} .$$

Since $(\Delta_S + 1)^{-m/2}$ is pseudodifferential operator of order $-m$, there exists C such that $s_j\left((\Delta_S+1)^{-m/2}\right) \leq \frac{C}{j^{m/(N-1)}}$ (see, for instance, [7, Lemma A.4]). Henceforth

$$s_j\left(\left(\frac{-\sigma}{2\pi}\right)^{\frac{N-1}{2}} s(\sigma)\right) \leq C\frac{m^m}{j^{m/(N-1)}} e^{C\sigma} .$$

Taking the value of m which minimizes the right-hand side, we obtain

$$s_j\left(\left(\frac{-\sigma}{2\pi}\right)^{\frac{N-1}{2}} s(\sigma)\right) \leq \exp\left(C\sigma - \frac{1}{C} j^{\frac{1}{N-1}}\right).$$

It follows that the condition $s_j\left(\left(\frac{-\sigma}{2\pi}\right)^{\frac{N-1}{2}} s(\sigma)\right) > 1$ implies that $j \leq C\sigma^{N-1}$ for some constant C. Thus,

$$\#\left\{j \ , \ s_j\left(\left(\frac{-\sigma}{2\pi}\right)^{\frac{N-1}{2}} s(\sigma)\right) > 1\right\} \leq C\sigma^{N-1} .$$

From the above remarks, this gives the final estimate. □

We would like to point out a difference of notation between this paper and [9]. The resonant frequencies as defined here lie in the lower half plane of complex frequencies (see Theorem 16) whereas the resonant frequencies as defined in [9] lie in the upper half plane. This is just a matter of convenience and habit.

Let us now give some notation. By $\mathcal{L}(X, Y)$ is meant the set of all the linear operators that maps X onto Y continuously. $L^2(\mathcal{O})$ is the classical space of all square integrable distributions. $H^s(\mathcal{O})$ is the classical Sobolev space ($s \in \mathbb{R}$). $H^s_{loc}(\mathcal{O})$ is the Frechet space of the distributions whose restriction to each bounded domain $\mathcal{O}' \subset \mathcal{O}$ is in $H^s(\mathcal{O}')$. $\|.\|_{L^2(\mathcal{O})}$ and $\|.\|_{H^s(\mathcal{O})}$ are the classical norms in $L^2(\mathcal{O})$ and $H^s(\mathcal{O})$, respectively. B_R is the ball of center 0 and radius R. S_R is the sphere of center 0 and radius R. S_1 in the unit sphere. The complex scalar product in $L^2(\Gamma)$ is denoted by $\langle ., . \rangle$, where Γ is the boundary of an obstacle. $(., .)$ stands for the complex scalar product in $L^2(S_1)$. The two Hankel functions of order 0 and first and second kind are denoted by $H_0^{(1)}(z)$ and $H_0^{(2)}(z)$. For a linear operator B applying on complex valued functional spaces such as L^2 or H^1, let us define its conjugate $\overline{B}$ as follows: $\overline{B}g$ is the complex conjugate of $B\overline{g}$. For a function u defined in either Ω^{int} or Ω, we denote by $u_{|\Gamma}$ the restriction of u on Γ. Let us now consider a function v defined on $\Omega^{\text{int}} \cup \Omega = \mathbb{R}^N \backslash \Gamma$. When a function v is considered on Γ, v^{int} or ${v^{\text{int}}}_{|\Gamma}$ denotes the value on Γ of the restriction to Ω^{int}, whereas v or $v_{|\Gamma}$ means that we take the value on Γ of the restriction to Ω. The jump of v on Γ is defined by $[\![v]\!] := {v^{\text{int}}}_{|\Gamma} - v_{|\Gamma}$. In this paper, vectors will be typed in bold characters, whereas scalar numbers will be typed with standard letters. For $\mathbf{x} \in \mathbb{R}^N$, we define $\hat{\mathbf{x}} := \frac{\mathbf{x}}{|\mathbf{x}|} \in S_1$.

The layout of this paper is as follows. In section 2, we study the nonphysical impedance problem (i.e., subject to (10)) and introduce the notion of incoming and outgoing solutions. Then we define the far field pattern of these solutions. We also give a very important relation between the incoming and the outgoing far field patterns. In section 3, we focus on the physical problem (i.e., subject to (8) and (10)). We define the resonant frequencies as the poles of the outgoing Green function. Then the expression of the scattering matrix is given. The resonant frequencies are proved to be exactly the poles of the scattering matrix. We show (9) and state the relation between the poles and the zeros of $\mathcal{S}$. In section 4, inequality (2) is proved (with the impedance $\zeta(k) = \lambda k$).

2. Definition and properties of the far field pattern. In this section, we aim to construct the far field pattern of the incoming and the outgoing solutions and give the link between these two quantities. Here we consider the general impedance boundary condition $\frac{\partial u}{\partial \mathbf{n}} + i\zeta(k)u = g$ on Γ, where $\zeta(k)$ is an analytic function of $k \in \mathbb{C}$ which satisfies

$$\Re(\zeta(k)) \neq 0 \quad \forall k \in \mathbb{R}^*. \tag{11}$$

This condition means that the energy of the system is not conserved (see Lemma 19). The impedance function ζ depends also on $\mathbf{x} \in \Gamma$, and will be denoted either $\zeta(k)$ or $\zeta(k, \mathbf{x})$. We assume furthermore that $\zeta(k)$ belongs to $C^2(\Gamma)$ and satisfies

$$\left|\Re\big(\zeta(k, \mathbf{x})\overline{k}\big)\right| \leq \lambda_m |k|^2 \quad \forall k \in \mathbb{C} \text{ with } |k| \geq K \text{ and } \forall \mathbf{x} \in \Gamma \tag{12}$$

for some $K \geq 0$ and $0 < \lambda_m < 1$.

2.1. Incoming and outgoing solutions. Let us consider the following problem for $\Im(k) > 0$:

$$\begin{cases} u^+ \in H^1(\Omega)\,, \\ -\Delta u^+ - k^2 u^+ = 0 \quad \text{in} \quad \Omega, \\ \frac{\partial u^+}{\partial \mathbf{n}} + i\zeta(k)u^+ = g \quad \text{on} \quad \Gamma. \end{cases} \tag{13}$$

LEMMA 2. *Let $\zeta(k)$ be an impedance function satisfying condition* (12)*. Then the problem* (13) *has a unique solution when the complex frequency k lies inside the set $\mathcal{C}^+$ defined by*

$$\Im(k) \geq \lambda_m |k| + \lambda_m C + 1 \text{ and } |k| \geq K,$$

where $C > 0$ depends only on the domain Ω (see Figure 1*).*

The set $\mathcal{C}^+$ is not empty since $\lambda_m < 1$. The condition $\lambda_m < 1$ is necessary to show the coerciveness of (13).

Proof. One can give the variational formulation of (13):

$$b^+(u^+, v) = -\int_\Gamma g\overline{v}\, d\gamma \quad \forall v \in H^1(\Omega),$$

where

$$b^+(u, v) := \int_\Omega \big(\nabla u \cdot \nabla \overline{v} - k^2 u\overline{v}\big) - \int_\Gamma i\zeta(k) u\overline{v}\, d\gamma.$$

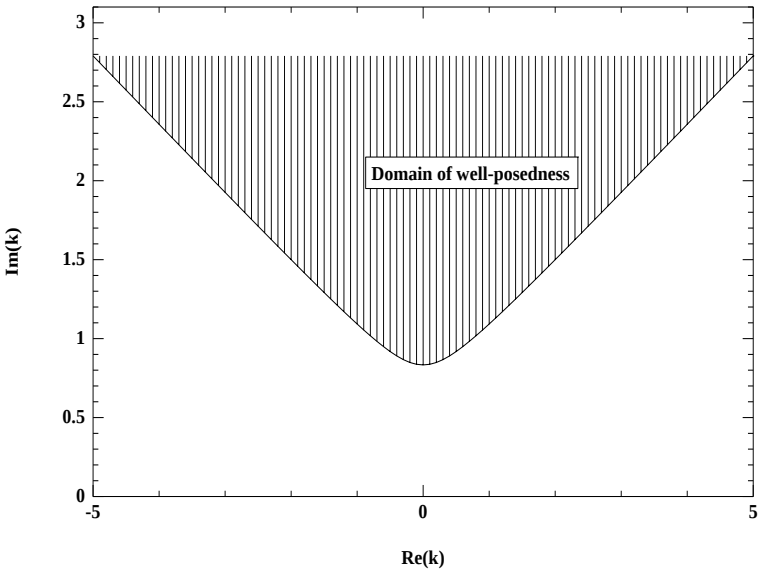

FIG. 1. *The set* $\mathcal{C}^+$.

In order to use Lax–Milgram's lemma, let us compute

$$\Re\big(i\overline{k}b^+(u,u)\big) = \Im(k)\int_\Omega |\nabla u|^2 + \Im(k)|k|^2\int_\Omega |u|^2 + \int_\Gamma \Re\big(\zeta(k)\overline{k}\big)\,|u|^2\,d\gamma. \tag{14}$$

By (12), we have for $|k| \geq K$

$$\int_\Gamma \Re\big(\zeta(k)\overline{k}\big)\,|u|^2\,d\gamma \geq -\lambda_m|k|^2\int_\Gamma |u|^2\,d\gamma.$$

From Lemma 3.3 in [2], for any domain $\mathcal{D}$ with a twice differentiable and bounded boundary, there exists a constant C depending only on $\mathcal{D}$ such that $\forall\ u \in H^1(\mathcal{D})$ and $\forall\ \epsilon > 0$

$$\int_{\partial\mathcal{D}} |u|^2 \leq \epsilon\int_{\mathcal{D}} |\nabla u|^2 + \left(C + \frac{1}{\epsilon}\right)\int_{\mathcal{D}} |u|^2. \tag{15}$$

Then, by (12), using (15) with $\mathcal{D} = \Omega$ and $\epsilon = \frac{1}{|k|}$, we get

$$\begin{aligned}\int_\Gamma \Re\big(\zeta(k)\overline{k}\big)\,|u|^2\,d\gamma &\geq -\lambda_m|k|^2\int_\Gamma |u|^2\,d\gamma \\ &\geq -\lambda_m|k|\|\nabla u\|^2_{L^2(\Omega)} - \lambda_m|k|^2(C+|k|)\|u\|^2_{L^2(\Omega)}\,,\end{aligned}$$

and

$$\Re\big(i\overline{k}b^+(u,u)\big) \geq (\Im(k) - \lambda_m|k|)\|\nabla u\|^2_{L^2(\Omega)} + |k|^2(\Im(k) - \lambda_m|k| - \lambda_m C)\|u\|^2_{L^2(\Omega)}\,.$$

Therefore, if $\Im(k) \geq \lambda_m|k| + \lambda_m C + 1$, then we have shown the coerciveness of $i\overline{k}b^+$:

$$\Re\big(i\overline{k}b^+(u,u)\big) \geq \min\big(\lambda_m C + 1, |k|^2\big)\|u\|^2_{H^1(\Omega)}\,.$$

This means, by Lax–Milgram's lemma, that (13) has a unique solution. The lemma is proved. □

Remark 3. It is well known (see [4]) that when $\Im(k) > 0$, the requirement that the solution of the Helmholtz equation belongs to $H^1(\Omega)$ is equivalent to the outgoing Sommerfeld condition [4]. Namely, whenever $\Im(k) > 0$, (13) is equivalent to the following problem

$$\begin{cases} u^+ \in H^1_{loc}(\Omega) \\ -\Delta u^+ - k^2 u^+ = 0 \quad \text{in} \quad \Omega, \\ \frac{\partial u^+}{\partial \mathbf{n}} + i\zeta(k) u^+ = g \quad \text{on} \quad \Gamma, \\ \lim_{r\to\infty} r^{\frac{N-1}{2}} \left(\frac{\partial u^+}{\partial r} - iku^+ \right) = 0 \quad \text{uniformly in all directions.} \end{cases}$$

This defines the *"outgoing"* solution of the Helmholtz equation.

For $k \in \mathcal{C}^+$ we define the operator $R^+(k, \zeta(k))$ by $R^+(k, \zeta(k))\, g = u^+$, where u^+ is the solution to (13). In order to extend R^+ in $\mathbb{C}\backslash\mathcal{C}^+$, we need a formulation of the solution by integral equations over the boundary Γ (see [5]). u^+ can be written as a combination of the single layer and the double layer potentials

$$u^+ = -i\tilde{V_k^+}\left(\zeta(k) v^+\right) - \tilde{K_k^+}\left(v^+\right) \qquad \text{in} \quad \Omega, \tag{16}$$

where the potential $v^+ \in H^{1/2}(\Gamma)$ defined on Γ must be determined. The integral operators

$$\begin{aligned} \tilde{V_k^+} v(\mathbf{x}) &:= \int_\Gamma G_k^+(\mathbf{x}, \mathbf{y})\, v(\mathbf{y})\ d\gamma(\mathbf{y}), \\ \tilde{K_k^+} v(\mathbf{x}) &:= \int_\Gamma \frac{\partial}{\partial \mathbf{n_y}} G_k^+(\mathbf{x}, \mathbf{y})\, v(\mathbf{y})\ d\gamma(\mathbf{y}) \end{aligned}$$

are defined for $\mathbf{x} \notin \Gamma$. We recall that the outgoing fundamental solution $G_k^+(\mathbf{x}, \mathbf{y})$ is equal to $\frac{i}{4} H_0^{(1)}(k|\mathbf{x} - \mathbf{y}|)$ for $N = 2$ and $\frac{\exp(ik|\mathbf{x}-\mathbf{y}|)}{4\pi|\mathbf{x}-\mathbf{y}|}$ for $N = 3$. The advantage of integral representations is that the Helmholtz equation and the outgoing Sommerfeld condition are automatically satisfied. Then the potential $v^+ \in H^{1/2}(\Gamma)$ is determined by requiring that the impedance boundary condition is satisfied, leading to [5]:

$$\begin{aligned} T^+(k, \zeta(k))\, v^+ := &-D_k^+\left(v^+\right) - i\Big(\zeta(k) K_k^+\left(v^+\right) + \left(K_k^+\right)^t\left(\zeta(k) v^+\right)\Big) \\ &+\zeta(k) V_k^+\left(\zeta(k) v^+\right) = g, \end{aligned} \tag{17}$$

where the integral operators

$$\begin{aligned} V_k^+(v)(\mathbf{x}) &:= \int_\Gamma G_k^+(\mathbf{x}, \mathbf{y})\, v(\mathbf{y})\ d\gamma(\mathbf{y}), \\ K_k^+(v)(\mathbf{x}) &:= \int_\Gamma \frac{\partial G_k^+(\mathbf{x}, \mathbf{y})}{\partial \mathbf{n_y}} v(\mathbf{y})\ d\gamma(\mathbf{y}), \\ \left(K_k^+\right)^t(v)(\mathbf{x}) &:= \int_\Gamma \frac{\partial G_k^+(\mathbf{x}, \mathbf{y})}{\partial \mathbf{n_x}} v(\mathbf{y})\, d\gamma(\mathbf{y}), \\ D_k^+(v)(\mathbf{x}) &:= \int_\Gamma \frac{\partial^2 G_k^+(\mathbf{x}, \mathbf{y})}{\partial \mathbf{n_x} \partial \mathbf{n_y}} v(\mathbf{y})\, d\gamma(\mathbf{y}) \end{aligned}$$

are defined for $\mathbf{x} \in \Gamma$. We recall that

$$V_k^+ \in \mathcal{L}\Big(H^{-1/2}(\Gamma), H^{1/2}(\Gamma)\Big) \quad , \quad K_k^+ \in \mathcal{L}\Big(H^{-1/2}(\Gamma), H^{1/2}(\Gamma)\Big),$$
$$\big(K_k^+\big)^t \in \mathcal{L}\Big(H^{-1/2}(\Gamma), H^{1/2}(\Gamma)\Big) \quad , \quad D_k^+ \in \mathcal{L}\Big(H^{1/2}(\Gamma), H^{-1/2}(\Gamma)\Big).$$

Note that (16) is only one possible representation of u^+. The reason for using (16) is that the associated integral equation, namely (17), is also the integral equation for the resolution of the interior impedance problem. We set

$$\tilde{\mathbb{C}} := \begin{cases} \mathbb{C}\backslash\{z \in \mathbb{R}, z \leq 0\} & \text{if } N \text{ is even,} \\ \mathbb{C} & \text{otherwise.} \end{cases}$$

LEMMA 4. *The operator $R^+ \in \mathcal{L}\big(H^{-1/2}(\Gamma), H^1(\Omega)\big)$, defined for $k \in \mathcal{C}^+$ by Lemma 2, has a meromorphic extension to $\tilde{\mathbb{C}}$, and the extension is an operator belonging to the space $\mathcal{L}\big(H^{-1/2}(\Gamma), H^1_{loc}(\Omega)\big)$.*

Proof. The inverse of the operator T^+ is labeled S^+. We have that T^+ belongs to the space $\mathcal{L}\big(H^{1/2}(\Gamma), H^{-1/2}(\Gamma)\big)$ and $S^+ \in \mathcal{L}\big(H^{-1/2}(\Gamma), H^{1/2}(\Gamma)\big)$ in $\mathcal{C}^+$. The three operators R^+, T^+, and S^+ are well-defined in $\mathcal{C}^+$. Moreover, by (16) and (17), R^+ and S^+ are linked by the relation

$$R^+(k, \zeta(k)) = \Big(-i\tilde{V_k^+}\zeta(k) - \tilde{K_k^+}\Big) S^+(k, \zeta(k)). \tag{18}$$

Since $\Big(-i\tilde{V_k^+}\zeta(k) - \tilde{K_k^+}\Big)$ is analytic in $\tilde{\mathbb{C}}$, it is equivalent to extend R^+ or S^+. Henceforth the extension of R^+ is done through T^+. First, by (17), one can see that T^+ is well-defined $\forall\ k \in \tilde{\mathbb{C}}$ and is analytic in k. Then, from [5], we notice that for k_0, such that $\Im(k_0) > 0$, the operator $D_{k_0}^+$ is invertible. We write for $k \in \tilde{\mathbb{C}}$

$$T^+(k, \zeta(k)) = -D_{k_0}^+ [\mathrm{I} + C(k, \zeta(k))],$$

where

$$\begin{aligned} C(k, \zeta(k)) := {D_{k_0}^+}^{-1}\big(D_k^+ - D_{k_0}^+\big) + i{D_{k_0}^+}^{-1}\zeta(k)K_k^+ \\ + i{D_{k_0}^+}^{-1}\big(K_k^+\big)^t\zeta(k) - {D_{k_0}^+}^{-1}\zeta(k)V_k^+\zeta(k). \end{aligned}$$

By subtracting the symbol of the pseudodifferential operators D_k^+ and $D_{k_0}^+$, one can easily show that ${D_{k_0}^+}^{-1}\big(D_k^+ - D_{k_0}^+\big)$ is compact (see [3, 14]). Moreover, from the mapping properties of ${D_{k_0}^+}^{-1}$, K_k^+, $\big(K_k^+\big)^t$, and V_k^+, the three remaining pseudodifferential operators appearing in the expression of $C(k, \zeta(k))$ are compact. We conclude that $C(k, \zeta(k))$ is compact. Finally by Lemma 2, $T^+(k, \zeta(k))$ is invertible $\forall\ k \in \mathcal{C}^+$. Consequently, by Steinberg's theorem [17], $\big(T^+(k, \zeta(k))\big)^{-1} = S^+(k, \zeta(k))$ has a meromorphic extension to $\tilde{\mathbb{C}}\backslash\mathcal{C}^+$. Hence, S^+ has a countable number of poles. Thanks to relation (18) and to the analycity of $\zeta(k)$ and of the two operators $\tilde{V_k^+}$ and $\tilde{K_k^+}$, R^+ is extended in the same way as S^+. ∎

Remark 5. The proof of Lemma 4 gives the way to define the outgoing solution of the Helmholtz equation for almost any frequency $k \in \tilde{\mathbb{C}}$. From now on, we will refer to this procedure when stating that a solution is outgoing.

As a consequence of the above two lemmas, we have the following theorem.

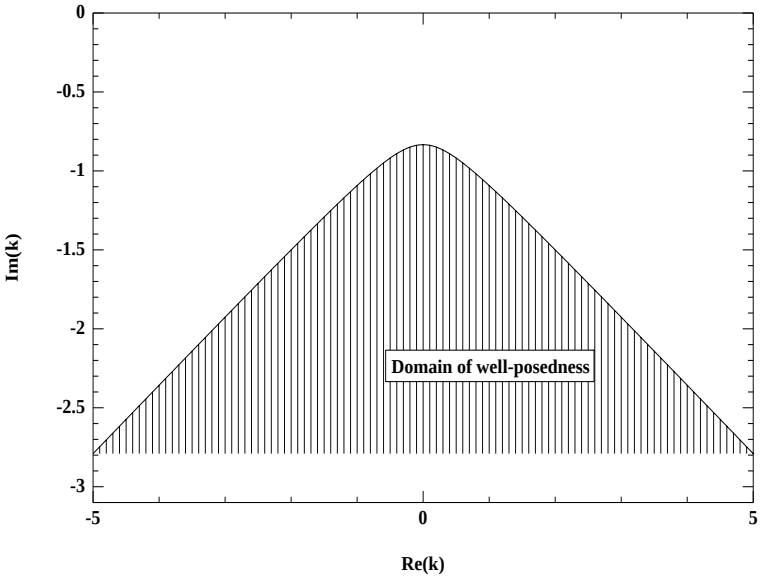

FIG. 2. *The set* $\mathcal{C}^-$.

THEOREM 6. *R^+ has a countable number of poles. These poles lie in $\tilde{\mathbb{C}}\backslash\mathcal{C}^+$.* Conversely, the incoming solution u^- is defined for $\Im(k) < 0$ by

$$\left\{\begin{array}{l} u^- \in H^1(\Omega)\,, \\ -\Delta u^- - k^2 u^- = 0 \quad \text{in} \quad \Omega, \\ \frac{\partial u^-}{\partial \mathbf{n}} + i\zeta(k) u^- = g \quad \text{on} \quad \Gamma. \end{array}\right. \tag{19}$$

As for the outgoing problem, one can show the following lemma.

LEMMA 7. *Let $\zeta(k)$ be an impedance function satisfying condition* (12)*. Then the problem* (19) *has a unique solution when the complex frequency k lies inside the set $\mathcal{C}^-$ defined by*

$$\Im(k) \leq -\lambda_m |k| - (\lambda_m C + 1) \quad \text{and} \quad |k| \geq K,$$

where $C > 0$ depends only on the domain Ω (see Figure 2*).*

Remark 8. When $\Im(k) < 0$, the requirement that the solution to the Helmholtz equation belongs to $H^1(\Omega)$ is equivalent to the incoming Sommerfeld condition [4]. Namely, whenever $\Im(k) < 0$, (19) is equivalent to the following problem:

$$\left\{\begin{array}{l} u^- \in H^1_{loc}(\Omega)\,, \\ -\Delta u^- - k^2 u^- = 0 \quad \text{in} \quad \Omega, \\ \frac{\partial u^-}{\partial \mathbf{n}} + i\zeta(k) u^- = g \quad \text{on} \quad \Gamma, \\ \lim_{r\to\infty} r^{\frac{N-1}{2}} \left(\frac{\partial u^-}{\partial r} + iku^-\right) = 0 \quad \text{uniformly in all directions.} \end{array}\right.$$

This defines the *"incoming"* solution of the Helmholtz equation.

We define the operator $R^-(k, \zeta(k))$ by $R^-(k, \zeta(k))\, g = u^-$ for $k \in \mathcal{C}^-$. All the previous integral operators can be defined for the incoming problem. The superscript $+$ has to be replaced by $-$. The incoming fundamental solution $G_k^-(\mathbf{x}, \mathbf{y})$ is equal to

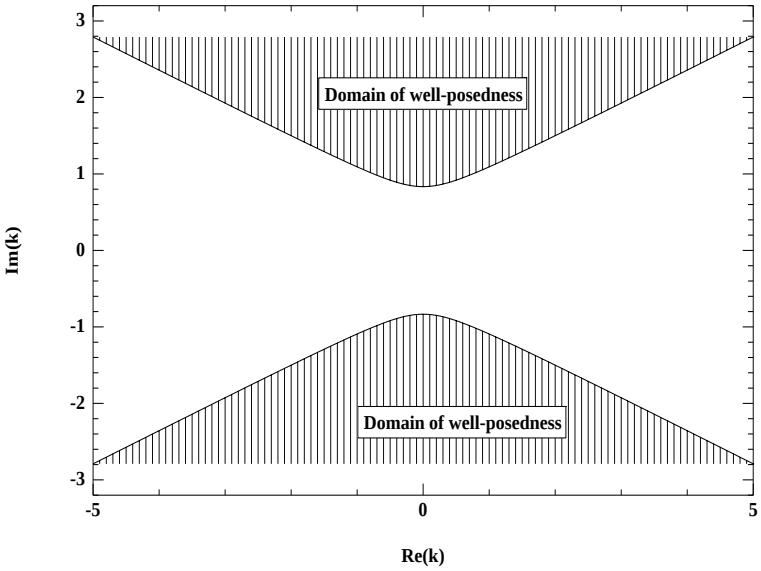

FIG. 3. *The set* $\mathcal{C}^{\text{int}}$.

$-\frac{i}{4}H_0^{(2)}(k|\mathbf{x}-\mathbf{y}|)$ for $N=2$ and $\frac{\exp(-ik|\mathbf{x}-\mathbf{y}|)}{4\pi|\mathbf{x}-\mathbf{y}|}$ for $N=3$. Equation (17) with the superscript $-$ instead of $+$ is the integral equation for the incoming problem and defines the operator T^-. The operators R^- and S^- are extended in a meromorphic way to $\mathbb{C}\backslash\mathcal{C}^-$, leading to the following lemma.

LEMMA 9. *The operator* $R^- \in \mathcal{L}\big(H^{-1/2}(\Gamma), H^1(\Omega)\big)$ *defined for* $k \in \mathcal{C}^-$ *by Lemma* 7 *has a meromorphic extension to* $\tilde{\mathbb{C}}$, *and the extension is an operator belonging to* $\mathcal{L}\big(H^{-1/2}(\Gamma), H^1_{loc}(\Omega)\big)$.

THEOREM 10. R^- *has a countable number of poles. These poles lie in* $\tilde{\mathbb{C}}\backslash\mathcal{C}^-$.

Finally, it appears useful to define the impedance interior problem,

$$\left\{\begin{array}{ll} u^{\text{int}} \in H^1\big(\Omega^{\text{int}}\big), & \\ -\Delta u^{\text{int}} - k^2 u^{\text{int}} = 0 & \text{in} \quad \Omega, \\ \frac{\partial u^{\text{int}}}{\partial \mathbf{n}} + i\zeta(k) u^{\text{int}} = g & \text{on} \quad \Gamma, \end{array}\right. \tag{20}$$

and the operator $R^{\text{int}}(k,\zeta(k))$ by $R^{\text{int}}(k,\zeta(k))\, g = u^{\text{int}}$ when u^{int} is well-defined. Similarly to Lemmas 2 and 7, we have the following.

LEMMA 11. *Let* $\zeta(k)$ *be an impedance function satisfying condition* (12). *The problem* (20) *has a unique solution when the complex frequency* k *lies inside the set* $\mathcal{C}^{\text{int}}$ *defined by* (*see Figure* 3)

$$|\Im(k)| \geq \lambda_m |k| + \lambda_m C + 1 \text{ and } |k| \geq K,$$

where $C > 0$ *depends only on the domain* Ω.

The solution u^{int} can be represented by an integral representation involving either the outgoing kernel G_k^+ or the incoming kernel G_k^-:

$$R^{\text{int}} = \left(-i\tilde{V_k^+}\zeta(k) - \tilde{K_k^+}\right) S^+(k,\zeta(k)),$$

or

$$R^{\rm int} = \left(-i\tilde{V_k^-}\zeta(k) - \tilde{K_k^-}\right) S^-(k,\zeta(k))\,.$$

Obviously, these two expressions are equivalent inside $\Omega^{\rm int}$. As in Lemmas 4 and 9, one can show that the problem (20) has a countable number of poles.

THEOREM 12. *$R^{\rm int}$ has a countable number of poles. These poles lie in $\tilde{\mathbb{C}}\backslash\mathcal{C}^{\rm int}$.*

The importance of the interior problem for the construction of the scattering matrix comes from the following two relations,

$$S^+(k,\zeta(k)) : g \mapsto v^+ = [\![u^+]\!] := {u^{\rm int}}_{|\Gamma} - {u^+}_{|\Gamma},$$
$$S^-(k,\zeta(k)) : g \mapsto v^- = [\![u^-]\!] := {u^{\rm int}}_{|\Gamma} - {u^-}_{|\Gamma},$$

where u^+, u^- and $u^{\rm int}$ are the solutions of (13), (19), and (20), respectively, with the right-hand side g.

2.2. Link between incoming and outgoing solutions. In fact, the two problems (13) and (19) are very close to one another. Thus, special relations link R^+ and R^-. This is what makes the relation (9) possible. First, if $u^+ = R^+(k,\zeta(k))\,g$ for $k \in \mathcal{C}^+$, we see that the incoming Sommerfeld condition holds with $(-k)$ instead of k. Then, since $-k \in \mathcal{C}^-$, by Lemma 7, we get

$$R^+(k,\zeta(k)) = R^-(-k,\zeta(k)) \tag{21}$$

whenever $k \in \mathcal{C}^+$. By analyticity arguments, this relation holds $\forall\ k \in \tilde{\mathbb{C}}$ such that $R^+(k,\zeta(k))$ is defined. This shows that the poles of $R^+(k,\zeta(k))$ are exactly those of $R^-(-k,\zeta(k))$.

On the other hand, if one sets $u = R^+(k,\zeta(k))\,\overline{g}$, then $\overline{u}$ satisfies for $k \in \mathcal{C}^+$

$$\begin{cases} -\Delta\overline{u} - \overline{k}^2\overline{u} = 0 & \text{in} \quad \Omega, \\ \frac{\partial\overline{u}}{\partial\mathbf{n}} - i\,\overline{\zeta(k)}\overline{u} = g & \text{on} \quad \Gamma, \\ \lim_{r\to\infty} r^{\frac{N-1}{2}}\left(\frac{\partial\overline{u}}{\partial r} + i\overline{k}\overline{u}\right) = 0. \end{cases}$$

By Lemma 7, this problem has a unique solution since $\overline{k} \in \mathcal{C}^-$ and the couple $\left(\overline{k}, -\overline{\zeta(k)}\right)$ satisfies (12). Hence $\overline{u} = R^-\left(\overline{k}, -\overline{\zeta(k)}\right) g$. Then

$$\overline{R^+(k,\zeta(k))} = R^-\left(\overline{k}, -\overline{\zeta(k)}\right) \tag{22}$$

for $k \in \mathcal{C}^+$. Using the same argument as for (21), relation (22) holds for almost all $k \in \tilde{\mathbb{C}}$. With the same argument, we also have

$$R^{\rm int}(k,\zeta(k)) = R^{\rm int}(-k,\zeta(k))\,, \qquad \overline{R^{\rm int}(k,\zeta(k))} = R^{\rm int}\left(\overline{k}, -\overline{\zeta(k)}\right). \tag{23}$$

If $T^\pm$ stands for either T^+ or T^-, we have

$$\begin{aligned} \left\langle T^\pm(k,\zeta(k))\,v, v'\right\rangle = &-\int_{\Gamma\times\Gamma} \frac{\partial^2}{\partial\mathbf{n_x}\partial\mathbf{n_y}} G_k^\pm(\mathbf{x},\mathbf{y})\,v(\mathbf{x})\overline{v}'(\mathbf{y})\,d\gamma(\mathbf{x})\;d\gamma(\mathbf{y}) \\ -i\int_{\Gamma\times\Gamma} &\left[\frac{\partial}{\partial\mathbf{n_y}} G_k^\pm(\mathbf{x},\mathbf{y})\,\zeta(k,\mathbf{x}) + \frac{\partial}{\partial\mathbf{n_x}} G_k^\pm(\mathbf{x},\mathbf{y})\,\zeta(k,\mathbf{y})\right] v(\mathbf{x})\overline{v}'(\mathbf{y})\,d\gamma(\mathbf{x})\;d\gamma(\mathbf{y}) \\ +\int_{\Gamma\times\Gamma} &G_k^\pm(\mathbf{x},\mathbf{y})\,\zeta(k,\mathbf{x})\,\zeta(k,\mathbf{y})\,v(\mathbf{x})\overline{v}'(\mathbf{y})\,d\gamma(\mathbf{x})\;d\gamma(\mathbf{y})\,. \end{aligned}$$

One can easily check the relation $\overline{G_k^{\pm}(\mathbf{x},\mathbf{y})} = G_{-\overline{k}}^{\pm}(\mathbf{x},\mathbf{y})$ for both the incoming and the outgoing solutions. Let $(T^{\pm}(k,\zeta(k)))^*$ be the adjoint operator of $T^{\pm}(k,\zeta(k))$. Since the kernel of $T^{\pm}$ is symmetric with respect to $\mathbf{x}$ and $\mathbf{y}$, we have $(T^{\pm}(k,\zeta(k)))^* = \overline{T^{\pm}(k,\zeta(k))}$, and thus

$$\left\langle \left(T^{\pm}(k,\zeta(k))\right)^* v, v' \right\rangle = \left\langle \overline{T^{\pm}(k,\zeta(k))} v, v' \right\rangle = \left\langle T^{\pm}\left(-\overline{k}, -\overline{\zeta(k)}\right) v, v' \right\rangle$$

for almost all $k \in \tilde{\mathbb{C}}$. Hence

$$\left(T^{\pm}(k,\zeta(k))\right)^* = \overline{T^{\pm}(k,\zeta(k))} = T^{\pm}\left(-\overline{k}, -\overline{\zeta(k)}\right) \tag{24}$$

for almost all $k \in \tilde{\mathbb{C}}$. If $S^{\pm}$ stands for S^+ or S^-, then we also have

$$\left(S^{\pm}(k,\zeta(k))\right)^* = \overline{S^{\pm}(k,\zeta(k))} = S^{\pm}\left(-\overline{k}, -\overline{\zeta(k)}\right) \tag{25}$$

for almost all $k \in \tilde{\mathbb{C}}$. Similarly, the relation $G_{-k}^{+}(\mathbf{x},\mathbf{y}) = G_k^{-}(\mathbf{x},\mathbf{y})$ enables us to show the following equality

$$S^-(k,\zeta(k)) = S^+(-k,\zeta(k)) \tag{26}$$

for almost all $k \in \tilde{\mathbb{C}}$.

2.3. The far field patterns. The outgoing and incoming solutions share a special behavior at infinity (i.e., very far away from the obstacle): the solution at a point $\mathbf{x} \in \mathbb{R}^N$ is asymptotically equal to a function of $|\mathbf{x}|$ times a function of $\hat{\mathbf{x}} := \frac{\mathbf{x}}{|\mathbf{x}|}$. This latter function is called the far field pattern. The main interest of the far field for what we are concerned with lies in the fact that it gives a characterization of the scattering matrix.

The outgoing kernel satisfies

$$G_k^+(\mathbf{x},\mathbf{y}) = \frac{e^{ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N-1}{2}}} e^{-ik\hat{\mathbf{x}}\cdot\mathbf{y}} \chi(k) + O\left(\frac{e^{ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N+1}{2}}}\right), \qquad \text{where } \chi(k) = \frac{(-ik)^{\frac{N-3}{2}}}{2(2\pi)^{\frac{N-1}{2}}},$$

and

$$\frac{\partial G_k^+}{\partial \mathbf{n_y}}(\mathbf{x},\mathbf{y}) = \frac{e^{ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N-1}{2}}} \frac{\partial e^{-ik\hat{\mathbf{x}}\cdot\mathbf{y}}}{\partial \mathbf{n_y}} \chi(k) + O\left(\frac{e^{ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N+1}{2}}}\right).$$

Recalling that $v^+ = S^+(k,\zeta(k))\, g = [\![u^+]\!]$ and using (18), we get

$$R^+(k,\zeta(k))\, g(\mathbf{x}) = \frac{e^{ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N-1}{2}}} A_{+,g}(\hat{\mathbf{x}},k,\zeta(k)) + O\left(\frac{e^{ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N+1}{2}}}\right), \tag{27}$$

where for any $\hat{\mathbf{x}} \in S_1$

$$A_{+,g}(\hat{\mathbf{x}},k,\zeta(k)) := -\chi(k) \int_\Gamma \left(\frac{\partial e^{-ik\hat{\mathbf{x}}\cdot\mathbf{y}}}{\partial \mathbf{n_y}} + i\zeta(k,\mathbf{y}) e^{-ik\hat{\mathbf{x}}\cdot\mathbf{y}}\right) [\![u^+(\mathbf{y})]\!]\, d\gamma(\mathbf{y}).$$

For the incoming solution, we have

$$G_k^-(\mathbf{x},\mathbf{y}) = \frac{e^{-ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N-1}{2}}} e^{ik\hat{\mathbf{x}}\cdot\mathbf{y}} \chi(-k) + O\left(\frac{e^{-ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N+1}{2}}}\right)$$

and

$$\frac{\partial G_k^-}{\partial \mathbf{n_y}}(\mathbf{x},\mathbf{y}) = \frac{e^{-ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N-1}{2}}}\frac{\partial e^{ik\hat{\mathbf{x}}\cdot\mathbf{y}}}{\partial \mathbf{n_y}}\chi(-k) + O\left(\frac{e^{-ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N+1}{2}}}\right).$$

Hence

$$R^-(k,\zeta(k))\, g(\mathbf{x}) = \frac{e^{-ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N-1}{2}}}A_{-,g}(\hat{\mathbf{x}},k,\zeta(k)) + O\left(\frac{e^{-ik|\mathbf{x}|}}{|\mathbf{x}|^{\frac{N+1}{2}}}\right), \tag{28}$$

where for any $\hat{\mathbf{x}} \in S_1$

$$A_{-,g}(\hat{\mathbf{x}},k,\zeta(k)) := -\chi(-k)\int_\Gamma \left(\frac{\partial e^{ik\hat{\mathbf{x}}\cdot\mathbf{y}}}{\partial \mathbf{n_y}} + i\zeta(k,\mathbf{y})e^{ik\hat{\mathbf{x}}\cdot\mathbf{y}}\right)[\![u^-(\mathbf{y})]\!]\, d\gamma(\mathbf{y}).$$

$A_{+,g}$ and $A_{-,g}$ are the scattering amplitudes, or far field patterns of, respectively, the outgoing and the incoming solution.

From (21), we automatically infer that

$$A_{-,g}(\hat{\mathbf{x}},k,\zeta(k)) = A_{+,g}(\hat{\mathbf{x}},-k,\zeta(k)), \tag{29}$$

and (22) implies that

$$\overline{A_{+,g}(\hat{\mathbf{x}},k,\zeta(k))} = A_{-,\overline{g}}\left(\hat{\mathbf{x}},\overline{k},-\overline{\zeta(k)}\right). \tag{30}$$

Now we study more closely the case of the plane wave incidence. This is important for several reasons. First, it is a very important case physically. Second, the far field pattern can be expressed as a superposition of plane waves. More precisely, for the incident wave $u_0(\mathbf{x}) = e^{-ik\hat{\mathbf{y}}\cdot\mathbf{x}}$ where $|\hat{\mathbf{y}}| = 1$, the boundary condition reads

$$\frac{\partial u}{\partial \mathbf{n}} + i\zeta(k)u = \frac{\partial u_0}{\partial \mathbf{n}} + i\zeta(k)u_0 = q_{\hat{\mathbf{y}},k,\zeta(k)},$$

where

$$\left(q_{\hat{\mathbf{y}},k,\zeta(k)}\right)(\mathbf{x}) := \frac{\partial}{\partial \mathbf{n_x}}e^{-ik\hat{\mathbf{y}}\cdot\mathbf{x}} + i\zeta(k,\mathbf{x})e^{-ik\hat{\mathbf{y}}\cdot\mathbf{x}}. \tag{31}$$

The far field pattern, with respect to the plane wave, is labeled $s_\pm$, i.e.,

$$s_\pm(\hat{\mathbf{y}},\hat{\mathbf{x}},k,\zeta(k)) := A_{\pm,q_{\hat{\mathbf{y}},k,\zeta(k)}}(\hat{\mathbf{x}},k,\zeta(k)). \tag{32}$$

Putting together (27), (28), and (31), we have that

$$\begin{aligned} A_{+,g}(\hat{\mathbf{x}},k,\zeta(k)) &= -\chi(k)\int_\Gamma q_{\hat{\mathbf{x}},k,\zeta(k)}\, S^+(k,\zeta(k))\, g\, d\gamma \\ A_{-,g}(\hat{\mathbf{x}},k,\zeta(k)) &= -\chi(-k)\int_\Gamma q_{-\hat{\mathbf{x}},k,\zeta(k)}\, S^-(k,\zeta(k))\, g\, d\gamma. \end{aligned} \tag{33}$$

2.4. Two fundamental relationships between incoming and outgoing far field patterns.

LEMMA 13. *We have*

$$\begin{aligned} A_{-,g}(-\hat{\mathbf{x}},k,\zeta(k)) &= -1^{\frac{N+1}{2}} A_{+,g}(\hat{\mathbf{x}},k,\zeta(k)) \\ &\quad + \frac{ik}{2\pi}^{\frac{N-1}{2}} \int_{|\hat{\mathbf{y}}|=1} s_-(\hat{\mathbf{x}},\hat{\mathbf{y}},k,\zeta(k))\, A_{+,g}(\hat{\mathbf{y}},k,\zeta(k))\, dS(\hat{\mathbf{y}}), \end{aligned} \tag{34}$$

$$\begin{aligned} A_{+,g}(\hat{\mathbf{x}},k,\zeta(k)) &= -1^{\frac{N+1}{2}} A_{-,g}(-\hat{\mathbf{x}},k,\zeta(k)) \\ &\quad + \left(\frac{-ik}{2\pi}\right)^{\frac{N-1}{2}} \int_{|\hat{\mathbf{y}}|=1} s_+(\hat{\mathbf{x}},-\hat{\mathbf{y}},k,\zeta(k))\, A_{-,g}(-\hat{\mathbf{y}},k,\zeta(k))\, dS(\hat{\mathbf{y}}). \end{aligned} \tag{35}$$

Proof. For $k \in \tilde{\mathbb{C}}$ and $g \in H^{-1/2}(\Gamma)$ fixed, let us compute

$$\begin{aligned} \mathcal{H} &= -\frac{A_{+,g}(\hat{\mathbf{x}},k,\zeta(k))}{\chi(k)} + \frac{A_{-,g}(-\hat{\mathbf{x}},k,\zeta(k))}{\chi(-k)} \\ &= \int_\Gamma \left[S^+(k,\zeta(k))\, g - S^-(k,\zeta(k))\, g\right] q_{\hat{\mathbf{x}},k,\zeta(k)}\, d\gamma. \end{aligned}$$

Thanks to (26), one may write

$$\mathcal{H} = \left\langle S^+(k,\zeta(k))\, g, \overline{q_{\hat{\mathbf{x}},k,\zeta(k)}} \right\rangle - \left\langle g, \left(S^+(-k,\zeta(k))\right)^* \overline{q_{\hat{\mathbf{x}},k,\zeta(k)}} \right\rangle.$$

Due to (25), we arrange the previous equation as

$$\mathcal{H} = \left\langle S^+(k,\zeta(k))\, g, \overline{q_{\hat{\mathbf{x}},k,\zeta(k)}} \right\rangle - \left\langle g, S^+\left(\overline{k}, -\overline{\zeta(k)}\right) \overline{q_{\hat{\mathbf{x}},k,\zeta(k)}} \right\rangle.$$

By (31), the plane wave satisfies $q := \overline{q_{\hat{\mathbf{x}},k,\zeta(k)}} = q_{-\hat{\mathbf{x}},\overline{k},-\overline{\zeta(k)}}$. We define the function v by $v = R^+\left(\overline{k}, -\overline{\zeta(k)}\right) q$ in Ω and by $v = R^{\text{int}}\left((\overline{k}, -\overline{\zeta(k)}\right) q$ in Ω^{int}. In fact, v is the outgoing solution of $\Delta v + \overline{k}^2 v = 0$. Moreover, we have $S^+\left(\overline{k}, -\overline{\zeta(k)}\right)\overline{q_{\hat{\mathbf{x}},k,\zeta(k)}} = S^+\left(\overline{k}, -\overline{\zeta(k)}\right) q = [\![v]\!]$ and $\frac{\partial v}{\partial \mathbf{n}} - i\overline{\zeta(k)} v = q = \overline{q_{\hat{\mathbf{x}},k,\zeta(k)}}$ on both sides of Γ. From (27) and (32), the asymptotic behavior of v is

$$v(\mathbf{y}) \overset{|\mathbf{y}|\to\infty}{\sim} \frac{e^{i\overline{k}|\mathbf{y}|}}{|\mathbf{y}|^{\frac{N-1}{2}}} s_+\left(-\hat{\mathbf{x}}, \hat{\mathbf{y}}, \overline{k}, -\overline{\zeta(k)}\right),$$

where s_+ is defined in (32).

On the other hand, let us denote by $u = R^+(k,\zeta(k))\, g$ in Ω and $u = R^{\text{int}}(k,\zeta(k))\, g$ in Ω^{int}, the outgoing solution with the initial data g. We have

$$S^+(k,\zeta(k))\, g = [\![u]\!], \qquad \frac{\partial u}{\partial \mathbf{n}} + i\zeta(k) u = g \quad \text{on} \quad \Gamma$$

and

$$u(\mathbf{y}) \overset{|\mathbf{y}|\to\infty}{\sim} \frac{e^{ik|\mathbf{y}|}}{|\mathbf{y}|^{\frac{N-1}{2}}} A_{+,g}(\hat{\mathbf{y}},k,\zeta(k)).$$

Therefore

$$\begin{aligned}\mathcal{H} &= \left\langle [\![u]\!], \frac{\partial v}{\partial \mathbf{n}} - i\overline{\zeta(k)}v \right\rangle - \left\langle \frac{\partial u}{\partial \mathbf{n}} + i\zeta(k)u, [\![v]\!] \right\rangle \\ &= \int_\Gamma \left\{ [\![u]\!] \left(\frac{\partial \overline{v}}{\partial \mathbf{n}} + i\zeta(k)\overline{v} \right) - \left(\frac{\partial u}{\partial \mathbf{n}} + i\zeta(k)u \right) [\![\overline{v}]\!] \right\}.\end{aligned}$$

Let us denote by $\tilde{\Omega}_R$ the domain $\Omega^{\text{int}} \cup (\Omega \cap B_R)$ for some $R > 0$ large enough. Then Green's formula applied to $\tilde{\Omega}_R$ turns into the two following relations:

$$\begin{aligned}\int_{\tilde{\Omega}_R} \nabla u \cdot \nabla \overline{v} - k^2 u\overline{v} &= \int_{\tilde{\Omega}_R} \nabla u \cdot \nabla \overline{v} + \Delta u\, \overline{v} \\ &= \int_\Gamma \left(\frac{\partial u^{\text{int}}}{\partial \mathbf{n}} \overline{v}^{\text{int}} - \frac{\partial u}{\partial \mathbf{n}} \overline{v} \right) d\gamma + \int_{S_R} \frac{\partial u}{\partial r} \overline{v}\, dS_R\end{aligned}$$

and

$$\begin{aligned}\int_{\tilde{\Omega}_R} \nabla u \cdot \nabla \overline{v} - k^2 u\overline{v} &= \int_{\tilde{\Omega}_R} \nabla u \cdot \nabla \overline{v} + u\Delta \overline{v} \\ &= \int_\Gamma \left(u^{\text{int}} \frac{\partial \overline{v}^{\text{int}}}{\partial \mathbf{n}} - u \frac{\partial \overline{v}}{\partial \mathbf{n}} \right) d\gamma + \int_{S_R} u \frac{\partial \overline{v}}{\partial r}\, dS_R.\end{aligned}$$

By subtracting these last two equations, we have

$$\begin{aligned}&- \int_{S_R} \left(\frac{\partial u}{\partial r} \overline{v} - u \frac{\partial \overline{v}}{\partial r} \right) dS_R \\ &= \int_\Gamma \left\{ \left(\frac{\partial u^{\text{int}}}{\partial \mathbf{n}} \overline{v}^{\text{int}} - \frac{\partial u}{\partial \mathbf{n}} \overline{v} \right) - \left(u^{\text{int}} \frac{\partial \overline{v}^{\text{int}}}{\partial \mathbf{n}} - u \frac{\partial \overline{v}}{\partial \mathbf{n}} \right) \right\} d\gamma \\ &= \int_\Gamma \left\{ \left[\left(\frac{\partial u^{\text{int}}}{\partial \mathbf{n}} + i\zeta(k)u^{\text{int}} \right) \overline{v}^{\text{int}} - \left(\frac{\partial u}{\partial \mathbf{n}} + i\zeta(k)u \right) \overline{v} \right] \right. \\ &\quad - \left. \left[u^{\text{int}} \left(\frac{\partial \overline{v}^{\text{int}}}{\partial \mathbf{n}} + i\zeta(k)\overline{v}^{\text{int}} \right) - u \left(\frac{\partial \overline{v}}{\partial \mathbf{n}} + i\zeta(k)\overline{v} \right) \right] \right\} d\gamma.\end{aligned}$$

Since

$$\frac{\partial u^{\text{int}}}{\partial \mathbf{n}} + i\zeta(k)u^{\text{int}} = \frac{\partial u}{\partial \mathbf{n}} + i\zeta(k)u$$

and

$$\frac{\partial \overline{v}^{\text{int}}}{\partial \mathbf{n}} + i\zeta(k)\overline{v}^{\text{int}} = \frac{\partial \overline{v}}{\partial \mathbf{n}} + i\zeta(k)\overline{v},$$

the last equality becomes

$$\int_{S_R} \left(\frac{\partial u}{\partial r} \overline{v} - u \frac{\partial \overline{v}}{\partial r} \right) dS_R = \int_\Gamma \left\{ [\![u]\!] \left(\frac{\partial \overline{v}}{\partial \mathbf{n}} + i\zeta(k)\overline{v} \right) - \left(\frac{\partial u}{\partial \mathbf{n}} + i\zeta(k)u \right) [\![\overline{v}]\!] \right\} d\gamma. \tag{36}$$

Now on S_R, the asymptotic behavior of u and v enables one to write

$$\frac{\partial u(r\hat{\mathbf{y}})}{\partial r} \overline{v(r\hat{\mathbf{y}})} - u(r\hat{\mathbf{y}}) \frac{\partial \overline{v(r\hat{\mathbf{y}})}}{\partial r} \overset{r\to\infty}{\sim} \frac{2ik}{r^{N-1}} \overline{s_+\left(-\hat{\mathbf{x}}, \hat{\mathbf{y}}, \overline{k}, -\overline{\zeta(k)}\right)} A_{+,g}(\hat{\mathbf{y}}, k, \zeta(k)).$$

Thus,

$$\mathcal{H} = \int_{S_R} \left(\frac{\partial u}{\partial r} \overline{v} - u \frac{\partial \overline{v}}{\partial r} \right) \, dS_R$$

with

$$\int_{S_R} \left(\frac{\partial u}{\partial r} \overline{v} - u \frac{\partial \overline{v}}{\partial r} \right) \, dS_R \overset{R\to\infty}{\sim} \frac{2ik}{R^{N-1}} \int_{S_R} \overline{s_+\Big(-\hat{\mathbf{x}}, \hat{\mathbf{y}}, \overline{k}, -\overline{\zeta(k)}\Big)} A_{+,g}(\hat{\mathbf{y}}, k, \zeta(k)) \, dS_R.$$

By (30) and (32)

$$\begin{aligned} \overline{s_+\Big(-\hat{\mathbf{x}}, \hat{\mathbf{y}}, \overline{k}, -\overline{\zeta(k)}\Big)} &= \overline{A_{+,q_{-\hat{\mathbf{x}},\overline{k},-\overline{\zeta(k)}}}\Big(\hat{\mathbf{y}}, \overline{k}, -\overline{\zeta(k)}\Big)} \\ &= \overline{A_{+,\overline{q_{\hat{\mathbf{x}},k,\zeta(k)}}}\Big(\hat{\mathbf{y}}, \overline{k}, -\overline{\zeta(k)}\Big)} \\ &= A_{-,q_{\hat{\mathbf{x}},k,\zeta(k)}}(\hat{\mathbf{y}}, k, \zeta(k)) = s_-(\hat{\mathbf{x}}, \hat{\mathbf{y}}, k, \zeta(k)) \, . \end{aligned}$$

Thus,

$$\overline{s_+\Big(-\hat{\mathbf{x}}, \hat{\mathbf{y}}, \overline{k}, -\overline{\zeta(k)}\Big)} = s_-(\hat{\mathbf{x}}, \hat{\mathbf{y}}, k, \zeta(k)) \tag{37}$$

and

$$\int_{S_R} \left(\frac{\partial u}{\partial r} \overline{v} - u \frac{\partial \overline{v}}{\partial r} \right) \, dS_R \overset{R\to\infty}{\longrightarrow} 2ik \int_{|\hat{\mathbf{y}}|=1} s_-(\hat{\mathbf{x}}, \hat{\mathbf{y}}, k, \zeta(k)) \, A_{+,g}(\hat{\mathbf{y}}, k, \zeta(k)) \, dS(\hat{\mathbf{y}}).$$

Since $\mathcal{H}$ does not depend on R, it follows that

$$\mathcal{H} = 2ik \int_{|\hat{\mathbf{y}}|=1} s_-(\hat{\mathbf{x}}, \hat{\mathbf{y}}, k, \zeta(k)) \, A_{+,g}(\hat{\mathbf{y}}, k, \zeta(k)) \, dS(\hat{\mathbf{y}}).$$

Finally from the relations $\frac{\chi(k)}{\chi(-k)} = (-1)^{\frac{N-3}{2}} = (-1)^{\frac{N+1}{2}}$ and $2ik\chi(-k) = \left(\frac{ik}{2\pi}\right)^{\frac{N-1}{2}}$, we have proved (34).

Let us now explicitly write down the mapping $A_- \to A_+$. We proceed as previously. Thanks to (25) and (26), $\mathcal{H}$ is given by

$$\begin{aligned} \mathcal{H} &= -\int_\Gamma \left\{ S^-(k, \zeta(k)) \, g - S^-(-k, \zeta(k)) \, g \right\} q_{\hat{\mathbf{x}},k,\zeta(k)} \, d\gamma \\ &= -\left\langle S^-(k, \zeta(k)) \, g, \overline{q_{\hat{\mathbf{x}},k,\zeta(k)}} \right\rangle + \left\langle g, S^-\Big(\overline{k}, -\overline{\zeta(k)}\Big) \, \overline{q_{\hat{\mathbf{x}},k,\zeta(k)}} \right\rangle . \end{aligned}$$

We now set

$$\begin{cases} v = R^-\Big(\overline{k}, -\overline{\zeta(k)}\Big) \, \overline{q_{\hat{\mathbf{x}},k,\zeta(k)}} & \text{in } \Omega \\ v = R^{\text{int}}\Big(\overline{k}, -\overline{\zeta(k)}\Big) \, \overline{q_{\hat{\mathbf{x}},k,\zeta(k)}} & \text{in } \Omega^{\text{int}} \end{cases} \quad \text{and} \quad \begin{cases} u = R^-(k, \zeta(k)) \, g & \text{in } \Omega \\ u = R^{\text{int}}(k, \zeta(k)) \, g & \text{in } \Omega^{\text{int}}. \end{cases}$$

Hence

$$\mathcal{H} = \int_\Gamma \left\{ \left(\frac{\partial u}{\partial \mathbf{n}} + i\zeta(k) u \right) [\![\overline{v}]\!] - [\![u]\!] \left(\frac{\partial \overline{v}}{\partial \mathbf{n}} + i\zeta(k) \overline{v} \right) \right\} .$$

Formula (36) also holds with the new choice of u and v. Thus,

$$\begin{aligned}\mathcal{H} &= -\int_{S_R}\left(\frac{\partial u}{\partial r}\overline{v} - u\frac{\partial \overline{v}}{\partial r}\right) dS_R \\ &= 2ik\int_{|\hat{\mathbf{y}}|=1} \overline{s_-\Big(-\hat{\mathbf{x}},\hat{\mathbf{y}},\overline{k},-\overline{\zeta(k)}\Big)}A_{-,g}(\hat{\mathbf{y}},k,\zeta(k))\,dS(\hat{\mathbf{y}}).\end{aligned}$$

Finally we have proved (35) by (37) and by changing $\hat{\mathbf{y}}$ into $-\hat{\mathbf{y}}$ in the integral. ∎

3. The scattering matrix. In section 2, we have introduced several notions in the case of a general impedance boundary condition. We are going to apply them to the case of an impedance that satisfies the physical assumption

$$0 \le \Re\big(\zeta(k,\mathbf{x})\overline{k}\big) \le \lambda_m\,|k|^2 \quad \forall k\in\mathbb{C} \text{ with } |k|\ge K \quad \text{and} \quad \forall \mathbf{x}\in\Gamma \tag{38}$$

for some $K \ge 0$ and $0 < \lambda_m < 1$. We use the notation of section 2.

3.1. Notion of resonant frequency. The calculations of section 2.1 are also valid in the case of (38). However few results can be improved. In particular, Lemma 2 becomes the following.

LEMMA 14. *Let $\zeta(k)$ be an impedance function satisfying condition* (38)*. The problem* (13) *has a unique solution when the complex frequency k lies inside the upper half plane $\mathbb{C}^+ := \{k\in\mathbb{C}\ ,\ \Im(k) > 0\}$.*

Proof. We proceed as in the proof of Lemma 2. From (14) and (38), one can automatically deduce that $i\overline{k}b^+$ is coercive when $\Im(k) > 0$. We conclude the proof by using the Lax–Milgram lemma. ∎

As in section 2.1, we define $R^+(k,\zeta(k)) : g \mapsto u^+$, where u^+ is solution to (13). Using Lemma 4, one can extend R^+ to $\tilde{\mathbb{C}}\backslash\mathbb{C}^+$. Hence R^+ has a countable number of poles in $\tilde{\mathbb{C}}\backslash\mathbb{C}^+$.

DEFINITION 15. *The "resonant frequencies" are defined as the poles of the operator $R^+(k,\zeta(k))$, where $\zeta(k)$ is a physical impedance.*

Combining Lemmas 4 and 14, we get the following theorem.

THEOREM 16. *The resonant frequencies lie in $\tilde{\mathbb{C}}\backslash\mathbb{C}^+$.*

3.2. Definition of the scattering matrix and derivation of the fundamental relation. In [9], the scattering matrix for the Dirichlet or the Neumann boundary condition is defined from the problem in time. However, in [10, formula (A.16)], it is shown that the scattering matrix satisfies a relation which involves only the far fields of the outgoing and incoming solutions. For the impedance boundary condition, if the scattering matrix is denoted by $\mathcal{S}(k,\zeta(k))$, this relation writes formally

$$\mathcal{S}(k,\zeta(k)) \ :\ A_{-,g}(-\hat{\mathbf{x}},k,\zeta(k)) \ \mapsto\ A_{+,g}(\hat{\mathbf{x}},k,\zeta(k)) \tag{39}$$

$\forall\ g \in H^{-1/2}(\Gamma)$. In order to infer from this property a definition of the scattering matrix, we must get rid of the term g in (39). To this end, let us introduce the far field operators $A_\pm(k,\zeta(k))$ defined by

$$\big(A_\pm(k,\zeta(k))\,g\big)(\hat{\mathbf{x}}) = A_{\pm,g}(\hat{\mathbf{x}},k,\zeta(k))\,.$$

If W stands for the symmetry operator (i.e., $[Wa]\,(\hat{\mathbf{y}}) = a(-\hat{\mathbf{y}})$), then (39) turns into

$$\mathcal{S}(k,\zeta(k))\,W A_-(k,\zeta(k))\,g = A_+(k,\zeta(k))\,g$$

$\forall\ g \in H^{-1/2}(\Gamma)$. Hence $\mathcal{S}(k,\zeta(k))\, W A_-(k,\zeta(k)) = A_+(k,\zeta(k))$, which implies the following definition.

DEFINITION 17. *The "scattering matrix" $\mathcal{S}(k,\zeta(k))$ associated with the frequency k and the impedance $\zeta(k)$ is defined by*

$$\mathcal{S}(k,\zeta(k)) := A_+(k,\zeta(k))\,(A_-(k,\zeta(k)))^{-1}\, W^{-1}.$$

The operators $A_\pm(k,\zeta(k))$ map $H^{-1/2}(\Gamma)$ to $L^2(S_1)$. We will show in the proof of Theorem 18 that $A_\pm(k,\zeta(k))$ is one-to-one. Hence $A_\pm(k,\zeta(k))$ is an isomorphism from $H^{-1/2}(\Gamma)$ onto the space $A_\pm(k,\zeta(k))H^{-1/2}(\Gamma)$. Actually, the space $A_\pm(k,\zeta(k))H^{-1/2}(\Gamma)$ is strictly included in $L^2(S_1)$. We do not know how to characterize the far field patterns of waves scattered by an obstacle in $L^2(S_1)$ [5]. Hence the scattering matrix is only defined on $WA_\pm(k,\zeta(k))H^{-1/2}(\Gamma)$. However, we will show later on that the scattering matrix can be extended to any function of $L^2(S_1)$.

THEOREM 18. *The poles of the scattering matrix are the poles of the far field operator $A_+(k,\zeta(k))$.*

Proof. From Definition 17, the poles of the scattering matrix are composed of the poles of $A_+(k,\zeta(k))$ plus the zeros of $A_-(k,\zeta(k))$. Thus the property is proved if we show that there is no zero of $A_-(k,\zeta(k))$.

Suppose by contradiction that k is a zero of $A_-(k,\zeta(k))$. Then 0 is eigenvalue of $A_-(k,\zeta(k))$. Hence there exists a nonzero function $g \in H^{-1/2}(\Gamma)$ such that the far field $A_-(k,\zeta(k))\, g := u^\infty$ of the incoming solution u to the extension of the problem (19) vanishes (see Lemma 9). Hence from [5, Theorem 2.13], we have $u \equiv 0$ outside a ball containing the obstacle Ω^{int}, and thus by analytic continuation (see [4]) $u \equiv 0$ in Ω. Taking the restriction of u on the boundary, we get $\frac{\partial u}{\partial \mathbf{n}} + i\zeta(k)u = 0$ on Γ. Finally, since $g \not\equiv 0$, the impedance boundary condition cannot be satisfied, which leads to a contradiction. ∎

3.3. Expression of the scattering matrix. We set

$$[Q_+(k,\zeta(k))\, A]\,(\hat{\mathbf{x}}) = \int_{|\hat{\mathbf{y}}|=1} s_+(\hat{\mathbf{x}},-\hat{\mathbf{y}},k,\zeta(k))\, A(\hat{\mathbf{y}}) dS(\hat{\mathbf{y}}),$$
$$[Q_-(k,\zeta(k))\, A]\,(\hat{\mathbf{x}}) = \int_{|\hat{\mathbf{y}}|=1} s_-(\hat{\mathbf{x}},\hat{\mathbf{y}},k,\zeta(k))\, A(\hat{\mathbf{y}}) dS(\hat{\mathbf{y}}).$$

By (35) and (39), the scattering matrix writes

$$\mathcal{S}(k,\zeta(k)) = (-1)^{\frac{N+1}{2}} \left[\mathrm{I} - \left(\frac{ik}{2\pi}\right)^{\frac{N-1}{2}} Q_+(k,\zeta(k)) \right]. \tag{40}$$

From this expression of the scattering matrix, it is now clear that the domain of definition of $\mathcal{S}$ can be extended to the whole space $L^2(S_1)$. Thanks to (34), the inverse of $\mathcal{S}$ is given by

$$\mathcal{S}^{-1}(k,\zeta(k)) = (-1)^{\frac{N+1}{2}} \left[\mathrm{I} - \left(\frac{-ik}{2\pi}\right)^{\frac{N-1}{2}} Q_-(k,\zeta(k)) \right]. \tag{41}$$

The conjugate of the scattering matrix is

$$\mathcal{S}^*(k,\zeta(k)) = (-1)^{\frac{N+1}{2}} \left[\mathrm{I} - \left(\frac{-i\bar{k}}{2\pi}\right)^{\frac{N-1}{2}} Q_+(k,\zeta(k))^* \right].$$

The kernel of $Q_+(k,\zeta(k))$ is $s_+(\hat{\mathbf{x}},-\hat{\mathbf{y}},k,\zeta(k))$, so that the kernel of $Q_+(k,\zeta(k))^*$ is $\overline{s_+(\hat{\mathbf{y}},-\hat{\mathbf{x}},k,\zeta(k))}$. From the reciprocity relation [5, 9], we have $s_+(\hat{\mathbf{y}},-\hat{\mathbf{x}},k,\zeta(k)) = s_+(-\hat{\mathbf{x}},\hat{\mathbf{y}},k,\zeta(k))$. Thus, by relation (37), $s_-\big(\hat{\mathbf{x}},\hat{\mathbf{y}},\overline{k},-\overline{\zeta(k)}\big)$ is the kernel of the operator $Q_+(k,\zeta(k))^*$, which implies that $Q_+((k,\zeta(k))^* = Q_-\big(\overline{k},-\overline{\zeta(k)}\big)$. Hence

$$\mathcal{S}^*(k,\zeta(k)) = \mathcal{S}^{-1}\Big(\overline{k},-\overline{\zeta(k)}\Big)\,,$$

and we obtain the fundamental relation

$$\mathcal{S}\Big(\overline{k},-\overline{\zeta(k)}\Big) = [\mathcal{S}^*(k,\zeta(k))]^{-1}\,. \tag{42}$$

Hence relation (9) is shown. We have insisted in the introduction on the fact that this relation plays a central role in this work. We now give a simple consequence of (42).

It is important for applications to see whether or not the scattering matrix is unitary on the real axis. Indeed, the scattering matrix is unitary on the real axis if and only if the time translation operator $U(t)$ is unitary. This latter property means that the energy of the systems is conserved. Because of the surface impedance which introduces some absorption, we expect the scattering matrix to be not unitary. The answer to this question is given in the next lemma.

LEMMA 19. *The scattering matrix is unitary on the real axis if and only if* $\zeta(k)$ *is purely imaginary on the real axis.*

As a consequence of this lemma, the assumption (11) implies that the scattering matrix is not unitary on the real axis. In fact, if (11) is not satisfied, then the impedance boundary condition degenerates into the Robin boundary condition on the real axis.

Proof. The scattering matrix is unitary on the real axis if and only if

$$\mathcal{S}^*(k,\zeta(k)) = [\mathcal{S}(k,\zeta(k))]^{-1}$$

for almost all $k \in \mathbb{R}\cap\tilde{\mathbb{C}}$. Hence by (42), the scattering matrix is unitary on the real axis if and only if $\mathcal{S}(k,\zeta(k)) = \mathcal{S}\big(k,-\overline{\zeta(k)}\big)$. By (40), this is equivalent to $s_+(\hat{\mathbf{x}},-\hat{\mathbf{y}},k,\zeta(k)) = s_+\big(\hat{\mathbf{x}},-\hat{\mathbf{y}},k,-\overline{\zeta(k)}\big)$ for almost all $\hat{\mathbf{x}} \in S_1$ and almost all $\hat{\mathbf{y}} \in S_1$. From the uniqueness of the recovery of the impedance (on a known and fixed boundary) from the far field pattern (see Theorem 6.13 in [4]), we conclude that the scattering matrix is unitary on the real axis if and only if $\zeta(k) = -\overline{\zeta(k)}$ for k real. ∎

3.4. Relation between the resonant frequencies and the zeros of the scattering matrix. The main interest of the scattering matrix lies in the following result.

THEOREM 20. *The poles of the scattering matrix* $\mathcal{S}(k,\zeta(k))$ *are exactly the resonant frequencies* (*see Definition* 15).

Proof. From Theorem 18 and relation (33), the poles of the scattering matrix are the poles of the jump operator $S^+(k,\zeta(k))$. Since $S^+(k,\zeta(k))\,g$ corresponds to the jump between the outgoing solution $R^+(k,\zeta(k))\,g$ and the interior solution $R^{\text{int}}(k,\zeta(k))\,g$, the poles of the scattering matrix are a priori composed of the poles of $R^+(k,\zeta(k))$ (namely the resonant frequencies) and the poles of R^{int}. We are going to show that the poles of the interior problem disappear so that the theorem is proved.

From (40), to show this we have only to show that the kernel s_+ of the operator Q_+ is independent of the interior problem. We recall that the interior problem appears in the jump operator S^+, i.e.,

$$s_+(\hat{\mathbf{x}},\hat{\mathbf{y}},k,\zeta(k)) = A_{+,q_{\hat{\mathbf{x}},k,\zeta(k)}}(\hat{\mathbf{y}},k,\zeta(k))$$

$$= -\chi(k) \int_\Gamma q_{\hat{\mathbf{y}},k,\zeta(k)} S^+(k,\zeta(k))\, q_{\hat{\mathbf{x}},k,\zeta(k)}\, d\gamma$$
$$= -\chi(k) \int_\Gamma q_{\hat{\mathbf{y}},k,\zeta(k)} \left(u^{\text{int}} - u^+\right)\, d\gamma,$$

where u^{int} is solution to (20) with $g = q_{\hat{\mathbf{x}},k,\zeta(k)}$. We set $e_{\hat{\mathbf{x}}}(\mathbf{y}) = e^{-ik\,\hat{\mathbf{x}}.\mathbf{y}}$. We notice that $\forall\ k \in \mathbb{C}$, $e_{\hat{\mathbf{x}}}$ is solution to (20) with $g = q_{\hat{\mathbf{x}},k,\zeta(k)}$. When k is not a pole of (20), we have uniqueness of (20) and thus $u^{\text{int}}(\mathbf{y}) = e_{\hat{\mathbf{x}}}(\mathbf{y})$. Now when k is a pole of (20), we do not want to single out the particular solution $e_{\hat{\mathbf{x}}}$. We assume that u^{int} is any solution to (20). Green's formula then gives

$$0 = \int_{\Omega^{\text{int}}} e_{\hat{\mathbf{y}}} \Delta u^{\text{int}} - \Delta e_{\hat{\mathbf{y}}}\, u^{\text{int}} = \int_\Gamma e_{\hat{\mathbf{y}}} \frac{\partial u^{\text{int}}}{\partial \mathbf{n}} - \frac{\partial e_{\hat{\mathbf{y}}}}{\partial \mathbf{n}} u^{\text{int}}\, d\gamma.$$

Thus, since $\frac{\partial u^{\text{int}}}{\partial \mathbf{n}} + i\zeta(k) u^{\text{int}} = \frac{\partial e_{\hat{\mathbf{x}}}}{\partial \mathbf{n}} + i\zeta(k) e_{\hat{\mathbf{x}}}$ on Γ, it follows that

$$\int_\Gamma q_{\hat{\mathbf{y}},k,\zeta(k)} u^{\text{int}}\, d\gamma = \int_\Gamma e_{\hat{\mathbf{y}}} \left(\frac{\partial u^{\text{int}}}{\partial \mathbf{n}} + i\zeta(k) u^{\text{int}}\right)\, d\gamma = \int_\Gamma e_{\hat{\mathbf{y}}} \left(\frac{\partial e_{\hat{\mathbf{x}}}}{\partial \mathbf{n}} + i\zeta(k) e_{\hat{\mathbf{x}}}\right)\, d\gamma.$$

We can also show that, by Green's formula,

$$\int_\Gamma e_{\hat{\mathbf{y}}} \frac{\partial e_{\hat{\mathbf{x}}}}{\partial \mathbf{n}}\, d\gamma = \int_\Gamma \frac{\partial e_{\hat{\mathbf{y}}}}{\partial \mathbf{n}} e_{\hat{\mathbf{x}}}\, d\gamma.$$

Thus,

$$\int_\Gamma q_{\hat{\mathbf{y}},k,\zeta(k)} u^{\text{int}}\, d\gamma = \int_\Gamma \left(\frac{\partial e_{\hat{\mathbf{y}}}}{\partial \mathbf{n}} + i\zeta(k) e_{\hat{\mathbf{y}}}\right) e_{\hat{\mathbf{x}}}\, d\gamma = \int_\Gamma q_{\hat{\mathbf{y}},k,\zeta(k)} e_{\hat{\mathbf{x}}}\, d\gamma$$

and

$$s_+(\hat{\mathbf{x}},\hat{\mathbf{y}},k,\zeta(k)) = -\chi(k) \int_\Gamma q_{\hat{\mathbf{y}},k,\zeta(k)} \left(e_{\hat{\mathbf{x}}} - u^+\right)\, d\gamma. \tag{43}$$

We notice that the interior problem disappears: the spurious poles (of the interior problem) are not poles of $\mathcal{S}$. □

Remark 21. The scattering matrix gives the relationship between incoming and outgoing solutions. In order to give an explicit form of $\mathcal{S}$ in the previous section, we used integral equations on the boundary of the obstacle. The main drawback to the use of integral equations is that they introduce the interior problem and its singularities in the formulation of $\mathcal{S}$. In particular, we know that the problem (20) is singular for a countable number of poles. Theorem 20 shows that these poles do not create spurious poles for $\mathcal{S}$, that is to say, the poles of the scattering matrix are in fact the resonant frequencies of the exterior problem.

THEOREM 22. *k is a resonant frequency (i.e., a pole of $\mathcal{S}$ for the impedance $\zeta(k)$) if and only if $\overline{k}$ is a zero of $\mathcal{S}$ for the impedance $-\overline{\zeta(k)}$.*

Proof. From (42), k is a pole of $\mathcal{S}^*$ for the impedance $\zeta(k)$ if and only if $\overline{k}$ is a zero of $\mathcal{S}$ for the impedance $-\overline{\zeta(k)}$. To conclude, we use Theorem 20 and Lemma 23 below. □

LEMMA 23. *Let $B(k)$ be an operator-valued meromorphic function. Then $B(k)$ and $B(k)^*$ have their poles at the same complex numbers k.*

Proof. Assume that k be a pole of $B(k)$. Let k_n be a sequence which converge to k. Then there exists a sequence u_n such that $\|u_n\| = 1$ and $\|B(k_n)u_n\|$ tends to infinity. We set $v_n = B(k_n)u_n$. We have

$$\|v_n\| = \left(B(k_n)u_n \, , \, \frac{v_n}{\|v_n\|} \right) = \left(u_n \, , \, B(k_n)^* \frac{v_n}{\|v_n\|} \right) \leq \|u_n\| \left\| B(k_n)^* \frac{v_n}{\|v_n\|} \right\|.$$

We conclude that $\left\| B(k_n)^* \frac{v_n}{\|v_n\|} \right\|$ tends to infinity, which implies that k is a pole of $B(k)^*$. ∎

4. Purely imaginary resonant frequencies. In this section, some estimates on the location of the purely imaginary poles are given. Thanks to Theorem 22, we are able to use the work of P. Lax and R. Phillips [9, 10] and J. Beale [2]. Here we are concerned with an impedance of the form

$$\zeta(k, \mathbf{x}) = k\lambda(\mathbf{x}), \tag{44}$$

where $0 \leq \lambda(\mathbf{x}) < 1$ for any $\mathbf{x} \in \Gamma$. Relation (11) is satisfied. Moreover, $\lambda_m := \max_{\mathbf{x}\in\Gamma} \lambda(\mathbf{x}) < 1$, which implies that (12) holds. Condition (38) is trivially satisfied so that all the results of previous section hold with the choice (44). Equation (44) is the impedance function which is most broadly used in the literature.

We first give the expression of the scattering matrix on the purely imaginary axis. It is of the form (4) where $Q(i\sigma)$ is a compact self-adjoint operator when $\sigma \in \mathbb{R}$.

4.1. The transmission coefficient. As in [10, 2], we wish to study the location of the zeros of $\mathcal{S}$ instead of the location of the poles of $\mathcal{S}$.

THEOREM 24. *The resonant frequencies are the poles of the extension of the problem* (13) *with the impedance* (44)*. These resonant frequencies lie in the lower half plane* $\tilde{\mathbb{C}}\backslash\mathbb{C}^+$*.*

Moreover, $-i\sigma$ *(with* $\sigma \in \mathbb{R}$*) is a resonant frequency if and only if* 0 *is an eigenvalue of the operator* $\mathcal{S}(i\sigma, -i\lambda\sigma)$*.*

Proof. The first part of the theorem is a simple consequence of Definition 15 and Theorem 16.

By Theorem 22, $k = -i\sigma$ is a resonant frequency (i.e., a pole of $\mathcal{S}$ for the impedance $\zeta(k) = -i\lambda\sigma$) if and only if $\overline{k} = i\sigma$ is a zero of $\mathcal{S}$ for the impedance $-\overline{\zeta(k)} = -i\lambda\sigma$. ∎

As stated in the introduction, we do not consider, for the study of the zeros of $\mathcal{S}$, the problem (13) at the frequency $k = i\sigma$ with the impedance (44), i.e., $\zeta(i\sigma) = i\sigma\lambda$. We consider instead the problem (13) at the frequency $k = i\sigma$ with the impedance $-i\sigma\lambda$. Thus we have to find the location of the zeros of the scattering matrix $\mathcal{S}\big(i\sigma, \tilde{\zeta}(i\sigma)\big)$, with the impedance $\tilde{\zeta}(k, x) = -\lambda(x)k$. From (40),

$$\mathcal{S}(i\sigma, -i\sigma\lambda) = (-1)^{\frac{N+1}{2}} \left[\mathrm{I} - \left(\frac{-\sigma}{2\pi} \right)^{\frac{N-1}{2}} s(\sigma) W \right], \tag{45}$$

where the operator W is defined by the relation $[Wa](\hat{\mathbf{y}}) = a(-\hat{\mathbf{y}})$, and where $s(\sigma)$ is the operator of $L^2(S_1)$ whose kernel is $s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma) := s_+(\hat{\mathbf{x}}, \hat{\mathbf{y}}, i\sigma, -i\lambda\sigma)$. By (27) and (32), $s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma)$ is given by

$$s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma) = \lim_{r\to\infty} \left[r^{\frac{N-1}{2}} e^{\sigma\rho} v(\rho\hat{\mathbf{y}}, \hat{\mathbf{x}}; \sigma) \right],$$

where

$$\left\{ \begin{array}{l} \left(\sigma^2 - \Delta\right) v(\mathbf{y}, \hat{\mathbf{x}}; \sigma) = 0 \quad \text{in} \quad \Omega, \\ \left(\frac{\partial}{\partial \mathbf{n}} + \lambda(\mathbf{y})\sigma\right) v(\mathbf{y}, \hat{\mathbf{x}}; \sigma) = \left(\frac{\partial}{\partial \mathbf{n}} + \lambda(\mathbf{y})\sigma\right) e^{\sigma\, \hat{\mathbf{x}}\cdot\mathbf{y}} \quad \text{on} \quad \Gamma. \end{array} \right. \tag{46}$$

This problem is elliptic and has a real-valued solution, so that $s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma)$ is real valued. Moreover, from the reciprocity relation [5, 9], we have $s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma) = s(\hat{\mathbf{y}}, \hat{\mathbf{x}}; \sigma)$. Consequently, the operator $s(\sigma)$ is self-adjoint. That $s(\sigma)$ is compact follows from the fact that $s(\sigma)$ is a Hilbert–Schmidt operator. $s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma)$ is called the *"transmission coefficient"*.

Let us now finish this section by giving an integral representation of the transmission coefficient s. To this end, we set $v_{\hat{\mathbf{x}}}(\mathbf{z}) = v(\mathbf{z}, \hat{\mathbf{x}}; \sigma)$ and $e_{\hat{\mathbf{y}}}(\mathbf{z}) = e^{\sigma \hat{\mathbf{y}}\cdot\mathbf{z}}$.

LEMMA 25. *For $\sigma > 0$, the transmission coefficient is given by*

$$s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma) = \frac{\sigma^{\frac{N-3}{2}}}{2\,(2\pi)^{\frac{N-1}{2}}} \left[-\int_{\Omega^{\text{int}}} p_\sigma(e_{\hat{\mathbf{x}}}, e_{\hat{\mathbf{y}}}) - \int_\Omega p_\sigma(v_{\hat{\mathbf{x}}}, v_{\hat{\mathbf{y}}}) - \int_\Gamma \lambda\sigma(e_{\hat{\mathbf{x}}} e_{\hat{\mathbf{y}}} - v_{\hat{\mathbf{x}}} v_{\hat{\mathbf{y}}})\, d\gamma \right],$$

where $p_\sigma(u, v) = \nabla u \cdot \nabla v + \sigma^2 uv$.

Proof. From (43), we have (with $k = i\sigma$, and $\zeta(k) = -i\lambda\sigma$)

$$s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma) = -\chi(i\sigma) \int_\Gamma \left(\frac{\partial e_{\hat{\mathbf{y}}}}{\partial \mathbf{n}} + \lambda\sigma e_{\hat{\mathbf{y}}} \right) \left(e_{\hat{\mathbf{x}}} - v_{\hat{\mathbf{x}}} \right)\, d\gamma,$$

where $\chi(i\sigma) = \frac{\sigma^{\frac{N-3}{2}}}{2(2\pi)^{\frac{N-1}{2}}}$. Since $\frac{\partial v_{\hat{\mathbf{y}}}}{\partial \mathbf{n}} + \lambda\sigma v_{\hat{\mathbf{y}}} = \frac{\partial e_{\hat{\mathbf{y}}}}{\partial \mathbf{n}} + \lambda\sigma e_{\hat{\mathbf{y}}}$, we get

$$s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma) = -\frac{\sigma^{\frac{N-3}{2}}}{2(2\pi)^{\frac{N-1}{2}}} \left\{ \int_\Gamma \left(\frac{\partial e_{\hat{\mathbf{y}}}}{\partial \mathbf{n}} + \lambda\sigma e_{\hat{\mathbf{y}}} \right) e_{\hat{\mathbf{x}}}\, d\gamma - \int_\Gamma \left(\frac{\partial v_{\hat{\mathbf{y}}}}{\partial \mathbf{n}} + \lambda\sigma v_{\hat{\mathbf{y}}} \right) v_{\hat{\mathbf{x}}}\, d\gamma \right\}.$$

Let us set $L_\sigma u = \left(\sigma^2 - \Delta\right) u$. Since $L_\sigma v_{\hat{\mathbf{y}}} = 0$ and $L_\sigma e_{\hat{\mathbf{y}}} = 0$, Green's formula leads to

$$0 = \int_{\Omega^{\text{int}}} e_{\hat{\mathbf{x}}} L_\sigma e_{\hat{\mathbf{y}}} = \int_{\Omega^{\text{int}}} p_\sigma(e_{\hat{\mathbf{x}}}, e_{\hat{\mathbf{y}}}) - \int_\Gamma e_{\hat{\mathbf{x}}} \frac{\partial e_{\hat{\mathbf{y}}}}{\partial \mathbf{n}}\, d\gamma$$

and

$$0 = \int_\Omega v_{\hat{\mathbf{x}}} L_\sigma v_{\hat{\mathbf{y}}} = \int_\Omega p_\sigma(v_{\hat{\mathbf{x}}}, v_{\hat{\mathbf{y}}}) + \int_\Gamma v_{\hat{\mathbf{x}}} \frac{\partial v_{\hat{\mathbf{y}}}}{\partial \mathbf{n}}\, d\gamma.$$

Hence, putting these two expressions in $s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma)$, we have proved the lemma. ∎

4.2. Properties of the zeros of $\mathcal{S}$. The problem (46) does not correspond to a physical impedance (i.e., the impedance does not satisfy the condition (38)). However, the impedance satisfies the condition (12).

THEOREM 26. *Assume that $0 < \lambda_m := \max_{\mathbf{x}\in\Gamma} \lambda(\mathbf{x}) < 1$. Then for*

$$\sigma \geq \sigma_0' := \frac{\lambda_m C + 1}{1 - \lambda_m},$$

(where C is a constant which depends only on Ω) the problem (46) has a unique solution in $H^1(\Omega)$.

Proof. We only have to use Lemma 2 with the frequency $k = i\sigma$ and the impedance $\tilde{\zeta}(k) = -\lambda k$. We check that this impedance satisfies the condition (12) with $K = 0$.

Hence there exists a constant C depending only on Ω such that the problem (46) has a unique solution whenever $\sigma \geq \lambda_m \sigma + \lambda_m C + 1$. ∎

In the remaining, an impedance function λ will be said to be admissible if $\lambda(\mathbf{x}) \geq 0$ $\forall\ \mathbf{x} \in \Gamma$ and if $0 < \lambda_m := \max_{\mathbf{x}\in\Gamma} \lambda(\mathbf{x}) < 1$.

LEMMA 27. *Assume that* $0 < \lambda_m := \max_{\mathbf{x}\in\Gamma} \lambda(\mathbf{x}) < 1$. *Then the operator* $s(\sigma)$ *is negative for*

$$\sigma \geq \sigma_0'' := \frac{\lambda_m C}{1 - {\lambda_m}^2},$$

where C *is the same constant as in Theorem* 26.

Proof. If we set

$$E_a(\mathbf{x}) = \int_{|\hat{\mathbf{y}}|=1} e^{\sigma\, \hat{\mathbf{y}}\cdot\mathbf{x}} a(\hat{\mathbf{y}}) dS(\hat{\mathbf{y}}) \quad \text{and} \quad V_a(\mathbf{x}) = \int_{|\hat{\mathbf{y}}|=1} v(\mathbf{x}, \hat{\mathbf{y}}; \sigma)\, a(\hat{\mathbf{y}}) dS(\hat{\mathbf{y}}),$$

then one can write

$$(s(\sigma)a, a) = \frac{\sigma^{\frac{N-3}{2}}}{2\,(2\pi)^{\frac{N-1}{2}}} \left[-\int_{\Omega^{\text{int}}} p_\sigma(E_a, E_a) - \int_\Omega p_\sigma(V_a, V_a) - \int_\Gamma \lambda\sigma \left({E_a}^2 - {V_a}^2 \right) d\gamma \right].$$

The only positive term in the right-hand side of above equation is $\int_\Gamma \lambda\sigma {V_a}^2\, d\gamma$. Using (15) with $\mathcal{D} = \Omega$ and $\epsilon = \frac{1}{\lambda_m \sigma}$, we have

$$\lambda_m \sigma \int_\Gamma {V_a}^2\, d\gamma \leq \int_\Omega |\nabla V_a|^2 + \lambda_m \sigma (C + \lambda_m \sigma) \int_\Omega {V_a}^2.$$

Therefore for $\sigma \geq \sigma_0''$, we have $\sigma^2 \geq \lambda_m \sigma (C + \lambda_m \sigma)$, which proves that

$$(s(\sigma)a, a) \leq \frac{\sigma^{\frac{N-3}{2}}}{2\,(2\pi)^{\frac{N-1}{2}}} \left[-\int_{\Omega^{\text{int}}} p_\sigma(E_a, E_a) - \int_\Gamma \lambda\sigma {E_a}^2\, d\gamma \right] \leq 0. \quad ∎$$

We set $\sigma_0 := \max(\sigma_0', \sigma_0'')$. For $\sigma \geq \sigma_0$, the above theorem shows that the eigenvalues of $s(\sigma)$ are all negative. But when $\sigma < \sigma_0$, some eigenvalues may be positive. More precisely, Beale showed in [2] that the number of positive eigenvalues counted with multiplicities is finite. In the same way, most of the results of [2] are also valid in our case of interest.

The kernel $s(\hat{\mathbf{x}}, \hat{\mathbf{y}}; \sigma)$ is square integrable. Thus $s(\sigma)$ is an Hilbert–Schmidt operator. $s(\sigma)$ is then compact, which implies that the eigenvalues of $s(\sigma)$ are bounded and that zero is the only possible cluster point.

As for Theorem 3.7 in [2], the next theorem shows that $s(\sigma)$ is an increasing function of the interior domain.

THEOREM 28. *Let us introduce two bounded domains* Ω_1^{int} *and* Ω_2^{int} *such that* $\Omega_1^{\text{int}} \subset \Omega_2^{\text{int}}$. *The associated admissible impedances are respectively denoted by* λ_1 *and* λ_2. *We set* $s_i(\sigma)$ *the transmission operator with respect to* Ω^{int}. *Then for* $\sigma \geq \sigma_0$

$$s_2(\sigma) \leq s_1(\sigma) \leq 0.$$

Proof. For $a \in L^2(S_1)$, we set

$$E(\mathbf{x}) = \int_{|\hat{\mathbf{y}}|=1} e^{\sigma\, \hat{\mathbf{y}}\cdot\mathbf{x}} a(\hat{\mathbf{y}}) dS(\hat{\mathbf{y}}), \qquad V_i(\mathbf{x}) = \int_{|\hat{\mathbf{y}}|=1} v_i(\mathbf{x}, \hat{\mathbf{y}}; \sigma)\, a(\hat{\mathbf{y}}) dS(\hat{\mathbf{y}}).$$

We set $\Omega_j = \mathbb{R}^N \backslash \overline{\Omega_i^{(j)}}$. Then

$$\begin{aligned}
&2\,(2\pi)^{\frac{N-1}{2}}\,\sigma^{\frac{3-N}{2}}\,[(s_1(\sigma)a,a)-(s_2(\sigma)a,a)]\\
&=\int_{\Omega_1\cap\Omega_2^{\mathrm{int}}}(p_\sigma(E,E)-p_\sigma(V_1,V_1))+\int_{\Omega_2}(p_\sigma(V_2,V_2)-p_\sigma(V_1,V_1))\\
&\quad-\int_{\Gamma_1}\lambda_1\sigma\left(E^2-{V_1}^2\right)\,d\gamma+\int_{\Gamma_2}\lambda_2\sigma\left(E^2-{V_2}^2\right)\,d\gamma\\
&=\int_{\Omega_1\cap\Omega_2^{\mathrm{int}}}p_\sigma(E-V_1,E-V_1)+\int_{\Omega_2}p_\sigma(V_2-V_1,V_2-V_1)\\
&\quad+2\int_{\Omega_1\cap\Omega_2^{\mathrm{int}}}p_\sigma(E-V_1,V_1)+2\int_{\Omega_2}p_\sigma(V_2-V_1,V_1)\\
&\quad-\int_{\Gamma_1}\lambda_1\sigma\left(E^2-{V_1}^2\right)\,d\gamma+\int_{\Gamma_2}\lambda_2\sigma\left(E^2-{V_2}^2\right)\,d\gamma.
\end{aligned}$$

Using Green's formula, we have that

$$\begin{aligned}
0=\int_{\Omega_1\cap\Omega_2^{\mathrm{int}}}L_\sigma(E-V_1)\,V_1&=\int_{\Omega_1\cap\Omega_2^{\mathrm{int}}}p_\sigma(E-V_1,V_1)\\
&\quad-\int_{\Gamma_1}\lambda_1\sigma\,(E-V_1)\,V_1\,d\gamma-\int_{\Gamma_2}\frac{\partial(E-V_1)}{\partial\mathbf{n}}V_1\,d\gamma
\end{aligned}$$

and

$$0=\int_{\Omega_2}L_\sigma(V_2-V_1)\,V_1=\int_{\Omega_2}p_\sigma(V_2-V_1,V_1)+\int_{\Gamma_2}\frac{\partial(V_2-V_1)}{\partial\mathbf{n}}V_1\,d\gamma.$$

Thus

$$\begin{aligned}
&\int_{\Omega_1\cap\Omega_2^{\mathrm{int}}}p_\sigma(E-V_1,V_1)+\int_{\Omega_2}p_\sigma(V_2-V_1,V_1)\\
&\qquad=\int_{\Gamma_1}\lambda_1\sigma\,(E-V_1)\,V_1\,d\gamma-\int_{\Gamma_2}\frac{\partial(V_2-E)}{\partial\mathbf{n}}V_1\,d\gamma\\
&\qquad=\int_{\Gamma_1}\lambda_1\sigma\,(E-V_1)\,V_1\,d\gamma+\int_{\Gamma_2}\lambda_2\sigma\,(V_2-E)\,V_1\,d\gamma.
\end{aligned}$$

Hence

$$\begin{aligned}
2\,(2\pi)^{\frac{N-1}{2}}\,\sigma^{\frac{3-N}{2}}\,[(s_1(\sigma)a,a)-(s_2(\sigma)a,a)]&=\int_{\Omega_1\cap\Omega_2^{\mathrm{int}}}p_\sigma(E-V_1,E-V_1)\\
&\quad+\int_{\Omega_2}p_\sigma(V_2-V_1,V_2-V_1)-\int_{\Gamma_1}\lambda_1\sigma\,(E-V_1)^2\,d\gamma\\
&\quad+\int_{\Gamma_2}\lambda_2\sigma\,(E-V_1)^2\,d\gamma-\int_{\Gamma_2}\lambda_2\sigma\,(V_1-V_2)^2\,d\gamma.
\end{aligned}$$

Only two terms are nonpositive in the right-hand side of this equation. By (15) with $\mathcal{D}=\Omega_1\cap\Omega_2^{\mathrm{int}}$ and $\epsilon=(\lambda_1)_m\,\sigma$, we have

$$-(\lambda_1)_m\,\sigma\int_{\Gamma_1}(E-V_1)^2\,d\gamma\geq(\lambda_1)_m\,\sigma\int_{\Gamma_2}(E-V_1)^2\,d\gamma-\int_{\Omega_1\cap\Omega_2^{\mathrm{int}}}|\nabla(E-V_1)|^2$$

$$-(\lambda_1)_m\,\sigma\,(C+(\lambda_1)_m\,\sigma)\int_{\Omega_1\cap\Omega_2^{\rm int}}|E-V_1|^2$$
$$\geq(\lambda_1)_m\,\sigma\int_{\Gamma_2}(E-V_1)^2\;d\gamma-\int_{\Omega_1\cap\Omega_2^{\rm int}}p_\sigma(E-V_1,E-V_1)$$

since $(\lambda_1)_m<1$ and $\sigma\geq\sigma_0$. Similarly, one can show that

$$-(\lambda_2)_m\,\sigma\int_{\Gamma_2}(V_1-V_2)^2\;d\gamma\geq-\int_{\Omega_2}p_\sigma(V_1-V_2,V_1-V_2)\,.$$

Therefore,

$$(s_1(\sigma)a,a)\geq(s_2(\sigma)a,a)\,.\qquad\square$$

As in [2, Corollary 3.8], we have the following corollary.

COROLLARY 29. *Suppose that in the above theorem* $\Omega_2^{\rm int}=\Omega^{\rm int}$ *is star-like with respect to the origin, and* $\Omega_1^{\rm int}=t\Omega^{\rm int}$, $0<t<1$. *We assume that* $\lambda_2(\mathbf{x})=\lambda(\mathbf{x})$ *and* $\lambda_1(\mathbf{x})=\frac{1}{t}\lambda\big(\frac{\mathbf{x}}{t}\big)$, $\mathbf{x}\in\Gamma$. *Then the number* σ_0 *in Theorem* 28 *can be chosen independent of* t.

Following [2, Theorem 3.9], we also have the following theorem.

THEOREM 30. *If* $\Omega^{\rm int}$ *is star-like, then* $\sigma^{\frac{N-1}{2}}s(\sigma)$ *is a decreasing function of* σ, *for* $\sigma\geq\sigma_0$.

We do not give a proof of this theorem since the proof done in [2] for the Robin boundary condition can clearly be extended to our case.

We turn now to study the eigenvalues of the scattering matrix (see (45)). Since the operator $s(\sigma)$ is compact, so is $K(\sigma):=-\big(\frac{-\sigma}{2\pi}\big)^{\frac{N-1}{2}}s(\sigma)W$. Therefore the eigenvalues have no cluster point, except possibly zero. In each compact set that does not include zero, there are at most a finite number of eigenvalues of $K(\sigma)$. Moreover, since $s(\hat{\mathbf{x}},\hat{\mathbf{y}};\sigma)$ is real, the eigenvalues of $s(\sigma)$ are real. Hence the eigenvalues of $K(\sigma)$ are real if N is odd. In this case, the positive eigenvalues μ_m and the negative ones κ_m of $K(\sigma)$ are labeled by

$$\mu_1\geq\mu_2\geq\cdots>0>\cdots\geq\kappa_2\geq\kappa_1,$$

where $\lim_{m\to\infty}\mu_m=\lim_{m\to\infty}\kappa_m=0$.

Our aim is to find the positive values of σ for which -1 is an eigenvalue of $K(\sigma)$. This problem turns into that of studying the negative eigenvalues $\kappa_m(\sigma)$ and picking out the values of σ such that $\kappa_m(\sigma)=-1$.

From the expression of $s(\hat{\mathbf{x}},\hat{\mathbf{y}};\sigma)$ stated in Lemma 25, it is easy to show that the operator $s(\sigma)$ is bounded and analytic when $\sigma\to0$, if $N>2$. When $N=2$, the factor $\sigma^{\frac{N-3}{2}}$ in the expression of s implies that $s(\sigma)$ tends to infinity when $\sigma\to0$. And for $N>2$, from the expression of $K(\sigma)$ we automatically can infer that $\lim_{\sigma\to0}K(\sigma)=0$, which proves that for any m, $\lim_{\sigma\to0}\mu_m(\sigma)=\lim_{\sigma\to0}\kappa_m(\sigma)=0$. With the same argument, we have $\kappa_m(\sigma)\overset{\sigma\to\infty}{\longrightarrow}-\infty$.

In fact, κ is an eigenvalue of $K(\sigma)$ if $\big(\pm\big(\frac{2\pi}{-\sigma}\big)^{\frac{N-1}{2}}\kappa\big)$ is an eigenvalue of $s(\sigma)$. The sign $\pm$ comes from the operator W. The presence of W in the expression of $K(\sigma)$ complicates the study of the eigenvalues and the eigenvectors of $K(\sigma)$. However, one can show, as in [2, Theorem 4.3], that the results on $s(\sigma)$ can be extended to $K(\sigma)$.

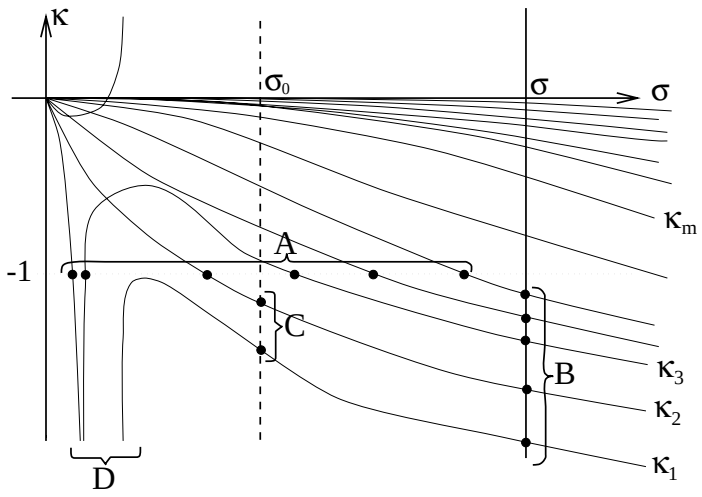

FIG. 4. *The function $\sigma \mapsto \kappa_m(\sigma)$ and its intersection with the line $\kappa = -1$. We have $A = N(0,\sigma;\Gamma,\lambda)$, $B = M(\sigma;\Gamma,\lambda)$, $C = M(\sigma_0;\Gamma,\lambda)$, and $D = N_{\mathrm{p}}(\Gamma,\Lambda)$.*

THEOREM 31. *Assume that $\sigma \geq \sigma_0$.*

- *If $\Omega_1^{\mathrm{int}} \subset \Omega_2^{\mathrm{int}}$ and if we denote by $\kappa_m^{(1)}$ and $\kappa_m^{(2)}$ (respectively, $\mu_m^{(1)}$ and $\mu_m^{(2)}$) the negative eigenvalues (respectively, the positive eigenvalues) with respect to Ω_1^{int} and Ω_2^{int}, then*

$$\kappa_m^{(2)}(\sigma) \leq \kappa_m^{(1)}(\sigma) \leq 0, \qquad \mu_m^{(2)}(\sigma) \geq \mu_m^{(1)}(\sigma) \geq 0.$$

- *$\kappa_m(\sigma)$ is a decreasing function of σ.*

We can also establish another result shown in [2, Theorem 4.4]: if N is even, then there are at most a finite number of zeros of $\mathcal{S}$. The reason for this comes from the relation

$$K(\sigma) = -i^{N-1}\Big(\frac{\sigma}{2\pi}\Big)^{\frac{N-1}{2}} s(\sigma)W.$$

We know by Lemma 27 that all the eigenvalues of $s(\sigma)$ are negative when $\sigma \geq \sigma_0$. In this case, the eigenvalues of $K(\sigma)$ are purely imaginary and thus cannot be equal to -1. On the other hand, if N is odd, there is an infinite sequence of zeros for each $\sigma > 0$. From now on, we assume that N is odd.

Let us denote by $N(\sigma_1,\sigma_2;\Gamma,\lambda)$ the number of zeros of the scattering matrix $\mathcal{S}(i\sigma,-i\lambda\sigma)$ when σ describes the slab $[\sigma_1,\sigma_2]$ (see Figure 4). Thanks to Theorem 31, it is quite clear what is going on for $\sigma \geq \sigma_0$: since $\kappa_m(\sigma)$ is decreasing and tends to minus infinity as $\sigma \to \infty$, then the equation $\kappa_m(\sigma) = -1$ has at most one solution $\sigma \geq \sigma_0$. Moreover, if $\kappa_m(\sigma_0) \geq -1$, then the equation $\kappa_m(\sigma) = -1$ has exactly one solution $\sigma \geq \sigma_0$. But in $[0,\sigma_0]$, $\kappa_m(\sigma)$ is not monotone and even can have some poles.

First let us show that the overall number of poles $\forall\ \kappa_m$ is bounded. $i\sigma$ is a pole of $\mathcal{S}(i\sigma,-i\lambda\sigma)$ if and only if σ is a pole of an eigenvalue κ_m. The set of all the poles of $\mathcal{S}(i\sigma,-i\lambda\sigma)$ has no cluster point, except at infinity. Furthermore, the multiplicity of each pole is finite. For any compact set of $\mathbb{C}$, there is at most a finite number of poles of $\mathcal{S}(i\sigma,-i\sigma\lambda)$. Therefore for $\sigma \in [0,\sigma_0]$ there is a finite number of poles and by Theorem 26, there are only a finite number of poles of $\mathcal{S}(i\sigma,-i\sigma\lambda)$ for $\sigma > 0$. The

finite number of poles for $\sigma > 0$ is denoted by $N_{\mathrm{p}}(\Gamma, \lambda)$. Each pole of the scattering matrix corresponds to a pole of one eigenvalue $\kappa_m(\sigma)$. We conclude that there exists an integer m_0 such that κ_m has no pole for $m \geq m_0$.

Using the same argument to the scattering matrix $\mathcal{S}(-i\sigma, -i\sigma\lambda)$ in the lower half plane, we conclude that this operator has only a finite number of poles in any compact set of $\mathbb{C}\backslash\{0\}$, and by Theorem 24 that $\mathcal{S}(i\sigma, -i\sigma\lambda)$ has a finite number of zeros in any finite compact set of $\sigma > 0$. To show that there is no cluster point at zero, we note that

$$\|K(\sigma)\| \leq \max(|\kappa_1(\sigma)|, \mu_1(\sigma)) \overset{\sigma\to 0}{\longrightarrow} 0.$$

Hence $\|K(\sigma)\| < 1$ in a compact set surrounding zero, which proves that $\mathcal{S}(i\sigma, -i\sigma\lambda)$ is invertible in this set. Therefore, zero cannot be a cluster point, and in the interval $[\sigma_1, \sigma_2]$ the number of zeros of $\mathcal{S}(i\sigma, -i\sigma\lambda)$ is finite for any $\sigma_1 \geq 0$. This number is clearly $N(\sigma_1, \sigma_2; \Gamma, \lambda)$.

LEMMA 32. *Assume that Ω^{int} is star-shaped. If $M(\sigma; \Gamma, \lambda)$ denotes the number of eigenvalues such that $\kappa_m(\sigma) \leq -1$ (see Figure 4), then for $\sigma > \sigma_0$*

$$N(\sigma_0, \sigma; \Gamma, \lambda) = M(\sigma; \Gamma, \lambda) - M(\sigma_0; \Gamma, \lambda)\,.$$

Moreover,

$$N(0, \sigma; \Gamma, \lambda) \geq M(\sigma; \Gamma, \lambda) - N_{\mathrm{p}}(\Gamma, \lambda)\,.$$

Proof. Since $\kappa_m(\sigma)$ is a decreasing function of σ for each m, we conclude that there are exactly $M(\sigma; \Gamma, \lambda) - M(\sigma_0; \Gamma, \lambda)$ eigenvalues κ_m such that $\kappa_m(\sigma_0) > -1$ and $\kappa_m(\sigma) \leq -1$. From Theorem 31, one can infer that each of these eigenvalues crosses the line -1 exactly once in $[\sigma_0, \sigma]$. The other eigenvalues cannot cross the straight line -1 in $[\sigma_0, \sigma]$, which proves the first equality.

For the second inequality, since $\kappa_m(0) = 0$ for any m, we notice that the $M(\sigma; \Gamma, \lambda)$ eigenvalues that are lower than -1 at the frequency σ must cross the line -1 at least once in $[0, \sigma]$ if and only if $\kappa_m(\sigma)$ is continuous in $[0, \sigma]$. The function $\kappa_m(\sigma)$ is continuous in $[0, \sigma]$ if there is no pole in $[0, \sigma]$. Since at most $N_{\mathrm{p}}(\Gamma, \lambda)$ eigenvalues have one pole or more, the theorem is proved. ∎

COROLLARY 33. *If $\Omega_1^{\mathrm{int}} \subset \Omega_2^{\mathrm{int}}$ with Ω_1^{int} star-shaped, and λ_1, λ_2 are two admissible impedances defined on Γ_1, Γ_2, respectively, then we have for $\sigma > \sigma_0$*

$$N(0, \sigma; \Gamma_2, \lambda_2) \geq N(\sigma_0, \sigma; \Gamma_1, \lambda_1) - N_{\mathrm{p}}(\Gamma_2, \lambda_2)\,.$$

Proof. From Lemma 32, we have

$$M := M(\sigma; \Gamma_1, \lambda_1) \geq N(\sigma_0, \sigma; \Gamma_1, \lambda_1)\,.$$

There are exactly M eigenvalues of Ω_1^{int} lower than -1 at the frequency σ, i.e.,

$$\kappa_1^{(1)}(\sigma) \leq -1, \ldots, \qquad \kappa_M^{(1)}(\sigma) \leq -1.$$

Thus by Theorem 31, $\kappa_1^{(2)}(\sigma) \leq -1$, …, $\kappa_M^{(2)}(\sigma) \leq -1$, which means that

$$M(\sigma; \Gamma_2, \lambda_2) \geq M.$$

Finally, by Lemma 32,

$$\begin{aligned} N(0, \sigma; \Gamma_2, \lambda_2) &\geq M(\sigma; \Gamma_2, \lambda_2) - N_{\mathrm{p}}(\Gamma_2, \lambda_2) \\ &\geq N(\sigma_0, \sigma; \Gamma_1, \lambda_1) - N_{\mathrm{p}}(\Gamma_2, \lambda_2)\,. \end{aligned}$$ ∎

THEOREM 34. *Assume that there exist two balls B_{R_1} and B_{R_2} of radii R_1 and R_2, respectively, such that $\overline{B}_{R_1} \subset \Omega^{\text{int}}$, $\overline{\Omega}_i \subset B_{R_2}$. Assume furthermore that Ω^{int} is star-shaped. Let λ, λ_1, and λ_2 be admissible impedances on Γ, S_{R_1}, and S_{R_2}, respectively. Then for $\sigma > \sigma_0$*

$$\begin{aligned} N(0,\sigma;\Gamma,\lambda) &\geq M(\sigma;S_{R_1},\lambda_1) - M(\sigma_0;S_{R_1},\lambda_1) - N_{\text{p}}(\Gamma,\lambda)\,, \\ N(0,\sigma;\Gamma,\lambda) &\leq M(\sigma;S_{R_2},\lambda_2) - M(\sigma_0;S_{R_2},\lambda_2) + N(0,\sigma_0;S_{R_2},\lambda_2) \\ &\quad + N_{\text{p}}(S_{R_2},\lambda_2) + N(0,\sigma_0;\Gamma,\lambda)\,. \end{aligned}$$

Proof. From Corollary 33, we have that

$$N(0,\sigma;\Gamma,\lambda) \geq N(\sigma_0,\sigma;S_{R_1},\lambda_1) - N_{\text{p}}(\Gamma,\lambda)\,.$$

Then by Lemma 32, the first inequality is proved.

Corollary 33 now enables us to write

$$N(0,\sigma;S_{R_2},\lambda_2) \geq N(\sigma_0,\sigma;\Gamma,\lambda) - N_{\text{p}}(S_{R_2},\lambda_2)\,.$$

Hence one may infer that

$$\begin{aligned} N(0,\sigma;\Gamma,\lambda) &= N(0,\sigma_0;\Gamma,\lambda) + N(\sigma_0,\sigma;\Gamma,\lambda) \\ &\leq N(0,\sigma;S_{R_2},\lambda_2) + N_{\text{p}}(S_{R_2},\lambda_2) + N(0,\sigma_0;\Gamma,\lambda)\,. \end{aligned}$$

By Lemma 32, we have

$$\begin{aligned} N(0,\sigma;S_{R_2},\lambda_2) &= N(0,\sigma_0;S_{R_2},\lambda_2) + N(\sigma_0,\sigma;S_{R_2},\lambda_2) \\ &= M(\sigma;S_{R_2},\lambda_2) - M(\sigma_0;S_{R_2},\lambda_2) + N(0,\sigma_0;S_{R_2},\lambda_2)\,. \end{aligned}$$

This, combined with previous relation, proves the second inequality of the theorem. ∎

In the right-hand side of the two inequalities of Theorem 34, only the first term depends on σ. If N is odd, these two terms tend to infinity as $\sigma \to \infty$, and hence gives the leading behavior of $N(0,\sigma;\Gamma,\lambda)$ for σ large. These two factors, namely $M(\sigma;S_{R_1},\lambda_1)$ and $M(\sigma;S_{R_2},\lambda_2)$ can be computed as in [2, section 5]. In fact, the asymptotic number of zeros on the imaginary axis for the case of the sphere is independent of the boundary condition. More precisely, the number of zeros on the imaginary axis between 0 and $i\sigma$ for the case of a sphere a radius R is asymptotically equal to $\frac{1}{(N-1)!}\left(\frac{R}{\gamma_0}\right)^{N-1}$, where $\gamma_0 \approx 0.6627$ [2]. Noting that $N_{\text{I}}(\sigma) = N(0,\sigma;\Gamma,\lambda)$, we can infer the following theorem.

THEOREM 35. *Assume N is odd. Assume further that $\overline{B}_{R_1} \subset \Omega^{\text{int}}$, $\overline{\Omega}_i \subset B_{R_2}$ and that Ω^{int} is star-shaped. Then*

$$\lim_{\sigma\to\infty} \frac{N_{\text{I}}(\sigma)}{\sigma^{N-1}} \geq \frac{1}{(N-1)!}\left(\frac{R_1}{\gamma_0}\right)^{N-1},$$

$$\lim_{\sigma\to\infty} \frac{N_{\text{I}}(\sigma)}{\sigma^{N-1}} \leq \frac{1}{(N-1)!}\left(\frac{R_2}{\gamma_0}\right)^{N-1},$$

where γ_0 is the unique solution of the equation

$$e^{\sqrt{1+\gamma_0{}^2}}\,\frac{\sqrt{1+\gamma_0{}^2}-1}{\gamma_0} = 1.$$

5. Conclusion. The motivation of this paper was to answer the following question: What can we infer of the obstacle from the location of the resonant frequencies? It is well known that the asymptotic repartition of eigenvalues of the interior acoustic problem gives the volume and the perimeter of the obstacle. This leads us to consider counting functions of the resonant frequencies for the exterior of an obstacle. It is not easy at all to link the global counting function with some geometrical quantities on the obstacle. However, a special study can be performed on the purely imaginary axis. There are infinitely many resonant frequencies on this axis. Let $N_{\mathrm{I}}(\sigma)$ be the number of purely imaginary poles whose modulus is lower than σ. We set

$$R_\Gamma = \gamma_0 \left[(N-1)! \lim_{\sigma \to \infty} \frac{N_{\mathrm{I}}(\sigma)}{\sigma^{N-1}} \right]^{\frac{1}{N-1}}.$$

Then for the acoustic waves with the impedance boundary condition (in odd space dimensions), we have

$$R_1 \leq R_\Gamma \leq R_2,$$

where R_1 is the radius of the largest sphere contained in the obstacle and R_2 is the radius of the smallest sphere containing the obstacle. Without further a priori information on the obstacle Ω^{int}, this relation is not of great interest for the inverse problem: it simply states that the boundary of the obstacle is crossing a sphere of radius R_Γ. This does not give a very precise idea of the size of the obstacle. For the inverse problem, it would be more interesting to have an upper bound on R_2 or a lower bound on R_1.

However, we are sometimes looking for an obstacle belonging to a special class of targets. For instance, for radar identification, one can look for an airplane. Since the shape of an airplane is always roughly the same, we can figure out that R_Γ gives a good idea of the size of the airplane. It is in this sense that the last inequality has to be used.

Acknowledgment. The author is grateful to David L. Colton for suggesting this subject and for many useful discussions.

NONUNIQUENESS FOR SECOND-ORDER ELLIPTIC EQUATIONS WITH MEASURABLE COEFFICIENTS*

MIKHAIL V. SAFONOV†

Abstract. We consider the Dirichlet problem for uniformly elliptic operators $L = \sum a_{ij} D_{ij}$ with measurable coefficients a_{ij} in the unit ball $B_1 \subset \boldsymbol{R}^d$. A recent sensational result of Nikolai Nadirashvili states that there is no uniqueness of "weak" solutions to this problem if $d \geq 3$. He constructed two sequences of linear elliptic operators with smooth coefficients $\{a_{ij}^{0,k}\}$ and $\{a_{ij}^{1,k}\}$, which have the same ellipticity constant $\nu > 0$ and converge to the same functions a_{ij} almost everywhere (a.e.) in B_1 as $k \to \infty$, while the corresponding sequences of solutions $\{u^{0,k}\}$ and $\{u^{1,k}\}$ converge to two different functions; i.e., the Dirichlet problem has at least two "weak" solutions. In the present paper, we popularize and slightly generalize Nadirashvili's result: for an arbitrary constant $\Lambda > 0$, we construct two sequences of linear elliptic operators with the same ellipticity constant $\nu = \nu(\Lambda) > 0$ and the additional restriction $|a_{ij}^{0,k} - a_{ij}^{1,k}| \leq \Lambda$ for all i, j, k, which define two different "weak" solutions to the Dirichlet problem [N. S. Nadirashvili, *Ann. Scuola Norm. Sup. Pisa Cl. Sci.* (4), 24 (1997), pp. 537–550].

1. Introduction.

Let Ω be a bounded domain in $\boldsymbol{R}^d$, $d \geq 1$, with the boundary $\partial\Omega$ of class C^2. Let $a = (a_{ij}(x))$ be a real, symmetric, measurable $d \times d$ matrix function on Ω, satisfying the *uniform ellipticity condition*

$$\nu|\xi|^2 \leq \sum_{i,j=1}^{d} a_{ij}\xi_i\xi_j \leq \nu^{-1}|\xi|^2 \quad \text{for all} \quad \xi \in \boldsymbol{R}^d, \tag{1.1}$$

where $\nu = \text{const} \in (0, 1]$. We consider the *Dirichlet problem*

$$Lu = \sum_{i,j=1}^{d} a_{ij} D_{ij} u = 0 \quad \text{in} \quad \Omega, \qquad u = g \quad \text{on} \quad \partial\Omega, \tag{1.2}$$

where $D_{ij}u = \partial^2 u/\partial x_i \partial x_j$, and g is a given continuous function. If $a_{ij} \in C(\overline{\Omega})$, then this problem has a unique strong solution, which belongs to the Sobolev space $W^{2,p}(\Omega')$ for any subdomain $\Omega' \subset \overline{\Omega'} \subset \Omega$ and $1 < p < \infty$ (see [15, section 9.6]). For discontinuous a_{ij}, there is no definition of solution to the problem (1.2), which preserves simultaneously all the basic properties of strong solutions, such as the existence, uniqueness, maximum principle, etc. For arbitrary approximation a_{ij} by smooth functions a_{ij}^k, $k = 1, 2, \ldots$, the solutions u^k to the corresponding Dirichlet problems are uniformly bounded and equicontinuous on $\overline{\Omega}$ (see [23], [27], and also [15, section 9.8]). Therefore, there exists a subsequence (we call it $\{u^k\}$ again) converging to some function $u \in C(\overline{\Omega})$. In the following definition, this function is called

†School of Mathematics, University of Minnesota, 127 Vincent Hall, 206 Church Street, Minneapolis, MN 55455 (safonov@math.umn.edu).

a weak solution to the problem (1.2), and so our previous argument shows that the weak solutions always exist.

DEFINITION 1.1. *A function* $u = u(x) \in C(\overline{\Omega})$ *is a* weak solution *to the problem* (1.2) *if there exists a sequence of real symmetric matrices of coefficients* $\{a^k\} = \{(a^k_{ij}(x))\}$, $k = 1, 2, \dots$, *such that*

(i) $a^k_{ij} \in C^\infty(\overline{\Omega})$ *and satisfy* (1.1) *for each* k *with the same constant* $\nu \in (0, 1]$;

(ii) $a^k_{ij} \to a_{ij}$ *a.e. in* Ω *as* $k \to \infty$;

(iii) *the (classical) solutions* $\{u^k\}$ *to the problems*

$$L^k u^k = \sum_{i,j=1}^{d} a^k_{ij} D_{ij} u^k = 0 \quad \text{in} \quad \Omega, \qquad u^k = g \quad \text{on} \quad \partial\Omega \tag{1.3}$$

converge in $C(\overline{\Omega})$ *to* u:

$$\lim_{k\to\infty} \sup_{\Omega} |u^k - u| = 0. \tag{1.4}$$

The properties of classical or strong solutions, which do not depend on the smoothness of coefficients, such as the Hölder estimates, the Harnack inequality, and different forms of the maximum principle, are automatically extended to the weak solutions. As regards the uniqueness of weak solutions, the situation is different. For classical solutions, the uniqueness follows from the maximum principle, because the difference of two solutions to a linear homogeneous equation $Lu = 0$ satisfies the same equation. This reasoning does not work for weak solutions because different weak solutions may be obtained by means of different sequences $\{a^k\}$. Many mathematicians tried to solve this so-called weak uniqueness problem for discontinuous a_{ij} (see [3], [4], [5], [9], [10], [11], [22], [29], and references therein), but positive results were obtained only under additional restrictions on a_{ij}. We will discuss some of these results in section 2 below.

A recent sensational result of Nikolai Nadirashvili [25] states that the weak uniqueness may fail if $d \geq 3$. He constructed two sequences of operators with smooth coefficients $\{a^{0,k}_{ij}\}$ and $\{a^{1,k}_{ij}\}$, which satisfy the ellipticity condition (1.1) with the same constant $\nu \in (0, 1]$ and converge to the same functions a_{ij} a.e. in the unit ball $B_1 = \{|x| < 1\} \subset \boldsymbol{R}^3$ as $k \to \infty$, while the corresponding sequences of solutions converge to two different functions. In other words, there are at least two different weak solutions to the problem (1.2) in $\Omega = B_1 \subset \boldsymbol{R}^3$. In this paper, we show that the weak uniqueness still fails under the additional restriction

$$\sup_{\Omega} |a^{0,k}_{ij} - a^{1,k}_{ij}| \leq \Lambda \qquad \text{for all} \quad i, j, k \tag{1.5}$$

with a constant $\Lambda > 0$ which can be made arbitrarily small. Namely, we have the following result.

THEOREM 1.2. *For any constant* $\Lambda > 0$, *there exist two sequences* $\{a^{0,k}\} = \{(a^{0,k}_{ij})\}$ *and* $\{a^{1,k}\} = \{(a^{1,k}_{ij})\}$ *of real, symmetric,* 3×3 *matrix functions on* $B_1 \subset \boldsymbol{R}^3$, *and a function* $g \in C^\infty(\overline{B_1})$, *such that*

(i) *for each* k, *functions* $\{a^{0,k}_{ij}\}$, $\{a^{1,k}_{ij}\} \subset C^\infty(\overline{B_1})$, *satisfy* (1.5) *with the given constant* Λ, *and* (1.1) *with a constant* $\nu = \nu(\Lambda) \in (0, 1]$;

(ii) $a^{0,k}_{ij}, a^{1,k}_{ij}$ *converge to the same functions* a_{ij} *a.e. in* B_1 *as* $k \to \infty$;

(iii) *for* $m = 0$ *and* 1, *the sequences* $u^{m,k}$ *of solutions to the problems*

$$L^{m,k}u^{m,k} = \sum_{i,j=1}^{3} a_{ij}^{m,k} D_{ij} u^{m,k} = 0 \quad \text{in} \quad B_1, \ u^{m,k} = g \quad \text{on} \quad \partial B_1 \tag{1.6}$$

converge to two different functions u^0 *and* u^1, *respectively:*

$$\lim_{k\to\infty} \sup_{B_1} |u^{m,k} - u^m| = 0, \qquad u^0(0) \neq u^1(0). \tag{1.7}$$

By Definition 1.1, these limit functions u^0 and u^1 are two different weak solutions to the problem (1.2) for $\Omega = B_1$.

Proof. The proof of this theorem is given below in section 4. As in the Nadirashvili paper [25], we use some special "piecewise periodic" approximations of a_{ij}, though the technical details here are different from those in [25].

Theorem 1.2 is easily extended to higher dimensions $d > 3$, with minimal modifications in the proof.

Remark 1.1. The definition of weak solution here and in [22], [29] is equivalent to the definition of "good" solution in [9], [10], [11], [25]. Jensen [16] (see also [8]) proved that the concept of weak solution to (1.2) coincides with that of viscosity solution. Our preference is motivated by the following reasons. By Corollary 2.2 below, any strong solution $u \in W^{2,d}(\Omega)$ of (1.2) is a weak solution, but not vice versa. Moreover, the weak uniqueness problem of (1.2) with arbitrary g is equivalent to the weak uniqueness problem for corresponding diffusion processes (see [19], [21]). This means Nadirashvili's example automatically gives the negative answer to the latter problem.

The following *martingale problem* is also equivalent to the weak uniqueness problem for (1.2) with arbitrary $g \in C(\boldsymbol{R}^d)$ (see [19], [21], and a discussion in [9]). Let an operator $L = \sum a_{ij} D_{ij}$ with coefficients a_{ij} satisfying (1.1) be defined on the whole space $\boldsymbol{R}^d$. Using a "selection" procedure initiated by Krylov [20], Stroock and Varadhan [30] proved that for each $x \in \boldsymbol{R}^d$, there exists a probability measure P_x on $C([0,\infty), \boldsymbol{R}^d) = \{\xi_t, t \geq 0\}$, such that

(i) $P_x(\xi_0 = x) = 1$,

(ii) $\varphi(\xi_t) - \varphi(\xi_0) - \int_0^t L\varphi(\xi_s)\, ds$ is a P_x-local martingale for all $\varphi \in C^2(\boldsymbol{R}^d)$.

They also showed that the solution to the martingale problem is unique if a_{ij} are continuous or $d \leq 2$ (see [31] and [30, Chapter 7]). It remained unknown if the solution was unique for $d \geq 3$ and discontinuous a_{ij}. Nadirashvili's result gives a negative answer to this question as well: the martingale problem may have different solutions.

In section 2, we discuss different conditions on the coefficients, which provide the uniqueness of weak solutions. Section 3 contains some preparatory material. Finally, section 4 is devoted to the proof of Theorem 1.2.

2. Uniqueness of weak solutions. Many positive results on the weak uniqueness are based on the following Aleksandrov–Bakelman–Pucci estimate for functions in the Sobolev space $W^{2,d}(\Omega)$. Having in mind the imbedding $W^{2,d}(\Omega) \subset C(\overline{\Omega})$, we always consider only such "representatives" of functions in $W^{2,d}(\Omega)$ which are continuous on $\overline{\Omega}$.

THEOREM 2.1. *Let* $a = (a_{ij}(x))$ *be a real, symmetric, measurable* $d \times d$ *matrix function on a bounded domain* $\Omega \subset \boldsymbol{R}^d$, $d \geq 2$. *Then for any function* $u \in W^{2,d}(\Omega)$,

we have

$$\sup_{\Omega} |u| \le \sup_{\partial\Omega} |u| + N\|Lu\|_{\mathcal{L}^d(\Omega)}, \tag{2.1}$$

where $L = \sum a_{ij} D_{ij}$*, and the constant* N *depends only on* d*,* ν*, and* $\operatorname{diam}\Omega$*.*

Proof. The proof is contained in [1] (see also [15, Chapter 9]).

COROLLARY 2.2. *If the problem* (1.2) *has a strong solution* $u \in W^{2,d}(\Omega)$*, then* u *is also a unique weak solution to this problem.*

Proof. Let $a^k = (a^k_{ij}(x))$, $k = 1, 2, \dots$, be real, symmetric, smooth matrix functions, such that $a^k_{ij} \to a_{ij}$ a.e. in Ω as $k \to \infty$, and let $\{u^k\}$ be a sequence of solutions to the problems (1.3). Then

$$L^k(u^k - u) = -L^k u = (L - L^k)u \quad \text{in } \Omega, \qquad u^k - u = 0 \text{ on } \partial\Omega.$$

By Theorem 2.1,

$$\begin{aligned} \sup_{\Omega} |u^k - u| &\le N \cdot \|(L - L^k)u\|_{\mathcal{L}^d(\Omega)} \\ &= N \left(\int_\Omega \left| \sum_{i,j} (a_{ij} - a^k_{ij}) D_{ij} u \right|^d dx \right)^{1/d}, \end{aligned} \tag{2.2}$$

with a constant N independent on k. Since the integral function converges to 0 a.e. in Ω as $k \to \infty$ and is dominated by $\text{const} \cdot \sum |D_{ij}u|^d \in \mathcal{L}^1(\Omega)$, we have (1.4). This means u is the only weak solution to the problem (1.2). □

Using suitable approximations of $g \in C(\overline{\Omega})$ by smooth functions, we can reduce the weak uniqueness problem to the case $g \in C^\infty(\overline{\Omega})$. Further, we set $v = u - g$, so that the problem (1.2) is transformed to the equivalent one:

$$Lv = \sum_{i,j} a_{ij} D_{ij} v = f \quad \text{in} \quad \Omega, \qquad v = 0 \quad \text{on} \quad \partial\Omega, \tag{2.3}$$

where $f = -Lg \in \mathcal{L}^\infty(\Omega)$. The problem (2.3) has a unique strong solution in $W^{2,d}(\Omega)$, even for $f \in \mathcal{L}^d(\Omega)$, if the estimate

$$\max_{i,j} \|D_{ij} v\|_{\mathcal{L}^d(\Omega)} \le N \|Lv\|_{\mathcal{L}^d(\Omega)} \quad \text{for} \quad v \in C^2(\overline{\Omega}), \quad v = 0 \quad \text{on} \quad \partial\Omega, \tag{2.4}$$

holds with a constant N independent of v (see [15, Chapter 9]). This is true in the following cases (i), (ii), and (iii).

(i) $a_{ij} \in C(\overline{\Omega})$. By the Calderon–Zygmund inequality (see [15, Chapter 9]), the estimate (2.4) remains true also for norms in $\mathcal{L}^p(\Omega)$, $1 < p < \infty$.

(ii) $d = 2$. The estimate (2.4) is due to S. N. Bernstein when Ω is a ball in $\boldsymbol{R}^2$. It is generalized to bounded domains Ω with $\partial\Omega \in C^2$ (see [24, Chapter 3, section 19]).

(iii) The coefficients a_{ij} are close to some constants a^0_{ij} (cf. [12]):

$$|a_{ij} - a^0_{ij}| \le \varepsilon_0, \tag{2.5}$$

where $\varepsilon_0 = \varepsilon_0(d, \nu)$ is a small positive constant. The estimate (2.4) for $L = \sum a_{ij} D_{ij}$ is obtained by easy perturbation arguments. Indeed, as a particular case of (i), this

estimate holds for $L^0 = \sum a^0_{ij} D_{ij}$; i.e., for arbitrary $v \in C^2(\overline{\Omega})$ satisfying $v = 0$ on $\partial\Omega$, we have

$$M = \sum_{i,j} \|D_{ij} v\| \le N_0 \|L^0 v\|,$$

where $N_0 = N_0(\nu, \Omega)$ and $\|\cdot\|$ is the norm in $\mathcal{L}^d(\Omega)$. Using (2.5), we get

$$\|L^0 v\| \le \|Lv\| + \|(L - L^0)v\| \le \|Lv\| + \varepsilon_0 M,$$

$$M \le N_0 \|L^0 v\| \le N_0 \|Lv\| + N_0 \varepsilon_0 M.$$

For $0 < \varepsilon_0 < 1/N_0$, the last inequality implies (2.4) with $N = (1 - N_0\varepsilon_0)^{-1} N_0$.

Summarizing the above considerations, we obtain the weak uniqueness for the problem (1.2) with arbitrary $g \in C(\overline{\Omega})$ in the cases (i), (ii), and (iii).

Corollary 2.2 does not cover all the cases when the weak uniqueness holds. If the coefficients a_{ij} are discontinuous at a single point, the weak solution to the problem (1.2) may not belong to $W^{2,p}(\Omega)$ if $p > \frac{3}{2}$ (see [28, Remark 8.1]). However, Luis Caffarelli proved that in this case the weak solution is unique. Relying on this result, Cerutti, Escauriaza, and Fabes [9], [10] proved the uniqueness when $a_{ij} \in C(\Omega \setminus E)$, where E is a countable set having at most one cluster point. Further generalizations were made by Krylov [22] for E with countable closure and by Safonov [29] for closed E of small Hausdorff dimension $\alpha = \alpha(d, \nu)$; i.e., $\alpha \to 0$ as $\nu \to 0$. Nevertheless, many special questions remain open, e.g., whether or not the weak uniqueness holds when E is a segment in $\Omega \subset \boldsymbol{R}^d$, $d \ge 3$.

For other related results, see [3], [5], [4], [11]. We only mention a paper by Bass and Pardoux [5], where the weak uniqueness is proved when Ω is the union of a finite number of disjoint polyhedrons and a_{ij} are constants on each of them.

Since the problems (1.2) and (2.3) are equivalent, the weak uniqueness can be treated in terms of properties of the Green function for Ω (see [9], [10], [11], [22]). By this approach, Krylov [22] showed that the weak uniqueness is a local property of coefficients a_{ij}, i.e., it holds for a neighborhood of each point $x_0 \in \Omega$, if and only if it holds for Ω.

Both (1.2) and (2.3) are the particular cases of the problem

$$Lu = \sum_{i,j} a_{ij} D_{ij} u = f \quad \text{in} \quad \Omega, \qquad u = g \quad \text{on} \quad \partial\Omega, \tag{2.6}$$

where $f \in \mathcal{L}^d(\Omega)$, $g \in C(\overline{\Omega})$. The weak uniqueness for (1.2) with arbitrary $g \in C(\overline{\Omega})$ implies the uniqueness for (2.6) in the following sense. Let smooth functions $a^k_{ij} = a^k_{ji}$, f^k, g^k be given for $i, j = 1, 2, \dots, d$; $k = 1, 2, \dots$. Suppose a^k_{ij} satisfy (1.1) for each k, $a^k_{ij} \to a_{ij}$ a.e. in Ω, $f^k \to f$ in $\mathcal{L}^d(\Omega)$, and $g^k \to g$ in $C(\overline{\Omega})$ as $k \to \infty$. Let u^k be a (classical) solution to the problem

$$L^k u^k = \sum_{i,j} a^k_{ij} D_{ij} u^k = f^k \quad \text{in} \quad \Omega, \qquad u^k = g^k \quad \text{on} \quad \partial\Omega. \tag{2.7}$$

Then $u^k \to u$ in $C(\overline{\Omega})$ as $k \to \infty$, where the limit function u does not depend on the choice of a^k_{ij}, f^k, g^k (see [29, section 2]). The weak uniqueness is also preserved after perturbation of L by zero order terms (see [22], [11]). However, this is not true for

approximations of f in $\mathcal{L}^p(\Omega)$ with $p < d$, as the following example shows (cf. [14], [2], [26]). This example also shows that the estimate (2.1) fails for $\mathcal{L}^p$-norms, $p < d$, in place of the $\mathcal{L}^d$-norm.

Example 2.1. Let $d \geq 2$, $0 < p < d$ be fixed. We choose $\alpha = \text{const} \in (0,1)$, such that $(2-\alpha)p < d$, and consider the function $u(x) = 1 - |x|^\alpha$ on $B_1 \subset \boldsymbol{R}^d$. Since $D_{ij}u(x) = O(|x|^{\alpha-2})$, the function u belongs to $W^{2,p}(B_1)$ and satisfies

$$Lu = \sum_{i,j} a_{ij} D_{ij} u = 0 \quad \text{in} \quad B_1, \qquad u = 0 \quad \text{on} \quad \partial B_1, \tag{2.8}$$

where

$$a_{ij} = \delta_{ij} + \beta \frac{x_i x_j}{|x|^2}, \qquad \beta = \frac{d-2+\alpha}{1-\alpha}.$$

Obviously, the only weak solution to (2.8) is identically zero. Although our function $u(x)$ has a singularity at 0, we can approximate it by functions u^ε, $0 < \varepsilon < 1$, such that

$$u^\varepsilon \in C^\infty(\overline{\Omega}), \quad u^\varepsilon = u \quad \text{on} \quad B_1 \setminus B_\varepsilon; \qquad |D_{ij}u^\varepsilon| \leq N\varepsilon^{\alpha-2} \quad \text{on} \quad B_\varepsilon,$$

with a constant N which is independent on ε. Therefore,

$$Lu^\varepsilon = f^\varepsilon \quad \text{in} \quad B_1, \qquad u^\varepsilon = 0 \quad \text{on} \quad \partial B_1,$$

where

$$f^\varepsilon = 0 \quad \text{on} \quad B_1 \setminus B_\varepsilon, \qquad |f^\varepsilon| \leq N\varepsilon^{\alpha-2} \quad \text{on} \quad B_\varepsilon.$$

In particular, $f^\varepsilon \to 0$ in $\mathcal{L}^p(B_1)$, while $u^\varepsilon \to u \neq 0$ in $C(\overline{B_1})$ as $\varepsilon \to 0$.

3. Auxiliary results. In this section, we consider linear elliptic operators $L = \sum a_{ij} D_{ij}$ with the coefficients $a_{ij} \in C^\infty(\boldsymbol{R}^d)$, $d \geq 1$. As usual, we assume that the matrix function $a = (a_{ij}(x))$ is real, symmetric, and satisfies (1.1) with a constant $\nu \in (0,1]$. In addition, suppose a_{ij} are periodic with period 1 in each of the variables. We may treat a_{ij} as functions in $C^\infty(\boldsymbol{T}^d)$, where $\boldsymbol{T}^d$ is the d-dimensional torus. We will identify $\boldsymbol{T}^d$ with $[-\frac{1}{2}, \frac{1}{2})^d \subset \boldsymbol{R}^d$ and the functions on $\boldsymbol{T}^d$ with 1-periodic functions on $\boldsymbol{R}^d$, so that

$$u(x) \equiv u(x+z) \quad \text{on} \quad \boldsymbol{T}^d = \left[\frac{1}{2}, \frac{1}{2}\right)^d \tag{3.1}$$

for some vector z with integer components.

The following theorem is a version of the Fredholm alternative for equations with periodic coefficients.

THEOREM 3.1.

(i) *The equation*

$$Lu = \sum_{i,j} a_{ij} D_{ij} u = f \tag{3.2}$$

with $f \in C^\infty(\boldsymbol{T}^d)$ has a solution in $C^\infty(\boldsymbol{T}^d)$ if and only if

$$(f, \rho) = \int_{\boldsymbol{T}^d} f\rho \, dx = 0 \tag{3.3}$$

for every solution $\rho \in C^\infty(\boldsymbol{T}^d)$ *of the adjoint homogeneous equation*

$$L^*\rho = \sum_{i,j} D_{ij}(a_{ij}\rho) = 0. \tag{3.4}$$

(ii) *The homogeneous equations* $Lu = 0$ *and* $L^*\rho = 0$ *have the same finite number of linearly independent solutions.*

Proof. The proof is given in [7, part 2, section 3.6], even for more general equations of higher order. For second-order equations, we specify these statements as follows.

COROLLARY 3.2. *Under the additional restriction*

$$\int_{\boldsymbol{T}^d} \rho\, dx = 1, \tag{3.5}$$

equation (3.4) *has a unique solution* $\rho \in C^\infty(\boldsymbol{T}^d)$. *Moreover,* $\rho \geq 0$ *on* $\boldsymbol{T}^d$. *Equation* (3.2) *with* $f \in C^\infty(\boldsymbol{T}^d)$ *has a solution in* $C^\infty(\boldsymbol{T}^d)$ *if and only if* f *satisfies* (3.3) *with this* ρ.

Proof. By the strong maximum principle (see [7, part 2, section 2.2], or [15, Theorem 3.5]), from $Lu = f \geq 0$ on $\boldsymbol{T}^d$ it follows that $u = \text{const}$, $f = 0$. Therefore, the number of linearly independent solutions for each of two equations $Lu = 0$ and $L^*\rho = 0$ is one. This implies that the problem (3.4), (3.5) has a unique solution $\rho \in C^\infty(\boldsymbol{T}^d)$, and the last statement here is equivalent to Theorem 3.1(i).

To prove the inequality $\rho \geq 0$ on $\boldsymbol{T}^d$, suppose otherwise. Then there exists a positive function $f \in C^\infty(\boldsymbol{T}^d)$ satisfying (3.3) with this ρ. In turn, this provides the solvability of (3.2) for $f > 0$, which is impossible. This contradiction gives $\rho \geq 0$, and the proof is completed. □

DEFINITION 3.3. *Let* $a = (a_{ij})$ *be a real, symmetric* $d \times d$ *matrix function, where* $a_{ij} \in C^\infty(\boldsymbol{T}^d)$ *and satisfy* (1.1) *with a constant* $\nu \in (0, 1]$. *A* homogenized matrix *of* a *is the constant matrix*

$$a^0 = (a^0_{ij}) = H(a) = \int_{\boldsymbol{T}^d} a\rho\, dx, \tag{3.6}$$

where $\rho \in C^\infty(\boldsymbol{T}^d)$ *is a (unique) solution to the problem* (3.4), (3.5).

The following theorem was proved by Freidlin [13]. He used an interpretation of $\rho(x)$ as the density of limit distributions on $\boldsymbol{T}^d$ of Markov processes corresponding to $L = \sum a_{ij}D_{ij}$. Here we give an alternative proof which is closer to [6], [17]. We do not use this theorem here; however, its proof presents in a "pure" form the basic element in the proof of Theorem 1.2.

THEOREM 3.4. *Let* $d \times d$ *matrices* $a(x)$ *and* a^0 *be as in Definition* 3.3. *For* $\varepsilon > 0$, *we set* $a^\varepsilon(x) = a(\varepsilon^{-1}x)$, *so that* a^ε *are defined for all* $\varepsilon \geq 0$. *Let* Ω *be a bounded domain in* $\boldsymbol{R}^d$ *with the boundary* $\partial\Omega \in C^\infty$, *and let a function* $g \in C^\infty(\overline{\Omega})$ *be given. Then the solutions* u^ε, $\varepsilon \geq 0$, *to the problems*

$$L^\varepsilon u^\varepsilon = \sum_{i,j} a^\varepsilon_{ij} D_{ij} u^\varepsilon = 0 \quad \text{in } \Omega, \quad u^\varepsilon = g \quad \text{on } \partial\Omega, \tag{3.7}$$

satisfy

$$\lim_{\varepsilon \to 0+} \sup_{\Omega} |u^\varepsilon - u^0| = 0. \tag{3.8}$$

Proof. We have the matrix equality

$$(a-a^0,\rho)=\int_{\boldsymbol{T}^d}(a-a^0)\rho\,dx=\int_{\boldsymbol{T}^d}a\rho\,dx-a^0\int_{\boldsymbol{T}^d}\rho\,dx=a^0-a^0=0.$$

By Corollary 3.2 applied to each entry of the matrix $a-a^0$, there exists a matrix function $v=(v_{ij})$ with $v_{ij}\in C^\infty(\overline{\Omega})$, such that

$$Lv(x)=\sum_{i,j}a_{ij}D_{ij}v(x)=a(x)-a^0. \tag{3.9}$$

For $\varepsilon>0$, we have

$$\varepsilon^2L^\varepsilon(v(\varepsilon^{-1}x))=(L^\varepsilon v)(\varepsilon^{-1}x)=a(\varepsilon^{-1}x)-a^0=a^\varepsilon(x)-a^0. \tag{3.10}$$

Consider the functions

$$w^\varepsilon(x)=u^\varepsilon(x)-u^0(x)+\varepsilon^2\sum_{i,j}v_{ij}(\varepsilon^{-1}x)D_{ij}u^0(x).$$

Since the coefficients and the boundary data in (3.7) are smooth, all the functions u^ε, u^0, v_{ij} belong to $C^\infty(\overline{\Omega})$. Using the identities $L^\varepsilon u^\varepsilon=L^0u^0=0$ and (3.10), we get

$$L^\varepsilon w^\varepsilon=L^\varepsilon u^\varepsilon-L^\varepsilon u^0+\varepsilon^2\sum_{i,j}L^\varepsilon(v_{ij}(\varepsilon^{-1}x))\cdot D_{ij}u^0(x)+F^\varepsilon$$

$$=L^\varepsilon u^\varepsilon-L^\varepsilon u^0+(L^\varepsilon-L^0)u^0+F^\varepsilon=F^\varepsilon,$$

where

$$F^\varepsilon(x)=\varepsilon^2\sum_{i,j}\left[L^\varepsilon(v_{ij}(\varepsilon^{-1}x)D_{ij}u^0(x))-L^\varepsilon(v_{ij}(\varepsilon^{-1}x))\cdot D_{ij}u^0(x)\right]$$

satisfies $|F^\varepsilon|\le N\varepsilon$ with a constant N which is independent of ε. Moreover, since $u^\varepsilon=u^0=g$ on $\partial\Omega$, we also have $|w^\varepsilon|\le N\varepsilon^2$ on $\partial\Omega$. By the comparison principle for second-order elliptic equations, $|w^\varepsilon|\le N\varepsilon$ in Ω for $0<\varepsilon<1$, which gives us equation (3.8). □

As in the Nadirashvili paper [25], our approach to Theorem 1.2 is based on the fact that two different constant 3×3 matrices A^0 and A^1 may be obtained by homogenization of smooth matrices a^0 and a^1 correspondingly, which coincide on a portion of $\boldsymbol{T}^3$, and on the fact that locally the structure of a^m is similar to that of A^m ($m=0$ and 1) on the remaining part of $\boldsymbol{T}^3$. The details are given in the following technical lemma.

LEMMA 3.5. *For any constants $\Lambda\ge\lambda_0>0$ and $\theta>0$, there exists an open set $G=G(\Lambda,\theta)\subset\boldsymbol{T}^3$ of the Lebesgue measure $|G|\le\theta$ and two real symmetric, 3×3 matrix functions $a^0=(a^0_{ij}(x))$, $a^1=(a^1_{ij}(x))$, such that*

(i) *functions $a^0_{ij},a^1_{ij}\in C^\infty(\boldsymbol{T}^3)$, satisfy* (1.1) *with a constant $\nu=\nu(\Lambda,\theta)\in(0,1]$, and*

$$a^0=I,\quad a^1=I+\lambda\,l^tl\quad\text{on}\quad G,\qquad a^0=a^1\quad\text{on}\quad\boldsymbol{T}^3\setminus G, \tag{3.11}$$

where $I=(\delta_{ij})$ is the unit matrix, $\lambda\in C^\infty(\boldsymbol{T}^3)$, $l=(l_1,l_2,l_3)$ with $l_i\in C^\infty(G)$, l^t is the corresponding column vector, and

$$0\le\lambda\le\Lambda,\ \ |l|^2=\sum_i l_i^2=1\quad\text{on}\quad G,\qquad\lambda\equiv0\quad\text{on}\quad\boldsymbol{T}^3\setminus G; \tag{3.12}$$

(ii) *the homogenized matrices*

$$A^0 = H(a^0) = I, \qquad A^1 = H(a^1) = c(I + \lambda_0 e_3^t e_3), \tag{3.13}$$

where $1 \le c = \text{const} \le 1 + \Lambda$, $e_3 = (0, 0, 1)$.

Proof. Step 1. We will find G in the form $G = G' \times \boldsymbol{T}^1 \subset \boldsymbol{T}^3$, where

$$G' = \{x' = (x_1, x_2) : r_0 < |x'| < r_1\} \subset \boldsymbol{T}^2 = \left[-\frac{1}{2}, \frac{1}{2}\right)^2, \tag{3.14}$$

$r_1 = \min(\frac{1}{4}, \sqrt{\frac{\theta}{\pi}})$, and a small constant $r_0 \in (0, \frac{1}{4} r_1]$ will be chosen later. We have $|G| = |G'| < \pi r_1^2 \le \theta$. Next, we choose a smooth function λ on $\boldsymbol{R}^1$ with compact support in (r_0, r_1) such that

$$0 \le \lambda \le \Lambda \quad \text{on } \boldsymbol{R}^1, \qquad \lambda = \Lambda \quad \text{on } \left[2r_0, \frac{1}{2} r_1\right]. \tag{3.15}$$

We will use the same notation λ for the function $\lambda = \lambda(r)$, $r = |x'| = \sqrt{x_1^2 + x_2^2}$ on $\boldsymbol{R}^2 \subset \boldsymbol{R}^3$. Further, we set

$$l = (l_1, l_2, l_3) = r^{-1}(x_1, x_2, 0), \quad r = |x'| \quad \text{on} \quad G. \tag{3.16}$$

Then λ and l satisfy (3.12), and the matrices a^0, a^1 are well defined on G by the identities (3.11). We will extend $a^0_{33} = a^1_{33} = 1$ from G to $\boldsymbol{T}^3$ by the formula

$$a^0_{33} = a^1_{33} = 1 + c_0 \zeta_0(r) - c_1 \zeta_1(r), \qquad r = |x'| \tag{3.17}$$

with some constants $c_0 \ge 0$, $0 \le c_1 \le \frac{1}{2}$. Here ζ_0 and ζ_1 are smooth functions on $\boldsymbol{R}^1$ with compact supports in $(-r_0, r_0)$ and $(\frac{1}{4}, \frac{1}{2})$, correspondingly, satisfying $0 \le \zeta_0, \zeta_1 \le 1$ on $\boldsymbol{R}^1$, $\zeta_0 = 1$ on $[-\frac{1}{2} r_0, \frac{1}{2} r_0]$, and $\zeta_1 = 1$ on a fixed subinterval of $(\frac{1}{4}, \frac{1}{2})$. The remaining coefficients

$$a^0_{ij} = a^1_{ij} = \delta_{ij} \quad \text{on} \quad \boldsymbol{T}^3 \setminus G, \quad i + j < 6. \tag{3.18}$$

Together with (3.11), the formulas (3.17), (3.18) determine the matrices $a^0, a^1 \in C^\infty(\boldsymbol{T}^3)$ satisfying all the properties (i). The properties (ii) will be obtained by a suitable choice of the constants r_0, c_0, c_1.

Step 2. For $m = 0$ and 1, we denote by ρ_m the solution to the problem (3.4), (3.5) with $d = 3$, $a_{ij} = a^m_{ij}$. Since $a^m = (a^m_{ij})$ depend only on $x' = (x_1, x_2)$, ρ_m coincide with the (unique) solutions to the problem

$$(L^m)^* \rho_m = \sum_{i,j=1}^{2} D_{ij}(a^m_{ij} \rho_m(x')) = 0, \qquad \int_{\boldsymbol{T}^2} \rho_m(x')\, dx' = 1. \tag{3.19}$$

Therefore, $\rho_m(x) = \rho_m(x') = \rho_m(x_1, x_2)$ do not depend on x_3. By (3.11) and (3.18), $a^0_{ij} = \delta_{ij}$ for $i + j < 6$. Hence $\rho_0 \equiv 1$, and the homogenized matrix $A^0 = H(a^0)$ has the entries

$$A^0_{ij} = \int_{\boldsymbol{T}^2} a^0_{ij}\, dx' = \delta_{ij}, \quad i + j < 6.$$

We do not have any explicit representations for ρ_1. However, from the symmetry it follows that $\rho_1 = \rho_1(x_1, x_2)$ is an even function of x_1 and x_2. By (3.11), (3.15)–(3.18), we get

$$A^1_{ij} = \int_{\boldsymbol{T}^2} a^1_{ij}\rho_1\,dx' = \delta_{ij} + \int_{\boldsymbol{T}^2} \lambda r^{-2}x_ix_j\rho_1\,dx' = 0, \qquad i \neq j,$$

$$1 \le A^1_{11} = A^1_{22} = 1 + \int_{\boldsymbol{T}^2} \lambda r^{-2}x_1^2\rho_1\,dx' \le 1 + \Lambda,$$

so that

$$A^1_{ij} = c\delta_{ij} \qquad \text{for} \quad i + j < 6, \qquad \text{where} \quad 1 \le c \le 1 + \Lambda. \tag{3.20}$$

Now it remains to get the equalities $A^0_{33} = 1$, $A^1_{33} = c(1 + \lambda_0)$, which by virtue of (3.17) are equivalent to the system

$$\rho_{00}c_0 - \rho_{01}c_1 = 0, \qquad \rho_{10}c_0 - \rho_{11}c_1 = b,$$

where

$$0 \le \rho_{mn} = \int_{\boldsymbol{T}^2} \zeta_n\rho_m\,dx', \qquad 0 \le b = (1 + \lambda_0)c - 1 \le (2 + \Lambda)\Lambda.$$

The solution of this system is

$$c_1 = \frac{b}{K\rho_{01} - \rho_{11}}, \quad c_0 = \frac{\rho_{01}}{\rho_{00}}c_1, \quad \text{where} \quad K = \frac{\rho_{10}}{\rho_{00}}.$$

We also need the inequalities $0 \le c_1 \le \frac{1}{2}$, which guarantee the uniform ellipticity of the matrices a^0, a^1. We may assume that ζ_1 is fixed and for different $r_0 > 0$ the functions ζ_0 are obtained by rescaling $x \longrightarrow \text{const} \cdot x$, so that now everything depends only on $r_0 \in (0, \frac{1}{4}r_0]$. Since ρ_{01} does not depend on r_0 and $\rho_{11} \le 1$, the desired inequalities $0 \le c_1 \le \frac{1}{2}$ hold automatically for small $r_0 > 0$ if we show that

$$K = \frac{\rho_{10}}{\rho_{00}} \to +\infty \quad \text{as} \quad r_0 \to 0+. \tag{3.21}$$

Step 3. We set $B = B_A = \{y' = (y_1, y_2) : |y'| < A\} \subset \boldsymbol{R}^2$, where $A = \frac{\sqrt{2}}{2}$. Notice that for each $x' = (x_1, x_2) \in \boldsymbol{T}^2 = [-\frac{1}{2}, \frac{1}{2})^2$, there exist at least one and at most two points $y' = (y_1, y_2) \in B$, such that both $x_1 - y_1$ and $x_2 - y_2$ are integers. Therefore, considering $\rho_m \in C^\infty(\boldsymbol{T}^2)$ as periodic functions on $\boldsymbol{R}^2$ for $m = 0$ and 1, we obtain

$$1 = \int_{\boldsymbol{T}^2} \rho_m\,dx' \le \int_B \rho_m\,dx' \le 2. \tag{3.22}$$

Further, since $\lambda(r) = 0$, $\zeta_0(r) = 1$ on $[0, \frac{1}{2}r_0]$, the ordinary differential equation

$$(1 + m\lambda)w_m'' + \frac{1}{r}w_m' = \zeta_0 \tag{3.23}$$

has a solution $w_m(r) = \frac{1}{4}r^2$ on $(0, \frac{1}{2}r_0]$. This solution is uniquely extended to $(0, A]$. The function

$$W_m(r) = w_m(r) - \frac{w_m'(A)}{2A}r^2, \quad \text{where} \quad r = |x'| = \sqrt{x_1^2 + x_2^2},$$

belongs to $C^\infty(\overline{B})$ and satisfies

$$L^m W_m = \sum_{i,j=1}^{2} a_{ij}^m D_{ij} W_m = (1+m\lambda)W_m'' + \frac{1}{r}W_m' = \zeta_0 - \frac{w_m'(A)}{A}(2+m\lambda) \tag{3.24}$$

in B, $D_i W_m = 0$ on ∂B. Integrating by parts twice, using (3.19) and then (3.24), we have

$$\int_B L^m W_m \cdot \rho_m \, dx' = \int_B L^m (W_m - W_m(A)) \cdot \rho_m \, dx'$$

$$= \int_B (W_m - W_m(A)) \cdot (L^m)^* \rho_m \, dx' = 0,$$

$$\rho_{m0} = \int_{\boldsymbol{T}^2} \zeta_0 \rho_m \, dx' = \int_B \zeta_0 \rho_m \, dx' = \frac{w_m'(A)}{A} \int_B (2+m\lambda)\rho_m \, dx'.$$

By the inequalities (3.22), we get

$$K = \frac{\rho_{10}}{\rho_{00}} \geq \frac{1}{2} f(A), \qquad \text{where} \quad f(r) = \frac{w_1'(r)}{w_0'(r)}. \tag{3.25}$$

Since $\lambda = 0$ on $[0, r_0]$, we have $w_1 \equiv w_0$ on $[0, r_0]$; in particular, $f(r_0) = 1$. Moreover, since $\zeta_0 = 0$ on $[r_0, \infty)$, and $\lambda = \Lambda$ on $[2r_0, \frac{1}{2}r_1]$, we also have

$$(\ln f)' = \frac{w_1''}{w_1'} - \frac{w_0''}{w_0'} = \frac{-1}{(1+\lambda)r} + \frac{1}{r} = \frac{\lambda}{(1+\lambda)r} \quad \text{on} \quad [r_0, \infty),$$

$$\ln f(A) = \int_{r_0}^{A} \frac{\lambda \, dr}{(1+\lambda)r} \geq \frac{\Lambda}{1+\Lambda} \int_{2r_0}^{\frac{1}{2}r_1} \frac{dr}{r} = \frac{\Lambda}{1+\Lambda} \ln \frac{r_1}{4r_0}.$$

The last relation shows that by the choice of small $r_0 \in (0, \frac{1}{4}r_1]$, $f(A)$ can be made arbitrarily large. Then (3.25) gives us the desired estimate (3.24), and so Lemma 3.5 is proved. □

4. Proof of Theorem 1.2. *Step* 1. For the given constant $\Lambda > 0$ and $\theta = \frac{1}{2}$, we fix the open set $G \subset \boldsymbol{T}^3$ and the constant $\nu = \nu(\Lambda) \in (0, 1]$ from Lemma 3.5. Starting from the unit ball B_1 in $\boldsymbol{R}^3$, we will construct a decreasing sequence of open sets

$$B_1 = G_0 \supset G_1 \supset \cdots \supset G_k \supset G_{k+1} \supset \cdots \tag{4.1}$$

of the Lebesgue measures

$$|G_k| \leq 2^{-k} |B_1|, \qquad k = 0, 1, \ldots, \tag{4.2}$$

and two sequences of real, symmetric, smooth 3×3 matrix functions $\{a^{0,k}\}$ and $\{a^{1,k}\}$ on $\overline{B_1}$, satisfying (1.1) with the chosen constant $\nu = \nu(\Lambda)$, and such that

$$a^{0,k} = I, \quad a^{1,k} = I + \lambda_k (l^k)^t l^k \ \text{ on } \ G_k; \quad a^{0,k} = a^{1,k} = a \ \text{ on } \ B_1 \setminus G_k, \tag{4.3}$$

where $\lambda_k \in C^\infty(\overline{B_1})$, $l^k = (l_1^k, l_2^k, l_3^k)$ with $l_i^k \in C^\infty(\overline{G_k})$, and

$$0 \le \lambda_k \le \Lambda, \quad |l^k| = 1 \quad \text{on} \quad G_k; \qquad \lambda_k \equiv 0 \qquad \text{on} \quad B_1 \setminus G_k. \tag{4.4}$$

Our goal is to construct $\{a^{0,k}\}$ and $\{a^{1,k}\}$ in such a manner that for some $g \in C^\infty(\overline{B_1})$, the sequences $\{u^{0,k}\}$ and $\{u^{1,k}\}$ of solutions to the problems (1.6) uniformly converge to two different functions u^0 and u^1.

Notice that from (4.2)–(4.3) the convergence follows of $a_{ij}^{0,k}$, $a_{ij}^{1,k}$ to a_{ij} a.e. on B_1 as $k \to \infty$; i.e., see statement (ii) of Theorem 1.2.

We set $G_0 = B_1$, $\lambda_0 = \Lambda$, $l^0 = e_3 = (0,0,1)$, $g = x_1^2 - x_3^2$. Then $a^{0,0} = I$, $a^{1,0} = I + \Lambda e_3^t e_3$, the corresponding solutions to the problems (1.6), $u^{0,0} \equiv g$, and $u^{1,0}$ are different; hence

$$|u^{0,0} - u^{1,0}|_0 \ge H \tag{4.5}$$

with some constant $H > 0$. Here and in the remaining part of the proof, $|\cdot|_0$ denotes the norm in $C(\overline{B_1})$.

Step 2. Now we have G_k, $a^{0,k}$, $a^{1,k}$ satisfying (4.2)–(4.4) for $k = 0$. Assuming that they are given for some integer $k \ge 0$, we will construct G_{k+1}, $a^{0,k+1}$, $a^{1,k+1}$. By induction, we get all of these objects for all integers $k \ge 0$.

We divide G_k into a finite number of regular sets $G_{k,n}$, $n = 1, 2, \dots$, fix an arbitrary point $P_{k,n} \in G_{k,n}$ for each n, and introduce the piecewise constant matrix function on G_k,

$$\overline{a} = (\overline{a}_{ij}) = I + \overline{\lambda}\, \overline{l}^t \overline{l}, \quad \text{where} \quad \overline{\lambda} = \lambda_k(P_{k,n}), \ \ \overline{l} = l^k(P_{k,n}) \quad \text{on} \quad G_{k,n}. \tag{4.6}$$

For arbitrary constant $\delta_k > 0$, we can choose $G_{k,n}$ of appropriately small diameters, such that

$$|a_{ij}^{1,k} - \overline{a}_{ij}| \le \delta_k \qquad \text{on} \quad G_k = \bigcup_n G_{k,n}. \tag{4.7}$$

Further, for arbitrary constant $\mu_k > 0$, there exists a function $\eta_k \in C^\infty(\overline{B_1})$, such that $0 \le \eta_k \le 1$ on B_1, $\eta_k = 0$ on $B_1 \setminus G_k$ and near $\partial G_{k,n}$ for each n, and

$$|G_k \setminus G_k'| \le \mu_k, \quad \text{where} \quad G_k' = \{x \in G_k : \eta_k(x) = 1\}. \tag{4.8}$$

The constants δ_k, μ_k will be selected later.

Next, we concentrate on $G_{k,n}$ for fixed n. We change the coordinates by the formula

$$x = yQ_n, \qquad y = xQ_n^t, \tag{4.9}$$

where Q_n is a matrix of rotation satisfying $\overline{l} = e_3 Q_n$. Let $\tilde{a}^0(y)$, $\tilde{a}^1(y)$ be matrix functions a^0, a^1 in Lemma 3.5 applied with $\lambda_0 = \overline{\lambda}$. By (3.13), we have

$$\tilde{A}^0 = H(\tilde{a}^0) = I, \quad \tilde{A}^1 = H(\tilde{a}^1) = c(I + \overline{\lambda} e_3^t e_3), \quad 1 \le c \le 1 + \Lambda.$$

As in (3.9), there exist 3×3 matrix functions $\tilde{v}^m(y) = (\tilde{v}_{ij}^m(y))$ for $m = 0$ and 1, with entries in $C^\infty(\boldsymbol{T}^3)$, satisfying

$$\sum_{i,j} \tilde{a}_{ij}^m(y) D_{ij} \tilde{v}^m(y) = \tilde{a}^m(y) - \tilde{A}^m.$$

One can see from the proof of Lemma 3.5 that the smoothness of $\tilde{a}^m$ does not depend on n (i.e., on the choice of $\lambda_0 = \overline{\lambda}$). Moreover, replacing $\tilde{v}^m$ by $\tilde{v}^m + \text{const}$, we may assume $\tilde{v}^m(0) = 0$. Then by the well-known properties of solutions of elliptic equations with smooth coefficients, the bounds for $\tilde{v}^m$ and their derivative of any order do not depend on n. In the x-coordinates, the matrices $\tilde{a}^m(y)$, $\tilde{v}^m(y)$, $\tilde{A}^m$ are replaced by

$$a^m(x) = Q_n^t \tilde{a}^m(xQ_n^t)Q_n, \quad v^m(x) = Q_n^t \tilde{v}^m(xQ_n^t)Q_n, \quad A^m(x) = Q_n^t \tilde{A}^m Q_n,$$

correspondingly. As a result, we obtain

$$\sum_{i,j} a_{ij}^m D_{ij} v^m(x) = a^m(x) - A^m. \tag{4.10}$$

By (4.6) and the choice of the orthogonal matrix Q_n in (4.9),

$$A^0 = I, \quad A^1 = c(I + \overline{\lambda}\,\overline{l}^t\overline{l}) = c\,\overline{a}, \quad 1 \le c \le 1 + \Lambda. \tag{4.11}$$

Step 3. For $m = 0$ and 1, we define

$$a^{m,k+1}(x) = (1 - \eta_k(x))a^{0,k}(x) + \eta_k(x)\, a^m(\varepsilon^{-1}x) \quad \text{on} \quad B_1 \tag{4.12}$$

with a small $\varepsilon > 0$. Here and in (4.10), the matrix functions a^m, v^m depend also on k, n: these functions satisfy (4.10), (4.11) on $G_{k,n}$ with $\overline{a}$ depending on k, n, so that

$$\varepsilon^2 \sum_{i,j} a_{ij}^m(\varepsilon^{-1}x) D_{ij} v^m(\varepsilon^{-1}x) = a^m(\varepsilon^{-1}x) - A^m, \tag{4.13}$$

but they may be discontinuous on $G_k = \bigcup_n G_{k,n}$. However, since η_k vanishes on $B_1 \setminus G_k$ and near $\partial G_{k,n}$, the functions $a^{0,k+1}$ and $a^{1,k+1}$ are well defined, belong to $C^\infty(\overline{B_1})$, and satisfy (1.1) with the constant $\nu = \nu(\Lambda)$.

Further, we denote by Z^3 the set of all vectors in $\boldsymbol{R}^3$ with integer components and define

$$\boldsymbol{T}_{\varepsilon,n}(z) = \left\{ x \in \boldsymbol{R}^3 : \varepsilon^{-1} x Q_n^t - z \in \boldsymbol{T}^3 = \left[-\frac{1}{2}, \frac{1}{2}\right)^3 \right\},$$

$$G_{\varepsilon,n}(z) = \{x \in \boldsymbol{R}^3 : \varepsilon^{-1} x Q_n^t - z \in G \subset \boldsymbol{T}^3\},$$

where Q_n is the matrix of rotation in (4.9). For different $z \in Z^3$, $\boldsymbol{T}_{\varepsilon,n}(z)$ are disjoint cubes in $\boldsymbol{R}^3$ with the edge length ε, which are obtained from the "standard" cube $\boldsymbol{T}^3 = [-\frac{1}{2}, \frac{1}{2})^3$ by the mapping

$$\boldsymbol{T}^3 \ni y \quad \longrightarrow \quad x = \varepsilon(y + z)Q_n,$$

and $G_{\varepsilon,n}(z)$ is the image of $G \subset \boldsymbol{T}^3$ by the same mapping. Obviously,

$$|G_{\varepsilon,n}(z)| \le \theta |\boldsymbol{T}_{\varepsilon,n}(z)| = \frac{1}{2} |\boldsymbol{T}_{\varepsilon,n}(z)|. \tag{4.14}$$

Finally, we define

$$G_{k+1} = \bigcup_n \bigcup_{z \in Z_n} G_{\varepsilon,n}(z) \quad \text{where} \quad Z_n = \{z \in Z^3 : \boldsymbol{T}_{\varepsilon,n}(z) \subset G_{k,n}\}. \tag{4.15}$$

Since the components $G_{\varepsilon,n}(z)$ of this set are disjoint, from (4.14) and (4.2) it follows

$$|G_{k+1}| = \sum_n \sum_{z\in Z_n} |G_{\varepsilon,n}(z)| \le \frac{1}{2}\sum_n \sum_{z\in Z_n} |\boldsymbol{T}_{\varepsilon,n}(z)| \le \frac{1}{2}\sum_n |G_{k,n}| = \frac{1}{2}|G_k| \le 2^{-(k+1)}|B_1|;$$

i.e., the estimate (4.2) holds for $k+1$.

In order to get the representation (4.3) for the matrix functions $a^{m,k+1}$, we will use the fact that $x \in G_{\varepsilon,n}(z)$ if and only if $y = \varepsilon^{-1}xQ_n^t - z \in G \subset \boldsymbol{T}^3$. By the periodicity, $\tilde{a}^m(y) \equiv \tilde{a}^m(y+z)$, and hence

$$a^m(\varepsilon^{-1}x) = Q_n^t \tilde{a}^m(\varepsilon^{-1}xQ_n^t)Q_n = Q_n^t \tilde{a}^m(y)Q_n$$

for all $x \in G_{\varepsilon,n}(z)$. Since $a^{0,k} = I$ on $G_k \supset G_{\varepsilon,n}(z)$, we have

$$a^{m,k+1}(x) = (1-\eta_k(x))I + \eta_k(x)\, Q_n^t \tilde{a}^m(y)Q_n \quad \text{on} \quad G_{\varepsilon,n}(z).$$

The properties (3.11) in Lemma 3.5 for $\tilde{a}^m$ imply $\tilde{a}^0 = I$, $\tilde{a}^1 = I + \lambda l^t l$, with $\lambda = \lambda(y)$, $l = l(y)$ satisfying (3.12). Hence

$$a^{0,k+1} = I, \quad a^{1,k+1} = I + \lambda_{k+1}(l^{k+1})^t l^{k+1} \quad \text{on} \quad G_{\varepsilon,n}(z),$$

where

$$\lambda_{k+1}(x) = \eta_k(x)\lambda(y), \quad l^{k+1}(x) = l(y)Q_n, \quad y = \varepsilon^{-1}xQ_n^t - z.$$

Thus λ_{k+1}, l^{k+1} are defined and smooth on $G_{k+1} = \bigcup G_{\varepsilon,n}(z)$. From $\lambda \in C^\infty(\boldsymbol{T}^3)$, $\lambda \equiv 0$ on $\overline{B}_1 \setminus G_{k+1}$, we obtain $\lambda_{k+1} \in C^\infty(\overline{B}_1)$.

The properties (4.4) for λ_{k+1}, l^{k+1} are obvious. In (4.3), we only need to show that

$$a^{0,k+1} = a^{1,k+1} \quad \text{on} \quad B_1 \setminus G_{k+1}. \tag{4.16}$$

This equality on $\boldsymbol{T}_{\varepsilon,n}(z)\setminus G_{\varepsilon,n}(z)$ for $z \in Z_n$ follows from $\tilde{a}^0(y) = \tilde{a}^1(y)$ on $\boldsymbol{T}^3 \setminus G_k$. The remaining points in $B_1 \setminus G_{k+1}$ lie either in $B_1 \setminus G_k$ or in the 2ε-neighborhood of $\partial G_{k,n}$ for some n. Since $\eta_k = 0$ on $B_1 \setminus G_k$ and near $\partial G_{k,n}$, we have (4.16), provided $\varepsilon > 0$ is small enough.

Step 4. We will show that the solutions $u^{m,k+1}$ to the problems (1.6) can be made arbitrarily close to $u^{m,k}$; i.e., for arbitrary constant $h_k > 0$, by the appropriate choice of constants $\delta_k, \mu_k, \varepsilon$ in (4.7), (4.8), (4.12), we have

$$|u^{m,k+1} - u^{m,k}|_0 \le h_k \tag{4.17}$$

for $m = 0$ and 1. For fixed m, k, ε, we introduce the function

$$w = u^{m,k+1} - u^{m,k} + \varepsilon^2\eta_k V, \quad \text{where} \quad V = V(x) = \sum_{i,j} v_{ij}(\varepsilon^{-1}x)D_{ij}u^{m,k}(x),$$

$(v_{ij}) = v^m$ is the matrix function from (4.13), which is smooth on each set $G_{k,n}$. Since $\eta_k = 0$ on $B_1 \setminus G_k$ and near $\partial G_{k,n}$ for each n, the function w is well defined, belongs to $C^\infty(\overline{B_1})$, and $w = 0$ on ∂B_1. Obviously,

$$|u^{m,k+1} - u^{m,k}|_0 \le |w|_0 + \varepsilon^2|V|_0 \le |w|_0 + N\varepsilon^2. \tag{4.18}$$

Here and in the rest of the proof, N denotes different constants not depending on ε and the constants δ_k, μ_k in (4.7), (4.8). By Theorem 2.1,

$$|w|_0 \le N\|F\|_{\mathcal{L}^3(B_1)}, \quad \text{where} \quad F = L^{m,k+1}w. \tag{4.19}$$

Therefore, we will get the estimate (4.17) if we show that the norm of F in $\mathcal{L}^3(B_1)$ can be made arbitrarily small.

On the set $B_1 \setminus G_k$, we have $\eta_k = 0$, $a^{m,k+1} = a^{m,k} = a^{0,k}$; hence

$$F = L^{m,k+1}(u^{m,k+1} - u^{m,k}) = L^{m,k+1}u^{m,k+1} - L^{m,k}u^{m,k} = 0.$$

The estimate of F on G_k is more delicate. We write $F = L^{m,k+1}w = F_1 + F_2$, where

$$F_1(x) = -L^{m,k+1}u^{m,k}(x) + \varepsilon^2\eta_k(x)\sum_{i,j} L^{m,k+1}v^m_{i,j}(\varepsilon^{-1}x)\cdot D_{ij}u^{m,k}(x),$$

$$F_2 = \varepsilon^2\sum_{i,j}\left[L^{m,k+1}(\eta_k v^m_{i,j}(\varepsilon^{-1}x)D_{ij}u^{m,k}(x)) - L^{m,k+1}v^m_{i,j}(\varepsilon^{-1}x)\cdot\eta_k D_{ij}u^{m,k}(x)\right].$$

Using the identity (4.13), we have

$$F_1 = -\sum_{i,j} A^m_{ij}D_{ij}u^{m,k}u = \sum_{i,j}(a^m_{ij} - A^m_{ij})D_{ij}u^{m,k}u \quad \text{on} \quad G'_k = \{\eta_k = 1\} \subset G_k.$$

By virtue of (4.7), (4.8),

$$|F_1| \le N\delta_k \quad \text{on } G'_k, \qquad |F_1| \le N \quad \text{on } G_k \setminus G'_k.$$

Hence the norm of F_1 in $\mathcal{L}^3(B_1)$ is bounded by $N(\delta_k + \mu^{\frac{1}{3}})$ and can be made arbitrarily small. The same is true for $F = F_1 + F_2$ because of the estimate $|F_2| \le N_1\varepsilon$ with a constant N_1, which does not depend on ε. Now the desired approximation (4.17) follows from (4.19).

Step 5. Using (4.5) and (4.17), it is easy to complete our construction. We choose a sequence $\{h_k\}$ satisfying $\sum h_k \le \frac{1}{4}H$. By the Cauchy criterion, sequences $\{u^{0,k}\}, \{u^{1,k}\}$ converge in $C(\overline{B_1})$ to some functions u^0, u^1:

$$|u^{0,k} - u^0|_0,\ |u^{1,k} - u^1|_0 \ \to 0 \quad \text{as} \quad k \to \infty.$$

By the triangle inequality, for any natural K,

$$|u^{0,K} - u^{1,K}|_0 \ge |u^{0,0} - u^{1,0}|_0 - \sum_{k=0}^{K-1}|u^{0,k+1} - u^{0,k}|_0 - \sum_{k=0}^{K-1}|u^{1,k+1} - u^{1,k}|_0$$

$$\ge H - 2\sum_{k=0}^{\infty} h_k \ge \frac{1}{2}H > 0.$$

Therefore,

$$|u^0 - u^1|_0 = \lim_{K\to\infty}|u^{0,K} - u^{1,K}|_0 \ge \frac{1}{2}H > 0.$$

Theorem 1.2 is completely proved. □

Acknowledgments. The author is grateful to N. S. Nadirashvili for an opportunity to learn about his result before its publication, to N. V. Krylov and P. Manselli for very useful discussions on the topics of this paper, and to Yu Yuan for corrections of misprints. The author is also deeply indebted to the late Eugene Fabes for his valuable suggestions and critical remarks.

A DENSENESS THEOREM WITH AN APPLICATION TO A TWO-DIMENSIONAL INVERSE POTENTIAL REFRACTION PROBLEM*

BERND HOFMANN†

Abstract. In this paper we will be concerned with the problem of reconstructing a region $D \subset \Omega \subset \mathbb{R}^2$, from the knowledge of the boundary potential $u|_{\partial\Omega}$, where u satisfies

$$\operatorname{div}((\chi_{\bar{\Omega}\setminus D} + a\chi_D)\nabla u) = 0 \quad \text{in } \Omega \qquad \text{and} \qquad \frac{\partial u}{\partial \nu} = I \quad \text{on } \partial\Omega,$$

with a a real, positive constant. We will show that the domain derivative of the corresponding forward mapping is injective. This is done by proving the denseness of a certain subspace of $L^1(\partial D)$. The novelty of the result is that our proof is valid without any restriction on the Neumann boundary data I.

1. Introduction.

The denseness theorem proved in this paper is related to an inverse problem in electrical impedance tomography. Its relation to this problem was first worked out in [2], [3]. Here we will briefly outline its relevance without any proofs.

We start by introducing some notations. If $D \subset \mathbb{R}^n$ is bounded with smooth boundary ∂D, we will denote the outward unit normal of ∂D by ν or, to avoid ambiguities, more precisely by ν_D. The Euclidean scalar product in $\mathbb{R}^n$ is denoted by $\langle \cdot, \cdot \rangle$. The symbols for the standard function spaces will always stand for the spaces of real valued functions. A lower index $\mathbb{C}$ will be added for the corresponding space of complex valued functions. In particular, $C(D)$ and $C(D)_{\mathbb{C}}$ denote the spaces of real and complex valued, continuous functions on D, respectively. For a nonnegative integer k and $0 < \alpha < 1$, we set

$$\mathcal{P}^{k,\alpha}(D) := \{f \in C^{k,\alpha}(\bar{D}) : f \text{ is harmonic in } D\},$$
$$\mathfrak{X}^{k,\alpha}(\partial D) := C^{k,\alpha}(\partial D, \mathbb{R}^n).$$

The spaces $\mathfrak{X}^{k,\alpha}(\partial D)$ will be interpreted as vector fields on ∂D. If $Z \in \mathfrak{X}^{k,\alpha}(\partial D)$, then we will denote its normal component $\langle Z, \nu \rangle$ by Z_ν. As usual, the upper indices k and α will be dropped if they are zero. In the two-dimensional case $D \subset \mathbb{R}^2$ we will identify $\mathbb{R}^2 \simeq \mathbb{C}$ via $(x, y) \simeq x + iy$ and set

$$\mathcal{H}^{\alpha}(D) := \{f \in C^{\alpha}(\bar{D})_{\mathbb{C}} : f \text{ is holomorphic in } D\}.$$

Further, the unit tangent on ∂D with positive orientation will be denoted by τ or τ_D.

Let $\Omega \subset \mathbb{R}^n$ be an open bounded set with smooth boundary $\partial\Omega$. Consider the elliptic boundary value problem

$$\operatorname{div}(\sigma \nabla u) = 0 \qquad \text{in } \Omega, \tag{1.1a}$$

$$\sigma \frac{\partial u}{\partial \nu} = I \qquad \text{on } \partial\Omega, \tag{1.1b}$$

$$\int_{\partial\Omega} u \, ds = 0. \tag{1.1c}$$

Here $\partial/\partial\nu$ denotes the outward normal derivative on $\partial\Omega$, div the divergence, and ∇ the gradient. In the applications σ is a positive electrical conductivity, I a boundary current satisfying $\int_{\partial\Omega} I \, ds = 0$, and u the potential of the electric field generated by I. A suitable weak formulation of (1.1) can be shown to have a unique solution.

We will exclusively consider the case in which $I \in C(\partial\Omega)$ and the conductivity is of the form

$$\sigma = \chi_{\bar{\Omega}\setminus D} + a\chi_D,$$

where a is a real positive constant, D is an open subset with C^2-smooth boundary such that $\bar{D} \subset \Omega$, and χ_M denotes the characteristic function of a subset $M \subset \mathbb{R}^n$. Then the solution u of (1.1) is in $C(\bar{\Omega}) \cap C^2(\Omega \setminus \partial D)$. Setting $u_+ := u|_{\Omega\setminus D}$ and $u_- := u|_D$, (1.1) can be rewritten in the form

$$\triangle u = 0 \qquad \text{in } \Omega \setminus \partial D, \tag{1.2a}$$

$$\frac{\partial u_+}{\partial \nu} - a\frac{\partial u_-}{\partial \nu} = 0 \qquad \text{on } \partial D, \tag{1.2b}$$

$$\frac{\partial u_+}{\partial \nu} = I \qquad \text{on } \partial\Omega, \tag{1.2c}$$

$$\int_{\partial\Omega} u_+ \, ds = 0. \tag{1.2d}$$

For the remainder of this section we will assume that ∂D is $C^{2,\alpha}$-smooth for some $0 < \alpha < 1$. Then the first and second derivatives of u_- and u_+ can be extended Hölder-continuously onto ∂D.

We are interested in the inverse problem of reconstructing the conductivity inside Ω from the boundary potential $u|_{\partial\Omega}$. It can be seen from simple counterexamples that, in general, it is not possible to reconstruct D and a simultaneously from a single pair $I, u|_{\partial\Omega}$. Therefore it is assumed that the conductivity constant a is known. Then the conductivity depends only on the region D, and we can define the forward mapping

$$F : D \mapsto u|_{\partial\Omega}.$$

This mapping can be linearized at D in the following manner. For Z in some sufficiently small neighborhood U of 0 in $\mathfrak{X}^{2,\alpha}(\partial D)$ the set

$$\{x + Z(x) : x \in \partial D\}$$

is again the $C^{2,\alpha}$-smooth boundary of an open set D_Z. For a compact subset $K \subset \bar{\Omega} \setminus \partial D$ we can choose U small enough such that $K \cap \bar{D}_Z = \emptyset$ for any $Z \in U$. We then may consider the mapping

$$\Psi_K : \mathfrak{X}^{2,\alpha}(\partial D) \supset U \to C(K), \quad Z \mapsto u_Z|_K, \tag{1.3}$$

where u_Z is the solution of (1.2) with conductivity $\chi_{\bar\Omega\setminus D_Z}+a\chi_{D_Z}$, so that $\Psi_{\partial\Omega}(D_Z)=F(D_Z)$.

THEOREM 1.1. *For each compact $K\subset\bar\Omega\setminus\partial D$ the mapping* (1.3) *is Fréchet differentiable. Exhausting $\bar\Omega\setminus\partial D$ by compact sets, for $Z\in\mathfrak{X}^{2,\alpha}(\partial D)$ we can define the differentiated potential*

$$u' := \frac{d}{ds}\bigg|_{s=0}\Psi_K(D_{sZ})$$

as a function in $C(\bar\Omega\setminus\partial D)$. Then u'_+ and u'_- together with their first partial derivatives can be continuously extended to ∂D. If u is the solution of (1.2) *with respect to the region D, then u' is the unique solution of the transmission problem*

$$\triangle u' = 0 \qquad \text{in } \Omega\setminus\partial D, \tag{1.4a}$$

$$u'_+ - u'_- = -Z_\nu\Big(\frac{\partial u_+}{\partial\nu}-\frac{\partial u_-}{\partial\nu}\Big) \qquad \text{on } \partial D, \tag{1.4b}$$

$$\frac{\partial u'_+}{\partial\nu} - a\frac{\partial u'_-}{\partial\nu} = (1-a)\,\mathrm{Div}(Z_\nu\,\mathrm{Grad}\,u) \qquad \text{on } \partial D, \tag{1.4c}$$

$$\frac{\partial u'_+}{\partial\nu} = 0 \qquad \text{on } \partial\Omega, \tag{1.4d}$$

$$\int_{\partial\Omega} u'_+\,ds = 0. \tag{1.4e}$$

Here Div *and* Grad *denote the surface divergence and surface gradient on ∂D, which, in the two-dimensional case, may both be replaced by the derivative with respect to the arc length.*

Theorem 1.1 can be obtained by representing the solution of (1.2) by single layer potentials over the boundaries $\partial\Omega$ and ∂D and then using results by Potthast [7], [8] on the Fréchet differentiability of the classical boundary integral operators. A proof using weak formulations for the analogous result, when Dirichlet data $u|_{\partial\Omega}$ are prescribed and Neumann data $\partial u/\partial\nu$ on $\partial\Omega$ are measured, can be found in [4].

Denoting by $\mathfrak{X}^{2,\alpha}_T(\partial D)$ the space of vector fields in $\mathfrak{X}^{2,\alpha}(\partial D)$, which are tangential on ∂D, the above Fréchet derivative of F at D may be viewed as a mapping

$$F'_D : \mathfrak{X}^{2,\alpha}(\partial D)/\mathfrak{X}^{2,\alpha}_T(\partial D) \to C(\partial\Omega), \quad [Z]\mapsto u'|_{\partial\Omega}. \tag{1.5}$$

The uniqueness of the linearized inverse problem amounts to proving the injectivity of F'_D. Again, it can be seen from counterexamples that a general uniqueness result is false, unless $\mathbb{R}^n\setminus D$ is assumed to be connected. If we suppose that this condition is fulfilled, the injectivity of F'_D can then be obtained from the denseness of a certain subspace of $C^\alpha(\partial D)$ in $L^1(\partial D)$. This is one of the main results of [2], and it is proved without using the characterization of the derivative in Theorem 1.1.

THEOREM 1.2. *Assume that $\mathbb{R}^n\setminus D$ is connected and let the notations be as in Theorem* 1.1. *If Z is in the kernel of F'_D and $a\neq 1$, then for any $v\in\mathcal{P}^{1,\alpha}(D)$ we have*

$$\int_{\partial D} Z_\nu\langle\nabla u_+,\nabla v\rangle\,ds = 0. \tag{1.6}$$

Proof. The trivial Cauchy data $F'_D(Z)=u'_+|_{\partial\Omega}=0$ and (1.4d) imply $u'_+=0$ by Holmgren's uniqueness theorem. Now the statement follows by plugging the Cauchy

data of u'_- from (1.4b), (1.4c) into Green's second theorem applied to u'_- and v in D. □

For $a > 0$ define a refraction operator on the space of vector fields on ∂D by

$$R_a^{\partial D} : \mathfrak{X}(\partial D) \to \mathfrak{X}(\partial D), \quad X \mapsto X - (a-1)\langle X, \nu\rangle \nu. \tag{1.7}$$

The operator $R_a^{\partial D}$ multiplies the normal component of X by a and leaves the tangential component unchanged. Clearly, the zeros of X and $R_a^{\partial D}(X)$ coincide. Set $\nabla_a f = R_a^{\partial D}(\nabla f|_{\partial D})$, $f \in C^1(\bar{D})$. The main result can now be formulated as follows.

THEOREM 1.3. *Let $D \subset \mathbb{R}^2$ be an open, bounded, connected, and simply connected set with C^2-smooth boundary. If $u \in \mathcal{P}^{1,\alpha}(D)$ is not constant and $a > 0$, then the function space*

$$\mathcal{F}_{\partial D}(\nabla_a u) := \{\langle \nabla_a u, \nabla v\rangle : v \in \mathcal{P}^{1,\alpha}(D)\} \subset C^\alpha(\partial D) \tag{1.8}$$

is dense in $L^1(\partial D)$.

Observing that for the solution of (1.2) we have from (1.2b) and the continuity of u

$$\nabla u_+|_{\partial D} = R_a^{\partial D}(\nabla u_-|_{\partial D}) = \nabla_a u_-|_{\partial D},$$

the injectivity of F'_D in the two-dimensional case is now almost immediate.

COROLLARY 1.4. *Let D be an open, bounded, connected, and simply connected set with $C^{2,\alpha}$-smooth boundary and assume that $I \neq 0$ and $a > 0$, $a \neq 1$. Then the Fréchet derivative* (1.5) *is injective.*

The denseness of the spaces $\mathcal{F}(\nabla_a u)$ is well known if the vector field $\nabla_a u$ has no zeros. This can be deduced from the standard theory of Hilbert problems, as will be explained in the next section. The results in [9], [1] on the local uniqueness of F are restricted to injections I which ensure $\nabla u_+(x) \neq 0$, $x \in \partial D$ independently of D. In Theorem 1.3 we have not excluded vector fields with zeros on ∂D and therefore we need no restrictions on I in Corollary 1.4.

2. Sketch of the proof. Obviously, $h \in C^\alpha(\partial D)$ is an element of $\mathcal{F}_{\partial D}(\nabla_a u)$, if the oblique derivative problem

$$\text{Find } v \in \mathcal{P}^{1,\alpha}(D) \text{ satisfying } \langle \nabla_a u, \nabla v\rangle = h \text{ on } \partial D \tag{2.1}$$

is solvable. In arbitrary dimensions a solution theory for the Laplace equation with boundary condition $\langle X, \nabla v\rangle = h$ on ∂D, where X is some vector field on ∂D, is available only if the normal component of X has no zeros on ∂D (see [11]). Since u is harmonic in D, we have

$$\int_{\partial D} \langle \nabla_a u, \nu\rangle \, ds = a \int_{\partial D} \partial u/\partial \nu \, ds = 0,$$

and therefore this condition will never be satisfied for (2.1). In two dimensions oblique derivative problems are more thoroughly investigated through their equivalent formulation as Hilbert problems for holomorphic functions (see [6]). This provides a solution theory for the case where X has no zeros on ∂D. Unfortunately, this condition in general also will not be satisfied for (2.1). However, unlike the normal derivative, the gradient of a nonconstant harmonic function can vanish only on a set of measure zero on ∂D. Using this and the multiplicative structure on $\mathbb{R}^2 \simeq \mathbb{C}$, it is possible to

show the solvability of (2.1) for *enough inhomogeneities* h by considering a suitable modification of (2.1). On the other hand, this procedure restricts the proof to the two-dimensional case.

For $z \in \mathbb{C}$ we denote the real and imaginary part by $\operatorname{Re} z$ and $\operatorname{Im} z$, respectively. The complex conjugate of z is denoted by $\overline{z}$.

If f is holomorphic in D, then $\operatorname{Re} f$ and $\operatorname{Im} f$ are harmonic in D. If u is harmonic in D, then ∇u is antiholomorphic, i.e., $\partial u/\partial x_1 - i\partial u/\partial x_2$ is holomorphic in D. Since D is assumed to be simply connected, the converse is also true. If f is holomorphic in D, then there exists a harmonic function u on D with $\overline{f} \simeq \nabla u$. This sets up a one-to-one correspondence between $\mathcal{H}^\alpha(D)$ and the gradients of functions in $\mathcal{P}^{1,\alpha}(D)$. If $z, w \in \mathbb{C}$, then $\operatorname{Re}(z\overline{w})$ is equal to the Euclidean scalar product of z and w, both interpreted as vectors in $\mathbb{R}^2$.

Now let $u, v \in \mathcal{P}^{1,\alpha}(D)$ and define $f, g \in \mathcal{H}^\alpha(D)$ by $\nabla u \simeq \overline{f}$ and $\nabla v \simeq \overline{g}$. Define the refraction operator (1.7) on the complex functions on ∂D through the identification $\mathbb{R}^2 \simeq \mathbb{C}$, and set

$$\varphi_a := \overline{R_a^{\partial D}(\overline{f}|_{\partial D})} \in C^\alpha(\partial D)_{\mathbb{C}}. \tag{2.2}$$

Then we have $\nabla_a u \simeq \overline{\varphi}_a$. From the above we find $\operatorname{Re}(\overline{\varphi}_a g) = \langle \nabla_a u, \nabla v \rangle$, hence

$$\mathcal{F}_{\partial D}(\nabla_a u) = \mathcal{F}^c_{\partial D}(\varphi_a), \tag{2.3}$$

where

$$\mathcal{F}^c_{\partial D}(\varphi_a) := \{\operatorname{Re}(\overline{\varphi}_a g) : g \in \mathcal{H}^\alpha(D)\}. \tag{2.4}$$

Now we can reformulate Theorem 1.3 in terms of holomorphic functions.

THEOREM 2.1. *Assume that $f \in \mathcal{H}^\alpha(D)$ is not identically zero and that $a > 0$, and define φ_a as in* (2.2). *Then the function space $\mathcal{F}^c_{\partial D}(\varphi_a)$ is dense in $L^1(\partial D)$.*

The oblique derivative problem (2.1) is equivalent to the Hilbert problem

$$\text{Find } g \in \mathcal{H}^\alpha(D) \text{ satisfying } \operatorname{Re}(\overline{\varphi}_a g) = h \text{ on } \partial D. \tag{2.5}$$

Therefore Theorems 1.3 and 2.1 state that the inhomogeneities $h \in C^\alpha(\partial D)$ admitting a solution of (2.5) are dense in $L^1(\partial D)$. This denseness is fairly simple to show, if $\varphi_a(z) \neq 0$ for all $z \in \partial D$. For this we need the notion of the index of φ_a defined as the integer

$$\operatorname{Ind}(\varphi_a) = \frac{1}{2\pi} \arg \varphi_a \Big|_{\partial D}.$$

The Hilbert problem is solvable for all $h \in C^\alpha(\partial D)$ if and only if the index is non-negative (see [6]). The functions

$$\varphi_\lambda = \overline{R_\lambda^{\partial D}(\overline{f}|_{\partial D})}, \qquad \lambda = (1-t)a + t, \quad t \in [0,1],$$

have no zeros for all t. Therefore a continuity argument implies

$$\operatorname{Ind}(\varphi_a) = \operatorname{Ind}(f|_{\partial D}). \tag{2.6}$$

Since f is holomorphic, the index of $f|_{\partial D}$ is equal to the number of zeros of f in D. We thus have $\operatorname{Ind}(\varphi_a) \geqslant 0$, and therefore $C^\alpha(\partial D) \subset \mathcal{F}^c_{\partial D}(\varphi_a)$, which clearly implies the asserted $L^1(\partial D)$-denseness.

In [3] it is shown that the relation between the index of the boundary values of a holomorphic function and its zeros inside the region is still valid for the sectionally holomorphic function f_u with $\overline{f}_u|_D = \nabla u_-$, $\overline{f}_u|_{\Omega\setminus\bar{D}} = \nabla u_+$, provided that ∂D is analytic. In [9] Powell has proved under suitable restrictions on the Neumann data I that$\nabla u_+|_{\partial\Omega}$ has no zeros and its index is zero. By the above argument, this implies $\nabla u_+|_{\partial D} \neq 0$, whence the denseness of $\mathcal{F}_{\partial D}(\nabla_a u_-)$ follows. In [9] the condition $\nabla u_+(z) \neq 0$, $z \in \partial D$, is used to derive local injectivity of F. These results are generalized in [1].

For general currents I, there is no guarantee that ∇u_+ has no zeros on ∂D. If we have $\varphi_a(z) = 0$ for some $z \in \partial D$, then it is obvious that (2.5) can be solvable only if the inhomogeneity h also vanishes in z. Thus in this case $C^\alpha(\partial D) \not\subset \mathcal{F}^c_{\partial D}(\varphi_a)$, and therefore the difficulty in the proof of Theorem 2.1 is to work around the zeros of φ_a.

The proof, presented in the next section, consists of the following steps:

(i) With the aid of the Riemann mapping theorem, we will show that without loss of generality we may assume that

$$D = \mathcal{D} := \{z \in \mathbb{C} : |z| < 1\}, \qquad \partial D = \mathbf{S}^1 := \{z \in \mathbb{C} : |z| = 1\}.$$

(ii) We divide the boundary condition in (2.5) by $|\varphi_1|^2$, $\varphi_1 := \overline{R_1^{\mathbf{S}^1}(\overline{f}|_{\mathbf{S}^1})} = f|_{\mathbf{S}^1}$ and obtain

$$\operatorname{Re}(\overline{\varphi}_a g)/|\varphi_1|^2 = \operatorname{Re}\left(\overline{\varphi_a/\varphi_1}\cdot g/\varphi_1\right) = h/|\varphi_1|^2. \tag{2.7}$$

Noting that $\mathcal{F}^c_{\partial D}(\varphi_a)$ is a linear subspace of $L^1(\mathbf{S}^1)$, it is clear that the solvability of (2.5) need be shown only for some subset $\mathcal{I} \subset C^\alpha(\mathbf{S}^1)$ whose linear span is a dense subspace of $L^1(\mathbf{S}^1)$. We choose this subset so that the supports of its functions do not intersect with a neighborhood of the zeros of φ_1 which, by definition, coincide with those of φ_a. Then the right-hand side in (2.7) can be considered a function in $C^\alpha(\mathbf{S}^1)$ by setting it equal to zero outside the support of h. For a function φ on $\mathbf{S}^1$ we will denote the set of its zeros by $\mathrm{N}(\varphi)$ and define a set of suitable inhomogeneities for (2.5) by setting

$$C^\alpha(\mathbf{S}^1, J) := \{h \in C^\alpha(\mathbf{S}^1) : \operatorname{supp} h \subset J\}, \qquad J \subset \mathbf{S}^1, \tag{2.8}$$

$$\mathcal{I}(\varphi_a) := \bigcup_{\substack{J\subset\mathbf{S}^1\setminus\mathrm{N}(\varphi_a)\\ J \text{ closed, connected}}} C^\alpha(\mathbf{S}^1, J). \tag{2.9}$$

The span of $\mathcal{I}(\varphi_a)$ is dense in $L^1(\mathbf{S}^1)$.

If f is assumed to admit an extension to a holomorphic function in some neighborhood of $\bar{\mathcal{D}}$, then the set $\mathrm{N}(\varphi_1) = \mathrm{N}(f|_{\mathbf{S}^1})$ is finite. We prove that in this case $\psi := \varphi_a/\varphi_1$ can be extended into $\mathrm{N}(\varphi_1)$ as an analytic function ψ on $\mathbf{S}^1$. Furthermore, ψ vanishes nowhere on $\mathbf{S}^1$ and the index of ψ is zero. Thus the Hilbert problem

$$\text{Find } g \in \mathcal{H}^\alpha(\mathcal{D}) \text{ satisfying } \operatorname{Re}(\overline{\psi}g) = h \text{ on } \mathbf{S}^1 \tag{2.10}$$

is solvable for all $h \in C^\alpha(\mathbf{S}^1)$. Now if $h \in \mathcal{I}(\varphi_a)$ and $\tilde{g} \in \mathcal{H}^\alpha(\mathcal{D})$ is a solution of $\operatorname{Re}(\overline{\psi}\tilde{g}) = h/|\varphi_1|^2$ on $\mathbf{S}^1$, then $g := f\tilde{g} \in \mathcal{H}^\alpha(\mathcal{D})$ satisfies

$$\operatorname{Re}(\overline{\varphi}_a g) = \operatorname{Re}(\overline{\psi\varphi}_1 \cdot \varphi_1\tilde{g}) = |\varphi_1|^2 \operatorname{Re}(\overline{\psi}\tilde{g}) = h \text{ on } \mathbf{S}^1. \tag{2.11}$$

Thus if f is holomorphic in a neighborhood of $\bar{\mathcal{D}}$ we have

$$\mathcal{I}(\varphi_a) \subset \mathcal{F}^c_{\mathbf{S}^1}(\varphi_a), \tag{2.12}$$

hence for this case Theorem 2.1 is proven.

Note that in step (ii), we will make no use of $D = \mathcal{D}$. Only the assumption that ∂D is analytic will be needed. In this case it follows from elliptic regularity results that the interior potential u_- in (1.2) can be extended as a harmonic function in a neighborhood of $\bar{D}$. Thus for analytic boundaries Corollary 1.4 already can be deduced at this point of the proof.

The formulation of step (ii) with $D = \mathcal{D}$ is motivated by the fact that there exist explicit formulas for the solution of (2.10) for the unit disk. These formulas will be used in the next step.

(iii) Finally, we treat the general case $f \in \mathcal{H}^\alpha(\mathcal{D})$. For $r < 1$ we set

$$f_r(z) := f(rz), \quad |z| < 1/r, \qquad \varphi_a^{(r)} := \overline{R_a^{\mathbf{S}^1}(\overline{f}_r|_{\mathbf{S}^1})}, \quad \varphi_1^{(r)} := f_r|_{\mathbf{S}^1}.$$

Obviously, we have

$$\varphi_a^{(r)} \xrightarrow[r\to 1]{} \varphi_a, \quad \varphi_1^{(r)} \xrightarrow[r\to 1]{} \varphi_1 \qquad (C^\alpha(\mathbf{S}^1)_{\mathbb{C}}\text{-convergence}). \tag{2.13}$$

Since the functions f_r are holomorphic in a neighborhood of $\bar{\mathcal{D}}$, from step (ii) we have

$$\mathcal{I}(\varphi_a^{(r)}) \subset \mathcal{F}^c_{\mathbf{S}^1}(\varphi_a^{(r)}).$$

Let $h \in \mathcal{I}(\varphi_a)$ and $J \subset \mathbf{S}^1 \setminus \mathrm{N}(\varphi_a)$ be closed and connected with $\operatorname{supp} h \subset J$. By definition, φ_1 has no zeros in J. From the uniform convergence $\varphi_1^{(r)} \to \varphi_1$ it follows that there exists $r_0 < 1$, such that $\varphi_1^{(r)}$ has no zeros in J for $r_0 < r < 1$. Therefore, for these r we have $h \in \mathcal{I}(\varphi_a^{(r)})$. Consequently, there exist $g_r \in \mathcal{H}^\alpha(\mathcal{D})$ with boundary values satisfying

$$\mathrm{Re}(\overline{\varphi_a^{(r)}} g_r) = h, \qquad r_0 < r < 1. \tag{2.14}$$

Since the $\varphi_a^{(r)}$ approximate φ_a, we intend to show that

$$\mathrm{Re}(\overline{\varphi}_a g_r) \xrightarrow[r\to 1]{} h \qquad (L^1(\mathbf{S}^1)\text{-convergence}). \tag{2.15}$$

This establishes that $\mathcal{I}(\varphi_a)$ is contained in the closure of $\mathcal{F}^c_{\mathbf{S}^1}(\varphi_a)$ in $L^1(\mathbf{S}^1)$, which completes the proof of Theorem 2.1.

Bearing in mind that $\mathrm{Re}(\overline{z}w)$, $z, w \in \mathbb{C}$, is the Euclidean scalar product of z and w, we obtain the estimate

$$\begin{aligned}
\|\mathrm{Re}(\overline{\varphi}_a g_r) - h\|_{L^1(\mathbf{S}^1)} &= \left\|\mathrm{Re}(\overline{\varphi}_a g_r) - \mathrm{Re}(\overline{\varphi_a^{(r)}} g_r)\right\|_{L^1(\mathbf{S}^1)} \\
&= \left\|\mathrm{Re}\left((\overline{\varphi}_a - \overline{\varphi_a^{(r)}}) g_r\right)\right\|_{L^1(\mathbf{S}^1)} \\
&\leqslant \|\varphi_a - \varphi_a^{(r)}\|_{L^\infty(\mathbf{S}^1)_{\mathbb{C}}} \|g_r\|_{L^1(\mathbf{S}^1)_{\mathbb{C}}}.
\end{aligned}$$

From (2.13) we have $\|\varphi_a - \varphi_a^{(r)}\|_{L^\infty(\mathbf{S}^1)_{\mathbb{C}}} \to 0$. Thus, for the proof of (2.15), we have to show that the functions g_r can be chosen such that the restrictions $g_r|_{\mathbf{S}^1}$ are uniformly $L^1(\mathbf{S}^1)_{\mathbb{C}}$-bounded for $r \to 1$.

3. Proof of Theorem 2.1. Let D be as in Theorem 2.1 and $f \in \mathcal{H}^\alpha(D)$. The Riemann mapping theorem asserts the existence of a $C^{1,\alpha}$-diffeomorphism

$$\Phi : \bar{D} \to \bar{\mathcal{D}}$$

such that $\Phi|_D : D \to \mathcal{D}$ is biholomorphic. Let $u \in \mathcal{P}^{1,\alpha}(D)$ with $\nabla u \simeq \overline{f}$. Then $u^* := u \circ \Phi^{-1} \in C^{1,\alpha}(\bar{\mathcal{D}})$ is harmonic in $\mathcal{D}$. Let $f^* \in \mathcal{H}^\alpha(\mathcal{D})$ be defined by $\nabla u^* \simeq \overline{f}$,

$$\varphi_a := \overline{R_a^{\partial D}(\overline{f}|_{\partial D})}, \quad \text{and} \quad \varphi_a^* := \overline{R_a^{\mathbf{S}^1}(\overline{f^*}|_{\mathbf{S}^1})} \in C^\alpha(\mathbf{S}^1).$$

As usual, we denote the complex derivative of Φ by Φ'. If $z \in \mathbb{C}$, $z = a + ib$, $a, b \in \mathbb{R}$, then the multiplication by z under the identification $\mathbb{R}^2 \simeq \mathbb{C}$ is equivalent to the multiplication by the matrix $\left(\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right)$. Therefore we have

$$\det(J\Phi) = |\Phi'|^2,$$

where $J\Phi$ denotes the Jacobi matrix of Φ. In particular, Φ preserves the orientation and Φ' has no zeros. The multiplication of a line vector in $\mathbb{R}^2$ by $\left(\begin{smallmatrix} a & -b \\ b & a \end{smallmatrix}\right)$ from the right corresponds to multiplication by $\overline{z}$. Define

$$\Phi^* : L^1(\mathbf{S}^1) \to L^1(\partial D), \quad \phi \mapsto \phi \circ \Phi,$$

and for $q \in C(\partial D)$ let M_q be the multiplication mapping

$$M_q : L^1(\partial D) \to L^1(\partial D), \quad \psi \mapsto q \cdot \psi.$$

LEMMA 3.1. *The functions φ_a, φ_a^* and the spaces $\mathcal{F}^c_{\partial D}(\varphi_a)$, $\mathcal{F}^c_{\mathbf{S}^1}(\varphi_a^*)$ are related by*

$$\Phi^*(\varphi_a^*) = \varphi_a/\Phi' \quad \textit{and} \quad \mathcal{F}^c_{\partial D}(\varphi_a) = M_{|\Phi'|^2}\big(\Phi^*(\mathcal{F}^c_{\mathbf{S}^1}(\varphi_a^*))\big).$$

Proof. If

$$\gamma : [0, L) \to \partial D$$

denotes a parametrization of ∂D by the arclength with positive orientation, then

$$\Phi \circ \gamma : [0, L) \to \mathbf{S}^1$$

is a regular $C^{1,\alpha}$-parametrization of $\mathbf{S}^1$ with positive orientation. Let $z \in \partial D$, $z = \gamma(t)$, and $w = \Phi(z) \in \mathbf{S}^1$. Then from $(\Phi \circ \gamma)^{\cdot}(t) = \Phi'(z) \cdot \dot{\gamma}(t)$ and $\dot{\gamma}(t) = \tau_D(z)$ we obtain that

$$\tau_{\mathcal{D}}(w) = \tfrac{\Phi'(z)}{|\Phi'(z)|}\tau_D(z) \quad \text{and} \quad \nu_{\mathcal{D}}(w) = \tfrac{\Phi'(z)}{|\Phi'(z)|}\nu_D(z). \tag{3.1}$$

The gradients of u and u^* are related by

$$\nabla u^*(w) = \nabla(u \circ \Phi^{-1})(w) = \nabla u(z) \circ J\Phi^{-1}(w).$$

By the above remarks the multiplication by $J\Phi^{-1}(w)$ corresponds to the complex multiplication by $\overline{(\Phi^{-1})'(w)} = 1/\overline{\Phi'(z)}$, hence

$$f^*(w) = f(z)/\Phi'(z). \tag{3.2}$$

In two dimensions the refraction operator can be written $R_a^{\partial D}(X) = \langle X, \tau\rangle\tau + a\langle X, \nu\rangle\nu$, $X \in \mathfrak{X}(\partial D)$. Rewriting the scalar products in complex notation, we obtain

$$\varphi_a^*(w) = \operatorname{Re}\big(f^*(w)\tau_{\mathcal{D}}(w)\big)\overline{\tau_{\mathcal{D}}(w)} + a\operatorname{Re}\big(f^*(w)\nu_{\mathcal{D}}\big)\overline{\nu_{\mathcal{D}}(w)}.$$

From this, inserting (3.1) and (3.2), we derive

$$\begin{aligned}\varphi_a^*(w) &= \operatorname{Re}\Big(\tfrac{f(z)\tau_D(z)}{|\Phi'(z)|}\Big)\overline{\Big(\tfrac{\Phi'(z)}{|\Phi'(z)|}\,\tau_D(z)\Big)} + a\operatorname{Re}\Big(\tfrac{f(z)\nu_D(z)}{|\Phi'(z)|}\Big)\overline{\Big(\tfrac{\Phi'(z)}{|\Phi'(z)|}\,\nu_D(z)\Big)}\\ &= \tfrac{\overline{\Phi'(z)}}{|\Phi'(z)|^2}\big\{\operatorname{Re}\big(f(z)\tau_D(z)\big)\cdot\overline{\tau_D(z)} + a\operatorname{Re}\big(f(z)\nu_D(z)\big)\cdot\overline{\nu_D(z)}\,\big\}\\ &= \varphi_a(z)/\Phi'(z).\end{aligned}$$

This, in view of $\Phi^*(\varphi_a^*)(z) = \varphi_a^*(w)$, proves the first statement of the lemma.

For the second statement let $h \in \mathcal{F}^c_{\mathbf{S}^1}(\varphi_a^*)$. By definition there exists $g \in \mathcal{H}^\alpha(\mathcal{D})$ such that

$$\operatorname{Re}(\overline{\varphi_a^*}g) = h \quad \text{on } \mathbf{S}^1.$$

Then the boundary values of $\hat{g} := \Phi' \cdot (g \circ \Phi) \in \mathcal{H}^\alpha(D)$ satisfy

$$\begin{aligned}\operatorname{Re}\big(\overline{\varphi_a(z)}\hat{g}(z)\big) &= \operatorname{Re}\big(\overline{\varphi_a^*(w)\Phi'(z)}\Phi'(z)g(w)\big)\\ &= |\Phi'(z)|^2 h(w) = |\Phi'(z)|^2\Phi^*(h)(z),\end{aligned}$$

whence $M_{|\Phi'|^2}\big(\Phi^*(\mathcal{F}^c_{\mathbf{S}^1}(\varphi_a^*))\big) \subset \mathcal{F}^c_{\partial D}(\varphi_a)$. The converse inclusion is derived in an analogous manner, by replacing Φ by its inverse Φ^{-1}. □

In particular, the mappings Φ^* and $M_{|\Phi|^2}$ are continuous and continuously invertible. Hence they map dense subsets of $L^1(\mathbf{S}^1)$ and $L^1(\partial D)$ onto dense subsets of $L^1(\partial D)$. Therefore the $L^1(\partial D)$-denseness of $\mathcal{F}^c_{\partial D}(\varphi_a)$ is equivalent to the $L^1(\mathbf{S}^1)$-denseness of $\mathcal{F}^c_{\mathbf{S}^1}(\varphi_a^*)$. Consequently, without loss of generality from now on we may assume that $D = \mathcal{D}$.

LEMMA 3.2. *The set of zeros* $\mathrm{N}(\varphi_1)$ *is closed and has measure zero in* $\mathbf{S}^1$. *The linear span of* $\mathcal{I}(\varphi_a)$ *is dense in* $L^p(\mathbf{S}^1)$ *for any* $1 \leqslant p \leqslant 2$.

Proof. The first statement is trivial. Proof that the set $\{z \in \mathbf{S}^1 : f(z) = 0\}$ has measure zero in $\mathbf{S}^1$ can be found in [12, Theorem 1.9, p. 203].

Since the $L^p(\mathbf{S}^1)$-norms, $p < 2$, are weaker than the $L^2(\mathbf{S}^1)$-norm, it suffices to show $L^2(\mathbf{S}^1)$-denseness of $\mathcal{I}(\varphi_a)$. Let $h' \in L^2(\mathbf{S}^1)$ be orthogonal to $\mathcal{I}(\varphi_a)$. Then for any $z_0 \in \mathbf{S}^1 \setminus \mathrm{N}(\varphi_a)$ we choose a closed and connected neighborhood $J \subset \mathbf{S}^1 \setminus \mathrm{N}(\varphi_a)$ of z_0 and a function

$$\chi \in C^\alpha(\mathbf{S}^1, J) \quad \text{such that} \quad \chi \geqslant 0, \quad \chi(z_0) > 0.$$

We select a sequence $(h_k)_{k\in\mathbb{N}}$ in $C^\alpha(\mathbf{S}^1)$ converging to h' in $L^2(\mathbf{S}^1)$. Then, since $\chi h_k \in \mathcal{I}(\varphi_a)$, we have

$$\int_{\mathbf{S}^1} h'\chi h_k\, ds = 0 \quad \text{for all } k \in \mathbb{N}.$$

Passing to the limit $k \to \infty$ we find $\int_{\mathbf{S}^1}\chi(h')^2\, ds = 0$. Therefore h' vanishes almost everywhere in the neighborhood $\{z \in \mathbf{S}^1 : \chi(z) > 0\}$ of z_0. Since $\mathrm{N}(\varphi_a)$ has measure

zero, this implies $h' = 0$ almost everywhere. Thus $\mathcal{I}(\varphi_a)^\perp = \{0\}$, and the third assertion is established. □

LEMMA 3.3. *Let* arg *be the argument function on* $\mathbb{C} \setminus \{0\}$ *with values in* $(-\pi, \pi]$. *Then for all* $z \in \mathbf{S}^1 \setminus \mathrm{N}(\varphi_a)$

$$\min(1, a) \leqslant |\varphi_a(z)/\varphi_1(z)| \leqslant \max(1, a), \tag{3.3}$$

$$|\arg(\varphi_a(z)/\varphi_1(z))| \leqslant \arccos\left(2\sqrt{a}/(1+a)\right) < \frac{\pi}{2}. \tag{3.4}$$

Proof. If $\nu(z)$, $\tau(z)$ is used as a coordinate system, then we have $\varphi_a(z) = (ax_1, x_2)$ provided that $\varphi_1(z) = (x_1, x_2)$. From this it follows that

$$\begin{aligned} |\varphi_1(z)| \leqslant |\varphi_a(z)| \leqslant a|\varphi_1(z)| \qquad & \text{if } a \geqslant 1, \\ a|\varphi_1(z)| \leqslant |\varphi_a(z)| \leqslant |\varphi_1(z)| \qquad & \text{if } a \leqslant 1, \end{aligned}$$

which establishes the first assertion. Interpreting $\nu(z)$ and $\tau(z)$ as complex numbers we define

$$\zeta_a(x_1, x_2) := \frac{ax_1\nu(z) + x_2\tau(z)}{x_1\nu(z) + x_2\tau(z)}, \quad (x_1, x_2) \in \mathbb{R}^2 \setminus \{0\},$$

and

$$\vartheta_a^* := \sup_{(x_1,x_2)\in\mathbb{R}^2\setminus\{0\}} |\arg(\zeta_a(x_1, x_2))|. \tag{3.5}$$

From these definitions it is obvious that $\left|\arg\left(\varphi_a(z)/\varphi_1(z)\right)\right| \leqslant \vartheta_a^*$. A simple computation shows that

$$\mathrm{Re}(\zeta_a(x_1, x_2)) = \frac{ax_1^2 + x_2^2}{x_1^2 + x_2^2} > 0, \quad (x_1, x_2) \in \mathbb{R}^2 \setminus \{0\}. \tag{3.6}$$

Since the function arg has discontinuities only on the half-line $\{z \in \mathbb{R} : z \leqslant 0\}$, the function $|\arg \circ \zeta_a|$ is continuous on $\mathbb{R}^2 \setminus \{0\}$. Since from the definitions it is obvious that ζ_a does depend only on the argument of (x_1, x_2), it suffices to take the supremum in (3.5) over the unit circle. Since continuous functions on compact sets assume their maximum, there exists (x_1^*, x_2^*) on $\mathbf{S}^1$ such that

$$\vartheta_a^* = |\arg(\vartheta_a(x_1^*, x_2^*))|.$$

From (3.6) we obtain $\vartheta_a^* < \frac{\pi}{2}$. Finally, the explicit expression

$$\vartheta_a^* = \arccos(2\sqrt{a}/(1+a))$$

follows from elementary calculations. □

LEMMA 3.4. *Suppose that* f *admits an extension as a holomorphic function in some neighborhood of* $\overline{\mathcal{D}}$. *Then the set* $\mathrm{N}(\varphi_1)$ *is finite and the function* $\varphi_a(z)/\varphi_1(z)$, $z \in \mathbf{S}^1 \setminus \mathrm{N}(\varphi_1)$ *can be extended as an analytic function* ψ *into* $\mathrm{N}(\varphi_1)$. *The extension* ψ *has no zeros and its index is zero.*

Proof. The smoothness of ψ need only be shown for points in the finite set $\mathrm{N}(\varphi_1)$. Let $z_0 \in \mathbf{S}^1$ with $\varphi_1(z) = 0$ and let u be the harmonic function with $\nabla u \simeq \overline{f}$. We claim that there exists a holomorphic function f_a defined in some ε-neighborhood $U_\varepsilon(z_0) := \{z \in \mathbb{C} : |z - z_0| < \varepsilon\}$ of z_0 such that

$$f_a|_{\mathbf{S}^1\cap U_\varepsilon} = \varphi_a. \tag{3.7}$$

Indeed, if ε is small enough, by the Cauchy–Kowalevski theorem there exists a solution v of

$$\triangle v = 0 \quad \text{in } U_\varepsilon(z_0) \qquad \text{and} \qquad v = u,\ \frac{\partial v}{\partial \nu} = a\frac{\partial u}{\partial \nu} \quad \text{on } \mathbf{S}^1 \cap U_\varepsilon(z_0).$$

Then obviously $\nabla v = R_a(\nabla u)$, and therefore the holomorphic function f_a defined by $\overline{f}_a \simeq \nabla v$ satisfies (3.7).

Thus in some neighborhood of z_0 on $\mathbf{S}^1$ the function φ_a/φ_1 is equal to the restriction of the meromorphic function f_a/f. If this function would have a pol in z_0, the values of $f_a(z)/f(z)$, $z \neq z_0$, would be unbounded in any neighborhood of z_0 in $\mathbf{S}^1$, and this contradicts (3.3) of Lemma 3.3. Consequently, f_a/f is holomorphic in some neighborhood of z_0, and this proves that φ_a/φ_1 admits an analytic extension onto all of $\mathbf{S}^1$.

Clearly, the estimates of Lemma 3.3 are valid on all of $\mathbf{S}^1$. From this, the last statement of Lemma 3.4 is obvious. □

For the solution of the Hilbert problem (2.10), we will have to define a logarithm of the function $-\psi/\overline{\psi}$ on $\mathbf{S}^1$. At this point, in the solution theory of a general Hilbert problem the index of ψ is important. In our special case we can use the estimate (3.4) to define a logarithm of $-\psi/\overline{\psi}$ somewhat more directly. Therefore the index of ψ will implicitly enter only in the proof of Theorem 2.1. Let $\vartheta_a^* := \arccos(2\sqrt{a}/(1+a))$ as in the proof of Lemma 3.3. With $\vartheta_a := \pi/2 - \vartheta_a^* > 0$ we can rewrite (3.4) in the form

$$\arg(\psi) \in [-\pi/2 + \vartheta_a, \pi/2 - \vartheta_a],$$

whence

$$\arg(\psi/\overline{\psi}) = \arg(\psi^2/|\psi|^2) = \arg(\psi^2) \in [-\pi + 2\vartheta_a, \pi - 2\vartheta_a]$$

follows. Defining a second argument function Arg with values in $[0, 2\pi)$, we get

$$\operatorname{Arg}(-\psi/\overline{\psi}) \in [2\vartheta_a, 2\pi - 2\vartheta_a].$$

If Log denotes the branch of the logarithm corresponding to Arg, that is, $\operatorname{Log}(z) = \log|z| + i\operatorname{Arg}(z)$ where log stands for the usual real logarithm, then the function

$$\operatorname{Log}(-\psi/\overline{\psi}) : \mathbf{S}^1 \to \mathbb{C}$$

is analytic on $\mathbf{S}^1$. Since the values of $-\psi/\overline{\psi}$ are on the unit circle, the values of $\operatorname{Log}(-\psi/\overline{\psi})$ are purely imaginary. For later use we note

$$\tfrac{1}{i}\operatorname{Log}\big(-\psi(z)/\overline{\psi}(z)\big) \in [2\vartheta_a, 2\pi - 2\vartheta_a], \qquad z \in \mathbf{S}^1. \tag{3.8}$$

There exist explicit formulas for the solution of (2.10) in terms of the Cauchy integral operator, which is defined by

$$A(\phi)(z) := \frac{1}{\pi i}\int_{\mathbf{S}^1} \frac{\phi(\zeta)}{\zeta - z}\, d\zeta, \qquad z \in \mathbb{C}, \quad \phi \in C^\alpha(\mathbf{S}^1)_{\mathbb{C}}.$$

We collect some properties of A from [5].

The function $A(\phi)$ is holomorphic in $\mathbb{C} \setminus \mathbf{S}^1$. The functions $A(\phi)_+ := A(\phi)|_{\mathbb{C}\setminus\overline{\mathcal{D}}}$ and $A(\phi)_- := A(\phi)|_{\mathcal{D}}$ can be extended onto $\mathbf{S}^1$ as functions in $C^\alpha(\mathbb{C}\setminus\mathcal{D})$ and $C^\alpha(\overline{\mathcal{D}})$, respectively. We have $\lim_{|z|\to\infty} A(\phi)(z) = 0$ uniformly in all directions. For $z \in \mathbf{S}^1$

the integral $A(\phi)(z)$ exists as a Cauchy principal value and $A(\phi)|_{\mathbf{S}^1} \in C^\alpha(\mathbf{S}^1)$. To avoid ambiguities, we define

$$\mathbf{A}(\phi) := A(\phi)|_{\mathbf{S}^1}, \qquad \phi \in C^\alpha(\mathbf{S}^1)_{\mathbb{C}}.$$

The mappings

$$C^\alpha(\mathbf{S}^1)_{\mathbb{C}} \to C^\alpha(\mathbf{S}^1)_{\mathbb{C}},\, C^\alpha(\mathbb{C}\setminus\mathcal{D})_{\mathbb{C}},\, C^\alpha(\bar{\mathcal{D}})_{\mathbb{C}}, \quad \phi \mapsto \mathbf{A}(\phi),\, A(\phi)_+,\, A(\phi)_-$$

are continuous. Their values on $\mathbf{S}^1$ are related by the Sokhotski–Plemelj formulas

$$A(\phi)_- - A(\phi)_+ = 2\phi \quad \text{and} \quad A(\phi)_- + A(\phi)_+ = 2\mathbf{A}(\phi) \quad \text{on } \mathbf{S}^1.$$

Later in the proof we will also need the facts that $\mathbf{A}^2 = \mathrm{Id}_{C^\alpha(\mathbf{S}^1)_{\mathbb{C}}}$ and that $\mathbf{A}$ can be extended as a continuous linear operator $L^2(\mathbf{S}^1)_{\mathbb{C}} \to L^2(\mathbf{S}^1)_{\mathbb{C}}$.

THEOREM 3.5. *If f admits an extension as a holomorphic function in some neighborhood of $\bar{\mathcal{D}}$, then the Hilbert problem* (2.5) *is solvable for any inhomogeneity $h \in \mathcal{I}(\varphi_a)$, that is, $\mathcal{I}(\varphi_a) \subset \mathcal{F}^c_{\mathbf{S}^1}(\varphi_a)$. If ψ is as in Lemma* 3.4*, then a solution g is given by*

$$H(z) := \exp\big(\tfrac{1}{2}A(\mathrm{Log}(-\psi/\overline{\psi}))\big)(z), \qquad z \in \mathbb{C}, \tag{3.9a}$$

$$G(z) := \tfrac{1}{2}H(z)\cdot A\big(-h/(|\varphi_1|^2\psi H_+)\big)(z), \qquad z \in \mathbb{C}, \tag{3.9b}$$

$$\tilde{g}(z) := G_-(z) + \overline{G_+(1/\overline{z})}, \qquad z \in \mathcal{D}, \tag{3.9c}$$

$$g(z) := f(z)\tilde{g}(z), \qquad z \in \mathcal{D}. \tag{3.9d}$$

Proof. As described in the preceding section, $\tilde{g}$ is the solution of

$$\tilde{g} \in \mathcal{H}^\alpha(\mathcal{D}) \text{ with } \mathrm{Re}(\overline{\psi}\tilde{g}) = h/|\varphi_1|^2. \tag{3.10}$$

The formulas (3.9a)–(3.9c) summarize the solution of (3.10) by transforming it into a Riemann problem (see [6]).

The Sokhotski–Plemelj formulas yield

$$\tfrac{1}{2}A(\mathrm{Log}(-\psi/\overline{\psi}))_- - \tfrac{1}{2}A(\mathrm{Log}(-\psi/\overline{\psi}))_+ = \mathrm{Log}(-\psi/\overline{\psi}) \quad \text{on } \mathbf{S}^1.$$

Taking the exponential, we deduce that H is a solution of the homogeneous Riemann problem

$$\overline{\psi}H_- + \psi H_+ = 0 \quad \text{on } \mathbf{S}^1.$$

Since $\exp z \neq 0$ for all $z \in \mathbb{C}$ the boundary values H_+ have no zeros. For brevity we set $\delta := -h/(|\varphi_1|^2\psi H_+)$. We recall the fact that we have set $\delta(z) = 0$ if $z \notin \operatorname{supp} h$, implying that $\delta \in C^\alpha(\mathbf{S}^1)_{\mathbb{C}}$. On $\mathbf{S}^1$ we have

$$\begin{aligned}\overline{\psi}G_- + \psi G_+ &= \tfrac{1}{2}(\overline{\psi}H_-A(\delta)_- + \psi H_+A(\delta)_+) = \tfrac{1}{2}\psi H_+(-A(\delta)_- + A(\delta)_+)\\ &= -\psi H_+\delta = h/|\varphi_1|^2.\end{aligned}$$

From $1/z = \overline{z}$, $z \in \mathbf{S}^1$, we find $\overline{G_+(1/\overline{z})} = \overline{G_+(z)}$, $z \in \mathbf{S}^1$, whence

$$\begin{aligned}\mathrm{Re}(\overline{\psi}\tilde{g}) &= \mathrm{Re}(\overline{\psi}G_- + \overline{\psi G_+}) = \mathrm{Re}(\overline{\psi}G_- + \psi G_+)\\ &= h/|\varphi_1|^2\end{aligned}$$

follows. Therefore the boundary values of g satisfy

$$\mathrm{Re}(\overline{\varphi}_a g) = |\varphi_1|^2 \,\mathrm{Re}(\overline{\psi}\tilde{g}) = h. \qquad \square$$

Now we consider the case of a general $f \in \mathcal{H}^\alpha(\mathcal{D})$ and for $0 < r < 1$ define

$$f_r(z) = f(rz), \quad \varphi_1^{(r)} := f_r|_{\mathbf{S}^1}, \quad \varphi_a^{(r)} := \overline{R_a^{\mathbf{S}^1}(\overline{f}_r|_{\mathbf{S}^1})}, \quad \psi_r := \varphi_a^{(r)}/\varphi_1^{(r)}.$$

The functions f_r are holomorphic in a neighborhood of $\bar{\mathcal{D}}$ and hence the functions ψ_r are analytic on $\mathbf{S}^1$. The function H in (3.9a) does not depend on the inhomogeneity h. Let

$$H(r;z) := \exp(A(i\phi_r)(z)), \quad z \in \mathbb{C}, \qquad \phi_r := \tfrac{1}{2i}\,\mathrm{Log}(-\psi_r/\overline{\psi}_r)$$

be formed correspondingly for f_r. From (3.8) we have

$$\phi_r(z) \in [\vartheta_a, \pi - \vartheta_a], \qquad z \in \mathbf{S}^1, \quad 0 < r < 1. \tag{3.11}$$

In the investigation of the convergence of $H(r;\cdot)$ for $r \to 1$, we will frequently use the fact that for a compact set $M \subset \mathbb{C}$ the multiplication mapping

$$C^\alpha(M)_{\mathbb{C}} \times C^\alpha(M)_{\mathbb{C}} \to C^\alpha(M)_{\mathbb{C}}, \quad (f,g) \mapsto fg,$$

and the inverse mapping

$$\{f \in C^\alpha(M)_{\mathbb{C}} : f(z) \neq 0,\, z \in M\} \to C^\alpha(M)_{\mathbb{C}}, \quad f \mapsto 1/f,$$

are continuous. Further, if $U \subset \mathbb{C}$ is open, then $C^\alpha(M,U)_{\mathbb{C}} := \{f \in C^\alpha(M)_{\mathbb{C}} : f(M) \subset U\}$ is open in $C^\alpha(M)_{\mathbb{C}}$ and, for $F \in C^\alpha(U)_{\mathbb{C}}$, the mapping

$$C^\alpha(M,U)_{\mathbb{C}} \to C^\alpha(M)_{\mathbb{C}}, \quad f \mapsto F \circ f,$$

is continuous. The fact that the images of these mappings are in $C^\alpha(M)_{\mathbb{C}}$ was already used above.

LEMMA 3.6. *If $J \subset \mathbf{S}^1 \setminus \mathrm{N}(\varphi_a)$ is closed and connected, then the one-sided boundary values $H(r;\cdot)_\pm|_J$ are convergent in $C^\alpha(J)_{\mathbb{C}}$. The limit functions have no zeros in J.*

Proof. Let $\tilde{J} \subset \mathrm{N}(\varphi_a)$ be closed and connected. Since $\varphi_1^{(r)}$, $\varphi_a^{(r)}$ converge in $C^\alpha(\mathbf{S}^1)_{\mathbb{C}}$ to φ_1 and φ_a, both of which have no zeros on $\tilde{J}$, it follows that

$$(\psi_r/\overline{\psi}_r)|_{\tilde{J}} = (\varphi_a^{(r)}/\varphi_1^{(r)} \cdot \overline{\varphi_1^{(r)}}/\overline{\varphi_a^{(r)}})|_{\tilde{J}} \quad \text{converges for } r \to 1 \text{ in } C^\alpha(\tilde{J})_{\mathbb{C}}.$$

Hence

$$\phi_r|_{\tilde{J}} \text{ converges for } r \to 1 \text{ in } C^\alpha(\tilde{J})_{\mathbb{C}}. \tag{3.12}$$

In particular, ϕ_r is pointwise convergent outside the set $\mathrm{N}(\varphi_a)$ of measure zero. From (3.11) and Lebesgue's convergence theorem we obtain that

$$\phi_r \text{ converges for } r \to 1 \text{ in any } L^p(\mathbf{S}^1)_{\mathbb{C}},\ 1 \leqslant p < \infty. \tag{3.13}$$

Now, if $J \subset \mathbf{S}^1 \setminus \mathrm{N}(\varphi_a)$ is closed and connected, the $C^\alpha(J)_{\mathbb{C}}$-convergence of $\mathbf{A}(i\phi_r)|_J$ follows by a suitable splitting of the integral. For this we choose a closed

and connected set $\tilde{J} \subset \mathbf{S}^1 \setminus \mathrm{N}(\varphi_a)$ containing J in the interior and a real-valued $\chi \in C^\alpha(\mathbf{S}^1)$ such that

$$\operatorname{supp}\chi \subset \tilde{J}, \quad \chi \geqslant 0, \quad \chi = 1 \text{ on a neighborhood of } J.$$

Then $\chi\phi_r$, and in turn $\mathbf{A}(i\chi\phi_r)$, is $C^\alpha(\mathbf{S}^1)_{\mathbb{C}}$ convergent as $r \to 1$. The second part of the density $(1-\chi)\phi_r$ is $L^1(\mathbf{S}^1)_{\mathbb{C}}$-convergent and equal to zero in a neighborhood of J, which is independent of r. Hence $\mathbf{A}(i(1-\chi)\phi_r)|_J$ converges together with all its derivatives. Therefore

$$\mathbf{A}(i\phi_r)|_J = \mathbf{A}(i\chi\phi_r)|_J + \mathbf{A}(i(1-\chi)\phi_r)|_J \text{ converges for } r \to 1 \text{ in } C^\alpha(J)_{\mathbb{C}}.$$

The Sokhotski–Plemelj formulas imply $A(i\phi_r)_\pm = \mathbf{A}(i\phi_r) \mp i\phi_r$ on $\mathbf{S}^1$, whence, in view of (3.12), the $C^\alpha(J)_{\mathbb{C}}$ convergence of $A(i\phi_r)_\pm|_J$ follows. Since the application of the exponential preserves this convergence, the lemma is proved. □

The crucial point in part (iii) of the sketch of the proof is to show the uniform $L^1(\mathbf{S}^1)_{\mathbb{C}}$-boundedness of $H(r;\cdot)_\pm$. If it were possible to extend $\mathbf{A}$ to an endomorphism of $L^\infty(\mathbf{S}^1)_{\mathbb{C}}$, this would follow immediately from (3.11). But it is known that for a continuous, but not Hölder-continuous, density ϕ the function $\mathbf{A}(\phi)$ might have unbounded singularities. So $\mathbf{A}(L^\infty(\mathbf{S}^1)_{\mathbb{C}})$ is not even contained in $L^\infty(\mathbf{S}^1)_{\mathbb{C}}$. From (3.13) the density ϕ_r, and hence $\mathbf{A}(i\phi_r)$ and $A(i\phi_r)_\pm$, is $L^2(\mathbf{S}^1)_{\mathbb{C}}$-convergent as $r \to 1$. Thus we need a statement that the singularities of $\lim_{r\to 1}\mathbf{A}(i\phi_r)$ in $\mathrm{N}(\varphi_a)$ are weak enough such that $\exp(\mathbf{A}(i\phi_r))$ is still uniformly $L^1(\mathbf{S}^1)_{\mathbb{C}}$-bounded. This is achieved with the aid of the next theorem, which is due to Smirnov ([10, Hilfssatz 2]).

THEOREM 3.7. *Assume that $\phi \in C^\alpha(\mathbf{S}^1)$ satisfies $\phi(z) \in [\vartheta, \pi - \vartheta]$ for all $z \in \mathbf{S}^1$ and some $\vartheta > 0$. Then*

$$\|\exp(\mathbf{A}(i\phi))\|_{L^1(\mathbf{S}^1)_{\mathbb{C}}} \leqslant e^{\|\mathrm{Re}(\mathbf{A}(i\phi))\|_{L^1(\mathbf{S}^1)}} / \sin\vartheta.$$

Here we have set $\|F\|_{L^1(\mathbf{S}^1)_{\mathbb{C}}} := \frac{1}{2\pi}\int_0^{2\pi} \big|F(e^{it})\big|\,dt$, $F \in L^1(\mathbf{S}^1)_{\mathbb{C}}$.

Proof. Clearly, it suffices to prove the estimate for $\|\exp(\tilde{\phi})\|_{L^1(\mathbf{S}^1)}$ with $\tilde{\phi} := \mathrm{Re}(\mathbf{A}(i\phi))$. In the sequel we identify $C^\alpha(\mathbf{S}^1)_{\mathbb{C}}$ with $C^\alpha(\mathbb{R}/2\pi)_{\mathbb{C}}$ by the parametrization $t \mapsto e^{it}$.

On the unit circle the Cauchy integral operator can be written in the form

$$\begin{aligned}\mathbf{A}(\delta)(z) &= \frac{1}{\pi i}\int_{\mathbf{S}^1} \frac{\delta(\zeta)}{\zeta - z}\,d\zeta \\ &= \frac{1}{2\pi i}\int_0^{2\pi} \Big(\cot\frac{\tau - t}{2} + i\Big)\delta(\tau)\,d\tau, \qquad \delta \in C^\alpha(\mathbf{S}^1)_{\mathbb{C}}, \quad z = e^{it}.\end{aligned}$$

Denoting by $\mathbf{1}_{\mathbf{S}^1}$ the density equal to 1 everywhere on $\mathbf{S}^1$, it follows that $\mathbf{A}(i\phi) = \tilde{\phi} + ic_\phi\mathbf{1}_{\mathbf{S}^1}$, where $c_\phi = \frac{1}{2\pi}\int_0^{2\pi}\phi(\tau)\,d\tau$. Together with the formulas $\mathbf{A}^2 = \mathrm{Id}_{\mathbf{S}^1}$, $\mathbf{A}(\mathbf{1}_{\mathbf{S}^1}) = \mathbf{1}_{\mathbf{S}^1}$, and $\tilde{\phi} = \mathbf{A}(i\phi) - i\,\mathrm{Im}(\mathbf{A}(i\phi)) = \mathbf{A}(i\phi) - ic_\phi\mathbf{1}_{\mathbf{S}^1}$, this implies that

$$\begin{aligned}\mathbf{A}(\tilde{\phi} + i\phi) &= \mathbf{A}(\mathbf{A}(i\phi) - ic_\phi\mathbf{1}_{\mathbf{S}^1}) + \tilde{\phi} + ic_\phi\mathbf{1}_{\mathbf{S}^1} \\ &= i\phi + \tilde{\phi}.\end{aligned}$$

Now, from the Sokhotski–Plemelj formulas it can be seen that the holomorphic function

$$g(z) := \frac{1}{2\pi i}\int_{\mathbf{S}^1}\frac{\tilde{\phi}(\zeta) + i\phi(\zeta)}{\zeta - z}\,d\zeta = \tfrac{1}{2}\mathbf{A}(\tilde{\phi} + i\phi)(z), \quad z \in \mathcal{D},$$

has boundary values $g_- = \tilde{\phi} + i\phi$. Hence $e^g \in \mathcal{H}^\alpha(\mathcal{D})$ has boundary values $e^{\tilde{\phi}+i\phi}$. The Cauchy integral formula yields

$$e^{g(0)} = \frac{1}{2\pi i} \int_{\mathbf{S}^1} e^{(\tilde{\phi}+i\phi)(\zeta)} \, \frac{d\zeta}{\zeta} = \frac{1}{2\pi} \int_0^{2\pi} e^{\tilde{\phi}(\tau)+i\phi(\tau)} \, d\tau. \tag{3.14}$$

Taking the imaginary part of this equation we arrive at

$$\operatorname{Im}(e^{g(0)}) = \frac{1}{2\pi} \int_0^{2\pi} e^{\tilde{\phi}(\tau)} \sin(\phi(\tau)) \, d\tau.$$

Clearly $e^{\tilde{\phi}(\tau)} > 0$, and the assumption $\phi(\tau) \in [\vartheta, \pi - \vartheta]$ implies $\sin(\phi(\tau)) \geqslant \sin\vartheta > 0$. Thus

$$\operatorname{Im}(e^{g(0)}) / \sin\vartheta \geqslant \frac{1}{2\pi} \int_0^{2\pi} e^{\tilde{\phi}(\tau)} \, d\tau = \|\exp\tilde{\phi}\|_{L^1(\mathbf{S}^1)}.$$

If to the left-hand side we apply the estimate

$$\operatorname{Im}(e^{g(0)}) \leqslant \left| e^{g(0)} \right| = e^{\operatorname{Re} g(0)} = \exp\Big(\frac{1}{2\pi} \int_0^{2\pi} \tilde{\phi}(\tau) \, d\tau \Big) \leqslant e^{\|\tilde{\phi}\|_{L^1(\mathbf{S}^1)}},$$

the claim of the theorem follows. □

The asserted boundedness of the $H(r;\cdot)_\pm$ can now be proved.

COROLLARY 3.8. *The boundary values of the functions $H(r;\cdot)_\pm$ are uniformly $L^1(\mathbf{S}^1)_\mathbb{C}$-bounded as $r \to 1$.*

Proof. From Theorem 3.7 together with (3.11) we obtain that

$$\|H(r;\cdot)\|_{L^1(\mathbf{S}^1)_\mathbb{C}} \leqslant e^{\|\operatorname{Re}(\mathbf{A}(i\phi_r))\|_{L^1(\mathbf{S}^1)}} / \sin\vartheta_a. \tag{3.15}$$

In (3.12) we have already seen that ϕ_r and, consequently, $\mathbf{A}(i\phi_r)$ converge as $r \to 1$ in $L^2(\mathbf{S}^1)_\mathbb{C}$. Since on compact sets L^2-convergence is stronger than L^1-convergence, the right-hand side in (3.15) is convergent for $r \to 1$. Hence $H(r;\cdot)|_{\mathbf{S}^1}$ is uniformly bounded as $r \to 1$. Since the ϕ_r are real-valued, the assertion follows from

$$H(r;\cdot)_\pm = \exp(\mathbf{A}(i\phi_r) \mp i\phi_r) = H(r;\cdot)|_{\mathbf{S}^1} e^{\mp i\phi_r} \qquad \text{on } \mathbf{S}^1. \qquad \square$$

Now suppose we are given $h \in \mathcal{I}(\varphi_a)$ and $r_0 < 1$ is big enough to ensure that $h \in \mathcal{I}(\varphi_a^{(r)})$ for $r_0 < r < 1$. Then define functions $G(r;\cdot)$, $\tilde{g}_r$, and g_r by replacing φ_1, φ_a in the definitions (3.9b)–(3.9d) by $\varphi_1^{(r)}$ and $\varphi_a^{(r)}$, respectively, so that $g_r \in \mathcal{H}^\alpha(\mathcal{D})$ satisfy $\operatorname{Re}(\overline{\varphi_a^{(r)}} g_r) = h$ on $\mathbf{S}^1$. In view of the remarks at the end of (iii) in the preceding section, the proof of Theorem 2.1 is finished by the following lemma.

LEMMA 3.9. *The functions $g_r|_{\mathbf{S}^1}$ are uniformly $L^1(\mathbf{S}^1)_\mathbb{C}$-bounded for $r \to 1$.*

Proof. Let $J \subset \mathbf{S}^1 \setminus \mathrm{N}(\varphi_a)$ be a closed and connected set such that $\operatorname{supp} h \subset J$. Consider the density

$$\delta_r := -h / \big(|\varphi_1^{(r)}|^2 \psi_r H(r;\cdot)_+ \big) = -h / \Big(\varphi_a^{(r)} \overline{\varphi_1^{(r)}} H(r:\cdot)_+ \Big),$$

of $\mathbf{A}$ in the definition (3.9b) of $G(r;\cdot)$. If $\tilde{J} \subset \mathbf{S}^1 \setminus \mathrm{N}(\varphi_a)$ is closed and connected and contains J in its interior, then by Lemma 3.6 the functions $\varphi_a^{(r)} \overline{\varphi_1^{(r)}} H(r;\cdot)_+|_{\tilde{J}}$ converge in $C^\alpha(\tilde{J})$ to some function without zeros in $\tilde{J}$. Since we have defined δ_r to

be zero outside the support of h, the density δ_r is $C^\alpha(\mathbf{S}^1)_{\mathbb{C}}$-convergent. Thus $\mathbf{A}(\delta_\mathbf{r})$ is convergent in $C^\alpha(\mathbf{S}^1)_{\mathbb{C}}$. The one-sided boundary values of $G(r;\cdot)$ are given by

$$G(r;z)_\pm = \tfrac{1}{2}H(r;z)_\pm \cdot (\mathbf{A}(\delta_r) \mp \delta_r(z)), \qquad z \in \mathbf{S}^1.$$

From

$$\|F_1F_2\|_{L^1(\mathbf{S}^1)_{\mathbb{C}}} \leqslant \|F_1\|_{L^1(\mathbf{S}^1)_{\mathbb{C}}}\|F_2\|_{L^\infty(\mathbf{S}^1)_{\mathbb{C}}}, \quad F_1 \in L^1(\mathbf{S}^1)_{\mathbb{C}},\ F_2 \in L^\infty(\mathbf{S}^1)_{\mathbb{C}},$$

the functions $G(r;\cdot)_\pm|_{\mathbf{S}^1}$ can be seen to be uniformly $L^1(\mathbf{S}^1)_{\mathbb{C}}$-bounded for $r \to 1$. Now it is easily checked from

$$\tilde{g}_r|_{\mathbf{S}^1} = G(r;\cdot)|_{\mathbf{S}^1} + \overline{G(r;\cdot)}|_{\mathbf{S}^1} \quad \text{and} \quad g_r = f_r\tilde{g}_r = \varphi_1^{(r)}\tilde{g}_r$$

that $\tilde{g}_r|_{\mathbf{S}^1}$ and $g_r|_{\mathbf{S}^1}$ are $L^1(\mathbf{S}^1)_{\mathbb{C}}$-bounded for $r \to 1$. □

Acknowledgments. I thank Professor Rainer Kress for his guidance during my research and his various suggestions for the improvement of this text.

A STEFAN PROBLEM FOR A PROTOCELL MODEL*

AVNER FRIEDMAN† AND BEI HU‡

Abstract. The paper considers a simple model of a radially symmetric cell which undergoes growth due to a continuous supply of nutrient, and disintegration as a result of the various tasks the cell performs. The boundary of the cell is a "free boundary," unknown in advance, which evolves by responding to both the growth and disintegration processes. If the nutrient concentration (at infinity) exceeds a certain critical number, then two stationary solutions exist. It is established, by rigorous mathematical proofs, that the stationary solution with the smaller radius is unstable, whereas the stationary solution with the larger radius is stable.

Key words. protocell, parabolic system, free boundary problem

1. The model. In this paper we consider a physico-chemical model of a self-maintaining protocell which undergoes a process of growth and dissolution that mimics (but greatly simplifies) biological cells. The model is somewhat different from the one that was initiated and studied in [4], [5]. The protocell can be visualized as having a porous structure maintained by building materials with concentration C; the structure is sustained only as long as C exceeds a critical concentration C^*. Metabolism is maintained by nutrient material with concentration σ which is distributed in the entire space with $\sigma = \tau$ at ∞ ($\tau > 0$). C and σ satisfy a coupled system of reaction diffusion equations:

$$c\frac{\partial C}{\partial t} - \Delta C = \sigma, \quad \Delta\sigma - \sigma = 0 \quad \text{in the cell,}$$

$$\Delta\sigma = 0 \quad \text{outside the cell,}$$

where c is a positive constant. The constant c is the quotient of the time scale of diffusion to the time scale of cell doubling. In cases of interest, such as in tumor growth [1], [2], c is a very small constant.

On the boundary of the protocell $C = C^*$. The various tasks that the cell continuously performs take their toll on the cell: they cause it to shrink. This is modelled by disintegration at the boundary at a rate β, $\beta > 0$. On the other hand the flux of building material at the boundary causes the cell to grow. The total result of these two effects is

$$V_n = -\frac{\partial C}{\partial n} - \beta,$$

where n is the exterior normal, and V_n is the velocity of the boundary points in the direction n.

We shall consider here only the case of a spherical cell (in three dimensions). Setting

$$r = \sqrt{x_1^2 + x_2^2 + x_3^2}, \quad u = C - C^*$$

and denoting the boundary of the cell by $r = s(t)$, we then have the following system for $u = u(r,t), \sigma = \sigma(r,t)$ and $r = s(t)$:

$$\Big(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r}\Big)\sigma = \sigma\chi_{\{r<s(t)\}}(r,t) \quad \text{in } \mathbb{R}^3, \tag{1.1}$$

$$\sigma \to \tau \quad \text{as } |x| \to \infty, \tag{1.2}$$

and

$$cu_t - \Big(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r}\Big)u = \sigma \quad \text{if } r < s(t),\ t > 0, \tag{1.3}$$

$$u = 0 \quad \text{on } r = s(t),\ t > 0, \tag{1.4}$$

$$u = u_0(r) \quad \text{for } t = 0, \tag{1.5}$$

and finally, the free boundary condition

$$s'(t) = -u_r(s(t),t) - \beta. \tag{1.6}$$

As shown in [4], if τ/β is less than a critical number μ^*, then no steady state solutions exist, whereas if τ/β is larger than μ^*, then there exist two steady state solutions, with free boundary radii R_0^- and R_0^+, $R_0^- < R_0^+$. Numerical results and some heuristic arguments are given in [4] to show that the solution with R_0^- is unstable, whereas the solution with R_0^+ is stable. The purpose of this paper is to give rigorous mathematical proofs of these results.

In sections 2 and 3 we establish various estimates and prove the existence and uniqueness of the solution to (1.1)–(1.6). In section 4 we prove that the stationary solution corresponding to R_0^- is unstable. In section 5 we prove that the stationary solution corresponding to R_0^+ is stable if c is suitably small.

2. A priori bounds on the solution. The function

$$g(r) = \frac{r^2}{r - \tanh r} \quad (0 < r < \infty) \tag{2.1}$$

will play a fundamental role in what follows. One can easily verify that $r - \tanh r > 0$, so that $g(r) > 0$; furthermore, $g(r) \to \infty$ if $r \to 0$ or $r \to \infty$ and there is a unique $r = R^*$, where $g(r)$ attains its minimum μ^*, i.e.,

$$\min_{0<r<\infty} g(r) = g(R^*) = \mu^*. \tag{2.2}$$

One can compute that

$$R^* \approx 1.6061486 \quad \text{and} \quad \mu^* \approx 3.7739398.$$

The steady state solutions with free boundary $r = R_0$ are given by

$$u(r) = \frac{\tau}{\cosh R_0}\Big(\frac{\sinh R_0}{R_0} - \frac{\sinh r}{r}\Big) \quad \text{for } r < R_0, \tag{2.3}$$

where R_0 satisfies

$$\frac{\tau}{\beta} = \frac{R_0^2}{R_0 - \tanh R_0} = g(R_0). \tag{2.4}$$

If $\tau/\beta < \mu^*$, then there are no steady state solutions, whereas if $\tau/\beta > \mu^*$, then there are two solutions, $u_{R_0^+}$ and $u_{R_0^-}$, corresponding to $R_0 = R_0^+$ and $R_0 = R_0^-$, where $R_0^- < R^* < R_0^+$. As τ/β increases from μ^* to ∞, R_0^- decreases from R^* to 0 and R_0^+ increases from R^* to $+\infty$.

For a given $s(t)$, (1.1) with the boundary condition (1.2) can be solved explicitly (see [4, Eqs. (8) and (9)]):

$$\sigma(r,t) = \begin{cases} \tau\Big(1 - \dfrac{s(t) - \tanh s(t)}{r}\Big) & \text{for } r \geqslant s(t), \\ \tau\, \dfrac{1}{\cosh s(t)}\, \dfrac{\sinh r}{r} & \text{for } r < s(t). \end{cases} \tag{2.5}$$

Substituting (2.5) into (1.3), we get an equation for u involving the free boundary:

$$cu_t - \Big(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r}\Big)u = \tau\, \frac{1}{\cosh s(t)}\, \frac{\sinh r}{r} \quad \text{if } r < s(t),\ t > 0. \tag{2.6}$$

Further,

$$u = 0 \quad \text{on } r = s(t),\ t > 0, \tag{2.7}$$

$$s'(t) = -u_r(s(t),t) - \beta \quad \text{if } t > 0, \tag{2.8}$$

and

$$u = u_0(r) \quad \text{for } t = 0. \tag{2.9}$$

LEMMA 2.1. *If a solution of* (2.6)–(2.9) *exists for the time interval* $[0,T]$, *then*

$$\begin{aligned} \frac{4\pi}{3}s^3(t) = \frac{4\pi}{3}s^3(0) &+ c\int_{\{r<s(0)\}} u_0(r)dV - c\int_{\{r<s(t)\}} u(r,t)dV \\ &+ 4\pi\tau\int_0^t \Big[\frac{1}{g(s(\xi))} - \frac{\beta}{\tau}\Big]s^2(\xi)d\xi \end{aligned} \tag{2.10}$$

for $0 < t \leqslant T$.

Proof. By integration of (2.6) we get

$$\begin{aligned} &c\int_{\{r<s(t)\}} u(r,t)dV - c\int_{\{r<s(0)\}} u_0(r)dV \\ &= c\int_0^t \int_{\{r<s(\xi)\}} u_t(r,\xi)dV\,d\xi \\ &= \int_0^t \int_{\{r=s(\xi)\}} \frac{\partial u}{\partial r}dS + \tau\int_0^t \int_0^{s(\xi)} \frac{1}{\cosh s(t)}\frac{\sinh r}{r}4\pi r^2 dr\,d\xi \\ &= 4\pi\int_0^t \Big\{s^2(\xi)[-s'(\xi) - \beta] + \tau[s(\xi) - \tanh s(\xi)]\Big\}d\xi \\ &= \frac{4\pi}{3}[s^3(0) - s^3(t)] + 4\pi\int_0^t \{\tau[s(\xi) - \tanh s(\xi)] - \beta s^2(\xi)\}d\xi, \end{aligned}$$

from which the lemma follows. □

We shall henceforth assume that

$$0 \leqslant u_0(r) \leqslant C_0(s(0)-r) \quad \text{for } 0 \leqslant r < s(0), \tag{2.11}$$

where C_0 is a positive constant.

THEOREM 2.2. *If a solution* $(u(r,t), s(t))$ *of* (2.6)–(2.9) *exists for all* $0 < t < T$ $(T < \infty)$, *then*

$$s(t) < R \quad \textit{for all } 0 < t < T, \tag{2.12}$$

where R *is a constant independent of* T.

Proof. We distinguish the following two cases.

Case (i): $\tau/\beta \leqslant \mu^*$. Since $u_0(r) \geqslant 0$, we have, by the maximum principle, $u(r,t) > 0$ for $0 \leqslant r < s(t)$. From (2.10) and the definition of μ^* we obtain

$$\frac{4\pi}{3}s^3(t) \leqslant \frac{4\pi}{3}s^3(0) + c\int_{\{r<s(0)\}} u_0(r)dV - 4\pi\beta\int_0^t \Big(1 - \frac{1}{\mu^*}\frac{\tau}{\beta}\Big)s^2(\xi)d\xi. \tag{2.13}$$

It follows that

$$s(t) \leqslant \Big(s^3(0) + 3c\int_0^{s(0)} u_0(r)r^2dr\Big)^{1/3}. \tag{2.14}$$

Case (ii): $\tau/\beta > \mu^*$. In this case, the equation (2.3) has exactly two solutions R_0^- and R_0^+.

Setting

$$C_1 = \max(R_0^+, s(0)), \tag{2.15}$$

we can choose (using (2.11)) a constant R such that

$$C_1^3 + \frac{\tau}{2}cC_1^3R \leqslant R^3, \qquad \text{and } 0 \leqslant u_0(r) \leqslant \frac{\tau}{2}(R-r),\ 0 < r < s(0). \tag{2.16}$$

We shall prove that (2.12) holds for this choice of R. Indeed, if this is not true, then there is a first $t^* > 0$ such that $s(t^*) = R$. Since $s(t) < R$ for $0 < t < t^*$, we have, by comparison (using the maximum principle),

$$0 \leqslant u(r,t) \leqslant \frac{\tau}{2}(R-r), \quad 0 < r < s(t),\ 0 < t \leqslant t^*. \tag{2.17}$$

Take $t_1 \in [0, t^*)$ such that

$$s(t_1) = C_1, \quad C_1 < s(t) < R \quad \text{for } t_1 < t < t^*.$$

Then $\Big\{\frac{\tau}{\beta}[s(\xi) - \tanh s(\xi)] - s^2(\xi)\Big\} \leqslant 0$ for $t_1 < t < t^*$ and (2.10) yields

$$\begin{aligned} s^3(t) &< s^3(t_1) + 3c\int_0^{s(t_1)} u(r,t_1)r^2dr + 3\beta\int_{t_1}^t \Big\{\frac{\tau}{\beta}[s(\xi) - \tanh s(\xi)] - s^2(\xi)\Big\}d\xi \\ &\leqslant C_1^3 + \frac{\tau}{2}cC_1^3R \leqslant R^3 \quad \text{for } t_1 < t \leqslant t^*. \end{aligned}$$

Thus $s(t^*) < R$, which is a contradiction. □

From the uniform boundedness of $s(t)$ we can infer (by comparison) the uniform boundedness of $u(r,t)$:

$$0 \leqslant u(r,t) \leqslant C(R-r), \quad \text{where } R > \sup_{0\leqslant t\leqslant T} s(t). \tag{2.18}$$

The next lemma gives a sharper estimate on $u(r,t)$ for r near $s(t)$, as well as a useful estimate for $s'(t)$.

LEMMA 2.3. *Let R, C_1 be positive constant for which*

$$\begin{gathered} R > \sup_{0\leqslant t\leqslant T} s(t), \\ 0 \leqslant u_0(r) \leqslant C_1 \tanh(c\beta s(0)) \left\{1 - e^{-c\beta(s(0)-r)}\right\} \quad \textit{for } 0 \leqslant r < s(0). \end{gathered} \tag{2.19}$$

Then there is a constant K depending only on C_1, R, τ, c, and β such that

$$0 \leqslant u(r,t) \leqslant K \tanh(c\beta s(t)) \left\{1 - e^{-c\beta(s(t)-r)}\right\} \quad \textit{for } 0 < t \leqslant T, \tag{2.20}$$

and

$$-\beta < s'(t) < -\beta + cK \tanh(c\beta s(t)) \quad \textit{for } 0 < t \leqslant T. \tag{2.21}$$

Proof. By the maximum principle, $u(r,t) > 0$ if $r < s(t)$ and $u_r(s(t),t) < 0$; hence,

$$s'(t) > -\beta \quad \text{for } t > 0. \tag{2.22}$$

Let

$$w(r,t) = K \tanh(c\beta s(t)) \left\{1 - e^{-c\beta(s(t)-r)}\right\},$$

where we choose K large enough so that

$$w(r,0) \geqslant u_0(r). \tag{2.23}$$

Clearly,

$$\begin{aligned} & cw_t - \Big(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r}\Big) w \\ & = Kc\beta \tanh(c\beta s(t)) e^{-c\beta(s(t)-r)} \Big\{ cs'(t) + c\beta + \frac{2}{r} + \frac{c\left[e^{c\beta(s(t)-r)} - 1\right] s'(t)}{\sinh(c\beta s(t)) \cosh(c\beta s(t))} \Big\} \\ & \geqslant Kc\beta \tanh(c\beta s(t)) e^{-c\beta(s(t)-r)} \Big\{ \frac{2}{r} - \frac{2c\beta}{\cosh(c\beta s(t))} \Big\} \\ & \geqslant (2-\sqrt{2}) Kc\beta \tanh(c\beta s(t)) e^{-c\beta(s(t)-r)} \frac{1}{r}; \end{aligned}$$

in deriving the above inequalities, we made use of (2.22) and of the inequalities:

$$\begin{aligned} & e^{\xi} - 1 \leqslant 2\sinh\xi \quad \text{for } \xi \geqslant 0, \\ & \cosh(\xi) \geqslant 1 + \frac{\xi^2}{2} \geqslant \sqrt{2}\xi. \end{aligned}$$

We claim that for a suitable choice of the constant K,

$$(2-\sqrt{2})Kc\beta\tanh(c\beta s(t))e^{-c\beta(s(t)-r)}\frac{1}{r}\geqslant\tau\frac{1}{\cosh(s(t))}\frac{\sinh r}{r}\quad\text{for } 0<r<s(t); \tag{2.24}$$

the proof of this inequality will be given later. If (2.24) holds, then by the maximum principle,

$$u(r,t)\leqslant w(r,t). \tag{2.25}$$

(Note that $w_r|_{r=0}<0, u_r|_{r=0}=0$ so $w-u$ cannot take minimum at $r=0$.) It follows that

$$u_r(s(t),t)\geqslant w_r(s(t),t)=-Kc\beta\tanh(c\beta s(t)), \tag{2.26}$$

thus

$$s'(t)\leqslant-\beta+Kc\beta\tanh(c\beta s(t)).$$

To finish the proof of the lemma, it remains to verify (2.24). Observe that (2.24) is equivalent to

$$(2-\sqrt{2})K\tanh(c\beta s(t))\geqslant\frac{\tau}{c\beta}\,\frac{e^{c\beta s(t)}}{\cosh s(t)}e^{-c\beta r}\sinh r\quad\text{for } 0<r<s(t). \tag{2.27}$$

The function $e^{-c\beta r}\sinh r$ is monotonically increasing in the following cases:

Case (i). $c\beta\leqslant 1$;

Case (ii). $c\beta>1$, $r\leqslant s(t)\leqslant\frac{1}{2}\log\frac{c\beta+1}{c\beta-1}$ for all $0\leqslant t\leqslant T$.

In these two cases, it suffices to prove (2.27) for $r=s(t)$ so that (2.27) holds if K is such that

$$(2-\sqrt{2})K\geqslant\frac{\tau}{c\beta}\sup_{0<\xi<\infty}\frac{\tanh(\xi)}{\tanh(c\beta\xi)}\equiv\frac{\tau}{c\beta}\max\Big(1,\frac{1}{c\beta}\Big). \tag{2.28}$$

Finally, if $c\beta>1$ and $\max_{0\leqslant t\leqslant T}s(t)>\frac{1}{2}\log\frac{c\beta+1}{c\beta-1}$, we rewrite (2.24) in the form

$$(2-\sqrt{2})K\tanh(c\beta s(t))e^{-(c\beta-1)(s(t)-r)}\geqslant\frac{\tau}{c\beta}\,\frac{e^{s(t)}}{\cosh s(t)}e^{-r}\sinh r\quad\text{for } 0<r<s(t) \tag{2.29}$$

and observe that the function $e^{-r}\sinh r$ is monotonically increasing. It therefore suffices to prove (2.29) just for $r=s(t)$ on the right-hand side. But, since $s(t)<R$, this is a consequence of

$$(2-\sqrt{2})Ke^{-(c\beta-1)R}\geqslant\frac{\tau}{c\beta}\sup_{0<\xi<\infty}\frac{\tanh(\xi)}{\tanh(c\beta\xi)}\equiv\frac{\tau}{c\beta} \tag{2.30}$$

which holds if K is chosen sufficiently large. □

3. Existence and uniqueness. In this section we assume, in addition to (2.11), that

$$u_0'(r)\text{ is continuous if } 0\leqslant r\leqslant s(0). \tag{3.1}$$

THEOREM 3.1. *Let* (2.11) *and* (3.1) *hold. Then*

(i) *there exists a unique solution* $(u(r,t), s(t))$ *of* (2.6)–(2.9) *with* $s'(t)$ *continuous for a time interval* $0 \leqslant t < \delta_0$;

(ii) *if a solution* $(u(r,t), s(t))$ *exists for* $0 \leqslant t < T$ *and* $\liminf_{t \to T-0} s(t) > 0$, *then the solution can be continued to* $0 \leqslant t \leqslant T + \delta$ *for some* $\delta > 0$.

The proof, by a fixed point theorem for a contraction mapping, is similar to the corresponding proof for the Stefan problem [3, Chap. 8] and is therefore omitted.

THEOREM 3.2. *If*

$$\frac{\tau}{\beta} < \mu^*,$$

then there exists a finite t^* *such that the solution exists for* $0 \leqslant t < t^*$ *and* $s(t) \to 0$ *for* $t \to t^*$*; i.e., the cell shrinks to zero at time* t^*.

Proof. From (2.13) we get

$$s^3(t) + \delta \int_0^t s^2(\xi) d\xi \leqslant \widetilde{C}_1$$

for some positive constants $\widetilde{C}_1$ and δ.

By Theorem 3.1, the solution can be continued as long as $s(t)$ remains uniformly positive. If the assertion of the theorem is not true, then the solution exists (and $s(t)$ is positive) for all $0 < t < \infty$. Let K be as in Lemma 2.3 and take s_0 such that $K \tanh(\beta s_0) < \beta/2$. Since $\int_0^t s^2(\xi) d\xi$ is uniformly bounded, there exists a $\widetilde{t} > 0$ such that $s(\widetilde{t}) < s_0$. By Lemma 2.3 and a continuation argument, we then have $s'(t) \leqslant -\beta/2$ for all $t > \widetilde{t}$. This is a contradiction to the assumption that $s(t) > 0$ for all $t > 0$. □

In view of Theorems 2.2 and 3.1, a solution $(u(r,t), s(t))$ exists for all $0 \leqslant t < \infty$ if and only if, for any $T > 0$, there is $s > 0$ such that

$$\inf_{0 \leqslant t < T} s(t) \geqslant s > 0.$$

Furthermore, by Lemma 2.3, the constant s can be chosen to be independent of T if a global solution exists.

Next we establish a lower bound for $s(t)$ in the case $\tau/\beta > \mu^*$.

Let C_1, C_2 and D_1, D_2 be positive constants such that

$$C_1 \geqslant R_0^+, \quad C_1^3 + \frac{\tau}{2} c C_1^3 C_2 = C_2^3, \tag{3.2}$$

$$D_2 \geqslant R_0^-, \quad D_1 = D_2 \Big(\frac{\tau}{2} c C_2 + 1 \Big)^{1/3}. \tag{3.3}$$

THEOREM 3.3. *Assume that*

$$D_1 < R_0^+. \tag{3.4}$$

If $s(0), u_0(r)$ *satisfy*

$$D_1 \leqslant s(0) \leqslant C_1, \tag{3.5}$$

$$0 \leqslant u_0(r) \leqslant \frac{\tau}{2}(C_2 - r) \quad \text{for } 0 < r < s(0), \tag{3.6}$$

then there exists a global solution $(u(r,t), s(t))$ *of* (2.6)–(2.9) *with*

$$s(t) > D_2 \quad \text{for all } t > 0. \tag{3.7}$$

Proof. In view of (3.2), we can apply Case (ii) of Theorem 2.2 to conclude that $s(t) \leqslant C_2$ and then, by the maximum principle,

$$0 \leqslant u(r,t) \leqslant \frac{\tau}{2}(C_2 - r). \tag{3.8}$$

It follows that if

$$\begin{aligned} &R_0^- < s(t) < R_0^+ \quad \text{for } t_1 < t < t_2, \\ &s(t_1) = \min[s(0), R_0^+], \quad s(t_2) = D_2, \end{aligned}$$

then

$$3\int_0^{s(t_2)} u(r,t_2) r^2 dr - 3\int_0^{s(t_1)} u(r,t_1) r^2 dr \leqslant \frac{\tau}{2} C_2 D_2^3 = \frac{1}{c}(D_1^3 - D_2^3), \tag{3.9}$$

where the inequality follows from (3.8).

To prove the theorem it suffices to show that (3.7) holds as long as the solution exists. If this is not true then there is a smallest $t = t_2$ such that $s(t_2) = D_2$. By (3.4), (3.5) there exists a t_1 such that $t_1 < t_2$, $s(t_1) = \min[s(0), R_0^+]$ and $s(t_2) < s(t) < s(t_1)$ for $t_1 < t < t_2$. As in Case (ii) of Theorem 2.2,

$$s^3(t_1) - D_2^3 < 3c\int_0^{D_2} u(r,t_2) r^2 dr - 3c\int_0^{s(t_1)} u(r,t_1) r^2 dr,$$

and since $D_1^3 \leqslant \min[s^3(0), (R_0^+)^3]$, this is a contradiction to (3.9). □

Remark 3.1. If c is suitably small, then (3.4) is satisfied. In this case we have, by (3.7), (3.8),

$$D_2 < s(t) < C_2 \quad \text{for all } t > 0.$$

In particular, if

$$R_0^- + 2\delta < s(0) < C_1 \qquad (\delta > 0) \tag{3.10}$$

and c is sufficiently small, depending on δ and C_1, then

$$R_0^- + \delta < s(t) < C_1 + \delta \quad \text{for all } t > 0. \tag{3.11}$$

4. R_0^- is unstable. From Lemma 2.3 we infer that if $s(0)$ is very small, then $s'(t)$ remains uniformly negative as long as the solution exists. In this section we shall prove, under more general assumptions on $s(0)$, that $s(t)$ is monotone decreasing, and in particular, we shall deduce that the stationary solution corresponding to R_0^- is unstable.

THEOREM 4.1. *Suppose that*

$$u_r(r,0) \geqslant -\frac{\tau}{\cosh s(0)} \frac{r\cosh r - \sinh r}{r^2} - \frac{\tau}{s(0)}\Big[\frac{\beta}{\tau} - \frac{1}{g(s(0))}\Big] r, \tag{4.1}$$

$$u_r(s(0),0) > -\beta, \tag{4.2}$$

and

$$s(0) \leqslant R_0^-. \tag{4.3}$$

Then $s'(t) < 0$ as long as $s(t)$ remains positive, and $s(t)$ shrinks to zero in finite time.

Proof. From (4.2) we deduce that $s'(0) < 0$ and, by continuity, $s'(t) < 0$ for small $t > 0$. If $s'(t)$ does not remain negative while $s(t)$ is positive, then there exists a first t^* such that $s(t^*) > 0,\ s'(t^*) = 0$. Since $s'(t) < 0$ for $0 \leqslant t < t^*$, we have

$$\begin{aligned} &u_r(s(t), t) > -\beta \quad \text{for } 0 \leqslant t < t^*, \\ &0 < s(t) < s(0) \leqslant R_0^- \quad \text{for } 0 \leqslant t < t^*. \end{aligned}$$

We introduce the auxiliary function

$$w = u_r(r,t) + \frac{\tau}{\cosh s(t)} \frac{r\cosh r - \sinh r}{r^2} + \frac{\tau}{s(t)}\Big[\frac{\beta}{\tau} - \frac{1}{g(s(t))}\Big] r,$$

where $g(r)$ is defined in (2.1).

Since $g'(r) < 0$ for $0 < r \leqslant R_0^-$, $g(R_0^-) = \tau/\beta$, and $0 < s(t) \leqslant R_0^-$, we have

$$\Big[\frac{\beta}{\tau} - \frac{1}{g(s(t))}\Big] > 0 \quad \text{for } 0 < t < t^*. \tag{4.4}$$

Using the relation $(r\cosh r - \sinh r)/r^2 = (\partial/\partial r)(\sinh r/r)$, we easily deduce that

$$\begin{aligned} &-\Delta\Big(\frac{r\cosh r - \sinh r}{r^2}\Big) + \frac{2}{r^2}\Big(\frac{r\cosh r - \sinh r}{r^2}\Big) \\ &\quad = -\frac{\partial}{\partial r}\Delta\frac{\sinh r}{r} = -\frac{\partial}{\partial r}\frac{\sinh r}{r} = -\frac{r\cosh r - \sinh r}{r^2}. \end{aligned}$$

Combining this relation with (4.4) and the inequality $s'(t) < 0$, we find that

$$cw_t - w_{rr} - \frac{2}{r}w_r + \frac{2}{r^2}w > 0 \quad \text{for } 0 < t < t^*.$$

Clearly, $w(s(t), t) > 0$ for $0 < t < t^*$, and by (4.1), $w(r, 0) \geqslant 0$. It follows, by the maximum principle, that $w(r,t) > 0$ for $0 < t < t^*$. Since $s'(t^*) = 0$, we have also (from the definition of w and g) that $w(s(t^*), t^*) = 0$ and, therefore, by the maximum principle,

$$w_r(s(t^*), t^*) < 0.$$

That is,

$$u_{rr}(s(t^*), t^*) < -\frac{\tau}{s(t^*)}\Big[\frac{\beta}{\tau} - \frac{3}{s(t^*)} + \frac{3\tanh s(t^*)}{s^2(t^*)} + \tanh s(t^*)\Big].$$

On the other hand, from $s'(t^*) = 0$ we deduce that $u_t(s(t^*), t^*) = 0$ so that

$$\begin{aligned} 0 \;=\; cu_t(s(t^*), t^*) &= u_{rr}(s(t^*), t^*) + \frac{2}{s(t^*)}u_r(s(t^*), t^*) + \frac{\tau}{\cosh s(t^*)}\,\frac{\sinh s(t^*)}{s(t^*)} \\ &< -\frac{\tau}{s(t^*)}\Big[\frac{3\beta}{\tau} - \frac{3}{s(t^*)} + \frac{3\tanh s(t^*)}{s^2(t^*)}\Big] \\ &= -\frac{3\tau}{s(t^*)}\Big[\frac{\beta}{\tau} - \frac{1}{g(s(t^*))}\Big] \;\leqslant\; 0 \quad \text{by (4.4)}, \end{aligned}$$

which is a contradiction. Having now proved that $s'(t) < 0$ as long as $s(t)$ remains positive, we next show that $s(t)$ converges to zero in finite time. Indeed, otherwise the limit $s_0 = \lim_{t\to\infty} s(t)$ lies in the interval $(0, R_0^-)$. By a standard theorem on parabolic equations [3, Chap. 6], $(u(r,t), s(t))$ converges to a stationary solution, and consequently, s_0 must coincide with either R_0^- or R_0^+, which is a contradiction. □

If, in Theorem 4.1, we take $s(0) = R_0^-$, then we get the following.

COROLLARY 4.2. *Suppose*

$$u_r(r,0) \geqslant -\frac{\tau}{\cosh R_0^-}\frac{r\cosh r - \sinh r}{r^2} \quad \text{for } 0 < r < R_0^-, \tag{4.5}$$

$$s(0) = R_0^-, \qquad u_r(R_0^-, 0) > -\beta. \tag{4.6}$$

Then $s'(t) < 0$ as long as $s(t)$ remains positive, and $s(t)$ shrinks to zero in finite time.

Since there are arbitrarily small perturbations of the stationary solution

$$\frac{\tau}{\cosh R_0^-}\Big(\frac{\sinh R_0^-}{R_0^-} - \frac{\sinh r}{r}\Big)$$

which satisfies (4.5), (4.6), we conclude the following.

COROLLARY 4.3. *The stationary solution* (4.5) *is unstable.*

One can even choose small perturbations of the stationary solution with $s(0) > R_0^-$ (but $s(0) - R_0^-$ small) for which $s(t)$ shrinks to zero in finite time.

The method of proof of Theorem 4.1 can be extended to establish monotonic decrease of $s(t)$ under different assumptions on the data. We give one example.

THEOREM 4.4. *Suppose*

$$u_r(r,0) \geqslant -\beta\frac{r}{s(0)}, \qquad u_r(s(0),0) > -\beta, \tag{4.7}$$

$$\tau \leqslant \frac{3\beta}{\tanh s(0)}. \tag{4.8}$$

Then $s'(t) < 0$ as long as $s(t)$ remains positive.

The proof is essentially the same as the proof of Theorem 4.1, with w replaced by $u_r(r,t) + \beta r/s(t)$.

We note that Theorem 4.4 is not contained in Theorem 4.1 since, in general, $-\beta r/s(0)$ is not larger than the right-hand side of (4.1).

5. R_0^+ is stable. In this section we prove that the stationary solution corresponding to R_0^+ is stable provided the coefficient c is sufficiently small. As noted in the introduction, in actual biological cells of interest, c may indeed be very small. In the case $c = 0$, the solution $(\varphi(r,t), R(t))$ of (2.6)–(2.9) can be computed explicitly [4]:

$$\varphi(r,t) = \frac{\tau}{\cosh R(t)}\Big(\frac{\sinh R(t)}{R(t)} - \frac{\sinh r}{r}\Big) \quad \text{for } r < R(t),$$

where the free boundary $R(t)$ satisfies

$$\frac{dR}{dt} = \tau\frac{R - \tanh R}{R^2} - \beta = \tau\Big[\frac{1}{g(R)} - \frac{\beta}{\tau}\Big] \equiv \tau\Big(h(R) - \frac{\beta}{\tau}\Big). \tag{5.1}$$

Note that

$$h(R) > \frac{\beta}{\tau} \quad \text{and} \quad \dot{R} > 0 \quad \text{for } R_0^- < R < R_0^+,$$
$$h(R) < \frac{\beta}{\tau} \quad \text{and} \quad \dot{R} < 0 \quad \text{for } R > R_0^+,$$

and $h'(R_0^+) < 0$. Hence, by standard ODE analysis it follows that if $R(0) > R_0^-$, then

$$|R(t) - R_0^+| \leqslant Ce^{-\alpha t} \quad \text{for all } t > 0, \tag{5.2}$$

where C, α are positive constants.

In this section we want to extend this result to the case where c is positive and small.

THEOREM 5.1. *Let $s(0) > R_0^-$. If c is sufficiently small, then the solution $(u(r,t), s(t))$ of (2.6)–(2.9) exists for all $t > 0$,*

$$\lim_{t\to\infty} s(t) = R_0^+, \tag{5.3}$$

and the convergence is exponentially fast.

This establishes a global asymptotic stability of the stationary solution corresponding to R_0^+.

From Remark 3.1 we already know that the solution exists for all $t > 0$ and that (3.11) holds; i.e.,

$$R_0^- < \underline{S} \leqslant s(t) \leqslant \overline{S} < \infty \quad \text{for all } t > 0. \tag{5.4}$$

LEMMA 5.2. *Define*

$$\underline{R} = \liminf_{t\to\infty} s(t), \quad \overline{R} = \limsup_{t\to\infty} s(t).$$

If c is sufficiently small, then $\overline{R} = \underline{R} = R_0^+$.

Proof. By (5.4)

$$R_0^- < \underline{R} \leqslant \overline{R} \leqslant \overline{S}.$$

We claim that

$$R_0^- < \underline{R} \leqslant R_0^+ \leqslant \overline{R} \leqslant \overline{S}. \tag{5.5}$$

In fact, if $\underline{R} > R_0^+$, then $g(s(\xi)) > \tau/\beta + \varepsilon$ for some small $\varepsilon > 0$ and all sufficiently large ξ. Therefore,

$$\int_0^\infty \Big[\frac{1}{g(s(\xi))} - \frac{\beta}{\tau}\Big] s^2(\xi) d\xi = -\infty,$$

which is a contradiction to Lemma 2.1. This proves that $\underline{R} \leqslant R_0^+$. Similarly, $R_0^+ \leqslant \overline{R}$.

Next, we claim that

$$\liminf_{t\to\infty} u(r,t) \geqslant \frac{\tau}{\cosh \overline{R}} \Big(\frac{\sinh \underline{R}}{\underline{R}} - \frac{\sinh r}{r} \Big) \quad \text{uniformly for } r < s(t), \tag{5.6}$$

$$\limsup_{t\to\infty} u(r,t) \leqslant \frac{\tau}{\cosh \underline{R}} \Big(\frac{\sinh \overline{R}}{\overline{R}} - \frac{\sinh r}{r} \Big) \quad \text{uniformly for } r < s(t). \tag{5.7}$$

To prove (5.6), let $\varphi(r,t)$ be the solution of the following problem:

$$\begin{aligned} &c\varphi_t - \Delta\varphi = \frac{\tau}{\cosh(\overline{R}+\varepsilon)}\frac{\sinh r}{r} \quad \text{for } r < \underline{R}-\varepsilon,\ t > T,\\ &\varphi(\underline{R}-\varepsilon,t) = 0 \quad \text{for } t > T,\\ &\varphi(r,T) = 0 \quad \text{for } r < \underline{R}-\varepsilon, \end{aligned}$$

where $\varepsilon > 0$ is small. If we take $T = T(\varepsilon)$ to be large enough, then

$$\underline{R} - \varepsilon \leqslant s(t) \leqslant \overline{R} + \varepsilon \quad \text{for } t > T,$$

and, by maximum principle, $u(r,t) \geqslant \varphi(r,t)$ for $t > T$. Hence

$$\liminf_{t\to\infty} u(r,t) \geqslant \lim_{t\to\infty} \varphi(r,t) = \frac{\tau}{\cosh(\overline{R}+\varepsilon)}\Big(\frac{\sinh(\underline{R}-\varepsilon)}{\underline{R}-\varepsilon} - \frac{\sinh r}{r}\Big).$$

Letting $\varepsilon \to 0+$, we obtain the inequality (5.6). The inequality (5.7) can be established in a similar way.

Next, we estimate $\overline{R} - R_0^+$ in case $\overline{R} > R_0^+$. Choose a sequence $t_j \to \infty$ such that $s(t_j) \to \overline{R}$ and take $\widetilde{t}_j < t_j$ such that

$$R_0^+ + \frac{1}{j} = s(\widetilde{t}_j) < s(t) \quad \text{for } \widetilde{t}_j < t < t_j;$$

since $\liminf_{t\to\infty} s(t) \leqslant R_0^+ < \overline{R}$, such a choice of $\widetilde{t}_j$ is possible. Then $g(s(\xi)) > \tau/\beta$ for $\widetilde{t}_j < \xi < t_j$ and Lemma 2.1 implies that

$$s^3(t_j) - s^3(\widetilde{t}_j) \leqslant 3c\int_0^{s(\widetilde{t}_j)} u(r,\widetilde{t}_j)r^2dr - 3c\int_0^{s(t_j)} u(r,t_j)r^2dr.$$

Using (5.6), (5.7) in the last inequality, and letting $j \to \infty$, we obtain

$$\begin{aligned} \overline{R}^3 - (R_0^+)^3 &\leqslant 3c\int_0^{R_0^+} \frac{\tau}{\cosh\underline{R}}\Big(\frac{\sinh\overline{R}}{\overline{R}} - \frac{\sinh r}{r}\Big)r^2dr\\ &\quad -3c\int_0^{\underline{R}} \frac{\tau}{\cosh\overline{R}}\Big(\frac{\sinh\underline{R}}{\underline{R}} - \frac{\sinh r}{r}\Big)r^2dr\\ &\leqslant 3c\tau\int_0^{R_0^+} \Big(\frac{1}{\cosh\underline{R}}\frac{\sinh\overline{R}}{\overline{R}} - \frac{1}{\cosh\overline{R}}\frac{\sinh\underline{R}}{\underline{R}}\Big)r^2dr\\ &\quad +3c\tau\int_0^{R_0^+} \Big(\frac{1}{\cosh\overline{R}} - \frac{1}{\cosh\underline{R}}\Big)r\sinh r dr. \end{aligned}$$

Since the last integrand is $\leqslant 0$, we obtain

$$\begin{aligned} \overline{R}^3 - (R_0^+)^3 &\leqslant c\tau\Big(\frac{1}{\cosh\underline{R}}\frac{\sinh\overline{R}}{\overline{R}} - \frac{1}{\cosh\overline{R}}\frac{\sinh\underline{R}}{\underline{R}}\Big)(R_0^+)^3\\ &= \frac{c\tau}{\cosh\underline{R}\cosh\overline{R}}[k(\overline{R}) - k(\underline{R})](R_0^+)^3, \end{aligned} \tag{5.8}$$

where $k(r) = \sinh r\cosh r/r$; note that $k'(r) > 0$. Similarly, we have (with $s(\tau_j) \to \underline{R}, s(\widetilde{\tau}_j) = R_0^+ - 1/j, s(t) < R_0^+ - 1/j$ if $\widetilde{\tau}_j < t < \tau_j$)

$$\underline{R}^3 - (R_0^+)^3 \geqslant -\frac{c\tau}{\cosh\underline{R}\cosh\overline{R}}[k(\overline{R}) - k(\underline{R})](R_0^+)^3, \tag{5.9}$$

provided $\underline{R} < R_0^+$. Notice that if $\overline{R} = R_0^+$ (or $\underline{R} = R_0^+$) then (5.8) (or (5.9)) is trivially satisfied. Combining (5.8) with (5.9) we get

$$\overline{R} - \underline{R} \leqslant \frac{c\tau}{A}(\overline{R} - \underline{R}), \tag{5.10}$$

where

$$A = \frac{(\overline{R}^2 + \overline{R}\underline{R} + \underline{R}^2)\cosh \underline{R} \cosh \overline{R}}{2(R_0^+)^3 k'(\overline{R})} \geqslant A_0,$$

and A_0 is a positive constant depending only on $\underline{S}$, $\overline{S}$, and R_0^+. If $c\tau/A_0 < 1$, then $\overline{R} - \underline{R} = 0$ and the lemma is proved. □

Having proved (5.2), we shall next prove local stability of R_0^+ with exponential convergence of $s(t)$. Introduce the functions

$$\varphi(r,t) = \frac{\tau}{\cosh s(t)}\left(\frac{\sinh s(t)}{s(t)} - \frac{\sinh r}{r}\right), \tag{5.11}$$

and $v = u - \varphi$. A direct computation shows that

$$cv_t - \Big(\frac{\partial^2}{\partial r^2} + \frac{2}{r}\frac{\partial}{\partial r}\Big)v = -c\varphi_t \quad \text{for } 0 \leqslant r < s(t), \tag{5.12}$$

$$v(s(t),t) = 0, \tag{5.13}$$

$$s'(t) = -v_r(s(t),t) - \beta + \tau\frac{s(t) - \tanh s(t)}{s^2(t)}. \tag{5.14}$$

LEMMA 5.3. *Suppose that $c\tau < 3/2$. Then there exists an $\varepsilon > 0$ such that if*

$$|s(0) - R_0^+| < \varepsilon^2, \quad |s'(0)| < \varepsilon,$$

and

$$\left|u_0(r) - \frac{\tau}{\cosh s(0)}\Big(\frac{\sinh s(0)}{s(0)} - \frac{\sinh r}{r}\Big)\right| < \frac{\tau}{7}\varepsilon\Big(s(0) - \frac{r^2}{s(0)}\Big),$$

then a global solution $(u(r,t), s(t))$ exists and $s(t)$ converges to the steady state (corresponding to R_0^+) exponentially fast.

The proof requires the fact that $g'(R_0^+) > 0$ (g is defined in (2.1)) and, thus, does not apply to R_0^- (since $g'(R_0^-) < 0$).

Proof. Clearly,

$$\begin{aligned}
|\varphi_t| &= \tau|s'(t)|\left|\frac{s(t) - \tanh s(t)}{s^2(t)} - \frac{\sinh s(t)}{\cosh^2 s(t)}\Big(\frac{\sinh s(t)}{s(t)} - \frac{\sinh r}{r}\Big)\right| \\
&\leqslant \tau|s'(t)| \max\Big[\frac{s(t) - \tanh s(t)}{s^2(t)}, \frac{\sinh s(t)}{\cosh^2 s(t)}\Big(\frac{\sinh s(t)}{s(t)} - \frac{\sinh r}{r}\Big)\Big] \\
&\leqslant \tau|s'(t)| \max\Big[\frac{s(t) - \tanh s(t)}{s^2(t)}, \frac{\sinh^2 s(t)}{s(t)\cosh^2 s(t)}\Big] \\
&\leqslant \tau|s'(t)|\frac{1}{s(t)}.
\end{aligned} \tag{5.15}$$

We claim that

$$|s'(t)| < \varepsilon e^{-\varepsilon t} \quad \text{for } 0 < t < \infty. \tag{5.16}$$

By assumption, (5.16) is satisfied for $t = 0$. If the assertion (5.16) is not true, then there is a first t^* such that $|s'(t^*)| = \varepsilon e^{-\varepsilon t^*}$. Introduce the function

$$w(r,t) = \frac{c\tau\varepsilon}{6 - C^*\varepsilon} e^{-\varepsilon t}\Big(s(t) - \frac{r^2}{s(t)}\Big) \quad \text{for } 0 \leqslant t \leqslant t^*,$$

where $C^* > s^2(t) + 2c$ for all $0 < t < \infty$. Then

$$\begin{aligned} cw_t - \Delta w &= \frac{c\tau\varepsilon}{6 - C^*\varepsilon}\ \frac{1}{s(t)}\ \Big[6 + c\Big(1 + \frac{r^2}{s^2(t)}\Big)s'(t) - \varepsilon(s^2(t) - r^2)\Big]e^{-\varepsilon t} \\ &\geqslant \frac{c\tau\varepsilon}{6 - C^*\varepsilon}\ \frac{1}{s(t)}(6 - C^*\varepsilon)e^{-\varepsilon t} \\ &\geqslant \frac{c\tau\varepsilon}{s(t)} e^{-\varepsilon t}, \end{aligned}$$

and, by assumption, $w(r,0) > |v(r,0)|$. Recalling (5.15) and (5.12), (5.13), we can use the maximum principle to compare $\pm v$ with w and conclude that

$$|v(r,t)| \leqslant w(r,t).$$

Since $v(s(t),t) = w(s(t),t)$, we have also

$$|v_r(s(t),t)| \leqslant \frac{2c\tau\varepsilon}{6 - C^*\varepsilon} e^{-\varepsilon t}.$$

Thus

$$\Big|s'(t) + \beta - \tau\frac{s(t) - \tanh s(t)}{s^2(t)}\Big| \leqslant \frac{2c\tau\varepsilon}{6 - C^*\varepsilon} e^{-\varepsilon t}. \tag{5.17}$$

Let

$$h(r) = \frac{1}{g(r)}, \qquad f(t) = \tau\frac{h(R_0^+) - h(s(t))}{s(t) - R_0^+},$$

where $g(r)$ is defined by (2.1). Then we can rewrite (5.17) in the form

$$\Big|(s(t) - R_0^+)' + f(t)(s(t) - R_0^+)\Big| \leqslant \frac{2c\tau\varepsilon}{6 - C^*\varepsilon} e^{-\varepsilon t}. \tag{5.18}$$

It follows that

$$|s(t) - R_0^+| \leqslant |s(0) - R_0^+| \exp\Big(-\int_0^t f(\xi)d\xi\Big) + \frac{2c\tau\varepsilon}{6 - C^*\varepsilon}\int_0^t \exp\Big(-\varepsilon\eta - \int_\eta^t f(\xi)d\xi\Big)d\eta.$$

Notice that for $s(t)$ near R_0^+, $(h(R_0^+) - h(s(t)))/(s(t) - R_0^+) \sim -h'(R_0^+) \equiv \delta > 0$. Thus, for $s(t)$ near R_0^+, $\tau(\delta + C^*\varepsilon) \geqslant f(t) \geqslant \tau(\delta - C^*\varepsilon)$. Consequently,

$$|s(t) - R_0^+| \leqslant \frac{\varepsilon^2}{\tau(\delta - C^*\varepsilon)} e^{-\tau(\delta - C^*\varepsilon)t} + \frac{2c\tau\varepsilon}{6 - C^*\varepsilon}\ \frac{1}{\tau(\delta - C^*\varepsilon) - \varepsilon} e^{-\varepsilon t}. \tag{5.19}$$

Using this in (5.18) we obtain

$$\begin{aligned} |s'(t)| &\leqslant \frac{2c\tau\varepsilon}{6 - C^*\varepsilon} e^{-\varepsilon t} + |f(t)||s(t) - R_0^+| \\ &\leqslant \frac{2c\tau\varepsilon}{6 - C^*\varepsilon} e^{-\varepsilon t} \\ &\qquad + \tau(\delta + C^*\varepsilon)\left(\frac{\varepsilon^2}{\tau(\delta - C^*\varepsilon)} e^{-\tau(\delta - C^*\varepsilon)t} + \frac{2c\tau\varepsilon}{6 - C^*\varepsilon}\ \frac{1}{\tau(\delta - C^*\varepsilon) - \varepsilon} e^{-\varepsilon t}\right) \\ &< \varepsilon e^{-\varepsilon t} \quad \text{for } 0 < t \leqslant t^*, \end{aligned}$$

provided

$$\frac{2c\tau}{6-C^*\varepsilon}+\Big[\frac{\tau(\delta+C^*\varepsilon)\varepsilon}{\tau(\delta-C^*\varepsilon)}+\frac{2c\tau}{6-C^*\varepsilon}\,\frac{\tau(\delta+C^*\varepsilon)}{\tau(\delta-C^*\varepsilon)-\varepsilon}\Big]<1,$$

which is satisfied if $c\tau<3/2$ and ε is sufficiently small, and this is a contradiction to the assumption that $|s'(t^*)|$ is equal to $e^{-\varepsilon t^*}$. Finally, from (5.19), we deduce that $s(t)$ converges to R_0^+ exponentially fast. □

Proof of Theorem 5.1. From Lemma 5.2 and (5.6), (5.7), we see that the assumptions of Lemma 5.3 are satisfied at some sufficiently large time $t=T$. It follows that

$$|s(t)-R_0^+|\leqslant Ce^{-\alpha t},$$
$$|s'(t)|\leqslant Ce^{-\alpha t}$$

for all large enough t, where C,α are positive constants, and this completes the proof of Theorem 5.1. □

Remark 5.1. The above proof shows that if (3.6) and (3.10) hold, then the assertion of Theorem 5.1 holds for any $0<c<c^*$, where c^* depends only on δ, C_1, and C_2 in addition to τ and β.

AN ANALYTICAL PROOF OF THE LINEAR STABILITY OF THE VISCOUS SHOCK PROFILE OF THE BURGERS EQUATION WITH FOURTH-ORDER VISCOSITY*

SHLOMO ENGELBERG†

Abstract. In this paper we establish the exponential decay of solutions of the equation

$$u_t + \varphi(x)u_x = -\partial_x^4 u$$

in an exponentially weighted norm. Here $\varphi(x)$ is the viscous shock profile corresponding to the Burgers equation with fourth-order viscosity:

$$u_t + uu_x = -\partial_x^4 u.$$

Because of the fact that the profile is not monotone, showing the stability is nontrivial. We extend the techniques of Koppel and Howard (*Adv. Math.* 18 (1975), pp. 306-358), techniques that they employ to prove the existence of the viscous shock profile, and we use the techniques to prove the stability of the viscous shock profile. We have previously shown that the viscous shock profile is a stable solution in an exponentially weighted norm by making use of numerical results. The main advantage of our current method is that it is analytical. One sees more clearly what properties of the viscous shock profile cause it to be a stable solution of the PDE.

Key words. viscous shock profiles, stability

1. Introduction.

In this paper we establish the exponential decay of solutions of the equation

$$u_t + \varphi(x)u_x = -\partial_x^4 u \tag{1.1}$$

in an exponentially weighted norm. Here $\varphi(x)$ is the stationary (i.e., time-independent) viscous shock profile corresponding to the Burgers equation with fourth-order viscosity,

$$u_t + (f(u))_x = -\partial_x^4 u, \quad f(u) = u^2/2, \tag{1.2}$$

that satisfies the condition $\varphi(x) \to \mp 1$ as $x \to \pm\infty$.

Equation (1.2) occurs in many contexts. Sivashinsky [10] has shown that (1.2) can be used to model burning on a Bunsen burner. Additionally, the modified equations that correspond to stable third-order methods for approximating the solutions of

$$u_t + uu_x = 0 \tag{1.3}$$

have the general form

$$u_t + uu_x = -k(u)u_{xxxx}. \tag{1.4}$$

We show that the stationary viscous profile of (1.4) is linearly stable when $k(u) \equiv 1$.

Furthermore, the problems that arise in the study of the fourth-order version of Burgers's equation are similar to the problems that come up in the study of the stability of viscous shock profiles of systems of equations. Work on the stability of viscous shock profiles of systems of equations has been done by Goodman [3], Liu [5], Szepessy and Xin [11], and Matsumura and Nishihara [6].

We have shown previously [2] that showing the exponential decay of solutions of (1.1) in a slightly different exponentially weighted norm is sufficient to show that the viscous shock profile is a nonlinearly stable solution of (1.2) in that exponentially weighted norm. It is simple to extend that proof to show that our results here are sufficient to guarantee that the solution is nonlinearly stable in our other, slightly different norm.

In [2], we made use of rigorous numerical results of Michelson [8] and the theory of sectorial operators to show that the solutions of (1.1) are exponentially stable in an exponentially weighted norm. Our current technique is completely analytical and does not use the theory of sectorial operators.

The function $\varphi(x)$ is the odd solution of the ODE $\varphi''' = \frac{1}{2}(1-\varphi^2)$ subject to the condition $\varphi(\infty) = -1$. Koppel and Howard [4] established the existence of the oddly symmetric viscous shock profile by showing that there exists a ν such that the solution of the ODE $\varphi''' = \frac{1}{2}(1-\varphi^2)$ with initial values $\varphi = 0, \varphi' = -\nu, \varphi'' = 0$ must intersect the stable manifold of the solution -1. Later, McKord [7] showed that this is the *unique* solution of the ODE subject to the conditions that the solution be odd and tend to -1 as $x \to \infty$. We show that zero is a stable solution of the linearization of the integrated Burgers equation about the viscous shock profile, i.e., of (1.1), by making use of some estimates contained in the existence proof given by Koppel and Howard [4].

As has been pointed out by Alexander, Gardner, and Jones [1], some existence proofs contain within them the seeds of stability proofs. In [1], there are results of this nature for systems of second-order PDEs. In this paper, we deal with solutions of a fourth-order equation in an exponentially weighted space.

Existence proofs for $\varphi(x)$ abound. The earliest proof is by Koppel and Howard [4]. It is a *tour de force*. Mock [9] presents a proof of the existence of viscous shock profiles for equations of the type we are studying. His proof is somewhat more general than that of Koppel and Howard. Finally, McKord [7] presents an index theoretic proof of the existence of the viscous shock profile. We show that Koppel and Howard's methods can be extended to a proof of stability in an exponentially weighted space.

As it seems that Koppel and Howard's general method can also be used to prove the existence of viscous shock profiles for Burgers's equation with more general fluxes than $f(u) = u^2/2$, it seems likely that our method can be used to prove the stability of such profiles in an exponentially weighted space. Then the methods of our previous article should suffice to show that the profiles are nonlinearly stable as well.

2. Conditions sufficient for decay to prevail. We look at the behavior of solutions of (1.1) in the w_ϵ norm which is defined as

$$\|g\|^2_{L^2_{w,\epsilon}} = \int_{-\infty}^{\infty} w_\epsilon(x) g^2(x)\, dx, \qquad w_\epsilon(x) = \cosh(\epsilon x).$$

We prove that the derivative of the w_ϵ norm of the solutions of (1.1) is negative.

Calculating the derivative and integrating by parts, we find that

$$\frac{d}{dt}\|u(t)\|^2_{L^2_{w,\epsilon}} = \epsilon \int \sinh(\epsilon x)\varphi(x)u^2(x)\,dx + \int w_\epsilon(x)\varphi'(x)u^2\,dx - 2\int (w_\epsilon u)_{xx}u_{xx}\,dx.$$

We note that if $\varphi'(x) \le 0$, then $\epsilon = 0$ is sufficient to force the norm of the solution not to increase. It is because our profile is not monotone that we must make use of a weighted norm in order to get any sort of linear stability result.

A simple calculation shows that

$$\int (w_\epsilon u)_{xx}u_{xx}\,dx = \int (\epsilon^2 w_\epsilon u + 2\epsilon \sinh(\epsilon x)u_x + w_\epsilon u_{xx})u_{xx}\,dx.$$

Integration by parts leads to

$$\int \epsilon^2 w_\epsilon u u_{xx}\,dx = \int \frac{\epsilon^4}{2} w_\epsilon u^2\,dx - \epsilon^2 \int w_\epsilon u_x^2\,dx,$$

and

$$\int 2\epsilon \sinh(\epsilon x)u_x u_{xx} = -\epsilon^2 \int w_\epsilon(x)u_x^2\,dx.$$

Finally, we find that

$$\begin{aligned}\frac{d}{dt}\|u(t)\|^2_{L^2_{w,\epsilon}} &= \epsilon \int \sinh(\epsilon x)\varphi(x)u^2(x)\,dx + \int w_\epsilon(x)\varphi'(x)u^2\,dx \\ &\quad -2\int w_\epsilon(x)(u_{xx})^2\,dx + 4\epsilon^2 \int w_\epsilon(x)u_x^2\,dx - \epsilon^4 \int w_\epsilon u^2\,dx.\end{aligned}$$

To finish off our calculations, we estimate these terms in such a way that they can be written as the integral of the product the weight, $w_\epsilon(x)$, a function to be determined, $\Psi(x)$, and $u^2(x)$. To do this we bound $\int w_\epsilon u_x^2\,dx$ as follows:

$$\begin{aligned}\int w_\epsilon u_x^2\,dx &= \frac{1}{2}\epsilon^2 \int w_\epsilon u^2\,dx - \int w_\epsilon u u_{xx}\,dx \\ &\le \frac{1}{2}\epsilon^2 \int w_\epsilon u^2\,dx + \sqrt{\int w_\epsilon u^2\,dx \int w_\epsilon u_{xx}^2\,dx} \\ &\le \frac{1}{2}\epsilon^2 \int w_\epsilon u^2\,dx + \frac{c}{2}\int w_\epsilon u^2\,dx + \frac{1}{2c}\int w_\epsilon u_{xx}^2\,dx.\end{aligned}$$

Picking $c = \epsilon^2$ we find that

$$\frac{d}{dt}\|u(t)\|^2_{L^2_{w,\epsilon}} \le \int w_\epsilon \left(\varphi'(x) + \epsilon \tanh(\epsilon x)\varphi(x) + 3\epsilon^4\right) u^2(x)\,dx.$$

We have shown that a sufficient condition for the derivative to be decreasing at the rate $a\|u\|^2_{L^2_{w,\epsilon}}$ is

$$\Psi(x) \equiv \varphi'(x) + \epsilon \tanh(\epsilon x)\varphi(x) + 3\epsilon^4 < -a < 0.$$

We note that the balancing that occurs here—between $\varphi(x)$, $\varphi'(x)$, and $3\epsilon^4$—is expected. As a rule, exponential weights tend to destabilize parabolic PDEs [2].

Therefore, the $3\epsilon^4$ which comes from the parabolic part of (1.1) *should* tend to destabilize the problem.

The other two terms come from the fundamentally hyperbolic part of the problem. If we were dealing with the equation $u_t+\varphi(x)u_x=0$, then the fact that $\varphi(x)\to\mp 1$ as $x\to\pm\infty$ would force the solutions to "flow in from infinity." Thus, the term involving $\varphi(x)$ *should* help us. Similarly, if we were dealing with the hyperbolic PDE, then the solution would "focus" where $\varphi'(x)$ is negative, and hence, its $L^2_{w_\epsilon}$ norm would shrink at a rate related to $\varphi'(x)$. The solution would "spread" where $\varphi'(x)$ is positive, and there would be an increase in the $L^2_{w_\epsilon}$ norm.

The condition on $\Psi(x)$ says that the "focusing" (or "spreading") due to $\varphi'(x)$, the drift in from infinity due to $\varphi(x)$, and the smearing caused by the parabolic term must balance properly. If they balance properly, then we can show that the solutions of (1.1) decay in our weighted norm. In the next section we will show that $\Psi(x)\le -a$ by using various estimates on the size of $\varphi(x)$ and $\varphi'(x)$ for various regions of the real line. That is, we will show that for certain values of ϵ the three effects balance properly.

Remark. If we show that $\Psi(x)\le -a$, then we will have shown that $\|u\|_{L^2_{w_\epsilon}}\le e^{-at/2}\|u_0\|_{L^2_{w_\epsilon}}$. This is a more precise result than our result in [2]. Using a combination of the theory of sectorial operators and Michelson's results the most that one can say is that there exists a constant C such that $\|u\|_{L^2_{w_\epsilon}}\le Ce^{-at/2}\|u_0\|_{L^2_{w_\epsilon}}$. In this sense, the analytical method gets better results than our previous method got.

3. The proof that $\Psi(x)<-a$. First we note that as $\tanh(\epsilon x)$ and $\varphi(x)$ are odd and $\varphi'(x)$ is even, $\Psi(x)$ is even. Therefore, if $\Psi(x)<-a$ in the region $x\ge 0$, then $\Psi(x)<-a$ on the whole real line.

Looking at the computer drawn plot of $\varphi(x)$ (for purposes of illustration) it is clear that if $\Psi(x)$ is to be negative for small x, then φ' must be rather negative for small x. Because $\varphi(x)$ itself is small for small x, the $\varphi'(x)$ must be quite negative in order to force $\Psi(x)$ to be negative. Similarly, for large x it is clear that $\varphi'(x)$ is small. Therefore, for large x we will have to show that $\varphi(x)$ is relatively large and negative. From Figure 3.1, it seems that it should be possible to prove these results.

There are two major steps in our proof. First, we extend the methods of Koppel and Howard. They proved the existence of a solution $\varphi(x)$ by showing that two curves must intersect. We determine how the curves intersect. We then show that in each of four regions $\varphi(x)$ and $\varphi'(x)$ are small enough that $\Psi(x)$ is negative in those four regions. The four regions are as follows:

1. Region I, which goes from $x=0$ until the first point at which $\varphi(x)=-.5$.
2. Region II, which goes from the first point at which $\varphi(x)=-.5$ to the first point at which $\varphi(x)=-1$.
3. Region III, which goes from the first point at which $\varphi(x)=-1$ to the first point at which $\varphi'(x)=0$.
4. Region IV, which is the region to the right of Region III.

(In Figure 3.1, the four regions are delineated by dotted lines. The first region starts to the right of the first dotted line.) In all of these steps we make use of estimates contained in Koppel and Howard.

3.1. Locating the intersection—An introduction. Before proceeding, we explain the nature of the method used by Koppel and Howard. (Note that their results are stated for $-\varphi(t)$. We convert all of their results to results about $\varphi(x)$.) Following Koppel and Howard, we denote $\frac{d}{dx}$ by $\dot{}$ and $\frac{d^2}{dx^2}$ by $\ddot{}$. Koppel and Howard

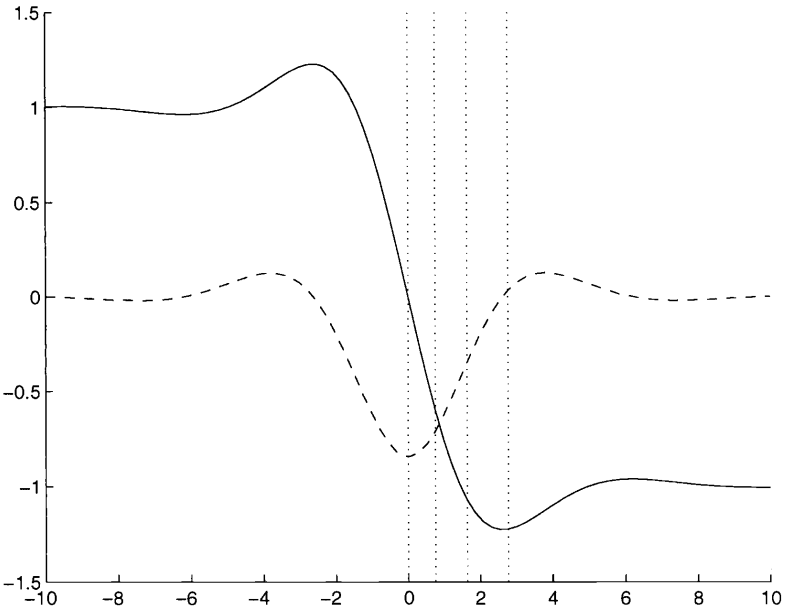

FIG. 3.1. $\varphi(x)$ *(solid line) and* $\varphi'(x)$ *(dashed line).*

look at solutions of the equation

$$\frac{d^3}{dx^3}p(x,\nu) = \frac{1}{2}(1 - p^2(x,\nu)) \tag{3.1}$$

subject to the initial conditions $p(0,\nu) = \ddot{p}(0,\nu) = 0, \dot{p}(0,\nu) = -\nu$. They find analytical bounds for $p(x,\nu)$ and its first two derivatives. They show that the function $p_2(x,\nu)$ is an upper-bound of $p(x,\nu)$ in the region $0 \le x \le 2\sqrt{\nu}$ (see fact I.1 below) and that $Q_3(x,\nu) = p_2(x,\nu) - 6\nu^3 x^9/9!$ is a lower-bound as long as $p(x,\nu)$ has not yet hit -1 (see fact I.2 below).

They proceed to show that the stable manifold, $u(x,\kappa)$ (where κ parameterizes the manifold), of the solution $(-1,0,0)$ can be approximated by $-1 + u_2(x,\kappa)$ where $u_2(x,\kappa)$ is defined below (in fact II.5). Looking at fact II.5, we see that the parameter κ is essentially the "amplitude" of the perturbation. They proceed to estimate the first point at which p hits -1 and the first point after $x = 0$ at which u hits -1. They show that there exists a ν_0 and a κ_* and points x_0 and x_* such that $p(x_0,\nu_0) = (-1,\alpha,\beta)$ and $u(x_*,\kappa_*) = (-1,\alpha,\beta)$. Since the equation is autonomous, this shows that there exists an odd solution of the ODE that is equal to $(0,-\nu,0)$ when $x = 0$ and that tends towards -1 as x gets large.

Koppel and Howard do not try to evaluate ν_0 and κ_*. As we need to make use of particular properties of the solution, we must know these values more precisely.

In our proof we make use of the following facts proven in Koppel and Howard [4].

Facts from Koppel and Howard.

I. Facts related to $p(x,\nu)$.

1. The function $p_2(x,\nu) = -\nu x + x^3/12 - \nu^2 x^5/120 + \nu x^7/2520 - x^9/145,152$ is an upper-bound of p in the region $0 \le x \le 2\sqrt{\nu}$. Furthermore, in this region $\dot{p}_2$ and $\ddot{p}_2$ are upper-bounds of the first two derivatives of p as well [4, p. 318].

2. The function $Q_3(x,\nu) = p_2(x,\nu) - 6\nu^3 x^9/9!$ is a lower-bound for $p(x,\nu)$ as long as $p(x,\nu)$ has not yet hit -1. Furthermore, in this region $\dot{Q}_3$ and $\ddot{Q}_3$ are lower-bounds of the first two derivatives of p as well [4, p. 319].
3. For all $x \geq 0$, $\dot{p}(x,\nu) \leq -\nu + x^2/4$ [4, p. 318, Eq. 6.1].
4. Let $x_{0,\nu}$ be the first point at which $p(x,\nu) = 0$. Let T be the curve of points $(\dot{p}(x_{0,\nu},\nu), \ddot{p}(x_{0,\nu},\nu))$. Then T slopes upward [4, p. 321].

II. Facts related to $u(x,\kappa)$.

5. The function

$$u_2(x,\kappa) = -\kappa e^{-x/2}\sin\left(\frac{\sqrt{3}}{2}x\right) + \frac{\kappa^2}{8}e^{-x}\left(1 + \frac{2}{7}\cos(\sqrt{3}x)\right)$$

satisfies the inequality

$$|u(x,\kappa) - (-1 + u_2(x,\kappa))| \leq .0714\kappa^3 e^{-3x/2} \quad [4, \text{p. } 327].$$

6. Similarly, the function

$$\dot{u}_2(x,\kappa) = -\kappa e^{-x/2}\cos\left(\frac{\sqrt{3}}{2}x + \frac{\pi}{6}\right) - \frac{\kappa^2}{8}e^{-x}\left(1 + \frac{4}{7}\cos\left(\sqrt{3}x - \frac{\pi}{3}\right)\right)$$

satisfies

$$|\dot{u}(x,\kappa) - \dot{u}_2(x,\kappa)| \leq .1363\kappa^3 e^{-3x/2} \quad [4, \text{p. } 327\text{–}328].$$

7. Let $x_{0,\kappa}$ be the first nonnegative point at which $u(x,\kappa) = 0$. Let S_1 be the curve of points $(\dot{u}(x_{0,\kappa},\kappa), \ddot{u}(x_{0,\kappa},\kappa))$. Then for $0 \leq \kappa \leq .856$, S_1 slopes downward [4, p. 330].
8. For $0 \leq \kappa \leq 1$ the curve S_1 lies between the curves $y = -x$ and $y = -x + .175x^2 - .3x^3$ [4, p. 329].
9. For any $\kappa \leq 1$, $u(x,\kappa)$ crosses zero exactly once in the region $0 \leq x \leq .3\kappa$ [4, Lem. 6.5, p. 328].

3.2. A refinement of the method of Koppel and Howard. In their paper, Koppel and Howard establish the existence of $\varphi(x)$ by showing that the manifold of the solutions of (3.1) that have initial data $p(0,\nu) = \ddot{p}(0,\nu) = 0, \dot{p}(0,\nu) = -\nu$ intersects the stable manifold of the solution $u \equiv -1$. We are interested in actually figuring out roughly how the intersection occurs.

From fact II.8, we see that if we can estimate $\dot{u}(x_{0,\nu},\nu)$, then we automatically have an estimate of $\ddot{u}(x_{0,\nu},\nu)$ as well. From facts II.7 and II.8 we see that if we can locate two points on S_1, we can say quite a bit about the locations of all the points on S_1 between these two points. We note that if $\kappa = 0$ then $u_2 \equiv 0$. Thus, the intersection with -1 occurs when $\dot{u} = \ddot{u} = 0$. Therefore, $(0,0)$ is one point on S_1.

Next, we would like to estimate the point on S_1 that corresponds to $\nu = .67$. Using fact II.5, it is easy to see that $u(.09,.67) > -1$ and $u(.17,.67) < -1$. Thus, $u(x,.67)$ must cross -1 somewhere in the region $.09 \leq x \leq .17$. Making use of fact II.6, we see that the function $\dot{u}_2 + .1363\kappa^3 e^{-3x/2}$ is an upper bound for $\dot{u}(x,\kappa)$. It is easy to see that $\dot{u}_2 + .1363\kappa^3 e^{-3x/2}$ is an increasing function of x if $\kappa \leq .7$ and $x \leq .2$. (Just check its derivative.) Therefore, we evaluate $\dot{u}_2 + .1363\kappa^3 e^{-3x/2}$ at $x = .17$ in order to get an upper-bound on the derivative at the point at which $u(x,.67)$ first

crosses -1. We find that $\dot{u}(x, .67) \leq -.5174$ as long as $x \leq .17$. Using facts II.7 and II.8 we see that any curve that must cross the crosshatched region in Figure 3.2 must cross the curve S_1, and $0 \leq \kappa \leq .67$ at the point at which the curves cross.

We now show that T crosses the crosshatched region for a value of ν between .8 and .9. If $\nu = .8$, then at the point at which p crosses -1, Koppel and Howard have shown that $-.2831 \leq \dot{p} \leq -.2770$ [4, p. 319–320] and $.472 \leq \ddot{p} \leq .493$. Following Koppel and Howard we find a similar estimate for $\nu = .9$. We note that $Q_3(1.28, .9) = -.9986$ and $p_2(1.29, .9) = -1.0042$. As Q_3 is a lower-bound, and p_2 is an upper-bound, we see that there exists $1.28 \leq x_{0,.9} \leq 1.29$ such that $p(x_{0,.9}, .9) = -1$. A simple calculation shows that if $\nu = .9$, then both $\ddot{p}_2$ and $\ddot{Q}_3$ are positive in the $1.28 \leq x \leq 1.29$. Therefore, both $\dot{p}_2$ and $\dot{Q}_3$ are increasing in this region. Thus,

$$-.5712 = \dot{Q}_3(1.28, .9) \leq \dot{p}(x_{0,.9}, .9) \leq \dot{p}_2(1.29) = -.5664.$$

As p is decreasing when it passes through $x_{0,.9}$, we see from (3.1) that the third derivative of p goes from positive to negative as it crosses through $x_{0,.9}$. That is, $x_{0,.9}$ is a local maximum of $\ddot{p}(x, .9)$. Thus, $\ddot{p}(x_{0,.9}, .9) \geq \ddot{Q}_3(1.28, .9) = .4007$. Note that $\frac{d^3}{dx^3} p_2 = \frac{1}{2}(1 - p_1^2)$ with $p_1(x, \nu) = -\nu x + x^3/12$. Clearly, p_1 is decreasing in the interval, and we see that $p_1(1.29, .9) = -.9821 > -1$. Thus, we find that the third derivative of p_2 is positive in the whole interval. That implies that $\ddot{p}_2$ is increasing in the interval. Thus, $\ddot{p}(x_{0,.9}, \nu) \leq \ddot{p}_2(1.29, .9) = .4058$. We see then that $.4007 \leq \ddot{p} \leq .4058$.

Remark. In evaluating p_2 and Q_3, we are evaluating polynomials with rational coefficients at rational numbers. Such calculations can be made with perfect accuracy. A simple way to keep such calculations exact is to do the calculations using Mathematica. All critical calculations involving polynomials with rational coefficients were performed in this fashion. Only after the calculations were finished were the results rounded to four places.

Looking at Figure 3.2 we see that because T slopes up (see fact I.4), T must cross the crosshatched region.

Thus, we see that the intersection of T and S_1 takes place when κ is between 0 and .67 and ν is between .8 and .9.

The behavior of $\varphi(x)$ can now be studied by studying the behavior of $p(x, \nu)$ *until* its first positive -1 crossing and by studying the behavior of $u(x, \kappa)$ *after* its first -1 crossing. In section 3.3 we study the behavior of $\varphi(x)$ in regions I and II by making use of our knowledge of $p(x, \nu)$. In section 3.4 we study the behavior of $\varphi(x)$ by making use of our knowledge of $u(x, \kappa)$.

3.3. Estimates for regions I and II. From fact I.3, we see that for any ν we know that $p_2(x, \nu)$ decreases until at least $x = 2\sqrt{\nu}$. We want to find a value, $x_\dagger$, such that for all $.8 \leq \nu \leq .9$ we know $p_2(x_\dagger, \nu)$ is less than $-.5$. We will then estimate the values of the derivative in the region $0 \leq x \leq x_\dagger$—a region that includes region I. By showing that in region I the derivative is suitably small, we will later be able to show that $\Psi(x)$ is negative.

If $.8 \leq \nu \leq .9$, we find that

$$\begin{aligned} p_2 &= -\nu x + x^3/12 - v^2 x^5/120 + \nu x^7/2520 - x^9/145,152 \\ &\leq -.8x + x^3/12 - .64x^5/120 + .9x^7/2520 - x^9/145,152. \end{aligned}$$

From fact I.3, we know that $p(x, \nu)$ decreases as long as $x \leq 2\sqrt{\nu} \leq 2\sqrt{.8} = 1.79$. We find that the right-hand side first falls below $-.5$ for some $x \leq .66$; we let $x_\dagger = .66$. From fact I.3, we see that for all $0 \leq x \leq x_\dagger$, the derivative of the solution is less

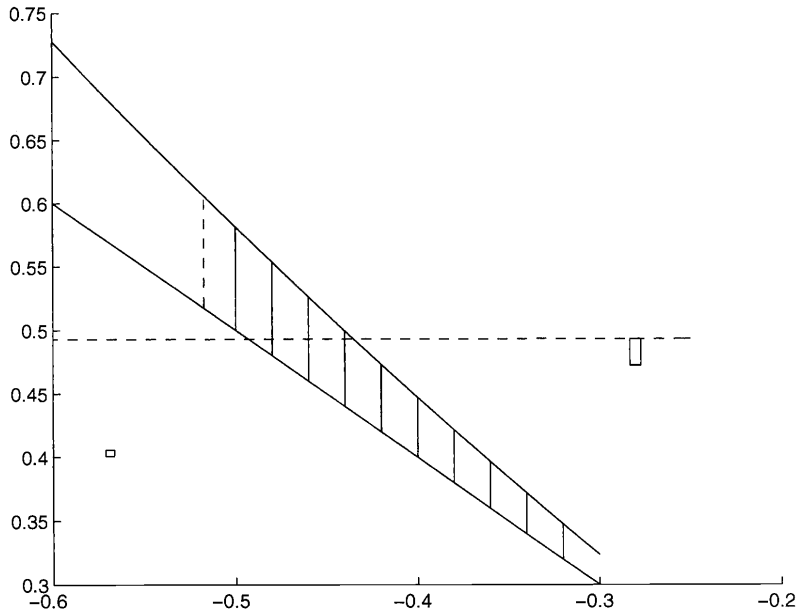

FIG. 3.2. *The crossing of T and S_1. The small box to the left shows the rigorous bounds on $(\dot{p}(x_{0,.8},.8),\ddot{p}(x_{0,.8},.8))$. The small box on the right shows the rigorous bounds on $(\dot{p}(x_{0,.9},.9),\ddot{p}(x_{0,.9},.9))$. The crosshatched region must contain the curve S_1, and T must start from the box on the left and move up to the box on the right. Clearly, T crosses the crosshatched region and, therefore, S_1.*

than or equal to $-\nu + .66^2/4 \le -.6911$. Also, we find that the right-hand side is less than -1 when $x = 1.66$. Therefore, the first -1 crossing occurs before this point. For $0 \le x \le 1.66$ and $.8 \le \nu \le .9$, we find that $p'(x,\nu) \le -.8 + 1.66^2/4 = -.1111$.

Because of the fact that $\tanh(\epsilon x)$ appears in $\Psi(x)$, it will be important to know what the earliest point at which the profile may hit $-.5$ or -1 is. To determine this, we look for the last point at which $Q_3(x)$ cannot be less than $-.5$ or -1 for values of ν between .8 and .9.

$$\begin{aligned} Q_3 &= -\nu x + x^3/12 - \nu^2 x^5/120 + \nu x^7/2520 - x^9/145,152 - 6\nu^3 x^9/9! \\ &\ge -.9x + x^3/12 - .81x^5/120 + .8x^7/2520 - x^9/145,152 - 6.7290x^9/9!. \end{aligned}$$

We find that when $x = .55$ the right-hand side is equal to $-.4815$. Thus, the first $-.5$ crossing does not come before $x = .55$. When $x = 1.2$, the right-hand side is $-.9516$. Thus, the first -1 crossing cannot come before $x = 1.2$.

3.4. Estimates for region III and region IV. We show that as long as $\kappa \le .67$, $\varphi'(x)$ cannot get too positive in region IV. (By definition, $\varphi'(x)$ is nonpositive in region III.) From fact II.6 we see that

$$\begin{aligned} \dot{u} &\le -\kappa e^{-x/2}\cos\left(\frac{\sqrt{3}}{2}x + \frac{\pi}{6}\right) - \frac{\kappa^2}{8}e^{-x}\left(1 + \frac{4}{7}\cos\left(\sqrt{3}x - \frac{\pi}{3}\right)\right) + .1363\kappa^3 e^{-3x/2} \\ &\le -\kappa e^{-x/2}\cos\left(\frac{\sqrt{3}}{2}x + \frac{\pi}{6}\right) + .67^2\left(-\frac{1}{8} + \frac{1}{14} + .1363 \times .67\right)e^{-x} \end{aligned}$$

Region	Does not begin before $x =$	$\varphi \leq$	$\varphi' \leq$
I	0	0	$-.6911$
II	.55	$-.5$	$-.1111$
III	1.2	$-.8292$	0
IV	2.208	$-.8979$	.1783

TABLE 3.1
A summary of our results about φ and φ'.

$$\leq -\kappa e^{-x/2}\cos\left(\frac{\sqrt{3}}{2}x+\frac{\pi}{6}\right)+.0169e^{-x}.$$

A simple calculus argument shows that

$$-e^{-x/2}\cos\left(\frac{\sqrt{3}}{2}x+\frac{\pi}{6}\right)\leq -e^{-\frac{2\pi}{3\sqrt{3}}}\cos(5\pi/6)=.1732.$$

As $-\kappa^2 e^{-x}/8+.1363\kappa^3 e^{-3x/2}$ is always negative if $x\geq 0$ and $\kappa\leq .67$, it is clear that for $x\geq 0$ $\dot{u}$ cannot get positive until one of the sinusoids above gets negative. It is easy to see that the first point at which this happens is $x=\frac{2\pi}{3\sqrt{3}}\geq 1.209$. We will need this fact later as well. We find that the largest value of $\dot{u}$ cannot exceed $.1732+.0169e^{-1.209}=.1783$.

Looking at u region III and making use of fact II.5, we find that

$$\begin{aligned}u&\leq -1-\kappa e^{-x/2}\sin\left(\frac{\sqrt{3}}{2}x\right)+\frac{\kappa^2}{8}e^{-x}\left(1+\frac{2}{7}\cos(\sqrt{3}x)\right)+.0714\kappa^3e^{-3x/2}\\&\leq -1-\kappa e^{-x/2}\sin\left(\frac{\sqrt{3}}{2}x\right)+e^{-x}\frac{9\kappa^2}{56}+.0714\kappa^3e^{-3x/2}\\&\leq -1-\kappa e^{-x/2}\sin\left(\frac{\sqrt{3}}{2}x\right)+.0963.\end{aligned}$$

A simple calculus argument shows that $-\kappa e^{-x/2}\sin(\frac{\sqrt{3}}{2}x)\leq .0771$. This shows that $u\leq -1+.1708=-.8292$. Thus, we see that in region III the value of φ never gets above $-.8292$. The region in which φ' may be positive, region IV, starts no earlier than when the x used in u_2 is equal to 1.209. In this region we find that $\varphi(x)$ never gets above $-1+.0771+e^{-1.209}\frac{9}{56}.67^2+.0714(.67^3)e^{-3\cdot 1.209/2}=-.8979$ and φ' never gets above .1783.

From fact II.9 we see that the first -1 crossing of u never occurs later than $.3\cdot .67=.201$. We have seen that the derivative never gets positive earlier than 1.209. Thus, the derivative never gets positive earlier than 1.008 units past the point at which the solution first crosses -1. Combining this with our earlier result, we find that the $\varphi'(x)$ never gets positive before $x=2.208$. We summarize these results in Table 1.

We now evaluate $\Psi(x)$ in each of our regions. Recall that $\Psi(x)=\varphi'(x)+\epsilon\tanh(\epsilon x)\varphi(x)+3\epsilon^4$. In region I, we see that $\Psi(x)\leq -.6911+3\epsilon^4$. In region II,

we know that $x \geq .55$. Thus, in region II $\Psi(x) \leq -.1111 - .5\epsilon \tanh(.55\epsilon) + 3\epsilon^4$. In region III, $\Psi(x) \leq -.8292\epsilon \tanh(1.2\epsilon) + 3\epsilon^4$. Finally, in region IV we find that $\Psi(x) \leq .1783 - .8979\epsilon \tanh(2.2\epsilon) + 3\epsilon^4$.

We find that $-.6911 + 3\epsilon^4$ is negative as long as $\epsilon \leq .69$. Similarly, $-.1111 - .5\epsilon \tanh(.55\epsilon) + 3\epsilon^4$ is negative as long as $\epsilon \leq .49$. Additionally, $-.8292\epsilon \tanh(1.2\epsilon) + 3\epsilon^4$ is negative until $\epsilon > .54$. Finally, $.1783 - .8979\epsilon \tanh(2.2\epsilon) + 3\epsilon^4$ is negative as long as $.43 \leq \epsilon \leq .47$. Thus, if $.43 \leq \epsilon \leq .47$ we find that Ψ is negative and all solutions of the PDE must decay exponentially quickly in the w_ϵ norm.

We have shown that there exist values of ϵ for which solution of (1.1) decay exponentially quickly in the w_ϵ norm. Using Michelson's rigorous numerical results, one can show that a larger range of ϵ gives this decay. That these methods give somewhat better results is not surprising—the estimates we use here are rather crude. Conversely, we have seen that where our method works, it gives us somewhat more information than we got using the numerical results. Using our current method, we find that there is no possibility of the solution increasing even momentarily. Our results also have the advantage of all analytical results. They are easy to understand and simple to check.

Acknowledgment. We would like to thank Professor Steve Schochet of Tel Aviv University for many helpful discussions and for suggesting that it was possible to show that there exist epsilon for which $\Psi(x)$ is strictly negative.

BEHAVIOR OF SOLUTIONS OF 2D QUASI-GEOSTROPHIC EQUATIONS*

PETER CONSTANTIN† AND JIAHONG WU‡

Abstract. We study solutions to the 2D quasi-geostrophic (QGS) equation

$$\frac{\partial\theta}{\partial t} + u\cdot\nabla\theta + \kappa(-\Delta)^{\alpha}\theta = f$$

and prove global existence and uniqueness of smooth solutions if $\alpha \in (\frac{1}{2}, 1]$; weak solutions also exist globally but are proven to be unique only in the class of strong solutions. Detailed aspects of large time approximation by the linear QGS equation are obtained.

Key words. quasi-geostrophic equation, existence, uniqueness, large time approximation

1. Introduction.

This paper is concerned with the 2D surface quasi-geostrophic (QGS) equation

$$\frac{\partial\theta}{\partial t} + u\cdot\nabla\theta + \kappa(-\Delta)^{\alpha}\theta = f,$$

where $\alpha \in [0,1]$, $\kappa > 0$, and $\theta = \theta(x,t)$ is a real scalar function of two space variables x and a time variable t. The velocity $u = (u_1, u_2)$ is incompressible and determined from θ by a stream function ψ:

$$(u_1, u_2) = \left(-\frac{\partial\psi}{\partial x_2}, \frac{\partial\psi}{\partial x_1}\right), \tag{1.1}$$

and the stream function ψ satisfies

$$(-\Delta)^{\frac{1}{2}}\psi = -\theta. \tag{1.2}$$

The nonlocal operator $(-\Delta)^{\beta}$ $(\beta \geq 0)$ is defined through the Fourier transform

$$\widehat{(-\Delta)^{\beta} f}(\xi) = |\xi|^{2\beta}\widehat{f}(\xi),$$

where $\widehat{f}$ is the Fourier transform of f [11]. For notational convenience, we write Λ for $(-\Delta)^{\frac{1}{2}}$.

The variable θ in the 2D QGS equation represents the potential temperature, u is the fluid velocity, and the stream function ψ can be identified with the pressure. When the fractional power $\alpha = 1/2$, the equation, derived from the more general quasi-geostrophic models (see pages 345–368 and 653–670 of [7]), describes the evolution

of the temperature on the 2D boundary of a rapidly rotating half-space with small Rossby and Ekman numbers. Dimensionally, the 2D QGS equation with $\alpha = 1/2$ is the analogue of the 3D Navier–Stokes equations. The general fractional power α is considered here in order to observe the minimal power of Laplacian necessary in the analysis and thus make a comparison with the 3D Navier–Stokes equations [3], [6].

Recently, this equation has been intensively investigated because of both its mathematical importance and its potential for applications in meteorology and oceanography [4], [7], [5]. Mathematically, the behavior of solutions to the 2D QGS equation is strikingly similar to that of the potentially singular solutions to the 3D hydrodynamics equations. Despite exhibiting a number of similar features, the 2D QGS equation is considerably simpler than the 3D Euler or Navier–Stokes equations.

The smooth solution of the QGS equation is unique but, if $\kappa = 0$, it is known to exist only for a finite time [4]. On the other hand, weak solutions are global but their uniqueness is unknown [8]. Whether the smooth solution develops singularity in finite time and whether weak solutions are unique are fundamental mathematical issues related to the QGS equation. We show in section 2 that the solution remains smooth for all time for $\alpha \in (\frac{1}{2}, 1]$ and any weak solution must coincide with a more regular solution as long as such a strong solution exists.

Large time behavior of weak solutions is investigated in sections 3 and 4. In section 3, the L^2 decay rate of order $t^{-\frac{1}{2\alpha}}$ is obtained. For generic initial data, this rate is optimal. The solution θ of the nonlinear equation may be approximated by the solution Θ of the linear equation with a higher-order correction. An explicit form for the higher-order correction is attempted in section 4. A rate of order $t^{\frac{1}{2}-\frac{1}{\alpha}}$ is first obtained without any smoothness assumption. With the assumption that

$$\|\Lambda^{2-2\alpha+\delta}\theta(\cdot,t)\|_{L^2} \quad \sim \quad t^{-\epsilon},$$

the ratio and the difference are shown to behave as follows:

$$\frac{\|\theta(\cdot,t)\|_{L^2}}{\|\Theta(\cdot,t)\|_{L^2}} \sim 1 + O(t^{-\min\{\frac{1}{2\alpha},\epsilon\}}), \quad \|\theta(\cdot,t) - \Theta(\cdot,t)\|_{L^2} \sim t^{-\frac{1}{2\alpha}-\min\{\frac{1}{2\alpha},\epsilon\}},$$

which imply that the effect of the nonlinearity is felt only in the higher-order correction.

We conclude this introduction by mentioning the global existence result of weak solutions obtained in [8]. When not specified, the spatial domain can be either the whole $\mathbb{R}^2$ or the 2D torus $\mathbb{T}^2$.

PROPOSITION 1.1. *Let $T > 0$ be arbitrary. Then for every $\theta_0 \in L^2$ and $f \in L^2([0,T]; H^{-\alpha})$, there exists a weak solution of*

$$\partial_t\theta + u \cdot \nabla\theta + \kappa\Lambda^{2\alpha}\theta = f, \tag{1.3}$$

$$\theta\,|_{t=0} = \theta_0 \tag{1.4}$$

which satisfies

$$\theta \in L^\infty([0,T]; L^2) \cap L^2([0,T]; H^\alpha).$$

2. Global smooth solution and uniqueness. It is shown here that weak solutions of the QGS equation are globally smooth for $\alpha \in (\frac{1}{2}, 1]$ and "strong" solutions are unique. The spatial domain here is the 2D torus $\mathbb{T}^2$.

THEOREM 2.1. *Let $\alpha \in (\frac{1}{2}, 1]$, $\beta \geq 0$, and $\beta + 2\alpha > 2$. If $\theta_0 \in H^\beta(\mathbb{T}^2)$ and if, for $T > 0$,*

$$f \in L^2([0,T]; H^{\beta-\alpha}), \quad \int_0^T \|f(\tau)\|_{L^q} d\tau < \infty,$$

where $q = \infty$ for $\beta \geq 1$ and $q = 2/(1-\beta)$ for $\beta < 1$, then the solution θ of (1.3) and (1.4) obeys for all $t \leq T$

$$\|\Lambda^\beta \theta(t)\|_{L^2} \leq C, \tag{2.1}$$

where C is constant depending only on T, $\|\theta_0\|_{H^\beta}$, $\|f\|_{L^2([0,T];H^{\beta-\alpha})}$, and $\int_0^T \|f(\tau)\|_{L^q} d\tau$.

Proof. We sketch the proof. Taking the scalar product of (1.3) with $\Lambda^{2\beta}\theta$

$$\frac{1}{2}\frac{d}{dt}\int |\Lambda^\beta \theta|^2 + \kappa \int |\Lambda^{\alpha+\beta}\theta|^2 = -\int (u \cdot \nabla\theta)\Lambda^{2\beta}\theta + \int \Lambda^{2\beta}\theta f$$

and using the estimates

$$\left| \int \Lambda^{2\beta}\theta f \right| \leq \frac{\kappa}{4}\|\Lambda^{\alpha+\beta}\theta\|_{L^2}^2 + \frac{1}{\kappa}\|\Lambda^{\beta-\alpha} f\|_{L^2}^2, \tag{2.2}$$

$$\left| \int (u \cdot \nabla\theta)\Lambda^{2\beta}\theta \right| \leq \frac{\kappa}{4}\|\theta\|_{H^{\alpha+\beta}}^2 + C(\kappa, \theta_0, f)\|\theta\|_{H^\beta}^2, \tag{2.3}$$

where $C(\kappa, \theta_0, f)$ is constant, we obtain (2.1) after applying Gronwall's inequality. The estimate (2.3) is obtained by using the calculus inequality (see page 61 of [8] and inequality (3.1.59) on page 74 of [12])

$$\|\Lambda^s(gh)\|_{L^2} \leq C(\|g\|_{L^q}\|\Lambda^s h\|_{L^p} + \|h\|_{L^q}\|\Lambda^s g\|_{L^p})$$

with $1/p + 1/q = 1/2$, $g = u$, $h = \theta$, $s = \beta + 1 - \alpha$, and the maximum principle

$$\|\theta\|_{L^q} \leq \|\theta_0\|_{L^q} + \int_0^t \|f(\tau)\|_{L^q} d\tau. \qquad \square$$

Although weak solutions may not be unique, there is at most one solution in the class of "strong" solutions.

THEOREM 2.2. *Assume that $\alpha \in (\frac{1}{2}, 1]$, $T > 0$, p and q satisfy*

$$p \geq 1, \quad q > 0, \qquad \frac{1}{p} + \frac{\alpha}{q} = \alpha - \frac{1}{2}; \tag{2.4}$$

then there is at most one solution θ of the QGS equation with initial data $\theta_0 \in L^2$ such that

$$\theta \in L^\infty([0,T]; L^2) \cap L^2([0,T]; H^\alpha), \tag{2.5}$$

$$\theta \in L^q([0,T]; L^p). \tag{2.6}$$

We make two remarks.

Remark 2.3. It is clear from the proof given below that we can assume that only one of the two solutions is "strong," i.e., in the class (2.5), (2.6), the other being only a weak solution.

Remark 2.4. By taking $\alpha = 1$, (2.6) with (2.4) reduces exactly to the regularity assumptions in obtaining uniqueness for weak solutions to the 3D Navier–Stokes equations (cf. Temam [13, p. 299]). Theorem 2.2 is a sort of generalization in the sense that it holds for a range of $\alpha \in (\frac{1}{2}, 1]$.

Proof of Theorem 2.2. The difference $\theta = \theta_A - \theta_B$ of two solutions θ_A and θ_B satisfies

$$\partial_t \theta + u \cdot \nabla \theta_A + u_B \cdot \nabla \theta + \kappa \Lambda^{2\alpha} \theta = 0 \tag{2.7}$$

in which $u = u_A - u_B$ with u_A and u_B being the velocities corresponding to θ_A and θ_B. We take the scalar product of (2.7) with $\psi = -\Lambda^{-1}\theta$ and use

$$\int_{\mathbb{T}^2} \psi u \cdot \nabla \theta_A = 0,$$

$$\left| \int_{\mathbb{T}^2} \theta u_B \cdot \nabla \psi \right| \le \kappa \|\psi\|^2_{H^{\alpha+\frac{1}{2}}} + C(\kappa) \|\theta_B\|^{\frac{1}{1-\beta}}_{L^p} \|\psi\|^2_{H^{\frac{1}{2}}},$$

where $\beta = \frac{1}{\alpha}\left(\frac{1}{2} + \frac{1}{p}\right)$ and $C(\kappa) = C\kappa^{-\frac{\beta}{1-\beta}}$ (see page 32 of [8]). It then follows that

$$\frac{d}{dt}\|\psi\|^2_{H^{\frac{1}{2}}} \le C(\kappa) \|\theta_B\|^{\frac{1}{1-\beta}}_{L^p} \|\psi\|^2_{H^{\frac{1}{2}}},$$

which implies that $\psi = 0$ and thus $\theta = 0$. □

3. Large time behavior. The large time behavior of weak solutions is investigated in this section. We adapt well-known ideas of Amick, Bona, and Schonbek [1] and Schonbek [9], [10].

We first analyze the case when the force $f = 0$ and the result can be stated as follows.

THEOREM 3.1. *Let $\alpha \in (0, 1]$ and $\theta_0 \in L^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^2)$. Then there exists a weak solution θ of the 2D QGS equation*

$$\partial_t \theta + u \cdot \nabla \theta + \Lambda^{2\alpha} \theta = 0, \qquad \theta\,|_{t=0} = \theta_0 \tag{3.1}$$

such that

$$\|\theta(\cdot, t)\|_{L^2(\mathbb{R}^2)} \le C(1+t)^{-\frac{1}{2\alpha}}, \tag{3.2}$$

where C is a constant depending on L^1 and L^2 norms of θ_0.

Remark 3.2. For generic initial data, the rate obtained in Theorem 3.1 is optimal, as implied by Theorem 4.6 of section 4.

The proof of Theorem 3.1 consists of two major steps. The first step is a formal argument to show that (3.2) holds for smooth solutions. In the second step the formal argument is applied to a sequence of "retarded mollifications" [2] and we obtain Theorem 3.1 after passing to the limit. We will need a simple estimate.

LEMMA 3.3. *Assume that $\theta_0 \in L^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^2)$. Then θ satisfies the a priori estimate*

$$|\widehat{\theta}(\xi,t)| \le \|\theta_0\|_{L^1} + |\xi| \int_0^t \|\theta(\tau)\|_{L^2}^2 d\tau.$$

Proof. We have from (3.1)

$$(*) \qquad \partial_t \widehat{\theta} + |\xi|^{2\alpha} \widehat{\theta} = -\widehat{u \cdot \nabla \theta}.$$

Since $\nabla \cdot u = 0$,

$$|\widehat{u \cdot \nabla \theta}| \le |\xi| \|\theta(t)\|_{L^2}^2.$$

After integrating $(*)$, we obtain

$$|\widehat{\theta}(\xi,t)| \le |\widehat{\theta_0}(\xi)| + |\xi| \int_0^t \|\theta(\tau)\|_{L^2}^2 d\tau \le \|\theta_0\|_{L^1} + |\xi| \|\theta_0\|_{L^2}^2 t. \qquad \square$$

Proof of Theorem 3.1. Taking the scalar product of (3.1) with θ we obtain

$$\frac{1}{2} \frac{d}{dt} \int_{\mathbb{R}^n} |\theta|^2 + \int_{\mathbb{R}^n} (\Lambda^\alpha \theta)^2 = 0.$$

Using Plancherel's theorem,

$$\frac{d}{dt} \int_{\mathbb{R}^2} |\widehat{\theta}|^2 + 2 \int_{\mathbb{R}^2} |\xi|^{2\alpha} |\widehat{\theta}|^2 = 0.$$

For the second term

$$\int_{\mathbb{R}^2} |\xi|^{2\alpha} |\widehat{\theta}|^2 \ge \int_{B(t)^c} |\xi|^{2\alpha} |\widehat{\theta}|^2 \ge g^{2\alpha}(t) \int_{B(t)^c} |\widehat{\theta}|^2$$

$$= g^{2\alpha}(t) \int_{\mathbb{R}^2} |\widehat{\theta}|^2 - g^{2\alpha}(t) \int_{B(t)} |\widehat{\theta}|^2,$$

where $g \in C([0,\infty); \mathbb{R}^+)$ remains to be determined and $B(t)^c$ is the complement of $B(t)$ with

$$B(t) = \left\{ \xi \in \mathbb{R}^2 : \quad |\xi| < g(t) \right\}.$$

By Lemma 3.3, we obtain

$$\frac{d}{dt} \int_{\mathbb{R}^2} |\widehat{\theta}|^2 + 2 g^{2\alpha}(t) \int_{\mathbb{R}^2} |\widehat{\theta}|^2$$

$$(3.3) \qquad \le 2\pi g^{2\alpha}(t) \int_0^{g(t)} \left[\|\theta_0\|_{L^1} + r \int_0^t \|\theta(\tau)\|_{L^2}^2 d\tau \right]^2 r dr.$$

By integrating (3.3), we have

$$e^{2\int_0^t g^{2\alpha}(\tau)d\tau}\int_{\mathbb{R}^2}|\widehat{\theta}|^2 \le \|\theta_0\|_{L^2}^2$$

$$+\int_0^t e^{2\int_0^s g^{2\alpha}(\tau)d\tau}\left[C_1 g^{2\alpha+2}(s)+C_2 s g^{2\alpha+4}(s)\int_0^s \|\theta(\tau)\|_{L^2}^4 d\tau\right]ds, \tag{3.4}$$

where $C_1 = 2\pi\|\theta_0\|_{L^1}^2$ and $C_2 = \pi$.

To obtain a basic estimate, we take $g^{2\alpha}(t) = \left(\frac{1}{2}+\frac{1}{2\alpha}\right)[(e+t)\ln(e+t)]^{-1}$ and thus $e^{2\int_0^t g^{2\alpha}(\tau)d\tau} = [\ln(e+t)]^{(1+\frac{1}{\alpha})}$. We then obtain from (3.4)

$$\|\theta\|_{L^2}^2 \le C[\ln(e+t)]^{-1-\frac{1}{\alpha}}.$$

To obtain the sharp decay result, we take $g^{2\alpha}(t) = \frac{1}{2\alpha(t+1)}$ and thus $e^{2\int_0^t g^{2\alpha}(\tau)d\tau} = (1+t)^{\frac{1}{\alpha}}$. From (3.4),

$$\|\theta(t)\|_{L^2}^2 \le C(t+1)^{-\frac{1}{\alpha}} + C(t+1)^{(1-\frac{2}{\alpha})}\int_0^t \|\theta(s)\|_{L^2}^2[\ln(e+s)]^{-1-\frac{1}{\alpha}}ds.$$

Using Gronwall's inequality and the fact that $\alpha \le 1$,

$$\|\theta(t)\|_{L^2}^2 \le C(1+t)^{-\frac{1}{\alpha}}, \tag{3.5}$$

where the constant C depends on the L^1 and L^2 norms of θ_0. We note here that (3.5) is actually obtained by first taking $g^{2\alpha}(t) = \left(\frac{1}{2\alpha}-\epsilon\right)\frac{1}{1+t}$ and then passing to the limit as $\epsilon \to 0$. This completes the formal argument step.

Next we construct a sequence of retarded mollifications θ_n and carry over the formal arguments to θ_n. We will present here only the main ideas. We approximate the QGS equation by a sequence of equations

$$\partial_t\theta_n + u_n\cdot\nabla\theta_n + \Lambda^{2\alpha}\theta_n = 0, \tag{3.6}$$

where $\delta_n \to 0$ and $u_n = S_{\delta_n}(\theta_n)$ is obtained from θ_n by

$$S_{\delta_n}(\theta_n) = \int_0^\infty \phi(\tau)\mathcal{R}^\perp\theta_n(t-\delta_n\tau)d\tau.$$

We denote here $\mathcal{R}^\perp = (-\partial_{x_2}\Lambda, \partial_{x_1}\Lambda)$ as the Riesz transform. The smooth function ϕ is nonnegative with compact support in $[1,2]$ and $\int_0^\infty \phi(t)dt = 1$. For each n, (3.6) is a linear equation since the values of $u_n(t)$ depend only on the values of θ_n in $[t-2\delta_n, t-\delta_n]$.

Without giving details, we point out that θ_n converges to a weak solution θ strongly in L^2 for almost every t. Hence

$$\|\theta(t)\|_{L^2} \le \|\theta_n(t)-\theta(t)\|_{L^2} + \|\theta_n(t)\|_{L^2} \le C(1+t)^{-\frac{1}{2\alpha}},$$

where C is a constant depending only on the L^1 and L^2 norms of θ_0. This completes the proof of Theorem 3.1. □

We now consider the case when the force f is not zero.

THEOREM 3.4. *Let $\alpha \in (0,1]$ and $\theta_0 \in L^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^2)$. Assume that $f \in L^1([0,\infty); L^2)$, satisfying*

$$\|f(\cdot,t)\|_{L^2} \le C(1+t)^{-\frac{1}{\alpha}-1}, \qquad |\widehat{f(\xi,t)}| \le C|\xi|^\alpha \tag{3.7}$$

for some constant C. Then there is a weak solution of the QGS equation

$$\partial_t\theta + u\cdot\theta + \Lambda^{2\alpha}\theta = f$$

such that

$$\|\theta(\cdot,t)\|_{L^2} \le C(1+t)^{-\frac{1}{2\alpha}}. \tag{3.8}$$

Proof. The arguments of Theorem 3.1 work here and we will point out only the difference. It is easy to see that

$$\|\theta(t)\|_{L^2} \le \|\theta_0\|_{L^2} + \int_0^t \|f(\tau)\|_{L^2} d\tau \le C$$

by energy estimates. When the force f is present, the estimate for $\widehat{\theta}$ is given by

$$|\widehat{\theta}(\xi,t)| \le e^{-|\xi|^{2\alpha}t}|\widehat{\theta_0}| + \int_0^t e^{-|\xi|^{2\alpha}(t-\tau)}\left[\widehat{f} + |\xi|\|\theta\|_{L^2}^2\right] d\tau.$$

Then the procedures of the proof of Theorem 3.1 can be repeated and the assumptions (3.7) are sufficient in establishing (3.8). □

4. Large time approximation. In this section we intend to understand the higher-order correction in the large time approximation of the solution θ to the nonlinear equation by the solution Θ to the linear equation. The approach is to study the difference and the ratio

$$\|\theta(\cdot,t) - \Theta(\cdot,t)\|_{L^2}, \qquad \frac{\|\theta(\cdot,t)\|_{L^2}}{\|\Theta(\cdot,t)\|_{L^2}}.$$

We start with some estimates for the linear equation. The solution of the linear equation on $\mathbb{R}^n$

$$\partial_t\theta + \Lambda^{2\alpha}\theta = 0, \qquad \theta\,|_{t=0} = \theta_0 \tag{4.1}$$

is given by

$$\Theta(t) = k_t^\alpha * \theta_0, \tag{4.2}$$

where the kernel k_t^α is defined by its Fourier transform

$$\widehat{k}_t^\alpha(\xi) = e^{-|\xi|^{2\alpha}t}. \tag{4.3}$$

PROPOSITION 4.1. *Assume that $\alpha > 0$ and the initial data $\theta_0 \in L^1(\mathbb{R}^n)$. Then we have*

$$\lim_{t\to\infty} t^{\frac{n}{2\alpha}}\|\Theta(\cdot,t)\|_{L^2}^2 = A(n,\alpha)\left[\int_{\mathbb{R}^n}\theta_0(x)dx\right]^2, \tag{4.4}$$

$$\lim_{t\to\infty} t^{\frac{n+2}{2\alpha}}\|\nabla\Theta(\cdot,t)\|_{L^2}^2 = B(n,\alpha)\left[\int_{\mathbb{R}^n}\theta_0(x)dx\right]^2, \tag{4.5}$$

where the constants $A(n,\alpha)=\int_{\mathbb{R}^n} e^{-2|\eta|^2}d\eta$ *and* $B(n,\alpha)=\int_{\mathbb{R}^n}|\eta|^2e^{-2|\eta|^2}d\eta$.

Especially for $n=2$, *the* L^2 *decay rates of* Θ *and* $\nabla\Theta$ *are* $t^{-\frac{1}{2\alpha}}$ *and* $t^{-\frac{1}{\alpha}}$, *respectively.*

Proof. We first prove (4.4). By Plancherel's theorem,

$$\lim_{t\to\infty} t^{\frac{n}{2\alpha}}\|\Theta(\cdot,t)\|_{L^2}^2=\lim_{t\to\infty} t^{\frac{n}{2\alpha}}\|\widehat{\Theta}(\cdot,t)\|_{L^2}^2$$

$$=\lim_{t\to\infty} t^{\frac{n}{2\alpha}}\int_{\mathbb{R}^n} e^{-2|\xi|^{2\alpha}t}|\widehat{\theta}_0|^2(\xi)d\xi=\lim_{t\to\infty}\int_{\mathbb{R}^n} e^{-2|\eta|^2}|\widehat{\theta}_0|^2(\eta t^{-\frac{1}{2\alpha}})d\eta.$$

Since for any $t\in[0,\infty)$

$$\int_{\mathbb{R}^n} e^{-2|\eta|^2}|\widehat{\theta}_0|^2(\eta t^{-\frac{1}{2\alpha}})d\eta$$

$$\le\|\widehat{\theta}_0\|_{L^\infty}^2\int_{\mathbb{R}^n} e^{-2|\eta|^2}d\eta\le A(n,\alpha)\|\theta_0\|_{L^1}^2,$$

we can apply the dominated convergence theorem, which leads to (4.4).

The proof of (4.5) is similar to that of (4.4). We have

$$\lim_{t\to\infty} t^{\frac{n+2}{\alpha}}\|\nabla\Theta(\cdot,t)\|_{L^2}^2=\lim_{t\to\infty} t^{\frac{n+2}{\alpha}}\int_{\mathbb{R}^n}|\xi|^2e^{-2|\xi|^{2\alpha}t}|\widehat{\theta}_0|^2(\xi)d\xi$$

$$=\lim_{t\to\infty}\int_{\mathbb{R}^n}|\eta|^2e^{-2|\eta|^2}|\widehat{\theta}_0|^2(\eta t^{-\frac{1}{2\alpha}})d\eta=B(n,\alpha)\left[\int_{\mathbb{R}^n}\theta_0(x)dx\right]^2.\qquad\square$$

PROPOSITION 4.2. *Let* $\alpha\in(0,1]$ *and* $\theta_0\in L^2(\mathbb{R}^2)$. *Then the solution* Θ *of* (4.1) *satisfies*

$$\|\nabla\Theta(t)\|_{L^\infty(\mathbb{R}^2)}\le Ct^{-\frac{1}{\alpha}},$$

where the constant C *depends only on the* L^2 *norm of* θ_0.

Proof. We have by (4.2) and (4.3)

$$\|\nabla\Theta\|_{L^\infty}\le\int_{\mathbb{R}^2}|\xi||\widehat{\Theta}(\xi)|d\xi=\int_{\mathbb{R}^2}|\xi|e^{-|\xi|^{2\alpha}t}|\widehat{\theta}_0(\xi)|d\xi$$

$$\le\|\theta_0\|_{L^2}\left(\int_{\mathbb{R}^2}|\xi|^2e^{-2|\xi|^{2\alpha}t}d\xi\right)^{\frac{1}{2}}\le C\left(\int_0^\infty r^3e^{-2r^{2\alpha}t}dr\right)^{\frac{1}{2}}\le Ct^{-\frac{1}{\alpha}},$$

where the constant C depends only on the L^2 norm of θ_0. $\square$

THEOREM 4.3. *Let* $\alpha\in(0,1]$ *and* $\theta_0\in L^1(\mathbb{R}^2)\cap L^2(\mathbb{R}^2)$. *Then the difference* $\theta-\Theta$ *between a weak solution* θ *of the QGS equation and the solution* Θ *of the linear QGS equation with the data* θ_0 *satisfies*

$$\|\theta(t)-\Theta(t)\|_{L^2(\mathbb{R}^2)}\le C(1+t)^{\frac{1}{2}-\frac{1}{\alpha}},$$

where the constant C *depends only on the* L^1 *and* L^2 *norms of* θ_0.

Remark 4.4. By comparing the rates in Theorems 3.1 and 4.3, we see that $\theta - \Theta$ decays faster than θ does for large time for $\alpha < 1$.

Proof. We will present only a formal argument. The justification process can be done similarly as in the proof of Theorem 3.1. The difference $w = \theta - \Theta$ satisfies

$$\partial_t w + \Lambda^{2\alpha} w = -u \cdot \nabla \theta. \tag{4.6}$$

Taking the scalar product of (4.6) with w and using the fact that

$$\int_{\mathbb{R}^2} (u \cdot \nabla \theta) \theta dx = 0,$$

we obtain

$$\frac{d}{dt} \int_{\mathbb{R}^2} |w|^2 + 2 \int_{\mathbb{R}^2} |\Lambda^\alpha w|^2 = \int_{\mathbb{R}^2} \Theta (u \cdot \nabla \theta) dx.$$

Using the results of Proposition 4.2 and Theorem 3.1, we bound the right-hand term by

$$\left| \int_{\mathbb{R}^2} \Theta (u \cdot \nabla \theta) dx \right| \le \|\nabla \Theta\|_{L^\infty} \|\theta\|_{L^2}^2 \le C(1+t)^{-\frac{2}{\alpha}}.$$

As in the proof of Theorem 3.1,

$$\frac{d}{dt} \int_{\mathbb{R}^2} |\widehat{w}|^2 + 2g^{2\alpha}(t) \int_{\mathbb{R}^2} |\widehat{w}|^2 \le 2g^{2\alpha}(t) \int_{|\xi| \le g(t)} |\widehat{w}|^2 + C(1+t)^{-\frac{2}{\alpha}}, \tag{4.7}$$

where $g(t)$ remains to be decided.

We need an estimate of $\widehat{w}$, which can be obtained by taking the Fourier transform of (4.6) and proceeding as in Lemma 3.3. By Theorem 3.1 and noticing $\alpha \le 1$,

$$|w(\xi, t)| \le |\xi| \int_0^t \|\theta(\tau)\|_{L^2}^2 d\tau \le |\xi| \int_0^t (1+\tau)^{-\frac{1}{\alpha}} d\tau \le C|\xi|.$$

Taking $g^{2\alpha} = \frac{\beta}{2(1+t)}$, we obtain, by integrating (4.7),

$$(1+t)^\beta \int_{\mathbb{R}^2} |\widehat{w}|^2 \le C \left[\int_0^t (1+\tau)^{\beta - \frac{2}{\alpha}} d\tau + \int_0^t (1+\tau)^\beta g^4(\tau) d\tau \right].$$

Therefore,

$$\|w\|_{L^2}^2 \le C(1+t)^{1-\frac{2}{\alpha}}.$$

This completes the proof of Theorem 4.3. □

We can consider lower bounds for the decay of θ with the aid of Theorem 4.3. It is easy to see that Θ can decay exponentially fast. For example, if $\widehat{\theta_0} = 0$ for $|\xi| \le \gamma$, then

$$\|\Theta(t)\|_{L^2}^2 = \int e^{-2|\xi|^{2\alpha} t} |\widehat{\theta_0}(\xi)|^2 \le \|\theta_0\|_{L^2}^2 e^{-2\gamma^2 t}.$$

However, for those θ_0 satisfying

$$|\widehat{\theta_0}(\xi)| \ge \lambda \qquad \text{for} \qquad |\xi| \le \gamma, \tag{4.8}$$

we have the following.

PROPOSITION 4.5. *Let $\alpha \in (0,1]$ and $\theta_0 \in L^2(\mathbb{R}^2)$ satisfy (4.8). Then if Θ is a solution of the linear QGS equation,*

$$\|\Theta(t)\|_{L^2(\mathbb{R}^2)} \geq C(1+t)^{-\frac{1}{2\alpha}},$$

where C is a constant depending only on λ, γ, and the L^2 norm of θ_0.

As a corollary of Theorem 4.3 and Proposition 4.5, we have the following.

THEOREM 4.6. *Let $\alpha \in (0,1]$ and $\theta_0 \in L^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^2)$ satisfy (4.8). Then for a weak solution θ of the QGS equation with data θ_0,*

$$\|\theta(\cdot,t)\|_{L^2(\mathbb{R}^2)} \geq C(1+t)^{-\frac{1}{2\alpha}},$$

where C depends on λ, γ, and the L^1 and L^2 norms of θ_0.

The following theorem reveals more detailed aspects of the higher-order correction.

THEOREM 4.7. *Let $\alpha \in (\frac{1}{2}, 1]$ and $\delta > 0$ such that $2\alpha - 1 - \delta \geq 0$. Assume that θ is a weak solution of the 2D QGS equation*

$$\partial_t \theta + u \cdot \nabla \theta + \Lambda^{2\alpha}\theta = 0$$

with initial data $\theta_0 \in L^1(\mathbb{R}^2) \cap L^2(\mathbb{R}^2)$ and that satisfies

$$\|\Lambda^{2-2\alpha+\delta}\theta(\cdot,t)\|_{L^2} \leq Ct^{-\epsilon} \tag{4.9}$$

for some constant C and $\epsilon > 0$. Let Θ be the solution of the linear equation with the same initial data θ_0. Then

$$\frac{\|\theta(\cdot,t)\|_{L^2}}{\|\Theta(\cdot,t)\|_{L^2}} = 1 + O(t^{-\min\{\frac{1}{2\alpha},\epsilon\}}), \tag{4.10}$$

$$t^{\frac{1}{2\alpha}+\min\{\frac{1}{2\alpha},\epsilon\}}\|\theta(\cdot,t) - \Theta(\cdot,t)\|_{L^2} = O(1). \tag{4.11}$$

Proof. By taking the Fourier transform of the equation for θ

$$\partial_t \theta + \Lambda^{2\alpha}\theta = -u \cdot \nabla \theta,$$

we obtain

$$\widehat{\theta}(\xi,t) = e^{-|\xi|^{2\alpha}t}\widehat{\theta_0}(\xi) - \int_0^t e^{-|\xi|^{2\alpha}(t-s)}\widehat{u \cdot \nabla \theta}(\xi,s)ds.$$

Then the ratio

$$\frac{\|\theta(\cdot,t)\|_{L^2}^2}{\|\Theta(\cdot,t)\|_{L^2}^2} = \frac{\|\widehat{\theta}(\cdot,t)\|_{L^2}^2}{\|\widehat{\Theta}(\cdot,t)\|_{L^2}^2} = 1 + 2\mathcal{J}(t) + \mathcal{J}^2(t),$$

where $\mathcal{J}$ is given by

$$\mathcal{J}(t) = \frac{\int_{\mathbb{R}^2}\left|\int_0^t e^{-|\xi|^{2\alpha}(t-s)}\widehat{u \cdot \nabla \theta}(\xi,s)ds\right|^2 d\xi}{\|\Theta\|_{L^2}^2}.$$

To prove (4.10), it suffices to show that

$$\mathcal{J}(t) = O(t^{-\min\{\frac{1}{2\alpha},\epsilon\}}).$$

The difference $w = \theta - \Theta$ satisfies

$$\partial_t w + \Lambda^{2\alpha} w = -u \cdot \nabla \theta.$$

Since $w(x,0) = \theta(x,0) - \Theta(x,0) = 0$,

$$\widehat{w}(\xi,t) = -\int_0^t e^{-|\xi|^{2\alpha}(t-s)} \widehat{u \cdot \nabla \theta}(\xi,s) ds,$$

$$\|w(\cdot,t)\|_{L^2}^2 = \|\widehat{w}(\cdot,t)\|_{L^2}^2 = \int_{\mathbb{R}^2} \left| \int_0^t e^{-|\xi|^{2\alpha}(t-s)} \widehat{u \cdot \nabla \theta}(\xi,s) ds \right|^2 d\xi.$$

Thus, to prove (4.10) and (4.11), we need only to estimate the integral

$$I \equiv \int_{\mathbb{R}^2} \left| \int_0^t e^{-|\xi|^{2\alpha}(t-s)} \widehat{u \cdot \nabla \theta}(\xi,s) ds \right|^2 d\xi.$$

To this end, we divide the integral I into the following two parts:

$$II = \int_{\mathbb{R}^2} \left| \int_0^{t/2} \cdots \right|^2 d\xi \quad \text{and} \quad III = \int_{\mathbb{R}^2} \left| \int_{t/2}^t \cdots \right|^2 d\xi.$$

Since $\nabla \cdot u = 0$, $\widehat{u \cdot \nabla \theta} = i\xi \cdot \widehat{u\theta}$ and we obtain, by setting $\eta = t^{\frac{1}{2\alpha}} \xi$,

$$II = t^{-\frac{2}{\alpha}} \int_{\mathbb{R}^2} e^{-2|\eta|^{2\alpha}} \left| \int_0^{t/2} e^{\frac{s}{t}|\eta|^2} \eta \cdot \widehat{u\theta}(\eta t^{-\frac{1}{2\alpha}}, s) ds \right|^2 d\eta.$$

Since

$$\|\widehat{u\theta}(\cdot,s)\|_{L^\infty} \le \|u\theta(\cdot,s)\|_{L^1} \le \|u(\cdot,s)\|_{L^2} \|\theta(\cdot,s)\|_{L^2} \le C \|\theta(\cdot,s)\|_{L^2}^2,$$

we have the bound

$$II \le C t^{-\frac{2}{\alpha}} \int_{\mathbb{R}^2} |\eta|^2 e^{-\frac{7}{4}|\eta|^2} \left[\int_0^\infty \|\theta(\cdot,s)\|_{L^2}^2 ds \right]^2 d\eta$$

$$\le C t^{-\frac{2}{\alpha}} \left(\int_{\mathbb{R}^2} |\eta|^2 e^{-\frac{7}{4}|\eta|^2} d\eta \right) \|\theta\|_{L^2([0,\infty);L^2)}^4.$$

The estimate of III seems tricky. Intuitively, the idea is to split the whole derivative ∇ into two fractional parts $\Lambda^{2\alpha-1-\delta}$ and $\Lambda^{2-2\alpha+\delta}$:

$$III = \int_{\mathbb{R}^2} \left| \int_{t/2}^t e^{-|\xi|^{2\alpha}(t-s)} \widehat{u \cdot \nabla \theta}(\xi,s) ds \right|^2 d\xi$$

$$\le \int_{\mathbb{R}^2} e^{-2|\xi|^{2\alpha} t} |\xi|^{2(2\alpha-1-\delta)} \sup_{t/2 \le s \le t} |u \cdot \widehat{\Lambda^{2-2\alpha+\delta}\theta}|^2(\xi,s) \left[\int_{t/2}^t e^{s|\xi|^{2\alpha}} ds \right]^2 d\xi.$$

Using the assumption (4.9), we obtain

$$|u \cdot \widehat{\Lambda^{2-2\alpha+\delta}\theta}|(\xi,s) \le \|u \cdot \widehat{\Lambda^{2-2\alpha+\delta}\theta}(\cdot,s)\|_{L^\infty}$$

$$\le \|(u \cdot \Lambda^{2-2\alpha+\delta}\theta)(\cdot,s)\|_{L^1} \le C\|u(\cdot,s)\|_{L^2}\|\Lambda^{2-2\alpha+\delta}\theta(\cdot,s)\|_{L^2} \le Cs^{-\frac{1}{2\alpha}-\epsilon},$$

where C is a constant. Therefore

$$III \le Ct^{-\frac{1}{\alpha}-2\epsilon}\int_{\mathbb{R}^2} |\xi|^{-2-\delta}(1-e^{-\frac{1}{2}|\xi|^{2\alpha}t})^2 d\xi \le Ct^{-\frac{1}{\alpha}-2\epsilon}.$$

Combining the estimates for II and III, we conclude that

$$I \equiv \int_{\mathbb{R}^2}\left|\int_0^t e^{-|\xi|^{2\alpha}(t-s)}\widehat{u\cdot\nabla\theta}(\xi,s)ds\right|^2 d\xi \le Ct^{-\frac{1}{\alpha}-\min\{\frac{1}{\alpha},2\epsilon\}},$$

and (4.10), (4.11) are therefore established. □

LARGE EIGENVALUES AND TRACE FORMULAS FOR MATRIX STURM–LIOUVILLE PROBLEMS*

ROBERT CARLSON†

Abstract. This work describes the location of large eigenvalues for Sturm–Liouville operators with matrix coefficients. Eigenvalue asymptotics of arbitrary order are characterized for operators with smooth coefficients and "elementary" boundary conditions. In addition, an effective method is given for computing traces of these operators. These techniques are employed to verify a previously conjectured trace formula.

Key words. trace formulas, eigenvalue asymptotics, Sturm–Liouville problems

AMS subject classifications. 34B24, 34L20

PII. S0036141098340417

1. Introduction. Although ordinary differential operators do not have a trace in the usual sense, it was observed some time ago [2] that one could often make sense of $\sum_n(\mu_n-\nu_n)$, where $\{\mu_n\}$ and $\{\nu_n\}$ are the eigenvalues of two differential operators. Moreover, these traces are often given by explicit expressions in the coefficients of the operators. Beyond their aesthetic appeal, trace formulas play an important role in inverse spectral theory [4, 6, 10, 12].

Several authors [5, 11] have raised the problem of establishing and analyzing trace formulas for the one-dimensional matrix Schrödinger equation

$$-Y'' + Q(x)Y = \lambda Y, \quad Y \in \mathbf{C}^K, \quad \lambda \in \mathbf{C}, \tag{1a}$$

subject to certain boundary conditions. In particular, Papanicolaou [11] established a trace formula for the Dirichlet boundary conditions $Y(0) = 0 = Y(1)$ when the $K \times K$ matrix $Q(x)$ is real symmetric, subject to a conjectured asymptotic behavior of the eigenvalue sequence.

In this work we will show how to establish eigenvalue estimates of any order using classical asymptotic expansions for solutions of (1a). Eigenvalues for (1a) subject to certain separated boundary conditions are identified with the vanishing of $\det \mathcal{T}(\lambda)$, where $\mathcal{T}(\lambda)$ is an entire $K \times K$ matrix-valued function. A novel feature of our approach is the use of perturbation theory to analyze the location of the eigenvalues of $\mathcal{T}(\lambda)$ or a closely related matrix. This approach appears to offer advantages over the direct consideration of the equation $\det \mathcal{T}(\lambda) = 0$. We also extend some old ideas for computing (higher order) traces. These techniques downplay the role of self-adjoint operators.

2. Regularized traces. It is common to use infinite product representations [1] to relate the eigenvalue sequence for an ordinary differential operator to an entire function having the eigenvalues as zeroes. The first lemma considers the computation of power sums

$$\sum_{n=1}^{\infty}(\nu_n^k - \mu_n^k)$$

based on the asymptotic behavior of such entire functions. A similar treatment is given in [8, pp. 84–88], where the ideas are attributed to F. Schäfke.

LEMMA 2.1. *Suppose that $f(\lambda)$ and $g(\lambda)$ are entire functions not vanishing on a real half line $(-\infty, b)$, which are given by absolutely convergent products*

$$f(\lambda) = \prod_{n=1}^{\infty} \left(1 - \frac{\lambda}{\mu_n}\right), \quad g(\lambda) = \prod_{n=1}^{\infty} \left(1 - \frac{\lambda}{\nu_n}\right).$$

(*For notational convenience we assume that $f(0)g(0) \neq 0$.*)

If all but finitely many μ_n, ν_n lie in the right half plane, and

$$\sum |\mu_n - \nu_n|[|\mu_n|^{K-1-\epsilon} + |\nu_n|^{K-1-\epsilon}] < \infty, \quad 0 \leq \epsilon < 1,$$

for an integer $K \geq 2$, then as $\lambda \to -\infty$ along the real axis,

$$\log\left(\frac{f(\lambda)}{g(\lambda)}\right) = C + \sum_{k=1}^{K-1} \Big[\frac{1}{k\lambda^k} \sum_{n=1}^{\infty} (\nu_n^k - \mu_n^k)\Big] + O(\lambda^{-K+\epsilon}).$$

Proof. For $\lambda \in (-\infty, b)$ define

$$\begin{aligned} h(\lambda) &= \partial_\lambda \log\left(\frac{f}{g}\right) = \partial_\lambda \log\left(\prod \frac{\lambda - \mu_n}{\lambda - \nu_n}\right) \\ &= \sum_n \left(\frac{1}{\lambda - \mu_n} - \frac{1}{\lambda - \nu_n}\right) = \sum_n \frac{1}{\lambda}\left(\frac{1}{1 - \mu_n/\lambda} - \frac{1}{1 - \nu_n/\lambda}\right). \end{aligned}$$

Use of the identity $1/(1-x) = 1 + x + \cdots + x^{K-1} + x^K/(1-x)$ gives

$$h(\lambda) = \sum_n \left[\frac{1}{\lambda} \sum_{k=1}^{K-1} \frac{\mu_n^k - \nu_n^k}{\lambda^k} + \frac{1}{\lambda}\left[\frac{(\mu_n/\lambda)^K}{1 - \mu_n/\lambda} - \frac{(\nu_n/\lambda)^K}{1 - \nu_n/\lambda}\right]\right].$$

A rearrangement of these sums is justified if the sums

$$\sum_n |\mu_n^k - \nu_n^k|, \quad k = 1, \ldots, K-1, \tag{2a}$$

and

$$\sum_n \left|\frac{\mu_n^K}{1 - \mu_n/\lambda} - \frac{\nu_n^K}{1 - \nu_n/\lambda}\right| \tag{2b}$$

are convergent. Using the fundamental theorem of calculus to write the difference $\mu_n^k - \nu_n^k$ as a contour integral over the line segment joining the endpoints, we find

$$\sum_n |\mu_n^k - \nu_n^k| = \sum_n \left|\int_{\nu_n}^{\mu_n} kz^{k-1}\, dz\right| \leq k \sum_n |\mu_n - \nu_n|[|\mu_n|^{k-1} + |\nu_n|^{k-1}].$$

There are only finitely many μ_n, ν_n inside the unit disk. Except for this finite collection we have

$$|\mu_n - \nu_n|[|\mu_n|^{k-1} + |\nu_n|^{k-1}] \leq |\mu_n - \nu_n|[|\mu_n|^{K-2} + |\nu_n|^{K-2}], \quad 1 \leq k \leq K-1.$$

Thus the sums in (2a) are absolutely convergent.

As for (2b) the same technique gives

$$\sum_n \left| \frac{\mu_n^K}{1-\mu_n/\lambda} - \frac{\nu_n^K}{1-\nu_n/\lambda} \right| = \sum_n \left| \lambda \int_{\nu_n}^{\mu_n} \frac{Kz^{K-1}}{\lambda - z} + \frac{z^K}{(\lambda - z)^2}\, dz \right|. \tag{2c}$$

If μ_n, ν_n have positive real parts, $0 \le \epsilon < 1$, and $\lambda \in (-\infty, 0)$, then

$$|\lambda - z|^{-1} \le |\lambda|^{-1+\epsilon} |z|^{-\epsilon}, \quad |\lambda - z|^{-2} \le |\lambda|^{-1+\epsilon} |z|^{-1-\epsilon}.$$

Thus after dropping finitely many terms, the right-hand side of (2c) is bounded by

$$[K+1]|\lambda|^{\epsilon} \sum_n |\mu_n - \nu_n| [|\mu_n|^{K-1-\epsilon} + |\nu_n|^{K-1-\epsilon}].$$

Rearrangement now gives

$$h(\lambda) = \partial_\lambda \log\left(\frac{f}{g}\right) = \sum_{k=1}^{K-1} \Big[\lambda^{-k-1} \sum_n (\mu_n^k - \nu_n^k)\Big] + O(\lambda^{-K-1+\epsilon}),$$

and integration gives the desired result. □

3. Asymptotic expansions for solutions of (1a). Estimates for solutions to the initial value problem for (1a) may be established using familiar techniques from the scalar case. With the exception of some minor notational changes, and the rearrangement of some terms which do not commute in the vector case, the form of our estimates is very close to that of [3]. Since the arguments from the scalar case are also applicable, the reader may consult this reference for the proof of Lemmas 3.1 and 3.2. Related problems are treated with a somewhat different approach in [9, pp. 50–100].

It will be helpful to establish some notational conventions. For $\lambda \in \mathbf{C}$ let $\omega = \sqrt{\lambda}$, the root chosen continuously for $-\pi \le \arg(\lambda) < \pi$ and positive for $\lambda > 0$. The imaginary part of ω is denoted by $\Im\omega$. An element $Y \in \mathbf{C}^K$ will have the usual norm

$$|Y| = \left[\sum_{k=1}^K |y_k|^2\right]^{1/2}, \quad Y = \begin{pmatrix} y_1 \\ \vdots \\ y_K \end{pmatrix},$$

and a $K \times K$ matrix Q will have the operator norm

$$\|Q\| = \sup_{|Y|=1} |QY|.$$

The $K \times K$ identity matrix is I_K, and the zero matrix is 0_K.

A brief discussion will introduce the ideas. The model equation $-Y'' = \lambda Y$ has a basis of $2K$ solutions which are the columns of the $K \times K$ diagonal matrix-valued functions $\cos(\omega x) I_K$, $\omega^{-1} \sin(\omega x) I_K$. Adapting the variation of parameters formula to this setting, a solution of (1a) satisfying $Y(0,\lambda) = \alpha$, $Y'(0,\lambda) = \beta$, with $\alpha, \beta \in \mathbf{C}^K$, may be written as a solution of the integral equation

$$Y(x,\lambda) = \cos(\omega x)\alpha + \omega^{-1} \sin(\omega x)\beta + \omega^{-1} \int_0^x \sin(\omega[x-t]) Q(t) Y(t,\lambda)\, dt. \tag{3a}$$

Differentiation with respect to x gives

$$Y'(x,\lambda) = -\omega \sin(\omega x)\alpha + \cos(\omega x)\beta + \int_0^x \cos(\omega[x-t])Q(t)Y(t,\lambda)\ dt.$$

When $Q(x)$ is sufficiently differentiable an expansion of $Y(x,\lambda)$, together with error estimates, may be obtained by an iteration scheme based on (3a) and integration by parts. For $J \geq 1$ let C^J denote the Banach space of $K \times K$ matrix-valued functions $Q(x)$ whose components have J continuous derivatives on $[0,1]$. We can equip C^J with the norm

$$\|Q\|_J = \max \|Q^{(j)}(x)\|, \quad 0 \leq j \leq J, \quad 0 \leq x \leq 1.$$

For notational convenience define $\mathcal{A}_j(x) = Q(x)A_j(x)$ and $\mathcal{B}_j(x) = Q(x)B_j(x)$.

LEMMA 3.1. *Suppose that $Q \in C^J$, and $Y(x,\lambda)$ is the solution of* (1a) *satisfying $Y(0,\lambda) = \alpha$ and $Y'(0,\lambda) = \beta$, with $|\alpha| + |\beta| \leq 1$, $0 \leq x \leq 1$, and $|\omega| \geq 1$. Then there are $\mathbf{C}^K$ valued functions $A_j(x)$ and $B_j(x)$ such that*

$$\left| Y(x,\lambda) - \sum_{j=0}^{J} \omega^{-j}[\cos(\omega x)A_j(x) + \sin(\omega x)B_j(x)] \right| = O(\omega^{-J-1}e^{|\Im\omega|x}).$$

The coefficients $A_j(x), B_j(x)$ satisfy

$$A_0(x) = \alpha, \quad A_1(x) = 0,$$
$$A_2(x) = 2^{-2}[Q(x) - Q(0)]\alpha - 2^{-1}\int_0^x Q(t)\left[\beta + 2^{-1}\int_0^t Q(s)\alpha\ ds\right] dt,$$
$$B_0(x) = 0, \quad B_1(x) = \beta + 2^{-1}\int_0^x Q(t)\alpha\ dt, \quad B_2(x) = 0,$$

and for $j \geq 3$, the coefficients satisfy the recursion relations

$$A_j(x) = \sum_{k=0}^{\lfloor (j-2)/2 \rfloor} (-1)^k 2^{-2k-2}[\mathcal{A}_{j-2k-2}^{(2k)}(x) - \mathcal{A}_{j-2k-2}^{(2k)}(0)]$$
$$- 2^{-1}\int_0^x \mathcal{B}_{j-1}(t)\ dt + \sum_{k=0}^{\lfloor (j-3)/2 \rfloor} (-1)^k 2^{-2k-3}[\mathcal{B}_{j-2k-3}^{(2k+1)}(x) - \mathcal{B}_{j-2k-3}^{(2k+1)}(0)],$$
$$B_j(x) = -\sum_{k=0}^{\lfloor (j-3)/2 \rfloor} (-1)^k 2^{-2k-3}[\mathcal{A}_{j-2k-3}^{(2k+1)}(x) + \mathcal{A}_{j-2k-3}^{(2k+1)}(0)]$$
$$+ 2^{-1}\int_0^x \mathcal{A}_{j-1}(t)\ dt + \sum_{k=0}^{\lfloor (j-2)/2 \rfloor} (-1)^k 2^{-2k-2}[\mathcal{B}_{j-2k-2}^{(2k)}(x) + \mathcal{B}_{j-2k-2}^{(2k)}(0)].$$

The function $Y'(x,\lambda)$ has a similar expansion obtained from that of $Y(x,\lambda)$ by termwise differention.

LEMMA 3.2. *Under the hypotheses of Lemma* 3.1 *there are $\mathbf{C}^K$ valued functions $C_j(x)$ and $D_j(x)$ such that*

$$\left| Y'(x,\lambda) - \sum_{j=-1}^{J-1} \omega^{-j}[\cos(\omega x)C_j(x) + \sin(\omega x)D_j(x)] \right| = O(\omega^{-J}e^{|\Im\omega|x}).$$

The coefficients $C_j(x), D_j(x)$ *satisfy* $C_{-1}(x) = 0$, $D_{-1}(x) = -\alpha$, *and*

$$C_j(x) = A_j'(x) + B_{j+1}(x), \quad D_j(x) = B_j'(x) - A_{j+1}(x), \quad j = 0, \dots, J-1.$$

In particular, one has the following expression:

$$\begin{aligned}
Y'(x,\lambda) &= -\omega \sin(\omega x)\alpha + \cos(\omega x)\beta + 2^{-1}\cos(\omega x)\int_0^x Q(t)\ dt\ \alpha \\
&\quad + 2^{-2}\omega^{-1}\sin(\omega x)[Q(x)+Q(0)]\alpha + 2^{-1}\omega^{-1}\sin(\omega x)\int_0^x Q(t)\ dt\ \beta \\
&\quad + 2^{-2}\omega^{-1}\sin(\omega x)\int_0^x Q(t)\int_0^t Q(s)\ ds\ dt\ \alpha \\
&\quad + 2^{-3}\omega^{-2}\cos(\omega x)[Q'(x)-Q'(0)]\alpha - 2^{-2}\omega^{-2}\cos(\omega x)[Q(x)-Q(0)]\beta \\
&\quad - 2^{-3}\omega^{-2}\cos(\omega x)Q(x)\int_0^x Q(t)\ dt\ \alpha \\
&\quad + 2^{-3}\omega^{-2}\cos(\omega x)\int_0^x Q(t)[Q(t)-Q(0)]\ dt\ \alpha \\
&\quad - 2^{-2}\omega^{-2}\cos(\omega x)\int_0^x Q(t)\int_0^t Q(s)\ ds\ dt\ \beta \\
&\quad - 2^{-3}\omega^{-2}\cos(\omega x)\int_0^x Q(t)\int_0^t Q(s)\int_0^s Q(u)\ du\ ds\ dt\ \alpha \\
&\quad + O(\omega^{-3}\exp(|\Im(\omega)|)).
\end{aligned}$$

It will be convenient to introduce the $K \times K$ matrix solutions $C(x,\lambda), S(x,\lambda)$ of (1a) which satisfy

$$\begin{aligned}
C(0,\lambda) &= I_K, \quad C'(0,\lambda) = 0_K, \\
S(0,\lambda) &= 0_K, \quad S'(0,\lambda) = I_K.
\end{aligned}$$

The columns of these matrices are a basis of solutions to (1a). The asymptotic expansions for $Y(x,\lambda)$ and $Y'(x,\lambda)$ specialize to give expansions for the matrix functions $C(1,\lambda)$, $C'(1,\lambda)$, $S(1,\lambda)$, and $S'(1,\lambda)$.

Defining $Q_0 = \int_0^1 Q(t)\ dt$, the following explicit formulas will be needed:

(3b)

$$\begin{aligned}
C(1,\lambda) &= \cos(\omega)I_K + 2^{-1}\omega^{-1}\sin(\omega)Q_0 \\
&\quad + 2^{-2}\omega^{-2}\cos(\omega)\Big[Q(1)-Q(0)-\int_0^1 Q(t)\int_0^t Q(s)\ ds\ dt\Big] + O(\omega^{-3}e^{|\Im\omega|}). \\
S(1,\lambda) &= \omega^{-1}\sin(\omega)I_K - 2^{-1}\omega^{-2}\cos(\omega)Q_0 \\
&\quad + 2^{-2}\omega^{-3}\sin(\omega)\Big[Q(1)+Q(0)-\int_0^1 Q(t)\int_0^t Q(s)\ ds\ dt\Big] + O(\omega^{-4}e^{|\Im\omega|}), \\
C'(1,\lambda) &= -\omega\sin(\omega)I_K + 2^{-1}\cos(\omega)Q_0 \\
&\quad + 2^{-2}\omega^{-1}\sin(\omega)\Big[Q(1)+Q(0)+\int_0^1 Q(t)\int_0^t Q(s)\ ds\ dt\Big] + O(\omega^{-2}e^{|\Im\omega|}), \\
S'(1,\lambda) &= \cos(\omega)I_K + 2^{-1}\omega^{-1}\sin(\omega)Q_0 \\
&\quad - 2^{-2}\omega^{-2}\cos(\omega)\left[Q(1)-Q(0)+\int_0^1 Q(t)\int_0^t Q(s)\ ds\ dt\right] + O(\omega^{-3}e^{|\Im\omega|}).
\end{aligned}$$

4. Eigenvalues and traces. Eigenvalue problems given by (1a), together with separated boundary conditions, will be considered next. For simplicity the eigenvalue problem is assumed to have the form

$$\text{(4a)} \qquad \begin{aligned} &-Y'' + Q(x)Y = \lambda Y, \quad Y \in \mathbf{C}^K, \quad \lambda \in \mathbf{C}, \\ &Y_i^{(j(i))}(0) = 0 = Y_i^{(k(i))}(1), \quad i = 1, \dots, K, \quad j(i), k(i) \in \{0, 1\}, \end{aligned}$$

so that for each component either the value of the function or its derivative vanishes at each endpoint. To further facilitate the development, assume that the matrix Q_0 is diagonal, $Q_0 = \operatorname{diag}[q_1, \dots, q_K]$. Each of the expansions (3b) now has diagonal matrix coefficients for the first two terms. Under the weaker assumption that Q_0 is similar to a diagonal matrix, a simple linear change of variables reduces (1a) to the case of diagonal Q_0. Some of the results below would require modifications to account for this transformation.

For each λ there is a K-dimensional space of solutions to the eigenvalue equation satisfying the boundary conditions at 0. A basis for these solutions is given by the columns of the $K \times K$ matrix $T(x, \lambda)$, obtained by selecting K columns from the $K \times 2K$ matrix $(C(x, \lambda)\ S(x, \lambda))$, where the ith boundary condition at 0 dictates the selection of column i if the derivative vanishes and the $(K + i)$th column if the function vanishes. The problem (4a) will have an eigenvalue at λ if and only if some nontrivial linear combination of these basis functions satisfies the boundary conditions at 1.

Define the $K \times K$ matrix $\mathcal{T}(\lambda)$ whose entries $T_{ij}^{(k(i))}(1, \lambda)$ are obtained by applying the ith boundary functional at 1 from (4a) to the jth column of T. The ijth entry of $\mathcal{T}(\lambda)$ is, therefore, the ijth entry of one of the matrices $C(1, \lambda)$, $S(1, \lambda)$, $C'(1, \lambda)$, or $S'(1, \lambda)$. The problem (4a) has an eigenvalue at λ if and only if $\det \mathcal{T}(\lambda) = 0$ or, equivalently, if one of the eigenvalues of $\mathcal{T}(\lambda)$ is 0.

The eigenvalues of (4a) will be compared to the eigenvalues of $-D^2 + Q_0$ with the same boundary conditions. Since Q_0 is diagonal and the boundary conditions respect the decoupling of the system of equations, we may partition the eigenvalues into K subsequences $\lambda_{n,k}^0$ which are the eigenvalues of the kth component problem. For each k the subsequence is listed with increasing real parts. The eigenvalues $\lambda_{n,k}^0$ are the roots of one of the functions $\cos(\sqrt{\lambda - q_k})$, $\sin(\sqrt{\lambda - q_k})/\sqrt{\lambda - q_k}$, or $\sqrt{\lambda - q_k}\sin(\sqrt{\lambda - q_k})$, respectively, giving

$$\lambda_{n,k}^0 = \left\{ \begin{matrix} [n - \frac{1}{2}]^2\pi^2 & + & q_k, \\ n^2\pi^2 & + & q_k, \\ [n - 1]^2\pi^2 & + & q_k, \end{matrix} \right\} \quad n = 1, 2, 3, \dots.$$

THEOREM 4.1. *Suppose that Q_0 is a diagonal matrix and $Q(x) \in C^2$. There is a sequence $d_{n,k}$ of disks containing the $\lambda_{n,k}^0$ with radii $\alpha_{n,k} = O(n^{-1})$ such that every disk contains at least one eigenvalue of* (4a) *and every eigenvalue of* (4a) *lies inside a disk.*

If the off-diagonal entries of the matrices $Q(1)$, $Q(0)$, and $\int_0^1 Q(t) \int_0^t Q(s)\, ds\, dt$ vanish, or if the boundary conditions have the form $Y_i^{(j)}(0) = 0 = Y_i^{(k)}(1)$ for $j, k \in \{0, 1\}$ (not depending on i), then this estimate improves to $\alpha_{n,k} = O(n^{-2})$.

Proof. For $\omega \neq 0$ define diagonal matrices Ω_1, Ω_2 as follows. Ω_1 has ith diagonal entry 1 (respectively, ω^{-1}) if the ith boundary condition at 1 requires the function (respectively, derivative) to vanish. Ω_2 has ith diagonal entry ω (respectively, 1) if the

ith boundary condition at 0 requires the function (respectively, derivative) to vanish. Now define $R = \Omega_1 \mathcal{T} \Omega_2$.

The matrix $R = (r_{ij})$ has off-diagonal entries which are $O(\omega^{-2} e^{|\Im\omega|})$. The kth diagonal entry r_{kk} of R has one of the forms

$$r_{kk} = \cos(\omega) + 2^{-1} q_k \omega^{-1} \sin(\omega) + c_k \omega^{-2} \cos(\omega) + O(\omega^{-3} e^{|\Im\omega|})$$

or

$$\pm r_{kk} = \sin(\omega) - 2^{-1} q_k \omega^{-1} \cos(\omega) + c_k \omega^{-2} \cos(\omega) + O(\omega^{-3} e^{|\Im\omega|}).$$

The constant $\pm c_k$, which may be obtained from (3b), is the kth diagonal entry of one of the matrices

$$Q(1) \pm Q(0) \pm \int_0^1 Q(t) \int_0^t Q(s).$$

Since

$$\cos(\sqrt{\lambda - q_k}) = [1 - 2^{-3}\omega^{-2} q_k^2] \cos(\omega) + 2^{-1}\omega^{-1} q_k \sin(\omega) + O(\omega^{-3} \exp(|\Im\omega|)),$$
$$\sin(\sqrt{\lambda - q_k}) = [1 - 2^{-3}\omega^{-2} q_k^2] \sin(\omega) - 2^{-1}\omega^{-1} q_k \cos(\omega) + O(\omega^{-3} \exp(|\Im\omega|)),$$

the diagonal entries of R may be written as $\rho_k + O(\omega^{-3} e^{|\Im\omega|})$, where

$$\rho_k = \left(1 + \omega^{-2}[2^{-3} q_k^2 + c_k]\right) \cos(\sqrt{\lambda - q_k})$$

or

$$\pm\rho_k = \left(1 + \omega^{-2}[2^{-3} q_k^2 + c_k]\right) \sin(\sqrt{\lambda - q_k}).$$

If $\lambda \neq 0$, the matrix $\mathcal{T}(\lambda)$ has an eigenvalue 0 if and only if $R(\lambda)$ does. Write $R = R_0 + R_1$, where R_0 is diagonal with entries ρ_k and $R_1 = O(\omega^{-2} e^{|\Im\omega|})$. If $\Sigma(R)$ denotes the set of eigenvalues of R, then since R_0 is normal, we have the estimate [7, p. 291]

$$dist(\Sigma(R), \Sigma(R_0)) \leq \|R_1\|.$$

Now if $|\Im z| > 1$, we have

$$|\sin(z)| \geq \frac{\exp(|\Im z|)}{4}, \quad |\cos(z)| \geq \frac{\exp(|\Im z|)}{4},$$

and for $|\Im z| \leq 1$, there is a $C > 0$ such that

$$|\sin(z)| \geq C\ dist(z, \{m\pi\}),\ |\cos(z)| \geq C\ dist\left(z, \left\{\left[m + \frac{1}{2}\right]\pi\right\}\right),\ m = 0, \pm 1, \pm 2, \ldots.$$

These estimates show that if $R(\lambda)$ has 0 as an eigenvalue for $|\lambda| \geq 1$, then $|\Im\omega| \leq C$, and for some k the diagonal entry $\rho_k(\lambda) \leq C|\omega|^{-2}$. Suppose $\rho_k \simeq \sin(\sqrt{\lambda - q_k})$ and consider λ satisfying $(n - 1/2)^2\pi^2 \leq |\lambda| < (n + 1/2)^2\pi^2$. If such a λ is an eigenvalue, then $\sqrt{\lambda - q_k} = n\pi + O(n^{-2})$, or $\lambda = n^2\pi^2 + q_k + O(n^{-1})$. The result is similar if $\rho_k \simeq \cos(\sqrt{\lambda - q_k})$. This shows that if λ is an eigenvalue, then $|\lambda - \lambda_{n,k}^0| = O(n^{-1})$ for some $\lambda_{n,k}^0$.

A perturbation argument [7, pp. 368–371] will show that for some C and $n \geq 1$, every disk $|\lambda - \lambda^0_{n,k}| \leq Cn^{-1}$ contains at least one eigenvalue. Consider the family of operators $L(t) = -D^2 + Q_0 + t[Q - Q_0]$ for $0 \leq t \leq 1$ whose domain is determined by the boundary conditions of (4a). Each of these operators on $\oplus_K L^2[0,1]$ has compact resolvent. The spectrum consists of the eigenvalues $\lambda^0_{n,k}$ when $t = 0$, and by the previous discussion, there is a family of open disks such as in the statement of the theorem whose complement is in the resolvent set for the entire family $L(t)$. If necessary, this sequence of disks may be modified so that any two disks $d_{n,k}$ are either the same or disjoint. Since the boundary of each disk is in the resolvent set for $0 \leq t \leq 1$, the corresponding family of spectral projections, which is continuous in t, has constant rank, and so each disk contains at least one eigenvalue.

The additional hypotheses provide improved estimates since they guarantee that $R_1 = O(\omega^{-3} e^{|\Im\omega|})$. This is clear from (3b) in case the off-diagonal entries of the matrices $Q(1)$, $Q(0)$, and $\int_0^1 Q(t) \int_0^t Q(s)\, ds\, dt$ vanish. In the cases of Dirichlet and Neumann boundary conditions, the trigonometric function in the third term of (3b) is $O(n^{-1})$ when $|\lambda - \lambda^0_{n,k}| = O(n^{-1})$. □

The conclusion of the previous theorem may be strengthened if $Q(x) = Q^*(x)$, since the operators $-D^2 + Q_0 + t[Q(x) - Q_0]$ associated to the eigenvalue problem (4a) form a self-adjoint holomorphic family on $\oplus_K L^2[0,1]$, each operator having compact resolvent. In this case [7, p. 392], the eigenvalues $\lambda^0_{n,k}$, counted with multiplicity, may be extended from $t = 0$ to $t = 1$, yielding the next result.

COROLLARY 4.2. *Suppose that Q_0 is a diagonal matrix, $Q(x) = Q^*(x)$, and $Q(x) \in C^2$. Then the eigenvalues of the problem* (4a)*, counted with multiplicity, may be indexed as $\lambda_{n,k}$ such that*

$$|\lambda_{n,k} - \lambda^0_{n,k}| \leq Cn^{-1}.$$

The supplementary conditions in Theorem 4.1 *will again improve these estimates to*

$$|\lambda_{n,k} - \lambda^0_{n,k}| \leq Cn^{-2}.$$

The next goal is to refine the eigenvalue estimates of Theorem 4.1 and Corollary 4.2. If $Q(x) \in C^J$, then a more precise description of $R(\lambda)$ may be obtained using the expansions of Lemmas 3.1 and 3.2. This expansion has the form

$$R(\lambda) = \sum_{j=0}^{J} \omega^{-j} [\alpha_j \cos(\omega) + \beta_j \sin(\omega)] + O(\omega^{-J-1} e^{|\Im\omega|}),$$

where α_j, β_j are constant $K \times K$ matrices. If Q_0 is a diagonal matrix with distinct diagonal entries, and $Q(x) \in C^J$, $J \geq 2$, then by Theorem 4.1 eigenvalues of (4a) with sufficiently large magnitude will be simple and may be indexed as $\lambda_{n,k}$ such that

$$|\lambda_{n,k} - \lambda^0_{n,k}| \leq Cn^{-1}.$$

The same remarks apply also for the large zeroes $\lambda^J_{n,k}$ of the function $\det R_J(\lambda)$, where

$$R_J(\lambda) = \sum_{j=0}^{J} \omega^{-j} [\alpha_j \cos(\omega) + \beta_j \sin(\omega)].$$

According to Theorem 4.1, the eigenvalues of (4a) are contained in disks δ_m of the form $\delta_m = \{|\lambda - m^2\pi^2| \le C\}$ or disks of the form $\{|\lambda - [m+1/2]^2\pi^2| \le C\}$. Since the cases are similar we will examine only the first case.

Consider the diagonal matrix $R_0(\lambda)$ with diagonal entries $\rho_k(\lambda)$ for λ inside a disk δ_m. Since $\sqrt{\lambda - q_k} = m\pi + O(m^{-1})$, the eigenvalues ρ_k of R_0 are $\pm 1 + O(m^{-2})$ or $O(m^{-1})$. For $\lambda \in \delta_m$ the matrices $R(\lambda)$ and $R_J(\lambda)$ are perturbations of $R_0(\lambda)$ satisfying

$$R(\lambda) - R_0(\lambda) = O(m^{-2}), \quad R_J(\lambda) - R_0(\lambda) = O(m^{-2}).$$

Since $R_0(\lambda)$ is normal, the spectra of the matrices $R(\lambda)$ and $R_J(\lambda)$ satisfy [7, p. 94]

(4b) $dist(\Sigma(R), \Sigma(R_0)) = O(m^{-2}), \quad dist(\Sigma(R_J), \Sigma(R_0)) = O(m^{-2}), \quad \lambda \in \delta_m.$

For m sufficiently large, and $\lambda \in \delta_m$, these eigenvalues may be partitioned into three groups, lying, respectively, in the disks $|\zeta| \le 1/4$ and $|\zeta \pm 1| \le 1/4$. For each of the matrices $R(\lambda)$, $R_0(\lambda)$, and $R_J(\lambda)$, the number of eigenvalues in each group, counted with algebraic multiplicity, is the same. For $l = 1, \dots, L$, denote by $\tau_l(\lambda)$, $\tau_l^0(\lambda)$, and $\tau_l^J(\lambda)$, respectively, the corresponding eigenvalues of $R(\lambda)$, $R_0(\lambda)$, and $R_J(\lambda)$ in the disk $|\zeta| \le 1/4$.

LEMMA 4.3. *Suppose that Q_0 has distinct diagonal entries, and $Q(x) \in C^J$, $J \ge 2$. For $\lambda \in \delta_m$ with m sufficiently large, the eigenvalues $\tau_l(\lambda)$, $\tau_l^0(\lambda)$, and $\tau_l^J(\lambda)$ are simple and analytic in λ. In addition*

$$\tau_l(\lambda)' = \frac{\pm 1}{2m\pi} + O(m^{-2})$$

in the disks $\tilde{\delta}_m$ centered at $m^2\pi^2$ with half the radius of δ_m.

Proof. By definition of R_0

$$\pm\tau_l^0(\lambda) = (1 + \omega^{-2}[2^{-3}q_l^2 + c_l])\sin(\sqrt{\lambda - q_l}).$$

A Taylor expansion of the sine function near $\lambda = m^2\pi^2$ shows that for m sufficiently large and $\lambda \in \delta_m$

$$|\tau_k^0 - \tau_l^0| \ge \frac{|q_k - q_l|}{4m}.$$

By (4b) the same type of estimate holds for $\tau_l(\lambda)$ and $\tau_l^J(\lambda)$ as well. The analyticity now follows from the analyticity of the matrices R, R_0, and R_J.

The derivative estimate follows from the Cauchy integral representation

$$\tau_l(\lambda)' - \tau_l^0(\lambda)' = \frac{1}{2\pi i}\int_{\partial\delta_m} \frac{\tau_l(z) - \tau_l^0(z)}{(z-\lambda)^2}\, dz.$$

Since

$$|\tau_l(\lambda) - \tau_l^0(\lambda)| = O(m^{-2})$$

for $\lambda \in \delta_m$, it follows that

$$|\tau_l(\lambda)' - \tau_l^0(\lambda)'| = O(m^{-2})$$

inside the disks $\tilde{\delta}_m$. The desired estimate follows from the elementary calculation $\tau_l^0(\lambda)' = \pm 1/(2m\pi) + O(m^{-3})$. □

THEOREM 4.4. *Suppose that Q_0 is a diagonal matrix with distinct diagonal entries, and $Q(x) \in C^J$, $J \geq 2$. For n sufficiently large the eigenvalues $\lambda_{n,k}$ of* (4a) *satisfy*

$$|\lambda_{n,k} - \lambda_{n,k}^J| \leq Cn^{-J}.$$

Proof. Our main goal is to show that the resolvent $[R(\lambda) - \zeta]^{-1}$ satisfies an estimate

$$\|[R(\lambda) - \zeta]^{-1}\| \leq \frac{C}{dist(\zeta, \Sigma(R))}$$

for $|\zeta| \leq 1/4$, the estimate holding uniformly for $\lambda \in \tilde{\delta}_m$ for m large (and in corresponding disks centered at $[m + 1/2]^2\pi^2$).

Define the projections

$$P_0 = \frac{-1}{2\pi i} \int_{|\zeta|=1/4} [R(\lambda) - \zeta]^{-1}\, d\zeta, \quad P_{\pm 1} = \frac{-1}{2\pi i} \int_{|\zeta \pm 1|=1/4} [R(\lambda) - \zeta]^{-1}\, d\zeta.$$

These projections may be used to decompose the operator R [7, pp. 40–43]. Since $R(\lambda) - R_0(\lambda) = O(m^{-2})$ and $\|[R_0(\lambda) - \zeta]^{-1}\| = 1/dist(\zeta, \Sigma(R_0))$, the expression

$$[R(\lambda) - \zeta]^{-1} = [R_0(\lambda) - \zeta]^{-1}[I + (R - R_0)[R_0 - \zeta]^{-1}]^{-1} \tag{4c}$$

shows that the projections $P_0, P_{\pm 1}$ converge to the corresponding orthogonal projections $\widetilde{P_0}, \widetilde{P_{\pm 1}}$ for R_0. The convergence is uniform for large m and $\lambda \in \delta_m$.

Decompose $X \in \mathbf{C}^K$ as $X = X_0 + X_1 + X_{-1}$ where X_i is in the range of P_i. Since $R(\lambda)$ is bounded in the disks δ_m, and $P_i(\lambda) \to \widetilde{P_i(\lambda)}$, we have, for $i = \pm 1$,

$$\begin{aligned} \|(R - \zeta)X_i\| &\geq \|(R - \zeta)\widetilde{P}_i X_i\| - \|(R - \zeta)(P_i - \widetilde{P}_i)X_i\| \\ &\to |i - \zeta| \|\widetilde{P}_i X_i\|, \quad |\zeta| \leq \frac{1}{4}. \end{aligned}$$

The convergence $P_i(\lambda) \to \widetilde{P_i(\lambda)}$ then implies

$$\|(R - \zeta)X_i\| \geq \frac{1}{4}\|X_i\|$$

for m large, or

$$\|[R(\lambda) - \zeta]^{-1} P_i\| \leq 4, \quad \lambda \in \delta_m, \quad |\zeta| \leq \frac{1}{4}.$$

We next consider $\|[R(\lambda) - \zeta]^{-1} P_0\|$, for $\lambda \in \delta_m$, and $|\zeta| \leq 1/4$. The proof of Lemma 4.3 shows that for m large and $\lambda \in \delta_m$, the eigenvalues τ_l^0 of R_0 are distinct and $|\tau_k^0 - \tau_l^0| \geq C/m$. Let γ_l be a collection of circular contours centered at τ_l^0 with radius $C/(4m)$. Define projections

$$\mathcal{P}_l = \frac{-1}{2\pi i} \int_{\gamma_l} [R(\lambda) - \zeta]^{-1}\, d\zeta, \quad \widetilde{\mathcal{P}_l} = \frac{-1}{2\pi i} \int_{\gamma_l} [R_0(\lambda) - \zeta]^{-1}\, d\zeta.$$

Since $\|R(\lambda) - R_0(\lambda)\| = O(m^{-2})$ the expression (4c) leads to the estimate

$$\|\mathcal{P}_l - \widetilde{\mathcal{P}_l}\| = \left\| \frac{-1}{2\pi i} \int_{\gamma_l} [R(\lambda) - \zeta]^{-1} - [R_0(\lambda) - \zeta]^{-1} \, d\zeta \right\| = O(m^{-1}), \quad \lambda \in \delta_m.$$

Thus, the part of the operator $R(\lambda)$ on the L-dimensional range of P_0 has L distinct eigenvalues and may be diagonalized with a matrix S whose columns are eigenvectors of $R(\lambda)$. The comparison of $\mathcal{P}_l$ with $\widetilde{\mathcal{P}_l}$ shows that these eigenvectors may be chosen to converge to standard basis vectors, so that $\|S(\lambda)\|$ and $\|S^{-1}(\lambda)\|$ converge to 1 as $\lambda \to \infty$. This easily gives the estimate

$$\|[R(\lambda) - \zeta]^{-1} P_0\| \leq \frac{C}{dist(\zeta, \Sigma(R(\lambda))}, \quad |\zeta| \leq \frac{1}{4}.$$

Putting the pieces together we find

$$\begin{aligned} \|[R(\lambda) - \zeta]^{-1}\| &= \|[R(\lambda) - \zeta]^{-1}[P_0 + P_1 + P_{-1}\| \\ &\leq \|[R(\lambda) - \zeta]^{-1} P_0\| + \|[R(\lambda) - \zeta]^{-1} P_1\| + \|[R(\lambda) - \zeta]^{-1} P_{-1}\| \\ &\leq \frac{C}{dist(\zeta, \Sigma(R(\lambda))} \end{aligned}$$

as desired.

To conclude the proof, recall that $R(\lambda) - R_J(\lambda) = O(m^{-J-1})$. Similar to the argument about perturbations of the normal matrix R_0, we find that $|\tau_l - \tau_l^J| = O(m^{-J-1})$. Now Lemma 4.3 states that $\tau_l(\lambda)' = \pm 1/(2m\pi) + O(m^{-2})$ for $\lambda \in \tilde{\delta_m}$. For some l, $\tau_l(\lambda_{n,k}) = 0$, which implies $\tau_l^J(\lambda_{n,k}) = O(m^{-J-1})$ or

$$|\lambda_{n,k} - \lambda_{n,k}^J| = O(m^{-J}). \qquad \square$$

The eigenvalue estimate of Corollary 4.2 for the Dirichlet boundary conditions $Y(0) = 0 = Y(1)$ was conjectured in [11] and served as the basis for development of a trace formula. We develop an alternative approach to trace formulas of any order based on Lemma 2.1 and some observations about the entire function $\det(\mathcal{T}(\lambda))$.

Suppose first that Q_0 is diagonal and $Q(x) \in C^2$. Since the determinant of R has the form

$$\det(R) = \sum_{\sigma} \prod_{k=1}^{K} (-1)^{sgn(\sigma)} r_{k,\sigma(k)},$$

the sum taken over permutations σ of $1, \ldots, K$, each summand is either the product of all the diagonal entries or has two off-diagonal factors. Each off-diagonal entry of R is $O(\omega^{-2} e^{|\Im\omega|})$, so that any product in the determinant with two off-diagonal factors is $O(\omega^{-4} e^{K|\Im\omega|})$.

This analysis may be improved when $Q(x) \in C^J$, and the expansions of Lemmas 3.1 and 3.2 refine the estimates (3b). Recall that $p_j(\omega)$ is a trigonometric polynomial of degree at most K if

$$p_j(\omega) = \sum_{k=-K}^{K} c_k e^{ik\omega}.$$

The next result summarizes the nature of $\det(\mathcal{T}(\lambda))$.

THEOREM 4.5. *The function* $\det(\mathcal{T}(\lambda))$ *is an entire function of order* $1/2$. *The zeroes of* $\det(\mathcal{T}(\lambda))$ *are precisely the eigenvalues of* (4a), *and their orders agree with the algebraic multiplicity of the eigenvalue. If* $Q(x) \in C^J$, *then for some integer* L

$$\det(\mathcal{T}(\lambda)) = \omega^L \Big[\sum_{j=0}^{J} \omega^{-j} p_j(\omega) + O(\omega^{-J-1} e^{K|\Im\omega|}) \Big],$$

where the functions p_j *are trigonometric polynomials of degree at most* K *whose coefficients are determined by the coefficients* $A_j(1), \ldots, D_j(1)$, *for* $j \leq J$ *of Lemmas* 3.1 *and* 3.2. *In particular if* $J \geq 2$, *then*

$$\det(\mathcal{T}(\lambda)) = \omega^L \Big[\prod_{k=1}^{K} \rho_k + O(\omega^{-3} e^{K|\Im\omega|}) \Big].$$

The only claim in Theorem 4.5 that requires further comment is that the order of the zeroes of $\det(\mathcal{T}(\lambda))$ agrees with the algebraic multiplicity of the eigenvalues of (4a). We sketch the argument. The claim is easy to check directly if $Q(x)$ is diagonal and all eigenvalues are simple. In the general case connect $Q(x)$ to a diagonal coefficient $Q_1(x)$ with all eigenvalues simple by an analytic path $Q_1(x) + z[Q(x) - Q_1(x)]$. The eigenvalues (depending now on z) for (4a) may be partitioned into finite systems, and for each system [7, p. 370] the eigenvalues are simple except for a finite set of z with $|z| < 2$. As long as all the eigenvalues in a finite system remain simple, the result holds by analytic continuation, and the exceptional points are handled by continuity.

We are now prepared to compute the traces appearing in Lemma 2.1.

THEOREM 4.6. *Suppose that* $Q(x), \widetilde{Q}(x) \in C^J$, $J \geq 2$, *and that the matrices* $R_J(\lambda)$ *and* $\widetilde{R}_J(\lambda)$ *agree. The matrix* Q_0 *is assumed to have distinct diagonal entries.*

The respective eigenvalues μ_n *and* ν_n *of the problems* (4a) *may be ordered such that*

$$\sum_n |\mu_n^l - \nu_n^l| < \infty, \quad l = 1, \ldots, \left\lfloor \frac{J}{2} \right\rfloor.$$

Moreover, the traces

$$\sum_n \mu_n^l - \nu_n^l$$

may be expressed as polynomials in the coefficients of the trigonometric polynomials p_j *of Theorem* 4.5.

Proof. The arguments of Theorem 4.4 show that there is a $C_1 > 0$ such that the eigenvalues μ_n and ν_n with magnitude greater than C_1 may be paired by choosing the closest member from the other sequence. In addition C_1 may be chosen so that the circle $|\lambda| = C_1$ is in the resolvent set for all the operators $-D^2 + \widetilde{Q}(x) + t[Q(x) - \widetilde{Q}(x)]$ for $0 \leq t \leq 1$. It follows that the algebraic multiplicity for the system of eigenvalues inside the circle is independent of t, and these eigenvalues μ_n and ν_n, represented with algebraic multiplicity, may be paired arbitrarily.

With this indexing scheme Theorem 4.4 shows that

$$|\mu_n - \nu_n| = O(n^{-J}).$$

Since $|\mu_n| \le Cn^2$ we have

$$\sum_n |\mu_n - \nu_n|[|\mu_n|^{j-1-\epsilon} + |\mu_n|^{j-1-\epsilon}] < \infty,$$

as long as $j \le (J+2)/2$ and $\epsilon > 1/2$. Lemma 2.1 now applies to give the existence of the traces.

By Theorem 4.5 and the Hadamard product theorem [1], the functions $\det(\mathcal{T}(\lambda))$ and $\det(\widetilde{\mathcal{T}}(\lambda))$ play the role of the functions f and g of Lemma 2.1. What remains, then, is to compute the asymptotics for

$$\log\Big(\frac{\det(\mathcal{T}(\lambda))}{\det(\widetilde{\mathcal{T}}(\lambda))}\Big)$$

as $\lambda \to -\infty$ along the real axis. Divide $\det(\mathcal{T}(\lambda))$ and $\det(\widetilde{\mathcal{T}}(\lambda))$ by $\omega^L \exp(K|\Im\omega|)$. By Theorem 4.5 the expression

$$\frac{\det(\mathcal{T}(\lambda))}{\omega^L \exp(-iK\Im\omega)}$$

and the corresponding expression for $\widetilde{\mathcal{T}}$ are a sum of a polynomial in ω^{-1} of degree J and terms that decay like $O(\omega^{-J-1})$ as $\lambda \to -\infty$. In addition, the order zero coefficients are not zero. The computations are completed using a power series expansion for $\log(1+z)$. □

These techniques may be used to resolve a question [11] about the computation of traces for systems of the form (4a) with the Dirichlet boundary conditions $Y_i(0) = 0 = Y_i(1)$. In this case it is sufficient to assume that Q_0 is similar to a diagonal matrix since the application of the similarity transformation to (4a) will leave the boundary conditions fixed.

THEOREM 4.7. *Suppose that $Q \in C^2$ is real symmetric and the boundary conditions $Y_i(0) = 0 = Y_i(1)$ are used for the problem* (4a). *Let $\lambda_{n,k}$ be the eigenvalues with coefficient $Q(x)$ and $\lambda^0_{n,k}$ be the eigenvalues with coefficient Q_0. Then*

$$\sum_n \sum_k (\lambda_{n,k} - \lambda^0_{n,k}) = \operatorname{tr} \frac{Q(1) + Q(0) - 2Q_0}{4}.$$

Proof. Consider the two functions $\mathcal{T}(\lambda)$ and $\mathcal{T}_0(\lambda)$ associated, respectively, with the coefficients $Q(x)$ and its integral Q_0. From (3b) the constants c_k in the diagonal entries ρ_k of $R_0(\lambda)$ are the diagonal entries α_k of

$$2^{-2}\Big[Q(1) + Q(0) - \int_0^1 Q(t) \int_0^t Q(s)\, ds\, dt\Big],$$

for $Q(x)$, and they are the diagonal entries $\beta_k = 2^{-1}q_k - 2^{-3}q_k^2$ of $2^{-1}Q_0 - 2^{-3}Q_0^2$ for the diagonal matrix Q_0. Theorem 4.5 shows that

$$\frac{\det(\mathcal{T}(\lambda))}{\det(\mathcal{T}_0(\lambda))} = \frac{\prod_k (1 + \omega^{-2}[2^{-3}q_k^2 - \alpha_k]) + O(\omega^{-3})}{\prod_k (1 + \omega^{-2}[2^{-3}q_k^2 - \beta_k]) + O(\omega^{-3})},$$

and a Taylor expansion gives

$$\log\Big(\frac{\det(\mathcal{T}(\lambda))}{\det(\mathcal{T}_0(\lambda))}\Big) = \lambda^{-1} \sum_k (\beta_k - \alpha_k) + O(\omega^{-3}).$$

By Corollary 4.2, the Dirichlet boundary conditions imply that $|\lambda_{n,k} - \lambda^0_{n,k}| = O(n^{-2})$. Lemma 2.1 applies with $1/2 < \epsilon < 1$ to give

$$\sum_n \sum_k (\lambda_{n,k} - \lambda^0_{n,k}) = \sum_k (\beta_k - \alpha_k).$$

Notice that if A and B are symmetric matrices, then

$$(AB)_{ii} = \sum_j a_{ij} b_{ji} = \sum_j a_{ji} b_{ij} = \sum_j b_{ij} a_{ji} = (BA)_{ii}.$$

Thus, if $Q(t)$ is symmetric, the diagonal entries of $\int_0^1 Q(t) \int_0^t Q(s)\ ds\ dt$ will agree with those of $\int_0^1 \int_0^t Q(s)\ dsQ(t)\ dt$. Differentiation gives

$$\partial_x \left(\int_0^x Q(t)\ dt \right)^2 = Q(x) \int_0^x Q(t)\ dt + \int_0^x Q(t)\ dtQ(x),$$

and integration shows that the diagonal entries of $\int_0^1 Q(t) \int_0^t Q(s)\ ds\ dt$ are $2^{-1} q_k^2$. These common contributions drop out of the differences $\alpha_k - \beta_k$, showing that

$$\sum_n \sum_k (\lambda_{n,k} - \lambda^0_{n,k}) = \mathrm{tr} \frac{Q(1) + Q(0) - 2Q_0}{4}. \qquad \square$$

ATTRACTORS OF SOME REACTION DIFFUSION PROBLEMS*

JACK K. HALE† AND JOSÉ DOMINGO SALAZAR GONZÁLEZ‡

Abstract. In this paper we study the existence and stability properties of certain solutions of a semilinear parabolic equation with Robin boundary conditions. We are actually interested in solutions that exhibit both boundary and internal layers. We give an extension of the Sturm–Liouville theory to treat this problem and compute the number of stable solutions. We also completely determine the attractor for a few examples. Finally, we show that our results are robust and that, in particular, the structure of these attractors persist under small perturbations.

Key words. reaction diffusion, singular perturbation, attractors, time maps

1. Introduction.

If $u(x,t)$ is a smooth function, we let $\dot{u} = \partial u/\partial t$, $u' = \partial u/\partial x$, $u'' = \partial^2 u/\partial x^2$. We are interested in the study of the flow defined by the scalar reaction diffusion equation

$$\dot{u} = \epsilon^2 u'' + f(x,u), \qquad 0 < x < 1, \quad t \geq 0, \quad \epsilon > 0, \tag{1}$$

with the boundary conditions

$$\begin{cases} \alpha_0 u(0,t) - (1-\alpha_0)u'(0,t) = \beta_0, \\ \alpha_1 u(1,t) + (1-\alpha_1)u'(1,t) = \beta_1, \end{cases} \tag{2}$$

where $0 \leq \alpha_0, \alpha_1 \leq 1$ and β_0, β_1 are real constants.

The function f is assumed to be smooth in u and we consider the solutions of (1) with initial value in $H^1(0,1)$. We suppose also that f satisfies a dissipative condition for large u which will ensure that there is a compact global attractor. This will be the case, for example, if f and u have opposite signs for large values of $|u|$. A typical example and the one that will be the center of our attention in this paper is the case where f is a cubic polynomial in u and is given explicitly by

$$f(x,u) = u(1-u)(u-c(x)), \qquad 0 < c(x) < 1. \tag{3}$$

Zelenyak [14] proved that the ω-limit set of each solution of (1) is an equilibrium point; that is, a solution of the equation

$$\epsilon^2 u'' + f(x,u) = 0, \qquad 0 < x < 1, \quad t \geq 0, \quad \epsilon > 0,$$

with the boundary conditions (2).

For homogeneous boundary conditions (2) ($\beta_0 = \beta_1 = 0$) and $f(x,u)$ independent of x, it is a consequence of results of Yanagida [13] that any nonconstant equilibrium

solution u of (1) is unstable if it has the property that there are two values in $[0,1]$ for which $u'=0$.

In particular, if we take homogeneous Neumann boundary conditions ($\alpha_0=\alpha_1=0$), we deduce that any nonconstant equilibrium solution is unstable. Therefore, the stable solutions of (1) with homogeneous Neumann boundary conditions are the zeros of $f(u)$ which are stable as solutions of the ODE $\dot{u}=f(u)$. In particular, for the cubic in (3) with $c(x)=c_0\in(0,1)$ with c_0 constant, the only stable solutions are the constant functions 0 and 1.

If we consider (1) and (3) with homogeneous Neumann boundary conditions and allow $c(x)$ to depend upon x but still belong to the open interval $(0,1)$, then the problem becomes much more complicated, and there are situations where it is possible to obtain stable nonconstant equilibrium solutions. In fact, suppose that $c\in C^1([0,1])$ with $c\neq 0,\ c'\neq 0$ at $x=0,\ x=1$ and, if $c(x)=1/2$, then $c'(x)\neq 0$. If $c(x)=1/2$ at M points in the interval $(0,1)$, then there is an $\epsilon_0>0$ such that, for every $\epsilon\in(0,\epsilon_0)$; there is exactly the Mth Fibonacci number of stable solutions (Angenent, Mallet-Paret, and Peletier [1]). A stable nonconstant solution u has the property that, if it takes the value $1/2$ near some point x_0 where $c(x_0)=1/2$, then it develops a sharp transition layer at x_0 as $\epsilon\to 0$ and $c'(x_0)u'(x_0)<0$. There are equilibrium solutions u_0 for which there is a sharp transition layer as above at x_0 and $c'(x_0)u'(x_0)>0$ (Hale and Sakamoto [6]). Kwapisz [8] has obtained some extensions to the case where the graph of c and the graph of the constant function $1/2$ are not transversal. Kurland [7] proved that there could be highly oscillatory solutions (automatically unstable) at the points where $c=1/2$.

If the function $c(x)$ is a step function, Rocha [12] has obtained the same result as Angenent, Mallet-Paret, and Peletier [1] with the number M being the number of times that the function c jumps across $1/2$. His method also allows one to obtain all of the equilibrium solutions since it is based upon phase plane methods. In this case, under certain conditions on the jumps, the number of equilibrium solutions is bounded independently of ϵ in contrast to the situation for smooth functions c.

In this paper, we consider the case with c a step function and the general boundary conditions (2). The objective is to understand how the index of an equilibrium point depends upon the boundary conditions. As we will see, there are limitations on the number of stable equilibrium solutions as well as the total number of equilibrium solutions. We follow the methods of Rocha [11, 12], making the appropriate generalizations to the more general boundary conditions. The main result is contained in Theorem 3.3. We also give numerical results which indicate the method used to obtain the solutions as well as yield the permutation matrix of Fiedler and Rocha [4] which gives the manner in which the equilibrium points are connected by heteroclinic orbits. Fiedler and Rocha [3] also have shown that this connection matrix characterizes the topological properties of the flow on the compact global attractor; that is, if c_1, c_2 have the same connection matrix, then the flows on the compact global attractors are topologically equivalent.

Although our cubic nonlinearity (3) depends on x, we have that for every value of x, $f(x,0)=f(x,1)=0$. Also note that since

$$f_u(x,u)=-3u^2+2(c(x)+1)u-c(x),$$

the derivatives with respect to u of f at $u=0$ and at $u=1$ are

$$f_u(x,0)=-c(x)\qquad\text{and}\qquad f_u(x,1)=c(x)-1,$$

so they are both negatives due to (3).

As we said before, this problem has a gradient structure that guarantees that the attractor consists of equilibrium solutions and their unstable manifolds. Also, it is known that the ω-limit set of any bounded solution is a singleton [9, 14]. Thus, in order to gain information about the dynamics of this problem, we are going to concentrate our attention on the stationary solutions. They verify the following boundary value problem for $u = u(x)$ ($0 \le \alpha_0, \alpha_1 \le 1$; $\beta_0, \beta_1 \in \mathbb{R}$):

$$\begin{cases} \epsilon^2 u'' + f(x,u) = 0, & 0 < x < 1, \quad \epsilon > 0, \\ \alpha_0 u(0) - (1-\alpha_0) u_x(0) = \beta_0, \\ \alpha_1 u(1) + (1-\alpha_1) u_x(1) = \beta_1. \end{cases} \tag{4}$$

2. Sturm–Liouville properties. Following Rocha [11, 12], we are going to characterize the existence and hyperbolic nature of the equilibria of (1) in the case of homogeneous conditions, by defining some appropriate angles in the phase planes corresponding to (4) and its variational equation as is done is the classical Sturm–Liouville theory. For the nonhomogeneous case, we will be able to define only the angle corresponding to the variational equation. Since the results are identical, we will write $a(x)$ instead of ϵ^2, where $a : [0,1] \to \mathbb{R}$ with $a(x) > 0$.

Thus, in most of this section we are going to be concerned with the study of the equilibria of the problem

$$\begin{cases} u_t = (a(x)u_x)_x + f(x,u), & 0 < x < 1, \\ \alpha_0 u(0) - (1-\alpha_0) u_x(0) = 0, \\ \alpha_1 u(1) + (1-\alpha_1) u_x(1) = 0. \end{cases} \tag{5}$$

Let us represent by $\mathcal{E}$ the set of stationary solutions of (5). Thus, if $u = u(x) \in \mathcal{E}$, then u will have to satisfy

$$\begin{cases} (a(x)u')' + f(x,u) = 0, & 0 < x < 1, \\ \alpha_0 u(0) - (1-\alpha_0) u_x(0) = 0, \\ \alpha_1 u(1) + (1-\alpha_1) u_x(1) = 0 \end{cases} \tag{6}$$

for $0 \le \alpha_0, \alpha_1 < 1$. The cases in which α_0 or α_1 are equal to 1 will be considered in a remark at the end of this section.

In order to study this boundary value problem, we are going to set up a *shooting method* and for that we will work with the equivalent first-order system of equations

$$\begin{cases} u_x = v/a(x), & v_x = -f(x,u); \\ u(0) = u_0, & v(0) = \alpha_0 u_0/(1-\alpha_0). \end{cases} \tag{7}$$

The maximum principle allows us to conclude that the equilibria are in the interval $[0,1]$. Therefore, we need only consider $u_0 \in [0,1]$. Changing to polar coordinates $u := p\cos q$, $v := -p\sin q$, the angle $q := q(x,u_0)$ will satisfy

$$\begin{cases} q_x = \sin^2 q/a(x) + (1-u)(u-c(x))\cos^2 q, & 0 < x < 1, \\ q(0,u_0) = q_0, \end{cases} \tag{8}$$

where $-\pi/2 < q_0 < 0$ is the corresponding initial angle that verifies $\tan q_0 = -\alpha_0/(1-\alpha_0)$.

If we define $\sigma(u_0) := q(1,u_0)$, then $\sigma : [0,1] \to (-\pi/2, +\infty)$ and we arrive at the following proposition.

PROPOSITION 2.1. *The set of nontrivial equilibria of* (5) *is in one-to-one correspondence with the set*

$$\{u_0 : \sigma(u_0) = q_1 + k\pi, \quad k \in \mathbb{N} \cup \{0\}\},$$

where $\tan q_1 = \alpha_1/(1-\alpha_1)$.

Proof. This is a simple consequence of the flow direction of (8) and the general Sturm–Liouville theory. □

We can apply a similar analysis to the variational equation

$$\begin{cases} \eta_x = \mu/a(x), & \mu_x = -f_u(x,u)\eta; \\ \eta(0) = 1, & \mu(0) = \alpha_0/(1-\alpha_0), \end{cases} \tag{9}$$

where $\eta := du/du_0$ and $\mu := a(x)\eta_x$. If we make the change to the polar coordinates $\eta := \psi\cos\phi$, $\mu := -\psi\sin\phi$, then the angle ϕ will verify

$$\begin{cases} \phi_x = \sin^2\phi/a(x) + f_u(x,u)\cos^2\phi, & 0 < x < 1, \\ \phi(0,u_0) = q_0. \end{cases} \tag{10}$$

Now we define the function $\theta(u_0) := \phi(1,u_0)$, so $\theta : [0,1] \to (-\pi/2, +\infty)$. This function will allow us to determine the stability properties of the equilibria of (5) as stated in the following theorem.

THEOREM 2.2. *An equilibrium point* $u = u(\cdot,u_0)$ *of* (5) *is hyperbolic if and only if* $\theta(u_0) \neq q_1 + k\pi$ *for any* $k \in \mathbb{N} \cup \{0\}$. *Moreover, if* $W^u(u)$ *denotes the unstable manifold of* $u = u(\cdot,u_0) \in \mathcal{E}$ *and* u *is hyperbolic, then*

$$\dim W^u(u) = 1 + \left[\frac{\theta(u_0) - q_1}{\pi}\right],$$

where $[\cdot]$ *represents the integer part. Consequently,* $u = u(\cdot,u_0) \in \mathcal{E}$ *is hyperbolic and asymptotically stable if and only if* $\theta(u_0) < q_1$.

Proof. These results are a consequence of comparing the variational problem (9) with the eigenvalue problem for $\lambda = 0$ around an equilibrium solution $u = u(x,u_0)$ $(u \longmapsto u + w)$

$$\begin{cases} (a(x)w')' + f_u(x,u)w = \lambda w, & 0 < x < 1, \\ \alpha_0 w(0) - (1-\alpha_0)w_x(0) = 0, \\ \alpha_1 w(1) + (1-\alpha_1)w_x(1) = 0; \end{cases} \tag{11}$$

written as a first-order system with $\nu = a(x)w_x$,

$$\begin{cases} w_x = \nu/a(x), & \nu_x = (\lambda - f_u(x,u))w; \\ w(0) = w_0, & \nu(0) = \alpha_0 w_0/(1-\alpha_0), \end{cases}$$

and then changed to polar coordinates $(w := z\cos\zeta,\ \nu := -z\sin\zeta)$ to obtain

$$\begin{cases} \zeta_x = \sin^2\zeta/a(x) + (\lambda - f_u(x,u))\cos^2\zeta, & 0 < x < 1, \\ \zeta(0,\lambda) = q_0, \quad \zeta(1,\lambda) = q_1 + n\pi. \end{cases}$$

Thus for $\lambda = 0$ the eigenvalue angle equation is identical to (10).

In order to prove the rest of the theorem, we have to recall from the Sturm–Liouville theory (see [2]) that $\zeta(1,\lambda)$ is a strictly decreasing function of λ and that

the eigenvalues are ordered by the number of zeros of their corresponding eigenfunctions. ∎

Additionally, we can obtain the following characterizations of the nonhyperbolic equilibria in terms of the end-point angles σ and θ.

LEMMA 2.3. *Let $u = u(\cdot, u_0)$ be an equilibrium point not identically zero. Then $\theta(u_0) = q_1 + k\pi$ if and only if $\sigma'(u_0) = 0$.*

LEMMA 2.4. *A critical point u_0 of σ (that is, $\sigma'(u_0) = 0$) is nondegenerate (so $\sigma''(u_0) \neq 0$) if and only if $\theta'(u_0) \neq 0$.*

Proof. If we make the following changes to polar coordinates: for $u = u(x, u_0)$, $v = a(x)u_x$, $\eta = du/du_0$, and $\mu = a(x)\eta$, we have

$$\begin{cases} u = p\cos q, \\ v = -p\sin q, \end{cases} \qquad \begin{cases} \eta = \psi\cos\phi, \\ \mu = -\psi\sin\phi. \end{cases}$$

Differentiating the first two equations with respect to u_0 and equating them with respect to the second ones, we deduce that

$$\begin{aligned} \frac{\partial p}{\partial u_0}\cos q - p\sin q\frac{\partial q}{\partial u_0} &= \psi\cos\phi, \\ \frac{\partial p}{\partial u_0}\sin q + p\cos q\frac{\partial q}{\partial u_0} &= \psi\sin\phi, \end{aligned}$$

which, eliminating $\partial p/\partial u_0$ in these equations and setting $x = 1$, leads us to

$$r\sigma' = \rho\sin(\theta - \sigma), \tag{12}$$

where $r(u_0) := p(1, u_0)$ and $\rho(u_0) := \psi(1, u_0)$. Because $(0, 0)$ is an equilibrium point of (7) and (9), r and ρ cannot be zero if $u(x, u_0)$ is not identically zero. Thus if $u(x, u_0)$ is an equilibrium point then $\sigma(u_0) = q_1 + k\pi$; if we assume $\theta(u_0) = q_1 + k\pi$ also, then $\sin(\theta - \sigma) = 0$ and vice versa. From here we can obtain the conclusion of Lemma 2.3.

If now we differentiate (12) with respect to u_0, we will get

$$r\sigma'' = \pm\rho\theta'$$

for any critical point of σ. From here, the conclusion of Lemma 2.4 is clear. ∎

Let us now define the *lifted manifold* $\mathcal{M}$ to be the solution manifold $\mathcal{M} = \{(x, u, v) : u = u(x, u_0), v = v(x, u_0) \text{ for } u_0 \in [0, 1]\}$. Let us also define L_y to be the section curve of $\mathcal{M}$ at $x = y$. Then the function σ is the angle that a point of the curve L_1 makes with the u-axis and θ corresponds to the angle of the tangent at that point. See Figure 1.

We can obtain similar results to the previous ones if we consider the backward shooting method

$$\begin{cases} \bar{u}_x = \bar{v}/a(x), & \bar{v}_x = -f(x, u); \\ \bar{u}(1) = u_0, & \bar{v}(1) = -\alpha_1 u_0/(1 - \alpha_1). \end{cases} \tag{13}$$

Then if we define $\bar{\mathcal{M}}$ and $\bar{L}_y$ relative to problem (13), we can prove the following proposition.

PROPOSITION 2.5. *There is a one-to-one correspondence between the set of equilibria $\mathcal{E}$ and the set $L_y \cap \bar{L}_y$ for any $y \in [0, 1]$.*

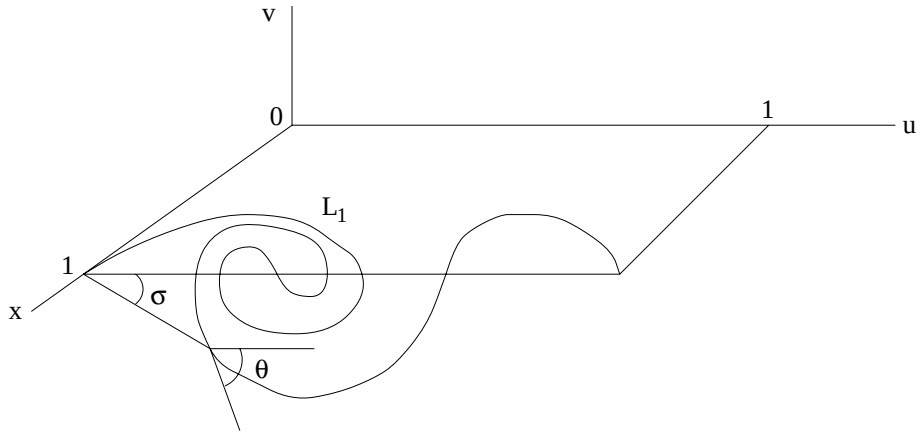

FIG. 1. *Time map* L_1.

Finally, we obtain stability information about a particular equilibrium $u = u(\cdot, u_0)$ by looking at the intersection $L_y \cap \bar{L}_y$. Actually, let $\bar{\phi} = \bar{\phi}(x, u_0)$ be the angle corresponding to the backward version of the variational problem (10) which has the initial value $\bar{\phi}(1, u_0) = q_1$. If we now define $\Omega(y, u_0) = \phi(y, u_0) - \bar{\phi}(y, u_0)$, we can conclude the following.

THEOREM 2.6. *An equilibrium point* $u = u(\cdot, u_0)$ *of* (5) *is hyperbolic if and only if* L_y *transversally intersects* $\bar{L}_y$ *for any* $y \in [0, 1]$. *Moreover, if* $W^u(u)$ *denotes the unstable manifold of* $u = u(\cdot, u_0) \in \mathcal{E}$ *and* u *is hyperbolic, then*

$$\dim W^u(u) = 1 + \left[\frac{\Omega(y, u_0)}{\pi}\right]$$

at any $y \in [0, 1]$, *where* $[\cdot]$ *represents the integer part. Consequently,* $u = u(\cdot, u_0) \in \mathcal{E}$ *is hyperbolic and asymptotically stable if and only if* $\Omega(y, u_0) < 0$ *at any* $y \in [0, 1]$.

Proof. Observe that $\Omega(1, u_0) = \theta(u_0) - q_1$. Let us prove first that if the intersection is not transversal at a certain $y \in [0, 1]$, then Ω is constant in y.

We can rewrite the equation for Ω

$$\Omega_y = \frac{\sin^2 \phi - \sin^2 \bar{\phi}}{a(x)} + f_u(x, u)(\cos^2 \phi - \cos^2 \bar{\phi})$$

in the following way:

$$\Omega_y = \left[f_u(x, u) - \frac{1}{a(x)}\right][\cos^2 \phi - \cos^2(\phi - \Omega)].$$

If for any point y, $\Omega(y, u_0) = k\pi$, then $\Omega_y = 0$. Thus the angle Ω will be constant in y. But then $\theta(u_0) = k\pi + q_1$, which implies that u is not hyperbolic, against our assumptions. Consequently,

$$\left[\frac{\Omega(y, u_0)}{\pi}\right] = \left[\frac{\Omega(1, u_0)}{\pi}\right]$$

for any $y \in [0, 1]$. Now we can get the rest of the stated conclusion by applying Theorem 2.2. ∎

Remark. For the nonhomogeneous case, we cannot define an angle similar to σ. But the variational equation (9) remains unchanged and (11) is still the eigenvalue problem in this case. Thus we can still claim the thesis of Theorems 2.2 and 2.6.

On the other hand, for Dirichlet boundary conditions, the maximum principle again tells us that the equilibria are in the interval $[0,1]$. Thus if $\alpha_0 = 1$ or $\alpha_1 = 1$ then we will assume that $\beta_0 \in [0,1]$ or $\beta_1 \in [0,1]$, respectively.

If $\alpha_0 = 1$, we should change the initial values for our shooting method to

$$u(0) = \beta_0, \qquad v(0) = v_0. \tag{14}$$

Then v_0 would substitute u_0 as our "shooting" parameter (which would imply that the initial values for the variational equation (9) now would be $\eta(0) = 0$, $\mu(0) = 1$). The results presented in this section would still hold true for $q_0 = -\pi/2$.

If $\alpha_1 = 1$, we would have to impose an initial value like

$$u(1) = \beta_1, \qquad v(1) = v_1$$

to the backward initial value problem (13). Then $q_1 = \pi/2$ and the results presented in this section would be unchanged otherwise.

In the next section we are going to study a case in which $c(x)$ is a discontinuous function. That will not alter Propositions 2.1 and 2.5 or Theorems 2.2 and 2.6, because they are based on comparisons between angle equations.

3. Discrete space dependence. Let us now assume that $c = c(x) : [0,1] \to \mathbb{R}$ is a step function defined in the following way: c takes the value $c_i \in (0,1) \setminus \{1/2\}$ in the intervals $[x_i, x_{i+1}]$, $i = 0, 1, \ldots, m$; where $0 = x_0 < x_1 < \cdots < x_m < x_{m+1} = 1$.

In each interval $[x_i, x_{i+1}]$, the boundary value problem (4) is a Hamiltonian system, so the orbits of the stationary solutions correspond to the level curves of $H = H(u_0, u_1, c_i)$:

$$H(u_0, u_1, c_i) = \frac{1}{2}(u')^2 + \int_{u_0}^{u_1} u(1-u)(u-c_i)\,du. \tag{15}$$

The linearization of (4) in each interval $[x_i, x_{i+1}]$ is given by the matrix

$$\begin{pmatrix} 0 & 1 \\ -f_u(x,u) & 0 \end{pmatrix},$$

so the eigenvalues $\lambda(u)$ and eigenvectors at $u = 0$ and $u = 1$ are

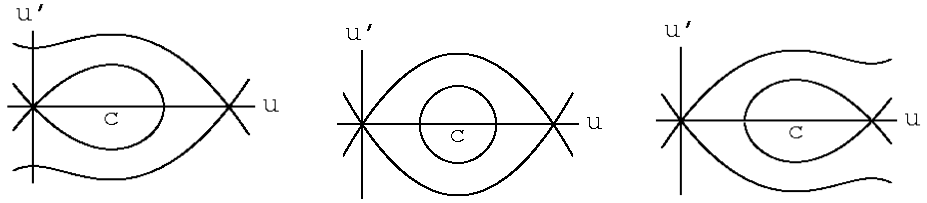
$$\lambda(0) = \pm\sqrt{c_i}: \quad (1, \pm\sqrt{c_i})^T, \tag{16}$$

$$\lambda(1) = \pm\sqrt{1-c_i}: \quad (1, \pm\sqrt{1-c_i})^T. \tag{17}$$

The typical phase portraits (u, u') for different values of c_i are shown in Figure 2. As we can see, for $c_i = 1/2$, there is a heteroclinic orbit connecting the saddle points 0 and 1. For other values of c_i, there is a homoclinic orbit connecting 0 (resp., 1) with itself if $c_i < 1/2$ (resp., $c_i > 1/2$). We will label $\gamma(c_i)$ the point at which the homoclinic orbit crosses the axis $u' = 0$.

It is easy to compute $\gamma(c)$ as a function of c by using the expression (15). In fact, it can be shown that

$$\gamma(c) = \begin{cases} (2 + 2c - \sqrt{4 - 10c + 4c^2})/3 & \text{if } c < 1/2, \\ (-1 + 2c + \sqrt{2}\sqrt{-1 + c + 2c^2})/3 & \text{if } c > 1/2. \end{cases} \tag{18}$$



(a) $c < 1/2$ (b) $c = 1/2$ (c) $c > 1/2$

FIG. 2. *Phase portraits for different values of c.*

We now want to discuss the existence and stability implications of boundary layers at $x = 0$ and $x = 1$. If α_0 and α_1 are different from 1 and ϵ is small enough, the situation is basically the same as that of homogeneous Neumann conditions. We can see this by making the change $x = \epsilon y$, in which case the left boundary condition becomes

$$\epsilon\,\alpha_0\,u(0) - (1-\alpha_0)\,u_y(0) = \epsilon\,\beta_0.$$

Therefore, as in the Neumann case, we can have solutions of (4) which do not exhibit any boundary layer; we also can have solutions with a boundary layer if $u_0 = \gamma(c_1)$, as it is obvious from Figure 2 (namely, the boundary layer would be the upper half of the homoclinic solution).

Nevertheless, the presence of a boundary layer will make the solution unstable.

PROPOSITION 3.1. *If $\alpha_0 \neq 1$ (resp., $\alpha_1 \neq 1$), for any $\delta > 0$ there is $\epsilon_0 > 0$ such that for $\epsilon \in (0, \epsilon_0)$ all the equilibria $u = u(\cdot, u_0) \in \mathcal{E}$ with $u_0 \in [\delta, 1-\delta]$ (resp., $u(1, u_0) \in [\delta, 1-\delta]$) are unstable.*

Proof. Let us assume $\alpha_0 \neq 1$ and $c_1 > 1/2$. (The case $c_1 \leq 1/2$ can be discussed in a similar way.) In order to analyze what happens in the left boundary layer, let us make the change of variables $x = \epsilon y$ in which case we are dealing with the initial value problem:

$$\begin{cases} u_{yy} + u(1-u)(u-c_1) = 0, & 0 < y < x_1/\epsilon, \\ \epsilon\,\alpha_0 u(0) - (1-\alpha_0)\,u_y(0) = \epsilon\,\beta_0. \end{cases} \tag{19}$$

Since $u(0)$ must be a number between 0 and 1, if ϵ is very small, then $u_y(0)$ must be very small in order to verify the initial condition of (19). Also, the initial conditions of the variational equation (9) are going to be

$$\eta(0) = 1, \qquad \mu(0) = \epsilon\,\alpha_0/(1-\alpha_0).$$

Thus, for ϵ small enough, $\mu(0)$ is going to be as small as we wish.

Following Rocha [12], we are going to denote by U a small neighborhood of $(1, 0)$, and by Γ_u and Γ_s the connected components of the unstable and stable manifolds of $(1, 0)$ inside U. The *λ-lemma* shows us (see [10]) that, for $y = x_1/\epsilon$ with ϵ small enough, the curve L_y has a nonempty intersection with U and that $L_y \cap U$ and Γ_u are C^k-close manifolds for any $k \geq 1$. Let us denote by (ζ_0, ζ_1), with $\zeta_0 = \zeta_0(\epsilon)$ and $\zeta_1 = \zeta_1(\epsilon)$, the interval of initial values corresponding to the set $L_y \cap U$ that includes $\gamma(c_1)$.

Now, it is clear from (10) that for $u_0 \in (\zeta_0, \zeta_1)$, we have $\phi(y, u_0) > \pi/2$ and consequently, by Theorem 2.2, the stationary solution $u(x, u_0)$ is unstable. On the order hand, the solutions with $u_0 \in [\delta, \zeta_0]$ leaves the interval $[0, 1]$ for $x \in [0, x_1)$ if ϵ is small enough. Finally, the solutions with $u_0 \in [\zeta_1, 1 - \delta]$, wind around $(c_1, 0)$ and therefore cannot be stable ($\phi(y, u_0) > \pi/2$, again). □

The situation for Dirichlet boundary conditions ($\alpha_0 = 1$ or $\alpha_1 = 1$) is richer, because a solution must have boundary layers if β_0 and β_1 are not 0 or 1. Actually, if $\alpha_0 = 1$, for any $\beta_0 \in (0, 1)$, we may have solutions that exhibit a boundary layer on the left end point of the interval that goes from β_0 to 0 (resp., from β_0 to 1) if $c_1 \geq 1/2$ (resp., $c_1 \leq 1/2$); namely, a piece of the stable manifold of 0 (resp., 1). Analogous things can happen at the right end of the interval $(0, 1)$ but in the reverse sense. In addition to this, if $c > 1/2$ (resp., $c < 1/2$), we can also have a left boundary layer that is a piece of the corresponding homoclinic orbit and starts at β_0 and ends at 1 (resp., 0), or in the reverse sense for a right boundary layer. These layers may exist if we have the following.

1. *Condition* D0: For a left boundary layer,
   (i) $c_1 > 1/2$ and $\gamma(c_1) < \beta_0 < 1$, or
   (ii) $c_1 < 1/2$ and $0 < \beta_0 < \gamma(c_1)$.
2. *Condition* D1: For a right boundary layer,
   (i) $c_m > 1/2$ and $\gamma(c_1) < \beta_1 < 1$, or
   (ii) $c_m < 1/2$ and $0 < \beta_1 < \gamma(c_1)$.

They can be monotone or reach $\gamma(c_1)$ before getting at 1 (resp., 0), but now, only the nonmonotone layers introduce instability.

LEMMA 3.2. *If $u \in \mathcal{E}$ is such that it has a nonmonotone boundary layer at $x = 0$ or $x = 1$ or both, then u is unstable.*

Proof. As it was discussed in the proof of Proposition 3.1, just observe that if u has to wind around the homoclinic orbit, then the angle $\phi(x, u_0)$ corresponding to the variational equation (9) would be greater than $\pi/2$, so the solution $u = u(x, u_0)$ would be unstable. □

Now let us analyze what happens in the interior part of the interval $(0, 1)$. At the beginning, after a possible boundary layer, the solutions that we are considering are located close to $u = 0$ or $u = 1$. Let us study the case of a solution that jumps between 0 and 1, n times in $(0, 1)$. Let us denote by $\{\bar{x}_1, \bar{x}_2, \ldots, \bar{x}_n\} \subset \{x_1, x_2, \ldots, x_m\}$ the jumping points. Let us also call $\bar{x}_0 := 1$ and $\bar{x}_{n+1} := 1$. Then we can prove the following result.

THEOREM 3.3. *There is an $\epsilon_0 > 0$ such that for every $\epsilon \in (0, \epsilon_0)$ the number N_n of stable solutions of* (1) *follows a Fibonacci sequence (that is, $N_k = N_{k-1} + N_{k-2}$, $k = 2, 3, \ldots$) that starts with*

1. *$N_0 = 2$, $N_1 = 3$; if $\alpha_0 \neq 1$ and $\alpha_1 \neq 1$ or if $\alpha_i = 1$ then the condition* Di *is verified, for $i = 0, 1$.*
2. *$N_0 = 1$, $N_1 = 2$; if either*
   (i) *$\alpha_0 = 1$ and the condition* D0 *is not verified but if $\alpha_1 = 1$ then condition* D1 *is verified; or*
   (ii) *$\alpha_1 = 1$ and the condition* D1 *is not verified but if $\alpha_0 = 1$ then condition* D0 *is verified.*
3. *$N_0 = 1$, $N_1 = 1$; if $\alpha_0 = \alpha_1 = 1$ and neither* D0 *nor* D1 *are verified.*

Furthermore, as $\epsilon \downarrow 0$, u approaches 0 or 1 in each open interval $(\bar{x}_i, \bar{x}_{i+1})$ with $i \in \{0, \ldots, n\}$ and it has a monotone transition layer at $\bar{x}_i$ only if

$$[c(\bar{x}_i^+) - c(\bar{x}_i^-)]\, u_x(\bar{x}_i) < 0.$$

Proof. As before, let us assume that $c_1 > 1/2$. The other case can be dealt with by a similar analysis. Also, we are going to consider only the subcase (i) in 2 because we can apply the same analysis to (ii) by going backwards in time.

In situations 2 and 3 of Theorem 3.3, we have a unique stable solution that may exhibit a left boundary layer that goes from β_0 to 0 or may just stay around zero, depending on the initial condition. If there are no changes in the value of $c = c(x)$, there cannot be other stable solutions, so $N_0 = 1$ (in both cases, there may be an end-point boundary layer from 0 to β_1). In case 1, in addition to the previous one, we have another stable solution that may exhibit a left boundary layer that goes from β_0 to 1 monotonically or just remains close to 1, depending also on the initial condition. Thus $N_0 = 2$ in this case.

We can now consider a small neighborhood V of $(0,0)$ similar to U, the small neighborhood of $(1,0)$ used in the proof of Proposition 3.1. If at $x_1 < 1$ the function c jumps to a value $c_2 > 1/2$, no new stable solutions are introduced. But if $c_2 < 1/2$, then we can have a stable solution that exhibits an internal layer from 0 to 1, because the new stable manifold of the equilibrium $(1,0)$ has a transversal intersection to the previous unstable manifold of the origin (and the point of intersection is unique). The λ-lemma shows us that for $y = \bar{x}_2/\epsilon$, $L_y \cap U$ is nonempty and it is C^k-closed to $\Gamma^u \cap U$, the piece of the unstable manifold of $(1,0)$ inside U.

This solution with an internal transition will be stable because the angle corresponding to its variational equation is negative. (Observe that $L_y \cap U$ intersect transversally with $\bar{L}_y \cap U$.)

If there are no more jumps in c, we have that $N_2 = 3$ if we are in situation 1, and $N_2 = 2$ if we are in situation 2; in both cases, there actually exists a solution that exhibits an internal layer because it can satisfy any boundary condition at the end point either by staying at 1 or by having a left homoclinic boundary layer to β_1 (by the hypothesis in 2, if we have a Dirichlet end-point condition, the line $x = \beta_1$ must cross the homoclinic orbit of $(1,0)$). But there is no way of getting to β_1 from 0 in case 3. Thus the only stable solution in 3 is the one with the internal transition from 0 to 1.

We can proceed doing the same analysis at every jumping point. Actually, at each $\bar{x}_k$, there will be a new transversal intersection between the unstable manifold of one of the equilibrium points $(0,0)$ or $(1,0)$, and the stable manifold of the other one. This allows the solutions that are close to the first equilibrium point either to stay there or cross to the other equilibrium point without losing their stability.

Thus let us denote by N_k^U and N_k^V the number of intersections existing at the jump point $\bar{x}_k$ in the neighborhoods U and V, respectively. Let us assume that the jump crosses $1/2$ positively, that is, $c(\bar{x}_k^+) - c(\bar{x}_k^-) > 0$. Then

$$\begin{aligned} N_{k+1}^V &= N_k^V + N_k^U, \\ N_{k+1}^U &= N_k^U. \end{aligned}$$

Moreover, since the jump at $\bar{x}_{k-1}$ has the opposite sign, we have

$$\begin{aligned} N_k^V &= N_{k-1}^V, \\ N_k^U &= N_{k-1}^U + N_{k-1}^V. \end{aligned}$$

Now, in cases 1 and 2, we can verify the end-point boundary condition either from 0 or 1. Thus $N_k = N_k^U + N_k^V$, and then we have

$$N_{k+1} = N_{k+1}^U + N_{k+1}^V = N_k^U + N_k^V + N_k^U = N_k + N_{k-1}^U + N_{k-1}^V.$$

Consequently, $N_{k+1} = N_k + N_{k-1}$. In case 3 only the solutions that are close to 0 after the jump $k+1$ will be able to verify the end-point boundary condition. Thus

$$N_{k+1} = N_{k+1}^V = N_k^V + N_k^U = N_{k-1}^V + N_k = N_{k-1} + N_k,$$

and this finishes the proof. □

We can also study the existence of solutions that exhibit nonmonotone boundary layers. They are going to exist in cases 1 and 2 of Theorem 3.3. Their *Morse index* (dimension of the unstable manifold) is at least 1, due to the nonmonotonicity of the boundary layer. In case 1 of Theorem 3.3, we can even have solutions that exhibit two nonmonotone boundary layers (consequently, their Morse index will be at least 2).

4. Some examples. It is very difficult to determine the existence and stability properties of the unstable solutions of (1) in the same way that we did with the stable ones in Theorem 3.3, because in these problems there are several sources of unstable solutions. Thus we are going to study some particular examples taken from [11], in order to determine completely both the attractors and the flow in them.

The first example analyzed in [11] has as $c(x)$ the step function ($n = 1$)

$$c(x) = \begin{cases} 1/2 + c_1, & x < c_3, \\ 1/2 - c_2, & x \geq c_3, \end{cases} \tag{20}$$

where $c_1, c_2 \in (0, 1/2)$ and $c_3 \in (0, 1)$. Thus $c(x)$ has a negative jump at $x = c_3$ from $1/2 + c_1$ to $1/2 - c_2$. A similar example can be constructed by using a $\bar{c}(x) = c(-x)$ which exhibit a positive jump.

Across this jump at $x = c_3$, the phase diagram changes from having a homoclinic orbit around $u = 1$ to having another one around $u = 0$. As we did before, we are going to denote the intersection of the homoclinic orbit, that exists around zero for $x \geq c_3$, with the u-axis by $\gamma(c_2)$. But for $x < c_3$, we will represent the corresponding intersection by $1 - \gamma(c_1)$. Thus if we have that $\gamma(c_1) + \gamma(c_2) \leq 1$ then there is at most a contact point between the two homoclinic orbit. Having this in mind, we state the following theorem.

THEOREM 4.1. *Consider the equation* (1)*, with boundary conditions* (2) *and* $c(x)$ *defined as in* (20)*. If* c_1 *and* c_2 *satisfy the condition* $\gamma(c_1) + \gamma(c_2) \leq 1$*, then there exists* ϵ_0 *such that for every* $\epsilon \in (0, \epsilon_0)$ *the attractor of this problem can be represented by a linear segment* (*see Figure* 3) *and is described as follows:*

1. *For the case in which* $\alpha_0 \neq 1$ *and* $\alpha_1 \neq 1$ *or if* $\alpha_i = 1$*, then the condition* Di *is verified for* $i = 0, 1$*; we have that the attractor has exactly* 5 *stationary solutions:* 3 *stable ones and* 2 *unstable ones. The unstable ones have Morse index* 1*, and the unstable manifolds of each unstable solution are made of two heteroclinic orbits, one connecting to the equilibrium that exhibits a monotone internal transition from* 0 *to* 1*, and the other to one of the other stable solutions.*

2. *For the case in which either*

(i) $\alpha_0 = 1$ *and the condition* D0 *is not verified, but if* $\alpha_1 = 1$*, then condition* D1 *is verified, or*

(ii) $\alpha_1 = 1$ *and the condition* D1 *is not verified, but if* $\alpha_0 = 1$*, then condition* D0 *is verified;*

the attractor has exactly 3 *stationary solutions:* 2 *stable ones and* 1 *unstable one. One of the stable solutions exhibits a monotone internal transition from* 0 *to* 1*, and the unstable solution has Morse index* 1*. The unstable manifold of the unstable solution*

is made of two heteroclinic orbits, one connecting to the equilibrium that exhibits a monotone internal transition layer from 0 *to* 1*, and the other one to the other stable solution.*

3. *For the case in which* $\alpha_0 = \alpha_1 = 1$ *and neither* D0 *nor* D1 *are verified, the attractor is made of a unique stable solution that exhibits a monotone internal transition from* 0 *to* 1.

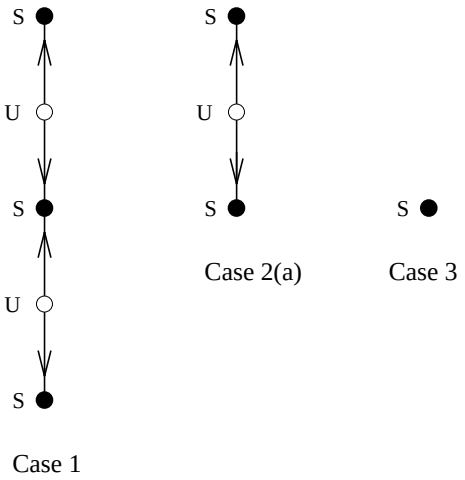


FIG. 3. *Attractors of Theorem* 4.1.

Proof. Let us analyze the last case first. In case 3, we have Dirichlet boundary conditions at both ends of the interval and both of the end points are outside the homoclinic orbits of their corresponding phase portraits (see Figure 4). By the λ-lemma, the time maps L_y and $\bar{L}_y$ are C^k-close to the unstable manifold of 0 before the jump in $c(x)$ and the stable manifold of 1 after the jump, respectively. Thus L_y and $\bar{L}_y$ have only one intersection that is going to be close to the intersections of these invariant manifolds. Consequently, the intersection angle $\Omega(y, v_0)$ is going to be very close to the angle of the intersection of the invariant manifolds.

In order to determine the sign of the intersection angle between the unstable manifold of 0 before the jump in $c(x)$ and the stable manifold of 1 after the jump, let us write down the orbital equation that can be obtained from (7),

$$\frac{dv}{du} = -\frac{f(x,u)}{v}.$$

Thus the difference in the derivatives at an intersection point (u^*, v^*) of the invariant manifolds is

$$\frac{dv_1}{du_1} - \frac{dv_2}{du_2} = -\frac{f_2(x,u^*) - f_1(x,u^*)}{v^*} = \frac{u^*(1-u^*)}{v^*}(c_2 + c_1) > 0. \tag{21}$$

The angle at the intersection point of the two invariant manifolds is negative in the sense defined by Theorem 2.6. Then the stationary solution corresponding to the unique intersection of L_y and $\bar{L}_y$ is stable (thus this is the only stationary solution in this case, which we already knew from Theorem 3.3). This solution exhibits an internal transition layer between 0 and 1.

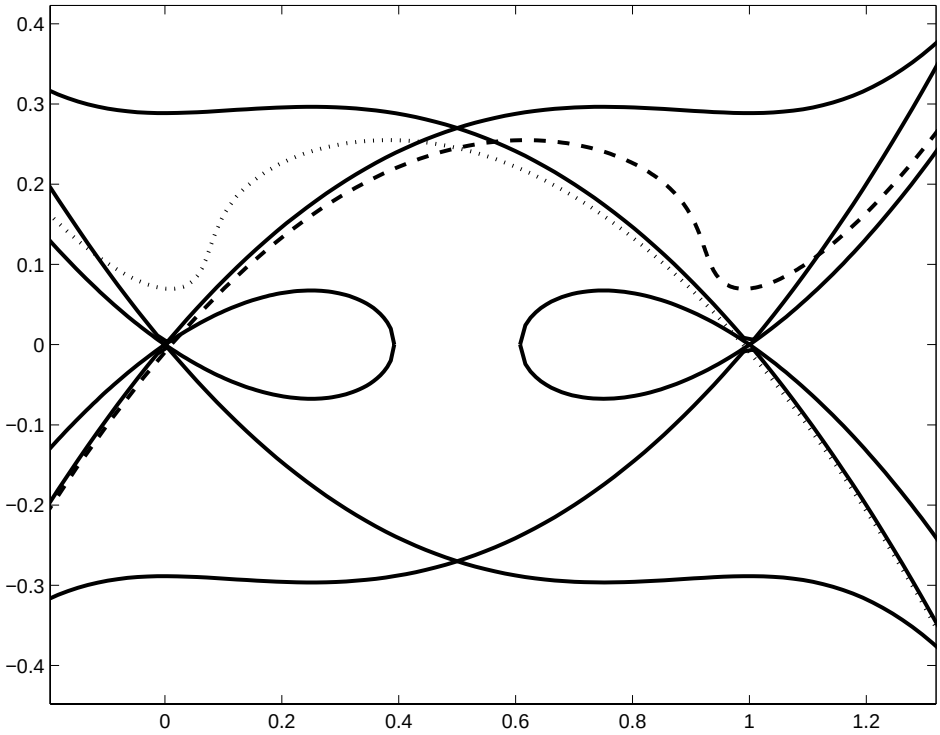

FIG. 4. *Numerical approximations of the time maps L_y (dashed line) and $\bar{L}_y$ (dotted line) in case 3 with $\beta_0 = 0.55$, $\beta_1 = 0.45$, and $c_1 = c_2 = 0.25$.*

This solution also is going to exist in the other cases and is always going to be stable (this can be proven in the same fashion as before). In case 2, say (i), the initial condition is also of Dirichlet type, but the initial point β_0 is now inside the homoclinic orbit that exists around 1 for $c(x) = c_1$. This produces a more complicated geometry for the forward time map. By again using the λ-lemma, we can conclude L_y is still going to be C^k-close to the unstable manifold of 0 before the jump in $c(x)$, but then it will have to curve around, get close to the unstable manifold of 1 before the jump, turn around again inside the homoclinic orbit, and get close again to the unstable solution of 1 before the jump (see Figure 5). This introduces two new crossings between L_y and $\bar{L}_y$ because the backward time map $\bar{L}_y$ is C^k-close to the unstable manifold of 1 for $c(x) = c_2$ (it will include the point $(1, 0)$ if the end-point boundary condition is of Neumann type).

The closest intersection to zero corresponds to a stable equilibrium while the other intersection nearby corresponds to an equilibrium that is unstable (it exhibits a nonmonotone boundary layer). We can see this by using formulas (16) and (17) that directly give us

$$\arctan\sqrt{1/2 - c_1} - \arctan\sqrt{1/2 + c_2},$$

as the angle between the two corresponding invariant manifolds at their intersection point, which is negative in the sense defined by Theorem 2.6. Thus the first intersection corresponds to a stable solution. The second one is unstable because the

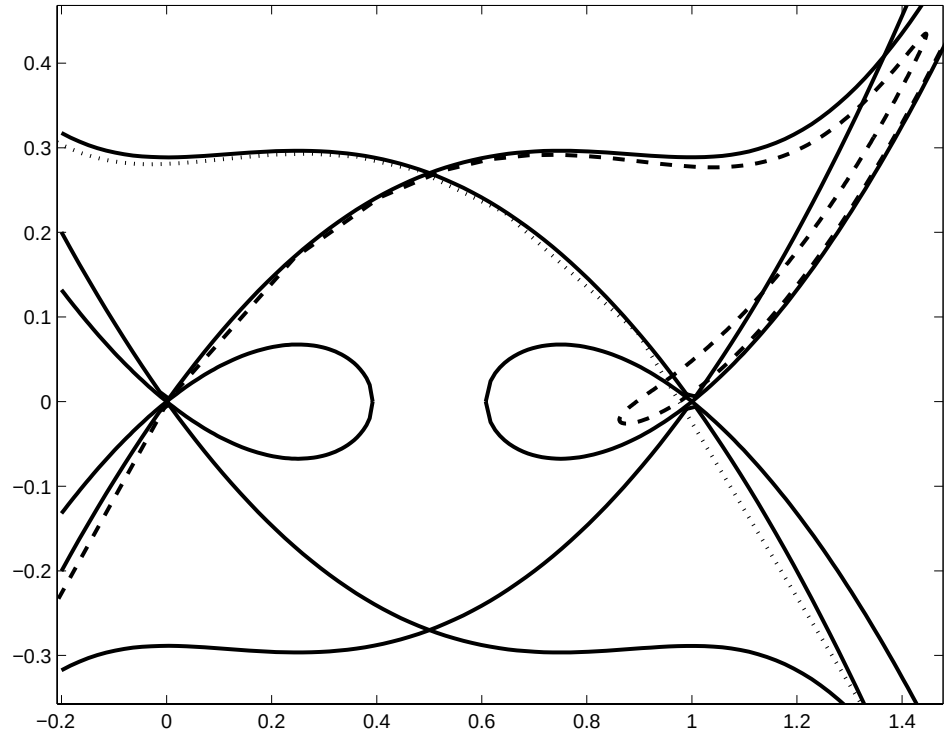

FIG. 5. *Numerical approximations of the time maps L_y (dashed line) and $\bar{L}_y$ (dotted line) in case* 2(i) *with* $\beta_0 = 0.65$, $\beta_1 = 0.45$, *and* $c_1 = c_2 = 0.25$.

intersection angle is increased at least by 2π with respect to the previous one. We could have gotten the same conclusion by analyzing (21).

Finally, in case 1, we have a similar situation to the right side of case 2(i), but now in both ends. Consequently, we have a total of 5 equilibria: 3 stable and 2 unstable (see Figure 6). If the boundary conditions are of Neumann type, then two of the stable intersections between L_y and $\bar{L}_y$ happen at the points $(0,0)$ and $(1,0)$, which are the end points of L_y and $\bar{L}_y$. Otherwise, they happen nearby and they are true crossings.

To determine the connections, we can use the method describe in [4]. In this case, we have to use a permutation matrix formed by the derivatives of the solutions at $x = 0$ and $x = 1$. The computation is straightforward.

As ϵ decreased, the geometry of the time maps inside the homoclinic orbits becomes more complicated. But we know that there are at most two intersections between a time map and the corresponding homoclinic orbit. Outside the homoclinic orbits, the time maps behave much more nicely, approaching the corresponding invariant manifolds of 0 and 1, more and more as $\epsilon \downarrow 0$. □

An example with two jumps in $c(x)$ can be also analyzed. Let $c(x)$ be the step function ($n = 2$)

$$c(x) = \begin{cases} 1/2 + c_1, & x < c_3, \\ 1/2 - c_2, & c_3 \le x < c_5, \\ 1/2 + c_4, & c_5 \le x, \end{cases} \tag{22}$$

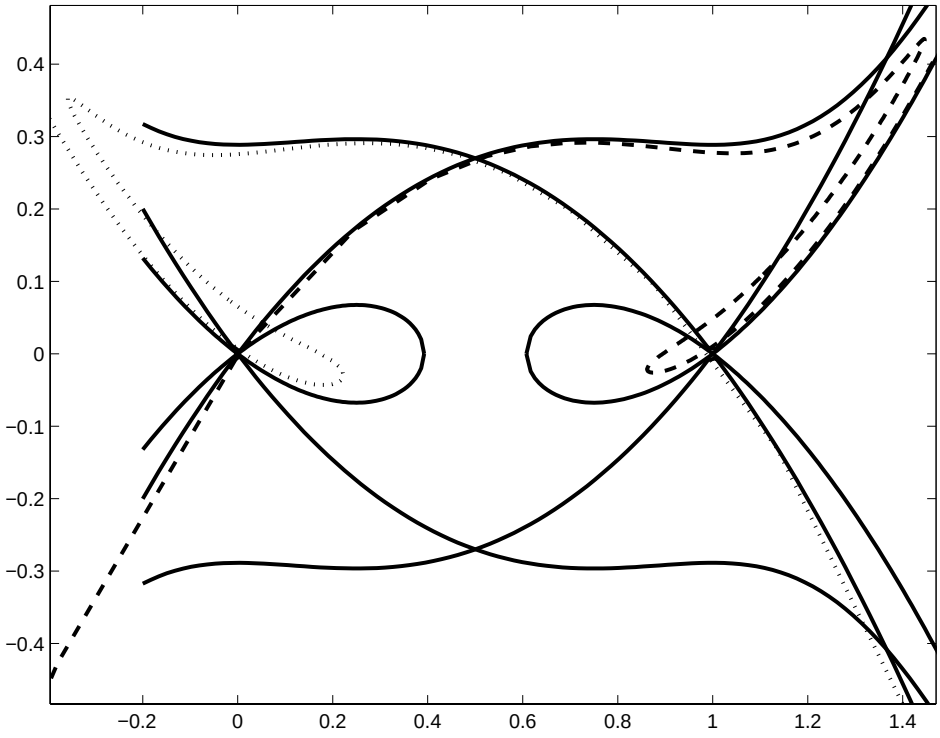

FIG. 6. *Numerical approximations of the time maps L_y (dashed line) and $\bar{L}_y$ (dotted line) in case* 1 *with* $\beta_0 = 0.65$, $\beta_1 = 0.3$, *and* $c_1 = c_2 = 0.25$.

where $c_1, c_2, c_4 \in (0, 1/2)$ and $c_3, c_5 \in (0, 1)$. Therefore $c(x)$ has a negative jump at $x = c_3$ from $1/2 + c_1$ to $1/2 - c_2$ and a positive jump at $x = c_5$ from $1/2 - c_2$ to $1/2 + c_4$. We can now state the following theorem. (Here, $\gamma(c_3)$ is defined as $\gamma(c_1)$ in Theorem 4.1.)

THEOREM 4.2. *Consider* (1), *with boundary conditions* (2) *and* $c(x)$ *defined as in* (22). *If* c_1, c_2, *and* c_4 *satisfy the conditions* $\gamma(c_1) + \gamma(c_2) \leq 1$ *and* $\gamma(c_2) + \gamma(c_4) \leq 1$, *then there exists* ϵ_0 *such that for every* $\epsilon \in (0, \epsilon_0)$ *the attractor of this problem can be represented as in Figure* 7 *and is described as follows:*

1. *For the case in which* $\alpha_0 \neq 1$ *and* $\alpha_1 \neq 1$ *or if* $\alpha_i = 1$ *then the condition* Di *is verified for* $i = 0, 1$; *we have that the attractor has exactly* 11 *stationary solutions:* 5 *stable ones,* 5 *unstable ones of Morse index* 1, *and* 1 *unstable one of Morse index* 2. *The unstable manifolds of the unstable stationary solutions of Morse index* 1 *are made of two heteroclinic orbits which connect them with the stable solutions next to them. The unstable stationary solution of Morse index* 2 *is connected with all the other equilibria except two of them, forming a "racquet"-like attractor* (*see Figure* 7).

2. *For the case in which either*

(i) $\alpha_0 = 1$ *and the condition* D0 *is not verified but if* $\alpha_1 = 1$ *then condition* D1 *is verified, or*

(ii) $\alpha_1 = 1$ *and the condition* D1 *is not verified but if* $\alpha_0 = 1$ *then condition* D0 *is verified,*

we have that the attractor has exactly 5 *stationary solutions:* 3 *stable ones and* 2

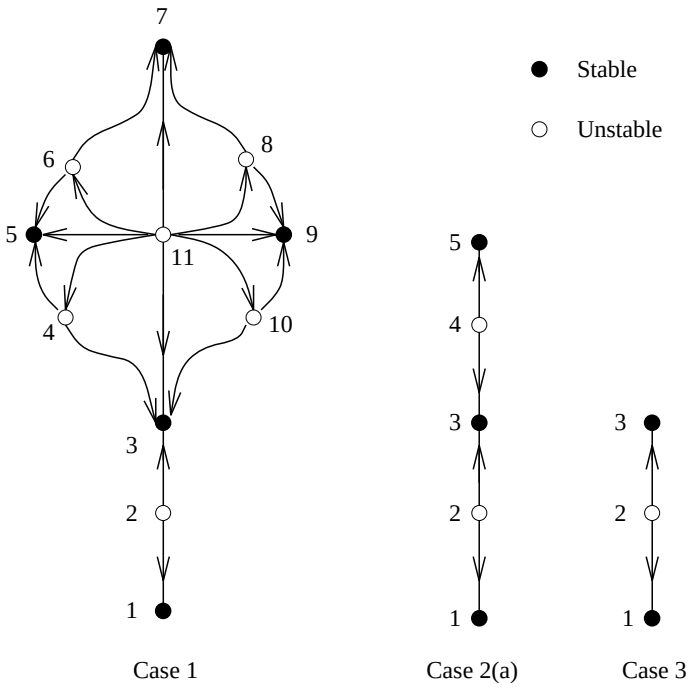

FIG. 7. *Attractors of Theorem* 4.2.

unstable ones. The unstable ones have Morse index 1 *and the unstable manifolds of each unstable solutions are made of two heteroclinic orbits, one connecting to the equilibrium that exhibits two monotone internal transitions (one from* 0 *to* 1 *and the other back from* 1 *to* 0*), and the other one connecting to one of the other stable solutions.*

3. *For the case in which* $\alpha_0 = \alpha_1 = 1$ *and neither* D0 *nor* D1 *are verified; we have that the attractor is made of* 3 *stationary solutions:* 2 *stable ones and* 1 *unstable one. One of the stable ones exhibits two monotone internal transitions (one from* 0 *to* 1 *and the other back from* 1 *to* 0*), and the unstable one has Morse index* 1*. The unstable manifold of the unstable solution is made of two heteroclinic orbits that connect it to the stable solutions.*

Proof. Observe that since now we have two jump points (which, once we make the change of variable $y = x/\epsilon$, will be represented by y_1 and y_2), it may be interesting to look at the intersections between the time maps L_y and $\bar{L}_y$ at the points $y = y_1$ and $y = y_2$. As in the proof of Theorem 4.1, we start now by the simplest case, which is the last one.

Case 3 is very similar to case 2(i) in Theorem 4.1. Because the line $u = \beta_0$ does not intersect the homoclinic orbit around 1 that exists for $x < c_3$, L_{y_1} is C^k-close to the unstable manifold of 0 for ϵ small enough by the λ-lemma. Therefore L_{y_1} does intersect the homoclinic solution that exists around 0 for $c_3 \leq x < c_5$. That means that L_{y_2} will exhibit a "finger" that would go inside the homoclinic orbit around zero. That finger will cross the homoclinic orbit exactly twice and it will have to turn around and join the rest of the curve L_{y_2} that will be now C^k-close to the unstable manifold of 1. On its left side, the finger will leave the interval $[0, 1]$ by being C^k-close to the unstable manifold of 0. See Figure 8.

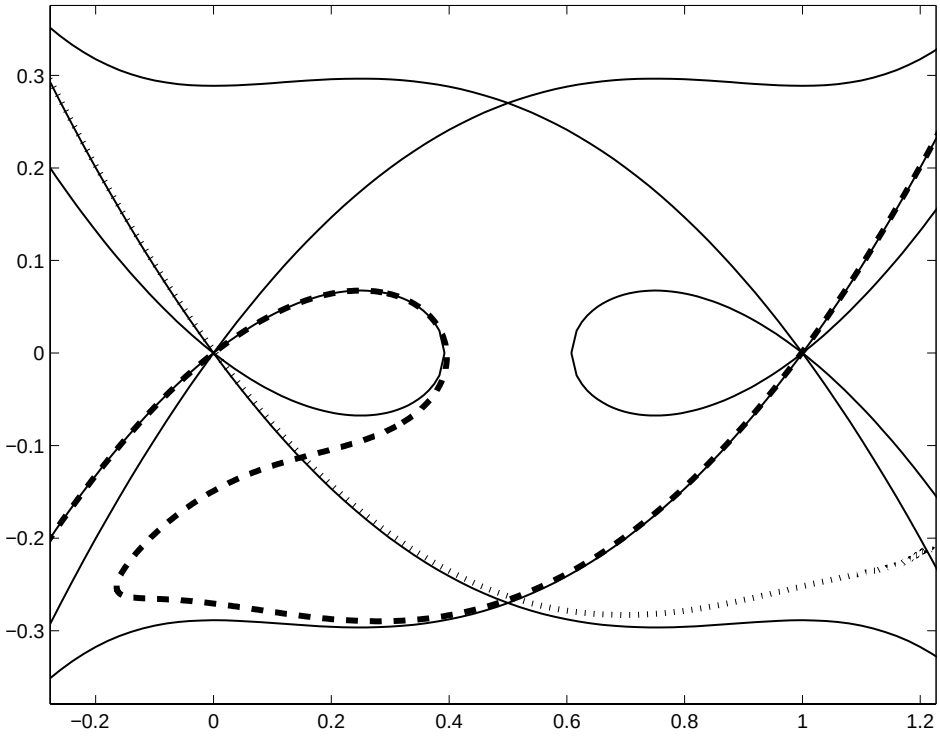

FIG. 8. *Numerical approximations of the time maps L_{y_2} (dashed line) and $\bar{L}_{y_2}$ (dotted line) in case 3 with $\beta_0 = 0.55$, $\beta_1 = 0.45$, and $c_1 = c_2 = c_4 = 0.25$.*

The curve $\bar{L}_{y_2}$, on the other hand, will be C^k-close to the stable manifold of 0 (inside the interval $[0, 1]$). Thus it will intersect L_{y_2} three times. Numbering those intersections in increasing order as one progress along $\bar{L}_{y_2}$ from $u = 0$ to $u = 1$, we have that the first intersection corresponds to a stable solution (the intersection angle gets close to the value

$$\arctan\sqrt{1/2 + c_4} - \arctan\sqrt{1/2 - c_2},$$

as ϵ goes to 0), the second to an unstable solution, and the third to a stable solution. (The angle at this last intersection gets close to the angle of intersection between the stable manifold of 0 for $c_3 \le x < c_5$ and the unstable manifold of 1 for $x > c_5$, which is negative—to see this requires a computation similar to (21).)

The first solution stays close to 0 most of the time but exhibits two monotone boundary layers connecting 0 with β_0 and β_1. The other two stationary solutions exhibit the same boundary layers, but the unstable one exhibits a "bump" between $y = y_1$ and $y = y_2$ (it goes around the homoclinic orbit of 0 for $c_3 \le x < c_5$; that is what makes it unstable) and the other stable solution exhibits two internal jumps: one form 0 to 1 at $y = y_1$ and the other back from 1 to 0 at $y = y_2$. These three solutions also exist in all the other cases.

In case 2 (i), L_{y_1} will also be C^k-close to the unstable manifold of 0 for $x < c_3$, but then it will turn around and have a finger that goes inside the homoclinic orbit around 1 because the line $u = \beta_0$ does now intersect that homoclinic orbit. The time

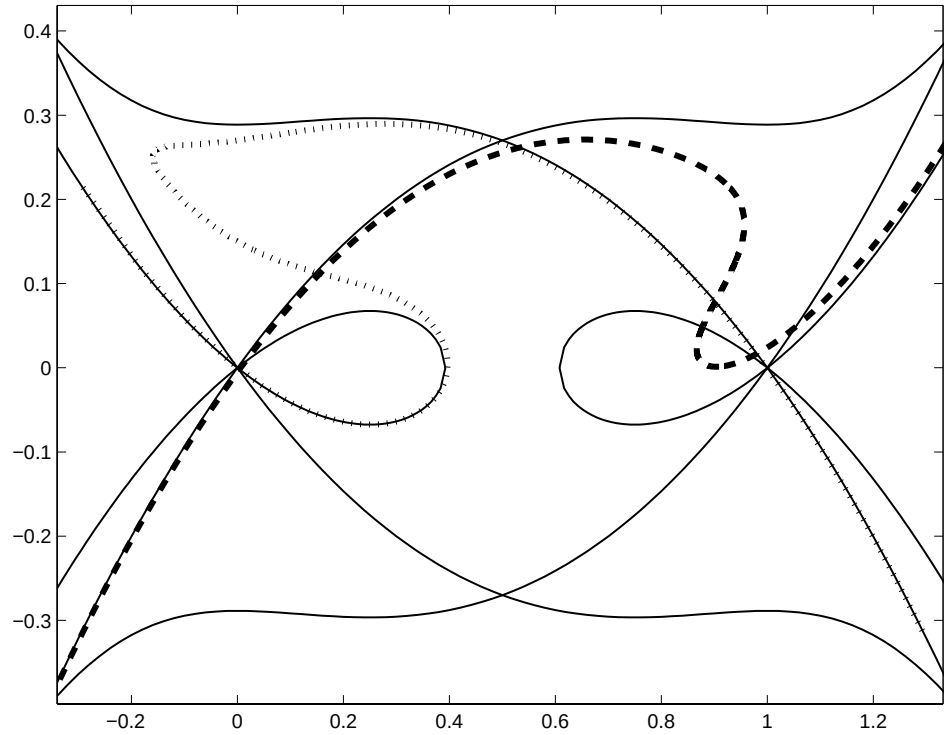

FIG. 9. *Numerical approximations of the time maps L_{y_1} (dashed line) and $\bar{L}_{y_1}$ (dotted line) in case* 2(i) *with* $\beta_0 = 0.65$, $\beta_1 = 0.45$, *and* $c_1 = c_2 = c_4 = 0.25$.

map $\bar{L}_{y_1}$, on the other hand, will have a similar finger that goes inside the homoclinic orbit around 0 that exist for $c_3 \leq x < c_5$ (as in the previous case but backwards in time). This introduces two new crossings. Numbering all intersections consecutively as we progress along $\bar{L}_{y_1}$ from $u = 0$ to $u = 1$, the three first correspond to the same equilibria as that in the previous case. The number 4 is unstable of index 1 (it exhibits a nonmonotone boundary layer at $x = 0$) and the number 5 is stable (similar argument that for number 3 in the previous case). This last equilibrium point exhibits an internal transition layer from 1 to zero at $y = y_2$. See Figure 9.

If we now look at the situation for $y = y_2$, we will see that L_{y_2} has a finger going inside the homoclinic orbit around 0 that exists for $c_3 \leq x < c_5$, then turns around and gets C^k-close to the unstable manifold of 1. But now, it has three pleats along that unstable manifold. They are elongations of the finger that L_{y_1} has close to 1. The five intersections that L_{y_2} and $\bar{L}_{y_2}$ have, when look at along $\bar{L}_{y_2}$ from $u = 0$ to $u = 1$, correspond to the stationary solutions 1, 2, 5, 4, and 3. Thus the order is not preserved. But this intersection (and this ordering) is preserved in case 1, as we can see in Figure 10.

Actually the diagram for case 1 at $y = y_2$ looks very much the same than in the previous case except that now $\bar{L}_{y_2}$ also has a finger that goes inside the homoclinic orbit that exists around 1 for $x \geq c_5$ (see Figure 10).

This new finger introduces six new intersections. The properties and layers of these new equilibria can be deduced by looking at which side of the finger in $\bar{L}_{y_2}$ and

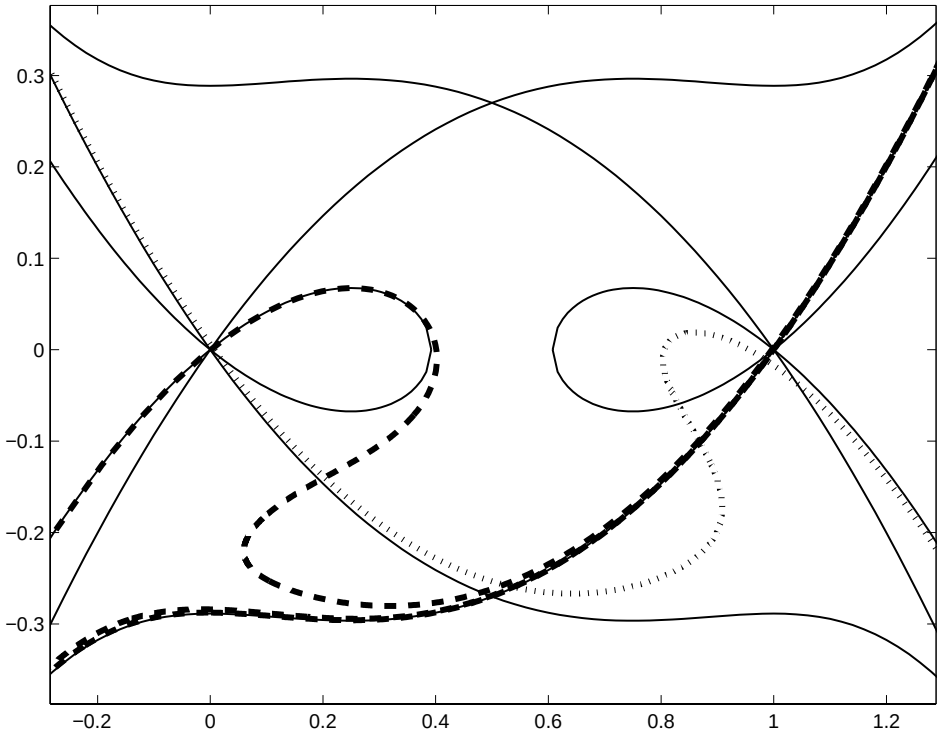

FIG. 10. *Numerical approximations of the time maps L_{y_2} (dashed line) and $\bar{L}_{y_2}$ (dotted line) in case* 1 *with $\beta_0 = 0.65$, $\beta_1 = 0.7$, and $c_1 = c_2 = c_4 = 0.25$. L_{y_2} folds three times along the unstable manifold of* 1.

which pleat of L_{y_2} they are. For example, along the same pleat as solution number 5 we find two new intersections, corresponding to solution numbers 6 and 7. That means that until $y = y_2$, solutions 5, 6, and 7 behave very much alike. But while solution number 5, being outside the finger, makes a transition at $y = y_2$ from 1 to zero, solution number 6 exhibits a nonmonotone layer from 1 to β_1 (becoming unstable of Morse index 1 as a consequence), and solution number 7 exhibits a monotone layer from 1 to β_1 (resulting in a stable solution; this can be checked in a similar fashion as before).

In the same side of the finger as solution number 7 we find solution numbers 8 and 9. Because they occupy such positions, solution numbers 8 and 9 also exhibit monotone boundary layers from 1 to β_1. But they are in the two consecutive pleats of L_{y_2} after solution number 7, so solution number 8 exhibits a nonmonotone boundary layer from β_0 to 1 (becoming unstable of index 1) and solution number 9 exhibits a monotone layer from β_0 to 0; it follows an internal transition layer from 0 to 1 at $y = y_1$. Thus solution number 9 is stable.

On the same pleat as solution number 9 on the other side of the finger we find solution number 10. The only difference between these two solutions is that the left boundary layer of solution number 10 is nonmonotone. Consequently, solution number 10 is unstable of index 1.

Finally, on the second pleat of L_{y_2} and on the left side of the finger of $\bar{L}_{y_2}$, we find solution number 11. From this location we conclude that solution number 11 must

behave like solution numbers 4 and 8 before $y = y_2$ (therefore having a nonmonotone left boundary layer) and like solution numbers 6 and 10 afterwards (therefore having a nonmonotone right boundary layer). Thus solution number 11 must be unstable of Morse index 2.

The method given in [4] allows us again to prove that solution number 11 is connected to all the other solutions except numbers 1 and 2. The cascading property then implies all the other stated connections. □

5. Persistence of solutions after smoothing *c*. We would like to prove that close to every stationary solution $u = u(x)$ of the discrete case—where $c = c(x)$ is a step function—there is a stationary solution $\tilde{u} = u + v$ for the continuous case $\tilde{c} = c + \chi^\delta$. We also would like to prove that the stability properties of u are preserved.

Consequently we want v to verify

$$\begin{cases} \epsilon^2 D^2 v + g^\epsilon(\delta, v) = 0 & \text{in } (0,1), \\ \alpha_0\, v(0) - (1-\alpha_0)\, v'(0) = 0, \\ \alpha_1\, v(1) + (1-\alpha_1)\, v'(1) = 0, \end{cases} \tag{23}$$

where D^2 stands for the second derivative and

$$g^\epsilon(\delta, v) = \epsilon^2 D^2 u + f^\delta(x, u+v),$$

with

$$f^\delta(x,u) = u(1-u)(u - c(x) - \chi^\delta).$$

In order to use the Implicit Function theorem (IFT), let $\epsilon \in (0, \epsilon_0)$, and let us define the operator $F^\epsilon : [0,\delta_0] \times W_0^{2,\,p}([0,1]) \longrightarrow L^p([0,1])$ as

$$F^\epsilon(\delta, v) = \epsilon^2 v + D^{-2} g^\epsilon(\delta, v).$$

Observe that if v belongs to $W_0^{2,\,p}([0,1])$, it verifies the boundary conditions in (23). Also notice that we can always invert the operator D^2 in $W_0^{2,\,p}([0,1])$.

For simplicity's sake, let us study the case in which c has only one jump at the point $x = x_1$. Then c will look like

$$c(x) = \begin{cases} c_0 > 1/2, & x \in [0, x_1], \\ c_1 < 1/2, & x \in (x_1, 1]. \end{cases}$$

The functional χ^δ is a perturbation of c such that

$$\chi^\delta(x) = \chi\left(\frac{x - x_1}{\delta}\right),$$

where $\chi \in Z = L^p(-\infty, +\infty)$. Actually, we are particularly interested in a perturbation like

$$\chi(x) = \begin{cases} -Je^x, & x \in (-\infty, 0), \\ Je^{-x}, & x \in [0, +\infty) \end{cases} \tag{24}$$

for $J = (c_0 - c_1)/2$ (see Figure 11) that would make $c + \chi^\delta$ a continuous function, although we will treat all perturbations in $Y = L^p([0,1])$.

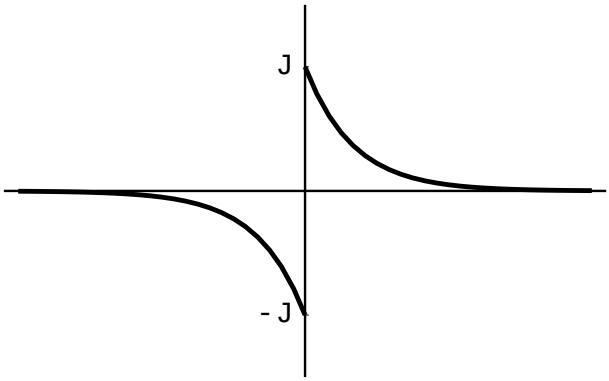

FIG. 11. *Desired perturbation function* $\chi(x)$.

The functional $g^\epsilon(\delta, v) : [0, \delta_0] \times L^p([0,1]) \longrightarrow L^p([0,1])$ is C^∞ with respect to v and is Hölder continuous of exponent $1/p$ with respect to δ, because

$$\|\chi^\delta\|_Y^p = \int_0^1 \left|\chi\left(\frac{x - x_1}{\delta}\right)\right|^p \mathrm{d}x = \int_{-\frac{x_1}{\delta}}^{\frac{1-x_1}{\delta}} |\chi(y)|^p \, \delta \mathrm{d}y \leq \delta \|\chi\|_Z^p.$$

Since F^ϵ is then Hölder continuous of exponent $1/p$ with respect to δ and differentiable with respect to v, $F^\epsilon(0,0) = 0$, and F_v^ϵ is invertible because u is hyperbolic, we can apply the IFT and obtain $\delta_1 = \delta_1(\epsilon) > 0$, such that for every $\delta \in [0, \delta_1)$, $\tilde{u}(\delta) = u + v(\delta)$ is a stationary solution of (1) that is close to u and is a Hölder continuous function of δ of exponent $1/p$.

Now, since $v(\delta)$ belongs to the space $W_0^{2,\,p}$, then by the general Sobolev inequalities, $v \in C^{1,\,q}([0,1])$ with $q = 1 - 1/p$ if $p > 1$ and $v(\delta) \in C^{0,\,q}([0,1])$ for any $0 < q < 1$ if $p = 1$. Thus if in addition to $p > 1$, we choose the perturbation χ^δ such that $c + \chi^\delta$ is a continuous function—selecting it as in (24), for example—then $\tilde{u} \in C^2([0,1])$.

We can execute a similar procedure for every discontinuous term c. We will represent by $\mathcal{E}(0) = \mathcal{E}$ the set of stationary solution for each c and by $\mathcal{E}(\delta)$ the set of stationary solutions that arise from the perturbation χ^δ.

Due to the continuity of the functional χ^δ with respect to δ, the eigenvalues of the linearization of (1) around $\tilde{u}$ are continuous functions of δ. Thus there exists a $\delta_2 = \delta_2(\epsilon) > 0$ such that for $\delta \in [0, \delta_2)$, the stability properties of $\tilde{u}$ are the same as u.

Finally, we want to prove that there exists a $\delta_3 > 0$, such that for $\delta \in [0, \delta_3)$, all the stationary solutions of (1) are in $\mathcal{E}(\delta)$. For that, we will need the following result.

LEMMA 5.1. *Let u be a stationary solution of* (1) *for $\epsilon \in (0, \epsilon_0)$. Then $|u(x)| \leq 1$ for all $x \in [0,1]$ and if $\exists x \in [0,1]$ such that $u(x) = 0$ (resp., $u(x) = 1$), then u is constant equal to* 0 *(resp., equal to* 1*) in* $[0,1]$.

Proof. Let us assume that $\exists x_0 \in [0,1]$ such that $u(x_0) = 0$. If $u'(x_0) = 0$, then by uniqueness of solutions of the initial value problem, $u \equiv 0$.

If $u'(x_0) < 0$, then in order for u to be a stationary solution, $u''(x) < 0$ for all $x \in (x_0, 1]$ because $f(x,u) > 0$ for all $u < 0$. Then u could not arrive at $x = 1$ to a value in $[0,1]$. This implies that for ϵ_0 small enough, u cannot be a stationary solution. The other case could be discussed similarly. □

Let us now assume that there is no such δ_3. Then we can construct a sequence $\{\delta_n\}_{n=1}^\infty$ such that for every δ_n, there is a stationary solution $u_n \notin \mathcal{E}(\delta_n)$. By the IFT,

this implies that all the u_n are outside the uniqueness neighborhoods of the functions in $\mathcal{E}(\delta_n)$. For simplicity's sake, let us assume that u_n is a classical solution, that is, $u_n \in C^2$, although the following argument would still be true with weaker smoothness assumptions after making the appropriate corrections.

Consequently, $\{u_n\}_{n=1}^{\infty}$ is a sequence of continuous functions defined in $[0,1]$, which is a compact subset of $\mathbb{R}$. This sequence is equibounded by Lemma 5.1. Their first and second derivatives are also equibounded, because

$$|u_n''| \leq \frac{|f(x,u_n)|}{\epsilon^2} \leq M(\epsilon).$$

Thus both $\{u_n\}_{n=1}^{\infty}$ and $\{u_n'\}_{n=1}^{\infty}$ converge uniformly when $n \to \infty$, by the Arzelà–Ascoli theorem. The limit function u_0 is a C^2 stationary solution that is not in $\mathcal{E}$. This is a contradiction. Therefore, taking $\delta_0(\epsilon) = \min\{\delta_1, \delta_2, \delta_3\}$, we have proved the following.

THEOREM 5.2. *There exists an $\epsilon_0 > 0$ such that for every $\epsilon \in (0, \epsilon_0)$, there exists a $\delta_0 = \delta_0(\epsilon)$ such that for every $\delta \in [0, \delta_0)$, the attractor $\mathcal{A}$ of (1) for a discrete c and the attractor $\mathcal{A}_\delta$ of (1) for $c + \chi_\delta$ are topologically equivalent. That is, $\mathcal{A} \cong \mathcal{A}_\delta$.*

This theorem also could have been deduced from more general results proven in [5].

A FREE BOUNDARY PROBLEM FOR SCALAR CONSERVATION LAWS*

ANDREA TERRACINA†

Abstract. We investigate a class of free boundary problems for scalar conservation laws, which is suggested by a model of ion etching. First we give an entropy formulation of the problem; then we prove existence, uniqueness, continuous dependence, and comparison properties of solutions for a large class of initial data.

Key words. conservation laws, free boundary

1. Introduction. There is a very rich literature about Stefan problems for parabolic and elliptic equations and systems (e.g., see [Da] and references therein). On the other hand, free boundary problems for hyperbolic equations and systems are much less investigated.

Nevertheless, many physical models (for instance, in gas dynamics or in heat conduction; see [Hi], [Ge], [SG], [FH], [SAWD], [SW], [Sh]) give rise to very interesting hyperbolic free boundary problems, which call for a thorough investigation. Problems of this kind also arise for systems of conservation laws, when existence and stability of multidimensional shock waves are addressed (see [Ma1], [Ma2], [Me]). In this connection, let us mention that quasi-linear and linear first-order hyperbolic problems with unknown boundaries are investigated in [LY], [Li], [KM].

In all the above references only *smooth* solutions are considered. On the other hand, it is well known that for first-order conservation laws we cannot expect to have global classical solutions (see [La], [Ol]). Hence in these cases a weak entropy formulation is unavoidable, both for Cauchy and for initial-boundary value problems (e.g., see [Kr], [BLN]).

To our knowledge, no *entropy formulation of free boundary problems* involving first-order conservation laws has been given so far. This is our concern in the present paper. More precisely, we consider the following Stefan problem:

$$\begin{cases} u_t + f(u)_x = 0 & \text{in } \Lambda(s(\cdot), T), \\ u(x,0) = u_0(x) & \text{in } \mathbb{R}^+ \times \{0\}, \\ s'(t) = K(u(s(t),t), s(t)), \\ s(0) = 0, \end{cases} \tag{1.1}$$

where f, u_0, K are given and u, s must be determined; here

$$\Lambda(s(\cdot), T) := \{(x,t) \in \mathbb{R} \times (0,T) \,:\, 0 \le t < T,\, s(t) < x\}\,.$$

To understand the nature of the problem some other comments are in order. As is well known, a typical feature of the entropy formulation of initial-boundary

value problems for scalar conservation laws is that the data are not strongly achieved; instead, boundary conditions have to be formulated as compatibility conditions in a suitable sense (see [BLN]). Roughly speaking, such compatibility conditions involve properties both of the flux function f and of the boundary (see Definition B.1 in Appendix B). Clearly, giving an entropy formulation for a free boundary problem like (1.1), where *the boundary is a priori unknown*, raises interesting, nontrivial questions.

Since the equation for the boundary $\{(s(t), t)\}$ in problem (1.1) involves the function K, we cannot expect this problem to be well defined unless the function has suitable properties. Investigating this point for a general Stefan problem like (1.1) appears to be a very difficult task. In this paper we limit ourselves to the following choice:

$$K(u, v) = \frac{f(u)}{u - g'(v)}\ , \tag{1.2}$$

which is suggested by a model for ion-etching proposed in [Ro] (see Appendix A). Here f is the flux and g is a regular decreasing function; in [Ro] the case was considered

$$g(x) \equiv -cx, \qquad c > 0, \tag{1.3}$$

with a constant initial datum $u_0(x) \equiv p$, $p > 0$.

Problem (1.1) with the function K given in (1.2) will be referred to as problem (FB) in the following. It is the purpose of this paper to investigate thoroughly this case, regarded as a "case study" toward the investigation of the general Stefan problem (1.1). As we shall see, some results concerning the general free boundary problem (1.1) can be proved using the same ideas (Proposition 2.4).

The main technical tool used in this paper is the comparison principle for mixed valued problems of scalar conservation laws which will be recalled in Appendix B.

2. The main results. In this section we introduce our mathematical framework and state the main results of the paper.

Concerning the flux f the following assumptions will be used:

(f_1) $f \in C^2(\mathbb{R})$;

(f_2) $f > 0$;

(f_3) $f(x) = f(-x)$ for any $x \in \mathbb{R}$;

(f_4) $f(x) \underset{|x|\to\infty}{\to} \longrightarrow 0$;

(f_5) f has a finite number of inflection points.

As for g, we assume that

(g) $g \in C^1(\mathbb{R}^+)$ is decreasing.

We also assume $u_0 \geq 0$.

Let us first state a local existence result concerning classical solutions of problem (1.1).

PROPOSITION 2.1. *Let $u_0 \in C^1(\mathbb{R}^+)$, $K \in C^1(\mathbb{R} \times \mathbb{R})$. Then there is $T > 0$ such that for $t \in (0, T)$ there exists at least one regular solution (s, u) of the free boundary problem* (1.1).

It was observed in [Ro] that even smooth solutions of problem (1.1) need not be unique. Hence the class of solutions we consider has to be restricted using a criterion of physical admissibility, which was introduced in [Ro] assuming (1.3) and constant initial data. Define

$$F_c(p) := \inf\left\{ q \in (p, \infty)\ :\ \frac{f(q)}{q + c} \geq \frac{f(r)}{r + c} \text{ for any } r \in (q, \infty) \right\}. \tag{2.1}$$

Then an admissible solution of problem (1.1)–(1.3) is given by a couple (s,u), such that $s(t)\equiv F_c(p)t$ and u solves the initial-boundary value problem:

$$\begin{cases} u_t+f(u)_x=0 & \text{in } \Lambda(s(\cdot),T),\\ u(x,0)=p & \text{in } \mathbb{R}^+\times\{0\},\\ u(F_c(p)t,t)=F_c(p) & \text{for every } t\in(0,T). \end{cases}$$

This characterizes the admissible solution as the one for which the speed of the interface is maximal. Observe that the function F_c is well defined, due to the properties of the flux function f. In some intervals this is equal to the identity; in other intervals it is constant. Since the flux f is decreasing for large x, the same is true for the function $\frac{f(p)}{p+c}$—hence the function F_c is equal to the identity for large x.

Similar ideas can be used to obtain the weak entropy formulation of problem (FB). We recall that in the standard space BV of functions with (locally) bounded total variation it is possible to define the notion of trace; see, for instance, [EG]. For simplicity we denote by $u(s(t),t)$ the trace (in the L^1 sense) of the boundary value function u along the (smooth) curve $s=s(t)$.

Let us introduce the following definition.

DEFINITION 2.1. *Let $u_0\in BV(\mathbb{R}^+)\cap L^\infty(\mathbb{R}^+)$. We say that the couple $s(t)\in Lip(0,T)$, $u\in BV_{loc}(\Lambda(s(\cdot),T))\cap L^\infty(\Lambda(s(\cdot),T))$, $u\geq 0$, is an entropy solution of problem* (FB) *if it is an entropy solution of the initial-boundary value problem*

$$\begin{cases} u_t+f(u)_x=0 & \text{in}\quad \Lambda(s(\cdot),T),\\ u(x,0)=u_0(x) & \text{in}\quad \mathbb{R}^+\times\{0\},\\ u(s(t),t)=F_{|g'(s(t))|}(u(s(t),t)),\\ s'(t)=\dfrac{f(F_{|g'(s(t))|}(u(s(t),t)))}{F_{|g'(s(t))|}(u(s(t),t))+|g'(s(t))|}. \end{cases}\tag{2.2}$$

The definition of entropy solution of an initial-boundary value problem for scalar conservation laws is recalled in Appendix B (see Definition B.1).

In particular, the boundary condition is satisfied in the following sense: For almost any $t\in(0,T)$ there holds

$$\frac{f(u(s(t),t))-f(k)}{u(s(t),t)-k}\leq\frac{f(F_{|g'(s(t))|}(u(s(t),t)))}{F_{|g'(s(t))|}(u(s(t),t))+|g'(s(t))|}$$

for any $k\in(u(s(t),t),F_{|g'(s(t))|}(u(s(t),t))]$.

Consider the set

$$\mathcal{S}(c):=\{p\in\mathbb{R}\,:\,F_c(p)=p\}.\tag{2.3}$$

The above set plays a crucial role in the entropy formulation of problem (FB), as the following proposition shows.

PROPOSITION 2.2. *Let $u_0\in BV(\mathbb{R}^+)\cap L^\infty(\mathbb{R}^+)$. The couple $s(t)\in Lip(0,T)$, $u\in BV_{loc}(\Lambda(s(\cdot),T))\cap L^\infty(\Lambda(s(\cdot),T))$ is an entropy solution of the problem* (FB) *if and only if this couple is an entropy solution of*

$$\begin{cases} u_t+f(u)_x=0 & \text{in}\quad \Lambda(s(\cdot),T),\\ u(x,0)=u_0(x) & \text{in}\quad \mathbb{R}^+\times\{0\},\\ u(s(t),t)\in S(|g'(s(t))|) & \text{almost everywhere (a.e.) in } (0,T),\\ s'(t)=\dfrac{f(u(s(t),t))}{u(s(t),t)+|g'(s(t))|}. \end{cases}\tag{2.4}$$

It follows that the trace $u(s(t),t)$ of any entropy solution of problem (FB) takes values in the set $\mathcal{S}(c)$. This implies that no characteristic starting from the boundary and pointing inwards toward the domain exists (Proposition 3.1 (v)).

The following proposition gives a maximality property of the entropy solutions of the free boundary problem in $\Lambda(s(\cdot),T)$.

PROPOSITION 2.3. *Let (s,u) be an entropy solution of problem* (FB). *Let v be any entropy solution of the conservation law in $\Lambda(s(\cdot),T)$, which satisfies the same initial condition as u. Then $v \le u$ a.e. in $\Lambda(s(\cdot),T)$.*

In the spirit of the previous proposition we can prove the following theorem, which gives an a priori estimate for the entropy solutions of problem (FB).

THEOREM 2.1. *Let $u_0 \in BV_{loc}(\mathbb{R}^+)\cap L^\infty(\mathbb{R}^+)$. Let the couple (s,u) be an entropy solution of the free boundary problem* (FB). *Then*

$$\text{ess inf}(u_0) \le u \le F_{J(T)}(\text{ess sup}\, u_0) \qquad \text{for a.e. } (x,t) \in \Lambda(s(\cdot),T), \tag{2.5}$$

where

$$J(T) := \sup_{t\in(0,T)} |g'(s(t))|.$$

Moreover, the function u is an entropy solution of the following boundary value problem:

$$\begin{cases} u_t + f(u)_x = 0 & \text{in} \quad \Lambda(s(\cdot),T), \\ u(x,0) = u_0(x) & \text{in} \quad \mathbb{R}^+ \times \{0\}, \\ u(s(t),t) = F_{J(T)}(\text{ess sup}\, u_0). \end{cases}$$

As discussed in section 1, it is natural to ask whether the previous results are still true for the general Stefan problem (1.1). In this connection let us make the following definition.

DEFINITION 2.2. *Let $u_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$. We say that the couple $s(t) \in Lip(0,T)$, $u \in BV_{loc}(\Lambda(s(\cdot),T)) \cap L^\infty(\Lambda(s(\cdot),T))$ is an entropy solution of problem* (1.1) *if*

(i) *the function u is an entropy solution in $\Lambda(s(\cdot),T)$ of problem* (1.1);

(ii) $s'(t) = K(u(s(t),t),s(t))$;

(iii) $u(s(t),t) \in \overline{\mathcal{S}}(s(t))$, *where the set $\overline{\mathcal{S}}(s(t))$ is a finite union of closed intervals and verifies the following property:*

$$u \in \overline{\mathcal{S}}(s(t)) \Leftrightarrow K(u,s(t)) \ge \frac{f(u)-f(p)}{u-p} \qquad \text{for every } u,p \in \overline{\mathcal{S}}(s(t)). \tag{2.6}$$

Following the proof of Proposition 2.3 (see section 3) we obtain the proposition below.

PROPOSITION 2.4. *Let (s,u) be an entropy solution of problem* (1.1). *Then the conclusion of Proposition* 2.3 *holds. Moreover,*

$$\sup\{q > \text{ess inf}\, u_0 \,:\, q \in \overline{\mathcal{S}}(s(t)) \ \forall t \in [0,T]\} \le u \le$$

$$\inf\{q > \text{ess sup}\, u_0 \,:\, q \in \overline{S}(s(t)) \ \forall t \in [0,T]\} \quad \text{a.e. in } \Lambda(s(\cdot),T).$$

Let us now restrict ourselves to the case $g(x) = -cx$, $c > 0$, which is easier since the admissible set of free boundary value $\mathcal{S}(|g'(s(t))|)$ does not depend on t. The

general case, namely, for any g satisfying assumption (g), will be the object of further investigation.

Let us introduce the following classes of initial data:

Class A: u_0 takes values in an interval $[a,b] \subset \mathcal{S}(c)$;

Class B: u_0 takes values in an interval $(p,q) \subset \mathbb{R}^+ \setminus \mathcal{S}(c)$;

Class C: u_0 has a finite number of oscillations outside a set of zero Lebesgue measure, namely, there exist a null set E and $n \in \mathbb{N}$ such that for any $n+1$ points $\{x_i\}$, $x_i < x_{i+1}$ $(i = 1, \dots, n)$ in $\mathbb{R}^+ \setminus E$, $u_0(x_j) \neq u_0(x_{(j+1)})$ there holds

$$sgn(u_0(x_{i+1}) - u_0(x_i)) = -sgn(u_0(x_{i+2}) - u_0(x_{i+1})), \qquad 1 \leq i \leq n-2,$$

implying

$$sgn(u_0(x_{n+1}) - u_0(x_n)) = sgn(u_0(x_n) - u_0(x_{n-1})).$$

Let us observe that $\mathcal{S}(c) = \mathbb{R}^+$ when $f' \leq 0$ (see Proposition 3.1 (i) below), in which case all the data belong to Class A.

The following existence and uniqueness theorem for problem (FB) can be proved (see sections 4–6).

THEOREM 2.2. *Let* (1.3) *hold. Let* $u_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$ *be in any Class* A, B, *or* C. *Then there exists a unique entropy solution of the free boundary problem* (FB).

If the initial data are in Class A, the following estimates can be proved.

THEOREM 2.3. *Let* (1.3) *hold. Let* (s_1, u), (s_2, v) *be solutions of the free boundary problem* (FB) *with data* u_0, v_0, *respectively, of Class* A. *Then*

$$\|s_1 - s_2\|_{L^\infty(0,T)} \leq \frac{2}{c} \|u_0 - v_0\|_{L^1((0,R_T))},$$

and for any $C \in \mathbb{R}^+$ *and almost any* t

$$\int_{\overline{s}(t)}^{\overline{s}(t)+C} |u(x,t) - v(x,t)|\, dx \leq \|u_0 - v_0\|_{L^1((0,C+R_T))},$$

where

$$\overline{s}(t) = \max\{s_1(t), s_2(t)\},$$

$$R_T := \left(\sup_{|u| \leq M} |f^{'}(u)| + \|s'\|_{L^\infty(0,T)} \right) T,$$

and

$$M := \max(\|u_0\|_{L^\infty}, \|v_0\|_{L^\infty}).$$

Moreover, suppose $u_0 \leq v_0$ *a.e. Then*

$$s_1 \geq s_2 \qquad \text{in } (0,T),$$

$$u \leq v \qquad \text{a.e. in } \Lambda(s_1(t), T).$$

3. Proofs of general results. In this section we prove local existence of classical solutions of the general free boundary problem (1.1) (Proposition 2.1), as well as the characterization of the entropy solutions of the free boundary problem (FB) (Proposition 2.3) and the a priori estimates stated in Proposition 2.4 and Theorem 2.1, respectively.

Proof of Proposition 2.1. Let us extend u_0, in an arbitrary way, to a function $\overline{u}_0 \in C^1(\mathbb{R})$.

By the method of characteristics, there exists a time T_0 and a regular solution u to the Cauchy problem

$$\begin{cases} u_t + f(u)_x = 0 & \text{in} \quad \mathbb{R} \times (0, T_0), \\ u(x,0) = \overline{u}_0 & \text{in} \quad \mathbb{R} \times \{0\}. \end{cases}$$

We look for a solution $s(t)$ of

$$s'(t) = K(u(s(t),t), s(t)).$$

Set

$$B := \{s \in Lip(0,T) \,:\, s(0) = 0,\, 0 \le s \le M\,,\, 0 \le s' \le L \,\text{a.e.}\},$$

where $T < T_0$ is a constant to be fixed later,

$$L := \max_{\substack{|u| \le \|\overline{u}_0\|_{L^\infty(\mathbb{R})} \\ |v| \le 1}} |K(u,v)| \text{ and } M := \min\{LT, 1\}.$$

Observe that B is a closed subspace of the Banach space $C(0,T)$; consider the following operator G from B into itself:

$$G(s)(t) := \int_0^t K(u(s(t),t), s(t))\, d\tau.$$

Let us choose T such that G is a contraction. We have

$$\|G(s) - G(\overline{s})\|_{L^\infty} = \sup_{t \in [0,T]} \left| \int_0^t K(u(s(\tau),\tau), s(\tau)) - K(u(\overline{s}(\tau),\tau), \overline{s}(\tau))\, d\tau \right|.$$

Since K and u are smooth functions there exists a constant k such that

$$|K(u(x,t),x) - K(u(\overline{x},t),x)| \le k|x - \overline{x}|$$

for every $-M \le x, \overline{x} \le M$, $0 \le t \le T_0$.

Thus we have

$$\|G(s) - G(\overline{s})\|_{L^\infty} \le Tk \|s - \overline{s}\|_{L^\infty}.$$

Choosing $T < \frac{1}{k}$ we obtain that T is a contraction operator and we can apply the contraction fixed point theorem. □

Observe that the above result cannot give any information about uniqueness, since we consider an arbitrary extension of u_0. However, the following holds.

LEMMA 3.1. *Suppose $u_0 \in C^1(\mathbb{R}^+)$. Let u be a local regular solution given in the previous proof such that the trace $u(s(t),t)$ lies in the set $\overline{\mathcal{S}}(s(t))$ given by* (2.6)*. Then the function u does not depend on the arbitrary extension of u_0.*

Proof. Let us prove that $s(t)$ depends only on the data on the positive semiaxis.

For any $x_0 \geq 0$ the characteristic issued from x_0 is given by the solution of the problem

$$\begin{cases} x' = f(u), \quad u' = 0, \\ x(0) = x_0, \quad u(0) = u(x(0)) = u(x_0). \end{cases}$$

Then we have

$$x(t) = x_0 + tf'(u_0(x_0)), \quad u(x(t), t) = u_0(x_0).$$

Let $(x(t), 0)$ be the starting point of the characteristic reaching the point $(s(t), t)$; then

$$s(t) = x_0(t) + tf'(u_0(x_0(t))) \;\; s(0) = 0 = x_0(0). \tag{3.1}$$

Let us derive (3.1) obtaining

$$s'(t) = x_0'(t) + f'(u_0(x_0(t))) + tf''(u_0(x_0(t)))x_0'(t)u_0'(x_0(t)).$$

Since $s'(t) = K(u(s(t), t), s(t))$, we obtain by (2.6)

$$x_0'(1 + tf''u_0') = s'(t) - f'(u_0(x_0(t))) = K(u(s(t), t), t) - f'(u(s(t), t)) \geq 0.$$

Thus for small time $x_0' \geq 0$ and $x_0(t) \geq 0$. □

Let us now state some properties of the function F_c and of the set $S(c)$ (see (2.1), (2.3)), which are needed in the following. The elementary proofs are omitted.

PROPOSITION 3.1. *Assume* (f_1)–(f_5) *for the flux function* f. *Then*

(i) $F_c(p) \geq p$ *for any* $p \geq 0$;

(ii) *let* $F_c(p) > p$. *Then* $\frac{f(F_c(p))}{F_c(p)+c} = f'(F_c(p))$ *and* $\frac{f(F_c(p))}{F_c(p)+c} > \frac{f(p)}{p+c}$;

(iii) *there exists a finite number of points* n, $0 = p_0 \leq p_1 < p_2 < \cdots < p_n = +\infty$, *such that*

$$F(p) = \begin{cases} p & \text{in } (p_{2j}, p_{2j+1}], \\ F(p_{2j+2}) & \text{in } (p_{2j+1}, p_{2j+2}]; \end{cases}$$

(iii) F *is continuous from the left;*

(iv) *let* $u \in \mathcal{S}(c)$, $u < v$. *Then*

$$\min\left\{\frac{f(u)}{u+c}, \frac{f(v)}{v+c}\right\} \geq \frac{f(u) - f(v)}{u - v};$$

(v) *for any given interval* $(a, b) \subset \mathcal{S}(c)$, *the function* $\frac{f(x)}{x+c}$ *is nonincreasing in* (a, b) *and*

$$\frac{f(x)}{x + c} - f'(x) \geq 0.$$

Let us discuss a more precise characterization of the set $\mathcal{S}(c)$. For this purpose, let $0 < p_1 < \cdots < p_k$ local strictly positive maximum of f'. Define the functions

$$L(x) = x - \frac{f(x)}{f'(x)},$$

$$p_j(c) := \begin{cases} \min\{x \geq p_j : L(c) = -c,\ f''(x) \geq 0\}, & j = 1, \ldots, k, \\ 0, & j = 0. \end{cases}$$

Set also

$$N(c) := \{j \in \{0, \dots, k\} \,:\, p_j(c) \in \mathcal{S}(c)\},$$

and for any $j \in K(c) \setminus \{0\}$

$$\overline{p}_j(c) := \max\left\{p_{j-1}(c) \le x < p_j(c) : \frac{f(x)}{x+c} = f'(p_j(c))\right\}.$$

The following result can be proved.

PROPOSITION 3.2. (i) *If $f' \le 0$, then $\mathcal{S}(c) = \mathbb{R}^+$ for every c.*

(ii) *The function $p_j(c)$ is an increasing function of c for every $j = 1, \dots, k$.*

(iii) *The function $\overline{p}_j(c)$ is a decreasing function of c for every $j \in N(c) \setminus \{0\}$.*

(iv) *There holds*

$$\mathcal{S}(c) = \bigcup_{j \in N(c) \setminus \{\max\{k \in N(c)\}\}} [p_j(c), \overline{p}(c)_{\min\{k \in N(c),\, k > j\}}] \cup [p(c)_{\max\{k \in N(c)\}}, \infty).$$

(v) *$\mathcal{S}(c_1) \subset \mathcal{S}(c_2)$ for any $c_1 > c_2$.*

We can now prove Propositions 2.2 and 2.3.

Proof of Proposition 2.2. If u is an entropy solution of (2.4), then it is obviously an entropy solution of (2.2). Now suppose that the function u is an entropy solution of (2.2). We want to show that the trace $u(s(t), t) \in S(|g'(s(t))|)$ a.e.

For simplicity set $u(s(t), t) = \tilde{u}$ for a fixed t. If $\tilde{u} < F_{|g'(s(t))|}(\tilde{u})$ then for the compatible boundary conditions we have

$$\frac{f(\tilde{u}) - f(k)}{\tilde{u} - k} \le s'(t) = \frac{f(F_{|g'(s(t))|}(\tilde{u}))}{F_{|g'(s(t))|}(\tilde{u}) + |g'(s(t))|} \qquad \text{for every } k \in (\tilde{u}, F_{|g'(s(t))|}(\tilde{u})].$$

Taking $k = F_{|g'(s(t))|}(\tilde{u})$, we obtain by computations

$$\frac{f(F_{|g'(s(t))|}(\tilde{u}))}{F_{|g'(s(t))|}(\tilde{u}) + |g'(s(t))|} \le \frac{f(\tilde{u})}{\tilde{u} + |g'(s(t))|}.$$

This is in contradiction with Proposition 3.1 (iv). □

Let us associate with any given function $s \in Lip(0, T)$ and $u \in BV(\Lambda(s(\cdot), T)) \cap L^\infty(\Lambda(s(\cdot), T))$, the function

$$u^s(x, t) := u(x + s(t), t) \tag{3.2}$$

defined in $\Pi_T^+ := \mathbb{R}^+ \times (0, T)$.

Proof of Proposition 2.3. We have to compare the functions u and v in $\Lambda(s(\cdot), T)$. Consider the functions u^s, v^s associate, respectively, to $(s(t), u)$ and $(s(t), v)$ (see (3.2)). Using the inequality (B.4) of Theorem B.1 (see Appendix B), we obtain

$$\begin{aligned} &\int_{\mathbb{R}^+} [v^s(x,t) - u^s(x,t)]_+ \, dx \\ &\qquad \le \int_0^t H(v^s(0,\tau) - u^s(0,\tau))(f(v^s(0,\tau)) - f(u^s(0,\tau)) \\ &\qquad - \frac{f(u^s(0,\tau))}{u^s(0,\tau) + |g'(s(t))|}(v^s(0,\tau) - u^s(0,\tau))) \, d\tau. \end{aligned} \tag{3.3}$$

Let us show that the right-hand side of inequality (3.3) is negative. In fact, for the values of τ such that $v^s(0,\tau) \le u^s(0,\tau)$ the integrand is negative. Suppose $v^s(0,\tau) > u^s(0,\tau)$. Since $u^s \in \mathcal{S}(|g'(s(\tau))|)$, we have from Proposition 3.1 (iv)

$$\frac{f(v^s(0,\tau)) - f(u^s(0,\tau))}{v^s(0,\tau) - u^s(0,\tau)} \le \frac{f(u^s(0,\tau))}{u^s(0,\tau) + |g'(s(\tau))|}.$$

Therefore also in this case the integrand is negative. This completes the proof. ∎

Let us prove Theorem 2.1.

Proof of Theorem 2.1. Set $p := F_{J(T)}(\operatorname{ess\,sup} u_0)$. Consider in $\Lambda(s(\cdot),T)$ the functions u and $v \equiv p$ and the associated functions u^s and v^s given by (3.2). Since $v^s \equiv p$ is an entropy solution of the problem with initial data $v_0 \equiv p$, we can compare the functions u^s and v^s by inequality (B.4). In this case we have

$$\int_{\mathbb{R}^+} [u^s(x,t) - p]_+ \, dx \le \int_{\mathbb{R}^+} [u(x,0) - p]_+ \, dx$$

$$+ \int_0^t H(u^s(0,\tau) - p) \left(f(u^s(0,\tau)) - f(p) - \frac{f(u^s(0,\tau))}{u^s(0,\tau) + c}(u^s(0,\tau) - p) \right) d\tau. \tag{3.4}$$

Again using Proposition 3.1 (iv) and Proposition 3.2 (v) we obtain that the right-hand side of inequality (3.4) is negative. In the same way we can prove that $u^s \ge \operatorname{ess\,inf} u_0$.

The rest of the proof is a consequence of Theorem B.2 (see Appendix B), Proposition 2.3, and estimate (2.5). ∎

Let us prove for future reference a further result. Set

$$M_0 = \max\{\|u_0\|_{L^\infty}, F_{J(T)}(\operatorname{ess\,sup} u_0)\},$$

where

$$J(T) := \sup_{t \in (0,T)} |g'(s(t))|.$$

Then the following holds.

PROPOSITION 3.3. *Let $u_0 \in BV_{loc}(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$. Let (s,u) be an entropy solution of the free boundary problem* (FB). *Let $\overline{u}_0 \in BV_{loc}(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$ such that $\|\overline{u}_0\|_{L^\infty} \le \|u_0\|_{L^\infty}$ and*

$$\overline{u}_0 \equiv u_0 \qquad \text{in } [0,R]$$

for some $R > (\sup_{|u| \le M_0} |f'(u)| + \|s'\|_{L^\infty(0,T)})T$. Then a solution of the free boundary problem with initial data $\overline{u}_0$ is given by $(s,\overline{u})$, where $\overline{u}$ is the solution of the following mixed value problem:

$$\begin{cases} \overline{u}_t + f(\overline{u})_x = 0 & \text{in} \quad \Lambda(s(\cdot),T), \\ \overline{u}(x,0) = \overline{u}_0(x) & \text{in} \quad \mathbb{R}^+ \times \{0\}, \\ \overline{u}(s(t),t) = F_{J(T)}(\operatorname{ess\,sup} u_0). \end{cases}$$

Proof. Using Proposition B.1, Theorem B.2, Proposition 2.3, and Theorem 2.1 we easily obtain $\overline{u}(s(t),t) = u(s(t),t)$ for almost any t in $(0,T)$. ∎

4. Initial data of Class A. In this section we prove Theorem 2.2 for initial data u_0 in the Class A, as well as Theorem 2.3. Observe that by Theorem 2.1 any entropy solution of problem (FB) takes values in the interval $[a,b] \subset \mathcal{S}(c)$.

We first prove the uniqueness claim of Theorem 2.2, as well as stability and comparison results which imply plainly Theorem 2.3 (see subsection (a)). Then the existence part of Theorem 2.2 is proved by a suitable adaptation of the Godunov method (see subsection (b)).

(a) *Uniqueness and comparison results.*

PROPOSITION 4.1. *Let* (1.3) *hold; let* $u_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$ *belong to Class* A. *Then there is at most one entropy solution of problem* (FB).

Proof. Let (s_1,u_1), (s_2,u_2) be two entropy solutions of problem (FB). Let $\overline{s}(t) = \max\{s_1(t), s_2(t)\}$. Obviously $\overline{s}(t) \in Lip(0,T)$.

Consider the associate functions ${u_1}^{\overline{s}}$, ${u_2}^{\overline{s}}$ relative to u_1, u_2 with respect to the function $\overline{s}$ (see (3.2)). Then by Proposition B.1, functions ${u_1}^{\overline{s}}$, ${u_2}^{\overline{s}}$ are both entropy solutions of the problem

$$\begin{cases} u_t + f(u)_y - \overline{s}'(t)u_y = 0 & \text{in} \quad \Pi_T^+, \\ u(y,0) = u_0(y) & \text{in} \quad \mathbb{R}^+ \times \{0\}. \end{cases}$$

Now, using Theorem B.1, we have for almost any $t \in (0,T)$

$$\int_{\mathbb{R}^+} |{u_1}^{\overline{s}}(x,t) - {u_2}^{\overline{s}}(x,t)|\,dx \tag{4.1}$$

$$\leq \int_0^t sgn({u_1}^{\overline{s}}(0,\tau) - {u_2}^{\overline{s}}(0,\tau))(f({u_1}^{\overline{s}}(0,\tau))$$

$$- f({u_2}^{\overline{s}}(0,\tau)) - \overline{s}'(\tau)({u_1}^{\overline{s}}(0,\tau) - {u_2}^{\overline{s}}(0,\tau)))\,d\tau.$$

Let us show that the right-hand side in inequality (4.1) is negative.

For almost any $t \in (0,T)$ there is $i \in \{1,2\}$ such that $\overline{s}'(t) = \frac{f({u_i}^{\overline{s}}(0,t))}{{u_i}^{\overline{s}}(0,t)+c}$. Fix a t in the set in which the previous equality holds.

The integrand of the right-hand side of inequality (4.1) can be written

$$|{u_1}^{\overline{s}}(0,t) - {u_2}^{\overline{s}}(0,t)| \left(\frac{f({u_1}^{\overline{s}}(0,t)) - f({u_2}^{\overline{s}}(0,t))}{{u_1}^{\overline{s}}(0,t) - {u_2}^{\overline{s}}(0,t)} - \overline{s}'(t) \right). \tag{4.2}$$

Since ${u_1}^{\overline{s}}(0,t)$, ${u_2}^{\overline{s}}(0,t)$ lay in $\mathcal{S}(c)$, we have that (4.2) is negative by Proposition 3.1 (iv). Then ${u_1}^{\overline{s}}$ and ${u_2}^{\overline{s}}$ coincide. Therefore $u_1 \equiv u_2$ in $\Lambda(\overline{s}(t),T)$.

Hence $(\overline{s}, u_1(\equiv u_2))$ is another entropy solution of problem (FB).

Let us show that such a solution is equal to (s_i,u_i) $(i=1,2)$. To obtain this, it is enough to prove that $s_1 \equiv s_2 \equiv \overline{s}$. By Proposition 3.3 it is not restrictive to assume $u_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+) \cap L^1(\mathbb{R}^+)$.

Using conservation formula (B.6) in the cases $s(t) = s_i(t)$ and $s(t) = \overline{s}(t)$, we have

$$\int_{s_1(t)}^\infty u_1(x,t)\,dx = \int_{\mathbb{R}^+} u_0(x)\,dx + cs_1(t) - tf(0)$$

and

$$\int_{\overline{s}(t)}^\infty u_1(x,t)\,dt = \int_{\mathbb{R}^+} u_0(x)\,dx + c\overline{s}(t) - tf(0).$$

Subtracting the previous equalities, we obtain

$$\int_{s_1(t)}^{\infty} u_1(x,t)\,dx - \int_{\overline{s}(t)}^{\infty} u_1(x,t)\,dx = c(s_1(t) - \overline{s}(t)).$$

Hence

$$0 \geq c(s_1(t) - \overline{s}(t)) = \int_{s_1(t)}^{\overline{s}(t)} u_1(x,t)\,dx \geq 0,$$

which implies $\overline{s} \equiv s_1$. The same is true for $i = 2$ and so $s_2 \equiv s_1$ and $u_2 = u_1$. □

By using a similar argument we can prove the following stability result. Let us set, for any u_0, $v_0 \in BV_{loc}(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$,

$$M := \max(\|u_0\|_{L^\infty}, \|v_0\|_{L^\infty})$$

and

$$R_T := \left(\sup_{|u| \leq M} |f^{'}(u)| + \|s'\|_{L^\infty(0,T)} \right) T.$$

PROPOSITION 4.2. *Let* (1.3) *hold; let* u_0, $v_0 \in BV_{loc}(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$ *and belong to Class* A. *Let* (s_1, u), (s_2, v) *be solutions of problem* (FB) *with data* u_0, v_0, *respectively. Then*

$$\|s_1 - s_2\|_{L^\infty(0,T)} \leq \frac{2}{c} \|u_0 - v_0\|_{L^1((0,R_T))}.$$

Moreover, for any $C \in \mathbb{R}^+$ *we have for almost any* t

$$\int_{\overline{s}(t)}^{\overline{s}(t)+C} |u(x,t) - v(x,t)|\,dx \leq \|u_0 - v_0\|_{L^1((0,C+R_T))},$$

where $\overline{s}(t) = \max\{s_1(t), s_2(t)\}$.

Proof. Proceeding as in the proof of Proposition 4.1 and using Theorem B.1 we obtain

$$\int_{\overline{s}(t)}^{\overline{s}(t)+C} |u(x,t) - v(x,t)|\,dx \leq \|u_0 - v_0\|_{L^1((0,C+R))}.$$

Let $\overline{u}_0 \equiv \chi_{(0,R_T)} u_0$, $\overline{v}_0 \equiv \chi_{(0,R_T)} v_0$, where $\chi_{(0,R_T)}$ is the characteristic function of the interval $(0, R_T)$. Then by Proposition 3.3 we see that there exist $(s_1, \overline{u})$, $(s_2, \overline{v})$, respectively, solutions of the free boundary with initial data $\overline{u}_0$, $\overline{v}_0$, respectively.

Obviously for the functions $\overline{u}$, $\overline{v}$ the previous inequality is still true. Moreover we have the conservation equalities

$$\int_{s_1(t)}^{\infty} \overline{u}(x,t)\,dx = \int_{\mathbb{R}^+} \overline{u}_0(x)\,dx + cs_1(t) - tf(0),$$

$$\int_{s_2(t)}^{\infty} \overline{v}(x,t)\,dx = \int_{\mathbb{R}^+} \overline{v}_0(x)\,dx + cs_2(t) - tf(0).$$

Fix t and suppose, for example, that $s_1(t) > s_2(t)$. Subtracting the previous equalities we have

$$c(s_1(t) - s_2(t))$$

$$= \int_{s_1(t)}^{\infty} \overline{u}(x,t) - \overline{v}(x,t)\,dx - \int_{s_2(t)}^{s_1(t)} \overline{v}(x,t)\,dx$$

$$+ \int_{\mathbb{R}^+} \overline{v}_0(x) - \overline{u}_0(x)\,dx \le 2\|\overline{u}_0 - \overline{v}_0\|_{L^1(\mathbb{R}^+)} = 2\|u_0 - v_0\|_{L^1((0,R))}.$$

From the arbitrariness of t we obtain the assert. □

Finally, let us state a comparison result.

PROPOSITION 4.3. *Let* (1.3) *hold; let* $u_0, v_0 \in BV_{loc}(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$ *belong to Class* A *with* $u_0 \le v_0$ *a.e. Then* $s_1 \ge s_2$ *and* $u \le v$ *a.e. in* $\Lambda(s_1(t), T)$, *where* (s_1, u), (s_2, v) *are the solutions of the free boundary problem* (FB) *with data* u_0, v_0, *respectively.*

Proof. Let $\overline{s}(t) = \max\{s_1(t), s_2(t)\}$. As was shown previously we compare u and v in $\Lambda(\overline{s}(t), T)$.

Using inequality (B.4) and proceeding as in the proof of Proposition 2.3 we conclude that $u \le v$ a.e. in $\Lambda(\overline{s}(t), T)$.

It remains to prove that $s_1 \ge s_2$. As in the proof of Proposition 4.1 we can reduce ourselves to the case $u_0, v_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+) \cap L^1(\mathbb{R}^+)$.

Let $t \in (0, T)$ and suppose $s_2(t) > s_1(t)$. Considering the conservation equalities for u, v we have

$$c(s_2(t) - s_1(t)) + \int_{\mathbb{R}^+} v_0(x) - u_0(x)\,dx$$

$$= \int_{s_2(t)}^{\infty} v(x,t) - u(x,t)\,dx - \int_{s_1(t)}^{s_2(t)} u(x,t)\,dx \le \int_{\mathbb{R}^+} v_0(x) - u_0(x)\,dx.$$

Hence we conclude that $s_2(t) \le s_1(t)$, which is a contradiction. □

(b) *Existence.*

Let us introduce the following standard notations. Let V_n be the space of the functions which are constant on any interval of the type

$$\left[\frac{i}{n}, \frac{i+1}{n}\right) \qquad (i \in \mathbb{N}).$$

Define for any $n \in \mathbb{N}$

$$P_n : BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+) \to V_n,$$

$$P_n(u)(t) := n \int_{\frac{i}{n}}^{\frac{i+1}{n}} u(\tau)\,d\tau, \qquad t \in \left[\frac{i}{n}, \frac{i+1}{n}\right).$$

The following lemma gives some interesting properties of P_n (see [Le1], [Le2], [Te2]).

LEMMA 4.1. *For any* $n \in \mathbb{N}$, $u_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+) \cap L^1(\mathbb{R}^+)$, *the operator* P_n *has the following properties:*

(i) $\|P_n(u_0)\|_{L^\infty(\mathbb{R}^+)} \le \|u_0\|_{L^\infty(\mathbb{R}^+)}$;
(ii) $TV(P_n(u_0), \mathbb{R}^+) \le TV(u_0, \mathbb{R}^+)$;
(iii) $\|P_n(u_0)\|_{L^1(\mathbb{R}^+)} \le \|u_0\|_{L^1(\mathbb{R}^+)}$;
(iv) $\|P_n(u_0) - u_0\|_{L^1(\mathbb{R}^+)} \le \frac{1}{2n} TV(u_0, \mathbb{R}^+)$.

Let us prove the following proposition.

PROPOSITION 4.4. *Let* (1.3) *hold; let* $u_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$ *be initial data of Class* A. *Then there exists an entropy solution of problem* (FB).

Proof. It is not restrictive to assume $u_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+) \cap L^1(\mathbb{R}^+)$.

By Proposition 2.2 it is enough to look for an entropy solution of the problem

$$\text{(4.3)} \qquad \begin{cases} u_t + f(u)_x - \frac{f(u(0,t))}{u(0,t)+c} u_x = 0 & \text{in } \Pi_T^+, \\ u(0,t) \in \mathcal{S}(c) & \text{a.e.}, \\ u(x,0) = u_0(x) & \text{in } \mathbb{R}^+ \times \{0\}. \end{cases}$$

Namely, we search $u \in BV(\Pi_T^+) \cap L^\infty(\Pi_T^+)$ such that for any $\phi \in C_0^1((0,\infty) \times (0,T))$, $\phi \geq 0$, for any $k \in \mathbb{R}$,

$$\text{(4.4)} \qquad \int_{\Pi_T^+} |u-k|\phi_t + sgn(u-k)(f(u)-f(k))\phi_x - |u-k|\frac{f(u(0,t))}{u(0,t)+c}\phi_x \, dtdx \geq 0;$$

$$\operatorname{ess\,lim}_{t\to 0} \int_I |u(x,t) - u_0(x)| \, dx = 0.$$

Let us consider the following scheme.

Let $u_{0n} = P_n u_0$. Let

$$l := \sup_{p\in\mathbb{R}^+} |f'(p)| + \sup_{p\in\mathbb{R}^+} \left|\frac{f(p)}{p+c}\right|;$$

$$r := \frac{1}{2l}, \ \Delta t = \frac{r}{n};$$

we denote with u_i^0 the constant value of the function $P_n(u_0)$ on the interval $(\frac{i}{n}, \frac{i+1}{n})$.

Let us solve the following problem until time $t_1 = \Delta t$:

$$\begin{cases} u_t + f(u)_x - \frac{f(u_0^0)}{u_0^0+c} u_x = 0 & \text{in } \mathbb{R}^+ \times (0,t_1), \\ u(x,0) = P_n u_0 & \text{in } \mathbb{R}^+ \times \{0\}, \\ u(0,t) = u_0^0 & \text{in } \{0\} \times (0,t_1). \end{cases}$$

Denote the solution of such problems with u_{1n}. For the given choice of t_1, we observe that the solution is obtained by solving Riemann problems between the constant values. Such problems are not interacting within the definition of Δt.

At time t_1 we consider a new boundary value problem with initial data $P_n(u_{1n}(x,t_1))$. More precisely we consider the following problem:

$$\begin{cases} u_t + f(u)_x - \frac{f(u_0^1)}{u_0^1+c} u_x = 0 & \text{in } \mathbb{R}^+ \times (t_1,t_2), \\ u(x,0) = P_n(u_{1n}(x,t_1)) & \text{in } \mathbb{R}^+ \times \{t_1\}, \\ u(0,t) = u_0^1 & \text{in } \{0\} \times (t_1,t_2), \end{cases}$$

where u_0^1 is the value of $P_n(u_{1n}(x,t_1))$ in the interval $(0, \frac{1}{n})$ and $t_2 = 2t_1$. We call the solution of such problem u_{2n}.

By induction we can define a function u_n until time T.

Set

$$u_i^j := P_n(u_{(j-1)n}(\cdot, t_j)) \qquad \text{in the interval } \left(\frac{i}{n}, \frac{i+1}{n}\right).$$

Moreover we denote with $u^j_{i+\frac{1}{2}}$ the constant value of u_{jn} in the points $(\frac{i+1}{n}, t)$ (the dependence on n is understood in the previous notations).

Finally define

$$u_{n|_{\mathbb{R}^+\times(t_j,t_{j+1})}} := u_{jn}, \qquad j = 0, 1, \dots.$$

We obtain the proof in three steps:

(i) there exists a subsequence of $\{u_n\}$, still denoted by $\{u_n\}$, converging in the L^1 norm to a function $u \in BV(\Pi^+_T) \cap C([0,T], L^1_{loc}(\mathbb{R}^+)) \cap L^\infty(\Pi^+_T)$;

(ii) $u_n(0,\cdot) \in BV(0,T)$, with $\|u_n(0,\cdot)\|_{BV(0,T)} \le C$, where C is a constant independent of n;

(iii) the function u is an entropy solution of the free boundary problem (FB).

To prove (i), let us consider the total variation of $u_{jn}(\cdot, t_j)$,

$$TV(u_{jn}(\cdot,t_j), \mathbb{R}^+) = \sum_{i=0}^{\infty} |u^j_{i+1} - u^j_i|.$$

Since the function $u_{(j-1)n}$ is given by solving the Riemann problem we have the following estimate by standard results on the Godunov scheme (see [Le1], [Te2]):

$$\sum_{i=0}^{\infty} |u^j_{i+1} - u^j_i| \le \sum_{i=0}^{\infty} |u^{j-1}_{i+1} - u^{j-1}_i| \le TV(u_0)$$

for any j.

Then, for any t in $(0,T)$, there exists j such that $t_j \le t \le t_{j+1}$ and

$$TV(u_n(\cdot,t)) = TV(u_{jn}(\cdot,t)) \le TV(u_{jn}(\cdot,t_j)) \le TV(u_0) \tag{4.5}$$

obtaining an estimate independent of n.

In the same way we can prove the following estimate:

$$\sum_{i=0}^{\infty} |u^{j+1}_i - u^j_i| \le \sum_{i=0}^{\infty} |u^j_{i+1} - u^j_i| \le TV(u_0). \tag{4.6}$$

Let t, $s \in (0,T)$. Let us estimate $\|u_n(\cdot,t) - u_n(\cdot,s)\|_{L^1(\mathbb{R}^+)}$.

Suppose $t \in (t_j, t_{j+1})$, $s \in (t_l, t_{l+1})$, $l > j$. Then by (4.6)

$$\begin{aligned}
\|u_n(\cdot,t) - u_n(\cdot,s)\|_{L^1(\mathbb{R}^+)} &\le \|u_n(\cdot,t) - u_n(\cdot,t_{j+1})\|_{L^1(\mathbb{R}^+)} \\
&+ \sum_{k=j+1}^{l-1} \|u_n(\cdot,t_{k+1}) - u_n(\cdot,t_k)\|_{L^1(\mathbb{R}^+)} + \|u_n(\cdot,t_l) - u_n(\cdot,s)\|_{L^1(\mathbb{R}^+)} \\
&\le \|u_n(\cdot,t) - u_{jn}(\cdot,t_{j+1})\|_{L^1(\mathbb{R}^+)} + \|u_{jn}(\cdot,t_{j+1}) - u_n(\cdot,t_{j+1})\|_{L^1(\mathbb{R}^+)} \\
&+ \sum_{k=j+1}^{l-1} \sum_{i=0}^{\infty} \int_{\frac{i}{n}}^{\frac{i+1}{n}} |u^k_i - u^{k+1}_i|\, dx + \|u_n(\cdot,t_l) - u_n(\cdot,s)\|_{L^1(\mathbb{R}^+)} \\
&\le \|u_n(\cdot,t) - u_{jn}(\cdot,t_{j+1})\|_{L^1(\mathbb{R}^+)} + \frac{1}{2n} TV(u_0) \\
&+ \frac{(l-j-1)r}{rn} TV(u_0) + \|u_n(\cdot,t_l) - u_n(\cdot,s)\|_{L^1(\mathbb{R}^+)}.
\end{aligned}$$

Since u_{jn}, u_{ln} are piecewise smooth solutions, respectively, of the conservation laws

$$u_t + f(u)_x - \frac{f(u_0^j)}{u_0^j + c} = 0 \quad \text{in} \quad \mathbb{R}^+ \times (t_j, t_{j+1}),$$
$$u_t + f(u)_x - \frac{f(u_0^l)}{u_0^l + c} = 0 \quad \text{in} \quad \mathbb{R}^+ \times (t_l, t_{l+1}),$$

we see that the first and the fourth addendum in the last term of the previous inequality can be estimated by $\frac{(t_{j+1}-t)}{r} TV(u_0)$, respectively, $\frac{(s-t_l)}{r} TV(u_0)$ (see [Le2]). Therefore we have

$$\begin{aligned} &\|u_n(\cdot,t) - u_n(\cdot,s)\|_{L^1(\mathbb{R}^+)} \\ &\le \frac{(t_{j+1}-t)}{r} TV(u_0) + \frac{(s-t_l)}{r} TV(u_0) + \frac{(l-j-1)r}{rn} TV(u_0) + \frac{1}{2n} TV(u_0) \\ &= \frac{TV(u_0)}{r} \left(t_{j+1} - t + s - t_l + (l-j-1)\frac{r}{n} \right) TV(u_0) + \frac{1}{2n} TV(u_0) \\ &= (s-t)\frac{TV(u_0)}{r} + \frac{1}{2n} TV(u_0). \end{aligned} \tag{4.7}$$

The estimates (4.5)–(4.7) ensure us that step (i) holds. Moreover by the previous estimates we see that $u_n \in BV(\Pi_T^+)$ for any n. Observe that it is not restrictive to suppose that the sequence converges a.e. in Π_T^+ to u.

Let us consider assertion (ii). Fix n and consider $u_n(0,\cdot)$; then

$$TV(u_n(0,\cdot)) = \sum_{i=1}^{k(n)} |u_0^i - u_0^{i-1}|,$$

where $k(n)$ is the last step to reach T.

Let us prove the following estimate. For every l, $s \in \mathbb{N}$

$$\sum_{k=1}^{s} |u_k^l - u_{k-1}^l| + |u_0^l - u_0^{l-1}| \le \sum_{k=1}^{s+1} |u_k^{l-1} - u_{k-1}^{l-1}|. \tag{4.8}$$

Consider the following Cauchy problem:

$$\begin{cases} u_t + f(u)_x - \frac{f(u_0^{l-1})}{u_0^{l-1}+c} u_x = 0 \qquad \text{in} \quad \mathbb{R}^+ \times (t_{l-1}, t_l), \\ u(x, t_{l-1}) = \begin{cases} u_0^{l-1}, & x \le 0, \\ u_n(x, t_{l-1}), & x > 0, \end{cases} \qquad \text{in} \quad \mathbb{R} \times \{t_{l-1}\}. \end{cases}$$

We know that

$$TV(u(\cdot, t_{l-1}, \mathbb{R})) = \sum_{k=1}^{\infty} |u_k^{l-1} - u_{k-1}^{l-1}|;$$

moreover, by standard arguments (see, for instance, [Df]), we have

$$TV\left(u(\cdot,t_l),\, \left(-\infty, \frac{s}{n}\right)\right) \le TV\left(u(\cdot,t_{l-1}),\, \left(-\infty, \frac{s+1}{n}\right)\right).$$

Let us observe that $u(\cdot,t_l) = u_0^{l-1}$ when $x < 0$.

Moreover

$$\sum_{k=1}^{s} |u_k^l - u_{k-1}^l| + |u_0^l - u_0^{l-1}|$$

$$= TV\left(P_n(u(\cdot,t_l)),\left(-\infty,\frac{s}{n}\right)\right) \le TV\left(u(\cdot,t_l),\left(-\infty,\frac{s}{n}\right)\right)$$

$$\le TV\left(u(\cdot,t_{l-1}),\left(-\infty,\frac{s+1}{n}\right)\right) = \sum_{k=1}^{s+1} |u_k^{l-1} - u_{k-1}^{l-1}|$$

and then inequality (4.8) holds.

Let us show now that for any $s \in \mathbb{N},\ 0 \le s \le k(n)$,

$$\sum_{k=k(n)-s}^{k(n)} |u_0^k - u_0^{k-1}| \le \sum_{m=1}^{s+1} |u_m^{k(n)-s-1} - u_{m-1}^{k(n)-s-1}|. \tag{4.9}$$

We prove inequality (4.9) by induction.

By the explicit solution of Riemann problem we have

$$|u_0^{k(n)} - u_0^{k(n)-1}| \le |u_0^{k(n)-1} - u_1^{k(n)-1}|,$$

which corresponds to the case $s = 0$. Suppose that inequality (4.9) is true for $s-1$; then we have

$$\sum_{k(n)-s}^{k(n)} |u_0^k - u_0^{k-1}| = \sum_{k(n)-s+1}^{k(n)} |u_0^k - u_0^{k-1}| + |u_0^{k(n)-s} - u_0^{k(n)-s-1}|$$

$$\le \sum_{m=1}^{s} |u_m^{k(n)-s} - u_{m-1}^{k(n)-s}| + |u_0^{k(n)-s} - u_0^{k(n)-s-1}|.$$

Now applying inequality (4.8) with $l = k(n) - s$, we see that

$$\sum_{k(n)-s}^{k(n)} |u_0^k - u_0^{k-1}| \le \sum_{m=1}^{s+1} |u_m^{k(n)-s-1} - u_{m-1}^{k(n)-s-1}|$$

and (4.9) holds.

Putting $s = k(n) - 1$ in (4.9) we obtain

$$\sum_{k=1}^{k(n)} |u_0^k - u_0^{k-1}| \le \sum_{m=1}^{k(n)} |u_m^0 - u_{m-1}^0| \le TV(u_0).$$

Since we estimate $TV(u_n(0,\cdot),(0,T))$ independently on n, we see that there exists a subsequence that converges in L^1 norm and a.e. to a function $w \in L^1((0,T)) \cap L^\infty((0,T))$ and $w(t) \in \mathcal{S}(c)$ for almost any t.

Let us consider step (iii). We have to prove that u verifies (4.4) for any nonnegative $\phi \in C_0^1((0,\infty)\times(0,T))$ and any $k \in \mathbb{R}$.

For any n, j, $\phi \in C_0^1([0,\infty)\times(0,T))$ we obtain

$$\int_{\mathbb{R}^+}\int_{t_j}^{t_{j+1}} |u_{jn}-k|\phi_t + sgn(u_{jn}-k)(f(u_{jn})-f(k))\phi_x - \frac{f(u_0^j)}{u_0^j+c}|u_{jn}-k|\phi_x\,dtdx$$

$$+\int_{t_j}^{t_{j+1}}\left(sgn(u_0^j-k)(f(u_0^j)-f(k)) - \frac{f(u_0^j)}{u_0^j+c}|u_0^j-k|\right)\phi(0,t)\,dt$$

$$\geq \int_{\mathbb{R}^+} |u_{jn}(x,t_{j+1})-k|\phi(x,t_{j+1}) - |u_{jn}(x,t_j)-k|\phi(x,t_j)\,dx.$$

Then summing on j

$$\int_{\Pi_T^+} |u_n-k|\phi_t + sgn(u_n-k)(f(u_n)-f(k))\phi_x - \frac{f(u_n(0,\cdot))}{u_n(0,\cdot)+c}|u_n-k|\phi_x\,dtdx$$

$$+\int_0^T\left(sgn(u_n(0,\cdot)-k)(f(u_n(0,\cdot))-f(k)) - \frac{f(u_n(0,\cdot))}{u_n(0,\cdot)+c}|u_n(0,\cdot)-k|\right)\phi(0,t)\,dt$$

$$\geq \sum_{j=1}^{k(n)}\int_{\mathbb{R}^+}(|u_{(j-1)n}(x,t_j)-k| - |P_n(u_{(j-1)n})(x,t_j)-k|)\phi(x,t_j)\,dx. \tag{4.10}$$

Consider inequality (4.10) for the converging subsequence given in (i), (ii) and take the limit. Then the first member of the inequality (4.10) tends to

$$\int_{\Pi_T^+} |u-k|\phi_t + sgn(u-k)(f(u)-f(k))\phi_x - \frac{f(w)}{w+c}|u-k|\phi_x\,dtdx \tag{4.11}$$

$$+\int_0^T sgn(w-k)(f(w)-f(k))\phi_x - \frac{f(w)}{w+c}|w-k|\phi\,dt.$$

Moreover (see, for example, [Le2], [Te2]) we see that

$$\limsup_{n\to\infty}\sum_{j=1}^{k(n)}\int_{\mathbb{R}^+}(|u_{(j-1)n}(x,t_j)-k| - |P_n(u_{(j-1)n})(x,t_j)-k|)\phi(x,t_j)\,dx \geq 0.$$

Therefore the expression (4.11) is positive. To conclude the proof, we have to prove that $u(0,t) = w(t)$ for almost every $t \in (0,T)$. Using a suitable test function we obtain

$$sgn(w(t)-k)(f(w(t))-f(k)) - \frac{f(w(t))}{w(t)+c}|w(t)-k|$$

$$\geq sgn(u(0,t)-k)(f(u(0,t))-f(k)) - \frac{f(w(t))}{w(t)+c}|u(0,t)-k| \qquad \text{for almost every } t.$$

Choosing $k > \max\{u(0,t), w(t)\}$ we have

$$f(u(0,t)) - f(w(t)) \geq \frac{f(w(t))}{w(t)+c}(u(0,t)-w(t)),$$

whereas $k < \min\{u(0,t), w(t)\}$ gives

$$f(u(0,t)) - f(w(t)) \le \frac{f(w(t))}{w(t)+c}(u(0,t) - w(t)).$$

Thus we conclude $\frac{f(w(t))}{w(t)+c} = \frac{f(u(0,t))}{u(0,t)+c}$, since w and u are in $\mathcal{S}(c)$ this implies $w(t) = u(0,t)$ for almost any t. □

Observe that the uniqueness result in Proposition 4.1 ensures that all the sequence $\{u_n\}$, constructed in the previous proof, converges to the solution u.

5. Initial data of Class B. In this section we prove Theorem 2.2 for initial data of Class B. Due to Theorem 2.1, any solution of problem (FB) now takes values in the interval $[q, F_c(p)]$.

PROPOSITION 5.1. *Let* (1.3) *hold; let* u_0 *be of Class* B. *Then there exists a unique entropy solution of problem* (FB) *with the free boundary given by* $s(t) = \frac{f(p)}{p+c}t$.

Proof. Since $u(s(t),t) \in \{p,q\} \cap \mathcal{S}(c)$, we have $s'(t) = \frac{f(p)}{p+c}$ $(= \frac{f(q)}{q+c}$ if $q \in \mathcal{S}(c))$.

Let $\overline{u}$ be the entropy solution of the following free boundary problem:

$$\begin{cases} \overline{u}_t + f(\overline{u})_x - \dfrac{f(p)}{p+c}\overline{u}_x = 0 & \text{in} \quad \Pi_T^+, \\ \overline{u}(x,0) = u_0(x) & \text{in} \quad \mathbb{R}^+ \times \{0\}, \\ \overline{u}(0,t) = p & \text{in} \quad \{0\} \times (0,T). \end{cases}$$

Let us prove that the function $u = \overline{u}(x - s(t), t)$ is an entropy solution of the free boundary problem (FB). This follows by proving that for almost every $t \in ((0,T))$ $\overline{u}(0,t) \in \{q, p\}$ when $q \in \mathcal{S}(c)$ and $\overline{u}(0,t) = p$ when $q \notin \mathcal{S}(c)$.

For the compatibility condition along the boundary we have for almost every $t \in (0,T)$

$$\frac{f(\overline{u}(0,t)) - f(k)}{\overline{u}(0,t) - k} \le \frac{f(p)}{p+c} \qquad \text{for every } k \in (\overline{u}(0,t), p].$$

If $q \in \mathcal{S}(c)$ and $\overline{u}(0,t) = q$ the previous inequality holds. Otherwise, reasoning as in the proof of Proposition 4.2 we obtain $\overline{u}(0,t) = p$. When $q \notin \mathcal{S}(c)$ we necessarily have $\overline{u}(0,t) = p$.

We prove uniqueness using the estimate (4.1). In such a case the free boundary is a priori known. Consider two solutions (s, u_1) and (s, u_2). Let u_1^s, u_2^s be the associate functions (see (3.2)) defined in Π_T^+. We obtain

$$\int_{\mathbb{R}^+} |u_1^s(x,t) - u_2^s(x,t)|\, dx$$

$$\le \int_0^t sgn(u_1^s(0,\tau) - {u_2}^s(0,\tau))(f(u_1^s(0,\tau)) - f(u_2^s(0,\tau)) - s'(\tau)(u_1^s(0,\tau) - u_2^s(0,\tau)))\, d\tau$$

$$= 0.$$

Since for almost every $t \in (0,T)$, we have

$$\frac{f(u_1^s(0,t))}{u_1^s(0,t)+c} = \frac{f(u_2^s(0,t))}{u_2^s(0,t)+c} = s'(t). \qquad \square$$

6. Initial data of Class C. In this last section we prove Theorem 2.2 for initial data in Class C, using the results of sections 4 and 5 and the finite speed of propagation of the characteristics.

PROPOSITION 6.1. *Let* (1.3) *hold; let* $u_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$ *be of Class* C. *Then for any entropy solution* u *of the free boundary problem* (FB), $u(\cdot, t)$ *is in the Class* C *for any* t *in* $(0,T)$.

Proof. This can be shown by observing that any entropy solution of the free boundary problem (FB) is the solution of an opportune mixed value problem (Theorem 2.1) that can be thought in Π_T^+ by Proposition B.1. Then using a Godunov-type approximation method for mixed value problems (as in the proof of Proposition 4.4), we can approximate the solution u of the problem in the $C([0,T], L^1_{loc}(\mathbb{R}^+))$ norm by functions having a bounded number of oscillations for any fixed t (solving Riemann problem the number of oscillations do not increase). Therefore the solution u has, for any fixed t, a finite number of oscillations outside a set of null measure. □

LEMMA 6.1. *Let* v *be a function from* $\mathbb{R}^+$ *to* $\mathbb{R}^+$ *belonging to Class* C. *Let* $\{I_k\}$, $\{k = 0, \dots, n\}$, *some intervals of* $\mathbb{R}^+$ *such that* $I_j \neq I_l$ *when* $j \neq l$, *and* $\mathbb{R}^+ = \bigcup_{k=0}^n I_k$. *Then there exists* $k \in \{0, \dots, n\}$ *and* $\epsilon > 0$ *such that* $v((0,\epsilon)) \subset I_k$ *for almost any* $x \in (0,\epsilon)$.

Proof. Consider the interval $[0,1)$. There exists k_1 such that $\mu\{x \in [0,1) : v(x) \in I_{k_1}\} > 0$, where μ is the Lebesgue measure; hence there exists j_1 such that

$$\mu(\{x \in [2^{-j_1}, 1) : v(x) \in I_{k_1}\}) > 0.$$

If

$$\mu\left(\left\{x \in [0, 2^{-j_1}) : v(x) \in \bigcup_{l \neq k_1} I_l\right\}\right) = 0$$

the claim is proved; otherwise there exists $k_2 \neq k_1$ such that

$$\mu(\{x \in [0, 2^{-j_1}) : v(x) \in I_{k_2}\}) > 0,$$

and analogously we can find j_2 such that

$$\mu(\{x \in [2^{-j_2}, 2^{-j_1}) : v(x) \in I_{k_2}\}) > 0.$$

Suppose that the claim is false. Then proceeding as above, we can construct a sequence of integers $\{j_s\}$, $j_s < j_{s+1}$ and a sequence of sets $\{I_{k_s}\}$, $k_s \neq k_{s+1}$ such that

$$\mu(\{x \in [2^{-j_s}, 2^{-j_{s-1}}) : v(x) \in I_{k_s}\}) > 0.$$

Since the interval I_k are only $n+1$, this implies that v does not belong to the Class C, hence the contradiction. □

PROPOSITION 6.2. *Let* $u_0 \in L^\infty(\mathbb{R}^+) \cap BV(\mathbb{R}^+)$ *be an initial data in Class* C. *Then there exists at most one entropy solution of problem* (FB).

Proof. Suppose there exists two entropy solutions (u_1, s_1), (u_2, s_2). Let

$$t_1 = \sup\{t \in [0,T) : s_1 \equiv s_2 \text{ in } (0,t)\}.$$

Let us show that $t_1 = T$. Suppose that $t_1 < T$; we see that $u_1(\cdot, t_1) = u_2(\cdot, t_1)$, and there exists a finite number of points n, $0 = p_0 \leq p_1 < p_2 < \cdots < p_n = +\infty$ such

that $S(c) = \cup_{i=1}^{n}[p_{2i}, p_{2i+1}]$ (Proposition 3.1 (iii) and Proposition 3.2 (iii)). From Proposition 6.1 the function $u_1(\cdot, t_1)$ is in Class C. Therefore, from Lemma 6.1 there exists $i \in \{0, \dots, n-1\}$ and $\epsilon > 0$ such that

$$u_1(\cdot, t_1) \in (p_i, p_{i+1}] \quad \text{a.e. in } (s_1(t_1), s_1(t_1) + \epsilon).$$

In this way, near the boundary we are either in the situation of Proposition 4.1 or in that of Proposition 5.1.

Let us change $u_1(\cdot, t_1)$ outside the interval $(s_1(t_1), s_1(t_1) + \epsilon)$ in such a way that the function takes values in the interval $(p_i, p_{i+1}]$ and preserves its regularity. Let us call this function $\tilde{u}_1(\cdot, t_1)$.

To simplify the notations we assume that $t_1 = 0$.

Let

$$M = \sup_{p \in \mathbb{R}^+} |f'(p)|,$$

where M is an upper bound for the speed of the characteristics. Let

$$C_i := \Lambda(s_i(t), T) \cap \{(x, t) \in \Pi_T^+ \,:\, x - s_i(t) < \epsilon - Mt\}, \qquad i = 1, 2.$$

We see that $u_1 \equiv u_2$ in $C_1 \cap C_2$. In fact, let v be the solution of the following mixed value problem:

$$\begin{cases} v_t + f(v)_x = 0 & \text{in } \Lambda(s_1(t), T), \\ v(x, 0) = \tilde{u}_1(x, 0) & \text{in } \mathbb{R}^+ \times \{0\}, \\ v(s_1(t), t) = u_1(s_1(t), t). \end{cases}$$

From the finite speed of propagation of characteristics $u_1 \equiv v$ in C_1. Then the function v is a solution of the free boundary problem.

On the other hand, let w be the solution of the problem

$$\begin{cases} w_t + f(w)_x = 0 & \text{in } \Lambda(s_2(t), T), \\ w(x, 0) = \tilde{u}_1(x, 0) & \text{in } \mathbb{R}^+ \times \{0\}, \\ w(s_2(t), t) = u_2(s_2(t), t). \end{cases}$$

In the same way we see that $w \equiv u_2$ in C_2. Therefore w is an entropy solution of the free boundary problem. Hence, from Propositions 4.1 and 5.1 we have $(v, s_1) \equiv (w, s_2)$. Then $u_1 \equiv u_2$ in $C_1 \cap C_2$ and there exists a positive δ such that $s_1 \equiv s_2$ in $(0, \delta)$. This is a contradiction with the definition of t_1. □

PROPOSITION 6.3. *Let $u_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$ be an initial data in Class* C. *Then there exists an entropy solution of the free boundary problem* (FB) *in $\mathbb{R}^+ \times \mathbb{R}^+$.*

Proof. Since u_0 is in Class C, we can construct a local entropy solution of problem (FB). In fact, as in the proof of Proposition 6.2 there exists an $\epsilon > 0$ such that for almost any $x \in (0, \epsilon)$, $u_0(x) \in (p_i, p_{i+1}]$ using the existence theorem of the previous sections and the finite propagation of characteristics, we obtain that there exists the entropy solution of the free boundary problem until a time $\bar{t} > 0$.

Let

$$T := \sup\{t \in \mathbb{R}^+ : \text{ there exists a solution of the free boundary problem in } \Pi_t^+\}.$$

Then $T > 0$. Assume $T < \infty$, and define a solution $\overline{u}$ in Π_T^+ such that $\overline{u}(\cdot, t) = u(\cdot, t)$, where for every $t < T$ function u is a solution of the free boundary problem in $\Pi_{t+\delta}^+$ $(t + \delta < T)$.

This function is well defined for the uniqueness result and is a solution of the free boundary problem (FB). Therefore $\overline{u}$ verifies for time T the condition of the Case C. Then $T = +\infty$ by standard continuation arguments.

Proof of Theorem 2.2. The proof follows by Propositions 4.1–4.4, Proposition 5.1, and Propositions 6.2–6.3.

Appendix A. As we said in section 1, the present study is motivated by a model introduced in [Ro] (see also [Fr]). In this appendix we introduce briefly the model for convenience to the reader.

Consider a homogeneous material exposed to ion beams (this procedure is called *ion etching*). Denote by $y = y(x,t)$ the surface of the material at time t. This function satisfies the following Hamilton–Jacobi equation:

$$y_t = -f(y_x)\,, \tag{A.1}$$

where the function f—referred to as *sputtering function*—depends in general on the material.

It is interesting for the applications to study the situation when different materials with different "sputtering functions" are masked together. For example, in the construction of semiconductor devices the technique of ion etching is used to shape the material in a proper way. To this aim, the semiconductor material is masked with photoresistant materials.

In [Ro] the problem of two materials with surface equation, respectively, y_1, y_2, was considered (see Figure 1). Such materials are separated by an interface which is given by a function $g(x)$. Using the continuity condition along the interface we have

$$y_1(s(t),t) = g(s(t)) = y_2(s(t),t), \tag{A.2}$$

where the function $s(t)$ denotes the separation point of the materials at time t.

Let f^1 (respectively, f^2) be the sputtering functions of the materials with surface equation $y_1(x,t)$ (respectively, $y_2(x,t)$). Let $p_1 = y_{1x}$, $p_2 = y_{2x}$, $s(0) = 0$. Deriving the Hamilton–Jacobi equation (A.1) for each material the problem can be written as follows:

$$\begin{cases} p_{2t} + f^2(p_2)_x = 0 & \text{in } \Lambda(s(\cdot),T), \\ p_{1t} + f^1(p_1)_x = 0 & \text{in } \mathbb{R}\times(0,T)\setminus\Lambda(s(\cdot),T), \\ \dfrac{f^1(p_1(s(t),t))}{p_1(s(t),t) - g'(s(t))} = s'(t) = \dfrac{f^2(p_2(s(t),t))}{p_2(s(t),t) - g'(s(t))}, & \\ p_1(x,0) = p_1^0(x) & \text{in } \mathbb{R}^-\times\{0\}, \\ p_2(x,0) = p_2^0(x) & \text{in } \mathbb{R}^+\times\{0\}, \\ s(0) = 0. & \end{cases} \tag{A.3}$$

Observe that the interface condition is obtained by deriving (A.2).

Problem (A.3) is a free boundary problem in which the unknowns are the functions s, p_1, p_2.

Let us point out that problem (A.3) is a generalization of a Cauchy problem ($g' = \infty$, $s(t) \equiv 0$)

$$\begin{cases} u_t + F(u,x)_x = 0 & \text{in } \mathbb{R}\times\mathbb{R}, \\ u(x,0) = u_0(x), & \end{cases}$$

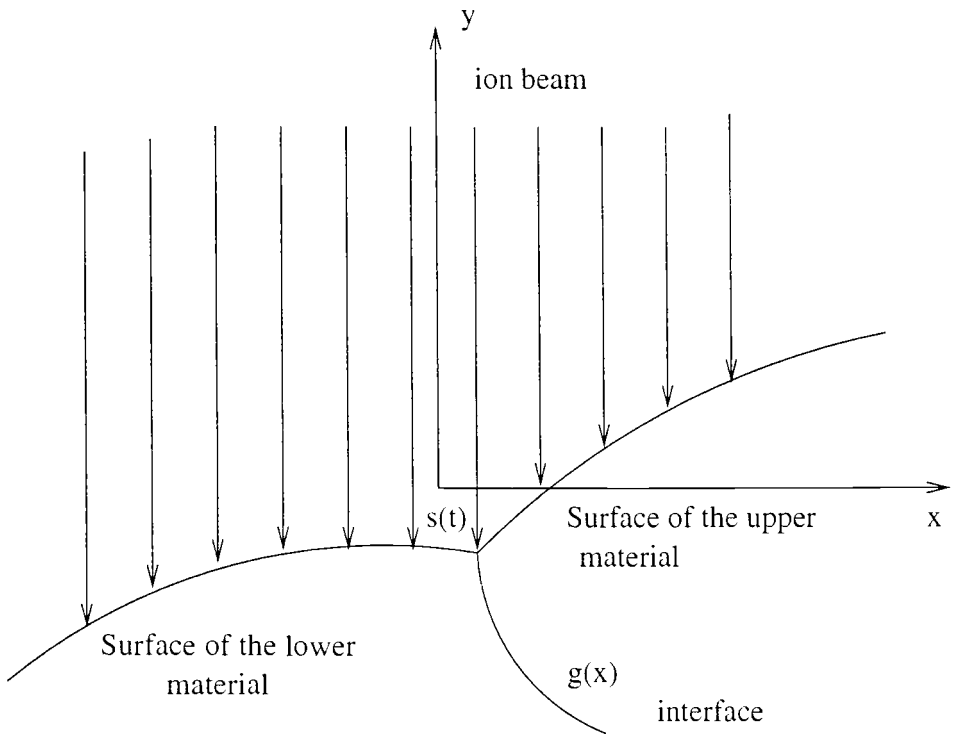

FIG. 1.

where

$$F(u,x) = \begin{cases} f^1(u) & \text{per } x < 0, \\ f^2(u) & \text{per } x \geq 0. \end{cases}$$

This problem arises in several applications: in continuous sedimentation of solid particles in a liquid [GR], [DW], [Ca], in two phase flow in porous media [GHR], and in traffic flow analysis [Mo].

To simplify the free boundary problem (A.3) we suppose that the second material lays over the first material (i.e., $g'(x) < 0$). In this way, following [Ro], by physical considerations, we expect that the evolution of the boundary is affected only by the second material.

Therefore, we can divide problem (A.3) into two separate problems. In the first one, we look for s, p_2 such that

$$\text{(A.4)} \qquad \begin{cases} p_{2t} + f^2(p_2)_x = 0 & \text{in } \Lambda(s(\cdot), T), \\ \dfrac{f^2(p_2(s(t),t))}{p_2(s(t),t) - g'(s(t))} = s'(t), & \\ p_2(x,0) = p_2^0(x) & \text{in } \mathbb{R}^+ \times \{0\}. \end{cases}$$

In the second one we search for p_1 such that

$$\text{(A.5)}\qquad \begin{cases} p_{1t} + f^1(p_1)_x = 0 & \text{in } \mathbb{R}\times(0,T)\setminus\Lambda(s(\cdot),T),\\ \dfrac{f^1(p_1(s(t),t))}{p_1(s(t),t)-g'(s(t))} = s'(t), & \\ p_1(x,0) = p_1^0(x) & \text{in } \mathbb{R}^-\times\{0\}. \end{cases}$$

Observe that problem (A.4) is the free boundary problem (FB), while problem (A.5) is a moving boundary problem. The latter can be easily solved using the existing theory of initial-boundary value problems for scalar conservation laws, when the interface $s(t)$ is known solving the previous problem (see [BLN], [Te1], [Te2]).

Appendix B. In this appendix we collect some results concerning entropy solutions of initial-boundary value problems for conservation laws in noncylindrical domains. We refer the reader to [Te1] for a more complete discussion of this topic.

We denote by $u(s(t),t)$ the trace of the BV function u along the (smooth) curve $s = s(t)$.

DEFINITION B.1. *Let $s \in Lip(0,T)$, $s(0) = 0$. Let $u_0 \in BV_{loc}(\mathbb{R}^+)\cap L^\infty(\mathbb{R}^+)$, $a_0 \in BV((0,T))$. We say that $u \in BV_{loc}(\Lambda(s(\cdot),T))\cap L^\infty(\Lambda(s(\cdot),T))$ is an entropy solution of the problem*

$$\text{(B.1)}\qquad \begin{cases} u_t + f(u)_x = 0 & in \quad \Lambda(s(\cdot),T),\\ u(x,0) = u_0(x) & in \quad \mathbb{R}^+\times\{0\},\\ u(s(t),t) = a_0(t) & in \quad (0,T), \end{cases}$$

if (i) *for any $\phi \in C_0^1(\Lambda(s(\cdot),T))$, $\phi \geq 0$, and any $k \in \mathbb{R}$*

$$\int_{\Lambda(s(\cdot),T)} |u-k|\phi_t + sgn(u-k)(f(u)-f(k))\phi_x\,dxdt + \int_{\mathbb{R}^+} |u_0-k|\phi(x,0)\,dx \geq 0\,;$$

(ii) *for almost every $t \in (0,T)$ the trace $u(s(t),t)$ verifies*

$$\frac{f(u)-f(k)}{u-k} \leq s' \qquad k \in [\min\{a_0(t),u\},\max\{a_0(t),u\}]\setminus\{u\}\,.$$

According to the above definition, the boundary condition in problem (A.1) is not assumed in the strong sense—instead, it is only a *compatibility condition* for the valued assumed by the solution on the boundary. More precisely, condition (ii) in the previous definition means that the admissible discontinuities between the boundary value and the trace of the solution are those for which the characteristics of the discontinuity point outwards.

It is worth noting that we can reduce ourselves to an initial-boundary problem in a cylindric domain by a suitable change of coordinates. We associate with any given function $s \in Lip(0,T)$ and $u \in BV(\Lambda(s(\cdot),T))\cap L^\infty(\Lambda(s(\cdot),T))$, the function

$$\text{(B.2)}\qquad u^s(x,t) = u(x+s(t),t)$$

defined in $\Pi_T^+ = \mathbb{R}^+\times(0,T)$.

PROPOSITION B.1. *The function u is an entropy solution of problem* (B.1) *if and only if the associate function $u^s(y,t) = u(y + s(t), t)$ is an entropy solution of the problem*

$$\text{(B.3)} \qquad \begin{cases} u^s_t + f(u^s)_y - s'(t)u^s_y = 0 & \text{in} \quad \Pi^+_T, \\ u^s(y,0) = u_0(y) & \text{in} \quad \mathbb{R}^+ \times \{0\}, \\ u^s(0,t) = a_0(t) & \text{in} \quad \{0\} \times (0,T). \end{cases}$$

This equivalence follows easily by changing the x coordinate in the integral formulation of the problem (B.1) and by observing that it is not restrictive to use Lipschitz continuous functions vanishing at the boundary instead of C^1_0 functions.

We refer the reader to [BLN] for existence and uniqueness results concerning initial-boundary problems.

Let us mention the following comparison result that is used in the paper.

THEOREM B.1. *Let u_0, $v_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+)$. Let u (respectively, v) be the entropy solution of problem* (A.3) *with initial data u_0, a_0 (respectively, v_0, b_0). Then for any fixed $R > 0$ the following inequality holds for almost any $t \in (0,T)$:*

$$\text{(B.4)} \qquad \int_0^R [v(x,t) - u(x,t)]_+ \, dx \le \int_0^{R+Mt} [v_0(x) - u_0(x)]_+ \, dx$$

$$+ \int_0^t H(v(0,\tau) - u(0,\tau))(f(v(0,\tau)) - f(u(0,\tau)) - s'(\tau)(v(0,\tau) - u(0,\tau))) \, d\tau,$$

where H is the standard Heaviside function and

$$\text{(B.5)} \qquad M := \sup_{|u| \le \max(\|u\|_{L^\infty}, \|v\|_{L^\infty})} |f'(u)| + \|s'\|_{L^\infty(0,T)}.$$

Moreover if $u_0 \in BV(\mathbb{R}^+) \cap L^\infty(\mathbb{R}^+) \cap L^1(\mathbb{R}^+)$, any entropy solution of the problem (B.3) *verifies the conservation equality*

$$\text{(B.6)} \qquad \int_{\mathbb{R}^+} u^s(y,t) \, dx = \int_{\mathbb{R}^+} u_0(y) \, dx + \int_0^t (f(u^s(0,\tau)) - f(0)) \, d\tau - \int_0^t s'(\tau) u(0,\tau) \, d\tau.$$

For a proof of this result see [Te1, Theorem 1.1 and Proposition 3.4], where actually we considered only flux functions $f(u)$. The extension to flux of the type $f(u) + h(t)u$ with $h(t) \in L^\infty(0,T)$ follows by simple modifications.

The following comparison theorem is a consequence of the previous one (see again [Te1]).

THEOREM B.2. *Assume the hypothesis of Theorem* B.1. *Then for almost every $t \in (0,T)$ there holds*

$$\int_0^R [u(x,t) - v(x,t)]_+ dx \le \int_0^{R+Mt} [u_0(x) - v_0(x)]_+ dx$$

$$+ M \int_0^t [a_0(\tau) - b_0(\tau)]_+ d\tau,$$

where the constant M is given by (B.5).

DETERMINATION OF A THIRD-ORDER OPERATOR FROM TWO OF ITS SPECTRA*

L. AMOUR†

Abstract. We consider a complex third-order differential operator on a bounded interval with boundary conditions presenting a mixed aspect of the Dirichlet and the periodic problems. It is proved that two spectra are sufficient to determine the operator. This result is valid under applying readily verifiable hypotheses simultaneously to the two spectra.

Key words. inverse spectral theory, third-order operator, determination of coefficients

1. Introduction and result.

Consider the third-order differential operator

$$L_{p,q} = iD^3 + iDq + iqD + p$$

defined on $[0,1]$ with the boundary conditions

$$(DP^+) \quad \begin{cases} y(1) = 0, \\ y'(1) = y'(0), \\ y''(0) = 0. \end{cases}$$

Here $(p,q) \in L^2_{\mathbf{R}}[0,1] \times H^1_{\mathbf{R}}[0,1]$. When $q(0) = 0$ this operator is self-adjoint in $L^2_{\mathbf{C}}[0,1]$ with the scalar product $(f,g) = \int_0^1 f\ \overline{g}\, dx$ and has a discrete spectrum. We denote by $\mu^+(p,q) = \left(\mu_j^+(p,q)\right)_{j\in\mathbf{Z}}$ the increasing sequence of eigenvalues. Each eigenvalue is real and is of multiplicity of at most *two*.

The same considerations hold when $L_{p,q}$ is associated with the boundary conditions

$$(DP^-) \quad \begin{cases} y(1) = 0, \\ y'(1) = -y'(0), \\ y''(0) = 0. \end{cases}$$

Then we denote by $\mu^-(p,q) = \left(\mu_j^-(p,q)\right)_{j\in\mathbf{Z}}$ the increasing sequence of eigenvalues, each eigenvalue being real and of multiplicity of at most *two*.

Let $\lambda^+ = (\lambda_j^+)_{j\in\mathbf{Z}}$ and $\lambda^- = (\lambda_j^-)_{j\in\mathbf{Z}}$ be two sequences of real numbers. We write $\lambda^+ \cap \lambda^- = \phi$ if and only if $\lambda_i^+ \neq \lambda_j^-\ \forall (i,j) \in \mathbf{Z}\times\mathbf{Z}$.

The main result of the paper is as follows.

THEOREM 1.1. *Let $(p,q) \in L^2_R \times H^1_R$ with $q(0) = 0$. Suppose $\mu^+(p,q) \cap \mu^-(p,q) = \phi$. Then*

(i) *all eigenvalues $\mu_j^+(p,q)$ and $\mu_j^-(p,q)$ are of multiplicity one;*

(ii) *the set $(\mu^+(p,q), \mu^-(p,q), q(1))$ determines uniquely (p,q).*

*Received by the editors October 27, 1997; accepted for publication (in revised form) July 23, 1998; published electronically July 22, 1999.

Part (i) provides a sufficient condition for having a simple spectra for both DP^+ and DP^- boundary conditions: each eigenvalue for the DP^+ boundary conditions is not an eigenvalue for the DP^- boundary conditions. It is proved in Theorem 3.1.

Given μ^+ (resp., μ^-), the additional knowledge of μ^- (resp., μ^+) gives the multiplicity number (one) of all the μ_j^+ (resp., μ_j^-) when $\mu^+ \cap \mu^- = \phi$.

Part (ii) says the following. Let $(p,q) \in L_R^2 \times H_R^1$ and $(\tilde{p},\tilde{q}) \in L_R^2 \times H_R^1$, suppose $\mu^+(p,q) \cap \mu^-(p,q) = \phi$, if $\mu^+(p,q) = \mu^+(\tilde{p},\tilde{q}), \mu^-(p,q) = \mu^-(\tilde{p},\tilde{q}), q(1) = \tilde{q}(1)$, $q(0) = \tilde{q}(0) = 0$; then $p = \tilde{p}$ a.e. in $[0,1]$ and $q = \tilde{q}$ in $[0,1]$.

Theorem 1.1 is not valid, replacing the DP^+ and DP^- boundary conditions with the boundary conditions $y(0) = y(1) = 0,\ y'(1) = y'(0)$, and $y(0) = y(1) = 0,\ y'(1) = -y'(0)$. It easy to check that $L_{p(x),q(x)}$ and $L_{p(1-x),q(1-x)}$ associated with one of these boundary conditions give the same spectrum.

Let us mention here that the indexation of the $\mu_j(p,q)$'s follows from *the counting lemma* (Lemma 3.4). Furthermore we have $\mu^{\pm}(p,q) = \mu^{\pm}(r,s) \Longleftrightarrow \mu_j^{\pm}(p,q) = \mu_j^{\pm}(r,s) \forall j \in \mathbf{Z}$. The counting lemma yields also that only a finite number of eigenvalues are of multiplicity two, with or without the hypothesis $\mu^+(p,q) \cap \mu^-(p,q) = \phi$.

For the second-order case $-y'' + qy = \lambda y$ with boundary conditions of the type $\cos\alpha y(0) + \sin\alpha y'(0) = 0$, $\cos\beta y(1) + \sin\beta y'(1) = 0$, the determination of q from two of its spectra has been extensively studied, giving numerous results through various methods. These are mainly based on Volterra operator transformations and contour integrations, using spectral functions or norming constants (see, for example, [Bo], [Ma], [Ge-Le], [Le-Ga], [Da-Tr]). The problem is solved for first-order differential systems in [Am]. The fourth-order case is also largely studied; see [Ca-Pe-Sc] for recent results and references. Two sequences of spectral data are not sufficient to determine the two coefficients of a self-adjoint fourth-order operator with separated boundary conditions. This can be seen from the exact solution reconstructive method given in [McLa1] and [McLa2]. Let us mention [Gl] and [Ba] where conditions are given for three sequences to be spectral data for a fourth-order self-adjoint boundary value problem with separated boundary conditions.

For the third-order operator the unique result in this direction is given by Leibenzon [Le] in 1966. The equation $y''' + p_1 y + p_2 y = \lambda y$ is associated with three boundary conditions of the type $y(a) + \alpha y'(a) + \beta y''(a) = 0$, $a = 0$ or 1. This is not a self-adjoint problem. It is proved that p_1 and p_2 are determined by two spectra also with the so-called matrix functions. It is supposed as in Theorem 1.1 that the two sets of eigenvalues do not intersect. It is also assumed that some other weight numbers exist. The result is actually generalized for nth-order differential equations, $n > 2$.

In Theorem 1.1 the two boundary conditions are of a different kind than those of Leibenzon. They allow the determination of the operator from only two spectra and use only one of the assumptions of Leibenzon. The proof of Theorem 1.1(ii) is mainly based on the methods of Pöschel and Trubowitz [P-Tr], a contour integration and a counting lemma.

A first generalization of the boundary conditions DP^+ or DP^- should be $y(1) = 0,\ y'(1) = e^{i\phi}y'(0),\ y''(0) = 0$ for some $\phi \in \mathbf{R}/2\pi\mathbf{Z}$ and one may expect that two sequences of spectral data for two different ϕ determine the operator together with the boundary conditions. This is a problem.

The counting lemma gives a rough asymptotic expansion of the $\mu_j^{\pm}(p,q)$'s. Namely, $\mu_j^+(p,q) - (2j\pi)^3$ and $\mu_j^-(p,q) - (2(j+1)\pi)^3$ are bounded as $|j| \to \infty$. More precise asymptotic expansions are given in the following theorem.

THEOREM 1.2. *Suppose* $(p,q) \in L^2_R \times H^1_R$ *with* $q(0)=0$ *and let* $[q]=\int_0^1 q(t)\,dt$*:*

$$\mu_j^+(p,q) = (2j\pi)^3 - 2j\pi[q] + O(1)$$

and

$$\mu_j^-(p,q) = ((2j+1)\pi)^3 - (2j+1)\pi[q] + O(1),$$

as $|j| \to \infty$.

Let us mention the work of McKean [McKe] devoted to the Boussinesq equation but give numerous results in inverse spectral theory for the non-self-adjoint operator $D^3+qD+Dq+p$ for the periodic case and also for the conditions $y(0)=y(1)=y(2)$, p and q being sufficiently small.

This article is organized as follows. In section 2 the estimates used in sections 3 and 4 are established. Then in section 3, Theorem 1.1(i) is proved. Next the counting lemma is derived. This involves the construction of $Z_1(1,\cdot,p,q)$ (resp., $Y_1(1,\cdot,p,q)$), the analytic extensions of the function vanishing at the $\mu_j^+(p,q)$'s (resp., the $\mu_j^-(p,q)$'s). Theorem 1.1(ii) is proved in section 4. Finally, the proof of Theorem 1.2 is given in section 5.

2. Notations, estimates, analyticity. Consider $(p,q) \in L^2_R \times H^1_R$ and let $\lambda \in \mathbf{C}$. The purpose of this section is to give estimates and analyticity results for the fundamental basis of the solutions to $L_{p,q}y = \lambda y$.

We will often use the abbreviated notation $' = \partial/\partial x$.

The functions $y_1(x,\lambda,p,q)$, $y_2(x,\lambda,p,q)$, $y_3(x,\lambda,p,q)$ are defined as the unique solutions to $L_{p,q}y(x) = \lambda y(x)$, for a.e. $x \in [0,1]$, satisfying the initial conditions

$$\begin{pmatrix} y_1(0) & y_2(0) & y_3(0) \\ y_1'(0) & y_2'(0) & y_3'(0) \\ y_1''(0) & y_2''(0) & y_3''(0) \end{pmatrix} = Identity.$$

In particular, every solution to $L_{p,q}y = \lambda y$ can be expressed as $y(x) = a\,y_1(x,\lambda,p,q) + b\,y_2(x,\lambda,p,q) + c\,y_3(x,\lambda,p,q)$, where $(a,b,c) = (y(0),y'(0),y''(0))$.

Since there is no second-order derivative in the definition of $L_{p,q}$, the Wronskian of y_1, y_2, and y_3 is independent of x. Therefore, for a.e. $x \in [0,1]$,

$$\begin{vmatrix} y_1(x) & y_2(x) & y_3(x) \\ y_1'(x) & y_2'(x) & y_3'(x) \\ y_1''(x) & y_2''(x) & y_3''(x) \end{vmatrix} = 1. \tag{2.1}$$

In particular,

$$\forall x_0 \in [0,1], \quad (y(x_0),y'(x_0),y''(x_0)) \neq (0,0,0). \tag{2.2}$$

Let $\omega = e^{\frac{2i\pi}{3}}$ and $k^3 = \lambda$. When $(p,q) \equiv (0,0)$ it is easy to obtain

$$\begin{aligned} y_1(x,\lambda,0,0) &= \frac{1}{3}\left(e^{ikx} + e^{i\omega kx} + e^{i\omega^2 kx}\right), \\ y_2(x,\lambda,0,0) &= \frac{1}{3ik}\left(e^{ikx} + \omega^2 e^{i\omega kx} + \omega e^{i\omega^2 kx}\right), \\ y_3(x,\lambda,0,0) &= \frac{1}{3(ik)^2}\left(e^{ikx} + \omega e^{i\omega kx} + \omega^2 e^{i\omega^2 kx}\right). \end{aligned} \tag{2.3}$$

Note that $\lambda = 0$ is a removable singularity for $y_2(x,\lambda,0,0)$ and $y_3(x,\lambda,0,0)$.

LEMMA 2.1. *We have that*

$$\begin{aligned}
y_1(x,\lambda,0,0) &= \frac{1}{3}\left(4\cos\left(\frac{kx}{2}\right)\cos\left(\frac{\omega kx}{2}\right)\cos\left(\frac{\omega^2 kx}{2}\right) - 1\right.\\
&\quad \left. -4i\sin\left(\frac{kx}{2}\right)\sin\left(\frac{\omega kx}{2}\right)\sin\left(\frac{\omega^2 kx}{2}\right)\right),\\
y_2(x,\lambda,0,0) &= \frac{1}{3ik}\left(4\cos\left(\frac{kx}{2}\right)\cos\left(\frac{\omega kx}{2}-\frac{\pi}{3}\right)\cos\left(\frac{\omega^2 kx}{2}+\frac{\pi}{3}\right) - 1\right.\\
&\quad \left. -4i\sin\left(\frac{kx}{2}\right)\sin\left(\frac{\omega kx}{2}-\frac{\pi}{3}\right)\sin\left(\frac{\omega^2 kx}{2}+\frac{\pi}{3}\right)\right),\\
y_3(x,\lambda,0,0) &= \frac{1}{3(ik)^2}\left(4\cos\left(\frac{kx}{2}\right)\cos\left(\frac{\omega kx}{2}+\frac{\pi}{3}\right)\cos\left(\frac{\omega^2 kx}{2}-\frac{\pi}{3}\right) - 1\right.\\
&\quad \left. -4i\sin\left(\frac{kx}{2}\right)\sin\left(\frac{\omega kx}{2}+\frac{\pi}{3}\right)\sin\left(\frac{\omega^2 kx}{2}-\frac{\pi}{3}\right)\right).
\end{aligned} \tag{2.4}$$

Lemma 2.1 is elementary but fundamental in achieving all estimates in the *whole* complex plane. Combining (2.4) and the inequality $|\sin z| \le e^{|\Im m z|}$, $z \in \mathbf{C}$, the functions y_1, y_2, and y_3 for $(p,q) \equiv (0,0)$ can be estimated as follows.

LEMMA 2.2. *On* $[0,1]\times\mathbf{C}$,

$$\begin{aligned}
|y_1(x,\lambda,0,0)| &\le 3e^{\left(|\Im m\frac{k}{2}|+|\Im m\frac{\omega k}{2}|+|\Im m\frac{\omega^2 k}{2}|\right)x},\\
|y_2(x,\lambda,0,0)| &\le \frac{3}{|k|}e^{\left(|\Im m\frac{k}{2}|+|\Im m\frac{\omega k}{2}|+|\Im m\frac{\omega^2 k}{2}|\right)x},\\
|y_3(x,\lambda,0,0)| &\le \frac{3}{|k|^2}e^{\left(|\Im m\frac{k}{2}|+|\Im m\frac{\omega k}{2}|+|\Im m\frac{\omega^2 k}{2}|\right)x}.
\end{aligned} \tag{2.5}$$

Let us define for $x \in [0,1]$ and $\lambda \in \mathbf{C}$

$$\Xi(x,\lambda) = e^{\left(|\Im m\frac{k}{2}|+|\Im m\frac{\omega k}{2}|+|\Im m\frac{\omega^2 k}{2}|\right)x}. \tag{2.6}$$

We also have Lemma 2.3.

LEMMA 2.3. *Let* $j = 1,2,3$ *and suppose* $n \le j-1$. *On* $[0,1]\times\mathbf{C}$,

$$\left|\frac{\partial^n}{\partial x^n} y_j(x,\lambda,0,0)\right| \le 3\Xi(x,\lambda). \tag{2.7}$$

Proof. Clearly, for $x \in [0,1]$ and $\lambda \in \mathbf{C}$,

$$y_2(x,\lambda,0,0) = \int_0^x y_1(t,\lambda,0,0)\,dt, \quad y_3(x,\lambda,0,0) = \int_0^x y_2(t,\lambda,0,0)\,dt. \tag{2.8}$$

Equalities in (2.8) show successively with Lemma 2.2 that

$$|y_2(x,\lambda,0,0)| \le \Xi(x,\lambda), \quad |y_3(x,\lambda,0,0)| \le \Xi(x,\lambda). \tag{2.9}$$

Besides,

$$y_3'(x,\lambda,0,0) = y_2(x,\lambda,0,0), \quad y_3'(x,\lambda,0,0) = y_2'(x,\lambda,0,0) = y_1'(x,\lambda,0,0). \tag{2.10}$$

Then (2.9) and (2.10) finish the proof. □

The $L^2_R \times H^1_R$ norm is chosen for convenience as

$$\|(p,q)\|^2_{L^2_R \times H^1_R} = 2\|q\|^2_{L^2_R} + \|q'\|^2_{L^2_R} + \|p\|^2_{L^2_R}.$$

THEOREM 2.4. *For $(x,\lambda,p,q) \in [0,1] \times \mathbf{C} \times L^2_R \times H^1_R$ with $q(0) = 0$,*

$$|y_j(x,\lambda,p,q)| \le \frac{3}{|k|^{j-1}} \Xi(x,\lambda) e^{\sqrt{x}\|(p,q)\|_{L^2_R \times H^1_R}}, \quad j = 1,2,3. \tag{2.11}$$

Proof. For $j = 1,2,3$ we have the integral equation

$$\begin{aligned} y_j(x,\lambda,p,q) = y_j(x,\lambda,0,0) + \int_0^x y_3(x-t,\lambda,0,0)\big(-2q(t)y_j'(t,\lambda,p,q) \\ +(-q'(t) + ip(t))y_j(t,\lambda,p,q)\big)\,dt. \end{aligned} \tag{2.12}$$

Integrating (2.12) by parts gives

$$\begin{aligned} y_j(x,\lambda,p,q) = y_j(x,\lambda,0,0) + \int_0^x \Big(-2y_3'(x-t,\lambda,0,0)q(t) \\ +y_3(x-t,\lambda,0,0)(q'(t) + ip(t))\Big) y_j(t,\lambda,p,q)\,dt \\ - \left[2y_3(x-t,\lambda,0,0)q(t)y_j(t,\lambda,p,q)\right]|_{t=0}^{t=x}. \end{aligned} \tag{2.13}$$

The last term in (2.13) is zero since $q(0) = 0$.

Following Picard's iteration we write

$$y_j(x,\lambda,p,q) = y_j(x,\lambda,0,0) + \sum_{n\ge 1} c_n^j(x,\lambda,p,q), \tag{2.14}$$

where

$$\begin{aligned} c_0^j(x,\lambda,p,q) &= y_j(x,\lambda,0,0), \\ c_n^j(x,\lambda,p,q) &= \int_0^x \Big(-2y_3'(x-t,\lambda,0,0)q(t) + y_3(x-t,\lambda,0,0)(q'(t) \\ &\qquad +ip(t))\Big) c_{n-1}^j(t,\lambda,p,q)\,dt. \end{aligned} \tag{2.15}$$

From (2.15) we have for each $n \ge 1$,

$$\begin{aligned} c_n^j(x,\lambda,p,q) \le \int_{t_1 \le t_2 \le \cdots \le t_{n+1} = x} y_j(t_1,\lambda,0,0) \prod_{m=1}^{n} \Big(-2y_3'(t_{m+1}-t_m,\lambda,0,0) \\ q(t_m) + y_3(t_{m+1}-t_m,\lambda,0,0)(q'(t_m) + ip(t_m))\Big)\,dt_1 \cdots dt_n. \end{aligned} \tag{2.16}$$

From Lemma 2.3

$$|y_3(x,\lambda,0,0)| \le 3\Xi(x,\lambda), \quad |y_3'(x,\lambda,0,0)| \le 3\Xi(x,\lambda), \quad (x,\lambda) \in [0,1] \times \mathbf{C}. \tag{2.17}$$

Then using (2.17) and $|y_j(t_1,\lambda,0,0)| \le 3|k|^{1-j}\Xi(x,\lambda)$ (2.16) gives

$$\begin{aligned}|c_n^j(x,\lambda,p,q)| &\le 3\frac{\Xi(x,\lambda)}{n!|k|^{j-1}}\left(\int_0^x 2|q(t)| + |q'(t)+ip(t)|\,dt\right)^n \\ &\le 3\frac{\Xi(x,\lambda)}{n!|k|^{j-1}}\left(\sqrt{x}\|(p,q)\|_{L_R^2\times H_R^1}\right)^n, \quad n\ge 1. \end{aligned} \tag{2.18}$$

Inequalities of Lemma 2.3 and (2.18) together with (2.14) finish the proof. ∎

THEOREM 2.5. *Let $j = 1,2,3$. For $(x,\lambda,p,q) \in [0,1]\times\mathbf{C}\times L_R^2\times H_R^1$ with $q(0)=0$,*

$$|y_j(x,\lambda,p,q) - y_j(x,\lambda,0,0)| \le \frac{3}{|k|^j}\Xi(x,\lambda)e^{\sqrt{x}\|(p,q)\|_{L_R^2\times H_R^1}}. \tag{2.19}$$

Proof. It is a repetition of the proof of Theorem 2.4 except that in (2.16) we replace once in the product, say, for $m=1$, the inequalities (2.17) by the inequalities

$$|y_3(x,\lambda,0,0)| \le \frac{3}{|k|}\Xi(x,\lambda), \quad |y_3'(x,\lambda,0,0)| \le \frac{3}{|k|}\Xi(x,\lambda), \quad (x,\lambda)\in[0,1]\times\mathbf{C}. \tag{2.20}$$

Inequalities (2.20) can be easily derived in a similar way as those in Lemma 2.3. ∎

THEOREM 2.6. *Let $j=1,2,3$. For each $x\in[0,1]$ and each $(p,q)\in L_R^2\times H_R^1$ with $q(0)=0$,*

$$y_j(x,\lambda,p,q), \quad y_j'(x,\lambda,p,q), \quad y_j''(x,\lambda,p,q) \tag{2.21}$$

are entire functions of λ.

Remark. It can be proved that these functions are also analytic functions of (λ,p,q).

Proof. Fix $j=1,2,3$. The coefficient $c_n^j(x,\lambda,p,q)$, nth term in the power series of $y_j(x,\lambda,p,q)$ is an entire function of λ. The convergence in (2.14) is locally uniform in λ by (2.18). Then $y_j(x,\lambda,p,q)$ is an entire function of λ according to Weierstrass's theorem.

The first derivative with respect to x of the integral equation (2.13) is

$$\begin{aligned}y_j'(x,\lambda,p,q) = y_j'(x,\lambda,0,0) + \int_0^x \Big(&-2y_3''(x-t,\lambda,0,0)q(t) \\ &+ y_3'(x-t,\lambda,0,0)(q'(t)+ip(t))\Big)y_j(t,\lambda,p,q)\,dt. \end{aligned} \tag{2.22}$$

The analyticity of $y_j(x,\lambda,p,q)$ gives the analyticity of $y_j'(x,\lambda,p,q)$. Similarly,

$$\begin{aligned}y_j''(x,\lambda,p,q) = y_j''(x,\lambda,0,0) + \int_0^x \Big(&-2y_3'''(x-t,\lambda,0,0)q(t) \\ &+ y_3''(x-t,\lambda,0,0)(q'(t)+ip(t))\Big)y_j(t,\lambda,p,q)\,dt - 2q(x) \end{aligned} \tag{2.23}$$

proves the analyticity result of $y_j''(x,\lambda,p,q)$.

The estimates for the derivatives of $y_j(x,\lambda,p,q)$ are given in Theorem 2.7.

THEOREM 2.7. *Let $j = 1, 2, 3$. For $(x, \lambda, p, q) \in [0, 1] \times \mathbf{C} \times L^2_R \times H^1_R$ with $q(0) = 0$,*

$$|y'_j(x, \lambda, p, q) - y'_j(x, \lambda, 0, 0)| \leq 3 \frac{\|(p, q)\|_{L^2_R \times H^1_R}}{|k|^{j-1}} \Xi(x, \lambda) e^{\sqrt{x}\|(p,q)\|_{L^2_R \times H^1_R}} \tag{2.24}$$

and

$$|y''_j(x, \lambda, p, q) + 2q(x) - y''_j(x, \lambda, 0, 0)| \leq 3 \frac{\|(p, q)\|_{L^2_R \times H^1_R}}{|k|^{j-2}} \Xi(x, \lambda) \times e^{\sqrt{x}\|(p,q)\|_{L^2_R \times H^1_R}}. \tag{2.25}$$

The proof of (2.24) and (2.25) is a consequence of (2.22) and (2.23), respectively. □

3. Proof of Theorem 1.1(i) and the counting lemma. We begin this section by proving Theorem 1.1(i). It is Theorem 3.1(iii).

THEOREM 3.1. *Let $(p, q) \in L^2_R \times H^1_R$ satisfying $q(0) = 0$.*

(i) *$\mu^+(p, q) \cap \mu^-(p, q) = \phi$ if and only if $y_1(1, \lambda, p, q)$ has no zero in $\mathbf{C}$.*

(ii) *Any $\lambda \in \mathbf{R}$ is a simple eigenvalue of $L_{p,q}$ associated with the DP^+ boundary conditions if and only if*

$$\begin{cases} \Im\mathrm{m}\, y_1(1, \lambda, p, q) = 0 \\ \Re\mathrm{e}\, y_1(1, \lambda, p, q) \neq 0 \end{cases} \quad \text{or} \quad \begin{cases} \Im\mathrm{m}\, y_1(1, \lambda, p, q) = 0 \\ \Re\mathrm{e}\, y'_1(1, \lambda, p, q) \neq 0 \end{cases}.$$

Any $\lambda \in \mathbf{R}$ is a simple eigenvalue of $L_{p,q}$ associated with the DP^- boundary conditions if and only if

$$\begin{cases} \Re\mathrm{e}\, y_1(1, \lambda, p, q) = 0 \\ \Im\mathrm{m}\, y_1(1, \lambda, p, q) \neq 0 \end{cases} \quad \text{or} \quad \begin{cases} \Re\mathrm{e}\, y_1(1, \lambda, p, q) = 0 \\ \Im\mathrm{m}\, y'_1(1, \lambda, p, q) \neq 0 \end{cases}.$$

(iii) *If $\mu^+(p, q) \cap \mu^-(p, q) = \phi$, then $\mu^+(p, q)$ and $\mu^-(p, q)$ are both simple spectra.*

The proof uses the following preliminary observations.

Let $[y, z] = y'z - yz'$.

LEMMA 3.2. *Let $\lambda \in \mathbf{C}$ and suppose $(p, q) \in L^2_R \times H^1_R$. Then*

$$\begin{aligned} [y_3(x, \lambda, p, q), y_2(x, \lambda, p, q)] &= \bar{y}_3(x, \bar{\lambda}, p, q), \\ [y_3(x, \lambda, p, q), y_1(x, \lambda, p, q)] &= \bar{y}_2(x, \bar{\lambda}, p, q), \\ [y_2(x, \lambda, p, q), y_1(x, \lambda, p, q)] &= \bar{y}_1(x, \bar{\lambda}, p, q) - 2q(0)\bar{y}_3(x, \bar{\lambda}, p, q). \end{aligned} \tag{3.1}$$

This result is given by McKean [McKe].

Proof. Check that the left- and right-hand sides of each identity in (3.1) satisfy $L_{-p,q}y = -\lambda y$ and the same initial conditions at $x = 0$. □

Let

$$M^{\pm}(\lambda, p, q) = \begin{pmatrix} y_1(1, \lambda, p, q) & y_2(1, \lambda, p, q) \\ y'_1(1, \lambda, p, q) & y'_2(1, \lambda, p, q) \mp 1 \end{pmatrix}. \tag{3.2}$$

LEMMA 3.3. *Fix* (p,q) *in* $L^2_R \times H^1_R$ *and suppose* $q(0)=0$. *For all* $\lambda \in \mathbf{R}$ *we have*

$$\text{(i)} \quad \begin{cases} y_1(1,\lambda,p,q)=0, \\ \Re\mathrm{e}\, y_1''(1,\lambda,p,q)=0 \end{cases} \iff M^+(\lambda,p,q)=0, \tag{3.3}$$

$$\text{(ii)} \quad \begin{cases} y_1(1,\lambda,p,q)=0, \\ \Im\mathrm{a}\, y_1''(1,\lambda,p,q)=0 \end{cases} \iff M^-(\lambda,p,q)=0. \tag{3.4}$$

Proof. Suppose $q(0)=0$ and fix $\lambda \in \mathbf{R}$. We omit (p,q) from the notation for brevity. From $\bar{y}_1(1,\lambda)=y_2'(1,\lambda)y_1(1,\lambda)-y_2(1,\lambda)y_1'(1,\lambda)$ we have $y_1(1,\lambda)=0 \Rightarrow y_1'(1,\lambda)=0$ or $y_2(1,\lambda)=0$. The equality $\bar{y}_2(1,\lambda)=y_3'(1,\lambda)y_1(1,\lambda)-y_3(1,\lambda)y_1'(1,\lambda)$ gives $y_1(1,\lambda)=y_1'(1,\lambda)=0 \Rightarrow y_2(1,\lambda)=0$. Therefore,

$$y_1(1,\lambda)=0 \Rightarrow y_2(1,\lambda)=0. \tag{3.5}$$

Similarly, $\bar{y}_1'(1,\lambda)=y_2''(1,\lambda)y_1(1,\lambda)-y_2(1,\lambda)y_1''(1,\lambda)$ yields $y_1(1,\lambda)=y_2(1,\lambda)=0 \Rightarrow y_1'(1,\lambda)=0$. Thus, with (3.5) we obtain

$$y_1(1,\lambda)=0 \Leftrightarrow y_1(1,\lambda)=y_1'(1,\lambda)=y_2(1,\lambda)=0.$$

Since $y_1''(1,\lambda)\neq 0$ when $y_1(1,\lambda)=y_1'(1,\lambda)=0$, the proof is finished using $\bar{y}_1''(1,\lambda)=y_2''(1,\lambda)y_1'(1,\lambda)-y_2'(1,\lambda)y_1''(1,\lambda)$. □

Proof of Theorem 3.1. Looking for a solution $y(x)$ to $L_{p,q}y=\lambda y$, for a.e. $x\in[0,1]$ and satisfying the $DP^{\pm}$ boundary conditions, we write

$$y(x)=a\,y_1(x,\lambda,p,q)+b\,y_2(x,\lambda,p,q)+c\,y_3(x,\lambda,p,q)$$

with $(a,b,c)\in \mathbf{C}^3\backslash 0$.

Clearly

$$\begin{cases} a\,y_1(1,\lambda,p,q)+b\,y_2(1,\lambda,p,q)+c\,y_3(1,\lambda,p,q)=0, \\ a\,y_1'(1,\lambda,p,q)+b\,y_2'(1,\lambda,p,q)+c\,y_3'(1,\lambda,p,q)=\pm b, \\ c=0, \end{cases} \tag{3.6}$$

that is to say,

$$M^{\pm}(\lambda,p,q)\begin{pmatrix} a \\ b \end{pmatrix}=\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad (a,b)\neq(0,0).$$

Then any real λ is an eigenvalue of $L_{p,q}$ associated with the $DP^{\pm}$ boundary conditions if and only if $\dim Ker\, M^{\pm}(\lambda,p,q)\geq 1$, i.e., if and only if

$$\det M^{\pm}(\lambda,p,q)=0. \tag{3.7}$$

Using Lemma 3.2 we have $\det M^{\pm}(\lambda,p,q)=\bar{y}_1(1,\lambda,p,q)\mp y_1(1,\lambda,p,q)$. Therefore,

$$\Im m y_1(1,\lambda,p,q)=0 \text{ (resp., } \Re e y_1(1,\lambda,p,q)=0) \tag{3.8}$$

gives the eigenvalues for the DP^+ boundary conditions (resp., for the DP^- boundary conditions). This proves (i).

Any real λ is a *simple* eigenvalue $L_{p,q}$ associated with the $DP^{\pm}$ boundary conditions if and only if dim $Ker\, M^{\pm}(\lambda,p,q)=1$, i.e., if and only if

$$\det M^{\pm}(\lambda,p,q)=0 \quad \text{and} \quad M^{\pm}(\lambda,p,q)\neq \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}. \tag{3.9}$$

This proves (ii) with Lemma 3.3. Then (iii) follows from (i) and (ii). □

When λ is a *simple* eigenvalue, an immediate consequence of (3.2) and (3.9) is that either the two expressions

$$\begin{aligned} &y_2(1,\lambda,p,q)y_1(x,\lambda,p,q)-y_1(1,\lambda,p,q)y_2(x,\lambda,p,q)\\ &\text{and}\\ &(y_2'(1,\lambda,p,q)\mp 1)y_1(x,\lambda,p,q)-y_1'(1,\lambda,p,q)y_2(x,\lambda,p,q) \end{aligned} \tag{3.10}$$

are equivalent up to a multiplicative constant $\neq 0$ or one (and only one) of the two expressions is identically zero. This provides the eigenfunction (up to a multiplicative constant $\neq 0$) corresponding to λ.

When λ is a *double* eigenvalue, $y_1(\cdot,\lambda,p,q)$ and $y_2(\cdot,\lambda,p,q)$ are two linearly independent eigenfunctions corresponding to λ.

Now we construct explicitly the analytic extensions in $\mathbf{C}$ of $\lambda\mapsto \Im m y_1(1,\lambda,p,q)$ and $\lambda\mapsto \Re e y_1(1,\lambda,p,q)$.

For this, just define the operator

$$l_{p,q}=\begin{pmatrix} p & -D^3-Dq-qD \\ D^3+Dq+qD & p \end{pmatrix}$$

on the *real*-valued function space $\mathrm{L}^2_{\mathbf{R}}[0,1]\times \mathrm{L}^2_{\mathbf{R}}[0,1]$ and consider the eigenvalue problem

$$l_{p,q}\begin{pmatrix} Y(x) \\ Z(x) \end{pmatrix}=\lambda\begin{pmatrix} Y(x) \\ Z(x) \end{pmatrix} \quad \text{for a.e. } x\in[0,1]$$

with either the dl^+ or the dl^- boundary conditions defined by

$$(dl^{\pm}) \quad \begin{cases} Y(1)=Z(1)=0,\\ Y'(1)=\pm Y'(0), \quad Z'(1)=\pm Z'(0),\\ Y''(0)=Z''(0)=0. \end{cases}$$

The operator $l_{p,q}$ with the dl^+ or dl^- boundary conditions is self-adjoint on $\mathrm{L}^2_{\mathbf{R}}[0,1]\times \mathrm{L}^2_{\mathbf{R}}[0,1]$ with the inner scalar product

$$\left\langle \begin{pmatrix} Y(x) \\ Z(x) \end{pmatrix}, \begin{pmatrix} \tilde{Y}(x) \\ \tilde{Z}(x) \end{pmatrix} \right\rangle = \int_0^1 Y(x)\tilde{Y}(x)+Z(x)\tilde{Z}(x)\,dx.$$

Write $y=Y+iZ$, Y and Z being real-valued functions, and observe that $L_{p,q}y=\lambda y$ is equivalent to

$$l_{p,q}\begin{pmatrix} Y(x) \\ Z(x) \end{pmatrix}=\lambda\begin{pmatrix} Y(x) \\ Z(x) \end{pmatrix}$$

for *real* λ. It is different for all complex λ because of right-hand sides.

The spectrum of $L_{p,q}$ with the DL^+ (resp., DL^-) boundary conditions is then the spectrum of $l_{p,q}$ with the dl^+ (resp., dl^-) boundary conditions.

For each $\lambda \in \mathbf{C}$, $\binom{Y_1(x)}{Z_1(x)}$ denotes the solution to

$$l_{p,q}\begin{pmatrix} Y(x) \\ Z(x) \end{pmatrix} = \lambda \begin{pmatrix} Y(x) \\ Z(x) \end{pmatrix}$$

satisfying the initial condition

$$(Y_1 + iZ_1)(0,\lambda,p,q) = 1, \quad (Y_1' + iZ_1')(0,\lambda,p,q) = 0, \quad (Y_1'' + iZ_1'')(0,\lambda,p,q) = 0.$$

We have

$$y_1(x,\lambda,p,q) = Y_1(x,\lambda,p,q) + iZ_1(x,\lambda,p,q) \quad \text{for a.e } x \in [0,1]\ \forall \lambda \in \mathbf{R}. \tag{3.11}$$

Again (3.11) is not satisfied for all $\lambda \in \mathbf{C}$.

Moreover, it is clear that

$$\begin{aligned} \left\{\mu_j^+(p,q), \quad j \in \mathbf{Z}\right\} &= \left\{\lambda \in \mathbf{C}, Z_1(1,\lambda,p,q) = 0\right\}, \\ \left\{\mu_j^-(p,q), \quad j \in \mathbf{Z}\right\} &= \left\{\lambda \in \mathbf{C}, Y_1(1,\lambda,p,q) = 0\right\}. \end{aligned} \tag{3.12}$$

The same considerations (the integral equation and the Picard iteration) as those for $y_1(x,\lambda,p,q)$ in section 2 show that $Y_1(1,\lambda,p,q)$ and $Z_1(1,\lambda,p,q)$ are entire functions of λ (see [Am-Gu, appendix] for a very similar treatment with a first-order system). They are the analytic extensions in $\mathbf{C}$ of $\lambda \mapsto \Im m y_1(1,\lambda,p,q)$ and $\lambda \mapsto \Re e y_1(1,\lambda,p,q)$. Moreover, under the same assumptions of Theorem 2.5, it can be seen that

$$\begin{aligned} &|Y_1(x,\lambda,p,q) - Y_1(x,\lambda,0,0)| \le \frac{3}{|k|}\Xi(x,\lambda)e^{\sqrt{x}\|(p,q)\|_{L^2_R \times H^1_R}} \\ &\text{and} \\ &|Z_1(x,\lambda,p,q) - Z_1(x,\lambda,0,0)| \le \frac{3}{|k|}\Xi(x,\lambda)e^{\sqrt{x}\|(p,q)\|_{L^2_R \times H^1_R}} \end{aligned} \tag{3.13}$$

$\forall \lambda \in \mathbf{C}$.

The final part of this section is concerned with the proof of the counting lemma.

Let

$$\begin{aligned} \Omega_j^- &= \left\{z \in \mathbf{C},\ |\omega^{j-1}z - (2j+1)\pi| \ge \frac{\pi}{2}\right\}, \\ \Omega_j^+ &= \left\{z \in \mathbf{C},\ |\omega^{j-1}z - 2j\pi| \ge \frac{\pi}{2}\right\} \end{aligned} \tag{3.14}$$

for $j = 1,2,3$ and define

$$\Omega^{\pm} = \bigcap_{j=1}^{3} \Omega_j^{\pm}. \tag{3.15}$$

Using this notation we have Lemma 3.4.

LEMMA 3.4 (the counting lemma). *Suppose* $(p,q) \in L^2_{\mathbf{C}} \times H^1_{\mathbf{C}}$ *with* $q(0) = 0$.

(i) *Let the integer* J *satisfy* $(2J+1)\pi > 48e^{\|(p,q)\|}$. *Then* $Z_1(1,\lambda,p,q)$ *has exactly* $2J+1$ *roots, counted with multiplicity in the open k-disc*

$$\{k \in \mathbf{C},\ |k| < (2J+1)\pi\}$$

and exactly one simple root noted $\mu_j^+(p,q)$ *in each open k-disc* $\{k \in \mathbf{C},\ |k-2j\pi| < \pi\}$ *for* $|j| > J$.

(ii) *Let the integer* J *satisfy* $2J\pi > \min(\ln 32, 96e^{\|(p,q)\|})$. *Then* $Y_1(1,\lambda,p,q)$ *has exactly* $2J$ *roots, counted with multiplicity in the open k-disc*

$$\{k \in \mathbf{C},\ |k| < 2J\pi\}$$

and exactly one simple root noted $\mu_j^-(p,q)$ *in each open k-disc* $\{k \in \mathbf{C},\ |k-(2j+1)\pi| < \pi\}$ *for* $|j| \geq J$.

The proof of Lemma 3.4 involves the following inequalities.

LEMMA 3.5.

$$\begin{aligned} &\text{(i) } 96|Y_1(1,\lambda,0,0)| \geq \Xi(1,\lambda) \quad \forall k \in \Omega^- \setminus \{|k| \leq \ln 32\}, \\ &\text{(ii) } 48|Z_1(1,\lambda,0,0)| \geq \Xi(1,\lambda) \quad \forall k \in \Omega^+. \end{aligned} \tag{3.16}$$

The definition of Ξ is given in (2.6).

Proof. (i) Similarly as in Lemma 2.1 it can be seen that

$$Y_1(1,\lambda,0,0) = \frac{1}{3}\left(4\cos\left(\frac{k}{2}\right)\cos\left(\frac{\omega k}{2}\right)\cos\left(\frac{\omega^2 k}{2}\right) - 1\right) \ \forall \lambda \in \mathbf{C}.$$

Then

$$|Y_1(1,\lambda,0,0)|^2 = 16|\Lambda|^2 - 8\Re e\,\Lambda + 1,$$

where

$$\Lambda = \cos\left(\frac{k}{2}\right)\cos\left(\frac{\omega k}{2}\right)\cos\left(\frac{\omega^2 k}{2}\right).$$

Therefore, for any $0 < \varepsilon < 4$,

$$9|Y_1(1,\lambda,0,0)|^2 \geq \varepsilon^2|\Lambda|^2 \tag{3.17}$$

if

$$(16-\varepsilon^2)|\Lambda|^2 - 8|\Lambda| + 1 \geq 0,$$

that is to say, if

$$|\Lambda| \geq (4-\varepsilon)^{-1}. \tag{3.18}$$

Inequality $e^{|\Im m z|} \leq 4|\sin z|$ in $\{z \in \mathbf{C},\ |z| \geq \pi/4\}$ [P-Tr, Lemma 2.1] yields

$$\begin{aligned} &\left|\cos\left(\frac{k}{2}\right)\right| \geq \frac{1}{4}e^{|\Im m\frac{k}{2}|} \geq \frac{1}{4} \ \text{ for } \ k \in \Omega_1^-, \\ &\left|\cos\left(\frac{\omega k}{2}\right)\right| \geq \frac{1}{4}e^{|\Im m\omega\frac{k}{2}|} \geq \frac{1}{4} \ \text{ for } \ k \in \Omega_2^-, \\ &\left|\cos\left(\frac{\omega^2 k}{2}\right)\right| \geq \frac{1}{4}e^{|\Im m\omega^2\frac{k}{2}|} \geq \frac{1}{4} \ \text{ for } \ k \in \Omega_3^-. \end{aligned} \tag{3.19}$$

From (3.19) we have

$$|\Lambda| \geq \frac{1}{4^3}e^{|\Im m\omega\frac{k}{2}|} \quad \text{and} \quad |\Lambda| \geq \frac{1}{4^3}e^{|\Im m\omega^2\frac{k}{2}|} \quad \forall k \in \Omega^-.$$

Consequently

$$|\Lambda| \geq \frac{1}{2}$$

$$\text{if} \quad k \in \left(\left\{ \left| \Im m\omega \frac{k}{2} \right| \geq \ln 32 \right\} \cup \left\{ \left| \Im m\omega^2 \frac{k}{2} \right| \geq \ln 32 \right\} \right) \cap \Omega^- . \tag{3.20}$$

Therefore, (3.18) is satisfied for $\varepsilon = 2$ and for $k \in \Omega^- \setminus \{|k| \leq \ln 32\}$. Then

$$|Y_1(1,\lambda,0,0)| \geq \frac{2}{3}|\Lambda| \quad \forall k \in \Omega^- \setminus \{|k| \leq \ln 32\}, \tag{3.21}$$

and again using (3.19) we have

$$|\Lambda| \geq \frac{1}{4^3}\Xi(1,\lambda) \quad \text{for} \quad k \in \Omega^- . \tag{3.22}$$

Inequalities (3.21) and (3.22) prove (i).

The proof of (ii) is immediate since

$$\begin{aligned} |Z_1(1,\lambda,0,0)| &= \frac{1}{3}\left| 4\sin\left(\frac{k}{2}\right)\sin\left(\frac{\omega k}{2}\right)\sin\left(\frac{\omega^2 k}{2}\right)\right| \quad \forall k \in \mathbf{C} \\ &\geq \frac{1}{48} e^{\left(|\Im m\frac{k}{2}|+|\Im m\frac{\omega k}{2}|+|\Im m\frac{\omega^2 k}{2}|\right)x} \quad \forall k \in \Omega^+ . \end{aligned}$$

□

Proof of Lemma 3.4. (i) Combining (3.13) and (3.16) we obtain

$$|Z_1(1,\lambda,p,q) - Z_1(1,\lambda,0,0)| < |Z_1(1,\lambda,0,0)|$$

$\forall\, k \in \Omega^+$ satisfying $|k| \geq 48e^{\|(p,q)\|}$.

Consequently, Rouché's theorem can be applied on the k-circles $|k| = (2J+1)$ and $|k-2j\pi| = \pi$ for $|j| > J$. Then $Z_1(1,\lambda,p,q)$ and $Z_1(1,\lambda,0,0) = \frac{4}{3}\sin(\frac{kx}{2})\sin(\frac{\omega kx}{2})\sin(\frac{\omega^2 kx}{2})$ have the same number of zeros, counted with multiplicity, in the corresponding open k-discs, the zeros of $Z_1(1,\lambda,0,0)$ being the $(2j\pi)^3$'s, $j \in \mathbf{Z}$.

(ii) Similarly, (3.13) and (3.16) give

$$|Y_1(1,\lambda,p,q) - Y_1(1,\lambda,0,0)| < |Y_1(1,\lambda,0,0)|$$

$\forall\, k \in \Omega^-$ satisfying $|k| \geq \max(\ln 32, 96e^{\|(p,q)\|})$. Then $Y_1(1,\lambda,p,q)$ and $Y_1(1,\lambda,0,0)$ have the same number of zeros in the open k-discs defined in Lemma 3.3(ii), the zeros of $Y_1(1,\lambda,0,0)$ being the $((2j+1)\pi)^3$'s, $j \in \mathbf{Z}$, up to an irrelevant additive $O(e^{-c|k|})$ term, c being a positive numerical constant. □

4. Proof of Theorem 1.1(ii). Let us mention first that the indexing of the $\mu_j^{\mp}(p,q)$'s following Lemma 3.4 has the property

$$\mu^{\pm}(p_1,q_1) = \mu^{\pm}(p_2,q_2) \Longleftrightarrow \mu_j^{\pm}(p_1,q_1) = \mu_j^{\pm}(p_2,q_2) \quad \forall\, j \in \mathbf{Z}.$$

Define

$$y(x,\lambda,p,q) = y_2(1,\lambda,p,q)y_1(x,\lambda,p,q) - y_1(1,\lambda,p,q)y_2(x,\lambda,p,q) \tag{4.1}$$

$\forall \lambda \in \mathbf{C}$ and a.e. $x \in [0,1]$.

Let us recall that under the assumptions of Theorem 1.1, $y(\cdot, \mu_j^{\pm}, p, q)$ is the eigenfunction corresponding to the eigenvalue $\mu_j^{\pm}(p,q)$.

We will often use the abbreviated notation $\dot{\cdot} = \partial/\partial\lambda$. We now have Lemma 4.1.

LEMMA 4.1. *Let* $(p,q) \in L^2_R \times H^1_R$. *Suppose* $q(0) = 0$. *Then*

$$\begin{aligned} \int_0^1 |y(x, \mu_j^+(p,q), p, q)|^2 \, dx &= -2(Y_1 \dot{Z}_1)(1, \mu_j^+(p,q), p, q), \\ \int_0^1 |y(x, \mu_j^-(p,q), p, q)|^2 \, dx &= 2(Z_1 \dot{Y}_1)(1, \mu_j^-(p,q), p, q) \end{aligned} \tag{4.2}$$

$\forall j \in \mathbf{Z}$.

Remark. When $\mu^+(p,q) \cap \mu^-(p,q) = \phi$, the geometric multiplicity of each $\mu_j^+(p,q)$ (resp., $\mu_j^-(p,q)$) is one. Besides, from Lemma 4.1, its algebraic multiplicity, defined as its order as a root in $Z_1(1, \lambda, p, q)$ (resp., $Y_1(1, \lambda, p, q)$), is also one.

Proof. Let $\lambda \in \mathbf{C}$. We have

$$i\dot{y}''' + 2iq\dot{y}' + (iq' + p)\dot{y} = \lambda \dot{y} + y \tag{4.3}$$

and

$$i\bar{\dot{y}}''' + 2iq\bar{\dot{y}}' + (iq' - p)\bar{\dot{y}} = -\bar{\lambda}\bar{\dot{y}}. \tag{4.4}$$

Combining (4.3) and (4.4) we have for $\lambda \in \mathbf{R}$

$$\begin{aligned} |y|^2 \quad &= 2i(q\dot{y}\bar{\dot{y}})' + i\dot{y}'''\bar{\dot{y}} + i\dot{y}\bar{\dot{y}}''' \\ &= i(\dot{y}\bar{\dot{y}}'' - \dot{y}'\bar{\dot{y}}' + \dot{y}''\bar{\dot{y}} + 2q\dot{y}\bar{\dot{y}})'. \end{aligned} \tag{4.5}$$

Suppose $\lambda = \mu_j^{\pm}$. From (4.5), since $q(0) = 0$ and $y(0) = 0$, we obtain

$$\int_0^1 |y|^2 \, dx = i[\dot{y}\bar{\dot{y}}'' - \dot{y}'\bar{\dot{y}}' + \dot{y}''\bar{\dot{y}}]|_{x=0}^{x=1}. \tag{4.6}$$

Besides, it is easy to compute

$$\begin{aligned} &\dot{y}(1) = 0, \quad \dot{y}''(0) = 0, \quad \dot{y}'(0) = -\dot{y}_1(1), \\ &\bar{\dot{y}}'(0) = -\bar{\dot{y}}_1(1), \quad \bar{\dot{y}}'(1) = -y_1(1), \quad \dot{y}'(1) = -\dot{\bar{y}}_1(1), \end{aligned} \tag{4.7}$$

where all functions in (4.7) are evaluated at $\mu_j^{\pm}(p,q)$, $j \in \mathbf{Z}$.

Finally, since

$$\begin{aligned} y_1(1, \lambda, p, q) &= \bar{y}_1(1, \lambda, p, q) \quad \text{for } \lambda = \mu_j^+(p,q), \\ y_1(1, \lambda, p, q) &= -\bar{y}_1(1, \lambda, p, q) \quad \text{for } \lambda = \mu_j^-(p,q), \end{aligned} \tag{4.8}$$

we have from (4.5), (4.6), and (4.7),

$$\int_0^1 |y(x, \lambda, p, q)|^2 \, dx = -iy_1(1, \lambda, p, q) \frac{\partial}{\partial \lambda} \left(y_1(1, \lambda, p, q) \pm \bar{y}_1(1, \lambda, p, q) \right)$$

at $\lambda = \mu_j^{\pm}(p,q)$, $j \in \mathbf{Z}$.

The proof is finished since $\Re e y_1(1, \cdot, p, q)$ coincides with $Y_1(1, \cdot, p, q)$ and $\Im m y_1(1, \cdot, p, q)$ coincides with $Z_1(1, \cdot, p, q)$ on the real axis. □

For $g \in L^2_{\mathbf{R}}[0,1]$, g^* is defined by $g^*(x) = g(1-x)$ for a.e. $x \in [0,1]$.

LEMMA 4.2. *Let* $(p,q) \in L^2_R \times H^1_R$, $\lambda \in \mathbf{C}$ *and suppose* $q(0) = 0$. *Then*

$$\begin{pmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{pmatrix}(1,\lambda,p^*,q^*) = \begin{pmatrix} y_3'' & y_3' & y_3 \\ y_2'' & y_2' & y_2 \\ y_1'' & y_1' & y_1 \end{pmatrix}(1,\lambda,p,q). \tag{4.9}$$

Remark. The equality $y_3(1,\lambda,p,q) = y_3(1,\lambda,p^*,q^*)$ may be explained. The eigenvalues corresponding to the boundary conditions $y(0) = y(1) = 0$, $y'(0) = e^{i\phi}y'(1)$ with $\phi \in [0,2\pi)$ are the zeros of $\cos(\phi/2)\Re e y_3(1,\lambda,p,q) - \sin(\phi/2)\Im m y_3(1,\lambda,p,q)$. Take $\phi = 0$. One should expect, using a Weierstrass product for the analytic extension of $\Re e y_3(1,\lambda,p,q)$, that these eigenvalues determine $\Re e y_3(1,\lambda,p,q)$. The sequence of eigenvalues corresponding to $\phi = \pi$ should determine $\Im m y_3(1,\lambda,p,q)$. These two sequences of eigenvalues do not change replacing (p,q) by (p^*,q^*), the upshot being the symmetry of the boundary conditions.

Proof. Since $y_j(1-x,\bar\lambda,p^*,q^*)$ solves $L_{p,q}y_j = \lambda y_j$, $j = 1,2,3$, then

$$\begin{pmatrix} \bar y_1(1-x,\bar\lambda,p^*,q^*) \\ \bar y_2(1-x,\bar\lambda,p^*,q^*) \\ \bar y_3(1-x,\bar\lambda,p^*,q^*) \end{pmatrix} = N \begin{pmatrix} y_1(x,\lambda,p,q) \\ y_2(x,\lambda,p,q) \\ y_3(x,\lambda,p,q) \end{pmatrix}, \tag{4.10}$$

where N is a 3×3 matrix with complex coefficients independent of x.

At $x = 1$, (4.10) gives

$$N \begin{pmatrix} y_1 & -y_1' & y_1'' \\ y_2 & -y_2' & y_2'' \\ y_3 & -y_3' & y_3'' \end{pmatrix}(1,\lambda,p,q) = Identity.$$

Thus $\det N = -1$,

$$N = \begin{pmatrix} y_3''y_2' - y_3'y_2'' & y_1''y_3' - y_1'y_3'' & y_2''y_1' - y_2'y_1'' \\ y_3''y_2 - y_3y_2'' & y_1''y_3 - y_1y_3'' & y_2''y_1 - y_2y_1'' \\ y_3'y_2 - y_3y_2' & y_1'y_3 - y_1y_3' & y_2'y_1 - y_2y_1' \end{pmatrix}(1,\lambda,p,q)$$

and

$$N = \begin{pmatrix} \bar y_3'' & -\bar y_2'' & \bar y_1'' \\ \bar y_3' & -\bar y_2' & \bar y_1' \\ \bar y_3 & -\bar y_2 & \bar y_1 \end{pmatrix}(1,\bar\lambda,p,q) \tag{4.11}$$

using (3.1) and $q(0) = 0$. The lemma follows from (4.11) together with (4.10) and its derivatives evaluated at $x = 0$. □

Next we consider the $DP^\pm_*$ boundary conditions

$$(DP^\pm_*) \quad \begin{cases} z(0) = 0, \\ z'(1) = \pm z'(0), \\ z''(1) = 0. \end{cases}$$

Using the map $(p,q) \mapsto (p^*,q^*)$, Lemma 4.2 and section 2, it is easy to see that the increasing sequence $\left(\nu_j^\pm(p,q)\right)_{j\in\mathbf{Z}}$ of eigenvalues of $L_{p,q}$ with the $DL^\pm_*$ boundary conditions are the roots of $y_3''(1,\lambda,p,q) \pm \bar y_3''(1,\lambda,p,q)$. Lemma 3.4 holds for the

$\nu_j^{\pm}(p,q)$'s with the self-evident changes of notation. In particular, $\nu_j^{\pm}(p,q)$ is defined. Furthermore,

$$\nu_j^{\pm}(p,q) = \mu_j^{\pm}(p^*,q^*) \quad \forall\, j \in \mathbf{Z}.$$

Each $\nu_j^{\pm}(p,q)$ is of multiplicity one if $y_3''(1,\nu_j^{\pm}(p,q),p,q) \neq 0$.

Then, define for a.e. $x \in [0,1]$ and for $\lambda \in \mathbf{C}$,

$$z(x,\lambda,p,q) = y_3''(1,\lambda,p,q)y_2(x,\lambda,p,q) - y_2''(1,\lambda,p,q)y_3(x,\lambda,p,q). \tag{4.12}$$

For every $j \in \mathbf{Z}$, $z(\cdot,\nu_j^{\pm}(p,q),p,q)$ is the eigenfunction associated with the eigenvalue $\nu_j^{\pm}(p,q)$ if $y_3''(1,\nu_j^{\pm}(p,q),p,q) \neq 0$.

The $DP_*^{\pm}$ boundary conditions will be considered only for the operator L_{p^*,q^*}. Then observe that

$$y_3''(1,\lambda,p^*,q^*) \neq 0 \Longleftrightarrow y_1(1,\lambda,p,q) \neq 0 \quad \forall \lambda \in \mathbf{C}.$$

Of course we can replace above the statement $\forall\lambda \in \mathbf{C}$ with $\forall\lambda = \mu_j^{\pm}(p,q),\ j \in \mathbf{Z}$. All these conditions are also equivalent to the basic one $\mu^+(p,q) \cap \mu^-(p,q) = \phi$.

Now fix $(p,q) \in L_R^2 \times H_R^1$ and $(\tilde{p},\tilde{q}) \in L_R^2 \times H_R^1$ with $q(0) = \tilde{q}(0) = 0$. Suppose

$$\mu^+(p,q) \cap \mu^-(p,q) = \phi. \tag{4.13}$$

Also suppose that

$$\mu_j^+(p,q) = \mu_j^+(\tilde{p},\tilde{q}) \quad \text{and} \quad \mu_j^-(p,q) = \mu_j^-(\tilde{p},\tilde{q}). \tag{4.14}$$

For all $\lambda \in \mathbf{C}$, define

$$f(\lambda) = \frac{\left[\dfrac{y(x,\lambda,p,q)}{y_1(1,\lambda,p,q)} - \dfrac{y(x,\lambda,\tilde{p},\tilde{q})}{y_1(1,\lambda,\tilde{p},\tilde{q})}\right]\left[\dfrac{z(1-x,\lambda,p^*,q^*)}{y_3''(1,\lambda,p^*,q^*)} - \dfrac{z(1-x,\lambda,\tilde{p}^*,\tilde{q}^*)}{y_3''(1,\lambda,\tilde{p}^*,\tilde{q}^*)}\right]}{Y_1(1,\lambda,p,q)Z_1(1,\lambda,p,q)}. \tag{4.15}$$

The function $f(\lambda)$ is meromorphic and has simple poles at $\mu_j^+(p,q)$ and $\mu_j^-(p,q)$, $j \in \mathbf{Z}$.

For $\lambda = \mu_j^{\pm}(p,q) = \nu_j^{\pm}(p^*,q^*)$, $y(x,\lambda,p,q)$, and $\overline{z(1-x,\lambda,p^*,q^*)}$ are eigenfunctions of $L_{p,q}$ for the $DL^{\pm}$ boundary conditions. Then for some complex number $c_k^{\pm}(p,q)$,

$$\frac{y(x,\mu_j^{\pm}(p,q),p,q)}{y_1(1,\mu_j^{\pm}(p,q),p,q)} = c_j^{\pm}(p,q)\,\frac{\overline{z(1-x,\nu_j^{\pm}(p^*,q^*),p^*,q^*)}}{\overline{y_3''(1,\nu_j^{\pm}(p^*,q^*),p^*,q^*)}}. \tag{4.16}$$

Differentiate (4.16) with respect to x, then take $x = 1$, use $y'(1,\mu_j^{\pm}(p,q),p,q) = -\overline{y_1(1,\mu_j^{\pm}(p,q),p,q)}$ and $z'(0,\nu_j^{\pm}(p^*,q^*),p^*,q^*) = y_3''(1,\nu_j^{\pm}(p^*,q^*),p^*,q^*)$ to obtain

$$c_j^{\pm}(p,q) = \frac{\overline{y_1(1,\mu_j^{\pm}(p,q),p,q)}}{y_1(1,\mu_j^{\pm}(p,q),p,q)}. \tag{4.17}$$

Then (4.17) gives

$$c_j^+(p,q) = 1, \qquad c_j^-(p,q) = -1$$

$\forall j \in \mathbf{Z}$.

The computation of the residues of f is as follows. From (4.16)

$$\begin{aligned} &Res\left(f, \mu_j^+(p,q)\right) \\ &\quad = \frac{1}{(Y_1\dot{Z}_1)(1,\mu_j^+(p,q),p,q)}\left|\frac{y(x,\mu_j^+(p,q),p,q)}{y_1(1,\mu_j^+(p,q),p,q)} - \frac{y(x,\mu_j^+(\tilde{p},\tilde{q}),\tilde{p},\tilde{q})}{y_1(1,\mu_j^+(\tilde{p},\tilde{q}),\tilde{p},\tilde{q})}\right|^2 \end{aligned} \tag{4.18}$$

and

$$\begin{aligned} &Res\left(f, \mu_j^-(p,q)\right) \\ &\quad = -\frac{1}{(Z_1\dot{Y}_1)(1,\mu_j^-(p,q),p,q)}\left|\frac{y(x,\mu_j^-(p,q),p,q)}{y_1(1,\mu_j^-(p,q),p,q)} - \frac{y(x,\mu_j^-(\tilde{p},\tilde{q}),\tilde{p},\tilde{q})}{y_1(1,\mu_j^-(\tilde{p},\tilde{q}),\tilde{p},\tilde{q})}\right|^2 \end{aligned} \tag{4.19}$$

$\forall j \in \mathbf{Z}$.

Therefore (4.18), (4.19), and Lemma 4.1 give

$$\forall\, j \in \mathbf{Z}, \quad Res\left(f, \mu^+(p,q)\right) \le 0, \text{ and } Res\left(f, \mu^-(p,q)\right) \le 0. \tag{4.20}$$

Besides, the numerator $n(\lambda)$ of f is bounded from above using

$$\frac{y(x,\lambda,p,q)}{y_1(1,\lambda,p,q)} = \frac{y(x,\lambda,0,0)}{y_1(1,\lambda,0,0)} + O\left(\frac{e^{\left(|\Im m\frac{k}{2}|+|\Im m\frac{\omega k}{2}|+|\Im m\frac{\omega^2 k}{2}|\right)x}}{|k|^2}\right) \tag{4.21}$$

and

$$\begin{aligned} &\frac{z(x,\lambda,p,q)}{y_3''(1,\lambda,p,q)} + 2q(1)\frac{y_3(x,\lambda,0,0) - y_2(x,\lambda,0,0)}{y_3''(x,\lambda,0,0)} \\ &\qquad = \frac{z(x,\lambda,0,0)}{y_3''(1,\lambda,0,0)} + O\left(\frac{e^{\left(|\Im m\frac{k}{2}|+|\Im m\frac{\omega k}{2}|+|\Im m\frac{\omega^2 k}{2}|\right)x}}{|k|^2}\right). \end{aligned} \tag{4.22}$$

Identities (4.21) and (4.22) are derived using (2.24) and (2.25).

Observe that $y_1(1,\lambda,0,0)$ and $y_3''(1,\lambda,0,0)$ never vanish on $\mathbf{C}$.

From (4.21) and (4.22), if $q(1) = \tilde{q}(1)$ we have $|n(\lambda)| = O(\frac{\Xi(x,\lambda)}{|k|^2})O(\frac{\Xi(1-x,\lambda)}{|k|^2})$; thus

$$|n(\lambda)| = O\left(\frac{\Xi(1,\lambda)}{|k|^4}\right). \tag{4.23}$$

The denominator $d(\lambda)$ of $f(\lambda)$ is easily bounded from below as follows.

Combining (3.13) and (4.10) we have

$$|Y_1(1,\lambda,p,q)| \ge \frac{1}{192}\Xi(1,\lambda) \text{ for } k \in \Omega^- \text{ with } |k| > 192e^{\|(p,q)\|_{L^2_R\times H^1_R}}$$

and

$$|Z_1(1,\lambda,p,q)| \ge \frac{1}{96}\Xi(1,\lambda) \text{ for } k \in \Omega^+ \text{ with } |k| > 96e^{\|(p,q)\|_{L^2_R\times H^1_R}}.$$

Therefore,

$$|d(\lambda)| > C\Xi(1,\lambda) \text{ for } k \in \Omega^+ \cap \Omega^- \text{ with } |k| > 192e^{\|(p,q)\|_{L^2_R \times H^1_R}}, \tag{4.24}$$

where C is a fixed numerical constant.

Finally (4.23) and (4.24) prove

$$f(\lambda) = O\left(\frac{1}{|k|^4}\right) \text{ for } k \in \Omega^+ \cap \Omega^- \text{ with } |k| > 192e^{\|(p,q)\|_{L^2_R \times H^1_R}}. \tag{4.25}$$

We now conclude that the sum of the residues is zero using the classical integration contour or, equivalently (see [P-Tr, Lemma 3.2]), by proving that $\sup_{|\lambda|=r_n} |f(\lambda)| = o(1/r_n)$ as $n \to +\infty$ for an unbounded sequence of positive real number r_n. From (4.25) this condition is verified by the function f defined in (4.15) with $r_n = (n+\frac{1}{2})^3\pi^3$, n sufficiently large.

Consequently, using (4.20) all residues of f are zero. In particular, there exists a function ϕ satisfying $L_{p,q}\phi = \mu_0^+(p,q)\phi$ and $L_{\tilde{p},\tilde{q}}\phi = \mu_0^+(p,q)\phi$. Then

$$2i(q-\tilde{q})\phi' + (i(q-\tilde{q})' + (p-\tilde{p}))\,\phi = 0. \tag{4.26}$$

Multiply (4.26) by $\overline{\phi}$ and subtract ϕ multiplied by the complex conjugate of (4.26) to have

$$\left((q-\tilde{q})|\phi|^2\right)' = 0. \tag{4.27}$$

Similarly, multiply (4.26) by $\overline{\phi}$ and add to ϕ multiplied by the complex conjugate of (4.26) to obtain

$$(p-\tilde{p})|\phi|^2 = 0. \tag{4.28}$$

Using (2.2), $q(0) = \tilde{q}(0) = 0$ and the continuity of q and $\tilde{q}$, the proof follows (4.28) and (4.27). □

5. Proof of Theorem 1.2. We now prove the asymptotic behavior of $\mu_j^+(p,q)$ given in Theorem 1.2. The proof of the asymptotic behavior of $\mu_j^-(p,q)$ is similar and we will omit it.

From (2.14), (2.16), (3.11), we have

$$\begin{aligned} 0 &= Z_1(1, \mu_j^+(p,q), p, q) \\ &= Z_1(1, \mu_j^+(p,q), 0, 0) + \Im m\, c_j^1(1, \mu_j^+(p,q), p, q) + O\left(\frac{\Xi(1,k_j)}{|k_j|^2}\right), \end{aligned} \tag{5.1}$$

where $\mu_j^+(p,q) = k_j^3$. Using (2.15)

$$\begin{aligned} &c_j^1(1, \mu_j^+(p,q), p, q) \\ &= -2\int_0^1 y_1(t, \mu_j^+(p,q), 0, 0) y_3'(1-t, \mu_j^+(p,q), 0, 0) q(t)\, dt + O\left(\frac{\Xi(1,k_j)}{|k_j|^2}\right). \end{aligned} \tag{5.2}$$

Besides, for $p = q \equiv 0$, $\lambda \in \mathbf{C}$, and $x, t \in [0,1]$, it is easy to check using (2.3) that

$$3y_1(t)y_3'(x-t) = y_2(x) + y_2\left(x - t(1-\omega)\right) + y_2\left(x - t(1-\omega^2)\right). \tag{5.3}$$

Integrating by part (5.2) and using $q \in H^1$ and (5.3) at $x = 1$, we obtain

$$c_j^1(1, \mu_j^+(p,q), p, q) = -\frac{2}{3}[q] y_2(1, \mu_j^+(p,q), p, q) + O\left(\frac{\Xi(1,k_j)}{|k_j|^2}\right).$$

Then

$$\begin{aligned} &\Im m c_j^1(1, \mu_j^+(p,q), p, q) \\ &\quad = \frac{2}{9k_j}[q]\left(\cos k_j + e^{-\frac{\sqrt{3}}{2}k_j}\cos\left(\frac{k_j}{2} + \frac{2\pi}{3}\right) + e^{\frac{\sqrt{3}}{2}k_j}\cos\left(\frac{k_j}{2} - \frac{2\pi}{3}\right)\right) \\ &\quad\quad + O\left(\frac{\Xi(1,k_j)}{|k_j|^2}\right). \end{aligned} \tag{5.4}$$

Besides, using Lemma 2.1

$$\begin{aligned} Z_1(1, \mu_j^+(p,q), 0, 0) &= -\frac{4}{3}\sin\frac{k_j}{2}\left|\sin\omega\frac{k_j}{2}\right|^2 \\ &\sim -\frac{1}{3}\sin\frac{k_j}{2}e^{\frac{\sqrt{3}}{2}|k_j|}. \end{aligned} \tag{5.5}$$

The counting lemma gives $k_j = 2(\pi j + \delta_j)$ with $|\delta_j| < \pi$.

Therefore, using (5.4), (5.5), and

$$O\left(\Xi(1,k_j)\right) = O\left(e^{\frac{\sqrt{3}}{2}|k_j|}\right),$$

we obtain from (5.1)

$$\sin\delta_j = \frac{2}{3k_j}[q]\cos\left(\pm\delta_j - \frac{2\pi}{3}\right) + O\left(\frac{1}{|k_j|^2}\right). \tag{5.6}$$

The irrelevant sign before δ_j in (5.6) depends on the sign of k_j. Then $\delta_j \to 0$ as $j \to +\infty$. Furthermore,

$$\delta_j = -\frac{[q]}{3k_j} + O\left(\frac{1}{|k_j|^2}\right), \tag{5.7}$$

which completes the proof. □

ORTHOGONAL POLYNOMIALS AND THE CONSTRUCTION OF PIECEWISE POLYNOMIAL SMOOTH WAVELETS*

G. C. DONOVAN†, J. S. GERONIMO‡, AND D. P. HARDIN§

Abstract. Orthogonal polynomials are used to construct families of C^0 and C^1 orthogonal, compactly supported spline multiwavelets. These families are indexed by an integer which represents the order of approximation. We indicate how to obtain from these multiwavelet bases for $L^2[0,1]$ and present a C^2 example.

Key words. orthogonal polynomials, multiwavelets, splines

AMS subject classification. 41A15

1. Introduction.

Wavelet bases [2] for $L^2(\mathbf{R})$ have the nice property that once one of the basis functions is known the rest may be obtained by dilation and integer translation of this function. In this case the basis has one generator. Multiwavelets [1], [5], [9], [11], [13], [14], [19] are similar to wavelets except that the basis is obtained by the dilation and integer translation of several functions instead of just one. The construction of most wavelets and multiwavelets is based on multiresolution analysis (MRA) [17], [16]. Let $\phi^0, \dots, \phi^r$ be compactly supported L^2-functions, and suppose that $V_0 = \mathrm{cl}_{L^2} \operatorname{span}\{\phi^i(\cdot - j)\colon\ i = 0, 1, \dots, r,\ j \in \mathbf{Z}\}$. Then V_0 is called a *finitely generated shift invariant* (FSI) *space*. Let $(V_p)_{p\in\mathbf{Z}}$ be given by $V_p = \{\phi(2^p\cdot)\colon\ \phi \in V_0\}$. Each space V_p may be thought of as approximating L^2 at a different resolution depending on the value of p. The sequence (V_p) is called a *multiresolution analysis* generated by $\phi^0, \dots, \phi^r$ if (a) the spaces are nested, $\cdots \subset V_{-1} \subset V_0 \subset V_1 \subset \cdots$, and (b) the generators $\phi^0, \dots, \phi^r$ and their integer translates form a Riesz basis for V_0. Because of (a) and (b), we can write

$$V_{j+1} = V_j \oplus W_j \quad \forall j \in \mathbf{Z}. \tag{1.1}$$

The space W_0 is called the *wavelet space*, and if $\psi^0, \dots, \psi^r$ generate a shift-invariant basis for W_0, then these functions are called *wavelet functions*. If, in addition, $\phi^0, \dots, \phi^r$ and their integer translates form an orthogonal basis for V_0, then (V_p) is called an *orthogonal MRA*. It has been shown in Lemma 2.1 of [5] that we can always assume that ϕ^j, $j = 0, \dots, r$ can be chosen so that they are *minimally supported* on $[-1, 1]$; i.e., each scaling function has support in $[-1, 1]$, and the nonzero restrictions of the scaling functions and their integer translates to $[0, 1]$ are linearly independent. Set $\Phi = (\phi^0, \dots, \phi^r)^*$. Then (a) and (b) imply that Φ satisfies the matrix dilation equation

$$\Phi(t) = \sum C_i \Phi(2t - i). \tag{1.2}$$

In order to obtain orthogonal MRAs it is useful to divide $V_0|_{[0,1]}$ into the following subspaces:

- $A_0 = \operatorname{span}\{\phi \in \Phi\colon \ \operatorname{supp}\phi \subset [0,1]\} = \{g \in V_0\colon \ \operatorname{supp} g \subset [0,1]\}$,
- $C_0 = \operatorname{span}\{\phi(\cdot)\chi_{[0,1]}\colon \ \phi \in \Phi\} \ominus A_0$,
- $C_1 = \operatorname{span}\{\phi(\cdot - 1)\chi_{[0,1]}\colon \ \phi \in \Phi\} \ominus A_0$.

Since the functions in A_0 are orthogonal to their integer translates and by Gram–Schmidt may be made mutually orthogonal, it is not difficult to see [5] the following.

THEOREM 1.1. *(V_p) is orthogonal iff $C_0 \perp C_1$.*

In general it is not possible to obtain an orthogonal basis for V_0 by taking finite linear combinations of the original basis functions that generate it. However, we can modify V_0 by adding appropriate functions so that $C_0 \perp C_1$. The notion of intertwining MRAs arises from the observation that some functions can be moved from one level of an MRA to another without destroying the defining properties of an MRA. Suppose that (V_p) is an MRA as defined above and that W is an FSI subspace of V_1 with Riesz basis $\{\phi^{r+1}(\cdot - j)\colon \ j \in \mathbf{Z}\}$ for some compactly supported ϕ^{r+1}. With this we can generate a new space $\tilde{V}_0 = V_0 + W$ together with associated dilation spaces $\tilde{V}_p = \{\phi(2^p\cdot)\colon \ \phi \in \tilde{V}_0\}$. Then $(\tilde{V}_p)$ is also a multiresolution analysis. Indeed, it is clear that $V_0 \subset \tilde{V}_0$. It is also the case that $\tilde{V}_0 \subset V_1$, since both V_0 and W are subspaces of V_1. From these two inclusions and the definition of the dilated spaces, it follows that

$$\cdots \subset V_{-1} \subset \tilde{V}_{-1} \subset V_0 \subset \tilde{V}_0 \subset V_1 \subset \tilde{V}_1 \cdots \tag{1.3}$$

and hence

$$\cdots \subset \tilde{V}_{-1} \subset \tilde{V}_0 \subset \tilde{V}_1 \subset \cdots.$$

It is easy to see how the other conditions necessary for $(\tilde{V}_p)$ to be an MRA also follow from (1.3). Of course this process can be repeated if more functions are needed. Let $A_1 = \{\phi \in V_1\colon \ \operatorname{supp}\phi \subseteq [0,1]\}$. If $W \subset A_1 \ominus A_0$ such that $(I - P_W)C_0 \perp (I - P_W)C_1$, where P_W is the orthogonal projection onto W, then the intertwining MRA will be an orthogonal MRA. In Theorem 1 of [5] the following theorem was proved.

THEOREM 1.2. *If (V_p) is a multiresolution analysis generated by compactly supported scaling functions, then there is some pair of integers (q, n) and some orthogonal multiresolution analysis $(\tilde{V}_p)$ such that*

$$V_q \subset \tilde{V}_0 \subset V_{q+n}.$$

We call $(\tilde{V}_p)$ an *intertwining MRA* and the theorem implies in particular that for those MRAs generated by splines there exist orthogonal intertwining MRAs also generated by splines. The main results of this paper give explicit constructions of orthogonal intertwining MRAs for C^0 and C^1 spline MRAs with various orders of approximation. In this paper we will use the notation

$$f_{i,j} = 2^{i/2} f(2^i \cdot - j) \tag{1.4}$$

and $P_{\{f_1, f_2, \ldots, f_k\}}$, $f_i \in L^2(\mathbf{R})$, will denote the orthogonal projection onto the subspace spanned by $f_1, \ldots, f_k$. In section 2 we make precise which MRAs we will be studying and examine the spaces A_0, C_0, and C_1 associated with these MRAs. It is here where orthogonal polynomials play a role since the A_0 spaces for the MRAs we will be considering will be spanned by subclasses of ultraspherical polynomials (see also [18], [15], and [10]). Furthermore, we introduce the functions that will span W, which we

will "borrow" in order to construct an orthogonal intertwining MRA. These functions are chosen so as to be smooth as possible and symmetric or antisymmetric with respect to $x = \frac{1}{2}$. In section 3 we derive various properties of these functions needed to carry out the construction. In section 4 we give a description of how to construct wavelets from scaling functions. This explicit computation of the multiwavelets functions in terms of the scaling functions allows us to preserve symmetry or antisymmetry. Also indicated in this section is how to construct multiwavelet bases for $L^2[0,1]$. In section 5 we construct families of compactly supported continuous orthogonal scaling functions having an axis of symmetry. Each family is indexed by an integer which represents the order of approximation. In section 6 families of C^1 scaling functions and wavelets are constructed. Finally, in section 7, a C^2 example is given.

2. Piecewise polynomial MRA. The MRAs we will study are those associated with piecewise polynomial splines. Let S_k^n be the space of polynomial splines of degree n with C^k knots at the integers, and set $V_0^{n,k} = S_k^n \cap L^2(\mathbf{R})$. With $V_p^{n,k}$ as above it is known that these spaces form a multiresolution analysis [1], [5], [11], [19]; however, with the exception of S_{-1}^n, which were studied by Alpert, it is not possible to find compactly supported, orthogonal generators for these spaces. We will consider S_k^n when $n > 2k+1$.

In order to construct orthogonal intertwining MRAs we examine the spaces $A_0^{n,k}$, $C_0^{n,k}$, and $C_1^{n,k}$, associated with $V_0^{n,k}$ as described above, as well as $A_1^{n,k}$, defined by analogy with $A_0^{n,k}$ to be $A_1^{n,k} = \{g \in V_1\colon \operatorname{supp} g \subset [0,1]\}$. Our goal is to find a space $W \subset A_1^{n,k} \ominus A_0^{n,k}$ so that

$$(I - P_W)C_0^{n,k} \perp (I - P_W)C_1^{n,k}. \tag{2.1}$$

We begin by describing a convenient basis for $A_0^{n,k}$. Note that from the description of $A_0^{n,k}$, $g \in A_0^{n,k}$ iff $g(t) = t^{k+1}(1-t)^{k+1}q(t)$ for some polynomial q of degree at most $n-2k-2$. Thus the linear dimension of $A_0^{n,k}$ is $n-2k-1$. If $\{t^{k+1}(1-t)^{k+1}q_{j-2k-2}\colon j = 2k+2,\dots,n\}$ forms an orthogonal basis for $A_0^{n,k}$, then

$$\int_0^1 t^{2k+2}(1-t)^{2k+2}q_{i-2k-2}(t)q_{j-2k-2}(t)\,dt = c_i\delta_{i,j},$$

and we see that the q_i's are orthogonal with respect to the measure $t^{2k+2}(1-t)^{2k+2}\,dt$ on $[0,1]$. The monic ultraspherical polynomials p_i^λ are monic polynomials of degree $i = 0,1,\dots,$ which are orthogonal on $[-1,1]$ with respect to the measure $(1-t^2)^{\lambda-\frac{1}{2}}dt$ (Szegö [20]). From the above equation, we can choose $q_i(t) = p_i^{2k+\frac{5}{2}}(2t-1)$, $i = 0,\dots,n-2k-2$. This leads to ([7], [8]) the following lemma.

LEMMA 2.1. *A basis for $A_0^{n,k}$ is $\{t^{k+1}(1-t)^{k+1}p_i^{2k+\frac{5}{2}}(2t-1)\colon i = 0,\dots,n-2k-2\}$, where each $p_i^{2k+\frac{5}{2}}$ is a monic ultraspherical polynomial of degree i.*

The ultraspherical polynomials already have been used in the construction of wavelets from fractal interpolation functions (Donovan, Geronimo, and Hardin [6], Donovan [4]). For later computations we define the set $\{\phi_i^k\}$, where $\phi_i^k(t) = (1-t^2)^{k+1}p_{i-2k-2}^{2k+\frac{5}{2}}(t)$ for $i \geq 2k+2$ with $\phi_{2k+1}^k = 0$.

Some important properties of the ultraspherical polynomials that we will use later [20] follow.

(a) The Rodriguez formula:

$$(1-t^2)^m p_n^{m+\frac{1}{2}}(t) = (-1)^n \frac{(n+2m)!}{(2n+2m)!} D^n(1-t^2)^{n+m}.$$

(b) The recurrence formula:

$$p_{n+1}^{m+\frac{1}{2}}(t) = tp_n^{m+\frac{1}{2}}(t) - a_n p_{n-1}^{m+\frac{1}{2}}(t), \quad n = 1, 2, \ldots$$

with $a_n = \frac{(n+2m)n}{(2n+2m+1)(2n+2m-1)}$, $p_0(t) = 1$ and $p_1(t) = t$.

(c)

$$p_n^{m+\frac{1}{2}}(t) = \frac{1}{(n+2)(n+1)} D^2 p_{n+2}^{m-2+\frac{1}{2}}(t).$$

The polynomials also have the following useful representation in term of hypergeometric functions [20]:

$$p_n^{m+\frac{1}{2}}(t) = \frac{2^n (m+1)_n}{(n+2m+1)_n} \, {}_2F_1\left(\begin{matrix} -n & n+2m+1 \\ & m+1 \end{matrix}; \ \frac{1-t}{2}\right), \tag{2.2}$$

where formally

$${}_pF_q\left(\begin{matrix} a_1 & \ldots & a_p \\ b_1 & \ldots & b_q \end{matrix}; \ t\right) = \sum_{i=0}^{\infty} \frac{(a_1)_i \ldots (a_p)_i}{(b_1)_i \ldots (b_q)_i (1)_i} t^i$$

with $(a)_i = (a)(a+1)\ldots(a+i-1)$. Since one of the numerator parameters in the hypergeometric function in (2.2) is a negative integer, the series has finitely many nonzero terms and the result is a polynomial.

From the recurrence formula is it not difficult to see that

$$\int_{-1}^{1} p_n^{m+\frac{1}{2}}(t)^2 (1-t^2)^m dt = \frac{2(n+2m)!n!}{(2n+2m-1)!!(2n+2m+1)!!}, \tag{2.3}$$

where $m!! = m(m-2)\ldots$. Thus

$$\|\phi_n^k\|_{L^2}^2 = \frac{2(n+2k+2)!(n-2k-2)!}{(2n-1)!!(2n+1)!!}. \tag{2.4}$$

We now consider the spaces $C_i^{n,k}$, $i = 0, 1$. Since the dimension of $V_0^{n,k}|_{[0,1]}$ is $n+1$ and the dimension of $A_0^{n,k}$ is $n-2k-1$, the dimension of $C_0^{n,k}$ is $k+1$ and the same is true for $C_1^{n,k}$. For computational compatibility with the ultraspherical polynomials, we scale these spaces so that they are defined on $[-1, 1]$ instead of $[0, 1]$ and denote them as $C_i^{n,k}(\frac{\cdot+1}{2})$ and $A_0^{n,k}(\frac{\cdot+1}{2})$.

Let $r_i^k(t) = (1-t)^i(1+t)^{k+1}$, $l_i^k(t) = r_i^k(-t)$, and $P^{n,k}$ denote the orthogonal projection onto $A_0^{n,k}$. Then a basis for $C_0^{n,k}(\frac{\cdot+1}{2})$ is $r_i^{n,k} = (I - P^{n,k})r_i^k$, $i = 0, \ldots, k$, while for $C_1^{n,k}(\frac{\cdot+1}{2})$ the analogous basis is $l_i^{n,k} = (I - P^{n,k})l_i^k$. We shall refer to the families of r_i^k and l_i^k, respectively, as right and left "ramps," where right and left denote on which side of the interval $[-1, 1]$ the unprojected functions *do not* vanish $k+1$ times.

The action of the projection can be readily computed from the following inner product:

$$\langle r_i^k, \phi_n^k \rangle = \frac{2^{k+i+n+2} n!(i+k+1)!(n-k-i-2)!(n+2k+2)!}{(k-i)!(k+i+n+2)!(2n)!}, \tag{2.5}$$

where $k \geq i$ and $n \geq 2k+2$ (Gradshteyn and Ryzhik [12, p. 826]). This formula can be derived for instance by substituting (2.2) into the above inner product, integrating term by term, then using Saalschutz's formula for summing a ${}_3F_2$ hypergeometric function (Bailey [3, p. 49]). The symmetry between r_i^k and l_i^k and the fact that the ultraspherical polynomials are of definite parity imply that $\langle l_i^k, \phi_n^k \rangle = (-1)^n \langle r_i^k, \phi_n^k \rangle$.

There are several simple useful relations among the ramp functions which we now derive. The first is the obvious relation

$$r_i^{n,k} = r_i^{n-1,k} - \frac{\langle r_i^k, \phi_n^k \rangle}{\langle \phi_n^k, \phi_n^k \rangle} \phi_n^k. \tag{2.6}$$

Note that for $n \geq 2k+2$, the polynomial $r_{i+1}^{n,k}$ is uniquely determined by the order of its zeros at ± 1, its orthogonality to $A_0^{n,k}$, its degree, and its leading coefficient. The polynomial $(1-t)r_i^{n,k}$ vanishes at ± 1 the same number of times as $r_{i+1}^{n,k}$, is of degree $n+1$, and is orthogonal to $A_0^{n-1,k}$. Subtracting off ϕ_{n+1}^k times an appropriate constant then projecting out ϕ_n^k yields the following relation:

$$r_{i+1}^{n,k}(t) = (1-t)r_i^{n,k}(t) + \frac{\langle r_i^k, \phi_{n+1}^k \rangle}{\langle \phi_n^k, \phi_n^k \rangle} \phi_n^k(t) - \frac{\langle r_i^k, \phi_n^k \rangle}{\langle \phi_n^k, \phi_n^k \rangle} \phi_{n+1}^k(t). \tag{2.7}$$

Since $(1-t^2)\frac{d}{dt} r_i^k(t) = (k+1+i)r_{i+1}^k - 2ir_i^k$, an argument similar to that given above leads to

$$\begin{aligned}(1-t^2)\frac{d}{dt} r_i^{n,k}(t) = (k+1+i)r_{i+1}^{n,k} - 2ir_i^{n,k} + (n+2)\frac{\langle r_i^k, \phi_{n+1}^k \rangle}{\langle \phi_n^k, \phi_n^k \rangle} \phi_n^k(t) \\ + n\frac{\langle r_i^k, \phi_n^k \rangle}{\langle \phi_n^k, \phi_n^k \rangle} \phi_{n+1}^k(t).\end{aligned} \tag{2.8}$$

Likewise,

$$\begin{aligned}\frac{d}{dt}\big((1-t^2)r_i^{n,k}(t)\big) = (k+3+i)r_{i+1}^{n,k} - 2(i+1)r_i^{n,k} + n\frac{\langle r_i^k, \phi_{n+1}^k \rangle}{\langle \phi_n^k, \phi_n^k \rangle} \phi_n^k(t) \\ + (n+2)\frac{\langle r_i^k, \phi_n^k \rangle}{\langle \phi_n^k, \phi_n^k \rangle} \phi_{n+1}^k(t).\end{aligned} \tag{2.9}$$

Analogous formulas are easily obtained for $l_i^{n,k}$. In the multiresolution analysis given above, $V_1^{n,k}$ is a spline space with knots at the half-integers. Thus, to do the intertwining step, we will borrow from the space of splines supported on $[0,1]$ with a knot at $\frac{1}{2}$. Once again, for purposes of compatibility with the ϕ_i^k, we dilate these functions so that they are supported on $[-1,1]$ and have a knot at 0. The dilated functions will be denoted u_n^k. To construct these, we first define a sequence of spline functions $\{\bar{u}_n^k\} \in C^k(\mathbf{R})$, where

$$\bar{u}_n^k(t) = \begin{cases} 1 - |t|\, t^{n-1} + \sum_{i=1}^k \frac{(-1)^i n!!}{2^i i!\,(n-2i)!!}(1-t^2)^i & \text{if } t \in [-1,1], \\ 0 & \text{otherwise} \end{cases}$$

for odd $n \geq 2k+1$, and

$$\bar{u}_n^k(t) = \begin{cases} t - |t|\, t^{n-1} + \sum_{i=1}^k \frac{(-1)^i (n-1)!!}{2^i i!\,(n-2i-1)!!} t(1-t^2)^i & \text{if } t \in [-1,1], \\ 0 & \text{otherwise} \end{cases}$$

for even $n \geq 2k+2$. It should be noted that the parity of the function $\bar{u}_n^k$ is always the opposite of the parity of n. From this sequence, we obtain new sequences by applying the projection $I - P^{n,k}$:

$$u_{n,m}^k = (I - P^{n,k})\bar{u}_{n-m}^k.$$

The functions to be borrowed from $V_1(\frac{\cdot+1}{2})$ to give an orthogonal multiresolution analysis are obtained as appropriate linear combinations of this latter class of splines. To calculate the above projections, it is necessary to find the inner products

$$c_{k,n,j} = \int_{-1}^{1} \bar{u}_j^k(t)\phi_n^k(t)dt$$

for $n,\ j \geq 2k+1$, which are given in the following lemma.

LEMMA 2.2. *With $n, j \geq 2k+2$, if $(n-j)$ is even, then $c_{k,n,j} = 0$, and if $(n-j)$ is odd and $j > n$, then*

$$\begin{aligned} c_{k,n,j} &= \frac{-2^{\frac{n-j+4k+3}{2}}(n-2k-2)!j!(\frac{j-2k-n}{2})_{k+1}}{(n+1)_n(j-n)!!(\frac{j-2k+n-1}{2})!} \\ &\qquad \times {}_3F_2\left(\begin{matrix} -k-1 & \frac{j+2}{2} & \frac{j+1}{2} \\ \frac{j-2k-n}{2} & \frac{j-2k+n+1}{2} \end{matrix};\ 1\right), \\ &= \frac{-2^{\frac{n-j+4k+3}{2}}(\frac{n-2k}{2})_{k+1}(\frac{-2k-n-1}{2})_{k+1}(n-2k-2)!j!}{(n+1)_n(j-n)!!(\frac{j+n+1}{2})!} \\ &\qquad \times {}_3F_2\left(\begin{matrix} -k-1 & \frac{j+1}{2} & k+1 \\ & \frac{-n}{2} & \frac{n+1}{2} \end{matrix};\ 1\right), \end{aligned} \tag{2.10}$$

while if $(n-j)$ is odd and $n > j$, then

$$\begin{aligned} c_{k,n,j} &= \frac{2\,(-1)^{\frac{n-j+1}{2}+k+1}(n-2k-2)!j!(n+2k-j+1)!}{(n+1)_n(\frac{n-2k+j-1}{2})!(\frac{n-j+2k+1}{2})!} \\ &\qquad \times {}_3F_2\left(\begin{matrix} -k-1 & \frac{j+2}{2} & \frac{j+1}{2} \\ \frac{j-2k-n}{2} & \frac{j-2k+n+1}{2} \end{matrix};\ 1\right) \\ &= \frac{(-1)^{\frac{n-j+1}{2}}2^{2k+3}(\frac{n-2k}{2})_{k+1}(\frac{-2k-n-1}{2})_{k+1}\ (n-2k-2)!j!(n-j-1)!}{(n+1)_n(\frac{n+j+1}{2})!(\frac{n-j-1}{2})!} \\ &\qquad \times {}_3F_2\left(\begin{matrix} -k-1 & \frac{j+1}{2} & k+1 \\ & \frac{-n}{2} & \frac{n+1}{2} \end{matrix};\ 1\right). \end{aligned} \tag{2.11}$$

Remark. When $n = 2k+2$ the ${}_3F_2$ in the second part of (2.11) reduces to a truncated ${}_2F_1$.

Proof. The fact that $c_{k,n,j} = 0$ for $(n-j)$ even follows from the parity of $\bar{u}_j^k$ and ϕ_n^k. From property (c) above we find the $p_n^{2k+\frac{5}{2}} = \frac{n!}{(n+2k+2)!}D^{2k+2}p_{n+2k+2}^{1/2}$, where $p_n^{1/2}$ is the monic Legendre polynomial of degree n [20]. Therefore from the definition of ϕ_n^k we find that $\phi_n^k(t) = (1-t^2)^{k+1}\frac{(n-2k-2)!}{n!}D^{2k+2}p_n^{1/2}(t)$. Substitute this into the integral for $c_{m,n,j}$ and integrate by parts $2k+2$ times. Since $j \geq 2k+2$, $\bar{u}_j^k$ has $2k+1$

continuous derivatives in $(-1,1)$ and $D^i(1-t^2)^{k+1}\bar{u}_j^k = 0$ for $t = \pm 1$, $i = 0, \ldots, 2k+1$. Therefore

$$c_{k,n,j} = \frac{(n-2k-2)!}{n!}\int_{-1}^{1} D^{2k+2}[(1-t^2)^{k+1}\bar{u}_j^k(t)]p_n^{1/2}(t)dt.$$

Observe that for $i < k+1$, $D^{2k+2}(1-t^2)^{k+i+1}$ is a polynomial of degree less than $2k+2$. Consequently the orthogonality of $p_n^{1/2}$ implies that only the term $|t|t^{j-1}$ in $\bar{u}_j^k$ will be nonzero in the above integral. Using the parity of $\bar{u}_j^k$ and ϕ_n^k to integrate on $[0,1]$, then expanding $(1-t^2)^{k+1}$ and differentiating yields

$$c_{k,n,j} = -2\frac{(n-2k-2)!}{n!}\sum_{i=0}^{k+1}\binom{k+1}{i}(-1)^i\frac{(j+2i)!}{(j+2i-2k-2)!}\int_0^1 t^{j+2i-2k-2}p_n^{1/2}(t)dt.$$

With $l = j+2i-2k-2$ we find, using (2.2) with $m=0$, that

$$\begin{aligned}\int_0^1 t^l p_n^{1/2}(t)dt &= \frac{2^n n!l!}{(n+1)_n(l+1)!}{}_2F_1\left(\begin{matrix}-n & n+1\\ & l+2\end{matrix};\ \tfrac{1}{2}\right)\\ &= \frac{2^n n!l!\Gamma(\frac{l+3}{2})\Gamma(\frac{l+2}{2})}{(n+1)_n(l+1)!\Gamma(\frac{l+3+n}{2})\Gamma(\frac{l+2-n}{2})},\end{aligned}$$

where Kummer's Theorem has been used in summing the ${}_2F_1$ [3, p. 11]. If n is even, l is odd and we find

$$\frac{\Gamma(\frac{l+3+n}{2})}{\Gamma(\frac{l+3}{2})} = \frac{(\frac{l+n+3-2i}{2})_i(\frac{l+n-2i+1}{2})!}{(\frac{l+1}{2})!}$$

and

$$\frac{\Gamma(\frac{l+2}{2})}{\Gamma(\frac{l+2-n}{2})} = \frac{(\frac{l-2i+2-n}{2})_{k+1}l!!2^{\frac{j-n-l}{2}}}{(\frac{l-2i+2-n}{2})_i(j-n)!!}.$$

The above formulas and the substitutions $(j+2i)! = 2^{2i}j!(\frac{j+1}{2})_i(\frac{j+2}{2})_i$ and $(-1)^i\binom{k+1}{i} = \frac{(-k-1)_i}{(1)_i}$ yield the first line of (2.10) for n even. To obtain the second line of (2.10), use the transformation formula [3, p. 85]

$$\begin{aligned}&{}_3F_2\left(\begin{matrix}-(k+1) & a & b\\ e & f\end{matrix};\ 1\right)\\ &\quad= \frac{(e-b)_{k+1}(f-b)_{k+1}}{(e)_{k+1}(f)_{k+1}}{}_3F_2\left(\begin{matrix}-(k+1) & b & a+b-k-e-f\\ b-e-k & b-f-k\end{matrix};\ 1\right).\end{aligned}$$

To arrive at the first line of (2.11) for n odd perform manipulations similar to those described above on $\frac{\Gamma(\frac{l+3+n}{2})}{\Gamma(\frac{l+2}{2})}$ and $\frac{\Gamma(\frac{l+3}{2})}{\Gamma(\frac{l+2-n}{2})}$. The second line of (2.11) is obtained in a similar manner. □

The above formulas show that the hypergeometric functions have a fixed number of terms for fixed smoothness. Furthermore, the hypergeometric functions given in the second lines of (2.10) and (2.11) are a sum of positive terms. Any zero appearing in the denominator of the above formulas cancels with a zero in the numerator.

3. Recurrence formulas and inner products. As in the case of the ramp functions there are useful difference and differential difference equations relating the $u^k_{n,m}$'s. The spline $u^k_{n,m}$ is uniquely defined in terms of the degree of its zeros at ± 1, the $n-m-1$ continuous derivatives at zero, the values of the left and right $(n-m)$th derivatives at zero, its degree, and its orthogonality to $A_0^{n,k}$. Denoting by "rem" the remainder of integer division (i.e., $p \operatorname{rem} q \equiv q(\frac{p}{q} - \lfloor \frac{p}{q} \rfloor)$), we find from the definition of $\bar{u}^k_{n-m}$ that $t\bar{u}^k_{n-m-1} = \bar{u}^k_{n-m} + ((n-m) \operatorname{rem} 2) K_{k,n,m}(1-t^2)^{k+1}$. Furthermore, $\int_{-1}^{1} t u^k_{n-1,m}(t)\phi^k_i(t)dt = 0$ for $i \le n-2$. The recurrence formula for ϕ^k_n, the fact that $(1-t^2)^{k+1} \in A_0^{n,k}(\frac{\cdot+1}{2})$, and parity considerations now imply that for $n-m-1 \ge 2k+1$

$$u^k_{n,m} = t u^k_{n-1,m} - \epsilon_{k,n,m}\phi^k_{n-1+(m \operatorname{rem} 2)}, \tag{3.1}$$

where

$$\epsilon_{k,n,m} = \frac{c_{k,n+(m \operatorname{rem} 2),n-1-m}}{\langle \phi^k_{n-1+(m \operatorname{rem} 2)}, \phi^k_{n-1+(m \operatorname{rem} 2)} \rangle}. \tag{3.2}$$

Analogues of (2.8) and (2.9) can also be derived. To this end, note that $(1-t^2)D\bar{u}^k_{n-m} = -(n-m)\bar{u}^k_{n+1-m} + (n-m)\bar{u}^k_{n-1-m}$ and that

$$\begin{aligned} \langle (1-t^2)Du^k_{n,m}(t), \phi^k_i(t) \rangle &= \langle u^k_{n,m}(t), D\big((1-t^2)\phi^k_i(t)\big) \rangle \\ &= 0, \qquad i \le n-1 \end{aligned}$$

since $u^k_{n,m}$ is orthogonal to all functions of the form $(1-t^2)^{k+1}\pi_{n-2k-2}$, where π_{n-2k-2} is an arbitrary polynomial of degree less than or equal to $n-2k-2$. The parity of $Du^k_{n,m}$ now implies that

$$(1-t^2)Du^k_{n,m}(t) = -(n-m)u^k_{n+1,m}(t) + (n-m)u^k_{n-1,m}(t) + \delta_{k,n,m}\phi^k_{n+(m \operatorname{rem} 2)}, \tag{3.3}$$

where

$$\begin{aligned} \delta_{k,n,m} = &-(n-m)\frac{c_{k,n+(m \operatorname{rem} 2),n+1-m}}{\langle \phi^k_{n+(m \operatorname{rem} 2)}, \phi^k_{n+(m \operatorname{rem} 2)} \rangle} \\ &+ (n-1+(m \operatorname{rem} 2))\frac{c_{k,n-1+(m \operatorname{rem} 2),n-m}}{\langle \phi^k_{n-1+(m \operatorname{rem} 2)}, \phi^k_{n-1+(m \operatorname{rem} 2)} \rangle}. \end{aligned} \tag{3.4}$$

Another similar formula is

$$D\big((1-t^2)u^k_{n,m}(t)\big) = -(n-m+2)u^k_{n+1,m}(t) + (n-m)u^k_{n-1,m}(t) + \gamma_{k,n,m}\phi^k_{n+(m \operatorname{rem} 2)} \tag{3.5}$$

with

$$\begin{aligned} \gamma_{k,n,m} = &(n+1+(m \operatorname{rem} 2))\frac{c_{k,n-1+(m \operatorname{rem} 2),n-m}}{\langle \phi^k_{n-1+(m \operatorname{rem} 2)}, \phi^k_{n-1+(m \operatorname{rem} 2)} \rangle} \\ &+ (n+2-m)\frac{c_{k,n+(m \operatorname{rem} 2),n+1-m}}{\langle \phi^k_{n+(m \operatorname{rem} 2)}, \phi^k_{n+(m \operatorname{rem} 2)} \rangle}. \end{aligned} \tag{3.6}$$

One final useful formula is

$$u^k_{n,n-m} = u^k_{n-2,n-m-2} - \frac{c_{k,n-1,n-m+(m \operatorname{rem} 2)}}{\langle \phi^k_{n-1+(m \operatorname{rem} 2)}, \phi^k_{n-1+(m \operatorname{rem} 2)} \rangle}\phi^k_{n-1+(m \operatorname{rem} 2)}. \tag{3.7}$$

Note that the above formulas hold for $k \geq 0$ and $n - m \geq 2k + 3$. In order to find appropriate linear combinations of $\{u_{n,m}^k\}$ that solve (2.1) we need to compute the inner products of the various functions defined above. We begin with the following lemma.

LEMMA 3.1. *Given $r_i^{n,k}$ and $l_j^{n,k}$, $i, j \leq k$, as above,*

$$\langle r_i^{n,k}, l_j^{n,k}\rangle = \frac{(-1)^{n+1}2^{2k+i+j+3}(k+i+1)!(k+j+1)!(n-k-i-1)!(n-k-j-2)!(n+2k+3)!}{(k-i)!(k-j)!(k+n+j+3)!(k+n+i+2)!(n-2k-2)!} \times {}_3F_2\left(\begin{matrix} -(k-j) & 2k+i+j+4 & 1 \\ -(n-k-j-2) & k+n+j+4 \end{matrix}; 1\right). \tag{3.8}$$

Proof. Multiply (2.8) by $l_j^{n,k}$ and integrate by parts to find

$$-\langle r_i^{n,k}, D\big((1-t^2)l_j^{n,k}\big)\rangle = (k+1+i)\langle r_{i+1}^{n,k}, l_j^{n,k}\rangle - 2i\langle r_i^{n,k}, l_j^{n,k}\rangle + (n+2)\frac{\langle r_i^k, \phi_{n+1}^k\rangle\langle l_j^k, \phi_n^k(t)\rangle}{\langle \phi_n^k, \phi_n^k\rangle},$$

where the fact that $\langle l_j^{n,k}, \phi_{n+1}^k\rangle = \langle l_j^k, \phi_{n+1}^k\rangle$ has been used. Now eliminate $D\big((1-t^2)l_j^{n,k}\big)$ using the analogue of (2.9) for $l_j^{n,k}$ and collect terms to get

$$0 = (k+i+1)\langle r_{i+1}^{n,k}, l_j^{n,k}\rangle + 2(j+1-i)\langle r_i^{n,k}, l_j^{n,k}\rangle - (k+j+3)\langle r_i^{n,k}, l_{j+1}^{n,k}\rangle + n\frac{\langle r_i^k, \phi_n^k\rangle\langle l_j^k, \phi_{n+1}^k\rangle}{\langle \phi_n^k, \phi_n^k\rangle} + (n+2)\frac{\langle r_i^k, \phi_{n+1}^k\rangle\langle l_j^k, \phi_n^k\rangle}{\langle \phi_n^k, \phi_n^k\rangle}.$$

Multiply (2.7) by $l_j^{n,k}$ and integrate to obtain

$$\langle r_{i+1}^{n,k}, l_j^{n,k}\rangle = -\langle r_i^{n,k}, l_{j+1}^{n,k}\rangle + 2\langle r_i^{n,k}, l_j^{n,k}\rangle + \frac{\langle r_i^k, \phi_{n+1}^k\rangle\langle l_j^k, \phi_n^k\rangle}{\langle \phi_n^k, \phi_n^k\rangle} + \frac{\langle r_i^k, \phi_n^k\rangle\langle l_j^k, \phi_{n+1}^k\rangle}{\langle \phi_n^k, \phi_n^k\rangle}.$$

Using the above two equations to eliminate $\langle r_{i+1}^{n,k}, l_j^{n,k}\rangle$, solving for $\langle r_i^{n,k}, l_j^{n,k}\rangle$, and then using (2.5) gives

$$\langle r_i^{n,k}, l_j^{n,k}\rangle = \frac{(2k+i+j+3)}{2(k+j+2)}\langle r_i^{n,k}, l_{j+1}^{n,k}\rangle + \frac{(-1)^{n+1}2^{2k+i+j+3}(n+2k+3)!(k+j+1)!(k+i+1)!(n-k-j-2)!(n-k-i-1)!}{(k-j)!(k-i)!(k+j+n+3)!(k+i+n+2)!(n-2k-2)!}.$$

Iterating this formula from $j+1$ to k and utilizing the fact that l_{k+1}^k is in $A_0^{n,k}$ yields the formula

$$\langle r_i^{n,k}, l_j^{n,k}\rangle = \frac{(-1)^{n+1}2^{2k+i+j+3}(k+i+1)!(k+j+1)!(n-k-i-1)!(n+2k+3)!}{(k-i)!(k+n+i+2)!(n-2k-2)!} \times \sum_{m=0}^{k-j}\frac{(n-k-m-j-2)!(2k+i+j+4)_m}{(k-m-j)!(n+k+m+j+3)!}.$$

Finally, with the substitutions $(n+k+m+j+3)! = (n+k+j+3)!(n+k+j+4)_m$, $(a-j)! = (-1)^j\frac{a!}{(-a)_j}$, and $a \in \{k-m, n-k-m-2\}$ we obtain (3.8). ∎

An analogous argument gives

$$\begin{aligned}2(i+j+1)\langle r_i^{n,k}, r_j^{n,k}\rangle &= (k+i+1)\langle r_{i+1}^{n,k}, r_{j+1}^{n,k}\rangle + (k+j+3)\langle r_i^{n,k}, r_{j+1}^{n,k}\rangle \\ &\quad + (n+k+1+i)\frac{\langle r_i^{n,k}, \phi_n^k\rangle\langle r_j^{n,k}, \phi_{n+1}^k\rangle}{\langle \phi_n^k, \phi_n^k\rangle} \\ &\quad + (n-k-i+1)\frac{\langle r_i^{n,k}, \phi_{n+1}^k\rangle\langle r_j^{n,k}, \phi_n^k\rangle}{\langle \phi_n^k, \phi_n^k\rangle}.\end{aligned} \tag{3.9}$$

Since $\langle r_i^{n,k}, u_{n,m}^k\rangle = \langle r_i^k, u_{n,m}^k\rangle$ the following recurrence formula is easily obtained from (3.1) using the relation $r_i^k(t) = (1-t)r_{i-1}^k$:

$$\langle r_i^{n,k}, u_{n,m}^k\rangle = \langle r_i^{n-1,k}, u_{n-1,m}^k\rangle - \langle r_{i+1}^{n,k}, u_{n,m}^k\rangle + \epsilon_{k,n,m}\langle r_i^k, \phi_{n+(m \text{ rem } 2)}^k\rangle. \tag{3.10}$$

To obtain the next formula we will need the following lemma.

LEMMA 3.2. *Formally*

$$\begin{aligned}{}_3F_2\left(\begin{matrix}a & b & c\\ d & e\end{matrix};\ 1\right) &= \frac{c(e-a)}{de}{}_3F_2\left(\begin{matrix}a & b+1 & c+1\\ d+1 & e+1\end{matrix};\ 1\right) \\ &\quad + \frac{d-c}{d}{}_3F_2\left(\begin{matrix}a & b+1 & c\\ d+1 & e\end{matrix};\ 1\right).\end{aligned}$$

Proof. The proof will be based on the contiguous relations for ${}_3F_2$ hypergeometric functions found in Wilson's paper [21]. Although the proof will be formal in practice we will apply the result when one of the numerator parameters is a negative integer, in which case the series has only a finite number of nonzero terms.

Term by term subtraction yields

$${}_3F_2\left(\begin{matrix}a & b & c\\ d & e\end{matrix};\ 1\right) = \frac{bc}{de}{}_3F_2\left(\begin{matrix}a & b+1 & c+1\\ d+1 & e+1\end{matrix};\ 1\right) + {}_3F_2\left(\begin{matrix}a-1 & b & c\\ d & e\end{matrix};\ 1\right),$$

and equation 8 in [21] implies that

$$\begin{aligned}de\,{}_3F_2\left(\begin{matrix}c & d & a-1\\ & d & e\end{matrix};\ 1\right) &= c(d+e-a-b-c){}_3F_2\left(\begin{matrix}c+1 & b+1 & a\\ & d+1 & e+1\end{matrix};\ 1\right) \\ &\quad + (d-c)(e-c){}_3F_2\left(\begin{matrix}c & b+1 & a\\ d+1 & e+1\end{matrix};\ 1\right).\end{aligned}$$

Finally equation 7 in [21] gives

$$\begin{aligned}{}_3F_2\left(\begin{matrix}c & b+1 & a\\ d+1 & e+1\end{matrix};\ 1\right) &= \frac{e}{e-c}{}_3F_2\left(\begin{matrix}c & b+1 & a\\ & d+1 & e\end{matrix};\ 1\right) \\ &\quad - \frac{c}{e-c}{}_3F_2\left(\begin{matrix}c+1 & b+1 & a\\ & d+1 & e+1\end{matrix};\ 1\right).\end{aligned}$$

Utilizing the above formulas and simplifying yields the result. ∎

LEMMA 3.3. *Let $r_i^{n,k}$ and $u_{n,m}^k$ be as above. Then for $n-2m \geq 2k+1$, $k = 0, 1,$ or 2,*

$$\begin{aligned}\langle r_k^{n,k}, u_{n,2m}^k\rangle &= \frac{(-1)^{m+k}2^{2k+2-n}(n-2k-1)!(2k+1)!(n-2m)!(2m+2k)!}{(n+2k+1)!(n-k-m)!(m+k)!} \\ &\quad \times {}_3F_2\left(\begin{matrix}-k & \frac{n-2m+2}{2} & \frac{n-2m+1}{2}\\ \frac{-2m-2k+1}{2} & n-m-k+1\end{matrix};\ 1\right).\end{aligned} \tag{3.11}$$

Proof. Although this result is true more generally we will use it only for the cases indicated, which simplifies the proof considerably. The above formula can be verified by hand for $m = 0,\ k \in \{0, 1, 2\}$ and $n \in \{2k + 1, 2k + 2\}$. With m even set $i = k$ in (3.10) to obtain

$$\langle r_k^{n+1,k}, u_{n+1,m}^k\rangle = \langle r_k^{n,k}, u_{n,m}^k\rangle - \epsilon_{k,n+1,m}\langle r_k^k, \phi_{n+1}^k\rangle. \tag{3.12}$$

From (3.1) and (2.10) we find that

$$\epsilon_{k,n+1,m}\langle r_k^k, \phi_n^k\rangle = \frac{(-1)^{\frac{m}{2}+k+2}2^{2k+1-n}(n-2k-1)!(2k-3)!(n-m)!(m+2k+2)!}{(n+2k+2)!(\frac{2n-2k-m}{2})!(\frac{m+2k+2}{2})!}$$
$$\times\, {}_3F_2\left(\begin{matrix}-k-1 & \frac{n-m+2}{2} & \frac{n-m+1}{2}\\ \frac{-m-2k-1}{2} & \frac{2n-m-2k+2}{2}\end{matrix};\ 1\right).$$

Set $a = \frac{n-m+2}{2}$, $b = -k-1$, $c = a - \frac{1}{2}$, and $d = \frac{-m-2k-1}{2}$. Then the hypergeometric functions associated with $\langle r_k^{n,k}, u_{n,m}^k\rangle$, $\langle r_k^{n+1,k}, u_{n+1,m}^k\rangle$, and $\epsilon_{k,n+1,m}$ are ${}_3F_2\left(\begin{matrix}a & b+1 & c\\ d+1 & e\end{matrix};\ 1\right)$, ${}_3F_2\left(\begin{matrix}a & b+1 & c+1\\ d+1 & e+1\end{matrix};\ 1\right)$, and ${}_3F_2\left(\begin{matrix}a & b & c\\ d & e\end{matrix};\ 1\right)$, respectively. From Lemma 3.2 we find that (3.11) satisfies (3.12) for $n \geq 2k + 1 + 2m$. Multiply (3.7) by r_k^k and integrate to obtain

$$\langle r_k^{n,k}, u_{n,2m}^k\rangle = \langle r_k^{n-2,k}, u_{n-2,n-2m-2}^k\rangle - \frac{c_{k,n-1,n-2m}}{\langle \phi_{n-1}^k, \phi_{n-1}^k\rangle}\langle r_k^k, \phi_{n-1}^k\rangle. \tag{3.13}$$

Since

$$c_{k,n-1,n-2m}\frac{\langle r_k^k, \phi_{n-1}^k\rangle}{\langle \phi_{n-1}^k, \phi_{n-1}^k\rangle} = \frac{(-1)^{m+k}2^{2k-n+3}(2n-1)(2k+1)!(n-2k-3)!(2k+2m)!}{(n-2k+1)!(n-k-m-1)!(m+k)!}$$
$$\times\, {}_3F_2\left(\begin{matrix}-k-1 & \frac{n-2m+2}{2} & \frac{n-2m+1}{2}\\ \frac{-2m-2k+1}{2} & n-m-k\end{matrix};\ 1\right), \tag{3.14}$$

it is not difficult to show that (3.11) satisfies (3.13). To see this interchange d and e in Lemma 3.2, eliminate ${}_3F_2\left(\begin{matrix}a & b+1 & c+1\\ d+1 & c+1\end{matrix};\ 1\right)$ and make the substitutions $a = \frac{n-2m+2}{2}$, $b = -k-1$, $c = \frac{n-2m+1}{2}$, $d = n-m-k$, and $e = \frac{-2m-2k+1}{2}$. Now multiply by

$$\frac{(-1)^{m+k}2^{2k-n+3}(2n-1)(2k+1)!(n-2k-3)!(2k+2m)!}{(n-2k+1)!(n-k-m-1)!(m+k)!}$$

and use (3.11) and (3.14). The result follows since (3.11) satisfies (3.12), (3.13), and the initial conditions mentioned above. □

The relation

$$\langle r_i^{n,k}, u_{n,2m+1}^k\rangle = \langle r_i^{n+1,k}, u_{n+1,2m+2}^k\rangle \tag{3.15}$$

shows that we need only compute the above inner products for m even. This relation can be obtained by observing that $\bar{u}_{n-(2m+1)}^k = \bar{u}_{(n+1)-(2m+2)}^k$ and that from the parity of $\bar{u}_{n+1-2m-2}^k$, $\langle \bar{u}_{n+1-2m-2}^k, \phi_{n+1}^k\rangle = 0$. Since $l_i^k(t) = r_i^k(-t)$ the parity of $u_{n,m}^k$ implies that

$$\langle l_i^{n,k}, u_{n,m}^k\rangle = (-1)^{n+m+1}\langle r_i^{n,k}, u_{n,m}^k\rangle. \tag{3.16}$$

We finish this section by obtaining a recurrence formula for the inner products $\langle u^k_{n,j}, u^k_{n,i}\rangle$. We will do this only for i and j even since the same reasoning as above shows $\langle u^k_{n,2j+1}, u^k_{n,2i+1}\rangle = \langle u^k_{n+1,2j+2}, u^k_{n+1,2i+2}\rangle$. Set $m = 2i$ and increment n by one in (3.3). Then multiply by $u^k_{n,2j}$ and integrate by parts to get

$$\begin{aligned}&-\langle u^k_{n+1,2i}(t), D[(1-t^2)u^k_{n,2j}(t)]\rangle\\ &\quad = -(n-2i)\langle u^k_{n+2,2i}, u^k_{n,2j}\rangle + (n-2i)\langle u^k_{n,2i}, u^k_{n,2j}\rangle + \delta_{k,n+1,2i}c_{k,n+1,n-2j}.\end{aligned}$$

From (3.5) we find that the term on the left-hand side of the above equation can be eliminated, giving

$$\begin{aligned}&-(n-2j)\langle u^k_{n+1,2i}, u^k_{n-1,2j}\rangle + (n-2j+2)\langle u^k_{n+1,2i}, u^k_{n+1,2j}\rangle\\ &= -(n-2i)\langle u^k_{n+2,2i}, u^k_{n,2j}\rangle + (n-2i)\langle u^k_{n,2i}, u^k_{n,2j}\rangle + \delta_{k,n+1,2i}c_{k,n+1,n-2j}.\end{aligned}$$

Another useful equation is

$$\langle u^k_{n+2,2i}, u^k_{n,2j}\rangle = \langle u^k_{n+1,2i}, u^k_{n+1,2j}\rangle + \epsilon_{k,n+2,2i}c_{k,n+1,n-2j},$$

which can be obtained from (3.1). The above two equations can be combined to give

$$(2n-2j-2i+3)\langle u^k_{n+1,2i}, u^k_{n+1,2j}\rangle = (2n-2j-2i+1)\langle u^k_{n,2i}, u^k_{n,2j}\rangle + \kappa_{k,n,2i,2j}, \tag{3.17}$$

where

$$\kappa_{k,n,2i,2j} = (\delta_{k,n+1,2i} - (n-2i+1)\epsilon_{k,n+2,2i})c_{k,n+1,n-2j} + (n-2j)\epsilon_{k,n+1,2i}c_{k,n,n-1-2j}. \tag{3.18}$$

4. Wavelets. Before we begin the actual construction of spline wavelets some general results will be given that will help in the construction and also show how to modify the bases constructed to obtain wavelet bases for compact intervals. Let the multiresolution analysis (V_p) be generated by n orthonormal scaling functions $\phi^0, \ldots, \phi^{n-1}$ minimally supported on $[-1, 1]$, with exactly k of these functions, $\phi^0, \ldots, \phi^{k-1}$ not having support in $[0, 1]$. Then from the theory of paraunitary operators there are n orthonormal wavelet functions $\psi^0, \ldots, \psi^{n-1}$, which we may assume are also minimally supported on $[-1, 1]$. Below, we give a method for constructing the wavelet functions from the scaling functions. In the case of symmetric or antisymmetric scaling functions, this method allows the construction of symmetric or antisymmetric wavelet functions.

Using the notation given in (1.4), define $Q_0 = \operatorname{span}\{\phi^0, \ldots, \phi^{k-1}\}$, $Q_1 = \operatorname{span}\{\phi^0_{1,0}, \ldots, \phi^{k-1}_{1,0}\}$, $Y = Q_0 \cap Q_1$, and $\dim Y = m$. Also, let $Y_0 = Q_0\chi_{[-1,0]} \cap Q_1\chi_{[-1,0]}$ and $Y_1 = Q_0\chi_{[0,1]} \cap Q_1\chi_{[0,1]}$ with dimensions m_0 and m_1, respectively.

LEMMA 4.1. *The number of wavelet functions ψ^j such that $P_{Q_1}\psi^j \neq 0$ is at least $k - m$.*

Proof. Suppose that there are $\hat{k} < k - m$ such wavelet functions $\psi^0, \ldots, \psi^{\hat{k}-1}$. Suppose then that $v \in Q_1 \ominus Y$ is chosen to have unit length and to be orthogonal to $P_{Q_1}\operatorname{span}\{\psi^0, \ldots, \psi^{\hat{k}-1}\}$. Such a choice is possible because $Q_1 \ominus Y$ has $k - m$ dimensions while $P_{Q_1}\operatorname{span}\{\psi^0, \ldots, \psi^{\hat{k}-1}\}$ has at most $\hat{k}$ dimensions. Let $y = (I - P_{Q_0})v \in V_1 \ominus V_0$. Since $\operatorname{span}\{\phi^k, \ldots, \phi^{n-1}\} \perp Q_1$, (1.1) implies that $y \in W_0$.

On the other hand, we claim that y cannot be written as a linear combination of the wavelet functions. Indeed, suppose y can be expressed as a linear combination of

wavelet functions. Then in particular $P_{Q_1}y$ must be in $P_{Q_1}\text{span}\{\psi^0,\dots,\psi^{\hat{k}-1}\}$ and hence orthogonal to v. That is,

$$\begin{aligned}0 &= P_v P_{Q_1} y\\ &= P_v P_{Q_1}(I - P_{Q_0})v\\ &= P_v(P_{Q_1} - P_{Q_1}P_{Q_0})v\\ &= P_v(v - P_{Q_1}P_{Q_0}v)\\ &= v - P_v P_{Q_1}P_{Q_0}v\end{aligned}$$

or

$$v = P_v P_{Q_1} P_{Q_0} v.$$

Because these projections are orthogonal, the above equality is possible only if $v \in Q_0$, which is not the case since $v \in Q_1 \ominus Y$. □

LEMMA 4.2. *The number of wavelet functions not supported on* $[0,1]$ *is at least* $j = 2k - m_0 - m_1$.

Proof. Suppose that there are fewer than j such wavelet functions. By the above lemma, there must be at least $k-m$ of them, whose span will be denoted by Ψ^{s}, such that $P_{Q_1}\psi \neq 0$ for $\psi \in \Psi^{\text{s}} \setminus \{0\}$. In addition, there are $\hat{\jmath} < k - m_0 - m_1 + m$ others, spanning Ψ^{a}. We assume that Ψ^{s} has exactly $k-m$ dimensions and $P_{Q_1}\Psi^{\text{a}} = \{0\}$. Since every wavelet function is orthogonal to the generators of V_0,

$$P_{Q_1}(\Psi^{\text{s}} \oplus \Psi^{\text{a}}) = P_{Q_1 \ominus Y}(\Psi^{\text{s}} \oplus \Psi^{\text{a}}),$$

where $Q_1 \ominus Y$ has at most $k-m$ dimensions. Thus, by taking linear combinations if necessary, one can always arrange for this assumption to be correct. Let Ψ^1 be the span of the remaining wavelets supported on $[0,1]$.

We begin by defining the following five spaces:

$$\begin{aligned}T &= (I - P_{Q_1})Q_0,\\ T_0 &= \{t \in T\colon\ \text{supp}\, t \subset [-1,0]\},\\ T_1 &= \{t \in T\colon\ \text{supp}\, t \subset [0,1]\},\\ U &= T \ominus T_0 \ominus T_1,\\ Z &= (\chi_{[0,1]} - \chi_{[-1,0]})U\end{aligned}$$

for which the dimensions are $k-m$, m_0-m, m_1-m, $k-m_0-m_1+m$, and $k-m_0-m_1+m$, respectively. Note that since $U \perp Q_1$, multiplying by characteristic functions to construct Z does not destroy the membership of these functions in V_1. Also, since the supports of T_0 and T_1 are $[-1,0]$ and $[0,1]$, it follows that these spaces are orthogonal to U on each of said intervals and thus are orthogonal to Z.

Next, we observe that $Q_0 \oplus \Psi^{\text{s}} = T \oplus Q_1$. It is easy to show that both spaces have dimension $2k-m$. Furthermore, $T \oplus Q_1 = Q_0 + Q_1 \subset Q_0 \oplus \Psi^{\text{s}}$ because among the wavelet functions and their translates, only those in Ψ^{s} are not orthogonal to Q_1.

Now, by its construction, Z is orthogonal to any translates of Ψ^1 as well as nonzero translates of Ψ^{s}, Ψ^{a}, and Q_0. It is also orthogonal to arbitrary translates of the scaling functions supported on $[0,1]$. However, $Z \subset V_1$, so we have

$$\begin{aligned}Z &\subset Q_0 \oplus \Psi^{\text{s}} \oplus \Psi^{\text{a}}\\ &= T \oplus Q_1 \oplus \Psi^{\text{a}}\\ &= U \oplus T_0 \oplus T_1 \oplus Q_1 \oplus \Psi^{\text{a}},\end{aligned}$$

and since $Z \perp T_0 \oplus T_1 \oplus Q_1$, it follows that

$$Z \subset U \oplus \Psi^{\mathrm{a}}.$$

But Z has more dimensions than Ψ^{a}, so there exists a nonzero $z \in Z$ which is also in U. By the definition of Z, there is some $u \in U$ such that $(\chi_{[0,1]} - \chi_{[-1,0]})u = z$. Finally, consider the function $x = u + z$. Since both u and z are in U, we know that $x \in U \perp T_1$. On the other hand, $x \in U \subset T$, and clearly $\operatorname{supp} x \subset [0,1]$, so $x \in T_1$. The only way for both of these to be true is to have $x = 0$, which yields a contradiction. ∎

For the scaling vectors constructed in the next section, we find that $m_0 = m_1 = m = 0$. In this event we have the following corollary.

COROLLARY 4.3. *If $m_0 = m_1 = m = 0$, then the number of wavelet functions not supported on $[0,1]$ is at least $2k$.*

From the above lemmas we have the following theorem.

THEOREM 4.4. *Let the multiresolution analysis (V_p) be generated by n orthonormal scaling functions $\phi^0, \ldots, \phi^{n-1}$ minimally supported on $[-1,1]$. Let k, m, m_0, and m_1 be defined as above. Then there exists n orthonormal wavelet functions $\psi^0, \ldots, \psi^{n-1}$ minimally supported on $[-1,1]$ such that exactly $2k - m_0 - m_1$ are not supported in $[0,1]$.*

Proof. As indicated above, $k - m$ wavelets Ψ^{s} not supported in $[0,1]$ may be constructed as an orthonormal basis for $(I - P_{Q_0})Q_1$ since this basis is in V_1 and is orthogonal to V_0. We construct $k - m_0 - m_1 + m$ more functions in the following way. As indicated in Lemma 4.2, Z is orthogonal to $V_0 \ominus \big(Q_0 \ominus (Q_0 \cap Q_1)\big)$ as well as any wavelet functions supported on $[0,1]$. Thus the wavelet functions we seek are found by taking an orthonormal basis for $\operatorname{span}(I - P_{Q_0 \cup \Psi^{\mathrm{s}}})Z$.

We now show that the remaining $n - 2k + m_0 + m_1$ may be chosen so that they are supported in $[0,1]$. Since the dimensions of A_0 and A_1 are $n-k$ and $2n-k$, respectively, $A_1 \ominus A_0$ is n-dimensional. From this space we select a subspace K perpendicular to $\{\phi^i|_{[0,1]}\}_{i=0}^{k-1}$ and $\{\phi^i(\cdot - 1)|_{[0,1]}\}_{i=0}^{k-1}$. The dimension of this space will determine the maximum number of wavelets with support contained in $[0,1]$. If after an appropriate change of basis $\phi^0|_{[0,1]}$ is in Y_0, then ϕ^0 is perpendicular to $A_1 \ominus A_0$. Thus K needs to be chosen perpendicular only to a $(k-1)$-dimensional subspace of $\operatorname{span}\{\phi^i|_{[0,1]}\}_{i=1}^{k-1}$ and a k-dimensional subspace of $\operatorname{span}\{\phi^i(\cdot - 1)|_{[0,1]}\}_{i=0}^{k-1}$. Proceeding in this way we find that the dimension of K is $n - 2k + m_0 + m_1$, which completes the proof. ∎

Suppose Φ is a set of n scaling functions all supported on $[-1,1]$ and let Ψ be a set of wavelet functions constructed as above. Since the wavelet functions are all supported on $[-1,1]$ they satisfy the following equation:

$$\Psi(t) = \sum_{i=-2}^{1} D_i \Phi(2t - i), \tag{4.1}$$

where each D_i is an $n \times n$ matrix.

The above decomposition of the wavelet basis allows a description of how to obtain a basis when the multiresolution analysis is restricted to $[0,1]$. To this end let Ψ^{s}, Ψ^{a}, and Ψ^1 be as above and set $\Psi_{n,j} = \Psi(2^n \cdot - j)$.

THEOREM 4.5. *Let the multiresolution analysis (V_p) be generated by orthogonal scaling functions $\Phi = \{\phi^0, \ldots, \phi^{n-1}\}$, minimally supported on $[-1,1]$, and let k, m, m_0, and m_1 be defined as above. If $\Phi\chi_{[0,1]}$ is an orthogonal set, then for $q \geq 0$ $\{\phi^i_{q,j}\chi_{[0,1]}\colon\ i = 0, \ldots, n-1,\ j = 0, \ldots, 2^q\} \backslash \{0\}$ is an orthogonal basis for $\bar{V}_q = V_q\chi_{[0,1]}$.*

Furthermore, there exist orthogonal bases

$$\bar{\Psi}_q = \left(\bigcup_{j=0}^{2^q-1} \Psi^1_{q,j} \cup \bigcup_{j=0}^{2^q} \Psi^2_{q,j} \cup \bigcup_{j=0}^{2^q-1} \Psi^3_{q,j} \cup \bigcup_{j=1}^{2^q} \Psi^4_{q,j} \cup \bigcup_{j=1}^{2^q-1} \Psi^5_{q,j} \right) \chi_{[0,1]} \tag{4.2}$$

for the wavelet spaces $\bar{W}_q = W_q\chi_{[0,1]}$ *such that* $\bar{V}_0 \oplus \bigoplus_{q\geq 0} \bar{W}_q = L^2[0,1]$.

Proof. First note that if $\Phi\chi_{[0,1]}$ is orthogonal, then $\Phi\chi_{[-1,0]}$ is as well. From this it is easy to see that $\{\phi^i_{q,j}\chi_{[0,1]}\colon\ i = 0,\dots,n-1,\ j = 0,\dots,2^q\} \setminus \{0\}$ is an orthogonal basis for $\bar{V}_q$.

Now, for the wavelet spaces, we know that $\bar{W}_q = \bar{V}_{q+1} \ominus \bar{V}_q$. Thus, if $\bar{\Psi}$ is any orthogonal basis for $\Psi^{\mathrm{a}} \oplus \Psi^{\mathrm{s}}$, a basis for $\bar{W}_q$ may include

$$\bigcup_{j=0}^{2^q-1} \Psi^1_{q,j} \cup \bigcup_{j=1}^{2^q-1} \bar{\Psi}_{q,j}.$$

To complete the basis, however, it is necessary to see what happens near the ends of the interval $[0,1]$ and to choose a suitable $\bar{\Psi}$.

Consider first the left endpoint. Since the remaining basis functions must be orthogonal to those given above as well as the generators for $\bar{V}_q$, it is clear that they must be obtained from span $\bar{\Psi}_{q,0}$ by truncation to the interval $[0,1]$. In addition, they must be orthogonal to $\Phi_{q,0}\chi_{[0,1]}$. The number of functions needed can be found by counting the dimensions associated with their support and subtracting the number of orthogonality restrictions. For the former, note that $q \geq 0$ $\bar{\Psi}_{q,0}\chi_{[0,1]} \subset \operatorname{span}(\Phi_{q+1,0}\chi_{[0,1]} \cup \Phi_{q+1,1})$, a $2n$-dimensional space. For the latter, note that these functions must be orthogonal to $\operatorname{span}(\Phi_{q,0}\chi_{[0,1]} \cup \Psi^1_{q,0})$, which has $2n-2k+m_0+m_1$ dimensions, as well as a $(k-m_0)$-dimensional subspace of span $\Phi_{q,1}$. Thus $2n-(2n-2k+m_0+m_1)-(k-m_0) = k-m_1$ wavelet functions are required to complete the basis on the left. Similar arguments show that there are $k-m_0$ on the right and that these two groups have $\hat{k} = \max\{k-m_0-m_1, 0\}$ functions in common (before truncation). We remark that while it is unusual for an MRA to have nonzero m, m_0, or m_1, it is even more unusual, but still possible, to have $k-m_0-m_1 < 0$.

Finally, we choose $\bar{\Psi}$ so that it can be partitioned into four sets:

- Ψ^2, with $\hat{k}$ functions used on both ends,
- Ψ^3, with $k-m_1-\hat{k}$ functions used only on the left,
- Ψ^4, with $k-m_0-\hat{k}$ functions used only on the right, and
- Ψ^5, with $\hat{k}$ functions not used on either end.

With Ψ^2, Ψ^3, Ψ^4, and Ψ^5 defined in this fashion, (4.2) gives an orthogonal basis for $\bar{W}_q$. ∎

5. Construction of continuous spline wavelets. We now set $k = 0$ so that S^n_0 is the space of piecewise C^0 polynomials with knots at the integers and $V^{n,0}_0 = S^n_0 \cap L^2(\mathbf{R})$. By Lemma 2.1, $\{\phi^0_2,\dots,\phi^0_n\}$ forms an orthogonal basis for $A^{n,0}_0(\frac{\cdot+1}{2})$, where $\phi^0_n(t) = (1-t^2)p^{5/2}_{n-2}(t)$. In this case $r^0_0(t) = 1+t$ while $l^0_0(t) = 1-t$, and $C^{n,0}_0(\frac{\cdot+1}{2})$ and $C^{n,0}_1(\frac{\cdot+1}{2})$ are each one dimensional. Hence from Theorem 1.1 we see that an orthogonal intertwining MRA can be constructed if we can find a function $w \in A^{n,0}_1(\frac{\cdot+1}{2}) \ominus A^{n,0}_0(\frac{\cdot+1}{2})$ satisfying $\langle (I-P_w)r^{n,0}_0, (I-P_w)l^{n,0}_0\rangle = 0$, which for nonzero w is equivalent to

$$\langle r^{n,0}_0, l^{n,0}_0\rangle\langle w,w\rangle = \langle r^{n,0}_0, w\rangle\langle w, l^{n,0}_0\rangle. \tag{5.1}$$

As a member of $A_0^{n,0}(\frac{\cdot+1}{2})$, w must be a spline of degree n with knots at the integers. Since we would like to construct wavelets that are symmetric or antisymmetric we shall choose w so that it is symmetric or antisymmetric and also so that the knot at zero is as smooth as possible. Since the dimension of the space of piecewise polynomial functions in $A_1^{n,0}(\frac{\cdot+1}{2}) \ominus A_0^{n,0}(\frac{\cdot+1}{2})$ that are C^{n-2} at zero is two, there exists a basis x_1, x_2 for this space where x_1 is symmetric and x_2 is antisymmetric (one of them being a multiple of $u_{n,0}$). Thus if we wish to find a symmetric or antisymmetric w satisfying (5.1), it will be at most C^{n-3} at zero. Naturally, if symmetry is not important, a smoother w may be constructed from the space spanned by x_1 and x_2. Because of (5.3) below we see that w must be chosen having the same parity as $(-1)^{n+1}$. Thus for symmetry and the greatest possible smoothness we are forced to choose

$$w_n^0 = \alpha_0(n) u_{n,0}^0 + u_{n,2}^0 \tag{5.2}$$

for $n \geq 3$. From (3.8), (3.11), and (3.16) we have

$$\langle r_0^{n,0}, l_0^{n,0} \rangle = \frac{(-1)^{n+1} 8}{(n+2)(n+1)n}, \tag{5.3}$$

$$\langle r_0^{n,0}, u_{n,2m}^0 \rangle = \frac{(-1)^m (n-1)!(n-2m)!(2m)!}{2^{n-2}(n+1)!(n-m)!(m)!}, \tag{5.4}$$

and

$$\langle l_0^{n,0}, u_{n,m}^0 \rangle = (-1)^{m+n+1} \langle r_0^{n,0}, u_{n,m}^0 \rangle. \tag{5.5}$$

Also from (3.9) we find

$$\langle r_0^{n,0}, r_0^{n,0} \rangle = (n+1) \frac{\langle r_0^0, \phi_n^0 \rangle \langle r_0^0, \phi_{n+1}^0 \rangle}{\langle \phi_n^0, \phi_n^0 \rangle} = \frac{8}{n(n+2)}. \tag{5.6}$$

With this (5.1) becomes

$$\begin{aligned} 0 = &\begin{vmatrix} \langle u_{n,0}^0, u_{n,0}^0 \rangle & \langle r_0^{n,0}, u_{n,0}^0 \rangle \\ \langle r_0^{n,0}, u_{n,0}^0 \rangle & |\langle r_0^{n,0}, l_0^{n,0} \rangle| \end{vmatrix} \alpha_0(n)^2 + 2 \begin{vmatrix} \langle u_{n,0}^0, u_{n,2}^0 \rangle & \langle r_0^{n,0}, u_{n,2}^0 \rangle \\ \langle r_0^{n,0}, u_{n,0}^0 \rangle & |\langle r_0^{n,0}, l_0^{n,0} \rangle| \end{vmatrix} \alpha_0(n) \\ &+ \begin{vmatrix} \langle u_{n,2}^0, u_{n,2}^0 \rangle & \langle r_0^{n,0}, u_{n,2}^0 \rangle \\ \langle r_0^{n,0}, u_{n,2}^0 \rangle & |\langle r_0^{n,0}, l_0^{n,0} \rangle| \end{vmatrix}, \end{aligned} \tag{5.7}$$

where we have used the sign structure of (5.3) and (5.5). In order to find solutions to this equation we need the following formula, for $n \geq 2\max\{i,j\}+1$ with $i,j \in \{0,2\}$:

$$\langle u_{n,2i}^0, u_{n,2j}^0 \rangle = \frac{(-1)^{i+j}(n-2i)!(n-2j)!(2i)!(2j)!(n-1)!(n^2+5n+2-2i-2j)}{2^{2n-1} i!j!(n-i)!(n-j)!(n+1)!(2n+1-2i-2j)}. \tag{5.8}$$

For the cases $n > 2\max\{i,j\}+1$ the above formula follows by induction using (3.17) with

$$\kappa_{0,n,2i,2j} = \frac{(-1)^{i+j+1}(2i)!(2j)!(n-2i)!(n-2j)!(n-1)!}{2(2n-1)i!j!(n+1-i)!(n+1-j)!(n+2)!} \Pi_n,$$

where

$$\begin{aligned} \Pi_n = &3n^5 + (27-i-j)n^4 + (85-14(i+j))n^3 + (117-51(i+j)+2(i+j)^2)n^2 \\ &+ (72-62(i+j)+10(i^2+j^2)+24ij)n \\ &+ 16 - 24(i+j) - 4ij(i+j) + 20ij + 8(i^2+j^2), \end{aligned}$$

as well as the initial conditions $\langle u^0_{2,0}, u^0_{2,0}\rangle = \frac{1}{15}$, $\langle u^0_{4,2}, u^0_{4,0}\rangle = -\frac{17}{13440}$, and $\langle u^0_{4,2}, u^0_{4,2}\rangle = \frac{1}{960}$. For $n = 3, i = 0, j = 1$ and $n = 3, i = 1, j = 1$ (5.8) can be verified by hand.

Substituting the above formulas into (5.7) and solving for $\alpha_0(n)$ yields two solutions,

$$\alpha_0(n) = 2\frac{\frac{(n-2)(2n+1)}{(n-1)} \pm 2\sqrt{3}\sqrt{\frac{(2n+1)(n+1)}{(2n-3)(n-1)}}}{n(2n-1)}, \tag{5.9}$$

either of which will suffice to give w as in (5.2). This w is then used to construct orthogonal the scaling functions. For $j = 2, \ldots, n$, set

$$\tilde{\phi}^j = \begin{cases} \phi^0_j(2\cdot - 1) & \text{if } t \in [0,1), \\ 0 & \text{otherwise,} \end{cases}$$

$$\tilde{\phi}^1 = \begin{cases} w(2\cdot - 1) & \text{if } t \in [0,1), \\ 0 & \text{otherwise,} \end{cases}$$

and $\tilde{\phi}^0 = (I - P_{\{\tilde{\phi}^1, \ldots, \tilde{\phi}^n, \tilde{\phi}^1(\cdot+1), \ldots, \tilde{\phi}^n(\cdot+1)\}})h$, where

$$h(t) = \begin{cases} (1 - |t|) & \text{if } t \in [-1,1), \\ 0 & \text{otherwise,} \end{cases}$$

where P_x is the orthogonal projection onto the subspace spanned by x.

THEOREM 5.1 (see [7], [8]). *For $n \geq 3$ and $\alpha_0(n)$ given by* (5.9), $\tilde{\Phi} = \{\tilde{\phi}^0, \ldots, \tilde{\phi}^n\}^\top$ *generates an orthogonal multiresolution analysis $\{\tilde{V}^{n,0}_k\}$. Furthermore, the last n functions are symmetric or antisymmetric about $\frac{1}{2}$ while the first function is symmetric about* 0.

Proof. Since $V^{n,0}_0 = \mathrm{cl}_{L^2}\,\mathrm{span}\{h(\cdot - i), \tilde{\phi}^2(\cdot - i), \ldots, \tilde{\phi}^n(\cdot - i)\ \forall i \in \mathbf{Z}\}$ and $\tilde{V}^{n,0}_0 = \mathrm{cl}_{L^2}\,\mathrm{span}\{\tilde{\phi}^0(\cdot - i), \ldots, \tilde{\phi}^n(\cdot - i)\ \forall i \in \mathbf{Z}\}$ we find that $V^{n,0}_0 \subset \tilde{V}^{n,0}_0$. The result now follows from the above construction.

Remark. As we have shown, the generators of $\tilde{\Phi}$ are the smoothest functions derived from Φ having the support, symmetry, and orthogonality properties indicated above.

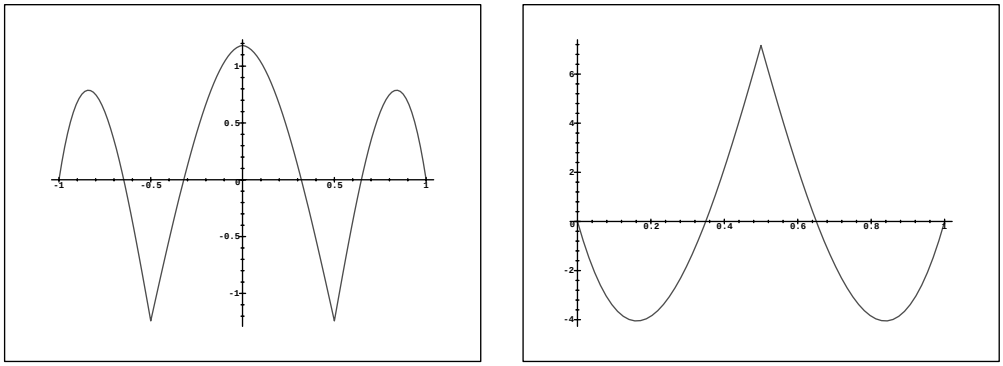
With the scaling functions above we may now construct the coefficients $C^0_{n,i}$, $i = -2, -1, 0, 1$ in the matrix refinement equation. In light of Theorem 4.4, two of the wavelets will not be supported only in $[0,1]$ while the remaining $n - 1$ will be supported on $[0,1]$. In particular, the following holds.

COROLLARY 5.2. *Let*

$$\tilde{\psi}^0 = \sqrt{2}(I - P_{\tilde{\phi}^0})\tilde{\phi}^0_{1,0},$$
$$\tilde{\psi}^1 = \sqrt{2}(\chi_{[0,1]} - \chi_{[-1,0]})(I - P_{\tilde{\phi}^0_{1,0}})\tilde{\phi}^0,$$

and $\{\tilde{\psi}^i\colon\ i = 2, \ldots, n\}$ be an orthonormal basis for Ψ^1 consisting of functions that are symmetric or antisymmetric with respect to $\frac{1}{2}$. Then $\{\tilde{\psi}^0, \ldots, \tilde{\psi}^n\}$ generates a shift-invariant orthonormal basis for W_0. Furthermore, $\tilde{\psi}^0(0) = \tilde{\phi}^0(0)$.

Proof. Up to the constants, the formulas for $\tilde{\psi}^0$ and $\tilde{\psi}^1$ follow directly from Theorem 4.4. It is true in general that $\langle \tilde{\phi}^0, \tilde{\phi}^0_{0,1}\rangle = \frac{1}{\sqrt{2}}$, and hence the normalization factors for both $\tilde{\psi}^0$ and $\tilde{\psi}^1$ are as shown. To see why this is the case, observe that $\tilde{\phi}^0_{1,0}$ is the only generator of V_1 that does not vanish at 0, and $\tilde{\phi}^0_{1,0}(0) = \sqrt{2}\phi^0(0)$. It is also for this reason that $\tilde{\psi}^0(0) = \tilde{\phi}^0(0)$.



$\tilde{\phi}^0$ $\tilde{\phi}^1$

FIG. 1. *Selected C_0 scaling functions with approximation order 4 ($n = 3$).*

TABLE 1
Formulas for the scaling functions.

$$\tilde{\phi}^0(t) = \begin{cases} \frac{\sqrt{30}\sqrt{327+56\sqrt{14}}(1855-256\sqrt{14})}{25235210}(2002t^3 - (645\sqrt{14}+658)t^2 & \\ \quad -(1106-285\sqrt{14})t + 322 - 16\sqrt{14}) & \text{for } 0 \le t < \frac{1}{2} \\ \frac{\sqrt{30}\sqrt{327+56\sqrt{14}}(-6433+1040\sqrt{14})}{25235210}(20818t^2 + (1835\sqrt{14}-17024)t & \\ \quad +2254 - 1176\sqrt{14})(t-1) & \\ & \text{for } \frac{1}{2} \le t \le 1 \\ \tilde{\phi}^0(-t) & \text{for } -1 \le t < 0 \\ 0 & \text{elsewhere} \end{cases}$$

$$\tilde{\phi}^1(t) = \begin{cases} \frac{3\sqrt{15}(\sqrt{7}+21\sqrt{2})}{1750}(280t^2 - (75\sqrt{14}+665)t + 322 + 54\sqrt{14})t & \text{for } 0 \le t \le \frac{1}{2} \\ \tilde{\phi}^1(1-t) & \text{for } \frac{1}{2} < t \le 1 \\ 0 & \text{elsewhere} \end{cases}$$

$$\tilde{\phi}^2(t) = \sqrt{30}t(1-t)\chi_{[0,1]}$$

$$\tilde{\phi}^3(t) = \sqrt{210}t(1-t)(2t-1)\chi_{[0,1]}$$

In the examples given by Theorem 5.1, Ψ^1 is symmetrical about $\frac{1}{2}$, and hence it must have an orthonormal basis consisting of symmetrical and antisymmetrical functions. □

An example is given in Figure 1, where the minus sign is chosen in (5.9), and the analytic formulas associated with this example can be found in Table 1.[1] The wavelets with support $[-1, 1]$ may be computed using Corollary 5.2 while those supported in $[0, 1]$ can be obtained by finding $n-1$ orthogonal functions, symmetrical or antisymmetrical with respect to $\frac{1}{2}$, from the space $(I - P_{\{\tilde{\phi}^0, \tilde{\phi}^0(\cdot-1)\}})A_1^{n,0} \ominus A_0^{n,0}$. The matrix coefficients in the refinement equation for the scaling function may be easily calculated using the orthogonality of these functions. This also holds for the matrix coefficients in the expansion for the wavelets.

As a final remark to this section we note that because of the symmetry of the scaling functions and wavelets, these bases can easily be modified to bases for compact intervals. Using the notation $\tilde{\phi}^i_{k,j}(x) = \tilde{\phi}^i(2^k x - j)$, let $\bar{\phi}^i_{k,j} = \tilde{\phi}^i_{k,j}|_{[0,1]}$, $\bar{\psi}^m_{k,j} = \tilde{\psi}^m_{k,j}|_{[0,1]}$

[1] Wavelets and the matrices in the refinement equation for this and other examples can be found at www.math.gatech.edu/∼geronimo.

for $m \neq 1$, and

$$\bar{\psi}^1_{k,j} = \begin{cases} 0 & \text{if } \operatorname{supp} \tilde{\psi}^1_{k,j} \cap [0,1]^c \neq \emptyset, \\ \tilde{\psi}^1_{k,j} & \text{otherwise;} \end{cases}$$

we find the following theorem.

THEOREM 5.3. *The set* $\{\bar{\phi}^i_{k,j}\colon\ k \geq 0,\ i = 1, \ldots, n,\ 0 \leq j \leq 2^k - 1 + \delta_{0,i}\}$ *is an orthogonal basis for* $\bar{V}^{n,0}_k = \tilde{V}^{n,0}_k \cap L^2[0,1]$ *while* $\{\bar{\psi}^i_{k,j}\colon\ k \geq 0,\ i = 1, \ldots, n,\ \delta_{1,i} \leq j \leq 2^k - 1 + \delta_{0,i}\}$ *forms an orthogonal basis for* $\bar{W}^{n,0}_k = \tilde{W}^{n,0}_k \cap L^2[0,1]$. *Furthermore,* $\operatorname{cl}_{L^2} \bar{V}^{n,0}_0 \oplus \bigoplus_{k \geq 0} \bar{W}^{n,0}_k = L^2[0,1]$.

6. Construction of differentiable spline wavelets. For differentiable splines, we take $k = 1$ and consider the space $V^{n,0}_1 = S^n_1 \cap L^2(\mathbf{R})$. Lemma 2.1 says that $\{\phi^1_4, \ldots, \phi^1_n\}$ forms an orthogonal basis for $A^{n,1}_0(\frac{\cdot+1}{2})$, where $\phi^1_n(t) = (1-t^2)^2 p^{9/2}_{n-4}(t)$. In this case we have $r^1_i(t) = (1+t)^2(1-t)^i$ and $l^1_i(t) = (1-t)^2(1+t)^i$, $i = 0, 1$. The spaces $C^{n,1}_0(\frac{\cdot+1}{2})$ and $C^{n,1}_1(\frac{\cdot+1}{2})$ are each two dimensional. Hence from Theorem 1.1 we see that an orthogonal intertwining MRA can be constructed if we can find two functions $w_1, w_2 \in A^{n,1}_1(\frac{\cdot+1}{2}) \ominus A^{n,1}_0(\frac{\cdot+1}{2})$ such that

$$\langle (I - P_{\{w_1,w_2\}}) r^{n,1}_i, (I - P_{\{w_1,w_2\}}) l^{n,1}_j \rangle = 0,\ i \leq j = 0, 1. \tag{6.1}$$

In order to construct scaling functions with a symmetry axis one of these functions will be constructed symmetric and the other antisymmetric. From (3.8) we find

$$\langle r^{n,1}_0, l^{n,1}_0 \rangle = \frac{128(-1)^{n+1}(n^2+2n-9)(n-2)!}{(n+3)!}, \tag{6.2}$$

$$\langle r^{n,1}_0, l^{n,1}_1 \rangle = \frac{768(-1)^{n+1}(n-2)!}{(n+3)!},$$

and

$$\langle r^{n,1}_1, l^{n,1}_1 \rangle = \frac{4608(-1)^{n+1}(n-3)!}{(n+4)!}. \tag{6.3}$$

With $k = 1$, (3.11) yields

$$\begin{aligned} \langle r^{n,1}_1, u^1_{n,2m} \rangle &= \langle r_{n,1}, u^1_{n,2m} \rangle \\ &= \frac{3(-1)^{m+1}(2m)!(n-2m)!(n^2+5n+2-8m)(n-3)!}{2^{(n-5)} m!(n-m)!(n+3)!}. \end{aligned} \tag{6.4}$$

Combining (6.4) with (3.7) and (3.10) and using initial condition $\langle r^{2,1}_0, u^1_{2,2} \rangle = \frac{10}{3}$, we obtain

$$\langle r^{n,1}_0, u^1_{n,2m} \rangle = \frac{(-1)^{m+1}(2m)!(n-2m)!(n^2+7n+4-12m)(n-2)!}{2^{(n-4)} m!(n-m)!(n+2)!}. \tag{6.5}$$

In order to simplify the computations somewhat we biorthogonalize the ramp functions. Set $r_{n,0} = r^{n,1}_0$, $l_{n,0} = l^{n,1}_0$, $r_{n,1} = r^{n,1}_1 - \frac{\langle r^{n,1}_1, l_{n,0} \rangle}{\langle r_{n,0}, l_{n,0} \rangle} r_{n,0}$, and $l_{n,1} = l^{n,1}_1 - \frac{\langle l^{n,1}_1, r_{n,0} \rangle}{\langle r_{n,01}, l_{n,1} \rangle} l_{n,1}$. With the help of the inner products given above, we find

$$\langle r_{n,1}, l_{n,1} \rangle = \frac{(-1)^n 4608(n-3)!}{(n+4)!(n^2+2n-9)}, \tag{6.6}$$

$$\langle r_{n,1}, u^1_{n,2m}\rangle = \frac{96(-1)^m(2m)!(n-2m)!(n-3)!(n^2-4mn+3n+6)}{2^n m!(n-m)!(n^2+2n-9)(n+3)!}, \tag{6.7}$$

and

$$\langle r_{n,1}, u^1_{n,2m+1}\rangle = \frac{96(-1)^m(2m+1)!(n-2m-1)!(n+3)(n-2)!(3n^2-4mn+9n-8m)}{2^n m!(n-m)!(n^2+2n-9)(n+4)!}. \tag{6.8}$$

As in the C^0 case we can use (3.17) to compute the inner products $\langle u^1_{n,2i}, u^1_{n,2j}\rangle$; $i, j = 0, 1$, or 2; and $n > 2\max\{i, j\} + 3$. This computation was done using Maple and yielded

$$\langle u^1_{n,2i}, u^1_{n,2j}\rangle = \frac{(-1)^{i+j}(n-2i)!(n-2j)!(2i)!(2j)!(n-3)!q(n,i,j)}{2^{2n-1}(2n+1-i-j)(n+3)!i!j!(n-i)!(n-j)!}, \tag{6.9}$$

where

$$\begin{aligned} q(n,i,j) = {} & n^6 + 19n^5 + (131 - 8(i+j))n^4 + (368 - 112(i+j))n^3 \\ & + (372 - 424(i+j) + 24(i+j)^2)n^2 \\ & + (212 - 320(i+j) + 120(i^2+j^2) + 432ij)n \\ & + 2(24 - 48((i+j)(1+ij) + (i^2+j^2)) + 81ij). \end{aligned}$$

We now construct three orthogonal functions $v_0 = b_{0,0}(n)u^1_{n,0} + b_{0,2}(n)u^1_{n,2} + u^1_{n,4}$, $v_2 = b_{2,0}(n)u^1_{n,0} + b_{2,2}(n)u^1_{n,2} + u^1_{n,4}$, and $v_4 = b_{4,0}(n)u^1_{n,0} + b_{4,2}(n)u^1_{n,2} + u^1_{n,4}$, with the additional constraints that v_0 be orthogonal to $r_{n,0}$ and $r_{n,1}$, v_2 be orthogonal to $r_{n,1}$ and v_0, and v_4 be orthogonal to v_0 and v_2. Using the inner product formulas and a symbolic manipulation package such as Maple, we find $b_{0,0}(n) = \frac{12}{(n-3)(n-2)}$, $b_{0,2}(n) = \frac{12(n-1)}{(n-3)(n-2)}$, $b_{2,0}(n) = \frac{12(2n+1)(7n^2-17n+18)}{(2n-7)(n-2)(n-3)(7n^2-n+18)}$, $b_{2,2}(n) = \frac{12(14n^2-25n+54)(n-1)^2}{(2n-7)(n-2)(n-3)(7n^2-n+18)}$,

$$b_{4,0}(n) = \frac{4(2n+1)(2n-1)(9n^5+175n^4+285n^3-5695n^2+12786n-8280)}{(2n-7)(2n-5)(n-3)(n-2)(n^2+11n-6)(3n^3+28n^2-67n+28)},$$

and

$$b_{4,2}(n) = \frac{4(n-1)(2n-1)(9n^5+179n^4+477n^3-4163n^2+7458n-4392)}{(2n-7)(n-3)(n-2)(n^2+11n-6)(3n^3+28n^2-67n+28)}.$$

These equations allow us to compute the following inner products between the new functions with the biorthogonal ramps:

$$\langle v_2, r_{n,0}\rangle = \frac{18432(n^2+2n-9)(n-4)!}{2^n(n+1)!(2n-7)(7n^2-n+18)},$$

$$\langle v_4, r_{n,0}\rangle = \frac{-7680(n^2+15n-24)}{2^n(2n-7)(2n-5)(n+2)n(n-3)(3n^3+28n^2-67n+28)},$$

and

$$\langle v_4, r_{n,1}\rangle = \frac{3072q(n)(n-1)(n-4)!}{2^n(2n-7)(2n-5)(n-2)(n+3)!(n^2+11n-6)(n^2+2n-9)(3n^3+28n^2-67n+28)},$$

where

$$q(n) = 107n^7 + 1230n^6 - 3580n^5 - 9546n^4 + 21437n^3 + 30204n^2 - 70956n + 25920.$$

Also, we have

$$\langle v_0(n), v_0(n)\rangle = \frac{11052(2n-9)!!}{2^{2n}(2n+1)!!(n-2)^2(n-3)^2},$$

$$\langle v_2(n), v_2(n)\rangle = \tfrac{11052(2n-9)!!q(n)}{2^{2n}(2n-1)!!(2n-7)(n-1)n(n+1)(7n^2-n+18)^2(n-3)^2(n-2)^2},$$

and

$$\langle v_4(n), v_4(n)\rangle = \tfrac{2048(n^2+13n-18)q(n)q_1(n)(n-1)!(2n-3)((2n-9)!!)^2}{2^{2n}(n+3)!(n-2)^3((n-3)(2n-3)!!(3n^3+28n^2-67n+28)(n^2+11n-6))^2}$$

with

$$q_1(n) = n^6 + 39n^5 + 445n^4 + 585n^3 - 7286n^2 + 9816n - 2880.$$

From (6.1) we see that we will need to borrow two functions in order to make an orthogonal intertwining MRA, and in order for these to be symmetric or antisymmetric we will set $w_{1,n} = \alpha_{1,0}(n)v_0 + \alpha_{1,2}(n)v_2 + v_4$ and $w_{2,n} = \alpha_{2,1}(n)u^1_{n,1} + u^1_{n,3}$. Taking note of the sign structure in (6.2), (5.5), and (6.6), (6.1) becomes the three equations

$$\begin{aligned}
|\langle r_{n,0}, l_{n,0}\rangle| &= \langle r_{n,0}, w_{1,n}\rangle^2 - \langle r_{n,0}, w_{2,n}\rangle^2,\\
0 &= \langle r_{n,0}, w_{1,n}\rangle\langle w_{1,n}, r_{n,1}\rangle - \langle r_{n,0}, w_{2,n}\rangle\langle w_{2,n}, r_{n,1}\rangle,\\
|\langle r_{n,1}, l_{1,n}\rangle| &= -\langle r_{n,1}, w_{1,n}\rangle^2 + \langle r_{n,1}, w_{2,n}\rangle^2.
\end{aligned}$$

These can be solved to give

$$\begin{aligned}
\frac{\langle r_{n,1}, w_{1,n}\rangle}{\sqrt{\langle w_{1,n}, w_{1,n}\rangle}} &= \sqrt{|\langle r_{n,1}, l_{1,n}\rangle| - \frac{\langle r_{n,1}, w_{2,n}\rangle^2}{\langle w_{2,n}, w_{2,n}\rangle}},\\
\frac{\langle r_{n,0}, w_{1,n}\rangle}{\sqrt{\langle w_{1,n}, w_{1,n}\rangle}} &= \frac{\langle r_{n,0}, w_{2,n}\rangle\langle r_{n,1}, w_{2,n}\rangle}{\sqrt{|\langle r_{n,1}, l_{1,n}\rangle|\langle w_{2,n}, w_{2,n}\rangle^2 - \langle r_{n,1}, w_{1,n}\rangle^2\langle w_{2,n}, w_{2,n}\rangle}},\\
0 &= |\langle r_{n,1}, l_{1,n}\rangle|\,|\langle r_{n,1}, l_{1,n}\rangle|\,\langle w_{2,n}, w_{2,n}\rangle + |\langle r_{n,1}, l_{1,n}\rangle|\,\langle r_{n,0}, w_{2,n}\rangle^2\\
&\quad - |\langle r_{n,1}, l_{1,n}\rangle|\,\langle r_{n,1}, w_{2,n}\rangle^2. \qquad (6.10)
\end{aligned}$$

With the definition of w_2 the last of the above equations can be rewritten as

$$\begin{aligned}
0 = &\begin{vmatrix} \langle u^1_{n,1}, u^1_{n,1}\rangle & -\langle u^1_{n,1}, r_{n,0}\rangle & \langle u^1_{n,1}, r_{n,1}\rangle\\ \langle u^1_{n,1}, r_{n,0}\rangle & \langle r_{n,0}, r_{n,0}\rangle & 0\\ \langle u^1_{n,1}, r_{n,0}\rangle & 0 & \langle r_{n,1}, r_{n,1}\rangle \end{vmatrix}\alpha^2_{2,1}\\
&+ 2\begin{vmatrix} \langle u^1_{n,1}, u^1_{n,3}\rangle & -\langle u^1_{n,3}, r_{n,0}\rangle & \langle u^1_{n,3}, r_{n,1}\rangle\\ \langle u^1_{n,1}, r_{n,0}\rangle & \langle r_{n,0}, r_{n,0}\rangle & 0\\ \langle u^1_{n,1}, r_{n,1}\rangle & 0 & \langle r_{n,1}, r_{n,1}\rangle \end{vmatrix}\alpha_{2,1}\\
&+ \begin{vmatrix} \langle u^1_{n,3}, u^1_{n,3}\rangle & -\langle u^1_{n,3}, r_{n,0}\rangle & \langle u^1_{n,3}, r_{n,1}\rangle\\ \langle u^1_{n,3}, r_{n,0}\rangle & \langle r_{n,0}, r_{n,0}\rangle & 0\\ \langle u^1_{n,3}, r_{n,1}\rangle & 0 & \langle r_{n,1}, r_{n,1}\rangle \end{vmatrix}.
\end{aligned}$$

Given the values of the inner products appearing in this equation, we find that either of the two values

$$\alpha_{2,1}(n) = \frac{2}{(n-1)(2n-3)}\left\{\frac{(2n-1)(3n-8)}{(n-2)} \pm 2\sqrt{7}\sqrt{\frac{(2n-1)(n+2)}{(2n-5)(n-2)}}\right\} \tag{6.11}$$

will suffice for $\alpha_{2,1}$. The first equation in (6.10) can be used to eliminate $\sqrt{\langle w_{1,n}, w_{1,n}\rangle}$ in the middle equation, and we have

$$\alpha_{1,2}(n) = \frac{(7n^2-n-18)\left\{q_3(n)(n-1)(n+1)(n+2)+q(n)\sqrt{7}\sqrt{(2n-1)(2n-5)(n+2)(n-2)}\right\}}{108(2n-5)(n+2)(n^2+11n-6)(3n^3+28n^2-67n+28)(n^4-6n^3-31n^2-22n+72)} \tag{6.12}$$

with

$$q_3(n) = 152n^6 + 3893n^5 + 19240n^4 - 76625n^3 - 105912n^2 + 330372n - 129600.$$

Now we solve for $\alpha_{1,0}(n)$ to find

$$\alpha_{1,0}(n) = \frac{\sqrt{10}}{108}\frac{q(n)\left\{\frac{(n-4)(n-2)(2n+1)}{n(n+2)(2n-7)}\left(q_4(n)+q_5(n)\sqrt{7}\sqrt{(2n-1)(2n-5)(n+2)(n-2)}\right)\right\}^{1/2}}{(2n-5)(n^2+11n-6)(3n^3+28n^2-67n+28)(n^4-6n^3-31n^2-22n+27)} \tag{6.13}$$

with

$$q_4(n) = 62n^6 + 2n^5 + 1480n^4 - 4526n^3 - 2250n^2 + 9774n - 5508$$

and

$$q_5(n) = 8n^4 + 95n^3 - 126n^2 + 297n - 162.$$

Knowing w_1 and w_2, we are now able to construct the orthogonal C^1 scaling functions. Let

$$h_0(t) = \begin{cases} 2|t|^3 - 3|t|^2 + 1 & \text{if } t \in [-1,1), \\ 0 & \text{otherwise} \end{cases}$$

and

$$h_1(t) = \begin{cases} (1-|t|)^2 t & \text{if } t \in [-1,1), \\ 0 & \text{otherwise.} \end{cases}$$

For $j = 4, \ldots, n$, set

$$\tilde{\phi}^j(\cdot) = \begin{cases} \phi_j^1(2\cdot - 1) & \text{if } t \in [0,1), \\ 0 & \text{otherwise,} \end{cases}$$

$$\tilde{\phi}^2(\cdot) = \begin{cases} w_1(2\cdot - 1) & \text{if } t \in [0,1), \\ 0 & \text{otherwise,} \end{cases}$$

$$\tilde{\phi}^3(\cdot) = \begin{cases} w_2(2\cdot - 1) & \text{if } t \in [0,1), \\ 0 & \text{otherwise,} \end{cases}$$

and $\tilde{\phi}^i = (I - P_{\{\tilde{\phi}^2,\ldots,\tilde{\phi}^n,\tilde{\phi}^2(\cdot+1),\ldots,\tilde{\phi}^n(\cdot+1)\}})h_i$, $i = 0, 1$. Then the above computations give the following theorem.

THEOREM 6.1. *For $n \geq 6$, $\alpha_{1,0}(n)$, $\alpha_{1,2}(n)$, and $\alpha_{2,1}(n)$ given by (5.9), $\tilde{\Phi} = \{\tilde{\phi}^0, \ldots, \tilde{\phi}^n\}^*$ generates an orthogonal multiresolution analysis $\{\tilde{V}_k^{n,1}\}$. Furthermore, the last $n-1$ functions are symmetric or antisymmetric about $\frac{1}{2}$. The first function $\tilde{\phi}^0$ is symmetric about 0 while $\tilde{\phi}^1$ is antisymmetric about 0.*

Proof. Since h_0 and h_1 are linear combinations of similarly scaled versions of $r_j^1,\ j = 0, 1$ and $l_j^1,\ j = 0, 1$ the result follows from the computations above. □

With the scaling functions above we construct the coefficients $C_{n,i}^1,\ i = -2, -1, 0, 1$, in the matrix refinement equation. Theorem 4.4 implies that there will be four wavelets not supported in $[0, 1]$. Using arguments similar to Corollary 5.2 leads to the following.

COROLLARY 6.2. *Suppose $\tilde{\psi}^0, \ldots, \tilde{\psi}^3$ are chosen so that*

$$\begin{aligned}
\tilde{\psi}^0 &= \sqrt{2}(I - P_{\tilde{\phi}^0})\tilde{\phi}_{1,0}^0,\\
\tilde{\psi}^1 &\propto (I - P_{\{\tilde{\psi}^0, \tilde{\phi}^0\}})(\chi_{[0,1]} - \chi_{[-1,0]})(I - P_{\tilde{\phi}_{1,0}^1})\tilde{\phi}^1,\\
\tilde{\psi}^2 &\propto (I - P_{\{\tilde{\psi}^3, \tilde{\phi}^1\}})(\chi_{[0,1]} - \chi_{[-1,0]})(I - P_{\tilde{\phi}_{1,0}^0})\tilde{\phi}^0,\\
\tilde{\psi}^3 &= \frac{2\sqrt{2}}{\sqrt{7}}(I - P_{\tilde{\phi}^1})\tilde{\phi}_{1,0}^1
\end{aligned}$$

and $\tilde{\psi}^4, \ldots, \tilde{\psi}^n$ form a basis for Ψ^0 consisting only of functions symmetrical or antisymmetrical about $\frac{1}{2}$. Then $\{\tilde{\psi}^0, \ldots, \tilde{\psi}^n\}$ generates a shift-invariant orthonormal basis for W_0. Furthermore, $\tilde{\psi}^0(0) = \tilde{\phi}^0(0)$, $(\tilde{\psi}^3)'(0) = \sqrt{7}(\tilde{\phi}^1)'(0)$, $\tilde{\psi}^1(0) = 0$, and $(\tilde{\psi}^2)'(0) = 0$.

An example is given in Figure 2. In Figure 3 explicit formulas for these functions, accurate at least to 10 digits, are given. The coefficients in the refinement equation may be calculated using inner products. The wavelets supported on $[-1, 1]$ can be computed using Corollary 6.2. The wavelets supported in $[0, 1]$ can be obtained by finding $n-3$ orthogonal set of functions, symmetrical or antisymmetrical with respect to $\frac{1}{2}$, from the space $(I - P_{\{\tilde{\phi}^4, \ldots, \tilde{\phi}^{n-1}\}})A_1^{n,1} \ominus A_0^{n,1}$.

Theorem 4.5 shows that in order to construct a wavelet basis for $[0, 1]$ we need to rotate the scaling functions so that $\{\chi_{[0,1]}\tilde{\phi}^i\}_{i=0,1}$ is an orthogonal set as well as $\{\chi_{[-1,0]}\tilde{\phi}^i\}_{i=0,1}$. Exploiting the symmetry of $\tilde{\phi}^0$ and $\tilde{\phi}^1$, we find that $\hat{\phi}^0 = -\frac{1}{\sqrt{2}}\tilde{\phi}^0 - \frac{1}{\sqrt{2}}\tilde{\phi}^1$ and $\hat{\phi}^1 = -\frac{1}{\sqrt{2}}\tilde{\phi}^0 + \frac{1}{\sqrt{2}}\tilde{\phi}^1$ have the desired property. Let $\bar{\phi}_{k,j}^i = \hat{\phi}_{k,j}^i|_{[0,1]}$, $\bar{\psi}_{k,j}^m = \hat{\psi}_{k,j}^m|_{[0,1]}$, $m \neq 1, 3$, and for $m = 1, 3$ set

$$\bar{\psi}_{k,j}^m = \begin{cases} 0 & \text{if } \operatorname{supp} \hat{\psi}_{k,j}^m \cap [0,1]^c \neq \emptyset,\\ \hat{\psi}_{k,j}^m & \text{otherwise.} \end{cases}$$

Then from Theorem 4.5 we have the following theorem.

THEOREM 6.3. *The set $\{\bar{\phi}_{k,j}^i\colon\ k \geq 0,\ i = 1, \ldots, n,\ 0 \leq j \leq 2^k - 1 + \chi_{\{0,1\}}(i)\}$ is an orthogonal basis for $\bar{V}_k^{n,1} = \tilde{V}_k^{n,1} \cap L^2[0, 1]$ while $\{\bar{\psi}_{k,j}^i\colon\ k \geq 0,\ i = 1, \ldots, n,\ \chi_{\{1,3\}}(i) \leq j \leq 2^k - 1 + \chi_{\{0,2\}}(i)\}$ forms an orthogonal basis for $\bar{W}_k^{n,1} = \tilde{W}_k^{n,1} \cap L^2[0, 1]$. Furthermore, $\operatorname{cl}_{L^2} \bar{V}_0^{n,1} \oplus \bigoplus_{k \geq 0} \bar{W}_k^{n,1} = L^2[0, 1]$.*

Examples of these functions for $n = 6$ can be found in Figure 4.[2]

[2]Wavelets as well as the matrices in the refinement equation for this and other examples may be found at the web site www.math.gatech.edu/∼geronimo.

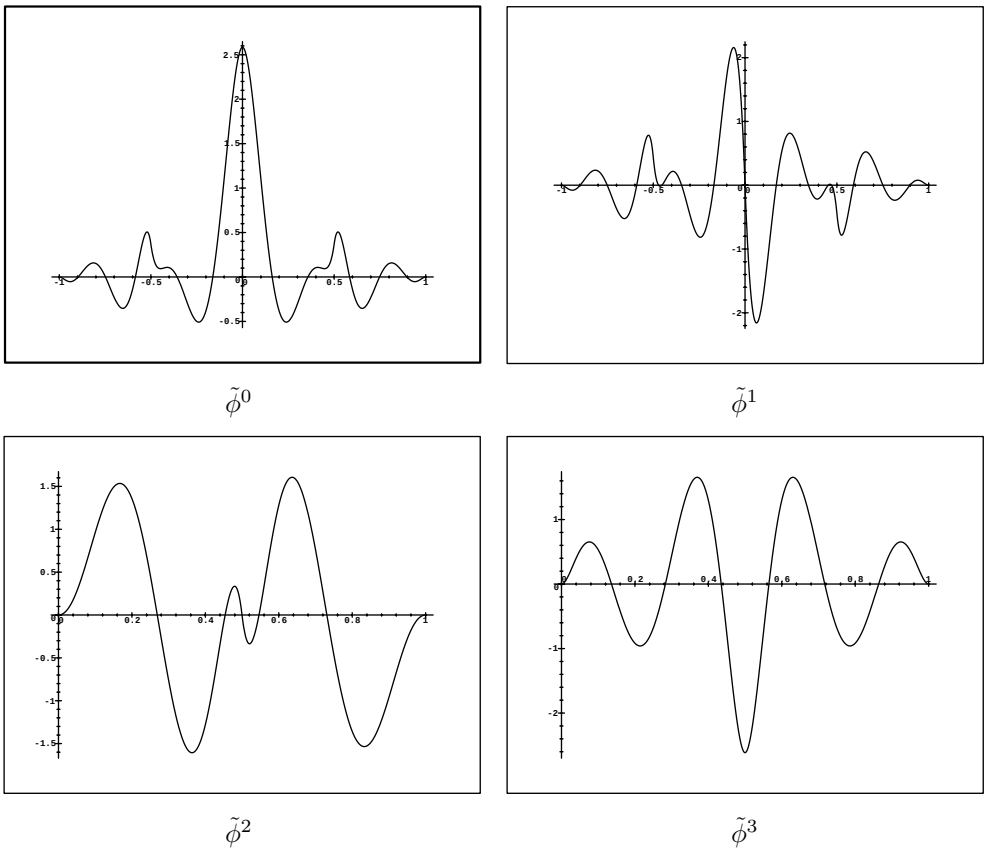


FIG. 2. *Selected C^1 scaling functions with approximation order* 7 ($n = 6$).

7. A C^2 example. The methods of the previous sections can be used to construct C^2 multiwavelets as well, although the formulas become extremely complicated. We will therefore content ourselves with briefly describing the procedure and exhibiting an example which may be of use. We do not prove that the procedure works for arbitrary n; however, we have verified it for a number of cases. For the C^2 case $k = 2$, $r_i^2 = (1+t)^3(1-t)^i$ and $l_i^2(t) = (1-t)^3(1+t)^i$, $i = 0, 1, 2$. The spaces $C_0^{n,2}(\frac{\cdot+1}{2})$ and $C_1^{n,2}(\frac{\cdot+1}{2})$ are each three dimensional. Hence we search for three orthonormal functions $w_1, w_2, w_3 \in A_1^{n,2}(\frac{\cdot+1}{2}) \ominus A_0^{n,2}(\frac{\cdot+1}{2})$ such that

$$\langle (I - P_{\{w_1,w_2,w_3\}}) r_i^{n,2}, (I - P_{\{w_1,w_2,w_3\}}) l_j^{n,2} \rangle = 0, \ i \le j = 0, 1, 2. \tag{7.1}$$

The above equation yields six nonlinear equations and in order to ease the computation somewhat we impose that $\langle w_3, r_0^{n,2} \rangle = 0$. By examining (7.1) we find that w_1 must satisfy four equations, w_3 five equations, and w_2 two equations. Thus, we choose $w_1 = a_{1,0}u_{n,0}^2 + a_{1,2}u_{n,2}^2 + a_{1,4}u_{n,4}^2 + a_{1,6}u_{n,6}^2$, $w_3 = a_{3,0}u_{n,0}^2 + a_{3,2}u_{n,2}^2 + a_{3,4}u_{n,4}^2 + a_{3,6}u_{n,6}^2 + a_{3,8}u_{n,8}^2$, and $w_2 = a_{2,1}u_{n,1}^2 + a_{2,3}u_{n,3}^2$ and observe that, as a consequence, n must be at least 11 for these functions all to have C^2 smoothness. For $n = 11$, we used Maple to obtain the following solution to 60 digits of accuracy:

$$\tilde{\phi}^0(t) = \begin{cases} 4067.904397t^6 - 3085.517213t^5 - 739.5537604t^4 \\ \quad +1113.129531t^3 - 249.0932934t^2 + 2.585173201 & \text{for } 0 \le t \le \frac{1}{2} \\ (-10946.18252t^4 + 29698.96665t^3 - 29673.11423t^2 \\ \quad +12935.83259t - 2076.394058)(t-1)^2 & \text{for } \frac{1}{2} < t \le 1 \\ \tilde{\phi}^0(-t) & \text{for } -1 \le t < 0 \\ 0 & \text{elsewhere} \end{cases}$$

$$\tilde{\phi}^1(t) = \begin{cases} t(-12435.14749t^5 + 11555.74525t^4 - 175.1583524t^3 \\ \quad -2704.493962t^2 + 885.9596767t - 79.47577362) & \text{for } 0 \le t \le \frac{1}{2} \\ (17496.63084t^4 - 47730.65634t^3 + 47977.37771t^2 \\ \quad -21054.27094t + 3403.826649)(t-1)^2 & \text{for } \frac{1}{2} < t \le 1 \\ -\tilde{\phi}^1(-t) & \text{for } -1 \le t < 0 \\ 0 & \text{elsewhere} \end{cases}$$

$$\tilde{\phi}^2(t) = \begin{cases} (2t-1)t^2(-12193.17741t^3 + 8033.232335t^2 \\ \quad -923.0732055t - 95.73716085) & \text{for } 0 \le t \le \frac{1}{2} \\ -\tilde{\phi}^2(1-t) & \text{for } \frac{1}{2} < t \le 1 \\ 0 & \text{elsewhere} \end{cases}$$

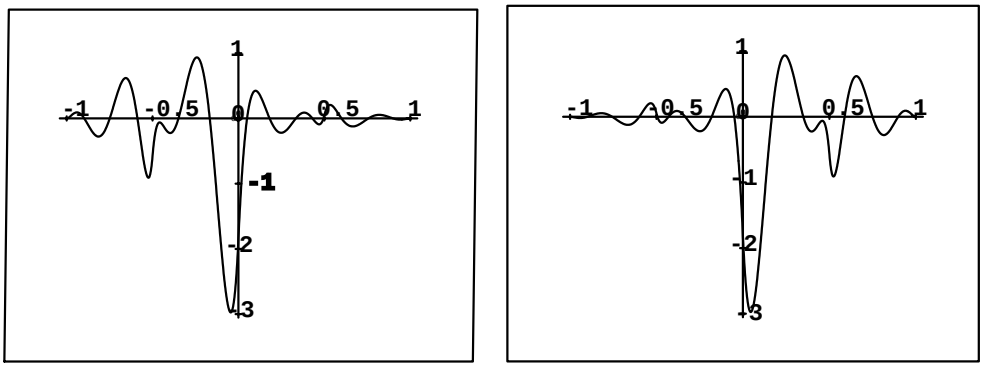
$$\tilde{\phi}^3(t) = \begin{cases} (54655.48659t^4 - 76071.45058t^3 + 37177.81845t^2 \\ \quad -7410.133638t + 493.1155758)t^2 & \text{for } 0 \le t \le \frac{1}{2} \\ \tilde{\phi}^3(1-t) & \text{for } \frac{1}{2} < t \le 1 \\ 0 & \text{elsewhere} \end{cases}$$

$$\tilde{\phi}^4(t) = 3\sqrt{70}t^2(t-1)^2\chi_{[0,1]}$$

$$\tilde{\phi}^5(t) = 3\sqrt{770}t^2(2t-1)(t-1)^2\chi_{[0,1]}$$

$$\tilde{\phi}^6(t) = 3\sqrt{182}t^2(22t^2 - 22t + 5)(t-1)^2\chi_{[0,1]}$$

FIG. 3. *Formulas for the C^1 scaling functions.*



$\hat{\phi}^0$ $\hat{\phi}^1$

FIG. 4. *Modified C^1 scaling functions of degree 6 for truncation to $[0,1]$.*

The corresponding functions are given with 10 digits of accuracy in Figure 5, and their graphs are shown in Figure 6. The orthonormal wavelets can be calculated using techniques similar to those of sections 5 and 6. One final Gram–Schmidt step is necessary since two of the three functions in $(I - P_{Q_0})Q_1$ are symmetric. The same is true of $(I - P_{Q_0 \cup \Psi^s})Z$.

INFINITE PRODUCTS AND NORMALIZED QUOTIENTS OF HYPERGEOMETRIC FUNCTIONS*

S.-L. QIU† AND M. VUORINEN‡

Abstract. For $r \in (0,1)$ and $a \in (0,1)$ the authors consider the quotient of hypergeometric functions

$$\mu_a(r) \equiv cF(a,1-a;1;1-r^2)/F(a,1-a;1;r^2),$$

where the normalizing coefficient $c = \pi/(2\sin(\pi a))$. With this choice of c, $\mu(r) \equiv \mu_{1/2}(r)$, where $\mu(r)$ is the modulus of the Grötzsch ring $B^2 \setminus [0,r]$ in the plane. A new infinite product expansion is given for $\mu(r)$. It is shown that several well-known properties of the function $\mu(r)$ have their counterparts for $\mu_a(r)$.

Key words. zero-balanced hypergeometric functions, modulus of Grötzsch ring, infinite product

1. Introduction.

As usual, for real numbers a, b, and c with $c \neq 0, -1, -2, \ldots$, let

$$F(a,b;c;x) := {}_2F_1(a,b;c;x) \equiv \sum_{n=0}^{\infty} \frac{(a,n)(b,n)}{(c,n)} \frac{x^n}{n!} \tag{1.1}$$

for $x \in (-1,1)$ denote the *Gaussian hypergeometric function* [AS], [Ask1], [R]. Here $(a,0) = 1$ for $a \neq 0$ and (a,n) is the shifted factorial function

$$(a,n) := a(a+1)(a+2)\cdots(a+n-1)$$

for $n \in \mathbf{N} \equiv \{k : \ k \text{ is a positive integer}\}$. The function $F(a,b;c;x)$ is said to be *zero balanced* if $c = a+b$. It is well known that $F(a,b;c;x)$ has many important applications, and many classes of special functions in mathematical physics are particular or limiting cases of this function. For these and for properties of $F(a,b;c;x)$, see, for example, [AS], [Ao], [Ask1], [Ask2], [Be1], [Be2], [Be3], [Be4], [CC], [E], [R], [Var], [Va], [WW], and [WZ]. Here we recall that only in the special cases when $a = b = 1/2$ and $-a = b = 1/2$, we have for $x \in (0,1)$ and $x' = \sqrt{1-x^2}$,

$$\mathcal{K}(x) \equiv \frac{\pi}{2} F\Big(\frac{1}{2}, \frac{1}{2}; 1; x^2\Big) = \int_0^{\pi/2} (1 - x^2 \sin^2 t)^{-1/2} dt, \quad \mathcal{K}'(x) \equiv \mathcal{K}(x'), \tag{1.2}$$

and

$$\mathcal{E}(x) = \frac{\pi}{2} F\Big(-\frac{1}{2}, \frac{1}{2}; 1; x^2\Big) = \int_0^{\pi/2} (1 - x^2 \sin^2 t)^{1/2} dt, \quad \mathcal{E}'(x) \equiv \mathcal{E}(x'), \tag{1.3}$$

which are known as the *complete elliptic integrals of the first kind and of the second kind*, respectively [Bo], [BF].

Let B^2 be the unit disk in the plane and $\mu(r)$ the *modulus of the plane Grötzsch ring* $B^2 \setminus [0,r]$ for $r \in (0,1)$ [LV]. It is well known that $\mu(r)$ has the following explicit expression [LV, p. 60]:

$$\mu(r) = \frac{\pi}{2}\frac{\mathcal{K}'(r)}{\mathcal{K}(r)}, \quad \text{for} \quad 0 < r < 1 \quad \text{and} \quad r' = \sqrt{1-r^2}. \tag{1.4}$$

The special function $\mu(r)$ plays a very important role in geometric function theory, quasi-conformal theory, and quasi-regular theory (cf. [AVV2], [LV], and [Vu]). It also has applications in some other mathematical fields such as the theory of analytic functions and number theory. In number theory, for example, it appears in the *classical modular equation of signature* 2 *and degree* p, $p > 1$, i.e., the equation

$$\mu(s) = p\mu(r), \quad 0 < r < 1,$$

(see [Be3] and [BB]), while in the theory of analytic functions, by [M, Theorem 1.1], the Schottky upper bound can be expressed in terms of $\mu(r)$. Numerous properties of $\mu(r)$ have been obtained (see, for instance, [AV], [AVV2], and [LV]).

A natural generalization of $\mu(r)$ is the homeomorphism $\mu_a : (0,1) \to (0,\infty)$ defined by

$$\mu_a(r) \equiv \frac{\pi}{2\sin\pi a}\frac{F(a,1-a;1;1-r^2)}{F(a,1-a;1;r^2)} \tag{1.5}$$

for $a, r \in (0,1)$. Clearly, $\mu_{1-a}(r) = \mu_a(r)$. Hence, we may assume that $0 < a \le 1/2$. Using the function $\mu_a(r)$, one can write the so-called *generalized modular equation of signature* $1/a$ *and degree* p, $p > 1$, as

$$\mu_a(s) = p\mu_a(r), \quad 0 < r < 1, \tag{1.6}$$

which was studied by S. Ramanujan (cf. [Ask2] and [Be2]), and was recently studied in [BBG], [Be5], and [Ga]. In particular, several beautiful identities satisfied by r and s were obtained in [BBG]. Properties of $\mu_a(r)$, of course, are indispensable in the study of (1.6).

Since $\mu_{1/2}(r) \equiv \mu(r)$, and since as a function of the parameter a, $\mu_a(r)$ is analytic on $(0,1/2]$, it is natural to ask whether every known result for $\mu(r)$ has a counterpart with $\mu(r)$ replaced by $\mu_a(r)$, and how to extend the well-known results for $\mu(r)$ to the function $\mu_a(r)$.

On the other hand, it is well known that [J, p. 146]

$$\exp(\mu(r) + \log r) = 4\prod_{n=1}^{\infty}\left(\frac{1+q^{2n}}{1+q^{2n-1}}\right)^4 \tag{1.7}$$

for $r \in (0,1)$, where $q = \exp(-2\mu(r))$. By virtue of (1.7), several infinite-product representations and inequalities have been obtained for $\mu^{-1}(x)$ and for the Hersch–Pfluger φ-distortion function [HP]

$$\begin{cases} \varphi_K(r) \equiv \mu^{-1}(\mu(r)/K), \\ \varphi_K(0) = \varphi_K(1) - 1 = 0 \end{cases} \tag{1.8}$$

for $r \in (0,1)$ and $K \in (0,\infty)$ (see [AV], [AVV2], and [VV]). However, since the Jacobi product on the right side of (1.7) involves $\mu(r)$, it is not very convenient for one to employ (1.7) to do numerical computation for $\mu(r)$ and to study some related special functions such as $\varphi_K(r)$.

One purpose of the present paper is to find a new infinite-product representation for $\mu(r)$ which involves only r, and to extend this representation to the function $\mu_a(r)$. We shall prove the following result.

THEOREM 1.1. *For $a \in (0,1/2]$, let $R(a) \equiv R(a,1-a)$, where $R(a,b)$ is defined by (2.5), and for $r \in (0,1), n \in \mathbf{N}$, let $r_0 = r' = \sqrt{1-r^2}$, and*

$$r_1 = \varphi_2(r') = \frac{2\sqrt{r'}}{1+r'}, \ldots, r_n = \varphi_2(r_{n-1}) = \frac{2\sqrt{r_{n-1}}}{1+r_{n-1}} = \varphi_{2^n}(r'). \tag{1.9}$$

Then

$$\prod_{n=0}^{\infty}(1+r_n)^{2^{-n}} \le \exp(\mu_a(r)+\log r) \le \frac{1}{4}\exp(R(a)/2)\ \prod_{n=0}^{\infty}(1+r_n)^{2^{-n}}, \tag{1.10}$$

with equality for all $r \in (0,1)$ in each inequality if and only if $a = 1/2$. In particular, for all $r \in (0,1)$,

$$\exp(\mu(r)+\log r) = \prod_{n=0}^{\infty}(1+r_n)^{2^{-n}} \tag{1.11}$$

or equivalently,

$$\mu(r) = \log\frac{1}{r} + \sum_{n=0}^{\infty}\frac{1}{2^n}\log(1+r_n).$$

Another purpose of this paper is to extend some well-known properties of $\mu(r)$ to $\mu_a(r)$ and to show that some other properties of $\mu(r)$ cannot be extended to $\mu_a(r)$ for $a \in (0,1/2)$.

Throughout this paper, we let $r' = \sqrt{1-r^2}$ for $r \in [0,1]$, and let *arth* denote the inverse of the hyperbolic tangent *th* and $R(a)$ be as in Theorem 1.1.

We now state some of our other main results, which serve the second purpose of this paper.

THEOREM 1.2. *Let $a \in (0,1/2]$. Then we have the following:*

1. *The function $f(r) \equiv r'\mu_a(r)/\log(1/r)$ is strictly increasing from $(0,1)$ onto $(1,\infty)$.*
2. *The function $g(r) \equiv \mu_a(1/r)/\log r$ is strictly decreasing and convex from $(1,\infty)$ onto $(1,\infty)$. However, the function $G(r) \equiv g(1/r)$ is neither concave nor convex on $(0,1)$.*
3. *The function $h(r) \equiv \mu_a(r)/\{[R(a)/2]+\log(1/r)\}$ is strictly decreasing and concave from $(0,1)$ onto $(0,1)$.*
4. *The function $H(r) \equiv h(r)/\sqrt{r'}$ is strictly increasing from $(0,1)$ onto $(1,\infty)$. Moreover, for all $a \in (0,1/2]$ and $r \in (0,1)$,*

$$\left[\frac{1}{2}R(a)-\log r\right]\sqrt{r'} < \mu_a(r) < \frac{1}{2}R(a)-\log r. \tag{1.12}$$

THEOREM 1.3. *Let $a \in (0,1/2]$. Then we have the following:*

1. *The function* $f(r) \equiv \mu_a(e^{-r})$ *is strictly increasing and concave from* $(0,\infty)$ *onto* $(0,\infty)$. *In particular, for all* $a \in (0,1/2]$, *and* $x, y, p \in (0,1)$,

$$p\mu_a(x) + (1-p)\mu_a(y) \le \mu_a(x^p y^{1-p}) \tag{1.13}$$

and

$$\mu_a(x) + \mu_a(y) \le 2\mu_a(\sqrt{xy}). \tag{1.14}$$

Equality holds in (1.13) *and in* (1.14) *if and only if* $x = y$.

2. *The function* $g(r) \equiv \mu_a(1/r)$ *is strictly increasing and concave from* $(1,\infty)$ *onto* $(0,\infty)$. *In particular, for all* $a \in (0,1/2]$ *and* $x, y, p \in (0,1)$,

$$p\mu_a(x) + (1-p)\mu_a(y) \le \mu_a\left(\frac{xy}{(1-p)x + py}\right), \tag{1.15}$$

with equality if and only if $x = y$.

3. *For each* $t \in (0,1)$, *the function* $h(r) \equiv \mu_a(\frac{rt}{1+r't'}) - \mu_a(r)$ *is strictly increasing from* $(0,1)$ *onto* $(arth\, t', \mu_a(t))$. *Moreover, for all* $a \in (0,1/2]$ *and* $r, t \in (0,1)$,

$$\begin{cases} \mu_a(r) + \mu_a(t) - \dfrac{1}{2}[R(a) - \log 4] < \mu_a(r) + artht' \\ \qquad\qquad < \mu_a\left(\dfrac{rt}{1+r't'}\right) < \mu_a(r) + \mu_a(t). \end{cases} \tag{1.16}$$

4. *The function* $G(r) \equiv \mu_a(r)/\mu_a(\sqrt{r})$ *is strictly decreasing from* $(0,1)$ *onto* $(1,2)$. *In particular, for all* $a \in (0,1/2]$ *and* $r \in (0,1)$,

$$\mu_a(r) < \mu_a(r^2) < 2\mu_a(r). \tag{1.17}$$

THEOREM 1.4. *Let* $a \in (0,1/2]$. *Then the following apply:*

1. *Both of the functions* $f(r) \equiv \mu_a(r)$ *and* $1/f(r)$ *have exactly one inflection point on* $(0,1)$.
2. *The function* $g(r) \equiv \mu_a(r) + \log(r/r')$ *is strictly increasing and convex from* $(0,1)$ *onto* $(R(a)/2, \infty)$.
3. *The function* $h(r) \equiv r\exp(\mu_a(r))$ *is strictly decreasing and concave from* $(0,1)$ *onto* $(1, \exp(R(a)/2))$.
4. *Define the function* G *on* $(0,1)$ *by*

$$G(r) = \mu_a(r) + \log(r/\sqrt{r'}).$$

Then we have the following:

i. G *is strictly increasing on* $(0,1)$ *if and only if* $a = 1/2$.

ii. G *is convex on* $(0,1)$ *if and only if* $a = 1/2$.

iii. *If* $a \in (0,1/2)$, *then there exists a unique* $r_0 \in (0,1)$ *such that* G *is strictly decreasing on* $(0,r_0]$, *and increasing on* $[r_0,1)$, *with* $G(0^+) = R(a)/2$ *and* $G(1^-) = \infty$. *Moreover,* G *is neither concave nor convex on* $(0,1)$ *in this case.*

Remark 1. 1. It should be indicated that in addition to (1.7), there is a classical infinite-product representation [BB, Formula (2.5.15), p. 52]

$$\exp(\mu(r) + \log r) = 4\sqrt{r'} \prod_{n=1}^{\infty} \left(\frac{a_n}{b_n}\right)^{3/2^{n+1}} \tag{1.18}$$

for $r \in (0,1)$, where

$$a_0 = 1, \quad b_0 = r', \quad a_n = (a_{n-1} + b_{n-1})/2 \quad \text{and} \quad b_n = \sqrt{a_{n-1}b_{n-1}}$$

for $n \in \mathbf{N}$. However, as we can see, it is more convenient for one to use (1.11) to obtain some properties of $\mu(r)$ and some other related special functions such as $\varphi_K(r)$ than to use (1.18). For example, from (1.11) we get

$$\mu(r) - arth\ r' = \sum_{n=1}^{\infty} \frac{1}{2^n} \log(1 + r_n). \tag{1.19}$$

It is well known that as a function of r, $\varphi_K(r)$ is strictly concave on $(0,1)$ if $K > 1$ (cf. [AVV2, Exercises 10.18(9)]). Clearly, r' is concave on $(0,1)$, and $\log x$ is strictly increasing and concave on $(0,\infty)$. Hence, the right side of (1.19) is a sum of strictly decreasing and concave functions of r on $(0,1)$ (cf. [AQV, Lemma 2.1(1)]), so that as we know, $\mu(r) - arth\ r'$ is strictly decreasing and concave from $(0,1)$ onto $(0, \log 2)$.

2. In the special case when $a = 1/2$, the results in Theorems 1.2, 1.3, and 1.4 can be found in [AVV2] and in references therein.

3. Several known results for $\mu(r)$ have been generalized to $\mu_a(r)$ in [BPV] and [QVu2].

4. The inequality (1.14) has been proved by two different methods in [BPV, Theorem 1.5] and [QVu2, Theorem 1.18(1)]. In Theorem 1.3 item 2, we use a new method to obtain a more general inequality (1.13). We observe that (1.14) is the second part of [AVV1, Open Problem 10, p. 80].

5. The results in Theorems 1.1, 1.2, 1.3 and 1.4 enable us to show some properties of the solution of the generalized modular equation (1.6)

$$s = \varphi^a_{1/p}(r) \equiv \mu_a^{-1}(p\mu_a(r)). \tag{1.20}$$

These and some other applications will appear in a separate paper [AQVV].

2. Some properties of $F(a, b; c; x)$. In this section, we study some monotonicity properties of the function $F(a, b; c; x)$ and certain of its combinations. These are needed in the proofs of the main theorems stated in section 1. But first, we recall some known results for the function $F(a, b; c; x)$, which will be frequently used in what follows.

It is well known that the properties of the hypergeometric functions are closely related to those of the *gamma function* $\Gamma(x)$, the *psi function* $\Psi(x)$, and the *beta function* $B(x, y)$. For positive numbers x and y, these functions are defined by

$$\Gamma(x) = \int_0^{\infty} e^{-t} t^{x-1} dt, \quad \Psi(x) = \frac{\Gamma'(x)}{\Gamma(x)}, \quad B(x,y) = \frac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)}, \tag{2.1}$$

respectively (cf. [WW]). It is well known that the gamma function satisfies the *difference equation* [WW, p. 237]

$$\Gamma(x+1) = x\Gamma(x) \tag{2.2}$$

if x is not a nonpositive integer and has the so-called *reflection property* [WW, p. 239]

$$\Gamma(x)\Gamma(1-x) = \frac{\pi}{\sin \pi x} = B(x, 1-x) \tag{2.3}$$

if x is not an integer. From (2.2), it follows that [AS, 6.3.6]

$$\Psi(x+n)=\sum_{k=1}^{n}\frac{1}{x+n-k}+\Psi(x) \tag{2.4}$$

for $n\in\mathbf{N}$. We shall also need the function

$$R(a,b)=-2\gamma-\Psi(a)-\Psi(b), R(1/2,1/2)=\log 16, \tag{2.5}$$

where γ is the *Euler–Mascheroni constant* defined by

$$\gamma=\lim_{n\to\infty}\left(\sum_{k=1}^{n}\frac{1}{k}-\log n\right)=0.577215\ldots. \tag{2.6}$$

By [QVu2, Lemma 2.14(2)], for $a\in(0,1/2]$,

$$R(a)\equiv R(a,1-a)\geq A[(1/2)-a]^2+\log 16, \tag{2.7}$$

with equality if and only if $a=1/2$, where $A=14\zeta(3)=16.82879\ldots$ and $\zeta(x)$ is the *Riemann zeta function*.

Two of the important tools we shall need in our work are Ramanujan's asymptotic formula (see [Ask1], [Be2], and [E])

$$B(a,b)F(a,b;a+b;r)+\log(1-r)=R(a,b)+\mathrm{O}((1-r)\log(1-r)) \tag{2.8}$$

(for $a,b\in(0,\infty)$) as r tends to 1, which is a special case of [AS, 15.3.10], and the following Ramanujan's derivative formula [Be2, Corollary, p. 86]

$$\frac{d}{dx}\left[\frac{F(a,1-a;1;1-x)}{F(a,1-a;1;x)}\right]=-\frac{\sin\pi a}{\pi x(1-x)F(a,1-a;1;x)^2} \tag{2.9}$$

for $a,x\in(0,1)$. From (2.9) we immediately get the derivative of $\mu_a(r)$ with respect to r: For $a,r\in(0,1)$,

$$\frac{d\mu_a(r)}{dr}=-\frac{1}{rr'^2F(a,1-a;1;r^2)^2}. \tag{2.10}$$

By (1.1) we have

$$\frac{d}{dx}F(a,b;c;x)=\frac{ab}{c}F(a+1,b+1;c+1;x). \tag{2.11}$$

It follows from (2.9) and (2.11) that

$$F(1+a,2-a;2;1-x)F(a,1-a;1;x) \tag{2.12}$$

$$+F(1+a,2-a;2;x)F(a,1-a;1;1-x)=\frac{\sin\pi a}{\pi a(1-a)x(1-x)}$$

for $a,x\in(0,1)$.

Other important tools in the rest of this paper are the following Landen inequalities.

THEOREM 2.1 (see [QVu1, Theorem 1.9(1)]). *For $a, b \in (0,1)$ with $c = a + b \le 1$ (< 1, respectively), the function*

$$f(r) \equiv (1+r)F(a,b;c;r^2) - F(a,b;c;4r/(1+r)^2)$$

is increasing (strictly, respectively) from $(0,1)$ onto $(0, [R(a,b) - \log 16]/B(a,b))$. In particular, for all $a, b, r \in (0,1)$ with $c = a + b \le 1$,

$$\begin{cases} F\Big(a,b;c;\Big(\dfrac{2\sqrt{r}}{1+r}\Big)^2\Big) \le (1+r)F(a,b;c;r^2) \\ \le F\Big(a,b;c;\Big(\dfrac{2\sqrt{r}}{1+r}\Big)^2\Big) + \dfrac{1}{B(a,b)}[R(a,b) - \log 16] \end{cases} \tag{2.13}$$

and

$$\begin{cases} \dfrac{1+r}{2}F(a,b;c;1-r^2) \le F\Big(a,b;c;\Big(\dfrac{1-r}{1+r}\Big)^2\Big) \\ \le \dfrac{1+r}{2}\Big\{F(a,b;c;1-r^2) + \dfrac{1}{B(a,b)}[R(a,b) - \log 16]\Big\}, \end{cases} \tag{2.14}$$

with equality in each instance if and only if $a = b = 1/2$.

In what follows, we let

$$m_a(r) \equiv \frac{\pi}{2\sin \pi a} r'^2 F(a, 1-a; 1; r^2) F(a, 1-a; 1; r'^2) \tag{2.15}$$

for $a \in (0, 1/2]$ and $r \in (0,1)$. This function is the counterpart of the function

$$m(r) \equiv \frac{2}{\pi} r'^2 \mathcal{K}(r)\mathcal{K}'(r), \quad 0 < r < 1, \tag{2.16}$$

which plays an important role in the study of the distortion functions in quasiconformal theory (cf. [AVV2] and [Hü]). Clearly, $m_{1/2}(r) \equiv m(r)$. As we shall see, the function $m_a(r)$ has applications in the study of $F(a,b;c;x)$, $\mu_a(r)$, and the solution $s = \varphi^a_{1/p}(r)$ (see (1.20)) of the generalized modular equation (1.6). We first obtain the derivative formula for $m_a(r)$.

LEMMA 2.2. *For $a \in (0, 1/2]$, and $r \in (0,1)$,*

$$\begin{aligned} m_a'(r) = -\frac{1}{r} - \frac{\pi r}{\sin \pi a} F(a, 1-a; 1; r'^2)[F(a, 1-a; 1; r^2) \\ - 2a(1-a)F(a, 1-a; 2; r^2)]. \end{aligned} \tag{2.17}$$

In particular, for $r \in (0,1)$,

$$m'(r) = -\frac{1}{r} - \frac{4}{\pi r}\mathcal{K}'(r)[\mathcal{K}(r) - \mathcal{E}(r)] = \frac{1}{r}\left[1 - \frac{4}{\pi}\mathcal{K}(r)\mathcal{E}'(r)\right]. \tag{2.18}$$

Proof. By differentiation, (2.11), and (2.12), we get

$$\begin{aligned} m_a'(r) = -\frac{1}{r} - \frac{\pi r}{\sin \pi a} F(a, 1-a; 1; r'^2)[F(a, 1-a; 1; r^2) \\ -2a(1-a)r'^2 F(a+1, 2-a; 2; r^2)]. \end{aligned} \tag{2.19}$$

Hence, (2.17) follows from [R, Theorem 21, p. 60] and (2.19).

From (1.2), (2.11), and (2.19), we obtain

$$m'(r) = -\frac{1}{r} - \frac{4}{\pi} r\mathcal{K}'(r)\left[\mathcal{K}(r) - \frac{\pi}{4} r'^2 F\left(\frac{3}{2}, \frac{3}{2}; 2; r^2\right)\right]$$
$$= -\frac{1}{r} - \frac{4}{\pi} r\mathcal{K}'(r)\left[\mathcal{K}(r) - \frac{r'^2}{r}\frac{d\mathcal{K}(r)}{dr}\right].$$

Hence, (2.18) follows from the well-known derivative formula for $\mathcal{K}(r)$ and the *Legendre relation* [BF, 110.10]. □

It is well known that the function $f(r) \equiv \mathcal{K}(r)/\log(4/r')$ is strictly decreasing from $[0,1)$ onto $(1, \pi/\log 16]$ (cf. [AVV2, Theorem 3.21(10)] and [QVa, Theorem 1.4]). The next result provides an analogue of this property for $F(a,b;a+b;x)$.

THEOREM 2.3. *Let $a, b \in (0,\infty)$ with $c = a+b$. Then the function*

$$f(x) \equiv F(a,b;c;x)/[R(a,b) - \log(1-x)]$$

is strictly decreasing from $[0,1)$ onto $(1/B(a,b), 1/R(a,b)]$. In particular, $\mathcal{K}(r)/\log(4/r')$ is strictly decreasing from $[0,1)$ onto $(1, \pi/\log 16]$.

Proof. Clearly, $f(0) = 1/R(a,b)$. Since

$$F(a_1, b_1; c_1; 1) = \frac{\Gamma(c_1)\Gamma(c_1 - a_1 - b_1)}{\Gamma(c_1 - a_1)\Gamma(c_1 - b_1)} \tag{2.20}$$

if $c_1 > a_1 + b_1$ and if $c_1 \neq 0, -1, -2, \ldots$ (see [AS, 15.1.20, p. 213] or [R, Theorem 18, p. 49]), by l'Hôpital's rule, [R, Theorem 21, p. 60], and by (2.2), we obtain

$$f(1^-) = \frac{ab}{c}\lim_{x\to 1^-}(1-x)F(a+1, b+1; c+1; x)$$
$$= \frac{ab}{c}F(a,b;c+1;1) = \frac{ab\Gamma(c+1)\Gamma(1)}{c\Gamma(a+1)\Gamma(b+1)} = \frac{1}{B(a,b)}.$$

Next, by differentiation, (2.11), and [R, Theorem 21, p. 60], we get

$$f'(x) = \frac{F(a,b;c+1;x)}{(1-x)[R(a,b) - \log(1-x)]^2} f_1(x), \tag{2.21}$$

where

$$f_1(x) = \frac{ab}{c}[R(a,b) - \log(1-x)] - \frac{F(a,b;c;x)}{F(a,b;c+1;x)}.$$

Clearly, $f_1(0) = [abR(a,b)/c] - 1$, and $(1-x)[R(a,b) - \log(1-x)]^2$ is strictly decreasing in x on $(0,1)$ by (2.7). By (2.20) and (2.2), it holds that

$$F(a,b;c+1;1) = c/[abB(a,b)]. \tag{2.22}$$

By l'Hôpital's rule, we have

$$\lim_{x\to 1^-} \frac{1}{\sqrt{1-x}}\left[\frac{ab}{c}B(a,b)F(a,b;c+1;x) - 1\right] \tag{2.23}$$
$$= -2\frac{(ab)^2 B(a,b)}{c(c+1)}\lim_{x\to 1^-}\sqrt{1-x}F(a+1, b+1; c+2; x) = 0.$$

It follows from (2.8), (2.22), and (2.23) that

$$f_1(1^-) = \lim_{x\to 1^-} \frac{1}{F(a,b;c+1;x)} \left\{ \frac{ab}{c}[R(a,b) - \log(1-x) \right.$$
$$\left. -B(a,b)F(a,b;c;x)]F(a,b;c+1;x) + F(a,b;c;x)\left[\frac{ab}{c}B(a,b)F(a,b;c+1;x) - 1\right]\right\}$$
$$= \frac{1}{F(a,b;c+1;1)} \lim_{x\to 1^-} \left\{ \sqrt{1-x}F(a,b;c;x) \cdot \frac{[abB(a,b)F(a,b;c+1;x)/c] - 1}{\sqrt{1-x}} \right\} = 0.$$

Again we use the formula $F(a,b;a+b+1;z) = (1-z)F(a+1,b+1;a+b+1;z)$ from [R, Theorem 21, p. 60], and because $c = a+b$ we obtain

$$f_1'(x) = \frac{ab}{c(1-x)} - \frac{1}{F(a,b;c+1;x)^2}\left[\frac{ab}{c}F(a+1,b+1;c+1;x)F(a,b;c+1;x)\right.$$
$$\left. - \frac{ab}{c+1}F(a,b;c;x)F(a+1,b+1;c+2;x)\right]$$
$$= \frac{ab}{c+1}\frac{F(a,b;c;x)F(a+1,b+1;c+2;x)}{F(a,b;c+1;x)^2} > 0.$$

Hence f_1 is strictly increasing from $(0,1)$ onto $([abR(a,b)/c] - 1, 0)$, and the monotonicity of f follows from (2.21).

Take $a = b = 1/2$. Then $R(a,b) = \log 16$ by (2.7), $B(a,b) = \pi$ by (2.3), and hence, the second conclusion follows. □

LEMMA 2.4. *Let $a \in (0,1/2]$. Then the function $f(x) \equiv (2-x)F(a,1-a;1;x)^2 - 2$ is strictly increasing and convex from $(0,1)$ onto $(0,\infty)$ if and only if $a = 1/2$. If $a \in (0,1/2)$, then there exists a unique $x_0 \in (0,1)$ such that f is strictly decreasing on $(0,x_0]$, and increasing on $[x_0,1)$, so that f' has a unique zero on $(0,1)$.*

Proof. Clearly, $f(0) = 0$ and $f(1^-) = \infty$. Differentiation gives

$$f'(x) = F(a,1-a;1;x)g(x), \tag{2.24}$$

where

$$g(x) = 2a(1-a)(2-x)F(a+1,2-a;2;x) - F(a,1-a;1;x).$$

Using the series expansion of $F(a,b;c;x)$, we get

$$g(x) = 4\sum_{n=0}^{\infty} \frac{(a,n+1)(1-a,n+1)}{(n+1)!n!}x^n$$
$$- 2\sum_{n=0}^{\infty}\frac{n(a,n)(1-a,n)}{(n!)^2}x^n - \sum_{n=0}^{\infty}\frac{(a,n)(1-a,n)}{(n!)^2}x^n$$
$$= \sum_{n=0}^{\infty}\frac{(a,n)(1-a,n)}{(n+1)!n!}[2n^2+n+4a(1-a)-1]x^n.$$

Since $2n^2+n+4a(1-a)-1 > 0$ for all $n \in \mathbf{N}$, we see that g is strictly increasing on $(0,1)$. Clearly, $g(0) = 4a(1-a)-1 = -(2a-1)^2$. By [R, Theorem 21, p. 60] and (2.22), we find

$$g(1^-) = \lim_{x\to 1^-}\frac{1}{1-x}[2a(1-a)(2-x)F(a,1-a;2;x) - (1-x)F(a,1-a;1;x)] = \infty.$$

Hence, the result follows from (2.24). □

We now prove some properties of the function $m_a(r)$ defined by (2.15).

THEOREM 2.5. *Let $a \in (0, 1/2]$, and $C = R(a)/2$. Then we have the following conclusions:*

1. *The function $f(r) \equiv m_a(r) + \log r$ is strictly decreasing and concave from $(0, 1)$ onto $(0, C)$. In particular, for all $a \in (0, 1/2]$ and $r \in (0, 1)$,*

$$C(1 - r) < m_a(r) + \log r < C. \tag{2.25}$$

2. *The function $g(r) \equiv \{C - [m_a(r) + \log r]\}/r$ is strictly increasing from $(0, 1)$ onto $(0, C)$.*
3. *The function $h(r) \equiv m_a(r)/\log(1/r)$ is strictly increasing from $(0, 1)$ onto $(1, \infty)$.*
4. *For any fixed $t \in (0, 1)$, the function $G(r) \equiv m_a(rt) - m_a(r)$ is strictly increasing from $(0, 1)$ onto $(-\log t, m_a(t))$. In particular, for all $a \in (0, 1/2]$ and $r, t \in (0, 1)$,*

$$\max\{m_a(r) - \log t,\ m_a(t) - \log r\} < m_a(rt) < m_a(r) + m_a(t), \tag{2.26}$$

and

$$m_a(r) - \log r < m_a(r^2) < 2m_a(r). \tag{2.27}$$

Proof. 1. It follows from (2.17) that

$$-\frac{\sin \pi a}{\pi} f'(r) = f_1(r) f_2(r) \equiv f_3(r), \tag{2.28}$$

where

$$f_1(r) = rF(a, 1-a; 1; r'^2) \quad \text{and} \quad f_2(r) = F(a, 1-a; 1; r^2) - 2a(1-a)F(a, 1-a; 2; r^2).$$

Clearly, $f_2(0) = 1 - 2a(1 - a) = a^2 + (1 - a)^2$. By (2.22), we see that $f_2(1^-) = \infty$. Using the series expansion of $F(a, b; c; x)$, we get

$$f_2(r) = \sum_{n=0}^{\infty} \frac{(a, n)(1 - a, n)}{(n + 1)!n!} [n + a^2 + (1 - a)^2] r^{2n},$$

from which it can be easily seen that f_2 is strictly increasing from $(0, 1)$ onto $(a^2 + (1 - a)^2, \infty)$. Hence, by [QVu2, Lemma 2.15(1)], f_3 is a product of two positive and strictly increasing functions on $(0, 1)$ so that the monotonicity and concavity of f follows from (2.28).

The limiting value $f(1^-) = 0$ is clear. It follows from (2.8) and (2.3) that

$$\begin{aligned} f(0^+) &= \frac{1}{2} \lim_{r \to 0^+} [B(a, 1 - a) r'^2 F(a, 1 - a; 1; r^2) F(a, 1 - a; 1; r'^2) + \log r^2] \\ &= \frac{1}{2} \lim_{r \to 0^+} \Bigg\{ [B(a, 1 - a) F(a, 1 - a; 1; r'^2) + \log r^2] \\ &\quad + B(a, 1 - a) r^2 F(a, 1 - a; 1; r'^2) \cdot \frac{r'^2 F(a, 1 - a; 1; r^2) - 1}{r^2} \Bigg\} \\ &= \frac{1}{2} R(a, 1 - a) = \frac{1}{2} R(a) = C, \end{aligned}$$

since by l'Hôpital's rule

$$\lim_{r\to 0^+}\frac{1}{r^2}[r'^2F(a,1-a;1;r^2)-1]=a(1-a)-1.$$

The double inequality (2.25) is clear.

2. Let $g_1(r)=C-[m_a(r)+\log r]=C-f(r)$ and $g_2(r)=r$. Then $g_1(0^+)=g_2(0)=0$, and

$$g_1'(r)/g_2'(r)=-f'(r),$$

which is strictly increasing on $(0,1)$ by part 1. Hence, the monotonicity of g follows from the monotone version of l'Hôpital's rule [AVV2, Theorem 1.24].

Clearly, $g(1^-)=R(a)/2$. By l'Hôpital's rule and (2.28), $g(0^+)=-f'(0^+)=0$.

3. By (2.22), (2.3), [R, Theorem 21, p. 60], and l'Hôpital's rule, we have

$$h(0^+)=\frac{\pi}{2\sin\pi a}\lim_{r\to 0^+}\frac{F(a,1-a;1;r'^2)}{\log(1/r)}=\frac{a(1-a)\pi}{\sin\pi a}F(a,1-a;2;1)=1.$$

Since $\lim_{r\to 1}r'^2/\log(1/r)=2$, we see that $h(1^-)=\infty$.

Next, let $h_1(r)=\log(1/r)$. Then $m_a(1^-)=h_1(1)=0$, and by (2.17),

$$\frac{m_a'(r)}{h_1'(r)}=1+\frac{\pi}{\sin\pi a}rf_1(r)f_2(r)\equiv h_2(r),$$

where f_1 and f_2 are as in (2.28). From the proof of part 1, we see that h_2 is strictly increasing on $(0,1)$, and hence, so is h by [AVV2, Theorem 1.24].

4. Let $x=rt$. Then $x<r$, and

$$rG'(r)=xm_a'(x)-rm_a'(r)=G_1(r)=xf'(x)-rf'(r),$$

where f is as in part 1. From the proof of part 1, we see that $uf'(u)$ is strictly decreasing on $(0,1)$. Hence, $G_1(r)>0$ for all $r\in(0,1)$ so that the monotonicity of G follows.

Clearly, $G(1^-)=m_a(t)$. Since

$$G(r)=[m_a(x)+\log x]-[m_a(r)+\log r]-\log t,$$

it follows from part 1 that $G(0^+)=-\log t$.

The inequalities in (2.26) and (2.27) are clear. □

Remark 2. For $a=1/2$, parts 1–3 of Theorem 2.5 reduce to corresponding well-known results for the function $m(r)$ (cf. [AVV2, Theorem 3.30 parts 1, 2, and 4]).

3. Proofs of the main theorems. In this section, we prove the results stated in section 1.

3.1. Proof of Theorem 1.1. Consider the function

$$f(r)\equiv\mu_a(r)-arth\ r'=\mu_a(r)+\log r-\log(1+r') \tag{3.1}$$

for $a\in(0,1/2]$ and $r\in(0,1)$. In [QVu2, Theorem 1.23(1)], it was shown that f is strictly decreasing and concave from $(0,1)$ onto $(0,[R(a)-\log 4]/2)$.

Let $r_1 = \varphi_2(r')$. Then by [AVV2, Theorem 10.5(4)], $r_1 = 2\sqrt{r'}/(1+r'), r' = \varphi_{1/2}(r_1) = (1-r_1')/(1+r_1')$ and $r = \varphi_2(r_1') = 2\sqrt{r_1'}/(1+r_1')$ so that

$$f(r) = \mu_a\left(\frac{2\sqrt{r_1'}}{1+r_1'}\right) - \frac{1}{2}\log\frac{1+\varphi_{1/2}(r_1)}{1-\varphi_{1/2}(r_1)} = \mu_a\left(\frac{2\sqrt{r_1'}}{1+r_1'}\right) + \frac{1}{2}\log r_1'. \tag{3.2}$$

Let $g(x) = 2\mu_a(2\sqrt{x}/(1+x)) - \mu_a(x)$ for $x \in (0,1)$ and $a \in (0,1/2]$. Then (3.2) can be written as

$$f(r) - \frac{1}{2}\log r_1' - \frac{1}{2}arth\ r_1 = \frac{1}{2}[g(r_1') + f(r_1')],$$

that is

$$f(r) - \frac{1}{2}\log(1+r_1) = \frac{1}{2}[g(r_1') + f(r_1')]. \tag{3.3}$$

Similarly, putting $r_2 = \varphi_2(r_1) = \varphi_4(r')$, we get

$$f(r_1') - \frac{1}{2}\log(1+r_2) = \frac{1}{2}[g(r_2') + f(r_2')],$$

and hence, by (3.3),

$$f(r) - \frac{1}{2}\log(1+r_1) - \frac{1}{4}\log(1+r_2) = \frac{1}{2}g(r_1') + \frac{1}{4}g(r_2') + \frac{1}{4}f(r_2').$$

Generally, assuming

$$f(r) - \sum_{k=1}^{n-1}\frac{1}{2^k}\log(1+r_k) = \sum_{k=1}^{n-1}\frac{1}{2^k}g(r_k') + \frac{1}{2^{n-1}}f(r_{n-1}') \tag{3.4}$$

for $n \in \mathbf{N}$ and $n \geq 2$, we let $r_n = \varphi_2(r_{n-1}) = \varphi_{2^n}(r')$, and from (3.4) it follows that

$$f(r) - \sum_{k=1}^{n}\frac{1}{2^k}\log(1+r_k) = \sum_{k=1}^{n}\frac{1}{2^k}g(r_k') + \frac{1}{2^n}f(r_n'). \tag{3.5}$$

Hence, by induction, (3.5) holds for all $n \in \mathbf{N}$, $a \in (0,1/2]$, and $r \in (0,1)$.

It follows from (3.5), Theorem 2.1, and [QVu2, Theorems 1.14(1) and 1.23(1)] that

$$\begin{aligned}\frac{1}{2^{n+1}}[R(a) - \log 4](1-r_n') < f(r) &- \sum_{k=1}^{n}\frac{1}{2^k}\log(1+r_k)\\ &< \frac{1}{2}[R(a) - \log 16]\sum_{k=1}^{n}\frac{1}{2^k} + \frac{1}{2^n}\left[\frac{1}{2}R(a) - \log 2\right]\\ &= \frac{1}{2}[R(a) - \log 16]\left(1 - \frac{1}{2^n}\right) + \frac{1}{2^n}\left[\frac{1}{2}R(a) - \log 2\right]\\ &= \frac{1}{2}[R(a) - \log 16] + \frac{1}{2^n}\log 4.\end{aligned}$$

Letting $n \to \infty$, we get

$$\sum_{k=1}^{\infty} \frac{1}{2^k} \log(1+r_k) \le f(r) \le \sum_{k=1}^{\infty} \frac{1}{2^k} \log(1+r_k) + \frac{1}{2}[R(a) - \log 16]. \tag{3.6}$$

The double inequality (1.10) now follows from (3.1) and (3.6). Equality (1.11) follows immediately, if we set $a = 1/2$ in (1.10) and apply (2.7).

If $a \in (0, 1/2)$, then by (2.7) and (1.11), the first equality in (1.10) cannot hold since as a function of a, $\mu_a(r)$ is strictly decreasing from $(0, 1/2]$ onto $[\mu(r), \infty)$ by [QVu2, Theorem 1.22]. Suppose that the second equality in (1.10) holds for some $a \in (0, 1/2)$ and for all $r \in (0, 1)$. Then it follows from (1.10) and (1.11) that

$$\mu_a(r) = \mu(r) + \frac{1}{2}[R(a) - \log 16]. \tag{3.7}$$

Letting $r \to 1^-$ in (3.7), we obtain

$$R(a) \equiv \log 16, \quad 0 < a < 1/2.$$

This is a contradiction since $R(a) = \log 16$ if and only if $a = 1/2$ (see the equality case of (2.7)). Consequently, the equality holds in (1.10). □

The next result follows immediately from Theorem 1.1.

COROLLARY 3.1. *For $a \in (0, 1/2]$ and $r \in (0, 1)$,*

$$\mu(r) \le \mu_a(r) \le \mu(r) + \frac{1}{2}(R(a) - \log 16), \tag{3.8}$$

with equality if and only if $a = 1/2$.

3.2. Proof of Theorem 1.2. 1. First we observe that $f(r)$ can be rewritten as

$$f(r) = \frac{m_a(r)}{\log(1/r)} \cdot \frac{1}{r' F(a, 1-a; 1; r^2)^2}. \tag{3.9}$$

Since $r' F(a, 1-a; 1; r^2)$ is strictly decreasing in r from $(0, 1)$ onto $(0, 1)$ by [ABRVV, Theorem 1.7], the right side of (3.9) is a product of two positive and strictly increasing functions on $(0, 1)$ by Theorem 2.5, part 3. Hence, part 1 follows.

2. The monotonicity and the limiting values of g follows from part 1. In order to prove the convexity of g, we let $x = 1/r$ for $r \in (1, \infty)$. Then, by differentiation and (2.10), we obtain

$$\begin{aligned} g'(r) = -g_1(x) &\equiv \frac{x}{[\log(1/x)]^2} \left\{ \frac{\log(1/x)}{[x' F(a, 1-a; 1; x^2)]^2} - \mu_a(x) \right\} \\ &= -\frac{x}{\log(1/x)} \cdot \frac{1}{[x' F(a, 1-a; 1; x^2)]^2} \cdot \left[\frac{m_a(x)}{\log(1/x)} - 1 \right]. \end{aligned} \tag{3.10}$$

Clearly, $x/\log(1/x)$ is strictly increasing in x on $(0, 1)$. Since $x' F(a, 1-a; 1; x^2)$ is strictly decreasing in x on $(0, 1)$ by [ABRVV, Theorem 1.7], it follows from Theorem 2.5, part 3 that $g_1(x)$ is a product of three positive and strictly increasing functions of x on $(0, 1)$. Hence, g_1 is strictly decreasing in r on $(1, \infty)$ so that g' is strictly increasing in r on $(1, \infty)$, and the convexity of g follows.

Next, using (3.10), we get

$$G'(r) = -g'(1/r)/r^2 = g_1(r)/r^2 \tag{3.11}$$
$$= \frac{1}{[r'F(a,1-a;1;r^2)]^2} \cdot \frac{m_a(r)+\log r}{r[\log(1/r)]^2}$$
$$= \frac{1}{r\log(1/r)} \cdot \frac{1}{[r'F(a,1-a;1;r^2)]^2} \cdot \left[\frac{m_a(r)}{\log(1/r)} - 1\right].$$

By l'Hôpital's rule, Theorem 2.5, part 1, and (2.28),

$$\lim_{r\to 0^+} \frac{[m_a(r)+\log r]/r}{[\log(1/r)]^2} = \frac{1}{2}\lim_{r\to 0^+} \frac{[\pi r f_3(r)/\sin\pi a] + m_a(r) + \log r}{r\log(1/r)} = \infty,$$

where f_3 is as in (2.28). Hence, from the third equality in (3.11) we see that $G'(0^+) = \infty$. On the other hand, it follows from the fourth equality in (3.11) and Theorem 2.5, part 3 that $G'(1^-) = \infty$. Consequently, $G'(r)$ is neither decreasing nor increasing on $(0,1)$, and the assertion about $G(r)$ follows.

3. By differentiation and (2.10), we obtain

$$-h'(r) = h_1(r) \equiv \frac{1}{\{[(R(a)/2)+\log(1/r)]r'F(a,1-a;1;r^2)\}^2} \cdot \frac{[R(a)/2]-[m_a(r)+\log r]}{r}.$$

Since $r'F(a,1-a;1;r^2)$ is strictly decreasing from $(0,1)$ onto $(0,1)$ by [ABRVV, Theorem 1.7], by Theorem 2.5, part 2, $h_1(r)$ is a product of two positive and strictly increasing functions on $(0,1)$. Hence, the monotonicity and concavity of h follow.

Clearly, $h(1^-) = 0$, while the limit $h(0^+) = 1$ follows from part 1.

4. The function $H(r)$ can be written as

$$H(r) = \frac{\pi}{\sin\pi a} \frac{1}{\sqrt{r'}F(a,1-a;1;r^2)} \cdot \frac{F(a,1-a;1;r'^2)}{R(a)-\log r^2}. \tag{3.12}$$

Since $\sqrt{r'}F(a,1-a;1;r^2) = \sqrt[4]{1-r^2}F(a,1-a;1;r^2)$ is strictly decreasing from $(0,1)$ onto $(0,1)$ [ABRVV, Theorem 1.7], the result for H follows from (3.12), Theorem 2.3, and (2.3).

The first and second inequalities in (1.12) follow from the monotonicity of H and part 3, respectively. □

3.3. Proof of Theorem 1.3. 1. Put $x = e^{-r}$. Then $x \in (0,1)$, and by differentiation and (2.10), we get

$$f'(r) = [x'F(a,1-a;1;x^2)]^{-2},$$

which is strictly decreasing in r on $(0,\infty)$ by [ABRVV, Theorem 1.7]. Hence, the concavity of f follows.

The inequalities (1.13), (1.14) and their equality case are clear.

2. This follows immediately from part 1.

3. Let $x = rt/(1+r't')$. Then $x < rt < r$ and

$$\frac{dx}{dr} = \frac{t(r'+t')}{r'(1+r't')^2} = \frac{xx'}{rr'}.$$

Differentiation and (2.10) give

$$h'(r) = \frac{x'F(a,1-a;1;x^2)^2 - r'F(a,1-a;1;r^2)^2}{rx'[r'F(a,1-a;1;r^2)F(a,1-a;1;x^2)]^2},$$

which is positive for all $r \in (0,1)$ since $r'F(a,1-a;1;r^2)^2$ is strictly decreasing on $(0,1)$ by [ABRVV, Theorem 1.7] and since $x < r$. Hence the monotonicity of h follows.

Clearly, $h(1^-) = \mu_a(t)$. It follows from [QVu2, Corollary 3.12] that

$$h(0^+) = \lim_{r\to 0^+} \left\{ [\mu_a(x) + \log x] - [\mu_a(r) + \log r] + \log \frac{1+r't'}{t} \right\} = \log \frac{1+t'}{t} = arth\, t'.$$

The second and third inequalities in (1.16) are clear, while the first inequality in (1.16) follows from [QVu2, Theorem 1.23(1)].

4. Let $x = \sqrt{r}$. Then by differentiation, (1.5), (2.10), and (2.15), we get

$$\frac{r}{2}\left[\frac{\pi}{\sin \pi a} r'x'F(a,1-a;1;r^2)F(a,1-a;1;x'^2)\right]^2 G'(r) = m_a(r) - 2m_a(x),$$

which is negative for all $r \in (0,1)$ by (2.27). This yields the monotonicity of G.

By (1.5) and (2.8), we have

$$G(0^+) = \lim_{r\to 0^+} \frac{F(a,1-a;1;r'^2)}{F(a,1-a;1;1-r)} = \lim_{r\to 0^+} \frac{\log r^2}{\log r} = 2,$$

and

$$G(1^-) = \lim_{r\to 1^-} \frac{F(a,1-a;1;r)}{F(a,1-a;1;r^2)} = \lim_{r\to 1^-} \frac{\log(1-r)}{\log(1-r^2)} = 1.$$

The double inequality (1.17) is clear. □

3.4. Proof of Theorem 1.4. 1. Let $f_1(r) = r[r'F(a,1-a;1;r^2)]^2$. Then by differentiation and [R, Theorem 21, p. 60],

$$[F(a,1-a;1;r^2)]^{-1} f_1'(r) = f_3(r) \equiv r'^2 F(a,1-a;1;r^2) - 2rf_2(r),$$

where f_2 is as in the proof of Theorem 2.5, part 1. In the proof of Theorem 2.5, part 1, we have shown that f_2 is strictly increasing from $(0,1)$ onto $(a^2 + (1-a)^2, \infty)$. Hence, by [ABRVV, Theorem 1.7], f_3 is strictly decreasing from $(0,1)$ onto $(-\infty, 1)$, so that there exists a unique $r_0 \in (0,1)$ such that f_1 is strictly increasing on $(0, r_0]$, and decreasing on $[r_0, 1)$ with range $(0, f_1(r_0)]$.

Next, by (2.10),

$$f'(r) = -1/f_1(r), \tag{3.13}$$

which is strictly increasing on $(0, r_0]$, and decreasing on $[r_0, 1)$. This yields the assertion about f.

Let $f_4(r) = r[r'F(a,1-a;1;r'^2)]^2$, and

$$f_5(r) = r'^2 F(a,1-a;1;r^2) + 2a(1-a)r^2 F(a,1-a;2;r^2).$$

Then by differentiation, (2.10), and [R, Theorem 21, p. 60], we get

$$\frac{d}{dr}\left(\frac{1}{f(r)}\right) = \left(\frac{2\sin \pi a}{\pi}\right)^2 \frac{1}{f_4(r)}, \tag{3.14}$$

and

$$[F(a,1-a;1;r'^2)]^{-1}f_4'(r)=f_6(r)\equiv r'^2F(a,1-a;1;r'^2)-2f_5(r'). \tag{3.15}$$

Using the series expansion of $F(a,b;c;x)$, we obtain

$$\begin{aligned}f_5(r)&=(1-r^2)\sum_{n=0}^{\infty}\frac{(a,n)(1-a,n)}{(n!)^2}r^{2n}+2a(1-a)\sum_{n=0}^{\infty}\frac{(a,n)(1-a,n)}{(n+1)!n!}r^{2(n+1)}\\&=\sum_{n=0}^{\infty}\frac{(a,n)(1-a,n)}{(n!)^2}r^{2n}-\sum_{n=1}^{\infty}\frac{(a,n-1)(1-a,n-1)}{[(n-1)!]^2}r^{2n}\\&\quad+2a(1-a)\sum_{n=1}^{\infty}\frac{(a,n-1)(1-a,n-1)n}{(n!)^2}r^{2n}\\&=1+\sum_{n=1}^{\infty}\frac{(a,n-1)(1-a,n-1)}{(n!)^2}\{a(1-a)-[a^2+(1-a)^2]n\}r^{2n},\end{aligned}$$

which is strictly decreasing on $(0,1)$ since

$$a(1-a)-[a^2+(1-a)^2]n\le 3a(1-a)-1<0$$

for all $n\in\mathbf{N}$. Hence, f_6 is strictly decreasing on $(0,1)$. Clearly, $f_6(1^-)=-2$. By (2.22) and (2.3), $f_5(1^-)=(2\sin\pi a)/\pi$ so that $f_6(0^+)=\infty$. Thus, there exists a unique $r_1\in(0,1)$ such that f_4 is strictly increasing on $(0,r_1]$ and decreasing on $[r_1,1)$ with $f_4(0^+)=f_4(1^-)=0$. Consequently, the assertion about $1/f(r)$ follows from (3.14).

2. Differentiation and (2.10) give

$$g'(r)=\frac{F(a,1-a;1;r^2)+1}{[r'F(a,1-a;1;r^2)]^2}\cdot\frac{F(a,1-a;1;r^2)-1}{r},$$

which is a product of two positive and strictly increasing functions on $(0,1)$ since by (1.1)

$$\frac{1}{r}[F(a,1-a;1;r^2)-1]=\sum_{n=1}^{\infty}\frac{(a,n)(1-a,n)}{(n!)^2}r^{2n-1},$$

and since $r'F(a,1-a;1;r^2)$ is strictly decreasing on $(0,1)$ by [ABRVV, Theorem 1.7]. Hence, the monotonicity and convexity of g follow.

The limiting values follow from [QVu2, Corollary 3.12].

3. By differentiation and (2.10), we get

$$-h'(r)=\Big[\frac{r}{r'}\exp(\mu_a(r))\Big]\cdot\frac{1}{r'F(a,1-a;1;r^2)^2}\cdot\frac{1-[r'F(a,1-a;1;r^2)]^2}{r},$$

which is a product of three positive and strictly increasing functions on $(0,1)$ by part 2 and [QVu2, Lemma 2.16 (2) & (3)]. Hence the monotonicity and concavity of h follow.

Clearly, $h(1^-)=1$. By part 2, we have $h(0^+)=\exp(R(a)/2)$.

4. Differentiation gives

$$G'(r)=\frac{(2-r^2)F(a,1-a;1;r^2)^2-2}{2r[r'F(a,1-a;1;r^2)]^2}, \tag{3.16}$$

which is positive for all $r \in (0,1)$ if and only if $a = 1/2$, by Lemma 2.4. Hence, part 4i and the piecewise monotonicity stated in part 4iii of Theorem 1.4 follow from (3.16) and Lemma 2.4.

Next, let

$$G_1(r) = [(2-r)F(a,1-a;1;r)^2 - 2]/r, \quad G_2(r) = (2-r)F(a,1-a;1;r)^2 - 2,$$

and $G_3(r) = r$. Then $G_2(0) = G_3(0) = 0$, and by (2.24),

$$G_2'(r)/G_3'(r) = F(a,1-a;1;r)G_4(r), \tag{3.17}$$

where

$$G_4(r) = 2a(1-a)(2-r)F(a+1,2-a;2;r) - F(a,1-a;1;r).$$

It was proved in the proof of Lemma 2.4 that G_4 is strictly increasing from $(0,1)$ onto $(-(2a-1)^2, \infty)$. Hence, if $a = 1/2$, then by (3.17), $G_2'(r)/G_3'(r)$ is strictly increasing on $(0,1)$, and so is G_1 by [AVV2, Theorem 1.24] with $G_1(0^+) = G_4(0) = 0$. Consequently, by (3.16) and [ABRVV, Theorem 1.7], G' is strictly increasing on $(0,1)$ if $a = 1/2$, so that G is convex on $(0,1)$.

Now suppose that $a \in (0, 1/2)$. By (3.16), (2.24), [R, Theorem 21, p. 60], and by differentiation, we get

$$\begin{aligned} 2r'^4 F(a,1-a;1;r^2)^3 G''(r) = G_5(r) \equiv 2[r'F(a,1-a;1;r^2)]^2 G_4(r^2) \\ - G_1(r^2)[(1-3r^2)F(a,1-a;1;r^2) + 4a(1-a)r^2 F(a,1-a;2;r^2)]. \end{aligned} \tag{3.18}$$

Clearly, $G_5(1^-) = \infty$. It follows from (3.17), l'Hôpital's rule, and the discussion in the previous paragraph that

$$G_5(0^+) = 2G_4(0) - G_1(0^+) = 2G_4(0) - G_4(0) = -(2a-1)^2 < 0.$$

Therefore, by (3.18), G' is not monotone on $(0,1)$ if $a \in (0,1/2)$, so that part 4ii and the second assertion in part 4iii follow.

Finally, the limiting values of G follow from [QVu2, Corollary 3.12]. □

Conjecture 1. For $a \in (0,1/2)$, the function $g(r) \equiv \mu_a(r)/arth\ \sqrt[4]{r'}$ is strictly increasing from $(0,1)$ onto $(1,\infty)$.

4. Open problem. It was proved in [QVa, Theorem 1.4(1)&(2)] that the function $f(r) \equiv \mathcal{K}(r)/\log(4/r')$ is not only strictly decreasing but also strictly concave on $[0,1)$, while $g(r) \equiv f(r')$ is strictly convex on $(0,1]$. In Theorem 2.3, we obtained the analogue of the monotonicity property of $f(r)$ for its generalization $h(r) \equiv F(a,b;a+b;r^2)/[R(a) - \log(1-r^2)]$ for $a,b \in (0,\infty)$. What are the analogues of the concavity of $f(r)$ and the convexity of $g(r)$ for $h(r)$ and $h(r')$, respectively? Our computational work seems to show that for small values of a and b, say $a+b<1$, $h(r)$ and $h(r')$ are concave and convex on $(0,1)$, respectively, and for large values of a and b, say $a,b \in (1,\infty)$, $h(r)$ and $h(r')$ are convex and concave on $(0,1)$, respectively, while for some values of a and b, both $h(r)$ and $h(r')$ are neither concave nor convex on $(0,1)$.

Acknowledgments. This research was completed during the first author's visit to the University of Helsinki on grants from the Finnish Academy of Sciences and Letters, the Academy of Finland, and from the Commission on Development and Exchanges of International Mathematical Union. He wishes to express his thanks to

these institutions and to the Department of Mathematics of the University of Helsinki for its excellent research facilities. Both authors are indebted to the referees, whose remarks were very valuable.

UNSTABLE OSCILLATORY-TAIL WAVES IN COLLISIONLESS PLASMAS*

YAN GUO† AND WALTER A. STRAUSS‡

Abstract. Consider a collisionless relativistic neutral plasma. An oscillatory-tail equilibrium is a state whose magnetic field connects two different constant states at $x = -\infty$ and $x = +\infty$ and whose electric field oscillates as $x \to -\infty$. We prove that such a state is nonlinearly dynamically unstable under certain perturbations of the initial data.

Key words. collisionless plasma, instability, BGK mode, oscillatory electric field, relativistic particles

1. Introduction.

A collisionless plasma of electrons and ions is described by the Vlasov–Maxwell system. In such a plasma, collisions are relatively rare; here we assume no collisions at all. In many plasmas, some of the particles are expected to travel at relativistic speeds. However, in a nonrelativistic Vlasov model, particles can travel at arbitrarily great speed. We avoid this anomaly by assuming a relativistic model. Thus we consider the relativistic Vlasov–Maxwell system (RVM):

$$
\begin{aligned}
&\partial_t f_\pm + \hat{v}_\pm \cdot \nabla_x f_\pm + e_\pm(\mathbf{E} + \hat{v}_\pm \times \mathbf{B}) \cdot \nabla_v f_\pm = 0,\\
&\partial_t \mathbf{E} - c\ \mathrm{curl}\ \mathbf{B} = -\mathbf{j} = -\int_{\mathbf{R}^3} [e_+ \hat{v}_+ f_+ + e_- \hat{v}_- f_-] dv,\\
&\partial_t \mathbf{B} + c\ \mathrm{curl}\ \mathbf{E} = 0,\\
&\mathrm{div}\ \mathbf{E} = \rho = \int_{\mathbf{R}^3} [e_+ f_+ + e_- f_-] dv, \quad \mathrm{div}\ \mathbf{B} = 0,
\end{aligned}
\tag{1}
$$

where $m_\pm$ and $e_\pm$ are the masses and charges of the ions $(+)$ and electrons $(-)$, respectively. Here f_+ is the distribution of the ions, f_- the distribution of the electrons at time t, $\mathbf{E}$ the electric field, $\mathbf{B}$ the magnetic field, $\mathbf{x}$ the position, $\mathbf{v}$ the momentum, and $\hat{\mathbf{v}}_\pm$ the velocity.

For notational simplicity, we set all constants equal to 1 and $e_\pm = \pm 1$, so that the velocity is $\hat{\mathbf{v}} = \mathbf{v}/\sqrt{1 + |\mathbf{v}|^2}$. We consider the simplest scenario where there can be a magnetic field, the so-called $1\frac{1}{2}$-dimensional system $1\frac{1}{2}$RVM, where the position is $\mathbf{x} = (x, 0, 0)$, the momentum is $\mathbf{v} = (v_1, v_2, 0)$, the electric field is $\mathbf{E} = (E_1, E_2, 0)$, and the magnetic field is $\mathbf{B} = (0, 0, B)$.

A fundamental feature of this collisionless model is the multiplicity of its steady states. The question of their dynamical stability has played a crucial role in plasma physics and is related to plasma control and turbulence. We consider equilibria of the

form

$$f_\pm = \mu_\pm(\langle v\rangle \mp \Phi(x), v_2 \pm \Psi(x)),\ E_1 = \partial_x\Phi,\quad E_2 = 0,\quad B = \partial_x\Psi, \tag{2}$$

which are a generalization of the Bernstein–Greene–Kruskal (BGK) modes [BGK]. It was observed in [GR] that such a state satisfies $1\frac{1}{2}$RVM if Φ and Ψ satisfy the coupled pair of ODEs

$$\begin{aligned}\Phi_{xx} &= \int_{\mathbf{R}^2}[\mu_+(\langle v\rangle - \Phi, v_2 + \Psi) - \mu_-(\langle v\rangle + \Phi, v_2 - \Psi)]dv,\\ \Psi_{xx} &= -\int_{\mathbf{R}^2}\hat{v}_2[\mu_+(\langle v\rangle - \Phi, v_2 + \Psi) - \mu_-(\langle v\rangle + \Phi, v_2 - \Psi)]dv.\end{aligned} \tag{3}$$

Furthermore some of these states are of the oscillatory-tail type, that is, $\Phi(x)$ approaches a periodic solution $\beta(x)$ as $x \to -\infty$ and a constant as $x \to +\infty$, while Ψ approaches two different constants at $+\infty$ and $-\infty$. The periodic function $\beta(x)$ satisfies the following ODE:

$$\beta_{xx} = \rho = \int_{\mathbf{R}^2}[\mu_+(\langle v\rangle - \beta, v_2) - \mu_-(\langle v\rangle + \beta, v_2)]dv_1dv_2. \tag{4}$$

We consider quintuples $u = [f_+, f_-, E_1, E_2, B]$. On such quintuples we consider the sum of the L^1 norms of the five components. Let $\beta(x)$ be a periodic solution to (4) so that

$$\Gamma_0 = [\mu_\pm(\langle v\rangle \mp \beta(x), v_2); \partial_x\beta, 0; 0] \tag{5}$$

is a periodic solution to (3), where $E_1 = \partial_x\beta$, $E_2 \equiv 0$, $B = 0$. Assume a solution $\Phi(x), \Psi(x)$ to (3) so that

$$\Gamma \equiv \Gamma(\Phi, \Psi)(x, v) = [\mu_\pm(\langle v\rangle \mp \Phi(x), v_2 \pm \Psi(x)); \partial_x\Phi, 0; \partial_x\Psi], \tag{6}$$

where $E_1 = \partial_x\Phi, E_2 \equiv 0, B = \partial_x\Psi$, satisfies

$$\lim_{x\to-\infty}\{|\Phi - \beta| + |\partial_x(\Phi - \beta)| + |\Psi| + |\partial_x\Psi|\} = 0. \tag{7}$$

Thus Γ_0 is a periodic solution, while Γ has an oscillatory tail. As mentioned above, such oscillatory-tail solutions exist [GR].

Our goal is to prove the following theorem on the instability of such states Γ. We will consider the class of solutions of (1) given by Theorem 4 of the appendix.

THEOREM 1. *Let $\mu_\pm$ satisfy $\mu_\pm = O(\langle v\rangle^{-l})$ for some $l > 3$ and* (11), (12), (14), (61), *and* (62). *Let $\beta(x)$ in* (5) *have period P_β and $\|\beta\|_{C^2}$ be sufficiently small. If Γ satisfies* (7), *then there exist $\epsilon_0 > 0$ and $C_1 > 0$ and a family of solutions $u^\delta(t) = [f_+^\delta, f_-^\delta, E_1^\delta, E_2^\delta, B^\delta]$ of $1\frac{1}{2}$RVM for $0 < \delta < \delta_0$ (with $f_\pm^\delta \geq 0$), as well as a family of intervals K^δ, each of length $2P_\beta$, such that*

$$||u^\delta(0) - \Gamma||_{W^{1,1}(\mathbf{R}\times\mathbf{R}^2)} < \delta$$

but

$$\sup_{0\leq t\leq C_1|\ln\delta|}\|u^\delta(t) - \Gamma\|_{L^1(K^\delta\times\mathbf{R}^2)} \geq \epsilon_0.$$

Notice that the solution escapes from a δ neighborhood of the equilibrium in a time $O(|\log \delta|)$. This property characterizes an exponential instability. Conditions (11), (61), and (62) require that $\mu_\pm$ be smooth and positive and satisfy certain decay conditions at infinity.

A major difficulty of this problem is that the spatial variable is unbounded. Therefore the growing plane wave solutions do not belong to any natural function space like L^p and correspond to the *continuous spectrum* of the linearized operator. Now the asymptotic solution Γ_0 satisfies the reduced system with $E_2 = B = 0$ and periodic boundary conditions, which system we denote by $1\frac{1}{4}$RVM. This system is analyzed by linearization to produce a linear system which we denote by $1\frac{1}{4}$L. While the periodic linear problem still has continuous spectrum (because of the unbounded v variable), it has less of it and we prove that it has some unstable point spectrum. We reduce the original problem to the periodic one using the causality property of RVM.

Thus there are four levels of instability that appear in this paper. The simplest level is that of the system linearized around a simple homogeneous state. This level is easily reduced to a dispersion relation for which explicit sufficient (and almost necessary) conditions are found following [P]. The second level is that of the system $1\frac{1}{4}$L linearized around the periodic equilibrium $\beta(x)$. The third level is that of the nonlinear system $1\frac{1}{4}$RVM. Our goal is to reach the fourth level, the full nonlinear system $1\frac{1}{2}$RVM which possesses the oscillatory-tail equilibrium solutions. Normally it is expected that exponential growth of the linearized system (the second level) should imply the nonlinear instability of the equilibrium (the third level). We are aware of no previous work other than ours [GS1], [GS2], [GS3], [GS4] that proves the instability of spatially dependent equilibria either on the linearized or the nonlinear level.

Although this paper is closely related to our previous ones, there are some major differences. Our earlier papers treated only the one-dimensional case, and there were no magnetic effects. In this paper there is a second momentum variable v_2 as well as a magnetic field. Furthermore the asymptotic behavior of the equilibrium as $x \to -\infty$ now is oscillatory instead of constant.

Some other related references are the following. Several classes of equilibria are constructed in [GR]. Stability of a homogeneous equilibrium μ within the Vlasov–Poisson theory has been discussed since the 1960s, beginning with the linear instability analysis of [P]. The nonlinear stability has been proven only for monotonically decreasing distributions μ that do not depend on the space variable. [G1] and [G2] prove the stability of various spatially dependent states. In particular, [G1] proves the stability of flat-tail equilibria, which possess nonoscillatory behavior as $x \to \pm\infty$. [G2] proves, for the three-dimensional RVM, the stability of general axially symmetric magnetic equilibria that are given variationally as minimizers of a natural action functional.

Section 2 of this paper is devoted to the periodic equilibria Γ_0 of the periodic system $1\frac{1}{4}$RVM. In section 3 such an equilibrium is proven to be linearly unstable due to a point eigenvalue. The analysis is similar to that of [GS3] except that the variable v_2 appears nontrivially in many places. The density profiles $\mu_\pm$ are required to decay in v_2 as well as in the energy $\langle v \rangle$. Section 4 is devoted to the regularity and certain pointwise estimates of the unstable eigenfunctions. In section 5 we prove the nonlinear instability of the periodic equilibrium Γ_0. Again, the variable v_2 appears in a significant way in some key places, for instance in the crucial Lemma 15. In section 6 we finally prove the main theorem by deriving the nonlinear instability of the oscillatory-tail equilibrium Γ in the $1\frac{1}{2}$ dimensional system from the nonlinear

instability of Γ_0 within the periodic $1\frac{1}{4}$ dimensional system. The key property that is required is that $\Gamma \to \Gamma_0$ as $x \to -\infty$.

2. BGK periodic waves. We consider the system that is obtained from $1\frac{1}{2}$ RVM by letting $E_2 \equiv 0, B \equiv 0$ and by considering functions that are even in v_2. This is the system $1\frac{1}{4}$ RVM:

$$
\begin{aligned}
&(\partial_t + \hat{v}_1\partial_x \pm E_1\partial_{v_1})f_\pm = 0,\\
&\partial_t E_1 = -j_1 = -\int\int \hat{v}_1(f_+ - f_-)dv_1dv_2,\\
&\partial_x E_1 = \rho = \int\int (f_+ - f_-)dv_1dv_2,
\end{aligned}
\tag{8}
$$

where

$$f(t,x,v_1,v_2) = f(t,x,v_1,-v_2), \tag{9}$$

$$f(t,x+P,v_1,v_2) = f(t,x,v_1,v_2) \tag{10}$$

with $P > 0$ fixed. We emphasize that $\langle v\rangle = (1+v_1^2+v_2^2)^{1/2}$ and $\hat{v}_1 = v_1\langle v\rangle^{-1}$ in (8). This system is well posed. (See appendix.)

We assume $\mu_\pm$ are C^2 functions on $\mathbf{R}^2$ such that

$$\sum_{|\sigma|\le 2} |\partial^\sigma \mu_\pm(s,v_2)| \le Cs^{-\gamma}\langle v_2\rangle^{-\tilde{\gamma}}, \qquad \gamma > 1, \gamma+\tilde{\gamma} > 2, C > 0, \tag{11}$$

$$\int_{\mathbf{R}^2} [\mu_+(\langle v\rangle, v_2) - \mu_-(\langle v\rangle, v_2)]dv = 0, \qquad \mu_\pm(\cdot, v_2) = \mu_\pm(\cdot, -v_2) \ge 0. \tag{12}$$

Note that the decay condition (11) implies that

$$\mu_\pm(\langle v\rangle, v_2) \in W^{2,1}(\mathbf{R}^2).$$

We let the potential function $H(\phi)$ satisfy

$$-H'(\phi) = \int_{\mathbf{R}^2} [\mu_+(\langle v\rangle - \phi, v_2) - \mu_-(\langle v\rangle + \phi, v_2)]dv$$

and we define $H(0) = 0$. This integral is easily shown to be finite.

Remark. With slightly more decay assumed on $\mu_\pm$, we derive the following formula (13) for H. Substituting $s = \langle v\rangle \mp \phi$ and letting $\langle v_2\rangle = \sqrt{1+v_2^2}$, we obtain

$$
\begin{aligned}
-H'(\phi) =& \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} [\mu_+(\langle v\rangle - \phi, v_2) - \mu_-(\langle v\rangle + \phi, v_2)]dv_1dv_2\\
=& 2\int_{-\infty}^{\infty}\int_{\langle v_2\rangle - \phi}^{\infty} \mu_+(s,v_2)\frac{(s+\phi)dsdv_2}{\sqrt{(s+\phi)^2 - 1 - v_2^2}}\\
&-2\int_{-\infty}^{\infty}\int_{\langle v_2\rangle + \phi}^{\infty} \mu_-(s,v_2)\frac{(s-\phi)dsdv_2}{\sqrt{(s-\phi)^2 - 1 - v_2^2}}\\
=& 2\frac{\partial}{\partial\phi}\int_{-\infty}^{\infty}\int_{\langle v_2\rangle - \phi}^{\infty} \mu_+(s,v_2)\sqrt{(s+\phi)^2 - 1 - v_2^2}dsdv_2\\
&+2\frac{\partial}{\partial\phi}\int_{-\infty}^{\infty}\int_{\langle v_2\rangle + \phi}^{\infty} \mu_-(s,v_2)\sqrt{(s-\phi)^2 - 1 - v_2^2}dsdv_2.
\end{aligned}
$$

Therefore,

$$H(\phi) = C - 2\int_{-\infty}^{\infty}\int_{\langle v_2\rangle-\phi}^{\infty}\mu_+(s,v_2)\sqrt{(s+\phi)^2-1-v_2^2}\,ds dv_2$$
$$-2\int_{-\infty}^{\infty}\int_{\langle v_2\rangle+\phi}^{\infty}\mu_-(s,v_2)\sqrt{(s-\phi)^2-1-v_2^2}\,ds dv_2, \tag{13}$$

where $C = 2\int_{-\infty}^{\infty}\int_{\langle v_2\rangle}^{\infty}[\mu_+(s,v_2)+\mu_-(s,v_2)]\sqrt{s^2-1-v_2^2}\,ds dv_2$. Notice that as $\phi \to \pm\infty$, $H(\phi) \to -\infty$ unless $\mu_\pm \equiv 0$.

We also have

$$H''(0) = \int_{\mathbf{R}^2}[\partial_e\mu_+(\langle v\rangle, v_2) + \partial_e\mu_-(\langle v\rangle, v_2)]dv,$$

where e represents the first argument of $\mu_\pm$. (In the proof given below, we show this is finite.)

LEMMA 1 (periodic BGK equilibria). *Let $\mu_\pm$ satisfy* (11) *and* (12), *and let*

$$\left(\frac{2\pi}{P_0}\right)^2 = \int_{\mathbf{R}^2}[\partial_e\mu_+(\langle v\rangle, v_2) + \partial_e\mu_-(\langle v\rangle, v_2)]dv > 0. \tag{14}$$

Then there exists $\delta_0 > 0$ such that for all $\delta < \delta_0$, there exists a periodic function $\beta(x)$ with period P_β satisfying (4), *and*

$$|\beta|_\infty = \delta, \qquad \lim_{\delta\to 0} P_\beta = P_0, \tag{15}$$
$$\beta(0) = \beta(P_\beta) = \min_{0\le x\le P_\beta}\beta(x), \quad \beta(P_\beta/2) = \max_{0\le x\le P_\beta}\beta(x).$$

Here P_0 is defined by (14) *and we can take $\delta_0 = \sup\{s : H''(s) > 0\}$.*

For fixed β, we shall sometimes drop the subscript on P_β.

Proof. Clearly $H(\cdot)$ is a C^3 function, since

$$\int_{\mathbf{R}^2}\langle v\rangle^{-\gamma}\langle v_2\rangle^{-\tilde\gamma}dv_1 dv_2 < \infty.$$

Consider the ODE (4). Obviously $\beta \equiv 0$ is a solution to (4) by (12). Note that $H'(0) = 0$ and

$$H''(0) = \int_{\mathbf{R}^2}[\partial_e\mu_+(\langle v\rangle, v_2) + \partial_e\mu_-(\langle v\rangle, v_2)]dv > 0$$

by (14). Thus the origin is a center for the ODE. In the phase space (β, β_x), let $(a,0)$ and $(b,0)$ be two points that lie on a periodic orbit such that $a < 0$ and $b > 0$. Then we have

$$\frac{1}{2}P_\beta = \int_0^b \frac{du}{(2H(b)-2H(u))^{1/2}} + \int_a^0 \frac{du}{(2H(a)-2H(u))^{1/2}}.$$

In order to prove (15), we shall take the limits as $b \to 0$ and $a \to 0$. We have already proven $H'(0) = 0$ and $H''(0) = (2\pi/P_0)^2$. Expanding in Taylor series around 0, we have for $|u| \le b$,

$$H(b) - H(u) = H''(0)(b^2-u^2)/2 + O(b^3).$$

Hence

$$\int_0^b \{2H(b)-2H(u)\}^{-1/2}du = H''(0)^{-1/2}\int_0^b (b^2-u^2)^{-1/2}du + O(b)$$
$$= (P_0/2\pi)(\pi/2) + O(b) = P_0/4 + O(b).$$

We can handle the second integral similarly. Hence $P_\beta/2 = P_0/2 + O(|b|+|a|)$. We finally arrange β to have its minimum at the ends of $[0, P_\beta]$ and its maximum at the middle by a translation of x. This proves (15). □

The linearized form of $1\frac{1}{4}$ RVM (see (8)) around the homogeneous state $[\mu_\pm(\langle v\rangle, v_2)$, $E_1 \equiv 0]$ is

$$\begin{aligned}
&(\partial_t + \hat{v}_1\partial_x)g_\pm = \mp E_1\partial_{v_1}\mu_\pm(\langle v\rangle, v_2),\\
&\partial_t E_1 = -\int_{\mathbf{R}^2} \hat{v}_1(g_+ - g_-)dv = -j_1,\\
&\partial_x E_1 = \int_{\mathbf{R}^2}(g_+ - g_-)dv = \rho.
\end{aligned} \tag{16}$$

We emphasize that system (16) is *not* RVM in (1) linearized around the BGK equilibrium but only around the corresponding *homogeneous* state.

LEMMA 2 (homogeneous growing modes). *Let $\mu_\pm(e, v_2)$ satisfy conditions* (11), (12), *and* (14). *Then there exists a growing exponential solution for* (16) *of period* $2P_0$:

$$g_\pm(t) = \pm\frac{\hat{v}_1\partial_e\mu_\pm(\langle v\rangle, v_2)}{\hat{v}_1 - \omega_0/k}e^{ikx - i\omega_0 t}, \quad E_1(t) = -ike^{ikx-i\omega_0 t}, \tag{17}$$
$$\int_0^{2P_0} E_1(t,x)dx = \int_0^{2P_0} j_1(t,x)dx = 0.$$

Here $k = \frac{\pi}{P_0} > 0$ and ω_0 is a pure imaginary number. Moreover,

$$\operatorname{Im}\omega_0 > 0. \tag{18}$$

Proof. Notice that the function

$$Z(i\lambda) = \int_{\mathbf{R}^2} \frac{\hat{v}_1[\partial_e\mu_+(\langle v\rangle, v_2) + \partial_e\mu_-(\langle v\rangle, v_2)]dv}{\hat{v}_1 - i\lambda}$$

is real and continuous for $0 \le \lambda < \infty$ by integration by parts because $\partial_e\mu_\pm$ are odd functions of v_1. Moreover, $Z(0) = (2\pi/P_0)^2$ and $\lim_{\lambda\to\infty} Z(i\lambda) = 0$. Hence there exists $\lambda > 0$ such that $Z(i\lambda) = (\pi/P_0)^2$. It follows directly that the following triple is a solution of (16):

$$g_\pm = \pm\frac{\hat{v}_1\partial_e\mu_\pm(\langle v\rangle, v_2)}{\hat{v}_1 - i\lambda}e^{k[ix+\lambda t]}, \quad E_1 = -ike^{k[ix+\lambda t]}.$$

Here $k = \pi/P_0$. We deduce the lemma by letting $\omega_0 = ik\lambda, k \ne 0$. Clearly this is a growing mode since it has the factor $\exp(k\lambda t)$ with $k\lambda > 0$. □

Remark. If $Z(i\lambda_0) \ge (2\pi/P_0)^2$ for some $\lambda_0 > 0$, then there is a growing mode with period P_0 instead of $2P_0$.

3. Linear instability for periodic BGK waves. In this section, we shall prove the instability for the linearized Vlasov–Maxwell system around periodic BGK waves by using a perturbation method. We formulate the linearized problem equivalently in terms of the Poisson equation and a complicated operator $\mathcal{C}$ involving the Vlasov characteristics. Then through detailed estimates along the trajectories, we conclude that the linear operator is a nice perturbation of the homogeneous case, whereby it indeed has a growing mode.

Let $\beta = \beta(x)$ be any given periodic BGK wave with period P. We study the linearized Vlasov–Maxwell system around the generalized BGK wave

$$[\mu_\pm(\langle v\rangle \mp \beta, v_2), \beta_x, 0, 0] \equiv [f_\pm, E_1, E_2, B].$$

In this section, we assume $E_2 = B = 0$, and we denote E_1 by E. Thus we have the system ($1\frac{1}{4}$L):

$$\begin{aligned} &(\partial_t + \hat{v}_1\partial_x \pm \beta'\partial_{v_1})g_\pm \pm E\partial_{v_1}\mu_\pm(\langle v\rangle \mp \beta, v_2) = 0,\\ &\partial_t E = -\int_{\mathbf{R}^2} \hat{v}_1[g_+ - g_-]dv_1dv_2 = -j_1,\\ &\partial_x E = \int_{\mathbf{R}^2} (g_+ - g_-)dv_1dv_2 = \rho, \end{aligned} \tag{19}$$

with the P-periodic boundary condition. We will consider pairs of functions $g = [g_+(x,v), g_-(x,v)]$ and triples $u = [g_+(x,v), g_-(x,v), E(x)]$. We sometimes write $e = \langle v\rangle \mp \beta$ and $v = (v_1, v_2)$.

DEFINITION. *Let $\mathcal{M}$ be the Banach space of triples $u = [g_+(x,v), g_-(x,v), E(x)]$ of finite measures on $\mathbf{R}_P \times \mathbf{R}^2$, $\mathbf{R}_P \times \mathbf{R}^2$, and $\mathbf{R}_P$, respectively, which are periodic in x with period P, respectively, and satisfy*

$$\begin{aligned} &\int_0^P \int_{\mathbf{R}^2} g_- dvdx = \int_0^P \int_{\mathbf{R}^2} g_+ dvdx \quad \text{(neutrality)},\\ &\partial_x E = \int_{\mathbf{R}^2} [g_+ - g_-]dv \quad \text{(Poisson equation)},\\ &g_\pm(x, v_1, v_2) = g_\pm(x, v_1, -v_2) \quad \text{(evenness)}. \end{aligned} \tag{20}$$

We denote the norm $\|u\|_m = \|g_+\|_m + \|g_-\|_m + |E|_m$ where $\|\cdot\|_m$ and $|\cdot|_m$ are the corresponding measure norms in $\mathbf{R}_P \times \mathbf{R}^2$ and $\mathbf{R}_P$.

DEFINITION. *We define the operator $\mathcal{A}$ acting on pairs $g = [g_+, g_-]$ into pairs and the operator $\mathcal{K}$ acting on E into pairs by*

$$\begin{aligned} \mathcal{A}g &= \begin{pmatrix} \mathcal{A}_+(g_+) \\ \mathcal{A}_-(g_-) \end{pmatrix} = \begin{pmatrix} \hat{v}_1\partial_x g_+ + \beta'\partial_{v_1} g_+ \\ \hat{v}_1\partial_x g_- - \beta'\partial_{v_1} g_- \end{pmatrix},\\ \mathcal{K}E &= \begin{pmatrix} \mathcal{K}_+E \\ \mathcal{K}_-E \end{pmatrix} = \begin{pmatrix} \partial_{v_1}\mu_+(\langle v\rangle - \beta, v_2)E \\ -\partial_{v_1}\mu_-(\langle v\rangle + \beta, v_2)E \end{pmatrix}. \end{aligned} \tag{21}$$

Here the domain of $\mathcal{A}$ is the set of pairs of measures g such that $\mathcal{A}g$ is a pair of measures. Furthermore, we define $\mathcal{L}$ from triples to triples by

$$\mathcal{L}u = \begin{pmatrix} \mathcal{A}_+g_+ + \mathcal{K}_+E \\ \mathcal{A}_-g_- + \mathcal{K}_-E \\ \int_{\mathbf{R}^2} \hat{v}_1[g_+ - g_-]dv \end{pmatrix}. \tag{22}$$

LEMMA 3 (linearized well-posedness). *Let $\mu_\pm$ satisfy* (11), (12) *and let β be any solution of* (4) *of period P. If $u_0 \in \mathcal{M}$, there is unique solution $u(t) \in \mathcal{M}$ of*

$$\frac{du}{dt} + \mathcal{L}u = 0, \qquad u(0) = u_0.$$

Sketch of the proof. We split the operator $\mathcal{L}$ as

$$\mathcal{L}u = \begin{pmatrix} \mathcal{A}(g) \\ \int_{\mathbf{R}^2} \hat{v}_1[g_+ - g_-]dv \end{pmatrix} + \begin{pmatrix} \mathcal{K}(E) \\ 0 \end{pmatrix} \equiv \mathcal{L}_1 u + \mathcal{L}_2 u. \tag{23}$$

Notice that the Vlasov operator $e^{-\mathcal{A}t}$ has norm 1 and $|j_1|_m \le \|g_+\|_m + \|g_-\|_m$. The operator $\mathcal{L}_1$ thus generates a strongly continuous semigroup on $\mathcal{M}$ with

$$\|e^{-\mathcal{L}_1 t}u_0\|_m \le C(1+t)\|u_0\|_m. \tag{24}$$

Now

$$|\partial_x E|_m = \|\rho\|_m \le \|g_+\|_m + \|g_-\|_m,$$

so that $\mathcal{L}_2$ is a compact operator on $\mathcal{M}$ and our lemma thus follows.

We introduce the characteristics $X^\pm(t;0,x',v_1',v_2')$ and $V^\pm(t;0,x',v_1',v_2')$ as the solutions of

$$\frac{dX^\pm}{dt} = \hat{V}^\pm, \quad \frac{dV_1^\pm}{dt} = \pm\beta'(X^\pm), \quad \frac{dV_2^\pm}{dt} = 0,$$
$$X^\pm(0) = x', \quad V_1^\pm(0) = v_1', \quad V_2^\pm(0) = v_2'.$$

Let $L^1(\mathbf{R}_P)$ be the space of P-periodic integrable functions of x and let $L^1(\mathbf{R}_P \times \mathbf{R}^2)$ be the similar space of functions of x and $v = (v_1, v_2)$ with the norms

$$|h(\cdot)|_1 = \int_0^P |h(x)|dx, \qquad \|h(\cdot,\cdot)\|_1 = \int_0^P \int_{\mathbf{R}^2} |h(x,v)|dvdx.$$

Let $W^{1,1}(\mathbf{R}_P)$ and $W^{1,1}(\mathbf{R}_P \times \mathbf{R}^2)$ be the subspaces of $L^1(\mathbf{R}_P)$ and $L^1(\mathbf{R}_P \times \mathbf{R}^2)$ with the norms $|h|_{1,1} = |\partial_x h|_1 + |h|_1$ and $\|h\|_{1,1} = \|\partial_x h\|_1 + \|\partial_v h\|_1 + \|h\|_1$.

DEFINITION. *For* $\operatorname{Im}\omega > 0$, *we define*

$$R_\pm = -\int_0^\infty e^{-s\mathcal{A}_\pm} e^{i\omega s}\mathcal{K}_\pm E ds, \tag{25}$$

$$\rho(x) = \int_{\mathbf{R}^2} [R_+(x,v) - R_-(x,v)]dv, \tag{26}$$

$$j_1(x) = \int_{\mathbf{R}^2} \hat{v}_1[R_+(x,v) - R_-(x,v)]dv, \tag{27}$$

$$[\mathcal{C}(\omega,\beta)E](x) = \int_0^x \rho(y)dy + \frac{1}{P}\int_0^P \left\{ \frac{1}{i\omega} j_1(y)dy - \int_0^y \rho(z)dz \right\} dy. \tag{28}$$

LEMMA 4. *Assume* (11) *and* (12).

(a) *If* $\operatorname{Im}\omega > 0$, *then $\mathcal{C}(\omega,\beta)$ is a bounded linear operator on $L^1(\mathbf{R}_P)$.*

(b) *Suppose that $E \in L^1(\mathbf{R}_P)$ satisfies the equation*

$$E = \mathcal{C}(\omega,\beta)E$$

for some $\operatorname{Im}\omega > 0$. *Then there exist* $R_\pm(x,v) \in L^1(\mathbf{R}_P \times \mathbf{R}^2)$ *such that*

$$\begin{aligned} &\hat{v}_1 \partial_x R_\pm \pm \beta \partial_{v_1} R_\pm \pm \partial_{v_1}\mu_\pm(\langle v\rangle \mp \beta, v_2)E(x) = i\omega R_\pm, \\ &j_1 = i\omega E, \quad \partial_x E = \rho. \end{aligned} \tag{29}$$

That is, $-i\omega$ *is an eigenvalue with a positive real part of the linearized Vlasov–Maxwell generator* $-\mathcal{L}$.

(c) *In terms of the characteristics, we have*

$$\int_0^x \rho(y)dy = \int_{\mathbf{R}} K(x,x')E(x')dx', \tag{30}$$

where $K = K^+ + K^-$,

$$K^\pm = -\int_0^\infty \int_{\mathbf{R}^2} \mathcal{H}\partial_{v_1}\mu_\pm(e, v_2')e^{is\omega}dv'ds,$$

where $\mathcal{H} = H(x - X^\pm(s;0,x',v')) - H(-X^\pm(s;0,x',v'))$ *and* $H(\cdot)$ *is the Heaviside function.*

(d) *We also have*

$$\begin{aligned} &\int_0^x j_1(y)dy = \int_{\mathbf{R}^2} J(x,x')E(x')dx', \qquad J = J^+ + J^-, \\ &J^\pm = -\int_0^\infty \int_{\mathbf{R}^2} \hat{V}_1^\pm(s;0,x,v)\mathcal{H}\partial_{v_1}\mu_\pm(e', v_2')e^{is\omega}dv'ds, \end{aligned}$$

where $e' = \langle v'\rangle \mp \beta(x')$.

Remark. Notice that for fixed $(s;0,x',v')$ and x, we have

$$\mathcal{H} = \int_0^x \delta(y - X^\pm(s;0,x',v'))dy,$$

where δ is the Dirac measure. Therefore, $\mathcal{C}(\omega,\beta)$ could also be defined equivalently by

$$\begin{aligned} &\rho(x) = \partial_x[\mathcal{C}(\omega,\beta)E](x) = \int_{\mathbf{R}} E(x')k(x,x')dx', \\ &\text{where } k = k^+ + k^- \text{ and } k^\pm(x,x') = \partial_x K^\pm(x,x'). \end{aligned} \tag{31}$$

Everywhere that $k(x,x')$ is used in the following proofs, it will appear under an integral sign, and therefore all the integrals are rigorous classical expressions.

Proof. Notice that $\mathcal{A}_\pm$ are unbounded linear operators on $L^1(\mathbf{R}_P \times \mathbf{R}^2)$ that generate groups of isometries $e^{-s\mathcal{A}_\pm}$ on $L^1(\mathbf{R}_P \times \mathbf{R}^2)$. So by (25) we have

$$\begin{aligned} \|R_\pm\|_1 &\le \int_0^\infty |e^{i\omega s}|\|E\partial_{v_1}\mu_\pm\|_1 ds \\ &\le (\operatorname{Im}\omega)^{-1}|E|_1 \sup_x \int_{\mathbf{R}^2} |\partial_e \mu_\pm(\langle v\rangle \mp \beta(x), v_2)\hat{v}_1|dv \\ &\le 2(\operatorname{Im}\omega)^{-1}|E|_1 \int_{\mathbf{R}^2} |\partial_e\mu_\pm(e,v_2)|dedv_2 < \infty \end{aligned} \tag{32}$$

for any $E \in L^1(\mathbf{R}_P)$. It follows easily that $\rho, j_1 \in L^1(\mathbf{R}_P)$ and $\mathcal{C}(\omega,\beta)E \in L^1(\mathbf{R}_P)$.

To prove (b), notice that $i\omega$ belongs to the resolvent set of $\mathcal{A}_\pm$, so that $R_\pm$ can be written as

$$R_\pm = \pm(i\omega I - \mathcal{A}_\pm)^{-1}(E\partial_{v_1}\mu_\pm).$$

That is, $R_\pm$ satisfies $\mathcal{A}_\pm R_\pm \pm E\partial_{v_1}\mu_\pm = i\omega R_\pm$, which is the first pair of equations in (29). Integrating (29) over x and v, we have $\int_0^P \int R_\pm dvdx = 0$. Finally, from the assumption $E = \mathcal{C}E$, we obtain

$$\partial_x E = \partial_x \mathcal{C}E = \rho = \int (R_+ - R_-)dv.$$

Notice that by integrating (29) over v, we have $\partial_x j_1 = i\omega\rho = i\omega\partial_x E$. From the definition of $\mathcal{C}$, $i\omega E$ has the same average over P as j_1, so that $i\omega E = j_1$.

We now prove part (c). By (25),

$$\int_{\mathbf{R}^2} R_\pm(x,v)dv = \mp \int_{\mathbf{R}^2}\int_0^\infty e^{-s\mathcal{A}_\pm} E\partial_{v_1}\mu_\pm e^{i\omega s} dsdv.$$

For any function $f(x,v)$,

$$\begin{aligned}
&\int_0^x \int_{\mathbf{R}^2} (e^{-s\mathcal{A}_\pm} f)(y,v)dvdy \\
&= \int_0^x \int_{\mathbf{R}^2} f(X^\pm(0;s,y,v), V^\pm(0;s,y,v))dvdy \\
&= \int_{\mathbf{R}} \int_{\mathbf{R}^2} \mathbf{1}_{0\le y\le x} f(X^\pm(0;s,y,v), V^\pm(0;s,y,v))dvdy \\
&= \int_{\mathbf{R}^2}\int_{\mathbf{R}} [H(x - X^\pm(s;0,x',v')) - H(-X^\pm(s;0,x',v'))]f(x',v')dx'dv'
\end{aligned}$$

by making the change of variables

$$x' = X^\pm(0;s,y,v), \quad v' = V^\pm(0;s,y,v).$$

The inverse transformation is

$$y = X^\pm(s;0,x',v'), \quad v = V^\pm(s;0,x',v')$$

and the Jacobian is 1. Using this identity, we have

$$\begin{aligned}
&\int_0^x \int_{\mathbf{R}^2} R_\pm(y,v)dvdy \\
&= \mp \int_{\mathbf{R}} \int_0^\infty \int_{\mathbf{R}^2} [H(x - X^\pm(s;0,x',v')) - H(-X^\pm(s;0,x',v'))]E(x')\partial_{v_1}\mu_\pm e^{is\omega} dv'dsdx'.
\end{aligned}$$

This immediately implies (c).

To prove (d), we have the similar

$$\int_0^x \int_{\mathbf{R}^2} \hat{v}_1 (e^{-s\mathcal{A}_\pm} f)(y,v)dvdy = \int_{\mathbf{R}^2}\int_{\mathbf{R}} \hat{V}_1^\pm(s;0,x',v')\mathcal{H}f(x',v')dx'dv'$$

so that

$$\int_0^x \int_{\mathbf{R}} \hat{v}_1 R_\pm(y,v)dvdy = \mp \int_{\mathbf{R}}\int_0^\infty \int_{\mathbf{R}^2} \hat{V}_1^\pm(s;0,x',v')\mathcal{H}E(x')\partial_{v_1}\mu_\pm e^{is\omega} dv'dsdx',$$

which immediately implies (d). □

In order to analyze the operator $\mathcal{C}$, we have to estimate along the trajectories. Consider the particle paths given by

$$\frac{dx}{dt} = \hat{v}_1, \qquad \frac{dv_1}{dt} = \pm\beta'(x), \qquad \frac{dv_2}{dt} = 0, \tag{33}$$

whose solutions are $X^{\pm}(t;0,x',v')$, $V_1^{\pm}(t;0,x',v')$, v_2'. We define the *untrapped* region of the + flows as

$$F^+ = \{(x',v')|\ \langle v'\rangle - \beta(x') > 1 - \min\ \beta = a\}.$$

In F^+ the trajectories can go from $-\infty$ to $+\infty$. We also define the *trapped* region of the + flows as

$$T^+ = \{(x',v')|\ \langle v'\rangle - \beta(x') \le 1 - \min\ \beta\},$$

where the flows will never move out of each interval $[nP,(n+1)P]$, by our choice of β in (15). Similarly, we define the *untrapped* region of the − flows as

$$F^- = \{(x',v')|\ \langle v'\rangle + \beta(x') > 1 - \max\ \beta = b\},$$

where the flows can go from $-\infty$ to $+\infty$ and the *trapped* region of the − flows as

$$T^- = \{(x',v')|\ \langle v'\rangle + \beta(x') \le 1 + \max\ \beta\},$$

where the flows will never move out of each interval $[nP - P/2, nP + P/2]$, by our choice of β in (15). Let

$$\Sigma^{\pm}(t,x,x',v_2) = \{v_1' \in \mathbf{R} \mid X^{\pm}(t;0,x',v_1',v_2') = x\}$$

be the initial velocity of a particle travelling from x' to x in time t. Notice that $\Sigma^{\pm}$ could, inside the trapped region $T^{\pm}$, consist of more than one point. The flows with different initial velocities could come back to the same position in the same time, as long as the consumed time interval is a common multiple of their different periods. However, in the untrapped region $\Sigma^{\pm}$ is a single point.

LEMMA 5. (a) *If* $(x',v') \in F^{\pm}$ *and* $v_1' \in \Sigma^{\pm}(t,x,x',v_2')$, *then* $\Sigma^{\pm}(t,x,x',v_2')$ *consists of a unique point* $\mathcal{V}_{1\pm}(t,x,x',v_2')$. *Moreover*

$$\mathcal{V}_{1\pm}(t,x+P,x'+P,v_2') = \mathcal{V}_{1\pm}(t,x,x',v_2'). \tag{34}$$

(b) $\mathcal{C}(\omega,\beta)$ *maps* P*-periodic functions to* P*-periodic functions.*

Notation. We define $\mathcal{V}_{\pm} = (\mathcal{V}_{1\pm}, v_2')$ and

$$\langle \mathcal{V}_{\pm}\rangle = \sqrt{1 + \mathcal{V}_{1\pm}^2 + |v_2'|^2}.$$

We also define the free velocity and the free energy by

$$\hat{\mathcal{V}}_{10}(t,x,x') = (x-x')/t, \tag{35}$$

$$\langle \mathcal{V}_0(t,x,x',v_2')\rangle = \sqrt{1+|v_2'|^2}\left[1 - \left(\frac{x-x'}{t}\right)^2\right]^{-1/2}. \tag{36}$$

Proof. For part (a), without loss of generality we may consider just the + part, since similar arguments apply to the − part. If $v_1' \in \Sigma^+(t, x, x', v_2')$, then

$$\langle V^+\rangle - \beta(X^+) = \langle v'\rangle - \beta(x'), \tag{37}$$

where $X^+ = X^+(0; t, x', v')$, $V^+ = V^+(0; t, x', v')$. Notice that for every $v = (v_1, v_2) \in \mathbf{R}^2$,

$$\langle v\rangle^2 - v_2^2 - 1 = v_1^2, \quad \hat{v}_1 = \pm\frac{\sqrt{\langle v\rangle^2 - 1 - v_2^2}}{\langle v\rangle}.$$

Therefore from the characteristic ODEs (33) and from (37), we have

$$\frac{dX^+}{dt} = \hat{V}_1^+ = \pm\frac{[(\langle v'\rangle - \beta(x') + \beta(X^+))^2 - 1 - v_2^2]^{1/2}}{\langle v'\rangle - \beta(x') + \beta(X^+)}.$$

Because $v_1' \in \Sigma^+(t, x, x', v_2)$, we have

$$t = \pm\int_{x'}^{x} \frac{\langle v'\rangle - \beta(x') + \beta(y)}{[(\langle v'\rangle - \beta(x') + \beta(y))^2 - 1 - v_2^2]^{1/2}}\,dy. \tag{38}$$

Here we let $x = X^+(t; 0, x', v')$ and use + if $t > 0$ and $x > x'$. If we take $x > x'$, then $t > 0$ and $(x', v') \in F^+$. Then $v_1' > 0$. As we choose the plus sign in (38), t is a strictly decreasing function of $\langle v'\rangle$ and a strictly increasing function of x. Hence v_1' is uniquely determined and we write $v_1' = \mathcal{V}_{1+}(t, x, x', v_2)$.

To show the periodicity (34) of $\mathcal{V}_\pm$, notice that $X^+(t; 0, x'+P, v') - P$ satisfies the same ODE and initial conditions as $X^+(t; 0, x', v')$, and hence they are equal. Thus

$$X^+(t; 0, x' + P, v') = X^+(t; 0, x', v') + P. \tag{39}$$

So by the definition of $\mathcal{V}_+$,

$$\mathcal{V}_+(t; x, x', v_2) = \mathcal{V}_+(t; x + P, x' + P, v_2).$$

Similarly for the − case.

Next we shall prove part (b). By (25), it suffices to show that if E has period P, then

$$\int_x^{x+P} dy \int_{\mathbf{R}} dx' E(x')k(y, x') = 0 \tag{40}$$

for all x. Notice that, by the definitions of k and K, by the periodicity of β, and by (39),

$$k^\pm(y, x') = k^\pm(y + P, x' + P).$$

Hence the x-derivatives of both integrals $\int_x^{x+P} dy \int_{\mathbf{R}} dx' E(x')k^\pm(y, x')$ are zero. We thus have for all x,

$$\int_x^{x+P} dy \int_{\mathbf{R}} dx' E(x')k^\pm(y, x') = \int_0^P dy \int_{\mathbf{R}} dx' E(x')k^\pm(y, x').$$

Therefore, in order to prove (40), it suffices to show

$$\int_0^P dx \int_{\mathbf{R}} dx' E(x')k(x, x') = 0. \tag{41}$$

Notice that $[0,P]$ is a period for two connected trapped regions in the + case. If $v_1' \in \Sigma^+(\tau,x,x',v_2)$ and $(x',v') \in F^+$, then $v_1' = \mathcal{V}_{1+}(\tau,x,x',v_2)$ is also an increasing function of x. Hence for $x' \le 0$ and for $P \le x'$, we have

$$\{v_1' |\ 0 \le X^+(\tau;0,x',v_1',v_2) \le P\} = \{\mathcal{V}_+(\tau;x,x',v_2)|\ 0 \le x \le P\}$$
$$= \text{the interval } [\mathcal{V}_+(\tau,0,x',v_2), \mathcal{V}_+(\tau,P,x',v_2)] = J.$$

Now let $0 < x' < P$. For $0 < x' < P$, there is an interval I of velocities v_1' that are trapped. Of course for any $v_1' \in I$,

$$0 < X^+(t;0,x',v') < P$$

for *all* t. Notice that $I \subset J$. In this case, J is the interval from $\mathcal{V}_{1+}(\tau;0,x',v_2) < 0$ to $\mathcal{V}_{1+}(\tau;P,x',v_2) > 0$. Notice that for fixed (τ,x',v_2),

$$\int_0^P \delta(x - X^+(\tau;0,x',v'))dx = \mathbf{1}_J(v_1'),$$

where $\mathbf{1}$ is the standard characteristic function. In order to prove (41), we use the definitions of $k(x,x')$ and $K(x,x')$ below (30). We first treat the + part in (41) as

$$\begin{aligned}
&-\int_0^P dx \int_{\mathbf{R}} dx' E(x') k^+(x,x') \\
&= \int_0^\infty d\tau e^{i\omega\tau} \int_{\mathbf{R}^3} dv' dx' E(x') \partial_{v_1'} \mu_+ \left[\int_0^P dx\ \delta(x - X^+(\tau;0,x',v')) \right] \\
&= \int_{\mathbf{R}} dx' E(x') \int_0^\infty d\tau e^{i\omega\tau} \int_{\mathbf{R}} dv_2 \int_J dv_1' \partial_{v_1'} \mu_+(\langle v' \rangle - \beta(x'), v_2) \\
&= \int_{\mathbf{R}} dx' E(x') \int_0^\infty d\tau e^{i\omega\tau} \int_{\mathbf{R}} dv_2 [\mu_+(\langle \mathcal{V}_+(\tau,P,x',v_2) \rangle - \beta(x'), v_2) \\
&\qquad\qquad -\mu_+(\langle \mathcal{V}_+(\tau,0,x',v_2) \rangle - \beta(x'), v_2)] \\
&= I_1 + I_2
\end{aligned}$$

Letting $x' = z + P$ in I_1, we obtain

$$\begin{aligned}
I_1 &= \int_{\mathbf{R}} dz E(z+P) \int_0^\infty d\tau e^{i\omega\tau} \int_{\mathbf{R}} dv_2 \mu_+(\langle \mathcal{V}_+(\tau,P,z+P,v_2) \rangle - \beta(z+P), v_2) \\
&= \int_{\mathbf{R}} dz E(z) \int_0^\infty d\tau e^{i\omega\tau} \int_{\mathbf{R}} dv_2 \mu_+(\langle \mathcal{V}_+(\tau,0,z,v_2) \rangle - \beta(z), v_2) = -I_2,
\end{aligned}$$

where we have used the P-periodicity of E and β as well as (34). Therefore we conclude that the + part of (41) is zero.

The − part is also zero by the same argument. The only difference is that now we consider the period $[P/2, 3P/2]$ instead of $[0,P]$. This is a period for two connected trapped regions of the − flow. This completes the proof of the lemma. □

Let $X^\pm(\tau;0,x',v')$ be the trajectories in (33) and $X^0(\tau;0,x',v') = x' + \tau \hat{v}_1'$, $V^0(\tau;0,x',v') = v'$ be the unperturbed trajectories (straight lines). Recalling the definitions of $k^\pm$, $\hat{\mathcal{V}}_{10}$ and $\langle \mathcal{V}_0 \rangle$ in (35) and (36), we also define

$$\begin{aligned}
(42) \qquad k_0^\pm(x,x') &= \mp \int_0^\infty \left[\int \delta(x - x' - \hat{v}_1'\tau) \partial_{v_1'} \mu_\pm(\langle v' \rangle, v_2') dv' \right] e^{i\omega\tau} d\tau \\
&= \mp \int_0^\infty \int_{\mathbf{R}} \partial_e \mu_\pm(\langle \mathcal{V}_0 \rangle, v_2) \hat{\mathcal{V}}_{10} \langle \mathcal{V}_0 \rangle^3 (1+v_2^2)^{-1} dv_2 \tau^{-1} e^{i\omega\tau} d\tau.
\end{aligned}$$

Recalling the definitions (21), (25), (26), and (27), we similarly define

$$\mathcal{A}^0 = \hat{v}_1 \partial_x, \qquad \mathcal{K}^0 E = \begin{pmatrix} \mathcal{K}^0_+ E \\ \mathcal{K}^0_- E \end{pmatrix} = \begin{pmatrix} \partial_{v_1} \mu_+(\langle v \rangle, v_2) E \\ -\partial_{v_1} \mu_-(\langle v \rangle, v_2) E \end{pmatrix},$$

$$R^0_\pm = -\int_0^\infty e^{-\tau \mathcal{A}^0} e^{i\omega\tau} \mathcal{K}^0_\pm E d\tau,$$

$$\rho^0 = \int_{\mathbf{R}^2} (R^0_+ - R^0_-) dv, \qquad j^0_1 = \int_{\mathbf{R}^2} \hat{v}_1 (R^0_+ - R^0_-) dv.$$

Our key estimate is the following.

LEMMA 6. *Let $\mu_\pm$ satisfy* (11) *and* (12), *and let β be any solution of* (4) *of period P. Let* $\operatorname{Im} \omega > 0$. *With ρ and j_1 defined by* (26), (27), *we have*

$$|\rho - \rho^0|_1 + |j_1 - j^0_1|_1 \le C \|\beta\|^{1/2} |E|_1$$

for all $E \in L^1(\mathbf{R}_P)$, where $\|\beta\| = |\beta|_{C^2}$.

We shall show that this lemma follows from the next one.

LEMMA 7. *Under the same conditions,*

$$\int_0^P \left| \int_{\mathbf{R}} \int_0^\infty \int_{\mathbf{R}^2} \{\delta(x - X^\pm) \partial_{v_1} \mu_\pm(e', v'_2) - \delta(x - X^0) \partial_{v_1} \mu_\pm(\langle v' \rangle, v'_2)\} \right.$$

$$\left. \times e^{-\operatorname{Im}\omega\tau} E(x') dv' d\tau dx' \right| dx \le C \|\beta\|^{1/2} |E|_1 \tag{43}$$

for all $E \in L^1(\mathbf{R}_P)$, where $\|\beta\| = |\beta|_{C^1}$, $X^\pm = X^\pm(\tau; 0, x', v')$, and $X^0 = X^0(\tau; 0, x', v')$.

Remark. It is easy to estimate the integral in Lemma 7 by $C|E|_1$, but we will require the small constant $\|\beta\|$. We first illustrate our technique by estimating the free part of the integral as

$$\int_{\mathbf{R}} \int_0^P \int_0^\infty \int_{\mathbf{R}^2} |\delta(x - X^0) \partial_{v'_1} \mu_\pm(\langle v' \rangle, v'_2)| e^{-\operatorname{Im}\omega\tau} |E(x')| dv' d\tau dx dx' \tag{44}$$

$$= \int_0^\infty \int_0^P \int_{\mathbf{R}} \int_{\mathbf{R}^2} e^{-\operatorname{Im}\omega\tau} |E(x')| |\delta(x - x' - \hat{v}'_1 \tau)| |\partial_{v'_1} \mu_+(\langle v' \rangle, v'_2) \hat{v}'_1| dv' dx' dx d\tau$$

$$= \int_0^\infty \int_0^P \int_{x-\tau}^{x+\tau} \int_{\mathbf{R}} e^{-\operatorname{Im}\omega\tau} |E(x') \partial_e \mu_+(\langle \mathcal{V}_0 \rangle, v_2) \hat{\mathcal{V}}_{10}| \langle \mathcal{V}_0 \rangle^3 \tau^{-1} (1 + v_2^2)^{-1} dv_2 dx' dx d\tau,$$

where we have integrated v'_1 first, and computed $\partial_{v'_1}[x - x' - \hat{v}'_1 \tau] = -\tau \langle v' \rangle^{-3} (1 + v_2^2)$. We notice that

$$\int_{x'-\tau}^{x'+\tau} \langle \mathcal{V}_0 \rangle^{3-\gamma} \frac{dx}{\tau} = (1 + v_2^2)^{\frac{3-\gamma}{2}} \int_{x'-\tau}^{x'+\tau} \left(1 - \left| \frac{x - x'}{\tau} \right|^2 \right)^{\frac{\gamma-3}{2}} \tau^{-1} dx$$

$$= (1 + v_2^2)^{\frac{3-\gamma}{2}} \int_{-1}^1 (1 - y^2)^{\frac{\gamma-3}{2}} dy < \infty, \tag{45}$$

since $\gamma > 1$. Thus the free part is bounded by

$$\int_0^\infty e^{-\operatorname{Im}\omega\tau} \int_0^P \int_{x-\tau}^{x+\tau} \int_{\mathbf{R}} |E(x')| \langle \mathcal{V}_0 \rangle^{3-\gamma} \langle v_2 \rangle^{-2-\tilde{\gamma}} \tau^{-1} dv_2 dx' dx d\tau.$$

Since $\tilde\gamma+\gamma>2$ and $\gamma>1$, $\langle v_2\rangle^{1-\tilde\gamma-\gamma}$ is integrable so that we have the bound

$$C\int_0^\infty e^{-\mathrm{Im}\omega\tau}\int_{-\tau}^{P+\tau}|E(x')|dx'd\tau\le C\int_0^\infty e^{-\mathrm{Im}\omega\tau}d\tau(\tau+1)|E|_1\le C|E|_1, \tag{46}$$

where we have used the fact that $\int_{-\tau}^{P+\tau}|E(x')|dx'\le C(\tau+1)|E|_1$.

Proof of Lemma 6. From (31), ρ takes the form

$$\int_{\mathbf{R}}\int_0^\infty\int_{\mathbf{R}^2}\left\{-\delta(x-X^+)\partial_{v_1'}\mu_+(e',v_2')+\delta(x-X^-)\partial_{v_1'}\mu_-(e',v_2')\right\}e^{is\omega}E(x')dv'dsdx'$$

and $\rho^0(x)$ is given by a similar expression. Clearly from Lemma 7, $|\rho-\rho^0|_1\le C\|\beta\|^{1/2}|E|_1$. Similarly $j_1(x)$ takes the form

$$\int_{\mathbf{R}}\int_0^\infty\int_{\mathbf{R}^2}\left\{-\hat V_1^+\delta(x-X^+)\partial_{v_1'}\mu_+(e',v_2')+\hat V_1^-\delta(x-X^-)\partial_{v_1'}\mu_-(e',v_2')\right\}e^{is\omega}E(x')dv'dsdx'$$

and $j_1^0(x)$ is given by a similar expression. Hence (with $j_1=j_{1+}-j_{1-}$, $j_1^0=j_{1+}^0-j_{1-}^0$),

$$\begin{aligned}&\int_0^P|j_{1+}-j_{1+}^0|dx\\&\le\int_0^P\Big|\int_{\mathbf{R}}\int_0^\infty\int_{\mathbf{R}^2}\{\hat V_1^+\left[\delta(x-X^+)\partial_{v_1'}\mu_+(e',v_2')-\delta(x-X^0)\partial_{v_1'}\mu_+(\langle v'\rangle,v_2')\right]\\&\qquad+(\hat V_1^+-\hat V_1^0)\delta(x-X^0)\partial_{v_1'}\mu_+(\langle v'\rangle,v_2')\}e^{-\mathrm{Im}\omega\tau}E(x')dv'd\tau dx'\Big|dx.\end{aligned}$$

Since $|\hat V_1^+|\le1$, the first term is bounded by $C\|\beta\|^{1/2}|E|_1$ because of Lemma 7. On the other hand, since $dV_1^+/d\tau=\beta'(X^+)$, $dV_2^+/d\tau=0$, and $V^0(\tau;0,x',v')=v'$,

$$|\hat V_1^+(s;0,x',v')-\hat v_1'|=\left|\int_0^\tau\beta'(X^+(s;0,x',v'))ds\right|\le\tau\|\beta\|.$$

Thus the second term is bounded by

$$C\|\beta\|\int_0^P\int_{\mathbf{R}}\int_0^\infty\int_{\mathbf{R}^2}\delta(x-X^0)|\partial_{v_1'}\mu_+(\langle v'\rangle,v_2')|\tau e^{-\mathrm{Im}\omega\tau}|E(x')|dv'd\tau dx'dx.$$

This expression is identical to (44) except for the extra factor τ and is therefore estimated in exactly the same way. This proves Lemma 6, assuming Lemma 7.

Proof of Lemma 7. For notational simplicity, we prove only the case of $+$, as the case of $-$ is the same. We split the integral into two major parts according to the time variable. Let

$$T=\min\left\{\frac12|x-x'|^{1/2},\frac1M|x-x'|\right\}\|\beta\|^{-1/2}, \tag{47}$$

where $M=\max\{4,4(P)^{1/2}\}$. We then split (43) as

$$\int_0^P\int_{\mathbf{R}^3}\int_0^\infty d\tau dv'dx'dx=\int_0^P\int_{\mathbf{R}^3}\int_T^\infty+\int_0^P\int_{\mathbf{R}^3}\int_0^T\equiv L+S.$$

The large-time estimate *L*. We further split the integral L into L_1+L_2, where

$$\begin{aligned}L_1&=\int_{\mathbf{R}^3}\int_{\{|x-x'|\ge M^2/4\}\cap[0,P]}\int_T^\infty d\tau dxdx'dv',\\L_2&=\int_{\mathbf{R}^3}\int_{\{|x-x'|<M^2/4\}\cap[0,P]}\int_T^\infty d\tau dxdx'dv'.\end{aligned}$$

We first consider L_1. Since $|x| \le P$ and $|x - x'| \ge 2P$, we are in the untrapped region and it follows that $|x - x'| \ge P/2 + |x'|/2$. Hence

$$T \ge \frac{1}{2}|x - x'|^{1/2}\|\beta\|^{-1/2} \ge c(|x'| + 1)^{1/2}\|\beta\|^{-1/2}.$$

We now employ the exponential decay of $e^{-\mathrm{Im}\omega\tau}$ as

$$\begin{aligned}
L_1 &\le \int_{\mathbf{R}^3} \int_{c(|x'|+1)^{1/2}\|\beta\|^{-1/2}}^{\infty} e^{-\mathrm{Im}\omega\tau}|E(x')| \\
&\times \left\{ \int_0^P \left[\delta(x - X^+)|\partial_{v_1'}\mu_+(e', v_2')| + \delta(x - X^0)|\partial_{v_1'}\mu_+(\langle v'\rangle, v_2')|\right] dx \right\} d\tau dv' dx' \\
&\le C \int_{\mathbf{R}} \int_{c[|x'|+1]^{1/2}\|\beta\|^{-1/2}}^{\infty} e^{-\mathrm{Im}\omega\tau}|E(x')| \int_{\mathbf{R}^2} \left[|\partial_{v_1'}\mu_+(e', v_2')| + |\partial_{v_1'}\mu_+(\langle v'\rangle, v_2')|\right] dv' d\tau dx' \\
&\le C \int_{\mathbf{R}} e^{-c[|x'|+1]^{1/2}\|\beta\|^{-1/2}}|E(x')|dx' \le C \int_{\mathbf{R}} [|x'| + 1]^{-2}\|\beta\|^2|E(x')|dx' \\
&= C\|\beta\|^2 \sum_n \int_{2nP}^{2(n+1)P} [1 + |x'|]^{-2}|E(x')|dx' \le C\|\beta\|^2|E|_1,
\end{aligned} \tag{48}$$

since $\int[|\partial_{v_1'}\mu_+(e', v_2')| + |\partial_{v_1'}(\langle v'\rangle, v_2')|]dv$ is finite because of the decay rate in (11).

For L_2, we have $|x - x'| \le M^2/4$ bounded. Given x and v_2', pick any v_1' such that $X^+(\tau; 0, x', v') = x$. We thus have

$$x - x' = \int_0^\tau \hat{V}_1^+(\theta, x', v')d\theta.$$

By the mean value theorem,

$$\hat{\mathcal{V}}_{10} = \frac{x - x'}{\tau} = \frac{1}{\tau}\int_0^\tau \hat{V}_1^+(\theta; 0, x', v')d\theta = \hat{V}_1^+(s; 0, x', v')$$

for some $s \in [0, \tau]$. Thus $\mathcal{V}_{10} = V_1^+$ and $\mathcal{V}_{20} = v_2' = V_2^+$, so that

$$\langle \mathcal{V}_0\rangle = \langle V^+(s; 0, x', v')\rangle.$$

But by energy conservation along the trajectory, we have

$$\langle v'\rangle + \beta(x') = \langle V^+(s; 0, x', v')\rangle + \beta(X^+(s; 0, x', v')).$$

Therefore

$$|\langle v'\rangle - \langle \mathcal{V}_0\rangle| \le 2\|\beta\|. \tag{49}$$

Since $\tau \ge T = \frac{1}{4}|x - x'|\|\beta\|^{-1/2}$ in the integral L_2, we have

$$|\hat{\mathcal{V}}_{10}| = \left|\frac{x - x'}{\tau}\right| \le 4\|\beta\|^{1/2}$$

so that

$$\langle v'\rangle \le 2\|\beta\| + \langle \mathcal{V}_0\rangle = 2\|\beta\| + \sqrt{\frac{1 + {v_2'}^2}{1 - \hat{\mathcal{V}}_0^2}} \le (1 + C\|\beta\|)\sqrt{1 + {v_2'}^2}.$$

We deduce that $\sqrt{1+{v_1'}^2+{v_2'}^2}-\sqrt{1+{v_2'}^2}\le C\|\beta\|\sqrt{1+{v_2'}^2}$, so that

$$ {v_1'}^2 \le C\|\beta\|\left[\sqrt{1+{v_1'}^2+{v_2'}^2}\sqrt{1+{v_2'}^2}+1+{v_2'}^2\right]\le \frac{C}{2}\|\beta\|\left[{v_1'}^2+5({v_2'}^2+1)\right] $$

and

$$ |v_1'|\le C\|\beta\|^{1/2}\sqrt{1+{v_2'}^2}\equiv m. $$

Therefore, employing the smallness of v_1' and the boundedness of x', we get the term L_2 bounded by

$$ \int_0^\infty\int_{-C}^{C}\int_{\mathbf{R}}\int_{-m}^{m}\left\{\int_0^P|\partial_e\mu_+||\hat v_1'|\delta(x-X^+)dx\right\}|E(x')|e^{-\mathrm{Im}\omega\tau}dv_1'dv_2'dx'd\tau $$

plus the same term with X^+ replaced by X^0. Therefore, we get the bound

$$ \begin{aligned} &C|E|_1\int_0^\infty\int_{\mathbf{R}}\int_{-m}^{m}\langle v_2'\rangle^{-\tilde\gamma-\gamma}dv_1'dv_2'e^{-\mathrm{Im}\omega\tau}d\tau\\ &\le C|E|_1\|\beta\|^{1/2}\int_0^\infty e^{-\mathrm{Im}\omega\tau}d\tau\le C\|\beta\|^{1/2}|E|_1, \end{aligned} $$

since $\tilde\gamma+\gamma>1$. Combining this with (48), we have the large-time estimate

$$ L=L_1+L_2\le C|E|_1\|\beta\|^{1/2}. \tag{50} $$

The small-time estimate *S*. Now in (43) we consider the case $\tau\le T$. Since

$$ 0\le\tau\le\frac{1}{2}|x-x'|^{1/2}\|\beta\|^{-1/2}, $$

we have

$$ \left|\frac{x-x'}{\tau}\right|\ge 2|x-x'|^{1/2}\|\beta\|^{1/2}\ge 4\tau\|\beta\|\ge 4\left|\frac{1}{\tau}\int_0^\tau\int_0^\theta\beta'(X^+(s))dsd\theta\right|. $$

Now for any v' such that $x=X^+(\tau;0,x',v')$, we have the trajectory equation

$$ x=x'+\hat v_1'\tau\pm\int_0^\tau\int_0^\theta\langle V^+\rangle^{-3}\beta'(X^+)dsd\theta. $$

Thus,

$$ \begin{aligned} &|\hat v_1'|\ge\left|\frac{x-x'}{\tau}\right|-\left|\frac{1}{\tau}\int_0^\tau\int_0^\theta\beta'(X^+(s))dsd\theta\right|\ge\frac{3}{4}\left|\frac{x-x'}{\tau}\right|\ge 3\|\beta\|^{1/2},\\ &|\hat v_1'|\le\left|\frac{x-x'}{\tau}\right|+\left|\frac{1}{\tau}\int_0^\tau\int_0^\theta\beta'(X^+(s))dsd\theta\right|\le\frac{5}{4}\left|\frac{x-x'}{\tau}\right|. \end{aligned} \tag{51} $$

We have used the fact $\tau\le\frac{1}{4}|x-x'|\|\beta\|^{-1/2}$ by the definition of T in (47). Therefore, v' must lie in the *untrapped region*. Indeed, by (37), in the trapped region all the

velocities are bounded by $2\|\beta\|^{1/2}$ and this contradicts (51). By Lemma 5, only one such $\mathcal{V}_{1+}$ exists. Hence,

$$\int_{\mathbf{R}} \partial_{v_1'}\mu_+(e', v_2')\delta(x - X^+)dv_1' = \hat{\mathcal{V}}_{1+}\partial_e\mu_+'(W_+, v_2')\mathcal{J},$$

where $W_+ = \langle\mathcal{V}_+\rangle - \beta(X^+)$ and

$$\mathcal{J} = \left\{ \left[\frac{\partial X^+}{\partial v_1'}\right]\Big|_{v_1'=\mathcal{V}_{1+}} \right\}^{-1}.$$

In the free case, $\hat{\mathcal{V}}_{10} = (x - x')/\tau$, and $(\partial X_0/\partial v_1')^{-1} = \tau^{-1}\langle\mathcal{V}_0\rangle^3$. Therefore, by first integrating over the v' variable, we get the small-time integral equal to

$$\begin{aligned} S &= \int |E(x')|e^{-\mathrm{Im}\omega\tau}|\hat{\mathcal{V}}_{1+}\partial_e\mu_+(W_+, v_2')\mathcal{J} - \hat{\mathcal{V}}_{10}\partial_e\mu_+(\langle\mathcal{V}_0\rangle, v_2')\tau^{-1}\langle\mathcal{V}_0\rangle^3| \\ &\le \int |E(x')|e^{-\mathrm{Im}\omega\tau}|\partial_e\mu_+(W_+, v_2')\{\mathcal{J} - (1 + {v_2'}^2)^{-1}\hat{\mathcal{V}}_{1+}(x - x')^{-1}\langle\mathcal{V}_+\rangle^3\}| \\ &+ \int \frac{|E(x')|}{|x - x'|(1 + {v_2'}^2)}e^{-\mathrm{Im}\omega\tau}|\partial_e\mu_+(W_+, v_2')\hat{\mathcal{V}}_{1+}^2\langle\mathcal{V}_+\rangle^3 - \partial_e\mu_+(\langle\mathcal{V}_0\rangle, v_2')\hat{\mathcal{V}}_{10}^2\langle\mathcal{V}_0\rangle^3| \\ &\equiv S_1 + S_2, \end{aligned} \tag{52}$$

where $\int = \int_0^P \int_{\mathbf{R}} \int_0^T \int_{\mathbf{R}} dv_2' d\tau dx' dx$.

We now estimate S_1. In order to compute $\mathcal{J}$, we take the v_1' derivative in (38) to get (for $t > 0$)

$$\begin{aligned} 0 =& \frac{\partial X^+}{\partial v_1'}\frac{\langle v'\rangle - \beta(x') + \beta(X^+(v'))}{\{[\langle v'\rangle - \beta(x') + \beta(X^+(v'))]^2 - 1 - v_2^2\}^{1/2}} \\ &- \int_{x'}^{X^+(v')} [(\langle v'\rangle - \beta(x') + \beta(y))^2 - 1 - v_2^2]^{-3/2}\hat{v}_1'(1 + v_2^2)dy. \end{aligned}$$

Put $v' = \mathcal{V}_+(\tau, x, x')$, so that $X^+(\tau, 0, x', v') = x$ and

$$\mathcal{J}^{-1} = (1 - (1 + v_2^2)A(x)^{-2})^{1/2}\hat{\mathcal{V}}_{1+}Q(1 + v_2^2),$$

where $A(y) = \langle\mathcal{V}_+(\tau, x, x')\rangle - \beta(x') + \beta(y)$, $\mathcal{V}_+ = \mathcal{V}_+(\tau, x, x')$, and

$$Q = \int_{x'}^{x} (A(y)^2 - 1 - v_2^2)^{-3/2}dy.$$

From (51), we have

$$|\hat{\mathcal{V}}_{1+}| \ge \frac{3}{4}\left|\frac{x - x'}{\tau}\right| \ge 3\|\beta\|^{1/2}. \tag{53}$$

To estimate Q, notice that $|A(y) - \langle\mathcal{V}_+\rangle| \le 2\|\beta\|$ and therefore $A(y)$ is comparable to $\langle\mathcal{V}_+\rangle$. Hence,

$$\begin{aligned} A^2 - 1 - v_2^2 &= \mathcal{V}_{1+}^2 + (A - \langle\mathcal{V}_+\rangle)(A + \langle\mathcal{V}_+\rangle) \\ &\ge \mathcal{V}_{1+}^2 - 2\|\beta\|(2\langle\mathcal{V}_+\rangle + 2\|\beta\|) \\ &\ge \mathcal{V}_{1+}^2 - \frac{4}{3}\|\beta\|^{1/2}|\mathcal{V}_{1+}| - 4\|\beta\|^2 \\ &\ge \frac{5}{9}\mathcal{V}_{1+}^2 - 4\|\beta\|^2 \ge \frac{1}{2}\mathcal{V}_{1+}^2 \end{aligned}$$

by (53) and the smallness of β. Letting $g(A) = (A^2 - 1 - v_2^2)^{-3/2}$, we have

$$|g'(A)| = 3(A^2 - {v_2'}^2 - 1)^{-5/2} A \le C|\mathcal{V}_{1+}|^{-5}\langle \mathcal{V}_+\rangle.$$

Therefore, we have

$$|Q(\tau, x, x') - (x - x')|\mathcal{V}_{1+}|^{-3}| \le C\|\beta\||\mathcal{V}_{1+}|^{-5}\langle \mathcal{V}_+\rangle |x - x'|$$

so that Q is comparable to $(x - x')|\mathcal{V}_{1+}|^{-3}$ and

$$\begin{aligned}
&|Q^{-1}(\tau, x, x') - (x - x')^{-1}|\mathcal{V}_{1+}|^3| \\
&\le C\|\beta\||\mathcal{V}_{1+}|^{-5}\langle \mathcal{V}_+\rangle |x - x'|\{(x - x')^{-1}|\mathcal{V}_{1+}|^3\}^2 \\
&= C\|\beta\||x - x'|^{-1}|\mathcal{V}_{1+}|\langle \mathcal{V}_+\rangle.
\end{aligned}$$

Also, inside $\mathcal{J}$ we have

$$(1 - (1 + v_2^2)A^{-2})^{-1/2} = \langle \mathcal{V}_+\rangle |\mathcal{V}_{1+}|^{-1} + O[\|\beta\|(1 + v_2^2)|\mathcal{V}_{1+}|^{-3}].$$

We thus estimate $\mathcal{J}$ as

$$\begin{aligned}
&|\mathcal{J} - (1 + v_2^2)^{-1}\langle \mathcal{V}_+\rangle^2 \mathcal{V}_{1+}(x - x')^{-1}| \\
&= \frac{1}{(1 + v_2^2)}\left|(1 - (1 + v_2^2)^{-1}A^{-2})^{-1/2} \cdot \hat{\mathcal{V}}_{1+}^{-1} Q^{-1} - \langle \mathcal{V}_+\rangle |\mathcal{V}_{1+}|^{-1} \cdot \hat{\mathcal{V}}_{1+}^{-1}|\mathcal{V}_{1+}|^3 (x - x')^{-1}\right| \\
&\le C\|\beta\||x - x'|^{-1}|\hat{\mathcal{V}}_{1+}^{-1}|[1 + \langle \mathcal{V}_+\rangle^2 (1 + v_2^2)^{-1}] \\
&\le C\|\beta\|^{1/2}\tau^{-1}\hat{\mathcal{V}}_{1+}^{-1}\langle \mathcal{V}_+\rangle^2 (1 + v_2^2)^{-1}.
\end{aligned}$$

In the last step, we have used the fact that $\tau|x - x'|^{-1} \le \frac{1}{4}\|\beta\|^{-1/2}$ from (47). Moreover, from the trajectory equation and (51), (49) with $v' = \mathcal{V}_+$, we have

$$\frac{3}{4}\left|\frac{x - x'}{\tau}\right| \le |\hat{\mathcal{V}}_{1+}| \le \frac{5}{4}\left|\frac{x - x'}{\tau}\right|, \quad |\hat{\mathcal{V}}_{1+} - \hat{\mathcal{V}}_{10}| \le \tau\|\beta\|.$$

Using the energy conservation along the trajectory, we estimate $W_+ \equiv \langle \mathcal{V}_+\rangle - \beta(x')$ as $|W_+ - \langle \mathcal{V}_+\rangle| \le \|\beta\|$. Since $\langle \mathcal{V}_0\rangle$ dominates $\|\beta\|$, we also have

$$c\langle \mathcal{V}_0\rangle \le \langle \mathcal{V}_+\rangle \le C\langle \mathcal{V}_0\rangle. \tag{54}$$

We therefore estimate S_1 by

$$\begin{aligned}
&\int_0^P \int_{x-\tau}^{x+\tau} \int_0^T \int_{\mathbf{R}} |E(x')| e^{-\mathrm{Im}\omega\tau} \left|\partial_e \mu_+(W_+, v_2')\hat{\mathcal{V}}_{1+}\left\{\mathcal{J} - (1 + v_2^2)^{-1}\hat{\mathcal{V}}_{1+}(x - x')^{-1}\langle \mathcal{V}_+\rangle^3\right\}\right| \\
&\le C\int_0^P \int_{x-\tau}^{x+\tau} \int_0^T \int_{\mathbf{R}} e^{-\mathrm{Im}\omega\tau}|\partial_e \mu_+(W_+, v_2')\left[\|\beta\|^{1/2}\tau^{-1}\langle \mathcal{V}_+\rangle^2\right]|E(x')|(1 + {v_2'}^2) \qquad (55)
\end{aligned}$$

with the volume element $dv_2' d\tau dx' dx$. In this integral we have

$$|\partial_e \mu_+(W_+, v_2')|\langle \mathcal{V}_+\rangle^2 \le C\langle \mathcal{V}_+\rangle^{2-\gamma} \le C\langle \mathcal{V}_0\rangle^{2-\gamma}$$

with $\gamma > 1$ so that

$$S_1 \le C\|\beta\|^{1/2}|E|_1$$

just as in (46).

From (54) and the decay condition in (11), we now estimate the main part of the integrand in S_2 as

$$\begin{aligned} J_2 \equiv & |\partial_e\mu_+(W_+, v_2')\hat{\mathcal{V}}_{1+}^2\langle\mathcal{V}_+\rangle^3 - \partial_e\mu_+(\langle\mathcal{V}_0\rangle, v_2')\hat{\mathcal{V}}_{10}^2\langle\mathcal{V}_0\rangle^3| \\ & \le \left|[\partial_e\mu_+(W_+, v_2') - \partial_e\mu_+(\langle\mathcal{V}_0\rangle, v_2')]\,\hat{\mathcal{V}}_{1+}^2\langle\mathcal{V}_+\rangle^3\right| \\ & + \left|\partial_e\mu(W_0, v_2')[\hat{\mathcal{V}}_{10}^2\langle\mathcal{V}_0\rangle^3 - \hat{\mathcal{V}}_{1+}^2\langle\mathcal{V}_+\rangle^3]\right|. \end{aligned}$$

Notice that

$$\begin{aligned} & |\hat{\mathcal{V}}_{10}^2\langle\mathcal{V}_0\rangle^3 - \hat{\mathcal{V}}_{1+}^2\langle\mathcal{V}_+\rangle^3| = |\mathcal{V}_{10}^2\langle\mathcal{V}_0\rangle - \mathcal{V}_{1+}^2\langle\mathcal{V}_+\rangle| \\ & = |\langle\mathcal{V}_0\rangle - \langle\mathcal{V}_+\rangle|(\langle\mathcal{V}_0\rangle^2 + \langle\mathcal{V}_0\rangle\langle\mathcal{V}_+\rangle + \langle\mathcal{V}_+\rangle^2 - 1 - {v_2'}^2) \\ & \le C|\langle\mathcal{V}_0\rangle - \langle\mathcal{V}_+\rangle|\langle\mathcal{V}_0\rangle^2. \end{aligned}$$

By (49) and (11), we thus estimate the main part of the integrand in S_2 by

$$\begin{aligned} J_2 \le & \{\sup_{\theta\in[\langle\mathcal{V}_0\rangle, W_+]} \partial_{ee}\mu_+(\theta, v_2')|[W_+ - \langle\mathcal{V}_0\rangle]\hat{\mathcal{V}}_{1+}^2\langle\mathcal{V}_+\rangle^3| \\ & + C|\partial_e\mu_+(\langle\mathcal{V}_0\rangle, v_2')||\langle\mathcal{V}_0\rangle - \langle\mathcal{V}_+\rangle|\langle\mathcal{V}_0\rangle^2\} \\ & \le C\|\beta\|\langle\mathcal{V}_0\rangle^{3-\gamma}\langle v_2'\rangle^{-\tilde{\gamma}}. \end{aligned}$$

From the definition of T in (47), we have $|x - x'|^{-1} \le \frac{1}{4\tau}\|\beta\|^{-1/2}$. We plug this into S_2 in (52) to get

$$\begin{aligned} S_2 = & \int_0^P \int_0^T \int_{x-\tau}^{x+\tau} \int_{\mathbf{R}} e^{-\mathrm{Im}\omega\tau} \frac{|E(x')|}{|x - x'|(1 + {v_2'}^2)} \\ & \times \left|\partial_e\mu_+(W_+, v_2')\hat{\mathcal{V}}_{1+}^2\langle\mathcal{V}_+\rangle^3 - \partial_e\mu_+(\langle\mathcal{V}_0\rangle, v_2')\hat{\mathcal{V}}_{10}^2\langle\mathcal{V}_0\rangle^3\right| dv_2'dx'd\tau dx \\ & \le C\|\beta\|^{1/2}\int_0^P \int_0^T \int_{x-\tau}^{x+\tau} \int_{\mathbf{R}} e^{-\mathrm{Im}\omega\tau}|E(x')|\langle\mathcal{V}_0\rangle^{3-\gamma}\langle v_2'\rangle^{-2-\tilde{\gamma}}\tau^{-1}dv_2'dx'd\tau dx \\ (56) \ & \le C\|\beta\|^{1/2}|E|_1, \end{aligned}$$

where we have again used (45) to integrate over x. Thus we deduce the small-time estimate

$$S \le S_1 + S_2 \le C\|\beta\|^{1/2}|E|_1. \tag{57}$$

The lemma follows from (50) and (57). □

LEMMA 8. *The same estimate as in Lemma* 7 *is valid if* $\exp[-\mathrm{Im}\omega\tau]$ *is replaced by* $\tau^m \exp[-\mathrm{Im}\omega\tau]$ *for any* $m \ge 1$.

The proof is identical to the preceding one.

Now we are ready for our main theorem about the linear operator $\mathcal{C}$. Recall the definition of $\mathcal{C}(\omega, \beta)$ in (25). We shall write $P = 2P_\beta$. Furthermore, we define $\mathcal{C}(\omega, 0)$ from $L^1(\mathbf{R}_P)$ into itself by

$$\mathcal{C}(\omega, 0)E(x) = \int_0^x \rho^0(y)dy + \frac{1}{i\omega P}\int_0^P j_1^0(y)dy - \frac{1}{P}\int_0^P \int_0^z \rho^0(y)dydz. \tag{58}$$

We define the closely related operator $\mathcal{C}_0$ from $L^1(\mathbf{R}_{2P_0})$ to itself, to be given by the same formula but acting on functions in $L^1(\mathbf{R}_{2P_0})$ and with P replaced by $2P_0$.

THEOREM 2 (growing mode for periodic BGK equilibria). *Let $P = 2P_\beta$ and $\operatorname{Im}\omega > 0$ and $\gamma > 1$, and $\mu_\pm$ satisfy* (11), (12), *and* (14). *Then*

(a) *$\mathcal{C}(\omega,\beta)$ and $\mathcal{C}(\omega,0)$ are compact operators from $L^1(\mathbf{R}_P)$ to $L^1(\mathbf{R}_P)$ such that*

$$\|\mathcal{C}(\omega,\beta) - \mathcal{C}(\omega,0)\|_{L^1(\mathbf{R}_P)\to L^1(\mathbf{R}_P)} \le C\|\beta\|_{C^1}^{1/2},$$

where $\mathcal{C}(\omega,0)$ is the unperturbed linearized operator. The constant C is uniform for $\operatorname{Im}\omega >$ constant > 0.

(b) *$\mathcal{C}(\omega,\beta)$ is analytic in ω for $\operatorname{Im}\omega > 0$.*

(c) *There exists $\eta > 0$ such that if $\|\beta\|_{C^1} < \eta$, there exists a growing mode $[g^\pm, E]$ with period P for the linearized Vlasov–Maxwell system* (19) *around $[\mu_\pm(\langle v\rangle \mp \beta(x), v_2), \beta']$.*

Proof. By definition

$$(\mathcal{C}(\omega,\beta)E - \mathcal{C}(\omega,0)E)(x) = \int_0^x [\rho(y) - \rho^0(y)]dy + \frac{1}{i\omega P}\int_0^P [j_1(y) - j_1^0(y)]dy - \frac{1}{P}\int_0^P\int_0^z [\rho(y) - \rho^0(y)]dydz.$$

By Lemma 6,

$$|\mathcal{C}(\omega,\beta)E - \mathcal{C}(\omega,0)E|_1 \le C\|\beta\|^{1/2}|E|_1$$

where C may depend on P and ω. Now by (32)

$$|\partial_x\{\mathcal{C}(\omega,\beta)E\}|_1 = |\rho|_1 \le C|E|_1$$

and, by definition of $\mathcal{C}(\omega,\beta)$,

$$|\mathcal{C}(\omega,\beta)E|_1 \le C|\rho|_1 + C|j_1|_1/|\omega| \le C|E|_1.$$

Since $W^{1,1}(\mathbf{R}_P)$ is compact in $L^1(\mathbf{R}_P)$, $\mathcal{C}(\omega,\beta)$ is a compact operator. This proves (a).

For part (b), notice that $\mathcal{C}(\omega,\beta)E$ is given by an absolutely convergent integral, in which ω appears as $e^{i\omega\tau}$. The integral converges uniformly in each half-plane $\{\operatorname{Im}\omega \ge c > 0\}$. By Lemma 8 with $m = 1$ and by repeating the argument in part (a), we get

$$\left\|\frac{d}{d\omega}[\mathcal{C}(\omega,\beta) - \mathcal{C}(\omega,0)]\right\| \le C\|\beta\|^{1/2}.$$

We thus deduce part (b).

To prove part (c), we define the dilation operator G_β from $L^1(\mathbf{R}_{2P_0})$ to $L^1(\mathbf{R}_P)$ as $G_\beta : E(x) \to E(x/\lambda)$ where $\lambda = P_\beta/P_0$. Clearly G_β is a one-to-one and bounded linear operator from $L^1(\mathbf{R}_{2P_0})$ to $L^1(\mathbf{R}_P)$. We *claim that*

$$\|G_\beta^{-1}\mathcal{C}(\omega,\beta)G_\beta - \mathcal{C}_0\|_{L^1\to L^1} \le C\|\beta\|^{1/2}$$

for $\|\beta\|$ small.

Proof of the claim. Notice that

$$\begin{aligned}
&\|G_\beta^{-1}\mathcal{C}(\omega,\beta)G_\beta - \mathcal{C}_0\| \\
&\le \|G_\beta^{-1}\{\mathcal{C}(\omega,\beta)-\mathcal{C}(\omega,0)\}G_\beta\| + \|G_\beta^{-1}\mathcal{C}(\omega,0)G_\beta - \mathcal{C}_0\| \\
&\le \|G_\beta^{-1}\|\|\mathcal{C}(\omega,\beta)-\mathcal{C}(\omega,0)\|\|G_\beta\| + \|G_\beta^{-1}\mathcal{C}(\omega,0)G_\beta - \mathcal{C}_0\| \\
&\le C\|\beta\|^{1/2} + \|G_\beta^{-1}\mathcal{C}(\omega,0)G_\beta - \mathcal{C}_0\|,
\end{aligned}$$

where we have used part (a). Now we consider $G_\beta^{-1}\mathcal{C}(\omega,0)G_\beta$. Notice that by changing variables $x'' = x'/\lambda$ and $y = \lambda y'$, we have by (28), (31), and (42)

$$\begin{aligned}
G_\beta^{-1}\mathcal{C}(\omega,0)G_\beta E(x) &= \int_0^{\lambda x}\int_{\mathbf{R}} E(x'/\lambda)k_0(y,x')dx'dy + \frac{1}{i\omega P}\int_0^P j_1^0(x'/\lambda)dx' \\
&\quad -\frac{1}{P}\int_0^P\int_0^z\int_{\mathbf{R}} E(x'/\lambda)k_0(y,x')dx'dydz \\
&= \int_0^x\int_{\mathbf{R}} E(x'')k_0(\lambda y',\lambda x'')dx''dy' + \frac{1}{2i\omega P_0}\int_0^{2P_0} j_1^0(x'')dx'' \\
&\quad -\frac{1}{2P_0}\int_0^{2P_0}\int_0^z\int_{\mathbf{R}} E(x'')k_0(\lambda y',\lambda x'')dx''dy'dz.
\end{aligned}$$

Therefore we have

$$|\partial_x(G_\beta^{-1}\mathcal{C}(\omega,0)G_\beta E) - \partial_x(\mathcal{C}_0E)|_{L^1} \le \int_0^{2P_0}\int_{\mathbf{R}} |E(x')||k_0(\lambda x,\lambda x') - k_0(x,x')|dx'dx.$$

We notice that

$$k_0^\pm(x,x',\omega) = \mp\int_0^\infty \hat{k}_0^\pm(x,x',t)e^{i\omega t}dt,$$

where $\hat{k}_0^\pm(x,x',t) = \int_{\mathbf{R}^2}\delta(x-x'-\hat{v}_1't)\partial_{v_1'}\mu_\pm(\langle v'\rangle, v_2')dv'$. Hence,

$$\begin{aligned}
&k_0^\pm(\lambda x,\lambda x',\omega) = \mp\int_0^\infty \hat{k}_0^\pm(\lambda x,\lambda x',t)e^{i\omega t}dt = \mp\int_0^\infty \hat{k}_0^\pm(\lambda x,\lambda x',\lambda s)e^{i\omega\lambda s}\lambda ds \\
&= \mp\int_0^\infty \hat{k}_0^\pm(x,x',s)e^{i\omega\lambda s}ds = k_0^\pm(x,x',\lambda\omega)
\end{aligned}$$

since $\hat{k}_0^\pm(\lambda x,\lambda x',\lambda t) = \lambda^{-1}\hat{k}_0^\pm(x,x',t)$. Therefore,

$$\begin{aligned}
&k_0^\pm(\lambda x,\lambda x',\omega) - k_0^\pm(x,x',\omega) = k_0^\pm(x,x',\lambda\omega) - k_0^\pm(x,x',\omega) \\
&= \mp\int_0^\infty \hat{k}_0^\pm(x,x',t)[e^{i\lambda\omega t} - e^{i\omega t}]dt \\
&\le |\lambda-1|\int_0^\infty |\hat{k}_0^\pm(x,x',t)||\omega t|e^{-\lambda^* t\mathrm{Im}\omega}dt,
\end{aligned}$$

where $\lambda^* = \max(\lambda,1)$. Hence as in (44)–(46),

$$\begin{aligned}
&|\partial_x(G_\beta^{-1}\mathcal{C}(\omega,0)G_\beta E) - \partial_x(\mathcal{C}_0E)|_{L^1} \\
&\le |\lambda-1||\omega|\int_0^{2P_0}\int_{\mathbf{R}}\int_0^\infty |E(x')||\hat{k}_0^\pm(x,x',t)||t|e^{-\lambda^* t\mathrm{Im}\omega}dtdx'dx \\
&\le |\lambda-1|C|E|_{L^1(\mathbf{R}_{2P_0})}.
\end{aligned}$$

The claim is proved.

We define for $0 \le s \le 1$, $T(\omega, s) = \mathcal{C}_0 + s(G_\beta^{-1}\mathcal{C}(\omega,\beta)G_\beta - \mathcal{C}_0)$. By parts (a) and (b), $I - T(\omega, s)$ is a compact operator from $L^1(\mathbf{R}_{2P_0})$ to itself, is analytic in ω, and is continuous in s. By Lemma 2, $I - \mathcal{C}_0$ has a nontrivial nullspace, so that there is a pole ω_0, fixed, of $(I - \mathcal{C}_0)^{-1} = (I - T(\omega, 0))^{-1}$ with $\operatorname{Im}\omega_0 > 0$. We choose $\epsilon_0 > 0$ so small that for $|\omega - \omega_0| = \epsilon_0$, the operator $(I - T(\omega, 0))$ is invertible and $\operatorname{Im}\omega > 0$. If $\|\beta\|_{C^1} < \eta$ is small enough, then from the claim

$$\|T(\omega, s) - T(\omega, 0)\| \le s\|G_\beta^{-1}\mathcal{C}(\omega,\beta)G_\beta - \mathcal{C}_0\| \le C\eta^{1/2}.$$

Hence $I - T(\omega, s)$ is also invertible on $|\omega - \omega_0| = \epsilon_0$ for all $0 \le s \le 1$. Since the poles of $(I - T(\omega, s))^{-1}$ are continuous in s, as is well known [St], there is a pole of $(I - T(\omega, 1))^{-1}$ in $|\omega - \omega_0| < \epsilon_0$. In particular, let ω_β be a pole of $(I - T(\omega, 1))^{-1} = (I - G_\beta^{-1}\mathcal{C}(\omega,\beta)G_\beta)$ in $|\omega - \omega_0| < \epsilon_0$. Then $\operatorname{Im}\omega_\beta > 0$ and $G_\beta^{-1}\mathcal{C}(\omega_\beta,\beta)G_\beta$ has the eigenvalue 1. Hence there exists an $E_0 \ne 0$ and $E_0 \in L^1(\mathbf{R}_{2P_0})$ such that $G_\beta^{-1}\mathcal{C}(\omega_\beta,\beta)G_\beta E_0 = E_0$. Therefore

$$\mathcal{C}(\omega_\beta,\beta)G_\beta E_0 = G_\beta E_0.$$

By Lemma 4, part (b), we complete the proof. □

4. Properties of periodic eigenfunctions. The following lemma of Vidav [V, Sh] will be used to obtain the linearized estimate.

LEMMA 9. *Let Y be a Banach space and A be a linear operator that generates a strongly continuous semigroup on Y such that $\|e^{-tA}\| \le Me^{\alpha t}$ for all $t \ge 0$. Let K be a compact operator from Y to Y. Then $A + K$ generates a strongly continuous semigroup $e^{-t(A+K)}$, and the spectrum of $(-A - K)$ consists of a finite number of eigenvalues of finite multiplicity in $\{\operatorname{Re}\lambda > \delta\}$ for every $\delta > \alpha$. These eigenvalues can be labeled by*

$$\operatorname{Re}\lambda_1 \ge \operatorname{Re}\lambda_2 \ge \cdots \ge \operatorname{Re}\lambda_n \ge \delta.$$

Furthermore, for every $\Lambda > \operatorname{Re}\lambda_1$, there is a constant C_Λ such that

$$\|e^{-t(A+K)}\|_{L(Y,Y)} \le C_\Lambda e^{\Lambda t}.$$

Applying this lemma and Lemma 3 to the linearized periodic Vlasov–Maxwell system $1\frac{1}{4}$L in (8), we deduce the following.

LEMMA 10 (linear Vlasov–Maxwell). *Let $\mu_\pm$ satisfy* (11) *and* (12), *and let β be any solution of* (4) *of period P. Then for all $\delta > 0$, the spectrum of $-\mathcal{L}$ in $\{\operatorname{Re}\lambda > \delta\}$ consists of a finite number of eigenvalues of finite multiplicity. If λ_1 denotes the eigenvalue of the maximal real part, and $\Lambda > \max\{0, \operatorname{Re}\lambda_1\}$, then there exists $C_\Lambda > 0$ such that*

$$\|e^{-t\mathcal{L}}u_0\|_m \le C_\Lambda e^{\Lambda t}\|u_0\|_m.$$

Proof. We apply the previous lemma to the space $Y = \mathcal{M}$ and the operator $\mathcal{L} = \mathcal{L}_1 + \mathcal{L}_2$ given by (23). By (24) we may take any $\delta > 0$. □

LEMMA 11 (regularity of eigenfunctions). *Let $\mu_\pm$ satisfy* (11) *and* (12), *and let β be any solution of* (4) *of period P. Let λ be any eigenvalue of $-\mathcal{L}$ with $\operatorname{Re}\lambda > 0$ and $[R_\pm, E_0]$ its eigenfunction triple. Assume $\|\beta\| < (\operatorname{Re}\lambda)^2$. Then $R_\pm \in W^{1,1}(\mathbf{R}_P \times \mathbf{R}^2)$ and there exists a constant C depending only on λ and $\mu_\pm$ such that*

$$|E_0|_{1,1} + \|R\|_{1,1} \le C\|R\|_1.$$

Proof. We begin with $u = [R_\pm, E_0] \in \mathcal{M}$. We first claim that

$$R = -\int_0^\infty e^{-t\mathcal{A}} e^{-\lambda t} \mathcal{K}(E_0) dt. \tag{59}$$

In order to prove this, notice that $g(t) = e^{\lambda t} R$ and $E(t) = e^{\lambda t} E_0$ satisfy $\partial_t g + \mathcal{A} g = -\mathcal{K} E$. Hence

$$e^{\lambda t} R = e^{-(t-s)\mathcal{A}} e^{\lambda s} R + \int_s^t e^{-(t-\tau)\mathcal{A}} \mathcal{K} e^{\lambda \tau} E_0 d\tau.$$

Letting $s \to -\infty$, we get

$$e^{\lambda t} R = -\int_{-\infty}^t e^{-(t-\tau)\mathcal{A}_\pm} \mathcal{K} E_0 e^{\lambda \tau} d\tau = -\int_0^\infty e^{-\tau \mathcal{A}} \mathcal{K} E_0 e^{\lambda(t-\tau)} d\tau,$$

which is the same as (59). The integral converges because $\mathrm{Re}\lambda > 0$.

Since $[R_\pm, E_0] \in \mathcal{M}$, we have $\partial_x E_0 = \rho = \int (R_+ - R_-) dv$ so that $E_0 \in L^1(\mathbf{R}_P)$ and $\mathcal{K}(E_0) \in L^1(\mathbf{R}_P \times \mathbf{R}^2)$. Writing $\exp(-t\mathcal{A})$ in terms of the characteristics as in the proof of Lemma 4(c), we see that $\exp(-t\mathcal{A})$ also maps L^1 into itself and $W^{1,1}$ into itself. So (59) implies that $R \in L^1(\mathbf{R}_P \times \mathbf{R}^2)$. Hence $\rho \in L^1(\mathbf{R}_P)$ and

$$|E_0|_{1,1} \le C \|R\|_1.$$

Next we let $h(t) = \exp(-t\mathcal{A})(\mathcal{K} E_0)$. Since $\mathcal{K} E_0 \in W^{1,1}$, it follows that $h(t) \in W^{1,1}$. Thus $(\partial_t + \mathcal{A}) h = 0, h(0) = \mathcal{K} E_0$. Differentiating this equation with respect to x, we get

$$(\partial_t + \mathcal{A})(\partial_x h) = [\mathcal{A}, \partial_x] h = \begin{pmatrix} -\beta'' & 0 \\ 0 & \beta'' \end{pmatrix} \partial_{v_1} h, \quad \partial_x h(0) = \partial_x \mathcal{K} E_0,$$

where $[\mathcal{A}, \partial_x]$ is the commutator. Hence

$$\partial_x h(t) = e^{-t\mathcal{A}} \partial_x \mathcal{K} E_0 + \int_0^t e^{-(t-\tau)\mathcal{A}} \begin{pmatrix} -\beta'' & 0 \\ 0 & \beta'' \end{pmatrix} \partial_{v_1} h(\tau) d\tau.$$

Similarly,

$$\partial_{v_1} h(t) = e^{-t\mathcal{A}} \partial_{v_1} \mathcal{K} E_0 - \int_0^t e^{-(t-\tau)\mathcal{A}} \langle v \rangle^{-3} (1 + v_2^2) \partial_x h(\tau) d\tau,$$
$$\partial_{v_2} h(t) = e^{-t\mathcal{A}} \partial_{v_2} \mathcal{K} E_0 + \int_0^t e^{-(t-\tau)\mathcal{A}} v_1 v_2 \langle v \rangle^{-3} \partial_x h(\tau) d\tau.$$

Taking L^1-norms, we get

$$\|\partial_x h(t)\|_1 + \|\partial_v h(t)\|_1 \le (\|\partial_x (\mathcal{K} E_0)\|_1 + \|\partial_v (\mathcal{K} E_0)\|_1) e^{t \|\beta\|_{C^2}^{1/2}}.$$

We put this estimate into the integrand of (59) to get

$$\|\partial_x R\|_1 + \|\partial_v R\|_1 \le \left(\int_0^\infty e^{[\|\beta\|_{C^2}^{1/2} - \lambda] t} dt \right) (\|\partial_x \mathcal{K} E_0\|_1 + \|\partial_v \mathcal{K} E_0\|_1).$$

By the definition of (21) of $\mathcal{K}$, the decay condition (11) on $\mu_\pm$, and the boundedness of β, we deduce that $\mathcal{K} E_0 \in W^{1,1}$, and we have the desired estimate. ∎

LEMMA 12. *Let $\underline{u}$ be an eigenvector of $-\mathcal{L}$ with its eigenvalue λ, $\mathrm{Re}\lambda > 0$. If λ is not real, then there is a constant $\zeta > 0$ such that for all $t > 0$*

$$\|e^{-\mathcal{L}t}(\mathrm{Im}\ \underline{u}\ )\|_1 \geq \zeta e^{\mathrm{Re}\lambda t}\|\mathrm{Im}\ \underline{u}\ \|_1 > 0.$$

Proof. We prove it by contradiction. Notice that

$$e^{-\mathcal{L}t}(\mathrm{Im}\ \underline{u}\ ) = \mathrm{Im}(e^{-\mathcal{L}t}\underline{u}) = e^{\mathrm{Re}\lambda t}(\sin[\mathrm{Im}\ \lambda t]\mathrm{Re}\ \underline{u}\ + \cos[\mathrm{Im}\ \lambda t]\mathrm{Im}\ \underline{u}\ ).$$

If the lemma were false, by passing through a convergent subsequence of $\sin[\mathrm{Im}\ \lambda t_n]$, and $\cos[\mathrm{Im}\ \lambda t_n]$ with $n \to \infty$, we would have $a\mathrm{Im}\ \underline{u}\ + b\mathrm{Re}\ \underline{u}\ = 0$, with $a^2 + b^2 = 1$. Therefore either $\mathrm{Im}\ \underline{u}$ or $\mathrm{Re}\ \underline{u}$ would be a real eigenvector and λ would be real, a contradiction. ∎

LEMMA 13 (pointwise estimate of eigenfunctions). *Let $\mu_\pm$ satisfy* (11), (12) *and let β be any solution of* (4) *of period P. Let $[R_+, R_-, E_0]$ be an eigenvector with $\|R\|_{1,1} + |E_0|_1 = 1$ with eigenvalue λ satisfying $\mathrm{Re}\lambda > 0$. Let $h(\cdot)$ satisfy $|h'| \leq C_1 h$ for some constant C_1. If*

$$|\partial_e \mu_\pm(\langle v\rangle \mp \beta, v_2)| \leq C_2 h(\langle v\rangle)\mu_\pm(\langle v\rangle \mp \beta, v_2) \tag{60}$$

and $|\beta|_{C^1}$ is sufficiently small, then

$$|R_\pm(x,v)| \leq C_3 h(\langle v\rangle)\mu_\pm(\langle v\rangle \mp \beta, v_2),$$

where C_3 depends only on C_1, C_2, $\mathrm{Re}\lambda$, and $|\beta'|_\infty$.

Proof. Omit the subscripts $\pm$. The eigenfunction satisfies

$$[\hat{v}_1\partial_x \pm \beta'(x)\partial_{v_1}]R \pm E_0\partial_{v_1}\mu = -\lambda R$$

where $\mu = \mu_\pm(\langle v\rangle \mp \beta'(x), v_2)$. Then $S = (h\mu)^{-1}R$ satisfies

$$[\hat{v}_1\partial_x \pm \beta'(x)\partial_{v_1}]S \pm E_0\frac{\partial_{v_1}\mu}{h\mu} \pm \beta'\frac{\partial_{v_1}h}{h}S = -\lambda S,$$

where we have used the fact that $\hat{v}_1\partial_x\mu_\pm \pm \beta'\partial_{v_1}\mu_\pm = 0$. As in (25), this may be written as

$$S = \mp\int_0^\infty e^{-t\mathcal{A}}e^{-\lambda t}\left[E_0\frac{\partial_{v_1}\mu}{h\mu} + \beta'\frac{\partial_{v_1}h}{h}S\right]dt.$$

Since $\exp(-t\mathcal{A})$ has norm one on L^∞, for $\mathrm{Re}\lambda > 0$ we have

$$\begin{aligned}\|S\|_\infty &\leq \left[|E_0|_\infty\left\|\frac{\partial_{v_1}\mu}{h\mu}\right\|_\infty + |\beta'|_\infty\left\|\frac{\partial_{v_1}h}{h}\right\|_\infty\|S\|_\infty\right](\mathrm{Re}\lambda)^{-1}\\ &\leq [C_2|E_0|_\infty + C_1|\beta'|_\infty\|S\|_\infty](\mathrm{Re}\lambda)^{-1}.\end{aligned}$$

Since $|E_0|_\infty \leq |E_0|_{1,1} \leq C\|R\|_1$, the lemma thus follows if $|\beta'|_\infty$ is small. ∎

The following lemma gives an improved bound for a cut-off eigenfunction.

LEMMA 14 (approximate eigenfunctions). *Let $[R_\pm, E_0]$ and β be as in the preceding lemma. Let $h(s)$ be either s^σ or $\exp(ls)$, for some $\sigma > 0$ or $l > 0$. Assume there are constants C_2, C_5, and $m_0 > 0$ such that for sufficiently large s,*

$$|\partial_e \mu_\pm(s, v_2)| \leq C_2 h(s)\mu_\pm(s, v_2), \tag{61}$$

$$\mu_\pm(s, v_2) \leq C_5 h'(s)[h(s)]^{-(2+m_0)}s^{-1}. \tag{62}$$

Then there exists $\delta_0 > 0$ such that for $0 < \delta < \delta_0$, there exist approximate eigenfunctions $R^\delta_\pm \in L^1(\mathbf{R}_P \times \mathbf{R})$, $E^\delta_0 \in L^1(\mathbf{R}_P)$ such that all of the following hold:

$$\delta |R^\delta_\pm(x,v)| \le \mu_\pm(\langle v\rangle \mp \beta(x), v_2), \tag{63}$$

$$\|R^\delta_\pm - R_\pm\|_1 + |E^\delta_0 - E_0|_1 \le \delta^m, \tag{64}$$

$$\int_0^P \int_{\mathbf{R}} (R^\delta_+ - R^\delta_-) dv dx = 0, \tag{65}$$

$$\partial_x E^\delta_0 = \int_{\mathbf{R}} (R^\delta_+ - R^\delta_-) dv, \tag{66}$$

$$\|R^\delta\|_{1,1} \le C\|R\|_1, \tag{67}$$

where $0 < m < m_0$. Furthermore, there exists a disk Ω^δ independent of x such that $R^\delta(x,v)$ has support in $\mathbf{R} \times \Omega^\delta$.

Proof. We prove this lemma in two steps.

Step 1. *Cut-off approximation.* Let $\eta(\langle v\rangle)$ be a smooth cut-off function, $\eta(\langle v\rangle) = 1$ for $\langle v\rangle \le w$, $\eta(\langle v\rangle) = 0$ for $\langle v\rangle \ge w+1$, with w to be chosen later. Notice that (61) implies (60). By Lemma 13,

$$|\eta(\langle v\rangle) R_\pm(x,v)| \le |R_\pm(x,v)| \le C_3 h(\langle v\rangle) \mu_\pm(\langle v\rangle \mp \beta(x), v_2).$$

Define w by the equation $\delta = [2C_3 h(w+1)]^{-1}$. Then $\delta\eta(v)|R_\pm(x,v)| \le \frac{1}{2}\mu_\pm(\langle v\rangle \mp \beta(x), v_2)$ since h is an increasing function. Now from (62) we have

$$\mu_\pm(s, v_2) = o[h'(s)(h(s))^{-(2+m)}] s^{-1}$$

as $s \to \infty$ uniformly in v_2. Hence

$$\int_0^P \mu_\pm(\langle v\rangle \mp \beta(x), v_2) dx = o\left\{ \frac{h'(\langle v\rangle)}{[h(\langle v\rangle)]^{2+m}\langle v\rangle} \right\}$$

as $\langle v\rangle \to \infty$. Integrating this equality, we get

$$\int_{\langle v\rangle \ge w} \int_0^P h(\langle v\rangle) \mu_\pm(\langle v\rangle \mp \beta(x), v_2) dx dv = o\left\{ \int_{\langle v\rangle \ge w} \int_0^P \frac{h'(\langle v\rangle)}{[h(\langle v\rangle)]^{1+m}\langle v\rangle} dx dv \right\} \le \delta^m$$

for sufficiently small δ, by the definition of w. Hence,

$$\int_{\mathbf{R}^2} \int_0^P |\eta R_\pm - R_\pm| dx dv \le \int_{\langle v\rangle \ge w} \int |R_\pm| dx dv$$

$$\le C \int_{\langle v\rangle \ge w} \int_0^P h(\langle v\rangle) \mu_\pm(\langle v\rangle \mp \beta, v_2) dx dv \le C_6 \delta^m$$

for sufficiently large w. Reducing m slightly eliminates the constant C_6.

Step 2. *Neutrality and Poisson conditions.* We now further perturb the cut-off eigenfunctions. Let $0 \le Q(v) \in C^1_0(\mathbf{R}^2)$, $P\int Q(v) dv = 1$. By Step 1, we define for every $\delta > 0$,

$$R^\delta_+ = \eta R_+ + aQ, \qquad R^\delta_- = \eta R_-$$

where a is a complex number satisfying (65)

$$\int_0^P \int_{\mathbf{R}} (R^\delta_+ - R^\delta_-) dx dv = a + \int_0^P \int_{\mathbf{R}} \eta(R_+ - R_-) dv dx = 0.$$

By Step 1 and the neutrality condition (20),

$$|a| = \left| \int \int \eta(R_+ - R_-)dxdv \right| = \left| \int \int (1-\eta)(R_+ - R_-)dxdv \right| \le \delta^m.$$

We also deduce (63) from Step 1 because δ is sufficiently small and $\mu_+ > 0$. By an easy calculation and the bound on a, $\|R_\pm^\delta\|_{1,1} \le C\delta^m + C\|R_\pm\|_{1,1} \le C'\|R\|_1$. The last inequality follows from Lemma 11 and the normalization. We finally define E^δ to satisfy

$$\partial_x E_0^\delta = \int_{\mathbf{R}^2} (R_+^\delta - R_-^\delta)dv$$

with the same average as E_0: $\int_0^P E_0^\delta dx = \int_0^P E_0 dx$. Hence

$$|E_0^\delta - E_0|_1 \le C \left| \partial_x [E_0^\delta - E_0] \right|_1 \le C\delta^m.$$

We deduce (64) and (67) for small δ and the lemma follows. □

Remark. Conditions (61) and (62) are very general. They allow $\mu_\pm$ to go to zero at a polynomial, exponential, or even super-exponential rate but they exclude $\mu_\pm$ of compact support. An example is $\mu(s) = \exp[-s^\alpha]$ with $\alpha \ge 1$ and $h(s) = s^{\alpha-1}$. Another example is $\mu(s) = \exp[-\exp s]$ and $h(s) = \exp s$.

5. Nonlinear instability for periodic BGK waves. Let us abbreviate

$$f = [f_+, f_-], \qquad \mu_\beta = [\mu_+(\langle v \rangle - \beta, v_2), \mu_-(\langle v \rangle + \beta, v_2)],$$
$$u = [f_+, f_-, E], \quad \nu_\beta = [\mu_+(\langle v \rangle - \beta, v_2), \mu_-(\langle v \rangle + \beta, v_2), \partial_x \beta].$$

We define the norm

$$\|u\|_1 = \int_{\mathbf{R}^2} \int_0^P (|f_+| + |f_-|)dxdv + \int_0^P |E|dx. \tag{68}$$

Our goal is to show that the P-periodic BGK equilibrium ν_β is nonlinearly unstable under $\|\cdot\|_1$ with $P = 2P_\beta$.

LEMMA 15. *Let $\mu_\pm$ satisfy* (11), (12), (14), (61), *and* (62). *Let $[f_+, f_-, E]$ be a BV solution of the nonlinear Vlasov–Maxwell system as in Theorem* 5 *in the appendix. Let $\omega > 0$ and $\|\beta\|_{C^2} < \omega^2$. Let $\delta > 0$. Assume there are positive constants δ, T, b_0, and C_0 such that*

$$\begin{aligned} &\|f(0) - \mu_\beta\|_{1,1} \le b_0\delta, \\ &\|f(t) - \mu_\beta\|_1 \le C_0\delta e^{\omega t} \end{aligned} \tag{69}$$

for $0 \le t \le T$. Then there are positive constants θ and D depending only on b_0, C_0, and ω such that

$$\|\partial_x[f(t) - \mu_\beta]\|_m + \|\partial_{v_1}[f(t) - \mu_\beta]\|_m \le D\delta e^{\omega t} \tag{70}$$

in $0 \le t \le \min\{T, \frac{1}{\omega}\ln(\theta/\delta)\}$. Here m denotes the measure norm.

Proof. We let $L^1 = L^1(\mathbf{R}_P \times \mathbf{R}^2)$ throughout this proof for notational simplicity. Without loss of generality (by a smooth approximation), we may assume $f_\pm \in W^{1,1}$ so that the measure norms in (70) are replaced by L^1 norms. Taking the x derivative of the Vlasov equation, we get

$$(\partial_t + \hat{v}_1\partial_x \pm E\partial_{v_1})(\partial_x f_\pm) \pm \partial_x E \partial_{v_1} f_\pm = 0.$$

Taking the x-derivative of the stationary Vlasov equation for $\mu_\pm$ yields

$$\hat{v}_1\partial_{xx}\mu_\pm \pm \beta_{xx}\partial_{v_1}\mu_\pm \pm \beta_x\partial_{xv_1}\mu_\pm = 0.$$

The difference of these two equations is

$$\begin{aligned}&(\partial_t + \hat{v}_1\partial_x \pm E\partial_{v_1})[\partial_x(f_\pm - \mu_\pm)]\\ &= \mp E_x\partial_{v_1}(f_\pm - \mu_\pm) \mp (\beta_{xx} - E_x)\partial_{v_1}\mu_\pm \pm (E - \beta_x)\partial_{xv_1}\mu_\pm\end{aligned} \tag{71}$$

where $\mu_\pm = \mu_\pm(\langle v\rangle \mp \beta(x), v_2)$. Notice that $\int(|\partial_{v_1}\mu_\pm| + |\partial_x\partial_{v_1}\mu_\pm|)dv$ is bounded in x from (11). Now multiplying (71) by $sgn[\partial_x(f_\pm - \mu_\pm)]$ and integrating over $[0,P]\times\mathbf{R}^2$, we get for some $\epsilon > 0$,

$$\begin{aligned}&\frac{d}{dt}\|\partial_x[f_\pm - \mu_\pm]\|_1\\ &\le |E_x|_\infty\|\partial_{v_1}[f_\pm - \mu_\pm]\|_1 + C(|\beta_{xx} - E_x|_1 + |\beta_x - E|_1)\\ &\le (|\beta_{xx}|_\infty + |E_x - \beta_{xx}|_\infty)\|\partial_{v_1}[f_\pm - \mu_\pm]\|_1 + C(|\beta_{xx} - E_x|_1 + |\beta_x - E|_1)\\ &\le (|\beta_{xx}|_\infty + \|\partial_x[f_\pm - \mu_\pm]\|_1)\|\partial_{v_1}[f_\pm - \mu_\pm]\|_1 + C(\|f_\pm - \mu_\pm\|_1 + |\beta_x - E|_1)\end{aligned} \tag{72}$$

since $E_x - \beta_{xx}$ has average zero.

Similarly, by taking the v_1 derivative of the Vlasov equation, we get

$$\begin{aligned}&\partial_t\partial_{v_1}f_\pm + \hat{v}_1\partial_{v_1}\partial_x f_\pm \pm E\partial_{v_1}\partial_{v_1}f_\pm = -\langle v\rangle^{-3}(1+v_2^2)\partial_x f_\pm,\\ &\hat{v}_1\partial_x\partial_{v_1}\mu_\pm \pm \beta_x\partial_{v_1}\partial_{v_1}\mu_\pm = -\langle v\rangle^{-3}(1+v_2^2)\partial_x\mu_\pm.\end{aligned}$$

Taking the difference yields

$$(\partial_t + \hat{v}_1\partial_x \pm E\partial_{v_1})(\partial_{v_1}[f_\pm - \mu_\pm]) = -\langle v\rangle^{-3}(1+v_2^2)\partial_x[f_\pm - \mu_\pm] \mp (E - \beta_x)\partial_{v_1}\partial_{v_1}\mu_\pm. \tag{73}$$

We also have

$$\|(E - \beta_x)\partial_{v_1}\partial_{v_1}\mu_\pm\|_1 \le C|E - \beta_x|_1.$$

We have used the fact that $\sup_x \int_{\mathbf{R}^2} |\partial_{v_1}\partial_{v_1}\mu_\pm|dv < \infty$ by (11). Multiplying (73) by $sgn(\partial_{v_1}(f_\pm - \mu_\pm))$ and integrating over $[0,P]\times\mathbf{R}$, we get

$$\frac{d}{dt}\|\partial_{v_1}[f_\pm - \mu_\pm]\|_1 \le \|\partial_x[f_\pm - \mu_\pm]\|_1 + C|E - \beta_x|_1.$$

With D to be chosen later larger than b_0, define T' so that $[0,T']$ is the maximal interval in which (70) is valid. Since $\|\beta\|_{C^2} < \omega^2$, we may fix $0 < \epsilon < \omega - \|\beta\|^{1/2}$. Then choose θ so small that $\|\beta\| + C_1\theta < (\omega - \epsilon)^2$ and define T'' by $\delta\exp(\omega T'') = \theta$. Then T'', T, and θ depend on D but the other constants C and C_ϵ (below) do not. Then

$$\|\beta_{xx}\|_\infty + \|\partial_x[f_\pm - \mu_\pm]\|_1 < (\omega - \epsilon)^2$$

for $0 \le t \le \min\{T, T', T''\}$. Therefore, integrating (72) and plugging it into the above inequality, we have for $0 \le t \le \min\{T, T', T''\}$,

$$\begin{aligned}\frac{d}{dt}\|\partial_{v_1}[f_\pm - \mu_\pm]\|_1 \le&(\omega - \epsilon)^2\int_0^t \|\partial_{v_1}[f_\pm(\tau) - \mu_\pm]\|_1 d\tau + \|f_\pm(0) - \mu_\pm\|_{1,1}\\ &+C\int_0^t \{\|f_\pm(\tau) - \mu_\pm\|_1 + |E(\tau) - \beta_x|_1\}d\tau + C|E(t) - \beta_x|_1.\end{aligned}$$

Because of the identity $\partial_t(E-\beta_x)=-j$, we have $\frac{d}{dt}|E-\beta_x|_1 \le \|f-\mu\|_1$, so that $|E(t)-\beta_x|_1 \le C\delta e^{\omega t}$ by (69). Letting $V(t)=\int_0^t \|\partial_{v_1}[f_\pm(\tau)-\mu_\pm]\|_1 d\tau$, we therefore have by (69)

$$V'' \le (\omega-\epsilon)^2 V + \frac{1}{2}C\delta e^{\omega t}$$

for some constant C. Multiplying by $2V'$ on both sides, we get

$$[(V')^2]' \le [(\omega-\epsilon)^2 V^2]' + C\delta e^{\omega t} V'.$$

Integrating over time, we get

$$\begin{aligned}(V')^2 &\le (V'(0))^2 + (\omega-\epsilon)^2V^2 + C\delta\left[e^{\omega t}V - \omega\int_0^t e^{\omega t}V(\tau)d\tau\right]\\ &\le b_0^2\delta^2 + (\omega-\epsilon)^2V^2 + C\delta e^{\omega t}V\\ &\le (\omega-\epsilon/2)^2V^2 + C_\epsilon^2\delta^2 e^{2\omega t}.\end{aligned}$$

Taking the square root of both sides, we obtain $V' \le (\omega-\epsilon/2)V + C_\epsilon\delta e^{\omega t}$. It follows from this inequality and (72) that

$$\|\partial_x[f(t)-\mu]\|_1 + \|\partial_{v_1}[f(t)-\mu]\|_1 \le C'_\epsilon\delta e^{\omega t}$$

in $[0,\min\{T,T',T''\}]$ for some constant C'_ϵ independent of D. We choose $D > C'_\epsilon$. Then $\min\{T,T''\} \le T'$ and the lemma follows. □

We now are ready to prove the nonlinear instability of periodic BGK waves.

THEOREM 3. *Let $\mu_\pm$ satisfy* (11), (12), (14), (61), *and* (62). *Let β be a solution of* (4) *of period P_β with $\|\beta\|_{C^2} \le \beta_0$, where β_0 is sufficiently small. Consider $1\frac{1}{4}$RVM with $P=2P_\beta$. Then there exist positive constants ϵ_0 and C_1 and a family of solutions $u^\delta(t)=[f^\delta_\pm(t),E^\delta_1(t)]$ of $1\frac{1}{4}$ RVM with $f^\delta_\pm \ge 0$ defined for δ sufficiently small, such that*

$$\sum_\pm \|f^\delta_\pm(0)-\mu_\pm(\langle v\rangle \mp \beta, v_2)\|_{W^{1,1}(\mathbf{R}_P\times\mathbf{R}^2)} + |E^\delta_1(0)-\partial_x\beta|_{W^{1,1}(\mathbf{R}_P)} \le \delta$$

and

$$\sup_{0\le t\le C_1|\ln\delta|} \|u^\delta(t)-\nu_\beta\|_1 \ge \epsilon_0.$$

Proof of Theorem 3. We are given nonnegative $\mu_\pm$ that satisfy (11), (12), (14), (61), and (62). Furthermore, β is a solution of (4) of period P_β with $\|\beta\|_{C^2}$ sufficiently small as in Lemma 1 and $\nu_\beta=[\mu_\beta,\beta_x]$. We must find a family of solutions $u^\delta(t)=[f^\delta_\pm(t),E^\delta(t)]$ of the nonlinear Vlasov–Maxwell system satisfying the conclusions of Theorem 5, such that

$$\begin{aligned}&\|f^\delta(0)-\mu_\beta\|_{1,1} + |E^\delta(0)-\beta_x|_{1,1} \le \delta,\\ &\sup_{0\le t<C_1|ln\delta|}\|u^\delta(t)-\nu_\beta\|_1 \ge \epsilon_0 > 0\end{aligned} \tag{74}$$

with $\|\cdot\|_1$ defined by (68).

By Lemma 1, the BGK equilibria exist because of (11), (12), and (14). By Theorem 2 and Lemma 11 and because of (11) and (12), we may choose $\Xi=[R_+,R_-,E_0]$

to be an eigenvector of $-\mathcal{L}$ satisfying (29) with $\|R\|_{1,1}+|E_0|_1=1$ such that its eigenvalue λ has the largest (positive) real part. If λ is not real, then $\|\mathrm{Im}\ \Xi\|_1 \equiv r>0$ by Lemma 12. We choose an approximation $\Xi^\delta=[\mathrm{Im}\ R^\delta_\pm, \mathrm{Im}\ E^\delta_0]$ to the imaginary part of Ξ by Lemma 14. In case λ is real we simply do not take the imaginary parts; but without loss of generality, we will assume λ is not real.

We choose the family of solutions $u^\delta(t,x,v)=[f^\delta_\pm(t,x,v), E^\delta(t,x)]$ by specifying the initial data $u^\delta(0,x,v)=\nu_\beta+\delta\Xi^\delta$. That is,

$$f^\delta_\pm(0,x,v)=\mu_\pm(\langle v\rangle \mp \beta(x), v_2)+\delta\mathrm{Im}\ R^\delta_\pm(x,v), E^\delta(0,x)=\beta_x(x)+\delta\mathrm{Im}\ E^\delta_0(x).$$

Because of (63), $f^\delta_\pm(0,x,v)\ge 0$ for all x, v and for all sufficiently small δ. Because of Lemma 14, all of the conditions of Theorem 5 are satisfied. Note that

$$|\|u(0)-\nu_\beta\|_1-\delta r| = \delta(\|\Xi^\delta\|_1-r)\le \delta\|\Xi-\Xi^\delta\|_1\le \delta^{m+1}\le \delta r/2 \tag{75}$$

by (64) for δ sufficiently small. By (67)

$$\begin{aligned}\|f(0)-\mu_\beta\|_{1,1}+|E(0)-\beta_x|_1 &= \delta\|\mathrm{Im}\ R^\delta\|_{1,1}+\delta|\mathrm{Im}\ E^\delta_0|_1\\ &\le C\delta[\|\mathrm{Im}\ R^\delta\|_1+|\mathrm{Im}\ E^\delta_0|_1]=C\delta r.\end{aligned} \tag{76}$$

Let $u^\delta(t)=u(t)=[f_+(t),f_-(t),E(t)]$ denote the solution, where we drop the superscript δ.

By the nonlinear Vlasov–Maxwell system

$$u(t)-\nu_\beta=\delta e^{-\mathcal{L}t}\Xi^\delta+\int_0^t e^{-\mathcal{L}(t-\tau)}\begin{pmatrix}\mp(E(\tau)-\beta_x)\partial_{v_1}(f_\pm(\tau)-\mu_\pm)\\ 0\end{pmatrix}d\tau. \tag{77}$$

We choose Λ such that

$$\mathrm{Re}\lambda<\Lambda<\min(1+m,2)\mathrm{Re}\lambda. \tag{78}$$

Let $\|\beta\|<(\mathrm{Re}\lambda)^2=\omega^2$. We define S by

$$\delta e^{\mathrm{Re}\lambda S}=\{\zeta r/(2C_\Lambda)\}^{1/m}.$$

Let C_Λ be the constant in Lemma 10 and ζ be the constant in Lemma 12. Let

$$T=\sup\left\{s:\ \|u(t)-\nu_\beta-\delta e^{-\mathcal{L}t}\Xi^\delta\|_1\le\frac{\zeta}{4}\,\delta e^{\mathrm{Re}\lambda t}r,\ \text{for } 0\le t\le s\right\}. \tag{79}$$

For $0\le t\le\min\{S,T\}$, from Lemma 10 and (64) and (78),

$$\|e^{-\mathcal{L}t}(\mathrm{Im}\ \Xi-\Xi^\delta)\|_1\le C_\Lambda e^{\Lambda t}\delta^m\le C_\Lambda e^{\omega t}\{\delta e^{\omega t}\}^m\le\frac{1}{2}\zeta r e^{\omega t}$$

by choice of S. Hence, by (79) for such t,

$$\begin{aligned}\|u(t)-\nu_\beta\|_1&\le\delta e^{\mathrm{Re}\lambda t}\|\Xi\|_1+\delta\|e^{-\mathcal{L}t}(\mathrm{Im}\ \Xi-\Xi^\delta)\|_1+\frac{\zeta}{4}\delta e^{\mathrm{Re}\lambda t}r\\ &\le(1+3\zeta r/4)\delta e^{\mathrm{Re}\lambda t}.\end{aligned} \tag{80}$$

Hence for such t, from

$$\partial_x(E-\beta_x)=\rho-\beta_{xx}=\int_{\mathbf{R}^2}[(f_+-\mu_+)-(f_--\mu_-)]dv,$$

we deduce

$$
\begin{aligned}
|E(t)-\beta_x|_\infty \le & \frac{1}{P}|E(t)-\beta_x|_1+\sum_{\pm}\|f_\pm(t)-\mu_\pm\|_1 \\
\le & C\|u(t)-\nu_\beta\|_1 \le C\delta e^{t\mathrm{Re}\lambda}. \qquad (81)
\end{aligned}
$$

By Lemma 15, there exist D and $\theta>0$ such that if $\delta e^{\mathrm{Re}T^*}=\theta$ and $0\le t\le \min\{T,S,T^*\}$, then

$$
\|\partial_{v_1}[f(t)-\mu_\beta]\|_m \le D\delta e^{\mathrm{Re}\lambda t}.
$$

We may assume $\theta \le \{\zeta r/(2C_\Lambda)\}^{1/m}$ so that $T^*\le S$. Hence for such t, by Lemma 10 and (77) and (81),

$$
\begin{aligned}
&\|u(t)-\nu_\beta-\delta e^{-\mathcal{L}t}\Xi^\delta\|_1 \\
&\le C\int_0^t e^{\Lambda(t-\tau)}|E(\tau)-\partial_x\beta|_\infty \sum_{\pm}\|\partial_{v_1}[f_\pm(\tau)-\mu_\pm]\|_m d\tau \\
&\le C\int_0^t e^{\Lambda(t-\tau)}(\delta e^{\tau\mathrm{Re}\lambda})^2 d\tau \le C_2(\delta e^{\mathrm{Re}\lambda t})^2 \qquad (82)
\end{aligned}
$$

since $\Lambda<2\mathrm{Re}\lambda$, with a constant C_2 independent of θ, δ, and t. Thus for $0\le t\le \min\{T,T^*\}$, we also have

$$
\begin{aligned}
\|u(t)-\nu_\beta\|_1 &\ge \delta\|e^{-\mathcal{L}t}\Xi^\delta\|_1-\|u(t)-\nu_\beta-\delta e^{-\mathcal{L}t}\Xi^\delta\|_1 \\
&\ge \delta\|e^{-\mathcal{L}t}\mathrm{Im}\Xi\|_1-\delta\|e^{-\mathcal{L}t}(\mathrm{Im}\Xi-\Xi^\delta)\|_1-C_2(\delta e^{\mathrm{Re}\lambda t})^2 \qquad (83) \\
&\ge \frac{1}{2}\delta r\zeta e^{\mathrm{Re}\lambda t}-C_2(\delta e^{\mathrm{Re}\lambda t})^2
\end{aligned}
$$

by Lemma 12 and as in (80).

If $T<T^*$, then by (82) with $t=T$, we have

$$
\begin{aligned}
\|u(T)-\nu_\beta-\delta e^{-\mathcal{L}T}\Xi^\delta\|_1 &\le C_2(\delta e^{\mathrm{Re}\lambda T})^2 \\
&< C_2(\delta e^{\mathrm{Re}\lambda T})\theta < \frac{\zeta}{4}r\delta e^{T\mathrm{Re}\lambda}
\end{aligned}
$$

by also choosing $0<\theta<\frac{\zeta r}{4C_2}$. This contradicts (79). Therefore $T^*\le T$. By (83) with $t=T^*$, we have

$$
\|u(T^*)-\nu_\beta\|_1 \ge \frac{r\zeta}{2}\delta e^{\omega T^*}-C_2(\delta e^{\omega T^*})^2=\frac{r\zeta}{2}\theta-C_2\theta^2>\frac{r\zeta}{4}\theta
$$

since $0<\theta<\frac{r\zeta}{4C_2}$. □

6. Instability of oscillatory-tail solutions. In this section, we study the instabilities of oscillatory-tail solutions of (1). A major difficulty lies in the unboundedness of the spatial variable, so that the plane wave growing mode does not decay as $x\to\infty$. They do not belong in any L^p space, and they correspond to continuous spectrum. We shall overcome this by employing the finite propagation speed property of the relativistic model. We approximate the original problem on the whole line by the asymptotic periodic problem.

Consider a plasma which consists of electrons and ions in one space dimension with orthogonal electric and magnetic fields $(E_1, E_2, 0)$ and $(0, 0, B)$. By normalizing all the physical constants to be one, we derive the $1\frac{1}{2}$-dimensional RVM system as

$$\begin{aligned} &\partial_t f_\pm + \hat{v}_1 \partial_x f_\pm \pm [E_1 + \hat{v}_2 B]\partial_{v_1} f_\pm \pm [E_2 - \hat{v}_1 B]\partial_{v_2} f_\pm = 0, \\ &\partial_t E_1 = -j_1, \qquad \partial_x E_1 = \rho, \\ &\partial_t E_2 = -\partial_x B - j_2, \qquad \partial_t B = -\partial_x E_2. \end{aligned} \tag{84}$$

Here $f_\pm(t, x, v_1, v_2)$ are the microscopic distribution functions for ions $(+)$ and electrons $(-)$ at time t, position x, and momentum (v_1, v_2). The relativistic velocity is $\hat{v} = \frac{v}{\sqrt{1+|v|^2}}$. The charge and current densities are defined by

$$\rho = \int_{\mathbf{R}^2} [f_+ - f_-] dv_1 dv_2, \qquad j_k = \int_{\mathbf{R}^2} \hat{v}_k [f_+ - f_-] dv_1 dv_2$$

for $k = 1, 2$.

For the well-posedness of (84) see Theorem 4 in the appendix. For any interval $A \subset \mathbf{R}$, define the norm

$$\|u\|_A = \sum_\pm \|f_\pm\|_{1,1} + |E|_1 + |E_2|_1 + |B|_1,$$

where the x-norms are taken over the interval A. Recalling Γ and Γ_0 in (6) and (5), we have a lemma.

LEMMA 16. *Let I be the interval $I = [a - b, a + b]$. Then for all b,*

$$\lim_{a \to -\infty} \|\Gamma - \Gamma_0\|_I = 0.$$

Proof of Lemma 16. We write $\|\Gamma - \Gamma_0\|_{L^1(I)} = I_1 + I_2 + I_3$ where we abbreviate $\mu_\pm = \mu_\pm(\langle v \rangle \mp \Phi(x), v_2 \pm \Psi(x))$,

$$\begin{aligned} I_1 &= \sum_\pm \int_{\mathbf{R}^2} \int_I |\mu_\pm - \mu_\pm(\langle v \rangle \mp \beta(x), v_2)| \, dx dv, \\ I_2 &= \int_I \{|\partial_x(\Phi - \beta)| + |\partial_x \Psi|\} dx, \\ I_3 &= \sup_{x \in I} \left| \int_{\mathbf{R}^2} \{\mu_+ - \mu_+(\langle v \rangle - \beta(x), v_2) - \mu_- + \mu_-(\langle v \rangle + \beta(x), v_2)\} dv \right|. \end{aligned}$$

By (7) it follows immediately that $\lim_{a \to -\infty} I_2 = 0$. By the decay assumption on $\mu_\pm$ in (11),

$$\begin{aligned} \Delta &= |\mu_\pm(\langle v \rangle \mp \Phi(x), v_2 \pm \Psi(x)) - \mu_\pm(\langle v \rangle \mp \beta(x), v_2)| \\ &\le C \langle \langle v \rangle \mp \beta(x) \pm \theta_1 \rangle^{-\gamma} \langle v_2 \pm \theta_2 \rangle^{-\tilde{\gamma}} |\Phi(x) - \beta(x)| \\ &\quad + C \langle \langle v \rangle \mp \beta(x) \pm \theta_1 \rangle^{-\gamma} \langle v_2 \pm \theta_2 \rangle^{-\tilde{\gamma}} |\Psi(x)|, \end{aligned}$$

where θ_1 lies between 0 and $\Phi(x) - \beta(x)$, and θ_2 between 0 and $\Psi(x)$. Hence

$$\Delta \le C \langle v \rangle^{-\gamma} \langle v_2 \rangle^{-\tilde{\gamma}} (|\Phi(x) - \beta(x)| + |\Psi(x)|).$$

By assumption (11), these factors of v are integrable over $\mathbf{R}^2$. Hence

$$\int_{\mathbf{R}^2} \Delta dv \le C|\Phi(x) - \beta(x)| + C|\Psi(x)| \tag{85}$$

so that, by (7), $\lim_{a\to-\infty}(I_1+I_3)=0$.

Now we write $\|\|\Gamma-\Gamma_0\|\|_I=\|\Gamma-\Gamma_0\|_{L^1(I)}+I_4+I_5$, where

$$I_4=\sum_{\pm}\int_{\mathbf{R}^2}\int_I\sum_{|\sigma|=1}|\partial^\sigma\{\mu_\pm-\mu_\pm(\langle v\rangle\mp\beta(x),v_2)\}|\,dxdv,$$

$$I_5=\int_I\{|\partial_x(\Phi-\beta)|+|\partial_x\Psi|\}dx.$$

Now

$$I_5\le 2b\sup_I\{|\partial_x(\Phi-\beta)|+|\partial_x\Psi|\}\to 0,$$

provided a is chosen sufficiently near $-\infty$. This takes care of I_5. Now I_4 consists of several terms. The first one is estimated as

$$\begin{aligned}|\partial_{v_1}\{\mu_\pm-\mu_\pm(\langle v\rangle\mp\beta(x),v_2)\}|&\le|\partial_e\mu_\pm-(\partial_e\mu_\pm)(\langle v\rangle\mp\beta(x),v_2)|\\&\le C\langle v\rangle^{-\gamma}\langle v_2\rangle^{-\tilde\gamma}(|\Phi-\beta|+|\Psi|)\end{aligned}$$

in the same way as we treated Δ above. Similarly, by (11), the second term is

$$\begin{aligned}|\partial_{v_2}\{\mu_\pm-\mu_\pm(\langle v\rangle\mp\beta(x),v_2)\}|&\le\sup(|\partial_e^2\mu|+|\partial_e\partial_{v_2}\mu|+|\partial_{v_2}^2\mu|)(|\Phi-\beta|+|\Psi|)\\&\le C\langle v\rangle^{-\gamma}\langle v_2\rangle^{-\tilde\gamma}(|\Phi-\beta|+|\Psi|).\end{aligned}$$

The third term is

$$\begin{aligned}&|\partial_x\{\mu_\pm-\mu_\pm(\langle v\rangle\mp\beta(x),v_2)\}|\\&=|\mp\Phi'(x)\partial_e\mu_\pm\pm\Psi'(x)\partial_{v_2}\mu_\pm\pm\beta'(x)\partial_e\mu_\pm(\langle v\rangle\mp\beta(x),v_2)|\\&\le|\Phi'-\beta'|\sup|\partial_e\mu_\pm|+|\Psi'|\sup|\partial_{v_2}\mu_\pm|\\&+|\beta'||\Phi-\beta|\sup|\partial_e^2\mu_\pm|+|\beta'||\Psi'|\sup|\partial_e\partial_{v_2}\mu_\pm|\\&\le C\langle v\rangle^{-\gamma}\langle v_2\rangle^{-\tilde\gamma}\{|\Phi'-\beta'|+|\Psi'|+|\Phi-\beta|+|\Psi|\}.\end{aligned}$$

These terms are treated in the same way as (85) to obtain

$$I_4\le\int_I\{|\Phi'-\beta'|+|\Psi'|+|\Phi-\beta|+|\Psi|\}dx\to 0$$

provided $a\to-\infty$. This proves the lemma. □

Proof of the main theorem. We will break the x-axis into certain intervals. Let N be a positive integer and $\delta=\exp[-NP/C_1]$, where C_1 will be chosen later. We also choose a number a near $-\infty$ and define intervals

$$I=\{x:\ |x-a|\le(N+2)P\},\qquad J=\{x:\ |x-a|\le(N+1)P\},$$

and $K=\{x:\ |x-a|\le P/2\}$. In Theorem 3 on periodic equilibria, we constructed, for some $\epsilon_0>0$, a family of periodic initial data

$$u_P^\delta(0,x,v)=[f_{P+}^\delta,f_{P-}^\delta,E_{P1}^\delta,0,0]$$

with $f_{P\pm}^\delta\ge 0$, $E_2^\delta=0, B^\delta=0$. This family is defined for all sufficiently small $\delta>0$ and satisfies

$$\epsilon_0<\sup_{0\le t\le C_1|\ln\delta|}\|u_P^\delta(t)-\Gamma_0\|_{L^1[0,P]}\tag{86}$$

but

$$\|u_P^\delta(0) - \Gamma_0\|_{W^{1,1}[0,P]} < \delta. \tag{87}$$

We now define *nonperiodic* initial data for (84) as

$$u^\delta(0) = u_P^\delta(0) \qquad \text{for } x \in J, \qquad u^\delta(0) = \Gamma \qquad \text{for } x \notin I. \tag{88}$$

In the transition zones $L^\pm = \{(N+1)P < \pm(x-a) < (N+2)P\}$, we define the initial data $u^\delta(0) = [f_\pm^\delta(0), E_1^\delta(0), 0, B^\delta(0)]$ as follows. It is consistent with (88) to define $E_2^\delta(0,x) \equiv 0$. We define $B^\delta(0,x)$ as the linear interpolate between 0 and $\partial_x \Psi$. We define $\overline{f}_\pm^\delta(0,x,v)$ as the linear interpolate between $f_{\pm P}^\delta(0)$ and $\mu_\pm(\langle v\rangle \mp \Phi(x), v_2 \pm \Psi(x))$. By Theorem 3 and the decay of $\mu_\pm$ as in (11),

$$\begin{aligned} &\|\overline{f}_\pm^\delta(0,x,v) - \mu_\pm(\langle v\rangle \mp \beta(x), v_2)\|_{W^{1,1}(L)} + |B^\delta(0,x)|_{L^1(L)} \\ &\le C\delta + C\|\Gamma - \Gamma_0\|_L. \end{aligned} \tag{89}$$

We then define for $x \in L^+$

$$f_\pm^\delta(0,x,v) = \bar{f}_\pm^\delta(0,x,v) + \alpha_\pm Q(x,v),$$

where $0 \le Q \in C_c^\infty(L^+ \times \mathbf{R}^2)$ with $\int_{L^+}\int_{\mathbf{R}^2} Q = 1$. The constants $\alpha_\pm \ge 0$ are chosen so that

$$\int_{L^+}\int_{\mathbf{R}^2} [f_+^\delta(0) - f_-^\delta(0)]dvdx = \Phi'(a+(N+2)P) - E_{1P}^\delta(0, a+(N+1)P). \tag{90}$$

This requires

$$\alpha_+ - \alpha_- = -\int_{L^+}\int_{\mathbf{R}^2} \left[\overline{f}_+^\delta(0) - \overline{f}_-^\delta(0)\right] dvdx + \Phi'(a+(N+2)P) - E_{1P}^\delta(0, a+(N+1)P)$$

so that by (89)

$$\begin{aligned} |\alpha_+ - \alpha_-| \le{}& C\delta + C\|\Gamma - \Gamma_0\|_L + \left|\int_{L^+}\int_{\mathbf{R}^2} [\mu_+(\langle v\rangle - \beta, v_2) - \mu_-(\langle v\rangle + \beta, v_2)]dvdx\right| \\ &+ |\Phi'(b+P) - \beta'(b+P)| + |\beta'(b) - E_{1P}^\delta(0,b)|, \end{aligned}$$

where $b = a + (N+1)P$. The integral vanishes because of the periodicity of $\beta(x)$. By (87) and (7) we deduce

$$|\alpha_+ - \alpha_-| \le C\delta + C\|\Gamma - \Gamma_0\|_L. \tag{91}$$

Therefore from (89) and (91) we have

$$\|f_\pm^\delta(0) - \mu_\pm(\langle v\rangle \mp \beta, v_2)\|_{W^{1,1}(L^+)} \le C\delta + C\|\Gamma - \Gamma_0\|_L. \tag{92}$$

We then define $E_1^\delta(0,x)$ in L^+ as

$$E_1^\delta(0,x) = E_{1P}^\delta(0, a+(N+1)P) + \int_{a+(N+1)P}^x \int_{\mathbf{R}^2} (f_+^\delta(0,y,v) - f_-^\delta(0,y,v))dydv.$$

It follows that $E_1^\delta(0,x)$ is continuous at $a+(N+2)P$ and that $\partial_x E_1^\delta(0,x)=\rho^\delta(0,x)$ for $x\in L^+$. Furthermore,

$$E_1^\delta(0,x)-\partial_x\beta(x)=E_{1P}^\delta(0,b)-\partial_x\beta(b)$$
$$+\int_b^x\int_{\mathbf{R}^2}\left[f_+^\delta(0)-\mu_+(\langle v\rangle-\beta,v_2)-f_-^\delta(0)+\mu_-(\langle v\rangle+\beta,v_2)\right]dydv$$

so that by (87) we have

$$|E_1^\delta(0)-\partial_x\beta|_{L^1(L^+)}\le C\delta. \tag{93}$$

We define these functions on L^- by the same method. Therefore, by (89), (92), and (93),

$$\|u^\delta(0)-\Gamma_0\|_L\le C\delta+C\|\Gamma-\Gamma_0\|_L$$

where C is independent of N and δ.

Then we have

$$\|u^\delta(0)-\Gamma\|_{\mathbf{R}}=\|u^\delta(0)-\Gamma_0\|_J+\|u^\delta(0)-\Gamma_0\|_L+\|\Gamma-\Gamma_0\|_I.$$

By definition and by (87),

$$\|u^\delta(0)-\Gamma_0\|_J=\|u_P^\delta(0)-\Gamma_0\|_J<C(N+1)\delta\le C\delta|\ln\delta|.$$

From the three preceding inequalities and Lemma 16, it follows that for a sufficiently near $-\infty$,

$$\|u^\delta(0)-\Gamma\|_{\mathbf{R}}\le C\delta|\ln\delta|.$$

We claim that

$$\|u^\delta(0)-\Gamma\|_{W^{1,1}(\mathbf{R})}<C\delta|\ln\delta|. \tag{94}$$

Proof of the claim (94). It suffices to prove that

$$|\partial_x[E_1^\delta(0)-\partial_x\Phi]|_{L^1}+|\partial_x[E_2^\delta(0)]|_{L^1}+|\partial_x[B^\delta(0)-\partial_x\Psi]|_{L^1}<C\delta|\ln\delta|.$$

Now $E_2^\delta(0,x)\equiv 0$. Next, $\partial_x E_1^\delta(0)=\rho^\delta(0)$ so that

$$|\partial_x[E_1^\delta(0)-\partial_x\Phi]|_{L^1}=\int[f_+^\delta(0)-\mu_+-f_-^\delta(0)+\mu_-]dv,$$

where $\mu_\pm=\mu_\pm(\langle v\rangle\mp\Phi(x),v_2\pm\Psi(x))$. Hence

$$|\partial_x[E_1^\delta(0)-\partial_x\Phi]|_{L^1}\le\sum_\pm|f_\pm^\delta-\mu_\pm|_1<C\delta|\ln\delta|.$$

Finally, $\partial_x[B^\delta(0)-\partial_x\Psi]=-\partial_x^2\Psi$ in J, is equal to 0 outside I, and is equal to $\pm P^{-1}\partial_x\Psi(a\pm(N+1)P)$ in $L^\pm$. Then

$$|\partial_x[B^\delta(0)-\partial_x\Psi]|_{L^1}\le\int_J|\partial_x^2\Psi|dx+\sum_\pm|\partial_x\Psi(a\pm(N+1)P)|<C\delta|\ln\delta|$$

by choosing a sufficiently near $-\infty$. This proves (94).

We apply the existence theorem in the appendix to these initial data. By *causality* and because $NP = C_1|\ln\delta|$, we have on $K = [a - P/2, a + P/2]$ the inequality

$$\sup_{0\le t\le NP} \|u^\delta(t) - \Gamma_0\|_{L^1(K)} = \sup_{0\le t\le C_1|\ln\delta|} \|u_P^\delta(t) - \Gamma_0\|_{L^1(K)} > \epsilon_0$$

by (86). The instability of Γ follows, since

$$\sup_{0\le t\le C_1|\ln\delta|} \|u^\delta(t) - \Gamma\|_{L^1(K)} > \epsilon_0 - \|\Gamma - \Gamma_0\|_{L^1(K)} \ge \epsilon_0/2$$

by Lemma 16 for a sufficiently near $-\infty$. Now let $\delta' = \delta|\ln\delta|$. Then $|\ln\delta'| > \frac{1}{2}|\ln\delta|$ so that

$$\sup_{0\le t\le 2C_1|\ln\delta'|} \|u_P^\delta(t) - \Gamma_0\|_{L^1(K)} > \epsilon_0.$$

This proves Theorem 1 with δ replaced by δ' and C_1 replaced by $2C_1$. ∎

7. Appendix. In this appendix we present the well-posedness theorems required in the body of the paper. We begin with the full $1\frac{1}{2}$ RVM in (84) on the whole line.

THEOREM 4. *Let $f_\pm^0 \in BV(\Omega_x \times \mathbf{R}^2)$, $f_\pm^0 \ge 0$, $\langle v\rangle^l f_\pm^0 \in L^\infty(\Omega_x \times \mathbf{R}^2)$ for $l > 3$, E^0, $B^0 \in W^{1,\infty}(\Omega_x)$, for every bounded open set $\Omega_x \in \mathbf{R}$ and $\partial_x E_1^0 = \int(f_+^0 - f_-^0)dv$. Then there exists a unique solution $[f_+, f_-, E_1, E_2, B]$ to (84) with initial data $[f_+^0, f_-^0, E_1^0, E_2^0, B^0]$ such that, for any bounded open sets $\Omega_x \in \mathbf{R}$ and $\Omega_t \in \mathbf{R}$, $0 \le f_\pm \in L^\infty(\Omega_t; BV(\Omega_x \times \mathbf{R}^2))$, $\langle v\rangle^l f_\pm \in L^\infty(\Omega_t; L^\infty(\Omega_x \times \mathbf{R}^2))$, E and $B \in L^\infty(\Omega_t; W^{1,\infty}(\Omega_x))$.*

Remark. Greater regularity can be obtained with extra assumptions on the initial data.

Proof. By the method of [GSc], there is a unique global solution provided the initial data are smooth with compact support. So for existence we require only appropriate a priori bounds for *smooth* solutions. Notice that from the causality principle, we need only to estimate solutions locally in space. By the local energy identity over the dependent region of $[x - A, x + A]$, at time t, we have

$$\begin{aligned}
&\sum_\pm \int_{x-A}^{x+A}\int_{R^2} \langle v\rangle f_\pm(t,y,v)dvdy + \frac{1}{2}\int_{x-A}^{x+A}[|E(t,y)|^2 + B(t,y)^2]dy \\
&+ \sum_\pm \int_0^t \int_{R^2} (\langle v\rangle \mp v_1)[f_+ + f_-](\tau, x \mp A \mp [t-\tau], v)dvd\tau \qquad (95)\\
&\le \sum_\pm \int_{x-A-t}^{x+A+t}\int_{R^2} \langle v\rangle f_\pm(0,y,v)dydv + \frac{1}{2}\int_{x-A-t}^{x+A+t}[|E(0,y)|^2 + B(0,y)^2]dy.
\end{aligned}$$

It then follows that $f_\pm \in L^\infty(\Omega_t; L^1(\Omega_x \times \mathbf{R}^2))$ for every Ω_t and Ω_x, and $E, B \in L^\infty_{loc}(L^2_{loc})$. Moreover, $\rho \in L^\infty_{loc}(L^1_{loc})$ so that $E_1 \in L^\infty_{loc}(W^{1,1}_{loc})$ from $\partial_x E_1 = \rho$.

Next we employ the representation formulas for E_2 and B (equations (13) and (14) of [GSc]):

$$\begin{aligned}
E_2(t,x) =& \frac{1}{2}[E_2(0,x-t) + E_2(0,x+t) + B(0,x-t) - B(0,x+t)] \\
&- \int_0^t [j_2(\tau, x-t+\tau) + j_2(\tau, x+t-\tau)]d\tau, \qquad (96)
\end{aligned}$$

$$B(t,x) = \frac{1}{2}[E_2(0,x-t) - E_2(0,x+t) + B(0,x-t) + B(0,x+t)] \\ - \int_0^t [j_2(\tau, x-t+\tau) - j_2(\tau, x+t-\tau)]d\tau.$$

Since $\langle v\rangle \pm v_1 \geq |\hat{v}_2|$, it follows from (95) with $A = 0$ that

$$\left| \int_0^t j_2(\tau, x \mp (t-\tau))d\tau \right| \leq C \int_0^t \int_{\mathbf{R}^2} (\langle v\rangle \mp v_1)[f_+ + f_-](\tau, x \mp (t-\tau), v)dvd\tau$$

is bounded locally in x and t. Therefore (96) implies that $E_2(t,x)$ and $B(t,x)$ are pointwise bounded locally in x and t.

To obtain the weighted estimates for $f_\pm$, we multiply the Vlasov equations by $\langle v\rangle^l$ to get

$$\{\partial_t + \hat{v}_1\partial_x \pm (E + \hat{v}\times B)\cdot\nabla_v\}(\langle v\rangle^l f_\pm) = \pm l\langle v\rangle^{l-1}\hat{v}\cdot E f_\pm$$

where $E + \hat{v}\times B = [E_1 + \hat{v}_2 B, E_2 - \hat{v}_1 B, 0]$, $\nabla_v f_\pm = [\partial_{v_1} f_\pm, \partial_{v_2} f_\pm, 0]$, and we have used the fact that $\hat{v}\times B\cdot\nabla_v(\langle v\rangle^l) = 0$. By the standard L^∞ estimate for $\langle v\rangle^l f_\pm$ along the backward trajectory $\frac{dx}{dt} = \hat{v}_1$, $\frac{dv}{dt} = \pm[E + \hat{v}\times B]$, we have

$$\sup_{\mathbf{R}^2}\{\langle v\rangle^l f_\pm(t,x,v)\} \leq \sup_{[x-t,x+t]\times\mathbf{R}^2}\{\langle v\rangle^l f_\pm(0,y,v)\} \\ + l\int_0^t \sup_{[x-(t-\tau),x+(t-\tau)]\times\mathbf{R}^2}\{|E(\tau,y)|\langle v\rangle^l f_\pm(\tau,y,v)\}d\tau.$$

Since E is bounded on bounded sets, we obtain

$$\langle v\rangle^l f_\pm(t) \in L^\infty(\Omega_t\times\Omega_x\times\mathbf{R}^2)$$

for all Ω_t and Ω_x. Since $l > 2$, we deduce

$$|\rho(t,x)| = \left|\int_{\mathbf{R}^2}(f_+ - f_-)dv\right| \leq \sum_\pm \int \sup_{\mathbf{R}^2}\left\{\langle v\rangle^l |f_\pm(t,x,v)|\right\}\langle v\rangle^{-l}dv$$

is also bounded on bounded sets. Since $\partial_x E_1 = \rho$, it follows that $E_1 \in L^\infty_{loc}(W^{1,\infty}_{loc})$.

In order to estimate the derivatives of E_2 and B, it suffices by (96) to estimate $\partial_x\int_0^t j_2(\tau, x\mp t\pm\tau)d\tau$. To this end, we use the splitting method of Lemma 3 of [GSc]. Define $T_\pm = \partial_t \pm \partial_x$ and $S = \partial_t + \hat{v}_1\partial_x$. From Lemma 3 of [GSc], we obtain

$$\partial_x\int_0^t j_2(\tau, x-t+\tau)d\tau = \int_0^t\int \frac{\hat{v}_2}{1-\hat{v}_1}(T_+ - S)[(f_+ - f_-)(\tau, x-t+\tau, v)]dvd\tau \\ = I^+ + I^-.$$

Notice that $T_+ f_+(\tau, x-t+\tau, v) = \frac{d}{d\tau}f_+(\tau, x-t+\tau, v)$ and $Sf_+ = -\nabla_v\{(E+\hat{v}\times B)f_+\}$. By integrating along a side of the dependent triangle, we estimate I^+ as

$$I^+ = \int_0^t \frac{d}{d\tau}\int \frac{\hat{v}_2}{1-\hat{v}_1}f_+(\tau, x-t+\tau, v)dvd\tau \\ + \int_0^t\int \frac{\hat{v}_2}{1-\hat{v}_1}\nabla_v([E+\hat{v}\times B]f_+)(\tau, x-t+\tau, v)dvd\tau \\ = \int \frac{\hat{v}_2}{1-\hat{v}_1}f_+(t,x,v)dv - \int \frac{\hat{v}_2}{1-\hat{v}_1}f_+(0, x-t, v)dv \\ - \int_0^t\int \nabla_v\left(\frac{\hat{v}_2}{1-\hat{v}_1}\right)([E+\hat{v}\times B]f_+)(\tau, x-t+\tau, v)dvd\tau.$$

Since $|\frac{\hat{v}_2}{1-\hat{v}_1})| \le \langle v\rangle$, we get $|\frac{\hat{v}_2}{1-\hat{v}_1} f_+(t,x,v)| \le C\langle v\rangle^{-l+1}$ on bounded sets, thereby bounding the first term in I^+. Notice that

$$\partial_{v_1}\left(\frac{\hat{v}_2}{1-\hat{v}_1}\right) = \frac{v_2}{\langle v\rangle(\langle v\rangle - v_1)} = O(1)$$

and

$$\partial_{v_2}\left(\frac{\hat{v}_2}{1-\hat{v}_1}\right) = -\frac{1}{\langle v\rangle}\left[\frac{v_1}{\langle v\rangle - v_1} - \frac{1}{(\langle v\rangle - v_1)^2}\right] = O(\langle v\rangle)$$

since $\langle v\rangle - v_1 \ge \frac{1}{2\langle v\rangle}$. Since E and B are also bounded locally and $\langle v\rangle^l f_\pm$ is bounded locally in x and in t, it follows that the last term in I^+ is bounded by

$$C\int_0^t \int_{\mathbf{R}^2} \langle v\rangle^{1-l} dv d\tau < \infty$$

because $l > 3$. It follows that I^+ is locally bounded and therefore so are $|\partial_x E|$ and $|\partial_x B|$.

Finally, we take derivatives of the Vlasov equation with respect to x, v_1, and v_2 to obtain

$$\begin{aligned}
L_\pm \partial_x f_\pm &= \mp(\partial_x E + \hat{v}\times\partial_x B)\cdot\nabla_v f_\pm,\\
L_\pm \partial_{v_1} f_\pm &= -\frac{1+v_2^2}{\langle v\rangle^3}\partial_x f_\pm \mp \frac{\partial(\hat{v})}{\partial v_1}\times B\cdot\nabla_v f,\\
L_\pm \partial_{v_2} f_\pm &= -\frac{v_1 v_2}{\langle v\rangle^3}\partial_x f_\pm \mp \frac{\partial(\hat{v})}{\partial v_2}\times B\cdot\nabla_v f,
\end{aligned}$$

where $L_\pm = \partial_t + \hat{v}_1\partial_x \pm (E+\hat{v}\times B)\cdot\nabla_v$. Let us also denote $\|\partial f\|_{1,A} = \sum_\pm \int_{|x|\le A}\int(|\partial_x f_\pm| + |\nabla_v f_\pm|)dvdx$. Then these equations directly lead to the local L^1 estimate

$$\begin{aligned}
&\|\partial f(t)\|_{1,A} \le \|\partial f(0)\|_{1,A+t}\\
&+C\int_0^t (1 + |\partial_x E(\tau)|_{\infty,A+t-\tau} + |\partial_x B(\tau)|_{\infty,A+t-\tau})\,\|\partial f(\tau)\|_{1,A+t-\tau} d\tau.
\end{aligned}$$

Since E and B are locally bounded in $W^{1,\infty}$, Gronwall's inequality implies the boundedness of $\|\partial f(t)\|_{1,A}$ for bounded t and A. Upon passage to the limit we obtain $f_\pm \in L^\infty(\Omega_t; BV(\Omega_x\times\mathbf{R}^2))$ for any Ω_t and Ω_x.

The uniqueness proof is standard. □

For $1\frac{1}{4}$RVM with periodic boundary conditions, we have the following theorem.

THEOREM 5. *Let $f_\pm^0(x,v_1,v_2) = f_\pm^0(x,v_1,-v_2)$. Let $f_\pm^0 \in BV(\mathbf{R}_P\times\mathbf{R}^2)$, $f_\pm^0 \ge 0$, $\langle v\rangle^l f_\pm^0 \in L^\infty(\mathbf{R}_P\times\mathbf{R}^2)$ for some $l > 2$, $E_1^0 \in W^{1,\infty}(\mathbf{R}_P)$,*

$$\int_0^P\int_{\mathbf{R}^2}(f_+^0 - f_-^0)dvdx = 0, \qquad \partial_x E_1^0 = \int_{\mathbf{R}^2}(f_+^0 - f_-^0)dv.$$

Then there exists a unique solution, of period P in x, with initial data $[f_+^0, f_-^0, E_1^0]$ such that $f_\pm \in L^\infty_{loc}(\mathbf{R}; BV(\mathbf{R}_P\times\mathbf{R}^2))$, $\langle v\rangle^l f_\pm \in L^\infty_{loc}(\mathbf{R}; L^\infty(\mathbf{R}_P\times\mathbf{R}^2))$, and $E_1 \in L^\infty_{loc}(\mathbf{R}; W^{1,\infty}(\mathbf{R}_P))$.

Proof. If $l > 3$, let $u = [f_+, f_-, E_1, E_2, B]$ be the solution of $1\frac{1}{2}$RVM with the initial data $[f_+^0, f_-^0, E_1^0, 0, 0]$. Let $\check{f}_\pm(t,x,v_1,v_2) = f_\pm(t,x,v_1,-v_2)$. It is easy to verify

that $[\check{f}_+, \check{f}_-, E_1, -E_2, -B]$ is another solution of $1\frac{1}{2}$RVM with the same initial data. By uniqueness in Theorem 4, they are equal. Therefore f_+ and f_- are even functions of v_2, and $E_2 \equiv B \equiv 0$. Thus Theorem 5 is a special case of Theorem 4. On the other hand, if $2 < l \leq 3$, we can prove our theorem directly just as in Theorem 4 except that all the discussion of E_2 and B can be eliminated. □

ON THE ZERO RELAXATION LIMIT FOR A SYSTEM MODELING THE MOTIONS OF A VISCOELASTIC SOLID*

WEN SHEN†, ASLAK TVEITO†, AND RAGNAR WINTHER†

Abstract. We consider a simple model of the motions of a viscoelastic solid. The model consists of a two-by-two system of conservation laws including a strong relaxation term. We establish the existence of a BV-solution of this system for any positive value of the relaxation parameter. We also show that this solution is stable with respect to the perturbations of the initial data in L^1. By deriving the uniform bounds, with respect to the relaxation parameter, on the total variation of the solution, we obtain the convergence of the solutions of the relaxation system towards the solutions of a scalar conservation law as the relaxation parameter δ goes to zero. Due to the Lip^+ bound on the solutions of the relaxation system, an estimate on the rate of convergence towards equilibrium is derived. In particular, an $\mathcal{O}(\sqrt{\delta})$ bound on the L^1-error is established.

Key words. hyperbolic conservation laws, relaxation terms, nonequilibrium, convergence towards equilibrium, viscoelasticity, finite difference schemes

1. Introduction.

In this paper we study the following system of conservation laws:

$$u_t + \sigma_x = 0, \tag{1.1}$$
$$(\sigma - f(u))_t + \frac{1}{\delta}(\sigma - \mu f(u)) = 0,$$

where the parameters μ and δ satisfy $0 < \mu < 1$ and $0 < \delta \ll 1$. Here μ is a fixed parameter, while we are, in particular, interested in the limit as the relaxation parameter δ tends to zero.

If $\delta \to 0$, we formally obtain the equilibrium relation

$$\bar{\sigma} = \mu f(\bar{u}),$$

and hence the equilibrium model

$$\bar{u}_t + \mu f(\bar{u})_x = 0. \tag{1.2}$$

The purpose of this paper is to study the limit process rigorously. We will prove that under proper conditions on the initial data, the solutions of the nonequilibrium model converge to the solutions of the equilibrium model in L^1, uniformly in δ at a rate of $\mathcal{O}(\sqrt{\delta})$.

The system (1.1) arises in the modeling of motions of a viscoelastic solid, where the relaxation phenomenon presents the strength of memory. The Riemann problem for the system with $\delta = 1$ is studied by Greenberg and Hsiao [4]. The zero relaxation limit

of this viscoelasticity model with vanishing memory is analyzed in the fundamental paper of Chen and Liu [1], where nonlinear stability in the zero relaxation limit is established for the model. This is achieved by first deriving energy estimates from proper construction of entropy pairs, and then applying the theory of compensated compactness. More recent results can be found in the paper by Chen, Levermore, and Liu [2]. In this paper, we will establish similar results, but in the BV-framework. For any positive values of the relaxation parameter, we will prove the existence of a BV-solution of the system. The bound on the total variation of the solution, and a proper stability estimate with respect to perturbations of the initial data in L^1, are both independent of the relaxation parameter. Furthermore, a uniform Lip^+ bound, similar to Oleinik's entropy condition (cf. [12]), is obtained. By following the framework of Tadmor, Nessyahu, and Kurganov [15, 11, 6], this bound is used to establish an $\mathcal{O}(\sqrt{\delta})$ estimate for the L^1 difference between the solution of the relaxation system (1.1) and the solution of the equilibrium model (1.2).

Hyperbolic conservation laws with relaxation terms arise in modeling of many physical phenomena, such as chromatography, traffic modeling, water waves, and viscoelasticity (see, e.g., the book of Whitham [17]). General relaxation effect was analyzed by Liu [8], and the convergence was studied by Natalini [10]. For a system modeling chromatography, convergence and rate of convergence towards equilibrium are proved (cf., [13, 16] for the 1D case and [14] for the 2D case). Sharper estimates on the rate of convergence for this model have been recently derived by Kurganov and Tadmor [6]. The approach here resembles the techniques used in [6, 13, 16]. The same model problem is also studied independently by Yong [18] and Luo and Natalini [9]. However, these papers do not derive a rate for the convergence to equilibrium.

The structure of the paper is as follows. In section 2, we give the preliminaries for the model, and we also state the main results of the paper. Then the properties of the finite difference solutions are studied in section 3, where we establish the uniform bound, the TV bound, and the bound on the deviation from the equilibrium state. In section 4, we prove that the limit of the finite difference solution is the entropy solution of the system, and the stability in L^1 is then proved by Kruzkov-type arguments. Finally, the proof of the convergence of the solution of the nonequilibrium model towards the solution of the equilibrium model is given in section 5.

2. Preliminaries and statement of the main results. In this section, we will give the preliminaries of the paper and state the main result. Throughout this paper we will assume that the flux function $f = f(u)$ is a smooth function with the following properties:

$$f(0) = 0, \quad f'(u) > 0, \quad f''(u) \geq 0 \quad \text{for all } u \geq 0.$$

We introduce the variable $v = f(u) - \sigma$ such that $u = g(\sigma + v)$, where the function $g = f^{-1}$. Under the assumption that $u \geq 0$, we obtain a reformulation of the system (1.1):

$$\begin{aligned} g(\sigma + v)_t + \sigma_x &= 0, \\ v_t &= \frac{1}{\delta} R(\sigma, v), \end{aligned} \tag{2.1}$$

where $R(\sigma, v) = ((1 - \mu)\sigma - \mu v)$. The associated equilibrium model is

$$g\left(\frac{\bar{\sigma}}{\mu}\right)_t + \bar{\sigma}_x = 0. \tag{2.2}$$

We observe that the "reaction function" R has the monotonicity property

$$R(\sigma, v)(\operatorname{sgn}(\sigma) - \operatorname{sgn}(v)) \geq 0. \tag{2.3}$$

We seek solutions of (2.1) in the *state space*

$$\mathcal{S} = \{(\sigma, v) : 0 \leq \sigma \leq \mu \ , 0 \leq v \leq 1 - \mu\} \tag{2.4}$$

and solutions of (2.2) in $[0, \mu]$. For a scalar function $u(x)$, let $TV(u)$ denote the total variation defined as

$$TV(u) := \sup_{h \neq 0} \int_{\mathbb{R}} \frac{|u(x+h) - u(x)|}{h} \, dx,$$

and the L^1 norm is defined as

$$\|u\|_{L^1} := \int_{\mathbb{R}} |u(x)| \, dx.$$

Furthermore, we define

$$\operatorname{Lip}^+(u) := \max\left(0, \ \operatorname{ess} \sup_{x \neq y} \frac{u(x) - u(y)}{x - y}\right).$$

Let $p = R(\sigma, v)$ denote the residual. We assume the initial data (σ^0, v^0) satisfies the following requirements:

$$\begin{aligned}
&\text{i) } (\sigma^0(x), v^0(x)) \in \mathcal{S}, \quad \forall x \in \mathbb{R}, \\
&\text{ii) } TV(\sigma^0) + TV(v^0) \leq M, \\
&\text{iii) } \left\|p^0\right\|_{L^1} \leq M\delta, \\
&\text{iv) } \sigma^0(\pm\infty) = v^0(\pm\infty) = 0, \\
&\text{v) } \operatorname{Lip}^+(\sigma^0) \leq M, \ \ \operatorname{Lip}^+(v^0) \leq M.
\end{aligned} \tag{2.5}$$

Here, and throughout this paper, M denotes a generic positive finite constant independent of δ and the grid parameters $(\Delta x, \Delta t)$. Let $G = G(\sigma, v, k, q)$ be defined as

$$G(\sigma, v, k, q) = \frac{g(\sigma + v) - g(k + q)}{(\sigma + v) - (k + q)},$$

and for any $T > 0$, let $\mathcal{D}_+(T)$ be the set of all nonnegative $\mathcal{C}^\infty$-functions with compact support in $\mathbb{R} \times [0, T]$. Then the entropy solutions of (2.1) are defined as follows.

DEFINITION 2.1. *Let (σ^0, v^0) be the initial data of* (2.1) *which satisfies the assumptions in* (2.5). *Then a pair of functions (σ, v) is called the entropy solution of* (2.1) *with initial data (σ^0, v^0) if the following requirements are satisfied:*

i) $(\sigma, v) \in \mathcal{S}, \quad \forall (x, t) \in \mathbb{R} \times \mathbb{R}_0^+$,
ii) $TV(\sigma(\cdot, t)) + TV(v(\cdot, t)) \leq M, \quad \forall t \geq 0$,
iii) $\|\sigma(\cdot, t) - \sigma(\cdot, \tau)\|_{L^1} + \|v(\cdot, t) - v(\cdot, \tau)\|_{L^1} \leq M|t - \tau|, \quad \forall t, \tau \geq 0$,
iv) $Lip^+(\sigma(\cdot, t)) \leq M, \ Lip^+(v(\cdot, t)) \leq M, \quad \forall t \geq 0$,
v) *for any $(k, q) \in \mathcal{S}$ and any $\phi \in \mathcal{D}_+(T)$, the following inequality is valid for all $T > 0$:*

$$
\begin{aligned}
(2.6)\quad & \int_0^T \int_{\mathbb{R}} [G(\sigma,v,k,q)(|\sigma-k|+|v-q|)\phi_t + |\sigma-k|\phi_x]\,dx\,dt \\
& + \int_{\mathbb{R}} G(\sigma^0,v^0,k,q)(\left|\sigma^0-k\right|+\left|v^0-q\right|)\phi(x,0)\,dx \\
& - \int_{\mathbb{R}} G(\sigma(x,T),v(x,T),k,q)(|\sigma(x,T)-k|+|v(x,T)-q|)\ \phi(x,T)\,dx \\
& + M\int_0^T \int_{\mathbb{R}} [|v-q|-(v-q)sgn(\sigma-k)]\,\phi\,dx\,dt \\
& \geq \frac{1}{\delta}\int_0^T \int_{\mathbb{R}} G(\sigma,v,k,q)R(\sigma,v)[sgn(\sigma-k)-sgn(v-q)]\phi\,dx\,dt.
\end{aligned}
$$

Note that the entropy inequality in (2.6) is the weak formulation of an inequality of the form

$$\mathcal{E}_t + \mathcal{F}_x \leq -\frac{1}{\delta}\mathcal{G} + M\mathcal{H},$$

where

$$
\begin{aligned}
\mathcal{E} &= [G(\sigma,v,k,q)\big(|\sigma-k|+|v-q|\big)], \\
\mathcal{F} &= |\sigma-k|, \\
\mathcal{G} &= G(\sigma,v,k,q)R(\sigma,v)[\mathrm{sgn}(\sigma-k)-\mathrm{sgn}(v-q)], \\
\mathcal{H} &= |v-q|-(v-q)\mathrm{sgn}(\sigma-k).
\end{aligned}
$$

Remarks. In order to motivate the weak entropy formulation above, let us assume that (σ,v) and $(\bar\sigma,\bar v)$ are two smooth solutions of the system (2.1). The errors, $\sigma-\bar\sigma$ and $v-\bar v$, will then be governed by the system

$$
\begin{aligned}
[G\big((\sigma-\bar\sigma)+(v-\bar v)\big)]_t + (\sigma-\bar\sigma)_x &= 0, \\
(v-\bar v)_t &= \frac{1}{\delta}R,
\end{aligned}
$$

where $G = G(\sigma,v,\bar\sigma,\bar v)$ and $R = R(\sigma-\bar\sigma, v-\bar v)$. The system can also be rewritten as

$$
\begin{aligned}
G_t\,(\sigma-\bar\sigma) + G\,(\sigma-\bar\sigma)_t + (\sigma-\bar\sigma)_x &= -G_t\,(v-\bar v) - \frac{1}{\delta}GR, \\
G(v-\bar v)_t + G_t\,(v-\bar v) &= G_t\,(v-\bar v) + \frac{1}{\delta}GR.
\end{aligned}
$$

By multiplying the first equation above by $\mathrm{sgn}(\sigma-\bar\sigma)$ and the second one by $\mathrm{sgn}(v-\bar v)$, and summing, we obtain

$$
\begin{aligned}
(2.7)\quad & [G(|\sigma-\bar\sigma|+|v-\bar v|)]_t + (|\sigma-\bar\sigma|)_x \\
& = G_t[|v-\bar v|-(v-\bar v)\mathrm{sgn}(\sigma-\bar\sigma)] - \frac{1}{\delta}GR(\mathrm{sgn}(\sigma-\bar\sigma)-\mathrm{sgn}(v-\bar v)).
\end{aligned}
$$

If the function $G = G(x,t)$ satisfies a one-sided Lipschitz condition of the form

$$G_t(x,t) \leq M, \tag{2.8}$$

then clearly (2.7) implies that

$$[G(|\sigma-\bar\sigma|+|v-\bar v|)]_t+(|\sigma-\bar\sigma|)_x \le M\,[|v-\bar v|-(v-\bar v)\mathrm{sgn}(\sigma-\bar\sigma)]-\frac{1}{\delta}GR(\mathrm{sgn}\ (\sigma-\bar\sigma)-\mathrm{sgn}(v-\bar v)). \tag{2.9}$$

The weak entropy formulation above is motivated from this differential inequality. We also note that since $G\ge 0$, it follows from (2.3) and (2.9) that

$$[G(|\sigma-\bar\sigma|+|v-\bar v|)]_t+(|\sigma-\bar\sigma|)_x \le 2M|v-\bar v|.$$

This formal inequality indicates the continuous dependence result which will be established rigorously in this paper.

The motivation for the entropy formulation above relies on the one-sided bound (2.8). Since

$$G(\sigma,v,\bar\sigma,\bar v)=\int_0^1 g'(\theta(\sigma+v)+(1-\theta)(\bar\sigma+\bar v))\,d\theta,$$

and

$$(g'(\sigma+v))_t=-\frac{g''(\sigma+v)}{g'(\sigma+v)}\sigma_x\le M\sigma_x,$$

the bound (2.8) will follow from an estimate of the form

$$\mathrm{Lip}^+(\sigma(\cdot,t)),\mathrm{Lip}^+(\bar\sigma(\cdot,t))\le M.$$

As we shall see below, this property for solutions of the system (2.1) will essentially follow from the corresponding assumption (2.5v) on the initial data. This ends our discussion on the motivation for the weak entropy formulation.

For the scalar equilibrium equation, the entropy solutions are defined in the sense of Kruzkov [5]. For a given $T>0$, the entropy solutions satisfy the following inequality for any $k\in\mathcal{S}$ and any $\phi\in\mathcal{D}_+(T)$,

$$\int_0^T\int_{\mathbb{R}}\left(\left|g\left(\frac{\bar\sigma}{\mu}\right)-g\left(\frac{k}{\mu}\right)\right|\phi_t+|\sigma-k|\phi_x\right)\,dx\,dt + \int_{\mathbb{R}}\left[\left|g\left(\frac{\bar\sigma^0}{\mu}\right)-g\left(\frac{k}{\mu}\right)\right|\phi(x,0)-\left|g\left(\frac{\bar\sigma(x,T)}{\mu}\right)-g\left(\frac{k}{\mu}\right)\right|\phi(x,T)\right]\,dx\ge 0.$$

Our main tool in analyzing the system will be a finite difference scheme derived from the formulation (2.1). Let Δt and Δx denote the steplengths in the t and x directions, respectively. We consider a semi-implicit difference scheme of the form

$$\frac{g\left(\sigma_j^{n+1}+v_j^{n+1}\right)-g\left(\sigma_j^n+v_j^n\right)}{\Delta t}+\frac{\sigma_j^n-\sigma_{j-1}^n}{\Delta x}=0, \qquad \frac{v_j^{n+1}-v_j^n}{\Delta t}=\frac{1}{\delta}R\left(\sigma_j^{n+1},v_j^{n+1}\right). \tag{2.10}$$

Here σ_j^n and v_j^n denote approximations of $\sigma(x,t)$ and $v(x,t)$ over the gridblocks

$$B_j^n=[x_{j-1/2},x_{j+1/2})\times[t_n,t_{n+1}),$$

where $x_j = j\Delta x$ and $t_n = n\Delta t$. Let $u_m = g(1) > 0$, and let

$$M_f = \max_{u\in[0,u_m]} f'(u) = \left(\min_{\theta\in[0,1]} g'(\theta)\right)^{-1}.$$

Throughout the paper we shall assume that the CFL-condition

$$\lambda M_f \le 1 \tag{2.11}$$

is satisfied, where $\lambda \equiv \Delta t/\Delta x$ is the mesh ratio which we assume to be a constant. The discrete initial data is taken to be the cell averages

$$\sigma_i^0 := \frac{1}{\Delta x}\int_{x_{i-1/2}}^{x_{i+1/2}} \sigma^0(x)\,dx, \qquad v_i^0 := \frac{1}{\Delta x}\int_{x_{i-1/2}}^{x_{i+1/2}} v^0(x)\,dx.$$

The total variation of a grid function u_i is defined as

$$TV(u) := \sum_i |u_i - u_{i-1}|,$$

and the discrete L^1-norm is

$$\|u\|_{L^1} := \Delta x \sum_i |u_i|.$$

We assume that the following requirements are satisfied:

$$\begin{aligned}
&\text{i) } (\sigma_i^0, v_i^0) \in \mathcal{S}, \quad \forall j,\\
&\text{ii) } TV(\sigma^0) + TV(v^0) \le M,\\
&\text{iii) } \left\|p^0\right\|_{L^1} \le M\delta,\\
&\text{iv) } \sigma_{\pm\infty}^0 = v_{\pm\infty}^0 = 0,\\
&\text{v) } \sup_j(\sigma_j^0 - \sigma_{j-1}^0) \le M\Delta t,\ \sup_j(v_j^0 - v_{j-1}^0) \le M\Delta t, \quad \forall j.
\end{aligned} \tag{2.12}$$

Note that the requirement (v) follows directly from the assumption in (2.5v).

The existence of an entropy solution of the Cauchy problem can be obtained based on the properties of the finite different solutions of the scheme (2.10). Furthermore, the well-posedness of the initial value problem, independent of δ, is also proved.

THEOREM 2.2. *Let (σ^0, v^0) be the initial data of* (2.1) *satisfying the conditions* (2.5)*, and let (σ_i^0, v_i^0) be the discrete initial data for scheme* (2.10)*. Let $(\sigma_\Delta, v_\Delta)$ be the piecewise constant representation of the grid data (σ_i^n, v_i^n) generated by scheme* (2.10)*. Then the family $\{(\sigma_\Delta, v_\Delta)\}$ of approximate solutions converge in $(L^1_{loc}(\mathbb{R}\times\mathbb{R}_0^+))^2$ towards a pair of functions (σ, v) as the grid parameters $(\Delta x, \Delta t)$ tend to zero. The limit is the unique entropy solution which satisfies the requirements in Definition* 2.1*, and the following bounds are valid:*

$$\begin{aligned}
&\|p(\cdot,t)\|_{L^1} \le M\delta,\\
&Lip^+(\sigma(\cdot,t)) \le M, \quad Lip^+(v(\cdot,t)) \le M.
\end{aligned}$$

Moreover, the solution is stable with respect to perturbations in initial data in the following sense: Let $(\bar\sigma, \bar v)$ be another entropy solution of (2.1) *with initial data $(\bar\sigma^0, \bar v^0)$. Then the following bound holds for all $t > 0$:*

$$\|\sigma(\cdot,t) - \bar\sigma(\cdot,t)\|_{L^1} + \|v(\cdot,t) - \bar v(\cdot,t)\|_{L^1} \le \bar M e^{Mt}\left[\left\|\sigma^0 - \bar\sigma^0\right\|_{L^1} + \left\|v^0 - \bar v^0\right\|_{L^1}\right],$$

where $\bar{M}$ and M are finite constants independent of δ.

This theorem eventually leads to the main result of this paper, i.e., the convergence of the solutions of the nonequilibrium system towards the solutions of the equilibrium equation as δ tends to zero, and an estimate of the rate of convergence. The error estimates are derived by following the framework of Tadmor, Nessyahu, and Kurganov [15, 11, 6]. Hence, we estimate the Lip$'$-norm of the error. For any function $\phi \in L^1$ with $\int \phi = 0$, we define

$$\|\phi\|_{\mathrm{Lip}'} := \sup_{\psi} \frac{\int_{\mathbb{R}} \phi\psi dx}{\|\psi\|_{W^{1,\infty}}}.$$

Here the supremum is taken over all smooth functions ψ with compact support and

$$\|\psi\|_{W^{1,\infty}} := \max\left(\|\psi\|_{L^\infty}, ||\psi||_{Lip}\right).$$

The following convergence result will be proved in section 5.

THEOREM 2.3. *Let (σ^0, v^0) and $\bar{\sigma}^0$ be the initial data for* (2.1) *and* (2.2)*, respectively. We assume that the initial data (σ^0, v^0) for the nonequilibrium system satisfies the requirements in* (2.5) *and that $\bar{\sigma}^0 = \sigma^0$. Let $(\sigma_\delta, v_\delta)$ be the entropy solution of* (2.1) *with initial data (σ^0, v^0) and $\bar{\sigma}$ the corresponding entropy solution of* (2.2)*. For each $T > 0$ there is a constant M, independent of δ, such that*

$$\|u_\delta(\cdot, t) - \bar{u}(\cdot, t)\|_{Lip'} \le M\delta, \quad 0 \le t \le T,$$

where $u_\delta = g(\sigma_\delta + v_\delta)$ and $\bar{u} = g(\frac{\bar{\sigma}}{\mu})$.

We note that the variables $(u_\delta, \sigma_\delta)$ and $(\bar{u}, \bar{\sigma})$ in the theorem above correspond to the solutions of the original models (1.1) and (1.2). The following corollary is a consequence of Theorem 2.3.

COROLLARY 2.4. *Let $(u_\delta, \sigma_\delta)$ and $(\bar{u}, \bar{\sigma})$ be as stated in Theorem* 2.3*. For each $T > 0$ there is a constant M, independent of δ, such that for any $p \in [1, \infty)$*

$$\|u_\delta(\cdot, t) - \bar{u}(\cdot, t)\|_{L^p} \le M\delta^{\frac{1}{2p}}, \quad 0 \le t \le T.$$

Furthermore,

$$\|\sigma_\delta(\cdot, t) - \bar{\sigma}(\cdot, t)\|_{L^1} \le M\sqrt{\delta}, \quad 0 \le t \le T.$$

3. Existence of a weak solution. The purpose of this section is to use the finite difference scheme (2.10) to establish the existence of weak solutions of Cauchy problem for (2.1) (or (1.1)). We first show that the finite difference solution is well defined.

LEMMA 3.1. *Assume that $\{\sigma_j^0\}$ and $\{v_j^0\}$ for $j \in \mathcal{Z}$ are given. Then the solutions $\{\sigma_j^n\}$ and $\{v_j^n\}$ are uniquely determined by* (2.10) *for all $j \in \mathcal{Z}$ and $n \ge 0$.*

Proof. Assume that $\{\sigma_j^n\}$ and $\{v_j^n\}$ are computed. Let

$$r_j^n = g\left(\sigma_j^n + v_j^n\right) - \lambda\left(\sigma_j^n - \sigma_{j-1}^n\right).$$

The solutions $\{\sigma_j^{n+1}\}$ and $\{v_j^{n+1}\}$ then satisfy the linear system

$$A\begin{pmatrix} \sigma_j^{n+1} \\ v_j^{n+1} \end{pmatrix} = \begin{pmatrix} f\left(r_j^n\right) \\ v_j^n \end{pmatrix},$$

where the 2×2 matrix A is given by

$$A = \begin{pmatrix} 1 & 1 \\ -(1-\mu)\frac{\Delta t}{\delta} & 1+\mu\frac{\Delta t}{\delta} \end{pmatrix}.$$

Since $\det(\mathrm{A}) = 1 + \frac{\Delta t}{\delta} > 0$, the results follows by induction. ∎

The following results show that the state space $\mathcal{S}$ defined in (2.4), is an invariant region for the scheme (2.10).

LEMMA 3.2. *Assume $(\sigma_j^0, v_j^0) \in \mathcal{S}$ for all $j \in \mathcal{Z}$. Then $(\sigma_j^n, v_j^n) \in \mathcal{S}$ for all $j \in \mathcal{Z}$ and $n \geq 0$.*

Proof. For given $\bar{\sigma}, \sigma_L$ and $\bar{v}$, let (σ, v) be the unique solution of the system

$$\begin{aligned} g(\sigma + v) &= g(\bar{\sigma} + \bar{v}) - \lambda\left(\bar{\sigma} - \sigma_L\right), \\ \left(1 + \frac{\Delta t}{\delta}\mu\right) v - \frac{\Delta t}{\delta}(1-\mu)\sigma &= \bar{v}. \end{aligned} \tag{3.1}$$

This system defines functions $\sigma = \sigma(\bar{\sigma}, \sigma_L, \bar{v})$ and $v = v(\bar{\sigma}, \sigma_L, \bar{v})$. Furthermore, $\sigma_j^{n+1} = \sigma(\sigma_j^n, \sigma_{j-1}^n, v_j^n)$ and $v_j^{n+1} = v(\sigma_j^n, \sigma_{j-1}^n, v_j^n)$. Hence, the lemma can be established by studying the functions σ and v.

Assume that $(\bar{\sigma}, \bar{v}) \in \mathcal{S}$ and $\sigma_L \in [0, \mu]$. By differentiating the system (3.1) with respect to $\bar{\sigma}$ and by using the CFL-condition (2.11), we obtain

$$\begin{aligned} g'(\sigma + v)\left(\frac{\partial \sigma}{\partial \bar{\sigma}} + \frac{\partial v}{\partial \bar{\sigma}}\right) &= g'(\bar{\sigma} + \bar{v}) - \lambda > 0, \\ \left(1 + \frac{\Delta t \mu}{\delta}\right)\frac{\partial v}{\partial \bar{\sigma}} &= \frac{\Delta t}{\delta}(1-\mu)\frac{\partial \sigma}{\partial \bar{\sigma}}. \end{aligned}$$

From this we easily conclude that $\frac{\partial \sigma}{\partial \bar{\sigma}}, \frac{\partial v}{\partial \bar{\sigma}} > 0$, and by a similar calculation we also obtain $\frac{\partial \sigma}{\partial \sigma_L}, \frac{\partial v}{\partial \sigma_L} > 0$.

Assume now that $\sigma_L = \bar{\sigma}$. Then we obtain from (3.1) that

$$\sigma + v = \bar{\sigma} + \bar{v},$$

and hence

$$\frac{\partial \sigma}{\partial \bar{v}} + \frac{\partial v}{\partial \bar{v}} = 1.$$

Furthermore, from the second equation of (3.1) we have

$$\frac{\Delta t}{\delta}\mu\frac{\partial v}{\partial \bar{v}} = \left(1 + \frac{\Delta t}{\delta}(1-\mu)\right)\frac{\partial \sigma}{\partial \bar{v}},$$

and hence we can conclude that

$$\frac{\partial \sigma}{\partial \bar{v}}(\bar{\sigma}, \bar{\sigma}, \bar{v}) > 0, \quad \frac{\partial v}{\partial \bar{v}}(\bar{\sigma}, \bar{\sigma}, \bar{v}) > 0.$$

From the monotonicity properties derived above we now have for $(\bar{\sigma}, \bar{v}) \in \mathcal{S}$ and $\sigma_L \in [0, \mu]$

$$\sigma(\bar{\sigma}, \sigma_L, \bar{v}) \geq \sigma(0, 0, \bar{v}) \geq \sigma(0, 0, 0) = 0$$

and

$$\sigma(\bar{\sigma}, \sigma_L, \bar{v}) \leq \sigma(\mu, \mu, \bar{v}) \leq \sigma(\mu, \mu, 1-\mu) = \mu.$$

Similarly, we obtain

$$0 \leq v(\bar{\sigma}, \sigma_L, \bar{v}) \leq 1-\mu,$$

and the invariance of $\mathcal{S}$ follows by induction. □

We let p_j^n denote the residual, i.e., $p_j^n = (1-\mu)\sigma_j^n - \mu v_j^n$.

LEMMA 3.3. *Assume that* $\|p^0\|_1$, $TV(\sigma^0)$ *and* $TV(v^0)$ *are finite. Then*

$$TV(\sigma^n) + TV(v^n) \leq TV(\sigma^0) + TV(v^0) \ . \tag{3.2}$$

Furthermore, there is a constant M_1*, depending only on* μ*,* g*,* $TV(\sigma^0)$*, and* $TV(v^0)$ *such that*

$$\frac{\|p^n\|_1}{\delta} \leq \max\left(M_1, \frac{\|p^0\|_1}{\delta}\right).$$

Proof. We first establish the total variation estimate. Let

$$a_j^n = \frac{\left(\sigma_j^{n+1} + v_j^{n+1}\right) - \left(\sigma_j^n + v_j^n\right)}{g\left(\sigma_j^{n+1} + v_j^{n+1}\right) - g\left(\sigma_j^n + v_j^n\right)}.$$

It follows from the monotonicity of g and the CFL-condition (2.11) that

$$0 \leq \lambda a_j^n \leq 1.$$

Furthermore, the difference scheme (2.10) can be written in the form

$$\begin{aligned} \sigma_j^{n+1} &= \sigma_j^n - \lambda a_j^n \left(\sigma_j^n - \sigma_{j-1}^n\right) - \frac{\Delta t}{\delta} R\left(\sigma_j^{n+1}, v_j^{n+1}\right), \\ v_j^{n+1} &= v_j^n + \frac{\Delta t}{\delta} R\left(\sigma_j^{n+1}, v_j^{n+1}\right). \end{aligned} \tag{3.3}$$

Hence, if we let

$$\alpha_j^n = \sigma_{j+1}^n - \sigma_j^n, \quad \beta_j^n = v_{j+1}^n - v_j^n,$$

we obtain

$$\begin{aligned} \alpha_j^{n+1} &= \alpha_j^n - \lambda a_{j+1}^n \alpha_j^n + \lambda a_j^n \alpha_{j-1}^n - \frac{\Delta t}{\delta} R\left(\alpha_j^{n+1}, \beta_j^{n+1}\right), \\ \beta_j^{n+1} &= \beta_j^n + \frac{\Delta t}{\delta} R\left(\alpha_j^{n+1}, \beta_j^{n+1}\right). \end{aligned} \tag{3.4}$$

By multiplying the first equation in (3.4) by sgn (α_j^{n+1}), the second equation by sgn (β_j^{n+1}), using the monotonicity property (2.3), and by summation with respect to j, we obtain

$$\sum_j \left(\left|\alpha_j^{n+1}\right| + \left|\beta_j^{n+1}\right|\right) \leq \sum_j \left(\left|\alpha_j^n\right| + \left|\beta_j^n\right|\right),$$

and this is exactly the total variation bound.

From (3.3) it also follows that

$$p_j^{n+1} = p_j^n - (1-\mu)\lambda a_j^n \left(\sigma_j^n - \sigma_{j-1}^n\right) - \frac{\Delta t}{\delta} p_j^{n+1}.$$

Therefore, it follows from the total variation estimate above that

$$\|p^{n+1}\|_1 \leq \|p^n\|_1 + M_1 \Delta t - \frac{\Delta t}{\delta}\|p^{n+1}\|_1,$$

and this implies that

$$\frac{\|p^{n+1}\|_1}{\delta} \leq \max\left(M_1, \frac{\|p^n\|_1}{\delta}\right).$$

This completes the proof of Lemma 3.3. ∎

We recall that the initial data satisfies

$$\|p^0\|_1 \leq M\delta,$$

where M is independent of δ and the grid parameters Δt and Δx. Hence, by induction, we have

$$\|p^n\|_1 \leq M\delta \quad \text{for all} \quad n \geq 0. \tag{3.5}$$

From the total variation estimate (3.2) and (3.5), we now obtain

$$\|\sigma^{n+1} - \sigma^n\|_1 + \|v^{n+1} - v^n\|_1 \leq M\Delta t,$$

and hence we obtain L^1-Lipschitz continuity with respect to time, i.e.,

$$\|\sigma^n - \sigma^m\|_1 + \|v^n - v^m\|_1 \leq M|n-m|\Delta t,$$

where M is independent of δ and the grid parameters.

4. Entropy solutions and stability in L^1. The purpose of this section is to derive bounds for $\mathrm{Lip}^+(\sigma)$ and $\mathrm{Lip}^+(v)$, which can be used to obtain stability results with respect to perturbations of the initial data which are independent of the relaxation parameter δ. The extra regularity results will technically be derived for the finite difference solutions (σ_j^n, v_j^n).

Define coefficients b_j^n by

$$b_j^n = \frac{a_{j+1}^n - a_j^n}{\alpha_j^{n+1} + \beta_j^{n+1} + \alpha_j^n + \beta_j^n},$$

where as above $\alpha_j^n = \sigma_{j+1}^n - \sigma_j^n$ and $\beta_j^n = v_{j+1}^n - v_j^n$. Observe that if we let $u_j^n = g(\sigma_j^n + v_j^n)$, then

$$a_j^n = \int_0^1 f'\left(u_j^n + \theta\left(u_j^{n+1} - u_j^n\right)\right)\, d\theta.$$

Hence, it follows from the monotonicity of f' and f that there is a positive constant M_b such that

$$0 < b_j^n \leq M_b.$$

We claim that for sufficiently small Δt and δ, the initial data (σ_j^0, v_j^0) of (2.10) satisfies the following one-side bound:

$$\sup_j \left\{(1-\mu)\alpha_j^0\ , \mu\beta_j^0\right\} \le (1-\mu)\mu^2 \frac{\Delta t}{2\delta + \mu\Delta t}. \tag{4.1}$$

Indeed, since $\alpha_j^0 \le \mu$ and $\beta_j^0 \le 1-\mu$ for all j, then by (2.12v), there exists a finite constant M^* and a sufficiently small Δt^* satisfying the relation $M^* \cdot \Delta t^* \le 1$ such that

$$\sup_j \left\{\alpha_j^0\right\} \le M^*\Delta t\mu, \quad \sup_j \left\{\beta_j^0\right\} \le M^*\Delta t(1-\mu),$$

for all $\Delta t \le \Delta t^*$. Then it follows that

$$\sup_j \left\{(1-\mu)\alpha_j^0, \mu\beta_j^0\right\} \le (1-\mu)\mu M^*\Delta t,$$

for all $\Delta t \le \Delta t^*$. By choosing δ sufficiently small, i.e.,

$$\delta \le \frac{\mu(1-M^*\Delta t)}{2M^*},$$

the relation (4.1) follows.

In order to derive the proper results for the solution of the finite difference scheme, we will need a strengthened CFL-condition. We will assume throughout this section that

$$\lambda\left(M_f + (2+\mu)M_b\right) \le 1. \tag{4.2}$$

LEMMA 4.1. *Assume that the initial data* (σ_j^0, v_j^0) *of* (2.10) *satisfies* (4.1) *for sufficiently small* δ *and* Δt. *Then*

$$\sup_j \left\{(1-\mu)\alpha_j^n, \mu\beta_j^n, 0\right\} \le \sup_j \left\{(1-\mu)\alpha_j^0, \mu\beta_j^0, 0\right\}.$$

Proof. Define function $\alpha = \alpha(\bar\alpha, \bar\beta, \alpha_L)$ and $\beta = \beta(\bar\alpha, \bar\beta, \alpha_L)$ implicitly by

$$\begin{aligned} \alpha &= \bar\alpha - \lambda a\left(\bar\alpha - \alpha_L\right) - \lambda b\left(\alpha + \beta + \bar\alpha + \bar\beta\right)\bar\alpha - \frac{\Delta t}{\delta}((1-\mu)\alpha - \mu\beta), \\ \beta &= \bar\beta + \frac{\Delta t}{\delta}((1-\mu)\alpha - \mu\beta). \end{aligned} \tag{4.3}$$

Here a and b are positive constants, bounded by M_f and M_b, respectively.

Recall that it follows from (3.4) that if $a = a_j^n$ and $b = b_j^n$, then $\alpha_j^{n+1} = \alpha(\alpha_j^n, \beta_j^n, \alpha_{j-1}^n)$ and $\beta_j^{n+1} = \beta(\alpha_j^n, \beta_j^n\ , \alpha_{j-1}^n)$. Recall also that Lemma 3.2 implies that $|\alpha_j^n| \le \mu$ and $|\beta_j^n| \le 1-\mu$.

We will first show that, under the assumptions that $|\bar\alpha|, |\alpha_L| \le \mu$, $|\bar\beta| \le 1-\mu$ and

$$\bar\alpha \le \mu^2 \frac{\Delta t}{2\delta + \mu\Delta t}, \tag{4.4}$$

the functions α and β are monotonically increasing in all three arguments. Observe that the second equation of (4.3) implies that

$$\beta = \frac{\delta}{\delta + \mu\Delta t}\bar\beta + \frac{(1-\mu)\Delta t}{\delta + \mu\Delta t}\alpha. \tag{4.5}$$

Hence we can eliminate β from the first equation. We obtain the equation

$$c\alpha = r, \tag{4.6}$$

where

$$c = c(\bar{\alpha}) = 1 + \lambda b \frac{\delta + \Delta t}{\delta + \mu \Delta t}\bar{\alpha} + \frac{(1-\mu)\Delta t}{\delta + \mu \Delta t} = (1 + \lambda b \bar{\alpha}) \frac{\delta + \Delta t}{\delta + \Delta t \mu}$$

and

$$r = r(\bar{\alpha}\ , \bar{\beta}\ , \alpha_L) = (1 - \lambda a)\bar{\alpha} + \lambda a \alpha_L - \lambda b \bar{\alpha}^2 - \lambda b \frac{2\delta + \mu \Delta t}{\delta + \mu \Delta t}\bar{\alpha}\bar{\beta} + \frac{\mu \Delta t}{\delta + \mu \Delta t}\bar{\beta}.$$

Note that since $\bar{\alpha} \geq -\mu$, it follows that

$$c \geq c(-\mu) \geq \frac{\delta + \Delta t}{\delta + \mu \Delta t}\left(1 - \mu \lambda M_b\right),$$

and hence (4.2) implies that $c > 0$. Observe that

$$\frac{\partial r}{\partial \alpha_L} = \lambda a > 0,$$

which implies that $\frac{\partial \alpha}{\partial \alpha_L} > 0$.

Similarly, by (4.2) and (4.4), we get

$$\frac{\partial r}{\partial \bar{\beta}} = \frac{\mu \Delta t - \lambda b(2\delta + \mu \Delta t)\bar{\alpha}}{\delta + \mu \Delta t} \geq \frac{\mu \Delta t}{\delta + \mu \Delta t}(1 - \lambda b \mu) \geq 0,$$

which implies that

$$\frac{\partial \alpha}{\partial \bar{\beta}} \geq 0.$$

Finally, we observe that

$$\begin{aligned} c\frac{\partial \alpha}{\partial \bar{\alpha}} &= \frac{\partial r}{\partial \bar{\alpha}} - \alpha \frac{dc}{d\bar{\alpha}} \\ &= (1 - \lambda a) - 2\lambda b \bar{\alpha} - \lambda b \frac{2\delta + \mu \Delta t}{\delta + \mu \Delta t}\bar{\beta} - \lambda b \frac{\delta + \Delta t}{\delta + \mu \Delta t}\alpha \\ &\geq (1 - \lambda a) - 2\lambda b \mu - \lambda b \frac{2\delta + \mu \Delta t}{\delta + \mu \Delta t}(1 - \mu) - \lambda b \frac{\delta + \Delta t}{\delta + \mu \Delta t}\mu. \end{aligned}$$

This implies that

$$c\frac{\partial \alpha}{\partial \bar{\alpha}} \geq 1 - \lambda(a + b(2 + \mu)).$$

Hence, it follows from (4.2) that

$$\frac{\partial \alpha}{\partial \bar{\alpha}} \geq 0.$$

We have therefore established that the function α is an increasing function in all three of its arguments. Furthermore, from (4.5) we easily derive that β has the corresponding property. We now use induction to complete the proof. Assume that

$$z^n \equiv \sup_j \left\{(1 - \mu)\alpha_j^n\ , \mu \beta_j^n\ , 0\right\} \leq z^0.$$

In particular, this implies that (cf. (4.4))

$$\alpha_j^n \le \mu^2 \frac{\Delta t}{2\delta + \mu\Delta t}.$$

Hence, the monotonicity property of α implies that

$$\alpha_j^{n+1} \le \alpha\left(\frac{z^n}{1-\mu}, \frac{z^n}{\mu}, \frac{z^n}{1-\mu}\right).$$

Furthermore, since $z^n \ge 0$,

$$c\left(\frac{z^n}{1-\mu}\right) \ge \frac{\delta + \Delta t}{\delta + \mu\Delta t}$$

and

$$r\left(\frac{z^n}{1-\mu}, \frac{z^n}{\mu}, \frac{z^n}{1-\mu}\right) \le \frac{z^n}{1-\mu} + \frac{\Delta t\, z^n}{\delta + \mu\Delta t} = \frac{z^n}{1-\mu}\left(\frac{\delta + \Delta t}{\delta + \mu\Delta t}\right).$$

We therefore obtain from (4.6) that

$$\alpha_j^{n+1} = \frac{r\left(\frac{z^n}{1-\mu}, \frac{z^n}{\mu}, \frac{z^n}{1-\mu}\right)}{c\left(\frac{z^n}{1-\mu}\right)} \le \frac{z^n}{1-\mu}.$$

Finally, from (4.5), we derive

$$\beta_j^{n+1} \le \beta\left(\frac{z^n}{1-\mu}, \frac{z^n}{\mu}, \frac{z^n}{1-\mu}\right) \le \frac{\delta}{\delta + \mu\Delta t}\frac{z^n}{\mu} + \frac{(1-\mu)\Delta t}{\delta + \mu\Delta t}\frac{z^n}{1-\mu} = \frac{z^n}{\mu}.$$

Hence, we conclude that $z^{n+1} \le z^n$. □

Next we will show that the finite difference solution satisfies a "discrete entropy inequality." Recall that the initial data (σ^0, v^0) satisfies a one-sided bound of the form (cf. (2.12v))

$$\sup_j \left\{\sigma_j^0 - \sigma_{j-1}^0, v_j^0 - v_{j-1}^0\right\} \le M\Delta t, \tag{4.7}$$

where $M > 0$ is a finite constant independent of δ and the mesh parameters. For $(\sigma, v), (k, q) \in \mathcal{S}$, we define

$$G(\sigma, v, k, q) = \frac{g(\sigma + v) - g(k + q)}{(\sigma + v) - (k + q)}.$$

Hence,

$$G(\sigma, v, k, q) \ge M_f^{-1} > 0.$$

For a fixed $(k, q) \in \mathcal{S}$, let

$$G_j^n = G\left(\sigma_j^n, v_j^n, k, q\right),$$

where $\{(\sigma_j^n, v_j^n)\}$ denotes the solution of the difference scheme (2.10). Observe that it follows from (2.10) that

$$G_j^{n+1} - G_j^n = -\lambda \, \frac{G_j^{n+1} - G_j^n}{\left(\sigma_j^{n+1} + v_j^{n+1}\right) - \left(\sigma_j^n + v_j^n\right)} \cdot \frac{f\left(u_j^{n+1}\right) - f\left(u_j^n\right)}{u_j^{n+1} - u_j^n} \left(\sigma_j^n - \sigma_{j-1}^n\right).$$

Therefore, since f is increasing and g is concave (because $g'' = -f''/(f')^3 \le 0$), it follows that there is a positive constant M, depending only on f (or g), such that

$$G_j^{n+1} - G_j^n \le M \max\left(0, \sigma_j^n - \sigma_{j-1}^n\right). \tag{4.8}$$

Hence, we obtain from (4.8), (4.7), and Lemma 4.1 that

$$G_j^{n+1} - G_j^n \le M \Delta t, \tag{4.9}$$

where $M > 0$ is independent of δ and the mesh parameters.

LEMMA 4.2. *There is a positive constant M, independent of δ and the mesh parameters such that for any $(k, q) \in \mathcal{S}$ the solution of* (2.10) *satisfies*

$$\begin{aligned} &G_j^{n+1}\left(\left|\sigma_j^{n+1} - k\right| + \left|v_j^{n+1} - q\right|\right) \\ &\quad \le G_j^n\left(\left|\sigma_j^n - k\right| + \left|v_j^n - q\right|\right) - \lambda\left(\left|\sigma_j^n - k\right| - \left|\sigma_{j-1}^n - k\right|\right) \\ &\quad -\frac{\Delta t}{\delta} G_j^n R\left(\sigma_j^{n+1}, v_j^{n+1}\right)\left[sgn\left(\sigma_j^{n+1} - k\right) - sgn\left(v_j^{n+1} - q\right)\right] \\ &\quad +M\Delta t\left[\left|v_j^{n+1} - q\right| - \left(v_j^{n+1} - q\right)\, sgn\, \left(\sigma_j^{n+1} - q\right)\right], \end{aligned}$$

where, as above, $G_j^n = G(\sigma_j^n, v_j^n, k, q)$.

Proof. Let $(k, q) \in \mathcal{S}$. From the first equation in (2.10) we directly obtain

$$\begin{aligned} G_j^{n+1}\left(\sigma_j^{n+1} - k\right) = G_j^n\left(\sigma_j^n - k\right) - \lambda\left(\sigma_j^n - \sigma_{j-1}^n\right) \\ - \left(G_j^{n+1} - G_j^n\right)\left(v_j^{n+1} - q\right) - G_j^n\left(v_j^{n+1} - v_j^n\right). \end{aligned}$$

Hence, by using the second equation of (2.10), this can be written in the form

$$\begin{aligned} G_j^{n+1}\left(\sigma_j^{n+1} - k\right) = G_j^n\left(\sigma_j^n - k\right) - \lambda\left[\left(\sigma_j^n - k\right) - \left(\sigma_{j-1}^n - k\right)\right] \\ - \left(G_j^{n+1} - G_j^n\right)\left(v_j^{n+1} - q\right) - \frac{\Delta t}{\delta} G_j^n R_j^{n+1}, \end{aligned} \tag{4.10}$$

where $R_j^{n+1} = R(\sigma_j^{n+1}, v_j^{n+1})$.

The next step in the derivation is to multiply (4.10) by sgn $(\sigma_j^{n+1} - k)$. Observe that since $0 < \lambda \le M_f^{-1} \le G_j^n$, the inequality

$$\begin{aligned} \left\{G_j^n\left(\sigma_j^n - k\right) - \lambda\left[\left(\sigma_j^n - k\right) - \left(\sigma_{j-1}^n - k\right)\right]\right\} \operatorname{sgn}\left(\sigma_j^{n+1} - k\right) \\ \le G_j^n\left|\sigma_j^n - k\right| - \lambda\left(\left|\sigma_j^n - k\right| - \left|\sigma_{j-1}^n - k\right|\right) \end{aligned}$$

holds. Hence, from (4.10), we obtain

$$\begin{aligned} G_j^{n+1}\left|\sigma_j^{n+1} - k\right| \le G_j^n\left|\sigma_j^n - k\right| - \lambda\left(\left|\sigma_j^n - k\right| - \left|\sigma_{j-1}^n - k\right|\right) \\ - \left[\left(G_j^{n+1} - G_j^n\right)\left(v_j^{n+1} - q\right) + \frac{\Delta t}{\delta} G_j^n R_j^{n+1}\right] \operatorname{sgn}\left(\sigma_j^{n+1} - k\right). \end{aligned} \tag{4.11}$$

Next, write the second equation of (2.10) in the form

$$G_j^{n+1}\left(v_j^{n+1}-q\right)=G_j^n\left(v_j^n-q\right)+\left(G_j^{n+1}-G_j^n\right)\left(v_j^{n+1}-q\right)+\frac{\Delta t}{\delta}G_j^nR_j^{n+1}.$$

Hence, if we multiply this equation by $\operatorname{sgn}\left(v_j^{n+1}-q\right)$ and add the result to (4.11) we obtain the inequality

$$\begin{aligned}G_j^{n+1}\left(\left|\sigma_j^{n+1}-k\right|+\left|v_j^{n+1}-q\right|\right)&\le G_j^n\left(\left|\sigma_j^n-k\right|+\left|v_j^n-q\right|\right)\\&-\lambda\left(\left|\sigma_j^n-k\right|-\left|\sigma_{j-1}^n-k\right|\right)\\&-\frac{\Delta t}{\delta}G_j^nR_j^{n+1}\left[\operatorname{sgn}\left(\sigma_j^{n+1}-k\right)-\operatorname{sgn}\left(v_j^{n+1}-q\right)\right]\\&+\left(G_j^{n+1}-G_j^n\right)\left(v_j^{n+1}-q\right)\left[\operatorname{sgn}\left(v_j^{n+1}-q\right)-\operatorname{sgn}\left(\sigma_j^{n+1}-k\right)\right].\end{aligned}\tag{4.12}$$

However, note that

$$0\le\left(v_j^{n+1}-q\right)\left[\operatorname{sgn}\left(v_j^{n+1}-q\right)-\operatorname{sgn}\left(\sigma_j^{n+1}-k\right)\right];$$

therefore, it follows from the one-sided bound (4.9) that

$$\begin{aligned}&\left(G_j^{n+1}-G_j^n\right)\left(v_j^{n+1}-q\right)\left[\operatorname{sgn}\left(v_j^{n+1}-q\right)-\operatorname{sgn}\left(\sigma_j^{n+1}-k\right)\right]\\&\quad\le M\Delta t\left[\left|v_j^{n+1}-q\right|-\left(v_j^{n+1}-q\right)\operatorname{sgn}\left(\sigma_j^{n+1}-q\right)\right],\end{aligned}$$

and hence the desired inequality follows from (4.12). □

Consider a real valued function $\mathcal{E}:\mathcal{S}\mapsto\mathbb{R}$ of the form

$$\mathcal{E}(\sigma,v)=\mathcal{L}(g(\sigma+v))+\int_{\mathcal{S}}P(k,q)G(\sigma,v,k,q)(|\sigma-k|+|v-q|)\,dk\,dq.$$

Here, $\mathcal{L}$ is a linear function and $P:\mathcal{S}\mapsto\mathbb{R}$ is a smooth, nonnegative function. Define, correspondingly,

$$\begin{aligned}\mathcal{F}(\sigma)&=\mathcal{L}(\sigma)+\int_{\mathcal{S}}P(k,q)|\sigma-k|\,dk\,dq,\\\mathcal{G}(\bar\sigma,\bar v,\sigma,v)&=\int_{\mathcal{S}}P(k,q)G(\bar\sigma,\bar v,k,q)R(\sigma,v)[\operatorname{sgn}(\sigma-k)-\operatorname{sgn}(v-q)]\,dk\,dq,\\\mathcal{H}(v)&=\int_{\mathcal{S}}P(k,q)\left[|v-q|-(v-q)\operatorname{sgn}(\sigma-k)\right]\,dk\,dq.\end{aligned}$$

It follows from (2.10) and by integrating the inequality of Lemma 4.2 that the solution of (2.10) satisfies the discrete entropy inequality

$$\begin{aligned}\mathcal{E}\left(\sigma_j^{n+1},v_j^{n+1}\right)&\le\mathcal{E}\left(\sigma_j^n,v_j^n\right)-\lambda\left[\mathcal{F}\left(\sigma_j^n\right)-\mathcal{F}\left(\sigma_{j-1}^n\right)\right]\\&\quad-\frac{\Delta t}{\delta}\mathcal{G}\left(\sigma_j^n,v_j^n,\sigma_j^{n+1},v_j^{n+1}\right)+M\Delta t\mathcal{H}\left(v_j^{n+1}\right).\end{aligned}\tag{4.13}$$

The properties of the entropy solutions of the system (2.1) will be derived from the corresponding properties of the finite difference solutions generated by the scheme (2.10). The convergence of the finite difference solutions is first established by a proper application of Helly's theorem, cf., e.g., [16].

LEMMA 4.3. *Suppose* (σ^0, v^0) *is the initial data which satisfies all the assumptions in* (2.12) *and let* $(\sigma^N, v^N)_\Delta$ *be the piecewise constant representation of the data generated by the scheme* (2.10). *Then, as the mesh parameters* Δx *and* Δt *tend to zero, there is a subsequence of* $(\sigma^N, v^N)_\Delta$, *which converges in* $(L^1_{loc}(\mathbb{R}\times\mathbb{R}))^2$ *to a pair of functions* (σ, v). *Furthermore,* $\sigma(\cdot,t), v(\cdot,t) \in BV$, *for all* $t \geq 0$, *and* $(\sigma(x,y), v(x,t)) \in \mathcal{S}$ *for* $(x,t) \in \mathbb{R}\times\mathbb{R}^+_0$, *and the following estimates hold:*

1. $(\sigma(x,t), v(x,t)) \in \mathcal{S}, \quad \forall (x,t) \in \mathbb{R}\times\mathbb{R}^+_0,$
2. $TV(\sigma(\cdot,t)) + TV(v(\cdot,t)) \leq TV(\sigma^0) + TV(v^0),$
3. $\|p(\cdot,t)\|_1 \leq M\delta,$
4. $\|\sigma(\cdot,t) - \sigma(\cdot,\tau)\|_1 + \|v(\cdot,t) - v(\cdot,\tau)\|_1 \leq M|t-\tau|,$
5. $Lip^+(\sigma(\cdot,t)) \leq MLip^+(\sigma^0), \quad Lip^+(v(\cdot,t)) \leq MLip^+(v^0), \quad \forall t \geq 0.$

Here, M *is a constant independent of* t *and* δ.

From the entropy inequality in (4.13), we derived that the limit solution is the entropy solution of (2.1).

LEMMA 4.4. *The limit solution* (σ, v) *constructed in Lemma* 4.3 *is the entropy solution of the system* (2.1), *which satisfies the following Kruzkov-type inequality:*

$$
\begin{aligned}
(4.14)\ \int_0^T \int_{\mathbb{R}} & [G(\sigma,v,k,q)(|\sigma-k| + |v-q|)\phi_t + |\sigma-k|\phi_x]\, dx\, dt \\
& + \int_{\mathbb{R}} G\left(\sigma^0, v^0, k, q\right)\left(\left|\sigma^0 - k\right| + \left|v^0 - q\right|\right)\phi(x,0)\, dx \\
& - \int_{\mathbb{R}} G(\sigma(x,T), v(x,T), k, q)(|\sigma(x,T)-k| + |v(x,T)-q|)\phi(x,T)\, dx \\
& + M\int_0^T \int_{\mathbb{R}} [|v-q| - (v-q)sgn\ (\sigma-k)]\,\phi\, dx\, dt \\
& \geq \frac{1}{\delta}\int_0^T \int_{\mathbb{R}} G(\sigma,v,k,q)R(\sigma,v)[sgn\ (\sigma-k) - sgn\ (v-q)]\phi\, dx\, dt.
\end{aligned}
$$

Here, $(k,q) \in \mathcal{S}$ *and* $\phi \in \mathcal{D}_+(T)$ *is any test function with compact support. We recall that the function* $G = G(\sigma,v,k,q)$ *is defined as*

$$
G(\sigma,v,k,q) = \frac{g(\sigma+v) - g(k+q)}{(\sigma+v) - (k+q)}.
$$

Proof. Let $\phi \in \mathcal{D}_+(T)$ be a test function with compact support. We multiply the inequality in (4.13) by $\phi(x_j, t_n)$, then sum over $0 \leq n \leq N-1$ and $j \in \mathcal{Z}$, and apply summation by parts with respect to n and j, and we obtain the following:

$$
\begin{aligned}
\Delta t \sum_{n=0}^{N-1} \Delta x \sum_{j\in\mathcal{Z}} & \left[\mathcal{E}\left(\sigma_j^{n+1}, v_j^{n+1}\right)\frac{\phi\left(x_j, t_{n+1}\right) - \phi\left(x_j,t_n\right)}{\Delta t}\right. \\
& \left. +\ \mathcal{F}\left(\sigma_j^n\right)\frac{\phi\left(x_{j+1},t_n\right) - \phi\left(x_j,t_n\right)}{\Delta x}\right] \\
& + \Delta x \sum_{j\in\mathcal{Z}} \mathcal{E}\left(\sigma_j^0, v_j^0\right)\phi\left(x_j, t^0\right) - \Delta x \sum_{j\in\mathcal{Z}} \mathcal{E}\left(\sigma_j^N, v_j^N\right)\phi\left(x_j, t^N\right)
\end{aligned}
$$

$$+\Delta t\sum_{n=0}^{N-1}\Delta x\sum_{j\in\mathcal{Z}}M\mathcal{H}\left(v_j^{n+1}\right)\phi\left(x_j,t_n\right)$$
$$\geq\frac{1}{\delta}\Delta t\sum_{n=0}^{N-1}\Delta x\sum_{j\in\mathcal{Z}}\mathcal{G}\left(\sigma_j^n,v_j^n,\sigma_j^{n+1},v_j^{n+1}\right)\phi\left(x_j,t_n\right).$$

Now, by letting $\Delta x,\Delta t\to 0$ in the previous inequality, we get

$$\int_0^T\int_{\mathbb{R}}[\mathcal{E}(\sigma,v)\phi_t+\mathcal{F}(\sigma)\phi_x+M\mathcal{H}(v)\phi]\,dx\,dt$$
$$+\int_{\mathbb{R}}[\mathcal{E}(\sigma^0,v^0)\phi(x,0)-\mathcal{E}(\sigma(x,T),v(x,T))\phi(x,T)]\,dx$$
$$\geq\frac{1}{\delta}\int_0^T\int_{\mathbb{R}}\mathcal{G}(\sigma,v,\sigma,v)\phi\,dx\,dt.$$

Hence, by choosing a sequence of smooth function pairs $(\mathcal{E}_\theta,\mathcal{F}_\theta,\mathcal{G}_\theta,\mathcal{H}_\theta)$ such that, as $\theta\to 0$,

$$\mathcal{E}_\theta\to G(\sigma,v,k,q)(|\sigma-k|+|v-q|),$$
$$\mathcal{F}_\theta\to|\sigma-k|,$$
$$\mathcal{G}_\theta\to G(\sigma,v,k,q)R(\sigma,v)[\ \mathrm{sgn}\ (\sigma-k)-\ \mathrm{sgn}\ (v-q)],$$
$$\mathcal{H}_\theta\to|v-q|-(v-q)\ \mathrm{sgn}\ (\sigma-k),$$

uniformly, and we get the inequality (4.14) in Lemma 4.4 by the dominated convergence theorem. □

The uniqueness and continuous dependence with respect to the initial data in L^1 is then obtained by the Kruzkov-type argument.

LEMMA 4.5. *Let (σ,v) and $(\bar\sigma,\bar v)$ be two entropy solutions of the system* (2.1) *with initial data (σ^0,v^0) and $(\bar\sigma^0,\bar v^0)$, respectively. Then,*

$$\|\sigma(\cdot,t)-\bar\sigma(\cdot,t)\|_{L^1}+\|v(\cdot,t)-\bar v(\cdot,t)\|_{L^1}\leq\bar Me^{Mt}\left[\left\|\sigma^0-\bar\sigma^0\right\|_{L^1}+\left\|v^0-\bar v^0\right\|_{L^1}\right].$$

Proof. The uniqueness of the entropy solutions is proved by generalizing the arguments by Kruzkov [5] for scalar conservation laws. In this paper, only the sketch of the proof is given, and we refer to [14, 16] for the details in the proof.

For any $\theta\in(0,1]$, we introduce the mollifier function ω_θ on $\mathbb{R}$ as

$$\omega_\theta(x)=\frac{1}{\theta}\Omega\left(\frac{x}{\theta}\right),$$

where $\Omega:\mathbb{R}\to\mathbb{R}$ is a nonnegative, symmetric $\mathcal{C}^\infty$-function with support in $[-1,1]$ and satisfying

$$\int_{\mathbb{R}}\Omega(x)\,dx=1.$$

Let $T>0$. In (4.14), we choose $(k,q)=(\bar\sigma(y,\tau),\bar v(y,\tau))$ and $\phi(x,t)=\omega_\theta(x-y)\omega_\theta(t-\tau)$ for solution (σ,v), and integrate over $\mathbb{R}\times[0,T]$ with respect to y and τ, and we get an inequality. For the solution $(\bar\sigma,\bar v)$, we perform a similar operation, but

where we reverse the role of the variable (x,t) and (y,τ), we get another inequality. Now, adding these two inequalities, we get

$$L(\theta)+\frac{1}{\delta}l(\theta)\leq R(\theta)+2Mr(\theta),$$

where

$$\begin{aligned}L(\theta)=&\int_0^T\int_{\mathbb{R}}\int_{\mathbb{R}}G(\sigma(x,T),v(x,T),\bar\sigma,\bar v)(|\sigma(x,T)-\bar\sigma|+|v(x,T)-\bar v|)\\&\qquad\omega_\theta(x-y)\omega_\theta(T-\tau)\,dx\,dy\,d\tau\\&+\int_0^T\int_{\mathbb{R}}\int_{\mathbb{R}}G(\bar\sigma(y,T),\bar v(y,T),\sigma,v)(|\bar\sigma(y,T)-\sigma|+|\bar v(y,T)-v|)\\&\qquad\omega_\theta(x-y)\omega_\theta(T-\tau)\,dx\,dy\,d\tau\end{aligned}$$

and

$$\begin{aligned}R(\theta)=&\int_0^T\int_{\mathbb{R}}\int_{\mathbb{R}}G(\sigma(x,0),v(x,0),\bar\sigma,\bar v)(|\sigma(x,0)-\bar\sigma|+|v(x,0)-\bar v|)\\&\qquad\omega_\theta(x-y)\omega_\theta(\tau)\,dx\,dy\,d\tau\\&+\int_0^T\int_{\mathbb{R}}\int_{\mathbb{R}}G(\bar\sigma(y,0),\bar v(y,0),\sigma,v)(|\bar\sigma(y,0)-\sigma|+|\bar v(y,0)-v|)\\&\qquad\omega_\theta(x-y)\omega_\theta(\tau)\,dx\,dy\,d\tau\end{aligned}$$

$$\begin{aligned}l(\theta)=&\int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}}G(\sigma,v,\bar\sigma,\bar v)[\ \mathrm{sgn}\ (\sigma-\bar\sigma)-\ \mathrm{sgn}\ (v-\bar v)]\\&\qquad[R(\sigma,v)-R(\bar\sigma,\bar v)]\omega_\theta(x-y)\omega_\theta(t-\tau)\,dx\,dt\,dy\,d\tau\end{aligned}$$

and

$$r(\theta)=2\int_0^T\int_{\mathbb{R}}\int_0^T\int_{\mathbb{R}}|v-\bar v|\omega_\theta(x-y)\omega_\theta(t-\tau)\,dx\,dt\,dy\,d\tau.$$

First we note that $l(\theta)$ is non-negative. In order to estimate the turns $L(\theta)$ and $R(\theta)$, we introduce the function $\mathcal{N}(t)$ as

$$\mathcal{N}(t)=\int_{\mathbb{R}}G(\sigma(x,t),v(x,t),\bar\sigma(x,t),\bar v(x,t))(|\sigma(x,t)-\bar\sigma(x,t)|+|v(x,t)-\bar v(x,t)|)\,dx.$$

Note that the function $\mathcal{N}(t)$ is equivalent to

$$A(t):=\|\sigma(\cdot,t)-\bar\sigma(\cdot,t)\|_{L^1}+\|v(\cdot,t)-\bar v(\cdot,t)\|_{L^1}$$

in the sense that there exist two positive constants, M_1,M_2, such that

$$M_1A(t)\leq\mathcal{N}(t)\leq M_2A(t). \tag{4.15}$$

Then, as $\theta\to 0$, we get(cf., e.g., [16])

$$L(\theta)\to\mathcal{N}(T),\quad R(\theta)\to\mathcal{N}(0),$$

and

$$r(\theta) \to 2M \int_0^T \|v(\cdot,t) - \bar{v}(\cdot,t)\|_{L^1}\, dt.$$

Combining these estimates we conclude, in the limit case as $\theta \to 0$, that

$$\mathcal{N}(T) \le \mathcal{N}(0) + M \int_0^T \mathcal{N}(t)\, dt,$$

where M is a finite constant independent of δ. Thus, it follows that

$$\mathcal{N}(T) \le \mathcal{N}(0) e^{MT},$$

and again, using (4.15), we get

$$\|\sigma(\cdot,t) - \bar{\sigma}(\cdot,t)\|_{L^1} + \|v(\cdot,t) - \bar{v}(\cdot,t)\|_{L^1} \le \bar{M} e^{Mt} \left[\left\|\sigma^0 - \bar{\sigma}^0\right\|_{L^1} + \left\|v^0 - \bar{v}^0\right\|_{L^1} \right],$$

where $\bar{M}$ and M are finite constants independent of δ. This completes the proof of Theorem 2.2. ∎

5. Rate of convergence towards equilibrium: Proof of Theorem 2.3 and Corollary 2.4. We recall that Lemma 4.3 establishes bounds, uniformly with respect to δ, on the solutions $(\sigma_\delta, v_\delta)$ of the non-equilibrium model (1.1) or (2.1). By combining these estimates with standard compactness arguments we could have concluded, more or less directly, that these solutions converge to a solution of the equilibrium model (1.2) or (2.2) as the relaxation parameter δ tends to zero. However, we are not only interested in convergence, but also in a rate of convergence. Hence, in order to prove the error estimates in Theorem 2.3 and Corollary 2.4, we shall follow the work of Tadmor [15] and Kurganov and Tadmor [6]. First we observe that the entropy solutions of (1.1) are weak solutions of a scalar equation with an "error term."

LEMMA 5.1. *Let (u,σ) (resp., (σ,v)) be the entropy solutions of* (1.1) (*resp.,* (2.1)). *Then the solutions u are weak solutions of the following "error equation"*

$$u_t + \mu f(u)_x = -R(\sigma,v)_x$$

in the sense that the following integral equation holds for all test functions $\phi \in \mathcal{D}_+(T)$:

$$\int_0^T \int_{\mathbb{R}} (u\phi_t + \mu f(u)_x \phi_x)\, dx\, dt + \int_{\mathbb{R}} [u(x,0)\phi(x,0) - u(x,T)\phi(x,T)]\, dx = -\int_0^T \int_{\mathbb{R}} R(\sigma,v)\phi_x\, dx\, dt.$$

In addition, u satisfies the Lip$^+$ bound

$$\mathrm{Lip}^+(u(\cdot,t)) \le M, \quad \forall t \ge 0.$$

Proof. Let (σ,v) be the entropy solutions of (2.1). Then they satisfy the Kruzkov-type inequality given in (2.6). Choosing $(k = \sigma_m, q = v_m)$, where $\sigma_m = \min(\sigma)$ and $v_m = \min(v)$, (one can use, e.g., $k = q = 0$), the last terms on the left-hand side and the right-hand side are 0. Using the definition of G, the relation $u = g(\sigma + v)$, and the fact that (k,q) are constants, we get

$$\int_0^T \int_{\mathbb{R}} [u\phi_t + \sigma\phi_x]\, dx\, dt + \int_{\mathbb{R}} (u(x,0)\phi(x,0) - u(x,T)\phi(x,T)) \ge 0.$$

Similarly, by choosing $(k = \sigma_M, q = v_M)$, where $\sigma_M = \max(\sigma)$ and $v_M = \max(v)$ (e.g., $k = \mu, q = 1 - \mu$), we get

$$\int_0^T \int_{\mathbb{R}} [u\phi_t + \sigma\phi_x] \, dx \, dt + \int_{\mathbb{R}} (u(x,0)\phi(x,0) - u(x,T)\phi(x,T)) \leq 0.$$

These two inequalities lead to

$$\int_0^T \int_{\mathbb{R}} [u\phi_t + \sigma\phi_x] \, dx \, dt + \int_{\mathbb{R}} [u(x,0)\phi(x,0) - u(x,T)\phi(x,T)] = 0.$$

Furthermore, using the relation

$$\sigma - \mu f(u) = \sigma - \mu(\sigma + v) = (1 - \mu)\sigma - \mu v = R(\sigma, v),$$

we get the weak formulation in Lemma 5.1, and thus u is a weak solution of the error equation. Finally, the Lip^+ bound follows from the monotonicity of the function g. ∎

Let $T > 0$ be given and define $E = -R_x = -p_x$. Hence, $u = u_\delta$ is a weak solution of the inhomogeneous equation

$$u_t + \mu f(u)_x = E,$$

and $\bar{u}$ is a solution of the corresponding homogeneous equation (1.2). Furthermore, these solutions satisfy an Oleinik condition of the form

$$\mathrm{Lip}^+(u(\cdot,t)),\ \mathrm{Lip}^+(\bar{u}(\cdot,t) \leq M, \quad \forall t \geq 0.$$

Since the flux function f is convex, we can therefore conclude from the arguments in Kurganov and Tadmor [6] that the following stability estimate holds:

$$\|u(\cdot,t) - \bar{u}(\cdot,t)\|_{\mathrm{Lip}'} \leq M \sup_{0 \leq \tau \leq t} \|E(\cdot,\tau)\|_{\mathrm{Lip}'}, \quad 0 \leq t \leq T.$$

From Lemma 4.3 we obtain that

$$\|E(\cdot,t)\|_{\mathrm{Lip}'} \leq \|p(\cdot,t)\|_{L^1} \leq M\delta.$$

This completes the proof of Theorem 2.3.

The L^p estimate in Corollary 2.4 can be proved by interpolation between the Lip'-error estimate in Theorem 2.3 and the BV-boundness of the error, exactly in the same way as is done in Nessyahu and Tadmor [11]. We therefore omit the details.

The L^1 estimate for $\sigma - \bar{\sigma}$ follows from the L^1 estimate for $u - \bar{u}$. To be precise, since $\bar{\sigma} = \mu f(\bar{u})$, we have

$$\begin{aligned}
\|\sigma - \bar{\sigma}\|_{L^1} &= \|\sigma - \mu f(u) + \mu f(u) - \bar{\sigma}\|_{L^1} \leq \|\sigma - \mu f(u)\|_{L^1} + \|\mu(f(u) - f(\bar{u}))\|_{L^1} \\
&\leq \|p\|_{L^1} + M\|u(\cdot,t) - \bar{u}(\cdot,t)\|_{L^1} \\
&\leq M\sqrt{\delta},
\end{aligned}$$

which gives the second estimate in Corollary 2.4.

Acknowledgments. The authors are grateful to one of the referees for pointing out possible ways of improving the results in an earlier version of this paper. We also thank Professor Natalini for informing us about the works of Yong [18] and Luo and Natalini [9].

ALMOST EVERYWHERE SOLUTIONS OF PARTIAL DIFFERENTIAL EQUATIONS AND SYSTEMS OF ANY ORDER*

LAURA POGGIOLINI†

Abstract. We prove existence of $W^{k,\infty}(\Omega)$ solutions to some differential problems related to nonlinear partial differential equations and systems of order $k \geq 1$. The results will be proved by means of Baire's lemma.

Key words. quasi-convexity, almost everywhere solutions, systems of PDEs

AMS subject classification. 35G30

PII. S0036141098336121

1. Introduction.

In this paper we deal with the existence of almost everywhere (a.e.) solutions to differential problems of the following kind:

$$\begin{cases} F(x, D^{[k-1]}u(x), D^k u(x)) = 0, & \text{a.e. } x \in \Omega, \\ u \in \phi + W_0^{k,\infty}(\Omega), \end{cases} \tag{1.1}$$

where k is an integer greater than or equal to 1 (for notations and definitions see the next section) and F is a given function which must satisfy certain coercivity conditions; in particular our hypotheses will rule out functions F which are linear with respect to the higher-order derivatives $D^k u$. We shall prove the following theorem.

THEOREM 1.1. *Let $\Omega \subset \mathbb{R}^n$ be an open Lipschitz set. Let $F\colon \Omega \times \cdots \times ((\mathbb{R}^n)^{\otimes_k})_s \to \mathbb{R}$ be a continuous function, quasi-convex and coercive in a rank-1 direction (see Definition 2.3) with respect to the last variable. Let $\phi\colon \overline{\Omega} \to \mathbb{R}$ be a $C^k(\overline{\Omega})$ function such that*

$$F(x, D^{[k-1]}\phi(x), D^k\phi(x)) \leq 0 \qquad \forall x \in \overline{\Omega}.$$

Then there exists a function $u \in \phi + W_0^{k,\infty}(\Omega)$ such that

$$F(x, D^{[k-1]}u(x), D^k u(x)) = 0, \qquad \text{a.e. } x \in \Omega. \tag{1.2}$$

As we already said, the definition of quasi-convexity is discussed in section 2. Note however that quasi-convexity in the context of Theorem 1.1 is equivalent to the usual convexity in the first-order case $k = 1$.

Theorem 1.1 extends to the higher-order case $k \in \mathbb{N}$ an analogous result recently proved by Dacorogna and Marcellini in the first-order case $k = 1$ (see [7], [6], [8] and [9]) and in the second-order case $k = 2$ (see [10]). We will use the same techniques based on Baire category method, exploited by Dacorogna and Marcellini to study vector valued problems and originally introduced by Cellina in [3] in the context of ordinary differential inclusions (see also De Blasi and Pianigiani [11], [12] and Bressan and Flores [2]).

We should refer also to some previous research for the first- and second-order cases in the context of viscosity solutions (see, for example, Crandall and Lions [4];

*Received by the editors March 20, 1998; accepted for publication (in revised form) November 2, 1998; published electronically August 26, 1999.

†Dipartimento di Matematica "U. Dini," Viale Morgagni 67/a, 50134 Firenze, Italy (laura.poggiolini@math.unifi.it).

see also [10] for some other references). We should also mention the recent works by Müller and Svërak, [21] and [22] using the method of convex integration introduced by Gromov [14].

A main difficulty in considering $k \geq 2$ instead of $k = 1$ is the loss of approximating a given $W^{k,\infty}(\Omega)$ function u by a sequence of piecewise polynomials of degree k. In our context of higher-order $k \in \mathbb{N}$, the main tool to apply Baire category method is the density argument obtained in Lemma 3.1. Other parts are treated in similar ways to [10].

If we consider for a moment the case $k = 4$ and $F = F(D^4u(x))$, it is evident that we can't deal with a linear function F; in fact the problem

$$\begin{cases} \Delta^2 u(x) - 1 = 0, & \text{a.e. } x \in \Omega, \\ u \in \phi + W_0^{4,\infty}(\Omega) \end{cases} \tag{1.3}$$

(here Δ^2 denotes the bilaplacian operator) is over determined, while we shall provide a solution, for example, to the problem

$$\begin{cases} |\Delta^2 u(x)| - 1 = 0, & \text{a.e. } x \in \Omega, \\ u \in \phi + W_0^{4,\infty}(\Omega). \end{cases} \tag{1.4}$$

Actually we shall deal only with coercive functions F (see Definition 2.3), such as $F(D^4u(x)) = |\Delta^2 u(x)|$ in the previous example (1.4). In section 6 we shall deal more generally with k-order systems of the type

$$\begin{cases} F_i(x, D^{[k-1]}u(x), D^k u(x)) = 0, & \text{a.e. } x \in \Omega, \quad i = 1, \dots, N, \\ u \in \phi + W_0^{k,\infty}(\Omega) \end{cases}$$

and we will prove an existence theorem for such systems.

2. Notation and definitions. If $v \in \mathbb{R}^n$ and $k \in \mathbb{N}$ we denote by $v^{\otimes_k}$ the tensor product $\overbrace{v \otimes \cdots \otimes v}^{k\text{-times}}$. The symbol $((\mathbb{R}^n)^{\otimes_k})_s$ will denote the subset of symmetric tensors of the space $(\mathbb{R}^n)^{\otimes_k} \equiv \underbrace{\mathbb{R}^n \otimes \cdots \otimes \mathbb{R}^n}_{k\text{-times}}$.

If $\Omega \subset \mathbb{R}^n$ is a Lebesgue measurable set, the symbol $|\Omega|$ will denote its n-dimensional Lebesgue measure. If $u\colon \Omega \subset \mathbb{R}^n \to \mathbb{R}$ is a weakly k-differentiable function we denote $D^k u = (D^\alpha u)_{|\alpha|=k}$ and $D^{[k]}u = (u, Du, \dots, D^k u)$.

If ψ is a $C^0(\overline{\Omega})$ function, let $\|\psi\|_{\infty,\Omega} \equiv \sup_{x\in\Omega} |\psi(x)|$, while if $\phi \in C^l(\overline{\Omega})$, let $\|\phi\|_{l,\infty,\Omega} \equiv \sum_{i=0}^{l} \sup_{x\in\Omega} |D^i\psi(x)|$.

The following definitions of convexity are known extensions for the higher-order case $k > 1$ of analogous convexity conditions for the first-order vector valued case (see Morrey [19], [20], Meyers [17], Dacorogna [5], and Ball, Currie, and Olver [1]).

DEFINITION 2.1. *We say that $\Lambda \in ((\mathbb{R}^n)^{\otimes_k})_s$ is a rank-1 tensor if there exist $\mu \in \mathbb{R}$, $v \in \mathbb{R}^n$ such that*

$$\Lambda = \mu v^{\otimes_k}. \tag{2.1}$$

We remark that in Definition 2.1 we can always assume that the Euclidean norm of v, $|v|$ is 1.

DEFINITION 2.2. *We say that a function $F\colon ((\mathbb{R}^n)^{\otimes_k})_s \to \mathbb{R}$ is quasi-convex if*

$$\int_\Omega F(A + D^k\phi(x))\,dx \geq |\Omega| F(A) \quad \forall A \in ((\mathbb{R}^n)^{\otimes_k})_s \tag{2.2}$$

$$\forall \Omega \subset \mathbb{R}^n \text{ open bounded set and } \forall \phi \in C_0^\infty(\Omega).$$

DEFINITION 2.3. *Let Y be a metric space. We say that a function $F: Y \times ((\mathbb{R}^n)^{\otimes_k})_s \to \mathbb{R}$ is coercive in a rank-1 direction Λ if for any bounded subset B of $Y \times ((\mathbb{R}^n)^{\otimes_k})_s$ there exist m, $q \in \mathbb{R}$, with $m > 0$ such that*

$$F(y, \xi + t\Lambda) \geq m|t| - q \qquad \forall t \in \mathbb{R},\ \forall (y, \xi) \in B. \tag{2.3}$$

DEFINITION 2.4. *We denote $P_\varepsilon(\Omega)$ the class of the functions $u \in W^{k,\infty}(\Omega)$ such that there exist Ω_0, Ω_j, $j \in \mathbb{N}$ open Lipschitz pairwise disjoint subsets of Ω such that*

$$\begin{aligned} &|\Omega_0| < \varepsilon, \\ &\bigcup_{j \geq 0} \overline{\Omega_j} = \overline{\Omega}, \\ &D^k u = \xi_j, \qquad \text{a.e. } x \in \Omega_j \quad \forall j \in \mathbb{N}. \end{aligned}$$

Most of the proofs will be carried out by means of Baire's lemma (see, e.g., Kolmogorov and Fomin [16]).

LEMMA 2.5 (Baire's lemma). *If V is a complete metric space and V^m, $m \in \mathbb{N}$ are open dense subsets of V, then also $\bigcap_{m \in \mathbb{N}} V^m$ is dense in V.*

3. The main approximation lemma. We begin with a fundamental technical lemma.

LEMMA 3.1. *Let $\Omega \subset \mathbb{R}^n$ be an open Lipschitz set. Let $t \in [0,1]$ and let A, $B \in ((\mathbb{R}^n)^{\otimes_k})_s$ be such that $\operatorname{rank}\{A - B\} = 1$. Let $\phi: \Omega \to \mathbb{R}$ be such that $D^k \phi(x) = tA + (1-t)B = B + t(A - B)$ for every $x \in \Omega$. Then for any $\varepsilon > 0$ there exist a function $u \in \phi + W_0^{k,\infty}(\Omega)$ and two open Lipschitz disjoint subsets of Ω, Ω_A and Ω_B, such that*

$$\|\Omega_A| - t|\Omega\| \leq \varepsilon, \quad ||\Omega_A| - (1-t)|\Omega|| \leq \varepsilon, \tag{3.1}$$

$$\|u - \phi\|_{k-1,\infty} < \varepsilon, \tag{3.2}$$

$$D^k u(x) = \begin{cases} A, & x \in \Omega_A, \\ B, & x \in \Omega_B, \end{cases} \tag{3.3}$$

$$\operatorname{dist}(D^k u(x),\ co(A, B)) \leq \varepsilon, \qquad \text{a.e. } x \in \Omega. \tag{3.4}$$

Proof. We divide the proof into several steps.

1. Let us assume that $A - B = \mu e_1^{\otimes_k}$, where $e_1 = (1, 0, \ldots, 0)$ is the first vector of the canonical basis of $\mathbb{R}^n$.

2. We can write Ω as the disjoint union of cubes whose faces are parallel to the coordinates axes and of a set of small measure. If we define $u = \phi$ in this set, then up to homotheties and translations we can always assume that $\Omega = (0,1)^n$.

3. Let $\Omega_\varepsilon \subset\subset \Omega$ be such that $|\Omega \setminus \Omega_\varepsilon| < \varepsilon$ and let $\eta \in C_0^k(\Omega)$ be such that

$$\begin{aligned} &0 \leq \eta(x) \leq 1 \qquad \forall x \in \Omega, \\ &\eta(x) = 1 \qquad \forall x \in \Omega_\varepsilon, \\ &|D^l \eta(x)| \leq \frac{L}{\varepsilon^l} \qquad \forall l = 1, \ldots, k \ \text{ and } \ \forall x \in \Omega \setminus \Omega_\varepsilon. \end{aligned}$$

We now define a new function $v\colon (0,1) \to \mathbb{R} \quad v\colon x_1 \to v(x_1)$. Let $\delta > 0$, $x_1 \in (0,1)$ and let I, $J \subset (0,1)$ be such that I and J are the disjoint union of open disjoint intervals and

$$\begin{aligned}
&I \cap J = \emptyset, \quad \overline{I} \cup \overline{J} = [0,1],\\
&|I| = t, \quad |J| = 1 - t,\\
&v^{(k)}(x_1) = \begin{cases} (1-t)\mu x_1 \in I,\\ -t\mu x_1 \in J,\end{cases}\\
&|v^l(x_1)| < \delta \qquad \forall x_1 \in (0,1) \text{ and } \forall l = 1, \dots, k.
\end{aligned}$$

Now let us define $u(x) = u(x_1, x') = \phi(x) + \eta(x)v(x_1) = \eta(x)(v(x_1) + \phi(x)) + (1 - \eta(x))\phi(x)$ and set

$$\begin{aligned}
\Omega_A &\equiv \{x \in \Omega_\varepsilon\colon x_1 \in I\},\\
\Omega_B &\equiv \{x \in \Omega_\varepsilon\colon x_1 \in J\}.
\end{aligned}$$

Then the function u satisfies all the requests of our thesis:

$$D_{i_1,\dots,i_n} u = D_{i_1,\dots,i_n}\phi + \sum_{\substack{l_s + m_s = i_s\\ s=1,\dots,n}} D_{l_1,\dots,l_n}\eta D_{m_1,\dots,m_n} v.$$

If $x \in \Omega_A$ we have

$$\begin{aligned}
&D_{l_1,\dots,l_n}\eta = 0 \text{ whenever } l_1 + \cdots + l_n > 0,\\
&D_{m_1,\dots,m_n} v = (1-t)\mu\delta_{1m_1}, \dots, \delta_{1m_n} \text{ whenever } m_1 + \cdots + m_n = k,
\end{aligned}$$

hence,

$$D^k u = D^k\phi + (1-t)\mu e_1^{\otimes k} = B + t(A-B) + (1-t)(A-B) = A,$$

while, if $x \in \Omega_B$ we have

$$\begin{aligned}
&D_{l_1,\dots,l_n}\eta = 0 \text{ whenever } l_1 + \cdots + l_n > 0,\\
&D_{m_1,\dots,m_n} v = -t\mu\delta_{1m_1}, \dots, \delta_{1m_n}, \text{ whenever } m_1 + \cdots + m_n = k,
\end{aligned}$$

hence,

$$D^k u = D^k\phi - t\mu e_1^{\otimes k} = B + t(A-B) - t(A-B) = B.$$

To obtain (3.3) we only need to choose $\delta < C(n,k)\min\{1, \varepsilon, \dots, \varepsilon^k\}$.

Now let us prove inequality (3.4):

$$D^k\phi(x) = tA + (1-t)B \in co(A,B),$$

$$D^k\phi + D^k v = \begin{cases} tA + (1-t)B + (1-t)(A-B) = A, & x_1 \in I,\\ tA + (1-t)B - t(A-B) = B, & x_1 \in J,\end{cases}$$

which belong to $co(A,B)$. But

$$\begin{aligned}
D_{i_1,\dots,i_n} u &= D_{i_1,\dots,i_n}\phi + \sum_{\substack{l_s + m_s = i_s\\ s=1,\dots,n}} D_{l_1,\dots,l_n}\eta D_{m_1,\dots,m_n} v\\
&= \eta D_{i_1,\dots,i_n}\phi + (1-\eta) D_{i_1,\dots,i_n}\phi + \eta D_{i_1,\dots,i_n} v\\
&\quad + \sum_{\substack{l_1 + \cdots + l_n > 0\\ l_s + m_s = i_s}} D_{l_1,\dots,l_n}\eta D_{m_1,\dots,m_n} v,
\end{aligned}$$

which means

$$D^k u = \eta(D^k\phi + D^k v) + (1-\eta)D^k\phi + P_k$$

where

$$(P_k)_{i_1,\dots,i_n} = \sum_{\substack{l_s+m_s=i_s \\ l_1+\cdots+l_s>0}} D_{l_1,\dots,l_s}\eta D_{m_1,\dots,m_n}v.$$

Therefore

$$\operatorname{dist}(D^k u, co(A,B)) \le \|P_k\|_\infty \le C(n,k)L\max\{\varepsilon^{-1},\dots,\varepsilon^{-k+1}\}\delta.$$

We choose

$$\delta \le (C(n,k))^{-1}\min\{\varepsilon^2,\dots,\varepsilon^k\}$$

and obtain inequality (3.4).

4. Let us see why Lemma 3.1 holds also when $v \neq e_1$. Let us define a matrix R in the following way. We define $r_{i1} = v^i\ \forall i = 1,\dots,n$. We can choose the other elements of R in such a way that R is an orthogonal matrix and $v = Re_1$, hence $A - B = \mu(Re_1)^{\otimes_k}$. If $\phi\colon \overline{\Omega} \subset \mathbb{R}^n \to \mathbb{R}$ is a C^k function, we define $\widetilde{\phi}\colon R^t\Omega \to \mathbb{R}$ $\widetilde{\phi}\colon y \to \phi(Ry)$. If we compute the partial derivatives of order k we have

$$\frac{\partial^k\widetilde{\phi}}{\partial y_{j_1},\dots,\partial y_{j_k}}(y) = \sum_{i_1,\dots,i_k=1}^{n} \frac{\partial^k\phi}{\partial x_{i_1},\dots,\partial x_{i_k}}(Ry)r_{i_1j_1},\dots,r_{i_kj_k}.$$

But, since $D^k\phi(x) = \mu v^{\otimes_k} = \mu(Re_1)^{\otimes_k}$, we get

$$\left(D^k\phi\right)_{i_1,\dots,i_k}(x) = \mu r_{i_1 1},\dots,r_{i_k 1}.$$

Therefore

$$\begin{aligned}\frac{\partial^k\widetilde{\phi}}{\partial y_{j_1},\dots,\partial y_{j_k}}(y) &= \sum_{i_1,\dots,i_k=1}^{n} \mu r_{i_1 1},\dots,r_{i_k 1}r_{i_1j_1},\dots,r_{i_kj_k} \\ &= \sum_{i_1,\dots,i_k=1}^{n} \mu(R^t)_{1i_1},\dots,(R^t)_{1i_k}(R)_{i_1j_1},\dots,(R)_{i_kj_k} \\ &= \mu\delta_{1j_1},\dots,\delta_{1j_k} = \mu(e_1^{\otimes_k})_{j_1,\dots,j_k},\end{aligned}$$

which means

$$D^k\widetilde{\phi}(y) = \mu(e_1)^{\otimes_k}.$$

So, applying the previous steps, we can find a function $\widetilde{u}$ and two open disjoint Lipschitz subsets $\widetilde{\Omega}_{\widetilde{A}}$ and $\widetilde{\Omega}_{\widetilde{B}}$ that solve the problem in $\widetilde{\Omega}$ for the datum $\widetilde{\phi}$ and the tensors $\widetilde{A}$ and $\widetilde{B}$ defined as follows:

$$\begin{aligned}(\widetilde{A})_{j_1,\dots,j_k} &= \sum_{i_1,\dots,i_k=1}^{n} (A)_{i_1,\dots,i_k}r_{i_1j_1},\dots,r_{i_kj_k}, \\ (\widetilde{B})_{j_1,\dots,j_k} &= \sum_{i_1,\dots,i_k=1}^{n} (B)_{i_1,\dots,i_k}r_{i_1j_1},\dots,r_{i_kj_k}.\end{aligned}$$

The function $u\colon \Omega \to \mathbb{R}$ $u\colon x \to \widetilde{u}(R^t x)$ and the sets $\Omega_A \equiv R\widetilde{\Omega}_{\widetilde{A}}$ and $\Omega_B \equiv R\widetilde{\Omega}_{\widetilde{B}}$ will satisfy the thesis of the lemma. □

4. A model case. Now we give a first existence result which holds when F depends only on the highest-order derivatives and when the boundary datum ϕ is a polynomial.

THEOREM 4.1. *Let $\Omega \subset \mathbb{R}^n$ be an open Lipschitz set. Let $F\colon ((\mathbb{R}^n)^{\otimes_k})_s \to \mathbb{R}$ be a quasi-convex function, coercive in a rank-1 direction Λ. Let $\phi\colon \overline{\Omega} \to \mathbb{R}$ be a polynomial of degree less than or equal to k such that $F(D^k\phi(x)) = F(\xi_0) \le 0$. Then there exists a function $u \in \phi + W_0^{k,\infty}(\Omega)$ such that $F(D^k u(x)) = 0$, a.e. $x \in \Omega$.*

Proof. We can assume that Ω is bounded and that $F(\xi_0) < 0$, otherwise $u = \phi$ is a solution to our problem.

For $r > 0$ we define

$$K = \left\{\eta \in ((\mathbb{R}^n)^{\otimes_k})_s\colon \eta = \xi + t\Lambda, \quad \xi \in \overline{B(\xi_0, r)}, \quad t \in \mathbb{R}\colon m|t| - q \le 0\right\}.$$

K is a convex compact set and

$$\left\{\eta \in ((\mathbb{R}^n)^{\otimes_k})_s\colon \eta = \xi + t\Lambda, \quad \xi \in \overline{B(\xi_0, r)}, \quad F(\eta) \le 0\right\} \subset K.$$

Let

$$\begin{aligned} V = \{u \in \phi + W_0^{k,\infty}(\Omega)\colon \quad & \exists \varepsilon_l \downarrow 0 \exists u_l \in P_{\varepsilon_l} \text{ such that} \\ & \|u - u_l\|_{k-1,\infty,\Omega} \le \varepsilon, \\ & D^k u_l(x) \in \operatorname{int} K, \text{ a.e. } x \in \Omega, \\ & F(D^k u_l(x)) < 0, \text{ a.e. } x \in \Omega, \\ & u_l \in u + W_0^{k,\infty}(\Omega)\}. \end{aligned}$$

Since ϕ is in V, V is nonempty and $(V, C^{k-1}(\overline{\Omega}))$ is a complete metric space. But K is bounded, hence V is bounded in $W_0^{k,\infty}(\Omega)$: Let $u \in V$ and let u_l be a sequence approximating u; since $\|D^k u_l\|_\infty \le C$ there exists a function $g \in L^\infty(\Omega, ((\mathbb{R}^n)^{\otimes_k})_s)$ such that $D^k u_l$ converges (up to a subsequence) to g in the weak*-topology of L^∞. We want to prove that $g = D^k u_l$ a.e. Let g_s be one of the components of g (s is a multi-index). Let $s = (s_1, s')$, $s_1 \in \mathbb{N}$ and let $\psi \in C_0^1(\Omega)$. Then

$$\begin{aligned} \int_\Omega \psi g_s \, dx = \lim_{l\to\infty} \int_\Omega \psi D_s u_l \, dx = \lim_{l\to\infty} - \int_\Omega \left\langle \frac{\partial \psi}{\partial x_{s_1}}, D_{s'} u_l \right\rangle dx \\ - \int_\Omega \left\langle \frac{\partial \psi}{\partial x_{s_1}}, D_{s'} u \right\rangle dx = \int_\Omega \psi D_s u \, dx, \end{aligned}$$

which implies $g(x) = D^k u(x)$, a.e. $x \in \Omega$.

Therefore u_l converges to u in the weak*topology of $W_0^{k,\infty}(\Omega)$. Let $\eta \in C_0^\infty(\Omega)$ be a nonnegative function; by the quasi-convexity of F (see Meyers [18], Fusco [13], and Guidorzi and Poggiolini [15]) we have

$$0 \ge \liminf_{l\to\infty} \int_\Omega F(D^k u_l(x))\eta(x) \, dx \ge \int_\Omega F(D^k u(x))\eta(x) \, dx,$$

which implies

$$F(D^k u(x)) \le 0, \qquad \text{a.e. } x \in \Omega$$

and therefore

$$V \subset \{u \in \phi + W_0^{k,\infty}(\Omega)\colon F(D^k u(x)) \le 0, \text{ a.e. } x \in \Omega\}.$$

For each $m \in \mathbb{N}$ let us consider the set

$$V^m = \left\{ u \in V \colon \int_\Omega F(D^k u(x)) \geq \frac{-1}{m} \right\}.$$

V^m is an open subset of V, indeed by quasi-convexity of F, $V \setminus V^m$ is closed (see again [18], [13], [15]).

We want to prove that V^m is also a dense subset of $(V, C^{k-1}(\Omega))$. Let $v \in V$; by definition there exist $\varepsilon > 0$ and v_ε such that

$$\begin{aligned}
&v_\varepsilon \in P_\varepsilon(\Omega),\\
&D^k v_\varepsilon(x) \in \operatorname{int} K, \ \text{ a.e. } x \in \Omega,\\
&F(D^k v_\varepsilon(x)) < 0, \ \text{ a.e. } x \in \Omega,\\
&v_\varepsilon \in \phi + W_0^{k,\infty}(\Omega),\\
&\|v_\varepsilon - v\|_{k-1,\infty,\Omega} < \frac{\varepsilon}{2}.
\end{aligned}$$

These mean that there exist Ω_0, Ω_j, $j \in \mathbb{N}$ open Lipschitz pairwise disjoint subsets of Ω such that

$$\begin{aligned}
&\bigcup_{j \geq 0} \overline{\Omega_j} = \overline{\Omega},\\
&|\Omega_0| \leq \varepsilon,\\
&D^k v_\varepsilon(x) = \xi_j \in \operatorname{int} K, \ \text{ a.e. } x \in \Omega,\\
&F(\xi_j) < 0 \quad \forall j \in N.
\end{aligned}$$

For each $j \in \mathbb{N}$ let us consider the application $\tau_j \colon t \in \mathbb{R} \to \xi_j + t\Lambda \in ((\mathbb{R}^n)^{\otimes_k})_s$. Since $F(\xi_j + t\Lambda) \geq m|t| - q \quad \forall t \in \mathbb{R}$ and $F(\xi_j) < 0$, there exist t_1, t_2, $t_1 < 0 < t_2$, such that

$$F(\tau_j(t_1)) = F(\tau_j(t_2)) = 0$$

and therefore, there exist $\widetilde{t_1}$, $\widetilde{t_2}$, $t_1 < \widetilde{t_1} < 0 < \widetilde{t_2} < t_2$, such that

$$F(\tau_j(\widetilde{t_1})) > -\varepsilon, \qquad F(\tau_j(\widetilde{t_2})) > -\varepsilon, \tag{4.1}$$

$$\tau_j(\widetilde{t_1}) \in \operatorname{int} K, \qquad \tau_j(\widetilde{t_2}) \in \operatorname{int} K. \tag{4.2}$$

Moreover, since $\tau_j(\widetilde{t_2}) - \tau_j(\widetilde{t_1}) = (\widetilde{t_2} - \widetilde{t_1})\Lambda$ is a rank-1 tensor, we can apply Lemma 3.1 in the open Lipschitz set Ω_j to the tensors $A_j = \tau_j(\widetilde{t_1})$ and $B_j = \tau_j(\widetilde{t_2})$ with the boundary value v_ε.

There exist $\Omega_j^1, \Omega_j^2 \subset \Omega_j$, and a function v_e^j such that

$$\begin{aligned}
&|\Omega_j \setminus (\Omega_j^1 \cup \Omega_j^2)| < \varepsilon 2^{-j},\\
&v_\varepsilon^j \in v_\varepsilon + W_0^{k,\infty}(\Omega_j),\\
&D^k v_\varepsilon^j(x) = \xi_j + \widetilde{t_1}\Lambda, \ \text{ a.e. } x \in \Omega_j^1,\\
&D^k v_\varepsilon^j(x) = \xi_j + \widetilde{t_2}\Lambda, \ \text{ a.e. } x \in \Omega_j^2,\\
&\|v_\varepsilon^j - v_\varepsilon\|_{k-1,\infty,\Omega_j} < \varepsilon 2^{-j},\\
&D^k(v_\varepsilon^j(x)) \in \operatorname{int} K, \ \text{ a.e. } x \in \Omega_j,\\
&F(D^k(v_\varepsilon^j(x))) < 0, \ \text{ a.e. } x \in \Omega_j.
\end{aligned}$$

If we define

$$u_\varepsilon(x) = \begin{cases} v_\varepsilon(x), & x \in \Omega_0, \\ v_\varepsilon^j(x), & x \in \Omega_j, \quad j \in \mathbb{N}, \end{cases}$$

we have $u_\varepsilon \in P_{2\varepsilon}(\Omega)$, $\|u_\varepsilon - v_\varepsilon\|_{k-1,\infty,\Omega} < \varepsilon$; we need to show that $u_\varepsilon \in V^m$:

$$\begin{aligned} \int_\Omega F(D^k u_\varepsilon(x))\,dx &= \int_{\Omega_0} F(D^k v_\varepsilon(x))dx \\ &\quad + \sum_{j\in\mathbb{N}} \left[\int_{\Omega_j^1 \cup \Omega_j^2} F(D^k v_\varepsilon^j(x))\,dx + \int_{\Omega_j \setminus (\Omega_j^1 \cup \Omega_j^2)} F(D^k v_\varepsilon^j(x))\,dx \right] \\ &\geq -|\Omega_0|C - \sum_{j\in\mathbb{N}} \left[\varepsilon |\Omega_j \setminus (\Omega_j^1 \cup \Omega_j^2)| - C\varepsilon 2^{-j} \right] \\ &\geq -\varepsilon\,[C + |\Omega| + C] \geq \frac{-1}{m} \end{aligned}$$

for $\varepsilon > 0$ sufficiently small. To conclude our proof we only must apply Baire's lemma: the subsets V^m are open and dense in the complete metric space V, therefore $\bigcap_{m\in\mathbb{N}} V^m$ is also dense in V. Let $u \in \bigcap_{m\in\mathbb{N}} V^m$:

$$\begin{aligned} &F(D^k u(x)) \leq 0, \ \text{ a.e. } x \in \Omega \ \text{ because } \ u \in V; \\ &\int_\Omega F(D^k u(x))\,dx \geq 0 \ \text{ because } \ u \in \bigcap_{m\in\mathbb{N}} V^m; \end{aligned} \tag{4.3}$$

so it must be

$$F(D^k u(x)) = 0, \text{ a.e. } x \in \Omega. \qquad \square$$

5. Equation with lower-order terms. In this section we prove our main theorem concerning the case of only one equation, i.e., Theorem 1.1.

LEMMA 5.1. *Let $\Omega \subset \mathbb{R}^n$ be an open Lipschitz set. Let $F\colon \Omega \times \cdots \times ((\mathbb{R}^n)^{\otimes_k})_s \to \mathbb{R}$ be a continuous function, quasi-convex and coercive in a rank-1 direction Λ with respect to the last variable. Let $\phi\colon \widetilde{\Omega} \to \mathbb{R}$ be a $C^k(\overline{\Omega})$ function such that $F(x, D^{[k-1]}\phi(x), D^k\phi(x)) < 0$ $\forall x \in \overline{\Omega}$.*

Then there exists a function $u \in \phi + W_0^{k,\infty}(\Omega)$ such that

$$F(x, D^{[k-1]}u(x), D^k u(x)) = 0, \ \textit{a.e. } x \in \Omega. \tag{5.1}$$

Proof. As in the previous lemmas we can assume that Ω is bounded. Let us consider the function

$$G(x, s, \xi) \equiv F(x, s + D^{[k-1]}\phi(x), D^k\phi(x) + \xi).$$

G is a continuous function, coercive in the rank-1 direction Λ and quasi-convex with respect to the variable ξ, and

$$G(x, 0, 0) = F(x, D^{[k-1]}\phi(x), D^k\phi(x)) < 0 \quad \forall x \in \overline{\Omega}.$$

So our problem is equivalent to the following one: find

$$\begin{cases} w \in W_0^{k,\infty}, \\ G(x, D^{[k-1]}w(x), D^k w(x)) = 0, \quad \text{a.e. } x \in \Omega. \end{cases} \tag{5.2}$$

Let $r > 0$. If $v \in W_0^{k,\infty}(\Omega)$ and $|D^k v(x)| \le r$, a.e. $x \in \Omega$, we know that $\|D^{[k-1]}v\|_\infty \le Lr$, $L = L(\mathrm{diam}(\Omega))$. We consider the coercivity condition (2.3) with $x \in \overline{\Omega}$, $|s| \le Lr$, $|\xi| \le r$:

There exist m, $q \in \mathbb{R}$, $m > 0$ such that $G(x, s, \xi + t\Lambda) \ge m|t| - q \ \forall t \in \mathbb{R}$. We define

$$K = \left\{\eta \in ((\mathbb{R}^n)^{\otimes_k})_s \colon \eta = \xi + t\Lambda, \quad |\xi| \le r, \quad t \in \mathbb{R} \colon m|t| - q \le 0\right\}.$$

K is a convex compact set and

$$\left\{\eta \in ((\mathbb{R}^n)^{\otimes_k})_s \colon \eta = \xi + t\Lambda, \quad |\xi| \le r, \quad G(x, s, \eta) \le 0 \quad \forall x \in \overline{\Omega} \quad \forall s \colon |s| \le Lr\right\} \subset K.$$

Let

$$W = \Big\{u \in W_0^{k,\infty}(\Omega) \colon \exists \varepsilon_l \downarrow 0 \exists u_l \in P_{\varepsilon_l}(\Omega) \text{ such that}$$

$$\begin{cases} \|u - u_l\|_{k-1,\infty,\Omega} \le \varepsilon_l, \\ D^k u_l(x) \in \mathrm{int}K, & \text{a.e. } x \in \Omega, \\ G(x, D^{[k-1]}u_l(x), D^k u_l(x)) < 0 & \forall x \in \Omega, \\ u_l \in W_0^{k,\infty}(\Omega). \end{cases}$$

Since $\psi \equiv 0$ is in W, W is nonempty and, as in Lemma 4.1, $(W, C^{k-1}(\overline{\Omega}))$ is a complete metric space. Moreover, since G is quasi-convex we have

$$W \subset \{u \in W_0^{k,\infty}(\Omega) \colon G(x, D^{[k-1]}u(x), D^k u(x)) \le 0, \text{ a.e. } x \in \Omega\};$$

see [18], [13], [15]. For each $m \in \mathbb{N}$ let us consider the set

$$W^m = \left\{u \in W \colon \int_\Omega G(x, D^{[k-1]}u(x), D^k u(x)) \ge \frac{-1}{m}\right\}.$$

W^m is an open subset of W; indeed, since G is quasi-convex, $W \setminus W^m$ is closed.

We want to prove that W^m is also a dense subset of $(W, C^{k-1}(\Omega))$. Let $w \in W$; by definition there exist $\varepsilon > 0$ and w_ε such that

$$\begin{aligned} &w_\varepsilon \in P_\varepsilon(\Omega), \\ &D^k w_\varepsilon(x) \in \mathrm{int}K, \ \text{ a.e. } x \in \Omega, \\ &G(x, D^{[k-1]}w_\varepsilon(x), D^k w_\varepsilon(x)) < 0, \ \text{ a.e. } x \in \Omega, \\ &w_\varepsilon \in \phi + W_0^{k,\infty}(\Omega), \\ &\|w_\varepsilon - w\|_{k-1,\infty,\Omega} < \frac{\varepsilon}{2}. \end{aligned}$$

By definition of $P_\varepsilon(\Omega)$, there exist Ω_0, Ω_j, $j \in \mathbb{N}$ open Lipschitz pairwise disjoint subsets of Ω such that

$$\begin{aligned} &\bigcup_{j \ge 0} \overline{\Omega_j} = \overline{\Omega}, \\ &|\Omega_0| \le \varepsilon, \\ &D^k w_\varepsilon(x) = \xi_j \in \ \mathrm{int}K, \ \text{ a.e. } x \in \Omega_j \quad \forall j \in \mathbb{N}, \\ &\xi_j \in \ \mathrm{int}K, \\ &G(x, D^{[k-1]}w_\varepsilon(x), \xi_j) < 0 \quad \forall x \in \Omega_j \quad \forall j \in N. \end{aligned}$$

Since G is continuous and $\overline{\Omega_j}$ is compact, there exists $\delta_j > 0$ such that $\delta_j \le \delta\ \forall j \in \mathbb{N}$ such that

$$G(x, D^{[k-1]}w_\varepsilon(x), \xi_j) < -\delta_j \quad \forall x \in \overline{\Omega_j}.$$

The functions $D^{[k-1]}v(\bullet)$ are equicontinuous for $v \in W$; hence there exist Ω_{jh}, $h = 1, \dots, H_j$, open Lipschitz pairwise disjoint subsets such that $\bigcup_{h=1}^{H_j} \overline{\Omega_{jh}} = \overline{\Omega_j}$ and

$$\begin{aligned}(5.3)\quad & |G(x_1, D^{[k-1]}v_1(x_1), \xi) - G(x_2, D^{[k-1]}v_2(x_2), \xi)| < -\delta_j \qquad \forall x_1, x_2 \in \Omega_{jh},\\ & \forall v_1, v_2 \in W^{k,\infty}(\Omega_{jh}), \quad v_1 - v_2 \in W_0^{k,\infty}(\Omega_{jh}),\\ & D^k v_1(x), D^k v_2(x) \in K,\\ & \text{a.e. } x \in \Omega_{jh}, \quad \text{and} \quad \forall \xi \in K.\end{aligned}$$

For each $h = 1, \dots, H_j$ let us fix $x_h \in \Omega_{jh}$; we have

$$(5.4)\qquad G(x_h, D^{[k-1]}w_\varepsilon(x_h), \xi_j) < -\delta_j \quad \forall h = 1, \dots, H_j.$$

We can therefore solve the following problem:

$$(5.5)\qquad \begin{cases} G(x_h, D^{[k-1]}w_\varepsilon(x_h), D^k v(x)) = -\delta_j, & \text{a.e. } x \in \Omega_{jh},\\ v \in w_\varepsilon + W_0^{k,\infty}(\Omega_{jh}). \end{cases}$$

By Lemma 4.1, in fact there exists a solution v_{jh} to problem (5.5) and v_{jh} has a sequence of approximating functions. More precisely, there exists $v_{jhl} \in P_{\varepsilon_l}(\Omega_{jh})$ such that

$$\begin{cases} \|v_{jhl} - v_{jh}\|_{k-1,\infty,\Omega} \le \varepsilon_l,\\ D^k v_{jhl}(x) \in \operatorname{int} K, & \text{a.e. } x \in \Omega,\\ v_{jhl} \in v_{jh} + W_0^{k,\infty}(\Omega_{jh}) = w_\varepsilon + W_0^{k,\infty}(\Omega_{jh}),\\ G(x_h, D^{[k-1]}w_\varepsilon(x_h), D^k v_{jhl}(x)) < -\delta_j, & \text{a.e. } x \in \Omega_{jh}. \end{cases}$$

By (5.3) we get

$$(5.6)\qquad G(x, D^{[k-1]}w_{jhl}(x), D^k v_{jhl}(x)) < -0, \text{ a.e. } x \in \Omega_{jh}.$$

We can now define the function $v \in W^m$ approximating w:

$$(5.7)\qquad v(x) = \begin{cases} w_\varepsilon(x), & x \in \overline{\Omega_0},\\ v_{jh}(x), & x \in \Omega_{jh}, \quad h = 1, \dots, H_j,\ j \in \mathbb{N}. \end{cases}$$

So, by construction, $v \in w + W_0^{k,\infty}(\Omega) = W_0^{k,\infty}(\Omega)$.

Let us compute $\int_\Omega G(x, D^{[k-1]}v(x), D^k v(x))\,dx$:

$$\begin{aligned}&\int_\Omega G(x, D^{[k-1]}v(x), D^k v(x))\,dx\\ &= \int_{\Omega_0} G(x, D^{[k-1]}w_\varepsilon(x), D^k w_\varepsilon(x))\,dx + \sum_{j\in\mathbb{N}}\sum_{h=1}^{H_j}\int_{\Omega_{jh}} G(x, D^{[k-1]}v_{jh}(x), D^k v_{jh}(x))\,dx\\ &= \int_{\Omega_0} G(x, D^{[k-1]}w_\varepsilon(x), D^k w_\varepsilon(x))\,dx + \sum_{j\in\mathbb{N}}\sum_{h=1}^{H_j}\int_{\Omega_{jh}} G(x, D^{[k-1]}w_\varepsilon(x), D^k v_{jh}(x))\,dx\\ &\quad + \sum_{j\in\mathbb{N}}\sum_{h=1}^{H_j}\int_{\Omega_{jh}} \Big[G(x, D^{[k-1]}v_{jh}(x), D^k v_{jh}(x)) - G(x, D^{[k-1]}w_\varepsilon(x), D^k v_{jh}(x))\Big]\,dx.\end{aligned}$$

We have $\int_{\Omega_0} G(x, D^{[k-1]}w_\varepsilon(x), D^k w_\varepsilon(x))\,dx \geq -C|\Omega_0|$ because $D^k w_\varepsilon(x)$ is in the compact set K a.e. $x \in \Omega_0$ and G is continuous;

$$\sum_{j\in\mathbb{N}}\sum_{h=1}^{H_j}\int_{\Omega_{jh}}\Big[G(x, D^{[k-1]}v_{jh}(x), D^k v_{jh}(x)) - G(x, D^{[k-1]}w_\varepsilon(x), D^k v_{jh}(x))\Big]\,dx$$
$$\geq \sum_{j\in\mathbb{N}} -\delta_j|\Omega_j| \geq -\delta|\Omega| \text{ by (5.3);}$$
$$\sum_{j\in\mathbb{N}}\sum_{h=1}^{H_j}\int_{\Omega_{jh}} G(x, D^{[k-1]}w_\varepsilon(x), D^k v_{jh}(x))\,dx = -\delta_j \text{ by construction.}$$

Therefore

$$\int_\Omega G(x, D^{[k-1]}v(x), D^k v(x))\,dx \geq -C\varepsilon - 2|\Omega|\delta \geq \frac{-1}{m}$$

if ε and δ are small enough. The thesis follows from Baire's lemma. □

We now shall prove our main theorem.

THEOREM 5.2 (Theorem 1.1). *Let $\Omega \subset \mathbb{R}^n$ be an open Lipschitz set. Let $F\colon \Omega \times \cdots \times ((\mathbb{R}^n)^{\otimes_k})_s \to \mathbb{R}$ be a continuous function, quasi-convex and coercive in a* rank-1 *direction Λ with respect to the last variable. Let $\phi\colon \overline{\Omega} \to \mathbb{R}$ be a $C^k(\overline{\Omega})$ function such that $F(x, D^{[k-1]}\phi(x), D^k\phi(x)) \leq 0 \quad \forall x \in \overline{\Omega}$.*

Then there exists a function $u \in \phi + W_0^{k,\infty}(\Omega)$ such that

$$F(x, D^{[k-1]}u(x), D^k u(x)) = 0, \qquad \text{a.e. } x \in \Omega. \tag{5.8}$$

Proof. As in the previous lemmas we can assume that Ω is bounded. Let us define

$$\Omega_0 \equiv \Big\{x \in \Omega\colon F(x, D^{[k-1]}\phi(x), D^k\phi(x)) = 0\Big\}.$$

Since $D^k\phi$ and F are continuous, Ω_0 is closed, hence $\Omega \setminus \Omega_0$ is open. It might not be a Lipschitz set, but $\Omega \supset \Omega_0$, hence $D^k\phi(x)$ is defined on $\partial\Omega_0$ and we can consider the following problem:

$$\begin{cases} F(x, D^{[k-1]}u(x), D^k u(x)) = 0, & \text{a.e. } x \in \Omega \setminus \Omega_0, \\ u \in \phi + W_0^{k,\infty}(\Omega_0). \end{cases} \tag{5.9}$$

The boundary datum ϕ doesn't satisfy the compatibility condition

$$F(x, D^{[k-1]}\phi(x), D^k\phi(x)) < 0 \quad \forall x \in \overline{\Omega \setminus \Omega_0}.$$

Nevertheless we can solve (5.9): For $t > 0$ let us consider the set

$$\Omega^t \equiv \Big\{x \in \Omega \setminus \Omega_0\colon F(x, D^{[k-1]}\phi(x), D^k\phi(x)) = t\Big\}.$$

We want to prove that the set

$$\big\{t < 0\colon |\Omega^t| = 0\big\}$$

is dense in $(-\infty, 0)$. Let

$$T_l \equiv \left\{t < 0\colon \frac{|\Omega \setminus \Omega_0|}{l+1} < |\Omega^t| < \frac{|\Omega \setminus \Omega_0|}{l}\right\}.$$

We have

$$\Omega \setminus \Omega_0 = \bigcup_{t<0} \Omega^t \supset \bigcup_{t\in T_l} \Omega^t$$

which implies

$$+\infty > |\Omega \setminus \Omega_0| > \sum_{t\in T_l} |\Omega^t| > \frac{\Omega \setminus \Omega_0}{l+1} \#(T_l).$$

Hence T_l must be a finite set and $\bigcup_{l\in\mathbb{N}} T_l$ is countable, therefore its complementary set $\{t<0\colon |\Omega^t| = 0\}$ is dense in $(-\infty, 0)$. In particular there exists a sequence $t_l \uparrow 0$ such that $|\Omega^{t_l}| = 0$. Let us define

$$\Omega_l \equiv \left\{ x \in \Omega \setminus \Omega_0 \colon t_l < F(x, D^{[k-1]}\phi(x), D^k\phi(x)) < t_{l+1} \right\}. \tag{5.10}$$

We can find a solution u_l to the problem

$$\begin{cases} F(x, D^{[k-1]}u(x), D^k u(x)) = 0, & \text{a.e. } x \in \Omega_l, \\ u \in \phi + W_0^{k,\infty}(\Omega_l). \end{cases} \tag{5.11}$$

Let us define

$$u(x) = \begin{cases} \phi(x), & x \in \Omega_0, \\ u_l(x), & x \in \Omega_l. \end{cases} \tag{5.12}$$

Then u is a solution to our problem. □

6. Systems of partial differential equations. We begin this section with a structure lemma whose proof can be found in [9].

PROPOSITION 6.1. *Let $E \subset ((\mathbb{R}^n)^{\otimes_k})_s$. Let us define*

$$RcoE = E$$

and, by induction,

$$\begin{aligned} R_{i+1}coE = \big\{ \xi \in ((\mathbb{R}^n)^{\otimes_k})_s \colon \xi = tA + (1-t)B, \quad t \in [0,1], \\ A, B \in \mathbb{R}_i coE \quad \operatorname{rank}\{A - B\} = 1 \big\}. \end{aligned}$$

Then

$$RcoE = \bigcup_{i\in N} R_i coE. \tag{6.1}$$

The next lemma is an extension of Lemma 3.1.

LEMMA 6.2. *Let $E \subset ((\mathbb{R}^n)^{\otimes_k})_s$ be a bounded set. Let $\Omega \subset \mathbb{R}^n$ be an open Lipschitz set. Let $\xi \in RcoE$. Let $\phi\colon \overline{\Omega} \to \mathbb{R}$ be such that $D^k\phi(x) \equiv \xi$ for every $x \in \Omega$. Then for any $\varepsilon > 0$ there exist a function $u \in \phi + W_0^{k,\infty}(\Omega)$ and an open Lipschitz set $\widetilde{\Omega} \subset \Omega$ such that*

$$u \in P_\varepsilon(\Omega), \tag{6.2}$$

$$\|u - \phi\|_{k-1,\infty,\Omega} < \varepsilon, \tag{6.3}$$

$$|\Omega \setminus \widetilde{\Omega}| < \varepsilon, \tag{6.4}$$

$$D^k u(x) \in E, \quad \text{a.e. } x \in \widetilde{\Omega}, \tag{6.5}$$

$$\operatorname{dist}(D^k u(x), RcoE) \le \varepsilon, \quad \text{a.e. } x \in \Omega. \tag{6.6}$$

Proof. The proof consists of an iteration of Lemma 3.1. Let $\xi \in \mathrm{Rco}E = \bigcup_{i\in\mathbb{N}} \mathrm{R}_i\mathrm{co}E$; then there exists $i \in \mathbb{N}$ such that $\xi \in \mathrm{R}_i\mathrm{co}E$. If $i = 0$, there is nothing to prove; we only need to take $u = \phi$. If $i = 1$, then $\xi = tA + (1-t)B$ where $A, B \in E$, $\mathrm{rank}\{A - B\} = 1$, and $t \in [0,1]$, so we only need to apply Lemma 3.1.

We shall prove Lemma 6.2 by induction on i. Let us assume $\xi \in \mathrm{R}_{i+1}\mathrm{co}E$; then $\xi = tA + (1-t)B$ where $A, B \in \mathrm{R}_i\mathrm{co}E$, $\mathrm{rank}\{A - B\} = 1$, and $t \in [0,1]$. We apply Lemma 3.1 to A and B: there exist $v \in P_\varepsilon(\Omega)$, Ω_A, $\Omega_B \subset \Omega$ open Lipschitz subsets such that

$$
\begin{aligned}
&v \in \phi + W_0^{k,\infty}(\Omega),\\
&D^k v(x) = \begin{cases} Ax \in \Omega_A,\\ Bx \in \Omega_B,\end{cases}\\
&\mathrm{dist}(D^k v(x), \mathrm{Rco}E) < \mathrm{dist}(D^k v(x), \mathrm{R}_i\mathrm{co}E) < \varepsilon, \quad \text{a.e. } x \in \Omega,\\
&\|v - \phi\|_{k-1,\infty,\Omega} < \frac{\varepsilon}{2}.
\end{aligned}
$$

Since A, $B \in \mathrm{Rco}E$, and Ω_A, Ω_B are open Lipschitz sets where v is a polynomial whose degree is less or equal than k we have

$$
\begin{aligned}
&\exists \widetilde{\Omega_A} \subset \Omega_A, \quad \exists v_A \in P_\varepsilon(\Omega_A) \text{ such that}\\
&v_A \in v + W_0^{k,\infty}(\Omega_A),\\
&D^k v_A \in E, \text{ a.e. } x \in \widetilde{\Omega_A},\\
&\mathrm{dist}(D^k v_A(x), \mathrm{Rco}E) < \varepsilon, \text{ a.e. } x \in \Omega_A,\\
&\|v - v_A\|_{k-1,\infty,\Omega_A} < \frac{\varepsilon}{2},\\
&\exists \widetilde{\Omega_B} \subset \Omega_B, \quad \exists v_B \in P_\varepsilon(\Omega_B) \text{ such that}\\
&v_B \in v + W_0^{k,\infty}(\Omega_B),\\
&D^k v_B \in E, \text{ a.e. } x \in \widetilde{\Omega_B},\\
&\mathrm{dist}(D^k v_B(x), \mathrm{Rco}E) < \varepsilon, \text{ a.e. } x \in \Omega_B,\\
&\|v - v_B\|_{k-1,\infty,\Omega_B} < \frac{\varepsilon}{2},
\end{aligned}
$$

so we just need to set

$$
\widetilde{\Omega} = \widetilde{\Omega_A} \cup \widetilde{\Omega_B};
$$

$$
u(x) = \begin{cases} v(x), & x \in \Omega \setminus (\Omega_A \cup \Omega_B),\\ v_A(x), & x \in \Omega_A,\\ v_B(x), & x \in \Omega_B. \end{cases} \qquad \square
$$

We omit the proofs of the following lemma and theorem which can be found in Dacorogna and Marcellini [10] for the case $k = 2$.

LEMMA 6.3. *Let $\Omega \subset \mathbb{R}$ be an open Lipschitz set. Let $F_i^\delta : ((\mathbb{R}^n)^{\otimes_k})_s \to \mathbb{R}$, $i = 1, \dots, N$ be quasi-convex functions, continuous with respect to the parameter $\delta \in [0, \delta_0)$, $\delta_0 > 0$ such that*

$$
\begin{aligned}
&Rco\left\{\xi \in ((\mathbb{R}^n)^{\otimes_k})_s : F_i^\delta(\xi) = 0 \quad \forall i = 1, \dots, N\right\}\\
&= \left\{\xi \in ((\mathbb{R}^n)^{\otimes_k})_s : F_i^\delta(\xi) \le 0 \quad \forall i = 1, \dots, N\right\} \quad \textit{bounded set of } ((\mathbb{R}^n)^{\otimes_k})_s, \qquad (6.7)
\end{aligned}
$$

$$
\begin{aligned}
&\left\{\xi \in ((\mathbb{R}^n)^{\otimes_k})_s : F_i^\delta(\xi) = 0 \quad \forall i = 1, \dots, N\right\}\\
&\subset \left\{\xi \in ((\mathbb{R}^n)^{\otimes_k})_s : F_i^0(\xi) < 0 \quad \forall i = 1, \dots, N\right\} \quad \forall \delta \in (0, \delta_0). \qquad (6.8)
\end{aligned}
$$

Let $\phi\colon \overline{\Omega} \to \mathbb{R}$ be a polynomial of degree less than or equal to k such that

$$F_i^0(D^k\phi(x)) \equiv F_i^0(\xi_0) < 0 \quad \forall i = 1, \dots, N. \tag{6.9}$$

Then there exists $u \in \phi + W_0^{k,\infty}(\Omega)$ such that $F_i^0(D^k u(x)) = 0$ a.e. $x \in \Omega$ $\forall i = 1, \dots, N$.

THEOREM 6.4. *Let $\Omega \subset \mathbb{R}$ be an open Lipschitz set. Let $F_i^\delta\colon \overline{\Omega} \times \cdots \times ((\mathbb{R}^n)^{\otimes_k})_s \to \mathbb{R}$, $i = 1, \dots, N$ be continuous functions, quasi-convex functions with respect to the last variable, continuous with respect to the parameter $\delta \in [0, \delta_0)$, $\delta_0 > 0$. Moreover, let us assume that for every $(x, s) \in \overline{\Omega} \times \mathbb{R} \times \cdots \times ((\mathbb{R}^n)^{\otimes_{k-1}})_s$,*

$$\begin{aligned} &Rco\left\{\xi \in ((\mathbb{R}^n)^{\otimes_k})_s \colon F_i^\delta(x, s, \xi) = 0 \quad \forall i = 1, \dots, N\right\} \\ &= \left\{\xi \in ((\mathbb{R}^n)^{\otimes_k})_s \colon F_i^\delta(x, s, \xi) \le 0 \quad \forall i = 1, \dots, N\right\} \quad \textit{bounded set of } ((\mathbb{R}^n)^{\otimes_k})_s; \end{aligned} \tag{6.10}$$

$$\begin{aligned} &\left\{\xi \in ((\mathbb{R}^n)^{\otimes_k})_s \colon F_i^\delta(x, s, \xi) = 0 \quad \forall i = 1, \dots, N\right\} \\ &\subset \left\{\xi \in ((\mathbb{R}^n)^{\otimes_k})_s \colon F_i^0(x, s, \xi) < 0 \quad \forall i = 1, \dots, N\right\} \quad \forall \delta \in (0, \delta_0). \end{aligned} \tag{6.11}$$

Let $\phi\colon \overline{\Omega} \to \mathbb{R}$ be a (piecewise $C^k(\overline{\Omega})$) function such that

$$F_i^0(x, D^{[k-1]}\phi(x), D^k\phi(x)) < 0 \quad \forall i = 1, \dots, N. \tag{6.12}$$

Then there exists $u \in \phi + W_0^{k,\infty}(\Omega)$ such that $F_i^0(x, D^{[k-1]}u(x), D^k u(x)) = 0$ a.e. $x \in \Omega$ $\forall i = 1, \dots, N$.

SPATIAL DECAY SOLUTIONS OF THE BOLTZMANN EQUATION: CONVERSE PROPERTIES OF LONG TIME LIMITING BEHAVIOR*

XUGUANG LU†

Abstract. We prove some converse properties of long time limiting behavior (along the particle paths) of a class of spatial decay solutions of the Boltzmann equation. It is shown that different initial data f_0 determine different long time limit functions $f_\infty(x,v) = \lim_{t\to\infty} f(x+tv,v,t)$, and for any given function $F(x,v)$ which belongs to a function set, there exists a solution f such that $f_\infty = F$. Existence of such spatial decay solutions are proven for the inverse power potentials with weak angular cut-off condition and for the initial data f_0 satisfying $f_0(x,v) \le C(1+|x|^2+|v|^2)^{-k}$, or $f_0(x,v) \le C(1+|x-v|^2)^{-k}$, etc. For the soft potentials, the solutions may have "locally infinite particles," i.e., $\int_{\mathbf{R}^3} f(x,v,t)dv \equiv \infty$.

Key words. Boltzmann equation, spatial decay solution, long time limit, converse property, weak angular cut-off, initial data, final value problem

1. Introduction.

In this paper we study long time limiting behavior of spatial decay solutions of the Cauchy problem for the Boltzmann equation

$$\frac{\partial}{\partial t} f + v\cdot\nabla_x f = Q(f,f) \quad \text{in } \mathbf{R}^3\times\mathbf{R}^3\times(0,\infty), \tag{B}$$

$$f|_{t=0} = f_0 \qquad \text{on} \qquad \mathbf{R}^3\times\mathbf{R}^3,$$

which describes the time evolution of the particle number density $f = f(x,v,t)$ (at time $t\in[0,\infty)$, position $x\in\mathbf{R}^3$, and velocity $v\in\mathbf{R}^3$) of a simple monoatomic gas of identical particles. $v\cdot\nabla_x$ denotes differentiation with respect to x in the direction of v, and $Q(f,f)$ is the so-called collision integral, which describes the rate of change of f due to a binary collision. Let us first recall some basic facts about (B), which are also used later. Under some assumption of angular cut-off, the collision operator Q can be written as the difference of two positive bilinear forms (i.e., the gain term and the loss term):

$$Q(f,g)(v) = Q^+(f,g)(v) - Q^-(f,g)(v), \tag{1.1}$$

where

$$Q^+(f,g)(v) = \iint_{\mathbf{R^3}\times\mathbf{S^2}} B(v-v_*,\omega) f(v') g(v'_*) d\omega dv, \tag{1.2}$$

$$Q^-(f,g)(v) = f(v)L(g)(v), \tag{1.3}$$

$$L(g)(v) = \int_{\mathbf{R}^3} A(v-v_*)g(v_*)dv_*, \quad A(z) = \int_{\mathbf{S^2}} B(z,\omega)d\omega.$$

Of course in (B), $Q(f,f)(x,v,t)$ means $Q(f(x,\cdot,t),f(x,\cdot,t))(v)$. In (1.2) and (1.3), v, v_* are the velocities of two particles before they collide, and v', v'_* are their velocities after the collision. According to the conservation laws of momentum and kinetic energy, v', v'_* and v, v_* have the relations

$$v' + v'_* = v + v_*, \quad |v'|^2 + |v'_*|^2 = |v|^2 + |v_*|^2, \tag{1.4}$$

which are equivalent to the explicit representation:

$$v' = v - \langle v - v_*, \omega\rangle\omega, \quad v'_* = v_* + \langle v - v_*, \omega\rangle\omega, \ \ \omega \in \mathbf{S}^2, \tag{1.5}$$

where $\langle\cdot,\cdot\rangle$ is the inner product in $\mathbf{R}^3$, $|x|^2 = \langle x, x\rangle$, and $\mathbf{S}^2 = \{\omega \in \mathbf{R}^3 \mid |\omega| = 1\}$. The collision kernel $B(z,\omega)$ is a nonnegative Borel function of $|z|$ and $|\langle z,\omega\rangle|$ only. For the interaction potentials of inverse power laws, $B(z,\omega)$ takes the form (see, for instance, [Ce], [T,M])

$$B(z,\omega) = b(\theta)|z|^\gamma, \qquad \theta = \arccos(|z|^{-1}|\langle z,\omega\rangle|), \quad -3 < \gamma \le 1, \tag{1.6}$$

where the nonnegative function $b(\theta)$ is at least assumed to satisfy the weak angular cut-off assumption (for defining (1.1)):

$$B_0 := \int_0^{\pi/2} b(\theta)\sin(\theta)d\theta < \infty; \tag{1.7}$$

thus $A(z) = 4\pi B_0|z|^\gamma$ is in $L^1_{loc}(\mathbf{R}^3)$. The exponent γ is related to the models of potentials of intermolecular forces, namely, the soft potentials ($-3 < \gamma < 0$), the Maxwell molecular model ($\gamma = 0$), the hard potentials ($0 < \gamma < 1$), and the hard sphere model ($\gamma = 1$, $b(\theta) = \text{const.}\cos(\theta)$). All these potentials are simultaneously contained in a general form:

$$B(z,\omega) \le b(\theta)(|z|^{\gamma_1} + |z|^{\gamma_2}), \quad -3 < \gamma_1 \le 0 \le \gamma_2 \le 1, \tag{1.8}$$

which includes the Grad cut-off condition [Gr]:

$$B(z,\omega) \le \text{const.}\cos(\theta)(|z|^{-\delta} + |z|^{1-\delta}), \quad 0 \le \delta < 1. \tag{1.9}$$

Due to the mathematical difficulties in dealing with (B), one usually considers, after integration along the particle paths, the mild form:

$$f^\sharp(x,v,t) = f_0(x,v) + \int_0^t Q(f,f)^\sharp(x,v,s)ds, \quad t \in [0,\infty), \tag{1.10}$$

where

$$f^\sharp(x,v,t) = f(x+tv,v,t), \quad Q(f,f)^\sharp(x,v,t) = Q(f,f)(x+tv,v,t), \quad \text{etc.}$$

A measurable function f is called a (global) mild solution of (B) if it is nonnegative on $[0,\infty)\times\mathbf{R}^3\times\mathbf{R}^3$ and satisfies for almost everywhere (a.e.) $(x,v) \in \mathbf{R}^3\times\mathbf{R}^3$; $Q^+(f,f)^\sharp(x,v,t)$ and $Q^-(f,f)^\sharp(x,v,t)$ are both in $L_{loc}[0,\infty)$ and (1.10) (with $f|_{t=0} = f_0$) holds $\forall\ t \in [0,\infty)$. If f is a mild solution of (B) and satisfies that $L(f)^\sharp(x,v,t) \in L^1_{loc}[0,\infty)$ for $(x,v) \in \mathbf{R}^3\times\mathbf{R}^3$ a.e., then (1.10) can also be written as the following exponential multiplier form:

$$f^\sharp(x,v,t) = f_0(x,v)\, e^{-\int_0^t L(f)^\sharp(x,v,s)ds} + \int_0^t Q^+(f,f)^\sharp(x,v,s)\, e^{-\int_s^t L(f)^\sharp(x,v,\tau)d\tau}ds. \tag{1.11}$$

Equilibrium (mild) solutions of (B) are called local Maxwellians which have the form

$$M(x,v,t) = a(x,t)\exp\{-|v-u(x,t)|^2/c(x,t)\}, \quad a(x,t) \geq 0,\ c(x,t) > 0. \tag{1.12}$$

As is well known, many results on the global existence of strong (classical), mild, and renormalized solutions of (B) have been obtained, respectively, for certain classes of initial data [I,S], [H], [B,T], [T1], [Po], [B,P,T] and for generally large L^1 initial data [D,L 1], [L1], [L2], [L3], [M,P]. In the kinetic theory of gases, after the existence of global solutions of (B) are proven, a further problem is about their long time behavior, including those along the particle paths. In the case of periodic box, i.e., the solutions $f(x,v,t)$ are periodic in each x_i with period $T_i \in (0,\infty), 1 \leq i \leq 3$, which includes the spatially homogeneous solutions, it has been proved that [A,E,P], [W] for certain classes of such solutions f, $f(x,v,t)$ always converge in $L^1(\mathbf{T}^3 \times \mathbf{R}^3)$ ($\mathbf{T}^3 = \Pi_{i=1}^3[0,T_i]$), as $t \to \infty$, to global Maxwellians $M(v) = a\exp\{-|v-u|^2/c\}$ (i.e., the coefficients in (1.12) are constants) and therefore, due to the spatial periodicity, this implies that

$$\lim_{t\to\infty} f^\sharp(x,v,t) = M(v) \quad \text{in} \quad L^1(\mathbf{T}^3 \times \mathbf{R}^3),$$

where the constant coefficients a, u, c depend only on the initial moments $\iint_{\mathbf{T}^3 \times \mathbf{R}^3} f_0(x,v)(1, v, |v|^2)dxdv$. Even for generally large L^1 initial data, a similar result (except for the uniqueness of $M(v)$) has also been obtained in [L1].

In nonperiodic cases, the conclusion on these long time behaviors may be quite different. First of all, for a class of spatial decay solutions and for generally large L^1 solutions, we must have $\lim_{t\to\infty} f(x,v,t) = 0$ in pointwise (see, for instance, [B,P,T]) and, respectively, in $L^1(\Omega \times \mathbf{R}^3)$-norm for all bounded domain $\Omega \subset \mathbf{R}^3$ [D,L 1]. Some quantitative estimates in L^1-norm on the time decay of large L^1 (or renormalized) solutions have been also established in [Pe]. On the other hand, under the Gard cut-off condition (1.9), Toscani [T1], [T2] proved that for any $p > 1/2,\ k > 3/2$, there exists a constant $C > 0$ such that if the initial datum satisfies $f_0(x,v) \leq C(1+|x|^2)^{-p}(1+|v|^2)^{-k}$ then the corresponding mild solution satisfying $f(x,v,t) \leq 2C(1+|x-tv|^2)^{-p}(1+|v|^2)^{-k}$ exists and satisfies for some function $f_\infty \geq 0$

$$\lim_{t\to\infty} \sup_{(x,v)\in\mathbf{R}^3\times\mathbf{R}^3} |f^\sharp(x,v,t) - f_\infty(x,v)| = 0$$

or equivalently, $\lim_{t\to\infty} \sup_{(x,v)\in\mathbf{R}^3\times\mathbf{R}^3} |f(x,v,t) - f_\infty(x-tv,v)| = 0$ (see also Polewczak [Po] for more strong convergence of classical solutions). Moreover, if for some constant $\varepsilon > 0$

$$f_0(x,v) \geq \varepsilon(1+|x|^2)^{-p}(1+|v|^2)^{-k} \quad \text{on} \quad \mathbf{R}^3 \times \mathbf{R}^3$$

then there exists a constant $\varepsilon' > 0$ such that (thanks to the exponential multiplier form (1.11))

$$f_\infty(x,v) \geq \varepsilon'(1+|x|^2)^{-p}(1+|v|^2)^{-k} \quad \text{on} \quad \mathbf{R}^3 \times \mathbf{R}^3.$$

This implies that $f_\infty(x-tv,v)$ cannot be any local Maxwellian because it does not decay exponentially at infinity in the velocity variable. As a consequence (for $p > 5/2,\ k > 7/2$), if T_M is the traveling Maxwellian

$$T_M(x,v) = c_1\exp(-c_2|x-\bar{x}_0|^2 - c_3|v-\bar{v}_0|^2),\ c_i > 0,$$

determined by the moments of the initial datum f_0

$$\iint_{\mathbf{R}^3\times\mathbf{R}^3} T_M(x,v)\,\varphi\,dxdv = \iint_{\mathbf{R}^3\times\mathbf{R}^3} f_0(x,v)\,\varphi\,dxdv, \quad \varphi = 1, x, v, |x|^2, |v|^2, \tag{1.13}$$

then $\inf_{t\geq 0} H(f)(t) > H(T_M)$, where H is the Boltzmann H-functional:

$$H(f)(t) = \iint_{\mathbf{R}^3\times\mathbf{R}^3} f(x,v,t)\log f(x,v,t)dxdv \quad (= H(f^\sharp)(t)).$$

Continuing this investigation, it is natural to ask which kind of initial data f_0 can imply that the long time limits $f_\infty(x,v) = \lim_{t\to\infty} f^\sharp(x,v,t)$ of the corresponding solutions satisfy that the functions $f_\infty(x-tv,v)$ are local Maxwellians? Or on the analogy of the gross determinism for long time limits in the case of periodic box, which kind of different solutions can have the same long time limit f_∞? In this paper, our main results on these questions can be roughly stated as follows: For the collision model (1.8) ($-2 < \gamma_1 \leq 0 \leq \gamma_2 \leq 1$) with the weak angular cut-off condition (1.7), and for continuous mild solutions $f, g, \ldots$ (their initial data may be different) which have upper-bounds $C\Phi$ on $\mathbf{R}^3\times\mathbf{R}^3\times[0,\infty)$ where Φ is one of the following three types of functions:

$$\Phi(x,v,t) = \left(1 + \left|\frac{x-tv-x_0}{a}\right|^2 + \left|\frac{v-v_0}{b}\right|^2\right)^{-k}, \tag{1.14}$$

(1.15)

$$\Phi(x,v,t) = \left(1 + \left|\frac{x-tv-x_0}{a}\right|^2 + \left|\frac{v-v_0}{b}\right|^2\right)^{-k} e^{-\alpha|v-v_0|^\beta}, \quad \alpha > 0, \quad 0 \leq \beta \leq 2,$$

$$\Phi(x,v,t) = \left(1 + \left|\frac{x-tv-x_0}{a} - \frac{v-v_0}{b}\right|^2\right)^{-k} \tag{1.16}$$

with constants $a > 0$, $b > 0$, $(x_0, v_0) \in \mathbf{R}^3\times\mathbf{R}^3$ and with a suitably large $k > 0$ (here the third bounds (1.16) are used only for soft potentials and Maxwell model $\gamma_1 \leq 0 = \gamma_2$), we have the following:

(1) All such solutions' long time limits f_∞ exist in pointwise; and if $f_\infty(x-tv,v)$ is a local Maxwellian M, then $f \equiv M$; if $\inf_{t\geq 0} H(f)(t) = H(T_M)$, then $f \equiv T_M(x-tv,v)$, especially, $f_0 = T_M$, where the traveling Maxwellian T_M is determined by the moment condition (1.13). Therefore, if $f_0 \neq T_M$, then $\inf_{t\geq 0} H(f)(t) > H(T_M)$.

(2) If $f_\infty = g_\infty$, then $f \equiv g$, especially, $f_0 = g_0$. That is, different initial data determine different long time limits (along the particle paths).

(3) If initial data f_0 are continuous satisfying $f_0(x,v) \leq C\Phi(x,v,0)$ with a suitable constant $C > 0$, then such continuous mild solutions exist on $\mathbf{R}^3\times\mathbf{R}^3\times[0,\infty)$.

(4) For any continuous function $F(x,v)$ satisfying $C_1\Phi(x,v,0) \leq F(x,v) \leq C_2\Phi(x,v,0)$ with suitable constants $C_2 > C_1 > 0$, there exists a continuous mild solution f such that $f_\infty = F$.

The results (1), (2), and (4) give some converse properties for long time limiting behavior (along the particle paths) of spatial decay or $L^1(\mathbf{R}^3\times\mathbf{R}^3)$ solutions, and show that there are some essential differences between spatial decay and nonspatial

decay (e.g., spatially periodic) solutions. Detailed statements and proofs of these results are given in section 3 for (1), (2) and section 4 for (3), (4), where under the weak angular cut-off condition (1.7) the collision kernel $B(z,\omega)$ is taking only the inverse power laws (1.6) ($-2<\gamma\le 1$) in order to simplify our notation and proofs (including those in section 2). As one will see, this treatment on the collision model does not influence the results (1)–(4) above for the collision model (1.8)($-2<\gamma_1\le 0\le\gamma_2\le 1$) since the collision operators $Q^{\pm}$ are linear and increasing with respect to kernels B. To avoid interrupting our proofs for the main results, we first prove several technical lemmas in section 2. These lemmas are also useful for further investigation of the Boltzmann equation.

2. Some lemmas. For any $z\in\mathbf{R}^3\setminus\{0\}$, let $\mathbf{S}^1(z)=\{\omega\in\mathbf{S}^2 \mid \omega\perp z\}$, and let $d^\perp\omega$ denote the Lebesgue measure on the circle $\mathbf{S}^1(z)$, i.e.,

$$\int_{\mathbf{S}^1(z)} g(\omega)d^\perp\omega := \int_0^{2\pi} g(\cos(\phi)\,\mathrm{i}+\sin(\phi)\,\mathrm{j})d\phi,\quad g\in C(\mathbf{S}^2),$$

where $\mathrm{i},\ \mathrm{j}\in\mathbf{S}^1(z)$, $\mathrm{i}\perp\mathrm{j}$. It is easily verified that the right-hand side of the integrals is independent of the choice of i, j. The following homogeneity is obvious and will be often used in this section:

$$\mathbf{S}^1(-z)=\mathbf{S}^1(z),\quad \mathbf{S}^1(\lambda z)=\mathbf{S}^1(z),\quad z\in\mathbf{R}\setminus\{0\},\quad \lambda>0. \tag{2.1}$$

LEMMA 2.1. *Let $G\in C(\mathbf{S}^2\times\mathbf{S}^2), 0\le F\in C(\mathbf{R}^3\times\mathbf{R}^3), 0\le f\in C(\mathbf{R}^3)$, and let $\rho\ge 0$ be measurable on $(0,\infty)$. Then*

$$\int_{\mathbf{S}^2}\left[\int_{\mathbf{S}^1(\sigma)} G(\sigma,\omega)d^\perp\omega\right]d\sigma=\int_{\mathbf{S}^2}\left[\int_{\mathbf{S}^1(\omega)} G(\sigma,\omega)d^\perp\sigma\right]d\omega, \tag{2.2}$$

$$\int_{\mathbf{R^3}}\rho(|z|)\left[\int_{\mathbf{S}^1(z)} F(z,|z|\omega)d^\perp\omega\right]dz=\int_{\mathbf{R^3}}\rho(|z|)\left[\int_{\mathbf{S}^1(z)} F(|z|\omega,z)d^\perp\omega\right]dz, \tag{2.3}$$

$$\int_{\mathbf{R^3}}\rho(|z|)\left[\int_{\mathbf{S}^1(z)} f(|z|\omega)d^\perp\omega\right]dz=2\pi\int_{\mathbf{R^3}}\rho(|z|)f(z)dz. \tag{2.4}$$

Proof. Choose $\delta\in C(\mathbf{R}), \delta\ge 0$ satisfying $\mathrm{supp}\delta\subset[-1,1]$, $\int_{-1}^1\delta(t)dt=1$. Let $\delta_n(t)=n\delta(nt)$. Then, by the Fubini theorem, we have

$$\int_{\mathbf{S}^2}\left[\int_{\mathbf{S}^2} G(\sigma,\omega)\delta_n(\langle\sigma,\omega\rangle)d\omega\right]d\sigma=\int_{\mathbf{S}^2}\left[\int_{\mathbf{S}^2} G(\sigma,\omega)\delta_n(\langle\sigma,\omega\rangle)d\sigma\right]d\omega.$$

On the other hand, $\forall\ \sigma\in\mathbf{S}^2$, we compute

$$\int_{\mathbf{S^2}} G(\sigma,\omega)\delta_n(\langle\sigma,\omega\rangle)d\omega=\int_0^\pi \delta_n(\cos(\theta))\sin(\theta)\int_{\mathbf{S}^1(\sigma)} G(\sigma\,,\cos(\theta)\sigma+\sin(\theta)\omega)d^\perp\omega\,d\theta$$

$$=\int_{-1}^1\delta(t)\int_{\mathbf{S}^1(\sigma)} G(\,\sigma\,,\,(t/n)\sigma+\sqrt{1-(t/n)^2}\ \,\omega\,)d^\perp\omega\,dt\to\int_{\mathbf{S}^1(\sigma)} G(\sigma,\omega)d^\perp\omega,\quad n\to\infty.$$

Similarly,

$$\lim_{n\to\infty}\int_{\mathbf{S}^2} G(\sigma,\omega)\delta_n(\langle\sigma,\omega\rangle)d\sigma=\int_{\mathbf{S}^1(\omega)} G(\sigma,\omega)d^\perp\sigma\quad\forall\ \omega\in\mathbf{S}^2.$$

Therefore (2.2) follows from the Lebesgue dominated convergence theorem. Equation (2.3) is easily proved by first using spherical coordinate transform and the Fubini–Tonelli theorem with the two integrals, and then applying (2.2) to their inner integrals of angular variables. Equation (2.4) is a special case of (2.3). ∎

LEMMA 2.2. *Let $B(z,\omega)=\bar{B}(|z|,|z|^{-1}|\langle z,\omega\rangle|)$ be a collision kernel. Then for any nonnegative function $F\in C(\mathbf{R}^3\times\mathbf{R}^3)$,*

(2.5)
$$\iint_{\mathbf{R}^3\times\mathbf{S}^2} B(v-v_*,\omega)F(v',v'_*)d\omega\,dv_*$$

$$=2\int_0^{\pi/2}\sin(\theta)\int_{\mathbf{R}^3}\bar{B}(|z|,\cos(\theta))\left[\int_{\mathbf{S}^1(z)}F(v-\cos(\theta)z,v-\sin(\theta)|z|\omega)d^{\perp}\omega\right]dz\,d\theta$$

and $\forall\ \theta\in(0,\pi/2), v\in\mathbf{R}^3$,

(2.6)
$$\int_{\mathbf{R}^3}\bar{B}(|z|,\cos(\theta))\left[\int_{\mathbf{S}^1(z)}F(v-\cos(\theta)z\,,\,v-\sin(\theta)|z|\omega)d^{\perp}\omega\right]dz$$
$$=\int_{\mathbf{R}^3}\bar{B}(|z|,\cos(\theta))\left[\int_{\mathbf{S}^1(z)}F(v-\cos(\theta)|z|\omega\,,\,v-\sin(\theta)z)d^{\perp}\omega\right]dz.$$

Furthermore, if $B(z,\omega)=b(\theta)|z|^{\gamma}$ and $f,\ g\in C(\mathbf{R}^3)$ are nonnegative, then

$$Q^+(f,g)(v)=2\int_0^{\pi/2}b(\theta)\sin(\theta)I(f,g)(\theta,v)d\theta \tag{2.7}$$

and

$$I(f,g)(\theta,v)\equiv I(g,f)(\pi/2-\theta,v),\qquad \theta\in[0,\pi/2],\quad v\in\mathbf{R}^3, \tag{2.8}$$

where

$$I(f,g)(\theta,v)=\int_{\mathbf{R}^3}|z|^{\gamma}f(v-\cos(\theta)z)\left[\int_{\mathbf{S}^1(z)}g(v-\sin(\theta)|z|\omega)d^{\perp}\omega\right]dz. \tag{2.9}$$

Proof. Let $Q^+(F)(v)$ be the left-hand side of (2.5). By (1.5) and the spherical coordinate transform we have

$$Q^+(F)(v)=\int_0^{\infty}\int_{\mathbf{S}^2}\int_{\mathbf{S}^2}r^2\bar{B}(r,|\langle\sigma,\omega\rangle|)F(v-\langle\sigma,\omega\rangle r\omega\,,\,v-r\sigma+\langle\sigma,\omega\rangle r\omega)d\omega\,d\sigma\,dr$$
$$=\int_{\mathbf{R}^3}\left[\int_{\mathbf{S}^2}\bar{B}\left(|z|\left|\left\langle\sigma,\frac{z}{|z|}\right\rangle\right|\right)F\left(v-\left\langle\sigma,\frac{z}{|z|}\right\rangle z\,,\,v-|z|\sigma+\left\langle\sigma,\frac{z}{|z|}\right\rangle z\right)d\sigma\right]dz$$
$$=\int_{\mathbf{R}^3}\int_0^{\pi}\bar{B}(|z|,|\cos(\theta)|)\sin(\theta)\left[\int_{\mathbf{S}^1(z)}F(v-\cos(\theta)z\,,\,v-\sin(\theta)|z|\omega)d^{\perp}\omega\right]d\theta\,dz$$

=the right-hand side of (2.5),

where the factor 2 in (2.5) is due to $\mathbf{S}^1(-z)=\mathbf{S}^1(z)$. Equations (2.6) and (2.8) follow from Lemma 2.1. Equation (2.7) is a special case of (2.5). ∎

The "reciprocity" relation (2.8) and the formula (2.4) are important for the following estimation of gain term (Lemma 2.3) because they allow us to estimate (2.8) alone, so that the angular function $b(\theta)$ is needed only to satisfy the weak angular cut-off (1.7). In this sense, the application of (2.7)–(2.9) and (2.4) are more convenient than those of the Carleman representation of gain term [Ca]; see also [Gu].

LEMMA 2.3. *Let $B(z,\omega)$ satisfy* (1.6), (1.7), *and let $k > (3+\gamma)/2$. Then there exist positive constants $C^{\pm} = C^{\pm}(B_0,\gamma,k) < \infty$ depending only on B_0,γ, and k such that if*

$$\Phi(v) = (a + b|v-u|^2)^{-k}, \qquad a > 0,\ b > 0,\ u \in \mathbf{R},^3$$

then

$$\frac{Q^{\pm}(\Phi,\Phi)(v)}{\Phi(v)} \le C^{\pm}\left(\frac{1}{a}\right)^{k-(3+\nu)/2}\left(\frac{1}{b}\right)^{(3+\gamma)/2}(a+b|v-u|^2)^{\mu/2}, \quad v \in \mathbf{R}^3, \tag{2.10}$$

where $\mu = \max\{\gamma,0\}$, $\nu = \min\{\gamma,0\}$.

Proof. Let $\hat{\Phi}(v) = (1+|v|^2)^{-k}$. Then using, for instance, (2.7), (2.9), and (2.1) with the change of integration variable z we have

$$\frac{Q^{\pm}(\Phi,\Phi)(v)}{\Phi(v)(a+b|v-u|^2)^{\mu/2}} = \left(\frac{1}{a}\right)^{k-(3+\nu)/2}\left(\frac{1}{b}\right)^{(3+\gamma)/2}\frac{Q^{\pm}(\hat{\Phi},\hat{\Phi})(w)}{\hat{\Phi}(w)(1+|w|^2)^{\mu/2}},$$

where $w = \sqrt{\frac{b}{a}}\,(v-u)$. Thus the estimate (2.10) is equivalent to its standard case, i.e., $a = b = 1$ and $u = 0$, so that in the following we can suppose that $\Phi(v) = (1+|v|^2)^{-k}$. Since

$$\frac{Q^{-}(\Phi,\Phi)(v)}{\Phi(v)} = L(\Phi)(v) = 4\pi B_0 \int_{\mathbf{R}^3} |z|^{\gamma}\,\Phi(v-z)dz$$

and, by Lemma 2.2,

$$Q^{+}(\Phi,\Phi)(v) \le 2B_0 \sup_{\theta\in[0,\pi/4]} I(\Phi,\Phi)(\theta,v),$$

we see that to prove the standard case of (2.10) it suffices to prove that there exists a positive constant $C = C(\gamma,k) < \infty$ such that

$$\int_{\mathbf{R}^3} |z|^{\gamma}\,\Phi(v-z)dz \le C(1+|v|^2)^{\mu/2}, \tag{2.11}$$

$$\sup_{\theta\in[0,\pi/4]} I(\Phi,\Phi)(\theta,v) \le C\Phi(v)(1+|v|^2)^{\mu/2}. \tag{2.12}$$

In the following, the same C always denotes different finite constants which depend only on γ and k. If $\gamma \ge 0$, then $\mu = \gamma$ and $|z|^{\gamma} \le (1+|v-z|^2)^{\gamma/2}(1+|v|^2)^{\gamma/2}$ which implies (2.11); if $-3 < \gamma < 0$, then $\mu = 0$ and

$$\int_{\mathbf{R}^3} |z|^{\gamma}\Phi(v-z)dz = \int_{|z|\le|v-z|} |z|^{\gamma}\Phi(v-z)dz + \int_{|z|>|v-z|} |z|^{\gamma}\Phi(v-z)dz$$
$$\le \int_{\mathbf{R}^3} |z|^{\gamma}\Phi(z)dz + \int_{\mathbf{R}^3} |v-z|^{\gamma}\Phi(v-z)dz = 8\pi\int_0^{\infty} r^{2+\gamma}(1+r^2)^{-k}dr < \infty;$$

(2.11) still holds. For any $z \in \mathbf{R}^3 \setminus \{0\}$ and any $\omega \in \mathbf{S}^1(z)$, we have, since $\omega \perp z$,

$$|z|^2 = |\cos(\theta)z - \sin(\theta)|z|\omega\ |^2 \le 2|v - \cos(\theta)z|^2 + 2|v - \sin(\theta)|z|\omega\ |^2, \tag{2.13}$$

$$|v - \cos(\theta)z|^2 + |v - \sin(\theta)|z|\omega\ |^2 = |v|^2 + |v - \cos(\theta)z - \sin(\theta)|z|\omega\ |^2 \ge |v|^2. \tag{2.14}$$

Using (2.13) we get

$$\begin{aligned}&\Phi(v - \cos(\theta)z)\Phi(v - \sin(\theta)|z|\omega)\\ &\le (1 + |v - \cos(\theta)z|^2 + |v - \sin(\theta)|z|\omega|^2)^{-k} \le \Phi\left(\frac{z}{\sqrt{2}}\right)\end{aligned}$$

which together with (2.9) implies that $I(\Phi, \Phi)$ is bounded:

$$I(\Phi, \Phi)(\theta, v) \le 2\pi \int_{\mathbf{R}^3} |z|^\gamma \Phi\left(\frac{z}{\sqrt{2}}\right) dz \le C.$$

Thus (2.12) holds for $|v| \le 1$. In the following we suppose that $|v| > 1$, and consider two cases for large and small θ in $[0, \pi/4]$.

Case 1. $\arctan(1/4) \le \theta \le \pi/4$. By (2.14) we have

$$\Phi(v - \cos(\theta)z)\Phi(v - \sin(\theta)|z|\omega) \le \Phi\left(\frac{v}{\sqrt{2}}\right)[\Phi(v - \cos(\theta)z) + \Phi(v - \sin(\theta)|z|\omega)].$$

Then, applying Lemma 2.1 and (2.4) we obtain

$$\begin{aligned}&I(\Phi, \Phi)(\theta, v) \le \Phi\left(\frac{v}{\sqrt{2}}\right)\\ &\times\left[\int_{\mathbf{R}^3} |z|^\gamma \int_{\mathbf{S}^1(z)} \Phi(v - \cos(\theta)z) d^\perp\omega dz + \int_{\mathbf{R}^3} |z|^\gamma \int_{\mathbf{S}^1(z)} \Phi(v - \sin(\theta)|z|\omega) d^\perp\omega dz\right]\\ &= 2\pi\, \Phi\left(\frac{v}{\sqrt{2}}\right)\left[\int_{\mathbf{R}^3} |z|^\gamma \Phi(v - \cos(\theta)z) dz + \int_{\mathbf{R}^3} |z|^\gamma \Phi(v - \sin(\theta)z) dz\right]\\ &= \pi\, \Phi\left(\frac{v}{\sqrt{2}}\right)\left[\left(\frac{1}{\cos(\theta)}\right)^{3+\gamma} + \left(\frac{1}{\sin(\theta)}\right)^{3+\gamma}\right] \int_{\mathbf{R}^3} |z|^\gamma \Phi(v - z) dz \le C\Phi(v)(1 + |v|^2)^{\mu/2},\end{aligned}$$

where the last inequality is due to (2.11) and also due to the fact that $\Phi(\frac{v}{\sqrt{2}}) \le C\Phi(v)$.

Case 2. $0 \le \theta \le \arctan(1/4)$. We have, by homogeneity (2.1),

$$\begin{aligned}I(\Phi, \Phi)(\theta, v) &= \left(\frac{1}{\cos(\theta)}\right)^{3+\gamma} \int_{\mathbf{R}^3} |z|^\gamma \Phi(v - z) \int_{\mathbf{S}^1(z)} \Phi(v - \tan(\theta)|z|\omega) d^\perp\omega\, dz\\ &\le C[I_1(\Phi, \Phi)(\theta, v) + I_2(\Phi, \Phi)(\theta, v)],\end{aligned}$$

where

$$\begin{aligned}I_1(\Phi, \Phi)(\theta, v) &= \int_{\tan(\theta)|z| \le \frac{1}{2}|v|} |z|^\gamma \Phi(v - z) \int_{\mathbf{S}^1(z)} \Phi(v - \tan(\theta)|z|\omega) d^\perp\omega\, dz,\\ I_2(\Phi, \Phi)(\theta, v) &= \int_{\tan(\theta)|z| > \frac{1}{2}|v|} |z|^\gamma \Phi(v - z) \int_{\mathbf{S}^1(z)} \Phi(v - \tan(\theta)|z|\omega) d^\perp\omega\, dz.\end{aligned}$$

By (2.11) we have

$$I_1(\Phi, \Phi)(\theta, v) \le 2\pi\, \Phi(\frac{v}{2}) \int_{\tan(\theta)|z| \le \frac{1}{2}|v|} |z|^\gamma \Phi(v - z) dz \le C\Phi(v)(1 + |v|^2)^{\mu/2}.$$

For $I_2(\Phi,\Phi)(\theta,v)$, since $\tan(\theta)|z| > \frac{1}{2}|v|$ implies $|v-z| \geq (\frac{1}{2\tan(\theta)} - 1)|v| \geq \frac{|v|}{4\tan(\theta)}$, it follows from (2.4) and (2.11) that

$$\begin{aligned} I_2(\Phi,\Phi)(\theta,v) &\leq \Phi\left(\frac{v}{4\tan(\theta)}\right)\int_{\mathbf{R}^3}|z|^\gamma \int_{\mathbf{S}^1(z)} \Phi(v-\tan(\theta)|z|\omega)d^\perp\omega\, dz \\ &= \Phi\left(\frac{v}{4\tan(\theta)}\right) 2\pi \left(\frac{1}{\tan(\theta)}\right)^{3+\gamma}\int_{\mathbf{R}^3}|z|^\gamma \Phi(v-z)dz \\ &\leq C\,\Phi\left(\frac{v}{4\tan(\theta)}\right)\left(\frac{1}{\tan(\theta)}\right)^{3+\gamma}(1+|v|^2)^{\mu/2} \\ &\leq C\left(\frac{1}{|v|}\right)^{2k}(\tan(\theta))^{2k-3-\gamma}(1+|v|^2)^{\mu/2} \leq C\,\Phi(v)(1+|v|^2)^{\mu/2}. \end{aligned}$$

Therefore, combining these estimates then leads to (2.12). ∎

LEMMA 2.4. *Let $h \in L^1[0,\infty)$ be positive and decreasing on $[0,\infty)$. Then $\forall$ $(x,v) \in \mathbf{R}^3 \times \mathbf{R}^3$*

$$\int_0^\infty h\left(\frac{|x+tv|}{\sqrt{1+t^2}}\right)\frac{dt}{1+t^2} \leq C\,(1+|x|^2+|v|^2)^{-1/2}, \tag{2.15}$$

where $C = \max\{\frac{\sqrt{2}\,\pi}{2}h(0), \sqrt{2}\,\pi\|h\|_{L^1[0,\infty)}\}$.

Proof. Denote by $I_{x,v}$ the left-hand side of (2.15), and let $\rho = \sqrt{|x|^2+|v|^2}$. Since $I_{x,v} \leq \frac{\pi}{2}h(0)$, (2.15) holds for $\rho \leq 1$. Suppose that $\rho > 1$. Let $\sin(\alpha) = |x|/\rho$ with $\alpha \in [0,\pi/2]$. Then

$$\begin{aligned} I_{x,v} &= \int_0^{\pi/2} h(|\cos(\theta)x + \sin(\theta)v|)d\theta \\ &\leq \int_0^{\pi/2} h(|\cos(\theta)|x| - \sin(\theta)|v|\,|)d\theta = \int_0^{\pi/2} h(\rho|\sin(\theta-\alpha)|)d\theta \\ &\leq \int_{-\pi/2}^{\pi/2} h\left(\frac{2}{\pi}\rho|\theta|\right)d\theta \leq \frac{\pi}{\rho}\|h\|_{L^1[0,\infty)} \leq \sqrt{2}\,\pi\|h\|_{L^1[0,\infty)}(1+\rho^2)^{-1/2}. \end{aligned}$$ ∎

Introducing polynomials

$$P(x,v,t) = 1 + \left|\frac{x-tv-x_0}{a}\right|^2 + \left|\frac{v-v_0}{b}\right|^2, \tag{2.16}$$

$$\widetilde{P}(x,v,t) = 1 + \left|\frac{x-tv-x_0}{a} - \frac{v-v_0}{b}\right|^2 \tag{2.17}$$

the functions (1.14)–(1.16) can then be written, respectively,

$$\Phi = P^{-k}, \quad P^{-k}e^{-\alpha|v-v_0|^\beta}, \quad \widetilde{P}^{-k}.$$

LEMMA 2.5. *Assume that $B(z,\omega)$ satisfy* (1.6), (1.7) *with $-2 < \gamma \leq 1$. Let $k > (3+\gamma)/2$, $\mu = \max\{\gamma,0\}$, $\nu = \min\{\gamma,0\}$, and let Φ be given by* (1.14) *or* (1.15)*, or given by* (1.16) *for $\gamma \leq 0$. Then*

(i)

$$C_p^\pm := \sup_{(x,v)\in\mathbf{R}^3\times\mathbf{R}^3} \frac{1}{\Phi(x,v,0)}\left[\int_0^\infty (1+t^2)^{\frac{3+\gamma}{2}(p-1)}(Q^\pm(\Phi,\Phi)^\sharp(x,v,t))^p dt\right]^{1/p} < \infty, \tag{2.18}$$

where $p \ge 1$ is arbitrary for $\gamma \le 0$, and $p = 1/\gamma$ for $0 < \gamma \le 1$.

$$\sup_{(x,v)\in\mathbf{R}^3\times\mathbf{R}^3} \frac{1}{\Phi(x,v,0)} \int_0^\infty Q^{\pm}(\Phi,\Phi)^{\sharp}(x,v,t)dt \le D^{\pm}\, a\, b^{2+\gamma}. \tag{2.19}$$

(iii) *There exists a positive constant $C = C(B_0, \gamma, k, a, b) < \infty$ such that*

$$\sup_{(x,v)\in\mathbf{R}^3\times\mathbf{R}^3} \frac{1}{\Phi(x,v,0)} \int_t^\infty Q^{\pm}(\Phi,\Phi)^{\sharp}(x,v,s)ds \le C\,(1+t)^{-2-\nu}, \quad t \ge 0, \tag{2.20}$$

$$Q^{\pm}(\Phi,\Phi)(x,v,t) \le C\,(1+t^2)^{-(3+\gamma)/2}\,\Phi(x,v,t)(P(x,v,t))^{\mu/2}, \tag{2.21}$$

$$L(\Phi)(x,v,t) \le C\,(1+t^2)^{-(3+\nu)/2}(1+|v-v_0|^{\mu}). \tag{2.22}$$

(iv) *If $f, g \in C(\mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty))$ are nonnegative and satisfy $f, g \le C\Phi$ for some constant $C < \infty$, then the functions*

(2.23)

$$Q^{+}(f,g), \quad L(f), \quad \int_0^t Q^{\pm}(f,g)^{\sharp}(x-tv,v,s)ds, \quad \int_t^\infty Q^{\pm}(f,g)^{\sharp}(x-tv,v,s)ds$$

are all continuous on $\mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty)$.

Proof. (i)–(iii). Since $0 \le \beta \le 2$, we have, by the second equation (1.4),

$$|v'-v_0|^{\beta}+|v'_*-v_0|^{\beta} \ge (|v'-v_0|^2+|v'_*-v_0|^2)^{\beta/2} = (|v-v_0|^2+|v_*-v_0|^2)^{\beta/2} \ge |v-v_0|^{\beta}.$$

This implies that if Φ is given by (1.14) and Ψ is given by (1.15) then

$$\Psi(x,v',t)\Psi(x,v'_*,t) \le e^{-\alpha|v-v_0|^{\beta}}\,\Phi(x,v',t)\Phi(x,v'_*,t)$$

which together with $\Phi^{\sharp}(x,v,t) \equiv \Phi(x,v,0)$, $\Psi^{\sharp}(x,v,t) \equiv \Psi(x,v,0)$ imply

$$\frac{Q^{\pm}(\Psi,\Psi)^{\sharp}(x,v,t)}{\Psi(x,v,0)} \le \frac{Q^{\pm}(\Phi,\Phi)^{\sharp}(x,v,t)}{\Phi(x,v,0)}.$$

Therefore we need only to prove (2.18)–(2.22) for functions (1.14) and (1.16). Suppose first that Φ is given by (1.14), i.e., $\Phi = (P)^{-k}$, where P is defined by (2.16). Then using the identity

$$P(x,v,t) \equiv 1 + \frac{|x-tv_0-x_0|^2}{a^2+b^2\,t^2} + \left(\frac{t^2}{a^2}+\frac{1}{b^2}\right)|v-u(x,t)|^2, \tag{2.24}$$

where $u(x,t) = (a^2+b^2t^2)^{-1}(b^2t(x-x_0)+a^2v_0)$, and using Lemma 2.3 we have

$$\begin{aligned} &Q^{\pm}(\Phi,\Phi)(x,v,t)/\Phi(x,v,t) = Q^{\pm}(\Phi(x,\cdot,t),\Phi(x,\cdot,t))(v)/\Phi(x,v,t) \\ &\le C^{\pm}\left(1+\frac{|x-tv_0-x_0|^2}{a^2+b^2\,t^2}\right)^{-k+(3+\nu)/2}\left(\frac{t^2}{a^2}+\frac{1}{b^2}\right)^{-(3+\gamma)/2}(P(x,v,t))^{\mu/2}, \end{aligned} \tag{2.25}$$

where $C^{\pm} = C^{\pm}(B_0,\gamma,k)$ are the constants in Lemma 2.3. Obviously, (2.25) implies that (2.18)–(2.20) and (2.22) hold for $\gamma \le 0$ (i.e., for $\mu = 0, \nu = \gamma$), and (2.21) holds $\forall\ -2 < \gamma \le 1$. Now let $\gamma > 0$. Then $\mu = \gamma,\ \nu = 0$, and $p = 1/\gamma$. Let

$$h(r) = \left(\frac{1}{1+r^2}\right)^{\frac{k-3/2}{\gamma}}, \quad \widetilde{x} = \frac{x-x_0}{a}, \quad \widetilde{v} = \frac{v-v_0}{b}.$$

Then $h \in L^1[0,\infty)$ since $k > (3+\gamma)/2$ and so by (2.25) and Lemma 2.3 we have (with different constants $C_{\gamma,k,a,b}$)

$$\begin{aligned}
&\frac{1}{\Phi(x,v,0)}\left[\int_0^\infty (1+t^2)^{\frac{3+\gamma}{2}(\frac{1}{\gamma}-1)}(Q^{\pm}(\Phi,\Phi)^\sharp(x,v,t)\,)^{\frac{1}{\gamma}}\,dt\right]^\gamma\\
&\le C_{\gamma,k,a,b}\left[\int_0^\infty h\Big(\frac{|x-x_0+t(v-v_0)|}{\sqrt{a^2+b^2\,t^2}}\Big)\Big(\frac{t^2}{a^2}+\frac{1}{b^2}\Big)^{-(3+\gamma)/2}dt\right]^\gamma (P(x,v,0))^{\gamma/2}\\
&= C_{\gamma,k,a,b}\left[\int_0^\infty h\Big(\frac{|\widetilde{x}+t\widetilde{v}|}{\sqrt{1+t^2}}\Big)\Big(\frac{1}{1+t^2}\Big)^{(3+\gamma)/2}dt\right]^\gamma (P(x,v,0))^{\gamma/2}\\
&\le C_{\gamma,k,a,b}\left[\int_0^\infty h\Big(\frac{|\widetilde{x}+t\widetilde{v}|}{\sqrt{1+t^2}}\Big)\frac{dt}{1+t^2}\right]^\gamma (P(x,v,0))^{\gamma/2} \le C_{\gamma,k,a,b}.
\end{aligned}$$

Similarly, for $0<\gamma<1$ we have by the Hölder inequality $\forall\ t\ge 0$

$$\begin{aligned}
&\frac{1}{\Phi(x,v,0)}\int_t^\infty Q^{\pm}(\Phi,\Phi)^\sharp(x,v,s)ds\\
&\le C^{\pm}\,a\,b^{2+\gamma}\int_{\frac{b}{a}t}^\infty \left(h\Big(\frac{|\widetilde{x}+s\widetilde{v}|}{\sqrt{1+s^2}}\Big)\right)^\gamma\Big(\frac{1}{1+s^2}\Big)^{(3+\gamma)/2}ds\,(P(x,v,0))^{\gamma/2}\\
&\le C^{\pm}\,a\,b^{2+\gamma}\left[\int_{\frac{b}{a}t}^\infty h\Big(\frac{|\widetilde{x}+s\widetilde{v}|}{\sqrt{1+s^2}}\Big)\frac{ds}{1+s^2}\right]^\gamma\left[\int_{\frac{b}{a}t}^\infty\Big(\frac{1}{1+s^2}\Big)^{\frac{3-\gamma}{2(1-\gamma)}}ds\right]^{1-\gamma}(P(x,v,0))^{\gamma/2}\\
&\le C^{\pm}\,a\,b^{2+\gamma}\,C_{\gamma,k}\left[\int_{\frac{b}{a}t}^\infty\Big(\frac{1}{1+s^2}\Big)^{\frac{3-\gamma}{2(1-\gamma)}}ds\right]^{1-\gamma}\le C^{\pm}_{\gamma,k}a\,b^{2+\gamma}\,\Big(1+\frac{b}{a}t\Big)^{-2},
\end{aligned}$$

and for $\gamma=1$ using inequality $(1+s^2)^{-2}\le(1+s^2)^{-1}(1+(\frac{b}{a}t)^2)^{-1}\quad(s\ge\frac{b}{a}t)$ we still have

$$\frac{1}{\Phi(x,v,0)}\int_t^\infty Q^{\pm}(\Phi,\Phi)^\sharp(x,v,s)ds\le C^{\pm}_{1,k}a\,b^3\,\left(1+\Big(\frac{b}{a}t\Big)^2\right)^{-1},t\ge 0.$$

Next, by inequality $A(v-v_*)=4\pi B_0|v-v_*|^\gamma\le C\,(1+|v-v_0|^\gamma)(P(t,x,v_*))^{\gamma/2}$ and by identity (2.24) we have

$$\begin{aligned}
L(\Phi)(x,v,t)&\le C\,(1+|v-v_0|^\gamma)\Big(\frac{t^2}{a^2}+\frac{1}{b^2}\Big)^{-3/2}\int_{\mathbf{R}^3}(1+|z|^2)^{-k+\gamma/2}dz\\
&\le C(1+t^2)^{-3/2}(1+|v-v_0|^\gamma).
\end{aligned}$$

Therefore (2.18)–(2.20) and (2.22) also hold for $\gamma>0$. Now suppose that Φ is given by (1.16), i.e., $\Phi=\widetilde{P}^{-k}$, where $\widetilde{P}$ is defined by (2.17). This case corresponds to $\gamma\le 0$ by our assumption. Then starting from the identity

$$\widetilde{P}(x,v,t)\equiv 1+\Big(\frac{t}{a}+\frac{1}{b}\Big)^2|v-u(x,t)|^2,$$

where $u(x,t)=(a+bt)^{-1}(b(x-x_0)+av_0)$, and using only Lemma 2.3 we easily obtain (2.18)–(2.22).

(iv) Let $(x,v,t),(x_n,v_n,t_n)\in \mathbf{R}^3\times\mathbf{R}^3\times[0,\infty)$ and $(x_n,v_n,t_n)\to(x,v,t)$ $(n\to\infty)$. By Lemma 2.2 we have

$$Q^+(f,g)(x_n,v_n,t_n)=2\int_0^{\pi/2}b(\theta)\sin(\theta)\int_{\mathbf{R}^3}|z|^\gamma F_n(\theta,z)dz\,d\theta,$$

where $F_n(\theta,z)=F(\theta,z,x_n,v_n,t_n)$,

$$F(\theta,z,x,v,t)=f(x,v-\cos(\theta)z,t)\int_{\mathbf{S}^1(z)}g(x,v-\sin(\theta)|z|\omega,t)d^\perp\omega,\quad z\neq 0.$$

The continuity of f,g implies that $\lim_{n\to\infty}F_n(\theta,z)=F(\theta,z,x,v,t)\ \forall\ \theta\in[0,\pi/2],z\in\mathbf{R}^3\setminus\{0\}$. We may assume that $|x_n-x|+|v_n-v|\le 1$. Then by definition of Φ we have for some $0<C_{x,v}<\infty,\Phi(x_n,v_n-z,t_n)\le C_{x,v}\hat\Phi(z)$, where $\hat\Phi(z)=(1+|z|^2)^{-k}$. Since $0\le f,g\le C\Phi$, this gives

$$F_n(\theta,z)\le C^2C_{x,v}^2\,\hat\Phi(\cos(\theta)z)\int_{\mathbf{S}^1(z)}\hat\Phi(\sin(\theta)|z|\omega)d^\perp\omega.$$

Since the integral $Q^+(\hat\Phi,\hat\Phi)(0)<\infty$, it follows from the dominated convergence theorem that $\lim_{n\to\infty}Q^+(f,g)(x_n,v_n,t_n)=Q^+(f,g)(x,v,t)$. Thus $Q^+(f,g)$ is continuous on $\mathbf{R}^3\times\mathbf{R}^3\times[0,\infty)$. The continuity of $L(f)$ is obvious. Finally, using the estimate (2.21) we have $\forall\ (x,v,t)\in\mathbf{R}^3\times\mathbf{R}^3\times[0,\infty)$,

$$Q^\pm(f,g)^\sharp(x-tv,v,s)\le C(1+s^2)^{-(3+\gamma)/2},\quad s\in[0,\infty).$$

This and the continuity of $Q^\pm(f,g)$ imply the continuity of the third and fourth functions in (2.23). □

LEMMA 2.6. *Let f,f_*,f',f'_* be nonnegative and $\phi,\phi_*,\phi',\phi'_*$ be positive real numbers. Then*

$$\left[(ff_*-f'f'_*)\log\frac{(f'+\phi')(f'_*+\phi'_*)}{(f+\phi)(f_*+\phi_*)}\right]^+\le f'\phi'_*+f'_*\phi'+f\phi_*+f_*\phi+\phi'\phi'_*+\phi\phi_*,$$

$$\left[(f'f'_*-ff_*)\log\frac{(f'+\phi')(f'_*+\phi'_*)}{(f+\phi)(f_*+\phi_*)}\right]^+\le E(f'f'_*\ ,\ ff_*)+f'\phi'_*+f'_*\phi'+f\phi_*+f_*\phi,$$

where $(y)^+=\max\{y,0\}$ and $E(\cdot,\cdot)\ge 0$ is given by

$$E(a,b)=\begin{cases}(a-b)\log(\frac{a}{b}), & a>0,\ b>0;\\ \infty, & a>0,\ b=0\quad\text{or}\quad a=0,\ b>0;\\ 0, & a=b=0.\end{cases}$$

Proof. Denote by Δ_1,Δ_2 the left-hand sides of the two inequalities above, respectively. By symmetry and definition of E, consider, only the case that $(f'+\phi')(f'_*+\phi'_*)\ge(f+\phi)(f_*+\phi_*)$ and $ff_*>0$. If $f'f'_*\ge ff_*$, then $\Delta_1=0$ and, since $\log(1+y)\le y$,

$$\begin{aligned}\Delta_2&\le E(f'f'_*\ ,\ ff_*)+(f'f'_*-ff_*)[\log(1+\phi'/f')+\log(1+\phi'_*/f'_*)]\\&\le E(f'f'_*\ ,\ ff_*)+f'_*\phi'+f'\phi'_*.\end{aligned}$$

If $f'f'_*<ff_*$, then $\Delta_2=0$ and

$$\begin{aligned}\Delta_1&\le(ff_*-f'f'_*)\left[\ \frac{(f'+\phi')(f'_*+\phi'_*)}{(f+\phi)(f_*+\phi_*)}-\ 1\ \right]\\&\le(f'+\phi')(f'_*+\phi'_*)-(f+\phi)(f_*+\phi_*)\le f'\phi'_*+f'_*\phi'+\phi'\phi'_*.\end{aligned}$$

□

LEMMA 2.7 (see [Cs], [Ku]). *Let $\mathcal{D} \subset \mathbf{R}^N$ be a measurable set and let $F, \varphi : \mathcal{D} \to [0,\infty)$ be measurable functions satisfying $F(1+|\log F|) \in L^1(\mathcal{D})$ and*

$$\int_{\mathcal{D}} F(z)dz = \int_{\mathcal{D}} M(z)dz > 0, \quad \int_{\mathcal{D}} F(z)\varphi(z)dz \le \int_{\mathcal{D}} M(z)\varphi(z)dz < \infty,$$

where $M(z) = C\exp(-\varphi(z)), C$ is a positive constant. Then for the H-functional $H(f) = \int_{\mathcal{D}} f(z)\log f(z)dz$,

$$H(F) \ge H(M) + [\,2\|M\|_{L^1(\mathcal{D})}\,]^{-1}[\,\|F-M\|_{L^1(\mathcal{D})}\,]^2. \tag{2.26}$$

Equation (2.26) is the Csiszar–Kullback inequality which can be directly proved by the following elementary inequality:

$$|b-a| \le \left(\frac{4}{3}a + \frac{2}{3}b\right)^{1/2} [\,b\log b - a\log a - (1+\log a)(b-a)\,]^{1/2}, \quad a>0,\ b\ge 0.$$

The last lemma below is a Gronwall-type inequality, which in this paper is essentially used to deal with the case of $\gamma = 1$ of the collision model (1.6) for proving converse properties of the long time limits f_∞.

LEMMA 2.8. *Let κ be nonnegative and c be positive constants.*
(i) *Let $0 < T \le \infty, 0 \le \varrho \in L^1(0,T)$, and $0 \le u \in L^\infty(0,T)$ satisfy $\forall R \in [0,\infty)$*

$$u(t) \le \kappa + R\int_0^t \varrho(s)u(s)ds + ce^{-R}, \qquad t \in (0,T). \tag{2.27}$$

Then

$$u(t) \le \kappa + c(T)\kappa^{\theta(T)}, \qquad t \in (0,T), \tag{2.28}$$

where

$$\theta(T) = \frac{1}{2}\exp\left(-\int_0^T \varrho(s)ds\right), \quad c(T) = (ec)^{1-\theta(T)}\left(1+\int_0^T \varrho(s)ds\right).$$

(ii) *Let $0 \le \varrho \in L^1(0,\infty), 0 \le u \in L^\infty(0,\infty)$ satisfy $\forall R \in [0,\infty)$*

$$u(t) \le \kappa + R\int_t^\infty \varrho(s)u(s)ds + ce^{-R}, \qquad t \in (0,\infty).$$

Then

$$u(t) \le \kappa + c_\infty \kappa^\theta, \qquad t \in (0,\infty),$$

where

$$\theta = \frac{1}{2}\exp\left(-\int_0^\infty \varrho(s)ds\right), \quad c_\infty = (ec)^{1-\theta}\left(1+\int_0^\infty \varrho(s)ds\right).$$

Proof. By substitution $\tilde{u}(t) = u(\frac{1}{t}), \tilde{\varrho}(t) = \frac{1}{t^2}\varrho(\frac{1}{t}), t \in (0,\infty)$, part (ii) is reduced to part (i) with $T = \infty$. Thus we need only to prove part (i). In the following we set $\theta = \theta(T)$. Taking $R = 0$ in (2.27) we first obtain $u(t) \le \kappa + c\ \forall t \in (0,T)$. If

$\kappa \geq ce^{-\frac{1}{2\theta}}$, then $c \leq c(\frac{\kappa}{c}\, e^{\frac{1}{2\theta}})^{\theta} \leq (ec)^{1-\theta}\kappa^{\theta}$ and so $u(t) \leq \kappa + c(T)\kappa^{\theta}, t \in (0,T)$. Now we suppose that $\kappa < c\, e^{-\frac{1}{2\theta}}$. Let

$$C = ec\left(1 + \int_0^T \varrho(s)ds\right), \quad U_\delta(t) = \frac{1}{C}\int_0^t \varrho(s)u(s)ds + \delta, \quad t \in [0,T),$$

where δ is a positive constant. By definition of $\theta = \theta(T)$ we have $\int_0^T \varrho(s)ds < e^{\frac{1}{2\theta}}$ which together with the bounds $u(t) \leq \kappa + c$ and $\kappa < c\, e^{-\frac{1}{2\theta}}$ imply that for sufficiently small $\delta > 0$

$$\delta \leq U_\delta(t) \leq 1/e,\ t \in [0,T); \qquad \delta \leq \kappa_\delta := \frac{\kappa}{C}\int_0^T \varrho(s)ds + \delta \leq e^{-\frac{1}{2\theta}}. \tag{2.29}$$

Now taking $R = -\log(eU_\delta(t))$ in (2.27) and noticing that $ce^{-R} = ceU_\delta(t) \leq CU_\delta(t)$ we obtain

$$u(t) \leq \kappa + CU_\delta(t)|\log U_\delta(t)|, \quad t \in (0,T). \tag{2.30}$$

Multiplying $\varrho(t)/C$ to both sides of (2.30) and taking integration leads to

$$U_\delta(t) \leq \kappa_\delta + \int_0^t \varrho(s)U_\delta(s)|\log U_\delta(s)|ds, \quad t \in [0,T).$$

Let

$$G(U) = \int_\delta^U \frac{dy}{y|\log y|} = -\log\left(\frac{\log U}{\log \delta}\right), \quad U \in [\delta,\ 1/e].$$

Then $G^{-1}(V) = \exp\{(\log\delta)e^{-V}\},\ V \in [0\,,\ G(1/e)]$. Since $y \mapsto y|\log y|$ is positive and increasing on $[\delta, 1/e]$, it follows from the generalized Gronwall inequality (e.g., Bihari's inequality [B,B]) that

$$U_\delta(t) \leq G^{-1}\left(G(\kappa_\delta) + \int_0^t \varrho(s)ds\right) \leq G^{-1}\left(G(\kappa_\delta) + \int_0^T \varrho(s)ds\right) = (\kappa_\delta)^{2\theta}, \quad t \in [0,\ T).$$

Here we have checked by the second equation in (2.29) that $G(\kappa_\delta) + \int_0^T \varrho(s)ds$ lies in the domain $[0,\ G(1/e)]$ of G^{-1}. Therefore, using (2.30) and the inequality $U|\log U| \leq \sqrt{U},\ U \in [0,1]$, we obtain

$$u(t) \leq \kappa + C\sqrt{U_\delta(t)} \leq \kappa + C(\kappa_\delta)^{\theta}, \quad t \in (0,T),$$

which implies (2.28) by letting $\delta \to 0^+$. □

3. Some converse properties of long time limits. Throughout this section and the next couple of sections we will always assume that the collision kernel $B(z,\omega)$ satisfies (1.6), (1.7) with $-2 < \gamma \leq 1$. Let Φ be given by (1.14) or (1.15), or given by (1.16) for $\gamma \leq 0$. Define $\Phi_0(x,v) = \Phi(x,v,0)$ and introduce function spaces:

$$\mathcal{B}(\Phi_0) = \{f \in C(\mathbf{R}^3 \times \mathbf{R}^3) \ \mid\ \|f\|_{\Phi_0} := \sup_{(x,v)\in\mathbf{R}^3\times\mathbf{R}^3} |f(x,v)|/\Phi_0(x,v) < \infty\},$$

$$\mathcal{B}(\Phi) = \{f \in C(\mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty)) \ \mid\ \|f\|_{\Phi} := \sup_{t\geq 0} \|f^\sharp(t)\|_{\Phi_0} < \infty\},$$

where $f^\sharp(t) = f^\sharp(\cdot,\cdot,t)$. Note that since $\Phi(x,v,t) \equiv \Phi_0(x-tv,v)$, the norm for $\mathcal{B}(\Phi)$ can also be written

$$\|f\|_\Phi = \sup_{(x,v,t)\in \mathbf{R}^3\times\mathbf{R}^3\times[0,\infty)} |f(x,v,t)|/\Phi(x,v,t)$$

so that both $(\mathcal{B}(\Phi), \|\cdot\|_\Phi)$ and $(\mathcal{B}(\Phi_0), \|\cdot\|_{\Phi_0})$ are Banach spaces. It is obvious that if $0 < \Psi \le \Phi$ then $\mathcal{B}(\Psi) \subset \mathcal{B}(\Phi)$. Suppose $k > (3+\gamma)/2$ and let $f \in \mathcal{B}(\Phi)$ be a mild solution of (B). Then Lemma 2.5 ensures that f satisfies (1.10) on whole $\mathbf{R}^3\times\mathbf{R}^3\times[0,\infty)$ and the functions $\int_0^\infty Q^\pm(f,f)^\sharp(x,v,s)ds$, and therefore the function

$$f_\infty(x,v) := f_0(x,v) + \int_0^\infty Q(f,f)^\sharp(x,v,s)ds \tag{3.1}$$

are all in $\mathcal{B}(\Phi_0)$, where $f_0 = f|_{t=0}$. From (3.1), $f^\sharp$ can be written

$$f^\sharp(x,v,t) = f_\infty(x,v) - \int_t^\infty Q(f,f)^\sharp(x,v,s)ds. \tag{3.2}$$

This implies that f_∞ is the long time limit of $f^\sharp(t)$ in $\mathcal{B}(\Phi_0)$. In fact by Lemma 2.5 we have for a positive constant $C = C(B_0,\gamma,k,a,b) < \infty$ and for $\nu = \min\{\gamma,0\}$,

$$\|f^\sharp(t) - f_\infty\|_{\Phi_0} \le C\|f\|_\Phi^2(1+t)^{-(2+\nu)} \to 0 \qquad (t\to\infty). \tag{3.3}$$

THEOREM 3.1. *Assume that* $-2 < \gamma < 1$, $k > (3+\gamma)/2$. *Let* Φ *be given by* (1.14) *or* (1.15), *or given by* (1.16) *for* $\gamma \le 0$, *and let* $f, g \in \mathcal{B}(\Phi)$ *be mild solutions of* (B) *(their initial data may be different). Then,*

(i) *There exists* $0 < C < \infty$ *such that*

$$C^{-1}\|f_\infty - g_\infty\|_{\Phi_0} \le \|f^\sharp(t) - g^\sharp(t)\|_{\Phi_0} \le C\|f_\infty - g_\infty\|_{\Phi_0} \quad \forall\, t \ge 0. \tag{3.4}$$

(ii) *If* $f_\infty(x-tv,v)$ *is a local Maxwellian* $M(x,v,t)$, *then* $f(x,v,t) \equiv M(x,v,t)$ *on* $\mathbf{R}^3\times\mathbf{R}^3\times[0,\infty)$. *In particular,* $f_0 = M_0$.

Proof. (i) From (3.2) and $ff_* - gg_* = \frac{1}{2}[(f+g)(f_*-g_*) + (f_*+g_*)(f-g)]$ we have

$$\begin{aligned}
&|f^\sharp(x,v,t) - g^\sharp(x,v,t)| \\
&\le |f_\infty(x,v) - g_\infty(x,v)| + \|f+g\|_\Phi \int_t^\infty u(s)[Q^+(\Phi,\Phi) + Q^-(\Phi,\Phi)]^\sharp(x,v,s)ds,
\end{aligned}$$

where $u(t) = \|f^\sharp(t) - g^\sharp(t)\|_{\Phi_0}$. Choose $p = 2$ for $\gamma \le 0$ and $p = 1/\gamma$ for $0 < \gamma < 1$. Let $q = p/(p-1)$, $\eta = (3+\gamma)/2$. Then by Lemma 2.5 we have

$$\begin{aligned}
&\int_t^\infty u(s)[Q^+(\Phi,\Phi) + Q^-(\Phi,\Phi)]^\sharp(x,v,s)ds \le \left[\int_t^\infty [u(s)]^q(1+s^2)^{-\eta}ds\right]^{1/q} \\
&\times\left[\int_t^\infty (1+s^2)^{\eta(p-1)}[(Q^+(\Phi,\Phi)^\sharp + Q^-(\Phi,\Phi)^\sharp)(x,v,s)]^p ds\right]^{1/p} \\
&\le \left[\int_t^\infty [u(s)]^q(1+s^2)^{-\eta}ds\right]^{1/q} (C_p^+ + C_p^-)\Phi_0(x,v).
\end{aligned}$$

Therefore, for $c = 2^{q-1}[(C_p^+ + C_p^-)\|f+g\|_\Phi]^q$,

$$[u(t)]^q \le 2^{q-1}[\|f_\infty - g_\infty\|_{\Phi_0}]^q + c\int_t^\infty [u(s)]^q(1+s^2)^{-\eta}ds, \quad t \ge 0$$

and so, by the Gronwall inequality,

$$[u(t)]^q \le 2^{q-1}[\|f_\infty - g_\infty\|_{\Phi_0}]^q \exp\{c\int_t^\infty (1+s^2)^{-\eta} ds\}, \quad t \ge 0.$$

This gives the right-hand-side inequality in (3.4) with $C = 2^{1/p}\exp\{\frac{c}{q}\int_0^\infty (1+s^2)^{-\eta} ds\}$. Similarly for each $t \ge 0$ starting from

$$f^\sharp(x,v,\tau) = f^\sharp(x,v,t) + \int_t^\tau Q(f,f)^\sharp(x,v,s) ds, \quad \tau \ge t \tag{3.5}$$

we obtain $u(\tau) \le C\|f^\sharp(t) - g^\sharp(t)\|_{\Phi_0}\ \forall\ \tau \ge t$. Applying (3.3) leads to $\lim_{\tau\to\infty} u(\tau)$ $= \|f_\infty - g_\infty\|_{\Phi_0}$ and the left-hand-side inequality in (3.4) also holds.

(ii) Suppose that $M(x,v,t) := f_\infty(x - tv, v)$ is a local Maxwellian. Then $M^\sharp(x,v,t)$ $\equiv f_\infty(x,v)$ and $M \in \mathcal{B}(\Phi)$ since $f_\infty \in \mathcal{B}(\Phi_0)$. Therefore $M_\infty = f_\infty$ and so by (3.4) $f \equiv M$ on $\mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty)$. □

The restriction $\gamma < 1$(which excludes only the hard sphere model) will be removed in our next theorem, but the estimates like (3.4) will be given in L^1-norm for solutions $f, g \in \mathcal{B}(\Phi)$, where Φ is of type (1.15).

When dealing with the long time behavior of solutions of (B), one naturally considers the (formal) entropy equality (write $f' = f(x,v',s), f'_* = f(x,v'_*,s), f_* = f(x,v_*,s)$)

$$H(f)(t) = H(f_0) - \frac{1}{4}\int_0^t ds \iint_{\mathbf{R}^9\times\mathbf{S}^2} B(v-v_*,\omega) E(f'f'_*, ff_*) d\omega\, dv_*\, dx\, dv, t \ge 0 \tag{3.6}$$

or entropy inequality [D,L 2] (i.e., $H(f)(t) \le$ the right-hand side of (3.6)), where $E(\cdot,\cdot)$ is defined in Lemma 2.7. Unlike the cases of spatially homogeneous or spatially periodic solutions, our next theorem further shows that even though the entropy equality (3.6) can be rigorously proven for spatial decay solutions (in $\mathcal{B}(\Phi)$), this equality does not essentially help to determine what are trends of the solutions (along the particle paths).

THEOREM 3.2. *Assume that* $-2 < \gamma \le 1$. *Let* $\mu = \max\{\gamma, 0\}$.

(i) *Let* $f \in \mathcal{B}(\Phi)$ *be a mild solution of* (B), *where* Φ *is given by* (1.14) *with* $k > 3 + \frac{1}{2}\mu$. *Then the entropy equality* (3.6) *holds on* $[0,\infty)$.

(ii) *Let* Φ *be given by* (1.15) *with* $k > 3$, $\beta = \mu$, *and let* $f, g \in \mathcal{B}(\Phi)$ *be mild solutions of* (B) *(their initial data may be different). Then there exists* $0 < \theta < 1$ *and* $0 < C < \infty$ *such that*

$$[C^{-1}\|f_\infty - g_\infty\|_{L^1(\mathbf{R}^6)}]^{1/\theta} \le \|f^\sharp(t) - g^\sharp(t)\|_{L^1(\mathbf{R}^6)} \le C[\,\|f_\infty - g_\infty\|_{L^1(\mathbf{R}^6)}]^\theta \quad \forall\, t \ge 0. \tag{3.7}$$

As a consequence, the conclusion in part (ii) *of Theorem* 3.1 *still holds. Moreover, if* $k > 4$ *and if* T_M *is the traveling Maxwellian determined by* f_0 *through* (1.13), *then there exists* $0 < C < \infty$ *such that*

$$\inf_{t\ge 0} H(f)(t) = H(f_\infty) \ge H(T_M) + C\sup_{t\ge 0}[\,\|f^\sharp(t) - T_M\|_{L^1(\mathbf{R}^6)}]^{2/\theta}. \tag{3.8}$$

Proof. (i) Consider $f + \phi^n$ where $\phi^n = \frac{1}{n}\Phi$, $n \ge 1$. By $f \in \mathcal{B}(\Phi)$ and $\Phi = P^{-k}$ where P is the polynomial (2.16), one easily obtains the following estimates on $\mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty)$:

$$(f+\phi^n)|\log(f+\phi^n)| \le C\Phi(1+\log P), \quad |\log(f+\phi^n)| \le C\, n(1+\log P) \quad \forall n \ge 1.$$

Here and below $C \in (0,\infty)$ are independent of t, x, v, and n . Since $\phi^{n\sharp}(x,v,t) = \phi_0^n(x,v)$ are independent of t, it follows that

$$\begin{aligned}&[(f+\phi^n)\log(f+\phi^n)]^\sharp(x,v,t)\\ &= [(f_0+\phi_0^n)\log(f_0+\phi_0^n)](x,v) + \int_0^t [Q(f,f)(1+\log(f+\phi^n)]^\sharp(x,v,s)ds.\end{aligned}$$

On the other hand, by Lemma 2.5 and (2.21) we have

$$Q^\pm(f,f)(x,v,t) \le \|f\|_\Phi^2 Q^\pm(\Phi,\Phi)(x,v,t) \le C(1+t^2)^{-(3+\gamma)/2}\Phi(x,v,t)[P(x,v,t)]^{\mu/2}.$$

This implies that $Q^\pm(f,f)(1+|\log(f+\phi^n)|) \in L^1(\mathbf{R}^3\times\mathbf{R}^3\times[0,\infty))$ since $k > 3+\mu/2$. Thus according to classical derivation we have

$$H(f+\phi^n)(t) = H(f_0+\phi_0^n) - \frac{1}{4}\int_0^t ds \iint_{\mathbf{R}^9\times\mathbf{S}^2} B(v-v_*,\omega)E_n(f',f'_*,f,f_*)d\omega\, dv_*\, dx\, dv,$$

where

$$E_n(f',f'_*,f,f_*) = (f'f'_* - ff_*)\log\frac{(f'+\phi^{n\prime})(f'_*+\phi^{n\prime}{}_*)}{(f+\phi^n)(f_*+\phi^n{}_*)}.$$

Let

$$\begin{aligned}e_n^+(t) &= \frac{1}{4}\int_0^t ds \iint_{\mathbf{R}^9\times\mathbf{S}^2} B(v-v_*,\omega)[E_n(f',f'_*,f,f_*)]^+ d\omega\, dv_*\, dx\, dv,\\ e_n^-(t) &= \frac{1}{4}\int_0^t ds \iint_{\mathbf{R}^9\times\mathbf{S}^2} B(v-v_*,\omega)[-E_n(f',f'_*,f,f_*)]^+ d\omega\, dv_*\, dx\, dv.\end{aligned}$$

Then

$$e_n^+(t) = H(f_0+\phi_0^n) - H(f+\phi^n)(t) + e_n^-(t). \tag{3.9}$$

By definition of $E(\cdot,\cdot)$ it is easily shown that $\lim_{n\to\infty}[E_n(f',f'_*,f,f_*)]^+ = E(f'f'_*\,,\, ff_*)$ in pointwise. Moreover, by Lemma 2.6, we have

$$\begin{aligned}&[E_n(f',f'_*,f,f_*)]^+ \le E(f'f'_*\,,\, ff_*) + C(\Phi'\Phi'_* + \Phi\Phi_*),\\ &[-E_n(f',f'_*,f,f_*)]^+ \le \frac{C}{n}(\Phi'\Phi'_* + \Phi\Phi_*)\end{aligned} \tag{3.10}$$

so that

$$e_n^-(t) \le \frac{C}{n}\int_0^t ds \iint_{\mathbf{R}^3\times\mathbf{R}^3} Q^-(\Phi,\Phi)(x,v,s)dx\, dv \to 0 \qquad (n\to\infty).$$

Thus, by (3.9), Fatou's lemma, and the dominated convergence theorem we obtain $\forall\ t \ge 0$

$$\frac{1}{4}\int_0^t ds \iint_{\mathbf{R}^9\times\mathbf{S}^2} B(v-v_*,\omega)E(f'f'_*\,,\, ff_*)d\omega\, dv_*\, dx\, dv \le H(f_0) - H(f)(t) < \infty.$$

This integrability together with (3.10) and the dominated convergence theorem for (3.9) then implies the entropy equality (3.6).

(ii) The proof for (3.7) relies on Lemma 2.8. Let

$$u(t) = \|f^\sharp(t) - g^\sharp(t)\|_{L^1(\mathbf{R}^6)} \ \ (= \|f(\cdot,\cdot,t) - g(\cdot,\cdot,t)\|_{L^1(\mathbf{R}^6)}).$$

From (3.2) and the basic fact (see (1.4), (1.5)) that $(v, v_*) \mapsto (v', v'_*)$ is an orthogonal transform (for each fixed $\omega \in \mathbf{S}^2$) and $|v' - v'_*| = |v - v_*|, |\langle v' - v'_*, \omega\rangle| = |\langle v - v_*, \omega\rangle|$ and $B(v - v_*, \omega)$ depends only on $|v - v_*|$ and $|\langle v - v_*, \omega\rangle|$, we have

$$\begin{aligned} u(t) &\le \|f_\infty - g_\infty\|_{L^1(\mathbf{R}^6)} + \int_t^\infty ds \iint_{\mathbf{R}^3\times\mathbf{R}^3} |Q(f,f) - Q(g,g)|dx\,dv \\ &\le \|f_\infty - g_\infty\|_{L^1(\mathbf{R}^6)} + 2\int_t^\infty ds \iint_{\mathbf{R}^3\times\mathbf{R}^3} |f-g|L(f+g)dx\,dv. \end{aligned}$$

Therefore by $L(f+g) \le \|f+g\|_\Phi L(\Phi)$, Lemma 2.5, and (2.22) we obtain with $\nu = \min\{\gamma, 0\}$

$$\begin{aligned} (3.11)\ u(t) &\le \|f_\infty - g_\infty\|_{L^1(\mathbf{R}^6)} \\ &\quad + C_1 \int_t^\infty (1+s^2)^{-(3+\nu)/2} \iint_{\mathbf{R}^3\times\mathbf{R}^3} |f-g|(1+|v-v_0|^\mu)dx\,dv\,ds. \end{aligned}$$

Here and below $C_1, C_2, \ldots$ are positive and finite constants depending only on the constants $B_0, \gamma, k, a, b, \alpha$ and on the norm $\|f+g\|_\Phi$. Using the inequality

$$1 + |v - v_0|^\mu \le \left(1 + \frac{1}{\alpha}\right) R + \left(1 + \frac{1}{\alpha}\right) e^{\alpha|v-v_0|^\mu - R} \quad \forall R \ge 0$$

and recalling that $\Phi(x,v,s) = (P(x,v,s))^{-k} e^{-\alpha|v-v_0|^\mu}$ which implies

$$\begin{aligned} &\int_0^\infty (1+s^2)^{-(3+\nu)/2} \iint_{\mathbf{R}^3\times\mathbf{R}^3} |f-g| e^{\alpha|v-v_0|^\mu} dx\,dv\,ds \\ &\le \|f-g\|_\Phi \int_0^\infty (1+s^2)^{-(3+\nu)/2} ds \iint_{\mathbf{R}^3\times\mathbf{R}^3} (P(x,v,0))^{-k} dx\,dv < \infty \end{aligned}$$

we obtain by (3.11) $\forall\ R \ge 0$

$$u(t) \le \|f_\infty - g_\infty\|_{L^1(\mathbf{R}^6)} + R\int_t^\infty \varrho(s)u(s)ds + C_3\, e^{-R}, \quad t \in [0,\infty),$$

where $\varrho(s) = C_2(1+s^2)^{-(3+\nu)/2}$ $(\in L^1[0,\infty))$. It is easily seen that u is bounded and continuous on $[0,\infty)$. Then Lemma 2.8 ensures that with the number $\theta = \frac{1}{2}\exp\{-\int_0^\infty \varrho(s)ds\}$,

$$u(t) \le C[\,\|f_\infty - g_\infty\|_{L^1(\mathbf{R}^6)}\,]^\theta, \quad t \in [0,\infty).$$

In the same way, starting from (3.5) we also obtain $\forall t \ge 0, \forall R \ge 0$,

$$u(\tau + t) \le u(t) + R\int_0^\tau \varrho(s)u(s+t)ds + C_3\, e^{-R}, \quad \tau \in [0,\infty)$$

since $\varrho(s+t) \le \varrho(s)$. Therefore by Lemma 2.8 we have (with the same θ) $u(\tau+t) \le C[u(t)]^\theta\ \forall\, \tau \ge 0$. Letting $\tau \to \infty$ then leads to (by Fatou's lemma)

$$\|f_\infty - g_\infty\|_{L^1(\mathbf{R}^6)} \le C[u(t)]^\theta, \quad t \in [0,\infty).$$

These two estimates of $u(t)$ give (3.7). Finally we prove (3.8). We may suppose that $\|f_0\|_{L^1(\mathbf{R}^6)} > 0$. For otherwise, $f_0(x,v) \equiv 0$ and so applying (3.7) (take $g \equiv 0$ and then choose $t = 0,\dots$) we get $f \equiv 0$ and (3.8) is trivial. Now let $\varphi(x,v) = c_2|x - \bar{x}_0|^2 + c_3|v - \bar{v}_0|^2$ be such that $T_M(x,v) = c_1 \exp(-\varphi(x,v))$ is the traveling Maxwellian determined by f_0 through the moment condition (1.13). Since $f \in \mathcal{B}(\Phi)$, it is easily shown from Lemma 2.5 and (2.21) that $Q^{\pm}(f,f)^{\sharp}(x,v,t)(1+|x|^2+|v|^2) \in L^1(\mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty))$. Thus the classical derivation shows that all moments in (1.13) are conserved by $f^{\sharp}(\cdot,\cdot,t)$. Therefore using dominated convergence we have

$$\iint_{\mathbf{R}^3\times\mathbf{R}^3} f_\infty(x,v)\{1,\varphi(x,v)\}dx\,dv = \iint_{\mathbf{R}^3\times\mathbf{R}^3} T_M(x,v)\{1,\varphi(x,v)\}dx\,dv,$$

and so by Csiszar–Kullback inequality (2.26) we obtain

$$H(f_\infty) \geq H(T_M) + [\,2\|f_0\|_{L^1(\mathbf{R}^6)}\,]^{-1}[\,\|f_\infty - T_M\|_{L^1(\mathbf{R}^6)}\,]^2. \tag{3.12}$$

Because all the coefficients c_i $(i = 1,2,3)$ are positive and $\mu \leq 1$, the solution $T_M(x - tv, v)$ is in $\mathcal{B}(\Phi)$. If we choose $g(x,v,t) = T_M(x - tv, v)$, then $g^{\sharp}(t) \equiv g_\infty = T_M$ and so (3.12) and the inequality in the right-hand side of (3.7) imply the inequality in (3.8). The equality in (3.8) is due to the monotonicity of $H(f)(t)(= H(f^{\sharp})(t))$ and $\lim_{t\to\infty} H(f)(t) = H(f_\infty)$ which follows from $f^{\sharp}(t)|\log f^{\sharp}(t)| \leq C\Phi_0(1+|\log\Phi_0|)$ and dominated convergence. □

Remarks. 1. In Theorems 3.1 and 3.2, we do not assume the solutions are small in the norm $\|\cdot\|_\Phi$ of $\mathcal{B}(\Phi)$, and for the entropy equality (3.6) we also do not assume the solutions are positive everywhere.

2. The right-hand-side estimates in (3.4) and (3.7) may also be viewed as the uniqueness of a "final" value problem of (B) (existence results for this problem will be given in the next section). The proofs for this uniqueness are different from those of the uniqueness of the initial value problem; see [L2], [Lu], where the two solutions f, g need not be both strong (say bounded or spatial decay) solutions. This difference is essentially due to the irreversibility of the time evolution of (B), i.e., due to the different collision order $Q^+ - Q^-$ and $Q^- - Q^+$.

4. Two kinds of existence results. In this section the existence of the solutions in Theorems 3.1 and 3.2 will be proven for the initial value problem and for the "final" value problem, respectively. Throughout this section, the collision kernel is assumed to satisfy the same conditions in section 3; i.e., $B(z,\omega)$ satisfies (1.6), (1.7) with $-2 < \gamma \leq 1$, and the functions Φ are given by (1.14) or (1.15), or given by (1.16) for $\gamma \leq 0$, with their constants $k > (3+\gamma)/2,\ a > 0,\ b > 0$, etc. For the initial value problem, we consider the following "interim" equation of nonnegative functions f:

$$f^{\sharp}(x,v,t) = f_0(x,v) + \int_0^t Q(f\wedge\phi, f\wedge\phi)^{\sharp}(x,v,s)ds \quad \text{on} \quad \mathbf{R}^3\times\mathbf{R}^3\times[0,\infty), \tag{4.1}$$

where $f_0 \in \mathcal{B}(\Phi_0)$, $\phi \in \mathcal{B}(\Phi)$ are nonnegative, and

$$(f\wedge\phi)(x,v,t) = \min\{f(x,v,t), \phi(x,v,t)\}.$$

In the following, the positive constants $D^{\pm} = D^{\pm}(B_0,\gamma,k)$ appeared in Lemma 2.5, and (2.19) will be used.

THEOREM 4.1. (i) *If $\gamma < 1$, then for any $0 \leq f_0 \in \mathcal{B}(\Phi_0)$ and any $0 \leq \phi \in \mathcal{B}(\Phi)$,* (4.1) *has a unique nonnegative global solution $f \in \mathcal{B}(\Phi)$. Furthermore, if*

$$\|f_0\|_{\Phi_0} \leq (4D^+\,a\,b^{2+\gamma})^{-1}, \tag{4.2}$$

then for any $\phi \in \mathcal{B}(\Phi)$ *satisfying* $\phi \geq 2\|f_0\|_{\Phi_0}\Phi$, *the corresponding solution* f *is the unique mild solution of* (B) *in* $\mathcal{B}(\Phi)$ *and satisfies* $\|f\|_\Phi \leq 2\|f_0\|_{\Phi_0}$.
(ii) *If* $\gamma = 1$ *and* $0 \leq f_0 \in \mathcal{B}(\Phi_0)$ *satisfying*

$$\|f_0\|_{\Phi_0} \leq (a\,b^3)^{-1}d(1 - dD^+), \qquad 0 < d < [2(D^+ + D^-)]^{-1}, \tag{4.3}$$

then (B) *has a mild solution* $f \in \mathcal{B}(\Phi)$ *satisfying* $\|f\|_\Phi \leq 2\|f_0\|_{\Phi_0}$.

Proof. Consider the operator K_ϕ given by

$$K_\phi(f)(x,v,t) = f_0(x - tv, v) + \int_0^t Q(|f| \wedge \phi, |f| \wedge \phi)^\sharp(x - tv, v, s)ds.$$

By Lemma 2.5 part (iv), K_ϕ maps $C(\mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty))$ into $\mathcal{B}(\Phi)$. We first prove that if $f \in \mathcal{B}(\Phi)$ is a fixed point of K_ϕ, then $f \geq 0$ on $\mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty)$ and so f is a global nonnegative solution of (4.1). In addition we have

$$f^\sharp(x,v,t) \leq (\|f_0\|_{\Phi_0} + \|\phi\|_\Phi^2 D^+ a\,b^{2+\gamma})\Phi_0(x,v) \quad \text{on} \quad \mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty). \tag{4.4}$$

The estimate (4.4) follows easily from $f = K_\phi(f)$, Lemma 2.5, and (2.19). Let $\chi(y) = \chi_{[0,\infty)}(y)$ be the characteristic function of $[0,\infty)$. Then, since $f_0 \geq 0$, we have $\forall (x,v) \in \mathbf{R}^3 \times \mathbf{R}^3$

$$\begin{aligned}
(-f^\sharp(x,v,t))^+ &= \int_0^t [-Q(|f| \wedge \phi, |f| \wedge \phi)^\sharp(x,v,s)]\,\chi(-f^\sharp(x,v,s))ds \\
&\leq \int_0^t Q^-(|f| \wedge \phi, |f| \wedge \phi)^\sharp(x,v,s)\,\chi(-f^\sharp(x,v,s))ds \\
&= \int_0^t (|f| \wedge \phi)^\sharp(x,v,s)\,\chi(-f^\sharp(x,v,s))L(|f| \wedge \phi)^\sharp(x,v,s)ds \\
&\leq \|\phi\|_\Phi \int_0^t (-f^\sharp(x,v,s))^+ L(\Phi)^\sharp(x,v,s)ds, \quad t \in [0,\infty).
\end{aligned}$$

Since $L(\Phi)^\sharp(x,v,s)$ is bounded with respect to s (see (2.22)), it follows from the Gronwall inequality that $(-f^\sharp(x,v,t))^+ \equiv 0$, i.e., $f \geq 0$ on $\mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty)$.

(i) $\gamma < 1$. For any $\tau > 0$, define

$$\mathcal{B}(\Phi,\tau) = \{f \in C(\mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty)) \mid \|f\|_{\Phi,\tau} := \sup_{t \geq 0} e^{-\tau t}\|f^\sharp(t)\|_{\Phi_0} < \infty\}.$$

Then $\mathcal{B}(\Phi,\tau)$ is a Banach space with the norm $\|f\|_{\Phi,\tau}$. Choose $p = 2$ for $\gamma \leq 0$ and $p = 1/\gamma$ for $0 < \gamma < 1$, and let $q = p/(p-1)$. Then for any $f, g \in \mathcal{B}(\Phi,\tau)$ we have, by $|\,|f| \wedge \phi - |g| \wedge \phi\,| \leq |f - g|$, Lemma 2.5 and (2.18),

$$\begin{aligned}
&|K_\phi(f)^\sharp(x,v,t) - K_\phi(g)^\sharp(x,v,t)| \\
&\leq \int_0^t |\,Q(|f| \wedge \phi, |f| \wedge \phi)^\sharp - Q(|g| \wedge \phi, |g| \wedge \phi)^\sharp\,|(x,v,s)\,ds \\
&\leq 2\|\phi\|_\Phi\,\|f - g\|_{\Phi,\tau} \int_0^t e^{\tau s}[Q^+(\Phi,\Phi)^\sharp + Q^-(\Phi,\Phi)^\sharp](x,v,s)ds \\
&\leq 2\|\phi\|_\Phi\,\|f - g\|_{\Phi,\tau}\,\frac{e^{\tau t}}{(q\tau)^{1/q}}\,(C_p^+ + C_p^-)\Phi_0(x,v), \quad (x,v,t) \in \mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty).
\end{aligned}$$

This implies

$$\|K_\phi(f) - K_\phi(g)\|_{\Phi,\tau} \le \frac{2\|\phi\|_\Phi (C_p^+ + C_p^-)}{(q\tau)^{1/q}} \|f - g\|_{\Phi,\tau}.$$

Let $\tau > 0$ be sufficiently large such that $K_\phi : \mathcal{B}(\Phi,\tau) \to \mathcal{B}(\Phi) \subset \mathcal{B}(\Phi,\tau)$ is contractive. Then K_ϕ has a unique fixed point $f \in \mathcal{B}(\Phi)$, which is therefore the unique nonnegative continuous global solution of (4.1). Now suppose that f_0 satisfies the condition (4.2). Let $0 \le f \in \mathcal{B}(\Phi)$ be the solution of (4.1) corresponding to a "minimum" function $\phi = \underline{\phi} := 2\|f_0\|_{\Phi_0}\Phi$. Then by (4.4) we have $\forall (x,v,t) \in \mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty)$

$$\begin{aligned} f^\sharp(x,v,t) &\le (\|f_0\|_{\Phi_0} + 4\|f_0\|_{\Phi_0}^2 D^+ a\, b^{2+\gamma})\Phi_0(x,v) \\ &\le 2\|f_0\|_{\Phi_0}\Phi_0(x,v) = \underline{\phi}^\sharp(x,v,t). \end{aligned}$$

Therefore $f \le \underline{\phi}$ and so f is a mild solution of (B). The remainder of the conclusion of part (i) follows easily from the uniqueness of solutions of (4.1).

(ii) $\gamma = 1$. Suppose f_0 satisfies (4.3). Choose $\lambda \in [\,0, d\,]$ such that

$$(a\, b^3)^{-1}\lambda(1 - \lambda D^+) = \|f_0\|_{\Phi_0}. \tag{4.5}$$

Let $\phi = (a\, b^3)^{-1}\lambda\Phi$. For any $f, g \in \mathcal{B}(\Phi)$ we have, as above (using Lemma 2.5 and (2.19)),

$$\|K_\phi(f) - K_\phi(g)\|_\Phi \le 2\lambda(D^+ + D^-)\|f - g\|_\Phi.$$

Because $2\lambda(D^+ + D^-) < 1$, K_ϕ has a unique fixed point $f \in \mathcal{B}(\Phi)$, and $f \ge 0$. Since $\|\phi\|_\Phi = (a\, b^3)^{-1}\lambda$, applying (4.4), (4.5) we obtain $f \le \phi$. Thus f is a mild solution of (B) and, by (4.5), $\|f\|_\Phi \le (a\, b^3)^{-1}\lambda \le 2\|f_0\|_{\Phi_0}$. □

THEOREM 4.2. *For any $F \in C(\mathbf{R}^3 \times \mathbf{R}^3)$ satisfying for $0 < d < [2(D^+ + D^-)]^{-1}$,*

$$(a\, b^{2+\gamma})^{-1} d^2 D^+ \Phi_0 \le F \le (a\, b^{2+\gamma})^{-1} d(1 - dD^-)\Phi_0 \qquad \text{on} \quad \mathbf{R}^3 \times \mathbf{R}^3, \tag{4.6}$$

there exists a mild solution $f \in \mathcal{B}(\Phi)$ of (B) *such that $f_\infty = F$.*

Moreover, if $\gamma < 1$, or $\gamma = 1$ and Φ is given by (1.15) *with $k > 3$ and $\beta = 1$, then the solution f is unique in $\mathcal{B}(\Phi)$.*

Proof. Similar to the existence proof of the initial value problem, in this case we consider the operator $\widetilde{K}_\phi$:

$$\widetilde{K}_\phi(f)(x,v,t) = F(x - tv, v) - \int_t^\infty Q(|f| \wedge \phi, |f| \wedge \phi)^\sharp(x - tv, v, s)ds. \tag{4.7}$$

Let $F \in C(\mathbf{R}^3 \times \mathbf{R}^3)$ satisfy (4.6) and let $\phi = (a\, b^{2+\gamma})^{-1} d\Phi$. Then, by Lemma 2.5, $\widetilde{K}_\phi$ maps $\mathcal{B}(\Phi)$ into $\mathcal{B}(\Phi)$, and as the proof of Theorem 4.1 part (ii) we have

$$\|\widetilde{K}_\phi(f) - \widetilde{K}_\phi(g)\|_\Phi \le 2d(D^+ + D^-)\|f - g\|_\Phi \quad \forall\ f, g \in \mathcal{B}(\Phi).$$

Since $2d(D^+ + D^-) < 1$, $\widetilde{K}_\phi$ has a unique fixed point $f \in \mathcal{B}(\Phi)$. From this and condition (4.6) we have $\forall\ (x,v,t) \in \mathbf{R}^3 \times \mathbf{R}^3 \times [0,\infty)$,

$$\begin{aligned} f^\sharp(x,v,t) &\ge F(x,v) - (a\, b^{2+\gamma})^{-1} d^2 D^+ \Phi_0(x,v) \ge 0, \\ f^\sharp(x,v,t) &\le (a\, b^{2+\gamma})^{-1} d(1 - dD^-)\, \Phi_0(x,v) + (a\, b^{2+\gamma})^{-1} d^2 D^- \Phi_0(x,v) = \phi^\sharp(x,v,t). \end{aligned}$$

Therefore

$$f^\sharp(x,v,t) = F(x,v) - \int_t^\infty Q(f,f)^\sharp(x,v,s)ds \qquad \text{on} \quad \mathbf{R}^3\times\mathbf{R}^3\times[0,\infty) \tag{4.8}$$

and so f is a mild solution of (B) and satisfies $f_\infty = F$ by (3.2) and (3.3). The uniqueness of f in $\mathcal{B}(\Phi)$ follows from Theorems 3.1 and 3.2. □

Remarks. 1. It is easy to show that the class of solutions of Eq.(B) obtained in Theorem 4.1 contains such a subclass of solutions that for $0 \le \gamma \le 1$ the total number of particles is always infinity and for $-2 < \gamma < 0$ the local numbers of particles are always infinity! To see for instance the second case (soft potentials), we use the exponential multiplier form (1.11) to the solutions f and use the estimate (2.19) in Lemma 2.5 for $L(\Phi)^\sharp = Q^-(\Phi,\Phi)^\sharp/\Phi_0$. Then we obtain $f(x,v,t) \ge cf_0(x-tv,v)$ on $\mathbf{R}^3\times\mathbf{R}^3\times[0,\infty)$ where $c = \exp(-\|f\|_\Phi D^- a\, b^{2+\gamma}) > 0$. This implies that if Φ is given by (1.14) or (1.16) with $3/2 \ge k > (3+\gamma)/2$ and if for a small constant $\varepsilon > 0$, the initial data f_0 (in Theorem 4.1) satisfy $f_0 \ge \varepsilon\Phi_0$, then $\int_{\mathbf{R}^3} f(x,v,t)dv \equiv \infty$, $(x,t) \in \mathbf{R}^3\times[0,\infty)$.

For the initial data with infinite total number of particles, as one of their recent results, Mischler and Perthame proved that (see [M,P, Theorem 3.2 for $N = 3$]) if for $q \in (3/2,\ \infty]$ the function $A(z) = \int_{\mathbf{S}^2} B(z,\omega)d\omega$ belongs to $L^q(\mathbf{R}^3)$ and if the initial data f_0 (which need not to be continuous) satisfy $0 \le f_0(x,v) \le \frac{C_0}{6}\exp(-\frac{1}{2}|\frac{x-x_0}{a} - \frac{v-v_0}{b}|^2)$ with $a > 0$, $b > 0$ satisfying $C_0\, a\, b^{\frac{3}{p}-1} < \frac{3-p}{p\|A\|_{L^q(\mathbf{R}^3)}}(\frac{p}{2\pi})^{\frac{3}{2p}}$, $\frac{1}{p} + \frac{1}{q} = 1$, then there exist distributional solutions $f \in L^\infty(\mathbf{R}^3\times\mathbf{R}^3\times(0,\infty))$ of (B) such that $0 \le f(x,v,t) \le \frac{C(t)}{6}\exp(-\frac{1}{2}|\frac{x-tv-x_0}{a} - \frac{v-v_0}{b}|^2)$, where $C(t)$ is bounded on $[0,\infty)$. Comparing this result with our Theorem 3 part (i) (for $-2 < \gamma \le 0$ and for Φ given by (1.16)) one sees that the above condition $A \in L^q(\mathbf{R}^3)$ is too restrictive, and the class of initial data given above is relatively small. However, this was the first global existence result which does not require the initial data decay to zero uniformly in both variables x and v. And our function (1.16), $\Phi_0(x,v) = (1+|\frac{x-x_0}{a} - \frac{v-v_0}{b}|^2)^{-k}$, is referred to this version.

2. In Theorem 4.2, the lower bounds given for F seems too large; it is used only to guarantee the nonnegativity of the solution of the final value problem. A simple example shows that (applying the exponential multiplier form (1.11)) this lower bound cannot be replaced by 0. But we do not know whether this lower bound can be replaced by a small one, for instance, by a traveling Maxwellian $c_1\exp(-c_2|x-x_0|^2 - c_3|v-v_0|^2)$.

3. For soft potentials and the Maxwell model (i.e., $-2 < \gamma \le 0$), a special case of Theorem 4.2 is that the final data $F(x,v)$ is only a function of velocity variable: $F(x,v) = h_1(v - \frac{1}{T}(x-x_0))$, $(T > 0)$. In this case, Theorem 4.2 implies the existence of nonnegative solutions of the future value problem of the spatially homogeneous Boltzmann equation

$$\frac{\partial}{\partial t}h(v,t) = Q(h,h)(v,t), \quad (v,t) \in \mathbf{R}^3\times[0,t_1]; \quad h(v,t_1) = h_1(v), \quad v \in \mathbf{R}^3 \tag{4.9}$$

for certain future data $h_1 > 0$ and for a small $t_1 > 0$, and the corresponding solution f obtained in Theorem 4.2 must be a Nikol'skii's solution (see [N], [T,M, p. 291], or [Ce], [Ko]). That is, f can be written

$$f(x,v,t) = h(v - \frac{1}{T}(x-tv-x_0), Z(t)), \qquad (x,v,t) \in \mathbf{R}^3\times\mathbf{R}^3\times[0,\infty), \tag{4.10}$$

where h is a spatially homogeneous solution on $\mathbf{R}^3 \times [0, t_1]$ with $t_1 = \frac{T}{2+\gamma}$, and

$$Z(t) = \frac{T}{2+\gamma}\left[1 - \left(1 + \frac{t}{T}\right)^{-2-\gamma}\right], \quad t \in [0, \infty) \tag{4.11}$$

To clarify this, let $0 < T < [2(D^+ + D^-)]^{-1}$ and let Φ be given by (1.16) with $a = Tb$, i.e., $\Phi(x, v, t) = \widetilde{\Phi}_0(v - \frac{1}{T}(x - tv - x_0))$, where

$$\widetilde{\Phi}_0(v) = \left(1 + \left|\frac{v - v_0}{b}\right|^2\right)^{-k}, \quad k > (3+\gamma)/2, \quad b > 0.$$

Suppose that $h_1 \in C(\mathbf{R}^3)$ satisfy

$$T(b^{3+\gamma})^{-1} D^+ \widetilde{\Phi}_0(v) \le h_1(v) \le (b^{3+\gamma})^{-1}(1 - TD^-)\widetilde{\Phi}_0(v), \quad v \in \mathbf{R}^3.$$

Let $f \in \mathcal{B}(\Phi)$ be the unique mild solution of (B) obtained in the proof of Theorem 4.2 ($d = T$) corresponding to $f_\infty(x, v) = F(x, v) = h_1(v - \frac{1}{T}(x - x_0))$. By the special form of the final data, we assert first that $f(x, v, t)$ is a function of $(v - \frac{1}{T}(x - tv - x_0), t)$ only. In fact, for any nonnegative function $\widetilde{g} \in C(\mathbf{R}^3 \times [0, \infty))$, let $g(x, v, t) = \widetilde{g}(v - \frac{1}{T}(x - tv - x_0), t)$, then by translation and dilation transforms of velocity variables in collision integrals we have $\forall t \in [0, \infty)$

$$\int_t^\infty Q^\pm(g, g)^\sharp(x, v, s)ds = \int_t^\infty \left(1 + \frac{s}{T}\right)^{-3-\gamma} Q^\pm(\widetilde{g}, \widetilde{g})\left(v - \frac{1}{T}(x - x_0), s\right) ds. \tag{4.12}$$

Thus the operator $\widetilde{K}_\phi$ given by (4) with $F(x - tv, v) = h_1(v - \frac{1}{T}(x - tv - x_0))$ and $\phi(x, v, t) = (b^{3+\gamma})^{-1}\widetilde{\Phi}_0(v - \frac{1}{T}(x - tv - x_0))$ maps the functions of $(v - \frac{1}{T}(x - tv - x_0), t)$ into the same kind of functions. Since $\widetilde{K}_\phi$ is contractive and the solution f is the fixed point of $\widetilde{K}_\phi$, this proves the above assertion. Next, write $f(x, v, t) = \widetilde{f}(v - \frac{1}{T}(x - tv - x_0), t)$. Then $f^\sharp(x, v, t) = \widetilde{f}(v - \frac{1}{T}(x - x_0), t)$. Take $x = x_0$ and replace t by the inverse function of $Z(t)$:

$$Z^{-1}(t) = T\left[\left(1 - \frac{2+\gamma}{T}t\right)^{-1/(2+\gamma)} - 1\right], \qquad t \in [0, t_1), \quad t_1 = T/(2+\gamma).$$

Then by (4.8), (4.12), and change of integral variable s we obtain

$$\widetilde{f}(v, Z^{-1}(t)) = h_1(v) - \int_t^{t_1} Q(\widetilde{f}, \widetilde{f})(v, Z^{-1}(s))ds, \qquad t \in [0, t_1).$$

Moreover, since $f \in \mathcal{B}(\Phi)$, it follows that

$$0 \le \widetilde{f}(v, Z^{-1}(t)) \le C\widetilde{\Phi}_0(v), \quad \lim_{t \to t_1^-} \widetilde{f}(v, Z^{-1}(t)) = h_1(v) \quad \forall v \in \mathbf{R}^3.$$

Therefore, the function $h(v, t) = \widetilde{f}(v, Z^{-1}(t)),\ t \in [0, t_1);\ h(v, t_1) = h_1(v)$, is a classical solution of (4.9), and conversely, f is a Nikol'skii's solution (4.10), (4.11).

Acknowledgments. I would like to thank Prof. Tianquan Chen for valuable discussions on the manuscript. I also wish to thank the referees for their helpful suggestions including pointing out a by-product result at the end of the final Remarks.

BOUNDS ON RESONANCES FOR THE LAPLACIAN ON PERTURBATIONS OF HALF-SPACE*

JULIAN EDWARD† AND DAVID PRAVICA‡

Abstract. The resonances of the Laplacian on perturbations of half-spaces of dimensions greater than or equal to two, with either Dirichlet or Neumann boundary conditions, are studied. An upper bound for the resonance counting function is proven. If the domain has an elliptic, nondegenerate, nonglancing periodic billiard trajectory, it is shown that there exists a sequence of resonances that converge to the real axis.

Key words. Laplacian, spectral resonances, resolvent estimates, half-space

1. Introduction.

The resonances of the Laplace operator on unbounded manifolds has been the object of considerable study both for exterior domains and for hyperbolic manifolds (see [21] for survey). Less well understood are the resonances for the Laplacian on domains whose boundary extends to infinity.

In this article we study the resonances associated with the Laplacian on compact perturbations of the half-space

$$H^n_+ = \{(x_1, \overline{x}) \in \mathbf{R} \times \mathbf{R}^{n-1},\ x_1 > 0\}.$$

Here we assume $n \geq 2$.

Denote the Laplacian by

$$\Delta = -\frac{\partial^2}{\partial x_1^2} - \cdots - \frac{\partial^2}{\partial x_n^2}.$$

In what follows we will assume either Dirichlet or Neumann boundary conditions.

Let Ω be a connected domain in $\mathbf{R}^n$. Although weaker hypotheses are possible, we assume that the boundary of Ω is a finite, disjoint union of smooth, simple curves and that there exists a positive constant M such that

$$\Omega \cap \{|x| > M\} = H^n_+ \cap \{|x| > M\}.$$

Then by standard methods, for either of the boundary conditions above, the Laplacian can be defined as a self-adjoint operator whose spectrum is given by $\sigma(\Delta) = \sigma_{ac}(\Delta) = [0, \infty)$.

THEOREM 1. *Let $\chi \in C_0^\infty(\mathbf{R}^n)$, and denote its restriction to Ω again by χ. Then the mapping from $\{\Im(k) > 0\}$ to $\mathcal{L}(L^2(\Omega))$ given by*

$$k \to \chi(\Delta - k^2)^{-1}\chi$$

extends to a meromorphic function in $\mathbf{C}$ *for odd dimensions and to a meromorphic function in* Λ *(the logarithmic plane) in even dimensions.*

Theorem 1 is a simple adaptation of the analogous result in [12], where "black-box" perturbations of $\mathbf{R}^n$ are studied. We remark that the methods of this paper also apply to black-box perturbations of half-space.

We define the resonances of Δ as the poles of $\chi(\Delta - k^2)^{-1}\chi$ and we define the multiplicity of a resonance k_j as the dimension of the image of the projection

$$\frac{i}{\pi}\int_\gamma \chi(\Delta - s^2)^{-1}\chi \; sds$$

with γ a sufficiently small loop around k_j. Let $\{k_j\}_{j\in\mathbf{N}}$ be the list of resonances including multiplicities.

We then prove an upper bound on the number of resonances. Define

$$N(r) = \#\{k_j,\ |k_j| < r\}.$$

For even dimensions, it is more convenient to define

$$N(r,\alpha,\epsilon) = \#\{k_j,\ \epsilon < |k_j| < r,\ |\arg(k_j)| < \alpha\}.$$

THEOREM 2. *For* $n \geq 3$ *odd, there exists a constant* $C > 0$ *such that*

$$N(r) \leq Cr^n.$$

For n *even and for any* $\alpha \in (0,\pi)$, $\epsilon > 0$, *there exists a constant* $C > 0$ *such that*

$$N(r,\alpha,\epsilon) \leq Cr^n.$$

Theorem 2 is proven using the Fredholm determinant method (see [11] and the discussion in section 2). The key estimates on the free resolvent, $(\Delta_{H^n_+} - k^2)^{-1}$, come from observing that the associated Green's function on H^n_+ is determined (via the method of images) by the Green's function on $\mathbf{R}^n$ for either Dirichlet or Neumann boundary conditions.

The restrictions on α, ϵ in even dimensions are not necessary: the arguments in [20] apply in our setting to give a bound on $N(r,\alpha,0)$ which holds $\forall\ \alpha$. However, the proof is much easier for our (weaker) statement, which essentially follows from the proof of the odd dimensional case, after Jensen's formula is replaced by a theorem of Carleman [7]. This fact was kindly pointed out to us by the referee.

If we strengthen our hypotheses about Ω, we can also prove the following.

COROLLARY 1. *Assume that* Ω *satisfies the hypotheses of Theorem* 1*, and furthermore suppose there exists a single, nonglancing, elliptic, nondegenerate trapped ray in* Ω *(see Figure* 1*). Then there exists a sequence of resonances* k'_j *such that* $\Im k'_j \to 0$ *as* $|k'_j| \to \infty$.

Corollary 1 gives an affirmative answer to a conjecture of Lax and Phillips [5] in this setting. We had originally been planning to prove the corollary only in odd dimensions, following the outline of an argument found in [14], [15]. However, the referee kindly suggested an argument that would apply in even dimensions as well and furthermore furnishes lower bounds for the counting function for resonances near the real axis. In proving Corollary 1 we shall adopt the referee's argument.

In our original (odd-dimensional) proof, we began with a global a priori estimate for the cutoff resolvent. Such an estimate was obtained by Zworski [23] for obstacle

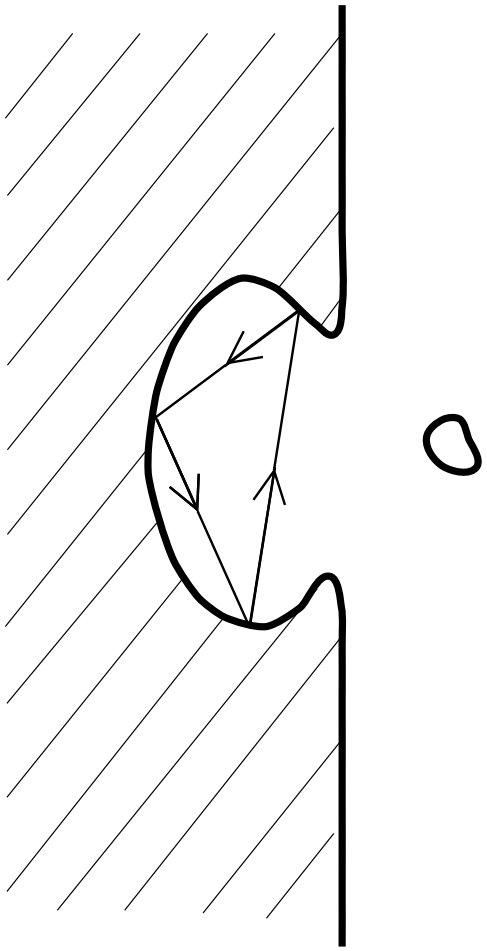

FIG. 1. *Typical domain Ω consisting of a hole in a wall. Dirichlet conditions are imposed on the boundary.*

scattering in odd dimensions, adapting techniques found in [8] and using as a key ingredient the minimodulus theorem for entire functions [17]; the method was then extended to more general perturbations in [14], [15]. Arguing as in [14], [15], we then proved that the existence of quasimodes (see [10], [1], [9], [6]) implies Corollary 1.

The referee pointed out that an a priori bound on the cutoff resolvent can be proven in a neighborhood of the positive real axis near infinity, using the minimodulus theorem of Cartan [7]. Then, using arguments appearing in [16] where they apply to black-box perturbations of $\mathbf{R}^n$, one shows that the existence of quasimodes implies a linear lower bound on the number of resonances converging to the real axis. In [16] it is also noted that under a certain hypothesis on the spacing of the quasimodes, a finer lower bound on the resonances can be obtained.

The arguments of [16] have recently been refined by Stefanov [13], who again studied black-box perturbations of $\mathbf{R}^n$ but without any hypothesis on the spacing of quasimodes. Let $N_q(r)$ be the number of quasimodes less than or equal to r, and let $N_{res}(r)$ be the number of resonances in the set $\{z : \Re z \in [1, r], \Im z \in [0, S(\Re z)]\}$; here

S is a certain function which decays faster than the reciprocal of any polynomial. Then Stefanov proves that for any $k \geq 1$, there exists C_k such that

$$N_{res}(r) \geq N_q(r - r^{-k}) - C_k \ \forall r \geq 1.$$

Stefanov then uses Popov's [9] lower bounds on the counting function for the quasi-modes associated to nondegenerate, elliptic trapped rays whose associated linearized Poincaré map is $2N + 1$ elementary for some half-integer $N \geq 2$, to bound the resonances close to the real axis below by cr^n. The arguments in [13] apply in our setting too, and thus our $O(r^n)$ upper bound on the number of resonances is optimal.

2. Proofs. We will prove the theorems for Dirichlet boundary conditions, and at the end of the section we will state the modifications necessary to treat Neumann conditions.

Denote by $L^2(\Omega)$ the set of square integrable functions on Ω, and denote the set of bounded operators on $L^2(\Omega)$ by $\mathcal{L}(L^2(\Omega))$. Denote by $B(a, r)$ the ball centered at a of radius r. If the related domain is Ω, then $B(a, r)$ refers to the ball intersected with Ω. Denote the Dirichlet Laplacian on Ω (resp., H^n_+) by Δ (resp., Δ_0). Denote the associated resolvent $(\Delta_0 - k^2)^{-1}$ by $R_0(k)$. Denote $(\Delta - k^2)^{-1}$ by $R(k)$. Define the Sobolev spaces $H^i(\Omega)$ as the domains of $(\Delta+1)^{i/2}$. We define a smooth partition of unity $\chi_1 + \chi_2 = 1$ such that $\chi_i \geq 0$, $\text{supp}(\chi_1) \subset B(0, M + 2)$, and $\chi_1 = 1$ on $B(0, M + 1)$. We also define smooth cutoff functions $\tau_i \geq 0$ such that $\tau_1 = 1$ on $\text{supp}(\chi_1)$ and $\text{supp}(\tau_1) \subset B(0, M+3)$, and $\tau_2 = 1$ on $\text{supp}(\chi_2)$ and $\tau_2 = 0$ on $B(0, M)$. Finally, we define a cutoff function $\rho \in C_0^\infty(\mathbf{R}^n)$ such that the $\text{supp}(\rho) \subset B(0, M+4)$ and

$$\rho|_{B(0,M+3)} = 1. \tag{1}$$

LEMMA 1. *Let n be odd (resp., even). Let ψ_1, ψ_2 be smooth functions of bounded support on Ω. Then the mapping from $\{\Im(k) > 0\}$ to $\mathcal{L}(L^2(\Omega))$ given by*

$$k \to \psi_2 R_0(k) \psi_1$$

extends to an entire function on $\mathbf{C}$ (resp., Λ). Also, the same is true for the mapping

$$k \to \frac{\partial}{\partial x_i} \psi_2 R_0(k) \psi_1$$

for $i = 1, \ldots, n$. Furthermore, for $\Im(k) \geq 0$ and $|k| > 1$,

$$\|\psi_2 R_0(k) \psi_1\|_{L^2 \to H^i} \leq C_i (1 + |k|)^{i-1}, \qquad i = 0, 1, 2. \tag{2}$$

Finally, if $\text{supp}(\psi_1) \cap \text{supp}(\psi_2) = \emptyset$, then (2) holds $\forall$ i.

Proof. For $x = (x_1, \overline{x}) \in \mathbf{R} \times \mathbf{R}^{n-1}$ define the mapping $U : \mathbf{R}^n \to \mathbf{R}^n$ by $U(x_1, \overline{x}) = (-x_1, \overline{x})$. Let $\tilde{R}(k) = (\Delta_{\mathbf{R}^n} - k^2)^{-1}$. By the method of images,

$$R_0(k) = \tilde{R}(k) - U^{-1} \tilde{R}(k) U,$$

the right-hand side being restricted to elements of $L^2(H^n_+)$. Hence, dropping the k dependence,

$$\chi_1 R_0 \chi_1 = \chi_1 \tilde{R} \chi_1 - U^{-1} \chi_1 \tilde{R} \chi_1 U.$$

Since U is an isometry on $H^i(\mathbf{R}^n)$, Lemma 1 now follows immediately from the analogous results for $\tilde{R}(k)$ proven in [18] for n odd and [3], [4], [18], [19] for n even. □

Proof of Theorem 1. We prove the result for n odd; the even-dimensional case is a simple adaptation of this. The argument follows closely along the lines of the corresponding result in [12]. We define an approximation of $R(k)$ as follows. Let

$$R_a(k) = \tau_1 R(k_0)\chi_1 + \tau_2 R_0(k)\chi_2. \tag{3}$$

Here k_0 is a parameter to be chosen below.

We have

$$(\Delta - k^2)R_a(k) = I + K \tag{4}$$

with

$$K = (k_0^2 - k^2)\tau_1 R(k_0)\chi_1 + [\Delta, \tau_1]R(k_0)\chi_1 + [\Delta, \tau_2]R_0(k)\chi_2. \tag{5}$$

By (4) we have for $\Im k > 0$

$$R_a = (\Delta - k^2)^{-1}(I + K).$$

By (5) and (1) we have $\rho K = K$; hence

$$R_a\rho = (\Delta - k^2)^{-1}\rho(I + K\rho).$$

For $k = k_0$ and $\operatorname{Im}(k_0) >> 0$, we have by the spectral theorem that $\|K\rho\|_{L^2\to L^2} < 1$ and hence we can write

$$\rho R_a(k)\rho(I + K\rho)^{-1} = \rho R(k)\rho. \tag{6}$$

Fix such a k_0. Now $\rho R_a(k)\rho$ is an entire function of k with values in $\mathcal{L}(L^2(\Omega))$, and therefore meromorphy of $\rho R(k)\rho$ is equivalent to meromorphy of $(I + K\rho)^{-1}$.

On the other hand, since χ_1 and ρ are compactly supported, it follows that $K\rho$ is an entire compact operator-valued function of k. It now follows from the meromorphic Fredholm theorem that $k\to\rho R(k)\rho$ extends to a meromorphic function on $\mathbf{C}$. Finally, it is easy to see that the function ρ can be replaced by any smooth cutoff function. This completes the proof of Theorem 1. □

Proof of Theorem 2. In what follows, let C be various positive constants. A simple Neumann series argument shows that $(I + K\rho)$ is invertible if and only if $(I - (-K\rho)^{n+1})$ is invertible. On the other hand, since $K\rho$ is a pseudodifferential operator of order -1 in $\mathcal{L}(L^2(\Omega))$, with compactly supported Schwartz kernel, it follows that $(K\rho)^{n+1}$ is trace class. Thus the Fredholm determinant $\det(I-(-K\rho)^{n+1})$ is entire on $\mathbf{C}$ for n odd and on Λ for n even. Furthermore, the following lemma applies.

LEMMA 2. *The resonances of* Δ *(counted with their multiplicities) are among the zeros of the function*

$$k\to h(k) \equiv \det(I - (-K\rho)^{n+1}(k)),$$

counted with their multiplicities.

The reader is referred to [20] for a proof of this result.

We shall now complete the proof of Theorem 2 for n odd, after which the modifications necessary for n even will be indicated.

Because of Lemma 2, the bound appearing in Theorem 2 will follow from Jensen's inequality and the estimate

$$|h(k)| \leq C \exp C|k|^n. \tag{7}$$

To obtain this estimate, we first write $K\rho = K_1 + K_2$ with $K_2 = [\Delta, \tau_2]R_0(k)\chi_2\rho$. We then apply the theory of characteristic values developed in [2] and adapted to exterior problems in [8], [22], [18]. The characteristic values $\mu_j(A)$ of a compact operator A are the eigenvalues, listed in increasing order and counting multiplicities, of the operator $|A|$. We recall the following inequalities from [2]: $\mu_{j+k-1}(AB) \leq \mu_j(A)\mu_k(B)$, $\mu_{j+k-1}(A+B) \leq \mu_j(A) + \mu_k(B), and\ \mu_j(AB) \leq \|A\|\mu_j(B)$.

Applying inequalities on Fredholm determinants appearing in [2], we get

$$\begin{aligned}\det(I - (-K\rho)^{n+1}) &\leq \det(I + 2^n|K_1|^{n+1})^{2n+2}\ \det(I + 2^n|K_2|^{n+1})^{2n+2} \\ &\leq \left(\prod_{j=1}^{\infty}(1 + 2^n\mu_j(|K_1|)^{n+1})\right)^{2n+2}\left(\prod_{j=1}^{\infty}(1 + 2^n\mu_j(|K_2|)^{n+1})\right)^{2n+2}. \end{aligned} \tag{8}$$

We estimate first the term involving K_1. Recall

$$K_1 = (k^2 - k_0^2)\tau_1 R(k_0)\chi_1\rho + [\Delta, \tau_1]R(k_0)\chi_1\rho.$$

Since τ_1, χ_1 are compactly supported, it follows by standard eigenvalue asymptotics for pseudodifferential operators [11] that

$$\mu_j(|\tau_1 R(k_0)\chi_1\rho|) \sim Cj^{-2/n}$$

and

$$\mu_j(|[\Delta, \tau_1]R(k_0)\chi_1\rho|) \sim Cj^{-1/n}.$$

It follows that, denoting the largest integer below x by $\lfloor x \rfloor$,

$$\mu_{j-1}(|K_1|) \leq C|k|^2\lfloor j/2 \rfloor^{-2/n} + C\lfloor j/2 \rfloor^{-1/n}.$$

Hence we get

$$\begin{aligned}\mu_j(|K_1|^{n+1}) &\leq (\mu_{(\lfloor j/(n+1)\rfloor+1)}(|K_1|))^{n+1} \\ &\leq (C|k|^2(\lfloor j/2(n+1) + 2\rfloor^{-2/n} + C(\lfloor j/2(n+1)\rfloor + 2)^{-1/n})^{n+1} \\ &\leq (C|k|^2\lfloor j/2(n+1)\rfloor^{-2/n} + C\lfloor j/2(n+1)\rfloor^{-1/n})^{n+1} \\ &\leq C|k|^{2n+2}j^{-(2n+2)/n} + Cj^{-1-1/n}.\end{aligned}$$

We have, for $|k|$ sufficiently large,

$$\begin{aligned}&\prod_{j=1}^{\infty}(1 + 2^n\mu_j(|K_1|)^{n+1}) \\ &\quad\leq \prod_{j\leq k^{2n}}(1 + C|k/j^{1/n}|^{2n+2}) \prod_{j>k^{2n}}(1 + C|j^{-1/2n}|^{2n+2} + Cj^{-1-1/n}).\end{aligned}$$

These two factors are bounded as in [22]; we sketch the argument. The first factor is bounded by comparing it to

$$\exp\left(\int_1^{|k|^2} \ln(1 + C|k/x^{1/n}|^{2n+2})dx\right),$$

which is bounded by $e^{C|k|^n}$. The second factor is treated similarly. Thus

$$\prod_{j=1}^{\infty}(1+2^n\mu_j(|K_1|)^{n+1}) \le e^{C|k|^n}. \tag{9}$$

Note that this estimate holds for all $k \in \mathbf{C}$.

Next, we estimate the terms involving K_2. The argument sketched below is an adaptation of one originally implemented by Vodev in [18].

LEMMA 3. *Suppose* $\Im k \ge 0$. *Then* $\det(I+2^n|K_2|^{n+1}) < C$ *for some positive constant* C.

Proof. We have, using (2) with $i=3$,

$$\begin{aligned}\mu_j(K_2) &= \mu_j(\rho(I+\Delta)^{-1}(I+\Delta)K_2)\\ &\le \mu_j(\rho(I+\Delta)^{-1})\|(I+\Delta)K_2)\|\\ &\le Cj^{-2/n}|k|^2.\end{aligned}$$

Now the arguments leading to (9) are easily adapted to this case. The details are omitted.

LEMMA 4. *Suppose* $\Im k < 0$. *Then*

$$\det(I+2^n|K_2|^{n+1}) \le \exp(C|k|^n).$$

Proof. We use the notation of Lemma 1. We first observe that for $\Im k < 0$,

$$\begin{aligned}&\det(I+2^n|K_2(k)|^{n+1})\\ &\quad\le \det(I+2^n|K_2(-k)|^{n+1})^{2n+2}\det(I+2^n|K_2(k)-K_2(-k)|^{n+1})^{2n+2}.\end{aligned} \tag{10}$$

The first term on the right-hand side is bounded by Lemma 3. To bound the second, we begin by recalling Stone's theorem for the Laplacian on $\mathbf{R}^n$,

$$\tilde{R}(k)-\tilde{R}(-k) = c_n k^{n-2}\int_{S^{n-1}} e^{ik<\omega,x-y>}d\omega.$$

It follows that

$$(R_0(k)-R_0(-k))(x,y) = c_n k^{n-2}\int_{S^{n-1}} e^{ik\langle\omega,x-y\rangle} - e^{-ik\omega_1(x_1-y_1)}e^{ik\langle\overline{\omega},\overline{x}-\overline{y}\rangle}d\omega.$$

This allows us the factorization for $\Im k > 0$

$$\rho(R_0(k)-R_0(-k))\rho = c_n k^{n-2}\rho E^*(k)E(k)\rho,$$

with $E(k)$ being a mapping from $L^2(H^n_+)$ to $L^2(S^{n-1})$ whose Schwartz kernel is given by

$$e^{-ik\langle\omega,y\rangle} - e^{ik\omega_1 y_1}e^{-ik\langle\overline{\omega},\overline{y}\rangle}.$$

Observe that this kernel is an entire function in k, and we have the estimate

$$\|\rho E^*(k)\|_{L^2\to L^2} \le e^{(M+2)|\Im k|},$$

with M as in (1). Also, observe that

$$\begin{aligned}\mu_j(E(k)\rho) &\le \mu_j((\Delta_{S^{n-1}}+1)^{-m})\|(\Delta_{S^{n-1}}+1)^m E(k)\rho\|\\ &\le C^m(j)^{-2m/(n-1)}\|(\Delta_{S^{n-1}}+1)^m E(k)\rho\|.\end{aligned}$$

On the other hand, the estimate $|k|^p e^{C|k|} \leq Cp!\ e^{(C+1)|k|}$ together with a combinatorial argument yield

$$\|(\Delta_{S^{n-1}} + 1)^m E(k)\rho\| \leq (2m)!\ e^{C|k|}.$$

Thus

$$\mu_j(E(k)\rho) \leq (2m)!\ C^m (j)^{-2m/(n-1)} e^{C|k|}.$$

Optimizing over m, we get

$$\mu_j(E(k)\rho) \leq e^{-(1/j^{(n-1)})/C} e^{C|k|}.$$

Hence

$$\mu_j(\rho(R_0(k) - R_0(-k))\rho) \leq e^{-(1/j^{(n-1)})/C} e^{C|k|}.$$

A similar argument yields

$$\mu_j\left(\rho \frac{\partial}{\partial x_i}(R_0(k) - R_0(-k))\rho\right) \leq e^{-(j^{1/(n-1)})/C} e^{C|k|}, \qquad i = 1, \ldots, n.$$

Combining these yields for $\Im k < 0$,

$$\mu_j\left([\Delta, \tau_2](R_0(k) - R_0(-k))\chi_2\rho\right) \leq e^{C|k|} e^{-(j^{1/(n-1)})/C}.$$

Thus, setting $T(k) = K_2(k) - K_2(-k)$,

$$\begin{aligned}
\det(I + 2^n |T(k)|^{n+1}) &\leq \prod_{j < C|k|^{n-1}} (1 + 2^n \mu_j(|T(k)|^{n+1})) \\
&\qquad \times \exp\left(\sum_{j \geq C|k|^{n-1}} 2^n \mu_j(|T(k)|^{n+1})\right) \\
&\leq \prod_{j < C|k|^{n-1}} e^{C|k|} \exp\left(\sum_{j \geq C|k|^{n-1}} \left(e^{C|k|} e^{-(j^{1/(n-1)})/C}\right)^{n+1}\right) \\
&\leq e^{C|k|^n}.
\end{aligned}$$

This completes the proof of the lemma. □

Combining (8) and (9) and Lemmas 3 and 4, we obtain (7) and hence Theorem 2 for n odd.

We now complete the proof for n even. In place of Jensen's formula, we use Carleman's theorem [7, Thm. 5.1.1]. The bounds on the determinant for large k are proven as in the odd-dimensional case (set the branch line on the negative real axis in Lemma 4), and the bounds for k near the origin are obtained simply by analyticity.

Proof of Corollary 1.

LEMMA 5. *Let* $\Lambda_{\alpha,N} = \{k : |\arg k| < \alpha,\ |k| > N\}$. *Fix* $\epsilon > 0$, $\alpha \in (0, \pi/2)$. *Let* $\{k_j\}$ *denote the resonances in* $\Lambda_{\alpha,N}$. *Then there exist constants* N, C *such that*

$$\|\rho R(k)\rho\| \leq C e^{C|k|^n \log k} \tag{11}$$

$\forall\ k \in \Lambda_{\alpha,N} - \cup_{k_j} B(k_j, |k_j|^{-n-\epsilon})$.

Proof. In what follows we assume $|k| > 1$. We recall

$$\rho R_a(k)\rho(I + K\rho)^{-1} = \rho R(k)\rho. \tag{12}$$

It follows from (3), Lemma 1, and the proof of Lemma 4 that for $\alpha \in (0, \pi)$ and $k \in \Lambda_\alpha$,

$$\|\rho R_a \rho\|_{L^2 \to L^2} \leq e^{C|k|^n}. \tag{13}$$

To bound $(1 + K\rho)^{-1}$, we proceed as follows: From [2, Chap. 5, Thm. 5.1.], we have

$$\|(I + K\rho)^{-1}\|_{L^2 \to L^2} \leq |\det(I + (K\rho)^{n+1})|^{-1} \det(I + |K\rho|^{n+1})^{n+1}.$$

By the proof of Theorem 2, we have

$$\det(I + |K\rho|^{n+1})^{n+1} \leq e^{C|k|^n}. \tag{14}$$

To obtain the lower bound on $f(k) \equiv |\det(I + (K\rho)^{n+1})|$, we first note that

$$\begin{aligned} |\det(I + (K\rho)^{n+1})|^{n+1} &\leq \det(I + |K\rho|^{n+1})^{n+1} \\ &\leq e^{C|k|^n}. \end{aligned}$$

Next, we apply the minimodulus theorem of Cartan (see [7, p. 21]). Thus let $\eta, c > 0$. Suppose $l >> 0$. Clearly, $|f(k)| \leq e^{Cl^n}$ for $k \in B(l, 2ecl)$. It follows that in $B(l, cl)$, and outside a system of disks of radii whose sum is no greater than $4cl\eta$, we have

$$|f(k)| > (e^{C|k|^n})^{-2-\log(3e/2\eta)}, \tag{15}$$

with C a constant independent of l, k. Setting $\eta = l^{-n-2}$ and combining the inequality above with (14), (15), (13), and (12), the inequality appearing in (11) holds in $B(l, cl)$ in the complement of the system of disks. We decompose the system of disks into the union $\cup U_j$, where U_j are connected, mutually disjoint, and have diameter at most $4cl^{-n-1}$. By increasing c slightly if necessary, we also have that $U_j \subset B(l, cl)$. Finally, we can assume that each U_j contains a resonance. For if not, then (11) holds on U_j by the maximum principle.

Now we suppose l is sufficiently large that $l^{-n-\epsilon} > 8cl^{-n-1}$. Then it follows that for each j, $U_j \subset B(k_i, |k_i|^{-n-\epsilon})$ for some resonance $k_i \in B(l, cl)$. With α, N determined by c, ϵ, the lemma now follows. □

The proof of Corollary 1 is completed as follows: applying Lemma 5 of this paper, along with Lemma 2 of [16] (with $h = 1/k^2$), the proofs of Theorems 1 and 2 in [16] carry over immediately, yielding a linear lower bound on the resonances converging to the real axis.

In the case of Neumann boundary conditions, it suffices to observe that by the method of images, the associated resolvent of half-space satisfies

$$R_0(k) = \tilde{R}(k) + U^{-1}\tilde{R}(k)U.$$

The preceding arguments carry over without difficulty.

Acknowledgments. The first author thanks Maciej Zworski for guiding him through the intricacies of scattering theory. The second author would like to thank ECU for providing a summer research grant. We also thank the referee, whose suggestions improved both the presentation and the content of this paper.

ON A CONJECTURE RELATIVE TO THE MAXIMA OF HARMONIC FUNCTIONS ON CONVEX DOMAINS*

LUCIO R. BERRONE†

Abstract. We consider a harmonic function u defined on a bounded domain $\Omega \subset \mathbb{R}^2$ and satisfying the mixed boundary conditions $u|_{\Gamma_0} = 0$, $(\partial u/\partial n)|_{\Gamma_1} = 1$, where Γ_1 is composed by a finite number of arcs of $\partial\Omega$ and $\Gamma_0 = \partial\Omega \sim \overline{\Gamma_1}$. In [Berrone, *Subsistencia de Modelos Matematicos que Involucran a la Ecuacion del Calor-Difusion*, Ph.D. thesis, Universidad Nacional de Rosario, Argentina, 1994] it was conjectured that if Ω is convex and the subset Γ_1 is made to vary on $\partial\Omega$ so as to maintain its measure equal to a constant $C > 0$, then $\Gamma_1 \mapsto \sup_{x\in\Omega} u$ attains its maximum value when Γ_1 is a certain *connected* arc of measure C. The present paper has evolved from attempts to prove this conjecture. When certain geometric restrictions are satisfied by the components of Γ_1, the property stated by the conjecture is shown to hold for every regular domain Ω, convex or not, and *every* connected arc, provided that the measure $|\Gamma_1|$ is sufficiently small (see Theorem 5). However, convexity becomes a necessary condition in order that the full conjecture can be supportable (see section 2). In addition, some variations of the conjecture are proposed.

Key words. harmonic functions, mixed boundary value problems

AMS subject classifications. 35J05, 35B99

1. Introduction.

Let Ω be a bounded plane domain whose boundary curve $\partial\Omega$ is composed of two families of relatively open arcs Γ_0 and Γ_1 such that $\partial\Omega = \overline{\Gamma_0 \cup \Gamma_1}$, $\Gamma_0 \cap \Gamma_1 = \emptyset$. In this paper we are concerned with the following mixed boundary value problem:

$$\left|\begin{array}{ll} \Delta u(x) = 0, & x \in \Omega, \\ u(x) = 0, & x \in \Gamma_0, \\ \frac{\partial u}{\partial n}(x) = 1, & x \in \Gamma_1. \end{array}\right. \tag{1}$$

In (1), we have denoted by n the unit outward-pointing normal vector to $\partial\Omega$. In regard to the required regularity of Ω, a Dini-smooth boundary $\partial\Omega$ will be assumed in the developments of sections 3 and 4. Moreover, an interior sphere condition on every point of $\partial\Omega$ will be supposed in order that the strong maximum principle and Hopf's lemma may hold. As is well known, the solution to problem (1) is continuous up to the boundary provided that the family Γ_1 is finite, as we shall assume henceforth. This solution will be denoted by $u[\Gamma_1]$ to indicate its dependence on Γ_1. It is also well known that many physical phenomena are modeled by problem (1). A nonexhaustive list of these is given in [15] (see also [14]) but, for our purpose, it will be illustrative to think about problem (1) as giving the equilibrium position of an elastic membrane Ω which is subjected to a unit normal force on Γ_1, while it is fixed at level zero along the remaining portion Γ_0 of the boundary of Ω.

Our main interest focuses on the behavior of the functional $\Gamma_1 \mapsto \sup_{x\in\Omega} u[\Gamma_1]$. Concretely, in the thesis [2] the following conjecture has been posed.

*Received by the editors March 6, 1998; accepted for publication (in revised form) January 11, 1999; published electronically October 4, 1999. This work was supported by a Beca Externa from "Consejo Nacional de Investigaciones Científicas y Técnicas" de la República Argentina.

CONJECTURE 1. *Let Ω be a convex domain and C be a constant such that $0 < C < |\partial\Omega|$. If Γ_1 is made to vary on all finite families of arcs of $\partial\Omega$ with measure $|\Gamma_1| = C$, then $\Gamma_1 \mapsto \sup_{x\in\Omega} u[\Gamma_1]$ reaches its maximum value when Γ_1 is a certain* connected *arc of $\partial\Omega$.*

In terms of the above-given mechanical interpretation of problem (1), the conjecture states that if a convex membrane initially fixed at zero is lifted by a unitary normal force on portions Γ_1 of its boundary with a constant total measure C, then the membrane will reach a maximum height when Γ_1 is a certain connected arc of measure C. As we explained in [4], this conjecture arose from attempts to estimate the solution to boundary value problems like (1) through sub- and supersolutions: in general, simple sub- and supersolutions to problem (1) are more easily calculated when Γ_1 is connected (cf. [3]). Furthermore, exact solutions to (1) are known for particular domains in this situation, Ghizzetti's solution for the circle (see [7]) being a good example. Ghizzeti's solution will be of capital importance in the developments of sections 3 and 4.

In [4], Conjecture 1 is studied for unbounded domains and it is shown there to be not generally true in this case. For instance, Conjecture 1 holds for the half-plane but it fails for an infinite strip. Section 2 of this paper is devoted to supporting the hypothesis of convexity of the domain Ω in the conjecture by showing an example of a nonconvex domain such that connected arcs of its boundary are not generally optimal for $\Gamma_1 \mapsto \sup_{x\in\Omega} u[\Gamma_1]$.

Up to now, we have been unable generally to prove or to construct a counterexample to Conjecture 1. Nevertheless, some variations of the conjecture seem to be more manageable. An interesting variation is obtained when the functional $\Gamma_1 \mapsto \|u[\Gamma_1]\|_p = \left(\int_{\partial\Omega} |u[\Gamma_1]|^p \, ds\right)^{1/p}$, $1 \le p < +\infty$, is taken instead of $\Gamma_1 \mapsto \sup_{x\in\Omega} u[\Gamma_1]$ in Conjecture 1, giving rise to the following.

CONJECTURE 2. *Let Ω be a convex domain and C be a constant such that $0 < C < |\partial\Omega|$. If Γ_1 is made to vary on all possible finite families of arcs of $\partial\Omega$ with total measure $|\Gamma_1| = C$, then $\Gamma_1 \mapsto \left(\int_{\partial\Omega} |u[\Gamma_1]|^p \, ds\right)^{1/p}$ reaches its maximum value when Γ_1 is a certain* connected *arc of $\partial\Omega$.*

In mechanical terms, Conjecture 2 for $p = 1$ asserts that in order to maximize the mean height of the boundary of the membrane by lifting a portion of measure C of its boundary, a connected portion of measure C must be lifted. Now, if the Green formula $\int_\Omega u\,\Delta u\,dx = \int_{\partial\Omega} u\frac{\partial u}{\partial n} ds - \int_\Omega |\nabla u|^2\,dx$ is applied to the solution $u[\Gamma_1]$ to problem (1), we obtain

$$\int_{\partial\Omega} u[\Gamma_1]\,ds = \int_{\Gamma_1} u[\Gamma_1]\,ds = \int_\Omega |\nabla u[\Gamma_1]|^2\,dx,$$

so that maximizing $\int_{\partial\Omega} u[\Gamma_1]\,ds$ amounts to the same as maximizing the Dirichlet integral $\int_\Omega |\nabla u[\Gamma_1]|^2\,dx$. On the other hand, there exists a point $P \in \Omega$ such that $|\partial\Omega|\,u[\Gamma_1](P) = \int_{\partial\Omega} u[\Gamma_1]\,ds$ and then, the following variation of Conjecture 2 is suggested which says that the height of the membrane at the interior point P is a maximum when Γ_1 is connected.

CONJECTURE 3. *Let Ω be a convex domain and fix $P \in \Omega$. Moreover, let C be a constant such that $0 < C < |\partial\Omega|$. If Γ_1 is made to vary on all possible finite families of arcs of $\partial\Omega$ with total measure $|\Gamma_1| = C$, then $u[\Gamma_1](P)$ reaches its maximum value when Γ_1 is a certain* connected *subarc of $\partial\Omega$.*

Observe that if Ω is a circle of radius R centered at the origin, we have $\int_{\partial\Omega} u[\Gamma_1]\,ds = 2\pi R\,u[\Gamma_1](0)$ and then Conjecture 2 for $p = 1$ and Conjecture 3 with $P = 0$ are equiv-

alent statements. Recently, a proof of this particular instance was obtained (see [5]) by relating it to a nice result of Beurling on capacities of subsets of the circumference.

Of course, many other variations and extensions of these conjectures are viable but in this paper we discuss two concrete results related to Conjecture 1. To properly state these results, first we need to introduce some preliminary concepts and notations. Let us consider in the following a Jordan domain Ω with a sufficiently regular boundary curve γ. We suppose that γ is parametrized by its arc length s measured from some point $O \in \gamma$. A relatively open subset Γ_1 of γ with a finite number of components can be described as follows:

$$\Gamma_1 = \{\gamma(s) : a_k < s < b_k,\ k = 1, 2, \ldots, n\}, \tag{2}$$

but, for the sake of brevity, we will identify a point $\gamma(s)$ belonging to γ with its corresponding arc length s, so that the more condensed notations

$$\Gamma_1 = \cup_{k=1}^{n}(a_k, b_k) = \cup_{k=1}^{n}\Gamma_1^{(k)}, \tag{3}$$

$$\Gamma_1^{(k)} = (a_k, b_k),\ k = 1, 2, \ldots, n \tag{4}$$

will be used throughout this paper to denote the family of arcs given by (2). We indicate by Γ_1^* a generic connected arc of γ, i.e.,

$$\Gamma_1^* = (a, b). \tag{5}$$

Furthermore, if Γ_1 is given by (3), for $0 < \varepsilon \leq 1$ we define

$$\Gamma_1(\varepsilon) = \cup_{k=1}^{n}\left(a_k(\varepsilon), b_k(\varepsilon)\right), \tag{6}$$

where

$$a_k(\varepsilon) = \frac{a_k + b_k}{2} - \frac{\varepsilon}{2}\left(b_k - a_k\right)$$

and

$$b_k(\varepsilon) = \frac{a_k + b_k}{2} + \frac{\varepsilon}{2}\left(b_k - a_k\right).$$

Note that $\Gamma_1(\varepsilon)$ corresponds to a shrinkage of Γ_1 of magnitude ε and therefore, $|\Gamma_1(\varepsilon)| = \varepsilon\ |\Gamma_1|$.

A proof is given in section 3 of the following result.

THEOREM 4. *Let Ω be a Jordan domain with a Dini-smooth boundary γ and satisfying an interior sphere condition at every point of γ. Moreover, let Γ_1 and Γ_1^* be two subsets of γ respectively given by* (3) *and* (5) *with $b - a = \sum_{k=1}^{n}(b_k - a_k)$. Then, the inequality*

$$\sup_{\Omega} u[\Gamma_1(\varepsilon)] < \sup_{\Omega} u[\Gamma_1^*(\varepsilon)] \tag{7}$$

holds for every sufficiently small ε.

Recall that a uniformly continuous function φ defined on a connected set $A \subset \mathbb{C}$ is said to be Dini-continuous when

$$\int_0^{\delta} \frac{\omega(\varphi, t)}{t}\, dt < +\infty,$$

where $\omega(\varphi,t)=\sup\{|\varphi(z_1)-\varphi(z_2)|:z_1,\,z_2\in A,\ |z_1-z_2|\le t\}$ is the modulus of continuity of φ and $\delta>0$. If $\partial\Omega$ admits a parametrization $\gamma(t)$, $a\le t\le b$, such that γ' is Dini-continuous and $\gamma'(t)\neq 0$, $a\le t\le b$, then we say the domain Ω has a Dini-smooth boundary. This regularity condition on $\partial\Omega$ suffices for a conformal map $f:B_1(0)\to\Omega$ to have a derivative f' which can be continuously extended to $\overline{\Omega}$ (cf. [12, Theorem 3.5, p. 48]), a fact we exploit often in sections 3 and 4.

For a finite family of arcs $\Gamma_1\subset\partial\Omega$, we define the quantity $d=d(\Gamma_1)$ to be the minimum distance in $\partial\Omega$ existing between adjacent components of Γ_1. Thus, if Γ_1 is represented by (3), then we set

$$d(\Gamma_1)=\min\left\{\min_{1\le k\le n-1}\left(a_{k+1}-b_k\right),a_1-b_n\right\}. \tag{8}$$

The quantities

$$H(\Gamma_1)=\frac{|\Gamma_1|}{\sin\left[d(\Gamma_1)/\left(2\left\|f'\right\|_\infty\right)\right]} \tag{9}$$

and

$$\rho(\Gamma_1)=\frac{1}{|\Gamma_1|}\max_{1\le k\le n}\left|\Gamma_1^{(k)}\right|, \tag{10}$$

where f is a conformal mapping of $B_1(0)$ onto Ω, are shown to be useful in the developments of section 4. We remark that $\left\|f'\right\|_\infty=\sup_{B_1(0)}|f'|$ does not depend on the particular choice of the mapping f but only on the geometry of Ω. The same property, that is, independent of the chosen mapping f, is enjoyed by the quantity $M(f)=\inf_{\partial B_1(0)}|f'|$. Taking into account that $|\partial\Omega|=\int_0^{2\pi}\left|f'(e^{i\theta})\right|d\theta\le 2\pi\left\|f'\right\|_\infty$ and $d/|\partial\Omega|<1/2$, we see that $0<d/\left(2\left\|f'\right\|_\infty\right)\le\pi d/|\partial\Omega|<\pi/2$. Therefore, $H(\Gamma_1)$ is a decreasing function of $d(\Gamma_1)$. It should also be noted that $nd\le|\Gamma_0|$; hence the number of components n is bounded by $|\Gamma_0|/d$.

Using the quantities $H(\Gamma_1)$ and $\rho(\Gamma_1)$, a distinguished class $\mathcal{F}$ of finite families of arcs of $\partial\Omega$ is now defined as follows:

$$\mathcal{F}=\left\{\Gamma_1\subset\partial\Omega:\rho(\Gamma_1)\le\delta_1,\ \frac{\left\|f'\right\|_\infty}{8\pi\,M(f')}H^2(\Gamma_1)\le 1-\delta_2,\ 0<\delta_1<\delta_2<1\right\}.$$

Section 4 is devoted to proving the following generalization of Theorem 4.

THEOREM 5. *Let Ω be a Jordan domain with a Dini-smooth boundary γ and satisfying an interior sphere condition at every point of γ. Then, for every family $\Gamma_1\in\mathcal{F}$* with sufficiently small measure*, the inequality*

$$\sup_\Omega u[\Gamma_1]<\sup_\Omega u[\Gamma_1^*]$$

holds provided that $\Gamma_1^*\subset\partial\Omega$ is a connected arc *with $|\Gamma_1^*|=|\Gamma_1|$.*

For the shrinkage $\Gamma_1(\varepsilon)$ of a finite family of arcs Γ_1, the minimum distance $d(\Gamma_1(\varepsilon))$ increases as $\varepsilon\downarrow 0$ while the measure $|\Gamma_1(\varepsilon)|$ decreases. Moreover, the quantity $\rho(\Gamma_1(\varepsilon))$ does not change as ε varies and therefore, $\Gamma_1(\varepsilon)$ belongs to the class $\mathcal{F}$ for small enough ε's. Then, Theorem 5 contains Theorem 4.

Section 5 concludes the paper with some brief remarks on diverse questions related to Conjectures 1–3. In particular, the possible validity of n-dimensional versions of these conjectures is pointed out.

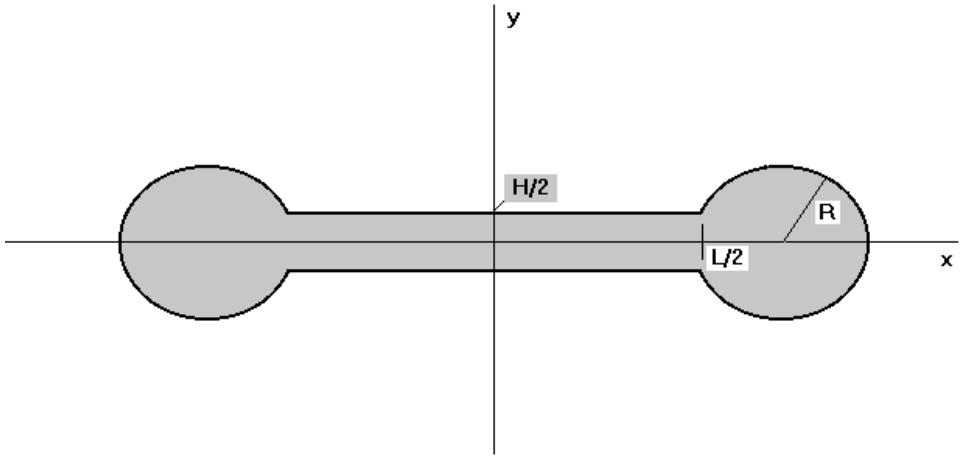

FIG. 1.

2. The role of the convexity of the domain. The convexity of the domain Ω is a condition which cannot be dropped if the property of the solutions to problem (1) stated by Conjecture 1 was generally true. To clarify this point, in this section an example is exhibited of a nonconvex domain where the conjecture fails. Thus, let us consider a domain Ω with the shape depicted in Figure 1. For this domain Ω, the solutions to problem (1) corresponding to different Γ_1's will be estimated by constructing appropriate sub- and supersolutions. By a supersolution to problem (1) we mean a function $w \in \mathcal{C}^2(\Omega) \cap \mathcal{C}(\overline{\Omega})$ satisfying

$$\left| \begin{array}{ll} \Delta w(x) \leq 0, & x \in \Omega, \\ w(x) \geq 0, & x \in \Gamma_0, \\ \frac{\partial w}{\partial n}(x) \geq 1, & x \in \Gamma_1. \end{array} \right. \tag{11}$$

A function $v \in \mathcal{C}^2(\Omega) \cap \mathcal{C}(\overline{\Omega})$ that satisfies the reverse inequalities is said to be a subsolution to problem (1). Let v and w be a sub and a supersolution, respectively, to problem (1). Since the domain Ω we are considering satisfies an interior sphere condition at every point of its boundary, the strong maximum principle and Hopf's lemma (see [1], [9], [13]) guarantee that the inequalities

$$v(x) \leq u(x) \leq w(x), \ x \in \overline{\Omega}$$

are satisfied by the solution u to problem (1). In the discussion below, affine, quadratic, and potential sub- and supersolutions are utilized which are simple enough to make the calculations feasible and, at the same time, to provide estimates which suffice for our purpose. As a general presentation of the method of sub- and supersolution to obtain approximations in boundary value problems of elliptic type, we cite [13]. For a more systematic study of estimates of the solution to problems like (1) using potential or affine sub- and supersolution we refer to [3].

As can be observed in Figure 1, the geometry of the domain under consideration is completely determined by the positive parameters L, R, and H $(R > H/2)$. Note that the smallest ball centered at the origin that contains Ω is given by $B_{r_0}(0)$ with $r_0 = L/2 + R + \sqrt{R^2 - H^2/4}$. This fact will be used later to obtain appropriate estimates. Moreover, we denote by a the length of Γ_1; i.e., $a = |\Gamma_1|$, assuming that

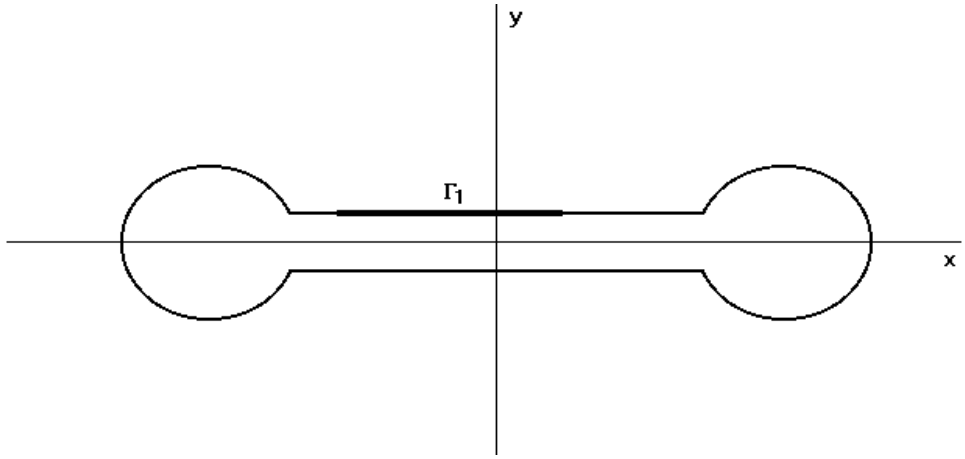

FIG. 2.

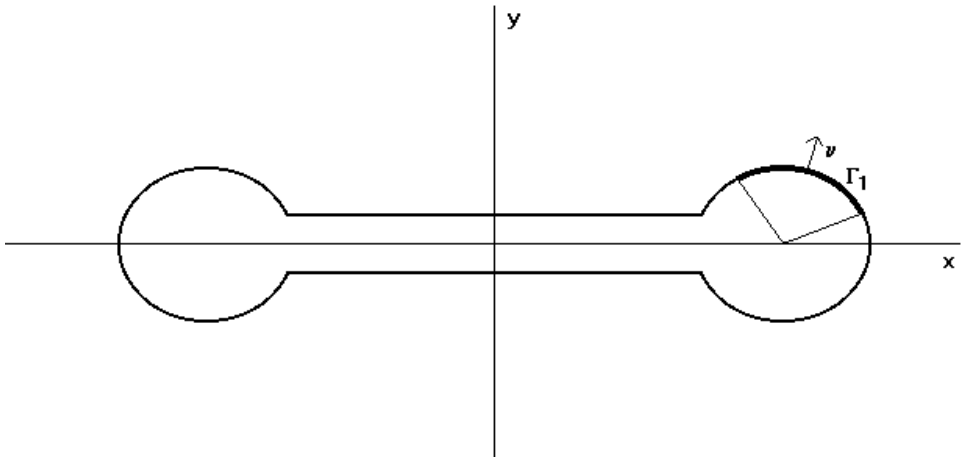

FIG. 3.

$a < \min\{L,\ \pi R/2\}$. First we will construct several supersolutions to problem (1) which depend on the relative position occupied by a connected arc Γ_1 on $\partial\Omega$. By the symmetry of the domain and the assumption made on a, it will be sufficient to analyze three situations which are respectively characterized by Figures 2, 3, and 4.

In the following discussion, we always denote by u the solution to the instance of problem (1) that is being analyzed.

Consider first the case illustrated in Figure 2. The function $v_1(x,y) = R + y$ is a supersolution to problem (1) in this case. In fact, v_1 is harmonic and

$$(v_1|_{\Gamma_0})(x,y) \geq R - R = 0,\ (x,y) \in \Gamma_0,$$
$$\left(\frac{\partial v_1}{\partial n}\right)\Big|_{\Gamma_1}(x,y) = 1,\ (x,y) \in \Gamma_1.$$

Thus, $u \leq v_1$ in $\overline{\Omega}$ and then

$$\sup_{\Omega} u \leq \sup_{\Omega} v_1 = 2R. \tag{12}$$

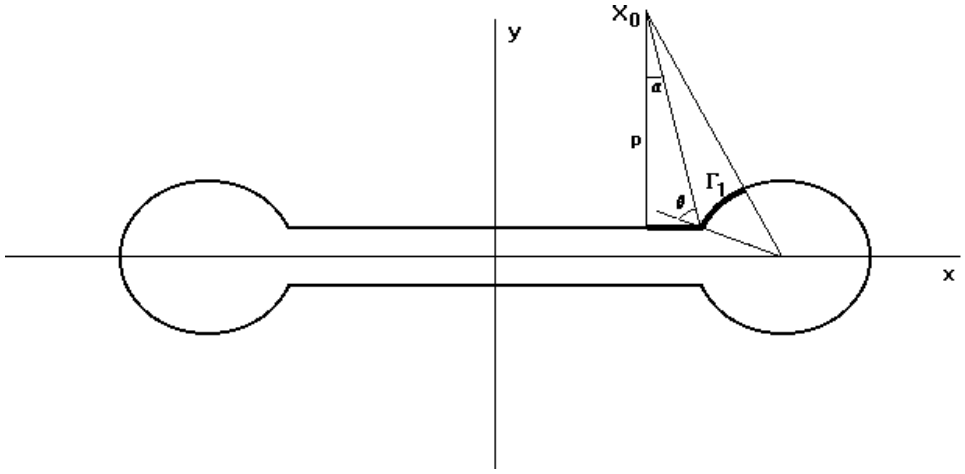

FIG. 4.

When Γ_1 is an arc of circle (see Figure 3) we denote by ν the unit outward-pointing normal vector to the circle corresponding to the midpoint of Γ_1. Then, the affine function

$$v_2(x,y) = \frac{1}{\cos(a/(2R))}\left(\frac{L}{2} + R + \sqrt{R^2 - \frac{H^2}{4}} + \langle \nu, (x,y)\rangle\right),$$

where $\langle\cdot,\cdot\rangle$ indicates the inner product in $\mathbb{R}^2$, is a supersolution to problem (1). Indeed, from the above-mentioned inclusion $\Omega \subset B_{r_0}(0)$, $r_0 = L/2 + R + \sqrt{R^2 - H^2/4}$ and using the Cauchy–Schwarz inequality we deduce

$$(v_2|_{\Gamma_0})(x,y) \geq \frac{1}{\cos(a/(2R))}\left(\frac{L}{2} + R + \sqrt{R^2 - \frac{H^2}{4}} - |(x,y)|\right) \geq 0,\ (x,y) \in \Gamma_0,$$

and, if $n(x,y)$ indicates the unitary outward-pointing normal vector at the point $(x,y) \in \partial\Omega$,

$$\left(\frac{\partial v_2}{\partial n}\right)\Big|_{\Gamma_1}(x,y) = \frac{\langle \nu, n(x,y)\rangle}{\cos(a/(2R))} \geq \frac{\cos(a/(2R))}{\cos(a/(2R))} = 1,\ (x,y) \in \Gamma_1.$$

Therefore,

$$\sup_{\Omega} u \leq \sup_{\Omega} v_2 \leq \frac{2\left(L/2 + R + \sqrt{R^2 - H^2/4}\right)}{\cos(a/(2R))} \leq \frac{L + 4R}{\cos(a/(2R))}. \tag{13}$$

The second inequality in (13) follows from a new application of the Cauchy–Schwarz inequality. For the case described by Figure 4 we propose a potential supersolution of the form (cf. [3])

$$v_3(x,y) = \frac{D(X_0,\Gamma_1)}{h(X_0,\Gamma_1)}\ \ln\left(\frac{D(X_0,\Gamma_0)}{|(x,y) - X_0|}\right),$$

where X_0 is a point not belonging to $\overline{\Omega}$ and, if Γ is a subset of $\partial\Omega$,

$$D(X_0,\Gamma)=\sup_{(x,y)\in\Gamma}|(x,y)-X_0|\,,\quad h(X_0,\Gamma)=\inf_{(x,y)\in\Gamma}\left\langle\frac{X_0-(x,y)}{|(x,y)-X_0|},n(x,y)\right\rangle.$$

In fact, we obviously have

$$v_3(x,y)\geq 0,\ (x,y)\in\Gamma_0,$$

and placing X_0 as in Figure 4 we obtain

$$\begin{aligned}\left(\frac{\partial v_3}{\partial n}\right)\Big|_{\Gamma_1}(x,y)&=\frac{D(X_0,\Gamma_1)}{h(X_0,\Gamma_1)}\,\frac{1}{|(x,y)-X_0|}\left\langle\frac{X_0-(x,y)}{|(x,y)-X_0|},n(x,y)\right\rangle\\&\geq\frac{D(X_0,\Gamma_1)}{|(x,y)-X_0|}\geq 1,\qquad (x,y)\in\Gamma_1.\end{aligned}$$

Thus, the following estimate for u is deduced:

$$\sup_\Omega u\leq\sup_\Omega v_3\leq\frac{D(X_0,\Gamma_1)}{h(X_0,\Gamma_1)}\,\ln\left(\frac{D(X_0,\Gamma_0)}{d(X_0,\Omega)}\right),\tag{14}$$

where, as usual, $d(X_0,\Omega)$ denotes the distance of X_0 to Ω. Now, simple calculations show that an upper bound independent of the parameter H can be found for the estimate of $\sup_\Omega u$ given by (14). This property, which is also shared by the bounds provided by (12) and (13), is to be exploited further on to complete the argument. To find such an upper bound we set $a=a_1+a_2$ with a_2 denoting the length of the part of Γ_1 placed on the circle. Let $(L/2-a_1,H/2+p)$ be the coordinates of X_0 with the value of p given by

$$p=\left(a_1+\sqrt{R^2-\frac{H^2}{4}}\right)\tan\left(\frac{a_2}{R}+\arcsin\left(\frac{H}{2R}\right)\right)-\frac{H}{2};$$

then we can write

$$D(X_0,\Gamma_1)=\sqrt{a_1^2+p^2},\tag{15}$$

$$D(X_0,\Gamma_0)=R+\sqrt{\left(p+\tfrac{H}{2}\right)^2+\left(L-a_1+\sqrt{R^2-\tfrac{H^2}{4}}\right)^2},\tag{16}$$

$$d(X_0,\Omega)=\min\left\{p,\sqrt{\left(a_1+\sqrt{R^2-\tfrac{H^2}{4}}\right)^2+\left(p+\tfrac{H}{2}\right)^2}-R\right\}.\tag{17}$$

Furthermore, taking into account that

$$\cos\alpha=\tfrac{p}{\sqrt{a_1^2+p^2}},\quad\cos\theta=\tfrac{H}{2R}\,\cos\alpha+\sqrt{1-\tfrac{H^2}{4R^2}}\,\sin\alpha\geq\sqrt{1-\tfrac{H^2}{4R^2}}\,\tfrac{a_1}{\sqrt{a_1^2+p^2}},$$

where α and θ are the angles specified in Figure 4, we obtain

$$h(X_0,\Gamma_1)=\min\{\cos\alpha,\cos\theta\}\geq\frac{1}{\sqrt{a_1^2+p^2}}\min\left\{p,a_1\sqrt{1-\frac{H^2}{4R^2}}\right\}.\tag{18}$$

By introducing (15)–(18) in (14) and taking $H < R$, after some algebraic manipulations we conclude

$$\sup_{\Omega} u \leq \frac{a_1^2 + p^2}{\min\{p, \frac{\sqrt{3}}{2}a_1\}} \ln\left(\frac{\frac{5}{2}R + p + L - a_1}{\min\left\{p, \sqrt{\left(a_1 + \frac{\sqrt{3}}{2}R\right)^2 + p^2} - R\right\}} \right). \tag{19}$$

Finally, in view of $\lim_{H\downarrow 0} p = (a_1 + R)\tan(a_2/R)$, an estimate independent of H for $\sup_{\Omega} u$ can be easily deduced from (19).

Next, we will consider the instance of problem (1) in which Γ_1 splits into two symmetric segments of length $a/2$ as shown in Figure 5. On the subdomain $\Omega' = (-a/4, a/4) \times (-H/2, H/2)$ (in gray in Figure 5), the harmonic function

$$w(x,y) = \frac{1}{H}\left(y^2 - x^2 + \frac{a^2}{16} - \frac{H^2}{4}\right)$$

satisfies

$$\left(\frac{\partial w}{\partial n}\right)\Big|_{\Gamma_1}(x,y) = 1,\ (x,y) \in \Gamma_1,$$
$$w\left(\pm\frac{a}{4}, y\right) = \frac{1}{H}\left(y^2 - \frac{H^2}{4}\right) \leq 0,\ |y| < \frac{H}{2}.$$

By the strong maximum principle and Hopf's lemma (see [13], [9], [1]), the solution u to problem (1) satisfies $u > 0$ in Ω; hence

$$u\left(\pm\frac{a}{4}, y\right) > 0,\ |y| < \frac{H}{2};$$

moreover, the symmetry of Ω and Γ_1 guarantees that $\sup_{\Omega} u = u(0, \pm H/2)$. Then we see that w is a subsolution in Ω' of u and therefore,

$$\sup_{\Omega} u \geq \sup_{\Omega'} w = w\left(0, \pm\frac{H}{2}\right) = \frac{a^2}{16H}. \tag{20}$$

Now, the fact that a domain shaped like that in Figure 1 does not satisfy the property stated in Conjecture 1 quickly follows from inequalities (12), (13), (19), and (20). In effect, the lower bound for $\sup_{\Omega} u$ given by (20) depends on the reciprocal of H, unlike the upper bounds provided by the remaining inequalities. Therefore, Conjecture 1 is violated by the domain Ω under consideration when a sufficiently small H is chosen.

3. Proof of Theorem 4. The technique we employ to prove Theorem 4 consists of several steps. Broadly speaking, we use Ghizzetti's exact solution to problem (1) in the circle and conformal maps to estimate the right-hand side of (7) for small enough ε. An estimate of the other side is obtained through the maximum principles and more involved estimations of normal derivatives. To begin with, using the notation settled in the Introduction, for $k = 1, 2, \ldots, n$ let us consider the mixed boundary value problems

$$\left|\begin{array}{ll} \Delta u_k(x) = 0, & x \in \Omega, \\ u_k(x) = 0, & x \in \Gamma_0, \\ \frac{\partial u_k}{\partial n}(x) = 1, & x \in \Gamma_1^{(k)}, \\ \frac{\partial u_k}{\partial n}(x) = 0, & x \in \Gamma_1^{(j)},\ j \neq k, \end{array}\right. \tag{21}$$

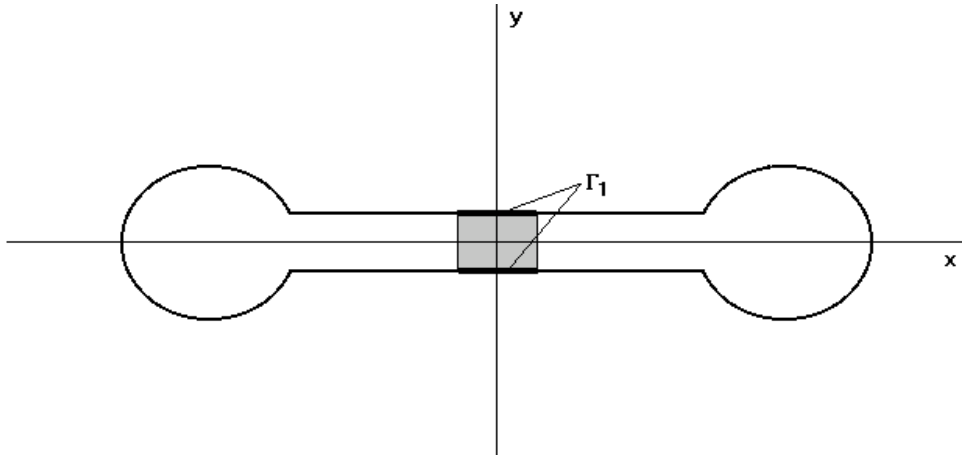

FIG. 5.

and

$$
(22)\qquad \left|\begin{array}{ll} \Delta v_k(x)=0, & x\in\Omega,\\ v_k(x)=0, & x\in\Gamma_0,\\ \frac{\partial v_k}{\partial n}(x)=1, & x\in\Gamma_1^{(k)},\\ v_k(x)=0, & x\in\Gamma_1^{(j)},\ j\neq k. \end{array}\right.
$$

The normal derivative $\partial v_k/\partial n$ of the solution v_k to (22) is a bounded and (at least) continuous function on Γ_1 and therefore, it makes sense to consider also the following problem:

$$
(23)\qquad \left|\begin{array}{ll} \Delta w_k(x)=0, & x\in\Omega,\\ w_k(x)=0, & x\in\Gamma_0,\\ \frac{\partial w_k}{\partial n}(x)=0, & x\in\Gamma_1^{(k)},\\ \frac{\partial w_k}{\partial n}(x)=-\frac{\partial v_k}{\partial n}(x), & x\in\Gamma_1^{(j)},\ j\neq k. \end{array}\right.
$$

From the strong maximum principle and Hopf's lemma (see [9],[13]), we deduce that the functions $u_k,\ v_k$, and w_k are nonnegative on $\overline{\Omega}$. Take, for instance, the function u_k. In view of the imposed boundary conditions, u_k is not constant on Ω; then, $\inf_\Omega u_k = u_k(x_0)$ for a certain $x_0\in\partial\Omega$ by the strong maximum principle. But Hopf's lemma ensures the normal derivative $(\partial u_k/\partial n)(x_0)$ is negative at the point x_0, so that $x_0\in\Gamma_0$ and therefore $\inf_\Omega u_k = u_k(x_0)=0$. The nonnegativity of v_k and w_k follows in a similar way.

Several relationships hold among functions $u_k,\ v_k, w_k$, and the solution $u[\Gamma_1]$ to (1). The most useful of these are listed in the following lemma.

LEMMA 6. *If $u[\Gamma_1],\ u_k,\ v_k$, and w_k respectively denote the solutions to problems* (1), (21), (22), *and* (23), *then the following relationships hold:*
(i) $u[\Gamma_1]=\sum_{k=1}^n u_k$;
(ii) $u_k = v_k + w_k,\ k=1,2,\dots,n$;
(iii) $v_k \le u_k \le v_k + \max_{j\neq k}\left\|(\partial v_k/\partial n)|_{\Gamma_1^{(j)}}\right\|_\infty \sum_{j\neq k} u_j$.

Furthermore, if the inequality $\sum_{k=1}^n \max_{j\neq k}\left\|(\partial v_k/\partial n)|_{\Gamma_1^{(j)}}\right\|_\infty < 1$ *holds, then*

(iv)

$$\max_{1\le k\le n}\sup_{\Omega} v_k \le \sup_{\Omega} u[\Gamma_1] \le \frac{\max_{1\le k\le n}\sup_{\Omega} v_k}{1-\sum_{k=1}^{n}\max_{j\neq k}\left\|(\partial v_k/\partial n)|_{\Gamma_1^{(j)}}\right\|_{\infty}}.$$

Proof. Assertions (i) and (ii) are immediate from the definitions of $u[\Gamma_1]$, u_k, v_k, and w_k. The first inequality in (iii) follows from (ii) and the nonnegativity of w_k. To derive the second inequality in (iii), we consider the function $\widetilde{w}_k$ that solves the problem

$$\left|\begin{array}{ll} \Delta\widetilde{w}_k(x)=0, & x\in\Omega,\\ \widetilde{w}_k(x)=0, & x\in\Gamma_0,\\ \frac{\partial\widetilde{w}_k}{\partial n}(x)=0, & x\in\Gamma_1^{(k)},\\ \frac{\partial w_k}{\partial n}(x)=\max_{j\neq k}\left\|\frac{\partial v_k}{\partial n}\big|_{\Gamma_1^{(j)}}\right\|_{\infty}, & x\in\Gamma_1^{(j)},\ j\neq k. \end{array}\right.$$

The strong maximum principle and Hopf's lemma provide $w_k\le\widetilde{w}_k$ on $\overline{\Omega}$. On the other hand, it is obvious that

$$\widetilde{w}_k=\max_{j\neq k}\left\|\frac{\partial v_k}{\partial n}\Big|_{\Gamma_1^{(j)}}\right\|_{\infty}\sum_{j\neq k}u_j,$$

and thus, from (ii) we obtain

$$u_k=v_k+w_k\le v_k+\widetilde{w}_k=v_k+\max_{j\neq k}\left\|\frac{\partial v_k}{\partial n}\Big|_{\Gamma_1^{(j)}}\right\|_{\infty}\sum_{j\neq k}u_j.$$

In order to prove the inequalities (iv), we take $\sum_{k=1}^{n}$ in the second inequality (iii) to obtain

$$\sum_{k=1}^{n}u_k\le\sum_{k=1}^{n}v_k+\sum_{k=1}^{n}\left(\max_{j\neq k}\left\|(\partial v_k/\partial n)|_{\Gamma_1^{(j)}}\right\|_{\infty}\sum_{j\neq k}u_j\right), \tag{24}$$

or, taking into account (i) and the nonnegativity of u_k, $k=1,2,\dots,n$,

$$\begin{aligned} u[\Gamma_1] &\le \sum_{k=1}^{n}v_k+\sum_{k=1}^{n}\left(\max_{j\neq k}\left\|(\partial v_k/\partial n)|_{\Gamma_1^{(j)}}\right\|_{\infty}\sum_{j\neq k}u_k\right)\\ &\le \sum_{k=1}^{n}v_k+u[\Gamma_1]\sum_{k=1}^{n}\max_{j\neq k}\left\|(\partial v_k/\partial n)|_{\Gamma_1^{(j)}}\right\|_{\infty}. \end{aligned} \tag{25}$$

By the strong maximum principle and Hopf's lemma, there exists a point $P\in\Gamma_1$ such that $\sup_{\Omega}u[\Gamma_1]=u[\Gamma_1](P)$. Without loss of generality we can assume $P\in\Gamma_1^{(1)}$. From (25) we then obtain

$$\sup_{\Omega}u[\Gamma_1]=u[\Gamma_1](P)\le v_1(P)+u[\Gamma_1](P)\sum_{k=1}^{n}\max_{j\neq k}\left\|(\partial v_k/\partial n)|_{\Gamma_1^{(j)}}\right\|_{\infty},$$

and using the hypothesis $\sum_{k=1}^{n} \max_{j\neq k} \left\| (\partial v_k/\partial n)|_{\Gamma_1^{(j)}} \right\|_\infty < 1$,

$$\begin{aligned}\sup_\Omega u[\Gamma_1] &\leq \frac{v_1(P)}{1-\sum_{k=1}^{n} \max_{j\neq k} \left\| (\partial v_k/\partial n)|_{\Gamma_1^{(j)}} \right\|_\infty} \\ &\leq \frac{\sup_\Omega v_1}{1-\sum_{k=1}^{n} \max_{j\neq k} \left\| (\partial v_k/\partial n)|_{\Gamma_1^{(j)}} \right\|_\infty} \\ &\leq \frac{\max_{1\leq k\leq n} \sup_\Omega v_k}{1-\sum_{k=1}^{n} \max_{j\neq k} \left\| (\partial v_k/\partial n)|_{\Gamma_1^{(j)}} \right\|_\infty},\end{aligned}$$

which proves the second inequality in (iv). As for the first inequality in (iv), from the first one in (iii) we deduce

$$\sup_\Omega v_k \leq \sup_\Omega u[\Gamma_1],$$

whence

$$\max_{1\leq k\leq n} \sup_\Omega v_k \leq \sup_\Omega u[\Gamma_1].$$

This completes the proof. □

The second inequality from Lemma 6(iv) can be employed to prove Theorem 4. In fact, assume for a moment that the expressions

$$\sup_\Omega u[\Gamma_1^*(\varepsilon)] = C_0\ ((b-a)\,\varepsilon)^p + o(\varepsilon^p), \tag{26}$$

$$\left\| (\partial v_k/\partial n)|_{\Gamma_1^{(j)}(\varepsilon)} \right\|_\infty \leq C_{j.k}\ ((b_k-a_k)\,\varepsilon)^q + o(\varepsilon^q) \tag{27}$$

hold for sufficiently small ε's with $p,\ q > 0$ and constants C_0 and $C_{j.k}$ which are independent of a, b and a_k, b_k, $k = 1, 2, \ldots, n$, respectively. A proof of (26) and (27) for a Dini-smooth domain (with $p = 1$ and $q = 2$) is furnished by Theorem 8 below. With the inequalities (26) and (27) at hand, we succeed in proving Theorem 4 as follows.

Proof of Theorem 4. By using (26), $\sup_\Omega v_k$ admits the following representation:

$$\sup_\Omega v_k = C_0\ ((b_k-a_k)\,\varepsilon)^p + o(\varepsilon^p),\ k = 1, 2, \ldots, n,$$

and, since the hypothesis of item (iv) of Lemma 6 is satisfied when ε is small enough (for instance, $\varepsilon^q < 1/[2\sum_{k=1}^{n}(b_k-a_k)^q \max_{j\neq k} C_{j.k}]$), the second inequality from Lemma 6(iv) and (27) provide for these ε's

$$\begin{aligned}\sup_\Omega u[\Gamma_1(\varepsilon)] &\leq \frac{C_0 \max_{1\leq k\leq n} ((b_k-a_k)\,\varepsilon)^p + o(\varepsilon^p)}{1-\sum_{k=1}^{n} \max_{j\neq k} C_{j.k}\ ((b_k-a_k)\,\varepsilon)^q + o(\varepsilon^q)} \\ &= C_0 \max_{1\leq k\leq n} ((b_k-a_k)\,\varepsilon)^p + o(\varepsilon^p). \qquad (28)\end{aligned}$$

By recalling that $b-a = \sum_{k=1}^{n}(b_k-a_k)$ and $b_k-a_k > 0,\ k = 1, 2, \ldots, n$, from (26) and (28) we get

$$\begin{aligned}\sup_\Omega u[\Gamma_1(\varepsilon)] &\leq C_0 \max_{1\leq k\leq n} ((b_k-a_k)\,\varepsilon)^p + o(\varepsilon^p) \\ &< C_0\ ((b-a)\,\varepsilon)^p + o(\varepsilon^p) = \sup_\Omega u[\Gamma_1^*(\varepsilon)],\end{aligned}$$

for sufficiently small ε's, as Theorem 4 asserts. □

The remainder of this section is devoted to justifying the validity of the expressions (26) and (27) under reasonable hypotheses on the regularity of the domain Ω. Let us begin by showing that (26) and (27) hold for $\Omega = B_1(0)$, the circle of radius 1; then, the technique of conformal maps will be applied to extend their validity to Dini-smooth domains which satisfy an interior sphere condition. Thus, we assume that $\Omega = B_1(0)$ in the following. As usual, polar coordinates are employed to denote points belonging to the circle.

An explicit solution to the general mixed boundary value problem

$$\left|\begin{array}{ll} \Delta u(\rho,\phi) = \frac{1}{\rho}\left((\rho u_\rho)_\rho + \frac{1}{\rho}\, u_{\phi\phi}\right) = 0, & (\rho,\phi) \in B_1(0), \\ u(1,\phi) = F(\phi), & \alpha < \phi < 2\pi, \\ \frac{\partial u}{\partial \rho}(1,\phi) = G(\phi), & 0 < \phi < \alpha \end{array}\right. \tag{29}$$

was found by Ghizzetti in [7] (see also [8]). Under suitable hypotheses of regularity on the functions F and G it is shown by this author that the solution $u(\rho,\phi)$ to (29) can be expressed as follows:

$$\begin{aligned} u(\rho,\phi) = {} & \tfrac{1}{2\pi}\int_0^\alpha \ln\left(\frac{\sqrt{H(\rho,\phi,\theta)}+\sqrt{M(\rho,\phi)-N(\rho,\phi)}+\sqrt{K(\rho,\phi,\theta)}}{\sqrt{H(\rho,\phi,\theta)}-\sqrt{M(\rho,\phi)-N(\rho,\phi)}+\sqrt{K(\rho,\phi,\theta)}}\right) G(\theta)\, d\theta \\ & + \tfrac{1}{2\pi}\,\frac{1-\rho^2}{\sqrt{M(\rho,\phi)+N(\rho,\phi)}}\int_\alpha^{2\pi} \frac{\sqrt{H(\rho,\phi,\theta)}+\sqrt{K(\rho,\phi,\theta)}}{1-2\rho\cos(\phi-\theta)+\rho^2}\, F(\theta)\, d\theta, \end{aligned} \tag{30}$$

where

$$H(\rho,\phi,\theta) = \frac{\sin(|\alpha-\theta|/2)}{\sin(\theta/2)}\,(1-2\rho\cos\phi+\rho^2), \tag{31}$$

$$K(\rho,\phi,\theta) = \frac{\sin(\theta/2)}{\sin(|\alpha-\theta|/2)}\,(1-2\rho\cos(\phi-\alpha)+\rho^2), \tag{32}$$

$$M(\rho,\phi) = 2\sqrt{(1-2\rho\cos\phi+\rho^2)(1-2\rho\cos(\phi-\alpha)+\rho^2)}, \tag{33}$$

$$N(\rho,\phi) = 2\,(\cos(\alpha/2) - 2\rho\cos(\phi-\alpha/2)+\rho^2\cos(\alpha/2)). \tag{34}$$

Note that $M = 2\sqrt{HK}$. From (30) and (31)–(34) we easily derive an explicit solution to the instance of problem (1) in which $\Omega = B_1(0)$ and $\Gamma_1 = (0,\alpha)$. In fact, denoting this solution by u_α we can write

$$u_\alpha(\rho,\phi) = \tfrac{1}{2\pi}\int_0^\alpha \ln\left(\frac{\sqrt{H(\rho,\phi,\theta)}+\sqrt{M(\rho,\phi)-N(\rho,\phi)}+\sqrt{K(\rho,\phi,\theta)}}{\sqrt{H(\rho,\phi,\theta)}-\sqrt{M(\rho,\phi)-N(\rho,\phi)}+\sqrt{K(\rho,\phi,\theta)}}\right) d\theta, \tag{35}$$

where H, K, M, and N are defined by (31)–(34). Now we prove that the supremum $\sup_{B_1(0)} u_\alpha$ is attained at the boundary point $(1,\alpha/2)$. In fact, the strong maximum principle and Hopf's lemma show that $\sup_{B_1(0)} u_\alpha$ is attained at a point $(1,\phi_0)$ such that $0 < \phi_0 < \alpha$, and so, we must look for the maximum of the boundary value $\phi \mapsto h(\phi) = u_\alpha(1,\phi)$, $0 < \phi < \alpha$. Since u_α is symmetric with respect to the line $\phi = \alpha/2$, the point $\phi = \alpha/2$ is a point of symmetry for the function h; i.e., $h(\alpha/2-\phi) = h(\alpha/2+\phi)$, $0 \le \phi < \alpha/2$. Furthermore, h is a strictly concave function in $(0,\alpha)$ which, jointly with its symmetry, implies that $\sup_{B_1(0)} u_\alpha = \sup_{0<\phi<\alpha} h(\phi) = h(\alpha/2) = u_\alpha(1,\alpha/2)$. That h is really a strictly concave function can be seen by using once again the maximum principle and Hopf's lemma. On the one hand, h is a smooth function and then the equation

$$\Delta u_\alpha(\rho,\phi) = \frac{1}{\rho}\left(\left(\rho\,(u_\alpha)_\rho\right)_\rho + \frac{1}{\rho}\,(u_\alpha)_{\phi\phi}\right) = 0$$

holds up to the boundary $\rho = 1,\ 0 < \phi < \alpha$, so that we can write

$$h''(\phi) = (u_\alpha)_{\phi\phi}(1,\phi) = -\left(\rho\,(u_\alpha)_\rho\right)_\rho(1,\phi),\ 0 < \phi < \alpha. \tag{36}$$

On the other hand, the function defined by $v = \rho\,(u_\alpha)_\rho,\ (\rho,\phi) \in B_1(0)$, is harmonic and its maximum value (equal to 1) on $\overline{B_1(0)}$ is reached at every point $(1,\phi)$, $0 < \phi < \alpha$. Thus, Hopf's lemma shows that the normal derivative $(v)_\rho(1,\phi) = \left(\rho\,(u_\alpha)_\rho\right)_\rho(1,\phi) > 0$, $0 < \phi < \alpha$, and so, from (36) we obtain $h''(\phi) < 0,\ 0 < \phi < \alpha$; that is, h is strictly concave.

Once it is known that $\sup_{B_1(0)} u_\alpha = u_\alpha(1,\alpha/2)$, Ghizzetti's formula (36) becomes useful in deriving an explicit expression for $\sup_{B_1(0)} u_\alpha$. Indeed, we have

$$\begin{aligned}
&\sup_{B_1(0)} u_\alpha = u_\alpha(1,\alpha/2)\\
&= \tfrac{1}{2\pi}\int_0^\alpha \ln\left(\frac{\sqrt{H(1,\alpha/2,\theta)}+\sqrt{M(1,\alpha/2)-N(1,\alpha/2)}+\sqrt{K(1,\alpha/2,\theta)}}{\sqrt{H(1,\alpha/2,\theta)}-\sqrt{M(1,\alpha/2)-N(1,\alpha/2)}+\sqrt{K(1,\alpha/2,\theta)}}\right)d\theta,
\end{aligned}$$

or, realizing that

$$\begin{aligned}
H(1,\alpha/2,\theta) &= 2\,\tfrac{\sin(|\alpha-\theta|/2)}{\sin(\theta/2)}\,(1-\cos(\alpha/2)),\\
K(1,\alpha/2,\theta) &= 2\,\tfrac{\sin(\theta/2)}{\sin(|\alpha-\theta|/2)}\,(1-\cos(\alpha/2)),\\
M(1,\alpha/2) &= 4\,(1-\cos(\alpha/2)),\\
N(1,\alpha/2) &= 4\,(\cos(\alpha/2)-1) = -M(1,\alpha/2),
\end{aligned}$$

and after some simplifications,

$$\begin{aligned}
\sup_{B_1(0)} u_\alpha &= \tfrac{1}{\pi}\int_0^\alpha \ln\left|\frac{\sqrt{\sin((\alpha-\theta)/2)}+\sqrt{\sin(\theta/2)}}{\sqrt{\sin((\alpha-\theta)/2)}-\sqrt{\sin(\theta/2)}}\right|d\theta\\
&= \tfrac{\alpha}{\pi}\int_0^1 \ln\left|\frac{\sqrt{\sin(\frac{\alpha}{2}(1-\lambda))}+\sqrt{\sin(\frac{\alpha}{2}\lambda)}}{\sqrt{\sin(\frac{\alpha}{2}(1-\lambda))}-\sqrt{\sin(\frac{\alpha}{2}\lambda)}}\right|d\lambda.
\end{aligned} \tag{37}$$

The expression (35) may be further used to compute the radial derivative $\partial u_\alpha/\partial\rho$ at a point $(1,\phi)$ belonging to $\Gamma_0 = (\alpha, 2\pi)$. With this purpose, we note that $u_\alpha(1,\phi) = 0$ for every $\alpha < \phi < 2\pi$, and so, from (35) we obtain

$$\begin{aligned}
&\tfrac{\partial u_\alpha}{\partial\rho}(R,\phi) = \lim_{\rho\uparrow 1}\tfrac{u_\alpha(\rho,\phi)}{\rho-1}\\
&= \tfrac{1}{2\pi}\lim_{\rho\uparrow 1}\int_0^\alpha \ln\left(\frac{\sqrt{H(\rho,\phi,\theta)}+\sqrt{M(\rho,\phi)-N(\rho,\phi)}+\sqrt{K(\rho,\phi,\theta)}}{\sqrt{H(\rho,\phi,\theta)}-\sqrt{M(\rho,\phi)-N_R(\rho,\phi)}+\sqrt{K(\rho,\phi,\theta)}}\right)^{\frac{1}{\rho-1}}d\theta\\
&= \tfrac{1}{2\pi}\lim_{\rho\uparrow 1}\int_0^\alpha \ln\left(\frac{1+\frac{\sqrt{M(\rho,\phi)-N(\rho,\phi)}}{\sqrt{H(\rho,\phi,\theta)}+\sqrt{K(\rho,\phi)}}}{1-\frac{\sqrt{M(\rho,\phi)-N(\rho,\phi)}}{\sqrt{H(\rho,\phi,\theta)}+\sqrt{K(\rho,\phi)}}}\right)^{\frac{1}{\rho-1}}d\theta.
\end{aligned} \tag{38}$$

Routine calculations applied to the expressions (31)–(34) show that

$$\sqrt{M(\rho,\phi)-N(\rho,\phi)} = \frac{\sin(\alpha/2)}{\sqrt{\sin(\phi/2)\sin((\phi-\alpha)/2)}}\,(1-\rho)+O((1-\rho)^2)$$

and

$$\sqrt{H(\rho,\phi,\theta)}+\sqrt{K(\rho,\phi,\theta)}=2\left(\sin\tfrac{\phi}{2}\sqrt{\tfrac{\sin((\alpha-\theta)/2)}{\sin(\theta/2)}}+\sin\tfrac{\phi-\alpha}{2}\sqrt{\tfrac{\sin(\theta/2)}{\sin((\alpha-\theta)/2)}}\right)$$
$$+O(1-\rho),$$

whence

$$\begin{aligned}&\lim_{\rho\uparrow 1}\ln\left(\frac{1+\frac{\sqrt{M(\rho,\phi)-N(\rho,\phi)}}{\sqrt{H(\rho,\phi,\theta)+\sqrt{K(\rho,\phi)}}}}{1-\frac{\sqrt{M(\rho,\phi)-N(\rho,\phi)}}{\sqrt{H(\rho,\phi,\theta)+\sqrt{K(\rho,\phi)}}}}\right)^{\frac{1}{\rho-1}}\\&=-\frac{\sin(\alpha/2)}{\sqrt{\sin(\phi/2)\sin((\phi-\alpha)/2)}\left(\sin\frac{\phi}{2}\sqrt{\frac{\sin((\alpha-\theta)/2)}{\sin(\theta/2)}}+\sin\frac{\phi-\alpha}{2}\sqrt{\frac{\sin(\theta/2)}{\sin((\alpha-\theta)/2)}}\right)}.\end{aligned}\tag{39}$$

On the other hand, using the Taylor's series of $x\mapsto\ln((1+x)/(1-x))$ and the inequality $Ax+Bx^{-1}\geq 2\sqrt{AB}$ which holds for $A,B,x>0$, we see that for ρ close enough to 1 there exists a constant $L>0$ such that

$$\begin{aligned}&\left|\ln\left(\frac{1+\frac{\sqrt{M(\rho,\phi)-N(\rho,\phi)}}{\sqrt{H(\rho,\phi,\theta)+\sqrt{K(\rho,\phi)}}}}{1-\frac{\sqrt{M(\rho,\phi)-N(\rho,\phi)}}{\sqrt{H(\rho,\phi,\theta)+\sqrt{K(\rho,\phi)}}}}\right)^{\frac{1}{\rho-1}}\right|\\&\leq\frac{L\sin(\alpha/2)}{\sqrt{\sin(\phi/2)\sin((\phi-\alpha)/2)}\left(\sin\frac{\phi}{2}\sqrt{\frac{\sin((\alpha-\theta)/2)}{\sin(\theta/2)}}+\sin\frac{\phi-\alpha}{2}\sqrt{\frac{\sin(\theta/2)}{\sin((\alpha-\theta)/2)}}\right)}\\&\leq\frac{L\sin(\alpha/2)}{2\sin(\phi/2)\sin((\phi-\alpha)/2)},\ 0<\theta<\alpha.\end{aligned}\tag{40}$$

In view of (39) and (40) we can apply the dominated convergence theorem to the last member of (38) to obtain

$$\begin{aligned}\frac{\partial u_\alpha}{\partial\rho}(1,\phi)&=-\frac{\sin(\alpha/2)}{2\pi\sqrt{\sin(\phi/2)\sin((\phi-\alpha)/2)}}\int_0^\alpha\frac{d\theta}{\sin\frac{\phi}{2}\sqrt{\frac{\sin((\alpha-\theta)/2)}{\sin(\theta/2)}}+\sin\frac{\phi-\alpha}{2}\sqrt{\frac{\sin(\theta/2)}{\sin((\alpha-\theta)/2)}}}\\&=-\frac{\alpha\sin(\alpha/2)}{2\pi\sqrt{\sin(\phi/2)\sin((\phi-\alpha)/2)}}\int_0^1\frac{d\lambda}{\sin\frac{\phi}{2}\sqrt{\frac{\sin(\alpha(1-\lambda)/2)}{\sin(\alpha\lambda/2)}}+\sin\frac{\phi-\alpha}{2}\sqrt{\frac{\sin(\alpha\lambda/2)}{\sin(\alpha(1-\lambda)/2)}}}.\end{aligned}\tag{41}$$

Now we are in the position to prove that expressions like (26) and (27) hold for the circle.

THEOREM 7. *By employing the above notation, we have*

$$\sup_{B_1(0)}u_\alpha=\tfrac{1}{2}\alpha+o(\alpha).\tag{42}$$

Moreover, if $\alpha<\phi_1<\phi_2<2\pi$, *then*

$$\sup_{\phi_1<\phi<\phi_2}\left|\frac{\partial u_\alpha}{\partial\rho}(1,\phi)\right|\leq\frac{1}{8\pi\min_{\phi\in[\phi_1,\phi_2]}[\sin(\phi/2)\sin((\phi-\alpha)/2)]}\,\alpha^2+o(\alpha^2).\tag{43}$$

Proof. With the purpose of proving the validity of expression (42), we observe that

$$\lim_{\alpha\downarrow 0}\int_0^1\ln\left|\frac{\sqrt{\sin(\frac{\alpha}{2}(1-\lambda))}+\sqrt{\sin(\frac{\alpha}{2}\lambda)}}{\sqrt{\sin(\frac{\alpha}{2}(1-\lambda))}-\sqrt{\sin(\frac{\alpha}{2}\lambda)}}\right|d\lambda=\int_0^1\ln\left|\frac{\sqrt{1-\lambda}+\sqrt{\lambda}}{\sqrt{1-\lambda}-\sqrt{\lambda}}\right|d\lambda=\tfrac{\pi}{2}.$$

The expression (42) immediately follows from this equality and from (37). On the other hand, it follows from the arithmetic mean-geometric mean inequality that, for every $0 < \lambda < 1$ and $\alpha < \phi < 2\pi$,

$$\sin\tfrac{\phi}{2}\sqrt{\tfrac{\sin(\alpha(1-\lambda)/2)}{\sin(\alpha\lambda/2)}} + \sin\tfrac{\phi-\alpha}{2}\sqrt{\tfrac{\sin(\alpha\lambda/2)}{\sin(\alpha(1-\lambda)/2)}} \geq 2\sqrt{\sin\tfrac{\phi}{2}\sin\tfrac{\phi-\alpha}{2}}\ ,$$

and hence

$$\int_0^1 \frac{d\lambda}{\sin\frac{\phi}{2}\sqrt{\frac{\sin(\alpha(1-\lambda)/2)}{\sin(\alpha\lambda/2)}}+\sin\frac{\phi-\alpha}{2}\sqrt{\frac{\sin(\alpha\lambda/2)}{\sin(\alpha(1-\lambda)/2)}}} \leq \frac{1}{2\sqrt{\sin\frac{\phi}{2}\sin\frac{\phi-\alpha}{2}}}. \tag{44}$$

Therefore, from (41) and (44) we see that

$$\begin{aligned}\left|\frac{\partial u_\alpha}{\partial\rho}(1,\phi)\right| &\leq \frac{\alpha\sin(\alpha/2)}{2\pi\sqrt{\sin(\phi/2)\sin((\phi-\alpha)/2)}}\,\frac{1}{2\sqrt{\sin(\phi/2)\sin((\phi-\alpha)/2)}}\\ &= \frac{1}{8\pi\sin(\phi/2)\sin((\phi-\alpha)/2)}\,\alpha^2+o(\alpha^2),\end{aligned}$$

whence we finally get expression (43). □

It should be observed that if $u_{R,\alpha}$ is the solution to problem (1) for $\Omega = B_R(0)$ and $\Gamma_1 = (0, R\alpha)$, then we have $u_{R,\alpha}(\rho,\phi) \equiv R\,u_\alpha(\rho/R,\phi)$. In this way, by setting $\varepsilon = |\Gamma_1| = R\alpha$, from Theorem 7 we conclude

$$\sup_{B_R(0)} u_{R,\alpha} = \tfrac{1}{2}\varepsilon + o(\varepsilon), \tag{45}$$

and, for $\alpha < \phi_1 < \phi_2 < 2\pi$,

$$\sup_{\phi_1<\phi<\phi_2}\left|\frac{\partial u_{R,\alpha}}{\partial\rho}(R,\phi)\right| \leq \frac{1}{8\pi R^2\min_{\phi\in[\phi_1,\phi_2]}[\sin(\phi/2)\sin((\phi-\alpha)/2)]}\,\varepsilon^2+o(\varepsilon^2). \tag{46}$$

Now we turn to consider the case of a Jordan domain Ω with a Dini-smooth boundary curve γ. Choose a point $O \in \gamma$ and take O as the origin of arcs. To facilitate the following calculations $\gamma(s)$ is given in complex form, $\gamma(s) = \gamma_1(s) + i\gamma_2(s)$. By translating Ω if necessary, we can take O as the origin of coordinates; i.e., we set $O = \gamma'(0) = (0,0)$. Furthermore, a rotation of Ω around O can be done in such a way so as to get $\gamma'(0) = 1$. As before, we symbolize by $u[\Gamma_1]$ the solution to problem (1) for $\Gamma_1 = (0,\varepsilon)$. Among the conformal maps f from $B_1(0)$ onto Ω, we select that one which verifies $f(1) = 0$ and $f'(1) = -i\,|f'(1)|$. In this way, the function $v = u[\Gamma_1]\circ f$ satisfies

$$\left|\begin{array}{cc}\Delta v(\rho,\phi) = 0, & (\rho,\phi)\in B_1(0),\\ v(1,\phi) = 0, & \alpha(\varepsilon)<\phi<2\pi,\\ \frac{\partial v}{\partial\rho}(1,\phi) = \left|f'(e^{i\phi})\right|, & 0<\phi<\alpha(\varepsilon),\end{array}\right. \tag{47}$$

where $\alpha(s)$ is such that $f(e^{i\alpha(s)}) = \gamma(s)$, $0 \leq s \leq |\partial\Omega|$. Differentiating this last equality with respect to s, we obtain $f'(e^{i\alpha(s)})\,e^{i\alpha(s)}i\alpha'(s) = \gamma'(s)$ and then, from the assumptions made on γ and f, we deduce $\alpha(0) = 0$ and $\alpha'(0) = 1/|f'(1)|$, so that for $\varepsilon \downarrow 0$ we can write

$$\alpha(\varepsilon) = \frac{1}{|f'(1)|}\varepsilon + o(\varepsilon). \tag{48}$$

By Ghizzetti's formula (30), the function v solving (47) can be represented as

$$v(\rho,\phi) = \tfrac{1}{2\pi}\int_0^{\alpha(\varepsilon)} \ln\left(\frac{\sqrt{H(\rho,\phi,\theta)}+\sqrt{M(\rho,\phi)-N(\rho,\phi)}+\sqrt{K(\rho,\phi,\theta)}}{\sqrt{H(\rho,\phi,\theta)}-\sqrt{M(\rho,\phi)-N(\rho,\phi)}+\sqrt{K(\rho,\phi,\theta)}}\right)\left|f'(e^{i\theta})\right|\,d\theta,$$

whence

$$
\begin{aligned}
v(1,\phi) &= \tfrac{1}{2\pi}\int_0^{\alpha(\varepsilon)} \ln\left(\frac{\sqrt{H(1,\phi,\theta)}+\sqrt{M(1,\phi)-N(1,\phi)}+\sqrt{K(1,\phi,\theta)}}{\sqrt{H(1,\phi,\theta)}-\sqrt{M(1,\phi)-N(1,\phi)}+\sqrt{K(1,\phi,\theta)}}\right)\left|f'(e^{i\theta})\right|\,d\theta \\
&= \tfrac{1}{\pi}\int_0^{\alpha(\varepsilon)} \ln\left|\frac{\sqrt{\sin((\alpha(\varepsilon)-\theta)/2)\sin(\phi/2)}+\sqrt{\sin(\theta/2)\sin((\alpha(\varepsilon)-\phi)/2)}}{\sqrt{\sin((\alpha(\varepsilon)-\theta)/2)\sin(\phi/2)}-\sqrt{\sin(\theta/2)\sin((\alpha(\varepsilon)-\phi)/2)}}\right|\left|f'(e^{i\theta})\right|\,d\theta
\end{aligned}
\tag{49}
$$

and

$$
\begin{aligned}
\frac{\partial v}{\partial \rho}(1,\phi) &= -\frac{\sin(\alpha(\varepsilon)/2)}{2\pi\sqrt{\sin(\phi/2)\sin((\phi-\alpha(\varepsilon))/2)}} \\
&\quad\times\int_0^{\alpha(\varepsilon)} \frac{\left|f'(e^{i\theta})\right|d\theta}{\sin\frac{\phi}{2}\sqrt{\frac{\sin((\alpha(\varepsilon)-\theta)/2)}{\sin(\theta/2)}}+\sin\frac{\phi-\alpha(\varepsilon)}{2}\sqrt{\frac{\sin(\theta/2)}{\sin((\alpha(\varepsilon)-\theta)/2)}}}.
\end{aligned}
\tag{50}
$$

Compare (49) and (50) with (35) and (41), respectively. Now we prove that a result like Theorem 7 holds for Jordan domains with a Dini-smooth boundary.

THEOREM 8. *Let Ω be a Jordan domain with a Dini-smooth boundary and Γ_1 denote a connected arc of $\partial\Omega$ such that $|\Gamma_1| = \varepsilon$. If $u[\Gamma_1]$ is the solution to problem (1) for Ω and Γ_1, then we have*

$$
\sup_\Omega u[\Gamma_1] = \tfrac{1}{2}\varepsilon + o(\varepsilon). \tag{51}
$$

Moreover, if the conformal map $f : B_1(0) \to \Omega$ and $\alpha(\varepsilon)$ are defined as above, then for $\alpha(\varepsilon) < \phi_1 < \phi_2 < 2\pi$,

$$
\sup_{\phi_1<\phi<\phi_2}\left|\frac{\partial u[\Gamma_1]}{\partial n}(f(e^{i\phi}))\right| \le \frac{\|f'\|_\infty}{8\pi\, M^3(f')\min_{\phi\in[\phi_1,\phi_2]}[\sin(\phi/2)\sin((\phi-\alpha)/2)]}\varepsilon^2 + o(\varepsilon^2), \tag{52}
$$

where $M(f') = \min_{0\le\phi\le 2\pi}|f'(\phi)|$.

Proof. By making an appropriate change of variable in the integral of the last member of (49), for $0 < \phi < \alpha(\varepsilon)$ we obtain

$$
\begin{aligned}
v(1,\phi) &= \tfrac{\alpha(\varepsilon)}{\pi}\int_0^1 \ln\left|\frac{\sqrt{\sin(\alpha(\varepsilon)(1-\lambda)/2)\sin(\phi/2)}+\sqrt{\sin(\alpha(\varepsilon)\,\lambda/2)\sin((\alpha(\varepsilon)-\phi)/2)}}{\sqrt{\sin(\alpha(\varepsilon)(1-\lambda)/2)\sin(\phi/2)}-\sqrt{\sin(\alpha(\varepsilon)\,\lambda/2)\sin((\alpha(\varepsilon)-\phi)/2)}}\right| \\
&\quad\times\left|f'(e^{i\alpha(\varepsilon)\,\lambda})\right|d\lambda.
\end{aligned}
\tag{53}
$$

Taking into account (48) and the continuity up to the boundary of f', we realize that, when $\varepsilon \downarrow 0$, the integral of the right-hand side of (53) converges to

$$
\left|f'(1)\right|\int_0^1 \ln\left|\frac{\sqrt{1-\lambda}+\sqrt{\lambda}}{\sqrt{1-\lambda}-\sqrt{\lambda}}\right|d\lambda = \tfrac{\pi}{2}\,\left|f'(1)\right|;
$$

thus

$$
\begin{aligned}
u[\Gamma_1](f(e^{i\phi})) &= v(1,\phi) \\
&= \tfrac{1}{\pi}\left(\tfrac{1}{|f'(1)|}\varepsilon + o(\varepsilon)\right)\left(\tfrac{\pi}{2}\left|f'(1)\right| + O(1)\right) = \tfrac{1}{2}\varepsilon + o(\varepsilon),
\end{aligned}
$$

so proving the expression (51). On the other hand, from (50) we deduce

$$\begin{aligned}\frac{\partial u[\Gamma_1]}{\partial n}(f(e^{i\phi})) &= \frac{1}{|f'(e^{i\phi})|}\frac{\partial v}{\partial \rho}(1,\phi)\\ &= -\frac{\sin(\alpha(\varepsilon)/2)}{2\pi|f'(e^{i\phi})|\sqrt{\sin(\phi/2)\sin((\phi-\alpha(\varepsilon))/2)}}\\ &\times\alpha(\varepsilon)\int_0^1 \frac{\left|f'(e^{i\alpha(\varepsilon)\,\lambda})\right|d\lambda}{\sin\frac{\phi}{2}\sqrt{\frac{\sin(\alpha(\varepsilon)\,(1-\lambda)/2)}{\sin(\alpha(\varepsilon)\,\lambda/2)}}+\sin\frac{\phi-\alpha(\varepsilon)}{2}\sqrt{\frac{\sin(\alpha(\varepsilon)\,\lambda/2)}{\sin(\alpha(\varepsilon)\,(1-\lambda)/2)}}}.\end{aligned} \tag{54}$$

By proceeding as in the proof of (43) we obtain

$$\begin{aligned}\left|\frac{\partial u[\Gamma_1]}{\partial n}(f(e^{i\phi}))\right| &\le \frac{\alpha(\varepsilon)\sin(\alpha(\varepsilon)/2)}{2\pi\,|f'(e^{i\phi})|\sqrt{\sin(\phi/2)\sin((\phi-\alpha(\varepsilon))/2)}}\,\frac{\int_0^1\left|f'(e^{i\alpha(\varepsilon)\,\lambda})\right|d\lambda}{2\sqrt{\sin(\phi/2)\sin((\phi-\alpha(\varepsilon))/2)}}\\ &\le \frac{\left\|f'\right\|_\infty\alpha(\varepsilon)\sin(\alpha(\varepsilon)/2)}{4\pi\,|f'(e^{i\phi})|\sin(\phi/2)\sin((\phi-\alpha(\varepsilon))/2)}\\ &= \frac{\left\|f'\right\|_\infty}{8\pi\,|f'(e^{i\phi})|\sin(\phi/2)\sin((\phi-\alpha(\varepsilon))/2)}\,\frac{\varepsilon^2}{\left|f'(1)\right|^2}+o(\varepsilon^2)\\ &\le \frac{\left\|f'\right\|_\infty}{8\pi\,M^3(f')\sin(\phi/2)\sin((\phi-\alpha(\varepsilon))/2)}\varepsilon^2+o(\varepsilon^2),\end{aligned} \tag{55}$$

where we have again used (48), the continuity up to the boundary of f', and the fact that f' does not vanish in $\overline{\Omega}$. Inequality (52) follows by taking $\sup_{\phi_1<\phi<\phi_2}$ in the first and last members of inequalities (55). □

As a simple example of an application of Theorem 8 we now set $\Omega = B_R(0)$. The function $f(z) = iR\,(1-z)$ is the Riemann mapping from $B_1(0)$ onto $iR + B_R(0)$ verifying $f(1) = 0,\ f'(1) = -iR = -i\,|f'(1)|$. Since $|f'(z)| \equiv R$ for this mapping, expressions (45) and (46) are respectively recovered from the general expressions (51) and (52) appearing in the theorem.

Observe that expression (51) from Theorem 8 is just a proof of (26) for Jordan domains with a Dini-smooth boundary. In order to derive the corresponding expression (27) for these domains, we introduce suitable coordinates so that $a_1 = 0$, $\gamma(0) = O$, and $\gamma'(0) = 1$. As before, denote by f the function that conformally maps $B_1(0)$ onto Ω and satisfies $f(1) = 0,\ f'(1) = -i\,|f'(1)|$. For $k = 1, 2, \ldots, n$ and $0 < \varepsilon \le 1$, define the rotations $g_k(z) = e^{i\alpha(a_k(\varepsilon))}z$ and consider the mappings $f_k : B_1(0) \to \Omega$ such that $f_k = f \circ g_k$. These mappings verify $f_k(1) = f(e^{i\alpha(a_k(\varepsilon))}) = \gamma(a_k(\varepsilon))$, $f_k\left(e^{i(\alpha(b_k(\varepsilon))-\alpha(a_k(\varepsilon)))}\right) = f(e^{i\alpha(b_k(\varepsilon))}) = \gamma(b_k(\varepsilon))$, $\|f_k'\|_\infty = \|f'\|_\infty$, and $M(f_k') = M(f')$; then, an application of the inequality (52) with $u[\Gamma_1]$ and f substituted by v_k and f_k, respectively, give us

$$\sup_{\phi_1<\phi<\phi_2}\left|\frac{\partial v_k}{\partial n}(f_k(e^{i\phi}))\right| \le \frac{\left\|f'\right\|_\infty((b_k-a_k)\varepsilon)^2}{8\pi\,M^3(f')\min_{\phi\in[\phi_1,\phi_2]}\left[\sin\frac{\phi}{2}\sin\frac{\phi-\left(\alpha(b_k(\varepsilon))-\alpha(a_k(\varepsilon))\right)}{2}\right]}+o(\varepsilon^2),$$

where $\alpha(b_k(\varepsilon)) - \alpha(a_k(\varepsilon)) < \phi_1 < \phi_2 < 2\pi$. Therefore, for small enough ε 's, we have

$$\left\|\left(\partial v_k/\partial n\right)|_{\Gamma_1^{(j)}(\varepsilon)}\right\|_\infty \le \frac{\left\|f'\right\|_\infty((b_k-a_k)\varepsilon)^2}{8\pi\,M^3(f')\min_{\phi\in[\alpha(a_j(\varepsilon)),\alpha(b_j(\varepsilon))]}\left[\sin\frac{\phi-\alpha(a_k(\varepsilon))}{2}\sin\frac{\phi-\alpha(b_k(\varepsilon))}{2}\right]}+o(\varepsilon^2). \tag{56}$$

Since

$$\min_{\phi\in[\alpha(a_j(\varepsilon)),\alpha(b_j(\varepsilon))]}\left[\sin\tfrac{\phi-\alpha(a_k(\varepsilon))}{2}\sin\tfrac{\phi-\alpha(b_k(\varepsilon))}{2}\right]\to\sin^2\left(\tfrac{\alpha((a_j+b_j)/2)-\alpha((a_k+b_k)/2)}{2}\right)$$

when $\varepsilon\downarrow 0$, we see from (56) that expression (27) holds for the constants $C_{j,k}$ given by

$$C_{j,k}=\frac{\|f'\|_\infty}{4\pi\, M^3(f')\min_{j\neq k}\left[\sin^2\left(\frac{\alpha((a_j+b_j)/2)-\alpha((a_k+b_k)/2)}{2}\right)\right]}.$$

4. Proof of Theorem 5. In order to prove Theorem 5, better estimates for normal derivatives are needed. For the sake of clarity, we first discuss the case $\Omega=B_1(0)$. Notations are the same as those used in the previous section.

From (41) and (44) we obtain, for $\alpha<\phi<2\pi$,

$$\begin{aligned}\left|\tfrac{\partial u_\alpha}{\partial\rho}(1,\phi)\right|&\le\tfrac{\alpha\sin(\alpha/2)}{4\pi\sin(\phi/2)\sin((\phi-\alpha)/2)}\\&=\tfrac{\alpha}{4\pi}\tfrac{\sin(\phi/2)\cos((\phi-\alpha)/2)-\cos(\phi/2)\sin((\phi-\alpha)/2)}{\sin(\phi/2)\sin((\phi-\alpha)/2)}\\&=\tfrac{\alpha}{4\pi}\left(\cot((\phi-\alpha)/2)-\cot(\phi/2)\right).\end{aligned}$$

By the mean value theorem, we can write

$$\cot((\phi-\alpha)/2)-\cot(\phi/2)=\sin^{-2}\left((\phi-\alpha)/2+\mu\alpha/2\right)\alpha/2$$

for a certain $0<\mu=\mu(\phi)<1$, and then

$$\left|\tfrac{\partial u_\alpha}{\partial\rho}(1,\phi)\right|\le\tfrac{\alpha^2}{8\pi\sin^2((\phi-\alpha)/2+\mu(\phi)\alpha/2)},\ \alpha<\phi<2\pi. \tag{57}$$

In this way, for a given $\tau>0$ we have

$$\begin{aligned}\sup_{\alpha+\tau<\phi<2\pi-\tau}\left|\tfrac{\partial u_\alpha}{\partial\rho}(1,\phi)\right|&\le\tfrac{\alpha^2}{8\pi\min_{\alpha+\tau<\phi<2\pi-\tau}[\sin^2((\phi-\alpha)/2+\mu(\phi)\alpha/2)]}\\&\le\tfrac{\alpha^2}{8\pi\sin^2(\tau/2)}.\end{aligned} \tag{58}$$

Now consider a finite family of arcs $\Gamma_1=\cup_{k=1}^n\Gamma_1^{(k)}$ with $\Gamma_1^{(k)}=(\alpha_k,\beta_k)\subset\partial B_1(0)$ and let δ denote the minimum distance on $\partial B_1(0)$ between adjacent components of Γ_1; i.e., $\delta=\min\{\min_{1\le k\le n-1}(\alpha_{k+1}-\beta_k),\alpha_1-\beta_n\}$. By using (58), we find

$$\left\|\left.\frac{\partial v_k}{\partial n}\right|_{\Gamma_1^{(j)}}\right\|_\infty\le\frac{(\beta_k-\alpha_k)^2}{8\pi\sin^2(\delta/2)}, \tag{59}$$

so that

$$\sum_{k=1}^n\left\|\left.\frac{\partial v_k}{\partial n}\right|_{\Gamma_1^{(j)}}\right\|_\infty\le\frac{1}{8\pi\sin^2(\delta/2)}\sum_{k=1}^n(\beta_k-\alpha_k)^2\le\frac{|\Gamma_1|^2}{8\pi\sin^2(\delta/2)}. \tag{60}$$

Now, inequalities like (59) and (60) will be analogously derived for a domain with a Dini-smooth boundary. With this purpose, the starting point we will choose is a general representation formula for the normal derivative of the solution to the problem

$$\left|\begin{array}{ll}\Delta u(\rho,\phi)=\frac{1}{\rho}\left((\rho u_\rho)_\rho+\frac{1}{\rho}\,u_{\phi\phi}\right)=0, & (\rho,\phi)\in B_1(0),\\ u(1,\phi)=0, & \beta<\phi<\alpha+2\pi,\\ \frac{\partial u}{\partial\rho}(1,\phi)=\left|f'(e^{i\phi})\right|, & \alpha<\phi<\beta,\end{array}\right.$$

where the function f conformally maps $B_1(0)$ onto Ω. Denote by $u_{\alpha,\beta}$ the solution to this problem. After the developments of the previous section, it is not difficult to see that, for $\beta < \phi < \alpha + 2\pi$,

$$\frac{\partial u_{\alpha,\beta}}{\partial \rho}(1,\phi) = -\frac{\sin((\beta-\alpha)/2)}{2\pi\sqrt{\sin\frac{\phi-\alpha}{2}\sin\frac{\phi-\beta}{2}}}\int_\alpha^\beta \frac{\left|f'(e^{i\theta})\right|d\theta}{\sin\frac{\phi-\alpha}{2}\sqrt{\frac{\sin((\beta-\theta)/2)}{\sin((\theta-\alpha)/2)}}+\sin\frac{\phi-\beta}{2}\sqrt{\frac{\sin((\theta-\alpha)/2)}{\sin((\beta-\theta)/2)}}},$$

whence we deduce

$$\begin{aligned}\frac{\partial v_k}{\partial n}(f(e^{i\phi})) &= -\frac{\sin((\beta_k-\alpha_k)/2)}{2\pi\left|f'(e^{i\phi})\right|\sqrt{\sin\frac{\phi-\alpha_k}{2}\sin\frac{\phi-\beta_k}{2}}}\\ &\quad\times\int_{\alpha_k}^{\beta_k}\frac{\left|f'(e^{i\theta})\right|d\theta}{\sin\frac{\phi-\alpha_k}{2}\sqrt{\frac{\sin((\beta_k-\theta)/2)}{\sin((\theta-\alpha_k)/2)}}+\sin\frac{\phi-\beta_k}{2}\sqrt{\frac{\sin((\theta-\alpha_k)/2)}{\sin((\beta_k-\theta)/2)}}}.\end{aligned} \tag{61}$$

In estimating the integral in the second member of (61) we again use the arithmetic mean-geometric mean inequality and the fact that $\int_\alpha^\beta \left|f'(e^{i\theta})\right| d\theta = b - a$ to obtain

$$\begin{aligned}\left|\frac{\partial v_k}{\partial n}(f(e^{i\phi}))\right| &\le \frac{\sin((\beta_k-\alpha_k)/2)}{4\pi\left|f'(e^{i\phi})\right|\sin\frac{\phi-\alpha_k}{2}\sin\frac{\phi-\beta_k}{2}}\int_{\alpha_k}^{\beta_k}\left|f'(e^{i\theta})\right|d\theta\\ &= \frac{b_k-a_k}{4\pi\left|f'(e^{i\phi})\right|}\frac{\sin\frac{\beta_k-\alpha_k}{2}}{\sin\frac{\phi-\alpha_k}{2}\sin\frac{\phi-\beta_k}{2}}.\end{aligned} \tag{62}$$

As before, we have

$$\frac{\sin\frac{\beta_k-\alpha_k}{2}}{\sin\frac{\phi-\alpha_k}{2}\sin\frac{\phi-\beta_k}{2}} = \frac{\beta_k-\alpha_k}{2\sin^2[\phi-((1-\mu)\alpha_k+\mu\beta_k))]},$$

for $0 < \mu = \mu(\phi) < 1$, and then inequality (62) becomes

$$\left|\frac{\partial v_k}{\partial n}(f(e^{i\phi}))\right| \le \frac{b_k-a_k}{8\pi\left|f'(e^{i\phi})\right|}\frac{\beta_k-\alpha_k}{\sin^2[\phi-((1-\mu)\alpha_k+\mu\beta_k))]}. \tag{63}$$

Now let d be the minimum distance between adjacent components of Γ_1 as defined by (8). Since $M(f') \le \left|f'(e^{i\theta})\right| \le \|f'\|_\infty$, we have

$$M(f')\delta \le d \le \|f'\|_\infty \delta,$$

where $\delta = \min\{\min_{1\le k\le n-1}(\alpha_{k+1}-\beta_k), \alpha_1-\beta_n\}$ is the minimum distance on $\partial B_1(0)$ between adjacent components of $f^{-1}(\Gamma_1)$. Thus, from (62) we deduce

$$\begin{aligned}\left\|\frac{\partial v_k}{\partial n}\Big|_{\Gamma_1^{(j)}}\right\|_\infty &\le \sup_{\alpha_k-\delta<\phi<\beta_k+\delta}\left|\frac{\partial v_k}{\partial n}(f(e^{i\phi}))\right|\\ &\le \sup_{\alpha_k-\delta<\phi<\beta_k+\delta}\left[\frac{b_k-a_k}{8\pi\left|f'(e^{i\phi})\right|}\frac{\beta_k-\alpha_k}{\sin^2[\phi-((1-\mu)\alpha_k+\mu\beta_k)]}\right]\\ &\le \frac{\|f'\|_\infty(b_k-a_k)^2}{8\pi M(f')}\sup_{\alpha_k-d/\|f'\|_\infty<\phi<\beta_k+d/\|f'\|_\infty}\left[\frac{1}{\sin^2[\phi-((1-\mu)\alpha_k+\mu\beta_k)]}\right]\\ &\le \frac{\|f'\|_\infty(b_k-a_k)^2}{8\pi M(f')}\frac{1}{\sin^2\left[d/\left(2\|f'\|_\infty\right)\right]},\end{aligned} \tag{64}$$

and summing on $k = 1, 2, \ldots, n$,

$$\sum_{k=1}^{n} \left\| \frac{\partial v_k}{\partial n}\Big|_{\Gamma_1^{(j)}} \right\|_\infty \leq \frac{\|f'\|_\infty}{8\pi\, M(f')} \frac{1}{\sin^2\left[d/\left(2\|f'\|_\infty\right)\right]} \sum_{k=1}^{n} (b_k - a_k)^2$$

$$\leq \frac{\|f'\|_\infty}{8\pi\, M(f')} \frac{|\Gamma_1|^2}{\sin^2\left[d/\left(2\|f'\|_\infty\right)\right]} \tag{65}$$

$$= \frac{\|f'\|_\infty}{8\pi\, M(f')} H^2(\Gamma_1),$$

where $H(\Gamma_1)$ was defined by (9).

Finally, with inequalities (64) and (65) at hand, we can proceed to prove Theorem 5 as follows. Assume that $\Gamma_1 \in \mathcal{F}$; i.e., that there exist δ_1 and δ_2, $0 < \delta_1 < \delta_2 < 1$, such that

$$\rho(\Gamma_1) \leq \delta_1, \tag{66}$$

$$\frac{\|f'\|_\infty}{8\pi\, M(f')} H^2(\Gamma_1) \leq 1 - \delta_2. \tag{67}$$

Furthermore, take $0 < \varepsilon \leq (\delta_2 - \delta_1) / [2(\delta_2 + \delta_1)]$ and assume that $|\Gamma_1|$ is so small that expression (51) from Theorem 8 can be applied to write

$$\max_{1\leq k\leq n} \sup_\Omega v_k < \frac{1}{2} \max_{1\leq k\leq n} \left|\Gamma_1^{(k)}\right| + \varepsilon \max_{1\leq k\leq n} \left|\Gamma_1^{(k)}\right| \tag{68}$$

and

$$\sup_\Omega u[\Gamma_1^*] > \frac{1}{2} |\Gamma_1| - \varepsilon |\Gamma_1|, \tag{69}$$

where $\Gamma_1^* \subset \partial\Omega$ is an arc with $|\Gamma_1^*| = |\Gamma_1|$. From inequalities (65) and (67) we see that the second inequality in Lemma 6(iv) is applicable so that, in view of (68), (66), and (67), we obtain

$$\begin{aligned}
\sup_\Omega u[\Gamma_1] &\leq \frac{\max_{1\leq k\leq n} \sup_\Omega v_k}{1 - \sum_{k=1}^{n} \left\| (\partial v_k/\partial n)|_{\Gamma_1^{(j)}} \right\|_\infty} \\
&< \frac{\frac{1}{2} \max_{1\leq k\leq n} \left|\Gamma_1^{(k)}\right| + \varepsilon \max_{1\leq k\leq n} \left|\Gamma_1^{(k)}\right|}{1 - \frac{\|f'\|_\infty}{8\pi\, M(f')} H^2(\Gamma_1)} \\
&= \frac{\frac{1}{2} + \varepsilon}{1 - \frac{\|f'\|_\infty}{8\pi\, M(f')} H^2(\Gamma_1)} \rho(\Gamma_1) |\Gamma_1| \\
&\leq \frac{\delta_1}{\delta_2} \left(\frac{1}{2} + \varepsilon\right) |\Gamma_1|. \qquad (70)
\end{aligned}$$

From (70) and (69) we deduce

$$\sup_\Omega u[\Gamma_1] < \frac{\delta_1}{\delta_2} \left(\frac{1}{2} + \varepsilon\right) |\Gamma_1| \leq \left(\frac{1}{2} - \varepsilon\right) |\Gamma_1| < \sup_\Omega u[\Gamma_1^*].$$

This finishes the proof of Theorem 5.

5. Final remarks. Results that are to Conjectures 2 and 3 as Theorem 4 is to Conjecture 1 can reasonably be proved. Namely, if Ω is a sufficiently regular Jordan domain, $P \in \Omega$ and $1 \leq p < +\infty$, then the inequalities

$$\|u[\Gamma_1(\varepsilon)]\|_p < \|u[\Gamma_1^*(\varepsilon)]\|_p ,$$
$$u[\Gamma_1(\varepsilon)](P) < u[\Gamma_1^*(\varepsilon)](P),$$

hold for ε small enough, provided that Γ_1 and Γ_1^* are two subsets of γ respectively given by (3) and (5) with $\beta - \alpha = \sum_{k=1}^{n}(\beta_k - \alpha_k)$.

Although questions of regularity of the domain Ω may well be considered of secondary interest in relation to the proposed conjectures, some commentaries are in order on this matter. Domains Ω with a Dini-smooth boundary were assumed in the developments of sections 4 and 5. By eventually restricting the placement on $\partial\Omega$ of the arcs composing Γ_1, this assumption may be relaxed to include domains with corners too. The technique of conformal maps could be employed again in such a generalization (cf. [12]). On the other side, the domain Ω studied in section 2 is one with corners, but these corners can be mollified to obtain a smooth domain $\Omega_* \supset \Omega$ so close to Ω that the solution u_* corresponding to problem (4) for Ω_* (and an appropriate Γ_1) is a small "perturbation" of the solution u to that problem (4) for Ω. This domain Ω_* would then afford an example of a nonconvex smooth domain for which the optimality of connected arcs is not true.

In this paper we have treated plane domains but n-dimensional versions of Conjectures 1–3 could, we hope, also be supportable. Of course, additional precisions will then be needed on the geometry of the admissible family Γ_1. For the sphere, the optimal Γ_1 would presumably be bounded by circles.

Acknowledgments. The author is gratefully indebted to Prof. Luis A. Caffarelli for his many useful observations and valuable suggestions on the subject of this paper. He also wishes to thank the hospitality of the Courant Institute of Mathematical Sciences, New York University, where the research conducted for this paper was carried out. Finally, the author expresses his gratitude to the anonymous referee whose clever comments and criticism helped this paper to attain the present form.

FIRST-ORDER CORRECTOR FOR THE HOMOGENIZATION OF THE CRITICALITY EIGENVALUE PROBLEM IN THE EVEN PARITY FORMULATION OF THE NEUTRON TRANSPORT*

GUILLAUME BAL†

Abstract. We consider the homogenization of the criticality eigenvalue problem for the even parity flux of neutron transport in a domain with isotropic and periodically oscillating coefficients. We prove that the neutron density is factored in the product of two terms. The first one describes local behavior of the density at the cell level. It is a solution of a heterogeneous transport problem with periodic boundary conditions. The second term gives global behavior on the whole domain. It satisfies a homogeneous diffusion equation posed on the whole domain with Dirichlet boundary conditions. We also give the asymptotic analysis of the corresponding eigenvalues. This expansion gives rise to errors of the order of the cell size. It does not account for neutron leakage at the boundary of the core and yields unacceptable errors in practice. We derive a more accurate expansion of the eigenelements in the case of a symmetric and cubic domain. The analysis of a boundary layer allows us to derive modified boundary conditions for the diffusion eigenvalue problem. The resulting approximation for the leading transport eigenvalue is proven to be accurate to one order higher than previously. Numerical experiments confirm the accuracy of the reconstructed eigenvectors in realistic settings.

1. Introduction.

Transport equations are solved in industrial applications in order to determine the power distribution of neutrons in nuclear reactors. In the case of a stable reactor, only a steady-state solution is required. Hence the time variable can be eliminated. An eigenvalue problem, called the criticality problem for neutron transport, is solved to figure out whether a steady state exists. The unknowns are the multiplicative factor k_{eff}, which expresses the balance between the production of neutrons by fission and its absorption and leakage at the boundary of the core, and the neutron density $\phi(x,\mu)$, defined in phase space at position x and velocity μ. They are the largest eigenvalue and the associated positive eigenvector of the following equation:

$$(1)\quad (\mu\cdot\nabla\phi+\Sigma\phi)(x,\mu)=\int_V \Sigma_s(x,\mu',\mu)\phi(x,\mu')d\mu'+\frac{1}{k_{eff}}\int_V \sigma_f(x,\mu',\mu)\phi(x,\mu')d\mu'$$

posed with appropriate boundary conditions in an open bounded domain $\Omega\in\mathbb{R}^d$ for a velocity space V. With the usual notation, $\mu\cdot\nabla=\sum_{i=1}^d \mu_i\frac{\partial}{\partial x_i}$, where $\mu=(\mu_1,\dots,\mu_d)$ and $d\in\mathbb{N}^*$ is the spatial dimension. It turns out that the eigenvector $\phi(x,v)$ is the only positive normalized eigenvector of (1); hence the only one of physical interest. We have the following interpretation for the multiplicative factor k_{eff}. If $k_{eff}=1$, the core is stable and fission exactly compensates for absorption and leakage. When

$k_{eff} > 1$, fission is too important and the reactor is supercritical. If $k_{eff} < 1$, fission must be increased, or the chain reaction dies out.

In (1), Σ, Σ_s, and σ_f are the total cross section, the scattering cross section, and the fission cross section, respectively. They characterize the nuclear reactors, which are highly heterogeneous. Therefore, numerical simulations with the transport equation are very demanding.

A first approximation consists in assuming that the core is periodic. It allows us to homogenize the transport equation (1), which yields a homogeneous second-order elliptic eigenvalue problem. We consider here a physical domain Ω^ε composed of roughly $\frac{1}{\varepsilon^d}$ identical cells. The cross sections Σ, Σ_s, and σ_f are supposed to be isotropic, i.e., only depend on the spatial position x, and to be Y-periodic in the domain Ω^ε, where Y is the unit cell. For simplicity, the velocity space V will be here the unit sphere $V = S^{d-1} = \{\mu \in \mathbb{R}^d,\ |\mu| = 1\}$.

The homogenization of transport equations has been studied at length in the past, physically [12, 15, 21] and mathematically [14, 26, 27, 31, 33]. We have recently revisited the criticality eigenvalue problem in [4, 5, 8]. To the best of our knowledge, no theory is available for the homogenization of eigenvalue problems with periodic coefficients taking account for neutron leakage at the boundary of the core. In the same spirit, let us mention the works of [6, 7, 29] concerning the homogenization of heterogeneous diffusion eigenvalue problems. Notice that various results on the homogenization of transport equations have been obtained in different contexts [1, 22, 23].

The theory of transport is usually done using (1). However, it is also interesting to analyze the so-called even parity flux formulation. The *even parity flux* is defined by

$$\psi^+(x,\mu) = \frac{1}{2}(\phi(x,\mu) + \phi(x,-\mu)).$$

When no direction is privileged with respect to its opposite one, such as in the diffusion limit, this symmetrized flux can be of interest. We deduce from (1) and Appendix A the following equation in $\Omega^\varepsilon \times V$:

$$-\mu\nabla\frac{1}{\Sigma(x)}\mu\nabla\psi^+(x,\mu)+\Sigma(x)\psi^+(x,\mu) = \left(\Sigma_s(x) + \frac{1}{k^\varepsilon_{eff}}\sigma_f(x)\right)\int_V \psi^+(x,\mu')d\mu. \tag{2}$$

The derivation of this symmetrized transport equation requires that the cross sections be isotropic. By definition of the even parity flux, we have $\psi^+(x,-\mu) = \psi^+(x,\mu)$. Consequently, we need to consider only solutions of (2) satisfying this symmetry condition. It is well known that the homogenization of transport equations yields homogeneous second-order elliptic equations. Thus, the second-order differential operator in the even parity formulation is similar to that of diffusion. More precisely, we will see that the variational formulation associated with the transport equation (2) is well suited to the derivation of the variational formulation of diffusion and simplifies the analysis of the leakage at the boundary of the core and of the associated boundary layer problem.

Let us now define our main framework. It is convenient to recast the sequence of problems (2), parameterized by ε, on a fixed domain. By change of variables $x \to \varepsilon x$, the spatial domain becomes Ω. Since the core is periodic, Ω is composed of roughly ε^{-d} identical cells of the kind $\varepsilon Y = (0,\varepsilon)^d$, where $Y = (0,1)^d$ is the unit cell. The

period of the heterogeneities in Ω is thus given by $\varepsilon > 0$. No further geometrical assumption is needed when no leakage is accounted for. However, in order to derive a more accurate approximation for the leading eigenvalue, neutron leakage at the boundary cannot be ignored. We have to make more precise the local geometry at the boundary of the core. We assume here that Ω is the unit cube and that ε^{-1} is an integer. The main characteristic is that the boundary of Ω always coincides with the boundary of a unit cell.

Let us define

$$\Sigma^\varepsilon(x) = \Sigma\left(\frac{x}{\varepsilon}\right), \Sigma_s^\varepsilon(x) = \Sigma_s\left(\frac{x}{\varepsilon}\right), \sigma_f^\varepsilon(x) = \sigma_f\left(\frac{x}{\varepsilon}\right), \tag{3}$$

where Σ, Σ_s, and σ_f are Y-periodic measurable functions, bounded from above and below by positive constants and such that the absorption cross section $\Sigma - \Sigma_s$ be also bounded from below by a positive constant. The latter condition ensures that absorption is positive everywhere; hence fission is allowed. For simplicity, we introduce $\lambda_\varepsilon = \frac{1}{k_{eff}}$. We consider here an absorbing boundary condition. It means that no particle enters the core. The solution to (1) satisfies

$$\phi = 0 \text{ on } \Gamma_- = \{(x,\mu) \in \partial\Omega \times V \text{ subject to (s.t.) } \mu \cdot n(x) < 0\},$$

where $n(x)$ denotes the outward unit normal to $\partial\Omega$ at $x \in \partial\Omega$. In practice, this boundary condition is a first approximation only. The addition of a reflector around the core yields a correction of order ε. Its analysis is much more involved and is not considered here.

Let us define $\varphi^{\varepsilon+}(x,\mu) = \psi^+(\frac{x}{\varepsilon},\mu)$. These assumptions enable us to recast (2) as

$$\begin{aligned} &-\varepsilon^2 \mu\cdot\nabla \frac{1}{\Sigma^\varepsilon(x)} \mu\cdot\nabla\varphi^{\varepsilon+}(x,\mu) + \Sigma^\varepsilon(x)\varphi^{\varepsilon+}(x,\mu) \\ &\qquad = (\Sigma_s^\varepsilon(x) + \lambda^\varepsilon \sigma_f^\varepsilon(x)) \int_V \varphi^{\varepsilon+}(x,\mu')d\mu' \quad \text{in } \Omega \times V, \\ &\varphi^{\varepsilon+}(x,\mu) - \frac{\varepsilon}{\Sigma^\varepsilon(x)} \mu\cdot\nabla\varphi^{\varepsilon+}(x,\mu) = 0 \quad \text{on } \Gamma_-. \end{aligned} \tag{4}$$

The boundary conditions have been obtained following rules recalled in Appendix A.

An outline of this paper is as follows. In section 2, we recall existing results on problem (4) at ε given. We also address the transport problem with periodic boundary conditions, which characterizes the neutron density at the small scale. In section 3, we present our main results on the asymptotic behavior of the eigenvalues and eigenvectors of (4) as $\varepsilon \to 0$. First an analysis is given without accounting for the leakage at the boundary of the core. Second, a first-order correction of the previous results is given for the largest eigenvalue k_{eff}. This correction characterizes the amount of neutron leakage at the boundary of a nuclear reactor. We give in sections 4 to 6 a detailed proof of these results. In section 4, we give some a priori estimates and existence results with ε fixed. Our results are based on the analysis of a source problem introduced in section 3. The asymptotic expansion of this problem is given in section 5. The analysis of a genuine multidimensional boundary layer problem, or Milne problem, that is used in section 5, is given in section 6. Finally, we present some numerical experiments in section 7.

2. The criticality eigenvalue problem in bounded and periodic domain. In this section, we state some results of existence and regularity for the eigenvalues and eigenvectors of the even parity transport. They are very close to known results

on eigenvalue problems in transport theory (see [20, Chapter 21]). We recall them here for the sake of completeness. The proofs are sketched only and we refer to the thesis [8] for the details and to the equivalence between the first-order formulation and the even parity flux formulation given in Appendix A. Our main hypothesis on the physical data is given now.

HYPOTHESIS 2.1.

(H1) Ω *is a convex open bounded subset of* $\mathbb{R}^d$.

(H2) $V = S^{d-1} = \{v \in \mathbb{R}^d \text{ s.t. } |v| = 1\}$.

(H3) *The cross sections* $\Sigma(x)$, $\Sigma_s(x)$, *and* $\sigma_f(x)$ *are positive functions in* $L^\infty(\Omega)$. *Moreover they are* Y*-periodic, where* $Y = (0,1)^d$ *is the periodicity cell.*

(H4) *There exists a constant* $\eta > 0$ *such that* $\Sigma(x) - \Sigma_s(x) \geq \eta$ *and* $\sigma_f(x) \geq \eta$.

Let us introduce the Hilbert space

$$W^2(\Omega \times V) = \{u \in L^2(\Omega \times V),\ \mu \cdot \nabla u \in L^2(\Omega \times V)\}. \tag{5}$$

We deduce from [8, Theorem II.2.1.1] and Appendix A the following result.

THEOREM 2.2. *Assume that Hypothesis* 2.1 *is satisfied. Then problem* (4) *admits a countable number of real eigenvalues and of associated eigenvectors, which are elements of* $W^2(\Omega \times V)$. *Moreover there exists a simple, positive, and real eigenvalue of smallest modulus, such that its associated eigenvector be the unique normalized positive eigenvector of* (4).

The solutions of (4) can be seen as the eigenvalues and eigenvectors of a positive compact operator. The reality of these eigenvalues, which holds true in the simplified setting of isotropic cross sections, is given in [34], for instance. The first part of the theorem is then proven. The second part relies on the Krein–Rutman theory of positive operators, which asserts that the spectral radius of this compact operator is an eigenvalue and that the corresponding eigenvector is positive. Following a proof given in [20, Chapter 21], one proves that this eigenvalue is simple and that there exists a unique positive normalized eigenvector.

As we shall see in the next section, the asymptotic limit as $\varepsilon \to 0$ of the solutions to (4) involves the small scale behavior of the neutron density. It is obtained by considering the solutions of the following criticality eigenvalue problem in periodic domain:

Find the smallest eigenvalue λ_∞ and the associated positive eigenvector ψ_∞^+ of

$$\begin{aligned} &-\mu \cdot \nabla_y \frac{1}{\Sigma} \mu \cdot \nabla_y \psi_\infty^+ + \Sigma \psi_\infty^+ \ = \ (\Sigma_s + \lambda_\infty \sigma_f) \int_V \psi_\infty^+(y, \mu') d\mu' \quad \text{in } Y \times V, \\ &y \mapsto \psi_\infty^+(y, \mu) \ \text{ is } Y\text{-periodic.} \end{aligned} \tag{6}$$

Still following the equivalence between the first-order formulation and the even parity flux formulation given in Appendix A, we deduce from [8, Theorems II.2.2.4 and II.2.2.7] the following theorem.

THEOREM 2.3. *Assume that Hypothesis* 2.1 *is satisfied. Then problem* (6) *admits a simple, positive, and real eigenvalue of smallest modulus, such that its associated eigenvector be the unique normalized positive eigenvector of* (6). *Moreover assume that the cross sections* Σ, Σ_s, *and* σ_f *belong to* $C^m(Y)$ *for* $m \in \mathbb{N}^*$. *Then we have that* $\psi_\infty^+ \in H^m(Y \times V)$.

REMARK 2.4. *The regularity result stated in the previous theorem is a characteristic property of the criticality problem with periodic boundary conditions. It is well known that the solutions to* (4) *are not arbitrarily regular, even with smooth physical data (see* [30]*). For example, we have a nonvanishing outgoing density at the boundary*

of the core, whereas the incoming density is zero by hypothesis. Let us also mention the following regularity result [5]. *Assume that the cross sections are bounded from above and below by positive constants. Then* ψ^+_∞ *and* $\frac{1}{\psi^+_\infty}$ *belong to* $L^\infty(Y\times V)$.

Consider the associated source problem:

$$\begin{aligned} &-\mu\cdot\nabla_y\frac{1}{\Sigma}\mu\cdot\nabla_y\psi^+ + \Sigma\psi^+ \;=\; (\Sigma_s+\lambda_\infty\sigma_f)\int_V \psi^+(y,\mu')d\mu' \;+\; S \quad \text{in } Y\times V,\\ &y\mapsto\psi^+(y,\mu) \;\text{ is } Y\text{-periodic,}\end{aligned} \tag{7}$$

where S is a given function in $L^2(Y\times V)$ satisfying $S(y,\mu)=S(y,-\mu)$. Then we deduce from [8, Theorems II.2.2.5 and II.2.2.8] the following result.

THEOREM 2.5. *Let* $(\lambda_\infty,\psi^+_\infty)$ *be the solution to* (6). *Then problem* (7) *admits a solution if and only if the source term* S *satisfies the following compatibility condition:*

$$\int_Y\int_V S(y,\mu)\psi^+_\infty(y,\mu)\,d\mu\,dy = 0. \tag{8}$$

Furthermore, if a solution exists, it is unique up to the addition of a multiple of ψ^+_∞. *Assume moreover that the cross sections* Σ, Σ_s, *and* σ_f *are of class* $C^m(Y)$ *and the source term* S *belongs to* $H^m(Y\times V)$ *for* $m\in\mathbb{N}^*$. *Then we have that* $\psi^+\in H^m(Y\times V)$.

3. Main results on the asymptotic analysis. In this section, we present our main results on the asymptotic analysis of the criticality eigenvalue problem (4). Let us introduce the function $\psi^+_\varepsilon(x,\mu)=\psi^+_\infty(\frac{x}{\varepsilon},\mu)$, where ψ^+_∞ is the positive normalized eigenvector of (6) extended by Y-periodicity on $\mathbb{R}^d\times V$. Clearly, ψ^+_ε is εY-periodic and satisfies (4) on $\Omega\times V$. The difference between ψ^+_ε and $\varphi^{\varepsilon+}$ is the definition of their boundary conditions on $\partial\Omega$. Therefore, we can expect some similarities in the behavior of both solutions away from the boundary. This is confirmed more precisely in Theorem 3.2 below. It is based on the asymptotic expansion of solutions to source problems, which requires sufficient regularity for the physical parameters. We do not dwell on optimal regularity results here and assume the physical parameters to be smooth.

HYPOTHESIS 3.1.

(H5) *In addition to Hypothesis* 2.1, *we assume the cross sections* Σ, Σ_s, *and* σ_f *to be of class* $C^\infty(\Omega)$.

(H6) *The domain* Ω *is either cubic or has a boundary* $\partial\Omega$ *of class* C^∞.

THEOREM 3.2. *Assume that Hypothesis* 3.1 *is satisfied. Let* $0<\lambda^\varepsilon_1<\lambda^\varepsilon_2\le\lambda^\varepsilon_3\le\cdots\le\infty$ *be the eigenvalues of* (4) *ranked in increasing order, and* $\varphi^{\varepsilon+}_l$ *the normalized eigenvector associated with* λ^ε_l. *Then, up to a subsequence, we have*

$$\varphi^{\varepsilon+}_l(x,\mu) \;=\; u_l(x)\psi^+_\infty(\frac{x}{\varepsilon},\mu)+O(\varepsilon) \quad \text{and} \quad \lambda^\varepsilon_l \;=\; \lambda_\infty+\varepsilon^2\nu_l+O(\varepsilon^3), \tag{9}$$

where λ_∞ *is the first eigenvalue of* (6), ψ^+_∞ *its associated normalized eigenvector and where* (ν_l,u_l) *are the* l*th eigenvalue (in the sense that* $0<\nu_1<\nu_2\le\nu_3\le\cdots\le\infty$*) and corresponding normalized eigenvector of the homogenized diffusion problem*

$$\begin{aligned} -\nabla D\nabla u &= \nu\overline{\sigma_f}u \quad \text{in } \Omega,\\ u &= 0 \qquad \text{on } \partial\Omega.\end{aligned} \tag{10}$$

In the convergence of the eigenvectors, $O(\varepsilon)$ *is to be understood in the sense of the* $L^2(\Omega\times V)$*-norm. The positive definite homogeneous tensor* $D=(D_{ij})_{1\le i,j\le d}$ *and the*

homogeneous fission cross section $\overline{\sigma_f}$ *in* (10) *are defined by*

$$
\begin{aligned}
D_{ij} &= \int_V \int_Y \frac{(\psi_\infty^+(y,\mu))^2}{\Sigma(y)} \left(\mu_i + \mu\cdot\nabla\theta^i(y,\mu)\right) \mu_j d\mu\, dy, \\
\overline{\sigma_f} &= \int_Y \sigma_f(y) \left(\int_V \psi_\infty^+(y,\mu) d\mu\right)^2 dy,
\end{aligned} \tag{11}
$$

where $(\mu_i)_{1\le i\le d}$ *are the coordinates of* μ *in* $\mathbb{R}^d$ *and* $(\theta^i)_{1\le i\le d}$ *are the zero mean solutions of*

$$
\begin{aligned}
&-\mu\cdot\nabla_y \frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\theta^i + Q\theta^i = \mu_i \left(\mu\cdot\nabla_y \frac{(\psi_\infty^+)^2}{\Sigma}\right), \\
&y \mapsto \theta^i(y,\mu) \ \textit{is } Y\textit{-periodic}
\end{aligned} \tag{12}
$$

with the local scattering operator being defined by

$$
\begin{aligned}
Qw &= \Sigma^\infty \left(\psi_\infty^+ w \int_V \psi_\infty^+(x,\mu')d\mu' - \psi_\infty^+ \int_V w(x,\mu')\psi_\infty^+(x,\mu')d\mu'\right), \\
\Sigma^\infty &= \Sigma_s + \lambda_\infty \sigma_f.
\end{aligned} \tag{13}
$$

Due to the even parity formulation, the homogeneous coefficients given in this theorem are nonstandard. However, they are similar to those obtained in the homogenization of heterogeneous diffusion problems [29], and it can be shown [8] that they correspond to those derived in the setting of first-order transport [5, 26, 27] . Notice, however, that they slightly differ from the coefficients derived physically in [12].

REMARK 3.3. *Hypothesis* (H6) *is not optimal. We do not need it to prove the convergence of the eigenvalues and eigenvectors, i.e., to replace the rates of convergence* $O(\varepsilon)$ *and* $O(\varepsilon^3)$ *in* (9) *by* $o(1)$ *and* $o(\varepsilon^2)$*, respectively. Hypothesis* (H5) *can also be considerably weakened. We obtained in* [5] *the convergence of the eigenelements for cross sections that are only uniformly bounded from above and below by positive constants.*

In practical nuclear reactor computations, the number of assemblies, or equivalently ε^{-1}, is not very large, and the expansion given in the previous theorem is not sufficiently accurate. The aim of the next theorem is to give a third-order corrector for the smallest eigenvalue λ_1^ε, the only one of physical interest. Numerical simulations also show a better accuracy for the associated positive eigenvector [9], even if a theoretical proof is given only for source problems.

First-order correctors have already been addressed in homogeneous transport theory [33] as well as in heterogeneous diffusion theory [3, 32]. The results obtained in these works show that the first-order corrector for the eigenvalues can strongly depend on the geometry. In transport theory, the first-order corrector is driven by the neutron leakage at the boundary of the core. Since the neutron mean free path is comparable to the size of the unit cell, the boundary $\partial\Omega$ has a direct influence on the leakage. We need to define our geometry more precisely in order to obtain an asymptotic neutron leakage. We study here the case of a cubic domain with symmetric cells as follows.

HYPOTHESIS 3.4.

(H7) Ω *is the unit cube* $(0,1)^d$*. It is composed of* N^d *identical cells, where* $N = \frac{1}{\varepsilon} \in \mathbb{N}$.

(H8) *Hypotheses* (H5) *and* (H6) *are satisfied.*

(H9) *The periodicity cell* Y *is symmetric in the following sense. The cross sections* Σ*,* Σ_s*, and* σ_f *are symmetric with respect to the (hyper)planes parallel to the*

sides of Y and splitting Y in two identical parts. Furthermore these cross sections are invariant by the rotations that preserve Y (rotations of angle $\pi/2$).

Then we have the following first-order corrector for the smallest eigenvalue.

THEOREM 3.5. *Assume that Hypothesis* 3.4 *is satisfied. Then there exists a constant extrapolation length L such that the first eigenvalue ω_1^ε of the elliptic problem*

$$\begin{aligned} -\nabla D\nabla\Phi^\varepsilon &= \omega^\varepsilon\overline{\sigma_f}\Phi^\varepsilon \text{ in } \Omega, \\ \Phi^\varepsilon + \varepsilon L\frac{\partial\Phi^\varepsilon}{\partial n} &= 0 \qquad \text{on } \partial\Omega, \end{aligned} \tag{14}$$

satisfies

$$\lambda_1^\varepsilon = \lambda_\infty + \varepsilon^2\omega_1^\varepsilon + O(\varepsilon^{7/2}). \tag{15}$$

REMARK 3.6. *To our knowledge, this extrapolation length can unfortunately not be computed explicitly. In the case of homogeneous cells, the value of L can be derived from Chandrasekhar's H function* [18]. *An approximate value is $L_0 = 0.7104$ (see, e.g.,* [20, *Chapter* 21]*). In general, L is defined as the limit when the first coordinate $x_1 \to \infty$ of the solution to a conservative transport problem posed on the half space $x_1 > 0$ with some suitable boundary conditions. The analysis of this problem is part of our section* 6. *Since the neutron leakage is positive, we believe that L is always positive, although we do not have a mathematical proof for it. In case $L < 0$, which is physically unrealistic,* (14) *is well posed for ε small enough only.*

REMARK 3.7. *Up to some slight modifications in the proof, the theorem can be extended to the case of cells satisfying all symmetries stated in* (H9) *but the invariance by rotation. Then L is constant on each side of $\partial\Omega$, but not necessarily on the whole $\partial\Omega$.*

We now give a proof for Theorems 3.2 and 3.5. They will rely on some results interesting in themselves for related source problems. We present them in the remaining part of this section and postpone the proofs to the following sections. The proof of Theorem 3.2 relies on the analysis of an equivalent eigenvalue problem for the factored function u_ε defined by

$$u_\varepsilon = \frac{\varphi^{\varepsilon+}}{\psi_\varepsilon^+}, \tag{16}$$

where $\varphi^{\varepsilon+}$ is a solution of (4). Since ψ_∞^+ is positive and regular by virtue of Theorem 2.3, $\varphi^{\varepsilon+} \mapsto u_\varepsilon$ is uniquely defined by (16). The derivation of a transport equation for u_ε uses the following identity:

$$\mu\cdot\nabla\frac{1}{\Sigma}\mu\cdot\nabla(u\psi) = u\mu\cdot\nabla\frac{1}{\Sigma}\mu\cdot\nabla\psi + \frac{1}{\psi}\mu\cdot\nabla\frac{\psi^2}{\Sigma}\mu\cdot\nabla u. \tag{17}$$

An analogous relation was first used in the homogenization of heterogeneous diffusion eigenvalue problems [29]. Plugging (16) into (4) and using (6) and (17), we obtain

$$\begin{aligned} &-\varepsilon^2\mu\cdot\nabla\frac{(\psi_\varepsilon^+)^2}{\Sigma^\varepsilon}\mu\cdot\nabla u_\varepsilon + \Sigma_s^\varepsilon\left(\psi_\varepsilon^+ u_\varepsilon\int_V \psi_\varepsilon^+(x,\mu')d\mu' - \psi_\varepsilon^+\int_V u_\varepsilon(x,\mu')\psi_\varepsilon^+(x,\mu')d\mu'\right) \\ &\quad = \lambda^\varepsilon\sigma_f^\varepsilon\psi_\varepsilon^+\int_V u_\varepsilon(x,\mu')\psi_\varepsilon^+(x,\mu')d\mu' - \lambda_\infty\sigma_f^\varepsilon u_\varepsilon\psi_\varepsilon^+\int_V \psi_\varepsilon^+(x,\mu')d\mu' \quad \text{in } \Omega\times V. \end{aligned} \tag{18}$$

Let us now derive the boundary conditions satisfied by u_ε. We deduce from (4) and (16) that

$$u_\varepsilon(\psi_\varepsilon^+ - \frac{\varepsilon}{\Sigma^\varepsilon}\mu\cdot\nabla\psi_\varepsilon^+) - \frac{\varepsilon}{\Sigma^\varepsilon}\psi_\varepsilon^+\mu\cdot\nabla u_\varepsilon \quad = \quad 0 \qquad \text{on } \Gamma_-.$$

Introduce $\psi_\varepsilon = \psi_\varepsilon^+ - \frac{\varepsilon}{\Sigma^\varepsilon}\mu\cdot\nabla\psi_\varepsilon^+$. From the equivalence presented in Appendix A, ψ_ε is the solution of the first-order criticality eigenvalue problem

$$\frac{1}{\varepsilon}\mu\cdot\nabla\psi_\varepsilon + \frac{1}{\varepsilon^2}\left(\Sigma^\varepsilon\psi_\varepsilon - \Sigma_\infty^\varepsilon\psi_\varepsilon\right) = 0, \tag{19}$$

where $\Sigma_\varepsilon^\infty = \Sigma_s^\varepsilon + \lambda_\infty\sigma_f^\varepsilon$. It is positive (see [5] and [8, Theorem II.2.1.1]). Thus we obtain the boundary conditions for u_ε:

$$u_\varepsilon - \frac{\varepsilon\psi_\varepsilon^+}{\psi_\varepsilon\Sigma^\varepsilon}\mu\cdot\nabla u_\varepsilon = 0 \qquad \text{on } \Gamma_-\,. \tag{20}$$

This enables us to recast (18) as

$$\begin{array}{rcll} A_\varepsilon u_\varepsilon & = & \nu^\varepsilon F_\varepsilon u_\varepsilon & \text{in } \Omega\times V, \\ u_\varepsilon - \dfrac{\varepsilon\psi_\varepsilon^+}{\psi_\varepsilon\Sigma^\varepsilon}\mu\cdot\nabla u_\varepsilon & = & 0 & \text{on } \Gamma_-, \end{array} \tag{21}$$

where we have defined

$$A_\varepsilon u = -\mu\cdot\nabla\frac{(\psi_\varepsilon^+)^2}{\Sigma^\varepsilon}\mu\cdot\nabla u + \frac{1}{\varepsilon^2}Q_\varepsilon u, \tag{22}$$

$$\nu^\varepsilon = \frac{\lambda^\varepsilon - \lambda_\infty}{\varepsilon^2}, \tag{23}$$

$$Q_\varepsilon u = \Sigma_\varepsilon^\infty\left(\psi_\varepsilon^+ u\int_V \psi_\varepsilon^+(x,\mu')d\mu' - \psi_\varepsilon^+\int_V u(x,\mu')\psi_\varepsilon^+(x,\mu')d\mu'\right), \tag{24}$$

$$F_\varepsilon u = \psi_\varepsilon^+\sigma_f^\varepsilon\int_V \psi_\varepsilon^+(x,\mu')\,u(x,\mu')d\mu'. \tag{25}$$

Following the results given in section 2, ψ_ε^+ is smooth and uniformly positive. Thus problems (4) and (21) are equivalent in $W^2(\Omega\times V)$. We write (21) as

$$\begin{array}{rcl} \dfrac{1}{\nu^\varepsilon}u_\varepsilon & = & S_\varepsilon u_\varepsilon, \\ S_\varepsilon & = & A_\varepsilon^{-1}F_\varepsilon. \end{array} \tag{26}$$

We will see in Theorem 3.9 that $S_\varepsilon \in \mathcal{L}(L^2(\Omega\times V))$. The first step in the asymptotic analysis of problem (26), or equivalently (4), consists in studying the following source problem:

$$\begin{array}{ll} A_\varepsilon w_\varepsilon = F_\varepsilon q & \text{in } \Omega\times V, \\ w_\varepsilon - \dfrac{\varepsilon\psi_\varepsilon^+}{\psi_\varepsilon\Sigma^\varepsilon}\mu\cdot\nabla w_\varepsilon = 0 & \text{on } \Gamma_-, \end{array} \tag{27}$$

where $q(x,\mu) \in L^2(\Omega\times V)$ is a given source term satisfying $q(x,\mu) = q(x,-\mu)$. Let us recall that we are interested only in solutions of the form $w_\varepsilon(x,-\mu) = w_\varepsilon(x,\mu)$. We first state an a priori estimate for the solutions of source problems.

LEMMA 3.8. *Let $q(x,\mu) \in L^2(\Omega \times V)$ and $g \in L^2(\Gamma_-, d\xi)$. Assume that w_ε is a solution to*

$$\begin{aligned} &A_\varepsilon w_\varepsilon = F_\varepsilon q \quad \text{in } \Omega \times V, \\ &w_\varepsilon - \frac{\varepsilon \psi_\varepsilon^+}{\psi_\varepsilon \Sigma^\varepsilon} \mu \cdot \nabla w_\varepsilon = g \quad \text{on } \Gamma_-. \end{aligned} \tag{28}$$

Then we have

$$\begin{aligned} &\|\mu \cdot \nabla w_\varepsilon\| + \|w_\varepsilon\| + \frac{1}{\sqrt{\varepsilon}} \|w_\varepsilon\|_{L^2(\partial\Omega \times V, d\xi)} + \frac{1}{\varepsilon} \|w_\varepsilon - \int_V w_\varepsilon\| \\ \leq \;& C\|q\| + \frac{C}{\sqrt{\varepsilon}} \|g\|_{L^2(\Gamma_-, d\xi)}, \end{aligned} \tag{29}$$

where $\|\cdot\|$ is the $L^2(\Omega \times V)$-norm and where the measure $d\xi$ on $\partial\Omega \times V$ is given by $d\xi = |\mu \cdot n(x)| d\mu d\sigma$, with $d\sigma$ the surface measure on $\partial\Omega$.

The proof of this lemma is given in section 4. This energy estimate is a key result in our analysis. It enhances the interest of the variational formulation associated with the even parity flux formulation. The asymptotic behavior of the source problem is stated in the following result.

THEOREM 3.9. *Assume that Hypothesis 3.1 is satisfied. Let $q \in L^2(\Omega \times V)$ be a given source term. Then problem (27) admits a unique solution w_ε, which converges strongly to $w \in H_0^1(\Omega)$ in $L^2(\Omega \times V)$ as $\varepsilon \to 0$, where w is the solution of the diffusion problem*

$$\begin{aligned} -\nabla D \nabla w &= \overline{q} \quad \text{in } \Omega, \\ w &= 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{30}$$

Here we have

$$\overline{q}(x) = \int_Y \sigma_f(y) \left\{ \int_V \psi_\infty^+(y,\mu') d\mu' \int_V \psi_\infty^+(y,\mu) q(x,\mu) d\mu \right\} dy.$$

Moreover, assume that there exists $M \in \mathbb{N}$ such that $q(x,\mu) = \sum_{m=1}^M q_m(x) h_m(\mu)$, where $q_m \in C^{2,\alpha}(\Omega)$ and $h_m \in L^2(V)$, $1 \leq m \leq M$. Then we have the error estimate in $L^2(\Omega \times V)$:

$$w_\varepsilon - w = O(\varepsilon).$$

The proof of the well-posedness of (27) is given in section 4. The proof of the asymptotic behavior stated in this theorem is postponed to section 5. We deduce from this theorem the pointwise convergence of S_ε to the homogenized operator $S \in \mathcal{L}(L^2(\Omega \times V))$ defined by

$$q \mapsto Sq = w,$$

where w is the solution to (30). The *compact convergence* of the sequence S_ε (in the sense given in Appendix B) is asserted by the following lemma.

LEMMA 3.10. *Let x_ε be a sequence of elements in the unit ball of $L^2(\Omega \times V)$. Then $S_\varepsilon x_\varepsilon$ is relatively compact.*

Proof. We deduce from the a priori estimate (29) of Lemma 3.8 that

$$\|\mu \cdot \nabla (S_\varepsilon x_\varepsilon)\|^2 + \|S_\varepsilon x_\varepsilon\| + \|S_\varepsilon x_\varepsilon\|^2_{L^2(\partial\Omega \times V, d\xi)} \leq C.$$

Then the averaging lemma given in [25] yields that $\int_V S_\varepsilon x_\varepsilon \, d\mu$ is relatively compact in $L^2(\Omega)$. Using (29) once again, we have

$$\|S_\varepsilon x_\varepsilon - \int_V S_\varepsilon x_\varepsilon \, d\mu\| \quad \leq \quad C\varepsilon,$$

which asserts that $S_\varepsilon x_\varepsilon$ is also relatively compact. This completes the proof of this lemma. □

We deduce from Theorem 3.9 and Lemma 3.10 that the sequence of operators S_ε converges compactly to S. Theorem 3.2 is then a straight consequence of Theorem B.1. Since the eigenvectors of the diffusion eigenvalue problem are regular, the error estimates (9) given in Theorem 3.2 are easily derived from Theorem B.2.

In order to prove Theorem 3.5, we need to characterize first-order correctors for the source problem (27). The source term in the criticality eigenvalue problem, coming from the fission term, is regular and isotropic. Therefore, we consider only source terms $q = q(x) \in C^{3,\alpha}(\Omega)$ with $\alpha > 0$.

THEOREM 3.11. *Let w_ε be the solution to* (28) *with $g = 0$ and $(\theta^i)_{1\leq i\leq d}$ defined by* (12). *Assume that Hypothesis* 3.4 *is satisfied and that $q = q(x) \in C^{3,\alpha}(\Omega)$. Then there exists a constant L, independent of q, such we have the following result.*

Let w_0 and w_{10} be the solutions of

$$\left\{ \begin{array}{rcll} -\nabla D \nabla w_0 & = & q & \text{in } \Omega, \\ w_0 & = & 0 & \text{on } \partial\Omega, \end{array} \right. \tag{31}$$

$$\left\{ \begin{array}{rcll} -\nabla D \nabla w_{10} & = & 0 & \text{in } \Omega, \\ w_{10} + L\dfrac{\partial w_0}{\partial n} & = & 0 & \text{on } \partial\Omega. \end{array} \right. \tag{32}$$

Then, denoting by $\theta^i_\varepsilon(x,\mu) = \theta^i(\frac{x}{\varepsilon},\mu)$, we have

$$\left\| w_\varepsilon - \left[w_0 + \varepsilon \left(\theta^i_\varepsilon \frac{\partial w_0}{\partial x_i} + w_{10} \right) \right] \right\|_{L^2(\Omega\times V)} = O(\varepsilon^{3/2}). \tag{33}$$

This theorem is proven in section 5. Let us focus on the proof of Theorem 3.5. We obtained in Theorem 3.2 that $\lambda^\varepsilon = \lambda_\infty + \varepsilon^2 \nu^\varepsilon$, where the lth eigenvalue ν^ε_l converges to ν_l as $\varepsilon \to 0$. Now we are interested in the limit of the corrector for the smallest eigenvalue $\xi^\varepsilon_1 = \frac{\nu^\varepsilon_1 - \nu_1}{\varepsilon}$. Denote by s^ε the solution of

$$A_\varepsilon s^\varepsilon = \nu_1 F_\varepsilon u_1.$$

This problem admits a unique solution, as seen in Theorem 3.9. Multiplying this equation by u_ε, the solution of $A_\varepsilon u_\varepsilon = \nu^\varepsilon_1 F_\varepsilon u_\varepsilon$, and integrating over $\Omega \times V$, we obtain, since A_ε is self-adjoint, that

$$\begin{aligned} \nu^\varepsilon_1 (s^\varepsilon, F_\varepsilon u_\varepsilon) &= \nu_1 (u_1, F_\varepsilon u_\varepsilon), \\ (\nu^\varepsilon_1 - \nu_1)(u_1, F_\varepsilon u_\varepsilon) &= \nu^\varepsilon_1 (u_1 - s^\varepsilon, F_\varepsilon u_\varepsilon), \\ \left(\frac{\nu^\varepsilon_1 - \nu_1}{\varepsilon} \right) (u_1, F_\varepsilon u_\varepsilon) &= \nu^\varepsilon_1 \left(\frac{u_1 - s^\varepsilon}{\varepsilon}, F_\varepsilon u_\varepsilon \right). \end{aligned} \tag{34}$$

Since u_1 is sufficiently smooth, we deduce from Theorem 3.11 the following expansion in $L^2(\Omega \times V)$:

$$s^\varepsilon = u_1 + \varepsilon \theta^i_\varepsilon \frac{\partial u_1}{\partial x_i} + \varepsilon w + O(\varepsilon^{3/2}), \tag{35}$$

where w is the solution to (32) with w_0 replaced by u_1. Then

$$\left(\frac{s^\varepsilon - u_1}{\varepsilon}, F_\varepsilon u_1\right) \quad = \quad (w, F_\varepsilon u_1) + \left(F_\varepsilon \theta^i_\varepsilon \frac{\partial u_1}{\partial x_i}, u_1\right) + O(\varepsilon).$$

The first term on the right-hand side clearly converges to $\overline{\sigma}_f(u_1, w)$. The second term is given by

$$\int_\Omega \left[\int_V \theta^i\left(\frac{x}{\varepsilon}, \mu\right) \sigma_f\left(\frac{x}{\varepsilon}\right) \psi^+_\infty\left(\frac{x}{\varepsilon}, \mu\right) d\mu \int_V \psi^+_\infty\left(\frac{x}{\varepsilon}, \mu'\right) d\mu'\right] \frac{\partial u_1}{\partial x_i}(x) u_1(x) dx.$$

From the symmetry properties of Y given in Hypothesis 3.4, we easily deduce (see also Lemma 5.1 in section 5) that

$$\int_Y \int_V \theta^i(y, \mu) \sigma_f(y) \psi^+_\infty(y, \mu) d\mu \int_V \psi^+_\infty(y, \mu') d\mu' dy = 0.$$

Since u_1 is regular, a Taylor expansion of u_1 yields that $(F_\varepsilon \theta^i_\varepsilon \frac{\partial u_1}{\partial x_i}, u_1) = O(\varepsilon)$. Therefore, since $u_\varepsilon = u_1 + O(\varepsilon)$, the right-hand side of (34) is equal to $-\nu_1 \overline{\sigma}_f(u_1, w) + O(\varepsilon^{1/2})$. The left-hand side of (34) is equal to $\xi^\varepsilon_1 \overline{\sigma}_f + O(\varepsilon)$. The first-order corrector for the eigenvalue takes the form

$$\xi^\varepsilon_1 \; = \; -\nu_1(u_1, w) + O(\varepsilon^{1/2}).$$

At last we deduce from [20, Proposition 3, section 5, Chapter 21], or from elementary computations on the eigenvalues of a homogeneous diffusion problem in a cube, that the smallest eigenvalue of

$$\begin{array}{rcll} -\nabla D \nabla \Phi^\varepsilon & = & \omega^\varepsilon \overline{\sigma_f} \Phi^\varepsilon & \text{in } \Omega, \\ \Phi^\varepsilon + \varepsilon L \dfrac{\partial \Phi^\varepsilon}{\partial n} & = & 0 & \text{on } \partial\Omega, \end{array} \tag{36}$$

satisfies u_1 and Φ^ε being normalized in $L^2(\Omega)$,

$$\omega^\varepsilon_1 = \nu_1 - \varepsilon \nu_1(u_1, w) + O(\varepsilon^{3/2}). \tag{37}$$

This concludes the proof of Theorem 3.5.

4. A priori estimates and analysis of the source problem. This section presents some preliminary results on the source problem (27), which will prove useful in the study of its asymptotic behavior as $\varepsilon \to 0$. We give a proof for Lemma 3.8 and for the well-posedness of problem (27) as stated in Theorem 3.9. We will use the notation

$$\langle u \rangle = \int_V u(\mu) d\mu.$$

One of the interesting properties of the even parity flux is that it allows us to use a variational formulation. Introduce the bilinear form $a_\varepsilon(u, v)$

$$\begin{array}{rcl} a_\varepsilon(u, v) & = & \displaystyle\int_\Omega \int_V \frac{(\psi^+_\varepsilon)^2}{\Sigma^\varepsilon} \mu \cdot \nabla u \, \mu \cdot \nabla v \, d\mu \, dx + \frac{1}{\varepsilon} \int_{\partial\Omega} \int_V |\mu \cdot n| \, h_\varepsilon \, uv \, d\mu \, d\sigma \\ & + & \displaystyle\frac{1}{\varepsilon^2} \int_\Omega \int_V (Q_\varepsilon u) \, v \, d\mu \; dx, \end{array} \tag{38}$$

where the function h_ε is defined on $\partial\Omega \times V$ by $h_\varepsilon = \psi_\varepsilon \psi_\varepsilon^+$ on Γ_- and $h_\varepsilon(x,\mu) = h_\varepsilon(x,-\mu)$. According to the results of section 2, h_ε is uniformly positive. An integration by parts shows that (28) is equivalent to finding $w_\varepsilon \in \mathcal{V}$ such that

$$a_\varepsilon(w_\varepsilon, v) = (F_\varepsilon q, v) + \frac{1}{\varepsilon}\int_{\partial\Omega}\int_V |\mu\cdot n| h_\varepsilon\, g\, v\, d\mu\, d\sigma \qquad \forall v \in \mathcal{V}, \tag{39}$$

where $\mathcal{V}$ is the Hilbert space

$$\mathcal{V} = \{v \in W^2(\Omega\times V) \text{ s.t. } v \in L^2(\partial\Omega\times V, d\xi),\ v(x,\mu) = v(x,-\mu)\}. \tag{40}$$

The bilinear form a_ε is bicontinuous in $\mathcal{V}$. We deduce that a_ε is symmetric from the identity $\int_V (Q_\varepsilon u) v\, d\mu = \int_V u(Q_\varepsilon v)\, d\mu$. Now choosing $v = w_\varepsilon$ in (39), we obtain that

$$\begin{aligned} &\|\mu\cdot\nabla w_\varepsilon\|^2 + \frac{1}{\varepsilon}\|w_\varepsilon\|^2_{L^2(\partial\Omega\times V,d\xi)} + \frac{1}{\varepsilon^2}(Q_\varepsilon w_\varepsilon, w_\varepsilon) \\ \le\ & C a_\varepsilon(w_\varepsilon,w_\varepsilon) \le C\|q\|\,\|w_\varepsilon\| + \frac{C}{\varepsilon}\|g\|_{L^2(\partial\Omega\times V,d\xi)}\|w_\varepsilon\|_{L^2(\partial\Omega\times V,d\xi)}. \end{aligned} \tag{41}$$

A Poincaré-like inequality in transport theory (see [5, 8]) yields that

$$\|w_\varepsilon\| \le C\,(\|\mu\cdot\nabla w_\varepsilon\| + \|w_\varepsilon\|_{L^2(\partial\Omega\times V,d\xi)}), \tag{42}$$

where C is a constant independent of w_ε. Therefore, the coercivity of a_ε is easily deduced from the positiveness of the collision operator Q_ε that we prove now.

LEMMA 4.1. *Let $f \in L^\infty(V)$ be a positive function. Then the operator $\mathcal{Q}$ defined by*

$$\mathcal{Q}u(\mu) = f(\mu)u(\mu)\langle f\rangle - f(\mu)\langle f\,u\rangle$$

satisfies the property

$$(\mathcal{Q}u, u) \ge (\inf_V f)^2 \|u - \langle u\rangle\|^2_{L^2(V)},$$

where $(\cdot,\cdot)$ is the usual scalar product of $L^2(V)$.

Proof. Some computations yield

$$\begin{aligned} (\mathcal{Q}u,u) &= \int_V\int_V f(\mu)f(\mu')u(\mu)(u(\mu)-u(\mu'))d\mu d\mu' \\ &= \frac{1}{2}\int_V\int_V f(\mu)f(\mu')(u(\mu)-u(\mu'))^2 d\mu d\mu' \\ &\ge (\inf_V f)^2\frac{1}{2}\int_V\int_V (u(\mu)-u(\mu'))^2 d\mu d\mu' \ =\ (\inf_V f)^2\int_V (u(\mu)-\langle u\rangle)^2\, d\mu. \end{aligned}$$

This concludes the proof of the lemma. ∎

From this lemma and the Poincaré inequality (42), we obtain that

$$\begin{aligned} &\|\mu\cdot\nabla w_\varepsilon\| + \|w_\varepsilon\| + \frac{1}{\sqrt{\varepsilon}}\|w_\varepsilon\|_{L^2(\partial\Omega\times V,d\xi)} + \frac{1}{\varepsilon}\|w_\varepsilon - \int_V w_\varepsilon\| \\ \le\ & C\sqrt{a_\varepsilon(w_\varepsilon,w_\varepsilon)} \le C\left(\|q\| + \frac{1}{\sqrt{\varepsilon}}\|g\|_{L^2(\partial\Omega\times V,d\xi)}\right). \end{aligned} \tag{43}$$

This concludes the proof of Lemma 3.8. Moreover, the existence and uniqueness of a solution to (28) is a straight consequence of the Lax–Milgram theory. This also asserts the well-posedness and boundedness of S_ε in $\mathcal{L}(L^2(\Omega\times V))$, and the first part of Theorem 3.9 is complete. We also need an analogous result for nonhomogeneous boundary conditions. We have the maximum principle as follows.

PROPOSITION 4.2. *Let $g\in L^\infty(\Gamma_-)$. There exists a unique solution to* (28) *with $q=0$ in $L^\infty(\Omega\times V)$. Furthermore, we have that $\|w_\varepsilon\|_{L^\infty(\Omega\times V)}\le\|g\|_{L^\infty(\Gamma_-)}$.*

Proof. We use the maximum principle stated for first-order transport equations in [20, Chapter 21] and the equivalence presented in Appendix A. Let $\alpha>0$ and the sequence of problems

$$\begin{aligned} -\mu\cdot\nabla\frac{(\psi_\varepsilon^+)^2}{\Sigma^\varepsilon}\mu\cdot\nabla w_\alpha^\varepsilon+\frac{1}{\varepsilon^2}Q_\varepsilon w_\alpha^\varepsilon+\alpha w_\alpha^\varepsilon &= 0 \quad \text{in } \Omega\times V,\\ w_\alpha^\varepsilon-\frac{\varepsilon\psi_\varepsilon^+}{\psi_\varepsilon\Sigma^\varepsilon}\mu\cdot\nabla w_\alpha^\varepsilon &= g \quad \text{on } \Gamma_-. \end{aligned}$$

We denote $\check f(\mu)=f(-\mu)$ for every function f. We deduce from the results recalled in Appendix A that

$$w_\alpha^\varepsilon=\frac{\psi_\varepsilon\psi_\alpha^\varepsilon+\check\psi_\varepsilon\check\psi_\alpha^\varepsilon}{\psi_\varepsilon+\check\psi_\varepsilon}.$$

Here, ψ_ε is the positive solution of (19) and ψ_α^ε is the solution to

$$\begin{aligned} \frac{1}{\varepsilon}\mu\cdot\nabla\psi_\alpha^\varepsilon+\frac{\Sigma_\varepsilon^\infty}{\varepsilon^2}\left(\frac{1}{\psi_\varepsilon}\psi_\alpha^\varepsilon\int_V\psi_\varepsilon-\frac{1}{\psi_\varepsilon}\int_V\psi_\alpha^\varepsilon\psi_\varepsilon\right)+\alpha\psi_\alpha^\varepsilon &= 0 \quad \text{in } \Omega\times V,\\ \psi_\alpha^\varepsilon &= g \quad \text{on } \Gamma_-. \end{aligned}$$

We deduce from [20, Proposition 7, Chapter 21, section 2] that $\|\psi_\alpha^\varepsilon\|_{L^\infty}\le\|g\|_{L^\infty}$ independently of α. Therefore, $\|w_\alpha^\varepsilon\|_{L^\infty}\le\|g\|_{L^\infty}$ independently of α. Thus there exists a subsequence of w_α^ε that converges to w_ε in $L^\infty(\Omega\times V)$ weak$*$ as $\alpha\to0$. Using standard techniques (see Bardos [10] and Appendix A), we verify that w_ε is a solution of (28) and satisfies $\|w_\varepsilon\|_{L^\infty(\Omega\times V)}\le\|g\|_{L^\infty(\Gamma_-)}$. We know from Lemma 3.8 that

$$\|w_\varepsilon\|\le\frac{C}{\sqrt{\varepsilon}}\|g\|_{L^2(\Gamma_-,d\xi)}.$$

Therefore, the solution to (28) in $L^\infty(\Omega\times V)$ is unique. ∎

Before addressing the asymptotic convergence of the solutions to (27), we need one more result on source problems in infinite media. Let us introduce the factored flux φ^+ defined by $\psi^+=\psi_\infty^+\varphi^+$. Then we easily obtain the following corollary for Theorem 2.5.

COROLLARY 4.3. *Assume that the hypotheses of Theorem* 2.5 *are satisfied. Then problem*

$$\begin{aligned} &-\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\varphi^+ + Q\varphi^+ = S \quad \text{in } Y\times V,\\ &y\mapsto\varphi^+(y,\mu) \text{ is } Y\text{-periodic} \end{aligned} \tag{44}$$

admits a unique zero mean solution if and only if

$$\int_Y\int_V S(y,\mu)dy\,d\mu = 0.$$

The same regularity results as in Theorem 2.5 *hold true.*

Since ψ_∞^+ is periodic, we deduce from this corollary that (12) admits a unique zero mean solution. Then the diffusion coefficients are uniquely defined by (11) and do not depend on the mean over $Y \times V$ of the functions θ^i. The following lemma asserts the positive definiteness of the diffusion tensor D and consequently the well-posedness of the diffusion problem (10).

LEMMA 4.4. *The homogeneous tensor D defined by* (11) *is positive definite.*

Proof. Let us multiply (12) by a Y-periodic smooth test function. After integration by parts, we obtain

$$\begin{aligned}&\int_Y\int_V \frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\theta^i\mu\cdot\nabla_y v\,d\mu dy + (Q\theta^i,v) - \int_{\partial Y}\int_V \frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\theta^i(\mu\cdot n)v\,d\mu d\sigma\\ =\ & -\int_Y\int_V \mu_i\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y v\,d\mu dy + \int_{\partial Y}\int_V \mu_i\frac{(\psi_\infty^+)^2}{\Sigma}v(\mu\cdot n)\,d\mu d\sigma.\end{aligned}$$

The boundary terms in this equation cancel out since $\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\theta^i v$ and $\mu_i\frac{(\psi_\infty^+)^2}{\Sigma}v$ are Y-periodic, whereas the sign of $(\mu\cdot n)$ is reversed from one side of Y to the opposite one. Thus we have

$$\int_Y\int_V \frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_y\theta^i+\mu_i)\mu\cdot\nabla_y v\,d\mu dy + (Q\theta^i,v) = 0$$

for any periodic test function v and in particular for the functions θ^j. We recall that the coefficients D_{ij} are defined by (11). For each vector $\xi\in\mathbb{R}^n$, of components ξ_i, we deduce that (with the convention of summation over the repeated indexes)

$$\begin{aligned}D_{ij}\xi_i\xi_j &= \int_Y\int_V \frac{(\psi_\infty^+)^2}{\Sigma}\mu_j\xi_j(\mu\cdot\nabla_y\theta^i+\mu_i)\xi_i\,d\mu dy\\ &= \int_Y\int_V \frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_y\theta^j+\mu_j)\xi_j(\mu\cdot\nabla_y\theta^i+\mu_i)\xi_i\,d\mu dy\\ &\quad -\int_Y\int_V \frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\theta^j\xi_j(\mu\cdot\nabla_y\theta^i+\mu_i)\xi_i\,d\mu dy\\ &= \int_Y\int_V \frac{(\psi_\infty^+)^2}{\Sigma}\left\{\left(\sum_{i=1}^n(\mu\cdot\nabla_y\theta^i+\mu_i)\xi_i\right)^2 + \left(Q(\sum_{i=1}^n\xi_i\theta^i),\sum_{i=1}^n\xi_i\theta^i\right)\right\}d\mu dy.\end{aligned}$$

We deduce from Lemma 4.1 that this expression is nonnegative. Therefore, D is positive. Assume now that it is not definite. Then there exists a vector $\xi\neq 0$ such that $(\mu\cdot\nabla_y\theta^i+\mu_i)\xi_i = 0$ almost everywhere (a.e.) $(y,\mu)\in Y\times V$. Integrate this equality over Y for $\mu\in V$ given. We deduce from the Y-periodicity of θ^i that $\int_Y \mu_i\xi_i = \mu_i\xi_i = 0$ a.e. $\mu\in V$. This yields $\xi = 0$ and a contradiction. Thus the tensor D is positive definite. ∎

5. Analysis of the source problem. This section is devoted to the proof of Theorems 3.9 and 3.11. It is based on the classical method of two-scale asymptotic expansions. Notice that the two-scale convergence introduced in [2] represents a natural framework to prove the convergence stated in Theorem 3.9 [5]. It allows for very mild regularity assumptions on the physical data; however, it does not enable us to obtain the rates of convergence stated in section 3.

5.1. Asymptotic convergence of the source problem. The pointwise convergence of the operator S_ε is stated in Theorem 3.9. We now give a proof of this result.

Proof. It is based on a two-scale analysis of the neutron density. Let us define the ansatz

$$w_\varepsilon(x,\mu) = w_0\left(x,\frac{x}{\varepsilon},\mu\right) + \varepsilon w_1\left(x,\frac{x}{\varepsilon},\mu\right) + \varepsilon^2 w_2\left(x,\frac{x}{\varepsilon},\mu\right) + \zeta^\varepsilon(x,\mu), \tag{45}$$

where the functions $y \mapsto w_k(x,y,\mu)$ are Y-periodic for $0 \le k \le 2$. We derive the equations that $w_k(x,y,\mu)$ must verify to justify this asymptotic expansion. This provides us with an explicit choice for $w_k(x,y,\mu)$. Next, we prove that ζ^ε defined by (45) is of order $O(\varepsilon)$ in $L^2(\Omega\times V)$. This is done first for a source term $q(x,\mu) = \tilde q(x)h(\mu)$ and then extended to the case $q \in L^2(\Omega\times V)$ by density.

(i) We remark that the differentiation operator is now given by $\mu\nabla = \mu\nabla_x + \frac{1}{\varepsilon}\mu\nabla_y$. Inserting (45) into (27) and neglecting ζ_ε, we obtain

$$\begin{aligned} &- \left(\mu\cdot\nabla_x + \frac{1}{\varepsilon}\mu\cdot\nabla_y\right)\frac{(\psi_\infty^+)^2}{\Sigma}\left(\mu\cdot\nabla_x + \frac{1}{\varepsilon}\mu\cdot\nabla_y\right)(w_0+\varepsilon w_1+\varepsilon^2 w_2)\\ &+ \frac{1}{\varepsilon^2}Q(w_0+\varepsilon w_1+\varepsilon^2 w_2) = \sigma_f\psi_\infty^+\int_V \psi_\infty^+(x,\mu')q(x,\mu')d\mu'. \end{aligned} \tag{46}$$

The term of order -2 in the expansion in powers of ε yields

$$-\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y w_0 + Qw_0 = 0. \tag{47}$$

Following the same development as in section 3 we obtain that $w_0\psi_\infty^+$ is a solution of (6) for any given x. Then by virtue of Theorem 2.3, we have $w_0 = w_0(x)$. From the boundary conditions for w_ε we deduce that w_0 must vanish on $\partial\Omega$.

Taking into account the form of w_0, we obtain for the terms of order ε^{-1} that

$$-\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y w_1 + Qw_1 = \mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_x w_0. \tag{48}$$

This equation was posed on $Y\times V$ for every given $x\in\Omega$ and we deduce from Corollary 4.3 that $w_1(y,\mu) = \theta^i(y,\mu)\frac{\partial w_0}{\partial x_i}(x) + w_{10}(x)$, where θ^i is defined by (12) and $w_{10}(x)$ is still undetermined. We choose here $w_{10}(x) = 0$.

Consider now the zeroth-order equation. We have

$$\begin{aligned} &-\frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_x)^2 w_0 - \left(\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_x + \mu\cdot\nabla_x\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\right)w_1\\ &-\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y w_2 + Qw_2 = \sigma_f\psi_\infty^+\int_V \psi_\infty^+(y,\mu')q(x,\mu')d\mu'. \end{aligned} \tag{49}$$

Following Corollary 4.3, this equation admits a solution when the source term is of zero mean. It implies that w_0 satisfies the equation

$$\begin{aligned} &\int_V\int_Y\left[-\frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_x)^2 w_0 - \left(\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_x + \mu\cdot\nabla_x\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\right)w_1\right]d\mu dy\\ =\ &\int_V\int_Y\left(\sigma_f(y)\psi_\infty^+(y,\mu)\int_V\psi_\infty^+(y,\mu')q(x,\mu')d\mu'\right)d\mu dy. \end{aligned}$$

Replacing w_1 by its expression in terms of w_0, we obtain that w_0 is a solution to (30). Since D is positive definite according to Lemma 4.1, we deduce that w_0 is uniquely defined in $H_0^1(\Omega)$. The expression of w_1 is also known. It remains to define w_2. Equation (49) can be recast as

$$-\mu\cdot\nabla_y \frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y w_2 + Qw_2 = \left(\sigma_f\psi_\infty^+\int_V \psi_\infty^+ q \,-\, \overline{q}\right) + (h_{ij}(y,\mu) - D_{ij})\,\frac{\partial^2 w_0}{\partial x_j \partial x_i}$$

owing to the expression of w_1 and (30), where

$$h_{ij} = \frac{(\psi_\infty^+)^2}{\Sigma}\mu_j(\mu_i + \mu\cdot\nabla_y\theta^i) + \mu_j\,\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\theta^i.$$

We define the functions w_{2a} and w_{2ij}, $1\le i,j\le n$, recalling that $q(x,\mu)=\tilde{q}(x)h(\mu)$, by

$$-\mu\cdot\nabla_y \frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y w_{2a} + Qw_{2a} = \sigma_f\psi_\infty^+\int_V \psi_\infty^+ h\,d\mu' \,-\, \int_Y\int_V\left(\sigma_f\psi_\infty^+\int_V\psi_\infty^+ h\,d\mu'\right)d\mu dy$$

$$-\mu\cdot\nabla_y \frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y w_{2ij} + Qw_{2ij} = h_{ij} - D_{ij}.$$

We easily check that the source terms have zero mean. Consequently the functions w_{2a} and w_{2ij} are defined up to an additive constant and are smooth according to Corollary 4.3. By linearity of transport, we obtain that w_2 is equal to

$$w_2(x,y,\mu) = w_{2a}(y,\mu)\tilde{q}(x) + w_{2ij}(y,\mu)\frac{\partial^2 w_0}{\partial x_j\partial x_i}(x) + w_{20}(x),$$

where w_{20} is undetermined. We choose here $w_{20}=0$.

(ii) It remains to derive an equation for ζ^ε and prove that this error term is small. Inserting (45) in (27), we obtain from the explicit expressions of w_0, w_1, and w_2 that

$$\begin{aligned} -\mu\cdot\nabla\frac{(\psi_\varepsilon^+)^2}{\Sigma^\varepsilon}\mu\cdot\nabla\zeta^\varepsilon + \frac{1}{\varepsilon^2}Q_\varepsilon\zeta^\varepsilon &= \varepsilon\zeta_1^\varepsilon + \varepsilon^2\zeta_2^\varepsilon \quad \text{in } \Omega\times V,\\ \zeta^\varepsilon - \frac{\varepsilon\psi_\varepsilon^+}{\psi_\varepsilon\Sigma^\varepsilon}\mu\cdot\nabla\zeta^\varepsilon &= \varepsilon\zeta_3^\varepsilon + \varepsilon^2\zeta_4^\varepsilon + \varepsilon^3\zeta_5^\varepsilon \qquad \text{on } \Gamma_-, \end{aligned} \tag{50}$$

where $\zeta_i^\varepsilon(x,\mu) = \zeta_i(x,\frac{x}{\varepsilon},\mu)$ and

$$\begin{aligned} \zeta_1 &= -\frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_x)^2 w_1 - \mu\cdot\nabla_x\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y w_2 - \mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_x w_2,\\ \zeta_2 &= -\frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_x)^2 w_2, \qquad \zeta_3 = -w_1 + \frac{\psi_\infty^+}{\psi_\infty\Sigma}(\mu\cdot\nabla_x w_0 + \mu\cdot\nabla_y w_1),\\ \zeta_4 &= -w_2 + \frac{\psi_\infty^+}{\psi_\infty\Sigma}(\mu\cdot\nabla_x w_1 + \mu\cdot\nabla_y w_2), \qquad \zeta_5 = \frac{\psi_\infty^+}{\psi_\infty\Sigma}\mu\cdot\nabla_x w_2. \end{aligned} \tag{51}$$

Assume first that $\tilde{q}$ is of class $C^{2,\alpha}(\Omega)$. Since D is positive definite, we deduce from [24] that w_0 is of class $C^{4,\alpha}(\Omega)$. The terms w_1 and w_2 are the sums of products of functions depending only on x and of functions depending only on (y,μ). The part depending only on x in the expression of w_1: $\frac{\partial w_0}{\partial x_i}$ is of class $C^{3,\alpha}(\Omega)$, and the one in the expression of w_2: $\tilde{q}$ and $\frac{\partial^2 w_0}{\partial x_j x_i}$ is of class $C^{2,\alpha}(\Omega)$. The parts depending on

(y,μ) in terms θ^i, w_{2a}, and w_{2ij} are regular according to Corollary 4.3. Therefore, the terms ζ_i^ε are of class $C^{0,\alpha}(\Omega\times V)$. From the variational formulation of (50) (see Lemma 3.8 and Proposition 4.2), we deduce that $\|\zeta^\varepsilon\|\le C\varepsilon$, where C is independent of ε. Therefore, we have proven that $w_\varepsilon - w = O(\varepsilon)$, provided q is of the form $q(x,\mu)=\sum_{m=1}^M q_m(x)h_m(\mu)$, where all q_m are of class $C^{2,\alpha}(\Omega)$.

The proof of the convergence in the general case follows from two density arguments. Let us first assume that $\tilde q$ belongs to $L^2(\Omega)$. Consider a sequence $\tilde q_i$ of functions of class $C^{2,\alpha}(\Omega)$ converging to $\tilde q$ strongly in $L^2(\Omega)$. Then for any $\eta>0$ and i large enough we have $\|\tilde q_i-\tilde q\|\le C\eta$. Let w_i^ε be the solution of (27). From the linearity of the transport equation and from its variational formulation, we deduce that $\|w_i^\varepsilon - w_\varepsilon\|\le C\eta$ independently of η and ε. On the other hand we have proven that $w_i^\varepsilon\to w_i$, where w_i is defined as the solution of the diffusion solution with a source term equal to $\tilde q_i$ instead of $\tilde q$. We easily check that $\|w_i-w_0\|\le C\eta$, where w_0 is the solution of (30) with source term $\tilde q$, and deduce the convergence of w_ε to w_0 as $\varepsilon\to 0$.

The same argument is used for the general case $q\in L^2(\Omega\times V)$. Every function $q\in L^2(\Omega\times V)$ admits a spectral decomposition in the canonical Schauder basis of $L^2(\Omega\times V)$

$$q(x,\mu) \;=\; \sum_{m=1}^\infty\sum_{p=1}^\infty \alpha_{mp}\tilde q_m(x)h_p(\mu),$$

where the functions $\tilde q_m$ are vectors of an orthogonal basis in $L^2(\Omega)$ and h_p are vectors of an orthogonal basis in $L^2(V)$. We have that $\sum_{m=1}^\infty\sum_{p=1}^\infty \alpha_{mp}^2<\infty$. Thus the sequence

$$q_{MP}=\sum_{m=1}^M\sum_{p=1}^P \alpha_{mp}\tilde q_m(x)h_p(\mu)$$

converges strongly to q in $L^2(\Omega\times V)$. We deduce that $\|w_{MP}^\varepsilon - w_{MP}\|$ converges to 0 independently of ε and that w_{MP} converges strongly to w (using obvious notation) as $M,P\to\infty$. On the other hand for fixed M,P large enough, the linearity of the transport and diffusion equations yields the strong convergence in $L^2(\Omega\times V)$ of w_{MP}^ε to w_{MP} as $\varepsilon\to 0$. ∎

5.2. First-order corrector for the source problem. This subsection is devoted to the derivation of the first-order corrector of the source problem (27) as stated in Theorem 3.11.

First we introduce some notation. To simplify we assume here that the spatial dimension is $d=3$. Let O be the center of Y. We denote by $\mathcal{P}_p$ the plane (O,x_m,x_n), $m,n\in\{i,j,k\}$ spanned by the vectors e_m, e_n and such that $O\in\mathcal{P}_p$. The index $p\in\{i,j,k\}$ is such that $p\ne m$ and $p\ne n$.

We say that two pairs (y,μ) and (y',μ') of $Y\times V$ are symmetric with respect to $\mathcal{P}_p$ if they satisfy

$$d(y,\mathcal{P}_p)=d(y',\mathcal{P}_p),\quad (y'-y)\;\|\;e_p,\quad \mu'=\mu-2(\mu\cdot e_p)e_p.$$

For a pair (y,μ) and (y',μ') of symmetric points we say that a function ψ is symmetric with respect to $\mathcal{P}_p$ if $\psi(y',\mu')=\psi(y,\mu)$, and that it is skew symmetric if $\psi(y',\mu')=-\psi(y,\mu)$. We now state Lemma 5.1.

LEMMA 5.1. *Assume that the cross sections Σ and Σ_s are symmetric in Y with respect to the planes $\mathcal{P}_p$, $p = i, j, k$. Let (y, μ) and (y', μ') be symmetric points with respect to $\mathcal{P}_p$ for $p \in \{i, j, k\}$.*

(i) *Let f be a source term satisfying $\check{f} = f$ and $f(y, \mu) = \pm f(y', \mu')$ a.e. $(y, \mu) \in Y \times V$. Then the solution of*

$$\begin{aligned} &-\mu\cdot\nabla_y \frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\varphi + Q\varphi = f \quad \text{in } Y \times V,\\ &y \mapsto \varphi(y,\mu) \text{ is } Y\text{-periodic} \end{aligned}$$

satisfies the following relation of symmetry $\varphi(y, \mu) = \pm\varphi(y', \mu')$.

(ii) *Let f be a function satisfying that $f(y, \mu) = \pm f(y', \mu')$ a.e. $(y, \mu) \in Y \times V$. Then we have*

$$\mu'\cdot\nabla_{y'} f(y', \mu') = \mu\cdot\nabla_y f(y, \mu).$$

Proof. (i) Define $h(y', \mu') = \varphi(y, \mu)$. We check that $\mu'\cdot\nabla_{y'} h(y', \mu') = \mu\cdot\nabla_y\varphi(y, \mu)$. Since Y is symmetric, the solution ψ_∞^+ and the cross sections are also symmetric. Then

$$-\mu'\cdot\nabla_{y'} \frac{(\psi_\infty^+)^2}{\Sigma}(y', \mu')\mu'\cdot\nabla_{y'} h(y', \mu') = \mu\cdot\nabla_y \frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\varphi$$

and

$$(Qh)(y', \mu') = (Q\varphi)(y, \mu).$$

Therefore, h is solution of the equation

$$-\mu'\cdot\nabla_{y'} \frac{(\psi_\infty^+)^2}{\Sigma}(y', \mu')\mu'\cdot\nabla_{y'} h(y', \mu') + (Qh)(y', \mu') = \pm f(y', \mu').$$

We deduce from the uniqueness of the solution for this equation that $h(y', \mu') = \pm\varphi(y, \mu)$. It concludes the first part of the proof.

(ii) Consider the plane of symmetry $\mathcal{P}_k$. We have $\mu\cdot\nabla_y f = \mu_i \frac{\partial f}{\partial y_i}$. If $i = k$, then $\frac{\partial f}{\partial y_i}(y', \mu') = -\frac{\partial f}{\partial y_i}(y, \mu)$ and $(\mu_i)' = \mu_i' = -\mu_i$. If $i \neq k$, then $\frac{\partial f}{\partial y_i}(y', \mu') = \frac{\partial f}{\partial y_i}(y, \mu)$ and $(\mu_i)' = \mu_i$. In any case we have $(\mu_i \frac{\partial f}{\partial y_i})(y', \mu') = (\mu_i \frac{\partial f}{\partial y_i})(y, \mu)$, and the proof is complete. ∎

We are now in a position to prove Theorem 3.11.

Proof of Theorem 3.11. The first part of the proof is very similar to that of Theorem 3.9. We assume the following ansatz on w_ε:

$$w_\varepsilon(x, \mu) = w_0\left(x, \frac{x}{\varepsilon}, \mu\right) + \varepsilon w_1\left(x, \frac{x}{\varepsilon}, \mu\right) + \varepsilon^2 w_2\left(x, \frac{x}{\varepsilon}, \mu\right) + \varepsilon^3 w_3\left(x, \frac{x}{\varepsilon}, \mu\right) + \zeta^\varepsilon(x, \mu), \tag{52}$$

where the functions $y \mapsto w_i(x, y, \mu)$ are Y-periodic for $0 \leq i \leq 3$. Our objective is to derive some conditions on the terms w_i such that ζ^ε be of order $O(\varepsilon^{3/2})$. The main difference with the proof of Theorem 3.9 is that the asymptotic expansion does not provide suitable boundary conditions for the functions w_i. This difficulty will be overcome by the analysis of a boundary layer problem, which allows us to find boundary conditions for the terms w_i such that the error ζ^ε be of order ε in the vicinity of the boundary but of order $\varepsilon^{3/2}$ globally in $L^2(\Omega \times V)$.

(i) Plugging (52) into (27) and neglecting ζ^ε, we obtain

$$
\begin{aligned}
&-\left(\mu\cdot\nabla_x+\frac{1}{\varepsilon}\mu\cdot\nabla_y\right)\frac{(\psi_\infty^+)^2}{\Sigma}\left(\mu\cdot\nabla_x+\frac{1}{\varepsilon}\mu\cdot\nabla_y\right)(w_0+\varepsilon w_1+\varepsilon^2w_2+\varepsilon^3w_3)\\
&+\frac{1}{\varepsilon^2}Q_\varepsilon(w_0+\varepsilon w_1+\varepsilon^2w_2+\varepsilon^3w_3)=\sigma_f\psi_\infty^+\int_V\psi_\infty^+(y,\mu')q(x)d\mu'.
\end{aligned}
\tag{53}
$$

From the terms of order ε^{-2}, we have $w_0=w_0(x)$, and from the terms of order ε^{-1}, $w_1=\theta^i\frac{\partial w_0}{\partial x_i}+w_{10}$. Here we cannot choose $w_{10}=0$ since it is of order ε. The term of order ε^0 is given by

$$
\begin{aligned}
&-\frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_x)^2w_0-\left(\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_x+\mu\cdot\nabla_x\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\right)w_1\\
&-\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_yw_2+Qw_2=\sigma_f\psi_\infty^+\int_V\psi_\infty^+(y,\mu')q(x)d\mu'.
\end{aligned}
$$

This equation admits a solution when (31) is satisfied. We recast the equation for w_2 as follows:

$$
\begin{aligned}
&-\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_yw_2+Qw_2\\
=\;&\left(\sigma_f\psi_\infty^+\int_V\psi_\infty^+q-\overline{q}\right)+(h_{ij}(y,\mu)-D_{ij})\frac{\partial^2w_0}{\partial x_j\partial x_i}+\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_xw_{10},
\end{aligned}
$$

where $h_{ij}=\frac{(\psi_\infty^+)^2}{\Sigma}\mu_j(\mu_i+\mu\cdot\nabla_y\theta^i)+\mu_j\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\theta^i$. Since $q=q(x)$, we have

$$
\begin{aligned}
&\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_yw_{2a}+Qw_{2a}=\sigma_f\psi_\infty^+\int_V\psi_\infty^+\,d\mu'-\int_Y\int_V\left(\sigma_f\psi_\infty^+\int_V\psi_\infty^+\,d\mu'\right)d\mu dy\\
&-\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_yw_{2ij}+Qw_{2ij}=h_{ij}-D_{ij}.
\end{aligned}
$$

In these equations the source term has zero mean. Thus w_2 can be written as

$$
w_2(x,y,\mu)=w_{2a}(y,\mu)q(x)+w_{2ij}(y,\mu)\frac{\partial^2w_0}{\partial x_j\partial x_i}(x)+\theta^i\frac{\partial w_{10}}{\partial x_i}+w_{20}(x).
$$

Because we are not interested in the terms of order ε^2 we can choose $w_{20}=0$. Let us go one step further in the expansion in powers of ε. The term of order ε yields

$$
\begin{aligned}
&-\frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_x)^2w_1-\left(\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_x+\mu\cdot\nabla_x\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\right)w_2\\
&-\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_yw_3+Qw_3=0.
\end{aligned}
$$

This equation admits a solution if and only if the source term

$$
\frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_x)^2w_1+\left(\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_x+\mu\cdot\nabla_x\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y\right)w_2
$$

has zero mean. Replacing the functions w_i by their expressions in terms of w_0, w_{10}, and q, and denoting for simplicity by $\partial_i=\frac{\partial}{\partial x_i}$, we rewrite this compatibility condition

as

$$\left(\int_V\int_Y \frac{(\psi_\infty^+)^2}{\Sigma}\left[(\mu_k\mu_j\theta^i)+\mu\cdot\nabla_y(\mu_k w_{2ij})\right]d\mu dy\right)\partial^3_{kji}w_0$$
$$+\left(\int_V\int_Y \frac{(\psi_\infty^+)^2}{\Sigma}\mu_i\mu\cdot\nabla_y w_{2a}d\mu dy\right)\partial_i q$$
$$+\left(\int_V\int_Y \frac{(\psi_\infty^+)^2}{\Sigma}\left[(\mu\cdot\nabla_x)^2 w_{10}+\mu\cdot\nabla_y\theta^i\mu\cdot\nabla_x\partial_i w_{10}\right]d\mu dy\right)=0.$$

The last term of the left side is given by

$$\left(\int_V\int_Y \frac{(\psi_\infty^+)^2}{\Sigma}\left[(\mu\cdot\nabla_x)^2 w_{10}+\mu\cdot\nabla_y\theta^i\mu\cdot\nabla_x\partial_i w_{10}\right]d\mu dy\right)=\nabla D\nabla w_{10}.$$

Using the hypotheses of symmetry on Y, we prove now that the other terms in this expression vanish. We use results stated in Lemma 5.1. First, we easily obtain that

$$\int_V\int_Y \frac{(\psi_\infty^+)^2}{\Sigma}(\mu_k\mu_j\theta^i)d\mu dy=0.$$

Indeed θ^i and μ_j are skew symmetric with respect to the plane $\mathcal{P}_i$ and symmetric with respect to the other planes $\mathcal{P}_k$ for $k\neq i$. The product of three skew symmetric functions being skew symmetric at least with respect to one hyperplane, we deduce from the symmetries of $\frac{(\psi_\infty^+)^2}{\Sigma}$ that the integral vanishes. Consider now the term

$$\int_V\int_Y \frac{(\psi_\infty^+)^2}{\Sigma}\mu_k\mu\cdot\nabla_y(w_{2ij})d\mu dy.$$

We easily check by symmetry that $D_{ij}=0$ if $i\neq j$. Thus the source term in the equation for w_{2ij} equals h_{ij}. Since θ^i is skew symmetric with respect to $\mathcal{P}_i$,

$$\left(\mu_i+\mu\cdot\nabla_y\theta^i+\mu\cdot\nabla\left(\frac{(\psi_\infty^+)^2}{\Sigma}\theta^i\right)\right)$$

is also skew symmetric. Then w_{2ij} and therefore $\mu\cdot\nabla_y w_{2ij}$ are skew symmetric with respect to $\mathcal{P}_i$. Here again, for all values of k, the integral vanishes. The last term is

$$\int_V\int_Y \frac{(\psi_\infty^+)^2}{\Sigma}\mu_i\mu\cdot\nabla_y w_{2a}d\mu dy.$$

The source terms in the equation for w_{2a} and then w_{2a} and $\mu\cdot\nabla_y w_{2a}$ are symmetric. Since μ_i is skew symmetric with respect to $\mathcal{P}_i$, the corresponding integral vanishes. It follows that w_{10} satisfies (32) on $\Omega\times V$.

We do not give here the equation satisfied by w_3 explicitly. However, w_3, like w_2, is the sum of products of functions of (y,μ) and of functions of x. The terms depending on (y,μ) are regular by hypothesis, and the terms depending on x depend on fifth-order derivatives of w_0, first-order derivatives of q, and second-order derivatives of w_{10}. By hypothesis for q, w_0 and w_{10} are sufficiently regular. This yields that w_3 is well defined and has continuous second-order derivatives. Again w_3 is defined up to an additive function $w_{30}(x)$. We choose $w_{30}=0$.

(ii) It remains to define a constant L such that the term ζ^ε are small. Assume that L is given and insert the expressions of the functions w_i given by (52) into (27). We obtain

$$\begin{aligned} -\mu\cdot\nabla\frac{(\psi_\varepsilon^+)^2}{\Sigma^\varepsilon}\mu\cdot\nabla\zeta^\varepsilon+\frac{1}{\varepsilon^2}Q_\varepsilon\zeta^\varepsilon &= \varepsilon^2\zeta_1^\varepsilon+\varepsilon^3\zeta_2^\varepsilon \qquad \text{in } \Omega\times V,\\ \zeta^\varepsilon-\frac{\varepsilon\psi_\varepsilon^+}{\psi_\varepsilon\Sigma^\varepsilon}\mu\cdot\nabla\zeta^\varepsilon &= \varepsilon\zeta_3^\varepsilon+\varepsilon^2\zeta_4^\varepsilon+\varepsilon^3\zeta_5^\varepsilon+\varepsilon^4\zeta_6^\varepsilon \qquad \text{on } \Gamma_-, \end{aligned} \tag{54}$$

where $\zeta_i^\varepsilon(x,\mu)=\zeta_i(x,\frac{x}{\varepsilon},\mu)$ and

$$\begin{aligned} \zeta_1 &= -\frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_x)^2w_2-\mu\cdot\nabla_x\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y w_3-\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_x w_3,\\ \zeta_2 &= -\frac{(\psi_\infty^+)^2}{\Sigma}(\mu\cdot\nabla_x)^2w_3, \qquad \zeta_3 = -w_1+\frac{\psi_\infty^+}{\psi_\infty\Sigma}(\mu\cdot\nabla_x w_0+\mu\cdot\nabla_y w_1),\\ \zeta_4 &= -w_2+\frac{\psi_\infty^+}{\psi_\infty\Sigma}(\mu\cdot\nabla_x w_1+\mu\cdot\nabla_y w_2),\\ \zeta_5 &= -w_3+\frac{\psi_\infty^+}{\psi_\infty\Sigma}(\mu\cdot\nabla_x w_2+\mu\cdot\nabla_y w_3), \qquad \zeta_6 = \frac{\psi_\infty^+}{\psi_\infty\Sigma}\mu\cdot\nabla_x w_3. \end{aligned} \tag{55}$$

Each term ζ_i gives rise to contributions of order ε^2 except ζ_3. We would like to derive some boundary conditions on w_{10}, which would enable us to cancel out this first-order term. This cannot be done in general because ζ_3 depends on the variables x, y, and μ, whereas w_{10} depends only on x. Replacing w_1 by its expression in terms of w_0 and w_{10}, we find that

$$\zeta_3(x,y,\mu)=\kappa_i(y,\mu)\frac{\partial w_0}{\partial x_i}(x)-w_{10}(x),$$

where $\kappa_i(y,\mu)=(\frac{\psi_\infty^+}{\psi_\infty\Sigma}(\mu_i+\mu\cdot\nabla_y\theta^i)-\theta^i)(y,\mu)$. Let us define the first-order term b^ε as a solution of

$$\begin{aligned} A_\varepsilon b^\varepsilon &= 0 \qquad \text{in } \Omega\times V,\\ b^\varepsilon-\frac{\varepsilon\psi_\varepsilon^+}{\psi_\varepsilon\Sigma^\varepsilon}\mu\cdot\nabla b^\varepsilon &= \zeta_3^\varepsilon \qquad \text{on } \Gamma_-. \end{aligned} \tag{56}$$

From the linearity of the transport equations, the function b^ε is the sum of $2d$ terms having vanishing boundary conditions on each side of Ω but one. For all $x\in\mathbb{R}^d$, we introduce the notation $x=(x_1,x')$, where x_1 is the first coordinate of x and x' the last $(d-1)$th ones. By symmetry we consider only the side $x_1=0$. Denote by b_1^ε the function satisfying the same equation as b^ε on $\Omega\times V$, with the same condition on the boundary where $x_1=0$ and vanishing boundary conditions on the other sides of Ω. For conciseness, we do not write the equation satisfied by b_1^ε. Since $w_0=0$ on $\partial\Omega$, we obtain for $x=(0,x')$ the relation

$$\zeta_3^\varepsilon(x,\mu)=\kappa_1\left(\frac{x}{\varepsilon},\mu\right)\frac{\partial w_0}{\partial x_1}(x)-w_{10}(x).$$

We are interested in the asymptotic behavior of b_1^ε. Let ε go to 0 and consider a point $(0,x')$ on the side $x_1=0$. We perform a stretching around the point $(0,x')$ in

order to obtain an equation for $b_1^\varepsilon(\varepsilon x,\mu)$. In the limit $\varepsilon=0$ we obtain formally the following equation for $b_\infty(y,\mu)$, where x' is a parameter:

$$\begin{aligned} -\mu\cdot\nabla_y\frac{(\psi_\infty^+)^2}{\Sigma}\mu\cdot\nabla_y b_\infty + Qb_\infty &= 0 \qquad \text{in } \mathbb{R}^+\times\mathbb{R}^{d-1}\times V,\\ b_\infty - \frac{\psi_\infty^+}{\psi_\infty\Sigma}\mu\cdot\nabla_y b_\infty &= \kappa_1(y,\mu)\left[\frac{\partial w_0}{\partial x_1}(0,x')\right] - [w_{10}(0,x')] \qquad \text{on } \Gamma_-. \end{aligned} \tag{57}$$

This problem is similar to the Milne problem presented, for instance, in [14, 20, 33]. For some particular matching conditions between w_{10} and $\frac{\partial w_0}{\partial x_i}$ we obtain that b_∞ decays exponentially fast as $x_1\to+\infty$. This problem is studied in Lemma 6.2, given in section 6. We deduce from this lemma that (57) admits a unique solution in $W^2(\mathbb{R}^+\times\mathbb{R}^{d-1}\times V)$, which converges, as x_1 goes to infinity, to a constant term $G(\kappa_1\frac{\partial w_0}{\partial x_1}-w_{10}) = G(\kappa_1)\frac{\partial w_0}{\partial x_1} - w_{10}$, where $G(\kappa_1)=L$ is a constant. We obtain that the layer b_∞ vanishes when $x_1\to\infty$ provided $G(\kappa_1\frac{\partial w_0}{\partial x_1}-w_{10})=0$. In other words,

$$L\frac{\partial w_0}{\partial n} + w_{10} = 0. \tag{58}$$

This corresponds to the boundary conditions (32).

Let us now prove that b^ε is of order $O(\varepsilon^{1/2})$ in $L^2(\Omega\times V)$ when (58) is satisfied. We define

$$\gamma^0 = \{x\in\partial\Omega \text{ s.t. } x_1=0\}.$$

The variational formulation for b_1^ε is given for every test function $v\in\mathcal{V}$ by

$$\begin{aligned} &\int_\Omega\int_V \frac{(\psi_\varepsilon^+)^2}{\Sigma^\varepsilon}\mu\cdot\nabla b_1^\varepsilon\,\mu\cdot\nabla v\,d\mu dx + \frac{1}{\varepsilon^2}\int_\Omega\int_V (Q_\varepsilon b_1^\varepsilon)v\,d\mu dx\\ &+\frac{1}{\varepsilon}\int_{\partial\Omega}\int_V |\mu\cdot n|h_\varepsilon b_1^\varepsilon v\,d\mu d\sigma = \frac{1}{\varepsilon}\int_{\gamma^0}\int_V |\mu\cdot n|h_\varepsilon\left(\kappa_1\left(\frac{x}{\varepsilon},\mu\right)-L\right)\partial_1 w_0(x')v\,d\mu d\sigma. \end{aligned} \tag{59}$$

Let us introduce

$$d^\varepsilon(x_1,x',\mu) = -\partial_1 w_0(x')U(x_1)b\left(\frac{x}{\varepsilon},\mu\right), \tag{60}$$

where $U(x_1)\in C^\infty(\mathbb{R}^+)$ is such that $U(0)=1$ and $U(x_1)=0$ for $x_1\geq 1$, and where b is the solution to (66) with $g=\kappa_1-L$, $S=0$, and $T=0$. According to Lemma 6.2, b is exponentially decaying to 0. We have that

$$\begin{aligned} A_\varepsilon d^\varepsilon &= \tilde S - \mu\cdot\nabla\tilde T \quad \text{in } X,\\ d^\varepsilon - \frac{\varepsilon\psi_\varepsilon^+}{\psi_\varepsilon\Sigma^\varepsilon}\mu\cdot\nabla d^\varepsilon &= \left(L-\kappa_1\left(\frac{x}{\varepsilon},\mu\right)\right)\partial_1 w_0(x') \quad \text{on } \Gamma_-^0, \end{aligned} \tag{61}$$

with the notation of section 6. Here we have

$$\begin{aligned} \tilde T &= 2b\left(\frac{x}{\varepsilon},\mu\right)\mu\cdot\nabla(-\partial_1 w_0(x')U(x_1))\frac{(\psi_\varepsilon^+)^2}{\Sigma^\varepsilon},\\ \tilde S &= (\mu\cdot\nabla)^2(-\partial_1 w_0(x')U(x_1))\frac{(\psi_\varepsilon^+)^2}{\Sigma^\varepsilon}b\left(\frac{x}{\varepsilon},\mu\right). \end{aligned}$$

According to the Y'-periodicity of b (see section 6 for the notation), we obtain the following variational formulation for d^ε:

$$\begin{aligned}
&\int_X \frac{(\psi_\varepsilon^+)^2}{\Sigma^\varepsilon} \mu\cdot\nabla d^\varepsilon\, \mu\cdot\nabla v\, d\mu dx + \frac{1}{\varepsilon^2}\int_X (Q_\varepsilon d^\varepsilon) v\, d\mu dx + \frac{1}{\varepsilon}\int_{\Gamma^0} |\mu\cdot n| h_\varepsilon d^\varepsilon v\, d\mu d\sigma \\
&= \frac{1}{\varepsilon}\int_{\Gamma^0} \left[|\mu\cdot n| h_\varepsilon \left(\kappa_1\left(\frac{x}{\varepsilon},\mu\right) - L\right) \partial_1 w_0(x') v - \varepsilon(\mu\cdot n)\tilde{T} v \right] d\mu d\sigma \\
&\quad + \int_X (\tilde{S} v + \tilde{T}\mu\cdot\nabla v) d\mu dx. \qquad (62)
\end{aligned}$$

Let us define $\delta^\varepsilon = d^\varepsilon - b_1^\varepsilon$. Since $w_0 = 0$ on $\partial\Omega$, we have $d^\varepsilon = 0$ on $\partial\Omega\backslash\gamma^0$. Therefore, subtracting (59) from (62), we obtain that

$$\begin{aligned}
&\int_\Omega \int_V \Big(\frac{(\psi_\varepsilon^+)^2}{\Sigma^\varepsilon} \mu\cdot\nabla\delta^\varepsilon\, \mu\cdot\nabla v\, d\mu dx + (Q_\varepsilon \delta^\varepsilon) v \Big) d\mu dx + \frac{1}{\varepsilon}\int_{\partial\Omega}\int_V |\mu\cdot n| h_\varepsilon \delta^\varepsilon v\, d\mu d\sigma \\
&= -\int_{\gamma^0}\int_V (\mu\cdot n)\tilde{T} v d\mu d\sigma + \int_\Omega \int_V (\tilde{S} v + \tilde{T}\mu\cdot\nabla v) d\mu dx. \qquad (63)
\end{aligned}$$

Because b decays exponentially fast, we deduce that

$$\left\| b\left(\frac{x}{\varepsilon},\mu\right)\right\| \le C\sqrt{\varepsilon}.$$

Therefore, the source terms $\tilde{T}$ and $\tilde{S}$ satisfy the same bound. Choose $v = \delta^\varepsilon$ in this expression. We have

$$\|\mu\cdot\nabla\delta^\varepsilon\|^2 + \frac{1}{\varepsilon}\|\delta^\varepsilon\|^2_{L^2(\Gamma_-,d\xi)} \le C\|\delta^\varepsilon\|_{L^2(\Gamma_-,d\xi)} + C\sqrt{\varepsilon}(\|\delta_\varepsilon\| + \|\mu\cdot\nabla\delta^\varepsilon\|).$$

Recalling the Poincaré inequality (42), we easily obtain that

$$\|\delta^\varepsilon\| + \|\mu\cdot\nabla\delta^\varepsilon\| + \varepsilon^{-1/2}\|\delta^\varepsilon\|_{L^2(\Gamma_-,d\xi)} \le C\sqrt{\varepsilon}.$$

Since $b_1^\varepsilon = d^\varepsilon - \delta^\varepsilon$, we deduce that $\|b_1^\varepsilon\| \le C\sqrt{\varepsilon}$. This concludes the proof of the theorem. ∎

6. The conservative multidimensional Milne problem in a periodic half space. In this section, we state the lemma we used in the proof of Theorem 3.11. The study of problem (57) plays a crucial role in the construction of the first-order corrector. For homogeneous problems in slab geometry, it is often referred to as the conservative Milne problem. It has been studied by many authors in the setting of the first-order integrodifferential form of the transport equation. First introduced by astrophysicists [18], it has been analyzed in [14] using probabilistic techniques. More recently, it has been revisited in [11] using results of functional analysis. The tools introduced by these authors, such as the exponential decay analysis, are used here. The specific structure of the second-order formulation in a genuine multidimensional geometry necessitates employing additional methods.

Although we do not need it in the proof of convergence, we also study the half space problem with an exponentially decaying source term away from the boundary. Similar results were derived in diffusion theory for first-order correctors of source problems [13].

Let us introduce some notation. For $x \in \mathbb{R}^d$, we have $x = (x_1, x')$. We denote by $Y' = (0,1)^{d-1}$ and for $A \in \mathbb{R}^+$, $\Gamma^A = \{A\} \times Y' \times V$. Let $X_{AB} = (A, B) \times Y' \times V$ and $X = X_{0,+\infty}$. Its boundary is decomposed as $\partial X = \Gamma^\# \cup \Gamma^0$. The functional space $D(X)$ is defined by

$$\begin{aligned} &D(X) = \{u \in W^2_{\#,loc}(X), \|u\|_{D(X)} < +\infty\}, \\ &\|u\|_{D(X)} = \|\mu \cdot \nabla u\|_{L^2(X)} + \|u - \langle u\rangle\|_{L^2(X)} + \|u\|_{L^2(\Gamma^0_-, d\xi)}. \end{aligned} \tag{64}$$

Here $W^2_{\#,loc}(X)$ is the space of functions of $W^2_{loc}(X)$ that are Y'-periodic with respect to x' and Γ^0_- is the set of incoming boundary conditions for X at side Γ^0.

LEMMA 6.1. *The space $D(X)$ defined in* (64) *is Hilbert.*

Proof. We have to prove that the seminorm given in (64) is a norm for $D(X)$. Actually we prove that

$$\|u\|_{X_{0M}} \leq CM(\|\mu \cdot \nabla u\|_{L^2(X)} + \|u - \langle u\rangle\|_{L^2(X)} + \|u\|_{L^2(\Gamma^0_-, d\xi)}).$$

This is enough to obtain the local integrability. We first replace the domain of integration of the velocity by a smaller set of positive directions. Let B be a ball centered at μ such that $\mu_1 = 0$ of a given radius. Let $\theta \in V = S^{d-1}$ and B_θ be the image of B by a rotation R_θ of angle θ. Let $f \in L^2(S^{d-1})$. We have

$$\begin{aligned} &\int_{B_\theta} f^2(\mu) d\mu = \int_{B_\theta} [(f - \langle f\rangle) - (R_{-\theta} f - \langle f\rangle) + R_{-\theta} f]^2 d\mu \\ \leq\ & 3\int_B f^2(\mu) d\mu + 6\int_V (f - \langle f\rangle)^2 d\mu. \end{aligned}$$

Let $B = \{\mu \in V \text{ s.t. } \mu_1 > 1/2\}$, for instance. A finite number of angles θ is sufficient so that the union of the corresponding B_θ covers V. Then we have that

$$\|u\|_{L^2(X_{0M})} \leq C(\|u\|_{(0,M)\times Y' \times B} + \|u - \langle u\rangle\|_{L^2(X)}),$$

where C is a universal constant. Since u is bounded at the boundary Γ^0_- and $\mu \cdot \nabla u$ is bounded in $L^2(X)$, it is not difficult to obtain a bound for $\|u\|_{(0,M)\times Y' \times B}$. We have that

$$u(x,\mu) = \int_0^{d(x,\mu)} \mu \cdot \nabla u(x - s\mu, \mu) ds + u(\overline{x}, \mu), \quad (x,\mu) \in (0,M) \times Y' \times B.$$

Here $d(x,\mu)$ is the distance between $x \in \mathbb{R}^+ \times \mathbb{R}^{d-1}$ and the surface $x_1 = 0$ in the direction $-\mu$ and $\overline{x}$ the point of the interface defined by $\overline{x} = x - d(x,\mu)\mu$. We deduce from the Cauchy–Schwartz inequality that

$$|u(x,\mu)|^2 \leq CM \int_0^{d(x,\mu)} (\mu \cdot \nabla u)^2 (x - s\mu, \mu) ds + 2|u(\overline{x}, \mu)|^2, \tag{65}$$

where C is a universal constant. For $\mu \in B$ given, we integrate and obtain

$$\int_0^M \int_{Y'} |u(x,\mu)|^2 dx \leq CM^2 \|\mu \cdot \nabla u\|^2_{L^2(X)} + CM\|u\|^2_{L^2(\Gamma^0_-, d\xi)}.$$

It remains to integrate this relation over B to complete the proof of the lemma. ∎

We can now state the main result of this section.

LEMMA 6.2. *Let $g \in L^2(\Gamma^0_-, d\xi)$, $S \in L^2(X)$, $T \in L^2(X)$ be sufficiently regular so that its trace on γ^0 is defined, and $\nu > 0$. We assume that $\check{S} = S$ and $\check{T} = -T$. We denote by $\mathcal{N} = \|g\|_{L^2(\Gamma^0_-,d\xi)} + \|S\|_{L^2(X)} + \|T\|_{L^2(X)} + \|T\|_{L^2(\gamma^0_-,d\xi)}$. There exists a unique solution in $D(X)$ to the following boundary layer problem:*

$$\begin{aligned} -\mu\cdot\nabla\frac{(\psi^+_\infty)^2}{\Sigma}\mu\cdot\nabla b_\infty + Qb_\infty &= Se^{-\nu x_1} - \mu\cdot\nabla(Te^{-\nu x_1}) \quad \text{in } X, \\ b_\infty - \frac{\psi^+_\infty}{\psi_\infty\Sigma}\mu\cdot\nabla b_\infty &= g \quad \text{on } \Gamma^0_-. \end{aligned} \tag{66}$$

The solution b_∞ satisfies $\check{b}_\infty = b_\infty$. Moreover, there exist three linear forms G and H and J such that b_∞ decays exponentially as $x_1 \to \infty$ to a constant $L = G(g) + H(S) + J(T)$ satisfying $|L| \le C\mathcal{N}$. More specifically, we have

$$\begin{aligned} &\|b_\infty - L\|_{L^2(X_{M,\infty})} + \|\mu\cdot\nabla b_\infty\|_{L^2(X_{M,\infty})} \\ &+ \|(\mu\cdot\nabla)^2 b_\infty\|_{L^2(X_{M,\infty})} + \|Qb_\infty\|_{L^2(X_{M,\infty})} \le C\mathcal{N}\, e^{-\beta M/2}, \end{aligned} \tag{67}$$

where C and β are constants independent of b_∞ and M. Notice that $G(1) = 1$.

Proof. (i) *Existence and uniqueness of the solution.* Let $v \in D(X)$ be a test function with compact support. Multiplying (66) by v and integrating by parts yields

$$\begin{aligned} &\int_X \left(\frac{(\psi^+_\infty)^2}{\Sigma}\mu\cdot\nabla b_\infty \mu\cdot\nabla v + Qb_\infty v\right) + \int_{\Gamma^0}(\psi^+_\infty\psi_\infty)|\mu\cdot n|(b_\infty - g)v \\ = &\int_X e^{-\nu x_1}Sv + e^{-\nu x_1}T\mu\cdot\nabla v - \int_{\Gamma^0}(\mu\cdot n)Tv. \end{aligned} \tag{68}$$

The measures of integration are $d\mu dx$ on X_{AB} and $d\mu dx'$ on Γ^A. We drop them for simplicity. By density, the same equation holds true for every $v \in D(X)$. With obvious notation, problem (66) is equivalent to

$$a(b_\infty, v) = \mathcal{F}(v) \quad \forall v \in D(X). \tag{69}$$

The form a is clearly bicontinuous and coercive in $D(X)$. We deduce from the proof of Lemma 6.1 that

$$\left|\int_X e^{-\nu x_1}T\mu\cdot\nabla v\right| + \left|\int_X e^{-\nu x_1}Sv\right| + \left|\int_{\Gamma^0}(\psi^+_\infty\psi_\infty)|\mu\cdot n|g\,v\right| + \left|\int_{\Gamma^0}|\mu\cdot n|T\,v\right| \le C\mathcal{N}\|v\|_{D(X)},$$

where C is a constant independent of g, S, and $v \in D(X)$. Therefore, the form $\mathcal{F}$ is linear in $D(X)$. By the Lax–Milgram lemma, there exists a unique solution to (66) in $D(X)$. From (66), we also deduce that $\mu\cdot\nabla_y b_\infty \in D(X)$.

(ii) *Convergence of b_∞ when $x_1 \to \infty$.* Let be $A < B$. Integrating (66) by parts yields

$$\begin{aligned} &\int_{X_{AB}}\left(\frac{(\psi^+_\infty)^2}{\Sigma}\mu\cdot\nabla b_\infty\mu\cdot\nabla v + Qb_\infty v\right) \\ &- \int_{\Gamma^A\cup\Gamma^B}\left(\frac{(\psi^+_\infty)^2}{\Sigma}\mu\cdot\nabla b_\infty - Te^{-\nu x_1}\right)(\mu\cdot n)v = \int_{X_{AB}} e^{-\nu x_1}Sv + e^{-\nu x_1}T\mu\cdot\nabla v. \end{aligned} \tag{70}$$

Let us choose $v = 1$ in this variational formulation. Recalling that $\mu \cdot n = \mu_1$ on Γ^B and $\mu \cdot n = -\mu_1$ on Γ^A, we have for $B = \infty$,

$$\int_{\Gamma^A} \frac{(\psi_\infty^+)^2}{\Sigma} \mu \cdot \nabla b_\infty \mu_1 = \int_{X_{A,\infty}} e^{-\nu x_1} S - \int_{\Gamma^A} (\mu \cdot n) e^{-\nu A} T. \tag{71}$$

Choosing $v = b_\infty$ now yields

$$\begin{aligned}
&\int_{\Gamma^A} \frac{(\psi_\infty^+)^2}{\Sigma} \mu \cdot \nabla b_\infty \mu_1 b_\infty \\
&= \int_{X_{A,\infty}} \left(-\frac{(\psi_\infty^+)^2}{\Sigma} (\mu \cdot \nabla b_\infty)^2 - (Q b_\infty) b_\infty + e^{-x_1 \nu} S b_\infty + e^{-x_1 \nu} T \mu \cdot \nabla b_\infty \right) \\
&- \int_{\Gamma^A} (\mu \cdot n) e^{-\nu A} T b_\infty \le \int_{X_{A,\infty}} (e^{-x_1 \nu} S b_\infty + e^{-x_1 \nu} T \mu \cdot \nabla b_\infty) - \int_{\Gamma^A} (\mu \cdot n) e^{-\nu A} T b_\infty.
\end{aligned}$$

We deduce from this equality, Lemma 4.1, and a classical trace theorem [16, 17] that

$$e^{A\nu/2} \int_{\Gamma^A} \frac{(\psi_\infty^+)^2}{\Sigma} \mu \cdot \nabla b_\infty \mu_1 b_\infty \le \|b_\infty\|_{D(X)} \mathcal{N}. \tag{72}$$

Let us now choose $v = b_\infty e^{\beta x_1}$ on X_{0B}, where $0 < \beta < \nu/2$ will be determined later. We obtain that

$$\begin{aligned}
&\int_{X_{0B}} \left(\frac{(\psi_\infty^+)^2}{\Sigma} (\mu \cdot \nabla b_\infty)^2 e^{\beta x_1} + \frac{(\psi_\infty^+)^2}{\Sigma} \mu \cdot \nabla b_\infty \mu_1 b_\infty \beta e^{\beta x_1} + (Q b_\infty) b_\infty e^{\beta x_1} \right) \\
&+ \int_{\Gamma^0} (\psi_\infty^+ \psi_\infty) |\mu \cdot n| b_\infty^2 \\
&= \int_{\Gamma^0} (\psi_\infty^+ \psi_\infty) |\mu \cdot n| b_\infty g + \int_{\Gamma^B} \frac{(\psi_\infty^+)^2}{\Sigma} \mu \cdot \nabla b_\infty \mu_1 b_\infty e^{\beta B} + \int_{X_{0B}} e^{-(\nu-\beta)x_1} S b_\infty \\
&+ \int_{X_{0B}} e^{-(\nu-\beta)x_1} T (\mu \cdot \nabla b_\infty + \mu_1 \beta b_\infty) - \int_{\Gamma^0} T (\mu \cdot n) b_\infty - \int_{\Gamma^B} e^{-(\nu-\beta)B} T (\mu \cdot n) b_\infty.
\end{aligned}$$

We deduce from (72) and Lemma 4.1 that there exist positive constants η and C independent of B such that

$$\int_{X_{0B}} \left[\frac{(\psi_\infty^+)^2}{\Sigma} (\mu \cdot \nabla b_\infty)^2 + \beta \frac{(\psi_\infty^+)^2}{\Sigma} \mu \cdot \nabla b_\infty \mu_1 b_\infty + \eta |b_\infty - \langle b_\infty \rangle|^2 \right] e^{\beta x_1} \le C \mathcal{N}^2. \tag{73}$$

The second term in the left-hand side in (73) has to be estimated in terms of the two other ones, which are positive. Let us introduce the following average operators, defined for every regular function u by

$$m_{\Gamma^B}(u) = \int_{\Gamma^B} u \, d\mu dx', \quad m_M(u) = \int_{X_{M,M+1}} u \, d\mu dx, \quad m_{Y_M}(u) = \int_{Y_M} u \, dx, \tag{74}$$

where $Y_M = (M, M+1) \times Y'$ is the Mth cell. Remark that m_{Y_M} is only a spatial averaging operator and that $m_M(u) = \int_V m_{Y_M}(u)$. We now prove that

$$\|u - m_M(u)\|_{L^2(X_{M,M+1})} \le C \left(\|\mu \cdot \nabla u\|_{L^2(X_{M,M+1})} + \|u - \langle u \rangle\|_{L^2(X_{M,M+1})} \right). \tag{75}$$

Let $\mu \in V$ be given. Since the cell Y_M is bounded, we easily check by integration of one-dimensional problems along the direction μ and along its transverse directions that

$$\|u(\cdot,\mu) - (m_{Y_M}(u))(\mu)\|^2_{L^2(Y_M)} \le C\|\mu\cdot\nabla u\|^2_{L^2(Y_M)},$$

where C is a constant independent of μ. Integrating over V yields

$$\|u - m_Y(u)\|_{L^2(X_{M,M+1})} \le C\|\mu\cdot\nabla u\|_{L^2(X_{M,M+1})}.$$

On the other hand we check that

$$\begin{aligned}\|m_{Y_M}(u) - m_M(u)\|^2_{L^2(X_{M,M+1})} &= \int_{X_{M,M+1}}\left(\int_{Y_M}(u- < u >)\right)^2 \\ &\le C\|u - \langle u\rangle\|^2_{L^2(X_{M,M+1})}.\end{aligned}$$

This proves (75). In addition, we obtain that

$$\|u - m_{\Gamma^{x_1}}(u)\|_{L^2(X_{M,M+1})} \le \|u - m_M(u)\|_{L^2(X_{M,M+1})}.$$

Therefore, we have

$$\|u - m_{\Gamma^{x_1}}(u)\|_{L^2(X_{M,M+1})} \le C\left(\|\mu\cdot\nabla u\|_{L^2(X_{M,M+1})} + \|u - \langle u\rangle\|_{L^2(X_{M,M+1})}\right).$$

This inequality holds for all $M \in \mathbb{R}^+$ and since $e^{\beta M} \le e^{\beta x_1} \le e^{\beta}e^{\beta M}$ for $x_1 \in (M, M+1)$, we obtain

$$\|(u - m_{\Gamma^{x_1}}(u))e^{\frac{\beta}{2}x_1}\|_{L^2(X)} \le C(\|(\mu\cdot\nabla u)e^{\frac{\beta}{2}x_1}\|_{L^2(X)} + \|(u - \langle u\rangle)e^{\frac{\beta}{2}x_1}\|_{L^2(X)}). \tag{76}$$

We deduce from (71) that

$$\begin{aligned}&\left|\int_X \frac{(\psi^+_\infty)^2}{\Sigma}\mu\cdot\nabla b_\infty \mu_1 m_{\Gamma^{x_1}}(b_\infty)e^{\beta x_1}\right| \\ =\ &\left|\int_X m_{\Gamma^{x_1}}(b_\infty)e^{\beta x_1}\left(\int_{X_{x_1\infty}} e^{-\nu y_1}S - \int_{\Gamma^{x_1}}(\mu\cdot n)e^{-\nu x_1}T\right)\right| \\ \le\ & C\int_X e^{-(\nu-\beta)x_1}|m_{\Gamma^{x_1}}(b_\infty)|(\|S\|_{L^2(X)} + \|T\|_{L^2(X)}) \le C\mathcal{N}^2.\end{aligned} \tag{77}$$

Here and in what follows, C denotes a constant independent of b_∞. Then according to (76) we can rewrite (73) and obtain for some constants $\eta > 0$ and $\theta > 0$,

$$\begin{aligned}&\int_X (\mu\cdot\nabla b_\infty)^2 e^{\beta x_1} - \theta\beta\int_X |(\mu\cdot\nabla b_\infty)\,(b_\infty - m_{\Gamma^{x_1}}(b_\infty))|\, e^{\beta x_1} \\ &+\eta\int_X (b_\infty - m_{\Gamma^{x_1}}(b_\infty))^2 e^{\beta x_1} \le C\mathcal{N}^2.\end{aligned} \tag{78}$$

Choosing now $\beta > 0$ small enough, we deduce from the Cauchy–Schwartz inequality that

$$\int_X (\mu\cdot\nabla b_\infty)^2 e^{\beta x_1} + \int_X (b_\infty - m_{\Gamma^{x_1}}(b_\infty))^2 e^{\beta x_1} \le C\mathcal{N}^2. \tag{79}$$

Owing to (73) and (77), we deduce from (79) and the Cauchy–Schwartz inequality that

$$\int_X |b_\infty - \langle b_\infty \rangle|^2 \, e^{\beta x_1} \leq C\mathcal{N}^2.$$

Therefore, we obtain

$$\int_X (\mu \cdot \nabla b_\infty)^2 e^{\beta x_1} + \int_X |b_\infty - \langle b_\infty \rangle|^2 \, e^{\beta x_1} \leq C\mathcal{N}^2. \tag{80}$$

It follows from (75) and (80) that

$$\|u - m_M(u)\|_{L^2(X_{M,M+1})} \leq Ce^{-\frac{\beta M}{2}}\mathcal{N},$$

and averaging over $x_1 \in (M, M+2)$ we have

$$\begin{aligned}\left\| u - \frac{m_M(u) + m_{M+1}(u)}{2} \right\|_{L^2(X_{M,M+1})} &\leq \left\| u - \tfrac{m_M(u)+m_{M+1}(u)}{2} \right\|_{L^2(X_{M,M+2})} \\ &\leq Ce^{-\frac{\beta M}{2}}\mathcal{N}.\end{aligned}$$

Then we readily show that

$$|m_{M+1}(u) - m_M(u)| \leq Ce^{-\frac{\beta M}{2}}\mathcal{N}.$$

This proves that $M \mapsto m_M(u)$ converges exponentially fast to a constant L by linearity of the transport equation. Moreover, due to the exponential rate of convergence, we have that

$$|L| \leq |G(g)| + |H(S)| + |J(T)| \leq C\mathcal{N}.$$

Let us introduce

$$m(u) = m_M(u) \qquad \text{for } x_1 \in (M, M+1).$$

Then $m(b_\infty)$ is an element of $L^2(X)$ that converges to L and

$$\|[b_\infty - m(b_\infty)]e^{\frac{\beta x_1}{2}}\|_{L^2(X)} \leq C\mathcal{N}.$$

Hence we can conclude that b_∞ converges to L in the following sense:

$$\|b_\infty - L\|_{L^2(X_{M,\infty})} \leq Ce^{-\frac{\beta M}{2}}\mathcal{N}.$$

The same results are derived for $\mu \cdot \nabla_y b$ and for Qb. This completes the proof of the lemma. ∎

7. Numerical application and conclusion. It goes beyond the scope of this paper to present an extensive numerical application of the theory we have described. We refer to [8, 9] for a more detailed analysis. However, we show the convergence of the eigenvalues for the homogenization of a core composed of $N \times N$ uranium assemblies, which are common in thermal reactors. In its two-dimensional approximation, each assembly is made of 17×17 fuel pins or control rods. We do not describe them here and refer to [9] for the details. We present the convergence of the eigenvalue

TABLE 1
Reference and reconstructed k_{eff} for cores composed of $N \times N$ uranium assemblies.

N	Reference	k_{eff}, $L = 0$	Error (10^{-5})	k_{eff}, $L = 0.71$	Error (10^{-5})
5	0.46598	0.45542	1056	0.46543	55
10	0.54521	0.54334	187	0.54515	6
20	0.57114	0.57089	25	0.57114	0
40	0.57825	0.57821	4	0.57825	0
∞	0.58070				

$k_{eff} = 1/\lambda_1^\varepsilon$ for different values of the number of assemblies $N = 1/\varepsilon$. In Table 1 are gathered the exact multiplication factor k_{eff}, the associated diffusion approximation given by $(\lambda_\infty + \varepsilon^2\nu_1)^{-1}$ corresponding to an extrapolation length $L = 0$, and the diffusion approximation $(\lambda_\infty + \varepsilon^2\omega_1^\varepsilon)^{-1}$ that corresponds to an extrapolation length of approximately $L = 0.71$. The exact extrapolation length has not been computed. Instead, we took the value of the extrapolation length in homogeneous media. This can be physically justified by the fact that uranium assemblies are not very heterogeneous.

As expected from the theory, the convergence of the eigenvalues without accounting for the leakage is of order ε^3. A numerical estimate is given by

$$v \;=\; \frac{\ln \frac{e_{20}}{e_{10}}}{\ln \frac{20}{10}} \simeq 2.9,$$

which is in good agreement with the theoretical value. When we account for the neutron leakage, the rate of convergence is too fast to be estimated numerically. Indeed two-dimensional computations are already highly demanding, especially for a number of assemblies equal to 20×20 and 40×40, which correspond to 115,600 and 462,400 rods, respectively. Hence we obtained an accuracy of 10^{-5} for the eigenvalues. Nevertheless the gain obtained by adding an extrapolation length is clear according to the numerical results presented in Table 1. We do not give here the reconstructed fluxes for both methods. However, in both cases the shape of the exact fluxes is well reproduced by the reconstructed fluxes [9]. In the case of a zero extrapolation length, the reconstructed flux is shifted downward. This is explained by the Dirichlet boundary conditions, which do not account for the neutron leakage. The error made is of the order of 5% for a core composed of 10×10 assemblies (usual cores have approximately 150 assemblies). When Robin-like boundary conditions are imposed for the diffusion approximation, the reconstructed flux has the correct shape, up to an error of less than 1%. Fine resolution close to the boundary also allows us to see the exponential decay of the boundary layer [9].

In this paper, we have presented the homogenization of the transport criticality eigenvalue problem and a numerical experiment for a one-velocity periodic neutron transport problem. The generalization to multigroup and anisotropic equations is straightforward and does not require new techniques [4, 5]. The results can also be readily extended [8] to cores that are periodic up to a perturbation of order ε^2, i.e., for instance, $\Sigma(\frac{x}{\varepsilon}, \mu) + \varepsilon^2\Sigma'(x, \frac{x}{\varepsilon}, \mu)$. However, the extension to genuinely nonperiodic cores is still open. Periodicity is needed in order to obtain separation of slow and fast variables. It would be interesting, theoretically as well as practically, to understand the homogenization of locally periodic domains. The analysis of boundary layers is replaced by that of interface layers, for which no theory is available at present.

Appendix A. Equivalence between the first-order and even parity flux formulations. A linear integrodifferential Boltzmann equation is usually solved to

model neutron transport. In the simplified setting of one-velocity and isotropic source problems, it is given as follows. Given the cross sections Σ and Σ_s and the source term q, we want to find the neutron angular flux $\psi(x,\mu)$ satisfying

$$\begin{aligned} \mu\cdot\nabla\psi(x,\mu)+\Sigma(x)\psi(x,\mu) &= \Sigma_s(x)\int_V \psi(x,\mu')d\mu'+q(x) \quad \text{in } \Omega\times V,\\ \psi(x,\mu) &= 0 \quad \text{on } \Gamma_-. \end{aligned} \tag{81}$$

The assumption of one-velocity neutrons is not essential in order to derive the even parity flux formulation, and the generalization to multigroup problems is straightforward. However, isotropy of the scattering operator can be hardly avoided, even if complicated generalizations exist for nonisotropic media. This restricts the use of the even parity formulation, although isotropy is a correct approximation in nuclear reactor computations.

The even parity flux formulation consists in deriving a second-order integrodifferential equation for the *even parity flux*, which is defined by

$$\psi^+(x,\mu)=\frac{\psi(x,\mu)+\psi(x,-\mu)}{2}. \tag{82}$$

The main features of this formulation are that the second-order differential operator allows for the use of a variational formulation, which is convenient in theory as well as for numerical implementations. For instance, standard finite element methods can be used as in the resolution of elliptic problems [28, Chapter 6]. Let us also emphasize that the number of angular directions, and therefore the computational cost, has been divided by two.

The derivation of the even parity flux equations from the first-order integrodifferential equation is done as follow. Let us first introduce the *odd parity flux*

$$\psi^-(x,\mu) = \frac{\psi(x,\mu)-\psi(x,-\mu)}{2}$$

and the *scalar flux*

$$\phi(x) = \int_V \psi(x,\mu')d\mu' = \int_V \psi^+(x,\mu')d\mu'.$$

Then (81) written at points (x,μ) and $(x,-\mu)$ yields

$$(\mu\cdot\nabla+\Sigma)(\psi^++\psi^-)=\Sigma_s\phi+q, \quad (-\mu\cdot\nabla+\Sigma)(\psi^+-\psi^-)=\Sigma_s\phi+q.$$

Summing and subtracting these equalities, we obtain that

$$\mu\cdot\nabla\psi^-+\Sigma\psi^+ = \Sigma_s\phi+q, \qquad \mu\cdot\nabla\psi^++\Sigma\psi^- = 0. \tag{83}$$

Since the total cross section Σ is positive, we have

$$\psi^-=-\frac{1}{\Sigma}\mu\cdot\nabla\psi^+. \tag{84}$$

It remains to insert this expression in (83) and obtain

$$-\mu\cdot\nabla\frac{1}{\Sigma(x)}\mu\cdot\nabla\psi^+(x,\mu)+\Sigma(x)\psi^+(x,\mu)=\Sigma_s(x)\int_V\psi^+(x,\mu')d\mu'+q(x). \tag{85}$$

From the boundary conditions for ψ, we deduce that

$$\begin{array}{rcll} \psi^+ + \psi^- & = & 0 & \text{on} \quad \Gamma_- = \{(x,\mu) \in \partial\Omega \times V;\ \mu \cdot n(x) < 0\}, \\ \psi^+ - \psi^- & = & 0 & \text{on} \quad \Gamma_+ = \{(x,\mu) \in \partial\Omega \times V;\ \mu \cdot n(x) > 0\}. \end{array}$$

Then, according to (84), we have

$$\psi^+ - \frac{1}{\Sigma}\mu\cdot\nabla\psi^+ = 0 \text{ on } \Gamma_-, \quad \psi^+ + \frac{1}{\Sigma}\mu\cdot\nabla\psi^+ = 0 \text{ on } \Gamma_+. \tag{86}$$

Remark that due to the symmetry of the even parity flux, these two boundary conditions are redundant, so we need to mention only one of them. Equations (85) and (86) are called the even parity flux formulation of the neutron transport. With the assumption of subcriticality given by

$$\Sigma(x) - \Sigma_s(x) \geq \eta > 0,$$

problem (81) admits a unique solution in $W^2(\Omega \times V)$ (see, e.g., [20, Chapter 21]). Then from the definition (82), we obtain a weak solution of (85)–(86) in $W^2(\Omega \times V)$. The even parity flux ψ^+ also belongs to $\mathcal{V}$, defined by (40). This follows from a trace theorem [16, 17], which ensures that $\psi|_{\Gamma_+} \in L^2(\Gamma_+, d\xi)$ when $\psi \in W^2(\Omega \times V)$ and $\psi = 0$ on Γ_-.

Assume now that $\psi^+ \in \mathcal{V}$ is a weak solution of (85)–(86) and define $\psi = \psi^+ - \frac{1}{\Sigma}\mu\cdot\nabla\psi^+$. From (85), we easily deduce that

$$\mu\cdot\nabla(\psi - \psi^+) + \Sigma\psi^+ = \Sigma_s \int_V \psi + q,$$

and then (81), since (86) clearly implies that $\psi = 0$ on Γ_-. From (81) we deduce that $\psi \in W^2(\Omega \times V)$, and both formulations are equivalent. The same equivalence holds true for eigenvalue problems in bounded or periodic domains.

Appendix B. Some results on operator convergence. The results presented here are derived from [19]. Let X be a Banach space and $\mathcal{L}(X)$ the set of bounded linear operators from X to X. Let $\{T_n\}_{n\in\mathbb{N}}$ be a sequence of operators in $\mathcal{L}(X)$. Then T_n is said to converge *compactly* to T if

- for all $x \in X$, $T_n x \to Tx$ as $n \to \infty$,
- for any bounded sequence $\{x_n\}_{n\in\mathbb{N}}$ with $\|x_n\| \leq 1$, the sequence $\{(T - T_n)x_n\}_{n\in\mathbb{N}}$ is relatively compact in X.

Then we have the following result.

THEOREM B.1. *Let $\{T_n\}_{n\in\mathbb{N}}$ be a sequence of operators in $\mathcal{L}(X)$ converging compactly to T. Let $\sigma(T)$ and $\sigma(T_n)$ be the spectra of T and T_n, respectively. Let λ be an isolated eigenvalue of T of finite multiplicity and let Γ be a closed Jordan curve in the complex plane around λ and isolating λ such that the domain Δ enclosed by Γ contains no other point of the spectrum $\sigma(T)$ than λ. Then $\sigma(T_n) \cap \Delta$ contains a number of eigenvalues equal to the multiplicity of λ provided n is large enough.*

Moreover, let λ_n be a sequence of eigenvalues of T_n converging to λ, and let u_n be a sequence of normalized associated eigenvectors. Then, up to a subsequence, u_n converges to a limit u in X, which is an eigenvector of T associated with λ.

The proof of this theorem relies on Theorem 5.5, p. 232; Proposition 5.6, p. 234; Theorem 5.10, p. 236; Theorem 5.20, p. 244; and Proposition 5.28, p. 24 of [19]. We also have the following error estimate result. Let λ be an eigenvalue of T of finite

multiplicity and Δ defined as above. Let P be the projection on the eigenvectors of T associated with λ and P_n the projection on the eigenvectors associated with eigenvalues of T_n included in Δ. We denote by λ_{in}, $1 \leq i \leq m$, the m eigenvalues counting their multiplicities of T_n in Δ for n large enough. We note $M = PX$ and $M_n = P_n X$. For P and Q two orthogonal projections on X, we define $M = PX$ and $N = QX$ and the distance between M and N by

$$\begin{aligned}\Theta(M,N) &= \max\left(\sup_{x\in M,\,\|x\|=1}\|(1-Q)x\|,\ \sup_{x\in N,\,\|x\|=1}\|(1-P)x\|\right)\\ &= \max\left(\sup_{x\in M,\,\|x\|=1}\operatorname{dist}\,(x,N),\ \sup_{x\in N,\,\|x\|=1}\operatorname{dist}\,(x,M)\right).\end{aligned}$$

Then we prove the following result.

THEOREM B.2. *With the hypotheses and notation of Theorem* B.1*, the following quantities are at least of order* $\|(T-T_n)u\|$*:*

$$\Theta(M,M_n), \qquad \lambda - \frac{1}{m}\sum_{i=1}^{m}\lambda_{in}, \qquad \frac{1}{\lambda} - \frac{1}{m}\sum_{i=1}^{m}\frac{1}{\lambda_{in}} \quad (\text{if } \lambda \neq 0).$$

Moreover if λ *is simple, then* $\lambda - \lambda_n$ *and* $u - u_n$ *are at least of order* $\|(T-T_n)u\|$.

Acknowledgments. The author wishes to thank G. Allaire and G. Papanicolaou for many discussions and comments during the preparation of this paper, and X. Warin for his contribution to the numerical analysis presented here. He also would like to acknowledge helpful comments and remarks from the anonymous referees.

ON THE TWO-DIMENSIONAL GIERER–MEINHARDT SYSTEM WITH STRONG COUPLING*

JUNCHENG WEI† AND MATTHIAS WINTER‡

Abstract. We construct solutions with a single interior condensation point for the two-dimensional Gierer–Meinhardt system with strong coupling. The condensation point is located at a nondegenerate critical point of the diagonal part of the regular part of Green's function for $-\Delta + 1$ under the Neumann boundary condition. Our method is based on the Liapunov–Schmidt reduction for a system of elliptic equations.

Key words. pattern formation, mathematical biology, singular perturbation, strong coupling

1. Introduction.

We study the Gierer–Meinhardt system (see [14]) which models biological pattern formation and can be written as follows (already suitably scaled):

$$\text{(GM)} \qquad \begin{cases} A_t = \epsilon^2 \Delta A - A + \frac{A^p}{H^q}, \quad A > 0 \quad \text{in } \Omega, \\ \tau H_t = D\Delta H - H + \frac{A^r}{H^s}, \quad H > 0 \quad \text{in } \Omega, \\ \frac{\partial A}{\partial \nu} = \frac{\partial H}{\partial \nu} = 0 \quad \text{on } \partial\Omega. \end{cases}$$

Here, the unknowns $A = A(x,t)$ and $H = H(x,t)$ represent the concentrations at a point $x \in \Omega \subset R^N$ and at time t of the biochemicals called activator and inhibitor, respectively; ϵ, τ, D are positive constants; $\Delta := \sum_{j=1}^N \frac{\partial^2}{\partial x_j^2}$ is the Laplace operator in R^N; Ω is a smooth bounded domain in R^N; $\nu(x)$ is the outer normal at $x \in \partial\Omega$. The exponents p, q, r, s are assumed to satisfy the conditions

$$\text{(A)} \qquad 1 < p < \left(\frac{N+2}{N-2}\right)_+, \; q > 0, \; r > 0, \; s \geq 0, \text{ and } 0 < \frac{p-1}{q} < \frac{r}{s+1},$$

where $(\frac{N+2}{N-2})_+ = \frac{N+2}{N-2}$ if $N \geq 3$; $= +\infty$ if $N = 1, 2$. For a related model, see [20].

In numerical simulations of the activator-inhibitor system (GM), it is observed that, when the ratio ϵ^2/D is small, (GM) seems to have stable stationary solutions with the property that the activator concentration is localized around a finite number of points in $\overline{\Omega}$. Moreover, as $\epsilon \to 0$ the pattern exhibits a *"point condensation phenomenon."* By this we mean that the activator concentration is localized in narrower and narrower regions around some points and eventually shrinks to a certain set of points as $\epsilon \to 0$. Hereby the maximum value of the inhibitor concentration diverges to $+\infty$.

The stationary equation for (GM) is the following system of elliptic equations:

$$\begin{cases} \epsilon^2 \Delta A - A + \frac{A^p}{H^q} = 0, \quad A > 0 \quad \text{in } \Omega, \\ D\Delta H - H + \frac{A^r}{H^s} = 0, \quad H > 0 \quad \text{in } \Omega, \\ \frac{\partial A}{\partial \nu} = \frac{\partial H}{\partial \nu} = 0 \quad \text{on } \partial\Omega. \end{cases} \tag{1.1}$$

Generally speaking, system (1.1) is quite difficult to solve since it has neither a variational structure nor a priori estimates. One way to study (1.1) is to examine the so-called shadow system. Namely, we let $D \to +\infty$ first.

It is known (see [23], [31], [34], [39]) that the study of the shadow system amounts to the study of the following single equation:

$$\begin{cases} \epsilon^2 \Delta u - u + u^p = 0, \quad u > 0 \quad \text{in } \Omega, \\ \frac{\partial u}{\partial \nu} = 0 \quad \text{on } \partial\Omega. \end{cases} \tag{1.2}$$

Equation (1.2) has a variational structure and has been studied by numerous authors. It is known that (1.2) has both boundary spike solutions and interior spike solutions. For boundary spike solutions, see [5], [9], [10], [15], [17], [22], [25], [29], [30], [31], [39], [44], [46], and the references therein. (When $p = \frac{N+2}{N-2}, N \geq 3$, boundary spike solutions of (1.2) have been studied in [1], [2], [3], [12], [13], [27], etc.) For interior spike solutions, please see [4], [6], [18], [21], [33], [38], [40], [41], [45]. For stability of spike solutions, please see [7], [19], [26], [32], [42], and [43].

In the case when D is finite and not large (this is the so-called strong coupling case), there are only very few results available. For $N = 1$, one can construct spike solutions for all $D \geq 1$; see [37]. In higher dimensions, as far as we know, there are no results yet. (See [8], [28], and [34] for the study of related systems.) In this paper, we consider the case $N = 2$ since it has a particular asymptotic behavior.

Remark. Our approach does not work for dimensions $N \geq 3$ due to a different asymptotic behavior of Green's function of $-\Delta + 1$ with the Neumann boundary condition.

From now on we suppose that $N = 2$. For simplicity, we let $D = 1$.

We construct solutions with a single interior condensation point. It turns out that the condensation points in this case are different from those in the shadow system. We need to introduce some notation. Let $G(P, x)$ be Green's function of $-\Delta + 1$ under the Neumann condition, i.e., G satisfies

$$\begin{cases} -\Delta G + G = \delta_P \quad \text{in } \Omega, \\ \frac{\partial G}{\partial \nu} = 0 \quad \text{on } \partial\Omega, \end{cases}$$

where δ_P is the Dirac delta distribution at point P. It is also known that

$$G(P, x) = K(|x - P|) - H(P, x),$$

where $K(|x|)$ is the fundamental solution of $-\Delta + 1$ in R^2 with singularity at 0 and $H(P, x)$ is C^2 in Ω. It is known that

$$K(r) = -\log r - \mu + O(r) \quad \text{for } r \text{ small}. \tag{1.3}$$

We call $h(P) := H(P, P)$ the diagonal part of $H(P, x)$.

We have Theorem 1.1.

THEOREM 1.1. *Let $P_0 \in \Omega$ be a nondegenerate critical point of $h(P)$. Then for ϵ sufficiently small, problem (1.1) has a solution (A_ϵ, H_ϵ) with the following properties:*

(1) $A_\epsilon(x) = \xi_\epsilon^{q/(p-1)}(w(\frac{x-P_\epsilon}{\epsilon}) + o(1))$ *uniformly for $x \in \bar{\Omega}$, where $\xi_\epsilon > 0$ will be determined later, $P_\epsilon \to P_0$ as $\epsilon \to 0$, and w is the unique solution of the problem*

$$\begin{cases} \Delta w - w + w^p = 0, \quad w > 0 \quad \text{in } R^2, \\ w(0) = \max_{y \in R^2} w(y), \quad w(y) \to 0 \text{ as } |y| \to \infty. \end{cases} \tag{1.4}$$

(2) $H_\epsilon(x) = \xi_\epsilon(1 + O(\frac{1}{|\log \epsilon|}))$ *uniformly for $x \in \bar{\Omega}$.*

(3) $\xi_\epsilon^{s+1-\frac{qr}{p-1}} = (1 + o(1))\epsilon^2 \log \frac{1}{\epsilon} \int_{R^2} w^r$.

Remark. It is known that the solution w to (1.4) is radial, unique, and decays exponentially. (See [16], [24].)

We now outline the proof of Theorem 1.1.

Our method is based on the Liapunov–Schmidt reduction, which was used in [11], [35], and [36] to study semiclassical solutions of the nonlinear Schrödinger equation

$$\frac{h^2}{2}\Delta U - (V - E)U + U^p = 0 \tag{1.5}$$

in R^N, where V is a potential function and E is a real constant. Namely, in [11], [35], and [36] solutions of (1.4) are constructed near a nondegenerate critical point of V provided that h is sufficiently small. Later this method was used in [17], [18], [41], [44], [45], [46] to construct spike solutions for (1.2).

Here we face a system of elliptic equations. Therefore, the process is more complicated. To lay down the basic idea of our proof, we let

$$A_\epsilon = \xi_\epsilon^{q/(p-1)} \bar{A}_\epsilon, \quad H_\epsilon = \xi_\epsilon \bar{H}_\epsilon,$$

where ξ_ϵ is to be chosen later. It is easy to see that system (1.1) is equivalent to the following:

$$\begin{cases} \epsilon^2 \Delta \bar{A}_\epsilon - \bar{A}_\epsilon + \bar{A}_\epsilon^p / \bar{H}_\epsilon^q = 0 \quad \text{in } \Omega, \\ \Delta \bar{H}_\epsilon - \bar{H}_\epsilon + c_\epsilon \bar{A}_\epsilon^r / \bar{H}_\epsilon^s = 0 \quad \text{in } \Omega, \\ \frac{\partial \bar{A}_\epsilon}{\partial \nu} = \frac{\partial \bar{H}_\epsilon}{\partial \nu} = 0 \quad \text{on } \Omega, \end{cases} \tag{1.6}$$

where

$$c_\epsilon = \xi_\epsilon^{\frac{qr}{p-1} - (s+1)}.$$

We fix a point $P \in \Omega$. We rescale

$$\tilde{A}_\epsilon(y) := \bar{A}_\epsilon(P + \epsilon y), \quad x = \epsilon y + P, \quad y \in \Omega_{\epsilon,P} := \{y | P + \epsilon y \in \Omega\}.$$

Then as $\epsilon \to 0$, if we assume that $\bar{H}_\epsilon(P + \epsilon y) \to 1$ in $L^\infty_{loc}(\Omega_{\epsilon,P})$, we have that $\tilde{A}_\epsilon \to V(y)$, where V satisfies

$$\begin{cases} \Delta V - V + V^p = 0, \quad V > 0 \quad \text{in } R^2, \\ V(0) = \max_{y \in R^2} V(y), \quad V \in H^1(R^2). \end{cases}$$

By a uniqueness result it is known that $V(y) = w(y)$, where w is the unique solution of (1.4). (See [16], [24].) Hence

$$\tilde{A}_\epsilon(y) \sim w(y).$$

(Here and thereafter $A \sim B$ means $A = (1 + o(1))B$ as $\epsilon \to 0$ in the corresponding norm.)

To ensure that $\bar{H}_\epsilon(P+\epsilon y) \sim 1$, we note that

$$\bar{H}_\epsilon(P) = \int_\Omega G(P,x)\xi_\epsilon^{\frac{qr}{p-1}-(s+1)} \frac{\bar{A}_\epsilon^r(x)}{\bar{H}_\epsilon^s(x)}dx$$

$$= \epsilon^2 \int_{\Omega_{\epsilon,P}} G(P,P+\epsilon y)\xi_\epsilon^{\frac{qr}{p-1}-(s+1)} \frac{\tilde{A}^r(y)}{\bar{H}_\epsilon^s(P+\epsilon y)}dy$$

(by (1.3), $K(r) = -\log r - \mu + O(r)$ for r small)

$$\sim \xi_\epsilon^{\frac{qr}{p-1}-(s+1)}\epsilon^2 \log\frac{1}{\epsilon}\int_{R^2} w^r(y)\,dy.$$

This suggests that we take

$$\xi_\epsilon^{\frac{qr}{p-1}-(s+1)}\epsilon^2 \log\frac{1}{\epsilon}\int_{R^2} w^r(y)\,dy \sim 1.$$

Hence we should look for solutions of (1.1) with the following properties:

$$A_\epsilon = \xi_\epsilon^{q/(p-1)}\bar{A}_\epsilon, \quad \bar{A}_\epsilon(y) = w(y) + \phi_\epsilon(y), \quad \phi_\epsilon \sim 0,$$

$$\text{where} \quad y = \frac{x-P_\epsilon}{\epsilon} \quad \text{and} \quad |P_\epsilon - P_0| = o(1) \ \text{ as } \ \epsilon \to 0,$$

$$H_\epsilon = \xi_\epsilon \bar{H}_\epsilon, \quad \bar{H}_\epsilon(x) = 1 + \psi_\epsilon(x), \quad \psi_\epsilon \sim 0,$$

and

$$\xi_\epsilon^{\frac{qr}{p-1}-(s+1)}\epsilon^2 \log\frac{1}{\epsilon}\int_{R^2} w^r(y)\,dy \sim 1.$$

There are three main difficulties: First, $w(\frac{x-P_\epsilon}{\epsilon})$ does not satisfy the Neumann boundary condition. Second, the linearized problem arising from (1.4) has the N-dimensional kernel $\text{span}\{\frac{\partial w}{\partial y_1}, \dots, \frac{\partial w}{\partial y_N}\}$. Therefore, if we linearize system (1.6) at $(w(\frac{x-P}{\epsilon}), 1)$, the linearized operator is not uniformly invertible with respect to ϵ. Third, we have two scales: $(\log\frac{1}{\epsilon})^{-1}$ and ϵ. They are simply incomparable.

The first difficulty can be overcome by introducing the following *projection*: Let $U \subset R^2$ be a smooth and open set. Suppose that $W \in H^1(R^2)$. The projection $\mathcal{P}_U W$ is defined by $\mathcal{P}_U W = W - \mathcal{Q}_U W$, where $\mathcal{Q}_U W$ satisfies

$$\begin{cases} \Delta \mathcal{Q}_U W - \mathcal{Q}_U W = 0 & \text{in } U, \\ \frac{\partial \mathcal{Q}_U W}{\partial \nu} = \frac{\partial W}{\partial \nu} & \text{on } \partial U. \end{cases} \tag{1.7}$$

The second difficulty is overcome by first "solving" (1.6) module approximate kernel and cokernel, respectively. Subsequently we use the nondegeneracy of the critical point of h at P_0 to choose P_ϵ near P_0 such that the finite-dimensional part lying in the approximate cokernel vanishes.

The third difficulty can be managed by choosing *suitable* approximate solutions.

From now on, we work with (1.6). The main points of the proof of Theorem 1.1 and the organization of this paper can be described as follows:

(A) Choose good approximate solutions.

We first study the solution $(A_{\epsilon,\mu}(x), H_{\epsilon,\mu}(x), c_{\epsilon,\mu})$ of the following problem:

$$\begin{cases} \epsilon^2 \Delta A - A + \frac{A^p}{(H(x)-\mu)^q} = 0, & x \in R^2, \\ \Delta H - H + c_{\epsilon,\mu} \frac{A^r}{(H(x)-\mu)^s} = 0, & x \in R^2, \\ H(0) = 1 + O(\frac{1}{\log \frac{1}{\epsilon}} + \mu), \end{cases} \tag{1.8}$$

where μ is small.

Next we choose $\mu := \mu_\epsilon(P)$ so that

$$\mu = \mathcal{Q}_\Omega(H_{\epsilon,\mu}(\cdot - P))(P). \tag{1.9}$$

Set

$$\hat{A}_{\epsilon,P}(x) := A_{\epsilon,\mu_\epsilon(P)}(x - P), \quad \hat{H}_{\epsilon,P}(x) := H_{\epsilon,\mu_\epsilon(P)}(x - P),$$

$$c_\epsilon = \xi^{\frac{qr}{p-1}-(s+1)}, \quad c_{\epsilon,P} := c_{\epsilon,\mu_\epsilon(P)}.$$

We now choose our approximate solutions:

$$A_{\epsilon,P}(y) := \mathcal{P}_{\Omega_{\epsilon,P}} \hat{A}_{\epsilon,P}(P + \epsilon y), \quad H_{\epsilon,P}(x) := \mathcal{P}_\Omega \hat{H}_{\epsilon,P}(x). \tag{1.10}$$

Set

$$\varphi_{\epsilon,P}(y) := \hat{A}_{\epsilon,P}(y) - A_{\epsilon,P}(y), \quad \psi_{\epsilon,P}(x) := \hat{H}_{\epsilon,P}(x) - H_{\epsilon,P}(x).$$

It will be proved that $\varphi_{\epsilon,P}(y) = O(e^{-d(P,\partial\Omega)/\epsilon})$ for almost everywhere (a.e.) $y \in \Omega_{\epsilon,P}$ and $\psi_{\epsilon,P} = \frac{1}{\log \frac{1}{\epsilon}}(H(P,x) + o(1))$ uniformly with respect to $x \in \Omega$.

We will analyze $A_{\epsilon,P}$ and $H_{\epsilon,P}$ in sections 2 and 3.

(B) The idea now is to look for a solution of (1.6) of the form

$$\bar{A}_\epsilon(P + \epsilon y) = A_{\epsilon,P}(y) + \phi(y), \quad \bar{H}_\epsilon(x) = H_{\epsilon,P}(x) + \psi(x).$$

We will show that, provided P is properly chosen, ϕ and ψ are expected to be insignificantly small.

We now write system (1.6) in operator form.

For any smooth and open set $U \subset R^2$, let

$$W_N^{2,t}(U) = \left\{ u \in W^{2,t}(U) | \frac{\partial u}{\partial \nu} = 0 \text{ on } \partial U \right\}, \quad H_N^2(U) = W_N^{2,2}(U).$$

For $A(y) \in H_N^2(\Omega_{\epsilon,P})$, $H(x) \in W_N^{2,t}(\Omega)$, where $1 < t < 1.1$. (We need $t > 1$ so that the Sobolev embedding $W^{2,t}(\Omega) \subset L^\infty(\Omega)$ is continuous.) Set

$$S_\epsilon \begin{pmatrix} A \\ H \end{pmatrix} = \begin{pmatrix} S_1(A,H) \\ S_2(A,H) \end{pmatrix},$$

where $S_1(A,H) = \Delta_y A - A + A^p/H^q$, $S_2(A,H) = \Delta_x H - H + c_{\epsilon,P} A^r/H^s$.

Then solving (1.6) is equivalent to

$$S_\epsilon \begin{pmatrix} A \\ H \end{pmatrix} = 0, \quad A \in H_N^2(\Omega_{\epsilon,P}), \quad H \in W_N^{2,t}(\Omega). \tag{1.11}$$

We now substitute $A = A_{\epsilon,P}(y) + \phi(y)$, $H = H_{\epsilon,P}(x) + \psi(x)$ into (1.11). The system determining ϕ and ψ can be written as

$$S'_\epsilon \begin{pmatrix} A_{\epsilon,P} \\ H_{\epsilon,P} \end{pmatrix} \begin{bmatrix} \phi \\ \psi \end{bmatrix} + \begin{pmatrix} E^1_{\epsilon,P} \\ E^2_{\epsilon,P} \end{pmatrix} + \begin{pmatrix} O(\|\phi\|^2_{L^2(\Omega_{\epsilon,P})} + \|\psi\|^2_{L^t(\Omega)}) \\ O(\|\phi\|^2_{L^2(\Omega_{\epsilon,P})} + \|\psi\|^2_{L_t(\Omega)}) \end{pmatrix} = 0,$$

where $E^i_{\epsilon,P}, i = 1, 2$ denote the error terms and $E^1_{\epsilon,P} = S_1(A_{\epsilon,P}, H_{\epsilon,P}), E^2_{\epsilon,P} = S_2(A_{\epsilon,P}, H_{\epsilon,P})$. We will estimate the error terms in section 3.

It is then natural to try to solve the equations for (ϕ, ψ) by a contraction mapping argument. The problem is that the linearized operator $S'_\epsilon(\begin{smallmatrix} A_{\epsilon,P} \\ H_{\epsilon,P} \end{smallmatrix})$ is not uniformly invertible with respect to ϵ.

Therefore, we now replace the above equation with

$$S'_\epsilon \begin{pmatrix} A_{\epsilon,P} \\ H_{\epsilon,P} \end{pmatrix} \begin{bmatrix} \phi \\ \psi \end{bmatrix} + \begin{pmatrix} E^1_{\epsilon,P} \\ E^2_{\epsilon,P} \end{pmatrix} + \begin{pmatrix} O(\|\phi\|^2_{L^2(\Omega_{\epsilon,P})} + \|\psi\|^2_{L^t(\Omega)}) \\ O(\|\phi\|^2_{L^2(\Omega_{\epsilon,P})} + \|\psi\|^2_{L_t(\Omega)}) \end{pmatrix} = \begin{pmatrix} v_{\epsilon,P} \\ 0 \end{pmatrix},$$

(1.12)

where $v_{\epsilon,P}$ lies in an appropriately chosen approximate cokernel of the linear operator

$$L_\epsilon := \Delta_y - 1 + pA^{p-1}_{\epsilon,P} H^{-q}_{\epsilon,P} - \frac{qr}{s+1} \frac{\int_{\Omega_{\epsilon,P}} A^{r-1}_{\epsilon,P} \cdot}{\int_{\Omega_{\epsilon,P}} A^r_{\epsilon,P}} A^p_{\epsilon,P},$$

$$L_\epsilon : H^2(\Omega_{\epsilon,P}) \to L^2(\Omega_{\epsilon,P}),$$

and ϕ is orthogonal in $L^2(\Omega_{\epsilon,P})$ to the corresponding approximate kernel of L_ϵ.

(C) We solve (1.12) for (ϕ, ψ) module the approximate kernel. To this end, we need a detailed analysis of the operators L_ϵ and S'_ϵ. This together with the contraction mapping argument is done in section 4.

(D) In the last step, we study a vector field $P \to W_\epsilon(P)$ such that $W_\epsilon(P) = 0$ implies $v_{\epsilon,P} = 0$ (and hence solutions of system (1.6) can be found). To discuss the zeros of $P \to W_\epsilon(P)$ we need very good estimates for the error terms $E^1_{\epsilon,P}$ and $E^2_{\epsilon,P}$. Much of section 3 is devoted to this analysis. With a good estimate of $E^i_{\epsilon,P}, i = 1, 2$, we discover that under the geometric condition described in Theorem 1.1 there is a point P_ϵ in a small neighborhood of $P_0 \in \Omega$ such that $W_\epsilon(P_\epsilon) = 0$. This will complete the proof of Theorem 1.1 and is done in section 5.

Finally, we remark that the stability of the solutions constructed in Theorem 1.1 should be related to the matrix $(\nabla_i \nabla_j h(P_0))$. This will be studied in a forthcoming paper.

Throughout this paper, we always assume that $P \in B_r(P_0)$ for some fixed small number $r > 0$. We shall frequently use the following technical lemma.

LEMMA 1.2. *Let u be a solution of*

$$\Delta u - u + f = 0 \quad \text{in } \Omega, \qquad \frac{\partial u}{\partial \nu} = 0 \quad \text{on } \partial\Omega.$$

Suppose

$$|f(x)| \le \eta e^{-\frac{\alpha|x-P|}{\epsilon}}$$

for some $\alpha > 0$. Then if $\epsilon > 0$ is small enough we have

$$|u(P)| \le C_1 \eta \epsilon^2 \log \frac{1}{\epsilon} \tag{1.13}$$

and

$$|u(P)-u(x)| \le C_2\eta\epsilon^2 \log\left(\frac{|x-P|}{\epsilon}+1\right), \tag{1.14}$$

where $C_1>0, C_2>0$ are generic constants (which are independent of $\epsilon>0$ and $\eta>0$).

Proof. By the representation formula we calculate

$$u(x)=\int_\Omega G(x,z)f(z)dz$$

and

$$u(P)=\int_\Omega G(P,z)f(z)dz=\epsilon^2\int_{\Omega_{\epsilon,P}} G(P,P+\epsilon y)f(P+\epsilon y)dy$$

$$\le C_1\eta\epsilon^2\log\frac{1}{\epsilon}.$$

Similarly we can obtain (1.14). ∎

2. Study of the approximate solutions. In this section, we define a good approximate solution and study its properties. We will use the implicit function theorem and perturbation arguments. To this end, it is essential that we have the following important lemma.

LEMMA 2.1. *The operator*

$$L:=\Delta-1+pw^{p-1}-\frac{qr}{s+1}\frac{\int_{R^2} w^{r-1}.}{\int_{R^2} w^r}w^p$$

with w defined in (1.4) *is an invertible map from $H_r^2(R^2)$ to $L_r^2(R^2)$, where $H_r^2(R^2)$ ($L_r^2(R^2)$) is the subset of those functions of $H^2(R^2)$ ($L_r^2(R^2)$) that are radially symmetric.*

Proof. We just need to prove that

$$\text{kernel}(L)\cap H_r^2(R^2)=\{0\},\quad \text{kernel}(L^*)\cap H_r^2(R^2)=\{0\},$$

where L^* is the conjugate operator of L.

In fact, let $L\phi=0$ for $\phi\in H_r^2(R^2)$. Then we have

$$L_0\left(\phi-\frac{qr}{(p-1)(s+1)}\frac{\int_{R^2} w^{r-1}\phi}{\int_{R^2} w^r}w\right)=0,$$

where $L_0:=\Delta-1+pw^{p-1}$. By Lemma 4.2 of [30], $\phi-\frac{qr}{(p-1)(s+1)}\frac{\int_{R^2} w^{r-1}\phi}{\int_{R^2} w^r}w=0$. Multiplying this equation by w^{r-1} and integrating over R^2 we see that

$$\int_{R^2} w^{r-1}\phi=0.$$

Since $\frac{qr}{(p-1)(s+1)}>1$ we conclude $\phi=0$.

Next we claim that $\text{kernel}(L^*)\cap H_r^2(R^2)=\{0\}$. Let $\phi\in H_r^2(R^2)$ be such that $L^*\phi=0$. Namely, we have

$$L_0\phi-\frac{qr}{s+1}\frac{\int_{R^2} w^p\phi}{\int_{R^2} w^r}w^{r-1}=0. \tag{2.1}$$

Multiplying (2.1) by w and integrating over R^2, we obtain

$$\left(p-1-\frac{qr}{s+1}\right)\int_{R^2} w^p\phi = 0.$$

Since $p-1-\frac{qr}{s+1} < 0$ we get

$$\int_{R^2} w^p\phi = 0.$$

Hence $L_0\phi = 0$ and $\phi = 0$. □

We now study the following system:

$$\begin{cases} \epsilon^2\Delta A - A + \frac{A^p}{(H-\mathcal{Q}_\Omega H(P))^q} = 0, \quad x\in R^2, \\ \Delta H - H + c_{\epsilon,P}\frac{A^r}{(H-\mathcal{Q}_\Omega H(P))^s} = 0, \quad x\in R^2, \\ H(P) = 1 + O(\frac{1}{\log\frac{1}{\epsilon}}). \end{cases} \tag{2.2}$$

We have Theorem 2.2.

THEOREM 2.2. *For $\epsilon << 1$, there exists a unique solution $(\hat A_{\epsilon,P}(x), \hat H_{\epsilon,P}(x), c_{\epsilon,P})$ of (2.2) with the following properties:*

(1) *$\hat A_{\epsilon,P}(x)$ and $\hat H_{\epsilon,P}(x)$ depend on $|x-P|$ only;*

(2) *$\hat A_{\epsilon,P} = (1+o(1))w(\frac{|x-P|}{\epsilon})$;*

(3) *$\hat H_{\epsilon,P}(0) = 1 + O(\frac{1}{\log\frac{1}{\epsilon}})$;*

(4) *$\hat H_{\epsilon,P}(x) = \frac{\sigma_P}{\log\frac{1}{\epsilon}}K(|x-P|) + \frac{\epsilon}{\log\frac{1}{\epsilon}}J_{\epsilon,P}(|x-P|)$ for $|x|\geq\delta$, where $\sigma_P = 1+o(1)$, $J_{\epsilon,P}(|x-P|)$, $\nabla_x J_{\epsilon,P}(|x-P|) = O(1)$.*

Proof of Theorem 2.2. The proof is divided into the following steps:

Step 1. We first look for radially symmetric solutions $(A_{\epsilon,\mu}, H_{\epsilon,\mu}, c_{\epsilon,\mu})$ of the following parametrized equation:

$$\begin{cases} \epsilon^2\Delta A - A + \frac{A^p}{(H-\mu)^q} = 0, \quad x\in R^2, \\ \Delta H - H + c_{\epsilon,\mu}\frac{A^r}{(H-\mu)^s} = 0, \quad x\in R^2, \\ A(x) = A(|x|), \quad H(x) = H(|x|), \quad H(0) = 1 + O(\frac{1}{\log\frac{1}{\epsilon}} + \mu) \end{cases} \tag{2.3}$$

for $0 < \mu << 1$.

Problem (2.3) can be solved by the contraction mapping principle. We first need suitable approximate solutions. We note that the problem

$$\begin{cases} \Delta_y A - A + \frac{A^p}{(1-\mu)^q} = 0, \quad y\in R^2, \\ \Delta_x H - H + c_{\epsilon,\mu,0}\frac{A^r}{(H-\mu)^s} = 0, \quad x\in R^2, \\ x = \epsilon y, A(y) = A(|y|), H(x) = H(|x|), H(0) = 1 \end{cases} \tag{2.4}$$

has a unique solution $(A_{\epsilon,\mu,0}(y), H_{\epsilon,\mu,0}(x), c_{\epsilon,\mu,0})$ for $0 < \mu << 1$. In fact, it is well known that (for given μ small) the first equation has the unique positive solution $A_{\epsilon,\mu,0}(y) = (1-\mu)^{q/(p-1)}w(y)$ with maximum at 0 and decaying to 0 at infinity (compare equation (1.4)). It is also easy to see that for given μ and $A\in H^2(R^2)$, the second equation has a unique solution $H_{\epsilon,\mu,0}(x)\in H^2(R^2)$ (note that the nonlinearity is concave). To ensure that $H_{\epsilon,\mu,0}(0) = 1$, we just need to choose $c_{\epsilon,\mu,0}$. In fact, by the standard representation formula

$$H_{\epsilon,\mu,0}(x) = \int_{R^2} K(|x-z|)\, c_{\epsilon,\mu,0}\,(1-\mu)^{rq/(p-1)}(H_{\epsilon,\mu,0}-\mu)^{-s}(z)w^r\left(\frac{z}{\epsilon}\right)\,dz.$$

Taking $x = 0$, we obtain

$$c_{\epsilon,\mu,0} = (1-\mu)^{s-rq/(p-1)} \left(\int_{R^2} K(|z|) \left(1 + O\left(\frac{1}{\log \frac{1}{\epsilon}} + \mu \right) \right) w^r \left(\frac{z}{\epsilon} \right) \, dz \right)^{-1}$$
$$= (1-\mu)^{s-rq/(p-1)} \left(\epsilon^2 \left(1 + O\left(\left(\log \frac{1}{\epsilon} \right)^{-1} \right) + \mu \right) \int_{R^2} K(|\epsilon y|) w^r(y) \, dy \right)^{-1}$$
$$= (1-\mu)^{s-rq/(p-1)} \frac{1}{\epsilon^2 \log(1/\epsilon)} \left(\int_{R^2} w^r(y) \, dy \right)^{-1} + O\left(\frac{1/\log(1/\epsilon) + \mu}{\epsilon^2 \log(1/\epsilon) 2} \right)$$

as $\epsilon \to 0$.

(Here we have used the fact that (by Lemma 1.2)

$$|H_{\epsilon,\mu,0}(x) - H_{\epsilon,\mu,0}(0)| \le C \frac{1}{\log \frac{1}{\epsilon}} \log \left(\frac{|x-P|}{\epsilon} + 1 \right)$$

for some generic constant $C > 0$.)

Using the ansatz

$$A_{\epsilon,\mu}(y) = A_{\epsilon,\mu,0}(y) + a_{\epsilon,\mu}(y),$$

$$H_{\epsilon,\mu}(x) = H_{\epsilon,\mu,0}(x) + h_{\epsilon,\mu}(x),$$

and inserting it into (2.3) (with $c_{\epsilon,\mu} = c_{\epsilon,\mu,0}$) gives us

$$\Delta_y a_{\epsilon,\mu} - a_{\epsilon,\mu} = \frac{A^p_{\epsilon,\mu,0}}{(1-\mu)^q} - \frac{(A_{\epsilon,\mu,0} + a_{\epsilon,\mu})^p}{(H_{\epsilon,\mu,0} + h_{\epsilon,\mu} - \mu)^q},$$

$$\Delta_x h_{\epsilon,\mu} - h_{\epsilon,\mu} = c_{\epsilon,\mu,0} \frac{A^r_{\epsilon,\mu,0}}{(H_{\epsilon,\mu,0} - \mu)^s} - c_{\epsilon,\mu,0} \frac{(A_{\epsilon,\mu,0} + a_{\epsilon,\mu})^r}{(H_{\epsilon,\mu,0} + h_{\epsilon,\mu} - \mu)^s}.$$

The first equation can be rewritten as follows:

$$\Delta_y a_{\epsilon,\mu} - a_{\epsilon,\mu} + \frac{p A^{p-1}_{\epsilon,\mu,0} a_{\epsilon,\mu}}{(1-\mu)^q} - \frac{q A^p_{\epsilon,\mu,0} h_{\epsilon,\mu}}{(1-\mu)^{q+1}} = e_1,$$

where

$$e_1 = \frac{(A_{\epsilon,\mu,0} + a_{\epsilon,\mu})^p}{(1 + h_{\epsilon,\mu} - \mu)^q} - \frac{(A_{\epsilon,\mu,0} + a_{\epsilon,\mu})^p}{(H_{\epsilon,\mu,0} + h_{\epsilon,\mu} - \mu)^q}$$
$$- \frac{(A_{\epsilon,\mu,0} + a_{\epsilon,\mu})^p}{(1 + h_{\epsilon,\mu} - \mu)^q} + \frac{A^p_{\epsilon,\mu,0}}{(1-\mu)^q} + \frac{p A^{p-1}_{\epsilon,\mu,0} a_{\epsilon,\mu}}{(1-\mu)^q} - \frac{q A^p_{\epsilon,\mu,0} h_{\epsilon,\mu}}{(1-\mu)^{q+1}}.$$

This implies

$$\|e_1(y)\|_{L^2(R^2)} = O\left(\|a_{\epsilon,\mu}(y)\|^2_{L^2(R^2)} \right) + O(\|h_{\epsilon,\mu}(x)\|^2_{L^\infty(\Omega)}) + O\left(\frac{1}{\log \frac{1}{\epsilon}} + \mu \right).$$

For a given $a_{\epsilon,\mu}$, we can solve the second equation directly since the nonlinearity is concave. Moreover, we have that $h_{\epsilon,\mu}$ satisfies

$$\Delta_x h_{\epsilon,\mu} - h_{\epsilon,\mu} + c_{\epsilon,\mu} \frac{r A^{r-1}_{\epsilon,\mu,0} a_{\epsilon,\mu}}{(H_{\epsilon,\mu,0} - \mu)^s} - c_{\epsilon,\mu} \frac{s A^r_{\epsilon,\mu,0} h_{\epsilon,\mu}}{(H_{\epsilon,\mu,0} - \mu)^{s+1}} = e_2,$$

where

$$e_2 = c_{\epsilon,\mu}\frac{A^r_{\epsilon,\mu,0}}{(H_{\epsilon,\mu,0}-\mu)^s} - c_{\epsilon,\mu}\frac{(A_{\epsilon,\mu,0}+a_{\epsilon,\mu})^r}{(H_{\epsilon,\mu,0}-\mu)^s}$$

$$+c_{\epsilon,\mu}\frac{rA^{r-1}_{\epsilon,\mu,0}a_{\epsilon,\mu}}{(H_{\epsilon,\mu,0}-\mu)^s} - c_{\epsilon,\mu}\frac{sA^r_{\epsilon,\mu,0}h_{\epsilon,\mu}}{(H_{\epsilon,\mu,0}-\mu)^{s+1}}.$$

This implies

$$\|e_2\|_{L^2(R^2)} = O(\|a_{\epsilon,\mu}\|^2_{L^2(R^2)}) + O(\|h_{\epsilon,\mu}\|^2_{L^\infty(\Omega)}\|A^{r-1}_{\epsilon,\mu,0}\|_{L^2(R^2)}).$$

Thus by Lemma 1.2

$$h_{\epsilon,\mu}(x) = h_{\epsilon,\mu}(0) + O\left(\frac{1}{\log\frac{1}{\epsilon}}\right)$$

and

$$h_{\epsilon,\mu}(0) = \int_{R^2} K(z)\left[c_{\epsilon,\mu}\frac{rA^{r-1}_{\epsilon,\mu,0}a_{\epsilon,\mu}}{(H_{\epsilon,\mu,0}-\mu)^s} - c_{\epsilon,\mu}\frac{sA^r_{\epsilon,\mu,0}h_{\epsilon,\mu}}{(H_{\epsilon,\mu,0}-\mu)^{s+1}}\right] + O(\|a_{\epsilon,\mu}\|^2_{L^2(R^2)})$$

$$= c_{\epsilon,\mu}\int_{R^2} rA^{r-1}_{\epsilon,\mu,0}a_{\epsilon,\mu}\left(1+O\left(\frac{1}{\log\frac{1}{\epsilon}}+\mu\right)\right)$$

$$-c_{\epsilon,\mu}sh_{\epsilon,\mu}(0)\int_{R^2} A^r_{\epsilon,\mu,0}\left(1+O\left(\frac{1}{\log\frac{1}{\epsilon}}+\mu\right)\right) + O(\|a_{\epsilon,\mu}\|^2_{L^2(R^2)}).$$

Therefore

$$h_{\epsilon,\mu}(0) = \frac{r}{s+1}\frac{\int A^{r-1}_{\epsilon,\mu,0}a_{\epsilon,\mu}}{\int A^r_{\epsilon,\mu,0}} + O\left(\frac{1}{\log\frac{1}{\epsilon}}+\mu\right) + O(\|a_{\epsilon,\mu}\|^2_{L^2(R^2)}).$$

Substituting this into the first equation, the equation for $a_{\epsilon,\mu}$ becomes

$$\Delta_y a_{\epsilon,\mu} - a_{\epsilon,\mu} + \frac{pA^{p-1}_{\epsilon,\mu,0}a_{\epsilon,\mu}}{(1-\mu)^q} - \frac{qrA^p_{\epsilon,\mu,0}}{(s+1)(1-\mu)^{q+1}}\frac{\int_{R^2} A^{r-1}_{\epsilon,\mu,0}a_{\epsilon,\mu}}{\int_{R^2} A^r_{\epsilon,\mu,0}}$$

$$= e_1 + O\left(\frac{1}{\log\frac{1}{\epsilon}}+\mu\right) + O(\|a_{\epsilon,\mu}\|^2_{L^2(R^2)})$$

in $L^2(R^2)$.

By Lemma 2.1 and a perturbation argument for $\epsilon << 1, \mu << 1$, the equation for $a_{\epsilon,\mu}$ can be solved and the solution is unique. Thus we have obtained a solution to (2.3).

Step 2. We choose μ such that

$$\mu = H_{\epsilon,\mu}(0) - \mathcal{P}_\Omega(H_{\epsilon,\mu}(\cdot - P))(P). \tag{2.5}$$

To this end, we note that this is equivalent to

$$\mu = \int_{R^2}(K(|z|) - G(P,P+z))\,c_{\epsilon,\mu}\,(H_{\epsilon,\mu}(z)-\mu)^{-s}A^r_{\epsilon,\mu}\left(\frac{z}{\epsilon}\right)\,dz$$

$$= \int_{R^2} H(P, P+z) c_{\epsilon,\mu} (H_{\epsilon,\mu}(z) - \mu)^{-s} A^r_{\epsilon,\mu}\left(\frac{z}{\epsilon}\right) dz$$

$$= H(P,P) c_{\epsilon,\mu} \int_{R^2} (H_{\epsilon,\mu}(z) - \mu)^{-s} A^r_{\epsilon,\mu}\left(\frac{z}{\epsilon}\right) dz$$

$$+ O(\epsilon) \int_{R^2} |z| c_{\epsilon,\mu} (H_{\epsilon,\mu}(z) - \mu)^{-s} A^r_{\epsilon,\mu}\left(\frac{z}{\epsilon}\right) dz.$$

Since $c_{\epsilon,\mu} \int_{R^2} (H_{\epsilon,\mu}(z) - \mu)^{-s} A^r_{\epsilon,\mu}(\frac{z}{\epsilon}) dz = \frac{1+o(1)}{\log \frac{1}{\epsilon}}$, it is easy to see that by the contraction mapping principle, (1.9) has a unique solution $\mu = \mu_\epsilon(P)$.

We further calculate

$$\mu = \frac{1+o(1)}{\log \frac{1}{\epsilon}} \left[H(P,P) + O\left(\frac{1}{\log \frac{1}{\epsilon}}\right)\right]$$

as $\epsilon \to 0$.

Now let

$$\hat{A}_{\epsilon,P}(x) = A_{\epsilon,\mu}(x-P), \quad \hat{H}_{\epsilon,P}(x) = H_{\epsilon,\mu}(x-P), \quad c_{\epsilon,P} = c_{\epsilon,\mu},$$

where $\mu := \mu_\epsilon(P)$ is given by (1.9).

It is easy to see that (1), (2), and (3) of Theorem 1.1 are satisfied. It remains to prove statement (4) of Theorem 2.2. We have for $|x| \geq \delta$,

$$\hat{H}_{\epsilon,P}(x) = \frac{\epsilon^2 \int_{R^2} K(|x-P-\epsilon y|) \frac{A^r_{\epsilon,\mu}(y)}{H^s_{\epsilon,\mu}} dy}{\int_{R^2} K(|\epsilon y|) \frac{A^r_{\epsilon,\mu}(y)}{H^s_{\epsilon,\mu}} dy}$$

$$= \frac{\sigma_P}{\log \frac{1}{\epsilon}} [K(|x-P|) + O(\epsilon)], \quad \sigma_P = 1 + o(1)$$

as $\epsilon \to 0$.

This implies Theorem 2.2. □

3. Estimates of the error terms. In this section, we give some preliminary estimates. These will be used in the later sections.

Recall that we choose our approximate solution as follows:

$$A_{\epsilon,P}(y) = \mathcal{P}_{\Omega_{\epsilon,P}} \hat{A}_{\epsilon,P}, \quad H_{\epsilon,P}(x) = \mathcal{P}_\Omega \hat{H}_{\epsilon,P}(x).$$

Note that in this case

$$\mu = \mathcal{Q}_\Omega \hat{H}_{\epsilon,P}(P).$$

Also recall that

$$\varphi_{\epsilon,P}(y) = \mathcal{Q}_{\Omega_{\epsilon,P}} \hat{A}_{\epsilon,P} = \hat{A}_{\epsilon,P} - A_{\epsilon,P}, \quad \psi_{\epsilon,P}(x) = \mathcal{Q}_\Omega \hat{H}_{\epsilon,P} = \hat{H}_{\epsilon,P} - H_{\epsilon,P}.$$

We note that $\varphi_{\epsilon,P}$ satisfies

$$\Delta_y \varphi_{\epsilon,P} - \varphi_{\epsilon,P} = 0 \quad \text{in } \Omega_{\epsilon,P},$$

$$\frac{\partial \varphi_{\epsilon,P}}{\partial \nu} = \frac{\partial \hat{A}_{\epsilon,P}}{\partial \nu} = O(e^{-d(P,\partial\Omega)/\epsilon}) \quad \text{on } \partial\Omega_{\epsilon,P}.$$

Hence

$$\|\varphi_{\epsilon,P}\|_{H^2(\Omega_{\epsilon,P})} = O(e^{-d(P,\partial\Omega)/\epsilon}). \tag{3.1}$$

By Theorem 2.2 we have

$$\mathcal{P}_\Omega \hat{H}_{\epsilon,P}(x) = \frac{\int_{\Omega_{\epsilon,P}} G(x, P+\epsilon y) \frac{\hat{A}^r_{\epsilon,P}(y)}{(\hat{H}_{\epsilon,P}-\mu_\epsilon(P))^s}\, dy}{\int_{R^2} K(|\epsilon y|) \frac{\hat{A}^r_{\epsilon,P}(y)}{(\hat{H}_{\epsilon,P}-\mu_\epsilon(P))^s}\, dy}$$

$$= \frac{1+o(1)}{\log\frac{1}{\epsilon}}[K(|x-P|) - H(x,P) + O(\epsilon)].$$

This implies

$$\psi_{\epsilon,P}(x) = \hat{H}_{\epsilon,P}(x) - \mathcal{P}_\Omega \hat{H}_{\epsilon,P}(x-P) = \frac{1+o(1)}{\log\frac{1}{\epsilon}}[H(x,P) + O(\epsilon)]$$

or, equivalently,

$$\psi_{\epsilon,P}(x) = \frac{1+o(1)}{\log\frac{1}{\epsilon}} H(P,x) + O\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right). \tag{3.2}$$

By (3.1) and (3.2), we see that the term involving $\varphi_{\epsilon,P}$ can be neglected. This is what we will do in the later sections.

The reason for choosing $A_{\epsilon,\mu}$ and $H_{\epsilon,P}$ as we did lies in the two following estimates:

$$S_1(A_{\epsilon,P}, H_{\epsilon,P}) = \Delta_y A_{\epsilon,P} - A_{\epsilon,P} + \frac{A^p_{\epsilon,P}}{H^q_{\epsilon,P}}$$

$$= \frac{(\hat{A}_{\epsilon,P}-\varphi_{\epsilon,P})^p}{(\hat{H}_{\epsilon,P}-\psi_{\epsilon,P})^q} - \frac{(\hat{A}_{\epsilon,P})^p}{(\hat{H}_{\epsilon,P}-\psi_{\epsilon,P}(P))^q}$$

$$= O(e^{-d(P,\partial\Omega)/\epsilon}) + (\hat{A}_{\epsilon,P})^p[(\hat{H}_{\epsilon,P}-\psi_{\epsilon,P})^{-q} - (\hat{H}_{\epsilon,P}-\psi_{\epsilon,P}(P))^{-q}] \quad \text{(by (3.1))}$$

$$= O(e^{-d(P,\partial\Omega)/\epsilon}) - q(\hat{A}_{\epsilon,P})^p(\hat{H}_{\epsilon,P})^{-q-1}(\psi_{\epsilon,P}(x)-\psi_{\epsilon,P}(P)) + O\left(\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right)^2 \hat{A}^p_{\epsilon,P}\right)$$

for a.e. $y \in \Omega_{\epsilon,P}$. Similarly we have

$$S_2(A_{\epsilon,P}, H_{\epsilon,P}) = \Delta_x H_{\epsilon,P} - H_{\epsilon,P} + c_{\epsilon,P}\frac{A^r_{\epsilon,P}}{H^s_{\epsilon,P}}$$

$$= O(e^{-d(P,\partial\Omega)/\epsilon}) - sc_{\epsilon,P}(\hat{A}_{\epsilon,P})^r(\hat{H}_{\epsilon,P})^{-s-1}(\psi_{\epsilon,P}(x)-\psi_{\epsilon,P}(P)) + O\left(c_{\epsilon,P}\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right)^2 \hat{A}^r_{\epsilon,P}\right)$$

for a.e. $x \in \Omega$.

We have thus obtained Lemma 3.1.

LEMMA 3.1. *We have*

$$\begin{aligned} S_1(A_{\epsilon,P}, H_{\epsilon,P}) &= O(e^{-d(P,\partial\Omega)/\epsilon}) - q(\hat{A}_{\epsilon,P})^p(\hat{H}_{\epsilon,P})^{-q-1}(\psi_{\epsilon,P}(x)-\psi_{\epsilon,P}(P)) \\ &+ O\left(\left(\tfrac{\epsilon}{\log\frac{1}{\epsilon}}\right)^2 \hat{A}^p_{\epsilon,P}\right) \end{aligned} \tag{3.3}$$

for a.e. $y \in \Omega_{\epsilon,P}$.

$$S_2(A_{\epsilon,P}, H_{\epsilon,P})$$

$$= O(e^{-d(P,\partial\Omega)/\epsilon}) - sc_{\epsilon,P}(\hat{A}_{\epsilon,P})^r(\hat{H}_{\epsilon,P})^{-s-1}(\psi_{\epsilon,P}(x) - \psi_{\epsilon,P}(P)) + O\left(c_{\epsilon,P}\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right)^2 \hat{A}^r_{\epsilon,P}\right)$$

(3.4)

for a.e. $x \in \Omega$.

Hence

$$\|S_1(A_{\epsilon,P}, H_{\epsilon,P})\|_{L^2(\Omega_{\epsilon,P})} = O\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right), \tag{3.5}$$

$$\|S_2(A_{\epsilon,P}, H_{\epsilon,P})\|_{L^t(\Omega)} = O\left(\epsilon^{2t^{-1}-1}\left(\frac{1}{\log\frac{1}{\epsilon}}\right)^2\right) \tag{3.6}$$

for any $1 < t < 1.1$.

Proof. The lemma is proved by direct computation. □

4. The Liapunov–Schmidt reduction method. This section is devoted to studying the linearized operator defined by

$$\tilde{L}_{\epsilon,P} := S'_\epsilon \begin{pmatrix} A_{\epsilon,P} \\ H_{\epsilon,P} \end{pmatrix},$$

$$\tilde{L}_{\epsilon,P} : H^2_N(\Omega_{\epsilon,P}) \times W^{2,t}_N(\Omega) \to L^2(\Omega_{\epsilon,P}) \times L^t(\Omega),$$

where $1 < t < 1.1$ is a fixed number.

Set

$$K_{\epsilon,P} := \text{span}\left\{\frac{\partial A_{\epsilon,P}}{\partial P_j}\middle| j = 1, \dots, N\right\} \subset H^2_N(\Omega_{\epsilon,P}),$$

$$C_{\epsilon,P} := \text{span}\left\{\frac{\partial A_{\epsilon,P}}{\partial P_j}\middle| j = 1, \dots, N\right\} \subset L^2(\Omega_{\epsilon,P}),$$

$$L_\epsilon := \Delta - 1 + pA^{p-1}_{\epsilon,P}H^{-q}_{\epsilon,P} - \frac{qr}{s+1}\frac{\int_{\Omega_{\epsilon,P}} A^{r-1}_{\epsilon,P}\cdot}{\int_{\Omega_{\epsilon,P}} A^r_{\epsilon,P}}A^p_{\epsilon,P},$$

and

$$L_{\epsilon,P} := \pi_{\epsilon,P} \circ L_\epsilon : K^\perp_{\epsilon,P} \to C^\perp_{\epsilon,P},$$

where $\pi_{\epsilon,P}$ is the projection in $L^2(\Omega_{\epsilon,P})$ onto $C^\perp_{\epsilon,P}$.

We remark that since $A_{\epsilon,P}(y) = (1 + O(\frac{1}{\log\frac{1}{\epsilon}}))w(y)$, it is easy to see that

$$l_{\epsilon,P} := \pi_{\epsilon,P} \circ (\Delta - 1 + pA^{p-1}_{\epsilon,P}) : K^\perp_{\epsilon,P} \to C^\perp_{\epsilon,P}$$

is a one to one and surjective map. For the proof please see the proof of Propositions 6.1–6.2 in [41].

The following proposition is the key estimate in applying the Liapunov–Schmidt reduction method.

PROPOSITION 4.1. *For ϵ sufficiently small, the map $L_{\epsilon,P}$ is a one-to-one and surjective map. Moreover the inverse of $L_{\epsilon,P}$ exists and is bounded uniformly with respect to ϵ.*

Proof. We will follow the method used in [11], [35], [36], [41], and [44]. We first show that there exist constants $C > 0, \bar{\epsilon} > 0$ such that for all $\epsilon \in (0, \bar{\epsilon})$,

$$\|L_{\epsilon,P}\Phi\|_{L^2(\Omega_{\epsilon,P})} \geq C\|\Phi\|_{H^2(\Omega_{\epsilon,P})} \tag{4.1}$$

for all $\Phi \in K^{\perp}_{\epsilon,P}$.

Suppose that (4.1) is false. Then there exist sequences $\{\epsilon_k\}$, $\{P_k\}$, and $\{\phi_k\}$ with $P_k \in \Omega$, $\phi_k \in K^{\perp}_{\epsilon_k,P_k}$ such that

$$\|L_{\epsilon_k,P_k}\phi_k\|_{L^2(\Omega_{\epsilon_k,P_k})} \to 0, \tag{4.2}$$

$$\|\phi_k\|_{H^2(\Omega_{\epsilon_k,P_k})} = 1, \qquad k = 1, 2, \ldots . \tag{4.3}$$

Namely, we have the following situation:

$$\Delta_y\phi_k - \phi_k + pA^{p-1}_{\epsilon_k,P_k}H^{-q}_{\epsilon_k,P_k}\phi_k - \frac{qr}{s+1}\frac{\int_{\Omega_{\epsilon_k,P_k}} A^{r-1}_{\epsilon_k,P_k}\phi_k}{\int_{\Omega_{\epsilon_k,P_k}} A^{r}_{\epsilon_k,P_k}}A^{p}_{\epsilon_k,P_k} = f_k, \tag{4.4}$$

where

$$\|f_k\|_{L^2(\Omega_{\epsilon_k,P_k})} \to 0,$$

$$\phi_k \in K^{\perp}_{\epsilon_k,P_k}, \quad \|\phi_k\|_{H^2(\Omega_{\epsilon_k,P_k})} = 1. \tag{4.5}$$

We now show that this is impossible. Set $A_k = A_{\epsilon_k,P_k}, \Omega_k = \Omega_{\epsilon_k,P_k}$.

Note that

$$H_{\epsilon_k,P_k} = 1 + o(1) \ \text{ in } L^{\infty}(\Omega),$$

$$(\Delta_y - 1 + pA^{p-1}_k)\frac{A_k}{p-1} = A^p_k + o(1) \text{ in } L^2(\Omega_k).$$

Thus we have

$$(\Delta_y - 1 + pA^{p-1}_k)\left(\phi_k - \frac{qr}{(s+1)(p-1)}\frac{\int_{\Omega_k} A^{r-1}_k\phi_k}{\int_{\Omega_k} A^r_k}A_k\right) = f_k + o(1) \text{ in } L^2(\Omega_k).$$

Since the projection of A_k into K_{ϵ_k,P_k} is $o(1)$ in $H^2(\Omega_k)$ and the operator

$$\Delta_y - 1 + pA^{p-1}_k$$

is a one-to-one and invertible map (with the inverse bounded uniformly with respect to ϵ) from $K^{\perp}_{\epsilon_k,P_k}$ to $C^{\perp}_{\epsilon_k,P_k}$, we have

$$\phi_k - \frac{qr}{(s+1)(p-1)}\frac{\int_{\Omega_k} A^{r-1}_k\phi_k}{\int_{\Omega_k} A^r_k}A_k = o(1) \text{ in } H^2(\Omega_k). \tag{4.6}$$

Since $\frac{qr}{(p-1)(s+1)} > 1$, (4.6) implies that

$$\|\phi_k\|_{H^2(\Omega_k)} = o(1).$$

This is a contradiction!

Thus (4.1) holds and $L_{\epsilon,P}$ is a one-to-one map.

Next we show that $L_{\epsilon,P}$ is also surjective. To this end, we just need to show that the conjugate of $L_{\epsilon,P}$ (denoted by $L^*_{\epsilon,P}$) is injective from $K^\perp_{\epsilon,P}$ to $C^\perp_{\epsilon,P}$.

Let $L^*_{\epsilon,P}\phi \in C^\perp_{\epsilon,P}$, $\phi \in K^\perp_{\epsilon,P}$. Namely, we have

$$\Delta_y\phi - \phi + pA^{p-1}_{\epsilon,P}H^{-q}_{\epsilon,P}\phi - \frac{qr}{s+1}\frac{\int_{\Omega_{\epsilon,P}} A^p_{\epsilon,P}\phi}{\int_{\Omega_{\epsilon,P}} A^r_{\epsilon,P}}A^{r-1}_{\epsilon,P} \in C_{\epsilon,P}. \tag{4.7}$$

We can assume that $\|\phi\|_{H^2(\Omega_{\epsilon,P})} = 1$.

Multiplying (4.7) by $A_{\epsilon,P}$ and integrating over $\Omega_{\epsilon,P}$, we obtain

$$\left(p - 1 - \frac{qr}{s+1}\right)\int_{\Omega_{\epsilon,P}} A^p_{\epsilon,P}\phi = o(1)$$

or, equivalently,

$$\int_{\Omega_{\epsilon,P}} A^p_{\epsilon,P}\phi = o(1).$$

Hence ϕ satisfies

$$\Delta_y\phi - \phi + pA^{p-1}_{\epsilon,P}H^{-q}_{\epsilon,P}\phi + o(1) \in C_{\epsilon,P}, \quad \phi \in K^\perp_{\epsilon,P},$$

which implies that $\|\phi\|_{H^2(\Omega_{\epsilon,P})} = o(1)$. This is a contradiction!

Therefore, $L_{\epsilon,P}$ is also surjective. □

We now deal with system (1.6).

$\tilde{L}_{\epsilon,P}$ is not uniformly invertible in ϵ due to the approximate kernel

$$\mathcal{K}_{\epsilon,P} := K_{\epsilon,P} \oplus \{0\} \subset H^2_N(\Omega_{\epsilon,P}) \times W^{2,t}_N(\Omega).$$

We choose the approximate cokernel as follows:

$$\mathcal{C}_{\epsilon,P} := C_{\epsilon,P} \oplus \{0\} \subset L^2(\Omega_{\epsilon,P}) \times L^t(\Omega).$$

We then define

$$\mathcal{K}^\perp_{\epsilon,P} := K^\perp_{\epsilon,P} \oplus W^{2,t}_N(\Omega) \subset H^2_N(\Omega_{\epsilon,P}) \times W^{2,t}_N(\Omega),$$
$$\mathcal{C}^\perp_{\epsilon,P} := C^\perp_{\epsilon,P} \oplus L^t(\Omega) \subset L^2(\Omega_{\epsilon,P}) \times L^t(\Omega).$$

Let $\pi_{\epsilon,P}$ denote the projection in $L^2(\Omega_{\epsilon,P}) \times L^t(\Omega)$ onto $\mathcal{C}^\perp_{\epsilon,P}$. (Here the projection in the second component is the identity map.) We then show that the equation

$$\pi_{\epsilon,P} \circ S_\epsilon \begin{pmatrix} A_{\epsilon,P} + \Phi_{\epsilon,P} \\ H_{\epsilon,P} + \Psi_{\epsilon,P} \end{pmatrix} = 0$$

has the unique solution

$$\Sigma_{\epsilon,P} = \begin{pmatrix} \Phi_{\epsilon,P}(y) \\ \Psi_{\epsilon,P}(x) \end{pmatrix} \in \mathcal{K}^\perp_{\epsilon,P}$$

if ϵ is small enough.

As a preparation in the following two propositions we show the invertibility of the corresponding linearized operator.

PROPOSITION 4.2. *Let $\mathcal{L}_{\epsilon,P} = \pi_{\epsilon,P} \circ \tilde{L}_{\epsilon,P}$. There exist positive constants $\overline{\epsilon}, \lambda$ such that for all $\epsilon \in (0, \overline{\epsilon})$,*

$$\|\mathcal{L}_{\epsilon,P}\Sigma\|_{L^2(\Omega_{\epsilon,P})\times L^t(\Omega)} \geq \lambda \|\Sigma\|_{H^2(\Omega_{\epsilon,P})\times W^{2,t}(\Omega)} \tag{4.8}$$

for all $\Sigma \in \mathcal{K}^{\perp}_{\epsilon,P}$.

PROPOSITION 4.3. *There exists a positive constant $\overline{\overline{\epsilon}}$ such that for all $\epsilon \in (0, \overline{\overline{\epsilon}})$, the map*

$$\mathcal{L}_{\epsilon,P} = \pi_{\epsilon,P} \circ \tilde{L}_{\epsilon} : \mathcal{K}^{\perp}_{\epsilon,P} \to \mathcal{C}^{\perp}_{\epsilon,P}$$

is surjective.

Proof of Proposition 4.2. This proposition follows from Proposition 4.1. In fact, suppose that (4.8) is false. Then there exist sequences $\{\epsilon_k\}$, $\{P_k\}$, and $\{\Sigma_k\}$ with

$$P_k \in \Omega, \qquad \Sigma_k = \begin{pmatrix} \phi_k(y) \\ \psi_k(x) \end{pmatrix} \in \mathcal{K}^{\perp}_{\epsilon_k,P_k}$$

such that

$$\|\mathcal{L}_{\epsilon_k,P_k}\Sigma_k\|_{L^2(\Omega_{\epsilon_k,P_k})\times L^t(\Omega)} \to 0, \tag{4.9}$$

$$\|\Sigma_k\|_{H^2(\Omega_{\epsilon_k,P_k})\times W^{2,t}(\Omega)} = 1, \qquad k = 1, 2, \ldots . \tag{4.10}$$

Namely, we have the following situation:

$$\Delta_y\phi_k - \phi_k + pA^{p-1}_{\epsilon_k,P_k}H^{-q}_{\epsilon_k,P_k}\phi_k - qA^{p}_{\epsilon_k,P_k}H^{-q-1}_{\epsilon_k,P_k}\psi_k = f_k, \quad \|f_k\|_{L^2(\Omega_{\epsilon_k,P_k})} \to 0, \tag{4.11}$$

$$\Delta_x\psi_k - \psi_k + rc_{\epsilon_k,P_k}A^{r-1}_{\epsilon_k,P_k}H^{-s}_{\epsilon_k,P_k}\phi_k - sc_{\epsilon_k,P_k}A^{r}_{\epsilon_k,P_k}H^{-s-1}_{\epsilon_k,P_k}\psi_k = g_k, \tag{4.12}$$

where

$$\|g_k\|_{L^t(\Omega)} \to 0,$$

$$\phi_k \in K^{\perp}_{\epsilon_k,P_k}, \tag{4.13}$$

$$\|\phi_k\|^2_{H^2(\Omega_{\epsilon_k,P_k})} + \|\psi_k\|^2_{W^{2,t}(\Omega)} = 1. \tag{4.14}$$

We now show that this is impossible. Set $A_k = A_{\epsilon_k,P_k}, \Omega_k = \Omega_{\epsilon_k,P_k}$.

We first note that by (4.12) we have

$$\|\psi_k\|_{L^\infty(\Omega)} \leq C$$

and hence by Lemma 1.2 and Sobolev embedding,

$$|\psi_k(x) - \psi_k(P_k)| \leq C|x - P_k|^\alpha + \frac{1}{\log\frac{1}{\epsilon}} \log\left(\frac{|x-P|}{\epsilon} + 1\right)$$

for some $\alpha > 0$ since $t > 1$. Thus

$$\|A^p_k(\psi_k - \psi_k(P_k))\|_{L^2(\Omega_k)} \to 0, \quad k = 1, 2, \ldots \quad \text{in} \quad L^2(\Omega_k). \tag{4.15}$$

Moreover by (4.12),

$$\psi_k(P_k) = \int_{\Omega_k} G(P,z)(rc_{\epsilon_k,P_k}A^{r-1}_k H^{-s}_{\epsilon_k,P_k}\phi_k - sc_{\epsilon_k,P_k}A^{r}_k H^{-s-1}_{\epsilon_k,P_k}\psi_k - g_k)$$

$$= (1+o(1))rc_{\epsilon_k,P_k}\log\frac{1}{\epsilon_k}\int_{\Omega_k}A^{r-1}_{\epsilon_k,P_k}\phi_k - (1+o(1))s\psi_k(P_k)c_{\epsilon_k,P_k}\int_{\Omega_k}A^r_k + o(1).$$

Therefore

$$\psi_k(P_k) = \frac{r}{s+1}\frac{\int_{\Omega_k}A^{r-1}_k\phi_k}{\int_{\Omega_k}A^r_k} + o(1).$$

Thus we have

$$L_{\epsilon_k,P_k}\phi_k = o(1) \quad \text{in} \quad L^2(\Omega_k), \quad \phi_k \in K^{\perp}_{\epsilon_k,P_k}. \tag{4.16}$$

By Proposition 4.1, $\|\phi_k\|_{H^2(\Omega_k)} = o(1)$. Hence $\psi_k(P_k) = o(1)$ and by elliptic estimates $\|\psi_k\|_{W^{2,t}(\Omega)} = o(1)$.

This contradicts assumption (4.14) and the proof of Proposition 4.2 is complete. □

Proof of Proposition 4.3. We just need to show that the conjugate operator of $\mathcal{L}_{\epsilon,P}$ (denoted by $\mathcal{L}^*_{\epsilon,P}$) is injective from $\mathcal{K}^{\perp}_{\epsilon,P}$ to $\mathcal{C}^{\perp}_{\epsilon,P}$. Suppose not. Then there exist $\phi \in K^{\perp}_{\epsilon,P}$, $\psi \in W^{2,t}(\Omega)$ such that

$$\Delta_y\phi - \phi + pA^{p-1}_{\epsilon,P}H^{-q}_{\epsilon,P}\phi + rc_{\epsilon,P}A^{r-1}_{\epsilon,P}H^{-s}_{\epsilon,P}\psi \in C^{\perp}_{\epsilon,P},$$

$$\Delta_x\psi - \psi - sc_{\epsilon,P}A^r_{\epsilon,P}H^{-s-1}_{\epsilon,P}\psi - qA^p_{\epsilon,P}H^{-q-1}_{\epsilon,P}\phi = 0,$$

$$\|\phi\|^2_{H^2(\Omega_{\epsilon,P})} + \|\psi\|^2_{W^{2,t}(\Omega)} = 1.$$

Similar to the proof of Proposition 4.2, we have

$$\psi(P) = -(1+o(1))c_{\epsilon,P}\frac{q}{s+1}\frac{\int_{\Omega_{\epsilon,P}}A^p_{\epsilon,P}\phi}{\int_{\Omega_{\epsilon,P}}A^r_{\epsilon,P}}$$

and substituting into the equation for ϕ we obtain

$$L_{\epsilon,P}\phi + o(1) \in C^{\perp}_{\epsilon,P}, \quad \phi \in K^{\perp}_{\epsilon,P}.$$

By Proposition 4.1, $\|\phi\|_{H^2(\Omega_{\epsilon,P})} = o(1)$, and hence $\|\psi\|_{W^{2,t}(\Omega)} = o(1)$. This is a contradiction! □

Now we are in a position to solve the equation

$$\pi_{\epsilon,P}\circ S_\epsilon\begin{pmatrix} A_{\epsilon,P}+\phi \\ H_{\epsilon,P}+\psi \end{pmatrix} = 0. \tag{4.17}$$

Since $\mathcal{L}_{\epsilon,P}|_{\mathcal{K}^{\perp}_{\epsilon,P}}$ is invertible (call the inverse $\mathcal{L}^{-1}_{\epsilon,P}$) we can rewrite

$$\Sigma = -(\mathcal{L}^{-1}_{\epsilon,P}\circ\pi_{\epsilon,P})\left(S_\epsilon\begin{pmatrix} A_{\epsilon,P} \\ H_{\epsilon,P}\end{pmatrix}\right) - (\mathcal{L}^{-1}_{\epsilon,P}\circ\pi_{\epsilon,P})N_{\epsilon,P}(\Sigma) \equiv M_{\epsilon,P}(\Sigma), \tag{4.18}$$

where

$$N_{\epsilon,P}(\Sigma) = S_\epsilon\begin{pmatrix} A_{\epsilon,P}+\phi \\ H_{\epsilon,P}+\psi\end{pmatrix} - S_\epsilon\begin{pmatrix} A_{\epsilon,P} \\ H_{\epsilon,P}\end{pmatrix} - S'_\epsilon\begin{pmatrix} A_{\epsilon,P} \\ H_{\epsilon,P}\end{pmatrix}\begin{bmatrix} \phi \\ \psi\end{bmatrix}$$

and the operator $M_{\epsilon,P}$ is defined by the last equation for $\Sigma \in H^2_N(\Omega_{\epsilon,P}) \times W^{2,t}(\Omega)$. We are going to show that the operator $M_{\epsilon,P}$ is a contraction on

$$B_{\epsilon,\delta} \equiv \{\Sigma \in H^2(\Omega_{\epsilon,P}) \times W^{2,t}(\Omega) | \|\Sigma\|_{H^2(\Omega_{\epsilon,P})\times W^{2,t}(\Omega)} < \delta\}$$

if δ is small enough. We have by Lemma 3.1 and Propositions 4.2 and 4.3,

$$\begin{aligned}
&\|M_{\epsilon,P}(\Sigma)\|_{H^2(\Omega_{\epsilon,P})\times W^{2,t}(\Omega)} \\
&\le \lambda^{-1}\left(\|\pi_{\epsilon,P}\circ N_{\epsilon,P}(\Sigma)\|_{L^2(\Omega_{\epsilon,P})\times L^t(\Omega)} + \left\|\pi_{\epsilon,P}\circ S_\epsilon\begin{pmatrix} A_{\epsilon,P} \\ H_{\epsilon,P}\end{pmatrix}\right\|_{L^2(\Omega_{\epsilon,P})\times L^t(\Omega)}\right) \\
&\le \lambda^{-1}C\left(c(\delta)\delta + \epsilon^{2t^{-1}-1}\frac{1}{\log\frac{1}{\epsilon}}\right) \qquad \text{(by Lemma 3.1)},
\end{aligned}$$

where $\lambda > 0$ is independent of $\delta > 0$ and $c(\delta) \to 0$ as $\delta \to 0$. Similarly we show

$$\|M_{\epsilon,P}(\Sigma) - M_{\epsilon,P}(\Sigma')\|_{H^2(\Omega_{\epsilon,P})\times W^{2,t}(\Omega)} \le \lambda^{-1}C(\epsilon^{1/2} + c(\delta)\delta)\|\Sigma - \Sigma'\|_{H^2(\Omega_{\epsilon,P})\times W^{2,t}(\Omega)},$$

where $c(\delta) \to 0$ as $\delta \to 0$. If we choose δ small enough, then $M_{\epsilon,P}$ is a contraction on $B_{\epsilon,\delta}$. The existence of a fixed point $\Sigma_{\epsilon,P}$ now follows from the contraction mapping principle and $\Sigma_{\epsilon,P}$ is a solution of (4.18).

We have thus proved Lemma 4.4.

LEMMA 4.4. *There exists $\bar\epsilon > 0$ such that for every pair of ϵ, P with $0 < \epsilon < \bar\epsilon$ there exists a unique $(\Phi_{\epsilon,P}, \Psi_{\epsilon,P}) \in \mathcal{K}^\perp_{\epsilon,P}$ satisfying*

$$S_\epsilon\left(\begin{pmatrix} A_{\epsilon,P} + \Phi_{\epsilon,P} \\ H_{\epsilon,P} + \Psi_{\epsilon,P}\end{pmatrix}\right) \in \mathcal{C}_{\epsilon,P}$$

and

$$\|(\Phi_{\epsilon,P}, \Psi_{\epsilon,P})\|_{H^2(\Omega_{\epsilon,P})\times W^{2,t}(\Omega)} \le C\epsilon^{2t^{-1}-1}. \tag{4.19}$$

We can improve the estimates in Lemma 4.4.

LEMMA 4.5. *Let $(\Phi_{\epsilon,P}, \psi_{\epsilon,P})$ be given by Lemma 4.4. Then we have*

$$\|\Phi_{\epsilon,P}\|_{L^\infty(\Omega_{\epsilon,P})} = O\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right), \quad \|\Psi_{\epsilon,P}\|_{L^\infty(\Omega)} = O\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right), \tag{4.20}$$

and

$$|\Psi_{\epsilon,P}(x) - \Psi_{\epsilon,P}(P)| \le C\frac{\epsilon}{(\log\frac{1}{\epsilon})^2}\log\left(\frac{|x-P|}{\epsilon} + 1\right) \quad \text{for } x \ne P. \tag{4.21}$$

Proof. The proof is divided into several steps.

First we note that by the equation for $\Phi_{\epsilon,P}$ and Lemmas 3.1 and 4.4,

$$\Delta_y\Phi_{\epsilon,P} - \Phi_{\epsilon,P} + pA^{p-1}_{\epsilon,P}H^{-q}_{\epsilon,P} - qA^p_{\epsilon,P}H^{-q-1}_{\epsilon,P}\Psi_{\epsilon,P} + f_1 \in C_{\epsilon,P},$$

where $\|f_1\|_{L^2(\Omega_{\epsilon,P})} = O(\frac{\epsilon}{\log\frac{1}{\epsilon}})$. Hence we obtain

$$\|\Phi_{\epsilon,P}\|_{H^2(\Omega_{\epsilon,P})} \le C\|A^p_{\epsilon,P}H^{-q-1}_{\epsilon,P}\Psi_{\epsilon,P}\|_{L^2(\Omega_{\epsilon,P})} + O\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right)$$

$$\leq C\|\Psi_{\epsilon,P}(x)\|_{L^\infty(\Omega)} + O\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right). \tag{4.22}$$

Next $\Psi_{\epsilon,P}$ satisfies

$$\Delta_x\Psi_{\epsilon,P} - \Psi_{\epsilon,P} = f_2 := c_{\epsilon,P}\frac{\hat{A}^r_{\epsilon,P}}{(\hat{H}_{\epsilon,P} - \psi_{\epsilon,P}(P))^s} - c_{\epsilon,P}\frac{(\hat{A}_{\epsilon,P} + \Phi_{\epsilon,P})^r}{(\hat{H}_{\epsilon,P} - \psi_{\epsilon,P}(x) + \Psi_{\epsilon,P})^s}.$$

We have

$$|f_2(x)| \leq Cc_{\epsilon,P}(w(y)^{r-1}|\Phi_{\epsilon,P}(y)| + w^r(y)|\Psi_{\epsilon,P}(x)|) + O\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}c_{\epsilon,P}w^r(y)\right) \tag{4.23}$$

for a.e. $x \in \Omega$.

Therefore, we have by Lemma 1.2 and (4.22)

$$\Psi_{\epsilon,P}(x) = O\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right) + O\left(\frac{1}{\log\frac{1}{\epsilon}}\|\Psi_{\epsilon,P}\|_{L^\infty(\Omega)}\right)$$

and so

$$\|\Psi_{\epsilon,P}\|_{L^\infty(\Omega)} = O\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right)$$

or, equivalently,

$$\|\Psi_{\epsilon,P}\|_{L^\infty(\Omega_{\epsilon,P})} = O\left(\frac{\epsilon}{\log\frac{1}{\epsilon}}\right),$$

where $y = (x - P)/\epsilon$.

Moreover by Lemma 1.2 and (4.23),

$$\Psi_{\epsilon,P}(x) - \Psi_{\epsilon,P}(P) = O\left(\frac{\epsilon}{(\log\frac{1}{\epsilon})^2}|\log|y| + 1|\right).$$

Lemma 4.5 is proved. □

5. The reduced problem. In this section we solve the reduced problem and prove our main theorem.

By Lemma 4.4 there exists a unique solution $(\Phi_{\epsilon,P}, \psi_{\epsilon,P}) \in \mathcal{K}^\perp_{\epsilon,P}$ such that

$$S_\epsilon\begin{pmatrix} A_{\epsilon,P} + \Phi_{\epsilon,P} \\ H_{\epsilon,P} + \Psi_{\epsilon,P} \end{pmatrix} = \begin{pmatrix} v_{\epsilon,P} \\ 0 \end{pmatrix} \in \mathcal{C}_{\epsilon,P}.$$

Our idea is to find P such that

$$S_\epsilon\begin{pmatrix} A_{\epsilon,P} + \Phi_{\epsilon,P} \\ H_{\epsilon,P} + \Psi_{\epsilon,P} \end{pmatrix} \perp \mathcal{C}_{\epsilon,P}.$$

Let

$$W_{\epsilon,j}(P) := \frac{\log\frac{1}{\epsilon}}{\epsilon^2}\int_\Omega \left(S_1(A_{\epsilon,P} + \Phi_{\epsilon,P}, H_{\epsilon,P} + \Psi_{\epsilon,P})\frac{\partial A_{\epsilon,P}}{\partial P_j}\right),$$

$$W_\epsilon(P) := (W_{\epsilon,1}(P), \dots, W_{\epsilon,N}(P)).$$

Then $W_\epsilon(P)$ is a continuous map in P and our problem is reduced to finding a zero of the vector field $W_\epsilon(P)$.

Let us now calculate $W_\epsilon(P)$.

By Lemma 4.5,

$$\Psi_{\epsilon,P}(x) - \Psi_{\epsilon,P}(P) = O\left(\frac{\epsilon}{(\log\frac{1}{\epsilon})^2}\log\left(\frac{|x-P|}{\epsilon}+1\right)\right). \tag{5.1}$$

By (3.3) and (3.4), we have

$$\int_\Omega \left(S_1(A_{\epsilon,P}+\Phi_{\epsilon,P}, H_{\epsilon,P}+\psi_{\epsilon,P})\frac{\partial A_{\epsilon,P}}{\partial P_j}\right)$$

$$= \epsilon^2 \int_{\Omega_{\epsilon,P}} (\Delta_y\Phi_{\epsilon,P} - \Phi_{\epsilon,P} + pA_{\epsilon,P}^{p-1}H_{\epsilon,P}^{-q}\Phi_{\epsilon,P} - qA_{\epsilon,P}^{p-1}H_{\epsilon,P}^{-q-1}\Psi_{\epsilon,P})\frac{\partial A_{\epsilon,P}}{\partial P_j}$$

$$+O\left(\epsilon^3\left(\frac{1}{\log\frac{1}{\epsilon}}\right)^2\right)$$

$$+\epsilon^2\int_{\Omega_{\epsilon,P}} -q(\hat{A}_{\epsilon,P})^p(\hat{H}_{\epsilon,P})^{-q-1}[\psi_{\epsilon,P}(P+\epsilon y)-\psi_{\epsilon,P}(P)]\frac{\partial A_{\epsilon,P}}{\partial P_j}(y)\,dy$$

$$+O(e^{-d(P,\partial\Omega)/\epsilon}) = I_1 + I_2,$$

where I_1, I_2 are defined by the last equality.

For I_1, we note that $\|\Psi_{\epsilon,P}\|_{L^\infty(\Omega_{\epsilon,P}} = O(\frac{\epsilon}{\log\frac{1}{\epsilon}})$, $\frac{\partial A_{\epsilon,P}}{\partial P_j} = -\frac{1+o(1)}{\epsilon}\frac{\partial w}{\partial y_j}$, and hence

$$I_1 = \epsilon\int_{\Omega_{\epsilon,P}} (qA_{\epsilon,P}^{p-1}H_{\epsilon,P}^{-q-1}\Psi_{\epsilon,P})\frac{\partial w}{\partial y_j} + O\left(\epsilon^2\left(\frac{1}{\log\frac{1}{\epsilon}}\right)^2\right)$$

$$= \epsilon\int_{\Omega_{\epsilon,P}} (qw^{p-1}\Psi_{\epsilon,P})\frac{\partial w}{\partial y_j} + O\left(\epsilon^2\left(\frac{1}{\log\frac{1}{\epsilon}}\right)^2\right)$$

$$= \epsilon\int_{\Omega_{\epsilon,P}} (qw^{p-1}(y)H_{\epsilon,P}^{-q-1}(\Psi_{\epsilon,P}(P+\epsilon y)-\Psi_{\epsilon,P}(P)))\frac{\partial w}{\partial y_j} + O\left(\epsilon^2\left(\frac{1}{\log\frac{1}{\epsilon}}\right)^2\right)$$

$$= O\left(\epsilon^2\frac{1}{(\log\frac{1}{\epsilon})^2}\right)$$

by (5.1).

For I_2 we have

$$I_2 = C\epsilon\int_{\Omega_{\epsilon,P}} [\psi_{\epsilon,P}(P+\epsilon y)-\psi_{\epsilon,P}(P)]\frac{\partial w}{\partial y_j}\,dy\left(1+O\left(\frac{1}{\log\frac{1}{\epsilon}}\right)\right)$$

$$= C\frac{\epsilon}{\log\frac{1}{\epsilon}}\int_{R^2} -[H(P,P+\epsilon y)-H(P,P)]w'(|y|)\frac{y_i}{|y|}\,dy\left(1+O\left(\frac{1}{\log\frac{1}{\epsilon}}\right)\right)$$

$$= -C\frac{\epsilon^2}{\log\frac{1}{\epsilon}}\frac{\partial}{\partial P_j}H(P,P)\int_{R^2} w'(|y|)|y|\,dy + O\left(\frac{\epsilon^N}{(\log\frac{1}{\epsilon})^2}\right)$$

as $\epsilon \to 0$ uniformly in P, where $w'(|y|) = \frac{d}{dr}w(r)$ for $r = |y|$ and $C \neq 0$ denotes a generic constant.

Combining I_1 and I_2, we have

$$W_\epsilon(P) = c_0\nabla_P H(P,P) + O\left(\frac{1}{\log\frac{1}{\epsilon}}\right),$$

where $c_0 \neq 0$ is a generic constant.

Suppose at P_0 we have $\nabla_P H(P_0,P_0) = 0, \det(\nabla_j\nabla_k H(P_0,P_0)) \neq 0$; then the standard Brouwer fixed point theorem shows that for $\epsilon << 1$ there exists a P_ϵ such that $W_\epsilon(P_\epsilon) = 0$ and $P_\epsilon \to P_0$.

Thus we have proved the following proposition.

PROPOSITION 5.1. *For ϵ sufficiently small there exist points P_ϵ with $P_\epsilon \to P_0$ such that $W_\epsilon(P_\epsilon) = 0$.*

Finally, we prove Theorem 1.1.

Proof of Theorem 1.1. By Proposition 5.1, there exists $P_\epsilon \to P_0$ such that $W_\epsilon(P_\epsilon) = 0$. In other words, $S_1(A_{\epsilon,P_\epsilon} + \Phi_{\epsilon,P_\epsilon}, H_{\epsilon,P_\epsilon} + \Psi_{\epsilon,P_\epsilon}) = 0$. Let $\xi_\epsilon^{\frac{qr}{(p-1)(s+1)-qr}} = c_{\epsilon,P_\epsilon}, A_\epsilon = \xi_\epsilon^{q/(p-1)}(A_{\epsilon,P_\epsilon} + \Phi_{\epsilon,P_\epsilon}), H_\epsilon = \xi_\epsilon(H_{\epsilon,P} + \Psi_{\epsilon,P_\epsilon})$. It is easy to see that $H_\epsilon = 1 + O(\frac{1}{\log\frac{1}{\epsilon}}) > 0$ and hence $A_\epsilon \geq 0$. By the maximum principle, $A_\epsilon > 0$. Moreover A_ϵ, H_ϵ satisfy Theorem 1.1. □

EXISTENCE OF THE GLOBAL CLASSICAL SOLUTION FOR A TWO-PHASE STEFAN PROBLEM*

M. A. BORODIN†

Abstract. In this work we prove the existence of the global classical solution in a two-phase multidimensional Stefan problem. We apply a method which consists of the following. First, we construct a special system of difference–differential approximating elliptic problems, then we prove some uniform estimates and pass to the limit. We prove that the free boundary is given by the graph of a function from the $H^{2+\alpha,1+\frac{\alpha}{2}}$ class.

Key words. two-phase Stefan problem, global classic solution, free boundary problem

AMS subject classification. 35R35

PII. S0036141097332530

Introduction. In this work we study the existence of the global classical solution for a two-phase multidimensional Stefan problem; see, e.g., [21, chap. 5, §9]. Let $D = \{x \in \mathbf{R^3} : \quad 0 < \mathrm{R}_1 < |\mathrm{x}| < \mathrm{R}_2\}$, $D_T = D \times (0,T)$, $B_i = \{x \in \mathbf{R^3} : |\mathrm{x}| < \mathrm{R_i}\}$; $\mathrm{i} = 1,2$, $T > 0$ is a fixed number. The problem is to find a function $u(x,t)$ and domains Ω_T, G_T, which satisfy

$$\Delta u - \frac{\partial u}{\partial t} = 0 \quad \text{in} \quad \Omega_T \cup G_T, \tag{0.1}$$

$$\Omega_T = \{(x,t) \in D_T : 0 < u(x,t) < 1\}, \quad G_T = \{(x,t) \in D_T : u(x,t) > 1\}.$$

On the known boundary

$$u(x,t) = \varphi_i(x,t) \quad \text{on} \quad \partial B_i \times (0,T),\ i = 1,2. \tag{0.2}$$

On the unknown (free) boundary $\gamma_T = \partial\Omega_T \cap D_T = \partial G_T \cap D_T$

$$u^+ = u^- = 1, \quad \sum_{k=1}^{3} \left(\frac{\partial u^-}{\partial x_i} - \frac{\partial u^+}{\partial x_i} \right) \cos(n, x_i) + \lambda \cos(n,t) = 0, \tag{0.3}$$

where λ is a positive constant, n is the normal to the surface γ_T directed to the side of increase of the function $u(x,t)$, and $u^+(x,t)$, $u^-(x,t)$ are the boundary values on the surface γ_T taken from the domains G_T, Ω_T, respectively.

The initial conditions are

$$u(x,0) = \psi(x) \quad \text{in} \quad \overline{D}, \ \ \psi(x) = \varphi_i(x,0) \quad \text{on} \quad \partial B_i, \tag{0.4}$$

$$0 \le \psi(x) < 1 \quad \text{on} \quad \partial B_1, \quad \psi(x) > 1 \quad \text{on} \quad \partial B_2,$$

$$\Omega_0 = \{x \in D : \psi(x) < 1\}, \quad G_0 = \{x \in D : \psi(x) > 1\}, \ \gamma_0 = \partial\Omega_0 \cap D = \partial G_0 \cap D.$$

Problem (0.1)–(0.4) represents a mathematical model that describes the spreading of heat in a medium with a varying phase state. The function $u(x,t)$ is interpreted as the temperature of the medium, γ_T is the interface between the liquid and solid phases, and $u(x,t)=1$ is the temperature of melting.

Multidimensional Stefan problems have been studied by many authors. The concept of weak solutions was introduced in [1], [2], where the existence and uniqueness of such solutions have been proved. Certain free boundary problems have been reduced to variational inequalities [3], [4]. Such reduction allowed us to prove [5] Lipschitz continuity of the free boundary in a one-phase Stefan problem. However, this was not enough to prove the existence of a classical solution. The existence of a classical solution in a one-phase Stefan problem was proved in [6]. The works by L. Caffarelli [7]–[9] played an important role here. A variational inequality equivalent to a two-phase Stefan problem was obtained by M. Fremon [10], but this allowed us to prove just continuity of the temperature.

Lipschitz continuity of the free boundary in a two-phase problem was proved in [11]. Moreover, in [12] it was shown that a viscosity solution with Lipschitz free boundary under certain nondegeneracy conditions is, actually, classical, and the free boundary is a C^1 graph in space and time. The existence of classical solutions for a small time interval was proved in [13]–[15]. The main result of this paper is the following theorem.

THEOREM 0.1. *Let the following conditions be satisfied:*

$$\psi(x)\in C^{2+\alpha}(\overline{D}),\quad \Delta\psi\le 0\quad in\quad \overline{D},\quad \frac{\partial\psi}{\partial\rho}>0\quad in\quad \overline{D},$$

$$\varphi_1(x,t)=0\quad on\quad \partial B_1,\quad \varphi_2(x,t)=q=\mathrm{const}>1\quad on\quad \partial B_2,$$

and assume that the corresponding compatibility conditions at $t=0$, $x\in\partial\Omega_T\cup\partial G_T$ hold. Then $\forall\, T>0$ there exists a unique solution of the problem (0.1)–(0.4) *and*

$$u(x,t)\in C(\overline{D}_T)\cap\Big(H^{2+\alpha,1+\frac{\alpha}{2}}(\overline{\Omega}_T)\times H^{2+\alpha,1+\frac{\alpha}{2}}(\overline{G}_T)\Big);$$

the free boundary is given by the graph $\rho=\omega(\theta_1,\theta_2,t)$ of a function $\omega(\theta_1,\theta_2,t)\in H^{2+\alpha,1+\frac{\alpha}{2}}(\overline{\Pi}_T)$, where (ρ,θ_1,θ_2) are spherical coordinates, $\Pi=\{(\theta_1,\theta_2):0<\theta_1<2\pi, 0<\theta_2<\pi\}$, $\Pi_T=\Pi\times(0,T)$.

This result has been announced in [16]. The theorem provides sufficient conditions for the existence of a global classical solution for a Stefan problem. Note that similar assumptions on the data have been used in [11]. Although our conditions are not necessary, examples [17], [18], [11], [12] show that the smoothness of initial and boundary conditions alone does not imply the smoothness of the free boundary.

The paper is organized as follows. In sections 1 and 2 we construct a difference–differential approximation of our problem and study its properties. Uniform estimates for the approximate solutions are obtained in section 3. In section 4 we pass to the limit and prove the main theorem.

In [19] we have also considered a contact Stefan problem with Neumann boundary conditions on the fixed part of the boundary.

For the sake of simplicity we consider three-dimensional space; the same method can be applied in the case of arbitrary space dimension.

1. Construction of the approximating problems. Let us construct a system of approximating problems. We divide the cylinder D_T by the planes $t=kh$, $1\le$

$k \le N$; N is a positive number. For any number $\varepsilon > 0$ we introduce a function $\chi_\varepsilon \in C^\infty(\mathbf{R^1})$ such that

$$\chi_\varepsilon(x) = 1 \quad \forall x \le 1, \quad \chi_\varepsilon(x) = 0 \quad \forall x \ge 1 + \varepsilon, \quad \chi'_\varepsilon(x) \le 0.$$

Define the functions $\{u_k(x,h,\varepsilon)\}$, $\{F_k(x,h,\varepsilon)\}$ as solutions of the following problem.

$$\Delta u_k - \frac{u_k - u_{k-1}}{h} = -\lambda \frac{\chi_\varepsilon(u_k) - \chi_\varepsilon(u_0)}{h} + \frac{F_{k-1}}{h} \text{ in } D,\ k = 1, 2, \dots, N, \tag{1.1}$$

$$u_k = \varphi_i(x, kh) \text{ on } \partial B_i,\ u_0 = \psi(x) \text{ in } D, \tag{1.2}$$

$$\Delta F_k - \frac{F_k}{h} = -\lambda \frac{\chi_\varepsilon(u_k) - \chi_\varepsilon(u_0)}{h} \text{ in } D, \tag{1.3}$$

$$F_k = 0 \text{ on } \partial B_1 \cup \partial B_2,\ F_0 = 0 \text{ in } D. \tag{1.4}$$

If $h > 0, \varepsilon > 0$ are fixed, the solvability of problem (1.1)–(1.4) is evident. It can be considered step by step starting with $k = 1$. First, we find the function $F_{k-1}(x,h,\varepsilon)$ ($F_0 = 0$), then we put it to the right-hand side of (1.1) and consider the boundary problem for the function $u_k(x,h,\varepsilon)$. We plug the function thus obtained into the right-hand side of (1.3) and find the function $F_k(x,h,\varepsilon)$, and so on. The existence of a solution for each of the above-mentioned problems is known [20, chap. 3, §1]. Thus, we obtain the following statement.

THEOREM 1.1. *Let the following conditions hold:*

$$\psi(x) \in C^{2+\alpha}(\overline{D}), \quad \varphi_i(x, kh) \in C^{2+\alpha}(\overline{D}), \quad \alpha \in (0,1),$$

and the functions $\psi(x)$, $\varphi_i(x,kh)$ on $x \in \partial B_i$, and $k = 0$ satisfy the corresponding compatibility conditions. Then problem (1.5)–(1.8) *is solvable and*

$$u_k(x,h,\varepsilon) \in C^{2+\alpha}(\overline{D}), \quad F_k(x,h,\varepsilon) \in C^{2+\alpha}(\overline{D}).$$

In what follows we shall show that the linear interpolations of the functions $\{u_k(x,h,\varepsilon)\}$ with respect to t converge to a solution of the Stefan problem (0.1)–(0.4) as $\varepsilon \to 0$, $h \to 0$.

Subtract (1.3) from (1.1) and set

$$w_k(x,h,\varepsilon) = u_k(x,h,\varepsilon) - F_k(x,h,\varepsilon) \tag{1.5}$$

Then the functions $\{w_k(x,h,\varepsilon)\}$ will satisfy the following problem.

$$\Delta w_k - \frac{w_k - w_{k-1}}{h} = 0 \quad \text{in} \quad D, \tag{1.6}$$

$$w_k(x,h,\varepsilon) = \varphi_i(x,kh) \quad \text{on} \quad \partial B_i, \quad w_0 = \psi(x) \quad \text{in} \quad D. \tag{1.7}$$

The equality (1.5) shows that the functions $u_k(x,h,\varepsilon)$ are sums of two summands; the first one $w_k(x,h,\varepsilon)$ is more smooth than the solution of the Stefan problem, while the second one $F_k(x,h,\varepsilon)$ contains information about the behavior of the solution near the free boundary. However, this second summand is the solution of a sufficiently simple problem. The exact meaning of these words will be clear from what follows.

2. Properties of $\{w_k(x,h,\varepsilon)\}$.

THEOREM 2.1. *Let the assumptions of Theorem* 1.1 *hold and suppose that*

$$|\varphi_i(x,(k-1)h)-\varphi_i(x,kh)|\le ch \quad \forall x\in\partial B_i, \tag{2.1}$$

where the constant c does not depend on h and k. Then there exists a constant M, such that

$$|w_{k-1}(x,h,\varepsilon)-w_k(x,h,\varepsilon)|\le Mh \quad \forall x\in\overline{D}, \tag{2.2}$$

where M does not depend on k, h, and ε.
If instead of (2.1) *the following condition holds:*

$$\Delta\psi<0 \quad in \quad \overline{D},\ 0<c_1h\le\varphi(x,(k-1)h)-\varphi(x,kh)\le c_2h, \tag{2.1*}$$

then

$$0<M_1h\le w_{k-1}(x,h,\varepsilon)-w_k(x,h,\varepsilon)\le M_2h, \tag{2.2*}$$

where the constants c_i, M_i do not depend on k, h, and ε.

Proof. On the boundary of the domain D the estimation (2.1) follows from the hypothesis of the theorem. Let us assume that

$$\max_{1\le k\le N,x\in\overline{D}}[w_{k-1}(x,h,\varepsilon)-w_k(x,h,\varepsilon)]=w_{n-1}(x_0,h,\varepsilon)-w_n(x_0,h,\varepsilon),$$

where $x_0\in D$. At a local maximum point we have $\Delta(w_{n-1}-w_n)\le 0$. Therefore, the equation

$$\Delta(w_{n-1}-w_n)-\frac{w_{n-1}-w_n}{h}=-\frac{w_{n-2}-w_{n-1}}{h} \tag{2.2}$$

implies

$$w_{n-1}(x_0,h,\varepsilon)-w_n(x_0,h,\varepsilon)\le w_{n-2}(x_0,h,\varepsilon)-w_{n-1}(x_0,h,\varepsilon).$$

From this estimate we conclude that

$$w_{n-1}(x_0,h,\varepsilon)-w_n(x_0,h,\varepsilon)\le w_0(x_0,h,\varepsilon)-w_1(x_0,h,\varepsilon),$$

but the function $w_0(x,h,\varepsilon)-w_1(x,h,\varepsilon)$ satisfies the equation

$$\Delta(w_0-w_1)-\frac{w_0-w_1}{h}=\Delta\psi. \tag{2.3}$$

Therefore,

$$\max_{1\le k\le N,x\in\overline{D}}[w_{k-1}(x,h,\varepsilon)-w_k(x,h,\varepsilon)]\le\max_{x\in\overline{D}}|\Delta\psi|h.$$

Similarly, we estimate the minimum of the functions $\{w_{k-1}(x,h,\varepsilon)-w_k(x,h,\varepsilon)\}$. The second part of the theorem is obvious. □

COROLLARY 2.1. *Let the assumptions of Theorem* 2.1 *hold and*

$$\|\varphi_i(x,kh)\|_{C^{2+\alpha}(\overline{D})}\le c_3.$$

Then $\exists M_3 > 0$, *such that*

$$\|w_k(x,h,\varepsilon)\|_{C^{1+\alpha}(\overline{D})} \le M_3, \tag{2.4}$$

where the constant M_3 *does not depend on* h, ε, *and* k.

Proof. From (2.1) and (1.6) we get

$$0 < M_1 \le -\Delta w_k \le M_2.$$

After that the estimation (2.4) follows from known properties of solutions of elliptic boundary problems. □

THEOREM 2.2. *Let the assumptions of Theorem* 1.1 *hold and*

$$\|\varphi_i(x,kh)\|_{C^{2+\alpha}(\overline{D})} + \Big\|\frac{\varphi_i[x,(k-1)h] - \varphi_i(x,kh)}{h}\Big\|_{C^{\alpha}(\overline{D})} \le c_4.$$

Then $\exists\ M_4 > 0$, *such that*

$$\|w_k\|_{C^{2+\alpha}(\overline{D})} + \Big\|\frac{w_{k-1}(x,h,\varepsilon) - w_k(x,h,\varepsilon)}{h}\Big\|_{C^{\alpha}(\overline{D})} \le M_4, \tag{2.5}$$

where the constant M_4 *does not depend on* h, ε, *and* k.

Proof. We use the method suggested in [20]. Let $\zeta_1(x), \zeta_2(x), \dots, \zeta_l(x)$ be nonnegative indefinitely differentiable functions with compact supports such that their sum is identically equal to one on $\overline{D}$, i.e.,

$$\sum_{k=1}^{l} \zeta_k(x) = 1, \quad x \in \overline{D}.$$

The functions $\{w_k(x,h,\varepsilon) - w_{k-1}(x,h,\varepsilon)\}$ have the form

$$\sum_{s=1}^{l} [w_k^s(x,h,\varepsilon) - w_{k-1}^s(x,h,\varepsilon)] = w_k(x,h,\varepsilon) - w_{k-1}(x,h,\varepsilon),\ k = 1,2,\dots,N,$$

where

$$w_k^s(x,h,\varepsilon) - w_{k-1}^s(x,h,\varepsilon) = \zeta_s(x)[w_k(x,h,\varepsilon) - w_{k-1}(x,h,\varepsilon)].$$

If the support of $\zeta_s(x)$ lies in the domain D, we can consider $\{w_k^s(x,h,\varepsilon) - w_{k-1}^s(x,h,\varepsilon)\}$ as compactly supported functions from $C^{2+\alpha}(\mathbf{R^3})$, satisfying the equations

$$\Delta(w_k^s - w_{k-1}^s) - \frac{w_k^s - w_{k-1}^s}{h} = -\frac{w_{k-1}^s - w_{k-2}^s}{h} - (f_k^s - f_{k-1}^s), \tag{2.6}$$

where $f_k^s = -2\nabla w_k \nabla \zeta_s - w_k \Delta \zeta_s$. Let x_0 belong to the support of the function $\zeta_s(x)$ and $K_R(x_0)$ be the ball with its center at the point x_0 and the radius R so large that its boundary lies outside of the support of $\zeta_s(x)$.

Let

$$\Gamma_{n-k+1}(|x-y|) = \frac{ih}{2\pi} \oint\limits_{\partial L^+(\rho)} \frac{Sh[\sqrt{z}(R-|x-y|)]}{4\pi|x-y|Sh(\sqrt{z}R)} \frac{dz}{(1-zh)^{n-k+1}}, \tag{2.7}$$

where $L^+(\rho) = \{z = \xi + i\eta : Rez > -\frac{\pi^2}{R^2}, |z| < \rho\}$, $\partial L^+(\rho)$ is the boundary of this set, $\rho \geq \frac{2}{h}, Sh(x) = \frac{e^x - e^{-x}}{2}$. The numerator and the denominator of the integrand have the same branch point. Therefore, in the domain $L^+(\rho)$ it is possible to choose a univalent branch of the integrand by setting, for example, $\sqrt{1} = 1$. We shall multiply both sides of (2.6) by $\Gamma_{n-k+1}(|x_0 - y|)$, sum up over k, $1 \leq k \leq n$, and then integrate over $K_R(x_0) \setminus K_\delta(x_0)$. After that we shall make the passage to the limit $\delta \to 0$. Thus, we shall construct an integral representation of a solution of (2.6)

$$w_n^s(x_0, h, \varepsilon) - w_{n-1}^s(x_0, h, \varepsilon) = \int\limits_{K_R(x_0)} \zeta_s(y) \Delta\psi \Gamma_n(|x_0 - y|)\, dy + \sum_{k=1}^{n} \int\limits_{K_R(x_0)} (f_k^s - f_{k-1}^s) \Gamma_{n-k+1}(|x_0 - y|)\, dy.$$

Let us transform the last term

$$\sum_{k=1}^{n} \int\limits_{K_R(x_0)} (f_k^s - f_{k-1}^s) \Gamma_{n-k+1}(|x_0 - y|)\, dy = - \int\limits_{K_R(x_0)} f_0^s \Gamma_n(|x_0 - y|)\, dy$$
$$+ \sum_{k=1}^{n} \int\limits_{K_R(x_0)} f_k^s [\Gamma_{n-k+1}(|x_0 - y|) - \Gamma_{n-k}(|x_0 - y|)]\, dy, \quad \Gamma_0(|x_0 - y|) \equiv 0.$$

Thus, we obtain the following integral representation:

$$w_n^s(x_0, h, \varepsilon) - w_{n-1}^s(x_0, h, \varepsilon) = \int\limits_{K_R(x_0)} (\zeta_s \Delta\psi - f_0^s) \Gamma_n(|x_0 - y|)\, dy + \sum_{k=1}^{n} \int\limits_{K_R(x_0)} f_k^s [\Gamma_{n-k+1}(|x_0 - y| - \Gamma_{n-k}(|x_0 - y|)]\, dy.$$

Let y_0 be a point in the support of the function $\zeta_s(x)$ such that $x_0 \neq y_0$ and $v_n^s(x, h, \varepsilon) = w_n^s(x, h, \varepsilon) - w_{n-1}^s(x, h, \varepsilon)$. Then for the difference

$$v_n^s(x_0, h, \varepsilon) - v_n^s(y_0, h, \varepsilon)$$

after several simplifications we get the following expression:

(2.8)

$$v_n^s(x_0, h, \varepsilon) - v_n^s(y_0, h, \varepsilon) = \int\limits_{K_R(x_0)} [\phi_s(y, h, \varepsilon) - \phi_s(y - x_0 + y_0, h, \varepsilon)] \Gamma_n(|x_0 - y|)\, dy$$
$$+ \sum_{k=1}^{n} \int\limits_{K_R(x_0)} [f_k^s(y, h, \varepsilon) - f_k^s(y - x_0 + y_0, h, \varepsilon)][\Gamma_{n-k+1}(|x_0 - y|) - \Gamma_{n-k}(|x_0 - y|)]\, dy,$$

where $\phi_s = \zeta_s \Delta\psi - f_0^s$. Note the following properties of the fundamental solutions $\{\Gamma_n(|x_0 - y|)\}$. Let $y \neq x_0$, then

$$\Delta\Gamma_1 - \frac{\Gamma_1}{h} = 0, \quad \Gamma_1(|x_0 - y|) = \frac{Sh\left[\sqrt{\frac{1}{h}}(R - |x_0 - y|)\right]}{4\pi |x_0 - y| Sh\left(\sqrt{\frac{1}{h}} R\right)},$$
$$\Delta\Gamma_{n-k+1} - \frac{\Gamma_{n-k+1} - \Gamma_{n-k}}{h} = 0, \quad \Gamma_{n-k+1}(R) = 0, \quad k = 1, 2, \ldots, n-1.$$

These formulas can be easily proved. They imply that

$$\Gamma_{n-k+1}(|x_0-y|)>0,$$

$$\int\limits_{K_R(x_0)} \frac{\Gamma_{n-k+1}(|x_0-y|)-\Gamma_{n-k}(|x_0-y|)}{h}\,dy = \int\limits_{\partial K_R(x_0)} \frac{\partial\Gamma_{n-k+1}}{\partial\nu}\,ds<0,$$

where ν is the outward pointing field to $\partial K_R(x_0)$. Therefore,

$$\int\limits_{K_R(x_0)} \frac{\Gamma_n(|x_0-y|)}{h}\,dy \le \int\limits_{K_R(x_0)} \frac{\Gamma_1(|x_0-y|)dy}{h} = 1-\frac{\sqrt{\frac{1}{h}}R}{Sh\sqrt{\frac{1}{h}}R}\le 1. \tag{2.9}$$

Let

$$\Gamma^1_{n-k+1}(|x_0-y|)=\frac{ih^2}{2\pi}\oint\limits_{\partial L^+(\rho)} \frac{zSh[\sqrt{z}(R-|x_0-y|)]}{4\pi|x_0-y|Sh(\sqrt{z}R)}\frac{dz}{(1-zh)^{n-k+1}},$$

then it follows from (2.7) that

$$\Gamma_{n-k+1}(|x_0-y|)-\Gamma_{n-k}(|x_0-y|)=\Gamma^1_{n-k+1}(|x_0-y|). \tag{2.10}$$

After that it is obvious that

$$\sum_{k=1}^{n}\int\limits_{K_R(x_0)} \frac{|\Gamma^1_{n-k+1}(|x_0-y|)|}{h}\,dy\le c, \tag{2.11}$$

where the constant c does not depend on h. From (2.8), taking into account the estimates (2.9) and (2.11), we obtain

$$\begin{aligned}|v^s_n(x_0,h,\varepsilon)-&v^s_n(y_0,h,\varepsilon)|\le c_1|x_0-y_0|^\alpha \int\limits_{K_R(x_0)}\Gamma_n(|x_0-y|)\,dy\\ &+\int\limits_{K_R(x_0)}\max_{1\le k\le n}|f^s_k(y,h,\varepsilon)-f^s_k(y-x_0+y_0,h,\varepsilon)|\sum_{k=1}^{n}\left|\Gamma^1_{n-k+1}(|x_0-y|)\right|dy\\ &\le c_1h|x_0-y_0|^\alpha+c_2h|x_0-y_0|^\alpha,\end{aligned}$$

where the constants c_1, c_2 do not depend on h, ε, n. Let the support of the function $\zeta_s(x)$ lie only partially in the domain D. By a parallel transport we may force the part of ∂D which belongs to the support to pass through the origin. The inversion $x\to y=x\setminus|x|^2$ is a diffeomorphism of $\mathbf{R^3}\setminus\{0\}$ onto itself and it maps a ball, such that its boundary passes through the origin onto a half-space. Let us denote by $\overline{v}^s_k$ the Kelvin transformation

$$\overline{v}^s_k(x,h,\varepsilon)=|x|^{-1}v^s_k(x/|x|^2,h,\varepsilon).$$

We take the fundamental solutions $\{\Gamma_{n-k+1}(|x_0-y|)-\Gamma_{n-k}(|x^*_0-y|)\}$, where x^*_0 is symmetric to x_0 with respect to the flat part of the boundary, and for $\overline{v}^s_k$ we repeat with small modifications the previous reasoning. After that, for the functions $\{w_k(x,h,\varepsilon)\}$ we get

$$\Delta w_k(x,h,\varepsilon)=\frac{w_k(x,h,\varepsilon)-w_{k-1}(x,h,\varepsilon)}{h}\in C^\alpha(\overline{D}).$$

Therefore, taking into account known properties of solutions of elliptic problems, we obtain the estimation (2.5). □

3. Uniform estimations of $\{u_k(x,h,\varepsilon)\}$.

THEOREM 3.1. *Let the assumptions of Theorem* 1.1 *and the estimation* (2.1) *hold. Then*

$$|u_k(x,h,\varepsilon) - u_{k-1}(x,h,\varepsilon)| \le M_1 h. \tag{3.1}$$

If instead of (2.1) *the condition* (2.1*) *holds, then*

$$0 \le u_{k-1}(x,h,\varepsilon) - u_k(x,h,\varepsilon) \le M_2 h, \tag{3.2*}$$

where the constants M_i do not depend on k, h, and ε.

Proof. In view of (2.1), it suffices to prove the estimation (3.1) in D. Using (1.5), we present (1.1) as follows:

$$\Delta u_k - \frac{u_k}{h} = -\frac{w_{k-1}}{h} - \lambda \frac{\chi_\varepsilon(u_k) - \chi_\varepsilon(u_0)}{h}. \tag{3.2}$$

Let us write down the equation for the difference $u_{k-1}(x,h,\varepsilon) - u_k(x,h,\varepsilon)$:

$$\Delta(u_{k-1} - u_k) - \frac{u_{k-1} - u_k}{h} = -\frac{w_{k-2} - w_{k-1}}{h} + \lambda \frac{\chi_\varepsilon(u_k) - \chi_\varepsilon(u_{k-1})}{h}. \tag{3.3}$$

Let us assume that the function $u_{k-1}(x,h,\varepsilon) - u_k(x,h,\varepsilon)$ has a negative minimum and attains it at an interior point. Then at this point $\Delta(u_{k-1} - u_k) \ge 0$. Therefore, (3.3) implies

$$u_{k-1} - u_k \ge w_{k-2} - w_{k-1} - \lambda[\chi_\varepsilon(u_k) - \chi_\varepsilon(u_{k-1})] \ge w_{k-2} - w_{k-1}.$$

If the function $u_{k-1}(x,h,\varepsilon) - u_k(x,h,\varepsilon)$ has a local maximum at an interior point, then at this point

$$u_{k-1} - u_k \le w_{k-2} - w_{k-1} - \lambda[\chi_\varepsilon(u_k) - \chi_\varepsilon(u_{k-1})] \le w_{k-2} - w_{k-1}.$$

The proof of the second part of the theorem is quite similar. □

Let us estimate $|\nabla u_k|$ in $\overline{D}$. First we shall prove a preliminary estimation.

THEOREM 3.2. *Let the assumptions of Theorem* 1.1 *and* (2.1*) *hold. Then*

$$\max_{x\in\partial D, 1\le k\le N} \left|\frac{\partial u_k}{\partial x_i}\right| \le c_1, \quad \max_{x\in\overline{D},, 1\le k\le N} \left|\frac{\partial u_k}{\partial x_i}\right| \le \frac{c_2}{\varepsilon}, \tag{3.4}$$

where the constants c_1, c_2 do not depend on h, ε.

Proof. By virtue of (1.5) and (2.4), the first estimate (3.4) will follow from the boundedness of $\frac{\partial F_k}{\partial x_i}$ on ∂D. The functions $F_k(x,h,\varepsilon)$ are the solutions of the problem (1.3), (1.4). By (3.2*) F_k is nonnegative in $\overline{D}$. Then (1.5) implies that

$$\{x \in D : w_k > 1 + \varepsilon\} \subset \{x \in D : u_k > 1 + \varepsilon\}.$$

By (2.4) there exists a positive constant d not depending on h, ε, k, such that

$$\operatorname{dist}(\{x \in D : u_k > 1 + \varepsilon\}, \partial B_2) \ge \operatorname{dist}(\{x \in D : w_k > 1 + \varepsilon\}, \partial B_2) \ge d.$$

We denote

$$w(x) = \lambda \frac{\sqrt{h}}{r} Sh \frac{R_2 - r}{\sqrt{h}}, \ r = |x|.$$

The function $w(x)$ in D satisfies the equation

$$\Delta w - \frac{w}{h} = 0.$$

Hence

$$\Delta(w - F_k) - \frac{w - F_k}{h} = 0 \text{ in } \quad D_d = \{x \in D : R_2 - d < |x| < R_2\}, \quad (w - F_k)|_{\partial D_d} \geq 0,$$

$w - F_k = 0$ on ∂B_2. This easily implies

$$\Big|\frac{\partial F_k}{\partial x_i}\Big|_{\partial B_2} \leq \frac{\lambda}{R_2}.$$

A similar estimate can be proved on ∂B_1 as well.

Furthermore, we differentiate (3.3) with respect to one of the variables x_i and transform it to the following form:

$$\Delta u_k' - [1 - \lambda\chi_\varepsilon'(u_k)]\frac{u_k'}{h} = -\frac{w_{k-1}'}{h} + \frac{\lambda}{h}\chi_\varepsilon'(u_0)u_0'. \tag{3.5}$$

From this relation at the points of a local extremum we obtain the second estimation of (3.4). □

Set

$$\omega_0(\varepsilon) = \{x \in \overline{D} : 1 < u_0(x) = \psi(x) < 1 + \varepsilon\}, \; D_\varepsilon = D \setminus \overline{\omega}_0(\varepsilon).$$

THEOREM 3.3. *Let the assumptions of Theorem* 3.2 *hold and* $\operatorname{dist}(\partial\omega_0, \partial D) \geq h^\sigma$, $\sigma \in (0, 1/2)$, $\varepsilon^4 \geq \sqrt{h}$. *Then there exists a constant* c, *which does not depend on* h, ε, *such that the following estimate holds:*

$$\max_{x \in \overline{D}_\varepsilon, 1 \leq k \leq N} \Big|\frac{\partial u_k}{\partial x_i}\Big| \leq c. \tag{3.6}$$

Proof. First of all, let us prove that $\frac{\partial u_k}{\partial x_i}$ are bounded on the boundary of the domain $\omega_0(\varepsilon)$. Let $x_0 \in \partial\omega_0(\varepsilon)$, $K_R(x_0) \subset D$, $a_0(x_0) = 1 - \lambda\chi_\varepsilon'[u_k(x_0, h, \varepsilon)]$, $a(x) = 1 - \lambda\chi_\varepsilon'[u_k(x, h, \varepsilon)]$,

$$E(|x - y|) = \frac{Sh\left(\sqrt{\frac{a_0(x_0)}{h}}(R - |x - y|)\right)}{4\pi|x - y|Sh\left(\sqrt{\frac{a_0(x_0)}{h}}R\right)}.$$

Let us construct an integral representation of a solution of (3.5).

$$\frac{\partial u_k}{\partial x_i} = \int\limits_{K_R(x_0)} \frac{\partial w_{k-1}}{\partial y_i}\frac{E(|x_0 - y|)}{h}\, dy - \int\limits_{\partial K_R(x_0)} \frac{\partial u_k}{\partial y_i}\frac{\partial E}{\partial n} ds$$

$$+ \int\limits_{K_R(x_0)} [a(x_0) - a(y)]\frac{\partial u_k}{\partial y_i}\frac{E(|x_0 - y|)}{h} dy - \lambda \int\limits_{K_R(x_0)} \chi_\varepsilon'(u_0)\frac{\partial u_0}{\partial y_i}\frac{E(|x_0 - y|)}{h} dy. \tag{3.7}$$

As

$$|a(x_0)-a(y)|\le\frac{c_1}{\varepsilon^3}|x_0-y|,\quad |\chi'_\varepsilon[u_0(y)]|=|\chi'_\varepsilon[u_0(y)]-\chi'_\varepsilon[u_0(x_0)]|$$

$$\le\frac{c_2}{\varepsilon^2}|x_0-y|\max_{x\in\overline{D}}|\nabla u_0|,\quad \frac{\partial E}{\partial n}\Big|_{\partial K_R(x_0)}=-\sqrt{\frac{a_0}{h}}\frac{1}{4\pi RSh\sqrt{\frac{a_0}{h}}R},$$

(3.7) implies

$$\Big|\frac{\partial u_k}{\partial x_i}\Big|\le\max_{y\in\overline{D},1\le k\le N}\Big|\frac{\partial w_{k-1}}{\partial y_i}\Big|\int\limits_{K_R(x_0)}\frac{E(|x_0-y|)}{h}dy+\sqrt{\frac{a_0}{h}}\frac{R}{Sh\sqrt{\frac{a_0}{h}}R}\max_{y\in\overline{D},1\le k\le N}\Big|\frac{\partial u_k}{\partial y_i}\Big|$$

$$+\left(\frac{c_3}{\varepsilon^3}\max_{y\in\overline{D},1\le k\le N}|\nabla u_k|+\max_{y\in\overline{D}}|\nabla u_0|^2\right)\int\limits_{K_R(x_0)}|x_0-y|\frac{E(|x_0-y|)}{h}dy. \tag{3.8}$$

Furthermore,

$$\int\limits_{K_R(x_0)}\frac{E(|x_0-y|)}{h}dy\le 1,\ \int\limits_{K_R(x_0)}|x_0-y|\frac{E(|x_0-y|)}{h}dy\le c_4\sqrt{h}. \tag{3.9}$$

Let us assume that $R\ge h^\sigma,\ \sigma\in(0,1/2)$. Hence, by the known inequality

$$x^m\exp(-x)\le m^m\exp(-m)\quad\forall x\ge 0,\ m>0, \tag{3.10}$$

we get

$$\sqrt{\frac{a_0}{h}}R\frac{1}{Sh\sqrt{\frac{a_0}{h}}R}\le ch^{\sigma_1},\quad \sigma_1>0. \tag{3.11}$$

From (3.8), taking into account (3.5), (3.9)–(3.11), we obtain

$$\Big|\frac{\partial u_k}{\partial x_i}\Big|\le\max_{x\in\overline{D},1\le k\le N}|\nabla w_{k-1}|+\frac{c}{\varepsilon}h^{\sigma_1}+\frac{c}{\varepsilon^4}\sqrt{h}+\frac{c}{\varepsilon^2}\sqrt{h}\max_{x\in\overline{D}}|\nabla u_0|^2.$$

From here, assuming that $\varepsilon^4\ge\sqrt{h}$, we obtain estimation (3.6) on the boundary of the domain $\omega_0(\varepsilon)$. On the boundary ∂D estimation (3.6) is proved in Theorem 3.2. To complete the proof it suffices to notice that in the domain $D_\varepsilon=D\setminus\overline{\omega}_0(\varepsilon)$ (3.5) has the following form:

$$\Delta u'_k-[1-\lambda\chi'_\varepsilon(u_k)]\frac{u'_k}{h}=-\frac{w'_{k-1}}{h}.$$

Therefore, if $u'_k(x,h,\varepsilon)$ attains its own extremum in D_ε, the estimation (3.6) is obvious. □

Corollary 3.1. *Let the assumptions of Theorem* 3.3 *hold and*

$$x_0\in\{x\in D:\psi(x)\ge 1+\varepsilon\},\ \ y_0\in\{x\in D:\psi(x)\le 1\}.$$

Then

$$\left|\frac{\partial u_k(x_0,h,\varepsilon)}{\partial x_i}-\frac{\partial u_k(y_0,h,\varepsilon)}{\partial x_i}\right|\le c_1|x_0-y_0|^\alpha+c_2h^{\sigma_1},$$

$$|u_k(x_0,h,\varepsilon)-u_k(y_0,h,\varepsilon)|\le |x_0-y_0|+c_2h^{\sigma_1}, \tag{3.11*}$$

where $c_i>0,\sigma_1>0$ do not depend on h,ε,k,x_0,y_0.

The proof of this statement can be carried out by the same techniques as that of Theorem 3.3.

Set $\omega_k(h,\varepsilon)=\{x\in D: 1<u_k<1+\varepsilon\}$.

THEOREM 3.4. *Let the assumptions of Theorem* 3.1 *hold. If $x\in\omega_k^+=\{x\in D: u_k(x,h,\varepsilon)\ge 1+\varepsilon\}$ and $\operatorname{dist}(x,\partial\omega_k^+)\ge h^\sigma$, $\sigma\in(0,1/2)$, then*

$$\max_x|F_k(x,h,\varepsilon)|\le c_1h^{\sigma_1},\quad \sigma_1>0. \tag{3.12}$$

If $x\in D_k(h,\varepsilon)=D\setminus[\omega_k(h,\varepsilon)\cup\omega_0(h,\varepsilon)]$ and $\operatorname{dist}(x,\partial D_k)\ge h^\sigma$, then

$$\max_x\Big|\frac{\partial^\beta F_k}{\partial x_1^{\beta_1}\partial x_2^{\beta_2}\partial x_3^{\beta_3}}\Big|\le\lambda c_2(\beta h^{\sigma_1})^\beta,\quad \sigma_1>0,\ \beta=\beta_1+\beta_2+\beta_3. \tag{3.13}$$

If $x\in D\setminus[\overline{\omega}_k(h,\varepsilon)\cup\overline{\omega}_{k-1}(h,\varepsilon)]$ and $\operatorname{dist}\Big(x,\partial\{D\setminus[\overline{\omega}_k(h,\varepsilon)\cup\overline{\omega}_{k-1}(h,\varepsilon)]\}\Big)\ge h^\sigma$, then

$$\max_x\Big|\frac{F_k-F_{k-1}}{h}\Big|\le c_3h^{\sigma_1},\quad \sigma_1>0. \tag{3.14}$$

The constants c_i,σ_1,β do not depend on k, h, ε.

Proof. From (1.3), (1.4) it follows that

$$\Big|F_k(x,h,\varepsilon)\Big|\le\lambda\quad\forall x\in\overline{D}.$$

Let $x_0\in\omega_k^+$ and $\operatorname{dist}(x_0,\partial\omega_k^+)\ge h^\sigma$, $R\ge h^\sigma$, $\sigma\in(0,1/2)$. Then

$$|F_k(x_0,h,\varepsilon)|\ \le\ -\int\limits_{\partial K_R(x_0)}|F_k|\frac{\partial E(|x_0-y|)}{\partial n}ds\le\lambda\sqrt{\frac{1}{h}}R\frac{1}{Sh\sqrt{\frac{1}{h}}R},$$

where

$$E(|x_0-y|)=\frac{Sh\sqrt{\frac{1}{h}}(R-|x_0-y|)}{4\pi|x_0-y|Sh\sqrt{\frac{1}{h}}R}.$$

After that (3.14) follows from (3.11).

Let us differentiate (1.3) with respect to x_i. It gives

$$\Delta\frac{\partial F_k}{\partial x_i}-\frac{1}{h}\frac{\partial F_k}{\partial x_i}=-\frac{\lambda}{h}\chi_\varepsilon'(u_k)\frac{\partial u_k}{\partial x_i}+\frac{\lambda}{h}\chi_\varepsilon'(u_0)\frac{\partial u_0}{\partial x_i}.$$

On $D_k(h,\varepsilon)$ this equation takes the form

$$\Delta\frac{\partial F_k}{\partial x_i}-\frac{1}{h}\frac{\partial F_k}{\partial x_i}=0.$$

Let $\operatorname{dist}(x_0,\partial D_k(h,\varepsilon))\ge h^\sigma$, $K_R(x_0)\subset D_k(h,\varepsilon)$. Then we have

$$\frac{\partial F_k(x_0,h,\varepsilon)}{\partial x_i}=-\int\limits_{\partial K_R(x_0)}\frac{\partial F_k}{\partial y_i}\frac{\partial E(|x_0-y|)}{\partial n}ds.$$

Taking into account that $\frac{\partial}{\partial n}E(|x_0-y|)$ on $\partial K_R(x_0)$ does not depend on the variable of integration, we divide by it both sides of the previous equality and integrate over R. We get

$$\frac{\partial F_k(x_0,h,\varepsilon)}{\partial x_i}\int\limits_0^R 4\pi\sqrt{h}\rho Sh\sqrt{\frac{1}{h}}\rho d\rho = -\int\limits_{K_R(x_0)}\frac{\partial F_k}{\partial y_i}dy.$$

As

$$\int\limits_0^R \sqrt{h}\rho Sh\frac{\rho}{\sqrt{h}}d\rho = RhCh\sqrt{\frac{1}{h}}R - h^{\frac{3}{2}}Sh\sqrt{\frac{1}{h}}R$$

and $R \geq h^\sigma$, using the inequality (3.11), we obtain

$$\Big|\frac{\partial F_k}{\partial x_i}\Big| \leq c_m h^{m(\frac{1}{2}-\sigma)-\frac{3}{2}}, \quad m>0.$$

We construct a sequence of domains $L_1, L_2, \ldots, L_{l+1}$ such that

$$L_{l+1} = D \setminus [\overline{\omega}_k(h,\varepsilon)\cup\overline{\omega}_0(\varepsilon)], L_j \subset L_{j+1},$$

and the distance between L_j and ∂L_{j+1} equals $\frac{h^\sigma}{l}$, $j=1,2,\ldots,l$. For any point x_0 in L_j the ball with the radius $\frac{h^\sigma}{l}$ and center x_0 is contained in L_{j+1} : $K_{\frac{h^\sigma}{l}}(x_0)\subset L_{j+1}$. Hence, applying the last inequality to the equation

$$\Delta D^{l+1-j}F_k - \frac{1}{h}D^{l+1-j}F_k = 0 \ \text{ in } L_j, \ \ D^j = \frac{\partial^j}{\partial x_1^{n_1}\partial x_2^{n_2}\partial x_3^{n_3}}, j = n_1+n_2+n_3,$$

we get

$$\max_{\overline{L}_j}|D^{l+1-j}F_k(x,h,\varepsilon)| \leq c_m h^{\frac{m}{l}(\sigma-\frac{1}{2})-\frac{3}{2}}\max_{\overline{L}_{j+1}}|D^{l-j}F_k(x,h,\varepsilon)|.$$

By considering these inequalites one by one for $j=1,2,\ldots,l$ and estimating the right-hand side of the jth inequality using the $(j+1)$th inequality, we finally get

$$\max_{x\in\overline{D}_k(h,\varepsilon}|D^lF_k(x,h,\varepsilon)| \leq [c_m h^{\frac{m}{l}(\sigma-\frac{1}{2})-\frac{3}{2}}]^l\max_{x\in\overline{D}}|F_k(x,h,\varepsilon)|.$$

Since m is an arbitrary positive number, we can choose it so that $\sigma_1 = m(\sigma-\frac{1}{2})-\frac{3}{2}l > 0$. The proof of (3.14) is quite similar. □

Denote

$$\begin{aligned}\omega_k(h,\varepsilon,\sigma) &= \{x\in D: 1-h^\sigma < u_k(x,h,\varepsilon) < 1+\varepsilon+h^\sigma,\}, \ \omega_k^1(h,\varepsilon,\sigma)\\ &= \{x\in D: 1-h^\sigma < u_{k-1}(x,h,\varepsilon) < 1+\varepsilon+h^\sigma\}\cup\omega_k(h,\varepsilon,\sigma), \ \omega_0(h,\varepsilon,\sigma)\\ &= \{x\in D: 1-h^\sigma < u_0 < 1+\varepsilon+h^\sigma\}.\end{aligned}$$

THEOREM 3.5. *Let the assumptions of Theorem* 3.2 *hold and*

$$\Big\|\frac{\varphi_k-\varphi_{k-1}}{h}\Big\|_{C^\alpha(\overline{D})} + \|\varphi_k\|_{C^{2+\alpha}(\overline{D})} \leq c.$$

Then $\forall h > 0, \varepsilon^3 \geq \sqrt{h}$ *the following estimations hold:*

$$\left\| \frac{u_k - u_{k-1}}{h} \right\|_{C^\alpha(\overline{\Omega}_k^1)} + \|u_k\|_{C^{2+\alpha}(\overline{\Omega}_k)} \leq \|w_k\|_{C^{2+\alpha}(\overline{D})} + c_1 h^{\sigma_1}, \sigma_1 > 0, \tag{3.15}$$

$$\Omega_k = \{x \in D \setminus [\overline{\omega}_k(h,\varepsilon,\sigma) \cup \overline{\omega}_0(h,\varepsilon)] : \ \operatorname{dist}(x, \partial D) \geq h^\sigma\},$$

$$\Omega_k^1 = \{x \in D \setminus [\overline{\omega}_k^1(h,\varepsilon,\sigma) \cup \overline{\omega}_0(h,\varepsilon)] : \ \operatorname{dist}(x, \partial D) \geq h^\sigma\},$$

$$\min_{x \in \overline{\Omega}_k^1} \frac{u_{k-1} - u_k}{h} \geq \min_{x \in \overline{D}} \frac{w_{k-1} - w_k}{h} - c_2 h^{\sigma_2}, \quad \sigma_2 > 0, \tag{3.16}$$

the constants c_i, σ_i *do not depend on* h, ε, *and* k.

Proof. Note that (3.17) and (3.18) follow from (3.13) and (3.14). After that the statements of the theorem become obvious. □

THEOREM 3.6. *Let* $\varphi_1(x,t) \equiv 0$, $\varphi_2(x,t) \equiv q = \text{const}$, $q > 1$,

$$\psi \in C^{2+\alpha}(\overline{D}) \ \ \frac{\partial \psi}{\partial \rho} > 0 \ in \ \overline{D}, \ \rho = |x|, \ \ \Delta\psi \leq 0 \quad in \quad \overline{D}, \tag{3.17}$$

then

$$\min_{x \in \overline{D}, 1 \leq k \leq N} \frac{\partial w_k}{\partial \rho} \geq c_2, \quad \min_{x \in \overline{\Omega}_k, 1 \leq k \leq N} \frac{\partial u_k}{\partial \rho} \geq \min_{x \in \overline{D}, 1 \leq k \leq N} \frac{\partial w_k}{\partial \rho} - c_3 h^{\sigma_1}, \quad \sigma_1 > 0, \tag{3.18}$$

where the constants $c_i, i = 1,2,3$, σ_1 *do not depend on* h, ε, *and* k.

Proof. As Theorem 2.1 implies,

$$\Delta w_k = \frac{w_k - w_{k-1}}{h} \leq 0.$$

Let $v(x)$ be a function which satisfies the following conditions:

$$\Delta v = 0 \ \text{ in } \ D, \ \ v = 0 \ \text{ on } \ \partial B_1, \ \ v = q \ \text{ on } \ \partial B_2.$$

Obviously,

$$v(x) \leq w_k(x,h,\varepsilon) \leq w_0 = \psi(x) \ \text{ in } \ D.$$

This implies

$$\left.\frac{\partial w_k}{\partial \rho}\right|_{\partial B_2} \geq \left.\frac{\partial \psi}{\partial \rho}\right|_{\partial B_2}, \ \ \left.\frac{\partial w_k}{\partial \rho}\right|_{\partial B_1} \geq \left.\frac{\partial v}{\partial \rho}\right|_{\partial B_1}.$$

Assume now that

$$\min_{x \in \overline{D}, 1 \leq k \leq N} \left(\rho \frac{\partial w_k}{\partial \rho}\right) = \left(\rho \frac{\partial w_n}{\partial \rho}\right)\Big|_{x = x_0}, \quad x_0 \in D.$$

We differentiate (1.6) with respect to ρ. It will give

$$\Delta\left(\rho \frac{\partial w_n}{\partial \rho}\right) - \frac{1}{h}\left(\rho \frac{\partial w_n}{\partial \rho} - \rho \frac{\partial w_{n-1}}{\partial \rho}\right) = 2\frac{w_n - w_{n-1}}{h}.$$

As at a point of local minimum of $\left(\rho\frac{\partial w_n}{\partial\rho}\right)$, $\Delta(\rho\frac{\partial w_n}{\partial\rho})\le 0$, we have

$$\rho\frac{\partial w_n}{\partial\rho}-\rho\frac{\partial w_{n-1}}{\partial\rho}\ge 2(w_{n-1}-w_n)\ge 0.$$

Hence, there exists a constant $c_1>0$ such that it does not depend on h, ε, and k, and

$$\min_{x\in\overline{D},1\le k\le N}\frac{\partial w_k}{\partial\rho}\ge c_1>0.$$

By (1.5) we get

$$\frac{\partial u_k}{\partial\rho}=\frac{\partial w_k}{\partial\rho}+\frac{\partial F_k}{\partial\rho}.$$

The relation (3.13) completes the proof of (3.20). □

4. Passage to the limit. Let the function $\eta(x,t)\in C^{2,1}(\overline{D})$ be equal to zero on $(\partial D\times(0,T))\cup(D\times(t=T))$, $\eta_k(x)=\eta(x,kh)$. Let us represent (1.1) as

$$\Delta u_k-\frac{u_k-u_{k-1}}{h}=-\frac{\lambda}{h}[\chi_\varepsilon(u_k)-\chi_\varepsilon(u_{k-1})]+\Delta F_{k-1}.$$

We multiply (1.1) by $h\eta_k(x)$, integrate it over D, and take the sum over k from 1 to N. After simple transformations we obtain

$$h\sum_{k=1}^{N}\int_D\Big\{\nabla u_k\nabla\eta_k+\frac{1}{h}(u_k-u_{k-1})\eta_k+\lambda\chi_\varepsilon(u_k)\frac{\eta_{k+1}-\eta_k}{h}\Big\}dy$$

$$+\lambda\int_D\chi_\varepsilon(u_0)\eta_1dy+h\sum_{k=1}^{N-1}\int_D\frac{F_k-F_{k-1}}{h}\psi_{k+1}dy=0, \tag{4.1}$$

where $\psi_k=h\sum\limits_{l=k}^{N}\Delta\eta_l$. Let us denote by $\{\overline{u}(x,t,h,\varepsilon)\}$ the piecewise linear interpolations of the functions $\{u_k(x,h,\varepsilon)\}$ with respect to the variable t. If $t\in[(k-1)h,kh]$, then

$$\overline{u}(x,t,h,\varepsilon)=u_{k-1}(x,h,\varepsilon)+\frac{u_k(x,h,\varepsilon)-u_{k-1}(x,h,\varepsilon)}{h}(t-(k-1)h).$$

Let

$$\begin{aligned}G_T(h,\varepsilon)&=\{(x,t)\in D_T:\overline{u}(x,t,h,\varepsilon)>1+\varepsilon+h^\sigma\},\ \ \Omega_T(h,\varepsilon)\\&=\{(x,t)\in D_T:\overline{u}(x,t,h,\varepsilon)<1-h^\sigma\},\ \ \gamma_T^-(h,\varepsilon)=\partial\Omega_T\cap D_T,\\\gamma_T^+(h,\varepsilon)&=\partial G_T\cap D_T,\\\gamma_0^+(\varepsilon)&=\{x\in D:\psi(x)=1+\varepsilon\}.\end{aligned}$$

THEOREM 4.1. *Let the following conditions be satisfied:*

$$\psi(x)\in C^{2+\alpha}(\overline{D}),\quad \Delta\psi\le 0\quad in\quad\overline{D},\quad \frac{\partial\psi}{\partial\rho}>0\quad in\quad\overline{D},$$

$$\varphi_1(x,t)=0 \quad on \quad \partial B_1, \quad \varphi_2(x,t)=q=\text{const}>1 \quad on \quad \partial B_2,$$

and assume that the corresponding compatibility conditions at $t=0$, $x\in\partial\Omega_T\cup\partial G_T$ *hold. Then* $\forall\, T>0$, *there exists a unique solution of the problem* (0.1)–(0.4) *and*

$$u(x,t)\in C(\overline{D}_T)\cap\Big(H^{2+\alpha,1+\frac{\alpha}{2}}(\overline{\Omega}_T)\times H^{2+\alpha,1+\frac{\alpha}{2}}(\overline{G}_T)\Big);$$

the free boundary is given by the graph $\rho=\omega(\theta_1,\theta_2,t)$ *of a function* $\omega(\theta_1,\theta_2,t)\in H^{2+\alpha,1+\frac{\alpha}{2}}(\overline{\Pi}_T)$, *where* (ρ,θ_1,θ_2) *are spherical coordinates,* $\Pi=\{(\theta_1,\theta_2):0<\theta_1<2\pi, 0<\theta_2<\pi\}$, $\Pi_T=\Pi\times(0,T)$.

Proof. From the estimations (3.2*) and (3.6) it follows that $\dfrac{\partial\overline{u}}{\partial t}$ is uniformly bounded everywhere in $\overline{D}_T$ and $|\nabla\overline{u}|$ is uniformly bounded everywhere in $\overline{D}_T$ excluding the set, whose measure vanishes as $h,\varepsilon\to 0$.

Denote

$$u(x,t)=\lim_{\varepsilon,h\to 0}\overline{u}(x,t,h,\varepsilon), \quad \varepsilon^4\geq\sqrt{h}.$$

From (3.20) it follows that

$$\frac{\partial\overline{u}}{\partial\rho}\geq c>0 \quad \text{on} \quad \Omega_T(h,\varepsilon)\cup G_T(h,\varepsilon). \tag{4.2}$$

Therefore, the level surfaces $\gamma_T^{\pm}(h,\varepsilon)$ can be given by the explicit equations

$$\rho=\omega^{+}(\theta,t,h,\varepsilon), \quad \rho=\omega^{-}(\theta,t,h,\varepsilon),$$

respectively, and

$$\omega_t^{\pm}=-\frac{\overline{u}_t^{\pm}}{\overline{u}_\rho^{\pm}}, \quad \omega_{\theta_i}^{\pm}=-\frac{\overline{u}_{\theta_i}^{\pm}}{\overline{u}_\rho^{\pm}}, \quad i=1,2,$$

are uniformly bounded. The functions $\frac{1}{h}[F_k(x,h,\varepsilon)-F_{k-1}(x,h,\varepsilon)]$ are nonnegative and uniformly bounded in $\overline{D}$, and, besides, the estimate (3.14) holds.

The assumptions of Theorem 4.1 on the initial conditions imply

$$\lim_{\varepsilon\to 0}\text{mes}\{1\leq\psi\leq 1+\varepsilon\}=0, \quad \lim_{\varepsilon\to 0}\gamma_0^{+}(\varepsilon)=\gamma_0,$$

and Corollary 3.1 implies that for $\overline{u}(x,t,h,\varepsilon)$, (3.11*) holds.

The facts stated above allow us to pass to the limit in (4.1) as $\varepsilon\to 0, h\to 0, \varepsilon^4\geq\sqrt{h}$. It gives

$$\int\limits_{D_T}\Big[\nabla u\nabla\eta+u_t\eta\Big]dxdt+\lambda\int\limits_{D_T\cap\{u<1\}}\eta_t dxdt+\lambda\int\limits_{\Omega_0}\eta(x,0)dx$$
$$+\lambda\int\limits_{D_T^1}\lim_{\varepsilon,h\to 0}\chi_\varepsilon(\overline{u})\eta_t dxdt+\int\limits_{D_T^1}\lim_{\varepsilon,h\to 0}F_t\int\limits_t^T\Delta\eta d\tau\, dxdt=0,$$

where $D_T^1=D_T\cap\{u=1\}$. This integral identity implies that

$$\Delta u-u_t=0 \ \text{ in } \ \Omega_T\cup G_T,$$

where $\Omega_T = \lim\limits_{\varepsilon,h\to 0} \Omega_T(h,\varepsilon)$, $G_T = \lim\limits_{\varepsilon,h\to 0} G_T(h,\varepsilon)$,

$$\lambda \int\limits_{D_T^1} \lim_{\varepsilon,h\to 0} \chi_\varepsilon(\overline{u})\eta_t dxdt + \int\limits_{D_T^1} \lim_{\varepsilon,h\to 0} F_t \int\limits_t^T \Delta\eta(x,\tau)d\tau dxdt$$
$$+ \int\limits_{\gamma_T^-} [\frac{\partial u}{\partial n^-} + \lambda\cos(n^-,t)]\eta ds + \int\limits_{\gamma_T^+} \frac{\partial u}{\partial n^+}\eta ds = 0,$$

where $n^\pm$ are the outward pointing normal vectors to $\partial\Omega_T, \partial G_T$, respectively. Let $\eta(x,t) = 0$ on γ_T^-. Then

$$\lambda \int\limits_{D_T^1} \lim_{\varepsilon,h\to 0} \chi_\varepsilon(\overline{u})\eta_t dxdt + \int\limits_{D_T^1} \lim_{\varepsilon,h\to 0} F_t \int\limits_t^T \Delta\eta(x,\tau)d\tau dxdt + \int\limits_{\gamma_T^+} \frac{\partial u}{\partial n^+}\eta ds = 0. \tag{4.3}$$

Let us take $\eta(x,t)$ as a solution of the following problem:

$$\begin{gathered} \Delta\eta - \eta_t = -f_t(x,t) \text{ in } D_T \setminus \overline{\Omega}_T, \\ \eta(x,t)\Big|_{\gamma_T^-} = 0, \ \ \eta(x,t)\Big|_{\partial D_2} = 0, \ \ \eta(x,0) = \Phi(x) \geq 0 \text{ in } D \setminus \Omega_0, \end{gathered} \tag{4.4}$$

where $f(x,t)$, $\Phi(x)$ are given smooth functions. The change of variables

$$\rho' = R_1 + \frac{\rho - \omega^-(\theta,t)}{R_2 - \omega^-(\theta,t)}, \ \theta' = \theta, \ t' = t$$

maps the domain $D_T \setminus \overline{\Omega}_T$ onto a cylinder, and (4.5) in new coordinates will have varying coefficients. The solvability of this problem follows from [11, chap. 4, §9]. Let us choose $f(x,t), \Phi(x)$ so that

$$f_t(x,t) \geq 0, f_{tt}(x,t) \leq 0, f(x,T) = 0, \Delta\Phi + f_t(x,0) \leq 0.$$

Then the maximum principle implies that

$$\eta(x,t) \geq 0, \ \ \eta_t(x,t) \leq 0.$$

Note also that $\frac{\partial u}{\partial n^+} \leq 0$ on γ_T^+. All these facts and the identity (4.4) imply

$$\int\limits_{D_T^1} \lim_{\varepsilon,h\to 0} F_t f(x,t)dxdt \geq 0.$$

Hence, $\text{mes}\,\{(x,t) \in D_T^1 : \lim\limits_{\varepsilon,h\to 0} F_t > 0\} = 0$. After that one can easily prove that $\text{mes}\,\{(x,t) \in D_T^1 : \lim\limits_{\varepsilon,h\to 0} \chi_\varepsilon(\overline{u}) > 0\} = 0$.

As a result we obtain that

$$\int\limits_{D_T} \Big\{\nabla u\nabla\eta + u_t\eta + \lambda\chi(u)\eta_t\Big\}dxdt + \lambda \int\limits_D \chi(\psi)\eta(x,0)dx = 0, \tag{4.5}$$

where $\chi(u)$ is the characteristic function of the domain Ω_T, $\chi(\psi)$ is the characteristic function of the domain Ω_0. Identity (4.6) implies $\gamma_T^+ = \gamma_T^- = \gamma_T = \partial\Omega_T \cap D = \partial G_T \cap D$, and the equation of the free boundary $\gamma_T = \partial\Omega_T \cap D = \partial G_T \cap D$ has the form $\rho = \omega(\theta, t)$, where ω_θ, ω_t are uniformly bounded. As follows from the estimation (3.17), $\|u_t(x,t)\|_{C^\alpha(\overline{\Omega}_T \cup \overline{G}_T)}$, $\|u_{xx}(x,t)\|_{C^\alpha(\overline{\Omega}_T \cup \overline{G}_T)}$ are bounded by a constant which does not depend on t. The domains obtained by cutting the domains Ω_T, G_T by planes $t = \text{const.}$ have the cone property. Then, by [21, chap. 2, §3] we get

$$u_x(x,t) \in H^{1,\alpha/2}(\overline{\Omega}_T) \times H^{1,\alpha/2}(\overline{G}_T).$$

Then (4.6) implies that the condition (0.3) holds everywhere on the free boundary. From this we obtain that

$$u(x,t) \in \left\{ H^{2+\alpha.1+\alpha/2}(\overline{\Omega}_T) \times H^{2+\alpha,1+\alpha/2}(\overline{G}_T) \right\} \cap C(\overline{D}_T), \frac{\partial u^\pm}{\partial \rho}\Big|_{\gamma_T} \geq c > 0,$$

the free boundary is given by the graph $\rho = \omega(\theta_1, \theta_2, t)$ of a function $\omega(\theta_1, \theta_2, t)$ $\in H^{2+\alpha,1+\frac{\alpha}{2}}(\overline{\Pi}_T)$, where $(\rho, \theta_1, \theta_2)$ are spherical coordinates, $\Pi = \{(\theta_1, \theta_2) : 0 < \theta_1 < 2\pi, 0 < \theta_2 < \pi\}$, $\Pi_T = \Pi \times (0, T)$.

The uniqueness of solution of the Stefan problem is proved, for example, in [21, chap. 5, §9]. □

Remark. If in the hypothesis of the theorem we omit the requirement $\psi_\rho > 0$ in $\overline{D}$, then the existence of global classical solution can be proved if we additionally assume that

$$\Delta\psi < 0 \quad \text{in} \quad \overline{D}, \quad \frac{\partial \varphi_i}{\partial t} < 0 \quad \text{in} \quad \overline{D}_T.$$

Then, the free boundary is the graph of a function of $C^{1+\frac{\alpha}{2}}$ class.

A MATHEMATICAL STUDY OF THE RELAXED OPTICAL FLOW PROBLEM IN THE SPACE $BV(\Omega)$*

G. AUBERT† AND P. KORNPROBST†

Abstract. This paper describes a variational approach for estimating a discontinuous optical flow from a sequence of images. Defined as the apparent motion of the image brightness pattern, the optical flow is very important in the computer vision community, where its accurate estimation is strongly needed. After a short overview of existing methods, we present a new variational method that we study in the space of bounded variations. We first present an integral representation of the optical flow problem which appears to be not lower semicontinuous. The relaxed functional is then calculated. We conclude by challenging questions about the possible numerical analysis of the abstract results.

Key words. measure theory, space of bounded variations, convex functions of measures, Γ-convergence, elliptic equations, relaxation of ill-posed problems, optical flow, computer vision

1. Introduction.

This paper deals with the estimation of the movement in a sequence of images. This velocity field will be called the optical flow. In the computer vision community, it is well known that the optical flow is a rich source of information about the geometrical structure of the world. Many numerical algorithms on the optical flow estimation and its applications have been performed. They have clearly shown how the optical flow can be used to recover information about slant and tilt of surface elements, ego-motion, shape information, time to collision, etc. [31, 32, 30, 34, 33, 29, 28, 38, 50, 24, 37, 49, 27, 9, 40, 41].

Almost all of these approaches use the classical brightness constancy assumption that relates the gradient of brightness to the components of the local flow to estimate. Because this problem is ill-posed, additional constraints are usually required. The most common approach is to add a quadratic smoothness constraint, as done originally by Horn and Schunk [29]. However, in order to estimate the optical flow more accurately, other constraints involving high order spatial derivatives have also been used [40]. Nevertheless, several of the proposed methods lacked robustness to the presence of occlusion and yielded smooth optical flow. The variational approach proposed in this paper is motivated by the need to recover the optical flow while preventing the method from trying to smooth the solution across the flow discontinuities. To cope with discontinuities, we propose in this article a complete mathematical study of the relaxed optical flow problem in the space $BV(\Omega)$. We first present an integral representation of the optical flow problem which does not appear to be lower semicontinuous.

This article is organized as follows.

In section 1, we define the problem and propose a variational approach to solve it. The general idea is based on a conservation law of the intensity along the trajectories. We will deal with an ill-posed problem that we will solve by regularizing the unknowns.

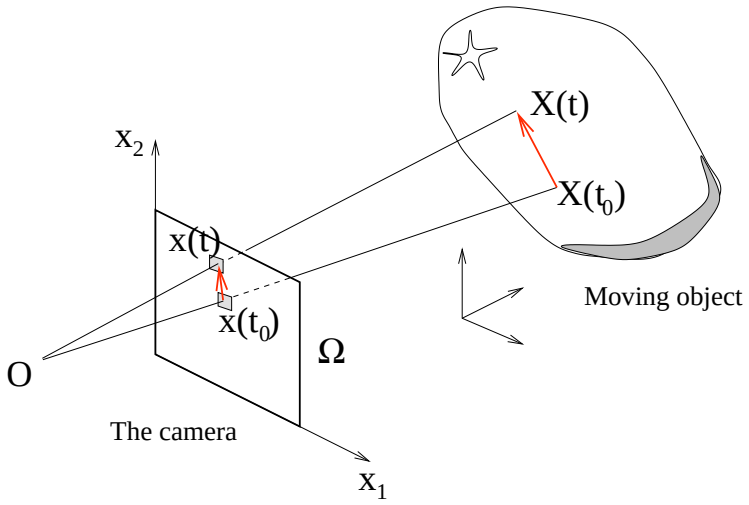

FIG. 2.1. *Pinhole model of camera. Ω is the domain of the image; O is the optical center.*

Section 3 presents some general recalls about the space of bounded variations (noted $BV(\Omega)$). Classically used for problems coming from computer vision, this space permits discontinuities along curves (in dimension 2).

In section 4, we concentrate on the meaning of the energy we defined. This will permit us to consider some integral representation results of the duality pairing of an integrable function with a measure. Similar results have been proved by Anzellotti [3], and we will extend them under weaker assumptions. This will enable us to obtain a fully developed expression for energy that we have to minimize. Unfortunately, the proposed energy is not lower semicontinuous for the weak topology of $BV(\Omega)$.

Section 5 is devoted to the computation of the relaxed functional. This part is mainly technical and is based on ideas developed by Bouchitté et al. [14, 13].

Finally, we prove in section 6 that there exists a solution in $\mathbf{BV}(\Omega)$ for the relaxed formulation.

2. The optical flow problem: Definition and modelization.

2.1. Definition. As shown in Figure 2.1, we can modelize a camera as a simple projective model. Consequently, the first idea is to say that the two-dimensional velocity field in the image corresponds to the projection of the three-dimensional velocity field of the objects. However, variations of intensity due to shadows do not correspond to any real motion. The importance of the light source can be seen toward other phenomena. For instance, if the object is sparkling, the reflected luminosity changes rapidly with the position. This is the case for bodywork, glasses, etc. Finally, notice the unavoidable problem of noise in images. These intensity variations may be interpreted as false motions which have no physical meaning.

Thanks to these remarks, we will define the optical flow as the two-dimensional velocity field describing the changes in intensity between images. In many cases, it can be interpreted as an approximation of the projection of the three-dimensional velocity field which animates physical objects. We will see in the next section how we can traduce it mathematically.

2.2. A short overview. In this last decade, numerous methods have been proposed to compute optical flow. Several ideas have been used: working with regions, curves, lines, or points. There is also a wide range of methodologies: wavelets, Markov random fields, Fourier analysis, and naturally partial differential equations [29, 28, 38, 50, 24, 37, 49, 27, 18, 40, 41]. We refer the interested reader to two (mainly computational) general surveys:

• Barron, Fleet, and Beauchemin [9] explain the main techniques and perform numerical quantitative experiments to compare them. (The database used for tests is also available.)

• Orkisz and Clarysse [39] propose an updated version of the preceding one.

In this article we will concentrate upon the class of *differential methods* (as named by Barron, Fleet, and Beauchemin) which have been proved to be among the best [9]. Their common point is the consistency intensity hypothesis of a point during its movement. More precisely, we will assume that

(2.1) *"The intensity of a point keeps constant along its trajectory."*

This hypothesis is called the *optical flow constraint* (OFC) hypothesis. We can consider it as reasonable, almost along short times, for which changes of the brightness are weak.

Let $x(t) = (x_1(t), x_2(t)) \in \Omega \subset R^2$ be the projection of the point $X(t) \in R^3$ at time t (see Figure 2.1,). For $x \in \Omega$, we denote by $u(t,x)$ the reflected intensity (the brightness) of the point x at time t. Let t_0 be fixed. Using these notations, a natural way to express (2.1) is

$$u(t, x(t)) = u(t_0, x(t_0)). \tag{2.2}$$

By differentiating (2.2) with respect to t, we obtain, for $t = t_0$,

$$\sigma(x) \cdot Du(t_0, x) + u_t(t_0, x) = 0, \qquad x \in \Omega,$$

where $\sigma = (\sigma_1, \sigma_2)^T = \left(\frac{dx_1}{dt}, \frac{dx_2}{dt}\right)^T$ is the unknown velocity field, $D\cdot$ is the spatial gradient operator, and u_t denotes the temporal derivative of $u(t,x)$. (Derivatives are written in the distributional sense.) This equation is the OFC. Naturally, this scalar equation is insufficient to compute both components of the flow field. This problem is usually called the *aperture problem*. Additional constraints are therefore required to reduce the space of admissible functions. Several possibilities are then possible: use additional constraints, consider special movements (rigid or fluids), regularize the velocity field, etc. We refer to [6], where we notably propose an overview of these different methods.

Our starting point will be the method proposed by Horn and Schunk in 1981 [29]. The idea is to minimize the following energy:

$$E_{HS}(\sigma) = \underbrace{\int_\Omega ((\sigma \cdot Du) + u_t)^2 dx}_{\mathtt{A}} + \alpha^r \sum_{j=1}^{2} \underbrace{\int_\Omega \|D\sigma_j\|^2 dx}_{\mathtt{B}}, \tag{2.3}$$

where α^r is a positive constant. The interpretation of this functional is the following: we would like the OFC to be zero (term A) and the gradient magnitude to be minimum (term B). Notice that term B is the classical Tikhonov–Arsenin [48] relaxation known to smooth isotropically. With this method, we obtain a smooth optical flow, and flow discontinuities are lost.

2.3. Setting the problem. The purpose of this work is to propose a model able to cope with the discontinuities of the optical flow. Starting from (2.3), we propose to minimize the energy

$$E(\sigma) = \underbrace{\int_\Omega |(\sigma \cdot Du) + u_t|}_{\mathtt{A}} + \alpha^r \underbrace{\sum_{j=1}^{2} \int_\Omega \phi(D\sigma_j)}_{\mathtt{B}} + \alpha^h \underbrace{\int_\Omega c(x)\|\sigma\|^2 dx}_{\mathtt{C}}, \tag{2.4}$$

where α^r, α^h are positive constants, $\phi(\cdot)$ and $c(\cdot)$ to be determined. We refer the interested reader to [35, 6] for the detailed construction of this model. Let us describe briefly the main differences:

(i) Term `A` is comparable to term `A` in (2.3). Here we choose the L^1 norm which must be interpreted in term of measures. As we will see in what follows, since the data u belongs a priori to $BV(\Omega)$, we cannot use the L^2 norm as done in (2.3).

(ii) Term `B` is again a regularization term. The functions $\phi(\cdot)$ have been chosen so that we can preserve discontinuities. The key idea is to forbid smoothing across discontinuities. Such ideas initially were proposed in the image restoration background [45, 20, 5, 7], and many functions have been proposed. Typically, admissible functions are convex functions with linear growth at infinity. For instance, we will choose the minimal hypersurface function

$$\phi(s) = \sqrt{s^2 + 1}.$$

We mention that term `B` will be interpreted as convex functions of measures.

(iii) Finally, term `C` permits us to handle the homogeneous regions. Typically, $c(x)$ is high for low spatial gradients of u (hence penalizing velocities in poor information zones) and low for high spatial gradients of u (no intervention).

3. General recalls. In this section we recall main notations and definitions. We refer to [1, 22, 25, 23, 53] for the complete theory.

Let Ω be a bounded open set in R^N with Lipschitz-regular boundary $\partial\Omega$. We denote by $\mathcal{L}^N$ or dx the N-dimensional Lebesgue measure in R^N and by $\mathcal{H}^\alpha$ the α-dimensional Hausdorff measure. We also set $|E| = \mathcal{L}^N(E)$, the Lebesgue measure of a measurable set $E \subset R^N$. $\mathcal{B}(\Omega)$ denotes the family of the Borel subsets of Ω. We will denote the strong, the weak, and weak$\star$ convergences in a space $V(\Omega)$ by $\xrightarrow[V(\Omega)]{}$, $\xrightarrow[V(\Omega)]{}$, and $\xrightarrow[V(\Omega)]{\star}$, respectively. Spaces of vector-valued functions will be denoted by bold characters.

Working with images requires that the functions we consider can be discontinuous along curves. This is impossible with classical Sobolev spaces such as $W^{1,1}(\Omega)$. This is why we need to use the space of bounded variations ($BV(\Omega)$) defined by

$$BV(\Omega) = \left\{ u \in L^1(\Omega); \sup \int_\Omega u \mathrm{div}(\varphi) dx < \infty : \varphi \in \mathcal{C}_0^1(\Omega)^N, |\varphi|_\infty \leq 1 \right\},$$

where $\mathcal{C}_0^1(\Omega)$ is the set of differentiable functions with compact support in Ω. We will note

$$|Du|(\Omega) = \sup \left\{ \int_\Omega u \mathrm{div}(\varphi) dx : \varphi \in \mathcal{C}_0^1(\Omega)^2, |\varphi|_\infty \leq 1 \right\}.$$

If $u \in BV(\Omega)$ and Du is the gradient in the sense of distributions, then Du is a vector-valued Radon measure and $|Du|(\Omega)$ is the total variation of Du on Ω. The set of Radon measure is noted $\mathcal{M}(\Omega)$

The product topology of the strong topology of $L^1(\Omega)$ for u and of the weak$\star$ topology of measures for Du will be called the weak$\star$ topology of BV and will be denoted by $BV - w\star$.

$$u^n \xrightarrow[BV-w\star]{} u \iff \begin{cases} u^n \xrightarrow[L^1(\Omega)]{} u, \\ Du^n \xrightarrow[\mathcal{M}(\Omega)]{\star} Du. \end{cases} \tag{3.1}$$

We recall that every bounded sequence in $BV(\Omega)$ admits a subsequence converging in $BV - w\star$.

We define the approximate upper limit $u^+(x)$ and the approximate lower limit $u^-(x)$ by

$$u^+(x) = \inf\left\{t \in [-\infty, +\infty] : \lim_{\rho \to 0^+} \frac{\mathcal{L}^N\left(\{u > t\} \cap B_\rho(x)\right)}{\rho^N} = 0\right\},$$
$$u^-(x) = \sup\left\{t \in [-\infty, +\infty] : \lim_{\rho \to 0^+} \frac{\mathcal{L}^N\left(\{u < t\} \cap B_\rho(x)\right)}{\rho^N} = 0\right\},$$

where $B_\rho(x)$ is the ball of center x and radius ρ. We denote by S_u the jump set, that is, the complement up to a set of $\mathcal{H}^{N-1}$ measures zero of the set of Lebesgue points; i.e., the set of points x where $u^+(x)$ is different $u^-(x)$, namely,

$$S_u = \{x \in \Omega / u^-(x) < u^+(x)\}.$$

After choosing a normal $n_u(x)$ $(x \in S_u)$ pointing toward the largest value of u, we recall the following decompositions (see [2] for more details):

$$Du = \nabla u \cdot \mathcal{L}_N + C_u + (u^+ - u^-) n_u \cdot \mathcal{H}^{N-1}_{|S_u}, \tag{3.2}$$

$$|Du|(\Omega) = \int_\Omega \|\nabla u\| dx + \int_{\Omega \setminus S_u} |C_u| + \int_{S_u} (u^+ - u^-) d\mathcal{H}^{N-1}, \tag{3.3}$$

where ∇u is the density of the absolutely continuous part of Du with respect to the Lebesgue measure, C_u is the Cantor part, and $\mathcal{H}^{N-1}$ is the Hausdorff measure of dimension $N-1$.

We then recall the definition of a convex function of measures. We refer to the works of Goffman–Serrin [26] and Demengel–Temam [19] for more details. Let $\phi(\cdot)$ be convex and finite on R with linear growth at infinity. Let ϕ^∞ be the asymptote (or recession) function defined by $\phi^\infty(z) = \lim_{s \to \infty} \frac{\phi(sz)}{s} \in [0; +\infty)$. Then, for $u \in BV(\Omega)$, using classical notations, we define

$$\int_\Omega \phi(Du) = \int_\Omega \phi(\|\nabla u\|) dx + \phi^\infty(1) \int_{S_u} (u^+ - u^-) d\mathcal{H}^{N-1} + \phi^\infty(1) \int_{\Omega \setminus S_u} |C_u|. \tag{3.4}$$

Finally, we mention that this function is lower semicontinuous for the $(BV - w\star)$-topology.

4. The integral representation of the optical flow problem.

4.1. The precise formulation. This section is devoted to the mathematical study of the optical flow model proposed in section 2.3. Let us recall it. Without loss of generality, we will assume that $\alpha^r = \alpha^h = 1$. For $u \in BV(R \times \Omega)$, the problem is to find σ minimizing the energy

$$E(\sigma) = \int_\Omega |(\sigma \cdot Du) + u_t| + \sum_{j=1}^{N} \int_\Omega \phi(D\sigma_j) + \int_\Omega c(x)\|\sigma\|^2 dx, \tag{4.1}$$

where the infimum is taken over the space $\mathbf{BV}(\Omega)$. The function $\phi(\cdot)$ verifies

$$\phi : R \to R^+ \text{ is an even and convex function, nondecreasing on } R^+. \tag{4.2}$$

There exist constants $d > 0$ and $b \geq 0$ such that

$$dx - b \leq \phi(x) \leq dx + b \text{ for all } x \in R, \tag{4.3}$$

$$\phi^\infty(1) = 1, \tag{4.4}$$

$$\phi^*(x^*) \leq k, \qquad \text{for all } x^* \in dom(\phi^*) \qquad (k \text{ constant}), \tag{4.5}$$

where ϕ^* is the Legendre–Fenchel conjugate function of ϕ. Note that hypotheses (4.3) and (4.5) permit the assertion that (see [43])

$$\phi(x) \geq \phi^\infty(x) - k. \tag{4.6}$$

Finally, we assume that the function $c(\cdot)$ verifies the following assumptions:

$$c \in \mathcal{C}^\infty(\Omega), \tag{4.7}$$

$$\text{there exists a constant } m_c > 0 \text{ such that } c(x) \in [m_c, 1] \text{ for all } x \text{ in } \Omega. \tag{4.8}$$

4.2. The duality pairing $(\sigma \cdot Du)$: An extended integral representation. This part is devoted to a better understanding of the functional to be minimized (4.1) and especially the product $(\sigma \cdot Du)$. In fact, what can we say about the product of an integrable function and a measure? This question has been treated for special cases, with suitable hypotheses on σ and u (see [3, 47, 12]). For example, Anzellotti [3] supposes

$$\sigma \in \mathbf{X}(\Omega) \cap \mathcal{C}^0(\Omega; R^N) \text{ and } u(t_0, \cdot) \in BV(\Omega),$$
$$\sigma \in \mathbf{X}(\Omega) \text{ and } u(t_0, \cdot) \in W^{1,1}(\Omega),$$

where $\mathbf{X}(\Omega) = \{\sigma \in \mathbf{L}^\infty(\Omega);\ \mathrm{div}(\sigma) \in L^N(\Omega)\}$. Our aim is to extend his results for a more general class of product $(\sigma \cdot Du)$. We suppose that

$$\sigma \in \mathbf{BV}(\Omega) \cap \mathbf{X}(\Omega), \tag{4.9}$$

$$u(t_0, \cdot) \in SBV(\Omega) \cap L^\infty(\Omega), \tag{4.10}$$

where $SBV(\Omega)$ is the space of special bounded variations (the Cantor part of Du is zero).

Remark. The hypothesis (4.10) is quite general. We mention to the interested reader a more applied work where we assumed only that the data u is Lipschitz [6]. In that case, there is no problem to define the L^1 norm of the optical flow constraint,

and we proved the existence and uniqueness of the minimization problem posed on $\mathbf{BV}(\Omega)$. We also proposed a convergent algorithm to approximate the solution (using Γ-convergence arguments) and showed some numerical results on synthetic and real sequences.

The space $\mathbf{X}(\Omega)$ is a Banach space endowed with the norm

$$\|\sigma\|_{\mathbf{X}(\Omega)} = \|\sigma\|_{\mathbf{L}^\infty(\Omega)} + \|\mathrm{div}(\sigma)\|_{L^N(\Omega)},$$

and we can define a weak$\star$ topology on $\mathbf{X}(\Omega)$ by

$$\sigma^n \xrightarrow[\mathbf{X}(\Omega)]{} \sigma \quad \Longleftrightarrow \quad \begin{cases} \sigma^n \xrightarrow[\mathbf{L}^\infty(\Omega)]{\star} \sigma, \\ \mathrm{div}(\sigma^n) \xrightarrow[L^N(\Omega)]{} \mathrm{div}(\sigma). \end{cases}$$

To make sense of the pairing $(\sigma \cdot Du)$, our first thought is to define it by duality:

$$\int_\Omega \varphi(\sigma \cdot Du) = -\int_\Omega u\varphi \mathrm{div}(\sigma)dx - \int_\Omega u\sigma\nabla\varphi dx \quad \text{for all} \quad \varphi \ \text{ in } \ \mathcal{C}_c^1(\Omega). \tag{4.11}$$

Note that with hypotheses (4.9) and (4.10), the right-hand side of (4.11) is completely defined. We can prove [3, 12] that $(\sigma \cdot Du)$ is a bounded measure, absolutely continuous with respect to $|Du|$.

Our aim is to find an integral representation of that measure.

To this end, we need to introduce the precise representation of σ, noted $\tilde{\sigma}$ and defined by

$$\tilde{\sigma}(x) = \lim_{r\to 0} \frac{1}{\mathcal{L}^N(B(x,r))} \int_{B(x,r)} \sigma(y)dy. \tag{4.12}$$

If σ is simply in $\mathbf{L^1}(\Omega)$, the right-hand side limit exists $\mathcal{L}^N$ almost everywhere (a.e.) and is equal to $\sigma(x)$. However, if σ is also in $\mathbf{BV}(\Omega)$, we can explicitely write the limit $\mathcal{H}^{N-1}$ a.e. using σ^+, σ^-. We have [52, 22]

$$\tilde{\sigma}(x) = \frac{\sigma^+(x) + \sigma^-(x)}{2}, \qquad \mathcal{H}^{N-1} \text{ a.e. on } S_\sigma. \tag{4.13}$$

Another interesting property of $\tilde{\sigma}$ is that we have the approximation result

$$\tilde{\sigma}(x) = \lim_{\varepsilon\to 0} \eta_\varepsilon \star \sigma(x), \qquad \mathcal{H}^{N-1} \text{ a.e.}, \tag{4.14}$$

where (η_ε) are the usual mollifiers: $\eta_\varepsilon \in \mathcal{C}_c^\infty(R^N), spt(\eta_\varepsilon) \subset B(0,\varepsilon), 0 \le \eta_\varepsilon \le 1$, $\int_{R^N} \eta_\varepsilon(x)dx = 1$. The function $\tilde{\sigma}$ is called the *precise representation* of σ since it permits us in some way to define $\sigma - \mathcal{H}^{N-1}$ a.e. Remark that $\tilde{\sigma}$ and σ are in fact the same elements in $\mathbf{BV}(\Omega)$ (they belong to the same equivalent class of $\mathcal{L}^N$a.e. equal functions) so that their distributional derivatives are the same.

From now on, we will consider that $N = 2$. For two measures μ and ν in $\mathcal{M}(\Omega)$, we will denote by $\frac{d\mu}{d\nu}$ the Radon–Nikodym derivative of μ with respect to ν (see [22] for more details).

The main result of this section is the following proposition.

PROPOSITION 4.1. *If $\sigma \in \mathbf{X}(\Omega) \cap \mathbf{BV}(\Omega)$ and $u(t_0, \cdot) \in SBV(\Omega) \cap L^\infty(\Omega)$, then we have*

$$\int_B (\sigma \cdot Du) = \int_B \tilde{\sigma}(x) \cdot \frac{dDu}{d|Du|}(x)|Du| \quad \text{for all Borel set } B \text{ in } \Omega. \tag{4.15}$$

Moreover, if $u \in SBV(\Omega)$, we obtain

$$\int_\Omega (\sigma \cdot Du) = \int_\Omega \sigma \cdot \nabla u dx + \int_{S_u} \tilde{\sigma} \cdot n_u (u^+ - u^-) d\mathcal{H}^{N-1}. \tag{4.16}$$

Before proving this result, we mention a convergence result which can be demonstrated using arguments from [3].

LEMMA 4.2. *Let $\sigma_\varepsilon = \eta_\varepsilon \star \sigma(x)$. If $\sigma \in \mathbf{BV}(\Omega) \cap \mathbf{X}(\Omega)$, then we have*

$$\sigma_\varepsilon \xrightarrow[\mathbf{L}^\infty(A)]{\star} \sigma, \tag{4.17}$$

$$\operatorname{div}(\sigma_\varepsilon) \xrightarrow[L^p(A)]{} \operatorname{div}(\sigma), \qquad p < \infty, \tag{4.18}$$

for all open sets $A \subset \Omega$. Moreover, for all $u \in BV_{loc}(\Omega) \cap L^\infty(\Omega)$, one has

$$(\sigma_\varepsilon \cdot Du) \xrightarrow[\mathcal{M}(\Omega)]{} (\sigma \cdot Du). \tag{4.19}$$

Proof of Proposition 4.1. If we denote $\sigma_\varepsilon = \eta_\varepsilon \star \sigma$, then for all $\varphi \in \mathcal{C}_c^1(\Omega)$, we have (see Lemma 4.2)

$$\langle (\tilde{\sigma} \cdot Du), \varphi \rangle = \lim_{\varepsilon \to 0} \langle (\sigma_\varepsilon \cdot Du), \varphi \rangle. \tag{4.20}$$

As $Du \ll |Du|$, by the Radon–Nikodym theorem, there exists a function $h \in L^1_{|Du|}(\Omega)$, $|h(x)| = 1$, such that $Du = h|Du|$. Thus, since $\sigma_\varepsilon \in L^\infty_{|Du|}(\Omega)$ ($\sigma_\varepsilon \in \mathcal{C}^\infty(\Omega)$) we can write

$$\langle (\sigma_\varepsilon \cdot Du), \varphi \rangle = \int_\Omega \varphi \sigma_\varepsilon \cdot h|Du|. \tag{4.21}$$

Equations (4.20) and (4.21) imply that

$$\langle (\sigma \cdot Du), \varphi \rangle \;=\; \lim_{\varepsilon \to 0} \int_\Omega \varphi \sigma_\varepsilon \cdot h|Du|. \tag{4.22}$$

What remains is to show the permutation between the limit and the integral in (4.22). To do this, we use the Lebesgue dominated convergence theorem. Classically, two requirements are necessary:

• The pointwise convergence of $\varphi(x)\sigma_\varepsilon(x) \cdot h(x)$ to $\varphi(x)\tilde{\sigma}(x) \cdot h(x)$. It comes from (4.14). Notice that the pointwise convergence is true $\mathcal{H}^{N-1}$ a.e. and consequently $|Du|$ a.e.

• Find a function which dominates the sequence. In fact, since Ω is bounded, it is sufficient to prove that the L^∞ norm of $\varphi(x)\sigma_\varepsilon(x) \cdot h(x)$ is bounded uniformly by a constant. Since φ is in $\mathcal{C}_c^1(\Omega)$ and $|h(x)| = 1$, it is enough to show that there exists a constant C such that $\|\sigma_\varepsilon\|_{\mathbf{L}^\infty{}_{Du}(\Omega)} \le C$. In fact we have

$$\|\sigma_\varepsilon\|_{\mathbf{L}^\infty_{\mathbf{Du}}(\Omega)}, \le \underset{R^N}{\sup} \; |\sigma_\varepsilon| \;\underset{[*]}{\le} \|\sigma\|_{\mathbf{L}^\infty_{\mathcal{L}^\mathbf{N}}(\Omega)} \le C,$$

where inequality [∗] is shown in [3]. Consequently, we can apply the Lebesgue dominated convergence theorem. This permits us to pass to the limit in (4.22) as $\varepsilon \to 0$, and we get (4.15). It is then an easy task to get (4.16) from (4.15) using the decomposition (3.2). □

4.3. Application to the optical flow problem. Now that we have found an expression of the product $(\sigma \cdot Du)$, we will give in the next proposition the integral representation of the functional E, which will be used in what follows.

We will assume that

$$u \in SBV(R \times \Omega) \cap L^{\infty}(R \times \Omega). \tag{4.23}$$

There exists $h_1 \in L^1(\Omega)$ and $h_2 \in L^1_{\mathcal{H}^1}(S_u)$ such that

$$u_t = h_1 \mathcal{L}^2 + h_2 \mathcal{H}^1|_{S_u}. \tag{4.24}$$

Notice that the assumption means that the measure u_t is absolutely continuous with respect to $|Du|$. This is physically correct, since when there is no texture (no gradient), no intensity variation should be observed.

PROPOSITION 4.3. *We assume that $N = 2$. Let u verifying hypotheses* (4.23)–(4.24). *Then the function E defined on $\mathbf{X} \cap \mathbf{BV}(\Omega)$ by*

$$E(\sigma) = \int_{\Omega} |(\sigma \cdot Du) + u_t| + \sum_{j=1}^{2} \int_{\Omega} \phi(D\sigma_j) + \int_{\Omega} c(x) \|\sigma\|^2 dx \tag{4.25}$$

with hypotheses (4.2)–(4.3), (4.4)–(4.6), (4.7)–(4.8)*can be rewritten as*

$$\begin{aligned} E(\sigma) = & \int_{\Omega} |\sigma \cdot \nabla u + h_1| dx + \int_{S_u} |\tilde{\sigma} \cdot n_u (u^+ - u^-) + h_2| d\mathcal{H}^1 \\ & + \sum_{j=1}^{2} \int_{\Omega} \phi(D\sigma_j) + \int_{\Omega} c(x) \|\sigma\|^2 dx. \end{aligned} \tag{4.26}$$

Proof. Thanks to [46, Theorem 6.13], we know that if ν is a positive measure on $\mathcal{M}(\Omega)$, $g \in L^1_{\nu}$, and λ is the measure defined by

$$\lambda(E) = \int_E g d\nu,$$

then we have

$$|\lambda|(E) = \int_E |g| d\nu.$$

Moreover, using the decomposition of the measure u_t and the result (4.16), we have

$$\int_{\Omega} (\sigma \cdot Du) + u_t = \int_{\Omega} (\sigma \cdot \nabla u + h_1) dx + \int_{S_u \cap \Omega} (\tilde{\sigma} \cdot n_u (u^+ - u^-) + h_2) d\mathcal{H}^1.$$

Using the fact that dx and $d\mathcal{H}^1$ are mutually singular and applying the above theorem, we can conclude the proof. □

COMMENTARY ABOUT PROPOSITION 4.3. The interesting point in the integral representation (4.26) is that we no longer need the divergence of σ to be integrable. Consequently, (4.26) can be viewed as an extension of E defined a priori for $\sigma \in \mathbf{BV}(\Omega)$. The next section is devoted to the theoretical study of that extension.

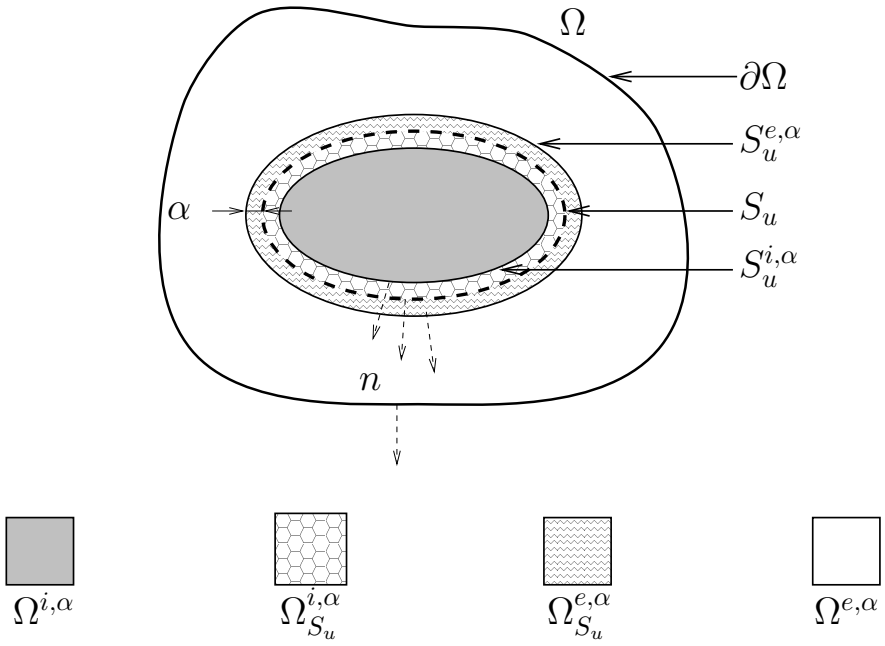

FIG. 5.1. *Notation of the simplified problem. Notice that the normals are all oriented toward the exterior.*

5. The relaxed problem. After introducing notation and assumptions in section 5.1, we show in section 5.2 that the functional that we are considering is not lower semicontinuous for the $BV - w\star$ topology. As a consequence, the existence of a solution cannot be shown for the initial problem. We then search for the relaxed functional for a suitable topology in section 5.4 after proving some preliminary results in section 5.3.

5.1. Notation and assumptions. To simplify proofs and notation, we will assume in this section that $N = 2$ and that S_u is a single $\mathcal{C}^1$ curve as shown in Figure 5.1, where the main notation is introduced. Notice that the parameter α corresponds to the distance between S_u and $S_u^{e,\alpha}$ (or $S_u^{i,\alpha}$). We will also use the superscript i (respectively, e) to mention that we are considering the restriction of the function to $\Omega^i \equiv \Omega^{i,0}$ (respectively, $\Omega^e \equiv \Omega^{e,0}$). The Hausdorff measure of dimension 1 is denoted by ds.

Using this notation we rewrite the integral on S_u of (4.26), which is

$$\int_{S_u} |\tilde{\sigma} \cdot n_u(u^+ - u^-) + h_2| ds. \tag{5.1}$$

Let $b = \pm 1$ be the function such that $n_u = bn$, where n is the normal oriented toward the exterior (Voir Figure 5.1). Let $\tilde{h}_2$ be the function defined by $\tilde{h}_2 = bh_2$. It is then easy to check that (5.1) may be rewritten as

$$\int_{S_u} \left| \frac{\sigma^i + \sigma^e}{2} \cdot n(u^+ - u^-) + \tilde{h}_2 \right| ds. \tag{5.2}$$

So, changing h_2 in $\tilde{h}_2$ allows us to have a normal independent of u. We will use this

expression, which is easier to handle. To simplify notation, we will omit the tilde superscript for h_2.

5.2. Statement of the problem. Let us first recall precisely the problem that we are going to study. Let $h_1 \in L^1(\Omega)$ and $h_2 \in L^1_{\mathcal{H}^1}(S_u)$. Let $\phi(\cdot)$ be a function verifying (4.2)–(4.3), (4.4)–(4.6), and c satisfying (4.7)–(4.8). Let E be the functional defined over $\mathbf{BV}(\Omega)$ by

$$\begin{aligned} E(\sigma) = & \int_\Omega |\sigma \cdot \nabla u + h_1| dx + \int_{S_u} |\tilde{\sigma} \cdot n(u^+ - u^-) + h_2| ds \\ & + \sum_{j=1}^{2} \int_\Omega \phi(D\sigma_j) + \int_\Omega c(x) \|\sigma\|^2 dx. \end{aligned} \tag{5.3}$$

We remark that it is well defined on $\mathbf{BV}(\Omega)$ thanks to the embedding of $\mathbf{BV}(\Omega)$ into $\mathbf{L^2}(\Omega)$ ($N = 2$) (see, for instance, [25]). Our aim is to study the existence of a solution to the minimization problem

$$\inf_{\sigma \in \mathbf{BV}(\Omega)} E(\sigma) \ . \tag{5.4}$$

Following the direct method of the calculus of variations, let (σ^n) be a minimizing sequence of (5.3). Thanks to hypotheses on functions $\phi(\cdot)$ and $c(\cdot)$, we can obtain a uniform majoration in $\mathbf{BV}(\Omega)$ and in $\mathbf{L^2}(\Omega)$, so we can extract a subsequence converging to some σ for the topology $BV - w\star$ and L^2-weak. The question is, Can we deduce an existence result for (5.4)? To answer this question, let us split the functional E in two parts, namely, P and L, defined by

$$P(\sigma) = \int_\Omega |\sigma \cdot \nabla u + h_1| dx + \sum_{j=1}^{2} \int_\Omega \phi(D\sigma_j) + \int_\Omega c(x) \|\sigma\|^2 dx, \tag{5.5}$$

$$L(\sigma) = \int_{S_u} \left| \frac{\sigma^i + \sigma^e}{2} \cdot n(u^+ - u^-) + h_2 \right| ds. \tag{5.6}$$

It is easy to show that we have

$$\lim_n P(\sigma^n) \geq P(\sigma),$$

but we cannot say anything about the term L. The reason is that the functional L is defined through traces and the trace application is not continuous for the weak$\star$ topology of $\mathbf{BV}(\Omega)$. Consequently, the functional E is not lower semicontinuous for the $BV - w\star$ topology. In such a situation, the idea is to study the relaxed functional.

We recall that for a functional F defined over a topological metrizable space X, the relaxed functional, noted $R(F)$, verifies that

$$\text{for all } u \in X, \forall u^n \to u. \liminf_n F(u^n) \geq R(F)(u), \tag{5.7}$$

$$\text{for all } u \in X, \exists u^n \to u. \limsup_n F(u^n) \leq R(F)(u). \tag{5.8}$$

$R(F)$ is in fact the higher lower semicontinuous functional less than or equal to F. We refer the interested reader to [36, 16] for a complete overview of the relaxation properties and consequences.

5.3. Preliminary results. As is usual when we have this kind of problem, we need to introduce additional variables and notation. Let us define the functionals $\tilde{L}$ and E_1 by

$$\tilde{L} : \mathbf{M}(S_u) \times \mathbf{M}(S_u) \to R, \qquad \tilde{L}(\mu^i, \mu^e) = \int_{S_u} d|\nu|, \tag{5.9}$$

where

$$\nu = \frac{\mu^i + \mu^e}{2} \cdot n(u^+ - u^-) + h_2 ds \tag{5.10}$$

and

$$E_1 : \mathbf{BV}(\Omega) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u) \to R, \qquad E_1(\sigma, \mu^i, \mu^e) = \begin{cases} P(\sigma) + \tilde{L}(\mu^i, \mu^e) & \text{if } \mu^i = \sigma^i ds \text{ and } \mu^e = \sigma^e ds, \\ +\infty & \text{otherwise.} \end{cases} \tag{5.11}$$

It is straightforward to see that

$$\inf_{\sigma \in BV(\Omega)} E(\sigma) = \inf_{(\sigma, \mu^i, \mu^e) \in \mathbf{BV}(\Omega) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u)} E_1(\sigma, \mu^i, \mu^e). \tag{5.12}$$

The functionals (5.3) and (5.11) are not weakly lower semicontinuous, so it is natural to search for the relaxed functionals of E and E_1, noted $R(E)$ and $R(E_1)$, for a suitable topology.

Thanks to classical results [36, 16], we have, using (5.12),

$$\inf_{\sigma \in BV(\Omega)} E(\sigma) = \inf_{\sigma \in BV(\Omega)} R(E)(\sigma) = \inf_{(\sigma, \mu^i, \mu^e) \in \mathbf{BV}(\Omega) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u)} R(E_1)(\sigma, \mu^i, \mu^e).$$

Moreover, since the relaxed functionals are lower semicontinuous, existence results can be proved. Our aim is then to compute these relaxed functionals, which is the main result of section 5. To this end, we will use the definitions (5.7) and (5.8). Difficulties are twofold:

- We must guess the expression of the functional which is a priori unknown. This will be done using the property (5.7) with some care.
- To check that the guess is really the relaxed functional, we need to verify (5.8). The main difficulty is that we must find the sequence (u^n) converging to a given u. However, we will see how we can avoid this difficulty.

We mention that the notion of relaxation is classical in many problems occurring in the calculus of variations: phase transition, fracture mechanics, and plasticity, to name a few. For recent advances and bibliography, we refer to [10].

The specificity of this work is that the surface energy is defined over a fixed set independent of the unknown σ. Moreover, we give an explicit representation of the

relaxed energy. We are going to establish that the functional $\overline{E}_1$ defined by

(5.13)

$$\overline{E}_1 : \mathbf{BV}(\Omega) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u) \to R,$$
$$\overline{E}_1(\sigma, \mu^i, \mu^e) = \int_\Omega |\sigma \cdot \nabla u + h_1| dx + \sum_{j=1}^{2} \int_{\Omega^i \cup \Omega^e} \phi(D\sigma_j) + \int_\Omega c(x) \|\sigma\|^2 + \int_{S_u} d|\nu| + \int_{S_u} \|\mu^i - \mu^e\|_1 + \int_{S_u} \|\mu^i - \sigma^i ds\|_1 + \|\mu^e - \sigma^e ds\|_1,$$

where $\|\eta\|_1 = |\eta_1| + |\eta_2|$ and the measure ν is defined by (5.10), is in fact the relaxed functional of E_1 for the topology $\mathbf{L^2}(\Omega^i \cup \Omega^e)$-strong $\times$ $\mathbf{M}(S_u)$-weak $\times$ $\mathbf{M}(S_u)$-weak. We are also going to prove that the functional defined by

(5.14)

$$\overline{E} : \mathbf{BV}(\Omega) \to R,$$
$$\overline{E}(\sigma) = \int_\Omega |\sigma \cdot \nabla u + h_1| dx + \sum_{j=1}^{2} \int_{\Omega^i \cup \Omega^e} \phi(D\sigma_j) + \int_\Omega c(x) \|\sigma\|^2 + \int_{S_u} \beta(x, \sigma^i, \sigma^e),$$

where

(5.15)

$$\beta(x, \lambda, \theta) = \mathrm{Inf} \left\{ |\lambda - s| + |\theta - t| + |s - t| + \left| \frac{s+t}{2} \cdot n(x)(u^+ - u^-) + h_2(x) \right| \ : \ (s,t) \in R^N \times R^N \right\},$$

is the relaxed functional of E. The expression of $\overline{E}$ will be deduced from $\overline{E_1}$.

Before finding (5.13) and (5.14), we first need to prove some preliminary results. The general idea is that, for technical reasons, we need to work with functions defined on more regular spaces. This is why we introduce the functionals E_2 and $\overline{E}_2$ defined by

(5.16)
$$E_2 : \mathbf{BV}(\Omega) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u) \to R,$$
$$E_2(\sigma, \mu^i, \mu^e) = \begin{cases} E_1(\sigma, \mu^i, \mu^e) & \text{if } \ \sigma \in \mathbf{W^{1,1}}(\Omega^i \cup \Omega^e), \\ +\infty & \text{otherwise} \end{cases}$$

and

(5.17)
$$\overline{E}_2 : \mathbf{BV}(\Omega) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u) \to R,$$
$$\overline{E}_2(\sigma, \mu^i, \mu^e) = \begin{cases} \overline{E}_1(\sigma, \mu^i, \mu^e) & \text{if } (\sigma, \mu^i, \mu^e) \in \mathbf{W^{1,1}}(\Omega^i \cup \Omega^e) \times \mathbf{L^1}(S_u) \times \mathbf{L^1}(S_u), \\ +\infty & \text{otherwise.} \end{cases}$$

The justification of considering $E_2, \overline{E}_2$ instead of $E_1, \overline{E}_1$ is given by Lemmas 5.2 and 5.3, where we prove that E_j and $\overline{E}_j (j = 1, 2)$ have the same relaxed functional for the topology $\mathbf{L^2}(\Omega^i \cup \Omega^e)$-strong $\times$ $\mathbf{M}(S_u)$-weak $\times$ $\mathbf{M}(S_u)$-weak. As this is equivalent to saying that they have the same dual functional [13], we will use (5.16) and (5.17) to

compute the dual functionals (Lemmas A.1, A.2) and to establish the main relaxation result.

Let us present a version of the slicing lemma of De Giorgi that will be useful in what follows.

THEOREM 5.1. *Let $\phi(\cdot)$ be a function verifying hypotheses* (4.2)–(4.3). *Let $u \in BV(\Omega) \cap L^2(\Omega)$. Then, for every open set $A \subset \Omega$ with Lipschitz boundary, we can find a sequence $u^n \in W^{1,1}(\Omega)$ such that*

$$u^n \xrightarrow[L^2(\Omega)]{} u, \tag{5.18}$$

$$u^n = u \quad on \quad \partial A, \tag{5.19}$$

$$\lim_{n\to\infty} \int_A \phi(\|\nabla u^n\|)dx = \int_A \phi(Du). \tag{5.20}$$

Notice that this theorem permits us to fix the trace at the boundaries.

Proof. The proof of this theorem is a consequence of Lemma 2.6 proposed in [11], which can be modified to obtain the strong convergence in L^2. □

LEMMA 5.2. *Let E_1 and E_2 be defined, respectively, by* (5.11) *and* (5.16). *Then E_1 and E_2 have the same lower semicontinuous relaxed functions for the topology $\mathbf{L^2}(\Omega^i \cup \Omega^e)$-strong $\times$ $\mathbf{M}(S_u)$-weak $\times$ $\mathbf{M}(S_u)$-weak.*

Proof. The proof contains two steps.

Step 1. Since we have $E_1 \leq E_2$, we deduce that

$$R(E_1) \leq R(E_2). \tag{5.21}$$

Step 2. The reverse inequality will be proven using an approximation argument. Let $(\sigma, \mu^i, \mu^e) \in \mathbf{BV}(\Omega) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u)$ such that E_1 be finite. Notice that this forces the measures μ^i, μ^e to be the traces of σ. We search for a sequence $(\sigma^n, \mu^{i^n}, \mu^{e^n}) \in \mathbf{W^{1,1}}(\Omega^i \cup \Omega^e) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u)$ converging to (σ, μ^i, μ^e) for the topology $\mathbf{L^2}(\Omega^i \cup \Omega^e)$-strong $\times$ $\mathbf{M}(S_u)$-weak $\times$ $\mathbf{M}(S_u)$-weak such that

$$\lim_{n\to\infty} E_2(\sigma^n, \mu^{i^n}, \mu^{e^n}) = E_1(\sigma, \mu^i, \mu^e). \tag{5.22}$$

If we can find such a sequence, then the proof is complete since equality (5.22) means that $E_1 \geq R(E_2)$. However, since $R(E_1)$ is the greatest lower semicontinuous function less than or equal to E_1, we deduce that

$$R(E_1) \geq R(E_2). \tag{5.23}$$

Inequalities (5.21) and (5.23) conclude the proof. The difficulty lies in finding such a sequence. The idea is to apply Theorem 5.1 in Ω^i and Ω^e, separately. In Ω^i, we obtain the existence of a sequence (σ^{i^n}) such that

$$\sigma^{i^n} \xrightarrow[L^2(\Omega^i)]{} \sigma,$$

$$\sigma^{i^n}|_{S_u} = \sigma^i|_{S_u},$$

$$\lim_{n\to\infty} \int_{\Omega^i} \phi(\|\nabla \sigma^{i^n}\|)dx = \int_{\Omega^i} \phi(D\sigma). \tag{5.24}$$

We proceed as we had done in Ω^e and define the sequence (σ^n)-$\mathcal{L}^2$ a.e. on Ω by

$$\sigma^n(x) = \begin{cases} \sigma^{i^n} & \text{if } x \in \Omega^i, \\ \sigma^{e^n} & \text{if } x \in \Omega^e. \end{cases}$$

It is easy to check that σ^n belongs to $\mathbf{W^{1,1}}(\Omega^i \cup \Omega^e)$. Using that sequence, we define the sequence of measures ${\mu^i}^n$ and ${\mu^e}^n$ defined on S_u by

$$ {\mu^i}^n = {\sigma^i}^n ds, \tag{5.25} $$

$$ {\mu^e}^n = {\sigma^e}^n ds. \tag{5.26} $$

Notice that since we have fixed the traces of σ^n on both sides of S_u, the sequences defined by (5.25)–(5.26) are in fact constant. So we have

$$ E_2(\sigma^n, {\mu^i}^n, {\mu^e}^n) = \underbrace{\int_\Omega |\sigma^n \cdot \nabla u + h_1| dx + \int_\Omega c(x) \|\sigma^n\|^2 dx}_{\text{continuous for the } L^2 \text{ strong topology}} + \sum_{j=1}^{2} \int_\Omega \phi(D\sigma_j^n) + \underbrace{\int_{S_u} d|\nu|}_{\text{constant}} $$

and, moreover,

$$ \begin{aligned} \int_\Omega \phi(D\sigma_j) &= \int_{\Omega^i} \phi(D\sigma_j) + \int_{\Omega^e} \phi(D\sigma_j) + \int_{S_u} |\sigma_j^i - \sigma_j^e| ds \\ &= \lim_{n\to\infty} \int_{\Omega^i} \phi(\|\nabla {\sigma_j^i}^n\|) dx + \lim_{n\to\infty} \int_{\Omega^e} \phi(\|\nabla {\sigma_j^e}^n\|) dx + \int_{S_u} |\sigma_j^i - \sigma_j^e| ds \\ &= \lim_{n\to\infty} \int_\Omega \phi(\|\nabla \sigma_j^n\|) dx. \end{aligned} $$

Thus condition (5.22) is satisfied, and this concludes the proof. ∎

LEMMA 5.3. *Let $\overline{E}_1$ and $\overline{E}_2$ be defined by* (5.13) *and* (5.17)*, respectively. Then $\overline{E}_1$ and $\overline{E}_2$ have the same lower semicontinuous relaxed functionals for the topology $\mathbf{L^2}(\Omega^i \cup \Omega^e)$-strong $\times$ $\mathbf{M}(S_u)$-weak $\times$ $\mathbf{M}(S_u)$-weak.*

Proof. This proof is inspired by the proof of Lemma 5.2. The first step is analogous, and the only difficulty is to find, for a given $(\sigma, \mu^i, \mu^e) \in \mathbf{BV}(\Omega) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u)$, a sequence $(\sigma^n, {\theta^i}^n, {\theta^e}^n) \in \mathbf{W^{1,1}}(\Omega^i \cup \Omega^e) \times \mathbf{L^1}(S_u) \times \mathbf{L^1}(S_u)$ such that

$$ \lim_{n\to\infty} \overline{E}_2(\sigma^n, {\theta^i}^n, {\theta^e}^n) = \overline{E}_1(\sigma, \mu^i, \mu^e). \tag{5.27} $$

Construction of the sequence σ^n uses the same arguments as in Lemma 5.2, that is, the use of Theorem 5.1 on Ω^i and Ω^e. We recall that the traces of σ^n on both sides of S_u are constant. The construction of the sequence approximating μ^i, μ^e is based on a result of Bouchitté–Valadier [14]. We recall that the part depending on the measures μ^i, μ^e in $\overline{E}_1$ is

$$ H(x, \mu^i, \mu^e, \sigma^i, \sigma^e) = \int_{S_u} d|\nu| + \int_{S_u} \|\mu^i - \mu^e\|_1 + \int_{S_u} \|\mu^i - \sigma^i ds\|_1 + \|\mu^e - \sigma^e ds\|_1, $$

where the measure ν is defined by (5.10). It is easy to check that the functional H is homogeneous, so that, using [14], we can find a sequence ${\theta^i}^n, {\theta^e}^n$ in $L^1(S_u)$ such that

$$ {\theta^i}^n \xrightarrow[\mathbf{M}(S_u)]{} \mu^i, $$

$$ {\theta^e}^n \xrightarrow[\mathbf{M}(S_u)]{} \mu^e, $$

$$ \lim_n H(x, {\theta^i}^n, {\theta^e}^n, \sigma^i, \sigma^e) = H(x, \mu^i, \mu^e, \sigma^i, \sigma^e). $$

Consequently, the constructed sequence $(\sigma^n, {\theta^i}^n, {\theta^e}^n)$ permits us to get (5.27), which concludes the proof. ∎

5.4. The relaxation results.

PROPOSITION 5.4. *Let E_1 be the functional defined by* (5.11) *with hypotheses* (4.23)–(4.24), (4.2)–(4.3), (4.4)–(4.6), (4.7)–(4.8). *Then the relaxed functional of E_1 for the topology $\mathbf{L^2}(\Omega^i \cup \Omega^e)$-strong $\times$ $\mathbf{M}(S_u)$-weak $\times$ $\mathbf{M}(S_u)$-weak is*

(5.28)

$$
\begin{aligned}
&R(E_1) : \mathbf{BV}(\Omega) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u) \to R,\\
&R(E_1)(\sigma, \mu^i, \mu^e) = \int_\Omega |\sigma \cdot \nabla u + h_1| dx + \sum_{j=1}^{2} \int_{\Omega^i \cup \Omega^e} \phi(D\sigma_j) + \int_\Omega c(x)\|\sigma\|^2\\
&\qquad + \int_{S_u} d|\nu| + \int_{S_u} \|\mu^i - \mu^e\|_1 + \int_{S_u} \|\mu^i - \sigma^i ds\|_1 + \|\mu^e - \sigma^e ds\|_1,\\
&\qquad \textit{where} \quad \nu = \frac{\mu^i + \mu^e}{2} \cdot n(u^+ - u^-) + h_2 ds.
\end{aligned}
$$

We can verify that we have $R(E_1) \leq E_1$ and that they are equal as soon as $\mu^e = \sigma^e ds$ and $\mu^i = \sigma^i ds$.

Proof. To simplify notations, we will note τ the topology $\mathbf{L^2}(\Omega^i \cup \Omega^e)$-strong $\times$ $\mathbf{M}(S_u)$-weak $\times$ $\mathbf{M}(S_u)$-weak and τ^d the topology $\mathbf{L^2}(\Omega^i \cup \Omega^e)$-weak $\times$ $\mathcal{C}^0(S_u)$-strong $\times$ $\mathcal{C}^0(S_u)$-strong. Notice that we will also use the notation M to denote a universal constant appearing in uniform bounds. This value may change from one line to another, but we will always write M.

We first remark that using Lemma 5.2 permits us to work on a more regular space, that is, with E_2. $R(E_2)$ is the relaxed functional of E_2 (or equivalently of E_1, thanks to Lemma 5.2) if and only if, for all $(\sigma, \mu^i, \mu^e) \in \mathbf{W^{1,1}}(\Omega^i \cup \Omega^e) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u)$, we have the following two conditions:

(i) for all $(\sigma^n, {\mu^i}^n, {\mu^e}^n) \underset{\tau}{\to} (\sigma, \mu^i, \mu^e)$, then

$$\liminf_{n\to\infty} E_2(\sigma^n, {\mu^i}^n, {\mu^e}^n) \geq R(E_2)(\sigma, \mu^i, \mu^e); \tag{5.29}$$

(ii) there exists $(\sigma^n, {\mu^i}^n, {\mu^e}^n) \underset{\tau}{\to} (\sigma, \mu^i, \mu^e)$ such that

$$\limsup_{n\to\infty} E_2(\sigma^n, {\mu^i}^n, {\mu^e}^n) \leq R(E_2)(\sigma, \mu^i, \mu^e). \tag{5.30}$$

The purpose of the two steps below is to establish that $R(E_2) = \overline{E}_2$.

Step 1. This part is devoted to proving that

$$\liminf_{n\to\infty} E_2(\sigma^n, {\mu^i}^n, {\mu^e}^n) \geq R(E_2)(\sigma, \mu^i, \mu^e)$$

for all the sequences $(\sigma^n, {\mu^i}^n, {\mu^e}^n)$ converging to (σ, μ^i, μ^e).

Let $(\sigma, \mu^i, \mu^e) \in \mathbf{W^{1,1}}(\Omega^i \cup \Omega^e) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u)$ and a sequence $(\sigma^n, {\mu^i}^n, {\mu^e}^n) \in \mathbf{BV}(\Omega) \times \mathbf{M}(S_u) \times \mathbf{M}(S_u)$ converging to (σ, μ^i, μ^e) for the τ-topology such that

$$E_2(\sigma^n, {\mu^i}^n, {\mu^e}^n) \leq M,$$

where M is a constant. Then, thanks to (4.3), we deduce that

$$\|\sigma^n\|_{BV(\Omega)} \leq M, \tag{5.31}$$

$$\text{on } S_u \text{ we have } \left\{ \begin{array}{l} \mu^{i^n} = \sigma^{i^n} ds, \\ \mu^{e^n} = \sigma^{e^n} ds, \end{array} \right. \quad \text{so} \quad \left\{ \begin{array}{l} \sigma^{i^n} ds \xrightarrow[\mathbf{M}(S_u)]{} \mu^i, \\ \sigma^{e^n} ds \xrightarrow[\mathbf{M}(S_u)]{} \mu^e. \end{array} \right. \tag{5.32}$$

Since the sequence (σ^n) is bounded in $BV(\Omega)$, we can deduce that there exists a measure $\tilde{\mu}$ such that

$$\sigma^n ds \xrightarrow[\mathcal{M}(\partial\Omega)]{} \tilde{\mu}. \tag{5.33}$$

Decomposing Ω permits us to write

$$\begin{aligned} E_2(\sigma^n, \mu^{i^n}, \mu^{e^n}) = & \int_\Omega |\sigma^n \cdot \nabla u + h_1| dx + \int_\Omega c(x) \|\sigma^n\|^2 dx \\ & + \sum_{j=1}^{2} \left(\int_{\Omega^i \cup \Omega^e} \phi(\|\nabla \sigma_j^n\|) dx \right) + \int_{S_u} \|\sigma^{i^n} - \sigma^{e^n}\|_1 ds \\ & + \int_{S_u} d|\nu^n|, \end{aligned}$$

where ν^n is given by (5.10). Thanks to the convergence properties, it is easy to check that

$$\begin{aligned} \liminf_{n\to\infty} \int_\Omega |\sigma^n \cdot \nabla u + h_1| dx + \int_\Omega c(x) \|\sigma^n\|^2 dx &\geq \int_\Omega |\sigma \cdot \nabla u + h_1| dx + \int_\Omega c(x) \|\sigma\|^2 dx, \\ \liminf_{n\to\infty} \int_{S_u} \|\sigma^{i^n} - \sigma^{e^n}\|_1 ds &\geq \int_{S_u} \|\mu^i - \mu^e\|_1 ds, \\ \liminf_{n\to\infty} \int_{S_u} d|\nu^n| &\geq \int_{S_u} d|\nu|. \end{aligned} \tag{5.34}$$

By classical arguments and for a fixed j, we also have

$$\liminf_{n\to\infty} \int_{\Omega^i \cup \Omega^e} \phi(\|\nabla \sigma_j^n\|) dx \geq \int_{\Omega^i \cup \Omega^e} \phi(D\sigma_j) dx.$$

However, this minoration will not allow us to conclude anything because we need to be more precise. Using the notation proposed in Figure 5.1, and especially the decomposition $\Omega^i \cup \Omega^e = \Omega^{i,\alpha} \cup \Omega^{e,\alpha} \cup \Omega_{S_u}^{i,\alpha} \cup \Omega_{S_u}^{e,\alpha}$, we can write

$$\int_{\Omega^i \cup \Omega^e} \phi(\|\nabla {\sigma_j}^n\|) dx = \underbrace{\int_{\Omega^{i,\alpha} \cup \Omega^{e,\alpha}} \phi(\|\nabla {\sigma_j}^n\|) dx}_{\mathtt{A}^\alpha} + \underbrace{\int_{\Omega_{S_u}^{i,\alpha} \cup \Omega_{S_u}^{e,\alpha}} \phi(\|\nabla {\sigma_j}^n\|) dx}_{\mathtt{B}^\alpha}. \tag{5.35}$$

We study both parts separately.

Integral A^α. By classical arguments [25], we can write

$$\liminf_{n\to\infty} \int_{\Omega^{i,\alpha} \cup \Omega^{e,\alpha}} \phi(\|\nabla \sigma_j^n\|) dx \geq \int_{\Omega^{i,\alpha} \cup \Omega^{e,\alpha}} \phi(D\sigma_j) dx. \tag{5.36}$$

Integral B^α. Thanks to (4.6), we have

$$\int_{\Omega^{i,\alpha}_{S_u}\cup\Omega^{e,\alpha}_{S_u}}\phi(\|\nabla\sigma_j{}^n\|)dx \geq \int_{\Omega^{i,\alpha}_{S_u}\cup\Omega^{e,\alpha}_{S_u}}\phi^\infty(\|\nabla\sigma_j{}^n\|)dx - k|\Omega^{i,\alpha}_{S_u}\cup\Omega^{e,\alpha}_{S_u}|.$$

However, since ϕ^∞ is convex, we have

$$\phi^\infty(\|\nabla\sigma_j{}^n\|) = \sup_{q^{Gj}\in R^2} q^{Gj}\cdot\nabla\sigma_j^n - (\phi^\infty)^*(q^{Gj}) \ ,$$

where

$$(\phi^\infty)^*(x^*) = \begin{cases} 0 & \text{if } x^*\in dom(\phi^*) = \{x^*\in R^2/|x^*|<1\},\\ +\infty & \text{otherwise.}\end{cases}$$

So, for any function $q^{Gj}(x)$ such that $q^{Gj}(x)\in dom(\phi^*)$ a.e. $x\in\Omega$ with q^{Gj} in K defined by

$$\begin{aligned} K = \{q\in&\mathbf{L^2}(\Omega) \text{ such that}\\ &\|q^i\|_{L^\infty(\Omega)}\leq 1, \|q^e\|_{L^\infty(\Omega)}\leq 1,\\ &\operatorname{div}(q^i) \text{ and } \operatorname{div}(q^e)\in L^2(\Omega),\\ &q^i\cdot n|_{S_u} \text{ and } q^e\cdot n|_{S_u}\in\mathcal{C}^0(S_u),\\ &q\cdot n|_{\partial\Omega}=0\},\end{aligned} \tag{5.37}$$

we have

$$\int_{\Omega^{i,\alpha}_{S_u}\cup\Omega^{e,\alpha}_{S_u}}\phi^\infty(\|\nabla\sigma_j{}^n\|) \geq \int_{\Omega^{i,\alpha}_{S_u}\cup\Omega^{e,\alpha}_{S_u}} q^{Gj}\cdot\nabla\sigma_j^n. \tag{5.38}$$

The set K has been introduced so that all the integrals that we are going to write below are well defined. The only remaining problem is to estimate the limit of the right-hand side. To this end, we first integrate by parts the same term, but on Ω. We have

$$\begin{aligned}\int_\Omega q^{Gj}\cdot\nabla\sigma_j^n dx &= \int_{\Omega^i} q^{Gj}\cdot\nabla\sigma_j^n dx + \int_{\Omega^e} q^{Gj}\cdot\nabla\sigma_j^n dx\\ &= -\int_{\Omega^i\cup\Omega^e}\operatorname{div}(q^{Gj})\sigma_j^n dx + \int_{S_u}(q^{Gj}{}^i\sigma_j^{i\,n} - q^{Gj}{}^e\sigma_j^{e\,n})\cdot n ds + \int_{\partial\Omega} q^{Gj}\sigma_j^n\cdot n ds.\end{aligned}$$

Thanks to the strong convergence in $\mathbf{L^2}(\Omega^i\cup\Omega^e)$ of the sequence σ^n and to (5.32) (5.33), we have

$$\begin{aligned}&\lim_{n\to\infty}\int_\Omega q^{Gj}\cdot\nabla\sigma_j^n\\ &\quad= -\int_{\Omega^i\cup\Omega^e}\operatorname{div}(q^{Gj})\sigma_j dx + \int_{S_u}(q^{Gj}{}^i\mu^i{}_j - q^{Gj}{}^e\mu^e{}_j)\cdot n + \int_{\partial\Omega} q^{Gj}\tilde{\mu}_j\cdot n.\end{aligned} \tag{5.39}$$

Moreover, if we consider $q^{Gj}\cdot\nabla\sigma_j^n$ as a measure, for $\varphi\in\mathcal{C}^1_c(\Omega)$, we have by (4.11)

$$\langle q^{Gj}\cdot\nabla\sigma_j^n,\varphi\rangle = -\int_\Omega\operatorname{div}(q^{Gj})\sigma_j^n\varphi dx - \int_\Omega q^{Gj}\cdot\nabla\varphi\sigma_j^n dx.$$

When n tends to infinity, we have

$$\lim_{n\to\infty}\langle q^{Gj}\cdot\nabla\sigma_j^n,\varphi\rangle = -\int_\Omega \mathrm{div}(q^{Gj})\sigma_j\varphi - \int_\Omega q^{Gj}\cdot\nabla\varphi\sigma_j$$
$$= \langle q^{Gj}\cdot\nabla\sigma_j,\varphi\rangle.$$

The last result is the same as saying that the measure $q^{Gj}\cdot\nabla\sigma_j^n$ converges to $q^{Gj}\cdot\nabla\sigma_j$ for the topology $\mathcal{M}(\Omega)$weak$\star$. Since Ω is bounded, we can prove in fact that

$$\lim_{n\to\infty}\int_{\Omega^{i,\alpha}\cup\Omega^{e,\alpha}} q^{Gj}\cdot\nabla\sigma_j^n dx = \int_{\Omega^{i,\alpha}\cup\Omega^{e,\alpha}} q^{Gj}\cdot\nabla\sigma_j dx. \tag{5.40}$$

Consequently, substracting (5.40) from (5.39) permits us to write

$$\lim_{n\to\infty}\int_{\Omega^{i,\alpha}_{S_u}\cup\Omega^{e,\alpha}_{S_u}} q^{Gj}\cdot\nabla\sigma_j^n dx = -\int_{\Omega^i\cup\Omega^e}\mathrm{div}(q^{Gj})\sigma_j dx - \int_{\Omega^{i,\alpha}\cup\Omega^{e,\alpha}} q^{Gj}\cdot\nabla\sigma_j dx$$
$$+\int_{S_u}(q^{Gj^i}\mu^i{}_j - q^{Gj^e}\mu^e{}_j)\cdot n + \int_{\partial\Omega} q^{Gj}\tilde{\mu}_j\cdot n,$$

and, after integrating by part the term $\displaystyle\int_{\Omega^{i,\alpha}\cup\Omega^{e,\alpha}} q^{Gj}\cdot\nabla\sigma_j dx$, we can rewrite (5.38):

$$\lim_{n\to\infty}\int_{\Omega^{i,\alpha}_{S_u}\cup\Omega^{e,\alpha}_{S_u}}\phi(\|\nabla\sigma_j^n\|)dx \geq -\int_{\Omega^i\cup\Omega^e}\mathrm{div}(q^{Gj})\sigma_j dx + \int_{\Omega^{i,\alpha}\cup\Omega^{e,\alpha}}\mathrm{div}(q^{Gj})\sigma_j dx$$
$$+\int_{S_u}(q^{Gj^i}\mu^i{}_j - q^{Gj^e}\mu^e{}_j)\cdot n$$
$$-\int_{S_u^{i,\alpha}} q^{Gj^i}\sigma_j^i\cdot n ds - \int_{S_u^{e,\alpha}} q^{Gj^e}\sigma_j^e\cdot n ds$$
$$+\int_{\partial\Omega} q^{Gj}\cdot n(\tilde{\mu}_j - \sigma_j ds). \tag{5.41}$$

Now that we have found a minoration for integrals A^α (5.36) and B^α (5.41), we merge both results and let α tend to 0. The obtained result is

$$\begin{aligned}
&\liminf_{n\to\infty} E_2(\sigma^n,\mu^{i^n},\mu^{e^n})\\
&\quad\geq \int_\Omega|\sigma\cdot\nabla u + h_1|dx + \sum_{j=1}^2\int_{\Omega^i\cup\Omega^e}\phi(D\sigma_j) + \int_\Omega c(x)\|\sigma\|^2 + \int_{S_u} d|\nu| + \int_{S_u}\|\mu^i-\mu^e\|_1\\
(\blacklozenge)\quad &+\sum_{j=1}^2\int_{S_u} q^{Gj^i}\cdot n(\mu^i{}_j - \sigma_j^i ds) - \sum_{j=1}^2\int_{S_u} q^{Gj^e}\cdot n(\mu^e{}_j - \sigma_j^e ds)\\
(\Diamond)\quad &+\sum_{j=1}^2\int_{\partial\Omega} q^{Gj}\cdot n(\tilde{\mu}_j - \sigma_j ds),
\end{aligned} \tag{5.42}$$

where $\nu = \dfrac{\mu^i+\mu^e}{2}\cdot n(u^+-u^-) + h_2 ds$. Since this inequality is true for all $\mathbf{q}^G = (q^{G1},q^{G2})\in K\times K$, it is still true when we take the supremum in $\mathbf{q}^G$. This supremum is taken for $q^{G1},q^{G2}\in K$ defined by (5.37). Next, we introduce the set

$$C(x) = \mathrm{closure}\{(q^i(x)\cdot n(x), q^e(x)\cdot n(x)),\quad (q^i,q^e)\in K\},$$

which can be rewritten as

$$
\begin{aligned}
C(x) = \text{closure}\{&(z^i,z^e) \in R^2 \text{ such that} \\
&\exists(\varphi^i,\varphi^e) \in [\mathcal{C}^0(S_u)]^2/\varphi^i(x) = z^i, \varphi^e(x) = z^e, \\
&\exists(q^i,q^e), \|q^i\|_\infty \le 1, \|q^e\|_\infty \le 1, \text{div}(q^i) \text{ and } \text{ div}(q^e) \in L^2(\Omega), \\
&q^i(x)\cdot n(x) = \varphi^i(x), q^e(x)\cdot n(x) = \varphi^e(x)\ ,\ x \in S_u \\
&q(x)\cdot n = 0 \quad x \in \partial\Omega\}.
\end{aligned}
$$

To compute the supremum of (5.42), we consider in (5.42) only the term noted with the symbol (⧫). Notice that the term noted with the symbol (◊) will not appear in the minimization thanks to the definition of the set K, where we have imposed $q\cdot n|_{\partial\Omega} = 0$. If we note

$$
W = \begin{pmatrix} (\mu^i{}_1 - \sigma^i_1, \mu^e{}_1 - \sigma^e_1) \\ (\mu^i{}_2 - \sigma^i_2, \mu^e{}_2 - \sigma^e_2) \end{pmatrix},
$$

we claim that

$$
\begin{aligned}
&\sup_{(q^{G1},q^{G2})\in K^2} \left\{ \sum_{j=1}^{2} \int_{S_u} q^{Gj\,i}\cdot n(\mu^i{}_j - \sigma^i_j ds) - \sum_{j=1}^{2}\int_{S_u} q^{Gj\,e}\cdot n(\mu^e{}_j - \sigma^e_j ds) \right\} \\
&= \sup_{Z} \int_{S_u} \sum_{j=1}^{2} Z^t_j \cdot W_j, \quad \text{where } Z = \begin{pmatrix} (z^i_1, z^e_1) \\ (z^i_2, z^e_2) \end{pmatrix} \in C(x)^2 \qquad (5.43) \\
&= \int_{S_u} \|\mu^i - \sigma^i ds\|_1 + \|\mu^e - \sigma^e ds\|_1. \qquad (5.44)
\end{aligned}
$$

Equality (5.43) corresponds to the permutation of the supremum. It is based on techniques developed in [15, 17]. We then need to express that supremum giving the expression (5.44) [14, 13]. We refer to [35] for the complete proof.

Finally, taking the supremum in (5.42) with respect to $q^{Gj\,i}$,$q^{Gj\,e}$ and using (5.44) permits us to have

$$
\liminf_{n\to\infty} E_2(\sigma^n, \mu^{i^n}, \mu^{e^n}) \ge \overline{E}_2(\sigma, \mu^i, \mu^e), \qquad (5.45)
$$

where $\overline{E}_2$ has been previously defined in (5.17). The functional $\overline{E}_2$ is then a candidate to be the relaxed functional of E_2. It remains to show the second condition (5.30) (with $R(E_2) = \overline{E}_2$), which is the aim of Step 2.

Step 2. The way to demonstrate (5.30) is based on the following assertion. Showing (5.30) is equivalent to proving that

$$
\begin{aligned}
&\text{for all } \ (f,\varphi^i,\varphi^e) \in \mathbf{L}^\infty(\Omega^i \cup \Omega^e) \times \mathcal{C}^0(S_u) \times \mathcal{C}^0(S_u) \\
&\text{there exists } (f^n, \varphi^{i^n}, \varphi^{e^n}) \underset{\tau^d}{\to} (f,\varphi^i,\varphi^e) \ \text{ such that} \\
&\liminf_{n\to\infty} E_2^*(f^n, \varphi^{i^n}, \varphi^{e^n}) \ge R(E_2)^*(f,\varphi^i,\varphi^e), \qquad (5.46)
\end{aligned}
$$

where the superscript $*$ denotes the conjugate functionals. This result is due to [8] (see also [13], where this idea has been used).

Naturally, the difficulty is to compute the conjugate functional of E_2 and $\overline{E_2}$. This is done in Lemmas A.1 and A.2 of the appendix. We have shown that

$$E_2^*(f,\varphi^i,\varphi^e) = \inf_{q\in\mathcal{A}(f,\varphi^i,\varphi^e)} J(q) \ ,$$

where the minimum is computed for $q=(q^\sigma,q^{G1},q^{G2},q^u,q^{T1},q^{T2},q^{S_u})$ in $(\mathbf{L}^\infty(\Omega^\mathbf{i}\cup\Omega^\mathbf{e}))^3 \times L^\infty(\Omega^i\cup\Omega^e)\times(\mathbf{L}^\infty(\mathbf{S_u}))^2\times L^\infty(S_u)$ verifying the conditions (A.2)–(A.10) (which defines the set $\mathcal{A}(f,\varphi^i,\varphi^e)$) and

$$\overline{E_2}^*(f,\varphi^i,\varphi^e) = \inf_{\overline{q}\in\overline{\mathcal{A}}(f,\varphi^i,\varphi^e)} \overline{J}(\overline{q})$$

when the minimum is computed for $\overline{q}=(\overline{q}^\sigma,\overline{q}^{G1},\overline{q}^{G2},\overline{q}^u,\overline{q}^{T1},\overline{q}^{T2},\overline{q}^{\mu^i},\overline{q}^{\mu^e},\overline{q}^{S_u})$ in $(\mathbf{L}^\infty(\Omega^\mathbf{i}\cup\Omega^\mathbf{e}))^3\times L^\infty(\Omega^i\cup\Omega^e)\times(\mathbf{L}^\infty(\mathbf{S_u}))^4\times L^\infty(S_u)$ verifying conditions (A.13)–(A.24) (which defines the set $\overline{\mathcal{A}}(f,\varphi^i,\varphi^e)$). For more details about the definitions of $J,\overline{J},\mathcal{A}(f,\varphi^i,\varphi^e)$ and $\overline{\mathcal{A}}(f,\varphi^i,\varphi^e)$, we refer to Lemmas A.1 and A.2.

Let $(f^n,{\varphi^i}^n,{\varphi^e}^n)$ be a sequence such that

$$\liminf_{n\to\infty} E_2^*(f^n,{\varphi^i}^n,{\varphi^e}^n) \le M, \tag{5.47}$$

where M is a constant. Then, for each n and using the definition of the conjugate function associated with E_2 (Lemma A.1), there exists a $q^n\in\mathcal{A}(f^n,{\varphi^i}^n,{\varphi^e}^n)$ so that

$$E_2^*(f^n,{\varphi^i}^n,{\varphi^e}^n) \ge J(q^n) - \frac{1}{n}. \tag{5.48}$$

Since $E_2^*(f^n,{\varphi^i}^n,{\varphi^e}^n)$ is uniformly bounded thanks to (5.47), it is easy to check that we can find an element $q\in\mathcal{A}(f,\varphi^i,\varphi^e)$ such that the sequence q^n converges to q for the weak topology of this space, that is to say, the topology

$$(\mathbf{L}^\infty(\Omega^\mathbf{i}\cup\Omega^\mathbf{e}))^3\text{weak}\times L^\infty(\Omega^i\cup\Omega^e)\text{weak}\times(\mathbf{L}^\infty(\mathbf{S_u}))^2\text{weak}\times L^\infty(S_u)\text{weak}.$$

As the function J is lower semicontinuous for this topology, we have

$$\liminf_{n\to\infty} J(q^n) \ge J(q) \ge \inf_{q\in\mathcal{A}(f,\varphi^i,\varphi^e)} J(q) \ . \tag{5.49}$$

Now, let us define the application T by

$$\begin{aligned} &T:\mathcal{A}(f,\varphi^i,\varphi^e)\to\overline{\mathcal{A}}(f,\varphi^i,\varphi^e),\\ &T(q)=\overline{q}, \end{aligned} \tag{5.50}$$

where $\overline{q}$ is defined by:

$$\begin{aligned}
\overline{q}^{\sigma} &= q^{\sigma},\\
\overline{q}^{Gj} &= q^{Gj}, \quad j = 1, 2,\\
\overline{q}^{u} &= q^{u},\\
\overline{q}^{S_u} &= q^{S_u},\\
\overline{q}^{Ti} &= \frac{1}{2} q^{S_u} \cdot n(u^+ - u^-) + q^{Ti},\\
\overline{q}^{Te} &= \frac{1}{2} q^{S_u} \cdot n(u^+ - u^-) + q^{Te},\\
\overline{q}^{\mu^i} &= \varphi^i - \frac{1}{2} q^{S_u} \cdot n(u^+ - u^-),\\
\overline{q}^{\mu^e} &= \varphi^e - \frac{1}{2} q^{S_u} \cdot n(u^+ - u^-).
\end{aligned}$$

An easy computation permits us to see that if q belongs to $\mathcal{A}(f, \varphi^i, \varphi^e)$, then $T(q)$ belongs to $\overline{\mathcal{A}}(f, \varphi^i, \varphi^e)$. Moreover, we can observe that

$$J(q) = \overline{J}(T(q)).$$

Consequently, using (5.48)–(5.49), the definition of the function T and Lemma A.2, we have

$$\begin{aligned}
\liminf_{n\to\infty} E_2^*(f^n, {\varphi^i}^n, {\varphi^e}^n) &\geq \inf_{q \in \mathcal{A}(f,\varphi^i,\varphi^e)} J(q) = \inf_{\overline{q} \in \overline{\mathcal{A}}(f,\varphi^i,\varphi^e) \cap Im(T)} \overline{J}(\overline{q})\\
&\geq \inf_{\overline{q} \in \overline{\mathcal{A}}(f,\varphi^i,\varphi^e)} \overline{J}(\overline{q}) = \overline{E}_2^*(f, \varphi^i, \varphi^e),
\end{aligned} \tag{5.51}$$

which is exactly the statement (5.46).

Conclusion. As we can observe, the functional $\overline{E}_2$ complies with conditions (5.45) and (5.51), that is to say, (5.29)–(5.30) (or, equivalently, (5.29)–(5.46)). As a conclusion, we have

$$R(E_2) = \overline{E}_2,$$

which is the desired statement. □

PROPOSITION 5.5. *The relaxed functional noted $R(E)$ of the functional E defined by* (5.3) *is given by*

(5.52)

$$R(E) : \mathbf{BV}(\Omega) \to R,$$

$$R(E)(\sigma) = \int_\Omega |\sigma \cdot \nabla u + h_1| dx + \sum_{j=1}^{2} \int_{\Omega^i \cup \Omega^e} \phi(D\sigma_j) + \int_\Omega c(x) \|\sigma\|^2 + \int_{S_u} \beta(x, \sigma^i, \sigma^e),$$

where

$$\beta(x, \lambda, \theta) = \operatorname{Inf} \left\{ |\lambda - s| + |\theta - t| + |s - t| + \left| \frac{s+t}{2} \cdot n(x)(u^+ - u^-) + h_2(x) \right| \ : \right. \tag{5.53}$$

$$\left. (s, t) \in R^N \times R^N \right\}.$$

Proof. This proposition is a direct consequence of Proposition 5.4, and we will just sketch the proof. Let us define

$$G(\sigma) = \inf_{(\mu^i,\mu^e)\in\mathcal{M}(\Omega)} \overline{E_1}(\sigma,\mu^i,\mu^e) \ .$$

By classical arguments, we prove that the functional G is lower semicontinuous, less than E, and also greater that $R(E)$; so in fact

$$G(\sigma) = R(E)(\sigma).$$

We deduce the final result from a Rockafellar theorem [42, 44] which permits to permute the infimum and the integral. □

6. Existence for the relaxed functional.

PROPOSITION 6.1. *Let $R(E)$ be defined by* (5.52) *and* (**??**), *where u verifies hypotheses* (4.23)–(4.24), *$\phi(\cdot)$ satisfies* (4.2)–(4.3), (4.4)–(4.6), *and $c(x)$ is a function verifying* (4.7)–(4.8). *Then the problem* $\mathrm{Inf}\{R(E)(\sigma) : \sigma \in \mathbf{BV}(\Omega)\}$ *admits a solution in* $\mathbf{BV}(\Omega)$.

Proof. The functional $R(E)$ is a convex function of measures which is lower semicontinuous by construction. Moreover, it is coercive, so we can uniformly bound minimizing sequences and deduce by classical arguments the existence of a solution. □

The above theorem proves an existence result for the relaxed functional associated to the optical flow problem. The main difficulty came from the product $(\sigma \cdot Du)$, for which we found an explicit integral representation. It will be interesting to study more general functionals involving terms of the form $f((\sigma \cdot Du))$. This question will be considered in a forthcoming paper.

Another challenging problem is the numerical analysis of these abstract results. This induces several difficulties. One of the first is to characterize the solution. No Euler equations can be written, but some partial answers have been given, using variational [4] or dual [51] formulations. Then it will be necessary to propose some suitable discretizations to take into account the discontinuities of the solution. These problems will be considered in the future.

Appendix A. The dual functionals E_2^* and $\overline{E}_2^*$. We give in the two lemmas below the detailed expressions of the dual functions associated to E_2 and $\overline{E}_2$.

LEMMA A.1. *Let E_2 be given by* (5.16). *Its dual functional is defined by*

$$\text{(A.1)} \qquad \begin{aligned} &E_2^* : \mathbf{L}^\infty(\Omega^i \cup \Omega^e) \times \mathcal{C}^0(S_u) \times \mathcal{C}^0(S_u) \to R, \\ &E_2^*(f,\varphi^i,\varphi^e) = \inf_{q\in\mathcal{A}(f,\varphi^i,\varphi^e)} J(q), \end{aligned}$$

where the infimum is taken over $q = (q^\sigma, q^{G1}, q^{G2}, q^u, q^{Ti}, q^{Te}, q^{S_u})$ belonging to $(\mathbf{L}^\infty(\Omega^\mathbf{i} \cup \Omega^\mathbf{e}))^3 \times L^\infty(\Omega^i \cup \Omega^e) \times (\mathbf{L}^\infty(\mathbf{S_u}))^2 \times L^\infty(S_u)$ and complying the following

conditions:

$$|q^u| \le 1 \quad \textit{a.e. on } \Omega, \tag{A.2}$$

$$|q^{Gj}| \le 1, j = 1, 2, \quad \textit{a.e. on } \Omega, \tag{A.3}$$

$$|q^{S_u}| \le 1 \quad \textit{a.e. on } S_u, \tag{A.4}$$

$$|q^{Ti} + \varphi^i| \le 1 \quad \textit{a.e. on } S_u, \tag{A.5}$$

$$q^u \nabla u + q^\sigma - \operatorname{div}(\mathbf{q}^{\mathbf{G}}) - f = 0 \quad \textit{on } \Omega, \tag{A.6}$$

$$\frac{1}{2} q^{S_u} n(u^+ - u^-) + q^{Ti} + \mathbf{q}^{\mathbf{G}^i} n = 0 \quad \textit{on } S_u, \tag{A.7}$$

$$\frac{1}{2} q^{S_u} n(u^+ - u^-) + q^{Te} + \mathbf{q}^{\mathbf{G}^e} n = 0 \quad \textit{on } S_u, \tag{A.8}$$

$$q^{Ti} + \varphi^i + q^{Te} + \varphi^e = 0 \quad \textit{on } S_u, \tag{A.9}$$

$$\mathbf{q}^{\mathbf{G}} n = 0 \quad \textit{on } \partial\Omega, \tag{A.10}$$

where $\mathbf{q}^{\mathbf{G}}$ *is the matrix defined by* $\mathbf{q}^{\mathbf{G}} = \begin{pmatrix} q^{G1^T} \\ q^{G2^T} \end{pmatrix}$ *and where the function* J *is defined by*

$$J(q) = \int_\Omega q^u h_1 dx + \int_\Omega \frac{1}{4c(x)^2} |q^\sigma|^2 dx + \sum_{j=1}^{2} \int_\Omega \phi^*(|q^{Gj}|) dx + \int_{S_u} q^{S_u} h_2 ds. \tag{A.11}$$

LEMMA A.2. *Let* $\overline{E}_2$ *given by* (5.17). *Its dual functional is defined by*

$$\begin{aligned} &\overline{E}_2^* : \mathbf{L}^\infty(\Omega^i \cup \Omega^e) \times \mathcal{C}^0(S_u) \times \mathcal{C}^0(S_u) \to R, \\ &\overline{E}_2^*(f, \varphi^i, \varphi^e) = \inf_{\overline{q} \in \overline{\mathcal{A}}(f, \varphi^i, \varphi^e)} \overline{J}(\overline{q}) \ , \end{aligned} \tag{A.12}$$

where the infimum is taken over $\overline{q} = (\overline{q}^\sigma, \overline{q}^{G1}, \overline{q}^{G2}, \overline{q}^u, \overline{q}^{Ti}, \overline{q}^{Te}, \overline{q}^{\mu^i}, \overline{q}^{\mu^e}, \overline{q}^{S_u})$ *belonging to* $(\mathbf{L}^\infty(\Omega^{\mathbf{i}} \cup \Omega^{\mathbf{e}}))^3 \times L^\infty(\Omega^i \cup \Omega^e) \times (\mathbf{L}^\infty(\mathbf{S_u}))^4 \times L^\infty(S_u)$ *and complying to the following conditions:*

$$|\overline{q}^u| \le 1 \quad \textit{a.e. on } \Omega, \tag{A.13}$$

$$|\overline{q}^{Gj}| \le 1 \quad (j = 1, 2) \quad \textit{a.e. on } \Omega, \tag{A.14}$$

$$|\overline{q}^{S_u}| \le 1 \quad \textit{a.e. on } S_u, \tag{A.15}$$

$$|\overline{q}^{Ti} + \overline{q}^{\mu^i}| \le 1 \quad \textit{a.e. on } S_u, \tag{A.16}$$

$$q^{Ti} \quad \textit{and} \quad q^{Te} \in \mathcal{C}(x) \quad \textit{a.e. on } S_u, \tag{A.17}$$

$$\overline{q}^u \cdot \nabla u + \overline{q}^\sigma - div(\overline{\mathbf{q}}^{\mathbf{G}}) - f = 0 \quad \textit{on } \Omega, \tag{A.18}$$

$$q^{Ti} + \overline{\mathbf{q}}^{\mathbf{G}^i} : n = 0 \quad \textit{on } S_u, \tag{A.19}$$

$$\overline{q}^{Te} + \overline{\mathbf{q}}^{\mathbf{G}^e} : n = 0 \quad \textit{on } S_u, \tag{A.20}$$

$$\frac{1}{2} \overline{q}^{S_u} n(u^+ - u^-) + \overline{q}^{\mu^i} - \varphi^i = 0 \quad \textit{on } S_u, \tag{A.21}$$

$$\frac{1}{2} \overline{q}^{S_u} n(u^+ - u^-) + \overline{q}^{\mu^e} - \varphi^e = 0 \quad \textit{on } S_u, \tag{A.22}$$

$$\overline{q}^{Ti} + \overline{q}^{\mu^i} + \overline{q}^{Te} + \overline{q}^{\mu^e} = 0 \quad \textit{on } S_u, \tag{A.23}$$

$$\overline{\mathbf{q}}^{\mathbf{G}} : n = 0 \quad \textit{on } \partial\Omega, \tag{A.24}$$

where $\overline{\mathbf{q}}^{\mathbf{G}}$ *is the matrix defined by* $\overline{\mathbf{q}}^{\mathbf{G}} = \begin{pmatrix} \overline{q}^{G1^T} \\ \overline{q}^{G2^T} \end{pmatrix}$ *and where the function* $\overline{J}$ *is defined by*

$$\overline{J}(\overline{q}) = \int_\Omega \overline{q}^u h_1 dx + \int_\Omega \frac{1}{4c(x)^2} |\overline{q}^\sigma|^2 dx + \sum_{j=1}^{2} \int_\Omega \phi^*(|\overline{q}^{Gj}|) dx + \int_{S_u} \overline{q}^{S_u} h_2 ds. \tag{A.25}$$

Proof of Lemmas A.1 *and* A.2. We refer to [35] for the complete proof, which is mainly technical. To get that result, we used classical techniques developed in [21], Rockafellar's theorem, and suitable choices of dual variables $q, \overline{q}$ to simplify calculus. □

Acknowledgments. We thank M. Bellieud, G. Bouchitté, and G. Buttazzo for their useful suggestions about relaxation results.

REPRESENTATION OF WEAK LIMITS AND DEFINITION OF NONCONSERVATIVE PRODUCTS*

PHILIPPE G. LEFLOCH† AND ATHANASIOS E. TZAVARAS‡

Abstract. The goal of this article is to show that the notion of generalized graphs is able to represent the limit points of the sequence $\{g(u_n)\,du_n\}$ in the weak-$\star$ topology of measures when $\{u_n\}$ is a sequence of continuous functions of uniformly bounded variation. The representation theorem induces a natural definition for the nonconservative product $g(u)\,du$ in a BV context. Several existing definitions of nonconservative products are then compared, and the theory is applied to provide a notion of solutions and an existence theory to the Riemann problem for quasi-linear, strictly hyperbolic systems.

Key words. nonconservative products, hyperbolic systems, shock wave, self-similar solution

1. Introduction.

The objective of this article is to present a theoretical frame for the definition and properties of nonconservative products in one space dimension. The issue of defining nonconservative products appears with Volpert's chain rule [31] for BV functions in several space dimensions. It is a central problem for defining a notion of weak solutions for a general quasi-linear hyperbolic system

$$\partial_t u + A(u)\,\partial_x u = 0, \qquad u(x,t) \in \mathbb{R}^N, \quad x \in \mathbb{R},\ t > 0. \tag{1.1}$$

Such systems appear in several models of the engineering and physics literature, e.g., [5, 8, 23, 24, 25, 28]. The origin of the nonconservative terms is usually a simplifying modeling assumption or a closure hypothesis. If (1.1) is conservative, i.e., $A(u) = \nabla F(u)$ for some $F : \mathbb{R}^N \to \mathbb{R}^N$, then weak solutions are defined in the sense of distributions. In the general case, however, the term $A(u)\,\partial_x u$ will contain products of discontinuous functions with measures, and its definition is not obvious. At present, successful definitions exist in the one-space dimensional BV framework by LeFloch [14, 15], Dal Maso, LeFloch, and Murat [10] and Raymond [27]. The definition in [10] is based on a family of Lipschitz paths, is stable under weak convergence, and leads to a solution of the Riemann problem in the class of genuinely nonlinear, strictly hyperbolic systems with Riemann data that are sufficiently close. It has prompted investigations on existence of weak solutions to (1.1), LeFloch and Liu [17], and on convergence of numerical schemes, Hou and LeFloch [12]. The concept of extended graphs is used in [27] to provide a general definition that is stable under weak convergence.

This research was completed while this author was visiting the Centre de Mathématiques Appliquées of Ecole Polytechnique and was partially supported by the National Science Foundation and the Office of Naval Research.

Related issues appear in studies of transport equations with discontinuous coefficients (e.g., LeFloch [15, 16], LeFloch and Xin [20], Poupaud and Rascle [22], Bouchut and James [4]) and in minimization of certain types of functionals in the space of functions of bounded variation (e.g., Aviles and Giga [1], Raymond and Seghir [26]). The reader is referred to Colombeau [6], Colombeau and Leroux [7] for a theory of nonconservative products in a weaker functional framework.

Let $g : \mathbb{R}^N \to \mathbb{R}^N$ be a continuous function and $u : [a, b] \to \mathbb{R}^N$ be a function of bounded variation. Our scope is to provide a justifiable definition for the inner product of $g(u)$ and $\frac{du}{dx}$, formally given by $g(u)\frac{du}{dx} = \sum_{i=1}^N g^i(u)\,\frac{du^i}{dx}$. This definition will be suggested by a representation theory of the limit points of sequences $\{g(u_n)\frac{du_n}{dx}\}$ in weak topologies when the functions u_n are *smooth*. This viewpoint reflects the premise that (1.1) arises in the limit of regularized problems as the dissipative mechanisms, such as viscosity or relaxation time, tend to zero. Accordingly, the nonconservative product will appear as a limit of regularized sequences.

If u is a *continuous* BV function, there is a natural definition of the product $\mu = g(u)\,\frac{du}{dx}$ as a Radon measure on $\mathcal{C}[a, b]$. This is done by setting

$$\langle \mu, \theta \rangle = \int_{[a,b]} \theta(x) g(u(x))\, du(x), \quad \theta \in \mathcal{C}[a, b], \tag{1.2}$$

where the right-hand side is viewed as a Borel–Stieltjes integral relative to the (vector-valued, signed) measure generated by $u \in \mathcal{C} \cap BV$. This definition is appropriate when u is continuous. If u has discontinuities, definition (1.2) is "not stable," because the integral $\int f du$, for $f \in L^1(du)$, changes values when changing f at the points of discontinuity of u.

Consider a sequence $\{u_n\}$ of continuous functions $u_n : [a, b] \to \mathbb{R}^N$ that are of uniformly bounded variation

$$\sup_{[a,b]} |u_n| + TV_{[a,b]}\,(u_n) \le C. \tag{1.3}$$

The products $g(u_n)du_n$ are well defined by (1.2) and belong to $\mathcal{M}[a, b] = \big[\mathcal{C}[a, b]\big]^\star$, the dual space of $\mathcal{C}\big([a, b]; \mathbb{R}^N\big)$. The space of Radon measures $\mathcal{M}[a, b]$ is usually equipped either with the strong topology, generated by the dual norm $\|.\|_{\mathcal{M}}$, or with the weak-$\star$ topology. On account of (1.3), the sequence $\{g(u_n)du_n\}$ satisfies $\|g(u_n)du_n\|_{\mathcal{M}} \le C'$. (Throughout $C, C', \dots$ will stand for constants that are independent of n.) Therefore, along a subsequence,

$$g(u_{n'})\,\frac{du_{n'}}{dx} \rightharpoonup \mu \quad \text{ weak-}\star \text{ in } \mathcal{M}[a, b] \tag{1.4}$$

to some measure μ. Example 1.1 illustrates that, even if $u_n(x) \to u(x)$ pointwise, the sequence $\{g(u_n)du_n\}$ may have multiple limit points in the weak-$\star$ topology.

Example 1.1. Let u_0, u_1 be two states in $\mathbb{R}^N$, $x_0 \in (a, b)$ and $\pi : [0, 1] \to \mathbb{R}^N$ be a Lipschitz continuous path satisfying $\pi(0) = u_0$ and $\pi(1) = u_1$. Consider the sequence of functions v_n, defined by

$$v_n(x) := \begin{cases} u_0 & \text{if } x \in [a, x_0 - 1/n], \\ \pi\big(\frac{x-(x_0-1/n)}{2/n}\big) & \text{if } x \in [x_0 - 1/n, x_0 + 1/n], \\ u_1 & \text{if } x \in [x_0 + 1/n, b]. \end{cases} \tag{1.5}$$

As $n \to \infty$, the sequence $\{v_n\}$ converges pointwise,

$$v_n(x) \to v(x) := \begin{cases} u_0 & \text{if } x \in [a, x_0), \\ \pi(1/2) & \text{if } x = x_0, \\ u_1 & \text{if } x \in (x_0, b], \end{cases} \tag{1.6}$$

and a calculation shows that

$$\int_a^b \varphi(x) g(v_n(x)) \frac{dv_n}{dx}\, dx \to \left(\int_0^1 g(\pi(s))\pi'(s) ds \right) \varphi(x_0)$$

for $\varphi \in \mathcal{C}[a, b]$. That is,

$$g(v_n)\frac{dv_n}{dx} \rightharpoonup c(g, \pi)\delta_{x_0} \quad \text{weak-}\star \text{ in } \mathcal{M}[a, b], \tag{1.7}$$

where δ_{x_0} stands for the Dirac measure at x_0 and the scalar $c(g, \pi)$ is given by the formula

$$c(g, \pi) := \int_0^1 g(\pi(s))\pi'(s) ds. \tag{1.8}$$

Therefore, first, the limit points of $\{g(v_n)\frac{dv_n}{dx}\}$ depend on the limiting graph selected by $\{v_n\}$, expressed via the path π. Second, by mixing sequences whose internal structure is described by several distinct paths π_j, it is easy to generate a sequence $\{v_n\}$ which converges pointwise to the (same) limit v, but where $\{g(v_n)\frac{dv_n}{dx}\}$ has multiple weak-$\star$ limit points. There exists a notable exception to these features: If $g = \nabla f$ for some $f : \mathbb{R}^N \to \mathbb{R}$, then $c(g, \pi) = f(u_1) - f(u_0)$ and the weak-$\star$ limit (1.7) is independent of π. □

To characterize the weak-$\star$ limit points of $\{g(u_n)du_n\}$ we follow the approach of Tartar [29], in his representation theory of weak limits via Young measures. Let $\mathcal{C}_0([a, b]\times\mathbb{R}^N)$ be the space of $\mathbb{R}^N$-valued continuous functions $f = f(x, \lambda)$ that tend to zero as $\lambda \in \mathbb{R}^N$ tends to infinity, equipped with the sup-norm, and let $\mathcal{M}([a, b]\times\mathbb{R}^N) = \big[\mathcal{C}_0([a, b] \times \mathbb{R}^N)\big]^\star$ be the dual space of Radon measures on $[a, b] \times \mathbb{R}^N$. Define the Radon measures p_n by

$$\langle p_n, f\rangle := \int_a^b f(x, u_n(x))\, du_n(x) \qquad \text{for } f \in \mathcal{C}_0([a, b] \times \mathbb{R}^N). \tag{1.9}$$

Then (1.3) implies that

$$|\langle p_n, f\rangle| \le \big(TV_{[a,b]}\,(u_n)\big) \sup_{x\in[a,b],|\lambda|\le C} |f(x, \lambda)|$$

and, hence, $\|p_n\|_{\mathcal{M}} \le C$. There exist a subsequence $\{p_{n_k}\}$ and a measure $p \in \mathcal{M}([a, b] \times \mathbb{R}^N)$ such that

$$p_{n_k} \rightharpoonup p \quad \text{weakly-}\star \text{ in } \mathcal{M}([a, b] \times \mathbb{R}^N). \tag{1.10}$$

The question becomes to characterize the weak-$\star$ limit points of the sequence $\{p_n\}$.

The characterization is effected by using the concept of *graph completion* or (as we prefer to call it) *generalized graph*. This concept was introduced by Bressan and

Rampazzo [3] in a context of control problems and turns out to be sufficiently discriminating to capture the limiting graphs of the sequence $\{u_n\}$. Generalized graphs were used by Dal Maso, LeFloch, and Murat [10] and Raymond [27] as intermediate steps in their definitions of nonconservative products.

DEFINITION 1.2 (see [3]). *A generalized graph of u is a map $(X,U):[0,1]\to[a,b]\times\mathbb{R}^N$ such that X, U are Lipschitz continuous and satisfy*

(1) $(X(0),U(0))=(a,u(a))$, $(X(1),U(1))=(b,u(b))$;

(2) *X is increasing: $s_1<s_2$ implies $X(s_1)\le X(s_2)$;*

(3) *given $y\in[a,b]$, there exists $s\in[0,1]$ such that $X(s)=y$, $U(s)=u(y)$.*

Our aim is to reveal the central role of generalized graphs in providing a geometrically motivated definition of nonconservative products. To this end we exploit an equivalence relation on the space of continuous functions, accounting for reparametrizations of graphs, and the associated pseudometric of uniform graph convergence [3]. By definition, a sequence of graphs $\{gr(u_n)\}$ is Cauchy in the sense of graph convergence, if upon reparametrizing its elements $gr(u_n)$ we obtain a Cauchy sequence in the uniform metric. We will show that, given a sequence of *continuous* functions $\{u_n\}$ that is bounded in $BV[a,b]$, generalized graphs emerge as and are in correspondence to limit points of the sequence of graphs of u_n, $\{gr(u_n)\}$, in the pseudometric of uniform graph convergence. Therefore, the terminology "graph completion" is somewhat misleading, in that it suggests that the completion of the graph is effected arbitrarily from the outside. Since such objects emerge as limits of graphs of sequences of continuous functions, we opt for the more pertinent terminology *generalized graph*. Using this notion we prove a representation theorem on the weak-$\star$ limits in (1.4) and (1.10).

THEOREM 1.3. (a) *Let $\{u_n\}$ be a sequence of continuous functions satisfying the uniform bounds* (1.3). *There exists a subsequence $\{u_{n_k}\}$ and a generalized graph (X,U) such that, for any continuous function $g=g(\lambda)$, we have*

$$\int_{[a,b]}\theta(x)g(u_{n_k}(x))\,du_{n_k}(x)\to\langle\mu(g),\theta\rangle\quad\text{for}\quad\theta\in\mathcal{C}[a,b],\tag{1.11}$$

where $\mu:\mathcal{C}_0(\mathbb{R}^N)\to\mathcal{M}[a,b]$ is defined by

$$\langle\mu(g),\theta\rangle=\int_0^1\theta(X(s))g(U(s))\,dU(s).\tag{1.12}$$

(b) *Conversely, given a generalized graph (X,U), let μ be defined by* (1.12). *There exists a sequence of Lipschitz functions $\{u_n\}$, uniformly bounded in BV, such that for any continuous g,*

$$g(u_n)du_n\rightharpoonup\mu(g)\quad\text{weak-}\star\text{ in }\mathcal{M}[a,b].\tag{1.13}$$

The plan of the article is as follows. Section 2 is preliminary, presenting a change of variable formula for Borel–Stieltjes integrals, an equivalence relation accounting for reparametrizations of continuous paths, and the notion of uniform graph convergence. The case of a continuous BV function is also considered; we introduce the arc-length (or canonical) parametrization of the graph of u and use it, in conjunction with the change of variable formula, to explore the ramifications of definition (1.2) for the nonconservative product $g(u)\,du$, with $u\in\mathcal{C}\cap BV$.

In sections 3 and 4 we study properties of sequences of continuous functions $\{u_n\}$ that are bounded in $BV[a,b]$. After presenting the notion of a generalized graph,

we show that, first, generalized graphs arise as limits of subsequences to $\{gr(u_n)\}$ in the pseudometric of graph convergence and, second, that a given generalized graph can always be approximated by a suitable sequence of graphs of continuous functions. The results are summarized in Theorem 3.2 and are put in a metric space framework at the end of section 3.1. Then in section 3.2 we prove a representation theorem.

The representation theorem suggests to define nonconservative products as measures based on generalized graphs. Two definitions, along with associated weak stability theorems, are pursued: In section 4.1, the nonconservative product is defined as a Radon measure (Definition 4.1), while, in section 4.2, it is defined as a signed Borel measure via its distribution function (Definition 4.4). The definitions are equivalent and invariant under reparametrizations of the geometric graph determined by (X, U); i.e., they depend on the equivalence class of the generalized graph (X, U) but not on the specific representative.

In sections 4.3 and 4.4, we compare various definitions of nonconservative products. To assess the issue, it is instructive to keep in mind the analogy to the solution of the Riemann problem for hyperbolic systems. There exist two approaches for solving the Riemann problem: In the first the solution is effected by patching together elementary solutions (shocks, rarefaction waves, and contact discontinuities), while in the second the whole wave fan is visualized to emerge as a single structure in a small parameter (viscosity, relaxation, etc.) limit of a higher-order theory. Accordingly, two viewpoints for defining nonconservative products can be taken: (i) the product is defined in a pointwise fashion by using a predetermined family of paths at points of jump discontinuity, (ii) the product is defined on the whole structure (the generalized graph). The comparison hinges on the relation between generalized graphs and graphs of functions of bounded variation (Propositions 4.7 and 4.8). The emerging definitions are consistent, with each being more adept for a different range of applications. Section 4.4 analyzes several typical examples of nonconservative products.

We complete the article with a study of the Riemann problem for quasi-linear hyperbolic systems. For genuinely nonlinear systems the solution of the Riemann problem is established in LeFloch [14] and Dal Maso, LeFloch, and Murat [10]. The main step is a construction of the shock curves in the nonconservative case, in the spirit of Lax [13]. The present result is based on an entirely different construction process, following the method of self-similar zero-viscosity limits (see Dafermos [9], Tzavaras [30]). It yields a solution for weak waves of the Riemann problem in the class of general strictly hyperbolic systems with no further assumptions (like genuine nonlinearity or finite number of inflection points) on the characteristic fields. The necessary a priori BV estimates are established in the companion articles [18, 19].

2. Preliminary notions.

2.1. Change of variables formula. Throughout, we work in the framework of functions of bounded variation. The total variation of an $\mathbb{R}^N$-valued function u on an interval $[a, b]$ is defined by

$$TV_{[a,b]}(u) := \sup \sum_{i=1}^{n} |u(x_i) - u(x_{i-1})|,$$

where $|\cdot|$ stands for the Euclidean length in $\mathbb{R}^N$ and the supremum is taken over all finite partitions $a = x_0 < x_1 < \cdots < x_n = b$. Let $u : [a, b] \to \mathbb{R}^N$ be a function of bounded variation and let $T_u : [a, b] \to [0, \infty)$ be the total variation function of u,

defined by

$$T_u(x) := TV_{[a,x]}(u) \qquad \text{for } x \in [a,b]. \tag{2.1}$$

The domain of u can be decomposed into two disjoint sets: $\mathcal{C}_u$ the set of points of continuity of u and $\mathcal{S}_u$ the set of points of discontinuity, respectively. The set $\mathcal{S}_u$ is at most countable, and the right and left limits $u(x+)$, $u(x-)$, for $x \in (a,b)$, and $u(a+)$, $u(b-)$ exist and are finite. We use the notation $u(a-) = u(a)$ and $u(b+) = u(b)$. Note that x is a point of (right or left) continuity for u if and only if x is a point of (right or left) continuity for T_u. In the particular case that u is Lipschitz continuous (or even when u is absolutely continuous, $u \in W^{1,1}\big(a,b)\big)$, the total variation function T_u can be computed by the formula

$$T_u(x) = \int_a^x |u'(y)|\, dy. \tag{2.2}$$

If u is of bounded variation and right continuous on (a,b), there exists a unique finite, signed Borel measure μ_u generated by u,

$$u(x) - u(a+) = \mu_u((a,x]) \quad \text{for } x \in (a,b], \qquad u(a+) - u(a) = \mu_u(\{a\}).$$

The measure μ_u is typically denoted by du, its total variation measure satisfies $|du| = dT_u$, and it can be decomposed into an absolutely continuous part $u'(x)dx$, an atomic part $d_a u$, and a singular part (relative to the Lebesgue measure) $d_s u$, according to the formula $du = u'(x)dx + d_a u + d_s u$.

For functions u, $v : [a,b] \to \mathbb{R}^N$ right continuous and of bounded variation, there is an integration by parts formula: If u and v have no common points of discontinuity, $\mathcal{S}_u \cap \mathcal{S}_v = \emptyset$, then

$$\int_{[\alpha,\beta]} v(x)du(x) + \int_{[\alpha,\beta]} u(x)dv(x) = v(\beta+)u(\beta+) - v(\alpha-)u(\alpha-) \tag{2.3}$$

for any $[\alpha,\beta] \subset [a,b]$. (Here and in what follows we use the notation $v\,du$ to mean the inner product $\sum_i v_i du_i$, where u_i and v_i are the components of u and v, respectively.) If v is absolutely continuous, (2.3) takes the more conventional form

$$\int_{[\alpha,\beta]} v(x)du(x) = -\int_{[\alpha,\beta]} u(x)v'(x)dx + v(\beta)u(\beta+) - v(\alpha)u(\alpha-). \tag{2.4}$$

We will need certain change of variable formulas that follow from a general measure theoretic construction. We first outline the general construction of image measures, taken out of Folland [11, p. 287]. Let $(\Omega, \mathcal{B}, \mu)$ be a measure space, let $(\Omega', \mathcal{B}')$ be a measurable space, and let $\varphi : \Omega \to \Omega'$ be a $(\mathcal{B}, \mathcal{B}')$-measurable map. Then μ induces an image measure μ^φ on Ω' by

$$\mu^\varphi(E) = \mu\big(\varphi^{-1}(E)\big) \qquad \text{for } E \in \mathcal{B}'. \tag{2.5}$$

It is easy to check that μ^φ defines a measure on $(\Omega', \mathcal{B}')$. (The reader is warned not to confuse the measure μ^φ with the Borel measure μ_u generated by the right continuous BV function u.) One also has the formula.

PROPOSITION 2.1. *If $f : \Omega' \to \mathbb{R}$ is a measurable function, then*

$$\int_{\Omega'} f\, d\mu^\varphi = \int_\Omega \big(f \circ \varphi\big) d\mu \tag{2.6}$$

whenever either side is defined.

The proof of (2.6) follows the familiar process of first proving it for characteristic functions $f = \mathbb{1}_E$ with $E \in \mathcal{B}'$, by using $\mathbb{1}_E \circ \varphi = \mathbb{1}_{\varphi^{-1}(E)}$ and (2.5), then for simple functions and finally for integrable functions; cf. [11, p. 287]. In probability theory, when μ is a probability measure and $\varphi : \Omega \to \mathbb{R}$ is a Borel-measurable real-valued function, the image measure μ^φ is called the distribution of the random variable φ.

For u a right continuous function of bounded variation, let $L^1(du)$ denote the integrable functions with respect to the (signed) vector measure du. For instance, all the bounded, Borel measurable functions belong to $L^1(du)$. Proposition 2.1 provides certain change of variable formulas for Borel–Stieltjes integrals that are used extensively in the sequel.

THEOREM 2.2. *Let $u : [a,b] \to \mathbb{R}^N$ be a right continuous function of bounded variation, and let $X : [0,1] \to [a,b]$ be a continuous increasing (not necessarily strictly increasing) change of variables with $X(0) = a$, $X(1) = b$.*

(a) *If X^{-1} denotes the left-continuous inverse of X, then, for $f \in L^1\big(d(u \circ X)\big)$, we have*

$$\int_{[0,1]} f(s)\, d\big(u \circ X\big)(s) = \int_{[a,b]} f \circ X^{-1}(x)\, du(x). \tag{2.7}$$

(b) *For any function $g \in L^1\big(du\big)$, we have*

$$\int_{[0,1]} \big(g \circ X\big)(s)\, d\big(u \circ X\big)(s) = \int_{[a,b]} g(x)\, du(x). \tag{2.8}$$

Formula (2.8) when du is the Lebesgue measure is stated as an exercise in Folland [11, p. 103]. It is easy to construct examples showing that (2.8) fails if the hypothesis "X continuous" is replaced by "X right continuous."

Proof. We first establish (2.7) and (2.8) under the hypotheses

$$\begin{aligned} &u : [a,b] \to \mathbb{R} \quad \text{increasing and right continuous,} \\ &f : [0,1] \to [0,\infty] \quad \text{Borel measurable,} \\ &g : [a,b] \to [0,\infty] \quad \text{Borel measurable.} \end{aligned} \tag{2.9}$$

Since X is increasing, the inverse of X is a multivalued increasing map. We select the single-valued left-continuous inverse $\varphi = X^{-1}$ of the map X. Note that $X \circ \varphi = id$, but in general $\varphi \circ X \neq id$. The function $\varphi : [a,b] \to [0,1]$ is single valued, increasing, and satisfies

$$\varphi^{-1}\big((s,\tau]\big) = (X(s), X(\tau)] \quad \text{for } s, \tau \in [0,1].$$

Since the half-open intervals generate the Borel σ-algebra, φ is a $(\mathcal{B}_{[a,b]}, \mathcal{B}_{[0,1]})$-measurable map, that is, a Borel measurable map. Also, $f \circ \varphi$ is Borel measurable as well.

Let μ_u be the Borel measure generated by u, and let μ_u^φ be the image measure of μ_u under φ. Then

$$\mu_u^\varphi\big((s,\tau]\big) = \mu_u\big(\varphi^{-1}\big((s,\tau]\big)\big) = \mu_u\big((X(s), X(\tau)]\big) = \mu_{u\circ X}\big((s,\tau]\big)\,.$$

Since μ_u^φ and $\mu_{u\circ X}$ agree on the half-open intervals, the extension theorems for premeasures (e.g., [11, Thms. 1.14 and 1.16]) imply $\mu_u^\varphi = \mu_{u\circ X}$ on the Borel sets $\mathcal{B}_{[0,1]}$. Formula (2.7) is then a consequence of Proposition 2.1. In turn, (2.8) follows from (2.7), upon setting $f = g \circ X$ and using the identity $X \circ \varphi = id$.

Once (2.7) and (2.8) are established under (2.9), they are extended to hold under the hypotheses of Theorem 2.2. Consider, for instance, (2.7). It is first extended to hold for Borel measurable functions $f : [0,1] \to \mathbb{R}$ that are integrable with respect to $d(u \circ X)$, by using the decomposition $f = f^+ - f^-$, with f^+, $f^- \in L^1\big(d(u \circ X)\big)$. Next, if $u : [a,b] \to \mathbb{R}$ is a function of bounded variation, it can be decomposed in the form $u = u_1 - u_2$, with u_1, u_2 increasing and thus du_1, du_2 positive measures. Using the induced decomposition $d(u \circ X) = d(u_1 \circ X) - d(u_2 \circ X)$ of the signed measure $d(u \circ X)$ into a difference of positive measures, we can extend (2.7) to hold in this case also. Finally, the extension to the vector-valued case is trivial. □

Theorem 2.2 also yields a simple proof of the chain rule for Lipschitz functions in the one-dimensional context (see Marcus and Mizel [21], Boccardo and Murat [2]).

COROLLARY 2.3. *Suppose that $u : [a,b] \to \mathbb{R}^N$ is absolutely continuous and $X : [0,1] \to [a,b]$ is increasing, continuous, and onto. Then*

$$d\big(u \circ X\big) = \big(u' \circ X\big)\, dX. \tag{2.10}$$

If X is absolutely continuous, then

$$\frac{d}{ds}\big(u \circ X\big)(s) = u'\big(X(s)\big)\, \frac{dX}{ds}(s) \qquad \text{for almost everywhere (a.e.)} \quad s \in [0,1]. \tag{2.11}$$

Proof. We will show that

$$\int_0^s d(u \circ X) = \int_0^s u'(X(s))\, dX(s) \qquad \text{for } s \in [0,1].$$

Fix $s \in [0,1]$ and let $y = X(s)$ and $\bar{s} = \inf\{s \in [0,1] : X(s) > y\}$. Then $X(\tau) = y$ on the interval $[s, \bar{s}]$, and (2.8) in Theorem 2.2 implies

$$\begin{aligned}\int_0^s d(u \circ X) = \int_0^{\bar{s}} d(u \circ X) = \int_{[a,y]} du(x) = \int_{[a,y]} u'(x)dx \\ = \int_0^{\bar{s}} u'(X(s))dX(s) = \int_0^s u'(X(s))dX(s).\end{aligned}$$

Hence, (2.10) follows.

If X is absolutely continuous, then $u \circ X$ is also absolutely continuous and (2.11) follows from (2.10). □

Let $BV[a,b]$ be the set of all functions $u : [a,b] \to \mathbb{R}^N$ of bounded variation. The space $BV[a,b]$ can be identified to the space of (equivalence classes of) functions u in $L^1(a,b)$ whose distributional derivative, du/dx, is a finite, signed Borel measure. To see that, let $u \in BV[a,b]$ and let $\bar{u}$ denote a right continuous BV function such that $u = \bar{u}$ a.e. (the function $\bar{u}$ is uniquely determined by the equivalence class of u). By the Riesz representation theorem, the signed Borel measure $d\bar{u}$, generated by $\bar{u}$, can be identified with a bounded linear functional $\nu_{\bar{u}}$ on $\mathcal{C}[a,b]$,

$$\langle \nu_{\bar{u}}, \theta \rangle = \int_{[a,b]} \theta(x) d\bar{u}(x) \qquad \text{for } \theta \in \mathcal{C}[a,b]. \tag{2.12}$$

Then (2.4) implies that, for $\varphi \in \mathcal{C}_c^1(a,b)$,

$$\langle \nu_{\bar{u}}, \varphi \rangle = \int_{(a,b)} \varphi(x) d\bar{u}(x) = -\int_{(a,b)} \varphi'(x) u(x) dx\,, \tag{2.13}$$

i.e., the distributional derivative of u satisfies $du/dx = \nu_{\bar{u}}$. Moreover,

$$|\nu_{\bar{u}}|\big([a,b]\big) = TV_{[a,b]}(\bar{u})\,. \tag{2.14}$$

We note that if another representative is used on the right of (2.14), then equality is in general replaced by a strict inequality. The space $BV[a,b]$, when equipped with the norm

$$\|u\|_{BV} = \|u\|_{L^1} + |\nu_{\bar{u}}|\big([a,b]\big),$$

becomes a Banach space. For functions of one variable, it is customary to use the equivalent norm

$$\|u\|_{BV} = \|u\|_{L^\infty} + |\nu_{\bar{u}}|\big([a,b]\big).$$

We refer to Folland [11] and Volpert [31] for further information on the theory of BV functions.

2.2. Reparametrizations and distance of graphs. We present first the notion of uniform graph convergence [3, 10], which emerges when continuous paths are studied from the viewpoint of identifying two paths if their ranges coincide. In $\mathcal{C}[0,1]$, the space of continuous paths $V : [0,1] \to \mathbb{R}^M$, an equivalence relation is introduced.

DEFINITION 2.4. *We say that V_1 and V_2 are equivalent, $V_1 \sim V_2$, if and only if there exist two continuous, increasing (but not necessarily strictly increasing) and surjective maps γ_1, $\gamma_2 : [0,1] \to [0,1]$ such that $V_1 \circ \gamma_1 = V_2 \circ \gamma_2$.*

The following lemma is proved in [3, Lemma 1].

LEMMA 2.5. *Let V_1, $V_2 \in \mathcal{C}[0,1]$. Given two continuous, increasing, and surjective maps γ_1, $\gamma_2 : [0,1] \to [0,1]$ there exist two increasing, surjective maps α_1, $\alpha_2 : [0,1] \to [0,1]$, Lipschitz continuous with Lipschitz constant 3, such that*

$$\max_{[0,1]} \big|V_1 \circ \alpha_1 - V_2 \circ \alpha_2\big| = \max_{[0,1]} \big|V_1 \circ \gamma_1 - V_2 \circ \gamma_2\big|.$$

Therefore, $V_1 \sim V_2$ if and only if there exist two Lipschitz continuous, increasing, and surjective maps α_1, $\alpha_2 : [0,1] \to [0,1]$ such that $V_1 \circ \alpha_1 = V_2 \circ \alpha_2$.

If V is continuous and of bounded variation (and $TV_{[0,1]}(V) \neq 0$), then $V^c : [0,1] \to \mathbb{R}^M$, the *canonical parametrization* of V, is defined by

$$V^c(\tau) = V(s),\ \tau = \frac{1}{L}\,T_V(s), \qquad \text{where } L := TV_{[0,1]}(V), \tag{2.15}$$

the total variation function T_V being defined by (2.1). It is easy to check that V^c is well defined and, for $\tau_1 < \tau_2$,

$$|V^c(\tau_2) - V^c(\tau_1)| = |V(s_2) - V(s_1)| \le T_V(s_2) - T_V(s_1) = L(\tau_2 - \tau_1). \tag{2.16}$$

Hence, $V = V^c \circ \gamma$ where V^c is a Lipschitz continuous path and $\gamma = (1/L)T_V$ is continuous. The equivalence relation separates $\mathcal{C}[0,1]$ into equivalence classes that satisfy the following properties:

(1) If $V_1 \sim V_2$ and V_1 is of bounded variation, then V_2 is of bounded variation.

(2) If V is of bounded variation, then a Lipschitz continuous representative of the class can be selected, V^c.

(3) If V_1, V_2 are of bounded variation, then $V_1 \sim V_2$ if and only if $V_1^c = V_2^c$.

Statements (1) and (2) are clear. To show (3), suppose that $V_1 \sim V_2$ are of bounded variation and introduce the canonical parametrizations $V_\iota = V_\iota^c \circ \gamma_\iota$, where $\gamma_\iota = (1/L_\iota)T_{V_\iota}$ for $\iota = 1, 2$. Let $\alpha_1, \alpha_2 : [0,1] \to [0,1]$ be Lipschitz continuous, increasing, surjective maps such that $V_1 \circ \alpha_1 = V_2 \circ \alpha_2$. Then $T_{V_1} \circ \alpha_1 = T_{V_2} \circ \alpha_2$, $\gamma_1 \circ \alpha_1 = \gamma_2 \circ \alpha_2$, and thus $V_1^c = V_2^c$.

On the space of continuous paths, we define a distance function:

$$\operatorname{dist}(V_1, V_2) := \inf_{\gamma_1, \gamma_2} \max_{s \in [0,1]} |(V_1 \circ \gamma_1)(s) - (V_2 \circ \gamma_2)(s)|, \tag{2.17}$$

where the infimum is taken over all continuous, increasing, and surjective maps $\gamma_1, \gamma_2 : [0,1] \to [0,1]$. Bressan and Rampazzo [3] introduce the distance and show that it defines a pseudometric,

$$\begin{aligned} &\operatorname{dist}(V_1, V_2) = \operatorname{dist}(V_2, V_1), \\ &\operatorname{dist}(V, V) = 0, \\ &\operatorname{dist}(V_1, V_3) \le \operatorname{dist}(V_1, V_2) + \operatorname{dist}(V_2, V_3), \end{aligned}$$

and that, by virtue of Lemma 2.5, the infimum in (2.15) is attained on two Lipschitz continuous paths α_1, α_2, so that the distance can be computed by

$$\operatorname{dist}(V_1, V_2) = \max_{s \in [0,1]} |(V_1 \circ \alpha_1)(s) - (V_2 \circ \alpha_2)(s)|.$$

In particular, that implies $\operatorname{dist}(V_1, V_2) = 0$ if and only if $V_1 \sim V_2$ and, thus, if the distance is viewed on the quotient space $\mathcal{X} = [\mathcal{C}([0,1]; \mathbb{R}^M)/\sim]$, it induces a metric. (Working with equivalence classes has the disadvantage of being cumbersome and identifying otherwise different functions; we will avoid doing that directly, but it is instructive to keep the structure in mind.) The associated convergence is called uniform graph convergence and is denoted by $V_n \xrightarrow{\mathrm{d}} V$: $\{V_n\}$ converges in graph to V if $\operatorname{dist}(V_n, V) \to 0$. Equivalently, $V_n \xrightarrow{\mathrm{d}} V$ if there exist two Lipschitz continuous, increasing, surjective maps $\alpha_n, \alpha : [0,1] \to [0,1]$ such that

$$\operatorname{dist}(V_n, V) = \max_{[0,1]} |V_n \circ \alpha_n - V \circ \alpha| \to 0 \quad \text{as } n \to \infty.$$

Finally we state a compactness result in Proposition 2.6.

PROPOSITION 2.6. *Let $\{V_n\}$ be a sequence of continuous functions on $[0,1]$ that are of uniformly bounded total variation. There exists a subsequence $\{V_{n_k}\}$ and a Lipschitz continuous representative $V^c : [0,1] \to \mathbb{R}^M$ such that $V_{n_k} \xrightarrow{d} V^c$.*

Proof. Let V_n^c be the canonical representatives of V_n, say, $V_n = V_n^c \circ \gamma_n$. By (2.15)–(2.16), V_n^c are uniformly Lipschitz continuous, with Lipschitz constant equal to the uniform variation bound of the sequence V_n. Since $V_n \sim V_n^c$, Lemma 2.5 implies there exist sequences α_n, β_n of uniformly Lipschitz continuous parametrizations such that $V_n \circ \alpha_n = V_n^c \circ \beta_n$. By the Ascoli–Arzela theorem there exist subsequences $V_{n_k}^c$, α_{n_k}, β_{n_k}, and Lipschitz continuous functions $V^c : [0,1] \to \mathbb{R}^M$ and α, $\beta : [0,1] \to [0,1]$ so that $V_{n_k}^c \to V^c$, $\alpha_{n_k} \to \alpha$, and $\beta_{n_k} \to \beta$ uniformly on $[0,1]$. Then

$$\begin{aligned} V_{n_k} \circ \alpha_{n_k} &= V_{n_k}^c \circ \beta_{n_k} \\ &= (V_{n_k}^c \circ \beta_{n_k} - V_{n_k}^c \circ \beta) + V_{n_k}^c \circ \beta \to V^c \circ \beta \end{aligned}$$

uniformly on $[0,1]$ and, thus, $V_{n_k} \xrightarrow{\mathrm{d}} V^c$. ∎

2.3. Nonconservative products for continuous BV functions. The concepts of canonical parametrization and distance of continuous paths have implications when applied to graphs of continuous functions of bounded variation.

Let $u : [a,b] \to \mathbb{R}^N$ be a continuous function of bounded variation. The graph of u,

$$gr(u) := \big\{(x, u(x)) : x \in [a,b]\big\}, \tag{2.18}$$

is a continuous curve in $\mathbb{R} \times \mathbb{R}^N$. We introduce a canonical representative in the spirit of (2.15) (cf. [10]). Let $\sigma : [a,b] \to [0,1]$ be defined by

$$\sigma(x) := \frac{1}{L}\big(x - a + T_u(x)\big), \quad \text{where } L := b - a + TV_{[a,b]}(u) > 0. \tag{2.19}$$

Then σ is strictly increasing, continuous, and surjective and satisfies $\sigma(a) = 0 < \sigma(x) < 1 = \sigma(b)$ for $x \in (a,b)$. The inverse of σ is a function $X : [0,1] \to [a,b]$, which is strictly increasing, continuous, and surjective. If we set $U := u \circ X$, the function $(X,U) : [0,1] \to [a,b] \times \mathbb{R}^N$ is a representative of the graph of u. Further, if $s_1 < s_2$ in $[0,1]$ and y_1, y_2 their respective images under X, $\sigma(y_1) = s_1$ and $\sigma(y_2) = s_2$, then

$$\begin{aligned} X(s_2) - X(s_1) = y_2 - y_1 \le L(\sigma(y_2) - \sigma(y_1)) = L(s_2 - s_1), \\ |U(s_2) - U(s_1)| = |u(y_2) - u(y_1)| \le T_u(y_2) - T_u(y_1) \le L(s_2 - s_1). \end{aligned} \tag{2.20}$$

Hence, (X,U) is Lipschitz continuous with Lipschitz constant L and will be referred to as the *arc-length parametrization* (or canonical representative) of the graph of $u \in \mathcal{C} \cap BV$.

The terminology "arc-length parametrization" is justified as follows: Since $T_u \circ X = T_{u \circ X} = T_U$, the parametrization (X,U) satisfies

$$s = \sigma(X(s)) = \frac{1}{L}\big(X(s) - a + T_U(s)\big) \tag{2.21}$$

for s in $[0,1]$. Therefore, (2.21) implies

$$\frac{dX}{ds} + \left|\frac{dU}{ds}\right| = L, \tag{2.22}$$

which means that the tangent vector to the curve $(X(s), U(s))$ has constant length equal to L. Strictly speaking, the arc-length parametrization corresponds to $L = 1$ in (2.22). This can be attained by stretching the interval $[0,1]$, but we avoid that here.

The graph of a continuous BV function u may be represented by several continuous, increasing, and surjective parametrizations $(Y,V) : [0,1] \to [a,b] \times \mathbb{R}^N$ with Y increasing. The representative can always be chosen to be a Lipschitz continuous path (X,U) with X strictly increasing. The distance between two graphs represented by (Y,V) and $(\bar{Y},\bar{V})$ is defined by $\operatorname{dist}\big((Y,V),(\bar{Y},\bar{V})\big)$ as in (2.17). The notion of distance and the equivalence relation $\sim$ provide a suitable tool for factoring representatives of the same graph (viewed as a geometric object). In what follows, we use the notation $(Y,V) \sim gr(u)$ to denote the general continuous representative (Y,V) of the graph of u and retain the notation (X,U) for the arc-length parametrization or for the associated notion of generalized graph defined in section 3.1.

The arc-length parametrization (X,U) may be used to express the Borel measure du generated by a continuous function of bounded variation u. Using Theorem 2.2,

for the change of variable $x = X(s)$, we obtain

$$\int_{[a,b]} \theta(x)\, du(x) = \int_0^1 \big(\theta \circ X\big)(s) \frac{dU}{ds}\, ds \quad \text{for } \theta \in \mathcal{C}[a,b]. \tag{2.23}$$

The left side in (2.23) is interpreted as a Borel–Stieltjes integral, while the right side is a Lebesgue integral; the formula is useful for theoretical computations involving the measure du. If (Y,V) is an equivalent continuous representative of $gr(u)$, $(Y,V) \sim (X,U)$, repeated use of Theorem 2.2 implies

$$\int_{[a,b]} \theta(x)\, du(x) = \int_0^1 \big(\theta \circ X\big)(s)\, dU(s) = \int_0^1 \big(\theta \circ Y\big)(s)\, dV(s).$$

That is, the Borel measure du depends on $gr(u)$ but not on the particular representative.

We turn now to the definition of nonconservative products for *continuous* functions of bounded variation. A natural way of defining $\mu = g(u)\frac{du}{dx}$ is as a Borel measure, via (1.2). The definition is invariant under reparametrizations of $gr(u)$ and reads

$$\left\langle g(u)\frac{du}{dx}, \theta \right\rangle = \int_0^1 \big(\theta \circ Y\big)(s) g(V(s))\, dV(s) = \int_0^1 \big(\theta \circ X\big)(s) g(U(s)) \frac{dU}{ds}\, ds,$$

where (X,U) is the arc-length parametrization and $(Y,V) \sim gr(u)$ stands for a general representative of the graph of u. This definition is consistent with the one proposed in section 4 for discontinuous BV functions.

3. Generalized graphs.

3.1. Generalized graphs of BV functions. The graph of a general function $u : [a,b] \to \mathbb{R}^N$ of bounded variation has jumps at the points of discontinuity of u. The notion of generalized graph (or graph completion), introduced by Bressan and Rampazzo [3], is an attempt to fill in the jumps by extending the idea of arc-length (or canonical) parametrization.

DEFINITION 3.1. *A generalized graph of u is a map $(X,U) : [0,1] \to [a,b] \times \mathbb{R}^N$ such that X, U are Lipschitz continuous and satisfy the following conditions:*

(1) $(X(0),U(0)) = (a,u(a))$, $(X(1),U(1)) = (b,u(b))$.

(2) *X is increasing: $s_1 < s_2$ implies $X(s_1) \le X(s_2)$.*

(3) *Given $y \in [a,b]$, there exists $s \in [0,1]$ such that $X(s) = y$, $U(s) = u(y)$.*

The range of (X,U) is a compact, connected set containing the graph of u. Let $\sigma = X^{-1}$ be the set theoretic inverse of X; then $\sigma : [a,b] \to [0,1]$ is a strictly increasing, *multivalued* map. The set $\mathcal{C}_\sigma$ of points of continuity of σ (that is, the point where σ is single valued) is dense in $[a,b]$. The set $\mathcal{S}_\sigma$ of points of discontinuity of σ (that is, the points where σ is truly multivalued) is countable and serves as a counter of the jumps and possible loops attached to the graph of u. In this paper, a point $x \in \mathcal{S}_\sigma$ is called a *point of jump* if $u(x-) \neq u(x+)$ and a *loop* if $u(x-) = u(x+)$.

The domain and range of σ admit the decompositions $[a,b] = \mathcal{C}_\sigma \cup \mathcal{S}_\sigma$ and

$$[0,1] = \sigma(\mathcal{C}_\sigma) \cup \sigma(\mathcal{S}_\sigma) = \Big(\bigcup_{y \in \mathcal{C}_\sigma} \{\sigma(y)\} \Big) \cup \Big(\bigcup_{y \in \mathcal{S}_\sigma} [\sigma(y-), \sigma(y+)] \Big), \tag{3.1}$$

respectively. The function u is recovered by the formula

$$u(y) = U(\sigma(y)) \quad \text{for } y \in \mathcal{C}_\sigma. \tag{3.2}$$

The following theorem indicates that the notion of generalized graph captures the limiting graphs selected by pointwise convergent sequences $\{u_n\}$ of *continuous* functions that are stable in $BV[a,b]$. Part (a) of the theorem below provides an extension (and an alternative proof) of the classical Helly selection principle.

THEOREM 3.2. (a) *Let $\{u_n\}$ be a sequence of continuous functions $u_n : [a,b] \to \mathbb{R}^N$ satisfying the uniform bounds* (1.3) *and let (X_n, U_n) be the arc-length parametrizations of $gr(u_n)$. There exists a subsequence $\{u_{n_k}\}$, a function of bounded variation $u : [a,b] \to \mathbb{R}^N$, and an associated generalized graph (X, U) such that*

(1) $(X_{n_k}, U_{n_k}) \xrightarrow{d} (X, U)$;

(2) $\sigma_{n_k}(y) \to \sigma(y)$, $u_{n_k}(y) \to u(y)$ *for all $y \in \mathcal{C}_\sigma$ and a.e. in $[a,b]$,*

where $\sigma_n = X_n^{-1}$ and $\sigma = X^{-1}$ are the set theoretic inverses of X_n and X, respectively.

(b) *Conversely, given a generalized graph (X,U) associated with a BV function u, there exists a sequence $\{u_n\}$ of Lipschitz continuous functions such that*

(1) $\{u_n\}$ *is uniformly bounded in BV,*

(2) $(Y_n, V_n) \xrightarrow{d} (X, U)$ *for any representative $(Y_n, V_n) \sim gr(u_n)$,*

(3) $u_n(y) \to u(y)$ *for $y \in \mathcal{C}_\sigma$ and a.e. in $[a,b]$.*

The proof is based on the following lemma.

LEMMA 3.3. *Suppose that $(X_n, U_n) : [0,1] \to [a,b] \times \mathbb{R}^N$ satisfy the following conditions:*

(1) X_n *is strictly increasing and surjective,*

(2) (X_n, U_n) *are uniformly Lipschitz continuous,*

(3) $(X_n, U_n) \to (X, U)$ *uniformly on $[0,1]$.*

Let $\sigma_n = X_n^{-1}$, $u_n = U_n \circ X_n^{-1}$. Then (X_n, U_n) is a Lipschitz continuous representative of $gr(u_n)$ and

$$\operatorname{dist}\big((Y_n, V_n), (X, U)\big) \to 0 \quad \text{for any representative } (Y_n, V_n) \sim gr(u_n),$$
$$\sigma_n(y) \to \sigma(y), \quad u_n(y) \to u(y) \quad \text{for all } y \in \mathcal{C}_\sigma.$$

Proof. Since X_n is strictly increasing, the functions $\sigma_n = X_n^{-1} : [a,b] \to [0,1]$ and $u_n = U_n \circ X_n^{-1}$ are well defined and continuous. The couple (X_n, U_n) is a representative of the graph of u_n.

Fix $y \in \mathcal{C}_\sigma$ and let $s = \sigma(y)$, $s_n = \sigma_n(y)$. We can write the chain of identities

$$\begin{aligned} s_n - s = \sigma_n(y) - \sigma(y) &= \sigma\Big(X\big(\sigma_n(y)\big)\Big) - \sigma\Big(X_n\big(\sigma_n(y)\big)\Big) \\ &= \sigma\Big(X(s_n)\Big) - \sigma\Big(X_n(s_n)\Big). \end{aligned}$$

Since $X_n \to X$ uniformly and $X_n(s_n) = y \in \mathcal{C}_\sigma$, we deduce $s_n \to s$.

Next, assumption (2) implies

$$|U_n(s_n) - U_n(s)| \le \operatorname{Lip}(U_n)\,|s_n - s| \to 0.$$

Hence, $u_n(y) = U_n(s_n) \to U(s) = u(y)$.

Finally, if (Y_n, V_n) is any continuous representative of $gr(u_n)$, then

$$\operatorname{dist}\big((Y_n, V_n), (X, U)\big) \le \operatorname{dist}\big((X_n, U_n), (X, U)\big) \to 0 \quad \text{as } n \to \infty.$$

This completes the proof. □

Proof of Theorem 3.2. (a) The sequence $\{u_n\}$ consists of continuous functions. Let (X_n, U_n) be the arc-length parametrizations of $gr(u_n)$, defined by inverting

$$\sigma_n(x) := \frac{1}{L_n}\big(x - a + T_{u_n}(x)\big), \qquad L_n := b - a + T_{u_n}(b),$$

and setting $X_n := {\sigma_n}^{-1}$, $U_n := u_n \circ X_n$. In view of (2.22) and (1.3), (X_n, U_n) are uniformly Lipschitz continuous. There exists a subsequence (X_{n_k}, U_{n_k}) and a Lipschitz continuous function $(X, U) : [0,1] \to [a,b] \times \mathbb{R}^N$ such that

$$X_{n_k} \to X, \quad U_{n_k} \to U \qquad \text{uniformly on } [0,1]. \tag{3.3}$$

Hence, $\operatorname{dist}((X_{n_k}, U_{n_k}), (X, U)) \to 0$ as $k \to \infty$, and (3.3), in conjunction with Lemma 3.3, yields the conclusion of part (a).

(b) Given a generalized graph (X, U), let (X_n, U_n) be defined by

$$X_n := \left(1 - \frac{1}{n}\right) X + \frac{1}{n}\big(a + (b-a)s\big), \qquad U_n := U.$$

Then $X_n : [0,1] \to [a,b]$ is strictly increasing, Lipschitz continuous, and surjective; $\{(X_n, U_n)\}$ are uniformly Lipschitz continuous, while $(X_n, U_n) \to (X, U)$ uniformly on $[0,1]$. The functions u_n, defined by $u_n = U_n \circ X_n^{-1}$, are Lipschitz continuous and satisfy

$$\begin{aligned} \sup_{[a,b]} |u_n| &= \sup_{[0,1]} |U|, \\ TV_{[a,b]}(u_n) &= TV_{[0,1]}(U) \le Lip(U). \end{aligned}$$

The conclusion of part (b) now follows from Lemma 3.3. ∎

It is instructive to place the above concepts in a functional analysis framework. Let

$$E = \big\{(Y,V) \in \mathcal{C}\big([0,1]; [a,b] \times \mathbb{R}^N\big) \ : \ Y(0) = a,\ Y(1) = b\big\} \tag{3.4}$$

and $\mathcal{X} := (E/\sim)$ be the quotient space of E over the equivalence relation $\sim$ introduced in Definition 2.4. The elements of $\mathcal{X}$ are equivalence classes of functions: (Y_1, V_1), (Y_2, V_2) are in the same equivalence class if and only if $(Y_1, V_1) \circ \alpha = (Y_2, V_2) \circ \beta$ for some Lipschitz and increasing reparametrizations of $[0,1]$; that is, the curves determined by the functions (Y_1, V_1) and (Y_2, V_2) coincide. The elements of $\mathcal{X}$ can thus be visualized as geometric curves in $[a,b] \times \mathbb{R}^N$ with $Y(0) = a$, $Y(1) = b$.

If $(Y, V) \in E \cap BV$, one can select, using (2.19), a Lipschitz continuous representative of the equivalence class $[(Y,V)]$. This representative is denoted here by (X, U) and is characteristic to the class. The reason is that, for (Y,V) and $(\bar{Y}, \bar{V})$ of bounded variation, $(Y,V) \sim (\bar{Y}, \bar{V})$ if and only if the corresponding canonical representatives of $[(Y,V)]$ and $[(\bar{Y}, \bar{V})]$ are identical, $(X,U) = (\bar{X}, \bar{U})$. We emphasize that we can talk about the canonical representative only for $\mathcal{C} \cap BV$ curves. (Recall that if one representative of the equivalence class is of bounded variation, any representative is of bounded variation.)

When $\mathcal{X}$ is equipped with the pseudometric $\operatorname{dist}((Y,V), (\bar{Y}, \bar{V}))$, defined in (2.17), it becomes a metric space. Consider now the sets

$$\begin{aligned} \mathcal{F} &= \big\{[(Y,V)] \in \mathcal{X} \ : \ (Y,V) \text{ is of bounded variation and } X \text{ is strictly increasing}\big\}, \\ \mathcal{G} &= \big\{[(Y,V)] \in \mathcal{X} \ : \ (Y,V) \text{ is of bounded variation and } X \text{ is increasing}\big\}, \end{aligned} \tag{3.5}$$

where (X,U) always refers to the canonical representative of $[(Y,V)]$. Section 2.3 indicates that $\mathcal{F}$ can be identified with the set of continuous functions of bounded variation, $(\mathcal{C} \cap BV)\big([a,b]; \mathbb{R}^N\big)$. The elements of $\mathcal{F}$ are viewed as the graphs of the functions

u, with the canonical representative coinciding with the arc-length parametrization of $gr(u)$ in (2.19). The set $\mathcal{G}$ is the closure of $\mathcal{F}$ in the metric induced by the distance function (2.17) and may itself be viewed as a complete metric space. The canonical representative of each equivalence class element of $\mathcal{G}$ is a generalized graph in the sense of Definition 3.1. Henceforth, elements of $\mathcal{G}$ are denoted by $gr(X,U)$ and are visualized as the geometric graphs generated by (X,U). We remark that elements of $\mathcal{G}$ are not in correspondence with the space of BV functions, but rather $\mathcal{G}$ consists of all possible limit points of $\mathcal{F}$ in the distance metric.

3.2. Representation of weak-$\star$ limits. Consider a sequence $\{u_n\}$ of *continuous* functions satisfying the uniform bounds (1.3). The sequence $\{g(u_n)du_n\}$ may have multiple limit points in the weak-$\star$ topology of $\mathcal{M}[a,b]$ (cf. Example 1.1). We now characterize such limits for any continuous g in the following representation theorem.

THEOREM 3.4. (a) *Let $\{u_n\}$ be a sequence of continuous functions satisfying the uniform bounds* (1.3). *There exists a subsequence $\{u_{n_k}\}$ and a generalized graph (X,U) such that, for any continuous function $g=g(\lambda)$, we have*

$$\int_{[a,b]} \theta(x) g(u_{n_k}(x))\, du_{n_k}(x) \to \langle \mu(g), \theta\rangle \quad \text{for} \quad \theta \in \mathcal{C}[a,b], \tag{3.6}$$

where $\mu : \mathcal{C}_0(\mathbb{R}^N) \to \mathcal{M}[a,b]$ is defined by

$$\langle \mu(g), \theta\rangle = \int_0^1 \theta(X(s)) g(U(s))\, dU(s). \tag{3.7}$$

(b) *Conversely, given a generalized graph (X,U), let μ be defined by* (3.7). *There exists a sequence of Lipschitz functions $\{u_n\}$, uniformly bounded in BV, such that for any continuous g,*

$$g(u_n)du_n \rightharpoonup \mu(g) \quad \text{weak-}\star \text{ in } \mathcal{M}[a,b]. \tag{3.8}$$

Theorem 3.4 is based on a characterization of the weak-$\star$ limit points to the sequence of Radon measures $\{p_n\}$ defined in (1.9). The key ingredient is the following weak stability type of theorem.

THEOREM 3.5. *Let $\{u_n\}$ be a sequence of continuous functions $u_n : [a,b] \to \mathbb{R}^N$ satisfying the uniform bounds* (1.3), *and let (X_n,U_n) be the arc-length parametrization of $gr(u_n)$. If*

$$(X_n,U_n) \xrightarrow{d} (X,U) \tag{3.9}$$

to some generalized graph (X,U) associated with a BV function u, then

$$\int_{[a,b]} f(x,u_n(x))\, du_n(x) \to \int_0^1 f(X(s),U(s))dU(s) \quad \text{for } f \in \mathcal{C}_0([a,b]\times\mathbb{R}^N). \tag{3.10}$$

Proof. Let (X_n,U_n) be the arc-length parametrizations of $gr(u_n)$, and let (X,U) be a generalized graph of u. Hypothesis (3.9) implies that for some α_n and α, Lipschitz continuous reparametrizations of the interval $[0,1]$, we have

$$\begin{aligned} Y_n &:= X_n \circ \alpha_n \to X \circ \alpha =: Y \qquad \text{uniformly on } [0,1],\\ V_n &:= U_n \circ \alpha_n \to U \circ \alpha =: V \qquad \text{uniformly on } [0,1]. \end{aligned}$$

By virtue of Theorem 2.2, we may express the integrals

$$\int_{[a,b]} f(x,u_n(x))\,du_n(x) = \int_0^1 f(X_n(s),U_n(s))dU_n(s) = \int_0^1 f(Y_n(s),V_n(s))dV_n(s),$$

$$\int_0^1 f(X(s),U(s))dU(s) = \int_0^1 f(Y(s),V(s))dV(s).$$

Fix $f \in \mathcal{C}_0\big([a,b]\times\mathbb{R}^N\big)$. Note that (Y_n,V_n) and (Y,V) are continuous and satisfy

$$\begin{aligned} &TV(V_n) = TV(U_n) \le C,\\ &(Y_n,V_n) \to (Y,V) \quad \text{uniformly on } [0,1]. \end{aligned} \tag{3.11}$$

It suffices to show that (3.11) implies

$$\int_0^1 f(Y_n(s),V_n(s))dV_n(s) \to \int_0^1 f(Y(s),V(s))dV(s). \tag{3.12}$$

Step 1. We first show that, if V_n, $V : [0,1] \to \mathbb{R}^N$ are functions of bounded variation (not necessarily continuous) such that

(1) $\|V_n - V\|_\infty \to 0$,

(2) $TV(V_n) \le C$,

then, for any $[\alpha,\beta] \subset [0,1]$ and $\varphi \in \mathcal{C}[\alpha,\beta]$, we have

$$\int_{[\alpha,\beta]} \varphi(s)\,dV_n(s) \to \int_{[\alpha,\beta]} \varphi(s)\,dV(s). \tag{3.13}$$

If $\psi \in \mathcal{C}^1[\alpha,\beta]$, then (2.4) implies

$$\begin{aligned} \int_{[\alpha,\beta]} \psi(s)\,dV_n(s) &= -\int_{[\alpha,\beta]} \psi'(s)\,V_n(s)ds + \psi(\beta)V_n(\beta+) - \psi(\alpha)V_n(\alpha-)\\ &\to -\int_{[\alpha,\beta]} \psi'(s)\,V(s)ds + \psi(\beta)V(\beta+) - \psi(\alpha)V(\alpha-)\\ &= \int_{[\alpha,\beta]} \psi(s)\,dV(s). \end{aligned} \tag{3.14}$$

Given $\varphi \in \mathcal{C}[\alpha,\beta]$, there exists for every $\varepsilon > 0$ a function $\psi \in \mathcal{C}^1[\alpha,\beta]$ such that $\|\psi - \varphi\|_\infty < \varepsilon$. The relation

$$\begin{aligned} &\left|\int_{[\alpha,\beta]} \varphi(s)\,dV_n(s) - \int_{[\alpha,\beta]} \varphi(s)\,dV(s)\right|\\ &\le \varepsilon\, TV_{[\alpha,\beta]}(V_n) + \left|\int_{[\alpha,\beta]} \psi(s)\,dV_n(s) - \int_{[\alpha,\beta]} \psi(s)\,dV(s)\right| + \varepsilon\, TV_{[\alpha,\beta]}(V), \end{aligned}$$

in conjunction with (3.14), yields (3.13).

Step 2. Step 1, in conjunction with (3.11), implies

$$\int_0^1 f(Y(s),V(s))dV_n(s) \to \int_0^1 f(Y(s),V(s))dV(s).$$

On the other hand, again by (3.11),

$$\left|\int_0^1 (f(Y_n,V_n) - f(Y,V))\,dV_n\right| \le (\max|f(Y_n,V_n) - f(Y,V)|)\int_{[0,1]} |dV_n| \to 0,$$

as $n \to \infty$. Hence, (3.12) follows. ∎

Proof of Theorem 3.4. (a) Let $\{u_n\}$ be the sequence of continuous functions satisfying (1.3), and let (X_n, U_n) be the arc-length parametrizations of $gr(u_n)$; the latter are uniformly Lipschitz continuous. Let $\{p_n\}$ be the sequence of Radon measures defined in (1.9). The sequence $\{p_n\}$ is bounded, $\|p_n\|_{\mathcal{M}} \le C$, by the uniform BV bound of $\{u_n\}$.

Let p be a weak-$\star$ limit point of $\{p_n\}$. For a subsequence

$$\langle p_{n_k}, f(x,\lambda)\rangle = \int_{[a,b]} f(x, u_{n_k}) du_{n_k} \to \langle p, f(x,\lambda)\rangle \text{ for } f \in \mathcal{C}_0([a,b]\times\mathbb{R}^N).$$

Using part (a) of Theorem 3.2 and passing to a further subsequence $\{u_{n_k}\}$, if necessary, we may assume that there is a generalized graph (X,U), so that the arc-length parametrizations $(X_{n_k}, U_{n_k}) \xrightarrow{\mathrm{d}} (X,U)$. Theorem 3.5 implies

$$\langle p, f(x,\lambda)\rangle = \int_0^1 f(X(s), U(s)) dU(s).$$

Taking $f(x,\lambda) = \theta(x)g(\lambda)$ gives the desired result for $g \in \mathcal{C}_0(\mathbb{R}^N)$ and, due to the uniform sup-norm bound of $\{u_n\}$, for any continuous g.

(b) Given a generalized graph (X,U), let μ be defined by (3.7) and let $\{u_n\}$ be the sequence of Lipschitz functions constructed in the proof of part (b) of Theorem 3.2. Then $\{u_n\}$ are uniformly bounded in BV, $\{(X_n, U_n)\}$ are uniformly Lipschitz continuous, and $(X_n, U_n) \to (X,U)$ uniformly on $[0,1]$. Theorem 3.5 for $f(x,\lambda) = \theta(x)g(\lambda)$ implies (3.8). ∎

4. Definition of nonconservative products.

4.1. Definition as a Radon measure. In view of Theorem 3.4, the definition of nonconservative products should be based on a given generalized graph $(X,U) : [0,1] \to [a,b]\times\mathbb{R}^N$ of the function u of bounded variation. The generalized graph (X,U) determines a geometric object (the graph of u together with paths filling the jumps and possible attached loops), call it $gr(X,U)$. We define $g(u)\frac{du}{dx}$ relative to $gr(X,U)$, first as a Radon measure in this section, and then as a finite Borel measure via its distribution function in section 4.2.

Definition 4.1. *Let $(Y,V) \sim gr(X,U)$ denote the general continuous representative of the graph determined by (X,U). Given a continuous map $g : \mathbb{R}^N \to \mathbb{R}^N$, define $\mu(g)$ by*

$$\begin{aligned}\langle \mu(g), \theta\rangle &= \int_0^1 \theta(Y(s)) g(V(s))\, dV(s)\\ &= \int_0^1 \theta(X(s)) g(U(s)) \frac{dU}{ds}\, ds \quad \text{for } \theta \in \mathcal{C}[a,b].\end{aligned} \tag{4.1}$$

Then $\mu(g) \in \mathcal{M}[a,b]$ is called the nonconservative product of $g(u)$ by $\frac{du}{dx}$ and is denoted by

$$\mu(g) = \Big[g(u)\frac{du}{dx}\Big]_{(X,U)}. \tag{4.2}$$

Remark 4.2. (a) We refer to Dal Maso, LeFloch, and Murat [10] for a slightly weaker definition of nonconservative products and to Raymond [27] for a definition

that is equivalent. Comparisons of the various definitions are carried out in section 4.4. References [10, 27] also contain various weak stability results.

(b) Suppose that (Y,V), $(\bar{Y},\bar{V})$ are two representatives of the same graph, that is, $(Y,V)\sim(\bar{Y},\bar{V})$. Then $(Y,V)\circ\beta=(\bar{Y},\bar{V})\circ\alpha$ for some Lipschitz reparametrizations α,β of $[0,1]$. Theorem 2.2 implies the nonconservative product remains invariant,

$$\int_0^1 \theta(Y(s))g(V(s))\,dV(s)=\int_0^1 \theta(\bar{Y}(s))g(\bar{V}(s))\,d\bar{V}(s). \tag{4.3}$$

The measure introduced in Definition 4.1 thus depends on the equivalence class determined by the generalized graph (X,U), i.e., on $gr(X,U)$ as a geometric object. When a Lipschitz representative, such as (X,U) itself is used, then $\langle\mu(g),\theta\rangle$ may be expressed via the last integral in (4.1).

(c) If μ is viewed as a map $\mu:\mathcal{C}_0(\mathbb{R}^N)\to\mathcal{M}[a,b]$, then μ is linear and bounded. The boundedness follows from the estimate

$$|\langle\mu(g),\theta\rangle|\le\big(TV_{[0,1]}(V)\big)\sup_{|\lambda|\le\max|U|}|g(\lambda)|\sup_{x\in[0,1]}|\theta(x)|, \tag{4.4}$$

which implies $\|\mu(g)\|_{\mathcal{M}}\le(TV_{[0,1]}(V))\,\|g\|_{\mathcal{C}_0}$. □

We state next a weak stability theorem for nonconservative products.

THEOREM 4.3. (i) *Let $\{(X_n,U_n)\}$ and (X,U) be generalized graphs. If*

(1) *$TV(U_n)$ is uniformly bounded,*

(2) *$(X_n,U_n)\xrightarrow{d}(X,U)$,*

then

$$\Big[g(u_n)\frac{du_n}{dx}\Big]_{(X_n,U_n)}\rightharpoonup\Big[g(u)\frac{du}{dx}\Big]_{(X,U)}\qquad\text{weak-}\star\text{ in }\mathcal{M}[a,b]. \tag{4.5}$$

(ii) *Let $\{u_n\}$ be a sequence of continuous functions satisfying (1.3), let (X_n,U_n) be the arc-length parametrizations of $gr(u_n)$, and let (X,U) be a generalized graph. If $(X_n,U_n)\xrightarrow{d}(X,U)$, then*

$$g(u_n)du_n\rightharpoonup\Big[g(u)\frac{du}{dx}\Big]_{(X,U)}\qquad\text{weak-}\star\text{ in }\mathcal{M}[a,b]. \tag{4.6}$$

Proof. Define the graphs determined by (X_n,U_n) and (X,U), and let $(Y_n,V_n)\sim gr(X_n,U_n)$ and $(Y,U)\sim gr(X,U)$ be continuous representatives such that $(Y_n,V_n)\to(Y,V)$ uniformly on $[0,1]$. Moreover, $TV(V_n)=TV(U_n)\le C$. The result follows from (3.10) in Theorem 3.5, together with part (b) of Remark 4.2. □

4.2. Distribution functions. We discuss next the properties of nonconservative products when viewed as signed Borel measures defined via their distribution functions. Recall, for a generalized graph (X,U), the set theoretic inverse $\sigma=X^{-1}:[0,1]\to[a,b]$ is a strictly increasing multivalued map.

THEOREM AND DEFINITION 4.4. *Let $(Y,V)\sim gr(X,U)$ be a representative of the graph determined by (X,U). For $x\in[a,b]$ define*

$$F(x)=\int_0^{Y^{-1}(x+)}g(V(s))\,dV(s)=\int_0^{X^{-1}(x+)}g(U(s))\frac{dU}{ds}\,ds, \tag{4.7}$$
$$F(a-)=0.$$

Then F is a right continuous BV function and generates a signed Borel measure μ, determined by

$$\mu((a,x]) = F(x) - F(a) \quad \text{for } x \in (a,b], \qquad \mu(\{a\}) = F(a). \tag{4.8}$$

Also μ coincides with the nonconservative product $[g(u)\frac{du}{dx}]_{(X,U)}$ in (4.1)–(4.2); that is,

$$\begin{aligned} \langle \mu, \theta \rangle &= \int_{[a,b]} \theta(x)\, dF(x) \\ &= \int_{[0,1]} \theta(Y(s))g(V(s))\, dV(s) = \int_0^1 \theta(X(s))g(U(s))\frac{dU}{ds}\, ds \end{aligned} \tag{4.9}$$

for any $\theta \in \mathcal{C}[a,b]$.

Proof. Consider $(Y,V) \sim gr(X,U)$, a general continuous representative of the graph determined by (X,U). We have the following conditions:

(i) $X : [0,1] \to [a,b]$ is Lipschitz continuous, increasing, and surjective with $X(0) = a$, $X(1) = b$, and $X^{-1}(X(s)) = s$ whenever $X(s) \in \mathcal{C}_{X^{-1}}$.

(ii) $Y : [0,1] \to [a,b]$ is continuous, increasing, and surjective with $Y(0) = a$, $Y(1) = b$, and $Y^{-1}(Y(s)) = s$ whenever $Y(s) \in \mathcal{C}_{Y^{-1}}$.

(iii) $(Y,V) \circ \beta = (X,U) \circ \alpha$ for some $\alpha, \beta : [0,1] \to [0,1]$ increasing, Lipschitz, and surjective reparametrizations.

Let $F : [a,b] \to \mathbb{R}^N$ be defined by

$$F(x) = \int_0^{Y^{-1}(x+)} g(V(s))\, dV(s), \quad F(a-) = 0.$$

Then F is a right continuous BV function and generates a signed Borel measure μ, through (4.8). Note that F satisfies

$$F(Y(s)) = \int_0^s g(V)dV \qquad \text{for } s \in Y^{-1}(\mathcal{C}_{Y^{-1}}). \tag{4.10}$$

Step 1. The definition of the distribution function F depends on the equivalence class of (X,U) but not on the specific representative.

It suffices to define F at points $x \in \mathcal{C}_{Y^{-1}}$ and to extend F so that it is right continuous. If $(Y,V) \sim (X,U)$ are two equivalent representatives of $gr(X,U)$, then $Y \circ \beta = X \circ \alpha$, $V \circ \beta = U \circ \alpha$, and $\mathcal{C}_{(X\circ\alpha)^{-1}} \subset \mathcal{C}_{X^{-1}}$, $\mathcal{C}_{(Y\circ\beta)^{-1}} \subset \mathcal{C}_{Y^{-1}}$. For $x \in \mathcal{C}_{(X\circ\alpha)^{-1}} = \mathcal{C}_{(Y\circ\beta)^{-1}}$, Theorem 2.2 implies

$$\begin{aligned} \big[F(x)\big]_{(X,U)} &:= \int_0^{X^{-1}(x)} g(U)dU = \int_0^{(X\circ\alpha)^{-1}(x)} g(U\circ\alpha)d(U\circ\alpha), \\ \big[F(x)\big]_{(Y,V)} &:= \int_0^{Y^{-1}(x)} g(V)dV = \int_0^{(Y\circ\beta)^{-1}(x)} g(V\circ\beta)d(V\circ\beta). \end{aligned}$$

Since such points are dense in $[a,b]$, any of these formulas generates the same distribution function $[F]_{(X,U)} = [F]_{(Y,V)}$ and we may use any representative for calculating F. This shows (4.7).

Step 2. For $\theta \in \mathcal{C}[a,b]$, we shall show that

$$\int_{[a,b]} \theta(x)\, dF(x) = \int_{[0,1]} \theta(X(s))g(U(s))\frac{dU}{ds} ds. \tag{4.11}$$

(Note that this formula is *not* a direct consequence of Theorem 2.2.)

Fix $\psi \in \mathcal{C}^1[a,b]$. Using (2.4), the change of variables $x = X(s)$, (4.7), (4.10), the property $\dot{X} = 0$ on each interval $[\sigma(y-), \sigma(y+)]$ with $y \in \mathcal{S}_\sigma$, and the chain rule for Lipschitz continuous functions, we obtain

$$\begin{aligned}
\int_{[a,b]} \psi(x)\, dF(x) =& \psi(b)F(b+) - \psi(a)F(a-) - \int_{[a,b]} \psi'(x)F(x)\, dx \\
=& \psi(b)F(b+) - \int_0^1 \psi'(X(s))F(X(s))\, \dot{X}(s)\, ds \\
=& \psi(b)F(b+) - \int_{\sigma(\mathcal{C}_\sigma)} \psi'(X(s))\dot{X}(s) \left(\int_0^s g(U)\frac{dU}{d\tau} d\tau \right) ds \\
& - \sum_{y \in \mathcal{S}_\sigma} \int_{\sigma(y-)}^{\sigma(y+)} \psi'(X(s))\dot{X}(s) \left(\int_0^{\sigma(X(s)+)} g(U)\frac{dU}{d\tau} d\tau \right) ds \\
=& \psi(X(1)) \int_0^1 g(U)\frac{dU}{d\tau} d\tau - \int_0^1 \frac{d}{ds}\big(\psi(X(s))\big) \left(\int_0^s g(U)\frac{dU}{d\tau} d\tau \right) ds;
\end{aligned}$$

thus

$$\int_{[a,b]} \psi(x)\, dF(x) = \int_0^1 \psi(X(s))g(U(s))\frac{dU}{ds}\, ds.$$

Since F is of bounded variation and U is Lipschitz continuous, a density argument yields (4.11). The proof of (4.9) follows from part (b) of Remark 4.2. □

Remark 4.5. In view of (4.7) and (4.8), the nonconservative product μ charges points $x \in \mathcal{S}_{X^{-1}}$ according to

$$\mu\big(\{x\}\big) = F(x+) - F(x-) = \int_{X^{-1}(x-)}^{X^{-1}(x+)} g(U(s))\, dU(s). \qquad \square$$

We state and prove a version of the weak stability theorem by using distribution functions.

THEOREM 4.6. *Suppose $\{u_n\}$ is a sequence of continuous functions satisfying (1.3). Let (X_n, U_n) be the arc-length parametrizations of $gr(u_n)$, let (X, U) be a generalized graph, and define the distribution functions*

$$F_n(x) = \int_a^x g(u_n(y))\, du_n(y), \tag{4.12}$$

and $F(x)$ associated with (X, U) by (4.7). If $(X_n, U_n) \xrightarrow{d} (X, U)$, then

$$F_n(x) \to F(x) \qquad \text{a.e. in } (a,b), \tag{4.13}$$

while μ_n and μ, generated by F_n and F, respectively, satisfy $\mu_n \rightharpoonup \mu$ weak-$\star$ in $\mathcal{M}[a,b]$.

Proof. Let (X_n, U_n) be the arc-length parametrizations of $gr(u_n)$; (X_n, U_n) are uniformly Lipschitz. There exist reparametrizations of the interval $[0,1]$, α_n, and α that are uniformly Lipschitz continuous such that $(\bar{X}_n, \bar{U}_n) = (X_n, U_n) \circ \alpha_n$, $(\bar{X}, \bar{U}) = (X, U) \circ \alpha$ satisfy the following: $(\bar{X}_n, \bar{U}_n)$ are uniformly Lipschitz and $\bar{X}_n \to \bar{X}$, $\bar{U}_n \to \bar{U}$ uniformly on $[0,1]$.

Let $\mathcal{S}_{\bar{X}_n^{-1}}$ and $\mathcal{S}_{\bar{X}^{-1}}$ be the points of discontinuity of $\bar{X}_n^{-1}$ and $\bar{X}^{-1}$, respectively, and set $\mathcal{T} = (\bigcup_n \mathcal{S}_{\bar{X}_n^{-1}}) \cup \mathcal{S}_{\bar{X}^{-1}}$. Then $\mathcal{T}$ is countable, and an argument as in the proof of Lemma 3.3 shows

$$\bar{X}_n^{-1}(x) \to \bar{X}^{-1}(x) \quad \text{for } x \in [a,b] \setminus \mathcal{T}. \tag{4.14}$$

Theorem 2.2, for the change of variables $y = \bar{X}_n(s)$, gives

$$F_n(x) = \int_a^x g(u_n(y))\, du_n(y) = \int_0^{\bar{X}_n^{-1}(x)} g(\bar{U}_n(s)) d\bar{U}_n(s) \quad \text{for } x \in \mathcal{C}_{\bar{X}_n^{-1}}. \tag{4.15}$$

An argument, as in the proof of (3.12), shows that

$$\int_0^{\bar{X}^{-1}(x)} g(\bar{U}_n(s)) d\bar{U}_n(s) \to \int_0^{\bar{X}^{-1}(x)} g(\bar{U}(s)) d\bar{U}(s) \quad \text{for } x \in \mathcal{C}_{\bar{X}^{-1}}. \tag{4.16}$$

In turn, (4.14)–(4.16) and the fact that $\bar{U}_n$ are uniformly Lipschitz imply

$$F_n(x) \to F(x) \quad \text{for } x \in [a,b] \setminus \mathcal{T}. \tag{4.17}$$

The distribution functions F_n and F satisfy the following properties: $F_n(a) = 0$, $F(a-) = 0$,

$$F_n(b) = \int_0^1 g(\bar{U}_n(s)) d\bar{U}_n(s)\, ds \to \int_0^1 g(\bar{U}(s)) d\bar{U}(s) = F(b). \tag{4.18}$$

For any test function $\psi \in \mathcal{C}^1[a,b]$, the integration by parts formula (2.4), in conjunction with (4.17)–(4.18), yields

$$\begin{aligned} \int_{[a,b]} \psi(x) dF_n(x) &= -\int_{[a,b]} \psi'(x) F_n(x)\, dx + \psi(b)F_n(b) - \psi(a)F_n(a) \\ &\to -\int_{[a,b]} \psi'(x) F(x)\, dx + \psi(b)F(b) - \psi(a)F(a-); \end{aligned}$$

hence

$$\int_{[a,b]} \psi(x) dF_n(x) \quad \to \quad \int_{[a,b]} \psi(x) dF(x). \tag{4.19}$$

Since F_n are of uniformly bounded variation, (4.19) and a density argument show that $\mu_n \rightharpoonup \mu$ weak-$\star$ in $\mathcal{M}[a,b]$. □

4.3. Generalized graphs and graphs of BV functions. In this section we examine the relation between a generalized graph (X,U) and the graph of the associated BV function u. First observe that Definition 3.1 directly implies the following proposition.

PROPOSITION 4.7. *Let (X,U) be a generalized graph and let $\sigma = X^{-1}$ be the set theoretic inverse of X. Then the following conditions hold:*

(i) *If $y \in \mathcal{C}_\sigma$, then $u(y) = U(\sigma(y))$.*

(ii) *If $y \in \mathcal{S}_\sigma$, then $X(\tau) = y$ and the function*

$$\phi_y(\tau) := U(\tau), \qquad \tau \in J_y := [\sigma(y-), \sigma(y+)],$$

determines a Lipschitz continuous curve that lies on the hyperplane $\{x = y\}$ *and connects* $(y, u(y-))$ *with* $(y, u(y+))$.

(1) *The Lipschitz path* $\phi_y : J_y \to \mathbb{R}^N$ *is either an arc when* $u(y-) \neq u(y+)$ *or a loop when* $u(y-) = u(y+)$.

(2) *The Lipschitz continuity of* U *implies*

$$\sum_{y\in\mathcal{S}_\sigma} \int_{[\sigma(y-),\sigma(y+)]} \left|\frac{\partial \phi_y}{\partial \tau}\right| d\tau \leq \int_0^1 \left|\frac{dU}{ds}\right| ds < \infty. \tag{4.20}$$

(iii) $\mathcal{C}_\sigma \subset \mathcal{C}_u$ *and* $\mathcal{S}_\sigma \supset \mathcal{S}_u$.

A generalized graph completely determines u and also specifies the paths connecting points of discontinuity and possible loops attached to the graph of u. There is no a priori mechanism, given u, for selecting a particular generalized graph. They may be induced by introducing paths at points of discontinuity in $\mathcal{S}_u$ (using straight lines [31] or families of Lipschitz paths [10]) and by possibly attaching loops at points of removable discontinuity or even at points of continuity in $\mathcal{C}_u$ (cf. the examples pointed out in [10] and the notion of extended graph in [27]). A converse to Proposition 4.7 has been proved by Raymond [27].

PROPOSITION 4.8 (see [27]). *Given a function* $u : [a, b] \to \mathbb{R}^N$ *of bounded variation, a countable set* $\mathcal{T}$, *with* $[a, b] \supset \mathcal{T} \supset \mathcal{S}_u$, *and a family of Lipschitz paths* $\Phi = \{\phi_y\}_{y\in\mathcal{T}}$ *such that*

$$\begin{aligned} &\phi_y : [0, 1] \to \mathbb{R}^N \ \textit{is Lipschitz continuous with} \\ &\phi_y(0) = u(y-),\ \phi_y(1) = u(y+) \quad \textit{for } y \in \mathcal{T}, \end{aligned} \tag{A_1}$$

$$\sum_{y\in\mathcal{T}} \int_0^1 \left|\frac{\partial \phi_y}{\partial \tau}\right| d\tau < \infty, \tag{A_2}$$

there exists a generalized graph (X, U) *associated with the triplet* $\big(u, \mathcal{T}, \Phi\big)$.

The triplet $\big(u, \mathcal{T}, \Phi\big)$ is called extended graph in [27]. Apart from its theoretical interest, the proof of the proposition provides a procedure for constructing examples.

Proof. The construction proceeds in two steps.

Step 1. Construction of a continuous, BV representative $(Y, V) : [0, 1] \to [a, b] \times \mathbb{R}^N$ of the graph determined by $\big(u, \mathcal{T}, \Phi\big)$.

Define $q : [a, b] \to [0, 1]$ by setting $q(b) = 1$ and

$$\begin{aligned} q(x) &:= \frac{1}{Q}\left(x - a + \sum_{y\in\mathcal{T}, y<x} \int_0^1 \left|\frac{\partial \phi_y}{\partial \tau}\right| d\tau\right) \qquad \text{for } x \in [a, b), \\ Q &:= b - a + \sum_{y\in\mathcal{T}} \int_0^1 \left|\frac{\partial \phi_y}{\partial \tau}\right| d\tau. \end{aligned} \tag{4.21}$$

Then q is a strictly increasing left-continuous (but generally discontinuous) function satisfying the properties $\mathcal{C}_q = [a, b] \setminus \mathcal{T}$, $\mathcal{S}_q = \mathcal{T}$,

$$\begin{aligned} q(y+) - q(y-) &= \frac{1}{Q} \int_0^1 \left|\frac{\partial \phi_y}{\partial \tau}\right| d\tau, \\ 0 < x_2 - x_1 &\leq Q\big(q(x_2) - q(x_1)\big) \qquad \text{for } x_1 < x_2, \end{aligned} \tag{4.22}$$

and $q(a) = 0 < q(x) < 1 = q(b)$ for $x \in (a, b)$.

The domain and range of q admit the decompositions

$$[a,b] = \mathcal{C}_q \bigcup \mathcal{S}_q,$$
$$[0,1] = q(\mathcal{C}_q) \bigcup \Big(\bigcup_{y\in\mathcal{T}} [q(y-), q(y+)] \Big),$$

where $q(\mathcal{C}_q)$ and each $J_y = [q(y-), q(y+)]$ are mutually disjoint. The closure of the set $q(\mathcal{C}_q)$ is

$$\overline{q(\mathcal{C}_q)} = \Big(\bigcup_{y\in\mathcal{C}_q} \{q(y)\} \Big) \bigcup \Big(\bigcup_{y\in\mathcal{T}} \{q(y-), q(y+)\} \Big).$$

Define now the function (Y, V) as follows:
(a) On each interval $J_y = [q(y-), q(y+)]$ with $y \in \mathcal{T}$, set

$$\begin{cases} Y(s) = y & \text{for } s \in J_y, \\ V(s) = \phi_y\Big(\frac{s-q(y-)}{q(y+)-q(y-)}\Big) & \text{for } s \in J_y. \end{cases} \tag{4.23}$$

(b) On the complement $[0,1] - \cup_{y\in T} J_y = q(\mathcal{C}_q)$, we have $s \in q(\mathcal{C}_q)$ if and only if $s = q(y)$ for precisely one $y \in \mathcal{C}_q$. We define

$$\begin{cases} Y(s) = y & \text{for } s \in q(\mathcal{C}_q), \\ V(s) = u(y) & \text{for } s \in q(\mathcal{C}_q). \end{cases} \tag{4.24}$$

Clearly, Y is an increasing function, (Y, V) are continuous on the interior of each interval J_y, and also for any $s_1, s_2 \in J_y$ with $s_1 < s_2$, we have

$$|V(s_2) - V(s_1)| \le \int_{\frac{s_1-q(y-)}{q(y+)-q(y-)}}^{\frac{s_2-q(y-)}{q(y+)-q(y-)}} \left| \frac{\partial \phi_y}{\partial \tau} \right| d\tau \le \int_0^1 \left| \frac{\partial \phi_y}{\partial \tau} \right| d\tau. \tag{4.25}$$

We proceed to show (Y, V) is continuous for each $s \in \overline{q(\mathcal{C}_q)}$. This follows by a case analysis:

(i) $s \in q(\mathcal{C}_q)$, $s_n \to s$ with $\{s_n\} \subset q(\mathcal{C}_q)$. Then $s_n = q(y_n)$, $s = q(y)$ for some $y_n, y \in \mathcal{C}_q$. By (4.22), $y_n \to y$ and thus

$$Y(s_n) = y_n \to y = Y(s), \quad V(s_n) = u(y_n) \to u(y) = V(s).$$

(ii) $s = q(y-)$ for some $y \in \mathcal{T}$, $s_n \to s$ with $\{s_n\} \subset q(\mathcal{C}_q)$. In this case for large n it is $s_n < s$, and the corresponding points $y_n \in \mathcal{C}_q$ satisfy $s_n = q(y_n)$ and $y_n < y$. Again (4.22) implies

$$0 < y - y_n < Q(q(y-) - q(y_n))$$

and thus, by (A_1),

$$Y(s_n) = y_n \to y- = Y(s), \quad V(s_n) = u(y_n) \to u(y-) = \phi_y(0) = V(s).$$

(iii) If $s = q(y+)$ for some $y \in \mathcal{T}$, $s_n \to s$ with $\{s_n\} \subset q(\mathcal{C}_q)$. Then, as in (ii),

$$Y(s_n) \to y+ = Y(s), \quad V(s_n) = u(y_n) \to u(y+) = \phi_y(1) = V(s).$$

(iv) Now let $s_n \to s$ with $\{s_n\} \subset \overline{q(\mathcal{C}_q)}$. For each n, let $\sigma_n \in q(\mathcal{C}_q)$ such that

$$|\sigma_n - s_n| < \frac{1}{n}, \quad |Y(\sigma_n) - Y(s_n)| < \frac{1}{n}, \quad |V(\sigma_n) - V(s_n)| < \frac{1}{n}.$$

Then $\sigma_n \to s$ and (i)–(iii) imply $Y(s_n) \to Y(s)$, $V(s_n) \to V(s)$.

(v) On the other extreme, let $s_n \to s$ with $\{s_n\} \subset \cup_{y\in\mathcal{T}} J_y$. Then $Y(s_n) = y_n$ with $y_n \in \mathcal{T}$. To simplify the exposition, consider the case $s_n < s$, $s_n \to s$. For each n, define $\sigma_n = q(y_n+)$. Then $\{\sigma_n\} \subset \overline{q(\mathcal{C}_q)}$, $\sigma_n \to s$ and (4.25) implies

$$\sum_n |V(\sigma_n) - V(s_n)| \le \sum_n \int_0^1 \left|\frac{\partial \phi_{y_n}}{\partial \tau}\right| d\tau.$$

It follows from (iv) and hypothesis (A_2) that $Y(s_n) = Y(\sigma_n) \to Y(s)$, $V(s_n) \to V(s)$.

(vi) For general sequences $s_n \to s$, the result follows by combining (iv) and (v).

The function Y is increasing and thus of bounded variation. The total variation of V may be explicitly computed

$$TV_{[0,1]}(V) \le TV_{[a,b]}(u) + \sum_{y\in\mathcal{T}} \left(\int_0^1 \left|\frac{\partial \phi_{y_n}}{\partial \tau}\right| d\tau - \big|u(y+) - u(y-)\big| \right).$$

Thus V is also of bounded variation.

Step 2. Construction of a Lipschitz continuous representative $(X, U) : [0, 1] \to [a, b] \times \mathbb{R}^N$ of the graph determined by $\big(u, \mathcal{T}, \Phi\big)$.

Using the reparametrization (2.15) and the analysis of section 2.2, we can construct the canonical representative of the curve (Y, V). This representative (X, U) is Lipschitz (with Lipschitz constant L) and satisfies

$$(Y, V) = (X, U) \circ \gamma, \text{where } \gamma(s) = \frac{1}{L} T_{(Y,V)}(s),\ s \in [0, 1], \text{ and } L = TV_{[0,1]}(Y, V)\ .$$

Also, X is increasing and (X, U) is a generalized graph. ∎

4.4. Comparison with definitions based on families of paths. In this section, we compare definitions based on families of paths with Theorem 3.4 based on generalized graphs.

We review the definition proposed by Dal Maso, LeFloch, and Murat [10]. This theory is based on a given family of Lipschitz continuous paths $\phi : [0, 1] \times \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R}^N$ that satisfy, for some $K > 0$ and for all u_0, $u_1 \in \mathbb{R}^N$ and $\tau \in [0, 1]$, the properties

$$\phi(0; u_0, u_1) = u_0, \quad \phi(1; u_0, u_1) = u_1, \tag{H1}$$

$$\phi(\tau; u_0, u_0) = u_0, \tag{H2}$$

$$\left|\frac{\partial \phi}{\partial \tau}(\tau; u_0, u_1)\right| \le K\,|u_0 - u_1|. \tag{H3}$$

THEOREM AND DEFINITION 4.9 (see [10]). *Let $u : (a, b) \to \mathbb{R}^N$ be a function of bounded variation and $g : \mathbb{R}^N \to \mathbb{R}^N$ be a continuous map. There exists a unique finite signed Borel measure μ on (a, b) such that*

(1) *if u is continuous on a Borel set $B \subset (a, b)$, then*

$$\mu(B) = \int_B g(u)\, du; \tag{4.26}$$

(2) *if u is discontinuous at a point $x \in (a,b)$, then*

$$\mu(\{x\}) = \int_0^1 g(\phi(\tau; u_-, u_+)) \frac{\partial \phi}{\partial \tau}(\tau; u_-, u_+) d\tau \qquad \text{with } u_\pm := u(x\pm). \tag{4.27}$$

The measure μ is called the nonconservative product of $g(u)$ by $\frac{du}{dx}$ and is denoted by

$$\mu = \left[g(u) \frac{du}{dx} \right]_\phi. \tag{4.28}$$

Remark 4.10. The stronger condition

$$\left| \frac{\partial \phi}{\partial \tau}(\tau; u_0, u_1) - \frac{\partial \phi}{\partial \tau}(\tau; v_0, v_1) \right| \le K \left| (u_0 - v_0) - (u_1 - v_1) \right| \tag{H3$'$}$$

is assumed in [10] in place of (H3), in connection with defining products of the form $g(u)\frac{dv}{dx}$, where u and v are BV functions. For instance, (H3$'$) guarantees that such products depend solely on the measure $\frac{dv}{dx}$ and not on the function v. It is straightforward to check that hypotheses (H1)–(H3) suffice for Definition 4.9, for most results presented in [10], and, in particular, for the theorem on weak stability.

It can be checked that the nonconservative product is independent of reparametrizations of the paths and that the definition is consistent with the usual distributional definition in the case of conservative products: if $f : \mathbb{R}^N \to \mathbb{R}$ is a continuously differentiable function, then

$$\left[(Df)(u) \frac{du}{dx} \right]_\phi = \frac{d}{dx}(f(u)). \tag{4.29}$$

The left-hand side in (4.29) is understood in the sense of Definition 4.9, while the right-hand side is understood in the sense of distributions.

Example 4.11. A simple example of paths is the *family of straight lines* ϕ_S, defined by

$$\phi_S(\tau; u_0, u_1) = u_0 + \tau(u_1 - u_0). \tag{4.30}$$

Then (4.27) reads

$$\left[g(u) \frac{du}{dx} \right]_S (\{x\}) = \left(\int_0^1 g(u_- + \tau(u_+ - u_-))\, d\tau \right) (u_+ - u_-)\,,$$

and the nonconservative product coincides with a product introduced by Volpert [31]. To see that, recall that the *averaged superposition* of a BV function $u : (a,b) \to \mathbb{R}^N$ by a continuous function g is the function $\hat{g}(u)$, defined for all $x \in (a,b)$ by

$$\hat{g}(u)(x) = \int_0^1 g(u_- + s(u_+ - u_-))\, ds, \qquad u_\pm := u(x\pm). \tag{4.31}$$

Of course, we have

$$\hat{g}(u)(x) = g(u(x)) \quad \text{for all } x \in \mathcal{C}_u.$$

The function $\hat{g}(u)$ is Borel measurable, and the product $\hat{g}(u)\frac{du}{dx}$ is well defined as a signed Borel measure. This nonconservative product coincides with the one in Definition 4.9 if one uses the family of straight lines:

$$\Big[g(u)\frac{du}{dx}\Big]_S = \hat{g}(u)\frac{du}{dx} \tag{4.32}$$

as Borel measures on (a,b).

A comparison of (4.20) with the hypotheses of Theorem 4.9 indicates that (H2) and (H3) are somewhat restrictive, ruling out the possibility of loops attached to the graph of the BV function u. The gap between the two definitions has been bridged in a definition given by Raymond [27]. It is proved in [27] that this definition is equivalent to Definition 4.1.

In practice, there should be no confusion between the notation introduced in Definitions 4.1 and 4.9, respectively, in view of the following result.

THEOREM 4.12. *Let $u : (a,b) \to \mathbb{R}^N$ be a function of bounded variation and $(X,U) : [0,1] \to [a,b]\times\mathbb{R}^N$ be a generalized graph of u. Suppose there exists a family of paths satisfying* (H1)–(H2) *such that, for every point of discontinuity $x \in \mathcal{S}_u$,*

$$\begin{aligned} &\phi(\tau; u_-, u+) := U\big(s_- + \tau(s_+ - s_-)\big), \qquad \tau\in[0,1],\\ &\text{where } s_\pm := X^{-1}(x\pm),\ \ u_\pm := u(x\pm), \end{aligned} \tag{4.33}$$

and satisfying the "no loop" condition

$$\text{for every } x\in\mathcal{C}_u,\ \text{there exists a unique } s\in[0,1] \text{ such that } X(s)=x. \tag{4.34}$$

Then the nonconservative products in Definitions 4.1 *and* 4.9*, respectively, coincide*

$$\Big[g(u)\frac{du}{dx}\Big]_\phi = \Big[g(u)\frac{du}{dx}\Big]_{(X,U)}$$

as Borel measures on (a,b).

Proof. It will be convenient to view the product in Definition 4.9 as a Borel–Stieltjes integral. Namely, by modifying $g(u)$ at most countably many points, we can construct a function $\overline{g(u)} : [a,b] \to \mathbb{R}^N$ satisfying

$$\overline{g(u)}(x) = g(u(x)) \quad \text{ for } x\in\mathcal{C}_u \tag{4.35}$$

and for $x\in\mathcal{S}_u$

$$\overline{g(u)}\cdot(u(x+)-u(x-)) = \int_0^1 g\big(\phi(\tau;u(x-),u(x+))\big)\partial_\tau\phi(\tau;u(x-),u(x+))\,d\tau. \tag{4.36}$$

Note that the value of $\overline{g(u)}(x)$ is not uniquely determined by points $x\in\mathcal{S}_u$, since any vector othogonal to the jump $u(x+)-u(x-)$ may be added to $\overline{g(u)}(x)$. From Definition 4.9, one deduces that

$$\Big[g(u)\frac{du}{dx}\Big]_\phi = \overline{g(u)}\,du \tag{4.37}$$

as Borel measures on (a,b), where the right-hand side is understood as a Borel–Stieltjes integral. Using the change of variable formula in Theorem 2.2, we thus have

$$\int_{[a,b]}\theta\,\Big[g(u)\frac{du}{dx}\Big]_\phi = \int_{[a,b]}\theta\,\overline{g(u)}\,du = \int_{[0,1]}(\theta\circ X)\,(\overline{g(u)}\circ X)\,d(u\circ X). \tag{4.38}$$

Consider the decomposition $\big([0,1]\setminus J_u\big)\cup J_u$ where $J_u:=\bigcup_x[s_-,s_+]$ with $s_\pm:=X^{-1}(x\pm)$. On one hand, by (4.35) one has $\overline{g(u)}(x)=g(u(x))$ for $x\in\mathcal{C}_u$ and thus, on the set $[0,1]\setminus J_u$, we obtain $u\circ X=U$ and $\overline{g(u)}\circ X=g(u\circ X)=g(U)$. Thus

$$\begin{aligned}\int_{[0,1]\setminus J_u}(\theta\circ X)\,(\overline{g(u)}\circ X)\,d(u\circ X)&=\int_{[0,1]\setminus J_u}(\theta\circ X)\,(g(u)\circ X)\,d(u\circ X)\\&=\int_{[0,1]\setminus J_u}(\theta\circ X)\,g(U)\,\frac{dU}{ds}\,ds.\end{aligned}\tag{4.39}$$

On the other hand, in view of condition (4.34), each interval $[s_-,s_+]\subset J_u$ corresponds to a jump in u, say, $u_\pm:=u(x\pm)$ for some $x\in\mathcal{S}_u$. Using (4.36) and (4.33), we obtain

$$\begin{aligned}\int_{[s_-,s_+]}(\theta\circ X)\,(\overline{g(u)}\circ X)\,d(u\circ X)&=\int_{[s_-,s_+]}\theta(x)\,\overline{g(u)}(x)\,d(u\circ X)\\&=\theta(x)\,\overline{g(u)}(x)\cdot\big(u_+-u_-\big)\\&=\theta(x)\int_0^1 g\big(\phi(\tau;u(x-),u(x+))\big)\,\partial_\tau\phi(\tau;u(x-),u(x+))\,d\tau\\&=\theta(x)\int_{[s_-,s_+]}g(U(s))\,\frac{dU}{ds}\,ds.\end{aligned}\tag{4.40}$$

Combining (4.38)–(4.40) we deduce that

$$\begin{aligned}\int_{[a,b]}\theta\Big[g(u)\frac{du}{dx}\Big]_\phi&=\int_{[0,1]}(\theta\circ X)\,(\overline{g(u)}\circ X)\,d(u\circ X)\\&=\int_{[0,1]}(\theta\circ X)\,g(U)\,\frac{dU}{ds}\,ds\\&=\int_{[a,b]}\theta\Big[g(u)\frac{du}{dx}\Big]_{(X,U)}\end{aligned}$$

for every test function θ. □

Next, we list examples in order to illustrate the relation between regularized sequences $\{v_n\}$, subject to (1.3), and the associated nonconservative products. Since all definitions of nonconservative products are equivalent within their range of applicability, we will use interchangeably the notation $[g(u)\frac{du}{dx}]_\phi$ and $[g(u)\frac{du}{dx}]_{(X,U)}$; the former is applicable when we are given a family of paths ϕ or an extended graph and the latter when we are given a generalized graph (X,U). In any case one can pass from ϕ to (X,U) and vice versa by using Propositions 4.7 and 4.8. We recall that, given a generalized graph (X,U), it is always possible to construct a sequence of smooth functions $\{v_n\}$ that approach (X,U) in the graph distance (cf. Theorem 3.2).

Example 4.13. We return to the sequence $\{v_n\}$ discussed in Example 1.1. With u_0, $u_1\in\mathbb{R}^N$, the functions $\{v_n\}$, v, and the path π defined in (1.5)–(1.6), we have

$$g(v_n)\frac{dv_n}{dx}\rightharpoonup\left(\int_0^1 g(\pi(s))\pi'(s)ds\right)\delta_{x_0}\quad\text{weak-}\star\text{ in }\mathcal{M}[a,b].\tag{4.41}$$

We select the family of paths ϕ so that $\phi(.;u_0,u_1)=\pi$ holds. Then the nonconservative product reads

$$\Big[g(v)\frac{dv}{dx}\Big]_\phi=c(g,\pi)\,\delta_{x_0},\qquad\text{where } c(g,\pi)=\int_0^1 g(\pi(s))\pi'(s)ds\ ,\tag{4.42}$$

and for any g continuous we have $g(v_n)\frac{dv_n}{dx} \rightharpoonup [g(v)\frac{dv}{dx}]_\phi$ weak-$\star$. This example illustrates the important fact that the path ϕ must be selected in agreement with the regularization under consideration. Different regularizations may give rise to different paths ϕ.

When $u_0 \neq u_1$, (4.42) may be interpreted in terms of Definition 4.9. When $u_0 = u_1$, this is no longer possible, because hypothesis (H_2) excludes the possibility of loops. However, it can be interpreted in terms of the more general Definition 4.1 as follows: By Proposition 4.8 the function v together with the location of the loop discontinuity x_0 and the path π determine a generalized graph. A representative (Y, V) of this graph is given by the formulas

(4.43)
$$Y(s) = \begin{cases} a + 3s(x_0 - a), & s \in [0, \frac{1}{3}], \\ x_0, & s \in [\frac{1}{3}, \frac{2}{3}], \\ x_0 + (3s-2)(b - x_0), & s \in [\frac{2}{3}, 1], \end{cases} \qquad V(s) = \begin{cases} u_0, & s \in [0, \frac{1}{3}], \\ \pi(3\,s - 1), & s \in [\frac{1}{3}, \frac{2}{3}], \\ u_1, & s \in [\frac{2}{3}, 1]. \end{cases}$$

Then Definition 4.1 gives

$$\Big[g(v)\frac{dv}{dx}\Big]_{(Y,V)} = c(g;\pi)\,\delta_{x_0} \tag{4.44}$$

and so, as $n \to \infty$,

$$g(v_n)\frac{dv_n}{dx} \rightharpoonup \Big[g(v)\frac{dv}{dx}\Big]_{(Y,V)} \qquad \text{weakly-}\star \in \mathcal{M}[a,b]. \tag{4.45}$$

Note that (4.44) holds for arbitrary u_0 and u_1 and that, when $u_0 = u_1$, the limiting graph (Y, V) contains a loop at the location x_0. □

Example 4.14. Consider next a piecewise constant function $v : [a, b] \to \mathbb{R}^N$ having three points of discontinuity:

$$v(x) = \begin{cases} u_0 & \text{for } x \in [a, c_1), \\ u_1 & \text{for } x \in [c_1, c_2), \\ u_2 & \text{for } x \in [c_2, c_3), \\ u_3 & \text{for } x \in [c_3, b], \end{cases} \tag{4.46}$$

where $a < c_1 < c_2 < c_3 < b$ are real constants, and the u_j's are constant vectors. Let π_j be Lipschitz continuous paths such that $\pi_j(0) = u_{j-1}$ and $\pi_j(1) = u_j$, $j = 1, 2, 3$. In a fashion similar to Example 1.1, we can define a sequence of smooth functions v_n by replacing the jumps in v with smooth transition layers based on the paths π_j such that $\{v_n\}$ are uniformly bounded and $v_n \to v$ pointwise. Then

$$g(v_n)\frac{dv_n}{dx} \rightharpoonup \sum_{j=1,2,3} c(g, \pi_j)\,\delta_{c_j}\,, \quad \text{where} \quad c(g, \pi_j) = \int_0^1 g\big(\pi_j\big)\frac{\partial \pi_j}{\partial s}\,ds\,. \tag{4.47}$$

Accordingly, the nonconservative product is defined so that

$$\Big[g(v)\frac{dv}{dx}\Big]_{(X,U)} = \Big[g(v)\frac{dv}{dx}\Big]_\phi = \sum_{j=1,2,3} c(g, \pi_j)\,\delta_{c_j}. \tag{4.48}$$

In most cases this is done by using Definition 4.9, upon selecting the family of paths ϕ so that $\phi(.; u_j, u_{j+1}) = \pi_j$. There are a few interesting exceptions when one needs

to use Definition 4.1. One is the case where the approximating sequence contains loops. This is discussed in the previous example. Another case is when the jumps of v at $x = c_1$ and $x = c_3$ coincide, $u_0 = u_2$ and $u_1 = u_3$. Then Definition 4.9 prevents us from using, in v_n, different paths for approximating the same jump at two different locations. This difficulty does not arise with Definition 4.1. Upon constructing a representative of the limiting graph, as in the previous example, we define the nonconservative product as in (4.48). ∎

Example 4.15. Given an increasing sequence of points $c_k \in [a,b)$, $k = 0, 1, 2, \dots$, with $c_0 = a$ and $c_\infty := \lim_{k\to\infty} c_k \in (a,b)$, we consider the saltus function $u : [a,b] \to \mathbb{R}^N$ defined by

$$v(x) = \begin{cases} u_0 & \text{for } x \in [a, c_1), \\ u_k & \text{for } x \in [c_k, c_{k+1}), \quad k = 1, 2, \dots, \\ u_\infty & \text{for } x \in [c_\infty, b], \end{cases} \tag{4.49}$$

for constants u_k and u_∞ in $\mathbb{R}^N$. For each jump connecting u_k to u_{k+1} in v, we consider a Lipschitz continuous path $\pi_k(s)$ for $s \in [0,1]$ satisfying $\pi_k(0) = u_{k-1}$ and $\pi_k(1) = u_k$.

Let $c_k^{\pm,n}$, for $k, n = 1, 2, \dots$, be a sequence of points in the interval (a,b) such that $c_k^{-,n} < c_k < c_k^{+,n} < c_{k+1}^{-,n}$, and $c_k^{\pm,n} \to c_k$ as $n \to \infty$. We construct the sequence of regularized functions $v_n : [a,b] \to \mathbb{R}^N$ by

$$v_n(x) = \begin{cases} u_0 & \text{for } x \in [a, c_1^{-,n}), \\ \pi_k\big(\frac{x - c_k^{-,n}}{c_k^{+,n} - c_k^{-,n}}\big) & \text{for } x \in [c_k^{-,n}, c_k^{+,n}), \quad k = 1, 2, \dots, \\ u_k & \text{for } x \in [c_k^{+,n}, c_{k+1}^{-,n}), \quad k = 1, 2, \dots, \\ u_\infty & \text{for } x \in [c_\infty, b]. \end{cases} \tag{4.50}$$

The functions v_n are continuous and

$$TV(v_n) = \sum_{k=1}^{\infty} \int_0^1 \left| \frac{d\pi_k}{ds}(s) \right| ds. \tag{4.51}$$

We assume that the right-hand side of (4.51) is finite, so that the sequence $\{v_n\}$ is of uniformly bounded variation. A calculation shows that

$$g(v_n) \frac{dv_n}{dx} \rightharpoonup \sum_{j=1}^{\infty} c(g, \pi_j)\, \delta_{c_j}, \qquad \text{weak-}\star \text{ in } \mathcal{M}[a,b], \tag{4.52}$$

which suggests that the nonconservative product $[g(v)\frac{dv}{dx}]_{(X,U)}$ should be defined by

$$\Big[g(v) \frac{dv}{dx} \Big]_{(X,U)} = \sum_{k=1}^{\infty} c(g, \pi_k)\, \delta_{c_k}. \tag{4.53}$$

Because of the uniform constant K in hypothesis (H_3) this cannot be handled in general by Definition 4.9. By contrast, Definition 4.1 is adequate to define the nonconservative product as in (4.53); this follows from (A_1)–(A_2) and the construction process in the proof of Proposition 4.8. ∎

5. The Riemann problem for nonconservative hyperbolic systems. The theory developed in the previous sections is now applied to the Riemann problem for first-order quasi-linear hyperbolic systems

$$\partial_t u + A(u)\,\partial_x u = 0, \qquad x \in \mathbb{R},\ t > 0\,, \tag{5.1}$$
$$u(x,0) = \begin{cases} u_- & \text{for } x < 0, \\ u_+ & \text{for } x > 0, \end{cases}$$

where the $N \times N$ matrix $A(u)$ is a smooth function of u, and u_+ and u_- are given vectors in $\mathbb{R}^N$. Because of the invariance of the Riemann problem under dilations $(x,t) \to (\alpha x, \alpha t)$, for $\alpha > 0$, the solution is expected to be a self-similar function of the variable $\xi = x/t$. Accordingly, $u = u(x/t)$ is sought by solving the boundary value problem

$$-\xi \frac{du}{d\xi} + A(u)\,\frac{du}{d\xi} = 0, \tag{P_0}$$
$$u(\pm\infty) = u_\pm\,.$$

In the nonconservative case $A(u)$ is not a Jacobian matrix, and one is confronted with the difficulty of giving an appropriate meaning to the product $A(u)\,du/d\xi$. To address this difficulty, we construct solutions of (P_0) as $\varepsilon \searrow 0$ limits of solutions to

$$-\xi \frac{du_\varepsilon}{d\xi} + A(u_\varepsilon)\,\frac{du_\varepsilon}{d\xi} = \varepsilon \frac{d}{d\xi}\left(B(u_\varepsilon)\,\frac{du_\varepsilon}{d\xi} \right), \tag{P_ε}$$
$$u_\varepsilon(\pm\infty) = u_\pm\,,$$

where $B(u)$ is a positive semidefinite $N \times N$ matrix. This approach for constructing solutions to the Riemann problem is called self-similar zero-viscosity limits. For conservative strictly hyperbolic systems, this method is known to select shocks having the internal structure of a traveling wave and to provide the unique solution to the Riemann problem for weak waves; see Tzavaras [30].

Throughout the paper we proceed under the hypothesis: There exists a family of smooth solutions u_ε to (P_ε), for $\varepsilon > 0$, that satisfy *uniform in* ε L^∞ and variation bounds,

$$|u_\varepsilon - u_-|_{L^\infty} + TV(u_\varepsilon) \le C\,, \tag{5.2}$$

as well as uniform convergence properties at infinity,

$$|u_\varepsilon(\xi) - u_\pm| \le C \exp(-\alpha\,\varepsilon) \qquad \text{for } \xi < a+1 \text{ and } \xi > b-1, \tag{5.3}$$

for some $a < b$ and $C, \alpha > 0$ independent of ε. Such solutions are constructed in LeFloch–Tzavaras [18, 19] under the following set of structural assumptions:

(i) System (1.1) is strictly hyperbolic; i.e., the matrix $A(u)$ has N real and distinct eigenvalues $\lambda_1(u) < \cdots < \lambda_N(u)$;

(ii) the initial jump $|u_+ - u_-|$ is sufficiently small;

(iii) the diffusion matrix $B(u)$ is the $N \times N$ identity matrix Id.

It is, however, expected that estimates (5.2) should hold, together with (5.3) or variants, under more general circumstances, and the analysis in this section requires only (5.2)–(5.3).

The uniform BV estimates provide a natural framework to study the notion of weak solutions for the nonconservative Riemann problem (P_0). Let $(X_\varepsilon, U_\varepsilon)$ be the arc-length reparametrization of the graph $(\xi, u_\varepsilon(\xi))$. Theorem 3.2 asserts that there exists a subsequence $\{u_{\varepsilon_n}\}$ and a generalized graph (X, U), determining a function u of bounded variation such that

$$
\begin{aligned}
&(X_{\varepsilon_n}, U_{\varepsilon_n}) \xrightarrow{\mathrm{d}} (X, U),\\
&\sigma_{\varepsilon_n}(\xi) \to \sigma(\xi)\,, \quad u_{\varepsilon_n}(\xi) \to u(\xi) \quad \text{for } \xi \in \mathcal{C}_\sigma.
\end{aligned} \tag{5.4}
$$

Recall that $\sigma_{\varepsilon_n} = X_{\varepsilon_n}^{-1}$ is a strictly increasing function, while $\sigma = X^{-1}$ is a strictly increasing multivalued map.

Using the results of sections 3 and 4, we can give a meaning to the nonconservative product $[A(u)\frac{du}{d\xi}]_{(X,U)}$, relative to the generalized graph (X, U), as a weak-$\star$ limit of $A(u_\varepsilon)\frac{du_\varepsilon}{dx}$. To this end, we use either Definition 4.1 to interpret $[A(u)\frac{du}{d\xi}]_{(X,U)}$ as a Radon measure or Definition 4.4 to define it via its distribution function F. It leads to a notion of solutions for $(\mathcal{P}_0)$ as in Definition 5.1.

DEFINITION 5.1. *Let $(X, U) : [0,1] \to [a,b]\times\mathbb{R}^N$ be a generalized graph associated with a function of bounded variation $u : [a,b] \to \mathbb{R}^N$. We say that (X, U) is a* weak solution *to the system*

$$
-\xi\,\frac{du}{d\xi} + A(u)\,\frac{du}{d\xi} = 0 \tag{5.5}
$$

if

$$
-\xi\,\frac{du}{d\xi} + \Big[A(u)\frac{du}{d\xi}\Big]_{(X,U)} = 0 \tag{5.6}
$$

in the sense of measures. Equivalently, if for any ζ, $\xi \in [a,b]$,

$$
-\Big[\xi\,u(\xi+) - \zeta\,u(\zeta-)\Big] + \int_\zeta^\xi u(\theta)d\theta + \int_{X^{-1}(\zeta-)}^{X^{-1}(\xi+)} A(U(s))\frac{dU}{ds}\,ds = 0. \tag{5.7}
$$

Remark 5.2. Relation (5.7) suggests that at points $\xi \in \mathcal{S}_{X^{-1}}$, the set where the inverse map X^{-1} is multivalued, the following analogue of the Rankine–Hugoniot conditions is satisfied:

$$
-\xi\Big[u(\xi+) - u(\xi-)\Big] + \int_{X^{-1}(\xi-)}^{X^{-1}(\xi+)} A(U(s))\frac{dU}{ds}\,ds = 0\,. \tag{5.8}
$$

Points $\xi \in \mathcal{S}_{X^{-1}}$ may correspond either to jumps or to loops.

The notion of weak solution depends on the equivalence class, but not on the specific representative, of the generalized graph.

PROPOSITION 5.3. *If a generalized graph (X, U) is a weak solution to* (5.4)*, then any path (Y, V) belonging to the same equivalence class as (X, U) is also a weak solution.*

Suppose there exists $f : \mathbb{R}^N \to \mathbb{R}^N$ such that $A = Df$. Let u of bounded variation be a solution to (5.4) *in the sense of distributions*

$$
\int_{\mathbb{R}} u\,\theta\,d\xi + \int_{\mathbb{R}} \big(\xi\,u + f(u)\,\big)\,\frac{d\theta}{d\xi}\,d\xi = 0 \tag{5.9}
$$

for every smooth function θ of compact support. Then any generalized graph associated with u is a weak solution in the sense of Definition 5.1.

The proof of Proposition 5.3 follows from the facts that the nonconservative product is independent of reparametrizations of the generalized graph (X, U), and, when $A(u) = Df(u)$, one has

$$\Big[A(u)\frac{du}{d\xi}\Big]_{(X,U)} = \frac{d}{d\xi} f(u)$$

as measures.

THEOREM 5.4. *Fix $u_\pm \in \mathbb{R}^N$. Let $u_\varepsilon : (-\infty, +\infty) \to \mathbb{R}^N$ be a family of smooth solutions to (P_ε) for $\varepsilon > 0$ that are of uniformly bounded variation and satisfy* (5.2)–(5.3). *Consider the arc-length parametrizations $(X_\varepsilon, U_\varepsilon)$ of the graphs of u_ε. There exists a subsequence $\{u_{\varepsilon_n}\}$, with $\varepsilon_n \to 0$, a generalized graph (X, U), and an associated BV function u, such that $(X_{\varepsilon_n}, U_{\varepsilon_n})$ converges to (X, U) as in* (5.4), *(X, U) is a weak solution of* (5.5), *and*

$$u(\xi) = \begin{cases} u_- & \text{for } -\infty < \xi < a + 1, \\ u_+ & \text{for } b - 1 < \xi < +\infty. \end{cases} \tag{5.10}$$

Combined with [18, 19], where the uniform bounds are established for strictly hyperbolic systems and small initial jumps $|u_+ - u_-|$, Theorem 5.4 provides an existence result for the Riemann problem (P_0). We refer to [19] for the structure of the resulting wave-fan solution of the Riemann problem and the admissibility restrictions that the process (P_ε) imposes on shocks. The relation with the solution of the Riemann problem for genuinely nonlinear systems, obtained in [14, 10], is also investigated in [19].

Proof. In view of the uniform estimates (5.2)–(5.3) and Theorem 3.2, the graphs $(X_\varepsilon, U_\varepsilon)$ converge along subsequences in the graph distance. Denote by (X, U) the limiting graph.

Observe that the right-hand side of the equation in (P_ε) tends to zero in the sense of distributions

$$\left| \varepsilon \int B(u_\varepsilon) \frac{du_\varepsilon}{d\xi} \frac{d\theta}{d\xi} \, dx \right| \le \varepsilon \, C \|\theta\|_{\mathcal{C}^1} \, TV(u_\varepsilon) \quad \longrightarrow 0 \tag{5.11}$$

for every test function θ.

To determine the limit of the right-hand side of the equation in (P_ε), one writes

$$A(u_\varepsilon) \frac{du_\varepsilon}{d\xi} = \Big[A(u_\varepsilon)\frac{du_\varepsilon}{d\xi}\Big]_{(X_\varepsilon, U_\varepsilon)}$$

and one uses the weak stability theorems, either Theorem 4.3 if the nonconservative product is viewed as a Radon measure or Theorem 4.6 if the distribution function is used instead. It follows that

$$\Big[A(u_\varepsilon)\frac{du_\varepsilon}{d\xi}\Big]_{(X_\varepsilon, U_\varepsilon)} \rightharpoonup \Big[A(u)\frac{du}{d\xi}\Big]_{(X,U)} \quad \text{weak-}\star \text{ in } \mathcal{M}[a, b].$$

Using (5.11), we conclude that (X, U) is a weak solution in the sense of Definition 5.1. Finally, the fact that $u(\xi)$ admits the boundary conditions as in (5.10) is a direct consequence of (5.3). ∎

ROBUSTNESS OF INSTABILITY FOR THE TWO-DIMENSIONAL EULER EQUATIONS*

SUSAN FRIEDLANDER†, WALTER STRAUSS‡, AND MISHA VISHIK§

Abstract. We prove that in two dimensions any steady, inviscid, incompressible flow that is sufficiently close to an unstable flow is also unstable.

Key words. instability, inviscid fluids, Euler equations, discrete spectrum

AMS subject classifications. 76, 35

PII. S0036141098339277

Introduction. The problem of stability or instability of a steady fluid flow has been studied by many authors (see, for example, Rayleigh [1], Chandrasekhar [2], Yudovich [3], Lin [4], and Drazin and Reid [5]). In this paper we study the following question. Consider a steady flow of an inviscid, incompressible fluid, i.e., an equilibrium for the Euler equations. Assume this steady flow is (linearly) unstable. Are all Euler equilibria that are in some sense "close" to this unstable flow also unstable?

This question requires us to study the spectrum of the linearized Euler operator, which is a degenerate operator. In general the spectrum is the union of an essential spectrum and some discrete eigenvalues. The concept of a fluid Lyapunov exponent introduced by Vishik and Friedlander [6] produces an effective sufficient condition for instability in the continuous spectrum. For example, it can be used to prove that any Euler flow with a hyperbolic stagnation point is unstable (see Friedlander and Vishik [7]). There are also some equilibria where instability arises in the discrete spectrum, e.g., plane parallel shear flow with an oscillatory profile (see Friedlander, Strauss, and Vishik [8]). On the other hand, not all Euler equilibria are unstable. The celebrated Rayleigh criterion tells us that a plane parallel shear flow with no inflection points in the profile is linearly stable. This result holds for both two- and three-dimensional disturbances. The techniques of Arnold [9] prove that in two dimensions such a flow is also, in some sense, nonlinearly stable.

The stability results cited in the preceding paragraph are proved in the energy (L^2) norm. The concept of stability and instability depends very strongly on the norm. For example, Yudovich [10] proves that, in a norm that measures the derivatives of the vorticity, even a shear flow with no inflection points is unstable.

In section 1 we recall a theorem of Vishik [11], which states that the fluid Lyapunov exponent μ determines the essential spectral radius for the linearized Euler equation. Thus the flows for which μ is positive have a nonempty essential spectrum and are linearly unstable. This theorem holds in any spatial dimension for periodic boundary

conditions and refers to the spectrum in L^2. Except for an occasional remark, we restrict ourselves in this paper to the case of periodic boundary conditions.

In sections 2 and 3 we prove the "robustness of instability" for ideal fluid flows in two dimensions. In two dimensions the fluid Lyapunov exponent μ is the same as the classical Lyapunov exponent. Furthermore, if a flow does not have a stagnation point, then $\mu = 0$ (see Friedlander, Strauss, and Vishik [8]). In section 2 we consider the situation where μ is positive. We prove that any two-dimensional nondegenerate flow for which $\mu > 0$ must contain a *hyperbolic* stagnation point. Hence for a nondegenerate Euler equilibrium in two dimensions, the existence of a hyperbolic stagnation point is both a necessary and sufficient condition for instability in the essential spectrum. It follows that such an instability is preserved under small perturbations of the equilibrium flow.

In section 3 we consider a two-dimensional flow that is unstable even though μ vanishes, that is, the spectrum contains some unstable eigenvalues but no unstable essential spectrum. Thus, for a given Euler equilibrium we assume the existence of an eigenvalue σ_0 with $\mathrm{Re}\sigma_0 > 0$. We prove that for any sufficiently nearby equilibrium there exists an eigenvalue σ near σ_0. To accomplish this, we first convert the eigenvalue problem for the velocity equation in L^2 to an eigenvalue problem for the vorticity equation in H^{-1}. In two dimensions the eigenvalue equation can then be converted to a condition of invertibility of an operator $(\mathrm{id} - T)$, where T is compact and depends analytically on the spectral parameter and continuously on the equilibrium. The poles of such a family of operators depend continuously on the equilibrium. This technique was developed by Guo and Strauss [12] to study the stability of BGK equilibria in collisionless plasmas. Because of the relatively simple nature of the two-dimensional vorticity equation, the proof works in two dimensions but cannot readily be extended to three.

Like most questions in fluid dynamics, the problem of the robustness of instability is much more difficult in three dimensions and in fact there is some evidence to suggest that the robustness might be false. In section 4 we exhibit a forced flow where the presence of a hyperbolic stagnation point gives a positive lower bound for the exponent μ. However, an infinitesimally small three-dimensional modification of this flow may destroy the stretching at the hyperbolic point so that the lower bound on μ collapses to zero. The behavior of the fluid exponent under perturbation is related to the problem of lower semicontinuity of the Lyapunov exponents of general dynamical systems.

In an appendix we prove the related but independent result that, for all flows with $\mu = 0$, the eigenfunctions associated with unstable eigenvalues must be C^∞.

1. The fluid Lyapunov exponent. The Euler equation for inviscid incompressible flow is

$$u_t + (u, \nabla)u + \nabla p = 0, \quad (\nabla, u) = 0.$$

The concept of a Lyapunov exponent for fluid flow was developed and utilized in a series of papers [6], [7], [10] and is summarized here. Let U be a C^∞-vector field that satisfies the steady Euler equations in a 2π-periodic domain $T^n = \mathbb{R}^n/2\pi\mathbb{Z}^n$:

$$-(U, \nabla)U - \nabla P = 0, \quad (\nabla, U) = 0, \tag{1.1}$$

where P is a C^∞-smooth pressure. We define the space of divergence-free vector fields

$$L^2_s = L^2(T^n)^n \cap \{v \mid (\nabla, v) = 0\}.$$

We consider the linearized Euler equation around U:

$$\dot{v} = -(U, \nabla)v - (v, \nabla)U - \nabla q \stackrel{\text{def}}{=} Lv, \tag{1.2}$$

$$(\nabla, v) = 0 \ , \quad v(x, 0) = v_0(x), \tag{1.3}$$

$$v_0(x) \in L^2_s. \tag{1.4}$$

The linear operator L is defined in (1.2) as acting on L^2_s with the domain

$$D(L) = \{v \in L^2_s \mid Lv \in L^2_s\}.$$

Let e^{Lt} denote the evolution operator for the linearized Euler equation. The *bicharacteristic-amplitude equations* are the system of ODEs

$$\dot{x} = U(x) \ , \quad x(0) = x_0, \tag{1.5.a}$$

$$\dot{\xi} = -\left(\frac{\partial U}{\partial x}\right)^T \xi \ , \quad \xi(0) = \xi_0, \tag{1.5.b}$$

$$\dot{b} = -\left(\frac{\partial U}{\partial x}\right) b + 2\left(\left(\frac{\partial U}{\partial x}\right) b, \xi\right) \frac{\xi}{|\xi|^2} \ , \quad b(0) = b_0. \tag{1.5.c}$$

We define the *fluid Lyapunov exponent* μ as

$$\mu \stackrel{\text{def}}{=} \mu(U) \stackrel{\text{def}}{=} \lim_{t\to\infty} \frac{1}{t} \log \sup_{\substack{|\xi_0|=1,\ |b_0|=1 \\ (\xi_0, b_0)=0}} |b(x_0, \xi_0, b_0; t)|. \tag{1.6}$$

Let $r_{\text{ess}}(e^{Lt})$ denote the essential spectral radius of the evolution operator e^{Lt} in L^2_s. It is proved in [11] that

$$\mu = \frac{1}{t} \log r_{\text{ess}}(e^{Lt}), \tag{1.7}$$

where the right side is independent of t. This identity (1.7) is valid in dimensions two and three, both for periodic boundary conditions and for equilibrium flows that are constant at infinity with perturbations in $L^2(\mathbb{R}^n)$.

The quantity μ, which can be interpreted as a Lyapunov exponent for ideal fluid flow, can be effectively computed for a number of specific flows U. For example, in [7] it is proved that any flow having exponential stretching even along a single Lagrangian trajectory has a positive μ and hence, by the theorem stated above in (1.7), is linearly unstable due to instability in the essential spectrum. On the other hand, it can be shown that $\mu = 0$ in some examples (see [8]) and hence any instability would have to occur in the discrete spectrum.

2. Perturbation of the essential spectrum for $n = 2$. Let U be a C^∞ solution to the steady Euler equation (1.1) on a torus T^2. Assume all the stagnation points (that is, points x_* where $U(x_*) = 0$) are nondegenerate (that is, $\frac{\partial U}{\partial x}(x_*)$ has both of its eigenvalues nonzero).

THEOREM 2.1. *Let V be another C^∞ solution to* (1.1) *with $\|U - V\|_{C^1(T^2)} < \varepsilon$. If the exponent μ defined in* (1.6) *is positive for the flow U and if ε is sufficiently small, then μ is also positive for the flow V.*

Proof. In two dimensions we claim that the positivity of μ for such a flow is equivalent to the existence of a hyperbolic stagnation point. To prove this claim, we appeal to results of Friedlander, Strauss, and Vishik [8, Sect. 4], concerning solutions

of the system (1.5.a)–(1.5.c) for two-dimensional flows. It is shown there that $\mu = 0$ for any flow U without a stagnation point. It is also shown that

$$|b|\,|\xi| = \text{constant} \tag{2.1}$$

along any trajectory, hence the condition $\mu > 0$ implies the existence of an exponentially decaying solution $\xi(t)$ of (1.5.b). The explicit formula for $\xi(t)$ proved in [8] is

(2.2)
$$\xi(t) = \frac{c_1 U(x(t))}{|U(x(t))|^2} + \left(c_2 - c_1 \int_0^t \left. \frac{\left(\left(\frac{\partial U}{\partial x}\right) U + \left(\frac{\partial U}{\partial x}\right)^T U, U^\perp \right)}{|U|^4} \right|_{x(\tau)} d\tau \right) U^\perp(x(t)),$$

where $\frac{\partial U}{\partial x} = U_x$ denotes the Jacobian matrix and $\perp$ is defined by $\langle u_1, u_2\rangle^\perp = \langle -u_2, u_1\rangle$. This expression is valid for any trajectory of $\dot{x} = U(x)$ *which is not itself a stagnation point*.

Since $|U|$ is bounded from above, the first term in (2.2) does not tend to zero as $t \to \infty$, so that the only way to get an exponentially decaying solution $\xi(t)$ along a sequence $t_j \to \infty$ is to have $c_1 = 0$. Thus it follows from $\mu > 0$ that for such a sequence we have $|U(x(t_j))| \le C \exp\{-\varepsilon t_j\}$ for an appropriate $\varepsilon > 0$ and $C > 0$. Because of compactness, there is a convergent subsequence $x(t_j) \to x_* \in T^2$, whence $U(x_*) = 0$. Since $x(t_j) \to x_*$, one of the eigenvalues of the Jacobian matrix $\frac{\partial U}{\partial x}(x_*)$ is negative. Since $\xi(t_j) \to 0$, one of the eigenvalues of $-(\frac{\partial U}{\partial x}(x_*))^T$ is negative. Therefore $\frac{\partial U}{\partial x}(x_*)$ has one negative and one positive eigenvalue. Thus x_* is hyperbolic. Conversely, if x_* is a hyperbolic stagnation point, then $-(\frac{\partial U}{\partial x}(x_*))^T$ has one negative eigenvalue, so that there is a solution ξ of (1.5.b) with $x(t) \equiv x_*$ that is exponentially decaying and a solution b of (1.5.c) that is exponentially growing. Hence the claim is proved.

Now we apply the Grobman–Hartmann theorem (cf. [13]) to conclude that the perturbed flow V also has a hyperbolic stagnation point for $\|U - V\|_{C^1(T^2)}$ small enough. This implies the positivity of μ for V and hence any such flow is linearly unstable. □

3. Perturbations of the discrete spectrum. Let $U \in C^\infty$ be a steady solution to the Euler equation in $T^2 = \mathbb{R}^2/2\pi\mathbb{Z}^2$:

$$-(U, \nabla)U - \nabla P = 0, \quad (\nabla, U) = 0, \qquad x \in T^2. \tag{3.1}$$

In this section we assume that $\mu = 0$ but that there is an unstable eigenvalue σ_0 (with an L^2 eigenfunction) of the generator of the corresponding linearized stability problem (1.2)–(1.4). We prove that any Euler equilibrium near U also has a nearby eigenvalue.

THEOREM 3.1. *Let $U \in C^\infty$ be a solution of* (3.1) *such that all the classical Lyapunov exponents vanish for the flow given by* (1.5.a). *Let σ_0 be an eigenvalue with* $\operatorname{Re}\sigma_0 > 0$. *Let $V \in C^\infty$ be another solution of* (3.1) *such that $\|U - V\|_{C^2(T^2)} < \varepsilon$. If ε is sufficiently small, then V also has an unstable eigenvalue σ, which is near σ_0. Thus V is linearly unstable.*

COROLLARY 3.2. *If, in addition, $\mu(U) = 0$ and U has no degenerate stagnation points, then both U and V are nonlinearly unstable.*

We denote by $\langle f\rangle$ the spatial average of a function or a distribution on T^2, by $L^2_{s,0}$ the subspace of vector fields in L^2_s with average zero, by L^2_0 the space of L^2 functions

with average zero, by H^1_0 the space of H^1 functions with average zero, and by H^{-1}_0 the subspace of H^{-1} distributions with average zero.

By *curl* we mean the scalar curl of a two-dimensional vector field: $\operatorname{curl} v = -\partial_2 v_1 + \partial_1 v_2$. If ω is a scalar function on T^2, we denote by $v = \operatorname{curl}^{-1}\omega$ the unique solution of

$$\operatorname{curl} v = \omega, \quad (\nabla, v) = 0 \quad \text{in } T^2.$$

We note that curl^{-1} maps H^{-1}_0 into $L^2_{s,0}$.

LEMMA 3.3. *Let* $\operatorname{Re}\sigma > 0$. *There is a solution of the linearized Euler equation* (1.2)–(1.4) *of the form* $e^{\sigma t}v(x)$ *with* $0 \neq v \in L^2_{s,0}$ *if and only if there is a nontrivial solution* $\omega \in H^{-1}_0$ *of the equation*

$$\sigma\omega + (U, \nabla)\omega + (\operatorname{curl}^{-1}\omega, \nabla)\operatorname{curl} U = 0. \tag{3.2}$$

Proof. Given v, we have

$$\sigma v + (U, \nabla)v + (v, \nabla)U + \nabla q = 0, \quad (\nabla, v) = 0, \quad \langle v \rangle = 0.$$

Differentiating and letting $\omega = \operatorname{curl} v$, we obtain

$$\sigma\omega + (U, \nabla)\omega + (v, \nabla)\operatorname{curl} U = 0.$$

This implies (3.2). Conversely, given ω satisfying (3.2), the function $v = \operatorname{curl}^{-1}\omega$ satisfies

$$\operatorname{curl}\,[\sigma v + (U, \nabla)v + (v, \nabla)U] = 0,$$

from which it follows that $e^{\sigma t}v(x)$ satisfies (1.2)–(1.4). ∎

It is convenient to define the operator $\Lambda = -(U, \nabla)$ with the domain $D(\Lambda) = \{\omega \in L^2_0 \mid (U, \nabla)\omega \in L^2\}$, considered as an operator on L^2_0. We denote the same operator considered on the larger space H^{-1}_0 by Λ_{-1}.

LEMMA 3.4. (a) *The operator* $e^{t\Lambda}$ *is an isometry on* L^2_0 *and its generator* Λ *has a purely imaginary spectrum.*

(b) *Assume that all the classical Lyapunov exponents vanish for the flow given by* (1.5.a). *Then* $\lim_{t\to\infty} \frac{1}{t} \log \|\exp\{t\Lambda_{-1}\}\|_{\mathcal{L}(H^{-1}_0)} = 0$ *and its generator* Λ_{-1} *also has purely imaginary spectrum.*

Proof. Let $X(x, t)$ denote the volume-preserving flow on T^2 corresponding to the vector field U (see (1.5.a)):

$$\dot{X}(x, t) = U(X(x, t)); \qquad X(x, 0) = 0, \qquad x \in T^2,\ t \in \mathbb{R}. \tag{3.3}$$

The group $\exp\{t\Lambda\}$ is given by the formula

$$(\exp\{t\Lambda\}f)(x) = f(X(x, -t)), \qquad x \in T^2,\ t \in \mathbb{R}.$$

The volume-preserving character of the flow immediately implies part (a).

We shall show that the smoothness of U guarantees that the operator $e^{t\Lambda_{-1}}$ is also well defined on H^{-1}_0. By duality it is enough to justify this statement for its adjoint Λ^*_{-1} on the space H^1_0. Indeed, $X(\cdot, t)$ is volume preserving so that for any $\psi \in H^1_0$ and $\varphi \in H^{-1}_0$ we have

$$\begin{aligned}\int_{T^2} \psi(x)\overline{(\exp\{t\Lambda_{-1}\}\varphi)(x)}\,dx &= \int_{T^2} \psi(x)\overline{\varphi(X(x, -t))}\,dx \\ &= \int_{T^2} \psi(X(x, t))\overline{\varphi(x)}\,dx = \int_{T^2} (\exp\{t\Lambda^*_{-1}\}\psi)(x)\overline{\varphi(x)}\,dx.\end{aligned}$$

Now $X(X(x,-t),t)=x$ so that we have the explicit formula for the inverse matrix $\frac{\partial X}{\partial x}(x,-t)=[\frac{\partial X}{\partial y}(X(x,-t),t)]^{-1}$. Thus the reversal of the sign of U preserves the vanishing condition on the Lyapunov exponents in a volume-preserving flow. Therefore all we have to prove is the statement for H_0^1 instead of H_0^{-1}.

Now for any $\psi\in H_0^1$ and any $t>0$,

$$\begin{aligned}\|\exp\{t\Lambda_{-1}^*\}\psi\|_{H^1}^2 &\le \int_{T^2}|\psi(X(x,t))|^2+|\nabla\psi(X(x,t))|^2\cdot\Big|\frac{\partial X(x,t)}{\partial x}\Big|^2\,dx\\ &\le C\|\psi\|_{H^1}^2\Big(1+\sup_{x\in T^2}\Big|\frac{\partial X(x,t)}{\partial x}\Big|^2\Big).\end{aligned}\tag{3.4}$$

The assumption in part (b) means that $\lim_{t\to\infty}\frac{1}{t}\log|\frac{\partial X(x,t)}{\partial x}|=0$ for all x. Thus for any $\delta>0$ and any $x\in T^2$, there is a $T(x)>0$ such that

$$\Big|\frac{\partial X(x,t)}{\partial x}\Big|\le e^{\delta t/2}\quad\text{for}\quad t\ge T(x).$$

By the smoothness of U, there is a neighborhood Q_x of x such that

$$\Big|\frac{\partial X(y,T(x))}{\partial y}\Big|\le e^{\delta T(x)},\qquad y\in Q_x.\tag{3.5}$$

By compactness, there exists a finite number of points $x_i\in T^2$ $(i=1,\dots,N)$ such that

1. $\bigcup_{i=1}^N Q_{x_i}=T^2$.
2. (3.5) is satisfied for $x=x_i$.

The inequality (3.5) now implies for *any* $y\in T^2$ and $k\in\mathbb{Z}_+$ that

$$\Big|\frac{\partial X(y,T_{i_1}+\cdots+T_{i_k})}{\partial y}\Big|\le\exp\delta(T_{i_1}+\cdots+T_{i_k}),$$

where the sequence $i_1,\dots,i_k$ is defined by the following conditions:

$$y\in U_{x_{i_1}};\ X(y,T_{x_{i_1}})\in U_{x_{i_2}};\dots;X(y,T_{x_{i_1}}+\cdots+T_{x_{i_{k-1}}})\in U_{x_{i_k}}.$$

It follows that, for *arbitrary* $t\ge 0$,

$$\Big|\frac{\partial X(y,t)}{\partial y}\Big|\le C\exp\delta t,\qquad t\ge 0,\tag{3.6}$$

where C is independent of t. Indeed, there is always a sequence $T_{i_1},\dots,T_{i_k}$ such that $T_{i_1}+\cdots+T_{i_k}\le t<T_{i_1}+\cdots+T_{i_k}+\max_i T_i$ constructed as above.

By (3.4) and (3.6), there is a $T>0$ such that

$$\|\exp\{t\Lambda_{-1}^*\}\|_{\mathcal{L}(H^1)}\le\exp\delta t,\qquad t\ge T.$$

Since $\delta>0$ is arbitrary, we deduce that the spectrum of $\exp\{t\Lambda_{-1}^*\}$ is contained in the unit circle. This proves the theorem. □

For $\operatorname{Re}\sigma>0$, we may rewrite (3.2) in terms of the resolvent of the operator Λ. We define

$$M\omega\equiv M(\sigma,U)\omega\equiv-(\sigma+(U,\nabla))^{-1}\{(\operatorname{curl}^{-1}\omega,\nabla)\operatorname{curl}U\}.\tag{3.7}$$

Thus (3.2) can be rewritten as $\omega = M\omega$.

LEMMA 3.5. (a) *M is a compact operator from H_0^{-1} to H_0^{-1}.*

(b) *M depends analytically on σ for* $\operatorname{Re}\sigma > 0$.

Proof. M is the composition of the following four continuous linear operators. The operator curl^{-1} carries H_0^{-1} into $L^2_{s,0}$. The operator of multiplication by $\nabla\operatorname{curl} U$ carries $L^2_{s,0}$ into L^2_0 because $U \in C^2$. By Lemma 3.4(a), the operator $-(\sigma+\Lambda)^{-1}$ carries L^2_0 into L^2_0. Finally, the embedding L^2_0 into H_0^{-1} is compact. This proves part (a).

The dependence on σ occurs only in the third of these operators. By Lemma 3.4(a),

$$-(\sigma+\Lambda)^{-1} = \int_0^\infty e^{-(\sigma+\Lambda)t}\, dt,$$

an integral that converges in operator norm and is analytic in the half-plane $\operatorname{Re}\sigma > 0$. Therefore M is analytic there. ∎

LEMMA 3.6. *M depends continuously on U in the following sense. Let V satisfy the same conditions as U. For any constant $C > 0$, there exists a constant C_1 such that*

$$\sup_{\operatorname{Re}\sigma \ge C} \|M(\sigma,U) - M(\sigma,V)\|_{\mathcal{L}(L^2_0)} \le C_1\ \|U-V\|_{C^2}.$$

Proof. Denote $M = M(\sigma,U)$ and $N = M(\sigma,V)$. For all $\omega \in L^2_0$, we write

$$\begin{aligned} M\omega - N\omega &= -[\sigma + (U,\nabla)]^{-1}(\operatorname{curl}^{-1}\omega,\nabla)\operatorname{curl} U \ +\ [\sigma+(V,\nabla)]^{-1}(\operatorname{curl}^{-1}\omega,\nabla)\operatorname{curl} V \\ &= I + II, \end{aligned}$$

where

$$I = [\sigma+(U,\nabla)]^{-1}(U-V,\nabla)\ [\sigma+(V,\nabla)]^{-1}\ (\operatorname{curl}^{-1}\omega,\nabla)\operatorname{curl} U$$

and

$$II = -[\sigma+(V,\nabla)]^{-1}(\operatorname{curl}^{-1}\omega,\nabla)\operatorname{curl}(U-V).$$

Now

$$\begin{aligned} \|II\|_{H_0^{-1}} &\le \|II\|_{L^2_0} \\ &\le \|U-V\|_{C^2}\ \ \|[\sigma+(V,\nabla)]^{-1}\|_{\mathcal{L}(L^2_0)}\ \|\operatorname{curl}^{-1}\omega\|_{L^2_0} \\ &\le C\|U-V\|_{C^2}\ \|\operatorname{curl}^{-1}\omega\|_{L^2_{s,0}} \\ &\le C\|U-V\|_{C^2}\ \|\omega\|_{H_0^{-1}} \end{aligned}$$

by Lemma 3.4(a). In the term I, we use Lemma 3.4(b) to estimate its first factor in the norm $\mathcal{L}(H_0^{-1}, H_0^{-1})$. Its second factor $(U-V,\nabla)\varphi$ may be written as $(\nabla,(U-V)\varphi)$. Therefore we may estimate

$$\begin{aligned} \|I\|_{H_0^{-1}} &\le C\|(U-V,\nabla)\ [\sigma+(V,\nabla)]^{-1}\ (\operatorname{curl}^{-1}\omega,\nabla)\operatorname{curl} U\|_{H_0^{-1}} \\ &\le C\|U-V\|_{L^\infty}\ \|[\sigma+(V,\nabla)]^{-1}\ (\operatorname{curl}^{-1}\omega,\nabla)\operatorname{curl} U\|_{L^2_0} \\ &\le C\|U-V\|_{L^\infty}\ \|(\operatorname{curl}^{-1}\omega,\nabla)\operatorname{curl} U\|_{L^2_0} \\ &\le C\|U-V\|_{L^\infty}\ \|U\|_{C^2}\ \|\operatorname{curl}^{-1}\omega\|_{L^2_{s,0}} \\ &\le C\|U-V\|_{L^\infty}\ \|U\|_{C^2}\ \|\omega\|_{H_0^{-1}}. \end{aligned}$$

This completes the proof of Lemma 3.6. □

Now we apply the following well-known theorem of Steinberg [14]; cf. Gohberg and Krein [15].

THEOREM 3.7. *Let $T(\sigma, s)$ be a family of compact operators on a Banach space analytic in σ and jointly continuous in (σ, s) for each $(\sigma, s) \in \Sigma \times S$, where Σ is an open set in $\mathbb{C}$ and S is an interval in $\mathbb{R}$. If for each s there exists a σ such that $I - T(\sigma, s)$ is invertible, then $(I - T(\sigma, s))^{-1}$ is meromorphic in $\sigma \in \Sigma$ for each s and the poles of $(I - T(\sigma, s))^{-1}$ depend continuously on s and can appear or disappear only at the boundary of Ω or at infinity.*

A special case of this theorem, called the analytic Fredholm theorem, which may be found in Reed and Simon [16], asserts that the set of σ such that $I - T(\sigma, s)$ is not invertible is a discrete subset of $\mathbb{C}$ and that each such σ is a pole of finite multiplicity.

We are now in a position to prove the main theorem.

Proof of Theorem 3.1. By Lemma 3.3 and (3.7), a point σ in the right half-plane is an eigenvalue of the linearized Euler equation if and only if 1 is an eigenvalue of $M(\sigma, U)$. By Theorem 3.7, the set of such σ is discrete. Now define the family of operators

$$T(\sigma, s) = (1 - s)\, M(\sigma, U) + s\, M(\sigma, V) \tag{3.8}$$

for $\operatorname{Re}\sigma > 0$ and $0 \le s \le 1$. These operators are compact on H_0^{-1}, analytic in σ, and satisfy the estimate

$$\|T(\sigma, s) - T(\sigma, 0)\| = |s|\ \|M(\sigma, U) - M(\sigma, V)\| \le C\|U - V\|_{C^2} \equiv \eta.$$

By assumption, $(I - T(\sigma, 0))^{-1}$ has a pole at some point σ_0 in the right half-plane. Fix ε_0 so small that on the circle $\Gamma = \{|\sigma - \sigma_0| = \varepsilon_0\}$ the operator $(I - T(\sigma, 0))^{-1}$, which has a discrete set of poles, exists. For η sufficiently small, $(I - T(\sigma, s))^{-1}$ also exists on the same circle Γ for all $0 \le s \le 1$. By Theorem 3.7, there exists a pole σ_1 of $(I - T(\sigma, 1))^{-1}$ within the disk $\{|\sigma - \sigma_0| < \varepsilon_0\}$. Then σ_1 is an eigenvalue for the perturbed problem with the equilibrium V. This proves the linear instability of V and completes the proof. □

Proof of Corollary 3.2. Because $\mu(U) = 0$ and U has no degenerate stagnation points, it follows from the proof of Theorem 2.1 that all the stagnation points are elliptic. So for ε sufficiently small, all the stagnation points of V are also elliptic. Therefore $\mu(V) = 0$. But we have shown that V has an unstable eigenvalue. By [8], V is *nonlinearly* unstable in the space $H_s^k = L^2_{s,0} \cap H^k(T^2)$ for any $k > 2$. □

4. A three-dimensional example. The question of the robustness of instability for steady fluid flows in three dimensions is much harder than in two dimensions and we give no answer here. The following example suggests that it may in fact not be true in complete generality since there may exist unstable flows U for which there is a stable flow arbitrarily close by.

We consider the following family of incompressible flows in $\mathbb{R}^3/2\pi\mathbb{Z}^3$ depending on a parameter $\varepsilon \in \mathbb{R}$:

$$\begin{cases} U_{1\varepsilon}(x_1, x_2, x_3) = -\sin x_3 \partial_2 \Psi(x_1, x_2), \\ U_{2\varepsilon}(x_1, x_2, x_3) = \sin x_3 \partial_1 \Psi(x_1, x_2), \\ U_{3\varepsilon}(x_1, x_2, x_3) = \varepsilon. \end{cases} \tag{4.1}$$

Although $(\nabla, U_\varepsilon) = 0$, (4.1) is not an equilibrium solution of the unforced Euler equation but only the solution of a *forced* Euler equation. However the description of the fluid Lyapunov exponent given by (1.6) still applies.

Let $\Psi \in C^\infty$ $(\mathbb{R}^2/2\pi\mathbb{Z}^2)$ and assume there exists a point (x_{01}, x_{02}), where $\nabla\Psi(x_{01}, x_{02}) = 0$ and that this point is hyperbolic for the vector field $\nabla\Psi$. The trajectory of the flow (4.1) through the point $x_0 = (x_{01}, x_{02}, x_{03})$ is the straight line on the torus $\mathbb{R}^3/2\pi\mathbb{Z}^3$

$$\begin{cases} x_1 = x_{01} & (\text{mod } 2\pi), \\ x_2 = x_{02} & (\text{mod } 2\pi), \\ x_3 = x_{03} + \varepsilon t & (\text{mod } 2\pi). \end{cases} \tag{4.2}$$

In this case equation (1.5.b) can be solved explicitly. The equation becomes

$$\dot{\xi} = -\sin(x_{03} + \varepsilon t)\ A^T \xi, \tag{4.3}$$

where

$$A = \begin{pmatrix} -\partial_{21}\Psi(x_0) & -\partial_{22}\Psi(x_0) & 0 \\ \partial_{11}\Psi(x_0) & \partial_{12}\Psi(x_0) & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Consider first the situation where $\varepsilon = 0$. Choose $\xi \equiv e_3$, which is clearly a solution to (4.3), where the vector e_j denotes a unit vector in the x_j-direction. In this case, equation (1.5.c) becomes

$$\dot{b} = -\sin x_{03}\ A\, b \quad \text{with} \quad b_3 = 0. \tag{4.4}$$

Since (x_{01}, x_{02}) is a hyperbolic point for $\nabla\Psi$, the matrix A has nonzero real eigenvalues $\pm\lambda$. Hence the exponent μ given by (1.6) has a positive bound from below. Thus such a flow, when $\varepsilon = 0$, is formally unstable.

We now turn to the case where $\varepsilon \neq 0$. The solution to (4.3) is given by

$$\xi = \exp\{-(\cos(x_{03} + \varepsilon t) - \cos x_{03})\, A^T/\varepsilon\}\ \xi_0. \tag{4.5}$$

Equation (1.5.c) becomes

$$\dot{b} = \sin(x_{03} + \varepsilon t)\ \{-A + 2|\xi|^{-2}(\xi \otimes \xi)A\}\ b. \tag{4.6}$$

This equation has the form

$$\dot{b}(t) = \dot{\varphi}(t)\ B(\varphi(t))\ b(t), \tag{4.7}$$

where $b(t)$ is vector valued, $\varphi(t) = \cos(x_{03} + \varepsilon t) - \cos x_{03}$ is a periodic scalar function, and B is a continuous matrix-valued function. The solution of (4.7) may be written as $b(t) = a(\varphi(t))$, where $da/ds = b(s)\, a(s)$ with $a(0) = b(0)$. Thus $b(t)$ is periodic. It follows that the exponent

$$\lim_{t\to\infty} \frac{1}{t} \log |b(t)| = 0.$$

Thus a fluid Lyapunov exponent that is nonzero due to stretching at the hyperbolic point when $\varepsilon = 0$ collapses to zero for a neighboring flow (4.1) with $\varepsilon \neq 0$.

Appendix A.

THEOREM A.1. *Let $U(x)$ be a C^∞ vector field on a compact n-dimensional Riemannian manifold E. Assume* $\operatorname{div} U = 0$. *Let $X(x,t)$ be the corresponding flow on E, i.e.,*

$$\dot{X}(x,t) = U(X(x,t)); \qquad X(x,0) = 0, \qquad x \in E,\ t \in \mathbb{R}.$$

Assume all forward Lyapunov exponents vanish:

$$\chi_+(x,\eta) = \overline{\lim_{t\to\infty}} \frac{1}{t} \log \left| \frac{\partial X}{\partial x}(x,t)\,\eta \right| = 0 \quad \forall\ x \in E,\ \forall\ \eta \in T_x E.$$

Let $H^k(E)$ be the Sobolev space of functions with k derivatives in $L^2(E)$. Then,

$$\lim_{t\to\infty} \frac{1}{t} \log \| \exp\{-t\,(U,\nabla)\} \|_{\mathcal{L}(H^k)} = 0.$$

Remark. As was mentioned above, the vanishing of the forward Lyapunov exponents implies the vanishing of the backward Lyapunov exponents, that is,

$$\chi_-(x,\eta) = \overline{\lim_{t\to-\infty}} \frac{1}{t} \log \left| \frac{\partial X}{\partial x}(x,t)\,\eta \right| = 0 \quad \forall\ x \in E,\ \forall\ \eta \in T_x E.$$

Proof. We use induction on k. The case $k = 1$ is proved by repeating word for word the proof of Lemma 3.4 and noting that, although $\frac{\partial X}{\partial x}$ is computed in a fixed finite system of charts, the exponential growth rate does not depend on the particular choice of this atlas. As before, $h = f \circ X(-t)$ satisfies the transport PDE

$$\frac{\partial h}{\partial t}(x,t) = -(U(x),\nabla)h, \qquad h(x,0) = f(x).$$

Now assume the theorem is proved for all H^s, $s \le k-1$. We have

$$\|h\|^2_{H^k} = \sum_{|\alpha|=k} \|D^\alpha h\|^2_{L^2} + \sum_{|\alpha|<k} \|D^\alpha h\|^2_{L^2},$$

where the second sum grows slower than any exponential. Taking β with $|\beta| = k-1$ and differentiating the equation, we arrive at

$$\frac{\partial}{\partial t}\nabla\ D^\beta h = -(U(x),\nabla)\nabla D^\beta h - \left(\frac{\partial U}{\partial x}\right)^T \nabla D^\beta h + \sum_{|\gamma|<k} b_\gamma(x) D^\gamma h,$$

with coefficients $b_\gamma(\cdot) \in C^\infty(E)$. Let $|\alpha| = k$. Using the variation of constants formula (i.e., Duhamel's principle) for solutions of an *inhomogeneous* transport equation, we get

$$\|D^\alpha h(t)\|_{L^2} \le \|G(t)\|_{L^2} \|D^\alpha h(0)\|_{L^2} + C \int_0^t \|G(t-\tau)\|_{L^2} \sum_{|\gamma|<|\alpha|} \|D^\gamma h(\tau)\|_{L^2}\, d\tau,$$

where $G(t-\tau)$ stands for the Green's function of the equation

$$\frac{\partial}{\partial t} q = -(U,\nabla)q - \left(\frac{\partial U}{\partial x}\right)^T q.$$

Again applying the induction assumption, we get for arbitrary small δ and all $t \geq 0$

$$\|G(\tau)\|_{\mathcal{L}(L^2)} \leq C_\delta \exp\{\delta t\} \quad \text{and}$$
$$\|D^\gamma h(\tau)\|_{L^2} \leq C_\delta \exp\{\delta t\} \|h(0)\|_{H^{k-1}}.$$

This implies

$$\|D^\alpha h(t)\|_{L^2} \leq C_\delta \exp\{\delta t\} \|h(0)\|_{H^k}.$$

This concludes the induction step. The proof of the theorem is complete. ∎

THEOREM A.2. *Let U be a solution to the Euler equation satisfying the conditions of Theorem* A.1. *Let σ be an eigenvalue as in Lemma* 3.3 *with* $\mathrm{Re}\sigma > 0$. *Then, the corresponding eigenfunction is in $C^\infty(E)$.*

Proof. Let $\omega \in H^{-1}$ be the eigenfunction, that is,

$$\sigma\omega + (U, \nabla)\omega + (\mathrm{curl}^{-1}\omega, \nabla)\mathrm{curl}\, U = 0. \tag{A.1}$$

Since $\mathrm{curl}^{-1}\omega \in L^2$, (A.1) implies that $\sigma\omega + (U, \nabla)\omega \in L^2$. But, according to Theorem A.1, the operator $\{\sigma + (U, \nabla)\}$ is an isomorphism on $H^k(E)$ for $\mathrm{Re}\sigma > 0$ and for integers $k \geq 0$. By duality the same statement is valid for all negative integers k as well. Since $\omega \in H^{-1}$, it follows that $\omega \in L^2$. Now by (A.1),

$$\sigma\omega + (U, \nabla)\omega \in H^1(E).$$

So by Theorem A.1, $\omega \in H^1$. Continuation of this bootstrapping argument yields

$$\omega \in \bigcap_{k=0}^{\infty} H^k(E) = C^\infty(E).$$

This proves the theorem. ∎

Remark. Under the condition that $\chi_\pm(x, \eta) \equiv 0$, it follows that any eigenfunction of M with $\mathrm{Re}\sigma > 0$ that is an arbitrary *distribution* has to be in $C^\infty(E)$. More precisely, let k be a positive integer and let $\mathrm{Re}\sigma > k\lambda$, where λ is the maximal Lyapunov exponent

$$\lambda = \lim_{t\to\infty} \frac{1}{t} \log \sup_{\pm} \sup_{(x,\eta)\in T_x E} \left| \frac{\partial X}{\partial x}(x, \pm t)\, \eta \right|.$$

Then it follows that $\omega \in H^k(E)$.

Acknowledgments. We acknowledge very helpful conversations with A. Neistadt, who suggested the idea of the example in section 4. Friedlander and Vishik thank the Mathematics Institute at Oberwolfach for the kind hospitality of its "Research in Pair" program supported by the Volkswagen Stiftung.

$\mathcal{A}$-QUASICONVEXITY, LOWER SEMICONTINUITY, AND YOUNG MEASURES*

IRENE FONSECA† AND STEFAN MÜLLER‡

Abstract. The notion of $\mathcal{A}$-quasiconvexity is introduced as a necessary and sufficient condition for (sequential) lower semicontinuity of

$$(u,v) \mapsto \int_\Omega f(x,u(x),v(x))\,dx$$

whenever $f : \Omega \times \mathbb{R}^m \times \mathbb{R}^d \to [0,+\infty)$ is a normal integrand, $\Omega \subset \mathbb{R}^N$ is open, bounded, $u_n \to u$ in measure, $v_n \rightharpoonup v$ in $L^p(\Omega;\mathbb{R}^d)$ ($\overset{*}{\rightharpoonup}$ if $p = +\infty$), and $\mathcal{A}v_n \to 0$ in $W^{-1,p}(\Omega)$ ($\mathcal{A}v_n = 0$ if $p = +\infty$). Here $\mathcal{A}v = \sum_{i=1}^N A^{(i)} \frac{\partial v}{\partial x_i}$ is a constant rank partial differential operator, $A^{(i)} \in \mathrm{Lin}(\mathbb{R}^d;\mathbb{R}^l)$, and $f(x,u,\cdot)$ is $\mathcal{A}$-quasi-convex if

$$f(x,u,v) \le \int_Q f(x,u,v+w(y))\,dy$$

for all $v \in \mathbb{R}^d$ and all $w \in C^\infty(Q;\mathbb{R}^d)$ such that $\mathcal{A}w = 0$, $\int_Q w(x)\,dx = 0$, and w is Q-periodic, $Q := (0,1)^N$. The characterization of Young measures generated by such sequences $\{v_n\}$ is obtained for $1 \le p < +\infty$, thus recovering the well-known results for the framework $\mathcal{A} = \mathrm{curl}$, i.e., when $v_n = \nabla\varphi_n$ for some $\varphi_n \in W^{1,p}(\Omega;\mathbb{R}^m)$, $d = N \times m$. In this case $\mathcal{A}$-quasiconvexity reduces to Morrey's notion of quasiconvexity.

Key words. $\mathcal{A}$-quasiconvexity, equi-integrability, Young measure, lower semicontinuity

1. Introduction.

Recently there has been extensive research on minimization and relaxation of nonconvex energies relevant to the study of equilibria for materials exhibiting interesting, and technologically powerful, elastic and magnetic behaviors. Often a starting point for this study directly addresses minimization of the energy, leading to the search for necessary and sufficient conditions ensuring sequential weak lower semicontinuity of integrals of the form

$$(u,v) \mapsto I(u,v) := \int_\Omega f(x,u(x),v(x))\,dx,$$

where $\Omega \subset \mathbb{R}^N$ is an open, bounded set, $(u,v) : \Omega \to \mathbb{R}^m \times \mathbb{R}^d$, and $f : \Omega \times \mathbb{R}^m \times \mathbb{R}^d \to \mathbb{R}$ is a normal integrand. On the other hand, there may be situations where we need to identify $\lim_{n\to\infty} I(u_n,v_n)$ for an oscillatory sequence $\{(u_n,v_n)\}$ which does not minimize the energy. Consequently, this will entail a full characterization of the Young

measures generated by the sequences under consideration, i.e., weak* measurable maps $\nu : \Omega \to \mathcal{P}$, where $\mathcal{P}$ is the space of probability measures on $\mathbb{R}^{m\times d}$, such that if $g : \Omega\times\mathbb{R}^m\times\mathbb{R}^d \to \mathbb{R}$ is a Carathéodory function and if $\{g(\cdot, u_n, v_n)\}$ is equi-integrable, then

$$\int_\Omega g(x, u_n(x), v_n(x))\,dx \to \int_\Omega \int_{\mathbb{R}^{m\times d}} g(x, y, z)\,d\nu_x(y, z)\,dx.$$

Although Young measures have been used for quite some time in the contexts of control theory and optimization [47], they were first introduced in a partial differential equations (PDE) framework by Tartar [41, 42, 43] in order to relate the information obtained from the linear balance equations via the method of compensated compactness with the information resulting from pointwise nonlinear constitutive relations. One application of this method was the study of quasi-linear hyperbolic equations [42], and later DiPerna [17, 18] and DiPerna and Majda [19] extended it to systems. (See [20] and [36] for further applications.) During the last few years several questions related to the study of (nonlinear) elastic materials and certain material instabilities have been successfully carried out via minimization techniques and through the understanding of the underlying Young measures [7, 8, 13, 16, 27]. Often, in this context v is the gradient ∇u of a Sobolev function $u \in W^{1,p}(\Omega;\mathbb{R}^m)$, $d = m \times N$, and coercivity of f provides boundedness of the admissible sequences in $W^{1,p}(\Omega;\mathbb{R}^m)$. If $p > 1$ then $u_n \rightharpoonup u$ in $W^{1,p}(\Omega;\mathbb{R}^m)$ (up to extraction of a subsequence). The work of Morrey [32], Ball [5], Acerbi and Fusco [1], and Marcellini [31] shows that $W^{1,p}$ (sequential) weak lower semicontinuity of

$$u \mapsto \int_\Omega f(x, u(x), \nabla u(x))\,dx$$

is equivalent to *quasiconvexity* of $f(x, u, \cdot)$ provided $0 \le f(x, u, \xi) \le a(x, u)(1 + |\xi|^p)$ for some locally bounded function $a : \Omega \times \mathbb{R}^m \to [0, +\infty)$ and for all $\xi \in \mathbb{R}^d$, almost everywhere (a.e.) $x \in \Omega$. We recall that a Borel function $f : \mathbb{M}^{m\times N} \to \mathbb{R}$ is said to be *quasi-convex* if

$$f(\xi) = \inf_{\varphi\in W_0^{1,\infty}(Q;\mathbb{R}^m)} \int_Q f(\xi + \nabla\varphi(x))\,dx, \tag{1.1}$$

where $Q := (0, 1)^N$. If f is quasi-convex then one can show that

$$f(\xi) = \inf_{\varphi\in W_{\mathrm{per}}^{1,\infty}(Q;\mathbb{R}^m)} \int_Q f(\xi + \nabla\varphi(x))\,dx, \tag{1.2}$$

where $W_{\mathrm{per}}^{1,\infty}(Q;\mathbb{R}^m)$ is the class of periodic functions in $W^{1,\infty}(Q;\mathbb{R}^m)$. Within this context, the characterization of all Young measures generated by sequences of gradients bounded in L^p was obtained by Kinderlehrer and Pedregal [28, 29]. They show that (see Theorem 2.6) in a simply connected domain Ω a weakly measurable mapping $\nu : \Omega \to \mathcal{P}$ is a Young measure generated by a sequence of gradients ∇u_n, with $\{u_n\}$ bounded in $W^{1,p}(\Omega;\mathbb{R}^m)$, if and only if three conditions are satisfied: ν is p-integrable, i.e.,

$$\int_\Omega \langle\nu_x, |\mathrm{id}|^p\rangle\,dx < +\infty;$$

the first moment $x \mapsto \langle \nu_x, \mathrm{id} \rangle$ satisfies the underlying PDE, i.e.,

$$\operatorname{curl}(\langle \nu_x, \mathrm{id} \rangle) = 0;$$

and, as suggested by (1.1), Jensen's inequality is satisfied for quasi-convex functions, i.e.,

$$\langle \nu_x, f \rangle \geq f(\langle \nu_x, \mathrm{id} \rangle)$$

for all quasi-convex functions f such that $|f(\xi)| \leq C(1 + |\xi|^p)$.

As emphasized by Tartar, in the setting of continuum mechanics and electromagnetism more general linear PDEs than $\operatorname{curl} v = 0$ arise, and the theory of compensated compactness was developed in that framework [34, 41, 42, 43, 44, 45]. To fix ideas, consider a collection of linear operators $A^{(i)} \in \mathrm{Lin}(\mathbb{R}^d, \mathbb{R}^l)$, $i = 1, \ldots, N$, and define

$$\mathcal{A}v := \sum_{i=1}^{N} A^{(i)} \frac{\partial v}{\partial x_i}, \qquad v : \mathbb{R}^N \to \mathbb{R}^d,$$

$$\mathbb{A}(w) := \sum_{i=1}^{N} A^{(i)} w_i \in \mathrm{Lin}(\mathbb{R}^d, \mathbb{R}^l), \quad w \in \mathbb{R}^N,$$

where $\mathrm{Lin(X, Y)}$ is the vector space of linear mappings from the vector space X into the vector space Y. Following Murat [34], we will assume that $\mathcal{A}$ satisfies the *constant rank* property, which states that there exists $r \in \mathbb{N}$ such that

$$\operatorname{rank} \mathbb{A}(w) = r \quad \text{for all } w \in S^{N-1}.$$

It is easy to see that the curl-free case is a particular case of this general framework (see Remark 3.3 (iii)). Other examples are discussed in Remarks 3.3 and 3.5 and in Examples 3.10 and 4.5.

We prove that a necessary and sufficient condition for weak lower semicontinuity of I, along sequences that satisfy $u_n \to u$ in measure, $v_n \rightharpoonup v$ in L^p, and $\mathcal{A}v_n \to 0$ in $W^{-1,p}(\Omega)$, is *$\mathcal{A}$-quasiconvexity* of $f(x, u, \cdot)$ (see Theorems 3.6, 3.7). The notion of $\mathcal{A}$-quasiconvexity and its implications for the lower semicontinuity of functionals $v \mapsto \int_\Omega f(v)\, dx$ were first investigated by Dacorogna, who studied, in particular, situations where the kernel of $\mathcal{A}$ contains the range of a suitable first order differential operator $\mathcal{B}$ [14, pp. 100–112] (in the general definition of $\mathcal{A}$-quasiconvexity as presented in [14, p. 13] one needs to add periodicity of the test functions to obtain necessity of $\mathcal{A}$-quasiconvexity; this leads to some difficulties in establishing sufficiency, which, under the assumption of constant rank, can be overcome using the methods presented below). Precisely and by analogy with (1.2), a function $f : \mathbb{R}^d \to \mathbb{R}$ is said to be *$\mathcal{A}$-quasi-convex* if

$$f(v) \leq \int_Q f(v + w(x))\, dx$$

for all $v \in \mathbb{R}^d$ and all Q-periodic $w \in C^\infty(Q, \mathbb{R}^d)$ such that $\mathcal{A}(w) = 0$ and $\int_Q w(x)\, dx = 0$. In addition, we obtain the generalization to the $\mathcal{A}$-free setting of the theorem by Kinderlehrer and Pedregal concerning the characterization of gradient Young measures (see Theorem 4.1). This issue has been independently raised by Pedregal in

[35], where he studied the case of divergence-free fields (see also Remarks 3.3 (iv), 3.5 (iv)).

We remark that continuity of $\mathcal{A}$-quasiconvex functions is only guaranteed along directions in the *characteristic cone* $\Lambda := \cup_{w \in S^{N-1}} \ker \mathbb{A}(w)$, and $\mathcal{A}$-quasi-convex functions need not be (lower semi)continuous (see Proposition 3.4 and Remark 3.5 (ii)).

We note that the method used in this $\mathcal{A}$-free framework departs from the case curl-free mostly due to the lack of potential functions associated with the v_n. Indeed, in the case of gradients we reduce to the notion of quasiconvexity by localization via covering lemmas, so that on each subdomain the target function is essentially affine, followed by matching of the boundary conditions. The latter can be easily done by simple convex combinations between the potentials and the target function, avoiding layers of high concentrations of the gradients of the v_n. Clearly, the gradient of the resulting convex combinations still satisfies curl $= 0$. In the general $\mathcal{A}$-free setting, we must work directly on the v_n, and we need to find a way to project back the modified fields onto $\ker \mathcal{A}$. We perform these projections via discrete Fourier multipliers (see Lemmas 2.15, 2.16, 2.17). It is at this point that the constant rank condition enters in a crucial way. Situations where the constant rank condition fails are little understood. Tartar [41] has studied the example where $v : \mathbb{R}^2 \to \mathbb{R}^2$ and $\mathcal{A}v = (\frac{\partial v^1}{\partial x_2}, \frac{\partial v^2}{\partial x_1})$. He showed that in this case $\mathcal{A}$-quasiconvexity reduces to separate convexity, the Young measures generated by sequences along which $\{\mathcal{A}v_n\}$ is bounded in L^∞ are tensor products, and this class is strictly smaller than the class defined by duality with separately convex functions (see condition (iii) in Theorem 4.1). The class of Young measures generated by sequences that satisfy $\mathcal{A}v_n \to 0$ in $W^{-1,p}$ is not known in general (see [10, 46]). Very recently there has been progress in the case of a nonconstant rank operator $\mathcal{A}$, and this question has been completely solved by Müller for $p = 2$ (see [33]).

2. Preliminaries. In this section we recall the notion of Young measures generated by sequences bounded in L^p and by curl-free sequences. We discuss some properties of a constant rank linear partial differential operator $\mathcal{A}$, and we conclude with the decomposition lemmas, Lemmas 2.15, 2.16, and 2.17, where we show that if $\{u_n\}$ is weakly convergent in L^p and if $\mathcal{A}u_n \to 0$ in the appropriate sense then $u_n = v_n + w_n$ where $\{v_n\} \in L^p \cap \ker \mathcal{A}$ is p-equi-integrable and $\{w_n\}$ converges to zero in measure.

In the sequel $\Omega \subset \mathbb{R}^N$ is an open, bounded domain, $B(x, \varepsilon)$ denotes the open ball centered at $x \in \mathbb{R}^N$ with radius $\varepsilon > 0$, $Q := (0,1)^N$, $Q(x_0, r) := x_0 + rQ^*$, $Q^* := Q - (1/2, \dots, 1/2)$, and $S^{N-1} := \{x \in \mathbb{R}^N : |x| = 1\}$ is the unit sphere in $\mathbb{R}^N$. The Lebesgue measure in $\mathbb{R}^N$ is designated by $\mathcal{L}^N$, and H^{N-1} will stand for the $(N-1)$-dimensional Hausdorff measure in $\mathbb{R}^N$. If $1 < p < +\infty$, then $W^{-1,p}(\Omega)$ is the dual of $W_0^{1,p'}(\Omega)$, with $1/p + 1/p' = 1$, and it is well known that $F \in W^{-1,p}(\Omega)$ if and only if $F = f + \sum_{i=1}^N \frac{\partial g_i}{\partial x_i}$ in the sense of distributions for some $f, g_1, \dots, g_N \in L^p(\Omega)$. We denote by $C_0(\Omega; \mathbb{R}^d)$ the set of $\mathbb{R}^d$-valued continuous functions with compact support in Ω, endowed with the supremum norm. It is well known that the dual of the closure of $C_0(\Omega; \mathbb{R}^d)$ may be identified with the set of $\mathbb{R}^d$-valued Radon measures with finite mass, $\mathcal{M}(\Omega; \mathbb{R}^d)$, through the duality

$$\langle \mu, \varphi \rangle := \int_\Omega \varphi \cdot d\mu, \qquad \varphi \in C_0(\Omega), \mu \in \mathcal{M}(\Omega).$$

In order to simplify the notation, and when there is no ambiguity, we will abbreviate

$C_0(\Omega;\mathbb{R}^d)$ and $\mathcal{M}(\Omega;\mathbb{R}^d)$ as $C_0(\Omega)$ and $\mathcal{M}(\Omega)$, respectively. If $\mu \in \mathcal{M}(\Omega)$ and $E \subset \Omega$ is a Borel set, then $\mu\lfloor E$ stands for the restriction of the measure μ to E, i.e.,

$$\mu\lfloor E(X) := \mu(E \cap X) \quad \text{for all Borel set } X \subset \Omega.$$

We recall that given $\lambda, \mu \in \mathcal{M}(\Omega)$ with $\mu \geq 0$, by the Radon–Nikodým theorem we may decompose λ relative to μ, precisely $\lambda = \lambda_a + \lambda_s$, where λ_s and μ are *mutually singular* ($\lambda_s \perp \mu$), i.e.,

$$\lambda_s(X) = \lambda_s(X \cap B),\ \mu(X) = \mu(X \setminus B)$$

for all Borel sets $X \subset \Omega$ and for some Borel set $B \subset \Omega$, and where λ_a is *absolutely continuous with respect to* μ, $\lambda_a << \mu$, i.e., $\lambda_a(X) = 0$ whenever $X \subset \Omega$ is a Borel set and $\mu(X) = 0$. By Besicovitch's differentiation theorem we have

$$\lambda_a(X) = \int_X \frac{\partial\lambda}{\partial\mu}(x)\, d\mu, \quad \frac{\partial\lambda}{\partial\mu}(x) := \lim_{\varepsilon\to 0} \frac{\lambda(B(x,\varepsilon))}{\mu(B(x,\varepsilon))} \quad \text{for } \mu \text{ a.e. } x \in \Omega$$

and for all Borel sets $X \subset \Omega$.

If $\{z_n\}$ is a sequence bounded in $L^1(\Omega)$, then it admits a subsequence converging weakly* in the sense of measures to a measure $\mu \in \mathcal{M}(\Omega)$,

$$\int_\Omega z_{n_k}\varphi\, dx \to \int_\Omega \varphi\, d\mu$$

for all $\varphi \in C_0(\Omega)$. The *equi-integrability condition*

$$\text{for all } \varepsilon > 0 \text{ there exists } \delta > 0 \text{ such that } \mathcal{L}^N(E) < \delta \Rightarrow \sup_n \int_E |z_n(x)|\, dx < \varepsilon$$

is a necessary and sufficient condition for weak compactness in L^1 of the sequence $\{z_n\}$ (recall that Ω is bounded). If equi-integrability holds then $\mu << \mathcal{L}^N$. We will say that $\{z_n\}$ is *p-equi-integrable* if $\{|z_n|^p\}$ is equi-integrable. The following Dunford–Pettits criteria for equi-integrability are well known.

PROPOSITION 2.1. *Let $\{z_n\}$ be a sequence bounded in $L^1(\Omega)$.*

(i) *The sequence $\{z_n\}$ is equi-integrable if and only if for all $\varepsilon > 0$ there exists $M > 0$ such that*

$$\sup_n \int_{\{x\in\Omega:|z_n(x)|>M\}} |z_n(y)|\, dy < \varepsilon.$$

(ii) *The sequence $\{z_n\}$ is equi-integrable if there exists a continuous function $g : [0,+\infty) \to [0,+\infty)$ such that*

$$\lim_{t\to+\infty} \frac{g(t)}{t} = +\infty, \quad \sup_n \int_\Omega g(|z_n(x)|)\, dx < +\infty.$$

(iii) *If $\{z_n\}$ is bounded in $L^p(\Omega)$ for some $1 \leq p < +\infty$, then $\{f(z_n)\}$ is equi-integrable whenever $f : \mathbb{R}^d \to [0,+\infty)$ is a continuous function such that*

$$\lim_{|y|\to+\infty} \frac{f(y)}{|y|^p} = 0.$$

A map $\mu : E \to \mathcal{M}(\Omega)$ is said to be *weak* measurable* if $x \mapsto \langle\mu(x), \varphi\rangle$ are measurable for all $\varphi \in C_0(\Omega)$. In order to simplify the notation we denote $\mu(x)$ by μ_x.

Often the study of the behavior of solutions of nonconvex problems leads to the need to determine the limiting energy

$$\lim_{n\to\infty}\int_E f(z_n)\,dx,$$

where E is a measurable subset of Ω, $f:\mathbb{R}^d\to\mathbb{R}$ is a nonlinear function, and $\{z_n\}$ is an oscillatory sequence of measurable functions $z_n: E\to\mathbb{R}^d$. In general, the presence of oscillations entails the inequality

$$\lim_{n\to\infty}\int_E f(z_n)\,dx \neq \int_E f(z)\,dx.$$

As it turns out, the Young measure generated by (a subsequence of) $\{z_n\}$ will provide the limiting energy.

We recall that a function $f:\Omega\times\mathbb{R}^d\to\mathbb{R}$ is said to be a *normal integrand* if f is Borel measurable and $v\mapsto f(x,v)$ is lower semicontinuous for all $x\in\Omega$. Also, f is *Carathéodory* if f and $-f$ are normal integrands.

THEOREM 2.2 (fundamental theorem on Young measures [6, 11, 41]). *Let $E\subset\mathbb{R}^N$ be a measurable set of finite measure and let $\{z_n\}$ be a sequence of measurable functions, $z_n: E\to\mathbb{R}^d$. Then there exists a subsequence $\{z_{n_k}\}$ and a weak* measurable map $\nu: E\to\mathcal{M}(\mathbb{R}^d)$ such that the following hold:*

(i) *$\nu_x\geq 0$, $||\nu_x||_{\mathcal{M}(\mathbb{R}^d)}=\int_{\mathbb{R}^d}d\nu_x\leq 1$ for a.e. $x\in E$;*

(ii) *one has* (i′) *$||\nu_x||_{\mathcal{M}}=1$ for a.e. $x\in E$ if and only if*

$$\lim_{M\to\infty}\sup_k \mathcal{L}^N(\{|z_{n_k}|\geq M\})=0; \tag{2.1}$$

(iii) *if $K\subset\mathbb{R}^d$ is a compact subset and* dist $(z_{n_k},K)\to 0$ *in measure, then*

$$\operatorname{supp}\nu_x\subset K \text{ for a.e. } x\in E;$$

(iv) *if* (i′) *holds, then in* (iii) *one may replace "if" with "if and only if";*

(v) *if $f:\Omega\times\mathbb{R}^d\to\mathbb{R}$ is a normal integrand, bounded from below, then*

$$\liminf_{n\to\infty}\int_\Omega f(x,z_{n_k}(x))\,dx\geq\int_\Omega \overline{f}(x)\,dx,$$

where

$$\overline{f}(x):=\langle\nu_x,f(x,\cdot)\rangle=\int_{\mathbb{R}^d}f(x,y)\,d\nu_x(y);$$

(vi) *if* (i′) *holds and if $f:\Omega\times\mathbb{R}^d\to\mathbb{R}$ is Carathéodory and bounded from below, then*

$$\lim_{n\to\infty}\int_\Omega f(x,z_{n_k}(x))\,dx=\int_\Omega\overline{f}(x)\,dx<+\infty$$

if and only if $\{f(\cdot,z_{n_k}(\cdot))\}$ is equi-integrable. In this case

$$f(\cdot,z_{n_k}(\cdot))\rightharpoonup\overline{f}\ \text{in}\ L^1(\Omega).$$

The map $\nu: E\to\mathcal{M}(\mathbb{R}^d)$ is called the *Young measure generated by the sequence* $\{z_{n_k}\}$. It can be shown that every weak* measurable map $\nu: E\to\mathcal{M}(\mathbb{R}^d)$ that satisfies (i) is generated by some sequence $\{z_n\}$. The Young measure ν is said to be *homogeneous* if there is a Radon measure $\nu_0\in\mathcal{M}(\mathbb{R}^d)$ such that $\nu_x=\nu_0$ for a.e. $x\in E$.

Remark 2.3.

(i) Condition 2.1 holds if for some $p > 0$

$$\sup_{n\in\mathbb{N}} \int_E |z_n|^p \, dx < +\infty.$$

(ii) As a consequence of (vi), if $\{z_n\}$ is bounded in L^p and if f is a continuous function in $\mathbb{R}^d$ such that $|f(y)| \le C(1 + |y|^q)$ for some $C > 0$, $0 < q < p$, then $f(z_{n_k}) \rightharpoonup \overline{f}$ in $L^{p/q}$. Also, if $\{z_n\}$ is equi-integrable, then taking $f \equiv \mathrm{id}$ we obtain

$$z_{n_k} \rightharpoonup \overline{z} \ \text{ in } L^1(\Omega), \quad \overline{z}(x) := \langle \nu_x, \mathrm{id} \rangle.$$

PROPOSITION 2.4. *If $\{v_n\}$ generates a Young measure ν and if $w_n \to w$ in measure, then $\{v_n + w_n\}$ generates the "translated" Young measure*

$$\overline{\nu}_x := \Gamma_{w(x)} \nu_x,$$

where

$$\langle \Gamma_a \mu, \varphi \rangle := \langle \mu, \varphi(\cdot + a) \rangle$$

for $a \in \mathbb{R}^d$, $\varphi \in C_0(\mathbb{R}^d)$. In particular, if $w_n \to 0$ in measure, then $\{v_n + w_n\}$ generates the Young measure ν.

PROPOSITION 2.5. *If $\{v_n\}$ generates a Young measure ν and $u_n \to u$ a.e. in Ω, then the pair $\{(u_n, v_n)\}$ generates the Young measure μ defined by*

$$\mu_x := \delta_{u(x)} \otimes \nu_x \qquad \text{a.e. } x \in \Omega.$$

A Young measure ν is called a *gradient Young measure* if it is generated by a sequence of gradients; more precisely, ν is a $W^{1,p}$ gradient Young measure if it is generated by $\{\nabla u_n\}$ and $u_n \rightharpoonup u$ in $W^{1,p}(\Omega; \mathbb{R}^m)$. A complete characterization of such Young measures has been obtained by Kinderlehrer and Pedregal [28, 29] (see also [2, 24, 30]). A key ingredient is the notion of *quasiconvexity*: a Borel function $f : \mathbb{M}^{m\times N} \to \mathbb{R}$ is said to be *quasi-convex* if

$$f(\xi) = \inf_{\varphi \in W_0^{1,\infty}(Q;\mathbb{R}^m)} \int_Q f(\xi + \nabla\varphi(x)) \, dx.$$

If f is quasi-convex then one can show that

$$f(\xi) = \inf_{\varphi \in W^{1,\infty}_{\mathrm{per}}(Q;\mathbb{R}^m)} \int_Q f(\xi + \nabla\varphi(x)) \, dx,$$

where $W^{1,\infty}_{\mathrm{per}}(Q;\mathbb{R}^m)$ is the class of periodic functions in $W^{1,\infty}(Q;\mathbb{R}^m)$. It has been established by Morrey [32] (see also [1, 3, 5, 14, 15, 22, 23]) that sequential weak lower semicontinuity in $W^{1,p}$ and quasiconvexity are essentially equivalent. More precisely, if $0 \le f(\xi) \le C(1 + |\xi|^p)$ for some $C > 0$ and all $\xi \in \mathbb{M}^{m\times N}$ (no growth condition is necessary if $p = +\infty$), then the implication

$$u_n \rightharpoonup u \text{ in } W^{1,p} (\overset{*}{\rightharpoonup} \text{ if } p = +\infty) \Rightarrow \int_\Omega f(\nabla u) \, dx \le \liminf_{n\to\infty} \int_\Omega f(\nabla u_n) \, dx$$

holds if and only if f is quasiconvex.

THEOREM 2.6. *Let $1 \le p \le +\infty$. A weak* measurable map $\nu : \Omega \to \mathcal{M}(\mathbb{M}^{m\times N})$ is a $W^{1,p}$ gradient Young measure if and only if $\nu_x \ge 0$ a.e. $x \in \Omega$ and*

(i) *there exists* $u \in W^{1,p}(\Omega;\mathbb{R}^m)$ *such that* $\langle \nu_x, \mathrm{id}\rangle = Du$ a.e. $x \in \Omega$;
(ii) $\int_\Omega \int_{\mathbb{M}^{m\times N}} |\xi|^p \, d\nu_x(\xi)dx < +\infty$ ($\mathrm{supp}\nu_x \subset K$ *a.e.* $x \in \Omega$ *for some compact* $K \subset \mathbb{M}^{m\times N}$ *if* $p = +\infty$);
(iii) $\langle \nu_x, f\rangle \geq f(\langle \nu_x, \mathrm{id}\rangle)$ *for a.e.* $x \in \Omega$ *and for all quasiconvex* $f : \mathbb{M}^{m\times N} \to \mathbb{R}$ *(with* $|f(\xi)| \leq C(1 + |\xi|^p)$ *for some* $C > 0$ *and all* $\xi \in \mathbb{M}^{m\times N}$ *if* $1 \leq p < +\infty$*).*

Consider a collection of linear operators $A^{(i)} \in \mathrm{Lin}(\mathbb{R}^{\mathrm{d}}, \mathbb{R}^{\mathrm{l}})$, $i = 1, \ldots, N$, and define

$$\mathcal{A}v := \sum_{i=1}^{N} A^{(i)} \frac{\partial v}{\partial x_i}, \qquad v : \mathbb{R}^N \to \mathbb{R}^d,$$

$$\mathbb{A}(w) := \sum_{i=1}^{N} A^{(i)} w_i \in \mathrm{Lin}(\mathbb{R}^d, \mathbb{R}^l), \quad w \in \mathbb{R}^N,$$

where $\mathrm{Lin(X, Y)}$ is the vector space of linear mappings from the vector space X into the vector space Y.

In the sequel we will assume that $\mathcal{A}$ satisfies the *constant rank* property, namely, there exists $r \in \mathbb{N}$ such that

$$\mathrm{rank}\ \mathbb{A}(w) = r \quad \text{for all } w \in S^{N-1}. \tag{2.2}$$

Fix $w \in \mathbb{R}^N$. We define

$$\mathbb{P}(w) : \mathbb{R}^d \to \mathbb{R}^d \quad \text{to be } \textit{the orthogonal projection of } \mathbb{R}^d \text{ onto } \ker \mathbb{A}(w),$$

$$\mathbb{Q}(w) : \mathbb{R}^l \to \mathbb{R}^d, \quad \mathbb{Q}(w)\mathbb{A}(w)z := z - \mathbb{P}(w)z,\ z \in \mathbb{R}^d, \quad \mathbb{Q}(w) \equiv 0 \text{ on } (\mathrm{range}\ \mathbb{A}(w))^{\perp}.$$

Proposition 2.7. *If* (2.2) *holds then the map* $\mathbb{P} : \mathbb{R}^N \setminus \{0\} \to \mathrm{Lin}(\mathbb{R}^{\mathrm{d}}; \mathbb{R}^{\mathrm{d}})$ *is smooth and homogeneous of degree zero, and the map* $\mathbb{Q} : \mathbb{R}^N \setminus \{0\} \to \mathrm{Lin}(\mathbb{R}^{\mathrm{l}}; \mathbb{R}^{\mathrm{d}})$ *is smooth and homogeneous of degree* -1.

Let $\Delta := \mathbb{Z}^N$ be the *unit lattice*, i.e., the additive group of points in $\mathbb{R}^N$ with integer coordinates. We say that $f : \mathbb{R}^N \to \mathbb{R}^d$ is Δ-*periodic* if

$$f(x + \lambda) = f(x) \quad \text{for all } x \in \mathbb{R}^N, \lambda \in \Delta.$$

A Δ-periodic function f may be identified with a function f_T on the N *torus*

$$T_N := \{(e^{2\pi i x_1}, \ldots, e^{2\pi i x_N}) \in \mathbb{C}^N : (x_1, \ldots, x_N) \in \mathbb{R}^N\}$$

through the relation

$$f_T(e^{2\pi i x_1}, \ldots, e^{2\pi i x_N}) := f(x_1, \ldots, x_N).$$

The space $L^p(T_N)$ is identified with $L^p(Q)$, and $C(T_N)$ is the set of Δ-periodic continuous functions on $\overline{Q}$.

Proposition 2.8 (see [9]). *Let* $w \in L^p(T_N; \mathbb{R}^d)$, $1 \leq p \leq +\infty$, *and set* $w_n(x) := w(nx), n \in \mathbb{N}$. *If* $E \subset \mathbb{R}^N$ *is a measurable set, then*

$$w_n \rightharpoonup \int_{T_N} w(y)\, dy \quad \textit{in } L^p(E; \mathbb{R}^d) \quad (\overset{*}{\rightharpoonup} \textit{ if } p = +\infty).$$

In particular, $\{w_n\}$ *generates the homogeneous Young measure* $\nu := \overline{\delta_w}$, *where*

$$\langle \overline{\delta_w}, \varphi \rangle := \int_{T_N} \varphi(w(y))\, dy \quad \text{for all } \varphi \in C_0(\mathbb{R}^d).$$

We recall some results on Fourier transforms of periodic functions (see [38, 39]). If $f \in L^1(T_N)$, then its *Fourier coefficients* are defined as

$$\hat{f}(\lambda) := \int_{T_N} f(x) \mathrm{e}^{-2\pi i x\cdot\lambda}\, dx, \qquad \lambda \in \Delta,$$

and the following hold.

THEOREM 2.9.

(i) *The trigonometric polynomials*

$$R(x) := \sum_{\lambda\in\Delta'} a_\lambda e^{-2\pi i x\cdot\lambda}, \quad \Delta' \text{finite subset of } \Delta, a_\lambda \in \mathbb{C},$$

are dense in $C(T_N)$ *and in* $L^p(T_N)$ *for all* $1 \le p < +\infty$.

(ii) *If* $\mu \in \mathcal{M}(T_N)$ *and* $\langle \mu, e^{-2\pi i x\cdot\lambda}\rangle = 0$ *for all* $\lambda \in \Delta$ *then* $\mu \equiv 0$.

(iii) *If* $f \in L^2(T_N)$ *then*

$$f(x) = \sum_{\lambda\in\Delta} \hat{f}(\lambda) e^{2\pi i x\cdot\lambda}, \quad \sum_{\lambda\in\Delta} |\hat{f}(\lambda)|^2 = ||f||_{L^2}.$$

COROLLARY 2.10. *If* $f \in L^1(T_N)$ *and* $\sum_{\lambda\in\Delta} |\hat{f}(\lambda)| < +\infty$, *then there exists a representative* $\overline{f}$ *of* f *such that* $\overline{f} \in C(T_N)$ *and for all* $x \in T_N$

$$\overline{f}(x) = \sum_{\lambda\in\Delta} \hat{f}(\lambda) e^{2\pi i x\cdot\lambda}.$$

COROLLARY 2.11. *If* $f \in C^k(T_N)$ *for some* $k > N/2$ *then*

$$\sum_{\lambda\in\Delta} |\hat{f}(\lambda)| < +\infty.$$

Let $(L^p(T_N), L^q(T_N))$ denote the class of (p, q) *Fourier multiplier operators*, i.e., the class of all bounded linear operators $T : L^p(T_N) \to L^q(T_N)$ which commute with translations,

$$\Gamma_h T = T \Gamma_h \quad \text{for all } h \in \mathbb{R}^N,$$

where $\Gamma_h f(x) := f(x - h)$.

THEOREM 2.12. *If* $1 \le p, q \le +\infty$ *and if* $T \in (L^p(T_N), L^q(T_N))$, *then there exists a bounded function* $\Theta : \Delta \to \mathbb{C}$ *such that*

$$Tf(x) := \sum_{\lambda\in\Delta} \Theta(\lambda)\hat{f}(\lambda) e^{2\pi i x\cdot\lambda} \quad \text{if } f \in L^p(T_N) \text{is given by } f(x) = \sum_{\lambda\in\Delta} \hat{f}(\lambda) e^{2\pi i x\cdot\lambda}.$$

The collection of coefficients $\{\Theta(\lambda)\}_{\lambda\in\Delta}$ *is called the Fourier multiplier associated with* T.

It can be shown that a certain class of continuous functions on the unit sphere S^{N-1} are Fourier multipliers. Precisely (see [38, Example iii, pp. 94], [39, Corollary 3.16, p. 263, and remark just below]),

PROPOSITION 2.13. *If Θ is homogeneous of degree zero and if it is infinitely differentiable on S^{N-1}, then the operator $T_\Theta : L^p(T_N) \to L^p(T_N)$ defined by*

$$T_\Theta f(x) := \sum_{\lambda \in \Delta \setminus \{0\}} \Theta(\lambda) \hat{f}(\lambda) e^{2\pi i x \cdot \lambda} \text{ if } f \in L^p(T_N) \text{ is given by } f(x) = \sum_{\lambda \in \Delta} \hat{f}(\lambda) e^{2\pi i x \cdot \lambda}$$

is a Fourier multiplier operator for $1 < p < +\infty$.

If (2.2) holds, then in light of Propositions 2.7 and 2.13 the functions

$$\Theta_{ij} : w \in \mathbb{R}^N \mapsto \mathbb{P}(w)_{ij}, \quad i, j \in \{1, \dots, d\},$$

generate the Fourier multipliers $\{\Theta_{ij}(\lambda)\}_{\lambda \in \Delta \setminus \{0\}}$ associated with the Fourier multiplier operators $T_{\Theta_{ij}}$, and we define the operators

$$(\mathbb{T}u)_i(x) := (T_{\Theta_{ij}} u_j)(x) \quad \text{for } u \in L^p(T_N; \mathbb{R}^d), \quad i = 1, \dots, N,$$

where the summation convention for repeated indices is used.

LEMMA 2.14. *Suppose that (2.2) holds and let $1 < p < +\infty$. Then*

(i) *$\mathbb{T} : L^p(T_N; \mathbb{R}^d) \to L^p(T_N; \mathbb{R}^d)$ is a linear, bounded operator that vanishes on constant mappings;*

(ii) *if $u \in L^p(T_N; \mathbb{R}^d)$ then $\mathbb{T} \circ \mathbb{T}u = \mathbb{T}u$, and $\mathcal{A}(\mathbb{T}u) = 0$;*

(iii) *$||u - \mathbb{T}u||_{L^p} \le C_p ||\mathcal{A}u||_{W^{-1,p}}$ for all $u \in L^p(T_N; \mathbb{R}^d)$, such that $\int_{T_N} u \, dx = 0$, and for some $C_p > 0$;*

(iv) *suppose that $\{u_n\}$ is a sequence bounded in $L^p(T_N; \mathbb{R}^d)$ and $\{|u_n|^p\}$ is equi-integrable. Then $\{|\mathbb{T}u_n|^p\}$ is still equi-integrable.*

Proof. Property (i) follows from the definition of $\mathbb{T}$ and from Propositions 2.7 and 2.13. Property (ii) is an immediate consequence of the fact that $\mathbb{P}$ is a projection.

To prove (iii), we note that by Corollaries 2.10 and 2.11 for $u \in C^\infty(T_N; \mathbb{R}^d)$, with $\int_{T_N} u \, dx = 0$, we have

$$\begin{aligned} u - \mathbb{T}u &= \Sigma_{\lambda \in \Delta \setminus \{0\}} \, \mathbb{Q}(\lambda) \mathbb{A}(\lambda) \hat{u}(\lambda) e^{2\pi i x \cdot \lambda} \\ &= \Sigma_{\lambda \in \Delta \setminus \{0\}} \, \mathbb{Q}\left(\frac{\lambda}{|\lambda|}\right) \mathbb{A}\left(\frac{\lambda}{|\lambda|}\right) \hat{u}(\lambda) e^{2\pi i x \cdot \lambda}, \end{aligned}$$

where we have used the linearity of $\mathbb{A}$ and the fact that $\mathbb{Q}$ is homogeneous of degree -1. By Proposition 2.7 the inequality in (iii) is obtained, and the result for L^p periodic functions with zero average follows via a density argument.

To prove (iv) consider the truncation $\tau_\alpha : \mathbb{R}^d \to \mathbb{R}^d$ given by

$$\tau_\alpha(z) := \begin{cases} z & \text{if} \quad |z| \le \alpha, \\ \alpha \frac{z}{|z|} & \text{if} \quad |z| > \alpha. \end{cases}$$

Since $\{\tau_\alpha u_n\}$ is bounded in L^∞ we have that$\{\mathbb{T}(\tau_\alpha u_n)\}$ is bounded in L^q for all $p \le q < +\infty$, and so $\{|T(\tau_\alpha u_n)|^p\}$ is equi-integrable. On the other hand, by the equi-integrability of $\{u_n\}$ we have that

$$\lim_{\alpha \to \infty} \sup_n ||u_n - \tau_\alpha u_n||_p = 0,$$

and by (i) we conclude that

$$\lim_{\alpha\to\infty}\sup_n ||\mathbb{T}(u_n-\tau_\alpha u_n)||_p=0,$$

and the assertion is proved. □

We note that, with the exception of Lemma 2.14 (iv), the above closely follows Murat's work (see [34]).

Decomposition results similar to the ones obtained below may be found in [24] and [30] in the particular case of curl-free fields.

LEMMA 2.15 ($1<p<+\infty$). *Let $1<p<+\infty$, let $\{u_n\}$ be a bounded sequence in $L^p(\Omega;\mathbb{R}^d)$ such that $\mathcal{A}u_n\to 0$ in $W^{-1,p}(\Omega)$, $u_n\rightharpoonup u$ in $L^p(\Omega;\mathbb{R}^d)$, and assume that $\{u_n\}$ generates the Young measure ν. Then there exists a p-equi-integrable sequence $\{v_n\}\subset L^p(\Omega;\mathbb{R}^d)\cap\ker\mathcal{A}$ such that*

$$\int_\Omega v_n\,dx=\int_\Omega u\,dx,\quad ||v_n-u_n||_{L^q(\Omega)}\to 0\quad \textit{for all } 1\le q<p$$

and, in particular, $\{v_n\}$ still generates ν.

Proof. After an affine rescaling, we may suppose that $\Omega\subset Q$. The assumptions imply that $\mathcal{A}u=0$, and by linearity (and Proposition 2.4) we may take $u=0$. By Theorem 2.2 (v) we have

$$\int_\Omega\int_{\mathbb{R}^d}|z|^p\,d\nu_x(z)\,dx<+\infty$$

and so, using Theorem 2.2 (vi), we obtain

$$\begin{aligned}\lim_{k\to\infty}\lim_{n\to\infty}\int_\Omega|\tau_k(u_n)|^p\,dx&=\lim_{k\to\infty}\int_\Omega\int_{\mathbb{R}^d}|\tau_k(z)|^p\,d\nu_x(z)\,dx\\&=\int_\Omega\int_{\mathbb{R}^d}|z|^p\,d\nu_x(z)\,dx.\end{aligned}$$

Therefore we may find an increasing sequence $\alpha_n\to+\infty$ such that the truncated sequence $\{\tau_{\alpha_n}\circ u_n\}$ satisfies

$$\lim_{n\to\infty}\int_\Omega|\tau_{\alpha_n}\circ u_n|^p\,dx=\int_\Omega\int_{\mathbb{R}^d}|z|^p\,d\nu_x(z)\,dx.\tag{2.3}$$

On the other hand, as $\{u_n\}$ is equi-integrable,

$$\tau_{\alpha_n}\circ u_n-u_n\to 0\quad\text{in measure and weakly in } L^p(\Omega).$$

Thus, by Proposition 2.4, the sequence $\{\tilde u_n\}:=\{\tau_{\alpha_n}\circ u_n\}$ still generates the Young measure ν. By Theorem 2.2 (vi) and (2.3) we conclude that $\{\tilde u_n\}$ is p-equi-integrable. Moreover, if $1<q<p$, then

$$\begin{aligned}||\tilde u_n-u_n||^q_{L^q(\Omega)}&\le\int_{\{|u_n|\ge\alpha_n\}}2^q|u_n|^q\,dx\\&\le\alpha_n^{q-p}\,2^q\int_{T_N}|u_n|^p\,dx\to 0\quad\text{as } n\to+\infty,\end{aligned}$$

and thus $\mathcal{A}\tilde{u}_n \to 0$ in $W^{-1,q}(\Omega)$. Also, by virtue of the compact imbedding $L^q(\Omega) \hookrightarrow W^{-1,q}(\Omega)$, we have for all $\varphi \in C_0^\infty(\Omega;[0,1])$

$$\mathcal{A}(\varphi\tilde{u}_n) = \varphi\mathcal{A}(\tilde{u}_n) + \sum_{i=1}^{N} A^{(i)}(\tilde{u}_n)\,\frac{\partial\varphi}{\partial x_i} \to 0 \text{ in } W^{-1,q}(\Omega).$$

Thus we may select a sequence $\{\varphi_n\} \subset C_0^\infty(\Omega;[0,1])$ with $\varphi_n \nearrow 1$, and such that, setting $\hat{u}_n := \varphi_n\,\tilde{u}_n$, $\{\hat{u}_n\}$ is p-equi-integrable,

$$\hat{u}_n \rightharpoonup 0 \quad \text{in } L^p(\Omega),\ \mathcal{A}\hat{u}_n \to 0 \text{ in } W^{-1,q}(\Omega).$$

Extend $\hat{u}_n$ by zero to $Q \setminus \Omega$ and then periodically. We define

$$\tilde{v}_n := \mathbb{T}\left(\hat{u}_n - \int_{T_N} \hat{u}_n\,dy\right).$$

By Lemma 2.14 (iv) the sequence $\{\tilde{v}_n\} \subset L^p(\Omega;\mathbb{R}^d) \cap \ker\mathcal{A}$ is p-equi-integrable, and we have

$$\begin{aligned}(2.4)\qquad ||\tilde{v}_n - u_n||_{L^q(\Omega)} &\le ||\tilde{v}_n - \tilde{u}_n||_{L^q(\Omega)} + ||\tilde{u}_n - u_n||_{L^q(\Omega)}\\ &\le ||\tilde{v}_n - \hat{u}_n||_{L^q(\Omega)} + ||\hat{u}_n - \tilde{u}_n||_{L^q(\Omega)} + ||\tilde{u}_n - u_n||_{L^q(\Omega)}\\ &=: I_1^n + I_2^n + I_3^n.\end{aligned}$$

We have already seen that $I_3^n \to 0$ as $n \to \infty$, and the p-equi-integrability of $\{\tilde{u}_n\}$ entails

$$\lim_{n\to\infty} I_2^n = 0.$$

Using Lemma 2.14 (iii) and the fact that $\int_{T_N} \hat{u}_n\,dy \to 0$, we obtain

$$\begin{aligned}\lim_{n\to\infty} I_1^n &\le \lim_{n\to\infty} \left|\left|\hat{u}_n - \int_{T_N} \hat{u}_n\,dy - \mathbb{T}\left(\hat{u}_n - \int_{T_N} \hat{u}_n\,dy\right)\right|\right|_{L^q(T_N)}\\ &\le \lim_{n\to\infty} C_q\,||\mathcal{A}\hat{u}_n||_{W^{-1,q}(T_N)}\\ &= 0.\end{aligned}$$

In particular, by Proposition 2.4 $\{\tilde{v}_n\}$ still generates ν. Finally, it suffices to set

$$v_n := \tilde{v}_n - \int_\Omega \tilde{v}_n\,dy.$$

Note that if the initial sequence $\{u_n\}$ is p-equi-integrable, then there is no need to construct the truncated sequence $\{\tilde{u}_n\}$, and from (2.4) it follows that $||v_n - u_n||_{L^p(T_N)} \to 0$. □

LEMMA 2.16 ($p = 1$). *Let $\{u_n\}$ be a sequence converging weakly in $L^1(\Omega;\mathbb{R}^d)$ to a function u, $\mathcal{A}u_n \to 0$ in $W^{-1,r}(\Omega_N)$ for some $r \in (1, N/(N-1))$, and assume that $\{u_n\}$ generates a Young measure ν. Then there exists an equi-integrable sequence $\{v_n\} \in L^1(\Omega;\mathbb{R}^d) \cap \ker\mathcal{A}$ such that*

$$\int_\Omega v_n\,dx = \int_\Omega u\,dx, \quad ||v_n - u_n||_{L^1(\Omega)} \to 0$$

and, in particular, $\{v_n\}$ still generates ν.

Proof. The proof is similar to the one given above, and once again we may assume that $\Omega \subset Q$ and $u = 0$. Due to the equi-integrability of $\{u_n\}$ we do not need to truncate the sequence, so we set $\tilde{u}_n := u_n$. Also, by mollification we may assume that $\hat{u}_n \in C_0^\infty(\Omega;\mathbb{R}^d)$, where in the diagonalization argument leading to the construction of $\hat{u}_n$ we use the compact imbedding $L^1(\Omega) \hookrightarrow W^{-1,r}(\Omega)$. We have

$$||\tilde{v}_n - u_n||_{L^1(\Omega)} \leq ||\tilde{v}_n - \hat{u}_n||_{L^1(\Omega)} + ||\hat{u}_n - u_n||_{L^1(\Omega)}$$

and the last term on the right-hand side converges to zero due to the equi-integrability of $\{u_n\}$. Finally,

$$\begin{aligned}\lim_{n\to\infty} ||\tilde{v}_n - \hat{u}_n||_{L^1(\Omega)} &\leq \lim_{n\to\infty} C_r \left|\left|\hat{u}_n - \int_{T_N} \hat{u}_n \, dy - \mathbb{T}\left(\hat{u}_n - \int_{T_N} \hat{u}_n \, dy\right)\right|\right|_{L^r(T_N)} \\ &\leq C_r \lim_{n\to\infty} ||\mathcal{A}\hat{u}_n||_{W^{-1,r}(T_N)} \\ &= 0,\end{aligned}$$

where we have used the fact that $\int_{T_N} \hat{u}_n \, dy \to 0$. ∎

LEMMA 2.17 ($p = +\infty$). *Let $\{u_n\}$ be a sequence that satisfies $u_n \overset{*}{\rightharpoonup} u$ in $L^\infty(T_N;\mathbb{R}^d)$, $\mathcal{A}u_n \rightharpoonup 0$ in $L^p(T_N)$ for some $p > N$, and assume that $\{u_n\}$ generates a Young measure ν. Then there exists a sequence $\{v_n\} \in L^\infty(T_N;\mathbb{R}^d) \cap \ker \mathcal{A}$ such that*

$$\int_{T_N} v_n \, dx = \int_{T_N} u \, dx, \quad ||v_n - u_n||_{L^\infty(T_N)} \to 0$$

and, in particular, $\{v_n\}$ still generates ν.

Proof. As before assume that $u = 0$ and set

$$v_n := \mathbb{T}\left(u_n - \int_{T_N} u_n \, dy\right).$$

Since $\int_{T_N} u_n \, dy \to 0$, we have

$$\sup_{n\in\mathbb{N}} ||v_n - u_n||_{W^{1,p}(T_N)} \leq C_p \sup_{n\in\mathbb{N}} ||\mathcal{A}u_n||_{L^p(T_N)} < +\infty$$

and

$$\lim_{n\to\infty} ||v_n - u_n||_{L^p(T_N)} \leq C_p \lim_{n\to\infty} ||\mathcal{A}u_n||_{W^{-1,p}(T_N)} = 0,$$

and we conclude that the functions $v_n - u_n$ converge to zero uniformly. ∎

The last result of this section will enable us in section 4 to focus our attention on the characterization of $\mathcal{A}$-1-Young measures, where a Young measure ν is said to be a *$\mathcal{A}$-p-Young measure* if it is generated by a sequence in $\ker \mathcal{A}$ which is weakly convergent in $L^p(\Omega)$.

COROLLARY 2.18. *Let $1 < p < +\infty$. If ν is a $\mathcal{A}$-1-Young measure with*

$$\int_\Omega \int_{\mathbb{R}^d} |z|^p \, d\nu_x(z) \, dx < +\infty,$$

then ν is a $\mathcal{A}$-p-Young measure generated by a p-equi-integrable sequence.

Proof. Assume that ν is generated by an equi-integrable sequence $\{u_n\} \subset L^1(\Omega) \cap \ker \mathcal{A}$, and

$$\int_\Omega \int_{\mathbb{R}^d} |z|^p \, d\nu_x(z) \, dx < +\infty.$$

Following the beginning of the proof of Lemma 2.15, we may find a sequence of truncations $\{\tilde{u}_n\} \subset \ker \mathcal{A}$, bounded in $L^p(\Omega; \mathbb{R}^d)$, that still generates ν since, by equi-integrability,

$$||\tilde{u}_n - u_n||_{L^1(\Omega)} \to 0.$$

The result now follows by direct application of Lemma 2.15 to the sequence $\{\tilde{u}_n\}$. □

3. $\mathcal{A}$-quasi-convexity: A necessary and sufficient condition for lower semicontinuity. Using the notation introduced in section 2, consider an operator $\mathcal{A}$ satisfying the constant rank property (2.2). In this section we will prove lower semicontinuity of functionals with normal integrands with respect to weakly convergent sequences with weak limits in the kernel of $\mathcal{A}$. In what follows Ω is a bounded, open subset of $\mathbb{R}^N$.

Given a normal integrand $f : \Omega \times \mathbb{R}^m \times \mathbb{R}^d \to \mathbb{R}$, we define

$$I(u, v) := \int_\Omega f(x, u(x), v(x)) \, dx$$

for measurable $(u, v) : \Omega \to \mathbb{R}^m \times \mathbb{R}^d$.

DEFINITION 3.1. *A function $f : \mathbb{R}^d \to \mathbb{R}$ is said to be* $\mathcal{A}$-quasi-convex *if*

$$f(v) \leq \int_Q f(v + w(x)) \, dx$$

for all $v \in \mathbb{R}^d$ and all $w \in C^\infty(T_N; \mathbb{R}^d)$ such that $\mathcal{A}(w) = 0$ and $\int_{T_N} w(x) \, dx = 0$.

DEFINITION 3.2. *Given a Borel function $f : \mathbb{R}^d \to \mathbb{R}$ we define the* $\mathcal{A}$-quasi-convex envelope *of f at $v \in \mathbb{R}^d$ as*

$$Q_{\mathcal{A}} f(v) := \inf \left\{ \int_{T_N} f(v + w(x)) \, dx : w \in C^\infty(T_N) \cap \ker \mathcal{A}, \int_{T_N} w \, dx = 0 \right\}. \tag{3.1}$$

Clearly $f = Q_{\mathcal{A}} f$ when f is *$\mathcal{A}$-quasi-convex*.

Remark 3.3.

(i) It follows immediately from Jensen's inequality that convex functions are $\mathcal{A}$-quasi-convex.

(ii) If f is upper semicontinuous and locally bounded from above, then $C^\infty(T_N)$ may be replaced by $L^\infty(T_N)$ in Definition 3.1. Indeed, it suffices to approximate a given function $w \in L^\infty(T_N) \cap \ker \mathcal{A}$, with $\int_{T_N} w \, dx = 0$, by the mollified sequence

$$w_\varepsilon := \rho_\varepsilon * w - \int_{T_N} \rho_\varepsilon * w \, dy,$$

where $w_\varepsilon \in C^\infty(T_N) \cap \ker \mathcal{A}$, are Q-periodic, and have zero average. The result now follows by Fatou's lemma. If, in addition, $|f(v)| \leq C(1 + |v|^p)$ for some $C > 0$ and all $v \in \mathbb{R}^d$, then $C^\infty(T_N)$ may be replaced by $L^p(T_N)$ in (3.1).

(iii) Given a matrix-valued function $V : \Omega \subset \mathbb{R}^N \to \mathbb{M}^{m\times n} \equiv \mathbb{R}^d$, $d := mn$, $n = N + \rho$, $\rho \geq 0$, we write

$$V = (F \mid \xi), \quad F \in \mathbb{M}^{m\times N},\ \xi \in \mathbb{M}^{m\times \rho},$$

where F is the matrix of the first N columns of V, and ξ is the matrix of the remaining ρ columns. In the context of membrane or film theories, $N = 2$, $m = 3$, $\rho = 1$, and F is the gradient of the membrane deformation. In the context of general nonlinear elasticity, $N = m = 3, \rho = 0$, and F is the gradient of the deformation of the elastic solid. The underlying PDE is then

$$\operatorname{curl} F = 0, \quad \text{i.e.,}\ \frac{\partial F_{jk}}{\partial x_i} - \frac{\partial F_{ji}}{\partial x_k} = 0, \quad 1 \leq j \leq m, 1 \leq i, k \leq N.$$

We may rewrite these PDEs as $\mathcal{A}V = 0$, where $l := N^2 m$ and

$$A^{(r)}_{(j,k,i),(q,p)} := \delta_{ri}\delta_{qj}\delta_{pk} - \delta_{rk}\delta_{qj}\delta_{pi}, \quad 1 \leq j, q \leq m,\ 1 \leq i, k, p, r \leq N,$$

$$A^{(r)}_{(j,k,i),(q,p)} = 0 \quad \text{if } p = N + 1, \ldots, n.$$

The constant rank condition (2.2) is satisfied, since $\dim(\ker \mathbb{A}(w)) = m + m \times \rho$ for all $w \in S^{N-1}$. Indeed,

$$\begin{aligned}\ker \mathbb{A}(w) &= \{V \in \mathbb{M}^{m\times n} : \mathbb{A}(w)V = 0\}\\ &= \{V = (F \mid \xi) \in \mathbb{M}^{m\times n} : w_i F_{jk} - w_k F_{ji} = 0,\ 1 \leq j \leq m, 1 \leq i, k \leq N\}\\ &= \{V = (F \mid \xi) \in \mathbb{M}^{m\times n} : F = a \otimes w \text{ for some } a \in \mathbb{R}^m\}.\end{aligned}$$

When $\rho = 0$ and f is locally bounded, then (3.1) reduces to the usual *quasi-convex envelope* of f,

$$\begin{aligned}Q_{\mathcal{A}} f(v) &:= \inf\left\{\int_{T_N} f(v + \nabla\varphi(x))\,dx : \varphi \in C^\infty(T_N; \mathbb{R}^m)\right\}\\ &= \inf\left\{\int_Q f(v + \nabla\varphi(x))\,dx : \varphi \in C_0^\infty(Q; \mathbb{R}^m)\right\}.\end{aligned}$$

(iv) Now we consider the div-free case (see also [35]). Here $d = N, l = 1$,

$$A^{(i)}_j := \delta_{ij},$$

so that

$$\mathcal{A}u = 0 \quad \text{if and only if } \operatorname{div} u = 0.$$

Once again, the constant rank condition (2.2) holds, as for all $w \in S^{N-1}$

$$\begin{aligned}\ker \mathbb{A}(w) &= \left\{v \in \mathbb{R}^N : \sum_{i=1}^N A^{(i)} w_i(v) = 0\right\}\\ &= \{v \in \mathbb{R}^N : v \cdot w = 0\}.\end{aligned}$$

Therefore $\dim(\ker \mathbb{A}(w)) = N - 1$.

PROPOSITION 3.4. *If $f : \mathbb{R}^d \to \mathbb{R}$ is upper semicontinuous, then $Q_{\mathcal{A}}f$ is $\mathcal{A}$-quasi-convex and upper semicontinuous. Moreover, the restriction of $Q_{\mathcal{A}}f$ to each cone $a + \Lambda$, $a \in \mathbb{R}^d$, is convex, i.e.,*

$$Q_{\mathcal{A}}f(\theta y + (1-\theta)z) \le \theta Q_{\mathcal{A}}f(y) + (1-\theta)Q_{\mathcal{A}}f(z)$$

for all $\theta \in (0,1)$, $y, z \in \mathbb{R}^d$ such that $y - z \in \Lambda$, where

$$\Lambda := \cup_{w \in S^{N-1}} \ker \mathbb{A}(w).$$

Remark 3.5.

(i) The *characteristic cone* Λ as defined in Proposition 3.4 was introduced in the work of Murat and Tartar (see [34, 41]).

(ii) There are $\mathcal{A}$-quasi-convex functions that are not continuous. Indeed, in the degenerate case $\ker \mathcal{A} = \{0\}$ all functions are $\mathcal{A}$-quasi-convex. Furthermore, in general, $Q_{\mathcal{A}}f$ need not be continuous in directions that are not in spanΛ even when f is smooth. As an example, let $N = 1$, $d = 2$, and $\mathcal{A}u := u_2'$. Fix $\varphi \in C^\infty(\mathbb{R})$ such that $0 \le \varphi \le 1$, $\varphi(0) = 1$, $\lim_{|t|\to\infty} \varphi(t) = 0$, and let

$$f(v_1, v_2) := \varphi(v_1 v_2^2).$$

Then $Q_{\mathcal{A}}f$ is obtained by convexification in the first component, and $Q_{\mathcal{A}}f(v_1, v_2) = 0$ if $v_2 \neq 0$, while $Q_{\mathcal{A}}f(v_1, 0) = 1$.

(iii) In the curl-free case and when $\rho = 0$, by Remark 3.3 (iii) we have that $\Lambda = \{a \otimes w : a \in \mathbb{R}^m, w \in S^{N-1}\}$. Thus Proposition 3.4 entails that a quasi-convex Borel measurable function is convex along any rank-one directions. It is then said to be *rank-one convex*. In particular, it is separately convex and so continuous. We remark that although Proposition 3.3 is stated for upper semicontinuous functions f, in the case of gradients the statement still holds if f is only assumed to be Borel measurable (see [21]).

(iv) In the div-free case and by Remark 3.3 (iv), we have $\Lambda = \mathbb{R}^N$, and by Proposition 3.3 we conclude that $Q_{\mathcal{A}}f$ is convex (see also [35]). Thus, since we always have $Q_{\mathcal{A}}f \le f$, $Q_{\mathcal{A}}f$ reduces to the convexification of f.

(v) It follows from the convexity of $t \mapsto Q_{\mathcal{A}}f(a + tz), z \in \Lambda$ (see Proposition 3.4), that $Q_{\mathcal{A}}f(a) > -\infty$ if and only if $Q_{\mathcal{A}}f > -\infty$ on $a + \Lambda$.

Proof of Proposition 3.4.

Case 1. Suppose that f is continuous.

For $R > 0$, $v \in \mathbb{R}^d$, define

$$Q_{\mathcal{A}}^R f(v) := \inf \left\{ \int_{T_N} f(v + w(x))dx \colon w \in C^\infty(T_N) \cap \ker \mathcal{A}, \right.$$
$$\left. \int_{T_N} w(x)dx = 0, \text{ and } ||w||_{L^\infty(T_N)} \le R \right\}.$$

We claim that

$$Q_{\mathcal{A}}^R f \quad \text{is continuous.} \tag{3.2}$$

Let $\rho > 0$, and let ω be the modulus of uniform continuity of f on $B(0, \rho + R)$, i.e.,

$$\omega(r) := \sup\{|f(v) - f(v')| : v, v' \in \overline{B}(0, \rho + R), |v - v'| \le r\}.$$

For all $v, v' \in B(0,\rho)$ and every $w \in C^\infty(T_N) \cap \mathcal{A}$, with $\int_{T_N} w(x)\,dx = 0$ and $||w||_{L^\infty(T_N)} \le R$, we have

$$\begin{aligned}\int_{T_N} f(v + w(x))\,dx &\ge \int_{T_N} f(v' + w(x))\,dx - \omega(|v - v'|)\\ &\ge Q^R_{\mathcal{A}} f(v') - \omega(|v - v'|).\end{aligned}$$

By definition of $Q_{\mathcal{A}} f(v)$ this implies that

$$Q^R_{\mathcal{A}} f(v) - Q^R_{\mathcal{A}} f(v') \ge \omega(|v - v'|)$$

and the uniform continuity of $Q^R_{\mathcal{A}} f$ in $B(0,\rho)$ follows by reversing the roles of v and v'.

Fix $\varepsilon > 0$, let $n \in \mathbb{N}$, and decompose Q into n^N cubes along the coordinate axes, $Q = \cup Q_{n,i}$, $Q_{n,i} = a_{n,i} + (1/n)\,Q$. Now we choose smooth cut-off functions $\varphi_{n,i}$ with the following properties: $0 \le \varphi_{n,i} \le 1$, $\varphi_{n,i} = 1$ on $a_{n,i} + (1/n - 1/n^2)Q$, and $\sum_{i=1}^{n^N} \chi_{Q_{n,i}} \varphi_{n,i} \nearrow 1$. For $w \in C^\infty(T_N) \cap \ker \mathcal{A}$ with average zero on Q, consider the piecewise constant approximations

$$w_n(x) := \sum_{i=1}^{n^N} \chi_{Q_{n,i}}\, w_{n,i}, \quad \text{where } w_{n,i} := n^N \int_{Q_{n,i}} w(x)\,dx.$$

Then $||w_n - w||_{L^\infty(Q)} \to 0$, and by the continuity of $Q^R_{\mathcal{A}} f$ (see (3.2)) we have for $n \ge n_1(\varepsilon)$

$$\begin{aligned}\int_{T_N} Q^R_{\mathcal{A}} f(v + w(x))\,dx &\ge \int_{T_N} Q^R_{\mathcal{A}} f(v + w_n(x))\,dx - \varepsilon\\ &= \sum_{i=1}^{n^N} \frac{1}{n^N}\, Q^R_{\mathcal{A}} f(v + w_{n,i}) - \varepsilon.\end{aligned} \tag{3.3}$$

On the other hand, due to the uniform continuity of f on compact sets, there exists $\delta > 0$ such that

$$\eta,\, \zeta \in L^\infty(\overline{B}(0,5R)), ||\eta - \zeta||_{L^\infty(Q)} < \delta \Rightarrow \left| \int_Q f(v + \eta(x))\,dx - \int_{T_N} f(v + \zeta(x))\,dx \right| < \varepsilon. \tag{3.4}$$

Choose $z_{n,i} \in C^\infty(T_N) \cap \ker \mathcal{A}$, with average zero, such that $||z_{n,i}||_{L^\infty(Q)} \le R$,

$$Q^R_{\mathcal{A}} f(v + w_{n,i}) \ge \int_{T_N} f(v + w_{n,i} + z_{n,i}(y))\,dy - \varepsilon, \tag{3.5}$$

and set

$$y_{n,k}(x) := w(x) + \sum_{i=1}^{n^N} \varphi_{n,i}(x) z_{n,i}(k n^N (x - a_{n,i})), \quad k \in \mathbb{N}.$$

Clearly

$$||y_{n,k}||_{L^\infty(T_N)} \le R + ||w||_{L^\infty(Q)}.$$

By Proposition 2.8, $z_{n,i}(kn^N(\cdot - a_{n,i})) \overset{*}{\rightharpoonup} 0$ in $L^\infty(Q_{n,i})$ as $k \to \infty$, for all $n \in \mathbb{N}$, $i = 1, \dots, n^N$, and so

$$\lim_{k\to\infty} \mathcal{A}y_{n,k} = 0 \quad \text{weak-* in } L^\infty(T_N), \quad \lim_{n\to\infty} \lim_{k\to\infty} \int_{T_N} y_{n,k}\, dx = 0. \tag{3.6}$$

Choose $n = n_2(\varepsilon) \geq n_1(\varepsilon)$ such that

$$n_2(\varepsilon) \to \infty \text{ as } \varepsilon \to 0, \quad ||w_n - w||_{L^\infty(Q)} < \delta, \quad \lim_{k\to\infty} \left| \int_{T_N} y_{n,k}\, dx \right| < \delta. \tag{3.7}$$

Now (3.3), (3.4), (3.5), and (3.7) yield

$$\begin{aligned} \int_{T_N} Q^R_{\mathcal{A}} f(v + w(x))\, dx & \\ &\geq \lim_{k\to\infty} \sum_{i=1}^{n^N} \int_{Q_{n,i}} f(v + w_{n,i} + z_{n,i}(kn^N(x - a_{n,i})))\, dx - 2\varepsilon \\ &\geq \limsup_{k\to\infty} \int_{T_N} f(v + y_{n,k}(x))\, dx - 3\varepsilon \\ &\quad - Cn^N \left[\frac{1}{n^N} - \left(\frac{1}{n} - \frac{1}{n^2} \right)^N \right] \max\{|f(z)| : z \in \overline{B}(v, 2R)\}. \end{aligned} \tag{3.8}$$

In view of Lemma 2.17 and (3.6) we may find $u_k \in L^\infty(T_N; \mathbb{R}^d) \cap \ker \mathcal{A}$ such that

$$\int_{T_N} u_k\, dx = 0, \quad u_k - \left(y_{n,k} - \int_{T_N} y_{n,k}(y)\, dy \right) \to 0 \quad \text{uniformly as} \quad k \to \infty.$$

Thus, by (3.4), (3.7), (3.8), and Remark 3.3 (ii) we have

$$\begin{aligned} \int_{T_N} Q^R_{\mathcal{A}} f(v + w(x))\, dx &\geq \limsup_{k\to\infty} \int_{T_N} f(v + y_{n,k}(x))\, dx - 3\varepsilon - O\left(\frac{1}{n}\right) \\ &\geq \limsup_{k\to\infty} \int_{T_N} f\left(v + y_{n,k}(x) - \int_{T_N} y_{n,k}(y)\, dy \right) dx - 4\varepsilon - O\left(\frac{1}{n}\right) \\ &\geq \limsup_{k\to\infty} \int_{T_N} f(v + u_k(x))\, dx - 5\varepsilon - O\left(\frac{1}{n}\right) \\ &\geq Q_{\mathcal{A}} f(v) - 5\varepsilon - O\left(\frac{1}{n}\right). \end{aligned} \tag{3.9}$$

For $\varepsilon \to 0$ we have, by (3.7), $n = n_2(\varepsilon) \to +\infty$. Hence taking first the limit $\varepsilon \to 0$ and then $R \to \infty$ in (3.9) and observing that $Q^R_{\mathcal{A}} f \searrow Q_{\mathcal{A}} f$ as $R \to \infty$, we deduce from Lebesgue's monotone convergence theorem that

$$\int_{T_N} Q_{\mathcal{A}} f(v + w(x))\, dx \geq Q_{\mathcal{A}} f(v).$$

Case 2. f is upper semicontinuous.

Let $\{f_n\}$ be a sequence of continuous functions converging decreasingly to f. By Case 1, given $v \in \mathbb{R}^d$, $w \in C^\infty(T_N) \cap \ker \mathcal{A}$, with $\int_{T_N} w\, dx = 0$, we have

$$\int_{T_N} Q_{\mathcal{A}} f_n(v + w(x))\, dx \geq Q_{\mathcal{A}} f_n(v), \quad n \in \mathbb{N}.$$

In view of Lebesgue's monotone convergence theorem, $\mathcal{A}$-quasiconvexity of $Q_{\mathcal{A}}f$ will follow provided we show that

$$Q_{\mathcal{A}}f_n \searrow Q_{\mathcal{A}}f. \tag{3.10}$$

Cleary $\{Q_{\mathcal{A}}f_n\}_{n\in\mathbb{N}}$ is decreasing and larger than $Q_{\mathcal{A}}f$. On the other hand, for fixed $v \in \mathbb{R}^d$ with $Q_{\mathcal{A}}f(v) > -\infty$, given $\delta > 0$ there exists $\eta \in C^\infty(T_N) \cap \ker \mathcal{A}$, with $\int_{T_N} \eta\, dx = 0$, such that

$$Q_{\mathcal{A}}f(v) \geq \int_{T_N} f(v + \eta(x))\, dx - \delta.$$

By Lebesgue's monotone convergence theorem it follows that

$$\begin{aligned} Q_{\mathcal{A}}f(v) &\geq \lim_{n\to\infty} \int_{T_N} f_n(v + \eta(x))\, dx - \delta \\ &\geq \limsup_{n\to\infty} Q_{\mathcal{A}}f_n(v) - \delta. \end{aligned}$$

It suffices to let $\delta \to 0$. The case where $Q_{\mathcal{A}}f(v) = -\infty$ is treated in a similar way. As proven in Case 1, the functions $Q_{\mathcal{A}}f_n$ are upper semicontinuous, so $Q_{\mathcal{A}}f = \inf_{n\in\mathbb{N}} Q_{\mathcal{A}}f_n$ is also upper semicontinuous.

Finally, we show that $Q_{\mathcal{A}}f$ is convex on the cones $a + \Lambda$, $a \in \mathbb{R}^d$, i.e.,

$$Q_{\mathcal{A}}f(\theta y + (1-\theta)z) \leq \theta Q_{\mathcal{A}}f(y) + (1-\theta)Q_{\mathcal{A}}f(z)$$

for all $\theta \in (0,1)$, $y, z \in \mathbb{R}^d$ such that $y - z \in \Lambda$. By (3.10) it suffices to prove this inequality in the case where f is a continuous function.

Let

$$\chi(t) := \begin{cases} -(1-\theta) & \text{if} \quad 0 < t < \theta, \\ \theta & \text{if} \quad \theta < t < 1 \end{cases}$$

and extend χ periodically to $\mathbb{R}$ with period one. Let $w \in S^{N-1}$ be such that $y - z \in \ker \mathbb{A}(w)$ and define

$$u_n(x) := (z - y)\, \chi(nx \cdot w).$$

Clearly $u_n \overset{*}{\rightharpoonup} 0$ in $L^\infty(Q)$, and if $\varphi \in C_0^\infty(Q; [0,1])$ is such that $\mathcal{L}^N(\{\varphi = 1\}) = 1 - \delta$, $\delta > 0$, then

$$\mathcal{A}(\varphi u_n) = \sum_{i=1}^N A^{(i)} u_n \frac{\partial \varphi}{\partial x_i} \overset{*}{\rightharpoonup} 0 \qquad \text{in } L^\infty(T_N).$$

Due to Lemma 2.17 we may find $\overline{u}_n \in L^\infty(T_N; \mathbb{R}^d) \cap \ker \mathcal{A}$ such that

$$\int_{T_N} \overline{u}_n = 0, \quad ||\overline{u}_n - \varphi\, u_n||_{L^\infty(Q)} \to 0.$$

By Remark 3.3 (ii), since $Q_{\mathcal{A}}f$ is a $\mathcal{A}$-quasi-convex function, upper semicontinuous, and bounded above by the locally bounded function f, by (3.2), and if $R > 0$ is large

enough, we have

$$\begin{aligned} Q_{\mathcal{A}}f(\theta y+(1-\theta)z) &\le \liminf_{n\to\infty}\int_{T_N} Q_{\mathcal{A}}f(\theta y+(1-\theta)z+\overline{u}_n)\,dx \\ &\le \liminf_{n\to\infty}\int_{T_N} Q^R_{\mathcal{A}}f(\theta y+(1-\theta)z+\overline{u}_n)\,dx \\ &\le \liminf_{n\to\infty}\int_{T_N} Q^R_{\mathcal{A}}f(\theta y+(1-\theta)z+u_n)\,dx + M\delta \\ &= \theta Q^R_{\mathcal{A}}f(\theta y+(1-\theta)z-(1-\theta)(z-y)) \\ &\quad +(1-\theta)Q^R_{\mathcal{A}}f(\theta y+(1-\theta)z+(z-y)\theta)+M\delta \\ &= \theta Q^R_{\mathcal{A}}f(y)+(1-\theta)Q^R_{\mathcal{A}}f(z)+M\delta, \end{aligned}$$

where $M := \max\{|f(z)| : z \in \overline{B}(0,R)\}$. It suffices for us to let $\delta \searrow 0$ and then $R \to \infty$. □

Next we prove that $\mathcal{A}$-quasiconvexity is a necessary condition for lower semicontinuity under the PDE constraint $\mathcal{A}u = 0$.

THEOREM 3.6 (necessity). *Let $f : \Omega \times \mathbb{R}^d \to \mathbb{R}$ be a Carathéodory function such that*

$$\int_\Omega f(x,v(x))\,dx \le \liminf_{n\to\infty}\int_\Omega f(x,v_n(x))\,dx$$

for all sequences $\{v_n\} \subset C^\infty(\overline{\Omega};\mathbb{R}^d)$ that satisfy

$$v_n \overset{*}{\rightharpoonup} v \text{ in } L^\infty(\Omega) \quad \text{and } \mathcal{A}v_n = 0.$$

Assume further that

$$\{f(\cdot,u_n)\} \text{ is equi-integrable}$$

whenever $\{u_n\}$ is a sequence bounded in $L^\infty(\Omega;\mathbb{R}^d)$. Then $f(x_0,\cdot)$ is $\mathcal{A}$-quasi-convex for a.e. $x_0 \in \Omega$.

Proof. Without loss of generality and using a rescaling argument, we may assume that $\Omega \subset Q$.

By the Scorza–Dragoni theorem, for all $i \in \mathbb{N}$ there exists a compact set $K_i \subset \Omega$ such that the restriction of f to $K_i \times \mathbb{R}^d$ is continuous and $\mathcal{L}^N(\Omega \setminus K_i) < 1/i$. Let $\mathcal{S}$ be a countable, dense subset (with respect to uniform convergence) of $\mathbb{W} := \{w \in C^\infty(T_N) : \mathcal{A}w = 0,\ \int_{T_N} w\,dx = 0\}$. Let $x_0 \in \Omega$ be a Lebesgue point for

$$x \mapsto f(x,v), \quad x \mapsto \int_Q f(x,v+w(y))\,dy$$

for all $v \in \mathbb{Q}^d$, $w \in \mathcal{S}$, and suppose that $z \mapsto f(x_0,z)$ is continuous. Fix $v \in \mathbb{Q}^N$, $w \in \mathcal{S}$. We claim that

$$f(x_0,v) \le \int_Q f(x_0,v+w(x))\,dx.$$

If so, by continuity of $z \mapsto f(x_0,z)$ this inequality still holds true for all $v \in \mathbb{R}^d$ and all $w \in \mathbb{W}$. To establish the inequality extend w to $\mathbb{R}^d$ periodically with period Q, fix $\varepsilon > 0$, $h \in \mathbb{N}$, and choose $i = i(h,\varepsilon) \in \mathbb{N}$ such that

$$\mathcal{L}^N\left(Q\left(x_0,\frac{1}{h}\right) \setminus K_i\right) < \frac{\varepsilon}{h^N}.$$

Let $n = n(h, \varepsilon)$ be such that

$$|x - x'| < \frac{1}{n},\ x, x' \in K_i,\ z \in \overline{B}\left(0, |v| + ||w||_{L^\infty(Q)}\right) \quad \Rightarrow |f(x,z) - f(x',z)| < \varepsilon.$$

Decompose the cube $Q\left(x_0, \frac{1}{h}\right)$ as $\cup_{j=1}^{n^N} Q\left(x_j, \frac{1}{hn}\right)$ and if $K_i \cap Q\left(x_j, \frac{1}{hn}\right) \neq \emptyset$ select a_j in this intersection. Choose a cut-off function $\varphi \in C_0^\infty(Q(x_0, 1/h))$ such that $\mathcal{L}^N(Q(x_0, 1/h) \cap \{\varphi \neq 1\}) < \frac{\varepsilon}{h^N}$.

Define

$$w_m(x) := \begin{cases} \varphi(x)\, w^*(hmn(x - x_j)) & \text{if } x \in Q\left(x_j, \frac{1}{hn}\right), j = 1, \dots, n^N, \\ 0, & x \in \mathbb{R}^N \setminus Q\left(x_0, \frac{1}{h}\right), \end{cases}$$

where $w^*(y) := w(y + (1/2, \dots, 1/2))$ for $y \in Q^*$. By Proposition 2.8 it is clear that

$$w_m \overset{*}{\rightharpoonup} 0 \text{ in } L^\infty(T_N), \quad \mathcal{A}w_m \overset{*}{\rightharpoonup} 0 \text{ in } L^\infty(T_N).$$

Using Lemma 2.17 we may find $\eta_m \in L^\infty(Q(0, L); \mathbb{R}^d) \cap \ker \mathcal{A}$ such that $||\eta_m - w_m||_{L^\infty(\Omega)} \to 0$, and so

$$\begin{aligned} \int_\Omega f(x, v)\, dx &\leq \liminf_{m\to\infty} \int_\Omega f(x, v + \eta_m(x))\, dx \\ &= \liminf_{m\to\infty} \int_\Omega f(x, v + w_m(x))\, dx, \end{aligned}$$

where we used Propositions 2.4 and 2.8 and Theorem 2.2 (vi). Taking into account the estimates for $\{\varphi \neq 1\}$ and $Q(x_0, 1/h) \setminus K_i$, we deduce that

$$\begin{aligned} &\int_{Q(x_0,1/h)} f(x, v)\, dx \leq \liminf_{m\to\infty} \int_{Q(x_0,1/h)} f(x, v + w_m(x))\, dx \\ &\quad \leq \liminf_{m\to\infty} \left\{ \sum_{j=1}^{n^N} \int_{Q\left(x_j, \frac{1}{hn}\right) \cap K_i} f(a_j, v + w^*(hmn(x - x_j)))\, dx \right. \\ &\qquad + \sum_{j=1}^{n^N} \int_{Q\left(x_j, \frac{1}{hn}\right) \cap K_i} |f(x, v + w^*(hmn(x - x_j))) - f(a_j, v + w^*(hmn(x - x_j)))|\, dx \\ &\qquad \left. + \sum_{j=1}^{n^N} \int_{Q\left(x_j, \frac{1}{hn}\right) \setminus K_i} f(x, v + w^*(hmn(x - x_j)))\, dx \right\} + M\, \frac{\varepsilon}{h^N} \\ &\quad \leq \sum_{j=1}^{n^N} \frac{1}{(hn)^N} \int_Q f(a_j, v + w(y))\, dy + 3M\, \frac{\varepsilon}{h^N} + \frac{\varepsilon}{h^N}, \end{aligned}$$

where $M := \text{ess sup}\left\{|f(x,z)| : x \in B(x_0, R_0) \subset\subset \Omega, |z| \leq |v| + ||w||_{L^\infty(T_N)}\right\}$.

Hence

$$\begin{aligned} \int_{Q(x_0,1/h)} f(x, v)\, dx &\leq \sum_{j=1}^{n^N} \int_{Q\left(x_j, \frac{1}{hn}\right) \cap K_i} \int_Q f(a_j, v + w(y))\, dy\, dx + \frac{O(\varepsilon)}{h^N} \\ &\leq \sum_{j=1}^{n^N} \int_{Q\left(x_j, \frac{1}{hn}\right)} \int_Q f(x, v + w(y))\, dy\, dx + \frac{O(\varepsilon)}{h^N} \\ &= \int_{Q\left(x_0, \frac{1}{h}\right)} \int_Q f(x, v + w(y))\, dy\, dx + \frac{O(\varepsilon)}{h^N}. \end{aligned} \tag{3.11}$$

Multiplying through (3.11) by h^N, letting $h \to +\infty$, and then $\varepsilon \to 0$, we conclude that

$$f(x_0, v) \le \int_Q f(x_0, v + w(y))\, dy. \qquad \square$$

Now we prove sufficiency of the $\mathcal{A}$-quasiconvexity property.

THEOREM 3.7 (sufficiency). *Let $1 \le p \le +\infty$ and suppose that $f : \Omega \times \mathbb{R}^m \times \mathbb{R}^d \to [0, +\infty)$ is a normal integrand such that $z \mapsto f(x, u, z)$ is $\mathcal{A}$-quasi-convex and continuous for a.e. $x \in \Omega$ and for all $u \in \mathbb{R}^d$. If $1 \le p < +\infty$, then assume further that there exists a locally bounded function $a : \Omega \times \mathbb{R}^d \to [0, +\infty)$ such that*

$$0 \le f(x, u, v) \le a(x, u)(1 + |v|^p).$$

If

$$u_n \to u \text{ in measure}$$

and

$$v_n \rightharpoonup v \text{ in } L^p(\Omega; \mathbb{R}^d) (\overset{*}{\rightharpoonup} \text{ if } p = +\infty),\ \mathcal{A}v_n \to 0 \text{ in } W^{-1,p}(\Omega)\, (\mathcal{A}v_n = 0 \text{ if } p = +\infty),$$

then

$$I(u, v) \le \liminf_{n \to \infty} I(u_n, v_n).$$

This theorem is a consequence of Propositions 3.8 and 3.9.

PROPOSITION 3.8. *Let $1 \le p < +\infty$, and let $\{v_n\}$ be a p-equi-integrable sequence in $L^p(\Omega; \mathbb{R}^d)$ such that $\mathcal{A}v_n \to 0$ in $W^{-1,p}(\Omega)$ if $1 < p < +\infty$, $\mathcal{A}v_n \to 0$ in $W^{-1,r}(\Omega)$ for some $r \in (1, N/(N-1))$ if $p = 1$, and $\{v_n\}$ generates the Young measure $\nu = \{\nu_x\}_{x \in \Omega}$. Let $v_n \rightharpoonup v$ in $L^p(\Omega; \mathbb{R}^d)$. Then for a.e. $a \in \Omega$ there exists a sequence $\{\overline{v}_n\} \subset L^p(T_N; \mathbb{R}^d) \cap \ker \mathcal{A}$ that is p-equi-integrable, generates the homogeneous Young measure ν_a, and satisfies*

$$\int_{T_N} \overline{v}_n\, dx = \langle \nu_a, \mathrm{id} \rangle = v(a).$$

In particular, one has

$$\langle \nu_a, f \rangle \ge f(\langle \nu_a, \mathrm{id} \rangle) = f(v(a))$$

for a.e. $a \in \Omega$ and for every continuous $\mathcal{A}$-quasi-convex f that satisfies

$$|f(z)| \le C(1 + |z|^p)$$

for some $C > 0$ and all $z \in \mathbb{R}^d$.

PROPOSITION 3.9. *Let $\{v_n\}$ be a bounded sequence in $L^\infty(\Omega; \mathbb{R}^d)$ that generates a Young measure $\nu = \{\nu_x\}_{x \in \Omega}$ and satisfies $\mathcal{A}v_n = 0$. Let $v_n \overset{*}{\rightharpoonup} v$ in $L^\infty(\Omega_N; \mathbb{R}^d)$. Then for* a.e. *$a \in \Omega$ and every subcube $Q' \subset\subset Q$, there exists a sequence $\{\overline{v}_n\} \subset L^\infty(T_N; \mathbb{R}^d)$ such that*

$$\overline{v}_n \overset{*}{\rightharpoonup} v(a) \text{ in } L^\infty(T_N),\ \mathcal{A}\overline{v}_n = 0,\ \int_{T_N} \overline{v}_n\, dx = \langle \nu_a, \mathrm{id} \rangle = v(a),$$

and $\{\overline{v}_n\}$ *generates a Young measure* μ *such that*

$$\left|\int_Q \psi(x)\,\langle \mu_x, g\rangle\,dx - \langle \nu_a, g\rangle \int_Q \psi(x)\,dx\right| \le ||g||_{L^\infty(B(0,3M))} \int_{Q\setminus Q'} |\psi(x)|\,dx$$

for all $\psi \in L^1(Q)$, $g \in C_0(\mathbb{R}^d)$, *and where* $M := \sup_{n\in\mathbb{N}} ||v_n||_{L^\infty(\Omega)}$. *In addition, if* $f : \mathbb{R}^d \to \mathbb{R}$ *is a continuous function, then*

$$\langle \nu_a, f\rangle \ge f(\langle \nu_a, \mathrm{id}\rangle) = f(v(a))$$

for a.e. $a \in \Omega$.

We leave the proofs of Propositions 3.8 and 3.9 to the end of this section, and we proceed with the proof of Theorem 3.7. We follow the argument of Kristensen (based on Balder's [4] reasoning for the case without constraints) in the context of the usual curl-free $\mathcal{A}$-quasiconvexity.

Proof of Theorem 3.7. Upon extracting a subsequence, we may assume that

$$\liminf_{n\to\infty} I(u_n, v_n) = \lim_{n\to\infty} I(u_n, v_n),$$

and $\{v_n\}$ generates a Young measure ν. By Proposition 2.5 the pair $\{(u_n, v_n)\}$ generates the Young measure $\{\mu_x = \delta_{u(x)} \otimes \nu_x\}_{x\in\Omega}$, and by Theorem 2.2 (v) we have

$$\begin{aligned}\lim_{n\to\infty} I(u_n, v_n) &\ge \int_\Omega \int_{\mathbb{R}^m\times\mathbb{R}^d} f(x,\eta,\xi)\,d\mu_x(\eta,\xi)\,dx\\ &= \int_\Omega \int_{\mathbb{R}^d} f(x, u(x), \xi)\,d\nu_x(\xi)\,dx.\end{aligned}$$

If $p = 1$ or $p = +\infty$ the result follows from direct application of Proposition 3.8 and Proposition 3.9, respectively, to the map $\xi \mapsto f(x, u(x), \xi)$ and integration over Ω. If $1 < p < +\infty$ then by Lemma 2.15 and by Proposition 2.4, there exists a p-equi-integrable sequence $\{y_n\}$ which generates ν and satisfies $\mathcal{A}y_n = 0$. Once again, it suffices to apply Proposition 3.8 to $\{y_n\}$ and to the map $\xi \mapsto f(x, u(x), \xi)$ for a.e. $x \in \Omega$ fixed. □

Proof of Proposition 3.8. Let $\mathcal{E}$ and $\mathcal{C}$ be countable dense subsets of $L^1(Q)$ and $C_0(\mathbb{R}^d)$, respectively. By Theorem 2.2 (vi) we have

$$g \circ v_n \overset{*}{\rightharpoonup} \langle \nu, g\rangle \text{ in } L^\infty(\Omega)$$

for all $g \in \mathcal{C}$. Let Ω_0 be the set of points $a \in \Omega$ which are Lebesgue points for v, for the functions

$$x \mapsto \int_{\mathbb{R}^d} |\xi|^p\,d\nu_x(\xi), \quad x \mapsto \langle \nu_a, \mathrm{id}\rangle,$$

and for all functions $x \mapsto \langle \nu_x, g\rangle$, $g \in \mathcal{C}$, in the sense that

$$\lim_{R\to 0} \int_Q |\langle \nu_{a+Rx}, g\rangle - \langle \nu_a, g\rangle|\,dx = 0.$$

Consider an increasing sequence of smooth cut-off functions $\varphi_j \in C_0^\infty(Q)$, $\varphi_j \nearrow 1$. For fixed $a \in \Omega_0$, $R > 0$, we define

$$v_{j,R,n}(z) := \varphi_j(z)(v_n(a + Rz) - \langle \nu_a, \mathrm{id}\rangle),\ z \in Q.$$

Recall that $\langle \nu_a, \mathrm{id}\rangle = v(a)$. We have $v_{j,R,n} \in L^p(T_N;\mathbb{R}^d)$, and for all $\psi \in \mathcal{E}$ and $g \in \mathcal{C}$ we have

$$\begin{aligned}\lim_{j\to\infty}\lim_{R\to 0}\lim_{n\to\infty}\int_Q \psi(z)g(v_{j,R,n}(z)+v(a))\,dz &= \lim_{R\to 0}\lim_{n\to\infty}\int_Q \psi(z)\, g(v_n(a+Rz))\,dz\\ &= \lim_{R\to 0}\int_Q \psi(z)\langle \nu_{a+Rz}, g\rangle\,dz\\ &= \langle \nu_a, g\rangle \int_Q \psi(z)\,dz.\end{aligned} \tag{3.12}$$

Moreover, as $\{|v_n|^p\}$ is equi-integrable,

$$\begin{aligned}\limsup_{j\to\infty}\limsup_{R\to 0}\limsup_{n\to\infty}\int_Q |v_{j,R,n}(z)+v(a)|^p\,dz &\le \lim_{R\to 0}\lim_{n\to\infty}\int_Q |v_n(a+Rz)|^p\,dz\\ &= \int_{\mathbb{R}^d}|\xi|^p\,d\nu_a(\xi).\end{aligned} \tag{3.13}$$

Also, $v_{j,R,n} \rightharpoonup 0$ in L^p as $n\to\infty$ and $R\to 0$. If $1 < p < +\infty$ we have, in view of the compact imbedding $L^p(T_N) \hookrightarrow W^{-1,p}(T_N)$ and the assumption $\mathcal{A}v_n \to 0$ in $W^{-1,p}(\Omega)$,

$$\lim_{j\to\infty}\lim_{R\to 0}\lim_{n\to\infty}\mathcal{A}v_{j,R,n} = 0 \quad \text{in } W^{-1,p}(T_N). \tag{3.14}$$

If $p = 1$ then

$$v_{j,R,n} \to 0 \text{ in } W^{-1,r}(T_N) \quad \text{for } r \in \left(1, \frac{N}{N-1}\right),$$

and so, due to (3.12), (3.13), (3.14), and by means of a diagonalization procedure, we may find a sequence of functions $\{w_j\}$ with the properties

$$w_j \rightharpoonup 0 \ \text{ in } L^p(T_N), \quad \mathcal{A}w_j \to 0 \quad \text{in } W^{-1,q}(T_N),$$

where $q = p$ if $1 < p < +\infty$ and $q = r$ if $p = 1$, and

$$\begin{aligned}&\lim_{j\to\infty}\int_Q |w_j(x)+v(a)|^p\,dx = \int_{\mathbb{R}^d}|\xi|^p\,d\nu_a(\xi),\\ &\lim_{j\to\infty}\int_Q \psi(x)g(w_j(x)+v(a))\,dx = \langle \nu_a, g\rangle\int_Q \psi(x)\,dx\end{aligned} \tag{3.15}$$

for all $\psi \in \mathcal{E}$ and $g \in \mathcal{C}$. By Lemmas 2.15 and 2.16 and by (3.15) we conclude that ν_a is generated by a p-equi-integrable sequence $\overline{w}_j \in L^p(T_N;\mathbb{R}^d) \cap \ker \mathcal{A}$ such that $\int_{T_N}\overline{w}_j\,dx = v(a)$. Finally, if f is a continuous function such that $|f(z)| \le C(1+|z|^p)$ for some $C > 0$ and all $z \in \mathbb{R}^d$, then $\{f(\overline{w}_j)\}$ is equi-integrable and by Theorem 2.2 (vi) we have

$$\langle \nu_a, f\rangle = \lim_{j\to\infty}\int_{T_N} f(\overline{w}_j)\,dx \ge f(v(a)),$$

where in the last inequality we used the $\mathcal{A}$-quasiconvexity of f together with Remark 3.2 (ii). ∎

Proof of Proposition 3.9. As in the previous proof, let $\mathcal{E}$ and $\mathcal{C}$ be countable dense subsets of $L^1(Q)$ and $C_0(\mathbb{R}^d)$, respectively, and let Ω_0 be the set of points $a \in \Omega$ which are Lebesgue points for $x \mapsto \langle \nu_x, \mathrm{id}\rangle$ and for all functions $x \mapsto \langle \nu_x, g\rangle$, $g \in \mathcal{C}$. Fix $Q' \subset\subset Q$ and consider a smooth cut-off function $\varphi \in C_0^\infty(Q)$, $0 \le \varphi \le 1$, $\varphi = 1$ in Q'.

For $a \in \Omega_0$, $R > 0$, we define

$$v_{R,n}(z) := \varphi(z)\,(v_n(a + Rz) - \langle \nu_a, \mathrm{id}\rangle) + \langle \nu_a, \mathrm{id}\rangle,\ z \in Q.$$

Then $v_{R,n}$ is bounded in $L^\infty(T_N; \mathbb{R}^d)$, and for all $\psi \in \mathcal{E}$ and $g \in \mathcal{C}$ we have

$$\begin{aligned}\lim_{R\to 0}\lim_{n\to\infty}\int_Q \psi(z) g(v_{R,n}(z))\,dz &= \lim_{R\to 0}\lim_{n\to\infty}\int_Q \psi(z)\, g(v_n(a+Rz))\,dz + \mathcal{E}(\psi, g)\\ &= \lim_{R\to 0}\int_Q \psi(z)\langle \nu_{a+Rz}, g\rangle\,dz + \mathcal{E}(\psi, g)\\ &= \langle \nu_a, g\rangle \int_Q \psi(z)\,dz + \mathcal{E}(\psi, g),\end{aligned}$$

where

$$|\mathcal{E}(\psi, g)| \le ||g||_{L^\infty(B(0,3M))}\int_{Q\setminus Q'} |\psi|\,dy.$$

Clearly, $v_n(a + R\cdot) - \langle \nu_a, \mathrm{id}\rangle \overset{*}{\rightharpoonup} 0$ in L^∞ as $n \to \infty$ and $R \to 0$, and

$$\lim_{R\to 0}\lim_{n\to\infty} \mathcal{A}v_{R,n} = 0 \quad \text{weakly-* in } L^\infty(T_N), \quad \sup_{R,n} ||\mathcal{A}v_{R,n}||_{L^\infty(T_N)} < +\infty.$$

Diagonalizing $\{v_{R,n}\}$, and extracting a further subsequence if necessary, we may find a sequence of functions $\{w_j\}$ with the properties

$$w_j \overset{*}{\rightharpoonup} v(a) \text{ in } L^\infty(T_N), \quad \mathcal{A}w_j \overset{*}{\rightharpoonup} 0 \quad \text{in } L^\infty(T_N),$$

and $\{w_j\}$ generates a Young measure μ such that ess supp$\mu_x \subset B(0, 3M)$ and

$$\left|\int_Q \psi(x)\,\langle \mu_x, g\rangle\,dx - \langle \nu_a, g\rangle \int_Q \psi(x)\,dx\right| \le |\mathcal{E}(\psi, g)|$$

for all $g \in \mathcal{C}, \psi \in \mathcal{E}$. By density this inequality extends to all $\psi \in L^1(Q)$, $g \in C_0(\mathbb{R}^d)$. Due to Lemma 2.17 we may find $\overline{w}_j \in L^\infty(T_N; \mathbb{R}^d) \cap \ker \mathcal{A}$ such that $||w_j - \overline{w}_j||_{L^\infty(T_N)} \to 0$, $\int_{T_N} \overline{w}_j\,dy = v(a)$. In particular, $\{\overline{w}_j\}$ generates the Young measure μ satisfying the statement, and if f is continuous, then

$$\begin{aligned}\lim_{j\to+\infty}\int_{T_N} f(\overline{w}_j)\,dx &= \int_{T_N}\langle \mu_x, f\rangle\,dx\\ &\le \langle \nu_a, f\rangle + \mathcal{L}^N(Q\setminus Q')||f||_{L^\infty(B(0,3R))}.\end{aligned} \tag{3.16}$$

On the other hand, since f is $\mathcal{A}$-quasi-convex and in view of Remark 3.3 (ii) we have directly from Definition 3.1

$$\int_{T_N} f(\overline{w}_j)\,dx \ge f(v(a)) \quad \text{for all } j \in \mathbb{N},$$

which, together with (3.16), and letting $\mathcal{L}^N(Q \setminus Q') \to 0$, concludes the proof. ∎

We end this section with some examples of problems involving PDE constraints which fall within the scope of the present study (for further examples, see [37, 41]).

Example 3.10. (a) Gradients and partial gradients.
The case where

$$\mathcal{A}v = 0 \quad \text{if and only if } v = \nabla u$$

for some function $u : \Omega \to \mathbb{R}^m$ was already treated in Remarks 3.3 (iii) and 3.5 (iii). It can be easily seen that this framework still applies when v is not a full gradient but a list of only some of the partial derivatives of u.

(b) Divergence free fields.
For the example where

$$\mathcal{A}v = 0 \quad \text{if and only if } \mathrm{div} v = 0,$$

we refer the reader to Remarks 3.3 (iv) and 3.5 (iv).

(c) Maxwell's equations.
In magnetostatics the *magnetization* $m : \mathbb{R}^3 \to \mathbb{R}^3$ and the *induced magnetic field* $h : \mathbb{R}^3 \to \mathbb{R}^3$ satisfy (in suitable units) the PDE constraints

$$\mathcal{A}\begin{pmatrix} m \\ h \end{pmatrix} := \begin{pmatrix} \mathrm{div} & (m+h) \\ & \mathrm{curl} h \end{pmatrix} = 0.$$

For $w \in S^2$ we have

$$\begin{aligned} \ker \mathbb{A}(w) &= \left\{(a,b) \in \mathbb{R}^3 \times \mathbb{R}^3 : w \cdot (a+b) = 0, w \otimes b - b \otimes w = 0\right\} \\ &= \left\{(a,b) \in \mathbb{R}^3 \times \mathbb{R}^3 : a \cdot w = -\lambda, b = \lambda w \quad \text{for some } \lambda \in \mathbb{R}\right\}, \end{aligned}$$

and so $\dim \ker \mathbb{A}(w) = 3$ and (2.2) is satisfied. Note also that

$$\Lambda = \left\{(a,b) \in \mathbb{R}^3 \times \mathbb{R}^3 : (a+b) \cdot b = 0\right\},$$

and the fact that Λ imposes no restrictions on a has important consequences in micromagnetics (see [16, 27, 45]). For the full system of Maxwell's equations we refer to [41].

(d) Higher gradients.
Obviously all results remain valid if we replace the target space $\mathbb{R}^d$ by an abstract d-dimensional vector space over $\mathbb{R}$. In order to treat the case of second order derivatives, consider the smooth maps $v : T_N \to E_2^m$, where E_k^m stands for the space of symmetric k-linear maps from $\mathbb{R}^N$ into $\mathbb{R}^m$. Define

$$\mathcal{A}_2 v := \left(\frac{\partial}{\partial x_i} v_{jk} - \frac{\partial}{\partial x_k} v_{ji}\right)_{1 \le i,j,k \le N}.$$

We claim that

$$\left\{v \in C^\infty(T_N; E_2^m) : \mathcal{A}v = 0, \int_{T_N} v \, dx = 0\right\} = \{D^2 u : u \in C^\infty(T_N; \mathbb{R}^m)\}.$$

Indeed, if $\mathcal{A}v = 0$ then $v_{jk} = \frac{\partial w_j}{\partial x_k}$, where $w_j \in C^\infty(\Omega; \mathbb{M}^{m \times N})$ has average zero and is periodic due to the periodicity of v and the fact that $\int_{T_N} v \, dx = 0$. By the

symmetry of v_{jk} we have that curl $w = 0$, and we conclude that $v_{jk} = \frac{\partial^2 u}{\partial x_k \partial x_j}$, where $u \in C^\infty(T_N; \mathbb{R}^m)$.

More generally, in order to study the kth order derivatives of functions $u \in C^\infty(T_N; \mathbb{R}^m)$, we set for $v \in C^\infty(T_N; E_k^m)$

$$\mathcal{A}_k v := \left(\frac{\partial}{\partial x_i} v_{i_1 \dots i_h \, j \, i_{h+2} \dots i_k} - \frac{\partial}{\partial x_j} v_{i_1 \dots i_h \, i \, i_{h+2} \dots i_k} \right)_{0 \le h \le k-1,\ 1 \le i,j,i_1,\dots,i_k \le N}.$$

Here $h = 0$ and $h = k-1$ correspond to the multi-indices $ji_2 \dots i_k$ and $i_1 \dots i_{k-1} j$, respectively. The constant rank condition is satisfied since for $w \in S^{N-1}$

$$\begin{aligned} \ker \mathbb{A}(w) = \{ X \in E_k^m : & \, w_i \, X_{i_1 \dots i_h \, j \, i_{h+2} \dots i_k} - w_j \, X_{i_1 \dots i_h \, i \, i_{h+2} \dots i_k} = 0, \\ & 1 \le h \le k,\ 1 \le i,j,i_1,\dots,i_k \le N \} \\ = \{ X \in E_k^m : & \, X = b \otimes w \dots \otimes w,\ b \in \mathbb{R}^m \} \end{aligned}$$

and so $\dim \ker \mathbb{A}(w) = m$. Moreover,

$$\left\{ v \in C^\infty(T_N; E_k^m) : \mathcal{A} v = 0,\ \int_{T_N} v \, dx = 0 \right\} = \{ D^k u : u \in C^\infty(T_N; \mathbb{R}^m) \}.$$

In fact, if $\mathcal{A} v = 0$, then

$$v_{i_1 \dots i_h j i_{h+2} \dots i_k} = \frac{\partial}{\partial x_j} w_{i_1 \dots i_h i_{h+2} \dots i_k}$$

for some smooth function $w_{i_1 \dots i_h i_{h+1} \dots i_k}$ with average zero. The periodicity of v and the fact that $\int_{T_N} v \, dx = 0$ entail the periodicity of w, and the symmetries of v, together with the zero average condition we imposed on w, imply the symmetry of w, so that $w \in C^\infty(T_N; E_{k-1}^m)$. Furthermore, and once again using the symmetries of v,

$$\begin{aligned} \mathcal{A}_{k-1} w := & \left(\frac{\partial}{\partial x_i} w_{i_1 \dots i_h \, j \, i_{h+2} \dots i_{k-1}} - \frac{\partial}{\partial x_j} w_{i_1 \dots i_h \, i \, i_{h+2} \dots i_{k-1}} \right)_{0 \le h \le k-2,\ 1 \le i,j,i_1,\dots,i_k \le N} \\ & = 0. \end{aligned}$$

The argument may now be completed via induction.

(e) Linear elasticity.

In the framework of linear elasticity, one has to deal with the symmetrized gradient, $v = e(u) := \frac{1}{2}(\nabla u + \nabla^T u)$, of the displacement $u : \Omega \to \mathbb{R}^3$, where $\Omega \subset \mathbb{R}^3$ is an open, bounded set. For $1 < p < +\infty$ one can use a local version of Korn's inequality to reduce the study of functionals

$$u \mapsto I(e(u))$$

to that of functionals

$$u \mapsto J(\nabla u), \quad \text{where } J(\xi) := I\left(\frac{1}{2}(\xi + \xi^T) \right)$$

and proceed as in (a). For $p = 1$ or $p = +\infty$ where one must avoid direct manipulation of the gradient, it is possible to adopt the present framework to treat the second-order operator

$$\tilde{\mathcal{A}} v := \left(\sum_{i=1}^N \frac{\partial^2 v_{ij}}{\partial x_i \partial x_k} + \frac{\partial^2 v_{ik}}{\partial x_i \partial x_j} - \frac{\partial^2 v_{ii}}{\partial x_j \partial x_k} - \frac{\partial^2 v_{jk}}{\partial x_i \partial x_i} \right)_{1 \le j,k \le N}.$$

It turns out that $\tilde{\mathcal{A}}v = 0$ if and only if $v_{ij} = \left(\frac{\partial u_j}{\partial x_i} + \frac{\partial u_i}{\partial x_j}\right)/2$ for some function u. In this setting we have

$$\tilde{\mathcal{A}}v = \sum_{i=1}^{N} A^{(ij)} \frac{\partial^2 v}{\partial x_i \partial x_j}, \quad \tilde{\mathbb{A}}(w) := \sum_{i=1}^{N} A^{(ij)} w_i w_j.$$

(f) Pseudodifferential operators.
The examples (a)–(e) may be treated in a unified way using pseudodifferential operators (see also [44, 45]). For (a)–(d), one considers (on T_N or $\mathbb{R}^N$)

$$\mathcal{B}v := (-\Delta)^{-1/2}\mathcal{A}v = \mathcal{R}_i A^{(i)} v,$$

where $\mathcal{R}_i$ denotes the Riesz transform. For (e) we take

$$\tilde{\mathcal{B}}v := (-\Delta)^{-1}\tilde{\mathcal{A}}u = \left(\sum_{i=1}^{N} \mathcal{R}_i\mathcal{R}_k v_{ij} + \mathcal{R}_i\mathcal{R}_j v_{ik} - \mathcal{R}_j\mathcal{R}_k v_{ii} - v_{jk}\right)_{1\le j,k\le N}. \tag{3.17}$$

The symbol of $\mathcal{B}$ is

$$b(\xi) := \frac{\xi_i}{|\xi|} A^{(i)},$$

and the constant rank condition becomes rank $b(\xi) = r$ for all $\xi \neq 0$. Similarly, for (3.17) the symbol takes values in $\mathrm{Lin}(\mathrm{E}_2, \mathrm{E}_2)$ and is given by

$$\tilde{b}(\xi)M := M\xi \otimes \xi + \xi \otimes M\xi - (\xi \otimes \xi)\,\mathrm{tr}M - M.$$

One can easily check that if $|\xi| = 1$, then

$$\ker \tilde{b}(\xi) = \left\{a \otimes \xi + \xi \otimes a : a \in \mathbb{R}^N\right\},$$

which has dimension N. Hence $\tilde{\mathcal{B}}$ satisfies the analogue of (2.2).

4. Characterization of Young measures. The result below is the generalization to the $\mathcal{A}$-free setting of the theorem by Kinderlehrer and Pedregal for the case of gradients [28, 29]. We roughly follow their strategy that relies on the Hahn–Banach separation theorem and the representation of the ($\mathcal{A}$-)quasi-convex envelope (see (3.1) and Proposition 3.4). Tartar [41] has earlier used the Hahn–Banach separation theorem to characterize Young measures in the case without differential constraints. (In a similar vein, Berliocchi and Lasry [11] used the Krein–Milman theorem.) Our presentation closely follows Kristensen's strategy for the case of gradients. We first establish the result for $p = 1$ and then deduce the assertion for $1 < p < +\infty$ by a truncation process. Some of our arguments are similar to those of Sychev [40] who, independently of our work, proposed an alternative approach to gradient Young measures.

THEOREM 4.1. *Let $1 \le p < +\infty$, and let $\{\nu_x\}_{x\in\Omega}$ be a weakly measurable family of probability measures on $\mathbb{R}^d$. There exists a p-equi-integrable sequence $\{v_n\}$ in $L^p(\Omega;\mathbb{R}^d)$ that generates the Young measure ν and satisfies $\mathcal{A}v_n = 0$ in Ω if and only if the following three conditions hold:*

(i) *there exists $v \in L^p(\Omega;\mathbb{R}^d)$ such that $\mathcal{A}v = 0$ and*

$$v(x) = \langle \nu_x, \mathrm{id}\rangle \quad \text{a.e. } x \in \Omega;$$

(ii)

$$\int_\Omega \int_{\mathbb{R}^d} |z|^p \, d\nu_x(z) \, dx < +\infty;$$

(iii) *for* a.e. $x \in \Omega$ *and all continuous functions* g *that satisfy* $|g(v)| \le C(1+|v|^p)$ *for some* $C > 0$ *and all* $v \in \mathbb{R}^d$ *one has*

$$\langle \nu_x, g \rangle \ge Q_{\mathcal{A}} g(\langle \nu_x, \mathrm{id} \rangle).$$

Remark 4.2.

(i) From Lemma 2.15 it follows that if $1 < p < +\infty$ properties (i)–(iii) are still necessary if the condition $\mathcal{A}v_n = 0$ is replaced by the weaker requirement $\mathcal{A}v_n \to 0$ in $W^{-1,p}(\Omega)$.

(ii) In view of Theorem 2.2 (i) it suffices to assume that $\nu_x \ge 0$ a.e. $x \in \Omega$. Condition (iii) then implies $\nu_x(\mathbb{R}^d) = 1$.

(iii) A similar statement is valid for operators with variable coefficients, as long as rank $\mathbb{A}(x, w)$ is constant for all $w \in S^{N-1}$ and a.e. $x \in \Omega$. Such results are, however, more naturally discussed in the context of pseudodifferential constraints and will appear elsewhere. For the quadratic case, see [45].

Proof of Theorem 4.1—Necessity. Necessity of (i) follows immediately from Theorem 2.2 (vi), where v is the weak limit in L^p of the sequence $\{v_n\}$. Property (ii) is deduced from Theorem 2.2 (v) with $f(z) = |z|^p$, and (iii) is a consequence of Proposition 3.8 (and Lemma 2.15 if $1 < p < +\infty$). □

The proof of sufficiency for $1 < p < +\infty$ follows from the case $p = 1$ and Corollary 2.18.

We proceed with the proof in the case of homogeneous $\mathcal{A}$-1-Young measures.

Let $\mathcal{P}$ be the set of probability measures on $\mathbb{R}^d$ and define

$$\mathbb{H} := \{\nu \in \mathcal{P}(\mathbb{R}^d) : \langle \nu, \mathrm{id} \rangle = 0, \text{ there exists an equi-integrable sequence } \{w_j\} \subset L^1(T_N) \cap \ker \mathcal{A} \text{ generating the Young measure } \nu\}.$$

Set

$$E := \left\{ g \in C(\mathbb{R}^d) : \lim_{|z| \to \infty} \frac{g(z)}{1+|z|} \quad \text{exists in } \mathbb{R} \right\}$$

equipped with the norm

$$||g||_E := \sup_{z \in \mathbb{R}^d} \frac{|g(z)|}{1+|z|}.$$

This space is isometrically isomorphic to the space $C(\mathbb{R}^d \cup \{\infty\}) \sim C(S^d)$ of continuous functions on the one-point compactification of $\mathbb{R}^d$, via the map

$$g \mapsto \frac{g(\cdot)}{1+|\cdot|}.$$

In particular, E is a separable Banach space, and its dual E' may be identified with the space of Radon measures on $\mathbb{R}^d \cup \{\infty\}$. Thus if $\nu \in \mathcal{P}$ is such that

$$\int_{\mathbb{R}^d} |z| \, d\nu(z) < +\infty,$$

then $\nu \in E'$ since for all $g \in E$

$$\left| \int_{\mathbb{R}^d} g \, d\nu \right| \leq ||g||_E \int_{\mathbb{R}^d} (1 + |z|) \, d\nu(z).$$

PROPOSITION 4.3. *Let $\nu \in \mathcal{P}(\mathbb{R}^d)$ with $\langle \nu, \mathrm{id} \rangle = 0$. Then $\nu \in \mathbb{H}$ if*

(i)

$$\int_{\mathbb{R}^d} |z| \, d\nu(z) < +\infty;$$

(ii)

$$\langle \nu, g \rangle \geq Q_{\mathcal{A}} g(0)$$

for all $g \in C(\mathbb{R}^d)$ such that $|g(z)| \leq C(1 + |z|)$.

Proof. We follow [28, 29] and use the Hahn–Banach theorem to show that measures satisfying (i) and (ii) cannot be separated from $\mathbb{H}$.

We will prove that $\mathbb{H}$ is convex and relatively closed in $\mathcal{P}$.

Claim 1. $\mathbb{H}$ is convex.

Fix $\nu, \mu \in \mathbb{H}$, $\theta \in (0,1)$. Let $\{v_j\}, \{w_j\} \subset L^1(T_N) \cap \ker \mathcal{A}$ be equi-integrable sequences generating the $\mathcal{A}$-1-Young measures ν and μ, respectively. By means of a mollification, we may take $v_j, w_j \in C^\infty(T_N)$. Also, as

$$\int_{T_N} v_j \, dx, \ \int_{T_N} w_j \, dx \to 0,$$

without loss of generality we may assume that

$$\int_{T_N} v_j \, dx = \int_{T_N} w_j \, dx = 0.$$

Since $v_j, w_j \to 0$ in $W^{-1,p}(T_N)$ for $p < \frac{N}{N-1}$, and as for all $\varphi \in C_0^\infty((0,\theta) \times T_{N-1})$

$$||\mathcal{A}(\varphi(w_j - v_j))||_{W^{-1,p}} = \left|\left| \frac{\partial \varphi}{\partial x_i} A^{(i)}(w_j - v_j) \right|\right|_{W^{-1,p}} \to 0,$$

we may find a sequence $\{\varphi_j\} \subset C_0^\infty((0,\theta) \times T_{N-1})$ such that $\varphi_j \nearrow \chi_{(0,\theta)\times T_{N-1}}$ and

$$||\mathcal{A}(\varphi_j(w_j - v_j))||_{W^{-1,p}} \to 0.$$

Define

$$u_j := v_j + \mathbb{T}\left(\varphi_j(w_j - v_j) - \int_{T_N} \varphi_j(w_j - v_j) \, dy \right).$$

Then $u_j \in L^1(T_N) \cap \ker \mathcal{A}$, $\int_{T_N} \varphi_j(w_j - v_j) \, dy \to 0$, and by Lemma 2.14 (iii),

$$u_j = v_j + \varphi_j(w_j - v_j) + h_j, \quad h_j \to 0 \text{ in } L^p(T_N), \, p < \frac{N}{N-1}.$$

In particular, $\{u_j\}$ is equi-integrable and generates the Young measure $\{\lambda_x\}_{x \in T_N}$ given by

$$\lambda_x = \begin{cases} \nu & \text{if } x_1 \in (0,\theta), \\ \mu & \text{if } x_1 \in (\theta,1). \end{cases}$$

Finally, let

$$\overline{u}_{j,m}(x) := u_j(mx),\ m \in \mathbb{N}.$$

Then $\overline{u}_{j,m} \in C^\infty(T_N) \cap \ker \mathcal{A}$, by periodicity $\sup_{j,m} ||\overline{u}_{j,m}||_{L^1(T_N)} < +\infty$, and due to the equi-integrability of $\{u_j\}$, for all $\psi \in C_0(\mathbb{R}^N)$, $g \in E$, we have

$$\begin{aligned}\lim_{j\to\infty}\lim_{m\to\infty}\int_{\mathbb{R}^N}\psi(x)g(\overline{u}_{j,m}(x))\,dx &= \lim_{j\to\infty}\int_{\mathbb{R}^N}\psi(x)\left(\int_{T_N} g(u_j(y))\,dy\right)dx \\ &= \int_{\mathbb{R}^N}\psi(x)\,dx\,(\theta\langle\nu,g\rangle + (1-\theta)\langle\mu,g\rangle). \qquad (4.1)\end{aligned}$$

Extracting a diagonal subsequence and taking $g = |\cdot|$ in (4.1), by Theorem 2.2 (vi) we conclude that $\theta\nu + (1-\theta)\mu$ is generated by an equi-integrable sequence in $\ker \mathcal{A}$ and thus belongs to $\mathbb{H}$.

Claim 2. $\mathbb{H}$ is relatively closed in $\mathcal{P}$ with respect to the weak-* topology in E', i.e.,

$$\overline{\mathbb{H}}^{E'} \cap \mathcal{P} = \mathbb{H}.$$

Let $\nu \in \overline{\mathbb{H}}^{E'} \cap \mathcal{P}$, let $\{f_i\}_{i\in\mathbb{N}} \subset C^\infty(T_N)$ be dense in $L^1(T_N)$, and let $\{g_j\}_{j\in\mathbb{N}} \subset C_0^\infty(\mathbb{R}^d)$ be dense in $C_0(\mathbb{R}^d)$. We take $f_0 = 1$ and $g_0(z) = |z|$. By definition of weak-* topology in E' there exist $\nu_k \in \mathbb{H}$ such that

$$|\langle \nu - \nu_k, g_j\rangle| < \frac{1}{2k}, \quad j = 0, \dots, k;$$

thus, by virtue of Theorem 2.2 (vi) we may find $w_k \in L^1(T_N) \cap \ker \mathcal{A}$ such that

$$\left|\langle\nu, g_j\rangle \int_{T_N} f_i\,dx - \int_{T_N} f_i g_j(w_k)\,dx\right| < \frac{1}{k}, \quad 0 \le i,j \le k. \qquad (4.2)$$

In particular, setting $i = 0 = j$ we deduce that $\{w_k\}$ is bounded in $L^1(T_N)$ and so (a subsequence) generates a Young measure μ. From (4.2) and the density properties of $\{f_i\}_{i\in\mathbb{N}}$ and $\{g_j\}_{j\in\mathbb{N}}$ it follows that $\mu = \nu$, and the choice $i = 0 = j$ yields

$$\int_{T_N} |w_k|\,dx \to \langle\nu, |\cdot|\rangle.$$

By Theorem 2.2 (vi) we conclude that $\{w_k\}$ is equi-integrable and so $\nu \in \mathbb{H}$. This proves Claim 2.

Consider $\nu \in \mathcal{P}$ such that $\langle\nu, \mathrm{id}\rangle = 0$ and ν satisfies (i), (ii). We want to prove that $\nu \in \mathbb{H}$. Suppose that $\nu \notin \mathbb{H}$. By Claims 1 and 2, $\nu \notin \overline{\mathrm{co}(\mathbb{H})}$ with respect to the weak-* topology of E'. Therefore, by the Hahn–Banach theorem and (ii) there exist $g \in E$, $\alpha \in \mathbb{R}$, such that

$$\langle\mu, g\rangle \ge \alpha \quad \text{for all } \mu \in \mathbb{H}, \qquad Q_{\mathcal{A}}g(0) \le \langle\nu, g\rangle < \alpha. \qquad (4.3)$$

Given $w \in C^\infty(T_N) \cap \ker \mathcal{A}$, with $\int_{T_N} w\,dx = 0$, by Proposition 2.8 we have $\overline{\delta_w} \in \mathbb{H}$ and thus

$$\int_{T_N} g(w)\,dx = \langle\overline{\delta_w}, g\rangle \ge \alpha,$$

which, by Definition 3.1 implies that $Q_{\mathcal{A}}g(0) \geq \alpha$, contradicting (4.3). We conclude that $\nu \in \mathbb{H}$. □

Next we treat the case of inhomogeneous $\mathcal{A}$-1-Young measures.

We define

$$\mathbb{X} := \Bigg\{ \nu : \Omega \to \mathcal{P}(\mathbb{R}^d) : \nu \text{ is weak* measurable,} \int_\Omega \int_{\mathbb{R}^d} |z| d\nu_x(z) dx < +\infty, \langle \nu_x, \mathrm{id} \rangle = 0 \text{ a.e. } x \in \Omega \Bigg\},$$

$$\mathbb{Y} := \Bigg\{ \nu \in \mathbb{X} : \nu \text{is generated by an equi-integrable sequence} \{w_n\} \in L^1(T_N) \cap \ker \mathcal{A} \Bigg\},$$

$$\mathbb{W} := \{ \nu \in \mathbb{X} : \langle \nu_x, g \rangle \geq Q_{\mathcal{A}} g(0) \text{ a.e. } x \in \Omega \text{ and for all } g \in E \},$$

and

$$\mathcal{E} := C(\overline{\Omega}; E) \sim C(\overline{\Omega} \times (\mathbb{R}^d \cup \{\infty\})).$$

Suppose that ν satisfies (i), (ii), and (iii) of Theorem 4.1, and set $\overline{\nu}_x := \Gamma_{-v(x)} \nu_x$. (The translation of a measure was defined in Proposition 2.4.) Clearly $\overline{\nu} \in \mathbb{W}$, and so if $\mathbb{W} \subset \mathbb{Y}$, then ν is generated by an equi-integrable sequence $\{v + w_j\}$ where $\mathcal{A} w_j = 0$. It thus suffices to verify the following assertion.

PROPOSITION 4.4.

$$\mathbb{W} \subset \mathbb{Y}. \tag{4.4}$$

Proof. The strategy to prove (4.4) is as follows.

Step 1. $\overline{\mathbb{Y}}^{\mathcal{E}'} \cap \mathbb{X} = \mathbb{Y}$ in the weak-* topology.

Step 2. It is possible to find a good subset $D \subset \mathbb{W}$ such that $\overline{D}^{\mathcal{E}'} \cap \mathbb{W} = \mathbb{W}$.

Step 3. $D \subset \mathbb{Y}$.

The proof of Step 1 is entirely identical to that of Claim 2 in the proof of Proposition 4.3. For Step 2, we define $\mathcal{G}_k$ to be the family of cubes of the form

$$\left\{ \frac{1}{k}(y + Q) : y \in \mathbb{Z}^N, \frac{1}{k}(y + Q) \subset \Omega \right\},$$

and we set

$$G_k := \cup_{\mathcal{U} \in \mathcal{G}_k} \mathcal{U}.$$

Consider the sets of piecewise homogeneous Young measures

$$\mathbb{W}_k := \left\{ \nu \in \mathbb{W} : \nu_{|\mathcal{U}} \text{ is homogeneous if } \mathcal{U} \in \mathcal{G}_k,\ \nu_{|(\Omega \setminus G_k)} = \delta_0 \right\},$$

and let

$$D := \cup_{k \in \mathbb{N}} \mathbb{W}_k.$$

In order to show that

$$\overline{D}^{\mathcal{E}'} \cap \mathbb{W} = \mathbb{W},$$

let $\nu \in \mathbb{W}$ and define

$$\nu_x^k := \begin{cases} \frac{1}{\mathcal{L}^N(\mathcal{U})} \int_{\mathcal{U}} \nu_y \, dy & \text{if } x \in \mathcal{U},\ \mathcal{U} \in \mathcal{G}_k, \\ \delta_0 & \text{otherwise.} \end{cases}$$

It is clear that $\nu^k \in \mathbb{W}_k$, so it suffices to show that

$$\langle \nu^k, f \rangle \to \langle \nu, f \rangle \qquad \text{for all } f \in \mathcal{E}. \tag{4.5}$$

Fix $f \in \mathcal{E}$, and for each $\mathcal{U} \in \mathcal{G}_k$ denote by $x_{\mathcal{U}} \in \left(\frac{1}{k}\mathbb{Z}\right)^N$ the lower left corner of $\mathcal{U}$ so that $\mathcal{U} = x_{\mathcal{U}} + \frac{1}{k}Q$. Let ω be a modulus of uniform continuity of f, i.e.,

$$\omega(\delta) := \sup\left\{ ||f(x,\cdot) - f(y,\cdot)||_E : \, x, y \in \overline{\Omega},\ |x-y| \le \delta \right\}.$$

We have

$$\begin{aligned} &\left| \int_{\mathcal{U}} \int_{\mathbb{R}^d} f(x,z) \, d\nu_x(z) dx - \int_{\mathcal{U}} \int_{\mathbb{R}^d} f(x,z) \, d\nu_x^k(z) \, dx \right| \\ &\quad \le \left| \int_{\mathcal{U}} \int_{\mathbb{R}^d} f(x_{\mathcal{U}},z) \, d\nu_x(z) \, dx - \int_{\mathcal{U}} \int_{\mathbb{R}^d} f(x_{\mathcal{U}},z) \, d\nu_x^k(z) \, dx \right| \\ &\qquad + \omega\left(\frac{1}{k}\right) ||f||_{\mathcal{E}} \left(\int_{\mathcal{U}} \int_{\mathbb{R}^d} (1+|z|) \, d\nu_x(z) \, dx + \int_{\mathcal{U}} \int_{\mathbb{R}^d} (1+|z|) \, d\nu_x^k(z) \, dx \right) \\ &\quad \le 2\omega\left(\frac{1}{k}\right) ||f||_{\mathcal{E}} \int_{\mathcal{U}} \int_{\mathbb{R}^d} (1+|z|) \, d\nu_x(z) dx. \end{aligned}$$

Therefore,

$$\begin{aligned} |\langle \nu^k, f \rangle - \langle \nu, f \rangle| \le\ & 2\omega\left(\frac{1}{k}\right) ||f||_{\mathcal{E}} \int_{G_k} \int_{\mathbb{R}^d} (1+|z|) \, d\nu_x(z) dx \\ & + 2||f||_{\mathcal{E}} \int_{\Omega \setminus G_k} \int_{\mathbb{R}^d} (1+|z|) \, d\nu_x(z) dx, \end{aligned}$$

and (4.5) follows by letting $k \to \infty$ and using assertion (ii) in Theorem 4.1.

Next, we carry out Step 3 by showing that

$$\mathbb{W}_k \subset \mathbb{Y} \quad \text{for all } k \in \mathbb{N}.$$

Using a rescaling argument, we may assume that $\Omega \subset Q$. Fix $k \in \mathbb{N}$ and let $\mathcal{G}_k = \{Q_i\}_{i=1}^m$ for some $m \in \mathbb{N}$. Fix $\nu \in \mathbb{W}_k$, with $\nu_{|Q_i} = \nu^i$. By Corollary 2.18 for each $i \in \{1, \dots, m\}$ there exists an equi-integrable sequence $\{w_j^i\} \subset L^1(T_N) \cap \ker \mathcal{A}$ generating ν^i. In particular, without loss of generality we may assume that w_j^i are smooth, and that we have

$$w_j^i \rightharpoonup 0 \quad \text{in } L^1(Q_i), \quad w_j^i \to 0 \quad \text{in } W^{-1,p}_{loc}(\mathbb{R}^N)$$

for $p < N/(N-1)$. Hence, we may find smooth cut-off functions $\varphi_j^i \in C_0^\infty(Q_i; [0,1])$ such that $\varphi_j^i \nearrow \chi_{Q_i}$ and

$$\mathcal{A}\left(\sum_{i=1}^m \varphi_j^i w_j^i \right) = \sum_{k=1}^N \sum_{i=1}^m A^{(k)} w_j^i \frac{\partial \varphi_j^i}{\partial x_k} \ \to 0 \quad \text{in } W^{-1,p}(\mathbb{R}^N).$$

Setting

$$u_j := \mathbb{T}\left(w_j - \int_{T_N} w_j\, dy\right), \quad \text{where } w_j := \sum_{i=1}^{m} \varphi_j^i\, w_j^i,$$

then $u_j \in \ker \mathcal{A}$, $\left|\left|u_j - \sum_{i=1}^m \varphi_j^i\, w_j^i\right|\right|_{L^p(\Omega)} \to 0$. In particular $\{u_j\}$ is equi-integrable and it generates ν, so $\nu \in \mathbb{Y}$. □

Example 4.5. (a) Gradients.

Using Remark 3.3 (iii) and Theorem 4.1, we recover the characterization of $W^{1,p}$ gradient Young measures as obtained by Kinderlehrer and Pedregal [28, 29] (see Theorem 2.6).

(b) Divergence-free fields.

It follows from Remarks 3.3 (iv), 3.5 (iv), and Theorem 4.1 that any weakly measurable family of probability measures $\{\nu_x\}_{x\in\Omega}$ satisfying

$$\operatorname{div}(\langle \nu_x, \mathrm{id}\rangle) = 0, \quad \int_\Omega \int_{\mathbb{R}^N} |z|^p\, d\nu_x(z) dx < +\infty,$$

is generated by a p-equi-integrable sequence of divergence-free fields $v_n \in L^p(\Omega; \mathbb{R}^N)$ (see also [35]).

(c) Micromagnetics.

In view of Example 3.10 c), we may apply Theorem 4.1 to the system of Maxwell equations. Moreover, if $1 < p < +\infty$, if ν is an $\mathcal{A}$-p-Young measure, and if we define the projection λ by

$$\lambda_x(U) := \nu_x(U \times \mathbb{R}^3) \quad \text{for any open subset } U \subset \mathbb{R}^3,$$

then supp $\lambda_x \subset S^2$ for a.e.$x \in \Omega$ if and only if ν is generated by a p-equi-integrable sequence $\{\tilde{m}_n, \tilde{h}_n)\} \subset \ker \mathcal{A}$ such that $|\tilde{m}_n(x)| = 1$ for a.e. $x \in \Omega$. Indeed, assuming that λ_x is supported on the unit sphere, let $\{(m_n, h_n)\} \subset \ker \mathcal{A}$ be a p-equi-integrable generating sequence, with $h_n = -\nabla u_n$, $u_n \in W_0^{1,p}(\Omega)$ ($h_n = -\nabla u_n + H_n$ with div $H_n =$ curl $H_n = 0$ if Ω is not simply connected). Consider the projection

$$\pi(x) := \begin{cases} \frac{x}{|x|} & \text{if } x \neq 0, \\ \\ x_0 & \text{if } x = 0, \end{cases}$$

where $x_0 \in S^2$ is fixed, and define $\tilde{m}_n := \pi m_n$. Since $\operatorname{dist}(m_n, S^2) \to 0$ as $n \to \infty$, we have that $\tilde{m}_n - m_n \to 0$ in measure, and, due to the p-equi-integrability, we conclude that $\tilde{m}_n - m_n \to 0$ in L^p. Let $\tilde{h}_n := -\nabla \tilde{u}_n$ ($\tilde{h}_n := -\nabla \tilde{u}_n + H_n$ if Ω is not simply connected), where $\tilde{u}_n \in W_0^{1,p}(\Omega)$ and $\operatorname{div}(\tilde{m}_n - \nabla \tilde{u}_n) = 0$. We have

$$\operatorname{div}((\tilde{m}_n - m_n) - (\nabla \tilde{u}_n - \nabla u_n)) = 0;$$

therefore $\Delta(\tilde{u}_n - u_n) \to 0$ in $W^{-1,p}$, and thus $\tilde{u}_n - u_n \to 0$ in $W^{1,p}$. We conclude that $\{(\tilde{m}_n, \tilde{h}_n)\}$ still generates ν.

ASYMMETRIC MODES IN SYMMETRIC NONLINEAR OPTICAL WAVEGUIDES*

DAVID ARCOYA†, SILVIA CINGOLANI‡, AND JOSÉ L. GÁMEZ†

Abstract. We study a symmetric nonlinear value problem in all $\mathbf{R}$, arising in nonlinear optics from the study of propagation of electromagnetic guided waves through a layered medium with a nonlinear response. By variational arguments, we prove the existence of a positive asymmetric solution of the problem, corresponding to an asymmetric guided wave.

Key words. electromagnetic guided wave, nonlinear eigenvalue problem, asymmetric positive solution

AMS subject classifications. 34B15, 35Q60, 49R05

1. Introduction.

The propagation of electromagnetic guided waves through a medium consisting of three layers of dielectric materials has been studied in several papers; see, for instance, [1, 13, 2]. The ability of such slab geometry to support guided waves depends upon the way in which the refractive index varies across the layers. For example, in the absence of nonlinear effects, the condition for guidance requires that the refractive index in the outer layers be smaller than that in the central region, as one might guess from Snell's law. As discussed in [1, 13], nonlinear effects can be used to obtain guidance properties.

In this paper, we consider the case where the medium is stratified in three layers of homogeneous composition perpendicular to the x-axis. In such a medium we seek solutions of Maxwell's equations corresponding to an electric field which is monochromatic, propagating in the direction z and polarized along the y-axis. A field of this kind is given by $E(x,y,z,t) = u(x)\cos(\beta z - \omega t)e_2$, where $\beta > 0$, e_i denotes the usual basis vector and $u : \mathbb{R} \to \mathbb{R}$. This ansatz leads to a second-order nonlinear eigenvalue problem on the real axis:

$$-\ddot{u}(x) + \beta^2 u(x) = \frac{\omega}{c^2} n^2 \left(x, \frac{1}{2}u^2(x) \right) u(x) \quad \text{for } x \in \mathbb{R},$$

where c is the speed of light in the vacuum and $n^2(x,s)$ is the dielectric function.

The guidance conditions require that all fields decay to zero as $|x| \to +\infty$ and that the total electromagnetic energy for unit length in z is finite in each plane $y \equiv$ const. This amounts to

$$\lim_{|x|\to\infty} u(x) = \lim_{|x|\to\infty} \dot{u}(x) = 0$$

and

$$\int_{\mathbb{R}} u^2(x)\,dx + \int_{\mathbb{R}} \dot{u}^2(x)\,dx < \infty.$$

This problem has been studied for special choices of the dielectric function n^2. In [1], the dielectric function is taken of the form

$$n^2(x,s) = \begin{cases} q^2 + c^2 & \text{if } |x| < d, \\ q^2 + s & \text{if } |x| > d, \end{cases}$$

where $q, c \in \mathbb{R}$ and $d > 0$ denotes the thickness of the internal layer. In such a case the equation can be integrated directly, and taking $\lambda = \beta^2$ as a bifurcation parameter, one can obtain a family of asymmetric solutions bifurcating from the branch of symmetric ones, at a certain value $\lambda = \lambda_0$, yielding the existence of asymmetric bound states for any $\lambda > \lambda_0$. (See also [5, 6] for discussions about stability.)

In a recent work [2], a class of equations which are not explicitly integrable is considered and a perturbative method is applied to yield existence of asymmetric guided waves when the internal layer of the medium is thin.

In this paper, our goal is to show how variational techniques can be applied to prove existence of asymmetric modes without restrictive assumptions on the thickness of the internal layer.

Precisely, we study a differential equation of the type

$$\begin{gathered} -\ddot{u}(x) + (\lambda - c^2 h(x))u(x) = b(x)|u(x)|^{p-2}u(x) \quad \text{for } x \in \mathbb{R}, \\ u \in H^1(\mathbb{R}), \end{gathered} \tag{1.1}$$

where $\lambda > 0$, $p > 2$, and h, b are even functions such that the supports of h and $1 - b$ are compact.

We point out that (1.1) fits into the Akhmediev setting provided that $\lambda = \beta^2$, $p = 4$, $h = \chi$, $b = 1 - \chi$, with $\chi(x)$ being the characteristic function of $(-d, d)$.

Specifically, we seek positive solutions of (1.1), under the following restrictions on $h, b : \mathbb{R} \to \mathbb{R}$:

(H1) h is a bounded function with $h \geq 0$, $h \not\equiv 0$, supp $h \subset [-1, 1]$;

(B1) b is a bounded function with $b(x) = 1$ for $x \notin [-1, 1]$, $b(x) \leq 0$ for $x \in (-1, 1)$.

We remark that, by making a simple change of variables, the role of the interval $[-1, 1]$ in the assumptions (H1) and (B1) can be played by any closed and bounded interval.

Our variational approach consists of minimizing the Euler functional in a suitable C^1-manifold. In order to do this, we need to check the compactness condition of Palais–Smale, which is obtained by following closely the arguments in [8] and [3]. (See also [9, 10].) By testing the levels of the possible symmetric solutions, we infer that for λ sufficiently large, the minimizer is asymmetric. Similar arguments are used in [4] in a different setting.

Precisely, our result is considered in the following theorem.

THEOREM 1.1. *Assume* (H1) *and* (B1). *If* $\lambda > c^2\|h\|_\infty$, *then the problem* (1.1) *has, at least, one asymmetric positive solution.*

The paper is organized as follows: section 2 is devoted to the proof of the Palais–Smale condition. The details of the minimization and the proof that minimizers are asymmetric are given in section 3.

2. The Palais–Smale condition. In order to prove these technical results, we need only assume the following (less restrictive) conditions on h and b:

(H2) h is a bounded function with $h \geq 0$, $\lim_{|x|\to\infty} h(x) = 0$;

(B2) b is a bounded function with $\limsup_{|x|\to\infty} b(x) = 1$.

Since h is a bounded function, the first eigenvalue $\lambda_1(-c^2 h)$ of the weighted eigenvalue problem associated with the Laplacian operator of weight $-c^2 h$ is given by

$$-c^2\|h\|_\infty \leq \lambda_1(-c^2 h) = \inf_{u\neq 0} \frac{\int_{\mathbb{R}} |\dot{u}|^2\,dx - c^2\int_{\mathbb{R}} h(x)|u|^2\,dx}{\int_{\mathbb{R}} u^2\,dx}.$$

Moreover, assume

$$\lambda > -\lambda_1(-c^2 h) \geq 0, \tag{2.1}$$

and set $q(x) := \lambda - c^2 h(x)$; then it is easy to see that

$$\|u\|^2 := \int_{\mathbb{R}} |\dot{u}|^2 + q(x)|u|^2\,dx, \qquad u \in H^1(\mathbb{R})$$

defines a norm on $H^1(\mathbb{R})$ which is equivalent to the usual norm $\|u\|_{H^1}^2 = \int_{\mathbb{R}} \left(|\dot{u}|^2 + |u|^2\right) dx$. Indeed, we can observe that

$$\|u\|^2 \leq \max\{\|q\|_\infty, 1\}\|u\|_{H^1}^2.$$

Otherwise, for k small enough, we get for any $u \in H^1(\mathbb{R})$,

$$\begin{aligned} \|u\|^2 - k\|u\|_{H^1}^2 &= (1-k)\int_{\mathbb{R}} \left(|\dot{u}|^2 - c^2 h u^2\right)\,dx \\ &\quad + \int_{\mathbb{R}} \left(\lambda - k - kc^2 h\right) u^2\,dx \\ &\geq \left[(1-k)\lambda_1(-c^2 h) + \lambda - k - kc^2\|h\|_\infty\right]\int_{\mathbb{R}} u^2\,dx \\ &\geq 0. \end{aligned} \tag{2.2}$$

From (2.2), it is easy to deduce that $\|u\| = 0$ implies $u = 0$. In addition, $\|\cdot\|$ satisfies the other properties of a norm and thus it is a norm equivalent to $\|\cdot\|_{H^1}$.

Let us consider $J : H^1(\mathbb{R}) \to \mathbb{R}$ the Euler functional associated with the problem (1.1), namely,

$$J(u) = \frac{1}{2}\int_{\mathbb{R}} |\dot{u}|^2 + q(x)|u|^2\,dx - \frac{1}{p}\int_{\mathbb{R}} b(x)|u|^p\,dx,\ u \in H^1(\mathbb{R}).$$

We now prove that the Euler functional satisfies the Palais–Smale condition on a certain sublevel. Let us define

$$m(\lambda) := \inf_{u\in H^1(\mathbb{R})\setminus\{0\}} \frac{\int_{\mathbb{R}} |\dot{u}|^2 + \lambda|u|^2}{\left(\int_{\mathbb{R}} |u|^p\right)^{2/p}}. \tag{2.3}$$

LEMMA 2.1. *Assume* (H2), (B2) *and* (2.1). *Then J satisfies the Palais–Smale condition on the sublevel $\Sigma := \{u \in H^1(\mathbb{R}) : J(u) < \frac{p-2}{2p}\, m(\lambda)^{p/(p-2)}\}$; that is, if u_n is a sequence in $H^1(\mathbb{R})$, such that*

(i) $J(u_n) \to c$,
(ii) $J'(u_n) \to 0$,
with $c < L \equiv \frac{p-2}{2p}\, m(\lambda)^{p/(p-2)}$, *then* u_n *admits a convergent subsequence.*

Proof. We follow closely the arguments in [8] and [3]. Let $\{u_n\}$ in $H^1(\mathbb{R})$ such that

$$J(u_n) = c + o(1), \qquad J'(u_n) = o(1) \quad \text{in} \quad H^{-1}, \tag{2.4}$$

as $n \to \infty$, and assume $c < L$. From (2.4), it follows that

$$\frac{p-2}{2p}\, \|u_n\|^2 \le c + |\langle o(1), u_n\rangle|,$$

and thus $\{u_n\}$ is bounded in $H^1(\mathbb{R})$ and, up to a subsequence, $\{u_n\}$ has a weak limit $u \in H^1(\mathbb{R})$. In order to show that $\{u_n\}$ converges to u strongly in $H^1(\mathbb{R})$, it suffices to prove that

$$\|u_n\| \to \|u\| \qquad \text{as} \quad n \to \infty.$$

Now we observe that for any $R > 0$, there results

$$\begin{aligned} \left| \|u_n\|^2 - \|u\|^2 \right| \le & \left| \int_{|x|\le R} \left(|\dot u_n|^2 + q(x)|u_n|^2 \right) - \int_{|x|\le R} \left(|\dot u|^2 + q(x)|u|^2 \right) \right| \\ & + \int_{|x|>R} \left(|\dot u_n|^2 + |q(x)||u_n|^2 \right) + \int_{|x|>R} \left(|\dot u|^2 + |q(x)||u|^2 \right). \end{aligned}$$

Therefore since the Sobolev imbedding is compact on bounded sets, it suffices to show that for any $\delta > 0$ there exists $R > 0$ such that for any $n \ge R$ there results

$$\int_{|x|\ge R} \left(|\dot u_n|^2 + |q(x)||u_n|^2 \right) < \delta$$

and then, by the weak lower semicontinuity of the above integral,

$$\int_{|x|\ge R} \left(|\dot u|^2 + |q(x)||u|^2 \right) < \delta.$$

By contradiction, assume that there exists δ_0 such that for any $R > 0$ there results

$$\int_{|x|\ge R} \left(|\dot u_n|^2 + |q(x)||u_n|^2 \right) \ge \delta_0$$

for some $n = n(R) \ge R$. As a consequence, there exists a subsequence $\{u_{n_k}\}$ such that

$$\int_{|x|\ge k} \left(|\dot u_{n_k}|^2 + |q(x)||u_{n_k}|^2 \right) \ge \delta_0 \tag{2.5}$$

for any $k \in \mathbf{N}$. For any $r > 0$, let us introduce the annulus

$$A_r = \left\{ x \in \mathbb{R} \ : \ r \le |x| \le r + 1 \right\}.$$

CLAIM. *For any $\xi > 0$ and for any $R > 0$ there exists $r > R$ such that*

$$\int_{A_r} \Big(|\nabla u_{n_k}|^2 + |q(x)||u_{n_k}|^2 \Big) < \xi \tag{2.6}$$

for infinitely many $k \in \mathbf{N}$.

By contradiction, assume that for some $\xi_0, R_0 > 0$ and for any integer $m \geq [R_0]$ there exists $\nu(m) \in \mathbf{N}$ such that

$$\int_{A_m} \Big(|\dot{u}_{n_k}|^2 + |q(x)||u_{n_k}|^2 \Big) \geq \xi_0$$

for any $k \geq \nu(m)$. Plainly, we can assume that the sequence $\{\nu(m)\}$ is nondecreasing. Therefore, for any integer $\overline{m} \geq [R_0]$, there exists an integer $\nu(\overline{m})$ such that

$$\begin{aligned} \int_{\mathbb{R}} \Big(|\dot{u}_{n_k}|^2 + |q(x)||u_{n_k}|^2 \Big) &\geq \int_{[R_0] \leq |x| \leq \overline{m}} \Big(|\dot{u}_{n_k}|^2 + |q(x)||u_{n_k}|^2 \Big) \\ &\geq (\overline{m} - [R_0])\xi_0 \end{aligned}$$

for any $k \geq \nu(\overline{m})$. This contradicts

$$\begin{aligned} \int_{\mathbb{R}} \Big(|\dot{u}_{n_k}|^2 + |q(x)||u_{n_k}|^2 \Big) &\leq \max\{1, \|q\|_\infty\} \int_{\mathbb{R}} \Big(|\dot{u}_{n_k}|^2 + |u_{n_k}|^2 \Big) \\ &\leq K \int_{\mathbb{R}} \Big(|\dot{u}_{n_k}|^2 + q(x)|u_{n_k}|^2 \Big) \leq K_1 \end{aligned}$$

with K, K_1 positive constants, and it proves the claim.

Now, let $\xi > 0$ be fixed such that $\lambda - \xi > \frac{\lambda}{2} > 0$. Taking into account (H2) and (B2), there exists $R(\xi) > 0$ such that

$$q(x) \geq \lambda - \xi \quad \text{for any } |x| \geq R(\xi), \tag{2.7}$$

$$b(x) \leq 1 + \xi \quad \text{for any } |x| \geq R(\xi). \tag{2.8}$$

Let $r = r(\xi) > R(\xi)$ be as in (2.6), and let $A = A_r$; up to a subsequence, there results

$$\int_A \Big(|\dot{u}_{n_k}|^2 + q(x)|u_{n_k}|^2 \Big) < \xi \tag{2.9}$$

for any $k \in \mathbf{N}$. Now let us choose any function $\rho \in C^\infty(\mathbb{R}, [0,1])$ such that $\rho(x) = 1$ for $|x| \leq r$, $\rho(x) = 0$ for $|x| \geq r + 1$, and $|\dot{\rho}(x)| \leq 2$ for any $x \in \mathbb{R}$. For any $k \in \mathbf{N}$, let $v_k = \rho u_{n_k}$ and $w_k = (1 - \rho)u_{n_k}$. It is not difficult to see that

$$|\langle J'(u_{n_k}), v_k \rangle - \langle J'(v_k), v_k \rangle| \leq C_1 \xi, \tag{2.10}$$

$$|\langle J'(u_{n_k}), w_k \rangle - \langle J'(w_k), w_k \rangle| \leq C_2 \xi, \tag{2.11}$$

where C_1 and C_2 are positive constants which do not depend on r. First, we prove (2.10):

$$\Big| \langle J'(u_{n_k}), v_k \rangle - \langle J'(v_k), v_k \rangle \Big|$$

$$
\begin{aligned}
&= \Big| \int_{\mathbb{R}} \big(\dot{w}_k \dot{v}_k + q(x) w_k v_k\big) + \int_{\mathbb{R}} b(x) \big(|v_k|^p - |u_{n_k}|^{p-1} v_k\big) \Big| \\
&= \Big| \int_A \rho(1-\rho)\big(|\dot{u}_{n_k}|^2 + q(x)|u_{n_k}|^2\big) + \int_A \dot{\rho}(1-2\rho) u_{n_k} \dot{u}_{n_k} \\
&\quad - \int_A \dot{\rho}^2 |u_{n_k}|^2 + \int_A b(x)\rho(\rho^{p-1}-1)|u_{n_k}|^p \Big| \\
&\le 2\int_A \big(|\dot{u}_{n_k}|^2 + q(x)|u_{n_k}|^2\big) + 6\int_A |\dot{u}_{n_k} u_{n_k}| + 4\int_A |u_{n_k}|^2 \\
&\quad + 2\|b\|_\infty \|u_{n_k}\|_\infty^{p-2} \int_A |u_{n_k}|^2 \le 2\int_A \big(|\dot{u}_{n_k}|^2 + q(x)|u_{n_k}|^2\big) \\
&\quad + 6\left(\int_A |\dot{u}_{n_k}|^2\right)^{1/2} \left(\int_A |u_{n_k}|^2\right)^{1/2} + M\int_A |u_{n_k}|^2 \\
&\le 2\int_A \big(|\dot{u}_{n_k}|^2 + q(x)|u_{n_k}|^2\big) \\
&\quad + 6\left(\int_A |\dot{u}_{n_k}|^2 + q(x)|u_{n_k}|^2\right)^{1/2} \left(\int_A |u_{n_k}|^2\right)^{1/2} + M\int_A |u_{n_k}|^2.
\end{aligned}
$$

By (2.7) and (2.9), we infer

$$(\lambda - \xi)\int_A |u_{n_k}|^2 \le \int_A q(x)|u_{n_k}|^2 < \xi,$$

and thus

$$\int_A |u_{n_k}|^2 < \frac{\xi}{(\lambda-\xi)} < \frac{2\xi}{\lambda}.$$

Hence we deduce that

$$\Big|\langle J'(u_{n_k}), v_k\rangle - \langle J'(v_k), v_k\rangle\Big| < 2\xi + 6\xi^{1/2}\left(\frac{\xi}{\lambda}\right)^{1/2} + 2M\frac{\xi}{\lambda} \le C_1\xi.$$

Similar arguments show that (2.11) holds. By (2.10) and (2.11), we deduce

$$o(1) = \langle J'(v_k), v_k\rangle + O(\xi), \qquad o(1) = \langle J'(w_k), w_k\rangle + O(\xi),$$

whence

$$\|v_k\|^2 = \int_{\mathbb{R}} b(x)|v_k|^p + O(\xi), \tag{2.12}$$

$$\|w_k\|^2 = \int_{\mathbb{R}} b(x)|w_k|^p + O(\xi). \tag{2.13}$$

By (2.7) and (2.13), we deduce

$$
\begin{aligned}
c + o(1) &= J(u_{n_k}) = J(v_k) + J(w_k) + O(\xi) \\
&\ge \frac{p-2}{2p}\int_{\mathbb{R}} \Big(|\dot{w}_k|^2 + \lambda|w_k|^2\Big) + O(\xi).
\end{aligned} \tag{2.14}
$$

By (2.5) and (2.8), we infer

$$\begin{aligned}\int_{\mathbb{R}} |w_k|^p &\geq \int_{\mathbb{R}} b(x)|w_k|^p + O(\xi) = \|w_k\|^2 + O(\xi)\\ &\geq \int_{|x|\geq r+1} \Big(|\dot{w}_k|^2 + q(x)|w_k|^2\Big) + O(\xi) \geq \frac{1}{2}\delta_0\end{aligned}$$

for ξ small and k large. Hence for ξ small,

$$\begin{aligned}\int_{\mathbb{R}} \Big(|\dot{w}_k|^2 + \lambda|w_k|^2\Big) &\geq m(\lambda)\Big(\int_{\mathbb{R}} |w_k|^p\Big)^{2/p}\\ &\geq m(\lambda)\Big(\int_{\mathbb{R}} \Big(|\dot{w}_k|^2 + \lambda|w_k|^2\Big) + O(\xi)\Big)^{2/p},\end{aligned}$$

and thus

$$\int_{\mathbb{R}} \Big(|\dot{w}_k|^2 + \lambda|w_k|^2\Big) \geq m(\lambda)^{p/(p-2)} + \frac{O(\xi)}{\Big(\int_{\mathbb{R}} |\dot{w}_k|^2 + \lambda|w_k|^2\Big)^{2/(p-2)}}.$$

Hence from (2.14), we infer

$$c + o(1) \geq \frac{p-2}{2p}\, m(\lambda)^{p/(p-2)} + O(\xi)$$

for ξ small and k large. Letting $k \to \infty$ and $\xi \to 0$ yields a contradiction and concludes the proof. □

3. Existence of asymmetric solution. Let us consider the C^1-manifold

$$M = \left\{ u \in H^1(\mathbb{R}) \,:\, \int_{\mathbb{R}} b(x)|u|^p\, dx = 1 \right\}.$$

As $J(u) = \frac{1}{2}\|u\|^2 - \frac{1}{p}$, for any $u \in M$, the minimization of $J_{|_M}$ is equivalent to the minimization of the functional $I : M \to \mathbb{R}$ defined by

$$I(u) = \|u\|^2, \quad u \in M.$$

LEMMA 3.1. *Assume* (2.1). *Then we have the following.*

(i) *M is a closed C^1-manifold of codimension one.*

(ii) *For any $v \in H^1(\mathbb{R})$ satisfying $\int_{\mathbb{R}} b(x)|v|^p\, dx \neq 0$, there exists a unique $\alpha > 0$ such that $\alpha v \in M$. Indeed,*

$$\alpha = \left(\int_{\mathbb{R}} b(x)|v|^p\, dx\right)^{-1/p} \quad \text{and} \quad I(\alpha v) = \frac{\|v\|^2}{\big(\int_{\mathbb{R}} b(x)|v|^p\, dx\big)^{2/p}}.$$

Proof. (i) Let $f(u) = \int_{\mathbb{R}} b(x)|u|^p\, dx$, $u \in H^1(\mathbb{R})$. Observe that for any $u \in M$, $f(u) = 1$; hence

$$\langle f'(u), u\rangle = -p \int_{\mathbb{R}} b(x)|u|^p\, dx = -p. \tag{3.1}$$

As a consequence, $f'(u) \neq 0$ if $u \in M$. This means that M is a C^1-manifold of codimension one. Trivially, it is closed by the continuity of the map $u \mapsto \int_{\mathbb{R}} b(x)|u|^p\, dx$.

(ii) Straightforward computations show this part. □

LEMMA 3.2. *Assume* (H1), (B1), *and* (2.1). *Then*

$$\inf_{v\in M} I(v) < m(\lambda).$$

Proof. By [12, Theorem 5.5], it is known that the infimum in (2.3) is attained at a symmetric function $z \in H^1(\mathbb{R})$ which is a solution of the problem

$$\begin{gathered} -\ddot{u}(x) + \lambda u(x) = |u(x)|^{p-2}u(x) \quad \text{for } x \in \mathbb{R}, \\ \lim_{|x|\to\infty} u(x) = 0. \end{gathered}$$

In addition, by [7, 11], such a function is unique and it is given by

$$z(x) = \left[\frac{p\lambda}{2\cosh^2(\frac{p-2}{2}\sqrt{\lambda}x)}\right]^{1/(p-2)}, \quad x \in \mathbb{R}.$$

For $\theta \in \mathbb{R}$, take the translate $z_\theta = z(\cdot + \theta)$ and consider, by (ii) of the preceding lemma, the positive number α_θ such that $\alpha_\theta z_\theta \in M$. The proof would be concluded if we show that $I(\alpha_\theta z_\theta) < m(\lambda)$ for some θ. In order to verify this, observe that from hypotheses (H1) and (B1), the existence of the positive limit of the function $z(x)e^{\sqrt{\lambda}x}$ as $x \to +\infty$ implies that for large θ,

$$\int_{\mathbb{R}} h(x)z_\theta^2 dx \geq C_1 e^{-2\sqrt{\lambda}\theta} \quad \text{and} \quad \int_{\mathbb{R}} (1-b(x))|z_\theta|^p dx \leq C_2 e^{-p\sqrt{\lambda}\theta}$$

for some positive constants C_1 and C_2. Then,

$$\begin{aligned} I(\alpha_\theta z_\theta) &= \frac{\displaystyle\int_{\mathbb{R}} (|\dot{z}|^2 + \lambda z^2)\,dx - c^2 \int_{\mathbb{R}} h(x) z_\theta^2\,dx}{\displaystyle\left[\int_{\mathbb{R}} |z|^p\,dx - \int_{\mathbb{R}} (1-b(x))|z_\theta|^p\,dx\right]^{2/p}} \\ &\leq \frac{\displaystyle\int_{\mathbb{R}} (|\dot{z}|^2 + \lambda z^2)\,dx - c^2 C_1 e^{-2\sqrt{\lambda}\theta}}{\displaystyle\left[\int_{\mathbb{R}} |z|^p\,dx - C_2 e^{-p\sqrt{\lambda}\theta}\right]^{2/p}} \\ &= \frac{\displaystyle\int_{\mathbb{R}} (|\dot{z}|^2 + \lambda z^2)\,dx}{\displaystyle\left[\int_{\mathbb{R}} |z|^p\,dx\right]^{2/p}} \; \frac{1 - C_3 e^{-2\sqrt{\lambda}\theta}}{\left(1 - C_4 e^{-p\sqrt{\lambda}\theta}\right)^{2/p}} \\ &= m(\lambda)\; \frac{1 - C_3 e^{-2\sqrt{\lambda}\theta}}{\left(1 - C_4 e^{-p\sqrt{\lambda}\theta}\right)^{2/p}}. \end{aligned}$$

Since $p > 2$, for large values of θ, one has $(1 - C_3 e^{-2\sqrt{\lambda}\theta})/(1 - C_4 e^{-p\sqrt{\lambda}\theta})^{2/p} < 1$ and consequently, $I(\alpha_\theta z_\theta) < m(\lambda)$. □

Now we are ready to prove Theorem 1.1.

Proof of Theorem 1.1. The solution of (1.1) is found as a minimizer of I constrained on M (up to a Lagrangian multiplier). In order to prove the existence of such a minimizer, and taking into account Lemmas 3.1 and 3.2, it suffices to show that I satisfies the Palais–Smale condition on the sublevel $M_\lambda := \{u \in M : I(u) < m(\lambda)\}$, that is, if $\{u_n\}$ is a sequence in M, such that

(a) $I(u_n) \to c$,
(b) $|I'(u_n)(v)| \le \varepsilon_n \|v\|$ for any $v \in T_{u_n}M$, with $\varepsilon_n \to 0$,
with $c < m(\lambda)$, then $\{u_n\}$ admits a convergent subsequence. Indeed, by (b), it follows that there exists a sequence $\{\theta_n\} \subset \mathbb{R}$ such that for any $n \in \mathbf{N}$

$$-\triangle u_n + q(x)u_n - \theta_n b(x)|u_n|^{p-2}u_n = o(1) \quad \text{in} \quad H^{-1}.$$

Testing the previous equation in u_n gives

$$\theta_n = I(u_n) - \langle o(1), u_n \rangle.$$

Therefore, setting $v_n(x) = I(u_n)^{1/(p-2)}\ u_n$, we plainly get

$$J'(v_n) = I(u_n)^{1/(p-2)} o(1) = o(1) \quad \text{in} \quad H^{-1}.$$

Moreover there results

$$J(v_n) = \frac{p-2}{2p} I(u_n)^{p/(p-2)} = c' + o(1)$$

with $c' < \frac{p-2}{2p} m(\lambda)^{p/(p-2)}$. Therefore, by Lemma 2.1, it follows that $\{v_n\}$ is precompact, and thus, taking into account (a), $\{u_n\}$ is precompact and the Palais–Smale condition holds.

Therefore, if v is a minimizer of $I_{|_M}$, setting $\overline{u} = I(v)^{1/(p-2)}v$, it results that $\overline{u}$ is a solution of (1.1). Moreover $J(\overline{u}) = J\big(I(v)^{1/(p-2)}v\big) < \frac{p-2}{2p} m(\lambda)^{p/(p-2)}$.

Therefore, the proof would be concluded if we show that $\overline{u}$ is not symmetric for $\lambda > c^2\|h\|_\infty$. This is a consequence of the fact that every possible symmetric positive solution u of (1.1) must have a level greater than $\frac{p-2}{2p}\, m(\lambda)^{p/(p-2)}$. Indeed, since $b(x) \le 0$ for any $x \in (-1,1)$, for such u,

$$-\ddot{u}(x) + (\lambda - c^2 h(x))u(x) \le 0 \quad \text{for } x \in (-1,1).$$

Hence, since $\lambda > c^2\|h\|_\infty$, we get $\ddot{u}(x) \ge (\lambda - c^2h(x))u(x) \ge 0$ for any $x \in (-1,1)$. Then u is convex in $(-1,1)$, and thus $\max\{u(x) : x \in [-1,1]\} = u(-1) = u(1)$, with $\dot{u}(1) > 0$, by the Hopf lemma. This means that the maximum of u in all $\mathbb{R}$ is attained in some point $x_0 \in \mathbb{R} - [-1,1]$.

Now, observing that supp $h \subset [-1,1]$, we obtain $-\ddot{u}(x) + \lambda u(x) = u(x)^{p-1}$, for $|x| > 1$, which together with the fact $\dot{u}(\pm x_0) = 0$ implies that

$$u(x) = z(|x| - x_0) \quad \text{for any } |x| \ge x_0.$$

As a consequence, since $\lambda > c^2\|h\|_\infty$, and $-\ddot{z} + \lambda z = z^{p-1}$, we obtain

$$\begin{aligned}
\frac{2p}{p-2}\ J(u) &= \int_{\mathbb{R}} \left[|\dot{u}|^2 + (\lambda - c^2h)u^2\right] dx \\
&\ge \int_{\mathbb{R}\setminus[-x_0,x_0]} \left[|\dot{u}|^2 + (\lambda - c^2h)u^2\right] dx \\
&= \int_{\mathbb{R}\setminus[-x_0,x_0]} |\dot{u}|^2 + \lambda u^2\, dx \\
&= \int_{\mathbb{R}} |\dot{z}|^2 + \lambda z^2\, dx
\end{aligned}$$

$$
\begin{aligned}
&= \left[\frac{\int_{\mathbb{R}} |\dot{z}|^2 + \lambda z^2 \, dx}{\left(\int_{\mathbb{R}} |\dot{z}|^2 + \lambda z^2 \, dx \right)^{2/p}} \right]^{p/(p-2)} \\
&\geq \left[\frac{\int_{\mathbb{R}} |\dot{z}|^2 + q(x)|z|^2 \, dx}{\left(\int_{\mathbb{R}} |z|^p \, dx \right)^{2/p}} \right]^{p/(p-2)} \\
&= m(\lambda)^{p/(p-2)},
\end{aligned}
$$

which concludes the proof. □
