THERE ARE ASYMMETRIC MINIMIZERS FOR THE ONE-DIMENSIONAL GINZBURG–LANDAU MODEL OF SUPERCONDUCTIVITY*

STUART P. HASTINGS† AND WILLIAM C. TROY†

Abstract. We study a boundary value problem associated with a system of two second-order differential equations with cubic nonlinearity which model a film of superconductor material subjected to a tangential magnetic field. We show that for an appropriate range of parameters there are *asymmetric* solutions and only trivial *symmetric* solutions. We then correct an error of the authors in [*Nonlinear Problems in Applied Mathematics*, SIAM, Philadelphia, PA, 1996, pp. 150–158] and show that the associated energy function is negative for the asymmetric solutions. Since the energy is zero for the trivial symmetric solution, it follows that a global minimizer of the energy is asymmetric. This property resolves a conjecture of Marcus [*Rev. Mod. Phys.*, 36 (1964), pp. 294–299].

1. Introduction.

In this paper we continue our recent studies [9], [10] of the one-dimensional Ginzburg–Landau model [8] for superconductors. Our main objective is to investigate the model for the existence of asymmetric minimizers of the appropriate energy integral. It is expected that the physically interesting solutions will be energy minimizers. These solutions satisfy a symmetric boundary value problem which was known to have a set of symmetric solutions. We will show, however, that in one space dimension, for some parameter values, the energy minimizer is an asymmetric solution to this symmetric boundary value problem.

The problem may be compared to studies in two dimensions, where the symmetry of the energy minimizer is unresolved. Recent papers on this include [12] and [14]. Work in two dimensions has largely dealt with a reduced problem in which variations in the magnetic field are ignored. In contrast, it is possible to include the magnetic field as a variable in the analysis of the one-dimensional model.

In order to properly describe our results we first need to give a brief development of the problem as well as a summary of our previous investigations.

In 1950 Ginzburg and Landau [8] proposed a model for the electromagnetic properties of a film of superconducting material of width d subjected to a tangential external magnetic field. Under the assumption that all quantities are functions only of the transverse coordinate, they proposed that the electromagnetic properties of the superconducting material are described by a pair $(\tilde{\phi}, \tilde{a})$, which minimizes the free energy functional

$$\mathcal{G} = \frac{1}{d}\int_{-d/2}^{d/2}\left(\tilde{\phi}^2(\tilde{\phi}^2-2) + \frac{2(\tilde{\phi}')^2}{k^2} + 2\tilde{\phi}^2\tilde{a}^2 + 2(\tilde{a}'-h_e)^2\right)dx. \tag{1.1}$$

The functional $\mathcal{G}$ is now known as the Ginzburg–Landau energy and provides a measure of the difference between normal and superconducting states of the material.

The variable $\tilde{\phi}$ is the order parameter which measures the density of superconducting electrons, and $\tilde{a}$ is the magnetic field potential. Also, h_e is the external magnetic field, and k is the dimensionless material constant distinguishing different superconductors, i.e., $0 < k < \frac{1}{\sqrt{2}}$ for type I superconductors and $k > \frac{1}{\sqrt{2}}$ for type II superconductors (see also [7]). The minimizer requirement, that $\mathcal{G}$ be stationary with respect to general first-order variations of the functions $\tilde{\phi}$ and $\tilde{a}$, leads to the boundary value problem

$$\tilde{\phi}'' = k^2\tilde{\phi}(\tilde{\phi}^2 + \tilde{a}^2 - 1), \tag{1.2}$$

$$\tilde{a}'' = \tilde{\phi}^2\tilde{a}, \tag{1.3}$$

$$\tilde{\phi}'\Big(\pm\frac{d}{2}\Big) = 0, \qquad \tilde{a}'\Big(\pm\frac{d}{2}\Big) = h_e. \tag{1.4}$$

It is routine to prove that $\mathcal{G}$ has a smooth minimizer satisfying (1.2)–(1.4) for any positive h_e. In 1964 Marcus [13] investigated the problem (1.2)–(1.4) and gave arguments which imply that a nontrivial minimizer of $\mathcal{G}$ should also satisfy

$$\tilde{\phi}(x) > 0 \quad \text{for all} \quad x \in \left[-\frac{d}{2}, \frac{d}{2}\right], \tag{1.5}$$

and, therefore, this is the only kind of solution we consider. A solution of (1.2)–(1.3) is called symmetric if

$$\tilde{\phi}'(0) = 0 \quad \text{and} \quad \tilde{a}(0) = 0. \tag{1.6}$$

It follows from (1.2) and (1.3) that if $\tilde{\phi}'(0) = \tilde{a}(0) = 0$, then $\tilde{\phi}$ is an even function and $\tilde{a}$ is odd. Thus $\tilde{\phi}$ is symmetric with respect to the origin and $\tilde{a}$ is antisymmetric. If (1.6) does not hold, then the solution is called asymmetric. Marcus makes the conjecture that a minimizer of $\mathcal{G}$ is probably a symmetric solution satisfying (1.2)–(1.6). However, he leaves open the possibility that asymmetric solutions may also exist.

In later work, Odeh [15] gave criteria for asymmetric solutions to exist by bifurcation as h_e increases, and in [2], [3], [4], [5], Bolley and Helffer give results implying that these criteria are satisfied for each $k > 0$. The existence of at least one symmetric solution has been investigated by Odeh [15], Wang and Yang [18], Yang [19], and also Bolley and Helffer [2], [3], [4], [5]. Numerical studies, such as the work of Seydel [16], [17] and also more recent theoretical work of Kwong [11], predict that a range of parameters exists for which asymmetric solutions and multiple symmetric solutions coexist. The work of Seydel [16] also predicts that there is a range of parameters for which no nontrivial symmetric solutions exist, yet asymmetric solutions do exist. In Figure 1 we show a solution found by Seydel. (The solution is rescaled from (1.2)–(1.4) by dividing $\tilde{\phi}$ through by $\tilde{\phi}(0)$.) Other papers, such as [6], considered the problem on an infinite interval, whereas in our work, the interval is large but finite. None of these studies addressed the physically important criterion of whether the solutions of the problem (1.2)–(1.5) are actually global minimizers of the energy functional $\mathcal{G}$. However, a recent paper by Aftalion [1] does discuss this problem and includes a conjecture that asymmetric solutions can have a lower energy than the symmetric solutions. This is confirmed in the current paper.

In two recent papers [9], [10] we began our investigation of the problem (1.2)–(1.5) with the goal of proving the existence of solutions predicted by the numerical studies

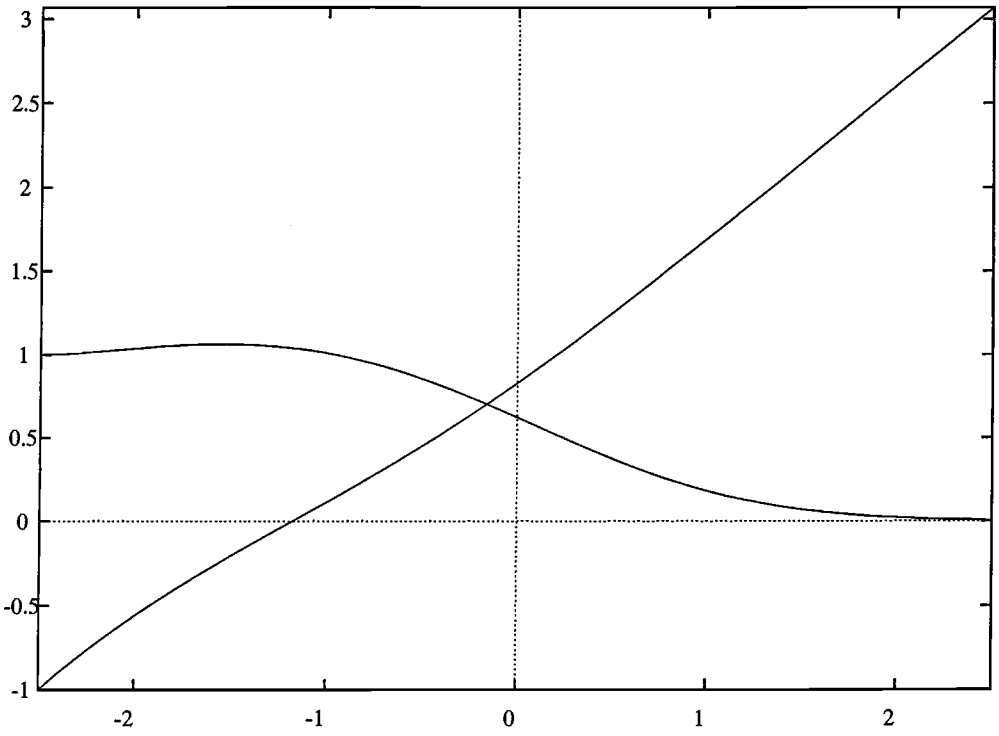

FIG. 1. *An asymmetric solution, showing* $\tilde{\phi}/\tilde{\phi}(0)$ *and* a*, found by Seydel. Here* $k = 1$.

described above. First, we studied the existence of multiple symmetric solutions and proved the following result.

THEOREM 1 (see [10]). (i) *Let* $k \in (0, \frac{1}{\sqrt{2}})$. *If* $d > 0$ *is sufficiently large, there is a range of values of* h_e *for which at least two symmetric solutions exist.*

(ii) *Let* $k > \frac{1}{\sqrt{2}}$. *If* $d > 0$ *is sufficiently large, there is a range of values of* h_e *for which at least three symmetric solutions exist.*

Remark. In related studies, Bolley and Helffer [2], [3], [4], [5] have investigated other properties of symmetric solutions, including bifurcation analysis and the uniqueness of solutions. Their analysis assumes that k tends to zero, whereas our results assume that $k > 0$ is fixed and d becomes large.

In [9] we shifted our attention from the symmetric solutions found in [10] to the study of asymmetric solutions. As mentioned above, the numerical experiments of Seydel (in particular, see Figure 6.10 in [16]) predict that there is a range of parameters in which there are no nontrivial symmetric solutions, yet asymmetric solutions do exist. This leaves open the possibility that in this parameter range the minimizer of $\mathcal{G}$ could be an asymmetric solution. Thus, our goal in [9] was to prove that there is a range of parameters in which only asymmetric solutions exist, and that the energy $\mathcal{G}$ is minimized by such solutions. The first step in proving this result is to find an upper bound on the values of h_e for which a symmetric solution exists. Thus, for fixed $k > 0$ and $d > 0$, we let h_e^* denote the supremum of the set of all positive h_e for which a *nontrivial* symmetric solution exists. Since we are assuming that $d \gg 1$ we define $h_e^{sym} = \overline{\lim}_{d\to\infty} h_e^*$.

In [9] we proved that if $k \geq \frac{1}{\sqrt{2.01}}$, then $h_e^{sym} < \sqrt{3}k$.

Unfortunately, a rescaling error led us to assert that this inequality was sufficient to prove that there are asymmetric minimizers. It turns out that we need a stronger estimate. We shall show below that the inequality

$$h_e^{sym} < 1.68k \tag{1.7}$$

suffices. This is obtained by a routine but tedious refinement of the proof in [9]. We shall not repeat that proof here. However, in the appendix we describe the changes which must be made in [9] to obtain (1.7). We add that the proof of (1.7) is considerably easier for large k. The proof for this case is in [9]. However, we want to include values in the range of type I superconductors, and this is more difficult.

Statement of main results. In this paper we will make use of (1.7) in proving that $\mathcal{G}$ has an asymmetric minimizer. We prove two main results. First, we fix $k \geq \frac{1}{\sqrt{2.01}}$ so that both type I and type II superconductors are included. There is no claim that this is a "best possible" estimate. It would be interesting to study the transition from asymmetric to symmetric minimizers as k decreases within the type I region. Then, in Theorem 2, we consider large d and prove that there exists a family of small amplitude asymmetric solutions of the problem (1.2)–(1.5). We will also prove that $\frac{h_e}{k} \geq 1.6831$ for large d, for each of the asymmetric solutions found in Theorem 2. This and (1.7) confirm the numerical prediction of Seydel in [16], that there is a parameter regime in which there are asymmetric solutions and only trivial symmetric solutions.

The work of Bolley and Helffer includes results which imply the existence of asymmetric solutions. The proofs, which must be pieced together from several papers, are by bifurcation theory, and do not appear to give the estimate of h_e which we obtain and which is essential in our discussion of whether these asymmetric solutions are energy minimizers.

The proof of Theorem 2 is given in section 2. Next, in Theorem 3 (proved in sections 3 and 4) we show that the energy is negative for the asymmetric solutions found in Theorem 2. This will allow us to prove that for large d a global minimizer of $\mathcal{G}$ must be asymmetric.

In addition to showing that asymmetric solutions exist and have small amplitude, we will prove that each of these has exactly one critical point (a relative maximum) in the open interval $(-\frac{d}{2}, \frac{d}{2})$ and that the relative maximum occurs at a value close to $-\frac{d}{2}$. Because of these properties, we find it convenient to rescale the problem. We introduce parameters r, h, m, and M and a new independent variable t by setting

$$r = \frac{1}{k^2},\ h = \frac{h_e}{k},\ m + M = kd,\ x = \frac{d}{2(m+M)}(2t + m - M). \tag{1.8}$$

Next, we define new dependent variables ψ and A by

$$\tilde{\phi}(x) = \beta\psi(t) \quad \text{and} \quad \tilde{a}(x) = A(t), \tag{1.9}$$

where $\beta = \tilde{\phi}(0)$. Then (1.1)–(1.5) become

$$\mathcal{G} = \frac{2\beta^2}{(m+M)} \int_{-m}^{M} \left(\psi^2 \left(\frac{\beta^2\psi^2}{2} - 1 + A^2 \right) + (\psi')^2 + \frac{1}{r\beta^2}(A' - h)^2 \right) dt, \tag{1.10}$$

$$\psi'' = \psi(\beta^2\psi^2 + A^2 - 1), \tag{1.11}$$

$$A'' = r\beta^2\psi^2 A, \tag{1.12}$$

$$\psi'(-m) = \psi'(M) = 0, A'(-m) = A'(M) = h > 0, \tag{1.13}$$

and

$$\psi > 0 \quad \text{in} \quad [-m, M]. \tag{1.14}$$

We now state our existence result in the following theorem.

THEOREM 2. *For sufficiently small $\beta > 0$ there is a value $h > 1.6831$ and a solution (ψ, A) of (1.11)–(1.14) defined on an interval $[-m, M]$ such that the following properties hold:*

(i) $m = m(\beta) > 0$, $M = M(\beta) > 0$, *and* $\lim_{\beta\to 0^+}(m, M) = (0, \infty)$;
(ii) $\psi' > 0$ *on* $(-m, 0)$, $\psi'(0) = 0$, *and* $\psi(0) = 1$;
(iii) $\psi' < 0$ *on* $(0, M)$;
(iv) *There is an* $h^0 > 1.6831$ *such that*

$$A'(-m) \to h^0 \quad \textit{as} \quad \beta \to 0^+. \tag{1.15}$$

Remark. Because of (1.8) and (1.9), each of the solutions (ψ, A) found in Theorem 2 corresponds to a solution $(\tilde\phi, \tilde a)$ of (1.2)–(1.5). Since ψ has a relative maximum at $t = 0$, (1.8) implies that $\tilde\phi'(x_{\max}) = 0$ where $x_{\max} = \frac{d}{2}\big(\frac{m-M}{m+M}\big)$. It follows from (1.9) and properties (i) and (iii) of Theorem 2 that for small $\beta > 0$, $x_{\max} < 0$, and $\tilde\phi' < 0$ for all $x \in (x_{\max}, \frac{d}{2})$. Therefore, $\tilde\phi'(0) < 0$, and (1.6) cannot hold. We conclude that $(\tilde\phi, \tilde a)$ is an asymmetric solution of (1.2)–(1.5).

We now state our second result. Recall that $\mathcal{G}$ gives the free energy of a solution.

THEOREM 3. *Let (ψ, A) be an asymmetric solution found in Theorem 2. There exists $\gamma > 0$ such that if $r \in (0, 2 + \gamma)$, then $\mathcal{G} < 0$ for sufficiently small $\beta > 0$.*

Asymmetric minimizers. We now return to the original system (1.1)–(1.5) and show that $\mathcal{G}$ has an asymmetric minimizer. Recall that $k \geq \frac{1}{\sqrt{2.01}}$ is fixed. Also, it follows from (1.7) that if $\frac{h_e}{k} \geq 1.6831$ and d is sufficiently large, then the only symmetric solution of (1.2)–(1.5) is the trivial solution $(\tilde\phi, \tilde a) = (0, h_e x)$, also known as the "normal state." Substitution of this pair into (1.1) shows that $\mathcal{G} = 0$. Next, we conclude from (1.8), (1.9), and the results of Theorems 2 and 3 that the problem (1.2)–(1.5) has an asymmetric solution for large d, that $\tilde a'(-\frac{d}{2}) \geq 1.6831\,k$, and that the corresponding energy $\mathcal{G}$ is negative. Therefore, in this parameter range, since $\mathcal{G}$ is zero for the trivial symmetric solution and negative for at least one asymmetric solution, a minimizer of $\mathcal{G}$ must be asymmetric.

2. Proof of Theorem 2. Our goal in this section is to show that for small $\beta > 0$ there is a solution (ψ, A) of the system

$$\psi'' = \psi(\beta^2\psi^2 + A^2 - 1), \tag{2.1a}$$

$$A'' = r\beta^2\psi^2 A \tag{2.1b}$$

on an interval $[-m, M]$, where $m > 0$ is small and $M > 0$ is large, and such that

$$\psi'(-m) = \psi'(M) = 0, \qquad A'(-m) = A'(M) = h > 0, \tag{2.2a}$$

$$\psi' > 0 \text{ on } (-m, 0), \qquad \psi' < 0 \text{ on } (0, M), \tag{2.2b}$$

$$\psi > 0 \text{ on } [-m, M], \tag{2.2c}$$

and

$$\psi(0) = 1, \qquad \psi'(0) = 0. \tag{2.2d}$$

Our method of proof uses a topological shooting argument. For this we begin by analyzing the important properties of solutions of the initial value problem (2.1a), (2.1b), (2.2d) when $\beta = 0$.

In this case A' is constant, and we set $A' = h$, where $h > 0$ is to be determined later. Setting $A(0) = A_0$, also to be determined later, we obtain the second-order linear equation

$$\psi'' = ((A_0 + ht)^2 - 1)\psi. \tag{2.3}$$

Because of (2.2d) we consider the solution of (2.3) such that the $\psi(0) = 1, \psi'(0) = 0$.

LEMMA 2.1. *Suppose that $-1 \le A_0 \le 0$. Then there is a unique $h_0 > 0$ (depending continuously on A_0) such that $\psi > 0, \psi' < 0$ on $(0, \infty)$, and $\psi(t) \to 0$ as $t \to \infty$. If $0 < h < h_0$, then $\psi = 0$ before $\psi' = 0$, while if $h > h_0$, then $\psi' = 0$ before $\psi = 0$.*

Proof. We consider the Riccati equation obtained by setting

$$\rho(s) = \frac{\psi'(s/h)}{\psi(s/h)}.$$

Then $\rho(0) = 0$ and

$$\rho' = \frac{H(s) - \rho^2}{h}, \tag{2.4}$$

where $H(s) = (A_0 + s)^2 - 1$. Since $A_0 \in [-1, 0], \rho$ initially decreases for any $h > 0$. Further, $\rho' < 0$ as long as $\rho(s)^2 > H(s)$. As long as $\rho' < 0$, the right side of (2.4) is an increasing and negative function of h and ρ. Suppose, for some first $s_0 > 0$, that $\rho'(s_0) = 0$. Then $H(s_0) = \rho(s_0)^2$ so that $A(s_0) > 1$. Therefore, $\rho''(s_0) = \frac{2A(s_0)}{h} > 0$. For $s > s_0$ it follows from the equation for ρ'' that $\rho'' > 0$ so that ρ increases until $\rho = 0$; i.e., $\psi' = 0$. Also, if ρ' becomes positive for some h_1, because ρ crosses the curve $\rho^2 = H(s)$, then the same must happen for any $h > h_1$. To see that there are values of h such that ρ' becomes positive we refer to (2.3). From that equation and our assumption that $\psi(0) = 1$, $\psi'(0) = 0$ we easily see that for large h, ψ' becomes positive before $\psi = 0$. This implies that ρ, and hence ρ', must become positive for large h. It then follows from continuity that the set of values of $h > 0$ such that this happens is open.

For small $h > 0$, on the other hand, we see that ρ decreases to below the curve $\rho = -s$. For example, if $-1 < A_0 < 0$ and $0 < h < 1 - A_0^2$, then $\rho'(0) < -1$, so immediately ρ decreases below $-s$. If $A_0 = -1$, then $\rho(0) = \rho'(0) = 0$. However, $\rho''(s) < \frac{2s-2}{h}$ and this integrates to show that for small h, $\rho(2) < -2$ and $\rho' < 0$ over $(0, 2]$. It follows from (2.4), and our assumption that $A_0 \in [-1, 0]$, that ρ' continues to decrease until $\rho \to -\infty$ at some finite s_1, that is, $\psi(s_1) = 0$. It is clear that the set of $h's$ such that $\rho(s) < -s$ for some s is an open subset of the interval $0 < h < \infty$.

Similarly, as we pointed out above, the set of $h's$ such that $\rho(s)^2 < H(s)$ for some s is also open.

Moreover, if ρ ever falls below $-s$, then we see from the equation for ρ'' that thereafter, $\rho' < -1$, and ρ decreases monotonically to $-\infty$. On the other hand, if ρ' is ever positive, then we see that ρ becomes positive, and because of (2.4) it must remain positive.

Hence, there is at least one h_0 such that on $0 \le s < \infty$, $\rho' \le 0$, and $0 > \rho > -s$. These bounds imply that the solution exists on the entire interval $[0, \infty)$. In order to complete the proof of Lemma 2.1 we need further properties of this solution. These are given in the following result.

LEMMA 2.2. *For such an* $h_0, \rho' < 0$, $-s < \rho(s)$ *on* $(0, \infty), \rho(s) < -\sqrt{H(s)}$ *if* $H(s) \ge 0$, *and* $\rho + \sqrt{H(s)} \to 0$ *as* $s \to \infty$.

Proof. The inequalities have already been proved. To see the limiting behavior of $\rho(s)$, we first note that for $h = h_0, \rho'(s)$ is bounded. If ρ' is unbounded, then it must get arbitrarily large and negative, but then the equation for ρ'' shows that ρ' remains large and negative and $\rho(s) < -s$ for some s.

Writing $\rho' = \frac{(\sqrt{H}-\rho)(\sqrt{H}+\rho)}{h}$ and noting that the first of these factors is unbounded, we see that $\sqrt{H(s)} + \rho(s)$ tends to zero, which implies Lemma 2.2.

To prove uniqueness we suppose that there is a second positive value of $h, h_1 < h_0$ for which this behavior occurs. Let ρ_1, ρ_0 denote the corresponding solutions. Then $\rho_1(0) = \rho_0(0) = 0$, and it is easily shown that

$$\frac{d}{ds}(\rho_1 - \rho_0) < 0$$

for all $s > 0$. Thus $\rho_1 - \rho_0$ could not approach zero as $s \to \infty$. However, Lemma 2.2 implies that $\rho_1 - \rho_0 = (\rho_1 + \sqrt{H}) - (\rho_0 + \sqrt{H}) \to 0$ as $s \to \infty$, a contradiction. Therefore, h_0 is unique.

To complete the proof of Lemma 2.1 we must show that h_0 depends continuously on A_0. This follows from the uniqueness of h by a standard argument.

Now let $A_0 = -1$, and define h^0 from Lemma 2.1 with $A_0 = -1$. We will find the desired solutions near the point $(A_0, h) = (-1, h^0)$.

LEMMA 2.3. $h^0 > 1.6831$.

Proof. Let

$$\hat{\rho}(t) = \frac{\psi'(t)}{\psi(t)},$$

so that

$$\hat{\rho}' = H(ht) - \hat{\rho}^2. \tag{2.5}$$

Here, because $A_0 = -1$, $H(s) = -2s + s^2$, where $s = ht$ as before. We use the following result about a solution $\hat{\rho}$ of (2.5) such that $\hat{\rho}(0) = 0$. If $\hat{\rho}''' < 0$ for some t_1, with $\hat{\rho}, \hat{\rho}', \hat{\rho}'' < 0$ on $(0, t_1)$, then $\hat{\rho}$ decreases monotonically to $-\infty$. To see this, compute the equation satisfied by $\hat{\rho}''''$, that is,

$$\hat{\rho}'''' + 2\hat{\rho}\hat{\rho}''' = -6\hat{\rho}'\hat{\rho}''.$$

If there were a first $y > t_1$ where $\hat{\rho}'''(y) = 0$, then $\hat{\rho}''''(y) \ge 0$. However, the last equation gives $\hat{\rho}''''(y) < 0$ since the definition of y implies that $\hat{\rho}'\hat{\rho}''$ is positive and

increasing on (t_1, y). From these derivative properties it follows that $\hat{\rho}$ decreases below $-s$, and, hence, $\hat{\rho}(s) \to -\infty$ at a finite value of s. Next, we define a sequence $\{\hat{\rho}_N\}$ of functions, all defined on $[0, 2]$ as follows:

$$\hat{\rho}_0(t) = \int_0^t (h^2 r^2 - 2hr)dr, \quad \hat{\rho}_{N+1}(t) = \hat{\rho}_0(t) - \int_0^t \hat{\rho}_N(r)^2 dr \quad \text{for} \quad N \geq 1.$$

From this definition it is evident that $\{\hat{\rho}_N\}$ forms a decreasing sequence of functions defined on [0,2], for all $N \geq 1$. Furthermore, it is easily shown that our solution $\hat{\rho}(t)$ satisfies $\hat{\rho}^{'''} < \hat{\rho}_i^{'''}$ on [0,2], for all $i \geq 1$. Setting $h = \frac{16831}{1000}$, we used computer algebra program Maple to compute $\hat{\rho}_6$, a polynomial of degree 225. All calculations are with integers and rational numbers so that there are no roundoff errors. From $\hat{\rho}_6$ and its first two derivatives we can compute $\hat{\rho}_7'''$ without having to compute $\hat{\rho}_7$. We find that $\hat{\rho}_7'''(6/5) < 0$ and that on [0,6/5], $\hat{\rho}, \hat{\rho}', \hat{\rho}^{''}$ are all negative. This completes the proof of the lemma.

Our solution (ψ, A) to (2.1a)–(2.2d) is obtained by perturbing $A(0)$ from -1, keeping $\beta = 0$, and then letting β be positive. Our argument is by "shooting," rather than by the use of bifurcation theory.

Thus, we will assume that

$$A(0) = -1 + \epsilon$$

for small $\epsilon \geq 0$, and we let $h_0 = h_0(\epsilon)$ denote the value of h found in Lemma 2.1.

In constructing solutions to (2.1)–(2.2), in order to get something meaningful at $\beta = 0$, we replace the boundary conditions on A in (2.2a) with

$$\int_{-m}^{M} \psi^2(t) A(t) dt = 0.$$

LEMMA 2.4. *Suppose that $\epsilon = 0$, (i.e., $A_0 = -1$) and let ψ_0 be the solution found in Lemma 2.1 where $h = h^0 = h_0(0)$. Then*

$$\int_0^\infty \psi_0(t)^2(-1 + h^0 t)dt = 0.$$

Proof. It is easily seen that $\psi_0(t) \to 0$ exponentially fast as $t \to \infty$. Thus, the integral in the lemma converges and $\lim_{t\to\infty}(-1 + h^0 t)^2 \psi_0(t)^2 = 0$. We set $\psi = \psi_0$ in (2.3), multiply by ψ_0', and integrate by parts to obtain the result.

From Lemma 2.1 and the definition of $h_0(\epsilon)$ we see that for each $h > h_0(\epsilon)$, there is a first $t = t_h > 0$ such that $\psi'(t_h) = 0, \psi' < 0$ and $\psi > 0$ on $(0, t_h)$, with $\psi(t_h) > 0$. By the implicit function theorem, t_h is continuous in h on $(h_0(\epsilon), \infty)$ since $\psi^{''}(t_h) > 0$. (If $\psi^{''}(t_h) = 0$, then $t_h = \frac{2}{h}$ and $\psi^{'''}(t_h) > 0$, a contradiction.) Further, $t_h \to \infty$ as $h \to h_0(\epsilon)$ from above.

Now consider small $\epsilon > 0$, set $h = h_0(\epsilon)$, and compute $\psi^{''}(0)$ and $\psi^{'''}(0)$. We find that $\psi''(0) = -2\epsilon + \epsilon^2$ and $\psi^{'''}(0) = 2(-1 + \epsilon)h_0(\epsilon)$. From this and the fact that $h_0(\epsilon) \to h^0 > 0$ as $\epsilon \to 0^+$, we see that for small $\epsilon, \psi'(-m) = 0$ for some $m = m_0(\epsilon) > 0$. Furthermore,

$$-m = \frac{-2\epsilon}{h_0(\epsilon)} + 0(\epsilon^2). \tag{2.6}$$

Here, $O(\epsilon^2) < L\epsilon^2$ for some L independent of ϵ. We now compute

$$I(\epsilon) = \int_{-m}^{\infty} \psi^2 A ds,$$

where $A(s) = -1+\epsilon+h_0(\epsilon)s$. Again, multiplying (2.3) by ψ' and integrating by parts give

$$0 = -\psi(-m)^2 A(-m)^2 + \psi(-m)^2 - 2h_0 \int_{-m}^{\infty} \psi(s)^2 A(s) ds.$$

Using (2.6) and the fact that $\psi(-m) = 1+O(\epsilon)$, we find that $I(\epsilon) = -\frac{\epsilon}{h_0} + O(\epsilon^2)$ as $\epsilon \to 0^+$. Thus, we have shown that with $h = h_0(\epsilon)$ for small ϵ, $I(\epsilon) < 0$. Fix $\epsilon > 0$ small enough so that this inequality holds for $h = h_0(\epsilon)$. Then for $h - h_0(\epsilon)$ positive but sufficiently small, $-m = -m(\epsilon, h)$ will still be defined as the largest negative zero of ψ', A is positive on (t_h, ∞), and therefore,

$$\int_{-m}^{t_h} \psi^2 A ds < 0.$$

Our goal now is to find an h and ϵ such that $-m$ and t_h are defined as the negative and positive zeros of ψ' closest to $t = 0$, with m small and t_h large, and such that

$$I = \int_{-m}^{t_h} \psi^2 A ds > 0.$$

We will see that it is not necessary to have the same m and t_h as before. Starting with $\epsilon = 0$ and $h = h_0(\epsilon)$, we now raise h, instead of ϵ. Thus, for small $h - h^0 > 0$ our solution satisfies $A(0) = -1$, $A'(0) = h > h^0 = h_0(0)$, $\psi'(t_h) = 0$ for some large t_h. In this case, we multiply (2.3) by ψ' and integrate from 0 to t_h, where t_h is the first positive zero of ψ'. Using integration by parts once again, we find that $I > 0$. We then keep h fixed and raise ϵ slightly, whereupon both $m = m(\epsilon, h)$ and t_h are defined, still with $I > 0$. We summarize these results in the following lemma.

LEMMA 2.5. *For each sufficiently small $\epsilon > 0$ there is an $h_1(\epsilon) > h_0(\epsilon)$ such that if $h_0(\epsilon) < h < h_1(\epsilon)$, then the solution of* (2.3) *with $A_0 = -1+\epsilon, \psi(0) = 1$, and $\psi'(0) = 0$ is decreasing on an interval $[0, M]$, increasing on an interval $[-m, 0]$, and $\psi'(-m) = \psi'(M) = 0$, and*

$$I(\epsilon, h) = \int_{-m}^{M} \psi^2 A ds < 0.$$

Furthermore, $\psi > 0$ on $[-m, M]$ and $h_1(\epsilon) \to h_0(0) = h^0$ as $\epsilon \to 0^+$. On the other hand, for each $h > h_0(0)$ sufficiently close to $h_0(0)$, there is an interval $(0, \epsilon_1(h))$ of $\epsilon's$ such that ψ has the same behavior, but $I(\epsilon, h) > 0$. As ϵ and $h - h_0(0)$ tend to zero, $m \to 0$ and $M \to \infty$.

COROLLARY 2.6. *For $\epsilon > 0$ sufficiently small, there is an $h_2 = h_2(\epsilon)$ such that if ψ is the solution of* (2.3) *with $A_0 = -1+\epsilon$ and $(\psi(0), \psi'(0)) = (1, 0)$, then there are values $M > m > 0$ such that*

$$\psi'(-m) = \psi'(M) = 0, \quad \psi' > 0 \text{ on } (-m, 0), \quad \psi' < 0 \text{ on } (0, M), \tag{2.7a}$$

$$\psi''(-m) \neq 0, \psi''(M) \neq 0. \tag{2.7b}$$

Further, $I(\epsilon, h_1(\epsilon)) < 0$ and $I(\epsilon, h_2(\epsilon)) > 0$. Finally, $h_2(\epsilon) \to h_0(0) = h^0$ as $\epsilon \to 0$.

With $\epsilon > 0$ sufficiently small so that Lemma 2.5 and Corollary 2.6 hold, we now raise β and consider solutions of (2.1) satisfying (2.2d). Since $\psi'' \neq 0$ at the zeros of ψ' when $\beta = 0$, it follows from the implicit function theorem that the zeros $-m < 0$ and $M > 0$ of ψ' persist as continuous functions of β and the values of $A(0)$ and $A'(0)$. For each sufficiently small $\epsilon > 0$ there exist functions $h_1(\epsilon)$ and $h_2(\epsilon)$ independent of β, such that for sufficiently small β (depending on ϵ) the solution (ψ, A) of (2.1) and (2.2d) with

$$A(0) = -1 + \epsilon, \quad A'(0) = h_1(\epsilon), \tag{2.8}$$

satisfies (2.7) on an interval $[-m, M]$, and

$$\int_{-m}^{M} \psi^2 A dt < 0.$$

Also, the solution of (2.1), (2.2d) with $A(0) = -1 + \epsilon$, $A'(0) = h_2(\epsilon)$ satisfies

$$\int_{-m}^{M} \psi^2 A dt > 0.$$

Furthermore, $\beta \to 0$ as $\epsilon \to 0$, and

$$(m, M) \to (0, \infty), \quad (h_1(\epsilon), h_2(\epsilon)) \to (h^0, h^0).$$

In addition, it follows from (2.1b) that A'' is uniformly bounded on $[-m, 0]$, and therefore, $A'(-m) = h \to h^0$ as $\epsilon \to 0$ and $\beta \to 0^+$. It then follows from continuity that for given fixed small ϵ, and sufficiently small $\beta \geq 0$, there is an $h \in (h_1(\epsilon), h_2(\epsilon))$ such that the solution $(\psi_{\epsilon,\beta}, A_{\epsilon,\beta})$ of (2.1), (2.2d), and (2.8) with $A'(-m) = h$ also satisfies $\int_{-m}^{M} \psi^2 A dt = 0$, so $A'(M) = h$. The conclusion of Theorem 2 now follows from the transformation (1.8)–(1.9).

In the next section we will turn to the proof of Theorem 3. For this we will use the following result, which is based on the construction given above. Let

$$\mathcal{E}(\psi, A) = \int_{-m}^{M} F(\psi, A)(t) dt,$$

where

$$F(\psi, A)(t) = r\left(\int_t^M \psi(s)^2 A(s) ds \right)^2 - \frac{\psi(t)^4}{2}.$$

LEMMA 2.7. *With $(\psi, A) = (\psi_{\epsilon,\beta}, A_{\epsilon,\beta})$ chosen as in the proof of Theorem 2, we have*

$$\lim_{\epsilon \to 0} \{ \lim_{\beta \to 0} \mathcal{E}(\psi, A) \} = \mathcal{E}(\psi_0, A^0),$$

where $A^0(s) = -1 + h^0 s$.

Proof. Our proof of Theorem 2 shows that

$$\lim_{\epsilon \to 0} \{ \lim_{\beta \to 0} (\psi_{\epsilon,\beta}(s), A_{\epsilon,\beta}(s)) \} = (\psi_0(s), A^0(s))$$

uniformly on compact intervals. Let $\delta > 0$ be given. We can choose $K_1 > 0$ such that

$$r\psi(K_1)^4 < \delta, \int_{K_1}^{\infty} \big|F(\psi_0, A^0)(t)\big|dt < \delta, \tag{2.9}$$

and

$$A^0(s)^2 - 2 > \frac{A^0(s)^2}{2} \tag{2.10}$$

for $s \geq K_1$. Then for sufficiently small $\epsilon > 0$ we choose $\beta_1 = \beta_1(\epsilon) > 0$ such that for $0 < \beta < \beta_1$,

$$\Big| \int_0^{K_1} (F(\psi, A)(t) - F(\psi_0, A^0)(t))dt \Big| < \delta. \tag{2.11}$$

Further, we can ensure that for $0 < \beta < \beta_1$, (2.10) also holds on $[K_1, M]$ with A substituted for A_0.

We consider two cases:

$$\frac{\psi_0'(K_1)}{\psi_0(K_1)} > -1 \tag{i}$$

and

$$\frac{\psi_0'(K_1)}{\psi_0(K_1)} \leq -1. \tag{ii}$$

Let $\rho = \frac{\psi'}{\psi}$, so that, from (2.1a),

$$\rho'(s) \geq A(s)^2 - 1 - \rho^2.$$

In case (i) we have $\rho' \geq \frac{A(s)^2}{2}$ on $[K_1, M]$ as long as $-1 \leq \rho < 0$, so that $\rho = 0$ (and hence $\psi' = 0$) before

$$\int_{K_1}^{t} \frac{A(s)^2}{2} ds = 1.$$

In other words,

$$\int_{K_1}^{M} \frac{A(s)^2}{2} ds \leq 1. \tag{2.12}$$

Thus, (2.10) implies that if $M \geq t \geq K_1$, then $\frac{A(s)}{2} \geq 1$ on $[t, M]$, and hence

$$\int_t^M \psi(s)^2 A(s) ds \leq \psi(K_1)^2 \int_t^M \frac{A(s)^2}{2} ds \leq \psi(K_1)^2.$$

Since (2.10) and (2.12) also imply that $M - K_1 < 1$, it follows from (2.12) and (2.9) that in case (i),

$$\int_{K_1}^{M} F(\psi, A)(t) dt < \delta \tag{2.13}$$

for sufficiently small ϵ and β.

In case (ii), since $\psi'(M) = 0$, there must be a $T \in [K_1, M)$ such that $\rho \leq -1$ on $[K_1, T]$ and $\rho \geq -1$ on $[T, M]$.

First consider $\int_{K_1}^{T} F(\psi, A)(t)dt$. On $[K_1, T]$ we have $\psi' \leq -\psi$, so that

$$\psi(t) \leq \psi(K_1)e^{K_1 - t}. \tag{2.14}$$

We now estimate the term

$$\int_t^M \psi(s)^2 A(s)ds$$

in $F(\psi, A)$ for $K_1 \leq t \leq T$. For this we use the following lemma.

LEMMA 2.8. $\lim_{t\to\infty} \psi_0(t)A^0(t) = 0$.

Proof. In our estimates of ψ_0 we saw that $\frac{\psi_0'}{\psi_0} + H_0(t) \to 0$. Since A^0 grows linearly, the result follows.

We now continue with the proof of Lemma 2.7. We choose K_1 so that in addition to the earlier constraints, $\psi_0(K_1)A^0(K_1) < 1$. For small ϵ and β, this inequality will also be satisfied by (ψ, A). If $t \leq T$, then

$$\begin{aligned}\int_t^M \psi(s)^2 A(s)ds &= \int_t^T \psi(s)^2 A(s)ds + \int_T^M \psi(s)^2 A(s)ds \\ &\leq \int_t^T \psi(s)^2 A(s)ds + \psi(T)^2 \int_T^M A(s)ds.\end{aligned}$$

The argument used earlier to get (2.12) shows that $\int_T^M A(s)ds \leq 1$, where we use (2.10) with A substituted for A^0. From an integration of $\frac{\psi'}{\psi} \leq -1$ we obtain

$$\int_t^T \psi(s)^2 A(s)ds \leq \psi(t)(\max_{t\leq s\leq T} \psi(s)A(s)) \int_t^T e^{t-s}ds.$$

In $[K_1, T]$, $\psi' \leq -\psi$, so $\frac{d}{ds}(\psi(s)A(s)) \leq -\psi(s)A(s) + \psi(s)A'(s)$. But $A'(s) \leq A'(M) = h \leq 2h^0$ for small ϵ and β, so $\psi(s)A(s)$ is decreasing in $[K_1, T]$. Hence, $\int_t^T \psi(s)^2 A(s)ds \leq \psi(t) \leq \psi(K_1)e^{K_1 - t}$. Using this we find that on $[K_1, T]$,

$$F(\psi, A) \leq r\psi(K_1)^2 e^{2(K_1 - t)}.$$

Thus, we can further restrict K_1 to ensure that for small positive ϵ and β,

$$\int_{K_1}^T F(\psi, A)(t)dt < \delta.$$

Finally, we consider $\int_T^M F(\psi, A)(t)dt$. As in case (i), we have

$$\int_T^M \frac{A(s)^2}{2}ds \leq 1.$$

Hence, we find that

$$\int_t^M \psi(s)^2 A(s)ds \leq \psi(T)^2 \leq \psi(K_1)^2$$

and

$$M - T \leq 1.$$

We then have (without further change in K_1) that

$$\int_T^M F(\psi, A)(t)dt < \delta.$$

Since δ was arbitrary, this completes the proof of Lemma 2.7.

3. Proof of Theorem 3. In order to prove Theorem 3 we need to show that the asymmetric solutions found in Theorem 2 have the additional property that their corresponding energy $\mathcal{G}$ is negative if $\epsilon > 0$ and $\beta > 0$ are small enough. Thus, we define

$$Q = \frac{2(m+M)}{\beta^4}\mathcal{G}. \tag{3.1}$$

Then, by (3.1) and (1.10), Q is given by

$$Q = \frac{1}{\beta^2}\int_{-m}^{M}\left(\psi^2\left(\frac{\beta^2\psi^2}{2} - 1 + A^2\right) + (\psi')^2 + \frac{1}{r\beta^2}(A' - h)^2\right)dt. \tag{3.2}$$

Therefore, if we show that $Q < 0$ for small $\epsilon > 0$ and $\beta > 0$ then $\mathcal{G}$ is also negative and Theorem 3 is proved. We need to simplify Q. For this we use (1.11) and conclude that

$$\psi^2\left(\frac{\beta^2\psi^2}{2} - 1 + A^2\right) + (\psi')^2 = \psi\psi'' + (\psi')^2 - \frac{\beta^2\psi^4}{2}. \tag{3.3}$$

Then substitution of (3.3) ino (3.2), together with the observation that $(\psi\psi')' = \psi\psi'' + (\psi')^2$, reduces Q to

$$Q = \frac{1}{\beta^2}\int_{-m}^{M}\left((\psi\psi')' - \frac{\beta^2\psi^4}{2} + \frac{1}{r\beta^2}(A' - h)^2\right)dt. \tag{3.4}$$

Since $\psi'(-m) = \psi'(M) = 0$, (3.4) further reduces to

$$Q = \frac{1}{\beta^2}\int_{-m}^{M}\left(\frac{1}{r\beta^2}(A' - h)^2 - \frac{\beta^2\psi^4}{2}\right)dt. \tag{3.5}$$

Next, it follows from an integration of (1.12) that

$$h - A' = r\beta^2\int_t^M \psi^2 A ds. \tag{3.6}$$

Finally, we substitute (3.6) into (3.5) and arrive at

$$Q = \int_{-m}^{M}\left(r\left(\int_t^M \psi^2 A ds\right)^2 - \frac{\psi^4}{2}\right)dt. \tag{3.7}$$

In view of Lemma 2.7 we conclude from (3.7) that

$$\lim_{\epsilon\to 0}\lim_{\beta\to 0} Q = \int_0^\infty \left(r\left(\int_t^\infty \psi_0^2 A^0 ds \right)^2 - \frac{\psi_0^4}{2} \right) dt, \tag{3.8}$$

where $A^0 = -1 + h^0 s$.

In the next section we prove the following lemma.

LEMMA 3.1. *There is a value $\gamma > 0$ such that*

$$\int_0^\infty \left(r\Big(\int_t^\infty \psi_0^2 A^0 ds \Big)^2 - \frac{\psi_0^4}{2} \right) dt < 0 \tag{3.9}$$

for all $r \in (0, 2+\gamma)$.

From Lemma 3.1 we observe that if $r \in (0, 2+\gamma)$, then $Q < 0$ for small $\epsilon > 0$ and $\beta > 0$. Therefore, $\mathcal{G}$ is also negative for small $\beta > 0$ and Theorem 3 is proved.

4. Proof of Lemma 3.1. For the proof of Lemma 3.1 we recall that ψ_0 satisfies

$$\psi_0'' = \psi_0(-2h^0 t + (h^0)^2 t^2), \tag{4.1}$$

$$\psi_0(0) = 1, \psi_0'(0) = 0, \tag{4.2}$$

where $h^0 > 0$ is the unique positive value for which ψ_0 satisfies $\psi_0' < 0$ for all $t > 0$, and

$$\lim_{t\to\infty} (\psi_0(t), \psi_0'(t)) = (0, 0). \tag{4.3}$$

The existence and uniqueness of h^0 were proved in Lemma 2.1. Thus, our main objective is to prove the following lemma.

LEMMA 4.1. *There is a value $\gamma > 0$ such that*

$$\int_0^\infty \left(r\Big(\int_t^\infty \psi_0^2(-1 + h^0 s) ds \Big)^2 - \frac{1}{2}\psi_0^4(t) \right) dt < 0 \tag{4.4}$$

for all $r \in (0, 2+\gamma)$.

The proof of Lemma 4.1 relies on an auxiliary result which we now establish.

Define the Riccati variable $q = \frac{\psi'(t)}{\psi(t)}$. Then q satisfies

$$q' + q^2 + 2h^0 t - (h^0)^2 t^2 = 0, \tag{4.5}$$

$$q(0) = q'(0) = 0. \tag{4.6}$$

LEMMA 4.2. *It follows from* (4.5) *and the definition of q that*

$$q < 0 \quad \textit{and} \quad q' < 0 \quad \textit{for all } t > 0, \tag{4.7}$$

$$q \le -\sqrt{(h^0)^2 t^2 - 2h^0 t} \quad \textit{for all } t \ge \frac{2}{h^0}, \tag{4.8}$$

$$q' > -h^0 \quad \textit{for all } t \ge 0. \tag{4.9}$$

Proof. Setting $h = h^0$ and $s = t\,h^0$, we observe that (4.7) and (4.8) follow immediately from Lemma 2.2. It remains to prove (4.9). It follows from (4.6) that $q'(0) = 0$. Thus $q' > -h^0$ on an interval $[0, \eta)$ for small $\eta > 0$. Suppose that (4.9) is false. Then there is a first $\hat{t} > 0$ for which $q'(\hat{t}) = -h^0$ and $q''(\hat{t}) \leq 0$. Two differentiations of (4.5) lead to

$$q''' + 2qq'' = 2((h^0)^2 - (q')^2). \tag{4.10}$$

One solution of (4.10) is $q' \equiv -h^0$ for all t. Thus, if $q''(\hat{t}) = 0$ then uniqueness of solutions implies that $q' = -h^0$ for all $t \geq 0$, and in particular, $q'(0) = -h^0$, contradicting the fact that $q'(0) = 0$. Therefore, it must be the case that

$$q'(\hat{t}) = h^0 \quad \text{and} \quad q''(\hat{t}) < 0. \tag{4.11}$$

It then follows from (4.10) and (4.11) that $q''(t) < 0$ for all $t > \hat{t}$ so that

$$\lim_{t\to\infty} q'(t) < -h^0. \tag{4.12}$$

We conclude from (4.12) that

$$\lim_{t\to\infty} q(t) + h^0 t < 0. \tag{4.13}$$

However, it follows from Lemma 2.2 that $\lim_{t\to\infty} q(t) + h^0 t = 0$, contradicting (4.13). Thus, it must be the case that $q' > -h^0$ for all $t > 0$ and the proof is complete.

We now return to the proof of Lemma 4.1. First, we conclude from (4.7) and (4.8), and the properties that $0 < \psi_0 < 1$ and $\psi_0' < 0$ for all $t > 0$, that the integral $\int_0^\infty \psi_0^4(t)dt$ is well defined and positive. The same reasoning shows that

$$J = \int_0^\infty \left(\int_t^\infty \psi_0^2(s)(-1 + h^0 s)ds \right)^2 dt \tag{4.14}$$

is well defined and positive. It remains to prove (4.4). For this we begin by estimating the integral

$$H = \int_t^\infty \psi_0^2(-1 + h^0 s)ds. \tag{4.15}$$

An integration by parts reduces (4.15) to

$$H = -\frac{\psi_0^2}{2h^0}(-1 + h^0 t)^2 - \frac{1}{h^0}\int_t^\infty \psi_0'\psi_0(-1 + h^0 s)^2 ds. \tag{4.16}$$

It follows from (4.1) that $\psi_0'\psi_0'' + \psi_0'\psi_0 = \psi_0'\psi_0(-1 + h^0 t)^2$, and therefore, (4.16) becomes

$$H = -\frac{\psi_0^2}{2h^0}(-1 + h^0 t)^2 + \frac{\psi_0^2(t)}{2h^0} + \frac{1}{2h^0}(\psi_0')^2. \tag{4.17}$$

Recall that $\psi' = q\psi$. Then (4.6) and (4.17) imply that

$$H = -\frac{\psi_0^2 q'}{2h^0}. \tag{4.18}$$

It follows from (4.18) and (4.14) that

$$J = \int_0^\infty H^2(t)dt \le \int_0^\infty \frac{\psi_0^4(t)}{4(h^0)^2}(q')^2 dt. \tag{4.19}$$

Because Lemma 4.2 gives $-h^0 < q' < 0$ for all $t > 0$, (4.19) further reduces to

$$J < \frac{1}{4}\int_0^\infty \psi_0^4(t)dt. \tag{4.20}$$

Finally, it follows from (4.4), (4.14), and (4.20) that there exists $\gamma > 0$ such that

$$\int_0^\infty \left(r\left(\int_t^\infty \psi_0^2(-1+h^0 s)ds \right)^2 - \frac{\psi_0^4}{2} \right) dt < 0$$

for all $r \in [0, 2+\gamma)$. This completes the proof of Lemma 4.1.

Appendix. In [9], when studying symmetric solutions, we used a different scaling from that used in this paper. That is, we rescaled (1.2)–(1.5) by setting

$$K = \frac{k^2 d^2}{4}, \quad h = \frac{h_e d}{2}, \quad r = \frac{1}{k^2}, \quad y = \frac{2x}{d},$$

and defined new dependent variables ϕ and a by

$$\phi(y) = \tilde{\phi}(x), \qquad a(y) = \tilde{a}(x).$$

This transforms the problem (1.2)–(1.5) into

$$\phi'' = K\phi(\phi^2 + a^2 - 1),$$

$$a'' = rK\phi^2 a,$$

$$\frac{d\phi}{dy}(\pm 1) = 0, \qquad \frac{da}{dy}(\pm 1) = h,$$

$$\phi > 0 \text{ on } [-1, 1].$$

Since we are considering symmetric solutions, we consider the initial values

$$\phi(0) = \beta, \;\; \phi'(0) = 0, \;\; a(0) = 0, \;\; a'(0) = \alpha.$$

In [11], Kwong proved that for each $\beta \in (0,1)$ there exists a unique $\alpha = \alpha(\beta) > 0$, continuously dependent and decreasing in β such that $\phi'(1, \beta, \alpha(\beta)) = 0$. He then set $h(\beta) = a'(1, \beta, \alpha(\beta))$ and proved that h is continuous, $h(0) > 0$, and $h(1) = 0$. Thus, to obtain the upper bound $h_{sym} \le \sqrt{3}$ given in [9] we found that it was sufficient to fix $r \in (0, 2.01]$ and estimate

$$h_{sym} = \overline{\lim}_{K\to\infty}\Big(\sup_{0\le\beta\le 1} \frac{h(\beta)}{\sqrt{K}} \Big).$$

In [9], our estimate for h_{sym} was obtained by carefully analyzing the behavior of (ϕ, a) for each $\beta \in (0,1)$. We considered three intervals of β, namely, $(0,.1], (.1, 1-\frac{1}{\sqrt{K}}]$, and $(1-\frac{1}{\sqrt{K}}, 1)$. We made repeated use of the "energy" function

$$\frac{\phi'^2}{K} + \frac{a'^2}{rK} - \frac{\phi^4}{2} + \phi^2 - a^2\phi^2,$$

which is constant for solutions of the system. We defined the function

$$Q(y) = \beta^2 - \frac{\beta^4}{2} + \frac{\phi(y)^4}{2} - \phi(y)^2 + a^2\phi(y)^2$$

and found the point y_0 where $Q(y_0) = 1$ to be important. The difficult part of the estimate required us to consider small intervals of values of $\phi(y_0)$, say, $I_1 < \phi(y_0) < I_2$. A priori, we know only that $0 < \phi(y_0) < 1$ and to get better estimates we had to subdivide $(0,1)$ into nine small subintervals $[I_1, I_2]$.

In this paper, to get the improved estimates required to show that $h_{sym} \le 1.68$ we have to use more subintervals. Thirty-four subintervals suffice. They are [0,.407], [.407,.56], [.56,.6], then 30 intervals from .6 to .9 in steps of .01, and finally [.9,1.0].

With this change, the proof in [9] gives the required upper bound for h_{sym}, and because of our rescaling this immediately leads to $h_e^{sym} \le 1.68k$ for $k \ge \frac{1}{\sqrt{2.01}}$. As we mentioned in [9], our estimate for h_{sym} is much easier for small r.

REGULARITY AND CONVERGENCE OF CRYSTALLINE MOTION*

KATSUYUKI ISHII† AND HALIL METE SONER‡

Abstract. We consider the motion of polygons by crystalline curvature. We show that "smooth" polygon evolves by crystalline curvature "smoothly" and that it shrinks to a point in finite time. We also establish the convergence of crystalline motion to the motion by mean curvature.

Key words. crystalline motion, motion by mean curvature, viscosity solutions

PII. S0036141097317347

1. Introduction.

Several models in phase transitions give rise to geometric equations relating the normal velocity of the interface to its curvature. The curvature term is related to surface tension and the surface energy is often an anisotropic function of the normal direction, indicating the preferred directions of the underlying crystal structure.

When the surface energy is isotropic, the resulting equation is the mean curvature flow and a variety of techniques have been used to analyze this flow. Huisken [25] showed that any convex set in higher than two space dimensions, shrinks to a point smoothly in finite time. We note that Huisken's method cannot be applied to the planar motion by mean curvature. Using different methods from those in [25], Gage and Hamilton [15] and Grayson [24] showed that a smooth planar embedded curve first becomes convex and then smoothly shrinks to a point in finite time. However, in general, in dimensions higher than two, embedded hypersurfaces may develop singularities and a weak formulation of the mean curvature flow is necessary to define the subsequent evolution after the onset of singularities. Brakke [8] was the first to study the mean curvature flow past the singularities. Using varifolds in geometric measure theory, he constructed global generalized solutions that are not necessarily unique. Almgren, Taylor, and Wang [2] used a time-step energy minimization approach together with geometric measure theory to analyze a very general class of equations.

An alternate approach, initially suggested in the physics literature by Ohta, Jasnaw, and Kawasaki [28], for numerical calculations by Osher and Sethian [26], represents the evolving surfaces as the level set of an auxiliary function solving an appropriate nonlinear differential equation. This level-set approach has been extensively developed by Chen, Giga, and Goto [9] and Evans and Spruck [12]. Evolution of hypersurfaces with codimension greater than one is studied by Ambrosio and Soner [3], and intrinsic definitions were developed by Soner [29] and Barles, Soner, and Souganidis [7]. Since the level-set equations are degenerate parabolic, the theory of viscosity solutions by Crandall and Lions [11] is used to define the level-set solutions. For more

information on viscosity solutions see the survey by Crandall, Ishii, and Lions [10] and the book by Fleming and Soner [13].

When the surface energy is convex, the evolution law is still degenerate parabolic and much of the above theory generalizes to these equations as well.

Nonsmooth energies are also of interest, and an interesting class of surface energies—called *crystalline* energies—have polygonal Frank diagrams. For these energies, the corresponding solutions are also polygonal, and the evolution law is a system of ordinary differential equations for the length of each side of the solution (see (2.3) below). An excellent introduction to crystalline motion is given in the recent book of Gurtin [22] and in the surveys of Taylor [32] and Taylor, Cahn, and Handwerker [34]. Short time existence and the other properties of the planar solutions are proved by Angenent and Gurtin [4] and Taylor [33]. Almgren and Taylor [1] showed that the crystalline flow is consistent with the variational approach developed in [2]. In a recent preprint Giga, Gurtin, and Mathias [19] study the classical solutions in three space dimensions and a deep viscosity theory for graph-like solutions of very general geometric equations have been developed by Giga and Giga [16] and the references therein. We also refer to Gurtin, Soner, and Souganidis [23] and Ohnuma and Sato [27], which treat a relaxed formulation of evolving surfaces by nonconvex interfacial energies.

In this paper, we consider a two-dimensional problem with a crystalline energy whose level sets are regular n-polygons and show the convergence of these solutions to the unique smooth solution of the mean curvature flow. This convergence has already been proved by Girao [20] for convex solutions and by Girao and Kohn [21] for graph-like solutions. They also obtained the rate of convergence. Here we generalize the convergence results in [20, 21] to general curves that are not necessarily convex. Our proof is a set theoretic analogue of the weak viscosity approach of Barles and Perthame [5, 6]. To describe our approach, let $\{\Omega_n(t)\}_{t\in[0,T)}$ be a sequence of open polygons each solving a crystalline flow. We define two possible limits:

$$\widehat{\Omega}(t) := \limsup_{n\to\infty,\ s\to t} \Omega_n(s),$$
$$\underline{\Omega}(t) := \liminf_{n\to\infty,\ s\to t} \Omega_n(s).$$

(Precise definitions are given in (4.2) below.) Then, with *only* L^∞ *estimates*, the Barles–Perthame approach enables us to show that $\widehat{\Omega}$ is a viscosity subsolution of the mean curvature flow, and $\underline{\Omega}$ is a viscosity supersolution of the mean curvature flow. Since, in two space dimensions, there is a smooth solution to the mean curvature flow, we show that both of these sets are equal to the smooth solution. This yields the convergence of Ω_n in the Hausdorff topology.

The paper is organized as follows. In the next section, we give the definition of crystalline motion and prove the existence of a regular solution in section 3. We define the weak viscosity limits in section 4 and prove their viscosity properties. Convergence is proved in the final section. Some properties of the viscosity solutions are gathered in the appendix.

After this work was completed, we were informed of a recent work of Giga and Giga [17] related to ours. They proved the stability of the periodic graph-like solutions for the motion by nonlocal weighted curvature. They also proved the motion by crystalline energy is shown to approximate the motion by regular interfacial energy if the crystalline energy approximates the regular interfacial energy. We also refer to Fukui and Giga [14] for an approximation property of the motion by nonsmooth weighted energy.

2. Crystalline motion and n-smooth polygons. Here we recall several standard definitions and equations. Gurtin's book [22] provides an excellent introduction to this subject. Also, see [31, 33].

2.1. Surface energy. All geometric flows that we consider are, formally, the gradient flows of the surface energy functional

$$I(\Gamma) := \int_\Gamma f(\vec{n})\, ds, \tag{2.1}$$

where Γ is a Jordan curve in $\mathcal{R}^2$, $\vec{n}$ is its outward unit normal vector, and $f : S^1 \to [0, \infty)$ is the *surface energy* function. It is customary to extend f to the whole $\mathcal{R}^2$ as a homogeneous function of degree one,

$$f(x) = |x| f\left(\frac{x}{|x|}\right) \qquad \forall x \neq 0,$$

and define

$$\hat{f}(\theta) := f(\cos\theta, \sin\theta).$$

Then the twice differentiability of f on $\mathcal{R}^2\backslash\{0\}$ is equivalent to the twice differentiability of $\hat{f}$, and f is convex if and only if $\hat{f}(\theta) + \hat{f}_{\theta\,\theta}(\theta) \geq 0$ for all θ.

The *Frank diagram* of the surface energy f is simply the polar graph of $\hat{f}^{-1}$, or equivalently, it is the one-level set of f, i.e.,

$$\mathcal{F}(f) := \{x \in \mathcal{R}^2 \ : \ f(x) = 1\} = \{r\,(\cos\theta, \sin\theta) \ : \ r\hat{f}(\theta) = 1\}.$$

When the surface tension f is smooth and convex, the gradient flow for the functional I has the form

$$\beta(\theta)V = (\hat{f}(\theta) + \hat{f}_{\theta\,\theta}(\theta))\ \kappa, \tag{2.2}$$

where V, κ, $(\cos\theta, \sin\theta)$ are, respectively, the normal velocity, the curvature, and the normal vector of the solution $\Gamma(t)$, and the given nonnegative function β is the kinetic coefficient. The mean curvature flow corresponds to $\hat{f} \equiv \beta \equiv 1$, and the other cases with strictly convex surface energy are qualitatively very similar to the mean curvature flow.

If f is not convex, we need to modify *both* f and β to obtain the correct relaxed equation. This relaxation procedure and the analytical properties of the relaxed equation was studied by Gurtin, Soner, and Souganidis [23] and, independently, by Ohnuma and Sato [27]. The common critical hypothesis in these works is the continuous differentiability of the relaxed surface energy function.

2.2. Crystalline flow. Nonsmooth energy functions are of interest in models for crystal growth, as it is well known that solid crystals can exist in polygonal shapes. An interesting class of nonsmooth energies are the *crystalline* energies. The Frank diagram of crystalline energy is a polygon.

Although the crystalline energies are only Lipschitz continuous, an appropriate weak formulation of (2.2) is possible and is called the crystalline flow; see [22, section 12.5] for the precise definition. The crystalline flow was derived by Taylor [31] and, independently, from thermodynamical considerations by Angenent and Gurtin [4].

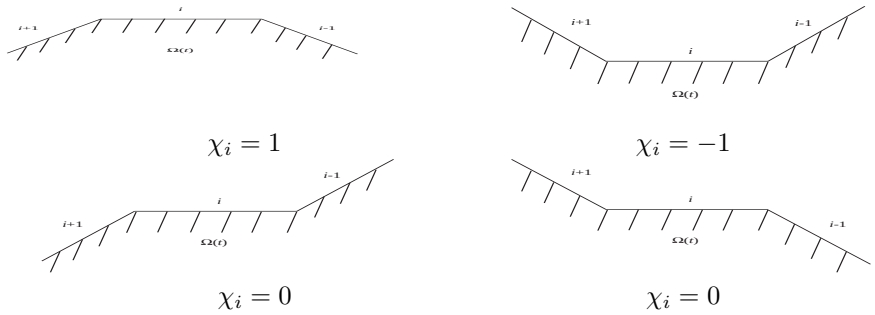

FIG. 1. *Definition of* χ_i.

Consider a crytalline energy function f, and let $\Theta := \{\theta_1, \dots, \theta_N\}$ be the angles corresponding to the corner points of the Frank digram of f. Suppose that the curve Γ is locally smooth around a point with a normal angle $\theta^* \notin \Theta$—say, $\theta^* \in (\theta_1, \theta_2)$. We can, then, decrease the energy $I(\Gamma)$ of Γ by infinitesimally alternating the normal angle between θ_1 and θ_2. Therefore, for crystalline energies, we consider only polygonal solutions with normal angles taking values in Θ.

In this paper, for simplicity, we consider only crystalline energies whose Frank diagrams are regular n-polygons, and kinetic coefficient $\beta \equiv 1$. Then

$$\Theta = \Theta_n := \left\{ \frac{2\pi k}{n} \ : \ k = 0, 1, \dots, (n-1) \right\}.$$

Here and hereafter $\theta \in \Theta$ means $\theta \equiv 2\pi k/n \mod 2\pi$ for some $k \in \{0, 1, \dots, n-1\}$. The evolution of side i, $L_i(t)$, is governed by

$$V_i(t) = -\frac{2\tan(\pi/n)}{l_i(t)}\ \chi_i, \tag{2.3}$$

where $V_i(t)$, $l_i(t)$, and χ_i, are, respectively, the normal velocity, the length, and the discrete curvature of $L_i(t)$. The discrete curvature $\chi_i \in \{-1, 0, +1\}$. It is equal to $+1$ if both edges of $L_i(t)$ have positive curvature, it is equal to -1 if both edges of $L_i(t)$ have negative curvature, and it is equal to zero otherwise; see Figure 1. ($\Omega(t)$ denotes the domain enclosed by $L_i(t)'s$.)

We close this subsection by stating the evolution rule for the length, $l_i(t)$, of the sides of a solution of the crystalline flow:

$$\frac{d}{dt} l_i(t) = \frac{1}{\cos^2(\pi/n)} \left(2\cos\left(\frac{2\pi}{n}\right) \cdot \frac{\chi_i^2}{l_i(t)} - \frac{\chi_{i+1}^2}{l_{i+1}(t)} - \frac{\chi_{i-1}^2}{l_{i-1}(t)} \right). \tag{2.4}$$

This equation follows from (2.3) and geometry; see [22, equation (12.39)].

2.3. *n*-smooth polygons. We continue by defining the notion of a "good" solution of (2.3). For a polygon Γ, let $N(\Gamma)$ be the total number of sides.

DEFINITION 2.1. *We say that a closed polygon* Γ *is an* n*-smooth polygon if* $N(\Gamma)$ *is finite and*

(1) Γ *encloses a simply-connected, bounded, open subset of* $\mathcal{R}^2$,
(2) *for every* $i = 1, \dots, N(\Gamma)$, *the normal angle* θ_i *of the side* i *belongs to* Θ_n,
(3) $|\theta_i - \theta_{i-1}| = 2\pi/n$ *for every* $i = 1, \dots, N(\Gamma)$, *where* $|\theta_i - \theta_{i-1}|$ *is understood as the infimum over its representatives.*

The third condition is formally equivalent to the "discrete continuity" of the normal angle, which explains the term "smooth."

By definition, any solution of (2.3) satisfies the second condition.

Let

$$N^+(\Gamma) := \{i \in \{1, \dots, N(\Gamma)\} \ : \chi_i = 1\},$$

$$N^-(\Gamma) := \{i \in \{1, \dots, N(\Gamma)\} \ : \chi_i = -1\},$$

$$N^0(\Gamma) := \{i \in \{1, \dots, N(\Gamma)\} \ : \chi_i = 0\}.$$

Then for any n-smooth polygon Γ,

$$N^+(\Gamma) - N^-(\Gamma) = \sum_{i=1}^{N(\Gamma)} \chi_i = n \tag{2.5}$$

is an identity which is the discrete version of

$$\int_C \kappa \, ds = 2\pi$$

for a smooth Jordan curve C.

3. Regularity. In this section, we will show that there is a unique n-smooth solution of (2.3) which evolves smoothly in time (i.e., remains n-smooth) and shrinks to a point in finite time. This is the discrete analogue of a theorem of Grayson [24] and Gage and Hamilton [15]. A more general statement is proved by Taylor [33, Theorem 3.1]. For the reader's convenience, we provide all the details of this result.

THEOREM 3.1 (Taylor [33]). *Let Γ_0 be an n-smooth polygon enclosing an open set Ω_0. Then there exist n-smooth polygons $\{\Gamma(t)\}_{t\in[0,T)}$ solving (2.3) with the initial condition $\Gamma(0) = \Gamma_0$. Moreover $\Gamma(t)$ shrinks to a point as $t \uparrow T$, and*

$$T = \frac{|\Omega_0|}{2n \tan(\pi/n)}. \tag{3.1}$$

Remark 3.2. Uniqueness follows from Giga and Gurtin [18] and Taylor [33].

We start with several results toward the proof of Theorem 3.1.

Clearly, for a short time there is a solution $\Gamma(t)$ satisfying initial data. Let $t_1 > 0$ be the first time this solution is no longer n-smooth. Since, by definition, the normal angles of any solution take values in Θ_n (cf. section 2.2), there are two possibilities at t_1: either the length of one or more sides tend to zero or the solution self-intersects at t_1. We will first show that the latter does not happen. Our proof is very similar to [33, Theorem 3.2(1)].

LEMMA 3.3. *Let t_1 and $\{\Gamma(t) = \partial\Omega(t)\}_{t\in[0,t_1)}$ be as above. Then*

$$\liminf_{t\uparrow t_1} \inf\{l_i(s) \ : \ s \in [0,t], \ i = 1, \dots, N(\Gamma(0))\} = 0.$$

Proof. Suppose the opposite. Then

$$\inf\{l_i(s) \ : \ s \in [0,t_1), \ i = 1, \dots, N(\Gamma(0))\} > 0.$$

Then, by (2.4), each $l_i(\cdot)$ is smooth on $(0,t_1)$ and therefore

$$\Omega(t_1) = \lim_{t\uparrow t_1} \Omega(t)$$

exists in the Hausdorff topology. By the definition of t_1, $\Gamma(t_1)$ self-intersects. Moreover, for all $t \in [0,t_1]$,

$$|\theta_i - \theta_{i-1}| = \frac{2\pi}{n},\ i = 1,\dots,N(\Gamma(t)) = N(\Gamma(0)), \tag{3.2}$$

so that at t_1 there are two possibilities: either two sides or two corner points touch each other. Note that, by (3.2), if a corner point touches a side, then necessarily two sides also touch each other. The following arguments are very similar to those in [18].

Case 1. Suppose that $L_i(t_1)$ intersects at $L_j(t_1)$.

Then a straightforward analysis argument shows that $(\chi_i,\chi_j) = (1,-1)$ or $(\chi_i,\chi_j) = (-1,1)$. Since the analyses of these cases are symmetric, we may assume $(\chi_i,\chi_j) = (1,-1)$. Then $l_i(t_1) \le l_j(t_1)$.

Subcase (1). $l_i(t_1) < l_j(t_1)$.

Then for some $\delta > 0$, $l_i(t) < l_j(t)$ in $(t_1-\delta,t_1]$, and therefore,

$$\alpha(t) := \frac{2\tan(\pi/n)}{l_j(t)} - \frac{2\tan(\pi/n)}{l_i(t)} > 0, \qquad t \in (t_1-\delta,t_1].$$

But $\alpha(t)$ is equal to the time derivative of the distance between $L_i(t)$ and $L_j(t)$ and this distance is equal to zero at t_1. Hence this case is not possible.

Subcase (2). $l_i(t_1) = l_j(t_1)$.

Then, the sides adjacent to $L_i(t)$ and $L_j(t)$ also touch each other at time t_1, and therefore, there have to be two sides satisfying the assumptions of the previous subcase, thus yielding a contradiction.

Case 2. Two corner points touch each other.

Let the intersection, $x_i(t)$ of $L_i(t)$ and $L_{i+1}(t)$ be the same as the intersection $x_j(t)$ of the sides $L_{j-1}(t)$ and $L_j(t)$. Then the angle between $L_i(t)$ and $L_j(t)$ and the one between $L_{i+1}(t)$ and $L_{j-1}(t)$ are equal to $2\pi/n$. By rotation, we may assume that $L_i(t)$ and $L_j(t)$ are parallel to the x-axis, and $L_{i+1}(t)$ is aligned with the $L_{j-1}(t)$ (cf. Figure 2). Moreover, $\chi_k \ge 0$ for $k = i, i+1, j, j-1$. Let $V_{x_i}(t)$ and $V_{x_j}(t)$ be the velocity vectors of the points $x_i(t)$ and $x_j(t)$, respectively. Then

$$(0,1)\cdot(V_{x_j} - V_{x_i}) \ge 0,$$

and the inequality is strict unless $\chi_k = 0$ for all $k = i, i+1, j, j-1$. Since $x_i(t_1) = x_j(t_1)$, we conclude that $\chi_k = 0$ for all $k = i, i+1, j, j-1$. But then $V_{x_i}(t) = V_{x_j}(t) = 0$ for $t < t_1$ close to t_1 and this contradicts the definition of t_1. □

Our next result is the following lemma.

LEMMA 3.4. *Let t_1 and $\{\Gamma(t) = \partial\Omega(t)\}_{t\in[0,t)}$ be as above. Suppose t_1 is strictly less than the extinction time. Then as $t \to t_1$, $\Omega(t)$ converges to an n-smooth polygon $\Omega(t_1)$ in the Hausdorff topology.*

Proof. By the previous lemma, there is a side i^* such that

$$\liminf_{t\to t_1} l_{i^*}(t) = 0.$$

The main step in this proof is to show $\chi_{i^*} = 0$ if the side L_{i^*} disappears at t_1. So we suppose that it is equal to $+1$ or -1. Since the analyses of these cases are similar, we may assume that $\chi_{i^*} = 1$. Set $\theta = 2\pi/n$.

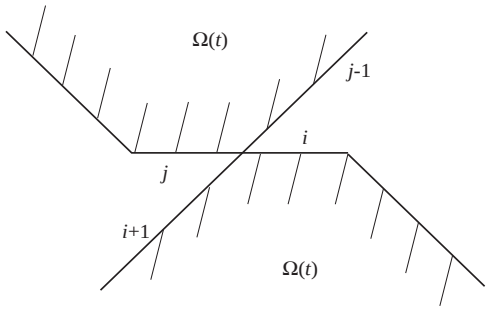

FIG. 2. *Case* 2.

1. In this step we will show that $l_{i^*}(\cdot)$ is continuous on $[0, t_1]$. For future reference, we will prove that, for any j, $l_j(\cdot)$ is continuous on $[0, t_1]$. By (2.4), all sides remain bounded, and we set

$$B := \limsup_{t \to t_1} l_j(t).$$

Suppose that

$$B > \liminf_{t \to t_1} l_j(t) := A.$$

Since $l_j(\cdot)$ is continuous in $[0, t_1)$, it crosses $(A + B)/2$ infinitely many times before t_1. In particular, by the mean value theorem, there is a sequence $t_k \uparrow t_1$ such that

$$l_j(t_k) \geq \frac{A+B}{2}, \quad \lim_{k \to +\infty} l_j'(t_k) = +\infty.$$

However, by (2.4),

$$l_j'(t_k) \leq \frac{2\cos\theta}{l_j(t_k)\cos^2(\theta/2)} \leq C$$

for some constant C independent of k. Hence $A = B$.

2. This step closely follows [33, Proposition 3.1].

Since t_1 is strictly less than the extinction time, there are at least two sides which have nonzero length at time t_1. Hence there are two sides L_{p_0} and L_{p_1} such that $p_0 < i^* < p_1$, $l_{p_0}(t)$ and $l_{p_1}(t)$ are uniformly positive in $[0, t_1]$, and

$$\lim_{t \uparrow t_1} l_j(t) = 0 \ \forall j = p_0 + 1, \ldots, p_1 - 1.$$

For any j, let $\mathcal{L}_j(t)$ be the line extending $L_j(t)$, $x_{j+1}(t)$ be the intersection between $\mathcal{L}_j(t)$ and $\mathcal{L}_{j+1}(t)$, and θ_j be the angle between the outward normal and the horizontal axis. Then, as $t \uparrow t_1$, all $x_{p_0+1}(t), \ldots, x_q(t)$ converge to the same point x^*.

We analyze several cases separately.

Case 1. $\chi_j \neq 0 \ \forall \ j = p_0 + 1, \ldots, p_1 - 1$.

Since we have assumed that $\chi_{i^*} = 1$, $\chi_j = 1 \ \forall \ j = p_0 + 1, \ldots, p_1 - 1$ and

$$x^* \in \bigcap_{0 \leq t < t_1} \bigcap_{j=p_0}^{p_1} \{y \in \mathcal{R}^2 \ : \ (y - x_j(t)) \cdot (\cos\theta_j, \sin\theta_j) \leq 0\}.$$

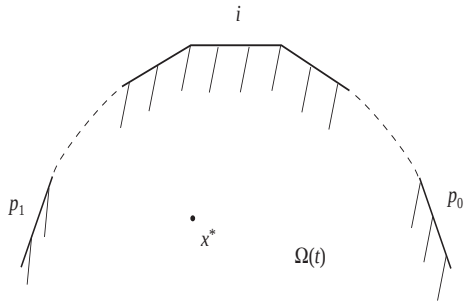

FIG. 3. *Position of* x^*.

See Figure 3.

By geometry, $|\theta_{p_0} - \theta_{p_1}| \leq \pi$.

Subcase 1. $|\theta_{p_0} - \theta_{p_1}| < \pi$.

Let $y(t)$ be the intersection between $\mathcal{L}_{p_0}(t)$ and $\mathcal{L}_{p_1}(t)$. We define

$$d(t) = (y(t) - x^*) \cdot (\cos\theta_{p_0+1}, \sin\theta_{p_0+1}),$$
$$d_{p_0+1}(t) = \operatorname{dist}(x^*, \mathcal{L}_{p_0+1}(t)).$$

Then $d_{p_0+1}(t) \leq d(t)\ \forall\ t \in [0, t_1)$ and $d_{p_0+1}(t_1) = d(t_1) = 0$. Moreover, $d(t)$ is Lipschitz continuous in t and

$$\frac{d}{dt} d_{p_0+1}(t) = V_{p_0+1}(t) = -\frac{2\tan(\theta/2)}{l_{p_0+1}(t)}.$$

Hence,

$$0 \geq -\int_t^{t_1} \frac{2\tan(\theta/2)}{l_{p_0+1}(\tau)} d\tau = d_{p_0+1}(t) \geq d(t) \geq -\|d'\|_{L^\infty(0,t_1)}(t_1 - t) \qquad \forall t < t_1.$$

This contradicts the fact $l_{p_0+1}(t) \to 0$ as $t \uparrow t_1$.

Subcase 2. $|\theta_{p_0} - \theta_{p_1}| = \pi$.

We repeat the argument used in the previous case with

$$\tilde{d}(t) = \operatorname{dist}(\mathcal{L}_{p_0}(t), \mathcal{L}_{p_1}(t)),$$
$$\tilde{d}_{p_0+1}(t) = \operatorname{dist}(L_{p_0+1}(t), \mathcal{L}_{p_1}(t)).$$

Case 2. $\chi_q = 0$ exactly for one $q \in \{p_0 + 1, \ldots, p_1 - 1\}$.

Then, $\chi_j = 1$ for $j = p_0 + 1, \ldots, q - 1$ and $\chi_j = -1$ for $j = q + 1, \ldots, p_1 - 1$, or $\chi_j = -1$ for $j = p_0 + 1, \ldots, q - 1$ and $\chi_j = 1$ for $j = q + 1, \ldots, p_1 - 1$. Since the arguments in both cases are similar, without loss of generality, we consider only the first possibility.

If $|\theta_{p_0} - \theta_q| \leq \pi$, we argue as in *Case* 1, using side $L_q(t)$ instead of $L_{p_1}(t)$. We also argue similarly, when $|\theta_q - \theta_{p_1}| \leq \pi$. Therefore, we may assume that $|\theta_{p_0} - \theta_q| > \pi$ and that there is a side $L_j(t)$ with $q < j < p_1$, which is parallel to $L_{p_0}(t)$. Let $\mathcal{L}$ be the line going through x^* and parallel to both $L_{p_0}(t)$ and $L_j(t)$. Set

$$d(t) = \operatorname{dist}(L_{p_0}(t), \mathcal{L}) - \operatorname{dist}(L_j(t), \mathcal{L}).$$

Then $0 = d(t_1)$ and since $|\theta_{p_0} - \theta_q| > \pi$, $0 < d(t)\ \forall\ (0, t_1)$; see Figure 4.

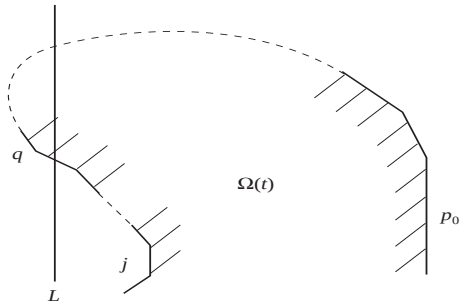

FIG. 4. *Case* 2.

However, this contradicts the fact that $d'(t) > 0 \ \forall\ t$ sufficiently close to t_1.

Case 3. $\chi_j = 0$ for more than one side.

Suppose that χ_q and χ_j are equal to zero. Then x^* belongs to both $L_q(t)$ and $L_j(t) \ \forall\ t$, and therefore, $j = q - 1$ or $q + 1$. Since $l_q(t)$ converges to zero, at least one side adjacent to $L_q(t)$ has nonzero discrete curvature. Hence there are two sides with zero discrete curvature and they are adjacent to each other. As in *Case* 1, all the other sides between $L_{p_0}(t)$ and $L_{p_1}(t)$ satisfy $\chi_k = 1$, and we argue as in *Case* 1.

Therefore, the case $\chi_{i^*} = 1$ is not possible. An entirely similar argument shows that the case $\chi_{i^*} = -1$ is not possible either. Hence $\chi_{i^*} = 0$ and L_{i^*-1} and L_{i^*+1} are parallel, and the normal angle of the "new" side is equal to that of these two ones. □

We are now in a position to prove Theorem 3.1.

Proof of Theorem 3.1. Since $\Gamma(0)$ is n-smooth for short time, there is an n-smooth solution $\Gamma(t)$. Moreover, by Lemma 3.4, this solution remains n-smooth until one side of $\Gamma(t)$ vanishes. Let t_1 be the first time a side vanishes. Then, $\Gamma(t)$ is n-smooth and $N(\Gamma(t)) = N(\Gamma(0)) \ \forall\ t \in [0, t_1)$. By Lemma 3.3, $\Gamma(t_1)$ is also n-smooth and $N(\Gamma(t_1)) \le N(\Gamma(0)) - 2$. We repeat this procedure starting from $\Gamma(t_1)$. Since $N(\Gamma(0))$ is finite, we have only to repeat finitely many times.

Let $t_1 < t_2 < \cdots < t_N$ be the times at which a side vanishes. Let $t_N > 0$ be the time when $N^-(\Gamma(t_N)) = N^0(\Gamma(t_N)) = 0$. Then, by (2.5), $N^+(\Gamma(t_N)) = n$ and $\Gamma(t)$ is convex for all $t \ge t_N$.

We see that $\Gamma(t)$ shrinks to a point at finite time. Indeed, by (2.5), we can calculate the rate of change of $|\Omega(t)|$:

$$\begin{aligned}\frac{d}{dt}|\Omega(t)| &= \sum_i V_i l_i \\ &= -\sum_{i \in N^+(\Gamma(t))} 2\tan\frac{\pi}{n} + \sum_{i \in N^-(\Gamma(t))} 2\tan\frac{\pi}{n} \\ &= -2n\tan\frac{\pi}{n}.\end{aligned}$$

From the foregoing calculation, we conclude that the solution shrinks to a point at some time T. Moreover, at time T,

$$0 = |\Omega(T)| = |\Omega_0| - 2n\tan\frac{\pi}{n}\cdot T,$$

and (3.1) follows. □

4. Weak viscosity limits. In this section, we will study the properties of the set-theoretic analogue of the weak viscosity limits of Barles and Perthame [5, 6]. Let $\{\Gamma_n(t)\}_{t\in[0,T)}$ be a sequence of n-smooth solutions of (2.3), and let $\Omega_n(t)$ be the open set enclosed by $\Gamma_n(t)$. Assume that there is a constant $R > 0$, independent of n, satisfying

$$\Omega_n(t) \subset B(0,R), \tag{4.1}$$

where $B(x,r) = \{y \in \mathcal{R}^2 \ : \ |y-x| \le r\}$. Following [6, 29], for $t \in [0,T)$, we define

$$\widehat{\Omega}(t) := \bigcap_{\substack{r>0\\N\ge 1}} \operatorname{cl}\left(\bigcup_{\substack{|s-t|\le r,\ 0\le s<T\\ n\ge N}} \Omega_n(s) \right), \tag{4.2}$$

$$\underline{\Omega}(t) := \bigcup_{\substack{r>0\\N\ge 1}} \operatorname{int}\left(\bigcap_{\substack{|s-t|\le r,\ 0\le s<T\\ n\ge N}} \Omega_n(s) \right),$$

where $\operatorname{cl} A$ and $\operatorname{int} A$ are, respectively, the closure and the interior of the set A. In view of (4.1), $\widehat{\Omega}(t)$ is a bounded closed set and $\underline{\Omega}(t)$ is a bounded open set. We will show that, respectively, $\widehat{\Omega}(t)$ is a weak subsolution and $\underline{\Omega}(t)$ is a weak supersolution of the mean curvature flow.

This type of stability results are typical in the theory of viscosity solutions and, in general, they are a simple consequence of the maximum principle. However, the crystalline flow is not defined for smooth curves and this fact is the major difficulty in the following analysis.

The notion of viscosity solutions we use is first introduced by the second author in [29] and further developed in [7, 30]. Here we only recall the definition; other relevant definitions and results are gathered in the appendix.

We continue by recalling several definitions that will be used in the subsequent analysis. For subsets $\{\Omega(t)\}_{0\le t<T}$ in $\mathcal{R}^2$, the *upper semicontinuous* (*u.s.c.*) *envelope* and, respectively, the *lower semicontinuous* (*(l.s.c.*) *envelope* are defined by

$$\Omega^*(t) = \bigcap_{r>0} \operatorname{cl}\left(\bigcup_{\substack{|s-t|\le r\\ 0\le s<T}} \Omega(s) \right), \quad \Omega_*(t) = \bigcup_{r>0} \operatorname{int}\left(\bigcap_{\substack{|s-t|\le r\\ 0\le s<T}} \Omega(s) \right), \quad t \in [0,T).$$

Then, it is clear that $(\underline{\Omega})_* = \underline{\Omega}$ and $(\widehat{\Omega})^* = \widehat{\Omega}$. For other properties of these envelopes, see [29, Lemma 3.1].

For a collection of closed subsets $\{O(t)\}_{0\le t<T}$ with smooth boundary, $V_O(x,t)$ is the normal velocity of $\partial O(t)$ at x and $\kappa_O(x,t)$ is the curvature of $\partial O(t)$ at x. We use the convention that the curvature of a convex curve is nonnegative.

We are now in a position to give the weak (viscosity) definition of the mean curvature flow we will use. This definition is very similar to the one given in [29]; see the appendix for the connection between these two definitions.

DEFINITION 4.1. *Let $\{\Omega(t)\}_{0\le t<T}$ be a collection of bounded subsets in $\mathcal{R}^2$ satisfying $\Omega_*(t) \neq \emptyset$ for every $t \in [0,T)$.*

We say $\{\Omega(t)\}_{0\le t<T}$ is a *weak subsolution* of the mean curvature flow, if for any closed, smooth subsets $\{O(t)\}_{0\le t<T}$,

$$V_O(x_0,t_0) \le -\kappa_O(x_0,t_0) \tag{4.3}$$

at each $t_0 \in (0,T)$ and $x_0 \in \partial O(t_0)$ satisfying

$$\Omega^*(t) \subset\subset O(t) \qquad \forall\, t \neq t_0, \tag{4.4}$$

$$\Omega^*(t_0) \subset O(t_0), \quad \partial\Omega^*(t_0) \cap \partial O(t_0) = \{x_0\}.$$

Similarly, we say $\{\Omega(t)\}_{0\le t<T}$ is a *weak supersolution* of the mean curvature flow if for any closed, smooth subsets $\{O(t)\}_{0\le t<T}$,

$$V_O(x_0,t_0) \ge -\kappa_O(x_0,t_0)$$

at each $t_0 \in (0,T)$ and $x_0 \in \partial O(t_0)$ satisfying

$$O(t) \subset\subset \Omega_*(t)\ \forall\, t \neq t_0, \quad O(t_0) \subset \Omega_*(t_0), \quad \partial\Omega_*(t_0) \cap \partial O(t_0) = \{x_0\}.$$

Condition (4.4) implies that $(x_0,t_0) \in \partial O(t_0) \times (0,T)$ is the *strict* maximizer of $-\mathrm{dist}(x, \partial\Omega^*(t))$ over all $(x,t) \in \partial O(t) \times (0,T)$. A similar conclusion also holds for supersolutions.

Following is the set theoretic analogue of the Barles and Perthame procedure [5, 6], [13, section 5], and it is the chief technical contribution of this paper.

Recall that $\Gamma_n(t) = \partial\Omega_n(t)$.

LEMMA 4.2. *$\widehat{\Omega}$ is a weak subsolution of the mean curvature flow, while $\underline{\Omega}$ is a weak supersolution.*

Before we give the proof of this lemma, we will first give a formal proof of the subsolution property.

In view of our definition of a weak solution, we start with smooth sets $\{O(t)\}_{0<t<T}$ and a point (x_0,t_0) satisfying (4.4). Our goal is to verify (4.3). By (4.4) there are a subsequence n_k and a sequence $(x_k,t_k) \to (x_0,t_0)$ satisfying $\Omega_{n_k}(t_k) \subset O(t_k)$ and that $x_k \in \Gamma_{n_k}(t_k)$. Although there are several other cases, assume that x_k is the intersection of $L_{i-1}(t_k)$ and $L_i(t_k)$ of $\Gamma_{n_k}(t_k)$, and $\chi_i = \chi_{i-1} = 1$. We choose a coordinate system so that x_k is the origin and the $L_i(t_k)$ side is included in the x_1-axis. Let $n_1 = (0,1)$, $n_2 = (\sin(2\pi/n_k), \cos(2\pi/n_k))$. Then, the unit normal vector of ∂O satisfies $n_O(x_k,t_k) = (\sin\alpha, \cos\alpha)$ for some $0 < \alpha < 2\pi/n_k$. By the crystalline equation (2.3),

$$V_{x_k} \cdot n_1 = V_i = -\frac{2\tan(\pi/n_k)}{l_i},$$
$$V_{x_k} \cdot n_2 = V_{i-1} = -\frac{2\tan(\pi/n_k)}{l_{i-1}},$$

and therefore,

$$V_{x_k} = 2\tan\frac{\pi}{n_k}\left(\frac{1}{\tan(2\pi/n_k)}\left(\frac{1}{l_i} - \frac{1}{l_{i-1}}\right), -\frac{1}{l_i}\right), \tag{4.5}$$

$$\begin{aligned} V_O(x_k,t_k) &= V_{x_k} \cdot n_O(x_k,t_k) \\ &= -\frac{1}{\cos^2(\pi/n_k)}\left(\frac{\sin(2\pi/n_k - \alpha)}{l_i} + \frac{\sin\alpha}{l_{i-1}}\right). \end{aligned} \tag{4.6}$$

Since $V_O(x_k,t_k)<0$, we may assume $\inf_{k\in\mathcal{N}}\kappa_O(x_k,t_k)>0$. This implies that, as $k\to\infty$, both l_i and l_{i-1} converge to zero. By elementary geometry, we obtain a sharper estimate: for every $\varepsilon>0$,

$$l_i\le\frac{2\sin\alpha}{\kappa_O(x_k,t_k)-\varepsilon},\qquad l_{i-1}\le\frac{2\sin(2\pi/n_k-\alpha)}{\kappa_O(x_k,t_k)-\varepsilon}$$

for sufficiently large k. Substitute these into (4.6):

$$\begin{aligned}V_O(x_k,t_k)&\le-\frac{\kappa_O(x_k,t_k)-\varepsilon}{2\cos^2(\pi/n_k)}\left(\frac{\sin(2\pi/n_k-\alpha)}{\sin\alpha}+\frac{\sin\alpha}{\sin(2\pi/n_k-\alpha)}\right)\\&\le-\kappa_O(x_k,t_k)+\varepsilon.\end{aligned}$$

In the foregoing argument, we crucially used the assumption that x_k is a "convex" corner point of Γ_{n_k}. Although this is the most likely situation, other cases may also arise, and for that we will perturb the test sets O in the preceding proof.

Proof. We will prove only the subsolution property. Proof of the supersolution case is similar.

Let $\{O(t)\}_{0<t<T}$ and (t_0,x_0) be as in (4.4). Our goal is to verify (4.3), i.e.,

$$v:=V_O(x_0,t_0)\le-\kappa:=-\kappa_O(x_0,t_0).$$

If necessary, by perturbing $O(\cdot)$, we may assume that $\kappa\neq0$. We analyze two cases separately.

Case 1. $\kappa>0$.

For $\varepsilon>0$, $x^*\in\mathcal{R}^2$, and a large constant K, let $D^\varepsilon(t:x^*)$ be the disk with center x^* and radius

$$R^\varepsilon(t)=\frac{1}{\kappa-\varepsilon}+v(t-t_0)+K(t-t_0)^2.$$

Set

$$x_0^\varepsilon:=x_0-R^\varepsilon(t_0)n_O(x_0,t_0).$$

By the smoothness of ∂O, for all sufficiently large K, there is a δ^ε such that

$$O(t)\cap B(x_0,2\delta^\varepsilon)\subset D^\varepsilon(t:x_0)\cap B(x_0,2\delta^\varepsilon)\tag{4.7}$$

for all $|t-t_0|\le2\delta^\varepsilon$. We fix K large enough so that the above inequality holds.

Next we approximate $D^\varepsilon(t:x^*)$ by regions with polygonal boundaries. Let

$$C_n:=\left\{\ x\in\mathcal{R}^2\ :\ x\cdot\left(\cos\left(\frac{2l\pi}{n}\right),\sin\left(\frac{2l\pi}{n}\right)\right)\le1\quad\forall\ l=0,1,\dots,(n-1)\ \right\},$$

and, for any x^*, set

$$D_n^\varepsilon(t:x^*):=\{x^*\}\oplus R^\varepsilon(t)C_n.$$

Since $D_n^\varepsilon(\cdot:x_0^\varepsilon)$ approximates $D^\varepsilon(\cdot:x_0^\varepsilon)$, by (4.4) and (4.7), there are a subsequence n_k and sequences $(x_k,t_k)\to(x_0,t_0)$, $y_k\to x_0^\varepsilon$ satisfying

$$x_k\in\Gamma_{n_k}(t_k)\cap\partial D_{n_k}^\varepsilon(t_k:y_k),$$

$$\Omega_{n_k}(t) \cap B(x_0, \delta^\varepsilon) \subset D^\varepsilon_{n_k}(t : y_k) \cap B(x_0, \delta^\varepsilon) \qquad \forall\ |t - t_0| \le \delta^\varepsilon.$$

A proof of this fact is given in the appendix in Lemma 6.2. To simplify the notations, we assume that $n_k = k$ and write $D_k(t)$ for $D^\varepsilon_{n_k}(t : y_k)$.

Let x_k be on the ith side of $\Gamma_k(t_k)$. Then the normal velocity, V_i, of this side is equal to the normal velocity of D_k at t_k. Hence,

$$V_i = v + 2K(t_k - t_0).$$

Since $D_k(t_k)$ is a regular k-polygon, $\chi_i(t_k) = 1$ and, therefore, the length $l_i(t_k)$ of side i of $\Gamma_k(t_k)$ is less than or equal to the length of any side of $D_k(t_k)$:

$$l_i(t_k) \le 2R^\varepsilon(t_k) \sin \frac{\pi}{k}.$$

Then, by (2.3) and the foregoing discussion,

$$v + 2K(t_k - t_0) = V_i = -\frac{2\tan(\pi/k)}{l_i(t_k)} \le -\frac{1}{R^\varepsilon(t_k)\cos(\pi/k)}.$$

Since $R^\varepsilon(t_k)$ converges to $1/\kappa$ and $t_k \to t_0$, we obtain (4.3) by first letting $k \to \infty$ and then $\varepsilon \downarrow 0$.

Case 2. $\kappa < 0$.

For small $\varepsilon > 0$ and any x^*, let $x_0^\varepsilon := x_0 + R^\varepsilon(t_0) n_O(x_0, t_0)$, and let $D^\varepsilon(t : x^*)$ be the complement of the disk with center x^*, radius

$$R^\varepsilon(t) = \frac{1}{-\kappa + \varepsilon} + v(t - t_0) - K(t - t_0)^2.$$

As in the previous case, there is a δ^ε such that

$$O(t) \cap B(x_0, 2\delta^\varepsilon) \subset D^\varepsilon(t : x_0^\varepsilon) \cap B(x_0, 2\delta^\varepsilon) \tag{4.8}$$

$\forall\ |t - t_0| \le 2\delta^\varepsilon$, and for any x^*, we set

$$D^\varepsilon_n(t : x^*) := \mathcal{R}^2 \setminus \{x^*\} \oplus R^\varepsilon(t) C_n.$$

Then, $D^\varepsilon_n(\cdot : x_0)$ approximates $D^\varepsilon(\cdot : x_0)$, and by (4.4) and (4.8), there are a subsequence n_k and sequences $(x_k, t_k) \to (x_0, t_0)$, $y_k \to x_0^\varepsilon$ satisfying

$$x_k \in \Gamma_{n_k}(t_k) \cap \partial D^\varepsilon_{n_k}(t_k : y_k),$$

$$\Omega_{n_k}(t) \cap B(x_0, \delta^\varepsilon) \subset D^\varepsilon_{n_k}(t : y_k) \cap B(x_0, \delta^\varepsilon) \qquad \forall\ |t - t_0| \le \delta^\varepsilon.$$

Again, we assume that $n_k = k$, write $D_k(t)$ for $D^\varepsilon_{n_k}(t : y_k)$, and let x_k belong to the ith side of $\Gamma_k(t_k)$. Since, in this case, the normal velocity of D_k at t_k is equal to $v - 2K(t_k - t_0)$,

$$V_i = v - 2K(t_k - t_0).$$

If $v \le 0$, (4.3) is immediately satisfied. Hence, we may assume that $v > 0$. So, for small $\varepsilon > 0$, $V_i > 0$, and by (2.3), $\chi_i = -1$. Consequently, $l_i(t_k)$ is greater than or equal to the length of any side of $D_k(t_k)$:

$$l_i(t_k) \ge 2R^\varepsilon(t_k) \sin \frac{\pi}{k},$$

and therefore,

$$v - C(t_k - t_0) = V_i = \frac{2\tan(\pi/k)}{l_i(t_k)} \leq \frac{1}{R^\varepsilon(t_k)\cos(\pi/k)}.$$

We first let $k \to \infty$ and then $\varepsilon \downarrow 0$. Since $R^\varepsilon(t_k)$ converges to $1/|\kappa| = -1/\kappa$, the result is (4.3). □

5. Convergence. Let $\Gamma_0 = \partial\Omega_0$ be a twice differentiable Jordan curve and $\Gamma_{n\,0} = \partial\Omega_{n\,0}$ be an n-smooth approximation of Γ_0 satisfying

$$\lim_{n\to\infty} d_H(\Omega_{n\,0}, \Omega_0) = 0, \tag{5.1}$$

where d_H is the Hausdorff distance. For each n, there is a unique n-smooth solution $\{\Gamma_n(t)\}_{t\in[0,T_n)}$ of (2.3) satisfying the initial condition $\Gamma_n(0) = \Gamma_{n\,0}$ by Theorem 3.1. Moreover,

$$T_n = \frac{|\Omega_{n\,0}|}{2n\tan(\pi/n)} \to T_0 := \frac{|\Omega_0|}{2\pi}, \qquad n \to +\infty. \tag{5.2}$$

Let $\widehat{\Omega}$ and $\underline{\Omega}$ be as in section 4 so that, by construction,

$$\operatorname{cl}\underline{\Omega}(t) \subset \widehat{\Omega}(t) \qquad \forall t \in [0, T_0). \tag{5.3}$$

Moreover, $\widehat{\Omega}$ is a weak subsolution of the mean curvature flow, and $\underline{\Omega}$ is a weak supersolution of the mean curvature flow. In general space dimension, there is no comparison between weak sub- and supersolutions; however, in dimension two, there is always a smooth solution of the mean curvature flow, $\Gamma(t) = \partial\Omega(t)$ and we will show that

$$\widehat{\Omega}(t) \subset \operatorname{cl}\Omega(t) \subset \operatorname{cl}\underline{\Omega}(t) \qquad \forall t \in [0, T_0). \tag{5.4}$$

Combining (5.3) and (5.4), we will then obtain the convergence of Ω_n to Ω in Hausdorff topology, thus generalizing the previous convergence results of Girao [20] and Girao and Kohn [21].

The foregoing outline of our convergence result is entirely analogous to the Barles and Perthame procedure of proving convergence with very weak L^∞ estimates [5, 6].

THEOREM 5.1. *Let $\Gamma_n(t) = \partial\Omega_n(t)$ be the solution of* (2.3) *with initial data $\Gamma_{n\,0}$, and let $\Gamma(t) = \partial\Omega(t)$ be the smooth solution of the mean curvature flow with initial data Ω_0. Assume* (5.1)*; then*

$$\lim_{n\to\infty} d_H(\Omega_n(t), \Omega(t)) = 0 \tag{5.5}$$

locally uniformly in $t \in [0, T_0)$.

We begin with the following lemma.

LEMMA 5.2. $\widehat{\Omega}(0) \subset \operatorname{cl}\Omega_0 \subset \operatorname{cl}\underline{\Omega}(0)$.

Proof. We will prove only the first inclusion. Proof of the second inclusion is similar.

Since $d_H(\Omega_n, \Omega_0) \to 0$, for any $x_0 \in \Omega_0$ there are $\delta_0 > 0$ and $n_0 \in \mathcal{N}$ satisfying

$$B(x_0, \delta_0) \subset\subset \Omega_n \qquad \forall n > n_0.$$

Let γ_n be the regular n-polygon enclosing $B(x_0, \delta_0)$. If necessary, by taking n_0 larger, we may assume that $\gamma_n \subset\subset \Omega_n \ \forall\ n > n_0$. Let $\gamma_n(t)$ be the solution of the crystalline flow (2.3) with initial data $\gamma_n(0) = \gamma_n$ and $\omega_n(t)$ be the open set enclosed by $\gamma_n(t)$. Then by the containment principle for crystalline motions (cf. Giga and Gurtin [18]),

$$B\left(x_0, \delta_0/2\right) \subset \omega_n(t) \subset \Omega_n(t) \qquad \forall n > n_0,\ 0 \le t \le \frac{1}{4}\delta_0^2.$$

Let $n \to +\infty$ and $t \downarrow 0$ to conclude that $B(x_0, \delta_0/2) \subset \underline{\Omega}(0)$; therefore $x_0 \in \underline{\Omega}(0)$. □

In our second step, we will show that the smooth mean curvature flow yields a viscosity sub- and supersolution of the following equation:

$$u_t + F(Du, D^2u) = 0, \qquad \mathcal{R}^2 \times (0, T),$$

where

$$F(p, X) = -\mathrm{tr}((I - \bar{p} \otimes \bar{p})X) \tag{5.6}$$

and $\bar{p} = p/|p|$. This step is very similar to Evans and Spruck [12, Section 6] and Ambrosio and Soner [3, section 3].

We refer to Crandall, Ishii, and Lions [10] and Fleming and Soner [13] for information on viscosity solutions and to Chen, Giga, and Goto [9], and Evans and Spruck [12] for the properties of the level set equations.

Let $\{\Gamma(t)\}_{0 \le t < T_0}$ be a unique smooth mean curvature flow satisfying $\Gamma(0) = \Omega_0$, and let $d(x, t)$ be the signed distance function to $\Gamma(t)$, i.e.,

$$d(x,t) = \begin{cases} \mathrm{dist}(x, \Gamma(t)) & \text{if } x \in \Omega(t), \\ -\mathrm{dist}(x, \Gamma(t)) & \text{otherwise,} \end{cases}$$

where $\Omega(t)$ is the open set enclosed by $\Gamma(t)$. For a scalar d, $d \wedge 0 = \min\{d, 0\}$ and $d \vee 0 = \max\{d, 0\}$.

LEMMA 5.3. *For any $\delta > 0$, there are constants $\sigma = \sigma(\delta) > 0$ and $K = K(\delta) > 0$ so that the function $u(x,t) := e^{-Kt}[(d \vee 0)(x,t) \wedge \sigma]$ is a viscosity subsolution of*

$$u_t + F(Du, D^2u) = 0 \qquad \text{in} \quad \mathcal{R}^2 \times (0, T_0).$$

Proof. For $\delta > 0$, there exists a $\sigma = \sigma(\delta) > 0$ such that d is smooth in $\{x \in \mathcal{R}^2 : |d(x,t)| < 2\sigma\} \times [0, T_0 - \delta]$, and in this tubular set,

$$\Delta d(x,t) = \frac{\kappa(y,t)}{1 - \kappa(y,t)d(x,t)}, \tag{5.7}$$

where $y \in \Gamma(t)$ is a unique point satisfying $|d(x,t)| = |x - y|$ and $\kappa(y,t)$ is the curvature of $\Gamma(t)$ at y. Since $\{\Gamma(t)\}_{0 \le t < T_0}$ is a smooth mean curvature flow,

$$d_t - \Delta d = 0 \qquad \text{in} \quad \Gamma(t) \times (0, T_0). \tag{5.8}$$

Since

$$C(\delta) := \sup\{|\kappa(x,t)| \ :\ (x,t) \in \partial\Omega(t) \times [0, T_0 - \delta]\} < \infty,$$

by (5.7) and (5.8), d is a classical subsolution of

$$d_t - \Delta d - Kd \le 0 \qquad \text{on} \quad \{x \ :\ 0 \le d(x,t) \le 2\sigma\} \times (0, T_0 - \delta]$$

for some $K \geq C(\delta)$. Since $|Dd| = 1$, d is also a classical subsolution of

$$d_t + F(Dd, D^2 d) - Kd = 0 \qquad \text{on} \quad \{x \,:\, 0 \leq d(x,t) \leq 2\sigma\} \times (0, T_0 - \delta].$$

Let h^ϵ be a bounded smooth function satisfying $h^\epsilon(r) = 0$ for $r \leq 0$, $h^\epsilon(r) = \sigma$ for $r \geq \sigma$, and as $\epsilon \downarrow 0$, $h^\epsilon(r)$ converges to $(r \vee 0) \wedge \sigma$. Since F is geometric, i.e.,

$$F(\lambda p, \lambda A + \mu p \otimes p) = \lambda F(p, A), \qquad \lambda, \mu \geq 0,$$

by calculus, we conclude that $u^\epsilon = e^{-Kt} h^\epsilon(d)$ is a classical subsolution of

$$u^\epsilon_t + F(Du^\epsilon, D^2 u^\epsilon) \leq 0 \qquad \text{on} \quad \mathcal{R}^2 \times (0, T_0 - \delta].$$

We let $\epsilon \downarrow 0$, $\delta \downarrow 0$ and use the celebrated stability property of viscosity solutions. □

An entirely similar argument yields the following lemma.

LEMMA 5.4. *For any $\delta > 0$, there are constants $\sigma = \sigma(\delta) > 0$ and $K = K(\delta) > 0$ so that the function $u(x,t) := e^{Kt}[(d \wedge 0)(x,t) \vee (-\sigma)]$ is a viscosity supersolution of*

$$u_t + F(Du, D^2 u) = 0 \qquad \text{in} \quad \mathcal{R}^2 \times (0, T_0).$$

We are now in a position to complete the proof of Theorem 5.1.

Proof of Theorem 5.1. For notational convenience, we set $\Omega_n(t) = \emptyset \;\forall\, n > 1,\ t > T_n$. Let $\widehat{\Omega}$ and $\underline{\Omega}$ be as in section 4, and let $\widehat{T}$, $\underline{T}$ be, respectively, the extinction time of $\widehat{\Omega}(t)$ and $\underline{\Omega}(t)$. Set $\tilde{T} = \min\{\underline{T}, T_0, \widehat{T}\}$.

By Lemma 5.3, $u(x,t) = e^{-Kt}[(d \ \vee 0)(x,t) \wedge \sigma]$ is a viscosity subsolution of

$$u_t + F(Du, D^2 u) = 0 \qquad \text{in} \quad \mathcal{R}^2 \times (0, \tilde{T} - \delta), \tag{5.9}$$

and by Lemma 4.2 and Proposition 6.1, $v(x,t) = \operatorname{dist}(x, \mathcal{R}^2 \backslash \underline{\Omega}(t))$ is a viscosity supersolution of (5.9). Moreover, by Lemma 5.2, $u(\cdot, 0) \leq v(\cdot, 0)$ in $\mathcal{R}^2$, and therefore the comparison principle for solutions of (5.9) (cf. Chen, Giga, and Goto [9], Evans and Spruck [12]) yields

$$u \leq v \qquad \text{in} \quad \mathcal{R}^2 \times [0, \tilde{T} - \delta).$$

We claim that this inequality implies that

$$\Omega(t) \subset \underline{\Omega}(t) \qquad \forall t \in [0, \tilde{T} - \delta).$$

Indeed, for $(x,t) \in \Omega(t) \times [0, \tilde{T} - \delta)$, $0 < u(x,t)$. Then, by the previous inequality, $0 < v(x,t)$ and, therefore, $x \in \underline{\Omega}(t)$.

Similarly, we show that $\widehat{\Omega}(t) \subset \operatorname{cl} \Omega(t) \;\forall\; t \in [0, \tilde{T} - \delta)$, and then we let $\delta \to 0$ to obtain (5.4) on $[0, \tilde{T})$.

A lengthy elementary argument shows that (5.4) is equivalent to (5.5). Hence, (5.5) holds on $[0, \tilde{T})$.

By (5.2) and the construction, $\underline{T} \leq \widehat{T} \leq T_0$. The uniform convergence of Ω_n to Ω implies that $\tilde{T} = T_0$. □

6. Appendix. In this section we gather several properties of the weak solutions.

Let $\{\Omega_n(t)\}_{0 \leq t < T_n}$, $\{\widehat{\Omega}(t)\}_{0 \leq t < T}$, and $\{\underline{\Omega}(t)\}_{0 \leq t < T}$ be as in section 4, and let $d_n(x,t)$ (resp., $\widehat{d}(x,t)$ and $\underline{d}(x,t)$) be the signed distance function for $\{\Omega_n(t)\}_{0 \leq t < T_n}$

(resp., for $\{\widehat{\Omega}(t)\}_{0\le t<T}$ and $\{\underline{\Omega}(t)\}_{0\le t<T}$). Then the definitions of $\widehat{\Omega}(t)$ and $\underline{\Omega}(t)$ are equivalent to

$$(\widehat{d}\wedge 0)(x,t)=\limsup_{\substack{(y,s)\to(x,t)\\ n\to+\infty}}(d_n\wedge 0)(y,s),$$
$$(\underline{d}\vee 0)(x,t)=\liminf_{\substack{(y,s)\to(x,t)\\ n\to+\infty}}(d_n\vee 0)(y,s).$$

The following weak regularity result in t follows from an attendant modification of [29, Lemma 7.3]:

$$\limsup_{y\to x,\ s\uparrow t}(\widehat{d}\wedge 0)(y,s)=(\widehat{d}\wedge 0)(x,t),\qquad (x,t)\in\mathcal{R}^2\times(0,T), \tag{6.1}$$

$$\liminf_{y\to x,\ s\uparrow t}(\underline{d}\vee 0)(y,s)=(\underline{d}\vee 0)(x,t),\qquad (x,t)\in\mathcal{R}^2\times(0,T). \tag{6.2}$$

These identities and the techniques of [29, section 14] yield the equivalence between the weak solutions defined in section 4 and the distance solutions defined by Soner in [29]. Let F be as in (5.6).

PROPOSITION 6.1. *$\{\Omega(t)\}_{0\le t<T}$ is a weak subsolution of the mean curvature flow satisfying* (6.1) *if and only if $d_{\Omega^*}(x,t)\wedge 0$ is a viscosity subsolution of*

$$u_t+F(Du,D^2u)=0\qquad in\quad \mathcal{R}^2\times(0,T). \tag{6.3}$$

$\{\Omega(t)\}_{0\le t<T}$ is a weak supersolution of the mean curvature flow satisfying (6.2) *if and only if $d_{\Omega_*}(x,t)\vee 0$ is a viscosity supersolution of* (6.3).

We close the appendix by proving an approximation result used in section 4.

LEMMA 6.2. *Let $\{O(t)\}_{0\le t<T}$ be a family of closed smooth sets, and let $t_0\in(0,T)$, $x_0\in\partial O(t_0)$ satisfy* (4.4). *Let $D^\varepsilon(t)$ and $D^\varepsilon_n(t:x^*)$ be the same sets as in the proof of* Lemma 4.1. *Assume that $D^\varepsilon(t:x_0^\varepsilon)$ satisfies* (4.7). *Then there are a subsequence n_k and sequences $(x_k,t_k)\to(x_0,t_0)$, $y_k\to x_0^\varepsilon$ as $k\to+\infty$ satisfying*

$$x_k\in\Gamma_{n_k}(t_k)\cap\partial D^\varepsilon_{n_k}(t_k:y_k),$$

$$\Omega_{n_k}(t)\cap B(x_0,\delta^\varepsilon)\subset D^\varepsilon_{n_k}(t:y_k)\cap B(x_0,\delta^\varepsilon)\qquad\forall\ |t-t_0|\le\delta^\varepsilon.$$

Proof. Fix $\varepsilon>0$ and recall $(\widehat{\Omega})^*=\widehat{\Omega}$. Let $d_n(x,t)$ be the signed distance to $D^\varepsilon_n(t:x_0^\varepsilon)$, $d(x,t)$ be the signed distance to $D^\varepsilon(t:x_0^\varepsilon)$, and let

$$\alpha_n:=\inf_{|t-t_0|\le\delta^\varepsilon}\inf\{d_n(x,t)\ :\ x\in\Omega_n(t)\cap B(x_0,\delta^\varepsilon)\}.$$

Choose $t_n\in[t_0-\delta^\varepsilon,t_0+\delta^\varepsilon]$, $x_n\in\Omega_n(t_n)\cap B(x_0,\delta^\varepsilon)$ and $w_n\in\partial D^\varepsilon_n(t_n:x_0^\varepsilon)$ such that

$$|w_n-x_n|=|\alpha_n|.$$

Set

$$y_n=x_0^\varepsilon-(w_n-x_n),$$

so that

$$\Omega_n(t) \cap B(x_0, \delta^\varepsilon) \subset D_n^\varepsilon(t : y_n) \cap B(x_0, \delta^\varepsilon) \quad \forall\ |t - t_0| \le \delta^\varepsilon.$$

Since $x_0 \in \widehat{\Omega}(t_0)$, by the definition of $\widehat{\Omega}$, there are a subsequence n_k and sequences $(z_k, s_k) \to (x_0, t_0)$ such that

$$z_k \in \Omega_{n_k}(s_k).$$

Then

$$\limsup_{k\to\infty} \alpha_{n_k} \le \limsup_{k\to\infty} d_{n_k}(z_k, s_k) = d(x_0, t_0) = 0.$$

A similar argument, using (4.7), shows that $\liminf \alpha_{n_k} \ge 0$. Hence $\alpha_{n_k} \to 0$ and, therefore, $y_{n_k} \to x_0^\varepsilon$.

It remains to show that $(x_{n_k}, t_{n_k}) \to (x_0, t_0)$. Suppose that on a further subsequence, denoted by n_k again,

$$(x_{n_k}, t_{n_k}) \to (\bar{x}, \bar{t}) \in B(x_0, 2\delta^\varepsilon) \times [t_0 - \delta^\varepsilon, t_0 + \delta^\varepsilon].$$

Since d_n converges to d uniformly,

$$d(\bar{x}, \bar{t}) = \lim_{k\to\infty} \alpha_{n_k} = 0 \le \lim_{k\to\infty} d_{n_k}(z_k, s_k) = d(x_0, t_0).$$

Since (x_0, t_0) is the strict minimizer of d, this implies that $(\bar{x}, \bar{t}) = (x_0, t_0)$. □

ON L^1 CONVERGENCE RATE OF VISCOUS AND NUMERICAL APPROXIMATE SOLUTIONS OF GENUINELY NONLINEAR SCALAR CONSERVATION LAWS*

WEI-CHENG WANG†

Abstract. We study the rate of convergence of the viscous and numerical approximate solution to the entropy solution of genuinely nonlinear scalar conservation laws with piecewise smooth initial data. We show that the $O(\epsilon|\log\epsilon|)$ rate in L^1 is indeed optimal for viscous Burgers equation. Through the Hopf–Cole transformation, we can study the detailed structure of $\|u(\cdot,t)-u^\epsilon(\cdot,t)\|_{L^1}$. For centered rarefaction wave, the $O(\epsilon|\log\epsilon|)$ error occurs on the edges where the inviscid solution has a corner, and persists as long as the edges remain. The $O(\epsilon|\log\epsilon|)$ error must also occur at the critical time when a new shock forms automatically from the decreasing part of the initial data; thus it is, in general, impossible to maintain $O(\epsilon)$ rate for all $t>0$. In contrast to the centered rarefaction wave case, the $O(\epsilon|\log\epsilon|)$ error at critical time is transient. It resumes the $O(\epsilon)$ rate right after the critical time due to nonlinear effect. Similar examples of some monotone schemes, which admit a discrete version of the Hopf–Cole transformation, are also included.

Key words. hyperbolic conservation laws, error estimates, viscosity methods, monotone schemes

1. Introduction.

The hyperbolic conservation law

$$\begin{aligned} &u_t + f(u)_x = 0, \quad x\in\mathbf{R}, \quad t>0,\\ &u(x,0)=u_0(x) \end{aligned} \tag{1.1}$$

can be analyzed using the method of characteristics. Due to nonlinearity of f, the characteristic lines can intersect each other in finite time, and the solution develops jump discontinuities even if the initial data is smooth. Due to the presence of jump discontinuities, we need to generalize the solution class to include "weak solutions." In addition, since the weak solutions are not unique, entropy conditions are needed to specify physically meaningful weak solutions.

There are several equivalent forms of the entropy condition for genuinely nonlinear (say, $f''>0$) scalar conservation laws. Among them is the method of vanishing viscosity, which asserts that the physically relevant solution is obtained by solving the following viscous approximate equation

$$\begin{aligned} &u^\epsilon_t + f(u^\epsilon)_x = \epsilon u^\epsilon_{xx}, \quad x\in\mathbf{R}, \quad t>0, \quad \epsilon>0,\\ &u^\epsilon(x,0)=u_0(x) \end{aligned} \tag{1.2}$$

and letting ϵ go to zero. It is known that u^ϵ converges strongly, and the limiting function, u, is a weak solution of (1.1). Furthermore, u is the unique solution that satisfies the following entropy condition:

$$\frac{u(x+a,t)-u(x,t)}{a}\le\frac{E}{t}, \quad t>0, \tag{1.3}$$

where E is a constant depending only on the flux function f and initial data (see, for example, [11] for details).

Monotone difference schemes are first-order numerical schemes used to compute approximate solutions of (1.1):

$$w_j^{n+1} = G(w_{j-p}^n, w_{j-p+1}^n, \dots, w_{j+q}^n) = w_j^n - \lambda[\bar{f}(w_{j-p+1}^n, \dots, w_{j+q}^n) - \bar{f}(w_{j-p}^n, \dots, w_{j+q-1}^n)], \tag{1.4}$$

where p and q are fixed nonnegative integers, G is a monotonely nondecreasing function in each of its arguments, $\bar{f}$ is a Lipchitz continuous function and is consistent with the scalar conservation law (1.1) in the sense

$$\bar{f}(w, \dots, w) = f(w), \tag{1.5}$$

and $\lambda = \Delta t/\Delta x$ is a constant satisfying the CFL condition $\lambda < |f'|$.

Most well-known first-order schemes such as the Lax–Friedrichs scheme, Godunov scheme, and Enquist–Osher scheme are monotone schemes. Monotone schemes are known to converge to the entropy solution of (1.1) as $\Delta x \to 0$ (see [2]) and they are at most first-order accurate [1].

Whether or not a viscous approximation/monotone scheme can be of order $O(\epsilon)/O(\Delta x)$ accurate is an issue of practical interest and has long been studied. Although viscous approximation and monotone schemes are formally first order, they can really lose half-order accuracy across discontinuities. For example, it is easy to see, using a scaling argument, that the solution of the heat equation with an initial jump discontinuity is indeed $O(\sqrt{\epsilon})$ in L^1 norm away from its zero viscosity limit. In fact, Tang and Teng [14] proved that the $O(\sqrt{\epsilon})$ or $O(\sqrt{\Delta x})$ rate is indeed optimal for *all* monotone schemes applied to linear advection equations with discontinuous data.

For general BV initial data with genuinely nonlinear flux, several authors have obtained $O(\sqrt{\epsilon})$ or $O(\sqrt{\Delta x})$ rate. See, for example, Kuznetsov [6], Lucier [8], Sanders [10], and Tadmor [13]. It turns out to be optimal for this case (i.e., beyond linear degeneracy); see Sabac [9]. For the special case of monotonely nondecreasing initial data, Harabetian [5] has obtained $O(\epsilon|\log\epsilon|)/O(\Delta x|\log(\Delta x)|)$ rate in L^1 norm and showed that it is indeed optimal in this case.

Although BV solution is a natural class for genuinely nonlinear scalar conservation law, we will consider here only the subclass of piecewise smooth solutions with finitely many shocks. This class is of practical interest in shock capturing for the following reason: We expect viscous solution or monotone schemes to have better resolutions across an isolated jump discontinuity if the flux function is genuinely nonlinear, since for a linearly degenerate flux function, the discontinuity is a contact one, thus the smearing is a result of diffusion only; while in case of a genuinely nonlinear flux, the entropy condition dictates that the characteristic curves impinge into the shock, and thus tend to squeeze the profile in shape.

The first result in this direction was Goodman and Xin [4], where the authors considered piecewise smooth flows with noninteracting shocks for *systems* of hyperbolic conservation laws with viscosity. They obtained an $O(\epsilon)$ estimate away from shock regions and an overall $O(\epsilon^\gamma)$ rate for any $\gamma < 1$. The proof uses a matched asymptotic analysis employing a superposition of outer solutions (asymptotic series off the shock) and inner solutions (asymptotic expansion near the shock in stretched variables), as well as a nonlinear stability analysis based on energy estimates.

Inspired by [4], Teng and Zhang [16], Tang and Teng [15] showed that, for genuinely nonlinear scalar conservation laws with piecewise smooth initial data having

finitely many inflection points, the convergence rate can be improved to $\sup_{t>0} \|u(\cdot,t) - u^\epsilon(\cdot,t)\| \le O(\epsilon|\log\epsilon|)$. And in case there is no centered rarefaction wave or shock formation at a later time, the rate is actually $O(\epsilon)$.

The corresponding counterpart for monotone schemes is more subtle. Engquist and Yu [3] and Smyrlis and Yu [12] obtained pointwise estimates for a wide class of finite difference schemes, which result in the $O(\Delta x)$ convergence rate in L^1 norm of monotone schemes for piecewise smooth initial data with noninteracting shocks provided no shocks form at a later time.

From the argument in [15], it is not clear whether the $O(\epsilon|\log\epsilon|)$ is optimal beyond the centered rarefaction wave case (the optimality of the centered rarefaction wave case was shown in Harabetian [5]). In this paper, we will study in detail the structure of $\|u(\cdot,t) - u^\epsilon(\cdot,t)\|$ through an example, the viscous Burgers equation, to gain more insight. It turns out that this rate is actually obtained at the critical time when a shock develops from the decreasing part of the initial data. Thus, it is in general impossible to maintain $O(\epsilon)/O(\Delta x)$ rate for all $t > 0$. However, in contrast to the centered rarefaction wave case, this phenomenon is transient; it resumes the $O(\epsilon)/O(\Delta x)$ rate right after the critical time. (This case was not covered in [14], [15], [3], and [12], where the authors considered the shocks coming from jumps in initial data.) This result is consistent with the following heuristic argument: The viscous approximation/monotone schemes are first-order accurate both before and after the critical time, but for different reasons. Before the critical time, the solution of (1.1) is smooth if the initial data is; therefore, the viscous term ϵu^ϵ_{xx} is an $O(\epsilon)\cdot O(1)$ quantity. After the critical time, the shock is already formed, and the impinging of characteristic lines counteract with diffusion. However, at the critical time, neither of these mechanisms is available, resulting in an underresolution.

The rest of this paper is arranged as follows: In section 2, we will review some basic facts about formation of shocks, the Hopf–Cole transformation, and a few lemmas to be used later. In section 3.1, we state and prove the main theorem concerning the convergence rate at and after critical time for the viscous Burgers equation using the Hopf–Cole transformation. In section 3.2, we give the same results for several monotone schemes with particular flux functions, including upwind, Lax–Friedrichs, and Godunov scheme, which admit a discrete version of Hopf–Cole transformation. It will be clear how these elementary arguments can be utilized to study the centered rarefaction wave case, and interactions of shocks and centered rarefaction waves, etc. The results are as stated in the abstract of this paper; we thus omit the details.

2. Preliminaries.

Notation: $\|\cdot\|$ is the L^1 norm. We'll also denote the local L^1 integral $\int_a^b |g(x)|dx$ by $\|g\|_{L^1(dx;[a,b])}$.

Consider the viscous and inviscid Burgers equation which are special cases of (1.1) and (1.2) with $f(u) = \frac{1}{2}u^2$,

$$\begin{aligned} &u_t + uu_x = 0, \quad x \in \mathbf{R}, \quad t > 0, \\ &u(x,0) = u_0(x) \end{aligned} \tag{2.1}$$

and

$$\begin{aligned} &u^\epsilon_t + u^\epsilon u^\epsilon_x = \epsilon u^\epsilon_{xx}, \quad x \in \mathbf{R}, \quad t > 0, \quad \epsilon > 0, \\ &u^\epsilon(x,0) = u_0(x). \end{aligned} \tag{2.2}$$

We first recall some facts about spontaneous formation of shocks. If the initial data is smooth and is such that $f'(u_0(\cdot))$ is not monotonely nondecreasing, the

characteristic lines can intersect each other and the shock forms. If $\xi_1 < \xi_2$ with $f'(u_0(\xi_1)) > f'(u_0(\xi_2))$, then the two characteristic lines starting from ξ_1 and ξ_2 intersect at time $t = \frac{\xi_2-\xi_1}{f'(u_0(\xi_1))-f'(u_0(\xi_2))}$; thus the first time at which neighboring characteristic lines intersect is when $t = t_c = \frac{-1}{\min_\xi \frac{d}{d\xi} f'(u_0(\xi))}$ and the initial shock is located at the characteristic line starting from ξ_0 where the minimum is taken.

Here in Burgers's equation, $f'(u_0) = u_0$. Up to a Galilean transformation, we may assume that $u_0(0) = 0$ and that $\xi = 0$ is where u_0' assumes its negative minimum which corresponds to the initial formation of the shock. Thus the local Taylor expansion near $\xi = 0$ reads

$$u_0(\xi) = -\frac{1}{t_c}\xi + a\xi^{2p+1} + \cdots, \tag{2.3}$$

where $a > 0$ and p is a positive integer. We'll carry out the analysis for $p = 1$; the proof for other values of p is similar.

By differentiating (2.1) with respect to x and then integrating along the characteristic lines, one can find that the derivative blows up near $t = t_c$ (for a detail derivation, see, for example, [11]),

$$u_x(0,t) = -\frac{O(1)}{t_c - t},\ t < t_c. \tag{2.4}$$

Our main tool is the classical Hopf–Cole transformation,

$$u^\epsilon = -2\epsilon(\log \phi^\epsilon)_x. \tag{2.5}$$

Through (2.5), (2.2) linearizes to the heat equation

$$\phi_t^\epsilon = \epsilon\phi_{xx}^\epsilon. \tag{2.6}$$

After transforming the initial data and solving the heat equation, we have

$$u^\epsilon(x,t) = -2\epsilon\left(\log \int_{-\infty}^{\infty} e^{-\frac{1}{2\epsilon}G(x,y,t)}dy\right)_x, \tag{2.7}$$

where $G(x,y,t) = \int_0^y u_0(y')dy' + \frac{(x-y)^2}{2t}$.

Since (2.7) gives an exact formula for $u^\epsilon(x,t)$, hence for $\int^x u^\epsilon(x',t)dx'$, we can estimate $\|u^\epsilon(\cdot,t) - u(\cdot,t)\|$ as long as we know the sign of $u^\epsilon(\cdot,t) - u(\cdot,t)$. The following lemma is based on this observation.

LEMMA 2.1. *Let u_0 be a smooth and bounded function satisfying*

(A.1) *$u_0(\xi) = -\frac{\xi}{t_c} + a\xi^3 + b\xi^4 + O(\xi^5)$ for $|\xi| < \delta$ where $a > 0$;*

(A.2) *$\xi = 0$ is the point corresponding to the first spontaneous formation of shocks, that is, $u_0'(\xi) > -\frac{1}{t_c}$ for all $\xi \neq 0$;*

(A.3) *u_0 is antisymmetric: $u_0(-\xi) = -u_0(\xi)$;*

(A.4) *u_0 is monotonely decreasing;*

(A.5) *u_0 is concave on $\xi < 0$, and, therefore, by Assumption* (A.3)*, convex on $\xi > 0$.*

Then

$$u(x,t_c) \geq (\leq) u^\epsilon(x,t_c) \quad \text{on } x < (>) 0. \tag{2.8}$$

Proof. By symmetry, we only need to prove the statement on $\{x < 0\}$. We will apply the maximum principle in the region $\{(x,t) : 0 < t < t_c, x < 0\}$ for $w = u^\epsilon - u$, which satisfies

$$w_t + (aw)_x - \epsilon w_{xx} = \epsilon u_{xx}, \tag{2.9}$$

where $a(x,t) = \frac{1}{2}(u^\epsilon(x,t) + u(x,t)) = \frac{1}{2}w(x,t) + u(x,t)$. Clearly, $w = 0$ on $\{(x,t) : t = 0, x < 0\}$ by definition and on $\{(x,t) : 0 < t < t_c, x = 0\}$ by symmetry. Since monotonicity and concavity of u is preserved under the characteristic flow (one can see this by differentiating (1.1) once and twice, then integrating along the characteristic lines), we have the correct signs on the right-hand side of (2.8) and the coefficient of w in order to apply the maximum principle, by which we conclude that $w \leq 0$ on $\{x < 0\}$. □

We'll also need the following lemma.

LEMMA 2.2 (L^1 stability). *If $u_i^\epsilon(x,t)$, $i = 1, 2$ satisfy*

$$\frac{\partial}{\partial t}u_i^\epsilon + \frac{\partial}{\partial x}f(u_i^\epsilon) - \epsilon\frac{\partial^2}{\partial x^2}u_i^\epsilon = g_i(x,t), \tag{2.10}$$

then

$$\|u_1^\epsilon(\cdot,t) - u_2^\epsilon(\cdot,t)\| \leq \|u_1^\epsilon(\cdot,0) - u_2^\epsilon(\cdot,0)\| + \int_0^t \|g_1(\cdot,s) - g_2(\cdot,s)\|ds. \tag{2.11}$$

Proof. Let $w = u_1^\epsilon - u_2^\epsilon$; then w solves the following equation:

$$w_t + (aw)_x - \epsilon w_{xx} = g_1 - g_2, \tag{2.12}$$

where $a(x,t) = \frac{1}{2}(u_1^\epsilon + u_2^\epsilon)$ for Burgers's equation. (For general flux, $a(x,t)$ is a proper average of $f'(u_1^\epsilon(x,t))$ and $f'(u_2^\epsilon(x,t))$.) Since the backward adjoint equation

$$\begin{aligned} &z_t + az_x + \epsilon z_{xx} = 0, \\ &z(\cdot,t) = \operatorname{sgn}(w(\cdot,t)) \end{aligned} \tag{2.13}$$

satisfies the maximum principle, we then complete the proof by integrating $z \cdot (2.12) + w \cdot (2.13)$ by parts. □

3. Convergence rate at and near critical time.

3.1. The Burgers equation.

THEOREM 3.1. *Let $u^\epsilon(x,t)$ and $u(x,t)$ be solutions of* (2.1) *and* (2.2)*, respectively, with the same initial data $u_0(x)$ satisfying* (A.1) *and* (A.2) *in Lemma* 2.1*, then for t near t_c, we have*

1. *If $t \neq t_c$, then*

$$\|u^\epsilon(\cdot,t) - u(\cdot,t)\| \leq C(t)\epsilon \quad \text{as} \quad \epsilon \to 0,$$

where $C(t) = O(\log \frac{1}{|t-t_c|})$.

2.

$$\|u^\epsilon(\cdot,t_c) - u(\cdot,t_c)\| = O(\epsilon|\log\epsilon|) \quad \text{as} \quad \epsilon \to 0.$$

Proof. The case $t < t_c$ of the first part is a direct consequence of Lemma 2.2 above, since $\|u_{xx}(\cdot,t)\| = TV(u_x(\cdot,t)) = 2\|u_x(\cdot,t)\|_{L^\infty} = -2u_x(0,t) = O(\frac{1}{t_c - t})$.

At $t = t_c$, we first prove the special case where the initial data satisfy the assumptions of Lemma 2.1. In this case we see that from (2.8),

$$\|u^\epsilon(\cdot,t_c) - u(\cdot,t_c)\|_{L^1(dx;[-1,0])} = \int_{-1}^0 u(x,t_c)dx - \int_{-1}^0 u^\epsilon(x,t_c)dx. \tag{3.1.1}$$

By the Hopf–Cole transformation,

$$\int_{-1}^{0} u^\epsilon(x,t)dx = -2\epsilon \log \left(\frac{\int e^{-\frac{1}{2\epsilon}G(0,y,t)}dy}{\int e^{-\frac{1}{2\epsilon}G(-1,y,t)}dy} \right), \tag{3.1.2}$$

where $G(x,y,t) = \int_0^y u_0(y')dy' + \frac{(x-y)^2}{2t}$ and the domain of integration in $int(\cdot)dy$ is the whole real line. Following the standard stationary phase method, we check that $G_{yy}(-1,\xi(-1,t_c),t_c) = u_0'(\xi) + \frac{1}{t_c} > 0$, where $\xi = \xi(x,t)$ is where $G(x,\cdot,t)$ assumes its global minimum,

$$u_0(\xi(x,t)) = \frac{x-\xi(x,t)}{t}. \tag{3.1.3}$$

Thus at $t = t_c$, the leading-order asymptotic expansion of the denominator in (3.1.2) is

$$\begin{aligned}
\int e^{-\frac{1}{2\epsilon}G(-1,y,t_c)}dy &= e^{-\frac{1}{2\epsilon}G(-1,\xi(-1,t_c),t_c)} \int e^{-\frac{1}{2\epsilon}[G(-1,y,t_c)-G(-1,\xi(-1,t_c),t_c)]}dy \\
&\sim e^{-\frac{1}{2\epsilon}G(-1,\xi(-1,t_c),t_c)} \int e^{-\frac{1}{2\epsilon}\frac{G_{yy}(-1,\xi(-1,t_c),t_c)}{2}(y-\xi(-1,t_c))^2}dy \\
&= \frac{2\sqrt{\pi}}{u_0'(\xi(-1,t_c)) + \frac{1}{t_c}} \cdot \epsilon^{\frac{1}{2}} \exp\left(-\frac{1}{2\epsilon}G(-1,\xi(-1,t_c),t_c) \right). \qquad (3.1.4)
\end{aligned}$$

The numerator, however, has a quartic exponent $G(0,y,t_c)$ at $(x,t) = (0,t_c)$, since $\xi(0,t_c) = 0$, $G_y(0,\xi(0,t_c),t_c) = G_{yy}(0,\xi(0,t_c),t_c) = G_{yyy}(0,\xi(0,t_c),t_c) = 0$ and $G_{yyyy}(0,\xi(0,t_c),t_c) = 6a > 0$. Thus the asymptotic expansion of the integral is, to leading order,

$$\begin{aligned}
\int e^{-\frac{1}{2\epsilon}G(0,y,t_c)}dy &= e^{-\frac{1}{2\epsilon}G(0,0,t_c)} \int e^{-\frac{1}{2\epsilon}[G(0,y,t_c)-G(0,0,t_c)]}dy \\
&\sim e^{-\frac{1}{2\epsilon}G(0,0,t_c)} \int e^{-\frac{1}{8\epsilon}ay^4}dy \\
&= I_0 (\frac{4\epsilon}{a})^{\frac{1}{4}} \exp\left(-\frac{1}{2\epsilon}G(0,0,t_c) \right), \qquad (3.1.5)
\end{aligned}$$

where $I_0 = \int_{-\infty}^{\infty} e^{-\frac{z^4}{2}}dz$ is a constant. Therefore,

$$\int_{-1}^{0} u^\epsilon(x,t_c)dx \sim G(0,0,t_c) - G(-1,\xi(-1,t_c),t_c) + \frac{1}{2}\epsilon\log\epsilon + \cdots. \tag{3.1.6}$$

By differentiating (3.1.3) with respect to x, we see that $\frac{\partial}{\partial x}G(x,\xi(x,t),t) = u(x,t)$, so

$$G(0,0,t_c) - G(-1,\xi(-1,t_c),t_c) = \int_{-1}^{0} u(x,t_c)dx. \tag{3.1.7}$$

From (3.1.2), (3.1.4), (3.1.5), (3.1.6), and (3.1.7), we conclude that

$$\|u^\epsilon(\cdot,t_c) - u(\cdot,t_c)\|_{L^1(dx;[-1,0])} \sim \frac{1}{2}\epsilon|\log\epsilon|. \tag{3.1.8}$$

The same estimate holds for $\|u^\epsilon(\cdot,t_c)-u(\cdot,t_c)\|_{L^1(dx;[0,1])}$ by symmetry. The integral outside of $[-1,1]$ is of lower order by virtue of Lemma 3.2 below. Thus the special case is proved.

To prove the general case, we note that, because of the structure of the initial data, the assumptions of Lemma 2.1, except (A.3), indeed hold for ξ near zero in general. Thus we only have to take care of the antisymmetry. We proceed as follows.

Let $\delta_0>0$ be a small number such that all the assumptions in Lemma 2.1, except (A.3), are valid for $|\xi|<2\delta_0$, and let the characteristic line starting from $(-\delta_0,0)$ intersect the line $\{t=t_c\}$ at $(-\delta_1,t_c)$. We will concentrate on the local deviation $\|u^\epsilon(\cdot,t_c)-u(\cdot,t_c)\|_{L^1(dx;[-\delta_1,0])}$. The following lemma allows us to modify the initial data in order to reduce to the antisymmetric case.

LEMMA 3.2. *Let v_0, w_0 be two bounded initial data such that $v_0(\xi)=w_0(\xi)$ on $\{\xi\ge\alpha\}$ for some $\alpha\in\mathbf{R}$ and let $v^\epsilon(x,t)$, $w^\epsilon(x,t)$ be corresponding solutions of the viscous Burgers equation. If for some $\beta>\alpha$, the characteristic flows of v_0 and w_0 left of α are strictly separated from those right of β up to some time $t_1>0$, that is, if there exist $\beta_1>\alpha_1$, such that the characteristic lines of v_0 and w_0 starting from left of $(\alpha,0)$ intersect the line $\{t=t_1\}$ at left of (α_1,t_1), and vice versa on the right of $(\beta,0)$ and (β_1,t_1), then*

$$\|v^\epsilon(\cdot,t_1)-w^\epsilon(\cdot,t_1)\|_{L^1(dx;[\beta_1,\infty))}=O(1)e^{-\frac{O(1)}{\epsilon}}. \tag{3.1.9}$$

Proof. Equation (3.1.9) can be proved by estimating the Green function of the backward adjoint equation, or one can prove it directly using the Hopf–Cole transformation. □

Therefore, by adjusting $u_0(\xi)$ on $\{\xi<-2\delta_0\}$ if necessary, we may assume that u_0 satisfies the assumptions (A.2), (A.4), and (A.5) globally on $\{\xi<0\}$. To reduce to the special case, we now construct an antisymmetric initial data

$$u_{a,0}(\xi)=\begin{cases}u_0(\xi) & \text{if } \xi<0,\\ -u_0(-\xi) & \text{if } \xi\ge 0.\end{cases} \tag{3.1.10}$$

Since the corresponding inviscid solutions agree on the interval under consideration,

$$u_a(x,t_c)=u(x,t_c)\quad\text{on}\quad -\delta_1\le x\le 0, \tag{3.1.11}$$

it suffices to estimate $\|u_a^\epsilon(\cdot,t_c)-u^\epsilon(\cdot,t_c)\|_{L^1(dx;[-\delta_1,0])}$.

By Assumption (A.1), we have $u_{a,0}(\xi)-u_0(\xi)\le(\ge)0$ on $\{\xi\le 2\delta_0\}$ if $b>(<)0$. By Lemma 3.2, we can adjust $u_0(\xi)$ on $\{\xi>2\delta_0\}$ if necessary, so we may assume, without loss of generality, that

$$u_{a,0}(\xi)-u_0(\xi)\le(\ge)0\ \text{ for all }\ \xi\in\mathbf{R}\ \text{ if }\ b>(<)0. \tag{3.1.12}$$

From the classical comparison lemma [2], (3.1.12) implies that

$$u_a^\epsilon(x,t)-u^\epsilon(x,t)\le(\ge)0\ \text{ if }\ b>(<)0, \tag{3.1.13}$$

and, therefore,

$$\|u_a^\epsilon(\cdot,t_c)-u^\epsilon(\cdot,t_c)\|_{L^1(dx;[-\delta_1,0])}=\left|\int_{-\delta_1}^0 u_a^\epsilon(x,t_c)dx-\int_{-\delta_1}^0 u^\epsilon(x,t_c)dx\right| \tag{3.1.14}$$

Equations (3.1.11), (3.1.13), and (3.1.14) together imply

$$\begin{aligned}&\|u^\epsilon(\cdot,t_c)-u(\cdot,t_c)\|_{L^1(dx;[-\delta_1,0])},\\ &=\begin{cases}\displaystyle\int_{-\delta_1}^0 u(x,t_c)dx-\int_{-\delta_1}^0 u^\epsilon(x,t_c)dx & \text{if } b<0,\\ \displaystyle\int_{-\delta_1}^0 u(x,t_c)dx+\int_{-\delta_1}^0 u^\epsilon(x,t_c)dx-2\int_{-\delta_1}^0 u_a^\epsilon(x,t_c)dx & \text{if } b>0;\end{cases}\end{aligned}\tag{3.1.15}$$

therefore, we can apply the Hopf–Cole transformation again,

$$\begin{aligned}&\|u^\epsilon(\cdot,t_c)-u(\cdot,t_c)\|_{L^1(dx;[-\delta_1,0])},\\ &=\begin{cases}\displaystyle -2\epsilon\log\left(\frac{\int e^{-\frac{1}{2\epsilon}G(-\delta_1,y,t_c)-G(-\delta_1,\xi(-\delta_1,t_c),t_c)}dy}{\int e^{-\frac{1}{2\epsilon}G(0,y,t_c)-G(0,0,t_c)}dy}\right) & \text{if } b<0,\\ \displaystyle -2\epsilon\Bigg[\log\left(\frac{\int e^{-\frac{1}{2\epsilon}G_a(-\delta_1,y,t_c)-G_a(-\delta_1,\xi(-\delta_1,t_c),t_c)}dy}{\int e^{-\frac{1}{2\epsilon}G_a(0,y,t_c)-G_a(0,0,t_c)}dy}\right)\\ \displaystyle +\log\left(\frac{\int e^{-\frac{1}{2\epsilon}G(0,y,t_c)}dy}{\int e^{-\frac{1}{2\epsilon}G_a(0,y,t_c)}dy}\right)\Bigg] & \text{if } b>0,\end{cases}\end{aligned}\tag{3.1.16}$$

where $G_a(x,y,t)=\int_0^y u_{a,0}(y')dy'+\frac{(x-y)^2}{2t}$, and $G_a(-\delta_1,\xi(-\delta_1,t_c),t_c)=G(-\delta_1,\xi(-\delta_1,t_c),t_c)$ cancel out in the second term of the case $b>0$ in (3.1.17). Since $u_0'''(0)$ is preserved under antisymmetrization, we see that from (3.1.5)

$$\frac{\int e^{-\frac{G(0,y,t_c)}{2\epsilon}}dy}{\int e^{-\frac{G_a(0,y,t_c)}{2\epsilon}}dy}=1+o(1).\tag{3.1.17}$$

In view of (3.1.17) and (3.1.17), we have

$$\|u^\epsilon(\cdot,t_c)-u(\cdot,t_c)\|_{L^1(dx;[-\delta_1,0])}\sim\frac{1}{2}\epsilon|\log\epsilon|.\tag{3.1.18}$$

The estimate for $\|u^\epsilon(\cdot,t_c)-u(\cdot,t_c)\|_{L^1(dx;[0,\delta_1])}$ is similar. The general case for $t=t_c$ is thus proved.

The case $t>t_c$ can be reduced to the case $t<t_c$ by constructing a new initial data which delays the formation of the shock. Let $t_0>t_c$ be given, with t_0-t_c sufficiently small. Denote by $s(t)$ the location of the shock at time t, and let $(\xi_-,0)$ be where the backward characteristic line from $(s(t_0)-0,t_0)$ intersects the x-axis. For t_0-t_c sufficiently small, ξ_- is close to 0 and the tangent line of $u_0(\cdot)$ at $(\xi_-,u_0(\xi_-))$ lies above u_0 in a neighborhood of ξ_-. Now define

$$\bar u_0(\xi)=\begin{cases}u_0(\xi) & \text{if } \xi<\xi_-,\\ \max(u_0(\xi),u_0(\xi)+u_0'(\xi_-)(\xi-\xi_-)\ ) & \text{if } \xi\ge\xi_-,\end{cases}$$

and let $\bar u(x,t)$ and $\bar u^\epsilon(x,t)$ be correponding inviscid and viscous solutions. It is easy to see that

(a) $\bar{u}(x,t_0) = u(x,t_0)$ for $x < s(t_0)$.
(b) The critical time for $\bar{u}_0$ is $\bar{t}_c = -\frac{1}{u_0'(\xi_-)} > t_0$; thus no shock forms in $\bar{u}(\cdot,\cdot)$ up to $t = t_0$. Moreover, $\bar{t}_c - t_0 = \frac{1}{2}(t_0 - t_c) + O((t_0 - t_c)^2)$.
(c) $\bar{u}_0(\xi) \geq u_0(\xi)$ and thus $\bar{u}^\epsilon(x,t) \geq u^\epsilon(x,t)$.

From (b), we have

$$\|\bar{u}^\epsilon(\cdot,t_0) - \bar{u}(\cdot,t_0)\| = O\left(\log\frac{1}{|t-t_c|}\right)\epsilon \quad \text{as} \quad \epsilon \to 0, \tag{3.1.19}$$

and from (c)

$$\begin{aligned}
&\|u^\epsilon(\cdot,t_0) - \bar{u}^\epsilon(\cdot,t_0)\|_{L^1(dx;[-1,s(t_0)])} \\
&= \int_{-1}^{s(t_0)} \bar{u}^\epsilon(x,t_0)dx - \int_{-1}^{s(t_0)} u^\epsilon(x,t_0)dx \\
&= -2\epsilon\left[\log\left(\frac{\int e^{-\frac{1}{2\epsilon}\bar{G}(s(t_0),y,t_0)}dy}{\int e^{-\frac{1}{2\epsilon}G(s(t_0),y,t_0)}dy}\right) - \log\left(\frac{\int e^{-\frac{1}{2\epsilon}\bar{G}(-1,y,t_0)}dy}{\int e^{-\frac{1}{2\epsilon}G(-1,y,t_0)}dy}\right)\right],
\end{aligned} \tag{3.1.20}$$

where $\bar{G}(x,y,t) = \int_0^y \bar{u}_0(y')dy' + \frac{(x-y)^2}{2t}$. A standard process of asymptotic expansion leads to

$$\frac{\int e^{-\frac{1}{2\epsilon}\bar{G}(-1,y,t_0)}dy}{\int e^{-\frac{1}{2\epsilon}G(-1,y,t_0)}dy} \sim 1 + O(\epsilon). \tag{3.1.21}$$

As to the first term in (3.1.20), we note that the exponent $G(s(t_0),\cdot,t_0)$ indeed has two global minima occurring at ξ_- and ξ_+ due to the presence of the shock. Here ξ_+ is where the backward characteristic line from $(s(t_0)+0,t_0)$ intersects the x-axis. Since $\bar{u}(\cdot,t_0)$ is smooth, there is only one global minimum of $\bar{G}(s(t_0),\cdot,t_0)$ occurring at ξ_-, therefore,

$$\frac{\int e^{-\frac{1}{2\epsilon}\bar{G}(s(t_0),y,t_0)}dy}{\int e^{-\frac{1}{2\epsilon}G(s(t_0),y,t_0)}dy} \sim \frac{(u_0'(\xi_-)+\frac{1}{t_0})^{\frac{1}{2}}}{(u_0'(\xi_-)+\frac{1}{t_0})^{\frac{1}{2}} + (u_0'(\xi_+)+\frac{1}{t_0})^{\frac{1}{2}}} + o(1) < 1. \tag{3.1.22}$$

From (a), (3.1.19), (3.1.20), (3.1.21), and (3.1.22), we conclude that

$$\|u^\epsilon(\cdot,t_0) - u(\cdot,t_0)\|_{L^1(dx;[-1,s(t_0)])} = O\left(\log\frac{1}{|t-t_c|}\right)\epsilon. \tag{3.1.23}$$

A similar estimate holds for $\|u^\epsilon(\cdot,t_0) - u(\cdot,t_0)\|_{L^1(dx;[s(t_0),1])}$, and the theorem is proved. □

Remark 1. It is clear from the proof that the $O(\epsilon|\log\epsilon|)$ rate is indeed optimal at the critical time. For a general exponent $2p+1$ in (2.3), the constant $\frac{1}{2}$ in (3.1.8) is replaced by $\frac{p}{p+1}$.

The idea used in the proof of Lemma 2.1 and Theorem 3.1 can be carried over to analyze the structure of the error in the case of a centered rarefaction wave. The

$O(\epsilon|\log\epsilon|)$ error is optimal and, roughly speaking, is restricted to the inner edges of the fan.

PROPOSITION 3.3. *Let the initial data $u_0(\xi)$ be a piecewise smooth function with a jump discontinuity at $\xi = 0$ and $u_0(0^-) < u_0(0^+)$ but smooth otherwise. Assume further that u_0 is concave on $\{\xi > 0\}$, convex on $\{\xi < 0\}$, and monotonely nondecreasing. Then the following local L^1 error estimates holds. For c, $d \in R$ satisfying*

$$\frac{u_0(0^+)+u_0(0^-)}{2}t < c < u_0(0^+)t < d,$$

$$\begin{array}{lll} \|u(\cdot,t)-u^\epsilon(\cdot,t)\|_{L^1(dx;[\frac{u_0(0^+)+u_0(0^-)}{2}t,c])} & \sim & C_1\epsilon, \\ \|u(\cdot,t)-u^\epsilon(\cdot,t)\|_{L^1(dx;[c,u_0(0^+)t])} & \sim & \epsilon|\log\epsilon|, \\ \|u(\cdot,t)-u^\epsilon(\cdot,t)\|_{L^1(dx;[u_0(0^+)t,d])} & \sim & C_2\epsilon, \end{array} \tag{3.1.24}$$

where

$$C_1 = 2\log\left(\frac{\frac{1}{\frac{c}{t}-u_0(0^-)}+\frac{1}{u_0(0^+)-\frac{c}{t}}}{\frac{4}{u_0(0^+)-u_0(0^-)}}\right), \quad C_2 = 2\log\left(2\sqrt{\frac{u_0(\xi(u_0(0^+)t,t))}{u_0(\xi(d,t))}}\right), \tag{3.1.25}$$

and $\xi(x,t)$ is defined implicitly by (3.1.3). *Similar estimates hold for intervals at left of the center $\frac{u_0(0_+)+u_0(0_-)}{2}t$.*

The proof is similar to the proof of Theorem 3.1; we omit the detail.

We remark here that the monotonicity and concavity (convexity) assumptions in Proposition 3.3 are not essential; one can treat the case of a general centered rarefaction wave up to the time when the edge is, if ever, merged into a shock. The estimates (3.1.24) remain valid except the constants C_1 and C_2 may become larger due to overestimates. After the edge is merged into a shock, the local L^1 error reduces to $O(\epsilon)$.

The precise form of the statement above is rather complicated; we illustrate with the following example instead.

Example. Consider (2.1) and (2.2) with initial data

$$u_0(\xi) = \begin{cases} -1, & \xi < 0, \\ 1-\frac{\xi}{2}, & 0 \le \xi < 1, \\ -\frac{\xi}{2}, & 1 \le \xi < 2, \\ -1, & 2 \le \xi. \end{cases} \tag{3.1.26}$$

At time $t < 1$, the solution to (1.1) has a rarefaction wave spanning over $-t \le x \le t$ and a standing shock at $\xi = 1$. At $t = 1$, the right edge of the centered rarefaction wave is confronted with the standing shock and merged into it afterward. The following local L^1 estimates hold.

For $0 < t < 1$, we have

$$\begin{array}{lll} \|u(\cdot,t)-u^\epsilon(\cdot,t)\|_{L^1(dx;[0,t])} & \sim & \epsilon|\log\epsilon|, \\ \|u(\cdot,t)-u^\epsilon(\cdot,t)\|_{L^1(dx;[t,1])} & \sim & O(\epsilon), \\ \|u(\cdot,t)-u^\epsilon(\cdot,t)\|_{L^1(dx;[1,\infty))} & \sim & O(\epsilon). \end{array} \tag{3.1.27}$$

At $t = 1$,

$$\begin{array}{lll} \|u(\cdot,1)-u^\epsilon(\cdot,1)\|_{L^1(dx;[0,1])} & \sim & \epsilon|\log\epsilon|, \\ \|u(\cdot,1)-u^\epsilon(\cdot,1)\|_{L^1(dx;[1,\infty))} & \sim & O(\epsilon). \end{array} \tag{3.1.28}$$

After the interaction, say, $1 < t < 1.5$, the shock begins to move. Denoting by $s(t)$ the shock location, we have

$$\begin{array}{lcl} \|u(\cdot,t) - u^\epsilon(\cdot,t)\|_{L^1(dx;[0,s(t)])} & \sim & O(\epsilon), \\ \|u(\cdot,t) - u^\epsilon(\cdot,t)\|_{L^1(dx;[s(t),\infty))} & \sim & O(\epsilon). \end{array} \tag{3.1.29}$$

We outline the computation for the first equation in (3.1.27); the rest is done in a similar way. Consider

$$\bar{u}_0(\xi) = \begin{cases} -1, & \xi < 0, \\ 1, & \xi > 0, \end{cases} \tag{3.1.30}$$

and denote the corresponding viscous and inviscid solutions by $\bar{u}^\epsilon$ and $\bar{u}$, respectively. By a variant of Lemma 2.1, we can conclude that $\bar{u}(x,t) \geq (\leq) \bar{u}^\epsilon(x,t)$ on $\{x > 0\}$ ($\{x < 0\}$). Thus one can apply the Hopf–Cole transformaton. A short calculation leads to $\bar{G}(x,y,t) = \int_0^y \bar{u}_0(y')dy' + \frac{(x-y)^2}{2t}$ near the absolute minimum,

$$\begin{array}{lcll} \bar{G}(0,y,t) & \sim & |y|, \text{ for } y \text{ near } 0, & \\ \bar{G}(t,y,t) & \sim & \begin{cases} \frac{t}{2} - 2y, \ y < 0 \\ \frac{t}{2} + \frac{y^2}{2t}, \ y > 0 \end{cases} & \text{for } y \text{ near } 0, \end{array} \tag{3.1.31}$$

from which one easily concludes that

$$\|\bar{u}(\cdot,t) - \bar{u}^\epsilon(\cdot,t)\|_{L^1(dx;[0,t])} \sim \epsilon |\log \epsilon|. \tag{3.1.32}$$

On the other hand, $\bar{u}_0 \geq u_0$, thus $\bar{u}^\epsilon \geq u^\epsilon$ and we can apply the Hopf–Cole transformation again. The same calculation leads to

$$\begin{array}{lcll} G(0,y,t) & \sim & |y|, \text{ for } y \text{ near } 0, & \\ G(t,y,t) & \sim & \begin{cases} \frac{t}{2} - 2y, \ y < 0 [1ex] \\ \frac{t}{2} + (\frac{1}{2t} - \frac{1}{4})y^2, \ y > 0 \end{cases} & \text{for } y \text{ near } 0; \end{array} \tag{3.1.33}$$

one thus concludes that

$$\|\bar{u}^\epsilon(\cdot,t) - u^\epsilon(\cdot,t)\|_{L^1(dx;[0,t])} \sim \epsilon \log\left(\frac{2-t}{2}\right). \tag{3.1.34}$$

We conclude with the first equation of (3.1.27), with the triangle inequality and the fact that $u(x,t)$ coincides with $\bar{u}(x,t)$ for $x \leq t$.

3.2. Hopf–Cole–Lax transformation for some monotone schemes. We now give another example in which the convergence rate is not first order at the critical time—Lax–Friedrichs scheme applied to the conservation law (1.1) with a specific flux function:

$$f_L(u) = \log\left(\frac{\cosh(u)+1}{2}\right).$$

The Lax–Friedrichs scheme for this particular flux admits a discrete version of Hopf–Cole transformation. This was first observed by Lax [7] for upwind scheme with a family of flux function $f(u) = \log(a + be^{-u})$, $a, b > 0$, $a + b = 1$. Here we adopt a variation of the original one in order to maintain symmetry, which simplifies the analysis.

The following properties of $f_L(u)$ are elementary:

(C.1) $f_L(u) = f_L(-u)$.
(C.2) $f_L(0) = 0$.
(C.3) $f_L'(u) = \frac{\sinh(u)}{\cosh(u)+1}$, $f_L'(0) = 0$.
(C.4) $f_L''(u) = \frac{1}{\cosh(u)+1} > 0$.

We now study the convergence rate for the Lax–Friedrichs scheme with f_L. Let $u^\Delta(x,t)$ be the approximate solution obtained via the Lax–Friedrichs scheme

$$u^\Delta(x,t+\Delta) = \frac{1}{2}(\, u^\Delta(x-\Delta,t)+u^\Delta(x+\Delta,t)\,) - \frac{1}{2}(\, f_L(u^\Delta(x+\Delta,t)) - f_L(u^\Delta(x-\Delta,t))\,), \tag{3.2.1}$$

where the argument (x,t) is restricted to grid points only, and we have put $\Delta x = \Delta t = \Delta$ for simplicity.

Now let $U^\Delta(x,t) = 2\Delta \sum_{k=-\infty^0} u^\Delta(x-2k\Delta,t)$. The equation for U^Δ is

$$U^\Delta(x,t+\Delta) = \frac{1}{2}(\, U^\Delta(x-\Delta,t)+U^\Delta(x+\Delta,t)\,) - \Delta f_L\left(\frac{U^\Delta(x+\Delta,t) - U^\Delta(x-\Delta,t)}{2\Delta}\right). \tag{3.2.2}$$

Now we apply the Hopf–Cole–Lax transformation

$$U^\Delta = G(V^\Delta) = -2\Delta \log(V^\Delta),$$

which brings (3.2.1) to

$$\begin{aligned} G(V^\Delta(x,t+\Delta)) = \quad & \frac{1}{2}[G(V^\Delta(x+\Delta,t)) + G(V^\Delta(x-\Delta,t))][1ex] \\ & -\Delta f_L\left(\frac{G(V^\Delta(x+\Delta,t)) - G(V^\Delta(x-\Delta,t))}{2\Delta}\right). \end{aligned} \tag{3.2.3}$$

The equation for V^Δ thus linearizes as the following identity holds for all V, $W \in R$,

$$\frac{1}{2}(G(V)+G(W)) - \Delta f_L\left(\frac{G(V)-G(W)}{2\Delta}\right) = G\left(\frac{V+W}{2}\right).$$

Thus

$$V^\Delta(x,t+\Delta) = \frac{1}{2}(\, V^\Delta(x+\Delta,t) + V^\Delta(x-\Delta,t)\,),$$

and, therefore,

$$V^\Delta(x,t) = \sum_{l=0}^{n} \binom{n}{l} \frac{1}{2^n} V^\Delta(x-n\Delta+2\Delta,0),$$

where $t = n\Delta$.

For fixed $x, z \in \mathbf{R}$, $t > 0$, we want to estimate

$$U^\Delta(x,t) - U^\Delta(z,t) = -2\Delta \log\left(\frac{\displaystyle\sum_{l=0}^{n}\binom{n}{l} e^{-\frac{1}{\Delta}U^\Delta(x-n\Delta+2l\Delta,0)}}{\displaystyle\sum_{l=0}^{n}\binom{n}{l} e^{-\frac{1}{\Delta}U^\Delta(z-n\Delta+2l\Delta,0)}}\right), \tag{3.2.4}$$

where we've used $U^\Delta(\cdot,0) = -2\Delta\log(V^\Delta(\cdot,0))$. For the sake of a simpler formula, we assume that (x,t) and (z,t) are always on the grid points as the mesh refines.

The following counterpart of Lemma 2.1 is crucial in establishing the ordering of $u^\Delta(\cdot,t_c)$ and $u(\cdot,t_c)$; therefore, we can estimate the L^1 difference of the two using (3.2.4).

LEMMA 3.4. *Let u_0 be a smooth and bounded function satisfying*

(B.1) $f_L'(u_0(\xi)) = -\frac{\xi}{t_c} + a\xi^3 + b\xi^4 + O(\xi^5)$ *for* $|\xi| < \delta$ *where* $a > 0$.

(B.2) $\xi = 0$ *is the point corresponding to the first spontaneous formation of shocks; that is,* $\frac{d}{d\xi} f_L'(u_0(\xi)) > -\frac{1}{t_c}$ *for all* $\xi \neq 0$.

(B.3) $f_L'(u_0)$ *is antisymmetric, and thus so is* u_0*:* $u_0(-\xi) = -u_0(\xi)$.

(B.4) $f_L'(u_0(\cdot))$*, and, therefore,* $u_0(\cdot)$ *is monotonely nonincreasing.*

(B.5) $f_L'(u_0(\cdot))$ *is concave on* $\xi < 0$*, and, therefore, by Assumption* (B.3)*, convex on* $\xi > 0$.

Then

$$u(x,\Delta) \geq u^\Delta(x,\Delta) \quad x < 0,\ (x,\Delta) \text{ on the grids.}$$

By induction and the monotonicity of Lax–Friedrichs scheme, $u(x,t) \geq u^\Delta(x,t)$ *for all* $x < 0$, $t > 0$, (x,t) *on the grids.*

Proof. Let $A = (x,\Delta), B = (x-\Delta,0), C = (x+\Delta,0)$, and $D = (x,0)$ be four-grid points on $x < 0$; then

- $u_A^\Delta = g(u_B,u_C) \equiv \frac{1}{2}(u_B + u_C) - \frac{1}{2}(f_L(u_C) - f_L(u_B))$;
- $u_B \geq u_C$, and $u_A = u_E$ for some (unique) point E on the line segment $\bar{BD}$.

Denote by $m = f_L'(u_E) = \mathit{distance}(D,E)/\Delta$, and define, for $0 \leq \theta \leq 1$, a family of functions $v(\theta,\xi)$ on $\bar{BC}$ by

$$f_L'(v(\theta,\xi)) = m + \theta(f_L'(u_0(\xi)) - m), \quad 0 \leq \theta \leq 1,\ x-\Delta \leq \xi \leq x+\Delta.$$

Obviously, $v(0,\xi) = u_E$ and $v(1,\xi) = u_0(\xi)$.

Now let $h(\theta) = g(v(\theta,x-\Delta), v(\theta,x+\Delta))$; then $h(0) = u_E$ and $h(1) = g(u_B,u_C) = u_A^\Delta$. A direct computation gives

$$\frac{dh}{d\theta} = \frac{1}{2}(\alpha + \theta\alpha\beta + m\beta),$$

where $\alpha = f'(u_B) + f'(u_C) - 2m < 0$ and $\beta = f'(u_B) - f'(u_C) > 0$. Due to concavity of $f'(u_0(\cdot))$, the graph of $f'(u_0(\cdot))$ lies above the line joining $(B, f'(u_B))$ and $(C, f'(u_C))$; therefore, $\alpha + m\beta \leq 0$. Thus $\frac{dh}{d\theta} \leq 0$ and $u_A \geq u_A^\Delta$. ∎

Now we come back to estimate the leading order term of (3.2.4) using Stirling's formula

$$n! = \left(\frac{n-1}{e}\right)^{n-1} (2\pi(n-1))^{\frac{1}{2}} + \cdots. \tag{3.2.5}$$

After elementary calculations, we have

$$U^\Delta(x,t) - U^\Delta(z,t) = -2\Delta\log\left(\frac{\sum_{l=0}^{n} e^{-\frac{1}{\Delta}[(tF(\frac{x-y}{t}) + U_0(y,o)) + E_1]}}{\sum_{l=0}^{n} e^{-\frac{1}{\Delta}[(tF(\frac{z-y}{t}) + U_0(y,o)) + E_2]}}\right), \tag{3.2.6}$$

where $F(s) = \log(1-s^2) + s\log(\frac{1+s}{1-s})$, $t = n\Delta$, and $x - y = t - 2l\Delta$. E_1 and E_2 are the errors introduced by Stirling's formula, and are of lower order.

We next replace sums by integrals. Again, the errors are of lower order since the integrals are at least $O(\Delta^{\frac{1}{2}})$ as we saw in section 3.1. This leads to

$$U^\Delta(x,t) - U^\Delta(z,t) = -2\Delta \log \left(\frac{\int_{x-t}^{x+t} e^{-\frac{1}{2\Delta}[(tF(\frac{x-y}{t}) + \int^y u_0(y')dy') + E_1]} dy}{\int_{z-t}^{z+t} e^{-\frac{1}{2\Delta}[(tF(\frac{z-y}{t}) + \int^y u_0(y')dy') + E_2]} dy} \right) + \cdots. \tag{3.2.7}$$

At $x = 0$, $t = t_c$, the integrand of the numerator has a quartic phase at its maximum $y = 0$, while the integrand of the denominator has a quadratic phase at $z =$, say, -1, $t = t_c$. Therefore,

$$U^\Delta(0,t_c) - U^\Delta(-1,t_c) = \int_{-1}^{0} u(.,t_c) - 2\Delta \log \left(\frac{\Delta^{\frac{1}{4}}}{\Delta^{\frac{1}{2}}} \right) + \cdots,$$

and

$$\|u(\cdot,t_c) - u^\Delta(\cdot,t_c)\|_{L^1(\Delta x;[-1,0])} \sim \frac{1}{2}\Delta|\log\Delta|.$$

The generalization to nonantisymmetric initial data is the same as for Burgers's equation in the previous subsection.

Remark 2.

1. The case $t \neq t_c$ can be proved in the same way; see [2] for a discrete version of Lemma 2.2. The discrete analogue of the comparison lemma is an immediate consequence of monotonicity.

2. Although we only carry out the analysis for the most dissipative first-order scheme, namely, the Lax–Friedrichs scheme, the same argument shows that even the upwind scheme cannot do better. Since the same transform applies to the upwind scheme with the flux function $f(u) = -\log(a+be^{-u})$, $a, b > 0, a+b = 1$. Even though we don't have symmetry in this case, we still have the lower bound for free:

$$\|u(\cdot,t_c) - u^\Delta(\cdot,t_c)\|_{L^1(\Delta x;[x_c-1,x_c])} \geq |U(x_c,t_c) - U^\Delta(x_c-1,t_c)| = O(\Delta|\log\Delta|) \tag{3.2.8}$$

3. Since $f'(u) = \frac{be^{-u}}{a+be^{-u}} > 0$, the Godunov scheme reduces to upwind scheme. Therefore, (3.2.8) also holds for Godunov scheme with the same family of flux.

Acknowledgments. The author would like to thank his advisor, Professor Z. Xin, for suggesting this problem and some helpful discussions. He would also like to thank Professor J. Goodman and Dr. S. H. Yu for reminding him of the discrete Hopf–Cole transformation in [7].

ON A WAVE EQUATION WITH A BOUNDARY CONDITION ASSOCIATED WITH CAPILLARY WAVES*

JONG UHN KIM†

Abstract. This paper discusses an initial-boundary value problem for a wave equation with a nonstandard boundary condition associated with linear capillary waves on the surface of a compressible liquid. We prove the well-posedness of this problem. Our main technical device is the Fourier transform.

Key words. wave equation, initial-boundary value problem, capillary waves

Introduction. In this paper we discuss the following initial-boundary value problem for a wave equation:

$$u_{tt} - \Delta u = 0 \qquad \text{for } t \in (0,T),\ (x,y,z) \in R^3_+, \tag{0.1}$$

$$\mathcal{B}u(t,x,y,0) = 0 \qquad \text{for } t \in (0,T),\ (x,y) \in R^2, \tag{0.2}$$

$$u(0,x,y,z) = u_0(x,y,z),\ \ u_t(0,x,y,z) = u_1(x,y,z) \quad \text{for } (x,y,z) \in R^3_+, \tag{0.3}$$

where $T > 0$ is arbitrarily given, $R^3_+ = \{(x,y,z) : (x,y) \in R^2,\ z > 0\}$, Δ is the Laplacian in (x,y,z), and the operator $\mathcal{B}$ is defined by

$$\mathcal{B}u = \Delta u + \frac{\partial}{\partial z}\big(u_{xx} + u_{yy}\big). \tag{0.4}$$

This nonstandard boundary condition arises in the linearized model of capillary waves. Let a compressible liquid occupy the half-space R^3_+, and let u denote its velocity potential. When the effects of gravity are neglected, u satisfies the following acoustic equation within the liquid:

$$u_{tt} - c^2\Delta u = 0, \tag{0.5}$$

where c is the speed of sound. We describe the free surface by $z = \zeta(t,x,y)$. By the Laplace formula (see Landau and Lifshitz [5]), we have

$$p - p_0 = \alpha\big(\zeta_{xx} + \zeta_{yy}\big), \tag{0.6}$$

where $\alpha > 0$ is the surface-tension coefficient, p is the pressure in the liquid near the surface, and p_0 is the constant external pressure. On the other hand, u is related to the pressure by

$$p - p_0 = -\rho_0 \frac{\partial u}{\partial t}, \tag{0.7}$$

†Department of Mathematics, Virginia Tech, Blacksburg, VA 24061-0123 (kim@math.vt.edu).

where ρ_0 is the constant equilibrium density and gravity has been neglected. On the surface, it holds that

$$\frac{\partial u}{\partial z} = \frac{\partial \zeta}{\partial t} \qquad \text{at } z = 0. \tag{0.8}$$

Combining (0.5)–(0.8), we have

$$\Delta u + \frac{\alpha}{\rho_0 c^2} \frac{\partial}{\partial z}\big(u_{xx} + u_{yy}\big) = 0 \qquad \text{at } z = 0. \tag{0.9}$$

By rescaling the variables, we arrive at (0.1) and (0.2).

For the Dirichlet boundary condition $u = 0$, or the Neumann boundary condition $\frac{\partial u}{\partial z} = 0$ at $z = 0$, a complete result on the well-posedness of the initial-boundary value problem is well known. The purpose of this work is to establish a similar result in the L^2 Sobolev spaces with the boundary condition (0.2). Bondi [2] constructed a fundamental solution of (0.1)–(0.2) and studied an interesting phenomenon of wave propagation along the surface with infinite speed. His result was also discussed by Duff [3]. Here our issue is to formulate the well-posedness of the initial-boundary value problem (0.1)–(0.3) as closely as possible to that of the standard initial-boundary value problems. One could use fundamental solutions to represent solutions. However, even for the pure Cauchy problem in the whole space, the explicit formula of the fundamental solution is not a good device to obtain the basic L^2 energy estimates, which trivially follow either by a multiplier technique or by the Fourier transform. In particular, it is not at all clear whether the fundamental solution obtained in [2] can be used to obtain estimates of solutions in the function classes of L^2 setting. Here we rely on the well-known theory of the Cauchy problem in the whole space. This involves a suitable extension of the given data to the whole space, where various compatibility conditions are naturally incorporated. The main tool is the Fourier transform. When the boundary operator consists of only odd (or only even) derivatives in the normal coordinate variable, this is a standard procedure. The novelty of the above problem is that the boundary operator is hybrid, and a simple reflection method does not work. So the main difficulty lies in handling the boundary condition. The boundary $z = 0$ is noncharacteristic, and the trace of any derivative of the solution is well-defined due to partial hypoellipticity; see Hörmander [4]. But we need some regularity condition for the uniqueness of the solution, which is justified by a simple example presented in the next section. Our starting point is the following observation made by Duff [3]. Since $\mathcal{B}$ is a differential operator with constant coefficients, $\mathcal{B}u$ satisfies the wave equation if u does. Consequently, $\mathcal{B}u$ is a solution of the initial-boundary value problem with the initial data $(\mathcal{B}u_0, \mathcal{B}u_1)$ and the Dirichlet boundary condition. However, it is only a weak solution unless u itself is sufficiently smooth. For this, we provide in the next section a definition of a weak solution which is suitable in our function classes such that each solution in the natural energy space is included. As the initial data are more regular with suitable compatibility conditions at the boundary $z = 0$, the regularity of the solution improves accordingly.

Following the notation for function classes in Lions and Magenes [6], we state the main result as follows.

THEOREM 0.1. *Let $u_0 \in H^2(R^3_+)$ and $u_1 \in H^1(R^3_+)$ with $\frac{\partial u_0}{\partial z}(x, y, 0) \in H^1(R^2)$. Then, there is a unique solution $u \in C([0,T]\,;\, H^2(R^3_+)) \cap C^1([0,T]\,;\, H^1(R^3_+))$ of (0.1)–(0.3) such that $\mathcal{B}u$ is a solution of (1.9) below with the initial data $(\mathcal{B}u_0, \mathcal{B}u_1)$.*

Furthermore, for each $t \in [0,T]$ the solution satisfies

$$\begin{aligned}(0.10)\qquad &\|u(t,\cdot)\|_{H^2(R^3_+)} + \|u_t(t,\cdot)\|_{H^1(R^3_+)}\\ &\quad\le M(T)\bigg(\|u_0\|_{H^2(R^3_+)} + \|u_1\|_{H^1(R^3_+)} + \Big\|\frac{\partial u_0}{\partial z}(\cdot,0)\Big\|_{H^1(R^2)}\bigg),\end{aligned}$$

where $M(T)$ is a positive constant depending on T.

We can also obtain more regular solutions.

COROLLARY 0.2. *If we suppose that $u_0 \in H^3(R^3_+)$ with $\mathcal{B}u_0 = 0$ at $z = 0$ and that $u_1 \in H^2(R^3_+)$ with $\frac{\partial u_1}{\partial z}(\cdot,0) \in H^1(R^2)$, the above solution belongs to $C([0,T]\,;\, H^3(R^3_+)) \cap C^1([0,T]\,;\, H^2(R^3_+))$, and it holds that for all $t \in [0,T]$,*

$$\begin{aligned}(0.11)\qquad &\|u(t,\cdot)\|_{H^3(R^3_+)} + \|u_t(t,\cdot)\|_{H^2(R^3_+)}\\ &\quad\le M(T)\bigg(\|u_0\|_{H^3(R^3_+)} + \|u_1\|_{H^2(R^3_+)} + \Big\|\frac{\partial u_1}{\partial z}(\cdot,0)\Big\|_{H^1(R^2)}\bigg)\end{aligned}$$

for some positive constant $M(T)$.

COROLLARY 0.3. *Let $m \ge 1$ be an integer. Suppose that $u_0 \in H^{2m+2}(R^3_+)$, $\mathcal{B}u_0 = 0$, $\Delta\mathcal{B}u_0 = 0, \dots, \Delta^{m-1}\mathcal{B}u_0 = 0$ at $z = 0$, $(\frac{\partial}{\partial z})^{2m+1}u_0(\cdot,0) \in H^1(R^2)$ and that $u_1 \in H^{2m+1}(R^3_+)$, $\mathcal{B}u_1 = 0$, $\Delta\mathcal{B}u_1 = 0, \dots, \Delta^{m-1}\mathcal{B}u_1 = 0$ at $z = 0$. Then, the above solution belongs to $C([0,T]\,;\, H^{2m+2}(R^3_+)) \cap C^1([0,T]\,;\, H^{2m+1}(R^3_+))$ and satisfies for all $t \in [0,T]$,*

$$\begin{aligned}(0.12)\quad &\|u(t,\cdot)\|_{H^{2m+2}(R^3_+)} + \|u_t(t,\cdot)\|_{H^{2m+1}(R^3_+)}\\ &\quad\le M(T,m)\bigg(\|u_0\|_{H^{2m+2}(R^3_+)} + \|u_1\|_{H^{2m+1}(R^3_+)} + \Big\|\frac{\partial^{2m+1}u_0}{\partial z^{2m+1}}(\cdot,0)\Big\|_{H^1(R^2)}\bigg),\end{aligned}$$

where $M(T,m)$ is a positive constant depending on T and m.

COROLLARY 0.4. *Let $m \ge 1$ be an integer. Suppose that $u_0 \in H^{2m+3}(R^3_+)$, $\mathcal{B}u_0 = 0$, $\Delta\mathcal{B}u_0 = 0, \dots, \Delta^m\mathcal{B}u_0 = 0$ at $z = 0$ and that $u_1 \in H^{2m+2}(R^3_+)$, $\mathcal{B}u_1 = 0$, $\Delta\mathcal{B}u_1 = 0, \dots, \Delta^{m-1}\mathcal{B}u_1 = 0$ at $z = 0$, $(\frac{\partial}{\partial z})^{2m+1}u_1(\cdot,0) \in H^1(R^2)$. Then, the above solution belongs to $C([0,T]\,;\, H^{2m+3}(R^3_+)) \cap C^1\big([0,T]\,;\, H^{2m+2}(R^3_+)\big)$ and satisfies for all $t \in [0,T]$,*

$$\begin{aligned}(0.13)\quad &\|u(t,\cdot)\|_{H^{2m+3}(R^3_+)} + \|u_t(t,\cdot)\|_{H^{2m+2}(R^3_+)}\\ &\quad\le M(T,m)\bigg(\|u_0\|_{H^{2m+3}(R^3_+)} + \|u_1\|_{H^{2m+2}(R^3_+)} + \Big\|\frac{\partial^{2m+1}u_1}{\partial z^{2m+1}}(\cdot,0)\Big\|_{H^1(R^2)}\bigg).\end{aligned}$$

If we assume that the support of the initial data is contained in R^3_+, then the result is essentially the same as that for the standard boundary conditions.

COROLLARY 0.5. *Let m be a nonnegative integer. Let $u_0 \in H^{m+2}(R^3_+)$ and $u_1 \in H^{m+1}(R^3_+)$ such that $\operatorname{supp} u_0 \cup \operatorname{supp} u_1 \subset R^3_+$. Then, the above solution belongs to $C([0,T]\,;\, H^{m+2}(R^3_+)) \cap C^1([0,T]\,;\, H^{m+1}(R^3_+))$ and satisfies for each $t \in [0,T]$,*

$$\begin{aligned}(0.14)\qquad &\|u(t,\cdot)\|_{H^{m+2}(R^3_+)} + \|u_t(t,\cdot)\|_{H^{m+1}(R^3_+)}\\ &\quad\le M(T,m)(\|u_0\|_{H^{m+2}(R^3_+)} + \|u_1\|_{H^{m+1}(R^3_+)}).\end{aligned}$$

We will prove these results in the next sections.

1. Preliminaries. We first review some facts about the Cauchy problem for a wave equation in R^3, which is formulated as follows:

$$\begin{cases} u_{tt} - \Delta u = 0 \qquad \text{in } (0,T)\times R^3, \\ u(0,x,y,z) = u_0(x,y,z) \qquad \text{in } R^3, \\ u_t(0,x,y,z) = u_1(x,y,z) \qquad \text{in } R^3, \end{cases} \tag{1.1}$$

where Δ is the Laplacian in $(x,y,z)\in R^3$, and $0<T<\infty$ is arbitrarily given.

LEMMA 1.1. *Let $u_0 \in H^s(R^3)$, and $u_1 \in H^{s-1}(R^3)$, for some $s \in R$. Then, there is a unique solution of the Cauchy problem* (1.1) *in $C([0,T]\,;\,H^s(R^3))\cap C^1([0,T]\,;\,H^{s-1}(R^3))$, and it holds that*

$$\|u(t,\cdot)\|_{H^s(R^3)} + \|u_t(t,\cdot)\|_{H^{s-1}(R^3)} \le M(T)(\|u_0\|_{H^s(R^3)} + \|u_1\|_{H^{s-1}(R^3)}) \tag{1.2}$$

for all $t\in[0,T]$ with some positive constant $M(T)$ independent of u_0 and u_1.

LEMMA 1.2. *In the same setting as above, assume that* supp $u_0 \cup$ supp $u_1 \subset \{(x,y,z) : z < -L\}$ *for some $L\in R$. Then, the support of the solution for $t\ge 0$ is contained in $\{(t,x,y,z) : t > z+L\}$.*

Next we define a function space $\mathcal{X}$ by

$$\begin{aligned} \mathcal{X} =\ & H^{-1}(R_z\,;\,H^{-1}(R^2)) + L^2(R_z\,;\,H^{-2}(R^2)) \\ & = \{f_1+f_2 \,:\, f_1(x,y,z)\in H^{-1}(R_z\,;\,H^{-1}(R^2)),\ \ f_2(x,y,z)\in L^2(R_z\,;\,H^{-2}(R^2))\}, \end{aligned}$$

equipped with the norm

$$\|f\|_{\mathcal{X}} = \inf_{f=f_1+f_2} (\|f_1\|_{H^{-1}(R_z;H^{-1}(R^2))} + \|f_2\|_{L^2(R_z;H^{-2}(R^2))}), \tag{1.3}$$

where R_z is for the z variable. Then, $\mathcal{X}$ is the dual of $H^1(R_z\,;\,H^1(R^2))\cap L^2(R_z\,;\,H^2(R^2))$. For this, see Bergh and Löfström [1]. We also need the following fact.

LEMMA 1.3. *The operator $(1-\Delta_{x,y})^{1/2}$ is an isomorphism from $H^{-1}(R^3)$ onto $\mathcal{X}$. Here, $\Delta_{x,y}$ is the Laplacian in (x,y).*

Proof. Choose any $f\in H^{-1}(R^3)$, and set

$$\hat{f}_1(\xi) = \frac{|\xi_3|}{1+|\xi_1|+|\xi_2|+|\xi_3|}\hat{f}(\xi)$$

and

$$\hat{f}_2(\xi) = \frac{1+|\xi_1|+|\xi_2|}{1+|\xi_1|+|\xi_2|+|\xi_3|}\hat{f}(\xi),$$

where $\hat{f}(\xi)$ is the Fourier transform of f and $\xi=(\xi_1,\xi_2,\xi_3)$ is the dual variable of (x,y,z). It is apparent that $f=f_1+f_2$ and

$$\|(1-\Delta_{x,y})^{1/2} f_1\|_{H^{-1}(R_z;H^{-1}(R^2))} \le M\|f\|_{H^{-1}(R^3)} \tag{1.4}$$

and

$$\|(1-\Delta_{x,y})^{1/2} f_2\|_{L^2(R_z;H^{-2}(R^2))} \le M\|f\|_{H^{-1}(R^3)} \tag{1.5}$$

for some positive constant M independent of f. In the meantime, $H^{-1}(R_z\,;\,L^2(R^2))$ and $L^2(R_z\,;\,H^{-1}(R^2))$ are continuously embedded into $H^{-1}(R^3)$. Hence, $(1-\Delta_{x,y})^{-1/2}$ is continuous from $\mathcal{X}$ into $H^{-1}(R^3)$. □

LEMMA 1.4. *Suppose that* $u_0 \in L^2(R_z\,;\,H^{-1}(R^2))$ *and* $u_1 \in \mathcal{X}$. *Then, there is a unique solution* u *of* (1.1) *in* $C\big([0,T]\,;\,L^2(R_z\,;\,H^{-1}(R^2))\big) \cap C^1([0,T]\,;\,\mathcal{X})$. *We also have*

$$\|u(t,\cdot)\|_{L^2(R_z;H^{-1}(R^2))} + \|u_t(t,\cdot)\|_{\mathcal{X}} \le M(T)\left(\|u_0\|_{L^2(R_z;H^{-1}(R^2))} + \|u_1\|_{\mathcal{X}}\right) \tag{1.6}$$

for all $t \in [0,T]$, *where* $M(T)$ *is a positive constant independent of* u_0 *and* u_1.

Proof. Let us set

$$v_0 = (1-\Delta_{x,y})^{-1/2}u_0, \qquad v_1 = (1-\Delta_{x,y})^{-1/2}u_1, \tag{1.7}$$

and consider the Cauchy problem (1.1) with (u_0,u_1) replaced by (v_0,v_1). Since $v_0 \in L^2(R^3)$ and $v_1 \in H^{-1}(R^3)$, it follows from Lemma 1.1 that there is a unique solution v in $C([0,T]\,;\,L^2(R^3)) \cap C^1([0,T]\,;\,H^{-1}(R^3))$. We then set

$$u = (1-\Delta_{x,y})^{1/2}v. \tag{1.8}$$

By virtue of Lemmas 1.1 and 1.3, we find that u is the unique solution of (1.1) in $C([0,T]\,;\,L^2(R_z\,;\,H^{-1}(R^2))) \cap C^1([0,T]\,;\mathcal{X})$ and that (1.6) is satisfied.

We now consider an initial-boundary value problem in a half-space:

$$\begin{cases} u_{tt} - \Delta u = 0 \qquad \text{in} \quad (0,T)\times R^3_+, \\ u(t,x,y,0) = 0 \qquad \text{in} \quad (0,T)\times R^2, \\ u(0,x,y,z) = u_0(x,y,z) \qquad \text{in} \quad R^3_+, \\ u_t(0,x,y,z) = u_1(x,y,z) \qquad \text{in} \quad R^3_+. \end{cases} \tag{1.9}$$

We define a function space $\mathcal{X}_1$ by

$$\mathcal{X}_1 = \{f_1 + f_2 \,:\, f_1 \in H^{-1}((0,\infty)\,;\,H^{-1}(R^2)),\ f_2 \in L^2(0,\infty\,;\,H^{-2}(R^2))\}$$

equipped with the norm

$$\|f\|_{\mathcal{X}_1} = \inf_{f=f_1+f_2}\left(\|f_1\|_{H^{-1}((0,\infty);H^{-1}(R^2))} + \|f_2\|_{L^2(0,\infty;H^{-2}(R^2))}\right), \tag{1.10}$$

so that $\mathcal{X}_1$ is the dual of $H^1_0((0,\infty)\,;\,H^1(R^2)) \cap L^2(0,\infty\,;\,H^2(R^2))$. We then adopt the following definition of a solution of (1.9).

DEFINITION 1.5. *Let* $u_0 \in L^2(0,\infty\,;\,H^{-1}(R^2))$ *and* $u_1 \in \mathcal{X}_1$. *We say that a function* $u \in C\big([0,T]\,;\,L^2(0,\infty;\,H^{-1}(R^2))\big) \cap C^1([0,T]\,;\,\mathcal{X}_1)$ *is a solution of* (1.9) *if it holds that*

$$\begin{aligned} -\langle u_1,\,\phi(0,x,y,z)\rangle_1 + \langle u_0,\,\phi_t(0,x,y,z)\rangle_2 \\ + \int_0^\infty \int_0^T \langle u,\ \phi_{tt} - \Delta\phi\rangle_3 \,dt\,dz = 0 \end{aligned} \tag{1.11}$$

for every $\phi \in C^2([0,T]\,;\,H^2(R^3_+))$ *such that*

$$\begin{cases} \phi(t,x,y,0) = 0 \qquad \textit{in} \quad [0,T]\times R^2, \\ \phi(T,x,y,z) = 0, \qquad \phi_t(T,x,y,z) = 0 \qquad \textit{in} \quad R^3_+. \end{cases} \tag{1.12}$$

Here, the bracket $\langle\cdot,\cdot\rangle_1$ *is the duality pairing between* $\mathcal{X}_1$ *and* $H^1_0((0,\infty)\,;\,H^1(R^2)) \cap L^2(0,\infty\,;\,H^2(R^2))$, $\langle\cdot,\cdot\rangle_2$ *is the duality pairing between* $L^2(0,\infty\,;\,H^{-1}(R^2))$ *and* $L^2(0,\infty\,;\,H^1(R^2))$, *and* $\langle\cdot,\cdot\rangle_3$ *is the duality pairing between* $H^{-1}(R^2)$ *and* $H^1(R^2)$.

First we note that the solution in the natural energy space $C([0,T]\,;\,H_0^1(R^3_+))\cap C^1([0,T]\,;\,L^2(R^3_+))$ satisfies the above condition (1.11). We will show that the condition (1.11) implies the boundary condition at $z=0$. Choose any $\psi\in C_0^\infty((0,T)\times R^2)$, and set

$$J(z)=\int_0^T \langle u(t,x,y,z),\,\psi(t,x,y)\rangle_3\,dt,$$

$$I(z)=\int_0^T \langle u(t,x,y,z),\;\psi_{tt}-\Delta_{x,y}\psi\rangle_3\,dt.$$

Then, $J(z)$ and $I(z)$ belong to $L^2((0,\infty))$, and it holds that

$$\frac{d^2J}{dz^2}(z)=I(z),\qquad \text{in}\quad \mathcal{D}'((0,\infty)), \tag{1.13}$$

since (1.11) implies that u satisfies the wave equation in $\mathcal{D}'((0,T)\times R^3_+)$. Thus, $J(z)\in H^2((0,\infty))\subset C^1([0,T])$. Next choose $p(z)\in C_0^\infty([0,\infty))$ with $p(0)=0$, and $\frac{dp}{dz}(0)=1$. It follows from (1.13) that

$$\int_0^\infty \frac{d^2J}{dz^2}(z)\,p(z)\,dz=\int_0^\infty I(z)p(z)\,dz. \tag{1.14}$$

But we have

$$\int_0^\infty \frac{d^2J}{dz^2}\,p(z)\,dz=J(0)+\int_0^\infty J(z)\,\frac{d^2p}{dz^2}(z)\,dz. \tag{1.15}$$

By (1.11), we find that

$$\begin{aligned}0&=\int_0^\infty\int_0^T \langle u,\psi_{tt}-\Delta_{x,y}\psi\rangle_3\,p(z)\,dt\,dz-\int_0^\infty\int_0^T\langle u,\psi\rangle_3\,\frac{d^2p}{dz^2}(z)\,dt\,dz\\ &=\int_0^\infty I(z)p(z)\,dz-\int_0^\infty J(z)\frac{d^2p}{dz^2}(z)\,dz.\end{aligned} \tag{1.16}$$

It follows from (1.14)–(1.16) that $J(0)=0$, which means that u satisfies the boundary condition. Next we show that (1.11) implies that the initial conditions are satisfied. Choose an arbitrary function $\theta(x,y,z)\in C_0^\infty(R^3_+)$, and set

$$K(t)=\int_0^\infty \langle u(t,x,y,z),\,\theta(x,y,z)\rangle_3\,dz,$$

$$L(t)=\int_0^\infty \langle u(t,x,y,z),\,\Delta\theta(x,y,z)\rangle_3\,dz.$$

Then, $K(t)$ and $L(t)$ are continuous in $t\in[0,T]$, and

$$\frac{d^2K}{dt^2}(t)=L(t)\qquad \text{holds in}\quad \mathcal{D}'((0,T)), \tag{1.17}$$

which yields $K(t) \in C^2([0,T])$. Next choose a function $q(t) \in C^\infty([0,T])$ such that $q(T) = q_t(T) = 0, \quad q(0) = 1,$ and $q_t(0) = 0$. It is obvious that

$$\int_0^T \frac{d^2K}{dt^2}(t)q(t)\,dt = \int_0^T L(t)q(t)\,dt, \tag{1.18}$$

and thus,

$$-\frac{dK}{dt}(0) + \int_0^T K(t)\frac{d^2q}{dt^2}(t)\,dt = \int_0^T L(t)q(t)\,dt. \tag{1.19}$$

By virtue of (1.11), it holds that

$$\begin{aligned} 0 = & -\langle u_1, \theta(x,y,z)\rangle_1 + \int_0^\infty \int_0^T \langle u,\, q_{tt}\theta - q\Delta\theta\rangle_3\,dt\,dz \\ & = -\langle u_1, \theta(x,y,z)\rangle_1 + \int_0^T K(t)q_{tt}(t)\,dt - \int_0^T L(t)q(t)\,dt. \end{aligned} \tag{1.20}$$

By combining (1.19) and (1.20), we have

$$\langle u_1,\, \theta(x,y,z)\rangle_1 \,=\, \frac{dK}{dt}(0) \,=\, \langle u_t(0,x,y,z),\, \theta(x,y,z)\rangle_1. \tag{1.21}$$

By choosing a different $q(t)$, it also holds that

$$\langle u_0,\, \theta(x,y,z)\rangle_2 \,=\, \langle u(0,x,y,z),\, \theta(x,y,z)\rangle_2. \tag{1.22}$$

Hence, u satisfies the initial conditions.

PROPOSITION 1.6. *Let $u_0 \in L^2(0,\infty\,;\, H^{-1}(R^2))$ and $u_1 \in \mathcal{X}_1$. Then, there is a unique solution of* (1.9) *in $C\big([0,T];\, L^2(0,\infty;\, H^{-1}(R^2))\big) \cap C^1([0,T];\, \mathcal{X}_1)$.*

Proof. We can choose a sequence of functions $\{u_0^n\}_{n=1}^\infty$ such that $u_0^n \in C_0^\infty(R^3_+)$ and

$$u_0^n \to u_0 \qquad \text{in} \quad L^2(0,\infty\,;\, H^{-1}(R^2)).$$

Since $u_1 \in \mathcal{X}_1$, we can write

$$u_1 = \frac{df}{dz} + g \tag{1.23}$$

for some $f \in L^2(0,\infty\,;\, H^{-1}(R^2))$ and $g \in L^2(0,\infty\,;\, H^{-2}(R^2))$. Let $\{f_n\}_{n=1}^\infty$ and $\{g_n\}_{n=1}^\infty$ be sequences in $C_0^\infty(R^3_+)$ such that

$$f_n \to f \qquad \text{in} \quad L^2(0,\infty\,;\, H^{-1}(R^2)),$$

$$g_n \to g \qquad \text{in} \quad L^2(0,\infty\,;\, H^{-2}(R^2))$$

as $n \to \infty$. We now define

$$v_0^n(x,y,z) = \begin{cases} u_0^n(x,y,z) & \text{for } z \geq 0, \\ -u_0^n(x,y,-z) & \text{for } z < 0; \end{cases} \tag{1.24}$$

$$\tilde{f}_n(x,y,z) = \begin{cases} f_n(x,y,z) & \text{for } z \geq 0, \\ f_n(x,y,-z) & \text{for } z < 0; \end{cases} \tag{1.25}$$

$$\tilde{g}_n(x,y,z) = \begin{cases} g_n(x,y,z) & \text{for } z \geq 0, \\ -g_n(x,y,-z) & \text{for } z < 0; \end{cases} \tag{1.26}$$

$$v_1^n(x,y,z) = \frac{d\tilde{f}_n}{dz}(x,y,z) + \tilde{g}_n(x,y,z). \tag{1.27}$$

Then, it is easy to see that as $n \to \infty$,

$$v_0^n \text{ converges in } L^2(R_z\,;\, H^{-1}(R^2)) \tag{1.28}$$

and

$$v_1^n \text{ converges in } \mathcal{X}. \tag{1.29}$$

With (u_0, u_1) replaced by (v_0^n, v_1^n) in the Cauchy problem (1.1), we obtain a solution $v^n \in C([0,T]\,;\, H^m(R^3)) \cap C^1([0,T]\,;\, H^m(R^3))$ for every $m \in R$. By Lemma 1.4, (1.28), and (1.29), we find that

$$v^n \to v \qquad \text{in} \quad C\big([0,T]\,;\, L^2(R_z; H^{-1}(R^2))\big) \cap C^1([0,T]\,;\, \mathcal{X}) \tag{1.30}$$

for some v. Since v_0^n and v_1^n are odd in z, it follows that v^n is odd in z. So $v^n(t,x,y,0) = 0$. Since v^n is a smooth solution, it is evident that the restriction of v^n to R^3_+ satisfies (1.11) with (u_0, u_1) replaced by the restriction of (v_0^n, v_1^n) to R^3_+. Now it follows from (1.30) that the restriction of v to R^3_+ is a solution of (1.9). For the uniqueness of the solution, choose an arbitrary function $\psi(t,x,y,z) \in C_0^\infty((0,T)\times R^3_+)$, and find the solution of

$$\begin{cases} \phi_{tt} - \Delta\phi = \psi & \text{in} \quad (0,T)\times R^3_+, \\ \phi(t,x,y,0) = 0 & \text{in} \quad (0,T)\times R^2, \\ \phi(T,x,y,z) = 0 & \text{in} \quad R^3_+, \\ \phi_t(T,x,y,z) = 0 & \text{in} \quad R^3_+. \end{cases} \tag{1.31}$$

Then ϕ is eligible as a test function for (1.11). Let w be the difference between two solutions satisfying (1.11). Then, it is apparent that

$$\int_0^\infty \int_0^T \langle w,\, \psi\rangle_3 \, dt\, dz = 0, \tag{1.32}$$

and hence, $w \equiv 0$. □

As mentioned earlier, some regularity conditions are necessary for the uniqueness of solution of (1.9). To see this, let us consider

$$u = \delta(t - z), \tag{1.33}$$

where δ is the Dirac delta measure. Then, u is obviously a weak solution of the wave equation and satisfies the homogeneous initial-boundary conditions in the following sense.

$$\lim_{t\to 0+} \langle u, \phi(x,y,z)\rangle = 0, \tag{1.34}$$

$$\lim_{t\to 0+} \langle u_t, \phi(x,y,z)\rangle = 0, \tag{1.35}$$

$$\lim_{z\to 0+} \langle u, \psi(t,x,y)\rangle = 0 \tag{1.36}$$

for every $\phi \in C_0^\infty(R^3_+)$ and $\psi \in C_0^\infty((0,T)\times R^2)$. The bracket denotes the duality pairing between distributions and test functions. In fact, this also satisfies the boundary condition $\mathcal{B}u = 0$ at $z = 0$ in the sense

$$\lim_{z\to 0+} \langle \mathcal{B}u,\, \psi(t,x,y)\rangle = 0 \tag{1.37}$$

for all $\psi \in C_0^\infty((0,T)\times R^2)$.

2. Proof of Theorem 0.1. We first outline the strategy of proof.

Step 1. For given $0 < T < \infty$, $u_0 \in H^2(R^3_+)$, and $u_1 \in H^1(R^3_+)$ with $\frac{\partial}{\partial z}u_0(x,y,0) \in H^1(R^2)$, we find $\tilde{u}_0 \in H^2(R^3)$ and $\tilde{u}_1 \in H^1(R^3)$ which satisfy the following conditions:

$$\tilde{u}_0 = u_0, \qquad \tilde{u}_1 = u_1 \qquad \text{for} \quad z \geq 0; \tag{2.1}$$

$$\mathcal{B}\tilde{u}_0 \in L^2(R_z\,;\, H^{-1}(R^2)), \qquad \mathcal{B}\tilde{u}_1 \in \mathcal{X}; \tag{2.2}$$

(2.3) there are sequences $\{w_0^n\}_{n=1}^\infty$, $\{w_1^n\}_{n=1}^\infty$ in $C_0^\infty(R^3)$ such that

(i) $$w_0^n \to \mathcal{B}\tilde{u}_0 \qquad \text{in} \quad L^2(R_z\,;\, H^{-1}(R^2)),$$

(ii) $$w_1^n \to \mathcal{B}\tilde{u}_1 \qquad \text{in} \quad \mathcal{X},$$

(iii)
$$w_0^n(x,y,z) = -w_0^n(x,y,-z), \quad w_1^n(x,y,z) = -w_1^n(x,y,-z) \quad \text{for } -2T < z < 2T.$$

Step 2. We proceed as in Proposition 1.6 with help of Lemmas 1.1 and 1.2. Find the solution w^n of the Cauchy problem (1.1) in $(0,2T)\times R^3$ with the initial data (w_0^n, w_1^n). Let w be the limit of $\{w^n\}_{n=1}^\infty$. Then, the restriction of w to $[0,T]\times R^3_+$ is a solution of (1.9) with initial data $(\mathcal{B}u_0, \mathcal{B}u_1)$.

Step 3. Find the solution u of the Cauchy problem (1.1) in $(0,2T)\times R^3$ with the initial data $(\tilde{u}_0, \tilde{u}_1)$. By the uniqueness of solution of (1.1), we have $w \equiv \mathcal{B}u$, and the restriction of u to $[0,T]\times R^3_+$ is a desired solution.

Step 4. Prove the uniqueness of solution of (0.1) - (0.3).

One might wonder if we can bypass Step 1 and use Proposition 1.6 directly with initial data $(\mathcal{B}u_0, \mathcal{B}u_1)$ to satisfy the boundary condition $\mathcal{B}u = 0$ at $z = 0$. This is not possible since the solution obtained by Proposition 1.6 cannot be properly related to the solution required in Theorem 0.1. The trouble lies in inverting the operator $\mathcal{B}$. We now present the details of the proof. Obviously, only Step 1 and Step 4 require technical details.

Construction of $\tilde{u}_0$ and $\tilde{u}_1$. Suppose that $u_0 \in H^2(R^3_+)$ is given with $\frac{\partial}{\partial z}u_0(x,y,0) \in H^1(R^2)$. Let us consider the following initial value problem:

$$\frac{\partial^2\hat{\phi}}{\partial s^2} + |\xi|^2\frac{\partial\hat{\phi}}{\partial s} - |\xi|^2\hat{\phi} = 2|\xi|^2\frac{\partial\hat{u}_0}{\partial s}(\xi,s), \qquad s>0, \tag{2.4}$$

$$\hat{\phi}(\xi,0) = 2\hat{u}_0(\xi,0), \tag{2.5}$$

$$\frac{\partial\hat{\phi}}{\partial s}(\xi,0) = 0, \tag{2.6}$$

where $\xi=(\xi_1,\xi_2)$ is the dual variable of (x,y) and $\hat{u}_0$ denotes the Fourier transform of u_0 with respect to (x,y). Here ξ is a parameter in this initial value problem, which is well posed for almost all $\xi \in R^2$. It is easy to find a solution $\hat{\phi}$ of (2.4)–(2.6) by the variation of constants formula:

$$\begin{aligned}\hat{\phi}(\xi,s) &= 2\int_0^s \frac{e^{\lambda_1(s-\eta)}}{\sqrt{|\xi|^4+4|\xi|^2}}|\xi|^2\frac{\partial\hat{u}_0}{\partial\eta}(\xi,\eta)\,d\eta \\ &\quad - 2\int_0^s \frac{e^{\lambda_2(s-\eta)}}{\sqrt{|\xi|^4+4|\xi|^2}}|\xi|^2\frac{\partial\hat{u}_0}{\partial\eta}(\xi,\eta)\,d\eta \\ &\quad - \frac{2(\lambda_2/\lambda_1)e^{\lambda_1 s}}{1-(\lambda_2/\lambda_1)}\hat{u}_0(\xi,0) \\ &\quad + \frac{2e^{\lambda_2 s}}{1-(\lambda_2/\lambda_1)}\hat{u}_0(\xi,0) \\ &= \hat{J}_1(\xi,s)+\hat{J}_2(\xi,s)+\hat{J}_3(\xi,s)+\hat{J}_4(\xi,s),\end{aligned} \tag{2.7}$$

where

$$\begin{cases}\lambda_1 = \dfrac{1}{2}(-|\xi|^2+\sqrt{|\xi|^4+4|\xi|^2}), \\ \lambda_2 = \dfrac{1}{2}(-|\xi|^2-\sqrt{|\xi|^4+4|\xi|^2}),\end{cases} \tag{2.8}$$

and

$$\hat{J}_1(\xi,s) = 2\int_0^s \frac{\lambda_1 e^{\lambda_1(s-\eta)}}{\sqrt{|\xi|^4+4|\xi|^2}}|\xi|^2\hat{u}_0(\xi,\eta)\,d\eta, \tag{2.9}$$

$$\hat{J}_2(\xi,s) = \frac{2|\xi|^2}{\sqrt{|\xi|^4+4|\xi|^2}}\hat{u}_0(\xi,s) + \frac{2\lambda_1 e^{\lambda_1 s}}{\sqrt{|\xi|^4+4|\xi|^2}}\hat{u}_0(\xi,0), \tag{2.10}$$

$$\hat{J}_3(\xi,s) = -2\int_0^s \frac{e^{\lambda_2(s-\eta)}}{\sqrt{|\xi|^4+4|\xi|^2}}|\xi|^2\frac{\partial\hat{u}_0}{\partial\eta}(\xi,\eta)\,d\eta, \tag{2.11}$$

$$\hat{J}_4(\xi,s) = \frac{2e^{\lambda_2 s}}{1-(\lambda_2/\lambda_1)}\hat{u}_0(\xi,0). \tag{2.12}$$

We fix a function $\rho \in C_0^\infty(R)$ such that

$$\rho(s) = 1 \qquad \text{for } |s| \le 2T \tag{2.13}$$

and estimate each $\rho(s)\hat{J}_i(\xi, s)$. There is a positive constant M such that for all $\xi \in R^2$,

$$0 \le \lambda_1 \le M, \tag{2.14}$$

$$|\lambda_2 + |\xi|^2| \le M. \tag{2.15}$$

By means of (2.14) and the inequality

$$\|(1+|\xi|)^{3/2}\hat{u}_0(\xi,0)\|_{L^2(R^2)} \le M\|u_0\|_{H^2(R^3_+)}, \tag{2.16}$$

it is evident that for $i = 1, 2$,

$$\int_0^\infty \left(\left\| \frac{\partial^2}{\partial s^2}(\rho(s)\hat{J}_i(\xi,s)) \right\|^2_{L^2(R^2)} + \left\| \rho(s)(1+|\xi|^2)\hat{J}_i(\xi,s) \right\|^2_{L^2(R^2)} \right) ds \le M\|u_0\|^2_{H^2(R^3_+)} \tag{2.17}$$

for some positive constant M. Next we recall some basic estimates of solutions of the heat equation, which follow directly from energy estimates:

$$\int_0^\infty \left\| e^{-|\xi|^2 s}\, |\xi|^2\, \hat{f}(\xi) \right\|^2_{L^2(R^2)} ds \le M\|f\|^2_{H^1(R^2)} \quad \text{for all } f \in H^1(R^2) \tag{2.18}$$

and

$$\int_0^\infty \left\| \int_0^s e^{-|\xi|^2(s-t)}\, |\xi|^2\, \hat{g}(\xi,t)\, dt \right\|^2_{L^2(R^2)} ds \le M\|g\|^2_{L^2(R^3_+)} \quad \text{for all } g \in L^2(R^3_+) \tag{2.19}$$

for some positive constant M. We can write $\lambda_2 = -|\xi|^2 + p(\xi)$ and

$$\hat{J}_4(\xi, s) = \frac{2e^{-|\xi|^2 s}}{1 - (\lambda_2/\lambda_1)}\, e^{p(\xi)s}\, \hat{u}_0(\xi, 0), \tag{2.20}$$

where $p(\xi)$ is uniformly bounded, which follows from (2.15). By virtue of (2.14), (2.16), and (2.18), it is apparent that

$$\int_0^\infty \left(\left\| \frac{\partial^2}{\partial s^2}(\rho(s)\hat{J}_4(\xi,s)) \right\|^2_{L^2(R^2)} + \left\| (1+|\xi|^2)\rho(s)\hat{J}_4(\xi,s) \right\|^2_{L^2(R^2)} \right) ds \le M\|u_0\|^2_{H^2(R^3_+)}. \tag{2.21}$$

We rewrite $\dfrac{\partial}{\partial s}\hat{J}_3$ as

$$\begin{aligned} \frac{\partial}{\partial s}\hat{J}_3(\xi,s) = & -2\frac{|\xi|^2 e^{\lambda_2 s}}{\sqrt{|\xi|^4 + 4|\xi|^2}} \frac{\partial \hat{u}_0}{\partial s}(\xi, 0) \\ & -2\int_0^s \frac{|\xi|^2 e^{\lambda_2(s-\eta)}}{\sqrt{|\xi|^4 + 4|\xi|^2}} \frac{\partial^2 \hat{u}_0}{\partial \eta^2}(\xi,\eta)\, d\eta, \\ & = \hat{I}_1(\xi,s) + \hat{I}_2(\xi,s), \end{aligned} \tag{2.22}$$

where $\hat{I}_1$ is the first term of the right-hand side, and $\hat{I}_2$ is the integral term. By the same argument as for $\hat{J}_4$, we have

$$\int_0^\infty \left\| \frac{\partial(\rho \hat{I}_1)}{\partial s}(\xi, s) \right\|^2_{L^2(R^2)} ds \le M \| \frac{\partial u_0}{\partial z}(x, y, 0) \|^2_{H^1(R^2)} \tag{2.23}$$

for some positive constant M. $\hat{I}_2$ can be written as

$$\hat{I}_2(\xi, s) = -2e^{p(\xi)s} \int_0^s \frac{|\xi|^2 e^{-|\xi|^2(s-\eta)}}{\sqrt{|\xi|^4 + 4|\xi|^2}} \, e^{-p(\xi)\eta} \, \frac{\partial^2 \hat{u}_0}{\partial \eta^2}(\xi, \eta) \, d\eta. \tag{2.24}$$

Since $p(\xi)$ is uniformly bounded, we can derive by (2.19)

$$\int_0^\infty \left\| \frac{\partial}{\partial s}(\rho(s) \hat{I}_2(\xi, s)) \right\|^2_{L^2(R^2)} ds \le M \| \frac{\partial^2 u_0}{\partial z^2} \|^2_{L^2(R^3_+)} \tag{2.25}$$

for some positive constant M. By a similar argument, we can also estimate $\rho(s)(1 + |\xi|^2)\hat{J}_3(\xi, s)$ and arrive at

$$\begin{aligned} \int_0^\infty \left(\left\| \frac{\partial^2}{\partial s^2}(\rho(s) \ \hat{J}_3(\xi, s)) \right\|^2_{L^2(R^2)} + \| (1 + |\xi|^2)\rho(s)\hat{J}_3(\xi, s) \|^2_{L^2(R^2)} \right) ds \\ \le M \left(\|u_0\|^2_{H^2(R^3_+)} + \left\| \frac{\partial u_0}{\partial z}(x, y, 0) \right\|^2_{H^1(R^2)} \right). \end{aligned} \tag{2.26}$$

Combining (2.17), (2.21), and (2.26), we have

$$\begin{aligned} \int_0^\infty \left(\left\| \frac{\partial^2}{\partial s^2}(\rho(s) \ \hat{\phi}(\xi, s)) \right\|^2_{L^2(R^2)} + \| (1 + |\xi|^2)\rho(s)\hat{\phi}(\xi, s) \|^2_{L^2(R^2)} \right) ds \\ \le M \left(\|u_0\|^2_{H^2(R^3_+)} + \left\| \frac{\partial u_0}{\partial z}(x, y, 0) \right\|^2_{H^1(R^2)} \right), \end{aligned} \tag{2.27}$$

where M is a positive constant depending on T through (2.13). We now define $\tilde{u}_0$ by

$$\tilde{u}_0(x, y, z) = \begin{cases} u_0(x, y, z) & \text{for } z \ge 0, \\ \rho(z)\phi(x, y, -z) - u_0(x, y, -z) & \text{for } z < 0, \end{cases} \tag{2.28}$$

where $\phi(x, y, s)$ is the Fourier inverse transform of $\hat{\phi}(\xi, s)$ above. Then, it follows that

$$\begin{cases} \lim\limits_{z \to 0+} \tilde{u}_0(\cdot, z) = \lim\limits_{z \to 0-} \tilde{u}_0(\cdot, z), \\ \lim\limits_{z \to 0+} \dfrac{\partial}{\partial z} \tilde{u}_0(\cdot, z) = \lim\limits_{z \to 0-} \dfrac{\partial}{\partial z} \tilde{u}_0(\cdot, z), \end{cases} \tag{2.29}$$

and consequently,

$$\|\tilde{u}_0\|_{H^2(R^3)} \le M \left(\|u_0\|^2_{H^2(R^3_+)} + \left\| \frac{\partial u_0}{\partial z}(x, y, 0) \right\|^2_{H^1(R^2)} \right), \tag{2.30}$$

and

$$\mathcal{B}\tilde{u}_0 \in L^2(R_z \, ; \, H^{-1}(R^2)). \tag{2.31}$$

It also follows that, for almost all $-2T < z < 2T$,

$$(\mathcal{B}\tilde{u}_0)(\cdot,-z) = -(\mathcal{B}\tilde{u}_0)(\cdot,z) \qquad \text{in } H^{-1}(R^2). \tag{2.32}$$

Since $\mathcal{B}\tilde{u}_0 \in L^2(R_z\,;H^{-1}(R^2))$, there are sequences $\{\zeta_1^n\}_{n=1}^\infty$ in $C_0^\infty((0,2T)\times R^2)$, $\{\zeta_2^n\}_{n=1}^\infty$ in $C_0^\infty((2T,\infty)\times R^2)$, and $\{\zeta_3^n\}_{n=1}^\infty$ in $C_0^\infty((-\infty,-2T)\times R^2)$ such that as $n\to\infty$,

$$\zeta_1^n \to \chi_1\,\mathcal{B}\tilde{u}_0 \qquad \text{in } L^2(R_z\,;H^{-1}(R^2)), \tag{2.33}$$

$$\zeta_2^n \to \chi_2\,\mathcal{B}\tilde{u}_0 \qquad \text{in } L^2(R_z\,;H^{-1}(R^2)), \tag{2.34}$$

and

$$\zeta_3^n \to \chi_3\,\mathcal{B}\tilde{u}_0 \qquad \text{in } L^2(R_z\,;H^{-1}(R^2)), \tag{2.35}$$

where $\chi_1(z)$ is a characteristic function for the interval $[0,2T]$, $\chi_2(z)$ is for the interval $[2T,\infty)$, and $\chi_3(z)$ is for $(-\infty,-2T]$. We then set

$$w_0^n(x,y,z) = \zeta_1^n(x,y,z) - \zeta_1^n(x,y,-z) + \zeta_2^n(x,y,z) + \zeta_3^n(x,y,z). \tag{2.36}$$

Then, all the conditions in (2.1)–(2.3) for u_0 are satisfied.

Next we suppose that $u_1 \in H^1(R^3_+)$ is given. We consider (2.4)–(2.6) with $\hat{u}_0$ replaced by $\hat{u}_1$. Then, the solution $\hat{\psi}$ of (2.4)–(2.6) is given by

$$\hat{\psi}(\xi,s) = \hat{H}_1(\xi,s) + \hat{H}_2(\xi,s) + \hat{H}_3(\xi,s) + \hat{H}_4(\xi,s), \tag{2.37}$$

where

$$\hat{H}_1(\xi,s) = 2\int_0^s \frac{\lambda_1 e^{\lambda_1(s-\eta)}}{\sqrt{|\xi|^4+4|\xi|^2}}|\xi|^2\hat{u}_1(\xi,\eta)\,d\eta, \tag{2.38}$$

$$\hat{H}_2(\xi,s) = \frac{2|\xi|^2}{\sqrt{|\xi|^4+4|\xi|^2}}\hat{u}_1(\xi,s) + \frac{2\lambda_1 e^{\lambda_1 s}}{\sqrt{|\xi|^4+4|\xi|^2}}\hat{u}_1(\xi,0), \tag{2.39}$$

$$\hat{H}_3(\xi,s) = -2\int_0^s \frac{e^{\lambda_2(s-\eta)}}{\sqrt{|\xi|^4+4|\xi|^2}}|\xi|^2\frac{\partial\hat{u}_1}{\partial\eta}(\xi,\eta)\,d\eta, \tag{2.40}$$

$$\hat{H}_4(\xi,s) = \frac{2e^{\lambda_2 s}}{1-(\lambda_2/\lambda_1)}\hat{u}_1(\xi,0). \tag{2.41}$$

Since $u_1 \in H^1(R^3_+)$ implies $u_1(x,y,0) \in H^{1/2}(R^2)$, we can easily derive

$$\int_0^\infty \left(\left\|\rho(s)\frac{\partial\hat{H}_i}{\partial s}(\xi,s)\right\|^2_{L^2(R^2)} + \left\|\rho(s)(1+|\xi|)\hat{H}_i(\xi,s)\right\|^2_{L^2(R^2)}\right) ds \le M\|u_1\|^2_{H^1(R^3_+)}, \tag{2.42}$$

for $i = 1, 2, 4$, where ρ is the same as defined by (2.13). For the estimate of $\hat{H}_3$, we write

$$\frac{\partial \hat{H}_3}{\partial s}(\xi, s) = -2\frac{|\xi|^2}{\sqrt{|\xi|^4 + 4|\xi|^2}}\frac{\partial \hat{u}_1}{\partial s}(\xi, s) - 2\int_0^s \frac{\lambda_2 |\xi|^2 e^{\lambda_2(s-\eta)}}{\sqrt{|\xi|^4 + 4|\xi|^2}}\frac{\partial \hat{u}_1}{\partial \eta}(\xi, \eta)\, d\eta, \tag{2.43}$$

and, by means of (2.15) and (2.19), we find that

$$\int_0^\infty \left\| \rho(s)\frac{\partial \hat{H}_3}{\partial s}(\xi, s) \right\|^2_{L^2(R^2)} ds \le M\|u_1\|^2_{H^1(R^3_+)} \tag{2.44}$$

for some positive constant M. It also holds that

$$\int_0^\infty \left\| \rho(s)(1 + |\xi|)\hat{H}_3(\xi, s) \right\|^2_{L^2(R^2)} ds \le M\|u_1\|^2_{H^1(R^3_+)}. \tag{2.45}$$

Let us define

$$\tilde{u}_1(x, y, z) = \begin{cases} u_1(x, y, z) & \text{for } z \ge 0, \\ \rho(z)\psi(x, y, -z) - u_1(x, y, -z) & \text{for } z < 0. \end{cases} \tag{2.46}$$

Then we have

$$\lim_{z \to 0+} \tilde{u}_1(\cdot, z) = \lim_{z \to 0-} \tilde{u}_1(\cdot, z) \quad \text{in } H^{1/2}(R^2), \tag{2.47}$$

which, together with (2.42), (2.44), and (2.45), yields

$$\frac{\partial \tilde{u}_1}{\partial z} \in L^2(R^3) \tag{2.48}$$

and

$$\|\tilde{u}_1\|_{H^1(R^3)} \le M\|u_1\|_{H^1(R^3_+)}, \tag{2.49}$$

for some positive constant M depending on T through (2.13). Next we choose a sequence $\{v^m\}_{m=1}^\infty$ in $H^3(R^3_+)$ such that

$$v^m \to u_1 \quad \text{in } H^1(R^3_+) \tag{2.50}$$

as $m \to \infty$. Let $\hat{\psi}^m$ be the solution of (2.4)–(2.6) with $\hat{u}_0$ replaced by $\hat{v}^m$, and define

$$\tilde{v}^m(x, y, z) = \begin{cases} v^m(x, y, z) & \text{for } z \ge 0, \\ \rho(z)\psi^m(x, y, -z) - v^m(x, y, -z) & \text{for } z < 0. \end{cases} \tag{2.51}$$

Then, by virtue of (2.49), we find that

$$\mathcal{B}\tilde{v}^m \to \mathcal{B}\tilde{u}_1 \quad \text{in } \mathcal{X}. \tag{2.52}$$

In the meantime, the result for u_0 implies that each $\mathcal{B}\tilde{v}^m$ can be approximated in $L^2(R_z\,;\,H^{-1}(R^2))$ by a sequence of functions in $C_0^\infty(R^3)$ which are odd in $z \in (-2T,\,2T)$. Hence, there is a sequence $\{w_1^n\}_{n=1}^\infty$ in $C_0^\infty(R^3)$ such that

$$w_1^n \to \mathcal{B}\tilde{u}_1 \qquad \text{in } \mathcal{X}, \tag{2.53}$$

and

$$w_1^n(x,y,-z) = -w_1^n(x,y,-z) \qquad \text{for } -2T < z < 2T. \tag{2.54}$$

Obviously, all the conditions (2.1)-(2.3) for u_1 are satisfied.

Solutions of (1.1) *with initial data* $(\tilde{u}_0, \tilde{u}_1)$. Consider the Cauchy problem (1.1) with the initial data (w_0^n, w_1^n). For each n, there is a unique solution $w^n \in C([0,2T]\,;\,H^m(R^3)) \cap C^1([0,2T]\,;\,H^{m-1}(R^3))$ for every $m \in R$. By Lemma 1.2 and the condition (iii) in (2.3), $w^n(t,x,y,0) = 0$ for all $(t,x,y) \in [0,T]\times R^2$. Hence, the restriction of w^n to $[0,T]\times R^3_+$ satisfies (1.11) with (u_0,u_1) replaced by the restriction of (w_0^n, w_1^n) to $z>0$. Meanwhile, we have, by Lemma 1.4,

$$w^n \to \mathcal{B}\tilde{u} \qquad \text{in } C\big([0,T]\,;\,L^2(R_z; H^{-1}(R^2))\big) \cap C^1([0,T]\,;\,\mathcal{X}), \tag{2.55}$$

where $\tilde{u}$ is the unique solution of (1.1) with the initial data $(\tilde{u}_0, \tilde{u}_1)$. Hence, the restriction of $\mathcal{B}\tilde{u}$ to $[0,T]\times R^3_+$ satisfies (1.11) with (u_0,u_1) replaced by the restriction of $(\mathcal{B}u_0, \mathcal{B}u_1)$ to $z>0$. Consequently, the restriction of $\tilde{u}$ to $[0,T]\times R^3_+$ is a desired solution in Theorem 0.1.

Uniqueness of the solution. Let Φ be the difference between two solutions in Theorem 0.1. Then, we have

$$\Phi \in C([0,T]\,;\,H^2(R^3_+)) \cap C^1([0,T]\,;\,H^1(R^3_+)), \tag{2.56}$$

$$\Phi(0,x,y,z) = 0, \qquad \Phi_t(0,x,y,z) = 0 \qquad \text{for } (x,y,z) \in R^3_+, \tag{2.57}$$

$$\Phi_{tt} - \Delta\Phi = 0 \qquad \text{in } (0,T)\times R^3_+. \tag{2.58}$$

Since $\mathcal{B}\Phi$ is a solution of (1.9) with

$$(\mathcal{B}\Phi)(0,\cdot) = 0, \qquad (\mathcal{B}\Phi_t)(0,\cdot) = 0, \tag{2.59}$$

it follows from Proposition 1.6 that

$$\mathcal{B}\Phi \equiv 0 \qquad \text{in } (0,T)\times R^3_+. \tag{2.60}$$

By virtue of (2.57) and the domain of dependence of the solution, we also have

$$\Phi = 0 \qquad \text{for } 0 \le t < z. \tag{2.61}$$

Since $\Phi \in C([0,T]\,;\,H^2(R^3_+))$, (2.60) implies that for each $t \in [0,T]$, $\xi \in R^2$,

$$\frac{\partial^2\hat{\Phi}}{\partial z^2}(t,\xi,z) - |\xi|^2\frac{\partial\hat{\Phi}}{\partial z}(t,\xi,z) - |\xi|^2\hat{\Phi}(t,\xi,z) = 0 \tag{2.62}$$

holds in $\mathcal{D}'((0,\infty))$. But it follows from (2.61) that

$$\hat{\Phi}(t,\xi,z) = 0 \qquad \text{for all } \xi \in R^2,\ 0 \le t < z, \tag{2.63}$$

which, together with (2.62), yields

$$\hat{\Phi} \equiv 0 \qquad \text{in } R^3_+. \tag{2.64}$$

Hence, the solution of Theorem 0.1 is unique.

Finally, the estimate (0.10) follows from Lemma 1.1, (2.30), and (2.49).

3. Proof of corollaries. For the proof of corollaries, it is enough to obtain necessary estimates of $\hat{\phi}(\xi, s)$ given by (2.7). We start from Corollary 0.2. Suppose $u_0 \in H^3(R^3_+)$ and $\mathcal{B}u_0 = 0$ at $z = 0$. By the same argument used before, it is easy to see for $i = 1, 2$,

(3.1)
$$\int_0^\infty \left(\left\| \frac{\partial^3}{\partial s^3}(\rho(s)\hat{J}_i(\xi, s)) \right\|^2_{L^2(R^2)} + \left\| \rho(s)(1+|\xi|)^3 \hat{J}_i(\xi, s) \right\|^2_{L^2(R^2)} \right) ds \le M\|u_0\|^2_{H^3(R^3_+)},$$

where $\rho(s)$ is the same as before. By means of (2.12) and (2.22), we write

$$\begin{aligned} \frac{\partial^2 \hat{J}_3}{\partial s^2}(\xi, s) + \frac{\partial^2 \hat{J}_4}{\partial s^2}(\xi, s) &= \frac{2\lambda_1\lambda_2^2 e^{\lambda_2 s}}{\sqrt{|\xi|^4 + 4|\xi|^2}} \hat{u}_0(\xi, 0) \\ &\quad - 2\frac{\lambda_2|\xi|^2 e^{\lambda_2 s}}{\sqrt{|\xi|^4 + 4|\xi|^2}} \frac{\partial \hat{u}_0}{\partial s}(\xi, 0) - 2\frac{|\xi|^2 e^{\lambda_2 s}}{\sqrt{|\xi|^4 + 4|\xi|^2}} \frac{\partial^2 \hat{u}_0}{\partial s^2}(\xi, 0) \\ &\quad - 2\int_0^s \frac{|\xi|^2 e^{\lambda_2(s-\eta)}}{\sqrt{|\xi|^4 + 4|\xi|^2}} \frac{\partial^3 \hat{u}_0}{\partial \eta^3}(\xi, \eta)\, d\eta. \end{aligned} \tag{3.2}$$

However, the first three terms in the right-hand side can be written as

$$\begin{aligned} -2\frac{|\xi|^2 e^{\lambda_2 s}}{\sqrt{|\xi|^4 + 4|\xi|^2}} \left(\frac{\partial^2 \hat{u}_0}{\partial s^2}(\xi, 0) - |\xi|^2 \frac{\partial \hat{u}_0}{\partial s}(\xi, 0) - |\xi|^2 \hat{u}_0(\xi, 0) \right) \\ + e^{\lambda_2 s} \left(p_1(\xi) \frac{\partial \hat{u}_0}{\partial s}(\xi, 0) + p_2(\xi)\hat{u}_0(\xi, 0) \right), \end{aligned} \tag{3.3}$$

where $p_1(\xi)$ and $p_2(\xi)$ are uniformly bounded in ξ. Since $\mathcal{B}u_0 = 0$ at $z = 0$, (3.2) is reduced to

$$\begin{aligned} \frac{\partial^2 \hat{J}_3}{\partial s^2}(\xi, s) + \frac{\partial^2 \hat{J}_4}{\partial s^2}(\xi, s) &= e^{\lambda_2 s} \left(p_1(\xi) \frac{\partial \hat{u}_0}{\partial s}(\xi, 0) + p_2(\xi)\hat{u}_0(\xi, 0) \right) \\ &\quad - 2\int_0^s \frac{|\xi|^2 e^{\lambda_2(s-\eta)}}{\sqrt{|\xi|^4 + 4|\xi|^2}} \frac{\partial^3 \hat{u}_0}{\partial \eta^3}(\xi, \eta)\, d\eta. \end{aligned} \tag{3.4}$$

It now follows from (2.18) and (2.19) that

$$\int_0^\infty \left\| \rho(s) \left(\frac{\partial^3 \hat{J}_3}{\partial s^3}(\xi, s) + \frac{\partial^3 \hat{J}_4}{\partial s^3}(\xi, s) \right) \right\|^2_{L^2(R^2)} ds \le M\|u_0\|^2_{H^3(R^3_+)}. \tag{3.5}$$

We can easily find that

$$\int_0^\infty \left\| \rho(s)(1+|\xi|)^3 (\hat{J}_3(\xi, s) + \hat{J}_4(\xi, s)) \right\|^2_{L^2(R^2)} ds \le M\|u_0\|^2_{H^3(R^3_+)}. \tag{3.6}$$

By virtue of (3.1) and (3.6), we can estimate ϕ;

$$\|\rho(z)\phi(x, y, z)\|_{H^3(R^3_+)} \le M\|u_0\|_{H^3(R^3_+)}, \tag{3.7}$$

for some positive constant M, which depends on T through (2.13). Recalling (2.4), (2.28), (2.29), and the boundary condition $\mathcal{B}u_0 = 0$ at $z = 0$ we derive

$$\lim_{z \to 0+} \frac{\partial^2 \tilde{u}_0}{\partial z^2}(\cdot, z) = \lim_{z \to 0-} \frac{\partial^2 \tilde{u}_0}{\partial z^2}(\cdot, z), \tag{3.8}$$

which, combined with (3.7), yields

$$\|\tilde{u}_0\|_{H^3(R^3)} \le M\|u_0\|_{H^3(R^3_+)}. \tag{3.9}$$

The estimate of $\tilde{u}_1$ defined by (2.46) follows directly from the estimate of $\tilde{u}_0$ in the previous section. This completes the proof of Corollary 0.2.

For the proof of the remaining corollaries, we first observe the following fact.

LEMMA 3.1. *Let $\hat{\phi}$ be a solution of* (2.4)–(2.6). *Assume that $u_0 \in H^{2m+4}(R^3_+)$, and $\mathcal{B}u_0 = 0$, $\Delta\mathcal{B}u_0 = 0, \dots, \Delta^m\mathcal{B}u_0 = 0$ at $z = 0$, where m is a nonnegative integer. Then, we have*

$$\frac{\partial^{2m+2}\hat{\phi}}{\partial s^{2m+2}}(\xi,0) = 2\,\frac{\partial^{2m+2}\hat{u}_0}{\partial s^{2m+2}}(\xi,0) \quad \textit{for almost all } \xi \in R^2, \tag{3.10}$$

$$\frac{\partial^{2m+3}\hat{\phi}}{\partial s^{2m+3}}(\xi,0) = 0 \quad \textit{for almost all } \xi \in R^2. \tag{3.11}$$

Proof. Suppose that $\mathcal{B}u_0 = 0$ at $z = 0$. Then, it follows from (2.4)–(2.6) that

$$\begin{aligned}\frac{\partial^2\hat{\phi}}{\partial s^2}(\xi,0) &= 2|\xi|^2\left(\hat{u}_0(\xi,0) + \frac{\partial\hat{u}_0}{\partial s}(\xi,0)\right)\\ &= 2\frac{\partial^2\hat{u}_0}{\partial s^2}(\xi,0) \quad \text{for almost all } \xi \in R^2.\end{aligned} \tag{3.12}$$

By differentiation of (2.4) in s, and using (3.12), we obtain

$$\frac{\partial^3\hat{\phi}}{\partial s^3}(\xi,0) = 0 \qquad \text{for almost all } \xi \in R^2. \tag{3.13}$$

Suppose that Lemma 3.1 is true for $0 \le m \le k$. By differentiation of (2.4), we have

$$\frac{\partial^{2k+4}\hat{\phi}}{\partial s^{2k+4}} + |\xi|^2\frac{\partial^{2k+3}\hat{\phi}}{\partial s^{2k+3}} - |\xi|^2\frac{\partial^{2k+2}\hat{\phi}}{\partial s^{2k+2}} = 2|\xi|^2\frac{\partial^{2k+3}\hat{u}_0}{\partial s^{2k+3}}, \tag{3.14}$$

which, combined with (3.10) and (3.11) for $m = k$, yields

$$\begin{aligned}\frac{\partial^{2k+4}\hat{\phi}}{\partial s^{2k+4}}(\xi,0) &= 2|\xi|^2\left(\frac{\partial^{2k+3}\hat{u}_0}{\partial s^{2k+3}}(\xi,0) + \frac{\partial^{2k+2}\hat{u}_0}{\partial s^{2k+2}}(\xi,0)\right)\\ &= 2\,\frac{\partial^{2k+4}\hat{u}_0}{\partial s^{2k+4}}(\xi,0) \quad \text{for almost all } \xi \in R^2.\end{aligned} \tag{3.15}$$

Here we also used the fact that $\Delta^m\mathcal{B}u_0 = 0$, $0 \le m \le k+1$ at $z = 0$ implies $\frac{\partial^{2m}}{\partial z^{2m}}\mathcal{B}u_0 = 0$, $0 \le m \le k+1$, at $z = 0$. Now (3.10) is true for $m = k+1$. By differentiation of (3.14), we also get (3.11) for $m = k+1$. The proof is complete. □

Under the same assumption as in Lemma 3.1, we consider the initial value problem for $0 \le k \le m+1$,

$$\frac{\partial^2\hat{\psi}_k}{\partial s^2} + |\xi|^2\frac{\partial\hat{\psi}_k}{\partial s} - |\xi|^2\hat{\psi}_k = 2|\xi|^2\frac{\partial^{2k+1}\hat{u}_0}{\partial s^{2k+1}}(\xi,s), \qquad s > 0, \tag{3.16}$$

$$\hat{\psi}_k(\xi,0) = 2\frac{\partial^{2k}\hat{u}_0}{\partial s^{2k}}(\xi,0), \tag{3.17}$$

$$\frac{\partial\hat{\psi}_k}{\partial s}(\xi,0) = 0. \tag{3.18}$$

By the above lemma, and the uniqueness of solution of (2.4)–(2.6), we find

$$\hat{\psi}_k \equiv \frac{\partial^{2k}\hat{\phi}}{\partial s^{2k}} \qquad \text{for } 0 \le k \le m+1. \tag{3.19}$$

Recalling (2.28), we derive

$$\lim_{z\to 0+}\frac{\partial^\nu}{\partial z^\nu}\tilde{u}_0(\cdot,z) = \lim_{z\to 0-}\frac{\partial^\nu}{\partial z^\nu}\tilde{u}_0(\cdot,z), \quad 0 \le \nu \le 2m+3. \tag{3.20}$$

Meanwhile, (2.27) yields

$$\begin{aligned}\int_0^\infty \left(\left\|\frac{\partial^2}{\partial s^2}(\rho(s)\ \hat{\psi}_{m+1}(\xi,s))\right\|^2_{L^2(R^2)} + \left\|(1+|\xi|^2)\rho(s)\hat{\psi}_{m+1}(\xi,s)\right\|^2_{L^2(R^2)}\right) ds \\ \le M\left(\|u_0\|^2_{H^{2m+4}(R^3_+)} + \left\|\frac{\partial^{2m+3}\hat{u}_0}{\partial z^{2m+3}}(x,y,0)\right\|^2_{H^1(R^2)}\right).\end{aligned} \tag{3.21}$$

By means of (2.18) and (2.19), we can obtain directly from (2.9)–(2.12)

$$\int_0^\infty \|\rho(s)(1+|\xi|)^{2m+4}\hat{J}_i(\xi,s)\|^2_{L^2(R^2)}\,ds \le M\|u_0\|^2_{H^{2m+4}(R^3_+)}, \qquad i = 1,\dots,4. \tag{3.22}$$

By (3.20)–(3.22), we arrive at

$$\|\tilde{u}_0\|_{H^{2m+4}(R^3)} \le M\left(\|u_0\|_{H^{2m+4}(R^3_+)} + \left\|\frac{\partial^{2m+3}u_0}{\partial z^{2m+3}}(x,y,0)\right\|_{H^1(R^2)}\right). \tag{3.23}$$

When $u_0 \in H^{2m+3}(R^3_+)$, with $\mathcal{B}u_0 = 0,\dots,\Delta^m\mathcal{B}u_0 = 0$ at $z = 0$, we apply the estimate (3.7) to $\psi_m = \frac{\partial^{2m}\phi}{\partial z^{2m}}$ so that

$$\|\tilde{u}_0\|_{H^{2m+3}(R^3)} \le M\|u_0\|_{H^{2m+3}(R^3_+)}. \tag{3.24}$$

Here, M is a positive constant depending on T and m. Since the esimates of $\tilde{u}_1$ are identical with those of $\tilde{u}_0$, the proof of Corollaries 0.3 and 0.4 is complete. Corollary 0.5 follows trivially from the previous ones.

Acknowledgment. I would like to thank Shuming Sun for a helpful discussion.

EXISTENCE OF TRAVELING WAVES IN A BIODEGRADATION MODEL FOR ORGANIC CONTAMINANTS*

REGAN MURRAY† AND J. X. XIN†

Abstract. We study a biodegradation model for the time evolution of concentrations of contaminant, nutrient, and bacteria. The bacteria has a natural concentration which will increase when the nutrient reaches the substrate (contaminant). The growth utilizes nutrients and degrades the substrate. Eventually, such a process removes all the substrate and can be described by traveling wave solutions. The model consists of advection-reaction-diffusion equations for the substrate and nutrient concentrations and a rate equation (ODE) for the bacteria concentration. We first show the existence of approximate traveling wave solutions to an elliptically regularized system posed on a finite domain using degree theory and the elliptic maximum principle. To prove that the approximate solutions do not converge to trivial solutions, we construct comparison functions for each component and employ integral identities of the governing equations. This way, we derive a priori estimates of solutions independent of the length of the finite domain and the regularization parameter. The integral identities take advantage of the forms of coupling in the system and help us obtain optimal bounds on the traveling wave speed. We then extend the domain to the infinite line limit, remove the regularization, and construct a traveling wave solution for the original set of equations satisfying the prescribed boundary conditions at spatial infinities. The contaminant and nutrient profiles of the traveling waves are strictly monotone functions, while the biomass profile has a pulse shape.

1. Introduction.

Thousands of chemical spills contaminate subsurface aquifers used for drinking water and agriculture in the United States. A promising technology for cleaning up subsurface organic contamination is in-situ bioremediation. This technique works by stimulating the bacteria already present in the soil to use the contaminant as a source of food, thereby transforming it into nontoxic components such as carbon dioxide and water. Among a variety of restoration technologies, in-situ bioremediation has been shown to be the most economical for remediating certain contaminants. Several experiments have shown that this method takes much less time and is less costly than the traditional pumping and filtering techniques. For example, one site was estimated to take 100 years to clean up using the pump and treat method; in-situ bioremediation took only 10 months [3]. Moreover, while many methods simply remove the contaminant from the site and thereby create a disposal problem, in-situ bioremediation has the potential to completely transform organic contaminants into neutral compounds by utilizing the indigenous bacteria [6].

In-situ bioremediation involves a complex combination of biological and chemical properties and fluid dynamics rendering scientific predictions difficult. Mathematical models are particularly useful in understanding the interplay between the various mechanisms in addition to making predictions, analyzing the significance of physical

parameters, and providing theoretical interpretations of experiments. Several models for in-situ bioremediation have been presented in the literature; see [2], [5]. In this paper, we consider the model presented in [7] and [8], for it is the simplest model to capture the fundamental aspects of degradation.

The biodegradation model is

$$R_f S_t + (vS - DS_x)_x = -R_s, \quad x \in R^1, \tag{1.1}$$

$$A_t + (vA - DA_x)_x = -\gamma R_s, \tag{1.2}$$

$$M_t = Y R_s - b(M - M_0), \tag{1.3}$$

where $R_f, b, M_0, \gamma, v, D, Y$ are all positive constants. The subscripts t and x denote time and space derivatives, while the subscripts s and f are used to distinguish between the reaction term R_s and retardation factor R_f. The variables are (S, A, M) where S is the aqueous phase concentration of the electron donor (substrate), A is the electron acceptor (nutrient concentration), and M is the biomass concentration. The constant M_0 is the neutral background biomass concentration. $R_f > 1$ is the retardation factor of the electron donor (substrate) S due to sorption. The parameter b is the cell decay coefficient for the bacteria population M. γ is a coefficient equal to the mass of A utilized by the bacteria per unit mass of S degraded. D is the diffusion coefficient and Y is the yield coefficient (mass of bacterial cells produced per mass of S degraded). The parameter v is the constant pore water velocity and M_0 is the background biomass concentration.

The biodegradation rate, R_s, is given by the Monod kinetic model

$$R_s = \frac{qMSA}{(K_S + S)(K_A + A)}, \tag{1.4}$$

where q is the maximum specific rate of substrate utilization, and K_S, K_A are the half-maximum rate concentrations of S and A. Note that the system assumes linear sorption of the electron donor (represented by the term R_f), no sorption for the electron acceptor, and a constant minimal background bacteria population M_0 (as an equilibrium between cell growth and decay). In this model, microbes are attached to the soil particles and only consume aqueous phase species.

The system (1.1)–(1.3) is one of the simplest systems in the literature; however, it contains very rich phenomena. Oya and Valocchi [8] and Valocchi [10] recently studied traveling waves in this system. They observed that "bioavailability" of the chemical constituents is an important requirement for successful biodegradation. Since the microbes are assumed to be attached to solids [5], the dissolved contaminant and nutrients must be transported to the bacteria. This is represented in the above system by the water velocity v and the sorption effect $R_f > 1$. When the nutrients reach the biomass, a biologically active zone forms and propagates. This zone supports respiration, that is, nutrient consumption, contaminant degradation, and an increase in the microbial population. [8] is the first paper to propose the idea that the biologically active zone can be mathematically modeled as traveling waves. The retreating dissolved solute concentration and the advancing nutrient concentration move together as traveling fronts, while the bacteria concentration tags along as a traveling pulse.

In this paper, we establish the existence of traveling waves in (1.1)–(1.3) under the sole condition that $R_f > 1$. The traveling wave solutions are of the form

$$S = S(x - ct),\ A = A(x - ct),\ M = M(x - ct), \tag{1.5}$$

where (S, A, M) as functions of $\xi \equiv x - ct$ satisfy the boundary conditions

$$S(-\infty) = 0, \quad S(+\infty) = S^+, \ A(-\infty) = A_-, \quad A(+\infty) = 0, \ M(\pm\infty) = M_0, \tag{1.6}$$

and A_- and S^+ are prescribed positive constants. Using (1.5), (1.1)–(1.3) are transformed into

$$DS_{\xi\xi} + (R_f c - v)S_\xi = R_s, \tag{1.7}$$

$$DA_{\xi\xi} + (c - v)A_\xi = \gamma R_s, \tag{1.8}$$

$$cM_\xi = -YR_s + b(M - M_0), \tag{1.9}$$

along with the boundary conditions

$$S(-\infty) = 0, \ S(+\infty) = S^+, \ A(-\infty) = A_-, \ A(+\infty) = 0, \ M(\pm\infty) = M_0. \tag{1.10}$$

To prove the existence of a solution to (1.7)–(1.9), we follow a framework similar to that of Berestyki, Nicolaenko, and Sheurer [1] and Xin [11], and consider the system on a bounded domain $[-d, d]$, $d > 0$. We define a fixed point map such that any solution to the fixed point problem is also a solution of (1.7)–(1.9) on the bounded domain. By determining the Leray–Schauder degree of the map (see [13] for details), we show that a solution exists to the fixed point problem. Finally, we extend the solution to the entire real line. This is a well-known technique.

It is important to note that equations (1.1)–(1.3) are substantially different than the two-equation, reaction-diffusion, combustion system studied in [1] and require new ingredients for the proof of existence. In the biodegradation model, the fronts propagate as a result of distinct advective velocities rather than reaction-diffusion. We believe traveling wave fronts in advection systems have not been much explored. In this case, although the method of [1] applies, many new steps are needed. For instance, finding good bounds on the wave speed requires a substantial amount of work on the advection and reaction terms. In addition, the two advection equations cannot be manipulated to define pointwise inequalities as in [1]. Instead, we develop *integral inequalities* based on the conserved quantity $\gamma R_f S - A$ (see Lemma 3.4).

Many other differences between the biodegradation system and [1] are noteworthy. First, while the fronts in [1] are strictly monotone, the biomass profile in (1.1)–(1.3) forms a pulse. Rather than following directly from the maximum principle, new arguments are necessary to estimate the maximum of M (see Proposition 2.1). Second, the condition to fix translation invariance, $A(0) = \theta$, is not a priori optimal as it is in [1], where θ is the ignition temperature. In this paper, the value of θ is updated three times to prevent the solutions of (1.1)–(1.3) from converging to trivial solutions in the limit $d \to \infty$ (see Proposition 3.1 and Lemmas 3.3 and 3.4). In particular, much work is required to show that S does not tend to zero as the domain extends to the real line. Finally, we develop integral identities to show that the boundary conditions remain as $d \to \infty$; see Theorem 4.1 and Lemma 5.1. Using integral identities instead of pointwise estimates to control wave speeds and large space asymptotic behavior of solutions is an efficient way of handling systems with more than two equations.

The main result of the paper is the following.

THEOREM 1.1 (existence of traveling waves). *Under the condition that the retardation factor $R_f > 1$, the system* (1.7)–(1.9) *with R_s given by* (1.4) *admits a classical traveling wave solution (S, A, M, c) of the form* (1.5) *satisfying the boundary conditions in* (1.10). *Moreover,*

$$0 < S(\xi) < S^+, \ S'(\xi) > 0, \ 0 < A(\xi) < A_-, \ A'(\xi) < 0 \quad \forall \xi \in R^1, \tag{1.11}$$

$$c = \frac{v(A_- + \gamma S^+)}{A_- + \gamma R_f S^+}, \tag{1.12}$$

$$M_0 < M \le M_0 + Y\frac{(R_f - 1)A_- S^+}{A_- + \gamma S^+} \quad \forall \xi \in R^1. \tag{1.13}$$

We see from Theorem 1.1 that the profiles of substrate and nutrient concentrations (S and A) are strictly monotone functions of ξ and that the wave speed c is independent of the parameters Y, b of the M equation. The explicit formula for the wave speed c in terms of the left and right states of solutions is reminiscent of the Rankine–Hugoniot formula for viscous shock waves in conservative equations; see [12] for such traveling waves arising in solute transport problems. The maximum norm bound of the biomass M, on the other hand, depends on the parameters and boundary conditions of the (S, A) equations as well as the yield constant Y of the M equation. Numerical simulations in [8] and those of the present authors show that M forms an asymmetric pulse with one maximum. The condition $R_f > 1$ physically means that the advective velocity of S is slower than that of A; hence, the two concentrations mix, which is essential for the biomass to grow and the three components to travel together. As pointed out in [8], there are no traveling waves if $R_f = 1$. In fact, it is obvious from (1.13) that $M \equiv M_0$ if $R_f = 1$, and no traveling pulse can form in M. It remains an interesting problem to find out if the traveling waves are unique up to a constant translation in ξ and if M always achieves one maximum.

The main result is significant, for it shows that there is a simple, well-understood solution to a very complicated phenomena. This solution occurs under a particular set of parameters; however, numerical studies suggest that this is the most common solution. In [8], the authors find waves with oscillating front shapes in time; this proof will be left for a future paper. Finally, many of the important factors required for the implementation of in-situ bioremediation are determined in Theorem 1.1, such as the speed of the traveling fronts and the maximum and minimum concentrations of the biomass.

The second result of the paper is the following.

THEOREM 1.2 (existence and uniqueness of traveling waves). *The system* (1.7)–(1.9) *with* $D = 0$ *and* R_s *given by* (1.4) *admits a* unique*, classical traveling wave solution* (S, A, M, c) *of the form* (1.5) *satisfying the boundary conditions in* (1.10) *and the bounds given in Theorem* 1.1.

Theorem 1.2 is proven in section 6. By eliminating the diffusion term ($D = 0$), the system of equations (1.7)–(1.9) can be reduced to a set of three, first-order ordinary differential equations. A conserved quantity enables us to reduce the system further to two equations. Thus, a phase portrait solution is easily obtained and we show that the traveling wave solution is unique. It is interesting to note that the question of existence and uniqueness for the system *with diffusion* can also be considered by examining the flow in the phase plane. In this case, the phase space has five dimensions although it is reduced to four via the conserved quantity. One of the equilibrium points is degenerate so it is difficult to determine the flow path. As such, we have elected to pursue the proof of existence by utilizing degree theory. Moreover, numerical studies [8] suggest that the traveling wave solution *with diffusion* is not unique.

The rest of the paper is organized as follows. In section 2, we show the existence of solutions to a regularized system on any finite interval via degree theory, based on maximum principles and preliminary a priori bounds. In section 3, we carry out refined a priori estimates of solutions as the length of the interval tends to infinity. In

particular, we obtain uniform estimates of the wave speed and bound it strictly inside the interval $(\frac{v}{R_f}, v)$. In section 4, utilizing the estimates of section 3, we pass to the infinite line limit of solutions and justify the validity of the boundary conditions of the limiting solutions. In section 5, we obtain further ε-independent bounds of solutions, pass to the $\varepsilon \to 0$ limit of solutions, and finish the proof of Theorem 1.1. In section 6, we prove Theorem 1.2.

2. A regularized system on finite intervals. In this section, we construct solutions to a regularized system with Dirichlet boundary conditions. In the following sections, these solutions are shown to converge to the desired traveling wave solutions of (1.7)–(1.9) as we pass to the infinite line limit and remove the regularization. We add an elliptic regularization term $\epsilon M_{\xi\xi}$ to the left side of (1.9) with $\epsilon \in (0,1)$ so that the existence problem is turned into a fixed point problem for which classical Leray–Schauder degree theory [4], [13] is available. We derive a priori bounds of solutions and compute the degree using its homotopic invariance as in [1] and [11]. The nonzero degree (equal to -1 in our case) implies the existence of a solution.

Let us first normalize the original system (1.7)–(1.9) so that K_S and K_A are scaled to one. Define $S = K_S\hat{S}$, $A = K_A\hat{A}$, $q = K_S\hat{q}$, $\gamma = \frac{K_A}{K_S}\hat{\gamma}$, and $Y = \frac{1}{K_S}\hat{Y}$. Then (1.7)–(1.9) remains the same under hat variables and parameters except that K_S and K_A are replaced by one. With no loss of generality, we also set $\hat{q} = 1$. The normalized system (without the hats) reads

$$DS_{\xi\xi} + (R_f c - v)S_\xi = MSA(1+S)^{-1}(1+A)^{-1}, \tag{2.1}$$

$$DA_{\xi\xi} + (c - v)A_\xi = \gamma MSA(1+S)^{-1}(1+A)^{-1}, \tag{2.2}$$

$$cM_\xi = -YMSA(1+S)^{-1}(1+A)^{-1} + b(M - M_0) \tag{2.3}$$

under the boundary conditions (1.10).

We propose to study the following regularized elliptic system and the associated boundary value problem on a finite interval $[-d, d]$:

$$DS_{\xi\xi} + (R_f c - v)S_\xi = R^{(1)}_{s,\varepsilon}, \tag{2.4}$$

$$DA_{\xi\xi} + (c - v)A_\xi = \gamma R^{(2)}_{s,\varepsilon}, \tag{2.5}$$

$$\varepsilon M_{\xi\xi} + cM_\xi = -YR^{(3)}_{s,\varepsilon} + b(M - M_0), \tag{2.6}$$

with $\varepsilon \in (0,1)$ and the boundary conditions

$$S(-d) = A(d) = 0,\ S(d) = S^+,\ A(-d) = A_-,\ M(\pm d) = M_0. \tag{2.7}$$

To remove the translation invariance of traveling wave solutions of an unknown speed c, we also impose the additional normalization condition

$$A(0) = \theta, \qquad \theta \in (0, A_-), \tag{2.8}$$

with θ prescribed. The modified reaction terms $R^{(i)}_s$, $i = 1, 2, 3$, are

$$\begin{aligned} R^{(1)}_{s,\varepsilon} &= \frac{|M|S|A|}{(1+\varepsilon|M|)(1+|S|)(1+|A|)}, \\ R^{(2)}_{s,\varepsilon} &= \frac{|M||S|A}{(1+\varepsilon|M|)(1+|S|)(1+|A|)}, \\ R^{(3)}_{s,\varepsilon} &= \frac{M|S||A|}{(1+\varepsilon|M|)(1+|A|)(1+|S|)}\,. \end{aligned} \tag{2.9}$$

Note that we modify the reaction terms by the factor $(1+\varepsilon|M|)$ which is crucial to obtain the first upper bound on M. The variables S, A, M, and c depend on both d and ε; however, to simplify the notation, we do not specify this dependence until it becomes necessary in the later sections.

In order to use degree theory, we consider a parametrized family of equations indexed by $\tau \in [0,1]$,

$$DS_{\xi\xi} + (R_f c - v)S_\xi = \tau R^{(1)}_{s,\varepsilon}, \tag{2.10}$$

$$DA_{\xi\xi} + (c-v)A_\xi = \gamma\tau R^{(2)}_{s,\varepsilon}, \tag{2.11}$$

$$\varepsilon M_{\xi\xi} + cM_\xi = -Y\tau R^{(3)}_{s,\varepsilon} + b(M - M_0), \tag{2.12}$$

under the boundary conditions (2.7) and the imposed condition (2.8).

Note that if $\tau = 0$, (2.10)–(2.12) under (2.7) and (2.8) has a unique solution. Without (2.8), the system is uniquely solvable for any given c, as a two-point boundary value problem for second-order ordinary differential equations. The solutions are

$$\begin{aligned} S(\xi) &= S^+ \frac{1 - e^{(-\frac{cR-v}{D})(\xi+d)}}{1 - e^{(-\frac{cR-v}{D})(2d)}}, \\ A(\xi) &= A_- \frac{1 - e^{(-\frac{c-v}{D})(\xi-d)}}{1 - e^{(\frac{c-v}{D})(2d)}}, \\ M(\xi) &= M_0. \end{aligned} \tag{2.13}$$

The extra condition $A(0) = \theta$ implies

$$\theta = A_- \frac{1 - e^{d(\frac{c-v}{D})}}{1 - e^{2d(\frac{c-v}{D})}} = A_- \frac{1}{1 + e^{d(\frac{c-v}{D})}},$$

which uniquely determines c, since the right-hand side is a monotone function of c and ranges between zero and A_-.

Next we derive a priori estimates on solutions of (2.10)–(2.12) under the boundary and normalization conditions (2.7) and (2.8) independent of $\tau \in [0,1]$.

PROPOSITION 2.1. *Let $\tau \in [0,1]$ and let (S, A, M, c) be a solution to* (2.10)–(2.12) *subject to the boundary conditions* (2.7). *Then $\forall \tau \in [0,1]$ and $\forall \xi \in [-d,d]$, we have the following inequalities:*

$$0 \le S(\xi) \le S^+, \quad 0 \le A(\xi) \le A_-, \tag{2.14}$$

$$M_0 \le M(\xi) \le \frac{1}{2\varepsilon}\left(\varepsilon M_0 + \frac{Y}{b} - 1 + \sqrt{\left(1 - \frac{Y}{b} - \varepsilon M_0\right)^2 + 4\varepsilon M_0}\right) \equiv M_{\max}, \tag{2.15}$$

$$S'(\xi) > 0, \quad A'(\xi) < 0. \tag{2.16}$$

Proof. In view of (2.10)–(2.11), both S and A satisfy the classical elliptic strong maximum principle; see, for example, [9]. The maximum and minimum of S and A are achieved at the end points. Hence, (2.14) follows from (2.7). To show that $M \ge M_0$ $\forall \xi \in [-d,d]$, suppose that $M < M_0$ at some point $\xi_0 \in (-d,d)$ for some $\tau = \tau_1 \in (0,1)$. Then, since M is continuous in τ and $\xi \in [-d,d]$, as τ varies, the minimum of M must pass through the interval $(0, M_0)$ before M becomes negative. Let us assume that at τ_1, $\min_{\xi\in[-d,d]} M \in (0, M_0)$. Hence, $\exists\ \xi_1 \in (-d,d)$ and $0 <$

$M(\xi_1) = \min_{\xi\in[-d,d]} M(\xi) < M_0$, for $\tau = \tau_1$. Evaluating (2.12) at $\xi = \xi_1$ and $\tau = \tau_1$, we have

$$-Y\tau_1 R^{(3)}_{s,\varepsilon}(\xi_1) + b(M(\xi_1) - M_0) = \varepsilon M_{\xi\xi}(\xi_1) + cM_\xi(\xi_1).$$

At the minimum, the first derivative is zero and the second derivative is nonnegative, which results in

$$-Y\tau_1 R^{(3)}_{s,\varepsilon}(\xi_1) = \varepsilon M_{\xi\xi}(\xi_1) + b(M_0 - M(\xi_1)) > 0.$$

Since $Y, \tau_1 > 0$, we have that $R^{(3)}_{s,\varepsilon}(\xi_1) < 0$. This is impossible since $M(\xi_1) > 0$. It follows that $M \geq M_0\ \forall\tau \in [0,1]$, $\xi \in [-d,d]$. By now, since $A \geq 0,\ S \geq 0,\ M \geq M_0$, we can identify $R^{(1)}_{s,\varepsilon} = R^{(2)}_{s,\varepsilon} = R^{(3)}_{s,\varepsilon} \equiv R_{s,\varepsilon}$.

To prove the upper bound in (2.15), we define $\max_{\xi\in[-d,d]} M(\xi) = M^* \geq M_0$. We only need to consider the case $M^* > M_0$. There exists $\xi^* \in (-d,d)$ such that $M(\xi^*) = M^*, M'(\xi^*) = 0, M''(\xi^*) \leq 0$. Evaluating (2.12) at $\xi = \xi^*$ implies that

$$b(M^* - M_0) \leq \left.\frac{Y\tau AS M^*}{(1+A)(1+\varepsilon M^*)(1+S)}\right|_{\xi=\xi^*} \leq \frac{YM^*}{1+\varepsilon M^*}. \tag{2.17}$$

This can be rewritten as $b(M^* - M_0)(1+\varepsilon M^*) \leq YM^*$, or

$$M^* \leq \frac{1}{2\varepsilon}\left(\varepsilon M_0 + \frac{Y}{b} - 1 + \sqrt{\left(\varepsilon M_0 + \frac{Y}{b} - 1\right)^2 + 4\varepsilon M_0}\ \right) = M_{\max}. \tag{2.18}$$

Notice that if $\frac{Y}{b} \geq 1$, then the right-hand side of (2.18) behaves like $O(\varepsilon^{-1})$ ($O(\varepsilon^{-1/2})$ if $Y = b$) as $\varepsilon \to 0$. If $\frac{Y}{b} < 1$, then in the limit $\varepsilon \to 0$, the right-hand side converges to $\frac{M_0}{1-b^{-1}Y} > M_0$. To prove (2.16), we rewrite (2.4) by multiplying both sides of the equation by $e^{\frac{(cR_f - v)\xi}{D}}$. Then, integrating from $-d$ to ξ, we obtain

$$e^{\frac{(cR_f-v)\xi}{D}} S'(\xi) = e^{\frac{-(cR_f-v)d}{D}} S'(-d) + \int_{-d}^{\xi} \frac{1}{D} e^{\frac{(cR_f-v)\xi'}{D}} R_s(\xi')d\xi'.$$

Since S is not identically constant and, as a result of the Hopf lemma, it is clear that $S'(-d) > 0$. Thus, the entire right-hand side is positive and $S' > 0$. Similarly, it can be shown that $A' < 0$. The proof of the proposition is complete. ∎

PROPOSITION 2.2. *Let $\tau \in [0,1]$ and let $d > 1$ be fixed. There exists a constant $\underline{c}$ independent of $\tau \in [0,1]$ such that the wave speed $c = c(\tau)$ in (2.10)–(2.12) satisfies*

$$\underline{c} \leq c(\tau) \leq v + \frac{D}{d}\ln\left(\frac{1}{\theta_0} - 1\right), \tag{2.19}$$

where $\theta_0 = \frac{\theta}{A_-} \in (0,1)$.

Proof. To establish the upper bound for c, we find an upper solution $\overline{A}(\xi)$ to $A(\xi)$ and use it to bound c from above. The upper solution solves

$$\begin{cases} D\overline{A}'' + (c-v)\overline{A}' = 0, & \xi \in [-d,d], \\ \overline{A}(-d) = A_-, \quad \overline{A}(d) = 0, \end{cases} \tag{2.20}$$

and is given by

$$\overline{A}(\xi) = \frac{A_-(1 - e^{-(\frac{c-v}{D})(\xi - d)})}{1 - e^{(\frac{c-v}{D})2d}}. \tag{2.21}$$

By definition, $A(\xi) \le \overline{A}(\xi)$, and in particular $A(0) \le \overline{A}(0)$. Evaluating $\overline{A}$ at $\xi = 0$ and solving for c, we have

$$c \le v + \frac{D}{d} \ln\left(\frac{A_-}{\theta} - 1\right) = v + \frac{D}{d} \ln\left(\frac{1}{\theta_0} - 1\right). \tag{2.22}$$

With (2.22), we have established the upper bound for the wave speed $c(\tau)$. To show the lower bound, we proceed similarly by defining a lower solution $\underline{A}(\xi)$ for $A(\xi)$ on $[-d, d]$ which solves

$$D\underline{A}'' + (c - v)\underline{A}' = ([S^+ - S(0, d)]H(\xi) + S(0, d))F\underline{A}, \tag{2.23}$$

where

$$F = F(\varepsilon) \equiv \frac{M_{\max}}{1 + \varepsilon M_0} \ge \frac{M}{1 + \varepsilon M}; \quad H(\xi) = \begin{cases} 1, & \xi \ge 0, \\ 0, & \xi < 0, \end{cases}$$

along with boundary and regularity conditions

$$\underline{A}(-d) = A_-, \quad \underline{A}(d) = 0, \quad \underline{A} \in C^1. \tag{2.24}$$

It follows from (2.23) that

$$\underline{A}(\xi) = \begin{cases} c_1 e^{r_1 \xi} + c_2 e^{r_2 \xi}, & \xi \in [-d, 0], \\ c_3 e^{r_3 \xi} + c_4 e^{r_4 \xi}, & \xi \in [0, d], \end{cases} \tag{2.25}$$

where $r_{1,2}$ and $r_{3,4}$ are given by

$$r_{1,2} = \frac{-(c - v) \pm \sqrt{(c - v)^2 + 4DFS(0, \tau)}}{2D}, \quad r_1 > 0, r_2 < 0; \tag{2.26}$$

$$r_{3,4} = \frac{-(c - v) \pm \sqrt{(c - v)^2 + 4DFS^+}}{2D}, \quad r_3 > 0, r_4 < 0. \tag{2.27}$$

Using boundary conditions (2.24) and the fact that $\underline{A}(0^+) = \underline{A}(0^-)$ and $\underline{A}'(0^-) = \underline{A}'(0^+)$, we solve for the constants

$$\begin{aligned} c_1 &= A_- e^{r_1 d} - c_2 e^{(r_1 - r_2)d}, \\ c_2 &= \frac{A_- e^{r_1 d}[(r_4 - r_3 e^{(r_4 - r_3)d}) - r_1(1 - e^{(r_4 - r_3)d})]}{(r_2 - r_1 e^{(r_1 - r_2)d})(1 - e^{(r_4 - r_3)d}) - (r_4 - r_3 e^{(r_4 - r_3)d})(1 - e^{(r_1 - r_2)d})}, \\ c_3 &= -c_4 e^{(r_4 - r_3)d}, \\ c_4 &= \frac{A_- e^{r_1 d} + c_2(1 - e^{(r_1 - r_2)d})}{1 - e^{(r_4 - r_3)d}}. \end{aligned} \tag{2.28}$$

The solution is

$$\underline{A}(\xi) = \begin{cases} A_- e^{r_1(\xi + d)} + c_2(e^{r_2 \xi} - e^{r_1 \xi} e^{(r_1 - r_2)d}), & \xi \in [-d, 0], \\ \left(\frac{A_- e^{r_1 d} + c_2(1 - e^{(r_1 - r_2)d})}{1 - e^{(r_4 - r_3)d}}\right)\left(e^{r_4 \xi} - e^{(r_4 - r_3)d} e^{r_3 \xi}\right), & \xi \in [0, d], \end{cases} \tag{2.29}$$

where c_2 is given in (2.28).

To find the lower bound for c, we assume there is no lower bound ($c \to -\infty$) and use the following two properties to deduce a contradiction: $\underline{A}(0) \le \theta$, $\underline{A}(0) = A_- e^{r_1 d} + c_2(1 - e^{(r_1 - r_2)d})$. Combining these with equations (2.28)–(2.29), we find that

$$\begin{aligned}\theta &\ge \underline{A}(0,\tau)\\ &= \frac{A_- e^{r_2 d}(1 - e^{(r_4 - r_3)d})(r_2 - r_1)}{(r_2 e^{(r_2 - r_1)d} - r_1)(1 - e^{(r_4 - r_3)d}) - (r_4 - r_3 e^{(r_4 - r_3)d})(e^{(r_2 - r_1)d} - 1)}.\end{aligned} \tag{2.30}$$

Fix any $\tau \in [0,1]$, and let $c \to -\infty$. We have from (2.26)–(2.27) that $r_1 \to +\infty$, $r_2 \to 0^-$, $r_3 \to +\infty$, and $r_4 \to 0^-$. It follows from (2.30) that $\lim_{c \to -\infty} \underline{A}(0,\tau) = A_- \le \theta$, contradicting the fact that $\theta \in (0, A_-)$. Since $S(0,\tau)$ is bounded between zero and S_+, it is easy to see that the limit of $A(0,\tau)$ as $c \to -\infty$ is uniform in $\tau \in [0,1]$. Hence, there exists a constant $\underline{c}$ independent of $\tau \in [0,1]$ such that $c(\tau) \ge \underline{c}$. The proof is complete. □

REMARK 2.1. *By Propositions* 2.1 *and* 2.2 *and by standard elliptic estimates, the maximum norms of the derivatives of solutions* (S', A', M') *are bounded independently of the parameter* $\tau \in [0,1]$.

Next we show the existence of solutions to (2.10)–(2.12), (2.7), and (2.8) on the bounded domain $[-d, d]$ by Leray–Schauder degree theory. The idea is to transform the system of equations into a fixed point problem. The solution of the fixed point problem solves the original system of equations ($\tau = 1$) which is topologically equivalent to a simpler system ($\tau = 0$) for which we can easily determine the degree. Thus, showing that the degree is not zero amounts to proving the existence of a solution to the original system ($\tau = 1$). The proof is similar to that given in [1]; thus, the definitions and propositions are listed but the details of the proof can be found by referring to [1].

We begin by fixing d and defining $I_d = [-d, d]$ and $X = (C^1(I_d))^3 \times R$. The set X is a Banach space equipped with the norm

$$\|(S, A, M, c)\|_X \equiv \max\left(\|S\|_{C^1(I_d)}, \|A\|_{C^1(I_d)}, \|M\|_{C^1(I_d)}, |c|\right). \tag{2.31}$$

For each element $(S, A, M, c) \in X$, we consider the unique solution $(\overline{S}, \overline{A}, \overline{M})$ of the following system indexed by $\tau \in [0,1]$:

$$D\overline{S}_{\xi\xi} + (R_f c - v)\overline{S}_\xi = \tau \frac{qSAM}{(1+S)(1+A)(1+\varepsilon M)}, \tag{2.32}$$

$$D\overline{A}_{\xi\xi} + (c - v)\overline{A}_\xi = \gamma\tau \frac{qSAM}{(1+S)(1+A)(1+\varepsilon M)}, \tag{2.33}$$

$$\varepsilon\overline{M}_{\xi\xi} + c\overline{M}_\xi - b(\overline{M} - M_0) = -Y\tau \frac{qSAM}{(1+S)(1+A)(1+\varepsilon M)} \tag{2.34}$$

subject to the boundary and normalization conditions (2.7) and (2.8). We define a compact map $K_\tau : (S, A, M, c) \in X \to (\overline{S}, \overline{A}, \overline{M}, c - \overline{A}(0) + \theta) \in X$. Every solution of (2.10)–(2.12) is a fixed point of the map K_τ given by $K_\tau[(S, A, M, c)] = (S, A, M, c)$. We define another map, $F_\tau = I - K_\tau$, where I is the identity map in X $F_\tau : (S, A, M, c) \to (S - \overline{S}, A - \overline{A}, M - \overline{M}, \overline{A}(0) - \theta)$. Every solution to (2.10)–(2.12) is a solution of $F_\tau = 0$.

The set Ω, upon which the degree is well defined, is

$$\Omega = \{(S, A, M, c) \in X \,|\, \|S\|_{C^1} \le N, \|A\|_{C^1} \le N, \|M\|_{C^1} \le N, |c| \le N\}, \tag{2.35}$$

where N is larger than the τ-independent a priori bounds of C^1 norms of (S, A, M) in Proposition 2.1 and Remark 2.1; N is also larger than the absolute value of the upper and lower bounds of $c(\tau)$ given in Proposition 2.2. The degree of F_τ at 0, or $deg(F_\tau, \overline{\Omega}, 0)$, is known to be well defined if $F_\tau(\partial\Omega) \neq 0$.

PROPOSITION 2.3. *For all* $\tau \in [0,1]$, $F_\tau(\partial\Omega) = (I - K_\tau)(\partial\Omega) \neq 0$.

Proof. See Proposition 7.3 in [1]. □

PROPOSITION 2.4. $F_\tau = (I - K_\tau)$ *satisfies,* $\forall \tau \in [0,1]$,

$$deg(F_\tau, \overline{\Omega}, 0) = deg(F_0, \overline{\Omega}, 0) = -1. \tag{2.36}$$

Proof. Equations (2.13) are the solutions denoted in this proof by (S^0, A^0, M^0). See Proposition 7.5 in [1] for more details. □

3. Further estimates on the regularized system. In this section, we obtain further estimates on solutions of the system (2.4)–(2.8) which enable us to extend the solutions to the entire real line in section 4. In particular, by carefully choosing the value of θ, we find the correct wave speed and prevent solutions from converging to the trivial solution as $d \to \infty$.

To begin, we rewrite the system of equations as

$$DS_{\xi\xi} + (R_f c - v)S_\xi = R_{s,\varepsilon}, \tag{3.1}$$

$$DA_{\xi\xi} + (c - v)A_\xi = \gamma R_{s,\varepsilon}, \tag{3.2}$$

$$\varepsilon M_{\xi\xi} + cM_\xi = -Y R_{s,\varepsilon} + b(M - M_0), \tag{3.3}$$

where $\varepsilon \in (0,1)$. The boundary conditions are

$$S(-d) = A(d) = 0,\ S(d) = S^+,\ A(-d) = A_-,\ M(\pm d) = M_0, \tag{3.4}$$

and the normalization condition is

$$A(0) = \theta, \qquad \theta \in (0, A_-). \tag{3.5}$$

The modified reaction term, $R_{s,\varepsilon}$, is

$$R_{s,\varepsilon} = \frac{MSA}{(1 + \varepsilon M)(1 + S)(1 + A)}.$$

PROPOSITION 3.1. *There exist* $\theta_0^* \in (0,1)$ *and constants* α, $d_0 > 0$ *independent of* d, *such that if* $\theta_0 \in (0, \theta_0^*)$, $\theta = \theta_0 A_-$, *and* $d \geq d_0$, *the wave speed* c *in* (3.1)–(3.3) *satisfies*

$$\frac{D}{dR_f}\ln\alpha + \frac{v}{R_f} - \frac{D}{dR_f}[\ln d + \ln S^+] \leq c \leq v + \frac{D}{d}\ln\left(\frac{1}{\theta_0} - 1\right), \tag{3.6}$$

implying in the limit $d \to \infty$

$$\frac{v}{R_f} \leq \liminf_{d\to\infty} c \leq \limsup_{d\to\infty} c \leq v. \tag{3.7}$$

Proof. In view of Proposition 2.2, we need only to establish the lower bound of (3.6). To find the lower bound, we use the same approach as in Proposition 2.2 but consider an upper solution for S (rather than A) which satisfies

$$\begin{cases} D\overline{S}'' + (cR_f - v)\overline{S}' = 0, & \xi \in [-d, d], \\ \overline{S}(-d) = 0, \quad \overline{S}(d) = S^+. \end{cases} \tag{3.8}$$

Solving this differential equation and evaluating it at $\xi = 0$, we obtain the inequality

$$c \geq \frac{v}{R_f} - \frac{D}{R_f d} \ln\left(\frac{S^+}{S(0)} - 1\right), \tag{3.9}$$

where $S(0) = S(0,d)$, due to the implicit dependence of $S(0)$ on d. To find the lower bound for c, we must bound $S(0,d)$ from below. Defining $L = \liminf_{d\to\infty} S(0,d)d$, consider the following two cases for L. First, suppose that $0 < L \leq \infty$. Then, $S(0,d) \geq \frac{\alpha}{d}$ for $\alpha \in (0, \frac{L}{2})$, and d large enough. By (3.9),

$$c \geq \frac{v}{R_f} - \frac{D}{R_f d} \ln\left[\frac{dS^+}{\alpha} - 1\right] \geq \frac{v}{R_f} - \frac{D}{dR_f}[\ln d + \ln S^+] + \frac{D}{dR_f} \ln \alpha, \tag{3.10}$$

and so, for $0 < L \leq \infty$, the proposition is proved.

Now suppose that $L = 0$; then $\forall \delta > 0$, $\exists\ d(\delta)$ such that if $d \geq d(\delta)$, $S(0,d) \leq \frac{\alpha}{d}$. Since $\limsup_{d\to\infty} c \leq v$, we can assume that $\liminf_{d\to\infty} c \leq \frac{v}{R_f}$; otherwise the proposition holds for large enough d. Therefore, there exists a sequence $\{d_j\} \to \infty$, such that $c(d_j) \to c^*$, with $c^* \leq \frac{v}{R_f}$.

Evaluating the lower solution $\underline{A}(\xi)$ in the proof of Proposition 2.2 (with $\tau = 1$, $d = d_j$) at $\xi = 0$, we have $\underline{A}(0) = A_- e^{r_1 d_j} + c_2(1 - e^{(r_1 - r_2)d_j})$, where $r_{1,2}$ and $r_{3,4}$ are given by (2.26)–(2.27) with $S(0,\tau)$ replaced by $S(0,d_j)$, and c_2 as in (2.28). It follows that

$$\begin{aligned} &\lim_{j\to\infty} r_1 = \frac{v - c^*}{D},\ \lim_{j\to\infty} r_2 = 0, \\ &\lim_{j\to\infty} r_{3,4} = \frac{(v-c^*) \pm \sqrt{(v-c^*)^2 + 4DFS^+}}{2D}. \end{aligned} \tag{3.11}$$

Using the assumption that $L = 0$,

$$\lim_{j\to\infty} r_2 d_j = \lim_{j\to\infty} \frac{-2FS(0,d_j)d_j}{(v-c) + \sqrt{(v-c)^2 + 4DFS(0,d_j)}} = 0. \tag{3.12}$$

Therefore, we infer from (3.11)–(3.12) that

$$\theta \geq \lim_{j\to\infty} \underline{A}(0) \geq A_- \frac{2}{1 + \sqrt{1 + \frac{4DFS^+}{v^2(1-\frac{1}{R_f})^2}}}. \tag{3.13}$$

Recall that $\theta = \theta_0 A_-$. We see from (3.13) that

$$\theta_0 \geq \theta_0^* \equiv \frac{2}{1 + \sqrt{1 + \frac{4DFS^+}{v^2(1-R_f^{-1})^2}}}.$$

Since $\theta_0 \in (0,1)$, we can choose $\theta_0 < \theta_0^*$ to deduce a contradiction. So for large d and $\theta_0 < \theta_0^*$, we conclude that $L > 0$. We have proven Proposition 3.1. □

COROLLARY 3.1. *If* $\liminf_{d\to\infty} c = \frac{v}{R_f}$ *and* $\theta \in (0, \theta_0^*)$, *then*

$$\liminf_{d\to\infty} S(0,d)d > 0.$$

Proof. In view of (3.12), the proof above implies that $\liminf_{d\to\infty} S(0,d)d > 0$ which is equivalent to saying that there exists a constant $\alpha = \alpha(\varepsilon) > 0$, such that for d large, $S(0,d) \geq \alpha d^{-1}$. In other words, if $S(0,d)$ tends to zero, then it goes to zero more slowly than $\frac{1}{d}$. ∎

LEMMA 3.1. *If* $\liminf_{d\to\infty} c = \frac{v}{R_f}$ *and* $\theta \in (0, \theta_0^*)$, *then the derivative* $A'(d)$ *satisfies*

$$\limsup_{d\to\infty} |A'(d)| \leq \frac{\theta}{D} \limsup_{d\to\infty} \sqrt{(v-c)^2 + \frac{4\gamma D S(0,d) M_0}{(1+S^+)(1+A_-)}}$$
$$\leq \frac{\theta}{D} \sqrt{\left(v - \frac{v}{R_f}\right)^2 + \frac{4\gamma D M_0}{1+A_-}}.$$

Proof. First, notice that $\forall \xi \in [0,d]$, we have $\gamma R_s \geq \eta_1(d) A$, where

$$\eta_1(d) = \frac{\gamma S(0,d) M_0}{(1+S^+)(1+A_-)(1+\varepsilon M_{\max})} \geq O(d^{-1}), \tag{3.14}$$

and the lower bound is given by Corollary 3.1. Now, define $\overline{A}(\xi)$ to solve

$$\begin{cases} D\overline{A}'' + (c-v)\overline{A}' - \eta_1(d)\overline{A} = 0, & \xi \in [0,d], \\ \overline{A}(0) = \theta, \quad \overline{A}(d) = 0. \end{cases} \tag{3.15}$$

Solving (3.15),

$$\overline{A}(\xi) = \theta e^{r_2 \xi} \frac{e^{(r_1-r_2)d} - e^{(r_1-r_2)\xi}}{e^{(r_1-r_2)d} - 1}, \; r_{1,2} = \frac{v - c \pm \sqrt{(v-c)^2 + 4\eta_1(d) D}}{2D}. \tag{3.16}$$

By the assumptions, Corollary 3.1, and (3.14), we see that $-(r_2 - r_1)d \to +\infty$, so $e^{(r_2-r_1)d} \to 0$ and $e^{r_2 d} \leq 1$. Therefore, by Proposition 3.1,

$$\lim_{d\to\infty} |A'(d)| \leq \lim_{d\to\infty} |\overline{A}'(d)| \leq \frac{\theta}{D} \sqrt{\left(v - \frac{v}{R_f}\right)^2 + \frac{4DM_0\gamma}{1+A_-}}. \tag{3.17}$$

The proof is complete. ∎

Note that if $\liminf_{d\to\infty} \eta_1(d) > 0$, $\lim_{d\to\infty} e^{r_2 d} = 0$. Then, $\lim_{d\to\infty} A'(d) = 0$. However, we need more results to deduce that $\eta_1(d)$, or rather $S(0,d)$, does not converge to zero as $d \to \infty$.

PROPOSITION 3.2. *If* $\theta \in (0, \theta_0^*)$, *then* $\lim_{d\to\infty} S'(-d) = \lim_{d\to\infty} A'(-d) = 0$.

Proof. Step 1. $\lim_{d\to\infty} |S'(-d)| = 0$. To prove this, we find an upper solution to S and use a resulting inequality to bound $\lim_{d\to\infty} |S'(-d)|$ by zero on both sides. To construct an upper solution, we note that on $[-d, 0]$, $R_s \geq \eta_2 S$, where we define $\eta_2 = \frac{M_0\theta}{(1+\varepsilon M_{\max})(1+A_-)(1+S^+)}$, which is a constant, independent of d. Let $\overline{S}$ solve (3.8) with the right-hand side equal to $\eta_2 \overline{S}$ and $\overline{S}(-d) = 0$, $\overline{S}(0) = S(0,d)$ for $\xi \in [-d, 0]$. Solving for $\overline{S}$, we obtain

$$\overline{S}(\xi) = S(0,d) e^{\bar{r}_1 \xi} \left(\frac{e^{(\bar{r}_1 - \bar{r}_2)d} - e^{(\bar{r}_2 - \bar{r}_1)\xi}}{e^{(\bar{r}_1 - \bar{r}_2)d} - 1} \right), \quad \xi \in [-d, 0], \tag{3.18}$$

where

$$\bar{r}_{1,2} = \frac{(v - cR_f)}{2D} \pm \frac{\sqrt{(v-cR_f)^2 + 4D\eta_2}}{2D}, \quad \bar{r}_1 > 0, \bar{r}_2 < 0.$$

From (3.18), we find $\overline{S}'(-d) = \frac{S(0,d)(\bar{r}_1-\bar{r}_2)}{e^{\bar{r}_1 d}-e^{\bar{r}_2 d}}$. Note that if $c \not\to \frac{v}{R_f}$ as $d \to \infty$, then by Proposition 3.1, $c > \frac{v}{R_f}$ for large d, and so $\bar{r}_2 < -\sqrt{\eta_2/D}$ for large d. If $c \to \frac{v}{R_f}$, as $d \to \infty$, then $\bar{r}_2 \to -\sqrt{\eta_2/D}$. In either case, $e^{\bar{r}_2 d}$ converges to zero, and $e^{\bar{r}_1 d}$ converges to infinity. Thus, $0 \le \limsup_{d\to\infty} S'(-d) \le \limsup_{d\to\infty} \overline{S}'(-d) = 0$, and the proof of Step 1 is complete.

Step 2. $\lim_{d\to\infty} A'(-d) = 0$. We infer from (3.18) that

$$\overline{S}(\xi) \le S(0,d)e^{\bar{r}_1\xi}\frac{e^{(\bar{r}_1-\bar{r}_2)d}}{e^{(\bar{r}_1-\bar{r}_2)d}-1} \le 2S^+ e^{\bar{r}_1\xi} \quad \forall \xi \in [-d,0], \tag{3.19}$$

where $\bar{r}_1$ is bounded away from zero uniformly in $d \to \infty$. Using (3.19), we find an upper bound for R_s to be $\gamma R_s \le \eta_3(d)A \ \forall \xi \in [-d,0]$, where η_3 is given in (3.20). We define a lower solution, $\underline{A}$, as the solution of

$$\begin{cases} D\underline{A}'' + (c-v)\underline{A}' - \eta_3\underline{A} = 0, \quad \eta_3(d) = \frac{2\gamma S^+ M_{\max} e^{-\bar{r}_1\frac{d}{2}}}{(1+\varepsilon M_0)(1+\theta)}. \\ \underline{A}(-d) = A_-, \quad \underline{A}\left(-\frac{d}{2}\right) = \theta \quad \forall \xi \in \left[-d, -\frac{d}{2}\right]. \end{cases} \tag{3.20}$$

We solve (3.20) to get $\underline{A}(\xi) = c_1 e^{r_1\xi} + c_2 e^{r_2\xi}$, with $r_{1,2}$ given by (2.26) with $FS(0,\tau)$ replaced by $\eta_3(d)$. Differentiating $\underline{A}(\xi)$, we find

$$\underline{A}'(-d) = r_1 A_- + \frac{(r_1-r_2)A_- + (r_2-r_1)\theta e^{-\frac{r_1 d}{2}}}{e^{(r_2-r_1)\frac{d}{2}}-1}. \tag{3.21}$$

Suppose that $c \to v$ along a subsequence $\{d_j\} \to \infty$; then $r_1 \to 0$ and $r_2 \to 0$. If, in addition $(r_2-r_1)d_j \to 0$, then $e^{\frac{(r_2-r_1)d_j}{2}} - 1 \sim (r_2-r_1)\frac{d_j}{2} + O((r_2-r_1)^2 d_j^2)$, and $\underline{A}'(-d_j) \to 0$. If $\liminf_{j\to\infty}(r_2-r_1)d_j > 0$, then the second term in (3.21) with $d = d_j$ goes to zero because its numerator converges to zero while its denominator does not. The first term clearly converges to zero. Hence, $\underline{A}'(-d_j) \to 0$ as $j \to \infty$.

Suppose now that $c \to c^* < v$ along a subsequence $d_j \to \infty$; then $r_1 \to \frac{|c^*-v|}{D}$ and $r_2 \to 0$ and also, $|r_2 - r_1| \to \beta > 0$, for a finite number β. Passing to the $d_j \to \infty$ limit in (3.21), we arrive at $\lim_{j\to\infty} \underline{A}'(-d_j) = 0$. It follows that we always have $\lim_{d\to\infty} A'(-d) = 0$. The proof is complete. □

LEMMA 3.2. *Let $\theta \in (0,\theta_0^*)$. There exists a positive constant K_1 depending only on $D, v, R_f, \gamma, M_{\max}$ such that* $\limsup_{d\to\infty} S'(d) \le K_1 S^+ \max(\theta, \sqrt{\theta})$.

Proof. In this proof, we construct a lower solution to S on half the finite domain to find an inequality for S'. To find the upper bound, we bound all the terms as $d \to \infty$. First, note that $A(\xi) \le \theta \ \forall \xi \in [0,d]$. Next, define the subsolution $\underline{S}$ as

$$\begin{cases} D\underline{S}'' + (cR_f - v)\underline{S}' - \eta_4\underline{S} = 0, \qquad \xi \in [0,d], \\ \underline{S}(0) = S(0,d), \quad \underline{S}(d) = S^+, \end{cases} \tag{3.22}$$

where $\eta_4 = \theta K$ and $K \equiv \gamma M_{\max}$ since $\gamma R_s \le \gamma\theta M_{\max} S$. Note that η_4 is a positive constant independent of d. The solution of (3.22) is $\underline{S} = c_1 e^{r_1\xi} + c_2 e^{r_2\xi}$, where $r_{1,2} = \bar{r}_{1,2}$ from Proposition 2.2 with η_2 replaced by η_4. Solving (3.22) and differentiating, it follows that

$$\underline{S}'(d) = \frac{(r_1-r_2)S(0,d)e^{r_2 d} - r_1 S^+ + r_2 e^{(r_2-r_1)d}S^+}{e^{(r_2-r_1)d}-1}, \tag{3.23}$$

where r_2 is rewritten as

$$r_2 = \frac{-4D\eta_4}{2D\cdot(v - cR_f + \sqrt{(v-cR_f)^2 + 4D\eta_4})}, \tag{3.24}$$

and $r_2 - r_1 = -\frac{1}{D}\sqrt{(v - cR_f)^2 + 4D\eta_4} \le -\frac{1}{D}2\sqrt{D\theta K}$. Thus, $e^{(r_2 - r_1)d} \to 0$ as $d \to \infty$. To find an upper bound on $S'(d)$, we must bound r_1 and r_2. If $v - cR_f \le 0$, then $|r_2| \ge \sqrt{\frac{\eta_4}{D}} = \sqrt{\frac{\theta K}{D}}$. If $v - cR_f > 0$, by Proposition 3.1, we see that $v - cR_f \le O(d^{-1} \ln d)$. Hence, we find a lower bound for r_2 in the limit $d \to \infty$ as

$$|r_2| \ge \frac{2\eta_4}{O(d^{-1} \ln d) + \sqrt{(O(d^{-1} \ln d))^2 + 4D\eta_4}} \to \sqrt{\frac{\eta_4}{D}},$$

and so $\limsup_{d\to\infty} r_2 \le -\sqrt{D^{-1}\eta_4} = -\sqrt{D^{-1}\theta K}$. Now, we see that $\lim_{d\to\infty} e^{r_2 d} \le \lim_{d\to\infty} e^{-\sqrt{D^{-1}\theta K} d} = 0$. We consider the same cases in order to bound r_1. If $v - cR_f \le 0$, then

$$r_1 \le \frac{2\eta_4}{((v + O(\frac{1}{d}))R_f - v) + \sqrt{((v + O(\frac{1}{d}))R_f - v)^2 + 4D\eta_4}} \tag{3.25}$$

by Proposition 3.1. Therefore,

$$\limsup_{d\to\infty} r_1 \le \frac{2\eta_4}{v(R_f - 1) + \sqrt{v^2(R_f - 1)^2 + 4D\eta_4}}. \tag{3.26}$$

If $v - cR_f > 0$, then by Proposition 3.1 again $v - cR_f \le O(d^{-1} \ln d)$ for large d, and so

$$r_1 \le \frac{O(d^{-1} \ln d) + \sqrt{O(d^{-2}(\ln d)^2) + 4D\eta_4}}{2D},$$

and finally,

$$\limsup_{d\to\infty} r_1 \le \sqrt{\frac{\theta K}{D}}. \tag{3.27}$$

In any case, we have the following:

$$\limsup_{d\to\infty} r_1 \le 2K_1(D, \gamma, v, R_f, M_{\max}) \max(\theta, \sqrt{\theta}) = K_1 \max(\theta, \sqrt{\theta}). \tag{3.28}$$

Combining (3.23) and (3.28), we obtain the result

$$\limsup_{d\to\infty} S'(d) \le S^+ \limsup_{d\to\infty} r_1 = K_1 S^+ \max(\theta, \sqrt{\theta}), \tag{3.29}$$

and the proof is complete. □

LEMMA 3.3. *There exist two positive constants δ_1 and δ_2 independent of d, and a positive number θ_0^{**} depending only on δ_1 and δ_2, $\theta_0^{**} \in (0, \theta_0^*)$. If $\theta_0 \in (0, \theta_0^{**})$, then*

$$\frac{v}{R_f} + \delta_1 \le \liminf_{d\to\infty} c \le \limsup_{d\to\infty} c \le v - \delta_2. \tag{3.30}$$

Proof. Combining the equations for S and A in (3.1)–(3.2) and integrating from $-d$ to d, we obtain

$$\gamma(DS'(d) + (cR_f - v)S^+ - DS'(-d)) = DA'(d) - DA'(-d) - (c - v)A_-.$$

We solve for c to get

$$c = \frac{D(A'(d) - A'(-d)) + \gamma D(S'(-d) - S'(d)) + vA_- + v\gamma S^+}{\gamma R_f S^+ + A_-}. \tag{3.31}$$

Using Proposition 2.1, we derive the inequality

$$\frac{DA'(d) - \gamma DS'(d) + vA_- + v\gamma S^+}{\gamma R_f S^+ + A_-} \le c \le \frac{-DA'(-d) + \gamma DS'(-d) + vA_- + v\gamma S^+}{\gamma R_f S^+ + A_-}.$$

Taking $d \to \infty$ and using Proposition 3.2, $\limsup_{d\to\infty} c < v$. If $\liminf_{d\to\infty} c > \frac{v}{R_f}$, then the proof is done if we define δ_i, $i = 1, 2$, to be the difference between c and $\frac{v}{R}$ and v, respectively. On the other hand, if $\liminf_{d\to\infty} c = \frac{v}{R_f}$, then by Lemmas 3.1 and 3.2, we have

$$\begin{aligned} &\liminf_{d\to\infty} c \\ &\quad \ge \frac{-\theta\sqrt{v^2(1 - R_f^{-1})^2 + \frac{4\gamma DM_0}{1+A_-}} - \gamma DK_1 S^+ \max(\theta, \theta^{\frac{1}{2}}) + vA_- + v\gamma S^+}{\gamma R_f S^+ + A_-}. \end{aligned} \tag{3.32}$$

Now, set $\delta_2 = (\gamma S^+(R_f - 1)v)/(\gamma S^+ R_f + A_-) > 0$, and

$$\delta_1 = \frac{v(1 - \frac{1}{R_f})(A_- + S^+\gamma) - \theta\sqrt{v^2(1 - R_f^{-1})^2 + \frac{4\gamma DM_0}{1+A_-}} - \gamma DK_1 S^+ \max(\theta, \theta^{\frac{1}{2}})}{\gamma S^+ R_f + A_-}.$$

Here δ_1 is the difference between the lower bound in (3.32) and $\frac{v}{R_f}$. There exists a $\theta_0^{**} \in (0, \theta_0^*)$ such that if $\theta_0 \in (0, \theta_0^{**})$, $\delta_1 > 0$. We end the proof. □

LEMMA 3.4. *There exists a positive constant, θ_0^{***}, depending on δ_1, δ_2 and less than θ_0^{**} such that if $\theta_0 \le \theta_0^{***}$, $\liminf_{d\to\infty} S(0, d) > 0$.*

Proof. Suppose $S(0, d_j) \to 0$ along a sequence $\{d_j\} \to \infty$; then $S(\xi) \to 0$, uniformly in $\xi \in [-d_j, 0]$. Proposition 3.1 says that $c_j = c(d_j)$ is uniformly bounded in d_j; (2.10)–(2.12) then imply that $(S, A, M)(\xi, d_j)$ is compact in $(C^1_{loc}(R))^3$. Up to a subsequence, we have $(S, A, M)(\xi, d_j) \to (\tilde{S}, \tilde{A}, \tilde{M})(\xi)$ as $j \to \infty$, $\tilde{S}' \ge 0$, $\tilde{A}' \le 0$, $\tilde{A}(0) = \theta$, $\tilde{S}(\xi) \equiv 0$ if $\xi \le 0$. By uniqueness of solutions to ordinary differential equations, we deduce from (2.10) that $\tilde{S} \equiv 0$ on R^1. Thus, $\tilde{A}$ is a bounded solution to the problem

$$\begin{cases} D\tilde{A}_{\xi\xi} + (c^* - v)\tilde{A}_\xi = 0, \quad \xi \in R^1, \\ \tilde{A}(0) = \theta. \end{cases} \tag{3.33}$$

As a consequence of Lemma 3.3, along a subsequence of $d_j \to \infty$, $c(d_j) \to c^* \in (\frac{v}{R_f} + \delta_1, v - \delta_2)$ as $j \to \infty$, where $\delta_i = \delta_i(D, v, R_f, \gamma, \theta_0, M_0, M_{\max}, S^+, A_-) > 0$ for $i = 1, 2$. The only bounded solution of (3.33) is $\tilde{A} \equiv \theta$.

Let us consider the equations for (S, A) on $[-d_j, d_j]$:

$$DS'' + (c_j R_f - v)S' = \frac{A}{1+A}\frac{M}{1+\varepsilon M}\frac{S}{1+S}, \tag{3.34}$$

$$DA'' + (c_j - v)A' = \gamma\frac{A}{1+A}\frac{M}{1+\varepsilon M}\frac{S}{1+S}. \tag{3.35}$$

Multiplying (3.34) by γ and subtracting (3.35) from the resulting equation, we obtain

$$\gamma D S'' - D A'' + \gamma(c_j R_f - v)S' - (c_j - v)A' = 0, \quad \xi \in [-d_j, d_j]. \tag{3.36}$$

Integrating once in ξ, we obtain

$$\begin{aligned} \gamma D S' - D A' + \gamma(c_j R_f - v)S - (c_j - v)A &= \gamma D S'(d_j) - D A'(d_j) + \gamma(c_j R_f - v)S^+, \\ &= Q(d_j) + \Gamma + o(1) \quad \forall \xi \in [-d_j, d_j], \end{aligned} \tag{3.37}$$

where $\Gamma = \lim_{j\to\infty} \gamma(c_j R_f - v)S^+$, and $Q(d_j) = \gamma D S'(d_j) - D A'(d_j) \geq 0$. It follows that

$$\gamma D \left(S' + \frac{c_j R_f - v}{D} S \right) = D A' + (c_j - v)A + \Gamma + Q(d_j) + o(1),$$

and so

$$\gamma D \left(e^{(\frac{c_j R_f - v}{D})\xi} S \right)' = e^{(\frac{c_j R_f - v}{D})\xi} \left[D A' + (c_j - v)A + \Gamma + Q(d_j) + o(1) \right]. \tag{3.38}$$

Integrating (3.38) over $[-d_j, \xi]$ gives

$$\begin{aligned} &\gamma D e^{(\frac{c_j R_f - v}{D})\xi} S = \int_{-d_j}^{\xi} e^{(\frac{c_j R_f - v}{D})\xi'} \left[D A' + (c_j - v)A + \Gamma + Q(d_j) + o(1) \right] d\xi' \\ &\geq D \int_{-d_j}^{\xi} e^{(\frac{c_j R_f - v}{D})\xi'} e^{(\frac{v - c_j}{D})\xi'} \cdot \left(e^{(\frac{c_j - v}{D})\xi'} A \right)' d\xi' + (\Gamma + o(1)) \int_{-d_j}^{\xi} e^{(\frac{c_j R_f - v}{D})\xi'} d\xi' \\ &= D e^{(\frac{c_j R_f - v}{D})\xi} A - D e^{-(\frac{c_j R_f - v}{D})d_j} A_- - c_j(R_f - 1) \int_{-d_j}^{\xi} e^{(\frac{c_j R_f - v}{D})\xi'} A(\xi') d\xi' \\ &\quad + (\Gamma + o(1)) \frac{D}{c_j R_f - v} e^{(\frac{c_j R_f - v}{D})\xi} + o(1). \end{aligned} \tag{3.39}$$

Recall that if $S(0, d_j) \to 0$ as $d_j \to \infty$, then $A(\xi, d_j) \to \theta$ and $S(\xi, d_j) \to 0$ as $d_j \to \infty$, $\forall \xi$, uniformly for a compact set of ξ. It follows that by the dominated convergence theorem

$$\begin{aligned} \lim_{d_j \to \infty} \int_{-d_j}^{\xi} e^{(\frac{c_j R_f - v}{D})\xi'} A(\xi') d\xi' &= \int_{-\infty}^{\xi} e^{(\frac{c^* R_f - v}{D})\xi'} \theta d\xi' \\ &= \theta \frac{D}{c^* R_f - v} e^{(\frac{c^* R_f - v}{D})\xi}, \end{aligned} \tag{3.40}$$

so (3.39) in the limit $d_j \to \infty$ reads

$$0 \geq D\theta_0 A_- - c^* D \theta_0 A_- \frac{(R_f - 1)}{(c^* R_f - v)} + \frac{\Gamma D}{c^* R_f - v}.$$

Substituting in $\Gamma = \gamma(c^* R_f - v)S^+$, we get $0 \geq \gamma S^+ D + D\theta_0 A_- \left[1 - \frac{c^*(R_f - 1)}{c^* R_f - v}\right]$, and finally

$$0 \geq S^+ + \gamma^{-1} \theta_0 A_- \left(\frac{c^* - v}{c^* R_f - v} \right) \geq S^+ - \gamma^{-1} \theta_0 A_- \frac{\delta_2}{R_f \delta_1}. \tag{3.41}$$

There exists $\theta_0^{***} \in (0, \theta_0^{**})$ depending on δ_1 and δ_2 such that the right-hand side of (3.41) is strictly positive. This implies a contradiction. Therefore, $S(0,d)$ does not tend to zero as $d \to \infty$. ∎

PROPOSITION 3.3. *If $\theta \in (0, \theta_0^{***})$, then $\lim_{d\to\infty} A'(d) = \lim_{d\to\infty} S'(d) = 0$.*

Proof. Let us follow the proof of Lemma 3.1 until the derivative of $\overline{A}$ at $\xi = d$ is found to be

$$\overline{A}'(d) = \frac{\theta e^{r_2 d}(r_2 - r_1)}{1 - e^{(r_2 - r_1)d}}, \tag{3.42}$$

where $|r_2 - r_1|$ is bounded. Now by Lemma 3.4, we can improve (3.14) so that $\liminf_{d\to\infty} \eta_1(d) > 0$. Hence, $v - c$ is bounded strictly away from zero as $d \to \infty$ by Lemma 3.3, and so $\lim_{d\to\infty} e^{r_2 d} = 0$ and $\lim_{d\to\infty} A'(d) = 0$.

For the second part of the proposition, we consider $S(\xi, d)$ over $\left[\frac{d}{2}, d\right]$. First, by (3.16),

$$A(\xi) \le \theta e^{\bar{r}_2 \frac{d}{2}} \quad \forall \xi \in \left[\frac{d}{2}, d\right], \quad \bar{r}_2 = \frac{v - c - \sqrt{(v-c)^2 + 4\eta_1(d)D}}{2D},$$

and $\limsup_{d\to\infty} \bar{r}_2 < 0$. Hence, $A(\xi, d)$ goes to zero exponentially fast in d.

Let $\eta_5(d) = M_{\max}\theta e^{\bar{r}_2 \frac{d}{2}}$, so that $R_s \le \eta_5 S$. Define a subsolution $\underline{S}$ on $[\frac{d}{2}, d]$ as in (3.22) with η_2 replaced by η_5 and $\underline{S}(\frac{d}{2}) = S(0,d)$, $\underline{S}(d) = S^+$. Solving for $\underline{S}$, taking the derivative, and evaluating it at $\xi = d$, we get

$$\underline{S}'(d) = \frac{(r_1 - r_2)S(0,d)e^{\frac{r_2 d}{2}} - r_1 S^+ + r_2 S^+ e^{(r_2 - r_1)\frac{d}{2}}}{e^{(r_2 - r_1)\frac{d}{2}} - 1} \ge S'(d) \ge 0. \tag{3.43}$$

Since c is bounded away from $\frac{v}{R_f}$ uniformly in d,

$$\lim_{d\to\infty} e^{(r_2 - r_1)\frac{d}{2}} = 0, \ \lim_{d\to\infty} e^{r_2 \frac{d}{2}} = 0, \text{ and } \lim_{d\to\infty} \eta_5(d) = 0.$$

In addition, $\lim_{d\to\infty} r_1 = 0$, and we deduce immediately that $\lim_{d\to\infty} S'(d) = 0$. The proof is complete. ∎

PROPOSITION 3.4.

$$\lim_{d\to\infty} c(d) = v\frac{(A_- + \gamma s^+)}{(A_- + \gamma R_f S^+)} = c. \tag{3.44}$$

Proof. The limit follows from (3.31) in the proof of Lemma 3.3 and Propositions 3.2 and 3.3. ∎

COROLLARY 3.2. *There exist positive constants β_1 and β_2 independent of d such that*

$$A(\xi, d) \le \theta e^{-\beta_1 \xi}, \quad \beta_1 > 0, \quad \forall \xi \in [0, d], \tag{3.45}$$

$$S(\xi, d) \le 2S^+ e^{\beta_2 \xi}, \quad \beta_2 > 0, \quad \forall \xi \in [-d, 0]. \tag{3.46}$$

Proof. To prove (3.45), we consider (3.16) from Lemma 3.1, defined on $[0, d]$. It is clear that $A(\xi, d) \le \theta e^{r_2 \xi}$, $\forall \xi \in [0, d]$. Note that $\limsup_{d\to\infty} r_2 < 0$. Letting $0 < \beta_1 \le -\limsup_{d\to\infty} r_2$ with β_1 bounded away from zero uniformly in d, we have shown (3.45). To prove (3.46), we use (3.19): $S(\xi, d) \le 2S^+ e^{\bar{r}_1 \xi}$, $\forall \xi \in [-d, 0]$. We see that $\liminf_{d\to\infty} \bar{r}_1 > 0$. Choosing $0 < \beta_2 \le \liminf_{d\to\infty} \bar{r}_1$, we have shown (3.46). ∎

4. Solutions of a regularized system on the real line. For a fixed $\varepsilon > 0$, we are interested in taking the limit $d \to \infty$. The ε dependence of solutions will not be specified until the next section. By Propositions 3.1–3.3, we know that the d dependent solutions denoted by (S_d, A_d, M_d) are compact in $(C^1_{loc}(R))^3$. So up to a subsequence in d, $(S_d, A_d, M_d) \to (S, A, M)$ uniformly on any compact set of ξ and the limiting system is

$$DS_{\xi\xi} + (R_f c - v)S_\xi = R_s, \tag{4.1}$$

$$DA_{\xi\xi} + (c - v)A_\xi = \gamma R_s, \tag{4.2}$$

$$\varepsilon M_{\xi\xi} + cM_\xi = -YR_s + b(M - M_0), \tag{4.3}$$

with boundary conditions

$$A(0) = \theta_0 A_-, \;\; \theta_0 \in (0, \theta_0^{***}), \;\; S(0) = S(0, \varepsilon) > 0. \tag{4.4}$$

Moreover, we have the following bounds:

$$0 \le S(\xi) \le S^+, \quad 0 \le A(\xi) \le A_-, \quad M_0 \le M(\xi) \le M_{\max}, \tag{4.5}$$

$$A'(\xi) \le 0, \quad S'(\xi) \ge 0. \tag{4.6}$$

Note that (4.4) is due to Lemma 3.4.

Corollary 3.2 holds for the limiting functions A and S. In particular,

$$\lim_{\xi \to +\infty} A(\xi) = 0, \quad \lim_{\xi \to -\infty} S(\xi) = 0.$$

Monotonicity of A and S in (4.6) implies that

$$\lim_{\xi \to -\infty} A(\xi) = \tilde{A}_- \quad \text{for } \tilde{A}_- \in (0, A_-], \tag{4.7}$$

$$\lim_{\xi \to +\infty} S(\xi) = \tilde{S}^+ \quad \text{for } \tilde{S}^+ \in (0, S^+]. \tag{4.8}$$

LEMMA 4.1. *For $\varepsilon \in (0,1)$, $\lim_{\xi \to \pm\infty} M(\xi) = M_0$.*

Proof. Let $m = M - M_0$; then $m \ge 0$ and $m \not\equiv 0$ (if $m \equiv 0$ by (4.3) $AS \equiv 0$ which contradicts (4.4) at $\xi = 0$). Therefore, there exists a ξ_1 such that $(M - M_0)(\xi_1) = m(\xi_1) > 0$. On $[\xi_1, \infty)$ by inequalities (4.5) and Corollary 3.2,

$$\frac{YSAM}{(1+S)(1+A)(1+\varepsilon M)} \le y_0 Y M_{\max} \theta e^{-\beta_1 \xi},$$

where $y_0 > 1$ is to be chosen and

$$\beta_1 \le \frac{c - v + \sqrt{(v-c)^2 + 4\eta_1(d)D}}{2D}, \;\; \eta_1(d) > 0.$$

Define $\bar{m}$ as a solution of $\varepsilon \overline{m}_{\xi\xi} + c\overline{m}_\xi - b\overline{m} = -y_0 Y M_{\max} \theta e^{-\beta_1 \xi}$ with $\overline{m}(\xi_1) \ge m(\xi_1) > 0$, for $\xi \in [\xi_1, \infty)$. Solving for a positive solution $\overline{m}$, we obtain

$$\overline{m} = -y_0 \frac{Y M_{\max} \theta}{(\varepsilon \beta_1^2 - c\beta_1 - b)} e^{-\beta_1 \xi}, \tag{4.9}$$

where $\beta_1 > 0$, $\varepsilon\beta_1^2 - c\beta_1 - b < 0$ for $\varepsilon \in (0,1)$ and $\beta_1 < \sqrt{b}$. So indeed $\bar{m} > 0$. We choose y_0 such that $\overline{m}(\xi_1) \geq m(\xi_1)$. By the maximum principle, $m(\xi) \leq \overline{m}(\xi)$. Since $\lim_{\xi\to+\infty} \overline{m}(\xi) = 0$, we find that $\lim_{\xi\to+\infty} m(\xi) = 0$ and $\lim_{\xi\to+\infty} M(\xi) = M_0$. A similar argument shows that $\lim_{\xi\to+\infty} M(\xi) = M_0$. □

LEMMA 4.2. *Consider M_d for $\xi \in [-d,d]$. Then $\lim_{d\to\infty} M_d'(\pm d) = 0$.*

Proof. This proof is similar to the proof of Lemma 4.1. We define $m_d = M_d - M_0$ on $[-d,d]$ and then construct an upper solution to m_d which solves

$$\begin{cases} \varepsilon\overline{m}_{d,\xi\xi} + c\overline{m}_{d,\xi} - b\overline{m}_d = -YM_{\max}\theta e^{-\beta_1\xi}, \\ \overline{m}_d(0) = m_d(0), \quad \overline{m}_d(d) = 0, \quad \xi \in [0,d], \end{cases} \tag{4.10}$$

where $c = c(d)$. We solve for $\overline{m}_d$ and find the derivative at $\xi = d$. Taking the limit as $d \to \infty$, we show that $\lim_{d\to+\infty} \overline{m'}_d(d) = 0$. It follows that $\lim_{d\to+\infty} |m_d'(d)| = \lim_{d\to+\infty} |(M_d - M_0)'(d)| = \lim_{d\to+\infty} |M_d'(d)| = 0$. A similar argument shows that $\lim_{d\to+\infty} M_d'(-d) = 0$. □

LEMMA 4.3. *There exists four constants k_1, k_2, k_3, and k_4 depending on Y, $M_{\max}$, θ, ε, b, c, R, v, and D such that*

$$(M - M_0)(\xi) \leq k_1 e^{-\sigma_1\xi} + k_2 e^{-\sigma_2\xi}, \quad \sigma_1 > 0,\ \sigma_2 > 0,\ \xi \geq 0, \tag{4.11}$$

$$(M - M_0)(\xi) \leq k_3 e^{\sigma_3\xi} + k_4 e^{\sigma_4\xi}, \quad \sigma_3 > 0,\ \sigma_4 > 0,\ \xi \leq 0, \tag{4.12}$$

where σ_i is a constant for $i = 1,2,3,4$.

Proof. The proof of (4.11) relies on bounding the upper solution $\overline{m}_d$ found in Lemma 4.2. The proof of (4.12) is similar. □

THEOREM 4.1. *For $\varepsilon \in (0,1)$, $\exists$ a smooth solution (S,A,M,c) solving the system (4.1)–(4.3) and the boundary conditions (4.4)–(4.6). Moreover, $M_0 < M \leq M_{\max}$ and $\lim_{\xi\to\pm\infty} M(\xi) = M_0$.*

Proof. We have shown that there exist solutions on the real line and that M reaches its limits at the spatial infinities. Now, we only need to show that the boundary conditions on S, A hold in the limit $d \to \infty$; i.e., we want to show that $A_- = \tilde{A}_-$ and $S^+ = \tilde{S}^+$. To that end, we multiply γ to (2.4), subtract (2.5), and integrate over $[-d,d]$. Taking the limit $d \to \infty$, using Propositions 3.2 and 3.3 and (4.7)–(4.8), we solve for c:

$$c = v\frac{(\tilde{A}_- + \gamma\tilde{S}^+)}{(\tilde{A}_- + \gamma\tilde{S}^+R_f)}. \tag{4.13}$$

Proposition 3.4 says that $c = v\frac{(A_- + \gamma S^+)}{(A_- + \gamma S^+ R_f)}$. Therefore, it is clear that $\frac{\tilde{S}^+}{S^+} = \frac{\tilde{A}_-}{A_-}$.

Multiplying (2.4) by Y, adding it to (2.6), and integrating over $[-d,d]$,

$$YD[S_d'(d) - S_d'(-d)] + Y(c_dR - v)S^+ + \varepsilon[M_d'(d) - M_d'(-d)] = b\int_{-d}^{d} (M_d - M_0)(\xi)d\xi.$$

By Propositions 3.2 and 3.3 and Lemmas 4.1 and 4.2, in the limit $d \to \infty$,

$$Y(cR_f - v)S^+ = b\lim_{d\to\infty}\int_{-d}^{d}(M_d - M_0)(\xi)d\xi = b\int_{-\infty}^{\infty}(M - M_0)(\xi)d\xi. \tag{4.14}$$

Multiplying (4.1) by Y, adding it to (4.3), integrating the resulting equation from $\xi = -\infty$ to $\xi = +\infty$, and using boundary conditions as well as the decay of the limiting functions at infinities, we end up with

$$Y(cR_f - v)\tilde{S}^+ = b\int_{-\infty}^{\infty}(M - M_0)(\xi)d\xi. \tag{4.15}$$

Combining (4.14)–(4.15), we find that $S^+ = \tilde{S}^+$, and similarly $A_- = \tilde{A}_-$. Thus, we have a solution (S, A, M) for the system (4.1)–(4.3) satisfying $S(\infty) = S^+$, $S(-\infty) = 0$, $A(\infty) = 0$, and $A(-\infty) = A_-$. The fact that $M(\xi) > M_0$ follows from the maximum principle. The proof is complete. □

5. Traveling waves on the real line. Through results of the last section, we have established the existence of the regularized solutions denoted by $(S_\varepsilon, A_\varepsilon, M_\varepsilon, c_\varepsilon)$ over the real line. We show that they converge to the desired traveling wave solutions as $\varepsilon \to 0$. We have found $c_\varepsilon = c$ independent of ε. However, we improve the previous bounds on $S_\varepsilon, A_\varepsilon, M_\varepsilon$ and their derivatives so that they are independent of ε. Moreover, we show that the boundary conditions are valid for limiting functions (S, A, M) as $\xi \to \infty$. The first step is to establish an upper bound on M_ε independent of ε.

LEMMA 5.1. *For M_ε of the system* (4.1)–(4.3)*, M_ε satisfies*

$$M_0 < M_\varepsilon \le M_0 + Y\left(R_f - \frac{v}{c}\right) S^+ \quad \forall \xi \in R^1. \tag{5.1}$$

Proof. As mentioned, $\lim_{\varepsilon \to 0} M_\varepsilon = M \not\equiv M_0$. By Proposition 2.1 and Theorem 4.1, we have that $M_0 < M_\varepsilon$. Therefore, $\exists\ \xi_1 \in (-\infty, \infty)$ such that $M_\varepsilon(\xi_1) = \sup_{\xi \in R^1} M_\varepsilon(\xi) = \overline{M}_\varepsilon > M_0$. Multiplying Y by (4.1), adding it to (4.3), and integrating from ξ_1 to ∞, we obtain

$$-Y D S'_\varepsilon(\xi_1) + Y(cR_f - v)(S^+ - S_\varepsilon(\xi_1)) + c(M_0 - \overline{M}_\varepsilon) = b \int_{\xi_1}^{\infty} (M_\varepsilon - M_0)(\xi) d\xi.$$

Note that $M'_\varepsilon(\xi_1) = 0$ and $\int_{\xi_1}^{+\infty} (M_\varepsilon - M_0) d\xi \ge 0$. Solving for $\overline{M}_\varepsilon$,

$$\overline{M}_\varepsilon \le M_0 + Y\left(R_f - \frac{v}{c}\right) S^+. \tag{5.2}$$

It is clear that $M_0 < M_\varepsilon(\xi) \le \overline{M}_\varepsilon \le M_0 + Y(R_f - v/c)S^+$. Substituting in the expression for c in Proposition 3.4, we obtain the bound given in the main theorem. The proof of the lemma is complete. □

Proof of the main theorem. First by Lemma 5.1, $(S_\varepsilon, A_\varepsilon, M_\varepsilon) \to (S, A, M)$ in C^1_{loc}. We want to show that S decays to zero as $\xi \to -\infty$ (as we showed previously in Corollary 3.2). We see that the upper bound for S_ε on $\xi \le 0$ depends on r_2 which in turn depends on $\eta_2(d, \varepsilon)$. We recall from Proposition 3.2 that η_2 is a lower bound for R_s/S_ε. Therefore, we can improve this lower bound by substituting in the upper bound for M_ε as given in Lemma 5.1. Then we have for $\varepsilon \in [0, 1]$,

$$\eta = \frac{M_0 \theta}{(1 + M_0 + Y(R_f - \frac{v}{c})S^+)(1 + S^+)(1 + A_-)} \le \eta_2^\varepsilon \le \frac{R_s^\varepsilon}{S_\varepsilon}. \tag{5.3}$$

We establish an upper bound for S_ε on the negative real line by following the proof of Corollary 3.2. In this way, we find a bound which is independent of ε and as such, $S_\varepsilon \to S$ and in the limit $\xi \to -\infty$ decays to zero.

We must also establish that $\liminf_{\varepsilon \to 0} S_\varepsilon(0) > 0$ so that the derivatives for S, A tend to zero at infinity. Following the proof of Lemma 3.3, we can derive the analogous inequality

$$0 \ge S^+ - \frac{\theta_0 \delta_2}{\gamma \delta_1}. \tag{5.4}$$

Since all these constants are independent of ε, θ_0 can be chosen small enough so that the right-hand side is positive without being dependent on ε. Thus the bound holds, and so $S(0) > 0$.

As such, it is easy to deduce that the second part of Corollary 3.2 can be reproduced independent of ε. The first inequality of Corollary 3.2 follows with β_1 independent of ε. Given the results of Lemma 5.1, and because $S(0) > 0$, we have that $\eta_1 > 0$ independent of ε. Therefore, $\lim_{\xi\to-\infty} S = 0$. Similarly, as $\xi \to \infty$, A decays to zero.

Next, we reproduce Lemma 4.1 to find the decay properties of M near infinity. We begin by improving the upper bound of R_s^ε in Lemma 4.1. We see that by Lemma 5.1,

$$R_s^\varepsilon \le \left(M_0 + Y\left(R_f - \frac{v}{c}\right)S^+\right)\theta e^{-\beta_1\xi}. \tag{5.5}$$

We construct an upper solution $\overline{m}_\varepsilon$ to $m_\varepsilon = M_\varepsilon - M_0$ on $[\xi_1, \infty]$ which solves

$$\begin{aligned} &\varepsilon\overline{m}_\varepsilon'' + c\overline{m}_\varepsilon' - b\overline{m}_\varepsilon = -Y\left(M_0 + Y\left(R_f - \frac{v}{c}\right)S^+\right)\theta e^{-\beta_1\xi}, \\ &\overline{m}_\varepsilon(\xi_1) \ge m_\varepsilon(\xi_1) > 0. \end{aligned} \tag{5.6}$$

The solution to (5.6) is

$$\overline{m}_\varepsilon = -y_1\frac{Y(M_0 + Y(R_f - \frac{v}{c})S^+)\theta e^{-\beta_1\xi}}{\varepsilon\beta_1^2 - c\beta_1 - b}, \tag{5.7}$$

where $0 < \beta_1 \le \frac{c-v+\sqrt{(v-c)^2+4D\eta_1}}{2D}$ and y_1 is a positive constant chosen so that the inequality in (5.6) holds at ξ_1. In the limit as $\varepsilon \to 0$,

$$\overline{m}_\varepsilon \to y_1\frac{Y(M_0 + Y(R_f - \frac{v}{c})S^+)\theta e^{-\beta_1\xi}}{(c\beta_1 + b)} \equiv \overline{m}_0. \tag{5.8}$$

Thus, in the limit $\xi \to +\infty$, we have that $\overline{m}_0 \to 0$, which implies that $m(\xi) \to 0$ as $\xi \to +\infty$ or $\lim_{\xi\to+\infty} M(\xi) = M_0$. Similarly, $\lim_{\xi\to-\infty} M(\xi) = M_0$.

Justifying the limits $\lim_{\xi\to-\infty} A = A_-$ and $\lim_{\xi\to+\infty} S = S^+$ as in the proof of Theorem 4.1, we have shown that the limiting functions (S, A, M, c) are traveling wave solutions satisfying all the boundary conditions.

Finally, we establish the strict inequalities for the wave profiles. By the strong elliptic maximum principle, $0 < S(\xi) < S^+$, and $0 < A(\xi) < A_-$ for any finite ξ. If $M(\xi_1) = M_0$, for a finite ξ_1, then $M'(\xi_1) = 0$. The M equation evaluated at $\xi = \xi_1$ cannot hold thanks to $S(\xi_1)A(\xi_1) > 0$. Hence, $M(\xi) > M_0$ for any finite ξ.

If $A'(\xi_2) = 0$ for a finite ξ_2, then by the A equation evaluated at $\xi = \xi_2$, we see that $A''(\xi_2) = \gamma R_s(\xi_2) > 0$. It follows that ξ_2 is a local minimal point, which contradicts the fact that A is monotone decreasing. Hence, $A' < 0$ for any finite ξ. Similarly, $S' > 0$, for any finite ξ. The proof of the main theorem is complete.

6. Existence of traveling waves in the zero-diffusion model. In this section, we prove Theorem 1.2. We have already shown that traveling wave solutions exist to (1.1)–(1.3) for $D > 0$. For the case when $D = 0$, the equations are reduced to first order. Using the conserved quantity, $\gamma R_f S - A$, and defining the new variables, $u = \gamma R_f S - A$ and $w = \gamma S - A$, (1.1)–(1.3) are transformed into conservative form

$$u_t + vw_x = 0, \tag{6.1}$$

$$w_t + v/R_f((R+1)w-u)_x = \varepsilon(u-R_f w)(u-w)/G, \tag{6.2}$$

$$M_t - b(M-M_0) = \frac{YM(u-R_f w)(u-w)}{\gamma(R-1)^2 K_S K_A G}, \tag{6.3}$$

where $\varepsilon = R_f^{-1}(R_f-1)^{-1}(K_A K_S)^{-1}$, and $G(A,S) = (1+K_A^{-1}A)(1+K_S^{-1}S)$. When rewritten in the traveling wave variable, ξ, (6.1) becomes $u_\xi = (v/c)w_\xi$. This relationship restricts the flow in the phase space to two-dimensional planes. The two-by-two dynamical system is then

$$w_\xi = -\frac{R_f\varepsilon(A_- + \gamma R_f S^+)(w-\gamma S)(w+A_-)M}{v(A_- + \gamma S^+)G},$$
$$M_\xi = \frac{b(A_- + \gamma R_f S^+)(M-M_0)}{v(A_- + \gamma S^+)} + \frac{YA_- S^+(A_- + \gamma R_f S^+)(w-\gamma S)(w+A_-)M}{v(A_- + \gamma S^+)^3 K_S K_A G}.$$

There are two equilibrium points in the phase plane (w, M): $(\gamma S^+, M_0)$ and $(-A_-, M_0)$. The eigenvalues governing the flow near $(\gamma S^+, M_0)$ are

$$\lambda_1 = \frac{b(A_- + \gamma R_f S^+)}{v(A_- + \gamma S^+)} > 0 \quad \text{and} \quad \lambda_2 = \frac{-R_f\varepsilon(A_- + \gamma R_f S^+)}{v} < 0.$$

The eigenvalues for the flow near $(-A_-, M_0)$ are both positive. Thus, $(\gamma S^+, M_0)$ is a saddle point and $(-A_-, M_0)$ is an unstable node. In order to have a traveling wave solution, at least one of the unstable manifolds emanating from the point $(-A_-, M_0)$ must intersect the two-dimensional stable manifold of $(\gamma S^+, M_0)$. It is straightforward to show that there is a unique path between the two equilibrium points. Thus, the proof of Theorem 1.2 is complete.

Acknowledgments. The authors would like to thank A. Valocchi and S. Oya for communicating their work in progress and the preprint of their paper [8]. J. X. Xin would like to thank Y. Oono for kindly introducing him to the biodegradation model studied in this paper. Both authors wish to thank J. Hyman and B. Travis of the Los Alamos National Laboratory for their interest in this work. The authors also wish to thank M. Brusseau and L. Xie for their constructive comments.

SHOCK WAVES FOR A MODEL SYSTEM OF THE RADIATING GAS*

SHUICHI KAWASHIMA† AND SHINYA NISHIBATA‡

Abstract. This paper is concerned with the existence and the asymptotic stability of traveling waves for a model system derived from approximating the one-dimensional system of the radiating gas. We show the existence of smooth or discontinuous traveling waves and also prove the uniqueness of these traveling waves under the entropy condition, in the class of piecewise smooth functions with the first kind discontinuities. Furthermore, we show that the C^3-smooth traveling waves are asymptotically stable and that the rate of convergence toward these waves is $t^{-1/4}$, which looks optimal. The proof of stability is given by applying the standard energy method to the integrated equation of the original one.

Key words. shock wave, traveling wave, radiating gas, asymptotic stability, energy method

1. Introduction.

Consider the system of equations

$$u_t + uu_x + q_x = 0 \tag{1.1a}$$

and

$$-q_{xx} + q + u_x = 0 \tag{1.1b}$$

for $x \in \mathbf{R}$ and $t \geq 0$. The first equation is a hyperbolic conservation law and the second is an elliptic equation. As the second equation is a linear elliptic equation, we express q in terms of u formally as

$$q = -Ku_x, \tag{1.2}$$

where K is the inverse of the operator $-\frac{d^2}{dx^2} + 1$ and has the expression

$$(Kf)(x) = \frac{1}{2}\int_{-\infty}^{\infty} e^{-|x-y|} f(y)dy. \tag{1.3}$$

Since (1.2), we have formally that

$$q_x = -Ku_{xx} = u - Ku. \tag{1.4}$$

Thus we see that (1.1) is formally equivalent to the following:

$$u_t + uu_x + u - Ku = 0 \tag{1.5a}$$

and

$$q = -Ku_x. \tag{1.5b}$$

We are concerned with the traveling wave solution of (1.1), which is expressed in the form $(u, q)(x, t) = (U, Q)(\xi)(\xi = x - st)$, where s is a constant called the speed of the traveling wave. We assume that the traveling wave connects the asymptotic state u_+ and u_-, i.e.,

$$u_\pm = \lim_{\xi \to \pm\infty} U(\xi). \tag{1.6}$$

Substituting $(u, q)(x, t) = (U, Q)(\xi)$ in (1.1), we have

$$-sU^{'} + UU^{'} + Q^{'} = 0 \tag{1.7a}$$

and

$$-Q^{''} + Q + U^{'} = 0. \tag{1.7b}$$

This system of autonomous ordinary differential equations (ODEs) does not have classical solutions satisfying (1.6) when the shock $|u_+ - u_-|$ is large (see section 2). So we must look for the solutions in weak sense, which is defined as $(U, Q)(\xi)$ satisfying the following integral equations.

DEFINITION 1.1. *We define an admissible traveling wave $(U, Q)(\xi)$ as a function $(U, Q) \in L^\infty$ which satisfies*

(D.1a)
$$\int_{-\infty}^{+\infty} -s|U-k|\varphi_\xi + sign(U-k)\left(\frac{1}{2}U^2 - \frac{1}{2}k^2\right)\varphi_\xi - sign(U-k)(U-KU)\varphi d\xi \geq 0$$

and

$$\int_{-\infty}^{+\infty} Q\psi d\xi = \int_{-\infty}^{+\infty} (KU)\psi_\xi d\xi \tag{D.1b}$$

for arbitrary $\varphi \in C_0^\infty$ with $\varphi(\xi) \geq 0$, arbitrary $\psi \in \mathcal{S}$, and arbitrary real number k. Here the function sign is defined as

$$sign(x) = \begin{cases} -1 & for \;\; x < 0, \\ 0 & for \;\; x = 0, \\ 1 & for \;\; x > 0. \end{cases} \tag{1.8}$$

Here we note that this definition corresponds to the equivalent system (1.5). In order to make the above definition of the admissible traveling waves clear, we introduce different definitions of traveling waves here.

DEFINITION 1.2. *We define a traveling wave $(U, Q)(\xi)$ as a function $(U, Q) \in L^\infty$ which satisfies*

$$\int_{-\infty}^{+\infty} \left(-sU + \frac{1}{2}U^2\right)\varphi_\xi - (U - KU)\varphi d\xi = 0 \tag{D.2}$$

and the equation (D.1b) *for arbitrary $\varphi \in C_0^\infty$ and arbitrary $\psi \in \mathcal{S}$.*

DEFINITION 1.3. *We define a traveling wave* $(U,Q)(\xi)$ *as a function* $(U,Q)\in L^\infty$ *which satisfies*

$$\int_{-\infty}^{+\infty}\left(-sU+\frac{1}{2}U^2+Q\right)\varphi_\xi d\xi=0 \tag{D.3a}$$

and

$$\int_{-\infty}^{+\infty}Q(-\psi_{\xi\xi}+\psi)-U\psi_\xi d\xi=0 \tag{D.3b}$$

for arbitrary $\varphi\in C_0^\infty$ *and arbitrary* $\psi\in\mathcal{S}$.

Obviously, Definitions 1.2 and 1.3 correspond to the systems (1.5) and (1.1), respectively.

When the traveling wave $(U,Q)(\xi)$ has discontinuities of the first kind, we denote the right state of each discontinuity by (u_r,q_r) and the left state by (u_l,q_l), respectively. Also, we denote by (u_r',q_r') and (u_l',q_l') the right and the left states of $(U',Q')(\xi)$, respectively. The following proposition makes the relationship among definitions of traveling waves clear.

PROPOSITION 1.4. (i) *Definitions of traveling waves in Definitions* 1.2 *and* 1.3 *are equivalent to each other. If the traveling wave* $(U,Q)(\xi)$, $\xi=x-st$, *is a piecewise smooth function with the first kind discontinuities, it satisfies the Rankine–Hugoniot condition*

$$s(u_r-u_l)=\frac{1}{2}({u_r}^2-{u_l}^2)\left(i.e.,\quad s=\frac{u_r+u_l}{2}\right), \tag{1.9a}$$

$$q_r=q_l, \tag{1.9b}$$

and

$$u_r-q_r^{'}=u_l-q_l^{'} \tag{1.9c}$$

at each discontinuity.

(ii) *Admissible traveling waves in the sense of Definition* 1.1 *are traveling waves in the sense of Definition* 1.2 *(or in the sense of Definition* 1.3*). If the admissible traveling wave is a piecewise smooth function with the first kind discontinuities, it satisfies not only the Rankine–Hugoniot condition* (1.9) *but also an entropy condition*

$$u_r<u_l \tag{1.10}$$

at each discontinuity.

(iii) *Suppose that the traveling wave* $(U,Q)(\xi)$ *in the sense of Definition* 1.2 *(or in the sense of Definition* 1.3*) is a piecewise smooth function with the first kind discontinuities and satisfies the entropy condition* (1.10) *at each discontinuity. Then* $(U,Q)(\xi)$ *is an admissible traveling wave in the sense of Definition* 1.1.

The proof of the previous proposition will be given in section 2. Here we note that (1.9b) implies the continuity of $Q(\xi)$. More precisely, it is shown in section 2 that $Q(\xi)$ is Lipschitz continuous even in the case where $U(\xi)$ has discontinuities. Also note that the entropy condition (1.10) is just the same as the one for the Burgers equation

$$u_t+uu_x=0.$$

By virtue of the entropy condition, when $u_+ < u_-$, we obtain the unique existence of a (discontinuous) traveling wave in the class of piecewise smooth functions whose discontinuities are of the first kind. This result can be stated as follows.

THEOREM 1.5.

(i) *Suppose that there exists an admissible traveling wave* $(U, Q)(x - st)$ *which satisfies the asymptotic condition* (1.6) *and is a piecewise smooth function with the first kind discontinuities. Then we have*

$$u_+ < u_-, \qquad s = \frac{1}{2}(u_+ + u_-) \tag{1.11}$$

and

$$\lim_{\xi \to \pm\infty} Q(\xi) = 0. \tag{1.12}$$

(ii) *Conversely, we suppose that* (1.11) *holds. Then there exists an admissible traveling wave* $(U, Q)(x - st)$ *satisfying* (1.6) *and* (1.12). *This admissible traveling wave is unique up to a shift in the class of piecewise smooth functions with the first kind discontinuities.*

(a) *When* $|u_+ - u_-| > \sqrt{2}$, $U(\xi)$ *is continuous except for one point, while* $Q(\xi)$ *is Lipschitz continuous. The conditions* (1.9), (1.10), *and* $u_r' = u_l' = -1$ *hold at the discontinuity of* $U(\xi)$.

(b) *If* $|u_+ - u_-| \le \sqrt{2}$, *then* $U(\xi)$ *is in* B^1 *and* $Q(\xi)$ *is in* B^2.

(c) *If* $|u_+ - u_-| < \frac{2\sqrt{2n}}{n+1}$, *then* $U(\xi)$ *is in* B^n *and* $Q(\xi)$ *is in* B^{n+1}, *where* $n = 2, 3, \ldots$.

Thus, when the shock strength $|u_+ - u_-|$ is less than or equal to $\sqrt{2}$, we have the C^1-smooth traveling waves. In proving the stability theorem in section 3, we require that $|u_+ - u_-| \le \frac{\sqrt{6}}{2}$ to make traveling waves C^3-smooth. In order to state the stability theorem, we define the function $(\phi, \psi)(x, t)$, expressing the perturbation from the traveling wave:

$$\phi(x, t) = u(x, t) - U(x - st) \tag{1.13a}$$

and

$$\psi(x, t) = q(x, t) - Q(x - st). \tag{1.13b}$$

As (u, q) and (U, Q) are solutions of (1.1), (ϕ, ψ) satisfies

$$\phi_t + \left(U\phi + \frac{1}{2}\phi^2\right)_x + \psi_x = 0, \tag{1.14a}$$

$$-\psi_{xx} + \psi + \phi_x = 0. \tag{1.14b}$$

We solve the above equations under the initial condition

$$\phi(x, 0) = \phi_0(x) \equiv u_0(x) - U(x), \tag{1.15}$$

where without loss of generality, we may assume that

$$\int_{-\infty}^{\infty} \phi_0(x)dx = 0. \tag{1.16}$$

In section 3, we prove the contraction property in L^1 that if $\phi_0 \in L^1$, then $\phi(\cdot,t) \in L^1$ and $|\phi(\cdot,t)|_1 \le |\phi_0|_1$ for each $t > 0$ (see Lemma 3.1). Based on this property, we define the integrated function Φ of ϕ as

$$\Phi(x,t) = \int_{-\infty}^{x} \phi(y,t)dy \tag{1.17}$$

and put

$$\Phi_0(x) = \int_{-\infty}^{x} \phi_0(y)dy. \tag{1.18}$$

The function Φ satisfies the following equation that is derived by integrating (1.14a) on the interval $(-\infty, x]$:

$$\Phi_t + U\Phi_x + \frac{1}{2}\Phi_x^2 + \psi = 0. \tag{1.19}$$

Now we state the stability result.

THEOREM 1.6. (i) *Let $u_+ < u_-$ and suppose that $|u_- - u_+| < \frac{\sqrt{6}}{2}$. Suppose also that $\phi_0 \in L^1 \cap H^2$ and $\Phi_0 \in L^2$. If $\|\Phi_0\|_3$ is sufficiently small, then the initial value problem* (1.14), (1.15) *has a unique global solution (ϕ, ψ) satisfying*

$$\lim_{t\to\infty} |(\phi,\psi)(\cdot,t)|_\infty = 0. \tag{1.20}$$

(ii) *In addition to the assumption of* (i)*, we suppose that $\Phi_0 \in L^1$. Then*

$$|(\phi,\psi)(\cdot,t)|_\infty = O(t^{-\frac{1}{4}}) \quad as \quad t \longrightarrow \infty. \tag{1.21}$$

The proof of the above theorem follows from the local existence theorem (Proposition 1.7) and a priori estimates (Propositions 1.8 and 1.9). As Proposition 1.7 is proved by the standard iteration method, we omit the proof. The derivation of the a priori estimates are given in section 3.

PROPOSITION 1.7. *Suppose that $U \in B^3$ and $\phi_0 \in H^2$. Then there exists a positive constant T_0, depending only on $\|\phi_0\|_2$, such that* (1.14), (1.15) *has a unique solution (ϕ, ψ) satisfying*

$$\phi \in C^0([0,T_0]; H^2) \cap C^1([0,T_0]; H^1) \tag{1.22a}$$

and

$$\psi \in C^0([0,T_0]; H^3). \tag{1.22b}$$

Furthermore, if $\phi_0 \in L^1$, then the solution verifies

$$\phi \in C^0([0,T_0]; L^1). \tag{1.22c}$$

By virtue of (1.22c), Φ is well defined by (1.17) and satisfies $\Phi \in C^0([0,T_0]; L^2)$ (and hence $\Phi \in C^0([0,T_0]; H^3)$), provided that $\Phi_0 \in L^2$. In this case our solution verifies

$$\|(\Phi,\psi)(t)\|_3 \le C\|\Phi_0\|_3 \quad \text{for} \quad t \in [0,T_0]. \tag{1.23}$$

We denote the supremum in time of the H^3 norm of Φ by N:

$$N(t) = \sup_{0\le\tau\le t} \|\Phi(\cdot,\tau)\|_3. \tag{1.24}$$

PROPOSITION 1.8. *Suppose that the assumptions of* (i) *in Theorem* 1.6 *holds. Let* $T > 0$ *and let* (ϕ,ψ) *be a solution of the problem* (1.14), (1.15), *which satisfies* (1.22) *with* T_0 *replaced by* T. *Then* $\Phi \in C^0([0,T];H^3)$. *Moreover, if* $N(T)$ *is so small that* $N(T) \le \frac{1}{10}$, *then we have the uniform estimate:*

$$\|(\Phi,\psi)(t)\|_3^2 + \int_0^t \|\phi(\tau)\|_2^2 + \|\psi(\tau)\|_3^2 d\tau + \int_0^t\int_{-\infty}^{\infty} |U_x|\Phi^2 dx\, d\tau \le C\|\Phi_0\|_3^2 \tag{1.25}$$

for $t \in [0,T]$, *where* C *is a positive constant independent of* T.

PROPOSITION 1.9. *Suppose that the assumptions of* (ii) *in Theorem* 1.6 *hold. Let* (ϕ,ψ) *be the global solution obtained in* (i) *of Theorem* 1.6. *Then we have the decay estimate:*

$$\|(\Phi,\psi)(t)\|_3 \le C(|\Phi_0|_1 + \|\Phi_0\|_3)(1+t)^{-1/4} \tag{1.26}$$

for $t \ge 0$.

Known results and outline of the paper. The system of equations (1.1) is derived as the third-order approximation of the full system describing the motion of radiating gas in thermo-nonequilibrium, while the second-order approximation gives the viscous Burgers equation $u_t + uu_x = u_{xx}$, and the first-order approximation gives the inviscid Burgers equation $u_t + uu_x = 0$. Hamer [3] studied these equations in the physical respect, especially for the steady progressive shock-wave solutions. Mathematically, Kawashima and Tanaka started the research of (1.1) in [6], which proved the local existence and uniqueness of the smooth solutions. Furthermore, under suitable conditions, [6] proved the global existence of smooth solutions and observed the asymptotic behaviors in the two cases $u_- = u_+$ and $u_- < u_+$. The first case gives diffusion waves which correspond to the viscous Burgers equation, while the second one gives rarefaction waves corresponding to the inviscid Burgers equation. On the other hand, Ito [4] proved the uniqueness and global existence of weak solutions in the space of functions of bounded variation. He also discussed the stability of rarefaction waves. These results in [6] and [4] indicate to us that the time asymptotic behavior for (1.1) is closely related to the one for the Burgers equation.

The purpose of this paper is to investigate the case $u_- > u_+$ for the same system. We will show the existence and stability of the traveling waves. It turns out that the condition $u_- > u_+$ is the necessary and sufficient condition to ensure the existence of traveling waves in weak sense. The magnitude of the quantity $|u_- - u_+|$ is shown to give information on the smoothness of the traveling waves. To obtain the smooth traveling waves, the condition $|u_- - u_+| \ll 1$ is required. The smaller $|u_- - u_+|$ gets, the smoother the traveling waves become. These phenomena are newly found by the authors. Although the discontinuous traveling waves are found and discussed in [8] and [10] for the relaxation models, these waves are C^∞ when they are differentiable. The phenomena mentioned above can occur because the viscosity derived from the elliptic equation (1.1b) is relatively weak, compared to that of the viscous conservation laws. However, when $|u_- - u_+|$ is small, the term q_{xx} in (1.1b) becomes small and our system (1.1) is well approximated by the viscous Burgers equation.

Furthermore, we prove the stability theorem which asserts that C^3-smooth traveling waves are time asymptotically stable, assuming that the antiderivative of the

initial perturbation is small in the Sobolev space H^3. Also, we obtain the convergence rate $t^{-1/4}$. The rate looks optimal, compared to the result given for the viscous Burgers equation.

The plan of this paper is as follows. After introducing the notations, we discuss the properties of traveling waves in section 2. In section 3, we give the proofs of the stability results. In section 2, we first discuss the unique existence of (discontinuous) traveling waves. The entropy condition (1.10), which is derived from Definition 1.1, play the essential role. Then we give necessary and sufficient conditions for making traveling waves differentiable. Furthermore, we show that the order of differentiability is determined by the shock strength $|u_- - u_+|$.

In section 3, we give the proof of stability theorem by proving the propositions in the case that $|u_- - u_+| < \frac{\sqrt{6}}{2}$ and the antiderivative of initial perturbation is small in the Sobolev space H^3. These results are given by applying the standard energy method not only to the system (1.14) but also to the integrated equation (1.19). The decay estimate is also given by the energy method which makes use of a time weight function.

Notations. For an integer $k \geq 0$, we denote by C^k the space of k-times continuously differentiable functions on $\mathbf{R}$. B^k denotes the space of C^k-functions whose derivatives up to order k are bounded. For $1 \leq p \leq \infty$, L^p denotes the usual Lebesgue space over $\mathbf{R}$ with the norm $|\cdot|_p$. For arbitrary integer $l \geq 0$, H^l denotes the lth order Sobolev space in the L^2-sense, equipped with the norm $\|\cdot\|_l$. We note $H^0 = L^2$ and $\|\cdot\|_0 = |\cdot|_2 \equiv \|\cdot\|$. We also denote by $C^k(I; H^l)$ the space of k-times continuously differentiable functions on the interval I with values in H^l.

We denote by $\mathcal{S}$ the space of all rapidly decreasing functions on $\mathbf{R}$. Also, ${C_0}^\infty$ denotes the space of C^∞-functions on $\mathbf{R}$, having compact supports.

Finally, by C or c we denote several constants without confusion.

2. Traveling waves. In this section we analyze the traveling waves. At first we discuss the properties of the traveling waves in weak sense to prove Proposition 1.4.

Traveling waves in weak sense (proof of Proposition 1.4). In this subsection we investigate definitions of traveling waves in weak sense. As we see function as distributions, we abbreviate that

$$\langle f, g \rangle = \int_{-\infty}^{+\infty} f g d\xi.$$

By direct calculation, it follows that the linear operator K in (1.3) is symmetric in the following sense.

LEMMA 2.1. *If $\psi \in \mathcal{S}$, then $K\psi \in \mathcal{S}$ and*

$$\langle KU, \psi \rangle = \langle U, K\psi \rangle$$

for arbitrary $U \in L^\infty$.

Proof of Proposition 1.4 (i). Assuming $(U, Q) \in L^\infty$ is a traveling wave in the sense of Definition 1.2, we have from (D.1b) that

$$\langle Q, \psi_\xi \rangle = \langle KU, \psi_{\xi\xi} \rangle = -\langle U - KU, \psi \rangle. \tag{2.1}$$

In deriving this equation, we used Lemma 2.1 and the equality $K\psi_{\xi\xi} = -(\psi - K\psi)$. By substituting (2.1) with $\psi = \phi \in C_0^\infty$ in (D.2), (D.3a) follows immediately.

By (2.1) and (D.1b),

$$\begin{aligned}\langle Q, -\psi_{\xi\xi} + \psi\rangle &= -\langle Q, \psi_{\xi\xi}\rangle + \langle Q, \psi\rangle \\ &= \langle U - KU, \psi_\xi\rangle + \langle KU, \psi_\xi\rangle \\ &= \langle U, \psi_\xi\rangle.\end{aligned} \tag{2.2}$$

This equation is (D.3b).

Next we assume that $(U, Q) \in L^\infty$ is a traveling wave in the sense of Definition 1.3. Let $\hat{\psi} = K\psi$ for arbitrary $\psi \in \mathcal{S}$. As $\psi = -\hat{\psi}_{\xi\xi} + \hat{\psi}$,

$$\begin{aligned}\langle Q, \psi\rangle &= \langle Q, -\hat{\psi}_{\xi\xi} + \hat{\psi}\rangle \\ &= \langle U, \hat{\psi}_\xi\rangle \\ &= \langle U, K\psi_\xi\rangle \\ &= \langle KU, \psi_\xi\rangle,\end{aligned} \tag{2.3}$$

where we used (D.3b) and Lemma 2.1. Thus we proved (D.1b). Noting that (D.1b) implies (2.1), we substitute (2.1) with $\psi = \phi \in {C_0}^\infty$ in (D.3a) to obtain (D.2). This proves the equivalence between Definitions 1.2 and 1.3.

The Rankine–Hugoniot condition (1.9) is proved by the standard computation employed in deriving the condition for the inviscid conservation laws. □

Let us note that $Q(\xi)$ for arbitrary traveling wave $(U, Q) \in L^\infty$ in the weak sense is not only continuous but also Lipschitz continuous because (2.1) implies $Q_\xi = U - KU \in L^\infty$.

Proof of Proposition 1.4 (ii) *and* (iii). As the first statement is apparent, we only prove the second statement of (ii) here. Let us assume that $(U, Q) \in L^\infty$ is an admissible traveling wave in the sense of Definition 1.1 and is a piecewise smooth function with the first kind discontinuities. Let $\{a_i; i = 1 \cdots N\}$ be the set of the discontinuous points of U contained in the support of $\varphi \in {C_0}^\infty$ with $\varphi \geq 0$. Also we denote by $u_{i,l}$ and $u_{i,r}$ the left and right limits of U at a_i, respectively. Since (U, Q) solves (D.2) and (D.1a), we see that (U, Q) satisfies the Rankine–Hugoniot condition (1.9) at each a_i and also the differential equations

$$-sU' + UU' + U - KU = 0 \tag{2.4a}$$

and

$$-Q'' + Q + U' = 0 \tag{2.4b}$$

on $\mathrm{supp}[\varphi] \setminus \{a_i\}$. Now the direct calculation using (1.9), (2.4a) shows that

$$\begin{aligned}\text{left-hand side of (D.1a)} = \frac{1}{2}\sum_i \{&sign(k - u_{i,r}) \\ &+ sign(u_{i,l} - k)\}\varphi(a_i)(k - u_{i,r})(u_{i,l} - k).\end{aligned} \tag{2.5}$$

In the above summation the suffix i runs over the set $\{i; u_{i,l} < k < u_{i,r}$ or $u_{i,l} > k > u_{i,r}\}$. Thus the entropy condition $u_{i,r} < u_{i,l}$ follows immediately from the observation using (2.5). The conclusion of (iii) follows from (i) and (2.5). The details are omitted. □

Existence of traveling waves (proof of Theorem 1.5). Here and after we look for the admissible traveling waves satisfying (1.6) in the class of piecewise smooth functions with the first kind discontinuities.

At first we suppose that there exists such an admissible traveling wave $(U,Q)(\xi)$. Integrating (1.7a) over the interval $[\xi,\xi']$, we have that

$$-sU(\xi)+\frac{1}{2}U(\xi)^2+Q(\xi)=-sU(\xi')+\frac{1}{2}U(\xi')^2+Q(\xi'). \tag{2.6}$$

Owing to the Rankine–Hugoniot conditions (1.9), the above equation holds true even if there are discontinuities in the interval $[\xi,\xi']$. Letting $\xi'\to\infty$ in (2.6) and using (1.6), we find that $Q(\xi')$ has a finite limit as $\xi'\to\infty$, which we denote by q_+. In a similar way, the limit $q_-=\lim_{\xi\to-\infty}Q(\xi)$ exists and is finite. Thus we get that

$$-sU(\xi)+\frac{1}{2}U(\xi)^2+Q(\xi)=-su_\pm+\frac{1}{2}u_\pm^2+q_\pm. \tag{2.7}$$

This equation implies that the state $(U,Q)(\xi)$ lies on the parabolic curve, which we denote by Γ, in the U-Q plane. Also we denote the apex of the curve Γ by $(\tilde{u},\tilde{q})$. Notice that $s=\tilde{u}$.

LEMMA 2.2. *If there exists a ξ_0 such that $(U,Q)(\xi)$ is differentiable for $\xi>\xi_0$ (resp., $\xi<\xi_0$), then $q_+=0$ (resp., $q_-=0$).*

Proof. We consider the case that $\xi>\xi_0$ only, since another case can be treated similarly. By (1.6),

$$u_+=\lim_{\xi\to\infty}U(\xi)=\lim_{\xi\to\infty}\frac{U(\xi)e^{-\xi}}{e^{-\xi}}=\lim_{\xi\to\infty}(U(\xi)-U'(\xi)).$$

Thus we have that $U'(\xi)\to 0$ as $\xi\to\infty$. Similarly, we see that $Q'(\xi)\to 0$ and $Q''(\xi)\to 0$ as $\xi\to\infty$. Substituting in (1.7b), we get the conclusion. ∎

Proof of Theorem 1.5 (i). It suffices to prove the following lemma.

LEMMA 2.3. (i) *$u_+<u_-$, $s=\frac{1}{2}(u_++u_-)$ and $q_\pm=0$.*

(ii) *Admissible traveling waves have at most one discontinuity.*

Proof. At first we prove that our admissible traveling waves have only finitely many discontinuities. Consider the case where $(u_+,q_+)\neq(\tilde{u},\tilde{q})$. We note that any admissible traveling wave $(U,Q)(\xi)$ laying on the curve Γ has the horizontal jump only in the U-Q plane, which goes from right to left, because it must satisfy the Rankine–Hugoniot condition (1.9b) and the entropy condition (1.10). On the other hand, the convergence (1.6) requires that $(U,Q)(\xi)$ is in a small neighborhood of (u_+,q_+) for any $\xi>R$, where R is a sufficiently large number. Since (u_+,q_+) is on the slope of Γ, we conclude that there is no discontinuity for $\xi>R$.

Similarly, if $(u_-,q_-)\neq(\tilde{u},\tilde{q})$, then there is no discontinuity for $\xi<-R$. Thus we have shown that when $(u_+,q_+)\neq(\tilde{u},\tilde{q})$ and $(u_-,q_-)\neq(\tilde{u},\tilde{q})$, the discontinuities appear only finitely many times. Consequently, applying Lemma 2.2, we have $q_\pm=0$ in this case.

Next we show that the case $(u_+,q_+)=(\tilde{u},\tilde{q})$ cannot occur by contradiction. Assume that $(u_+,q_+)=(\tilde{u},\tilde{q})$. Then $(u_-,q_-)\neq(\tilde{u},\tilde{q})$. It follows from the above consideration that there is no discontinuity for $\xi<-R$ so that $q_-=0$ by Lemma 2.2. Consequently, if we have infinitely many discontinuities, they should lie in a certain neighborhood of $(u_+,q_+)=(\tilde{u},\tilde{q})$. Since the discontinuity is a horizontal jump which goes from right to left in the U-Q plane, the point $(U,Q)(\xi)$ must move from left to right along the curve Γ, passing through the top $(\tilde{u},\tilde{q})$, as ξ increases from one jump point ξ_1 to the next one ξ_2. Therefore, there must exist a $\tilde{\xi}\in(\xi_1,\xi_2)$ such that $(U,Q)(\tilde{\xi})=(\tilde{u},\tilde{q})$. On the contrary, differentiating (1.7a) in ξ, we have that

$$Q''=(s-U)U''-(U')^2.$$

Substituting this in (1.7b) and evaluating the equation thus obtained at $\xi = \tilde{\xi}$, we find that

$$U'(\tilde{\xi}) = -U'(\tilde{\xi})^2 - \tilde{q} < 0,$$

where we used $\tilde{u} = s$ and $\tilde{q} > q_- = 0$.

This inequality implies that the point $(U, Q)(\xi)$ moves from right to left along the curve Γ around $(\tilde{u}, \tilde{q})$ as ξ increases. This is a contradiction. Therefore, we have only finitely many discontinuities and so $q_+ = 0$ by Lemma 2.2. This is a contradiction, too. Thus we have proved that the case $(u_+, q_+) = (\tilde{u}, \tilde{q})$ cannot occur. Similarly, we conclude that the case $(u_-, q_-) = (\tilde{u}, \tilde{q})$ does not happen, either.

Since $q_\pm = 0$, we have from (2.7) that $s = \frac{1}{2}(u_+ + u_-)$. Consequently, we see that $\tilde{q} = \frac{1}{8}|u_+ - u_-|^2 > 0$. By virtue of the property $\tilde{q} > 0$, we conclude that $u_+ < u_-$ by the same discussion. This proves (i). Also, employing the same discussion, we conclude that the jump can occur at most one point. The proof of the Lemma 2.3 is complete. □

Putting $s = \frac{1}{2}(u_+ + u_-)$ and $q_\pm = 0$ in (2.7), we can express Q in terms of U:

$$Q = -\frac{1}{2}(U - u_+)(U - u_-). \tag{2.8}$$

Substituting this in equation (1.7b), we have the second-order ordinary differential equation:

$$\left(U - \frac{u_+ + u_-}{2}\right) U'' + (U')^2 - \frac{1}{2}(U - u_+)(U - u_-) + U' = 0. \tag{2.9}$$

To simplify the equation, we change the dependent variable as $\hat{U} = U - \frac{u_+ + u_-}{2}$. Denoting this new variable $\hat{U}$ by U without confusion, we get the following system of the first-order ordinary differential equations:

$$\begin{pmatrix} U \\ V \end{pmatrix}' = \begin{pmatrix} V \\ -\frac{V^2 + V - \frac{1}{2}(U^2 - \alpha^2)}{U} \end{pmatrix}, \tag{2.10}$$

where $\alpha = \frac{|u_+ - u_-|}{2}$. Since $u_+ < u_-$, the asymptotic condition (1.6) is rewritten as

$$\lim_{\xi \to \pm\infty} (U, V)(\xi) = (\mp\alpha, 0). \tag{2.11}$$

We have to look for solutions of (2.10) under the condition (2.11). We denote by O the orbit of the solutions $(U, Q)(\xi)$ of (2.10), (2.11). Also we define the parabolic curve P in the U-V plane by

$$P = \left\{ (U, V); V^2 + V - \frac{1}{2}(U^2 - \alpha^2) = 0 \right\}. \tag{2.12}$$

By algebraic calculation, we know that the curve P intersects with the line $U = 0$ at the point $(0, v_0)$, where

$$v_0 = \frac{-1 + \sqrt{1 - 2\alpha^2}}{2}, \tag{2.13}$$

provided that $\alpha \le \frac{\sqrt{2}}{2}$, i.e., $|u_+ - u_-| \le \sqrt{2}$.

Otherwise, P does not meet the line $U = 0$.

The equilibrium points of (2.10) are $(\pm\alpha, 0)$. The Jacobian matrix of the vector on the right-hand side of (2.10), evaluated at $(\pm\alpha, 0)$, is

$$A_{\pm} = \begin{pmatrix} 0 & 1 \\ 1 & \mp\frac{1}{\alpha} \end{pmatrix}. \tag{2.14}$$

The eigenvalues of A_+ are

$$\mu_1 = \frac{-1+\sqrt{1+4\alpha^2}}{2\alpha} > 0, \quad \mu_2 = \frac{-1-\sqrt{1+4\alpha^2}}{2\alpha} < 0. \tag{2.15}$$

Thus $(\alpha, 0)$ is a saddle point. Similarly, another equilibrium point $(-\alpha, 0)$ is a saddle point, too.

LEMMA 2.4. *The trajectory O of solutions to* (2.10), (2.11) *is symmetric with respect to the line $U = 0$ in the U-V plane.*

Proof. Let $(U, V)(\xi)$ be a solution of (2.10) in a neighborhood of $\xi = \infty$ and satisfy the asymptotic condition (2.11) for $\xi \to \infty$. Then the function defined by

$$(\hat{U}, \hat{Q})(\xi) = (-U, Q)(-\xi)$$

is a solution of (2.10) around $\xi = -\infty$ and satisfies (2.11) for $\xi \to -\infty$. Since the equilibrium points $(\pm\alpha, 0)$ are saddle points, the conclusion follows easily. □

Lemma 2.4 and its proof show that if the shift in ξ is chosen appropriately, then U is an odd function and V is an even function with respect to ξ. Hence, it is enough to consider the case $U > 0$.

Next, comparing the eigenvector $(1, \mu_1)$ (row vector) of A_+ for μ_1 and the tangent of P, we have the following relation between the trajectory O and the curve P.

LEMMA 2.5. (i) *The trajectory O and the parabolic curve P do not intersect except for the points* $(\pm\alpha, 0)$ *and* $(0, v_0)$.

(ii) *The trajectory O is located above the curve P in the U-V plane.*

The above lemma implies that when $U > 0$, U and V are strictly decreasing functions of ξ.

Proof of Theorem 1.5 (ii-a). At first we prove that any admissible traveling wave satisfies

$$u'_r = u'_l = -1 \tag{2.16}$$

at each discontinuity. Let us consider the original dependent variable $(U, Q)(\xi)$. We have from (1.7a) that $q'_r = (s - u_r)u'_r$ and $q'_l = (s - u_l)u'_l$. Substituting these relations in (1.9c) and using $s = \frac{1}{2}(u_r + u_l)$, we see that

$$(u_l - u_r)\left(1 + \frac{1}{2}(u_l' + u_r')\right) = 0.$$

Since $u_l' = u_r'$ by Lemma 2.4, we have (2.16).

From now on we again write U in place of $U - \frac{1}{2}(u_+ + u_-)$. Consider the case where $|u_+ - u_-| > \sqrt{2}$. In this case the trajectory O goes to $-\infty$ as U goes to zero, and therefore any continuous traveling wave does not exist. But it is possible to connect the trajectory sprung from $(\alpha, 0)$ in $U > 0$ and the one from $(-\alpha, 0)$ in $U < 0$ by the horizontal jump between the two points (u_r, v_r) and (u_l, v_l). We require that

$$v_r = v_l = -1,$$

which ensures (2.16). As this jump satisfies the Rankine–Hugoniot condition (1.9) and the entropy condition (1.10) apparently, a discontinuous traveling wave exits. Thus we complete the proof of Theorem 1.5 (ii-a) with the fact that Q is Lipschitz continuous proved in the previous subsection. □

In order to obtain smooth traveling waves, we make a change of the independent variable as

$$U\frac{d}{d\xi} = \frac{d}{d\eta}$$

and transform (2.10) into

$$\frac{d}{d\eta}\begin{pmatrix} U \\ V \end{pmatrix} = \begin{pmatrix} UV \\ -V^2 - V + \frac{1}{2}(U^2 - \alpha^2) \end{pmatrix}. \tag{2.17}$$

This system has equilibrium points, $(\pm\alpha, 0)$ and $(0, v_0)$. The Jacobian matrix of the vector on the right-hand side of (2.17), evaluated at $(0, v_0)$, is given by

$$A = \begin{pmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{pmatrix}, \tag{2.18}$$

where

$$\lambda_1 = \frac{-1 + \sqrt{1 - 2\alpha^2}}{2} \equiv v_0 < 0 \quad \text{and} \quad \lambda_2 = -\sqrt{1 - 2\alpha^2} < 0. \tag{2.19}$$

The eigenvectors corresponding to λ_1 and λ_2 are

$$e_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \text{and} \quad e_2 = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \tag{2.20}$$

respectively.

Proof of Theorem 1.5 (ii-b). Let $|u_+ - u_-| \le \sqrt{2}$, i.e., $\alpha \le \frac{\sqrt{2}}{2}$. By the standard phase plane analysis, it is shown that the trajectory O connects the equilibrium points $(\alpha, 0)$ and $(0, v_0)$. Let us note that the change of the independent variable

$$\xi = -\int_\eta^\infty U(\zeta)d\zeta$$

gives the correspondence between $-\infty < \xi < 0$ and $-\infty < \eta < \infty$. Actually, this follows from the fact that $U(\eta) \to 0$ exponentially as $\eta \to \infty$. Obviously, $V \in B^0$ so that $U \in B^1$ as a function of ξ. Thus we have proved the existence of a desired traveling wave. □

Next, we show the following lemma.

LEMMA 2.6. (i) *If* $|u_+ - u_-| < \frac{4}{3}$, *then* $U \in B^2$.

(ii) *If* $|u_+ - u_-| < \frac{\sqrt{6}}{2}$, *then* $U \in B^3$.

Proof. By standard theory of autonomous ordinary differential equations, it is known that when $\lambda_1 < \lambda_2$, i.e., $|u_+ - u_-| > \frac{4}{3}$ (resp., $\lambda_1 > \lambda_2$, i.e., $|u_+ - u_-| < \frac{4}{3}$), the trajectory O tangents the eigenvector e_2 (resp., e_1) at the point $(0, v_0)$. Therefore, when $|u_+ - u_-| > \frac{4}{3}$, we see that $\frac{dV}{dU} \to \infty$ as $U \to 0_+$ so that $V \notin B^1$ and $U \notin B^2$ as functions of ξ. While in the case where $|u_+ - u_-| < \frac{4}{3}$, we have $\frac{dV}{dU} \to 0$ as $U \to 0_+$ so that $V \in B^1$ and $U \in B^2$. This proves (i).

To show (ii), we introduce

$$W_1 = \frac{V - \lambda_1}{U} \tag{2.21}$$

and transform (2.17) into

$$\frac{d}{d\eta}U = \lambda_1 U + U^2 W_1 \tag{2.22a}$$

and

$$\frac{d}{d\eta}W_1 = \frac{1}{2}U + (\lambda_2 - \lambda_1)W_1 - 2UW_1^2. \tag{2.22b}$$

We study the behavior of the trajectory of solutions for the system (2.22) around the equilibrium point $(0,0)$, which corresponds to $(0, v_0)$ for the system (2.17). The Jacobian matrix of the vector on the right-hand side of (2.22), evaluated at $(0,0)$, is

$$A_1 = \begin{pmatrix} \lambda_1 & 0 \\ \frac{1}{2} & \lambda_2 - \lambda_1 \end{pmatrix}. \tag{2.23}$$

The eigenvalues of A_1 are $\lambda_1^{(1)} = \lambda_1 < 0$ and $\lambda_2^{(1)} = \lambda_1 - \lambda_2 < 0$. The corresponding eigenvectors are

$$P_1^{(1)} = \begin{pmatrix} 1 \\ a_2 \end{pmatrix} \qquad \text{and} \qquad P_2^{(1)} = \begin{pmatrix} 0 \\ 1 \end{pmatrix} = e_2, \tag{2.24}$$

respectively, where $a_2 = \frac{1}{2(2\lambda_1 - \lambda_2)}$. By the standard theory of autonomous ordinary differential equations, when $\lambda_1^{(1)} < \lambda_2^{(1)}$, i.e., $|u_+ - u_-| > \frac{\sqrt{6}}{2}$ (resp., $\lambda_1^{(1)} > \lambda_2^{(1)}$, i.e., $|u_+ - u_-| < \frac{\sqrt{6}}{2}$), the trajectory tangents the eigenvector $P_2^{(1)}$ (resp., $P_1^{(1)}$) at the point $(0,0)$. Therefore, if $|u_+ - u_-| > \frac{\sqrt{6}}{2}$, then $\frac{dW_1}{dU} \to \infty$ as $U \to 0_+$. This shows that $\frac{d^2V}{dU^2} \to \infty$ as $U \to 0_+$ so that $V \notin B^2$ and $U \notin B^3$ as functions of ξ. On the other hand, if $|u_+ - u_-| < \frac{\sqrt{6}}{2}$, then $\frac{dW_1}{dU} \to a_2$ as $U \to 0_+$. Consequently, we have $\frac{d^2V}{dU^2} \to 2a_2$ as $U \to 0_+$, which shows that $V \in B^2$ and $U \in B^3$. This completes the proof. □

Proof of Theorem 1.5 (ii-c). It suffices to prove the following theorem that gives a more precise statement of Theorem 1.5 (ii-c).

THEOREM 2.7. *Let $n \geq 1$ be an integer and suppose that*

$$|u_+ - u_-| < b_n \equiv \frac{2\sqrt{2(n+1)}}{n+2}. \tag{2.25}$$

Then V is a B^n-function of U and has the expansion

$$V = a_0 + a_1 U + a_2 U^2 + \cdots + a_n U^n + o(U^n) \tag{2.26}$$

for $U \to 0_+$, where the coefficients a_n are given by the formula (2.27) *below. Moreover, $V \in B^n$ and $U \in B^{n+1}$ as functions of ξ:*

$$a_0 = \lambda_1, \tag{2.27a}$$

$$a_2 = \frac{1}{2(2\lambda_1 - \lambda_2)}, \tag{2.27b}$$

and

$$a_n = \frac{n+2}{4(n\lambda_1 - \lambda_2)} \sum a_i a_{n-i} \quad \textit{for} \quad n = 4, 6, 8, \dots, \tag{2.27c}$$

where the summation is taken over all even integers i with $2 \le i \le n-2$, and

$$a_n = 0 \quad \textit{for} \quad n = 1, 3, 5, \dots. \tag{2.27d}$$

Proof. The theorem has already been proved for $n = 1$ and 2 in Lemma 2.6. We use the induction with respect to n to prove the general case. As the arguments are essentially the same as those in Lemma 2.6, we give only a brief sketch of the proof here.

Let $k \ge 1$ be an integer and assume that the theorem is valid for $n = k$. Then we prove the theorem for $n = k+1$. Let $|u_+ - u_-| < b_k$. Put

$$W_k = \frac{1}{U^k} \left(V - \sum_{j=0}^{k} a_j U^j \right). \tag{2.28}$$

Then $W_k \to 0$ as $U \to 0_+$ by the induction hypothesis. Write (2.28) as

$$V = \sum_{j=0}^{k} a_j U^j + U^k W_k, \tag{2.29}$$

and substitute this in (2.17). This yields the system of (U, W_k) of the form

$$\frac{d}{d\eta} \begin{pmatrix} U \\ W_k \end{pmatrix} = \begin{pmatrix} f_k(U, W_k) \\ g_k(U, W_k) \end{pmatrix}. \tag{2.30}$$

By direct computation, we see that $(0, 0)$ is an equilibrium point of (2.30). Moreover, the Jacobian matrix of the vector on the right-hand side of (2.30), evaluated at $(0, 0)$, is given by

$$A_k = \begin{pmatrix} \lambda_1 & 0 \\ s_k & \lambda_2 - k\lambda_1 \end{pmatrix},$$

where $s_k = 0$ if k is even and $s_k = \{(k+1)\lambda_1 - \lambda_2\} a_{k+1}$ if k is odd. The eigenvalues of A_k are $\lambda_1^{(k)} = \lambda_1$ and $\lambda_2^{(k)} = \lambda_2 - k\lambda_1$. The corresponding eigenvectors are

$$P_1^{(k)} = \begin{pmatrix} 1 \\ a_{k+1} \end{pmatrix} \qquad \text{and} \qquad P_2^{(k)} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \tag{2.31}$$

respectively. Noting that $\lambda_1^{(k)} < \lambda_2^{(k)}$ (resp., $\lambda_1^{(k)} > \lambda_2^{(k)}$) is equivalent to $|u_+ - u_-| > b_{k+1}$ (resp., $|u_+ - u_-| < b_{k+1}$), we can deduce the desired conclusion of the theorem for $n = k+1$ by the same argument as in Lemma 2.6. In particular, we see that $U \in B^{k+2}$ for $|u_+ - u_-| < b_{k+1}$, but $U \notin B^{k+2}$ if $|u_+ - u_-| > b_{k+1}$. The proof is complete. □

Finally, in this section we summarize the result concerning the magnitude of traveling waves, which is necessary in the stability proof in section 3.

COROLLARY 2.8. *If* $|u_- - u_+| \le \sqrt{2}$, *then*

$$|U| \le \frac{1}{2}|u_- - u_+| \quad \textit{and} \quad |U'| \le \frac{1}{4}|u_- - u_+|^2. \tag{2.32a}$$

Moreover, we assume that $|u_- - u_+| < \frac{2\sqrt{2n}}{n+1}$ *for an integer* $n \ge 2$. *Then*

$$\left|\left(\frac{d}{d\xi}\right)^n U\right| \le C|u_- - u_+|^{n+1} \quad \textit{with} \quad C = \frac{C_0}{1-(n+1)|v_0|} \tag{2.32b}$$

and

$$|U'| \le |v_0| < \frac{1}{n+1}, \tag{2.33}$$

where C_0 *is a constant independent of* $|u_- - u_+|$ *and* v_0 *is the constant given in* (2.13) *with* $\alpha = \frac{|u_- - u_+|}{2}$.

Proof. It follows from Lemma 2.5 (ii) that $|U| \le \alpha$ and $|V| \le |v_0|$. Also, by simple calculation, using (2.13), we see that $|v_0| \le \alpha^2$ and that $|v_0| < \frac{1}{n+1}$ for $\alpha < \frac{\sqrt{2n}}{n+1}$. Thus we have proved (2.32a) and (2.33).

Next, we prove (2.32b) only for $n = 2$. The general case can be proved by the induction with respect to n. Observe that as U'' decays exponentially for $\xi \to \pm\infty$, $|U''|$ attains its maximum at a point ξ_0 where $U''' = V'' = 0$ holds. We have from (2.10) that

$$UV' + V^2 + V - \frac{1}{2}(U^2 - \alpha^2) = 0.$$

Differentiate the equation with respect to ξ and evaluate at $\xi = \xi_0$. Since $V''(\xi_0) = 0$, we obtain

$$U'' = V' = \frac{UV}{1+3V}$$

at $\xi = \xi_0$. Substituting the estimates $|U| \le \alpha$ and $|V| \le |v_0| \le \alpha^2$, we have

$$|U''| \le \frac{\alpha^3}{1-3|v_0|}$$

at $\xi = \xi_0$, which proves (2.32b) for $n = 2$. □

3. Stability. In this section, we discuss the stability of smooth traveling waves which are obtained in section 2. Here and after, we assume that $|u_- - u_+| < \frac{\sqrt{6}}{2}$ to make U of (1.6) being in B^3. Moreover, let (ϕ, ψ) be a solution of the problem (1.14), (1.15) satisfying (1.22) with T_0 replaced by T and assume that $N(T) \le \frac{1}{10}$.

***L*¹ estimates of *φ*.** At first, we give the L^1 estimate for ϕ. To this end, we introduce a_δ and A_δ by

$$a_\delta(\phi) = \rho_\delta * sign(\phi) \quad \text{and} \quad A_\delta(\phi) = \int_0^\phi a_\delta(\eta)d\eta, \tag{3.1}$$

where $\rho_\delta *$ denotes the Friedrichs mollifier. Note that $A_\delta(\phi) \to |\phi|$ as $\delta \to 0$. We have from (1.5b) that

$$\psi = -K\phi_x, \tag{3.2}$$

so that $\psi_x = \phi - K\phi$. Substitution of this in (1.14a) gives

$$\phi_t + \left(U\phi + \frac{1}{2}\phi^2\right)_x + \phi - K\phi = 0. \tag{3.3}$$

Multiplying $a_\delta(\phi)$ on this equation, we obtain that

$$\begin{aligned} &A_\delta(\phi)_t + U_x \int_0^\phi a'_\delta(\eta)\eta d\eta + a_\delta(\phi)(\phi - K\phi) \\ &\quad + \left\{ U\left(a_\delta(\phi)\phi - \int_0^\phi a'_\delta(\eta)\eta d\eta \right) + \int_0^\phi a_\delta(\eta)\eta d\eta \right\}_x = 0. \end{aligned} \tag{3.4}$$

We integrate this equation over $\mathbf{R} \times [0,t]$, obtaining

$$\begin{aligned} &\int_{-\infty}^{\infty} A_\delta(\phi)(x,t)dx + \int_0^t \int_{-\infty}^{\infty} U_x \left(\int_0^\phi a'_\delta(\eta)\eta d\eta \right) dx\, d\tau \\ &\qquad + \int_0^t \int_{-\infty}^{\infty} a_\delta(\phi)(\phi - K\phi) dx\, d\tau = \int_{-\infty}^{\infty} A_\delta(\phi_0) dx. \end{aligned} \tag{3.5}$$

Making $\delta \downarrow 0$, we have that

$$|\phi(t)|_1 + \int_0^t |\phi|_1 d\tau - \int_0^t \int_{-\infty}^{\infty} sign(\phi) K\phi dx\, d\tau = |\phi_0|_1. \tag{3.6}$$

Here we used the fact that second term on the left-hand side of (3.5) goes to zero as $\delta \to 0$ by the Lebesgue convergence theorem. Applying the estimate

$$\left| \int_{-\infty}^{\infty} sign(\phi) K\phi dx \right| \le |K\phi|_1 \le |\phi|_1$$

on (3.6), we obtain that $|\phi(t)|_1 \le |\phi_0|_1$. Thus we have proved the following lemma.

LEMMA 3.1. *If $\phi_0 \in L^1$, then*

$$|\phi(t)|_1 \le |\phi_0|_1. \tag{3.7}$$

***L^2* estimates (proof of Proposition 1.8).** Since we have assumed $\phi \in C^0([0,T]; L^1)$, Φ is well defined by (1.17) and satisfies $\Phi \in C^0([0,T]; L^2)$ if $\Phi_0 \in L^2$. Consequently, we have

$$\Phi \in C^0([0,T]; H^3), \tag{3.8}$$

and Φ satisfies (1.19). First we apply the standard energy method to equation (1.19) to derive the L^2-estimate for Φ. Multiplying Φ on (1.19), we have

$$\left(\frac{1}{2}\Phi^2\right)_t - \frac{1}{2}U_x\Phi^2 + \frac{1}{2}\Phi\phi^2 + \Phi\psi + \left(\frac{1}{2}U\Phi^2\right)_x = 0. \tag{3.9}$$

Since we have from (1.14b) that

$$\Phi\psi = \phi^2 - (\psi^2 + \psi_x^2) + \{(\Phi + \psi)(\psi_x - \phi)\}_x,$$

(3.9) is modified as

$$\left(\frac{1}{2}\Phi^2\right)_t - \frac{1}{2}U_x\Phi^2 + \phi^2 - (\psi^2 + \psi_x^2) + \frac{1}{2}\Phi\phi^2 + (\cdots)_x = 0, \tag{3.10}$$

where here and in what follows, $(\cdots)_x$ denotes terms which vanish after integration over $x \in \mathbf{R}$. We integrate (3.10) over $\mathbf{R} \times [0, t]$, obtaining

(3.11)
$$|\Phi(t)|_2^2 + 2\int_0^t |\phi|_2^2 d\tau + \int_0^t\int_{-\infty}^{\infty} |U_x|\Phi^2 dx\, d\tau = |\Phi_0|_2^2 + 2\int_0^t \|\psi\|_1^2 d\tau - \int_0^t\int_{-\infty}^{\infty} \Phi\phi^2 dx\, d\tau,$$

where we used the fact that $U_x < 0$, namely, U is a strictly decreasing function of $\xi = x - st$.

Next we derive the L^2-estimate for ϕ in a similar way. Multiplying ϕ and ψ on equations (1.14a) and (1.14b), respectively, and adding these two equations, we have

$$\left(\frac{1}{2}\phi^2\right)_t + \psi^2 + \psi_x^2 + \frac{1}{2}U_x\phi^2 + \left\{\frac{1}{2}U\phi^2 + \frac{1}{3}\phi^3 - \psi(\psi_x - \phi)\right\}_x = 0. \tag{3.12}$$

Integrating (3.12) over $\mathbf{R} \times [0, t]$ and using the fact that $U_x < 0$, we obtain

$$|\phi(t)|_2^2 + 2\int_0^t \|\psi\|_1^2 d\tau = |\phi_0|_2^2 + \int_0^t\int_{-\infty}^{\infty} |U_x|\phi^2 dx\, d\tau. \tag{3.13}$$

Now we add (3.11) and (3.13), obtaining

$$\begin{aligned} |\Phi(t)|_2^2 + |\phi(t)|_2^2 + 2\int_0^t |\phi|_2^2 d\tau + \int_0^t\int_{-\infty}^{\infty} |U_x|\Phi^2 dx\, d\tau &= |\Phi_0|_2^2 + |\phi_0|_2^2 \\ &\quad + \int_0^t\int_{-\infty}^{\infty} (|U_x| - \Phi)\phi^2 dx\, d\tau. \end{aligned} \tag{3.14}$$

We would like to estimate the last term on the right-hand side of (3.14). We recall that when $|u_+ - u_-| < \frac{\sqrt{6}}{2}$, Corollary 2.8 gives that

$$|U_x| < \frac{1}{4}, \qquad |U_{xx}| \le C, \tag{3.15a}$$

and

$$|U_{xxx}| < CM \quad \text{with} \quad M = \frac{1}{1 - 4|v_0|}. \tag{3.15b}$$

Using (3.15a) and $N(T) \le \frac{1}{10}$, we see that $|U_x| + |\Phi| < 1$. Therefore, we have from (3.14) that

$$|\Phi(t)|_2^2 + |\phi(t)|_2^2 + \int_0^t |\phi|_2^2 d\tau + \int_0^t\int_{-\infty}^{\infty} |U_x|\Phi^2 dx\, d\tau \le |\Phi_0|_2^2 + |\phi_0|_2^2. \tag{3.16}$$

Moreover, applying this estimate to the right-hand side of (3.13), we obtain

$$\int_0^t \|\psi\|_1^2 d\tau \le |\Phi_0|_2^2 + |\phi_0|_2^2. \tag{3.17}$$

Next we derive the estimate for ϕ_x. We differentiate (1.14) with respect to x and multiply ϕ_x and ψ_x on the first and the second equations thus obtained, respectively. Then we add these two equations, getting

$$\begin{aligned}\left(\frac{1}{2}\phi_x^2\right)_t &+ \psi_x^2 + \psi_{xx}^2 + \frac{3}{2}U_x\phi_x^2 + U_{xx}\phi\phi_x + \frac{1}{2}\phi_x^3 \\ &+ \left\{\frac{1}{2}U\phi_x^2 + \frac{1}{2}\phi\phi_x^2 - \psi_x(\psi_{xx} - \phi_x)\right\}_x = 0.\end{aligned} \tag{3.18}$$

On the other hand, by squaring (1.14b), we have

$$\phi_x^2 = \psi^2 + 2\psi_x^2 + \psi_{xx}^2 - 2(\psi\psi_x)_x. \tag{3.19}$$

We rewrite (3.18) by using (3.19) as

$$\left(\frac{1}{2}\phi_x^2\right)_t + \phi_x^2 - (\psi^2 + \psi_x^2) + \frac{3}{2}U_x\phi_x^2 + U_{xx}\phi\phi_x + \frac{1}{2}\phi_x^3 + (\cdots)_x = 0. \tag{3.20}$$

Here, applying (3.15a) and $N(T) \le \frac{1}{10}$, we see that

$$\left|\frac{3}{2}U_x\phi_x^2 + U_{xx}\phi\phi_x + \frac{1}{2}\phi_x^3\right| \le \frac{1}{2}\phi_x^2 + C\phi^2. \tag{3.21}$$

We integrate (3.20) over $\mathbf{R}\times[0,t]$ and substitute (3.21) in the resulting equation. This yields

$$|\phi_x(t)|_2^2 + \int_0^t |\phi_x|_2^2 d\tau \le |\phi_0'|_2^2 + C\int_0^t |\phi(\tau)|_2^2 d\tau + 2\int_0^t \|\psi(\tau)\|_1^2 d\tau \le C(|\Phi_0|_2^2 + \|\phi_0\|_1^2), \tag{3.22}$$

where we used the estimate (3.16) and (3.17). Also, from (3.19) and (3.22) we have

$$\int_0^t \|\psi(\tau)\|_2^2 d\tau \le C(|\Phi_0|_2^2 + \|\phi_0\|_1^2). \tag{3.23}$$

Finally, we derive the L^2-estimate for ϕ_{xx} by the similar method used in deriving the estimate for ϕ_x. We differentiate (1.14) twice with respect to x and multiply ϕ_{xx} and ψ_{xx} on the first and the second equations thus obtained, respectively. Then, adding the resulting two equations, we have

$$\begin{aligned}\left(\frac{1}{2}\phi_{xx}^2\right)_t &+ \psi_{xx}^2 + \psi_{xxx}^2 + \frac{5}{2}U_x\phi_{xx}^2 + 3U_{xx}\phi_x\phi_{xx} \\ &+ U_{xxx}\phi\phi_{xx}^2 + \frac{5}{2}\phi_x\phi_{xx}^2 + (\dots)_x = 0.\end{aligned} \tag{3.24}$$

Also, similarly to (3.19), we have

$$\phi_{xx}^2 = \psi_x^2 + 2\psi_{xx}^2 + \psi_{xxx}^2 - 2(\psi_x\psi_{xx})_x. \tag{3.25}$$

We rewrite (3.24) by using (3.25) and obtain as a counterpart of (3.20)

$$\begin{aligned}\left(\frac{1}{2}\phi_{xx}^2\right)_t + \phi_{xx}^2 - (\psi_x^2+\psi_{xx}^2) + \frac{5}{2}U_x\phi_{xx}^2 + 3U_{xx}\phi_x\phi_{xx} \\ + U_{xxx}\phi\phi_{xx}^2 + \frac{5}{2}\phi_x\phi_{xx}^2 + (\dots)_x = 0.\end{aligned} \tag{3.26}$$

Here, using (3.15) and $N(T) \le \frac{1}{10}$, we see that

$$\left|\frac{5}{2}U_x\phi_{xx}^2 + 3U_{xx}\phi_x\phi_{xx} + U_{xxx}\phi\phi_{xx} + \frac{5}{2}\phi_x\phi_{xx}^2\right| \le \frac{15}{16}\phi_{xx}^2 + CM^2\phi^2 + C\phi_x^2. \tag{3.27}$$

Now, integrating (3.26) over $\mathbf{R}\times[0,t]$ and substituting (3.27) in the resulting equation, we obtain

$$\begin{aligned}|\phi_{xx}(t)|_2^2 + \int_0^t |\phi_{xx}(\tau)|_2^2 d\tau &\le C|\phi_0''|_2^2 + C(M)\int_0^t \|\phi(\tau)\|_1^2 + \|\psi_x(\tau)\|_1^2 d\tau \\ &\le C(M)(|\Phi_0|_2^2 + \|\phi_0\|_2^2),\end{aligned} \tag{3.28}$$

where we used the estimates (3.16), (3.22), and (3.23). Here $C(M)$ denotes a constant depending on M in (3.15b). Also, from (3.25) and (3.28) we have

$$\int_0^t \|\psi_x(\tau)\|_2^2 \le C(M)(|\Phi_0|_2^2 + \|\phi_0\|_2^2). \tag{3.29}$$

To complete the proof of Proposition 1.8, we combine (3.16), (3.22), (3.23), (3.28), and (3.29), obtaining

$$\begin{aligned}|\Phi(t)|_2^2 + \|\phi(t)\|_2^2 + \int_0^t \|\phi(\tau)\|_2^2 + \|\psi(\tau)\|_3^2 d\tau \\ + \int_0^t\int_{-\infty}^{\infty} |U_x|\Phi^2 dx\, d\tau \le C(M)(|\Phi_0|_2^2 + \|\phi_0\|_2^2).\end{aligned} \tag{3.30}$$

This inequality combined with the inequality $\|\psi\|_3 \le \|\phi_x\|_1$, which is derived from (3.19) and (3.25), gives the desired estimate (1.25). This completes the proof of Proposition 1.8 and hence of Theorem 1.6 (i).

Decay estimates (proof of Proposition 1.9). In this subsection we derive the decay estimate (1.26). Let (ϕ,ψ) be the global solution to the problem (1.14), (1.15), which is obtained in Theorem 1.6. Note that this solution verifies

$$\sup_{0\le t\le\infty} \|\Phi(t)\|_3 \le C\|\Phi_0\|_3 \le \frac{1}{10}. \tag{3.31}$$

At first we prove the L^1-estimate of Φ, which plays an important role in getting the convergence rate.

LEMMA 3.2. *If $\Phi_0 \in L^1$, then $\Phi \in C^0([0,\infty); L^1)$ and*

$$|\Phi(t)|_1 + \int_0^t\int_{-\infty}^{\infty} |U_x||\Phi| dx\, d\tau \le |\Phi_0|_1 + \frac{1}{2}(|\Phi_0|_2^2 + |\phi_0|_2^2). \tag{3.32}$$

Proof. From (3.2), we have that

$$\psi_x = \phi - K\phi = (\Phi - K\Phi)_x.$$

By integrating this equation on the interval $(-\infty, x]$, we obtain

$$\psi = \Phi - K\Phi. \tag{3.33}$$

Substituting this equation in (1.19), we have that

$$\Phi_t + U\Phi_x + \frac{1}{2}\phi^2 + \Phi - K\Phi = 0. \tag{3.34}$$

Multiplying $a_\delta(\Phi)$ on this equation and integrating over $\mathbf{R} \times [0,t]$, we obtain that

$$\begin{aligned} &\int_{-\infty}^{\infty} A_\delta(\Phi(t))dx + \int_0^t \int_{-\infty}^{\infty} |U_x| A_\delta(\Phi) dx\, d\tau + \frac{1}{2}\int_0^t \int_{-\infty}^{\infty} a_\delta(\Phi)\phi^2 dx\, d\tau \\ &\qquad + \int_0^t \int_{-\infty}^{\infty} a_\delta(\Phi)(\Phi - K\Phi) dx\, d\tau = \int_{-\infty}^{\infty} A_\delta(\phi_0) dx. \end{aligned} \tag{3.35}$$

Letting $\delta \downarrow 0$ in (3.35), we have

$$|\Phi(t)|_1 + \int_0^t \int_{-\infty}^{\infty} |U_x||\Phi| dx\, d\tau \le |\Phi_0|_1 + \frac{1}{2}\int_0^t |\phi|_2^2 d\tau \le |\Phi_0|_1 + \frac{1}{2}(|\Phi_0|_2^2 + |\phi_0|_2^2),$$

where we used the estimate (3.16). This completes the proof. □

Next we derive the decay estimate for Φ and ϕ. Let $\mu > \frac{1}{2}$ be a sufficiently large number which is fixed. We multiply $(\tau+1)^\mu$ on equations (3.10) and (3.12), and integrate the resulting equations over $\mathbf{R} \times [0,t]$. This yields

$$\begin{aligned} &(t+1)^\mu |\Phi(t)|_2^2 + 2\int_0^t (\tau+1)^\mu |\phi(\tau)|_2^2 d\tau \\ &\qquad + \int_0^t \int_{-\infty}^{\infty} (\tau+1)^\mu |U_x| \Phi^2 dx\, d\tau = |\Phi_0|_2^2 + \mu \int_0^t (\tau+1)^{\mu-1} |\Phi(\tau)|_2^2 d\tau \\ &\qquad + 2\int_0^t (\tau+1)^\mu \|\psi(\tau)\|_1^2 d\tau - \int_0^t \int_{-\infty}^{\infty} (\tau+1)^\mu \Phi\phi^2 dx\, d\tau. \end{aligned} \tag{3.36}$$

and

$$\begin{aligned} &(t+1)^\mu |\phi(t)|_2^2 + 2\int_0^t (\tau+1)^\mu \|\psi(\tau)\|_1^2 d\tau = |\phi_0|_2^2 + \mu \int_0^t (\tau+1)^{\mu-1} |\phi(\tau)|_2^2 d\tau \\ &\qquad + \int_0^t \int_{-\infty}^{\infty} (\tau+1)^\mu |U_x| \phi^2 dx\, d\tau. \end{aligned} \tag{3.37}$$

Adding the above two equations, we obtain

$$\begin{aligned} &(t+1)^\mu (|\Phi(t)|_2^2 + |\phi(t)|_2^2) + 2\int_0^t (\tau+1)^\mu |\phi(\tau)|_2^2 d\tau \\ &\qquad + \int_0^t \int_{-\infty}^{\infty} (\tau+1)^\mu |U_x| \Phi^2 dx\, d\tau = |\Phi_0|_2^2 + |\phi_0|_2^2 \\ &\qquad + \mu \int_0^t (\tau+1)^{\mu-1} (|\Phi(\tau)|_2^2 + |\phi(\tau)|_2^2) d\tau \\ &\qquad + \int_0^t \int_{-\infty}^{\infty} (\tau+1)^\mu (|U_x| - \Phi)\phi^2 dx\, d\tau. \end{aligned} \tag{3.38}$$

We estimate the integrals on the right-hand side of (3.38). First, using (3.15a) and (3.31), we have

$$\int_0^t\int_{-\infty}^{\infty}(\tau+1)^{\mu}(|U_x|-\Phi)\phi^2 dx\,d\tau \le \frac{1}{2}\int_0^t(\tau+1)^{\mu}|\phi(\tau)|_2^2 d\tau. \tag{3.39}$$

Next, applying the Gagliardo–Nirenberg inequality

$$|\Phi|_2 \le C|\Phi_x|_2^{\frac{1}{3}}|\Phi|_1^{\frac{2}{3}} = C|\phi|_2^{\frac{1}{3}}|\Phi|_1^{\frac{2}{3}}$$

and the Hölder inequality, we see that

$$\begin{aligned}\mu\int_0^t(\tau+1)^{\mu-1}|\Phi(\tau)|_2^2 d\tau &\le C\sup_{\tau}|\Phi(\tau)|_1^{\frac{4}{3}}\int_0^t(\tau+1)^{\mu-1}|\phi(\tau)|_2^{\frac{2}{3}}d\tau\\ &\le C\sup_{\tau}|\Phi(\tau)|_1^{\frac{4}{3}}\left[\int_0^t(\tau+1)^{\mu}|\phi(\tau)|_2^2 d\tau\right]^{\frac{1}{3}}\left[\int_0^t(\tau+1)^{\mu-\frac{2}{3}}d\tau\right]^{\frac{2}{3}}\\ &\le \varepsilon\int_0^t(\tau+1)^{\mu}|\phi(\tau)|_2^2 d\tau + C(\varepsilon)(t+1)^{\mu-\frac{1}{2}}\sup_{0\le\tau\le t}|\Phi(\tau)|_1^2 \end{aligned}\tag{3.40}$$

for arbitrary $\varepsilon>0$, where $C(\varepsilon)$ is a constant depending on ε. Here we assumed that $\mu>\frac{1}{2}$. Finally, we show that

$$\mu\int_0^t(\tau+1)^{\mu-1}|\phi(\tau)|_2^2 d\tau \le \varepsilon\int_0^t(\tau+1)^{\mu}|\phi(\tau)|_2^2 d\tau + C(\varepsilon)\int_0^t|\phi(\tau)|_2^2 d\tau \tag{3.41}$$

for arbitrary $\varepsilon>0$. To see this, we choose T such that $\mu(T+1)^{-1}=\varepsilon$ and divide the integral on the left-hand side of (3.41) into two parts corresponding to $[0,T]$ and $[T,t]$, respectively. The first part is estimated as

$$\mu\int_0^T(\tau+1)^{\mu-1}|\phi(\tau)|_2^2 d\tau \le \mu(T+1)^{\mu-1}\int_0^T|\phi(\tau)|_2^2 d\tau \le C(\varepsilon)\int_0^t|\phi(\tau)|_2^2 d\tau,$$

while the second is

$$\mu\int_T^t(\tau+1)^{\mu-1}|\phi(\tau)|_2^2 d\tau \le \mu(T+1)^{-1}\int_T^t(\tau+1)^{\mu}|\phi(\tau)|_2^2 d\tau \le \varepsilon\int_0^t(\tau+1)^{\mu}|\phi(\tau)|_2^2 d\tau.$$

This proves (3.41). Now, substitute (3.39), (3.40), and (3.41) in (3.38). Then letting $\varepsilon=\frac{1}{4}$ on the inequality thus obtained, we obtain

$$\begin{aligned}&(t+1)^{\mu}(|\Phi(t)|_2^2+|\phi(t)|_2^2)+\int_0^t(\tau+1)^{\mu}|\phi(\tau)|_2^2 d\tau+\int_0^t\int_{-\infty}^{\infty}(\tau+1)^{\mu}|U_x|\Phi^2 dx\,d\tau\\ &\qquad\le |\Phi_0|_2^2+|\phi_0|_2^2+C(t+1)^{\mu-\frac{1}{2}}\sup_{0\le\tau\le t}|\Phi(\tau)|_1^2+C\int_0^t|\phi(\tau)|_2^2 d\tau\\ &\qquad\le C(t+1)^{\mu-\frac{1}{2}}(|\Phi_0|_1^2+|\Phi_0|_2^2+|\phi_0|_2^2),\end{aligned}\tag{3.42}$$

where we used the estimates (3.32) and (3.16). Moreover, applying (3.42) to the right-hand side of (3.37), we have

$$\int_0^t(\tau+1)^{\mu}\|\psi(\tau)\|_1^2 d\tau \le C(t+1)^{\mu-\frac{1}{2}}(|\Phi_0|_1^2+|\Phi_0|_2^2+|\phi_0|_2^2). \tag{3.43}$$

Next we derive the decay estimate for ϕ_x by multiplying $(\tau+1)^\mu$ on (3.20) and integrating it over $\mathbf{R}\times[0,t]$. Then, using (3.21), we obtain

$$(t+1)^\mu|\phi_x(t)|_2^2+\int_0^t(\tau+1)^\mu|\phi_x(\tau)|_2^2d\tau\le|\phi_0^{'}|_2^2+\mu\int_0^t(\tau+1)^{\mu-1}|\phi_x(\tau)|_2^2d\tau$$
$$+C\int_0^t(\tau+1)^\mu|\phi_x(\tau)|_2^2d\tau+2\int_0^t(\tau+1)^\mu\|\psi(\tau)\|_1^2d\tau. \tag{3.44}$$

We substitute the estimate (3.41) with ϕ replaced by ϕ_x to the second term on the right-hand side of (3.44). Then, using (3.22), (3.42), and (3.43), we obtain

$$(t+1)^\mu|\phi_x(t)|_2^2+\int_0^t(\tau+1)^\mu|\phi_x(\tau)|_2^2d\tau\le C(t+1)^{\mu-\frac12}(|\Phi_0|_1^2+|\Phi_0|_2^2+\|\phi_0\|_1^2). \tag{3.45}$$

Also, from (3.19) and (3.45) we have

$$\int_0^t(\tau+1)^\mu\|\psi(\tau)\|_2^2d\tau\le C(t+1)^{\mu-\frac12}(|\Phi_0|_1^2+|\Phi_0|_2^2+\|\phi_0\|_1^2). \tag{3.46}$$

Similarly, we derive the decay for ϕ_{xx}. We multiply $(\tau+1)^\mu$ on equation (3.26) and integrate it over $\mathbf{R}\times[0,t]$. Then, using (3.27), we obtain

$$(t+1)^\mu|\phi_{xx}(t)|_2^2+\int_0^t(\tau+1)^\mu|\phi_{xx}(\tau)|_2^2d\tau\le C|\phi_0^{''}|_2^2+\mu C\int_0^t(\tau+1)^{\mu-1}|\phi_{xx}(\tau)|_2^2d\tau$$
$$+C(M)\int_0^t(\tau+1)^\mu(\|\phi(\tau)\|_1^2+\|\psi_x(\tau)\|_1^2)d\tau. \tag{3.47}$$

By applying (3.41) with ϕ replaced by ϕ_{xx} and using (3.28), (3.42), (3.45), and (3.46), we have from (3.47) that

$$(t+1)^\mu|\phi_{xx}(t)|_2^2+\int_0^t(\tau+1)^\mu|\phi_{xx}(\tau)|_2^2d\tau\le C(M)(t+1)^{\mu-\frac12}(|\Phi_0|_1^2+|\Phi_0|_2^2+\|\phi_0\|_2^2). \tag{3.48}$$

Also, from (3.25) and (3.48) we have

$$\int_0^t(\tau+1)^\mu\|\psi_x(\tau)\|_2^2d\tau\le C(M)(t+1)^{\mu-\frac12}(|\Phi_0|_1^2+|\Phi_0|_2^2+\|\phi_0\|_2^2). \tag{3.49}$$

Finally, combining (3.42), (3.45), (3.46), (3.48), and (3.49), we arrive at the estimate

$$\begin{aligned}(t+1)^\mu(|\Phi(t)|_2^2+\|\phi(t)\|_2^2)+\int_0^t(\tau+1)^\mu(\|\phi(\tau)\|_2^2+\|\psi(\tau)\|_3^2)d\tau\\ +\int_0^t\int_{-\infty}^\infty(\tau+1)^\mu|U_x|\Phi^2dx\,d\tau\\ \le C(M)(t+1)^{\mu-\frac12}(|\Phi_0|_1^2+|\Phi_0|_2^2+\|\phi_0\|_2^2).\end{aligned} \tag{3.50}$$

In particular, we have shown that

$$|\Phi(t)|_2+\|\phi(t)\|_2\le C(M)(t+1)^{-\frac14}(|\Phi_0|_1+|\Phi_0|_2+\|\phi_0\|_2), \tag{3.51}$$

which together with the inequality $\|\psi\|_3\le C\|\phi\|_2$ gives

$$\|\psi(t)\|_3\le C(M)(t+1)^{-\frac14}(|\Phi_0|_1+|\Phi_0|_2+\|\phi_0\|_2). \tag{3.52}$$

This completes the proof of Proposition 1.9 and hence of Theorem 1.6 (ii).

Acknowledgment. The authors would like to express their deepest gratitude to Professor Xu-Yan Chen for stimulating discussions.

ENCAPSULATED-VORTEX SOLUTIONS TO EQUIVARIANT WAVE EQUATIONS: EXISTENCE*

JOSEPH IAIA† AND HENRY WARCHALL†

Abstract. We prove the existence of vector-valued exponentially localized solutions to a class of nonlinear elliptic equations with equivariant nonlinearities. The elliptic equations govern the spatial profiles of solitary wave solutions to nonlinear wave equations with globally regular solutions. These solitary waves are localized versions of nonlinear Schrödinger vortices. We use constructive methods to show that there are localized solutions with any prescribed number of nodal surfaces.

Key words. nonlinear wave equations, solitary waves, multidimensional solitons, vortices, equivariant wave equations, localized traveling waves

1. Introduction.

We consider nonlinear Schrödinger (NLS) and nonlinear Klein–Gordon (NLKG) equations

$$-J\,u_t - \Delta u = \vec{g}(u) \qquad \text{(NLS)} \tag{1.1}$$

and

$$u_{tt} - \Delta u = \vec{g}(u) \qquad \text{(NLKG)}, \tag{1.2}$$

where J is an invertible real skew-symmetric $M \times M$ matrix, and solutions u are $\mathbb{R}^M$-valued functions on spacetime $\mathbb{R}^{N+1}$. The nonlinearity $\vec{g} : \mathbb{R}^M \to \mathbb{R}^M$ is assumed to be a continuous radial vector field; in particular, $\vec{g}(0) = 0$ and

$$\vec{g}(y) = g(|y|)\hat{y} \qquad \text{for} \quad y \neq 0, \tag{1.3}$$

where $g : [0, \infty) \to \mathbb{R}$ is a continuous function with $g(0) = 0$ and $\hat{y} \equiv \frac{y}{|y|}$.

We study standing-wave solutions

$$u(x,t) \equiv e^{\nu t K}\, v(x) \tag{1.4}$$

to the nonlinear wave equations (NLS) and (NLKG), where ν is a real constant, K is a real skew-symmetric $M \times M$ matrix, and $v : \mathbb{R}^N \to \mathbb{R}^M$. For (NLS), we take $K \equiv J^{-1}$, so that $-J\frac{\partial}{\partial t}u = -\nu\, u$. For (NLKG), we take K to be skew-symmetric and such that $K^2 = -I$, so that $\frac{\partial^2}{\partial t^2}u = -\nu^2 u$. (These requirements on J and K necessitate that the range space $\mathbb{R}^M$ be even-dimensional.)

Because $e^{\nu t K}$ is an isometry on the Euclidean space $\mathbb{R}^M$, it follows that $\vec{g}\left(e^{\nu t K}\, v(x)\right) = e^{\nu t K}\vec{g}\,(v(x))$, and consequently, if $u(x,t) \equiv e^{\nu t K}\, v(x)$ is a solution of (NLS) or (NLKG), then the function v must satisfy the elliptic equation

$$\Delta v + \vec{f}(v) = 0, \tag{1.5}$$

where $\vec{f}(y) \equiv \vec{g}(y) + \omega\, y$, with

$$\omega \equiv \begin{cases} \nu & \text{for NLS,} \\ \nu^2 & \text{for NLKG.} \end{cases}$$

We note that by virtue of (1.3), the nonlinearity $\vec{f}$ has the analogous equivariant property

$$\vec{f}(y) = f(|y|)\hat{y} \qquad \text{for} \quad y \neq 0, \tag{1.6}$$

where the scalar-valued function f is defined by $f(s) \equiv g(s) + \omega s$. For convenience, we will also denote by f the odd extension of f to all of $\mathbb{R}$.

In this paper, we prove the existence of twice-differentiable solutions $v : \mathbb{R}^N \to \mathbb{R}^M$ with $N \geq 2$ and $M \geq 2$ such that $\nu(x) \to 0$ as $|x| \to \infty$. We remark that if v is such a solution of (1.5), then $u(x,t) \equiv e^{\nu t K}\, v(x)$ is a localized standing-wave solution of the corresponding nonlinear evolution equation (NLS) or (NLKG). Under a (Galilean or Lorentz) velocity boost, such a standing wave becomes a spatially-localized traveling wave solution of the wave equation, that is, a multidimensional solitary wave.

The set of spherically-symmetric ("radial") scalar-valued ($M = 1$) solutions to (1.5) has been extensively studied (see [1], [2], [3], [5], [6], [8], [9], [10], [12], [13], [14], [15]). Constructive techniques to establish the existence of localized solutions to (1.5) with prescribed nodal structure include [13], which treats real-valued radial solutions in $\mathbb{R}^N$ for nonlinearities that are superlinear at large amplitudes.

In [7] we used techniques analogous to those in [13] to investigate the existence and nodal structure of complex-valued ($M = 2$) nonradial solutions in $\mathbb{R}^2$ for nonlinearities that are superlinear at large amplitudes. The corresponding standing-wave solutions to (NLS) and (NLKG) carry nonzero (classical) angular momentum in the center-of-momentum frame and are thus "spinning" solitary waves.

The type of nonlinearity treated in [7] and [13], however, admits finite-time blowup of (some) solutions to the corresponding semilinear wave equation. In [8], we studied a different type of nonlinearity, compatible with global regularity of solutions, in which the energy density for the associated wave equation is positive definite. For such "hilltop" nonlinearities, [8] establishes the existence, in arbitrary spatial dimension, of spherical (real-valued, spinless) solitary-wave solutions to (NLS) and (NLKG) with a prescribed nodal structure. Here we establish the existence, in arbitrary spatial dimension, of nonspherical (spinning) solitary-wave solutions with prescribed nodal structure, for "hilltop" nonlinearities compatible with global regularity of solutions.

For complex-valued nonradial solutions in spatial dimensions $N \geq 3$, no ansatz has been found that reduces (1.5) to an ordinary differential equation. An ansatz for complex-valued nonradial solutions that transforms (1.5) to a partial differential equation with fewer independent variables is made in [11], where the existence of localized solutions is established through variational methods. In contrast, the vector-valued solutions we construct here (with range dimension $M \geq 3$ in the case $N \geq 3$) result from an ansatz that reduces (1.5) to an ordinary differential equation.

In particular, we look for solutions to the elliptic equation (1.5) of the separated form

$$v(x) = w(r)\, \hat{\psi}(\hat{x}), \tag{1.7}$$

where $r \equiv |x|$ and $\hat{x} \equiv \frac{x}{|x|}$. Here $w : [0,\infty) \to \mathbb{R}$, and $\hat{\psi} : S^{N-1} \to S^{M-1}$ is a function on the sphere S^{N-1} in $\mathbb{R}^N$, taking unit-vector values in $\mathbb{R}^M$. For $v(x)$ of this form, we have

$$\Delta v = (\Delta_r w)\hat{\psi} + \tfrac{1}{r^2} w\,(\Delta_S \hat{\psi}), \tag{1.8}$$

where $\Delta_r \equiv \frac{\partial^2}{\partial r^2} + \frac{N-1}{r}\frac{\partial}{\partial r}$ is the radial Laplacian, and where Δ_S is the Laplacian on the sphere $S^{N-1} \subset \mathbb{R}^N$, applied componentwise to $\hat{\psi}$.

We show in section 2 that there are functions $\hat{\psi} : S^{N-1} \to S^{M-1}$ whose coordinate functions are eigenfunctions of the spherical Laplacian with eigenvalue $\mu_\ell \equiv -\ell(\ell + N - 2)$, provided that the dimension M of the range space is at least as large as the multiplicity of μ_ℓ. Given that

$$\Delta_S \hat{\psi} = -\ell(\ell + N - 2)\hat{\psi}, \tag{1.9}$$

it follows from (1.5)–(1.9) that the radial profile w must then satisfy the ordinary differential equation

$$w'' + \frac{N-1}{r} w' - \frac{\ell(\ell + N - 2)}{r^2} w + f(w) = 0\,. \tag{1.10}$$

We use ordinary-differential-equation arguments to prove that, for each prescribed number of nodes, there is a solution $w : [0,\infty) \to \mathbb{R}$ to (1.10) that is exponentially decreasing far from the origin. We establish this result for $N \geq 2$ and $\ell \geq 1$, under hypotheses on the nonlinearity f that are compatible with global existence of finite-energy solutions to the associated nonlinear wave equations, as in [8]. For our nonlinearities, the corresponding standing-wave solutions for (NLS) have a structure consisting of a core region resembling a vortex (a nonlocalized solution with asymptotically constant amplitude), encapsulated by a membrane region that exponentially localizes the solution.

Let G be the primitive of g. The individual terms in the conserved energy densities $e_1[u] \equiv \frac{1}{2}|\nabla u|^2 - G(|u|)$ for (NLS) and $e_2[u] \equiv \frac{1}{2}|u_t|^2 + \frac{1}{2}|\nabla u|^2 - G(|u|)$ for (NLKG) are all nonnegative provided that G is nonpositive. In that case, the time-independence of the spatial integrals of $e_1[u]$ and $e_2[u]$ ensures global existence of finite-energy solutions. Because $f(s) = g(s) + \omega s$, the primitive F of f is related to G by $F(s) = G(s) + \frac{1}{2}\omega s^2$. Accordingly, we treat nonlinearities f in (1.10) whose primitives are quadratically bounded above, corresponding to nonpositive G.

Our hypotheses on f are essentially those for the "hilltop case" in [8]. We suppose that f is an odd locally Lipschitz-continuous function with $-\infty < -\sigma^2 \equiv \lim_{s\to 0} \frac{f(s)}{s} \leq 0$, and in case $\sigma = 0$ we require that $f(s) < 0$ for small positive s. We assume that there exist β and δ with $0 < \beta < \delta$ such that $f(\beta) = f(\delta) = 0$ and $f > 0$ on (β, δ). For simplicity, we assume that $f(s)$ is strictly decreasing for s near δ. In addition, we assume that the primitive $F(s) \equiv \int_0^s f(t)\,dt$ has a positive zero γ with $\beta < \gamma < \delta$ and that $F < 0$ on $(0, \gamma)$. We denote the smallest positive zero of f by α. Thus $0 < \alpha \leq \beta < \gamma < \delta$. See Figure 1. We make no assumptions on $f(s)$ for arguments with $|s| > \delta$.

To formulate a well-posed initial value problem for (1.10) with initial conditions given at $r = 0$, we make the change of variable $w(r) = r^\ell z(r)$ to obtain the equation

$$z'' + \tfrac{2\ell+N-1}{r} z' + \tfrac{1}{r^\ell} f(r^\ell z) = 0 \tag{1.11}$$

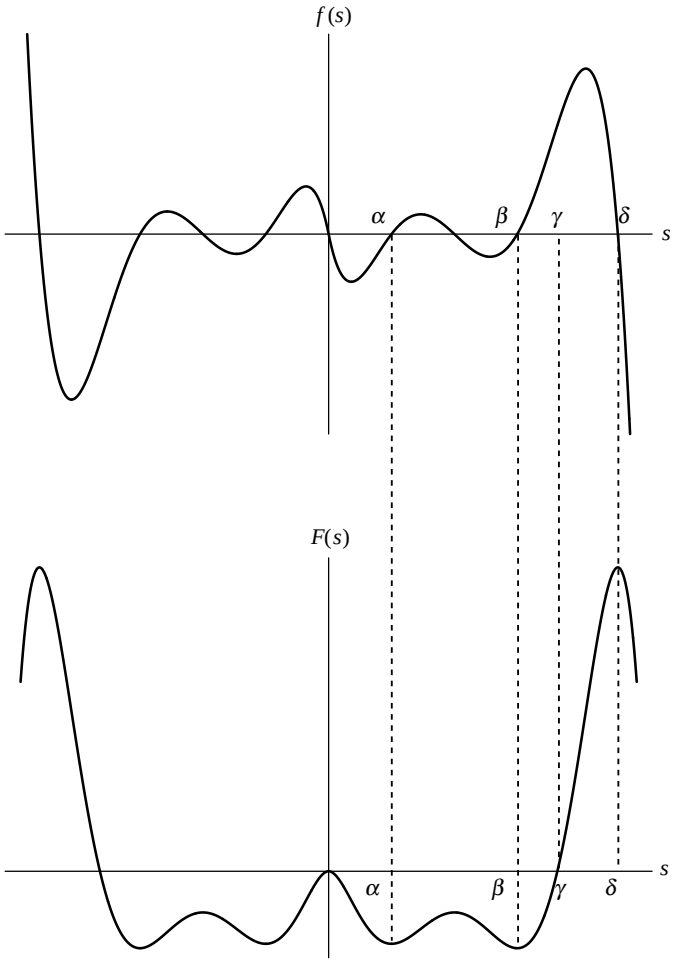

FIG. 1.

for z, which, by virtue of the condition on f at zero, has well-posed initial value problems obtained by specifying

$$z(0) = d \text{ and } z'(0) = 0. \tag{1.12}$$

Since f is odd it suffices to consider nonnegative d, and henceforth we assume $d \geq 0$. If z is a C^2 solution of such an initial value problem, it follows that $w(r) = r^\ell z(r)$ is a C^2 solution of the differential equation

$$w'' + \frac{N-1}{r} w' - \frac{\ell(\ell+N-2)}{r^2} w + f(w) = 0 \tag{1.13}$$

subject to

$$\lim_{r \to 0^+} \frac{w(r)}{r^\ell} = d \quad \text{and} \quad \lim_{r \to 0^+} \left(\frac{w(r)}{r^\ell} \right)' = 0 \tag{1.14}$$

and that the corresponding function $v(x) = w(|x|)\hat{\psi}(\hat{x})$ is C^2 on $\mathbb{R}^N$. We remark that the term $\frac{\ell(\ell+N-2)}{r^2} w$ in (1.13) makes the behavior of solutions significantly different

from that in the "radial" case $\ell = 0$. See [7] and [8] for commentary on the novel features of these initial value problems.

We remark that the equivalence of (1.10) and (1.11) shows that, for the case of superlinearly-growing f (not under consideration here), the analysis in [7] for the $N = 2$ case applies to establish the existence of localized standing-wave solutions to (NLS) and (NLKG) for such f and general N.

We prove the following main theorem.

MAIN THEOREM. *Let the nonlinearity f have the ("hilltop") properties specified. Let integers $N \geq 2$ and $\ell \geq 1$ be given. Then, for each nonnegative integer n, there is a positive number d and a C^2 solution w to* (1.13) *and* (1.14) *such that* $\lim_{r\to\infty} w(r) = 0$ *and w has exactly n positive zeros.*

Figure 2 shows the radial profiles $w(r)$ with $n = 0$ and $n = 1$ positive zeros in the case $N = 2$ and $\ell = 2$ for $f(s) \equiv -(4.3)s + 5s^3 - s^5$.

We remark that if $\sigma \neq 0$, then the solutions whose existence is established by the main theorem decay exponentially as $r \to \infty$. This can be established using the proof technique in section 6 of [7].

In section 2, we show that there are unit-vector-valued eigenfunctions of the Laplacian on the sphere. In section 3, we return to consideration of the ordinary differential equation and establish some general properties of solutions of (1.13)–(1.14). In section 4, we show that there is a value of d for which the solution to (1.13)–(1.14) is monotonically increasing to δ as $r \to \infty$. Section 5 contains the proof of the main theorem.

In the following, we write $r \to 0$ and $d \to 0$ to mean $r \to 0^+$ and $d \to 0^+$, respectively. Throughout, $N \geq 2$, $\ell \geq 1$, and $w(r) = r^\ell z(r)$.

We will make use of the identity

$$r^2(\tfrac{1}{2}w'^2 + F(w))|_{r_1}^{r_2} + (N-2)\int_{r_1}^{r_2} sw'^2\,ds = \tfrac{\ell(\ell+N-2)}{2}w^2|_{r_1}^{r_2} + 2\int_{r_1}^{r_2} sF(w(s))\,ds \tag{1.15}$$

which results from multiplying (1.13) by r^2w' to obtain $(\frac{1}{2}r^2w'^2)' + (N-2)rw'^2 - (\frac{\ell(\ell+N-2)}{2}w^2)' + r^2(F(w))' = 0$, and then integrating on (r_1, r_2).

2. Vector-valued eigenfunctions of the Laplacian on the sphere. In this section we show that unit-vector-valued eigenfunctions of the Laplacian on the sphere exist for suitably large dimension M of the range space. We first recall [4, section 2H] that the Laplacian Δ_S on the unit sphere S^{N-1} in $\mathbb{R}^N$ has scalar-valued eigenfunctions with eigenvalues $\mu_\ell \equiv -\ell(\ell+N-2)$, $\ell = 0,\ 1,\ 2,\ \ldots$; the subspace H_ℓ of $L^2(S^{N-1})$ consisting of eigenfunctions with eigenvalue μ_ℓ has dimension

$$D_\ell = \frac{(2\ell+N-2)(\ell+N-3)!}{(N-2)!\,\ell!}. \tag{2.1}$$

(In the case $N = 2$, we have $D_0 = 1$ and $D_\ell = 2$ for all $\ell \geq 1$.) For given N and ℓ, let $\{Y_{\ell m} \mid m = 1,\ 2,\ \ldots,\ D_\ell\}$ be an orthonormal basis for H_ℓ consisting of real-valued functions. Then the identity

$$\sum_{m=1}^{D_\ell} (Y_{\ell m}(\hat{x}))^2 = \frac{D_\ell}{\sigma_N} \tag{2.2}$$

holds for all $\hat{x} \in S^{N-1}$, where $\sigma_N \equiv \frac{2\pi^{N/2}}{\Gamma(N/2)}$ is the area of S^{N-1} in $\mathbb{R}^N$.

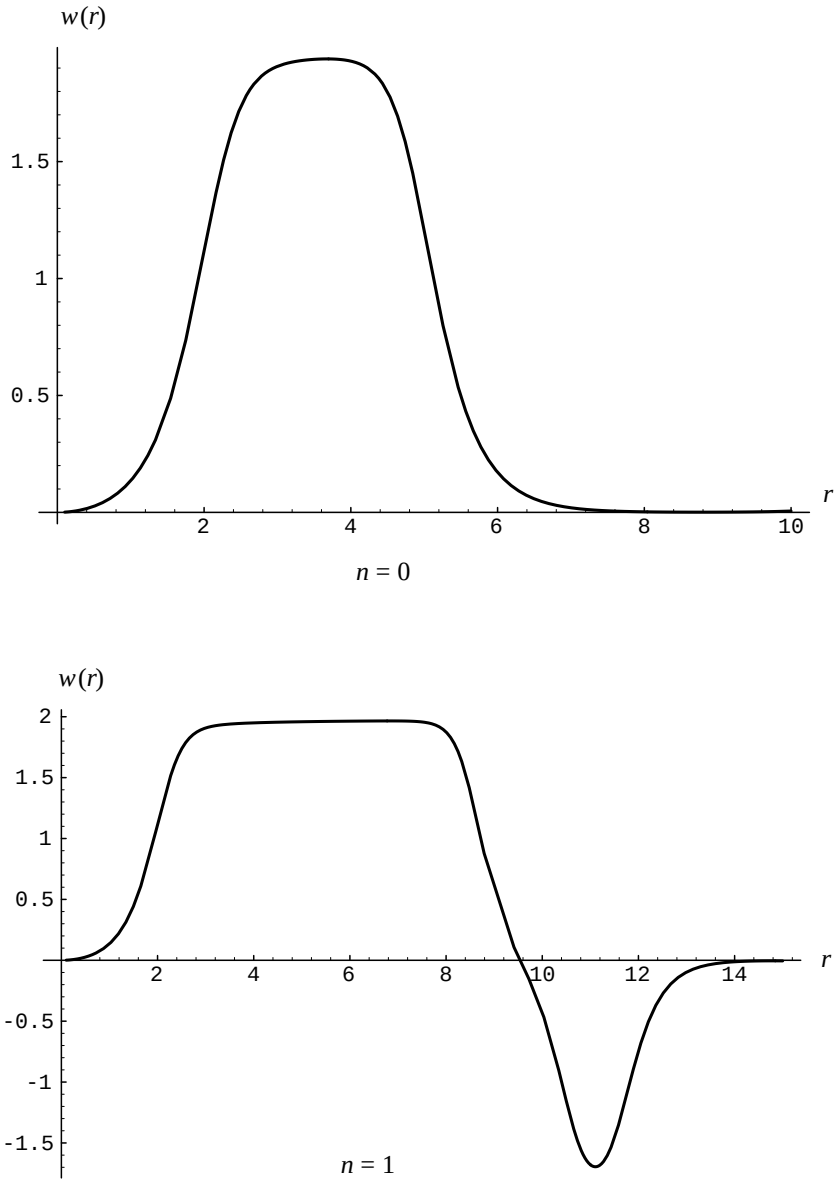

FIG. 2. *Radial profiles $w(r)$ in the case $N = 2$ and $l = 2$ for $f(s) = -(4.3)s + 5s^3 - s^5$.*

We now construct unit-vector-valued eigenfunctions. Given the spatial dimension N and a nonnegative integer ℓ, a vector-valued eigenfunction of Δ_S with eigenvalue μ_ℓ has the general form

$$\psi(\hat{x}) \equiv \sum_{m=1}^{D_\ell} a_m Y_{\ell m}(\hat{x}), \tag{2.3}$$

where each a_m is a (constant) vector in $\mathbb{R}^M$. The requirement that ψ be a unit vector

for all $\hat{x} \in S^{N-1}$ then becomes

$$1 = |\psi(\hat{x})|^2 = \sum_{m=1}^{D_\ell} \sum_{n=1}^{D_\ell} (a_m \cdot a_n)\, Y_{\ell m}(\hat{x}) Y_{\ell n}(\hat{x}), \tag{2.4}$$

where $a_m \cdot a_n$ is the ordinary Euclidean inner product of the vectors a_m and a_n. In view of the identity (2.2), we may satisfy this requirement by choosing the vectors $\{a_m \mid m = 1,\ 2,\ \ldots,\ D_\ell\}$ to be pairwise orthogonal and normalized by $|a_m| = \sqrt{\sigma_N / D_\ell}$.

We note that in order to accommodate the D_ℓ linearly independent vectors in this construction, the dimension M of the range space must be at least D_ℓ. In the case of $N = 2$ spatial dimensions, $D_\ell = 2$ for all $\ell \geq 1$, and the maps $\psi_\ell : S^1 \to S^1$ given by $\psi_\ell(\theta) \equiv (\cos\ell\theta, \sin\ell\theta)$ are eigenfunctions of Δ_S with eigenvalue $\mu_\ell = -\ell^2$. This is the situation treated in [7] (for growing nonlinearity f).

In higher spatial dimensions, D_ℓ is an increasing function of ℓ, so that the range of admissible values of ℓ in this construction depends on M. In particular, since our construction requires D_ℓ linearly independent vectors in $\mathbb{R}^M$, for fixed domain dimension N and range dimension M, there is a maximum value $\ell_{\max} = \max\{\ell : D_\ell \leq M\}$ of ℓ for which our construction can produce unit-vector-valued eigenfunctions of Δ_S with eigenvalue μ_ℓ. (This upper limit on the "spin" ℓ is of potential interest for the modeling of elementary particles with equations of these types.)

We note, however, that $D_1 = N$ for all N, so that a vector field ($M = N$) accommodates eigenvalue μ_1. In particular, $\psi_1 : S^{N-1} \to S^{N-1}$, defined by $\psi_1(\hat{x}) \equiv \hat{x}$, is an eigenfunction of Δ_S with eigenvalue $\mu_1 = -(N-1)$ for general N.

In all cases, given spatial dimension N and index ℓ, we may choose suitably-normed pairwise orthogonal vectors a_m so that (2.3) furnishes unit-vector-valued eigenfunctions of the Laplacian on S^{N-1} with eigenvalue μ_ℓ, provided that the dimension M of the range space is sufficiently large to accommodate D_ℓ linearly independent vectors.

3. Properties of solutions to the initial value problem. As in [7], it is a straightforward task to show that for any fixed $d \geq 0$, the initial value problem (1.13)–(1.14) has a unique C^2 solution on some small interval $(0, \epsilon)$ with $\epsilon > 0$. The solution $w(r) = w(r, d)$ of (1.13)–(1.14) may be continued in $r > 0$ as long as $|w(r)| \leq \delta$ and $|w'(r)|$ remains finite. Let $(0, R(d))$ be the resulting maximal open interval of existence for $w(r, d)$. If $R(d) = \infty$, then $|w(r, d)| \leq \delta$ for $r \in (0, \infty)$. If $0 < R(d) < \infty$, then, because f is bounded on $[-\delta, \delta]$, both limits $w(R(d), d) \equiv \lim_{r \to R(d)^-} w(r, d)$ and $w'(R(d), d) \equiv \lim_{r \to R(d)^-} w'(r, d)$ exist, which we can verify as follows.

For $r \in (0, R(d))$, we have $r^\ell |z| = |w| \leq \delta$. Multiplying (1.11) by $r^{2\ell+N-1}$ and integrating give

$$-z'(r, d) = \frac{1}{r^{2\ell+N-1}} \int_0^r s^{\ell+N-1} f(s^\ell z(s, d))\, ds. \tag{3.1}$$

Since f is bounded on $[-\delta, \delta]$, we see that $|z'(r, d)| \leq (\text{constant}) r^{1-\ell}$ for $r \in (0, R(d))$. Thus, $\lim_{r \to R(d)^-} z(r, d)$ exists. Furthermore, because f is bounded and $|z'|$ is bounded for r near $R(d)$, (1.11) shows that $|z''(r, d)|$ is also bounded for r near $R(d)$, and thus $\lim_{r \to R(d)^-} z'(r, d)$ exists as well. Because $w(r, d) = r^\ell z(r, d)$, it follows that the limits of w and w' as $r \to R(d)^-$ both exist, as asserted.

We now establish some qualitative properties of solutions $w(r)$ to (1.13)–(1.14).

LEMMA 3.1. *Suppose p is a local maximum for $|w|$ with $0 < p < R(d)$ and $0 < |w(p)| < \delta$. Then $F(w(r)) \le F(w(p))$ for $r > p$. In particular, if $|w(p)| \ge \gamma$, then $|w(r)| \le |w(p)|$ for $r > p$.*

Proof. Consider first the case $0 < w(p) < \delta$. Since p is a local maximum for w, we have that $w'(p) = 0$ and $w''(p) \le 0$. Therefore, from (1.13) we have $f(w(p)) \ge \frac{\ell(\ell+N-2)}{p^2} w(p) > 0$. Thus, F is increasing near $w(p)$. Since $w(r) \le w(p)$ for r near p, we then have that $F(w(r)) \le F(w(p))$ for r near p.

Next, suppose by way of contradiction that the lemma is false. Then there exists a finite number s with $p < s$ such that $[p, s]$ is the r-interval of maximal length on which $F(w(r)) \le F(w(p))$. It follows that $F(w(s)) = F(w(p))$.

We now evaluate the identity (1.15) with $r_1 = p$, $r_2 = s$. This gives

$$F(w(p))[s^2 - p^2] \le \tfrac{\ell(\ell+N-2)}{2}[w^2(s) - w^2(p)] + 2\int_p^s tF(w)\,dt. \tag{3.2}$$

Since $F(w(r)) \le F(w(p))$ on $[p, s]$, we have

$$2\int_p^s tF(w)\,dt \le F(w(p))[s^2 - p^2].$$

Thus (3.2) implies

$$w^2(p) \le w^2(s).$$

Therefore, there exists q with $p < q \le s$ such that $w(p) = |w(q)|$. Again, using identity (1.15), this time with $r_2 = q$ and $r_1 = p$, gives (since F is even and thus $F(w(q)) = F(w(p))$)

$$\frac{1}{2}q^2 w'(q)^2 + F(w(p))[q^2 - p^2] \le 2\int_p^q rF(w)\,dr. \tag{3.3}$$

We may assume that $F(w(r)) \not\equiv F(w(p))$ on $[p, q]$. (Otherwise, $w(r)$ would be constant, which is impossible). Thus (3.3) implies

$$\frac{1}{2}q^2 w'(q)^2 + F(w(p))[q^2 - p^2] \le 2\int_p^q rF(w)\,dr < F(w(p))[q^2 - p^2],$$

or equivalently, $q^2 w'(q)^2 < 0$, which is absurd. This contradiction completes the proof of Lemma 3.1 in the case where $w(p)$ is positive.

To treat the situation in which $w(p)$ is negative, we note that because f is odd, $\tilde{w}(r) \equiv -w(r)$ is also a solution to (1.13), and $\tilde{w}(p) > 0$ is a local maximum of $\tilde{w}$. Thus our arguments apply without change to $\tilde{w}$, and complete the proof of Lemma 3.1 in this case as well.

LEMMA 3.2. *Suppose that w is not identically zero and there exists $t \in (0, R(d))$ such that $w(t) = 0$. Then, there exists q with $0 < q < t$ such that $|w(q)| > \gamma$.*

Proof. The quantity $w'(t)^2$ is strictly positive, since otherwise $w \equiv 0$ by uniqueness of solutions of initial value problems. Using identity (1.15) with $r_2 = t$ and $r_1 = 0$, we thus obtain

$$0 < \frac{1}{2}t^2 w'(t)^2 \le 2\int_0^t sF(w(s))\,ds.$$

Thus the integrand is positive somewhere, that is, $F(w(q)) > 0$ for some $q \in (0,t)$. Hence $|w(q)| > \gamma$, as claimed.

LEMMA 3.3. *Suppose $w'(r) \geq 0$ on $(a,b) \subset (0,R(d))$, $w(a) \geq 0$, and $w \not\equiv 0$. Then in fact $w'(r) > 0$ on (a,b).*

Proof. Suppose there exists $p \in (a,b)$ with $w'(p) = 0$. Then $w(p) \geq w(a) \geq 0$ since $w' \geq 0$ on (a,b). In addition, $w(p) > 0$ because otherwise $w \equiv 0$ by the uniqueness of solutions of initial value problems. Now, since $w' \geq 0$ on (a,b), $w'(r)$ has a minimum at p, and therefore $w''(p) = 0$. We next observe that the composition $f(w(r))$ is differentiable at $r = p$ even though f is only locally Lipschitz, and $\frac{d}{dr} f(w(r))|_{r=p} = 0$. To see this, observe that $0 \leq \lim_{r\to p} |\frac{f(w(r))-f(w(p))}{r-p}| \leq K \lim_{r\to p} |\frac{w(r)-w(p)}{r-p}| = K|w'(p)| = 0$, where K is the Lipschitz constant for f near $w(p)$. Thus we may differentiate (1.13) at $r = p$, to obtain $w'''(p) = -\frac{2\ell(\ell+N-2)}{p^3} w(p) < 0$. But $w'''(p)$ cannot be negative if $w'(r)$ has a minimum at $r = p$. Thus there cannot be any point $p \in (a,b)$ with $w'(p) = 0$, which establishes the assertion of Lemma 3.3.

LEMMA 3.4. *If $w(q) = \delta$ for some finite $q \in (0,R(d)]$, then $w'(q) > 0$.*

Proof. Recall that $|w(r)| \leq \delta$ for $r \in (0,R(d)]$. Thus $w'(q) \geq 0$. Now suppose $w'(q) = 0$. Then $w''(q) \leq 0$. On the other hand, from (1.13) we have $w''(q) = \frac{\ell(\ell+N-2)}{q^2}\delta > 0$, a contradiction. Thus, $w'(q) > 0$ and the lemma is proved.

LEMMA 3.5. *$w(r) > -\delta$ for all $r \in (0,R(d))$. If $R(d) < \infty$, then also $w(R(d)) > -\delta$.*

Proof. Recall that $d \geq 0$, so that (from (1.14)) w is positive for small positive r. If there exists $r_0 \in (0,R(d)]$ with $w(r_0) = -\delta$, then w must have a local maximum, p, with $0 < p < r_0$ and $0 < w(p) \leq \delta$. By Lemma 3.4, $0 < w(p) < \delta$. Now by Lemma 3.1, $F(w(r)) \leq F(w(p)) < F(\delta)$ for $r > p$. Evaluating at r_0 gives $F(\delta) < F(\delta)$, a contradiction. The lemma is proved.

We now define

$$\tilde{E}(r) = \frac{\frac{1}{2}w'^2(r) + F(w(r)) - F_0}{r^{2\ell-2}} + \frac{\ell(\ell+N-2)}{2}\frac{w^2(r)}{r^{2\ell}}, \tag{3.4}$$

where

$$F_0 \equiv \min_{y\in[-\delta,\delta]} F(y) < 0. \tag{3.5}$$

We note that $\tilde{E}(r) \geq 0$, and from (1.14) we see that

$$\tilde{E}(0) = +\infty \quad \text{if} \quad \ell > 1$$

and

$$\tilde{E}(0) = \frac{N}{2}d^2 - F_0 > 0 \quad \text{if} \quad \ell = 1.$$

A computation shows that

$$\tilde{E}' = -\frac{(\ell+N-2)}{r^{2\ell-1}}\left(w' - \frac{\ell w}{r}\right)^2 - \frac{2(\ell-1)[F(w(r)) - F_0]}{r^{2\ell-1}} \leq 0. \tag{3.6}$$

For each solution $w(r)$, $\tilde{E}(r)$ is thus a nonnegative, nonincreasing quantity. Since the term $F(w(r)) - F_0$ is nonnegative, we have that

$$\frac{w'^2}{r^{2\ell-2}} + \frac{w^2}{r^{2\ell}} \leq \tilde{E}(r_0) < \infty \tag{3.7}$$

for $0 < r_0 < r < R(d)$. From this estimate and Lemmas 3.4 and 3.5, it follows that the only way in which a solution $w(r)$ can fail to extend to all positive r is if $w(r)$ attains the value δ. Furthermore, if $R(d) < \infty$ then $|w| < \delta$ on $[0, R(d))$ and $w(R(d)) = \delta$. Otherwise, if $R(d) = \infty$, then $|w| < \delta$ on $[0, \infty)$.

LEMMA 3.6. *Let $w(r, d)$ be the solution of the initial value problem* (1.13)–(1.14). *If $R(d) < \infty$, then $w'(r, d) > 0$ on $(0, R(d)]$.*

Proof. If $d = 0$, then w is identically zero, so then $R(d) = \infty$. Thus under the hypotheses here, $d > 0$. From (1.12) and the relation $w(r) = r^\ell z(r)$, it follows that $w'(r) > 0$ for small $r > 0$. Now suppose that w has a local maximum, p, with $0 < p < R(d)$ and $0 < w(p) < \delta$. By Lemma 3.1, $F(w(r)) \le F(w(p)) < F(\delta)$ for $r > p$. Evaluating at $R(d)$ gives $F(\delta) < F(\delta)$, a contradiction. Hence, $w'(r) \ge 0$ on $(0, R(d))$. Then, by Lemma 3.3, $w'(r) > 0$ on $(0, R(d))$, and by Lemma 3.4, $w'(R(d)) > 0$. This completes the proof of the lemma.

4. Existence of a positive, monotone solution with limiting value δ. Recall that $\ell \ge 1$ and $N \ge 2$. The proofs of Lemmas 4.1 and 4.2 below are implicit in [7, section 3].

LEMMA 4.1. *For $d > 0$ chosen small enough,* (1.13)–(1.14) *has a solution, $w(r, d)$, which satisfies $0 < w(r, d) < \gamma$ for all $r > 0$.*

LEMMA 4.2. *For any $d > 0$, there exists a smallest value of r, a_d, such that $w(a_d, d) = \alpha$, and $w' > 0$ for all $r \in (0, a_d)$.*

LEMMA 4.3. *For $r \in (0, a_d)$ we have $w(r) \ge dr^\ell$. (Consequently, taking limits as $r \to a_d^-$ gives $\alpha \ge da_d^\ell$. Therefore, $a_d \to 0$ as $d \to \infty$).*

Proof. On $[0, a_d]$ we have $f(w) \le 0$. Hence, from (1.11) we obtain

$$(r^{2\ell+N-1} z')' \ge 0.$$

Integrating on $(0, r)$ gives $z' \ge 0$, that is, $(w(r)/r^\ell)' \ge 0$. Thus, using (1.14) we have

$$w(r) \ge dr^\ell$$

on $(0, a_d)$. This completes the proof of Lemma 4.3.

LEMMA 4.4. *For $d > 0$ large enough, we have $R(d) < \infty$.*

Proof. Assume by way of contradiction that $R(d) = \infty$ for an unbounded sequence of positive values of d. For such values of d with $R(d) = \infty$, we know by Lemma 3.4 that $|w| < \delta$ on $(0, \infty)$. Then (1.13) gives

$$w'' + \frac{N-1}{r} w' - \frac{\ell(\ell+N-2)}{r^2} w + M \ge 0,$$

where $M \equiv \max_{y \in [-\delta, \delta]} f(y)$. Letting $w = r^\ell z$ yields

$$(r^{2\ell+N-1} z')' \ge -M r^{\ell+N-1}.$$

Hence, integrating on $(0, r)$ and using (1.12) gives

$$z' \ge -\frac{M}{\ell+N} r^{1-\ell}. \tag{4.1}$$

We now must consider three different cases.

Case I ($\ell = 1$). Integrating (4.1) on $(0, r)$ and using $z(0) = d$ give

$$z \ge d - \frac{M}{1+N} r$$

and thus

$$w \geq r\left(d - \frac{M}{1+N}r\right). \tag{4.2}$$

Evaluating at $r = 1$ gives

$$w(1) \geq d - \frac{M}{1+N}. \tag{4.3}$$

Clearly, for large enough d, we have $w(1) > \delta$, which is a contradiction to our assumption that $R(d) = \infty$ (for this implied that $|w| < \delta$). Thus, we must have that $R(d) < \infty$ for large enough d.

This completes the lemma for Case I.

Case II ($\ell = 2$). We begin by integrating (4.1) on (a_d, r) and we obtain

$$z(r) \geq z(a_d) - \frac{M}{2+N}[\log r - \log a_d] \quad \text{for} \quad r > a_d.$$

Since $w = r^2 z$, we have

$$\frac{w}{r^2} \geq \frac{\alpha}{a_d^2} + \frac{M}{2+N}\log a_d - \frac{M}{2+N}\log r \quad \text{for} \quad r > a_d.$$

By Lemma 4.3, $a_d \to 0$ as $d \to \infty$. Thus, $a_d < 1$ for large enough d. Evaluating the above inequality at $r = 1$ we obtain

$$w(1) \geq \frac{\alpha}{a_d^2} + \frac{M}{2+N}\log a_d = \frac{1}{a_d^2}\left(\alpha + \frac{M}{2+N}a_d^2 \log a_d\right).$$

Since $a_d \to 0$ as $d \to \infty$, it follows that $\lim_{d\to\infty} a_d^2 \log a_d = 0$. So, for large enough d, we have $w(1) > \delta$ which again is a contradiction to the fact that $R(d) = \infty$. Thus, $R(d) < \infty$ for large enough d. This completes Case II.

Case III ($\ell > 2$). We begin by integrating (4.1) on (a_d, r) and obtain

$$\frac{w}{r^\ell} = z(r) \geq z(a_d) + \frac{M}{(\ell+N)(\ell-2)}\left[\frac{1}{r^{\ell-2}} - \frac{1}{a_d^{\ell-2}}\right] = \frac{\alpha}{a_d^\ell} + \frac{M}{(\ell+N)(\ell-2)}\left[\frac{1}{r^{\ell-2}} - \frac{1}{a_d^{\ell-2}}\right]$$

$$= \frac{1}{a_d^{\ell-2}}\left[\frac{\alpha}{a_d^2} - \frac{M}{(\ell+N)(\ell-2)}\right] + \frac{M}{(\ell+N)(\ell-2)}\frac{1}{r^{\ell-2}}. \tag{4.4}$$

Because $a_d \to 0$ as $d \to \infty$, the term in brackets in (4.4) is positive if d is chosen large enough. Thus for sufficiently large d,

$$w \geq \frac{M}{(\ell+N)(\ell-2)}r^2 \quad \text{for } r > a_d. \tag{4.5}$$

Thus $w > \delta$ for large enough r, which contradicts the assumption that $R(d) = \infty$. Therefore, $R(d) < \infty$. This completes Case III and thus completes the proof of Lemma 4.4.

We now let D be the set of d-values for which the solution reaches the hilltop at a finite time. That is, we define

$$D = \{d > 0 | R(d) < \infty\}.$$

By Lemma 4.4, if d is chosen large enough, then $R(d) < \infty$. Thus the set D is nonempty. Also, by Lemma 4.1, we have $0 < w < \gamma < \delta$ for all $r > 0$ if d is chosen small enough. Thus, D is bounded away from zero.

We now let

$$d^* = \inf D.$$

Note that $d^* > 0$.

LEMMA 4.5. *For $d \in (0, d^*)$, the solution $z(r,d)$ of (1.11)–(1.12) satisfies*

$$|z(r,d)| \le C_1, \qquad |z'(r,d)| \le C_2, \quad \text{and} \quad |z''(r,d)| \le C_3$$

for all $r > 0$, where C_1, C_2, and C_3 are independent of d.

Proof. Since $d \in (0, d^*)$, in particular $d \notin D$. Thus $R(d) = \infty$ which implies (by Lemma 3.4) that

$$|w(r,d)| < \delta \ \text{ on } \ [0,\infty). \tag{4.6}$$

We now estimate $z(r,d)$. Integrating (3.1) gives

$$z(r,d) = d - \int_0^r \frac{\int_0^t s^{\ell+N-1} f(s^\ell z(s,d))\,ds}{t^{2\ell+N-1}}\,dt. \tag{4.7}$$

Next, note that $\frac{f(u)}{u}$ is bounded (since f is bounded and $\lim_{u\to 0}\frac{f(u)}{u} = -\sigma^2$) so that there is a $B > 0$ such that $|f(u)| \le B|u|$. Now let $s_0 \in [0, \sqrt{(2\ell+N)/B}]$ be such that

$$|z(s_0,d)| = \max_{\left[0,\sqrt{\frac{2\ell+N}{B}}\right]} |z(r,d)|.$$

Estimating (4.7) at s_0 gives

$$|z(s_0,d)| \le d + B|z(s_0,d)| \int_0^{s_0} \frac{\int_0^t s^{2\ell+N-1}\,ds}{t^{2\ell+N-1}}\,dt = d + \frac{B|z(s_0,d)|s_0^2}{2(2\ell+N)} \le d + \frac{1}{2}|z(s_0,d)|.$$

Consequently,

$$\max_{\left[0,\sqrt{\frac{2\ell+N}{B}}\right]} |z(r,d)| \le 2d \le 2d^*. \tag{4.8}$$

Further, by (4.6) we know that

$$\max_{\left[\sqrt{\frac{2\ell+N}{B}},\infty\right)} |z(r,d)| = \max_{\left[\sqrt{\frac{2\ell+N}{B}},\infty\right)} \frac{|w(r,d)|}{r^\ell} < \delta\left(\frac{B}{2\ell+N}\right)^{\ell/2}. \tag{4.9}$$

Combining (4.8) and (4.9), we then have for $0 < d < d^*$,

$$|z(r,d)| \le 2d^* + \delta\left(\frac{B}{2\ell+N}\right)^{\ell/2} = C_1(d^*, \delta, \ell, N, B).$$

Next, we estimate $z'(r,d)$. Equation (3.1) gives

$$|z'(r,d)| = \left|\frac{1}{r^{2\ell+N-1}}\int_0^r s^{\ell+N-1} f(s^\ell z(s,d))\,ds\right| \le \frac{BC_1}{2\ell+N} r. \tag{4.10}$$

On the other hand, we may obtain a different estimate for $|z'|$ by using the fact that $|f(y)| \le B\delta$ for $y \in [-\delta, \delta]$. Equation (3.1) gives

$$|z'(r,d)| \le \frac{B\delta}{r^{2\ell+N-1}} \int_0^r s^{\ell+N-1}\, ds = \left(\frac{B\delta}{\ell+N}\right) \frac{1}{r^{\ell-1}}. \tag{4.11}$$

Combining the two estimates (4.10) and (4.11) by locating the intersection of the graphs of the upper bounds as functions of r, we obtain

$$|z'(r,d)| \le B\left(\frac{\delta}{\ell+N}\right)^{1/\ell} \left(\frac{C_1}{2\ell+N}\right)^{(\ell-1)/\ell} = C_2(d^*, \delta, \ell, N, B).$$

Last, using (1.11) and the previous estimates, we obtain

$$|z''(r,d)| \le C_3(d^*, \delta, \ell, N, B).$$

This completes the proof of Lemma 4.5.

LEMMA 4.6. *$R(d^*) = \infty$.*

Proof. For $d \in (0, d^*)$, Lemma 4.5 establishes that all of $|z(r,d)|$, $|z'(r,d)|$, and $|z''(r,d)|$ are bounded uniformly in d for all $r \ge 0$. Thus, by the Arzelá–Ascoli theorem, there exists a sequence $\{d_j\}$ tending to d^* from below and a function $z^*(r)$ such that $z(r,d_j) \to z^*(r)$ and $z'(r,d_j) \to z^{*\prime}(r)$ as $j \to \infty$ (where the convergence is uniform on compact sets). In addition, taking limits in (1.11) as $d \to d^{*-}$ shows that z^* solves (1.11) on $[0,\infty)$.

Now suppose that the assertion of the lemma is false, that is, assume that $R(d^*) < \infty$. By uniqueness of solutions to initial value problems, we know that $z^*(r)$ is equal to $z(r,d^*)$ on $[0, R(d^*)]$. Thus, $w^*(r) \equiv r^\ell z^*(r)$ satisfies (1.13)–(1.14) on $[0,\infty)$ and $w^*(r) = w(r,d^*)$ on $[0,R(d^*)]$. We also have from (4.6) that $|w(r,d)| < \delta$ for $0 \le d < d^*$. Taking the limit as $d \to d^{*-}$, we see that $|w^*(r)| \le \delta$ for all $r > 0$. Since $w^*(R(d^*)) = w(R(d^*), d^*) = \delta$, we see that $w^*(r)$ has a local maximum at $R(d^*)$. This contradicts the fact that $w^{*\prime}(R(d^*)) = w'(R(d^*), d^*) > 0$, established by Lemma 3.4. Thus we must have $R(d^*) = \infty$. This completes the proof of Lemma 4.6.

LEMMA 4.7. *$w(r,d^*) > 0$ and $w'(r,d^*) > 0$ for $r > 0$, and $\lim_{r\to\infty} w(r,d^*) = \delta$.*

Proof. We adopt the shorthand $w^*(r) \equiv w(r,d^*)$. Since $R(d^*) = \infty$, we know that $|w^*(r)| < \delta$ for all $r \ge 0$. Also, since $d^* > 0$, from (1.14) we know that $w^*(r)$ is positive for small positive r.

We claim that $w^{*\prime}(r) \ge 0$ for $r > 0$. To verify this claim, we note that if $w^{*\prime}(r) < 0$ for some r, then $w^*(r)$ must have a local maximum. In that case, because solutions depend continuously on initial data, $w(r,d)$ must also have a local maximum for $d \in D$ sufficiently close to d^*. But Lemma 3.6 establishes that for $d \in D$, $w'(r,d) > 0$ on $(0, R(d)]$. Thus $w^*(r)$ cannot have a local maximum, hence $w^{*\prime}(r) \ge 0$ for all $r > 0$.

Lemma 3.3 then establishes that $w^{*\prime}(r) > 0$ for all $r > 0$. Since $w^*(r)$ is positive for small positive r, it immediately follows that $w^*(r) > 0$ for all $r > 0$.

It remains to show that $\lim_{r\to\infty} w^*(r) = \delta$. Since $w^*(r)$ is monotonically increasing and bounded above by δ, the limit $L \equiv \lim_{r\to\infty} w^*(r)$ exists, and $L \le \delta$.

We claim that $f(L) = 0$. To verify this claim, note that (1.15) yields

$$\frac{1}{2} w^{*\prime 2} + F(w^*) \le \frac{\ell(\ell+N-2)}{2} \frac{w^{*2}}{r^2} + \frac{2}{r^2} \int_0^r sF(w^*)\, ds.$$

Since $|w^*(r)| \le \delta$ we have

$$\frac{2}{r^2} \int_0^r sF(w^*)\, ds \le F(\delta).$$

Also, $F(w)$ is bounded below by F_0. Hence,

$$\frac{1}{2}w^{*\prime 2} < \frac{\ell(\ell+N-2)}{2}\frac{\delta^2}{r^2} + F(\delta) - F_0.$$

Since (from (1.14)) $w^{*\prime}(r)$ has a finite limit as $r \to 0$, we thus conclude that $|w^{*\prime}|$ is bounded. Taking the limit $r \to \infty$ in (1.13) then yields $\lim_{r\to\infty} w^{*\prime\prime}(r) = -f(L)$. Since $|w^{*\prime}|$ is bounded, the limiting value of $w^{*\prime\prime}$ must be zero. Therefore $f(L) = 0$, as claimed.

We have thus established that w^* limits to a positive zero L of f. It remains to show that $L = \delta$. Recall that $f(\beta) = f(\delta) = 0$ and $f(s) > 0$ on (β, δ). We will show for $d \in D$ that $w(r, d)$ reaches $\frac{\gamma+\beta}{2}$ at $r = b_d$ where b_d can be bounded independent of d. Given that fact, and the fact that the monotonic function w^* is approximated arbitrarily closely on any compact interval by a solution $w(r, d)$ with $d \in D$, it follows that $L \geq \frac{\gamma+\beta}{2} > \beta$, from which we conclude (since δ is the only zero of f greater than γ) that $L = \delta$.

To show that b_d is bounded, consider $d \in D$. Then w achieves δ. Thus, w reaches γ at some finite value, $r = c_d$, and since $w' > 0$ (by Lemma 3.6) we have $0 < w < \gamma$ on $(0, c_d)$. Using identity (1.15) at c_d gives

$$0 \leq \frac{1}{2}c_d^2 w'(c_d)^2 \leq \frac{\ell(\ell+N-2)}{2}\gamma^2 + 2\int_0^{c_d} rF(w(r))\,dr. \tag{4.12}$$

We now estimate the integral term on (a_d, b_d) and obtain (since $F \leq 0$ on $(0, c_d)$ and $0 < a_d < b_d < c_d$)

$$2\int_0^{c_d} rF(w(r))\,dr \leq 2\int_{a_d}^{b_d} rF(w(r))\,dr.$$

Next, on (a_d, b_d) we have $\alpha < w(r) < \frac{\beta+\gamma}{2}$. In particular, since $F < 0$ on $[\alpha, \frac{\beta+\gamma}{2}]$, there exists $C^2 > 0$ such that $F(s) \leq -C^2$ on $[\alpha, \frac{\beta+\gamma}{2}]$. Therefore,

$$2\int_{a_d}^{b_d} rF(w(r))\,dr \leq -C^2(b_d^2 - a_d^2).$$

Thus, (4.12) can be rewritten as

$$b_d^2 - a_d^2 \leq \frac{\ell(\ell+N-2)\gamma^2}{2C^2}.$$

Now recall that we proved in Lemma 4.3 that

$$a_d^\ell \leq \frac{\alpha}{d}.$$

Since $d \in D$, we have that $d > d^*$. Thus,

$$b_d^2 \leq \Big(\frac{\alpha}{d^*}\Big)^{2/\ell} + \frac{\ell(\ell+N-2)\gamma^2}{2C}.$$

Therefore,

$$b_d^2 \leq K,$$

where K is independent of $d \in D$, as claimed. This completes the proof of Lemma 4.7.

We now let B be the set of d-values for which the solution approaches the hilltop asymptotically. That is, we define

$$B = \{d > 0 \mid w(r,d) > 0 \text{ for } r > 0, \quad w'(r,d) > 0 \text{ for } r > 0, \text{ and } \lim_{r\to\infty} w(r,d) = \delta\}.$$

We know that $d^* \in B$ so that B is nonempty. Also, Lemma 4.1 shows that B is bounded away from zero. Now let

$$d_* = \inf B.$$

Remark. We have $0 < d_* \le d^*$. We expect in general that $B = \{d^*\}$, so that $d_* = d^*$, but we have not proven this assertion.

We now show that $d_* \in B$.

LEMMA 4.8. *$w(r,d_*) > 0$ for $r > 0$, $w'(r,d_*) > 0$ for $r > 0$ and $\lim_{r\to\infty} w(r,d_*) = \delta$.*

Proof. If $d_* \in B$, then the assertion of the lemma is trivially true. So suppose $d_* \notin B$. Then $d_* < d^*$. Consider a sequence $\{d_j \in B\}$ with $d_* < d_j < d^*$ such that $d_j \to d_*^+$. Because solutions depend continuously on initial conditions, the functions $w(r,d_j)$ converge uniformly on compact intervals to $w(r,d_*)$. Because each $d_j \in B$, it follows that $0 \le w(r,d_*) \le \delta$ and $w'(r,d_*) \ge 0$. Since $d_* > 0$, $w(r,d_*)$ is not identically zero. So, by Lemma 3.3, $w'(r,d_*) > 0$, hence $w(r,d_*) > 0$ for $r > 0$. Exactly as in the proof of Lemma 4.7, it can now be shown that $\lim_{r\to\infty} w(r,d_*) = \delta$. This completes the proof of Lemma 4.8.

LEMMA 4.9. *If $d < d_*$ and d is sufficiently close to d_*, then $w(r,d)$ has a local maximum.*

Proof. Since $0 < d < d_* \le d^*$, we have that $d \notin D$ and therefore $R(d) = \infty$. Now suppose $w(r,d)$ does not have a local maximum for all d sufficiently close to d_*. Then there is a sequence $\{d_j\}$ with $0 < d_j < d_*$ and $d_j \to d_*^-$ such that $w'(r,d_j) \ge 0$ on $[0,\infty)$. By Lemma 3.3, $w'(r,d_j) > 0$ on $(0,\infty)$ and thus $0 < w(r,d_j) < \delta$ on $(0,\infty)$. As in the proof of Lemma 4.7, $\lim_{r\to\infty} w(r,d_j) = L_j$, where $f(L_j) = 0$. But also by continuity of solutions of initial value problems, $w(r,d_j)$ converges uniformly on compact subsets to $w(r,d_*)$ as $j \to \infty$. Now since $w(r,d_*)$ limits to δ as $r \to \infty$, we can make L_j larger than β for d_j close enough to d_*. Since $f(L_j) = 0$, we must then have $L_j = \delta$. Hence, $d_j \in B$ for all sufficiently large j. This contradicts the hypothesis that $d_j < d_*$. Thus $w(r,d)$ must have a local maximum for all d sufficiently close to d_*. This proves Lemma 4.9.

As a consequence of Lemma 4.9, for d sufficiently close to d_*, the solution $w(r,d)$ of (1.13)–(1.14) has a first local maximum at $r = M_d$. We now show that this first local maximum occurs later and grows in amplitude as d approaches d_* from below.

LEMMA 4.10. *$\lim_{d\to d_*^-} M_d = \infty$ and $\lim_{d\to d_*^-} w(M_d,d) = \delta$.*

Proof. Lemma 4.9 establishes the existence of a first local maximum M_d for $d < d_*$ and d close to d_*. To prove that $M_d \to \infty$, suppose not. Then $M_d \le C < \infty$ and so there is a subsequence of the ds (again labeled d) and an M such that $M_d \to M$. By Lemma 4.5 we have then that $z(r,d) \to z(r,d_*)$ and $z'(r,d) \to z'(r,d_*)$ uniformly on $[0, M+1]$, and hence $w(r,d) \to w(r,d_*)$ and $w'(r,d) \to w'(r,d_*)$ uniformly on $[0, M+1]$. Since M_d is a local maximum for $w(r,d)$, we have that $w'(M_d,d) = 0$. On the other hand, $0 = w'(M_d,d) \to w'(M,d_*) > 0$ where the last inequality is from Lemma 4.8. This contradiction shows that $M_d \to \infty$ as $d \to d_*$.

To prove the second assertion of the lemma, consider $0 < d < d_*$ with d sufficiently close to d_* that $w(r,d)$ has a first local maximum at $r = M_d$. Because $w(r,d) > 0$ for small r, it follows that $0 < w(r,d) < w(M_d,d) < \delta$ for $r \in (0, M_d)$.

Since (by Lemma 4.8) $w(r,d_*) \to \delta$ as $r \to \infty$, given $\epsilon > 0$ there is r_ϵ such that $w(r,d_*) \geq \delta - \frac{\epsilon}{2}$ for all $r \geq r_\epsilon$. Because $w(r,d) \to w(r,d_*)$ uniformly on $[0,r_\epsilon]$ as $d \to d_*^-$, there is a number $d_\epsilon < d_*$ such that $|w(r,d) - w(r,d_*)| < \frac{\epsilon}{2}$ for all $r \in [0,r_\epsilon]$ whenever $d_\epsilon < d < d_*$. Because $M_d \to \infty$ as $d \to d_*^-$, we may furthermore choose d_ϵ such that additionally $M_d > r_\epsilon$ whenever $d_\epsilon < d < d_*$. Thus $\delta - \epsilon < w(r_\epsilon, d) < w(M_d, d) < \delta$ for $d_\epsilon < d < d_*$. Since ϵ may be chosen arbitrarily small, it follows that $w(M_d,d) \to \delta$ as $d \to d_*^-$, as claimed. This completes the proof of Lemma 4.10.

5. Energy analysis. We will now establish that there are solutions of the initial value problem (1.13)–(1.14) with arbitrarily many zeros. We will then finally prove the main theorem.

LEMMA 5.1. *Suppose that a solution $w(r)$ to (1.13) has successive local extrema $w_1 \equiv w(r_1)$ and $w_2 \equiv w(r_2)$, with $0 < r_1 < r_2 < \infty$ (and $w'(r) \neq 0$ for all $r \in (r_1, r_2)$.) Then $(w_1 - w_2)(f(w_1) - f(w_2)) > 0$. Thus f must be increasing somewhere in the interval between w_1 and w_2.*

Proof. First suppose $w_1 = w(r_1)$ is a local maximum of w. Then $w_2 = w(r_2)$ is a local minimum, and we have $w'(r_1) = 0$, $w''(r_1) \leq 0$, $w'(r_2) = 0$, $w''(r_2) \geq 0$, and $w_2 < w_1$. Evaluating (1.13) at r_1 and r_2 and subtracting, we obtain

$$(w''(r_2) - w''(r_1)) + \ell(\ell+N-2)\left[\frac{w_1}{r_1^2} - \frac{w_2}{r_2^2}\right] = f(w_1) - f(w_2). \tag{5.1}$$

Because $\frac{1}{r_1^2} > \frac{1}{r_2^2}$ and $w_1 > w_2$, the term in (5.1) in square brackets is strictly positive. Because $(w''(r_2) - w''(r_1)) \geq 0$, we see that $f(w_1) - f(w_2) > 0$, as claimed. This establishes the assertion of the lemma in the case when w_1 is a local maximum.

Next suppose $w_1 = w(r_1)$ is a local minimum of w. Then $w_2 = w(r_2)$ is a local maximum, and $w_2 > w_1$. Because f is odd, the function $\tilde{w}(r) \equiv -w(r)$ is also a solution to (1.13), and we note that $\tilde{w}_1 \equiv \tilde{w}(r_1) = -w_1$ is a local maximum of $\tilde{w}$, and that $\tilde{w}_2 \equiv \tilde{w}(r_2) = -w_2$ is a local minimum of $\tilde{w}$. Thus the reasoning in the first part of our proof applies to $\tilde{w}$, and we conclude that $f(\tilde{w}_1) - f(\tilde{w}_2) > 0$. Thus (again because f is odd) $f(w_1) - f(w_2) < 0$, while $w_1 - w_2 < 0$ also. This completes the proof of Lemma 5.1.

LEMMA 5.2. *If $w(r) = w(r,d)$ is a solution to (1.13)–(1.14) with $0 < d < d_*$, then*

$$|w'| \leq \sqrt{\ell(\ell+N-2)\frac{\delta^2}{r^2} + 2\,(F(\delta) - F_0)} \tag{5.2}$$

for all $r > 0$.

Proof. Identity (1.15) with the initial condition (1.14) yields

$$\tfrac{1}{2}w'^2 + F(w) \leq \frac{\ell(\ell+N-2)}{2}\frac{w^2}{r^2} + \frac{2}{r^2}\int_0^r s\,F(w(s))\,ds. \tag{5.3}$$

Since we know that $|w(r)| < \delta$ for all $r \geq 0$ and since $\max_{y\in[-\delta,\delta]} F(y) = F(\delta)$, we have $\int_0^r s\,F(w(s))\,ds \leq \frac{1}{2}r^2F(\delta)$. Hence (5.3) yields

$$\tfrac{1}{2}w'^2 \leq \frac{\ell(\ell+N-2)}{2}\frac{w^2}{r^2} + F(\delta) - F(w) < \frac{\ell(\ell+N-2)}{2}\frac{\delta^2}{r^2} + F(\delta) - F_0, \tag{5.4}$$

that is,

$$|w'| \le \sqrt{\ell(\ell+N-2)\frac{\delta^2}{r^2} + 2\,(F(\delta) - F_0)},$$

as asserted.

For a solution $w(r)$ to (1.13), we define the "energy"

$$E(r) \equiv \frac{1}{2}w'(r)^2 + F(w(r)). \tag{5.5}$$

Differentiating E and using (1.13), we find

$$E' = -\frac{N-1}{r}w'^2 + \frac{\ell(\ell+N-2)}{r^2}ww'. \tag{5.6}$$

We now estimate the loss of energy on an interval of monotonicity for the solution. Lemma 5.3 establishes that the energy loss is bounded independent of the length of the interval.

LEMMA 5.3. *Suppose $w(r) = w(r,d)$ is a solution to* (1.13)–(1.14) *with $0 < d < d_*$, such that $w'(r) \neq 0$ for all $r \in (r_1, r_2)$, where $0 < r_1 < r_2$. Then*

$$E(r_1) - E(r_2) \le \frac{C_1}{r_1} + \frac{C_2}{r_1^2}, \tag{5.7}$$

where C_1 and C_2 are positive constants that are independent of d, r_1, and r_2.

Proof. Since $w'(r) \neq 0$ for all $r \in (r_1, r_2)$, it follows that w' has a constant sign on (r_1, r_2), and that w can change sign at most once on (r_1, r_2). Thus ww' can change sign at most once on (r_1, r_2). Let (s_1, s_2) be the maximal subinterval of (r_1, r_2) on which $ww' < 0$. (The interval (s_1, s_2) could be empty, in which case the corresponding integrals below are taken to be zero.) Thus $0 < r_1 \le s_1 \le s_2 \le r_2$.

We now estimate $E(r_1) - E(r_2)$.

$$\begin{aligned}
E(r_1) - E(r_2) &= -\int_{r_1}^{r_2} E'(r)\, dr \\
&= \int_{r_1}^{r_2} \frac{N-1}{r}w'^2\, dr - \int_{r_1}^{r_2} \frac{\ell(\ell+N-2)}{r^2}\, ww'\, dr \\
&\le \int_{r_1}^{r_2} \frac{N-1}{r}w'^2\, dr - \int_{s_1}^{s_2} \frac{\ell(\ell+N-2)}{r^2}\, ww'\, dr \\
&\le \frac{N-1}{r_1}\int_{r_1}^{r_2} w'^2\, dr + \frac{\ell(\ell+N-2)}{r_1^2}\int_{s_1}^{s_2} (-ww')\, dr \\
&= \frac{N-1}{r_1}\int_{r_1}^{r_2} w'^2\, dr + \frac{\ell(\ell+N-2)}{2r_1^2}\left[w(s_1)^2 - w(s_2)^2\right] \\
&\le \frac{N-1}{r_1}\int_{r_1}^{r_2} w'^2\, dr + \frac{\ell(\ell+N-2)}{2}\frac{\delta^2}{r_1^2}.
\end{aligned} \tag{5.8}$$

To estimate the remaining integral we note that for $r \in (r_1, r_2)$, Lemma 5.2 yields

$$|w'(r)| \le \sqrt{\ell(\ell+N-2)\frac{\delta^2}{r_1^2} + 2\,(F(\delta) - F_0)}. \tag{5.9}$$

Thus

$$\int_{r_1}^{r_2} w'^2\, dr = \int_{r_1}^{r_2} |w'(r)|\ |w'(r)|\ dr \leq \sqrt{\ell(\ell+N-2)\delta^2 r_1^{-2} + 2F(\delta) - 2F_0}\ \int_{r_1}^{r_2} |w'(r)|\ dr.$$

Since $w'(r) \neq 0$ for $r \in (r_1, r_2)$, we have

$$\begin{aligned} \int_{r_1}^{r_2} w'^2\, dr &\leq \sqrt{\ell(\ell+N-2)\delta^2 r_1^{-2} + 2F(\delta) - 2F_0}\ |w(r_2) - w(r_1)| \\ &\leq 2\delta\sqrt{\ell(\ell+N-2)\delta^2 r_1^{-2} + 2F(\delta) - 2F_0} \\ &\leq 2\sqrt{2}\delta\sqrt{F(\delta) - F_0} + 2\delta^2 r_1^{-1}\sqrt{\ell(\ell+N-2)}. \end{aligned} \tag{5.10}$$

Substituting (5.10) into (5.8), we obtain (5.7), as claimed, with

$$C_1 = C_1(N, \ell, f) = 2\sqrt{2}(N-1)\delta\sqrt{F(\delta) - F_0}$$

and

$$C_2 = C_2(N, \ell, f) = \left(\tfrac{1}{2}\ell(\ell+N-2) + 2(N-1)\sqrt{\ell(\ell+N-2)}\right)\delta^2.$$

This completes the proof of Lemma 5.3.

For brevity, we define $h(r) \equiv \frac{C_1}{r} + \frac{C_2}{r^2}$, where C_1 and C_2 are the constants of Lemma 5.3.

LEMMA 5.4. *Suppose $w(r) = w(r, d)$ is a solution to* (1.13)–(1.14) *with $0 < d < d_*$. Suppose that $|w|$ has a local maximum at $r = p$, with $F(w(p)) - h(p) > 0$. Then w' has a zero for some value of r larger than p.*

Proof. Suppose by way of contradiction that $w' \neq 0$ for all $r > p$. Then, because $|w|$ is bounded, w has a limit $L \equiv \lim_{r\to\infty} w(r)$. Using the fact that $|w'|$ is bounded and taking limits in (1.13) shows that $\lim_{r\to\infty} w''(r) = -f(L)$. As earlier, this limiting value of w'' must vanish because $|w'|$ is bounded. Thus $f(L) = 0$ and $w'(r)$ has a limit as $r \to \infty$ which must then vanish because $|w|$ is bounded. It then follows that $\lim_{r\to\infty} E(r) = F(L)$.

Now from Lemma 5.3 we have $E(r) \geq E(p) - h(p) = F(w(p)) - h(p) > 0$ for all $r > p$. Thus $F(L) > 0$, hence $\gamma < |L| \leq \delta$. Since the only zeros of f with magnitude between γ and δ are $\pm\delta$, we find that $\lim_{r\to\infty} |w(r)| = \delta$. But Lemma 3.1 asserts that $|w(r)| \leq |w(p)| < \delta$ for all $r \geq p$. Thus $|w|$ cannot have limit δ. This contradiction establishes that w' must have a zero at $r > p$, and completes the proof of Lemma 5.4.

We next establish that there are solutions to the initial value problem (1.13)–(1.14) with arbitrarily many zeros. This result, in Lemma 5.5, elucidates the solution set structure as a function of d and is an essential part of the proof of the main theorem. Our proof of Lemma 5.5 is based on the fact, established by Lemma 5.3, that a solution's loss of energy on an interval of monotonicity is bounded independent of the length of the interval.

LEMMA 5.5. *Given any positive integer n, there is a number e_n between 0 and d_* such that the solution of* (1.13)–(1.14) *has at least n positive zeros for all $d \in (e_n, d_*)$.*

Proof. By hypothesis there is a number $\lambda \in (\gamma, \delta)$ such that f is strictly decreasing on $[\lambda, \delta]$. Recall that F is then positive, increasing, and concave downward on $[\lambda, \delta]$.

By Lemmas 4.9 and 4.10, $w(r,d)$ has a first local maximum $r = M_d$ for d sufficiently close to d_*, and $\lim_{d\to d_*^-} M_d = \infty$ and $\lim_{d\to d_*^-} w(M_d,d) = \delta$. Let $c \in (0,d_*)$ be such that $\lambda < w(M_d,d) < \delta$ for all $d \in (c,d_*)$.

Because $F(\delta) > F(\lambda)$, given n we may choose $e_n \in (c,d_*)$ so close to d_* that $F(w(M_d,d)) - nh(M_d) > F(\lambda)$ for all $d \in (e_n,d_*)$. Consider fixed $d \in (e_n,d_*)$. By Lemma 5.4, w' has a next zero $r = m_1 > M_d$. By Lemma 5.3, $E(m_1) \geq E(M_d) - h(M_d)$. Thus $F(w(m_1)) \geq F(w(M_d)) - h(M_d) > F(\lambda)$, and therefore $|w(m_1)| > \lambda$. Because f is strictly decreasing on $[\lambda,\delta]$ and because $w(M_d) \in (\lambda,\delta)$, by Lemma 5.1 it cannot be that $w(m_1) \in (\lambda,\delta)$. Thus $w(m_1) \in (-\delta,-\lambda)$. Hence w has a zero between $r = M_d$ and $r = m_1$.

If $n > 1$, we may now repeat the argument: Because

$$\begin{aligned} F(w(m_1)) - h(m_1) &> F(w(m_1)) - h(M_d) \\ &\geq F(w(M_d)) - 2h(M_d) \\ &> F(\lambda), \end{aligned}$$

by Lemma 5.4, w' has a next zero $r = m_2 > m_1$. By Lemma 5.3, $E(m_2) \geq E(m_1) - h(m_1)$. Thus $F(w(m_2)) \geq F(w(m_1)) - h(m_1) > F(\lambda)$, and hence $|w(m_2)| > \lambda$. Because f is strictly decreasing on $(-\delta,-\lambda)$ and because $w(m_1) \in (-\delta,-\lambda)$, by Lemma 5.1 we have $w(m_2) \in (\lambda,\delta)$. Hence w has another zero between $r = m_1$ and $r = m_2$.

We may continue in this fashion to show that there are n positive zeros of w. This concludes the proof of Lemma 5.5.

The last major result required for the proof of the main theorem is the fact that as d is varied new zeros in the solution to (1.13)–(1.14) appear one at a time, and changes in the number of zeros occur at isolated values of d. This result is established in Lemma 5.9. The following three lemmas are used in the proof of Lemma 5.9.

LEMMA 5.6. *Suppose w is a nontrivial solution of* (1.13) *with $w(t) = 0$ for some $t > 0$, and suppose $p < t$ is such that $w'(p) = 0$ and $w'(r) \neq 0$ for $r \in (p,t)$. Then $|w(p)| > \gamma$.*

Proof. Because $w'(r) \neq 0$ for $r \in (p,t)$, we have $w(r)w'(r) < 0$ for $r \in (p,t)$. So by (5.6), $E'(r) < 0$ for $r \in (p,t)$. Thus $E(p) > E(t) \geq 0$, hence $F(w(p)) = E(p) > 0$, hence $|w(p)| > \gamma$, as asserted.

LEMMA 5.7. *If w is a nontrivial solution to* (1.13) *such that $\lim_{r\to\infty} w(r) = 0$, then $w'(r) \neq 0$ for all sufficiently large r.*

Proof. Suppose on the contrary that w is nontrivial and there is a sequence $p_j \to \infty$ such that $w(p_j) \to 0$ as $j \to \infty$ and $w'(p_j) = 0$ for all j.

We note first that if $w''(p) = w'(p) = 0$ for some $p > 0$, then, by (1.13), either $w(p) = 0$, or $w(p) \neq 0$ and $f(w(p))$ has the same sign as w. Since w is nontrivial, by uniqueness of solutions to initial value problems we cannot have $w(p) = w'(p) = 0$, so it must be that $w(p)$ and $f(w(p))$ have the same sign. Thus $|w(p)| > \alpha$. Since $w(p_j) \to 0$ as $j \to \infty$, it must be that $w''(p_j) \neq 0$ for sufficiently large j.

Under our supposition, it follows that there is an increasing sequence of local maxima M_j of $|w|$, with $M_j \to \infty$ and $0 \neq w(M_j) \to 0$ as $j \to \infty$. Because $F(y) < 0$ for $|y| \in (0,\gamma)$, we have $F(w(M_J)) < 0$ for some sufficiently large J. Thus by Lemma 3.1, $F(w(M_j)) \leq F(w(M_J)) < 0$ for all $j > J$. This contradicts the fact that $\lim_{j\to\infty} F(w(M_j)) = F(0) = 0$. This contradiction shows that there cannot be a sequence p_j with the properties that we assumed, thereby proving the lemma.

LEMMA 5.8. *Suppose w is a nontrivial solution to* (1.13) *such that $\lim_{r\to\infty} w(r) = 0$. Suppose $w'(p) = 0$ and $w'(r) \neq 0$ for all $r > p$. Then $|w(p)| > \gamma$.*

Proof. Since $|w|$ is monotonically decreasing to 0 on (p,∞), as in Lemma 5.6 it follows that $E'(r) < 0$ for all $r > p$. Since $E(r)$ is bounded below (by F_0), $E(r) = \frac{1}{2}w'(r)^2 + F(w(r))$ has a limit as $r \to \infty$. Since $F(w(r)) \to 0$ as $r \to \infty$, it follows that $|w'|$ has a limit, which must vanish. Thus $F(w(p)) = E(p) > \lim_{r\to\infty} E(r) = 0$, hence $|w(p)| > \gamma$, as asserted.

LEMMA 5.9. *Suppose $w(r) = w(r, d_c)$ is a solution to (1.13)–(1.14) with $d = d_c \in (0, d_*)$, such that $w(r)$ has exactly k zeros, and such that $\lim_{r\to\infty} w(r, d_c) = 0$. If d is sufficiently close to d_c then the solution $w(r, d)$ has at most $(k+1)$ zeros.*

Proof. We wish to show that for d near d_c, $w(\cdot, d)$ has at most $(k+1)$ zeros in $(0,\infty)$. So we suppose there is a sequence of values $d_j \in (0, d_*)$ converging to d_c as $j \to \infty$ such that $w(\cdot, d_j)$ has at least $(k+1)$ zeros in $(0,\infty)$. (If there is no such sequence then the lemma is proven.) We write $w_j(r) \equiv w(r, d_j)$ and we denote by r_j the $(k+1)$st zero of w_j, counting from the smallest. We set $w_0(r) \equiv w(r, d_c)$.

By Lemma 5.7, $|w_0(r)|$ decreases monotonically to zero for sufficiently large r. Since $|w_0(r)| < \delta$ for all r, there is a largest number p_0 for which $w_0'(p_0) = 0$. By Lemma 5.8, $|w_0(p_0)| > \gamma$. Let $q_0 > p_0$ be such that $|w_0(q_0)| = \gamma$. We note that q_0 is unique because $|w_0(r)|$ is monotonically decreasing for $r > p_0$.

Let $\epsilon_2 \equiv \min\left\{\frac{1}{2}\beta, \frac{1}{2}(|w_0(p_0)| - \gamma)\right\}$. Given $\epsilon_1 \in (0, \epsilon_2)$, let $q_0^+ > q_0$ be defined by $|w_0(q_0^+)| = \gamma - \epsilon_1$, and let $q_0^- \in (p_0, q_0)$ be defined by $|w_0(q_0^-)| = \gamma + \epsilon_1$. Note that q_0^+ and q_0^- approach q_0 as $\epsilon_1 \to 0^+$.

Since $w_0'(q_0) \neq 0$, there is a number $m_0 > 0$ such that $\min_{r\in[q_0^-, q_0^+]} |w_0'(r)| > m_0 > 0$ independent of $\epsilon \in (0, \epsilon_1)$. Let $\epsilon_0 \equiv \min\left\{\frac{1}{2}m_0, \epsilon_1\right\}$. Let $L_0 > q_0$ be the unique number such that $|w_0(L_0)| = \frac{1}{2}\beta$.

Because solutions depend continuously on initial data, we know that $w_j \to w_0$ and $w_j' \to w_0'$ uniformly on compact sets as $j \to \infty$. Thus, given $\epsilon \in (0, \epsilon_0)$ and $L > L_0$, there is a number $J(\epsilon, L)$ so large that for all $j > J(\epsilon, L)$ we have $\sup_{r\in[0,L]} |w_j(r) - w_0(r)| < \epsilon$ and $\sup_{r\in[0,L]} |w_j'(r) - w_0'(r)| < \epsilon$. In particular,

$$|w_j(q_0^+)| \le |w_0(q_0^+)| + |w_j(q_0^+) - w_0(q_0^+)| < \gamma - \epsilon_1 + \epsilon < \gamma$$

and

$$|w_j(q_0^-)| \ge \big||w_0(q_0^-)| - |w_j(q_0^-) - w_0(q_0^-)|\big| > \gamma + \epsilon_1 - \epsilon > \gamma$$

and, for all $r \in [q_0^-, q_0^+]$,

$$\begin{aligned} |w_j'(r)| &= \big|w_0'(r) + (w_j'(r) - w_0'(r))\big| \\ &\ge \big||w_0'(r)| - |w_j'(r) - w_0'(r)|\big| \\ &> m_0 - \epsilon > \tfrac{1}{2}m_0 > 0. \end{aligned}$$

Therefore, $|w_j(q_j)| = \gamma$ for a unique $q_j \in (q_0^-, q_0^+)$. We note that because ϵ_1 may be chosen arbitrarily small, we have $q_j \to q_0$ as $j \to \infty$.

For $j > J(\epsilon, L)$ it also follows that $|w_j(r)| < \gamma$ for all $r \in (q_j, L]$. Furthermore, $|w_j(L)| < \beta$ for all $j > J(\epsilon, L)$.

CLAIM. *For all sufficiently large j, $|w_j(r)| < \gamma$ for all $r > q_j$.*

Proof of Claim. Fix $\epsilon \in (0, \epsilon_0)$ and $L > L_0$. We already know that for $j > J(\epsilon, L)$ we have $|w_j(r)| < \gamma$ for $r \in (q_j, L]$. So suppose by way of contradiction that there exists a subsequence $d_j \to d_c$ (again labeled by j) such that, for all $j > J(\epsilon, L)$, $|w_j(Q_j)| = \gamma$ for some smallest $Q_j > L$.

By Lemma 3.1, $|w_j|$ cannot have a local maximum at any point in (q_j, Q_j). It follows, because $|w_j(L)| < \beta$, that there are numbers s_j and t_j with $L < s_j < t_j < Q_j$ such that $|w_j(s_j)| = \beta$ and $|w_j(t_j)| = \frac{1}{2}(\beta + \gamma) > \beta$ and $|w_j|$ is increasing on (s_j, t_j).

We now apply (1.15) between q_j and Q_j to obtain

$$\frac{1}{2}Q_j^2 w'(Q_j)^2 + (N-2)\int_{q_j}^{Q_j} s w_j'(s)^2 ds = \frac{1}{2}q_j^2 w'(q_j)^2 + 2\int_{q_j}^{Q_j} sF(w(s))ds. \tag{5.11}$$

We now estimate the integral term on the right side of (5.11). Because $|w(s)| < \gamma$ for $s \in (q_j, Q_j)$, we have $F(w(s)) \le 0$ for $s \in (q_j, Q_j)$. Thus

$$\begin{aligned} 2\int_{q_j}^{Q_j} sF(w(s))ds &\le 2\int_{s_j}^{t_j} sF(w(s))ds \le 2F(\tfrac{1}{2}(\beta+\gamma))\int_{s_j}^{t_j} s\,ds \\ &= F(\tfrac{1}{2}(\beta+\gamma))(t_j - s_j)(t_j + s_j). \end{aligned} \tag{5.12}$$

Now, Lemma 5.2 establishes that $|w_j'(r)|$ is bounded for $r \ge p_0$ by

$$w'_{\max} \equiv \sqrt{\ell(\ell+N-2)\frac{\delta^2}{p_0^2} + 2\,(F(\delta) - F_0)}$$

independent of j. We thus have

$$\tfrac{1}{2}(\beta+\gamma) - \beta = |w_j(t_j) - w_j(s_j)| \le w'_{\max}(t_j - s_j),$$

that is, $t_j - s_j \ge \frac{(\gamma-\beta)}{2w'_{\max}}$. Thus, since $F(\frac{1}{2}(\beta+\gamma)) < 0$ and $L < s_j < t_j$, (5.12) yields

$$2\int_{q_j}^{Q_j} sF(w(s))ds \le \frac{(\gamma-\beta)F(\frac{1}{2}(\beta+\gamma))}{w'_{\max}} L. \tag{5.13}$$

Thus by choosing $L > L_0$ sufficiently large we may make the term $2\int_{q_j}^{Q_j} sF(w(s))ds$ in (5.11) negative and arbitrarily large in magnitude. Since $q_j \to q_0$ as $j \to \infty$, the term $\frac{1}{2}q_j^2 w'(q_j)^2$ on the right side of (5.11) is bounded independent of j. Thus by choosing L sufficiently large, we can make the right side of (5.11) negative. Since the left side of (5.11) is manifestly positive, we arrive at a contradiction, thus establishing that, for sufficiently large j, $|w_j(r)| < \gamma$ for all $r > q_j$, as claimed.

To complete the proof of Lemma 5.9, we note that if w_j has a zero z_j beyond r_j, then $|w_j|$ has a local maximum at some point p between r_j and z_j. By Lemma 5.6, this local maximum must occur at an amplitude $|w_j(p)| > \gamma$, which the claim shows is impossible for sufficiently large j. Therefore, for sufficiently large j, $w_j(r)$ has at most the single zero r_j for $r > q_j$. This completes the proof of Lemma 5.9.

Proof of the Main Theorem. To prove the main theorem, we follow exactly the same steps as in [7, section 5]. The same proof technique applies despite the different hypotheses on the large-amplitude behavior of f in [7] because the large-r behavior of the solutions under study is governed by the small-amplitude features of f, which are exactly the same here as in [7]. The only difference in the proof is that here we use identity (1.15), which is a generalization of the Pohozaev identity used in [7].

In particular, we define

$$A_0 = \{d \in (0, d_*) \,|\, w(r,d) > 0 \text{ for all } r > 0\}.$$

By Lemma 4.1, A_0 is nonempty. Also, A_0 is bounded above by d_*. Setting

$$d_0 = \sup A_0,$$

we know from Lemma 5.5 that $d_0 < d_*$. As in [7, section 5], we can show that $w(r, d_0) > 0$ for $r > 0$, $w'(r, d_0) < 0$ for large r, and $\lim_{r\to\infty} w(r, d_0) = 0$. Next, we define

$$A_1 = \{d \in (d_0, d_*) \,|\, w(r, d) \text{ has exactly one zero in } (0, \infty)\}.$$

First, if $d_0 < d < d_*$, then $w(r, d)$ must have at least one zero in $(0, \infty)$ (by definition of d_0). Also, by Lemma 5.9, $w(r, d)$ has at most one zero in $(0, \infty)$ if d is close enough to d_0. Thus, A_1 is nonempty, and clearly A_1 is bounded above by d_*. Setting

$$d_1 = \sup A_1,$$

we know from Lemma 5.5 that $d_1 < d_*$. And again as in [7, section 5], we can show that $w(r, d_1)$ has exactly one zero and vanishes as $r \to \infty$. Continuing by induction, the main theorem is proved.

WEAK ASYMPTOTIC STABILITY OF SECOND-ORDER EVOLUTION EQUATIONS BY NONLINEAR AND NONMONOTONE FEEDBACKS*

JUDITH VANCOSTENOBLE†

Abstract. We consider the problem of asymptotic decay as $t \to +\infty$ of solutions of an abstract evolution equation of second order with a nonlinear and nonmonotone feedback. Weak asymptotic stability of the global solutions is proved. This abstract result can be applied to different types of equations (wave, beam, and plate equations) and to different types of controls (interior, boundary, or pointwise controls). In particular, we significantly improve several earlier results on the asymptotic stability of the wave equation in a bounded domain with an interior or boundary control.

Key words. nonlinear second-order PDE, asymptotic behavior, stabilization, nonmonotone feedback, distributed control, boundary control, pointwise control

1. Introduction.

We consider the problem of asymptotic decay as $t \to +\infty$ of solutions of an abstract evolution equation of second order with a nonlinear and nonmonotone feedback. More precisely, we consider some evolution equations of second order for which strong compactness of trajectories does not hold while weak compactness does. We give general conditions for which weak asymptotic stability as $t \to +\infty$ of global solutions will occur. As an illustration, let us consider the following classical control problem.

EXAMPLE 1.1. *Let Ω be a bounded open subset of $\mathbb{R}^N, N \geq 1$ with a smooth boundary Γ, and let (Γ_0, Γ^*) be a nontrivial partition of Γ (i.e., Γ_0, Γ^* are closed, $\mathrm{int}(\Gamma^*) \neq \emptyset$, $\mathrm{int}(\Gamma_0) \neq \emptyset$, and $\mathrm{int}(\Gamma^*) \cap \mathrm{int}(\Gamma_0) = \emptyset$). Let $q : \mathbb{R} \to \mathbb{R}$ be continuous and such that*

$$\forall \lambda \in \mathbb{R},\ \lambda q(\lambda) \geq 0 \text{ and } \forall \lambda > 0,\ q(\lambda) > 0. \tag{1.1}$$

Let $a \in L^\infty(\Gamma_0)$ such that $a(.) > 0$ on Γ_0. We set $V = \{v \in H^1(\Omega) \mid v = 0 \text{ on } \Gamma^*\}$, and we consider the following equation:

$$\begin{cases} u_{tt} - \Delta u = 0 & \text{for } (t,x) \in \mathbb{R}_+ \times \Omega, \\ u = 0 & \text{for } (t,x) \in \mathbb{R}_+ \times \Gamma^*, \\ \frac{\partial u}{\partial \nu} = -a(x) q(u_t) & \text{for } (t,x) \in \mathbb{R}_+ \times \Gamma_0, \\ u(0) = u_0, u_t(0) = v_0 & \text{for } x \in \Omega, \end{cases} \tag{1.2}$$

where the initial data (u_0, v_0) are given in $V \times L^2(\Omega)$.

This work was done while the author was working for the Projet NUMATH, Institut Élie Cartan, Université Henri Poincaré Nancy 1, UMR CNRS 9973 et INRIA-Lorraine.

If q is monotone increasing and satisfies

$$|q(\lambda)| \leq A + B|\lambda|^r \begin{cases} \text{with } r \leq min(\frac{N}{N-2}, 2) & \text{if } N \geq 3, \\ \text{with } r \leq 2 & \text{if } N = 2, \\ \text{and no condition} & \text{if } N = 1, \end{cases} \tag{1.3}$$

then strong asymptotic stability of the solution is known (a proof and references can be found in [1]*). But if q does not verify the hypothesis* (1.3)*, the problem of strong asymptotic stability of the solution is still open even if q is monotone increasing. We will prove that in this case there is at least weak asymptotic stability of the solution. Actually if we suppress the hypothesis of monotonicity of q, and if we suppose only that $\forall \alpha > 0,\ \inf\{q(\lambda) \mid \lambda \geq \alpha\} > 0$, then we still obtain weak asymptotic stability of all global solutions.*

More generally, we will use an abstract framework and we will prove weak asymptotic stability of the global solutions of an abstract evolution equation of second order with a nonlinear and nonmonotone feedback. The use of this abstract framework underlines the essential properties of the considered equation which are necessary for the proof. Moreover, our abstract result of weak asymptotic stability can be applied to many equations (including, for example, wave- and platelike equations with interior feedbacks but also with boundary or pointwise controls). Our result improves significantly several earlier results on the subject (see, for example, [3] , [6] , [1] , [9]) insofar as we need neither hypothesis of monotonicity of the control nor condition restricting its asymptotic growth.

2. Results.

2.1. Abstract framework and theorem of weak asymptotic stability. We suppose the following.

• (H_1)(i): Let X be a locally compact space, and let μ be a positive measure such that $\mu(X) < +\infty$. We denote by $K(X)$ the space of continuous and compactly supported functions from X into $\mathbb{R}$, and we denote by H the Hilbert space $L^2(X, \mu)$ equipped with the scalar product

$$\forall u, v \in H,\ (u, v)_H = \int_X u(x)v(x)d\mu(x).$$

• (H_1)(ii): Let A be a linear operator on H with dense domain $D(A)$. We assume that A is self-adjoint and coercive and that the resolvent of A is compact. We define $V = D(A^{\frac{1}{2}})$ equipped with the scalar product

$$\forall u, v \in V,\ (u, v)_V = (A^{\frac{1}{2}}u, A^{\frac{1}{2}}v)_H = \langle \tilde{A}u, v\rangle_{V',V},$$

where $\tilde{A} \in \mathcal{L}(V; V')$ is defined by the bilinear form $(.,.)_V$ and extends A. As usual, we identify H with its dual. Then $V \hookrightarrow H \hookrightarrow V'$ with the following relation:

$$\forall h \in H, \forall v \in V,\ \langle h, v\rangle_{V',V} = (h, v)_H.$$

Moreover, we suppose that $\mathcal{E} = K(X) \cap V$ is dense in V.

• (H_1)(iii): Let Y be a subspace of X (i.e., $Y \subset X$), and let m be a positive measure on Y such that $m(Y) < +\infty$. For all $v \in K(X)$, we denote by $\tau(v)$ the restriction of v to Y and we suppose that

$$\exists C > 0/\ \forall v \in \mathcal{E},\ \|\tau(v)\|_{L^1(Y,m)} \leq C\|v\|_V.$$

Consequently, the linear mapping τ can be extended to a linear continuous application from $V \to L^1(Y,m)$. So we can define the restriction to Y of all elements of V. For all $v \in V$, we will simply denote by v this restriction (see the remark below for various examples).

• (H_2)(i): Let $q : \mathbb{R} \to \mathbb{R}$ be continuous and such that

$$\forall \lambda \in \mathbb{R},\ \lambda q(\lambda) \geq 0, \tag{2.1}$$

$$\forall \alpha > 0,\ \inf\{q(\lambda) \mid \lambda \geq \alpha\} > 0. \tag{2.2}$$

• (H_2)(ii): Let $a \in L^\infty(Y,m)$ with $a(y) \geq 0$ almost everywhere for measure m. We define $Q : D(Q) \to V'$ by

$$D(Q) = \Big\{ v \in V \mid \forall \varphi \in \mathcal{E},\ a(.)q(v)\varphi \in L^1(Y,m) \\ \text{and } \exists C_v > 0 \text{ such that } \left| \int_Y aq(v)\varphi dm \right| \leq C_v \|\varphi\|_V\ \forall \varphi \in \mathcal{E} \Big\} \tag{2.3}$$

and

$$\forall v \in D(Q),\ \forall \varphi \in \mathcal{E} \cup \{v\},\ \langle Q(v), \varphi \rangle_{V',V} = \int_Y a(y)q(v(y))\varphi(y)dm(y). \tag{2.4}$$

• (U): Moreover, for asymptotic stability we will need the following "uniqueness" property:

$$\big(\varphi \in V,\ A\varphi = \omega^2 \varphi \ \textbf{ and }\ a(y)\varphi(y) = 0 \text{ m-a.e. in } Y\big) \ \Rightarrow \varphi(x) = 0 \ \mu\text{-a.e. } x \in X.$$

We consider the following problem for (u_0, v_0) given in $V \times H$:

$$\begin{cases} u_{tt} + \tilde{A}u = -Q(u_t), & t \in \mathbb{R}_+, \\ u \in V, & t \in \mathbb{R}_+, \\ u(0) = u_0,\ u_t(0) = v_0, \end{cases} \tag{2.5}$$

and we obtain the following result of weak asymptotic stability.

THEOREM 2.1. *We assume (H_1), (H_2), and (U) hold. Let (u_0, v_0) be given in $V \times H$. We suppose that there exists $u(t; u_0, v_0)$, a solution of the problem* (2.5) *in the following sense:*

$$\begin{cases} (u, u_t) \in \mathcal{C}([0, +\infty[; V \times H), \\ u_t \in L^2_{loc}(]0, +\infty[; V), \\ u_{tt} \in L^2_{loc}(]0, +\infty[; H), \\ \tilde{A}u + Q(u_t) \in L^2_{loc}(]0, +\infty[; H), \end{cases} \tag{2.6}$$

and u satisfies the equation (2.5) *almost everywhere (a.e.) t in V'. Then $(u(t), u_t(t)) \rightharpoonup (0,0)$ weakly in $V \times H$ as $t \to +\infty$.*

Remark. The abstract framework can be applied to the different types of controls as follows:

- In the case of an equation in a bounded open Ω of $\mathbb{R}^N$, $N \geq 1$ with an interior control, we will set $X = Y = \Omega$ and $\mu = m = dx$ where dx is the Lebesgue's measure in $\mathbb{R}^N$.

- In the case of an equation in a bounded open Ω of $\mathbb{R}^N$, $N \geq 1$ with a boundary control on $\Gamma = \partial\Omega$, we will set $X = \overline{\Omega}$, $\mu = dx$, and $Y = \Gamma$, $m = d\nu$ where $d\nu$ is the superficial measure on Γ.
- In the case of an equation in a bounded open Ω of $\mathbb{R}^N$, $N \geq 1$ with a pointwise control at $p \in \Omega$, we will set $X = \Omega$, $\mu = dx$, $Y = \{p\}$, and m will be the Dirac masse $\delta(\cdot - p)$.
- More generally, we can choose $X = \Omega$, $\mu = dx$, and Y a set of positive "capacity" for the capacity associated with the norm of V and m carried by Y (see [1]).

Remark. Note that the hypothesis (U) is a *necessary condition* of weak asymptotic stability of all global solutions of (2.5). Indeed, if (U) is not satisfied then there exists $\varphi \in V$ and $\omega \in \mathbb{R}$ such that $A\varphi = \omega^2\varphi$ and $a(y)\varphi(y) = 0$ m-a.e. in Y but $\varphi \not\equiv 0$ on X. If we set $u(x,t) = \sin(\omega t)\varphi$, it is easy to see that u is a solution of (2.5) and that $u_t \not\rightharpoonup 0$ as $t \to +\infty$ weakly in H.

Remark. We deliberately chose here to a priori assume the existence of solutions on $(0, +\infty)$ rather than adding more or less classical assumptions ensuring existence of global solutions. Indeed, we concentrate here on the question of asymptotic stability. Note also that, in specific applications, existence may be provided by various means. For each of the examples below, we refer to the literature where existence results are given.

2.2. First example: A wave equation with a boundary control. In this section, we apply Theorem 2.1 to the example presented in the introduction. Note that we know in this example that global solutions of (1.2) exist at least if we suppose q continuous increasing (see, for example, [1]).

COROLLARY 2.1. *Let Ω, Γ_0, Γ^* be as in Example* 1.1. *Let $a : \Gamma_0 \to \mathbb{R}$ be such that $a(.) > 0$ on Γ_0, and let $q : \mathbb{R} \to \mathbb{R}$ be continuous and such that (H_2)(i) holds. Let (u_0, v_0) be given in $V \times L^2(\Omega)$ (where V is defined in Example* 1.1*). We suppose that there exists a solution of* (1.2) *in the following sense:*

$$\begin{cases} (u, u_t) \in \mathcal{C}([0, +\infty[; V \times L^2(\Omega)), \\ u_t \in L^2_{loc}(]0, +\infty[; V), \\ a(.)q(u_t) \in L^1_{loc}(]0, +\infty[\times\Gamma_0), \\ u_{tt} \in L^2_{loc}(]0, +\infty[; L^2(\Omega)), \end{cases} \tag{2.7}$$

and

$$\begin{cases} u_{tt} - \Delta u = 0 & \text{in } \mathcal{D}'(]0, +\infty[\times\Omega) \text{ and a.e. } (t,x) \in \mathbb{R}_+ \times \Omega, \\ \frac{\partial u}{\partial \nu} = -a(x)q(u_t) & \text{a.e. } (t,x) \in \mathbb{R}_+ \times \Gamma_0, \\ u(0) = u_0, u_t(0) = v_0 & \text{a.e. } x \in \Omega. \end{cases} \tag{2.8}$$

Then the solution satisfies

$$(u(t), u_t(t)) \rightharpoonup (0,0) \text{ weakly in } V \times L^2(\Omega) \text{ as } t \to +\infty.$$

Remark. In particular, this result is true for q continuous monotone increasing such that $q(0) = 0$ and $q(\lambda) > 0\ \forall \lambda > 0$.

Remark. This example is also treated in [10] by another method: there we use Young's measures to handle the weak limits.

2.3. Second example: A plate equation with interior control. In this section, we apply Theorem 2.1 to the following example.

EXAMPLE 2.1. *Let Ω be a connected bounded open subset of $\mathbb{R}^N$ with a smooth boundary Γ. Let $q : \mathbb{R} \to \mathbb{R}$ be continuous and such that (H_2)(i) holds, and let $a : [0,1] \to \mathbb{R}$ be such that $a(.) \in L^\infty(0,1)$, $a(.) \geq 0$, and meas$(\mathrm{supp}(a)) > 0$. We set $V = \{v \in H^2(\Omega) \mid v = 0 \text{ on } \Gamma\}$, and we consider the following problem:*

$$\begin{cases} u_{tt} + \Delta^2 u = -a(x)q(u_t) & \text{for } (t,x) \in \mathbb{R}_+ \times \Omega, \\ u = 0 & \text{on } \Gamma,\ t > 0, \\ \Delta u = 0 & \text{on } \Gamma,\ t > 0, \\ u(0) = u_0, u_t(0) = v_0 & \text{in } \Omega, \end{cases} \tag{2.9}$$

where (u_0, v_0) are given in $V \times L^2(\Omega)$.

Remark. In this case, we can prove that if we suppose q continuously differentiable such that

$$\exists m \in \mathbb{R} \mid \ \forall \lambda \in \mathbb{R},\ q'(\lambda) \geq -m,$$

then global solutions of (2.9) exist.

More generally, it is still true in the case of the abstract problem (2.5) with an interior control, i.e., when $X = Y = \Omega$ and $\mu = m = dx$ (for proofs, see [11]).

Applying Theorem 2.1 to this problem, we obtain the following result.

COROLLARY 2.2. *All global solutions of Example* 2.1 *satisfy*

$$(u(t), u_t(t)) \rightharpoonup (0,0) \text{ weakly in } V \times L^2(\Omega) \text{ as } t \to +\infty.$$

Remark. If we suppose $N = 1$, $\Omega =]0,1[$, and q globally Lipschitz continuous, then strong asymptotic stability was obtained by E. Feireisl (see [5]), i.e., $(u(t), u_t(t)) \to (0,0)$ strongly in $H^2(0,1) \times L^2(0,1)$ as $t \to +\infty$.

2.4. Third example: Rectangular Kirchhoff plates with an inner point control.

EXAMPLE 2.2. *We consider $\Omega =]0,a[\times]0,b[$ with $a > 0, b > 0$ and such that*

$$\frac{a^2}{b^2} \notin \mathbb{Q}. \tag{2.10}$$

Let $(x_0, y_0) \in \Omega$, and let $q : \mathbb{R} \to \mathbb{R}$ be continuous and such that (H_2)(i) holds. We set $V = \{v \in H^2(\Omega) \mid v = 0 \text{ on } \Gamma = \partial\Omega\}$, and we consider the following problem:

$$\begin{cases} u_{tt} + \Delta^2 u = -q(u_t(x_0,y_0))\delta(\cdot - x_0, \cdot - y_0) & \text{for } (t,x) \in \mathbb{R}_+ \times \Omega, \\ u = 0 & \text{on } \Gamma,\ t > 0, \\ \Delta u = 0 & \text{on } \Gamma,\ t > 0, \\ u(x,y,0) = u_0(x,y), u_t(x,y,0) = v_0(x,y) & \text{in } \Omega, \end{cases} \tag{2.11}$$

where (u_0, v_0) are given in $V \times L^2(\Omega)$.

This problem was studied for $q = C.Id$ in [12] and in [1], and strong asymptotic stability was obtained. Note that global solutions of (2.11) exist at least if we suppose q continuous increasing (see, for example, [1]). Applying Theorem 2.1, we obtain the following result.

COROLLARY 2.3. *If* (2.10) *is satisfied, then all global solutions of Example* 2.2 *satisfy* $(u(t), u_t(t)) \rightharpoonup (0,0)$ *weakly in* $V \times L^2(\Omega)$ *as* $t \to +\infty$ *if and only if* $\frac{x_0}{a} \notin \mathbb{Q}$ *and* $\frac{y_0}{b} \notin \mathbb{Q}$.

Remark. Theorem 2.1 can be applied to many other equations (see [10], [11] for other examples).

2.5. Remarks. It can be proved that in the case of an interior control ($X = Y = \Omega, m = \mu = dx$), the hypothesis (H_2)(i), (2.2) can be replaced by the weaker hypothesis

$$\forall \lambda > 0,\ q(\lambda) > 0$$

(for proof, see [11]). But we do not know if it is still true in the general case (and in particular in the case of a boundary control).

However, the hypothesis $\forall \lambda > 0,\ q(\lambda) > 0$, is absolutely necessary (at least in the case of a boundary control) since we have the following counterexample.

EXAMPLE 2.3. *Let* $q : \mathbb{R} \to \mathbb{R}$ *be defined by*

$$\begin{cases} q(\lambda) = 0 & \text{if } \lambda \le 0, \\ q(\lambda) = \lambda & \text{if } 0 \le \lambda \le 1, \\ q(\lambda) = 2 - \lambda & \text{if } 1 \le \lambda \le 2, \\ q(\lambda) = 0 & \text{if } 2 \le \lambda, \end{cases}$$

and let u *be the solution of*

$$\begin{cases} u_{tt} - u_{xx} = 0, & x \in]0,1[,\ t > 0, \\ u(0,t) = 0, & t > 0, \\ -u_x(1,t) = q(u_t(1,t)), & t > 0, \end{cases}$$

with

$$\begin{cases} u_0(x) = 0, & x \in]0,1[, \\ u_1(x) = 2\alpha, & x \in]0,1[. \end{cases}$$

Then, if $\alpha > 1$ *or* $\alpha < -1$, *we can prove that* $u(t) \not\to 0$ *weakly in* $H^1(0,1)$ *as* $t \to +\infty$. *To prove this, we make the calculus of the solution and we remark that the support of* u_t *is contained in the kernel of* q *(for details, see* [11]*).*

3. Proofs.

3.1. Proof of Theorem 2.1. Let (u_0, v_0) be given in $V \times H$, and let $u(t; u_0, v_0)$ be the solution of (2.5) associated with the initial data (u_0, v_0). From (2.6) and (H_1)(ii), we obtain

$$\langle u_{tt}, u_t \rangle_{V',V} + \langle \tilde{A}u + Q(u_t), u_t \rangle_{V',V} = 0 \text{ a.e. } t \in \mathbb{R}_+,$$

with

$$\langle u_{tt}, u_t \rangle_{V',V} = \frac{1}{2}\frac{d}{dt}\|u_t\|_H^2 \text{ a.e. } t \in \mathbb{R}_+,$$

and

$$\langle \tilde{A}u, u_t \rangle_{V',V} = (u, u_t)_V = \frac{1}{2}\frac{d}{dt}\|u\|_V^2 \text{ a.e. } t \in \mathbb{R}_+,$$

so that, a.e. $t \in \mathbb{R}_+$, from (2.4) we have

$$\frac{d}{dt}(\|u_t\|_H^2 + \|u\|_V^2) = -2\langle Q(u_t), u_t\rangle_{V',V} = -2\int_Y aq(u_t)u_t dm. \tag{3.1}$$

Hence, we obtain the following "energy" equality:

$$\|u(t)\|_V^2 + \|u_t(t)\|_H^2 + 2\int_0^t \int_Y aq(u_t)u_t dmds = \|u_0\|_V^2 + \|v_0\|_H^2 \text{ a.e. } t \in \mathbb{R}_+. \tag{3.2}$$

If we set $v = u_t$ and $U = \left(\begin{smallmatrix} u \\ v \end{smallmatrix}\right)$, then the problem (2.5) may be written in the first order form

$$\begin{cases} \frac{dU}{dt} = \mathcal{A}U + F(U), & t \in \mathbb{R}_+, \\ U(t) \in \mathcal{H}, & t \in \mathbb{R}_+, \\ U(0) = U_0, \end{cases} \tag{3.3}$$

where

$$\mathcal{A} = \begin{pmatrix} 0 & 1 \\ -\tilde{A} & 0 \end{pmatrix},\ F(U) = \begin{pmatrix} 0 \\ -Q(v) \end{pmatrix},\ U_0 = \begin{pmatrix} u_0 \\ v_0 \end{pmatrix},$$

and where $\mathcal{H} = V \times H$ is equipped with the scalar product

$$(U, \tilde{U})_{\mathcal{H}} = (u, \tilde{u})_V + (v, \tilde{v})_H \text{ for } U = \begin{pmatrix} u \\ v \end{pmatrix},\ \tilde{U} = \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \in \mathcal{H}.$$

We also note that

$$(U, \tilde{U})_{\mathcal{H}' \times \mathcal{H}} = \langle u, \tilde{u}\rangle_{V',V} + (v, \tilde{v})_H$$
$$\text{for } U = \begin{pmatrix} u \\ v \end{pmatrix} \in \mathcal{H}' = V' \times H \text{ and } \tilde{U} = \begin{pmatrix} \tilde{u} \\ \tilde{v} \end{pmatrix} \in \mathcal{H} = V \times H.$$

With these notations, (3.2) becomes

$$\|U(t; U_0)\|_{\mathcal{H}}^2 + 2\int_0^t \int_Y aq(u_t)u_t dmds = \|U_0\|_{\mathcal{H}}^2 \text{ a.e. } t \in \mathbb{R}_+. \tag{3.4}$$

By (2.1) and (3.4), we have

$$\|U(t; U_0)\|_{\mathcal{H}} \le \|U_0\|_{\mathcal{H}} \text{ a.e. } t \in \mathbb{R}_+. \tag{3.5}$$

Consequently, the weak ω-limit set $\omega_W(U_0)$ is nonempty. Let $\begin{pmatrix} \varphi \\ \psi \end{pmatrix}$ be in $\omega_W(U_0)$. By definition, there exists $t_n \to +\infty$ as $n \to +\infty$ such that

$$U(t_n; U_0) \rightharpoonup \begin{pmatrix} \varphi \\ \psi \end{pmatrix} \text{ in } \mathcal{H} \text{ as } n \to +\infty. \tag{3.6}$$

For this sequence t_n, we consider the translates defined by

$$U_n(t) = U(t + t_n; U_0). \tag{3.7}$$

For any fixed $T > 0$, we deduce from (3.5) that $(U_n)_n$ is a bounded sequence in $L^\infty(0, T; \mathcal{H})$. Hence it possesses a subsequence also denoted by $(U_n)_n$, and there exists $\bar{U} = \left(\begin{smallmatrix} \bar{u} \\ \bar{v} \end{smallmatrix}\right) \in L^\infty(0, T; \mathcal{H})$ such that

$$U_n = \begin{pmatrix} u_n \\ v_n \end{pmatrix} \rightharpoonup \bar{U} = \begin{pmatrix} \bar{u} \\ \bar{v} \end{pmatrix} \text{ weakly in } L^2(0, T; \mathcal{H}) \text{ as } n \to +\infty. \tag{3.8}$$

In particular, we can prove that for any $W \in \mathcal{H}$, the function $t \mapsto (U_n(t), W)_{\mathcal{H}}$ converges in $\mathcal{D}'(]0,T[)$ to the function $t \mapsto (\bar{U}(t), W)_{\mathcal{H}}$.

Our purpose is to prove that $\bar{U} \equiv 0$ on $X \times \mathbb{R}_+$. In particular, it will give $\bar{U}(0) = \binom{\varphi}{\psi} = \binom{0}{0}$ and so $\omega_W(U_0) = \{(0,0)\}$, which implies that $U(t;U_0) \rightharpoonup (0,0)$ weakly in $V \times H$. In the first part of the proof, we will write the equation satisfied by the translates U_n. Passing to the limit as $n \to +\infty$ in this equation, we will obtain an equation satisfied by $\bar{U}$. In the second part, we will use the representation of the solutions of this equation and the result of "uniqueness" (U) to prove that $\bar{U} \equiv 0$ on $X \times \mathbb{R}_+$.

Part 1. Since U_n is a solution of (3.3) with the initial data $U(t_n)$, we have for all $n \in \mathbb{N}$, $t \in [0,T]$, and $W = \binom{w_1}{w_2} \in V \times \mathcal{E}$,

$$(U_n(t), W)_{\mathcal{H}} - (U(t_n), W)_{\mathcal{H}} = \int_0^t (\mathcal{A}^* W, U_n(s))_{\mathcal{H}' \times \mathcal{H}} ds + \int_0^t \int_Y F(U_n(s)) \cdot W dm(y) ds. \tag{3.9}$$

By (3.8), the first term $(U_n(t), W)_{\mathcal{H}}$ converges in $\mathcal{D}'(]0,T[)$ to $(\bar{U}(t), W)_{\mathcal{H}}$ as $n \to +\infty$. By (3.6),

$$(U(t_n), W)_{\mathcal{H}} \to \left(\binom{\varphi}{\psi}, W \right)_{\mathcal{H}} \text{ as } n \to +\infty,$$

and by (3.8), we have for all $t \in [0,T]$,

$$\int_0^t (\mathcal{A}^* W, U_n(s))_{\mathcal{H}' \times \mathcal{H}} ds \to \int_0^t (\mathcal{A}^* W, \bar{U}(s))_{\mathcal{H}' \times \mathcal{H}} ds \text{ as } n \to +\infty.$$

Moreover, the Lebesgue dominated convergence theorem implies that these two last convergences hold in $\mathcal{D}'(]0,T[)$.

We will now prove that

$$a(y) q(v_n) \to 0 \text{ as } n \to +\infty \text{ strongly in } L^1(Y \times [0,T]), \tag{3.10}$$

which will imply that the last term of (3.9) converges to 0 in $\mathcal{D}'(]0,T[)$. Indeed, we will obtain for all $t \in [0,T]$,

$$\int_0^t \int_Y F(U_n(s)) \cdot W dm(y) ds = \begin{pmatrix} 0 \\ -\int_0^t \int_Y a(y) q(v_n) w_2 dm(y) ds \end{pmatrix} \to \binom{0}{0} \text{ as } n \to +\infty,$$

and the Lebesgue dominated convergence theorem will give the result since w_2 is bounded in Y.

To prove (3.10), we fix $\varepsilon > 0$. By continuity of $q(\lambda)$ at $\lambda = 0$, there exists $\eta(\varepsilon)$ such that

$$\iint_{\substack{Y \times [0,t] \\ |v_n(y,s)| \le \eta(\varepsilon)}} a(y) |q(v_n)| dm(y) ds \le \varepsilon. \tag{3.11}$$

So, we have

$$\begin{aligned} &\int_0^t \int_Y a(y) |q(v_n)| dm(y) ds \\ &\le \iint_{\substack{Y \times [0,t] \\ |v_n(y,s)| \ge \eta(\varepsilon)}} a(y) |q(v_n)| dm(y) ds + \iint_{\substack{Y \times [0,t] \\ |v_n(y,s)| \le \eta(\varepsilon)}} a(y) |q(v_n)| dm(y) ds \\ &\le \frac{1}{\eta(\varepsilon)} \int_0^t \int_Y a(y) q(v_n) v_n dm(y) ds + \varepsilon. \end{aligned} \tag{3.12}$$

From (3.4), we have for all $t \in [0,T]$ and $n \in \mathbb{N}$,

$$\|U_n(t)\|_{\mathcal{H}}^2 - \|U(t_n)\|_{\mathcal{H}}^2 = -2\int_0^t \int_Y a(y)q(v_n)v_n dm(y)ds. \tag{3.13}$$

Since the function $t \mapsto \|U(t;U_0)\|_{\mathcal{H}}$ is nonincreasing and bounded from below, its limit as $t \to +\infty$ exists. But since $U_n(t) = U(t+t_n)$, it follows that

$$\lim_{n\to+\infty} \|U_n(t)\|_{\mathcal{H}} = \lim_{n\to+\infty} \|U(t_n;U_0)\|_{\mathcal{H}},$$

and hence by (3.13),

$$\lim_{n\to+\infty} \int_0^t \int_Y a(y)q(v_n)v_n dm(y)ds = 0 \quad \forall t \in [0,T]. \tag{3.14}$$

We deduce from (3.12) and (3.14) that there exists $n_0 \in \mathbb{N}$ such that, for all $n \geq n_0$,

$$\int_0^t \int_Y a(y)|q(v_n)|dm(y)ds \leq 2\varepsilon.$$

So (3.10) is proved.

We can now write the limit in $\mathcal{D}'(]0,T[)$ of relation (3.9) as $\forall t \in [0,T]$, $\forall W = \left(\begin{smallmatrix} w_1 \\ w_2 \end{smallmatrix}\right) \in V \times \mathcal{E}$,

$$(\bar{U}(t),W)_{\mathcal{H}} - \left(\left(\begin{smallmatrix} \varphi \\ \psi \end{smallmatrix}\right), W\right)_{\mathcal{H}} = \int_0^t (\mathcal{A}^*W, \bar{U}(s))_{\mathcal{H}'\times\mathcal{H}} ds. \tag{3.15}$$

And we obtain that $\bar{U}$ is a solution of

$$\begin{cases} \frac{d}{dt}(\bar{U}(t),W)_{\mathcal{H}} = (\mathcal{A}^*W, \bar{U}(t))_{\mathcal{H}\times\mathcal{H}} \quad \forall W \in D(\mathcal{A}^*) \forall t \in [0,T], \\ \bar{U}(0) = \left(\begin{smallmatrix} \varphi \\ \psi \end{smallmatrix}\right). \end{cases} \tag{3.16}$$

Indeed, (3.15) implies that this equation is verified for all $W \in V \times \mathcal{E}$, and since $\mathcal{E}$ is dense in $D(A)$, it is still true for all $W \in V \times D(A) = D(\mathcal{A}^*)$. Moreover, since T is arbitrary and $\bar{U} \in L^\infty(0,\infty;\mathcal{H})$, it is always true for $t \in [0,+\infty[$. Finally, $\bar{U}$ is a solution of the equation

$$\begin{cases} \frac{d}{dt}\bar{U}(t) = \mathcal{A}\bar{U}(t), \qquad t \in \mathbb{R}_+, \\ \bar{U}(0) = \left(\begin{smallmatrix} \varphi \\ \psi \end{smallmatrix}\right), \end{cases} \tag{3.17}$$

and consequently, $\bar{u}$ is a solution of

$$\begin{cases} \bar{u}_{tt} + \tilde{A}\bar{u} = 0, \qquad t \in \mathbb{R}_+, \\ \bar{u}(0) = \varphi, \ \bar{u}_t(0) = \psi. \end{cases} \tag{3.18}$$

Part 2.

Step 1. Since $(\bar{u}, \bar{u}_t)$ is a solution of (3.18), and since A satisfies (H_1)(ii), we can write

$$\bar{u}(t) = \sum_{p\in\mathbb{N}} \left(-\cos(\omega_p t)\frac{\psi_p}{\omega_p} + \sin(\omega_p t)\frac{\varphi_p}{\omega_p}\right), \tag{3.19}$$

and

$$\bar{u}_t(t) = \sum_{p\in\mathbb{N}} \left(\cos(\omega_p t)\varphi_p + \sin(\omega_p t)\psi_p\right), \tag{3.20}$$

where φ_p, ψ_p are eigenfunctions of A, ω_p eigenvalues of A and where (3.19) (resp., (3.20)) converges in V (resp., in H) uniformly in t (for more details, see [1] or [11]).

Step 2. Fix $p \in \mathbb{N}$ and $\eta = \pm 1$. For $T > 0$, we set

$$\forall n \in \mathbb{N},\ w_{n,T} = \frac{1}{T}\int_0^T \frac{1+\eta\cos(\omega_p t)}{2} v_n(x,t)dt, \tag{3.21}$$

and

$$\bar{w}_T = \frac{1}{T}\int_0^T \frac{1+\eta\cos(\omega_p t)}{2} \bar{u}_t(x,t)dt. \tag{3.22}$$

The following convergence results can be proved (the proof appears later in this paper).

LEMMA 3.1.

$$\forall T > 1,\ w_{n,T}(y) \rightharpoonup \bar{w}_T(y) \text{ weakly in } V \text{ as } n \to +\infty, \tag{3.23}$$

$$\bar{w}_T(y) \rightharpoonup \frac{1}{4}\eta\varphi_p(y) \text{ weakly in } V \text{ as } T \to +\infty. \tag{3.24}$$

Step 3. Since q is such that (H_2)(i) holds, we can construct $\hat{q} : \mathbb{R} \to \mathbb{R}$ continuous increasing such that

$$\begin{cases} \forall \lambda \in \mathbb{R}, & 0 \le \hat{q}(\lambda)\lambda \le q(\lambda)\lambda, \\ \forall \lambda > 0, & \hat{q}(\lambda) > 0 \end{cases}$$

(indeed, we can choose $\hat{q}(\lambda) = 0$ for $\lambda \le 0$ and $\hat{q}(\lambda) = \inf\{q(s) \mid s \ge \lambda\}$ for $\lambda > 0$).

Then we denote by $\hat{\jmath} : \mathbb{R} \to [0, +\infty[$ the primitive of $\hat{q}$ such that $\hat{\jmath}(0) = 0$, and we set $\hat{\Psi}(v) = \int_Y a(y)\hat{\jmath}(v(y))dm(y)$ for $v \in V$.

$\hat{\Psi} : V \to]-\infty, +\infty]$ is proper, convex (since $\hat{\jmath}$ is convex), lower semicontinuous (l.s.c.). Indeed, since $\hat{\Psi}$ is convex, we just have to prove that

$$(v_n \to v \text{ strongly in } V \text{ as } n \to \infty) \implies (\hat{\Psi}(v) \le \liminf_{n\to+\infty} \hat{\Psi}(v_n)). \tag{3.25}$$

By (H_1)(iii), $v_n \to v$ strongly in V as $n \to +\infty$ implies that $v_n \to v$ strongly in $L^1(Y, m)$ as $n \to +\infty$ and so $v_n \to v$ m-a.e. in Y as $n \to +\infty$ for a subsequence still denoted by $(v_n)_n$. Then (3.25) is verified by Fatou's lemma.

Since $\forall \lambda \in \mathbb{R}, \hat{\jmath}(\lambda) \le \lambda\hat{q}(\lambda)$, we can prove that

$$\forall n \in \mathbb{N},\ 0 \le \hat{\Psi}(v_n) \le \int_Y a\hat{q}(v_n)v_n dm \le \int_Y aq(v_n)v_n dm,$$

which gives, for all $T > 0$,

$$\forall n \in \mathbb{N},\ \int_0^T \hat{\Psi}(v_n)dt \le \int_0^T \int_Y aq(v_n)v_n dmdt.$$

So from (3.14), we deduce that

$$\forall T>0,\ \int_0^T \hat{\Psi}(v_n)dt \to 0 \text{ as } n\to+\infty. \tag{3.26}$$

Moreover, since $\hat{\Psi}$ is convex with $\hat{\Psi}(0)=0$ and since $0\leq \frac{1+\eta\cos(\omega_p t)}{2}\leq 1$ for all $t\in[0,T]$, we have

$$\forall n\in\mathbb{N},\ 0\leq \hat{\Psi}\left(\frac{1}{T}\int_0^T \frac{1+\eta\cos(\omega_p t)}{2}v_n dt\right)\leq \frac{1}{T}\int_0^T \frac{1+\eta\cos(\omega_p t)}{2}\hat{\Psi}(v_n)dt$$
$$\leq \frac{1}{T}\int_0^T \hat{\Psi}(v_n)dt.$$

Therefore, by (3.26), all these integrals tend to 0 as $n\to+\infty$. From Lemma 3.1, and since $\hat{\Psi}$ is l.s.c. on V, we have for all $T>0$,

$$\hat{\Psi}(\bar{w}_T)\leq \liminf_{n\to+\infty}\hat{\Psi}(w_{n,T})=0,$$

and similarly

$$\hat{\Psi}\left(\frac{\eta}{4}\varphi_p\right)\leq \liminf_{T\to+\infty}\hat{\Psi}(\bar{w}_T)=0.$$

So, we obtain

$$\hat{\Psi}\left(\frac{\eta}{4}\varphi_p\right)=\int_Y a(y)\hat{\jmath}\left(\frac{\eta}{4}\varphi_p(y)\right)dm(y)=0,$$

which implies

$$a(y)\hat{\jmath}\left(\frac{\pm 1}{4}\varphi_p(y)\right)=0 \text{ m-a.e. on } Y. \tag{3.27}$$

Since $\hat{\jmath}'(\lambda)=\hat{q}(\lambda)>0\ \forall\lambda>0$, we know that $\hat{\jmath}$ is strictly increasing on $\mathbb{R}_+$. But $\hat{\jmath}(0)=0$, so $\hat{\jmath}(\lambda)>0\ \forall\lambda>0$. In particular, $\hat{\jmath}(\lambda)=\hat{\jmath}(-\lambda)=0$ implies $\lambda=0$. So, (3.27) implies that

$$a(y)\varphi_p(y)=0 \text{ m-a.e. on } Y.$$

And from the "uniqueness" hypothesis (U), we obtain

$$\varphi_p(x)=0 \text{ a.e. } x\in X\ \forall p\in\mathbb{N}. \tag{3.28}$$

Similarly, multiplying v_n by $\frac{1+\eta\sin(\omega_p t)}{2}$ instead of $\frac{1+\eta\cos(\omega_p t)}{2}$, we get

$$\psi_p(x)=0 \text{ a.e. } x\in X\ \forall p\in\mathbb{N}. \tag{3.29}$$

Finally, from (3.19) and (3.20), we get $(\bar{u},\bar{u}_t)\equiv(0,0)$ on $X\times\mathbb{R}_+$, which ends the proof of Theorem 2.1. □

Proof of Lemma 3.1. First, we will prove that

$$\exists C_p>0 \text{ such that } \forall n\in\mathbb{N},\ \forall T>1,\ \|w_{n,T}\|_V\leq C_p. \tag{3.30}$$

Indeed, for all $n \in \mathbb{N}$ and $T > 0$,

$$w_{n,T}(x) = \frac{1}{T}\int_0^T \frac{1+\eta\cos(\omega_p t)}{2} v_n(x,t)\mathrm{dt}$$
$$= \frac{1}{T}\left[\frac{1+\eta\cos(\omega_p t)}{2} u_n(x,t)\right]_0^T + \frac{1}{T}\int_0^T \frac{\eta\omega_p \sin(\omega_p t)}{2} u_n(x,t)\mathrm{dt}.$$

Hence,

$$\|w_{n,T}\|_V \leq \frac{1}{T}\left(\frac{1+\eta\cos(\omega_p t)}{2}\|u_n(T)\|_V + \frac{1+\eta}{2}\|u_n(0)\|_V\right) + \frac{1}{T}\int_0^T \frac{1}{2}\omega_p \|u_n(t)\|_V \mathrm{dt}.$$

From (3.5), we know that there exists $C > 0$ such that

$$\|u_n(t)\|_V \leq C \ \forall n \in \mathbb{N},\ \forall t \in \mathbb{R}_+.$$

Consequently,

$$\|w_{n,T}\|_V \leq \frac{2C}{T} + \frac{1}{2}\omega_p C \leq 2C + \frac{1}{2}\omega_p C = C_p \ \text{ for } T > 1,$$

which proves (3.30).

From (3.30), we deduce that for $T > 1$, $w_{n,T}$ converges weakly in V as $n \to +\infty$ (for a subsequence still denoted by $w_{n,T}$). But $v_n \rightharpoonup \bar{v} = \bar{u}_t$ weakly in $L^2(0,T;H)$ as $n \to +\infty$, hence for all $T > 1$, we have

$$w_{n,T} \rightharpoonup \bar{w}_T \text{ weakly in } H \text{ as } n \to +\infty.$$

So by uniqueness of the limit for the weak convergence in H, we obtain

$$w_{n,T} \rightharpoonup \bar{w}_T \text{ weakly in } V \text{ as } n \to +\infty, \tag{3.31}$$

which proves the first part of Lemma 3.1.

Using (3.31) and (3.30), we obtain

$$\|\bar{w}_T\| \leq C_p \text{ for all } T > 1. \tag{3.32}$$

We deduce that $\bar{w}_T$ converges weakly in V as $T \to +\infty$ (for a subsequence still denoted $\bar{w}_T$). But it can be proved that, for $\eta = \pm 1$ and for all $p \in \mathbb{N}$,

$$\frac{1}{T}\int_0^T \frac{1+\eta\cos(\omega_p t)}{2}\bar{u}_t(t)\mathrm{dt} \longrightarrow \frac{1}{4}\eta\varphi_p \text{ strongly in } H \text{ as } T \to +\infty, \tag{3.33}$$

$$\text{i.e., } \bar{w}_T \longrightarrow \frac{1}{4}\eta\varphi_p \text{ strongly in } H \text{ as } T \to +\infty.$$

This convergence is a consequence of the fact that (3.20) converges in H uniformly in t. It consists as in [1] in multiplying (3.20) by $\frac{1+\eta\cos(\omega_p t)}{2}$ and computing the limit. In [1], (3.20) converges in V uniformly in t and the convergence (3.33) is proved in V. Here the convergence is only true in H, but the proof is the same (for details, see [11]). So by uniqueness of the limit, we deduce that

$$\bar{w}_T \rightharpoonup \frac{1}{4}\eta\varphi_p \text{ weakly in } V \text{ as } T \to +\infty,$$

which proves the second part of Lemma 3.1. □

3.2. Remark concerning the definition of Q. In the following examples, for all $v \in D(Q)$, $Q(v)$ will be defined on $\mathcal{E}$ by

$$\forall \varphi \in \mathcal{E},\ \langle Q(v), \varphi \rangle_{V',V} = \int_Y a(y) q(v(y)) \varphi(y) dm(y) \tag{3.34}$$

(see (H_2)(ii)).

$Q(v)$ is linear continuous from $\mathcal{E}$ into $\mathbb{R}$ and it can be extended to a linear continuous application from V into $\mathbb{R}$ still denoted $Q(v)$. So for all $v \in D(Q)$, $Q(v)$ is defined and $Q(v) \in V'$. But in order to verify hypothesis (H_2)(ii), we still have to verify that equation (3.34) is still true for $\varphi = v$, i.e., we have to prove that

$$\forall v \in D(Q),\ \langle Q(v), v \rangle_{V',V} = \int_Y a(y) q(v(y)) v(y) dm(y). \tag{3.35}$$

In this paper, we will omit this technical point in the proofs of Corollaries 2.1, 2.2, and 2.3. It is generally based on "smooth truncation" results in Sobolev spaces. For details, see [11].

Note that, in the proof of Theorem 2.1, relation (3.35) is only used in (3.1) in order to obtain the "energy equality" (3.2). In most examples, if we add assumptions ensuring existence of global solutions, the "energy equality" (3.2) will be obtained naturally, and consequently, it will not be necessary to verify (3.35).

3.3. Proof of Corollary 2.1. We set the following:

- $(X, \mu) = (\overline{\Omega}, dx)$ where dx is the Lebesgue's measure on $\mathbb{R}^N$.
  $H = L^2(\Omega, dx)$.
- $V = \{v \in H^1(\Omega) \mid v_{|\Gamma^*} = 0\}$.
  $D(A) = \{u \in V \mid \Delta u \in L^2(\Omega) \text{ and } \frac{\partial u}{\partial \nu} = 0 \text{ on } \Gamma_0\}$ (note that $\frac{\partial u}{\partial \nu}_{|\Gamma}$ is defined and $\frac{\partial u}{\partial \nu}_{|\Gamma} \in H^{-\frac{1}{2}}(\Gamma)$ because $u \in H^1(\Omega)$ with $\Delta u \in L^2(\Omega)$, see [8] or [4]).
  For $u \in D(A)$, $Au = -\Delta u$, and for $(u, v) \in V \times V$, $\langle \tilde{A}u, v \rangle_{V',V} = \int_\Omega \nabla u \nabla v dx$.
- $(Y, m) = (\Gamma, d\sigma)$ where $d\sigma$ is the superficial measure on Γ.
  The trace mapping $\tau : V \to L^1(\Gamma, d\sigma)$ is continuous (it is actually continuous into $H^{\frac{1}{2}}(\Gamma, d\sigma)$) .
- $a(.)$ is defined on Γ_0 and we extend it in a function still denoted by $a(.)$ and defined on Γ by $a(x)$ for $x \in \Gamma_0$ and 0 for $x \in \Gamma^*$.

Then we can apply Theorem 2.1, and weak asymptotic stability is obtained if the following "uniqueness" result is true:

$$\left(-\Delta \varphi = \omega^2 \varphi \text{ in } \Omega,\ \varphi = 0 \text{ on } \Gamma^*,\ \frac{\partial \varphi}{\partial \nu} = 0 \text{ on } \Gamma_0 \textbf{ and } \varphi = 0 \text{ on } \Gamma_0 \right) \Longrightarrow \varphi \equiv 0 \text{ in } \Omega.$$

This result is true because Γ_0 is not too "thin" (for example Γ_0 contains $B(x_0, \varepsilon) \cap \Gamma$ where $x_0 \in \Gamma$, see [1]). □

3.4. Proof of Corollary 2.2. We set the following:

- $(X, \mu) = (Y, m) = (\Omega, dx)$ where dx is the Lebesgue's measure on $\mathbb{R}^N$.
  $H = L^2(\Omega, dx)$.
- $V = \{v \in H^2(\Omega) \mid v = 0 \text{ on } \Gamma\}$.

$D(A) = \{u \in V \mid \Delta^2 u \in L^2(\Omega)$ and $\Delta u_{|\Gamma} = 0$ on $\Gamma\}$ (note that $\Delta u_{|\Gamma}$ is defined and $\Delta u_{|\Gamma} \in H^{-\frac{1}{2}}(\Gamma)$ because $\Delta u \in L^2(\Omega)$ with $\Delta^2 u \in L^2(\Omega)$, see [8]).

For $u \in D(A)$, $Au = \Delta^2 u$ and for $(u, v) \in V \times V$, $\langle \tilde{A}u, v\rangle_{V',V} = \int_\Omega \Delta u \Delta v dx$.

Then we can apply Theorem 2.1 and weak asymptotic stability is obtained because the following "uniqueness" result is true:

$$\big(\varphi \in V,\ \Delta^2\varphi = \omega^2\varphi \text{ in } \Omega, \quad \textbf{and } \varphi(x) = 0 \text{ a.e. } x \in \mathrm{supp}(a)\big) \Longrightarrow \varphi \equiv 0 \text{ in } \Omega.$$

Indeed it implies that φ is analytic on Ω (see [4]), and consequently, $\varphi \equiv 0$ in Ω since Ω is connected and $\mathrm{meas}(\mathrm{supp}(a)) > 0$. □

3.5. Proof of Corollary 2.3. We set the following:

- $(X, \mu) = (\Omega, dxdy) = (]0, a[\times]0, b[, dxdy)$ where $dxdy$ is the Lebesgue's measure in $\mathbb{R}^2$.
  $H = L^2(]0, a[\times]0, b[, dxdy)$.
- $V = \{v \in H^2(\Omega) \mid v = 0 \text{ on } \Gamma = \partial\Omega\}$.
  $D(A) = \{u \in V \mid \Delta^2 u \in H$ and $\Delta u = 0$ on $\Gamma\}$.
  For $u \in D(A)$, $Au = \Delta^2 u$ and for $(u, v) \in V \times V$, $\langle \tilde{A}u, v\rangle_{V',V} = \int_\Omega \Delta u \Delta v dxdy$.
- $Y = \{(x_0, y_0)\}$ and m is the Dirac masse $\delta(\cdot - x_0, \cdot - y_0)$.
- We define $a : Y \to \mathbb{R}$ by $a(x_0, y_0) = 1$.

Then we can verify that (H_1) and (H_2) are satisfied. Indeed, A is self-adjoint, coercive on H, and the resolvent of A is compact (see, for example, [12]). Moreover, $V \subset H^2(\Omega) \hookrightarrow \mathcal{C}^0(\overline{\Omega})$ (because $\Omega \subset \mathbb{R}^2$) so that $\forall v \in V$, $v(x_0, y_0)$ exists and $v \mapsto v(x_0, y_0)$ is linear continuous from $V \to \mathbb{R}$. Finally, Theorem 2.1 can be applied and we obtain weak asymptotic stability of all global solutions if and only if the following "uniqueness" result is true:

$$\big(\varphi \in V,\ A\varphi = \omega^2\varphi \text{ on } \Omega \textbf{ and } \varphi(x_0, y_0) = 0\big) \Longrightarrow \varphi \equiv 0 \text{ on } \Omega. \tag{3.36}$$

As in [1], we can prove that (3.36) is verified as follows: let $\varphi \in V$ be such that $A\varphi = \omega^2\varphi$ on Ω. Then, we have

$$\varphi(x, y) = \sum_{r,s} \alpha_{r,s} \sin\frac{r\pi x}{a} \sin\frac{s\pi y}{b},$$

where $r, s \in \mathbb{N}$ are such that $\omega^4 = (\frac{r^2}{a^2} + \frac{s^2}{b^2})^2\pi^4$. But the eigenvalues are all simple because $\frac{a^2}{b^2} \notin \mathbb{Q}$. Indeed, if ω is not a simple eigenvalue, then there exists $(m, n) \in \mathbb{N}^2$ and $(m', n') \in \mathbb{N}^2$ such that $(m', n') \neq (m, n)$ and $\omega^2 = (\frac{m^2}{a^2} + \frac{n^2}{b^2})\pi^2 = (\frac{m'^2}{a^2} + \frac{n'^2}{b^2})\pi^2$. So, we obtain $\frac{m^2 - m'^2}{n'^2 - n^2} = \frac{a^2}{b^2} \notin \mathbb{Q}$, which is absurd. So the hypothesis (2.10) implies that

$$\varphi(x, y) = \alpha_{m,n} \sin\frac{m\pi x}{a} \sin\frac{n\pi y}{b},$$

with $\omega^2 = (\frac{r^2}{a^2} + \frac{s^2}{b^2})\pi^2$. Clearly, $\sin\frac{m\pi x_0}{a} \sin\frac{n\pi y_0}{b} \neq 0$ if and only if $\frac{x_0}{a} \notin \mathbb{Q}$ and $\frac{y_0}{b} \notin \mathbb{Q}$, so (3.36) is true if and only if $\frac{x_0}{a} \notin \mathbb{Q}$ and $\frac{y_0}{b} \notin \mathbb{Q}$, which ends the proof. □

Acknowledgments. The author is grateful to Professor M. Pierre for first suggesting this problem and for a number of instructive discussions. The author would also like to thank Professors V. Komornik and B. Rao for their comments and suggestions on this work.

APPROXIMATION BY RIDGE FUNCTIONS AND NEURAL NETWORKS*

PENCHO P. PETRUSHEV†

Abstract. We investigate the efficiency of approximation by linear combinations of ridge functions in the metric of $L_2(\mathbf{B}^d)$ with $\mathbf{B}^d$ the unit ball in $\mathbf{R}^d$. If X_n is an n-dimensional linear space of univariate functions in $L_2(I)$, $I = [-1,1]$, and Ω is a subset of the unit sphere $\mathbf{S}^{d-1}$ in $\mathbf{R}^d$ of cardinality m, then the space $Y_n := \text{span}\{r(\mathbf{x}\cdot\xi) : r \in X_n, \omega \in \Omega\}$ is a linear space of ridge functions of dimension $\le mn$. We show that if X_n provides order of approximation $O(n^{-r})$ for univariate functions with r derivatives in $L_2(I)$, and Ω are properly chosen sets of cardinality $O(n^{d-1})$, then Y_n will provide approximation of order $O(n^{-r-d/2+1/2})$ for every function $f \in L_2(\mathbf{B}^d)$ with smoothness of order $r+d/2-1/2$ in $L_2(\mathbf{B}^d)$. Thus, the theorems we obtain show that this form of ridge approximation has the same efficiency of approximation as other more traditional methods of multivariate approximation such as polynomials, splines, or wavelets. The theorems we obtain can be applied to show that a feed-forward neural network with one hidden layer of computational nodes given by certain sigmoidal function σ will also have this approximation efficiency. Minimal requirements are made of the sigmoidal functions and in particular our results hold for the unit-impulse function $\sigma = \chi_{[0,\infty)}$.

Key words. approximation error, ridge functions, neural networks

1. Introduction.

A ridge function is a multivariate function of the form $r(\mathbf{x}\cdot\omega)$, where r is a univariate function, ω is a fixed vector in $\mathbf{R}^d$, the variable $\mathbf{x} \in \mathbf{R}^d$, and $\mathbf{x}\cdot\omega$ is the inner product of $\mathbf{x}$ and ω. These functions appear naturally in harmonic analysis, special function theory, and in several applications such as tomography and neural networks. In most applications, we are interested in representing or approximating a general function f on a domain $\mathbf{\Omega} \subset \mathbf{R}^d$ by linear combinations of ridge functions. It is surprising therefore that the most fundamental questions concerning the efficiency of approximation by ridge functions are unanswered.

In this paper, we shall consider approximating functions in $L_2(\mathbf{B}^d)$, $\mathbf{B}^d$ the unit ball in $\mathbf{R}^d$, $d \ge 2$, by linear combinations of ridge functions. Using extension theorems, the set $\mathbf{B}^d$ can be replaced by more general sets $\mathbf{\Omega} \subset \mathbf{R}^d$.

Let X_n be a linear space of univariate functions in $L_2(I)$, $I := [-1,1]$ and let $\Omega_n \subset \mathbf{S}^{d-1}$ be a finite subset of the unit sphere $\mathbf{S}^{d-1}$ in $\mathbf{R}^d$. Then

$$Y_n := \text{span}\{r(\mathbf{x}\cdot\omega) : r \in X_n,\ \omega \in \Omega_n\} \tag{1.1}$$

is a space of multivariate ridge functions of dimension $\le n\#\Omega_n$, where $\#\Omega_n$ is the cardinality of Ω_n. We shall relate the approximation efficiency of Y_n to that of X_n and the distribution of the vectors of Ω_n in $\mathbf{S}^{d-1}$.

Let $W^s(L_2(I))$ denote the univariate Sobolev spaces. We say that a sequence of spaces $X_n, n = 1,2,\dots,$ $\dim(X_n) = n$, provides *approximation of order* s if

$$E(g,X_n)_{L_2(I)} \le c(s)n^{-s}\|g\|_{W^s(L_2(I))}, \quad g \in W^s(L_2(I)), \tag{1.2}$$

where

$$E(g, X_n)_{L_2(I)} := \inf_{r \in X_n} \|g - r\|_{L_2(I)}$$

is the error in approximating the univariate function g in the $L_2(I)$ norm by the elements of X_n. We denote similarly the multivariate Sobolev space $W^s(L_2(\mathbf{B}^d))$ on $\mathbf{B}^d$ and the approximation error

$$E(f, Y_n)_{L_2(\mathbf{B}^d)} := \inf_{R \in Y_n} \|f - R\|_{L_2(\mathbf{B}^d)}$$

for any $f \in L_2(\mathbf{B}^d)$. Our main result, given in section 8, shows that for any sequence of spaces $X_n, n = 1, 2, \dots$, which provide approximation of order s, and for appropriately chosen sets Ω_n with $\#\Omega_n = O(n^{d-1})$, the sequence of spaces $Y_n, n = 1, 2, \dots$, given in (1.1), provide the following approximation: for $\lambda := s + (d-1)/2$,

$$E(f, Y_n)_{L_2(\mathbf{B}^d)} \le c(\lambda) n^{-\lambda} \|f\|_{W^\lambda(L_2(\mathbf{B}^d))}, \quad f \in W^\lambda(L_2(\mathbf{B}^d)). \tag{1.3}$$

Note that there is in a certain sense an unexpected gain in the multivariate approximation order $s + (d-1)/2$ over the univariate order s. This gain will be explained later (see section 9).

One can generate the space Y_n appearing in (1.3) by using very general univariate spaces X_n such as splines or wavelets. In particular, our results apply to feed-forward neural networks using a very general activation function σ. A complete discussion of the application to neural networks is given in section 9. In this introduction, we wish to illustrate the typical result by considering the following simple example. Let $\sigma = \chi_{[0,\infty)}$ and define X_n as the univariate space spanned by $\sigma(x - k/n)$, $0 \le k < n$. Then, defining Y_n for this X_n as described above, we obtain a space of dimension $O(n^d)$ of certain piecewise constant functions. The space Y_n can be realized computationally by a feed-forward neural network with $O(n^{d-1})$ computational nodes. In this case (see section 9 for details), (1.3) provides the approximation order $1 + \frac{d-1}{2}$. One might expect the estimate (1.3) to be 1 since we are using piecewise constants in the approximation. As noted in (1.3), the gain of $\frac{d-1}{2}$ in the approximation rate persists in general (see also Theorem 8.2).

There is a standard method in approximation theory (see [DL, Chapter 7]) which derives from (1.3) the estimate

$$E(f, Y_n)_{L_2(\mathbf{B}^d)} \le c \left(\omega_r(f, n^{-1})_{L_2(\mathbf{B}^d)} + \|f\|_{L_2(\mathbf{B}^d)} n^{-r} \right), \quad f \in L_2(\mathbf{B}^d) \tag{1.4}$$

with ω_r the rth order modulus of smoothness of f. In the case that Y_n contains all polynomials of total degree $< r$ (in d variables), the last term on the right can be eliminated.

Since Y_n is a linear space of dimension $O(n^d)$ then it follows from the general theory of n-widths that for all $m > 0$,

$$\sup_{\|f\|_{W^m(L_2(\mathbf{B}^d))} \le 1} E(f, Y_n) \ge c_0 n^{-m} \tag{1.5}$$

with $c_0 > 0$ a constant depending only on m and d. In this sense, the estimates (1.3) cannot be improved.

We also note that (1.3) shows that, in general, linear spaces of ridge functions are at least as efficient as other methods of multivariate approximation such as polynomials, wavelets, and splines.

This paper is an extension of the results from [DOP], where we considered the case $d = 2$. Throughout the paper we assume that $d > 2$, although most of the statements hold when $d = 2$.

The results of this paper differ from other work in this field in the following respects. We are able to begin with a very general class of univariate spaces X_n. Other authors (most notably Mhaskar and Micchelli [MM], [MM1], and Mhaskar [M]) have also considered approximation problems of the type treated here. The work of Mhaskar and Micchelli does not give the best order of approximation. Mhaskar [M] has given best possible results but only in the case that X_n is generated using a rather restrictive class of sigmoidal functions.

Our results are, for the present, limited to approximation in L_2, and it remains an important open question in ridge approximation to understand to what extent results such as those presented in this paper are valid in L_p, $p \neq 2$.

It is also an interesting question to understand which sets $\Omega_n \subset \mathbf{S}^{d-1}$, when used in defining the spaces Y_n, will provide the approximation order of (1.3). In the case $d = 2$, as was shown in [DOP], n equally spaced points on $\mathbf{S}^1$ are the most natural choice. There is no direct analogy of equally spaced points in $\mathbf{S}^{d-1}$, $d > 2$. It will become clear from section 4 that any set Ω_n which permits a cubature formula that is exact for spherical polynomials of degree $\leq n$ and with good localization properties will provide spaces Y_n which satisfy (1.3). Since we could not find in the literature examples of such sets Ω_n, we construct some in section 4. There should be more elegant and more natural constructions than ours. In some sense, one might expect that a natural quadrature formula might provide the analogue of equally spaced points in $\mathbf{S}^{d-1}$, $d > 2$.

We prove (1.3) by first understanding well the structure of ridge polynomials. Our main vehicle (given in section 3) is a fundamental orthogonal decomposition of a general function $f \in L_2(\mathbf{B}^d)$ into ridge polynomials. This decomposition uses the univariate Gegenbauer polynomials.

An outline of this paper is the following. The properties we need about Gegenbauer polynomials are given in section 2. In section 3, we give the fundamental orthogonal decomposition of functions in $L_2(\mathbf{B}^d)$ in terms of ridge polynomials. In section 4, we give our construction of cubature (quadrature) formulas. In sections 5–6, we introduce smoothness spaces (the Sobolev spaces) and recall their characterization by polynomial approximation. In section 7, we prove the main theorem about approximation by ridge functions. In section 8, we discuss how to improve the theorem of section 7 to be more amenable to applications. In section 9, we give some applications of our results, in particular to feed-forward neural networks.

Throughout the paper, the constants are denoted by $c, c_1, \ldots$ and they may vary at every occurrence. The constants usually depend on some parameters (like the dimension d) that will be sometimes indicated explicitly.

2. The Gegenbauer (ultraspherical) polynomials. Special functions appear naturally when we represent a general function in terms of ridge polynomials as will be done in the next section. In particular, the Gegenbauer polynomials will play an important role in this paper. In this section, we shall present the essential properties of Gegenbauer polynomials and bring out their role in the Radon transform. We refer the reader to [E] and [Sz] as general references for this section.

The Gegenbauer polynomials are usually defined by the following generating function

$$(1-2tz+z^2)^{-\lambda}=\sum_{m=0}^{\infty}C_m^\lambda(t)z^m,$$

where $|z|<1$, $|t|\le 1$, and $\lambda>0$. The coefficients $C_m^\lambda(t)$ are algebraic polynomials of degree m which are called the Gegenbauer polynomials associated with λ. The family of polynomials $\{C_m^\lambda\}_{m=0}^\infty$ is a complete orthogonal system for the weighted space $L_2(I,w)$, $I:=[-1,1]$, $w(t):=w_\lambda(t):=(1-t^2)^{\lambda-\frac12}$ and we have

$$\int_I C_m^\lambda(t)C_n^\lambda(t)w(t)\,dt=\begin{cases}0, & m\ne n\\ h_{n,\lambda}, & m=n\end{cases}\quad\text{with } h_{n,\lambda}:=\frac{\pi^{1/2}(2\lambda)_n\Gamma(\lambda+\frac12)}{(n+\lambda)n!\Gamma(\lambda)},\tag{2.1}$$

where we use here and later the standard notation

$$(a)_0:=0,\quad (a)_n:=a(a+1)\dots(a+n-1)=\Gamma(a+n)/\Gamma(a).$$

Also, we have

$$C_n^\lambda(-t)=(-1)^nC_n^\lambda(t),\quad C_n^\lambda(1)=\frac{(2\lambda)_n}{n!},\qquad\text{and}\quad C_0^\lambda(t)=1.\tag{2.2}$$

The Gegenbauer polynomials can also be defined by the following identity (called Rodrigues' formula):

$$C_n^\lambda(t)=(-1)^n\alpha_{n,\lambda}(1-t^2)^{-\lambda+\frac12}\left(\frac{d}{dt}\right)^n(1-t^2)^{n+\lambda-\frac12},\ \alpha_{n,\lambda}:=\frac{(2\lambda)_n}{n!2^n(\lambda+\frac12)_n}.\tag{2.3}$$

There is an identity that relates Gegenbauer polynomials with different weights:

$$\left(\frac{d}{dt}\right)^m C_n^\lambda(t)=2^m(\lambda)_mC_{n-m}^{\lambda+m}(t),\quad m=1,2,\dots,n.\tag{2.4}$$

Special cases of the Gegenbauer polynomials are the Legendre polynomials P_n and the Chebyshev polynomials of second kind U_n which correspond to $\lambda=1/2$ and $\lambda=1$, respectively. Namely,

$$P_n(t):=\frac{(-1)^n}{2^nn!}\left(\frac{d}{dt}\right)^n(1-t^2)^n=C_n^{1/2}(t),$$
$$U_n(t):=\frac{\sin(n+1)\arccos t}{\sqrt{1-t^2}}=C_n^1(t).$$

The Chebyshev polynomials of the first kind $T_n(t):=\cos n\arccos t$ can be considered as the Gegenbauer polynomials C_n^0 associated with the weight $w_0(t)=(1-t^2)^{-\frac12}$.

We shall also need the Gegenbauer polynomials C_n^λ when $\lambda<0$ and, in particular, when $\lambda=-1,-2,\dots$. Note that $\alpha_{n,\lambda}=0$ when $\lambda=-1,-2,\dots$ and $n>2\nu$. Therefore, we cannot use (2.3) to define $C_n^{-\nu}$ when $\nu=1,2,\dots$. However, we can define (see [Sz, Chapter IV])

$$C_n^\lambda(t):=\alpha(1-t^2)^{-\lambda+\frac12}\left(\frac{d}{dt}\right)^n(1-t^2)^{n+\lambda-\frac12},\quad\lambda<0,\tag{2.5}$$

where α is any constant independent of t. To our goals the normalization of C_n^λ ($\lambda<0$) is not essential. Identity (2.4) remains valid except for a constant factor (see [Sz, Chapter IV]): for any λ, we have

$$\left(\frac{d}{dt}\right)^m C_n^\lambda(t)=cC_{n-m}^{\lambda+m}(t),\quad m=1,2,\dots,n,\tag{2.6}$$

where c is independent of t.

The Gegenbauer polynomials play a fundamental role in inverting the Radon transform. We shall show in Lemma 2.1 that follows that the Gegenbauer polynomials C_n^λ for $\lambda = k$ and $\lambda = k + 1/2$ (k an integer) are eigenfunctions for certain differential operators that occur in the Radon transform inversion formula. These operators will play an important role in defining an equivalent norm for the weighted Sobolev spaces $W^s(L_2(I, w))$ (see section 8).

We begin with a brief discussion of the Hilbert transform H on $\mathbf{R}$ and its analogue $\mathbf{H}$ for the interval $I := [-1, 1]$. For any $g \in L_1(I)$ we define

$$\mathbf{H}g := Hg^\diamond \qquad \text{with} \qquad g^\diamond(t) := \begin{cases} g(t), & t \in I, \\ 0, & t \in (-\infty, \infty)\backslash I, \end{cases} \tag{2.7}$$

where $Hg^\diamond$ is the Hilbert transform of $g^\diamond$. It follows that

$$\mathbf{H}g(t) = \frac{1}{\pi}\text{p.v.} \int_{\mathbf{R}^1} \frac{g^\diamond(s)}{t-s}\, ds = \frac{1}{\pi}\text{p.v.} \int_I \frac{g(s)}{t-s}\, ds.$$

The analogue of the Hilbert transform on the circle $\mathbf{T}$ is the conjugate operator (see [Z, Chapter II]). If $g \in L_1(\mathbf{T})$, we denote its conjugate function by

$$\tilde{g}(\tau) := \frac{1}{2\pi}\text{p.v.} \int_{\mathbf{T}} g(\theta) \cot \frac{\tau - \theta}{2}\, d\theta.$$

For any (nonnegative) weight function w, let $L_2^0(I, w)$ be the space of all $g \in L_2(I, w)$ with weighted mean value zero: $\int_I g(t)\, w(t) dt = 0$. The following proposition gives some properties of $\mathbf{H}$ which we shall use.

PROPOSITION 2.1. *If $g \in L_1(I)$, we define $Tg(\theta) := \operatorname{sgn}\theta g(\cos\theta)\sin\theta$ for $\theta \in [-\pi, \pi)$. The Hilbert transform $\mathbf{H}$ satisfies the following properties:*

(a) *If $g \in L_1(I)$ then*

$$\mathbf{H}g(\cos\tau) = -\frac{1}{\sin\tau}\widetilde{Tg}(\tau) \quad \text{a.e. on } (0, \pi). \tag{2.8}$$

(b) *We have, on $(-1, 1)$, $\mathbf{H}w_1^{-1} = 0$,*

$$\mathbf{H}[w_1^{-1}T_{n+1}] = -U_n \quad \text{and} \quad \mathbf{H}[w_1 U_n] = T_{n+1} \quad \text{for } n = 0, 1, \ldots, \tag{2.9}$$

and hence

$$\mathbf{H}\frac{d}{dt}[w_1 U_n] = (n+1)U_n. \tag{2.10}$$

(c) *The functions $V_n := w_1^{-1}T_n$, $n = 0, 1, \ldots$ (in analogy to $\{U_n\}_{n=0}^\infty$) form a complete orthogonal system for $L_2(I, w_1)$.*

(d) *$\mathbf{H}$ is a one-to-one mapping of $L_2^0(I, w_1)$ onto $L_2(I, w_1)$ with*

$$\mathbf{H}^{-1}h = -\frac{1}{w_1}\mathbf{H}(w_1 h) \quad \text{for } h \in L_2(I, w_1)$$

and

$$\|\mathbf{H}g\|_{L_2(I,w_1)} = \|g\|_{L_2(I,w_1)} \quad \text{for } g \in L_2^0(I, w_1). \tag{2.11}$$

(e) *The operators* $\mathbf{H}$ *and* $\frac{d}{dt}$ *commute: for any polynomial* P*, we have*

$$\mathbf{H}\left(\frac{d}{dt}(w_1 P)\right) = \frac{d}{dt}\left(\mathbf{H}(w_1 P)\right).$$

Proof. (a) We apply the substitution $s = \cos\theta$ to the integral that defines $\mathbf{H}g$ and replace t by $\cos\tau$, $0 < \tau < \pi$ and obtain

$$\begin{aligned}\mathbf{H}g(\cos\tau) &= \frac{1}{\pi}\text{p.v.}\int_0^\pi \frac{Tg(\theta)}{\cos\tau - \cos\theta}\,d\theta \\ &= \frac{1}{2\pi}\text{p.v.}\int_{-\pi}^\pi \frac{Tg(\theta)}{\cos\tau - \cos\theta}\,d\theta,\end{aligned}$$

since the integrand is even. Note that $\text{p.v.}\int_I \ldots ds = \text{p.v.}\int_0^\pi \ldots d\theta$ above since the substituting function and its inverse are smooth enough. Now, we use the identity

$$\frac{1}{\cos\tau - \cos\theta} = -\frac{1}{2\sin\tau}\left(\cot\frac{\tau-\theta}{2} + \cot\frac{\tau+\theta}{2}\right)$$

to obtain

$$\mathbf{H}g(\cos\tau) = -\frac{1}{2\sin\tau}\left[\frac{1}{2\pi}\text{p.v.}\int_{-\pi}^\pi Tg(\theta)\cot\frac{\tau-\theta}{2}\,d\theta + \frac{1}{2\pi}\text{p.v.}\int_{-\pi}^\pi Tg(\theta)\cot\frac{\tau+\theta}{2}\,d\theta\right].$$

After substituting $\theta = -\theta'$ in the second integral above and using that Tg is even, we see that the two integrals are equal and, therefore, we obtain (a).

(b) For any function $g \in L_1(I, w_1^{-1})$, we have $T[w_1^{-1}g](\theta) = g(\cos\theta)$. Since the conjugate function of $\cos n\theta$ is $\sin n\theta$, $n = 0, 1, \ldots$, the first two statements in (b) follow from (a). Similar calculations give the last two statements.

(c) This is trivial.

(d) This follows from (b) by using the two bases for $L_2(I, w_1)$ given in (c).

(e) This follows from (2.10). □

We shall next show that the Gegenbauer polynomials are eigenfunctions of certain differential operators that arise in inverting the Radon transform. For functions g defined on $\mathbf{B}^d$, we introduce the following differential operators:

$$\Lambda g := \left(\frac{d}{dt}\right)^{d-1}\left[w_{d/2}g\right], \tag{2.12}$$

and

$$\mathcal{D} := \Lambda,\ d \text{ odd}, \quad \mathcal{D} := \mathbf{H}\Lambda,\ d \text{ even}. \tag{2.13}$$

LEMMA 2.1. *Let* $d \geq 2$ *and define* $\mathcal{U}_n := C_n^{d/2}$ *for* $n = 0, 1, \ldots$*. Then we have*

$$\mathcal{D}\mathcal{U}_n = (-1)^{[\frac{d-1}{2}]}\mu_n\mathcal{U}_n, \quad n = 0, 1, \ldots, \tag{2.14}$$

and

$$\Lambda^2\mathcal{U}_n = (-1)^{d-1}\mu_n^2\mathcal{U}_n, \quad n = 0, 1, \ldots, \tag{2.15}$$

where

$$\mu_n = (n+1)_{d-1} \asymp n^{d-1}, \quad n = 0, 1, \ldots. \tag{2.16}$$

Proof. We first consider (2.14) in the case when d is odd, $d = 2k+1$. From (2.3) and (2.4), we find

$$\begin{aligned}\mathcal{D}\mathcal{U}_n = \mathcal{D}C_n^{k+1/2} &= \left(\frac{d}{dt}\right)^{2k}\left[w_1^{2k}C_n^{k+1/2}\right] = c\left(\frac{d}{dt}\right)^{n+2k} w_1^{2n+2k}\\ &= c_1\left(\frac{d}{dt}\right)^{k} C_{n+k}^{1/2} = c_2 C_n^{k+1/2} = c_2\mathcal{U}_n.\end{aligned}$$

By examining the coefficients of t^n we obtain that $c_2 = (-1)^k\mu_n$. Thus (2.14) is proved in this case.

Assume now that d is even, $d =: 2k$. Then, again using (2.3), (2.4), and (2.10) (recall that $C_n^1 = U_n$) and the commutativity of $\frac{d}{dt}$ and $\mathbf{H}$, we obtain

$$\begin{aligned}\mathcal{D}\mathcal{U}_n = \mathcal{D}C_n^k &= \left(\frac{d}{dt}\right)^{2k-1}\mathbf{H}\left[w_1^{2k-1}C_n^k\right] = c\left(\frac{d}{dt}\right)^{2k-1}\mathbf{H}\left(\frac{d}{dt}\right)^{n} w_1^{2n+2k-1}\\ &= c\left(\frac{d}{dt}\right)^{k-1}\mathbf{H}\left(\frac{d}{dt}\right)^{n+k} w_1^{2n+2k-1} = c_1\left(\frac{d}{dt}\right)^{k-1}\mathbf{H}\frac{d}{dt}\left[w_1 C_{n+k-1}^1\right]\\ &= c_2\left(\frac{d}{dt}\right)^{k-1} C_{n+k-1}^1 = c_3 C_n^k = c_3 C_n^{d/2} = c_3\mathcal{U}_n.\end{aligned}$$

We can calculate c_3 as follows. Let $C_n^k(t) =: c_n t^n + \cdots$ and $U_r(t) =: a_r t^r + \cdots$ with $r := n+2k-2$. We find

$$\begin{aligned}&\left(\frac{d}{dt}\right)^{2k-1}\mathbf{H}\left[w_1^{2k-1}C_n^k(t)\right] = c_n\left(\frac{d}{dt}\right)^{2k-1}\mathbf{H}\left[w_1(t)\left((-1)^{k-1}t^{n+2k-2}+\cdots\right)\right]\\ &= (-1)^{k-1}\frac{c_n}{a_r}\left(\frac{d}{dt}\right)^{2k-2}\left[\mathbf{H}\frac{d}{dt}\left[w_1(t)U_{n+k-2}(t)+\cdots\right]\right]\\ &= (-1)^{k-1}\frac{c_n}{a_r}(n+2k-1)\left(\frac{d}{dt}\right)^{2k-2}\left[U_{n+2k-2}(t)+\cdots\right]\\ &= (-1)^{k-1}c_n(n+2k-1)\left(\frac{d}{dt}\right)^{2k-2}\left(t^{n+2k-2}+\cdots\right)\\ &= (-1)^{k-1}(n+1)_{2k-1}c_n\left(t^n+\cdots\right) = (-1)^{k-1}(n+1)_{2k-1}C_n^k(t),\end{aligned}$$

where we used identities (2.3), (2.4), and (2.10). Thus (2.14) is proved in this case as well.

Finally, we consider (2.15). From (2.3) and (2.5), respectively, we have

$$\begin{aligned}\Lambda\mathcal{U}_n = \Lambda C_n^{d/2} &= c\left(\frac{d}{dt}\right)^{n+d-1}\left[(1-t^2)^{n+d/2-1/2}\right]\\ &= c\left(\frac{d}{dt}\right)^{n+d-1}\left[(1-t^2)^{n+d-1}(1-t^2)^{-d/2+1/2}\right]\\ &= c_1(1-t^2)^{-d/2+1/2}C_{n+d-1}^{-d/2+1}.\end{aligned}$$

Hence, applying Λ once again and using (2.6) gives

$$\Lambda^2\mathcal{U}_n = \Lambda^2 C_n^{d/2} = c_1\left(\frac{d}{dt}\right)^{d-1} C_{n+d-1}^{-d/2+1} = c_2 C_n^{d/2} = c_2\mathcal{U}_n.$$

By calculating the coefficients of t^n, we find that $c_2 = (-1)^{d-1}\mu_n^2$ and we arrive at (2.15). ∎

3. An orthogonal decomposition of $L_2(\mathbf{B}^d)$ in terms of ridge polynomials. Since we are interested in approximating functions $f \in L_2(\mathbf{B}^d)$ by elements from spaces of ridge functions, it is natural to find a decomposition of f in terms of fundamental building blocks of ridge functions. We shall show in this section that we can take as the building blocks certain ridge polynomials. We begin by describing this decomposition.

If $f, g \in L_2(\mathbf{B}^d)$, we define the inner product

$$\langle f, g\rangle := \int_{\mathbf{B}^d} f(\mathbf{x})\overline{g(\mathbf{x})}\,d\mathbf{x}. \tag{3.1}$$

This inner product induces the norm

$$\|f\|_{L_2(\mathbf{B}^d)} := \left(\int_{\mathbf{B}^d} |f(\mathbf{x})|^2\,d\mathbf{x}\right)^{1/2}.$$

We also define, for $f, g \in L_2(\mathbf{S}^{d-1})$, the inner product

$$(f, g) := \int_{\mathbf{S}^{d-1}} f(\xi)\overline{g(\xi)}\,d\xi \tag{3.2}$$

and the norm

$$\|f\|_{L_2(\mathbf{S}^{d-1})} := \left(\int_{\mathbf{S}^{d-1}} |f(\xi)|^2\,d\xi\right)^{1/2},$$

where $d\xi$ stands for the area (volume) element on $\mathbf{S}^{d-1}$ the unit sphere in $\mathbf{R}^d$.

The Gegenbauer polynomials $C_n^{d/2}$ are the building blocks for our decomposition. Let

$$\mathcal{U}_n := \left(h_{n,d/2}\right)^{-1/2} C_n^{d/2}, \quad n = 0, 1, \dots, \tag{3.3}$$

where $h_{n,d/2}$ is from (2.1). Then $\|\mathcal{U}_n\|_{L_2(I,w)} = 1$ and hence $\{\mathcal{U}_n\}_{n=0}^\infty$ is a complete orthonormal system for the weighted space $L_2(I, w)$, $w(t) := w_{d/2}(t) = (1-t^2)^{\frac{d-1}{2}}$. Of course, $\mathcal{U}_n$ depends on the space dimension d, but we are suppressing this dependence in our notation. The reader should think of the space dimension d as arbitrary but fixed throughout.

Let $\mathcal{P}_n$ denote the set of all algebraic polynomials of total degree n in d real variables. That is, each $P \in \mathcal{P}_n$ is a linear combination of monomials $\mathbf{x}^{\mathbf{m}} := x_1^{m_1} \dots x_d^{m_d}$ with $\mathbf{x} := (x_1, \dots, x_d)$, $\mathbf{m}$ is a d-tuple $(m_1, \dots, m_d)$ of nonnegative integers, and $|\mathbf{m}| := m_1 + \cdots + m_d \le n$.

The polynomials $\mathcal{U}_n(\xi \cdot \mathbf{x})$, $\xi \in \mathbf{S}^{d-1}$, are in $\mathcal{P}_n$ and $\mathcal{U}_n(\xi \cdot \mathbf{x})$ are orthogonal to $\mathcal{P}_{n-1}$ in $L_2(\mathbf{B}^d)$ (proved in the appendix):

$$\int_{\mathbf{B}^d} \mathcal{U}_n(\xi \cdot \mathbf{x})P(\mathbf{x})\,d\mathbf{x} = 0 \quad \text{for } \xi \in \mathbf{S}^{d-1} \text{ and } P \in \mathcal{P}_{n-1}. \tag{3.4}$$

This is why the ridge polynomials $\mathcal{U}_n(\xi \cdot \mathbf{x})$ occur in our decomposition of $L_2(\mathbf{B}^d)$.

THEOREM 3.1. *Each function $f \in L_2(\mathbf{B}^d)$ can be represented uniquely as*

$$f \overset{L_2}{=} \sum_{n=0}^\infty Q_n(f), \tag{3.5}$$

where

$$Q_n(f,\mathbf{x}) := \nu_n \int_{\mathbf{S}^{d-1}} A_n(f,\xi)\mathcal{U}_n(\xi\cdot\mathbf{x})\,d\xi \tag{3.6}$$

with

$$A_n(f,\xi) := \int_{\mathbf{B}^d} f(\mathbf{y})\mathcal{U}_n(\xi\cdot\mathbf{y})\,d\mathbf{y}, \tag{3.7}$$

and

$$\nu_n := \frac{(n+1)_{d-1}}{2(2\pi)^{d-1}} = \frac{(n+1)(n+2)\cdots(n+d-1)}{2(2\pi)^{d-1}}. \tag{3.8}$$

Moreover, the operators Q_n, $n = 0,1,\ldots$, are the orthogonal projectors from $L_2(\mathbf{B}^d)$ onto $\mathcal{P}_n \ominus \mathcal{P}_{n-1}$ and the following Parseval identity holds

$$\|f\|^2_{L_2(\mathbf{B}^d)} = \sum_{n=0}^{\infty} \|Q_n(f)\|^2_{L_2(\mathbf{B}^d)} = \sum_{n=0}^{\infty} \nu_n \|A_n\|^2_{L_2(\mathbf{S}^{d-1})}. \tag{3.9}$$

Next we make a few remarks which will help explain the nature of this decomposition.

(i) For each $n = 0,1,\ldots$, the function $Q_n(f)$ is an algebraic polynomial (in d variables) of degree n. Indeed, each of the $\mathcal{U}_n(\xi\cdot\mathbf{x})$ is a ridge polynomial of degree n and $Q_n(f)$ is a linear combination of these.

(ii) For each $n = 0,1,\ldots$, the function $A_n(f,\xi)$, $\xi \in \mathbf{S}^{d-1}$, is a spherical polynomial of degree n. This follows from the fact that each of the $\mathcal{U}_n(\xi\cdot\mathbf{x})$, $x \in \mathbf{B}^d$, is of this type.

(iii) The constants ν_n, $n = 0,1,\ldots$, are eigenvalues which occur in the Radon inversion formula (see (3.26)).

(iv) Among other reasons, the polynomials $\mathcal{U}_n$ occur in this formula because for each $\xi \in \mathbf{S}^{d-1}$ the weight $w_{d/2}(t) = (1-t^2)^{(d-1)/2}$ is a constant multiple of the $d-1$-dimensional volume of the intersection of $\mathbf{B}^d$ with the hyperplane $\mathbf{x}\cdot\xi = t$.

(v) The orthogonality of the functions $Q_n(f)$ occurs because for each $\xi \in \mathbf{S}^{d-1}$, the polynomial $\mathcal{U}_n(\mathbf{x}\cdot\xi)$ is orthogonal to all algebraic polynomials of degree $< n$ on $\mathbf{B}^d$ (see (3.4)).

(vi) One can imagine that the integral representation of $Q_n(f)$ can be rewritten as a discrete sum by using some sort of quadrature formula on $\mathbf{S}^{d-1}$ and thereby obtain a discrete decomposition of f in terms of ridge polynomials. In the case $d = 2$, one can simply take the canonical quadrature formula for integrating spherical polynomials (i.e., trigonometric polynomials) which uses equally spaced points on the unit circle. This then gives the orthonormal system $\{\mathcal{U}_n(\omega\cdot\mathbf{x})\}$, $\omega \in \Omega_n$, $n = 0,1,\ldots$, where $\Omega_n := \{(\cos k\pi/n, \sin k\pi/n)\}_{k=1}^n$. This was used in [DOP] as the vehicle for proving approximation results for ridge functions in two variables. In the case $d \geq 3$, we know no analogous quadrature formula. This necessitates a substantial effort (executed in the following section) to derive (less elegant) quadrature formulas which can be used to discretize the integral representation of $Q_n(f)$.

(vii) The decomposition of Theorem 3.1 is in essence known (see, e.g., [RK] and [LS] for the case $d = 2$). However, we could find no reference which gives it in the above form.

There are several ways in which the decomposition of Theorem 3.1 can be derived. One approach is to derive it from the theory of spherical harmonics. A second approach is Radon transforms and in particular (3.5) is a rewriting of the Radon inversion formula (see [RK]). We shall briefly explain this at the end of this section.

We shall give a simple and direct proof of this decomposition using fundamental identities for the ridge polynomials $\mathcal{U}_n(\xi \cdot \mathbf{x})$, $\xi \in \mathbf{S}^{d-1}$. To keep our exposition more fluid, we shall state these identities without proof and relegate the proofs to the appendix.

We start with the following two fundamental identities (proved in the appendix): for each $\xi, \eta \in \mathbf{S}^{d-1}$, we have

$$\int_{\mathbf{B}^d} \mathcal{U}_n(\xi \cdot \mathbf{x})\mathcal{U}_n(\eta \cdot \mathbf{x})\, d\mathbf{x} = \frac{\mathcal{U}_n(\xi \cdot \eta)}{\mathcal{U}_n(1)}, \tag{3.10}$$

and, for each $\eta \in \mathbf{S}^{d-1}$, we have

$$\int_{\mathbf{S}^{d-1}} \mathcal{U}_n(\xi \cdot \mathbf{x})\mathcal{U}_n(\xi \cdot \eta)\, d\xi = \frac{\mathcal{U}_n(1)}{\nu_n}\mathcal{U}_n(\eta \cdot \mathbf{x}). \tag{3.11}$$

Proof of Theorem 3.1. Let $f \in L_2(\mathbf{B}^d)$, $d > 2$. From remark (i) and (3.4), it follows that $Q_n(f)$ is in $\mathcal{P}_n \ominus \mathcal{P}_{n-1}$. From identities (3.10) and (3.11), we have $Q_n(g) = g$ whenever $g(\mathbf{x}) = \mathcal{U}_n(\eta \cdot \mathbf{x})$, $\eta \in \mathbf{S}^{d-1}$. Therefore, $Q_n^2 = Q_n$ and hence Q_n is a projector onto a subspace Y_n of $\mathcal{P}_n \ominus \mathcal{P}_{n-1}$. Thus, to prove (3.5), it remains only to show that

$$\dim(Y_n) = \dim(\mathcal{P}_n \ominus \mathcal{P}_{n-1}) = \dim(\mathcal{P}_n^h), \tag{3.12}$$

where $\mathcal{P}_n^h$ denotes the space of all homogeneous polynomials of degree n.

To prove (3.12), we recall a few well-known facts about spherical harmonics which can be found in Stein and Weiss [SW, Chapter 4]; see also [Se]. Let $\mathcal{H}_n$ denote the space of spherical harmonics of degree n; i.e., $\mathcal{H}_n$ is the set of those functions on $\mathbf{S}^{d-1}$ which are the restriction to $\mathbf{S}^{d-1}$ of a function from $\mathcal{P}_n^h$ which is harmonic in $\mathbf{B}^d$. The spherical harmonics of degree n are orthogonal to those of dimension $m \neq n$ with respect to the inner product (3.2). We have

$$\dim(\mathcal{H}_n) = N(d,n) := \left(\begin{array}{c} n+d-1 \\ n \end{array} \right) - \left(\begin{array}{c} n+d-3 \\ n-2 \end{array} \right) \tag{3.13}$$

and

$$\dim(\mathcal{P}_n^h) = \dim(\mathcal{H}_n \oplus \mathcal{H}_{n-2} \oplus \cdots \oplus \mathcal{H}_\epsilon), \tag{3.14}$$

where $\epsilon = 0$ if n is even and $\epsilon = 1$ if n is odd.

Write

$$K_n(t) := \frac{N(d,n)}{|\mathbf{S}^{d-1}| C_n^{(d-2)/2}(1)} C_n^{(d-2)/2}(t),$$

where $|\mathbf{S}^{d-1}| := \int_{\mathbf{S}^{d-1}} 1\, d\xi = \frac{2\pi^{d/2}}{\Gamma(d/2)}$ is the surface area of $\mathbf{S}^{d-1}$. The function $K_n(\xi \cdot \eta)$ is the reproducing kernel for $\mathcal{H}_n$; i.e.,

$$\int_{\mathbf{S}^{d-1}} S(\xi) K_n(\xi \cdot \eta) d\xi = S(\eta), \quad S \in \mathcal{H}_n. \tag{3.15}$$

Moreover, a simple identity for Gegenbauer polynomials (see Appendix A3) gives that

$$K_n + K_{n-2} + \cdots + K_\epsilon = \frac{C_n^{d/2}}{|\mathbf{S}^{d-1}|} = \frac{\nu_n \mathcal{U}_n}{\mathcal{U}_n(1)}. \tag{3.16}$$

Hence, the right side of (3.16) is the reproducing kernel for $\mathcal{H}_n \oplus \mathcal{H}_{n-2} \oplus \cdots \oplus \mathcal{H}_\epsilon$; i.e.,

$$\int_{\mathbf{S}^{d-1}} S(\xi) \frac{\nu_n}{\mathcal{U}_n(1)} \mathcal{U}_n(\xi \cdot \eta) d\xi = S(\eta), \quad S \in \mathcal{H}_n \oplus \mathcal{H}_{n-2} \oplus \cdots \oplus \mathcal{H}_\epsilon. \tag{3.17}$$

Note that $A_n(f, \xi)$ is a spherical polynomial of degree n since $\mathcal{U}_n(\xi \cdot \mathbf{y})$ is a spherical polynomial of degree n in ξ. We have $\mathcal{U}_n(-t) = (-1)^n \mathcal{U}_n(t)$ (see (2.2)) and hence $A_n(f, -\xi) = (-1)^n A_n(f, \xi)$. Therefore, $A_n(f) \in \mathcal{H}_n \oplus \mathcal{H}_{n-2} \oplus \cdots \oplus \mathcal{H}_\epsilon$. Thus, Q_n can be considered as a linear operator mapping $\mathcal{H}_n \oplus \mathcal{H}_{n-2} \oplus \cdots \oplus \mathcal{H}_\epsilon$ into Y_n. On the other hand, after multiplying both sides of (3.6) by $\mathcal{U}_n(\eta \cdot \mathbf{x})$ and integrating over $\mathbf{B}^d$ we obtain

$$\begin{aligned} \int_{\mathbf{B}^d} Q_n(f, \mathbf{x}) \mathcal{U}_n(\eta \cdot \mathbf{x}) \, d\mathbf{x} &= \int_{\mathbf{S}^{d-1}} A_n(f, \xi) \left(\nu_n \int_{\mathbf{B}^d} \mathcal{U}_n(\eta \cdot \mathbf{x}) \mathcal{U}_n(\xi \cdot \mathbf{x}) \, d\mathbf{x} \right) d\xi \\ &= \int_{\mathbf{S}^{d-1}} A_n(f, \xi) \frac{\nu_n}{\mathcal{U}_n(1)} \mathcal{U}_n(\eta \cdot \xi) \, d\xi = A_n(f, \xi), \end{aligned}$$

where we used (3.10) and (3.17). Hence, A_n is an operator mapping Y_n onto $\mathcal{H}_n \oplus \mathcal{H}_{n-2} \oplus \cdots \oplus \mathcal{H}_\epsilon$ and it is the inverse operator of Q_n. Therefore, $\dim(Y_n) = \dim(\mathcal{H}_n \oplus \mathcal{H}_{n-2} \oplus \cdots \oplus \mathcal{H}_\epsilon)$ which together with (3.14) implies (3.12).

Since $Q_n(f)$ is in $\mathcal{P}_n \ominus \mathcal{P}_{n-1}$, it is orthogonal to $Q_j(f)$, $j \neq n$, and therefore we have the first equality in (3.9). For the proof of the second equality in (3.9), we use (3.10) to write

$$\begin{aligned} \int_{\mathbf{B}^d} Q_n(f, \mathbf{x})^2 \, d\mathbf{x} &= \nu_n^2 \int_{\mathbf{S}^{d-1}} \int_{\mathbf{S}^{d-1}} \int_{\mathbf{B}^d} A_n(f, \xi) A_n(f, \eta) \mathcal{U}_n(\xi \cdot \mathbf{x}) U_n(\eta \cdot \mathbf{x}) \, d\mathbf{x} \, d\xi \, d\eta \\ &= \nu_n^2 \int_{\mathbf{S}^{d-1}} \int_{\mathbf{S}^{d-1}} A_n(f, \xi) A_n(f, \eta) \frac{\mathcal{U}_n(\xi \cdot \eta)}{\mathcal{U}_n(1)} d\xi \, d\eta. \end{aligned}$$

Since $A_n(f) \in \mathcal{H}_n \oplus \mathcal{H}_{n-2} \oplus \cdots \oplus \mathcal{H}_\epsilon$, then we can use (3.17) to complete the integral with respect to η above. We get

$$\int_{\mathbf{B}^d} Q_n(f, \mathbf{x})^2 \, d\mathbf{x} = \nu_n \int_{\mathbf{S}^{d-1}} A_n(f, \xi)^2 \, d\xi.$$

This completes the proof of (3.9) and the theorem. □

In the same way that we have proved (3.9) of Theorem 3.1 we obtain the following formulas for calculating inner products:

$$\langle f, g \rangle = \sum_{n=0}^{\infty} \nu_n \int_{\mathbf{S}^{d-1}} A_n(f, \xi) A_n(g, \xi) \, d\xi. \tag{3.18}$$

We next consider the decomposition (3.5) for ridge functions. Let r be a univariate function in $L_2(I, w)$, $w := w_{d/2}$. Then

$$r(t) = \sum_{n=0}^{\infty} \hat{r}(n) \mathcal{U}_n(t), \quad \hat{r}(n) := \int_I r(t) \mathcal{U}_n(t) w(t) \, dt. \tag{3.19}$$

It follows that for any $\rho \in \mathbf{S}^{d-1}$, the ridge function $R(\mathbf{x}) := r(\rho \cdot \mathbf{x})$ has the representation

$$R(\mathbf{x}) = \sum_{n=0}^{\infty} \hat{r}(n) \mathcal{U}_n(\rho \cdot \mathbf{x}). \tag{3.20}$$

Using (3.10) and (3.4), we see that

$$A_n(R, \xi) = \hat{r}(n) \frac{\mathcal{U}_n(\rho \cdot \xi)}{\mathcal{U}_n(1)}. \tag{3.21}$$

Moreover, if R_1 and R_2 are two such ridge functions corresponding to r_1, ρ_1 and r_2, ρ_2, respectively, then from (3.4), (3.11), and (3.18) we have

$$\langle R_1, R_2 \rangle = \sum_{n=0}^{\infty} \hat{r}_1(n) \hat{r}_2(n) \frac{\mathcal{U}_n(\rho_1 \cdot \rho_2)}{\mathcal{U}_n(1)}. \tag{3.22}$$

There is another approach to deducing the decomposition of Theorem 3.1 which we want to mention since it brings out the connections between this paper and Radon transforms. For each $f \in L_1(\mathbf{B}^d)$ the Radon transform is defined by

$$\mathcal{R}(f; \xi, t) := \int_{\xi^\perp \bigcap \mathbf{B}^d} f(t\xi + \mathbf{y})\, d\mathbf{y}, \tag{3.23}$$

where $\xi \in \mathbf{S}^{d-1}$, $t \in [-1, 1]$, and $\xi^\perp := \{\mathbf{y} \in \mathbf{R}^d : \mathbf{y} \cdot \xi = 0\}$. So, the integration is over the intersection of the hyperplane $\mathbf{y} \cdot \xi = t$ and $\mathbf{B}^d$.

We can recover f from its Radon transform by using the Radon transform inversion formula. The Radon transform inversion formula uses the operator (see, e.g., [L])

$$Kg(t) := K_t g(t) := \begin{cases} \frac{(-1)^{\frac{d-1}{2}}}{2(2\pi)^{d-1}} \left(\frac{d}{dt}\right)^{d-1} g(t) & \text{for } d \text{ odd}, \\ \\ \frac{(-1)^{\frac{d}{2}-1}}{2(2\pi)^{d-1}} \mathbf{H} \left(\frac{d}{dt}\right)^{d-1} g(t) & \text{for } d \text{ even}, \end{cases} \tag{3.24}$$

where $\mathbf{H}$ is the Hilbert transform (see (2.7)). The following relation is the Radon inversion formula for functions defined on $\mathbf{B}^d$: for every sufficiently smooth function f supported on $\mathbf{B}^d$

$$f(\mathbf{x}) = \int_{\mathbf{S}^{d-1}} h(\xi, \mathbf{x} \cdot \xi)\, d\xi \quad \text{with} \quad h(\xi, t) := K_t \mathcal{R}(f; \xi, t). \tag{3.25}$$

Lemma 2.1 gives that the functions $\mathcal{U}_n$ are eigenfunctions for the operator $K(w\bullet)$:

$$K(w\mathcal{U}_n) = \nu_n \mathcal{U}_n. \tag{3.26}$$

We now show the idea of using the Radon inversion formula to derive a representation of f in terms of the ridge polynomials $\{\mathcal{U}_n(\mathbf{x} \cdot \xi)\}$. Since $\{\mathcal{U}_n\}_{n=0}^{\infty}$ is a complete orthonormal system for $L_2(I, w)$, we can expand $\mathcal{R}(f; \xi, \bullet)/w$ in terms of the $\{\mathcal{U}_n\}_{n=0}^{\infty}$ to obtain

$$\frac{\mathcal{R}(f; \xi, \bullet)}{w} = \sum_{n=0}^{\infty} A_n(\xi)\, \mathcal{U}_n, \tag{3.27}$$

with

$$A_n(\xi) := \int_I \mathcal{R}(f;\xi,t)\,\mathcal{U}_n(t)\,dt = \int_{\mathbf{B}^d} f(\mathbf{y})\,\mathcal{U}_n(\mathbf{y}\cdot\xi)\,d\mathbf{y}. \tag{3.28}$$

After multiplying both sides of (3.27) by the weight w and applying the operator $K := K_t$ we get

$$K\mathcal{R}(f;\xi,\bullet) = \sum_{n=0}^{\infty} A_n(\xi) K\,[w\,\mathcal{U}_n] = \sum_{n=0}^{\infty} \nu_n A_n(\xi)\,\mathcal{U}_n,$$

where we used (3.26). Finally, we insert the above in (3.25) and find

$$f(\mathbf{x}) = \int_{\mathbf{S}^{d-1}} K\mathcal{R}(f;\xi,\mathbf{x}\cdot\xi)\,d\xi = \sum_{n=0}^{\infty} \nu_n \int_{\mathbf{S}^{d-1}} A_n(\xi)\mathcal{U}_n(\mathbf{x}\cdot\xi)\,d\xi$$

which is the decomposition from Theorem 3.1. We leave the details of verifying this approach to the reader.

4. Discrete representation of functions and norms. In this section we shall deduce from Theorem 3.1 a discrete representation of functions by ridge polynomials. To this end we shall use a cubature formula for integration on $\mathbf{S}^{d-1}$, $d > 2$. We need a cubature formula that is exact for all spherical polynomials of degree n. In the case $d = 2$ we used in [DOP] a quadrature formula with equally spaced nodes on the unit circle. Unfortunately, we do not know any "equally spaced points" on $\mathbf{S}^{d-1}$, $d > 2$. Also, we do not know effectively any cubature formula with near equally spaced nodes on $\mathbf{S}^{d-1}$. For this reason we shall use a cubature formula, determined by using spherical coordinates on $\mathbf{S}^{d-1}$. The results of this section are somewhat technical and the reader may just wish to read them briefly at first and proceed to section 5.

The spherical coordinates $(\theta,\phi) := (\theta_1,\theta_2,\dots,\theta_{d-2},\phi)$ on $\mathbf{S}^{d-1}$ are defined as usual by

$$\xi_1 = \cos\theta_1,\ \ \xi_2 = \sin\theta_1\cos\theta_2,\ \ \dots,\ \ \xi_{d-2} = \sin\theta_1\sin\theta_2\dots\sin\theta_{d-3}\cos\theta_{d-2},$$
$$\xi_{d-1} = \sin\theta_1\sin\theta_2\dots\sin\theta_{d-3}\sin\theta_{d-2}\cos\phi,\ \ \xi_d = \sin\theta_1\sin\theta_2\dots\sin\theta_{d-3}\sin\theta_{d-2}\sin\phi,$$

$0 \le \theta_j \le \pi$, $j = 1,2,\dots,d-2$; $0 \le \phi < 2\pi$. We shall denote these identities in vector form briefly by $\xi := \xi(\theta,\phi)$. In these coordinates, the surface element $d\xi$ of $\mathbf{S}^{d-1}$ becomes

$$d\xi = (\sin\theta_1)^{d-2}(\sin\theta_2)^{d-3}\dots\sin\theta_{d-2}\,d\theta_1\,d\theta_2\dots\,d\theta_{d-2}\,d\phi =: J(\theta)\,d\theta\,d\phi. \tag{4.1}$$

We have the following identity for integration in spherical coordinates

$$\int_{\mathbf{S}^{d-1}} f(\xi)\,d\xi = \int_0^{\pi}\dots\int_0^{\pi}\int_0^{2\pi} f(\xi(\theta,\phi))J(\theta)\,d\theta_1\dots\,d\theta_{d-2}\,d\phi, \tag{4.2}$$

where $J(\theta)$ is the Jacobian given by (4.1). We shall use this to define our cubature.

We wish to construct a cubature that is exact for all spherical polynomials of degree $2n$. Every spherical polynomial of degree $2n$ can obviously be represented in spherical coordinates as a linear combination of terms

$$(\cos\phi)^{k_{d-1}}(\sin\phi)^{\ell_{d-1}}\prod_{j=1}^{d-2}(\cos\theta_j)^{k_j}(\sin\theta_j)^{\ell_j}, \tag{4.3}$$

where $k_j, \ell_j \geq 0$, and $\max\{k_j+\ell_j : j = 1, 2, \ldots, d-1\} \leq 2(d-1)n$. Also, the Jacobian J is represented in the same terms (see (4.1)). So, we need quadrature formulas for integration over $[0, 2\pi]$ and $[0, \pi]$ that are exact for trigonometric polynomial of degree $2(d-1)n + d - 2$.

We shall use the following quadrature formula for integration on $[0, 2\pi]$ with respect to ϕ

$$Q_{\phi,k}(g) := \sum_{j=0}^{2k} \varrho_j g(\gamma_j) \quad \sim \quad \int_0^{2\pi} g(\phi)\, d\phi, \tag{4.4}$$

where $\gamma_j := \frac{\pi}{2k+1} + \frac{2\pi j}{2k+1}$ and $\varrho_j := \frac{2\pi}{2k+1}$. The quadrature (4.4) is exact for all trigonometric polynomials of degree k (see [Z, Chapter X]).

Since $0 \leq \theta_j \leq \pi$, we need a quadrature for integration over $[0, \pi]$ that is exact for all trigonometric polynomials of degree k. In addition to this, the quadrature should have good localization properties. We also need to control (asymptotically) the nodes and the coefficients of the quadrature. Since we do not know any quadrature like this, we shall construct one in the following lemma.

LEMMA 4.1. *For any $k = 1, 2, \ldots$, there exists a quadrature*

$$Q_{\theta,k}(g) = \sum_{j=0}^{2k} \lambda_j g(\beta_j) \quad \sim \quad \int_0^{\pi} g(\theta)\, d\theta \tag{4.5}$$

with the following properties:

(a) *$Q_{\theta,k}(g)$ is exact for all trigonometric polynomials of degree k;*

(b) $0 < \beta_0 < \beta_1 < \cdots < \beta_{2k} < \pi$,

$$\beta_j - \beta_{j-1} \leq \pi k^{-1}, \quad j = 0, 1, \ldots, 2k+1; \tag{4.6}$$

(c)

$$0 < \lambda_j \leq c\left(\beta_{j+1} - \beta_{j-1}\right), \quad j = 0, 1, \ldots, 2k, \tag{4.7}$$

where $\beta_{-1} := 0$, $\beta_{2k+1} := \pi$, and c is an absolute constant.

The exact values of the nodes β_j and the coefficients λ_j of the quadrature (4.5) *are given in Remark* 4.1 *below.*

Proof. For symmetry reasons we shall prove the lemma with the interval of integration $[0, \pi]$ replaced by $[-\pi/2, \pi/2]$. We shall build a quadrature

$$Q_k(g) = \sum_{j=-k}^{k} \lambda_j g(\theta_j) \quad \sim \quad \int_{-\pi/2}^{\pi/2} g(\theta)\, d\theta \tag{4.8}$$

with symmetric nodes θ_j and coefficients λ_j ($\theta_{-j} = \theta_j$, $\theta_0 := 0$, and $\lambda_{-j} = \lambda_j$). Then $Q_k(g)$ will be automatically exact for odd polynomials. Therefore, it is enough to construct $Q_k(g)$ exact only for all even trigonometric polynomials of degree k. To this end it is sufficient to have

$$Q_k(P(\cos\theta)) := \sum_{j=-k}^{k} \lambda_j P(\cos\theta_j) = \int_{-\pi/2}^{\pi/2} P(\cos\theta)\, d\theta = 2\int_0^{\pi/2} P(\cos\theta)\, d\theta \tag{4.9}$$

for each algebraic polynomial P of degree k. We shall apply the substitution $\theta := \theta(\alpha) := \arccos\left(\cos^2\frac{\alpha}{2}\right)$ to the last integral in (4.9). Simple calculations show that

$$\Delta(\alpha) := \frac{d}{d\alpha}\theta(\alpha) = \frac{\cos\frac{\alpha}{2}}{\sqrt{1+\cos^2\frac{\alpha}{2}}} \tag{4.10}$$

and hence $\theta(\alpha)$ is increasing on $[0,\pi]$ and maps $[0,\pi]$ on $[0,\pi/2]$. We obtain

$$\int_0^{\pi/2} P(\cos\theta)\,d\theta = \int_0^{\pi} P\left(\cos^2\frac{\alpha}{2}\right)\Delta(\alpha)\,d\alpha = \frac{1}{2}\int_{-\pi}^{\pi} P\left(\cos^2\frac{\alpha}{2}\right)\Delta(\alpha)\,d\alpha, \tag{4.11}$$

where we used that the integrand is even. We now extend $\Delta(\alpha)$ 2π-periodically by $\Delta(\alpha) := |\cos\frac{\alpha}{2}| \Big/ \sqrt{1+\cos^2\frac{\alpha}{2}}$.

We shall use the Dirichlet kernel $D_k(u) := \frac{\sin(k+1/2)u}{2\sin u/2}$ to interpolate the trigonometric polynomial of degree m: $P\left(\cos^2\frac{\alpha}{2}\right) = P\left(\frac{1+\cos\alpha}{2}\right)$ at the points $\alpha_j := \frac{2\pi j}{2k+1}$, $j = 0, \pm1, \dots, \pm k$. We have (see [Z, Chapter X])

$$P\left(\cos^2\frac{\alpha}{2}\right) = \frac{2}{2k+1}\sum_{j=-k}^{k} P\left(\cos^2\frac{\alpha_j}{2}\right) D_k(\alpha-\alpha_j).$$

This and (4.11) imply

$$\begin{aligned}\int_0^{\pi/2} P(\cos\alpha)\,d\alpha &= \frac{1}{2k+1}\sum_{j=-k}^{k} P\left(\cos^2\frac{\alpha_j}{2}\right)\int_{-\pi}^{\pi}\Delta(\alpha)D_k(\alpha-\alpha_j)\,d\alpha \\ &= \sum_{j=-k}^{k}\eta_j P\left(\cos^2\frac{\alpha_j}{2}\right) \qquad (4.12)\\ &= \eta_0 P\left(\cos^2\frac{\alpha_0}{2}\right) + \sum_{j=1}^{k} 2\eta_j P\left(\cos^2\frac{\alpha_j}{2}\right),\end{aligned}$$

where

$$\eta_j := \frac{1}{2k+1}\int_{-\pi}^{\pi}\Delta(\alpha)D_k(\alpha-\alpha_j)\,d\alpha \tag{4.13}$$

and we used that $\eta_{-j} = \eta_j$ since Δ is even and $\alpha_{-j} = -\alpha_j$.

We now define the nodes and the coefficients of our quadrature. Set

$$\theta_j := \arccos\left(\cos^2\frac{\alpha_j}{2}\right) \text{ for } j = 0,1,\dots,k \text{ and } \theta_j := -\theta_{-j} \text{ for } j = -1,-2,\dots,-k.$$

Also, set

$$\lambda_j := 2\eta_j \quad \text{for} \quad j = 0,1,\dots,k \quad \text{and} \quad \lambda_j := \lambda_{-j} \quad \text{for} \quad j = -1,-2,\dots,-k.$$

We obtain by (4.9), (4.12) and the symmetry that quadrature (4.8) with the above defined nodes and coefficients is exact for all trigonometric polynomials of degree m. It remains to prove that the nodes and the coefficients of the quadrature satisfy the required properties.

We have $\theta_j - \theta_{j-1} = \theta'(\zeta_j)(\alpha_j - \alpha_{j-1}) = \Delta(\zeta_j)(\alpha_j - \alpha_{j-1})$ for some $\zeta_j \in (\alpha_{j-1}, \alpha_j)$ and hence, by (4.10),

$$\frac{1}{\sqrt{2}}\left(\cos\frac{\alpha_j}{2}\right)\frac{2\pi}{2k+1} \le \theta_j - \theta_{j-1} \le \left(\cos\frac{\alpha_j}{2}\right)\frac{2\pi}{2k+1} < \frac{\pi}{k}, \quad j = 1, 2, \dots, k. \tag{4.14}$$

Therefore, the proof will be completed if we show that

$$0 < \eta_j \le ck^{-1}\cos\frac{\alpha_j}{2}, \quad j = 1, 2, \dots, k. \tag{4.15}$$

By (4.13) it follows that

$$\eta_j = \pi(2k+1)^{-1}S_k(\Delta)(\alpha_j), \quad \text{where} \quad S_k(\Delta)(\alpha) := \tfrac{1}{\pi}\textstyle\int_{-\pi}^{\pi}\Delta(\beta)D_k(\beta-\alpha)\,d\beta$$

is the kth partial Fourier sum of Δ. In order to simplify our further calculations we shift Δ by π and obtain

$$\varphi(\alpha) := \Delta(\alpha+\pi) = \left|\sin\frac{\alpha}{2}\right| \Big/ \sqrt{1+\sin^2\frac{\alpha}{2}}\,.$$

The function φ is even and, therefore, its Fourier coefficients associated with $\sin\nu\alpha$ are all equal to zero. Let

$$a_0 := \frac{1}{2\pi}\int_0^{2\pi}\varphi(\alpha)\,d\alpha \quad \text{and} \quad a_\nu := \frac{1}{\pi}\int_0^{2\pi}\varphi(\alpha)\cos\nu\alpha\,d\alpha, \quad \nu = 1, 2, \dots$$

be the Fourier coefficients of φ associated with $\cos\nu\alpha$. Obviously, $a_0 > 0$. Let $\nu = 1, 2, \dots$. Then using integration by parts (twice) we get

$$\begin{aligned} a_\nu &= -\frac{1}{\pi\nu}\int_0^{2\pi}\varphi'(\alpha)\sin\nu\alpha\,d\alpha \\ &= \frac{1}{\pi\nu^2}\left[\varphi'(2\pi^-) - \varphi'(0^+)\right] - \frac{1}{\pi\nu^2}\int_0^{2\pi}\varphi''(\alpha)\cos\nu\alpha\,d\alpha \\ &= \frac{1}{\pi\nu^2}\int_0^{2\pi}\varphi''(\alpha)(1-\cos\nu\alpha)\,d\alpha. \end{aligned}$$

Therefore,

$$a_\nu = \frac{2}{\pi\nu^2}\int_0^{2\pi}\varphi''(\alpha)\sin^2\frac{\nu\alpha}{2}\,d\alpha. \tag{4.16}$$

Simple calculations show that

$$\varphi'(\alpha) = \frac{1}{2}\cos\frac{\alpha}{2}\Big/\left(1+\sin\frac{\alpha}{2}\right)^{3/2} \text{ and } \varphi''(\alpha) < 0 \text{ for } 0 < \alpha < 2\pi.$$

This and (4.16) imply that $a_\nu < 0$ and

$$|a_\nu| \le \frac{2}{\pi\nu^2}\int_0^{2\pi}|\varphi''(\alpha)|\,d\alpha = -\frac{2}{\pi\nu^2}\int_0^{2\pi}\varphi''(\alpha)\,d\alpha = -\frac{2}{\pi\nu^2}\left[\varphi'(2\pi^-) - \varphi'(0^+)\right] = \frac{2}{\pi\nu^2}.$$

Thus, we have

$$-\frac{2}{\pi\nu^2} \le a_\nu < 0, \quad \nu = 1, 2, \dots. \tag{4.17}$$

Therefore $\varphi(\alpha) = a_0 + \sum_{\nu=1}^{\infty} a_\nu \cos \nu\alpha$, where $a_0 > 0$ and $a_\nu < 0$, $\nu = 1, 2, \dots$, and hence

$$S_k(\varphi)(\alpha) = a_0 + \sum_{\nu=1}^{k} a_\nu \cos \nu\alpha \geq a_0 + \sum_{\nu=1}^{k} a_\nu = S_k(\varphi)(0)$$

$$= S_k(\varphi)(0) - \varphi(0) = -\sum_{\nu=k+1}^{\infty} a_\nu > 0.$$

Thus $S_k(\varphi)(\alpha) > 0$ for $\alpha \in [-\pi, \pi)$ and hence $S_k(\Delta)(\alpha) > 0$ for $\alpha \in [-\pi, \pi)$ which implies the lower bound in (4.15).

The inequalities (4.17) imply

$$\|\Delta - S_k(\Delta)\|_C = \|\varphi - S_k(\varphi)\|_C \leq ck^{-1}.$$

Using this, we obtain

$$\begin{aligned} |\eta_j| &\leq ck^{-1}|S_k(\Delta)(\alpha_j)| \leq ck^{-1}\left(|\Delta(\alpha_j)| + \|\Delta - S_k(\Delta)\|_C\right) \\ &\leq ck^{-1}\left(\cos\frac{\alpha_j}{2} + k^{-1}\right) \leq ck^{-1}\left(\cos\frac{\alpha_j}{2} + \cos\frac{\alpha_k}{2}\right) \leq ck^{-1}\cos\frac{\alpha_j}{2}, \end{aligned}$$

where we used that $\cos(\alpha_k/2) = \cos(\pi k/(2k+1)) > ck^{-1}$. Thus the upper estimate in (4.15) is proved. Lemma 4.1 is proved. □

REMARK 4.1. *The exact values of the nodes β_j and the coefficients λ_j of the quadrature* (4.5) *from Lemma* 4.1 *are the following:*

$$\beta_j = \frac{\pi}{2} - \arccos\left(\cos^2\frac{(k-j)\pi}{2k+1}\right), \quad j = 0, 1, \dots, k,$$

and $\beta_j = \pi - \beta_{2k-j}$, $\quad j = k+1, k+2, \dots, 2k$;

$$\lambda_j = \frac{2}{2k+1}\int_{-\pi}^{\pi} \cos\frac{\alpha}{2}\left(1 + \cos^2\frac{\alpha}{2}\right)^{-1/2} D_k\left(\alpha - \frac{2\pi(k-j)}{2k+1}\right) d\alpha, \quad j = 0, 1, \dots, k,$$

and $\lambda_j = \lambda_{2k-j}$, $\quad j = k+1, k+2, \dots, 2k$, *where D_k is the Dirichlet kernel of degree k.*

We are now in a position to construct our cubature formula for integration over $\mathbf{S}^{d-1}$ ($d > 2$). We shall use (4.2), (4.3), and the quadratures from (4.4) and (4.5).

Definition of cubature $\mathbf{Q}_n$. Given $n = 1, 2, \dots$ we select $k := 2(d-1)n + d - 2$. Let $\mathcal{J}_n$ be the set of all indices $\mathbf{j} := (j_1, \dots, j_{d-1})$ such that $0 \leq j_\nu \leq 2k$; i.e., $\mathcal{J}_n := \{0, 1, \dots, 2k\}^{d-1}$. Note that the cardinality of $\mathcal{J}_n$ is $\#\mathcal{J}_n = (2k+1)^{d-1} \asymp n^{d-1}$. Set $\beta_{\mathbf{j}} := (\beta_{j_1}, \dots, \beta_{j_{d-2}})$, $\gamma_{\mathbf{j}} := \gamma_{j_{d-1}}$, $\omega_{\mathbf{j}} := \xi(\beta_{\mathbf{j}}, \gamma_{\mathbf{j}})$, and $\lambda_{\mathbf{j}} := J(\beta_{\mathbf{j}})\varrho_{j_{d-1}}\prod_{\nu=1}^{d-2}\lambda_{j_\nu}$, where γ_j, ϱ_j, β_j, and λ_j are the nodes and the coefficients of quadratures (4.4) and (4.5), respectively, and J is from (4.1). We define

$$\mathbf{Q}_n(f) := \sum_{\mathbf{j}\in\mathcal{J}_n} \lambda_{\mathbf{j}} f(\omega_{\mathbf{j}}) \quad \sim \quad \int_{\mathbf{S}^{d-1}} f(\xi)\, d\xi. \tag{4.18}$$

When it is possible we shall write this cubature with the following simpler indices. Let Ω_n be the set of all nodes $\omega = \omega_{\mathbf{j}}$, and $\lambda_\omega := \lambda_{\omega_{\mathbf{j}}} := \lambda_{\mathbf{j}}$, $\mathbf{j} \in \mathcal{J}_n$. Then cubature (4.18) can be rewritten in the form

$$\mathbf{Q}_n(f) := \sum_{\omega\in\Omega_n} \lambda_\omega f(\omega) \quad \sim \quad \int_{\mathbf{S}^{d-1}} f(\xi)\, d\xi. \tag{4.19}$$

Observe that $\#\Omega_n \asymp n^{d-1}$.

As we mentioned in the beginning of this section, every spherical polynomial of degree $2n$ can be represented in spherical coordinates as a linear combination of terms like those in (4.3) and the Jacobian J is represented in a similar way (see (4.1)). On the other hand, quadratures (4.4) and (4.5) are exact for trigonometric polynomials of degree $k := 2(d-1)n + d - 2$. Therefore (see (4.2)), cubature (4.18) (or (4.19)) is exact for all spherical polynomials of degree $2n$; i.e., for every spherical polynomial S of degree $\le 2n$ we have

$$\mathbf{Q}_n(S) := \sum_{\omega\in\Omega_n} \lambda_\omega S(\omega) = \int_{\mathbf{S}^{d-1}} S(\xi)\,d\xi. \tag{4.20}$$

Note that $\lambda_\omega > 0$ and, since (4.20) holds for $S = 1$, then

$$\sum_{\omega\in\Omega_n} \lambda_\omega = \int_{\mathbf{S}^{d-1}} 1\,d\xi =: |\mathbf{S}^{d-1}|. \tag{4.21}$$

Identity (4.20) implies discrete representations of the projection $Q_m(f)$ of any $f \in L_2(\mathbf{B}^d)$ onto $\mathcal{P}_m \ominus \mathcal{P}_{m-1}$ and $\|A_m(f)\|_{L_2(\mathbf{S}^{d-1})}$ (see (3.6) and (3.7) from Theorem 3.1). Namely, since $A_m(f,\xi)\mathcal{U}_m(\mathbf{x}\cdot\xi)$ and $A_m^2(f,\xi)$, for $m \le n$, are spherical polynomials of degree $\le 2m \le 2n$, then

$$Q_m(f,\mathbf{x}) := \nu_m \int_{\mathbf{S}^{d-1}} A_m(f,\xi)\mathcal{U}_m(\mathbf{x}\cdot\xi)\,d\xi = \nu_m \sum_{\omega\in\Omega_n} \lambda_\omega A_m(f,\omega)\mathcal{U}_m(\mathbf{x}\cdot\omega) \tag{4.22}$$

and

$$\|A_m\|^2_{L_2(\mathbf{S}^{d-1})} := \int_{\mathbf{S}^{d-1}} |A_m(f,\xi)|^2\,d\xi = \sum_{\omega\in\Omega_n} \lambda_\omega |A_m(f,\omega)|^2. \tag{4.23}$$

Since quadratures (4.4) and (4.5) have good localization properties, then cubature (4.18) (or (4.19)) has such properties. We shall use them to prove the following lemma.

LEMMA 4.2. *Let $n = 1, 2, \dots$, $m = 1, 2, \dots$, and let, for $\gamma \in (0, \pi]$, $\mathcal{K}_m(\cos\gamma) := c_0 \min\{m^{d-1}, m^{d-1}/(m\gamma)^d\}$ with $c_0 > 0$ a constant. Then we have*

$$\mathbf{Q}_n(\mathcal{K}_m(\bullet\cdot\eta)) \le c[1 + (m/n)^{d-1}] \quad \text{for } \eta \in \mathbf{S}^{d-1}, \tag{4.24}$$

where $\mathbf{Q}_n$ is the cubature from (4.19) and c depends only on d and c_0.

Proof. In what follows, we shall assume that $n > n_0$, where n_0 is sufficiently large and depends only on the dimension d. Estimate (4.24) obviously holds for $n \le n_0$ by (4.21). We first construct a tiling of $\mathbf{S}^{d-1}$ which is determined by the nodes of cubature (4.18). We associate with each node $\omega_{\mathbf{j}}$ the spherical box (tile) $T_{\mathbf{j}}$ consisting of all points $\xi \in \mathbf{S}^{d-1}$ for which $\xi = \xi(\theta,\phi)$ with

$$(\theta,\phi) \in [a_{j_1}, a_{j_1+1}) \times \cdots \times [a_{j_{d-2}}, a_{j_{d-2}+1}) \times [b_{j_{d-1}}, b_{j_{d-1}+1}),$$

where $a_j := \frac{1}{2}(\beta_j + \beta_{j-1})$ and $b_j := \frac{1}{2}(\gamma_j + \gamma_{j-1})$ with β_j from (4.5) and γ_j from (4.4). Observe that $\omega_{\mathbf{j}} \in T_{\mathbf{j}}$ is the (spherical) center of $T_{\mathbf{j}}$. Obviously $T_{\mathbf{j}} \bigcap T_{\mathbf{i}} = \emptyset$, $\mathbf{j} \ne \mathbf{i}$, and the tiles $T_{\mathbf{j}}$ cover $\mathbf{S}^{d-1}$ excluding small regions around the poles. The most important property of our cubature is that

$$0 < \lambda_{\mathbf{j}} \le c \int_{T_{\mathbf{j}}} 1\,d\xi =: c|T_{\mathbf{j}}| \quad \text{for } \mathbf{j} \in \mathcal{J}_n. \tag{4.25}$$

This property follows readily by (4.7), the definition of γ_j from (4.4), and the definition of our cubature (see (4.18)).

The second important property of our tiling is that the diameter of each tile $T_{\mathbf{j}}$ is $\le cn^{-1}$. We let $\rho(\xi,\eta) := \arccos \xi\cdot\eta,\ \xi,\eta\in\mathbf{S}^{d-1}$ denote the angular distance on $\mathbf{S}^{d-1}$ (the angle between vectors ξ and η). It is easily seen that $\rho(\xi,\eta)$ satisfies the axioms for a distance on $\mathbf{S}^{d-1}$. Since $\beta_j-\beta_{j-1}\le cn^{-1}$, by (4.6), and $\gamma_j-\gamma_{j-1}\le cn^{-1}$, by the definition of γ_j, then

$$\sup\{\rho(\xi,\eta):\xi,\eta\in T_{\mathbf{j}}\} < c_1 n^{-1}, \tag{4.26}$$

where c_1 depends only on d.

Suppose that $\eta\in\mathbf{S}^{d-1}$ is fixed. We select a new coordinate system such that $\eta = \mathbf{e}_1' := (1,0,\dots,0)$ is its first coordinate vector. This can be done by a suitable rotation of the old coordinate system. For $\xi\in\mathbf{S}^{d-1}$, we shall denote by $\theta' := (\theta_1',\dots,\theta_{d-2}')$ and ϕ' the new spherical coordinates of ξ.

We define, for $\nu = 1,2,\dots,n$,

$$\begin{aligned}\mathcal{Z}_\nu &:= \left\{\xi\in\mathbf{S}^{d-1} : \frac{\pi(\nu-1)}{n}\le \rho(\xi,\mathbf{e}_1')\le\frac{\pi\nu}{n}\right\}\\ &= \left\{\xi\in\mathbf{S}^{d-1} : \frac{\pi(\nu-1)}{n}\le \theta_1'\le\frac{\pi\nu}{n}\right\}\end{aligned}$$

and

$$\mathcal{Z}_\nu^* := \left\{\xi\in\mathbf{S}^{d-1} : \max\left\{\frac{\pi(\nu-1)-c_1}{n},\,-\pi\right\}\le\theta_1'\le\min\left\{\frac{\pi\nu+c_1}{n},\,\pi\right\}\right\},$$

where c_1 is from (4.26). Obviously $\bigcup_{\nu=1}^n \mathcal{Z}_\nu = \mathbf{S}^{d-1}$.

Let $\mathcal{T}_\nu$ be the set of all tiles $T_{\mathbf{j}}$ with centers $\omega_{\mathbf{j}}\in\mathcal{Z}_\nu$. It follows by (4.26) that $\bigcup_{T\in\mathcal{T}_\nu} T\subset\mathcal{Z}_\nu^*$ and hence

$$\sum_{T\in\mathcal{T}_\nu}|T| \le |\mathcal{Z}_\nu^*| := \int_{\mathcal{Z}_\nu^*} 1\,d\xi \le c\int_{\mathcal{Z}_\nu} 1\,d\xi =: c|\mathcal{Z}_\nu|,\quad \nu=1,2,\dots,n. \tag{4.27}$$

We are now ready to estimate $\mathbf{Q}_n(\mathcal{K}_m(\bullet\cdot\eta))$. If $\nu=1$, then we obtain, using (4.25), (4.27), and the assumptions of the lemma,

$$\begin{aligned}&\sum_{\omega_{\mathbf{j}}\in\mathcal{Z}_1}\lambda_{\mathbf{j}}\mathcal{K}_m(\omega_{\mathbf{j}}\cdot\mathbf{e}_1') \le c\max\{\mathcal{K}_m(\cos\theta_1):0\le\theta_1'\le\pi/n\}\sum_{T\in\mathcal{T}_1}|T|\\ &\le cm^{d-1}|\mathcal{Z}_1| \le cm^{d-1}\int_0^{\pi/n}\sin^{d-2}\theta_1'\,d\theta_1' \le c(m/n)^{d-1}.\end{aligned}$$

If $\nu\ge 2$, then

$$\begin{aligned}&\sum_{\omega_{\mathbf{j}}\in\mathcal{Z}_\nu}\lambda_{\mathbf{j}}\mathcal{K}_m(\omega_{\mathbf{j}}\cdot\mathbf{e}_1') \le c\max\{\mathcal{K}_m(\cos\theta_1'):\pi(\nu-1)/n\le\theta_1'\le\pi\nu/n\}\sum_{T\in\mathcal{T}_\nu}|T|\\ &\le c\mathcal{K}_m\left(\cos\frac{\pi(\nu-1)}{n}\right)|\mathcal{Z}_\nu^*| \le c\mathcal{K}_m\left(\cos\frac{\pi\nu}{n}\right)|\mathcal{Z}_\nu| \le c\int_{\mathcal{Z}_\nu}\mathcal{K}_m(\xi\cdot\mathbf{e}_1')\,d\xi,\end{aligned}$$

where we used that $\mathcal{K}_m(\cos\frac{\pi(\nu-1)}{n}) \le c\mathcal{K}_m\left(\cos\frac{\pi\nu}{n}\right)$, $\nu\ge 2$, which follows by the definition of $\mathcal{K}_m(\cos\gamma)$ from the assumptions of the lemma. Therefore,

$$\sum_{\mathbf{j}\in\mathcal{J}_n}\lambda_{\mathbf{j}}\mathcal{K}_m(\omega_{\mathbf{j}}\cdot\mathbf{e}_1') \le c(m/n)^{d-1} + c\int_{\mathcal{Z}}\mathcal{K}_m(\xi\cdot\mathbf{e}_1')\,d\xi, \tag{4.28}$$

where $\mathcal{Z} := \bigcup_{\nu=2}^{n} \mathcal{Z}_\nu$. We obtain, using again the definition of $\mathcal{K}_m(\cos\gamma)$,

$$\int_{\mathcal{Z}} \mathcal{K}_m(\xi\cdot\mathbf{e}_1')\,d\xi = |\mathbf{S}^{d-2}| \int_{\pi/n}^{\pi} \mathcal{K}_m(\cos\theta_1')\sin^{d-2}\theta_1'\,d\theta_1'$$
$$\le c\int_0^{\infty} \min\{m^{d-1}, m^{d-1}/(m\theta_1')^d\}(\theta_1')^{d-2}\,d\theta_1' \le c < \infty.$$

The above estimates and (4.28) imply (4.24). □

We shall deal with discrete sums of spherical polynomial values. For this, we need a rapidly decaying reproducing kernel for the space of spherical polynomials of degree m. The following well-known proposition gives us such a kernel.

PROPOSITION 4.1. *There exists a constant $m_0 = m_0(d)$ such that for every $m \ge m_0$ there exists an algebraic polynomial W_m of degree dm with the properties:*

(a)

$$S(\eta) = \int_{\mathbf{S}^{d-1}} W_m(\eta\cdot\xi)S(\xi)\,d\xi, \quad \eta\in\mathbf{S}^{d-1},$$

for each spherical polynomial S of degree $\le m$;

(b)

$$|W_m(\cos\tau)| \le c_0 \min\{m^{d-1}, m^{d-1}/(m\tau)^d\} \quad \textit{for} \quad 0<\tau\le\pi, \tag{4.29}$$

and hence

(c)

$$\int_{\mathbf{S}^{d-1}} |W_m(\eta\cdot\xi)|\,d\xi \le c < \infty, \quad \eta\in\mathbf{S}^{d-1}, \tag{4.30}$$

where c_0 and c are independent of m and η.

Since we do not have a good reference for Proposition 4.1, we shall show how it can be deduced from the following results of Kogbetliantz and Stein (see also [P]).

PROPOSITION 4.2 (see [K]). *Let $S_m(t) := \sum_{\nu=0}^{m}(\nu+\lambda)C_\nu^\lambda(t)$, $\lambda > 0$, $m = 0,1,\dots,$ and let $\sigma_m^{(\delta)}$ be the Cesàro means of order δ of S_m; i.e.,*

$$\sigma_m^{(\delta)}(t) := \left(A_m^\delta\right)^{-1}\sum_{\nu=0}^{m} A_{m-\nu}^\delta(\nu+\lambda)C_\nu^\lambda(t) \quad \textit{with } A_\nu^\delta := \tfrac{\Gamma(\nu+\delta+1)}{\Gamma(\delta+1)\Gamma(\nu+1)}. \tag{4.31}$$

Then, for $-1<\delta\le 2\lambda+1$,

$$|\sigma_m^{(\delta)}(\cos\gamma)| \le c\min\left\{(m+1)^{2\lambda+1}, (m+1)^{2\lambda-\delta}\Big/\left(\sin\frac{\gamma}{2}\right)^{\delta+1}\right\},\ 0<\gamma\le\pi, \tag{4.32}$$

with c depending only on λ.

PROPOSITION 4.3 (see [St]). *For each positive integer r and for $m = 0,1,\dots,$ there exist $r+1$ parameters $\alpha_1(m),\dots,\alpha_{r+1}(m)$ (depending only on m and r) which are uniformly bounded: $|\alpha_\nu(m)|\le A$, A independent of m, and there exists a fixed integer N, so that the following holds:*

If $\sum_{\nu=0}^{\infty} a_\nu$ is a series of real numbers and if $\sigma_m^{(r)}$, $m=0,1,\dots,$ are the Cesàro means of order r of the partial sums S_m, $m=0,1,\dots,$ of this series (see (4.31)), then

$$\tau_m^{(r)} := \alpha_1(m)\sigma_{m-1}^{(r)} + \alpha_2(m)\sigma_{2m-1}^{(r)} + \cdots + \alpha_{r+1}(m)\sigma_{(r+1)m-1}^{(r)}$$

can be represented in the form

$$\tau_m^{(r)} = \sum_{\nu=0}^{m} a_\nu + \sum_{\nu=m+1}^{(r+1)m} \beta_\nu a_\nu \quad \text{if } m \ge N,$$

where β_ν are constants depending on m and r.

Proof of Proposition 4.1. We have already mentioned in (3.15) that

$$K_m(t) := \frac{N(d,m)}{|\mathbf{S}^{d-1}| C_m^{(d-2)/2}(1)} C_m^{(d-2)/2}(t)$$

gives the reproducing kernel $K_m(\xi \cdot \eta)$ for $\mathcal{H}_m$. Therefore, $\sum_{\nu=0}^m K_\nu(\xi \cdot \eta)$ is a reproducing kernel for all spherical polynomials of degree $\le m$. Simple calculations show that

$$K_m(t) = 2\left[|\mathbf{S}^{d-1}|(d-2)\right]^{-1}(m+\lambda)C_m^\lambda(t) \quad \text{with } \lambda := (d-2)/2.$$

Therefore, $2\left[|\mathbf{S}^{d-1}|(d-2)\right]^{-1}\sum_{\nu=0}^m(\nu+\lambda)C_\nu^\lambda(t)$ gives a reproducing kernel for the spherical polynomials of degree $\le m$.

We now apply Proposition 4.2 with $\lambda := (d-2)/2$ and $\delta := 2\lambda + 1 = d-1$. Then we apply Proposition 4.3 to the resulting Cesàro means $\{\sigma_\nu^{(r)}\}$ with $r := \delta = d-1$ to conclude that $W_m := 2\left[|\mathbf{S}^{d-1}|(d-2)\right]^{-1}\tau_m^{(r)}$ satisfies (4.29) (by (4.32) and since $\alpha_\nu(m)$ are uniformly bounded) and $W_m(\xi \cdot \eta)$ is a reproducing kernel for the spherical polynomials of degree $\le m$ (by Proposition 4.3). □

Lemma 4.2 and Proposition 4.1 allow us to estimate discrete $l_p(\Omega_n)$ norms of spherical polynomials by their $L_p(\mathbf{S}^{d-1})$ norms. In this part we use ideas from [O].

LEMMA 4.3. *Let $n = 1, 2, \dots$, and let $m \ge m_0$, where m_0 is from Proposition* 4.1. *Then for every spherical polynomial S of degree m and for $1 \le p \le \infty$ we have*

$$\sum_{\omega \in \Omega_n} \lambda_\omega |S(\omega)|^p \le c[1 + (m/n)^{d-1}] \int_{\mathbf{S}^{d-1}} |S(\xi)|^p \, d\xi, \tag{4.33}$$

where λ_ω and Ω_n are from (4.19), *and c is independent of S, n, and m.*

Proof. By Proposition 4.1 we get $S(\omega) = \int_{\mathbf{S}^{d-1}} W_m(\omega \cdot \xi) S(\xi)\, d\xi$, $\omega \in \Omega_n$. We obtain, using Hölder's inequality,

$$\begin{aligned} |S(\omega)| &\le \int_{\mathbf{S}^{d-1}} |W_m(\omega \cdot \xi) S(\xi)|\, d\xi = \int_{\mathbf{S}^{d-1}} |W_m(\eta \cdot \xi)|^{1-1/p} |W_m(\omega \cdot \xi)|^{1/p} |S(\xi)|\, d\xi \\ &\le \left(\int_{\mathbf{S}^{d-1}} |W_m(\omega \cdot \xi)|\, d\xi \right)^{1-1/p} \left(\int_{\mathbf{S}^{d-1}} |W_m(\omega \cdot \xi)| |S(\xi)|^p \, d\xi \right)^{1/p} \end{aligned}$$

and hence

$$|S(\omega)|^p \le A^{p-1} \int_{\mathbf{S}^{d-1}} |W_m(\omega \cdot \xi)| |S(\xi)|^p \, d\xi, \quad \text{where } A := \textstyle\int_{\mathbf{S}^{d-1}} |W_m(\omega \cdot \xi)|\, d\xi.$$

We now multiply both sides of the above inequality by λ_ω and sum over $\omega \in \Omega_n$ to obtain

$$\begin{aligned} &\sum_{\omega \in \Omega_n} \lambda_\omega |S(\omega)|^p \le A^{p-1} \int_{\mathbf{S}^{d-1}} \left(\sum_{\omega \in \Omega_n} \lambda_\omega |W_m(\omega \cdot \xi)| \right) |S(\xi)|^p \, d\xi \\ &\le A^{p-1} \max_{\xi \in \mathbf{S}^{d-1}} \mathbf{Q}_n(|W_m(\bullet \cdot \xi)|) \int_{\mathbf{S}^{d-1}} |S(\xi)|^p \, d\xi. \end{aligned}$$

It follows, by (4.29), that $|W_m(\bullet\cdot\xi)| \le \mathcal{K}_m(\bullet\cdot\xi)$, where $\mathcal{K}_m$ is defined in Lemma 4.2 with c_0 from Proposition 4.1. Then Proposition 4.1 and Lemma 4.2 imply

$$\max_{\xi\in\mathbf{S}^{d-1}} \mathbf{Q}_n(|W_m(\bullet\cdot\xi)|) \le \max_{\xi\in\mathbf{S}^{d-1}} \mathbf{Q}_n(\mathcal{K}_m(\bullet\cdot\xi)) \le c[1+(m/n)^{d-1}] \quad \text{and} \quad A \le c$$

which completes the proof of Lemma 4.3. □

The following lemma relates the $L_2(\mathbf{S}^{d-1})$ norms and discrete $l_2(\Omega_n)$ norms of spherical polynomials written in terms of $\nu_m\mathcal{U}_m(\xi\cdot\omega)/\mathcal{U}_m(1)$, the reproducing kernel for the space $\mathcal{H}_m \oplus \mathcal{H}_{m-2} \oplus \cdots \oplus \mathcal{H}_\epsilon$ (see (3.17)).

LEMMA 4.4. *Let $n = 1, 2, \ldots$, and let $c(\omega)$, $\omega \in \Omega_n$, be real constants. Let $m \ge m_0$, where m_0 is from Proposition* 4.1. *Then the spherical polynomial*

$$S(\xi) := \sum_{\omega\in\Omega_n} \lambda_\omega c(\omega) \frac{\nu_m}{\mathcal{U}_m(1)} \mathcal{U}_m(\xi\cdot\omega)$$

satisfies

$$\|S\|^2_{L_2(\mathbf{S}^{d-1})} \le c[1+(m/n)^{d-1}] \sum_{\omega\in\Omega_n} \lambda_\omega |c(\omega)|^2. \tag{4.34}$$

Proof. Using (3.11) we get

$$\begin{aligned}
\|S\|^2_{L_2(\mathbf{S}^{d-1})} &= \int_{\mathbf{S}^{d-1}} |S(\xi)|^2\, d\xi \\
&= \sum_{\omega\in\Omega_n} \sum_{\eta\in\Omega_n} \lambda_\omega\lambda_\eta c(\omega)c(\eta) \left(\frac{\nu_m}{\mathcal{U}_m(1)}\right)^2 \int_{\mathbf{S}^{d-1}} \mathcal{U}_m(\xi\cdot\omega)\mathcal{U}_m(\xi\cdot\eta)\, d\xi \\
&= \sum_{\omega\in\Omega_n} \sum_{\eta\in\Omega_n} \lambda_\omega\lambda_\eta c(\omega)c(\eta) \frac{\nu_m}{\mathcal{U}_m(1)} \mathcal{U}_m(\omega\cdot\eta) = \sum_{\eta\in\Omega_n} \lambda_\eta c(\eta) S(\eta) \\
&\le \left(\sum_{\eta\in\Omega_n} \lambda_\eta |c(\eta)|^2\right)^{1/2} \left(\sum_{\eta\in\Omega_n} \lambda_\eta |S(\eta)|^2\right)^{1/2}.
\end{aligned}$$

By Lemma 4.3, the last quantity above does not exceed $c[1+(m/n)^{d-1}]^{\frac12} \|S\|_{L_2(\mathbf{S}^{d-1})}$. Finally, we divide by $\|S\|_{L_2(\mathbf{S}^{d-1})}$ to complete the proof of the lemma. □

5. Smoothness spaces in $L_2(\mathbf{B}^d)$. In this section, we shall recall results about approximation by algebraic polynomials. As earlier, we let $\mathcal{P}_n$ denote the space of algebraic polynomials in d-variables. For $n \ge 1$, let

$$E_n(f) := E_n(f)_{L_2(\mathbf{B}^d)} := \inf_{P\in\mathcal{P}_n} \|f - P\|_{L_2(\mathbf{B}^d)}$$

be the error in approximating $f \in L_2(\mathbf{B}^d)$ by algebraic polynomials P of degree $\le n$. By Theorem 3.1 we have the following representation of the polynomial $P_n(f,\mathbf{x})$ of best $L_2(\mathbf{B}^d)$-approximation to f:

$$P_n(f,\mathbf{x}) = \sum_{m=0}^{n} \nu_m \int_{\mathbf{S}^{d-1}} A_m(\xi)\mathcal{U}_m(\mathbf{x}\cdot\xi)\, d\xi, \tag{5.1}$$

where

$$A_n(\xi) := A_n(f,\xi) := \int_{\mathbf{B}^d} f(\mathbf{y})\mathcal{U}_m(\mathbf{y}\cdot\xi)\, d\mathbf{y}.$$

Since $A_m(\xi)U_m(\mathbf{x}\cdot\xi)$ is a spherical polynomial of degree $\le 2m \le 2n$ in ξ, we can use the quadrature formula (4.19) to obtain

$$P_n(f,\mathbf{x}) = \sum_{\omega\in\Omega_n} \lambda_\omega \sum_{m=0}^{n} \nu_m A_m(\omega)\mathcal{U}_m(\mathbf{x}\cdot\omega). \tag{5.2}$$

From Theorem 3.1, we have

$$\begin{aligned} E_n(f)^2 &= \|f - P_n(f)\|^2_{L_2(\mathbf{B}^d)} = \sum_{m>n} \nu_m \|A_m(f)\|^2_{L_2(\mathbf{S}^{d-1})} \\ &\asymp \sum_{m>n} m^{d-1}\|A_m(f)\|^2_{L_2(\mathbf{S}^{d-1})}. \end{aligned} \tag{5.3}$$

For $\alpha > 0$, let $W^\alpha(L_2(\mathbf{B}^d))$ be the Sobolev space for the domain $\mathbf{B}^d$. When $\alpha = k$ is an integer, then a function $f \in L_2(\mathbf{B}^d)$ is in $W^k(L_2(\mathbf{B}^d))$ if and only if its distributional derivatives $D^\nu f$ of order k are in $L_2(\mathbf{B}^d)$, and

$$|f|^2_{W^k(L_2(\mathbf{B}^d))} := \sum_{|\nu|=k} \|D^\nu f\|^2_{L_2(\mathbf{B}^d)}$$

gives the seminorm for $W^k(L_2(\mathbf{B}^d))$. The norm for $W^k(L_2(\mathbf{B}^d))$ is obtained by adding $\|f\|_{L_2(\mathbf{B}^d)}$ to $|f|_{W^k(L_2(\mathbf{B}^d))}$. For other values of α, we obtain W^α as the interpolation space

$$W^\alpha(L_2(\mathbf{B}^d)) = (L_2(\mathbf{B}^d), W^k(L_2(\mathbf{B}^d)))_{\theta,2}, \quad \theta = \alpha/k,\ 0 < \alpha < k,$$

given by the real method of interpolation (see, e.g., Bennett and Sharpley [BS]).

A fundamental result in approximation known as the Jackson theorem states that

$$E_n(f) \le c(k)n^{-k}\|f\|_{W^k(L_2(\mathbf{B}^d))}, \tag{5.4}$$

where the norm on the right can be replaced by the seminorm if k is an integer. This theorem can be deduced easily from the results on univariate approximation in Chapter 7 of [DL]. By interpolation (see, e.g., [DL, Chapter 7]), one obtains

$$\sum_{n=1}^{\infty} [n^\alpha E_n(f)]^2 n^{-1} \le c(\alpha)\|f\|^2_{W^\alpha(L_2(\mathbf{B}^d))}, \quad \alpha > 0, \tag{5.5}$$

with $c(\alpha)$ depending at most on α. From (5.3) and (5.5), it is easy to deduce that

$$\sum_{n=1}^{\infty} n^{2\alpha+d-1}\|A_n(f)\|^2_{L_2(\mathbf{S}^{d-1})} \le c(\alpha)\|f\|^2_{W^\alpha(L_2(\mathbf{B}^d))}, \quad \alpha > 0, \tag{5.6}$$

with $c(\alpha)$ depending at most on α.

6. Approximation of functions in $L_2(I, w)$. We shall also need certain results about the approximation of univariate functions in $L_2(I,w)$ where $I := [-1,1]$ and $w := w_{d/2}$. As we know by section 2, the Gegenbauer polynomials $\{\mathcal{U}_m\}_{m=0}^\infty$ form a complete orthonormal system for $L_2(I,w)$ (see (3.3)). For any $g \in L_2(I,w)$ we have

$$g = \sum_{m=0}^{n} \hat{g}(m)\mathcal{U}_m \quad \text{with} \quad \hat{g}(m) := \int_I g(s)\mathcal{U}_m(s)w(s)\,ds. \tag{6.1}$$

We shall use approximation of functions in $L_2(I,w)$ as an intermediate tool in establishing our results on ridge approximation. Let $\mathcal{P}_n(I)$ denote the space of univariate algebraic polynomials of degree $\le n$. For a function $g \in L_2(I,w)$, we let

$$E_n(g)_{L_2(I,w)} := \inf_{p\in\mathcal{P}_n(I)} \|g-p\|_{L_2(I,w)}$$

be the error in approximating g by the elements of $\mathcal{P}_n(I)$. The polynomial

$$p_n := \sum_{m=0}^{n} \hat{g}(m)\mathcal{U}_m \tag{6.2}$$

is the best $L_2(I,w)$ approximation to g by elements of $\mathcal{P}_n(I)$, and we have

$$E_n(g)^2_{L_2(I,w)} = \|g-p_n\|^2_{L_2(I,w)} = \sum_{m>n} |\hat{g}(m)|^2. \tag{6.3}$$

We introduce the univariate Sobolev spaces $W^\alpha(L_2(I,w))$, $\alpha \in \mathbf{R}$, whose norms are defined by

$$\|g\|^2_{W^\alpha(L_2(I,w))} := \sum_{m=0}^{\infty} [(m+1)^\alpha |\hat{g}(m)|]^2. \tag{6.4}$$

It follows that for each $g \in W^\alpha(L_2(I,w))$,

$$E_n(g)_{L_2(I,w)} \le c(\alpha) n^{-\alpha} \|g\|_{W^\alpha(L_2(I,w))}. \tag{6.5}$$

Moreover, similar to (5.5), we have

$$\sum_{n=1}^{\infty} [n^\alpha E_n(g)_{L_2(I,w)}]^2 n^{-1} \le c(\alpha)\|g\|^2_{W^\alpha(L_2(I,w))}, \quad \alpha > 0. \tag{6.6}$$

There is also a Bernstein-type inequality for polynomials in $\mathcal{P}_n(I)$ with respect to $L_2(I,w)$ which follows trivially from the definition: for every $p \in \mathcal{P}_n(I)$ and $\alpha > 0$,

$$\|p\|_{W^\alpha(L_2(I,w))} \le (n+1)^\alpha \|p\|_{L_2(I,w)}. \tag{6.7}$$

It is well known (see [DL, Chapter 7]) that companion inequalities like (6.5) and (6.7) imply a characterization of approximation spaces by interpolation spaces. In our context, the approximation spaces are the Sobolev spaces $W^\alpha(L_2(I,w))$ defined by (6.4) and we therefore obtain for each $0 < \alpha < k$,

$$W^\alpha(L_2(I,w)) = (L_2(I,w), W^k(L_2(I,w)))_{\theta,2}, \quad \theta = \alpha/k. \tag{6.8}$$

Further properties of the spaces $W^\alpha(L_2(I,w))$ are given in section 7.

7. Approximation by ridge functions. In this section, we assume that X_n is a subspace of $L_2(I,w)$, $w = w_{d/2}$, of dimension n with the following property. There is a real number $s > 0$ such that, for each univariate function $g \in W^s(L_2(I,w))$, there is a function $r \in X_n$ which provides the Jackson estimate

$$\|g-r\|_{L_2(I,w)} \le c_0 n^{-s} \|g\|_{W^s(L_2(I,w))}, \tag{7.1}$$

with c_0 a constant independent of g and n.

We define Y_n to be the space of functions R in d variables of the form

$$R(\mathbf{x}) = \sum_{\omega\in\Omega_n} r_\omega(\mathbf{x}\cdot\omega), \quad r_\omega \in X_n, \quad \omega \in \Omega_n, \tag{7.2}$$

where Ω_n is the set of vectors in $\mathbf{S}^{d-1}$ from (4.19). Then Y_n is a linear space of dimension $\le n\#\Omega_n \le cn^d$. We prove the following theorem about approximation from Y_n.

THEOREM 7.1. *Let X_n, $n = 1, 2, \dots$, satisfy inequality (7.1) for some $s > 0$. If f is a function from the space $W^{s+\frac{d-1}{2}}(L_2(\mathbf{B}^d))$, then there is a function R in Y_n such that*

$$\|f - R\|_{L_2(\mathbf{B}^d)} \le cn^{-s-\frac{d-1}{2}} \|f\|_{W^{s+\frac{d-1}{2}}(L_2(\mathbf{B}^d))} \tag{7.3}$$

with c a constant depending only on s and d.

REMARK 7.1. *If $s + (d-1)/2 - 1$ is an integer and the space Y_n contains $\mathcal{P}_{s+(d-1)/2-1}$, then we have that $\|f\|_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d))}$ can be replaced by the seminorm $|f|_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d))}$.*

An important element of the proof of Theorem 7.1 is the idea to get rid of the "low frequencies" when approximating. To this end we shall use the following geometric construction which was proven for us by Boris Kashin.

LEMMA 7.1. *Let H be a Hilbert space with norm $\|\cdot\|$ and let A, $B \subset H$ be finite-dimensional linear subspaces of H with $\dim A \le \dim B$. If there exists δ, $0 < \delta < 1/2$, such that*

$$\sup_{\substack{x\in A\\ \|x\|\le 1}} \inf_{y\in B} \|x - y\| \le \delta, \tag{7.4}$$

then there is a constant c depending only on δ and a linear operator $L : A \to B$ such that for every $x \in A$,

$$\|Lx - x\| \le c \inf_{y\in B} \|x - y\|, \tag{7.5}$$

and

$$Lx - x \perp A \quad (Lx - x \text{ is orthogonal to } A).$$

Proof. See [DOP, Lemma 6]. □

Proof of Theorem 7.1. Estimate (7.3) trivially holds if $n < m_0$, where $m_0 = m_0(d)$ is the constant from Proposition 4.1.

Suppose that $n \ge m_0$. Let $P = P_n$ be the polynomial in $\mathcal{P}_n$ given by (5.1) (or (5.2)). Since P is the best $L_2(\mathbf{B}^d)$ approximation of f, it satisfies (see (5.4))

$$\|f - P\|_{L_2(\mathbf{B}^d)} \le cn^{-s-(d-1)/2} \|f\|_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d))} \tag{7.6}$$

with c and all subsequent constants in this proof depending only on s and d. We shall approximate P by an element R of Y_N, $N = k_0 n$, where k_0 is a sufficiently large constant depending only on s and d.

We have $A_m(P, \xi) = A_m(f, \xi)$, $m \le n$, and $A_m(P, \xi) = 0$, $m > n$. Since $f \in W^{s+(d-1)/2}(L_2(\mathbf{B}^d))$, we know from (5.6) that

$$\sum_{m=0}^{n} (m+1)^{2s+2(d-1)} \|A_m(f)\|^2_{L_2(\mathbf{S}^{d-1})} \le c\|f\|^2_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d))}. \tag{7.7}$$

From this, using (4.23), we obtain

$$\sum_{m=0}^{n}(m+1)^{2s+2(d-1)}\sum_{\omega\in\Omega_n}\lambda_\omega|(A_m(f,\omega))|^2\le c\|f\|^2_{W^{r+(d-1)/2}(L_2(\mathbf{B}^d))}. \tag{7.8}$$

We introduce the univariate polynomials

$$p_\omega(t):=\sum_{m=0}^{n}\nu_m A_m(f,\omega)\mathcal{U}_m(t)=\sum_{m=0}^{n}\nu_m A_m(P,\omega)\mathcal{U}_m(t),\quad \omega\in\Omega_n. \tag{7.9}$$

We have, by (4.22) and (7.9),

$$P(\mathbf{x})=\sum_{m=0}^{n}\nu_m\sum_{\omega\in\Omega_n}\lambda_\omega A_m(P,\omega)\mathcal{U}_m(\mathbf{x}\cdot\omega)=\sum_{\omega\in\Omega_n}\lambda_\omega p_\omega(\mathbf{x}\cdot\omega). \tag{7.10}$$

According to (6.4), we have

$$\begin{aligned}\|\lambda_\omega^{1/2}p_\omega\|^2_{W^s(L_2(I,w))}&=\sum_{m=0}^{n}(m+1)^{2s}\nu_m^2\lambda_\omega|A_m(f,\omega)|^2\\&\asymp\sum_{m=0}^{n}(m+1)^{2s+2(d-1)}\lambda_\omega|A_m(f,\omega)|^2.\end{aligned}$$

Hence, from (7.8),

$$\begin{aligned}\sum_{\omega\in\Omega_n}\|\lambda_\omega^{1/2}p_\omega\|^2_{W^s(L_2(I,w))}&\le c\sum_{m=0}^{n}(m+1)^{2s+2(d-1)}\sum_{\omega\in\Omega_n}\lambda_\omega|(A_m(f,\omega))|^2\\&\le c\|f\|^2_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d))}.\end{aligned} \tag{7.11}$$

We shall approximate each polynomial p_ω by elements of X_N. We apply Lemma 7.1 in the following setting. We take for H the Hilbert space $L_2(I,w)$ and take $A=\mathcal{P}_n(I)$ and $B=X_N$ with $N\ge k_0 n$ and k_0 a positive integer. We next show that if k_0 is large enough then the assumption (7.4) is satisfied. We mentioned earlier in (6.7) that $\mathcal{P}_n(I)$ satisfies the Bernstein inequality

$$\|p\|_{W^s(L_2(I,w))}\le(n+1)^s\|p\|_{L_2(I,w)},\quad p\in\mathcal{P}_n(I).$$

If $p\in\mathcal{P}_n(I)$, then from this Bernstein inequality and from (7.1), there is an $r\in X_N$ such that

$$\|p-r\|_{L_2(I,w)}\le c_0N^{-s}\|p\|_{W^s(L_2(I,w))}\le c_0N^{-s}2^sn^s\|p\|_{L_2(I,w)}\le c_0 2^sk_0^{-s}\|p\|_{L_2(I,w)}.$$

Thus, if k_0 is large enough, condition (7.4) is satisfied. Therefore, for each $\omega\in\Omega_n$, we can find $r_\omega\in X_N$ such that $r_\omega-p_\omega\perp\mathcal{P}_n(I)$ with respect to the inner product in $L_2(I,w)$ and, by (7.1) and (7.5),

$$\|p_\omega-r_\omega\|^2_{L_2(I,w)}\le cn^{-2s}\|p_\omega\|^2_{W^s(L_2(I,w))}.$$

Therefore,

$$r_\omega-p_\omega=\sum_{m=n+1}^{\infty}\hat{r}_\omega(m)\mathcal{U}_m \tag{7.12}$$

with

$$\hat{r}_\omega(m) := \int_I r_\omega(s)\mathcal{U}_m(s)w(s)\,ds$$

and

$$\sum_{m=n+1}^{\infty} |\hat{r}_\omega(m)|^2 = \|p_w - r_\omega\|^2_{L_2(I,w)} \le cn^{-2s}\|p_\omega\|^2_{W^s(L_2(I,w))}. \tag{7.13}$$

We define

$$R(\mathbf{x}) := \sum_{\omega\in\Omega_n} \lambda_\omega r_\omega(\mathbf{x}\cdot\omega)$$

which is an element of Y_N. Then we have, by (7.10) and (7.12),

$$R(\mathbf{x}) - P(\mathbf{x}) = \sum_{\omega\in\Omega_n}\sum_{m=n+1}^{\infty} \lambda_\omega\hat{r}_\omega(m)\mathcal{U}_m(\omega\cdot\mathbf{x}) = \sum_{m=n+1}^{\infty}\sum_{\omega\in\Omega_n} \lambda_\omega\hat{r}_\omega(m)\mathcal{U}_m(\omega\cdot\mathbf{x}).$$

We write

$$R_m(\mathbf{x}) := \sum_{\omega\in\Omega_n} \lambda_\omega\hat{r}_\omega(m)\mathcal{U}_m(\mathbf{x}\cdot\omega).$$

We have by Theorem 3.1 (see also (3.19)–(3.21))

$$R_m(\mathbf{x}) = \nu_m \int_{\mathbf{S}^{d-1}} A_m(R_m,\xi)\mathcal{U}_m(\xi\cdot\mathbf{x})\,d\xi,$$

where

$$\begin{aligned} A_m(R_m,\xi) &= \int_{\mathbf{B}^d} R_m(\mathbf{y})\mathcal{U}_m(\mathbf{y}\cdot\xi)\,d\mathbf{y} = \sum_{\omega\in\Omega_n}\lambda_\omega\hat{r}_\omega(m)\int_{\mathbf{B}^d}\mathcal{U}_m(\omega\cdot\mathbf{y})\mathcal{U}_m(\xi\cdot\mathbf{y})\,d\mathbf{y} \\ &= \sum_{\omega\in\Omega_n}\lambda_\omega\hat{r}_\omega(m)\frac{\mathcal{U}_m(\xi\cdot\omega)}{\mathcal{U}_m(1)}. \end{aligned}$$

We now use Theorem 3.1 and Lemma 4.4 to obtain

$$\begin{aligned} \|R_m\|^2_{L_2(\mathbf{B}^d)} &= \nu_m\|A_m(R_m,\omega)\|^2_{L_2(\mathbf{S}^{d-1})} = \nu_m^{-1}\left\|\sum_{\omega\in\Omega_n}\lambda_\omega\hat{r}_\omega(m)\frac{\nu_m}{\mathcal{U}_m(1)}\mathcal{U}_m(\xi\cdot\omega)\right\|^2_{L_2(\mathbf{S}^{d-1})} \\ &\le c\nu_m^{-1}(m/n)^{d-1}\sum_{\omega\in\Omega_n}\lambda_\omega|\hat{r}_\omega(m)|^2 \le cn^{-d+1}\sum_{\omega\in\Omega_n}\lambda_\omega|\hat{r}_\omega(m)|^2, \end{aligned}$$

where we used that $\nu_m \asymp m^{d-1}$ (see (3.8)). From this, (7.11), and (7.13), we find, using the Parseval identity (3.9),

$$\begin{aligned} \|R-P\|^2_{L_2(\mathbf{B}^d)} &= \sum_{m=n+1}^{\infty}\|R_m\|^2_{L_2(\mathbf{B}^d)} \le cn^{-d+1}\sum_{m=n+1}^{\infty}\sum_{\omega\in\Omega_n}\lambda_\omega|\hat{r}_\omega(m)|^2 \\ &= cn^{-d+1}\sum_{\omega\in\Omega_n}\lambda_\omega\sum_{m=n+1}^{\infty}|\hat{r}_\omega(m)|^2 \\ &\le cn^{-2s-d+1}\sum_{\omega\in\Omega_n}\|\lambda_\omega^{1/2}p_\omega\|^2_{W^s(L_2(I,w))} \\ &\le cn^{-2s-d+1}\|f\|^2_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d))}. \end{aligned}$$

Thus there is a function $R \in Y_N$, $N = k_0 n$, such that (7.3) holds. Theorem 7.1 is now proved. □

REMARK 7.2. *As in* [DOP], *it is possible to prove Theorem* 7.1 *without using Lemma* 7.1. *In place of this lemma one uses a slightly stronger assumption than estimate* (7.1). *The corresponding proof would be more constructive than the present one. We do not provide the details of this approach but instead refer the reader to* [DOP].

8. Elimination of the weight w. The result of section 7 (Theorem 7.1) gives sufficient conditions on a sequence of univariate spaces X_n, $n = 1, 2, \dots$, in order that the spaces Y_n defined by (7.2) with Ω_n from (4.19) provide approximation rates for functions in Sobolev spaces $W^\alpha(L_2(\mathbf{B}^d))$ comparable with polynomials and splines. However, the assumption (7.1) imposed on X_n is inconvenient for direct application because of the appearance of the weight $w(t) := w_{d/2}(t) := (1-t^2)^{(d-1)/2}$. We shall show in this section how the weight factor w can be avoided so that the result of section 7 applies more directly. We shall consider approximation on the ball $\mathbf{B}^d_{1/2} := \{\mathbf{x} \in \mathbf{R}^d : |\mathbf{x}| \le 1/2\}$ rather than $\mathbf{B}^d$. Approximation on $\mathbf{B}^d$ or other balls follows by a change of variables.

We begin by assuming that we have in hand n-dimensional linear spaces Z_n of univariate functions defined on $J := [-1/2, 1/2]$ which satisfy a Jackson-type estimate similar to (7.1) but with weight $= 1$. Let $W^m(L_2(J))$, $m = 1, 2, \dots$, be the Sobolev space of functions $g \in L_2(J)$ such that $g^{(m)}$ is in $L_2(J)$. The seminorm and norm for $W^m(L_2(J))$ are defined by

$$|g|_{W^m(L_2(J))} := \|g^{(m)}\|_{L_2(J)} \quad ; \quad \|g\|_{W^m(L_2(J))} := \|g^{(m)}\|_{L_2(J)} + \|g\|_{L_2(J)}.$$

For $0 < s < m$ not an integer, we define $W^s(L_2(J))$ by interpolation:

$$W^s(L_2(J)) := (L_2(J), W^m(L_2(J)))_{\theta,2}, \quad \theta := s/m, \tag{8.1}$$

with the norm as the interpolation space norm. For a given value of s, different values of $m > s$ give equivalent norms (see [DL]).

Our assumption on Z_n is that for a certain fixed value of s, we have that for each $g \in W^s(L_2(J))$, there is a function $\zeta_n \in Z_n$ such that

$$\|g - \zeta_n\|_{L_2(J)} \le c(s) n^{-s} \|g\|_{W^s(L_2(J))} \tag{8.2}$$

with the constant $c(s)$ depending only on s.

Let X_n be the space of univariate functions r such that for some $p \in \mathcal{P}_n(I)$ and some $\zeta \in Z_n$,

$$r(t) = \begin{cases} p(t), & t \in I \setminus J, \\ \zeta(t), & t \in J. \end{cases} \tag{8.3}$$

We shall show that under the assumption (8.2) on the Z_n, the spaces X_n, $n = 1, 2, \dots$, satisfy the assumption (7.1). To prove this, we recall the definition (6.4) of the spaces $W^\alpha(L_2(I, w))$ and the operator Λ of (2.12):

$$\Lambda g := \left(\frac{d}{dt}\right)^{d-1} [wg]\,. \tag{8.4}$$

According to (2.15), we have $\Lambda^2 \mathcal{U}_n = (-1)^{d-1} \mu_n^2 \mathcal{U}_n$. Since $\mu_n \asymp n^{d-1}$ (see (2.16)), it follows that for each $g \in W^{m\lambda}(L_2(I, w))$, $\lambda = 2(d-1)$, $m = 1, 2, \dots$, we have

$$\|g\|_{W^{m\lambda}(L_2(I,w))} \asymp \|\Lambda^{2m} g\|_{L_2(I,w)} \tag{8.5}$$

with the constants of equivalency depending only on d.

LEMMA 8.1. *For each $m = k\lambda$, with $\lambda := 2(d-1)$ and k a nonnegative integer, we have*

$$\|g\|_{W^m(L_2(J))} \le c(d,m)\|g\|_{W^m(L_2(I,w))} \quad \text{for } g \in W^m(L_2(I,w)) \tag{8.6}$$

with the constant $c(d,m)$ depending only on d and m.

Proof. We first observe that the weight w is strictly positive on J and, therefore, w^{-1} is infinitely times differentiable on J. Then the following identity holds:

$$g^{(\ell(d-1))} = \sum_{j=0}^{\ell(d-1)-1} u_j g^{(j)} + u_{\ell(d-1)}\Lambda^\ell g, \quad \ell = 1,2,\dots, \tag{8.7}$$

where u_j are obtained from w^{-1} and its derivatives. Indeed, (8.7) can be proved by induction on ℓ. For $\ell = 1$, (8.7) follows from Leibniz's formula for differentiating the product $g = w^{-1}(wg)$. Suppose that (8.7) holds for some $\ell \ge 1$. Then one writes $\Lambda^\ell g$ as $w^{-1}\left(w\Lambda^\ell g\right)$ and differentiates both sides of (8.7) $d-1$ times to prove it for $\ell+1$.

It follows from (8.7), with $\ell = 2k$ and $m = k\lambda$, that

$$\|g^{(m)}\|_{L_2(J)} \le c\sum_{j=0}^{m-1} \|g^{(j)}\|_{L_2(J)} + c\|\Lambda^k g\|_{L_2(J)}. \tag{8.8}$$

We shall use next the following well-known inequality (see, e.g., [BS])

$$\|g^{(j)}\|_{L_2(J)} \le c\left(\delta^{-j}\|g\|_{L_2(J)} + \delta^{m-j}\|g^{(m)}\|_{L_2(J)}\right), \quad j = 1,2,\dots,m, \tag{8.9}$$

where $\delta > 0$ is arbitrary and c depends only on m. Combining (8.8) with (8.9) we get, for $0 < \delta < 1$,

$$\|g^{(m)}\|_{L_2(J)} \le c^*\delta^{-m+1}\|g\|_{L_2(J)} + c^*\delta\|g^{(m)}\|_{L_2(J)} + c^*\|\Lambda^k g\|_{L_2(J)}, \tag{8.10}$$

where $c^* > 1$ is independent of δ. We now select δ such that $c^*\delta = 1/2$ and bring the second term on the right in (8.10) to the left-hand side. We obtain

$$\begin{aligned}\|g^{(m)}\|_{L_2(J)} &\le c(\|g\|_{L_2(J)} + \|\Lambda^k g\|_{L_2(J)})\\ &\le c(\|wg\|_{L_2(I)} + \|w\Lambda^k g\|_{L_2(I)})\\ &\le c\|g\|_{W^m(L_2(I,w))}. \qquad \square\end{aligned}$$

THEOREM 8.1. *If the sequence of spaces Z_n, $n = 1,2,\dots$, satisfies* (8.2)*, then the spaces X_n, $n = 1,2,\dots$, defined by* (8.3) *satisfy the Jackson estimates* (7.1)*; i.e., for each univariate function $g \in W^s(L_2(I,w))$, there is a function $r \in X_n$ which provides the Jackson estimate*

$$\|g - r\|_{L_2(I,w)} \le cn^{-s}\|g\|_{W^s(L_2(I,w))}, \tag{8.11}$$

with c a constant independent of g and n.

Proof. Consider the linear operator T that associates with every function $g \in L_2(I,w)$ the restriction of g on J. Since w is strictly positive on J, T is a bounded operator from $L_2(I,w)$ into $L_2(J)$. By Lemma 8.1, T is bounded from $W^m(L_2(I,w))$ into $W^m(L_2(J))$ for each $m = 2k(d-1)$, $k = 1,2,\dots$. This implies that, for each

$0 < s \le 2k(d-1)$ and $\theta := s/(2k(d-1))$, we have by interpolation (see (6.8) and (8.1)) that for each $g \in W^s(L_2(I,w))$,

$$\begin{aligned}\|g\|_{W^s(L_2(J))} &\asymp \|g\|_{\left(L_2(J),W^{2k(d-1)}(L_2(J))\right)_{\theta,2}} \\ &\le c\|g\|_{\left(L_2(I,w),W^{2k(d-1)}(L_2(I,w))\right)_{\theta,2}} \asymp \|g\|_{W^s(L_2(I,w))}.\end{aligned}$$

Now, given $g \in W^s(L_2(I,w))$, we let $\zeta \in Z_n$ satisfy (8.2). Then, from (8.6),

$$\|g-\zeta\|_{L_2(J)} \le cn^{-s}\|g\|_{W^s(L_2(J))} \le cn^{-s}\|g\|_{W^s(L_2(I,w))}.$$

Similarly, let p be the best approximation in $L_2(I,w)$ to g from $\mathcal{P}_n(I)$. Then, from (6.5),

$$\|g-p\|_{L_2(I,w)} \le n^{-s}\|g\|_{W^s(L_2(I,w))}.$$

It now follows that the function $r \in X_n$ defined by (8.3) for these ζ and p satisfies (8.11). □

THEOREM 8.2. *If the sequence of spaces $Z_n, n = 1,2,\dots,$ satisfy* (8.2)*, then for any function $f \in W^{s+(d-1)/2}(L_2(\mathbf{B}^d_{1/2}))$, there are functions $r_\omega \in Z_n$ such that*

$$R(\mathbf{x}) = \sum_{\omega\in\Omega_n} r_\omega(\omega\cdot\mathbf{x}) \tag{8.12}$$

satisfies

$$\|f-R\|_{L_2(\mathbf{B}^d_{1/2})} \le cn^{-s-(d-1)/2}\|f\|_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d_{1/2}))} \tag{8.13}$$

with c independent of f and n.

Proof. We first recall (see, e.g., [A, Chapter IV]) that f can be extended to a function f_0 defined on all of $\mathbf{R}^d$ such that f_0 vanishes outside of $\mathbf{B}^d_{3/4}$ and

$$\|f_0\|_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d))} \le c\|f\|_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d_{1/2}))}$$

with a constant c depending only on s and d.

We define X_n as in (8.3). From Theorem 8.1, we obtain that condition (7.1) is satisfied. Therefore, from Theorem 7.1 there are functions $r_\omega \in X_n$, $\omega \in \Omega_n$, such that the function

$$R(\mathbf{x}) = \sum_{\omega\in\Omega_n} r_\omega(\omega\cdot\mathbf{x})$$

satisfies

$$\begin{aligned}\|f_0-R\|_{L_2(\mathbf{B}^d)} &\le cn^{-r-(d-1)/2}\|f_0\|_{W^{r+(d-1)/2}(L_2(\mathbf{B}^d))} \\ &\le cn^{-r-(d-1)/2}\|f\|_{W^{r+(d-1)/2}(L_2(\mathbf{B}^d_{1/2}))}.\end{aligned} \tag{8.14}$$

On the ball $\mathbf{B}^d_{1/2}$, $f_0 = f$ and r_ω is in Z_n for each $\omega \in \Omega_n$. Therefore, (8.13) follows from (8.14). □

9. Examples and further remarks. In this section, we shall give some applications of the results of section 8. Theorem 8.2 implies that for any sequence of spaces Z_n, $n = 1, 2, \ldots$, contained in $L_2(J)$, $J = [-1/2, 1/2]$, that satisfy (8.2) we have the estimate (8.13) for $f \in W^{s+(d-1)/2}(L_2(J))$. The condition (8.2) is satisfied by all the standard spaces of approximation such as algebraic polynomials and spline functions (discussed in more detail later in this section). We wish to single out, for further elaboration, one particular example which appears frequently in wavelet theory, as well as in computer aided design.

Let ϕ be a univariate function with compact support on $\mathbf{R}$. Let ℓ be the smallest integer such that ϕ or one of its shifts $\phi(x-k)$, $k \in \mathbf{Z}$, is supported on $[0, \ell]$. If necessary, we can redefine ϕ to be one of its integer shifts and thereby require that ϕ is supported on $[0, \ell]$. We denote by $\mathcal{S} := \mathcal{S}(\phi)$ the shift-invariant space which is the $L_2(\mathbf{R})$-closure of finite linear combinations of the shifts $\phi(\cdot - j)$, $j \in \mathbf{Z}$, of ϕ. By dilation, we obtain the univariate spaces

$$\mathcal{S}^k := \{S(2^k \cdot) : S \in \mathcal{S}\}, \quad k \in \mathbf{Z}.$$

The approximation properties of the family of spaces $\mathcal{S}^k$ is well understood. In [BDR], there is a complete characterization (in terms of the Fourier transform of ϕ) of when the spaces $\mathcal{S}^k$ provide the Jackson estimates

$$\operatorname{dist}(g, \mathcal{S}^k)_{L_2(\mathbf{R})} \le C 2^{-ks} \|g\|_{W^s(L_2(\mathbf{R}))}. \tag{9.1}$$

For an integer s, we say that ϕ satisfies the Strang–Fix conditions of order s if

$$\hat{\phi}(0) \neq 0, \text{ and } D^j \hat{\phi}(2k\pi) = 0, \ k \in \mathbf{Z}, \ k \neq 0, \ j = 0, 1, \ldots, s-1. \tag{9.2}$$

If ϕ satisfies (9.2) and ϕ is piecewise continuous and of bounded variation, then $\mathcal{S}^k$ provides the approximation estimate (9.1) (see, e.g., [DL, Chapter 13]).

We denote by $\mathcal{S}^k(J)$, $k \ge 1$, the restrictions of the spaces $\mathcal{S}^k$ to the interval $J := [-1/2, 1/2]$. The functions $\phi(2^k t - j)$, $j = -\ell + 1 - 2^{k-1}, \ldots, 2^{k-1} - 1$, span $\mathcal{S}^k(J)$. Each function g in $W^s(L_2(J))$ can be extended to $\mathbf{R}$ with

$$\|g\|_{W^s(L_2(\mathbf{R}))} \le c \|g\|_{W^s(L_2(J))}.$$

It follows therefore that the spaces $\mathcal{S}^k(J)$ provide the approximation property (8.2) and hence Theorem 8.2 applies with $n = 2^k$. The functions R appearing in Theorem 8.2 are of the form

$$R(\mathbf{x}) = \sum_{j=-\ell+1-2^{k-1}}^{2^k-1} \sum_{\omega \in \Omega_{2^k}} c(j, \omega) \phi(2^k \mathbf{x} \cdot \omega - j).$$

There is another representation of the functions in $\mathcal{S}^k(J)$ related to sigmoidal functions. Let

$$\sigma(t) := \sum_{j=0}^{\infty} \phi(t - j). \tag{9.3}$$

Then the functions $\sigma(2^k t - j)$, $j = -\ell + 1 - 2^{k-1}, \ldots, 2^{k-1} - 1$, also span $\mathcal{S}^k(J)$. The function σ is 0 for t sufficiently large negative and 1 for t sufficiently large positive. However, it is not necessarily monotone (without additional assumptions on ϕ).

COROLLARY 9.1. *Let ϕ satisfy the Strang–Fix conditions* (9.2) *of order s. Then for each function $f \in W^{s+(d-1)/2}(L_2(\mathbf{B}^d_{1/2}))$, there is a function*

$$R(\mathbf{x}) = \sum_{j=-\ell+1+2^{k-1}}^{2^{k-1}-1} \sum_{\omega \in \Omega_{2^k}} c(j,\omega)\sigma(2^k \mathbf{x}\cdot\omega - j)$$

such that

$$\|f - R\|_{L_2(\mathbf{B}^d_{1/2})} \le c\, 2^{-(s+(d-1)/2)k} \|f\|_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d_{1/2}))}, \quad k = 1, 2, \dots,$$

with c independent of f and k.

For certain choices of ϕ above, we obtain that σ of (9.3) is a sigmoidal function in the terminology of neural networks. We recall that a sigmoidal function is a nonnegative, monotone, univariate function which has limits $= 0$ as $t \to -\infty$ and $= 1$ as $t \to \infty$. To obtain examples of such sigmoidal functions, we can take ϕ to be a B-spline. Let $\phi := N_{0,s}$, where for each $j \in \mathbf{Z}$ and $s = 1, 2, \dots$, $N_{j,s} := s^{-1} M_{j,s}$ is the B-spline of order s (see [DL, Chapter 5]) with breakpoints $\frac{j}{2n}, \dots, \frac{j+s}{2n}$. The function

$$\sigma_s(t) := \sum_{j=-s+1}^{\infty} N_{j,s}(t), \quad t \in \mathbf{R}$$

of (9.3) is a sigmoidal function, and, in the case $s = 1$, it is the unit impulse function $\chi_{[0,\infty)}$. The functions $\sigma_s(t - \frac{j}{2n})$, $j = -n, \dots, n+s-1$, form a basis for $\mathcal{S}_{n,s}$ the space of all splines of degree $s-1$ defined on J with breakpoints belonging to the set $\{\frac{-n+1}{2n}, \frac{-n+2}{2n}, \dots, \frac{n-1}{2n}\}$. From Theorem 8.2, we obtain the following.

COROLLARY 9.2. *For any $f \in W^{s+(d-1)/2}(L_2(\mathbf{B}^d_{1/2}))$, there are constants $c(k,\omega)$, $\omega \in \Omega_n$, $k = -n, \dots, n+s-1$, such that*

$$R(\mathbf{x}) = \sum_{\omega \in \Omega_n} \sum_{k=-n}^{n+s-1} c(k,\omega)\sigma_s\left(\mathbf{x}\cdot\omega - \frac{k}{2n}\right) \tag{9.4}$$

satisfies

$$\|f - R\|_{L_2(\mathbf{B}^d_{1/2})} \le c n^{-s-(d-1)/2} \|f\|_{W^{s+(d-1)/2}(L_2(\mathbf{B}^d_{1/2}))}$$

with c independent of f and n.

The functions R in (9.4) correspond to the outputs of a feed-forward neural network with $O(n^{d-1})$ nodes of computation. Thus, the corollary shows that such neural networks have computational efficiency comparable with standard methods of approximation like splines and wavelets.

The special case $s = 1$ in Corollary 9.2 is also noteworthy. In this case the function σ is the unit-impulse function and the functions R are piecewise constant. The order of approximation provided by Corollary 9.2 is somewhat surprising. One might expect that such piecewise constants could only provide approximation order 1 while the corollary gives approximation order $(d+1)/2$.

10. Appendix.

A1. Proof of (3.4). Since $\mathcal{P}_n$ is invariant under rotations, it is sufficient to prove that $\langle P(\mathbf{x}),\mathcal{U}_n(x_1)\rangle = 0$ for each $P \in \mathcal{P}_{n-1}$ or that

$$\langle \mathbf{x}^{\mathbf{m}},\mathcal{U}_n(x_1)\rangle := \int_{\mathbf{B}^d} \mathbf{x}^{\mathbf{m}}\mathcal{U}_n(x_1)\,d\mathbf{x} = 0 \quad \text{when} \quad |\mathbf{m}| \le n-1.$$

Write

$$\mathbf{B}_{x_1} := \{\mathbf{x}' = (x_2,\dots,x_d) : x_2^2 + \cdots + x_d^2 \le 1 - x_1^2\}.$$

We have

$$\langle \mathbf{x}^{\mathbf{m}},\mathcal{U}_n(x_1)\rangle = \int_I x_1^{m_1}\left(\int_{\mathbf{B}_{x_1}} x_2^{m_2}\dots x_d^{m_d}\,d\mathbf{x}'\right)\mathcal{U}_n(x_1)\,dx_1.$$

Because of the symmetry it is obvious that the inner integral above is equal to zero if at least one of $m_2,\dots,m_d$ is odd. Consider the case when all $m_2,\dots,m_d$ are even. We now change the rectangular coordinates in the inner integral to spherical and find

$$\int_{\mathbf{B}_{x_1}} x_2^{m_2}\dots x_d^{m_d}\,d\mathbf{x}' = c\int_0^{(1-x_1^2)^{1/2}} r^{m_2+\cdots+m_d+d-2}\,dr = c(1-x_1^2)^{\frac{1}{2}(m_2+\cdots+m_d+d-1)},$$

where c depends on $d, m_2,\dots,m_d$. Therefore,

$$\langle \mathbf{x}^m, C_n(x_1)\rangle = c\int_I x_1^{m_1}(1-x_1^2)^{\frac{1}{2}(m_2+\cdots+m_d)}\mathcal{U}_n(x_1)(1-x_1^2)^{\frac{d-1}{2}}\,dx_1 = 0$$

since the univariate polynomial $\mathcal{U}_n$ is orthogonal to $\mathcal{P}_{n-1}(I)$ in $L_2(I,w)$ (see (3.3) and (2.1)). □

A2. Proof of (3.10). We first show that for each $g \in L_1(I, w_{(d-1)/2})$

$$\mathcal{R}(g(\eta\cdot\mathbf{x});\xi,t) = |B^{d-2}|(1-t^2)^{\frac{d-1}{2}}\int_I g(\cos\theta\cos\psi + u\sin\theta\sin\psi)(1-u^2)^{\frac{d-2}{2}}\,du, \tag{10.1}$$

where $t =: \cos\theta$, $t \in I$, $\psi \in [0,\pi]$ is the angle between ξ and η ($\cos\psi = \xi\cdot\eta$), $|B^{d-2}|$ is the volume of the unit ball B^{d-2} in $\mathbf{R}^{d-2}$, $|B^{d-2}| = \frac{2\pi^{d/2-1}}{(d-2)\Gamma(d/2-1)}$, and $\mathcal{R}$ is the Radon transform defined in (3.23). Indeed, it is easily seen that

$$\mathcal{R}(g(\eta\cdot\mathbf{x});\xi,t) = |B^{d-2}|\int_{-\sqrt{1-t^2}}^{\sqrt{1-t^2}} g(t\cos\psi + v\sin\psi)(1-t^2-v^2)^{\frac{d-2}{2}}\,dv.$$

Substituting $v = (1-t^2)^{1/2}u$ in the above integral we get (10.1).

Our second step is to prove that

$$\mathcal{R}(C_n^{d/2}(\eta\cdot\mathbf{x});\xi,t) = |B^{d-2}|\frac{2^{d-1}\Gamma^2(d/2)n!}{\Gamma(n+d)}(1-t^2)^{\frac{d-1}{2}}C_n^{d/2}(t)C_n^{d/2}(\xi\cdot\eta). \tag{10.2}$$

Indeed, the classical addition theorem for Legendre (Gegenbauer) polynomials can be written as follows (see [E, p. 178]):

$$\begin{aligned} &C_n^\lambda(\cos\theta\cos\psi + \sin\theta\sin\psi\cos\varphi)\\ &= \sum_{m=0}^n 2^m(2\lambda+2m-1)(n-m)!\frac{[(\lambda)_m]^2}{(2\lambda-1)_{n+m+1}}\\ &\times (\sin\theta)^m C_{n-m}^{\lambda+m}(\cos\theta)(\sin\psi)^m C_{n-m}^{\lambda+m}(\cos\psi)C_m^{\lambda-1/2}(\cos\varphi)\end{aligned}$$

and hence, for $\lambda = d/2$, and $u := \cos\varphi$, $u \in I$, we have

$$\begin{aligned} &C_n^{d/2}(\cos\theta\cos\psi + u\sin\theta\sin\psi) \\ &= \sum_{m=0}^{n} 2^m(d+2m-1)(n-m)!\frac{[(d/2)_m]^2}{(d-1)_{n+m+1}} \\ &\times (\sin\theta)^m C_{n-m}^{d/2+m}(\cos\theta)(\sin\psi)^m C_{n-m}^{d/2+m}(\cos\psi)C_m^{(d-1)/2}(u). \end{aligned}$$

We now insert this into (10.1) and use the fact that $C_m^{(d-1)/2}(u)$, $m = 1, 2, \ldots$, are orthogonal to the constants in $L_2(I, w_{(d-1)/2})$ to obtain

$$\begin{aligned} &\mathcal{R}(C_n^{d/2}(\eta\cdot\mathbf{x});\xi,t) \\ &= |B^{d-2}|(1-t^2)^{(d-1)/2}\frac{(d-1)n!}{(d-1)_{n+1}}C_n^{d/2}(\cos\theta)C_n^{d/2}(\cos\psi)\int_I (1-u^2)^{(d-2)/2}\,du. \end{aligned}$$

This implies (10.2).

We finally use (10.2) to obtain

$$\begin{aligned} &\int_{\mathbf{B}^d} C_n^{d/2}(\eta\cdot\mathbf{x})C_n^{d/2}(\xi\cdot\mathbf{x})\,d\mathbf{x} = \int_I \mathcal{R}(C_n^{d/2}(\eta\cdot\mathbf{x});\xi,t)C_n^{d/2}(t)\,dt \\ &= |B^{d-2}|\frac{2^{d-1}\Gamma^2(d/2)n!}{\Gamma(n+d)}C_n^{d/2}(\eta\cdot\xi)\int_I [C_n^{d/2}(t)]^2(1-t^2)^{(d-1)/2}\,dt \\ &= \gamma_{n,d}C_n^{d/2}(\eta\cdot\xi), \end{aligned}$$

where

$$\gamma_{n,d} := |B^{d-2}|\frac{2^{d-1}\Gamma^2(\frac{d}{2})n!}{\Gamma(n+d)}h_{n,d/2}.$$

Simple calculations show that this is (3.10). See [RK]. □

A3. Proof of (3.16). The following relation between contiguous Gegenbauer polynomials holds (see [E, p. 178], (36)):

$$(n+\lambda)C_{n+1}^{\lambda-1} = (\lambda-1)\left[C_{n+1}^{\lambda} - C_{n-1}^{\lambda}\right], \quad \lambda > 1.$$

Also, $C_0^\lambda(t) = 1$ and $C_1^\lambda(t) = 2\lambda t$. These identities readily imply

$$C_n^\lambda = \sum_{j=0}^{[n/2]} \frac{n-2j+\lambda-1}{\lambda-1}C_{n-2j}^{\lambda-1}. \tag{10.3}$$

Simple calculations show that (10.3) with $\lambda = d/2$ ($d > 2$) is (3.16). □

A4. Proof of (3.11). Identity (3.11) follows from the fact that $\mathcal{U}_n(\xi\cdot\mathbf{x})$ (as a function of ξ) is a spherical polynomial in $\mathcal{H}_n \oplus \mathcal{H}_{n-2} \oplus \cdots \oplus \mathcal{H}_\epsilon$ and $\nu_n\mathcal{U}_n(\xi\cdot\eta)/\mathcal{U}_n(1)$ is the reproducing kernel for this space (see (3.17)). □

BULK AND CONTACT ENERGIES: NUCLEATION AND RELAXATION*

IRENE FONSECA† AND GIOVANNI LEONI‡

Abstract. An integral representation formula in $BV(\Omega;\mathbb{R}^p)$ for the relaxation $\mathcal{H}(u,\Omega)$ with respect to the L^1 topology of functionals of the general form

$$H(u,\Omega) := \int_\Omega h(x,u(x),\nabla u(x))\,dx + \int_{\partial\Omega} \theta(x,T\,u(x))\,dH_{N-1}(x), \quad u \in W^{1,1}(\Omega;\mathbb{R}^p),$$

is obtained. Here $\Omega \subset \mathbb{R}^N$ is an open, bounded set of class C^2, T is the trace operator on $\partial\Omega$, and H_{N-1} is the $N-1$-dimensional Hausdorff measure. The main hypotheses on the functions h and θ are that $h(x,u,\cdot)$ is quasiconvex and has linear growth, and that $\theta(x,\cdot)$ is Lipschitz. The understanding of nucleation phenomena for materials undergoing phase transitions leads to the study of constrained minimization problems of the type

$$\inf\left\{\mathcal{H}(u,\Omega) + \int_\Omega \tau(x,u(x))\,dx :\ u \in BV(\Omega;K)\right\},$$

where K is a nonempty compact subset of $\mathbb{R}^p$, and $\tau : \Omega \times K \to \mathbb{R}$ is a continuous function. It is shown that if $\tau(x,\cdot)$ is a double well potential vanishing only at α and β, then minimizers u of the total energy are given by pure phases; that is, there exists $\Omega_u \subset \Omega$ such that $u(x) = \alpha$ for $\mathcal{L}^N$ a.e. $x \in \Omega_u$ (liquid) and $u(x) = \beta$ for $\mathcal{L}^N$ a.e. $x \in \Omega\backslash\Omega_u$ (solid). This conclusion is closely related to results previously obtained by Visintin, and where the interfacial energy is assumed to satisfy a *generalized co-area formula*. Here this condition is replaced by a property which may be verified by energies for which the co-area formula might not hold.

Key words. functions of bounded variation, nucleation, relaxation, bulk and contact energies, generalized co-area formula

1. Introduction.

This paper is divided into two parts. In the first part we obtain an integral representation formula in $BV(\Omega;\mathbb{R}^p)$ for the relaxation $\mathcal{H}(u,\Omega)$ with respect to the L^1 topology of functionals of the general form

(1.1)
$$H(u,\Omega) := \int_\Omega h(x,u(x),\nabla u(x))\,dx + \int_{\partial\Omega} \theta(x,T\,u(x))\,dH_{N-1}(x), \quad u \in W^{1,1}(\Omega;\mathbb{R}^p),$$

where $\Omega \subset \mathbb{R}^N$ is an open, bounded set of class C^2, T is the trace operator on $\partial\Omega$, and H_{N-1} is the $N-1$-dimensional Hausdorff measure. The main hypotheses on the functions h and θ are that $h(x,u,\cdot)$ is quasiconvex and has linear growth, and that $\theta(x,\cdot)$ is Lipschitz.

Part of this research was undertaken during the author's visit to the Center for Nonlinear Analysis under the CNA/CMU-CNR project.

Under a *degenerate* coercivity assumption on $h(x,u,\cdot)$ we obtain the following integral representation for $u \in BV(\Omega;\mathbb{R}^p)$:

$$\begin{aligned}\mathcal{H}(u,\Omega) = &\int_\Omega h(x,u(x),\nabla u(x))\,dx + \int_\Omega h^\infty(x,u(x),dC(u))\\ &+\int_{S(u)\cap\Omega} K_h(x,u^-(x),u^+(x),\nu_u(x))\,dH_{N-1}(x)\\ &+\int_{\partial\Omega}\theta(x,T\,u(x))\,dH_{N-1}(x),\end{aligned} \tag{1.2}$$

where ∇u is the density of the absolutely continuous part of the distributional derivative Du with respect to the N-dimensional Lebesgue measure $\mathcal{L}^N$, $(u^+ - u^-)$ is the jump across the interface $S(u)$, and $C(u)$ is the Cantor part of Du. For the canonical model where $h(x,u,\nabla u) := \sigma|\nabla u|$, $\sigma > 0$, the relaxed energy $\mathcal{H}(u,\Omega)$ reduces to

$$\mathcal{H}(u,\Omega) = \sigma\int_\Omega |Du| + \int_{\partial\Omega}\theta(x,T\,u)\,dH_{N-1}, \qquad u \in BV(\Omega;\mathbb{R}^p). \tag{1.3}$$

In the scalar case where $p = 1$, the lower semicontinuity of the functional (1.3) was proved by Massari and Pepe [MP] when $\theta(x,u) := \hat\sigma|u|$, with $|\hat\sigma| \le \sigma$, and by Modica [Mo2] under the assumption that

$$|\theta(x,u) - \theta(x,u_1)| \le \sigma|u - u_1| \tag{1.4}$$

for all $x \in \partial\Omega$ and all u, $u_1 \in \mathbb{R}$.

One of the motivations for the introduction of a relaxed energy is that nonconvex variational problems may not have a minimizer in the space of smooth functions; therefore, in order to apply the direct method of calculus of variations one has to extend the original functional. Although Sobolev spaces are considered to be the natural extension to the space of smooth functions, in recent years the theory of phase transitions, and the need to determine effective energies for materials exhibiting instabilities such as fractures and defects, have led us to further extend the domain of functionals of the form (1.1) in order to include functions u which present discontinuities along surfaces. Motivated somewhat by Lebesgue's definition of surface area, Serrin in [Se1, Se2] proposed the following notion for the relaxed energy of $H(u,\Omega)$ (in the case where $\theta \equiv 0$):

$$\mathcal{H}(u,\Omega) := \inf_{\{u_n\}}\left\{\liminf_{n\to\infty} H(u_n,\Omega) :\ u_n \in W^{1,1}(\Omega;\mathbb{R}^p),\ u_n \to u \quad \text{in} \quad L^1(\Omega;\mathbb{R}^p)\right\}.$$

One of the main issues in the calculus of variations concerns the search and characterization of an integral representation for $\mathcal{H}(u,\Omega)$ in the space $BV(\Omega;\mathbb{R}^p)$.

In the scalar case where $p = 1$ and $h(x,u,\cdot)$ is convex, the integral representation (1.2) was first obtained by Goffman and Serrin [GSe] when $h = h(\nabla u)$ (see also [Re]), and by Giaquinta, Modica, and Souček [GMS] for $h = h(x,\nabla u)$. These results were then extended by Dal Maso [DM] who considered the general case where $h = h(x,u,\nabla u)$ and emphasized the important role of the coercivity condition in establishing (1.2). Indeed, Dal Maso showed that, while (1.2) holds for nonnegative functions $h = h(u,\nabla u)$ without any lower bound on h, when $h = h(x,\nabla u)$, or, more generally, when $h = h(x,u,\nabla u)$, the representation (1.2) may fail unless one requires a weak coercivity assumption of the form

$$h(x,u,\nabla u) \ge g(x,u)|\nabla u|. \tag{1.5}$$

In the vectorial case where $p > 1$ and $h(x, u, \cdot)$ is quasiconvex, Ambrosio and Dal Maso [ADM2] proved (1.2) when $h = h(\nabla u)$ and without (1.5). Independently, Fonseca and Müller [FM2] obtained this result for general functions $h(x, u, \nabla u)$ which verify (1.5).

In all the works mentioned above $\theta \equiv 0$, and one of the purposes of this paper is to extend these results to the new case where possibly $\theta \not\equiv 0$. The relaxation of functionals of the type (1.1) arises in the van der Waals–Cahn–Hilliard theory of phase transitions for fluids (cf. [vdW, CH1, CH 2]). In this context the boundary term $\int_{\partial\Omega} \theta(x, T\,u)\, dH_{N-1}$ represents the contact energy between the fluid and the container walls, where $\theta(x, u)$ is the contact energy per unit area when the density is u (see [C, G, Mo1]).

We present here two relaxation results. In Theorem 3.5 we show that, without any a priori coercivity on the function h, the functional on the right-hand side of (1.2) actually gives the integral representation for the following relaxed energy:

$$\mathcal{H}_b(u,\Omega) = \inf_{\{u_n\}} \Big\{ \liminf_{n\to\infty} H(u_n,\Omega) :\ u_n \in W^{1,1}(\Omega;\mathbb{R}^p),\ u_n \to u \text{ in } L^1(\Omega;\mathbb{R}^p),\ \sup_n ||u_n||_{W^{1,1}} < \infty \Big\},$$

while in Theorem 3.2 we prove that $\mathcal{H}_b(u, \Omega) = \mathcal{H}(u, \Omega)$ if h satisfies a condition of the type (1.5). Therefore we may conclude that the right-hand side of (1.2) always coincides with $\mathcal{H}_b(u, \Omega)$, and we restate all the results mentioned above by saying that $\mathcal{H}_b(u, \Omega) = \mathcal{H}(u, \Omega)$ in the scalar case if either $h = h(u, \nabla u)$ or if $h = h(x, u, \nabla u)$ satisfies (1.5), and in the vectorial case if either $h = h(\nabla u)$ or if $h = h(x, u, \nabla u)$ satisfies (1.5). In the remaining cases it may happen that $\mathcal{H}(u, \Omega) < \mathcal{H}_b(u, \Omega)$.

It is worth mentioning that the fact that the relaxation $\mathcal{H}(u, \Omega)$ is simply given by the decoupled sum of the relaxation of the functional $\int_\Omega h(x, u, \nabla u)\, dx$ and the contact energy may be somewhat deceiving, since it hides the competition between the bulk energy and the contact energy. A more insightful way to look at (1.1), and consequently, at (1.2), is perhaps to consider the equivalent form

$$\begin{aligned} H(u,\Omega) = &\int_\Omega \big\{ h(x,u(x),\nabla u(x)) + \varphi(x)\cdot \nabla u^T(x) \nabla_u \theta(x,u(x)) \big\}\, dx \\ &+ \int_\Omega \theta(x,u(x)) \operatorname{div}\varphi(x)\, dx + \int_\Omega \varphi(x)\cdot \nabla_x \theta(x,u(x))\, dx, \end{aligned} \tag{1.6}$$

where $\varphi \in C^1(\mathbb{R}^N;\mathbb{R}^N)$ depends only on Ω and $|\varphi(x)| < 1$ in Ω (see Lemma 2.1). In particular, in the isotropic case where $h(x, u, \nabla u) := \sigma|\nabla u|$, $\sigma > 0$, we obtain

$$\begin{aligned} H(u,\Omega) = &\int_\Omega \big\{ \sigma\,|\nabla u(x)| + \varphi(x)\cdot \nabla u^T(x) \nabla_u \theta(x,u(x)) \big\}\, dx \\ &+ \int_\Omega \theta(x,u(x)) \operatorname{div}\varphi(x)\, dx + \int_\Omega \varphi(x)\cdot \nabla_x \theta(x,u(x))\, dx, \end{aligned}$$

and it is clear that the functional H is not bounded from below in general, unless one assumes a condition of the type

$$|\nabla_u \theta(x,u)| \le \sigma \qquad \text{for a.e. } x \in \Omega \quad \text{and for all } u \in \mathbb{R}^p,$$

which is essentially the condition found by Massari and Pepe [MP] and by Modica [Mo2]. We note that once (1.1) is written in the form (1.6), well-known integral

representation results for relaxation of bulk energy functionals apply (see [FM2, FR]). This is illustrated first in section 2 in the scalar case $p = 1$ and for a class of energies including the typical ones considered by Visintin (see [V1, V2]),

$$h(x, u, \xi) := \sigma\,|\xi|, \qquad \theta(x, u) := \hat{\sigma}\,u.$$

More general models, relevant to the study of anisotropic materials and nonlinear contact forces, are studied in section 3. In particular, degenerate bounds for the bulk energy density h, as introduced in [FM2] in the vectorial case, may prove to be useful in the analysis of phase transition problems.

In the second part of the paper, sections 4 and 5, we are concerned with constrained minimization problems of the type

$$\inf\left\{\mathcal{H}(u,\Omega) + \int_\Omega \tau(x, u(x))\,dx :\ u \in BV(\Omega; K)\right\},$$

where K is a nonempty compact set of $\mathbb{R}^p$, and $\tau : \Omega \times K \to \mathbb{R}$ is a continuous function. These kinds of problems have important applications in the study of phase transformations and in nucleation phenomena (cf. [V1, V2]). According to the van der Waals–Cahn–Hilliard theory of phase transitions (cf. [CH1, CH2, vdW]), the total energy of a fluid of total mass m and density $u(x)$, confined in a bounded container $\Omega \subset \mathbb{R}^N$, is given by

(1.7)
$$E_\varepsilon(u) := \varepsilon^2 \int_\Omega |\nabla u|^2\,dx + \int_\Omega W_1(u)\,dx + \varepsilon \int_{\partial\Omega} W_2(T\,u)\,dH_{N-1}, \qquad u \in W^{1,1}(\Omega;\mathbb{R}),$$

where the coarse-grain energy $W_1(u)$ is a double well potential vanishing only at α and β and corresponding to the stable two-phase configuration of the fluid, the gradient term $\varepsilon^2|\nabla u|^2$ models the interfacial energy across a smooth transition layer, with ε a small parameter, and W_2 represents the contact energy between the fluid and the container walls. The stable configurations of the fluid correspond to solutions of the problem (see [C])

$$\inf\left\{E_\varepsilon(u) :\ u \in W^{1,1}(\Omega;\mathbb{R}),\ \int_\Omega u\,dx = m\right\}.$$

Confirming a conjecture of Gurtin [G], Modica in [Mo2] was able to show that if a sequence of minimizers $\{u_\varepsilon\}$ converges in L^1 to a function u_0, then u_0 solves the *liquid-drop problem*

$$\inf\left\{\mathcal{H}(u,\Omega) :\ u \in BV(\Omega;\{\alpha,\,\beta\})\right\},$$

where $\mathcal{H}(u,\Omega)$ is the relaxed energy of

$$H(u,\Omega) = \int_\Omega |\nabla u|\,dx + \hat{\sigma}\int_{\partial\Omega} T\,u\,dH_{N-1}, \qquad u \in W^{1,1}(\Omega;\mathbb{R}).$$

Here $\hat{\sigma}$ depends only on W_1 and W_2. The liquid-drop problem admits a solution if and only if $|\hat{\sigma}| \le 1$. An analogous result is due to Alberti, Bouchitté, and Seppecher [ABS] who recently showed that if the parameter ε in front of the contact energy in (1.7) is replaced by λ_ε, where

$$\lim_{\varepsilon\to 0} \varepsilon \log \lambda_\varepsilon = K \in (0,\infty)$$

and W_2 is a double well potential which vanishes only at α_1 and β_1, then the limit problem is given by a different model for capillarity with line tension. It is worth noting that in this case the effective energy takes the form

$$\mathcal{H}(u,\Omega) = \int_\Omega |D(G(u))| + \inf\left\{\int_{\partial\Omega} |G(T\,u) - G(v)|\,dH_{N-1} + \frac{K}{\pi}\int_{\partial\Omega} |Dv|^2 : v \in BV(\partial\Omega;\{\alpha_1,\beta_1\})\right\}$$

for $u \in BV(\Omega;\{\alpha,\beta\})$ and $\mathcal{H}(u,\Omega) = \infty$ otherwise. Here G is a primitive of $2\sqrt{W_1}$. It can be seen immediately that in this capillarity model the contact energy is nonlocal and strongly nonlinear, and again this leads us to consider functions θ other than $\theta(x,u) = \hat{\sigma}\,u$ (see [V1, V2] and section 3).

In the last section of the paper we prove some minimization results which are related to solid nucleation. For a complete description of this phenomenon we refer to the recent monograph of Visintin [V1] and to the bibliography contained therein. By *solid nucleation* we mean the formation of a new solid phase, that is, of a connected component of solid in a liquid. If the new solid phase is formed in the interior of the liquid, the nucleation is called *homogeneous*, while if it is also in contact with other substances, such as the container, impurities dispersed in the liquid or nucleants, then we name it *heterogeneous* nucleation (cf. [V1, Ch. VII.2]). By thinking of these impurities or particles as holes in the domain Ω, we can represent the contact energy by an integral term over the boundary of Ω. Furthermore, since the new solid phase is formed through crystallization, and crystals are *anisotropic*, the classical isotropic interfacial energy $\sigma\int_\Omega |Du|$ is now replaced by $\int_\Omega h(x,Du)$. In the applications one sees often $h(x,Du) = |A(x)Du|$, where $A(x)$ is a nonnegative definite $N\times N$ tensor (cf. [V1, p. 157]).

The main results of this part are Theorems 5.1 and 5.4, where we show that minimizers u of the total energy are given by pure phases; that is, there exists $\Omega_u \subset \Omega$ such that $u(x) = \alpha$ for $\mathcal{L}^N$ a.e. $x \in \Omega_u$ (liquid) and $u(x) = \beta$ for $\mathcal{L}^N$ a.e. $x \in \Omega\backslash\Omega_u$ (solid). This result is closely related to Theorem 2 in [V2], where the interfacial energy is assumed to satisfy a *generalized co-area formula*. We replace here this condition by some hypotheses which are easy to verify and allow us to include interfacial energies of the form $\int_\Omega h(x,Du)$, where $h(x,\cdot)$ is convex and positively homogeneous of degree one, and for which the co-area formula might not hold.

2. Relaxation: A simple model problem. In what follows $\Omega \subset \mathbb{R}^N$ is an open, bounded set of class C^2, and T stands for the trace operator on $\partial\Omega$.

In this section we characterize the relaxed energy $\mathcal{H}$ when

(A_1) $h : \Omega\times\mathbb{R}^N \to [0,+\infty)$ is a continuous function;

(A_2) $h(x,\cdot)$ is convex for all $x \in \Omega$;

(A_3) $\sigma|\xi| \le h(x,\xi) \le C(1+|\xi|)$, for some $\sigma, C > 0$, and for all $(x,\xi) \in \Omega\times\times\mathbb{R}^N$;

(A_4) $\theta(x,u) := \hat{\sigma}\,u$, for some $|\hat{\sigma}| \le \sigma$ and for all $(x,u) \in \Omega\times\mathbb{R}$.

The main idea is to rewrite

$$H(u,\Omega) := \int_\Omega h(x,\nabla u(x))\,dx + \int_{\partial\Omega} \hat{\sigma}\,T\,u(x)\,dH_{N-1}(x), \quad u \in W^{1,1}(\Omega;\mathbb{R}^p),$$

as a bulk energy and then apply known relaxation results from $W^{1,1}$ to BV (see, e.g., [DM, FM2]).

We start with some notation. For any $\nu \in S^{N-1} := \{x \in \mathbb{R}^N : |x| = 1\}$ let $\{\nu_1,\dots,\nu_{N-1},\nu\}$ be an orthonormal basis of $\mathbb{R}^N$ varying continuously with ν, and

$Q_\nu := \{x \in \mathbb{R}^N : |x\cdot\nu_i| < 1/2,\ |x\cdot\nu| < 1/2,\ i = 1,\dots,N-1\}$ be a unit cube centered at the origin with two of its faces orthogonal to the direction ν.

If g is a positively homogeneous function of degree one and if μ is an $\mathbb{R}^m$-valued measure, then we define

$$\int_\Omega g(d\mu) := \int_\Omega g(\alpha(x))\, d|\mu(x)|,$$

where $|\mu|$ is the nonnegative total variation measure of μ, and $\alpha : \Omega \to S^{m-1}$ is the Radon–Nikodym derivative of μ with respect to $|\mu|$.

We recall briefly some facts about functions of bounded variation which will be useful in the sequel. A function $u \in L^1(\Omega;\mathbb{R}^p)$ is said to be of *bounded variation* if for all $i = 1,\dots,p$, and $j = 1,\dots,N$, there exists a Radon measure μ_{ij} such that

$$\int_\Omega u_i(x)\,\frac{\partial\varphi}{\partial x_j}\,(x)\,dx = -\int_\Omega \varphi(x)\,d\mu_{ij}$$

for every $\varphi \in C_0^1(\Omega;\mathbb{R})$. The distributional derivative Du is the matrix-valued measure with components μ_{ij}. Given $u \in BV(\Omega;\mathbb{R}^p)$ the *approximate upper* and *lower limit* of each component u_i, $i = 1,\dots,p$, are given by

$$u_i^+(x) := \inf\left\{t \in \mathbb{R} : \lim_{\varepsilon\to 0^+} \frac{1}{\varepsilon^N}\,\mathcal{L}^N\left(\{y \in \Omega \cap B(x,\varepsilon) :\ u_i(y) > t\}\right) = 0\right\}$$

and

$$u_i^-(x) := \sup\left\{t \in \mathbb{R} : \lim_{\varepsilon\to 0^+} \frac{1}{\varepsilon^N}\,\mathcal{L}^N\left(\{y \in \Omega \cap B(x,\varepsilon) :\ u_i(y) < t\}\right) = 0\right\},$$

while the *jump set* of u, or *singular set*, is defined by

$$S(u) := \cup_{i=1}^p \{x \in \Omega :\ u_i^-(x) < u_i^+(x)\}.$$

It is well known that $S(u)$ is $N-1$ rectifiable; i.e.,

$$S(u) = \cup_{n=1}^\infty K_n \cup E,$$

where $H_{N-1}(E) = 0$ and K_n is a compact subset of a C^1 hypersurface. If $x \in \Omega\backslash S(u)$, then $u(x)$ is taken as the common value of $(u_1^+(x),\dots,u_p^+(x))$ and $(u_1^-(x),\dots,u_p^-(x))$. It can be shown that $u(x) \in \mathbb{R}^p$ for H_{N-1} a.e. $x \in \Omega\backslash S(u)$. Furthermore, for H_{N-1} a.e. $x \in S(u)$ there exist a unit vector $\nu_u(x) \in S^{N-1}$, normal to $S(u)$ at x, and two vectors $u^-(x)$, $u^+(x) \in \mathbb{R}^p$ (the traces of u on $S(u)$ at the point x) such that

$$\lim_{r\to 0} \frac{1}{r^N} \int_{\{y\in B(x_0,r):\,(y-x)\cdot\nu_u(x)>0\}} |u(y) - u^+(x)|^{N/(N-1)} dy = 0$$

and

$$\lim_{r\to 0} \frac{1}{r^N} \int_{\{y\in B(x_0,r):\,(y-x)\cdot\nu_u(x)<0\}} |u(y) - u^-(x)|^{N/(N-1)} dy = 0.$$

Note that in general $(u_i)^+ \neq (u^+)_i$ and $(u_i)^- \neq (u^-)_i$. Moreover, the Sobolev inequality

$$\left(\int_\Omega |u(x)|^{N/(N-1)} dx\right)^{(N-1)/N} \leq C(N)||u||_{BV}$$

holds in $BV(\Omega;\mathbb{R}^p)$ when $N>1$. Finally, Du may be represented as

$$Du = \nabla u\,\mathcal{L}^N + (u^+ - u^-)\otimes \nu_u\, H_{N-1}\lfloor S(u) + C(u),$$

where ∇u is the density of the absolutely continuous part of Du with respect to the N-dimensional Lebesgue measure $\mathcal{L}^N$. These three measures are mutually singular.

LEMMA 2.1. *There exists $\varphi\in C_0^1(\mathbb{R}^N;\mathbb{R}^N)$ with $|\varphi(x)|<1$ in Ω such that for any $v\in BV(\Omega;\mathbb{R}^p)$,*

$$\int_{\partial\Omega} T\,v(x)\,dH_{N-1}(x) = \int_\Omega v(x)\mathrm{div}\,\varphi(x)\,dx + \int_\Omega \varphi(x)\cdot d(D(v(x))).$$

Proof. Since $\partial\Omega$ is compact and of class C^2, we can find a finite open covering $\{U_j\}_j$ of $\partial\Omega$, where U_j are balls centered at points of $\partial\Omega$, $j=1,\dots,P$, and for each U_j there is a C^2 diffeomorphism $\Phi_j: U_j\to\Phi_j(U_j)$ such that $\Phi_j(U_j)\subset B(0,R_j)\subset\mathbb{R}^N$ for some $R_j>0$,

$$\Omega\cap U_j = \{x\in U_j:\,(\Phi_j(x))_N<0\} \tag{2.1}$$

and for $x\in\partial\Omega\cap U_j$ the exterior normal to $\partial\Omega$ at x is given by

$$n(x,\Omega) = \frac{\nabla\Phi_j^T(x)\,e_N}{|\nabla\Phi_j^T(x)\,e_N|}.$$

Let Ψ be a partition of the unity for $\cup_{j=1}^P U_j$ subordinate to $\{U_j\}_j$. For any $\psi\in\Psi$ there exists $j\in\{1,\dots,P\}$ such that $\psi\in C_0^\infty(U_j)$, and we define

$$\varphi_\psi(x) := \frac{\nabla\Phi_j^T(x)\,e_N}{|\nabla\Phi_j^T(x)\,e_N|}\left(1+\frac{(\Phi_j(x))_N}{R_j}\right)\psi(x); \tag{2.2}$$

then $\varphi_\psi(x)\in C_0^1(U_j;\mathbb{R}^N)$ and $|\varphi_\psi(x)|<1$ for $x\in\Omega\cap U_j$. If we set φ_ψ to be zero outside U_j we obtain that $\varphi_\psi(x)\in C_0^1(\mathbb{R}^N;\mathbb{R}^N)$, and thus we can apply the trace theorem (cf. [EG, Thm. 5.3.1]) to the BV function v, and we have

$$\begin{aligned}\int_{\partial\Omega}\varphi_\psi(x)\cdot n(x,\Omega)\,T\,v(x)\,dH_{N-1}(x)&\\ = \int_\Omega v(x)\mathrm{div}\,\varphi_\psi(x)\,dx + \int_\Omega \varphi_\psi(x)\cdot d(D(v(x))).&\end{aligned}$$

On the other hand, since by (2.1) $\varphi_\psi(x) = n(x,\Omega)\,\psi(x)$ if $x\in\partial\Omega\cap U_j$, while $\varphi_\psi(x)=0$ if $x\in\partial\Omega\backslash U_j$, we get

$$\int_{\partial\Omega}\varphi_\psi(x)\cdot n(x,\Omega)\,T\,v(x)\,dH_{N-1}(x) = \int_{\partial\Omega}\psi(x)T\,v(x)\,dH_{N-1}(x).$$

Hence

$$\begin{aligned}\int_{\partial\Omega} T\,v(x)\,dH_{N-1}(x) &= \sum_{\psi\in\Psi}\int_{\partial\Omega}\psi(x)T\,v(x)\,dH_{N-1}(x)\\ &= \int_\Omega v(x)\,\mathrm{div}\left(\sum_{\psi\in\Psi}\varphi_\psi(x)\right)dx + \int_\Omega\left(\sum_{\psi\in\Psi}\varphi_\psi(x)\right)\cdot d(D(v(x))).\end{aligned}$$

The proof of Lemma 2.1 is complete if we show that $\varphi(x) := \sum_{\psi\in\Psi} \varphi_\psi(x)$ satisfies $|\varphi(x)| < 1$ in Ω. Fix $x \in \Omega$. If $x \notin \cup_{j=1}^P U_j$, then $\varphi(x) = 0$. If $x \in \cup_{j=1}^P U_j$, then $\sum_{\psi\in\Psi} \psi(x) = 1$, and so there exists at least one $\psi_0 \in \Psi$ such that $\psi_0(x) > 0$. Let $j \in \{1, \dots, P\}$ be such that $\psi_0 \in C_0^\infty(U_j)$. Then by (2.1) and (2.2)

$$|\varphi_{\psi_0}(x)| = \left(1 + \frac{(\Phi_j(x))_N}{R_j}\right) \psi_0(x) < \psi_0(x),$$

and consequently, since $\psi(x) = 0$ for all but finitely many $\psi \in \Psi$,

$$|\varphi(x)| \le \sum_{\psi\in\Psi} |\varphi_\psi(x)| < \sum_{\psi\in\Psi} \psi(x) = 1. \qquad \square$$

Using this lemma, we are now in position to obtain an integral representation for the relaxed energy

$$\mathcal{H}(u,\Omega) := \inf_{\{u_n\}} \left\{ \liminf_{n\to\infty} H(u_n,\Omega) :\ u_n \in W^{1,1}(\Omega;\mathbb{R}^p),\ u_n \to u \quad \text{in} \quad L^1(\Omega;\mathbb{R}^p) \right\}.$$

THEOREM 2.2. *We have that*

$$\begin{aligned}\mathcal{H}(u,\Omega) = &\int_\Omega h(x,\nabla u(x))\,dx + \int_\Omega h^\infty(x, dC(u)) \\ &+ \int_{S(u)\cap\Omega} h^\infty(x, (u^+(x) - u^+(x)) \otimes \nu_u(x))\, dH_{N-1}(x) \\ &+ \int_{\partial\Omega} \hat\sigma\, T\, u(x)\, dH_{N-1}(x),\end{aligned}$$

where the recession function h^∞ of h is defined as

$$h^\infty(x,\xi) := \lim_{t\to\infty} \frac{h(x, t\,\xi)}{t}.$$

Proof. In light of Lemma 2.1 we may rewrite the energy $H(u,\Omega)$ as

$$\begin{aligned}H(u,\Omega) &= \int_\Omega [h(x,\nabla u(x)) + \hat\sigma\, \varphi(x)\cdot\nabla u(x)]\,dx + \int_\Omega \hat\sigma\, u(x)\mathrm{div}\varphi(x)\,dx \\ &= \int_\Omega f(x,\nabla u(x))\,dx + \int_\Omega \hat\sigma\, u(x)\mathrm{div}\varphi(x)\,dx,\end{aligned}$$

where $|\varphi| < 1$ in Ω, and $f(x,\xi) := h(x,\xi) + \hat\sigma\,\varphi(x)\cdot\xi$. Since

$$(\sigma - \hat\sigma\,|\varphi(x)|)|\xi| \le f(x,\xi) \le C'(1 + |\xi|)$$

for some $C' > 0$, we may use the relaxation arguments introduced in [FM1, FM2], taking into account that the relaxation method is *local*, so that on each ball $B(x_0,\varepsilon) \subset\subset \Omega$ there is an upper bound $|\varphi(x)| < \alpha < 1$ and thus f is coercive. Therefore, and in view of the strong continuity in L^1 of the mapping

$$u \mapsto \int_\Omega \hat\sigma\, u(x)\mathrm{div}\varphi(x)\,dx,$$

we conclude that (see also [ADM2, DM])

$$\begin{aligned}\mathcal{H}(u,\Omega) &= \int_\Omega f(x,\nabla u(x))\,dx + \int_\Omega f^\infty(x,dC(u))\\ &+ \int_{S(u)\cap\Omega} f^\infty(x,(u^+(x)-u^+(x))\otimes\nu_u(x))\,dH_{N-1}(x) + \int_\Omega \hat\sigma\, u(x)\mathrm{div}\varphi(x)\,dx\\ &= \int_\Omega h(x,\nabla u(x))\,dx + \int_\Omega h^\infty(x,dC(u))\\ &+ \int_{S(u)\cap\Omega} h^\infty(x,(u^+(x)-u^+(x))\otimes\nu_u(x))\,dH_{N-1}(x) + \int_{\partial\Omega}\hat\sigma\, T\,u(x)\,dH_{N-1}(x),\end{aligned}$$

where we have used once again Lemma 2.1 in the last equality. □

3. Relaxation: A general model. Here we consider a more general model corresponding to the functional

$$H(u,\Omega) := \int_\Omega h(x,u(x),\nabla u(x))\,dx + \int_{\partial\Omega}\theta(x,T\,u(x))\,dH_{N-1}(x)$$

defined on the Sobolev space $W^{1,1}(\Omega;\mathbb{R}^p)$, where $\Omega\subset\mathbb{R}^N$ is an open, bounded set of class C^2, T is the trace operator on $\partial\Omega$, H_{N-1} is the $N-1$-dimensional Hausdorff measure, and the functions

$$h:\Omega\times\mathbb{R}^p\times\mathbb{M}^{p\times N}\to[0,\infty),\qquad \theta:\partial\Omega\times\mathbb{R}^p\to\mathbb{R}$$

satisfy the following hypotheses:

(H_1) h is continuous;

(H_2) $h(x,u,\cdot)$ is quasiconvex for all $(x,u)\in\Omega\times\mathbb{R}^p$;

(H_3) there exist a nonnegative, bounded, continuous function $g:\Omega\times\mathbb{R}^p\to[0,\infty)$ and a constant $C>0$ such that

$$g(x,u)|\xi| \le h(x,u,\xi) \le C\,g(x,u)(1+|\xi|) \tag{3.1}$$

for all $(x,u,\xi)\in\Omega\times\mathbb{R}^p\times\mathbb{M}^{p\times N}$, where $\mathbb{M}^{p\times N}$ is the vector space of $p\times N$ matrices;

(H_4) for every $x_0\in\Omega$ and $\delta>0$ there exists $\varepsilon>0$ such that

$$h(x_0,u,\xi) - h(x,u,\xi) \le \delta(1+g(x,u)\,|\xi|) \tag{3.2}$$

for all $x\in\Omega$ with $|x-x_0|\le\varepsilon$ and for all $(u,\xi)\in\mathbb{R}^p\times\mathbb{M}^{p\times N}$;

(H_5) there exist $C'>0$ and $m\in(0,1)$ such that

$$|h^\infty(x,u,\xi) - h(x,u,\xi)| \le C'g(x,u)(1+|\xi|^{1-m})$$

for all $(x,u,\xi)\in\Omega\times\mathbb{R}^p\times\mathbb{M}^{p\times N}$, where the *recession function* h^∞ of h is defined as

$$h^\infty(x,u,\xi) := \limsup_{t\to\infty}\frac{h(x,u,t\,\xi)}{t};$$

(H_6) θ admits an extension $\theta\in C(\overline{\Omega}\times\mathbb{R}^p;\mathbb{R})\cap C^1(\Omega\times\mathbb{R}^p;\mathbb{R})$ such that

$$|\nabla_x\theta(x,u)| \le a_1(x) + C_1(1+|u|^{q_c})$$

for $\mathcal{L}^N$ a.e. $x \in \Omega$ and all $u \in \mathbb{R}^p$, where $a_1 \in L^1(\Omega, \mathbb{R})$, $C_1 > 0$, and q_c is the Sobolev exponent $q_c := N/(N-1)$ if $N > 1$ and $q_c < \infty$ if $N = 1$. Moreover, for every $x_0 \in \Omega$ and $\delta > 0$ there exists $\varepsilon > 0$ such that

$$|\nabla_u \theta(x_0, u) - \nabla_u \theta(x, u)| \leq \delta\, g(x, u) \tag{3.3}$$

for all $x \in \Omega$ with $|x - x_0| \leq \varepsilon$ and for all $u \in \mathbb{R}^p$;

(H_7) $g(x, u) \geq |\nabla_u \theta(x, u)|$ for all $(x, u) \in \Omega \times \mathbb{R}^p$.

Remark 3.1. (i) Conditions (H_1)–(H_5) were considered by Fonseca and Müller (see [FM2]), who treated the case where $\theta \equiv 0$. Actually, in [FM2] hypothesis (H4) included:

(H4)$_1$ For every compact set $K \Subset \Omega \times \mathbb{R}^p$ there exists a continuous function $\omega : [0, \infty) \to [0, \infty)$, with $\omega(0) = 0$, such that

$$|h(x, u, \xi) - h(x_1, u_1, \xi)| \leq \omega(|x - x_1| + |u - u_1|)(1 + |\xi|)$$

for all (x, u, ξ), $(x_1, u_1, \xi) \in K \times \mathbb{M}^{p \times N}$.

As it turns out, this property follows from (H1), (H2), (H5). Indeed using the fact that the recession function h^∞ of h is still quasiconvex and is positively homogeneous of degree one in the ξ variable (see [FM2, M]), by (H1), (H2), (H5), it is possible to show that h^∞ is actually continuous in $\Omega \times \mathbb{R}^p \times \mathbb{M}^{p \times N}$ and, in turn, that h satisfies condition (H4)$_1$ of [FM2]. We omit the details.

(ii) By the mean value theorem and conditions (H_3) and (H_7) we have

$$|\theta(x, u) - \theta(x, u_1)| \leq |\nabla_u \theta(x, \hat{u})|\, |u - u_1| \leq ||g||_{L^\infty} |u - u_1| \tag{3.4}$$

for all $x \in \Omega$ and all u, $u_1 \in \mathbb{R}^p$. Taking $u_1 = 0$ it follows by (H_6) and (3.4) that

$$|\theta(x, u)| \leq ||g||_{L^\infty}\, |u| + ||\theta(x, 0)||_{L^\infty} \tag{3.5}$$

for all $(x, u) \in \Omega \times \mathbb{R}^p$. This growth condition, together with (3.1), implies in particular that the functional $H(u, \Omega)$ is well defined and finite for $u \in W^{1,1}(\Omega; \mathbb{R}^p)$.

(iii) A typical example of the energy densities is (see Visintin [V1, V2] and section 2)

$$h(x, u, \xi) := \sigma\, |\xi|, \qquad \theta(x, u) := \hat{\sigma}\, u, \tag{3.6}$$

where $\sigma > 0$ and $\hat{\sigma} \in \mathbb{R}$. It is easy to see that conditions (H_1)–(H_6) hold with $g(x, u) := \sigma$, while assumption (H_7) reduces to the inequality $|\hat{\sigma}| \leq \sigma$. More generally, ($H_6$) is trivially satisfied if $\theta = \theta(u)$.

(iv) If in (1.3) we take $\theta(x, u) := \hat{\sigma}|u|$ for $(x, u) \in \partial\Omega \times \mathbb{R}^p$ (cf. [MP]), then it is possible to extend θ to $\overline{\Omega} \times \mathbb{R}^p$ as follows:

$$\theta(x, u) := \hat{\sigma} \sqrt{|u|^2 + \psi^2(x)},$$

where $\psi \in C^1(\overline{\Omega}; \mathbb{R})$ is such that $\psi(x) > 0$ for $x \in \Omega$ and $\psi(x) = 0$ for $x \in \partial\Omega$. Conditions (H_1)–(H_7) are then verified with $g(x, u) := \sigma$, provided $|\hat{\sigma}| \leq \sigma$. The problem of finding an extension of $\theta : \partial\Omega \times \mathbb{R}^p \to \mathbb{R}$ to $\overline{\Omega} \times \mathbb{R}^p$ which satisfies (H_6)–(H_7) for the functional (1.3), and when (1.4) holds, will be addressed in a forthcoming paper.

Our goal in this section is to generalize the integral representation obtained in section 2 to the relaxed energy of $H(u, \Omega)$ in $BV(\Omega; \mathbb{R}^p)$ with respect to the L^1 topology; that is,

$$\mathcal{H}(u, \Omega) := \inf_{\{u_n\}} \left\{ \liminf_{n \to \infty} H(u_n, \Omega) :\ u_n \in W^{1,1}(\Omega; \mathbb{R}^p),\ u_n \to u \quad \text{in} \quad L^1(\Omega; \mathbb{R}^p) \right\}.$$

From the definition of $\mathcal{H}(u,\Omega)$ it follows immediately that the functional $\mathcal{H}(u,\Omega)$ is lower semicontinuous in $L^1(\Omega;\mathbb{R}^p)$.

Before stating the main theorems of this section we introduce the *surface energy* associated with the function h. For fixed a, $b \in \mathbb{R}^p$ we define $\mathcal{A}(a,b,\nu)$ as the class of all functions $\psi \in W^{1,1}(Q_\nu;\mathbb{R}^p)$ such that

$$T\,\psi(y) = \begin{cases} a & \text{if } y\cdot\nu = -1/2, \\ b & \text{if } y\cdot\nu = \ \ 1/2, \end{cases}$$

and which are periodic of period one in the remaining directions $\nu_1,\dots,\nu_{N-1}$. The surface energy associated with the function h, $K_h(x,a,b,\nu)$, is defined by

$$K_h(x,a,b,\nu) := \inf\left\{\int_{Q_\nu} h^\infty(x,\psi(y),\nabla\psi(y))\,dy :\ \psi\in\mathcal{A}(a,b,\nu)\right\}.$$

For a detailed study of the properties of the function $K_h(x,a,b,\nu)$ we refer to [FR].

For $u \in BV(\Omega;\mathbb{R}^p)$ we define the functional

$$\begin{aligned}\mathcal{L}(u,\Omega) := &\int_\Omega h(x,u(x),\nabla u(x))\,dx + \int_\Omega h^\infty(x,u(x),dC(u)) \\ &+ \int_{S(u)\cap\Omega} K_h(x,u^-(x),u^+(x),\nu_u(x))\,dH_{N-1}(x) + \int_{\partial\Omega}\theta(x,T\,u(x))\,dH_{N-1}(x).\end{aligned}$$

THEOREM 3.2. *Let* (H_1)–(H_7) *hold. If* $u\in BV(\Omega;\mathbb{R}^p)$, *then*

$$\mathcal{H}(u,\Omega) = \mathcal{L}(u,\Omega).$$

COROLLARY 3.3. *If* $h = h(x,\xi)$, *then*

$$\begin{aligned}\mathcal{H}(u,\Omega) = &\int_\Omega h(x,\nabla u(x))\,dx + \int_\Omega h^\infty(x,dC(u)) \\ &+ \int_{S(u)\cap\Omega} h^\infty(x,(u^+(x)-u^-(x))\otimes\nu_u(x))\,dH_{N-1}(x) \\ &+ \int_{\partial\Omega}\theta(x,T\,u(x))\,dH_{N-1}(x).\end{aligned}$$

The proof of Corollary 3.3 follows from Remark 2.17 in [FM2].

Remark 3.4. (i) Rather surprisingly, in general the functional $\mathcal{L}(u,\Omega)$ is not lower semicontinuous in L^1 if the domain Ω is only Lipschitz. This fact was first pointed out by Modica in [Mo2] who gave the following simple example. Let $\Omega := (0,1)\times(0,1)\subset\mathbb{R}^2$ and take h and θ as in (3.6), with $-\sigma \le \hat\sigma < -\sigma\sqrt{2}/2$. Then (H_1)–(H_7) are satisfied (see Remark 3.1(iii)), and

$$\mathcal{L}(u,\Omega) = \sigma\int_\Omega |Du| + \hat\sigma\int_{\partial\Omega} T\,u\,dH_1, \quad u\in BV(\Omega;\mathbb{R}).$$

Consider the sequence

$$u_n(x_1,x_2) := \begin{cases} 0 & \text{if } x_1+x_2 \ge 1/n, \\ n & \text{if } x_1+x_2 < 1/n. \end{cases}$$

Then $u_n(x)\to 0$ in $L^1(\Omega;\mathbb{R})$ but $\mathcal{L}(u_n,\Omega) = \sigma\sqrt{2}+2\hat\sigma < \mathcal{L}(0,\Omega) = 0$, and this shows that $\mathcal{H}(u,\Omega)\ne\mathcal{L}(u,\Omega)$ since $\mathcal{H}(u,\Omega)$ is lower semicontinuous in L^1.

It is worth noting that in the special case where $\theta(x,u) = \hat{\sigma}\,|u-\psi(x)|$ in (1.3), with $|\hat{\sigma}| \le \sigma$ and $\psi \in L^1(\partial\Omega;\mathbb{R})$, one can still prove lower semicontinuity of $\mathcal{L}$ for Lipschitz subdomains of $\mathbb{R}^N$. The first result in this direction is due to Massari and Pepe [MP] who treated the case where $\psi \equiv 0$. Modica [Mo2] then extended it to include $\psi \in L^1(\partial\Omega;\mathbb{R})$. The idea in [MP, Mo2] is to find a function $\hat{\psi} \in BV(\mathbb{R}^N \setminus \overline{\Omega};\mathbb{R})$ whose trace is ψ and then use an extension theorem (see [EG, Thm. 5.4.1]) to rewrite the integral $\int_{\partial\Omega} |T\,u - \psi|\,dH_{N-1}$ as

$$\int_{\partial\Omega} |T\,u - T\,\hat{\psi}|\,dH_{N-1} = \int_{\mathbb{R}^N} |D\hat{u}| - \int_{\Omega} |Du| - \int_{\mathbb{R}^N \setminus \overline{\Omega}} |D\hat{\psi}|,$$

where

$$\hat{u}(x) := \begin{cases} u(x) & \text{if } x \in \Omega, \\ \hat{\psi}(x) & \text{if } x \in \mathbb{R}^N \setminus \overline{\Omega}. \end{cases}$$

(ii) Without condition (H_7) Theorem 3.2 may fail. As an example, let $\Omega := (0,1) \subset \mathbb{R}$ and take h and θ as in (3.6). In this case condition (H_7) is equivalent to the inequality $|\hat{\sigma}| \le \sigma$. Assume that $\sigma < \hat{\sigma}$ and consider the sequence

$$u_n(x) := \begin{cases} -n^3(x-1) - n & \text{if } 1 - 1/n^2 \le x \le 1, \\ 0 & \text{otherwise.} \end{cases}$$

Then $u_n(x) \to 0$ in $L^1(\Omega;\mathbb{R})$ but $\mathcal{L}(u_n,\Omega) = (\sigma - \hat{\sigma})n < \mathcal{L}(0,\Omega) = 0$.

THEOREM 3.5. *Let* (H_1)–(H_6) *hold, with* (3.1) *and* (H_7) *replaced by the weaker hypothesis*

$$|\nabla_u \theta(x,u)|\,|\xi| \le h(x,u,\xi) \le C\,g(x,u)(1+|\xi|) \tag{3.7}$$

for all $(x,u,\xi) \in \Omega \times \mathbb{R}^p \times \mathbb{M}^{p\times N}$, *and some* $C > 0$. *Then the relaxation of* $H(u,\Omega)$

$$\mathcal{H}_b(u,\Omega) = \inf_{\{u_n\}} \Big\{ \liminf_{n\to\infty} H(u_n,\Omega):\ u_n \in W^{1,1}(\Omega;\mathbb{R}^p),\ u_n \to u \text{ in } L^1(\Omega;\mathbb{R}^p),\ \sup_n ||u_n||_{W^{1,1}} < \infty \Big\}$$

in $BV(\Omega;\mathbb{R}^p)$ *with respect to the* L^1 *topology has the integral representation*

$$\mathcal{H}_b(u,\Omega) = \mathcal{L}(u,\Omega).$$

Remark 3.6. Under the assumptions of Theorem 3.5, the functional $\mathcal{L}(u,\Omega)$ provides the correct integral representation for $\mathcal{H}_b(u,\Omega)$ but not necessarily for $\mathcal{H}(u,\Omega)$. Indeed, in the scalar case where $p = 1$ and when $\theta \equiv 0$, Dal Maso has shown in [DM] that $\mathcal{H}(u,\Omega) = \mathcal{L}(u,\Omega)$ when $h = h(u,\xi)$ satisfies only (3.7), while possibly $\mathcal{H}(u,\Omega) < \mathcal{L}(u,\Omega)$ for $h = h(x,\xi)$ unless one assumes a condition of the type (3.1).

In the vectorial case where $p > 1$ and when $\theta \equiv 0$, Ambrosio and Dal Maso [ADM2] proved that $\mathcal{H}(u,\Omega) = \mathcal{L}(u,\Omega)$ when $h = h(\xi)$ satisfies only (3.7). Independently, Fonseca and Müller [FM2] have obtained this result for general functions $h(x,u,\xi)$ which verify (3.1), still in the case where $\theta \equiv 0$.

We proceed with the proofs of Theorems 3.2 and 3.5. We start with some preliminary results. In what follows, and unless otherwise specified, we always assume that conditions (H_1)–(H_7) hold.

LEMMA 3.7. *If $u \in BV(\Omega;\mathbb{R}^p)$, then the function $v(x) := \theta(x, u(x)) \in BV(\Omega;\mathbb{R})$ and*

$$Dv = \begin{cases} \nabla_x \theta(x,u)\, \mathcal{L}^N + Du^T \nabla_u \theta(x,u) & \text{on } \Omega\backslash S(u), \\ (\theta(x,u^+) - \theta(x,u^-)) \otimes \nu_u \, H_{N-1} \lfloor S(u) & \text{on } S(u). \end{cases}$$

Moreover

$$T\, v(x) = \theta(x, T\, u(x)).$$

The proof of Lemma 3.7 is straightforward in light of related results on the chain rule for BV functions (see [ADM1] and the references contained therein).

By Lemmas 2.1 and 3.7, if $u \in BV(\Omega;\mathbb{R}^p)$, then

(3.8)
$$\int_{\partial\Omega} \theta(x, T\, u(x))\, dH_{N-1}(x) = \int_\Omega \theta(x,u(x)) \mathrm{div}\, \varphi(x)\, dx + \int_\Omega \varphi(x) \cdot d(D(\theta(x,u(x)))).$$

In turn, by (3.8) we can rewrite the functional $H(u,\Omega)$ as

(3.9)
$$\begin{aligned} H(u,\Omega) = &\int_\Omega \left\{ h(x,u(x),\nabla u(x)) + \varphi(x) \cdot \nabla u^T(x) \nabla_u \theta(x,u(x)) \right\} dx \\ &+ \int_\Omega \theta(x,u(x))\, \mathrm{div}\, \varphi(x)\, dx + \int_\Omega \varphi(x) \cdot \nabla_x \theta(x,u(x))\, dx. \end{aligned}$$

This equivalent form gives us a better insight into the competing roles played by the two energy integrals $\int_\Omega h(x,u,\nabla u)\, dx$ and $\int_{\partial\Omega} \theta(x, T\, u)\, dH_{N-1}$. In particular, it is now clear that without a condition of the type

$$h(x,u,\xi) \geq |\nabla_u \theta(x,u)|\, |\xi|$$

one may have $\mathcal{H}(u,\Omega) = -\infty$, as in the example in Remark 3.4(ii).

Define $f(x,u,\xi) := h(x,u,\xi) + \varphi(x) \cdot \xi^T \nabla_u \theta(x,u)$ for $(x,u,\xi) \in \Omega \times \mathbb{R}^p \times \mathbb{M}^{p\times N}$, set

$$F(u,\Omega) := \int_\Omega f(x,u(x),\nabla u(x))\, dx, \quad u \in W^{1,1}(\Omega;\mathbb{R}^p),$$

and let

$$\mathcal{F}(u,\Omega) := \inf_{\{u_n\}} \left\{ \liminf_{n\to\infty} F(u_n,\Omega) :\, u_n \in W^{1,1}(\Omega;\mathbb{R}^p),\, u_n \to u \quad \text{in} \quad L^1(\Omega;\mathbb{R}^p) \right\}.$$

LEMMA 3.8. *If $u \in BV(\Omega;\mathbb{R}^p)$, then*

$$\mathcal{H}(u,\Omega) = \mathcal{F}(u,\Omega) + \int_\Omega \theta(x,u(x))\, \mathrm{div}\, \varphi(x)\, dx + \int_\Omega \varphi(x) \cdot \nabla_x \theta(x,u(x))\, dx.$$

Proof. Clearly it is enough to show that

$$\begin{aligned} \liminf_{n\to\infty} H(u_n,\Omega) = &\liminf_{n\to\infty} F(u_n,\Omega) \\ &+ \int_\Omega \theta(x,u(x))\, \mathrm{div}\, \varphi(x)\, dx + \int_\Omega \varphi(x) \cdot \nabla_x \theta(x,u(x))\, dx \end{aligned}$$

for any sequence $\{u_n\} \subset W^{1,1}(\Omega;\mathbb{R}^p)$ such that $u_n \to u$ in $L^1(\Omega;\mathbb{R}^p)$. We first observe that, since $\varphi \in C_0^1(\mathbb{R}^N;\mathbb{R}^N)$, the functions φ and $\operatorname{div}\varphi$ are bounded in Ω. Moreover, by (3.4)

$$|\theta(x,u_n(x)) - \theta(x,u(x))| \le ||g||_{L^\infty}\,|u_n(x)-u(x)| \quad \text{for } \mathcal{L}^N \text{ a.e. } x \in \Omega.$$

Hence

$$\lim_{n\to\infty}\int_\Omega \theta(x,u_n)\operatorname{div}\varphi\,dx = \int_\Omega \theta(x,u)\operatorname{div}\varphi\,dx.$$

By (H_6), by virtue of the Sobolev inequality, and due to the fact that φ is bounded, the functional $u \mapsto \int_\Omega \varphi\cdot\nabla_x\theta(x,u(x))\,dx$ is continuous in $L^1(\Omega;\mathbb{R}^p)$ (see [K, Thm. 2.1]) and thus

$$\lim_{n\to\infty}\int_\Omega \varphi\cdot\nabla_x\theta(x,u_n)\,dx = \int_\Omega \varphi(x)\cdot\nabla_x\theta(x,u)\,dx. \qquad \square$$

We are now ready to prove Theorem 3.2.

Proof of Theorem 3.2. By Lemma 3.8, in order to find an integral representation for $\mathcal{H}(u,\Omega)$ in $BV(\Omega;\mathbb{R}^p)$ it is sufficient to determine one for $\mathcal{F}(u,\Omega)$. The idea is to apply Theorem 2.16 of [FM2]. In order to do so we need to show that the function

$$f(x,u,\xi) = h(x,u,\xi) + \varphi(x)\cdot\xi^T\nabla_u\theta(x,u)$$

satisfies conditions (H_1)–(H_5) which are essentially the same as [FM2].

Condition (H_1) is trivially verified since the functions θ and φ are of class C^1. As f is the sum of a quasiconvex function and a function linear in ξ, it is clear that $f(x,u,\cdot)$ is still quasiconvex and that

$$f^\infty(x,u,\xi) = h^\infty(x,u,\xi) + \varphi(x)\cdot\xi^T\nabla_u\theta(x,u),$$

which, in turn, implies that

$$|f^\infty(x,u,\xi) - f(x,u,\xi)| = |h^\infty(x,u,\xi) - h(x,u,\xi)| \le C'g(x,u)(1+|\xi|^{1-m})$$

by (H_5). Thus f verifies also (H_2) and (H_5).

We prove (3.2). Fix $x_0 \in \Omega$ and $\delta > 0$. There exists $\varepsilon > 0$ such that for $x \in \Omega$ with $|x-x_0| \le \varepsilon$ and $(u,\xi) \in \mathbb{R}^p \times \mathbb{M}^{p\times N}$,

$$\begin{aligned} h(x_0,u,\xi) - h(x,u,\xi) &\le \tfrac{1}{3}\,\delta(1+g(x,u)|\xi|), \qquad |\varphi(x)-\varphi(x_0)| \le \tfrac{1}{3}\,\delta,\\ |\nabla_u\theta(x_0,u) - \nabla_u\theta(x,u)| &\le \tfrac{1}{3}\,\delta\,g(x,u) \end{aligned}$$

by the continuity of φ, (3.2), and (3.3). Hence

$$\begin{aligned} f(x_0,u,\xi) &= h(x_0,u,\xi) + \varphi(x_0)\cdot\xi^T\nabla_u\theta(x_0,u)\\ &= f(x,u,\xi) + h(x_0,u,\xi) - h(x,u,\xi)\\ &\quad + [\varphi(x_0)-\varphi(x)]\cdot\xi^T\nabla_u\theta(x,u) + \varphi(x_0)\cdot\xi^T[\nabla_u\theta(x_0,u) - \nabla_u\theta(x,u)]\\ &\le f(x,u,\xi) + \tfrac{1}{3}\,\delta(1+g(x,u)|\xi|) + \tfrac{2}{3}\,\delta\,g(x,u)|\xi| \end{aligned}$$

which is (3.2), and where we have used (H_7) and the fact that $|\varphi(x_0)| \le 1$.

Finally, condition (H_3) is replaced by the condition

$$g(x,u)|\xi|(1-|\varphi(x)|) \le f(x,u,\xi) \le 2C\,g(x,u)(1+|\xi|), \tag{3.10}$$

which follows from (3.1) and (H_7). Although (3.10) is weaker than condition (H_3) in [FM2], the proof there carries out even with (3.10). Indeed, condition (H_3) was used in [FM2] only to show that

$$\mathcal{F}(u,\Omega) \geq \int_\Omega f(x,u,\nabla u)\,dx + \int_\Omega f^\infty(x,u,dC(u)) + \int_{S(u)\cap\Omega} K_f(x,u^-,u^+,\nu_u)\,dH_{N-1}(x).$$

The proof of this inequality relies on the blow-up argument introduced in [FM1] which is a *local* argument, in the sense that in order to prove the three main pointwise inequalities (2.10)–(2.11) in [FM2] at points $x_0 \in \Omega$, one is only interested in what happens in a ball $B(x_0,\varepsilon)$. Since in our case $|\varphi(x_0)| < \epsilon_0 < 1$ for some $\epsilon_0 > 0$, if we take ε sufficiently small we can assume that $|\varphi(x)| \leq \epsilon_0$ for all $x \in B(x_0,\varepsilon)$ and thus (3.10) reduces to

$$g(x,u)|\xi|(1-\epsilon_0) \leq f(x,u,\xi) \leq 2C\,g(x,u)(1+|\xi|)$$

for all $(x,u,\xi) \in B(x_0,\varepsilon)\times\mathbb{R}^p\times\mathbb{M}^{p\times N}$, which is the *local* version of (H_3) in [FM2].

In conclusion, we may apply Theorem 2.16 of [FM2] (see Remark 3.10 below) to obtain that for $u \in BV(\Omega;\mathbb{R}^p)$

$$\mathcal{F}(u,\Omega) = \int_\Omega \left\{h(x,u,\nabla u) + \varphi\cdot\nabla u^T\nabla_u\theta(x,u)\right\}\,dx + \int_\Omega h^\infty(x,u,dC(u)) + \int_\Omega (\varphi\otimes\nabla_u\theta(x,u))\cdot\,dC^T(u) + \int_{S(u)\cap\Omega} K_f(x,u^-,u^+,\nu_u)\,dH_{N-1},$$

where

$$K_f(x,a,b,\nu) = \inf\Big\{\int_{Q_\nu}\big[h^\infty(x,\psi(y),\nabla\psi(y)) + \varphi(x)\cdot\nabla\psi^T(y)\nabla_u\theta(x,\psi(y))\big]dy : \psi\in\mathcal{A}(a,b,\nu)\Big\}.$$

Given any $\psi \in \mathcal{A}(a,b,\nu)$ we have

$$\int_{Q_\nu}\varphi(x)\cdot\nabla\psi^T(y)\nabla_u\theta(x,\psi(y))\,dy = \int_{\partial Q_\nu}\varphi(x)\cdot n(y,Q_\nu)\,\theta(x,T\,\psi(y))\,dH_{N-1}(y) = \varphi(x)\cdot(\theta(x,b)-\theta(x,a))\,\nu,$$

and so

$$K_f(x,a,b,\nu) = K_h(x,a,b,\nu) + \varphi(x)\cdot(\theta(x,b)-\theta(x,a))\,\nu.$$

If we now use Lemmas 2.1, 3.7, and 3.8, we finally obtain that $\mathcal{H}(u,\Omega) = \mathcal{L}(u,\Omega)$. This concludes the proof of Theorem 3.2. □

Remark 3.9. The continuity hypotheses (H_1), (H_4), and (3.3) may be replaced by

(H_1)′ h is Carathéodory;

(H_4)′ for all $(x_0,u_0)\in\Omega\times\mathbb{R}^p$ and for all $\delta>0$ there exists $\varepsilon>0$ such that

$$|h(x,u_1,\xi) - h(x,u_2,\xi)| \leq \varepsilon(1+|\xi|)$$

for all $x \in \Omega$ with $|x - x_0| \le \varepsilon$, u_1, $u_2 \in B(u_0, \varepsilon)$, and $\xi \in \mathbb{M}^{p\times N}$, provided $\xi \mapsto f(x, u, \cdot)$ is coercive (e.g., if $g(x, u) \ge \alpha > ||\nabla_u \theta||_{L^\infty}$ for some $\alpha > 0$). In this case, in Theorem 3.2 we would use the integral representation obtained by Bouchitté, Fonseca, and Mascarenhas [BFM] in place of the corresponding result by Fonseca and Müller [FM2].

Proof of Theorem 3.5. By Lemma 3.8 it is enough to find an integral representation for the corresponding $\mathcal{F}_b(u, \Omega)$ in $BV(\Omega; \mathbb{R}^p)$. Let $f_\varepsilon(x, u, \xi) := f(x, u, \xi) + \varepsilon\,|\xi|$, for $\varepsilon \in (0, 1)$, where, as before, $f(x, u, \xi) := h(x, u, \xi) + \varphi(x) \cdot \xi^T \nabla_u \theta(x, u)$, and define

$$\mathcal{F}_\varepsilon(u, \Omega) := \inf_{\{u_n\}} \left\{ \liminf_{n\to\infty} F_\varepsilon(u_n, \Omega) : u_n \in W^{1,1}(\Omega; \mathbb{R}^p),\ u_n \to u \quad \text{in} \quad L^1(\Omega; \mathbb{R}^p) \right\},$$

where

$$F_\varepsilon(u, \Omega) := \int_\Omega f_\varepsilon(x, u(x), \nabla u(x))\, dx, \qquad u \in W^{1,1}(\Omega; \mathbb{R}^p).$$

We claim that

$$\lim_{\varepsilon\to 0} \mathcal{F}_\varepsilon(u, \Omega) = \mathcal{F}_b(u, \Omega).$$

Fix $u \in L^1(\Omega; \mathbb{R}^p)$. For any given $\delta > 0$ there exists a sequence $\{u_n\} \subset W^{1,1}(\Omega; \mathbb{R}^p)$, with $\sup_n ||u_n||_{W^{1,1}} = M < \infty$, such that $u_n \to u$ in $L^1(\Omega; \mathbb{R}^p)$ and

$$\mathcal{F}_b(u, \Omega) + \delta \ge \lim_{n\to\infty} \int_\Omega f(x, u_n(x), \nabla u_n(x))\, dx.$$

In turn, for all $\varepsilon > 0$,

$$\mathcal{F}_b(u, \Omega) + \delta \ge \liminf_{n\to\infty} \int_\Omega f_\varepsilon(x, u_n(x), \nabla u_n(x))\, dx - \varepsilon\, M,$$

and using the definition of $\mathcal{F}_\varepsilon(u, \Omega)$ we obtain

$$\mathcal{F}_b(u, \Omega) + \delta \ge \mathcal{F}_\varepsilon(u, \Omega) - \varepsilon\, M.$$

Therefore

$$\limsup_{\varepsilon\to 0} \mathcal{F}_\varepsilon(u, \Omega) \le \mathcal{F}_b(u, \Omega) + \delta,$$

and it suffices to let $\delta \to 0$ to conclude that

$$\limsup_{\varepsilon\to 0} \mathcal{F}_\varepsilon(u, \Omega) \le \mathcal{F}_b(u, \Omega).$$

Conversely, fix $u \in L^1(\Omega; \mathbb{R}^p)$ and $\varepsilon > 0$. Then there exists a sequence $\{u_n^\varepsilon\} \subset W^{1,1}(\Omega; \mathbb{R}^p)$ such that $u_n^\varepsilon \to u$ in $L^1(\Omega; \mathbb{R}^p)$ as $n \to \infty$ and

(3.11)

$$\mathcal{F}_\varepsilon(u, \Omega) + \varepsilon \ge \lim_{n\to\infty} \int_\Omega \left[f(x, u_n^\varepsilon, \nabla u_n^\varepsilon) + \varepsilon |\nabla u_n^\varepsilon| \right] dx \ge \liminf_{n\to\infty} \int_\Omega f(x, u_n^\varepsilon, \nabla u_n^\varepsilon)\, dx.$$

Without loss of generality we can assume that $\mathcal{F}_\varepsilon(u, \Omega) < \infty$. Since $|\varphi(x)| < 1$ in Ω, by (3.7) we have

$$f(x, u, \xi) = h(x, u, \xi) + \varphi(x) \cdot \xi^T \nabla_u \theta(x, u) \ge 0;$$

hence by (3.11) it follows that $\sup_n ||u_n^\varepsilon||_{W^{1,1}} < \infty$ and so

$$\mathcal{F}_\varepsilon(u,\Omega) + \varepsilon \geq \mathcal{F}_b(u,\Omega).$$

We conclude that

$$\liminf_{\varepsilon\to 0} \mathcal{F}_\varepsilon(u,\Omega) \geq \mathcal{F}_b(u,\Omega)$$

and the claim is proven.

It is not difficult to show that the function $f_\varepsilon(x,u,\xi)$ satisfies conditions (H_1)–(H_5). We omit the details since the proof is very similar to that of Theorem 3.2.

By Theorem 2.16 of [FM2] we obtain that for $u \in BV(\Omega;\mathbb{R}^p)$

$$\begin{aligned}\mathcal{F}_\varepsilon(u,\Omega) = &\int_\Omega \{f(x,u,\nabla u) + \varepsilon|\nabla u|\}\, dx + \int_\Omega f^\infty(x,u,dC(u)) + \varepsilon\int_\Omega |dC(u)| \\ &+ \int_{S(u)\cap\Omega} K_{f_\varepsilon}(x,u^-,u^+,\nu_u)\, dH_{N-1}.\end{aligned} \tag{3.12}$$

If we let $\varepsilon \to 0$ in (3.12) we obtain that

$$\begin{aligned}\lim_{\varepsilon\to 0}\mathcal{F}_\varepsilon(u,\Omega) = &\int_\Omega f(x,u,\nabla u)\, dx + \int_\Omega f^\infty(x,u,dC(u)) \\ &+ \int_{S(u)\cap\Omega} K_f(x,u^-,u^+,\nu_u)\, dH_{N-1},\end{aligned}$$

where we have used the fact that

$$\lim_{\varepsilon\to 0}\int_{S(u)\cap\Omega} K_{f_\varepsilon}(x,u^-,u^+,\nu_u)\, dH_{N-1} = \int_{S(u)\cap\Omega} K_f(x,u^-,u^+,\nu_u)\, dH_{N-1}. \tag{3.13}$$

This convergence follows easily from the Lebesgue dominated convergence theorem and because we may find a constant C_1 independent of ε such that (see the proof of Lemma 2.15 in [FM2])

$$0 \leq K_{f_\varepsilon}(x,a,b,\nu) \leq C_1|a-b|.$$

This concludes the proof of the theorem. □

Remark 3.10. In the proof of Theorem 2.16 of [FM2] the inequality

$$\mathcal{F}(u,S(u)\cap\Omega) \leq \int_{S(u)\cap\Omega} K_f(x,u^-,u^+,\nu_u)\, dH_{N-1}(x) \tag{3.14}$$

was derived by using a result of [FR] which requires the function $f(x,u,\cdot)$ to be coercive, that is, to satisfy the inequality

$$f(x,u,\xi) \geq c_1|\xi| - c_2 \tag{3.15}$$

for all $(x,u,\xi) \in \Omega\times\mathbb{R}^p\times\mathbb{M}^{p\times N}$, which is stronger than condition (H_3). To circumvent this difficulty consider the function $f_\varepsilon(x,u,\xi)$ defined as in the proof of Theorem 3.5. Since it satisfies conditions (H_1)–(H_5) and (3.15), the inequality (3.14) holds for f_ε. Also the inequality $f \leq f_\varepsilon$ clearly implies that

$$\mathcal{F}(u,S(u)\cap\Omega) \leq \mathcal{F}_\varepsilon(u,S(u)\cap\Omega) \leq \int_{S(u)\cap\Omega} K_{f_\varepsilon}(x,u^-,u^+,\nu_u)\, dH_{N-1}(x).$$

If we now let $\varepsilon \to 0$ and use (3.13), we conclude that (3.14) holds also for f.

4. Mesoscopic scale. We are interested in the following constrained minimization problem:

$$\inf\left\{\mathcal{H}(u,\Omega)+\int_\Omega \tau(x,u(x))\,dx:\ u\in BV(\Omega;\mathbb{R}^p),\ u(x)\in K\quad \text{for } \mathcal{L}^N \text{ a.e. } x\in\Omega\right\},$$

where K is a nonempty compact set of $\mathbb{R}^p$, and $\tau:\Omega\times K\to\mathbb{R}$ is a Carathéodory function such that

$$|\tau(x,u)|\le a_0(x)\quad \text{for } \mathcal{L}^N \text{ a.e. } x\in\Omega \text{ and for all } u\in K, \tag{4.1}$$

for some function $a_0\in L^1(\Omega;\mathbb{R})$. In applications in phase transitions, often $K=\{a,b\}$ or K is a convex set.

For $u\in L^1(\Omega;\mathbb{R}^p)$ we define the functional

$$\mathcal{I}(u,\Omega):=\mathcal{H}(u,\Omega)+I_K(u,\Omega),$$

where

$$I_K(u,\Omega):=\begin{cases}\int_\Omega \tau(x,u(x))\,dx & \text{if } u(x)\in K \quad \text{for } \mathcal{L}^N \text{ a.e. } x\in\Omega,\\ +\infty & \text{otherwise.}\end{cases}$$

LEMMA 4.1. *If* (H_1)–(H_7) *hold, then the functional* $\mathcal{I}(u,\Omega)$ *is lower semicontinuous in* $L^1(\Omega;\mathbb{R}^p)$.

Proof. Consider u_n, $u\in L^1(\Omega;\mathbb{R}^p)$ such that $u_n\to u$ in $L^1(\Omega;\mathbb{R}^p)$. If $\liminf_{n\to\infty}\mathcal{I}(u_n,\Omega)=\infty$ there is nothing to prove. Assume that $\liminf_{n\to\infty}\mathcal{I}(u_n,\Omega)<\infty$ and take a subsequence $\{u_{n_k}\}$ which converges pointwise to u for $\mathcal{L}^N$ a.e. $x\in\Omega$, and such that

$$\lim_{k\to\infty}\mathcal{I}(u_{n_k},\Omega)=\liminf_{n\to\infty}\mathcal{I}(u_n,\Omega)<\infty.$$

For k sufficiently large we can assume that $\mathcal{I}(u_{n_k},\Omega)<\infty$; hence

$$\mathcal{I}(u_{n_k},\Omega)=\mathcal{H}(u_{n_k},\Omega)+\int_\Omega \tau(x,u_{n_k}(x))\,dx$$

and $u_{n_k}(x)\in K$ for $\mathcal{L}^N$ a.e. $x\in\Omega$. Since $\{u_{n_k}\}$ converges pointwise to u for $\mathcal{L}^N$ a.e. $x\in\Omega$, we obtain that $u(x)\in K$ for $\mathcal{L}^N$ a.e. $x\in\Omega$. In turn $\mathcal{I}(u,\Omega)=\mathcal{H}(u,\Omega)+\int_\Omega\tau(x,u(x))\,dx$. The assertion now follows from the lower semicontinuity of $\mathcal{H}(u,\Omega)$ in $L^1(\Omega;\mathbb{R}^p)$ and the fact that

$$\lim_{k\to\infty}\int_\Omega \tau(x,u_{n_k}(x))\,dx=\int_\Omega\tau(x,u(x))\,dx$$

by (4.1) and by the Lebesgue dominated convergence theorem. □

In addition to conditions (H_1)–(H_7) we now assume the following hypotheses:

(F_1) There exist a function $\rho\in C(\overline{\Omega}\times\mathbb{R}^p;\mathbb{R}^p)\cap C^1(\Omega\times\mathbb{R}^p;\mathbb{R}^p)$ and a function $b\in L^1(\Omega;\mathbb{R})$ such that

$$|\nabla_x\rho(x,u)|\le b(x)\quad \text{for } \mathcal{L}^N \text{ a.e. } x\in\Omega \text{ and for all } u\in K, \tag{4.2}$$

and

$$h^\infty(x,u,\xi)\ge|\nabla_u\rho(x,u)|\,|\xi| \tag{4.3}$$

for all $(x,u,\xi) \in \Omega \times K \times \mathbb{M}^{p\times N}$;

(F_2) for $\mathcal{L}^N$ a.e. $x \in \Omega$ the function $\rho(x,\cdot) : K \Subset \mathbb{R}^p \to \rho(x,K) \Subset \mathbb{R}^p$ is invertible and $(x,y) \mapsto (\rho(x,\cdot))^{-1}(y)$ is Carathéodory. In addition, there exists a function $c \in L^1(\Omega;\mathbb{R})$ such that

$$|\rho(x,\cdot)^{-1}(v)| \le c(x) \quad \text{for } \mathcal{L}^N \text{ a.e. } x \in \Omega \text{ and for all } v \in \rho(x,K). \tag{4.4}$$

Let

$$D(\mathcal{I}) := \{u \in L^1(\Omega;\mathbb{R}^p) : \mathcal{I}(u,\Omega) < \infty\}.$$

Then

$$D_1 := \left\{u \in BV(\Omega;\mathbb{R}^p) : u(x) \in K \quad \text{for } \mathcal{L}^N \text{ a.e. } x \in \Omega\right\} \subset D(\mathcal{I})$$

but in general the two sets do not coincide, unless one assumes that $h(x,u,\cdot)$ is coercive.

THEOREM 4.2. *There exists a function $u \in D(\mathcal{I})$ such that*

$$\mathcal{I}(u,\Omega) \le \inf\left\{\mathcal{I}(w,\Omega) : w \in D_1\right\}.$$

Proof. Let $\{u_n\} \subset D_1$ be a minimizing sequence; that is,

$$\lim_{n\to\infty} \mathcal{I}(u_n,\Omega) = \inf\left\{\mathcal{I}(w,\Omega) : w \in D_1\right\} < M < \infty.$$

Then, for n sufficiently large,

$$\mathcal{I}(u_n,\Omega) = \mathcal{H}(u_n,\Omega) + \int_\Omega \tau(x,u_n(x))\,dx \le M. \tag{4.5}$$

We claim that $T\,u_n(x) \in K$ for H_{N-1} a.e. $x \in \partial\Omega$. Indeed let $E_n := \{x \in \partial\Omega : T\,u_n(x) \notin K\}$ and suppose for contradiction that $H_{N-1}(E_n) > 0$. Take $x_0 \in E_n$ for which (cf. [Z, Thm. 5.14.4])

$$\lim_{r\to 0} \frac{1}{\mathcal{L}^N(B(x_0,r)\cap\Omega)} \int_{B(x_0,r)\cap\Omega} |u_n(x) - T\,u_n(x_0)|^{N/(N-1)} dx = 0.$$

Since K is compact we have $\operatorname{dist}(T\,u_n(x_0),K) = \varepsilon_0 > 0$, while from the fact that $u_n(x) \in K$ for $\mathcal{L}^N$ a.e. $x \in \Omega$, it follows that

$$\varepsilon_0^{N/(N-1)} \le |u_n(x) - T\,u_n(x_0)|^{N/(N-1)}$$

for $\mathcal{L}^N$ a.e. $x \in B(x_0,r)\cap\Omega$. Taking the average over $B(x_0,r)\cap\Omega$ and letting $r \to 0$, we get a contradiction. Therefore the claim holds, and by (4.5), Theorem 3.2, and (3.5) we have

$$\begin{aligned}\int_\Omega h(x,u_n,\nabla u_n)\,dx + \int_\Omega h^\infty(x,u_n,dC(u_n)) \\ + \int_{S(u_n)\cap\Omega} K_h(x,u_n^-,u_n^+,\nu_{u_n})\,dH_{N-1} \le M_1\end{aligned} \tag{4.6}$$

for some constant M_1 independent of n. By (H_5), (3.1), and (4.6)

$$\begin{aligned}\int_\Omega h^\infty(x,u_n,\nabla u_n)\,dx &\le \int_\Omega (h^\infty(x,u_n,\nabla u_n)-h(x,u_n,\nabla u_n))\,dx + M_1\\ &\le C'||g||_{L^\infty} + C'||g||_{L^\infty}^m \int_\Omega h^{1-m}(x,u_n,\nabla u_n)\,dx + M_1.\end{aligned}$$

Using Hölder's inequality and (4.6) again, we conclude that there exists $M_2 \in (0,\infty)$ such that for all n,

$$\begin{aligned}\int_\Omega h^\infty(x,u_n,\nabla u_n)\,dx + \int_\Omega h^\infty(x,u_n,dC(u_n))\\ + \int_{S(u_n)\cap\Omega} K_h(x,u_n^-,u_n^+,\nu_{u_n})\,dH_{N-1} \le M_2.\end{aligned} \tag{4.7}$$

Define $v_n := \rho(x,u_n(x))$. As in Lemma 3.7, we can show that $v_n(x) \in BV(\Omega;\mathbb{R}^p)$ with

$$Dv_n = \begin{cases} \nabla_x\rho(x,u_n)\,\mathcal{L}^N + \nabla_u\rho(x,u_n)Du_n & \text{on } \Omega\backslash S(u_n),\\ (\rho(x,u_n^+)-\rho(x,u_n^-))\otimes\nu_{u_n}\,H_{N-1}\lfloor S(u_n) & \text{on } S(u_n).\end{cases} \tag{4.8}$$

Furthermore

$$\begin{aligned}\int_\Omega |Dv_n| = \int_\Omega |\nabla v_n|\,dx + \int_\Omega |\nabla_u\rho(x,u_n)\,dC(u_n)|\\ + \int_{S(v_n)\cap\Omega} |(v_n^+ - v_n^-)\otimes\nu_{v_n}|dH_{N-1}.\end{aligned} \tag{4.9}$$

By Remark 2.17 in [FM2] and the fact that $S(v_n) = S(u_n)$ and $\nu_{v_n} = \nu_{u_n}$, we can rewrite the last integral as

$$\int_{S(u_n)\cap\Omega} K_{|\cdot|}(x,v_n^-,v_n^+,\nu_{u_n})\,dH_{N-1},$$

where

$$K_{|\cdot|}(x,v_n^-,v_n^+,\nu_{u_n}) := \inf\left\{\int_{Q_{\nu_{u_n}}} |\nabla\psi(y)|\,dy : \psi\in\mathcal{A}(v_n^-(x),v_n^+(x),\nu_{u_n})\right\}.$$

Given $\eta \in \mathcal{A}(u_n^-(x),u_n^+(x),\nu_{u_n})$, it is clear that the function $\psi(y) := \rho(x,\eta(y))$ belongs to $\mathcal{A}(v_n^-(x),v_n^+(x),\nu_{u_n})$ and that $\nabla\psi(y) = \nabla_u\rho(x,\eta(y))\nabla\eta(y)$. By (4.3) this implies that

$$K_{|\cdot|}(x, v_n^-, v_n^+, \nu_{u_n})$$
$$\leq \inf\left\{\int_{Q_{\nu_{u_n}}} |\nabla_u \rho(x, \eta(y))|\,|\nabla \eta(y)|\,dy : \eta \in \mathcal{A}(u_n^-(x), u_n^+(x), \nu_{u_n})\right\}$$
$$\leq K_h(x, u_n^-, u_n^+, \nu_{u_n}).$$

Therefore, also by (4.2), (4.3), (4.7), (4.8), and (4.9)

$$\begin{aligned}\int_\Omega |Dv_n| &\leq \int_\Omega |\nabla_x \rho(x, u_n)|\,dx + \int_\Omega |\nabla_u \rho(x, u_n)|\,|\nabla u_n|\,dx \\ &+ \int_\Omega |\nabla_u \rho(x, u_n)|\,|dC(u_n)| \\ &+ \int_{S(u_n)\cap\Omega} K_h(x, u_n^-, u_n^+, \nu_{u_n}) dH_{N-1} \leq ||b||_{L^1} + M_2.\end{aligned} \tag{4.10}$$

Finally, since $v_n(x) \in \rho(x, K)$ for $\mathcal{L}^N$ a.e. $x \in \Omega$, $\rho(x, K)$ is a compact set of $\mathbb{R}^p$, and by (4.10) there exists a subsequence, still denoted $\{v_n\}$, which converges strongly in $L^1(\Omega; \mathbb{R}^p)$ and pointwise almost everywhere to a function $v \in BV(\Omega; \mathbb{R}^p)$ (see [Z, Cor. 5.3.4]), with $v(x) \in \rho(x, K)$ for $\mathcal{L}^N$ a.e. $x \in \Omega$. Define $u(x) := (\rho(x, \cdot))^{-1}(v(x))$. By (F_2) the function u is measurable. Since $u_n(x) = (\rho(x, \cdot))^{-1}(v_n(x))$ it follows that $u_n(x) \to u(x)$ for $\mathcal{L}^N$ a.e. $x \in \Omega$; thus, $u(x) \in K$ for $\mathcal{L}^N$ a.e. $x \in \Omega$. Moreover, by (4.4) we have that $|u_n(x)| \leq c(x)$ for $\mathcal{L}^N$ a.e. $x \in \Omega$; therefore, by the Lebesgue dominated convergence theorem $u_n \to u$ strongly in $L^1(\Omega; \mathbb{R}^p)$. By Lemma 4.1 we conclude that

$$\mathcal{I}(u, \Omega) \leq \inf\{\mathcal{I}(u, \Omega) : u \in D_1\}. \qquad \square$$

COROLLARY 4.3. *Assume that conditions* (F_1) *and* (F_2) *in Theorem* 4.2 *are replaced by the assumption*

$$h^\infty(x, u, \xi) \geq \alpha|\xi| \qquad \text{for all } (x, u, \xi) \in \Omega \times K \times \mathbb{M}^{p\times N}$$

for some $\alpha > 0$. *Then* $D_1 = D(\mathcal{I})$ *and there exists a function* $u \in D_1$ *such that*

$$\mathcal{I}(u, \Omega) = \inf\{\mathcal{I}(w, \Omega) : w \in D_1\}.$$

Proof. It suffices to take $\rho(x, u) := \alpha\, u$ in Theorem 4.2. Then $v_n = \alpha\, u_n$ converge strongly in $L^1(\Omega; \mathbb{R}^p)$ to a function $v \in BV(\Omega; \mathbb{R}^p)$, and therefore $u := \frac{1}{\alpha}\, v$ is the desired minimizer. $\square$

5. Nucleation: The scalar case. In this section we study the constrained minimization problem introduced in section 4, restricted to the scalar case $p = 1$, when K is a closed, connected subset of $\mathbb{R}$ (not necessarily bounded), and when the potential $\tau(x, u)$ is given by

$$\tau(x, u) := \tau_1(x, u) + \psi(x)\,\tau_2(u),$$

where $\tau_1(x, u)$ is a Carathéodory function, concave in the u variable, ψ is a nonnegative, measurable function, and τ_2 is a continuous function such that

(5.1)
all the connected components of $S := \{u \in \text{int } K : \tau_2^{**}(u) < \tau_2(u)\}$ are bounded,

where τ_2^{**} is the convex envelope of τ_2. As remarked in [V2], (5.1) holds if

$$\limsup_{|u|\to\infty} \frac{\tau_2(u)}{|u|} = \infty.$$

Furthermore we assume that

$$\tau(x,u) \geq -L_1 - L_2|u| \quad \text{for } \mathcal{L}^N \text{ a.e. } x \in \Omega \text{ and for all } u \in K \tag{5.2}$$

for some $L_1,\ L_2 > 0$.

Under appropriate assumptions on the functions h and θ, we prove that minimizers $u \in L^1(\Omega;\mathbb{R}^p)$ of

$$\mathcal{I} : v \in L^1(\Omega;K) \mapsto \mathcal{H}(v,\Omega) + \int_\Omega \tau(x,v(x))\,dx$$

have the phase structure

$$u(\Omega) \subset K\backslash S.$$

In particular, if $K=[a,b]$, if τ_2 is concave in $[a,b]$, and if u is a minimizer of $\mathcal{I}$, then u must have a two-phase structure, i.e., there exists a set $\Omega_0 \subset \Omega$ such that $u(x)=a$ for $\mathcal{L}^N$ a.e. $x \in \Omega_0$ and $u(x)=b$ for $\mathcal{L}^N$ a.e. $x \in \Omega\backslash\Omega_0$. This result has important applications in *nucleation phenomena* which have been studied extensively by Visintin in [V1, V2], where usually K is bounded, $\tau_1(x,u) := -\xi(x)\,u$, $\xi \in L^\infty(\Omega;\mathbb{R})$ is proportional to the relative temperature, and $\psi(x)\,\tau_2(u)$ is the double well potential $\psi(x)(b-u)(u-a)$ (see Remark 5.2 below). Given a simple function $u \in L^1(\Omega;K)$ of the form

$$u(x) = \sum_{i=1}^k c_i\,\chi_{\omega_i}(x), \tag{5.3}$$

with $c_i \in K$, $\mathcal{L}^N(\omega_i) > 0$ for all $i=1,\dots,k$, and $\mathcal{L}^N(\Omega\backslash \cup_{i=1}^k \omega_i) = 0$, without loss of generality we may assume that

$$\inf K \leq c_1 < c_2 < \cdots < c_k \leq \sup K. \tag{5.4}$$

THEOREM 5.1. *Let $\mathcal{E}$ be an algebra of measurable subsets of Ω, and consider a functional $\mathcal{V} : L^1(\Omega;\mathbb{R}) \to [0,\infty]$ such that*

$$\mathcal{S}_1 := \left\{ u \in L^1(\Omega;\mathbb{R}) :\ u = \sum_{i=1}^k c_i\,\chi_{\omega_i},\ \omega_i \in \mathcal{E}, k \in \mathbb{N} \right\} \subset D(\mathcal{V}),$$

where

$$D(\mathcal{V}) := \{u \in L^1(\Omega;\mathbb{R}) :\ \mathcal{V}(u) < \infty\},$$

and

(i) *for any $u \in D(\mathcal{V}) \cap L^1(\Omega;K)$ there exists a sequence $\{u_n\} \subset \mathcal{S}_1 \cap L^1(\Omega;K)$ converging to u in $L^1(\Omega;K)$ and such that*

$$\limsup_{n\to\infty} \mathcal{V}(u_n) \leq \mathcal{V}(u).$$

(ii) *For any* $u \in \mathcal{S}_1$ *of the form* (5.3)–(5.4)*, with* $k \geq 2$*, there holds*

$$\mathcal{V}(u) = \sum_{i=1}^{k-1} (c_{i+1} - c_i) \mathcal{V}(\chi_{\cup_{r=i+1}^{k} \omega_r}). \tag{5.5}$$

(iii) *The function* $c \mapsto \mathcal{V}(c)$ *is concave in* K*.*

In addition, suppose that the functional $u \mapsto \int_\Omega \tau(x, u(x))\, dx$ *is continuous in* $D(\mathcal{V}) \cap L^1(\Omega; K)$*. Then*

$$\inf \{\mathcal{V}(u) + I_K(u, \Omega) : u \in D(\mathcal{V})\} = \inf \big\{\mathcal{V}(u) + I_K(u, \Omega) : u \in D(\mathcal{V}),\, u(x) \in K \backslash S \text{ for } \mathcal{L}^N \text{ a.e. } x \in \Omega\big\}.$$

Remark 5.2. (i) The functional $\mathcal{V}(u) + I_K(u, \Omega)$ is well defined by (5.2).

(ii) Theorem 5.1 is closely related to Theorem 2 in [V2], where $K = \mathbb{R}$ and conditions (i) and (ii) are replaced by the assumption that $\mathcal{V}$ satisfies the *generalized co-area formula*

$$\mathcal{V}(u) = \int_{\mathbb{R}} \mathcal{V}(\chi_{\{x \in \Omega:\, u(x) \geq t\}})\, dt. \tag{5.6}$$

It is easy to see that (5.6) reduces to (5.5) for functions u of the form (5.3)–(5.4). Therefore, (5.5) is weaker than (5.6). On the other hand, conditions (i) and (5.6) do not seem to be related. Indeed, consider the functional

$$\mathcal{V}(u) := \int_\Omega |Du| + \begin{cases} \int_\Omega \max\{u(x), 0\} dx & \text{if } H_{N-1}(S(u) \cap \Omega) = 0, \\ 0 & \text{otherwise.} \end{cases}$$

From the proof of Theorem 5.4 below it follows that $\mathcal{V}$ satisfies hypotheses (i)–(iii) of Theorem 5.1. Take $u(x) := 1$ in (5.6); then $\mathcal{V}(1) = \mathcal{L}^N(\Omega)$, while the right-hand side of (5.6) is infinite. Therefore, (5.6) fails. We note that $\mathcal{V}$ is not lower semicontinuous in L^1.

We remark that Theorem 5.1 may be applied to a large class of functionals of the form (1.1), for which the co-area formula might not hold.

(iii) If, in addition to hypotheses (i)–(iii) in Theorem 5.1, we assume that $\mathcal{V}$ is lower semicontinuous in $L^1(\Omega; \mathbb{R})$, that $K = \mathbb{R}$, and that there exists a set $\omega \in \mathcal{E}$ with $0 < \mathcal{L}^N(\omega) < \mathcal{L}^N(\Omega)$, then $\mathcal{V}$ satisfies the following properties:

(1) $\mathcal{V}(c) = 0$ for all $c \in \mathbb{R}$;
(2) $\mathcal{V}(\lambda\, u) = \lambda\, \mathcal{V}(u)$ for all $\lambda > 0$ and $u \in D(\mathcal{V})$;
(3) $\mathcal{V}(u + c) = \mathcal{V}(u)$ for all $c \in \mathbb{R}$ and $u \in D(\mathcal{V})$;
(4) $\mathcal{V}(u) \geq \int_{\mathbb{R}} \mathcal{V}(\chi_{\{x \in \Omega:\, u(x) \geq t\}})\, dt$ for all $u \in D(\mathcal{V})$.

In order to prove the first property, define

$$u_n(x) := \begin{cases} c + \varepsilon_n & \text{if } x \in \omega, \\ c & \text{if } x \in \Omega \backslash \omega, \end{cases}$$

where $\varepsilon_n := \frac{1}{n} \min\{1, 1/\mathcal{V}(\chi_\omega)\}$ if $\mathcal{V}(\chi_\omega) > 0$, and $\varepsilon_n := \frac{1}{n}$ otherwise. Clearly $u_n \to c$ in $L^1(\Omega; \mathbb{R})$; therefore, by the lower semicontinuity of $\mathcal{V}$ and (5.5)

$$0 \leq \mathcal{V}(c) \leq \liminf_{n \to \infty} \mathcal{V}(u_n) = \lim_{n \to \infty} \varepsilon_n \mathcal{V}(\chi_\omega) = 0,$$

where we have used the fact that $\mathcal{V}(\chi_\omega) < \infty$ because $S_1 \subset D(\mathcal{V})$.

We omit the proofs of properties (2) and (3) since they follow quite easily from hypotheses (i) and (ii) of Theorem 5.1 and from the lower semicontinuity of $\mathcal{V}$.

In order to show (4), fix $u \in D(\mathcal{V})$. By (i) there exists a sequence $\{u_n\} \subset \mathcal{S}_1$ converging to u in $L^1(\Omega;\mathbb{R})$ and $\mathcal{L}^N$ a.e. $x \in \Omega$ such that

$$\mathcal{V}(u) \geq \lim_{n\to\infty} \mathcal{V}(u_n) = \lim_{n\to\infty} \int_{\mathbb{R}} \mathcal{V}(\chi_{\{x\in\Omega:\, u_n(x)\geq t\}})\, dt \geq \int_{\mathbb{R}} \liminf_{n\to\infty} \mathcal{V}(\chi_{\{x\in\Omega:\, u_n(x)\geq t\}})\, dt$$

by (5.5) and Fatou's lemma. Since $\mathcal{L}^N(\{x \in \Omega :\, u(x) = t\}) = 0$ for all $t \in \mathbb{R}\backslash M$, where $\mathcal{L}^1(M) = 0$, we fix $t \in \mathbb{R}\backslash M$ and take a subsequence $\{u_{n_k}\}$ of $\{u_n\}$ such that

$$\liminf_{n\to\infty} \mathcal{V}(\chi_{\{x\in\Omega:\, u_n(x)\geq t\}}) = \lim_{k\to\infty} \mathcal{V}(\chi_{\{x\in\Omega:\, u_{n_k}(x)\geq t\}}).$$

Then $\{\chi_{\{x\in\Omega:\, u_{n_k}(x)\geq t\}}\}$ converges pointwise to $\chi_{\{x\in\Omega:\, u(x)\geq t\}}$ for $\mathcal{L}^N$ a.e. $x \in \Omega$ and, by the Lebesgue dominated convergence theorem, also strongly in $L^1(\Omega;\mathbb{R})$. Therefore, by the lower semicontinuity of $\mathcal{V}$,

$$\liminf_{n\to\infty} \mathcal{V}(\chi_{\{x\in\Omega:\, u_n(x)\geq t\}}) \geq \mathcal{V}(\chi_{\{x\in\Omega:\, u(x)\geq t\}})$$

for $\mathcal{L}^1$ a.e. $t \in \mathbb{R}$, and we conclude that

$$\int_{\mathbb{R}} \liminf_{n\to\infty} \mathcal{V}(\chi_{\{x\in\Omega:\, u_n(x)\geq t\}})\, dt \geq \int_{\mathbb{R}} \mathcal{V}(\chi_{\{x\in\Omega:\, u(x)\geq t\}})\, dt.$$

We do not know if the reversed inequality of (4) holds, i.e., if the co-area formula (5.6) is satisfied.

Let

$$\beta := \inf\left\{\mathcal{V}(u) + I_K(u,\Omega) :\, u \in D(\mathcal{V}),\, u(x) \in K\backslash S \quad \text{for } \mathcal{L}^N \text{ a.e. } x \in \Omega\right\}.$$

LEMMA 5.3. *If $u \in \mathcal{S}_1$, then*

$$\mathcal{V}(u) + I_K(u,\Omega) \geq \beta.$$

Proof. As $I_K(u,\Omega) = \infty$ for $u \notin L^1(\Omega;K)$ it suffices to prove the result for $u \in \mathcal{S}_1 \cap L^1(\Omega;K)$. By (5.1) we can decompose the open set S as a disjoint union of bounded intervals

$$S = \cup_{r\in\mathcal{R}}(a_r, b_r).$$

Following Visintin [V2] we replace the function τ_2 by

$$\tilde{\tau}_2(u) := \begin{cases} \tau_2(u) & \text{if } u \in \mathbb{R}\backslash S, \\ \dfrac{\tau_2(b_r) - \tau_2(a_r)}{b_r - a_r}\,(u - a_r) + \tau_2(a_r) & \text{if } u \in (a_r, b_r), \end{cases}$$

and denote by $\tilde{\tau}$ and $\tilde{I}_K(u,\Omega)$ the corresponding functionals. Define

$$\beta_i := \mathcal{V}(\chi_{\cup_{r=i+1}^{k}\omega_r}), \qquad \alpha_i(c) := \int_{\omega_i} \tilde{\tau}(x,c)\, dx.$$

Then by (5.3), (5.4), and (5.5)

$$\mathcal{V}(u) + \tilde{I}_K(u,\Omega) = \sum_{i=1}^{k-1}(c_{i+1} - c_i)\beta_i + \sum_{i=1}^{k} \alpha_i(c_i).$$

Let $r \in \mathcal{R}$ be such that $c_i \in (a_r, b_r)$ for some $i \in \{1, \dots, k\}$. There can only be finitely many such r. Assume that $k \geq 2$, and suppose that $c_l \in (a_r, b_r)$, $l \in \{2, \dots, k-1\}$, $c_i \leq a_r$ for all $i < l$ (the cases where $l = 1$ or $l = k$ can be treated analogously). Define the function

$$\Phi(t) := \sum_{i=1,\, i\neq l-1,\, l}^{k-1} \beta_{i+1}(c_{i+1} - c_i) + \beta_l(t - c_{l-1}) + \beta_{l+1}(c_{l+1} - t) + \sum_{i=1,\, i\neq l}^{k} \alpha_i(c_i) + \alpha_l(t)$$

for $t \in [a_r, d]$, where $d := c_{l+1}$ if $c_{l+1} \leq b_r$ and $d := b_r$ if $c_{l+1} > b_r$. Since $\tau_2(u) \geq \tilde{\tau}_2(u)$ by construction, then clearly $\mathcal{V}(u) + I_K(u, \Omega) \geq \mathcal{V}(u) + \tilde{I}_K(u, \Omega) = \Phi(c_l)$. Observe that since $\tilde{\tau}(x, \cdot) = \tau_1(x, \cdot) + \psi(x)\, \tilde{\tau}_2(\cdot)$ is concave in $[a_r, d]$, then the function $\alpha_l(\cdot)$ is also concave in $[a_r, d]$, and $\Phi(t)$, being the sum of a linear function and a concave function, attains its minimum at one of the endpoints Q of $[a_r, d]$. It follows that

$$\mathcal{V}(u) + I_K(u, \Omega) \geq \mathcal{V}(u) + \tilde{I}_K(u, \Omega) = \Phi(c_l) \geq \Phi(Q) = \mathcal{V}(\bar{u}) + \tilde{I}_K(\bar{u}, \Omega),$$

where

$$\bar{u}(x) := \begin{cases} \sum_{i=1,\, i\neq l}^{k} c_i\, \chi_{\omega_i}(x) + a_r \chi_{\omega_l}(x) & \text{if } Q = a_r, \\ \sum_{i=1,\, i\neq l}^{k} c_i\, \chi_{\omega_i}(x) + b_r \chi_{\omega_l}(x) & \text{if } Q = b_r, \\ \sum_{i=1,\, i\neq l, l+1}^{k} c_i\, \chi_{\omega_i}(x) + c_{l+1} \chi_{\omega_l \cup \omega_{l+1}}(x) & \text{if } Q = c_{l+1}. \end{cases}$$

If $k = 1$, namely, if $u(x) \equiv c$, then

$$\mathcal{V}(u) + I_K(u, \Omega) \geq \mathcal{V}(u) + \tilde{I}_K(u, \Omega) = \mathcal{V}(c) + \int_\Omega \tilde{\tau}(x, c)\, dx. \tag{5.7}$$

Assume that $c \in (a_r, b_r)$ for some $r \in \mathcal{R}$. Since by (iii) in the statement of Theorem 5.1 and by the construction of $\tilde{\tau}_2$ the right-hand side of (5.7) is a concave function of $c \in [a_r, b_r]$, its infimum is attained at one of the endpoints, say, at b_r, and thus we can replace $u(x)$ by $\bar{u}(x) := b_r \in K \setminus S$.

We conclude that it is energetically possible to reduce at least by one the number of values c_i between a_r and b_r. Repeating this procedure for the finite number of intervals (a_r, b_r), which contain at least one of the c_i, by means of a finite induction argument we can construct a simple function $\hat{u}$ of the form

$$\hat{u}(x) = \sum_{i=1}^{\hat{k}} \hat{c}_i\, \chi_{\hat{\omega}_i}(x),$$

where $\hat{k} \leq k$, such that $\hat{u}(\Omega) \subset K \setminus (a_r, b_r)$ for any $r \in \mathcal{R}$ and $\mathcal{V}(u) + I_K(u, \Omega) \geq \mathcal{V}(\hat{u}) + \tilde{I}_K(\hat{u}, \Omega)$. Since $\tau_2(u) = \tilde{\tau}_2(u)$ for $u \in K \setminus S$, it follows that $I_K(\hat{u}, \Omega) = \tilde{I}_K(\hat{u}, \Omega)$ and thus $\mathcal{V}(u) + I_K(u, \Omega) \geq \mathcal{V}(\hat{u}) + I_K(\hat{u}, \Omega) \geq \beta$. This concludes the proof of the lemma. □

Proof of Theorem 5.1. Let $u \in D(\mathcal{V}) \cap L^1(\Omega; K)$. By (i) there exists a sequence $\{u_n\} \subset \mathcal{S}_1 \cap L^1(\Omega; K)$ converging to u in $L^1(\Omega; K)$ such that

$$\limsup_{n\to\infty} \mathcal{V}(u_n) \leq \mathcal{V}(u).$$

Moreover, by hypothesis,

$$\lim_{n\to\infty} \int_\Omega \tau(x, u_n(x))\, dx = \int_\Omega \tau(x, u(x))\, dx,$$

and since by Lemma 5.3 $\mathcal{V}(u_n) + I_K(u_n, \Omega) \geq \beta$, it follows that

$$\mathcal{V}(u) + I_K(u, \Omega) \geq \beta,$$

and we conclude that

$$\inf \{\mathcal{V}(u) + I_K(u, \Omega) : u \in D(\mathcal{V})\} \geq \beta.$$

The reversed inequality is trivially satisfied. □

In order to apply Theorem 5.1 to functionals of the form (1.1), we consider the special case where

$$h = h(x, \xi) \quad \text{is positively homogeneous of degree one in } \xi, \quad \theta(x, u) := \hat{\sigma}\, u, \quad \hat{\sigma} \neq 0,$$

and hypotheses (A_1)–(A_7) in section 2 are satisfied. Clearly $h(x, \xi) = h^\infty(x, \xi)$, and by Theorem 2.2 (see also Corollary 3.3, (3.9), and Lemma 3.8), for $u \in BV(\Omega; \mathbb{R})$ we have

$$\begin{aligned}\mathcal{H}(u, \Omega) = &\int_\Omega f(x, \nabla u)\, dx + \int_\Omega f(x, dC(u)) \\ &+ \int_{S(u)\cap\Omega} f(x, (u^+ - u^-)\nu_u)\, dH_{N-1} + \hat{\sigma} \int_\Omega u \operatorname{div} \varphi\, dx,\end{aligned}$$

where, we recall,

$$f(x, \xi) = h(x, \xi) + \hat{\sigma}\, \varphi(x) \cdot \xi \qquad \text{for all } (x, \xi) \in \Omega \times \mathbb{R}^N.$$

Furthermore, we assume that the potential τ also satisfies the growth condition

$$\tau(x, u) \leq b_1(x) + M_1(1 + |u|^{q_c}) \qquad \text{for } \mathcal{L}^N \text{ a.e. } x \in \Omega \text{ and all } u \in K, \tag{5.8}$$

where $b_1 \in L^1(\Omega, \mathbb{R})$, $M_1 > 0$, and, as before, q_c is the Sobolev exponent $q_c := N/(N-1)$ if $N > 1$ and $q_c < \infty$ if $N = 1$. Define

$$\mathcal{V}(u) := \begin{cases} \int_\Omega f(x, Du) & \text{if } u \in BV(\Omega; \mathbb{R}), \\ \infty & \text{otherwise,} \end{cases}$$

where

$$\int_\Omega f(x, Du) := \int_\Omega f(x, \nabla u)\, dx + \int_\Omega f(x, dC(u)) + \int_{S(u)\cap\Omega} f(x, (u^+ - u^-)\nu_u)\, dH_{N-1},$$

and take $\mathcal{E}$ to be the algebra generated by the class of open polyhedral subsets of Ω. If $u \in S_1 \cap L^1(\Omega; K)$ has the form (5.3), then either $\omega_i = E_i$ or $\omega_i = \Omega \backslash E_i$, where E_i is an open polyhedral set of Ω. Therefore, in both cases $\partial\omega_i \cap \Omega = \partial E_i \cap \Omega$, which is given by the intersection of a finite union of hyperplanes. Consequently, if $i < j$ for H_{N-1} a.e. $x \in \partial\omega_j \cap \partial\omega_i$, the outward unit normal $\nu_j(x)$ to the set ω_j at the point x coincides with $-\nu_i(x)$. Moreover, for $j < i < l$ we have

$$H_{N-1}(\partial\omega_j \cap \partial\omega_i \cap \partial\omega_l \cap \Omega) = 0 \tag{5.9}$$

and

(5.10)

$$\begin{aligned}&\Omega = \cup_{i=1}^k \overline{\omega}_i \cap \Omega, \qquad \partial\omega_i \cap \Omega = \cup_{j\neq i} \partial\omega_i \cap \partial\omega_j \cap \Omega, \\ &\partial\left(\cup_{l=i}^k \overline{\omega}_l \cap \Omega\right) = \partial\left(\cup_{l=i+1}^k \overline{\omega}_l \cap \Omega\right) \setminus \left(\cup_{l=i+1}^k \partial\omega_l \cap \partial\omega_i \cap \Omega\right) \cup \left(\cup_{j=1}^{i-1} \partial\omega_j \cap \partial\omega_i \cap \Omega\right).\end{aligned}$$

These properties will be useful in the sequel.

The main result of the section is the following theorem.

THEOREM 5.4. *If* (H_1)–(H_7) *and* (5.8) *are verified, then*

$$\inf\{\mathcal{I}(u,\Omega):\ u\in BV(\Omega;K)\}=\inf\{\mathcal{I}(u,\Omega):\ u\in BV(\Omega;K\backslash S)\}.$$

Remark 5.5. Theorem 5.4 no longer holds in general if $\theta(x,\cdot)$ is nonlinear. Indeed, consider the simple case where $\Omega:=(c,d)$, $K:=[-1,1]$,

$$\mathcal{H}(u,\Omega):=\sigma\int_\Omega|Du(x)|-\int_{\partial\Omega}\sin(\pi\,T\,u(x))\,dH_{N-1}(x),\quad u\in BV(\Omega;\mathbb{R}),$$

and $\tau(x,u):=a(1-u^2)$. Here $K\setminus S=\{-1,1\}$, and if $\sigma>\pi$, then all conditions (H_1)–(H_7) are satisfied. Let $u\in BV(\Omega;\mathbb{R})$, with $u(x)\in\{-1,1\}$ for $\mathcal{L}^N$ a.e. $x\in\Omega$. Then $\mathcal{I}(u,\Omega)=\sigma\int_\Omega|Du(x)|\geq 0$. On the other hand, if we take $\bar u(x)\equiv\frac12$, then $\mathcal{I}(\bar u,\Omega)=-2+\frac34\,a(d-c)<0$ provided $a(d-c)<\frac83$.

For the proof of the lemma below we refer to [F], [LM], and [Re].

LEMMA 5.6. *Let* $f:\Omega\times\mathbb{R}^N\to\mathbb{R}$ *be a continuous function such that* $\xi\in\mathbb{R}^N\mapsto f(x,\xi)$ *is positively homogeneous of degree one for all* $x\in\Omega$, *and*

$$0\leq f(x,\xi)\leq C(1+|\xi|)\quad \textit{for some } C>0,\ \textit{all } x\in\Omega \textit{ and } \xi\in\mathbb{R}^N.$$

Let $\{\mu_n\}$ *be a sequence of Radon measures converging weakly-*$\star$ *to a Radon measure* μ *and*

$$\lim_{n\to\infty}|\mu_n|(\Omega)=|\mu|(\Omega).$$

Then

$$\lim_{n\to\infty}\int_\Omega f(x,d\mu_n)=\int_\Omega f(x,d\mu).$$

Proof of Theorem 5.4. We claim that $\mathcal{V}$ satisfies conditions (i)–(iii) of Theorem 5.1. To prove (i) fix $u\in BV(\Omega;K)$. We can find a sequence $\{u_n\}$ of the form

$$u_n(x)=\sum_{i=1}^{k_n}c_{n,i}\,\chi_{\omega_{n,i}}(x)$$

such that u_n converges strongly to u in $L^1(\Omega;\mathbb{R})$ and $\int_\Omega|Du_n|\to\int_\Omega|Du|$ (see [AMT]). Here $c_{n,i}\in\mathbb{R}$, the sets $\omega_{n,i}$ are open polyhedral set of Ω, $\cup_{i=1}^{k_n}\overline{\omega}_{n,i}\cap\Omega=\Omega$, and as in (5.4)

$$c_{n,1}<c_{n,2}<\cdots<c_{n,k_n}.$$

By (5.10) it is not difficult to see that

$$S(u_n)=\cup_{(i,j)\in J_n}(\partial\omega_{n,i}\cap\partial\omega_{n,j}),$$

where $J_n=\{(i,j)\in\mathbb{N}^2:\ 1\leq i<j\leq k_n\}$. Furthermore, if $x_0\in\partial\omega_{n,i}\cap\partial\omega_{n,j}$, then $u_n^+(x_0)=c_{n,j}$, $u_n^-(x_0)=c_{n,i}$, and

$$\int_\Omega|Du_n|=\sum_{(i,j)\in J_n}(c_{n,j}-c_{n,i})H_{N-1}(\partial\omega_i\cap\partial\omega_j\cap\Omega).$$

Let $\bar{u}_n(x) := \sum_{i=1}^{k_n} d_{n,i}\,\chi_{\omega_{n,i}}(x)$, where

$$d_{n,i} = \begin{cases} \sup K & \text{if } c_{n,i} \geq \sup K, \\ c_{n,i} & \text{if } -\inf K < c_{n,i} < \sup K, \\ \inf K & \text{if } c_{n,i} \leq \inf K. \end{cases}$$

Since $0 \leq (d_{n,j} - d_{n,i}) \leq (c_{n,j} - c_{n,i})$, it follows that $\int_\Omega |D\bar{u}_n| \leq \int_\Omega |Du_n|$. Consequently

$$\limsup_{n\to\infty} \int_\Omega |D\bar{u}_n| \leq \int_\Omega |Du|.$$

On the other hand, since $u(x) \in K$ for $\mathcal{L}^N$ a.e. $x \in \Omega$, then $|u(x) - \bar{u}_n(x)| \leq |u(x) - u_n(x)|$ by construction, and so $\{\bar{u}_n\}$ converges strongly to u in $L^1(\Omega;\mathbb{R})$. By the lower semicontinuity of the total variation we have that $\int_\Omega |Du| \leq \liminf_{n\to\infty} \int_\Omega |D\bar{u}_n|$; thus

$$\lim_{n\to\infty} \int_\Omega |D\bar{u}_n| = \int_\Omega |Du|$$

and from Lemma 5.6 we conclude that

$$\lim_{n\to\infty} \int_\Omega f(x, D\bar{u}_n) = \int_\Omega f(x, Du).$$

In order to verify (ii) in the statement of Theorem 5.1, fix $u \in BV(\Omega;\mathbb{R})$ of the form (5.3)–(5.4), where $c_i \in K$, $\omega_i \in \mathcal{E}$, $\cup_{i=1}^k \overline{\omega}_i \cap \Omega = \Omega$, $k \geq 2$, and

$$c_1 < c_2 < \cdots < c_k.$$

Since by homogeneity $f(x,0) = 0$, we have

$$\mathcal{V}(u) = \sum_{(i,j)\in J} (c_j - c_i) \int_{\partial\omega_i \cap \partial\omega_j \cap \Omega} f(x, \nu_j)\, dH_{N-1}$$

with $J = \{(i,j) \in \mathbb{N}^2 : 1 \leq i < j \leq k\}$, or, equivalently,

(5.11)

$$\begin{aligned} \mathcal{V}(u) = {} & c_k \sum_{j=1}^{k-1} \int_{\partial\omega_k \cap \partial\omega_j \cap \Omega} f(x, \nu_k)\, dH_{N-1} - c_1 \sum_{l=2}^{k} \int_{\partial\omega_l \cap \partial\omega_1 \cap \Omega} f(x, \nu_l)\, dH_{N-1} \\ & + \sum_{i=2}^{k-1} c_i \left(\sum_{j=1}^{i-1} \int_{\partial\omega_i \cap \partial\omega_j \cap \Omega} f(x, \nu_i)\, dH_{N-1} - \sum_{l=i+1}^{k} \int_{\partial\omega_l \cap \partial\omega_i \cap \Omega} f(x, \nu_l)\, dH_{N-1} \right). \end{aligned}$$

By (5.9) and (5.10) we can rewrite the first two terms as, respectively,

$$c_k \int_{\partial\omega_k \cap \Omega} f(x, \nu_k)\, dH_{N-1} \quad \text{and} \quad -c_1 \int_{\partial(\cup_{l=2}^k \overline{\omega_l}) \cap \Omega} f(x, -\nu_1)\, dH_{N-1},$$

and for $i \in \{2, \ldots, k-1\}$

(5.12)

$$\begin{aligned} & \sum_{j=1}^{i-1} \int_{\partial\omega_i \cap \partial\omega_j \cap \Omega} f(x, \nu_i)\, dH_{N-1} - \sum_{l=i+1}^{k} \int_{\partial\omega_l \cap \partial\omega_i \cap \Omega} f(x, \nu_l)\, dH_{N-1} \\ & \qquad = \int_{\partial(\cup_{l=i}^k \overline{\omega_l}) \cap \Omega} f(x, \hat{\nu}_i)\, dH_{N-1} - \int_{\partial(\cup_{l=i+1}^k \overline{\omega_l}) \cap \Omega} f(x, \hat{\nu}_{i+1})\, dH_{N-1}, \end{aligned}$$

where $\hat{\nu}_i$ and $\hat{\nu}_{i+1}$ are, respectively, the outward unit normals to the sets $\cup_{l=i}^{k} \overline{\omega_l}$ and $\cup_{l=i+1}^{k} \overline{\omega_l}$. It now follows from (5.11)–(5.12) that

$$\mathcal{V}(u) = c_k \mathcal{V}(\chi_{\omega_k}) - c_1 \mathcal{V}(\chi_{\cup_{l=2}^{k}\omega_l}) + \sum_{i=2}^{k-1} c_i \mathcal{V}(\chi_{\cup_{l=i}^{k}\omega_l}) - \sum_{i=2}^{k-1} c_i \mathcal{V}(\chi_{\cup_{l=i+1}^{k}\omega_l}),$$

which is (ii) in the statement of Theorem 5.1.

Finally, by (5.2), (5.8), and the Sobolev inequality, the functional $u \mapsto \int_\Omega \tau(x, u(x))\, dx$ is continuous in $BV(\Omega; K)$ (see [K, Thm. 2.1]). Therefore, we can now apply Theorem 5.1 (with $\tau(x, u)$ replaced by $\tau(x, u) + \hat{\sigma}\, u \operatorname{div} \varphi(x)$) to obtain that

$$\inf \{\mathcal{I}(u, \Omega) : u \in BV(\Omega; K)\} = \inf \{\mathcal{I}(u, \Omega) : u \in BV(\Omega; K \backslash S)\}. \qquad \square$$

COROLLARY 5.7. *Assume that $K = [a, b]$ in Theorem 5.4. Then there exists a function $u \in BV(\Omega; [a, b]\backslash S)$ such that*

$$\mathcal{I}(u, \Omega) = \inf \{\mathcal{I}(u, \Omega) : u \in BV(\Omega; [a, b])\}.$$

Proof. By Theorem 5.4,

$$\inf \{\mathcal{I}(u, \Omega) : u \in BV(\Omega; [a, b])\} = \inf \{\mathcal{I}(u, \Omega) : u \in BV(\Omega; [a, b]\backslash S)\} = \beta.$$

To complete the proof it suffices to apply Corollary 4.3, with $K := [a, b]\backslash S$, to find $u \in BV(\Omega; [a, b]\backslash S)$ such that $\mathcal{I}(u, \Omega) = \beta$. $\square$

Remark 5.8. If we assume that τ_2 is concave in $[a, b]$, then $S = (a, b)$ and consequently the minimizer u in Corollary 5.7 has the property that $u(x) \in \{a, b\}$ for $\mathcal{L}^N$ a.e. $x \in \Omega$.

STABLE DETERMINATION OF BOUNDARIES FROM CAUCHY DATA*

E. BERETTA† AND S. VESSELLA‡

Abstract. The problem of determining a portion Γ of the boundary of a bounded planar domain Ω from Cauchy data arises in several contexts, for example, such as in corrosion detection from electrostatic measurements. We investigate this severely ill-posed problem establishing logarithmic continuous dependence of Γ from Cauchy data.

Key words. inverse problems, stability

1. Introduction. Let Ω be a bounded open subset of $\mathbf{R}^2$ and let Γ indicate a portion of the boundary of Ω. Let ψ be a function on $\partial\Omega$ having zero mean value and such that supp $(\psi)\gamma$, where $\gamma \subset \partial\Omega\backslash\Gamma$. Consider the Neumann problem

$$\begin{cases} \Delta u = 0 & \text{in } \Omega, \\ \frac{\partial u}{\partial n} = 0 & \text{on } \Gamma, \\ \frac{\partial u}{\partial n} = \psi & \text{on } \partial\Omega\backslash\Gamma, \end{cases} \tag{1.1}$$

where n denotes the outer unit normal to $\partial\Omega$. If we normalize u setting, for example,

$$\int_{\partial\Omega} u ds = 0, \tag{1.2}$$

then the solution u to (1.1) is uniquely determined.

In this paper we shall deal with the inverse problem of determining Γ from the knowledge of the additional boundary measurement

$$u|_\gamma = g$$

when one suitable Neumann datum ψ in (1.1) is assigned. This problem occurs, for example, in corrosion detection by electrostatic measurements [KS], [KSV]. In this case Γ represents the damaged part of the boundary of a conducting specimen and one tries to identify Γ by assigning a suitable flux ψ and measuring the corresponding potential u on the accessible part of the boundary, γ.

Another application of this problem is planar crack detection in nonferrous metals from electromagnetic measurements [McI], [AP], [ABJ].

In this paper we address the question of continuous dependence of Γ from the Cauchy data (ψ, g). Since it is necessary to determine the interior values of u from the Cauchy data, one expects the problem to be severely ill-posed. In fact, in [A1] Alessandrini proves that logarithmic type continuous dependence of Γ from the Cauchy data

(ψ, g) is the best possible. An indication of the ill-posedness of the problem is also given in [AP].

In this paper we prove that, under suitable a priori assumptions on the unknown curve Γ, the continuous dependence of Γ from the data is in fact of logarithmic type.

In order to give an idea of the proof of our result let us begin by illustrating the proof of the uniqueness of Γ. Let $\psi \neq 0$ and let Γ_1, Γ_2 be two simple curves having common endpoints. Let $u_1 = u_2$ on γ (here $u_j, j = 1, 2$, is harmonic in Ω_j, the bounded smooth subset corresponding to Γ_j). Let Λ be the connected component of $\overline{\Omega}_1 \cap \overline{\Omega}_2$ containing γ. Uniqueness of the Cauchy problem for the Laplace equation and analytic continuation of harmonic functions give that $u_1 = u_2$ in Λ. Therefore, if for instance $\Omega_1 \backslash \Omega_2 \neq \emptyset$, then by the inclusion $\partial(\Omega_1 \backslash \Lambda) \subset (\partial\Lambda \cap \Gamma_2) \cup \Gamma_1$, by the fact that $\frac{\partial u_2}{\partial n} = 0$ on Γ_2, and by the divergence theorem one has

$$\int_{\Omega_1 \backslash \Omega_2} |\nabla u_1|^2 dx \leq \int_{\Omega_1 \backslash \Lambda} |\nabla u_1|^2 dx = \int_{\partial\Lambda \cap \Gamma_2} u_1 \frac{\partial(u_1 - u_2)}{\partial n} ds. \tag{1.3}$$

Therefore, from (1.3) it follows that $|\nabla u_1| = 0$ in $\Omega_1 \backslash \Omega_2$ and by analytic continuation of harmonic functions it follows that $\nabla u_1 = 0$ in Ω_1, contradicting the assumption $\frac{\partial u_1}{\partial n}|_\gamma \neq 0$.

To prove our result we use (1.3) in order to estimate the Lebesgue measure of the set $\Omega_1 \triangle \Omega_2$. In fact, choosing a suitable function ψ, by [A2], it follows that u_1 has no critical points in $\overline{\Omega_1} \backslash \gamma$ and a pointwise lower bound on $|\nabla u_1|$ holds; cf. Lemma 3.3. Coupling this fact with stability estimates for the Cauchy problem applied to $u_1 - u_2$, using (1.3) we derive a first rough stability estimate for the Lebesgue measure of the set $\Omega_1 \triangle \Omega_2$. This estimate is refined in the second part of Theorem 2.1. Finally we obtain the desired estimate on the Hausdorff distance of Γ_1 from Γ_2 establishing an upper bound for the Hausdorff distance of Γ_1 from Γ_2 in terms of the Lebesgue measure of the set $\Omega_1 \triangle \Omega_2$, Proposition 3.4.

The paper is organized as follows. In section 2 we describe the a priori assumptions on Ω, Γ, and on the measurements and we state our main result (Theorem 2.1). In section 3 we derive some bounds on u and on the measure of Ω and of $\partial\Omega$, which are consequences of the a priori information illustrated in section 2. In section 4 we prove Theorem 2.1. Finally in the Appendix we give the proof of Proposition 3.4 of section 3.

2. The main result. We start by giving some notation and by listing the required a priori assumptions.

Let $x^0 \in \mathbf{R}^2$, $r > 0$, A, B be two measurable subsets of $\mathbf{R}^2$. In the sequel we will use the following notation:

(i) $B(x^0, r) = \{x \in \mathbf{R}^2 : |x - x^0| < r\}$;

(ii) $|A|$ denotes the measure of the set A; if ∂A is smooth, then $|\partial A|$ denotes the length of ∂A;

(iii) $d(x^0, A) = \inf_{x \in A} |x - x^0|$, $\quad d(A, B) = \inf_{x \in A} d(x, B)$;

(iv) $(A)_r = \{x \in A : d(x, \mathbf{R}^2 \backslash A) \geq r\}$;

(v) $\delta_{\mathcal{H}}(A, B) = \sup\{\sup_{x \in A} d(x, B), \sup_{x \in B} d(x, A)\}$, Hausdorff distance between the sets A and B;

(vi) $C = C(a, b, c, \ldots)$ indicates that C depends only on the parameters $a, b, c, \ldots$.

In the sequel we will indicate different constants with the same letter C.

Given the positive constants A, L_0, L_1, R we suppose that Ω indicates a simply connected bounded open C^2 subset of $\mathbf{R}^2$ satisfying the following conditions.

Prior information on Ω.

$$|\Omega| \leq A; \tag{2.1a}$$

$$\begin{cases} \forall x \in \partial\Omega \text{ there exist two disks of radius } R \text{ tangent in } x, \\ \text{the first contained in } \overline{\Omega} \text{ and the second in } \mathbf{R}^2\backslash\Omega. \end{cases} \tag{2.1b}$$

Prior information on the unknown boundary Γ. Let $\gamma \subset \partial\Omega$ denote an arc of endpoints a_0 and a_1 where we will make our measurements. Denote with Γ an arc with $\overline{\Gamma} \subset \text{int}(\partial\Omega\backslash\gamma)$ and of endpoints b_0 and b_1 such that

$$d(\gamma, \Gamma) \geq L_0 \tag{2.2a}$$

and

$$|\Gamma| \geq L_0. \tag{2.2b}$$

Prior information on the measurements. Given two points $p_1, p_2 \in \gamma$ such that

$$|p_1 - p_2| \geq L_1, \tag{2.3}$$

we consider two functions $\eta_1, \eta_2 \in C^2(\partial\Omega)$ such that

$$\int_{\partial\Omega} \eta_i ds = 1, \quad i = 1, 2, \tag{2.4a}$$

and

$$\text{supp}(\eta_i) \subset \gamma \cap B(p_i, h), \quad i = 1, 2, \tag{2.4b}$$

where $h \in (0, L_1/2)$.

Let

$$\psi = \eta_1 - \eta_2. \tag{2.5}$$

We will consider the solution u of the following Neumann problem

$$\begin{aligned} \Delta u &= 0 && \text{in } \Omega, \\ \tfrac{\partial u}{\partial n} &= 0 && \text{on } \Gamma, \\ \tfrac{\partial u}{\partial n} &= \psi && \text{on } \partial\Omega\backslash\Gamma, \\ \textstyle\int_{\partial\Omega} u ds &= 0, \end{aligned} \tag{2.6}$$

where n denotes the exterior unit normal to $\partial\Omega$. Observe that by (2.4a)–(2.4b) $\psi = 0$ on $\partial\Omega\backslash\gamma$.

Given two curves Γ_i, $i = 1, 2$, let u_1, u_2 indicate the solutions of problem (2.6) corresponding to the curves Γ_1, Γ_2, respectively. Then the following result holds.

THEOREM 2.1. *Assume conditions* (2.1)–(2.5). *Given* $\epsilon \in (0, 1)$, *if*

$$\max_{x\in\gamma} |u_1(x) - u_2(x)| \leq \epsilon,$$

then for any $\eta > 0$ *there exists a positive constant* $C = C(L_0, L_1, A, R, \eta)$ *such that*

$$\delta_{\mathcal{H}}(\Gamma_1, \Gamma_2) \leq C |\ln \epsilon|^{-\frac{1}{3}+\eta}.$$

See section 4 for the proof.

3. Some preliminary results. In this section we will expose and prove some consequences of the a priori information listed in the previous section.

PROPOSITION 3.1. *Let the a priori conditions* (2.1a) *and* (2.1b) *be satisfied. Let* $\kappa(x)$ *indicate the curvature at the point* $x \in \partial\Omega$. *Then, for any* $r \in [0, R]$, *the following bounds hold:*

$$|\kappa(x)| \leq \frac{1}{R} \tag{3.1}$$

for any $x \in \partial\Omega$. *We also have that*

$$|\partial\Omega| \leq c\frac{A}{R}, \tag{3.2}$$

$$|\Omega\backslash(\Omega)_r| \leq c\frac{A}{R}r, \tag{3.3}$$

and

$$|\partial(\Omega)_r| \leq c\frac{A}{R}, \tag{3.4}$$

where $c = 24\sqrt[3]{6}e^2$.

Proof. The bound (3.1) follows immediately from assumption (2.1b).

By [V] one has that for $r \in [0, R]$,

$$|\partial(\Omega)_r| = |\partial\Omega| - r\int_{\partial\Omega} \kappa(x)ds \tag{3.5}$$

and

$$|\Omega\backslash(\Omega)_r| = \int_0^r |\partial(\Omega)_t|dt = r|\partial\Omega| - \frac{r^2}{2}\int_{\partial\Omega} \kappa(x)ds. \tag{3.6}$$

Let $f(r) = |\Omega\backslash(\Omega)_r|$ for $r \in [0, R]$. By [G] the interpolation inequality for f follows:

$$\begin{aligned} |\partial\Omega| = f'(0) &\leq 12e^2\|f\|_\infty^{2/3}\left(\|f'''\|_\infty + \frac{6}{R^2}\|f\|_\infty\right)^{1/3} \\ &\leq 12\sqrt[3]{6}e^2\frac{|\Omega|}{R} \leq 12\sqrt[3]{6}e^2\frac{A}{R}, \end{aligned} \tag{3.7}$$

which gives estimate (3.2). From (3.5), (3.1), and (3.7) it follows that for $r \in [0, R]$

$$|\partial(\Omega)_r| \leq |\partial\Omega| + \frac{r}{R}|\partial\Omega| \leq 2|\partial\Omega| \leq 24\sqrt[3]{6}e^2\frac{A}{R}$$

from which one gets (3.4). Finally (3.6), (3.1), and (3.7) lead to

$$|\Omega\backslash(\Omega)_r| \leq r|\partial\Omega|\left(1 + \frac{r}{2R}\right) \leq 18\sqrt[3]{6}e^2\frac{A}{R}$$

for $r \in [0, R]$ and (3.3) follows, completing the proof. □

Observe that from bound (3.2) of Proposition 3.1 it follows immediately that

$$diam(\Omega) \leq c\frac{A}{R}. \tag{3.8}$$

Now we derive some upper and lower bounds for the solution u of problem (2.6).

PROPOSITION 3.2. *Let the a priori assumptions* (2.1a)–(2.1b) *be satisfied. Then for any $q > 2$ there exist three positive constants $E_i = E_i(A, R, \|\psi\|_{C^2(\partial\Omega)}, q)$, $i = 0, 1, 2$, such that*

$$\|u\|_{L^\infty(\Omega)} \le E_0, \quad \|\nabla u\|_{L^\infty(\Omega)} \le E_1, \quad \|D^2 u\|_{L^q(\Omega)} \le E_2. \tag{3.9}$$

Proof. Let $\phi(s) = \int_0^s \psi(t)dt$, where s is the arclength parameter on $\partial\Omega$. Then the harmonic conjugate v, of u, satisfies the Dirichlet problem

$$\begin{aligned} \Delta v &= 0 \qquad \text{in } \Omega, \\ v &= \phi \qquad \text{on } \partial\Omega. \end{aligned} \tag{3.10}$$

Let $\Phi \in C^2(\overline{\Omega})$ be an extension of ϕ to $\overline{\Omega}$ such that $\Phi|_{\partial\Omega} = \phi$ and $\|\Phi\|_{C^2(\overline{\Omega})} \le C\|\phi\|_{C^2(\partial\Omega)}$. Then a priori estimates for elliptic equations [GT] give

$$\|v\|_{2,q} \le C\|\psi\|_{C^2(\partial\Omega)}.$$

From Sobolev immersion theorem and by the fact that

$$|\nabla u(x)| = |\nabla v(x)|, \quad |D^2 u(x)| = |D^2 v(x)|,$$

it follows that

$$\|u\|_{L^\infty(\Omega)} \le E_0, \quad \|\nabla u\|_{L^\infty(\Omega)} \le E_1, \quad \|D^2 u\|_{L^q(\Omega)} \le E_2,$$

where E_0, E_1, E_2 depend on $A, R, \|\psi\|_{C^2(\partial\Omega)}$, and q, which then proves the proposition. □

LEMMA 3.3. *Assume conditions* (2.1)–(2.5) *hold and let u be the solution of problem* (2.6). *Then there exists a positive constant $C = C(L_0, A, R, \|\psi\|_{C^2(\partial\Omega)})$ such that*

$$|\nabla u(x)| \ge C \quad \textit{for any } x \in \Omega : d(x, \gamma) \ge \frac{L_0}{2}. \tag{3.11}$$

Proof. As in Proposition 3.2 we consider the harmonic conjugate of u, v satisfying

$$\begin{aligned} \Delta v &= 0 \qquad \text{in } \Omega, \\ v &= \phi \qquad \text{on } \partial\Omega, \end{aligned}$$

where $\phi = \int_0^s \psi(t)dt$. Let $z = x + iy$ and let $f(z) = \xi + i\eta = \zeta$ denote a conformal mapping such that

(a) f maps Ω one to one onto $B^+(0,1) = \{\zeta : |\zeta| < 1, \eta > 0\}$;
(b) $f(\gamma)$ consists of the semicircle $\{\zeta : |\zeta| = 1, \eta > 0\}$ and $f(\partial\Omega\backslash\gamma)$ consists of the segment $\{\zeta : \xi \in [-1, 1], \eta = 0\}$.

Then $f \in C^2(\overline{\Omega}\backslash\{a_0, a_1\})$ and the following bounds for $|f'|$ hold:

$$k_1^{-1}\frac{R}{A} \le |f'| \le k_2\frac{1}{L_0} \quad \text{in } \overline{\Omega}, \tag{3.12}$$

where $k_1 = (12\sqrt{2}\sqrt[3]{6}e^2)$ and $k_2 = \sqrt{2}\pi$.

The regularity of f follows from the fact that $\partial\Omega \in C^2$ and $f|_{\partial\Omega}$ is smooth except at the endpoints of γ, a_0, and a_1. To prove the lower bound in (3.12) let us consider

the inverse mapping $f^{-1} : B^+(0,1) \to \Omega$. Then $f^{-1} \in C^2(\overline{B^+(0,1)}\backslash\{q_0, q_1\})$, where q_0, q_1 are the singular points of $\partial B^+(0,1)$. Moreover, if $f^{-1}(\zeta) = \varphi + i\omega$, then by the Cauchy–Riemann equations and by estimate (3.2) of Proposition 3.1 it is easy to see that

$$|\varphi_\xi|, |\varphi_\eta| \le k_1 \frac{A}{R} \text{ on } \partial B^+(0,1). \tag{3.13}$$

By the weak maximum principle it follows that (3.13) holds in $\overline{B^+(0,1)}$. Hence

$$|(f^{-1})'| = |\nabla\varphi| \le k_1 \frac{A}{R} \quad \text{in } \overline{B^+(0,1)}$$

from which the lower bound in (3.12) follows. To show the upper bound for $|f'|$ we proceed similarly estimating $|\xi_x|, |\xi_y|$ on $\partial\Omega$ and using the a priori information (2.2b).

Let $w = v \circ f^{-1} : B^+(0,1) \to \mathbf{R}$ and consider the odd reflection of w, w^* satisfying

$$\begin{aligned} \Delta w^* &= 0 \qquad \text{in } B(0,1), \\ w^* &= \phi^* \qquad \text{on } \partial B(0,1). \end{aligned}$$

By our choice of ϕ, $\partial B(0,1)$ can be split into two arcs on which alternatively ϕ^* is a nondecreasing and nonincreasing function of the arclength parameter. Then, by Theorem 2.7 of [AM], w^* has no interior critical points. Furthermore by [A2] there exists a positive constant $C = C(d, \|\phi^*\|_{C^2(\overline{B(0,1)})})$ such that

$$|\nabla w^*(\zeta)| \ge C \quad \text{for any } \zeta \in B(0,1) : d(\zeta, \partial B(0,1)) \ge d > 0.$$

Hence

$$|\nabla w(\zeta)| \ge C \quad \text{for any } \zeta \in B^+(0,1) : d(\zeta, \partial B^+(0,1)\backslash\{\eta = 0\}) \ge d > 0. \tag{3.14}$$

Let $\zeta \in B^+(0,1)$ satisfy (3.14) and let $z \in \Omega$ be such that $\zeta = f(z)$. Then $d(z,\gamma) \ge \frac{dL_0}{k_1}$. Choose $d = \frac{k_1}{4}$. Then by (3.13) and (3.14) it follows that

$$|\nabla u(z)| = |\nabla v(z)| = |\nabla w(f(z))| \cdot |f'(z)| \ge C > 0$$

for $z \in \Omega$ such that $d(z,\gamma) \ge \frac{L_0}{4}$. Finally, since $\phi \circ f^{-1} \in C^2(\overline{B^+(0,1)})$, ψ has support in γ and $f^{-1} \in C^2(\overline{B^+(0,1)}\backslash\{q_0, q_1\})$ one has that $C = C(L_0, A, R, \|\psi\|_{C^2(\partial\Omega)})$, which completes the proof. □

PROPOSITION 3.4. *Let Ω_1, Ω_2 denote two bounded simply connected C^2 subsets of $\mathbf{R}^2$ satisfying conditions* (2.1a)–(2.1b) *and such that $\Omega_1, \Omega_2 \subset B(z, 2d)$, where $d = \max\{diam(\Omega_1), diam(\Omega_2)\}$ and $z \in \mathbf{R}^2$. Then*

$$\delta_{\mathcal{H}}(\partial\Omega_1, \partial\Omega_2) \le \frac{16d}{(\pi)^{1/3} R^{2/3}} |\Omega_1 \triangle \Omega_2|^{1/3}. \tag{3.15}$$

Since the proof is rather technical we postpone the proof to the Appendix.

4. Proof of Theorem 2.1. Let u_i be the solution of the problem

$$\begin{aligned} \Delta u_i &= 0 \qquad \text{in } \Omega_i, \\ \frac{\partial u_i}{\partial n} &= 0 \qquad \text{on } \Gamma_i, \\ \frac{\partial u_i}{\partial n} &= \psi \qquad \text{on } \partial\Omega_i\backslash\Gamma_i, \\ \int_{\partial\Omega_i} u_i ds &= 0, \end{aligned} \tag{4.1}$$

where Ω_i indicates the subset corresponding to Γ_i.

Proof of Theorem 2.1. Every time we will say in the sequel that a property is true for ϵ sufficiently small, we will mean that there exists a positive number $\epsilon_0 = \epsilon_0(A, R, L_0, L_1, \|\psi\|_{C^2(\partial\Omega)}, q)$ such that for every $\epsilon \in (0, \epsilon_0)$ the property holds.

Let $R_1 = \min(R, L_0)$ and $u = u_1 - u_2$ be defined in $\Omega_1 \cap \Omega_2$. Let

$$J_1 = \left\{ x \in \Omega_1 \cap \Omega_2 | d(x, \gamma) \leq R_1; d(x, a_0), d(x, a_1) \geq \frac{R_1}{4} \right\}$$

and

$$J_2 = \left\{ x \in \Omega_1 \cap \Omega_2 | d(x, \gamma) \leq R_1; d(x, a_0), d(x, a_1) \geq \frac{R_1}{3} \right\}.$$

Then by [P] it follows that for $x \in J_1$,

$$|\nabla u(x)| \leq C\epsilon^{\lambda}, \tag{4.2}$$

where $\lambda \in (0, 1)$ depends on γ and R_1.

We divide the proof into two steps.

Step 1. In this first part of the proof we establish a first rough estimate of $\delta_{\mathcal{H}}(\Gamma_1, \Gamma_2)$. For let $r \in (0, R_1/3)$. In the sequel we will indicate with γ_r the set $\gamma_r = \{x \in \Omega_1 | d(x, \gamma) = r\}$ and with Λ_r the connected component of $(\Omega_1)_r \cap (\Omega_2)_r$ containing γ_r. The following inclusions hold:

$$\Omega_1 \backslash \Omega_2 \subset [\Omega_1 \backslash (\Omega_1)_r] \cup [(\Omega_1)_r \backslash (\Omega_2)_r], \tag{4.3}$$

$$(\Omega_1)_r \backslash (\Omega_2)_r \subset (\Omega_1)_r \backslash \Lambda_r. \tag{4.3i}$$

Setting $\Gamma'_r = \partial\Omega_j \backslash \gamma$ for $j = 1, 2$, we have that the set $\Gamma'_{j,r}$ indicates the set $\Gamma'_{i,r} = \{x \in \Omega_i | d(x, \Gamma'_i) = r\}$:

$$\partial[(\Omega_1)_r \backslash \Lambda_r] \subset [\partial\Lambda_r \cap \Gamma'_{2,r}] \cup \Gamma'_{1,r}. \tag{4.3ii}$$

From (3.9), (4.3), and (4.3ii) it follows that

$$\int_{\Omega_1 \backslash \Omega_2} |\nabla u_1|^2 dx \leq E_1^2 |\Omega_1 \backslash (\Omega_1)_r| + \int_{(\Omega_1)_r \backslash \Lambda_r} |\nabla u_1|^2 dx. \tag{4.4}$$

From the divergence theorem, from (3.9), and from (4.3ii) one has

$$\begin{aligned} \int_{(\Omega_1)_r \backslash \Lambda_r} |\nabla u_1|^2 dx &= \int_{\partial[(\Omega_1)_r \backslash \Lambda_r]} u_1 \frac{\partial u_1}{\partial n} ds \\ &\leq E_0 \left(\int_{\partial\Lambda_r \cap \Gamma'_{2,r}} \left| \frac{\partial u_1}{\partial n} \right| ds + \int_{\Gamma'_{1,r}} \left| \frac{\partial u_1}{\partial n} \right| ds \right). \end{aligned} \tag{4.5}$$

Now, let $x \in \partial\Lambda_r \cap \Gamma'_{2,r}$ and let $y \in \Gamma'_2$ be such that $x = y - rn_y$, where n_y indicates the exterior outer unit normal at $\partial\Omega_2$ at the point y. Since $n_x = n_y$ and $\frac{\partial u_2}{\partial n} = 0$ on Γ'_2 it follows that

$$\left| \frac{\partial u_1}{\partial n}(x) \right| \leq |\nabla u(x)| + |\nabla u_2(x) - \nabla u_2(y)|. \tag{4.6}$$

From (3.9), from the Sobolev immersion theorem, and from (4.6) one derives

$$\left|\frac{\partial u_1}{\partial n}(x)\right| \le |\nabla u(x)| + Cr^{1-2/q} \text{ for } x \in \partial\Lambda_r \cap \Gamma'_{2,r} \text{ and } q > 2. \tag{4.7}$$

Furthermore by (3.9) and since $\frac{\partial u_1}{\partial n} = 0$ on Γ'_1 one has

$$\left|\frac{\partial u_1}{\partial n}(x)\right| \le Cr^{1-2/q} \text{ for } x \in \Gamma'_{1,r}. \tag{4.8}$$

Hence by (4.4)–(4.8) and by the a priori information we derive

$$\begin{aligned}\int_{\Omega_1\setminus\Omega_2} |\nabla u_1|^2 dx &\le E_1^2 |\Omega_1 \setminus (\Omega_1)_r| \\ &+ E_0 \left((|\Gamma'_{1,r}| + |\Gamma'_{2,r}|) Cr^{1-2/q} + |\Gamma'_{2,r}| \max_{\partial\Lambda_r\cap\Gamma'_{2,r}} |\nabla u| \right) \\ &\le C \left[\left(\frac{r}{R_1}\right)^{1-2/q} + \max_{\partial\Lambda_r\cap\Gamma'_{2,r}} |\nabla u| \right].\end{aligned} \tag{4.9}$$

We now estimate $\max_{\partial\Lambda_r\cap\Gamma'_{2,r}} |\nabla u|$. More precisely we will prove that

$$|\nabla u(x)| \le C(1+\epsilon^\lambda)^{1-\alpha^{N_r}} \epsilon^{\lambda\alpha^{N_r}} \text{ for } x \in \partial\Lambda_r \cap \Gamma'_{2,r}, \tag{4.10}$$

where $\alpha = \frac{\ln 4/3}{\ln 4}$, $N_r = \frac{A}{\pi(\frac{r}{4})^2} + 1$, and $\lambda \in (0,1)$.

Now let $\bar{x} \in \partial\Lambda_r \cap \Gamma'_{2,r}$ and $y \in \gamma_r \cap J_2$. Then one has that $B(y, r/4) \subset J_1$ for $r < R_1/3$. Set

$$\sigma = \max_{\overline{B(y,r/4)}} |\nabla u|. \tag{4.11}$$

Let $\mathcal{L}$ be a simple curve contained in Λ_r having $\bar{x}$ and y as endpoints. Then it is possible to construct a chain of closed balls centered in $\mathcal{L}$, of radius $r/4$, tangent two by two, and internally nonoverlapping; the first ball is centered in y; the last is at distance less than or equal to $r/4$ from $\bar{x}$. If the distance is less than $r/4$, we add to the chain the ball of radius $r/4$ whose center is $\bar{x}$. The repeated use of the three circles theorem leads to

$$\begin{aligned}\|\nabla u\|_{L^\infty(B(x_i,r/4))} &\le \|\nabla u\|_{L^\infty(B(x_{i-1},3r/4))} \\ &\le \|\nabla u\|^{1-\alpha}_{L^\infty(B(x_{i-1},r))} \cdot \|\nabla u\|^{\alpha}_{L^\infty(B(x_{i-1},r/4))}, \ i = 1,2,\dots,n,\end{aligned}$$

where $\alpha = \frac{\ln 4/3}{\ln 4}$. Hence from (4.11) we derive

$$|\nabla u(\bar{x})| \le (2E_1 + \sigma)^{1-\alpha^{n+1}} \sigma^{\alpha^{n+1}}.$$

On the other hand

$$n \le \frac{|\Lambda|}{\pi(\frac{r}{4})^2} \le \frac{A}{\pi(\frac{r}{4})^2},$$

where Λ is the connected component of $\overline{\Omega}_1 \cap \overline{\Omega}_2$ containing γ. This last bound and (4.2) give (4.10). From (4.9) and (4.10) it follows that for $r \in (0, R_1/3)$,

$$\int_{\Omega_1 \setminus \Omega_2} |\nabla u_1|^2 dx \leq C \left[\left(\frac{r}{R_1} \right)^{1-2/q} + (1+\epsilon^\lambda)^{1-\alpha^{N_r}} \cdot \epsilon^{\lambda \alpha^{N_r}} \right]. \tag{4.12}$$

Let $r = \frac{R_1}{4} \left[\frac{C}{\ln |\ln \epsilon^\lambda|} \right]^{1/2}$. Then from (4.12) for ϵ sufficiently small one has

$$\int_{\Omega_1 \setminus \Omega_2} |\nabla u_1|^2 dx \leq C \left(\ln |\ln \epsilon^\lambda| \right)^{-\frac{1}{2}(1-\frac{2}{q})},$$

and by (3.11) one gets

$$|\Omega_1 \setminus \Omega_2| \leq C \left(\ln |\ln \epsilon^\lambda| \right)^{-\frac{1}{2}(1-\frac{2}{q})}.$$

Since a similar bound holds for $|\Omega_2 \setminus \Omega_1|$, it follows that

$$|\Omega_1 \triangle \Omega_2| \leq C \left(\ln |\ln \epsilon^\lambda| \right)^{-\frac{1}{2}(1-\frac{2}{q})}. \tag{4.13}$$

Finally, (4.13) and (3.15) lead to

$$\delta_{\mathcal{H}}(\partial\Omega_1, \partial\Omega_2) \leq C \left(\ln |\ln \epsilon^\lambda| \right)^{-\frac{1}{6}(1-\frac{2}{q})} \tag{4.14}$$

for ϵ sufficiently small.

Step 2. From the divergence theorem and from (3.2) it follows that

$$\int_{\Omega_1 \setminus \Omega_2} |\nabla u_1|^2 dx \leq \frac{cE_0 A}{R} \cdot \sup_{(\partial\Lambda \cap \Gamma_2') \setminus \Gamma_1'} |\nabla u|. \tag{4.15}$$

We will assume that ϵ is sufficiently small in such a way that

$$C \left(\ln |\ln \epsilon^\lambda| \right)^{-\frac{1}{6}(1-\frac{2}{q})} \leq \frac{R_1}{2}. \tag{4.16}$$

Let $\bar{x} \in (\partial\Lambda \cap \Gamma_2') \setminus \Gamma_1'$ and let $r = d(\bar{x}, \partial\Omega_1)$. From (4.14) and (4.16) it follows that $\bar{x} \in \partial(\Omega_1)_r$ and, moreover, $(\Omega_1)_r$ has the interior sphere property with radius $R - r$ and the exterior sphere property with radius R.

Let $B_{int}(p, R_1/2)$ and $B_{ext}(q, R_1/2)$ indicate the interior and exterior disks to $(\Omega_1)_r$ tangent in $\bar{x}$ to $\partial(\Omega_1)_r$. Let $B_{int}(p', R_1/2)$ and $B_{ext}(q', R_1/2)$ be the interior and exterior disks to Ω_2 tangent in $\bar{x}$ to $\partial\Omega_2$. We have that

$$B_{int}(p', R_1/2) \cap B_{ext}(q, R_1/2) \subset \Omega_2 \setminus (\Omega_1)_r. \tag{4.17}$$

From (3.3), (4.13), (4.16), and (4.17) one has

$$B_{int}(p', R_1/2) \cap B_{ext}(q, R_1/2) \leq C \left(\ln |\ln \epsilon^\lambda| \right)^{-\frac{1}{6}(1-\frac{2}{q})}. \tag{4.18}$$

Let $\bar{y}$ be the second intersection of $\partial B_{int}(p, R_1/2)$ with $\partial B_{int}(p', R_1/2)$ and let δ denote the angle $\bar{y}\hat{\bar{x}}p'$. Since

$$\left| B_{int}\left(p', \frac{R_1}{2}\right) \cap B_{ext}\left(q, \frac{R_1}{2}\right) \right| = \frac{R_1^2}{4} \left(2\delta - \sin 2\delta\right),$$

by (4.18) it follows that

$$\delta \leq 2\delta(\epsilon),$$

where $\delta(\epsilon)$ is defined by the relation

$$\frac{R_1^2}{4}\left(2(2\delta(\epsilon)) - \sin 2(2\delta(\epsilon))\right) = C\left(\ln|\ln\epsilon^{\lambda}|\right)^{-\frac{1}{6}(1-\frac{2}{q})}.$$

Denote with $B(m,\rho)$ the disk centered at $m = \frac{p+p'}{2}$ of radius $\rho = 1 - \sin\delta$. Then it is easy to see that $B(m,\rho)$ is the maximum disk contained in $B_{int}(p, R_1/2) \cap B_{int}(p', R_1/2)$.

Let $\delta_0 \in (0, \pi/12)$ be fixed and let ϵ be sufficiently small so that

$$\delta(\epsilon) \leq \delta_0^2.$$

Let us describe the following geometric construction: consider the half-line originating from $\bar{x}$ intersecting $\partial B_{int}(p, R_1/2)$ at s and forming an angle of width $\pi/2 - \theta$, $\theta \in (4\delta_0, \pi/2)$, with the half-line $\bar{x}m$. Now let $m' = \frac{\bar{x}+s}{2}$. As θ varies in the interval $(4\delta_0, \pi/2)$, the point m' describes a curve of endpoints a and m. Now reflect this curve across the line $\bar{x}m$ and denote with β the entire curve. From the three circles theorem, one has

$$|\nabla u(x)| \leq (2E_1 + \sigma)^{1-\omega_0}\,\sigma^{\omega_0} \quad \forall x \in \beta,$$

where

$$\omega_0 = \frac{\ln\left(\frac{\cos 3\delta_0}{\cos 4\delta_0}\right)}{\ln 2}$$

and

$$\sigma = \max_{B(m,\rho/2)} |\nabla u|.$$

A Carleman estimate in a sector [C] leads to

$$|\nabla u(q)| \leq (2E_1 + \sigma)\left(\frac{\sigma}{2E_1+\sigma}\right)^{\omega_0\left(\frac{l}{R_1/2\sin 2\delta_0}\right)^{\frac{1}{1-\frac{8\delta_0}{\pi}}}},$$

where q lies on the segment $\bar{x}m$ at distance l from $\bar{x}$.

Setting $t = \frac{l}{\frac{R_1}{2}\sin 2\delta_0}$ one has that $t \in (0,1)$ and, moreover,

$$|\nabla u(\bar{x})| \leq C\left(\frac{tR_1}{2}\right)^{1-\frac{2}{q}} + (2E_1+\sigma)\left(\frac{\sigma}{2E_1+\sigma}\right)^{\omega_0 t^{\frac{1}{1-\frac{8\delta_0}{\pi}}}}. \tag{4.19}$$

For $\sigma < \frac{2E_1}{e}$ let $t = |\ln\left(\frac{\sigma}{2E_1+\sigma}\right)|^{-(1-\frac{9\delta_0}{\pi})}$. Then from (4.19) for σ small enough it follows that

$$|\nabla u(\bar{x})| \leq C\left|\ln\left(\frac{\sigma}{2E_1+\sigma}\right)\right|^{-(1-\frac{2}{q})(1-\frac{9\delta_0}{\pi})}.$$

Finally let us estimate σ. Using similar arguments as for the proof of estimate (4.10) one has

$$\sigma \leq C(1+\epsilon^{\lambda})^{1-\alpha^{N_0}}\epsilon^{\lambda\alpha^{N_0}},$$

where $\alpha = \frac{\ln 4/3}{\ln 4}$, $N_0 = \frac{2A}{\pi(\frac{R_1}{32})^2} + 1$, and $\lambda \in (0,1)$. Then for ϵ sufficiently small

$$|\nabla u(\bar{x})| \leq C|\ln\epsilon|^{-(1-\frac{2}{q})(1-\frac{9\delta_0}{\pi})}.$$

The last inequality, (4.15), and (3.11) give

$$|\Omega_1\backslash\Omega_2| \leq C|\ln\epsilon|^{-(1-\frac{2}{q})(1-\frac{9\delta_0}{\pi})}.$$

Since an analogous bound holds for $|\Omega_2\backslash\Omega_1|$ we derive

$$|\Omega_1 \triangle \Omega_2| \leq C|\ln\epsilon|^{-(1-\frac{2}{q})(1-\frac{9\delta_0}{\pi})}.$$

Finally Proposition 3.4, last inequality, and the fact that

$$\delta_{\mathcal{H}}(\partial\Omega_1, \partial\Omega_2) = \delta_{\mathcal{H}}(\Gamma_1, \Gamma_2)$$

give

$$\delta_{\mathcal{H}}(\Gamma_1, \Gamma_2) \leq C|\ln\epsilon|^{-\frac{1}{3}+\eta},$$

which proves Theorem 2.1. □

5. Appendix.

Proof of Proposition 3.4. In order to prove inequality (3.15) we prove preliminarily that

$$\delta_{\mathcal{H}}(\Omega_1, \Omega_2) \leq \frac{4d}{(\pi)^{1/3}R^{2/3}}|\Omega_1 \triangle \Omega_2|^{1/3}. \tag{5.1}$$

Let $\sigma = |\Omega_1 \triangle \Omega_2|$. If $\sigma \geq \frac{\pi R^2}{8}$, then

$$\delta_{\mathcal{H}}(\Omega_1, \Omega_2) \leq 2d \leq 2d\left(\frac{\sigma}{\frac{\pi R^2}{8}}\right)^{1/3} = \frac{4d}{R^{2/3}\pi^{1/3}}\sigma^{1/3},$$

which proves (5.1).

Let us consider the case $\sigma < \frac{\pi R^2}{8}$. Let $\bar{x} \in \overline{\Omega}_1\backslash\Omega_2$. From property (2.1b) there exists a point $p \in \Omega_1$ such that $B(p, R/2) \subset \Omega_1$ and $\bar{x} \in \partial B(p, R/2)$. Since $\sigma < \frac{\pi R^2}{8}$ it is easy to see that $\overline{B(p, R/2)} \cap \Omega_2 \neq \emptyset$.

Let $y \in \partial\Omega_2 \cap \overline{B(p, R/2)}$ be such that

$$|\bar{x} - y| = d(\bar{x}, \overline{\Omega}_2 \cap \overline{B(p, R/2)}). \tag{5.2}$$

Again by (2.1b) there exists a point $q \in \mathbf{R}^2\backslash\Omega_2$ such that $B(q, R) \subset \mathbf{R}^2\backslash\Omega_2$ and $\partial B(q, R)$ is tangent to $\partial\Omega_2$ at y. We now prove that

$$\bar{x} \in \overline{B(p, R/2)} \cap \overline{B(q, R)}. \tag{5.3}$$

We distinguish two cases

(i) $y \in B(p, R/2)$,

(ii) $y \in \partial B(p, R/2)$.

In case (i) observe that by construction $(\bar{x} - y) \perp \partial\Omega_2$. Moreover, $|\bar{x} - y| < diam B(p, R/2) = R$ from which (5.3) follows.

Let us now prove (5.3) in case (ii). From simple but lengthy geometric calculations it follows that the outer normal n at $\partial\Omega_2$ in y belongs to the angle $\bar{x}\hat{y}p$. This fact implies that the center q of the disk $B(q, R)$ must lie on the arc $\overset{\frown}{q_1 q_2}$ of the circle centered at y of radius R and with endpoints at q_1 and q_2, where q_1 is the contact point of $\partial B(p, R/2)$ and $\partial B(y, R)$ and q_2 is the intersection of the half-line $y\bar{x}$ with $\partial B(y, R)$. Then one easily verifies

$$|\bar{x} - q| \leq |\bar{x} - q_1| \leq |y - q_1| = R.$$

Therefore $\bar{x} \in \overline{B(q, R)}$ which concludes the proof of (5.3). Set $K = \overline{B(p, R/2)} \cap \overline{B(q, R)}$. Since $|\bar{x} - y| \leq diam K$, the rest of the proof consists of finding a bound for $diam K$ in terms of σ. Without loss of generality we may assume that $q = (0, 0)$ and that $p = (0, a)$ with $a \geq 0$. We observe that a cannot be greater than $3(R/2)$ since $K \neq \emptyset$; on the other hand $a \notin [0, \sqrt{3}R/2]$ since $\sigma < \frac{\pi R^2}{8}$. Let us now consider the case $a \in [R, \frac{3R}{2}]$. (For the case $a \in [\sqrt{3}R/2, R]$ we may proceed analogously observing that $|K| \geq |B(0, R) \cap B((0, R), R/2)|$.) Simple geometric arguments lead to the fact that $diam K = |m_1 - m_2|$, where m_1 and m_2 denote the intersections of $\partial B((0, a), R/2)$ with $\partial B((0, 0), R)$. Indicating with 2θ the angle $m_1 \overset{\wedge}{0} m_2$ one has

$$\sigma \geq |K| \geq R^2(2\theta - \sin 2\theta). \tag{5.4}$$

Finally from (5.4) it is easy to see that

$$\theta \leq \left(\frac{\sigma}{R^2}\right)^{1/3}. \tag{5.5}$$

By (5.5) we have that for $\bar{x} \in \Omega_1$,

$$d(\bar{x}, \Omega_2) = |\bar{x} - y| \leq diam K = |m_1 - m_2| = 2R \sin\theta \leq 2R \left(\frac{\sigma}{R^2}\right)^{1/3}. \tag{5.6}$$

Similarly if $\bar{x} \in \Omega_2$,

$$d(\bar{x}, \Omega_1) \leq 2R \left(\frac{\sigma}{R^2}\right)^{1/3},$$

which gives (5.1).

Let us finally prove (3.15). Let $\Omega_1' = B_{4d} \backslash \Omega_1$ and $\Omega_2' = B_{4d} \backslash \Omega_2$, where B_{4d} is a disk concentric with B_{2d} and radius $4d$.

Since $\Omega_1' \triangle \Omega_2' = \Omega_1 \triangle \Omega_2$ one has

$$\delta_{\mathcal{H}}(\Omega_1', \Omega_2') \leq \frac{16d}{R^{2/3}\pi^{1/3}} \sigma^{1/3} = \beta.$$

We claim that

$$\delta_{\mathcal{H}}(\partial\Omega_1, \partial\Omega_2) \leq \beta.$$

In fact, let $x \in \partial\Omega_1$.

If $x \notin \partial\Omega_2$, then

$$d(x, \partial\Omega_2) = d(x, \Omega_2) \leq \delta_{\mathcal{H}}(\Omega_1, \Omega_2) \leq \beta.$$

If $x \in \partial\Omega_2$, then

$$d(x, \Omega_2') \leq \delta_{\mathcal{H}}(\Omega_1', \Omega_2') \leq \beta. \tag{5.7}$$

Since

$$d(x, \Omega_2') = d(x, \partial\Omega_2)$$

from (5.7) we derive that

$$d(x, \partial\Omega_2) \leq \beta.$$

Analogously if $x \in \partial\Omega_2$, one has

$$d(x, \partial\Omega_1) \leq \beta,$$

which concludes the proof. □

MULTIVARIABLE ORTHOGONAL POLYNOMIALS AND COUPLING COEFFICIENTS FOR DISCRETE SERIES REPRESENTATIONS*

HJALMAR ROSENGREN†

Abstract. We study polynomials of several variables which occur as coupling coefficients for the analytic continuation of the holomorphic discrete series of $SU(1,1)$. There are three types of such polynomials, one corresponding to each conjugacy class of one-parameter subgroups. They may be viewed as multivariable generalizations of Hahn, Jacobi, and continuous Hahn polynomials and include many orthogonal and biorthogonal families occurring in the literature. We give a simple and unified approach to these polynomials using the group theoretic interpretation. We prove many formal properties, in particular a number of convolution and linearization formulas. We also develop the corresponding theory for the Heisenberg group, leading to multivariable generalizations of Krawtchouk and Hermite polynomials.

Key words. orthogonal polynomial, biorthogonal polynomials, coupling coefficient, spherical harmonic, multivariable hypergeometric function, convolution formula, linearization formula

1. Introduction.

In [R], we introduced three classes of polynomials in several variables. They appeared there as coupling coefficients for certain representations of the group $SU(1,1) \simeq SL(2,\mathbb{R})$ and its covering groups. Special cases occur in the work of many authors, cf. [A1], [A2], [AK], [E], [Ex], [FL], [KMT], [KM1], [KM2], [K1], [KS], [LT], [M], [MP], [Pr], [Ra], [T1], [T2], [T4], [T5], and [V]. In this paper we give a simple and unified approach to the study of these polynomials. We also consider the case of the oscillator or Heisenberg group, leading to two more classes of polynomials.

In many cases such multivariable polynomials arose naturally from problems in physics or statistics. In view of the group theoretic interpretation, this is not surprising, since symmetry groups play an important role in these sciences. There are also close connections with spherical harmonics, as well as with the Wigner symbols (recoupling coefficients) occurring in quantum mechanics.

We will work with the analytic continuation of the holomorphic discrete series of $SU(1,1) \simeq SL(2,\mathbb{R})$. We realize these representations on the Hilbert spaces $\mathcal{A}^\nu$ ($\nu > 0$) of analytic functions on the complex unit disc, with the scalar product

$$\langle f, g\rangle = \sum_{k=0}^{\infty} \frac{k!}{(\nu)_k} \hat{f}(k)\overline{\hat{g}(k)},$$

where $f(z) = \sum \hat{f}(k) z^k$ and

$$(\nu)_k = \frac{\Gamma(\nu+k)}{\Gamma(\nu)} = \nu(\nu+1)\cdots(\nu+k-1)$$

is the Pochhammer symbol. The norm is invariant under the transformations

$$f(z) \mapsto f\left(\frac{\alpha z+\beta}{\gamma z+\delta}\right)\frac{1}{(\gamma z+\delta)^\nu}, \qquad \begin{pmatrix}\alpha & \beta\\ \gamma & \delta\end{pmatrix} \in \mathrm{SU}(1,1).$$

This may be used to define a unitary representation of the universal covering group of $\mathrm{SU}(1,1)$ on each space $\mathcal{A}^\nu$, cf. [Sa] for the details.

We consider a Hilbert tensor product $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ of such spaces. It decomposes under the group action as

$$\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n} \simeq \bigoplus_{s=0}^{\infty}\binom{n+s-2}{n-2}\mathcal{A}^{|\nu|+2s} \tag{1.1}$$

(where $|\nu|=\sum\nu_i$). A highest weight vector Q is an image of the constant function 1 under an intertwining embedding

$$\mathcal{A}^{|\nu|+2s} \to \mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}. \tag{1.2}$$

In our realization, this means that Q is a homogeneous polynomial of degree s, which may be expressed as a function of differences z_i-z_j of the coordinates. Equivalently, Q satisfies the identity

$$Q(az_1+b,\dots,az_n+b) = a^sQ(z_1,\dots,z_n), \qquad a,b\in\mathbb{C}. \tag{1.3}$$

In agreement with (1.1), the space of such polynomials has dimension $\binom{n+s-2}{n-2}$.

In [R], we introduced three transforms which we will denote here by T_1, T_2, and T_3. Their role is to send highest weight vectors to coupling coefficients. They are defined on $z^k\in\mathcal{A}^\nu$ by

$$T_1z^k(m) = (-1)^k\frac{(-m)_k}{(\nu)_k}, \quad T_2z^k(\xi) = \frac{\xi^k}{(\nu)_k}, \quad T_3z^k(X) = (-1)^k\frac{(\frac{\nu}{2}-iX)_k}{(\nu)_k} \tag{1.4}$$

and extended to power series by linearity. We will also denote by T_i the extension $T_i\otimes\cdots\otimes T_i$ to a tensor product $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$. Thus if we let

$$Q(z) = \sum_{|t|=s} c_t\, z_1^{t_1}\cdots z_n^{t_n}$$

be a highest weight vector in $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ (throughout the paper we use multi-index notation freely), the three transforms of Q are given by

$$T_1Q(m_1,\dots,m_n) = (-1)^s\sum_{|t|=s} c_t\,\frac{(-m_1)_{t_1}\cdots(-m_n)_{t_n}}{(\nu_1)_{t_1}\cdots(\nu_n)_{t_n}}, \tag{1.5}$$

$$T_2Q(\xi_1,\dots,\xi_n) = \sum_{|t|=s} c_t\,\frac{\xi_1^{t_1}\cdots\xi_n^{t_n}}{(\nu_1)_{t_1}\cdots(\nu_n)_{t_n}}, \tag{1.6}$$

$$T_3Q(X_1,\dots,X_n) = (-1)^s\sum_{|t|=s} c_t\,\frac{(\frac{\nu_1}{2}-iX_1)_{t_1}\cdots(\frac{\nu_n}{2}-iX_n)_{t_n}}{(\nu_1)_{t_1}\cdots(\nu_n)_{t_n}}. \tag{1.7}$$

Note that the T_iQ are again polynomials of degree s, though only T_2Q is homogeneous. Moreover, T_1 and T_3 are connected by the equation

$$T_3Q(X) = T_1Q\left(iX-\frac{\nu}{2}\right). \tag{1.8}$$

One may also prove that

$$T_3Q(X) = (-1)^s\, T_3Q(-X), \tag{1.9}$$

which is not obvious from the definition.

In [R] we proved that if Q and Q' are two highest weight vectors, then the quantities

$$\sum_{m_1+\cdots+m_n=M} \frac{(\nu_1)_{m_1}\cdots(\nu_n)_{m_n}}{m_1!\cdots m_n!}\, T_1Q(m_1,\ldots,m_n)\,\overline{T_1Q'(m_1,\ldots,m_n)}$$

for $M = 0, 1, 2, \ldots$,

$$\int_{\xi\in\mathbb{R}^n_+\,:\,|\xi|=C} T_2Q(\xi)\,\overline{T_2Q'(\xi)}\,\xi_1^{\nu_1-1}\cdots\xi_n^{\nu_n-1}\,d\xi,$$

where $|\xi| = \xi_1 + \cdots + \xi_n$ and $C > 0$ is arbitrary, and

$$\int_{X\in\mathbb{R}^n\,:\,|X|=C} T_3Q(X)\,\overline{T_3Q'(X)}\,\left|\Gamma\left(\frac{\nu_1}{2}+iX_1\right)\right|^2\cdots\left|\Gamma\left(\frac{\nu_n}{2}+iX_n\right)\right|^2 dX,$$

where $C \in \mathbb{R}$ is arbitrary, are all proportional to the scalar product

$$\langle Q, Q'\rangle_{\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}}.$$

In particular, given an orthogonal basis for the highest weight vectors, our transforms give us three systems of orthogonal polynomials. The form of the orthogonality relations suggests that one eliminate one variable and consider, for instance, for fixed M,

$$T_1Q(m_1,\ldots,m_{n-1}, M-m_1-\cdots-m_{n-1})$$

as a polynomial in $n-1$ variables. This is how these polynomials usually occur in the literature.

In the case when all the ν_i are half-integers, there is a connection with spherical harmonics. If we introduce the polynomial

$$R(x_1,\ldots,x_{2|\nu|}) = (T_2Q)(x_1^2+\cdots+x_{2\nu_1}^2,\ldots,x_{2(\nu_1+\cdots+\nu_{n-1})+1}^2+\cdots+x_{2|\nu|}^2),$$

then the orthogonality relations for T_2Q give corresponding orthogonality relations for R on the unit sphere of $\mathbb{R}^{2\nu}$. Moreover, the conditions on Q ensure that R is harmonic. In fact one obtains precisely the space of harmonic polynomials of degree s invariant with respect to the subgroup

$$\mathrm{O}(2\nu_1)\times\cdots\times\mathrm{O}(2\nu_n)\subseteq\mathrm{O}(2|\nu|),$$

called *polyspherical harmonics* [V]. In [R] we gave an explanation of this, which involved the "Howe dual pair" $\mathrm{Mp}(1)\times\mathrm{O}(k)\subseteq\mathrm{Mp}(k)$.

The plan of the paper is as follows. In section 2 we describe some special cases of our polynomials, in particular those that we have found in the literature. In section 3 we review some fundamental facts on matrix elements of our representation due to Basu and Wolf [BW1]. In section 4 we obtain the polynomials T_iQ as coupling coefficients for our representation. The proof is based on certain factorizations of the Fourier transforms on $\mathcal{A}^\nu$ with respect to one-parameter subgroups. This is

different from the approach in [R]. In section 5 we prove convolution formulas for our polynomials. These generalize formulas recently found by Koelink and Van der Jeugt [KV1]. In section 6 we introduce some polynomials in $2n$ variables which we call coupling kernels. Whereas the coupling coefficients T_iQ are connected with matrix elements of the intertwining embeddings (1.2) (or of the corresponding projections $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}\to\mathcal{A}^{|\nu|+2s}$), the coupling kernels are connected with matrix elements for the projection of $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ onto the isotypic subspaces equivalent to $\binom{n+s-2}{n-2}\mathcal{A}^{|\nu|+2s}$ in (1.1). In section 7 we study formal properties of the coupling kernels. These include some linearization formulas, which generalize the classical Burchnall–Chaundy formula. In section 8 we prove that the coupling kernels may be expressed in terms of certain generalized hypergeometric functions. Finally, in section 9 we give the analogues of our results when $\mathrm{SU}(1,1)$ is replaced by the Heisenberg group and the spaces $\mathcal{A}^\nu$ are replaced by Fock spaces of entire functions.

2. Special cases. We will now describe some special cases of our polynomials. We have found many occurrences of them in the literature after writing [R], so here we will try to give more complete references. We first recall the definition of the generalized hypergeometric function

$$ {}_pF_q\left(\left.\begin{matrix}a_1,\dots,a_p\\ b_1,\dots,b_q\end{matrix}\right|x\right)=\sum_{k=0}^{\infty}\frac{(a_1)_k\cdots(a_p)_k\,x^k}{(b_1)_k\cdots(b_q)_k\,k!}. $$

When a and k are vectors, we write

$$ (a)_k=(a_1)_{k_1}\cdots(a_n)_{k_n},\qquad k!=k_1!\cdots k_n!. $$

We will also encounter Karlsson's generalized Kampé de Fériet functions [Ka], [SK], which we may then write, with a slight variation of Karlsson's notation, as

$$ \begin{aligned} &F^{p:q}_{r:s}\left(\left.\begin{matrix}a_1,\dots,a_p\ :\ b_1,\dots,b_q\\ c_1,\dots,c_r\ :\ d_1,\dots,d_s\end{matrix}\right|x\right)\\ &=\sum_{k_1,\dots,k_n=0}^{\infty}\frac{(a_1)_{|k|}\cdots(a_p)_{|k|}(b_1)_k\cdots(b_q)_k\,x^k}{(c_1)_{|k|}\cdots(c_r)_{|k|}(d_1)_k\cdots(d_s)_k\,k!}, \end{aligned} \tag{2.1} $$

where the a_i and c_i are scalar parameters while the b_i, d_i, and x are vectors of the same dimension n. For $n=1$, $F^{p:q}_{r:s}$ reduces to the function ${}_{p+q}F_{r+s}$.

2.1. The bilinear case. The simplest case is when $n=2$. Then the space of highest weight vectors of each degree s is one-dimensional and spanned by the single element

$$ Q(z_1,z_2)=(z_1-z_2)^s. $$

In this case, the polynomials T_1Q are Clebsch–Gordan coefficients, which may be expressed in terms of Hahn polynomials. In fact,

$$ \begin{aligned} T_1Q(m_1,m_2)&=\sum_{k=0}^{s}\binom{s}{k}(-1)^k\frac{(-m_1)_k(-m_2)_{s-k}}{(\nu_1)_k(\nu_2)_{s-k}}\\ &=\frac{(-m_1-m_2)_s}{(\nu_2)_s}\,Q_s(m_1;\nu_1-1,\nu_2-1;m_1+m_2), \end{aligned} $$

where Q_s is the Hahn polynomial of degree s in the notation of [VK]. The polynomials T_2Q and T_3Q are Clebsch–Gordan coefficients with respect to continuous bases; they may be expressed in terms of Jacobi polynomials and "Hahn polynomials of an imaginary argument," respectively; cf. [MR], [BW2], [P2], and [VK, section 8.7]. Still in the notation of [VK], we have

$$\begin{aligned} T_2Q(\xi_1,\xi_2) &= \sum_{k=0}^{s} \binom{s}{k} (-1)^{s-k} \frac{\xi_1^k\, \xi_2^{s-k}}{(\nu_1)_k (\nu_2)_{s-k}} \\ &= \frac{(-1)^s s!}{(\nu_1)_s (\nu_2)_s} (\xi_1+\xi_2)^s P_s^{(\nu_1-1,\nu_2-1)}\left(\frac{\xi_2-\xi_1}{\xi_1+\xi_2}\right), \\ T_3Q(X_1,X_2) &= \sum_{k=0}^{s} \binom{s}{k} (-1)^k \frac{(\frac{\nu_1}{2}-iX_1)_k (\frac{\nu_2}{2}-iX_2)_{s-k}}{(\nu_1)_k (\nu_2)_{s-k}} \\ &= \frac{(\frac{\nu_1+\nu_2}{2}-i(X_1+X_2))_s}{(\nu_2)_s}\, q_s(X_1; \tfrac{\nu_1}{2}, \tfrac{\nu_2}{2} - i(X_1+X_2)). \end{aligned}$$

Even in this case, the present paper gives new and simple deductions of properties of these polynomials.

2.2. Polynomials of Appell-type. In the case of general n, the polynomials

$$Q_t(z) = (z_1-z_n)^{t_1}\cdots(z_{n-1}-z_n)^{t_{n-1}}, \qquad t_1+\cdots+t_{n-1}=s, \tag{2.2}$$

form a basis for the space of highest weight vectors of degree s. Expanding Q_t by the binomial theorem, one finds that the polynomials T_iQ_t may be expressed in terms of Karlsson's generalized Kampé de Fériet functions (2.1) with the vector parameters of dimension $n-1$. In fact, one has

$$\begin{aligned} &T_1Q_t(m_1,\dots,m_n) \\ &= \frac{(-m_n)_s}{(\nu_n)_s} \sum_{k_1,\dots,k_{n-1}=0}^{\infty} \frac{(1-\nu_n-s)_{|k|}(-t_1)_{k_1}\cdots(-t_{n-1})_{k_{n-1}}(-m_1)_{k_1}\cdots(-m_{n-1})_{k_{n-1}}}{(1+m_n-s)_{|k|}(\nu_1)_{k_1}\cdots(\nu_{n-1})_{k_{n-1}} k_1!\cdots k_{n-1}!} \\ &= \frac{(-m_n)_s}{(\nu_n)_s} F^{1:2}_{1:1}\left(\begin{matrix} 1-\nu_n-s & : & -t, -(m_1,\dots,m_{n-1}) \\ 1+m_n-s & : & (\nu_1,\dots,\nu_{n-1}) \end{matrix}\,\middle|\, 1\right) \end{aligned}$$

(where, as is customary, we write the variable of the $F^{1:2}_{1:1}$-function as $1=(1,\dots,1)$). By (1.8), a similar expression is valid for T_3Q_t, while T_2Q_t is given by

$$\begin{aligned} &T_2Q_t(\xi_1,\dots,\xi_n) \\ &= \frac{(-\xi_n)^s}{(\nu_n)_s} F^{1:1}_{0:1}\left(\begin{matrix} 1-\nu_n-s & : & -t \\ - & : & (\nu_1,\dots,\nu_{n-1}) \end{matrix}\,\middle|\, -\frac{\xi_1}{\xi_n},\dots,-\frac{\xi_{n-1}}{\xi_n}\right) \end{aligned} \tag{2.3}$$

(Karlsson's $F^{1:1}_{0:1}$-function is also known as the Lauricella F_A-function).

2.3. Polynomials biorthogonal to the polynomials of Appell-type. The family (2.2) is obviously nonorthogonal for $n \geq 3$. Thus it is a problem to find the dual basis. Applying the T_i to these two families then gives biorthogonal polynomial systems. Though we have found no very simple expression for the basis dual to (2.2), the polynomials obtained after applying the T_i are also expressible in terms of Karlsson's functions; cf. Corollary 6.2 below.

The polynomials (2.3) were introduced by Appell [A1] for $n = 3$. The dual basis was found by him [A2] when $\nu_3 = 1$ and by Engelis [E] and, independently, by Fackerell and Littler [FL] in general. (For the work of Appell, see also the book [AK].) Lam and Tratnik [LT] generalized these polynomials to general n. The corresponding spherical harmonics occur in [KMT]. In the special case when all the ν_i equal 1, these harmonics go back to Hermite, Didon, and Kampé de Fériet; cf. again [AK]. The biorthogonal systems obtained using T_1 were introduced by Rahman [Ra] for $n = 3$ and by Tratnik [T2] in general. For the transform T_3, the corresponding polynomials are also due to Tratnik [T1].

2.4. Polynomials of Proriol-type. There seems to be no canonical choice of an orthogonal basis in the space of highest weight vectors. There is, however, a general procedure, known as binary coupling (the coupling of angular momenta in quantum physics), that allows one to construct many such bases. The corresponding polynomials T_iQ are given by products of $n-1$ factors, each factor being a Clebsch–Gordan coefficient, that is a Hahn, Jacobi, or continuous Hahn polynomial.

As an example, let us consider the case $n = 3$. Let $K_s^{\nu_1,\nu_2}$ denote the intertwining embedding

$$\mathcal{A}^{\nu_1+\nu_2+2s} \to \mathcal{A}^{\nu_1} \otimes \mathcal{A}^{\nu_2}$$

such that $K_s^{\nu_1,\nu_2}1 = (z_1 - z_2)^s$. Then the polynomials

$$Q_{st} = (K_s^{\nu_1,\nu_2} \otimes \mathrm{id}) \circ K_t^{\nu_1+\nu_2+2s,\nu_3}1, \qquad s + t = N$$

form an orthogonal basis for the space of highest weight vectors in $\mathcal{A}^{\nu_1} \otimes \mathcal{A}^{\nu_2} \otimes \mathcal{A}^{\nu_3}$ of degree N. In [R] we found that

$$\begin{aligned}
Q_{st}(z) &= (z_1 - z_2)^s \sum_{i+j=t} \frac{t!}{i!\,j!} \frac{(\nu_1 + s)_i (\nu_2 + s)_j}{(\nu_1 + \nu_2 + 2s)_t} (z_1 - z_3)^i (z_2 - z_3)^j, \\
T_1Q_{st}(m) &= \frac{(-m_1 - m_2)_s (s - m_1 - m_2 - m_3)_t}{(\nu_2)_s (\nu_3)_t} Q_s(m_1; \nu_1 - 1, \nu_2 - 1; m_1 + m_2) \\
&\quad \times Q_t(m_1 + m_2 - s; \nu_1 + \nu_2 + 2s - 1, \nu_3 - 1; m_1 + m_2 + m_3 - s), \\
T_2Q_{st}(\xi) &= \frac{(-1)^{s+t} s!\, t! (\xi_1 + \xi_2)^s (\xi_1 + \xi_2 + \xi_3)^t}{(\nu_1)_s (\nu_2)_s (\nu_1 + \nu_2 + 2s)_t (\nu_3)_t} \\
&\quad \times P_s^{(\nu_1 - 1, \nu_2 - 1)} \left(\frac{\xi_2 - \xi_1}{\xi_1 + \xi_2} \right) P_t^{(\nu_1 + \nu_2 + 2s - 1, \nu_3 - 1)} \left(\frac{\xi_3 - \xi_1 - \xi_2}{\xi_1 + \xi_2 + \xi_3} \right), \\
T_3Q_{st}(X) &= \frac{(\frac{\nu_1 + \nu_2}{2} - i(X_1 + X_2))_s (\frac{\nu_1 + \nu_2 + \nu_3 + 2s}{2} - i(X_1 + X_2 + X_3))_t}{(\nu_2)_s (\nu_3)_t} \\
&\quad \times q_s \left(X_1; \frac{\nu_1}{2}, \frac{\nu_2}{2} - i(X_1 + X_2) \right) \\
&\quad \times q_t \left(X_1 + X_2; \frac{\nu_1 + \nu_2 + 2s}{2}, \frac{\nu_3}{2} - i(X_1 + X_2 + X_3) \right).
\end{aligned}$$

The polynomials T_2Q_{st}, with Q_{st} as above, were introduced by Proriol in [Pr]. They were independently obtained and applied to genetics by Karlin and McGregor in [KM1] and have also found applications in physics [M], [MP]. See the survey [K1] for these and other two-variable analogues of Jacobi polynomials. The spherical harmonics constructible by this method were, for general n, introduced in [V], cf.

also [VK, section 10.5], and generalized further in [KMT]. For the special coupling procedure

$$Q_{s_1,\dots,s_{n-1}} = (K_{s_1}^{\nu_1,\nu_2} \otimes \mathrm{id}) \circ (K_{s_2}^{\nu_1+\nu_2+2s_1,\nu_3} \otimes \mathrm{id}) \circ \cdots \circ K_{s_{n-1}}^{\nu_1+\cdots+\nu_{n-1}+2(s_1+\cdots+s_{n-2}),\nu_n} 1,$$

the polynomials $T_1 Q_{s_1,\dots,s_{n-1}}$ were defined by Karlin and McGregor in [KM2], cf. also [T5]; again they appear in the context of genetics. The corresponding polynomials $T_3 Q_{s_1,\dots,s_{n-1}}$ were introduced by Tratnik in [T4]. An interesting product formula for the polynomials $T_2 Q_{s_1,\dots,s_{n-1}}$ is given in [KS].

3. Matrix elements. In this section we write down some basic facts, due to Basu and Wolf [BW1], cf. also [K2], about matrix elements of our representation. Whereas these authors work with the oscillator realization on $\mathrm{L}^2(\mathbb{R}_+)$, we will reformulate their results in terms of the analytic function spaces $\mathcal{A}^\nu$. This has computational advantages, allowing us to work with power series expansions.

Let $\mathbf{D}$ be the unit disc of $\mathbb{C}$ and $G \simeq \mathrm{SU}(1,1)/\{\pm 1\}$ be the group of conformal automorphisms of $\mathbf{D}$. There are three conjugacy classes of one-parameter subgroups in G. They may be described in terms of the fixed point sets in $\mathbb{C} \cup \{\infty\}$ of the corresponding Möbius maps. There are the *elliptic* elements, which fix one point in $\mathbf{D}$ and one in the outside, the *hyperbolic* elements, which fix two points on the boundary of $\mathbf{D}$, and finally the *parabolic* elements, which have a single fixed point on the boundary.

We choose a representative subgroup in each conjugacy class, namely, the elliptic subgroup

$$\phi_t^1 = \begin{pmatrix} e^{it/2} & 0 \\ 0 & e^{-it/2} \end{pmatrix},$$

corresponding to rotations $z \mapsto e^{it} z$ of the disc, the parabolic subgroup

$$\phi_t^2 = \begin{pmatrix} 1 + it/2 & it/2 \\ -it/2 & 1 - it/2 \end{pmatrix},$$

and the hyperbolic subgroup

$$\phi_t^3 = \begin{pmatrix} \cosh(t/2) & -\sinh(t/2) \\ -\sinh(t/2) & \cosh(t/2) \end{pmatrix}.$$

One may check that

$$\phi_s^i \phi_t^i = \phi_{s+t}^i, \qquad i = 1, 2, 3.$$

Note that if we choose ψ as the Cayley transform

$$\psi(z) = \frac{i - z}{i + z}$$

of the upper half-plane onto $\mathbf{D}$, then

$$(\psi^{-1} \phi_t^2 \psi)(z) = z + t,$$

so we may realize the parabolic subgroup as translations of the half-plane. Similarly

$$(\gamma^{-1} \phi_t^3 \gamma)(z) = z + t,$$

where

$$\gamma(z)=\frac{i-e^z}{i+e^z},$$

which realizes the hyperbolic subgroup as translations of the strip $\{z\,|\,0<\mathrm{Im}z<\pi\}$. (Hyperbolic transformations may also be realized as dilatations of the half-plane.)

To clarify the group theoretic meaning of our formulas, we employ certain notational conventions, which we will now state explicitly. Various objects connected with the subgroup ϕ_t^i $(i=1,2,3)$ will be labelled with the index i. The letter z will denote variables ranging in the disc (or polydisc). We will be concerned with three versions of the Fourier transform, one for each subgroup. For the elliptic subgroup, the variable dual to z is discrete; it will be denoted by k,l,m. For the parabolic and hyperbolic subgroup, the dual variables are continuous; they will be denoted by ξ,η and X,Y, respectively. The equations (1.5), (1.6), and (1.7) are examples of these conventions.

Recall now the function spaces $\mathcal{A}^\nu$ $(\nu>0)$ with scalar product

$$\langle f,g\rangle=\sum_{k=0}^{\infty}\frac{k!}{(\nu)_k}\hat{f}(k)\overline{\hat{g}(k)}.$$

We will use this notation also when f or g is not in $\mathcal{A}^\nu$, provided that the sum on the right-hand side converges. This space has the reproducing kernel

$$k_w(z)=\sum_{k=0}^{\infty}\frac{(\nu)_k}{k!}(z\bar{w})^k=\frac{1}{(1-z\bar{w})^\nu},$$

that is,

$$f(w)=\langle f,k_w\rangle,\qquad f\in\mathcal{A}^\nu,\ w\in\mathbb{D}.$$

We denote the group action by

$$(f*\phi)(z)=f(\phi(z))\phi'(z)^{\frac{\nu}{2}}=f\left(\frac{\alpha z+\beta}{\bar{\beta}z+\bar{\alpha}}\right)\frac{1}{(\bar{\beta}z+\bar{\alpha})^\nu},$$

where $\phi\in G$ is given by

$$\phi(z)=\frac{\alpha z+\beta}{\bar{\beta}z+\bar{\alpha}},\qquad |\alpha|^2-|\beta|^2=1.$$

We also write

$$\mathcal{U}_\phi(f)=f*\phi^{-1}$$

for the corresponding left action. Because of the indeterminacy of the power function, one must pass to the universal covering group to get a unitary representation on each space $\mathcal{A}^\nu$. (If $\nu\in 2\mathbb{Z}/k$ for an integer k, the k-fold cover is sufficient.)

It is easy to find joint eigenfunctions of our subgroups. Namely, since $e^{i\xi z}$ are eigenfunctions of the translations, it follows that

$$e^{i\xi\psi^{-1}(z)}((\psi^{-1})'(z))^{\frac{\nu}{2}},$$

with ψ as above, are eigenfunctions of ϕ_t^2. It will be convenient to normalize them so that they take the value 1 at the origin. This gives the functions

$$e_\xi^2(z) = \frac{1}{(1+z)^\nu} \exp\left(\frac{\xi z}{1+z}\right),$$

which indeed satisfy

$$e_\xi^2 * \phi_t^2 = e^{it\xi} e_\xi^2.$$

Replacing ψ by γ in this argument leads to the functions

$$e_X^3(z) = \frac{2^{\frac{\nu}{2}}}{(1-z)^{\frac{\nu}{2}-iX}(1+z)^{\frac{\nu}{2}+iX}}$$

(the factor $2^{\frac{\nu}{2}}$ being chosen for convenience), which satisfy

$$e_X^3 * \phi_t^3 = e^{itX} e_X^3.$$

Finally we write

$$e_k^1(z) = z^k$$

for the eigenfunctions of the elliptic subgroup. We call $(e_k^1)_{k=0}^\infty$ the elliptic basis of $\mathcal{A}^\nu$, while $(e_\xi^2)_{\xi>0}$ and $(e_X^3)_{X\in\mathbb{R}}$ are called the parabolic and the hyperbolic (generalized) basis, respectively.

Note that, whereas clearly e_k^1 is an element of $\mathcal{A}^\nu$, this is not true for e_ξ^2 or e_X^3. However, one may still define $\langle f, e_x^i\rangle$ $(i = 2, 3)$ for f in a dense subspace of $\mathcal{A}^\nu$. Natural choices are the space of polynomials and the linear hull of all reproducing kernels k_z, $z \in \mathbf{D}$. With either of these choices the following Plancherel theorem is true.

PROPOSITION 3.1. *The operator* $(\mathcal{F}_2 f)(\xi) = \langle f, e_\xi^2\rangle$ *extends to a Hilbert space isomorphism*

$$\mathcal{F}_2 : \mathcal{A}^\nu \to \mathrm{L}^2\left(\mathbb{R}_+, \frac{1}{\Gamma(\nu)}\, e^{-\xi}\xi^{\nu-1}\, d\xi\right).$$

Similarly, the operator $(\mathcal{F}_3 f)(X) = \langle f, e_X^3\rangle$ *extends to an isomorphism*

$$\mathcal{F}_3 : \mathcal{A}^\nu \to \mathrm{L}^2\left(\mathbb{R}, \frac{1}{2\pi\Gamma(\nu)}\left|\Gamma\left(\frac{\nu}{2}+iX\right)\right|^2 dX\right).$$

The transforms $\mathcal{F}_2$ and $\mathcal{F}_3$ are connected to the classical Fourier transform. For instance $\mathcal{F}_2 f$ is essentially the Fourier transform of the boundary value distribution of the function $f(\psi(z))\psi'(z)^{\nu/2}$ defined in the upper half-plane (they differ by a multiplicative factor). The proposition may be proved using this observation, cf. [P2], or alternatively using the orthogonality relations for Laguerre and Meixner–Pollaczek polynomials (whose role is made clear below).

By polarization, we have

$$\begin{aligned}\langle f, g\rangle &= \sum_{k=0}^\infty \frac{(\nu)_k}{k!}\langle f, e_k^1\rangle\langle e_k^1, g\rangle \\ &= \frac{1}{\Gamma(\nu)}\int_0^\infty \langle f, e_\xi^2\rangle\langle e_\xi^2, g\rangle\, e^{-\xi}\xi^{\nu-1}\, d\xi \\ &= \frac{1}{2\pi\Gamma(\nu)}\int_{-\infty}^\infty \langle f, e_X^3\rangle\langle e_X^3, g\rangle \left|\Gamma\left(\frac{\nu}{2}+iX\right)\right|^2 dX\end{aligned} \tag{3.1}$$

with a suitable interpretation of the last two expressions. Choosing $g = k_z$, it follows that

$$\begin{aligned} f(z) &= \sum_{k=0}^{\infty} \frac{(\nu)_k}{k!} (\mathcal{F}_1 f)(k) e^1_k(z) \\ &= \frac{1}{\Gamma(\nu)} \int_0^{\infty} (\mathcal{F}_2 f)(\xi) e^2_\xi(z) e^{-\xi} \xi^{\nu-1}\, d\xi \\ &= \frac{1}{2\pi\Gamma(\nu)} \int_{-\infty}^{\infty} (\mathcal{F}_3 f)(X) e^3_X(z) \left|\Gamma\left(\frac{\nu}{2} + iX\right)\right|^2 d\xi, \end{aligned} \tag{3.2}$$

where

$$\mathcal{F}_1 f(k) = \langle f, e^1_k \rangle = \frac{k!}{(\nu)_k} \hat{f}(k).$$

We now introduce the *matrix elements*

$$K^{ij}(x, y, \phi) = \langle e^i_x, e^j_y * \phi \rangle, \qquad i, j = 1, 2, 3,$$

where $\phi \in G$ is such that this makes sense. By unitarity,

$$K^{ij}(x, y, \phi) = \overline{K^{ji}(y, x, \phi^{-1})},$$

so there are six cases to consider. As remarked above, the K^{ij} were computed by Basu and Wolf [BW1]. We summarize their results in the following proposition.

PROPOSITION 3.2. *The matrix elements of $\mathcal{A}^\nu$ are given by*

$$K^{11}(k, l, \phi) = \begin{cases} \dfrac{\beta^k \bar{\beta}^l}{\alpha^{\nu+k+l}} (-1)^k \, {}_2F_1\left(\begin{matrix} -k, -l \\ \nu \end{matrix} \,\middle|\, -\dfrac{1}{|\beta|^2} \right) & \beta \neq 0, \\ \dfrac{k!}{(\nu)_k \alpha^{\nu+2k}}\, \delta_{kl} & \beta = 0, \end{cases}$$

$$K^{12}(k, \xi, \phi) = \frac{(-1)^k (\bar{\alpha} + \beta)^k}{(\alpha + \bar{\beta})^{\nu+k}} \exp\left(\frac{\bar{\beta}\xi}{\bar{\beta} + \alpha}\right) {}_1F_1\left(\begin{matrix} -k \\ \nu \end{matrix} \,\middle|\, \frac{\xi}{|\alpha + \bar{\beta}|^2} \right),$$

$$K^{13}(k, X, \phi) = \frac{2^{\frac{\nu}{2}} (\bar{\alpha} - \beta)^k}{(\alpha + \bar{\beta})^{\frac{\nu}{2} - iX} (\alpha - \bar{\beta})^{\frac{\nu}{2} + iX + k}} \, {}_2F_1\left(\begin{matrix} -k, \frac{\nu}{2} - iX \\ \nu \end{matrix} \,\middle|\, \frac{2}{(\alpha + \bar{\beta})(\bar{\alpha} - \beta)} \right),$$

$$\begin{aligned} K^{22}(\xi, \eta, \phi) = {} & \frac{1}{(2i\mathrm{Im}(\alpha - \beta))^\nu} \exp\left(-\frac{(\bar{\alpha} + \beta)\xi + (\bar{\alpha} - \bar{\beta})\eta}{2i\mathrm{Im}(\alpha - \beta)} \right) \\ & \times {}_0F_1\left(\begin{matrix} - \\ \nu \end{matrix} \,\middle|\, -\frac{\xi\eta}{4(\mathrm{Im}(\alpha - \beta))^2} \right), \end{aligned}$$

$$\begin{aligned} K^{23}(\xi, X, \phi) = {} & \frac{2^{\frac{\nu}{2}}}{(2\mathrm{Re}(\alpha - \beta))^{\frac{\nu}{2} + iX} (2i\mathrm{Im}(\alpha - \beta))^{\frac{\nu}{2} - iX}} \exp\left(\frac{(\bar{\alpha} - \beta)\xi}{2\mathrm{Re}(\alpha - \beta)} \right) \\ & \times {}_1F_1\left(\begin{matrix} \frac{\nu}{2} - iX \\ \nu \end{matrix} \,\middle|\, \frac{i\xi}{2\mathrm{Re}(\alpha - \beta)\mathrm{Im}(\alpha - \beta)} \right), \end{aligned}$$

$$\begin{aligned} K^{33}(X, Y, \phi) = {} & \frac{(i\mathrm{Im}(\alpha + \beta))^{i(X-Y)}}{(\mathrm{Re}(\alpha - \beta))^{\frac{\nu}{2} + iX} (\mathrm{Re}(\alpha + \beta))^{\frac{\nu}{2} - iY}} \\ & \times {}_2F_1\left(\begin{matrix} \frac{\nu}{2} + iX, \frac{\nu}{2} - iY \\ \nu \end{matrix} \,\middle|\, \frac{1}{\mathrm{Re}(\alpha + \beta)\mathrm{Re}(\alpha - \beta)} \right), \end{aligned}$$

where $\phi(z) = (\alpha z + \beta)/(\bar{\beta} z + \bar{\alpha})$, $|\alpha|^2 - |\beta|^2 = 1$.

One may check that these are well defined up to a choice of $(\phi')^{\nu/2}$. The matrix elements may be identified with classical orthogonal functions as follows, cf. [K2]:

K^{11}	:	Meixner polynomials,
K^{12}	:	Laguerre polynomials,
K^{13}	:	Meixner–Pollaczek polynomials,
K^{22}	:	Bessel functions,
K^{23}	:	Laguerre functions,
K^{33}	:	Meixner–Pollaczek functions.

By inserting basis elements $e_x^i * \phi$ into (3.1), one may deduce a host of addition theorems and orthogonality relations for these functions, cf. [VK, section 7.7].

The proposition does not give the matrix elements K^{22}, K^{23}, or K^{33} for $\phi = \mathrm{id}$. However, by (3.2) it is natural to define

$$K^{22}(\xi, \eta, \mathrm{id}) = \Gamma(\nu) e^{\xi} \xi^{1-\nu} \delta(\xi - \eta), \tag{3.3}$$

$$K^{33}(X, Y, \mathrm{id}) = 2\pi\Gamma(\nu) \left|\Gamma\left(\frac{\nu}{2} + iX\right)\right|^{-2} \delta(X - Y), \tag{3.4}$$

where δ is the Dirac measure. Similarly one may define

$$K^{23}(\xi, X, \mathrm{id}) = \frac{\Gamma(\nu) e^{\frac{\xi}{2}}}{\Gamma(\frac{\nu}{2} + iX) 2^{iX}} \, \xi^{-\frac{\nu}{2} + iX}$$

since this kernel has the property

$$e_X^3(z) = \frac{1}{\Gamma(\nu)} \int_0^\infty \overline{K^{23}(\xi, X, \mathrm{id})} \, e_\xi^2(z) e^{-\xi} \xi^{\nu-1} \, d\xi.$$

(This reduces to the usual definition of the Γ-function after a change of variables.) These identities can be made precise by extending the transforms $\mathcal{F}_i$ to suitable classes of distributions.

As for the proof, we remark that in the present realization, *all* of Proposition 3.2 may be deduced from Meixner's expansion formula [Me]

$$\begin{aligned} &\sum_{k=0}^{\infty} \frac{(\nu)_k}{k!} \, {}_2F_1\left(\begin{matrix} -k, \alpha \\ \nu \end{matrix} \,\middle|\, x \right) {}_2F_1\left(\begin{matrix} -k, \beta \\ \nu \end{matrix} \,\middle|\, y \right) z^k \\ &= \frac{1}{(1-z)^{\nu-\alpha-\beta}(1-z+xz)^{\alpha}(1-z+yz)^{\beta}} \, {}_2F_1\left(\begin{matrix} \alpha, \beta \\ \nu \end{matrix} \,\middle|\, \frac{xyz}{(1-z+xz)(1-z+yz)} \right). \end{aligned} \tag{3.5}$$

The case $x = 0$ gives the expressions for K^{11} and K^{13}. To proceed, one may use the expansion

$$K^{33}(X, Y, \phi) = \sum_{k=0}^{\infty} \frac{(\nu)_k}{k!} \, \overline{K^{13}(k, X, \mathrm{id})} \, K^{13}(k, Y, \phi),$$

which follows from the first identity in (3.1). The expression for K^{33} given in Proposition 3.2 now follows from the general case of Meixner's formula.

The matrix elements involving the parabolic subgroup are computed similarly, using two degenerate cases of Meixner's formula. If we replace y by y/β in (3.5) and let β tend to infinity, we obtain the expansion

$$\begin{aligned}&\sum_{k=0}^{\infty}\frac{(\nu)_k}{k!}\,{}_2F_1\left(\begin{matrix}-k,\alpha\\ \nu\end{matrix}\,\middle|\,x\right){}_1F_1\left(\begin{matrix}-k\\ \nu\end{matrix}\,\middle|\,y\right)z^k\\ &=\frac{1}{(1-z)^{\nu-\alpha}(1-z+xz)^{\alpha}}\exp\left(-\frac{yz}{1-z}\right){}_1F_1\left(\begin{matrix}\alpha\\ \nu\end{matrix}\,\middle|\,\frac{xyz}{(1-z+xz)(1-z)}\right),\end{aligned}\tag{3.6}$$

due to Weisner. Repeating this once more gives the Hardy–Hille formula

$$\begin{aligned}&\sum_{k=0}^{\infty}\frac{(\nu)_k}{k!}\,{}_1F_1\left(\begin{matrix}-k\\ \nu\end{matrix}\,\middle|\,x\right){}_1F_1\left(\begin{matrix}-k\\ \nu\end{matrix}\,\middle|\,y\right)z^k\\ &=\frac{1}{(1-z)^{\nu}}\exp\left(-\frac{z(x+y)}{1-z}\right){}_0F_1\left(\begin{matrix}-\\ \nu\end{matrix}\,\middle|\,\frac{xyz}{(1-z)^2}\right).\end{aligned}$$

We refer to [SM] for a large number of proofs of these formulas.

4. Coupling coefficients. In this section we will obtain the polynomials T_iQ as coupling coefficients of our representation. We consider transforms of the type

$$\mathcal{F}_i^{\phi}f(x)=\mathcal{F}_i\,\mathcal{U}_{\phi}f(x)=\langle f,e_x^i*\phi\rangle,\qquad i=1,2,3,\ \phi\in G,$$

that is, the Fourier transform with respect to an arbitrary one-parameter subgroup of G. We will factorize these into operators which interact nicely with the Lie algebra action. More precisely, we will find factorizations of the type

$$\mathcal{F}_i^{\phi}=M_i\,T_i\,\delta_a\tau_b,$$

where δ_a and τ_b are the dilatation and translation operators defined by

$$\delta_af(z)=f(az),\qquad \tau_bf(z)=f(z+b),$$

M_i are the multiplication operators

$$M_if(x)=\overline{e_x^i*\phi(0)}f(x)=(\mathcal{F}_i^{\phi}1)(x)f(x),$$

and T_i are the transforms defined in (1.4).

We will use the explicit expressions for the matrix elements given in Proposition 3.2 to obtain our factorizations. Note, however, that we only need them in the easiest special case, corresponding to $x=0$ in (3.5) and (3.6).

PROPOSITION 4.1. *In the notation above, we have for* $\phi=\left(\begin{smallmatrix}\alpha&\beta\\ \bar\beta&\bar\alpha\end{smallmatrix}\right)$ *the following factorizations of densely defined operators*:

$$\begin{aligned}\mathcal{F}_1^{\phi}&=M_1\,T_1\,\delta_{1/\alpha\bar\beta}\,\tau_{-\beta/\alpha}\qquad(\beta\neq0),\\ \mathcal{F}_2^{\phi}&=M_2\,T_2\,\delta_{1/(\alpha+\bar\beta)^2}\,\tau_{-(\bar\alpha+\beta)/(\alpha+\bar\beta)},\\ \mathcal{F}_3^{\phi}&=M_3\,T_3\,\delta_{2/(\alpha+\bar\beta)(\alpha-\bar\beta)}\,\tau_{(\bar\alpha-\beta)/(\alpha-\bar\beta)}.\end{aligned}\tag{4.1}$$

Proof. Test the action of both sides on the function $e_k^1(z)=z^k$. In general,

$$(\delta_a\tau_b\,e_k^1)(z)=(az+b)^k=b^k\sum_{j=0}^{\infty}\frac{(-k)_j}{j!}\left(-\frac{az}{b}\right)^j.$$

Thus one has for instance

$$\begin{aligned} M_1\,T_1\,\delta_{1/\alpha\bar\beta}\,\tau_{-\beta/\alpha}\,e_k^1(m) &= \frac{\bar\beta^m}{\alpha^{\nu+m}}\,T_1\left(\left(-\frac{\beta}{\alpha}\right)^k\sum_{j=0}^{\infty}\frac{(-k)_j}{j!}\left(\frac{z}{|\beta|^2}\right)^j\right)(m)\\ &= \frac{\bar\beta^m(-\beta)^k}{\alpha^{\nu+m+k}}\sum_{j=0}^{\infty}\frac{(-k)_j(-m)_j}{j!(\nu)_j}\left(-\frac{1}{|\beta|^2}\right)^j\\ &= \frac{\bar\beta^m(-\beta)^k}{\alpha^{\nu+k+m}}\,{}_2F_1\left(\begin{matrix}-k,-m\\ \nu\end{matrix}\,\middle|\,-\frac{1}{|\beta|^2}\right)\\ &= K^{11}(k,m,\phi) = \mathcal{F}_1^\phi e_k^1(m), \end{aligned}$$

which proves (4.1). The other two identities follow similarly. □

Now let us apply these factorizations to a general tensor product $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$. As in the case $n=1$, we write

$$(f_1\otimes\cdots\otimes f_n)*\phi(z) = f_1(\phi(z_1))\cdots f_n(\phi(z_n))\phi'(z_1)^{\frac{\nu_1}{2}}\cdots\phi'(z_n)^{\frac{\nu_n}{2}}$$

for the group action and $\mathcal{F}_i^\phi$ for the transforms

$$(\mathcal{F}_i^\phi f)(x_1,\dots,x_n) = \langle f,(e^i_{x_1}\otimes\cdots\otimes e^i_{x_n})*\phi\rangle,\qquad i=1,2,3,\ \phi\in G.$$

Applying Proposition 4.1 in each variable gives factorizations of these transforms.

We fix a highest weight polynomial Q of degree s and write

$$\mu = |\nu| + 2s.$$

Then there is a unique intertwining embedding $\mathcal{K}_Q$ of $\mathcal{A}^\mu$ into $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ such that $\mathcal{K}_Q 1 = Q$. We will henceforth denote by $\langle\,,\,\rangle_\mu$ and $\langle\,,\,\rangle_\nu$ the scalar product of $\mathcal{A}^\mu$ and $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$, respectively.

THEOREM 4.2. *For $g\in\mathcal{A}^\mu$ and $\phi\in G$, we have the equalities*

$$\begin{aligned} (\mathcal{F}_1^\phi\mathcal{K}_Q g)(m) &= T_1Q(m)(\mathcal{F}_1^\phi g)(|m|-s),\\ (\mathcal{F}_2^\phi\mathcal{K}_Q g)(\xi) &= T_2Q(\xi)(\mathcal{F}_2^\phi g)(|\xi|),\\ (\mathcal{F}_3^\phi\mathcal{K}_Q g)(X) &= T_3Q(X)(\mathcal{F}_3^\phi g)(|X|). \end{aligned}$$

Thus we may write

$$\langle\mathcal{K}_Q g,(z_1^{m_1}\cdots z_n^{m_n})*\phi\rangle_\nu = T_1Q(m_1,\dots,m_n)\langle g, z^{|m|-s}*\phi\rangle_\mu,$$

while for T_2 and T_3 similar equalities are valid with a suitable interpretation. In particular the matrix elements

$$\langle\mathcal{K}_Q e^i_x,(e^j_{y_1}\otimes\cdots\otimes e^j_{y_n})*\phi\rangle_\nu$$

of the embedding $\mathcal{K}_Q$ factor as $T_jQ(y)$ times a matrix element (in the sense of section 3) for $\mathcal{A}^{|\nu|+2s}$.

Proof. Since $\mathcal{K}_Q$ commutes with the group action, we may assume that $\phi=\mathrm{id}$. Moreover, it suffices to choose $g=k_w$ as a reproducing kernel. The first equality then reduces to

$$\langle\mathcal{K}_Q k_w, e^1_{m_1}\otimes\cdots\otimes e^1_{m_n}\rangle_\nu = T_1Q(m)\bar w^{|m|-s}. \tag{4.2}$$

First note that

$$k_w = (1-|w|^2)^{-\frac{\mu}{2}}\, 1 * \phi_w^{-1},$$

where ϕ_w is the disc automorphism $\phi_w(z) = (z+w)/(1+\bar{w}z)$, corresponding to the matrix $\left(\begin{smallmatrix}\alpha & \beta\\ \bar{\beta} & \bar{\alpha}\end{smallmatrix}\right)$, with

$$\alpha = \frac{1}{\sqrt{1-|w|^2}}, \qquad \beta = \frac{w}{\sqrt{1-|w|^2}}.$$

This gives

$$\mathcal{K}_Q k_w = (1-|w|^2)^{-\frac{\mu}{2}}\, Q * \phi_w^{-1}.$$

Thus we have

$$\begin{aligned}\langle \mathcal{K}_Q k_w, e^1_{m_1}\otimes\cdots\otimes e^1_{m_n}\rangle_\nu &= (1-|w|^2)^{-\frac{\mu}{2}}\langle Q*\phi_w^{-1}, e^1_{m_1}\otimes\cdots\otimes e^1_{m_n}\rangle_\nu\\ &= (1-|w|^2)^{-\frac{\mu}{2}}(\mathcal{F}_1^{\phi_w}Q)(m_1,\dots,m_n).\end{aligned}$$

We now apply the factorization (4.1) to each variable. Note that (1.3) may be written as

$$(\delta_a\tau_b)^{\otimes n}Q = a^s Q.$$

This gives

$$\begin{aligned}\langle \mathcal{K}_Q k_w, e^1_{m_1}\otimes\cdots\otimes e^1_{m_n}\rangle_\nu &= (1-|w|^2)^{-\frac{\mu}{2}}\frac{\bar{\beta}^{|m|}}{\alpha^{|\nu|+|m|}}(T_1(\delta_{1/\alpha\bar{\beta}}\,\tau_{-\beta/\alpha})^{\otimes s}Q)(m)\\ &= (1-|w|^2)^{-\frac{\mu}{2}}\frac{\bar{\beta}^{|m|-s}}{\alpha^{|\nu|+|m|+s}}\,T_1Q(m) = \bar{w}^{|m|-s}T_1Q(m),\end{aligned}$$

which proves (4.2). The rest of the theorem follows from the equalities

$$\mathcal{F}_2^{\phi_w}Q(\xi) = (1-|w|^2)^{\frac{\mu}{2}}\,T_2Q(\xi)\,\overline{e^2_{|\xi|}(w)},$$

$$\mathcal{F}_3^{\phi_w}Q(X) = (1-|w|^2)^{\frac{\mu}{2}}\,T_3Q(X)\,\overline{e^3_{|X|}(w)},$$

which are likewise easily obtained from Proposition 4.1. □

Choosing as in the proof, $g = k_w$, $\phi = \mathrm{id}$, and expressing the left-hand sides by means of the adjoint $\mathcal{K}_Q^*$, one sees that the theorem is equivalent to the equalities

$$\begin{aligned}\mathcal{K}_Q^*\, e^1_{m_1}\otimes\cdots\otimes e^1_{m_n} &= \overline{T_1Q(m)}\, e^1_{|m|-s},\\ \mathcal{K}_Q^*\, e^2_{\xi_1}\otimes\cdots\otimes e^2_{\xi_n} &= \overline{T_2Q(\xi)}\, e^2_{|\xi|},\\ \mathcal{K}_Q^*\, e^3_{X_1}\otimes\cdots\otimes e^3_{X_n} &= \overline{T_3Q(X)}\, e^3_{|X|}.\end{aligned}$$

This may also be proved using the explicit expression for $\mathcal{K}_Q^*$ as a differential operator *(transvectant)* given in [R]; cf. [P2] for the case $n=2$.

We now combine Theorem 4.2 with the equalities (3.2), choosing $f = \mathcal{K}_Q e^i_x$. This will give the expansions of $\mathcal{K}_Q e^i_x$ in tensor products of the e^j_y. By the theorem, the coefficients will involve the polynomial T_jQ times the matrix element K^{ij}. For $i=j$ this exhibits the polynomials T_iQ as coupling coefficients of our representation. We summarize this in a corollary.

COROLLARY 4.3. *In the notation above, we have the generalized Clebsch–Gordan formulas*

$$\frac{(\mu)_k}{k!}\mathcal{K}_Q e^1_k(z_1,\dots,z_n) = \sum_{|m|=k+s} \frac{(\nu_1)_{m_1}\cdots(\nu_n)_{m_n}}{m_1!\cdots m_n!}\, T_1Q(m) z_1^{m_1}\cdots z_n^{m_n},$$

$$\begin{aligned}&\frac{\xi^{\mu-1}}{\Gamma(\mu)}\mathcal{K}_Q e^2_\xi(z_1,\dots,z_n)\\ &= \frac{1}{\Gamma(\nu_1)\cdots\Gamma(\nu_n)}\int_{\eta\in\mathbb{R}^n_+\,:\,|\eta|=\xi} T_2Q(\eta)\, e^2_{\eta_1}(z_1)\cdots e^2_{\eta_n}(z_n)\eta_1^{\nu_1-1}\cdots\eta_n^{\nu_n-1}\,d\eta,\end{aligned} \tag{4.3}$$

$$\begin{aligned}&\frac{\left|\Gamma\left(\frac{\mu}{2}+iX\right)\right|^2}{\Gamma(\mu)}\mathcal{K}_Q e^3_X(z_1,\dots,z_n) = \frac{1}{(2\pi)^{n-1}\Gamma(\nu_1)\cdots\Gamma(\nu_n)}\\ &\times\int_{Y\in\mathbb{R}^n\,:\,|Y|=X} T_3Q(Y)\, e^3_{Y_1}(z_1)\cdots e^3_{Y_n}(z_n)\left|\Gamma\left(\frac{\nu_1}{2}+iY_1\right)\cdots\Gamma\left(\frac{\nu_n}{2}+iY_n\right)\right|^2 dY.\end{aligned}$$

To obtain the latter two equalities, one may formally use (3.3) and (3.4). This can be justified either by a duality argument or by first writing down an analogous expansion for $\mathcal{K}_Q e^i_x * \phi$ and then sending ϕ to id along a suitable one-parameter subgroup.

Choosing $i \neq j$ gives six additional expansion formulas. These follow, however, from formulas which have been obtained already. For instance, $i=1$, $j=2$ gives

$$\mathcal{K}_Q e^1_k(z) = \frac{(-1)^k}{\Gamma(\nu_1)\cdots\Gamma(\nu_n)}\int_{\mathbb{R}^n_+} {}_1F_1\left(\begin{array}{c|c} -k & \\ \mu & |\eta|\end{array}\right) T_2Q(\eta)\, e^{-|\eta|}\prod_{r=1}^n e^2_{\eta_r}(z_r)\eta_r^{\nu_r-1}\,d\eta.$$

Integrating over the hypersurfaces $|\eta|=\xi$ and assuming (4.3), we see that this reduces to

$$\mathcal{K}_Q e^1_k(z) = \frac{(-1)^k}{\Gamma(\mu)}\int_0^\infty {}_1F_1\left(\begin{array}{c|c} -k & \\ \mu & \xi\end{array}\right)\mathcal{K}_Q e^2_\xi(z) e^{-\xi}\xi^{\mu-1}\,d\xi.$$

However, this follows from applying $\mathcal{K}_Q$ to each side of

$$e^1_k(z) = \frac{1}{\Gamma(\mu)}\int_0^\infty K^{12}(k,\xi,\mathrm{id})\, e^2_\xi(z) e^{-\xi}\xi^{\mu-1}\,d\xi,$$

which is a special case of (3.2).

As a consequence of the interpretation as coupling coefficients, we recover the orthogonality relations for the polynomials T_iQ with the exact proportionality constants.

COROLLARY 4.4. *Let Q and $\tilde{Q}$ be two highest weight polynomials in*

$$\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n},$$

not necessarily of the same degree. Then if s is the degree of Q (or of $\tilde{Q}$) and $\mu = |\nu|+2s$, the quantities

$$\frac{k!}{(\mu)_k}\sum_{|m|=k+s}\frac{(\nu_1)_{m_1}\cdots(\nu_n)_{m_n}}{m_1!\cdots m_n!}\, T_1Q(m)\,\overline{T_1\tilde{Q}(m)},$$

$$\frac{\Gamma(\mu)B^{1-\mu}}{\Gamma(\nu_1)\cdots\Gamma(\nu_n)}\int_{\xi\in\mathbb{R}^n_+\,:\,|\xi|=B} T_2Q(\xi)\,\overline{T_2\tilde{Q}(\xi)}\,\xi_1^{\nu_1-1}\cdots\xi_n^{\nu_n-1}\,d\xi,$$

$$\frac{\Gamma(\mu)}{(2\pi)^{n-1}\left|\Gamma\left(\frac{\mu}{2}+iC\right)\right|^2}\int_{X\in\mathbb{R}^n\,:\,|X|=C} T_3Q(X)\,\overline{T_3\tilde{Q}(X)}\,\prod_{r=1}^n\frac{\left|\Gamma\left(\frac{\nu_r}{2}+iX_r\right)\right|^2}{\Gamma(\nu_r)}\,dX$$

are, for each $k=0,1,2,\ldots$, $B\in\mathbb{R}_+$ *and* $C\in\mathbb{R}$, *all equal to the scalar product* $\langle Q,\tilde{Q}\rangle_\nu$.

Proof. First note that, as a consequence of Schur's lemma,

$$\langle\mathcal{K}_Qf,\mathcal{K}_{\tilde{Q}}g\rangle_\nu=\langle Q,\tilde{Q}\rangle_\nu\langle f,g\rangle_\mu,$$

where we have used $\mathcal{K}_Q1=Q$. If we put $\xi=B$ in the equality (4.3) and then take the scalar product with $\mathcal{K}_{\tilde{Q}}e_B^2*\phi$ for a suitable ϕ, the left-hand side then equals

$$\frac{B^{\mu-1}}{\Gamma(\mu)}\langle Q,\tilde{Q}\rangle_\nu\langle e_B^2,e_B^2*\phi\rangle_\mu,$$

while the right-hand side equals

$$\begin{aligned}&\frac{1}{\Gamma(\nu_1)\cdots\Gamma(\nu_n)}\int_{\eta\in\mathbb{R}^n_+\,:\,|\eta|=B} T_2Q(\eta)\langle e^2_{\eta_1}\otimes\cdots\otimes e^2_{\eta_n},\mathcal{K}_{\tilde{Q}}e_B^2*\phi\rangle_\nu\,\eta_1^{\nu_1-1}\cdots\eta_n^{\nu_n-1}\,d\eta\\&=\frac{1}{\Gamma(\nu_1)\cdots\Gamma(\nu_n)}\int_{\eta\in\mathbb{R}^n_+\,:\,|\eta|=B} T_2Q(\eta)\,\overline{T_2\tilde{Q}(\eta)}\langle e_B^2,e_B^2*\phi\rangle_\mu\,\eta_1^{\nu_1-1}\cdots\eta_n^{\nu_n-1}\,d\eta.\end{aligned}$$

Dividing out the matrix element $\langle e_B^2,e_B^2*\phi\rangle_\mu$ we obtain the second part of the corollary. The remaining parts are similar. □

5. Convolution formulas. In this section we will obtain some convolution formulas for the polynomials T_iQ. The most general formulas of this type would follow from considering a scalar product

$$\langle\mathcal{K}_Qe_x^i*\phi,(e^j_{y_1}\otimes\cdots\otimes e^j_{y_n})*\psi\rangle_\nu$$

and expanding this by applying formula number k in (3.1) on each variable. For instance, with $(i,j,k)=(1,2,3)$ this gives

$$\begin{aligned}&\langle\mathcal{K}_Qe_k^1*\phi,(e^2_{\xi_1}\otimes\cdots\otimes e^2_{\xi_n})*\psi\rangle_\nu\\&=\int_{\mathbb{R}^n}\langle\mathcal{K}_Qe_k^1*\phi,e^3_{X_1}\otimes\cdots\otimes e^3_{X_n}\rangle_\nu\langle e^3_{X_1}\otimes\cdots\otimes e^3_{X_n},(e^2_{\xi_1}\otimes\cdots\otimes e^2_{\xi_n})*\psi\rangle_\nu\,dm(X),\end{aligned}$$

where

$$dm(X)=\frac{1}{(2\pi)^n\Gamma(\nu_1)\cdots\Gamma(\nu_n)}\left|\Gamma\left(\frac{\nu_1}{2}+iX_1\right)\cdots\Gamma\left(\frac{\nu_n}{2}+iX_n\right)\right|^2dX_1\cdots dX_n.$$

Now, by Theorem 4.2, this may be written as

$$T_2Q(\xi)\,K^{12}(k,|\xi|,\psi\phi^{-1})=\int_{\mathbb{R}^n}T_3Q(X)\,K^{13}(k,|X|,\phi^{-1})\prod_{r=1}^nK^{32}(X_r,\xi_r,\psi)\,dm(X).$$

Inserting the expressions for matrix elements from Proposition 3.2, we obtain an integral formula linking T_2Q and T_3Q.

We will not write down all such formulas since they may be deduced from a few special cases. Using addition formulas for the matrix elements we may reduce ourselves to the case $\phi = \mathrm{id}$. As in the previous section, we may also assume that $i = k$. In this case, the formulas follow from applying the transform $\mathcal{F}_j^{\psi}$ to both sides of the three generalized Clebsch–Gordan formulas of Corollary 4.3. Moreover, the formulas with $j = 3$ follow from those with $j = 1$, by means of (1.8). After these reductions, there remain the six cases

$$(i,j) = (1,1),\ (1,2),\ (2,1),\ (2,2),\ (3,1),\ (3,2),$$

which will give the following convolution formulas.

THEOREM 5.1. *Let, as above, Q be a highest weight polynomial in $\mathcal{A}^{\nu_1} \cdots \otimes \mathcal{A}^{\nu_n}$ of degree s and let $\mu = |\nu| + 2s$. Then the following formulas hold*:

$$\begin{aligned}(5.1)\quad & \frac{(\mu)_k}{k!} c^s \, {}_2F_1\left(\begin{matrix} -k, s-|l| \\ \mu \end{matrix} \,\middle|\, c \right) T_1 Q(l) \\ &= \sum_{|m|=k+s} \frac{(\nu_1)_{m_1} \cdots (\nu_n)_{m_n}}{m_1! \cdots m_n!} T_1 Q(m) \prod_{r=1}^{n} {}_2F_1\left(\begin{matrix} -m_r, -l_r \\ \nu_r \end{matrix} \,\middle|\, c \right), \\ & \frac{(\mu)_k}{k!} \, {}_1F_1\left(\begin{matrix} -k \\ \mu \end{matrix} \,\middle|\, |\xi| \right) T_2 Q(\xi) \\ &= (-1)^s \sum_{|m|=k+s} \frac{(\nu_1)_{m_1} \cdots (\nu_n)_{m_n}}{m_1! \cdots m_n!} T_1 Q(m) \prod_{r=1}^{n} {}_1F_1\left(\begin{matrix} -m_r \\ \nu_r \end{matrix} \,\middle|\, \xi_r \right), \end{aligned}$$

$$\begin{aligned}(5.2)\quad & \frac{\xi^{\mu-1}}{\Gamma(\mu)} \, {}_1F_1\left(\begin{matrix} s-|m| \\ \mu \end{matrix} \,\middle|\, \xi \right) T_1 Q(m) \\ &= \frac{(-1)^s}{\Gamma(\nu_1) \cdots \Gamma(\nu_n)} \int_{\eta \in \mathbb{R}_+^n \,:\, |\eta| = \xi} T_2 Q(\eta) \prod_{r=1}^{n} {}_1F_1\left(\begin{matrix} -m_r \\ \nu_r \end{matrix} \,\middle|\, \eta_r \right) \eta_1^{\nu_1 - 1} \cdots \eta_n^{\nu_n - 1} \, d\eta, \\ & \frac{\xi^{\mu-1}}{\Gamma(\mu)} \, {}_0F_1\left(\begin{matrix} - \\ \mu \end{matrix} \,\middle|\, -\xi|\zeta| \right) T_2 Q(\zeta) \\ &= \frac{(-1)^s}{\Gamma(\nu_1) \cdots \Gamma(\nu_n)} \int_{\eta \in \mathbb{R}_+^n \,:\, |\eta| = \xi} T_2 Q(\eta) \prod_{r=1}^{n} {}_0F_1\left(\begin{matrix} - \\ \nu_r \end{matrix} \,\middle|\, -\eta_r \zeta_r \right) \eta_1^{\nu_1 - 1} \cdots \eta_n^{\nu_n - 1} \, d\eta, \end{aligned}$$

$$\begin{aligned}(5.3)\quad & \frac{\left|\Gamma\left(\frac{\mu}{2} + iX\right)\right|^2}{\Gamma(\mu)} c^s \, {}_2F_1\left(\begin{matrix} s-|m|, \frac{\mu}{2} + iX \\ \mu \end{matrix} \,\middle|\, c \right) T_1 Q(m) \\ &= \frac{1}{(2\pi)^{n-1}} \int_{Y \in \mathbb{R}^n \,:\, |Y| = X} T_3 Q(Y) \prod_{r=1}^{n} \frac{\left|\Gamma\left(\frac{\nu_r}{2} + iY_r\right)\right|^2}{\Gamma(\nu_r)} \, {}_2F_1\left(\begin{matrix} -m_r, \frac{\nu_r}{2} + iY_r \\ \nu_r \end{matrix} \,\middle|\, c \right) dY, \\ & \frac{\left|\Gamma\left(\frac{\mu}{2} + iX\right)\right|^2}{\Gamma(\mu)} \, {}_1F_1\left(\begin{matrix} \frac{\mu}{2} + iX \\ \mu \end{matrix} \,\middle|\, |\xi| \right) T_2 Q(\xi) \\ &= \frac{i^s}{(2\pi)^{n-1}} \int_{Y \in \mathbb{R}^n \,:\, |Y| = X} T_3 Q(Y) \prod_{r=1}^{n} \frac{\left|\Gamma\left(\frac{\nu_r}{2} + iY_r\right)\right|^2}{\Gamma(\nu_r)} \, {}_1F_1\left(\begin{matrix} \frac{\nu_r}{2} + iY_r \\ \nu_r \end{matrix} \,\middle|\, i\xi_r \right) dY. \end{aligned}$$

The parameter c occurring in (5.1) and (5.3) depends on the choice of ψ. More precisely, in the first of these identities $c = -1/|\beta|^2$, where $\psi(z) = (\alpha z + \beta)/(\bar{\beta} z + \bar{\alpha})$,

and in the second one $c = 2/(\alpha+\bar\beta)(\bar\alpha-\beta)$. Since both sides are polynomials in c they are valid for arbitrary c. For the remaining four identities, different choices of ψ give essentially the same result.

Quite a lot of information is contained in these formulas. Many known identities follow from the three interesting special cases when (i) $Q = 1$, (ii) $n = 2$, or (iii) a numerator parameter in the hypergeometric function on the left-hand side is 0, so that this function reduces to 1. In particular, the case $n = 2$ of the first two identities occurs in [KV1] with a similar group theoretic interpretation; cf. also [Su], [VdJ].

It should be noted that if Q is constructed by binary coupling as in section 2.4, the theorem may be proved using the case $n = 2$ and induction on n. Since one may construct a basis for the space of highest weight vectors in this way, this actually gives an alternative proof of the general case.

Some degenerate cases of our convolution formulas seem interesting enough to state explicitly. First, the polynomials T_1Q (and thus T_3Q) satisfy some related identities.

COROLLARY 5.2. *In the notation of Theorem* 5.1*, the following additional formulas are valid*:

$$\frac{(\mu+|l|-s)_k}{k!}\,T_1Q(l) = \sum_{|m|=k+s} \frac{(\nu_1+l_1)_{m_1}\cdots(\nu_n+l_n)_{m_n}}{m_1!\cdots m_n!}\,T_1Q(m), \tag{5.4}$$

$$\frac{(\mu+|l|-s)_{k+s}}{(k+s)!}\,T_1Q(l) = \sum_{|m|=k+s} \frac{(\nu_1+l_1)_{m_1}\cdots(\nu_n+l_n)_{m_n}}{m_1!\cdots m_n!}\,T_1Q(m+l), \tag{5.5}$$

$$\frac{(s-|l|)_k}{k!}\,T_1Q(l) = (-1)^s \sum_{|m|=k+s} \frac{(-l_1)_{m_1}\cdots(-l_n)_{m_n}}{m_1!\cdots m_n!}\,T_1Q(m), \tag{5.6}$$

$$\frac{(s-|l|)_{k+s}}{(k+s)!}\,T_1Q(l) = \sum_{|m|=k+s} \frac{(-l_1)_{m_1}\cdots(-l_n)_{m_n}}{m_1!\cdots m_n!}\,T_1Q(l-m). \tag{5.7}$$

Proof. This follows from the convolution formula (5.1). As remarked above, it is valid for arbitrary values of c, though in the proof $c = -1/|\beta|^2$ is negative. Putting $c = 1$ and using the Chu–Vandermonde formula

$${}_2F_1\left(\begin{matrix}-m,-l\\ \nu\end{matrix}\,\middle|\,1\right) = \frac{(\nu)_{m+l}}{(\nu)_m(\nu)_l}$$

gives the equality (5.4). If we multiply both sides of (5.1) by c^{-k-s} and use the limit relation

$$\lim_{c\to\infty}\frac{1}{c^m}\,{}_2F_1\left(\begin{matrix}-m,-l\\ \nu\end{matrix}\,\middle|\,c\right) = (-1)^m\frac{(-l)_m}{(\nu)_m} \qquad (m,\,l = 0,1,2,\ldots),$$

we obtain (5.6). Incidentally, (5.6) also follows from (5.4) together with

$$T_1Q(m) = (-1)^s\,T_1Q(-\nu-m), \tag{5.8}$$

which in turn follows from (1.8) and (1.9).

If we instead multiply both sides of (5.1) by $c^{-|l|}$ and let $c\to\infty$, we get

$$(-1)^s\frac{(\mu)_k(-k)_{|l|-s}}{k!(\mu)_{|l|-s}}\,T_1Q(l) = \sum_{|m|=k+s} \frac{(\nu_1)_{m_1}\cdots(\nu_n)_{m_n}(-m_1)_{l_1}\cdots(-m_n)_{l_n}}{m_1!\cdots m_n!\,(\nu_1)_{l_1}\cdots(\nu_n)_{l_n}}\,T_1Q(m).$$

Replacing k by $k+|l|$ and m by $m+l$ gives (5.5). The equality (5.7) follows from (5.5) together with (5.8). ∎

We may also obtain two integral formulas for T_1Q from Theorem 5.1. In the bilinear case, the first of these is a known formula for the Hahn polynomials (see [VK, Formula 8.2.4(7)]), while we have not found the second one in the literature.

COROLLARY 5.3. *In the notation of Theorem* 5.1*, the following additional formulas are valid*:

$$\begin{aligned}
&\frac{1}{\Gamma(\mu+|m|-s)}\,T_1Q(m)\\
&\quad=\quad \frac{1}{\Gamma(\nu_1+m_1)\cdots\Gamma(\nu_n+m_n)}\int_{\eta\in\mathbb{R}^n_+\,:\,|\eta|=1} T_2Q(\eta)\,\eta_1^{m_1+\nu_1-1}\cdots\eta_n^{m_n+\nu_n-1}\,d\eta,\\
&\frac{\Gamma\left(\frac{\mu}{2}+iX\right)\Gamma\left(\frac{\mu}{2}-iX+|m|-s\right)}{\Gamma(\mu+|m|-s)}\,T_1Q(m)\\
&\quad=\quad \frac{1}{(2\pi)^{n-1}}\int_{Y\in\mathbb{R}^n\,:\,|Y|=X} T_3Q(Y)\prod_{r=1}^{m}\frac{\Gamma\left(\frac{\nu_r}{2}+iY_r\right)\Gamma\left(\frac{\nu_r}{2}-iY_r+m_r\right)}{\Gamma(\nu_r+m_r)}\,dY.
\end{aligned}$$

Proof. This follows from the convolution formulas (5.2) and (5.3), respectively. In the integral in (5.2), replace η by $\xi\eta$ so that the integration is over $\{|\eta|=1\}$. Then let $\xi\to\infty$ and use the homogeneity of T_2Q and the limit relation

$$\lim_{\xi\to\infty}\frac{1}{\xi^m}\,{}_1F_1\left(\begin{array}{c|c} -m & \\ \nu & \xi\eta\end{array}\right)=\frac{(-1)^m}{(\nu)_m}\eta^m\qquad(m=0,1,2,\ldots).$$

The other half of the corollary is the case $c=1$ of (5.3). ∎

6. Coupling kernels. In this section we introduce some polynomials in $2n$ variables which we call *coupling kernels*. Let V_s be the subspace of $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ consisting of highest weight polynomials of degree s, and let $Q_s(z,\bar w)$ be its reproducing kernel. The coupling kernels are obtained by applying one of the transforms T_i to each variable in $Q_s(z,\bar w)$. If

$$Q_s(z,\bar w)=\sum_{|t|=|u|=s}c_{t,u}\,\bar w^t z^u,$$

we define the coupling kernels P_s^{ij} as

$$P_s^{ij}(x,y)=\sum_{|t|=|u|=s}c_{t,u}\,\overline{(T_iw^t)(x)}\,(T_jz^u)(y),\qquad i,j=1,2,3.$$

Recall the decomposition

$$\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}\simeq\bigoplus_{s=0}^{\infty}\binom{n+s-2}{n-2}\mathcal{A}^{|\nu|+2s}.$$

Let Π_s denote the orthogonal projection of $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ onto the isotypic subspace equivalent to $\binom{n+s-2}{n-2}\mathcal{A}^{|\nu|+2s}$. By general Hilbert space arguments, we may express the reproducing kernel Q_s as

$$Q_s(z,\bar w)=\sum_{|t|=|u|=s}\frac{(\nu)_t(\nu)_u}{t!\,u!}\langle\Pi_sz^t,z^u\rangle_\nu\,\bar w^tz^u$$

or as

$$Q_s(z,\bar w)=\sum_{k\in\Lambda_s}\overline{Q_k(w)}\,Q_k'(z),$$

where $(Q_k)_{k\in\Lambda_s}$ is any basis of V_s and $(Q'_k)_{k\in\Lambda_s}$ is the dual basis (here Λ_s is a suitable index set of cardinality $\binom{n+s-2}{n-2}$). Thus the coupling kernels are given by

$$P_s^{ij}(x,y)=\sum_{|t|=|u|=s}\frac{(\nu)_t(\nu)_u}{t!\,u!}\langle\Pi_s z^t,z^u\rangle_\nu\overline{(T_iw^t)(x)}\,(T_jz^u)(y) \tag{6.1}$$

$$=\sum_{k\in\Lambda_s}\overline{T_iQ_k(x)}\,T_jQ'_k(y). \tag{6.2}$$

It will turn out that the coupling kernels may be expressed more explicitly in terms of Karlsson's generalized Kampé de Fériet functions (2.1). Moreover, we will recover as very special cases the dual Appell polynomials described in section 2.3.

To motivate the introduction of the coupling kernels, consider the matrix elements of the projection Π_s:

$$\langle\Pi_s(e^i_{x_1}\otimes\cdots\otimes e^i_{x_n}),(e^j_{y_1}\otimes\cdots\otimes e^j_{y_n})*\phi\rangle_\nu,\qquad i,j=1,2,3. \tag{6.3}$$

One may express Π_s as

$$\Pi_s=\sum_{k\in\Lambda_s}\mathcal{K}_{Q'_k}\mathcal{K}^*_{Q_k},$$

where (Q_k) and (Q'_k) are as above. Using Theorem 4.2 one finds that the matrix element (6.3) equals a matrix element (in the sense of section 3) for $\mathcal{A}^{|\nu|+2s}$ times the coupling kernel $P_s^{ij}(x,y)$. For instance, one has

$$\begin{aligned}
&\langle\Pi_s(e^1_{l_1}\otimes\cdots\otimes e^1_{l_n}),(e^2_{\xi_1}\otimes\cdots\otimes e^2_{\xi_n})*\phi\rangle_\nu\\
&=\sum_{k\in\Lambda_s}\langle\mathcal{K}^*_{Q_k}e^1_{l_1}\otimes\cdots\otimes e^1_{l_n},\mathcal{K}^*_{Q'_k}(e^2_{\xi_1}\otimes\cdots\otimes e^2_{\xi_n})*\phi\rangle_{|\nu|+2s}\\
&=\sum_{k\in\Lambda_s}\overline{T_1Q_k(l)}\,T_2Q'_k(\xi)\langle e^1_{|l|-s},e^2_{|\xi|}*\phi\rangle_{|\nu|+2s}\\
&=K^{12}(|l|-s,|\xi|,\phi)\,P_s^{12}(l,\xi).
\end{aligned}$$

We now give explicit expressions for the coupling kernels. It is clear that

$$P_s^{ij}(x,y)=\overline{P_s^{ji}(y,x)}, \tag{6.4}$$

so we may assume that $i\le j$. Moreover, it follows from (1.8) that

$$P_s^{i3}(x,Y)=P_s^{i1}\left(x,iY-\frac{\nu}{2}\right), \tag{6.5}$$

which leaves us with the three cases P_s^{11}, P_s^{12}, and P_s^{22}.

THEOREM 6.1. *The coupling kernels are given in terms of Karlsson's functions* (2.1) *by*

$$\begin{aligned}
P_s^{11}(k,l)&=\frac{(-1)^s(-|k|)_s(-|l|)_s}{(|\nu|+s-1)_s s!}\,F^{2:2}_{2:1}\left(\begin{matrix}|\nu|+s-1,-s\ :\ -k,-l\\ -|k|,-|l|\ :\ \nu\end{matrix}\,\middle|\,1\right),\\
P_s^{12}(k,\xi)&=\frac{(-|k|)_s|\xi|^s}{(|\nu|+s-1)_s s!}\,F^{2:1}_{1:1}\left(\begin{matrix}|\nu|+s-1,-s\ :\ -k\\ -|k|\ :\ \nu\end{matrix}\,\middle|\,\frac{\xi}{|\xi|}\right),\\
P_s^{22}(\xi,\eta)&=\frac{(-1)^s|\xi|^s|\eta|^s}{(|\nu|+s-1)_s s!}\,F^{2:0}_{0:1}\left(\begin{matrix}|\nu|+s-1,-s\ :\ -\\ -\ :\ \nu\end{matrix}\,\middle|\,\frac{\xi\eta}{|\xi||\eta|}\right).
\end{aligned}$$

The proof of this theorem will be deferred to section 8. The variable of the $F_{0:1}^{2:0}$-function should be interpreted as

$$\frac{\xi\eta}{|\xi||\eta|} = \frac{1}{(\xi_1+\cdots+\xi_n)(\eta_1+\cdots+\eta_n)}\,(\xi_1\eta_1,\dots,\xi_n\eta_n)\,.$$

We also remark that Karlsson's $F_{0:1}^{2:0}$-function is Lauricella's F_C-function.

These expressions should be compared with what one gets from choosing a particular basis (Q_k) in (6.2). This is particularly interesting when $n=2$, when the sum has only one term. In the case of P_s^{22} one gets an expression for the product of two Jacobi polynomials as an $F_{0:1}^{2:0}$-series of two variables, that is, as an Appell F_4-series. This is a classical result of Watson [W]. For P_s^{11} one gets a similar expression for the product of two Hahn polynomials due to Gasper [G1]; cf. also [G2]. For P_s^{12} one gets the identity

$$\begin{aligned}&\frac{(-1)^s s!}{(\nu_2)_s}\,P_s^{(\nu_1-1,\nu_2-1)}\left(\frac{\xi_2-\xi_1}{\xi_1+\xi_2}\right)Q_s(k_1;\nu_1-1,\nu_2-1;k_1+k_2)\\ &= F_{1:1}^{2:1}\left(\begin{matrix}\nu_1+\nu_2+s-1,-s & : & -(k_1,k_2)\\ -k_1-k_2 & : & (\nu_1,\nu_2)\end{matrix}\;\middle|\;\frac{\xi_1}{\xi_1+\xi_2},\frac{\xi_2}{\xi_1+\xi_2}\right)\end{aligned}$$

or equivalently

$$\begin{aligned}&{}_2F_1\left(\begin{matrix}-n,n+a\\ b\end{matrix}\;\middle|\;z\right){}_3F_2\left(\begin{matrix}-n,n+a,c\\ b,d\end{matrix}\;\middle|\;1\right)\\ &=\frac{(-1)^n(a-b+1)_n}{(b)_n}\,F_{1:1}^{2:1}\left(\begin{matrix}-n,n+a & : & (c,d-c)\\ d & : & (b,a-b+1)\end{matrix}\;\middle|\;z,1-z\right),\end{aligned}$$

which we have not found in the literature. For general n one may obtain generalizations of these formulas by choosing in (6.2) the basis (2.2) of V_s or a basis constructed by binary coupling as in section 2.4.

As we mentioned above, the dual Appell polynomials described in section 2.3 may be viewed as special cases of coupling kernels. This might first seem surprising, but is easily understood.

COROLLARY 6.2. *Let (Q_t) be the basis*

$$Q_t(z) = (z_1-z_n)^{t_1}\cdots(z_{n-1}-z_n)^{t_{n-1}},\qquad |t| = t_1+\cdots+t_{n-1} = s$$

of the space of highest weight polynomials in $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ of degree s. Let (Q'_t) be the dual basis. For $x=(x_1,\dots,x_n)$, let $\hat{x}=(x_1,\dots,x_{n-1})$. Then the polynomials $T_iQ'_t$ may be expressed in terms of Karlsson's functions as

$$\begin{aligned}T_1Q'_t(m) &= \frac{(\hat{\nu})_t(-|m|)_s}{t!\,(|\nu|+s-1)_s}\,F_{1:1}^{1:2}\left(\begin{matrix}|\nu|+s-1 & : & -t,-\hat{m}\\ -|m| & : & \hat{\nu}\end{matrix}\;\middle|\;1\right),\\ T_2Q'_t(\xi) &= \frac{(\hat{\nu})_t(-|\xi|)^s}{t!\,(|\nu|+s-1)_s}\,F_{0:1}^{1:1}\left(\begin{matrix}|\nu|+s-1 & : & -t\\ - & : & \hat{\nu}\end{matrix}\;\middle|\;\frac{\xi_1}{|\xi|},\dots,\frac{\xi_{n-1}}{|\xi|}\right),\\ T_3Q'_t(X) &= \frac{(\hat{\nu})_t(\frac{|\nu|}{2}-i|X|)_s}{t!\,(|\nu|+s-1)_s}\,F_{1:1}^{1:2}\left(\begin{matrix}|\nu|+s-1 & : & -t,\frac12\hat{\nu}-i\hat{X}\\ \frac12|\nu|-i|X| & : & \hat{\nu}\end{matrix}\;\middle|\;1\right).\end{aligned}$$

Note that the vector parameters in Karlsson's functions have dimension $n-1$ here but dimension n in Theorem 6.1.

Proof. If $u=(u_1,\dots,u_n)$, $|u|=s$, we may write

$$\Pi_s z^u = \sum_v \langle z^u, Q_v\rangle_\nu\, Q'_v = \sum_v \overline{T_1Q_v(u)}\,Q'_v.$$

Thus

$$T_i\Pi_s z^u(x) = \sum_v \overline{T_1 Q_v(u)}\, T_i Q'_v(x) = P_s^{1i}(u,x). \tag{6.6}$$

Now choose

$$u = (t,0) = (t_1,\dots,t_{n-1},0), \qquad |t| = s. \tag{6.7}$$

Then

$$\langle z^u, Q_v\rangle_\nu = \frac{t_1!\cdots t_{n-1}!}{(\nu_1)_{t_1}\cdots(\nu_{n-1})_{t_{n-1}}}\,\delta_{t,v},$$

so that in fact

$$Q'_t = \frac{(\nu_1)_{t_1}\cdots(\nu_{n-1})_{t_{n-1}}}{t_1!\cdots t_{n-1}!}\,\Pi_s z^u. \tag{6.8}$$

Combining (6.6) and (6.8) gives

$$T_i Q'_t(x) = \frac{(\nu_1)_{t_1}\cdots(\nu_{n-1})_{t_{n-1}}}{t_1!\cdots t_{n-1}!}\,P_s^{1i}(u,x), \qquad i=1,2,3.$$

It is now easy to check that the expressions for $P_s^{1i}(u,x)$ given in Theorem 6.1 simplify to those of the corollary when u is of the form (6.7). □

7. Further properties of the coupling kernels. We continue to study the formal properties of the coupling kernels. Some formulas follow from Corollary 4.4 and Theorem 5.1 by choosing highest weight vectors Q of the form

$$Q_{isx} = \sum_{k\in\Lambda_s} \overline{T_i Q_k(x)}\, Q'_k,$$

where as above $(Q_k)_{k\in\Lambda_s}$ is any basis of V_s and $(Q'_k)_{k\in\Lambda_s}$ is the dual basis. For such Q one has

$$\langle Q, Q_{isx}\rangle_\nu = T_i Q(x), \qquad Q\in V_s,$$

so Q_{isx} is the kernel of T_i, viewed as an operator on V_s. We will write down these formulas explicitly since we find them quite interesting.

Applying Corollary 4.4 with $\tilde{Q} = Q_{isx}$ gives the following identities.

PROPOSITION 7.1. *Let Q be a highest weight polynomial in $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ of degree s, and let $\mu = |\nu| + 2s$. Then, for $i=1,2,3$, $k=0,1,2,\dots$, $B\in\mathbb{R}_+$, and $C\in\mathbb{R}$, one has the equalities*

$$\begin{aligned} T_i Q(x) &= \frac{k!}{(\mu)_k}\sum_{|m|=k+s}\frac{(\nu_1)_{m_1}\cdots(\nu_n)_{m_n}}{m_1!\cdots m_n!}\,T_1 Q(m)\,P_s^{1i}(x,m) \\ &= \frac{\Gamma(\mu)B^{1-\mu}}{\Gamma(\nu_1)\cdots\Gamma(\nu_n)}\int_{\xi\in\mathbb{R}_+^n\,:\,|\xi|=B} T_2 Q(\xi)\,P_s^{2i}(x,\xi)\,\xi_1^{\nu_1-1}\cdots\xi_n^{\nu_n-1}\,d\xi \\ &= \frac{\Gamma(\mu)}{(2\pi)^{n-1}\left|\Gamma\left(\frac{\mu}{2}+iC\right)\right|^2}\int_{X\in\mathbb{R}^n\,:\,|X|=C} T_3 Q(X)\,P_s^{3i}(x,X)\prod_{r=1}^n\frac{\left|\Gamma\left(\frac{\nu_r}{2}+iX_r\right)\right|^2}{\Gamma(\nu_r)}\,dX. \end{aligned}$$

In particular, P_s^{ii} is essentially the reproducing kernel for the space of coupling coefficients T_iQ of degree s. If we recall the connection between the polynomials T_2Q and spherical harmonics, we see that the reproducing kernels for Vilenkin's polyspherical harmonics may be expressed in terms of P_s^{22} and thus in terms of Karlsson's function $F_{0:1}^{2:0}$. This is an interesting fact which we have not found in the literature.

If we choose $\tilde{Q} = Q_{isx}$ and $Q = Q_{jty}$ in Corollary 4.4, we obtain addition formulas for the coupling kernels.

PROPOSITION 7.2. *In the notation above, one has for $i, j = 1, 2, 3$ the equalities*

$$\begin{aligned} P_s^{ij}(x,y)\,\delta_{s,t} &= \frac{k!}{(\mu)_k} \sum_{|m|=k+s} \frac{(\nu_1)_{m_1}\cdots(\nu_n)_{m_n}}{m_1!\cdots m_n!}\, P_s^{i1}(x,m) P_t^{1j}(m,y) \\ &= \frac{\Gamma(\mu) B^{1-\mu}}{\Gamma(\nu_1)\cdots\Gamma(\nu_n)} \int_{\xi\in\mathbb{R}_+^n\,:\,|\xi|=B} P_s^{i2}(x,\xi) P_t^{2j}(\xi,y)\, \xi_1^{\nu_1-1}\cdots\xi_n^{\nu_n-1}\, d\xi \\ = \frac{\Gamma(\mu)}{(2\pi)^{n-1}\left|\Gamma\left(\frac{\mu}{2}+iC\right)\right|^2} &\int_{X\in\mathbb{R}^n\,:\,|X|=C} P_s^{i3}(x,X) P_t^{3j}(X,y) \prod_{r=1}^n \frac{\left|\Gamma\left(\frac{\nu_r}{2}+iX_r\right)\right|^2}{\Gamma(\nu_r)}\, dX. \end{aligned}$$

If we choose $Q = Q_{isx}$ in Theorem 5.1, we obtain eighteen convolution formulas.

PROPOSITION 7.3. *In the notation above, one has for $i = 1, 2, 3$ the equalities*

$$\begin{aligned} &\frac{(\mu)_k}{k!} c^s\, {}_2F_1\left(\begin{matrix} -k, s-|l| \\ \mu \end{matrix}\,\middle|\, c\right) P_s^{i1}(x,l) \\ &= \sum_{|m|=k+s} \frac{(\nu)_m}{m!} P_s^{i1}(x,m) \prod_{r=1}^n {}_2F_1\left(\begin{matrix} -m_r, -l_r \\ \nu_r \end{matrix}\,\middle|\, c\right), \\ &\frac{(\mu)_k}{k!}\, {}_1F_1\left(\begin{matrix} -k \\ \mu \end{matrix}\,\middle|\, |\xi|\right) P_s^{i2}(x,\xi) \\ &= (-1)^s \sum_{|m|=k+s} \frac{(\nu)_m}{m!}\, P_s^{i1}(x,m) \prod_{r=1}^n {}_1F_1\left(\begin{matrix} -m_r \\ \nu_r \end{matrix}\,\middle|\, \xi_r\right), \\ &\frac{\xi^{\mu-1}}{\Gamma(\mu)}\, {}_1F_1\left(\begin{matrix} s-|m| \\ \mu \end{matrix}\,\middle|\, |\xi|\right) P_s^{i1}(x,m) \\ &= \frac{(-1)^s}{\Gamma(\nu_1)\cdots\Gamma(\nu_n)} \int_{\eta\in\mathbb{R}_+^n\,:\,|\eta|=\xi} P_s^{i2}(x,\eta) \prod_{r=1}^n {}_1F_1\left(\begin{matrix} -m_r \\ \nu_r \end{matrix}\,\middle|\, \eta_r\right) \eta_1^{\nu_1-1}\cdots\eta_n^{\nu_n-1}\, d\eta, \\ &\frac{\xi^{\mu-1}}{\Gamma(\mu)}\, {}_0F_1\left(\begin{matrix} - \\ \mu \end{matrix}\,\middle|\, -\xi|\zeta|\right) P_s^{i2}(x,\zeta) \\ &= \frac{(-1)^s}{\Gamma(\nu_1)\cdots\Gamma(\nu_n)} \int_{\eta\in\mathbb{R}_+^n\,:\,|\eta|=\xi} P_s^{i2}(x,\eta) \prod_{r=1}^n {}_0F_1\left(\begin{matrix} - \\ \nu_r \end{matrix}\,\middle|\, -\eta_r\zeta_r\right) \eta_1^{\nu_1-1}\cdots\eta_n^{\nu_n-1}\, d\eta, \\ &\frac{\left|\Gamma\left(\frac{\mu}{2}+iX\right)\right|^2}{\Gamma(\mu)} c^s\, {}_2F_1\left(\begin{matrix} s-|m|, \frac{\mu}{2}+iX \\ \mu \end{matrix}\,\middle|\, c\right) P_s^{i1}(x,m) \\ &= \frac{1}{(2\pi)^{n-1}} \int_{Y\in\mathbb{R}^n\,:\,|Y|=X} P_s^{i3}(x,Y) \prod_{r=1}^n \frac{\left|\Gamma\left(\frac{\nu_r}{2}+iY_r\right)\right|^2}{\Gamma(\nu_r)}\, {}_2F_1\left(\begin{matrix} -m_r, \frac{\nu_r}{2}+iY_r \\ \nu_r \end{matrix}\,\middle|\, c\right) dY, \end{aligned}$$

$$\frac{\left|\Gamma\left(\frac{\mu}{2}+iX\right)\right|^2}{\Gamma(\mu)}\,{}_1F_1\left(\begin{matrix}\frac{\mu}{2}+iX\\ \mu\end{matrix}\,\middle|\, i|\xi|\right)P_s^{i2}(x,\xi)$$
$$=\frac{i^s}{(2\pi)^{n-1}}\int_{Y\in\mathbb{R}^n\,:\,|Y|=X}P_s^{i3}(x,Y)\prod_{r=1}^n\frac{\left|\Gamma\left(\frac{\nu_r}{2}+iY_r\right)\right|^2}{\Gamma(\nu_r)}\,{}_1F_1\left(\begin{matrix}\frac{\nu_r}{2}+iY_r\\ \nu_r\end{matrix}\,\middle|\, i\xi_r\right)dY.$$

Degenerate cases of these formulas are obtained by choosing $Q=Q_{isx}$ in Corollaries 5.2 and 5.3.

We will now give some expansions which are different in nature from those obtained so far. They are of a type known as *linearization formulas*, since they linearize a product of orthogonal functions, expressing it as a sum of functions from the same orthogonal system. Let Π_s be the orthogonal projection introduced in section 6. Then the scalar product of $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ decomposes as

$$\langle f,g\rangle_\nu=\sum_{s=0}^\infty\langle\Pi_s f,g\rangle_\nu. \tag{7.1}$$

We insert in this equality $f=e^i_{x_1}\otimes\cdots\otimes e^i_{x_n}$, $g=(e^i_{y_1}\otimes\cdots\otimes e^i_{y_n})*\phi$. Then the left-hand side is a product of matrix elements for the spaces $\mathcal{A}^{\nu_i}$, while, as we have observed, each term on the right-hand side is the product of a coupling kernel $P_s^{ij}(x,y)$ and a matrix element for $\mathcal{A}^{|\nu|+2s}$. In view of (6.4) and (6.5) it suffices to consider the three cases

$$(i,j)=(1,1),\ (1,2),\ (2,2).$$

This gives the following linearization formulas.

Proposition 7.4. *In the notation above,*

$$\prod_{r=1}^n{}_2F_1\left(\begin{matrix}-k_r,-l_r\\ \nu_r\end{matrix}\,\middle|\, c\right)=\sum_{s=0}^{\min(|k|,|l|)}P_s^{11}(k,l)\,c^s\,{}_2F_1\left(\begin{matrix}s-|k|,s-|l|\\ |\nu|+2s\end{matrix}\,\middle|\, c\right), \tag{7.2}$$
$$\prod_{r=1}^n{}_1F_1\left(\begin{matrix}-k_r\\ \nu_r\end{matrix}\,\middle|\,\xi_r\right)=\sum_{s=0}^{|k|}P_s^{12}(k,\xi)(-1)^s\,{}_1F_1\left(\begin{matrix}s-|k|\\ |\nu|+2s\end{matrix}\,\middle|\,|\xi|\right),$$
$$\prod_{r=1}^n{}_0F_1\left(\begin{matrix}-\\ \nu_r\end{matrix}\,\middle|\,-\xi_r\eta_r\right)=\sum_{s=0}^\infty P_s^{22}(\xi,\eta)\,{}_0F_1\left(\begin{matrix}-\\ |\nu|+2s\end{matrix}\,\middle|\,-|\xi||\eta|\right).$$

For $n=2$, when the coupling kernels factor as a product of two Clebsch–Gordan coefficients, the first of these formulas is the Burchnall–Chaundy formula [BC], while the third one is attributed to Bateman in [VK]. The bilinear case is also treated in [KV2].

It is not hard to prove these formulas directly or to obtain them as special cases of more general expansion formulas. For instance, one may prove that (assuming convergence)

$$\prod_{r=1}^n{}_2F_1\left(\begin{matrix}A_r,B_r\\ C_r\end{matrix}\,\middle|\,x\right)$$
$$=\sum_{s=0}^\infty\frac{(a)_s(b)_s(-1)^s}{s!(c+s-1)_s}\,F^{2:2}_{2:1}\left(\begin{matrix}c+s-1,-s\ :\ A,B\\ a,b\ :\ C\end{matrix}\,\middle|\,1\right)x^s\,{}_2F_1\left(\begin{matrix}a+s,b+s\\ c+2s\end{matrix}\,\middle|\,x\right), \tag{7.3}$$

which reduces to (7.2) for special values of the parameters and to Chaundy's formula [C]

$$
\begin{aligned}
&{}_2F_1\left(\begin{matrix}A,B\\C\end{matrix}\,\middle|\,x\right)\\
&=\sum_{s=0}^{\infty}\frac{(a)_s(b)_s(-1)^s}{s!(c+s-1)_s}\,{}_4F_3\left(\begin{matrix}c+s-1,-s,A,B\\a,b,C\end{matrix}\,\middle|\,1\right)x^s\,{}_2F_1\left(\begin{matrix}a+s,b+s\\c+2s\end{matrix}\,\middle|\,x\right)
\end{aligned}
\tag{7.4}
$$

for $n=1$. In fact, (7.3) is a special case of an even more general expansion formula due to H. M. Srivastava [S]; cf. also [SK, pp. 340–341, Formulas (251) and (254)]. (I would like to thank Professor Srivastava for pointing this out to me.) In [R], we gave a group theoretic interpretation of (7.4), where the ${}_4F_3$-series occur as Racah coefficients (or Wigner 6-j-symbols). It would be interesting to also have an interpretation of the more general formula (7.3).

We finally note some degenerate cases of (7.2). If we put $c=1$, we get

$$
\frac{(\nu_1)_{k_1+l_1}\cdots(\nu_n)_{k_n+l_n}}{(\nu_1)_{k_1}\cdots(\nu_n)_{k_n}(\nu_1)_{l_1}\cdots(\nu_n)_{l_n}}=\sum_{s=0}^{\min(|k|,|l|)}\frac{(|\nu|+2s)_{|k|+|l|-2s}}{(|\nu|+2s)_{|k|-s}(|\nu|+2s)_{|l|-s}}\,P_s^{11}(k,l).
$$

If we multiply (7.2) by $1/c^{|l|}$ and let $c\to\infty$, we get

$$
\frac{(-k_1)_{l_1}\cdots(-k_n)_{l_n}}{(\nu_1)_{l_1}\cdots(\nu_n)_{l_n}}=(-1)^s\sum_{s=0}^{|l|}\frac{(s-|k|)_{|l|-s}}{(|\nu|+2s)_{|l|-s}}\,P_s^{11}(k,l).
$$

The case $|k|=|l|$ of this equation reads

$$
\frac{k_1!\cdots k_n!}{(\nu_1)_{k_1}\cdots(\nu_n)_{k_n}}\,\delta_{k,l}=\sum_{s=0}^{|k|}\frac{(|k|-s)!}{(|\nu|+2s)_{|k|-s}}\,P_s^{11}(k,l),\qquad |k|=|l|.
$$

This may also be deduced by inserting $f=z_1^{k_1}\cdots z_n^{k_n}$, $g=z_1^{l_1}\cdots z_n^{l_n}$ in (7.1). For $n=2$, writing $P_s^{11}(k,l)$ as the product of two ${}_3F_2$-series gives the orthogonality relations for the dual Hahn polynomials (Eberlein polynomials).

8. Proof of Theorem 6.1. In this section we will prove the explicit expressions for the coupling kernels given in Theorem 6.1. The proof will be based on formula (6.1). Thus we will first compute the matrix elements

$$
\langle\Pi_s z^t, z^u\rangle_\nu,\qquad |t|=|u|=s \tag{8.1}
$$

of the projection Π_s.

We will work with the action of the universal enveloping algebra $\mathcal{U}(\mathfrak{sl}(2,\mathbb{C}))$ derived from the group action. This associative algebra has three generators E, F, and H. The action is given on $\mathcal{A}^\nu$ by the densely defined operators (cf. [R])

$$
E=-\frac{d}{dz},\qquad F=z^2\frac{d}{dz}+\nu z,\qquad H=-\left(2z\frac{d}{dz}+\nu\right)
$$

and on $\mathcal{A}^{\nu_1}\otimes\cdots\otimes\mathcal{A}^{\nu_n}$ by

$$
E=-\sum_{i=1}^n\frac{\partial}{\partial z_i},\qquad F=\sum_{i=1}^n\left(z_i^2\frac{\partial}{\partial z_i}+\nu_i z_i\right),\qquad H=-\sum_{i=1}^n\left(2z_i\frac{\partial}{\partial z_i}+\nu_i\right).
$$

These operators satisfy the structure equations

$$[EF] = H, \qquad [HE] = 2E, \qquad [HF] = -2F$$

and the reality conditions

$$E^* = -F, \qquad F^* = -E, \qquad H^* = H.$$

Let $\mathcal{H}_s$ be the subspace of $\mathcal{A}^{\nu_1} \otimes \cdots \otimes \mathcal{A}^{\nu_n}$ consisting of homogeneous polynomials of degree s. There is then an orthogonal decomposition

$$\mathcal{H}_s = V_s \oplus F\mathcal{H}_{s-1},$$

and we are interested in the orthogonal projection $\Pi_s|_{\mathcal{H}_s}$ onto the first summand.

LEMMA 8.1. *We have*

$$EF^k\big|_{\mathcal{H}_s} = F^k E - k(|\nu| + 2s + k - 1)F^{k-1}.$$

Proof. First we observe that

$$EF\big|_{\mathcal{H}_s} = (FE + H)\big|_{\mathcal{H}_s} = FE - (|\nu| + 2s)\mathrm{Id}.$$

Proceeding by induction on k, we find that

$$\begin{aligned} EF^{k+1}\big|_{\mathcal{H}_s} &= EF^k\big|_{\mathcal{H}_{s+1}} F\big|_{\mathcal{H}_s} = F^k EF - k(|\nu| + 2s + k + 1)F^k \\ &= F^k(FE - (|\nu| + 2s)) - k(|\nu| + 2s + k + 1)F^k \\ &= F^{k+1}E - (k+1)(|\nu| + 2s + k)F^k. \qquad \square \end{aligned}$$

LEMMA 8.2. *The orthogonal projection of $\mathcal{H}_s$ onto V_s is given by*

$$\sum_{k=0}^{\infty} \frac{(-1)^k}{k!(2 - |\nu| - 2s)_k} F^k E^k.$$

Note that since $E^{s+1}\big|_{\mathcal{H}_s} = 0$, the sum terminates.

Proof. We first show that the operator maps into V_s. Using the previous lemma, we find that in general

$$\begin{aligned} E\sum_{k=0}^{\infty} c_k F^k E^k\big|_{\mathcal{H}_s} &= \sum_{k=0}^{\infty} c_k EF^k\big|_{\mathcal{H}_{s-k}} E^k \\ &= \sum_{k=0}^{\infty} c_k (F^k E - k(|\nu| + 2s - k - 1)F^{k-1})E^k \\ &= \sum_{k=0}^{\infty} (c_k - c_{k+1}(k+1)(|\nu| + 2s - k - 2))F^k E^{k+1}. \end{aligned}$$

This vanishes if

$$c_{k+1} = \frac{1}{(k+1)(|\nu| + 2s - k - 2)} c_k,$$

which is indeed solved by

$$c_k = \frac{(-1)^k}{k!(2 - |\nu| - 2s)_k}.$$

We then have, for any f in $\mathcal{H}_s$,

$$f = \sum_{k=0}^{\infty} \frac{(-1)^k}{k!(2-|\nu|-2s)_k} F^k E^k f - \sum_{k=1}^{\infty} \frac{(-1)^k}{k!(2-|\nu|-2s)_k} F^k E^k f,$$

where the first term is in V_s. Since the second term is in the image of F, it is orthogonal to the first term. This completes the proof. □

We use this lemma to compute the matrix elements (8.1).

LEMMA 8.3. *For* $|t| = |u| = s$,

$$\langle \Pi_s z^t, z^u \rangle_\nu = \frac{(-1)^s s!}{(|\nu|+s-1)_s} F_{1:1}^{1:2}\left(\begin{matrix} |\nu|+s-1 \ : \ -t, -u \\ -s \ : \ \nu \end{matrix} \,\middle|\, 1 \right). \tag{8.2}$$

Proof. Since $F^* = -E$, the previous lemma gives

$$\langle \Pi_s z^t, z^u \rangle_\nu = \sum_{k=0}^{\infty} \frac{1}{k!(2-|\nu|-2s)_k} \langle E^k z^t, E^k z^u \rangle_\nu. \tag{8.3}$$

Since E is the sum of the commuting operators $-\frac{\partial}{\partial z_j}$, it follows from the multinomial theorem that

$$E^k(z^t) = (-1)^s k! \sum_{|j|=s-k} \frac{(-t)_j}{j!} z^j$$

and thus that

$$\langle E^k z^t, E^k z^u \rangle_\nu = (k!)^2 \sum_{|j|=s-k} \frac{(-t)_j (-u)_j}{j!\,(\nu)_j}.$$

Inserting this in (8.3), we obtain

$$\begin{aligned}
\langle \Pi_s z^t, z^u \rangle_\nu &= \sum_{k=0}^{\infty} \sum_{|j|=s-k} \frac{k!\,(-t)_j (-u)_j}{(2-|\nu|-2s)_k j!\,(\nu)_j} \\
&= \sum_{j_1,\dots,j_n=0}^{\infty} \frac{(s-|j|)!\,(-t)_j (-u)_j}{(2-|\nu|-2s)_{s-|j|} j!\,(\nu)_j} \\
&= \frac{(-1)^s s!}{(|\nu|+s-1)_s} \sum_{j_1,\dots,j_n=0}^{\infty} \frac{(|\nu|+s-1)_{|j|} (-t)_j (-u)_j}{(-s)_{|j|} j!\,(\nu)_j} \\
&= \frac{(-1)^s s!}{(|\nu|+s-1)_s} F_{1:1}^{1:2}\left(\begin{matrix} |\nu|+s-1 \ : \ -t, -u \\ -s \ : \ \nu \end{matrix} \,\middle|\, 1 \right). \qquad \square
\end{aligned}$$

We are now ready to prove Theorem 6.1.

Proof of Theorem 6.1. Insert the expression (8.2) in (6.1). In the case of P_s^{12} this gives

$$\begin{aligned}
P_s^{12}(k,\xi) &= \sum_{|t|=|u|=s} \frac{(\nu)_t (\nu)_u}{t!\,u!} \langle \Pi_s z^t, z^u \rangle_\nu (-1)^s \frac{(-k)_t\, \xi^u}{(\nu)_t (\nu)_u} \\
&= \sum_{|t|=|u|=s} \frac{s!}{(|\nu|+s-1)_s} F_{1:1}^{1:2}\left(\begin{matrix} |\nu|+s-1 \ : \ -t, -u \\ -s \ : \ \nu \end{matrix} \,\middle|\, 1 \right) \frac{(-k)_t\, \xi^u}{t!\,u!} \\
&= \frac{s!}{(|\nu|+s-1)_s} \sum_{|t|=|u|=s} \sum_{j_1,\dots,j_n=0}^{\infty} \frac{(|\nu|+s-1)_{|j|} (-t)_j (-u)_j (-k)_t\, \xi^u}{(-s)_{|j|} (\nu)_j j!\, t!\, u!}.
\end{aligned}$$

Since the terms for which $t_i \le j_i$ or $u_i \le j_i$ for some i vanish, we put

$$t = j + p, \qquad u = j + q$$

and interchange the order of summation. Then

$$\frac{(-t)_j (-u)_j}{t!\, u!} = \frac{(-j-p)_j (-j-q)_j}{(j+p)!\,(j+q)!} = \frac{1}{p!\, q!}$$

so that we get

$$\begin{aligned} &P_s^{12}(k,\xi) \\ &= \frac{s!}{(|\nu|+s-1)_s} \sum_{j\,:\,|j|\le s} \frac{(|\nu|+s-1)_{|j|}}{(-s)_{|j|}(\nu)_j j!} \sum_{|p|=s-|j|} \frac{(-k)_{j+p}}{p!} \sum_{|q|=s-|j|} \frac{\xi^{j+q}}{q!}. \end{aligned} \tag{8.4}$$

Now, by the generalized Chu–Vandermonde formula,

$$\begin{aligned} \sum_{|p|=s-|j|} \frac{(-k)_{j+p}}{p!} &= (-k)_j \sum_{|p|=s-|j|} \frac{(j-k)_p}{p!} = (-k)_j \frac{(|j|-|k|)_{s-|j|}}{(s-|j|)!} \\ &= (-1)^{|j|} \frac{(-|k|)_s}{s!} \frac{(-s)_{|j|}(-k)_j}{(-|k|)_{|j|}}. \end{aligned} \tag{8.5}$$

Similarly, the multinomial theorem gives

$$\sum_{|q|=s-|j|} \frac{\xi^{j+q}}{q!} = \xi^j \frac{|\xi|^{s-|j|}}{(s-|j|)!} = (-1)^{|j|} \frac{|\xi|^s}{s!} \frac{(-s)_{|j|} \xi^j}{|\xi|^{|j|}}.$$

Inserting these expressions in (8.4) we finally obtain

$$\begin{aligned} P_s^{12}(k,\xi) &= \frac{(-|k|)_s |\xi|^s}{(|\nu|+s-1)_s s!} \sum_{j_1,\dots,j_n=0}^{\infty} \frac{(|\nu|+s-1)_{|j|}(-s)_{|j|}(-k)_j \xi^j}{(-|k|)_{|j|}(\nu)_j |\xi|^{|j|}} \\ &= \frac{(-|k|)_s |\xi|^s}{(|\nu|+s-1)_s s!}\, F_{1:1}^{2:1}\left(\begin{matrix} |\nu|+s-1, -s \\ -|k| \end{matrix} \,\middle\vert\, \begin{matrix} -k \\ \nu \end{matrix} \,\middle\vert\, \frac{\xi}{|\xi|} \right). \end{aligned}$$

The remaining two cases are similar except that for P_s^{11} one uses the generalized Chu–Vandermonde formula twice and for P_s^{22} the multinomial theorem twice. □

9. The Fock space. So far our discussion has been based on the unit disc. However, one may study analogous problems for other Hermitean symmetric spaces. In dimension 1 one has, apart from the disc, the Riemann sphere and the plane. For the Riemann sphere, the spaces $\mathcal{A}^\nu$ should be replaced by finite-dimensional spaces of polynomials. Since the group SU(2) has only one conjugacy class of one-parameter subgroups, there will only be one analogue of the transforms T_i. This transform is similar to T_1 with the parameters ν_i replaced by *negative* integers.

A more interesting case is the plane $\mathbb{C}$. We will write down the analogues of our results in this section. Since most proofs are similar to the case of the disc, we will not give the details. First we introduce the Fock space $\mathcal{F}_\alpha$ ($\alpha > 0$), consisting of entire functions for which

$$\|f\|^2 = \frac{\alpha}{\pi} \int_{\mathbb{C}} |f(z)|^2 e^{-\alpha|z|^2}\, dxdy = \sum_{k=0}^{\infty} \frac{k!}{\alpha^k} |\hat{f}(k)|^2 < \infty.$$

This space may be viewed as a limit of $\mathcal{A}^\nu$ when $\nu \to \infty$. In fact, if $\nu > 1$, the norm of $\mathcal{A}^\nu$ is given by

$$\|f\|^2 = \frac{\nu-1}{\pi} \int_{\mathbf{D}} |f(z)|^2 (1-|z|^2)^{\nu-2}\, dxdy.$$

If we replace $\mathbf{D}$ with the disc $\{|z| < R\}$ and let ν and R tend to infinity so that $\nu/R^2 \to \alpha$, the weight tends to

$$\lim_{\nu,\, R\to\infty} \left(1 - \frac{|z|^2}{R^2}\right)^{\nu-2} = e^{-\alpha|z|^2}.$$

At the level of Lie algebras, this corresponds to deforming $\mathfrak{su}(1,1)$ into the Heisenberg algebra.

On the space $\mathcal{F}_\alpha$ we introduce the Heisenberg operators

$$\mathcal{U}_h f(z) = e^{-\alpha|h|^2/2 - \alpha\bar{h}z} f(z+h), \qquad h \in \mathbb{C}.$$

They satisfy the Heisenberg relation

$$\mathcal{U}_{h_1}\mathcal{U}_{h_2} = e^{i\alpha \mathrm{Im}(h_1\bar{h}_2)} \mathcal{U}_{h_1+h_2}$$

and are unitary operators.

As an analogue of the parabolic basis for $\mathcal{A}^\nu$ we introduce the Gauss–Weierstrass functions

$$e^2_x(z) = e^{-\alpha z^2/2 + xz},$$

and write $\mathfrak{F}_2$ for the transform

$$\mathfrak{F}_2 f(x) = \langle f, e^2_x \rangle.$$

We also write $e^1_k(z) = z^k$ and

$$\mathfrak{F}_1 f(k) = \langle f, e^1_k \rangle.$$

In analogy with (3.1), and with the same interpretation, we have the Plancherel formulas

$$\begin{aligned} \langle f, g\rangle &= \sum_{k=0}^{\infty} \frac{\alpha^k}{k!}\, \mathfrak{F}_1 f(k)\, \overline{\mathfrak{F}_1 g(k)} \\ &= \frac{1}{\sqrt{2\pi\alpha}} \int_{-\infty}^{\infty} \mathfrak{F}_2 f(x)\, \overline{\mathfrak{F}_2 g(x)}\, e^{-x^2/2\alpha}\, dx. \end{aligned} \tag{9.1}$$

The matrix elements of $\mathcal{U}_\langle$ are given by

$$\langle \mathcal{U}_h e^1_k, e^1_l \rangle = (-1)^l h^k \bar{h}^l e^{-\alpha|h|^2/2}\, {}_2F_0\left(\begin{matrix} -k, -l \\ - \end{matrix} \,\middle|\, -\frac{1}{\alpha|h|^2} \right),$$

which are essentially Charlier polynomials, and by

$$\begin{aligned} \langle e^1_k, e^2_x \rangle &= \frac{x^k}{\alpha^k}\, {}_2F_0\left(\begin{matrix} -\frac{k}{2}, \frac{1}{2} - \frac{k}{2} \\ - \end{matrix} \,\middle|\, -\frac{2\alpha}{x^2} \right) \\ &= \sum_{0 \le j \le \left[\frac{k}{2}\right]} \frac{(-1)^j k!\, x^{k-2j}}{(k-2j)!\, j!\, 2^j \alpha^{k-j}}, \end{aligned}$$

which are essentially Hermite polynomials. It will be convenient to denote the latter quantity by $H_k(x,\alpha)$, so that

$$e_x^2(z)=\sum_{k=0}^{\infty}\frac{\alpha^k}{k!}H_k(x,\alpha)z^k. \tag{9.2}$$

In the standard notation for Hermite polynomials, cf. [VK], one has

$$H_k(x,\alpha)=\frac{1}{(2\alpha)^{k/2}}H_k\left(\frac{x}{\sqrt{2\alpha}}\right),\qquad \alpha>0.$$

The operators $\mathcal{U}_h$ permute the functions e_x^2, and thus the matrix elements $\langle \mathcal{U}_h e_k^1, e_x^2\rangle$ are also given by Hermite polynomials. For the same reason, the matrix elements $\langle \mathcal{U}_h e_x^2, e_y^2\rangle$ are essentially Dirac measures. We will also consider the matrix elements $\langle \delta_c e_x^2, e_y^2\rangle$, where, as above, δ_c is the dilatation $(\delta_c f)(z)=f(cz)$. Expanding the scalar product as in (9.1), we get

$$\langle \delta_c e_x^2, e_y^2\rangle=\sum_{k=0}^{\infty}\frac{\alpha^k c^k}{k!}H_k(x,\alpha)H_k(y,\alpha). \tag{9.3}$$

Mehler's formula (see [VK, Formula 9.6.8(5)]) then gives

$$\langle \delta_c e_x^2, e_y^2\rangle=\frac{1}{\sqrt{1-c^2}}\exp\left(\frac{2cxy-c^2(x^2+y^2)}{2\alpha(1-c^2)}\right),\qquad |c|<1 \tag{9.4}$$

(cf. [P1] for another computation of this scalar product).

Later we will need power series expansions of $1/e_x^2$ and $1/\langle \delta_c e_x^2, e_y^2\rangle$. Since

$$\frac{1}{e_x^2(z)}=e^{\alpha z^2/2-xz}$$

is obtained from $e_x^2(z)$ by replacing α with $-\alpha$ and z with $-z$, it follows from (9.2) that

$$\frac{1}{e_x^2(z)}=\sum_{k=0}^{\infty}\frac{\alpha^k}{k!}H_k(x,-\alpha)z^k. \tag{9.5}$$

Similarly, if in the right-hand side of (9.4) we formally replace α by $-\alpha$ and multiply by $1-c^2$, we obtain the reciprocal quantity. Manipulating (9.3) in the same way gives

$$\begin{aligned}\frac{1}{\langle \delta_c e_x^2, e_y^2\rangle}&=(1-c^2)\sum_{k=0}^{\infty}\frac{(-1)^k\alpha^k c^k}{k!}H_k(x,-\alpha)H_k(y,-\alpha)\\&=\sum_{k=0}^{\infty}\frac{(-1)^k\alpha^k c^k}{k!}G_k(x,y,\alpha),\end{aligned} \tag{9.6}$$

where

$$\begin{aligned}G_k(x,y,\alpha)&=H_k(x,-\alpha)H_k(y,-\alpha)-\frac{k(k-1)}{\alpha^2}H_{k-2}(x,-\alpha)H_{k-2}(y,-\alpha)\\&=\sum_{0\le i,j\le\left[\frac{k}{2}\right]}\frac{k!\,(k-2)!\,(k(k-1)-4ij)x^{k-2i}y^{k-2j}}{(k-2i)!\,(k-2j)!\,i!\,j!\,2^{i+j}\alpha^{2k-i-j}}.\end{aligned} \tag{9.7}$$

Let us now consider an arbitrary tensor product

$$\mathcal{F}_{\alpha_1} \otimes \cdots \otimes \mathcal{F}_{\alpha_n}$$

of Fock spaces. It decomposes under the group action into infinitely many copies of the space $\mathcal{F}_{|\alpha|}$. To get a finer decomposition one may add to the group auxiliary operators of the form

$$f(z) \mapsto e^{im\theta} f(e^{i\theta} z),$$

where m is an integer; cf. [VK, section 8.6.1]. Temporarily writing $\mathcal{F}_{\alpha,m}$ for the corresponding representation space, we have a decomposition

$$\mathcal{F}_{\alpha_1,m_1} \otimes \cdots \otimes \mathcal{F}_{\alpha_n,m_n} = \bigoplus_{s=0}^{\infty} \binom{n+s-2}{n-2} \mathcal{F}_{|\alpha|,|m|+s}.$$

This means that the intertwining embeddings $\mathcal{F}_{|\alpha|,|m|+s} \to \mathcal{F}_{\alpha_1,m_1} \otimes \cdots \otimes \mathcal{F}_{\alpha_n,m_n}$ are required to increase homogeneity by s. If Q is an image of 1 under such an embedding, then Q must satisfy the same condition (1.3) as in the case of the disc. In the case at hand, there is a simple expression for the corresponding embedding $\mathcal{K}_Q$:

$$(\mathcal{K}_Q g)(z_1, \ldots, z_n) = Q(z_1, \ldots, z_n)\, g\left(\frac{(\alpha, z)}{|\alpha|}\right), \tag{9.8}$$

where

$$(\alpha, z) = \alpha_1 z_1 + \cdots + \alpha_n z_n.$$

From now on we write

$$\langle f, g\rangle_\alpha = \langle f, g\rangle_{\mathcal{F}_{\alpha_1} \otimes \cdots \otimes \mathcal{F}_{\alpha_n}}, \qquad \langle f, g\rangle_{|\alpha|} = \langle f, g\rangle_{\mathcal{F}_{|\alpha|}}.$$

To proceed in analogy with the case of the disc, we should now seek factorizations of the transforms

$$\mathfrak{F}_i^h = \mathfrak{F}_i \mathcal{U}_h, \quad i = 1, 2.$$

However, we get a useful factorization only in the case $i = 1$. Then we may write

$$\mathfrak{F}_1^h = M_1\, \mathfrak{T}_1\, \delta_{-1/\bar{h}}\, \tau_h \quad (h \neq 0),$$

where

$$M_1 f(k) = e^{-\alpha|h|^2/2} (-1)^k \bar{h}^k f(k)$$

and

$$\mathfrak{T}_1 z^k(m) = (-1)^k \frac{(-m)_k}{\alpha^k}.$$

Analogous to Theorem 4.2, we have

$$(\mathfrak{F}_1^h\, \mathcal{K}_Q g)(m) = \mathfrak{T}_1 Q(m) (\mathfrak{F}_1^h g)(|m| - s). \tag{9.9}$$

Thus if

$$Q(z) = \sum_{|t|=s} c_t\, z_1^{t_1} \cdots z_n^{t_n}$$

is a highest weight vector, we have a corresponding coupling coefficient

$$\mathfrak{T}_1 Q(m_1,\dots,m_n) = (-1)^s \sum_{|t|=s} c_t \, \frac{(-m_1)_{t_1}\cdots(-m_n)_{t_n}}{\alpha_1^{t_1}\cdots\alpha_n^{t_n}},$$

which is again a polynomial of degree s.

For $i=2$ we define

$$\mathfrak{T}_2 Q(x_1,\dots,x_n) = \langle Q, e_{x_1}^2 \otimes \cdots \otimes e_{x_n}^2 \rangle_\alpha,$$

where Q is a highest weight vector. There is no very simple expression for $\mathfrak{T}_2 Q$; we must be content with writing

$$\mathfrak{T}_2 Q(x_1,\dots,x_n) = \sum_{|t|=s} c_t \, H_{t_1}(x_1,\alpha_1)\cdots H_{t_n}(x_n,\alpha_n),$$

which shows that $\mathfrak{T}_2 Q$ is a polynomial of degree s. One may also show that

$$\mathfrak{T}_2 Q(x_1+b\alpha_1,\dots,x_n+b\alpha_n) = \mathfrak{T}_2 Q(x_1,\dots,x_n), \qquad b\in\mathbb{C}. \tag{9.10}$$

Note that in the case of the disc, the polynomial $T_2 Q$ is homogeneous. Thus in both cases something of the property (1.3) is preserved. As in Theorem 4.2, we have

$$(\mathfrak{F}_2^h \mathcal{K}_Q g)(x) = \mathfrak{T}_2 Q(x)(\mathfrak{F}_2^h g)(|x|) \tag{9.11}$$

and, for the dilatations,

$$(\mathfrak{F}_2 \delta_c \mathcal{K}_Q g)(x) = c^s \mathfrak{T}_2 Q(x)(\mathfrak{F}_2 \delta_c g)(|x|). \tag{9.12}$$

In the bilinear case, $n=2$, we may take $Q(z)=(z_1-z_2)^s$. Then $\mathfrak{T}_1 Q$ are essentially Krawtchouk polynomials; in the notation of [VK] we have

$$\mathfrak{T}_1 Q(m_1,m_2) = \frac{(-m_1-m_2)_s}{\alpha_2^s} \, K_s(m_1; \tfrac{\alpha_1}{\alpha_1+\alpha_2}; m_1+m_2),$$

while the polynomials $\mathfrak{T}_2 Q$ may be expressed in terms of Hermite polynomials. Indeed, we may write

$$\begin{aligned}\mathfrak{T}_2 Q(x_1,x_2) &= \sum_{k=0}^{s} \binom{s}{k} (-1)^{s-k} H_k(x_1,\alpha_1) H_{s-k}(x_2,\alpha_2) \\ &= \left(\frac{1}{\alpha_1}+\frac{1}{\alpha_2}\right)^s H_s\left(\frac{x_1}{\alpha_1}-\frac{x_2}{\alpha_2}, \frac{1}{\alpha_1}+\frac{1}{\alpha_2}\right),\end{aligned}$$

where the last equality is a special case of the addition formula for Hermite polynomials (see [VK, Formula 9.6.8(7)]), which is in turn easily derived from (9.2). Note that this expression is in agreement with (9.10). That Krawtchouk polynomials are Clebsch–Gordan coefficients for the Heisenberg algebra is well known, cf. [VK], while for the Hermite polynomial this fact, as far as we know, first occurs in [VdJ].

We now write down some properties of the coupling coefficients. First we have the Clebsch–Gordan type formulas analogous to Corollary 4.3. In this case we may use (9.8) to write them more explicitly as

$$Q(z)\frac{(\alpha,z)^k}{k!} = \sum_{|m|=k+s} \frac{\alpha_1^{m_1}\cdots\alpha_n^{m_n}}{m_1!\cdots m_n!} \, \mathfrak{T}_1 Q(m) \, z_1^{m_1}\cdots z_n^{m_n},$$

$$\begin{aligned}&Q(z)\exp\left(-\frac{(x-(\alpha,z))^2}{2|\alpha|}\right) = \frac{1}{(2\pi)^{\frac{n-1}{2}}}\sqrt{\frac{|\alpha|}{\alpha_1\cdots\alpha_n}} \\ &\times \int_{y\in\mathbb{R}^n\,:\,|y|=x} \mathfrak{T}_2 Q(y) \exp\left(-\left(\frac{(y_1-\alpha_1 z_1)^2}{2\alpha_1}+\cdots+\frac{(y_n-\alpha_n z_n)^2}{2\alpha_n}\right)\right) dy,\end{aligned}$$

where in the last equality we have written the product of the generalized basis elements and the weight of the Plancherel measures as

$$e_y^2(z)\, e^{-y^2/2\alpha} = e^{-(y-\alpha z)^2/2\alpha}.$$

Next we have orthogonality relations as in Corollary 4.4. If Q and $\tilde{Q}$ are two highest weight vectors, then their scalar product $\langle Q, \tilde{Q}\rangle_\alpha$ equals both the sum

$$\frac{k!}{|\alpha|^k} \sum_{|m|=k+s} \frac{\alpha_1^{m_1}\cdots\alpha_n^{m_n}}{m_1!\cdots m_n!}\, \mathfrak{T}_1 Q(m)\, \overline{\mathfrak{T}_1 \tilde{Q}(m)}$$

for each $k = 0, 1, 2, \ldots$ and, for each $x \in \mathbb{R}$, the integral

$$\frac{1}{(2\pi)^{\frac{n-1}{2}}} \sqrt{\frac{|\alpha|}{\alpha_1\cdots\alpha_n}} \int_{y\in\mathbb{R}^n\,:\,|y|=x} \mathfrak{T}_2 Q(y)\, \overline{\mathfrak{T}_2 \tilde{Q}(y)} \exp\left(-\left(\frac{y_1^2}{2\alpha_1} + \cdots + \frac{y_n^2}{2\alpha_n}\right)\right) dy.$$

There are also analogues of the convolution formulas of Theorem 5.1. If Q is a highest weight polynomial of degree s, we have

$$\begin{aligned}
&\frac{|\alpha|^k}{k!} c^s\, {}_2F_0\left(\begin{matrix} -k, s-|l| \\ - \end{matrix}\,\middle|\, \frac{c}{|\alpha|}\right) \mathfrak{T}_1 Q(l) \\
&= \sum_{|m|=k+s} \frac{\alpha_1^{m_1}\cdots\alpha_n^{m_n}}{m_1!\cdots m_n!}\, \mathfrak{T}_1 Q(m) \prod_{r=1}^n {}_2F_0\left(\begin{matrix} -m_r, -l_r \\ - \end{matrix}\,\middle|\, \frac{c}{\alpha_r}\right),
\end{aligned}$$

$$\begin{aligned}
&\frac{|\alpha|^k}{k!} H_k(|x|, |\alpha|)\, \mathfrak{T}_2 Q(x) \\
&= \sum_{|m|=k+s} \frac{\alpha_1^{m_1}\cdots\alpha_n^{m_n}}{m_1!\cdots m_n!}\, \mathfrak{T}_1 Q(m) \prod_{r=1}^n H_{m_r}(x_r, \alpha_r),
\end{aligned}$$

$$\begin{aligned}
&\exp\left(-\frac{x^2}{2|\alpha|}\right) H_{|m|-s}(x, |\alpha|)\, \mathfrak{T}_1 Q(m) = \frac{1}{(2\pi)^{\frac{n-1}{2}}} \sqrt{\frac{|\alpha|}{\alpha_1\cdots\alpha_n}} \\
&\quad \times \int_{y\in\mathbb{R}^n\,:\,|y|=x} \mathfrak{T}_2 Q(y) \prod_{r=1}^n H_{m_r}(y_r, \alpha_r) \exp\left(-\left(\frac{y_1^2}{2\alpha_1} + \cdots + \frac{y_n^2}{2\alpha_n}\right)\right) dy,
\end{aligned}$$

$$\begin{aligned}
&c^s \exp\left(\frac{2cx|z| - x^2 - c^2|z|^2}{2|\alpha|(1-c^2)}\right) \mathfrak{T}_2 Q(z) = \frac{1}{(2\pi(1-c^2))^{\frac{n-1}{2}}} \sqrt{\frac{|\alpha|}{\alpha_1\cdots\alpha_n}} \\
&\quad \times \int_{y\in\mathbb{R}^n\,:\,|y|=x} \mathfrak{T}_2 Q(y) \exp\left(\sum_{j=1}^n \frac{2cy_jz_j - y_j^2 - c^2z_j^2}{2\alpha_j(1-c^2)}\right) dy.
\end{aligned}$$

For $n = 2$, the first of these formulas is the addition formula for Charlier polynomials, cf. [VK, section 8.6.5], while the second one is a generalization of the addition formula for Hermite polynomials given in [VdJ] and [KV1]. As degenerate cases of the first of these formulas we obtain analogues of the equations (5.5) and (5.6):

$$\begin{aligned}
\frac{|\alpha|^{k+s}}{(k+s)!}\, \mathfrak{T}_1 Q(l) &= \sum_{|m|=k+s} \frac{\alpha_1^{m_1}\cdots\alpha_n^{m_n}}{m_1!\cdots m_n!}\, \mathfrak{T}_1 Q(m+l), \\
\frac{(s-|l|)_k}{k!}\, \mathfrak{T}_1 Q(l) &= (-1)^s \sum_{|m|=k+s} \frac{(-l_1)_{m_1}\cdots(-l_n)_{m_n}}{m_1!\cdots m_n!}\, \mathfrak{T}_1 Q(m).
\end{aligned}$$

They are proved similarly using the limit

$$\lim_{c\to\infty}\frac{1}{c^m}\,{}_2F_0\left(\begin{matrix}-m,-l\\-\end{matrix}\,\middle|\,\frac{c}{a}\right)=(-1)^m\frac{(-l)_m}{a^m}\qquad(m,\,l=0,1,2,\dots).$$

We now turn to the coupling kernels for the present situation. They are defined as in the case of the disc and have a similar group theoretic interpretation. We denote them by $\mathfrak{P}_s^{ij}$. We may reduce ourselves to the three cases

$$\mathfrak{P}_s^{11}(k,l),\qquad \mathfrak{P}_s^{12}(k,x),\qquad \mathfrak{P}_s^{22}(x,y).$$

We first give explicit expressions for the coupling kernels similar to those given in Theorem 6.1. It seems that the kernels $\mathfrak{P}_s^{12}$ and $\mathfrak{P}_s^{22}$ do not have simple expressions in terms of Karlsson's functions. Instead we give expansions involving Hermite polynomials. Our explicit expressions are

$$\mathfrak{P}_s^{11}(k,l)=\frac{(-1)^s(-|k|)_s(-|l|)_s}{|\alpha|^s s!}\,F^{1:2}_{2:0}\left(\begin{matrix}-s & : & -k,-l\\ -|k|,-|l| & : & -\end{matrix}\,\middle|\,\frac{|\alpha|}{\alpha}\right),\tag{9.13}$$

$$\begin{aligned}&\mathfrak{P}_s^{12}(k,x)\\ &=\frac{(-|k|)_s}{|\alpha|^s}\sum_{m\,:\,|m|\le s}\frac{(-1)^{|m|}|\alpha|^{|m|}(-k)_m}{(-|k|)_{|m|}m!}\sum_{|p|=s-|m|}\frac{\alpha^p}{p!}\mathbf{H}_{p+m}(x,\alpha)\qquad(9.14)\\ &=\frac{(-1)^s(-|k|)_s}{s!}\sum_{m_1,\dots,m_n=0}^{\infty}(-1)^{|m|}\frac{(-s)_{|m|}(-k)_m}{(-|k|)_{|m|}m!}H_{s-|m|}(|x|,-|\alpha|)\mathbf{H}_m(x,\alpha),\qquad(9.15)\end{aligned}$$

$$\begin{aligned}&\mathfrak{P}_s^{22}(x,y)\\ &=\frac{(-1)^s s!}{|\alpha|^s}\sum_{m\,:\,|m|\le s}\frac{|\alpha|^{|m|}\alpha^m}{(-s)_{|m|}m!}\sum_{|p|=s-|m|}\frac{\alpha^p}{p!}\mathbf{H}_{p+m}(x,\alpha)\sum_{|q|=s-|m|}\frac{\alpha^q}{q!}\mathbf{H}_{q+m}(y,\alpha)\qquad(9.16)\\ &=\frac{(-1)^s|\alpha|^s}{s!}\sum_{m_1,\dots,m_n=0}^{\infty}\frac{(-s)_{|m|}\alpha^m}{|\alpha|^{|m|}m!}G_{s-|m|}(|x|,|y|,|\alpha|)\mathbf{H}_m(x,\alpha)\mathbf{H}_m(y,\alpha),\qquad(9.17)\end{aligned}$$

where in (9.13) we write for short

$$\frac{|\alpha|}{\alpha}=\left(\frac{\alpha_1+\dots+\alpha_n}{\alpha_1},\dots,\frac{\alpha_1+\dots+\alpha_n}{\alpha_n}\right),$$

where

$$\mathbf{H}_m(x,\alpha)=H_{m_1}(x_1,\alpha_1)\cdots H_{m_n}(x_n,\alpha_n),$$

and where G is the polynomial defined in (9.7).

As for the proof, the expression (9.13) may be proved in a similar manner as in the case of the disc, using instead of Lemma 8.2 the formula

$$\Pi_s|_{\mathcal{H}_f}=\sum_{k=0}^{\infty}\frac{1}{k!|\alpha|^k}F^kE^k,$$

where Π_s is defined as the orthogonal projection of $\mathcal{F}_{\alpha_1}\otimes\cdots\otimes\mathcal{F}_{\alpha_n}$ onto the subspace spanned by all $\mathcal{K}_Q g$, where $g\in\mathcal{F}_{|\alpha|}$ and Q is a highest weight polynomial of degree s and where

$$E=-\sum_{i=1}^n\frac{\partial}{\partial z_i},\qquad F=\sum_{i=1}^n\alpha_i z_i$$

are Lie algebra operators derived from the group action. If one continues to imitate the proof of Theorem 6.1, one arrives at the expressions (9.14) and (9.16). However, in this case there is no "multinomial theorem" to sum the inner series. To prove (9.15) and (9.17), which we believe are the natural analogues of the expressions in Theorem 6.1, we use a different approach.

Proof of (9.15). Consider a tensor product $e^2_{x_1} \otimes \cdots \otimes e^2_{x_n}$. We try to decompose it as

$$e^2_{x_1} \otimes \cdots \otimes e^2_{x_n} = \sum_{s=0}^{\infty} \mathcal{K}_{Q_{sx}} g_{sx},$$

where Q_{sx} is a highest weight polynomial of degree s. Because of (9.11) we expect that one must take $g_{sx} = e^2_{|x|}$ for all s, and thus, in view of (9.8), that

$$e^2_{x_1}(z_1) \cdots e^2_{x_n}(z_n) = e^2_{|x|}\left(\frac{(\alpha, z)}{|\alpha|}\right) \sum_{s=0}^{\infty} Q_{sx}.$$

That there is such an expansion may be verified easily by checking that the function

$$\frac{e^2_{x_1}(z_1) \cdots e^2_{x_n}(z_n)}{e^2_{|x|}\left(\frac{(\alpha,z)}{|\alpha|}\right)} = \exp\left(\sum_{i=1}^{n}\left(-\frac{\alpha_i}{2} z_i^2 + x_i z_i\right) + \frac{(\alpha, z)^2}{2|\alpha|} - \frac{|x|(\alpha, z)}{|\alpha|}\right) \tag{9.18}$$

is in the kernel of E and thus that its homogeneous parts are highest weight polynomials. This may be made more transparent by rewriting the above expression as

$$\frac{e^2_{x_1}(z_1) \cdots e^2_{x_n}(z_n)}{e^2_{|x|}\left(\frac{(\alpha,z)}{|\alpha|}\right)} = \exp\left(-\frac{1}{2|\alpha|}\sum_{i<j} \alpha_i \alpha_j (z_i - z_j)^2 + 2(x_i\alpha_j - \alpha_i x_j)(z_i - z_j)\right).$$

Now, consider the matrix element

$$\langle \Pi_s e^2_x, e^1_k \rangle_\alpha = \langle \Pi_s\, e^2_{x_1} \otimes \cdots \otimes e^2_{x_n}, e^1_{k_1} \otimes \cdots \otimes e^1_{k_n} \rangle_\alpha$$

for Π_s. As for the disc, it factors as

$$\langle \Pi_s e^2_x, e^1_k \rangle_\alpha = \mathfrak{P}^{12}_s(k, x) \langle e^2_{|x|}, e^1_{|k|-s} \rangle_{|\alpha|}.$$

On the other hand, (9.9) gives

$$\langle \Pi_s e^2_x, e^1_k \rangle_\alpha = \langle \mathcal{K}_{Q^s_x} e^2_{|x|}, e^1_k \rangle_\alpha = \mathfrak{T}_1 Q_{sx}(k) \langle e^2_{|x|}, e^1_{|k|-s} \rangle_{|\alpha|}.$$

Thus we have found that

$$\mathfrak{P}^{12}_s(k, x) = \mathfrak{T}_1 Q_{sx}(k),$$

where Q_{sx} is the term of degree s in the homogeneous expansion of the function (9.18).

Now, by (9.2)

$$e^2_{x_1}(z_1) \cdots e^2_{x_n}(z_n) = \sum_{m_1, \ldots, m_n = 0}^{\infty} \frac{\alpha^m z^m}{m!} \mathbf{H}_m(x, \alpha),$$

and by (9.5)

$$\frac{1}{e^2_{|x|}\left(\frac{(\alpha,z)}{|\alpha|}\right)} = \sum_{l=0}^{\infty} \frac{(\alpha, z)^l}{l!} H_l(|x|, -|\alpha|).$$

Thus

$$Q_{sx}(z)=\sum_{m\,:\,|m|\le s}\frac{\alpha^m z^m}{m!}\mathbf{H}_m(x,\alpha)\,\frac{(\alpha,z)^{s-|m|}}{(s-|m|)!}H_{s-|m|}(|x|,-|\alpha|).$$

Expanding the power $(\alpha,z)^{s-|m|}$ gives

$$Q_{sx}(z)=\sum_{|m|+|p|=s}\frac{\alpha^{m+p}z^{m+p}}{m!\,p!}\,\mathbf{H}_m(x,\alpha)H_{s-|m|}(|x|,-|\alpha|).$$

By the definition of $\mathfrak{T}_1$, it follows that

$$\mathfrak{T}_1Q_{sx}(k)=(-1)^s\sum_{|m|+|p|=s}\frac{(-k)_{m+p}}{m!\,p!}\,\mathbf{H}_m(x,\alpha)H_{s-|m|}(|x|,-|\alpha|).$$

Summing in p, we have as in (8.5) that

$$\sum_{|p|=s-|m|}\frac{(-k)_{m+p}}{p!}=(-1)^{|m|}\frac{(-|k|)_s}{s!}\frac{(-s)_{|m|}(-k)_m}{(-|k|)_{|m|}}.$$

Inserting this in the previous formula gives the desired expression (9.15). □

Proof of (9.17). We consider the matrix element

$$\langle\delta_c e_x^2,e_y^2\rangle_\alpha=\langle(\delta_c)^{\otimes n}e_{x_1}^2\otimes\cdots\otimes e_{x_n}^2,e_{y_1}^2\otimes\cdots\otimes e_{y_n}^2\rangle_\alpha$$

of δ_c, $|c|<1$, and expand it as

$$\langle\delta_c e_x^2,e_y^2\rangle_\alpha=\sum_{s=0}^{\infty}\langle\Pi_s\delta_c e_x^2,e_y^2\rangle_\alpha.$$

By (9.12)

$$\langle\Pi_s\delta_c e_x^2,e_y^2\rangle_\alpha=c^s\,\mathfrak{P}_s^{22}(x,y)\langle\delta_c e_{|x|}^2,e_{|y|}^2\rangle_{|\alpha|}.$$

It follows that $\mathfrak{P}_s^{22}(x,y)$ is the coefficient of c^s in

$$\frac{\langle\delta_c e_x^2,e_y^2\rangle_\alpha}{\langle\delta_c e_{|x|}^2,e_{|y|}^2\rangle_{|\alpha|}}.$$

Using the expansions (9.2) and (9.6) one obtains the expression (9.17). □

For $n=2$, the coupling kernels factor as a product of two Clebsch–Gordan coefficients. Choosing $Q(z)=(z_1-z_2)^s$, we may write

$$\mathfrak{P}_s^{ij}((x_1,x_2),(y_1,y_2))=\frac{1}{\|Q\|_\alpha^2}\,\mathfrak{T}_iQ(x_1,x_2)\,\mathfrak{T}_jQ(y_1,y_2),\qquad i,\,j=1,2,$$

where the norm is easily computed;

$$\|Q\|_\alpha^2=s!\left(\frac{1}{\alpha_1}+\frac{1}{\alpha_2}\right)^s.$$

Comparing with the expressions for $\mathfrak{P}_s^{ij}$ given above leads to Watson-type formulas, which we have not found in the literature. The case $i=j=1$ gives the identity

$$\begin{aligned}&\frac{\alpha_1^s}{\alpha_2^s}K_s(k_1;\tfrac{\alpha_1}{\alpha_1+\alpha_2};k_1+k_2)\,K_s(l_1;\tfrac{\alpha_1}{\alpha_1+\alpha_2};l_1+l_2)\\&=(-1)^s\,F^{1:2}_{2:0}\left(\begin{matrix}-s & : & -(k_1,k_2),-(l_1,l_2)\\ -k_1-k_2,-l_1-l_2 & : & -\end{matrix}\,\middle|\,\frac{\alpha_1+\alpha_2}{\alpha_1},\frac{\alpha_1+\alpha_2}{\alpha_2}\right).\end{aligned}$$

Changing the names of the variables, this may be rewritten as

$$
\begin{aligned}
&{}_2F_1\left(\begin{matrix}-n,a\\ b\end{matrix}\,\middle|\, x\right){}_2F_1\left(\begin{matrix}-n,c\\ d\end{matrix}\,\middle|\, x\right)\\
&=(1-x)^n\,F^{1:2}_{2:0}\left(\begin{matrix}-n\ :\ (a,b-a),(c,d-c)\\ b,d\ :\ -\end{matrix}\,\middle|\, x,\frac{x}{x-1}\right),
\end{aligned}
$$

which is true for arbitrary a,b,c,d since the series terminate. The case $i=1$, $j=2$ gives

$$
\begin{aligned}
&\frac{1}{\alpha_2^s}\,K_s(k_1;\tfrac{\alpha_1}{\alpha_1+\alpha_2};k_1+k_2)H_s\left(\frac{x_1}{\alpha_1}-\frac{x_2}{\alpha_2},\frac{1}{\alpha_1}+\frac{1}{\alpha_2}\right)\\
&=(-1)^s\sum_{m_1,m_2=0}^{\infty}(-1)^{m_1+m_2}\frac{(-s)_{m_1+m_2}(-k_1)_{m_1}(-k_2)_{m_2}}{(-k_1-k_2)_{m_1+m_2}m_1!\,m_2!}\\
&\quad\times H_{s-m_1-m_2}(x_1+x_2,-\alpha_1-\alpha_2)H_{m_1}(x_1,\alpha_1)H_{m_2}(x_2,\alpha_2).
\end{aligned}
$$

Finally, the case $i=j=2$ gives

$$
\begin{aligned}
&H_s\left(\frac{x_1}{\alpha_1}-\frac{x_2}{\alpha_2},\frac{1}{\alpha_1}+\frac{1}{\alpha_2}\right)H_s\left(\frac{y_1}{\alpha_1}-\frac{y_2}{\alpha_2},\frac{1}{\alpha_1}+\frac{1}{\alpha_2}\right)\\
&=(-\alpha_1\alpha_2)^s\sum_{m_1,m_2=0}^{\infty}\frac{(-s)_{m_1+m_2}\alpha_1^{m_1}\alpha_2^{m_2}}{(\alpha_1+\alpha_2)^{m_1+m_2}m_1!\,m_2!}\,G_{s-m_1-m_2}(x_1+x_2,y_1+y_2,\alpha_1+\alpha_2)\\
&\quad\times H_{m_1}(x_1,\alpha_1)H_{m_2}(x_2,\alpha_2)H_{m_1}(y_1,\alpha_1)H_{m_2}(y_2,\alpha_2).
\end{aligned}
$$

We now discuss the biorthogonal polynomial systems analogous to the Appell and dual Appell polynomials of sections 2.2 and 2.3. Thus we introduce the basis

$$
Q_t(z)=(z_1-z_n)^{t_1}\cdots(z_{n-1}-z_n)^{t_{n-1}},\qquad t_1+\cdots+t_{n-1}=s
$$

of the space of highest weight vectors of degree s in $\mathcal{F}_{\alpha_1}\otimes\cdots\otimes\mathcal{F}_{\alpha_n}$ and let (Q'_t) denote the dual basis. As in the case of the disc, it is easy to find expressions for the polynomials $\mathfrak{T}_iQ_t$ using the definition of $\mathfrak{T}_i$ directly, while the polynomials $\mathfrak{T}_iQ'_t$ arise as special cases of the coupling kernels; in fact

$$
\mathfrak{T}_iQ'_t(x)=\frac{\alpha_1^{t_1}\cdots\alpha_{n-1}^{t_{n-1}}}{t_1!\cdots t_{n-1}!}\,\mathfrak{P}^{1i}_s((t_1,\dots,t_{n-1},0),(x_1,\dots,x_n)).
$$

Writing as above $\hat{x}=(x_1,\dots,x_{n-1})$, where $x=(x_1,\dots,x_n)$, we have

$$
\begin{aligned}
\mathfrak{T}_1Q_t(m)&=\frac{(-m_n)_s}{\alpha_n^s}\,F^{0:2}_{1:0}\left(\begin{matrix}-\ :\ -t,-\hat{m}\\ 1+m_n-s\ :\ -\end{matrix}\,\middle|\,-\frac{\alpha_n}{\alpha_1},\dots,-\frac{\alpha_n}{\alpha_{n-1}}\right),\\
\mathfrak{T}_1Q'_t(m)&=\frac{\hat{\alpha}^t(-|m|)_s}{t!\,|\alpha|^s}\,F^{0:2}_{1:0}\left(\begin{matrix}-\ :\ -t,-\hat{m}\\ -|m|\ :\ -\end{matrix}\,\middle|\,\frac{|\alpha|}{\alpha_1},\dots,\frac{|\alpha|}{\alpha_{n-1}}\right),\\
\mathfrak{T}_2Q_t(x)&=(-1)^s\sum_{k_1,\dots,k_{n-1}=0}^{\infty}\frac{(-t)_k}{k!}\prod_{j=1}^{n-1}H_{k_j}(x_j,\alpha_j)H_{s-|k|}(x_n,\alpha_n),\\
\mathfrak{T}_2Q'_t(x)&=\frac{\hat{\alpha}^t}{t!}\sum_{k_1,\dots,k_{n-1}=0}^{\infty}(-1)^{|k|}\frac{(-t)_k}{k!}\prod_{j=1}^{n-1}H_{k_j}(x_j,\alpha_j)H_{s-|k|}(|x|,-|\alpha|)
\end{aligned}
$$

(Karlsson's $F^{0:2}_{1:0}$-function equals Lauricella's F_B-function). The first of these biorthogonal systems is Tratnik's multivariable Krawtchouk polynomials [T3]. We have not found the second one in the literature.

Continuing this exposition of the Fock space analogues of our results, we should now proceed with section 7. Special choices of Q in the orthogonality and convolution formulas above lead to analogues of Propositions 7.1, 7.2, and 7.3. The details of this are left to the reader. There are also analogues of the linearization formulas of Proposition 7.4. For $\mathfrak{P}_s^{11}$ we have the linearization formula

$$\prod_{r=1}^{n} {}_2F_0\left(\begin{matrix}-k_r,-l_r\\-\end{matrix}\,\middle|\,\frac{c}{\alpha_r}\right)=\sum_{s=0}^{\min(|k|,|l|)}\mathfrak{P}_s^{11}(k,l)\,c^s\,{}_2F_0\left(\begin{matrix}s-|k|,s-|l|\\-\end{matrix}\,\middle|\,\frac{c}{|\alpha|}\right).$$

Degenerate cases of this formula are

$$\frac{(-k_1)_{l_1}\cdots(-k_n)_{l_n}}{\alpha_1^{l_1}\cdots\alpha_n^{l_n}}=(-1)^s\sum_{s=0}^{|l|}\frac{(s-|k|)_{|l|-s}}{|\alpha|^{|l|-s}}\,\mathfrak{P}_s^{11}(k,l),$$

$$\frac{k_1!\cdots k_n!}{\alpha_1^{k_1}\cdots\alpha_n^{k_n}}\,\delta_{k,l}=\sum_{s=0}^{|k|}\frac{(|k|-s)!}{|\alpha|^{|k|-s}}\,\mathfrak{P}_s^{11}(k,l),\qquad |k|=|l|.$$

For $\mathfrak{P}_s^{12}$ and $\mathfrak{P}_s^{22}$ the linearization formulas seem to be of a more trivial nature. For $\mathfrak{P}_s^{12}$ we obtain

$$\prod_{r=1}^{n}H_{k_r}(x_r,\alpha_r)=\sum_{s=0}^{|k|}\mathfrak{P}_s^{12}(k,x)H_{|k|-s}(|x|,|\alpha|).$$

This is, however, very easy to deduce from (9.15). For $\mathfrak{P}_s^{22}$, the linearization formula is

$$\prod_{r=1}^{n}\langle\delta_c e_{x_r},e_{y_r}\rangle_{\alpha_r}=\sum_{s=0}^{\infty}c^s\,\mathfrak{P}_s^{22}(x,y)\langle\delta_c e_{|x|},e_{|y|}\rangle_{|\alpha|},$$

which we have already used in the proof of (9.17). As for the disc, when $n=2$ we may factor $\mathfrak{P}_s^{ij}$ as a product of two Clebsch–Gordan coefficients and obtain formulas of Burchnall–Chaundy-type. In the case of $\mathfrak{P}_s^{11}$ we obtain the multiplication formula for Charlier polynomials in this way; cf. [VK, section 8.6.5].

Acknowledgments. I am grateful to Jaak Peetre for his careful reading of this manuscript, leading to many improvements. I would also like to thank the referees for several useful comments.

THE EVANS FUNCTION AND GENERALIZED MELNIKOV INTEGRALS*

TODD KAPITULA†

Abstract. The Evans function, $E(\lambda)$, is an analytic function whose zeros coincide with the eigenvalues of the operator, L, obtained by linearizing about a travelling wave. The algebraic multiplicity of the eigenvalue λ_0 is equal to the order of the zero of $E(\lambda)$. If m is the geometric multiplicity and p is the algebraic multiplicity of the eigenvalue, the term $\partial_\lambda^p E(\lambda_0)$ is shown to be proportional to the determinant of an $m \times m$ matrix whose entries are given by the L^2 inner products of the eigenfunctions of the adjoint operator L^* and the generalized eigenfunctions of L. Perturbation expressions are then derived for coefficients in the Taylor expansion of $E(\lambda)$ at $\lambda = \lambda_0$ in the circumstance that the algebraic multiplicity of the eigenvalue decreases under perturbation. The expressions are used to study the eigenvalue structure for operators obtained by linearizing about bright solitary wave solutions to perturbed nonlinear Schrödinger equations.

1. Introduction.

Consider the semilinear parabolic system

$$u_t = Bu_{xx} + f(u, u_x), \tag{1.1}$$

where $(x,t) \in \mathbf{R} \times \mathbf{R}^+$, B is a positive semidefinite invertible $n \times n$ matrix, $u \in \mathbf{R}^n$, and the nonlinearity f is at least C^3. A travelling wave solution $\phi(z)$ is a C^2 function of the variable $z = x - ct$ which is a solution to (1.1) and satisfies

$$\lim_{z \to \pm\infty} \phi(z) = \phi_\pm, \quad f(\phi_\pm, 0) = 0.$$

The approach to the constant states is assumed to be exponentially fast. For the rest of this paper, assume that the wave exists when $c = c^*$, so that the wave is then a time-independent solution to

$$u_t = Bu_{zz} + c^* u_z + f(u, u_z). \tag{1.2}$$

Once a wave has been shown to exist, one would then like to determine its stability relative to small perturbations. When attempting to determine the stability of the wave, it is natural to study the spectrum of the linear operator L, where

$$L = B\partial_z^2 + P(z)\partial_z + N(z), \tag{1.3}$$

and

$$P(z) = c^* + Df_{u_z}(\phi, \phi_z), \quad N(z) = Df_u(\phi, \phi_z).$$

†Department of Mathematics and Statistics, University of New Mexico, Albuquerque, NM 87131 (kapitula@math.unm.edu).

Note that the assumption on the wave implies that

$$\lim_{z\to\pm\infty} N(z) = N_\pm, \quad \lim_{z\to\pm\infty} P(z) = P_\pm,$$

with the approach being exponentially fast. By the assumption on the matrix B, L generates a C^0-semigroup [26]. The essential spectrum of L, hereby denoted $\sigma_e(L)$, is bounded by the curves

$$\Gamma_\pm = \{\lambda : |-B\tau^2 + iP_\pm\tau + N_\pm - \lambda I_n| = 0, \tau \in \mathbf{R}\}$$

(see [11]). Set

$$\Omega = \mathbf{C}\backslash\sigma_e(L). \tag{1.4}$$

The only spectrum of L in Ω is the point spectrum, i.e., isolated eigenvalues of finite multiplicity. If there exists a $\delta > 0$ such that $\sigma_e(L) \subset \{\lambda : \operatorname{Re}\lambda \leq \delta\}$, the constant solutions $u = \phi_\pm$ are stable solutions to (1.2) [11]. If the constant solutions are stable, the stability of the wave is determined by the location of the point spectrum. If there exists an eigenvalue λ_0 with $\operatorname{Re}\lambda_0 > 0$, then the wave is exponentially unstable; otherwise, the wave is marginally stable. If the only eigenvalue with $\operatorname{Re}\lambda \geq 0$ is the one at $\lambda = 0$, and if this eigenvalue is semisimple, then the wave is exponentially orbitally stable [6], [11].

The Evans function, $E(\lambda)$, is an analytic function for $\lambda \in \Omega$ with the property that the zeros coincide with the eigenvalues of L; furthermore, the order of the zero is the algebraic multiplicity (a.m.) of the eigenvalue ([1], [29], and the references contained therein). Once the location of an eigenvalue has been determined, i.e., once a $\lambda_0 \in \Omega$ has been found such that $E(\lambda_0) = 0$, one usually wishes to determine $\partial_\lambda^p E(\lambda_0)$, where p is the order of the zero. This is especially the case if $\lambda_0 = 0$ and one wishes to determine the location of small eigenvalues near zero. Examples of such a calculation are in a plethora of papers [1], [2], [3], [4], [7], [8], [9], [12], [15], [27], [28], [29], [30], [31], [33], so that it is clearly of interest to make such a computation.

Solutions to (1.2) are invariant under spatial translation, so that $L\phi_z = 0$; thus, $\lambda_0 = 0$ is an eigenvalue of L. If (1.2) possesses no other symmetry, then the eigenvalue $\lambda_0 = 0$ is generically simple, so that $E(0) = 0$ with $\partial_\lambda E(0) \neq 0$. Alexander and Jones [3], [4] developed the orientation index for determining the sign of $\partial_\lambda E(0)$, and showed that the index is related to the manner in which the wave is constructed in the ODE phase space. Rubin [32], Rubin and Jones [33], and Sandstede [34] have shown that the orientation index is equal to the formulation of $\partial_\lambda E(0)$ given in this paper. A limitation of the index is that if $\partial_\lambda E(0) = 0$, then one is unable to use it to determine if an eigenvalue is moving through the origin into the right- or left-half plane, unless it is known a priori that there is only one other eigenvalue near $\lambda = 0$. Thus, at a minimum it is of interest to find a calculable way to determine $\partial_\lambda^2 E(0)$.

Let $\lambda_0 \in \Omega$ be an eigenvalue with geometric multiplicity (g.m.) $= m$ and a.m. $= p$. Following Gardner and Jones [8] (see Lemma 2.1), the generalized eigenfunctions $\psi_{j,i}$, $i = 1, \ldots, m$, $j = 1, \ldots, a_i$, with $p = \sum_{i=1}^m a_i$, can be ordered such that

$$(L - \lambda_0)\psi_{j,i} = \psi_{j-1,i}, \quad \psi_{0,i} = 0. \tag{1.5}$$

Since g.m.$= m$, there exist adjoint solutions $v_i \in \mathcal{N}((L-\lambda_0)^*)$, $i = 1, \ldots, m$. In all that follows, let $\langle\cdot,\cdot\rangle$ represent the L^2 inner product of complex vector-valued functions.

THEOREM 1.1. *Suppose that λ_0 is an isolated eigenvalue with g.m. $= m$ and a.m. $= p$. Let the functions $\psi_{j,i}$ be as defined in* (1.5)*, and let v_i represent the adjoint eigenfunctions. Then*

$$\partial_\lambda^p E(\lambda_0) = (-1)^{m_s} p! \begin{vmatrix} \langle \psi_{a_1,1}, v_1 \rangle & \cdots & \langle \psi_{a_1,1}, v_m \rangle \\ \vdots & & \vdots \\ \langle \psi_{a_m,m}, v_1 \rangle & \cdots & \langle \psi_{a_m,m}, v_m \rangle \end{vmatrix},$$

where $m_s = \sum_{i=0}^{m-1} i$.

Remark 1.2. As is done in Gardner and Jones [8], the above result can be extended to the case where the differential operator has order higher than two.

For the moment, assume that $\lambda_0 = 0$ and g.m. = a.m. = 1. Then $\psi_{1,1} = \phi_z$, and as a consequence of the above theorem,

$$\partial_\lambda E(0) = \langle \phi_z, v \rangle,$$

where v is the unique (up to scalar multiplication) adjoint eigenfunction of L. As is discussed in Alexander and Jones [3], [4], $\partial_\lambda E(0)$ describes the manner in which the stable and unstable manifolds in the ODE phase space intersect each other at $c = c^*$; i.e., it determines the manner in which the manifolds separate as c is varied from c^*. Thus, the above theorem shows that there is a connection between the stability of the wave and the Melnikov integral $\langle \phi_z, v \rangle$ (see also [30], [32], [33], [34]). If $\lambda_0 = 0$ and g.m. = a.m. $= m \geq 2$, then the PDE (1.2) possesses more than one symmetry, so that $\partial_\lambda^m E(0)$, and hence the Melnikov integrals $\langle \psi_{1,i}, v_j \rangle$, measures the manner in which manifolds separate as the different symmetry parameters are varied. For example, when considering Ginzburg–Landau perturbations of the nonlinear Schrödinger equation, g.m. = a.m. = 2, and the PDE is invariant under both a $SO(2)$ rotation and a spatial translation. For this particular problem, the interested reader should consult Kapitula [15] for a discussion in which the connection is made between $\partial_\lambda^2 E(0)$ and the manner in which the stable and unstable manifolds intersect.

Pego and Weinstein [29] have formulated the Evans function in a manner which is similiar to that presented in Jones [12]. Their formulation is applicable only in the circumstance that the g.m. of an eigenvalue is necessarily one. Physical examples in which g.m. = 1 include the KdV and the KdV–Burgers equations. This formulation is less general than that given by Alexander, Gardner, and Jones [1]. Using Proposition 2.3, it can be shown that Pego and Weinstein's evaluation of $\partial_\lambda E(\lambda_0)$ coincides with that given in Theorem 1.1 in the case that g.m. = a.m. = 1. Pego and Weinstein have also derived expressions for higher derivatives of the Evans function; however, it is not immediately clear that the expressions are equivalent to those presented in Theorem 1.1. Alexander et al. [2] have generalized Pego and Weinstein's approach in the circumstance that g.m. ≥ 2. It is not immediately apparent that one can rederive the results of Theorem 1.1 using the formulation in [2], although one can hypothesize that this is indeed the case.

Now that expressions are available for the derivatives of the Evans function in terms of generalized Melnikov integrals, it will be of interest to determine the manner in which perturbation calculations can be performed. Assuming that some of the eigenvalues move under perturbation, one may naively attempt to take the partial derivative with respect to ϵ of the determinant expression given in Theorem 1.1. This approach is problematic, however, for if g.m. ≥ 2 and $j > m$ the choices of the generalized eigenfunctions must first be known for ϵ nonzero before taking derivatives. Furthermore, if g.m. ≥ 2, it may turn out that generically $\partial_\epsilon \partial_\lambda^j E(\lambda_0) = 0$, but

$\partial_\epsilon^2 \partial_\lambda^j E(\lambda_0) \neq 0$. Using this idea, it might then be necessary to take two derivatives with respect to ϵ of the eigenfunctions. As is seen in section 4 for the case g.m. $= 2$, these technical difficulties can be circumvented.

The linear operator L will be written as

$$L(\epsilon) = B(\epsilon)\partial_z^2 + P(z,\epsilon)\partial_z + N(z,\epsilon),$$

where the $n \times n$ matrices are assumed to be smooth in their arguments. Thus, the perturbation expansions given in section 4 do *not* apply to those problems in which the underlying wave is constructed via geometric singular perturbation theory. It will be assumed that when $\epsilon = 0$ the location and structure of the point eigenvalues for $L(0)$ are completely understood; thus, the zero set of $E(\lambda, 0)$ is assumed to be known. The determination of the eigenvalue structure for $\epsilon \neq 0$ but small, i.e., the zero set of $E(\lambda, \epsilon)$, can then be theoretically accomplished via a Lyapunov–Schmidt reduction. However, if the a.m. of an eigenvalue is larger than its g.m., there could be difficulties, i.e., the eigenvalues may not be smooth functions of ϵ. While this is not problematic if g.m. $= 1$ (see Theorem 1.3), it may cause difficulties if g.m. ≥ 2. As it turns out, g.m. $= 2$ for the nonlinear Schrödinger equation. It is desirable to avoid these potential difficulties if possible. Of course, in doing so some information likely will be lost; however, it may still be possible to recover that lost information via some symmetries present in the eigenvalue problem. This scenario will be illustrated in section 5.1 when the linearized stability of solitary wave solutions to the parametrically forced nonlinear Schrödinger equation is considered.

In section 4 expressions are derived for $\partial_\epsilon^j \partial_\lambda^k E(\lambda_0, 0)$, where λ_0 is the eigenvalue when $\epsilon = 0$ and j and k depend on the a.m. and g.m. of the eigenvalue for both $\epsilon = 0$ and $\epsilon \neq 0$. While the expressions are computed only for g.m. ≤ 2, the algorithm used to generate them can be used to find expressions when g.m. ≥ 3. It is of interest to note the relationship between the various derivatives and the eigenfunction solvability conditions. For example, consider the case that g.m. $= 1$ and a.m. $= p$ when $\epsilon = 0$. In Lemma 4.3 it is shown that

$$\partial_\epsilon E(\lambda_0, 0) = -\langle \partial_\epsilon L(0)\psi_{1,1}, v_1 \rangle.$$

Note that the solvability condition for $\psi_{1,1}$ to remain an eigenfunction for $\epsilon \neq 0$ is

$$\langle \partial_\epsilon L(0)\psi_{1,1}, v_1 \rangle = 0.$$

If $\partial_\epsilon E(\lambda_0, 0) = 0$, so that the eigenvalue persists for $\epsilon \neq 0$, and if a.m. ≥ 2 when $\epsilon = 0$, then as a consequence of Lemma 4.6

$$\partial_\epsilon \partial_\lambda E(\lambda_0, 0) = \langle -\partial_\epsilon L(0)\psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_1 \rangle.$$

It should be noted that setting the right-hand side of the above expression to zero is the solvability condition for $\psi_{2,1}$ to remain an eigenfunction for $\epsilon \neq 0$. Thus, the eigenvalue λ_0 will be simple for $\epsilon \neq 0$ only if the solvability condition for $\psi_{2,1}$ is not satisfied. Examination of the results in section 4.2, where it is assumed that g.m. $= 2$ when $\epsilon = 0$, also shows that there is a strong correlation between the derivatives of the Evans function with respect to ϵ and the eigenfunction solvability conditions.

When g.m. $= 1$, it turns out that the location of all of the eigenvalues can be determined for $\epsilon \neq 0$. This fact is a consequence of the Taylor expansion of the Evans function about $\lambda = \lambda_0$ and a result of Kato [18]. Unfortunately, if g.m. ≥ 2, it is not

clear at the moment as to how one would locate all of these perturbed eigenvalues. This topic will be the focus of a future paper.

THEOREM 1.3. *Suppose that when $\epsilon = 0$, λ_0 is an eigenvalue with g.m. $= 1$ and a.m. $= p$. Further suppose that for $\epsilon \neq 0$, λ_0 is an eigenvalue with a.m. $= j$, where $0 \leq j \leq p-1$. In this case,*

$$\partial_\epsilon \partial_\lambda^j E(\lambda_0, 0) = j! \langle -\partial_\epsilon L(0)\psi_{j+1,1} + \partial_\epsilon \psi_{j,1}, v_1 \rangle,$$

and the location of the remaining $p-j$ eigenvalues is given by

$$\lambda = \lambda_0 + \alpha_1 \omega^h \epsilon^{1/(p-j)} + O(\epsilon^{2/(p-j)}), \quad h = 0, \ldots, p-j-1,$$

where

$$\alpha_1 = -\frac{\langle -\partial_\epsilon L(0)\psi_{j+1,1} + \partial_\epsilon \psi_{j,1}, v_1 \rangle}{\langle \psi_{p,1}, v_1 \rangle}, \quad \omega = e^{2\pi i/(p-j)}.$$

In order to evaluate the expressions given in section 4 for a specific problem, it is necessary to have analytic expressions for the eigenfunctions of $L(0)$. In general, of course, this information will not be available. However, when one is considering the stability of solitary wave solutions to perturbed integrable problems there is a good likelihood that one can indeed compute the eigenfunctions. Examples of such integrable equations include the KdV equation, the focusing and defocusing nonlinear Schrödinger equation, and the Sine–Gordon equation. These eigenfunctions are called the *squared eigenfunctions* [19], [20], [21], [22], [23], [24] and have been used by Pego and Weinstein [29] for calculations with the KdV equation and Kapitula and Sandstede [16], [17] for calculations with perturbed nonlinear Schrödinger equations.

In section 5 the theoretical results of section 4 are applied to perturbed nonlinear Schrödinger equations. When considering the unperturbed problem, g.m. $= 2$ and a.m. $= 4$ for the isolated eigenvalue $\lambda = 0$. Since the nonlinear Schrödinger equation is integrable, analytic expressions are available for the eigenfunctions and adjoint eigenfunctions [36]. For the perturbations of the equation under consideration, the eigenvalue $\lambda = 0$ either becomes simple (section 5.1), ceases to exist (section 5.3), or has g.m. $= 2$ and $2 \leq$ a.m. ≤ 3 for $\epsilon \neq 0$ (section 5.2). It should be noted that in the first case $\partial_\epsilon^2 \partial_\lambda E(0)$ must be calculated, in the second case $\partial_\epsilon^2 E(0)$ must be determined, and in the final case $\partial_\epsilon^2 \partial_\lambda^2 E(0)$ must be found. In each case the first derivative with respect to ϵ is found to be zero.

The paper is organized as follows. In the second section some preliminary results are established. The proof of the theorem is given in the third section. In the fourth section, some perturbation expressions are derived for the Evans function, and in the final section some results are presented for perturbations of the nonlinear Schrödinger equation.

2. Preliminary results. Let $\lambda_0 \in \Omega$ be an eigenvalue of L. Set $T_{\lambda_0} = L - \lambda_0$. The ascent of T_{λ_0} is the smallest number a such that $\mathcal{N}(T_{\lambda_0}^{a+1}) = \mathcal{N}(T_{\lambda_0}^a)$ ($\mathcal{N}$ denotes the null space) (Taylor and Lay [35]). It is known that

$$X = \mathcal{N}(T_{\lambda_0}^a) \oplus \mathcal{R}(T_{\lambda_0}^a),$$

where $X = \mathrm{BU}(\mathbf{R}; \mathbf{R}^n)$ and $\mathcal{R}$ denotes the range space [35].

LEMMA 2.1 (Gardner and Jones [8]). *Let λ_0 be an eigenvalue of g.m. $= m$, a.m. $= p$, and ascent a. Then there exist functions $\psi_{j,i}$, $i = 1, \ldots, m$, $j = 1, \ldots, a_i$,*

with

$$p = \sum_{i=1}^{m} a_i$$

such that

$$T_{\lambda_0}\psi_{j,i} = \psi_{j-1,i}, \quad \psi_{0,i} = 0.$$

Furthermore,

$$\mathcal{N}(T_{\lambda_0}^a) = \text{Span}\{\psi_{j,i}\}, \quad i = 1, \dots, m,\ j = 1, \dots, a_i.$$

An observation yields the following proposition.

PROPOSITION 2.2. *Let $v \in \mathcal{N}(T_{\lambda_0}^*)$. Then*

$$\langle \psi_{j,i}, v\rangle = 0, \quad i = 1, \dots, m,\ j = 1, \dots, a_i - 1.$$

Proof. This follows immediately from

$$\begin{aligned} \langle T_{\lambda_0}\psi_{j,i}, v\rangle &= \langle \psi_{j-1,i}, v\rangle \\ &= \langle \psi_{j,i}, T_{\lambda_0}^* v\rangle \\ &= 0 \end{aligned}$$

as $v \in \mathcal{N}(T_{\lambda_0}^*)$. □

Upon setting $\mathbf{Y} = (u, u')$, where $' = d/dz$, the eigenvalue equation $(L - \lambda)u = 0$ can be rewritten as the first-order system

$$\mathbf{Y}' = M(\lambda, z)\mathbf{Y}, \tag{2.1}$$

where M is the $2n \times 2n$ matrix

$$M(\lambda, z) = \begin{bmatrix} 0 & I_n \\ -B^{-1}(N(z) - \lambda I_n) & -B^{-1}P(z) \end{bmatrix}. \tag{2.2}$$

PROPOSITION 2.3. *Let $\mathbf{Z} = (Z_1, Z_2)^T$ solve the adjoint equation*

$$\mathbf{Z}' = -M^*(\lambda_0, z)\mathbf{Z}.$$

Then

$$T_{\lambda_0}^*(B^{-T}Z_2) = 0,$$

where $B^{-T} = (B^{-1})^T$.

Proof. The operator $T_{\lambda_0}^* = L^* - \lambda_0^*$ is given by

$$(L^* - \lambda_0^*)u = B^T\partial_z^2 u - \partial_z(P^T u) + (N^T - \lambda_0^*)u.$$

An examination of the adjoint equation associated with (2.1), i.e.,

$$\begin{aligned} Z_1' &= (N^T - \lambda_0^* * I_n)B^{-T}Z_2, \\ Z_2' &= -Z_1 + P^T B^{-T} Z_2, \end{aligned}$$

reveals that $\tilde{Z}_2 = B^{-T}Z_2$ does indeed satisfy $(L^* - \lambda_0^*)\tilde{Z}_2 = 0$. □

For the rest of this article,

$$M_\lambda = \partial_\lambda M(\lambda_0, z).$$

LEMMA 2.4. *Let* $\mathbf{Z} = (Z_1, Z_2)^T$ *be a solution to the adjoint equation*

$$\mathbf{Z}' = -M^*(\lambda_0, z)\mathbf{Z}$$

such that $|\mathbf{Z}(z)| \to 0$ *as* $|z| \to \infty$. *Let* $\mathbf{G} : \mathbf{R} \to \mathbf{C}^{2n}$ *be a uniformly bounded continuous function. Then*

$$\langle M_\lambda \mathbf{G}, \mathbf{Z}\rangle = \langle \pi(\mathbf{G}), v\rangle,$$

where $\pi : \mathbf{C}^{2n} \to \mathbf{C}^n$ *is the projection onto the first* n *components and* $v = B^{-T} Z_2 \in \mathcal{N}(T^*_{\lambda_0})$.

Proof. Note that $M_\lambda \mathbf{G} = (0, B^{-1}\pi(\mathbf{G}))^T$. One can then write

$$\begin{aligned} \langle M_\lambda \mathbf{G}, \mathbf{Z}\rangle &= \langle B^{-1}\pi(\mathbf{G}), Z_2\rangle \\ &= \langle \pi(\mathbf{G}), v\rangle, \end{aligned}$$

where $v = B^{-T} Z_2$. As a consequence of Proposition 2.3, the function v is an element of $\mathcal{N}(T^*_{\lambda_0})$. □

Let $\phi_1, \ldots, \phi_{2n}$ be any linearly independent collection of solutions to (2.1). For each i, consider the scaled $(2n-1)$-form

$$e_i = m(\lambda, z)\, \phi_1 \wedge \cdots \wedge \phi_{i-1} \wedge \phi_{i+1} \wedge \cdots \wedge \phi_{2n},$$

where

$$m(\lambda, z) = \exp\left(- \int_0^z \operatorname{tr} M(\lambda, s)\, ds \right).$$

Note that Abel's formula implies that $\phi_i \wedge e_i$ is a nonzero constant for each i. The following was stated in Alexander, Gardner, and Jones [1] and Kapitula [14]; however, the proof will be given here for completeness.

PROPOSITION 2.5. *For each* $i = 1, \ldots, 2n$ *there exists a function* $\mathbf{Y}^{\mathbf{A}}{}_i$ *such that*

$$\mathbf{H} \wedge e_i = \mathbf{H} \cdot \mathbf{Y}^{\mathbf{A}}{}_i,$$

where $\mathbf{H} : \mathbf{R} \to \mathbf{C}^{2n}$ *is a uniformly bounded continuous function. Furthermore, the functions* $\mathbf{Y}^{\mathbf{A}}{}_i$ *form a linearly independent set of solutions to the adjoint equation associated with* (2.1) *and satisfy*

$$\mathbf{Y}^{\mathbf{A}}{}_i \cdot \phi_j = C_i \delta_{ij},$$

where $C_i \neq 0$ *for all* i.

Proof. By the Riesz representation theorem, for each i there exists a function $\mathbf{Y}^{\mathbf{A}}{}_i$ such that

$$\mathbf{H} \wedge e_i = \mathbf{H} \cdot \mathbf{Y}^{\mathbf{A}}{}_i.$$

Since $\phi_j \wedge e_i = C_i \delta_{ij}$, by the above statement

$$\phi_j \cdot \mathbf{Y}^{\mathbf{A}}{}_i = C_i \delta_{ij},$$

where the C_i's are nonzero. Differentiating yields that

$$(\mathbf{Y}^{\mathbf{A}}{}'_i + M^* \mathbf{Y}^{\mathbf{A}}{}_i) \cdot \phi_j = 0,$$

from which one can conclude, since the ϕ_i's are linearly independent, that $\mathbf{Y}^{\mathbf{A}}{}_i$ must be a solution to the adjoint equation. □

3. Proof of Theorem 1.1. For $\lambda \in \Omega$ there exist complex analytic functions $\mathbf{Y}_i(\lambda, z)$, $i = 1, \dots, 2n$, which are solutions to (2.1) and satisfy $|\mathbf{Y}_i(\lambda, z)| \to 0$, $i = 1, \dots, n$, exponentially fast as $z \to -\infty$ and $|\mathbf{Y}_i(\lambda, z)| \to 0$, $i = n+1, \dots, 2n$, exponentially fast as $z \to \infty$. Furthermore, these solutions can be chosen so that the n-forms

$$\mathbf{Y}^u(\lambda, z) = (\mathbf{Y}_1 \wedge \cdots \wedge \mathbf{Y}_n)(\lambda, z), \quad \mathbf{Y}^s(\lambda, z) = (\mathbf{Y}_{n+1} \wedge \cdots \wedge \mathbf{Y}_{2n})(\lambda, z) \tag{3.1}$$

are nonzero for $\lambda \in \Omega$ [1]. The Evans function is then given by

$$E(\lambda) = m(\lambda, z)\, \mathbf{Y}^u(\lambda, z) \wedge \mathbf{Y}^s(\lambda, z), \tag{3.2}$$

where

$$m(\lambda, z) = \exp\left(- \int_0^z \operatorname{tr} M(\lambda, s)\, ds \right).$$

There is a considerable amount of arbitrariness in defining the functions $\mathbf{Y}_i$. Order the functions so that

$$\mathbf{Y}_i(\lambda_0, z) = \mathbf{Y}_{n+i}(\lambda_0, z) = (\psi_{1,i}, \psi_{1,i}')^T, \quad i = 1, \dots, m, \tag{3.3}$$

and assume that this has been done in such a way that the definitions remain consistent for λ near λ_0. The Evans function can then be redefined to be

$$E(\lambda) = m(\lambda, z)\, \mathbf{Y}_1 \wedge \mathbf{Y}_{n+1} \wedge \cdots \wedge \mathbf{Y}_m \wedge \mathbf{Y}_{n+m} \wedge \Phi, \tag{3.4}$$

where $\Phi(\lambda, z) \in \Lambda^{2(n-m)}(\mathbf{C}^{2n}) \neq 0$ for λ near λ_0 is given by

$$\Phi = \mathbf{Y}_{m+1} \wedge \cdots \wedge \mathbf{Y}_n \wedge \mathbf{Y}_{n+m+1} \wedge \cdots \wedge \mathbf{Y}_{2n}.$$

LEMMA 3.1 (Gardner and Jones [8]). *Suppose that the g.m.=m and a.m.=p. Then*

$$\begin{aligned} \partial_\lambda^p E(\lambda_0) &= \frac{p!}{\prod_{i=1}^m a_i!} [\partial_\lambda^{a_1}(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \wedge \mathbf{Y}_1] \wedge \cdots \\ &\qquad \wedge [\partial_\lambda^{a_m}(\mathbf{Y}_m - \mathbf{Y}_{n+m}) \wedge \mathbf{Y}_m] \wedge [m(\lambda_0, z)\Phi] \\ &\neq 0, \end{aligned}$$

where

$$p = \sum_{i=1}^m a_i.$$

COROLLARY 3.2 (Gardner and Jones [8]). *Under the assumptions of the above lemma, the functions*

$$\partial_\lambda^{a_i}(\mathbf{Y}_i - \mathbf{Y}_{n+i}), \quad i = 1, \dots, m,$$

grow exponentially fast as $z \to \pm\infty$.

In the subsequent discussion, it will be useful to note that the expression given in Lemma 3.1 can be rewritten as

$$\begin{aligned} \partial_\lambda^p E(\lambda_0) &= (-1)^{m_s} \frac{p!}{\prod_{i=1}^m a_i!}\, \partial_\lambda^{a_1}(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \wedge \cdots \wedge \partial_\lambda^{a_m}(\mathbf{Y}_m - \mathbf{Y}_{n+m}) \\ &\qquad \wedge \mathbf{Y}_1 \wedge \cdots \wedge \mathbf{Y}_m \wedge [m(\lambda_0, z)\Phi], \end{aligned} \tag{3.5}$$

where

$$m_s = \sum_{i=0}^{m-1} i.$$

Using Corollary 3.2 as a guide, define the solutions $\tilde{\mathbf{Y}}_1, \ldots, \tilde{\mathbf{Y}}_m$ at $\lambda = \lambda_0$ to be such that the set $\{\tilde{\mathbf{Y}}_1, \ldots, \tilde{\mathbf{Y}}_m\}$ is linearly independent and $|\tilde{\mathbf{Y}}_i(z)| \to +\infty$ as $|z| \to +\infty$. Furthermore, let the solutions be scaled so that when $\lambda = \lambda_0$,

$$D = m(\lambda_0, z)\, \tilde{\mathbf{Y}}_1 \wedge \cdots \wedge \tilde{\mathbf{Y}}_m \wedge \mathbf{Y}_1 \wedge \cdots \wedge \mathbf{Y}_m \wedge \Phi = 1. \tag{3.6}$$

As a consequence of Proposition 2.5 there exist solutions, $\mathbf{Y}^{\mathbf{A}}{}_i$, to the adjoint equation such that

$$\tilde{\mathbf{Y}}_i \cdot \mathbf{Y}^{\mathbf{A}}{}_i = D, \quad i = 1, \ldots, m. \tag{3.7}$$

Since the functions $\tilde{\mathbf{Y}}_i$ grow exponentially fast as $|z| \to +\infty$, by (3.7) these adjoint solutions must satisfy

$$|\mathbf{Y}^{\mathbf{A}}{}_i(z)| \leq C_i e^{-\alpha_i |z|}, \quad i = 1, \ldots, m, \tag{3.8}$$

for some positive constants C_i and α_i. Now define the rest of the adjoint solutions, $\mathbf{Y}^{\mathbf{A}}{}_j$, $j = m+1, \ldots, 2n$, to be such that

$$\begin{aligned} \mathbf{Y}_i \cdot \mathbf{Y}^{\mathbf{A}}{}_{m+i} &= D, \qquad i = 1, \ldots, n, \\ \mathbf{Y}_i \cdot \mathbf{Y}^{\mathbf{A}}{}_i &= D, \qquad i = n+m+1, \ldots, 2n. \end{aligned} \tag{3.9}$$

As a consequence of the fact that the functions $|\mathbf{Y}_i| \to 0$ exponentially fast as $|z| \to \infty$ for $i = 1, \ldots, m$, there exist positive constants C_i and α_i such that

$$2C_i e^{(\alpha_i + \delta)|z|} \geq |\mathbf{Y}^{\mathbf{A}}{}_i(z)| \geq C_i e^{\alpha_i |z|}, \quad i = m+1, \ldots, 2m, \tag{3.10}$$

for some $0 \leq \delta \ll 1$. The remaining adjoint solutions are such that they approach zero exponentially fast in one direction while blowing up exponentially fast in the other.

Let $\mathbf{G}_\pm : \mathbf{R} \to \mathbf{C}^{2n}$ be a uniformly bounded continuous function such that

$$\begin{aligned} |\mathbf{G}_+(z)| &\leq C|z|^k e^{-\alpha z}, \qquad z \geq 1, \\ |\mathbf{G}_-(z)| &\leq C|z|^k e^{\alpha z}, \qquad z \leq -1, \end{aligned} \tag{3.11}$$

for some positive constants C, α, and k. By using variation of parameters, the solution to

$$\mathbf{Y}' = M(\lambda_0, z)\mathbf{Y} + \mathbf{G}_\pm \tag{3.12}$$

is given by

$$\begin{aligned} \mathbf{Y}_\pm = \frac{1}{D} \Bigg(& \sum_{i=1}^{m} c_i^{\pm}(\mathbf{G}_\pm)\tilde{\mathbf{Y}}_i + \sum_{i=1}^{m} \tilde{c}_i(\mathbf{G}_\pm)\mathbf{Y}_i \\ & + \sum_{i=m+1}^{n} c_i(\mathbf{G}_\pm)\mathbf{Y}_i + \sum_{i=n+m+1}^{2n} c_i(\mathbf{G}_\pm)\mathbf{Y}_i \Bigg) \\ & + \sum_{i=1}^{n} d_i^{-}\mathbf{Y}_i + \sum_{i=n+1}^{2n} d_i^{+}\mathbf{Y}_i, \end{aligned} \tag{3.13}$$

where

$$\begin{aligned} c_i^{\pm}(\mathbf{G}_{\pm}) &= \int_{\pm\infty}^{z} \mathbf{G}_{\pm}(s)\cdot \mathbf{Y}^{\mathbf{A}}{}_i(s)\,ds, \quad i=1,\dots,m, \\ \tilde{c}_i(\mathbf{G}_{\pm}) &= \int_{0}^{z} \mathbf{G}_{\pm}(s)\cdot \mathbf{Y}^{\mathbf{A}}{}_{m+i}(s)\,ds, \quad i=1,\dots,m, \\ c_i(\mathbf{G}_{\pm}) &= \begin{cases} \displaystyle\int_{+\infty}^{z} \mathbf{G}_{\pm}(s)\cdot \mathbf{Y}^{\mathbf{A}}{}_{m+i}(s)\,ds, & i=m+1,\dots,n, \\ \displaystyle\int_{-\infty}^{z} \mathbf{G}_{\pm}(s)\cdot \mathbf{Y}^{\mathbf{A}}{}_{i}(s)\,ds, & i=n+m+1,\dots,2n, \end{cases} \end{aligned} \tag{3.14}$$

and $d_i^{\pm}$ are constants [1], [14]. For the solution $\mathbf{Y}_-$ one fixes $d_i^+ = 0$ for $i = n+1,\dots,2n$, while for $\mathbf{Y}_+$ one fixes $d_i^- = 0$ for $i = 1,\dots,n$. As a consequence of the previous estimates and assumption (3.11),

$$\begin{aligned} |\mathbf{Y}_+(z)| &\leq C|z|^{k+1}e^{-\alpha z}, \qquad z \geq 1, \\ |\mathbf{Y}_-(z)| &\leq C|z|^{k+1}e^{\alpha z}, \qquad z \leq -1. \end{aligned} \tag{3.15}$$

LEMMA 3.3. *Define*

$$\mathbf{\Psi}_{j,i} = (\psi_{j,i}, \psi'_{j,i})^T$$

for $i = 1,\dots,m$ and $j = 1,\dots,a_i$. Then for each $i = 1,\dots,m$ and $j = 1,\dots,a_i - 1$,

$$\partial_\lambda^j \mathbf{Y}_i = \partial_\lambda^j \mathbf{Y}_{n+i} = j!\mathbf{\Psi}_{j+1,i}.$$

Proof. See Gardner and Jones [8]. □

Let $1 \leq i \leq m$ be given. For $1 \leq k \leq a_i$, differentiation of (2.1) with respect to λ and evaluating at λ_0 yields

$$(\partial_\lambda^k \mathbf{Y}_\alpha)' = M(\lambda_0,z)\,\partial_\lambda^k \mathbf{Y}_\alpha + kM_\lambda(\lambda_0,z)\,\partial_\lambda^{k-1}\mathbf{Y}_\alpha, \quad \alpha = i, n+i. \tag{3.16}$$

Upon substituting the expression in Lemma 3.3 into (3.16) with $k = a_i$, one then sees that

$$(\partial_\lambda^{a_i} \mathbf{Y}_\alpha)' = M(\lambda_0,z)\,\partial_\lambda^{a_i} \mathbf{Y}_\alpha + M_\lambda(\lambda_0,z)(a_i!\mathbf{\Psi}_{a_i,i}), \quad \alpha = i, n+i. \tag{3.17}$$

Upon requiring that $|\partial_\lambda^{a_i}\mathbf{Y}_i| \to 0$ as $z \to -\infty$ and $|\partial_\lambda^{a_i}\mathbf{Y}_{n+i}| \to 0$ as $z \to +\infty$, and using the solution formula (3.13), after subtracting the solutions one sees that

$$\begin{aligned} \partial_\lambda^{a_i}(\mathbf{Y}_i - \mathbf{Y}_{n+i}) &= \frac{a_i!}{D}\sum_{k=1}^{m} \langle M_\lambda \mathbf{\Psi}_{a_i,i}, \mathbf{Y}^{\mathbf{A}}{}_k\rangle\,\tilde{\mathbf{Y}}_k + \sum_{l=m+1}^{2n} d_l \mathbf{Y}_l \\ &= \frac{a_i!}{D}\sum_{k=1}^{m} \langle \psi_{a_i,i}, v_k\rangle\,\tilde{\mathbf{Y}}_k + \sum_{l=m+1}^{2n} d_l \mathbf{Y}_l, \end{aligned} \tag{3.18}$$

where the d_l's are some constants. In (3.18), $v_k \in \mathcal{N}(T^*_{\lambda_0})$ and the second equality is a consequence of Lemma 2.4.

Now substitute the expressions given in (3.18) into the derivative for the Evans function given in (3.5). Using the fact that D has been normalized to unity, it is then seen that

$$\partial_\lambda^p E(\lambda_0) = (-1)^{m_s} p! \begin{vmatrix} \langle \psi_{a_1,1}, v_1 \rangle & \cdots & \langle \psi_{a_1,1}, v_m \rangle \\ \vdots & & \vdots \\ \langle \psi_{a_m,m}, v_1 \rangle & \cdots & \langle \psi_{a_m,m}, v_m \rangle \end{vmatrix}. \tag{3.19}$$

The proof of Theorem 1.1 is now complete.

4. Perturbation expressions. Now that expressions in terms of the eigenfunctions and adjoint eigenfunctions are available for the derivatives of the Evans function, it will be of interest to determine the manner in which calculations can be performed under perturbation. In this section we will consider only a few special cases, which are motivated by specific problems. However, the ideas presented herein can be generalized. In this section the linear operator L will be written as

$$L(\epsilon) = B(\epsilon)\partial_z^2 + P(z,\epsilon)\partial_z + N(z,\epsilon),$$

where the $n \times n$ matrices are assumed to be smooth in their arguments. Furthermore, it will be assumed that when $\epsilon = 0$, the location and structure of the point eigenvalues for $L(0)$ are completely understood.

Before continuing, the following preliminary lemma will be necessary. In all that follows, the explicit dependence of the matrix M on ϵ will be suppressed. In addition, subscripted variables represent derivatives, and all derivatives will be evaluated at $(\lambda, \epsilon) = (\lambda_0, 0)$.

LEMMA 4.1. *Let $\mathbf{Y} = (\psi, \psi')^T$ be a bounded solution to $\mathbf{Y}' = M(\lambda_0, z)\mathbf{Y}$, and let $\mathbf{Z} = (Z_1, Z_2)^T$ be a bounded solution to the adjoint problem $\mathbf{Z}' = -M(\lambda_0^*, z)\mathbf{Z}$. Then*

$$\langle M_\epsilon \mathbf{Y}, \mathbf{Z} \rangle = -\langle L_\epsilon \psi, v \rangle,$$

where $v = B^{-T} Z_2$ is a bounded solution to the adjoint problem $(L^*(0) - \lambda_0^*)v = 0$. Furthermore,

$$\langle M_{\epsilon\lambda} \mathbf{Y}, \mathbf{Z} \rangle = -\langle B_\epsilon B^{-1} \psi, v \rangle,$$

and if $\mathbf{Y}$ varies smoothly with respect to ϵ, then

$$\langle M_\lambda \mathbf{Y}_\epsilon, \mathbf{Z} \rangle = \langle \partial_\epsilon \psi, v \rangle.$$

Proof. First suppose that $B_\epsilon \neq 0$, so that

$$(B^{-1})_\epsilon = -B^{-1} B_\epsilon B^{-1}.$$

A routine calculation then shows that

$$\langle M_\epsilon \mathbf{Y}, \mathbf{Z} \rangle = \langle B_\epsilon B^{-1}((N - \lambda_0 I_n)\psi + P\psi') - (N_\epsilon \psi + P_\epsilon \psi'), B^{-T} Z_2 \rangle.$$

Since

$$L_\epsilon = B_\epsilon \partial_z^2 + P_\epsilon \partial_z + N_\epsilon$$

and

$$(L(0) - \lambda_0)\psi = B(0)\partial_z^2 \psi + P(z,0)\partial_z \psi + (N(z,0) - \lambda_0 I_n)\psi = 0,$$

upon substitution one sees that

$$B_\epsilon B^{-1}((N-\lambda_0 I_n)\psi + P\psi') - (N_\epsilon \psi + P_\epsilon \psi') = -L_\epsilon \psi,$$

which completes the proof of the first part.

The second part of the lemma follows from the fact that

$$\langle M_{\epsilon\lambda}\mathbf{Y}, \mathbf{Z}\rangle = -\langle B_\epsilon B^{-1}\psi, B^{-T}Z_2\rangle,$$

while the last part follows from

$$\langle M_\lambda \mathbf{Y}_\epsilon, \mathbf{Z}\rangle = \langle \partial_\epsilon \psi, B^{-T}Z_2\rangle.$$

If $B_\epsilon = 0$, then it is routine to check that

$$\begin{aligned}\langle M_\epsilon \mathbf{Y}, \mathbf{Z}\rangle &= \langle -(N_\epsilon\psi + P_\epsilon\psi'), B^{-T}Z_2\rangle \\ &= \langle -L_\epsilon\psi, B^{-T}Z_2\rangle. \qquad \square\end{aligned}$$

The proof of the following corollary is similiar to the one of the above lemma, and is left for the interested reader.

COROLLARY 4.2. *Suppose that when* $\epsilon = 0$

$$(L(0)-\lambda_0)\psi_1 = 0, \quad (L(0)-\lambda_0)\psi_2 = \psi_1.$$

Then for $\mathbf{Y} = (\psi_2, \psi_2')^T$

$$\langle M_\epsilon \mathbf{Y}, \mathbf{Z}\rangle = -\langle L_\epsilon \psi_2, v\rangle + \langle B_\epsilon B^{-1}\psi_1, v\rangle.$$

4.1. G.m. = 1. In this subsection it will be assumed that the eigenvalue λ_0 has g.m. $= 1$ and a.m. $= p$ when $\epsilon = 0$. Thus,

$$(L(0)-\lambda_0)\psi_i = \psi_{i-1}$$

for $i = 1, \dots, p$, with $\psi_0 = 0$. Furthermore, there is a unique (up to scalar multiplication) bounded solution v to $(L^*(0)-\lambda_0^*)v = 0$, and as a consequence of Theorem 1.1

$$\partial_\lambda^p E(\lambda_0) = p!\langle \psi_p, v\rangle.$$

Two situations will be discussed. The first is the case in which λ_0 is not an eigenvalue for $\epsilon \neq 0$. In this scenario it will be desirable to calculate $\partial_\epsilon E(\lambda_0)$. The second case is one in which the eigenvalue becomes simple for nonzero ϵ. It will then be desirable to know $\partial_\epsilon \partial_\lambda E(\lambda_0)$.

LEMMA 4.3. *Suppose that* λ_0 *is not an eigenvalue for* $\epsilon \neq 0$. *Then*

$$\partial_\epsilon E(\lambda_0) = -\langle L_\epsilon \psi_1, v\rangle.$$

Proof. First recall from (3.5) that

$$\partial_\lambda^p E(\lambda_0) = \partial_\lambda^p(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \wedge \mathbf{Y}_1 \wedge [m(\lambda_0, z)\Phi].$$

In a similiar fashion it is not difficult to show that

$$\partial_\epsilon E(\lambda_0) = \partial_\epsilon(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \wedge \mathbf{Y}_1 \wedge [m(\lambda_0, z)\Phi].$$

The equation for $\partial_\epsilon \mathbf{Y}_\alpha$, $\alpha \in \{1, n+1\}$, is given by

$$(\partial_\epsilon \mathbf{Y}_\alpha)' = M(\lambda_0, z)\partial_\epsilon \mathbf{Y}_\alpha + M_\epsilon(\lambda_0, z)\mathbf{Y}_\alpha.$$

Upon requiring that $|\partial_\epsilon \mathbf{Y}_1| \to 0$ as $z \to -\infty$ and $|\partial_\epsilon \mathbf{Y}_{n+1}| \to 0$ as $z \to +\infty$, and by using the ideas leading to (3.13) and (3.18), it can be seen that

$$\partial_\epsilon(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) = \frac{1}{D}\left(\langle M_\epsilon \mathbf{Y}_1, \mathbf{Y^A}_1\rangle \tilde{\mathbf{Y}}_1 + \sum_{i=2}^{2n} c_i \mathbf{Y}_i\right).$$

Thus, upon substituting this expression into that for $\partial_\epsilon E(\lambda_0)$ and using the fact that $D = 1$, one gets that

$$\partial_\epsilon E(\lambda_0) = \langle M_\epsilon \mathbf{Y}_1, \mathbf{Y^A}_1\rangle,$$

which, as a consequence of Lemma 4.1, yields the final result. □

Remark 4.4. If λ_0 is a simple eigenvalue, then as a consequence of Theorem 1.1, the above lemma, and the implicit function theorem, it is seen that

$$\partial_\epsilon \lambda_0 = \frac{\langle L_\epsilon \psi_1, v\rangle}{\langle \psi_1, v\rangle}.$$

Remark 4.5. Using standard perturbation theory, ψ_1 will be an eigenfunction of $L(\epsilon)$ with corresponding eigenvalue λ_0 if $\partial_\epsilon E(\lambda_0) = 0$.

LEMMA 4.6. *Suppose that $p \geq 2$ and that $E(\lambda_0) = 0$ for $\epsilon \neq 0$. Then*

$$\partial_\epsilon \partial_\lambda E(\lambda_0) = \langle -L_\epsilon \psi_2 + \partial_\epsilon \psi_1, v\rangle.$$

Proof. Since $p \geq 2$, it is a consequence of Lemma 3.3 that

$$\partial_\lambda(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) = 0;$$

thus, a routine calculation shows that

$$\partial_\epsilon \partial_\lambda E(\lambda_0) = \partial^2_{\epsilon\lambda}(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \wedge \mathbf{Y}_1 \wedge [m(\lambda_0, z)\Phi].$$

Now,

$$(\partial^2_{\epsilon\lambda}\mathbf{Y}_\alpha)' = M\partial^2_{\epsilon\lambda}\mathbf{Y}_\alpha + M_{\epsilon\lambda}\mathbf{Y}_\alpha + M_\epsilon \partial_\lambda \mathbf{Y}_\alpha + M_\lambda \partial_\epsilon \mathbf{Y}_\alpha$$

for $\alpha \in \{1, n+1\}$. Upon requiring that $\partial^2_{\epsilon\lambda}\mathbf{Y}_1$ decay as $z \to -\infty$ and $\partial^2_{\epsilon\lambda}\mathbf{Y}_{n+1}$ decay as $z \to +\infty$, one then sees that

$$\partial^2_{\epsilon\lambda}(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) = \frac{1}{D}\left((c_1^- - c_1^+)\tilde{\mathbf{Y}}_1 + \sum_{i=2}^{2n} d_i \mathbf{Y}_i\right), \tag{4.1}$$

where

$$c_1^- - c_1^+ = \langle M_{\epsilon\lambda}\mathbf{Y}_1 + M_\epsilon \mathbf{\Psi}_2 + M_\lambda \partial_\epsilon \mathbf{Y}_1, \mathbf{Y^A}_1\rangle.$$

In the above expression, recall that Lemma 3.3 states that $\partial_\lambda \mathbf{Y}_1 = \partial_\lambda \mathbf{Y}_{n+1} = \mathbf{\Psi}_2$. Upon substituting back into the expression for $\partial_\epsilon \partial_\lambda E(\lambda_0)$ and using the fact that $D = 1$, it is now seen that

$$\partial_\epsilon \partial_\lambda E(\lambda_0) = c_1^- - c_1^+.$$

Upon using the results of Lemma 4.1 and Corollary 4.2, one gets

$$c_1^- - c_1^+ = -\langle B_\epsilon B^{-1}\psi_1, v\rangle - \langle L_\epsilon \psi_2, v\rangle + \langle B_\epsilon B^{-1}\psi_1, v\rangle + \langle \partial_\epsilon \psi_1, v\rangle.$$

The proof is now complete. □

Remark 4.7. Using standard perturbation theory, if $\partial_\epsilon \partial_\lambda E(\lambda_0) = 0$, then ψ_2 will remain as a generalized eigenfunction of $L(\epsilon)$ for $\epsilon \neq 0$.

By following the proofs of the above lemmas, the perturbation results can clearly be generalized for the case that a.m. $= j < p$ for $\epsilon \neq 0$. Furthermore, since g.m. $= 1$, the location of the remaining eigenvalues can also be given. The proof of Theorem 1.3 is now complete.

THEOREM 4.8. *Suppose that for $\epsilon \neq 0$ λ_0 is an eigenvalue with a.m. $= j$, where $0 \leq j \leq p-1$. In this case,*

$$\partial_\epsilon \partial_\lambda^j E(\lambda_0) = j!\langle -L_\epsilon \psi_{j+1} + \partial_\epsilon \psi_j, v\rangle.$$

Furthermore, the location of the remaining $p-j$ eigenvalues is given by

$$\lambda = \lambda_0 + \alpha_1 \omega^h \epsilon^{1/(p-j)} + O(\epsilon^{2/(p-j)}), \quad h = 0, \ldots, p-j-1,$$

where

$$\alpha_1 = -\frac{\langle -L_\epsilon \psi_{j+1} + \partial_\epsilon \psi_j, v\rangle}{\langle \psi_p, v\rangle}, \quad \omega = e^{2\pi i/(p-j)}.$$

Proof. The perturbation expression is a generalization of that given in the above lemmas, and hence the proof will be left to the interested reader. In order to prove the eigenvalue perturbation expression, consider the following argument. Set $\gamma = \lambda - \lambda_0$. For γ and ϵ small, the Evans function has the Taylor expansion

$$E(\lambda) = \gamma^j \left(\langle -L_\epsilon \psi_{j+1} + \partial_\epsilon \psi_j, v\rangle \epsilon + \cdots + \langle \psi_p, v\rangle \gamma^{p-j} + O(|\gamma|^{p-j+1}) \right),$$

where all the coefficients below γ^{p-j} are $O(\epsilon)$. Following Kato [18], the remaining zeros of the Evans function will be $O(\epsilon^{1/(p-j)})$. As such, it is then easy to see that they must be given by

$$\gamma = \alpha_1 \omega^h \epsilon^{1/(p-j)} + O(\epsilon^{2/(p-j)}), \quad h = 0, \ldots, p-j-1,$$

where

$$\alpha_1 = -\frac{\langle -L_\epsilon \psi_{j+1} + \partial_\epsilon \psi_j, v\rangle}{\langle \psi_p, v\rangle}, \quad \omega = e^{2\pi i/(p-j)}.$$

The result is now proved. □

4.2. G.m. = 2. In this subsection it will be assumed that when $\epsilon = 0$ the eigenvalue λ_0 has g.m. $= 2$ and a.m. $= p \geq 2$. Thus, we have two chains:

$$(L(0) - \lambda_0)\psi_{j,i} = \psi_{j-1,i}, \quad \psi_{0,i} = 0$$

for $i = 1, 2$ and $j = 1, \ldots, a_i$, with $a_1 + a_2 = p$. Without loss of generality it will be assumed in this section that $1 \leq a_1 \leq a_2$. As a consequence of Theorem 1.1, there exists two bounded adjoint solutions, v_1 and v_2, such that

$$\partial_\lambda^p E(\lambda_0) = -p! \begin{vmatrix} \langle \psi_{a_1,1}, v_1\rangle & \langle \psi_{a_1,1}, v_2\rangle \\ \langle \psi_{a_2,2}, v_1\rangle & \langle \psi_{a_2,2}, v_2\rangle \end{vmatrix}.$$

LEMMA 4.9. *Suppose that λ_0 is not an eigenvalue of $L(\epsilon)$ for $\epsilon \neq 0$. Then*

$$\partial_\epsilon E(\lambda_0) = 0,$$

and

$$\partial_\epsilon^2 E(\lambda_0) = -2 \begin{vmatrix} \langle L_\epsilon \psi_{1,1}, v_1 \rangle & \langle L_\epsilon \psi_{1,1}, v_2 \rangle \\ \langle L_\epsilon \psi_{1,2}, v_1 \rangle & \langle L_\epsilon \psi_{1,2}, v_2 \rangle \end{vmatrix}.$$

Proof. It is known that $\mathbf{Y}_1 = \mathbf{Y}_{n+1} = (\psi_{1,1}, \psi'_{1,1})^T$ and that $\mathbf{Y}_2 = \mathbf{Y}_{n+2} = (\psi_{1,2}, \psi'_{1,2})^T$. Using this information, a simple calculation shows that $\partial_\epsilon E(\lambda_0) = 0$.

A standard calculation shows that

$$\partial_\epsilon^2 E(\lambda_0) = -2\partial_\epsilon(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \wedge \partial_\epsilon(\mathbf{Y}_2 - \mathbf{Y}_{n+2}) \wedge \mathbf{Y}_1 \wedge \mathbf{Y}_2 \wedge [m(\lambda_0, z)\Phi].$$

Since

$$(\partial_\epsilon \mathbf{Y})' = M \partial_\epsilon \mathbf{Y} + M_\epsilon \mathbf{Y},$$

by following the ideas presented in the previous section it can be seen that

$$\partial_\epsilon(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) = \frac{1}{D}\left(\langle -L_\epsilon \psi_{1,1}, v_1 \rangle \tilde{\mathbf{Y}}_1 + \langle -L_\epsilon \psi_{1,1}, v_2 \rangle \tilde{\mathbf{Y}}_2 + \sum_{i=3}^{2n} c_i \mathbf{Y}_i \right)$$

and that

$$\partial_\epsilon(\mathbf{Y}_2 - \mathbf{Y}_{n+2}) = \frac{1}{D}\left(\langle -L_\epsilon \psi_{1,2}, v_1 \rangle \tilde{\mathbf{Y}}_1 + \langle -L_\epsilon \psi_{1,2}, v_2 \rangle \tilde{\mathbf{Y}}_2 + \sum_{i=3}^{2n} d_i \mathbf{Y}_i \right). \tag{4.2}$$

Upon substitution into the expression for $\partial_\epsilon^2 E(\lambda_0)$, and using the fact that $D = 1$, the conclusion of the lemma follows. □

Remark 4.10. The straightforward generalization of Lemma 4.9 to the case when g.m. ≥ 3 will be left to the interested reader.

For the rest of this section the primary interest will be the case that $a_1 > 1$. This is due to the fact that for the applications of interest in this paper, i.e., perturbations of the nonlinear Schrödinger equation, it turns out that $a_1 = a_2 = 2$. If $a_1 = 1$, the final results will be stated; however, the proof will be left to the interested reader.

LEMMA 4.11. *Suppose that for $\epsilon \neq 0$ λ_0 is a simple eigenvalue of $L(\epsilon)$. Further suppose that the eigenfunction for $\epsilon \neq 0$ is $\psi_{1,1}$. Then if $a_1 > 1$,*

$$\partial_\epsilon \partial_\lambda E(\lambda_0) = 0,$$

and

$$\partial_\epsilon^2 \partial_\lambda E(\lambda_0) = 2 \begin{vmatrix} \langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_1 \rangle & \langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_2 \rangle \\ \langle L_\epsilon \psi_{1,2}, v_1 \rangle & \langle L_\epsilon \psi_{1,2}, v_2 \rangle \end{vmatrix}.$$

Remark 4.12. If $a_1 = 1$, then substitution of the expression for $\partial_\epsilon(\mathbf{Y}_2 - \mathbf{Y}_{n+2})$ into (4.3) yields that

$$\partial_\epsilon \partial_\lambda E(\lambda_0) = \begin{vmatrix} \langle \psi_{1,1}, v_1 \rangle & \langle \psi_{1,1}, v_2 \rangle \\ \langle L_\epsilon \psi_{1,2}, v_1 \rangle & \langle L_\epsilon \psi_{1,2}, v_2 \rangle \end{vmatrix}.$$

Proof. The proof will be only sketched, as it has many similiar features to those given above.

Since $\psi_{1,1}$ is an eigenfunction for $\epsilon \neq 0$, a routine calculation shows that

$$\langle L_\epsilon \psi_{1,1}, v_1 \rangle = \langle L_\epsilon \psi_{1,1}, v_2 \rangle = 0.$$

This is the solvability condition needed in order to solve the equation $\partial_\epsilon \psi_{1,1} = -(L - \lambda_0)^{-1} L_\epsilon \psi_{1,1}$.

First note that

$$\partial_\epsilon \partial_\lambda E(\lambda_0) = -\partial_\lambda(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \wedge \partial_\epsilon(\mathbf{Y}_2 - \mathbf{Y}_{n+2}) \wedge \mathbf{Y}_1 \wedge \mathbf{Y}_2 \wedge [m(\lambda_0, z)\Phi]. \tag{4.3}$$

Since $a_1 > 1$, by Lemma 3.3

$$\partial_\lambda(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) = 0,$$

from which one immediately sees that $\partial_\epsilon \partial_\lambda E(\lambda_0) = 0$. Taking another derivative with respect to ϵ, it can be seen that

$$\partial_\epsilon^2 \partial_\lambda E(\lambda_0) = -2\, \partial_{\epsilon\lambda}(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \wedge \partial_\epsilon(\mathbf{Y}_2 - \mathbf{Y}_{n+2}) \wedge \mathbf{Y}_1 \wedge \mathbf{Y}_2 \wedge [m(\lambda_0, z)\Phi].$$

A slight modification of the argument leading to (4.1) yields that

$$\begin{aligned} &\partial_{\epsilon\lambda}^2(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \\ &\quad = \frac{1}{D}\left(\langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_1 \rangle \tilde{\mathbf{Y}}_1 + \langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_2 \rangle \tilde{\mathbf{Y}}_2 + \sum_{i=3}^{2n} d_i \mathbf{Y}_i \right). \end{aligned}$$

After recalling the expression for $\partial_\epsilon(\mathbf{Y}_2 - \mathbf{Y}_{n+2})$ given in (4.2), and using the fact that $D = 1$, upon substitution into the above expression for $\partial_\epsilon^2 \partial_\lambda E(\lambda_0)$ the final result is seen. □

LEMMA 4.13. *Suppose that for $\epsilon \neq 0$ λ_0 is an eigenvalue of $L(\epsilon)$ with g.m. = a.m. = 2. Then if $a_1 > 1$,*

$$\partial_\epsilon \partial_\lambda^2 E(\lambda_0) = 0,$$

and

$$\partial_\epsilon^2 \partial_\lambda^2 E(\lambda_0) = -4 \begin{vmatrix} \langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_1 \rangle & \langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_2 \rangle \\ \langle -L_\epsilon \psi_{2,2} + \partial_\epsilon \psi_{1,2}, v_1 \rangle & \langle -L_\epsilon \psi_{2,2} + \partial_\epsilon \psi_{1,2}, v_2 \rangle \end{vmatrix}.$$

Remark 4.14. If $a_1 = 1$, then the above expression reduces to

$$\partial_\epsilon \partial_\lambda^2 E(\lambda_0) = -2 \begin{vmatrix} \langle \psi_{1,1}, v_1 \rangle & \langle \psi_{1,1}, v_2 \rangle \\ \langle -L_\epsilon \psi_{2,2} + \partial_\epsilon \psi_{1,2}, v_1 \rangle & \langle -L_\epsilon \psi_{2,2} + \partial_\epsilon \psi_{1,2}, v_2 \rangle \end{vmatrix}.$$

Proof. This proof will be even sketchier than the previous one, since the idea is essentially the same. Since $a_2 \geq a_1 > 1$, by Lemma 3.3 it is known that

$$\partial_\lambda(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) = \partial_\lambda(\mathbf{Y}_2 - \mathbf{Y}_{n+2}) = 0.$$

Using this information, it can eventually be concluded that $\partial_\epsilon \partial_\lambda^2 E(\lambda_0) = 0$ and that

$$\partial_\epsilon^2 \partial_\lambda^2 E(\lambda_0) = -4\, \partial_{\epsilon\lambda}^2(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \wedge \partial_{\epsilon\lambda}^2(\mathbf{Y}_2 - \mathbf{Y}_{n+2}) \wedge \mathbf{Y}_1 \wedge \mathbf{Y}_2 \wedge [m(\lambda_0, z)\Phi].$$

The expression for $\partial^2_{\epsilon\lambda}(\mathbf{Y}_1 - \mathbf{Y}_{n+1})$ is exactly that as given in the previous proof. The expression for $\partial^2_{\epsilon\lambda}(\mathbf{Y}_2 - \mathbf{Y}_{n+2})$ is found simply by substituting $\psi_{1,2}$ for $\psi_{1,1}$ and $\psi_{2,2}$ for $\psi_{2,1}$ in that expression. Using the definition of $\partial^p_\lambda E(\lambda_0)$ then yields the final result. □

Clearly, this process can be continued ad nauseam, in that one can derive expressions for the case that g.m. = 3 or higher and the various subcases. This process will be left for the interested reader. This section will close with one final lemma, the result of which is needed for one of the applications considered in the following section. For the following lemma, note that if $a_2 = 2$ for all ϵ, so that $(L(\epsilon) - \lambda_0)\psi_{1,2} = 0$ and $(L(\epsilon) - \lambda_0)\psi_{2,2} = \psi_{1,2}$, then it is necessarily true that

$$\langle L_\epsilon \psi_{1,2}, v\rangle = \langle -L_\epsilon \psi_{2,2} + \partial_\epsilon \psi_{1,2}, v\rangle = 0 \tag{4.4}$$

for all bounded adjoint solutions v. Note that this implies that $\partial^2_\epsilon \partial^2_\lambda E(\lambda_0) = 0$.

LEMMA 4.15. *Suppose that $a_2 = 2$ for all $\epsilon \geq 0$, and that g.m. $= 2$ for $\epsilon \neq 0$. Further suppose that $a_1 > 1$ when $\epsilon = 0$. Then*

$$\partial_\epsilon \partial^3_\lambda E(\lambda_0) = -6 \begin{vmatrix} \langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_1\rangle & \langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_2\rangle \\ \langle \psi_{2,2}, v_1\rangle & \langle \psi_{2,2}, v_2\rangle \end{vmatrix}.$$

Proof. Again, it is only sketched. Since $a_1 > 1$, it is necessarily true that $\partial_\lambda(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) = 0$. This then implies that

$$\partial_\epsilon \partial^3_\lambda E(\lambda_0) = -3\, \partial^2_{\epsilon\lambda}(\mathbf{Y}_1 - \mathbf{Y}_{n+1}) \wedge \partial^2_\lambda(\mathbf{Y}_2 - \mathbf{Y}_{n+2}) \wedge \mathbf{Y}_1 \wedge \mathbf{Y}_2 \wedge [m(\lambda_0, z)\Phi].$$

Since $a_2 = 2$ for all ϵ, $\partial^2_\lambda(\mathbf{Y}_2 - \mathbf{Y}_{n+2}) \neq 0$ is given by (3.18), so that the above expression will be generically nonzero. Substituting in the expression for $\partial^2_{\epsilon\lambda}(\mathbf{Y}_1 - \mathbf{Y}_{n+1})$ yields the final result. □

5. Examples. In this section the theory of the previous sections will be applied to various perturbations of the nonlinear Schrödinger equation (NLS),

$$i\partial_t \phi + (\partial_x^2 - \omega)\phi + 4|\phi|^2\phi = \epsilon R(x, \phi, \phi^*), \tag{5.1}$$

where the perturbation term will be assumed to be smooth. When $\epsilon = 0$, there is a real-valued solitary wave solution given by

$$\Phi(x, \omega) = \sqrt{\frac{\omega}{2}}\, \mathrm{sech}(\sqrt{\omega}\, x). \tag{5.2}$$

Breaking ϕ into its real and imaginary parts and linearizing about the wave, one gets the linear operator L given by

$$L = \begin{bmatrix} 0 & -L_i \\ L_r & 0 \end{bmatrix}, \tag{5.3}$$

where

$$L_i = \partial_x^2 - \omega + 4\Phi^2, \quad L_r = \partial_x^2 - \omega + 12\Phi^2.$$

Note that $L_i(\Phi) = 0$ and $L_r(\partial_x \Phi) = 0$. Following Weinstein [36], one has the following information concerning the operator L.

PROPOSITION 5.1. *The eigenfunctions for the operator L are given by*

$$\psi_{1,1} = \begin{bmatrix} \partial_x \Phi \\ 0 \end{bmatrix}, \quad \psi_{2,1} = \begin{bmatrix} 0 \\ -\frac{1}{2} x \Phi \end{bmatrix}$$

and

$$\psi_{1,2} = \begin{bmatrix} 0 \\ \Phi \end{bmatrix}, \quad \psi_{2,2} = \begin{bmatrix} \partial_\omega \Phi \\ 0 \end{bmatrix}.$$

Furthermore, the bounded solutions to the adjoint equation are given by

$$v_1 = \frac{4}{\langle \Phi, \Phi \rangle} \begin{bmatrix} 0 \\ \partial_x \Phi \end{bmatrix}, \quad v_2 = \frac{2}{\partial_\omega \langle \Phi, \Phi \rangle} \begin{bmatrix} \Phi \\ 0 \end{bmatrix}.$$

Note that v_1 and v_2 have been scaled so that

$$\langle \psi_{2,1}, v_1 \rangle = \langle \psi_{2,2}, v_2 \rangle = 1.$$

Upon using the results of Theorem 1.1 one is able to conclude the following information about the Evans function at $\lambda = 0$. The information for $\lambda \neq 0$ follows immediately from the fact that the wave Φ is a stable solution to (5.1) [37].

LEMMA 5.2. *The Evans function for the operator L satisfies*

$$\partial_\lambda^i E(0) = 0, \quad i = 0, \dots, 3,$$

and

$$\partial_\lambda^4 E(0) = -24.$$

Furthermore, $E(\lambda) < 0$ for $Re\, \lambda > 0$.

For $\epsilon \neq 0$ the wave (assuming that it persists) will in general be complex-valued. After breaking it into its real and complex parts, it will henceforth be denoted by $\mathbf{\Phi}(x, \omega, \epsilon)$, with $\mathbf{\Phi}(x, \omega, 0) = (\Phi, 0)^T$.

5.1. Parametrically forced NLS. For the parametrically forced NLS (PFNLS) the perturbation term is given by

$$R(x, \phi, \phi^*) = -i(\gamma \phi - \mu \phi^* e^{-i2\theta}),$$

where $\gamma, \mu > 0$ and

$$\cos 2\theta = \frac{\gamma}{\mu}.$$

Here γ is the dissipation factor (linear loss) and μ is the parametric gain. For $\epsilon > 0$ the wave is still real-valued and is given by $\mathbf{\Phi} = (\Phi, 0)^T$, where

$$\Phi(x, \omega, \epsilon) = \sqrt{\frac{\beta}{2}}\, \mathrm{sech}(\sqrt{\beta}\, x), \tag{5.4}$$

and

$$\beta = \omega + \epsilon \mu \sin 2\theta. \tag{5.5}$$

Due to the fact that the perturbation R breaks the rotation symmetry, when $\epsilon > 0$ it will generically be true that $\partial_\lambda E(0) \neq 0$. Furthermore, the fact that the translation symmetry is not broken implies that $\psi_{1,1}$ remains as an eigenfunction for L. Since $a_1 = a_2 = 2$ at $\lambda = 0$ when $\epsilon = 0$, the result of Lemma 4.11 will then apply.

After linearizing the PFNLS about the wave, a simple calculation shows that

$$L_\epsilon = \begin{bmatrix} 0 & -\mu \sin 2\theta \\ -\mu \sin 2\theta & -2\gamma \end{bmatrix} + 4\partial_\epsilon(\Phi^2) \begin{bmatrix} 0 & -1 \\ 3 & 0 \end{bmatrix}.$$

Since

$$\partial_\epsilon(\Phi^2) = \frac{\mu \sin 2\theta}{\omega} \left(\Phi^2 + \frac{1}{2} x \partial_x(\Phi^2) \right)$$

and Φ is even in x, it is a routine calculation to see that

$$\langle \partial_\epsilon \psi_{1,1}, v_1 \rangle = \langle L_\epsilon \psi_{1,2}, v_1 \rangle = \langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_2 \rangle = 0.$$

Thus, as a consequence of Lemma 4.11

$$\partial_\epsilon^2 \partial_\lambda E(0) = -2 \langle L_\epsilon \psi_{2,1}, v_1 \rangle \langle L_\epsilon \psi_{1,2}, v_2 \rangle. \tag{5.6}$$

Since

$$\langle x\Phi^{2k}, \partial_x(\Phi^2) \rangle = -\frac{1}{k+1} \langle \Phi^{2k}, \Phi^2 \rangle, \quad \langle \Phi, \Phi \rangle = \omega^{1/2}, \quad \langle \Phi^2, \Phi^2 \rangle = \frac{1}{3} \omega^{3/2},$$

one can see that

$$\langle L_\epsilon \psi_{1,2}, v_2 \rangle = -8\omega\mu \sin 2\theta.$$

In addition, the fact that $\langle x\Phi, \partial_x \Phi \rangle = -1/2 \langle \Phi, \Phi \rangle$ implies that

$$\langle L_\epsilon \psi_{2,1}, v_1 \rangle = -2\gamma.$$

Therefore, by (5.6)

$$\partial_\epsilon^2 \partial_\lambda E(0) = -32\omega\gamma\mu \sin 2\theta. \tag{5.7}$$

LEMMA 5.3. *Consider the PFNLS. Suppose that* $0 < \epsilon \ll 1$. *If* $\sin 2\theta < 0$, *then the wave* Φ *is unstable. If* $\sin 2\theta > 0$, *then there are no positive eigenvalues which are of* $O(\epsilon)$.

Proof. The eigenvalues of L are symmetric about the lines $\operatorname{Re} \lambda = -\epsilon\gamma$ and $\operatorname{Im} \lambda = 0$. This is easily seen by noticing that $(L - \lambda)P = 0$ reduces to $L_i L_r P_1 = -\lambda(\lambda + 2\epsilon\gamma)P_1$ and $L_r L_i P_2 = -\lambda(\lambda + 2\epsilon\gamma)P_2$, where $P = (P_1, P_2)^T$.

If $\sin 2\theta < 0$, then as a consequence of (5.7), $\partial_\lambda E(0) > 0$ for $\epsilon > 0$ sufficiently small. By Lemma 5.2, it is necessarily true that $E(\lambda)$ is negative for real λ sufficiently large. This necessarily implies the existence of a real positive zero of $E(\lambda)$, which in turn implies the existence of a real positive eigenvalue.

Now suppose that $\sin 2\theta > 0$, so that $\partial_\lambda E(0) < 0$ for $\epsilon > 0$ sufficiently small. If there is a zero with positive real part, then there must be at two such zeros. Suppose that two such zeros exist. Then there must also exist two other zeros with negative real part which are symmetric with respect to the line $\operatorname{Re} \lambda = -\epsilon\gamma$. Thus, recalling that $\lambda = 0$ is always a zero, there must exist at least five zeros which are of $O(\epsilon)$. This contradicts the fact that there can only be four such zeros. ∎

Remark 5.4. Barashenkov, Bogdan, and Korobov [5] have previously shown that $\sin 2\theta < 0$ implies the existence of an unstable eigenvalue. Their proof, however, is a consequence of the results present in either Grillakis [10] or in Jones [13].

Remark 5.5. By (5.7) it is known that $\partial_\lambda E(0) > 0$ for $\epsilon > 0$ sufficiently small. It can be shown, however, that $\partial_\lambda E(0) > 0$ for all $\epsilon > 0$ [2], [17], [25].

5.2. Cubic-quintic NLS. For the cubic-quintic NLS (CQNLS) the perturbation term is given by

$$R(x,\phi,\phi^*) = i(d_1\partial_x^2\phi + d_2\phi + d_3|\phi|^2\phi + d_4|\phi|^4\phi).$$

The positive parameter d_1 describes spectral filtering, d_2 describes the linear gain ($d_2 > 0$) or loss ($d_2 < 0$) due to the fiber, and d_3 and d_4 describe the nonlinear gain or loss due to the fiber. Note that this perturbation preserves both the rotation and translation symmetry. One then generically expects that $\partial_\lambda^2 E(0) \neq 0$, so that the results of Lemma 4.13, and possibly Lemma 4.15, will apply.

In order for the solution $\phi = 0$ to be stable, one must require that $d_2 < 0$. Since this is a minimal requirement for the wave to be stable, this assumption will hold for the rest of the discussion. It is shown in Kapitula [15] that the wave persists if

$$H(x) = d_1\partial_x^2\Phi + d_2\Phi + d_3\Phi^3 + d_4\Phi^5 \tag{5.8}$$

satisfies

$$\langle H, \Phi\rangle = 0, \tag{5.9}$$

i.e.,

$$d_1 - \frac{3}{\omega}d_2 - d_3 - \frac{2}{5}\omega d_4 = 0.$$

This condition ensures that $L_i^{-1}(H)$ is a bounded function for all x. Using standard perturbation theory, and the fact that

$$L^{-1} = \begin{bmatrix} 0 & L_r^{-1} \\ -L_i^{-1} & 0 \end{bmatrix},$$

it is not difficult to see that

$$\partial_\epsilon \mathbf{\Phi} = \begin{bmatrix} 0 \\ L_i^{-1}(H) \end{bmatrix}. \tag{5.10}$$

The two solutions to $L_i w = 0$ are given by

$$w_1 = \Phi, \quad w_2 = x\Phi + \frac{1}{\sqrt{2}}\sinh(\sqrt{\omega}\,x);$$

thus, upon using variation of parameters one can explicitly construct $L^{-1}(H)$. This will not be done here, however, and will be left as an exercise for the interested reader. It is enough to recognize that $\partial_\epsilon\Phi$ is an even function in x.

Upon linearizing the CQNLS about the wave, a simple calculation shows that

$$L_\epsilon = (d_1\partial_x^2 + d_2)I_2 + d_3\Phi^2\begin{bmatrix} 3 & 0 \\ 0 & 1 \end{bmatrix} + d_4\Phi^4\begin{bmatrix} 5 & 0 \\ 0 & 1 \end{bmatrix} + 8\Phi L_i^{-1}(H)\begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix}.$$

Furthermore, another calculation shows that

$$\partial_\epsilon\psi_{1,1} = \begin{bmatrix} 0 \\ \partial_x L_i^{-1}(H) \end{bmatrix}, \quad \partial_\epsilon\psi_{1,2} = \begin{bmatrix} -L_i^{-1}(H) \\ 0 \end{bmatrix}.$$

Using the fact that Φ and $L_i^{-1}(H)$ are even in x, it is a trivial matter to show that

$$\langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_2 \rangle = \langle -L_\epsilon \psi_{2,2} + \partial_\epsilon \psi_{1,2}, v_1 \rangle = 0.$$

Therefore, after using the result of Lemma 4.13 it can be seen that

$$\partial_\epsilon^2 \partial_\lambda^2 E(0) = -4 \langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_1 \rangle \langle -L_\epsilon \psi_{2,2} + \partial_\epsilon \psi_{1,2}, v_2 \rangle.$$

The above expressions are difficult to compute, and as such the problem was considered in Kapitula [15] for a more general perturbation of the NLS. In the following, let C_i denote a positive constant. Assuming relation (5.9), i.e., after solving for d_3 in terms of the other variables, as a consequence of the calculations in [15] it can be shown that

$$\langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_1 \rangle = C_1 d_1$$

and that

$$\langle -L_\epsilon \psi_{2,2} + \partial_\epsilon \psi_{1,2}, v_2 \rangle = C_2 \left(d_2 - \frac{2}{15} \omega^2 d_4 \right).$$

As a consequence of Lemma 4.15, when

$$\langle -L_\epsilon \psi_{2,2} + \partial_\epsilon \psi_{1,2}, v_2 \rangle = 0,$$

then

$$\begin{aligned} \partial_\epsilon \partial_\lambda^3 E(0) &= -6 \langle -L_\epsilon \psi_{2,1} + \partial_\epsilon \psi_{1,1}, v_1 \rangle \\ &= -6 C_1 \, d_1. \end{aligned}$$

It is now possible to describe the location of all of the $O(\epsilon)$ eigenvalues.

LEMMA 5.6. *Let d_3 be such that the wave exists for $0 < \epsilon \ll 1$. Furthermore, suppose that $d_1 > 0$ and $d_2 < 0$. Then if*

$$d_2 < \frac{2}{15} \omega^2 d_4,$$

there exists a real positive eigenvalue and a real negative eigenvalue, both of which are $O(\epsilon)$. If

$$\frac{2}{15} \omega^2 d_4 < d_2 < 0,$$

then both $O(\epsilon)$ eigenvalues are real and negative.

Proof. From the above arguments it is seen that

$$\partial_\epsilon^2 \partial_\lambda^2 E(0) = -4 C_1 C_2 \, d_1 \left(d_2 - \frac{2}{15} \omega^2 d_4 \right),$$

and if $d_2 - 2/15 \, \omega^2 d_4 = 0$, then

$$\partial_\epsilon \partial_\lambda^3 E(0) = -6 C_1 \, d_1.$$

All that is left to recognize is that if $\partial_\lambda^2 E(0) > 0$, then since $\partial_\lambda^4 E(0) < 0$ there exists one positive real zero of $E(\lambda)$ which is of $O(\epsilon)$. When $\partial_\lambda^2 E(0) = 0$, the fact that $\partial_\lambda^3 E(0) < 0$ implies that the zero is moving to the left. ∎

Remark 5.7. For a more complete discussion, the interested reader should consult Kapitula [15] and Kapitula and Sandstede [17].

5.3. Nonhomogeneous PFNLS. As a final example, consider the nonhomogeneous PFNLS (NPFNLS), where the perturbation term is given by

$$R(x,\phi,\phi^*) = -i(\gamma\phi - \mu h(x)\phi^* e^{-i2\theta}).$$

Here $h(x)$ is assumed to be even and satisfy the estimate

$$0 \leq h(x) \leq Ce^{-\beta|x|}$$

for some $\beta > 0$. Unlike the PFNLS, it is being assumed here that the parametric gain is spatially dependent.

ASSUMPTION 5.8. *The wave perturbs smoothly for $\epsilon > 0$.*

Given that the wave perturbs smoothly, standard perturbation theory reveals that the parameters must satisfy

$$\cos 2\theta = \frac{\gamma}{\mu}\frac{\langle \Phi, \Phi\rangle}{\langle h(x)\Phi, \Phi\rangle} \tag{5.11}$$

and that

$$\partial_\epsilon \mathbf{\Phi} = \begin{bmatrix} \mu \sin 2\theta\, L_r^{-1}(h(x)\Phi) \\ L_i^{-1}([-\gamma + \mu\cos 2\theta\, h(x)]\Phi) \end{bmatrix}.$$

Equation (5.11) and the fact that $h(x)$ is even guarantee that $\partial_\epsilon \mathbf{\Phi}$ is uniformly bounded in x.

Due to the fact that R breaks both the rotation and translation symmetry, it is expected that $E(0) \neq 0$. The calculation of $\partial_\epsilon^2 E(0)$ will be accomplished via an application of Lemma 4.9. Set

$$G(x) = (-\gamma + \mu\cos 2\theta\, h(x))\Phi.$$

A routine calculation shows that

$$\begin{aligned} L_\epsilon &= 8\Phi L_i^{-1}(G)\begin{bmatrix} -1 & 0 \\ 0 & 1 \end{bmatrix} + 8\mu\sin 2\theta\, L_r^{-1}(h(x)\Phi)\begin{bmatrix} 0 & -1 \\ 3 & 0 \end{bmatrix} \\ &\quad -\gamma I_2 + \mu h(x)\begin{bmatrix} \cos 2\theta & -\sin 2\theta \\ -\sin 2\theta & -\cos 2\theta \end{bmatrix}. \end{aligned}$$

Since $h(x)$ being even implies that $\partial_\epsilon \mathbf{\Phi}$ is also even, it is straightforward to see that

$$\langle L_\epsilon \psi_{1,1}, v_2\rangle = \langle L_\epsilon \psi_{1,2}, v_1\rangle = 0.$$

Therefore, upon using the result of Lemma 4.9,

$$\partial_\epsilon^2 E(0) = -2\langle L_\epsilon \psi_{1,1}, v_1\rangle\langle L_\epsilon \psi_{1,2}, v_2\rangle. \tag{5.12}$$

In general, of course, it is impossible to explicitly compute the above quantities without greater knowledge of the function $h(x)$. As such, to facilitate the computation it will be assumed for the rest of this discussion that

$$h(x) = 8\alpha\Phi^2, \tag{5.13}$$

where $\alpha > 0$ is arbitrary. Note that the existence condition then reduces to

$$\cos 2\theta = \frac{\gamma}{\mu}\frac{3}{8\alpha\omega}.$$

For this particular $h(x)$,

$$L_r^{-1}(h(x)\Phi) = \alpha\Phi;$$

therefore,

$$\begin{aligned}\langle L_\epsilon \psi_{1,2}, v_2\rangle &= -\frac{2\mu\sin 2\theta}{\partial_\omega\langle\Phi,\Phi\rangle}(\langle h(x)\Phi,\Phi\rangle + 8\langle \Phi L_r^{-1}(h(x)\Phi),\Phi^2\rangle)\\ &= -\frac{64}{3}\alpha\mu\omega^2\sin 2\theta.\end{aligned}$$

In addition, upon using the fact that

$$(\partial_x\Phi)^2 = \omega\left(\Phi^2 - \frac{2}{\omega}\Phi^4\right),$$

it can be seen that

$$\begin{aligned}\langle L_\epsilon \psi_{1,1}, v_1\rangle &= -\frac{4\mu\sin 2\theta}{\langle\Phi,\Phi\rangle}(\langle h(x),(\partial_x\Phi)^2\rangle - 24\langle \Phi L_r^{-1}(h(x)\Phi),(\partial_x\Phi)^2\rangle)\\ &= \frac{64}{15}\alpha\mu\omega^2\sin 2\theta.\end{aligned}$$

Using (5.12), it is now seen that

$$\partial_\epsilon^2 E(0) = \frac{2^{13}}{3^2\cdot 5}\alpha^2\mu^2\omega^4\sin^2 2\theta. \tag{5.14}$$

LEMMA 5.9. *Consider the NPFNLS. When $h(x)$ is given by* (5.13)*, then the solitary wave is unstable.*

Proof. By (5.14), $E(0) > 0$ for $\epsilon > 0$ sufficiently small. Since $E(\lambda)$ is negative for real λ sufficiently large, there then exists a positive real zero for $E(\lambda)$, and hence a positive real eigenvalue. □

Acknowledgments. I would like to thank Jonathan Rubin for his remarks and suggestions, which helped to clarify the presentation. I would also like to thank Björn Sandstede for several illuminating discussions.

A SOBOLEV SPACE THEORY OF SPDEs WITH CONSTANT COEFFICIENTS ON A HALF LINE*

N. V. KRYLOV† AND S. V. LOTOTSKY‡

Abstract. Equations of the form $du = (au_{xx} + f_x)\,dt + \sum_k (\sigma^k u_x + g^k)\,dw_t^k$ are considered for $t > 0$ and $x > 0$. The unique solvability of these equations is proved in weighted Sobolev spaces with fractional positive or negative derivatives, summable to the power $p \in [2, \infty)$.

Key words. stochastic partial differential equations, Sobolev spaces with weights

AMS subject classifications. 60H15, 35R60

PII. S0036141097326908

Introduction. We are considering the equation

$$du = (au_{xx} + f_x)\,dt + \sum_{k=1}^{\infty} (\sigma^k u_x + g^k)\,dw_t^k$$

in one space dimension for $x > 0$ and $t > 0$ with some initial condition at $t = 0$ and zero boundary condition at $x = 0$. Here w_t^k are independent one-dimensional Wiener processes and f and g^k are some given functions of (ω, t, x). The functions a and σ^k are assumed to depend only on ω and t. Such equations with a finite number of the processes w_t^k appear, for instance, in nonlinear filtering problems for partially observable diffusions (see [11]). Considering infinitely many w_t^k turns out to be instrumental in treating equations for measure valued processes, for instance, driven by space–time white noise (see [8] or [6]).

Our main goal is to prove solvability of such equations in spaces similar to Sobolev spaces, in which derivatives are understood as generalized functions, the number of derivatives may be fractional or negative, and underlying power of summability is $p \in [2, \infty)$.

The motivation for this goal is explained in detail in [5] or [8], where an L_p-theory is developed for the equations in the whole space. We only mention that if $p = 2$, the theory was developed long ago and an account of it can be found, for instance, in [11]. The case of equations in domains is also treated in [11]. However, the solvability is only proved in spaces W_2^1 of functions having one generalized derivative in x square summable in (ω, t, x). It turns out that going to better smoothness of solutions is not possible in spaces W_2^n and one needs to consider Sobolev spaces with weights, allowing derivatives to blow up near the boundary. The theory of solvability in Hilbert spaces like W_2^n with weights is developed in [1] and [10], where n is an integer. Here we show what happens if one takes a fractional or negative number of derivatives and replaces 2 with any $p \geq 2$. By the way, according to [2], it is not possible to take $p < 2$ when stochastic terms are present in the equation.

Unlike the above mentioned works, we only concentrate on the one-dimensional case. There are several reasons for that, the main being that even in the case of Hilbert spaces in [1] the central estimates are first proved in the one-dimensional case and after this there is still a rather long way to go to get to multidimensional domains. Our treatment of the one-dimensional case is long itself.

One of main difficulties in developing the theory presented below was finding right spaces. The idea was to find a scale of spaces like in [11], [5], or [8] generated by fractional powers of a certain operator, which is $1-\Delta$ in [11], [5], and [8]. From the results of [1] and [10] one can guess that $xD = x\partial/\partial x$ should be such an operator in our case. Elliptic second-order operators are more appropriate if one wants to define fractional powers and expects them to have nice properties. Therefore, our first attempt was to try the operator $L = xD(xD) + xD - c$, which is formally self-adjoint for any constant c. However, after having constructed the theory we noticed that the same spaces can be defined as images of spaces from [5] or [8] under certain linear mapping. This made using the results from [5] and [8] easier and allowed us to avoid developing solvability theory for L and investigating the semigroup and the resolvent associated with this operator.

In [11], [5], and [8] the solution is sought for in the same scale of spaces (at least as far as the space variables are concerned) as the one to which the free terms f and g belong. Surprisingly enough this is not the case in our situation, and this causes many difficulties practically at each step. The origin of all unusual features of our theory lies in the fact that there are no operators commuting with $\partial/\partial x$ and generating our scale of spaces. To give one more example of what is unusual we state the following theorem, which can be obtained from Theorem 3.2 after changing variables $v(t,x) = e^{x(\alpha-1)}u(t,e^x)$, where $\alpha = \theta/p$.

THEOREM 0.1. *Let $\alpha \in (0,1)$, $p \in (1,\infty)$, $T \in (0,\infty]$, and $f \in L_p([0,\infty)\times\mathbb{R})$. Then in the class of functions $v(t,x)$, $t \in [0,T]$, $x \in \mathbb{R}$ such that*

$$\int_0^T \int_{\mathbb{R}} [|v_x|^p + |v|^p]\,dxdt < \infty,$$

the equation

$$e^{2x}v_t = v_{xx} + (1-2\alpha)v_x - (1-\alpha)\alpha v + f_x \tag{0.1}$$

on $(0,T)\times\mathbb{R}$ with zero initial condition has a unique solution. In addition, this solution satisfies

$$\int_0^T \int_{\mathbb{R}} [|v_x|^p + |v|^p]\,dxdt \le N(\alpha,p)\int_0^T \int_{\mathbb{R}} |f|^p\,dxdt.$$

Surprising in this theorem is that if we replace e^{2x} with 1 in (0.1), then the result becomes well known and is true for any finite T (now with N depending on T too). The presence of e^{2x} makes (0.1) degenerate, and usually results for degenerate equations differ very much from those for nondegenerate cases. Actually, we do not know much about (0.1). In particular, it would be interesting to know whether Theorem 0.1 remains true if we replace the term $(1-2\alpha)v_x$ in (0.1) with bv_x where b is an arbitrary constant.

The article is organized as follows. In section 1 we introduce and investigate basic spaces with weights of functions of $x \in (0,\infty)$. Section 2 is devoted to stochastic Banach spaces of functions of (ω,t,x) satisfying zero boundary condition at $x = 0$.

This condition is expressed by means of requirement (2.1). In section 3 we prove our main Theorem 3.2 about unique solvability of our equations. The reader will see the very core of our technique in the proof of Lemma 3.6. Rather long section 4 contains the proof of the main particular case of Theorem 3.2, which is stated as Lemma 3.5.

1. Sobolev spaces with weights. For $\gamma \in \mathbb{R}$ and $p \in (1, \infty)$ let $H_p^\gamma = H_p^\gamma(\mathbb{R})$ be the spaces of Bessel potentials (see, for instance, [13]) which are formally given by $H_p^\gamma = \Lambda^{-\gamma} L_p(\mathbb{R})$, where $\Lambda := (1 - D^2)^{1/2}$ and $D = d/dx$. One knows that the elements of H_p^γ are distributions and $C_0^\infty = C_0^\infty(\mathbb{R})$ is dense in H_p^γ. Let $\mathcal{D}(\mathbb{R})$ and $\mathcal{D}(\mathbb{R}_+)$ be the sets of all distributions on $C_0^\infty(\mathbb{R})$ and $C_0^\infty(\mathbb{R}_+)$, respectively, where $\mathbb{R}_+ = (0, \infty)$. If $f \in \mathcal{D}(\mathbb{R}_+)$ and $\theta \in \mathbb{R}$, then the expression $h(x) := f(e^x)e^{x\theta/p}$ is well defined and is a distribution on $\mathbb{R}$. Indeed, the action of h on a test function $\phi \in C_0^\infty(\mathbb{R})$ is defined as $(h, \phi) = (f, \psi)$, where $\psi(x) := \phi(\log x)x^{\theta/p-1}$. We denote $h = Q_{p,\theta} f$ in this way defining a one-to-one operator

$$Q_{p,\theta} : f(x) \to f(e^x)e^{x\theta/p}.$$

Definition 1.1. *We write $f \in H_{p,\theta}^\gamma$ $(= H_{p,\theta}^\gamma(\mathbb{R}_+))$ if and only if $Q_{p,\theta} f = h \in H_p^\gamma$. We write $L_{p,\theta} = H_{p,\theta}^0$. For $f \in H_{p,\theta}^\gamma$ we define*

$$||f||_{H_{p,\theta}^\gamma} = ||Q_{p,\theta} f||_{H_p^\gamma}.$$

Remark 1.2. Since H_p^γ is a Banach space, so is $H_{p,\theta}^\gamma$ with the norm introduced above. Also since $C_0^\infty(\mathbb{R})$ is dense in H_p^γ, the set $C_0^\infty(\mathbb{R}_+)$ is dense in $H_{p,\theta}^\gamma$.

Remark 1.3. Define $\Lambda_{p,\theta}^\gamma = Q_{p,\theta}^{-1} \Lambda^\gamma Q_{p,\theta}$. Then for any $\gamma, \mu, \theta \in \mathbb{R}$ the operator $\Lambda_{p,\theta}^\gamma$ is an isometric operator from $H_{p,\theta}^\mu$ onto $H_{p,\theta}^{\mu-\gamma}$.

Indeed, by definition,

$$||\Lambda_{p,\theta}^\gamma u||_{H_{p,\theta}^{\mu-\gamma}} = ||Q_{p,\theta}\Lambda_{p,\theta}^\gamma u||_{H_p^{\mu-\gamma}} = ||\Lambda^\gamma Q_{p,\theta} u||_{H_p^{\mu-\gamma}}$$

$$= ||Q_{p,\theta} u||_{H_p^\mu} = ||u||_{H_{p,\theta}^\mu}.$$

Remark 1.4. The norm in $H_{p,\theta}^\gamma$ contains norms of, so to speak, γ derivatives of u. However, it scales in the same way for any γ. We mean that, due to translation invariance of norms in H_p^γ, for any constant $a > 0$ and $u \in H_{p,\theta}^\gamma$,

$$||u(a\,\cdot)||_{H_{p,\theta}^\gamma}^p = a^{-\theta}||u||_{H_{p,\theta}^\gamma}^p.$$

Remark 1.5. Define M as the operator of multiplying by x, $M : u(x) \to xu(x)$. It turns out that for any $\gamma \in \mathbb{R}$ the operator MD is a bounded operator from $H_{p,\theta}^\gamma$ into $H_{p,\theta}^{\gamma-1}$ and if, in addition, $\theta \neq 0$, then MD maps $H_{p,\theta}^\gamma$ onto $H_{p,\theta}^{\gamma-1}$ and its inverse is also bounded.

Indeed, an easy computation shows that

$$Q_{p,\theta} MDu = LQ_{p,\theta} u, \quad MDu = Q_{p,\theta}^{-1} LQ_{p,\theta} u,$$

where $Lv = Dv - v\theta/p$. One knows (see, for instance, p. 263 in [12]) that for any constant ν the operator $v \to Dv + \nu v$ is a bounded operator from H_p^γ into $H_p^{\gamma-1}$ and if ν is real and $\nu \neq 0$, then it maps H_p^γ onto $H_p^{\gamma-1}$ and its inverse is bounded. This and the definition of $H_{p,\theta}^\gamma$ obviously imply our assertion.

Remark 1.6. Functions in $H^\gamma_{p,\theta}$ are different from those in H^γ_p only in what concerns their behavior near zero and infinity. More precisely, if $[a,b] \subset \mathbb{R}_+$ and $f = 0$ outside $[a,b]$, then by the results on changing variables and pointwise multipliers (see Theorem 4.3.2 and Corollary 4.2.2 of [13]) $||f||_{H^\gamma_{p,\theta}} \le N||f||_{H^\gamma_p} \le N||f||_{H^\gamma_{p,\theta}}$, where N is independent of f.

It is convenient here also to notice that for the same f we have

$$||f||_{H^\gamma_p} \le N||Df||_{H^{\gamma-1}_p} \le N||f||_{H^\gamma_p},$$

with N independent of f.

Indeed, the inequality on the right is known to be true even for any $f \in H^\gamma_p$. As far as the left inequality is concerned, by Remark 1.5 we have

$$||f||_{H^\gamma_p} \le N||f||_{H^\gamma_{p,1}} \le N||MDf||_{H^{\gamma-1}_{p,1}} \le N||\eta Df||_{H^{\gamma-1}_p},$$

where $\eta \in C_0^\infty(\mathbb{R})$ and $\eta(x) = x$ on $[a,b]$. It only remains to remember (see [13]) that such η is a pointwise multiplier in any space $H^{\gamma-1}_p$.

Remark 1.7. Upon noticing that $DMu = MDu+u$, as in Remark 1.5 we conclude that for any $\gamma \in \mathbb{R}$ the operator DM is a bounded operator from $H^\gamma_{p,\theta}$ into $H^{\gamma-1}_{p,\theta}$ and if, in addition, $\theta \ne p$, then DM maps $H^\gamma_{p,\theta}$ onto $H^{\gamma-1}_{p,\theta}$ and its inverse is also bounded.

Remark 1.8. Let $\theta \ne 0$, $u \in \bigcup_\mu H^\mu_{p,\theta}$, and $MDu \in H^\gamma_{p,\theta}$. Then $u \in H^{\gamma+1}_{p,\theta}$ and $||u||_{H^{\gamma+1}_{p,\theta}} \le N||MDu||_{H^\gamma_{p,\theta}}$.

Indeed, by Remark 1.5 there is $v \in H^{\gamma+1}_{p,\theta}$ such that $MDv = MDu$ and $||v||_{H^{\gamma+1}_{p,\theta}} \le N||MDu||_{H^\gamma_{p,\theta}}$. Then $v' = u'$ and $v-u = c$, where c is a constant. Since $v, u \in H^\mu_{p,\theta}$ for some μ, we have $c \in H^\mu_{p,\theta}$, which is only possible if $c = 0$. Therefore, $u = v \in H^{\gamma+1}_{p,\theta}$.

Remark 1.9. Let $\theta \ne p$, $u \in \bigcup_\mu H^\mu_{p,\theta}$, and $DMu \in H^\gamma_{p,\theta}$. Then $u \in H^{\gamma+1}_{p,\theta}$ and $||u||_{H^{\gamma+1}_{p,\theta}} \le N||DMu||_{H^\gamma_{p,\theta}}$.

Indeed, one can repeat the argument in Remark 1.8 relying on Remark 1.7 instead of Remark 1.5 and noticing that from the equality $DMv = DMu$ it follows that $v - u = c/x$, where c is a constant.

Remark 1.5 and the observation that $H^0_{p,\theta} = L_{p,\theta}$ is just an L_p-space of functions on $\mathbb{R}_+$ with measure $m_\theta(dx) = x^{\theta-1}\,dx$ yield inequalities (1.1) in the following useful result, which can also be restated in a natural way on the basis of Remark 1.7.

THEOREM 1.10. *If γ is an integer satisfying $\gamma \ge 1$ and $\theta \ne 0$, then for any $u \in H^\gamma_{p,\theta}$ we have*

$$||(MD)^\gamma u||_{L_p(\mathbb{R}_+,m_\theta)} \le N||u||_{H^\gamma_{p,\theta}} \le N||(MD)^\gamma u||_{L_p(\mathbb{R}_+,m_\theta)}, \tag{1.1}$$

$$\sum_{n=1}^\gamma ||M^n D^n u||_{L_p(\mathbb{R}_+,m_\theta)} \le N||u||_{H^\gamma_{p,\theta}} \le N\sum_{n=1}^\gamma ||M^n D^n u||_{L_p(\mathbb{R}_+,m_\theta)}, \tag{1.2}$$

where N is independent of u. Thus, the space $H^\gamma_{p,\theta}$ can also be defined as a closure of the set $C_0^\infty(\mathbb{R}_+)$ with respect to either of the norms

$$||(MD)^\gamma \cdot||_{L_p(\mathbb{R}_+,m_\theta)}, \qquad \sum_{n=1}^\gamma ||M^n D^n \cdot||_{L_p(\mathbb{R}_+,m_\theta)}.$$

To prove (1.2) observe that for any integer $k \geq 1$,

$$(MD)^k = \sum_{n=1}^{k} c^{k,n} M^n D^n, \tag{1.3}$$

where $c^{k,n}$ are some constants and $c^{k,k} = 1$. This and the inequality on the right in (1.1) give us the inequality on the right in (1.2). On the other hand, one can solve the triangular system (1.3) with respect to $M^n D^n$. Then from the inequality on the left in (1.1) we get

$$\sum_{n=1}^{\gamma} ||M^n D^n u||_{L_p(\mathbb{R}_+, m_\theta)} \leq N \sum_{n=1}^{\gamma} ||(MD)^n u||_{L_p(\mathbb{R}_+, m_\theta)}$$

$$\leq N \sum_{n=1}^{\gamma} ||u||_{H^n_{p,\theta}} \leq N ||u||_{H^\gamma_{p,\theta}},$$

which proves the inequality on the left in (1.2).

The following theorem will play the most important role in obtaining results for equations on $\mathbb{R}_+$ from those on $\mathbb{R}$.

THEOREM 1.11. *Let $\zeta \in C_0^\infty(\mathbb{R}_+)$, $\gamma, \theta \in \mathbb{R}$, and $p \in (1, \infty)$. Then there exists a constant N depending only on ζ, γ, p, and θ such that, for any $u \in H^\gamma_{p,\theta}$,*

$$\sum_{n=-\infty}^{\infty} e^{n\theta} ||\zeta u(e^n \cdot)||^p_{H^\gamma_p} \leq N ||u||^p_{H^\gamma_{p,\theta}}.$$

In addition, if there is a $\delta > 0$ such that

$$\sum_{n=-\infty}^{\infty} e^{(n-x)\theta} |\zeta(e^{x-n})|^p \geq \delta \tag{1.4}$$

for all $x \in [0,1]$, then

$$||u||^p_{H^\gamma_{p,\theta}} \leq N \sum_{n=-\infty}^{\infty} e^{n\theta} ||\zeta u(e^n \cdot)||^p_{H^\gamma_p},$$

where N depends on δ as well.

Proof. Since the functions $\zeta(x) u(e^n x)$ vanish outside the support of ζ, by the change of variables (see Theorem 4.3.2 in [13])

$$e^{n\theta} ||\zeta u(e^n \cdot)||^p_{H^\gamma_p} \leq N e^{n\theta} ||\zeta(e^\cdot) u(e^{\cdot + n})||^p_{H^\gamma_p}$$

with N independent of n, u. By translation invariance of the norm in H^γ_p the last expression equals

$$e^{n\theta} ||\zeta(e^{\cdot - n}) u(e^\cdot)||^p_{H^\gamma_p} = ||\eta(e^{\cdot - n}) Q_{p,\theta} u||^p_{H^\gamma_p},$$

where $\eta(e^{x-n}) = \zeta(e^{x-n}) e^{(n-x)\theta/p}$. Next it is easy to find a finite m such that for $x \in [0,1]$,

$$I(x) := \sum_{n=-\infty}^{\infty} |\eta(e^{x-n})|^p = \sum_{n=-\infty}^{\infty} |\zeta(e^{x-n})|^p e^{(x-n)\theta}$$

$$= \sum_{|n| \leq m} |\zeta(e^{x-n})|^p e^{(x-n)\theta}.$$

It follows that $I(x)$ is bounded on $[0,1]$. On the other hand $I(x)$ is obviously periodic with period 1. Thus $I(x)$ is bounded on $\mathbb{R}$. The same is true for

$$\sum_{n=-\infty}^{\infty} |(\eta(e^{x-n}))'|^p, \quad \sum_{n=-\infty}^{\infty} |(\eta(e^{x-n}))''|^p,$$

and so on. By Theorem 2.2 and Remark 2.1 of [2]

$$\sum_{n=-\infty}^{\infty} ||\eta(e^{\cdot-n})Q_{p,\theta}u||^p_{H^\gamma_p} \leq N||Q_{p,\theta}u||^p_{H^\gamma_p},$$

which yields our first assertion.

To prove the second one we use the same resources as above and get

$$||Q_{p,\theta}u||^p_{H^\gamma_p} \leq N\sum_{n=-\infty}^{\infty} ||\eta(e^{\cdot-n})Q_{p,\theta}u||^p_{H^\gamma_p} = N\sum_{n=-\infty}^{\infty} e^{n\theta}||\zeta(e^{\cdot-n})u(e^{\cdot})||^p_{H^\gamma_p}$$

$$= N\sum_{n=-\infty}^{\infty} e^{n\theta}||\zeta(e^{\cdot})u(e^{\cdot+n})||^p_{H^\gamma_p} \leq N\sum_{n=-\infty}^{\infty} e^{n\theta}||\zeta u(e^n\,\cdot)||^p_{H^\gamma_p}.$$

The theorem is proved.

Remark 1.12. Similar to properties of $I(x)$ in the above proof, we find that if $\zeta \in C_0^\infty(\mathbb{R}_+)$ and $\beta \in \mathbb{R}$, then $\sum_n e^{(n+x)\beta}\zeta(e^{n+x})$ is bounded on $\mathbb{R}$, which after substituting $\log x$ in place of x implies that $\sum_n e^{n\beta}\zeta(e^n x) \leq Nx^{-\beta}$ on $\mathbb{R}_+$.

The following theorem is used in establishing some properties of our stochastic Banach spaces.

THEOREM 1.13. *Recall that the operator M is defined by $Mu(x) = xu(x)$ and let $\theta, \gamma \in \mathbb{R}$, $\theta \neq p$. Then*

$$M^{-1}u \in H^{\gamma+1}_{p,\theta} \iff Du \in H^\gamma_{p,\theta} \text{ and } M^{-1}u \in \bigcup_\mu H^\mu_{p,\theta}. \tag{1.5}$$

In addition, under either one of the above conditions

$$||M^{-1}u||_{H^{\gamma+1}_{p,\theta}} \leq N||Du||_{H^\gamma_{p,\theta}} \leq N||M^{-1}u||_{H^{\gamma+1}_{p,\theta}}. \tag{1.6}$$

Proof. If $M^{-1}u \in H^{\gamma+1}_{p,\theta}$, then by Remark 1.7 we have

$$Du = DM(M^{-1}u) \in H^\gamma_{p,\theta}$$

and the right inequality in (1.6) holds. On the other hand, under the condition on the right in (1.5) we have

$$DM(M^{-1}u) \in H^\gamma_{p,\theta} \quad \text{and} \quad M^{-1}u \in \bigcup_\mu H^\mu_{p,\theta},$$

which by Remark 1.9 yields $M^{-1}u \in H^{\gamma+1}_{p,\theta}$ and the inequality on the left in (1.6). The theorem is proved.

The following result will also be used in the future.

LEMMA 1.14. *For any constants p, θ, α we have*

$$
\begin{gathered}
Q_{p,\theta}^{-1} D Q_{p,\theta} = bI + MD, \quad Q_{p,\theta}^{-1} D^2 Q_{p,\theta} = (bI + MD)^2, \quad DM = MD + I, \\
M^\alpha \Lambda_{p,\theta}^2 M^{-\alpha} = \Lambda_{p,\theta}^2 + c_1 I + c_2 MD, \quad M\Lambda_{p,\theta}^2 - \Lambda_{p,\theta}^2 M = MP_1, \\
\Lambda_{p,\theta}^2 D - D\Lambda_{p,\theta}^2 = P_1 D, \\
\Lambda_{p,\theta}^2 DM - D\Lambda_{p,\theta}^2 M = P_1 DM, \quad \Lambda_{p,\theta}^2 D^2 M - D^2 \Lambda_{p,\theta}^2 M = 4DP_2,
\end{gathered} \tag{1.7}
$$

where $b = \theta/p$, I is the identity operator, c_i are certain constants, and

$$
P_1 := (2b+1)I + 2MD, \quad P_2 := bDM + (MD)(DM).
$$

Furthermore, for any $\theta, \gamma \in \mathbb{R}$ there exists a constant $N = N(\gamma, \theta, p)$ such that for any $u \in H_{p,\theta}^{\gamma+2}$,

$$
||P_1 u||_{H_{p,\theta}^{\gamma+1}} + ||P_2 u||_{H_{p,\theta}^{\gamma}} \le N ||u||_{H_{p,\theta}^{\gamma+2}}. \tag{1.8}
$$

Indeed, equalities (1.7) are checked out by straightforward computations and (1.8) follows immediately from Remarks 1.5 and 1.7.

2. Stochastic Banach spaces on $\mathbb{R}_+$. Let $(\Omega, \mathcal{F}, P)$ be a complete probability space, $(\mathcal{F}_t, t \ge 0)$ be an increasing filtration of σ-fields $\mathcal{F}_t \subset \mathcal{F}$ containing all P-null subsets of Ω, and $\mathcal{P}$ be the predictable σ-field generated by $(\mathcal{F}_t, t \ge 0)$. Let $\{w_t^k; k = 1, 2, ...\}$ be a family of independent one-dimensional $\mathcal{F}_t$-adapted Wiener processes defined on $(\Omega, \mathcal{F}, P)$. We are going to use the Banach spaces $\mathbb{H}_p^\gamma(\tau)$, $\mathbb{H}_p^\gamma(\tau, l_2)$, and $\mathcal{H}_p^\gamma(\tau)$ introduced in [5] or [8], where we take $d = 1$. Also throughout the remaining part of the paper $\theta \ne 0$, $\theta \ne p$, and $p \ge 2$ unless another range of p is specified explicitly.

DEFINITION 2.1. *Let τ be a stopping time, f and g^k, $k = 1, 2...$, be $\mathcal{D}(\mathbb{R}_+)$-valued $\mathcal{P}$-measurable functions defined on $(\!(0, \tau]\!]$. We write $f \in \mathbb{H}_{p,\theta}^\gamma(\tau)$ and $g \in \mathbb{H}_{p,\theta}^\gamma(\tau, l_2)$ if and only if $Q_{p,\theta} f \in \mathbb{H}_p^\gamma(\tau)$ and $Q_{p,\theta} g \in \mathbb{H}_p^\gamma(\tau, l_2)$, respectively. We also denote*

$$
||f||_{\mathbb{H}_{p,\theta}^\gamma(\tau)} = ||Q_{p,\theta} f||_{\mathbb{H}_p^\gamma(\tau)}, \quad ||g||_{\mathbb{H}_{p,\theta}^\gamma(\tau, l_2)} = ||Q_{p,\theta} g||_{\mathbb{H}_p^\gamma(\tau, l_2)},
$$

$$
\mathbb{H}_{p,\theta}^\gamma = \mathbb{H}_{p,\theta}^\gamma(\infty), \quad \mathbb{H}_{p,\theta}^\gamma(l_2) = \mathbb{H}_{p,\theta}^\gamma(\infty, l_2), \quad \mathbb{L}_{...,...} = \mathbb{H}_{...,...}^0.
$$

In the case $f \in \mathbb{H}_{p,\theta}^\gamma(\tau)$, $g \in \mathbb{H}_{p,\theta}^{\gamma+1}(\tau, l_2)$ we write $(f, g) \in \mathcal{F}_{p,\theta}^\gamma(\tau)$ and

$$
||(f, g)||_{\mathcal{F}_{p,\theta}^\gamma(\tau)} = ||f||_{\mathbb{H}_{p,\theta}^\gamma(\tau)} + ||g||_{\mathbb{H}_{p,\theta}^{\gamma+1}(\tau, l_2)}.
$$

Finally, we introduce spaces of initial data. We write $u_0 \in U_{p,\theta}^\gamma$ if and only if $M^{2/p-1} u_0 \in L_p(\Omega, \mathcal{F}_0, H_{p,\theta}^{\gamma-2/p})$ and denote

$$
||u_0||_{U_{p,\theta}^\gamma}^p = E||M^{2/p-1} u_0||_{H_{p,\theta}^{\gamma-2/p}}^p.
$$

DEFINITION 2.2. *For a $\mathcal{D}(\mathbb{R}_+)$-valued function u defined on $\Omega \times [0, \infty)$ with $u(0, \cdot) \in U_{p,\theta}^{\gamma+1}$ and*

$$
M^{-1} u \in \bigcup_\mu \bigcap_{T>0} \mathbb{H}_{p,\theta}^\mu(\tau \wedge T), \tag{2.1}
$$

we write $u \in \mathfrak{H}^{\gamma+1}_{p,\theta}(\tau)$ *if and only if* $u_x \in \mathbb{H}^{\gamma}_{p,\theta}(\tau)$ *and there exists* $(f,g) \in \mathcal{F}^{\gamma-1}_{p,\theta}(\tau)$ *such that for any* $\phi \in C_0^\infty(\mathbb{R}_+)$ *we have*

$$(u(t,\cdot),\phi) = (u(0,\cdot),\phi) + \int_0^t (M^{-1}f(s,\cdot),\phi)\,ds + \sum_{k=1}^{\infty}\int_0^t (g^k(s,\cdot),\phi)\,dw^k_s \tag{2.2}$$

for all $t \le \tau$ *at once with probability one. In this situation we also write* $M^{-1}f = \tilde{\mathbb{D}}u$, $g = \tilde{\mathbb{S}}u$,

$$du = M^{-1}f\,dt + g^k\,dw^k_t$$

and define $\mathfrak{H}^{\gamma+1}_{p,\theta,0}(\tau) = \mathfrak{H}^{\gamma+1}_{p,\theta}(\tau) \cap \{u : u(0,\cdot) = 0\}$,

$$||u||^p_{\mathfrak{H}^{\gamma+1}_{p,\theta}(\tau)} = ||u_x||^p_{\mathbb{H}^{\gamma}_{p,\theta}(\tau)} + ||(f,g)||^p_{\mathcal{F}^{\gamma-1}_{p,\theta}(\tau)} + ||u(0,\cdot)||^p_{U^{\gamma+1}_{p,\theta}}. \tag{2.3}$$

As always, we drop τ *in* $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ *and* $\mathcal{F}^{\gamma}_{p,\theta}(\tau)$ *if* $\tau = \infty$.

Remark 2.3 (cf. Remark 3.3 in [8]). Given $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$, there exists only one pair of functions f and g in Definition 2.2. Therefore, the notation $M^{-1}f = \tilde{\mathbb{D}}u$, $g = \tilde{\mathbb{S}}u$, and (2.3) make sense.

It is also worth noting that the last series in (2.2) converges uniformly in t on each interval $[0, \tau \wedge T]$, $T \in (0,\infty)$, in probability.

Remark 2.4. It follows from Theorem 1.13 that, in Definition 2.2, the two requirements (2.1) and $u_x \in \mathbb{H}^{\gamma}_{p,\theta}(\tau)$ can be replaced with only one: $M^{-1}u \in \mathbb{H}^{\gamma+1}_{p,\theta}(\tau)$. In addition,

$$||M^{-1}u||_{\mathbb{H}^{\gamma+1}_{p,\theta}(\tau)} \le N||u_x||_{\mathbb{H}^{\gamma}_{p,\theta}(\tau)} \le N||M^{-1}u||_{\mathbb{H}^{\gamma+1}_{p,\theta}(\tau)},$$

where $N = N(\gamma,\theta,p)$.

Remark 2.5. The space $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ is *not* $Q^{-1}_{p,\theta}\mathcal{H}^{\gamma}_p(\tau)$. However, obviously ϕu lies in $Q^{-1}_{p,\theta}\mathcal{H}^{\gamma}_p(\tau)$ for any $\phi \in C_0^\infty(\mathbb{R}_+)$ if $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$. By Theorem 3.7 of [8] this easily implies that if $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ and $||u||_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)} = 0$, then u is indistinguishable from zero.

Of course, we identify elements of $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ which are indistinguishable.

Remark 2.6. The spaces $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ and $\mathfrak{H}^{\gamma}_{p,\theta,0}(\tau)$ are Banach spaces.

Indeed, their completeness is obtained as follows. If u_n is a Cauchy sequence in $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$, then $M^{-1}u_n$ is a Cauchy sequence in $\mathbb{H}^{\gamma}_{p,\theta}(\tau)$ by Remark 2.4 and hence it converges to some $M^{-1}u \in \mathbb{H}^{\gamma}_{p,\theta}(\tau)$. Also, $M\tilde{\mathbb{D}}u_n \to f$ and $\tilde{\mathbb{S}}u_n \to g$ for some $(f,g) \in \mathcal{F}^{\gamma-2}_{p,\theta}(\tau)$.

Next, for any $\phi \in C_0^\infty(\mathbb{R}_+)$ the sequence ϕu_n is a Cauchy sequence in $\mathcal{H}^{\gamma}_p(\tau)$, which is a Banach space by Theorem 3.7 of [8]. This easily implies that u has a modification $\bar{u}$ such that $\phi\bar{u}$ belongs to $\mathcal{H}^{\gamma}_p(\tau)$ for any $\phi \in C_0^\infty(\mathbb{R}_+)$, and $\bar{u}$ satisfies (2.2), so that $\bar{u} \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$. One treats $\mathfrak{H}^{\gamma}_{p,\theta,0}(\tau)$ similarly.

Remark 2.7. By Remark 1.5 it follows that $f \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau)$ if and only if there exists a unique $h \in \mathbb{H}^{\gamma}_{p,\theta}(\tau)$ such that $M^{-1}f = Dh$. In addition, the norms of f and h are equivalent. Hence, one obtains the same space $\mathfrak{H}^{\gamma+1}_{p,\theta}(\tau)$ if in Definition 2.2 one replaces $M^{-1}f$ with f_x and instead of the condition $(f,g) \in \mathcal{F}^{\gamma-1}(\tau)$ requires $f \in \mathbb{H}^{\gamma}_{p,\theta}(\tau)$, $g \in \mathbb{H}^{\gamma}_{p,\theta}(\tau, l_2)$. In this case one obtains an equivalent norm by replacing $||(f,g)||^p_{\mathcal{F}^{\gamma-1}_{p,\theta}(\tau)}$ in (2.3) with

$$||f||^p_{\mathbb{H}^{\gamma}_{p,\theta}(\tau)} + ||g||^p_{\mathbb{H}^{\gamma}_{p,\theta}(\tau,l_2)}.$$

Remark 2.8. If $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$, then $v := MDu \in \mathfrak{H}^{\gamma-1}_{p,\theta}(\tau)$ and

$$||MDu||_{\mathfrak{H}^{\gamma-1}_{p,\theta}(\tau)} \le N(\gamma,\theta,p)||u||_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)}.$$

Indeed, we have $M^{-1}v = Du \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau)$, which by Remark 2.4 gives us a part of the needed properties of v. Also by Remark 2.7, $du = f_x\,dt + g^k\,dw^k_t$ with $f \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau)$ and $g \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau, l_2)$, so that $dv = (MDf - f)_x\,dt + MDg^k\,dw^k_t$, where by Remark 1.5

$$||MDf - f||_{\mathbb{H}^{\gamma-2}_{p,\theta}(\tau)} \le N||f||_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau)}, \quad ||MDg||_{\mathbb{H}^{\gamma-2}_{p,\theta}(\tau,l_2)} \le N||g||_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau,l_2)},$$

$$||M^{2/p-1}v(0,\cdot)||_{H^{\gamma-1-2/p}_{p,\theta}} = ||MD(M^{2/p-1}u(0,\cdot)) - (2/p-1)M^{2/p-1}u(0,\cdot)||_{H^{\gamma-1-2/p}_{p,\theta}}$$
$$\le N||M^{2/p-1}u(0,\cdot)||_{H^{\gamma-2/p}_{p,\theta}}.$$

Remark 2.9. From Remark 1.3 we have

$$||\Lambda^{\gamma}_{p,\theta}u||_{\mathbb{H}^{\mu}_{p,\theta}(\tau)} = ||u||_{\mathbb{H}^{\mu+\gamma}_{p,\theta}(\tau)}.$$

The assertions of the following theorem are straightforward corollaries of Remark 2.4 and of two Sobolev theorems. One says that $H^{\gamma}_p \subset \mathcal{C}^{\delta}$ if $\delta := \gamma - 1/p > 0$, where $\mathcal{C}^{\delta} = \mathcal{C}^{\delta}(\mathbb{R})$ is the Zygmund space (which differs from the usual Hölder space $C^{\delta} = C^{\delta}(\mathbb{R})$ only if δ is an integer; see [13]). The second one says that $H^{\gamma}_p \subset H^{\mu}_q$ if $\mu < \gamma$ and $\gamma - 1/p = \mu - 1/q$. These theorems are easily rewritten in terms of our spaces $H^{\gamma}_{p,\theta} = Q^{-1}_{p,\theta}H^{\gamma}_p$.

THEOREM 2.10. (i) *If $\alpha := \gamma - 1/p > 0$ and $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$, then $Q_{p,\theta}M^{-1}u \in L_p(\langle\!\langle 0,\tau]\!],\mathcal{C}^{\alpha})$, where $\mathcal{C}^{\alpha}$ is the Zygmund space. In addition,*

$$E\int_0^{\tau} ||Q_{p,\theta}M^{-1}u(t,\cdot)||^p_{\mathcal{C}^{\alpha}}\,dt \le N(d,\gamma,p)||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)}.$$

(ii) *If $\mu < \gamma$, $\gamma - 1/p = \mu - 1/q$, and $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$, then*

$$E\int_0^{\tau} ||M^{-1}u(t,\cdot)||^p_{H^{\mu}_{q,\theta q/p}}\,dt \le N(d,\gamma,\mu,p)||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)}.$$

In order to prove the solvability even of the simplest equations we need the following embedding theorem. However, the way in which the right-hand side of (2.4) depends on T will not be used.

THEOREM 2.11. *Let $T \in (0,\infty)$ be a constant and let $\tau \le T$. Then for any function $u \in \mathfrak{H}^{\gamma}_{p,\theta,0}(\tau)$, we have*

$$E\sup_{t\le\tau} ||u(t,\cdot)||^p_{H^{\gamma-1}_{p,\theta}} \le N(p,\theta,\gamma)T^{(p-2)/p}||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)}. \tag{2.4}$$

To prove this theorem we use the following fact, which is similar to Remark 2.2 of [5] or Remark 4.11 of [8].

LEMMA 2.12. *Let $T \in (0,\infty)$ be a constant and let $\tau \le T$. Let $u \in \mathcal{H}^{\gamma}_{p,0}(\tau)$ and $du = f\,dt + g^k\,dw^k_t$. Then for any constant $c > 0$,*

$$E\sup_{t\le\tau} ||u_x(t,\cdot)||^p_{H^{\gamma-2}_p} \le N(p)T^{(p-2)/2}(c||u_{xx}||^p_{\mathbb{H}^{\gamma-2}_p(\tau)}$$
$$+c^{-1}||f||^p_{\mathbb{H}^{\gamma-2}_p(\tau)} + ||g_x||^p_{\mathbb{H}^{\gamma-2}_p(\tau,l_2)}). \tag{2.5}$$

Proof. As always, it suffices to prove (2.5) for any particular γ and $\tau = T$ (regarding τ see, for instance, the proof of Theorem 7.1 in [8]). We take $\gamma = 2$. Then (2.5) becomes

$$E\sup_{t\le T}||u_x(t,\cdot)||^p_{L_p} \le N(p)T^{(p-2)/2}(c||u_{xx}||^p_{\mathbb{L}_p(T)}$$

$$+c^{-1}||f||^p_{\mathbb{L}_p(T)} + ||g_x||^p_{\mathbb{L}_p(T,l_2)}). \tag{2.6}$$

It suffices to prove this inequality for $c = 1$. Indeed, for any constant $a > 0$ we have $du(t,ax) = f(t,ax)\,dt + g^k(t,ax)\,dw^k_t$ and if (2.6) holds with $c = 1$, then

$$a^{p-1}E\sup_{t\le T}||u_x(t,\cdot)||^p_{L_p} = E\sup_{t\le T}||(u(t,a\,\cdot))_x||^p_{L_p}$$

$$\le NT^{(p-2)/2}(||(u(\cdot,a\,\cdot))_{xx}||^p_{\mathbb{L}_p(T)} + ||f(\cdot,a\,\cdot)||^p_{\mathbb{L}_p(T)} + ||(g(\cdot,a\,\cdot))_x||^p_{\mathbb{L}_p(T,l_2)})$$

$$= NT^{(p-2)/2}(a^{2p-1}||u_{xx}||^p_{\mathbb{L}_p(T)} + a^{-1}||f||^p_{\mathbb{L}_p(T)} + a^{p-1}||g_x||^p_{\mathbb{L}_p(T,l_2)}).$$

This proves (2.6) with a^p in place of c.

We further transform (2.6) with $c = 1$ by denoting $v = u_x$ and $h^k = g^k_x$, so that $dv = f_x\,dt + h^k\,dw^k_t$ and $v \in \mathcal{H}^1_{p,0}(T)$. We see that we only need to prove that

$$E\sup_{t\le T}||v(t,\cdot)||^p_{L_p} \le N(p)T^{(p-2)/2}(||v_x||^p_{\mathbb{L}_p(T)}$$

$$+||f||^p_{\mathbb{L}_p(T)} + ||h||^p_{\mathbb{L}_p(T,l_2)}). \tag{2.7}$$

By Theorem 2.1 of [5] or Theorem 4.10 of [8] and by the observation that $dv = (v_{xx} + (f - v_x)_x)\,dt + h^k\,dw^k_t$, for any $\lambda, T > 0$ we have

$$E\sup_{t\le T}(e^{-p\lambda t}||v(t,\cdot)||^p_{L_p}) \le N(||e^{-\lambda t}\bar f||^p_{\mathbb{L}_p(T)} + ||e^{-\lambda t}h||^p_{\mathbb{L}_p(T,l_2)}),$$

where $N = N(p,\lambda)$ and $\bar f = f - v_x$. For $\lambda = 1/p$ this yields

$$E\sup_{t\le T}||v(t,\cdot)||^p_{L_p} \le Ne^T(||\bar f||^p_{\mathbb{L}_p(T)} + ||h||^p_{\mathbb{L}_p(T,l_2)}).$$

By using the self-similarity of the equation $dv = (v_{xx} + \bar f_x)\,dt + h^k\,dw^k_t$ (that is, by considering equations like (3.6)), for any constant $c > 0$ we get

$$E\sup_{t\le T}||v(c^2t,c\,\cdot)||^p_{L_p} \le Ne^T(||c\bar f(c^2t,c\,\cdot)||^p_{\mathbb{L}_p(T)} + ||ch(c^2t,c\,\cdot)||^p_{\mathbb{L}_p(T,l_2)})$$

with $N = N(p)$. Changing variables we obtain

$$E\sup_{t\le T}||v(t,\cdot)||^p_{L_p} \le Ne^{T/c^2}c^{p-2}(||\bar f||^p_{\mathbb{L}_p(T)} + ||h||^p_{\mathbb{L}_p(T,l_2)}).$$

For $c^2 = T$ this is even a little bit stronger than (2.7) and the lemma is proved.

Proof of Theorem 2.11. For an appropriate $\zeta \in C_0^\infty(\mathbb{R}_+)$ we have

$$E\sup_{t\le\tau}||u(t,\cdot)||^p_{H^{\gamma-1}_{p,\theta}} \le N\sum_{n=-\infty}^{\infty} e^{n\theta}E\sup_{t\le\tau}||\zeta u(t,e^n\cdot)||^p_{H^{\gamma-1}_p}. \tag{2.8}$$

Let $du = f_x\,dt + g^k\,dw^k_t$. Then

$$d(\zeta(x)u(t,e^nx)) = \zeta(x)(f_x)(t,e^nx)\,dt + \zeta(x)g^k(t,e^nx)\,dw^k_t.$$

By Lemma 2.12 for $u_n(t,x) := \zeta(x)u(t,e^nx)$, $f_n(t,x) := \zeta(x)(f_x)(t,e^nx)$, $g_n(t,x) := \zeta(x)g(t,e^nx)$, and $c = e^{-np}$ we have

$$E\sup_{t\le\tau}||u_{nx}(t,\cdot)||^p_{H^{\gamma-2}_p} \le NT^{(p-2)/2}(e^{-np}||u_{nxx}||^p_{\mathbb{H}^{\gamma-2}_p(\tau)}$$

$$+e^{np}||f_n||^p_{\mathbb{H}^{\gamma-2}_p(\tau)} + ||g_{nx}||^p_{\mathbb{H}^{\gamma-2}_p(\tau,l_2)}). \tag{2.9}$$

To transform this inequality notice that all the functions $u_n(t,x)$ as functions of x have supports inside the support of ζ which is bounded. Therefore (see Remark 1.6),

$$||\zeta u(t,e^n\cdot)||_{H^{\gamma-1}_p} = ||u_n(t,\cdot)||_{H^{\gamma-1}_p} \le N||u_{nx}(t,\cdot)||_{H^{\gamma-2}_p}.$$

Furthermore, $||g_{nx}||_{H^{\gamma-2}_p(l_2)} \le ||g_n||_{H^{\gamma-1}_p(l_2)}$ and

$$\sum_{n=-\infty}^{\infty} e^{n\theta}||g_n||^p_{\mathbb{H}^{\gamma-1}_p(\tau,l_2)} \le N||g||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau,l_2)} \le N||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)}.$$

Also,

$$\sum_{n=-\infty}^{\infty} e^{n(\theta+p)}||f_n||^p_{\mathbb{H}^{\gamma-2}_p(\tau)} = \sum_{n=-\infty}^{\infty} e^{n\theta}||(M^{-1}\zeta)(MDf)(\cdot,e^n\cdot)||^p_{\mathbb{H}^{\gamma-2}_p(\tau)}$$

$$\le N||MDf||^p_{\mathbb{H}^{\gamma-2}_{p,\theta}(\tau)} \le N||f||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau)} \le N||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)},$$

$$\sum_{n=-\infty}^{\infty} e^{n(\theta-p)}||u_{nxx}||^p_{\mathbb{H}^{\gamma-2}_p(\tau)} \le \sum_{n=-\infty}^{\infty} e^{n(\theta-p)}||u_n||^p_{\mathbb{H}^{\gamma}_p(\tau)}$$

$$= \sum_{n=-\infty}^{\infty} e^{n\theta}||(M\zeta)(M^{-1}u)(\cdot,e^n\cdot)||^p_{\mathbb{H}^{\gamma}_p(\tau)}$$

$$\le N||M^{-1}u||^p_{\mathbb{H}^{\gamma}_{p,\theta}(\tau)} \le N||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)}.$$

By combining this with (2.9) and (2.8) we get (2.4). The theorem is proved.

As always the main role is played by the spaces $\mathfrak{H}^{\gamma}_{p,\theta,0}(\tau)$ of functions with zero initial conditions. In connection with this it is worth noting that while constructing our theory we could replace

$$||u(0,\cdot)||^p_{U^{\gamma+1}_{p,\theta}} := E||M^{2/p-1}u(0,\cdot)||^p_{H^{\gamma+1-2/p}_{p,\theta}} \tag{2.10}$$

with

$$\inf\{||v_x||^p_{\mathbb{H}^{\gamma+1}_{p,\theta}} + ||M\tilde{\mathbb{D}}v||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}} + ||\tilde{\mathbb{S}}v||^p_{\mathbb{H}^{\gamma}_{p,\theta}} : u - v \in \mathfrak{H}^{\gamma+1}_{p,\theta,0}\}.$$

Such an axiomatic approach to defining a norm of $u(0,\cdot)$ yields, of course, the solvability results for the widest possible class of initial data, namely, for those which are extendible at least in some way for $t > 0$. However, in applications we often want to know how to describe "admissible" initial data by knowing only their analytic properties. A partial answer to this question is given in the following theorem, which also shows why we use the norm given by (2.10).

THEOREM 2.13. *If $0 < \theta < p$ and $\gamma = 2$ and $1 < p < \infty$, then for every u_0 satisfying $M^{2/p-1}u_0 \in H^{\gamma-2/p}_{p,\theta}$ there exists a deterministic $u \in \mathfrak{H}^{\gamma}_{p,\theta}$ such that $du = D^2u\,dt$, $u|_{t=0} = u_0$, and*

$$||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}} \le N(p,\gamma,\theta)||M^{2/p-1}u_0||^p_{H^{\gamma-2/p}_{p,\theta}}. \tag{2.11}$$

Proof. If $u_0 \in C_0^\infty(\mathbb{R}_+)$, then there is a unique function $u(t,x)$ which is bounded in $\mathbb{R}^2_+$ together with all its derivatives and which is a unique bounded solution of the heat equation $\partial u/\partial t = D^2u$, $t > 0$ in $\mathbb{R}^2_+$ with initial condition $u(0,x) = u_0(x)$ and boundary condition $u(t,0) = 0$. Observe that u is given by $u(t,\cdot) = p_t * \bar{u}_0$, where $p_t(x) = (4\pi t)^{-1/2}\exp(-|x|^2/(4t))$ and $\bar{u}_0$ is an odd extension of u_0 on $\mathbb{R}$. By the way, from this representation it follows that $u(t,x) \to 0$ exponentially fast as $x \to \infty$ and the same is true for any derivative of u.

Next, we observe that $\partial|u(t,x)|^p/\partial t = p|u|^{p-2}uD^2u$, multiply this equality by x^c, with $c := \theta + 1 - p \in (1-p, 1)$, and integrate by parts, and also use $|u(t,x)| \le N|x|$, $|u(t,x)|^{p-1}x^c \le Nx^\theta$, $|u(t,x)|^p x^{c-1} \le Nx^\theta$ for x close to zero. Finally we fix $T \in (0,\infty)$ and find that

$$\begin{aligned}\int_{\mathbb{R}_+} x^c|u(T,x)|^p\,dx - \int_{\mathbb{R}_+} x^c|u_0(x)|^p\,dx &= \int_0^T\int_{\mathbb{R}_+} px^c|u|^{p-2}uD^2u\,dxdt \\ &= -c\int_0^T\int_{\mathbb{R}_+} x^{c-1}D(|u|^p)\,dxdt - p(p-1)I = c(c-1)J - p(p-1)I,\end{aligned} \tag{2.12}$$

where

$$I := \int_0^T\int_{\mathbb{R}_+} x^c|u|^{p-2}(Du)^2\,dxdt, \quad J := \int_0^T\int_{\mathbb{R}_+} x^{c-2}|u|^p\,dxdt.$$

To estimate I from below through J, denote $v := |u|^{p/2}$ and observe that we have $|u|^{p-2}(Du)^2 = (2/p)^2(Dv)^2$ and by Minkowski's inequality

$$\int_0^\infty x^{c-2}|u|^p\,dx = \int_0^\infty x^{c-2}v^2\,dx = \int_0^\infty x^c\left(\int_0^1 v'(yx)\,dy\right)^2 dx$$

$$\le \left(\int_0^1 dy\left(\int_0^\infty x^c(v'(yx))^2\,dx\right)^{1/2}\right)^2 = \int_0^\infty x^c(v'(x))^2\,dx\left(\int_0^1 y^b\,dy\right)^2,$$

where $b = -1/2 - c/2 > -1$. By evaluating the last integral we get

$$\int_0^\infty x^{c-2}|u|^p\,dx \le p^2(1-c)^{-2}\int_0^\infty x^c|u|^{p-2}(Du)^2\,dx. \tag{2.13}$$

Hence $p(p-1)I \ge q^{-1}(1-c)^2 J$, where $1/q = 1 - 1/p$, and from (2.12) we get

$$[q^{-1}(1-c)^2 - c(c-1)]J \le \int_{\mathbb{R}_+} x^c|u_0(x)|^p\,dx = ||M^{2/p-1}u_0||^p_{L_{p,\theta}}. \tag{2.14}$$

Here $L_{p,\theta} \supset H^{2-2/p}_{p,\theta}$ with the corresponding inequality for the norms since $2-2/p > 0$. Also, one can easily check that $q^{-1}(1-c)^2 - c(c-1) > 0$ for $0 < \theta < p$ and therefore, after passing to the limit as $T \to \infty$, we obtain the following intermediate estimate:

$$\int_0^\infty ||M^{-1}u(t,\cdot)||^p_{L_{p,\theta}}\,dt \le N||M^{2/p-1}u_0||^p_{H^{2-2/p}_{p,\theta}}. \tag{2.15}$$

An attentive reader might have noticed that the above derivation of (2.13) and (2.15) falls into some trouble if $1 < p < 2$. Indeed, then we get terms containing $|u|$ to a negative power and also the absolute continuity of v is not clear. However, the following fact is true even if $1 < p < 2$:

(i) the functions $|u|^{p/2}$ and $|u|^{p-2}uu_x$ are absolutely continuous on $\mathbb{R}$;

(ii) almost everywhere on $\mathbb{R}$ ($\infty \cdot 0 := 0$)

$$(|u|^{p/2})_x = \tfrac{p}{2}|u|^{p/2-2}uu_x,$$

$$(|u|^{p-2}uu_x)_x = |u|^{p-2}uu_{xx} + (p-1)|u|^{p-2}(u_x)^2.$$

Above we have only used this fact. However, we do not prove (i) and (ii). Instead, we show how to get (2.15) for $1 < p < 2$ by using an approximation argument.

For $\varepsilon > 0$ define $G_\varepsilon(s) = (s^2+\varepsilon)^{p/2} - \varepsilon^{p/2}$. As it is easy to see, we have $|G_\varepsilon(u)| \le (1+\varepsilon^{p/2})|u|^p$ and, for $|u| \le 1$,

$$|G'_\varepsilon(u)| = p(u^2+\varepsilon)^{p/2-1}|u| \le N(\varepsilon)|u| \le N(\varepsilon)|u|^{p-1}.$$

Also $G''_\varepsilon \ge 0$. Hence, owing to $\partial G_\varepsilon(u)/\partial t = G'_\varepsilon(u)D^2u$ and introducing

$$v(t,x) := \int_0^{u(t,x)} (G''_\varepsilon(s))^{1/2}\,ds,$$

we get as above

$$\int_{\mathbb{R}_+} x^c G_\varepsilon(u(T,x))\,dx - \int_{\mathbb{R}_+} x^c G_\varepsilon(u_0(x))\,dx$$

$$= c(c-1)\int_0^T\int_{\mathbb{R}_+} x^{c-2}G_\varepsilon(u)\,dxdt - \int_0^T\int_{\mathbb{R}_+} x^c(v')^2\,dxdt$$

$$\le c(c-1)\int_0^T\int_{\mathbb{R}_+} x^{c-2}G_\varepsilon(u)\,dxdt - 4^{-1}(1-c)^2\int_0^T\int_{\mathbb{R}_+} x^{c-2}v^2\,dxdt.$$

By letting $\varepsilon \downarrow 0$, noticing that $\lim_{\varepsilon \downarrow 0} G''_\varepsilon(s) = p(p-1)|s|^{p-2}$ and $c < 1$, and using Fatou's lemma, we again arrive at (2.14) and (2.15).

Next, take a function $\zeta \in C_0^\infty(\mathbb{R}_+)$ and notice that for $u_n(t,x) := u(e^{2n}t, e^n x)$ we have

$$\frac{\partial}{\partial t}(\zeta u_n) = (\zeta u_n)_{xx} - 2(\zeta_x u_n)_x + \zeta_{xx} u_n. \tag{2.16}$$

Hence by inequalities (IV.3.1) and (IV.3.2) in [9] (also see Remark 2.3.2 in [13]) for any n we obtain

$$\int_0^\infty ||(\zeta u_n)_{xx}(t,\cdot)||^p_{H_p^{-1}}\,dt \le N||\zeta u_n(0,\cdot)||^p_{H_p^{1-2/p}}$$

$$+\int_0^\infty ||((2\zeta_x u_n)_x - \zeta_{xx}u_n)(t,\cdot)||^p_{H_p^{-1}}\,dt.$$

We make the change of variable t replacing it with $e^{2n}t$; then we multiply through the inequality by $e^{2n-np+\theta n}$ and observe that by Remark 1.6

$$||(\zeta u_n)_{xx}||_{H_p^{-1}} \ge N||(\zeta u_n)_x||_{L_p} \ge N||\zeta u_{nx}||_{L_p} - N||\zeta_x u_n||_{L_p},$$

where $N = N(\zeta, p)$. Also use the fact that

$$||(2\zeta_x u_n)_x - \zeta_{xx}u_n||_{H_p^{-1}} \le 2||(\zeta_x u_n)_x||_{H_p^{-1}} + N||\zeta_{xx}u_n||_{L_p} \le N||\eta u_n||_{L_p},$$

where $N = N(\zeta, p, \eta)$ and η is a more or less arbitrary function of class $C_0^\infty(\mathbb{R}_+)$ with support covering that of ζ.

Then we get

$$\int_0^\infty \sum_n e^{\theta n}||\zeta u_x(t,e^n\cdot)||^p_{L_p}\,dt \le N\sum_n e^{\theta n}||\xi(M^{2/p-1}u_0)(e^n\cdot)||^p_{H_p^{1-2/p}}$$

$$+N\int_0^\infty \sum_n e^{\theta n}||\eta_1 M^{-1}u(t,e^n\cdot)||^p_{L_p}\,dt,$$

where $\xi = M^{1-2/p}\zeta$ and η_1 is a function of type η. For the right choice of ζ we rewrite the last inequality as

$$\int_0^\infty ||u_x(t,\cdot)||^p_{L_{p,\theta}}\,dt \le N||M^{2/p-1}u_0||^p_{H^{1-2/p}_{p,\theta}} + N\int_0^\infty ||M^{-1}u(t,\cdot)||^p_{L_{p,\theta}}\,dt. \tag{2.17}$$

Next, we use (2.16) and inequalities (IV.3.1) and (IV.3.2) in [9] to write

$$\int_0^\infty ||(\zeta u_n)_{xx}(t,\cdot)||^p_{L_{p,\theta}}\,dt \le N||\zeta u_n(0,\cdot)||^p_{H_p^{2-2/p}}$$

$$+\int_0^\infty ||((2\zeta_x u_n)_x - \zeta_{xx}u_n)(t,\cdot)||^p_{L_{p,\theta}}\,dt.$$

If η_1 and η_2 are functions of class $C_0^\infty(\mathbb{R}_+)$ with supports covering that of ζ, then, for the same reasons as before, this inequality yields

$$\int_0^\infty ||\zeta u_{nxx}(t,\cdot)||^p_{L_{p,\theta}}\,dt \le N||\zeta u_n(0,\cdot)||^p_{H_p^{2-2/p}}$$

$$+\int_0^\infty ||\eta_1 u_{nx}(t,\cdot)||^p_{L_{p,\theta}}\,dt + \int_0^\infty ||\eta_2 u_n(t,\cdot)||^p_{L_{p,\theta}}\,dt,$$

and

$$\int_0^\infty ||Mu_{xx}(t,\cdot)||^p_{L_{p,\theta}}\,dt \le N||M^{2/p-1}u_0||^p_{H^{2-2/p}_{p,\theta}}$$

$$+N\int_0^\infty ||u_x(t,\cdot)||^p_{L_{p,\theta}}\,dt + N\int_0^\infty ||M^{-1}u(t,\cdot)||^p_{L_{p,\theta}}\,dt.$$

Together with (2.15), (2.17), and the equation $\partial u/\partial t = M^{-1}(Mu_{xx})$ the last inequality implies that $u \in \mathfrak{H}^2_{p,\theta}$ and that (2.11) holds with $\gamma = 2$.

Actually, above we have constructed a mapping $u_0 \in C_0^\infty(\mathbb{R}_+) \to u \in \mathfrak{H}^\gamma_{p,\theta}$. If we introduce an operator $\Pi : u_0 \to u$, then what is proved means that (for $\gamma = 2$)

$$||\Pi u_0||_{\mathfrak{H}^\gamma_{p,\theta}} \le N(p,\theta)||M^{2/p-1}u_0||_{H^{\gamma-2/p}_{p,\theta}} \tag{2.18}$$

if $u_0 \in C_0^\infty(\mathbb{R}_+)$. Remembering that $\mathfrak{H}^\gamma_{p,\theta}$ is a Banach space and relying on the usual continuity argument based on (2.18), we see that Π can be extended on all u_0 satisfying $M^{2/p-1}u_0 \in H^{\gamma-2/p}_{p,\theta}$ in such a way that $\partial \Pi u_0/\partial t = D^2\Pi u_0$, $\Pi u_0|_{t=0} = u_0$, and (2.18) holds. The theorem is proved.

Remark 2.14. We will see from Theorem 3.2 that Theorem 2.13 holds for any $\gamma \in \mathbb{R}$ and the solution is unique in $\mathfrak{H}^\gamma_{p,\theta}$.

In connection with this it is interesting to notice that Theorem 2.13 without weights and on $\mathbb{R}$ instead of $\mathbb{R}_+$ cannot hold for all $1 < p < 2$ if $\gamma = 1$. For instance, if $1 < p < 3/2$, then, for the solution u of the equation $du = D^2u\,dt$, $t > 0$, $x \in \mathbb{R}$, with initial condition given by the delta function, we have $u(0,\cdot) \in H_p^{1-2/p}$, but the pth power of the function u_x is not integrable over $\mathbb{R}^+ \times \mathbb{R}$.

3. SPDEs with constant coefficients on $\mathbb{R}_+$. Take a stopping time τ. On $\mathbb{R}_+$ we will be dealing with the following equation:

$$du = (au_{xx} + f_x)\,dt + (\sigma^k u_x + g^k)\,dw_t^k, \quad t \in (0,\tau), \tag{3.1}$$

where f and g^k are given $\mathcal{D}(\mathbb{R}_+)$-valued $\mathcal{P}$-measurable functions, a and σ^k are given real-valued $\mathcal{P}$-measurable functions, u is an unknown $\mathcal{D}(\mathbb{R}_+)$-valued function, and the equation is understood in the sense of distributions as follows. We say that u is a solution of (3.1) with given initial condition u_0 if for any test function $\phi \in C_0^\infty(\mathbb{R}_+)$ we have

$$\begin{aligned}(u(t,\cdot),\phi) &= (u_0,\phi)\\ &\quad + \int_0^t [a(s)(u(s,\cdot),\phi_{xx}) - (f(s,\cdot),\phi_x)]\,ds\\ &\quad + \sum_{k=1}^\infty \int_0^t [-\sigma^k(s)(u,\phi_x) + (g^k,\phi)]\,dw_t^k\end{aligned} \tag{3.2}$$

for all $t \leq \tau$ with probability one, where all integrals are assumed to have sense and the last series is also assumed to converge uniformly on each interval of time $[0, T \wedge \tau]$ in probability, where T is any finite constant.

Remark 3.1. If a function u belongs to $\mathfrak{H}^{\gamma+1}_{p,\theta}(\tau)$, then it satisfies (3.1) with $f = (MD)^{-1}M\tilde{\mathbb{D}}u - aDu$ and $g^k = \tilde{\mathbb{S}}^k u - \sigma^k Du$. In addition (see Remark 1.5), we have $f \in \mathbb{H}^{\gamma}_{p,\theta}(\tau)$ and $g \in \mathbb{H}^{\gamma}_{p,\theta}(\tau, l_2)$. Below we show that under an additional assumption on a and σ the mapping $u \to (f, g)$ is onto.

We always assume that for some constants $K \geq \delta > 0$ and all ω, t we have

$$K \geq 2a \geq 2a - |\sigma|^2_{l_2} \geq \delta.$$

Here is the main result of this section.

THEOREM 3.2. (i) *Let* $0 < \theta < p$, $1 < p < \infty$, $\gamma \in \mathbb{R}$, $f \in \mathbb{H}^{\gamma}_{p,\theta}(\tau)$, $g \in \mathbb{H}^{\gamma}_{p,\theta}(\tau, l_2)$, *and* $u_0 \in U^{\gamma+1}_{p,\theta}$. (ii) *Assume that one of the following conditions is satisfied:*

(a) $p \geq 2$ *and* $\theta \in [p-1, p)$;

(b) $p \geq 2$ *and* $\sigma \equiv 0$;

(c) $\sigma \equiv 0$ *and* $g \equiv 0$.

Then (3.1) *with initial data* u_0 *has a unique solution in class* $\mathfrak{H}^{\gamma+1}_{p,\theta}(\tau)$. *In addition, for this solution it holds that*

$$||u||_{\mathfrak{H}^{\gamma+1}_{p,\theta}(\tau)} \leq N\big(||f||_{\mathbb{H}^{\gamma}_{p,\theta}(\tau)} + ||g||_{\mathbb{H}^{\gamma}_{p,\theta}(\tau,l_2)} + ||u_0||_{U^{\gamma+1}_{p,\theta}}\big), \tag{3.3}$$

where $N = N(\gamma, \theta, p, K, \delta)$. *Finally, the uniqueness holds even if we replace condition* (a) *with:* $p \geq 2$ *and* $\theta \in (0, p)$.

Remark 3.3. In a subsequent paper on equations in $\mathbb{R}^d_+$ we will show that condition (a) can be relaxed to be $p \geq 2$ and $1 \leq \theta < p$. This could be done here too if one uses interpolation with respect to θ and the result of [7], where the case $\theta = 1$ is treated. However, there is a small gap in the arguments proving (2.9) of [7], so that strictly speaking we cannot use the result of [7].

Remark 3.4. Notice that when conditions (b) or (c) are satisfied, θ may be any number in $(0, p)$.

It is also worth noting that if $\theta \geq p$ or $\theta \leq 0$, then the statement of Theorem 3.2 is false even in the case of the heat equation. This can be shown by simple examples.

The proof of this theorem is based on two lemmas, the first of which we prove in section 4.

LEMMA 3.5. *Theorem* 3.2 *holds if* $\gamma = 1$.

LEMMA 3.6. *Let assumption* (i) *of Theorem* 3.2 *be satisfied and let* $\mu \leq \gamma$. *Assume that either* $p \geq 2$ *or* $\sigma \equiv g \equiv 0$. *Let* $\theta_1 \in \mathbb{R}$ *and let* $u \in \mathfrak{H}^{\mu+1}_{p,\theta_1}(\tau)$ *be a solution of* (3.1) *with initial condition* u_0. *Assume that* $M^{-1}u \in \mathbb{H}^{\mu+1}_{p,\theta}(\tau)$. *Then* $u \in \mathfrak{H}^{\gamma+1}_{p,\theta}(\tau)$ *and*

$$||u||_{\mathfrak{H}^{\gamma+1}_{p,\theta}(\tau)} \leq N\big(||f||_{\mathbb{H}^{\gamma}_{p,\theta}(\tau)} + ||g||_{\mathbb{H}^{\gamma}_{p,\theta}(\tau,l_2)} + ||u_x||_{\mathbb{H}^{\mu}_{p,\theta}(\tau)} + ||u_0||_{U^{\gamma+1}_{p,\theta}}\big),$$

where $N = N(\gamma, \mu, \theta, p)$.

Proof. For simplicity of notation we will only consider the case $\tau \equiv \infty$. The reader can easily make the necessary changes for general τ.

By virtue of (3.2) we have (2.2) with $x(au_{xx} + f_x)$ instead of f and $\sigma^k u_x + g^k$ instead of g^k. Upon taking into account the assumptions on f and g and remembering Remark 1.5, we conclude that we only need to prove that

$$||u_x||^p_{\mathbb{H}^{\gamma}_{p,\theta}} \leq N(||f||^p_{\mathbb{H}^{\gamma}_{p,\theta}} + ||g||^p_{\mathbb{H}^{\gamma}_{p,\theta}(l_2)} + ||u_x||^p_{\mathbb{H}^{\mu}_{p,\theta}} + ||u_0||^p_{U^{\gamma+1}_{p,\theta}}). \tag{3.4}$$

Since $||u_x||_{\mathbb{H}^\nu_{p,\theta}} \le ||u_x||_{\mathbb{H}^\mu_{p,\theta}}$ for $\nu \le \mu$, it suffices to prove (3.4) with some $\nu \le \mu$ in place of μ. This shows that we may assume that $\gamma - \mu$ is an integer. Also we can go from μ up to γ in several steps each time getting an increase by one. Therefore, without loss of generality we may and will assume that $\gamma = \mu + 1$, so that (3.4) becomes

$$||u_x||^p_{\mathbb{H}^\gamma_{p,\theta}} \le N(||f||^p_{\mathbb{H}^\gamma_{p,\theta}} + ||g||^p_{\mathbb{H}^\gamma_{p,\theta}(l_2)} + ||u_x||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}} + ||u_0||^p_{U^{\gamma+1}_{p,\theta}}). \tag{3.5}$$

Take a function $\zeta \in C_0^\infty(\mathbb{R}_+)$ with $M\zeta$ satisfying condition (1.4). One can easily check that the functions $u_n(t,x) := u(e^{2n}t, e^n x)$ satisfy the equation

$$du_n = (a_n u_{nxx} + f_n)\,dt + (\sigma^k_n u_{nx} + g^k_n)\,dw^k_t(n), \tag{3.6}$$

where

$$a_n(t) = a(e^{2n}t), \quad \sigma^k_n(t) = \sigma^k(e^{2n}t), \quad w^k_t(n) = e^{-n} w_{e^{2n}t},$$

$$f_n(t,x) = e^{2n}(f_x)(e^{2n}t, e^n x), \quad g^k_n(t,x) = e^n g^k(e^{2n}t, e^n x).$$

Observe that for any n, the processes $w^k_t(n)$ are independent Wiener processes. From (3.6) we get

$$d(\zeta u_n) = (a_n(\zeta u_n)_{xx} + \bar f_n)\,dt + (\sigma^k_n(\zeta u_n)_x + \bar g^k_n)\,dw^k_t(n), \tag{3.7}$$

where

$$\bar f_n = \zeta f_n - 2a_n \zeta_x u_{nx} - a_n \zeta_{xx} u_n, \quad \bar g^k_n = \zeta g^k_n - \sigma^k_n \zeta_x u_n.$$

Since $M^{-1}u \in \mathbb{H}^\gamma_{p,\theta}$, it is easy to see that for any $\eta \in C_0^\infty(\mathbb{R}_+)$ we have $\eta u_n \in \mathbb{H}^\gamma_p$ and $\eta u_{nx} \in \mathbb{H}^{\gamma-1}_p$, so that $\bar f_n \in \mathbb{H}^{\gamma-1}_p$ and $\bar g_n \in \mathbb{H}^\gamma_p(l_2)$. By Theorem 2.1 of [5] or Theorem 4.10 of [8] for $p \ge 2$ (with uniqueness in $\mathcal{H}^\gamma_p(\tau)$ and existence in $\mathcal{H}^{\gamma+1}_p(\tau)$, here we use $\zeta u_n \in \mathcal{H}^\gamma_p(\tau)$), (3.7) implies that

$$||(\zeta u_n)_{xx}||^p_{\mathbb{H}^{\gamma-1}_p} \le N(||\bar f_n||^p_{\mathbb{H}^{\gamma-1}_p} + ||\bar g_n||^p_{\mathbb{H}^\gamma_p(l_2)} + E||\zeta u_0(e^n\,\cdot)||^p_{H^{\gamma+1-2/p}_p}), \tag{3.8}$$

where $u_{0n}(x) = u_0(e^n x)$. Actually, Theorem 2.1 of [5] or Theorem 4.10 of [8] treats the case $u_0 = 0$. One deals with arbitrary u_0 as in the beginning of the proof of Theorem 5.1 of [8] by just subtracting the solution of the heat equation $\partial v/\partial t = v_{xx}$ with initial condition u_0. Owing to the fact that supports of all functions ζu_n coincide with that of ζ, from (3.8) by Remark 1.6, we get

$$||\zeta u_n||^p_{\mathbb{H}^{\gamma+1}_p} \le N(||\bar f_n||^p_{\mathbb{H}^{\gamma-1}_p} + ||\bar g_n||^p_{\mathbb{H}^\gamma_p(l_2)} + E||\zeta u_0(e^n\,\cdot)||^p_{H^{\gamma+1-2/p}_p}). \tag{3.9}$$

The same conclusions are true if $1 < p < 2$ and $\sigma \equiv g \equiv 0$, which can be seen from section 9, Chapter IV of [9] or from the proof of Theorem 2.1 of [5] or Theorem 4.10 of [8], where one can take any $p \in (1,\infty)$ if $\sigma \equiv g \equiv 0$. In particular, in all cases $\zeta u_n \in \mathbb{H}^{\gamma+1}_p$ and (3.9) holds.

Now we multiply (3.9) through by $e^{(2-p+\theta)n}$ and sum up over all n. We also use

$$\sum_{n=-\infty}^{\infty} e^{(2-p+\theta)n}||\zeta f_n||^p_{\mathbb{H}^{\gamma-1}_p} = \sum_{n=-\infty}^{\infty} e^{(2-p+\theta)n}||e^{2n}(f_x)(e^{2n}\cdot, e^n\cdot)\zeta||^p_{\mathbb{H}^{\gamma-1}_p}$$

$$= \sum_{n=-\infty}^{\infty} e^{\theta n}||e^n(f_x)(\cdot, e^n\cdot)\zeta||^p_{\mathbb{H}^{\gamma-1}_p} = \sum_{n=-\infty}^{\infty} e^{\theta n}||(Mf_x)(\cdot, e^n\cdot)M^{-1}\zeta||^p_{\mathbb{H}^{\gamma-1}_p}$$

$$\leq N||Mf_x||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}} \leq N||f||^p_{\mathbb{H}^{\gamma}_{p,\theta}},$$

$$\sum_{n=-\infty}^{\infty} e^{(2-p+\theta)n}||\zeta g_n||^p_{\mathbb{H}^{\gamma}_p(l_2)} = \sum_{n=-\infty}^{\infty} e^{\theta n}||g(\cdot, e^n\cdot)\zeta||^p_{\mathbb{H}^{\gamma}_p(l_2)} \leq N||g||^p_{\mathbb{H}^{\gamma}_{p,\theta}(l_2)},$$

$$\sum_{n=-\infty}^{\infty} e^{(2-p+\theta)n}||\zeta_x u_{nx}||^p_{\mathbb{H}^{\gamma-1}_p} = \sum_{n=-\infty}^{\infty} e^{(2-p+\theta)n}||e^n(u_x)(e^{2n}\cdot, e^n\cdot)\zeta_x||^p_{\mathbb{H}^{\gamma-1}_p}$$

$$= \sum_{n=-\infty}^{\infty} e^{\theta n}||(u_x)(\cdot, e^n\cdot)\zeta_x||^p_{\mathbb{H}^{\gamma-1}_p} \leq N||u_x||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}},$$

$$\sum_{n=-\infty}^{\infty} e^{(2-p+\theta)n}||\zeta_{xx} u_n||^p_{\mathbb{H}^{\gamma-1}_p} = \sum_{n=-\infty}^{\infty} e^{\theta n}||(M^{-1}u)(\cdot, e^n\cdot)M\zeta_{xx}||^p_{\mathbb{H}^{\gamma-1}_p}$$

$$\leq N||M^{-1}u||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}} \leq N||u_x||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}}.$$

Similarly, we estimate $\zeta_x u_n$, we notice that

$$\begin{aligned}\sum_n e^{(2-p+\theta)n} E||\zeta u_0(e^n\cdot)||^p_{H^{\gamma+1-2/p}_p} &= \sum_n e^{\theta n} E||(M^{2/p-1}u_0)(e^n\cdot)M^{1-2/p}\zeta||^p_{H^{\gamma+1-2/p}_p} \\ &\leq NE||M^{2/p-1}u_0||^p_{H^{\gamma+1-2/p}_{p,\theta}} = N||u_0||^p_{U^{\gamma+1}_{p,\theta}},\end{aligned}$$

and we get

$$\sum_{n=-\infty}^{\infty} e^{(2-p+\theta)n}||\zeta u_n||^p_{\mathbb{H}^{\gamma+1}_p} \leq I,$$

where I is the right-hand side of (3.5). Here the left-hand side equals

$$\sum_{n=-\infty}^{\infty} e^{\theta n}||(M^{-1}u)(\cdot, e^n\cdot)M\zeta||^p_{\mathbb{H}^{\gamma+1}_p} \geq N^{-1}||M^{-1}u||^p_{\mathbb{H}^{\gamma+1}_{p,\theta}} \geq N^{-1}||u_x||^p_{\mathbb{H}^{\gamma}_{p,\theta}}$$

and the lemma is proved.

Proof of Theorem 3.2. For simplicity of notation we only consider the case $\tau \equiv \infty$. Actually, as it is easy to see, the statement of existence for $\tau \equiv \infty$ implies the statement of existence for other τ, and the proof of uniqueness for general τ can be done in the same way as in the case $\tau \equiv \infty$.

Case $\gamma \geq 1$. The uniqueness follows from Lemma 3.5 and the fact that $\mathfrak{H}^2_{p,\theta,0} \supset \mathfrak{H}^{\gamma+1}_{p,\theta,0}$, which implies that the difference of two solutions belongs to $\mathfrak{H}^2_{p,\theta,0}$. The existence and estimate (3.3) follow from Lemmas 3.5 and 3.6 (applied with $\mu = 1$) and the observation that by Lemma 3.5

$$||u_x||^p_{\mathbb{H}^1_{p,\theta}} \leq N(||f||^p_{\mathbb{H}^1_{p,\theta}} + ||g||^p_{\mathbb{H}^1_{p,\theta}(l_2)} + ||u_0||^p_{U^2_{p,\theta}})$$

$$\leq N(||f||^p_{\mathbb{H}^\gamma_{p,\theta}} + ||g||^p_{\mathbb{H}^\gamma_{p,\theta}(l_2)} + ||u_0||^p_{U^{\gamma+1}_{p,\theta}}).$$

Case $\gamma < 1$. Denote by $\mathcal{R}$ the operator which maps (f, g, u_0) with $f \in \mathbb{H}^\gamma_{p,\theta}$, $g \in \mathbb{H}^\gamma_{p,\theta}(l_2)$, and $u_0 \in U^{\gamma+1}_{p,\theta}$ into the solution $u \in \mathfrak{H}^{\gamma+1}_{p,\theta}$ of (3.1) with initial data u_0. So far we know that $\mathcal{R}$ is well defined in spaces $\mathbb{H}^\gamma_{p,\theta} \times \mathbb{H}^\gamma_{p,\theta}(l_2) \times U^{\gamma+1}_{p,\theta}$ for $\gamma \geq 1$. If $\gamma < 1$, as a candidate for the solution of (3.1) we try

$$\tilde{u} = \Lambda^n_{p,\theta}\mathcal{R}(\Lambda^{-n}_{p,\theta}f, \Lambda^{-n}_{p,\theta}g, M^{1-2/p}\Lambda^{-n}_{p,\theta}M^{2/p-1}u_0),$$

where $n + \gamma \geq 1$ and (see Remark 1.3)

$$(\Lambda^{-n}_{p,\theta}f, \Lambda^{-n}_{p,\theta}g, M^{1-2/p}\Lambda^{-n}_{p,\theta}M^{2/p-1}u_0) \in \mathbb{H}^{n+\gamma}_{p,\theta} \times \mathbb{H}^{n+\gamma}_{p,\theta}(l_2) \times U^{n+\gamma+1}_{p,\theta}.$$

If the operators $\Lambda_{p,\theta}$, $M^{2/p-1}$, and D were commuting, then our candidate would be an exact solution of (3.1). Since this is not the case, we need an additional argument based on Lemma 1.14.

Take $n = 2$ and first let $1 > \gamma \geq 0$. Then by what we know in the case $\gamma \geq 1$, we have

$$v := \mathcal{R}(\Lambda^{-2}_{p,\theta}f, \Lambda^{-2}_{p,\theta}g, M^{1-2/p}\Lambda^{-2}_{p,\theta}M^{2/p-1}u_0) \in \mathfrak{H}^{\gamma+3}_{p,\theta},$$

$$dv = (av_{xx} + (\Lambda^{-2}_{p,\theta}f)_x)\,dt + (\sigma^k v_x + \Lambda^{-2}_{p,\theta}g^k)\,dw^k_t.$$

We apply $\Lambda^2_{p,\theta}$ to both parts of this equality, or in other words we substitute $(\Lambda^2_{p,\theta})^*\phi$, where $(\Lambda^2_{p,\theta})^*$ is the formal adjoint to $\Lambda^2_{p,\theta}$, in place of ϕ in (3.2). Now our candidate becomes

$$\tilde{u} = \Lambda^2_{p,\theta}v.$$

We claim that $\tilde{u}$ belongs to $\mathfrak{H}^{\gamma+1}_{p,\theta}$ and there exists

$$(\bar{f}, \bar{g}, \bar{u}_0) \in \mathbb{H}^{\gamma+1}_{p,\theta} \times \mathbb{H}^{\gamma+1}_{p,\theta}(l_2) \times U^{\gamma+2}_{p,\theta} \tag{3.10}$$

such that

$$d\tilde{u} = (a\tilde{u}_{xx} + f_x + \bar{f}_x)\,dt + (\sigma^k\tilde{u}_x + g^k + \bar{g}^k)\,dw^k_t, \tag{3.11}$$

$$\tilde{u}(0, \cdot) = u_0 + \bar{u}_0.$$

Indeed, by Remarks 2.4 and 2.8 and Lemma 1.14 we easily get that

$$\tilde{u} \in \mathfrak{H}^{\gamma+1}_{p,\theta}, \quad M^{-1}v \in \mathbb{H}^{\gamma+3}_{p,\theta}, \quad M^{-1}\tilde{u} = \Lambda^2_{p,\theta}M^{-1}v + P_1 M^{-1}v \in \mathbb{H}^{\gamma+1}_{p,\theta},$$

$$D\tilde{u} = \Lambda^2_{p,\theta}Dv + P_1 Dv \in \mathbb{H}^{\gamma}_{p,\theta}$$

and that $\tilde{u}$ satisfies (3.11) with

$$\bar{f} = 4P_2 M^{-1}v + ((2b-1)I + 2MD)\Lambda^{-2}_{p,\theta}f, \quad \bar{g}^k = \sigma^k P_1 Dv.$$

Obviously, $\bar{f}$ and $\bar{g}$ are as in (3.10). Also by Lemma 1.14 at $t = 0$,

$$M^{2/p-1}\tilde{u} = M^{2/p-1}\Lambda^2_{p,\theta}M^{1-2/p}(M^{2/p-1}v)$$

$$= \Lambda^2_{p,\theta}M^{2/p-1}v + c_1 M^{2/p-1}v + c_2 MDM^{2/p-1}v =: M^{2/p-1}u_0 + M^{2/p-1}\bar{u}_0,$$

where

$$M^{2/p-1}\bar{u}_0 \in L_p(\Omega, \mathcal{F}_0, H^{\gamma+2-2/p}_{p,\theta}).$$

This finishes the proofs of (3.10) and our claim.

Since $\gamma + 1 \geq 1$, it follows from (3.10) that the function $\bar{u} := \mathcal{R}(\bar{f}, \bar{g}, \bar{u}_0)$ is well defined, belongs to $\mathfrak{H}^{\gamma+2}_{p,\theta}$, and the function $u = \tilde{u} - \bar{u}$ is of class $\mathfrak{H}^{\gamma+1}_{p,\theta}$ and solves (3.1). For thus constructed u estimate (3.3) follows from the explicit representation and known estimates for $\mathcal{R}$, P_i, MD.

By repeating the above argument, we consider the case $0 > \gamma \geq -1$, this time using the fact that $\gamma + 1 \geq 0$ and relying upon the result for $\gamma \geq 0$. One can continue in the same way, and it only remains to prove the uniqueness of solutions in $\mathfrak{H}^{\gamma+1}_{p,\theta}$.

It suffices to consider the case $f = 0, g = 0, u_0 = 0$ (and $\gamma < 1$). In this case any solution $u \in \mathfrak{H}^{\gamma+1}_{p,\theta,0}$ also belongs to $\mathfrak{H}^{2}_{p,\theta,0}$ by Lemma 3.6 and its uniqueness follows from Lemma 3.5.

The theorem is thus proved.

Remark 3.7. In the above argument one can use $(MD)^2$ instead of $\Lambda^2_{p,\theta}$, which would make the argument shorter. We prefer $\Lambda^2_{p,\theta}$ bearing in mind a generalization to a multidimensional case.

Remark 3.8. From the above derivation of Theorem 3.2 from Lemma 3.5 it is seen that, if the assertions of Theorem 3.2 hold for some particular γ, p, θ, a, and σ satisfying the conditions of Theorem 3.2, then they hold for any $\gamma \in \mathbb{R}$ with the same p, θ, a, σ.

4. Proof of Lemma 3.5. First notice that by Theorem 2.13 for almost every ω the function $\bar{u} := \Pi u_0$ is well defined, $\bar{u} \in \mathfrak{H}^2_{p,\theta}$, $\bar{u}|_{t=0} = u_0$, $\partial\bar{u}/\partial t = \bar{f}_x$ with $\bar{f} \in \mathbb{H}^1_{p,\theta}$, and an appropriate estimate of $||\bar{u}_x||_{\mathbb{H}^1_{p,\theta}}$ and $||\bar{f}||_{\mathbb{H}^1_{p,\theta}}$ through $||u_0||_{U^2_{p,\theta}}$ holds. This implies that in the equation

$$du = (au_{xx} + (a\bar{u}_x + f - \bar{f})_x)\,dt + (\sigma^k u_x + (\sigma^k \bar{u}_x + g^k))\,dw^k_t$$

we have $a\bar{u}_x + f - \bar{f} \in \mathbb{H}^1_{p,\theta}$ and $\sigma\bar{u}_x + g \in \mathbb{H}^1_{p,\theta}(l_2)$. Also, obviously if we can solve the above equation in $\mathfrak{H}^2_{p,\theta,0}$, then by adding to the solution the function $\bar{u}$ we get a solution of (3.1) with initial data u_0. Therefore, in the proof of Lemma 3.5 without loss of generality, we may and will confine ourselves only to the case $u_0 \equiv 0$.

Furthermore, we may assume that $a \equiv 1$. Indeed, to get the result for the general case one only needs to use a random time change. Namely, let us define

$$\psi(t) = \int_0^t a(s)ds, \quad \tau(t) = \inf\{s \geq 0 : \psi(s) \geq t\},$$

$$\tilde{w}_k(t) = \int_0^{\tau(t)} \sqrt{a(s)}dw_k(s), \quad \tilde{f}(t,x) = f(\tau(t),x)/a(\tau(t)),$$

$$\tilde{\sigma}(t) = \sigma(\tau(t))/\sqrt{a(\tau(t))}, \quad \tilde{g}(t,x) = g(\tau(t),x)/\sqrt{a(\tau(t))},$$

$$\tilde{u}(t,x) = u(\tau(t),x).$$

Direct computations (see, for instance, Lemma IV.2.2 and Theorem IV.2.3 in [3]) show that $\tilde{w}_k(t)$ are independent Wiener processes and also that u is a solution of (3.1) if and only if $\tilde{u}$ is a solution of

$$d\tilde{u} = (\tilde{u}_{xx} + \tilde{f})\,dt + (\tilde{\sigma}_k\tilde{u}_x + \tilde{g}_k)\,d\tilde{w}_k(t).$$

Therefore, we easily get the desired result for general a from the result for $a \equiv 1$. Finally, obviously we may assume that $\tau \leq T$ where the constant $T < \infty$. Thus, we may and will assume that $u_0 = 0$, $a \equiv 1$, and unless stated explicitly otherwise $\tau \leq T$.

We divide the proof of the lemma in this case into the following subcases:

1. $p \geq 2$ and $\theta \in [p-1, p)$, existence;
2. $p \geq 2$ and $\theta \in (0, p)$, uniqueness;
3. $p \geq 2$ and $\sigma \equiv 0$;
4. $\sigma \equiv 0$ and $g \equiv 0$.

4.1. Case $p \geq 2$ and $\theta \in [p-1, p)$. Existence. We use the following simple lemma.

LEMMA 4.1. *Let functions f, h be defined on $\mathbb{R}_+$, be locally absolutely continuous, and satisfy*

$$\int_0^\infty |f(x)g(x)|\,dx < \infty. \tag{4.1}$$

Then

$$\int_0^\infty xf(x)g'(x)\,dx = -\int_0^\infty xf'(x)g(x)\,dx - \int_0^\infty f(x)g(x)\,dx$$

if at least one of the sides of this equality makes sense.

This fact easily follows if one integrates by parts between a, b with $0 < a < b < \infty$ and then lets $a \downarrow 0$ and $b \to \infty$ after noticing that (4.1) implies that

$$\liminf_{a\downarrow 0} |af(a)g(a)| = \liminf_{b\to\infty} |bf(b)g(b)| = 0.$$

Denote by $\mathcal{E}$ the collection of functions of the form

$$f(t,x) = \sum_{i=1}^m I_{(\tau_{i-1},\tau_i]\!]}(t)f_i(x),$$

where $f_i \in C_0^\infty(\mathbb{R}_+)$ and τ_i are stopping times, $\tau_i \le \tau_{i+1} \le \tau$. The set $\mathcal{E}$ is dense in $\mathbb{H}^1_{p,\theta}(\tau)$, which follows from a similar fact for spaces $\mathbb{H}^\gamma_p$ (see [5] or [8]) and the definition of $\mathbb{H}^\gamma_{p,\theta}(\tau)$. Also, the collection of sequences $g = (g_k)$, such that each g_k belongs to $\mathcal{E}$ and only finitely many of g_k are different from 0, is dense in $\mathbb{H}^1_{p,\theta}(\tau, l_2)$. It follows that in the proof of existence and estimate (3.3) we may assume that f and g are of this type.

Next, we use an argument from [7]. We continue $f(t,x)$ to be an even function and $g(t,x)$ to be an odd function of $x \in \mathbb{R}$. Also take an infinitely differentiable odd function $\alpha(x)$ such that $\alpha(x) = 1$ for large x, $\alpha(x) = 0$ for $|x| \le 2$ and on $\mathbb{R}$ consider the equation

$$du = (u_{xx} + f_x)\,dt + (\alpha\sigma^k u_x + g^k)\,dw^k_t. \tag{4.2}$$

The following lemma is proved in the end of this subsection.

LEMMA 4.2. *In $\mathcal{H}^0_p(\tau)$ there exists a unique solution u of* (4.2) *with zero initial condition. Moreover, $u \in \mathfrak{H}^0_{p,\theta}(\tau)$ and*

$$||u||_{\mathfrak{H}^0_{p,\theta}(\tau)} \le N||f||_{\mathbb{H}^1_{p,\theta}(\tau)} + N||g||_{\mathbb{L}_{p,\theta}(\tau,l_2)}, \tag{4.3}$$

where N is independent of τ, f, and g.

Now notice that the equation

$$du = (u_{xx} + f_x)\,dt + (\alpha_n\sigma^k u_x + g^k)\,dw^k_t, \tag{4.4}$$

where $\alpha_n(x) = \alpha(e^n x)$, also has a solution $u \in \mathfrak{H}^0_{p,\theta}(\tau)$ for which (4.3) holds with the same N. To prove this, it suffices to use scaling properties of the norms in $H^\gamma_{p,\theta}$ (see Remark 1.4) and to observe that if u is a solution of (4.2), then the function $u_n(t,x) = u(e^{2n}t, e^n x)$ satisfies (3.6) with the same f_n, g_n, and $w_t(n)$ and with $a_n = 1$ and $\sigma_n(t) = \alpha(e^n x)\sigma(e^{2n}t)$.

Denote u_n the solution of (4.4). Then u_n satisfies (4.3) and, in particular, $M^{-1}u_n$ form a bounded sequence in $\mathbb{L}_{p,\theta}(\tau)$. Denote u a weak limit of a subsequence of u_n. As in the proof of Theorem 3.11 of [8] we get that $u \in \mathfrak{H}^0_{p,\theta}(\tau)$. Then passing to the limit in (4.4) and observing that $\alpha(e^n x) \to 1$ for $x > 0$, we get that u satisfies (3.1) and estimate (4.3). It follows from Lemma 3.6 that $u \in \mathfrak{H}^2_{p,\theta}(\tau)$ and (3.3) holds with $\gamma = 1$ and $u_0 = 0$. This finishes the proof of existence.

Proof of Lemma 4.2. The existence and uniqueness of solution $u \in \mathcal{H}^1_p(\tau)$ of (4.2) is asserted in Theorem 3.2 of [5] or Theorem 5.1 of [8]. Therefore, we only need to prove that $u \in \mathfrak{H}^0_{p,\theta}(\tau)$ and that (4.3) holds.

By the definition of the norm in $\mathfrak{H}^\gamma_{p,\theta}(\tau)$ and by Remarks 2.4 and 2.7, it is sufficient to show that $M^{-1}u \in \mathbb{L}_{p,\theta}(\tau)$ and

$$||M^{-1}u||^p_{\mathbb{L}_{p,\theta}(\tau)} \le N||f||^p_{\mathbb{H}^1_{p,\theta}(\tau)} + N||g||^p_{\mathbb{L}_{p,\theta}(\tau,l_2)}. \tag{4.5}$$

Owing to our choice of f and g, from [5] or [8] we know that $u \in \mathcal{H}^\gamma_p(\tau)$ for any γ and, in particular, for almost any ω, the function $u(t,x)$ is infinitely differentiable with respect to x and all its derivatives are continuous in t. This implies that (4.2) holds pointwise (a.s.). In addition, by uniqueness the function $u(t,x)$ is odd with respect to x, so that, in particular, $u(t,0) = 0$.

Again by choice of f and g, the function u satisfies the heat equation $u_t = u_{xx}$ for $0 < x < 2$ with zero initial and zero boundary value for $x = 0$. If we set $u(t,x) = 0$

for $t<0$, then it satisfies the heat equation for all $t\leq T$ and $0<x<2$. For such functions it is well known (see, for instance, the maximum principle and Theorem 8.4.4 in [4]) that for any integer $n\geq 0$,

$$\sup_{0<x<1,t\leq T}|D^nu(t,x)|\leq N(n)\sup_{t\leq T}|u(t,2)|.$$

Therefore, for $\theta>0$,

$$E\int_0^\tau\int_0^1|u/x|^px^{\theta-1}\,dxdt\leq NE\sup_{0<x<1,t\leq T}|u_x|^p\leq NE\sup_{t\leq\tau}|u(t,2)|^p.$$

In addition, as has been mentioned above, we have $u\in\mathcal{H}^\gamma_p(\tau)$ for any γ. By embedding theorems (see [5] or [8])

$$E\sup_{[0,\tau]\times\mathbb{R}_+}|u|^p<\infty,$$

which proves that, for any $\theta>0$, we have $M^{-1}u\eta\in\mathbb{L}_{p,\theta}(\tau)$ if $\eta=\eta(x)$ is smooth and vanishes for $x\geq 1$. In the same way it is proved that for any integer $n\geq 0$ and $\theta>0$,

$$E\int_0^\tau\int_0^1|D^nu|^px^{\theta-1}\,dxdt<\infty. \tag{4.6}$$

On the other hand, $|M^{-1}u|^px^{\theta-1}\leq|u|^p$ if $x\geq 1$ and $\theta\leq p+1$. Hence, $M^{-1}u\in\mathbb{L}_{p,\theta}(\tau)$ not only for $\theta\in[p-1,p)$ but for all $\theta\in(0,p+1]$.

Next, we claim that, actually, for any $\theta\in(0,p+1]$ and $\gamma\geq 0$, we have

$$u\in\mathfrak{H}^\gamma_{p,\theta}(\tau). \tag{4.7}$$

To prove this claim, let $\zeta\in C^\infty(\mathbb{R})$ be such that $\zeta(x)=1$ for $x\leq 1/2$ and $\zeta(x)=0$ for $x\geq 1$. We want to apply Theorem 1.10 to prove that $\zeta u\in\mathfrak{H}^\gamma_{p,\theta}(\tau)$. Notice that we already know that $M^{-1}\zeta u\in\mathbb{L}_{p,\theta}(\tau)$. Also from (4.6) it follows that $M^nD^n(\zeta u)_x\in\mathbb{L}_{p,\theta}$ for any integer n. Hence the inclusion $\zeta u\in\mathfrak{H}^\gamma_{p,\theta}(\tau)$ follows indeed from Theorem 1.10.

To prove the claim it only remains to prove that $v:=(1-\zeta)u\in\mathfrak{H}^\gamma_{p,\theta}(\tau)$. Observe that $u\in\mathcal{H}^\gamma_p(\tau)$ and $v\in\mathcal{H}^\gamma_p(\tau)$ for any γ. Also, v satisfies

$$dv=(v_{xx}+\bar f)\,dt+(\alpha\sigma^kv_x+\bar g^k)\,dw^k_t, \tag{4.8}$$

where

$$\bar f=(1-\zeta)f_x+2\zeta_xu_x+\zeta_{xx}u,\quad \bar g^k=(1-\zeta)g^k+\alpha\sigma^k\zeta_xu.$$

Now, consider the following equation on $\mathbb{R}$:

$$d\tilde u=(\tilde u_{xx}-2\tilde u_x\tanh x+(2\tanh^2x-1)\tilde u+\bar f\cosh x)\,dt$$

$$+(\alpha\sigma^k\tilde u_x-\alpha\sigma^k\tilde u\tanh x+\bar g^k\cosh x)\,dw^k_t,$$

with zero initial condition. Because of compactness of supports of $\bar f$ and $\bar g$, by already cited results from [5] or [8] there is a unique solution $\tilde u$ in class $\mathcal{H}^\gamma_p(\tau)$ for any γ. Of

course, $\tilde{u}/\cosh x \in \mathcal{H}^\gamma_p(\tau)$ for any γ. In addition, one can easily check that $\tilde{u}/\cosh x$ satisfies (4.8). By the uniqueness of solutions of (4.8) in class $\mathcal{H}^\gamma_p(\tau)$, we conclude that $v = \tilde{u}/\cosh x$ and, in particular, $v\cosh x \in \mathcal{H}^\gamma_p(\tau)$ for any γ. Now the fact that $v \in \mathfrak{H}^\gamma_{p,\theta}(\tau)$ for any γ follows easily from the observation that $v = 0$ if $x \leq 1$ and $x^n/\cosh x$ is bounded.

Next we remember that (4.2) holds pointwise and we apply Itô's formula to $|u(t,x)|^p x^c$, where $c = \theta + 1 - p$. We get that, for any $x \in \mathbb{R}_+$ and $t \leq \tau$, a.s.

$$\int_0^t I(s,x)\,ds + \sum_k \int_0^t px^c|u|^{p-2}u(\alpha\sigma^k u_x - g^k)\,dw^k_s = |u(t,x)|^p x^c \geq 0, \tag{4.9}$$

where

$$I := px^{\theta-1}G(v)(xu_{xx}) + px^{\theta-1}G(v)(xf_x) + bx^{\theta-1}\sum_k |v|^{p-2}(\alpha\sigma^k u_x - g^k)^2,$$

$$b := p(p-1)/2, \quad v := u/x, \quad G(r) := |r|^{p-2}r.$$

It follows that for any $x \in \mathbb{R}_+$ there is a sequence of stopping times $\tau(n) \uparrow \tau$ localizing the stochastic integral in (4.9) so that

$$E\int_0^{\tau(n)} I(s,x)\,ds \geq 0. \tag{4.10}$$

It turns out that for almost any $x \in \mathbb{R}_+$, here one can replace $\tau(n)$ with τ and integrate with respect to x over $\mathbb{R}_+$. To prove this it suffices to prove that

$$E\int_0^\tau \int_{\mathbb{R}_+} |I(s,x)|\,dxds < \infty. \tag{4.11}$$

Observe that (4.7) for $\gamma = 2$ means that

$$M^{-1}u,\ u_x,\ Mu_{xx} \in \mathbb{L}_{p,\theta}(\tau), \tag{4.12}$$

which implies (4.11) since by Hölder's inequality

$$\begin{aligned} &E\int_0^\tau \int_0^\infty |G(v)|\,|xu_{xx}|x^{\theta-1}\,dxdt \\ &\quad = E\int_0^\tau \int_0^\infty |u(t,x)/x|^{p-1}|xu_{xx}(t,x)|x^{\theta-1}\,dxdt \\ &\quad \leq ||M^{-1}u||^{p-1}_{\mathbb{L}_{p,\theta}(\tau)}||Mu_{xx}||_{\mathbb{L}_{p,\theta}(\tau)}, \end{aligned}$$

$$E\int_0^\tau \int_0^\infty |G(v)|\,|xf_x|x^{\theta-1}\,dxdt \leq ||M^{-1}u||^{p-1}_{\mathbb{L}_{p,\theta}(\tau)}||Mf_x||_{\mathbb{L}_{p,\theta}(\tau)},$$

$$E\int_0^\tau \int_0^\infty |v|^{p-2}|u_x|^2x^{\theta-1}\,dxdt \leq ||M^{-1}u||^{p-2}_{\mathbb{L}_{p,\theta}(T)}||u_x||^2_{\mathbb{L}_{p,\theta}(\tau)},$$

$$E\int_0^\tau \int_0^\infty |v|^{p-2}|g|^2_{l_2}x^{\theta-1}\,dxdt \leq ||M^{-1}u||^{p-2}_{\mathbb{L}_{p,\theta}(\tau)}||g||^2_{\mathbb{L}_{p,\theta}(\tau,l_2)}.$$

Having thus proved (4.11), from (4.10) we conclude

$$E\int_0^\tau \int_{\mathbb{R}_+} I(s,x)\,dxds \geq 0. \tag{4.13}$$

While estimating the integral with respect to x in (4.13) we integrate by parts after noticing that (4.12) also implies that

$$E\int_0^\tau \int_0^\infty |G(u)||u_x|x^{\theta-1}\,dxdt < \infty.$$

By Lemma 4.1 for almost all $(\omega,t) \in (\!(0,\tau]\!]$ we get

$$p\int_0^\infty x^{\theta-1}G(v)(xu_{xx})\,dx = p\int_0^\infty x^c G(u)u_{xx}\,dx$$

$$= -p(p-1)\int_0^\infty |u|^{p-2}|u_x|^2x^c\,dx - c\int_0^\infty x^{c-1}(|u|^p)_x\,dx$$

$$= -p(p-1)\int_0^\infty |u|^{p-2}|u_x|^2x^c\,dx + c(c-1)\int_0^\infty |M^{-1}u|^p x^{\theta-1}\,dx.$$

Furthermore,

$$\left|\int_0^\infty x^{\theta-1}G(v)(xf_x)\,dx\right| \leq ||v||^{p-1}_{L_{p,\theta}}||Mf_x||_{L_{p,\theta}}$$
$$\leq \varepsilon||M^{-1}u||^p_{L_{p,\theta}} + N(\varepsilon,p)||f||^p_{H^1_{p,\theta}},$$

where $\varepsilon > 0$ is arbitrary. Finally, while estimating the terms in (4.13) which came from stochastic integrals we also use

$$(\alpha\sigma^k u_x - g^k)^2 \leq (1+\varepsilon)|\sigma^k|^2|u_x|^2 + (1+\varepsilon^{-1})|g^k|^2.$$

Then from (4.13) we conclude that for any $\varepsilon > 0$,

$$p(p-1)E\int_0^\tau\int_0^\infty [(1+\varepsilon)|\sigma|^2_{l_2}/2 - 1]|u|^{p-2}|u_x|^2x^c\,dxdt$$

$$+[(\theta+1-p)(\theta-p)+\varepsilon]E\int_0^\tau\int_0^\infty |M^{-1}u|^p x^{\theta-1}\,dxdt$$

$$+N(\varepsilon,p)(||f||^p_{\mathbb{H}^1_{p,\theta}(\tau)} + ||g||^p_{\mathbb{L}_{p,\theta}(\tau,l_2)})\,dxdt \geq 0. \tag{4.14}$$

Now comes the only place where we need $\theta \in [p-1,p)$. This condition implies that $(\theta+1-p)(\theta-p) \leq 0$. Also $|\sigma|^2_{l_2} \leq 2-\delta$. By using (2.13) we conclude that the first term in (4.14) is strong enough if ε is small and (4.14) implies (4.5). This brings the proof of Lemma 4.2 to an end.

4.2. Case $p \geq 2$ and $\theta \in (0, p)$. Uniqueness. Suppose that $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ is a solution of

$$du = u_{xx}\,dt + \sigma^k u_x\,dw^k_t \tag{4.15}$$

with zero initial condition. By Lemma 3.6 it follows that $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ for all γ and also $u\zeta \in \mathcal{H}^{\gamma}_{p}(\tau)$ for all $\zeta \in C_0^\infty(\mathbb{R}_+)$. Hence we again have (4.12) and the equation is satisfied pointwise. For $\theta \in [p-1, p)$, this makes it possible to estimate the norm $||u||_{\mathfrak{H}^0_{p,\theta}(\tau)}$ using the same computations as in Lemma 4.2. Since now $f = g_k = 0$, the result is $||u||_{\mathfrak{H}^1_{p,\theta}(\tau)} = 0$.

Next notice that, for any $\theta \in (0, p)$, there exists $\theta_1 \in (p-1, p)$ such that $\theta < \theta_1 < \theta + p$. Also as above, for any γ any solution of (4.15) in $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ with zero initial condition also belongs to $\mathfrak{H}^1_{p,\theta}(\tau)$. Hence, the following result implies the uniqueness for general $\theta \in (0, p)$.

LEMMA 4.3. *Let γ, θ_1, and p be such that the first two assertions of Theorem* 3.2 *hold for $u_0 \equiv 0$, any stopping time τ, and these γ, θ_1, and p (for instance, $\gamma = 1$, $\theta_1 \in [p-1, p)$, and $p \geq 2$). Let $q \geq p$, $\theta \neq 0$, and $\theta \neq q$ satisfy $\theta/q < \theta_1/p \leq \theta/q + 1$. Let τ be a stopping time and $u \in \mathfrak{H}^1_{q,\theta,0}(\tau)$ satisfy* (3.1) *with some $f \in \mathbb{L}_{p,\theta_1}(\tau)$ and $g \in \mathbb{L}_{p,\theta_1}(\tau, l_2)$. Then $u \in \mathfrak{H}^1_{p,\theta_1,0}(\tau)$.*

Proof. By Remark 3.8 we may assume that $\gamma = 0$. Let v be the unique solution of (3.1) in $\mathfrak{H}^1_{p,\theta,0}(\tau)$ with given f and g. To prove the lemma we prove that $u = v$.

Let κ be an infinitely differentiable function such that $\kappa(x) = 1$ for $|x| \leq 1$ and $\kappa(x) = 0$ for $|x| \geq 2$. Define $\kappa_n = \kappa(x/n)$.

First we prove that for any n,

$$u\kappa_n \in \mathfrak{H}^1_{p,\theta_1,0}(\tau). \tag{4.16}$$

To this end observe that

$$E\int_0^\tau \int_0^\infty |(u\kappa_n)_x|^p x^{\theta_1 - 1}\,dxdt \leq 2^{p-1} E\int_0^\tau \int_0^\infty |u_x\kappa_n|^p x^{\theta_1-1}\,dxdt$$

$$+2^{p-1}E\int_0^\tau \int_0^\infty |u\kappa_{nx}|^p x^{\theta_1-1}\,dxdt, \tag{4.17}$$

where by Hölder's inequality the first term on the right is less than a constant times

$$E\int_0^\tau \int_0^{2n} |u_x x^{(\theta-1)/q}|^p x^{\theta_1 - 1 - (\theta-1)p/q}\,dxdt$$

$$\leq \left(E\int_0^\tau \int_0^{2n} |u_x|^q x^{\theta-1}\,dxdt\right)^{p/q} T^{1-p/q}\left(\int_0^{2n} x^c\,dx\right)^{1-p/q},$$

with

$$c = [\theta_1 - 1 - (\theta-1)p/q]q/(q-p) = \frac{qp}{(q-p)}\left(\frac{\theta_1}{p} - \frac{\theta}{q}\right) - 1.$$

Since $c > -1$, the first term on the right in (4.17) is finite. One can similarly treat the second term after noticing that $|u\kappa_{nx}| \leq N|u/x|$ and $u/x \in \mathbb{L}_{q,\theta}(\tau)$. The same argument yields $u\kappa_n/x \in \mathbb{L}_{p,\theta_1}(\tau)$ and this proves (4.16).

Now, let $\bar{u} = u - v$. By what we have just proved, $\bar{u}\kappa_n$ belongs to $\mathfrak{H}^1_{p,\theta_1,0}(\tau)$. Also $\bar{u}\kappa_n$ satisfies the following equation similar to (3.7)

$$d(\bar{u}\kappa_n) = (a(\bar{u}\kappa_n)_{xx} + \bar{f}_{nx})\,dt + (\sigma^k(\bar{u}\kappa_n)_x + \bar{g}^k_n)\,dw^k_t,$$

where

$$\bar{f}_n(t,x) = a(t)\int_x^\infty [2\kappa_{nx}(y)\bar{u}_x(t,y) + \kappa_{nxx}(y)\bar{u}(t,y)]\,dy$$

$$= -2a\kappa_{nx}\bar{u} + (MD)^{-1}(Ma\kappa_{nxx}\bar{u}), \quad \bar{g}^k = -\sigma^k\kappa_{nx}\bar{u}.$$

Hence, by our assumptions and Remark 1.5

$$||\bar{u}\kappa_n||_{\mathfrak{H}^1_{p,\theta_1}(\tau)} \le N||\kappa_{nx}\bar{u}||_{\mathbb{L}_{p,\theta_1}(\tau)} + N||M\kappa_{nxx}\bar{u}||_{\mathbb{L}_{p,\theta_1}(\tau)}. \tag{4.18}$$

Here, for instance, ($\kappa_{nx} \le N/n$)

$$||\kappa_{nx}\bar{u}||^p_{\mathbb{L}_{p,\theta_1}(\tau)} \le Nn^{-p}E\int_0^\tau\int_n^{2n} |\bar{u}|^p x^{\theta_1-1}\,dxdt$$

$$\le NE\int_0^\tau\int_n^{2n} |v/x|^p x^{\theta_1-1}\,dxdt + Nn^{\theta_1-p-1}E\int_0^\tau\int_n^{2n} |u|^p\,dxdt.$$

The first term on the right tends to zero as $n \to \infty$ since $v/x \in \mathbb{H}^0_{p,\theta_1}(\tau)$. To prove the same for the second term use Hölder's inequality to get that it is less than

$$NT^{1-p/q}n^{\theta_1-p-p/q}\left(E\int_0^\tau\int_n^{2n} |u|^q\,dxdt\right)^{p/q}$$

$$\le Nn^c\left(E\int_0^\tau\int_n^{2n} |u|^q x^{\theta-1}\,dxdt\right)^{p/q}, \tag{4.19}$$

where $c = \theta_1 - p - p/q - (\theta-1)p/q \le 0$ by virtue of $\theta_1/p \le 1 + \theta/q$. Theorem 2.11 implies that the right-hand side of (4.19) tends to zero as $n \to \infty$.

In the same way using the fact that $|M\kappa_{nxx}| \le N/n$ we get that the second term on the right in (4.18) tends to zero as well. Thus (use Theorem 2.11)

$$E\sup_{t\le\tau}\int_0^\infty |\bar{u}(t,x)|^p x^{\theta_1-1}\,dxdt \le \liminf_{n\to\infty} E\sup_{t\le\tau}||\bar{u}(t,\cdot)\kappa_n||^p_{H^0_{p,\theta_1}}$$

$$\le N\liminf_{n\to\infty}||\bar{u}\kappa_n||^p_{\mathfrak{H}^1_{p,\theta_1}(\tau)} = 0.$$

The lemma is proved.

4.3. Case $\sigma \equiv 0$ and $p \ge 2$. Uniqueness follows directly from section 4.2. To prove existence notice that as has been emphasized in section 4.1 the only place where we used $\theta \in [p-1, p)$ is right after (4.14). But in our present situation $\sigma \equiv 0$ and from (4.14) and (2.13) we conclude that

$$[p^{-1}(p-1)(p-\theta)^2 + (\theta+1-p)(p-\theta) + \varepsilon]||M^{-1}u||^p_{\mathbb{L}_{p,\theta}(\tau)}$$

$$\le N(\varepsilon,p)(||f||^p_{\mathbb{H}^1_{p,\theta}} + ||g||^p_{\mathbb{L}_{p,\theta}(\tau,l_2)}). \tag{4.20}$$

Observe that the condition $0 < \theta < p$ is equivalent to $p^{-1}(p-1)(p-\theta)^2 + (\theta+1-p)(p-\theta) > 0$. Therefore, for ε small enough we again get (4.5). This takes care of the existence.

4.4. Case $\sigma \equiv 0$ and $g \equiv 0$. Actually, this is the case of the heat equation without any stochastic terms. In this case Lemma 3.6 is available for any $p > 1$ and as in section 4.1, to prove existence, it suffices to prove (4.5) for f as in section 4.1. This time we get (4.20) with $\varepsilon = 0$ even for $1 < p < 2$, which is proved by the same approximating argument as in the proof of Theorem 2.13 right after (2.15). Hence, we have existence.

The uniqueness is proved as in the beginning of section 4.2 observing that this time we do not need condition $\theta \in [p-1, p)$ to be satisfied and yet have (4.20).

This finishes the proof of Lemma 3.5.

STABLE DETERMINATION OF A CRACK IN A PLANAR INHOMOGENEOUS CONDUCTOR*

GIOVANNI ALESSANDRINI† AND LUCA RONDI‡

Abstract. We prove a stability estimate for the inverse problem of cracks under essentially minimal regularity assumptions on the crack and on the background conductivity.

1. Introduction. We consider the problem of determining a crack in an electrically conducting body from current and voltage measurements at the boundary. The mathematical theory for this inverse problem was initiated by A. Friedman and M. Vogelius [F-V], who proved uniqueness theorems for a crack in a planar conductor. Stability estimates were obtained in [A2], [A3], [DV] for the case of a single crack in a homogeneous isotropic planar conductor. For an extended account on the results for this problem and for further references the reader is referred to [A-DB], where a three-dimensional theory for this problem is developed.

In this paper we prove a stability estimate for the determination of a crack in an inhomogeneous planar conductor under essentially minimal regularity assumptions on the (unknown) crack and on the (known) background conductivity.

We shall consider the conductor Ω as a simply connected bounded domain in the plane with Lipschitz boundary. The conductivity within Ω is given by a bounded and measurable tensor A which satisfies a uniform ellipticity condition. A crack σ in Ω will be a simple open curve within Ω which we shall a priori assume to be Lipschitz. Given a zero average function ψ on $\partial\Omega$, representing the prescribed current density, the electrostatic potential u in Ω will be, in the presence of the crack σ, the weak solution of the following (direct) Neumann boundary value problem:

$$\begin{cases} \operatorname{div}(A\nabla u) = 0 & \text{in } \Omega\backslash\sigma, \\ A\nabla u \cdot \nu = 0 & \text{on either side of } \sigma, \\ A\nabla u \cdot \nu = \psi & \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where ν denotes the unit normal with outward orientation when on $\partial\Omega$.

The inverse problem consists of determining the crack σ from the voltage measurements $u|_\Sigma$, Σ being a portion of $\partial\Omega$, corresponding to one or more prescribed current densities ψ.

Notice that this model corresponds to the so-called case of a perfectly insulating crack; let us stress here that our present method would enable us also to treat, with analogous results, the so-called case of perfectly conducting cracks. For the sake of brevity, we shall not discuss this case any further.

As is well known since the work of A. Friedman and M. Vogelius, in order to uniquely determine σ it is necessary to perform measurements for at least two different choices ψ_1, ψ_2 of the current density ψ. We shall use here current densities ψ_1, ψ_2 analogous to those used in previous works on uniqueness [Br-V], [A-DV], [K-Se], which can be viewed as general models of a two-electrode configuration in which one electrode is kept fixed and the other is placed in two different locations. See the following section 2 for details.

Our main result (Theorem 2.1) is that the crack σ depends continuously on the boundary measurements at a rate which is of log–log type.

That is, we obtain a result which is comparable with those previously obtained for the case of a homogeneous conductor. See the concluding remarks for further details.

The present approach, however, is different from the one in [A2], [A3], [DV], which took advantage of the uniform conductivity by the use of special conformal transformations. Rather, it is closer to the approach used in [A-DV] to prove uniqueness of multiple cracks in an inhomogeneous conductor, the main novelty here being the need of stability estimates for a Cauchy problem for the elliptic equation in (1.1). In fact we shall show that the Cauchy problem for such elliptic equations has a stability character analogous to the one for the Laplace equation regardless of the smoothness of the coefficients. We shall prove this by a generalization of the classical method of harmonic measure, Theorem 4.5. We believe that this result can have some independent interest.

In section 2 we start by listing all the needed a priori assumptions and we state our main Theorem 2.1.

In section 3 we collect results based on the connections between elliptic equations in two variables, first-order Beltrami-type equations, and quasi-conformal mappings. The principal result of this section is contained in Proposition 3.7 stating Hölder continuity properties of the mappings f, f^{-1}, where f is given by $f = u + iv$, u is a solution to (1.1), and v is the associated stream function (i.e., a generalized harmonic conjugate).

Section 4 contains a treatment of a Cauchy problem and its stability properties, the main result for the rest of the paper being Proposition 4.1. Theorem 4.5 is instead a result of general type possibly useful in other contexts.

Section 5 consists of the completion of the proof of Theorem 2.1 and some concluding remarks.

2. The main theorem.

Prior information. For every $z = x + iy \in \mathbb{C}$ and for every $r > 0$ we denote with $B_r(z)$ the disk with center z and radius r. As usual, we shall identify complex numbers $z = x + iy \in \mathbb{C}$ with points $(x, y) \in \mathbb{R}^2$.

If γ is a simple curve (which could be closed) and z_0, z_1 are two points of γ, we define $\text{length}_\gamma(z_0, z_1)$ the length of the smallest arc in γ connecting z_0 to z_1.

If γ is a simple curve, r is a positive number, and z belongs to γ, we say that $\gamma \cap B_r(z)$ is a *Lipschitz graph with norm M* if there exists a system of Cartesian coordinates (x, y) with origin in z, with respect to which one has

$$\gamma \cap B_r(z) = \{(x, y) | y = \phi(x),\, x^2 + y^2 < r^2\},$$

where ϕ is a Lipschitz function on $[-r, r]$ and $\|\phi'\|_{L^\infty(-r,r)} \leq M$.

If γ is a simple open curve, r is a positive number and z is an endpoint of γ, we say that $\gamma \cap B_r(z)$ is a *half Lipschitz graph with norm M* if there exists a

system of Cartesian coordinates (x, y) with origin in z such that with respect to these coordinates one has

$$\gamma \cap B_r(z) = \{(x, y) | y = \phi(x),\ 0 \le x \le r,\ x^2 + y^2 < r^2\},$$

where ϕ is a Lipschitz function on $[0, r]$ and $\|\phi'\|_{L^\infty(0,r)} \le M$.

Let Ω be a bounded domain and $d > 0$; we denote

$$\Omega_d = \{z \in \Omega : \operatorname{dist}(z, \partial\Omega) > d\}. \tag{2.1}$$

Prior information on the domain. Let Ω be a bounded, simply connected domain in $\mathbb{R}^2$ and let its boundary $\partial\Omega$ be a simple, closed curve satisfying, for given positive constants L, δ, and M,

(2.2)(a) perimeter of $\Omega \le L$,
(2.2)(b) for every $z \in \partial\Omega$; then $\partial\Omega \cap B_\delta(z)$ is a Lipschitz graph with norm M.

Prior information on the crack. A crack σ in Ω will be a simple, open curve in Ω such that

(2.3)(a) the length of σ is less than L;
(2.3)(b) the distance of σ from $\partial\Omega$ is $\ge \delta$;
(2.3)(c) if V_1, V_2 are the endpoints of σ, then for every $i = 1, 2$ $\sigma \cap B_\delta(V_i)$ is a half Lipschitz graph with norm M; furthermore, for any $z \in \sigma \backslash (B_{\delta/2}(V_1) \cup B_{\delta/2}(V_2))$, $\sigma \cap B_{\delta/2}(z)$ is a Lipschitz graph with norm M.

Prior information on the boundary data. Let γ_0, γ_1, γ_2 be three fixed simple arcs in $\partial\Omega$, pairwise internally disjoint.

Given $\Gamma > 0$, let us fix three functions η_0, η_1, $\eta_2 \in L^2(\partial\Omega)$ such that for every $j = 0, 1, 2$,

(2.4)(a) $\eta_j \ge 0$ on $\partial\Omega$; $\operatorname{supp}(\eta_j) \subset \gamma_j$;
(2.4)(b) $\int_{\partial\Omega} \eta_j = 1$;
(2.4)(c) $\|\eta_j\|_{L^2(\partial\Omega)} \le \Gamma$.

Then we prescribe the current densities on the boundary ψ_1, ψ_2 to be given by

$$\psi_1 = \eta_0 - \eta_1, \quad \psi_2 = \eta_0 - \eta_2. \tag{2.5}$$

We have

(2.6)(a) $\int_{\partial\Omega} \psi_j = 0$ for every $j = 1, 2$;
(2.6)(b) $\|\psi_j\|_{L^2(\partial\Omega)} \le 2\Gamma$ for every $j = 1, 2$.

Moreover let us consider the following antiderivatives along $\partial\Omega$ of ψ_1, ψ_2:

$$\Psi_j(s) = \int \psi_j(s) \mathrm{d}s, \quad j = 1, 2, \tag{2.7}$$

where the indefinite integral is taken with respect to arclength on $\partial\Omega$ in the counterclockwise direction. The functions Ψ_1, Ψ_2 are defined up to an additive constant.

We remark that from the prior information on Ω, (2.2), we can find a constant M_1 depending on L, δ, and M only such that for all z_0, z_1 belonging to $\partial\Omega$ the following inequality holds:

$$\operatorname{length}_{\partial\Omega}(z_0, z_1) \le M_1 |z_0 - z_1|. \tag{2.8}$$

Hence Ψ_j verify the following property

$$|\Psi_j(z_0) - \Psi_j(z_1)| \le 2\Gamma (\operatorname{length}_{\partial\Omega}(z_0, z_1))^{1/2} \le \Gamma_1 |z_0 - z_1|^{1/2}, \tag{2.9}$$

for any z_0, z_1 belonging to the boundary of Ω, where $\Gamma_1 = 2\Gamma M_1^{1/2}$.

Prior information on the conductivity. Given $\lambda, \Lambda > 0$, let $A = A(z)$, $z \in \Omega$, be a 2×2 matrix with bounded measurable entries such that

(2.10)(a) $A(z)\xi \cdot \xi \geq \lambda |\xi|^2$ for every $\xi \in \mathbb{R}^2$ and for a.e. $z \in \Omega$;
(2.10)(b) $\|A\|_{L^\infty(\Omega)} \leq \Lambda$.

For any $i = 1, 2$, let $u_i \in W^{1,2}(\Omega \backslash \sigma)$ be the weak solution of the following Neumann-type boundary value problem:

$$\begin{cases} \operatorname{div}(A \nabla u_i) = 0 & \text{in } \Omega \backslash \sigma, \\ A \nabla u_i \cdot \nu = 0 & \text{on either side of } \sigma, \\ A \nabla u_i \cdot \nu = \psi_i & \text{on } \partial\Omega, \end{cases} \tag{2.11}$$

where ν denotes the unit normal, with the outward orientation when on $\partial\Omega$.

That is, we understand that u_i satisfies

$$\int_{\Omega \backslash \sigma} A \nabla u_i \cdot \nabla \varphi = \int_{\partial\Omega} \psi_i \varphi \quad \text{for every } \varphi \in W^{1,2}(\Omega \backslash \sigma). \tag{2.11$'$}$$

If σ' is another crack, that is, another curve satisfying conditions (2.3), we denote by u_i' the solutions to (2.11) when σ is replaced with σ'.

We denote by Σ a simple arc in $\partial\Omega$ whose length is at least δ.

The set of constants L, M, δ, Γ, λ, and Λ will be referred to as the *a priori data*.

We are now in position to state the main theorem.

THEOREM 2.1. *Under the previously stated assumptions, let $\varepsilon > 0$ be such that*

$$\max_{i=1,2} \|u_i - u_i'\|_{L^\infty(\Sigma)} \leq \varepsilon; \tag{2.12}$$

then the two cracks σ, σ' satisfy

$$\mathrm{d}_H(\sigma, \sigma') \leq \omega(\varepsilon), \tag{2.13}$$

where $\omega(\varepsilon)$ is a positive function on $(0, +\infty)$ that verifies

$$\omega(\varepsilon) \leq K(\log |\log \varepsilon|)^{-\alpha} \text{ for every } \varepsilon,\ 0 < \varepsilon < 1/e. \tag{2.14}$$

Here K and α are positive constants depending on the a priori data only.

Here d_H denotes the Hausdorff distance. We recall that the Hausdorff distance between bounded closed sets σ and σ' is given by

$$\mathrm{d}_H(\sigma, \sigma') = \max \left\{ \sup_{x \in \sigma'} \operatorname{dist}(x, \sigma), \sup_{x \in \sigma} \operatorname{dist}(x, \sigma') \right\}.$$

3. Stream functions and quasi-conformal mappings. We begin by reviewing some properties of quasi-conformal mappings which will be used in the sequel.

We shall make repeated use of the following notation for complex derivatives:

$$f_{\bar{z}} = \tfrac{1}{2}(f_x + i f_y), \quad f_z = \tfrac{1}{2}(f_x - i f_y).$$

We denote by $J = \left[\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right]$ the counterclockwise rotation of 90° and by $(\cdot)^T$ transpose.

PROPOSITION 3.1. *Let D be a bounded simply connected domain in $\mathbb{R}^2$. Let A satisfy* (2.10). *Let $u \in W^{1,2}(D)$ be a weak solution to the equation*

$$\operatorname{div}(A \nabla u) = 0 \quad \text{in } D. \tag{3.1}$$

There exists a function $v \in W^{1,2}(D)$ which satisfies

$$\nabla v = JA\nabla u \quad \text{almost everywhere in } D. \tag{3.2}$$

Moreover, letting $f = u + iv$, we have

$$f_{\overline{z}} = \mu f_z + \nu \overline{f_z} \quad \text{almost everywhere in } D, \tag{3.3}$$

where μ and ν are bounded measurable, complex valued coefficients, satisfying

$$|\mu| + |\nu| \le k < 1 \quad \text{almost everywhere in } D, \tag{3.4}$$

where k is a constant depending on λ, Λ only.

On the other hand, if $f = u+iv$, $f \in W^{1,2}(D, \mathbb{C})$, verifies (3.3) *with coefficients μ and ν satisfying* (3.4)*, then there exists a 2×2 matrix A such that u is a weak solution of* $\operatorname{div}(A\nabla u) = 0$ *in D and A verifies* (2.10) *with constants λ, $\Lambda > 0$ depending upon k only.*

The function v appearing above is usually called the *stream function* associated with u. Notice that v is uniquely determined up to an additive constant and also that v is a weak solution to

$$\operatorname{div}(B\nabla v) = 0 \quad \text{in } D, \tag{3.5}$$

where $B = (\det A)^{-1} A^T$.

Proof. For the existence of the stream function v see [A-M, Theorem 2.1]. Then by (3.2), (3.3) follows with μ, ν given by

$$\begin{aligned} \mu &= \tfrac{a_{22}-a_{11}-i(a_{12}+a_{21})}{a_{11}a_{22}-a_{12}a_{21}+a_{11}+a_{22}+1}, \\ \nu &= \tfrac{a_{12}a_{21}-a_{11}a_{22}+1+i(a_{12}-a_{21})}{a_{11}a_{22}-a_{12}a_{21}+a_{11}+a_{22}+1}. \end{aligned} \tag{3.6}$$

From these expressions and (2.10), one obtains, through elementary although lengthy computations, (3.4).

Conversely, given the coefficients μ, ν in (3.3) satisfying (3.4) one obtains (3.1) and (3.2) with A given by

$$A = \begin{bmatrix} \frac{|1-\mu|^2-|\nu|^2}{|1+\nu|^2-|\mu|^2} & \frac{2\Im(\nu-\mu)}{|1+\nu|^2-|\mu|^2} \\ \frac{-2\Im(\mu+\nu)}{|1+\nu|^2-|\mu|^2} & \frac{|1+\mu|^2-|\nu|^2}{|1+\nu|^2-|\mu|^2} \end{bmatrix} \tag{3.7}$$

and the thesis follows. □

We recall that a *quasi-conformal map* f in an open set D is an univalent $W^{1,2}(D, \mathbb{C})$ solution of an equation of the type (3.3), (3.4).

Now we state the following representation theorem, due to L. Bers and L. Nirenberg [B-N].

THEOREM 3.2. *Let $D \subset B_1(0)$, and let $f \in W^{1,2}(D, \mathbb{C})$ verify* (3.3) *where μ, ν satisfy* (3.4).

There exists a quasi-conformal map χ from $B_1(0)$ into itself and a holomorphic function F on $\chi(D)$ such that

$$f = F \circ \chi. \tag{3.8}$$

Moreover the function χ and its inverse χ^{-1} satisfy the following conditions:

$$\begin{aligned} &|\chi(x) - \chi(y)| \le C|x-y|^\alpha \qquad \forall x, y \in B_1, \\ &|\chi^{-1}(x) - \chi^{-1}(y)| \le C|x-y|^\alpha \quad \forall x, y \in B_1, \end{aligned} \tag{3.9}$$

where C and α, $0 < \alpha < 1$, depend upon k only.

Proof. See [B-N, page 116]. □

Let us define, as in [A-M], *geometric critical points* of solutions of elliptic equations like (3.1). That is, given u as in Proposition 3.1, let v be its stream function and let χ and F, respectively, be the quasi-conformal map and the holomorphic function appearing in the representation (3.8) for $f = u + iv$.

A point $z \in \Omega$ is called a *geometric critical point* of u if $\chi(z)$ is a critical point (in the standard sense) for $\Re F$. This definition does not depend on the choice of the representation.

According to [A-M], we define the *geometric index* of u at $z \in \Omega$ as the *winding number* of F' at $\chi(z_0)$.

Remark 3.3. We wish to stress that the representation theorem, 3.2, gives us that, up to the change of coordinates χ, v can be viewed as the harmonic conjugate to u. In particular we have that, with respect to the metric in $\chi(D)$, the level lines of v are lines of steepest descent of u and vice versa. Consequently we have that, away from the discrete set of geometric critical points, u is strictly monotone on each connected component of the level lines of v, and vice versa.

The following theorem shows that, although the domain $\Omega\backslash\sigma$ is doubly connected, for the particular case of solutions to (1.1) a single valued global stream function v exists.

THEOREM 3.4. *Let u be a weak solution to* (1.1) *with $\psi \in L^2(\partial\Omega)$, $\int_{\partial\Omega} \psi = 0$.*

There exists, and it is unique up to an additive constant, a global stream function $v \in W^{1,2}(\Omega\backslash\sigma)$ related to u.

Moreover v is a weak solution of the following Dirichlet-type boundary value problem:

$$\begin{cases} \operatorname{div}(B\nabla v) = 0 & \text{in } \Omega\backslash\sigma, \\ v = \text{const} & \text{on } \sigma, \\ v = \Psi & \text{on } \partial\Omega, \\ \int_{\partial\Omega} B\nabla v \cdot \nu = 0, \end{cases} \tag{3.10}$$

where $\Psi = \int \psi ds$ on $\partial\Omega$.

Here, as above, $B = (\det(A)^{-1})A^T$. Observe that the constant value of v on σ is part of the unknowns of the problem (3.10) and that its weak formulation is to find $v \in W^{1,2}(\Omega)$ such that $v =$ constant on σ, $v = \Psi$ on $\partial\Omega$ in the sense of traces and satisfies

$$\int_\Omega B\nabla v \cdot \nabla\varphi = 0 \quad \text{for every } \varphi \in W^{1,2}(\Omega) \text{ such that } \varphi = \text{constant on } \sigma. \tag{3.10'}$$

Proof. The reader is referred to [A-DV, Proposition 2.1]. □

We note that the above theorem applies in particular to u_1, u_2 given by (2.11) and to any linear combination of such solutions. Let a, b be any two real numbers such that $a^2 + b^2 = 1$ and let us define

$$u = au_1 + bu_2, \qquad v = av_1 + bv_2, \tag{3.11}$$

$$\psi = a\psi_1 + b\psi_2, \qquad \Psi = a\Psi_1 + b\Psi_2. \tag{3.12}$$

Clearly, u is the weak solution to (1.1) and v is its stream function, solving (3.10). When σ is replaced with σ', we define u', v' in the same fashion.

Remark 3.5. Observe that, by (2.9) we have

$$|\Psi(z) - \Psi(w)| \leq 2\Gamma_1 |z - w|^{1/2} \quad \text{for every } z, w \in \partial\Omega. \tag{3.13}$$

Moreover, by (2.4), (2.5) one easily obtains that there exist points $\tilde{P}, \tilde{Q} \in \partial\Omega$ such that Ψ is monotone on the two simple curves forming $\partial\Omega \backslash \{\tilde{P}, \tilde{Q}\}$. Finally note that

$$\operatorname{osc}_{\partial\Omega} \Psi = |\Psi(\tilde{P}) - \Psi(\tilde{Q})| \geq 1/\sqrt{2}. \tag{3.14}$$

In order to distinguish the one-sided limits as $z \to \sigma$, $z \in \Omega \backslash \sigma$, it is convenient to figure out σ as a degenerate closed curve. More precisely we present Definition 3.6.

DEFINITION 3.6. *Let $\tilde{\sigma}$ be the abstract simple closed curve obtained from two copies of σ and gluing two by two the corresponding endpoints. We denote by $\tilde{\Omega}$ the compact manifold obtained by the appropriate gluing of $\overline{\Omega} \backslash \sigma$ with $\tilde{\sigma}$ and by $\tilde{d}$ the geodesic distance on $\tilde{\Omega}$.*

For any d, $p > 0$, we denote

$$\Omega_{d,p} = \{z \in \Omega | \operatorname{dist}(z, \partial\Omega) > d, \operatorname{dist}(z, \sigma) > p\}.$$

PROPOSITION 3.7. *Let $f = u + iv$, where u, v are given by* (3.11). *We have the following conditions:*

(i) *v satisfies the Hölder estimate*

$$|v(z_1) - v(z_2)| \leq C_1 |z_1 - z_2|^{\alpha_1} \quad \textit{for every } z_1, z_2 \in \overline{\Omega}. \tag{3.15}$$

(ii) *u satisfies the estimate*

$$|u(z_1) - u(z_2)| \leq C_2 (\tilde{d}(z_1, z_2))^{\alpha_1} \quad \textit{for every } z_1, z_2 \in \tilde{\Omega}. \tag{3.16}$$

(iii) *f is a quasi-conformal mapping on $\Omega \backslash \sigma$.*

(iv) *f satisfies the lower bound*

$$|f(z_1) - f(z_2)| \geq C_3(d) p^{4/\alpha_1} |z_1 - z_2|^{1/\alpha_1} \quad \textit{for every } z_1, z_2 \in \Omega_{d,p}. \tag{3.17}$$

Here C_1, C_2, $\alpha_1 > 0$ depend on the a priori data only, whereas $C_3(d) > 0$ depends on the a priori data and on d only.

Remark 3.8. It is useful to stress the difference between the estimates (3.15), (3.16). In fact, since v attains to a constant Dirichlet data on σ, it is expected that v is continuous across σ. This is not the case for u, which may have different one-sided limits on σ. This is the main motivation for the introduction of the metric $\tilde{d}$.

The proof of Proposition 3.7 will be given through several steps. At several stages we shall use the change of coordinates described below.

LEMMA 3.9. *Let Ω be a simply connected bounded open set which verifies* (2.2) *and let σ be a curve in Ω which satisfies* (2.3). *Then there exists a sense-preserving bi-Lipschitz map χ from $\Omega \backslash \sigma$ onto $B_2 \backslash \overline{B_1}$, such that the $W^{1,\infty}$ norm of χ and its inverse are dominated by constants depending on the a priori data only.*

Here and in the following we say that χ is bi-Lipschitz if it is a homeomorphism such that χ and its inverse belong to $W^{1,\infty}$.

Proof (*sketch*). First, by locally deforming $\partial\Omega$ and σ one can construct a bi-Lipschitz mapping χ_1 from Ω onto a simply connected domain Ω_1 with C^∞ boundary

such that $\sigma_1 = \chi_1(\sigma)$ is a C^∞ simple curve. Second, one can find a C^∞ diffeomorphism χ_2 from Ω_1 onto the disk $B_2(0)$ such that $\sigma_2 = \chi_2(\sigma_1)$ is the segment $\{y = 0,\ |x| \le 1/2\}$. Next, one constructs a bi-Lipschitz mapping χ_3 from the upper half disk $\overline{B_2^+(0)} = \{|z| \le 2,\ y \ge 0\}$ onto the half annulus $\overline{B_2^+(0)}\backslash B_1^+(0) = \{1 \le |z| \le 2,\ y \ge 0\}$ in such a way that $\chi_3(\sigma_2)$ is the inner half circle $\{|z| = 1,\ y \ge 0\}$ and χ_3 is the identity mapping on the rest of the boundary. Finally one can extend χ_3 as a mapping from $B_2\backslash\sigma_2$ onto $B_2\backslash\overline{B_1}$ by symmetry. One can make sure that for each χ_i, $i = 1, 2, 3$, the Jacobian and its inverse are uniformly bounded by constants depending on the a priori data only. In conclusion we pick $\chi = \chi_3 \circ \chi_2 \circ \chi_1$. □

Proof of Proposition 3.7(i). Let χ be the bi-Lipschitz map constructed in Lemma 3.9 and let us call

$$\tilde{f}(z) = f \circ \chi^{-1}, \quad z \in B_2\backslash\overline{B_1}. \tag{3.18}$$

By the $W^{1,\infty}$ bounds on χ and its inverse obtained in Lemma 3.9, χ is also quasi-conformal; hence we can find $\tilde{\mu} \in L^\infty(B_2\backslash\overline{B_1})$ such that

$$\tilde{f}_{\bar{z}} = \tilde{\mu}\tilde{f}_z \quad \text{almost everywhere in } B_2\backslash\overline{B_1}, \tag{3.19}$$

where

$$\tilde{\mu} \le \tilde{k} < 1 \tag{3.20}$$

and $\tilde{k}$ depends on the a priori data only.

Let $\tilde{v} = v \circ \chi^{-1} = \Im\tilde{f}$; then $\tilde{v}$ is a weak solution to

$$\begin{cases} \operatorname{div}(\tilde{B}\nabla\tilde{v}) = 0 & \text{in } B_2\backslash\overline{B_1}, \\ \tilde{v} = \text{const} & \text{on } \partial B_1, \\ \tilde{v} = \Psi \circ \chi^{-1} & \text{on } \partial B_2, \\ \int_{\partial B_2} \tilde{B}\nabla\tilde{v} \cdot \nu = 0, \end{cases} \tag{3.21}$$

where $\tilde{B}$ satisfies uniform ellipticity bounds of the type (2.10), with constants depending on the a priori data only.

Since the Dirichlet data in (3.21) are given as Hölder continuous traces of a $W^{1,2}(B_2\backslash\overline{B_1})$ function, by standard results of regularity up to the boundary, we obtain that $\tilde{v}$ satisfies a uniform Hölder estimate in $\overline{B_2}\backslash B_1$, with constants depending on the a priori data only.

Hence by recalling $v = \tilde{v} \circ \chi$, $\tilde{v}|_{\partial B_1} = v|_\sigma = \text{constant}$, and by the estimate

$$|\chi(z_1) - \chi(z_2)| \le C_4\tilde{d}(z_1, z_2) \quad \text{for every } z_1, z_2 \in \Omega\backslash\sigma, \tag{3.22}$$

following from Lemma 3.9, (3.15) follows. □

Proof of Proposition 3.7(ii). Let us apply the representation Theorem 3.2 to $\tilde{f}$, which gives us that, up to a quasi-conformal change of coordinates, $\tilde{u} = u \circ \chi^{-1}$ is the conjugate function to $-\tilde{v}$.

Hence by a local use of Privaloff's Theorem (see, e.g., [B-J-S, Part II, Chapter 6, Theorem 5, page 279]) we obtain that also $\tilde{u}$ satisfies a uniform Hölder estimate in $\overline{B_2}\backslash B_1$, with constants only depending on the a priori data. Hence (3.16) follows from (3.22). □

In order to proceed with the proof of (iii) of Proposition 3.7 we shall need the following two lemmas.

Let us extend $\tilde{f}$, $\tilde{\mu}$ to $B_2\backslash\overline{B_{1/2}}$ by the reflection rules

$$\begin{cases} \tilde{f}(z) = \overline{\tilde{f}(1/\overline{z})} + 2ci, \\ \tilde{\mu}(z) = \overline{\tilde{\mu}(1/\overline{z})}, \end{cases} \qquad z \in B_2\backslash\overline{B_{1/2}}, \tag{3.23}$$

where $c = \tilde{v}|_{\partial B_1}$.

We obtain that $\tilde{f} \in W^{1,2}(B_2\backslash\overline{B_{1/2}}, \mathbb{C})$ and satisfies (3.19) on all of $B_2\backslash\overline{B_{1/2}}$ where $|\tilde{\mu}| \le \tilde{k} < 1$ obviously holds throughout. Note that (3.23) imply that $\tilde{u}$, $\tilde{v}$ satisfy the reflection rules

$$\begin{cases} \tilde{u}(z) = \tilde{u}(1/\overline{z}), \\ \tilde{v}(z) = 2c - \tilde{v}(1/\overline{z}), \end{cases} \qquad z \in B_2\backslash\overline{B_{1/2}}, \tag{3.24}$$

and according to Proposition 3.1 are solutions to uniformly elliptic equations in all of $B_2\backslash\overline{B_{1/2}}$.

LEMMA 3.10. *$\tilde{u}$ has exactly two geometric critical points $\tilde{P}_1$, $\tilde{P}_2$ of index one in $B_2\backslash\overline{B_{1/2}}$. $\tilde{P}_1$, $\tilde{P}_2$ belong to ∂B_1 and they are distinct.*

Remark. It may be useful to stress that $\tilde{P}_1$, $\tilde{P}_2$ are also the unique geometric critical points of $\tilde{v}$ in $B_2\backslash\overline{B_{1/2}}$.

Proof. This statement is proven in [A-DV, Proposition 3.2] except from the fact that $\tilde{P}_1$, $\tilde{P}_2$ are distinct. This can be obtained by the following contradiction argument, if we had $\tilde{P}_1 = \tilde{P}_2$ then, on $\partial B_1\backslash\{\tilde{P}_1\}$, $\tilde{v} \equiv$ *constant* and hence $\tilde{u}$ should be strictly monotone along such a simple curve, thus contradicting its continuity at $\tilde{P}_1$. □

Let us denote $m = \min_{\partial\Omega} \Psi$, $M = \max_{\partial\Omega} \Psi$, and $c = v|_\sigma$. Observe that by the use of the maximum principle in (3.10′) one obtains $m < c < M$.

LEMMA 3.11. *For any $t \in (m, M)$, $t \neq c$, the level line $\{z \in \Omega\backslash\sigma |\, v(z) = t\}$ is composed by a simple curve γ_t joining the two connected components of the level set $\{z \in \partial\Omega |\, \Psi(z) = t\}$.*

The level line $\{z \in \Omega\backslash\sigma |\, v(z) = c\}$ is composed of two simple curves γ_c^1, γ_c^2 each joining σ with one of the two connected components of $\{z \in \partial\Omega |\, \Psi(z) = c\}$, respectively. Moreover the limit points of γ_c^1, γ_c^2 on σ are given by two single points P_1, P_2 which are distinct as elements of $\tilde{\sigma}$.

Proof. By the continuity (3.15) of v we have that for every $t \in (m, M)$ the limit points of $\{z \in \Omega\backslash\sigma |\, v(z) = t\}$ on $\partial\Omega \cup \tilde{\sigma}$ all belong to $\{z \in \partial\Omega |\, \Psi(z) = t\}$ if $t \neq c$ and to $\{z \in \partial\Omega |\, \Psi(z) = c\} \cup \tilde{\sigma}$ if $t = c$.

Let $t \neq c$ and let $z_0 \in \Omega\backslash\sigma$ be such that $v(z_0) = t$. By Lemma 3.10 we have that $v = \tilde{v} \circ \chi$ has no geometric critical points in $\Omega\backslash\sigma$. Therefore, by the maximum principle, the connected component γ_t of $\{v = t\}$ containing z_0 is a simple curve having endpoints on $\partial\Omega$. Again, by the maximum principle, we obtain that $v \neq t$ outside of γ_t and hence $\{v = t\} = \gamma_t$. By the same reasoning, we may find two distinct arcs γ_c^1, γ_c^2 in $\Omega\backslash\sigma$ on which $v = c$, each joining σ to the two distinct components of $\{z \in \partial\Omega |\, \Psi(z) = c\}$. Such curves disconnect $\Omega\backslash\sigma$, and hence, by the maximum principle, they exhaust the level set $\{v = c\}$. Concerning the limit points of $\{v = c\}$ on σ, these coincide with the preimages through χ of the geometric critical points $\tilde{P}_1$, $\tilde{P}_2$ of $\tilde{v}$, and the thesis follows. □

Proof of Proposition 3.7(iii). It suffices to prove that f is univalent. We use the notation introduced in Lemma 3.11. Let $\tilde{\sigma}_1$, $\tilde{\sigma}_2$ the abstract simple curves forming $\tilde{\sigma}\backslash\{P_1, P_2\}$. Using the representation $u = \tilde{u} \circ \chi$ and the absence of geometric critical points for $\tilde{u}$ in $B_2\backslash(\overline{B_{1/2}} \cup \{\tilde{P}_1, \tilde{P}_2\})$ we have that u is strictly increasing on each of

the curves $\gamma_c^1 \cup \gamma_c^2 \cup \tilde{\sigma}_i$, $i = 1, 2$. Analogously, when $t \in (m, M)$, $t \neq c$, u is strictly increasing on γ_t. Therefore for any $\zeta = s + it \in f(\Omega \backslash \sigma)$ there exists a unique $z \in \Omega \backslash \sigma$ such that $v(z) = t$, $u(z) = s$. □

Proof of Proposition 3.7(iv). With the aid of Theorem 3.2 and of a suitable conformal mapping, we obtain that there exist $R > 1$ depending on the a priori data only and a quasiconformal mapping χ_1 from $B_2 \backslash \overline{B_{1/2}}$ onto $B_R \backslash \overline{B_1}$ and a holomorphic function F on $B_R \backslash \overline{B_1}$ such that

$$\tilde{f} = F \circ \chi_1;$$

moreover, χ_1, χ_1^{-1} satisfy uniform Hölder estimates with constants depending on the a priori data only.

Let U, V be the real and imaginary part of F, respectively.

We remark that, in view of Lemma 3.10, F has exactly two critical points, which are distinct and have multiplicity one, in $B_R \backslash \overline{B_1}$. We denote such points $\zeta_1 = \chi_1(\tilde{P}_1)$, $\zeta_2 = \chi_1(\tilde{P}_2)$. Let us denote $D = B_R \backslash \overline{B_1}$ and $D_d = B_{R-d} \backslash \overline{B_{1+d}}$, $d > 0$. We claim the following lower bound on $|F'|$, whose proof is deferred to the end of this section.

Claim. There exists a positive constant C_5 depending on the a priori data and on d only such that the following estimate holds

$$|F'(z)| \geq C_5 |z - \zeta_1||z - \zeta_2| \quad \text{for any } z \in D_d. \tag{3.25}$$

Let us now recall that $F = f \circ \chi^{-1} \circ \chi_1^{-1}$ and let us fix d, $p > 0$. Denote by γ the image through χ_1 of ∂B_1, that is, $\gamma = (\chi_1 \circ \chi)(\tilde{\sigma})$. Let $\alpha_2 > 0$ be a uniform Hölder exponent for $\chi_1 \circ \chi$ and its inverse. We recall that α_2 depends on the a priori data only.

For any $z \in \Omega_{d,p}$ we have

$$\begin{aligned} &\operatorname{dist}(\chi_1 \circ \chi(z), \partial B_R) \geq C_6 d^{1/\alpha_2}, \\ &\operatorname{dist}(\chi_1 \circ \chi(z), \gamma) \geq C_6 p^{1/\alpha_2}, \end{aligned}$$

where C_6 depends on the a priori data only.

We remark that $F(\gamma) = f(\sigma)$ is a horizontal segment l.

So using (3.25) we can show that the image through f of $\Omega_{d,p}$ is contained in a doubly connected open set $D_1 \subset f(\Omega \backslash \sigma)$ whose boundary is constituted by two curves γ_1 and γ_2. The outer one, γ_1, is a Jordan curve such that for any z_0, $z_1 \in \gamma_1$ the following estimate holds

$$\operatorname{length}_{\gamma_1}(z_0, z_1) \leq C_7 |z_0 - z_1|.$$

On the other hand, γ_2 is the set of points whose distance from the segment l is equal to $C_8 p^{3/\alpha_2}$.

Furthermore on D_1 we can find the following estimate:

$$|(F^{-1})'|(z) \leq C_9 p^{-3/\alpha_2} \quad \text{for any } z \in D_1.$$

Then, evaluating the geodetic distance on D_1, we have that for any z, $w \in D_1$ it holds that

$$|F^{-1}(z) - F^{-1}(w)| \leq C_{10} p^{-4/\alpha_2} |z - w|; \tag{3.26}$$

hence for any z, $w \in \Omega_{d,p}$ we have

$$|f(z) - f(w)| \geq C_{11} p^{4/\alpha_2} |z - w|^{1/\alpha_2}. \tag{3.27}$$

The constants C_7–C_{11} depend on d and on the a priori data only. So (3.17) follows. □

Proof of the Claim. We adapt arguments used in [A1, Theorem 1.3]. First, we notice that F is Hölder continuous in D. Hence $|F|$ can be bounded on D by a constant C_{12}, C_{12} depending on the a priori data only, and in view of (3.14) there exists d_1 small enough such that for any $0 < d \le d_1$ the oscillation of V on ∂D_d is greater than $1/2\sqrt{2}$.

Without loss of generality we can restrict our attention to the case $0 < d \le d_1$; then, by using estimates on Cauchy's integrals, we have

$$|F'| \le 2C_{12}/d \qquad \forall z \in D_{d/2}, \tag{3.28}$$

$$|F''| \le 8C_{12}/d^2 \qquad \forall z \in D_{d/2}. \tag{3.29}$$

We denote $\phi = \log \frac{|F'|}{|z-\zeta_1||z-\zeta_2|}$; this is a harmonic function in D. Let $M = \sup_{D_{d/2}} \phi$; then we apply the Harnack inequality to $M - \phi$ and obtain

$$\sup_{D_d}(M-\phi) \le c \inf_{D_d}(M-\phi),$$

where c depends on d and on R only. This, in turn, implies that

$$\inf_{D_d} \phi \ge M - c(M - \sup_{D_d} \phi). \tag{3.30}$$

Notice that we have

$$1/2\sqrt{2} \le \operatorname{osc}_{\partial D_d} V \le C_{13} \max_{D_d} |F'| \le C_{14} \max_{D_d} \exp \phi,$$

and hence $M \ge C_{15} > 0$. Using (3.29), possibly choosing a smaller value for the constant d_1, we can find an upper bound on $M - \sup_{D_d} \phi$. Hence we can find a constant C_{16}, depending on the a priori data and on d only, such that $\inf_{D_d} \phi \ge C_{16}$ and the claim follows. □

4. Stability for a Cauchy problem. Let u be given by (3.11) and let u' be given accordingly when σ is replaced with σ'. Let v and v' be the stream functions of u and u', respectively; we choose to normalize v, v' in such a way that they have the same Dirichlet data Ψ on $\partial\Omega$.

Let us denote $\Phi = W + iZ = u - u' + i(v - v') : \Omega \backslash (\sigma \cup \sigma') \mapsto \mathbb{C}$.

We have that Z is identically zero on $\partial\Omega$ and $|W| \le \sqrt{2}\varepsilon$ on Σ. We remember that, by Proposition 3.7(i), (ii), there exists a constant K_1 depending on the a priori data only such that

$$|\Phi(z)| \le K_1 \quad \text{for any } z \in \Omega \backslash (\sigma \cup \sigma'). \tag{4.1}$$

Furthermore by (3.15) the function Z is Hölder continuous on $\overline{\Omega}$ with constants depending on the a priori data only.

Φ satisfies the Cauchy problem

$$\begin{cases} \Phi_{\overline{z}} = \mu \Phi_z + \nu \overline{\Phi_z} & \text{in } \Omega \backslash (\sigma \cup \sigma'), \\ |\Phi| \le \sqrt{2}\varepsilon & \text{on } \Sigma, \\ \Im \Phi = 0 & \text{on } \partial\Omega, \end{cases} \tag{4.2}$$

where $|\mu| + |\nu| \le k < 1$.

We want to estimate $|Z|$ on $\overline{\Omega}$ in terms of ε.

PROPOSITION 4.1. *Under the previous assumptions we have*

$$|Z(z)| \leq \eta(\varepsilon) \quad \text{for any } z \in \overline{\Omega}, \tag{4.3}$$

where η is a positive function defined on $(0, +\infty)$ that verifies

$$\eta(\varepsilon) \leq K_2(\log|\log\varepsilon|)^{-\beta_1} \quad \text{for every } \varepsilon,\ 0 < \varepsilon < 1/e. \tag{4.4}$$

Here K_2 and β_1 are positive constants depending on the a priori data only.

Let us recall some notions from potential theory; see for instance the book by J. Heinonen, T. Kilpeläinen, and O. Martio, [H-K-Ma].

Let D be a bounded open set. Let $A \in L^\infty(D)$ be a 2×2 matrix which satisfies (2.10).

We denote by $\mathcal{L}_A$ the differential operator

$$\mathcal{L}_A u = -\mathrm{div}(A\nabla u). \tag{4.5}$$

DEFINITION 4.2. *A function $u : D \mapsto \mathbb{R} \cup \{+\infty\}$ is called* $\mathcal{L}_A$-superharmonic *in D if*

(i) *u is lower semicontinuous;*

(ii) *$u \not\equiv +\infty$ in any connected component of D;*

(iii) *for any open set $D_1 \subset\subset D$ and any $h \in C(\overline{D_1})$, such that $\mathcal{L}_A h = 0$ in the weak sense in D_1, if $u \geq h$ on ∂D_1 then $u \geq h$ in D_1.*

A function u is $\mathcal{L}_A$-subharmonic *in D if $-u$ is $\mathcal{L}_A$-superharmonic in D.*

DEFINITION 4.3. *Let E be a subset of ∂D and let χ_E be its characteristic function. We define the* $\mathcal{L}_A$-harmonic measure *of E with respect to D as the* upper Perron solution *with respect to χ_E; that is,*

$$\omega(z) = \omega(E, D, \mathcal{L}_A; z) = \inf\{u(z) |\, u \in \mathcal{U}_E\} \quad \text{for any } z \in D,$$

where $\mathcal{U}_E$ is the class of the $\mathcal{L}_A$-superharmonic functions u in D such that $u \geq 0$ and $\liminf_{x\to y} u(x) \geq \chi_E(y)$ for any $y \in \partial D$.

LEMMA 4.4. *Let D be a bounded domain. Let $f \in W^{1,2}(D, \mathbb{C})$ satisfy* (3.3), (3.4). *There exists a 2×2 matrix $A_1 \in L^\infty(D)$ satisfying* (2.10) *with constants λ, Λ depending on k only such that $\phi = \log|f|$ is $\mathcal{L}_{A_1}$-subharmonic.*

Proof. Let z be a point in D such that $f(z) \neq 0$. Locally, on a neighborhood of z, we can define the function $\phi_1 = \log f$ where log is any possible determination of the logarithm in the complex plane.

In this neighborhood ϕ_1 verifies the equation

$$(\phi_1)_{\overline{z}} = \mu(\phi_1)_z + \nu_1\overline{(\phi_1)_z}, \tag{4.6}$$

where $\nu_1 = \nu\overline{f}/f$ and hence $|\mu| + |\nu_1| \leq k < 1$.

Then we consider the matrix A_1 corresponding to μ and ν_1, as in (3.7). By Proposition 3.1 the function $\phi = \log|f| = \Re\log f$ locally verifies

$$\mathrm{div}(A_1\nabla\phi) = 0 \tag{4.7}$$

in the weak sense.

We remark that we can define $\phi = \log|f|$ globally as a $W^{1,2}_{loc}(D_1)$ function, where $D_1 = \{z \in D |\, f(z) \neq 0\}$; hence using a partition of unity it is easy to show that (4.7) holds weakly in D_1.

Clearly the set $\{z \in D |\, f(z) = 0\}$ consists of isolated points and ϕ goes uniformly to $-\infty$ as z converges to an element of such a set.

Using this remark and the maximum principle, we can prove in an elementary way that $\phi = \log|f|$ is $\mathcal{L}_{A_1}$-subharmonic. □

By the use of suitable $\mathcal{L}_{A_1}$-harmonic measure we obtain a Hölder stability estimate in the interior for Cauchy problems like (4.2), as follows.

THEOREM 4.5. *Let D be bounded domain and E a subset of ∂D. Let f satisfy* (3.3), (3.4).

If $C = \sup|f|$ on D and we have that, given $\varepsilon > 0$,

$$\limsup_{x \to y} |f(x)| \leq \varepsilon \tag{4.8}$$

for any $y \in E$, then for any $z \in D$ the following estimate holds

$$|f(z)| \leq C^{1-\omega(z)} \varepsilon^{\omega(z)}, \tag{4.9}$$

where $\omega = \omega(E, D, \mathcal{L}_{A_1})$ is the $\mathcal{L}_{A_1}$-harmonic measure of E with respect to D and the matrix A_1 is defined as in the thesis of the Lemma 4.4.

Proof. We can assume, without loss of generality, that $0 < \varepsilon < C$. Consider the function $\phi = \log|f|$, by the fact that Lemma 4.4 ϕ is $\mathcal{L}_{A_1}$-subharmonic. Let $\omega = \omega(E, D, \mathcal{L}_{A_1})$ be the $\mathcal{L}_{A_1}$-harmonic measure of E with respect to D.

Let us denote $\phi_2 = \frac{\phi - \log(C)}{\log(\varepsilon) - \log(C)}$. It is easy to see that ϕ_2 belongs to the upper class $\mathcal{U}_E$. Hence for any $z \in D$ we have $\omega(z) \leq \phi_2(z)$ and so

$$\phi(z) \leq \log(\varepsilon)(\omega(z)) + \log(C)(1 - \omega(z)). \tag{4.10}$$

And this clearly implies the thesis. □

Remark. Observe that in view of Proposition 3.1 the above Theorem 4.5 could be restated in terms of a Cauchy problem for an elliptic equation like (3.1).

Proof of Proposition 4.1 (*Sketch*). The proof of this proposition can be obtained along the same lines as in the proof of Theorem 3.1 in [A2], once Theorem 4.5 is available.

First consider curves γ, with the first endpoint on Σ, whose h-neighborhoods γ_h are contained in $\Omega \backslash (\sigma \cup \sigma')$.

Then we apply Theorem 4.5 inside such domains γ_h, and we consider a point $z \in \gamma_h$ and $\omega = \omega(\Sigma \cap \partial\gamma_h, \gamma_h; \mathcal{L}_{A_1})$ as in Theorem 4.5. We obtain, recalling (4.1), (4.2),

$$|\Phi(z)| \leq K_1^{1-\omega(z)} \varepsilon^{\omega(z)}.$$

We find a positive lower bound on $\omega(z)$ by a repeated use of the Harnack inequality; then through Hölder continuity of Z in $\overline{\Omega}$ we can evaluate an upper bound for $|Z|$ on $\overline{\gamma_h}$. Finally we use the maximum principle together with the fact that v and v' are constant on σ, σ', respectively, to obtain the desired bound for $|Z|$ on $\overline{\Omega}$. □

5. Proof of the main Theorem 2.1. The proof of Theorem 2.1 will be completed by combining Proposition 4.1 with the following result. □

PROPOSITION 5.1. *Let all the assumptions of Theorem* 2.1 *be satisfied with the exception of* (2.12). *Let v_i be the stream functions related to u_i and let v_i' be those related to u_i'. If we have*

$$\max_{i=1,2} \|v_i - v_i'\|_{L^\infty(\Omega)} \leq \eta, \tag{5.1}$$

then the two cracks σ, σ' satisfy

$$\mathrm{d}_H(\sigma,\sigma') \le K_3\eta^{\beta_2}, \tag{5.2}$$

where K_3, β_2, $K_3 > 0$, $0 < \beta_2 < 1$, only depend on the a priori data.

Proof. Up to reversing the role of σ and σ' we may fix $z_0 \in \sigma'\backslash\sigma$ in such a way that $p = \mathrm{dist}(z_0,\sigma) = d_H(\sigma,\sigma') > 0$.

There exists a positive constant $K_4 > 1$ only depending on the a priori data such that

(5.3)(a) $B_{p/K_4}(z_0) \subset \Omega_{\delta/2}\backslash\sigma$;
(5.3)(b) there exists a point $z_1 \in \sigma'$ such that $|z_1 - z_0| = p/2K_4$.

Hence we can determine two real numbers a, b such that $a^2 + b^2 = 1$ and

$$au_1(z_o) + bu_2(z_0) = au_1(z_1) + bu_2(z_1) \tag{5.4}$$

holds true.

So we define u and v as in (3.11) and it turns out that

$$u(z_o) = u(z_1). \tag{5.5}$$

Recall that u solves (1.1) and v is its stream function. Let, as usual, $f = u + iv$.

Then by (iv) of Proposition 3.7 there exists a constant K_5, depending on the a priori data only, such that

$$p^{5/\alpha_1} \le K_5|f(z_0) - f(z_1)|. \tag{5.6}$$

Note that, by (5.5), $|f(z_0) - f(z_1)| = |v(z_0) - v(z_1)|$. We have that z_0 and z_1 belong to σ'; hence $v'(z_0) = v'(z_1)$.

So we have

$$|f(z_0) - f(z_1)| \le 2\eta. \tag{5.7}$$

Consequently

$$p \le K_6\eta^{\alpha_1/5}, \tag{5.8}$$

where K_6 and α_1 only depend on the a priori data. ∎

Concluding remarks. Let us recall that, for the case of uniform background conductivity, a log-log–type stability like the present one was proven in [A2]. Subsequently, in [A3], it was shown that the stability could be improved to a log-type estimate. A $C^{2,\alpha}$ a priori bound on σ was assumed. It can be verified that the approach in [A3] could be used with minor adaptations also in the present case, at the cost of assuming a somewhat stronger a priori assumption on the crack. For instance, an analysis of this sort has been developed in [R] where it was assumed a $C^{1,\alpha}$ bound on σ and a Lipschitz bound on A. Let us stress here that in view of Theorem 4.5 in this paper any regularity assumption on A can be dropped.

Let us recall here also the examples in [A4] for the so-called inverse problem of corrosion detection, which is different, but strictly allied, to the crack problem. Such examples show that logarithmic stability is best possible for that problem and they strongly suggest that this is the case also for the crack problem.

From another point of view, we notice that the Lipschitz regularity assumptions on σ and on $\partial\Omega$ could be further relaxed. In fact we could cast our analysis within

the theory of *quasicircles* (see [P, Chapter 5] and [L]) and prescribe that σ and $\partial\Omega$ satisfy the so-called arc condition. This ensures that quasi-conformal mappings in $\Omega\backslash\tilde{\sigma}$ are Hölder continuous up to the boundary, thus permitting us to derive statements analogous to Proposition 3.7 and, consequently, to Theorem 2.1. However, we have preferred to confine ourselves within the Lipschitz class which, we believe, is sufficiently wide and manageable from the applications point of view.

THE BREAKDOWN OF SUPERCONDUCTIVITY DUE TO STRONG FIELDS FOR THE GINZBURG–LANDAU MODEL*

T. GIORGI† AND D. PHILLIPS‡

Abstract. We study the behavior of a superconducting material subjected to a constant applied magnetic field, $\mathbf{H}_a = h\mathbf{e}$ with $|\mathbf{e}| = 1$, using the Ginzburg–Landau theory. We analytically show the existence of a critical field $\overline{h}$, for which when $h > \overline{h}$, the normal states are the only solutions to the Ginzburg–Landau equations. We estimate $\overline{h}$. As $\kappa \downarrow 0$ we derive $\overline{h} = O(1)$, while as $\kappa \to \infty$ we obtain $\overline{h} = O(\kappa)$.

Key words. superconductivity, Ginzburg–Landau equations, upper critical fields, normal state

1. Introduction.

If a superconducting body is subjected to a sufficiently strong applied magnetic field, its ability to act as a superconductor breaks down and only the normally conducting (resistive) state is observed. In this paper we consider superconductivity as modeled by the Ginzburg–Landau theory and establish this type of phenomena. Here, superconductivity is characterized in terms of a complex valued order parameter, ψ (where $|\psi|^2$ represents the density of superconducting electron pairs), and a vector field $\mathbf{A}$—the magnetic potential.

Consider a superconducting body given by a bounded domain $\boldsymbol{\mathcal{D}} \subset \mathbb{R}^n$, where $n = 2$ or 3 and $\partial\boldsymbol{\mathcal{D}}$ is of class $C^{2,\alpha}$ for some $0 < \alpha < 1$. Assume the body has constant permeability normalized equal to one and that the exterior consists of a second material with constant permeability $\mu_e > 0$. Define the permeability density as follows:

$$\begin{aligned} \mu(\mathbf{x}) &= 1 \quad \text{for } \mathbf{x} \in \boldsymbol{\mathcal{D}} \\ &= \mu_e \quad \text{for } \mathbf{x} \in \mathbb{R}^n \setminus \overline{\boldsymbol{\mathcal{D}}}. \end{aligned}$$

A magnetic field is applied to all space in the form $\mathbf{H}_a = h\mathbf{e}$, where h is a positive constant and $\mathbf{e} \in \mathbb{R}^3$ is a fixed unit vector. The presence of $\boldsymbol{\mathcal{D}}$ produces an induced magnetic field, $\frac{1}{\mu}\operatorname{curl}\mathbf{A}$ in $\mathbb{R}^3$, and a supercurrent density $\mathbf{j} := \frac{-i}{2\kappa}(\psi^*\nabla\psi - \psi\nabla\psi^*) - \mathbf{A}|\psi|^2$ in $\boldsymbol{\mathcal{D}}$. Here $\kappa > 0$ is the Ginzburg–Landau constant determined from the superconducting material and the superscript $*$ denotes complex conjugation. According to this theory, the pair $(\psi, \mathbf{A})$ is an equilibrium state for the Gibbs free

$$G(\psi,\mathbf{A}) := \int_{\boldsymbol{\mathcal{D}}} \left(\left| \frac{i}{\kappa}\nabla\psi + \mathbf{A}\psi \right|^2 + \frac{1}{2}(1-|\psi|^2)^2 \right) d\mathbf{x} + \int_{\mathbb{R}^n} \mu \left| \frac{1}{\mu}\operatorname{curl}\mathbf{A} - h\mathbf{e} \right|^2 d\mathbf{x} + \frac{\gamma}{\kappa}\int_{\partial\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{s} \tag{1.1}$$

(see [5], [14]). The constant $\gamma \geq 0$ reflects the retarding effect of the material in the exterior domain on the density $|\psi|^2$ at $\partial\boldsymbol{\mathcal{D}}$; γ is taken to be zero if $\mathbb{R}^n \setminus \overline{\boldsymbol{\mathcal{D}}}$ is a vacuum and large if the exterior is a magnetic material. Thus, we consider pairs $(\psi, \mathbf{A})$ such that

$$\psi \in H^1(\boldsymbol{\mathcal{D}};\mathbb{C}) \equiv \mathcal{H}^1(\boldsymbol{\mathcal{D}}), \quad \mathbf{A} \in H^1_{\mathrm{loc}}(\mathbb{R}^n;\mathbb{R}^n),$$

which are weak solutions to

$$\begin{cases} \left(\dfrac{i}{\kappa}\nabla + \mathbf{A}\right)^2 \psi - \psi + |\psi|^2\psi = 0 & \text{in } \boldsymbol{\mathcal{D}}, \\ \operatorname{curl}\left(\dfrac{1}{\mu}\operatorname{curl}\mathbf{A}\right) + \left(\dfrac{i}{2\kappa}(\psi^*\nabla\psi - \psi\nabla\psi^*) + \mathbf{A}|\psi|^2\right)\chi_{\boldsymbol{\mathcal{D}}} = 0 & \text{in } \mathbb{R}^n, \\ \mathbf{n}\cdot\left(\dfrac{i}{\kappa}\nabla + \mathbf{A}\right)\psi = -i\gamma\psi & \text{on } \partial\boldsymbol{\mathcal{D}}, \\ \left(\dfrac{1}{\mu}\operatorname{curl}\mathbf{A} - h\mathbf{e}\right) \in L^2(\mathbb{R}^n;\mathbb{R}^3). \end{cases} \tag{1.2}$$

Here $\mathbf{n}$ is the outward normal to $\boldsymbol{\mathcal{D}}$ at $\partial\boldsymbol{\mathcal{D}}$ and $\chi_{\boldsymbol{\mathcal{D}}}$ is the characteristic function for $\boldsymbol{\mathcal{D}}$.

A principal feature of the energy (1.1) and the solutions to (1.2) is that they are invariant under the gauge transformation

$$(\psi,\mathbf{A}) \to (\psi',\mathbf{A}'),$$

where

$$\psi' = \psi e^{i\kappa\eta}, \quad \mathbf{A}' = \mathbf{A} + \nabla\eta$$

for an arbitrary real valued function $\eta \in H^2_{\mathrm{loc}}(\mathbb{R}^n)$. Moreover, the intrinsic quantities for a solution are preserved under this transformation: its density $|\psi'|^2 = |\psi|^2$, magnetic field $\frac{1}{\mu}\operatorname{curl}\mathbf{A}' = \frac{1}{\mu}\operatorname{curl}\mathbf{A}$, current $\mathbf{j}' = \mathbf{j}$, and the modulus of the derivative $|(\frac{i}{\kappa}\nabla + \mathbf{A}')\psi'| = |(\frac{i}{\kappa}\nabla + \mathbf{A})\psi|$.

A solution is in the *normal phase* if $\psi \equiv 0$ in $\boldsymbol{\mathcal{D}}$. This is written as $(\psi,\mathbf{A}) = (0, h\mathbf{a}_N)$, where $\mathbf{a}_N$ satisfies

$$\begin{aligned} &\operatorname{curl}\left(\frac{1}{\mu}\operatorname{curl}\mathbf{a}_N\right) = 0 \quad \text{in } \mathbb{R}^n, \\ &\left(\frac{1}{\mu}\operatorname{curl}\mathbf{a}_N - \mathbf{e}\right) \in L^2(\mathbb{R}^n;\mathbb{R}^3). \end{aligned} \tag{1.3}$$

Such a solution is called a *normal state*. It is uniquely determined by μ and $\boldsymbol{\mathcal{D}}$ up to a gauge transformation; that is, (1.3) uniquely determines $\operatorname{curl}\mathbf{a}_N$.

Let κ be fixed. We denote $\overline{h}$ as the *upper critical field* for the body

$$\overline{h} := \inf\{h' : \text{ normal states are the only solutions to (1.2) for all } h > h'\}.$$

For the case that the body is a bounded domain $\boldsymbol{\mathcal{D}} \subset \mathbb{R}^3$, we prove the following statement:

Let $\boldsymbol{\mathcal{D}} \subset \mathbb{R}^3$. Given κ, μ_e, and γ we have $\overline{h} = \overline{h}(\kappa, \mu_e, \gamma, \boldsymbol{\mathcal{D}}) < \infty$ (see Theorem 3.12).

We show the normal induction is continuous on $\overline{\boldsymbol{\mathcal{D}}}$. In the case that it does not vanish on $\overline{\boldsymbol{\mathcal{D}}}$, we can estimate $\overline{h}$.

If $\operatorname{curl} \mathbf{a}_N \neq \mathbf{0}$ in $\overline{\boldsymbol{\mathcal{D}}} \subset \mathbb{R}^3$, then there are constants m, $\phi \geq 0$, depending on μ_e and $\boldsymbol{\mathcal{D}}$ so that

$$\overline{h}(\kappa, \mu_e, \gamma, \boldsymbol{\mathcal{D}}) \leq \max\left(\frac{m}{\kappa}, \phi\kappa\right) \tag{1.4}$$

(see Theorem 3.9).

In the classic case where $\mu_e = 1$, it follows that $\operatorname{curl} \mathbf{a}_N \equiv \mathbf{e}$ and as such (1.4) applies.

If $\mu \equiv 1$, then there are constants m and ϕ such that $\overline{h} \leq \max(\frac{m}{\kappa}, \phi\kappa)$ (see Corollary 3.10).

We also consider the case of a cylindrical domain of the form $\boldsymbol{\mathcal{D}} \times \mathbb{R}$ where the cross section, $\boldsymbol{\mathcal{D}}$, is a bounded domain in $\mathbb{R}^2$ with a $C^{2,\alpha}$ boundary and the applied field $\mathbf{H}_a = h\mathbf{e} = h\mathbf{e}_3$ is perpendicular to the cross section. From symmetry the problem reduces to one in two dimensions. We consider $\psi(x, y)$ for $(x, y) \in \boldsymbol{\mathcal{D}}$ and $\mathbf{A} = (A_1(x, y), A_2(x, y))$ for $(x, y) \in \mathbb{R}^2$. The functional (1.1) then represents the Gibbs free energy per unit length for the cylinder. We prove the following theorem.

Let $\boldsymbol{\mathcal{D}} \times \mathbb{R}$ be a cylindrical body in a parallel applied field $h\mathbf{e}_3$. Given κ, μ_e, and γ there is a finite upper critical field $\overline{h}$, so that if $h > \overline{h}$ then the only solution to (1.2) *with $n = 2$ is normal. Moreover, there is a constant $\phi(\mu_e, \boldsymbol{\mathcal{D}})$ so that $\overline{h}(\kappa, \mu_e, \gamma, \boldsymbol{\mathcal{D}}) \leq \max(\frac{1}{\kappa}, \phi\kappa)$* (see Theorem 2.9).

Finally, we consider the case of small κ. We prove the following result.

Let $n = 2$ with $\mu_e > 0$ or $n = 3$ with $\mu_e = 1$. Then $\overline{h} = O(1)$ as $\kappa \downarrow 0$ (see Theorem 4.1).

It is of interest to compare these results with conjectures made by physicists. For κ fixed, de Gennes and St. James have studied the local problem of determining the smallest value of h for which all normal states are stable for $h' \geq h$. The infimum, denoted as h_{c_3}, is the value for which it is possible to have a family of superconducting solutions bifurcate away from the normal state. In [13] they discussed the case of an infinite slab $-d < x < d$, $-\infty < y, z < \infty$ in $\mathbb{R}^3$. The symmetry of the domain reduced the linear analysis to a one-dimensional problem. They gave an ansatz for determining h_{c_3} and predicted $\lim_{\kappa \to \infty} h_{c_3}/\kappa = c_0$ for some constant $1 < c_0 < 2$. This can be compared with our estimates for $\overline{h}$ from Theorems 2.9 and 3.9. We have $h_{c_3} \leq \overline{h} = O(\kappa)$ as $\kappa \to \infty$. For small κ, physicists have predicted that $\overline{h} = O(1)$ as $\kappa \to 0$ for a slab of finite thickness $-d < x < d$, $-\infty < y, z < \infty$ and that $\overline{h} = O(\kappa^{-\frac{1}{2}})$ as $\kappa \to 0$ for the infinitely thick slab $-\infty < x < 0$, $-\infty < y, z < \infty$ (see [4], [8], and [12]). Our estimate from Theorem 4.1 gives the result $\overline{h} = O(1)$ as $\kappa \to 0$ for our domain $\boldsymbol{\mathcal{D}}$.

To conclude, we comment on past analytic work. In [2] and [3], Bolley and Bolley and Helffer made the ansatz for the slab rigorous and proved asymptotic estimates for h_{c_3}. In [4] they obtained partial results for estimating an upper critical field for the slab. They considered a particular family of one-dimensional functions. For each fixed κ, they showed there is a finite upper critical field when considering only solutions in this family. In [1] Bauman, Phillips, and Tang estimated h_{c_3} for the case of a circular

cylinder, $B_r \times \mathbb{R}$. This estimate is relevant here as it plays a central role in our analysis of $\overline{h}$ for general domains.

In section 2 we consider cylindrical domains and establish Theorem 2.9. In section 3 we extend these ideas so as to treat bounded domains in $\mathbb{R}^3$. In section 4 we estimate $\overline{h}$ for small κ.

2. Superconductivity within an infinitely long cylinder in a parallel field. Let $(\psi, \mathbf{A})$ be a weak solution to (1.2) with $n = 2$ and $\boldsymbol{\mathcal{D}} \subset \mathbb{R}^2$. Recall that $\mathbf{H}_a = h\mathbf{e}_3$ is perpendicular to the cross section. We first examine the magnetic induction, $\operatorname{curl} \mathbf{A}$, in $\boldsymbol{\mathcal{D}}^c$.

LEMMA 2.1. *Let* $(\psi, \mathbf{A})$ *satisfy* (1.2). *Then* $\operatorname{curl} \mathbf{A}$ *is constant in each component of* $\overline{\boldsymbol{\mathcal{D}}}^c$. *Moreover,* $\operatorname{curl} \mathbf{A} = \mu_e h \mathbf{e}_3$ *in the unbounded component.*

Proof. From (1.2) we see that $\operatorname{curl}(\operatorname{curl} \mathbf{A}) = \mathbf{0}$ in each component of $\overline{\boldsymbol{\mathcal{D}}}^c$. Since

$$\operatorname{curl}(\operatorname{curl} \mathbf{A}) = (D_y(D_x A_2 - D_y A_1), -D_x(D_x A_2 - D_y A_1), 0),$$

we have that $\operatorname{curl} \mathbf{A} = (D_x A_2 - D_y A_1)\mathbf{e}_3$ is constant in each of these components. The last assertion follows from the fourth equation in (1.2). ∎

We now determine $\operatorname{curl} \mathbf{a}_N$.

LEMMA 2.2. *A normal state exists. Moreover, any normal state* $(0, h\mathbf{a}_N)$ *satisfies* $\operatorname{curl} \mathbf{a}_N = \mu \mathbf{e}_3$.

Proof. Consider $w = \Gamma_2 * (\mu - \mu_e)$, where $\Gamma_2(\mathbf{x}) = \frac{1}{2\pi} \ln(|\mathbf{x}|)$, $\mathbf{x} = (x, y)$. The function $\mu - \mu_e$ has bounded support. As a result w is well defined with $w \in H^2_{\text{loc}}(\mathbb{R}^2)$ and $\Delta w = (\mu - \mu_e)$ in $\mathbb{R}^2$. Set $\mathbf{b}_N = (-w_y, w_x) + \frac{\mu_e}{2}(-y, x)$. Then $\operatorname{curl} \mathbf{b}_N = \mu \mathbf{e}_3$ and we see $\mathbf{b}_N$ is a weak solution to (1.3), that is,

$$\int_{\mathbb{R}^2} \frac{1}{\mu} \operatorname{curl} \mathbf{b}_N \operatorname{curl} \varphi \, d\mathbf{x} = 0, \text{ for all } \varphi \in H^1(\mathbb{R}^2; \mathbb{R}^2)$$

such that φ has bounded support. Thus, a normal state exists.

Suppose $\mathbf{a}_N$ is another weak solution. Taking the difference of the equations for $\mathbf{b}_N$ and $\mathbf{a}_N$ we get

$$\int_{\mathbb{R}^2} \frac{1}{\mu} \operatorname{curl}(\mathbf{b}_N - \mathbf{a}_N) \cdot \operatorname{curl} \varphi \, d\mathbf{x} = 0. \tag{2.1}$$

Let $\boldsymbol{\mathcal{E}}$ be the unbounded component of $\overline{\boldsymbol{\mathcal{D}}}^c$. From Lemma 2.1 we have $\operatorname{curl} \mathbf{b}_N = \operatorname{curl} \mathbf{a}_N$ outside of the bounded set $\boldsymbol{\mathcal{E}}^c$. As a result we can take φ such that $\varphi = \mathbf{b}_N - \mathbf{a}_N$ in a neighborhood of $\boldsymbol{\mathcal{E}}^c$ in (2.1). Whence, $\operatorname{curl} \mathbf{b}_N \equiv \operatorname{curl} \mathbf{a}_N$. ∎

We can now show a weak solution has a gauge equivalent representative that satisfies a Sobolev estimate.

LEMMA 2.3. *Let* $(\zeta, \mathbf{B})$ *and* $(0, h\mathbf{a}_N)$ *be weak solutions to* (1.2). *Then there is a weak solution* $(\psi, \mathbf{A})$ *that is gauge equivalent to* $(\zeta, \mathbf{B})$ *such that*

$$\int_{\boldsymbol{\mathcal{D}}} |\mathbf{A} - h\mathbf{a}_N|^2 d\mathbf{x} \le C_0 \int_{\mathbb{R}^2} |\operatorname{curl}(\mathbf{A} - h\mathbf{a}_N)|^2 d\mathbf{x} \tag{2.2}$$

where C_0 *depends only on* $\boldsymbol{\mathcal{D}}$.

Proof. Set $\operatorname{curl}(\mathbf{B} - h\mathbf{a}_N) = f\mathbf{e}_3$. From Lemmas 2.1 and 2.2, we have that the support of f is contained in the bounded set $\boldsymbol{\mathcal{E}}^c$ and $f \in L^2(\mathbb{R}^2)$. Set $w = \Gamma_2 * f$; then standard estimates on the Newtonian potential give $w \in H^2_{\text{loc}}(\mathbb{R}^2)$, $\nabla w = \nabla \Gamma_2 * f$, $\|\nabla w\|_{L^2(\boldsymbol{\mathcal{E}}^c)} \le C_0(\boldsymbol{\mathcal{D}}) \|f\|_{L^2(\boldsymbol{\mathcal{E}}^c)}$, and $\Delta w = f$ (see [9]). Thus, setting $\widetilde{\mathbf{A}} = (-w_y, w_x)$

we have $\widetilde{\mathbf{A}} \in H^1_{\mathrm{loc}}(\mathbb{R}^2;\mathbb{R}^2)$ and $\operatorname{curl}\widetilde{\mathbf{A}} = \Delta w \mathbf{e}_3 = \operatorname{curl}(\mathbf{B} - h\mathbf{a}_N)$. Let $\mathbf{A} = \widetilde{\mathbf{A}} + h\mathbf{a}_N$. Then $\operatorname{curl}(\mathbf{B} - \mathbf{A}) = \mathbf{0}$. Hence, $\mathbf{A} = \mathbf{B} + \nabla\eta$ for some $\eta \in H^2_{\mathrm{loc}}(\mathbb{R}^2)$ and

$$\int_{\boldsymbol{\mathcal{D}}} |\mathbf{A} - h\mathbf{a}_N|^2 d\mathbf{x} \le \int_{\boldsymbol{\mathcal{E}}^c} |\nabla w|^2 d\mathbf{x} \le C_0 \int_{\boldsymbol{\mathcal{E}}^c} |f|^2 d\mathbf{x} = C_0 \int_{\mathbb{R}^2} |\operatorname{curl}(\mathbf{A} - h\mathbf{a}_N)|^2 d\mathbf{x}. \qquad \square$$

We need the following property for weak solutions.

PROPOSITION 2.4. (see [7]). *Let $(\psi, \mathbf{A})$ be a weak solution to* (1.2); *then $|\psi| \le 1$ almost everywhere in $\boldsymbol{\mathcal{D}}$.*

Next we write the weak formulation of (1.2):

$$\begin{aligned} &\int_{\boldsymbol{\mathcal{D}}} \left(\frac{i}{\kappa}\nabla\psi + \mathbf{A}\psi\right) \cdot \left(\frac{i}{\kappa}\nabla\varphi + \mathbf{A}\varphi\right)^* d\mathbf{x} + \int_{\boldsymbol{\mathcal{D}}} (|\psi|^2 - 1)\psi\varphi^* d\mathbf{x} \\ &\qquad = -\frac{\gamma}{\kappa}\int_{\partial\boldsymbol{\mathcal{D}}} \psi\varphi^* d\mathbf{s} \qquad \text{for any } \varphi \in \mathcal{H}^1(\boldsymbol{\mathcal{D}}), \\ &\int_{\mathbb{R}^2} \frac{1}{\mu}\operatorname{curl}\mathbf{A}\cdot\operatorname{curl}\mathbf{B}\, d\mathbf{x} + \int_{\boldsymbol{\mathcal{D}}} \left[\frac{i}{2\kappa}(\psi^*\nabla\psi - \psi\nabla\psi^*) + \mathbf{A}|\psi|^2\right]\cdot\mathbf{B}\, d\mathbf{x} = 0 \end{aligned} \tag{2.3}$$

for any $\mathbf{B} \in H^1(\mathbb{R}^2;\mathbb{R}^2)$ with bounded support. Considering $\frac{i}{\kappa}\nabla\psi + \mathbf{A}\psi$ for $(\psi, \mathbf{A}) \in \mathcal{H}^1(\boldsymbol{\mathcal{D}}) \times H^1_{\mathrm{loc}}(\mathbb{R}^2;\mathbb{R}^2)$, we have

$$\begin{aligned} \Re e\left[\left(\frac{i}{\kappa}\nabla\psi + \mathbf{A}\psi\right)\psi^*\right] &= \frac{i}{2\kappa}(\psi^*\nabla\psi - \psi\nabla\psi^*) + \mathbf{A}|\psi|^2, \\ \Im m\left[\left(\frac{i}{\kappa}\nabla\psi + \mathbf{A}\psi\right)\psi^*\right] &= \frac{1}{2\kappa}\nabla|\psi|^2. \end{aligned}$$

Thus,

$$\frac{i}{\kappa}\nabla\psi + \mathbf{A}\psi = \left\{\left[\frac{i}{2\kappa}(\psi^*\nabla\psi - \psi\nabla\psi^*) + \mathbf{A}|\psi|^2\right]|\psi|^{-1} + i\left[\frac{1}{\kappa}\nabla|\psi|\right]\right\}\frac{\psi}{|\psi|} \tag{2.4}$$

for almost every $\mathbf{x}$ such that $\psi \neq 0$. Moreover, since $\nabla\psi = 0$ almost everywhere on the set $\{\psi = 0\}$, it is consistent to define the term in braces equal to zero on this set. We conclude that (2.4) holds almost everywhere.

LEMMA 2.5. *Let $(\psi, \mathbf{A})$ and $(0, h\mathbf{a}_N)$ be weak solutions satisfying* (2.2). *Then there is a constant $C_1 = C_1(\boldsymbol{\mathcal{D}}, \mu_e)$ such that*

$$\int_{\boldsymbol{\mathcal{D}}} |(i\nabla + \kappa h\mathbf{a}_N)\psi|^2 d\mathbf{x} \le C_1\kappa^2 \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x}. \tag{2.5}$$

Proof. Let $\varphi = \psi$ in (2.3.1). Using (2.4), Proposition 2.4, and $\gamma \ge 0$, we obtain

$$\begin{aligned} &\int_{\boldsymbol{\mathcal{D}}} \left(\left|\frac{1}{\kappa}\nabla|\psi|\right|^2 + \left|\left[\frac{i}{2\kappa}(\psi^*\nabla\psi - \psi\nabla\psi^*) + \mathbf{A}|\psi|^2\right]|\psi|^{-1}\right|^2\right) d\mathbf{x} \\ &\qquad = \int_{\boldsymbol{\mathcal{D}}} \left|\left(\frac{i}{\kappa}\nabla + \mathbf{A}\right)\psi\right|^2 d\mathbf{x} \le \int_{\boldsymbol{\mathcal{D}}} (1 - |\psi|^2)|\psi|^2 d\mathbf{x} \le \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x}. \end{aligned} \tag{2.6}$$

This inequality is also valid for $n = 3$. Consider the second equation in (1.2) for the solutions $(\psi, \mathbf{A})$ and $(0, h\mathbf{a}_N)$. Taking the difference of their respective weak equations we have

$$\int_{\mathbb{R}^2} \frac{1}{\mu}\operatorname{curl}(\mathbf{A} - h\mathbf{a}_N)\cdot\operatorname{curl}\mathbf{B}\, d\mathbf{x} = -\int_{\boldsymbol{\mathcal{D}}} \left[\frac{i}{2\kappa}(\psi^*\nabla\psi - \psi\nabla\psi^*) + \mathbf{A}|\psi|^2\right]|\psi|^{-1}\cdot|\psi|\mathbf{B}\, d\mathbf{x}.$$

Using (2.6) and the Cauchy–Schwarz inequality, we see

$$\int_{\mathbb{R}^2} \frac{1}{\mu} \operatorname{curl}(\mathbf{A} - h\mathbf{a}_N) \cdot \operatorname{curl} \mathbf{B}\, d\mathbf{x} \leq \varepsilon^{-1} \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x} + \varepsilon \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 |\mathbf{B}|^2 d\mathbf{x}$$

for any $\varepsilon > 0$. Let $\mathbf{B}$ be such that $\mathbf{B} = \mathbf{A} - h\mathbf{a}_N$ in $\boldsymbol{\mathcal{E}}^c$ where $\boldsymbol{\mathcal{E}}$ is the unbounded component of $\boldsymbol{\mathcal{D}}^c$. Then since $\operatorname{curl}(\mathbf{A} - h\mathbf{a}_N) = \mathbf{0}$ in $\boldsymbol{\mathcal{E}}$ and $|\psi| \leq 1$ we derive

$$\int_{\mathbb{R}^2} \frac{1}{\mu} |\operatorname{curl}(\mathbf{A} - h\mathbf{a}_N)|^2 d\mathbf{x} \leq \varepsilon^{-1} \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x} + \varepsilon \int_{\boldsymbol{\mathcal{D}}} |A - h\mathbf{a}_N|^2 d\mathbf{x}.$$

Combining this inequality with (2.2), we see we can take ε sufficiently small so to have

$$\int_{\boldsymbol{\mathcal{D}}} |\mathbf{A} - h\mathbf{a}_N|^2 d\mathbf{x} \leq M \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x} \tag{2.7}$$

for some constant $M = M(\operatorname{diam} \boldsymbol{\mathcal{D}}, \mu_e)$.

Next we write

$$\left(\frac{i}{\kappa}\nabla + \mathbf{A}\right)\psi = \left(\frac{i}{\kappa}\nabla + h\mathbf{a}_N\right)\psi + (\mathbf{A} - h\mathbf{a}_N)\psi. \tag{2.8}$$

We will use the elementary inequality

$$\frac{1}{2}|\mathbf{c}|^2 - |\mathbf{b}|^2 \leq |\mathbf{c} + \mathbf{b}|^2 \quad \text{for } \mathbf{c}, \mathbf{b} \in \mathbb{C}. \tag{2.9}$$

Let $(\frac{i}{\kappa}\nabla + \mathbf{A})\psi = \mathbf{b}$ and $-(\frac{i}{\kappa}\nabla + h\mathbf{a}_N)\psi = \mathbf{c}$. Then using (2.6) and (2.8) we derive

$$\frac{1}{2}\int_{\boldsymbol{\mathcal{D}}} \left|\left(\frac{i}{\kappa}\nabla + h\mathbf{a}_N\right)\psi\right|^2 d\mathbf{x} \leq \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x} + \int_{\boldsymbol{\mathcal{D}}} |\mathbf{A} - h\mathbf{a}_N|^2 |\psi|^2 d\mathbf{x}.$$

Since $|\psi| \leq 1$, we can apply (2.7) to obtain

$$\int_{\boldsymbol{\mathcal{D}}} |(i\nabla + \kappa h\mathbf{a}_N)\psi|^2 d\mathbf{x} \leq 2(1 + M)\kappa^2 \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x}.$$

We set $C_1 = 2(1 + M)$ and the lemma is proved. □

We see that if a superconducting state (i.e., a solution with $\psi \not\equiv 0$) exists; then (2.5) implies that the principal eigenvalue for $(i\nabla + \kappa h\mathbf{a}_N)^2$ on $\boldsymbol{\mathcal{D}}$ is bounded by $C_1\kappa^2$. We will show that there exists a constant ϕ such that if $h > \max(\frac{1}{\kappa}, \phi\kappa)$, then the principal eigenvalue is greater than $C_1\kappa^2$. It then follows for such κ and h that there are only normal solutions to (1.2).

The corresponding eigenfunctions are expected to take the form of a boundary layer. The following lemma gives a way of measuring to what extent functions can concentrate near the boundary.

For a set $\boldsymbol{\mathcal{O}}$ we define the *τ-neighborhood in $\boldsymbol{\mathcal{O}}$ of $\partial\boldsymbol{\mathcal{O}}$* by

$$\boldsymbol{\mathcal{O}}_\tau = \{\mathbf{x} \in \boldsymbol{\mathcal{O}} : \operatorname{dist}(\mathbf{x}, \partial\boldsymbol{\mathcal{O}}) < \tau\}.$$

LEMMA 2.6. *Let $\boldsymbol{\mathcal{O}}$ be a bounded domain in $\mathbb{R}^n$ with a C^1 boundary. Given $\lambda_0 > 0$ there is a constant $d(\lambda_0, \boldsymbol{\mathcal{O}}) > 0$ such that whenever*

$$\int_{\boldsymbol{\mathcal{O}}} |\nabla f|^2 d\mathbf{x} \leq \lambda^2 \int_{\boldsymbol{\mathcal{O}}} |f|^2 d\mathbf{x} \tag{2.10}$$

for some $f \in H^1(\boldsymbol{\mathcal{O}})$ with $\lambda \geq \lambda_0$, then

$$\frac{1}{2}\int_{\boldsymbol{\mathcal{O}}} |f|^2 d\mathbf{x} \leq \int_{\boldsymbol{\mathcal{O}}\setminus\boldsymbol{\mathcal{O}}_{\frac{d}{\lambda}}} |f|^2 d\mathbf{x}. \tag{2.11}$$

Proof. Let $\cup_{k=0}^{N} F_k$ be an open cover for $\overline{\boldsymbol{\mathcal{O}}}$ such that $\overline{F}_0 \subset \boldsymbol{\mathcal{O}}$ and such that for each k, $1 \leq k \leq N$, we have

$$F_k \cap \boldsymbol{\mathcal{O}} = \{(x', x_n) : g_k(x') < x_n < g_k(x') + \delta_1, |x'| < \delta_2\},$$

where δ_1 and δ_2 are positive constants, (x', x_n) are suitably rotated and translated coordinates, and $g_k(x') = x_n$ characterizes $\partial\boldsymbol{\mathcal{O}} \cap F_k$. We can further assume without loss of generality that $g_k(\cdot)$ is defined for $|x'| \leq 2\delta_2$, $|\nabla g_k| < 1$, and

$$\begin{aligned} &\{(x', x_n) : g_k(x') < x_n < g_k(x') + 4\delta_1, |x'| < 2\delta_2\} \subset \boldsymbol{\mathcal{O}}, \\ &\{(x', x_n) : g_k(x') - 4\delta_1 < x_n < g_k(x'), |x'| < 2\delta_2\} \subset \mathbb{R}^n \setminus \overline{\boldsymbol{\mathcal{O}}}. \end{aligned} \tag{2.12}$$

Let $f \in H^1(\boldsymbol{\mathcal{O}})$, $0 \leq t$, $v \leq \delta_1$, and fix $k \geq 1$. We have

$$\begin{aligned} &\int_{\{x_n - g_k(x') = v\} \cap F_k} |f|^2 d\mathbf{s} - \int_{\{x_n - g_k(x') = t\} \cap F_k} |f|^2 d\mathbf{s} \\ &\quad \leq \int_{\{|x'| \leq \delta_2\}} |f^2(x', g_k(x') + v) - f^2(x', g_k(x') + t)| \sqrt{1 + |\nabla g_k|^2}\, dx' \\ &\quad \leq \int_{\boldsymbol{\mathcal{O}} \cap F_k} \left| \frac{\partial (f^2)}{\partial x_n} \right| d\mathbf{x}. \end{aligned}$$

Integrating in t from 0 to δ_1 and then dividing by δ_1 gives

$$\int_{\{x_n - g_k(x') = v\} \cap F_k} |f|^2 d\mathbf{s} \leq \frac{1}{\delta_1} \left(\int_{\boldsymbol{\mathcal{O}}} |f|^2 d\mathbf{x} + 2\delta_1 \int_{\boldsymbol{\mathcal{O}}} |f|\, |\nabla f| d\mathbf{x} \right).$$

Next integrate v from 0 to $\frac{2d}{\lambda}$, where $0 < d < \lambda_0 \delta_1 / 2$ is to be determined. We derive

$$\int_{\{0 < x_n - g_k(x') \leq \frac{2d}{\lambda}\} \cap F_k} |f|^2 d\mathbf{x} \leq \frac{2d}{\lambda \delta_1} \left(\int_{\boldsymbol{\mathcal{O}}} |f|^2 d\mathbf{x} + 2\delta_1 \int_{\mathcal{O}} |f|\, |\nabla f| d\mathbf{x} \right). \tag{2.13}$$

From the assumptions on g_k, for $1 \leq k \leq N$ we have

$$F_k \cap \boldsymbol{\mathcal{O}}_{\frac{d}{\lambda}} \subset F_k \cap \left\{ 0 < x_n - g_k(x') \leq \frac{2d}{\lambda} \right\} \tag{2.14}$$

if $\frac{d}{\lambda}$ is small enough. Indeed, if this is false for some k we can find $\mathbf{x} = (x', x_n)$ such that $|x'| \leq \delta_2$, $x_n > g_k(x') + \frac{2d}{\lambda}$, and $\mathbf{y} = (y', y_n) \in \partial\boldsymbol{\mathcal{O}}$ such that $|\mathbf{x} - \mathbf{y}| < \frac{d}{\lambda}$. If $\frac{d}{\lambda} < \min(\delta_1, \delta_2)$, we have $|x' - y'| < \frac{d}{\lambda} < \delta_2$ implying $|y'| < 2\delta_2$ and $|y_n - x_n| < \frac{d}{\lambda} < \delta_1$. We claim that $y_n = g_k(y')$. In fact,

$$|y_n - g_k(y')| \leq |y_n - x_n| + |x_n - g_k(x')| + |g_k(x') - g_k(y')|,$$

and each term on the right is bounded by δ_1. We have shown this for the first one. This is true for the second since $\mathbf{x} \in F_k \cap \boldsymbol{\mathcal{O}}$. For the last term we use $|\nabla g_k| < 1$ and

$|x' - y'| < \frac{d}{\lambda} < \delta_1$. Thus, $|y_n - g_k(y')| < 3\delta_1$. From (2.12) we see the only possibility for such a $\mathbf{y} \in \partial\mathcal{O}$ is $y_n = g_k(y')$. As a result,

$$|g_k(x') - g_k(y')| \geq |g_k(x') - x_n| - |g_k(y') - x_n| > \frac{2d}{\lambda} - \frac{d}{\lambda} = \frac{d}{\lambda}.$$

On the other hand, since $|\nabla g_k| < 1$ we have $|g_k(x') - g_k(y')| < |x' - y'| < \frac{d}{\lambda}$ and this is a contradiction.

Using (2.13) and (2.14) and summing on k for $1 \leq k \leq N$, we obtain

$$\int_{\mathcal{O}_{\frac{d}{\lambda}}} |f|^2 d\mathbf{x} \leq M_1 \frac{d}{\lambda} \left(\int_{\mathcal{O}} |f|^2 d\mathbf{x} + \lambda \int_{\mathcal{O}} |f|^2 d\mathbf{x} + \lambda^{-1} \int_{\mathcal{O}} |\nabla f|^2 d\mathbf{x} \right),$$

where $M_1 = M_1(\delta_1, N)$.

Using (2.10) we have

$$\int_{\mathcal{O}_{\frac{d}{\lambda}}} |f|^2 d\mathbf{x} \leq M_2 d \int_{\mathcal{O}} |f|^2 d\mathbf{x}$$

where $M_2 = M_2(\delta_1, N, \lambda_0)$. Setting $d = \min(\frac{1}{2M_2}, \frac{\lambda_0\delta_1}{2}, \frac{\lambda_0\delta_2}{2})$, we conclude

$$\int_{\mathcal{O}_{\frac{d}{\lambda}}} |f|^2 d\mathbf{x} \leq \frac{1}{2} \int_{\mathcal{O}} |f|^2 d\mathbf{x}.$$

The assertion (2.11) follows from this inequality. □

We will use the following result from [1] for $B_r(\mathbf{0}) \subset \mathbb{R}^2$.

PROPOSITION 2.7. *There is a continuous function $\sigma(\cdot) : t \in [0, \infty) \to \mathbb{R}$ with $\sigma(t) > 0$ for $t > 0$ for which $\lim_{t\to\infty} \sigma(t)$ exists with $0 < \lim_{t\to\infty} \sigma(t) < 1$, and such that*

$$\int_{B_r(\mathbf{0})} \left| \left(i\nabla + \frac{\omega^2}{2}(-y, x) \right) \zeta \right|^2 d\mathbf{x} \geq \omega^2 \sigma(\omega r) \int_{B_r(\mathbf{0})} |\zeta|^2 d\mathbf{x} \tag{2.15}$$

for all $\zeta \in \mathcal{H}^1(B_r(\mathbf{0}))$ and $\omega \geq 0$.

Indeed in [1, section 2], it is shown that

$$\inf_{\substack{\|\zeta\|_{L^2}=1 \\ \zeta \in W^{1,2}(B_r;\mathbb{C})}} \int_{B_r} \left| \left(i\nabla + \frac{\omega^2}{2}(-y, x) \right) \zeta \right|^2 d\mathbf{x} \equiv \omega^2 \sigma$$

where $\sigma = \sigma(\omega r)$. Furthermore, σ is characterized by $\sigma(t) = \inf_{n\in\mathbf{z}} \sigma(t, n)$ where for each n, $\sigma(t, n)$ is analytic and positive on $0 < t < \infty$. Moreover, $\lim_{t\to 0} \sigma(t, 0) = 0$. In [1, section 6], it is also shown that

$$\sigma(t) = \min_{0\leq n\leq n_0-1} \sigma(t, n) \qquad \text{for } 0 \leq t \leq n_0.$$

As a result, it follows that $\sigma(t)$ is positive and continuous. The $\lim_{t\to\infty} \sigma(t)$ is analyzed in [1, section 6], as well.

Remark. If $\mathbf{b}$ is another vector field such that $\mathbf{b} \in H^1(B_r(\mathbf{0}); \mathbb{R}^2)$ with $\operatorname{curl} \mathbf{b} = \mathbf{e}_3$, then (2.15) is also valid with $\frac{1}{2}(-y, x)$ replaced by $\mathbf{b}$. Indeed, we can define a function

$q \in H^2(B_r(\mathbf{0}))$ such that $\nabla q = \mathbf{b} - \frac{1}{2}(-y,x)$. With this we can define a local gauge transformation

$$\zeta' = \zeta e^{i\omega^2 q}, \qquad \mathbf{b} = \frac{1}{2}(-y,x) + \nabla q,$$

for which $\zeta' \in \mathcal{H}^1(B_r(\mathbf{0}))$ provided $\zeta \in \mathcal{H}^1(B_r(\mathbf{0}))$. Moreover,

$$|(i\nabla + \omega^2 \mathbf{b})\zeta'| = \left| \left(i\nabla + \frac{\omega^2}{2}(-y,x) \right) \zeta \right| \text{ and } |\zeta'| = |\zeta|$$

so that

$$\int_{B_r(\mathbf{0})} |(i\nabla + \omega^2 \mathbf{b})\zeta'|^2 d\mathbf{x} \geq \omega^2 \sigma(\omega r) \int_{B_r(\mathbf{0})} |\zeta'|^2 d\mathbf{x} \tag{2.16}$$

for all $\zeta' \in \mathcal{H}^1(B_r(\mathbf{0}))$, $\mathbf{b} \in H^1(B_r(\mathbf{0}); \mathbb{R}^2)$ such that $\operatorname{curl} \mathbf{b} = \mathbf{e}_3$.

We now derive an estimate similar to (2.16) for $\boldsymbol{\mathcal{D}}$ provided ω is bounded away from zero.

LEMMA 2.8. *Given $m > 0$ there is a constant $C_2 = C_2(m, \boldsymbol{\mathcal{D}})$, $0 < C_2 \leq 1$, such that if $\omega^2 \geq m$, then*

$$C_2 \omega^2 \int_{\boldsymbol{\mathcal{D}}} |\zeta|^2 d\mathbf{x} \leq \int_{\boldsymbol{\mathcal{D}}} |(i\nabla + \omega^2 \mathbf{b})\zeta|^2 d\mathbf{x} \tag{2.17}$$

for all $\zeta \in \mathcal{H}^1(\boldsymbol{\mathcal{D}})$ and $\mathbf{b} \in H^1(\boldsymbol{\mathcal{D}}; \mathbb{R}^2)$ for which $\operatorname{curl} \mathbf{b} = \mathbf{e}_3$.

Proof. Let $\zeta \in \mathcal{H}^1(\boldsymbol{\mathcal{D}})$ such that $\int_{\boldsymbol{\mathcal{D}}} |\zeta|^2 d\mathbf{x} > 0$ and

$$\int_{\boldsymbol{\mathcal{D}}} |(i\nabla + \omega^2 \mathbf{b})\zeta|^2 d\mathbf{x} \leq \omega^2 \int_{\boldsymbol{\mathcal{D}}} |\zeta|^2 d\mathbf{x}$$

for some ω, $\omega^2 \geq m$. If no such ζ exists, then (2.17) is valid with $C_2 = 1$ and we are done. From (2.4) we see $|\nabla |\zeta|\,| \leq |(i\nabla + \omega^2 \mathbf{b})\zeta|$. Thus,

$$\int_{\boldsymbol{\mathcal{D}}} |\nabla |\zeta|\,|^2 d\mathbf{x} \leq \omega^2 \int_{\boldsymbol{\mathcal{D}}} |\zeta|^2 d\mathbf{x}.$$

As a result, we can apply Lemma 2.6 to conclude

$$\frac{1}{2} \int_{\boldsymbol{\mathcal{D}}} |\zeta|^2 d\mathbf{x} \leq \int_{\boldsymbol{\mathcal{D}} \setminus \boldsymbol{\mathcal{D}}_{\frac{d}{\omega}}} |\zeta|^2 d\mathbf{x}. \tag{2.18}$$

Next we choose a cover for $\boldsymbol{\mathcal{D}} \setminus \boldsymbol{\mathcal{D}}_{\frac{d}{\omega}}$ consisting of a finite collection of disks $\{B_{\frac{d}{\omega}}(\mathbf{x}_k), k = 1, \ldots, N(\omega)\}$, each contained in $\boldsymbol{\mathcal{D}}$ in such a way that $\sum_{k=1}^{N(\omega)} \chi_{B_{\frac{d}{\omega}}(\mathbf{x}_k)} \leq K_1$ where K_1 is independent of ω.

We see

$$\begin{aligned} \int_{\boldsymbol{\mathcal{D}}} |(i\nabla + \omega^2 \mathbf{b})\zeta|^2 d\mathbf{x} &\geq \int_{\cup_{k=1}^N B_{\frac{d}{\omega}}(\mathbf{x}_k)} |(i\nabla + \omega^2 \mathbf{b})\zeta|^2 d\mathbf{x} \\ &\geq K_1^{-1} \sum_{k=1}^N \int_{B_{\frac{d}{\omega}}(\mathbf{x}_k)} |(i\nabla + \omega^2 \mathbf{b})\zeta|^2 d\mathbf{x}. \end{aligned}$$

Using Proposition 2.7, the last term bounds

$$K_1^{-1}\omega^2\sigma(d)\sum_{k=1}^{N}\int_{B_{\frac{d}{\omega}}(\mathbf{x}_k)}|\zeta|^2d\mathbf{x}\geq K_2(d)\omega^2\int_{\boldsymbol{\mathcal{D}}\setminus\boldsymbol{\mathcal{D}}_{\frac{d}{\omega}}}|\zeta|^2d\mathbf{x}\geq\frac{K_2}{2}\omega^2\int_{\boldsymbol{\mathcal{D}}}|\zeta|^2d\mathbf{x}$$

where the final inequality follows from (2.18). Set $C_2 = K_2/2$. This chain of inequalities establishes the lemma. □

We now establish the principal result in this section. Here we prove the existence of an upper critical field $\overline{h}$ and obtain a bound for it as $\kappa\to\infty$ and $\kappa\to 0$.

THEOREM 2.9. *There is a constant $\phi=\phi(\mu_e,\boldsymbol{\mathcal{D}})$ so that if $h>\max(\frac{1}{\kappa},\phi\kappa)$, then any weak solution for* (1.2) *with $n=2$ is normal.*

Proof. Let $(0,\mathbf{a}_N)$ be a normal state for (1.3) and $(\psi,\mathbf{A})$ be a weak solution for (1.2). A state is normal iff its entire gauge equivalence class is normal. Therefore, we can assume without loss of generality that $(\psi,\mathbf{A})$ and $(0,h\mathbf{a}_N)$ satisfy (2.2). Set $\omega^2=h\kappa$. Then $\omega^2\geq 1$ by hypothesis. We apply (2.17) with $m=1$ to derive

$$C_2h\kappa\int_{\boldsymbol{\mathcal{D}}}|\psi|^2d\mathbf{x}\leq\int_{\boldsymbol{\mathcal{D}}}|(i\nabla+h\kappa\mathbf{a}_N)\psi|^2d\mathbf{x},\tag{2.19}$$

and by Lemma 2.5, the right-hand side of (2.19) is bounded by $C_1\kappa^2\int_{\boldsymbol{\mathcal{D}}}|\psi|^2d\mathbf{x}$. Let $\phi=C_1/C_2$. We have

$$h\int_{\boldsymbol{\mathcal{D}}}|\psi|^2d\mathbf{x}\leq\phi\kappa\int_{\boldsymbol{\mathcal{D}}}|\psi|^2d\mathbf{x}.$$

By assumption $h>\phi\kappa$. Hence it must hold that $\int_{\boldsymbol{\mathcal{D}}}|\psi|^2d\mathbf{x}=0$. □

3. Three-dimensional bodies. In this section, we consider a superconducting body given by a bounded domain $\boldsymbol{\mathcal{D}}\subset\mathbb{R}^3$ subjected to a uniform applied field $\mathbf{H}_a = h\mathbf{e}$. We will assume without loss of generality that $\mathbf{e}=\mathbf{e}_3$ throughout this section.

Denote by $\check{H}^1(\mathbb{R}^3)$ the completion of $C_0^\infty(\mathbb{R}^3;\mathbb{R}^3)$ with respect to the norm

$$\|\mathbf{B}\|_{\check{H}^1(\mathbb{R}^3)}=\left(\int_{\mathbb{R}^3}|\nabla\mathbf{B}|^2d\mathbf{x}\right)^{\frac{1}{2}}.$$

One can show elements $\mathbf{B}\in\check{H}^1(\mathbb{R}^3)$ satisfy the following relationships:

$$\|\mathbf{B}\|_{L^6(\mathbb{R}^3;\mathbb{R}^3)}\leq\theta\|\mathbf{B}\|_{\check{H}^1(\mathbb{R}^3)}\tag{3.1}$$

where θ is independent of $\mathbf{B}$ and

$$\|\mathbf{B}\|^2_{\check{H}^1(\mathbb{R}^3)}=\int_{\mathbb{R}^3}(|\operatorname{div}\mathbf{B}|^2+|\operatorname{curl}\mathbf{B}|^2)d\mathbf{x}\tag{3.2}$$

(see [10]).

In order to represent magnetic fields we need the following lemma.

LEMMA 3.1. *Let $\mathbf{g}\in L^2(\mathbb{R}^3;\mathbb{R}^3)$ such that $\operatorname{div}\mathbf{g}=0$ in $\mathcal{D}'(\mathbb{R}^3)$. Then there is a unique $\mathbf{u}\in\check{H}^1(\mathbb{R}^3)$ such that $\operatorname{curl}\mathbf{u}=\mathbf{g}$ and $\operatorname{div}\mathbf{u}=0$.*

Proof. Consider $D_k\Gamma*\mathbf{g}$, where $\Gamma(\mathbf{x})=\Gamma_3(\mathbf{x})=\frac{-1}{3\omega_3|\mathbf{x}|}$ is the Newtonian potential for $\mathbb{R}^3$ and $1\leq k\leq 3$. We claim that $D_k\Gamma*\mathbf{g}\in\check{H}^1(\mathbb{R}^3)$. To see this, let us first assume that $\mathbf{g}$ has bounded support. Then, $D_k\Gamma*g$ exists as a weakly singular integral and

$$|D_k\Gamma*\mathbf{g}|=O(|\mathbf{x}|^{-2})$$

and

$$|\nabla(D_k\Gamma * \mathbf{g})| = O(|\mathbf{x}|^{-3}) \text{ as } |\mathbf{x}| \to \infty.$$

Let $\varphi_R(\mathbf{x})$ be a standard C^∞ cutoff function such that $\varphi_R = 1$ for $|\mathbf{x}| \le R$ and $\varphi_R = 0$ for $|\mathbf{x}| \ge R+1$. It follows directly that $\{\varphi_{R(n)}(D_k\Gamma * \mathbf{g})\}$ is a Cauchy sequence in $\check{H}^1(\mathbb{R}^3)$ that converges to $D_k\Gamma * \mathbf{g}$ pointwise for any sequence $R(n) \to \infty$. Thus, $D_k\Gamma * \mathbf{g} \in \check{H}^1(\mathbb{R}^3)$ assuming $\mathbf{g}$ has bounded support. Finally, by standard L^2-singular integral theory,

$$\|D_k\Gamma * \mathbf{g}\|_{\check{H}^1(\mathbb{R}^3)} \le \|\mathbf{g}\|_{L^2(\mathbb{R}^3;\mathbb{R}^3)}, \tag{3.3}$$

and as a consequence, $D_k\Gamma * \mathbf{g} \in \check{H}^1(\mathbb{R}^3)$ for all $\mathbf{g} \in L^2(\mathbb{R}^3;\mathbb{R}^3)$.

Define $\mathbf{u} : \mathbf{g} \in L^2(\mathbb{R}^3;\mathbb{R}^3) \to \check{H}^1(\mathbb{R}^3)$ by

$$\mathbf{u}(\mathbf{g}) = -(D_2\Gamma * g_3 - D_3\Gamma * g_2, D_3\Gamma * g_1 - D_1\Gamma * g_3, D_1\Gamma * g_2 - D_2\Gamma * g_1).$$

Let $\mathbf{g}_\varepsilon$ be a mollification of $\mathbf{g}$; then $\mathbf{g}_\varepsilon \to \mathbf{g}$ in L^2 as $\varepsilon \to 0$, and $\operatorname{div}\mathbf{g}_\varepsilon = 0$ for each $\varepsilon > 0$. We define $\mathbf{g}_{\varepsilon,R} = \varphi_R\mathbf{g}_\varepsilon$. Note $\operatorname{div}(\mathbf{g}_{\varepsilon,R}) = \nabla\varphi_R \cdot \mathbf{g}_\varepsilon$. If we choose sequences $\varepsilon(n) \to 0$ and $R(n) \to \infty$ as $n \to \infty$, then $\mathbf{g}_n = \varphi_{R(n)}\mathbf{g}_{\varepsilon(n)} \in C_0^\infty(\mathbb{R}^3;\mathbb{R}^3)$, $\mathbf{g}_n \to \mathbf{g}$ in L^2, and $\operatorname{div}\mathbf{g}_n \to 0$ in L^2 as $n \to \infty$.

Set $\mathbf{w}_n = \Gamma * \mathbf{g}_n$. These are well defined since $\mathbf{g}_n$ have bounded support. Using (3.3), we see

$$\operatorname{curl}\mathbf{w}_n = -\mathbf{u}(\mathbf{g}_n) \to -\mathbf{u}(\mathbf{g}) \text{ in } \check{H}^1 \text{ as } n \to \infty.$$

Consider

$$\operatorname{curl}\mathbf{u}(\mathbf{g}_n) = -\operatorname{curl}\operatorname{curl}\mathbf{w}_n = \Delta\mathbf{w}_n - \nabla(\operatorname{div}\mathbf{w}_n) = \mathbf{g}_n - \nabla(\operatorname{div}\mathbf{w}_n). \tag{3.4}$$

We know $\nabla(\operatorname{div}\mathbf{w}_n) = \nabla\Gamma * (\operatorname{div}\mathbf{g}_n) \to \mathbf{0}$ in $\check{H}^1(\mathbb{R}^3)$ as $n \to \infty$ since $\operatorname{div}\mathbf{g}_n \to 0$ in L^2. Thus, using (3.1) we conclude $\nabla(\operatorname{div}\mathbf{w}_n) \to \mathbf{0}$ in L^6, as $n \to \infty$. Furthermore, we have $\operatorname{curl}\mathbf{u}(\mathbf{g}_n) \to \operatorname{curl}\mathbf{u}(\mathbf{g})$ and $\mathbf{g}_n \to \mathbf{g}$ in L^2 as $n \to \infty$. As a consequence $\operatorname{curl}\mathbf{u}(\mathbf{g}) = \mathbf{g}$ in $\mathbb{R}^3$.

Since $\mathbf{u}(\mathbf{g}_n) = -\operatorname{curl}\mathbf{w}_n$ we have $\operatorname{div}\mathbf{u}(\mathbf{g}_n) = 0$, which implies $\operatorname{div}\mathbf{u}(\mathbf{g}) = 0$. Finally, using (3.2) we see that $\mathbf{u}$ is unique in $\check{H}^1(\mathbb{R}^3)$. ∎

We can apply the preceding lemma to characterize weak solutions.

LEMMA 3.2. *Let $(\zeta, \mathbf{B})$ be a weak solution to (1.2). Then there is a gauge equivalent solution $(\psi, \mathbf{A})$ such that $\operatorname{div}\mathbf{A} = 0$ and $(\mathbf{A} - \frac{\mu_e h}{2}(-y, x, 0)) \in \check{H}^1(\mathbb{R}^3)$. Moreover, if $(\tilde{\psi}, \tilde{\mathbf{A}})$ is another such solution, then $\tilde{\psi} = a\psi$ for some $a \in \mathbb{C}, |a| = 1$, and $\tilde{\mathbf{A}} = \mathbf{A}$.*

Proof. Set $\mathbf{g} = (\operatorname{curl}\mathbf{B} - \mu_e h\mathbf{e}_3) \in L^2(\mathbb{R}^3;\mathbb{R}^3)$. From the previous lemma there is a unique element $\mathbf{u} \in \check{H}^1(\mathbb{R}^3)$ such that $\operatorname{curl}\mathbf{u} = \mathbf{g}$ and $\operatorname{div}\mathbf{u} = 0$. Therefore, we find $\mathbf{A} = \mathbf{u} + \frac{\mu_e h}{2}(-y, x, 0)$. ∎

We now characterize the normal state in three dimensions.

LEMMA 3.3. *There is a unique normal state satisfying (1.3) such that $(\mathbf{a}_N - \frac{\mu_e}{2}(-y, x, 0)) \in \check{H}^1(\mathbb{R}^3)$ and $\operatorname{div}\mathbf{a}_N = 0$.*

Proof. Consider the strictly convex functional

$$E(\mathbf{b}) = G(0, \mathbf{b}) + \int_{\mathbb{R}^3} (\operatorname{div}\mathbf{b})^2 d\mathbf{x} = \int_{\boldsymbol{\mathcal{D}}} \frac{1}{2}\, d\mathbf{x} + \int_{\mathbb{R}^3} \left(\mu \left| \frac{1}{\mu} \operatorname{curl}\mathbf{b} - e_3 \right|^2 + (\operatorname{div}\mathbf{b})^2 \right) d\mathbf{x}$$

for the class $\boldsymbol{\mathcal{S}} = \{\mathbf{b} : (\mathbf{b} - \frac{\mu_e}{2}(-y, x, 0)) \in \check{H}^1(\mathbb{R}^3)\}$. A unique equilibrium exists which also minimizes $E(\cdot)$. Let $\widetilde{\mathbf{b}}$ be this equilibrium. If $\operatorname{div}\widetilde{\mathbf{b}} \neq 0$ then by Lemma 3.2 we can find another vector field $\widetilde{\widetilde{\mathbf{b}}} \in \boldsymbol{\mathcal{S}}$ such that $\operatorname{curl}\widetilde{\widetilde{\mathbf{b}}} = \operatorname{curl}\widetilde{\mathbf{b}}$ and $\operatorname{div}\widetilde{\widetilde{\mathbf{b}}} = 0$. This would imply $E(\widetilde{\widetilde{\mathbf{b}}}) < E(\widetilde{\mathbf{b}})$ which is impossible. Thus, $\operatorname{div}\widetilde{\mathbf{b}} = 0$. It follows that $\widetilde{\mathbf{b}}$ satisfies (1.3) and as a result a normal state $(0, \mathbf{a}_N)$ exists. Conversely, a normal state satisfying the hypothesis is an equilibrium for $E(\cdot)$, and so $\mathbf{a}_N$ is unique. ∎

Recall that the induction $\operatorname{curl}\mathbf{a}_N$, not $\mathbf{a}_N$, is the physically relevant quantity. Below we show it is uniquely determined.

LEMMA 3.4. *Let $(0, \mathbf{a}_N)$ be a normal state. Then $\operatorname{curl}\mathbf{a}_N$ is uniquely determined, $\operatorname{curl}\mathbf{a}_N$ is harmonic in $\mathbb{R}^3\backslash\partial\boldsymbol{\mathcal{D}}$ and*

$$\operatorname{curl}\mathbf{a}_N \in C^{1,\alpha}(\overline{\boldsymbol{\mathcal{D}}}) \cap C^{1,\alpha}(\boldsymbol{\mathcal{D}}^c).$$

Moreover, if $\operatorname{div}\mathbf{a}_N = 0$, then

$$\mathbf{a}_N \in C^{1,\alpha}(\overline{\boldsymbol{\mathcal{D}}}) \cap C^{1,\alpha}(\boldsymbol{\mathcal{D}}^c).$$

Proof. Using Lemma 3.2 we see any normal state is gauge equivalent to the normal state described in Lemma 3.3. Since a gauge transformation leaves the curl of a vector field invariant, we conclude that $\operatorname{curl}\mathbf{a}_N$ is uniquely determined for solutions to (1.3).

We can use the first equation in (1.3) to prove that there exists a function $p \in H^1_{\text{loc}}(\mathbb{R}^3)$ such that $\operatorname{curl}\mathbf{a}_N = \mu\nabla p$. Since

$$\operatorname{div}(\mu\nabla p) = 0 \text{ in } \mathbb{R}^3, \tag{3.5}$$

and μ is constant on the components of $\mathbb{R}^3 \setminus \partial\boldsymbol{\mathcal{D}}$, the function p (and thus $\operatorname{curl}\mathbf{a}_N$) is harmonic in each component. We apply the results from [11, Chapter 5, Section 4] to the solution p for (3.5), to derive that $p \in C^{2,\alpha}(\overline{\boldsymbol{\mathcal{D}}}) \cap C^{2,\alpha}(\boldsymbol{\mathcal{D}}^c)$ and as a consequence, $\operatorname{curl}\mathbf{a}_N \in C^{1,\alpha}(\overline{\boldsymbol{\mathcal{D}}}) \cap C^{1,\alpha}(\boldsymbol{\mathcal{D}}^c)$.

Assume $\operatorname{div}\mathbf{a}_N = 0$. Let $\boldsymbol{\mathcal{U}}$ be an open neighborhood of $\overline{\boldsymbol{\mathcal{D}}}$ and consider $\mathbf{w} \in H^2(\boldsymbol{\mathcal{U}};\mathbb{R}^3)$ such that $\Delta\mathbf{w} = \operatorname{curl}\mathbf{a}_N$ in $\boldsymbol{\mathcal{U}}$. From [11, Chapter 5], we have $\mathbf{w} \in C^{2,\alpha}(\overline{\boldsymbol{\mathcal{D}}}) \cap C^{2,\alpha}(\boldsymbol{\mathcal{U}} \setminus \boldsymbol{\mathcal{D}})$. The identity $\operatorname{curl}(\operatorname{curl}\mathbf{w}) + \Delta\mathbf{w} = \nabla(\operatorname{div}\mathbf{w})$ in $\boldsymbol{\mathcal{U}}$ yields

$$\operatorname{curl}(\operatorname{curl}\mathbf{w} + \mathbf{a}_N) = \nabla(\operatorname{div}\mathbf{w}),$$

from which we obtain

$$\operatorname{curl}\operatorname{curl}(\operatorname{curl}\mathbf{w} + \mathbf{a}_N) = \mathbf{0} \text{ in } \mathcal{D}'(\boldsymbol{\mathcal{U}}).$$

By hypothesis $\operatorname{div}(\operatorname{curl}\mathbf{w} + \mathbf{a}_N) = 0$. Whence, from the identity above

$$-\Delta(\operatorname{curl}\mathbf{w} + \mathbf{a}_N) = \operatorname{curl}\operatorname{curl}(\operatorname{curl}\mathbf{w} + \mathbf{a}_N) = \mathbf{0} \text{ in } \mathcal{D}'(\boldsymbol{\mathcal{U}}).$$

This implies $(\operatorname{curl}\mathbf{w} + \mathbf{a}_N) \in C^\infty(\boldsymbol{\mathcal{U}})$, and we conclude

$$\mathbf{a}_N \in C^{1,\alpha}(\overline{\boldsymbol{\mathcal{D}}}) \cap C^{1,\alpha}(\boldsymbol{\mathcal{D}}^c). \qquad ∎$$

Consider the case $\mu \equiv 1$. Given $\mathbf{e}$, we can find a linear function $\mathbf{a}(\mathbf{x})$ such that $\operatorname{curl}\mathbf{a} \equiv \mathbf{e}$. Clearly $\mathbf{a}$ satisfies (1.3). It follows from the previous lemma then that $\operatorname{curl}\mathbf{a}_N \equiv \mathbf{e}$ when $\mu \equiv 1$.

We now derive a Sobolev estimate analogous to Lemma 2.3.

LEMMA 3.5. *Let* $(\zeta, \mathbf{B})$ *be a weak solution to* (1.2). *Let* $(\psi, \mathbf{A})$ *be the gauge equivalent solution found in Lemma* 3.2 *and* $(0, h\mathbf{a}_N)$ *be the normal state found in Lemma* 3.3. *Then there is a constant* C_0 *depending only on* $\boldsymbol{\mathcal{D}}$ *such that*

$$\int_{\boldsymbol{\mathcal{D}}} |\mathbf{A} - h\mathbf{a}_N|^2 d\mathbf{x} \le C_0 \int_{\mathbb{R}^3} |\operatorname{curl}(\mathbf{A} - h\mathbf{a}_N)|^2 d\mathbf{x}.$$

Proof. Using (3.1) and (3.2) we see

$$\|\mathbf{A} - h\mathbf{a}_N\|_{L^6(\mathbb{R}^3;\mathbb{R}^3)} \le \theta \|\nabla(\mathbf{A} - h\mathbf{a}_N)\|_{L^2(\mathbb{R}^3;\mathbb{R}^3)} = \theta \|\operatorname{curl}(\mathbf{A} - h\mathbf{a}_N)\|_{L^2(\mathbb{R}^3;\mathbb{R}^3)}.$$

Since $\boldsymbol{\mathcal{D}}$ is bounded we have

$$\|\mathbf{A} - h\mathbf{a}_N\|_{L^2(\boldsymbol{\mathcal{D}};\mathbb{R}^3)} \le M(\boldsymbol{\mathcal{D}}) \|\mathbf{A} - h\mathbf{a}_N\|_{L^6(\boldsymbol{\mathcal{D}};\mathbb{R}^3)}$$

and the lemma follows. ∎

We proceed in deriving the three-dimensional counterpart to Lemma 2.5.

LEMMA 3.6. *Let* $(\psi, \mathbf{A})$ *and* $(0, h\mathbf{a}_N)$ *be as in Lemma* 3.5. *Then there is a constant* $C_1 = C_1(\boldsymbol{\mathcal{D}}, \mu_e)$ *so that*

$$\int_{\boldsymbol{\mathcal{D}}} |(i\nabla + h\kappa \mathbf{a}_N)\psi|^2 d\mathbf{x} \le C_1 \kappa^2 \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x}.$$

Proof. We proceed just as in Lemma 2.5 to obtain

$$\int_{\mathbb{R}^3} \frac{1}{\mu} [\operatorname{curl}(\mathbf{A} - h\mathbf{a}_N) \cdot \operatorname{curl} \mathbf{B}] d\mathbf{x} \le \varepsilon^{-1} \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x} + \varepsilon \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 |\mathbf{B}|^2 d\mathbf{x}$$

for any $\varepsilon > 0$ and $\mathbf{B} \in H^1(\mathbb{R}^3;\mathbb{R}^3)$ with bounded support. However, since $\mathbf{A} - h\mathbf{a}_N \in \check{H}^1(\mathbb{R}^3)$, we can take $\mathbf{B} = \mathbf{B}_j \to \mathbf{A} - h\mathbf{a}_N$ in $\check{H}^1(\mathbb{R}^3)$ as $j \to \infty$. As a result, we have

$$\int_{\mathbb{R}^3} \frac{1}{\mu} |\operatorname{curl}(\mathbf{A} - h\mathbf{a}_N)|^2 d\mathbf{x} \le \varepsilon^{-1} \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x} + \varepsilon \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 |\mathbf{A} - h\mathbf{a}_N|^2 d\mathbf{x}.$$

The remainder of the proof is just as before. ∎

We next give a three-dimensional analogue for the eigenvalue estimate from [1].

Let $\mathbf{v} \in \mathbb{R}^3 \setminus \{\mathbf{0}\}$ such that $|\mathbf{v}| = 1$ and $\mathbf{x}_0 \in \mathbb{R}^3$. Let $T(\mathbf{x}_0, r, \mathbf{v})$ be a cylinder with central axis parallel to $\mathbf{v}$, height $2r$, and middle cross section the disk of radius r with center $\mathbf{x}_0$.

LEMMA 3.7. *Let* $\mathbf{b} \in H^1(T(\mathbf{x}_0, r, \mathbf{v}); \mathbb{R}^3)$ *such that* $\operatorname{curl} \mathbf{b} = \mathbf{v}$. *Then*

$$\int_T |(i\nabla + \omega^2 \mathbf{b})\zeta|^2 d\mathbf{x} \ge \omega^2 \sigma(\omega r) \int_T |\zeta|^2 d\mathbf{x} \tag{3.6}$$

for all $\zeta \in \mathcal{H}^1(T)$ *where* $\sigma(\cdot)$ *is as in Proposition* 2.7.

Proof. We first transfer the problem to

$$T(\mathbf{0}, r, \mathbf{e}_3) = B_r(\mathbf{0}) \times (-r, r).$$

Let $Q \in SO(3)$ such that $\mathbf{e}_3 = Q\mathbf{v}$, and set $\mathbf{y}(\mathbf{x}) = Q(\mathbf{x} - \mathbf{x}_0)$. Then

$$\mathbf{y} : \mathbf{x} \in T(\mathbf{x}_0, r, \mathbf{v}) \to T(\mathbf{0}, r, \mathbf{e}_3).$$

Given $\zeta \in \mathcal{H}^1(T(\mathbf{x}_0, r, \mathbf{v}))$ we define $\xi(\mathbf{y}) = \zeta(\mathbf{x}(\mathbf{y}))$. Then

$$(i\nabla_{\mathbf{y}} + \omega^2 \mathbf{b} Q^t)\xi(\mathbf{y}) = (i\nabla_{\mathbf{x}} + \omega^2 \mathbf{b})\zeta(\mathbf{x}) Q^t.$$

By changing variables we see that (3.6) is equivalent to showing the following inequality:

$$\int_{T(\mathbf{0},r,\mathbf{e}_3)} |(i\nabla + \omega^2 \mathbf{b} Q^t)\xi|^2 d\mathbf{y} \geq \omega^2 \sigma(\omega r) \int_{T(\mathbf{0},r,\mathbf{e}_3)} |\xi|^2 d\mathbf{y}.$$

For any $\mathbf{w} \in \mathbb{R}^3$, we have

$$Q\mathbf{w} \cdot \operatorname{curl}_{\mathbf{y}}(\mathbf{b}Q^t) = \det \begin{bmatrix} \mathbf{w}^t Q^t \\ \nabla_{\mathbf{y}} \\ \mathbf{b} Q^t \end{bmatrix} = \det \begin{bmatrix} \mathbf{w}^t Q^t \\ \nabla_{\mathbf{x}} Q^t \\ \mathbf{b} Q^t \end{bmatrix} = \det \begin{bmatrix} \mathbf{w}^t \\ \nabla_{\mathbf{x}} \\ \mathbf{b} \end{bmatrix} = \mathbf{w} \cdot \operatorname{curl}_{\mathbf{x}} \mathbf{b}.$$

Therefore, $\operatorname{curl}_{\mathbf{y}}(\mathbf{b}Q^t) = Q(\operatorname{curl}_{\mathbf{x}} \mathbf{b}) = Q\mathbf{v} = \mathbf{e}_3$.

By changing the gauge if necessary, we can assume $\mathbf{b}Q^t = \frac{1}{2}(-y, x, 0)$. Then

$$\begin{aligned}
\int_{T(\mathbf{0},r,\mathbf{e}_3)} |(i\nabla + \omega^2 \mathbf{b} Q^t)\xi|^2 d\mathbf{y} &\geq \int_{T(\mathbf{0},r,\mathbf{e}_3)} |(i(D_x, D_y, 0) + \omega^2 \mathbf{b} Q^t)\xi|^2 d\mathbf{y} \\
&= \int_{-r}^{r} \int_{B_r} \left| \left(i(D_x, D_y, 0) + \frac{\omega^2}{2}(-y, x, 0) \right) \xi(x, y, z) \right|^2 dx\, dy\, dz \\
&\geq \int_{-r}^{r} \omega^2 \sigma(\omega r) \int_{B_r} |\xi(x, y, z)|^2 dx\, dy\, dz \\
&= \omega^2 \sigma(\omega r) \int_{T(\mathbf{0},r,\mathbf{e}_3)} |\xi|^2 d\mathbf{y},
\end{aligned}$$

where we have applied Proposition 2.7 for each $-r \leq z \leq r$. ∎

We go on to prove the three-dimensional counterpart to the eigenvalue estimate in Lemma 2.8.

LEMMA 3.8. *Let* $(0, \mathbf{a}_N)$ *be the normal state from Lemma* 3.3. *Assume* $\operatorname{curl} \mathbf{a}_N \neq \mathbf{0}$ *in* $\overline{\boldsymbol{\mathcal{D}}}$. *Then there exist constants* $m \geq 1$ *and* $0 < C_2 \leq 1$ *so that if* $\omega^2 \geq m$, *it holds that*

$$C_2 \omega^2 \int_{\boldsymbol{\mathcal{D}}} |\zeta|^2 d\mathbf{x} \leq \int_{\boldsymbol{\mathcal{D}}} |(i\nabla + \omega^2 \mathbf{a}_N)\zeta|^2 d\mathbf{x} \tag{3.7}$$

for all $\zeta \in \mathcal{H}^1(\boldsymbol{\mathcal{D}})$.

Proof. We argue as in Lemma 2.8. There exists a constant $d > 0$ so that given $\xi \in \mathcal{H}^1(\boldsymbol{\mathcal{D}})$ and $\omega \geq 1$ either (3.7) is true with $C_2 = 1$ and $\xi = \zeta$ or

$$\frac{1}{2} \int_{\boldsymbol{\mathcal{D}}} |\xi|^2 d\mathbf{x} \leq \int_{\boldsymbol{\mathcal{D}} \setminus \boldsymbol{\mathcal{D}}_{\frac{d}{\omega}}} |\xi|^2 d\mathbf{x}. \tag{3.8}$$

Assume the latter. In this case we cover $\boldsymbol{\mathcal{D}} \setminus \boldsymbol{\mathcal{D}}_{\frac{d}{\omega}}$ by a family of cylinders $\{T_k : k = 1, \ldots, N(\omega)\}$ such that $T_k = T(\mathbf{x}_k, \frac{d}{2\omega}, \operatorname{curl} \mathbf{a}_N(\mathbf{x}_k)/|\operatorname{curl} \mathbf{a}_N(\mathbf{x}_k)|)$ with $T_k \subset \boldsymbol{\mathcal{D}}$ for each k and $\sum_{k=1}^{N} \chi_{T_k} \leq K$ where K is independent of ω for $\omega \geq 1$. As a consequence,

$$\int_{\boldsymbol{\mathcal{D}}} |(i\nabla + \omega^2 \mathbf{a}_N)\xi|^2 d\mathbf{x} \geq K^{-1} \sum_{k=1}^{N} \int_{T_k} |(i\nabla + \omega^2 \mathbf{a}_N)\xi|^2 d\mathbf{x}. \tag{3.9}$$

In each T_k we write $\mathbf{a}_N(\mathbf{x}) = \ell_k(\mathbf{x}) + q_k(\mathbf{x})$ where $\ell_k(\mathbf{x}) = \mathbf{a}_N(\mathbf{x}_k) + \nabla \mathbf{a}_N(\mathbf{x}_k) \cdot (\mathbf{x} - \mathbf{x}_k)$. Note $\operatorname{curl} \ell_k(\mathbf{x}) = \operatorname{curl} \mathbf{a}_N(\mathbf{x}_k)$. Using (2.9) for each k we obtain

$$\int_{T_k} |(i\nabla + \omega^2 \mathbf{a}_N)\xi|^2 d\mathbf{x} \geq \frac{1}{2} \int_{T_k} |(i\nabla + \omega^2 \ell_k)\xi|^2 d\mathbf{x} - \omega^4 \int_{T_k} |q_k|^2 |\xi|^2 d\mathbf{x}.$$

From Lemma 3.7 we have

$$\begin{aligned}\int_{T_k} |(i\nabla + \omega^2 \ell_k)\xi|^2 d\mathbf{x} &\geq \omega^2 |\operatorname{curl} \mathbf{a}_N(\mathbf{x}_k)| \sigma\left(|\operatorname{curl} \mathbf{a}_N(\mathbf{x}_k)|^{\frac{1}{2}} \frac{d}{2} \right) \int_{T_k} |\xi|^2 d\mathbf{x} \\ &\geq \omega^2 M_0 \int_{T_k} |\xi|^2 d\mathbf{x},\end{aligned}$$

where $M_0 > 0$ depends on $\inf_{\boldsymbol{\mathcal{D}}} |\operatorname{curl} \mathbf{a}_N| > 0$ and the structure of $\sigma(\cdot)$ (see Proposition 2.7).

Since $\mathbf{a}_N \in C^{1,\alpha}(\overline{\boldsymbol{\mathcal{D}}})$ we have

$$|q_k| \leq M_1 (\operatorname{diam} T_k)^{1+\alpha} \leq M_2 \omega^{-1-\alpha} \quad \text{where } M_2 \text{ is independent of } k.$$

As a result, we see for each k that

(3.10)
$$\int_{T_k} |(i\nabla + \omega^2 \mathbf{a}_N)\xi|^2 d\mathbf{x} \geq \left(\frac{M_0}{2} \omega^2 - M_2^2 \omega^{2-2\alpha} \right) \int_{T_k} |\xi|^2 d\mathbf{x} \geq \frac{M_0}{4} \omega^2 \int_{T_k} |\xi|^2 d\mathbf{x},$$

provided $\omega^2 \geq m = m(\boldsymbol{\mathcal{D}}, \mu_e)$ sufficiently large.

From (3.9) and (3.10) then

$$\int_{\boldsymbol{\mathcal{D}}} |(i\nabla + \omega^2 \mathbf{a}_N)\xi|^2 d\mathbf{x} \geq M_3 \omega^2 \int_{\cup_{k=1}^N T_k} |\xi|^2 d\mathbf{x},$$

for some $M_3 > 0$ independent of the cover. Using $\boldsymbol{\mathcal{D}} \setminus \boldsymbol{\mathcal{D}}_{\frac{d}{\omega}} \subset \cup_{k=1}^N T_k$ and (3.8) we derive

$$\int_{\cup_{k=1}^N T_k} |\xi|^2 d\mathbf{x} \geq \int_{\boldsymbol{\mathcal{D}} \setminus \boldsymbol{\mathcal{D}}_{\frac{d}{\omega}}} |\xi|^2 d\mathbf{x} \geq \frac{1}{2} \int_{\boldsymbol{\mathcal{D}}} |\xi|^2 d\mathbf{x}.$$

Setting $C_2 = \frac{M_3}{2}$ we have our lemma. ∎

The following theorem is proved in the same manner as Theorem 2.9. We establish the existence of $\overline{h}$ and derive an upper bound for it provided $\operatorname{curl} \mathbf{a}_N$ does not vanish on $\overline{\boldsymbol{\mathcal{D}}}$.

THEOREM 3.9. *Assume that* $\operatorname{curl} \mathbf{a}_N \neq \mathbf{0}$ *in* $\overline{\boldsymbol{\mathcal{D}}}$. *There are constants* m *and* ϕ, *depending on* $\boldsymbol{\mathcal{D}}$ *and* μ_e, *so that if* $h > \max(\frac{m}{\kappa}, \phi\kappa)$ *then any weak solution to* (1.2) *with* $n = 3$ *is normal.*

For the case $\mu \equiv 1$, we have $|\operatorname{curl} \mathbf{a}_N| \equiv 1$ and we can recover the following result.

COROLLARY 3.10. *If* $\mu_e = 1$ *then there exist constants* m *and* ϕ *depending on* $\boldsymbol{\mathcal{D}}$ *so that if* $h > \max(\frac{m}{\kappa}, \phi\kappa)$; *then any weak solution to* (1.2) *with* $n = 3$ *is normal.*

In general, one does not know if $\operatorname{curl} \mathbf{a}_N$ vanishes somewhere in $\overline{\boldsymbol{\mathcal{D}}}$ or not. Nevertheless, since $\operatorname{curl} \mathbf{a}_N$ is harmonic in $\boldsymbol{\mathcal{D}}$ it can vanish only on a small set.

LEMMA 3.11. *Let* $(0, \mathbf{a}_N)$ *be a normal state. Then* $\mathcal{L}^3(\{\mathbf{x} \in \boldsymbol{\mathcal{D}} : \operatorname{curl} \mathbf{a}_N(\mathbf{x}) = \mathbf{0}\}) = 0$.

Proof. Since $\operatorname{curl} \mathbf{a}_N$ is harmonic in $\boldsymbol{\mathcal{D}}$ either $\mathcal{L}^3(\{\mathbf{x} \in \boldsymbol{\mathcal{D}} : \operatorname{curl} \mathbf{a}_N(\mathbf{x}) = \mathbf{0}\}) = 0$ or $\operatorname{curl} \mathbf{a}_N \equiv \mathbf{0}$ in $\boldsymbol{\mathcal{D}}$. From Lemma 3.4, we know there is a function $p \in C^{2,\alpha}(\overline{\boldsymbol{\mathcal{D}}}) \cap C^{2,\alpha}(\boldsymbol{\mathcal{D}}^c) \cap C(\mathbb{R}^3)$ such that

$$\operatorname{curl} \mathbf{a}_N = \mu \nabla p \text{ in } \mathbb{R}^3.$$

Hence, p satisfies

$$\begin{cases} \operatorname{div}(\mu \nabla p) = 0 & \text{in } \mathbb{R}^3, \\ (\nabla p - \mathbf{e}_3) \in L^2(\mathbb{R}^3). \end{cases} \tag{3.11}$$

Assume that $\operatorname{curl} \mathbf{a}_N \equiv \mathbf{0}$ in $\boldsymbol{\mathcal{D}}$. Then $p = \text{constant} = p_0$ in $\overline{\boldsymbol{\mathcal{D}}}$. It follows from the first equation in (3.11) that p solves

$$\begin{aligned} \Delta p = 0 \qquad & \text{in} \quad \boldsymbol{\mathcal{D}}^c, \\ p = p_0, \frac{\partial p}{\partial n} = 0 \quad & \text{on } \partial \boldsymbol{\mathcal{D}}^c, \end{aligned}$$

where $\mathbf{n}$ is the exterior normal to $\partial \boldsymbol{\mathcal{D}}$. The Cauchy problem has the unique solution $p = p_0$. This would contradict the second equation in (3.11). □

To conclude, we show there is a finite upper critical field for each κ.

THEOREM 3.12. *Let κ, μ_e, and γ be fixed. There is a constant $\overline{h} = \overline{h}(\kappa, \mu_e, \gamma, \boldsymbol{\mathcal{D}})$ so that if $h > \overline{h}$ then any weak solution to* (1.2) *with $n = 3$ is normal.*

Proof. Let $(0, \mathbf{a}_N)$ be as in Lemma 3.3. Assume there exists a sequence $\{(\psi_j, \mathbf{A}_j)\}$ where for each j the pair is as in Lemma 3.5 solving (1.2) with $h = h_j$ for which $\lim_{j\to\infty} h_j = \infty$ and $\int_{\boldsymbol{\mathcal{D}}} |\psi_j|^2 dx > 0$.

Set $\varphi_j(x) = |\psi_j(x)|/\|\psi_j\|_{L^2(\boldsymbol{\mathcal{D}})}$. From (2.6) we have

$$\int_{\boldsymbol{\mathcal{D}}} |\nabla \varphi_j|^2 d\mathbf{x} \leq \kappa^2,$$

and we can find a subsequence $\varphi_j \to \varphi_0$ in $L^2(\boldsymbol{\mathcal{D}})$ as $j \to \infty$ with $\|\varphi_0\|_{L^2(\boldsymbol{\mathcal{D}})} = 1$.

From Lemma 3.11 the set $\mathbf{Q} = \{\mathbf{x} \in \overline{\boldsymbol{\mathcal{D}}} : \operatorname{curl} \mathbf{a}_N(\mathbf{x}) = \mathbf{0}\}$ is a closed set of measure zero. It follows that there exists a ball $B_{2r} \subset \boldsymbol{\mathcal{D}} \setminus \mathbf{Q}$ such that $\int_{B_r} |\varphi_0|^2 d\mathbf{x} \equiv 2\delta > 0$ and $\inf_{B_{2r}} |\operatorname{curl} \mathbf{a}_N| > 0$. Note for j sufficiently large we have

$$\int_{B_r} |\psi_j|^2 d\mathbf{x} \geq \delta \int_{\boldsymbol{\mathcal{D}}} |\psi_j|^2 d\mathbf{x}.$$

For each j we cover B_r by a finite family of cylinders,

$$\{T(\mathbf{x}_k, \omega_j^{-1}, \operatorname{curl} \mathbf{a}_N(\mathbf{x}_k)/|\operatorname{curl} \mathbf{a}_N(\mathbf{x}_k)|)\} = \{T_{kj}, \quad 1 \leq k \leq N(j)\}$$

such that $\omega_j^2 = h_j \kappa$, $\mathbf{x}_k \in B_r$ and such that the family has overlap of at most K uniformly in $\mathbf{x} \in \boldsymbol{\mathcal{D}}$ independent of j. For j sufficiently large, each $T_{kj} \subset B_{2r}$ and as in Lemma 3.8 we derive,

$$\int_{T_{kj}} |(i\nabla + \omega_j^2 \mathbf{a}_N)\psi_j|^2 d\mathbf{x} \geq \omega_j^2 M_0 \int_{T_{kj}} |\psi_j|^2 d\mathbf{x},$$

where $M_0 > 0$ depends on $\inf_{B_{2r}} |\operatorname{curl} \mathbf{a}_N|$ and $\|\mathbf{a}_N\|_{C^{1,\alpha}(\overline{\boldsymbol{\mathcal{D}}})}$ but not on j. Whence, we can write

$$\int_{\boldsymbol{\mathcal{D}}} |(i\nabla + h_j\kappa \mathbf{a}_N)\psi_j|^2 d\mathbf{x} \geq K^{-1} \sum_{k=1}^{N(j)} \int_{T_{kj}} |(i\nabla + h_j\kappa \mathbf{a}_N)\psi_j|^2 d\mathbf{x}$$
$$\geq M_1 h_j \kappa \int_{\cup_{k=1}^{N(j)} T_{kj}} |\psi_j|^2 d\mathbf{x} \geq M_1 h_j \kappa \int_{B_r} |\psi_j|^2 d\mathbf{x} \geq M_2 h_j \kappa \int_{\boldsymbol{\mathcal{D}}} |\psi_j|^2 d\mathbf{x},$$

where M_1 and M_2 are positive and depend on $\inf_{B_{2r}} |\operatorname{curl} \mathbf{a}_N|$, $\mathbf{a}_N$ and δ. From Lemma 3.6 we know

$$\int_{\boldsymbol{\mathcal{D}}} |(i\nabla + h_j\kappa \mathbf{a}_N)\psi_j|^2 d\mathbf{x} \leq C_1 \kappa^2 \int_{\boldsymbol{\mathcal{D}}} |\psi_j|^2 d\mathbf{x},$$

which leads to

$$M_2 h_j \kappa \int_{\boldsymbol{\mathcal{D}}} |\psi_j|^2 d\mathbf{x} \leq C_1 \kappa^2 \int_{\boldsymbol{\mathcal{D}}} |\psi_j|^2 d\mathbf{x}$$

for all j sufficiently large. Since $h_j \to \infty$ as $j \to \infty$, we must have $\int_{\boldsymbol{\mathcal{D}}} |\psi_j|^2 d\mathbf{x} = 0$ for j large and this is a contradiction. ∎

4. Estimates for small κ. In this section we consider $\overline{h}$ for small κ in cases where $\operatorname{curl} \mathbf{a}_N \equiv \mathbf{e}$ in $\boldsymbol{\mathcal{D}}$.

THEOREM 4.1. *Let $n = 2$ with $\mu_e > 0$ or $n = 3$ with $\mu_e = 1$. Then $\overline{h} = O(1)$ as $\kappa \downarrow 0$.*

Proof. We consider the case $n = 3$. The argument for $n = 2$ is identical.

Let $\kappa \leq 1$ and assume (ψ, A) solves (1.2) with $\psi \not\equiv 0$. From (2.6) we have

$$\int_{\boldsymbol{\mathcal{D}}} |\nabla |\psi|\,|^2 d\mathbf{x} \leq \kappa^2 \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x} \leq \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x}.$$

If we apply Lemma 2.6 with $\lambda = \lambda_0 = 1$, we find there is a constant $d > 0$ so that

$$\frac{1}{2} \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x} \leq \int_{\boldsymbol{\mathcal{D}} \setminus \boldsymbol{\mathcal{D}}_d} |\psi|^2 d\mathbf{x}.$$

We take r, $0 < r < d$, to be determined and cover $\boldsymbol{\mathcal{D}} \setminus \boldsymbol{\mathcal{D}}_d$ by a family of cylinders $\{T(\mathbf{x}_k, r, \mathbf{e})\}$ such that the cylinders have finite overlap independent of r and each is contained in $\boldsymbol{\mathcal{D}}$. Then arguing just as in Lemma 2.8 there exists a constant $C_2 > 0$ for which

$$C_2 h\kappa\ \sigma((h\kappa)^{\frac{1}{2}} r) \int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x} \leq \int_{\boldsymbol{\mathcal{D}}} |(i\nabla + h\kappa \mathbf{a}_N)\psi|^2 d\mathbf{x}.$$

Applying Lemma 3.6 to the right-hand side, and recalling that $\int_{\boldsymbol{\mathcal{D}}} |\psi|^2 d\mathbf{x} > 0$ the following inequality holds:

$$C_2 h\kappa\ \sigma((h\kappa)^{\frac{1}{2}} r) \leq C_1 \kappa^2. \tag{4.1}$$

From Corollary 3.10 we have $h\kappa \leq M_1^2$ for some $M_1 < \infty$ for all $\kappa \leq 1$. We now choose r so that $M_1 r \leq 2^{\frac{1}{2}}$. The reason for this choice is that if $0 < t \leq 2^{\frac{1}{2}}$, then $\sigma(t)$ is the principal eigenvalue for the Sturm–Liouville problem:

$$g''(s) + \frac{g'(s)}{s} - \frac{s^2 g(s)}{4} = -\sigma(t) g(s) \qquad \text{for } 0 < s < t,$$
$$g'(t) = 0 \text{ and } g \text{ is bounded}$$

(see [1, Section 6]). As such, from [6, Proposition 3.4], we have $\sigma(t) = \frac{t^2}{8} + o(t^2)$ as $t \to 0$. It follows that there is a constant $M_2 > 0$ so that

$$M_2 t^2 \leq \sigma(t) \qquad \text{for } 0 \leq t \leq 2^{\frac{1}{2}}.$$

Combining this estimate with (4.1), we derive

$$h^2 \leq \frac{C_1}{C_2 M_2 r^2} \qquad \text{for } 0 < \kappa \leq 1.$$

Since this holds for all superconducting solutions we conclude

$$\overline{h}^2 \leq \frac{C_1}{C_2 M_2 r^2} \qquad \text{for } 0 < \kappa \leq 1. \qquad \square$$

The length scale for variations in superconducting solutions is $\frac{1}{\kappa}$. Because of this, it is of interest to consider domains with dimensions comparable to $\frac{1}{\kappa}$. To this end, let $\boldsymbol{\mathcal{D}} \subseteq \mathbb{R}^n$ and define the dilated domain

$$\boldsymbol{\mathcal{D}}(\kappa) = \{\mathbf{x} \in \mathbb{R}^n : \kappa \mathbf{x} \in \boldsymbol{\mathcal{D}}\}.$$

Then $\operatorname{diam}(\boldsymbol{\mathcal{D}}(\kappa)) = \frac{1}{\kappa} \operatorname{diam}(\boldsymbol{\mathcal{D}})$. Let $\mu \equiv 1$ so that $\operatorname{curl} \mathbf{a}_N \equiv \mathbf{e}$ in $\boldsymbol{\mathcal{D}}(\kappa)$. Consider (ψ, A) satisfying (1.2) on $\boldsymbol{\mathcal{D}}(\kappa)$. Let

$$\widetilde{\psi}(\mathbf{x}) = \psi(\kappa^{-1}\mathbf{x}) \quad \text{ for } \quad \mathbf{x} \in \boldsymbol{\mathcal{D}}$$

and

$$\widetilde{\mathbf{A}}(\mathbf{x}) = \mathbf{A}(\kappa^{-1}\mathbf{x}) \quad \text{for} \quad \mathbf{x} \in \mathbb{R}^3.$$

Then $(\widetilde{\psi}, \widetilde{\mathbf{A}})$ satisfies

$$\text{(4.2)} \qquad \begin{cases} (i\nabla + \widetilde{\mathbf{A}})^2 \widetilde{\psi} - \widetilde{\psi} + |\widetilde{\psi}|^2 \widetilde{\psi} = 0 & \text{in } \boldsymbol{\mathcal{D}}, \\ \operatorname{curl}^2 \widetilde{\mathbf{A}} = -\kappa^{-2} \left(\frac{i}{2} (\widetilde{\psi}^* \nabla \widetilde{\psi} - \widetilde{\psi} \nabla \widetilde{\psi}^*) + \widetilde{\mathbf{A}} |\psi|^2 \right) \chi_{\boldsymbol{\mathcal{D}}} & \text{in } \mathbb{R}^3, \\ n \cdot (i\nabla + \widetilde{\mathbf{A}}) \widetilde{\psi} = -i\gamma \widetilde{\psi} & \text{on } \partial\boldsymbol{\mathcal{D}}, \\ (\operatorname{curl} \widetilde{\mathbf{A}} - h\kappa^{-1}\mathbf{e}) \in L^2(\mathbb{R}^3; \mathbb{R}^3). \end{cases}$$

Assume that $0 < \kappa \leq 1$. Arguing as in Lemma 2.5, taking into account the multiple κ^{-2} of the right-hand side of the second equation in (4.2), we obtain the analogue of (2.7),

$$\int_{\boldsymbol{\mathcal{D}}} |\widetilde{\mathbf{A}} - h\kappa^{-1}\mathbf{a}_N|^2 d\mathbf{x} \leq \kappa^{-4} M \int_{\boldsymbol{\mathcal{D}}} |\widetilde{\psi}|^2 d\mathbf{x},$$

where $M = M(\operatorname{diam} \boldsymbol{\mathcal{D}})$. Using $\kappa \leq 1$ we then obtain the analogue of (2.5),

$$\int_{\boldsymbol{\mathcal{D}}} |(i\nabla + h\kappa^{-1}\mathbf{a}_N)\widetilde{\psi}|^2 d\mathbf{x} \leq C_1 \kappa^{-4} \int_{\boldsymbol{\mathcal{D}}} |\widetilde{\psi}|^2 d\mathbf{x}.$$

It follows as in Theorem 2.9 then that there is a constant ϕ so that if $h\kappa^{-1} \geq \phi\kappa^{-4}$ then $\widetilde{\psi} \equiv 0$. Returning to $(\psi, \mathbf{A})$ we conclude that

$$\overline{h}(\kappa, 1, \gamma, \boldsymbol{\mathcal{D}}(\kappa)) = O(\kappa^{-3}) \qquad \text{as } \kappa \downarrow 0.$$

As we alluded to in the introduction, there are superconducting solutions for the case of the slab $-\infty < x < 0$, $-\infty < y, z < \infty$ for which h diverges as $\kappa \downarrow 0$ (see [4]). However, this occurs at the slower rate $h = O(\kappa^{-\frac{1}{2}})$.

GLOBAL STABILITY AND PERMANENCE FOR A CLASS OF TYPE *K* MONOTONE SYSTEMS*

TU CAIFENG† AND JIANG JIFA†

Abstract. In this paper, the convergence of solutions of type K monotone systems is studied. The basic assumption is that the Jacobian matrix is stable for every point in R^n_+. The main results are the following. If the system has a positive steady state, then it is globally asymptotically stable in $\mathrm{Int}R^n_+$. A sufficient and necessary condition for a nonnegative steady state of the system to be globally asymptotically stable is presented. Moreover, we provide sufficient conditions for type K monotone systems to be permanent and for existence and uniqueness of a positive steady state.

Key words. type K monotone system, steady state, global stability, permanence

1. Introduction.

Beginning with the ground-breaking work of M. W. Hirsch [1], [2], [3] for cooperative systems and monotone semiflows, this direction has recently received considerable attention. H. L. Smith [4] has given a wonderful overview of the current state of the theory of monotone semiflows and has nicely illustrated the theory with applications to systems of ordinary and delay differential equations and reaction-diffusion equations. Hirsch [1], [2], [3] not only proved a series of important results on the long-run behavior of trajectories for monotone semiflows but also presented many powerful key ideas to deal with the asymptotic behavior of solutions of many sorts of differential equations preserving some type of order relation on initial data, boundary data, and inhomogeneous terms. As soon as one proves that a system preserves a suitable order relation on the state space, he can either apply the abstract results for monotone semiflows to such a system or directly study it by using the ideas presented by Hirsch.

In the paper [5], Smith studied general Kolmogorov-type models of competition between subcommunities which are described by the following ordinary differential equations:

$$\dot{x}_i = x_i f_i(x_1, x_2, \ldots, x_n), \quad 1 \le i \le n, \quad x_i \ge 0. \tag{S}$$

More precisely, he considered systems (S) for which, after suitable permutations of species indices, the community consists of two disjoint complementary subcommunities $I = \{1, 2, \ldots, k\}$ and $J = \{k+1, \ldots, n\}, 0 \le k \le n$. The interactions between every pair of species in subcommunity I are mutualistic and similarly for group J. On the other hand, the interaction between species $i \in I$ and species $j \in J$ is a

†Department of Mathematics, University of Science and Technology of China, Hefei, P.R. China (rengb@ustc.edu.cn).

competitive one. Mathematically speaking, the above situation can be expressed as

$$\text{(KM)} \qquad \begin{cases} \dfrac{\partial f_i}{\partial x_j} \geq 0 \quad \text{whenever} \quad i \neq j \quad \text{belongs to the same subcommunity,} \\ \dfrac{\partial f_i}{\partial x_j} \leq 0 \quad \text{whenever} \quad i, \quad j \quad \text{belong to different subcommunities.} \end{cases}$$

Smith called such a system (S) a type monotone system.

Earlier Takeuchi and Adachi [6], Takeuchi, Adachi, and Tokumaru [7], and Travis and Post [8] had investigated some particular sorts of such systems, most of which are Lotka–Volterra systems

$$\text{(S}^*\text{)} \qquad \dot{x} = \operatorname{diag}(x)(r + Mx), \quad x \in R_+^n, \quad r \in R^n,$$

in which $x = (x_1, x_2) \in R_+^k \times R_+^{n-k}$, $r = (r_1, r_2)$, and

$$M = \begin{pmatrix} A & -B \\ -C & D \end{pmatrix}, \tag{1.1}$$

where A is a $k \times k$ matrix with nonnegative off-diagonal elements, D is an $(n-k)\times(n-k)$ matrix with the same property, and $B \geq 0, C \geq 0$. Remarkable results for systems (S*) had been obtained by them in [6], [7], [8] without using the monotonicity properties of the semiflows. Some of these results rely on Lyapunov function arguments due to Goh [9].

Smith [5] first discovered that these systems preserve the partial ordering generated by the cone $K = R_+^k \times (-R_+^{n-k})$ and exploited the monotonicity of the semiflows to study such more general Kolmogorov models. In that paper, he extended Hirsch's ideas for cooperative systems to type K monotone systems (S) and found sufficient conditions for persistence of all species. In his analysis, two subsystems of (S) play a major role. These subsystems model the two mutualistic subcommunities I and J in isolation:

$$\text{(S}_\text{I}\text{)} \qquad \dot{x}_i = x_i f_i(x_1, \ldots, x_k, 0, \ldots, 0), \quad x_i \geq 0, \quad i \in I,$$

and

$$\text{(S}_\text{J}\text{)} \qquad \dot{x}_j = x_j f_j(0, \ldots, 0, x_{k+1}, \ldots, x_n), \quad x_j \geq 0, \quad j \in J.$$

He accomplished his persistent results in the case that (S$_\text{I}$) and (S$_\text{J}$) possess positive steady states and that each of these positive steady states can be successfully invaded by each of the competing species. These results are valid only for nonobligate species (that is, $f(0) > 0$). We generalized them to obligate cases in [10].

Takeuchi and Adachi [6] made use of results from mathematical programming and Lyapunov function arguments to type K Lotka–Volterra systems (S*) and obtained more sharp results. They proved that if M is stable, then (S*) has a unique nonnegative steady state x^* with the property that x^* attracts all solutions with positive initial conditions. Indeed, if $L = \{i : x_i^* > 0\}$, then the domain of attraction of x^* is $\{x \in R_+^n : x_i > 0 \quad \text{for all} \quad i \in L\}$. They also proved that if M is stable and x^* is a nonnegative steady state with $x_i^* > 0$ for $i \in L$ and $x_i^* = 0$ for $i \in N/L$ where $N = \{1, 2, \ldots, n\}$, then x^* is globally asymptotically stable relative to

$$\{x \in R_+^n : x_i > 0 \quad \text{for all} \quad i \in L\}$$

if and only if

$$r_p + \sum_{j=1}^{n} m_{p_j} x^*{}_j \le 0 \quad \text{for all} \quad p \in N/L, \tag{1.2}$$

which is equivalent to

$$r + Mx^* \le 0. \tag{1.3}$$

As a simple application of these results, one can easily obtain the following two propositions.

(P_1). If (S_I^*) and (S_J^*) have positive steady states x_1^0 and x_2^0, which are globally asymptotically stable in $\mathrm{Int}R_+^k$ and $\mathrm{Int}R_+^{n-k}$, respectively, and each is stable to invasion by every competing species,

$$r_2 - Cx_1^0 \le 0$$

and

$$r_1 - Bx_2^0 \le 0,$$

then (S^*) cannot have a stable positive steady state.

(P_2). If M is stable and x_2^0 is a positive steady state of (S_J^*) which cannot be invaded by species $i \in I$,

$$r_1 - Bx_2^0 \le 0,$$

then $(0, x_2^0)$ is globally asymptotically stable with respect to $\{x \in R_+^n : x_j > 0, \quad j \in J\}$.

The proposition (P_1) shows that if the two positive steady states of (S_I^*) and (S_J^*) representing stable persistence of each subcommunity I and J in the absence of competition are such that each is stable to invasion by every competing species, then there cannot be a stable positive steady state representing coexistence of the two subgroups. The proposition (P_2) shows that if a positive steady state of (S_J^*) is stable to invasion by each species $i \in I$, then all solutions approach that steady state; the species $i \in I$ die out.

Based on the above conclusions for Lotka–Volterra systems, Smith [5, p. 870] pointed out the following two questions:

"Are there sufficient conditions, symmetrical with respect to the two subgroups I and J, for the conclusion (P_1) to hold for the more general type K monotone systems (S)?" and

"Are there sufficient conditions, which need not be symmetrical with respect to I and J, for which the proposition (P_2) generalizes to type K monotone systems (S)?"

The main goal of this paper is to introduce suitable conditions to answer the above two questions. The first condition we shall introduce is

$$Df(x) \le_K M \quad \text{for every } x \in R_+^n, \tag{C_1}$$

where the constant matrix M is of type K and stable. Under this condition, we shall completely generalize those results of Takeuchi and Adachi [6] to more general type K monotone systems (S). More precisely, we shall prove that if type K monotone systems (S) satisfy (C_1), then (S) has a unique steady state $c \in R_+^n$ whose attraction

domain is $\Omega = \{x \in R_+^n : x_i > 0 \quad \text{for} \quad i \in L = \{i : c_i > 0\}\}$, and that a steady state c is globally asymptotically stable relative to Ω if and only if $f(c) \leq 0$. These results obviously give an answer to each of the above two questions.

The second condition we shall present is the concave one:

$$(C_2) \qquad Df(y) \leq_K Df(x) \quad \text{whenever} \quad 0 \leq x \leq_K y.$$

We shall verify that if type K monotone systems (S) satisfy (C_2), then the same conclusion as (P_1) holds. This result gives another answer to the first question. Moreover, we shall provide sufficient conditions for systems (S) to be permanent and for existence and uniqueness of a positive steady state.

2. Preliminary. In this section, we will introduce some notation, establish some conventions, and describe some results which are essential tools in the later sections.

Let $R_+^n = \{x \in R^n : x_i \geq 0 \quad \text{for} \quad 1 \leq i \leq n\}$ denote the nonnegative orthant and $\text{Int}R_+^n = \{x \in R_+^n : x_i > 0 \quad \text{for} \quad 1 \leq i \leq n\}$ denote its interior.

The idea of a cone in R^n and the associated partial ordering which the cone generates will be of fundamental importance in this paper. Recall that a cone K in R^n is a closed convex set of R^n with the property $K \cap (-K) = \{0\}$. It is easy to see that R_+^n and $K = \{x \in R^n : x_i \geq 0 \quad \text{for} \quad 1 \leq i \leq k \quad \text{and} \quad x_j \leq 0 \quad \text{for} \quad k+1 \leq j \leq n\}$ are two cones in R^n. We write $x \leq_K y$ $(x \leq y)$ whenever $y - x \in K$ $(y - x \in R_+^n)$ and $x <_K y$ $(x < y)$ whenever $y - x \in \text{Int}K$ $(y - x \in \text{Int}R_+^n)$. If $x, y \in R^n$ and K is a cone in R^n, we let $[x, y]_K = \{z \in R^n : x \leq_K z \leq_K y\}$.

If A is an $n \times m$ matrix, we write $A \geq 0$ if $a_{ij} \geq 0$ for all i and j. If M is an $n \times n$ matrix and $M(R_+^k \times (-R_+^{n-k})) \subset R_+^k \times (-R_+^{n-k})$, then it is easy to see that M has structure (1.1) where $A, B, C, D \geq 0$. If this is the case, we write $M \geq_K 0$ where $K = R_+^k \times (-R_+^{n-k})$. A matrix having structure (1.1) is called a type K matrix. For two $n \times n$ type K matrices M_1 and M_2, $M_1 \geq_K M_2$ if and only if $M_1 - M_2 \geq_K 0$; that is, $A_1 \geq A_2$, $B_1 \geq B_2$, $C_1 \geq C_2$, $D_1 \geq D_2$.

We will reserve the letter n for the dimension of space R^n and $N = \{1, 2, \ldots, n\}$. Let L be a nonempty subset of N and $\bar{L} = N/L$ be its complementary set in N. Then the set $H_L^+ = \{x \in R_+^n : x_p = 0 \quad \text{for} \quad p \in \bar{L}\}$ is an invariant set for (S). The $H_L^+, L \subset N$, make up the boundary of R_+^n. If $L \subset N$, $L = \{i_1 < \cdots < i_{r_1} < j_1 < \cdots < j_{r_2}\}$ for $i_h \in I, 1 \leq h \leq r_1$ and $j_m \in J, 1 \leq m \leq r_2$, then for $x \in R_+^n$ we write $x_L = \{x_{i_1}, \ldots, x_{i_{r_1}}, x_{j_1}, \ldots, x_{j_{r_2}}\} \in R_+^l$, where $r_1 + r_2 = l = \#L$. For any $x \in H_L^+$, we write $x = (x_L, 0)$ and $f_L(x_L, 0) = (f_{i_1}(x_L, 0), \ldots, f_{i_{r_1}}(x_L, 0), f_{j_1}(x_L, 0), \ldots, f_{j_{r_2}}(x_L, 0))$. Then the subsystem of (S) obtained by setting $x_p = 0$ for $p \in \bar{L}$ will be denoted by

$$(S_L) \qquad \dot{x}_L = \text{diag}(x_L) f_L(x_L, 0), \quad x_L \in R_+^l,$$

and the dynamics on H_L^+ is determined by (S_L). For systems (S) and (S_L), we make corresponding Lotka–Volterra systems (S^*) and (S_L^*) which will play an important role in our analysis:

$$(S^*) \qquad \dot{x} = \text{diag}(x)(r + Mx), \quad x \in R_+^n, \quad r \in R^n,$$

and

$$(S_L^*) \qquad \dot{x}_L = \text{diag}(x_L)(r_L + M_L x_L), \qquad x_L \in R_+^l, \quad r_L \in R^l,$$

where M is a stable type K matrix such that the condition (C_1) is satisfied. The meaning of the inequality $Df(x_L, 0) \leq_K M$ implies that $Df_L(x_L, 0) \leq_{K_L} M_L$, where

$Df_L(x_L,0)$ is an $l\times l$ submatrix of $Df(x_L,0)$ obtained by deleting rows and columns of $Df(x_L,0)$ indexed by $p\in\bar{L}$, M_L is an $l\times l$ submatrix of M obtained in the same way, and $K_L=R_+^{r_1}\times(-R_+^{r_2})$. Later $Df_L(x_L,0)$ and M_L will have the same meaning.

We let $s(M)=\max\ \mathrm{Re}\,\lambda$, where λ runs through the eigenvalues of M. M is stable if $s(M)<0$. From the Perron–Frobenius theory, $s(M)$ is an eigenvalue of M if M is of type K.

We write $\phi_t(x)$, $\psi_t(x)$ for the unique solutions $x(t)$ of (S) and $\widetilde{x}(t)$ of (S*), respectively, satisfying $x(0)=x$, $\widetilde{x}(0)=x$. Similarly, $\phi_t^L(x_L)$, $\psi_t^L(x_L)$ are the unique solutions $x_L(t)$ of ($\mathrm{S_L}$) and $\widetilde{x}_L(t)$ of ($\mathrm{S_L^*}$), respectively, satisfying $x_L(0)=x_L$ and $\widetilde{x}_L(0)=x_L$. $\{\phi_t(x)\}_i$ for $i\in N$ represents the ith component of $\phi_t(x)$. The components $\{\psi_t(x)\}_i$, $\{\phi_t^L(x_L)\}_i$, $\{\psi_t^L(x_L)\}_i$ for $i\in N$ are defined similarly.

One of the fundamental tools used in this paper is the generalized Kamke theorem. This theorem is extended in a natural way from cooperative systems to type K monotone systems (see [5, Theorem 2.4]).

THEOREM 2.1 (Kamke theorem). *Assume that the system* (S) *is of type K monotone, and $x(t),y(t)$ are the solutions of* (S) *defined on $a\le t\le b$ with $x(a)\le_K y(a)$. Then $x(t)\le_K y(t)$ for all $t\in[a,b]$.*

In the paper [5, p. 862], Smith developed a criterion for the monotonicity of every component of a solution for a cooperative system given by Selgrade [11] to the type K monotone system. Now we quote it here.

THEOREM 2.2. *Let the system* (S) *be a type K monotone system and let $f(x)\ge_K 0$ for some $x\in R_+^n$. Then $\{\phi_t(x)\}_i$ is nondecreasing if $i\in I$ and $\{\phi_t(x)\}_j$ is nonincreasing if $j\in J$ for all $t\ge 0$ for which the solution exists. A similar result holds if $f(x)\le_K 0$.*

The following result is from Perron–Frobenius theory (see [5, pp. 861 and 873]).

THEOREM 2.3. *Let M, N be of type K, where $K=R_+^k\times(-R_+^{n-k})$.*

(i) *If $N\ge_K M$, then $s(N)\ge s(M)$.*

(ii) *If $s(M)<0$, then $s(M_L)<0$ for any $L\subset N$.*

(iii) *If $s(M)<0$, then $(-M)^{-1}\ge_K 0$.*

3. The global stability for a positive steady state. The object of this section is to prove the following theorem.

THEOREM 3.1. *Let the conditions* (KM) *and* ($\mathrm{C_1}$) *hold. If* (S) *has a positive steady state $\bar{x}$, then $\bar{x}$ is globally asymptotically stable in* $\mathrm{Int}R_+^n$.

Proof. Let $\bar{x}$ be a positive steady state of (S), that is, $f(\bar{x})=0$. Then for any x in R_+^n, we have

$$f(x)-f(\bar{x})=\left[\int_0^1 Df(sx+(1-s)\bar{x})ds\right](x-\bar{x}).$$

The condition ($\mathrm{C_1}$) shows that

$$\int_0^1 Df(sx+(1-s)\bar{x})ds\le_K M. \tag{3.1}$$

Then the meaning of (3.1) implies that

$$f(x)\le_K M(x-\bar{x})\quad\text{for}\quad x\ge_K\bar{x} \tag{3.2}$$

and

$$f(x)\ge_K M(x-\bar{x})\quad\text{for}\quad x\le_K\bar{x}. \tag{3.3}$$

From (3.2) and (3.3), we obtain that

$$\operatorname{diag}(x)f(x) \leq_K \operatorname{diag}(x)(r + Mx) \quad \text{for} \quad x \geq_K \bar{x}$$

and

$$\operatorname{diag}(x)f(x) \geq_K \operatorname{diag}(x)(r + Mx) \quad \text{for} \quad x \leq_K \bar{x},$$

where $r = -M\bar{x}$.

Consider the systems (S) and (S*). It follows from standard differential inequality arguments and Theorem 2.1 that

$$\bar{x} \leq_K \phi_t(x) \leq_K \psi_t(x) \quad \text{for} \quad x \geq_K \bar{x}, \quad t \geq 0, \tag{3.4}$$

and

$$\bar{x} \geq_K \phi_t(x) \geq_K \psi_t(x) \quad \text{for} \quad x \leq_K \bar{x}, \quad t \geq 0. \tag{3.5}$$

Since $M\bar{x} + r = 0$, $\bar{x}$ is a positive steady state of (S*). Because $s(M) < 0$, it follows that

$$\lim_{t\to+\infty} \psi_t(x) = \bar{x} \quad \text{for any} \quad x \in \operatorname{Int}R^n_+$$

from the results of Takeuchi and Adachi [6] mentioned in the introduction. Then it deduces that

$$\lim_{t\to+\infty} \phi_t(x) = \bar{x} \quad \text{for} \quad x \in \operatorname{Int}R^n_+ \quad \text{with} \quad x \geq_K \bar{x} \quad \text{or} \quad x \leq_K \bar{x}$$

from (3.4) and (3.5).

For any $x \in \operatorname{Int}R^n_+$, there exist $y \in (\bar{x} + K) \cap \operatorname{Int}R^n_+$ and $z \in (\bar{x} - K) \cap \operatorname{Int}R^n_+$ such that $z \leq_K x \leq_K y$. In fact, we choose y and z as follows:

$$\begin{cases} y_i = \max(x_i, \bar{x}_i) & \text{for} \quad i \in I, \\ y_j = \min(x_j, \bar{x}_j) & \text{for} \quad j \in J, \end{cases} \tag{3.6}$$

and

$$\begin{cases} z_i = \min(x_i, \bar{x}_i) & \text{for} \quad i \in I, \\ z_j = \max(x_j, \bar{x}_j) & \text{for} \quad j \in J. \end{cases} \tag{3.7}$$

Applying Theorem 2.1, we have

$$\phi_t(z) \leq_K \phi_t(x) \leq_K \phi_t(y) \quad \text{for} \quad t \geq 0.$$

Because

$$\lim_{t\to+\infty} \phi_t(z) = \lim_{t\to+\infty} \phi_t(y) = \bar{x},$$

we have established that

$$\lim_{t\to+\infty} \phi_t(x) = \bar{x} \quad \text{for all} \quad x \in \operatorname{Int}R^n_+.$$

This completes the proof. □

4. The global stability for a saturated steady state. For convenience, we denote the set of steady states for (S) by E. A steady state $c \in E$ satisfying that $\operatorname{diag}(c)f(c) = 0$ and $f(c) \leq 0$ is called a saturated steady state.

THEOREM 4.1. *Let the assumption* (KM) *and the condition* (C_1) *hold. If there exists a steady state* $c \in \partial R^n_+$ *with* $c_P > 0$, $c_{\bar{P}} = 0$ *where we agree on* $c = 0$ *if* $P = \phi$, *then* c *attracts all solutions with initial conditions in* $\{x \in R^n_+ : x_P > 0\}$ *if and only if* $f(c) \leq 0$.

Before proving Theorem 4.1, we again stress some conventions which will be employed throughout the later work.

If $x \in R^n_+$, let $x_L = \{x_{i_1}, \ldots, x_{i_{r_1}}, x_{j_1}, \ldots, x_{j_{r_2}}\} \in R^l_+$, where $r_1 + r_2 = l = \#L$, $i_h \in I$, $1 \leq h \leq r_1$ and $j_m \in J$, $1 \leq m \leq r_2$. If $x \in H^+_L$, we write $x = (x_L, 0)$ and $f_L(x_L, 0) = (f_{i_1}(x_L, 0), \ldots, f_{i_{r_1}}(x_L, 0), f_{j_1}(x_L, 0), \ldots, f_{j_{r_2}}(x_L, 0))$.

In the proof of Theorem 4.1, we will use the following proposition, which can be found in [5, p. 864].

PROPOSITION 4.2. *Let* $x = (x_I, x_J) \in R^n_+$; *then* $\phi_t(x) \leq (\phi^I_t(x_I), \phi^J_t(x_J))$ *for* $t \geq 0$.

Proof of Theorem 4.1 (sufficiency). Assume that $P = \phi$; that is, $c = 0$ where ϕ is an empty set. In this case, $f(0) \leq 0$. Considering the subsystems (S_I) and cooperative system (S^*_I)

$$\dot{x}_I = \operatorname{diag}(x_I)[f_I(0) + M_I x_I],$$

we have

$$f_I(x_I, 0) - f_I(0) = \left[\int_0^1 Df_I(sx_I, 0)ds\right] x_I \leq M_I x_I.$$

Then

$$\operatorname{diag}(x_I)f_I(x_I, 0) \leq \operatorname{diag}(x_I)[f_I(0) + M_I x_I],$$

and

$$0 \leq \phi^I_t(x_I) \leq \psi^I_t(x_I) \quad \text{for} \quad t \geq 0.$$

Since $s(M_I) < s(M) < 0$ and $f_I(0) \leq 0$, by a result of Jiang (see [12, Theorem 3.4]), $\lim_{t\to+\infty} \psi^I_t(x_I) = 0_I$ holds. So $\lim_{t\to+\infty} \phi^I_t(x_I) = 0_I$. Similarly, we obtain that $\lim_{t\to+\infty} \phi^J_t(x_J) = 0_J$. Hence, $\lim_{t\to+\infty} \phi_t(x) = 0$ by Proposition 4.2.

If $P \neq \phi$, it is assumed that there exists a steady state $c \in \partial R^n_+$ with $c_P > 0$, $c_{\bar{P}} = 0$ for $P \subset N$, and $f(c) \leq 0$. Then we divide the proof into three cases.

$$\text{(i)} P \subset I, \qquad \text{(ii)} P \subset J, \qquad \text{(iii)} P \cap I \neq \phi, \quad P \cap J \neq \phi.$$

Case (i). Without loss of generality, we may assume that $P = \{1, 2, \ldots, p\}$, $p = \#P$, $1 \leq p \leq k$. Then $c = (c_1, \ldots, c_p, 0, \ldots, 0) = (c_P, 0)$.

Define a set

$$\Omega_1 = \{x \in R^n_+ : \quad x_i \geq c_i \quad \text{for} \quad i = 1, \ldots, k, \quad x_j = 0 \quad \text{for} \quad j = k+1, \ldots, n\}.$$

Consider the subsystem (S_I)

$$\dot{x}_I = \operatorname{diag}(x_I)f_I(x_I, 0), \quad x_I \in R^k_+.$$

For any $x_I \in R_+^k$, we have

$$f_I(x_I, 0) - f_I(c_I, 0) = \left[\int_0^1 Df_I(sx_I + (1-s)c_I, 0)ds\right](x_I - c_I).$$

The condition (C_1) implies that

$$\int_0^1 Df_I(sx_I + (1-s)c_I, 0)ds \le M_I.$$

Then

$$f_I(x_I, 0) \le f_I(c_I, 0) - M_I c_I + M_I x_I \quad \text{for} \quad x_I \ge c_I.$$

It is easy to obtain that

$$\text{diag}(x_I)f_I(x_I, 0) \le \text{diag}(x_I)(f_I(c_I, 0) - M_I c_I + M_I x_I) \quad \text{for} \quad x_I \ge c_I. \tag{4.1}$$

Make a corresponding cooperative system (S_I^*)

$$\dot{x}_I = \text{diag}(x_I)(f_I(c_I, 0) - M_I c_I + M_I x_I)$$

and write $\psi_t^I(x_I)$ for the unique solution $\widetilde{x}_I(t)$ of (S_I^*) satisfying $\widetilde{x}_I(0) = x_I$.

Obviously, $x_I = c_I$ is a steady state of (S_I^*) and

$$[f_I(c_I, 0) - M_I c_I + M_I x_I]_{x_I = c_I} = f_I(c_I, 0) \le 0.$$

Thus, Theorem 3.4 in [12] implies that

$$\lim_{t \to +\infty} \psi_t^I(x_I) = c_I \quad \text{for any} \quad x_I \in R_+^k \quad \text{with} \quad x_P > 0.$$

From (4.1), by standard differential inequality arguments, we have

$$c_I \le \phi_t^I(x_I) \le \psi_t^I(x_I) \quad \text{for} \quad x_I \ge c_I \quad \text{and} \quad t \ge 0.$$

Thus

$$\lim_{t \to +\infty} \phi_t^I(x_I) = c_I$$

for any $x_I \in R_+^k$ with $x_I \ge c_I$.

Observe that if $x \in \Omega_1$, then $x \ge_K c$ with $x_P > 0$. Because $\{\phi_t(x_I, 0)\}_j = 0$ for $j \in J$, we write $\phi_t(x) = (\phi_t^I(x_I), 0)$. Thus

$$\lim_{t \to +\infty} \phi_t(x) = \lim_{t \to +\infty} (\phi_t^I(x), 0) = (c_I, 0) = c$$

for $x \in \Omega_1$.

Define another set

$$\begin{aligned}\Omega_2 = \{x \in R_+^n : \quad & 0 < x_i \le c_i \quad \text{for} \quad i = 1, \dots, p, \quad x_i = 0 \\ & \text{for} \quad i = p+1, \dots, k, \quad x_j \ge 0 \quad \text{for} \quad j = k+1, \dots, n\}.\end{aligned}$$

Let $L = \{1, \dots, p, k+1, \dots, n\}$, $\#L = n - k + p$. We consider the subsystem (S_L)

$$\dot{x}_L = \text{diag}(x_L)f_L(x_L, 0), \quad x_L \in R_+^{n-k+p}.$$

For any $x_L \in R_+^{n-k+p}$, we have

$$f_L(x_L,0) - f_L(c_L,0) = \left[\int_0^1 Df_L(sx_L + (1-s)c_L, 0)ds\right](x_L - c_L). \tag{4.2}$$

If $x \in \Omega_2$, then $x_L \leq_{K_1} c_L$ with $x_P > 0$ where $K_1 = R_+^p \times (-R_+^{n-k})$. Since

$$\int_0^1 Df_L(sx_L + (1-s)c_L, 0)ds \leq_{K_1} M_L,$$

(4.2) shows that

$$f_L(x_L,0) \geq_{K_1} f_L(c_L,0) + M_L(x_L - c_L) = r_L + M_L x_L,$$

where $r_L = f_L(c_L,0) - M_L c_L$. It follows that

$$\operatorname{diag}(x_L) f_L(x_L,0) \geq_{K_1} \operatorname{diag}(x_L)(r_L + M_L x_L) \quad \text{for} \quad x_L \leq_{K_1} c_L. \tag{4.3}$$

Constructing a corresponding Lotka–Volterra system (S_L^*), we have that

$$\dot{x}_L = \operatorname{diag}(x_L)(r_L + M_L x_L), \quad x_L \in R_+^{n-k+p}, \quad r_L \in R^{n-k+p},$$

where $r_L = f_L(c_L,0) - M_L c_L$. Evidently,

$$\operatorname{diag}(c_L)(r_L + M_L c_L) = \operatorname{diag}(c_L) f_L(c_L,0) = 0.$$

This means that c_L is a steady state of (S_L^*) and

$$r_L + M_L c_L = f_L(c_L,0).$$

By assumption, $f_L(c_L,0) \leq 0$ is true. Then according to the results of Takeuchi and Adachi [6], we deduce that

$$\lim_{t\to+\infty} \psi_t^L(x_L) = c_L$$

for any $x_L \in \{u \in R_+^{n-k+p} : u_j > 0 \quad \text{for} \quad j \in P\}$. From (4.3), by standard differential inequality arguments, we have

$$c_L \geq_{K_1} \phi_t^L(x_L) \geq_{K_1} \psi_t^L(x_L) \quad \text{for} \quad t \geq 0.$$

Then

$$\lim_{t\to+\infty} \phi_t^L(x_L) = c_L$$

for any $x_L \in \{u \in R_+^{n-k+p} : u_j > 0 \quad \text{for} \quad j \in P\}$.

If $x \in \Omega_2$ which implies that $x \leq_K c$ with $x_i > 0$ for $i \in P$, then

$$\phi_t(x) = (\{\phi_t(x)\}_1, \ldots, \{\phi_t(x)\}_p, 0, \ldots, 0, \{\phi_t(x)\}_{k+1}, \ldots, \{\phi_t(x)\}_n) = (\phi_t^L(x_L), 0).$$

We have established that

$$\lim_{t\to+\infty} \phi_t(x) = \lim_{t\to+\infty} (\phi_t^L(x_L), 0) = (c_L, 0) = c \quad \text{for any} \quad x \in \Omega_2.$$

Hence, c attracts all points in Ω_1 and Ω_2.

For any $x \in R_+^n$ with $x_i > 0$ for $i \in P$, there exist $y \in \Omega_1$ and $z \in \Omega_2$ such that

$$z \leq_K x \leq_K y.$$

Indeed, we can choose y and z in a similar way as (3.6) and (3.7) if $\bar{x}$ is replaced by c. Theorem 2.1 shows that

$$\phi_t(z) \leq_K \phi_t(x) \leq_K \phi_t(y) \quad \text{for} \quad t \geq 0.$$

Since

$$\lim_{t\to+\infty} \phi_t(z) = \lim_{t\to+\infty} \phi_t(y) = c,$$

we conclude that

$$\lim_{t\to+\infty} \phi_t(x) = c.$$

Case (ii). If Case (ii) is true, then pick a transformation by $(x_1, \ldots, x_n)$ such that it is changed into Case (i). Actually, we only choose a suitable permutations of species indices for this purpose.

Case (iii). Without loss of generality, let

$$c = (c_1, \ldots, c_{r_1}, 0, \ldots, 0, c_{k+1}, \ldots, c_{k+r_2}, 0, \ldots, 0).$$

Then $P = \{1, \ldots, r_1, k+1, \ldots, k+r_2\}$, $1 \leq r_1 \leq k$, $1 \leq r_2 \leq n-k$, $r_1 + r_2 = p < n$.

Define a set

$$\begin{aligned}\Omega_3 = \{x \in R_+^n : x_i \geq c_i \quad &\text{for} \quad i = 1, \ldots, k, \quad 0 < x_j \leq c_j \quad \text{for} \quad j = k+1, \ldots, k+r_2,\\ &x_j = 0 \quad \text{for} \quad j = k+r_2+1, \ldots, n\}\\ = (c + K) \cap R_+^n \cap \{x \in R_+^n : x_P &> 0\}.\end{aligned}$$

Consider the systems $(\mathrm{S_L})$ and $(\mathrm{S_L^*})$ with $L = \{1, \ldots, k, k+1, \ldots, k+r_2\}$.

If $x \in \Omega_3$, then $x_L \geq_{K_2} c_L$ where $K_2 = R_+^k \times (-R_+^{r_2})$. Letting $r_L = f_L(c_L, 0) - M_L c_L$, similar to Case (i) we can obtain that

$$\operatorname{diag}(x_L) f_L(x_L, 0) \leq_{K_2} \operatorname{diag}(x_L)(r_L + M_L x_L), \quad x_L \in R_+^{k+r_2} \quad \text{with} \quad x_L \geq_{K_2} c_L,$$

and

$$c_L \leq_{K_2} \phi_t^L(x_L) \leq_{K_2} \psi_t^L(x_L) \quad \text{for} \quad x_L \geq_{K_2} c_L \quad \text{and} \quad t \geq 0.$$

We may argue as in Case (i) with the help of the results of Takeuchi and Adachi [6]. It deduces that

$$\lim_{t\to+\infty} \phi_t^L(x_L) = \lim_{t\to+\infty} \psi_t^L(x_L) = c_L$$

for any $x_L \geq_{K_2} c_L$ with $x_i > 0$ for $i \in P$. Therefore, if $x \in \Omega_3$, then

$$\lim_{t\to+\infty} \phi_t(x) = \lim_{t\to+\infty} (\phi_t^L(x_L), 0) = (c_L, 0) = c.$$

Define another set

$$\begin{aligned}\Omega_4 = \{&x \in R_+^n : 0 < x_i \le c_i \quad \text{for} \quad i = 1, \dots, r_1, \quad x_i = 0 \quad \text{for} \quad i = r_1 + 1, \dots, k,\\ &x_j \ge c_j \quad \text{for} \quad j = k+1, \dots, n\}\\ &= (c - K) \cap R_+^n \cap \{x \in R_+^n : x_P > 0\}.\end{aligned}$$

We also consider the subsystems $(\mathrm{S_L})$ and $(\mathrm{S_L^*})$ where $L = \{1, \dots, r_1, k+1, \dots, n\}$. By using the same process as in Case (i), we have that

$$\operatorname{diag}(x_L) f_L(x_L, 0) \ge_{K_3} \operatorname{diag}(x_L)(r_L + M_L x_L) \quad \text{for} \quad x_L \in R_+^{n-k+r_1} \quad \text{with} \quad x_L \le_{K_3} c_L,$$

and

$$c_L \ge_{K_3} \phi_t^L(x_L) \ge_{K_3} \psi_t^L(x_L) \qquad \text{for} \quad x_L \le_{K_3} c_L \quad \text{and} \quad t \ge 0,$$

where $r_L = f_L(c_L, 0) - M_L c_L$ and $K_3 = R_+^{r_1} \times (-R_+^{n-k})$.

In a similar way, one easily deduces that

$$\lim_{t \to +\infty} \phi_t^L(x_L) = \lim_{t \to +\infty} \psi_t^L(x_L) = c_L$$

for any $x_L \le_{K_3} c_L$ with $x_i > 0$ for $i \in P$.

If $x \in \Omega_4$ which implies that $x_L \le_{K_3} c_L$ with $x_i > 0$ for $i \in P$, then

$$\lim_{t \to +\infty} \phi_t(x) = \lim_{t \to +\infty} (\phi_t^L(x_L), 0) = (c_L, 0) = c.$$

Therefore, c attracts all points in Ω_3 and Ω_4 with $x_P > 0$. For any $x \in R_+^n$ with $x_P > 0$, just as in Case (i), we can choose $y \in \Omega_3$ and $z \in \Omega_4$ such that

$$z \le_K x \le_K y$$

by using the same method as in (3.6) and (3.7) if $\bar{x}$ is replaced by c. Then

$$\phi_t(z) \le_K \phi_t(x) \le_K \phi_t(y) \quad \text{for} \quad t \ge 0.$$

Since

$$\lim_{t \to +\infty} \phi_t(z) = \lim_{t \to +\infty} \phi_t(y) = c,$$

we conclude that

$$\lim_{t \to +\infty} \phi_t(x) = c$$

for all x in $\{x \in R_+^n : x_P > 0\}$. The proof of sufficiency is completed.

Necessity. Assume that $c \in \partial R_+^n$ attracts all points in $\{x \in R_+^n : x_i > 0,\ i \in P\}$ with $P = \{i : c_i > 0\}$. Then a linearized stability analysis of the steady state c begins with the coefficient matrix of the variational equation given below

$$DF(c) = \operatorname{diag}(f(c)) + \operatorname{diag}(c) Df(c). \tag{4.4}$$

It is easy to see that the necessary condition for c to be stable is $s(DF(c)) \le 0$, which implies that $f(c) \le 0$ by further analyzing equation (4.4). The proof of necessity is completed. □

THEOREM 4.3. *Suppose that the assumption* (KM) *and the condition* (C_1) *are satisfied. Then there exists a steady state* $c \in R^n_+$ *with* $c_P > 0$, $c_{\bar{P}} = 0$ *such that it attracts all solutions with initial conditions in* $\{x \in R^n_+ : x_P > 0\}$.

Before proceeding to the proof of Theorem 4.3, we present a proposition and some lemmas.

PROPOSITION 4.4. *Suppose the assumptions* (KM) *and* (C_1) *hold. Then every solution of* (S) *is bounded.*

Proof. In order to prove that $\phi_t(x)$ is bounded, we only have to prove that $\phi^I_t(x_I)$ and $\phi^J_t(x_J)$ are bounded by Proposition 4.2. Since $\phi^I_t(x_I)$ and $\phi^J_t(x_J)$ are solutions of cooperative systems (S_I) and (S_J), their boundedness can be proved as the proof of Proposition 3.2 in [12] where $Df(0)$ is replaced by M_I and M_J, respectively. □

LEMMA 4.5. *Suppose that* (S) *has no positive steady state. If it has a steady state* $c \in \partial R^n_+$ *with* $\#c = n - 1$, *then Theorem* 4.3 *holds.*

Proof. We may assume $c = (0, c_2, \ldots, c_n)$. If $f_1(c) \le 0$, then the conclusion of Theorem 4.3 is true by Theorem 4.1.

Suppose the contrary; in other words, $f_1(0, c_2, \ldots, c_n) > 0$. Then there exists a sufficiently small $x_1 > 0$ such that $f_1(x_1, c_2, \ldots, c_n) > 0$ by the continuity of f_1. If $i \in I/\{1\}$, then $f_i(x_1, c_2, \ldots, c_n) \ge 0$ because $\frac{\partial f_i}{\partial x_1} \ge 0$ for $i \in I/\{1\}$. If $j \in J$, then $f_j(x_1, c_2, \ldots, c_n) \le 0$ because $\frac{\partial f_j}{\partial x_1} \le 0$ for $j \in J$. Thus, $f(x_1, c_2, \ldots, c_n) \ge_K 0$.

Let $p = (x_1, c_2, \ldots, c_n)$ and $\phi_t(p)$ be a solution of (S) passing through p. Theorem 2.2 may be applied to conclude that $\{\phi_t(p)\}_i$ is nondecreasing for $i \in I$, $t \ge 0$ and $\{\phi_t(p)\}_j$ is nonincreasing for $j \in J$ and $t \ge 0$. Proposition 4.4 shows that $\phi_t(p)$ is bounded. Then we deduce that $\lim_{t\to+\infty} \phi_t(p) = q$. Clearly, q is a steady state of (S). From the type K monotonicity of $\phi_t(p)$ and differential equations (S), we obtain that

$$f_i(\phi_t(p)) \ge 0 \quad \text{for} \quad i \in I, \quad t \ge 0,$$

and

$$f_j(\phi_t(p)) \le 0 \quad \text{for} \quad j \in J, \quad t \ge 0.$$

As $t \to +\infty$, it follows that

$$f_i(q) \ge 0 \quad \text{for} \quad i \in I,$$

and

$$f_j(q) \le 0 \quad \text{for} \quad j \in J.$$

It is easy to see that $q_1 > x_1$, $q_i \ge c_i > 0$ for $i = 2, 3, \ldots, k$. Hence

$$f_i(q) = 0 \quad \text{for} \quad i \in I,$$

which implies that $f(q) \le 0$. Applying Theorem 4.1, we conclude that q attracts all points in $\{x \in R^n_+ : x_Q > 0\}$, where $Q = \{i : q_i > 0\}$. Therefore, Theorem 4.3 is true. □

LEMMA 4.6. *If* $n = 2$, *then the conclusion of Theorem* 4.3 *holds.*

Proof. If (S) has a positive steady state or $c = 0$ is a unique steady state, then by Theorem 3.1 and Theorem C in [13], Theorem 4.3 is true. If there is a steady state which is different from $c = 0$ on the "x_1-axis" or "x_2-axis," then Lemma 4.5 shows that Theorem 4.3 holds. □

Proof of Theorem 4.3. If a positive steady state exists, then the conclusion follows from Theorem 3.1. If $c = 0$ is a unique steady state of (S), then 0_I, 0_J are unique steady states of subsystems (S_I) and (S_J), respectively. By Proposition 4.4, $\phi_t^I(x_I)$ and $\phi_t^J(x_J)$ are bounded. Hence $\lim_{t\to+\infty}\phi_t^I(x_I) = 0_I$ for $x_I \in R_+^k$ and $\lim_{t\to+\infty}\phi_t^J(x_J) = 0_J$ for $x_J \in R_+^{n-k}$ by Theorem C in [13]. Then we obtain that $\lim_{t\to+\infty}\phi_t(x) = 0$ for $x \in R_+^n$ by Proposition 4.2.

If $E \cap \mathrm{Int}R_+^n = \phi$ and $E \neq \{0\}$, we shall prove this theorem by induction on the dimension n of type K monotone systems.

The statement is clear if $n = 2$ by Lemma 4.6. So assume for induction that the theorem is true for all type K systems with dimension less than n. Now, we consider an n-dimensional type K monotone system (S) satisfying (KM) and (C_1). Then we only have to consider the case that there is at least a steady state $c \neq 0$. We may assume that $c \in \{(x_1, x_2, \ldots, x_{n-1}, 0) \in R_+^n : x_i \geq 0 \quad \text{for} \quad i = 1, 2, \ldots, n-1\}$. Let $L = \{1, 2, \ldots, n-1\}$, $\#L = n-1$. We consider the subsystem (S_L)

$$\dot{x}_L = \mathrm{diag}(x_L) f_L(x_L, 0), \quad x_L \in R_+^{n-1}.$$

The condition (C_1) implies that $Df_L(x_L, 0) \leq_{K_4} M_L$ with $s(M_L) < 0$, where $K_4 = R_+^k \times (-R_+^{n-k-1})$. The induction assumption applies to the $(n-1)$-dimensional type K system (S_L). Then (S_L) has a steady state $p = (p_1, p_2, \ldots, p_{n-1})$ which attracts all points in $\{x_L \in R_+^{n-1} : x_Q > 0\}$ where $Q = \{i \in L, p_i > 0\}$. Then it follows that $\lim_{t\to+\infty}\phi_t^L(x_L) = p$ for $x_L \in \{x \in R_+^{n-1} : x_Q > 0\}$.

By the necessity of Theorem 4.1, we have

$$f_i(p_1, \ldots, p_{n-1}, 0) \leq 0 \quad \text{for} \quad i = 1, 2, \ldots, n-1.$$

If $f_n(p_1, \ldots, p_{n-1}, 0) \leq 0$, then $f(p_1, \ldots, p_{n-1}, 0) \leq 0$ and Theorem 4.3 is true by the sufficiency of Theorem 4.1. Otherwise, $f_n(p_1, \ldots, p_{n-1}, 0) > 0$ holds. Define $J_1 = \{j \in J : p_j > 0\} \cup \{n\}$. Then

$$f_j(p_1, \ldots, p_{n-1}, 0) \leq 0 \quad \text{for} \quad j \in J/J_1,$$

and

$$f_j(p_1, \ldots, p_{n-1}, 0) = 0 \quad \text{for} \quad j \in J_1/\{n\}.$$

Let $L_1 = I \cup J_1$ and consider the subsystem (S_{L_1})

$$\dot{x}_{L_1} = \mathrm{diag}(x_{L_1}) f_{L_1}(x_{L_1}, 0), \quad x_{L_1} \in R_+^{\#L_1},$$

where $x_{L_1} = (x_I, x_{J_1})$, $0 = 0_{J/J_1}$. By the continuity of f_n, there exists a sufficiently small $x_n > 0$ such that $f_n(p_1, \ldots, p_{n-1}, x_n) > 0$. If $j \in J_1/\{n\}$, then $f_j(p_1, \ldots, p_{n-1}, 0) = 0$ and $\frac{\partial f_j}{\partial x_n} \geq 0$, which implies that $f_j(p_1, \ldots, p_{n-1}, x_n) \geq 0$. If $i \in I$, $f_i(p_1, \ldots, p_{n-1}, 0) \leq 0$ and $\frac{\partial f_i}{\partial x_n} \leq 0$ which implies that $f_i(p_1, \ldots, p_{n-1}, x_n) \leq 0$. Let $v = (p_1, \ldots, p_{n-1}, x_n)$. Then $v = (p_I, p_{J_1/\{n\}}, 0_{J/J_1}, x_n) = (u, 0)$, where $u = (p_I, p_{J_1/\{n\}}, x_n) \in R_+^{\#L_1}$. Thus $f_{L_1}(u, 0) \leq_{K_5} 0$ where $K_5 = R_+^k \times (-R_+^{\#J_1})$. Theorem 2.2 may be applied to conclude that $\{\phi_t^{L_1}(u)\}_i$ is nonincreasing if $i \in I$ and $\{\phi_t^{L_1}(u)\}_j$ is nondecreasing if $j \in J_1$ for $t \geq 0$. Also, $\phi_t^{L_1}(u)$ is bounded by Proposition 4.4. Thus we obtain that $\lim_{t\to+\infty}\phi_t^{L_1}(u) = q_{L_1}$. Clearly, q_{L_1} is a steady state of (S_{L_1}).

On the other hand, the type K monotonicity of $\phi_t^{L_1}(u)$ implies that for any $t \geq 0$,

$$f_i(\phi_t^{L_1}(u), 0) \leq 0 \qquad \text{if} \quad i \in I,$$

and

$$f_j(\phi_t^{L_1}(u), 0) \geq 0 \qquad \text{if} \quad j \in J_1.$$

As $t \to +\infty$, we have

$$f_i(q_{L_1}, 0) \leq 0 \quad \text{for} \quad i \in I,$$

and

$$f_j(q_{L_1}, 0) \geq 0 \quad \text{for} \quad j \in J_1.$$

Since $q_n > x_n$, $q_j \geq p_i > 0$ for $j \in J_1/\{n\}$, it follows that

$$f_j(q_{L_1}, 0) = 0 \quad \text{for} \quad j \in J_1.$$

If $f_j(q_{L_1}, 0) \leq 0$ for $j \in J/J_1$, then the theorem holds by Theorem 4.1. Assume it is false. We define $J_2 = \{j \in J : f_j(q_{L_1}, 0) > 0\}$. Let $L_2 = I \cup J_1 \cup J_2$ and consider the subsystem $(\mathrm{S}_{\mathrm{L}_2})$

$$\dot{x}_{L_2} = \mathrm{diag}(x_{L_2}) f_{L_2}(x_{L_2}, 0), \quad x_{L_2} \in R_+^{\#L_2},$$

where $x_{L_2} = (x_I, x_{J_1}, x_{J_2}), 0 = 0_{J/(J_1 \cup J_2)}$.

Since

$$f_{J_2}(q_{L_1}, 0_{J_2}, 0_{J/(J_1 \cup J_2)}) > 0,$$

$$f_{J_1}(q_{L_1}, 0_{J_2}, 0_{J/(J_1 \cup J_2)}) = 0,$$

and

$$f_I(q_{L_1}, 0_{J_2}, 0_{J/(J_1 \cup J_2)}) \leq 0$$

hold, there exists $x_{J_2} > 0$ small enough such that $f_{J_2}(q_{L_1}, x_{J_2}, 0_{J/(J_1 \cup J_2)}) > 0$ by the continuity of f_{J_2}. Meanwhile, $\frac{\partial f_{J_1}}{\partial x_{J_2}} \geq 0$ implies that $f_{J_1}(q_{L_1}, x_{J_2}, 0_{J/(J_1 \cup J_2)}) \geq 0$, and $\frac{\partial f_I}{\partial x_{J_2}} \leq 0$ implies that $f_I(q_{L_1}, x_{J_2}, 0_{J/(J_1 \cup J_2)}) \leq 0$ for such x_{J_2}. Hence, $f_{L_2}(q_{L_1}, x_{J_2}, 0_{J/(J_1 \cup J_2)}) \leq_{K_6} 0$, where $K_6 = R_+^k \times (-R_+^{\#(J_1 \cup J_2)})$. Let $v = (q_{L_1}, x_{J_2})$. Then $\{\phi_t^{L_2}(v)\}_i$ is nonincreasing for $i \in I$ and $\{\phi_t^{L_2}(v)\}_j$ is nondecreasing for $j \in J_1 \cup J_2$ on $[0, +\infty)$ by Theorem 2.2. Because $\phi_t^{L_2}(v)$ is bounded, it deduces that $\lim_{t \to +\infty} \phi_t^{L_2}(v) = r_{L_2}$. Obviously, r_{L_2} is a steady state of $(\mathrm{S}_{\mathrm{L}_2})$. The type K monotonicity of $\phi_t^{L_2}(v)$ shows that for $t \geq 0$,

$$f_i(\phi_t^{L_2}(v), 0_{J/J_1 \cup J_2}) \leq 0 \qquad \text{if} \quad i \in I,$$

and

$$f_j(\phi_t^{L_2}(v), 0_{J/J_1 \cup J_2}) \geq 0 \qquad \text{if} \quad j \in J_1 \cup J_2.$$

Hence, as $t \to +\infty$, we have

$$f_i(r_{L_2}, 0) \le 0 \qquad \text{for} \quad i \in I,$$

and

$$f_j(r_{L_2}, 0) \ge 0 \qquad \text{for} \quad j \in J_1 \cup J_2.$$

Evidently, $r_{J_2} > x_{J_2}$, $r_{J_1} \ge q_{J_1} > 0$. Then

$$f_j(r_{L_2}, 0) = 0 \quad \text{for} \quad j \in J_1 \cup J_2.$$

If $j \in J/(J_1 \cup J_2)$, $f_j(r_{L_2}, 0) \le 0$ which is equivalent to $f(r_{L_2}, 0) \le 0$, then the theorem is true. If not, we define $J_3 = \{j \in J : f_j(r_{L_2}, 0) > 0\}$. Let $L_3 = I \cup J_1 \cup J_2 \cup J_3$ and discuss the subsystem $(\mathrm{S}_{\mathrm{L}_3})$ in a similar way. This process must be stopped at most at the $(n-k)$th step.

Hence, in this way, we can find a steady state c satisfying $f(c) \le 0$. Then by Theorem 4.1, c attracts all points in $\{x \in R^n_+ : x_Q > 0\}$ where $Q = \{i \in N, c_i > 0\}$. Therefore we have proved that the conclusion of Theorem 4.3 holds for n-dimensional type K monotone systems. This completes the proof. □

In order to give the first question in the introduction another answer, we present a different condition. Suppose that $(\mathrm{S_I})$ and $(\mathrm{S_J})$ have positive steady states x^0_1 and x^0_2. Let $p = (x^0_1, 0)$ and $q = (0, x^0_2)$. The system (S) is called to satisfy the condition (C'_2) if either

$$Df(x) \le_K Df(y) \quad \text{whenever} \quad q \le_K y \le_K x \le_K p \tag{4.5}$$

or

$$Df(x) \le_K Df(y) \quad \text{whenever} \quad q \le_K x \le_K y \le_K p. \tag{4.6}$$

THEOREM 4.7. *Let the hypotheses* (KM) *and* (C'_2) *hold. If* $(\mathrm{S_I})$ *and* $(\mathrm{S_J})$ *have steady states* x^0_1 *and* x^0_2 *which are globally asymptotically stable in* $\mathrm{Int}R^k_+$ *and* $\mathrm{Int}R^{n-k}_+$, *respectively, and each is stable to invasion by every competing species*

$$f_J(x^0_1, 0) \le 0$$

and

$$f_I(0, x^0_2) \le 0,$$

then (S) *cannot have a stable positive steady state.*

Proof. We only have to prove the case that the system (S) satisfies (4.5). Another case can be proved in the same method. In fact, suppose it is false. Then there exists at least a stable positive steady state $\bar{x}$ and $\bar{x} \le_K (x^0_1, 0) = p$ by Proposition 3.3 in [5, p. 864]. The calculation shows that

$$f(\bar{x}) - f(p) = \left[\int_0^1 Df(s\bar{x} + (1-s)p)ds\right](\bar{x} - p).$$

We denote the matrix in brackets by U. The condition (4.5) implies that $U \le_K Df(\bar{x})$. Because $\bar{x}$ is stable, $s(Df(\bar{x})) < 0$. It follows that $s(U) < 0$ from (i) of Theorem 2.3 and $(-U)^{-1} \ge_K 0$ from (iii) of Theorem 2.3. So $(-U)^{-1} f(p) \ge_K 0$. But $\bar{x} \le_K p$

implies that $(-U)^{-1}f(p) = (\bar{x} - p) \leq_K 0$ which implies that $\bar{x} - p = 0$ from the just-proved fact. However, $\bar{x} \neq p$. This is a contradiction. Therefore, (S) cannot have a stable positive steady state. □

Before finishing this section, we remark that Theorems 4.1 and 4.3 together with Theorem 3.1 completely generalize the results of Takeuchi and Adachi [6] to more general Kolmogorov systems with the conditions (KM) and (C_1). Theorem 4.1 implies that every saturated steady state is globally asymptotically stable and that it is not possible for both systems (S_I) and (S_J) to have positive steady states each of which cannot be invaded by the competing subcommunity as long as (KM) and (C_1) are satisfied. Therefore, these results provide an answer to each of the questions posed by Smith [5] which have been mentioned in the introduction. Theorem 4.7 gives the first question another answer.

5. The permanence for system (S). Consider the system

$$\dot{x}_i = x_i f_i(x_1, x_2, \ldots, x_n), \quad 1 \leq i \leq n, \quad x_i \geq 0, \tag{S}$$

which satisfies the assumption (KM).

In the paper [5], Smith exhibited sufficient conditions for the permanence of (S). His essential condition is

$$\text{(H)} \quad \begin{cases} (S_I) \text{ possesses a positive steady state } x_1^0 \text{ which is unstable to } R_+^{n-k} \\ \quad \text{(that is, } f_J(x_1^0, 0) > 0), \\ (S_J) \text{ possesses a positive steady state } x_2^0 \text{ which is unstable to } R_+^k \\ \quad \text{(that is, } f_I(0, x_2^0) > 0). \end{cases}$$

His additional assumption is

$$\text{(AH)} \quad \begin{cases} x_1^0 + R_+^k \text{ lies in the domain of attraction of } x_1^0 \text{ for } (S_I), \\ x_2^0 + R_+^{n-k} \text{ lies in the domain of attraction of } x_2^0 \text{ for } (S_J). \end{cases}$$

Under the hypothesis (H), Smith concluded that there exist positive steady states x^1 and x^2 of (S) satisfying that $0 < x^1, x^2 \leq (x_1^0, x_2^0)$, and $x^1 \leq_K x^2$ (see [5, Theorem 3.6]). Meanwhile, combining the hypothesis (H) with (AH), he deduced that $\omega(x) \subset [x^1, x^2]_K$ for all $x > 0$.

Recall that the system (S) is permanent if there exist constant numbers $\delta, D > 0$ such that for every solution $x(t)$ of (S) with $x(0) > 0$, $\delta \leq \liminf_{t \to +\infty} x_i(t) \leq \limsup_{t \to +\infty} x_i(t) \leq D$ for all $i \in N$. Then the system (S) is permanent under the hypotheses (H) and (AH).

Clearly, the species satisfying (H) is nonobligate (that is, $f(0) > 0$). In obligate cases, the authors gave the sufficient conditions to guarantee that the system (S) is permanent (see [10, Theorem 2.1]). In those situations, two subsystems (S_L) and (S_P) play an important role, where $L \subset N, L \supset I$ and $P \subset N, P \supset J$. Our essential condition is

$$\text{(H}_1\text{)} \quad \begin{cases} x_L^0 \text{ is a positive steady state of } (S_L),\ f_{\bar{L}}(x_L^0, 0) > 0, \\ x_P^0 \text{ is a positive steady state of } (S_P),\ f_{\bar{P}}(0, x_P^0) > 0. \end{cases}$$

Our additional assumption is

$$\text{(AH}_1\text{)} \quad \begin{cases} x_L^0 + K_1 \text{ lies in the domain of attraction of } x_L^0 \text{ for } (S_L), \\ x_P^0 - K_2 \text{ lies in the domain of attraction of } x_P^0 \text{ for } (S_P), \end{cases}$$

where $K_1 = R_+^k \times (-R_+^{l-k})$, $K_2 = R_+^{p+k-n} \times (-R_+^{n-k})$. We have the following result.

THEOREM 5.1. *Let the assumption* (H_1) *hold and* $(0, x_P^0) \leq_K (x_L^0, 0)$. *Then there exist positive steady states* $\bar{x}$ *and* $\widetilde{x}$ *for* (S) *satisfying* $0 < \bar{x}, \widetilde{x} \leq ((x_L^0)_I, (x_P^0)_J)$ *and* $\bar{x} \leq_K \widetilde{x}$. *In addition, if the assumption* (AH_1) *holds, then* $\omega(x) \subset [\bar{x}, \widetilde{x}]_K$ *for all* $x > 0$. *And* $\omega(x) = \{\bar{x}\}$ *for all* $x > 0$ *with* $x \leq_K \bar{x}$ *and* $\omega(x) = \{\widetilde{x}\}$ *for all* $x > 0$ *with* $x \geq_K \widetilde{x}$.

In Theorem 5.1, $(x_L^0)_I$, $(x_P^0)_J$ are components $(x_L^0)_i$ of x_L^0 for all $i \in I$ and $(x_P^0)_j$ of x_P^0 for all $j \in J$, respectively. These results generalize Smith's Theorem 3.6 in [5].

In the same paper, Smith also obtained the following result (see [5, Theorem 3.8]) under the assumption

$$(AH_2) \qquad \begin{cases} \frac{\partial f_I}{\partial x_I}(x_I, 0) \geq \frac{\partial f_I}{\partial x_I}(\bar{x}_I, 0), & 0 \leq x_I \leq \bar{x}_I, \\ \frac{\partial f_J}{\partial x_J}(0, x_J) \geq \frac{\partial f_J}{\partial x_J}(0, \bar{x}_J), & 0 \leq x_J \leq \bar{x}_J. \end{cases}$$

THEOREM 5.2. *Let the assumptions* (H) *and* (AH_2) *hold. Then* x_1^0 *is globally asymptotically stable for* (S_I) *with respect to* $\mathrm{Int}R_+^k$ *and* x_2^0 *is globally asymptotically stable for* (S_J) *with respect to* $\mathrm{Int}R_+^{n-k}$ *and there are positive steady states* $x^1 \leq_K x^2$. *If* $x > 0$, *then* $\omega(x) \subset [x^1, x^2]_K$. x^1 *attracts points* $x > 0$ *with* $x \leq_K x^1$ *and* x^2 *attracts points* $x > 0$ *with* $x \geq_K x^2$.

Then the system (S) is permanent in the case when (H) and (AH_2) hold. However, as Smith pointed out, "there may be several stable steady states representing persistence. It is easy to see that one cannot prove uniqueness of a positive stable steady state under the hypotheses of our Theorems 3.6 and 3.8 by simply considering two-dimensional competitive systems." "An interesting open problem is to give sufficient conditions for the uniqueness of a positive steady state in the context of Theorem 3.6 or 3.8" (see [5, p. 869]). One of the authors in [14] provided a sufficient condition such that a positive steady state is unique in the context of Smith's Theorem 3.6. His additional conditions are

$$s\left(\frac{\partial f_J}{\partial x_J}(0, x_2^0)\right) < 0$$

and

$$Df(y) \leq_K Df(x) \quad \text{whenever} \quad x, y \in [0, (x_1^0, x_2^0)] \quad \text{with} \quad x \leq_K y.$$

Together with Theorems 5.2 and 3.1, we know that (S) has a globally asymptotically stable steady state if the assumptions (H), (AH_2), and (C_1) hold. In this paper, as another application of Theorem 3.1, we give a sufficient condition for the uniqueness of a positive steady state.

THEOREM 5.3. *Let the hypotheses* (C_1) *and* (H_1) *hold. Then* (S) *has a globally asymptotically stable positive steady state.*

Proof. We only have to show that Theorem 5.3 satisfies that $(0, x_P^0) \leq_K (x_L^0, 0)$. Since x_L^0 is a positive steady state of (S_L) and x_P^0 is a positive steady state of (S_P), it follows that

$$\lim_{t \to +\infty} \phi_t^L(x_L) = x_L^0 \quad \text{for} \quad x_L \in \mathrm{Int}R_+^{\#L}$$

and

$$\lim_{t \to +\infty} \phi_t^P(x_P) = x_P^0 \quad \text{for} \quad x_P \in \mathrm{Int}R_+^{\#P}$$

from Theorem 3.1. It is easy to choose $x_L \in \mathrm{Int}R_+^{\#L}$ and $x_P \in \mathrm{Int}R_+^{\#P}$ such that $(0, x_P) \leq_K (x_L, 0)$. Theorem 2.1 shows that

$$\phi_t(0, x_P) \leq_K \phi_t(x_L, 0) \qquad \text{for} \quad t \geq 0;$$

that is,

$$(0, \phi_t^P(x_P)) \leq_K (\phi_t^L(x_L), 0) \qquad \text{for} \quad t \geq 0.$$

Then

$$(0, x_P^0) \leq_K (x_L^0, 0).$$

Applying Theorem 5.1, we conclude that (S) has a positive steady state and Theorem 3.1 implies that the positive steady state is globally asymptotically stable with respect to $\mathrm{Int}R_+^n$. □

Finally, we shall present the permanence result for system (S). Let us introduce the assumption

$$(\mathrm{AH}_3) \qquad \begin{cases} Df_L(x_L, 0) \leq_{K_1} M_L & \text{and} \quad s(M_L) < 0 \quad \text{for} \quad x_L \in R_+^l, \\ Df_P(0, x_P) \leq_{K_2} M_P & \text{and} \quad s(M_P) < 0 \quad \text{for} \quad x_P \in R_+^p, \end{cases}$$

where $N \supset L \supset I$, $N \supset P \supset J$, $l = \#L$, $p = \#P$, $K_1 = R_+^k \times (-R_+^{l-k})$, and $K_2 = R_+^{p+k-n} \times (-R_+^{n-k})$. Under the hypothesis (AH_3), if $(\mathrm{S_L})$ and $(\mathrm{S_P})$ have positive steady states x_L^0 and x_P^0, respectively, then x_L^0 is globally stable for $(\mathrm{S_L})$ with respect to $\mathrm{Int}R_+^l$ and x_P^0 is globally stable for $(\mathrm{S_P})$ with respect to $\mathrm{Int}R_+^p$ by Theorem 3.1. Hence, combining Theorems 5.1 and 3.1, we obtain the following permanence result.

THEOREM 5.4. *Let the hypotheses* (H_1) *and* (AH_3) *hold. Then* x_L^0 *is globally stable for* $(\mathrm{S_L})$ *with respect to* $\mathrm{Int}R_+^l$ *and* x_P^0 *is globally stable for* $(\mathrm{S_P})$ *with respect to* $\mathrm{Int}R_+^p$*, and there are positive steady states* $\bar{x} \leq_K \widetilde{x}$ *such that* $\omega(x) \subset [\bar{x}, \widetilde{x}]_K$ *for* $x > 0$. $\bar{x}$ *attracts points* $x > 0$ *with* $x \leq_K \bar{x}$ *and* $\widetilde{x}$ *attracts points* $x > 0$ *with* $x \geq_K \widetilde{x}$.

ANALYTIC REGULARITY FOR A SINGULARLY PERTURBED PROBLEM*

J. M. MELENK† AND C. SCHWAB†

Abstract. A singularly perturbed equation of elliptic-elliptic type in two dimensions is considered. We assume analyticity of the input data, i.e., the boundary of the domain is an analytic curve, the boundary data are analytic, and the right-hand side is analytic. We give asymptotic expansions of the solution and new error bounds that are uniform in the perturbation parameter as well as in the expansion order. Additionally, we provide growth estimates for higher derivatives of the solution where the dependence on the perturbation parameter appears explicitly. These error bounds and growth estimates are used in [J. M. Melenk and C. Schwab, *SIAM J. Numer. Anal.,* 35 (1998), pp. 1520–1557] to construct *hp* versions of the finite element method which feature *robust exponential convergence*, i.e., the rate of convergence is exponential and independent of the perturbation parameter ε.

1. Introduction.

Numerous partial differential equation models contain large or small parameters. Of interest in solid mechanics are, for example, the plate and shell equations at small thickness and nearly incompressible solids. The presence of small parameters often implies that the problem is singularly perturbed, and much attention has been devoted in the past decades to the asymptotic analysis of the solution; we mention here only [2, 3]. Typically, the solutions admit decompositions into a smooth part and so-called boundary layers. While the asymptotic structure of the solution is usually known (see, e.g., [4, 5, 6, 7]), the asymptotic expansions are often too complex for practical computations, and one has to resort to finite element solutions of the boundary value problem (BVP) of interest. Here the singular perturbation character of the problem and the boundary layer components of the solution cause approximability problems which often manifest themselves as loss of robustness, i.e., the performance of the numerical method depends strongly on the perturbation parameter. Given stability of a numerical method for a BVP, the key to its convergence is the regularity of the solution, particularly bounds on higher derivatives. In spectral and *hp* finite element methods (*hp* FEMs) that aim at exponential rates of convergence, analytic regularity results, i.e., results concerning the growth of the derivatives of the solution, are crucial. It is the purpose of the present paper to provide such analytic regularity results for the following, singularly perturbed elliptic-elliptic model problem:

$$\begin{aligned} L_\varepsilon u_\varepsilon \equiv -\varepsilon^2 \Delta u_\varepsilon + u_\varepsilon &= f \qquad \text{in } \Omega \subset \mathbb{R}^2, \\ u_\varepsilon &= g \qquad \text{on } \partial\Omega, \end{aligned} \tag{1.1}$$

where $\partial\Omega$ is a closed, nonselfintersecting, analytic curve, f is analytic on a neighborhood of $\overline{\Omega}$, g is analytic on $\partial\Omega$, and $\varepsilon \in (0, 1]$ is a small parameter.

As usual, we denote by $L^2(\Omega)$ the square integrable functions on Ω and by $H^1(\Omega)$ those functions of $L^2(\Omega)$ whose (distributional) derivative is also in $L^2(\Omega)$. The trace operator maps $H^1(\Omega)$ onto the space $H^{1/2}(\partial\Omega)$ by restricting the elements of $H^1(\Omega)$ to the boundary $\partial\Omega$. $H^1_0(\Omega)$ denotes the kernel of the trace operator; that is, it is given by those functions in $H^1(\Omega)$ whose trace on $\partial\Omega$ is zero.

The weak formulation of (1.1) is to find $u_\varepsilon \in H^1(\Omega)$ such that $u_\varepsilon|_{\partial\Omega} = g$ and

$$B_\varepsilon(u_\varepsilon, v) := \varepsilon^2 \int_\Omega \nabla u_\varepsilon \cdot \nabla v \, dxdy + \int_\Omega u_\varepsilon v \, dxdy = F(v) := \int_\Omega fv \, dxdy \tag{1.2}$$

holds for all $v \in H^1_0(\Omega)$. Associated with this problem is the notion of an energy

$$\|u\|^2_{\varepsilon,\Omega} := B_\varepsilon(u,u) = \varepsilon^2 \|\nabla u\|^2_{L^2(\Omega)} + \|u\|^2_{L^2(\Omega)}$$

and an energy norm, being the square root of the energy. We have the a priori estimate

$$\|u_\varepsilon\|_{\varepsilon,\Omega} \le \|f\|_{L^2(\Omega)} + C\|g\|_{H^{1/2}(\partial\Omega)} \tag{1.3}$$

for some $C > 0$ independent of ε.

As the input data f, g, and $\partial\Omega$ of (1.1) are analytic, standard elliptic regularity theory [8, 9] implies that the exact solution u_ε is analytic on a neighborhood of $\overline{\Omega}$, i.e., it satisfies estimates of the form

$$\|D^\alpha u_\varepsilon\|_{L^\infty(\Omega)} \le |\alpha|! C_\varepsilon K_\varepsilon^{|\alpha|} \qquad \forall \alpha = (\alpha_1, \alpha_2) \in \mathbb{N}_0^2,$$

where $\mathbb{N}$, $\mathbb{N}_0$ denote the set of positive and nonnegative integers, respectively. However, the constants C_ε and K_ε depend on ε in an unspecified way and our aim here is to control explicitly the dependence of the derivatives of u_ε on the perturbation parameter ε. By carefully tracking the ε-dependence of the constants in the standard results, we obtain in section 3 (Theorem 3.1) the following estimate:

$$\|D^\alpha u_\varepsilon\|_{L^2(\Omega)} \le C K^{|\alpha|} \max(|\alpha|, \varepsilon^{-1})^{|\alpha|} \qquad \forall \alpha \in \mathbb{N}_0^2 \tag{1.4}$$

with C, $K > 0$ independent of ε. Note that for $|\alpha| \ge \varepsilon^{-1}$ this yields an estimate independent of ε. This estimate is also sufficient to prove that polynomials of degree p can approximate the solution u_ε at a robust exponential rate provided that the polynomial degree p is at least $O(\varepsilon^{-1})$.

For derivatives of order $|\alpha| < \varepsilon^{-1}$, the estimates (1.4) are too pessimistic in that they do not capture accurately the boundary layer behavior of the solution. Typically, the solutions of (1.1) exhibit boundary layers for small ε; that is, the behavior of the solution normal to the boundary differs substantially from the behavior in the tangential direction. Classically, this anisotropic behavior of boundary layers can be described with asymptotic expansions. In section 2, we therefore provide analytic regularity results for the terms of the asymptotic expansion and estimates on the remainder (Theorem 2.2). The new feature of our results over the classical assertions for asymptotic expansions is that in all our estimates, the dependence on ε and the expansion order M is made explicit. This precise control over the asymptotic expansions is an essential ingredient in the design and convergence analysis of an *hp* FEM for (1.1) that converges at a robust exponential rate [1].

Remark 1.1. One of the difficulties in the analysis of singularly perturbed problems is the variety of phenomena that can arise already in the linear case: boundary layers, internal layers, corner layers, multiple length scales, etc. We analyze the model problem (1.1) with strong assumptions on the data f, g, $\partial\Omega$ in order to be able to concentrate on one of these phenomena, namely boundary layers.

2. Analysis of the asymptotic expansion. In this section we analyze the classical asymptotic expansions for the solution of (1.1). The asymptotic expansions (defined more precisely in section 2.2) allow us to decompose the solution u_ε as

$$u_\varepsilon = w_M + \chi u_M^{BL} + r_M, \tag{2.1}$$

where $M \in \mathbb{N}_0$ indicates the expansion order, w_M is the truncated outer expansion, u_M^{BL} is the truncated inner expansion, χ is a cutoff function supported by a neighborhood of $\partial\Omega$, and r_M is a remainder. Our results concerning w_M, u_M^{BL}, and r_M are collected in section 2.3, Theorem 2.2: We give analytic regularity results for w_M and u_M^{BL} that are uniform in ε and M, and we show that u_M^{BL} (together with all its derivatives) decays exponentially normal to $\partial\Omega$. Furthermore, we give new error bounds for the remainder r_M which are explicit in ε and the expansion order M.

2.1. Notation. We introduce *boundary fitted coordinates* to define the asymptotic expansions of the exact solution. Let $(X(\theta), Y(\theta))$, $\theta \in [0, L)$, be an analytic, L-periodic parametrization of the boundary $\partial\Omega$ by arc length such that the normal vector $(-Y'(\theta), X'(\theta))$ always points into the domain Ω. Introduce the notation $\kappa(\theta)$ for the curvature of the boundary curve and denote by $\mathbb{T}_L$ the one-dimensional torus of length L, i.e., $\mathbb{R}/L\mathbb{Z}$, endowed with the usual topology. The functions X, Y, and hence also κ are analytic on $\mathbb{T}_L$ by the analyticity of $\partial\Omega$. For the remainder of this section, let $\rho_0 > 0$ be fixed such that

$$0 < \rho_0 < \frac{1}{\|\kappa\|_{L^\infty(\mathbb{T}_L)}}. \tag{2.2}$$

Then the mapping

$$\begin{array}{rcl} \psi : [0,\rho_0] \times \mathbb{T}_L & \to & \overline{\Omega}, \\ (\rho, \theta) & \mapsto & (X(\theta) - \rho Y'(\theta), Y(\theta) + \rho X'(\theta)) \end{array} \tag{2.3}$$

is real analytic on (a neighborhood of) $[0, \rho_0] \times \mathbb{T}_L$. The function ψ maps the rectangle $(0, \rho_0) \times \mathbb{T}_L$ onto a half-tubular neighborhood Ω_0 of $\partial\Omega$. Furthermore, by the choice of ρ_0, the inverse $\psi^{-1} : \overline{\Omega}_0 \to [0, \rho_0] \times \mathbb{T}_L$ exists and is also real analytic on (a neighborhood of) the closed set $\overline{\Omega}_0$. For technical reasons we will be able to define the boundary layer expansion (the inner expansion) only in a neighborhood of the boundary $\partial\Omega$. Therefore, we introduce a cutoff function χ supported by a neighborhood of $\partial\Omega$. For ease of notation, let us define χ in the neighborhood of $\partial\Omega$ in boundary fitted coordinates (ρ, θ). Fix

$$0 < \rho_1 < \rho_0, \tag{2.4}$$

and let χ be a smooth cutoff function, defined on $[0, \infty) \times \mathbb{T}_L$, satisfying

$$\chi = \begin{cases} 1 \text{ for } 0 \le \rho \le \rho_1, \\ 0 \text{ for } \rho \ge (\rho_1 + \rho_0)/2. \end{cases} \tag{2.5}$$

Finally, as the right-hand side f of (1.1) is assumed to be analytic on (a neighborhood of) $\overline{\Omega}$, there is a complex neighborhood $\tilde{\Omega} \subset \mathbb{C} \times \mathbb{C}$ of $\overline{\Omega}$ and a holomorphic extension of f (for convenience again denoted by f) to $\tilde{\Omega}$. From Cauchy's integral theorem for derivatives, we therefore have, after passing to a compact subset of $\tilde{\Omega}$ which is again denoted $\tilde{\Omega}$, the existence of constants C_f, $\gamma \ge 0$ such that

$$\|\Delta^{(i)} f\|_{L^\infty(\tilde{\Omega})} \le C_f (2i)! \gamma^{2i} \qquad \forall i \in \mathbb{N}_0, \tag{2.6}$$

where $\Delta^{(i)}$ denotes the iterated Laplace operator, i.e., $\Delta^{(0)} = \mathrm{Id}$, $\Delta^{(1)} = \Delta$, $\Delta^{(2)} = \Delta\Delta$, etc.

2.2. Inner and outer expansion. For every $M \in \mathbb{N}_0$ the *outer expansion* of order $2M$ is defined by

$$w_M := \sum_{i=0}^{M} \varepsilon^{2i} \Delta^{(i)} f. \tag{2.7}$$

The function $u_\varepsilon - w_M$ then satisfies

$$L_\varepsilon(u_\varepsilon - w_M) = f - L_\varepsilon w_M = \varepsilon^{2M+2} \Delta^{(M+1)} f. \tag{2.8}$$

So, asymptotically as ε tends to zero, the functions w_M satisfy the differential equation in Ω. However, the functions w_M do not satisfy the given boundary conditions g. We therefore introduce a boundary layer correction u^{BL} of w_M, which will lead to the inner expansion. The correction u^{BL} is defined as the solution of

$$\begin{aligned} L_\varepsilon u^{BL} &= 0 && \text{in } \Omega, \\ u^{BL} &= g - \sum_{i=0}^{M} \varepsilon^{2i} \left[\Delta^{(i)} f \right]_{\partial\Omega} && \text{on } \partial\Omega. \end{aligned} \tag{2.9}$$

The *inner expansion* is an asymptotic expansion for this correction function u^{BL}. In order to define this expansion, we need to rewrite the differential operator L_ε in the boundary fitted coordinates (ρ, θ). With the curvature $\kappa(\theta)$ of $\partial\Omega$ and the function

$$\sigma(\rho, \theta) = \frac{1}{1 - \kappa(\theta)\rho}, \tag{2.10}$$

we have (see, for example, [4])

$$\Delta u(\rho, \theta) = \partial_\rho^2 u - \kappa(\theta)\sigma(\rho, \theta)\partial_\rho u + \sigma^2(\rho, \theta)\partial_\theta^2 u + \rho\kappa'(\theta)\sigma^3(\rho, \theta)\partial_\theta u.$$

Introducing now the *stretched variable* notation $\widehat{\rho} = \rho/\varepsilon$, we have

$$L_\varepsilon = -\partial_{\widehat{\rho}}^2 + \mathrm{Id} + \varepsilon\kappa(\theta)\sigma(\varepsilon\widehat{\rho}, \theta)\partial_{\widehat{\rho}} - \varepsilon^2\sigma^2(\varepsilon\widehat{\rho}, \theta)\partial_\theta^2 - \varepsilon^3\widehat{\rho}\kappa'(\theta)\sigma^3(\varepsilon\widehat{\rho}, \theta)\partial_\theta .$$

Expanding in power series in ε, we can write the operator L_ε formally as

$$L_\varepsilon = \sum_{i=0}^{\infty} \varepsilon^i L_i, \tag{2.11}$$

where the operators L_i have the form

$$L_0 = -\partial_{\widehat{\rho}}^2 + \mathrm{Id}, \quad L_i = -\widehat{\rho}^{i-1} a_1^{i-1} \partial_{\widehat{\rho}} - \widehat{\rho}^{i-2} a_2^{i-2} \partial_\theta^2 - \widehat{\rho}^{i-2} a_3^{i-3} \partial_\theta , \quad i \geq 1, \tag{2.12}$$

and the coefficients a_j^i are given by

$$a_1^i = -[\kappa(\theta)]^{i+1}, \; a_2^i = (i+1)[\kappa(\theta)]^i, \; a_3^i = \frac{(i+1)(i+2)}{2}[\kappa(\theta)]^i \kappa'(\theta), \; i \in \mathbb{N}_0, \tag{2.13}$$

$$a_1^i = a_2^i = a_3^i = 0 \qquad \text{for } i < 0. \tag{2.14}$$

We note that (2.11) in fact converges for $|\varepsilon\widehat{\rho}\kappa(\theta)| < 1$; this observation will be essential in our error estimates for the remainder in section 2.4.4.

Now, in order to define the inner expansion, we make the formal ansatz $u^{BL} = \sum_{i=0}^{\infty} \varepsilon^i \widehat{U}_i(\widehat{\rho}, \theta)$, where the functions $\widehat{U}_i$ are to be determined. Setting $L_\varepsilon u^{BL} = 0$ in (2.11) yields

$$\sum_{i=0}^{\infty} \varepsilon^i \sum_{j=0}^{i} L_j \widehat{U}_{i-j} = 0.$$

Hence, upon setting the coefficients of this formal power series in ε to zero, we obtain a recurrence relation for the sought functions $\widehat{U}_i$:

$$-\partial_{\widehat{\rho}}^2 \widehat{U}_i + \widehat{U}_i = \widehat{F}_i = \widehat{F}_i^1 + \widehat{F}_i^2 + \widehat{F}_i^3, \qquad i = 0, 1, \ldots, \tag{2.15}$$

$$\widehat{F}_i^1 = \sum_{j=0}^{i-1} \widehat{\rho}^j a_1^j \partial_{\widehat{\rho}} \widehat{U}_{i-1-j},\ \widehat{F}_i^2 = \sum_{j=0}^{i-2} \widehat{\rho}^j a_2^j \partial_\theta^2 \widehat{U}_{i-2-j},\ \widehat{F}_i^3 = \sum_{j=0}^{i-3} \widehat{\rho}^{j+1} a_3^j \partial_\theta \widehat{U}_{i-3-j}, \tag{2.16}$$

where we used the tacit convention that empty sums take the value zero. As we expect the boundary layer function u^{BL} to decay away from the boundary $\partial\Omega$ and as we want to satisfy the boundary conditions, we supplement these ODEs for the $\widehat{U}_i$ with the boundary conditions

$$\widehat{U}_i \to 0 \qquad \text{as } \widehat{\rho} \to \infty, \tag{2.17}$$

$$[\widehat{U}_i]_{\partial\Omega} = G_i : \begin{cases} = & g - [f]_{\partial\Omega} & \text{if } i = 0, \\ = & -[\Delta^{(i/2)} f]_{\partial\Omega} & \text{if } i \in \mathbb{N} \text{ is even}, \\ & 0 & \text{if } i \in \mathbb{N} \text{ is odd}. \end{cases} \tag{2.18}$$

The inner expansion of order $2M+1$ is defined as the function

$$u_M^{BL}(\rho, \theta) := \sum_{i=0}^{2M+1} \varepsilon^i \widehat{U}_i(\widehat{\rho}, \theta) = \sum_{i=0}^{2M+1} \varepsilon^i \widehat{U}_i(\rho/\varepsilon, \theta), \tag{2.19}$$

and it satisfies the desired boundary conditions

$$[u_M^{BL}]_{\partial\Omega} = g - \sum_{i=0}^{M} \varepsilon^{2i} [\Delta^{(i)} f]_{\partial\Omega}.$$

Remark 2.1. We defined u_M^{BL} as the inner expansion of order $2M+1$ so that the first neglected term of the formal asymptotic expansion $\sum_{i=0}^{\infty} \varepsilon^i \widehat{U}_i$ is of order ε^{2M+2}. This is precisely the same power of ε as the first neglected term of the outer expansion $\sum_{i=0}^{\infty} \varepsilon^{2i} \Delta^{(i)} f$ truncated after the ε^{2M} term.

Finally, the remainder r_M is defined such that (2.1) holds. We should note, however, that the boundary layer function u_M^{BL} and the cutoff function χ are defined in boundary fitted coordinates, whereas w_M is defined in the usual x, y coordinates so that, strictly speaking, the term χu_M^{BL} has to be understood as $(\chi u_M^{BL}) \circ \psi$ on the half-tubular neighborhood Ω_0 where ψ is the boundary fitted coordinate transformation defined in (2.3) and χu_M^{BL} is understood to vanish outside Ω_0.

2.3. Analytic regularity results for the asymptotic expansion. For every $M \in \mathbb{N}_0$ and cutoff function χ as in section 2.1 we can decompose the solution u_ε of (1.1) as in (2.1) where the outer expansion w_M, the inner expansion u_M^{BL}, and the remainder r_M are defined in the preceding section. The following theorem contains

bounds for w_M, u_M^{BL}, and r_M which are explicit in ε and M; the proof of this theorem is relegated to section 2.4.

THEOREM 2.2. *Let f, g, $\partial\Omega$ be analytic and let ρ_0, χ satisfy* (2.2), (2.5). *Let w_M, u_M^{BL}, r_M be defined by* (2.7), (2.19), (2.1). *Then there are constants C, K_1, and $K_2 > 0$ depending only on f, g, $\partial\Omega$, and ρ_0, χ such that*

(i) *For every $M \in \mathbb{N}_0$ the outer expansion w_M is analytic on Ω and there holds*

$$\|D^\alpha w_M\|_{L^\infty(\Omega)} \le C K_1^{|\alpha|} |\alpha|! (1 + (\varepsilon\, 2M\, K_2)^{2M}) \qquad \forall \alpha \in \mathbb{N}_0^2.$$

(ii) *For every $M \in \mathbb{N}_0$ the inner expansion u_M^{BL} is analytic on $(0,\rho_0)\times\mathbb{T}_L$. For every $\alpha \in [0,1)$ and all p, $m \in \mathbb{N}_0$, $(\rho,\theta) \in (0,\rho_0)\times\mathbb{T}_L$ there holds*

$$\left|\partial_\rho^p \partial_\theta^m u_M^{BL}(\rho,\theta)\right| \le C \left(1 + \left(\frac{\varepsilon(2M+1)K_2}{1-\alpha}\right)^{2M+1}\right) m! K_1^{m+p} \varepsilon^{-p} e^{-\alpha\rho/\varepsilon}.$$

(iii) *For every $M \in \mathbb{N}_0$ the remainder satisfies $r_M = 0$ on $\partial\Omega$ and*

$$\|r_M\|_{\varepsilon,\Omega} \le C \left(\varepsilon K_2 (2M+2)\right)^{2M+2}.$$

Remark 2.3. We notice that the crucial quantity in all three theorems is the product $\varepsilon(2M+2)$: If $\varepsilon(2M+2) \le q < K_2^{-1}$ then the remainder r_M is indeed small and we obtain bounds on the growth of the derivatives of w_M and u_M^{BL} which are independent of ε and M. In the complementary case, i.e., when $\varepsilon(2M+2)$ is not small, the asymptotic expansions lose their meaning.

We conclude this section with a few remarks concerning estimates on r_M.

Remark 2.4. Inspection of the proof of Theorem 2.2 (iii) below shows that in fact the following, slightly stronger results can be obtained:

1. There are C, $K > 0$ independent of ε and M such that

$$\|r_M\|_{\varepsilon,\Omega} \le C\Big\{\varepsilon^{2M+2}\|\Delta^{(M+1)} f\|_{L^\infty(\Omega)} + \varepsilon^{1/2}\left(K\varepsilon(2M+2)\right)^{2M+2}\Big\}.$$

   Hence, if the right-hand side f satisfies $\Delta^{(M+1)} f = 0$, e.g., if f is a polynomial of degree $2M+1$, then the ε-dependence of the estimate is actually improved by a factor $\varepsilon^{1/2}$.
2. In the proof of Theorem 2.2 (iii), with the exception of $\Delta^{(M+1)} f$, all the terms could be bounded in exponentially weighted spaces. This means that if $\Delta^{(M+1)} f = 0$, then we have estimates of the form

$$\|e^{\beta d(x)/\varepsilon} L_\varepsilon r_M\|_{L^2(\Omega)} \le C(\Omega,\beta)\varepsilon^{1/2}\left(K\varepsilon(2M+2)\right)^{2M+2},$$

   where $d(x) = \operatorname{dist}(x,\partial\Omega)$ and $\beta > 0$ appropriately. From this, one could infer estimates on r_M in exponentially weighted energy norms.
3. As $\|L_\varepsilon r_M\|_{L^\infty(\Omega)} \le C\left(K\varepsilon(2M+2)\right)^{2M+2}$ and $r_M = 0$ on $\partial\Omega$, the classical maximum principle gives us the pointwise bound

$$\|r_M\|_{L^\infty(\Omega)} \le C\left(K\varepsilon(2M+2)\right)^{2M+2}.$$

As the boundary $\partial\Omega$ is smooth, we can actually use the shift theorem for $-\Delta$ in order to control higher derivatives of r_M.

COROLLARY 2.5. *Assume the same hypotheses as in Theorem* 2.2. *Then for each $k \in \mathbb{N}_0$ there are constants C_k, $K > 0$ depending only on k, f, g, $\partial\Omega$, χ such that*

$$\|r_M\|_{H^k(\Omega)} \le C_k \varepsilon^{-k}\left(\varepsilon K(2M+2)\right)^{2M+2}, \qquad k \in \mathbb{N}_0.$$

Proof. The proof is an application of the classical shift theorem and an induction argument on k. We note that the corollary holds true for $k = 0$ and $k = 1$ by Theorem 2.2 (iii). Furthermore, r_M solves

$$-\Delta r_M = \varepsilon^{-2} L_\varepsilon r_M - \varepsilon^{-2} r_M \quad \text{in } \Omega, \qquad r_M = 0 \quad \text{on } \partial\Omega. \tag{2.20}$$

If we proceed as in the proof of Theorem 2.2 (iii) below but use the bounds on higher derivatives in Lemma 2.13 we can estimate

$$\|L_\varepsilon u_M^{BL}\|_{H^{k-2}(\Omega)} \le C_k \varepsilon^{2-k} \left(\varepsilon K(2M+2)\right)^{2M+2}, \qquad k \ge 2.$$

Hence the shift theorem allows us to conclude

$$\|r_M\|_{H^k(\Omega)} \le C_k \left(\varepsilon^{-k} \left(\varepsilon K(2M+2)\right)^{2M+2} + \varepsilon^{-2} \|r_M\|_{H^{k-2}(\Omega)}\right)$$

for $k \ge 2$. The obvious induction argument concludes the proof. ∎

2.4. Proof of Theorem 2.2.

2.4.1. Preliminaries. For $z \in \mathbb{C}$ and $\delta > 0$ we will denote by $B_\delta(z)$ the (open) disc in the complex plane of radius δ around z; $\partial B_\delta(z)$ denotes the positively oriented circle of radius δ with center z.

As the functions κ, G_i, and a_l^i are analytic on $\mathbb{T}_L$ these functions have holomorphic extensions to some complex neighborhood $S(\Theta)$ of the real line where

$$S(\Theta) := \{\theta \in \mathbb{C} \,|\, |\mathrm{Im}\theta| < \Theta\}, \quad \Theta > 0. \tag{2.21}$$

For future reference, let us note the following.

LEMMA 2.6. *Let f, g, $\partial\Omega$ be analytic. Then there are $\Theta > 0$ and C_G, C_A, γ_G, $A > 0$ with $A\rho_0 < 1$ such that $\forall \theta \in S(\Theta)$ and $\forall i \in \mathbb{N}_0$*

$$|G_i(\theta)| \le C_G i^i \gamma_G^i, \qquad |\kappa(\theta)| \le A, \qquad |a_1^i(\theta)| + |a_2^i(\theta)| + |a_3^i(\theta)| \le C_A A^i.$$

Proof. By (2.2) we may choose an A such that $\|\kappa\|_{L^\infty(\mathbb{T}_L)} < A < 1/\rho_0$. The bounds on G_i follow immediately from (2.6) and (2.18) for Θ sufficiently small. As $\rho_0 \|\kappa\|_{L^\infty(\mathbb{T}_L)} < 1$ the bound on κ follows from a continuity argument if Θ is sufficiently small. From this bound on κ, the bounds on the coefficients a_l^i can be obtained in view of (2.13) if Θ is taken sufficiently small and A is slightly enlarged. ∎

The following two lemmas can be proven by elementary considerations.

LEMMA 2.7. *$\forall\, q \ge 0$ and $\forall\, M \in \mathbb{N}_0$ there holds*

$$\sum_{i=0}^{M} q^i \le 2(1 + (4q)^M).$$

LEMMA 2.8. *Let $\alpha \in [0,1)$, $a \ge 0$, $M \ge 0$. Then*

$$\sup_{r \ge 0} \left| (M + a + r)^M e^{-(1-\alpha)r} \right| \le M^M (1-\alpha)^{-M} e^{(1-\alpha)a}.$$

2.4.2. Proof of Theorem 2.2 (i). In view of (2.6) the function w_M can be extended to a holomorphic function on a neighborhood $\tilde{\Omega} \subset \mathbb{C} \times \mathbb{C}$ of Ω which is independent of ε and M. Cauchy's theorem for derivatives allows us to infer the existence of C, $K > 0$ such that for each $(x, y) \in \Omega$ and all $\alpha \in \mathbb{N}_0^2$ there holds

$$|D^\alpha w_M(x,y)| \le CK^{|\alpha|}|\alpha|! \sum_{i=0}^{M} \varepsilon^{2i} \|\Delta^{(i)} f\|_{L^\infty(\tilde{\Omega})} \le CK^{|\alpha|}|\alpha|! \sum_{i=0}^{M} \gamma^{2i} (2i\varepsilon)^{2i}.$$

Estimating $\gamma(2i\varepsilon) \le \gamma(2M\varepsilon)$ we can easily obtain the desired result with the aid of Lemma 2.7.

2.4.3. Proof of Theorem 2.2 (ii). The proof of Theorem 2.2 (ii) is based on getting sharp bounds on the functions $\widehat{U}_i$ defined in (2.15)–(2.18). As the functions $\widehat{U}_i$ are solutions of ODEs whose right-hand sides depend on derivatives of the $\widehat{U}_j$, $0 \le j < i$, the following two lemmas will be necessary.

LEMMA 2.9. *Let f be an entire function satisfying for some $C_f > 0$, $j \in \mathbb{N}_0$*

$$|f(z)| \le C_f e^{-\mathrm{Re} z} (2 + j + |z|)^j \qquad \forall z \in \mathbb{C}.$$

Let $g \in \mathbb{C}$ and let $u : (0, \infty) \to \mathbb{C}$ be the solution of

$$-u'' + u = f \quad \text{on } (0,\infty), \qquad u(0) = g, \quad \lim_{x\to\infty} u(x) = 0.$$

Then u can be extended to an entire function (again denoted u) which satisfies

$$|u(z)| \le \left[C_f (2 + j + |z|)^{j+1} (j+1)^{-1} + |g| \right] e^{-\mathrm{Re} z} \qquad \forall z \in \mathbb{C}.$$

Proof. For $z \in (0, \infty)$, the use of a Green's function gives the following representation of the solution $u(z)$:

$$u(z) = \frac{1}{2} \left(e^{-z} \int_0^z e^y f(y)\, dy + e^z \int_z^\infty e^{-y} f(y)\, dy - e^{-z} \int_0^\infty e^{-y} f(y)\, dy \right) + g e^{-z}.$$

Analytic continuation then removes the restriction to $(0, \infty)$. In order to get the desired bound, we estimate each of these four terms separately. For the first integral, we use as the path of integration the straight line connecting 0 and z to get

$$\begin{aligned} \left| e^{-z} \int_0^z e^y f(y)\, dy \right| &\le e^{-\mathrm{Re} z} \int_0^1 C_f (2 + j + t|z|)^j |z|\, e^{-\mathrm{Re} tz} e^{\mathrm{Re} tz}\, dt \\ &\le C_f e^{-\mathrm{Re} z} \frac{1}{j+1} \left((2 + j + |z|)^{j+1} - (2+j)^{j+1} \right). \end{aligned}$$

For the second term, we calculate

$$\begin{aligned} \left| e^z \int_z^\infty e^{-y} f(y)\, dy \right| = \left| \int_0^\infty e^{-y} f(z+y)\, dy \right| &\le e^{-\mathrm{Re} z} C_f \int_0^\infty e^{-2y} (2 + j + |z| + y)^j\, dy \\ &= C_f e^{-\mathrm{Re} z} 2^{-(j+1)} e^{2(2+j+|z|)} \Gamma(j+1, 2(2+j+|z|)), \end{aligned}$$

where $\Gamma(\cdot,\cdot)$ denotes the incomplete Gamma function and we used Eq. 8.353.5 of [10] in the last step. Employing the estimate

$$|\Gamma(\alpha, \xi)| \le \frac{\left| e^{-\xi} \xi^\alpha \right|}{|\xi| - \alpha_0}, \qquad \alpha_0 = \max\{\alpha - 1, 0\}, \quad \mathrm{Re}\,\xi \ge 0, \quad |\xi| > \alpha_0$$

(see, e.g., Chap. 4, Sec. 10 of [11]) we finally arrive at

$$\left|e^z \int_z^\infty e^{-y} f(y)\, dy\right| \le C_f e^{-\mathrm{Re}z} \frac{(2+j+|z|)^{j+1}}{4+j+2|z|} \le C_f e^{-\mathrm{Re}z} \frac{(2+j+|z|)^{j+1}}{1+j}.$$

For the third term, we observe that the integral $\int_0^\infty f(y)e^{-y}\, dy$ is precisely the second term with $z = 0$. We conclude therefore that for the third term

$$\left|e^{-z} \int_0^\infty f(y)e^{-y}\, dy\right| \le C_f e^{-\mathrm{Re}z} \frac{(2+j)^{j+1}}{1+j}.$$

Combining these three estimates with the obvious one for the fourth term, we arrive at the desired bound. ∎

LEMMA 2.10. *Let U be holomorphic on $\mathbb{C} \times S(\Theta)$ for some $\Theta > 0$ and assume that there are $C_U > 0$, $i \in \mathbb{N}_0$ such that for all $\delta \in (0, \Theta)$*

$$\forall (z,\theta) \in \mathbb{C} \times S(\Theta - \delta) \qquad |U(z,\theta)| \le C_U (1+i+|z|)^i e^{-\mathrm{Re}z} \delta^{-i}.$$

Then $\forall\ \delta \in (0,\Theta)$ and $\forall\ (z,\theta) \in \mathbb{C} \times S(\Theta - \delta)$

$$\begin{aligned}
&|\partial_z U(z,\theta)| \le e\, C_U (2+i+|z|)^i e^{-\mathrm{Re}\ z} \delta^{-i},\\
&|\partial_\theta U(z,\theta)| \le e(i+1) C_U (1+i+|z|)^i e^{-\mathrm{Re}\ z} \delta^{-(i+1)},\\
&\left|\partial_\theta^2 U(z,\theta)\right| \le 2e(i+1)(i+2) C_U (1+i+|z|)^i e^{-\mathrm{Re}\ z} \delta^{-(i+2)}.
\end{aligned}$$

Proof. For the first estimate, we use Cauchy's integral theorem for derivatives:

$$|\partial_z U(z,\theta)| = \left|\frac{1}{2\pi i} \int_{|t|=1} \frac{U(z+t,\theta)}{t^2}\, dt\right| \le C_U (1+i+|z|+1)^i e^{-\mathrm{Re}z+1} \delta^{-i}.$$

For the second and third estimate, we again use Cauchy's integral theorem for derivatives but with the path of integration chosen as $\partial B_{\kappa\delta}(\theta)$ where $\kappa \in (0,1)$ is to be chosen below. For the second estimate, we arrive at

$$\begin{aligned}
|\partial_\theta U(z,\theta)| &= \left|\frac{1}{2\pi i} \int_{|t|=\kappa\delta} \frac{U(z,\theta+t)}{t^2}\, dt\right| \le C_U \frac{1}{(\kappa\delta)((1-\kappa)\delta)^i} (1+i+|z|)^i e^{-\mathrm{Re}z}\\
&\le C_U \frac{1}{\kappa(1-\kappa)^i} \delta^{-(i+1)} (1+i+|z|)^i e^{-\mathrm{Re}z}.
\end{aligned}$$

Choosing $\kappa = 1/(i+2)$ and observing that with this choice $e^{-1}(i+1)^{-1} \le \kappa(1-\kappa)^i$ holds for all $i \in \mathbb{N}_0$ we obtain the desired second bound. Finally, the third estimate is proved completely analogously. ∎

These two lemmas put us in a position to obtain results about the functions $\widehat{U}_i$ defined by (2.15)–(2.18). As $\widehat{F}_0 = 0$ we have $\widehat{U}_0(\widehat{\rho},\theta) = G_0(\theta)e^{-\widehat{\rho}}$. Therefore, $\widehat{F}_1(\widehat{\rho},\theta) = -a_1^0(\theta)G_0(\theta)e^{-\widehat{\rho}}$ and we get $\widehat{U}_1(\widehat{\rho},\theta) = -1/2\widehat{\rho}a_1^0(\theta)e^{-\widehat{\rho}} + G_1(\theta)e^{-\widehat{\rho}}$. It is easy to see that in general the functions $\widehat{U}_i$ are of the form $e^{-\widehat{\rho}}$ times a polynomial of degree i in $\widehat{\rho}$ whose coefficients involve the functions a_l^j and G_j and their derivatives. Furthermore, the lowest-order term of the polynomial of degree i is $G_i(\theta)$ which by Lemma 2.6 can be estimated by $C_G i^i \gamma_G^i$ for θ in a neighborhood of the real line. This suggests that bounds on $\widehat{U}_i$ of the form $|\widehat{U}_i(\widehat{\rho},\theta)| \le CK^i e^{-\mathbf{Re}\widehat{\rho}}(1+i+|\widehat{\rho}|)^i$ can be obtained.

LEMMA 2.11. *Let f, g, $\partial\Omega$ be analytic. Then there are C_U, K, $\Theta > 0$ depending only on f, g, $\partial\Omega$ such that the functions $\widehat{U}_i$ defined by (2.15)–(2.18) are holomorphic on $\mathbb{C} \times S(\Theta)$ and satisfy $\forall\, i \in \mathbb{N}_0$*

$$\left|\widehat{U}_i(\widehat{\rho},\theta)\right| \le C_U K^i (1+i+|\widehat{\rho}|)^i e^{-\mathrm{Re}\,\widehat{\rho}} \qquad \forall (\widehat{\rho},\theta) \in \mathbb{C}\times S(\Theta).$$

Proof. We prove the following result: There are C_U, K, Θ such that for all $i \in \mathbb{N}_0$

(2.22)

$$\forall\, \delta \in (0,\Theta) \quad \forall (\widehat{\rho},\theta) \in \mathbb{C}\times S(\Theta-\delta) \qquad |\widehat{U}_i(\widehat{\rho},\theta)| \le C_U K^i \delta^{-i} (1+i+|\widehat{\rho}|)^i e^{-\mathrm{Re}\,\widehat{\rho}}.$$

The claim of the lemma then follows by slightly decreasing Θ and adjusting the constant K. Let us assume that Θ, C_A, C_G, γ_G, A are chosen as in Lemma 2.6. From our preliminary discussion it is clear that we can (after possibly decreasing Θ slightly) choose C_U, K such that (2.22) is satisfied for $i = 0, 1, 2$. Let us furthermore assume that C_U and K are chosen so large such that $K > \max\{A\Theta, \gamma_G\Theta\}$ and that $\forall\, i \in \mathbb{N}_0$

$$\left[K^{-1}\frac{eC_A\Theta}{1-A\Theta/K} + K^{-2}\frac{2eC_A}{1-A\Theta/K} + K^{-3}\frac{eC_A\Theta^2}{1-A\Theta/K} + \frac{C_G}{C_U}\left(\frac{\gamma_G\Theta}{K}\right)^i\right] \le 1. \tag{2.23}$$

In order to proceed by induction on i, let $i \ge 3$ and assume that (2.22) holds for all $0 \le j \le i-1$. To get the desired bounds on $\widehat{U}_i$ by means of Lemma 2.9 we need to control $\widehat{F}_i^1$, $\widehat{F}_i^2$, $\widehat{F}_i^3$. Combining Lemma 2.10 and the induction hypothesis (2.22), we get for $(\widehat{\rho},\theta) \in \mathbb{C}\times S(\Theta-\delta)$

$$\begin{aligned}
|\widehat{F}_i^1(\widehat{\rho},\theta)| &\le \sum_{j=0}^{i-1} |\widehat{\rho}|^j |a_1^j(\theta)||\partial_{\widehat{\rho}}\widehat{U}_{i-1-j}(\widehat{\rho},\theta)| \\
&\le C_U K^i \delta^{-i} e^{-\mathrm{Re}\,\widehat{\rho}} C_A K^{-1}\delta e \sum_{j=0}^{i-1} |\widehat{\rho}|^j A^j K^{-j}\delta^j (i-j+1+|\widehat{\rho}|)^{i-1-j} \\
&\le C_U K^i \delta^{-i} K^{-1} \frac{eC_A\delta}{1-A\delta/K}(i+1+|\widehat{\rho}|)^{i-1} e^{-\mathrm{Re}\,\widehat{\rho}}.
\end{aligned}$$

Similarly, we obtain for $|\widehat{F}_i^2|$ and $|\widehat{F}_i^3|$ on $\mathbb{C}\times S(\Theta-\delta)$

$$\begin{aligned}
|\widehat{F}_i^2(\widehat{\rho},\theta)| &\le C_U K^i \delta^{-i} K^{-2} \frac{2eC_A}{1-A\delta/K}(i+|\widehat{\rho}|)^{i-2}(i-1) i e^{-\mathrm{Re}\,\widehat{\rho}}, \\
|\widehat{F}_i^3(\widehat{\rho},\theta)| &\le C_U K^i \delta^{-i} K^{-3} \frac{eC_A\delta^2}{1-A\delta/K}(i+|\widehat{\rho}|)^{i-2}(i-2) e^{-\mathrm{Re}\,\widehat{\rho}}.
\end{aligned}$$

Hence, applying Lemma 2.9 with $\widehat{F}_i^1$, $\widehat{F}_i^2$, $\widehat{F}_i^3$ as right-hand sides f (and initial condition $g = 0$) and finally with homogeneous right-hand side and initial condition $g = G_i(\theta)$, we obtain

$$\begin{aligned}
|\widehat{U}_i(\widehat{\rho},\theta)| \le C_U K^i \delta^{-i} e^{-\mathbf{Re}\widehat{\rho}} \Bigg[& K^{-1}\frac{eC_A\delta}{1-A\delta/K}\frac{(i+1+|\widehat{\rho}|)^i}{i} \\
& + K^{-2}\frac{2eC_A}{1-A\delta/K}(i+|\widehat{\rho}|)^{i-1}\frac{(i-1)i}{i-1}
\end{aligned}$$

$$
\begin{aligned}
&+K^{-3}\frac{eC_A\delta^2}{1-A\delta/K}(i+|\widehat{\rho}|)^{i-1}\frac{(i-2)}{i-1}+\frac{C_G}{C_U}\left(\frac{\delta\gamma_G}{K}\right)^i\Bigg]\\
&\le C_UK^i\delta^{-i}e^{-\mathbf{Re}\widehat{\rho}}(i+1+|\widehat{\rho}|)^i\times\\
&\quad\times\left[K^{-1}\frac{eC_A\delta}{1-A\delta/K}+K^{-2}\frac{2eC_A}{1-A\delta/K}+K^{-3}\frac{eC_A\delta^2}{1-A\delta/K}+\frac{C_G}{C_U}\left(\frac{\delta\gamma_G}{K}\right)^i\right]\\
&\le C_UK^i\delta^{-i}e^{-\mathbf{Re}\widehat{\rho}}(i+1+|\widehat{\rho}|)^i
\end{aligned}
$$

as the bracketed expression is bounded by 1 by the choice of K in (2.23). This concludes the induction argument. ∎

The proof of Theorem 2.2 (ii) is now straightforward.

Proof of Theorem 2.2 (ii). Let $\alpha\in[0,1)$ be given. By Lemma 2.11 the functions $\widehat{U}_i$ are holomorphic on $\mathbb{C}\times S(\Theta)$ for some $\Theta>0$. We obtain with Cauchy's integral formula for derivatives for p, $m\in\mathbb{N}_0$ and $\rho\ge0$, $\theta\in\mathbb{T}_L$

$$
\partial_\rho^p\,\partial_\theta^m\,\widehat{U}_i(\rho/\varepsilon,\theta)=-\varepsilon^{-p}\frac{p!m!}{4\pi^2}\int_{|z|=R}\int_{|t|=\Theta/2}\frac{\widehat{U}_i(\rho/\varepsilon+z,\theta+t)}{z^{p+1}t^{m+1}}\,dzdt.
$$

Now choosing $R=p+1$ and using Lemma 2.11 (note that we may choose $\delta=\Theta/2$), we get the existence of constants C, $K>0$ such that

$$
\left|\partial_\rho^p\,\partial_\theta^m\,\widehat{U}_i(\rho/\varepsilon,\theta)\right|=C\varepsilon^{-p}\frac{p!m!}{(p+1)^p}(2/\Theta)^mK^i(1+i+\rho/\varepsilon+p+1)^ie^{-\rho/\varepsilon+(p+1)}.
$$

Upon writing $e^{-\rho/\varepsilon}=e^{-(1-\alpha)\rho/\varepsilon}e^{-\alpha\rho/\varepsilon}$ and appealing to Lemma 2.8 (with $a=2+p$), we get, together with the estimate $p!\le Cp^pe^{-p}\sqrt{2\pi(p+1)}$ from Stirling's formula,

$$
\left|\partial_\rho^p\,\partial_\theta^m\,\widehat{U}_i(\rho/\varepsilon,\theta)\right|=C\varepsilon^{-p}e^{(1-\alpha)p}(p+1)^{1/2}m!(2/\Theta)^mK^ii^i(1-\alpha)^{-i}e^{-\alpha\rho/\varepsilon}. \tag{2.24}
$$

As $u_M^{BL}(\rho,\theta)=\sum_{i=0}^{2M+1}\varepsilon^i\widehat{U}_i(\rho/\varepsilon,\theta)$ estimating $i^i\le(2M+1)^i$ in (2.24) and summing gives the desired result after appealing to Lemma 2.7. ∎

2.4.4. Proof of Theorem 2.2 (iii). We start with a lemma concerning $L_\varepsilon u_M^{BL}$.

LEMMA 2.12. *Let u_M^{BL} be defined in* (2.19). *Then there are Θ, C, $K>0$ depending only on f, g, $\partial\Omega$ such that $L_\varepsilon u_M^{BL}$ is holomorphic on $B_{\rho_0}(0)\times S(\Theta)\subset\mathbb{C}\times\mathbb{C}$ and satisfies*

$$
|L_\varepsilon u_M^{BL}(\rho,\theta)|\le CK^{2M+2}(\varepsilon(2M+2)+|\rho|)^{2M+2}e^{-\mathbf{Re}\rho/\varepsilon}\qquad\forall(\rho,\theta)\in B_{\rho_0}(0)\times S(\Theta).
$$

Proof. As we observed above, the power series expansion (2.11) of L_ε converges absolutely for $|\varepsilon\widehat{\rho}\kappa(\theta)|<1$. In order to exploit this fact, let us choose with the aid of Lemma 2.6 $\Theta>0$, C_A, $A>0$ with $\rho_0A=:q<1$ such that $|\rho\kappa(\theta)|\le q<1$ $\forall$ $(\rho,\theta)\in B_{\rho_0}(0)\times S(\Theta)$. Furthermore, we may assume without loss of generality that Θ is so small that Lemma 2.11 holds.

By the construction of the functions $\widehat{U}_i$, we calculate directly (we write $\widehat{\rho}=\rho/\varepsilon$ whenever notationally convenient)

$$
L_\varepsilon u_M^{BL}(\rho,\theta)=\sum_{i=2M+2}^{\infty}\varepsilon^i\sum_{j=0}^{2M+1}L_{i-j}\widehat{U}_j(\rho/\varepsilon,\theta)
$$

$$= -\sum_{j=0}^{2M+1}\sum_{i=2M+2}^{\infty}\varepsilon^i\widehat{\rho}^{i-1-j}a_1^{i-1-j}\partial_{\widehat{\rho}}\widehat{U}_j - \sum_{j=0}^{2M+1}\sum_{i=2M+3}^{\infty}\varepsilon^i\widehat{\rho}^{i-2-j}a_2^{i-2-j}\partial_\theta^2\widehat{U}_j$$
$$- \sum_{j=0}^{2M+1}\sum_{i=2M+4}^{\infty}\varepsilon^i\widehat{\rho}^{i-2-j}a_3^{i-3-j}\partial_\theta\widehat{U}_j.$$

Each of these three terms can be estimated with the aid of Lemmas 2.11 and 2.10. For the first term, we have for $(\rho,\theta)\in B_{\rho_0}(0)\times S(\Theta)$ (which implies $|\rho|A\le q<1$)

$$\begin{aligned}
&\left|\sum_{j=0}^{2M+1}\sum_{i=2M+2}^{\infty}\varepsilon^i\widehat{\rho}^{i-1-j}a_1^{i-1-j}(\theta)\partial_{\widehat{\rho}}\widehat{U}_j(\widehat{\rho},\theta)\right|\\
&\le eC_UC_A\sum_{j=0}^{2M+1}\sum_{i=2M+2}^{\infty}\varepsilon^i|\widehat{\rho}|^{i-1-j}A^{i-1-j}K^j(2+j+|\widehat{\rho}|)^je^{-\mathrm{Re}\,\widehat{\rho}}\\
&\le eC_AC_U\varepsilon^{2M+2}\sum_{j=0}^{2M+1}\left(\sum_{i=0}^{\infty}\varepsilon^i|\widehat{\rho}|^iA^i\right)A^{2M+1-j}K^j\left\{|\widehat{\rho}|^{2M+1-j}(2M+3+|\widehat{\rho}|)^j\right\}e^{-\mathrm{Re}\widehat{\rho}}\\
&\le eC_AC_U\varepsilon^{2M+2}\frac{1}{1-q}\sum_{j=0}^{2M+1}A^{2M+1-j}K^j(2M+3+|\widehat{\rho}|)^{2M+1}e^{-\mathrm{Re}\,\widehat{\rho}}\\
&\le 2eC_AC_U\frac{1}{1-q}A^{2M+1}(1+(4K/A)^{2M+1})(\varepsilon(2M+3)+|\rho|)^{2M+2}e^{-\mathrm{Re}\,\widehat{\rho}},
\end{aligned}$$

where we exploited the assumption that $|\rho|A\le q<1$ and appealed to Lemma 2.7. The factor $(2M+3)$ can easily be replaced by $2M+2$ at the expense of a larger constant. Hence, the first sum leads to an estimate of the desired form; the remaining two sums are estimated similarly. ∎

A procedure similar to that of Theorem 2.2 (ii) gives bounds on higher derivatives.

LEMMA 2.13. *Let $\rho'<\rho_0$, $\alpha\in[0,1)$. Then there are constants C, K_1, $K_2>0$ independent of ε, M such that for all p, $m\in\mathbb{N}_0$ and all $(\rho,\theta)\in[0,\rho')\times\mathbb{T}_L$*

$$\left|\partial_\rho^p\partial_\theta^m L_\varepsilon u_M^{BL}(\rho,\theta)\right|\le C\varepsilon^{-p}p!m!K_1^{p+m}\left(\frac{\varepsilon(2M+2)K_2}{1-\alpha}\right)^{2M+2}e^{-\alpha\rho/\varepsilon}.$$

Proof. As $\rho'<\rho_0$ there is $\delta>0$ such that $B_{\delta\varepsilon}(\rho)\subset B_{\rho_0}(0)$ for all $\varepsilon\in(0,1]$ and $\rho\in[0,\rho')$. We apply Cauchy's integral theorem for derivatives to calculate $\partial_\rho^p\partial_\theta^m L_\varepsilon u_M^{BL}$; the path of integration is chosen as $\partial B_{\delta\varepsilon}(\rho)$ for the first variable and as $\partial B_{\Theta/2}(\theta)$ for the second variable. Together with Lemma 2.12 we get the existence of C, K_1, $K_2>0$ such that for $\rho\in[0,\rho')$, $\theta\in\mathbb{T}_L$

$$\begin{aligned}
\left|\partial_\rho^p\partial_\theta^m L_\varepsilon u_M^{BL}(\rho,\theta)\right| &\le C\varepsilon^{-p}p!m!K_1^{p+m}K_2^{2M+2}\left(\varepsilon(2M+2)+\rho+\varepsilon\delta\right)^{2M+2}e^{-\rho/\varepsilon}\\
&\le C\varepsilon^{-p}p!m!K_1^{p+m}K_2^{2M+2}\varepsilon^{2M+2}\left[\left((2M+2)+\rho/\varepsilon+\delta\right)^{2M+2}e^{-(1-\alpha)\rho/\varepsilon}\right]e^{-\alpha\rho/\varepsilon}.
\end{aligned}$$

Appealing to Lemma 2.8 to bound the expression in brackets allows us to conclude the argument. ∎

We are now in a position to estimate the accuracy of the asymptotic expansion, i.e., bound r_M.

Proof of Theorem 2.2 (iii). For any $M \in \mathbb{N}_0$ the remainder r_M is defined as $r_M = u_\varepsilon - w_M - \chi u_M^{BL}$, where w_M is defined by (2.7), u_M^{BL} is defined by (2.19), and χ is the cutoff function of (2.5). Hence, by construction of u_M^{BL}, $r_M = 0$ on $\partial\Omega$. Furthermore, the remainder r_M solves the following elliptic equation:

$$\begin{aligned} L_\varepsilon r_M &= L_\varepsilon \left(u_\varepsilon - w_M - \chi u_M^{BL}\right) = \varepsilon^{2M+2}\Delta^{(M+1)} f - L_\varepsilon(\chi u_M^{BL}) \\ &= \varepsilon^{2M+2}\Delta^{(M+1)} f + \varepsilon^2(\Delta\chi)u_M^{BL} + 2\varepsilon^2 \nabla\chi\cdot\nabla u_M^{BL} - \chi L_\varepsilon u_M^{BL}. \end{aligned}$$

From (1.3) we infer

$$\|r_M\|_{\varepsilon,\Omega} \le \|L_\varepsilon r_M\|_{L^2(\Omega)}. \tag{2.25}$$

We are therefore left with estimating the L^2 norm of the four terms that add up to $L_\varepsilon r_M$. By the assumptions on f, cf. (2.6), we have

$$\|\varepsilon^{2M+2}\Delta^{(M+1)} f\|_{L^\infty(\Omega)} \le C_f \left(\varepsilon\gamma(2M+2)\right)^{2M+2}. \tag{2.26}$$

Let us fix $\alpha \in (0,1)$ for the remainder of this proof. As $\chi \equiv 1$ for $0 < \rho < \rho_1$ and $\chi \equiv 0$ for $\rho > (\rho_1+\rho_0)/2$, we obtain with the aid of Theorem 2.2 (ii)

$$\begin{aligned} \varepsilon^2\|(\Delta\chi)u_M^{BL}\|_{L^2(\Omega)} &\le C\varepsilon^2 S_M e^{-\alpha\rho_1/\varepsilon}, \\ \varepsilon^2\|\nabla\chi\cdot\nabla u_M^{BL}\|_{L^2(\Omega)} &\le C\varepsilon S_M e^{-\alpha\rho_1/\varepsilon}, \end{aligned}$$

where $S_M = 1 + (\varepsilon(2M+1)K)^{2M+1}$ for some appropriate C, $K > 0$. We calculate further

$$\begin{aligned} S_M &= 1 + (\varepsilon(2M+1)K)^{2M+1} \le (1+\varepsilon(2M+2)K)^{2M+2} \\ &\le \varepsilon^{2M+2}K^{2M+2}(2M+2+K^{-1}/\varepsilon)^{2M+2}. \end{aligned}$$

Without loss of generality, $K^{-1} \le \rho_1$ and therefore we obtain by appealing to Lemma 2.8

$$\varepsilon S_M e^{-\alpha\rho_1/\varepsilon} \le \varepsilon\varepsilon^{2M+2}K^{2M+2}(2M+2+\rho_1/\varepsilon)^{2M+2}e^{-\alpha\rho_1/\varepsilon} \le \varepsilon(\varepsilon(2M+2)K\alpha^{-1})^{2M+2}.$$

Finally, exploiting the exponential decay normal to $\partial\Omega$, it is easy to deduce from Lemma 2.13 that

$$\|\chi L_\varepsilon u_M^{BL}\|_{L^2(\Omega)} \le C\varepsilon^{1/2}\left(K'\varepsilon(2M+2)\right)^{2M+2}$$

for some $K' > 0$ independent of ε and M. Inserting all these estimates into (2.25), we obtain for some $C > 0$ that

$$\begin{aligned} \|r_M\|_{\varepsilon,\Omega} \le C\Big(&(\varepsilon(2M+2)\gamma)^{2M+2} \\ &+ \varepsilon(\varepsilon(2M+2)K\alpha^{-1})^{2M+2} + \varepsilon^{1/2}(\varepsilon(2M+2)K')^{2M+2}\Big). \end{aligned}$$

As $\alpha \in (0,1)$ is fixed, the desired bound follows. ∎

3. Growth estimates for the derivatives. The main result of this section is the following bound on the growth of the derivatives of the solutions u_ε of (1.1).

THEOREM 3.1. *Let f, g, $\partial\Omega$ be analytic and let u_ε be the solution of* (1.1). *Then there are C and $K > 0$ depending only on f, g, and the geometry of Ω (in particular, C, K are independent of ε) such that*

$$\|D^\alpha u_\varepsilon\|_{L^2(\Omega)} \le CK^{|\alpha|}\max\left(|\alpha|,\varepsilon^{-1}\right)^{|\alpha|}\left(1+\|u_\varepsilon\|_{\varepsilon,\Omega}\right) \qquad \forall\alpha \in \mathbb{N}_0^2. \tag{3.1}$$

Remark 3.2. The proof of Theorem 3.1 below shows that (3.1) holds true for solutions u_ε of (1.1) with $\varepsilon \in \mathbb{C}$ (ε^{-1} has to be replaced with $|\varepsilon^{-1}|$ in (3.1)) and hence the case of Helmholtz's equation is also covered. Furthermore, (3.1) still holds true if the right-hand side f is allowed to have "boundary layer character" in the sense that there exist C, $K > 0$ such that

$$\|D^\alpha f\|_{L^2(\Omega)} \le CK^{|\alpha|} \max(|\alpha|, |\varepsilon^{-1}|)^{|\alpha|} \qquad \forall \alpha \in \mathbb{N}_0^2.$$

The remainder of this paper is devoted to the proof of Theorem 3.1. To that end, we will state and prove some local analytic regularity results for the solution u_ε in sections 3.1 and 3.2. The proof of Theorem 3.1 in section 3.3 then concludes the paper.

3.1. Local analytic regularity results. The proof of Theorem 3.1 rests on two local analytic regularity results: an interior result on discs (Proposition 3.3) and a boundary result on half-discs (Proposition 3.4). Due to their technical nature, the proofs of these results of this section are deferred to section 3.2.

Our local results are very similar to those of section 5.7 of [8] and we therefore use the same notation: For $r > 0$ we define discs B_r and half-discs G_r by

$$B_r := B_r(0) \subset \mathbb{R}^2, \qquad G_r := \{(x, y) \in B_r \,|\, y > 0\}.$$

Furthermore, for smooth functions u and $R > 0$ we introduce

$$|\nabla^p u(x)|^2 := \sum_{|\alpha|=p} \frac{|\alpha|!}{\alpha!} |D^\alpha u(x)|^2 = \sum_{\beta_1,\dots,\beta_p=1}^{2} |D^{\beta_1 \cdots \beta_p} u(x)|^2 \qquad \forall p \in \mathbb{N}_0, \tag{3.2}$$

$$[p] := \max(1, p) \qquad \forall p \in \mathbb{Z}, \tag{3.3}$$

$$N_{R,p}(u) := \frac{1}{[p]!} \sup_{R/2 \le r < R} (R - r)^{2+p} \|\nabla^{p+2} u\|_{L^2(B_r)}, \quad p \in \mathbb{N}_0 \cup \{-2, -1\}, \tag{3.4}$$

$$N'_{R,p,q}(u) := \frac{1}{[p+q]!} \sup_{R/2 \le r < R} (R - r)^{p+q+2} \|\partial_y^{q+2} \partial_x^p u\|_{L^2(G_r)}, \; p \ge 0, q \ge -2. \tag{3.5}$$

Then we have the following local results.

PROPOSITION 3.3. *Let $R \in (0, 1]$ and let u be a solution of*

$$-\varepsilon^2 \Delta u + bu = f \qquad \text{on } B_R, \tag{3.6}$$

where b and f are analytic on B_R and satisfy for some C_B, B, C_f, $\gamma > 0$

$$\|\nabla^p b\|_{L^\infty(B_R)} \le C_B B^p p! \qquad \forall p \in \mathbb{N}_0, \tag{3.7}$$

$$\|\nabla^p f\|_{L^2(B_R)} \le C_f \gamma^p [p^p R^{-p} + \max(p, \varepsilon^{-1})^p] \qquad \forall p \in \mathbb{N}_0. \tag{3.8}$$

Then there is $K > 0$ independent of ε and R such that for all $p \ge -2$

$$N_{R,p}(u) \le C_u K^{p+2} \frac{\max([p], R/\varepsilon)^{p+2}}{[p]!}, \tag{3.9}$$

$$C_u = \min(1, R/\varepsilon)\varepsilon \|\nabla u\|_{L^2(B_R)} + \|u\|_{L^2(B_R)} + C_f \min(1, (R/\varepsilon)^2). \tag{3.10}$$

PROPOSITION 3.4. *Let $R \in (0, 1]$ and let u be a solution of*

$$-\varepsilon^2 \Delta u + bu = f \quad \text{on } G_R, \qquad u = 0 \text{ on } \partial G_R \cap \{(x, y) \,|\, y = 0\}, \tag{3.11}$$

where b and f are analytic on B_R and satisfy for some C_B, B, C_f, $\gamma > 0$

$$\|\nabla^p b\|_{L^\infty(G_R)} \le C_B B^p p! \qquad \forall p \in \mathbb{N}_0, \tag{3.12}$$

$$\|\nabla^p f\|_{L^2(G_R)} \le C_f \gamma^p [p^p R^{-p} + \max(p, \varepsilon^{-1})^p] \qquad \forall p \in \mathbb{N}_0. \tag{3.13}$$

Then there are K_1, $K_2 > 0$ independent of ε and R such that $\forall p \ge 0$, $q \ge -2$

$$N'_{R,p,q}(u) \le C_u K_1^{p+2} K_2^{q+2} \frac{\max([p+q], R/\varepsilon)^{p+q+2}}{[p+q]!}, \tag{3.14}$$

$$C_u = \min(1, R/\varepsilon)\varepsilon \|\nabla u\|_{L^2(G_R)} + \|u\|_{L^2(G_R)} + C_f \min(1, (R/\varepsilon)^2). \tag{3.15}$$

Remark 3.5. The local results in Propositions 3.3 and 3.4 make much weaker assumptions on the right-hand side f than Theorem 3.1. The term $\max(p, \varepsilon^{-1})^p$ appearing in (3.8) and (3.13) indicates that right-hand sides with boundary layer character are admissible as right-hand sides. Furthermore, in Propositions 3.3 and 3.4 the dependence on the radius of the discs R is given explicitly; this explicit dependence could be used to obtain results similar to Theorem 3.1 for domains Ω with piecewise analytic boundary $\partial\Omega$.

Finally, we need the following.

LEMMA 3.6. *Let G, $G_1 \subset \mathbb{R}^2$ be bounded open sets. Assume that $g = (g_1, g_2) : \overline{G}_1 \to \mathbb{R}^2$ is analytic and injective on $\overline{G}_1$, $\det g' \ne 0$ on $\overline{G}_1$, and satisfies $g(G_1) \subset G$. Let $f : \overline{G} \to \mathbb{C}$ be analytic on $\overline{G}$ and assume that it satisfies for some ε, C_f, $\gamma > 0$*

$$\|\nabla^p f\|_{L^2(G)} \le C_f \gamma^p \max(p, \varepsilon^{-1})^p \qquad \forall p \in \mathbb{N}_0.$$

Then there are C, $K > 0$ depending only on C_f, γ, and the map g such that

$$\|\nabla^p (f \circ g)\|_{L^2(G_1)} \le C K^p \max(p, \varepsilon^{-1})^p \qquad \forall p \in \mathbb{N}_0.$$

3.2. Proof of local regularity results.

3.2.1. Interior estimates (proof of Proposition 3.3). In order to prove Proposition 3.3, it is convenient to introduce for smooth functions u the quantity

$$M_{R,p}(u) := \frac{1}{p!} \sup_{R/2 \le r < R} (R - r)^{2+p} \|\nabla^p u\|_{L^2(B_r)}, \qquad p \in \mathbb{N}_0.$$

From standard elliptic regularity theory one can infer the following.

LEMMA 3.7. *Let u solve $\Delta u = f$ on B_R. Then there is $C_1 > 0$ independent of u, R, f such that*

$$N_{R,p}(u) \le C_1 [M_{R,p}(f) + N_{R,p-1}(u) + N_{R,p-2}(u)] \qquad \forall p \in \mathbb{N}_0.$$

Proof. The proof can be found in [8, Lem. 5.7.3]. ∎

LEMMA 3.8. *Let b, u be analytic and assume that b satisfies* (3.7). *Then*

$$M_{r,p}(bu) \le C_b \sum_{q=0}^{p} \left(B\frac{R}{2}\right)^{p-q} \left(\frac{R}{2}\right)^2 \frac{[q-2]!}{q!} N_{R,q-2}(u).$$

Proof. From Leibniz's formula, we have (cf. Lemma 5.7.4 of [8])

$$|\nabla^p(bu)| \le \sum_{q=0}^{p} \binom{p}{q} |\nabla^{p-q} b|\, |\nabla^q u|.$$

This allows us to get

$$\begin{aligned} M_{R,p}(bu) &\le \frac{1}{p!} \sup_{R/2\le r<R} (R-r)^{p+2} \|\nabla^p(bu)\|_{L^2(B_r)} \\ &\le \frac{1}{p!} \sup_{R/2\le r<R} (R-r)^{p+2} \sum_{q=0}^{p} \binom{p}{q} \|\nabla^{p-q} b\|_{L^\infty(B_R)} \|\nabla^q u\|_{L^2(B_r)} \\ &\le C_b \sum_{q=0}^{p} \left(\frac{BR}{2}\right)^{p-q} \left(\frac{R}{2}\right)^2 \frac{[q-2]!}{q!} N_{R,q-2}(u), \end{aligned}$$

which concludes the proof. ∎

Proof of Proposition 3.3. Let C_1 be the generic constant of Lemma 3.7 and choose $2K > \max(2, \gamma, BR)$ such that

$$C_1 \frac{1}{2} K^{-2} \left(\frac{\gamma R}{2K}\right)^p + C_1 \left(\frac{C_b/4}{1 - BR/(2K)} K^{-2} + K^{-1} + K^{-2} \right) \le 1 \qquad \forall p \in \mathbb{N}_0. \tag{3.16}$$

We will proceed by induction on p. As $K \ge 1$, the claim (3.9) holds for $p = -2$ and $p = -1$. Let us therefore assume that (3.9) holds $\forall\ -2 \le p' < p$. As $-\Delta u = \varepsilon^{-2}(f - bu)$, we get for $p \in \mathbb{N}_0$ using Lemmas 3.7 and 3.8

$$\begin{aligned} N_{R,p}(u) &\le C_1 \left\{ \varepsilon^{-2} M_{R,p}(f - bu) + N_{R,p-1}(u) + N_{R,p-2}(u) \right\} \\ &\le C_1 \Big\{ \varepsilon^{-2} M_{R,p}(f) + \varepsilon^{-2} C_b \sum_{q=0}^{p} \left(\frac{BR}{2}\right)^{p-q} \left(\frac{R}{2}\right)^2 \frac{[q-2]!}{q!} N_{R,q-2}(u) \\ &\qquad + N_{R,p-1}(u) + N_{R,p-2}(u) \Big\}. \end{aligned}$$

From the induction hypothesis (3.9) we obtain

$$\begin{aligned} N_{R,p}(u) \le C_1 \varepsilon^{-2} M_{R,p}(f) + C_1 C_u \Big\{ C_b \sum_{q=0}^{p} \left(\frac{BR}{2}\right)^{p-q} \left(\frac{R}{2}\right)^2 \varepsilon^{-2} K^q \frac{\max([q-2], R/\varepsilon)^q}{q!} \\ + K^{p+1} \frac{\max([p-1], R/\varepsilon)^{p+1}}{[p-1]!} + K^p \frac{\max([p-2], R/\varepsilon)^p}{[p-2]!} \Big\}. \end{aligned}$$

As we have the estimates

$$\begin{aligned} R^2 \varepsilon^{-2} \frac{1}{p!} \frac{p!}{q!} \max([q-2], R/\varepsilon)^q &\le \frac{1}{p!} \max([p], R/\varepsilon)^{p+2}, \\ \frac{1}{p!} \frac{p!}{[p-1]!} \max([p-1], R/\varepsilon)^{p+1} &\le \frac{1}{p!} \max([p], R/\varepsilon)^{p+2}, \\ \frac{1}{p!} \frac{p!}{[p-2]!} \max([p-2], R/\varepsilon)^{p} &\le \frac{1}{p!} \max([p], R/\varepsilon)^{p+2}, \end{aligned}$$

we obtain

$$\begin{aligned} N_{R,p}(u) &\le C_1\varepsilon^{-2}M_{R,p}(f) + \frac{\max([p],R/\varepsilon)^{p+2}}{p!}K^{p+2}C_u \\ &\quad\times C_1\Big\{\frac{C_b}{4}\sum_{q=0}^{p}\left(\frac{BR}{2}\right)^{p-q}K^{q-p-2} + K^{-1} + K^{-2}\Big\} \\ &\le C_1\varepsilon^{-2}M_{R,p}(f) + \frac{\max([p],R/\varepsilon)^{p+2}}{p!}K^{p+2}C_u \\ &\quad\times C_1\Big\{\frac{C_b}{4}\frac{1}{1-BR/(2K)}K^{-2} + K^{-1} + K^{-2}\Big\}. \end{aligned}$$

Finally, we have the bound

$$\begin{aligned} M_{R,p}(f) &\le \frac{1}{p!}C_f\gamma^p\left(\frac{R}{2}\right)^{2+p}\left[p^pR^{-p} + \max(p,\varepsilon^{-1})^p\right] \\ &\le \left(\frac{\gamma}{2}\right)^p\frac{1}{p!}R^2C_f\frac{1}{4}\left[p^p + \max(Rp,R/\varepsilon)^p\right]. \end{aligned}$$

As $R \le 1$, we get $p^p + \max(Rp,R/\varepsilon)^p \le 2\max(p,R/\varepsilon)^p$ and, together with $(R/\varepsilon)^2 \le \min(1,(R/\varepsilon)^2)\max([p],(R/\varepsilon)^2)$, we can conclude

$$C_1\varepsilon^{-2}M_{R,p}(f) \le C_1\frac{1}{2}\left(\frac{\gamma}{2}\right)^p C_f\min(1,(R/\varepsilon)^2)\,\frac{\max([p],R/\varepsilon)^{p+2}}{p!}, \tag{3.17}$$

$$\begin{aligned} N_{R,p}(u) &\le K^{p+2}\frac{\max([p],R/\varepsilon)^{p+2}}{p!}C_u \\ &\quad\times\left[C_1\frac{1}{2}\left(\frac{\gamma}{2K}\right)^pK^{-2} + C_1\Big\{\frac{C_b/4}{1-BR/(2K)}K^{-2} + K^{-1} + K^{-2}\Big\}\right]. \end{aligned}$$

The fact that the bracketed expression is bounded by one by the choice of K in (3.16) concludes the induction argument. ∎

3.2.2. Estimates at the boundary (proof of Proposition 3.4). The strategy for proving Proposition 3.4 is first to get control over the tangential derivatives of the solution u of (3.11), i.e., the x-derivatives of u. This will be accomplished in Lemma 3.10. In the second step, the remaining normal derivatives, i.e., the y-derivatives, will be controlled.

In order to carry out this two-step approach, we introduce the following notation for smooth functions u:

$$\begin{aligned} M'_{R,p}(u) &= \frac{1}{p!}\sup_{R/2\le r<R}(R-r)^{p+2}\|\partial_x^p u\|_{L^2(G_r)}, \\ N'_{R,p}(u) &= \begin{cases} \dfrac{1}{p!}\displaystyle\sup_{R/2\le r<R}(R-r)^{p+2}\|\nabla^2\partial_x^p u\|_{L^2(G_r)} & \text{if } p\ge 0, \\ \displaystyle\sup_{R/2\le r<R}(R-r)^{p+2}\|\nabla^{2+p}u\|_{L^2(G_r)} & \text{if } p=-2,-1, \end{cases} \\ \tilde{M}_{R,p}(u) &= \frac{1}{p!}\sup_{R/2\le r<R}(R-r)^{p+2}\|\nabla^p u\|_{L^2(G_r)}. \end{aligned}$$

Note that we have $N'_{R,p,0} \le N'_{R,p}$. Lemma 3.9 is the analogue of Lemma 3.7.

LEMMA 3.9. *Let $u \in H^1(G_R)$ solve $\Delta u = f$ on G_R and assume that $u = 0$ on $\partial G_R \cap \{(x,y)\,|\,y=0\}$. Then there is a generic constant $C_2 > 0$ such that*

$$N'_{R,p}(u) \le C_2 \left\{ M'_{R,p}(f) + N'_{R,p-1}(u) + N'_{R,p-2}(u) \right\}.$$

Proof. The proof can be found in [8, Lem. 5.7.3′]. ∎

We start with a bound on the tangential derivatives.

LEMMA 3.10. *Assume the hypotheses of Proposition* 3.4. *Then there is $K_1 > 0$ independent of ε and R such that with C_u of* (3.15)

$$N'_{R,p}(u) \le C_u K_1^{p+2} \frac{\max([p], R/\varepsilon)^{p+2}}{[p]!}, \qquad p \ge -2.$$

Proof. The proof is almost verbatim the same as the proof of Proposition 3.3. Instead of using Lemma 3.7 we make use of Lemma 3.9. In particular, the constant K_1 will be chosen such that $K_1 > \max(1, \gamma/2, BR/2)$. ∎

Proof of Proposition 3.4. Let K_1 be the constant of Lemma 3.10 and choose $K_2 > \max(1, BR/2, \gamma/2)$ such that $\forall\ p \ge 0,\ q \ge 0$

$$\begin{aligned} &\Big[\frac{1}{2}\left(\frac{\gamma}{2K_1}\right)^p \left(\frac{\gamma}{2K_2}\right)^q K_1^{-2} K_2^{-2} \\ &\quad + K_1^2 K_2^{-2} + \frac{C_b/4}{(1 - BR/(2K_1))(1 - BR/(2K_2))} K_2^{-2}\Big] \le 1. \end{aligned} \tag{3.18}$$

We will proceed by induction on q. By Lemma 3.10 and our earlier observation that $N'_{R,p,0} \le N'_{R,p}$, the claim (3.14) is true for $q = 0$ and all $p \ge 0$, and it is easy to see that the claim is also true for $q = -2$, $q = -1$: We have for $q = -2$ and $q = -1$ and $p \ge 0$ by a straightforward calculation that

$$\begin{aligned} N'_{R,p,-2}(u) &= \frac{1}{[p-2]!} \sup_{R/2 \le r < R} (R-r)^p \|\partial_x^p u\|_{L^2(G_r)} \le N'_{R,p-2}(u), \\ N'_{R,p,-1}(u) &= \frac{1}{[p-1]!} \sup_{R/2 \le r < R} (R-r)^{p+1} \|\partial_y\, \partial_x^p u\|_{L^2(G_r)} \le N'_{R,p-1}(u). \end{aligned}$$

Let us now proceed with the induction argument on q and assume that the induction hypothesis is proven for $-2 \le q' < q$. We have

$$\begin{aligned} -\partial_y^2 u &= \partial_x^2 u + \varepsilon^{-2}(f - bu), \\ |\partial_x^p\, \partial_y^{q+2} u| &\le |\partial_x^{p+2}\, \partial_y^q u| + \varepsilon^{-2} |\partial_x^p\, \partial_y^q f| + \varepsilon^{-2} |\partial_x^p\, \partial_y^q (bu)|. \end{aligned}$$

Leibniz's formula and the assumptions on b yield

$$\begin{aligned} |\partial_x^p\, \partial_y^q (bu)| &\le \sum_{m=0}^{q} \sum_{n=0}^{p} \binom{p}{n} \binom{q}{m} |\partial_x^{p-n}\, \partial_y^{q-m} b|\, |\partial_x^n\, \partial_y^m u| \\ &\le C_b \sum_{m=0}^{q} \sum_{n=0}^{p} \binom{p}{n} \binom{q}{m} B^{p+q-m-n} (p-n)!(q-m)! |\partial_x^n\, \partial_y^m u| \\ &\le C_b \sum_{m=0}^{q} \sum_{n=0}^{p} B^{p+q-n-m} (p+q)^{p+q-n-m} |\partial_x^n\, \partial_y^m u|, \end{aligned}$$

where, in the last step, we used the bound

$$\binom{p}{n}\binom{q}{m}(p-n)!(q-m)! = \frac{p!}{n!}\frac{q!}{m!} \le p^{p-n}q^{q-m} \le (p+q)^{p+q-n-m}.$$

Hence, we obtain for $N'_{R,p,q}(u)$

$$\begin{aligned}
&N'_{R,p,q}(u) = \frac{1}{[p+q]!}\sup_{R/2\le r<R}(R-r)^{p+q+2}\|\partial_x^p\,\partial_y^{q+2}\,u\|_{L^2(G_r)}\\
&\le N'_{R,p+2,q-2}(u) + \varepsilon^{-2}\tilde{M}_{R,p+q}(f)\\
&+ C_b\varepsilon^{-2}\sum_{m=0}^{q}\sum_{n=0}^{p}\left(\frac{BR}{2}\right)^{p+q-m-n}\left(\frac{R}{2}\right)^2\frac{(p+q)^{p+q-n-m}![m-2+n]!}{[p+q]!}N'_{R,n,m-2}(u).
\end{aligned}$$

By the induction hypothesis we have with C_u of (3.15)

$$\begin{aligned}
[m-2+n]!N_{R,n,m-2}(u) &\le C_u K_1^{n+2}K_2^m\max\left([m-2+n],R/\varepsilon\right)^{m+n}\\
&\le C_u K_1^{n+2}K_2^m\max\left([p+q],R/\varepsilon\right)^{m+n}
\end{aligned}$$

and with the bound $(R/\varepsilon)^2 \le \max\left([p+q],R/\varepsilon\right)^2$ we obtain

$$\begin{aligned}
N'_{R,p,q}(u) &\le K_1^{p+4}K_2^q\frac{\max\left([p+q],R/\varepsilon\right)^{p+q+2}}{[p+q]!}C_u + \varepsilon^{-2}\tilde{M}_{R,p+q}(f)\\
&\quad+\frac{C_b}{4}C_u\sum_{m=0}^{q}\sum_{n=0}^{p}\left(\frac{BR}{2}\right)^{p+q-m-n}K_1^{n+2}K_2^m\frac{\max\left([p+q],R/\varepsilon\right)^{p+q+2}}{(p+q)!}\\
&\le K_1^{p+4}K_2^q\frac{\max\left([p+q],R/\varepsilon\right)^{p+q+2}}{[p+q]!}C_u + \varepsilon^{-2}\tilde{M}_{R,p+q}(f)\\
&\quad+C_uK_1^{p+2}K_2^q\frac{\max\left([p+q],R/\varepsilon\right)^{p+q+2}}{[p+q]!}\frac{C_b}{4}\sum_{m=0}^{q}\sum_{n=0}^{p}\left(\frac{BR}{2}\right)^{p+q-m-n}K_1^{n-p}K_2^{m-q}\\
&\le \varepsilon^{-2}\tilde{M}_{R,p+q}(f) + K_1^{p+2}K_1^{q+2}\frac{\max\left([p+q],R/\varepsilon\right)^{p+q+2}}{[p+q]!}C_u\\
&\quad\times\Big[K_1^2K_2^{-2}+\frac{C_b}{4}\frac{1}{(1-BR/(2K_1))(1-BR/(2K_2))}K_2^{-2}\Big].
\end{aligned}$$

Reasoning as in (3.17) we get

$$\varepsilon^{-2}\tilde{M}_{R,p+q}(f) \le \frac{1}{2}\left(\frac{\gamma}{2}\right)^{p+q}C_f\min\left(1,(R/\varepsilon)^2\right)\frac{\max\left([p+q],R/\varepsilon\right)^{p+q+2}}{[p+q]!}$$

and may therefore conclude that

$$\begin{aligned}
&N'_{R,p,q}(u) \le K_1^{p+2}K_2^{q+2}\frac{\max\left([p+q],R/\varepsilon\right)^{p+q+2}}{[p+q]!}C_u\\
&\times\left[\frac{1}{2}\left(\frac{\gamma}{2K_1}\right)^p\left(\frac{\gamma}{2K_2}\right)^q K_1^{-2}K_2^{-2}+K_1^2K_2^{-2}+\frac{C_b/4\,K_2^{-2}}{(1-BR/(2K_1))(1-BR/(2K_2))}\right].
\end{aligned}$$

As the bracketed expression is bounded by one by the choice of K_2 in (3.18), the induction argument is completed. ∎

3.2.3. Proof of Lemma 3.6. The growth conditions on the derivatives of f imply that f can be extended to a holomorphic function (also denoted f) on $\tilde{G} \subset \mathbb{C} \times \mathbb{C}$ with $\overline{G} \subset \tilde{G}$ and $\tilde{G}$ independent of $\varepsilon > 0$. First, we claim that there are δ_0, γ', $C > 0$ depending only on γ and C_f such that

$$\|f(\cdot + z_1(\cdot), \cdot + z_2(\cdot))\|_{L^2(G)} \leq C e^{\gamma' \delta/\varepsilon} \tag{3.19}$$

for all continuous functions $z_1,\ z_2 : G \to \mathbb{C}$ with $\|z_i\|_{L^\infty(G)} \leq \delta \leq \delta_0,\ i = 1, 2$. As f is holomorphic on $\tilde{G}$, there is $\delta_0 > 0$ such that $\forall\ (x, y) \in \overline{G}$ the power series expansion of f about (x, y) converges on a ball of radius $2\delta_0$. For functions $z_1,\ z_2$ with $\|z_i\|_{L^\infty(G)} \leq \delta \leq \delta_0$ we obtain

$$|f(x + z_1(x, y), y + z_2(x, y))| = \left| \sum_{\alpha \in \mathbb{N}_0^2} \frac{1}{\alpha!} D^\alpha f(x, y)(z_1, z_2)^\alpha \right| \leq \sum_{\alpha \in \mathbb{N}_0^2} \frac{1}{\alpha!} \left| D^\alpha f(x, y) \right| \delta^{|\alpha|}.$$

Therefore we get

$$\begin{aligned}
&\|f(\cdot + z_1(\cdot), \cdot + z_2(\cdot))\|_{L^2(G)} \leq \sum_{\alpha \in \mathbb{N}_0^2} \frac{1}{\alpha!} \|D^\alpha f\|_{L^2(G)} \delta^{|\alpha|} \\
&\leq \sum_{p=0}^{\infty} \sum_{|\alpha|=p} \left((p!)^{1/2} (\alpha!)^{-1/2} \|D^\alpha f\|_{L^2(G)} \right) \left((\alpha!)^{-1/2} p!^{-1/2} \delta^p \right) \\
&\leq \sum_{p=0}^{\infty} \|\nabla^p f\|_{L^2(G)} \left(\sum_{|\alpha|=p} \frac{1}{\alpha! p!} \delta^{2p} \right)^{1/2} = \sum_{p=0}^{\infty} \|\nabla^p f\|_{L^2(G)} \frac{1}{p!} 2^{p/2} \delta^p \\
&\leq C_f \sum_{0 \leq p \leq \varepsilon^{-1}} \frac{1}{p!} \left(\sqrt{2} \gamma \varepsilon^{-1} \delta \right)^p + C_f \sum_{p > \varepsilon^{-1}} \frac{p^p}{p!} \gamma^p 2^{p/2} \delta^p \\
&\leq C_f e^{\sqrt{2}\gamma\delta/\varepsilon} + C \sum_{p > \varepsilon^{-1}} \left(e \sqrt{2} \gamma \delta \right)^p \leq C_f e^{\sqrt{2}\gamma\delta/\varepsilon} + \frac{1}{1 - \sqrt{2}\gamma\delta_0} \leq C e^{\sqrt{2}\gamma\delta/\varepsilon},
\end{aligned}$$

where we used Stirling's formula in the form $p! \geq C p^p e^{-p}$ and made the tacit assumption that δ_0 is so small that $e\sqrt{2}\gamma\delta_0 < 1$ so that the second sum is finite. This proves (3.19).

As g is analytic on $\overline{G}_1$ there is a holomorphic extension (also denoted g) to $\tilde{G}_1 \subset \mathbb{C} \times \mathbb{C}$. Thus, there are $\eta,\ \delta_0' > 0$ such that $\forall (x, y) \in \overline{G}_1$

$$|g_i(x + z_1, y + z_2) - g_i(x, y)| \leq \eta\delta, \qquad i = 1, 2, \quad z_1, z_2 \in \mathbb{C} \text{ with } |z_1|, |z_2| \leq \delta \leq \delta_0'. \tag{3.20}$$

For any $0 < \delta \leq \min(\delta_0', \delta_0/\eta)$ we obtain by Cauchy's integral theorem for derivatives for every $(x, y) \in G_1$ and every $\alpha = (\alpha_1, \alpha_2) \in \mathbb{N}_0^2$

$$\begin{aligned}
D^\alpha (f \circ g)(x, y) &= -\frac{\alpha!}{4\pi^2} \int_{|z_1|=\delta} \int_{|z_2|=\delta} \frac{(f \circ g)(x + z_1, y + z_2)}{z_1^{\alpha_1+1} z_2^{\alpha_2+1}} \, dz_1 dz_2, \\
|D^\alpha (f \circ g)(x, y)|^2 &\leq \frac{\alpha!^2}{4\pi^2 \delta^{2|\alpha|+2}} \int_{|z_1|=\delta} \int_{|z_2|=\delta} |(f \circ g)(x + z_1, y + z_2)|^2 \, |dz_1| \, |dz_2|.
\end{aligned}$$

By (3.20), we can write

$$g_1(x+z_1,y+z_2)=g_1(x,y)+\zeta_1,\qquad g_2(x+z_1,y+z_2)=g_2(x,y)+\zeta_2,$$

where ζ_1, ζ_2 are smooth functions of x, y, z_1, z_2, and $|\zeta_i|\le\eta\delta$, $i=1,2$. Integrating over G_1, we obtain after the smooth change of variables $g(x,y)=(x',y')$ (note that $0<c_1\le|\det g'|\le c_2<\infty$) and denoting ζ_1', ζ_2' the functions corresponding to ζ_1, ζ_2 after the change of variables

$$\begin{aligned}&|D^\alpha(f\circ g)(x,y)|^2_{L^2(G_1)}\\&\le c_2\frac{(\alpha!)^2}{4\pi^2\delta^{2|\alpha|+2}}\int_{|z_1|=\delta}\int_{|z_2|=\delta}\int_G|f(x'+\zeta_1',y'+\zeta_2')|^2\,dx'dy'|dz_1|\,|dz_2|.\end{aligned}$$

As $|\zeta_1'|$, $|\zeta_2'|\le\eta\delta$ uniformly in $(x',y')\in G$, $|z_1|$, $|z_2|\le\delta$, estimate (3.19) yields

$$\|D^\alpha(f\circ g)\|_{L^2(G_1)}\le C\frac{\alpha!}{\delta^{|\alpha|}}e^{\gamma'\eta\delta/\varepsilon}\qquad\forall 0<\delta\le\min(\delta_0',\delta_0/\eta).$$

In order to extract from this estimate the claim of the lemma, we distinguish the cases $|\alpha|\varepsilon$ large and $|\alpha|\varepsilon$ small. If $|\alpha|\varepsilon/(\eta\gamma')<\min(\delta_0',\delta_0/\eta)$, choose $\delta:=|\alpha|\varepsilon/(\eta\gamma')$ to get with Stirling's formula

$$\|D^\alpha(f\circ g)\|_{L^2(G_1)}\le C(\eta\gamma')^{|\alpha|}\sqrt{1+|\alpha|}\,\varepsilon^{-|\alpha|}.$$

If $|\alpha|\varepsilon/(\eta\gamma')\ge\min(\delta_0',\delta_0/\eta)$, choose $\delta:=\min(\delta_0',\delta_0/\eta)$ and observe that this implies $\delta\eta\gamma'\varepsilon^{-1}\le|\alpha|$ to arrive at

$$\|D^\alpha(f\circ g)\|_{L^2(G_1)}\le C\alpha!\;\delta^{-|\alpha|}e^{|\alpha|},$$

which completes the proof of Lemma 3.6. ∎

3.3. Proof of Theorem 3.1. Let $B_R(x_0)\subset\Omega$ be a ball of radius $R\le1$. Proposition 3.3 yields the existence of C, $K>0$ independent of ε, p such that for all $p\in\mathbb{N}_0$

$$\|\nabla^p u_\varepsilon\|_{L^2(B_{R/2}(x_0))}\le CK^p\max(p,\varepsilon^{-1})^p\left(1+\|u_\varepsilon\|_{L^2(B_R(x_0))}+\varepsilon\|\nabla u_\varepsilon\|_{L^2(B_R(x_0))}\right).$$

Let us now consider estimates at the boundary. First, we see that we may consider the case of homogeneous Dirichlet data: As the boundary data g is analytic, it can be extended analytically into Ω, e.g., by taking as the extension function the function G defined by

$$-\Delta G=0\quad\text{ on }\Omega,\qquad G=g\quad\text{ on }\partial\Omega.$$

As $\partial\Omega$ and g are assumed to be analytic, standard elliptic theory [8, 9] gives that G is analytic on a neighborhood of $\overline{\Omega}$. Note that G is independent of ε. The auxiliary function $\tilde u=u-G$ solves

$$\begin{aligned}-\varepsilon^2\Delta\tilde u+\tilde u=\tilde f:=f+\varepsilon^2\Delta G-G=f-G\qquad&\text{on }\Omega,\\\tilde u=0\qquad&\text{on }\partial\Omega\end{aligned}$$

and by the triangle inequality

$$\|\nabla^p u\|_{L^2(B\cap\Omega)}\le\|\nabla^p\tilde u\|_{L^2(B\cap\Omega)}+\|\nabla^p G\|_{L^2(B\cap\Omega)}\qquad\forall p\in\mathbb{N}_0$$

for balls B. It suffices therefore to get the desired bounds for $\tilde{u}$.

In order to apply Proposition 3.4, we introduce a mapping to flatten the boundary locally: For $R > 0$ and a point $x_0 \in \partial\Omega$, we introduce the conformal map ζ which maps $Q := \Omega \cap B_{2R}(x_0)$ conformally onto G_{2R}. The transformed functions $\hat{u} = \tilde{u} \circ \zeta^{-1}$, $\hat{f} = \tilde{f} \circ \zeta^{-1}$ then solve

$$\begin{aligned} -\varepsilon^2 \Delta \hat{u} + |(\zeta^{-1})'|^2 \hat{u} &= \hat{f} |(\zeta^{-1})'|^2 \qquad \text{on } G_{2R}, \\ \hat{u} &= 0 \qquad \text{on } \partial G_{2R} \cap \{(x,y) \,|\, y = 0\}. \end{aligned}$$

Furthermore, by the analyticity of $\partial\Omega$, the function $|(\zeta^{-1})'|^2$ is (real) analytic on G_{2R} and hence Proposition 3.4 is applicable (note that $\tilde{f}$ and hence $\hat{f}|(\zeta^{-1})'|^2$ are independent of ε), and we get the desired estimate for $\hat{u}$, i.e.,

$$\|\nabla^p \hat{u}\|_{L^2(G_{R/2})} \le C K^p \max(p, \varepsilon^{-1})^p \left(1 + \|\hat{u}\|_{L^2(G_R)} + \varepsilon \|\nabla \hat{u}\|_{L^2(G_R)}\right) \qquad \forall p \in \mathbb{N}_0.$$

Applying Lemma 3.6 allows us to infer a similar estimate for $\tilde{u}$:

$$\|\nabla^p \tilde{u}\|_{L^2(B \cap \Omega)} \le C K'^p \max(p, \varepsilon^{-1})^p \left(1 + \|u_\varepsilon\|_{L^2(Q)} + \varepsilon \|\nabla u_\varepsilon\|_{L^2(Q)}\right) \qquad \forall p \in \mathbb{N}_0,$$

where B is a ball or radius $R' > 0$ with center x_0 such that $B_{R'} \cap \Omega \subset \zeta^{-1}(G_{R/2})$. The constants C, $K' > 0$ depend again on R, f, g, and the point x_0 but are independent of ε.

A compactness argument allows us to conclude the proof of the theorem. ∎

ON STABILITY OF CONSERVATION LAWS*

GUNILLA KREISS†, HEINZ-OTTO KREISS‡, AND JENS LORENZ§

Abstract. We consider the Cauchy problem for systems of PDEs of the general form

$$u_t = P_0 u + \varepsilon_1 P_1 u + \varepsilon_2 Q(u) + \sum_j D_j F_j(x,t), \quad u = u(x,t).$$

Here P_0 has constant coefficients. The terms $\varepsilon_1 P_1 u$ and $\varepsilon_2 Q(u)$ describe linear and nonlinear perturbations, respectively, and $\sum_j D_j F_j(x,t)$ is a forcing term, which decays to zero for $t \to \infty$. The perturbation terms are assumed to have conservation form. We call the system nonlinearly stable if the solution $u(x,t)$ with $u(x,0) = 0$ remains smooth for all $t \geq 0$ and the maximum norm of u tends to zero for $t \to \infty$, provided that $\varepsilon_1^2 + \varepsilon_2^2$ is sufficiently small. In the paper we give sufficient conditions for nonlinear stability.

If the unperturbed system $u_t = P_0 u$ is parabolic, then the Laplace transform technique is satisfactory to derive conditions for nonlinear stability. However, if $u_t = P_0 u$ is hyperbolic or coupled parabolic-hyperbolic, then the Laplace transform technique fails if the perturbation terms are first-order differential operators. In this case, we combine Laplace transformation for small wave vectors with an energy technique to control the large-wave–number projection of the solution.

1. Introduction.

We consider systems of partial differential equations of the form

$$u_t = P_0 u + \varepsilon_1 P_1 u + \varepsilon_2 \sum_{j=1}^{d} D_j g_j(x,t,u) + \sum_{j=1}^{d} D_j F_j(x,t), \quad x \in \mathbb{R}^d,\ t \geq 0, \tag{1.1}$$

with initial condition

$$u(x,0) = 0, \quad x \in \mathbb{R}^d. \tag{1.2}$$

Here $u = u(x,t)$ takes values in $\mathbb{R}^n$. The operator P_0 has constant coefficients,

$$P_0 = \sum_{|\alpha| \leq m} A_\alpha D^\alpha, \quad A_\alpha \in \mathbb{R}^{n \times n},$$
$$D^\alpha = D_1^\alpha \dots D_d^\alpha, \quad D_j = \partial/\partial x_j, \quad |\alpha| = \alpha_1 + \dots + \alpha_d.$$

The operator P_1 has conservation form,

$$P_1 u = \sum_{j=1}^{d} D_j \Big(B_j(x,t) u \Big)$$

with variable coefficients

$$B_j(x,t) \in \mathbb{R}^{n\times n}.$$

The nonlinear functions $g_j(x,t,u)$ vanish quadratically at $u = 0$. More specific assumptions on $P_0,\ P_1,\ g_j(x,t,u)$, and $F_j(x,t)$ will be given below. Note that all terms in (1.1) have conservation form, except for a zero-order term in P_0, which is allowed.

We call (1.1), (1.2) nonlinearly stable if the solution $u(x,t)$ remains smooth for all $t \geq 0$ and the maximum norm $|u(\cdot,t)|_\infty$ tends to zero for $t \to \infty$, provided that $\varepsilon_1^2 + \varepsilon_2^2$ is sufficiently small. The aim of the paper is to give sufficient conditions on P_0, P_1, g_j, F_j, which imply nonlinear stability.

Our results can easily be translated into nonlinear stability results for problems with more general initial data than (1.2); see section 4.1.

We now outline the results of our paper. In section 2 we will first assume that the constant coefficient operator P_0 has the form

$$P_0 = \Delta + \sum_{j=1}^{d} A_j D_j, \quad A_j \in \mathbb{R}^{n\times n},$$

where $\Delta = D_1^2 + \cdots + D_d^2$ is the Laplacian and where the corresponding system

$$u_t = \sum_j A_j D_j u$$

is strongly hyperbolic. The linear problem

$$u_t = P_0 u + \sum_j D_j F_j(x,t), \quad u = 0 \text{ at } t = 0, \tag{1.3}$$

can be discussed by Fourier–Laplace transformation. If

$$\tilde{u}(\omega,s) = (2\pi)^{-d/2} \int_0^\infty \int_{\mathbb{R}^d} e^{-st} e^{-i\omega\cdot x} u(x,t)dx\,dt$$

denotes the Fourier–Laplace transform, then (1.3) becomes

$$s\tilde{u} = \hat{P}_0(\omega)\tilde{u} + i\sum_j \omega_j \tilde{F}. \tag{1.4}$$

Throughout the paper, the derivation of solution estimates for small $|\omega|$ (long wavelengths) and large $|\omega|$ (short wavelengths) will proceed quite differently. We therefore decompose

$$\tilde{u} = \tilde{u}^I + \tilde{u}^{II}$$

with

$$\tilde{u}^I(\omega,s) = \begin{cases} \tilde{u}(\omega,s) & \text{if } |\omega| \leq 1, \\ 0 & \text{if } |\omega| > 1, \end{cases} \tag{1.5}$$

and obtain a corresponding decomposition of u,

$$u(x,t) = u^I(x,t) + u^{II}(x,t),$$

by inverting the Fourier–Laplace transform. (Note that the time dependence is irrelevant in determining the decomposition $u = u^I + u^{II}$. The decomposition is well defined for any L_2-function $u = u(x)$.) For operators

$$P_0 = \Delta + \sum_j A_j D_j, \tag{1.6}$$

solution estimates for the linear problem (1.3) can then be derived from the transformed equation (1.4). The estimate is stated in Theorem 2.1. To discuss the nonlinear problem (1.1), it suffices to apply the linear estimate with F_j replaced by

$$F_j + \varepsilon_1 B_j u + \varepsilon_2 g_j(x,t,u).$$

Then, using nothing more than Sobolev inequalities, we obtain nonlinear stability. The details are given in Theorem 2.2. At the end of section 2 we briefly discuss how to extend the results to more general parabolic systems (1.1).

In section 3 we drop the assumption that $u_t = P_0 u$ is parabolic and consider a general constant coefficient operator $P_0 = \sum_{|\alpha|\le m} A_\alpha D^\alpha$. We then formulate our assumptions on P_0 in terms of its symbol,

$$\hat{P}_0(\omega) = \sum_{|\alpha|\le m} A_\alpha (i\omega_1)^{\alpha_1} \cdots (i\omega_d)^{\alpha_d}, \quad \omega \in \mathbb{R}^d.$$

A main assumption will be the following eigenvalue condition.

Assumption 1. There is a constant $c_0 > 0$ such that

$$\operatorname{Re}\lambda \le \begin{cases} -c_0|\omega|^2 & \text{if } |\omega| \le 1, \\ -c_0 & \text{if } |\omega| \ge 1 \end{cases}$$

for all eigenvalues λ of $\hat{P}_0(\omega)$.

For the other assumptions, see section 3. Clearly, for the operator $P_0 = \Delta + \sum_j A_j D_j$ discussed in section 2, one has

$$\operatorname{Re}\lambda = -|\omega|^2 \quad \text{for all} \quad \lambda \in \sigma\Big(\hat{P}_0(\omega)\Big)$$

without restricting $|\omega|$. In Assumption 1 such a behavior of $\operatorname{Re}\lambda$ is required for small $|\omega|$ but not for large $|\omega|$. Therefore, the assumptions on P_0 in section 3 allow for systems $u_t = P_0 u$, which are coupled parabolic-hyperbolic or strongly hyperbolic with suitable zero-order terms. (In the appendix we give sufficient conditions which imply all the requirements on P_0 of section 3.)

Since the upper bound

$$\operatorname{Re}\lambda \le -c_0 < 0 \quad \text{for all} \quad \lambda \in \sigma\Big(\hat{P}_0(\omega)\Big), \quad |\omega| \ge 1,$$

on $\operatorname{Re}\lambda$ in Assumption 1 does not tend to $-\infty$ for $|\omega| \to \infty$, the perturbation terms

$$\varepsilon_1 \sum_j D_j(B_j u) + \varepsilon_2 \sum_j D_j g_j(x,t,u) \tag{1.7}$$

cannot be treated as forcing terms anymore for large $|\omega|$, because they are unbounded operators in L_2. Instead, to derive estimates for the large-$|\omega|$ part u^{II} of the solution, we will employ an energy estimate and consider

$$\frac{d}{dt} \|u^{II}(\cdot,t)\|^2_{\mathcal{H}} .$$

Here the $\mathcal{H}$-norm will be determined by an inner product

$$(u,v)_{\mathcal{H}} = \int_{\mathbb{R}^d} \hat{u}^*(\omega) H(\omega) \hat{v}(\omega) d\omega,$$

where

$$\hat{u}(\omega) = (2\pi)^{-d/2} \int_{\mathbb{R}^d} e^{-i\omega\cdot x} u(x) dx$$

is the Fourier transform and where $H(\omega)$ is a symmetrizer for $\hat{P}_0(\omega)$. The main idea, then, of section 3 is to combine the Laplace transform technique for $|\omega| \leq 1$ with energy estimates for $|\omega| > 1$.

Remark. One can try, of course, to use an energy technique for the small–$|\omega|$ part of the solution as well. However, since generally $\mathrm{Re}\lambda \approx -c_0|\omega|^2$ for $\lambda \in \sigma(\hat{P}(\omega))$ if $|\omega|$ is small, there is no exponential decay in time which is uniform in $|\omega|$. This is a well-known difficulty, and there are approaches different from ours to deal with it. See, for example, [2] and [5].

In section 3, we assume that the symmetrizer $H(\omega)$ will only depend on the symbol $\hat{P}_0(\omega)$ of the constant coefficient operator P_0 and will tend to the identity for $|\omega| \to \infty$,

$$|H(\omega) - I| \leq \frac{\text{const.}}{|\omega|}, \quad |\omega| \geq 1. \tag{1.8}$$

(For such a condition, see [1].) Then, to treat the perturbation terms (1.7), we will assume that the matrices $B_j(x,t)$ and $g_{ju}(x,t,u)$ are symmetric.

Symmetrizers and energy estimates can be used more generally; see, for example, [4]. Also, the combination of the Laplace transform technique for $|\omega| \leq 1$ with an energy technique for $|\omega| > 1$ does not depend on the specific properties of $H(\omega)$ in section 3. Therefore, condition (1.8) as well as the symmetry assumptions for B_j and g_{ju} can be modified. We formulate a corresponding result in section 4 as a conjecture. Details will be provided in a forthcoming paper.

Notations.

1.
$$|u|^2 = \sum_j |u_j|^2 : \quad \text{Euclidean norm;}$$

2.
$$|A| = \max\{|Au| : |u| = 1\} : \quad \text{corresponding matrix norm;}$$

3.
$$\hat{u}(\omega) = (2\pi)^{-d/2} \int_{\mathbb{R}^d} e^{-i\omega\cdot x} u(x) dx : \quad \text{Fourier transform;}$$

4.
$$u = u^I + u^{II} \text{ where } \hat{u}^I(\omega) = \begin{cases} \hat{u}(\omega) & \text{if } |\omega| \leq 1, \\ 0 & \text{if } |\omega| > 1 \end{cases} :$$

decomposition of u into a small-wave–vector projection u^I and a large-wave–vector projection u^{II};

5.

$$\tilde{u}(\omega, s) = (2\pi)^{-d/2} \int_0^\infty \int_{\mathbb{R}^d} e^{-st} e^{-i\omega\cdot x} u(x,t)dx\,dt : \quad \text{Fourier–Laplace transform;}$$

6.

$$(u, v) = \int_{\mathbb{R}^d} u^*(x)v(x)dx = \int_{\mathbb{R}^d} \hat{u}^*(\omega)\hat{v}(\omega)d\omega :$$

L_2-inner product of $u, v \in L_2(\mathbb{R}^d, \mathbb{R}^n)$;

7.

$$(u, v)_{\mathcal{H}} = \int_{\mathbb{R}^d} \hat{u}^*(\omega)H(\omega)\hat{v}(\omega)d\omega :$$

modified inner product determined by symmetrizer $H(\omega)$;

8.

$$\|u\|^2 = (u, u), \quad \|u\|^2_{\mathcal{H}} = (u, u)_{\mathcal{H}} : \quad \text{corresponding norms;}$$

9.

$$\|u\|^2_{H^p} = \sum_{|\alpha|\le p} \|D^\alpha u\|^2, \quad \|u\|^2_{p,\mathcal{H}} = \sum_{|\alpha|\le p} \|D^\alpha u\|^2_{\mathcal{H}} :$$

Sobolev and modified Sobolev norm;

10.

14.

$$|\cdot|_\infty : \quad \text{sup-norm.}$$

2. The parabolic case. In this section we first assume that P_0 has the form

$$P_0 = \Delta + \sum_{j=1}^d A_j D_j, \quad A_j \in \mathbb{R}^{n\times n},$$

where the system $u_t = \sum_j A_j D_j u$ is strongly hyperbolic. That is, we make the following assumption.

Assumption 2. There is a constant $C > 0$ and, for each $\omega \in \mathbb{R}^d$ with $|\omega| = 1$, there is a transformation $S(\omega) \in \mathbb{C}^{n\times n}$ such that

a) $|S(\omega)| + |S^{-1}(\omega)| \le C$;
b) $S^{-1}(\omega)(\sum_j \omega_j A_j)S(\omega)$ is real, diagonal.

At the end of the section, we consider more general operators P_0 for which $u_t = P_0 u$ is parabolic. Next, we list our assumptions on the coefficients

$$B_j(x,t),\ g_j(x,t,u),\ F_j(x,t), \quad j = 1, \dots, d.$$

Assumption 3.
a) $B_j(x,t)$, $g_j(x,t,u)$, $F_j(x,t)$ are C^∞-functions defined for $x \in \mathbb{R}^d$, $t \ge 0$, $u \in \mathbb{R}^n$;
b) $F_j(x,0) \equiv 0$;
c) $\int_0^\infty \int_{\mathbb{R}^d} |F_j(x,t)| dx\, dt < \infty$;
d) for all $p = 0, 1, \dots$, we have that

$$\int_0^\infty \Big\{ \|F(\cdot,t)\|^2_{H^p} + \|F_t(\cdot,t)\|^2_{H^p} \Big\} dt < \infty;$$

e) $\int_0^\infty \|B_j(\cdot,t)\|^2 dt < \infty$;
f) for all α, there is C_α with

$$|D^\alpha B_j(x,t)| + |D^\alpha B_{jt}(x,t)| \le C_\alpha \quad \text{for} \quad x \in \mathbb{R}^d,\ t \ge 0;$$

g) for all α, β and $L > 0$, there is $C(\alpha,\beta,L)$ with

$$|D_x^\alpha D_u^\beta g(x,t,u)| + |D_x^\alpha D_u^\beta g_t(x,t,u)| \le C(\alpha,\beta,L) \quad \text{for} \quad x \in \mathbb{R}^d,\ t \ge 0,\ |u| \le L;$$

h) for all $L > 0$, there is C_L with

$$|g(x,t,u)| \le C_L |u|^2 \quad \text{for } x \in \mathbb{R}^d,\ t \ge 0,\ |u| \le L;$$

i) for all α and all $L > 0$, there is $C(\alpha, L)$ with

$$|D_x^\alpha g_j(x,t,u)| + |D_x^\alpha g_{jt}(x,t,u)| + |D_x^\alpha g_{ju}(x,t,u)| \le C(\alpha,L)|u| \quad \text{for} \quad x \in \mathbb{R}^d,\ t \ge 0,\ |u| \le L.$$

Remark. These assumptions might seem very restrictive, but they can often be realized by simple transformations; see the discussion in section 4. The assumption $u(x,0) = F_j(x,0) \equiv 0$ is convenient since we will use the Laplace transformation.

We first consider the problem (1.1), (1.2) with $\varepsilon_1 = \varepsilon_2 = 0$ and show the following estimate of u in terms of F.

THEOREM 2.1. *Consider the equation* $u_t = P_0 u + \sum_j D_j F_j(x,t)$, $u = 0$ *at* $t = 0$, *under Assumptions* 2–3. *Then, for any* $p = 1, 2, \dots$ *there is a constant* R_p, *independent of* T *and* F, *such that*

(2.1)
$$\int_0^T \Big\{ \|u\|^2_{H^p} + \|u_t\|^2_{H^p} \Big\} dt \le R_p \left\{ M(F,T) + \int_0^T \Big\{ \|F\|^2_{H^{p-1}} + \|F_t\|^2_{H^{p-1}} \Big\} dt \right\}.$$

Here

$$M(F,T) = \sum_j \Big(\int_0^T \int_{\mathbb{R}^d} |F_j(x,t)| dx\, dt \Big)^2.$$

Proof.
1) Fourier–Laplace transformation yields

$$s\tilde{u} = \hat{P}_0(\omega)\tilde{u} + i\sum_j \omega_j \tilde{F}_j, \quad \omega \in \mathbb{R}^d,\ s = \eta + i\xi. \tag{2.2}$$

We decompose

$$\tilde{u} = \tilde{u}^I + \tilde{u}^{II},$$

where $\tilde{u}^I(\omega, s) = \tilde{u}(\omega, s)$ for $|\omega| \le 1$ and $\tilde{u}^I(\omega, s) = 0$ for $|\omega| > 1$. Clearly,

$$\hat{P}_0 = -|\omega|^2 I + i\sum_j \omega_j A_j.$$

For $\omega \neq 0$, let $\omega^0 = \omega/|\omega|$ and use the transformation $S = S(\omega^0)$ of Assumption 2 to obtain

$$S^{-1}(sI - \hat{P}_0)S = (s + |\omega|^2)I - i\Lambda.$$

Here $\Lambda = \operatorname{diag}(\lambda_k)$ contains the real eigenvalues of $\sum_j \omega_j A_j$ as diagonal entries. From (2.2) we find that

$$\begin{aligned} |\tilde{u}|^2 &\le |(sI - \hat{P}_0)^{-1}|^2 |\omega|^2 |\tilde{F}|^2 \\ &\le C_1 |\omega|^2 |\tilde{F}|^2 \sum_{k=1}^{n} \frac{1}{(\eta + |\omega|^2)^2 + (\xi - \lambda_k)^2} \end{aligned} \tag{2.3}$$

with $s = \eta + i\xi,\ \eta \ge 0$. Here

$$|\tilde{F}(\omega, s)|^2 = \sum_j |\tilde{F}_j(\omega, s)|^2,$$

$$\tilde{F}_j(\omega, s) = (2\pi)^{-d/2} \int_0^\infty \int_{\mathbb{R}^d} e^{-st - i\omega\cdot x} F_j(x, t)\, dx\, dt,$$

and therefore,

$$|\tilde{F}(\omega, s)|^2 \le C_2\, M(F, \infty) \quad \text{for} \quad s = \eta + i\xi,\ \eta \ge 0.$$

For $|\omega| \le 1$ we obtain from (2.3), using Parseval's relation,

$$\begin{aligned} \int_0^\infty e^{-2\eta t} \|u^I\|^2 dt &= \frac{1}{2\pi} \int_{|\omega|\le 1} \int_{-\infty}^{\infty} |\tilde{u}(\omega, \eta + i\xi)|^2 d\xi\, d\omega \\ &\le C_3\, M(F, \infty) \sum_{k=1}^{n} I_k \end{aligned}$$

with

$$I_k = \int_{|\omega|\le 1} \int_{-\infty}^{\infty} \frac{|\omega|^2}{(\eta + |\omega|^2)^2 + (\xi - \lambda_k)^2}\, d\xi\, d\omega.$$

It is crucial that the integrals I_k are finite for $\eta \geq 0$. In fact, for $\eta = 0$,

$$I_k = \int_{|\omega|\leq 1}\int_{-\infty}^{\infty} \frac{|\omega|^2}{|\omega|^4+\xi^2}\, d\xi\, d\omega = \int_{|\omega|\leq 1}\int_{-\infty}^{\infty} \frac{d\xi'}{1+(\xi')^2}\, d\omega < \infty.$$

This shows that, for $\eta = 0$,

$$\int_0^\infty \|u^I\|^2 dt \leq C_4\, M(F,\infty).$$

To estimate space derivatives $D^\alpha u^I$, just note that

$$|\widetilde{(D^\alpha u^I)}(\omega,s)| \leq |\omega|^{|\alpha|}|u^I(\omega,s)| \leq |u^I(\omega,s)|.$$

Then Parseval's relation implies, as above,

$$\int_0^\infty \|u^I\|^2_{H^p} dt \leq C_5\, M(F,\infty), \quad C_5 = C_5(p).$$

Also, using (2.2), we obtain that

$$|\tilde{u}^I_t| = |s\tilde{u}^I| \leq C\Big\{|\tilde{u}^I| + |\tilde{F}|\Big\}, \quad |\omega| \leq 1,$$

and a similar estimate holds for $|\widetilde{(D^\alpha u^I_t)}|$. Therefore,

$$\int_0^\infty \|u^I_t\|^2_{H^p} dt \leq C_6\Big\{M(F,\infty) + \int_0^\infty \|F\|^2 dt\Big\}, \quad C_6 = C_6(p).$$

2) It remains to estimate u^{II}, i.e., to consider (2.2) for $|\omega| \geq 1$. Clearly, we obtain from (2.3), for $\eta = 0$,

$$(|\omega|^2+1)\,|\tilde{u}^{II}|^2 \leq C_7|\tilde{F}|^2, \quad |\omega| \geq 1.$$

Then Parseval's relation yields

$$\int_0^\infty \|u^{II}\|^2_{H^1} dt \leq C_8 \int_0^\infty \|F\|^2 dt.$$

Also, we can apply D^α and $D^\alpha \partial/\partial t$ to the given differential equation and obtain a corresponding estimate for $D^\alpha u^{II}$ and for $D^\alpha u^{II}_t$. Thus, our estimates show that (2.1) holds for $T = \infty$. Since values of $F(x,t)$ for $t > T$ do not affect the solution $u(x,t)$ for $t \leq T$, we can replace $T = \infty$ by for any finite T.

Remark. Global existence for the linear problem considered here is well known, and the solution can grow at most exponentially. Therefore, the formal process of Laplace transformation in t is justified for $s = \eta + i\xi$ if $\eta \geq \eta_0$, η_0 sufficiently large. Then, in inverting the Laplace transformation, our estimates show that no singularities are encountered for $\eta \geq 0$, and, therefore, the contour of integration can be deformed to $\eta = 0$. This justifies the formal use of the Laplace transform in t and the choice $\eta = 0$ in deriving solution estimates.

Now consider the nonlinear problem (1.1) with $P_0 = \Delta + \sum_j A_j D_j$ and recall Assumptions 2 and 3. For any choice of ε_1, ε_2, there is a local solution $u(x,t) = u(x,t,\varepsilon_1,\varepsilon_2)$, which is C^∞-smooth in a maximal interval

$$0 \leq t < \bar{T} = \bar{T}(\varepsilon_1,\varepsilon_2).$$

We will show that $\bar{T}(\varepsilon_1, \varepsilon_2) = \infty$ if $\varepsilon_1^2 + \varepsilon_2^2$ is sufficiently small. Furthermore, we will show that the solution tends to zero as $t \to \infty$.

THEOREM 2.2. *Consider* (1.1), (1.2) *where* $P_0 = \Delta + \sum_j A_j D_j$, *and recall Assumptions* 2 and 3. *There exists* $\varepsilon_0 > 0$ *such that the solution is* C^∞ *for all* $t \geq 0$ *if*

$$\varepsilon_1^2 + \varepsilon_2^2 \leq \varepsilon_0.$$

Furthermore,

$$\lim_{t\to\infty} |u(\cdot, t)|_\infty = 0.$$

Proof. Choose a large constant κ. (We will see below that the choice

$$\kappa = 1 + 2R_p \left\{ M(F, \infty) + \int_0^\infty \{\|F\|_{H^{p-1}}^2 + \|F_t\|_{H^{p-1}}^2\} dt \right\} \tag{2.4}$$

is sufficient. Here $p = d + 2$ and d is the number of space dimensions.)

Fix $\varepsilon_1,\ \varepsilon_2$ and let $u = u(x, t, \varepsilon_1, \varepsilon_2)$ denote the solution of (1.1), (1.2). Assume first that there is a finite time $T = T(\kappa, \varepsilon_1, \varepsilon_2)$ with

$$\int_0^T \{\|u\|_{H^p}^2 + \|u_t\|_{H^p}^2\} dt = \kappa. \tag{2.5}$$

Set

$$|D^\alpha u|_{\infty,T} = \sup_{x\in\mathbb{R}^d,\, 0\leq t\leq T} |D^\alpha u(x, t)|.$$

By Sobolev's inequality, there is a constant C, independent of T, such that

$$|D^\alpha u|_{\infty,T}^2 \leq C\kappa \quad \text{if} \quad |\alpha| + \frac{d}{2} < p. \tag{2.6}$$

(Here we have used that

$$\max_{0\leq t\leq T} |v(t)|^2 \leq C \int_0^T \{|v(t)|^2 + |v_t(t)|^2\} dt$$

with C independent of T if $v(0) = 0$.) Now apply Theorem 2.1 with F_j replaced by

$$F_j + \varepsilon_1 B_j u + \varepsilon_2 G_j, \quad G_j(x, t) = g_j(x, t, u(x, t)).$$

Then (2.5) and Theorem 2.1 yield

$$\begin{aligned}
\kappa &\leq R_p M(F + \varepsilon_1 Bu + \varepsilon_2 G, T) \\
&\quad + R_p \int_0^T \{\|F + \varepsilon_1 Bu + \varepsilon_2 G\|_{H^{p-1}}^2 + \|(F + \varepsilon_1 Bu + \varepsilon_2 G)_t\|_{H^{p-1}}^2\} dt \\
&\leq 2R_p \Big\{ M(F, T) + \int_0^T \{\|F\|_{H^{p-1}}^2 + \|F_t\|_{H^{p-1}}^2\} dt \Big\} \\
&\quad + 4\varepsilon_1^2 R_p M(Bu, T) \ + \ 4\varepsilon_2^2 R_p M(G, T) \int_0^T \{\|Bu\|_{H^{p-1}}^2 + \|(Bu)_t\|_{H^{p-1}}^2\} dt \\
&\quad + 4\varepsilon_2^2 R_p \int_0^T \{\|G\|_{H^{p-1}}^2 + \|G_t\|_{H^{p-1}}^2\} dt.
\end{aligned}$$

It remains to show that all terms multiplied by ε_1^2 or ε_2^2 can be controlled in terms of κ, if κ and T are related by (2.5). Then, by choosing κ as in (2.4) and making $\varepsilon_1^2 + \varepsilon_2^2$ small, we arrive at a contradiction to (2.4). This contradiction shows that a finite T with (2.5) cannot exist, and, therefore,

$$\int_0^T \left\{ \|u\|_{H^p}^2 + \|u_t\|_{H^p}^2 \right\} dt < \kappa \ , \quad T \geq 0.$$

Then standard arguments show that the solution exists and is C^∞ for all $t \geq 0$.

We now treat the terms multiplied by ε_j^2 on the right side of the above estimate of κ separately. We have

$$\left\{ \int_0^T \int_{\mathbb{R}^d} |B_j(x,t)| \, |u(x,t)| dx \, dt \right\}^2 \leq C_B \int_0^T \int_{\mathbb{R}^d} |u(x,t)|^2 dx \, dt \leq C_B \kappa,$$

using Assumption 3e. Furthermore, by Leibnitz' rule,

$$D^\alpha (B_j u) = \sum_{\beta \leq \alpha} c_{\alpha\beta} (D^{\alpha-\beta} B_j) D^\beta u,$$

where

$$\sup_{x,t} |D^{\alpha-\beta} B_j(x,t)| \leq \text{ const.}$$

by Assumption 3f. Therefore,

$$\int_0^T \|Bu\|_{H^{p-1}}^2 dt \leq C_B \kappa,$$

and similarly,

$$\int_0^T \|(Bu)_t\|_{H^{p-1}}^2 dt \leq C_B \kappa.$$

We now treat the nonlinear terms and recall

$$G_j(x,t) = g_j(x,t,u(x,t)).$$

First note that

$$\int_0^T \int_{\mathbb{R}^d} |G_j(x,t)| dx \, dt \leq C \int_0^T \int_{\mathbb{R}^d} |u(x,t)|^2 dx \, dt \leq C\kappa,$$

where we have used that g_j vanishes quadratically at $u = 0$. This implies $M(G,T) \leq C_1 \kappa^2$.

Now consider $\int_0^T \|G\|_{H^{p-1}}^2 dt$, and let α be a multi-index with $|\alpha| \leq p-1$. Then $D^\alpha g_j(x,t,u(x,t))$ is a sum of terms

$$\varphi_j(x,t,\alpha,\sigma) D^{\sigma_1} u \ \cdots D^{\sigma_r} u, \tag{2.7}$$

where $\sigma_1, \ldots, \sigma_r$ are multi-indices with

$$|\sigma_1| + \cdots + |\sigma_r| \leq |\alpha| \leq p-1;$$

the function φ_j is a partial derivative of g_j evaluated at $(x,t,u(x,t))$. The index r satisfies $0 \le r \le p-1$. Since $|u|^2_{\infty,T} \le C\kappa$ by (2.6), we have

$$\sup_{x,0\le t\le T} |\varphi_j| \le C_0(\kappa).$$

Consider a term (2.7) and first assume $1 \le r \le p-1$. By (2.6),

$$|D^{\sigma_j} u|_{\infty,T} \le C_0(\kappa) \quad \text{if} \quad |\sigma_j| + \frac{d}{2} < p,$$

and we say that $D^{\sigma_j}u$ is estimated in sup-norm in terms of κ. Suppose there are two factors in (2.7), $D^{\sigma_1}u$ and $D^{\sigma_2}u$, say, which *cannot* be estimated in sup-norm in terms of κ. Then we have

$$|\sigma_1| + \frac{d}{2} \ge p \quad \text{and} \quad |\sigma_2| + \frac{d}{2} \ge p;$$

thus,

$$p - 1 + d \ge |\sigma_1| + |\sigma_2| + d \ge 2p.$$

But this implies $p \le d-1$, which contradicts our choice of $p = d+2$. We conclude that each factor in (2.7), except at most one, can be estimated in sup-norm in terms of κ. Therefore,

$$\|\varphi_j D^{\sigma_1} u \ \cdots \ D^{\sigma_r} u\| \le C_0(\kappa)\|u\|_{H^{p-1}}.$$

If $r = 0$ in (2.7), then

$$\varphi_j = D^\alpha_x g_j(x,t,u),$$

and Assumption 3i implies

$$|\varphi_j| \le C|u|.$$

These arguments show that

$$\int_0^T \|G\|^2_{H^{p-1}} dt \le C_1(\kappa).$$

Now consider

$$\int_0^T \|G_t\|^2_{H^{p-1}} dt.$$

Since $G_j(x,t) = g_j(x,t,u(x,t))$ we have

$$G_{jt} = g_{jt} + g_{ju}u_t$$

and, therefore,

$$D^\alpha G_{jt} = D^\alpha g_{jt} + D^\alpha(g_{ju}u_t).$$

The term $D^\alpha g_{jt}$ is treated in the same way as $D^\alpha g_j$ above. Finally, $D^\alpha(g_{ju}u_t)$ is a sum of terms

$$\psi_j(x,t,\alpha,\sigma) D^{\sigma_1} u \ \cdots \ D^{\sigma_r} u D^\beta u_t \tag{2.8}$$

with $|\sigma_1|+\cdots+|\sigma_r|+|\beta| \le |\alpha| \le p-1$. The function ψ_j is a derivative of g_{ju} evaluated at $(x,t,u(x,t))$. First let

$$|\beta| + 2 + \frac{d}{2} < p. \tag{2.9}$$

Then we use the differential equation (1.1) to express $D^\beta u_t$ in terms of space derivatives of u of order $\le |\beta|+2$. Since (2.9) is assumed, all these space derivatives can be bounded in sup-norm in terms of κ. Therefore,

$$|D^\beta u_t|_{\infty,T} \le C(\kappa) \quad \text{if} \quad |\beta| + 2 + \frac{d}{2} < p.$$

If $|\beta| + 2 + \frac{d}{2} \ge p$ and $|\sigma_1| + \frac{d}{2} \ge p$, say, then

$$p + 1 + d \ge |\beta| + |\sigma_1| + 2 + d \ge 2p.$$

But this implies $p \le d+1$, which contradicts our choice $p = d+2$. Thus, if $|\beta|+2+\frac{d}{2} \ge p$, then $|\sigma_j| + \frac{d}{2} < p$, and, consequently, all terms $D^{\sigma_j}u$ in (2.8) are bounded in sup-norm in terms of κ. Also, if $r = 0$ in (2.8), then ψ_j is a space derivative $D_x^\gamma g_{ju}(x,t,u)$, and we use

$$|D_x^\gamma g_{ju}(x,t,u)| \le C|u|.$$

These arguments show that

$$\|\psi_j D^{\sigma_1}u \ \cdots \ D^{\sigma_r}uD^\beta u_t\|^2 \le C_2(\kappa)\big\{\|u\|_{H^p}^2 + \|u_t\|_{H^p}^2\big\},$$

and therefore,

$$\int_0^T \|G_t\|_{H^{p-1}}^2 dt \le C_3(\kappa).$$

To summarize, we define κ by (2.4) with $p = d+2$. If we assume that there is a finite $T = T(\kappa,\varepsilon_1,\varepsilon_2)$ with (2.5), then our linear estimate (Theorem 2.1) yields

$$\kappa \le C(\kappa)(\varepsilon_1^2+\varepsilon_2^2) + 2R_p\left\{M(F,T) + \int_0^T \big\{\|F\|_{H^{p-1}}^2 + \|F_t\|_{H^{p-1}}^2\big\}dt\right\}.$$

Choosing $\varepsilon_1^2+\varepsilon_2^2 \le \varepsilon_0$ with $\varepsilon_0 = 1/(2C(\kappa))$, we arrive at a contradiction to (2.4). Therefore, if $\varepsilon_1^2+\varepsilon_2^2 \le \varepsilon_0$, then

$$\int_0^\infty \big\{\|u\|_{H^p}^2 + \|u_t\|_{H^p}^2\big\}dt < \infty.$$

Consequently,

$$\max_{T\le t<\infty} |u(\cdot,t)|_\infty^2 \le C\int_T^\infty \big\{\|u\|_{H^p}^2 + \|u_t\|_{H^p}^2\big\}dt \to 0 \text{ as } T\to\infty,$$

and in particular,

$$\lim_{t\to\infty} |u(\cdot,t)|_\infty = 0.$$

This proves Theorem 2.2.

Remark. Throughout the paper, we do not try to minimize smoothness assumptions. In the definition of κ by (2.4) the choice $p = d + 2$ can be improved if one uses Hölder's inequality and a Gagliardo–Nirenberg inequality instead of Sobolev's inequality; see, for example, [1].

Generalization. It is not difficult to extend the results of this section to more general parabolic systems. Consider (1.1), (1.2) where P_0 is a constant coefficient operator

$$P_0 = \sum_{|\alpha| \le m} A_\alpha D^\alpha, \quad A_\alpha \in \mathbb{R}^{n \times n},$$

and assume that its symbol

$$\hat{P}_0(\omega) = \sum_{|\alpha| \le m} A_\alpha (i\omega_1)^{\alpha_1} \cdots (i\omega_d)^{\alpha_d}, \quad \omega \in \mathbb{R}^d,$$

satisfies the following two conditions.

1. There is a constant C_0 such that
$$|e^{\hat{P}_0(\omega)t}| \le C_0$$
for all $\omega \in \mathbb{R}^d$ and all $t \ge 0$.
2. There is a constant $c_0 > 0$ such that
$$\mathrm{Re}\lambda \le -c_0|\omega|^2$$
for all $\lambda \in \sigma(\hat{P}_0(\omega))$ and all $\omega \in \mathbb{R}^d$.

If, in addition, the terms B_j, g_j, F_j satisfy our general Assumption 3, then the result formulated in Theorem 2 is valid. To prove this, it suffices to show that the solution of the linear problem

$$u_t = P_0 u + \sum_j D_j F_j$$

satisfies the estimate (2.1). By the Kreiss' matrix theorem [3], there is a transformation $S = S(\omega)$ with

$$S^{-1}\hat{P}_0 S = \begin{pmatrix} \lambda_1 & r_{12} & \cdots & \cdots & r_{1n} \\ & \ddots & \ddots & & \vdots \\ & & \ddots & \ddots & \vdots \\ & & & \ddots & r_{n-1,n} \\ 0 & & & & \lambda_n \end{pmatrix}$$

$$|r_{jl}| \le C_1 |\mathrm{Re}\lambda_j|, \quad 1 \le j < l \le n, \quad |S| + |S^{-1}| \le C_1.$$

If $\lambda_j = \alpha_j + i\beta_j, \alpha_j, \beta_j \in \mathbb{R}$, then, by assumption, $\alpha_j \le -c_0|\omega|^2$, and one obtains

$$\left|\left((\eta + i\xi)I - \hat{P}_0\right)^{-1}\right|^2 \le C_2 \sum_j \frac{1}{(\eta + |\omega|^2)^2 + (\xi - \beta_j)^2}.$$

Therefore, we obtain again the estimate (2.3), and (2.1) follows. The remaining arguments are the same as in the proof of Theorem 2.

3. The symmetric case. In this section, let P_0 denote a general constant coefficient operator,

$$P_0 = \sum_{|\alpha| \le m} A_\alpha D^\alpha, \quad A_\alpha \in \mathbb{R}^{n \times n},$$

with symbol

$$\hat{P}_0(\omega) = \sum_{|\alpha| \le m} A_\alpha (i\omega_1)^{\alpha_1} \cdots (i\omega_d)^{\alpha_d}, \quad \omega \in \mathbb{R}^d.$$

We do not assume here that the system $u_t = P_0 u$ is parabolic and, therefore, we do not require the estimate

$$\mathrm{Re}\lambda \le -c_0 |\omega|^2, \quad \lambda \in \sigma(\hat{P}_0(\omega))$$

for large $|\omega|$. In this case, the technique of section 2 cannot be used to treat the perturbation

$$\varepsilon_1 \sum_j D_j (B_j u) + \varepsilon_2 \sum_j D_j g_j$$

for large $|\omega|$, because we do not "gain" a derivative in the estimate for the linear equation $u_t = P_0 u + \sum_j D_j F_j$. If one makes the assumptions:

1. There is a constant $c_0 > 0$ such that

$$\hat{P}_0(\omega) + \hat{P}_0^*(\omega) \le -2c_0 I < 0 \tag{3.1}$$

for all $\omega \in \mathbb{R}^d$;

2. $B_j(x,t) = B_j^T(x,t), \quad g_{ju}(x,t,u) = g_{ju}^T(x,t,u), \quad j = 1, \dots, d;$

then one can use standard energy estimates to derive the conclusions of Theorem 2. However, in many applications the strict negativity assumption (3.1) is not fulfilled. Consider, for example, the (simplified) compressible Navier–Stokes equations, linearized about a constant state U, V,

$$\begin{pmatrix} u \\ v \\ p \end{pmatrix}_t + \begin{pmatrix} U & 0 & 1 \\ 0 & U & 0 \\ 1 & 0 & U \end{pmatrix} \begin{pmatrix} u \\ v \\ p \end{pmatrix}_x + \begin{pmatrix} V & 0 & 0 \\ 0 & V & 1 \\ 0 & 1 & V \end{pmatrix} \begin{pmatrix} u \\ v \\ p \end{pmatrix}_y = \begin{pmatrix} \Delta u \\ \Delta v \\ 0 \end{pmatrix}. \tag{3.2}$$

A simple calculation shows that

$$\hat{P}_0(\omega) + \hat{P}_0^*(\omega) \le 0, \tag{3.3}$$

and there is a constant $c_0 > 0$ with

$$\mathrm{Re}\lambda \le -c_0 \frac{|\omega|^2}{1 + |\omega|^2}, \quad \lambda \in \hat{P}_0(\omega), \tag{3.4}$$

for all ω. If one assumes the above two conditions (3.3), (3.4) for $\hat{P}_0$, then one can estimate u^I as in section 2, since (3.3) implies $|e^{\hat{P}_0(\omega)t}| \le 1$ for all $t \ge 0$. To estimate

u^{II}, one can apply an energy estimate in a modified L_2-norm if additional conditions are satisfied.

This motivates the following requirement on P_0.

Assumption 4.

a) There is $C_0 > 0$ such that

$$|e^{\hat{P}_0(\omega)t}| \le C_0 \quad \text{for} \quad t \ge 0,\ |\omega| \le 1;$$

b) there is $c_0 > 0$ such that

$$\operatorname{Re}\lambda \le -c_0|\omega|^2 \quad \text{for all} \quad \lambda \in \sigma(\hat{P}_0(\omega)) \quad \text{if } |\omega| \le 1;$$

c) there are $c_1 > 0$ and $C_1 > 0$, and there is a smooth Hermitian matrix function $H(\omega)$ defined for $|\omega| \ge 1$ which satisfies the following three conditions:

1. $\frac{1}{C_1} I \le H(\omega) \le C_1 I$;
2. $\operatorname{Re}(H(\omega)\hat{P}_0(\omega)) \le -c_1 H(\omega)$;
3. $|H(\omega) - I| \le C_1/|\omega|$.

Under Assumptions 4a and 4b, a symmetrizer $H(\omega)$ satisfying the above Assumptions 4c1 and 4c2 can always be constructed by the Kreiss' matrix theorem [3]. Assumption 4c3 adds an additional restriction, which is fulfilled, however, for a large class of operators P_0, for which $u_t = P_0 u$ is hyperbolic with suitable zero-order term or parabolic or coupled parabolic-hyperbolic. We show this in the appendix. For generalizations, where Assumption 4c3 is dropped, see section 4.2.

For the coefficients $B_j(x,t),\ g_j(x,t,u),\ F_j(x,t)$ of (1.1) we make Assumption 3 and a symmetry assumption.

Assumption 5. The coefficients $B_j,\ g_j,\ F_j$ satisfy Assumption 3 and

$$B_j(x,t) = B_j^T(x,t), \quad g_{ju}(x,t,u) = g_{ju}^T(x,t,u)$$
$$\text{for all} \quad x \in \mathbb{R}^d,\ t \ge 0,\ u \in \mathbb{R}^n.$$

First consider (1.1) with $\varepsilon_2 = 0$; i.e., consider the linear equation

$$u_t = P_0 u + \varepsilon_1 \sum_j D_j(B_j u) + \sum_j D_j F_j. \tag{3.5}$$

If u is a solution, we set

$$G_j(x,t) = \varepsilon_1 B_j(x,t)u(x,t) + F_j(x,t)$$

and obtain

$$u_t = P_0 u + \sum_j D_j G_j. \tag{3.6}$$

Then Fourier–Laplace transformation yields

$$(sI - \hat{P}_0)\tilde{u} = i\sum_j \omega_j \tilde{G}_j, \quad s = \eta + i\xi,\ \eta \ge 0. \tag{3.7}$$

For $|\omega| \le 1$, our estimates are based on the following bound of $(sI - \hat{P}_0(\omega))^{-1}$.

LEMMA 3.1. *Consider a symbol $\hat{P}_0(\omega)$ satisfying Assumptions* 4a,b. *There is $C > 0$ so that*

$$|\omega|^2 \int_{-\infty}^{\infty} \left| \left((\eta + i\xi)I - \hat{P}_0 \right)^{-1} \right|^2 d\xi \le C \quad for\ all \quad |\omega| \le 1,\ \eta \ge 0.$$

Proof. By the Kreiss' matrix theorem (see [3]), there is a transformation $S = S(\omega)$ with

$$S^{-1}\hat{P}_0 S = \begin{bmatrix} \lambda_1 & r_{12} & \cdots & r_{1n} \\ & \ddots & \ddots & \vdots \\ & & \ddots & r_{n-1,n} \\ 0 & & & \lambda_n \end{bmatrix},$$

$$|r_{jl}| \le C_1 |\mathrm{Re}\ \lambda_j|, \quad 1 \le j < l \le n, \quad |S| + |S^{-1}| \le C_1.$$

If $\lambda_j = \alpha_j + i\beta_j,\ \alpha_j, \beta_j \in \mathbb{R}$, then we have $\alpha_j \le -c_0|\omega|^2$ by Assumption 4b, and one obtains

$$\left| \left((\eta + i\xi)I - \hat{P}_0 \right)^{-1} \right|^2 \le C_2 \sum_j \frac{1}{(\eta - \alpha_j)^2 + (\xi - \beta_j)^2}\ .$$

Using the bound

$$\eta - \alpha_j \ge c_0 |\omega|^2,$$

one finds that

$$\int_{-\infty}^{\infty} \frac{d\xi}{(\eta - \alpha_j)^2 + (\xi - \beta_j)^2} \le C_3 |\omega|^{-2}.$$

This proves the lemma.

Recall (3.6) and recall the decomposition $u = u^I + u^{II}$ determined by (1.5). We obtain the following estimate of u^I in terms of G.

LEMMA 3.2. *Let u solve* (3.6) *and let $u = 0$ at $t = 0$; let $\hat{P}_0$ satisfy Assumptions* 4a,b. *Then, for all $p = 0, 1, \ldots$ there is R_p, independent of T and G, with*

$$\int_0^T \|u^I\|_{H^p}^2 dt \le R_p \left\{ M(G, T) + \int_0^T \|G\|^2 dt \right\}. \tag{3.8}$$

Proof. From (3.7) we obtain

$$|\tilde{u}|^2 \le |\omega|^2 |(sI - \hat{P}_0)^{-1}|^2 |\tilde{G}|^2 \tag{3.9}$$

with

$$|\tilde{G}|^2 = \sum_j |\tilde{G}_j|^2 \le M(G, \infty).$$

By Parseval's relation,

$$\int_0^\infty e^{-2\eta t} \|u^I\|^2 dt = \frac{1}{2\pi} \int_{|\omega| \le 1} \int_{-\infty}^{\infty} |\tilde{u}(\omega, \eta + i\xi)|^2 d\xi\, d\omega.$$

Using estimate (3.9) and the previous lemma, we obtain

$$\int_0^\infty \|u^I\|^2 dt \le C\ M(G,\infty).$$

Estimates for $D^\alpha u^I$ are then obtained in the same way as in the proof of Theorem 2.1. Since values $G(x,t)$ for $t > T$ do not change the solution $u(x,t)$ for $t \le T$, we may replace $T = \infty$ by any finite T. This proves the lemma.

Now recall our assumption that u solves the linear equation (3.5), and we have defined

$$G_j = \varepsilon_1 B_j u + F_j, \quad j = 1, \dots, d$$

to derive (3.6). Let us denote

$$|||\ B|||^{\ 2} = \int_0^\infty \|B(\cdot,t)\|^2 dt$$

and

$$|B|_\infty = \sup\big\{|B(x,t)|\ :\ x \in \mathbb{R}^d,\ t \ge 0\big\}.$$

We want to replace G on the right side of (3.8) by $G = \varepsilon_1 Bu + F$. First note

$$\Big(\int_0^\infty \int_{\mathbb{R}^d} |G_j| dx\, dt\Big)^2 \le 2\varepsilon_1^2 \Big(\int_0^\infty \int_{\mathbb{R}^d} |B_j|\, |u| dx\, dt\Big)^2 + 2\Big(\int_0^\infty \int_{\mathbb{R}^d} |F_j| dx\, dt\Big)^2$$

$$\le 2\varepsilon_1^2 |||\ B|||^{\ 2} \int_0^\infty \|u\|^2 dt + 2M(F,\infty).$$

Furthermore,

$$\int_0^\infty \|G\|^2 dt \le 2\varepsilon_1^2 |B|_\infty^2 \int_0^\infty \|u\|^2 dt + 2\int_0^\infty \|F\|^2 dt.$$

Substituting these estimates into (3.8), one obtains the following result.

LEMMA 3.3. *Let u solve (3.5), $u = 0$ at $t = 0$. For all $p = 0, 1, \dots$ there is R_p, depending only on p and P_0, such that*

$$\int_0^T \|u^I\|_{H^p}^2 dt \le R_p \left\{ M(F,T) + \int_0^T \|F\|^2 dt \right\} + \varepsilon_1^2 R_p C_B \int_0^T \|u^{II}\|^2 dt.$$

Here $C_B = |||\ B|||^2 + |B|_\infty^2$, and it is assumed that

$$\varepsilon_1^2 R_p C_B \le \frac{1}{4}.$$

Now we estimate the u^{II}-part of the solution u of (3.5). Recall the properties of the symmetrizer $H(\omega)$ for $|\omega| \ge 1$, formulated in Assumption 4c. We set

$$H(\omega) = I \quad \text{for} \quad |\omega| < 1$$

and introduce a new inner product on $L_2 = L_2(\mathbb{R}^d; \mathbb{R}^n)$ by

$$(u, v)_{\mathcal{H}} = \int_{\mathbb{R}^d} \hat{u}^*(\omega) H(\omega) \hat{v}(\omega) d\omega.$$

The corresponding norm is

$$\|u\|_{\mathcal{H}} = (u, u)_{\mathcal{H}}^{1/2}.$$

The following result is an immediate consequence of the properties of $H(\omega)$ and Parseval's relation.

LEMMA 3.4.

a) $\frac{1}{C_1}\|u\|^2 \le \|u\|_{\mathcal{H}}^2 \le C_1\|u\|^2 \quad for\ all\ u \in L_2$;

b) $Re\,(u^{II}, P_0 u^{II})_{\mathcal{H}} \le -c_1 \|u^{II}\|_{\mathcal{H}}^2 \quad for\ all\ u \in H^m$;

c) $|(u, D_j v) - (u, D_j v)_{\mathcal{H}}| \le \text{const.}\|u\|\ \|v\| \quad for\ all\ u \in L_2,\ v \in H^1,\ j = 1, \dots, d.$

Our basic energy estimate for u^{II} is the following.

LEMMA 3.5. *Let u solve* (3.5) *and recall Assumptions* 4c, 5. *Then we have*

$$\frac{d}{dt}\|u^{II}\|_{\mathcal{H}}^2 \le -\frac{3}{2} c_1 \|u^{II}\|_{\mathcal{H}}^2 + C_0 \|F\|_{H^1}^2 + \varepsilon_1^2 C_B \|u^I\|^2$$

for $|\varepsilon_1| \le \varepsilon_0(B)$. The constant $c_1 > 0$ is the same as the constant c_1 in Lemma 4b*; the constant C_0 depends only on P_0; the constants $\varepsilon_0(B) > 0$ and C_B depend on $|B|_\infty + |DB|_\infty$, where*

$$|B|_\infty = \sup\big\{|B(x,t)| \ :\ x \in \mathbb{R}^d,\ t \ge 0\big\},$$
$$|DB|_\infty = \max_j \ \sup\Big\{|D_j B_j(x,t)| \ :\ x \in \mathbb{R}^d,\ t \ge 0\Big\}.$$

Proof. We have

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|u^{II}\|_{\mathcal{H}}^2 &= \operatorname{Re}(u^{II}, u_t^{II})_{\mathcal{H}} \\ &= \operatorname{Re}(u^{II}, u_t)_{\mathcal{H}} \\ &= \operatorname{Re}(u^{II}, P_0 u^{II})_{\mathcal{H}} \\ &\quad + \sum_j \operatorname{Re}(u^{II}, D_j F_j)_{\mathcal{H}}.\end{aligned}$$

Here

$$\operatorname{Re}(u^{II}, P_0 u^{II})_{\mathcal{H}} \le -c_1 \|u^{II}\|_{\mathcal{H}}^2,$$

by Lemma 3.4b. The remaining terms on the right side of the above equality are estimated as follows.

First note

$$\begin{aligned}|(u^{II}, D_j F_j)_{\mathcal{H}}| &\le \text{ const. } \|u^{II}\|\ \|F\|_{H^1} \\ &\le \mu \|u^{II}\|^2 + \frac{C}{\mu}\|F\|_{H^1}^2\end{aligned}$$

for any $\mu > 0$. The term

$$\mathrm{Re}\,(u^{II}, D_j(B_j u))_{\mathcal{H}}, \quad u = u^I + u^{II},$$

is estimated in two parts. Since $\|D_j u^I\| \le \|u^I\|$, we have that

$$\begin{aligned}\left|\left(u^{II}, D_j(B_j u^I)\right)_{\mathcal{H}}\right| &\le C\|u^{II}\|\Big\{|B|_\infty + |DB|_\infty\Big\}\|u^I\| \\ &\le \mu\|u^{II}\|^2 + \frac{C_B}{\mu}\|u^I\|^2 \quad \text{for any } \mu > 0.\end{aligned}$$

Furthermore, to estimate

$$T_j := \mathrm{Re}\,(u^{II}, D_j(B_j u^{II}))_{\mathcal{H}}$$

we apply Lemma 3.4c to obtain

$$\begin{aligned}T_j &= \mathrm{Re}\,(u^{II}, D_j(B_j u^{II})) + T_j', \\ |T_j'| &\le C|B|_\infty\|u^{II}\|^2.\end{aligned}$$

Using integration by parts and the symmetry of B_j we also have

$$\left|\mathrm{Re}\left(u^{II}, D_j(B_j u^{II})\right)\right| \le \frac{1}{2}|DB|_\infty\|u^{II}\|^2.$$

To summarize, we have shown that

$$\begin{aligned}\frac{d}{dt}\|u^{II}\|_{\mathcal{H}}^2 \le -2c_1\|u^{II}\|_{\mathcal{H}}^2 + +\mu\|u^{II}\|^2 + \frac{1}{\mu}C\|F\|_{H^1}^2 \\ + \mu\|u^{II}\|^2 + \frac{\varepsilon_1^2}{\mu}C_B\,\|u^I\|^2 + |\varepsilon_1|C_B\,\|u^{II}\|^2.\end{aligned}$$

Choosing $\mu > 0$ sufficiently small, the result follows.

The basic energy estimate formulated in the previous lemma will now be used to derive similar estimates for space derivatives $D^\alpha u^{II}$. Applying D^α to (3.5), we obtain

$$D^\alpha u_t = P_0 D^\alpha u + \varepsilon_1 \sum_j D_j(B_j D^\alpha u) + \varepsilon_1 \sum_j D_j\Phi_j + \sum_j D_j D^\alpha F_j$$

with[1]

$$\Phi_j = D^\alpha(B_j u) - B_j(D^\alpha u) = \sum_{\beta<\alpha} c_{\alpha\beta}(D^{\alpha-\beta}B_j)D^\beta u. \tag{3.10}$$

Let us define

$$\|u\|_{p,\mathcal{H}}^2 = \sum_{|\alpha|\le p}\|D^\alpha u\|_{\mathcal{H}}^2.$$

[1]We use the notation $\beta < \alpha$ to mean $\beta_j \le \alpha_j$ for $j = 1, \dots, d$ with at least one strict inequality.

We will show the following generalization of the previous lemma.

LEMMA 3.6. *Let u solve* (3.5) *and recall Assumptions* 4c, 5. *For any $p = 0, 1, \ldots$ we have*

$$\frac{d}{dt}\|u^{II}\|^2_{p,\mathcal{H}} \le -c_1\|u^{II}\|^2_{p,\mathcal{H}} + C_p\|F\|^2_{H^{p+1}} + \varepsilon_1^2 C(B,p)\|u^I\|^2$$

for $|\varepsilon_1| \le \varepsilon_0(B,p)$. The constant $c_1 > 0$ is the same as the constant c_1 in Lemma 4b*; the constant C_p depends only on p and P_0; the constants $\varepsilon_0(B,p) > 0$ and $C(B,p)$ are independent of F.*

Proof. Let $|\alpha| \le p$. We apply Lemma 3.5 (with F replaced by $D^\alpha F + \varepsilon_1\Phi$) to obtain

$$\frac{d}{dt}\|D^\alpha u^{II}\|^2_{\mathcal{H}} \le -\frac{3c_1}{2}\|D^\alpha u^{II}\|^2_{\mathcal{H}} + C_1\Big\{\|D^\alpha F\|^2_{H^1} + \varepsilon_1^2\|\Phi\|^2_{H^1}\Big\} + \varepsilon_1^2 C_B\,\|u^I\|^2.$$

(Note that $\|D^\alpha u^I\| \le \|u^I\|$.) The main point is that Φ_j only contains derivatives of u of order $\le p-1$, and the coefficients $D^{\alpha-\beta}B_j$ in (3.10) are uniformly bounded. Therefore,

$$\|\Phi\|_{H^1} \le C(B,p)\|u\|_{H^p}.$$

Adding the resulting estimates of $(d/dt)\|D^\alpha u^{II}\|^2_{\mathcal{H}}$ for $|\alpha| \le p$, the lemma follows.

We now combine the estimates derived in Lemma 3.3 for u^I and in Lemma 3.6 for u^{II} and prove the following result.

THEOREM 3.7. *Consider the linear problem* (3.5) *with $u = 0$ at $t = 0$ and recall Assumptions* 4 *and* 5. *For any $p = 0, 1, \ldots$ there are positive constants $\varepsilon_0 = \varepsilon_0(B,p) > 0$ and R_p so that*

$$\int_0^\infty \Big\{\|u\|^2_{H^{p+m}} + \|u_t\|^2_{H^p}\Big\}dt \le R_p\Big\{M(F,\infty)dt\Big\}$$

if $|\varepsilon_1| \le \varepsilon_0(B,p)$. The constant R_p depends only on p and P_0. (In the above estimate, m is the order of P_0, or $m = 1$ if P_0 has order zero.) Consequently,

$$\lim_{t\to\infty} |u(\cdot,t)| = 0.$$

Proof. Let us abbreviate

$$\begin{aligned} y_1(t) &= \|u^I(\cdot,t)\|^2_{H^p},\\ y_2(t) &= \|u^{II}(\cdot,t)\|^2_{p,\mathcal{H}},\\ C_F &= M(F,\infty) + \int_0^\infty \|F(\cdot,t)\|^2 dt,\\ f(t) &= \|F(\cdot,t)\|^2_{H^{p+1}}. \end{aligned}$$

Then we have shown that there are positive constants $C = C(B,p), R_p$, and $\varepsilon_0 = \varepsilon_0(B,p)$ so that, for $|\varepsilon_1| \le \varepsilon_0$,

$$\begin{aligned} &\int_0^\infty y_1 dt \le R_p C_F + \varepsilon_1^2 C\int_0^\infty y_2 dt,\\ &\frac{d}{dt}y_2 \le -c_1 y_2 + R_p f + \varepsilon_1^2 C y_1. \end{aligned} \tag{3.11}$$

Since $y_2(0) = 0$ we obtain that

$$y_2(t) \le R_p \int_0^t e^{-c_1(t-\tau)} f(\tau) d\tau + \varepsilon_1^2 C \int_0^t e^{-c_1(t-\tau)} y_1(\tau) d\tau,$$

and, therefore,

$$\int_0^\infty y_2(t) dt \le R_p \int_0^\infty \int_0^t e^{-c_1(t-\tau)} f(\tau) d\tau dt + \varepsilon_1^2 C \int_0^\infty \int_0^t e^{-c_1(t-\tau)} y_1(\tau) d\tau dt.$$

Clearly,

$$\begin{aligned} \int_0^\infty \int_0^t e^{-c_1(t-\tau)} f(\tau) d\tau dt &= \int_0^\infty \int_\tau^\infty e^{-c_1(t-\tau)} f(\tau) dt d\tau \\ &\le \frac{1}{c_1} \int_0^\infty f(\tau) d\tau, \end{aligned}$$

and in the same way

$$\int_0^\infty \int_0^t e^{-c_1(t-\tau)} y_1(\tau) d\tau dt \le \frac{1}{c_1} \int_0^\infty y_1(\tau) d\tau.$$

This proves the estimate

$$\int_0^\infty y_2 dt \le \frac{R_p}{c_1} \int_0^\infty f dt + \varepsilon_1^2 \frac{C}{c_1} \int_0^\infty y_1 dt. \tag{3.12}$$

By adding the inequalities (3.11) and (3.12) and using the equivalence of the norms $\|\cdot\|_{H^p}$ and $\|\cdot\|_{p,\mathcal{H}}$, we have shown

$$\int_0^\infty \|u\|_{H^p}^2 dt \le R_p' \left\{ M(F, \infty) + \int_0^\infty \|F\|_{H^{p+1}}^2 dt \right\} \tag{3.13}$$

for $|\varepsilon_1| \le \varepsilon_0(B, p)$. To estimate $D^\alpha u_t$, we use the differential equation (3.5) to replace u_t. This gives us

$$\|u_t\|_{H^p}^2 \le C \Big\{ \|u\|_{H^{p+m}}^2 + \|F\|_{H^{p+1}}^2 \Big\}.$$

Integrating in time and applying (3.13) with p replaced by $p + m$, we obtain the desired estimate. Convergence of u to zero as $t \to \infty$ follows as before when $p > d/2$. This finishes the proof of the theorem.

Now consider the nonlinear problem (1.1), (1.2). By combining the techniques to prove Theorems 2 and 3, we show nonlinear stability.

THEOREM 3.8. *Consider the nonlinear problem* (1.1) *with* $u = 0$ *at* $t = 0$ *and recall Assumptions* 4 *and* 5. *There exists* $\varepsilon_0 > 0$ *so that the solution is* C^∞ *if* $\varepsilon_1^2 + \varepsilon_2^2 \le \varepsilon_0$. *Furthermore,*

$$\lim_{t \to \infty} |u(\cdot, t)| = 0.$$

Proof. Let κ denote a large constant to be determined below. Fix $\varepsilon_1, \varepsilon_2$ and let $u = u(x,t,\varepsilon_1,\varepsilon_2)$ denote the solution of (1.1), (1.2). Suppose there exists $T = T(\kappa,\varepsilon_1,\varepsilon_2)$ with

$$\int_0^T \Big\{ \|u\|^2_{H^{p+m}} + \|u_t\|^2_{H^p} \Big\} dt = \kappa. \tag{3.14}$$

Here $p = m + d + 2$; the number m is the order of P_0, or $m = 1$ if P_0 has order zero. In the following, C denotes a constant independent of $\varepsilon_1, \varepsilon_2, T, \kappa$; also, C_κ denotes a constant independent of $\varepsilon_1, \varepsilon_2$, and T, which may, however, depend on κ. The values of C and C_κ may change at different occurrences.

By Sobolev's inequality, there is C such that

$$\|D^\alpha u\|^2_{\infty,T} \le C\kappa \quad \text{if} \quad |\alpha| + \frac{d}{2} < p.$$

We abbreviate

$$\begin{aligned} y_1(t) &= \|u^I(\cdot,t)\|^2_{H^{p+m}}, \\ y_2(t) &= \|u^{II}(\cdot,t)\|^2_{p+m,\mathcal{H}}, \\ C_F &= M(F,\infty) + \int_0^\infty \|F(\cdot,t)\|^2 dt, \\ f(t) &= \|F(\cdot,t)\|^2_{H^{p+m+1}}. \end{aligned}$$

To estimate u^I, note that u satisfies

$$u_t = P_0 u + \sum_j D_j Y_j$$

with

$$Y_j = F_j + \varepsilon_1 B_j u + \varepsilon_2 G_j, \quad G_j(x,t) = g_j(x,t,u(x,t)).$$

We obtain by Lemma 2,

$$\begin{aligned} \int_0^T y_1 dt &\le R_{p+m} \Big\{ M(F + \varepsilon_1 Bu + \varepsilon_2 G, T) + \int_0^T \|F + \varepsilon_1 Bu + \varepsilon_2 G\|^2 dt \Big\} \\ &\le C C_F + (\varepsilon_1^2 + \varepsilon_2^2) C_\kappa. \end{aligned} \tag{3.15}$$

The last estimate follows as in the proof of Theorem 2.

To estimate u^{II}, we use $\|\cdot\|_{\mathcal{H}}$. For $1 \le |\alpha| \le p+m$ the function $D^\alpha u$ satisfies

$$\begin{aligned} D^\alpha u_t = P_0 D^\alpha u &+ \varepsilon_1 \sum_j D_j (B_j D^\alpha u) \\ &+ \varepsilon_2 \sum_j D_j (g_{ju} D^\alpha u) + \varepsilon_1 \sum_j D_j \Phi_j \\ &+ \varepsilon_2 \sum_j D_j \Psi_j + \sum D_j D^\alpha F_j. \end{aligned}$$

Here Φ_j is given in (3.10) and

$$\Psi_j = D^\alpha G_j - g_{ju} D^\alpha u$$

is a sum of terms

$$\psi_j(x,t,\alpha,\sigma) D^{\sigma_1} u \cdots D^{\sigma_r} u$$

where

$$|\sigma_1| + \cdots + |\sigma_r| \le p+m, \quad |\sigma_j| < p+m,\ j = 1, \ldots, r.$$

The function $\psi_j(x,t,\alpha,\sigma)$ is a derivative $D_x^\beta D_u^\gamma g_j$ evaluated at $(x,t,u(x,t))$. To estimate $D^\alpha u^{II}$ we apply Lemma 5 with $\varepsilon_1 B_j$ replaced by $\varepsilon_1 B_j + \varepsilon_2 g_{ju}$, and F replaced by $D^\alpha F + \varepsilon_1 \Phi + \varepsilon_2 \Psi$. This yields

$$\frac{d}{dt}\|D^\alpha u^{II}\|_{\mathcal{H}}^2 \le -\frac{3}{2} c_1 \|D^\alpha u^{II}\|_{\mathcal{H}}^2 + C\|D^\alpha F + \varepsilon_1 \Phi + \varepsilon_2 \Psi\|_{H^1}^2 + (\varepsilon_1^2 + \varepsilon_2^2) C_\kappa \|u^I\|^2.$$

Here $\|\Phi\|_{H^1} \le C\|u\|_{H^{p+m}}$ and $\|\Psi\|_{H^1} \le C_\kappa \|u\|_{H^{p+m}}$. The estimate of Ψ follows as in the proof of Theorem 2. (The main point is that all derivatives of u occurring in Ψ_j are of order strictly less than $p+m$. Also, $D_j \Psi_j$ is a sum of terms

$$\rho_j(x,t,\alpha,\sigma) D^{\sigma_1} u \cdots D^{\sigma_r} u$$

with

$$|\sigma_1| + \cdots + |\sigma_r| \le p+m+1.$$

If there were two factors, $D^{\sigma_1} u$ and $D^{\sigma_2} u$, say, which cannot be estimated in sup-norm in terms of κ, then

$$|\sigma_1| + \frac{d}{2} \ge p, \quad |\sigma_2| + \frac{d}{2} \ge p;$$

thus

$$p + m + 1 + d \ge |\sigma_1| + |\sigma_2| + d \ge 2p.$$

This contradicts our choice of $p = m + d + 2$.)

An estimate for

$$\frac{d}{dt}\|u^{II}\|_{\mathcal{H}}^2$$

(where u^{II} is undifferentiated), can also be obtained from Lemma 5 with $\varepsilon_2 g_j$ included as forcing term. Adding the resulting estimates for $|\alpha| \le p+m$, one obtains

$$\frac{d}{dt} y_2 \le -c_1 y_2 + Cf + (\varepsilon_1^2 + \varepsilon_2^2) C_\kappa \|u^I\|^2$$

for $\varepsilon_1^2 + \varepsilon_2^2 \le \varepsilon_0(\kappa)$. As in the proof of Theorem 3 we find

$$\int_0^T y_2 dt \le C \int_0^T f dt + (\varepsilon_1^2 + \varepsilon_2^2) C_\kappa. \tag{3.16}$$

Adding the estimates (3.15) and (3.16), we have shown that

$$\int_0^T \|u\|^2_{H^{p+m}} dt \le C\left(C_F + \int_0^T f dt\right) + (\varepsilon_1^2+\varepsilon_2^2)C_\kappa \tag{3.17}$$

for $\varepsilon_1^2+\varepsilon_2^2 \le \varepsilon_0(\kappa)$. We now use the differential equation (1.1) to estimate the H^p-norm of u_t. This yields

$$\|u_t\|^2_{H^p} \le C\|u\|^2_{H^{p+m}} + C\|F\|^2_{H^{p+1}} + (\varepsilon_1^2+\varepsilon_2^2)C_\kappa \|u\|^2_{H^{p+1}}.$$

Integrating in time and using (3.17) one finds

$$\int_0^T \left\{\|u\|^2_{H^{p+m}} + \|u_t\|^2_{H^p}\right\} dt \le C\left\{M(F,\infty) + \int_0^\infty \|F\|^2_{H^{p+m+1}} dt\right\} + (\varepsilon_1^2+\varepsilon_2^2)C_\kappa. \tag{3.18}$$

Therefore, we choose

$$\kappa = 1 + C\left\{M(F,\infty) + \int_0^\infty \|F\|^2_{H^{p+m+1}} dt\right\}$$

and let

$$(\varepsilon_1^2+\varepsilon_2^2)C_\kappa \le \frac{1}{2}.$$

Then the estimate (3.18) shows that a finite T with (3.14) does not exist. The remaining arguments are the same as in the proof of Theorem 2.

Remark. The more direct approach to estimate the time derivative u_t, which we have used in section 2, does not seem possible under the assumptions of section 3.

4. Discussion, conjecture.

4.1. Discussion of Assumption 3. To illustrate our assumption of the specific form of the Cauchy problem (1.1), (1.2) and our general Assumption 3 for $B_j(x,t), g_j(x,t,u), F_j(x,t)$, we consider a system

$$u_t = P_0 u + \sum_j D_j f_j(u), \tag{4.1}$$

where P_0 has constant coefficients and the $f_j : \mathbb{R}^n \to \mathbb{R}^n$ are smooth functions vanishing quadratically at $u = 0$. Thus, $u \equiv 0$ is a stationary solution. We consider (4.1) with small initial data,

$$u(x,0) = \varepsilon U_0(x), \quad U_0 \in C^\infty.$$

Requirements for U_0 will be derived below. For simplicity of presentation, let us assume that $f_j(u)$ is quadratic in u, i.e.,

$$f_j(u) = Q_j(u,u),$$

where $Q_j : \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}^n$ is bilinear. If we write $u(x,t) = \varepsilon v(x,t)$, then (4.1) becomes

$$v_t = P_0 v + \varepsilon \sum_j D_j f_j(v), \quad v(x,0) = U_0(x). \tag{4.2}$$

To enforce homogeneous initial data and Assumption 3b, we set

$$\bar{v}(x,t) = e^{-t}(U_0(x) + tV_0(x)),$$

where V_0 will be determined below. Then we define a new variable $w(x,t)$ by $v = \bar{v} + w$ and obtain from (4.2),

$$w_t = P_0 w + \varepsilon \sum_j D_j\big(Q_j(\bar{v}, w) + Q_j(w, \bar{v})\big) + \varepsilon \sum_j D_j f_j(w) + E(x,t)$$

with the forcing function

$$E(x,t) = P_0\bar{v} - \bar{v}_t + \varepsilon \sum_j D_j f_j(\bar{v}).$$

At $t = 0$ we have

$$E(x,0) = P_0 U_0 + U_0 - V_0 + \varepsilon \sum_j D_j f_j(U_0).$$

Thus, we can enforce $E(x,0) \equiv 0$ by a proper choice of V_0. Also, if the initial function $U_0(x)$ has the form

$$U_0(x) = \sum_j D_j U_{0j}(x), \quad U_{0j} \in C^\infty,$$

and we construct $V_0 = \sum_j D_j V_{0j}$ correspondingly, then

$$E = \sum_j D_j F_j(x,t) \quad \text{with} \quad F_j(x,0) \equiv 0.$$

It is not difficult to verify Assumption 3 for the resulting system for w if, for example,

$$D^\alpha U_{0j} \in L_1 \cap L_\infty, \quad j = 1, \dots, d,$$

for all α.

4.2. Conjecture. We assume here that $u_t = P_0 u$ is a coupled parabolic-hyperbolic system and write P_0 in the form

$$P_0 = \sum_{j,l=1}^{d} B_{jl} D_j D_l + \sum_{j=1}^{d} A_j D_j + L$$

with $B_{j,l}, A_j, L \in \mathbb{R}^{n\times n}$. The symbol of P_0 is

$$\hat{P}_0(\omega) = -B(\omega) + iA(\omega) + L$$

with

$$B(\omega) = \sum_{j,l=1}^{d} B_{jl}\omega_j\omega_l, \quad A(\omega) = \sum_{j=1}^{d} A_j\omega_j.$$

If $u_t = P_0 u$ is not parabolic, then the results of section 2 do not apply, and the results of section 3 require symmetry of $B_j(x,t)$ and $g_{ju}(x,t,u)$. We want to relax the symmetry requirement and formulate the following conditions on $\hat{P}_0(\omega)$.

Assumption 6.
a) There are positive constants C_0, c_0 such that

$$|e^{\hat{P}_0(\omega)t}| \le C_0 \quad \operatorname{Re}\lambda \le -c_0 \frac{|\omega|^2}{1+|\omega|^2} \text{ for all } \lambda \in \sigma(\hat{P}_0(\omega)).$$

b) There is a constant $c_1 > 0$ and, for every ω with $|\omega| = 1$, there is a nonsingular transformation $T(\omega)$ such that

$$T^{-1}(\omega)B(\omega)T(\omega) = \begin{pmatrix} B_1(\omega) & 0 \\ 0 & 0 \end{pmatrix}, \quad B_1 + B_1^* \ge 2c_1 I.$$

c) For $|\omega| = 1$, write

$$T^{-1}(\omega)A(\omega)T(\omega) = \begin{pmatrix} A_{11}(\omega) & A_{12}(\omega) \\ A_{21}(\omega) & A_{22}(\omega) \end{pmatrix},$$

where $T^{-1}AT$ has the same block structure as $T^{-1}BT$. Then the eigenvalues of $A_{22}(\omega)$ are real and distinct. *(*$A_{22}(\omega)$ defines a strictly hyperbolic pseudodifferential operator.)

We conjecture that the same conclusion as formulated in Theorem 2 is valid for the nonlinear problem (1.1), (1.2) if we make our general Assumption 3 for B_j, g_j, F_j. Thus, in contrast to our assumptions in section 3, we do *not* require *symmetry* of B_j, g_{ju} to obtain nonlinear stability.

We also conjecture that the assumption of strict hyperbolicity can be weakened as follows. If we set

$$\Psi(x,t,u,\omega,\varepsilon_1,\varepsilon_2) = \varepsilon_1 \sum_j \omega_j B_j(x,t) + \varepsilon_2 \sum_j \omega_j g_{ju}(x,t,u)$$

and, similarly as above, define the block Ψ_{22} by

$$T^{-1}(\omega)\Psi T(\omega) = \begin{pmatrix} \Psi_{11} & \Psi_{12} \\ \Psi_{21} & \Psi_{22} \end{pmatrix},$$

then we require that all eigenvalues of

$$A_{22}(\omega) + \Psi_{22}(x,t,u,\omega,\varepsilon_1,\varepsilon_2)$$

are real and have constant multiplicity for $\varepsilon_1^2 + \varepsilon_2^2$ small.

5. Appendix. Consider a constant coefficient operator

$$P = \sum_{j,l=1}^{d} B_{jl} D_j D_l + \sum_{j=1}^{d} A_j D_j + L \tag{5.1}$$

with $B_{jl}, A_j, L \in \mathbb{C}^{n\times n}$. The symbol of P is

$$\hat{P} = \hat{P}(\omega) = -B(\omega) + iA(\omega) + L, \quad \omega \in \mathbb{R}^d,$$

with

$$B(\omega) = \sum_{j,l=1}^{d} B_{jl}\omega_j\omega_l, \quad A(\omega) = \sum_{j=1}^{d} A_j\omega_j.$$

We make the following assumptions.

Assumption 7.

a) $A_j = A_j^*, \quad j = 1, \dots, d;$

b) for all $\omega^0 \in \mathbb{R}^d$ with $|\omega^0| = 1$ there is a unitary transformation $U = U(\omega^0)$ with

$$U^* B(\omega^0) U = \begin{bmatrix} B_1(\omega^0) & 0 \\ 0 & 0 \end{bmatrix}, \quad B_1 + B_1^* > 0;$$

c) there is a unitary transformation V with

$$V^* L V = \begin{bmatrix} L_1 & 0 \\ 0 & 0 \end{bmatrix}, \quad L_1 + L_1^* < 0;$$

d) for all $\omega^0 \in \mathbb{R}^d$ with $|\omega^0| = 1$ and all $\varphi \in \mathbb{C}^n$, the following holds. If

$$B(\omega^0)\varphi = L\varphi = 0,$$

then φ is not an eigenvector of $A(\omega_0)$.

Remarks. 1) Assumption 7b allows for $B(\omega^0) = 0$; the condition $B_1 + B_1^* > 0$ is only required if the block B_1 is not empty. A similar remark applies to L. In particular, the conditions allow for $B(\omega) \equiv 0$ (the hyperbolic case) or $L = 0$ (the case without zero order term).

2) For $L = 0$, condition 7d is called *interaction condition* in [1] since it requires interaction of the characteristic variables of the symmetric hyperbolic system $u_t = \sum_j A_j D_j u$ with the parabolic part of the whole system.

3) For real symmetric B_{jl} and L, the conditions are also used in [6].

THEOREM 5.1. *If P has the form* (5.1) *and satisfies Assumption* 7*, then P satisfies Assumption* 4.

Proof. 1) First fix $\omega^0 \in \mathbb{R}^d$ with $|\omega^0| = 1$ and abbreviate

$$A = \sum_{j=1}^{d} A_j \omega_j^0, \quad B = \sum_{j,l=1}^{d} B_{jl} \omega_j^0 \omega_l^0,$$
$$\hat{P} = \hat{P}(\omega^0) = -B + iA + L.$$

Let

$$\hat{P}\varphi = \lambda\varphi, \quad |\varphi| = 1.$$

Then we have

$$\varphi^*(\hat{P} + \hat{P}^*)\varphi = 2 \operatorname{Re} \lambda,$$

and, since

$$\hat{P} + \hat{P}^* = -(B + B^*) + L + L^* \le 0,$$

it follows that $\operatorname{Re} \lambda \le 0$.

Suppose that $\operatorname{Re} \lambda = 0$; then

$$\varphi^*(B + B^*)\varphi = \varphi^*(L + L^*)\varphi = 0.$$

This would imply $B\varphi = L\varphi = 0$. Since $\hat{P}\varphi = \lambda\varphi$, it would follow that φ is an eigenvector of A, in contradiction to Assumption 7d. Therefore, $\operatorname{Re}\lambda < 0$ for all eigenvalues of $\hat{P}(\omega^0),\ |\omega^0| = 1$.

2) Using a well-known construction[2] (see, e.g., [3]), one obtains that there are constants $c_0 > 0,\ C_0 > 0$ and, for every ω^0 with $|\omega^0| = 1$, there is a Hermitian matrix $H_0 = H_0(\omega^0)$ such that

$$H_0\hat{P}(i\omega^0) + \hat{P}^*(i\omega^0)H_0 \le -c_0 H_0, \tag{5.2}$$
$$0 < \frac{1}{C_0} I \le H_0 \le C_0 I.$$

The function $H_0(\omega^0)$ can be constructed as a C^∞-function on the unit sphere $|\omega^0| = 1$ in $\mathbb{R}^d$.

3) We now construct $H(\omega)$ for $|\omega| \ge 1$ as follows. Let

$$\omega = \varrho\omega^0, \quad |\omega^0| = 1, \quad \varrho = |\omega|,$$
$$\hat{P} = \hat{P}(\omega) = -\varrho^2 B + i\varrho A + L,$$
$$\hat{P}_0 = \hat{P}(\omega^0) = -B + iA + L.$$

We set

$$H(\omega) = I + \frac{\alpha}{\varrho} H_0(\omega^0),$$

where $\alpha > 0$ will be determined below as a sufficiently small constant. Then we have

$$\begin{aligned} H\hat{P} + \hat{P}^*H &= -\varrho^2(B + B^*) + L + L^* \\ &\quad -\alpha\varrho(H_0B + B^*H_0) + i\alpha(H_0A + A^*H_0) \\ &\quad +\frac{\alpha}{\varrho}(H_0L + L^*H_0) \\ &= \alpha\left\{H_0\hat{P}_0 + \hat{P}_0^*H_0\right\} + T_1 + T_2 \qquad (5.3) \\ &\le -\alpha c_0 H_0 + T_1 + T_2, \end{aligned}$$

where

$$T_1 = -\varrho^2(B + B^*) + (\alpha - \alpha\varrho)(H_0B + B^*H_0),$$
$$T_2 = L + L^* + \left(\frac{\alpha}{\varrho} - \alpha\right)(H_0L + L^*H_0),$$

and where (5.2) is used in the final estimate.

Assuming first that

$$B = \begin{bmatrix} B_1 & 0 \\ 0 & 0 \end{bmatrix}, \quad B_1 + B_1^* > 0, \tag{5.4}$$

and partitioning

$$\varphi = \begin{bmatrix} \varphi^I \\ \varphi^{II} \end{bmatrix}, \quad \varphi \in \mathbb{C}^n,$$

[2]Using Schur's theorem, there is a transformation $T = UD, D = diag(1, \varepsilon, \dots, \varepsilon^{n-1})$, so that $\operatorname{Re}(T^{-1}\hat{P}(\omega^0)T)) \le -c_0 I < 0$. Then $H_0 = (T^{-1})^*T^{-1}$ satisfies $\operatorname{Re}(H_0\hat{P}(\omega^0)) \le -c_0 H_0$. A partition of unity argument shows that one can construct $H_0(\omega^0)$ as C^∞-function on the unit sphere $|\omega^0| = 1$.

accordingly, one obtains

$$\begin{aligned}\varphi^* T_1 \varphi &\le -c_1 \varrho^2 |\varphi^I|^2 + C_1 \alpha \varrho |\varphi|\, |\varphi^I| \\ &\le -c_1 \varrho^2 |\varphi^I|^2 + \alpha \left\{ \mu |\varphi|^2 + C(\mu) \varrho^2 |\varphi^I|^2 \right\},\end{aligned}$$

for any $\mu > 0$. By first choosing $\mu > 0$ so small that

$$\mu |\varphi|^2 \le \frac{c_0}{4} \varphi^* H_0 \varphi$$

and then choosing $\alpha > 0$ so small that

$$\alpha C(\mu) \le c_1,$$

one obtains

$$\varphi^* T_1 \varphi \le \alpha \frac{c_0}{4} \varphi^* H_0 \varphi.$$

It is easy to see that Assumption (5.4) can be replaced by Assumption 7b. Estimating the term T_2 similarly, one obtains

$$H\hat{P} + \hat{P}^* H \le -\alpha \frac{c_0}{2} H_0 \le -\tilde{c}_0 H, \quad \tilde{c}_0 > 0. \tag{5.5}$$

This finishes the construction of $H(\omega)$ for $|\omega| \ge 1$ in Assumption 4c.

4) Now consider

$$\hat{P} = -\varrho^2 B + i\varrho A + L$$

for $0 < \varrho \le 1$. We set

$$H(\omega) = H(\varrho \omega^0) = I + \alpha \varrho H_0(\omega^0)$$

and obtain

$$\begin{aligned}H\hat{P} + \hat{P}^* H = \varrho^2 \Big\{ &- (B + B^*) + \varrho^{-2}(L + L^*) - \alpha\varrho (H_0 B + B^* H_0) \\ &+ i\alpha (H_0 A + A^* H_0) + \frac{\alpha}{\varrho} (H_0 L + L^* H_0) \Big\}.\end{aligned}$$

The term in the brackets $\{\dots\}$ agrees exactly with the right side of (5.3) if L and $(-B)$ are exchanged and ϱ is replaced by $1/\varrho$. Therefore, the estimate (5.5) implies

$$H\hat{P} + \hat{P}^* H \le -\tilde{c}_0 \varrho^2 H.$$

Consequently, if λ is an eigenvalue of $\hat{P}$, it follows that

$$2 \operatorname{Re} \lambda \le -\tilde{c}_0 \varrho^2.$$

Furthermore, the proven estimates

$$H\hat{P} + \hat{P}^* H \le 0,$$

together with the uniform bounds

$$0 < \frac{1}{C} I \le H \le CI,$$

imply

$$\left| e^{\hat{P}t} \right| \le K, \quad t \ge 0.$$

This finishes the proof of the theorem.

MATHEMATICAL ANALYSIS FOR RESERVOIR MODELS*

ZHANGXIN CHEN† AND RICHARD EWING‡

Abstract. In the first part of this paper, the mathematical analysis is presented in detail for the single-phase, miscible displacement of one fluid by another in a porous medium. It is shown that initial boundary value problems with various boundary conditions for this miscible displacement possess a weak solution under physically reasonable hypotheses on the data. In the second part of this paper, it is proven how the analysis can be extended to two-phase fluid flow and transport equations in a porous medium. The flow equations are written in a fractional flow formulation so that a degenerate elliptic-parabolic partial differential system is produced for a global pressure and a saturation. This degenerate system is coupled to a parabolic transport equation which models the concentration of one of the fluids. The analysis here does not utilize any regularized problem; a weak solution is obtained as a limit of solutions to discrete time problems.

Key words. porous medium, flow and transport, elliptic-parabolic system, degenerate equations, existence

1. Introduction.

Multiphase flow and transport of fluids in porous media is of importance socially and economically in a number of applications. For example, petroleum engineers have been interested in efficient recovery of energy resources, and hydrologists have been concerned with improvement of groundwater resource utilization for many years. Unfortunately, despite the great progress made in development of physical models of multiphase flow and transport of fluids in porous media, there has been limited mathematical theory behind these models. The difficulty stems from the fact that the equations modeling complex physical phenomena involving both flow and transport of fluids are often coupled systems of nonlinear, time-dependent degenerate partial differential equations. Hence, simplified models have been analyzed in the last 20 years.

The simplest porous media problem corresponds to the flow of a fluid where a whole porous medium is filled with the single fluid (usually gas or oil in petroleum engineering or water in groundwater hydrology). The usual equations for the single-phase flow model are of parabolic type for the fluid density or pressure and are well understood (see, e.g., [5, 8]).

A more complex case involves the single-phase, miscible displacement of one fluid by another in a porous medium. Under the assumption that no volume change results from the mixing of the two fluids, a coupled, nonlinear differential system of two equations is often utilized for this miscible displacement problem. One of the equations is of elliptic (respectively, parabolic) type for the fluid pressure if the fluids are incompressible (respectively, compressible), and the other is of parabolic type for the concentration of one fluid. This system is complicated by the facts that the pressure

equation can be degenerate due to the form of the concentration-dependent viscosity and that the transport and diffusion-dispersion coefficients in the concentration equation can be unbounded due to the potentially unbounded fluid velocity.

The miscible displacement problem was first studied by Sammon [20], where a one-dimensional model was theoretically analyzed and the viscosity of the fluid was assumed to be independent of the concentration. The latter assumption decouples the pressure equation from the concentration equation. Mikelić [18] later analyzed a three-dimensional stationary displacement problem. While the viscosity was allowed to be concentration-dependent, it was in fact assumed to be sufficiently close to a constant. Then the pressure and concentration equations were essentially separated so that well-posedness for the stationary problem can be established. Recently, Feng [14] considered a two-dimensional model for the displacement problem. The viscosity can be concentration-dependent, but the analysis was valid only for a two-dimensional problem. Furthermore, the analysis, following Kružkov and Sukorjanskiĭ [16] for two-dimensional two-phase immiscible flow, made use of the corresponding regularized system and required the coefficients of the regularized problem to be bounded uniformly with respect to the regularization parameter. The uniform boundedness is hardly satisfied due to the above mentioned feature for the transport and diffusion-dispersion coefficients. Finally, all the theoretical results in [20, 18, 14] were obtained solely for homogeneous Neumann boundary conditions and without gravity effects. The study of the single-phase, miscible displacement of one incompressible fluid by another from the numerical point of view using finite element methods has been extensively carried out (see, e.g., [12]); the case where the components are assumed to be slightly compressible also has been numerically studied (see, e.g., [13]).

In this paper the miscible displacement of one incompressible fluid by another in a porous medium is further investigated. A time-dependent, three-dimensional displacement problem with various boundary conditions and gravity effects, including mixed nonhomogeneous ones, is shown to possess a weak solution. The viscosity can be concentration-dependent, and the assumptions required on the data in the earlier papers are weakened; only physically reasonable assumptions are made. The analysis makes no use of the corresponding regularized problem; a weak solution is obtained as a limit of solutions to discrete time problems. It follows Alt and Luckhaus [3] for treating quasilinear elliptic-parabolic differential equations. The technique was later exploited by Alt and di Benedetto [2] and Arbogast [6] for handling the two-phase immiscible flow problem. However, we point out that the miscible displacement problem is different from the two-phase immiscible problem due to the above-mentioned difficulties. In particular, in the present problem special care must be taken on the transport and diffusion-dispersion coefficients in the concentration equation. We introduce here a solution-dependent space to handle this difficulty.

The above two cases deal with single-phase flow. Two-phase flow is more complex and is of greater practical interest. This case corresponds to the so-called secondary recovery in petroleum reservoirs where two fluid phases (usually water and oil) flow simultaneously, or to the fluid movement in an air-water porous media system in groundwater hydrology. In the last two decades, a considerable amount of effort has been made solely in the analysis of flow equations of two-phase incompressible, immiscible type. Transport equations have not been handled for the two-phase system. Existence of weak solutions for the flow equations has been established under various assumptions on physical data (see, e.g., [5, 16, 8, 15, 2, 6]). Numerical analyses of the flow equations of compressible type using finite elements have been carried out in [9, 10].

The second part of this paper extends the analysis for the single-phase, miscible displacement of one fluid by another to a two-phase flow and transport system. In addition to a strong coupling between flow and transport equations, the whole differential system combines the above difficulties for the displacement problem with those for the flow equations. In particular, the flow equations are usually degenerate, the number of equations is not known a priori at a given place of a porous medium, and the capillary pressure function is generally unbounded. Here we make an initial attempt to analyze both the flow and the transport equations for a two-phase system using the techniques for the single-phase, miscible displacement problem.

In the next section we consider the single-phase displacement problem. We begin with what is meant by a weak solution. Then we carefully state the assumptions on the physical data required for the major result obtained in this part. Most of this section is devoted to the proof of the major result. In section 3, we extend the results to a two-phase flow system. We shall follow the usual practice [4, 8] to write the flow equations of this system in a fractional flow formulation, i.e., in terms of a saturation and a global pressure so that the elliptic part of the system for this global pressure and the parabolic part for the saturation are separated. The concentration equation is obtained from the usual conservation law.

We end with a remark that uniqueness of the weak solution remains open. This is due to the coupling between the partial differential equations under consideration, which makes it difficult to obtain enough regularity of the solution. When the solution is assumed to have enough regularity (e.g., in the semiclassical sense), the uniqueness can be shown in the usual way [17].

2. Miscible displacement of one fluid by another. In section 2.1 the differential system for the single-phase, miscible displacement of one incompressible fluid by another in a porous medium $\Omega \subset \Re^d$ $(d \leq 3)$ is described. Then in section 2.2 we state the assumptions on the physical data, define what is meant by a weak solution, and state the major result shown in this section. The proof of the major result is presented in section 2.3, and two of the lemmas needed for the major result are proven in section 2.4.

2.1. The differential system. The usual equations describing two-component, incompressible, miscible displacement are given by (see, e.g., [7, 19])

$$\begin{aligned} &-\nabla \cdot \{k(x)(\nabla p - \rho g)/\mu(c)\} = q^I - q^P, \\ &\phi(x)\partial_t c - \nabla \cdot \big(D(u)\nabla c\big) + u \cdot \nabla c + q^I c = \hat{c} q^I \end{aligned} \tag{2.1}$$

for $(x,t) \in \Omega_T \equiv \Omega \times J$ with $J = (0,T]$ $(T > 0)$, where ϕ and k are the porosity and absolute permeability of the porous medium, μ and ρ are the viscosity and density of the fluid mixture, g denotes the gravitational, downward-pointing, constant vector, c indicates the concentration of one of the two components, p is the pressure of the fluid, D is the diffusion-dispersion coefficient, $\hat{c}$ is the injected concentration, q^I and q^P represent the sum of injection well source terms and production well sink terms, respectively, and u is the Darcy velocity of the fluid defined by

$$u = -\frac{k(x)}{\mu(c)}(\nabla p - \rho g). \tag{2.2}$$

For $\Gamma = \partial\Omega$, let

$$\Gamma = \Gamma_1^p \cup \Gamma_2^p = \Gamma_1^c \cup \Gamma_2^c, \quad \Gamma_1^p \cap \Gamma_2^p = \Gamma_1^c \cap \Gamma_2^c = \emptyset.$$

With this division of Γ, the boundary conditions are specified by

$$\begin{aligned} &u\cdot\nu - a_1(c)p = \varphi_1(c), && (x,t)\in\Gamma_1^p\times J,\\ &p = \varphi_2(x,t), && (x,t)\in\Gamma_2^p\times J,\\ &-(D\nabla c)\cdot\nu - a_2(c)c = \varphi_3(c), && (x,t)\in\Gamma_1^c\times J,\\ &c = \varphi_4(x,t), && (x,t)\in\Gamma_2^c\times J, \end{aligned} \tag{2.3}$$

where the a_i and φ_j are given functions ($i = 1, 2$, $1 \le j \le 4$) and ν is the outward unit normal to Γ. The initial condition is given by

$$c(x,0) = c_0(x), \quad x\in\Omega. \tag{2.4}$$

The differential system given by (2.1)–(2.4) for the main unknowns p and c will be studied in this section.

2.2. Assumptions and the major result. The usual Sobolev spaces $W^{l,\pi}(\Omega)$ with the norm $\|\cdot\|_{W^{l,\pi}(\Omega)}$ [1] will be used, where l is a nonnegative integer and $0 \le \pi \le \infty$. When $\pi = 2$, we simply write $H^l(\Omega) = W^{l,2}(\Omega)$. When $l = 0$, we have $L^2(\Omega) = H^0(\Omega)$. Below $(\cdot,\cdot)_Q$ denotes the $L^2(Q)$ inner product. (Q is omitted if $Q = \Omega$.) We now make the following assumptions:

(A1) $\Omega \subset \Re^d$ is a multiply connected domain with Lipschitz boundary Γ, $\Gamma = \Gamma_1^p \cup \Gamma_2^p = \Gamma_1^c \cup \Gamma_2^c$, $\Gamma_1^p \cap \Gamma_2^p = \Gamma_1^c \cap \Gamma_2^c = \emptyset$, each Γ_i^p and Γ_i^c is a $(d-1)$-dimensional domain, and $\Gamma_2^p \subset \Gamma_2^c$.

(A2) $\phi \in L^\infty(\Omega)$, $\phi(x) \ge \phi_* > 0$, and $k(x)$ is a bounded, symmetric, and uniformly positive definite matrix, i.e.,

$$0 < k_* \le |\xi|^{-2}\sum_{i,j=1}^{d} k_{ij}(x)\xi_i\xi_j \le k^* < \infty, \quad x\in\Omega,\ \xi\ne 0\in\Re^d.$$

(A3) The diffusion-dispersion term is given by

$$D(u) = \phi\{d_{mo}I + |u|\big(d_l E(u) + d_t E^\perp(u)\big)\},$$

where I is the d-by-d identity matrix, $d_{mo} > 0$ is the molecular diffusion coefficient, d_l and d_t are the longitudinal and transverse dispersion coefficients, respectively, the matrix $E(u)$ is the projection along the direction of flow determined by

$$E(u) = \left(\frac{u_i u_j}{|u|^2}\right), \quad |u| = \sqrt{u_1^2 + \ldots + u_d^2}, \quad u = (u_1, \ldots, u_d),$$

and $E^\perp(u) = I - E(u)$.

(A4) The following form is widely used for the viscosity μ:

$$\mu(c) = \mu(0)\big(1 + (\mathcal{M}^{1/4} - 1)c\big)^{-4} \quad \text{for } c\in[0,1],$$

where $\mathcal{M} = \mu(0)/\mu(1)$ is the mobility ratio.

(A5) q^I, $q^P \ge 0$, $q^I \in L^\infty(J; L^2(\Omega))$, and $q^P \in L^\infty(J; H^{-1}(\Omega))$.

(A6) In the case of $\Gamma_2^p = \emptyset$ and $a_1 \equiv 0$, φ_1 is independent of c and satisfies

$$\int_{\Gamma_1^p}\varphi_1 \mathrm{d}\sigma = \int_\Omega (q^I - q^P)\mathrm{d}x.$$

(A7) There is a subset $\Gamma_{1,*}^p \subset \Gamma_1^p$ (with nonzero measure only if $\Gamma_2^p = \emptyset$ and $a_1 \not\equiv 0$) such that $a_1 \geq a_{1,*} > 0$ on $\Gamma_{1,*}^p \times J \times [0,1]$.

(A8) The boundary data satisfy that φ_1 and φ_3 are continuous in c and

$$
\begin{aligned}
&|||\varphi_1|||_{L^\infty(J;H^{-1/2}(\Gamma_1^p))} < \infty, \quad |||\varphi_3|||_{L^\infty(J;H^{-1/2}(\Gamma_1^c))} < \infty,\\
&\varphi_2 \in L^\infty(J;H^1(\Omega)), \quad \varphi_4 \in L^2(J;W^{1,4}(\Omega)),\\
&\partial_t\varphi_4 \in L^1(\Omega_T), \quad 0 \leq \varphi_4(x,t) \leq 1 \quad \text{almost everywhere (a.e.) on } \Omega_T,\\
&\varphi_1(0) \geq 0, \quad \varphi_1(1) \geq 0 \quad \text{on } \Gamma_1^c,\\
&\varphi_3(0) \leq 0, \quad \varphi_3(1) \geq 0 \quad \text{on } \Gamma_1^c,
\end{aligned}
$$

where

$$
|||v||| = \Big\| \sup_{c\in[0,1]} |v(x,c)| \Big\|,
$$

for any given norm.

(A9) a_1, $a_2 \geq 0$; they are continuous in c; $|||a_1|||_{L^\infty(\Omega_T)}$ and $|||a_2|||_{L^\infty(\Omega_T)}$ are bounded; and

$$
a_1(0) = a_1(1) = 0 \quad \text{on } \Gamma_1^c.
$$

(A10) $\hat{c}$ and c_0 satisfy $0 \leq \hat{c} \leq 1$ a.e. on Ω_T and $0 \leq c_0 \leq 1$ a.e. on Ω.

We introduce the spaces

$$
\begin{aligned}
V &= \left\{ v \in H^1(\Omega) : v|_{\Gamma_2^p} = 0; \text{ if } \Gamma_2^p = \emptyset \text{ and } a_1 \equiv 0, \text{ then } \int_\Omega v \mathrm{d}x = 0 \right\},\\
W &= \{ v \in H^1(\Omega) : v|_{\Gamma_2^c} = 0 \}.
\end{aligned}
$$

Below V^* and W^* indicate the duals of V and W, respectively.

DEFINITION 2.1. *A weak solution of the system in* (2.1)–(2.4) *is a pair of functions* (p,c) *with* $p \in L^\infty(J;V) + \varphi_2$, $c \in L^2(J;W(u)) + \varphi_4$ *such that*

$$
\phi\partial_t c \in L^2(J;W^*(u)), \tag{2.5}
$$

$$
0 \leq c(x,t) \leq 1 \quad \text{a.e. on } \Omega_T, \tag{2.6}
$$

$$
\begin{aligned}
&(a(c)\{\nabla p - \rho g\}, \nabla v) + (a_1(c)p, v)_{\Gamma_1^p}\\
&\qquad = (q^I - q^P, v) - (\varphi_1(c), v)_{\Gamma_1^p} \quad \forall v \in L^\infty(J;V),
\end{aligned} \tag{2.7}
$$

$$
\begin{aligned}
&\int_J \langle \phi\partial_t c, v\rangle \, dt + \int_J (D(u)\nabla c, \nabla v)\, dt + \int_J (u\cdot\nabla c, v)\, dt\\
&\qquad + \int_J (q^I c, v)\, dt + \int_J (a_2(c)c, v)_{\Gamma_1^c}\, dt\\
&\qquad\qquad = \int_J (\hat{c}q^I, v)\, dt - \int_J (\varphi_3(c), v)_{\Gamma_1^c}\, dt \quad \forall v \in L^2(J;W(u)),
\end{aligned} \tag{2.8}
$$

$$
\begin{aligned}
&\int_J \langle \phi\partial_t c, v\rangle \, dt + \int_J (\phi(c - c_0), \partial_t v)\, dt = 0\\
&\qquad \forall v \in L^2(J;W(u)) \cap W^{1,1}(J;L^1(\Omega)), \quad v(x,T) = 0,
\end{aligned} \tag{2.9}
$$

where $a(c) = k(x)/\mu(c)$, u is given as in (2.2)*, and the space $W(u)$ is defined by*

$$W(u) = \{v \in W : (D(u)\nabla v, \nabla v) < \infty\}.$$

We now state the major result obtained in this section.

THEOREM 2.2. *Under assumptions* (A1)–(A10)*, the system in* (2.1)–(2.4) *has a weak solution in the sense of Definition* 2.1.

2.3. Proof of the major result. In this subsection we shall prove Theorem 2.2. We first state the following trivial lemma.

LEMMA 2.3. *It holds that*

$$d_{mo} + \min(d_l, d_t)|u| \le \phi^{-1}|\xi|^{-2} \sum_{i,j=1}^{d} D_{ij}(u)\xi_i\xi_j \le d_{mo} + \max(d_l, d_t)|u|, \quad \xi \ne 0 \in \Re^d.$$

For each positive integer M, divide J into $m = 2^M$ subintervals of equal length $h = T/m = 2^{-M}T$. Set $t_i = ih$ and $J_i = (t_{i-1}, t_i]$ for an integer i, $1 \le i \le m$. Denote the time difference operator by

$$\partial^\eta v(t) = \frac{v(t+\eta) - v(t)}{\eta}$$

for any function $v(t)$ and constant $\eta \in \Re$. Also, for any Hilbert space $\mathcal{H}$, define

$$l_h(\mathcal{H}) = \{v \in L^\infty(J; \mathcal{H}) : v \text{ is constant in time on each subinterval } J_i \subset J\}.$$

For $v^h \in l_h(\mathcal{H})$, set $v^i \equiv (v^h)^i = v^h|_{J_i}$ for notational convenience, when there is no ambiguity (i.e., h is omitted). Finally, let

$$\varphi_j^h(x,t) = \frac{1}{h}\int_{J_i} \varphi_j(x,\tau)\mathrm{d}\tau, \quad t \in J_i,\ j = 2, 4;$$

similar definitions $q^{I,h}$, $q^{P,h}$, and $\hat{c}^h$ are used for q^I, q^P, and $\hat{c}$, respectively.

Now, the discrete time solution is a pair of functions $p^h \in l_h(V) + \varphi_2^h$, $c^h \in l_h(W(u^h)) + \varphi_4^h$ satisfying

$$\begin{aligned}(a(c^h)\{\nabla p^h - \rho g\}, \nabla v) + (a_1(c^h)p^h, v)_{\Gamma_1^p} \\ = (q^{I,h} - q^{P,h}, v) - (\varphi_1(c^h), v)_{\Gamma_1^p} \quad \forall v \in l_h(V),\end{aligned} \tag{2.10}$$

and

$$\begin{aligned}\int_J (\phi\partial^{-h}c^h, v)\mathrm{d}t + \int_J (D(u^h)\nabla c^h, \nabla v)\mathrm{d}t + \int_J (u^h \cdot \nabla c^h, v)\mathrm{d}t \\ + \int_J (q^{I,h}c^h, v)\mathrm{d}t + \int_J (a_2(c^h)c^h, v)_{\Gamma_1^c}\mathrm{d}t \\ = \int_J (\hat{c}^h q^{I,h}, v)\mathrm{d}t - \int_J (\varphi_3(c^h), v)_{\Gamma_1^c}\mathrm{d}t \quad \forall v \in l_h(W(u^h)),\end{aligned} \tag{2.11}$$

with

$$u^h = -a(c^h)(\nabla p^h - \rho g). \tag{2.12}$$

This approximate scheme is extended such that $c^h = c_0$ for $t < 0$.

Below, C (with or without a subscript) indicates a generic constant independent of h, which will probably take on different values in different occurrences.

LEMMA 2.4. *For $h > 0$ small enough, the discrete scheme has a solution such that*

$$0 \le c^h(x,t) \le 1 \quad a.e.\ on \quad \Omega_T. \tag{2.13}$$

The proof of this lemma will be given in the next subsection.

LEMMA 2.5. *The solution to the discrete scheme also satisfies*

$$\|p^h\|_{L^\infty(J;H^1(\Omega))} + \|c^h\|_{L^2(J;H^1(\Omega))} + \|D^{1/2}(u^h)\nabla c^h\|_{L^2(\Omega_T)} \le C, \tag{2.14}$$

with constant C independent of h.

Proof. Take $v = p^h - \varphi_2^h \in l_h(V)$ in (2.10) to have

$$\begin{aligned}\|\nabla p^h\|^2_{L^2(\Omega)} + (a_1(c^h)p^h, p^h)_{\Gamma_1^p} \le C\{&\|\rho g\|^2_{L^2(\Omega)} + \|q^{I,h} - q^{P,h}\|^2_{H^{-1}(\Omega)} \\ &+|||\varphi_1|||^2_{H^{-1/2}(\Gamma_1^p)} + \|\varphi_2^h\|^2_{H^1(\Omega)}\} + \epsilon\|p^h\|^2_{L^2(\Omega)}, \quad t \in J,\end{aligned} \tag{2.15}$$

for any $\epsilon > 0$ (here and below $\epsilon > 0$ is an arbitrary constant as small as we please). Apply a variant of the Poincaré inequality

$$\|p^h\|_{L^2(\Omega)} \le C\{\|\nabla p^h\|_{L^2(\Omega)} + \|p_h\|_{L^2(\Gamma^p_{1,*})} + \|\varphi_2^h\|_{H^1(\Omega)}\} \tag{2.16}$$

and the inequality

$$\|\varphi_2^h\|_{H^1(\Omega)} \le \|\varphi_2\|_{H^1(\Omega)}$$

to obtain the bound for p^h in (2.14).

Now, choose $v = c^h - \varphi_4^h \in l_h(W(u^h))$ in (2.11) to see that

$$\begin{aligned}&\int_J (\phi\partial^{-h}c^h, c^h - \varphi_4^h)\mathrm{d}t + \int_J (D(u^h)\nabla c^h, \nabla(c^h - \varphi_4^h))\mathrm{d}t \\ &\quad + \int_J (u^h\cdot\nabla c^h, c^h - \varphi_4^h)\mathrm{d}t + \int_J (q^{I,h}c^h, c^h - \varphi_4^h)\mathrm{d}t \\ &\quad + \int_J (a_2(c^h)c^h, c^h - \varphi_4^h)_{\Gamma_1^c}\mathrm{d}t = \int_J (\hat{c}^h q^{I,h}, c^h - \varphi_4^h)\mathrm{d}t \\ &\qquad\qquad - \int_J (\varphi_3(c^h), c^h - \varphi_4^h)_{\Gamma_1^c}\mathrm{d}t.\end{aligned} \tag{2.17}$$

We now estimate each term in (2.17). We focus only on the transport and diffusion-dispersion terms; other terms can be easily estimated. By the definition of u^h, Lemma 2.3, the Hölder inequality, and the above bound on p^h, note that

$$\begin{aligned}\big|(D(u^h)\nabla c^h, \nabla\varphi_4^h)\big| &\le \epsilon(D(u^h)\nabla c^h, \nabla c^h) \\ &\quad + C\left(\|\nabla\varphi_4^h\|^2_{L^2(\Omega)} + \|u^h\|_{L^2(\Omega)}\|\nabla\varphi_4^h\|^2_{L^4(\Omega)}\right) \\ &\le \epsilon(D(u^h)\nabla c^h, \nabla c^h) + C\|\nabla\varphi_4^h\|^2_{L^4(\Omega)}.\end{aligned} \tag{2.18a}$$

Using (2.13), the same reasoning also yields that

$$\begin{aligned}\big|(u^h\cdot\nabla c^h, c^h)\big| &\le \epsilon(|u^h|\nabla c^h, \nabla c^h) + C(|u^h|c^h, c^h) \\ &\le \epsilon(D(u^h)\nabla c^h, \nabla c^h) + C(\Omega)\end{aligned} \tag{2.18b}$$

and that

$$\begin{aligned}\left|(u^h\cdot\nabla c^h,\varphi_4^h)\right|&\le \epsilon(|u^h|\nabla c^h,\nabla c^h)+C(|u^h|\varphi_4^h,\varphi_4^h)\\&\le \epsilon(D(u^h)\nabla c^h,\nabla c^h)+C\|\varphi_4^h\|^2_{L^4(\Omega)}.\end{aligned}\tag{2.18c}$$

Apply these estimates in (2.18a–c) to (2.17) to obtain

$$\begin{aligned}&\int_J(\phi\partial^{-h}c^h,c^h-\varphi_4^h)\mathrm{d}t+C_1\int_J(D(u^h)\nabla c^h,\nabla c^h)\mathrm{d}t\\&\le C(T,\Omega)\left\{1+\int_J\left(||q^{I,h}||^2_{H^{-1}(\Omega)}+|||\varphi_3|||^2_{H^{-1/2}(\Gamma_1^c)}\right.\right.\\&\qquad\left.\left.+\|\varphi_4^h\|^2_{H^1(\Omega)}+\|\varphi_4^h\|^4_{W^{1,4}(\Omega)}\right)\mathrm{d}t\right\}.\end{aligned}\tag{2.19}$$

Next, it is easy to see that

$$\int_J(\phi\partial^{-h}c^h,c^h)\mathrm{d}t=\sum_{i=1}^m(\phi(c^i-c^{i-1}),c^i)\ge\frac{1}{2}\{(\phi c^m,c^m)-(\phi c^0,c^0)\}.\tag{2.20}$$

Also, we find that [3, 6]

$$\begin{aligned}\int_J(\phi\partial^{-h}c^h,\varphi_4^h)\mathrm{d}t&=(\phi c^m,\varphi_4^m)-(\phi c^0,\varphi_4^1)-\int_0^{T-h}(\phi c^h,\partial^h\varphi_4^h)\mathrm{d}t\\&\le C\left\{\|\varphi_4^h\|_{L^\infty(J;L^1(\Omega))}+\int_0^{T-h}\|\partial^h\varphi_4^h\|_{L^1(\Omega)}\mathrm{d}t\right\}\\&\le C\left\{\|\varphi_4^h\|_{L^\infty(J;L^1(\Omega))}+\int_J\|\partial_t\varphi_4\|_{L^1(\Omega)}\mathrm{d}t\right\}.\end{aligned}\tag{2.21}$$

Finally, combine (2.17)–(2.21) to have the desired result for c^h. □

COROLLARY 2.6. *For any $2\le r<\infty$, for a subsequence $p^h\rightharpoonup p$ weakly in $L^r(J;H^1(\Omega))$ and $c^h\rightharpoonup c$ weakly in $L^2(J;H^1(\Omega))$. Furthermore, $p\in L^\infty(J;V)+\varphi_2$, $c\in L^2(J;W)+\varphi_4$, and*

$$0\le c(x,t)\le 1\quad a.e.\ on\quad \Omega_T.\tag{2.22}$$

Proof. It follows from Lemma 2.5 that $c^h-\varphi_4^h$ converges weakly in $L^2(J;W)$. Since $\varphi_4^h\rightharpoonup\varphi_4$ weakly in $L^2(J;H^1(\Omega))$, $c^h\rightharpoonup c$ weakly in $L^2(J;H^1(\Omega))$ with $c\in L^2(J;W)+\varphi_4$. The same argument shows that $p^h\rightharpoonup p$ weakly in $L^r(J;H^1(\Omega))$ with $p\in L^r(J;V)+\varphi_2$ for $2\le r<\infty$. Since $\|p\|_{L^r(J;H^1(\Omega))}\le C$ with C independent of r, in fact $p\in L^\infty(J;V)+\varphi_2$. Finally, (2.22) follows from (2.13). □

LEMMA 2.7. *There is a subsequence such that $c^h\to c$ strongly in $L^2(\Omega_T)$.*

This lemma also will be shown in section 2.4.

COROLLARY 2.8. *There is a subsequence such that $c^h\to c$ strongly in $L^2(J;H^{1-\pi}(\Omega))$ and $L^2(J;H^{1/2-\pi}(\partial\Omega))$ for any $0<\pi<1/2$, and $c^h\to c$ pointwise a.e. on Ω_T.*

Proof. Apply the interpolation inequality

$$\|v\|_{H^\sigma(\Omega)}\le\delta\|v\|_{H^1(\Omega)}+C_\delta\|v\|_{L^2(\Omega)}\tag{2.23}$$

for any $0<\sigma<1$ and $\delta>0$, the boundedness of the trace operator, and Lemma 2.7 to prove the desired statement. □

We are now ready to prove Theorem 2.2.

Proof of Theorem 2.2. From Corollaries 2.6 and 2.8, (2.10) implies (2.7) since $\cup_{M=1}^{\infty} l_h(V)$ is dense in $L^\infty(J;V)$. Also, it follows from (2.11) that

$$\begin{aligned}\lim_{h\to 0^+}\Big\{&\int_J(\phi\partial^{-h}c^h,v)\mathrm{d}t+\int_J(D(u^h)\nabla c^h,\nabla v)\mathrm{d}t+\int_J(u^h\cdot\nabla c^h,v)\mathrm{d}t\\ &+\int_J(q^{I,h}c^h,v)\mathrm{d}t+\int_J(a_2(c^h)c^h,v)_{\Gamma_1^c}\mathrm{d}t\Big\}\\ =\lim_{h\to 0^+}&\Big\{\int_J(\hat{c}^h q^{I,h},v)\mathrm{d}t-\int_J(\varphi_3(c^h),v)_{\Gamma_1^c}\mathrm{d}t\Big\}\ \forall v\in\cup_{M=1}^{\infty}l_h(W(u^h)).\end{aligned}\tag{2.24}$$

By (2.7) and (2.10), we see that

$$\begin{aligned}&(a(c^h)\nabla[p^h-p],\nabla[p^h-p])+(a(c^h)\nabla[p^h-p],\nabla p)\\ &-([a(c)-a(c^h)](\nabla p-\rho g),\nabla p^h)-(a_1(c^h)(p-p^h),p^h)_{\Gamma_1^p}\\ &-([a_1(c)-a_1(c^h)]p,p^h)_{\Gamma_1^p}=-([q^I-q^P]-[q^{I,h}-q^{P,h}],p^h)\\ &\qquad+(\varphi_1(c)-\varphi_1(c^h),p^h)_{\Gamma_1^p}.\end{aligned}$$

Then, by Corollaries 2.6 and 2.8 and Lebesgue's dominated convergence theorem, we see that $\nabla p^h\to\nabla p$ strongly in $(L^2(\Omega_T))^d$. Hence, from the definition of u^h, $u^h\to u$ strongly in $(L^2(\Omega_T))^d$ and by Lemma 2.3, $D(u^h)\to D(u)$ strongly in $(L^2(\Omega_T))^{d\times d}$. Therefore, by the strong convergence of $\{D(u^h)\}$ and weak convergence of $\{\nabla c^h\}$, we have

$$\lim_{h\to 0^+}\int_J(D(u^h)\nabla c^h,\nabla v)\mathrm{d}t=\int_J(D(u)\nabla c,\nabla v)\mathrm{d}t\quad\forall v\in\cup_{M=1}^{\infty}l_h(W(u^h)).$$

Similarly, by the strong convergence of $u^h\to u$ and weak convergence of $\nabla c^h\rightharpoonup\nabla c$, we see that

$$\lim_{h\to 0^+}\int_J(u^h\cdot\nabla c^h,v)\mathrm{d}t=\int_J(u\cdot\nabla c,v)\mathrm{d}t\quad\forall v\in\cup_{M=1}^{\infty}l_h(W(u^h)).$$

Next, by the definition of $q^{I,h}$ and $\hat{c}^h$, and the continuity of φ_3 and a_2 in c, it follows from Corollary 2.8 that

$$\lim_{h\to 0^+}\Big\{\int_J(q^{I,h}c^h,v)\mathrm{d}t+\int_J(a_2(c^h)c^h,v)_{\Gamma_1^c}\mathrm{d}t\Big\}=\int_J(q^Ic,v)\mathrm{d}t+\int_J(a_2(c)c,v)_{\Gamma_1^c}\mathrm{d}t\quad\forall v\in\cup_{M=1}^{\infty}l_h(W(u^h)),$$

and

$$\lim_{h\to 0^+}\Big\{\int_J(\hat{c}^h q^{I,h},v)\mathrm{d}t-\int_J(\varphi_3(c^h),v)_{\Gamma_1^c}\mathrm{d}t\Big\}=\int_J(\hat{c}q^I,v)\mathrm{d}t-\int_J(\varphi_3(c),v)_{\Gamma_1^c}\mathrm{d}t\quad\forall v\in\cup_{M=1}^{\infty}l_h(W(u^h)).$$

Also, for any $v\in L^2(J;W(u))$, $v^h\in l_h(W(u^h))$ for h sufficiently small, where $v^h(x,t)=h^{-1}\int_{J_k}v(x,\tau)\mathrm{d}\tau$. Then, by (2.11), (2.14), and the compact embedding relation $H^1(\Omega)\hookrightarrow L^4(\Omega)$, we observe that

$$\int_J(\phi\partial^{-h}c^h,v)\mathrm{d}t=\int_J(\phi\partial^{-h}c^h,v^h)\mathrm{d}t\le C\big\{\|D^{1/2}(u)\nabla v\|_{L^2(\Omega_T)}+\|v\|_{L^2(\Omega_T)}\big\}$$

for h sufficiently small. Consequently, for a subsequence $\phi\partial^{-h}c^h$ converges weakly in $L^2(J;W^*(u))$. If $v \in C_0^\infty(\Omega_T)$, with $h > 0$ small enough we see that

$$\int_J (\phi\partial^{-h}c^h, v)\mathrm{d}t = -\int_0^{T-h} (\phi c^h, \partial^h v)\mathrm{d}t \to -\int_J (\phi c, \partial_t v)\mathrm{d}t = \int_J \langle \phi\partial_t c, v\rangle \,\mathrm{d}t$$

as a distribution. Therefore, $\phi\partial^{-h}c^h \rightharpoonup \phi\partial_t c$ weakly in $L^2(J;W^*(u))$. Combining all these results, (2.8) follows from (2.24) since $\cup_{M=1}^\infty l_h(W(u^h))$ is dense in $L^2(J;W(u))$. Also, as for (2.19), it can be shown that $c \in L^2(J;W(u))$ from (2.8).

Finally, if $v \in L^2(J;W(u)) \cap W^{1,1}(J;L^1(\Omega))$ with $v(x,T) = 0$, we find that

$$\int_J (\phi\partial^{-h}c^h, v)\mathrm{d}t + \int_0^{T-h} (\phi[c^h - c^0], \partial^h v)\mathrm{d}t = \frac{1}{h}\int_{T-h}^T (\phi[c^h - c^0], v)\mathrm{d}t,$$

which yields (2.9). Thus the proof of Theorem 2.2 is complete. □

2.4. Proof of Lemmas 2.4 and 2.7. In this subsection the possibility that c is outside $[0,1]$ is allowed. All functions of c are extended constantly outside $[0,1]$.

Lemma 2.4 is purely an elliptic result and will obviously follow from the next proposition. For notational convenience the superscript h is omitted below.

PROPOSITION 2.9. *In addition to assumptions* (A1)–(A10)*, suppose that* $0 < \eta_* \le \eta_1(x) \in L^\infty(\Omega)$ *and* $0 \le \eta_2(x) \le \eta_1(x)$*. Then, for* η_* *sufficiently big, the following problem has a weak solution* $(p,c) \in (V+\varphi_2)\times(W(u)+\varphi_4)$*:*

$$\begin{aligned}(a(c)\{\nabla p - \rho g\}, \nabla v) + (a_1(c)p, v)_{\Gamma_1^p} \\ = (q^I - q^P, v) - (\varphi_1(c), v)_{\Gamma_1^p} \quad \forall v \in V,\end{aligned} \tag{2.25}$$

$$\begin{aligned}(\eta_1 c, v) + (D(u)\nabla c, \nabla v) + (u\cdot\nabla c, v) + (q^I c, v) + (a_2(c)c, v)_{\Gamma_1^c} \\ = (\hat{c}q^I, v) - (\varphi_3(c), v)_{\Gamma_1^c} + (\eta_2, v) \quad \forall v \in W(u),\end{aligned} \tag{2.26}$$

and

$$0 \le c(x,t) \le 1 \quad \text{a.e. on } \Omega_T, \tag{2.27}$$

where u *is given as in* (2.12).

Proof. Let $\{v_i^1\}_{i=1}^\infty$ and $\{v_i^2\}_{i=1}^\infty$ be bases for V and W, respectively, and set $V_m = \mathrm{span}\{v_1^1, \dots, v_m^1\}$ and $W_m = \mathrm{span}\{v_1^2, \dots, v_m^2\}$. With V_m and W_m replacing V and W in (2.25) and (2.26), respectively, we obtain a Galerkin procedure.

For $v^j = \sum_{i=1}^m \beta_i^j v_i^j$, $j = 1, 2$, we introduce the mapping $\Phi_m : \Re^{2m} \to \Re^{2m}$ by

$$\Phi_m \begin{pmatrix} \beta^1 \\ \beta^2 \end{pmatrix} = \begin{pmatrix} \hat{\beta}^1 \\ \hat{\beta}^2 \end{pmatrix},$$

where

$$\begin{aligned}\hat{\beta}_i^1 =& (a(v^2+\varphi_4)\{\nabla(v^1+\varphi_2) - \rho g\}, \nabla v_i^1) + (a_1(v^2+\varphi_4)(v^1+\varphi_2), v_i^1)_{\Gamma_1^p} \\ & -(q^I - q^P, v_i^1) + (\varphi_1(v^2+\varphi_4), v_i^1)_{\Gamma_1^p}, \\ \hat{\beta}_i^2 =& (\eta_1(v^2+\varphi_4), v_i^2) + (D(\hat{u})\nabla(v^2+\varphi_4), \nabla v_i^2) + (\hat{u}\cdot\nabla(v^2+\varphi_4), v_i^2) \\ & +(q^I(v^2+\varphi_4), v_i^2) + (a_2(v^2+\varphi_4)(v^2+\varphi_4), v_i^2)_{\Gamma_1^c} \\ & -(\hat{c}q^I, v_i^2) + (\varphi_3(v^2+\varphi_4), v_i^2)_{\Gamma_1^c} - (\eta_2, v_i^2),\end{aligned}$$

with $u = -a(v^2+\varphi_4)\{\nabla(v^1+\varphi_2)-\rho g\}$ and $\hat{u} = mu/(m+|u|)$. Note that to handle the difficulty associated with the transport and diffusion-dispersion terms, we have introduced $\hat{u}$ above. By the assumptions (A1)–(A10), Φ_m is continuous. Also, it can be easily seen that

$$\begin{aligned}\Phi_m\begin{pmatrix}\beta^1\\ \beta^2\end{pmatrix}\cdot\begin{pmatrix}\beta^1\\ \beta^2\end{pmatrix} \geq & C_1(m)\big\{\|\nabla v^1\|^2_{L^2(\Omega)}+\|\nabla v^2\|^2_{L^2(\Omega)}\big\}-\epsilon\|v^1\|^2_{L^2(\Omega)}\\ & +(\eta_1(v^2+\varphi_4)-\eta_2,v^2)+(q^I\varphi_4,v^2)\\ & -C\Big\{|||\varphi_1|||^2_{H^{-1/2}(\Gamma_1^p)}+|||\varphi_3|||^2_{H^{-1/2}(\Gamma_1^c)}+\|\varphi_2\|^2_{H^1(\Omega)}\\ & \quad +\|\varphi_4\|^2_{H^1(\Omega)}+\|q^I\|^2_{H^{-1}(\Omega)}+\|q^P\|^2_{H^{-1}(\Omega)}\\ & \quad +\|\rho g\|^2_{L^2(\Omega)}+\|v^2\|^2_{L^2(\Omega)}\Big\}\end{aligned}$$

for any $\epsilon>0$. Note that

$$(\eta_1(v^2+\varphi_4)-\eta_2,v^2)\geq\frac{1}{2}\eta_*\|v^2\|^2_{L^2(\Omega)}-C\big\{1+\|\varphi_4\|^2_{L^2(\Omega)}\big\}, \tag{2.28}$$

and, by the compact embedding relation $H^1(\Omega)\hookrightarrow L^4(\Omega)$ again,

$$\begin{aligned}(q^I\varphi_4,v^2)\leq & \|q^I\|_{L^2(\Omega)}\|\varphi_4\|_{L^4(\Omega)}\|v^2\|_{L^4(\Omega)}\\ \leq & C\|q^I\|_{L^2(\Omega)}\|\varphi_4\|_{L^4(\Omega)}\|v^2\|_{H^1(\Omega)}.\end{aligned}$$

Now, with Poincaré's inequality and η_* big enough, combining these results yields that

$$\Phi_m\begin{pmatrix}\beta^1\\ \beta^2\end{pmatrix}\cdot\begin{pmatrix}\beta^1\\ \beta^2\end{pmatrix}\geq C_1(m)\big\{\|v^1\|^2_{H^1(\Omega)}+\|v^2\|^2_{H^1(\Omega)}\big\}-C,$$

which is strictly positive for $|\beta^1|+|\beta^2|$ sufficiently big. As a result, Φ_m has a zero; i.e., there is a solution to the Galerkin approximation with $\hat{u}$ replacing u for each m.

As in the proof of Lemma 2.5, it can be seen that the modified Galerkin solutions p^m and c^m are uniformly bounded in $H^1(\Omega)$ (independently of m), so for a subsequence $p^m\rightharpoonup p$ and $c^m\rightharpoonup c$ weakly in $H^1(\Omega)$ with $p\in V+\varphi_2$ and $c\in W(u)+\varphi_4$. Moreover, $c_m\to c$ strongly in $H^{1-\pi}(\Omega)$ $(0<\pi<1/2)$ and pointwise a.e. both on Ω and $\partial\Omega$. Therefore, (p,c) is a weak solution to the system in (2.25) and (2.26).

Finally, we apply a standard maximum principle argument to (2.26) to show (2.27). Take $v=c^-=\min(c,0)\in W(u)$ in (2.26) to have

$$\begin{aligned}(\eta_1 c-\eta_2,c^-)= & -(D(u)\nabla c,\nabla c^-)-(u\cdot\nabla c,c^-)-(q^Ic,c^-)\\ & -(a_2(c)c,c^-)_{\Gamma_1^c}+(\hat{c}q^I,c^-)-(\varphi_3(c),c^-)_{\Gamma_1^c}.\end{aligned}$$

Note that $c^-\in V$ by assumption (A1) (if $\Gamma_2^p=\emptyset$ and $a_1\equiv 0$, consider $c^- - \int_\Omega c^-\mathrm{d}x$). Then, by (2.25) with $v=(c^-)^2$, we see that

$$\begin{aligned}(u\cdot\nabla c,c^-)= & \tfrac{1}{2}(u,\nabla(c^-)^2)\\ = & \tfrac{1}{2}\big\{(a_1(c)p,(c^-)^2)_{\Gamma_1^p}-(q^I-q^P,(c^-)^2)+(\varphi_1(c),(c^-)^2)_{\Gamma_1^p}\big\}.\end{aligned}$$

Use these two equations to see that

$$\begin{aligned}(\eta_1 c-\eta_2,c^-)= & -(D(u)\nabla c,\nabla c^-)-\tfrac{1}{2}\big\{(a_1(c)p,(c^-)^2)_{\Gamma_1^p}+(q^Ic,c^-)+(q^Pc,c^-)\big\}\\ & -\tfrac{1}{2}(\varphi_1(c),(c^-)^2)_{\Gamma_1^c}-(a_2(c)c,c^-)_{\Gamma_1^c}+(\hat{c}q^I,c^-)-(\varphi_3(c),c^-)_{\Gamma_1^c}\\ \leq & 0\end{aligned}$$

by assumptions (A5), (A8), and (A9), which, as in (2.28), shows that $c^- = 0$ a.e. on Ω_T provided η_* is sufficiently large. This concludes that $c \geq 0$ a.e. on Ω_T. Similarly, with $v = (c-1)^+ = \max(c-1, 0) \in W(u)$ in (2.26), we can see that $c \leq 1$ a.e. on Ω_T. This completes the proof of the proposition. ∎

The next lemma is related to Lemma 3 in [6] and is needed for proving Lemma 2.7. Both Lemma 2.10 and the proof of Lemma 2.7 are based on the ideas presented in [3].

LEMMA 2.10. *Let c^h satisfy* (2.11). *Then there exists C such that, for any $\zeta > 0$,*

$$\frac{1}{\zeta}\int_{\zeta}^{T} \|\phi^{1/2}\big(c^h(\cdot,t) - c^h(\cdot,t-\zeta)\big)\|^2_{L^2(\Omega)}\,dt \leq C.$$

Proof. Let k be fixed ($1 \leq k \leq m$); for $\tau \in J_i$, we define the interval $Q = Q(\tau) = ((i-k)h, ih]$ and the characteristic function χ_Q. Take $v(x,t) = kh\chi_Q(t)\partial^{-kh}(c^h - \varphi_4^h)(x,\tau) \in l_h(W)$ in (2.11) and apply the relation

$$\int_J \partial^{-h} c^h \chi_Q \mathrm{d}t = \sum_{j=i-k+1}^{i} (c^j - c^{j-1}) = kh\partial^{-kh} c^h(\cdot,\tau),$$

(2.13), and (2.14) to obtain

$$\begin{aligned} kh\int_{kh}^{T} \|\phi^{1/2}\partial^{-kh}c^h(\cdot,\tau)\|^2_{L^2(\Omega)}\mathrm{d}\tau &\leq C + kh\int_{kh}^{T}(\phi\partial^{-kh}c^h(\cdot,\tau), \partial^{-kh}\varphi_4^h(\cdot,\tau))\mathrm{d}\tau \\ &\leq C\left(1 + \|\partial_t\varphi_4\|_{L^1(\Omega_T)}\right), \end{aligned}$$

which implies the desired result since c^h is constant on each interval J_i. ∎

For m_1 a positive integer, let $\delta = T/m_1$ and $J_k^\delta = ((k-1)\delta, k\delta]$. Introduce the operator $A^\delta : L^1(J) \to L^1(J)$ by

$$A^\delta(v) = \frac{1}{\delta}\int_{J_k^\delta} v(\tau)\mathrm{d}\tau, \quad t \in J_k^\delta.$$

We are now in a position to prove Lemma 2.7.

Proof of Lemma 2.7. For any ζ, $N > 0$, define

$$\begin{aligned} Q = Q(c^h, \zeta, N) = \big\{ t \in (\zeta, T] : &\|c^h(\cdot,t)\|^2_{H^1(\Omega)} + \|c^h(\cdot,t-\zeta)\|^2_{H^1(\Omega)} \\ &+ \tfrac{1}{\zeta}\|\phi^{1/2}\big(c^h(\cdot,t) - c^h(\cdot,t-\zeta)\big)\|^2_{L^2(\Omega)} > N \big\}. \end{aligned}$$

Obviously, by (2.13), (2.14), and Lemma 2.10, the measure of Q is less than C/N with constant C independent of h. If $t \in (\zeta, T] \setminus Q$, then

$$\|c^h(\cdot,t) - c^h(\cdot,t-\zeta)\|^2_{L^2(\Omega)} \leq \frac{\zeta N}{\phi_*}.$$

Thus we see that

$$\int_{\zeta}^{T} \|c^h(\cdot,t) - c^h(\cdot,t-\zeta)\|^2_{L^2(\Omega)}\mathrm{d}t \leq \frac{\zeta N T}{\phi_*} + \frac{4C|\Omega|}{N}$$

so that, by the arbitrariness of N,

$$\int_{\zeta}^{T} \|c^h(\cdot,t) - c^h(\cdot,t-\zeta)\|^2_{L^2(\Omega)}\mathrm{d}t \to 0 \qquad \text{as } \zeta \to 0^+$$

uniformly in h. Therefore, by the definition of A^δ we see that

$$\int_J \|c^h - A^\delta(c^h)\|^2_{L^2(\Omega)} \mathrm{d}t \leq \underbrace{\frac{2}{\delta}\int_0^\delta \int_\zeta^T \|c^h(\cdot,t) - c^h(\cdot,t-\zeta)\|^2_{L^2(\Omega)} \mathrm{d}t\mathrm{d}\zeta}_{\to 0 \quad \text{as } \delta \to 0^+} \tag{2.29}$$

uniformly in h. Also, $\|A^\delta(c^h)\|_{L^2(J,H^1(\Omega))}$ is uniformly bounded, so for fixed $\delta > 0$, $A^\delta(c^h)$ converges strongly in $L^2(\Omega_T)$ as $h \to 0^+$. Consequently, apply (2.29) and the inequality

$$\|c^{h_1} - c^{h_2}\|_{L^2(\Omega_T)} \leq \sum_{j=1}^{2} \|c^{h_j} - A^\delta(c^{h_j})\|_{L^2(\Omega_T)} + \|A^\delta(c^{h_1}) - A^\delta(c^{h_2})\|_{L^2(\Omega_T)}$$

to complete the proof of Lemma 2.7. □

3. Two-phase flow and transport. In this section we consider two-phase flow and transport equations in a porous medium $\Omega \subset \Re^d$ $(d \leq 3)$. These equations will be reviewed in section 3.1. The differential system we shall study in this section will be derived in section 3.2. The major result in this section is stated in section 3.3 and proven in section 3.4 and section 3.5.

3.1. Flow and transport equations. The mass balance equation for each of the fluid phases is given by [7]

$$\phi \frac{\partial(\rho_\alpha s_\alpha)}{\partial t} + \nabla \cdot (\rho_\alpha u_\alpha) = \rho_\alpha q_\alpha, \quad \alpha = w, n, \tag{3.1}$$

where $\alpha = w$ denotes the wetting phase (e.g., water), $\alpha = n$ indicates the nonwetting phase (e.g., oil or air), ϕ is the porosity of the porous medium, and ρ_α, s_α, u_α, and q_α are, respectively, the density, (reduced) saturation, volumetric velocity, and external volumetric flow rate of the α-phase. The volumetric velocity u_α is given again by the Darcy law

$$u_\alpha = -\frac{k k_{r\alpha}}{\mu_\alpha}(\nabla p_\alpha - \rho_\alpha g), \quad \alpha = w, n, \tag{3.2}$$

where k is the absolute permeability of the porous medium and p_α, μ_α, and $k_{r\alpha}$ are the pressure, viscosity, and relative permeability of the α-phase, respectively. In addition to (3.1) and (3.2), the customary property for the saturations is

$$s_w + s_n = 1, \tag{3.3}$$

and the two pressures are related by the capillary pressure function

$$p_c = p_n - p_w. \tag{3.4}$$

With the flow of the fluids specified as above, an equation for the transport of a chemical constituent is needed. The constituent can be transported in each of the phases, so the equation is written for each phase. Let c_α denote the mass concentration of the constituent in the α phase. Then the mass balance law for the constituent in each phase reads as follows:

$$\phi \frac{\partial(\rho_\alpha s_\alpha c_\alpha)}{\partial t} + \nabla \cdot (\rho_\alpha u_\alpha c_\alpha - \phi \rho_\alpha s_\alpha D_\alpha \nabla c_\alpha) + \phi r_\alpha \rho_\alpha s_\alpha c_\alpha = \hat{c}_\alpha \rho_\alpha \hat{q}_\alpha \tag{3.5}$$

for $\alpha = w$, n, where D_α, r_α, and $\hat{c}_\alpha$ are the diffusion-dispersion coefficient, reaction rate, and concentration in the external flow for the α phase, respectively.

3.2. The differential system. The following functional dependence is physically reasonable:

$$k_{r\alpha} = k_{r\alpha}(x, s_\alpha), \quad p_c = p_c(x, s_w), \quad D_\alpha = D_\alpha(x, u_\alpha).$$

However, to extend the analysis of the last section to the present problem we assume that the viscosity μ_α is independent of c_α. The case that $\mu_\alpha = \mu_\alpha(c_\alpha)$ needs to be handled with a different argument and will be treated in a forthcoming paper. The model derived here is of interest in itself.

In order to separate the pressure and saturation equations, we introduce the phase mobility functions

$$\lambda_\alpha(x, s_\alpha) = k_{r\alpha}/\mu_\alpha, \quad \alpha = w, n,$$

and the total mobility

$$\lambda(x, s) = \lambda_w + \lambda_n,$$

where $s = s_w$. The fractional flow functions are defined by

$$f_\alpha(x, s) = \lambda_\alpha/\lambda, \quad \alpha = w, n.$$

Following [4, 8], we define the global pressure

$$p = p_n - \int_0^s \left(f_w \frac{\partial p_c}{\partial s} \right)(x, \xi)\mathrm{d}\xi. \tag{3.6}$$

Also, we shall use the complementary pressure [6]

$$\theta = -\int_0^s \left(f_w f_n \frac{\partial p_c}{\partial s} \right)(x, \xi). \tag{3.7}$$

Finally, we define the total velocity

$$u = u_w + u_n. \tag{3.8}$$

Now, under the assumption that the fluids are incompressible we apply (3.3) and (3.8) to (3.1) to see that

$$\nabla \cdot u = q \equiv q_w + q_n, \tag{3.9}$$

and we apply (3.4), (3.6), and (3.8) to (3.2) to obtain

$$u = -k(\lambda \nabla p + \gamma_1), \tag{3.10}$$

where

$$\gamma_1 = -\lambda_w \nabla_x p_c + \lambda \int_0^s \nabla_x \left(f_w \frac{\partial p_c}{\partial s} \right)(x, \xi)\mathrm{d}\xi - \big(\lambda_w \rho_w + \lambda_n \rho_n\big) g.$$

Similarly, apply (3.4), (3.6), and (3.7) to (3.1) and (3.2) with $\alpha = w$ to have

$$\phi \frac{\partial s}{\partial t} - \nabla \cdot \big\{ k\big(\lambda \nabla \theta + \lambda_w \nabla p + \gamma_2\big) \big\} = q_w, \tag{3.11}$$

where

$$\gamma_2 = -\lambda_w \nabla_x p_c + \lambda_w \int_0^s \nabla_x \left(f_w \frac{\partial p_c}{\partial s} \right)(x,\xi)\mathrm{d}\xi + \lambda \int_0^s \nabla_x \left(f_w f_n \frac{\partial p_c}{\partial s} \right)(x,\xi)\mathrm{d}\xi - \lambda_w \rho_w g.$$

Finally, it can be seen that the phase velocities are determined by

$$\begin{aligned} u_w &= -k\big(\lambda \nabla\theta + \lambda_w \nabla p + \gamma_2\big), \\ u_n &= k\big(\lambda \nabla\theta - \lambda_n \nabla p + \gamma_3\big), \end{aligned} \tag{3.12}$$

where

$$\gamma_3 = -\lambda_n \int_0^s \nabla_x \left(f_w \frac{\partial p_c}{\partial s} \right)(x,\xi)\mathrm{d}\xi + \lambda \int_0^s \nabla_x \left(f_w f_n \frac{\partial p_c}{\partial s} \right)(x,\xi)\mathrm{d}\xi + \lambda_n \rho_n g.$$

The pressure equation is given by (3.9) and (3.10), while the saturation equation is described by (3.11). In hydrology, it is common to replace the pressures by the pressure heads

$$h_\alpha = p_\alpha/(\rho_{sw} g), \quad \alpha = w, n,$$

where ρ_{sw} is the density of water at the standard temperature and pressure. With the pressure heads h_α, similar equations to those in (3.9)–(3.12) can be obtained; in this paper we shall use the pressures.

To derive the concentration equation, we make use of the usual equilibrium assumption on mass transfer. That is, the constituent instantaneously establishes an equilibrium distribution between the two phases. Then the concentration in each phase is proportional to that in the other phase:

$$c_n = H c_w,$$

where H is called the Henry constant and taken to be one for simplicity. Then under the incompressibility assumption, apply (3.3) and (3.8) to (3.5) to find that

$$\phi \frac{\partial c}{\partial t} - \nabla \cdot \big(D \nabla c - u c \big) + R c = \hat{c}\hat{q}, \tag{3.13}$$

where $c = c_w$, $D = \phi(s_w D_w + s_n D_n)$, and $R = \phi(s_w r_w + s_n r_n)$.

In summary, from (3.9)–(3.11) and (3.13) we have the differential system

$$\begin{aligned} &-\nabla \cdot \big\{ k(\lambda(s,c)\nabla p + \gamma_1(s,c)) \big\} = q(s,c), \\ &\phi \partial_t s - \nabla \cdot \big\{ k\big(\lambda(s,c)\nabla\theta + \lambda_w(s,c)\nabla p + \gamma_2(s,c)\big) \big\} = q_w(s,c), \\ &\phi \partial_t c - \nabla \cdot \big\{ D(s,u_w,u_n)\nabla c - u c \big\} + R(s) c = \hat{c}\hat{q}(s,c), \end{aligned} \tag{3.14}$$

where

$$\begin{aligned} u &= -k(\lambda(s,c)\nabla p + \gamma_1(s,c)), \\ u_w &= -k\big(\lambda(s,c)\nabla\theta + \lambda_w(s,c)\nabla p + \gamma_2(s,c)\big), \\ u_n &= k\big(\lambda(s,c)\nabla\theta - \lambda_n(s,c)\nabla p + \gamma_3(s,c)\big). \end{aligned} \tag{3.15}$$

Finally, s is related to θ through (3.7):

$$s = \mathcal{S}(\theta), \tag{3.16}$$

where $\mathcal{S}(x,\theta)$ is the inverse of (3.7) for $0 \le \theta \le \theta^*(x)$ with

$$\theta^*(x) = -\int_0^1 \left(f_w f_n \frac{\partial p_c}{\partial s}\right)(x,\xi)\mathrm{d}\xi.$$

The differential system in (3.14)–(3.16) determines the main unknowns p, s, θ, and c. The model is completed by specifying boundary and initial conditions.

The division of Γ is

$$\Gamma = \Gamma_1^p \cup \Gamma_2^p = \Gamma_1^\theta \cup \Gamma_2^\theta = \Gamma_1^c \cup \Gamma_2^c,$$
$$\emptyset = \Gamma_1^p \cap \Gamma_2^p = \Gamma_1^\theta \cap \Gamma_2^\theta = \Gamma_1^c \cap \Gamma_2^c.$$

The boundary conditions are specified by

$$\begin{aligned}
&u\cdot\nu - a_1(s,c)p = \varphi_1(s,c), && (x,t)\in\Gamma_1^p\times J,\\
&p = \varphi_2(x,t), && (x,t)\in\Gamma_2^p\times J,\\
&u_w\cdot\nu - a_2(s,c)\theta = \varphi_3(s,c), && (x,t)\in\Gamma_1^\theta\times J,\\
&\theta = \varphi_4(x,t), && (x,t)\in\Gamma_2^\theta\times J,\\
&(uc - D\nabla c)\cdot\nu - a_3(s,c)c = \varphi_5(s,c), && (x,t)\in\Gamma_1^c\times J,\\
&c = \varphi_6(x,t), && (x,t)\in\Gamma_2^c\times J,
\end{aligned} \tag{3.17}$$

where the a_i and φ_i are given functions. The initial conditions are given by

$$\begin{aligned}
&\theta(x,0) = \theta_0(x), \quad x\in\Omega,\\
&c(x,0) = c_0(x), \quad x\in\Omega.
\end{aligned} \tag{3.18}$$

The differential system has a clear structure. Note that while λ_w and λ_n can be zero, λ is always positive (see the assumptions below). That is, the pressure equation is elliptic, and the saturation and concentration equations are parabolic. This model has been analyzed from the computational point of view using finite elements in [9, 10, 11].

3.3. The major result. The assumptions on the physical data are stated below; some of the assumptions in the previous section are repeated for completedness.

(B1) Assume that $\Omega \subset \Re^d$ is a multiply connected domain with Lipschitz boundary Γ, $\Gamma = \Gamma_1^p \cup \Gamma_2^p = \Gamma_1^\theta \cup \Gamma_2^\theta = \Gamma_1^c \cup \Gamma_2^c$, $\Gamma_1^p \cap \Gamma_2^p = \Gamma_1^\theta \cap \Gamma_2^\theta = \Gamma_1^c \cap \Gamma_2^c = \emptyset$, each Γ_i^p, Γ_i^θ, and Γ_i^c is a $(d-1)$-dimensional domain, and $\Gamma_2^p \subset \Gamma_2^\theta \cap \Gamma_2^c$.

(B2) Assume that $\phi \in L^\infty(\Omega)$, $\phi(x) \ge \phi_* > 0$, and $k(x)$ is a bounded, symmetric, and uniformly positive definite matrix, i.e.,

$$0 < k_* \le |\xi|^{-2} \sum_{i,j=1}^d k_{ij}(x)\xi_i\xi_j \le k^* < \infty, \quad x\in\Omega,\ \xi\ne 0\in\Re^d.$$

(B3) The diffusion-dispersion term in (3.5) is assumed to be Fickian in form with the coefficient given by [7]

$$D_\alpha(u_\alpha) = d_{m_\alpha} I + |u_\alpha|\big(d_{l_\alpha}E(u_\alpha) + d_{t_\alpha}E^\perp(u_\alpha)\big), \quad \alpha = w,n,$$

where $d_{m_\alpha} > 0$ is the molecular diffusion coefficient, d_{l_α} and d_{t_α} are the longitudinal and transverse dispersion coefficients, respectively, for the α phase, the matrix $E(u_\alpha)$ is the projection along the direction of flow determined by

$$E(u_\alpha) = \left(\frac{u_{\alpha,i}u_{\alpha,j}}{|u_\alpha|^2}\right), \quad |u_\alpha| = \sqrt{u_{\alpha,1}^2 + \cdots + u_{\alpha,d}^2}, \quad u_\alpha = (u_{\alpha,1},\ldots,u_{\alpha,d}),$$

and $E^\perp(u_\alpha) = I - E(u_\alpha)$.

(B4) $\lambda_\alpha(x,s,c)$ is measurable in $x\in\Omega$ and continuous in s, $c\in[0,1]$ and satisfies that $\lambda_w(0,c)=0$, $\lambda_w(s,c)>0$ for $s>0$, $\lambda_n(1,c)=0$, $\lambda_n(s,0)>0$ for $s<1$, and $0<\lambda_*\le\lambda(x,s,c)\le\lambda^*<\infty$, $x\in\Omega$, s, $c\in[0,1]$.

(B5) Assume that $0<\theta^*\in H^1(\Omega)$ and that $\mathcal{S}:\{(x,\theta):x\in\Omega,\,0\le\theta\le\theta^*(x)\}\to[0,1]$ is measurable in x, continuous and strictly monotone increasing in θ, and satisfies that $\mathcal{S}(x,0)=0$ and $\mathcal{S}(x,\theta^*(x))=1$.

(B6) Suppose that γ_1, γ_2, γ_3, q, q_w, R, and $\hat q$ are continuous in s and c and the following norms are bounded:

$$|||\gamma_1|||_{L^\infty(J;L^2(\Omega))},\quad |||\gamma_2|||_{L^2(\Omega_T)},\quad |||\varphi_1|||_{L^\infty(J;H^{-1/2}(\Gamma_1^p))},\quad |||R|||_{L^2(\Omega_T)},$$
$$|||q_w|||_{L^2(J;H^{-1}(\Omega))},\quad |||\gamma_3|||_{L^2(\Omega_T)},\quad |||\varphi_3|||_{L^2(J;H^{-1/2}(\Gamma_1^\theta))},$$
$$|||\varphi_5|||_{L^2(J;H^{-1/2}(\Gamma_1^c))},\quad |||\hat q|||_{L^2(J;H^{-1}(\Omega))},\quad |||q|||_{L^\infty(J;L^2(\Omega))},$$

where for $v=v(x,s,c)$,

$$|||v||| = \Big\| \sup_{s,c\in[0,1]} |v(x,s,c)| \Big\|$$

for any given norm. Also, for $s,c\in[0,1]$, assume that

$$\gamma_2(0,c)=0,\quad \gamma_1(1,c)-\gamma_2(1,c)=\lambda(1,c)\nabla\theta^*\quad \text{on } \Omega_T,$$
$$\varphi_1(1,c)\le 0,\quad \varphi_3(0,c)\le 0,\quad \varphi_3(1,c)\ge 0\quad \text{on } \Gamma_1^\theta,$$
$$\varphi_1(s,0)\le 0,\quad \varphi_1(s,1)\le 0,\quad \varphi_5(s,0)\le 0,\quad \varphi_5(s,1)\ge 0\quad \text{on } \Gamma_1^c.$$

(B7) Assume that $\partial_t\varphi_4$, $\partial_t\varphi_6\in L^1(\Omega_T)$ and

$$\varphi_2\in L^\infty(J;H^1(\Omega)),\ \varphi_4\in L^2(J;H^1(\Omega)),\ \varphi_6\in L^2(J;W^{1,4}(\Omega)),$$
$$0\le\varphi_4(x,t)\le\theta^*(x),\ 0\le\varphi_6(x,t)\le 1\quad \text{a.e. on } \Omega_T.$$

(B8) In the case of $\Gamma_2^p=\emptyset$ and $a_1\equiv 0$, q and φ_1 are independent of s and c, and

$$\int_{\Gamma_1^p}\varphi_1 \mathrm{d}\sigma = \int_\Omega q\mathrm{d}x.$$

(B9) There is a subset $\Gamma_{1,*}^p\subset\Gamma_1^p$ (with nonzero measure only if $\Gamma_2^p=\emptyset$ and $a_1\not\equiv 0$) such that $a_1\ge a_{1,*}>0$ on $\Gamma_{1,*}^p\times J$.

(B10) $a_i\ge 0$, a_i is continuous in s and c, the norm $|||a_i|||_{L^\infty(\Omega_T)}$ is bounded, $i=1,2,3$, and

$$a_1(1,c)=0\quad \text{on } \Gamma_1^\theta,\quad a_1(s,0)=a_1(s,1)=0\quad \text{on } \Gamma_1^c.$$

(B11) Assume that $q_w(0,c)\ge 0$, $q_n(1,c)=q(1,c)-q_w(1,c)\ge 0$, $q(s,0)\ge 0$, $q(s,1)\ge 0$, $\hat q(s,0)\ge 0$, $R(s)\ge 0$, and $R(s)-\hat c\hat q(s,1)\ge 0$ in Ω_T for $s,c\in[0,1]$, and $0\le\hat c\le 1$ a.e. on Ω_T.

(B12) Let θ_0, $c_0\in L^2(\Omega)$ satisfy $0\le\theta_0\le\theta^*(x)$ and $0\le c_0\le 1$ a.e. on Ω.

Define the spaces

$$V=\left\{v\in H^1(\Omega): v|_{\Gamma_2^p}=0;\ \text{if } \Gamma_2^p=\emptyset \text{ and } a_1\equiv 0,\ \text{then } \int_\Omega v\mathrm{d}x=0\right\},$$
$$W=\{v\in H^1(\Omega): v|_{\Gamma_2^\theta}=0\},$$
$$\Lambda=\{v\in H^1(\Omega): v|_{\Gamma_2^c}=0\}.$$

DEFINITION 3.1. *A weak solution of the system in* (3.14)–(3.18) *is a triple of functions* (p, θ, c) *with* $p \in L^\infty(J; V)+\varphi_2$, $\theta \in L^2(J; W)+\varphi_4$, $c \in L^2(J; \Lambda(s, u_w, u_n))+\varphi_6$ *such that*

$$\phi\partial_t s \in L^2(J; W^*), \quad \phi\partial_t c \in L^2(J; \Lambda^*(s, u_w, u_n)),$$

$$0 \le \theta(x,t) \le \theta^*(x), \quad 0 \le c(x,t) \le 1 \quad \text{a.e. on } \Omega_T,$$

$$s = \mathcal{S}(\theta),$$

$$\begin{aligned}(k\{\lambda(s,c)\nabla p + \gamma_1(s,c)\}, \nabla v) + (a_1(s,c)p, v)_{\Gamma_1^p} \\ = (q(s,c), v) - (\varphi_1(s,c), v)_{\Gamma_1^p} \quad \forall v \in L^\infty(J; V),\end{aligned}$$

$$\begin{aligned}&\int_J \langle \phi\partial_t s, v\rangle\, dt + \int_J (k\{\lambda(s,c)\nabla\theta + \lambda_w(s,c)\nabla p + \gamma_2(s,c)\}, \nabla v)\, dt \\ &+ \int_J (a_2(s,c)\theta, v)_{\Gamma_1^\theta}\, dt = \int_J (q_w(s,c), v)\, dt - \int_J (\varphi_3(s,c), v)_{\Gamma_1^\theta}\, dt \quad \forall v \in L^2(J; W),\end{aligned}$$

$$\begin{aligned}\int_J \langle \phi\partial_t s, v\rangle\, dt + \int_J (\phi(s - s_0), \partial_t v)\, dt = 0 \\ \forall v \in L^2(J; W) \cap W^{1,1}(J; L^1(\Omega)), \quad v(x,T) = 0,\end{aligned}$$

$$\begin{aligned}&\int_J \langle \phi\partial_t c, v\rangle\, dt + \int_J (D(s, u_w, u_n)\nabla c - uc, \nabla v)\, dt + \int_J (R(s)c, v)\, dt \\ &+ \int_J (a_3(s,c)c, v)_{\Gamma_1^c}\, dt = \int_J (\hat{c}\hat{q}(s,c), v)\, dt - \int_J (\varphi_5(s,c), v)_{\Gamma_1^c}\, dt \\ &\qquad \forall v \in L^2(J; \Lambda(s, u_w, u_n)),\end{aligned}$$

$$\begin{aligned}\int_J \langle \phi\partial_t c, v\rangle\, dt + \int_J (\phi(c - c_0), \partial_t v)\, dt = 0 \\ \forall v \in L^2(J; \Lambda(s, u_w, u_n)) \cap W^{1,1}(J; L^1(\Omega)), \quad v(x,T) = 0,\end{aligned}$$

where $s_0 = \mathcal{S}(\theta_0)$*;* u*,* u_w*, and* u_n *are given in* (3.15)*; and*

$$\Lambda(s, u_w, u_n) = \{v \in \Lambda : (D(s, u_w, u_n)\nabla v, \nabla v) < \infty\}.$$

THEOREM 3.2. *Under assumptions* (B1)–(B12)*, the system in* (3.14)–(3.18) *has a weak solution in the sense of Definition* 3.1.

3.4. Proof of the major result. With the same notation as in section 2.3, the discrete counterpart of Definition 3.1 is as follows: Find $p^h \in l_h(V) + \varphi_2^h$, $\theta^h \in l_h(W) + \varphi_4^h$, and $c^h \in l_h(\Lambda(s^h, u_w^h, u_n^h)) + \varphi_6^h$ such that

$$\begin{aligned}(k\{\lambda(s^h, c^h)\nabla p^h + \gamma_1(s^h, c^h)\}, \nabla v) + (a_1(s^h, c^h)p^h, v)_{\Gamma_1^p} \\ = (q(s^h, c^h), v) - (\varphi_1(s^h, c^h), v)_{\Gamma_1^p} \quad \forall v \in l_h(V),\end{aligned} \tag{3.19}$$

$$
\begin{aligned}
&\int_J \left(\phi\partial^{-h}s^h, v\right)\mathrm{d}t + \int_J (k\{\lambda(s^h,c^h)\nabla\theta^h + \lambda_w(s^h,c^h)\nabla p^h\}, \nabla v)\mathrm{d}t \\
&+ \int_J (k\gamma_2(s^h,c^h), \nabla v)\mathrm{d}t + \int_J (a_2(s^h,c^h)\theta^h, v)_{\Gamma_1^\theta}\mathrm{d}t \\
&\quad = \int_J (q_w(s^h,c^h), v)\mathrm{d}t - \int_J (\varphi_3(s^h,c^h), v)_{\Gamma_1^\theta}\mathrm{d}t \quad \forall v \in l_h(W),
\end{aligned} \tag{3.20}
$$

and

$$
\begin{aligned}
&\int_J \left(\phi\partial^{-h}c^h, v\right)\mathrm{d}t + \int_J (D(s^h,u_w^h,u_n^h)\nabla c^h - u^h c^h, \nabla v)\mathrm{d}t \\
&+ \int_J (R(s^h)c^h, v)\mathrm{d}t + \int_J (a_3(s^h,c^h)c^h, v)_{\Gamma_1^c}\mathrm{d}t \\
&\quad = \int_J (\hat{c}^h\hat{q}(s^h,c^h), v)\mathrm{d}t - \int_J (\varphi_5(s^h,c^h), v)_{\Gamma_1^c}\mathrm{d}t \quad \forall v \in l_h(\Lambda(s^h,u_w^h,u_n^h)),
\end{aligned} \tag{3.21}
$$

with u^h, u_w^h, and u_n^h being defined as in (3.15) and $s^h = s_0$ and $c^h = c_0$ for $t < 0$.

LEMMA 3.3. *With $\alpha = w, n$, it holds that*

$$
\begin{aligned}
d_{m_\alpha} + \min(d_{l_\alpha}, d_{t_\alpha})|u_\alpha| \le& \phi^{-1}|\xi|^{-2}\sum_{i,j=1}^d D_{\alpha,ij}(u_\alpha)\xi_i\xi_j \\
&\le d_{m_\alpha} + \max(d_{l_\alpha}, d_{t_\alpha})|u_\alpha|, \quad \xi \neq 0 \in \Re^d,
\end{aligned}
$$

and for $s \in [0,1]$

$$
\begin{aligned}
&\min(d_{m_w}, d_{m_n}) + \min(d_{l_w}, d_{t_w}, d_{l_n}, d_{t_n})(s|u_w| + (1-s)|u_n|) \\
&\le \phi^{-1}|\xi|^{-2}\sum_{i,j=1}^d D_{ij}(s,u_w,u_n)\xi_i\xi_j \\
&\le \max(d_{m_w}, d_{m_n}) + \max(d_{l_w}, d_{t_w}, d_{l_n}, d_{t_n})(s|u_w| + (1-s)|u_n|), \quad \xi \neq 0 \in \Re^d.
\end{aligned}
$$

The first part follows from the definition of $D_\alpha(u_\alpha)$, while the second part comes from the definition of $D(s,u_w,u_n)$.

LEMMA 3.4. *For $h > 0$ small enough, the discrete scheme has a solution such that*

$$
0 \le \theta^h(x,t) \le \theta^*(x), \quad 0 \le c^h(x,t) \le 1 \quad \textit{a.e. on} \quad \Omega_T. \tag{3.22}
$$

This lemma will be shown in the next subsection.

LEMMA 3.5. *The solution to the discrete scheme also satisfies*

$$
\begin{aligned}
&\|p^h\|_{L^\infty(J;H^1(\Omega))} + \|\theta^h\|_{L^2(J;H^1(\Omega))} + \|c^h\|_{L^2(J;H^1(\Omega))} \\
&\quad + \|D^{1/2}(s^h,u_w^h,u_n^h)\nabla c^h\|_{L^2(\Omega_T)} \le C.
\end{aligned} \tag{3.23}
$$

Proof. The bound on p^h can be obtained as in Lemma 2.5 using (3.19); the estimate on θ^h also can be seen from (3.20) using an argument similar to that for proving c^h in Lemma 2.5 (also see [6]). It suffices to obtain a bound on c^h from (3.21). Again, attention is paid to the transport and diffusion-dispersion terms; other terms can be estimated similarly to the method in the proof of Lemma 2.5.

Take $v = c^h - \varphi_6^h \in l_h(\Lambda(s^h, u_w^h, u_n^h))$ in (3.21) to see that

$$\int_J \left(\phi \partial^{-h} c^h, c^h - \varphi_6^h\right) \mathrm{d}t + \int_J (D(s^h, u_w^h, u_n^h)\nabla c^h - u^h c^h, \nabla[c^h - \varphi_6^h])\mathrm{d}t$$
$$+ \int_J (R(s^h)c^h, c^h - \varphi_6^h)\mathrm{d}t + \int_J (a_3(s^h, c^h)c^h, c^h - \varphi_6^h)_{\Gamma_1^c}\mathrm{d}t$$
$$= \int_J (\hat{c}^h \hat{q}(s^h, c^h), c^h - \varphi_6^h)\mathrm{d}t - \int_J (\varphi_5(s^h, c^h), c^h - \varphi_6^h)_{\Gamma_1^c}\mathrm{d}t.$$

The transport and diffusion-dispersion terms can be estimated as follows. By Lemma 3.3, the definition of u_w^h and u_n^h, and the above bound on p^h and θ^h, we have

$$\begin{aligned}
&|(D(s^h, u_w^h, u_n^h)\nabla c^h, \nabla \varphi_6^h)| \\
&\quad \le \epsilon(D(s^h, u_w^h, u_n^h)\nabla c^h, \nabla c^h) + C(D(s^h, u_w^h, u_n^h)\nabla \varphi_6^h, \nabla \varphi_6^h) \\
&\quad \le \epsilon(D(s^h, u_w^h, u_n^h)\nabla c^h, \nabla c^h) + C\|\nabla \varphi_6^h\|_{L^4(\Omega)}^2.
\end{aligned}$$

Also, it follows from Lemmas 3.3 and 3.4 that

$$|(u^h c^h, \nabla c^h)| \le \|u^h\|_{L^2(\Omega)}\|\nabla c^h\|_{L^2(\Omega)} \le \epsilon(D(s^h, u_w^h, u_n^h)\nabla c^h, \nabla c^h) + C\|u^h\|_{L^2(\Omega)}^2$$

and

$$|(u^h c^h, \nabla \varphi_6^h)| \le C\left(\|u^h\|_{L^2(\Omega)}^2 + \|\nabla \varphi_6^h\|_{L^2(\Omega)}^2\right).$$

Apply these estimates and the argument used in the proof of Lemma 2.5 to yield the desired result. □

From this lemma, we have the following counterpart of Corollary 2.6; the proof is also the same.

COROLLARY 3.6. *For any $2 \le r < \infty$, for a subsequence $p^h \rightharpoonup p$ weakly in $L^r(J; H^1(\Omega))$ and $\theta^h \rightharpoonup \theta$ and $c^h \rightharpoonup c$ weakly in $L^2(J; H^1(\Omega))$. Furthermore, $p \in L^\infty(J; V) + \varphi_2$, $\theta \in L^2(J; W) + \varphi_4$, $c \in L^2(J; \Lambda) + \varphi_6$, and*

$$0 \le \theta(x,t) \le \theta^*(x), \quad 0 \le c(x,t) \le 1 \quad \text{a.e. on} \quad \Omega_T.$$

LEMMA 3.7. *There is a subsequence such that $\theta^h \to \theta$ and $c^h \to c$ strongly in $L^2(\Omega_T)$.*

This lemma can be shown in the same manner as in Lemma 2.7 (also see [3, 6]). From it, we have the next corollary, whose proof is the same as in Corollary 2.8. The pointwise convergence for $\{s^h\}$ follows from the continuity of $\mathcal{S}(\theta)$ in θ.

COROLLARY 3.8. *There is a subsequence such that $\theta^h \to \theta$ and $c^h \to c$ strongly in $L^2(J; H^{1-\pi}(\Omega))$ and $L^2(J; H^{1/2-\pi}(\partial\Omega))$ for any $0 < \pi < 1/2$, and $s^h \to s$ and $c^h \to c$ pointwise a.e. on Ω_T.*

Applying Corollaries 3.6 and 3.8 and the same techniques as in the proof of Theorem 2.2, Theorem 3.2 can be shown as before. Thus, it remains to prove Lemma 3.4, which will be carried out in the next subsection.

3.5. Proof of Lemma 3.4. Again, Lemma 3.4 is purely an elliptic result and will follow from the next proposition. For notational convenience the superscript h is omitted below. All functions of s and c are extended constantly outside $[0, 1]$ except $\mathcal{S}$, which is extended as follows [6]:

$$s = \text{extended } \mathcal{S}(\theta) = \begin{cases} \theta & \text{for} \quad \theta < 0, \\ \mathcal{S}(x, \theta) & \text{for} \quad 0 \le \theta \le \theta^*(x), \\ \theta + 1 - \theta^*(x) & \text{for} \quad \theta^*(x) < \theta. \end{cases}$$

PROPOSITION 3.9. *In addition to assumptions* (B1)–(B12)*, suppose that* $0 < \eta_* \le \eta_1(x) \in L^\infty(\Omega)$*,* $0 \le \eta_2(x) \le \eta_1(x)$*,* $0 < \zeta_* \le \zeta_1(x) \in L^\infty(\Omega)$*, and* $0 \le \zeta_2(x) \le \zeta_1(x)$*. Then, for* η_* *and* ζ_* *sufficiently big, the following problem has a weak solution* $(p, \theta, c) \in (V + \varphi_2) \times (W + \varphi_4) \times (\Lambda(s, u_w, u_n) + \varphi_6)$*:*

$$\begin{aligned}(k\{\lambda(s,c)\nabla p + \gamma_1(s,c)\}, \nabla v) + (a_1(s,c)p, v)_{\Gamma_1^p}\\ = (q(s,c), v) - (\varphi_1(s,c), v)_{\Gamma_1^p} \quad \forall v \in V,\end{aligned} \tag{3.24}$$

$$\begin{aligned}&(\eta_1 s, v) + (k\{\lambda(s,c)\nabla\theta + \lambda_w(s,c)\nabla p\}, \nabla v)\\ &\quad + (k\gamma_2(s,c), \nabla v) + (a_2(s,c)\theta, v)_{\Gamma_1^\theta}\\ &\quad = (q_w(s,c), v) - (\varphi_3(s,c), v)_{\Gamma_1^\theta} + (\eta_2, v) \quad \forall v \in W,\end{aligned} \tag{3.25}$$

$$\begin{aligned}&(\zeta_1 c, v) + (D(s, u_w, u_n)\nabla c - uc, \nabla v)\\ &\quad + (R(s)c, v) + (a_3(s,c)c, v)_{\Gamma_1^c}\\ &\quad = (\hat{c}\hat{q}(s,c), v) - (\varphi_5(s,c), v)_{\Gamma_1^c} + (\zeta_2, v) \quad \forall v \in \Lambda(s, u_w, u_n),\end{aligned} \tag{3.26}$$

and

$$0 \le \theta(x,t) \le \theta^*(x), \quad 0 \le c(x,t) \le 1 \quad \text{a.e. on } \Omega_T, \tag{3.27}$$

where u*,* u_w*, and* u_n *are given as in* (3.15)*.*

Proof. Let $\{v_i^j\}_{i=1}^\infty$ $(j = 1, 2, 3)$ be bases for V, W, and Λ, respectively, and set $V_m = \text{span}\{v_1^1, \dots, v_m^1\}$, $W_m = \text{span}\{v_1^2, \dots, v_m^2\}$, and $\Lambda_m = \text{span}\{v_1^3, \dots, v_m^3\}$. With V_m, W_m, and Λ_m replacing V, W, and Λ in (3.24)–(3.26), respectively, we again obtain a Galerkin procedure.

For $v^j = \sum_{i=1}^m \beta_i^j v_i^j$, $j = 1, 2, 3$, we introduce the mapping $\Phi_m : \Re^{3m} \to \Re^{3m}$ by

$$\Phi_m \begin{pmatrix} \beta^1 \\ \beta^2 \\ \beta^3 \end{pmatrix} = \begin{pmatrix} \hat{\beta}^1 \\ \hat{\beta}^2 \\ \hat{\beta}^3 \end{pmatrix},$$

where

$$\begin{aligned}\hat{\beta}_i^1 =& (k\{\lambda(\sigma, v^3 + \varphi_6)\nabla(v^1 + \varphi_2) + \gamma_1(\sigma, v^3 + \varphi_6)\}, \nabla v_i^1)\\ &+ (a_1(\sigma, v^3 + \varphi_6)(v^1 + \varphi_2), v_i^1)_{\Gamma_1^p} - (q(\sigma, v^3 + \varphi_6), v_i^1) + (\varphi_1(\sigma, v^3 + \varphi_6), v_i^1)_{\Gamma_1^p},\\ \hat{\beta}_i^2 =& \big(\eta_1\sigma, v_i^2\big) + (k\{\lambda(\sigma, v^3 + \varphi_6)\nabla(v^2 + \varphi_4) + \lambda_w(\sigma, v^3 + \varphi_6)\nabla(v^1 + \varphi_2)\}, \nabla v_i^2)\\ &+ (k\gamma_2(\sigma, v^3 + \varphi_6), \nabla v_i^2) + (a_2(\sigma, v^3 + \varphi_6)\theta, v_i^2)_{\Gamma_1^\theta}\\ &- (q_w(\sigma, v^3 + \varphi_6), v_i^2) + (\varphi_3(\sigma, v^3 + \varphi_6), v_i^2)_{\Gamma_1^\theta} - (\eta_2, v_i^2),\\ \hat{\beta}_i^3 =& \big(\zeta_1(v^3 + \varphi_6), v_i^3\big) + (D(\sigma, \hat{u}_w, \hat{u}_n)\nabla(v^3 + \varphi_6) - \hat{u}(v^3 + \varphi_6), \nabla v_i^3)\\ &+ (R(\sigma)(v^3 + \varphi_6), v_i^3) + (a_3(\sigma, v^3 + \varphi_6)(v^3 + \varphi_6), v_i^3)_{\Gamma_1^c}\\ &- (\hat{c}\hat{q}(\sigma, v^3 + \varphi_6), v_i^3) + (\varphi_5(\sigma, v^3 + \varphi_6), v_i^3)_{\Gamma_1^c} - (\zeta_2, v_i^3),\end{aligned}$$

where

$$\begin{aligned}&\sigma = \mathcal{S}(v^2 + \varphi_4),\\ &u = -k(\lambda(\sigma, v^3 + \varphi_6)\nabla(v^1 + \varphi_2) + \gamma_1(\sigma, v^3 + \varphi_6)),\\ &u_w = -k\big(\lambda(\sigma, v^3 + \varphi_6)\nabla(v^2 + \varphi_4) + \lambda_w(\sigma, v^3 + \varphi_6)\nabla(v^1 + \varphi_2) + \gamma_2(\sigma, v^3 + \varphi_6)\big),\\ &u_n = k\big(\lambda(\sigma, v^3 + \varphi_6)\nabla(v^2 + \varphi_4) - \lambda_n(\sigma, v^3 + \varphi_6)\nabla(v^1 + \varphi_2) + \gamma_3(\sigma, (v^1 + \varphi_2))\big),\\ &\hat{\xi} = m\xi/(m + |\xi|), \quad \xi = u, u_w, u_n.\end{aligned}$$

Again, we remark that to handle the difficulty associated with the transport and diffusion-dispersion terms, we have introduced $\hat{u}$, $\hat{u}_w$, and $\hat{u}_n$ above. By the assumptions (B1)–(B12), Φ_m is continuous, and in the same fashion as in the proof of Proposition 2.9, we obtain

$$\Phi_m \begin{pmatrix} \beta^1 \\ \beta^2 \\ \beta^3 \end{pmatrix} \cdot \begin{pmatrix} \beta^1 \\ \beta^2 \\ \beta^3 \end{pmatrix} \geq C_1(m)\{\|v^1\|^2_{H^1(\Omega)} + \|v^2\|^2_{H^1(\Omega)} + \|v^3\|^2_{H^1(\Omega)}\} - C,$$

which is strictly positive for $|\beta^1| + |\beta^2|$ sufficiently big. Consequently, Φ_m has a zero; i.e., there is a solution to the Galerkin approximation with $\hat{u}$ (respectively, $\hat{u}_w$ and $\hat{u}_n$) replacing u (respectively, u_w and u_n) for each m.

The rest of the proof is completed with a standard maximum principle argument on (3.25) and (3.26). First, take $v = \theta^- = \min(\theta, 0) \in W$ in (3.25) to see that

$$\begin{aligned}(\eta_1 s - \eta_2, \theta^-) = &-(k\lambda(s,c)\nabla\theta, \nabla\theta^-) - (k\lambda_w(s,c)\nabla p, \nabla\theta^-) - (k\gamma_2(s,c), \nabla\theta^-) \\ &-(a_2(s,c)\theta, \theta^-)_{\Gamma_1^\theta} + (q_w(s,c), \theta^-) - (\varphi_3(s,c), \theta^-)_{\Gamma_1^\theta} \leq 0\end{aligned}$$

by assumptions (B4), (B6), and (B11). This implies that $\theta^- = 0$ a.e. on Ω_T by the definition of $\mathcal{S}$ provided η_* is sufficiently large; i.e., $\theta \geq 0$ a.e. on Ω_T. Now, with $v = (\theta - \theta^*)^+ = \max(\theta - \theta^*, 0) \in W$ in (3.25) and use (3.24) ($(\theta - \theta^*)^+ \in V$ by (B1); if $\Gamma_2^p = \emptyset$ and $a_1 \equiv 0$, consider $v - \int_\Omega v\mathrm{d}x$) we see that

$$\begin{aligned}(\eta_1 s - \eta_2, (\theta - \theta^*)^+) = &-(k\{\lambda(s,c)\nabla\theta - \lambda_n(s,c)\nabla p - \gamma_1(s,c) + \gamma_2(s,c)\}, \nabla(\theta - \theta^*)^+) \\ &+(a_1(s,c)p + \varphi_1(s,c) - a_2(s,c)\theta - \varphi_3(s,c), (\theta - \theta^*)^+)_{\Gamma_1^\theta} \\ &-(q_n(s,c), (\theta - \theta^*)^+) \leq 0\end{aligned}$$

by assumptions (B4), (B6), (B10), and (B11), from which we conclude that $\theta \leq \theta^*$. The second part in (3.27) can be shown as in the proof of Proposition 2.9. Thus, the proof is complete. □

SINGULARITIES OF DISTRIBUTIONS VIA THE WAVELET TRANSFORM*

JAIME NAVARRO†

Abstract. For a given distribution u in $\mathcal{S}'(\mathbf{R}^2)$, a wavelet transform of u with respect to an admissible function is defined in such a way that the wavelet transform of u yields a function on phase space whose high-frequency singularities are precisely the elements in the wave front set of u.

Key words. admissible functions, wavelet transform, wave front set

AMS subject classifications. 42A38, 44A05

Introduction. The theory of distributions, or generalized functions, is a central tool in analysis, mathematical physics, and applied mathematics. A key element in distribution theory is the notion of the wave front set of a distribution. This set is a subset of phase space whose elements are pairs of locations and associated directions at which the distribution fails to be smooth. The wave front set plays several major roles in the theory of distributions, two of which are the following. First, the "pointwise" product of two distributions can be defined only when their wave front sets have empty intersection; knowledge of wave front sets proves crucial in discussions of singular solutions to certain nonlinear differential equations. Second, the wave front set of a distribution solution to a linear partial differential equation is invariant under flow of phase space that is associated with the partial differential operator; knowledge of the wave front set for Cauchy data allows very precise determination of the propagation of singularities in the corresponding solution.

Despite the utility and power of the concept, the definition of the wave front set is somewhat indirect. Suppose, for illustration purposes, that we wish to find the C^∞ wave front set for a distribution u that is defined pointwise (i.e., is an ordinary function) on $\mathbf{R}^n$.

Recall that a C^∞ function of compact support is characterized by the fact that its Fourier transform vanishes faster at large values of its argument k than the reciprocal of any polynomial in k. To determine whether the pair (x, k), where x is a point in $\mathbf{R}^n$ and k is a direction in the cotangent space to $\mathbf{R}^n$ at x, is in the C^∞ wave front set of u, we first localize u by multiplying it by a C^∞ function ϕ with compact support containing x. We then inspect the Fourier transform of ϕu in the direction k. If there is a bounded sequence of such cutoff functions ϕ whose supports converge to x for each of which the Fourier transform of ϕu in the direction k fails to fall off faster than the reciprocal of every polynomial in $|k|$, then the pair (x, k) is said to be in the wave front set for u. In this way, the wave front set specifies the directions k along which u fails to be smooth, at various points x.

The projection of the C^∞ wave front set onto configuration space $\boldsymbol{R^n}$ is the set of points x at which u fails to be C^∞. But the wave front set itself has not been identified as the set of singularities of any distribution on phase space. Especially in applications to partial differential equations, where many concepts are formulated using functions on phase space, the definition of the wave front subset of phase space without reference to an explicit function on phase space seems conceptually incomplete.

This paper supplies precisely this missing conceptual ingredient by formulating an explicit transform that, applied to any distribution in $\mathcal{S}'(\mathbf{R}^2)$, yields a function on phase space whose singularities are the wave front set of a distribution.

The definition of the wave front set of a distribution involves the high-frequency behavior of each member of a sequence of windowed Fourier transforms of the distribution. Finding singularities of a function through use of the windowed Fourier transform is known to be difficult; this difficulty is reflected in the wave front set definition. In contrast, the wavelet transform is well suited to the direction of singularities and offers an alternative to the windowed Fourier transform [1, 4]. Furthermore, the wavelet transform of a distribution can be regarded as a function on phase space. Rephrasing the definition of the wave front set in terms of the windowed Fourier transform thus leads to the following characterization: The C^∞ wave front set of a distribution is precisely the set of high-frequency singularities of the wavelet transform of the distribution with respect to a suitably chosen C^∞ basic wavelet.

The continuous wavelet transform thus provides a simple explicit constructive characterization for the wave front set. It also holds promise of far greater utility. The invariance of the wave front set of a solution to a partial differential equation under the bicharacteristic flow generated by the symbol of the differential operator is a very powerful tool. It is likely that the wavelet transform of a solution exhibits simple behavior under the bicharacteristic flow on phase space, with the high-frequency limit invariant under that flow. It is conceivable that the wavelet transform will provide a canonical decomposition of initial data for hyperbolic partial differential equations into component portions that propagate along bicharacteristic curves.

In this paper we construct a mother wavelet in $\mathcal{S}(\mathbf{R}^2)$ and an irreducible group action with the property that the associated wavelet transform of a distribution in $\mathcal{S}'(\mathbf{R}^2)$ is singular along the wave front set of the distribution.

Singularities in direction (1, 0) are treated only in frequency space, but rotation can be used to investigate the wave front set in other directions. A mother wavelet in $\mathcal{S}(\mathbf{R}^2)$ and an irreducible group action are constructed with the property that the associated wavelet transform of a distribution in $\mathcal{S}'(\mathbf{R}^2)$ is singular along the wave front set of the distribution. First, the definition of the wavelet transform of distributions in $\mathcal{S}(\mathbf{R}^2)$ is given, and then the main result is stated, which relates the notion of the wave front set and the wavelet transform of distributions in $\mathcal{S}'(\mathbf{R}^2)$.

Let us begin by defining an irreducible group action on $L^2(\mathbf{R}^2)$.

NOTATIONS.

1. *For a in $\mathbf{R} \setminus \{0\}$, let* $M(a) = \begin{pmatrix} a^2 & 0 \\ 0 & a \end{pmatrix}$.

2. *Let $Q = \{z \in \mathbf{C}: \mid z \mid = 1\}$. Identify Q with $[0,1)$ by associating with $r \in [0,1)$ the complex number $\zeta = e^{2\pi i r} \in Q$.*

DEFINITION 1. *For h in $L^2(\mathbf{R}^2)$, define the following operators:*

$$(J_a h)(x) = \frac{1}{\sqrt{|\det\ M(a)|}} h(M(a)^{-1}x), \quad x \in \mathbf{R}^2, \quad a \in \mathbf{R} \setminus \{0\},$$

$$(T_b h)(x) = h(x-b), \quad x, b \in \mathbf{R}^2,$$

$$(E_b h)(x) = e^{2\pi i x\cdot b} h(x), \quad x, b \in \mathbf{R}^2,$$
$$(T_\tau h)(x) = h(x_1, x_2 - \tau), \quad x = (x_1, x_2) \in \mathbf{R}^2, \quad \tau \in \mathbf{R},$$
$$(E_\tau h)(x) = e^{2\pi i x_2 \tau} h(x), \quad x = (x_1, x_2) \in \mathbf{R}^2, \quad \tau \in \mathbf{R}.$$

DEFINITION 2. *Let* $G = \{(a, b, \tau, \zeta) : a \in \mathbf{R} \setminus \{0\}, b \in \mathbf{R}^2, \tau \in \mathbf{R}, \text{and } \zeta \in Q\}$. *For* $(a_1, b_1, \tau_1, \zeta_1)$ *and* $(a_2, b_2, \tau_2, \zeta_2)$ *in* G, *define*

$$(a_1, b_1, \tau_1, \zeta_1) \cdot (a_2, b_2, \tau_2, \zeta_2) = \left(a_1 a_2, b_1 + M(a_1) b_2, \tau_1 + \frac{\tau_2}{a_1}, \zeta_1 \zeta_2 e^{-2\pi i b_{12} \frac{\tau_2}{a_1}} \right),$$

where $b_1 = (b_{11}, b_{12})$ *and* $b_2 = (b_{21}, b_{22})$ *are in* $\mathbf{R}^2$.

Remark 1. G is a nonunimodular, locally compact topological group, with identity $(1, 0, 0, 1)$ and

$$(a, b, \tau, \zeta)^{-1} = (a^{-1}, -M(a)^{-1} b, -a\tau, \zeta^{-1} e^{-2\pi i b_2 \tau}),$$

where $b = (b_1, b_2)$ *is in* $\mathbf{R}^2$. Furthermore, $d(a, b, \tau, \zeta) = \frac{1}{|\det\ M(a)|}\, da\, db\, d\tau\, dr$ and $d_1(a, b, \tau, \zeta) = \frac{1}{|a|}\, da\, db\, d\tau\, dr$ are the left and right Haar measures, respectively, with $\zeta = e^{2\pi i r}$.

DEFINITION 3. *For* (a, b, τ, ζ) *in* G, *define the* 4*-parameter family of operators* $U(a, b, \tau, \zeta) = \zeta E_\tau T_b J_a$. $U(a, b, \tau, \zeta)$ *acts on the Hilbert space* $L^2(\mathbf{R}^2)$ *by*

$$(U(a, b, \tau, \zeta) h)(x) \equiv (\zeta E_\tau T_b J_a h)(x) = \zeta e^{2\pi i x_2 \tau} \frac{1}{\sqrt{|\det\ M(a)|}} h(M(a)^{-1}(x - b)).$$

DEFINITION 4. *For* (a, b, τ, ζ) *in* G, h *in* $\mathcal{S}(\mathbf{R}^2)$, *and* u *in* $\mathcal{S}'(\mathbf{R}^2)$, *define the wavelet transform of* u *with respect to* h *as*

$$(L_h u)(a, b, \tau, \zeta) = u[\overline{\zeta E_\tau T_b J_a h}].$$

The action of G on $\mathcal{S}(\mathbf{R}^2)$ has been chosen to meet several criteria that will be explained in the proof of Theorem 1.

The most important property of the action of G is that, as $a \to 0$, the function $(U(a, b, \tau, \zeta)h)(x)$ concentrates near $x = b$ in coordinate space, while its Fourier transform $(\widehat{U(a, b, \tau, \zeta)h})(k) = (\zeta\, T_\tau E_{-b} J_{1/a} \hat{h})(k)$ concentrates in cones around $(1, 0)$ in Fourier transform space.

The action in G on the Fourier transform $\hat{h}$ is primarily through the operators T_τ and $J_{1/a}$ that transform the arguments of $\hat{h}$. To discuss this aspect of the action of G, we introduce the map $\mathcal{V} : \mathbf{R}^2 \to \mathbf{R}^2$ such that for each (a, τ) in $(\mathbf{R} \setminus \{0\}) \times \mathbf{R}$, $\mathcal{V}(a, \tau)(k_1, k_2) \equiv (\frac{k_1}{a^2}, \frac{k_2}{a} + \tau)$.

It is also convenient to define the set $\triangle_\xi$ of parameters (a, τ) for which the image of a rectangle Ω covers the point ξ.

DEFINITION 5. *Let* $\xi = (\xi_1, \xi_2)$ *be in* $\mathbf{R}^+ \times \mathbf{R}$. *Let* $\Omega = [c_1, c_2] \times [d_1, d_2]$, *where* $0 < c_1 < c_2$ *and* $d_1 < 0 < d_2$. *Define* $\triangle_\xi = \{(a, \tau) \in (\mathbf{R} \setminus \{0\}) \times \mathbf{R} : \mathcal{V}(a, \tau)\Omega \ni \xi\}$.

LEMMA 1. *Let* $\xi = (\xi_1, \xi_2)$ *be in* $\mathbf{R}^+ \times \mathbf{R}$. *Suppose that* $\Omega = [c_1, c_2] \times [d_1, d_2]$, *where* $0 < c_1 < c_2$ *and* $d_1 < 0 < d_2$. *Then*

$$\triangle_\xi = \left\{ (a, \tau) \in (\mathbf{R} \setminus \{0\}) \times \mathbf{R} : \sqrt{\frac{c_1}{\xi_1}} \le |a| \le \sqrt{\frac{c_2}{\xi_1}} \quad \text{and} \quad \xi_2 - \frac{d_2}{|a|} \le \tau \le \xi_2 - \frac{d_1}{|a|} \right\}.$$

See the appendix for the proof.

Remark 2. It follows by Lemma 1 that if $\Omega = [c_1, c_2] \times [d_1, d_2]$, where $0 < c_1 < c_2$ and $d_1 < 0 < d_2$, then for each (a, τ) in $\triangle_\xi$,

$$\mathcal{V}(a,\tau)\Omega = \left\{(\eta_1, \eta_2) \in \mathbf{R}^+ \times \mathbf{R} : \frac{c_1}{a^2} \le \eta_1 \le \frac{c_2}{a^2} \text{ and } \frac{d_1}{|a|} + \tau \le \eta_2 \le \frac{d_2}{|a|} + \tau\right\}.$$

LEMMA 2. *Let $\Omega = [c_1, c_2] \times [d_1, d_2]$, where $0 < c_1 < c_2$ and $d_1 < 0 < d_2$. Let Γ_1 be an open cone, symmetric with respect to $(1, 0)$ with opening half-angle $\beta, 0 < \beta < \frac{\pi}{2}$. Then there is a nonempty open cone $\Gamma \subset \Gamma_1$, symmetric with respect to $(1, 0)$ with opening half-angle $\alpha, 0 < \alpha < \frac{\pi}{2}$, such that for any ξ in Γ with $|\xi|$ sufficiently large, $\mathcal{V}(a, \tau)\Omega \subset \Gamma_1$ for all (a, τ) in $\triangle_\xi$.*

See the appendix for the proof.

DEFINITION 6. *Let $\Omega = [c_1, c_2] \times [d_1, d_2]$, where $0 < c_1 < c_2$ and $d_1 < 0 < d_2$, and let $X \subset \mathbf{R}^2$. For u in $\mathcal{S}'(\mathbf{R}^2)$ and h in $\mathcal{S}(\mathbf{R}^2)$, define*

$$(L_h u)|_{(X, \triangle_\xi)} = \text{ Sup } \{|(L_h u)(a, b, \tau, \zeta)| : (a, \tau) \in \triangle_\xi, b \in X, \text{ and } \zeta \in Q\},$$

where $\triangle_\xi = \{(a, \tau) \in (\mathbf{R} \setminus \{0\}) \times \mathbf{R} : \mathcal{V}(a, \tau)\Omega \ni \xi\}$, and $\mathcal{V}(a, \tau)(k_1, k_2) = (\frac{k_1}{a^2}, \frac{k_2}{a} + \tau)$.

The following two definitions of the wave front set for distributions are due to Hörmander [5].

DEFINITION 7. *Let u be in $\mathcal{E}'(V)$, where V is an open set in $\mathbf{R}^2$. Define the cone $\sum(u)$ as the set of all η in $\mathbf{R}^2 \setminus \{0\}$ having no open conic neighborhood Γ in which $(1 + |\xi|)^N |\hat{u}(\xi)|$ is bounded for all positive integers N and all ξ in Γ.*

DEFINITION 8. *Let u be in $\mathcal{D}'(V)$, where V is an open set in $\mathbf{R}^2$. Then the closed subset of $V \times (\mathbf{R}^2 \setminus \{0\})$ defined by $WF(u) = \{(x, \xi) \in V \times (\mathbf{R}^2 \setminus \{0\}) : \xi \in \sum_x(u)\}$ is called the wave front set of u, where $\sum_x(u) = \bigcap_\phi \sum(\phi u), \phi \in \mathcal{D}(V)$, and $\phi(x) \neq 0$.*

The main result of this paper is now given.

THEOREM 1. *Let u be in $\mathcal{S}'(\mathbf{R}^2)$. Let h be a function such that $\hat{h} \in \mathcal{D}(\mathbf{R}^2)$ and* supp $\hat{h} \subset \Omega$, *where $\Omega = [c_1, c_2] \times [d_1, d_2]$, $0 < c_1 < c_2$ and $d_1 < 0 < d_2$, and h is not identically zero. Let $\xi = (\xi_1, \xi_2)$ be in $\mathbf{R}^+ \times \mathbf{R}$. Let $\triangle_\xi$ be as defined. Let $(x_0, (1, 0))$ be in $\mathbf{R}^2 \times \mathbf{R}^2$.*

(1) *Suppose that $(x_0, (1, 0)) \notin WF(u)$. Then there is an open neighborhood X of x_0 and an open conic neighborhood Γ of $(1, 0)$ such that $(L_h u)|_{(X, \triangle_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ in Γ.*

(2) *Conversely, suppose that there is a function $\psi \in \mathcal{D}(\mathbf{R}^2)$ with $\psi = 1$ in a neighborhood of x_0, an open neighborhood X of* supp ψ, *and an open conic neighborhood Γ of $(1, 0)$ such that $(L_h \psi u)|_{(X, \triangle_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ in Γ. Then $(x_0, (1, 0)) \notin WF(u)$.*

The proof of Theorem 1 makes use of the following lemma.

LEMMA 3. *Let u be in $\mathcal{S}'(\mathbf{R}^2)$. Let h be a function such that $\hat{h} \in \mathcal{D}(\mathbf{R}^2)$ and* supp $h \subset \Omega$, *where $\Omega = [c_1, c_2] \times [d_1, d_2]$, with $0 < c_1 < c_2$ and $d_1 < 0 < d_2$. Let ϕ be a function in $\mathcal{E}(\mathbf{R}^2)$, each of whose derivatives is polynomially bounded. Let Z be a compact set in $\mathbf{R}^2$ with $Z \cap$ supp $\phi = \emptyset$. Let Γ be an open cone symmetric with respect to $(1, 0)$ with opening half-angle less than $\frac{\pi}{2}$. Then $(L_h \phi u)|_{(Z, \triangle_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ in Γ.*

See the appendix for the proof.

Proof of Theorem 1. Suppose that $(x_0, (1, 0)) \notin WF(u)$. Then $\widehat{\psi u}$ decreases rapidly in some open conic neighborhood Γ_1 around $(1, 0)$ for some ψ in $\mathcal{D}(\mathbf{R}^2)$ with $\psi = 1$ in a neighborhood of x_0.

Let $\xi = (\xi_1, \xi_2)$ be in $\mathbf{R}^+ \times \mathbf{R}$. Then by Lemma 2, there is a nonempty open cone $\Gamma \subset \Gamma_1$ around $(1,0)$ such that if $\xi \in \Gamma$ with $|\xi|$ sufficiently large,

$$O_\xi \equiv \bigcup\nolimits_{(a,\tau)\in\triangle_\xi} \mathcal{V}(a,\tau)\Omega \subset \Psi_\xi,$$

where

$$\Psi_\xi \equiv \left[\xi_1\frac{c_1}{c_2}, \xi_1\frac{c_2}{c_1}\right] \times \left[\xi_2 - (d_2-d_1)\sqrt{\frac{\xi_1}{c_1}},\ \xi_2 + (d_2-d_1)\sqrt{\frac{\xi_1}{c_1}}\right],$$

and $\Psi_\xi \subset \Gamma_1$ for all (a,τ) in $\triangle_\xi$.

Now, note that

$$\begin{aligned}(L_h u)(a,b,\tau,\zeta) &= u[\overline{\zeta E_\tau T_b J_a h}] \\ &= \psi u[\overline{\zeta E_\tau T_b J_a h}] + (1-\psi)u[\overline{\zeta E_\tau T_b J_a h}],\end{aligned}$$

and since $\psi u \in \mathcal{E}'(\mathbf{R}^2)$, it follows that

$$\begin{aligned}&(L_h \psi u)(a,b,\tau,\zeta) = \psi u[\overline{\zeta E_\tau T_b J_a h}] \\ &= \int_{\mathbf{R}^2} \widehat{\psi u}(\eta)\overline{(\zeta E_\tau T_b J_a h)\,\widehat{}\,(\eta)}\ d\eta \\ &= \int_{\mathbf{R}^2} \widehat{\psi u}(\eta)\overline{\zeta}\epsilon^{2\pi i b\cdot(\eta_1,\eta_2-\tau)}\sqrt{|\det M(a)|}\ \ \overline{\hat{h}(a^2\eta_1, a(\eta_2-\tau))}d\eta.\end{aligned}$$

The integrand is nonzero only if $(a^2\eta_1, a(\eta_2-\tau)) \in \operatorname{supp}\hat{h}$, which means that $(\eta_1,\eta_2) \in \mathcal{V}(a,\tau)\Omega$.

Thus for each b in $\mathbf{R}^2$, (a,τ) in $\triangle_\xi$, and ζ in Q,

$$\begin{aligned}&|(L_h\psi u)(a,b,\tau,\zeta)| \\ &\le \sqrt{|\det M(a)|}\ \|\hat{h}\|_\infty \int_{O_\xi} |\widehat{\psi u}(\eta)|d\eta.\end{aligned}$$

But $O_\xi \subset \Gamma_1$ for all ξ in Γ with $|\xi|$ sufficiently large, and since $\widehat{\psi u}$ decreases rapidly in Γ_1, for each $N = 1,2,\ldots$, there is a constant C_N such that

$$\begin{aligned}&|(L_h\psi u)(a,b,\tau,\zeta)| \le C_N\sqrt{|\det M(a)|}\ \|\hat{h}\|_\infty \int_{O_\xi} \frac{1}{(1+|\eta|)^N}d\eta \\ &\le \left|\xi_1\frac{c_2}{c_1}\right|^{\frac{3}{2}}\ \|\hat{h}\|_\infty\ C_N\frac{2(d_2-d_1)\sqrt{\frac{\xi_1}{c_1}}}{N-1}\ \frac{1}{(1+|\xi_1\frac{c_1}{c_2}|)^{N-1}} \\ &\to 0 \quad \text{as} \quad |\xi| \to \infty\end{aligned}$$

for all ξ in Γ, where N may be chosen arbitrarily large.

On the other hand, $(1-\psi)\,u\,[\overline{\zeta E_\tau T_b J_a h}] = (L_h(1-\psi)u)(a,b,\tau,\zeta)$.

Let X be an open neighborhood of x_0 with $\overline{X} \cap \operatorname{supp}(1-\psi) = \emptyset$. Since $(1-\psi)$ has bounded derivatives and since Γ_1 is an open cone around $(1,0)$, it follows by Lemma 3 that $L_h((1-\psi)u)|_{(X,\triangle_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ in Γ_1.

Thus $(L_h u)|_{(X,\triangle_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ in Γ.

This proves the first part of Theorem 1.

In order to prove the second part of Theorem 1, we will apply the following theorem by Grossmann, Morlet, and Paul.

THEOREM 2 (see [2]). *Let U be strongly continuous square integrable unitary representation of a locally compact topological group G, acting on the Hilbert space H. Then there exists in H a unique self-adjoint positive operator C such that the following hold:*

(i) *The set of admissible vectors coincides with the domain of C, where the admissibility condition for h means $\int_G |\langle h, U(\gamma)h\rangle|^2 d_\gamma < \infty$, with γ in G, and where d_γ is the left Haar measure on G.*

(ii) *For f, g, h in H with h admissible,*

$$\int_G \langle f, U(\gamma)h\rangle \, \overline{\langle g, U(\gamma)h\rangle} d\gamma = C_h \langle f, g\rangle,$$

where $C_h = \langle Ch, Ch\rangle$.

See [2, p. 2475] for the proof.

Remark 3. U is said to be square-integrable if U is irreducible and there is in H at least one nonzero admissible vector [3].

Now, by considering the 4-parameter family of operators $U(a, b, \tau, \zeta) = \zeta E_\tau T_b J_a$, where $(a, b, \tau, \zeta) \in G$, then U is a strongly continuous unitary irreducible representation of the group G acting on the Hilbert space $L^2(\mathbf{R}^2)$. Next, suppose that h satisfies the hypotheses of Theorem 1. Then, in particular, $\hat{h}(0, k_2) = 0$ for all k_2 in $\mathbf{R}$. This implies that

$$C_h \equiv \int_{\mathbf{R}} \int_{\mathbf{R}} |\hat{h}(k_1, k_2)|^2 \frac{1}{2|k_1|} dk_1 \, dk_2 < \infty.$$

But it can be shown that

$$\int_{\mathbf{R}} \int_{\mathbf{R}} |\hat{h}(k_1, k_2)|^2 \frac{1}{2|k_1|} dk_1 \, dk_2 < \infty$$

if and only if

$$\int_G |\langle h, U(a, b, \tau, \zeta)h\rangle|^2 d(a, b, \tau, \zeta) < \infty.$$

Thus h is admissible. Hence, by Theorem 2, for f, g in $L^2(\mathbf{R}^2)$,

$$\int_G \langle f, U(a, b, \tau, \zeta)h\rangle \, \overline{\langle g, U(a, b, \tau, \zeta)h\rangle} d(a, b, \tau, \zeta) = C_h \langle f, g\rangle.$$

Let us now give the proof of the second part of Theorem 1.

Suppose that there is a function ψ in $\mathcal{D}(\mathbf{R}^2)$ with $\psi = 1$ in a neighborhood of x_0, an open neighborhood X of supp ψ, and an open conic neighborhood Γ of (1, 0) such that $(L_h \psi u)|_{(X, \Delta_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ in Γ. Without loss of generality, it will be assumed that X is bounded.

Let $Y = \text{supp } \psi$. Let A be a closed ball centered at x_0 of radius $\mathbf{R} > 0$ such that $X \subset A$ and set $L = \text{dist}(\partial Y, \partial X)$. Note that $L > 0$ by hypothesis. Let $v = \psi u$. Then $v \in \mathcal{E}'(\mathbf{R}^2)$ and supp $v \subset Y$.

Then the following two claims are needed.

CLAIM 1. *Let $\widehat{w}(\xi) = \int_G (L_h v)(a, b, \tau, \zeta)(U(a, b, \tau, \zeta)h)\hat{}(\xi) d(a, b, \tau, \zeta)$. Then $\widehat{w}(\xi)$ is well defined for all ξ in the cone Γ, and $\widehat{w}$ is rapidly decreasing in Γ.*

CLAIM 2. *For any function ϕ with $\breve{\phi} \in \mathcal{D}(\Gamma)$,*

$$\frac{1}{C_h}\int_\Gamma \hat{w}(\xi)\breve{\phi}(\xi)\,d\xi = v[\phi].$$

Finally, note that by Claim 2, $\widehat{v}|_\Gamma = \frac{1}{C_h}\,\widehat{w}$, and by Claim 1, $\frac{1}{C_h}\,\widehat{w}$ decreases rapidly in Γ. Therefore, $(x_0,(1,0)) \notin WF(u)$.

This completes the proof of Theorem 1.

Proof of Claim 1. Let ξ be in Γ. Then

$$|\hat{w}\,(\xi)| \le \int_0^1 \int_{\mathbf{R^2}} \int_{\mathbf{R}} \int_{\mathbf{R}} |(L_h v)(a,b,\tau,\zeta)||\ \hat{h}(a^2\xi_1, a(\xi_2\,-\,\tau))|\frac{1}{\sqrt{|\det M(a)|}}\,da\,d\tau\,db\,dr.$$

Note that $\hat{h}(a^2\xi_1, a(\xi_2-\tau)) \neq 0$ only if $(a,\,\tau) \in\, \Delta_\xi$. Then

$$|\hat{w}(\xi)| \le ||\hat{h}||_\infty\,(I_1(\xi)\,+\,I_2(\xi)\,+I_3(\xi)),$$

where

$$I_1(\xi) = \int_0^1 \int_X \int_{\Delta_\xi} |(L_h v)(a,\,b,\,\tau,\,\zeta)|\frac{1}{\sqrt{|\det M(a)|}}\,da\,d\tau\,db\,dr,$$

$$I_2(\xi) = \int_0^1 \int_{A\setminus X} \int_{\Delta_\xi} |(L_h v)(a,\,b,\,\tau,\,\zeta)|\frac{1}{\sqrt{|\det M(a)|}}\ \ da\,d\tau\,db\,dr,$$

and

$$I_3(\xi) = \int_0^1 \int_{\mathbf{R}^2\setminus A} \int_{\Delta_\xi} |(L_h v)(a,\,b,\,\tau,\,\zeta)|\frac{1}{\sqrt{|\det M(a)|}}\ \ da\,d\tau\,db\,dr.$$

Now, by hypothesis, $(L_h v)|_{(X,\Delta_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ for all ξ in Γ. Then for each $N = 1,\,2,\ldots,$ there is a constant P_N such that for all ξ in Γ,

$$\begin{aligned} I_1(\xi) &\le \frac{P_N}{(1\,+\,|\xi|)^N}\ \ m(X)\int_{\Delta_\xi}\frac{1}{|a|^{\frac{3}{2}}}da\,d\tau \\ &\le \frac{P_N}{(1\,+\,|\xi|)^N}\ \ m(X)(d_2-d_1)\left(\sqrt{\frac{\xi_1}{c_1}}\right)^{\frac{5}{2}}\left(\sqrt{\frac{c_2}{\xi_1}}-\sqrt{\frac{c_1}{\xi_1}}\right) \\ &\to 0 \quad \text{as} \quad |\xi|\to\infty \quad \text{in} \quad \Gamma, \end{aligned}$$

where N may be chosen arbitrarily large.

Consider now

$$I_2(\xi) = \int_0^1 \int_{A\setminus X} \int_{\Delta_\xi} |(L_h v)(a,\,b,\,\tau,\,\zeta)|\frac{1}{\sqrt{|\det M(a)|}}\ \ da\,d\tau\,db\,dr.$$

Because $A\setminus X$ is a compact set and $(A\setminus X)\cap$ supp ψ is empty, and since

$$(L_h v)(a,\,b,\,\tau,\,\zeta) = u[\psi\overline{\zeta\,E_\tau T_b\,J_a\,h}],$$

it follows from Lemma 3 that $L_h(\psi u)|_{(A \setminus X, \Delta_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ in Γ.

Then for each $N = 1, 2, \ldots$, there is a constant R_N such that for all ξ in Γ,

$$I_2(\xi) \le \frac{R_N}{(1 + |\xi|)^N} m(A \setminus X)(d_2 - d_1) \left(\sqrt{\frac{\xi_1}{c_1}}\right)^{\frac{5}{2}} \left(\sqrt{\frac{c_2}{\xi_1}} - \sqrt{\frac{c_1}{\xi_1}}\right).$$

Thus, $I_2(\xi) \to 0$ rapidly as $|\xi| \to \infty$ in Γ.

Now for

$$I_3(\xi) = \int_0^1 \int_{\mathbf{R}^2 \setminus A} \int_{\Delta_\xi} |(L_h v)(a, b, \tau, \zeta)| \frac{1}{\sqrt{|\det M(a)|}} \, da \, d\tau \, db \, dr$$

note that, since $u \in \mathcal{S}'(\mathbf{R}^2)$ and supp $\psi = Y$, it follows that

$$(L_h v)(a, b, \tau, \zeta) = \int_Y (-1)^{|\alpha|} g(x) D_x^\alpha \psi \overline{\zeta E_\tau T_b J_a h(x)} \, dx$$

for some polynomially bounded continuous function g and some multiindex α.

Because $\psi \in \mathcal{D}(\mathbf{R}^2)$, there is a constant $M_1 > 0$ such that $|D^\delta \psi(x)| \le M_1$ for all multiindices δ with $|\delta| \le |\alpha|$ and all x in $\mathbf{R}^2$. Also, because $h \in \mathcal{S}(\mathbf{R}^2)$, for each $N = 1, 2, \ldots$, there is a constant $B_N > 0$ such that $|D^\gamma h(x)| \le \frac{B_N}{(1+|x|)^N}$ for all x in $\mathbf{R}^2$, and since g is a continuous function and Y is compact, it follows that there is a constant $M_2 > 0$ such that $|g(x)| \le M_2$ for all x in Y. Hence,

$$\begin{aligned} &|(L_h v)(a, b, \tau, \zeta)| \\ &\le M_1 M_2 B_N \sum_{\beta \le \alpha} \sum_{\substack{\gamma \le \beta \\ \gamma_1 = \beta_1}} \binom{\beta}{\gamma} \frac{|2\pi\tau|^{\beta_2 - \gamma_2}}{|a|^{\frac{3}{2}}} \int_Y \frac{1}{(1 + |M(a)^{-1}(x - b)|)^N} dx. \end{aligned}$$

Note that if $\xi \in \Gamma$ and $|\xi|$ is sufficiently large, then $|a| < 1$ for $(a, \tau) \in \Delta_\xi$.

In this case $\frac{1}{a^2} \le \frac{1}{a^4}$, and $\frac{1}{|a|}|x - b| \le |M(a)^{-1}(x - b)|$. Note also that for $x \in Y$ and $b \in \mathbf{R}^2 \setminus A$, we have $0 < L + (|x_0 - b| - R) \le |x - b|$. Then

$$\int_Y \frac{1}{(1 + \frac{1}{|a|}|x - b|)^N} dx \le m(Y) \frac{1}{(1 + \frac{1}{|a|}(L + |x_0 - b| - R))^N}.$$

Hence,

$$\begin{aligned} I_3(\xi) \le M_1 M_2 B_N \sum_{\alpha \le \beta} \sum_{\substack{\gamma \le \beta \\ \gamma_1 = \beta_1}} \binom{\beta}{\gamma} |2\pi|^{\beta_2 - \gamma_2} m(Y) \\ \cdot \int_{\mathbf{R}^2 \setminus A} \int_{\Delta_\xi} \frac{|\tau|^{\beta_2 - \gamma_2}}{|a|^3 (1 + \frac{L + |x_0 - b| - R}{|a|})^N} da \, d\tau \, db. \end{aligned}$$

Note that for (a, τ) in Δ_ξ, $\sqrt{c_1/\xi_1} \le |a| \le \sqrt{c_2/\xi_1}$ and $|\tau| \le |\xi_2| + (d_2 + |d_1|)\sqrt{\xi_1/c_1}$, and since $L + |x_0 - b| - R > 0$, it follows that

$$\frac{1}{1 + \frac{L + |x_0 - b| - R}{|a|}} \le \frac{1}{1 + (L + |x_0 - b| - R)\sqrt{\frac{\xi_1}{c_2}}}.$$

Hence,

$$\int_{\Delta_\xi} \frac{|\tau|^{\beta_2-\gamma_2}}{|a|^3\left(1+\frac{L+|x_0-b|-R}{|a|}\right)^N}da\,d\tau$$
$$\le (d_2-d_1)\left(\sqrt{\frac{c_2}{\xi_1}}-\sqrt{\frac{c_1}{\xi_1}}\right)\left(\frac{\xi_1}{c_1}\right)^2\left(|\xi_2|+(d_2+|d_1|)\sqrt{\frac{\xi_1}{c_1}}\right)^{\beta_2-\gamma_2}$$
$$\cdot\frac{1}{(1+(L+|x_0-b|-R)\sqrt{\frac{\xi_1}{c_2}})^N}.$$

But

$$\int_{\mathrm{R}^2\setminus A}\frac{1}{(1+(L+|x_0-b|-R)\sqrt{\frac{\xi_1}{c_2}})^N}db$$
$$=2\pi\left|\frac{c_2}{\xi_1}\right|\frac{1}{N-2}\frac{1}{\left(1+L\sqrt{\frac{\xi_1}{c_2}}\right)^{N-2}}$$
$$+2\pi\sqrt{\frac{c_2}{\xi_1}}\left(-\sqrt{\frac{c_2}{\xi_1}}-L+R\right)\frac{1}{N-1}\frac{1}{\left(1+L\sqrt{\frac{\xi_1}{c_2}}\right)^{N-1}}$$
$$\to 0\quad\text{as}\quad|\xi|\to\infty\quad\text{for } N \text{ sufficiently large.}$$

Thus, $\widehat{w}$ decreases rapidly in Γ. This completes the proof of Claim 1. The following lemma is used to prove Claim 2.

LEMMA 2. *Let v be in $\mathcal{E}'(\mathbf{R}^2)$. Then for h admissible in $\mathcal{S}(\mathbf{R}^2)$,*

$$(L_h v)(a,\,b,\,\tau,\,\zeta)=\sum_{\beta\le\alpha}\sum_{\substack{\gamma\le\beta\\ \gamma_1=\beta_1}}\binom{\beta}{\gamma}(-1)^{|\gamma|}(-2\pi i\tau)^{\beta_2-\gamma_2}D_b^\gamma(L_h g_\beta)(a,\,b,\,\tau,\,\zeta)$$

for some multiindex α and some compactly supported continuous functions g_β.

See the appendix for the proof.

Proof of Claim 2. Let ξ be in Γ. Then by Claim 1,

$$\hat{w}(\xi)=\int_G (L_h v)(a,\,b,\,\tau,\,\zeta)(U(a,\,b,\,\tau,\,\zeta)h)\widehat{\ }(\xi)d(a,\,b,\,\tau,\,\zeta)$$

is well defined for all ξ in Γ. Since $v=\psi u\in\mathcal{E}'(\mathbf{R}^2)$, it follows from Lemma 4 that

$$\hat{w}(\xi)=\int_G\sum_{\beta\le\alpha}\sum_{\substack{\gamma\le\beta\\ \gamma_1=\beta_1}}\binom{\beta}{\gamma}(-1)^{|\gamma|}(-2\pi i\tau)^{\beta_2-\gamma_2}D_b^\gamma(L_h g_\beta)(a,\,b,\,\tau,\,\zeta)$$
$$\cdot(U(a,\,b,\,\tau,\,\zeta)h)\widehat{\ }(\xi)d(a,\,b,\,\tau,\,\zeta)$$

for some multiindex α and some compactly supported continuous functions g_β. In particular, $g_\beta\in L^2(\mathbf{R}^2)$. Then for any function ϕ such that $\phi\in\mathcal{D}(\Gamma)$,

$$\int_\Gamma \hat{w}(\xi)\breve{\phi}(\xi)\,d\xi$$

$$
\begin{aligned}
&= \sum_{\beta\le\alpha}\int_G \sum_{\substack{\gamma\le\beta\\ \gamma_1=\beta_1}} \binom{\beta}{\gamma}(-1)^{|\gamma|}(-2\pi i\tau)^{\beta_2-\gamma_2}\ D_b^\gamma\ \langle g_\beta, U(a,b,\tau,\zeta)h\rangle \\
&\quad\cdot\left(\int_\Gamma (U(a,b,\tau,\zeta)h)\hat{}\,(\xi)\breve{\phi}(\xi)d\xi\right)\ d(a,b,\tau,\zeta) \\
&= \sum_{\beta\le\alpha}(-1)^{|\beta|}\int_G \sum_{\substack{\gamma\le\beta\\ \gamma_1=\beta_1}} \binom{\beta}{\gamma}(2\pi i\tau)^{\beta_2-\gamma_2} \\
&\quad\cdot\left(\int_\Gamma D_b^\gamma\langle g_\beta, U(a,b,\tau,\zeta)h\rangle(U(a,b,\tau,\zeta)h)(y)db\right)\phi(y)d(a,y,\tau,\zeta) \\
&= \sum_{\beta\le\alpha}(-1)^{|\beta|}\int_G \sum_{\substack{\gamma\le\beta\\ \gamma_1=\beta_1}} \binom{\beta}{\gamma}(2\pi i\tau)^{\beta_2-\gamma_2} \\
&\quad\cdot(-1)^{|\gamma|}\left(\int_{\mathbf{R}^2}\langle g_\beta, U(a,b,\tau,\zeta)h\rangle D_b^\gamma U(a,b,\tau,\zeta)h(y)db\right)\phi(y)d(a,y,\tau,\zeta) \\
&= \sum_{\beta\le\alpha}(-1)^{|\beta|}\int_G \langle g_\beta, U(a,b,\tau,\zeta)h\rangle \\
&\quad\cdot\left(\int_{\mathbf{R}^2}\sum_{\substack{\gamma\le\beta\\ \gamma_1=\beta_1}} \binom{\beta}{\gamma}(2\pi i\tau)^{\beta_2-\gamma_2}(-1)^{|\gamma|}D_b^\gamma U(a,b,\tau,\zeta)h(y)\phi(y)dy\right)d(a,b,\tau,\zeta) \\
&= \sum_{\beta\le\alpha}(-1)^{|\beta|}\int_G \langle g_\beta, U(a,b,\tau,\zeta)h\rangle \\
&\quad\cdot\left(\int_{\mathbf{R}^2} D_y^\beta U(a,b,\tau,\zeta)h(y)\phi(y)dy\right)d(a,b,\tau,\zeta) \\
&= \sum_{\beta\le\alpha}\int_G \langle g_\beta, U(a,b,\tau,\zeta)h\rangle\left(\int_{\mathbf{R}^2} U(a,b,\tau,\zeta)h(y)D_y^\beta\phi(y)dy\right)d(a,b,\tau,\zeta) \\
&= \sum_{\beta\le\alpha}\int_G \langle g_\beta, U(a,b,\tau,\zeta)h\rangle\overline{\langle\overline{D^\beta\phi},\ U(a,b,\tau,\zeta)h\rangle}d(a,b,\tau,\zeta) \\
&= \sum_{\beta\le\alpha} C_h\langle g_\beta, \overline{D^\beta\phi}\rangle \\
&= C_h v[\phi].
\end{aligned}
$$

This completes the proof of Claim 2.

Example. For $x=(x_1,x_2)$ in $\mathbf{R}^2$, let $u(x_1,x_2)=\delta(x_1)$. Then $u\in\mathcal{S}'(\mathbf{R}^2)$ and sing*supp* $u=\{(0,x_2): x_2\in\mathbf{R}\}$. Note that the action of u on a test function ϕ in $\mathcal{S}(\mathbf{R}^2)$ is given by

$$u[\phi]=\int_{-\infty}^{\infty}\phi(0,x_2)dx_2,$$

and the wave front set of u is

$$WF(u)=\{((0,x_2);(\xi_1,0)): x_2\in\mathbf{R}\ \text{ and }\ \xi_1\in\mathbf{R}\setminus\{0\}\}.$$

Let h be a function such that h is nonnegative, $\hat{h}\in\mathcal{D}(\mathbf{R}^2)$, $\hat{h}$ is not identically zero, and supp$\hat{h}\subset\Omega$, where $\Omega=[c_1,c_2]\times[d_1,d_2]$ with $0<c_1<c_2, d_1<0<d_2$.

Let $\xi = (\xi_1, \xi_2)$ be in $\mathbf{R}^+ \times \mathbf{R}$, and let Δ_ξ be as defined. For $(x_0, (1,0))$ in $\mathbf{R}^2 \times \mathbf{R}^2$, where $x_0 = (x_{01}, x_{02})$, let us consider two cases.

Case 1. Suppose that $x_{01} \neq 0$. Then $((x_{01}, x_{02}); (1,0)) \notin WF(u)$. So $\widehat{\psi u}$ decreases rapidly in some cone Γ around (1, 0) for some $\psi \in \mathcal{D}(\mathbf{R}^2)$ with $\psi = 1$ in a neighborhood X of $x_0 = (x_{01}, x_{02})$. Let us show that $(L_h u)|_{(X,\Delta_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ in Γ.

Let (a, τ) be in Δ_ξ, $b = (b_1, b_2)$ in X, and ζ in Q. Note that if $|\xi| \to \infty$ in Γ, then $a \to 0$. Also, if $b \in X$, then $b_1 > 0$.

Now,

$$(L_h u)(a,b,\tau,\zeta) = u[\overline{\zeta E_\tau T_b J_a h}] = \int_{-\infty}^{\infty} \overline{\zeta E_\tau T_b J_a h(0,x_2)} dx_2$$
$$= \int_{-\infty}^{\infty} \overline{\zeta} e^{-2\pi i \tau x_2} \frac{1}{|a|^{\frac{3}{2}}} \overline{h\left(-\frac{b_1}{a^2}, \frac{x_2 - b_2}{a}\right)} dx_2.$$

Then

$$|(L_h u)(a,b,\tau,\zeta)| \leq \frac{1}{|a|^{\frac{3}{2}}} \int_{-\infty}^{\infty} \left| h\left(-\frac{b_1}{a^2}, \frac{x_2 - b_2}{a}\right)\right| dx_2$$
$$= \frac{1}{|a|^{\frac{1}{2}}} \int_{-\infty}^{\infty} \left| h\left(-\frac{b_1}{a^2}, y\right)\right| dy.$$

Because $h \in \mathcal{S}(\mathbf{R}^2)$,

$$\left| h\left(-\frac{b_1}{a^2}, y\right)\right| \leq \frac{C_N}{\left(\sqrt{\frac{b_1^2}{a^4} + y^2}\right)^N}, \qquad N = 1, 2, \ldots.$$

Thus,

$$|(L_h u)(a,b,\tau,\zeta)| \leq C_N a^{2N} |a|^{-\frac{1}{2}} \int_{-\infty}^{\infty} \frac{1}{(\sqrt{b_1^2 + a^4 y^2})^N} dy$$
$$= C_N a^{2N} |a|^{-\frac{5}{2}} \int_{-\infty}^{\infty} \frac{1}{(b_1^2 + z^2)^{\frac{N}{2}}} dz$$
$$\to 0 \quad \text{as} \quad a \to 0,$$

where N can be chosen arbitrarily large.

Therefore, $(L_h u)|_{(X,\Delta_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ for all ξ in Γ.

Case 2. Suppose that $x_{01} = 0$. Then $((0, x_{02}); (1,0)) \in WF(u)$.

Let Γ be any open cone symmetric with respect to (1, 0). For $\xi = (\xi_1, 0)$ in Γ, Δ_ξ is the set of points (a, τ) in $(\mathbf{R} \setminus \{0\}) \times \mathbf{R}$ such that $\sqrt{c_1/\xi_1} \leq |a| \leq \sqrt{c_2/\xi_1}$ and $-\frac{d_2}{|a|} \leq \tau \leq -\frac{d_1}{|a|}$.

Let us show that $(L_h u)|_{(X,\Delta_\xi)}$ does not fall off rapidly as $|\xi| = \xi_1 \to \infty$, where X is any open neighborhood of $x_0 = (0, x_{02})$. Then for $b = (0, b_2)$ in X and $(a, 0)$ in $\Delta_{(\xi_1,0)}$,

$$(L_h u)(a,b,0,\zeta) = u[\overline{\zeta E_0 T_b J_a h}] = \int_{-\infty}^{\infty} \overline{\zeta E_0 T_b J_a h(0,x_2)} dx_2$$
$$= \int_{-\infty}^{\infty} \overline{\zeta} \frac{1}{|a|^{\frac{3}{2}}} \overline{h\left(0, \frac{x_2 - b_2}{a}\right)} dx_2 = \overline{\zeta} \frac{1}{\sqrt{|a|}} \int_{-\infty}^{\infty} \overline{h(0, z_2)} dz_2.$$

Let $A = \int_{-\infty}^{\infty} \overline{h(0, z_2)} dz_2$. Then A is independent of a and $0 < A < \infty$;

$$\sup_{\substack{b\in X\\(a,\tau)\in\Delta_\xi\\ \zeta\in Q}} |(L_h u)(a, b, \tau, \zeta)| \geq \frac{1}{\sqrt{|a|}} A \geq \left(\frac{\xi_1}{c_2}\right)^{\frac{1}{4}} A.$$

Thus, $(L_h u)|_{(X,\Delta_\xi)}$ does not fall off as $|\xi| = \xi_1 \to \infty$ in Γ.

Appendix.

Proof of Lemma 1. Let $\xi = (\xi_1, \xi_2)$ be in $\mathbf{R}^+ \times \mathbf{R}$. Then by Definition 4,

$$\begin{aligned}\Delta\xi &= \{(a,\tau) \in (\mathbf{R} \setminus \{0\}) \times \mathbf{R} : \ \mathcal{V}(a,\tau)\Omega \ni \xi\} \\ &= \{(a,\tau) \in (\mathbf{R} \setminus \{0\}) \times \mathbf{R} : \ \mathcal{V}^{-1}(a,\tau)\xi \in \Omega\},\end{aligned}$$

where by definition of $\mathcal{V}(a,\tau)$, $\mathcal{V}^{-1}(a,\tau)\xi = (a^2\xi_1, a(\xi_2 - \tau))$.

Then $\mathcal{V}^{-1}(a,\tau)\xi \in \Omega$ if $c_1 \leq a^2\xi_1 \leq c_2$ and $d_1 \leq a(\xi_2 - \tau) \leq d_2$; equivalently

$$\sqrt{c_1/\xi_1} \leq |a| \leq \sqrt{c_2/\xi_1} \ \text{ and } \ \xi_2 - \tfrac{d_2}{|a|} \leq \tau \leq \xi_2 - \tfrac{d_1}{|a|}.$$

This proves Lemma 1.

Proof of Lemma 2. Take $\alpha > 0$ such that $\tan\alpha < \frac{c_1}{c_2} \tan\beta$. Let $\epsilon = \tan\alpha$. Consider then $\Gamma = \{(\eta_1, \eta_2) \in \mathbf{R}^+ \times \mathbf{R} : |\eta_2| < \epsilon\eta_1\}$. Note that $\Gamma_1 \supset \{(\eta_1, \eta_2) \in \mathbf{R}^+ \times \mathbf{R} : |\eta_2| < \frac{c_2}{c_1}\epsilon\eta_1\}$ and since $0 < c_1 < c_2$, $\Gamma \subset \Gamma_1$.

Let $\xi = (\xi_1, \xi_2)$ be in Γ. Since $\Gamma \subset \mathbf{R}^+ \times \mathbf{R}$, it follows from Lemma 1 that

$$\Delta_\xi = \left\{(a,\tau) \in (\mathbf{R} \ \setminus \ \{0\}) \times \mathbf{R} : \sqrt{\frac{c_1}{\xi_1}} \leq |a| \leq \sqrt{\frac{c_2}{\xi_1}} \ \text{ and } \ \xi_2 - \frac{d_2}{|a|} \leq \tau \leq \xi_2 - \frac{d_1}{|a|}\right\}.$$

Now, let (η_1, η_2) be in $\mathcal{V}(a,\tau)\Omega$. Then by Remark 1, $\frac{c_1}{a^2} \leq \eta_1 \leq \frac{c_2}{a^2}$ and $\frac{d_1}{|a|} + \tau \leq \eta_2 \leq \frac{d_2}{|a|} + \tau$. Then for (a,τ) in Δ_ξ, $\frac{c_1}{c_2}\xi_1 \leq \eta_1 \leq \frac{c_2}{c_1}\xi_1$ and

$$\xi_2 - (d_2 - d_1)\sqrt{\tfrac{\xi_1}{c_1}} \leq \eta_2 \leq \xi_2 + (d_2 - d_1)\sqrt{\tfrac{\xi_1}{c_1}}.$$

That is, for (a,τ) in Δ_ξ, $\mathcal{V}(a,\tau)\Omega$ is contained in the rectangle

$$\Psi_\xi = \left[\tfrac{c_1}{c_2}\xi_1, \tfrac{c_2}{c_1}\xi_1\right] \times \left[\xi_2 - (d_2 - d_1)\sqrt{\tfrac{\xi_1}{c_1}}, \xi_2 + (d_2 - d_1)\sqrt{\tfrac{\xi_1}{c_1}}\right].$$

Suppose that $\xi_2 \geq 0$. Then $\xi_2 + (d_2 - d_1)\sqrt{\xi_1/c_1} > 0$. Let Θ be the upper left corner of the rectangle Ψ_ξ. That is, $\Theta = (\frac{c_1}{c_2}\xi_1, \xi_2 + (d_2 - d_1)\sqrt{\xi_1/c_1})$. Then the slope m_Θ of the line passing through (0, 0) and Θ is

$$m_\Theta = \frac{\xi_2 + (d_2 - d_1)\sqrt{\frac{\xi_1}{c_1}}}{\frac{c_1}{c_2}\xi_1} = \frac{c_2}{c_1}\frac{\xi_2}{\xi_1} + \frac{(d_2 - d_1)c_2}{{c_1}^{\frac{3}{2}}}\frac{1}{\sqrt{\xi_1}}.$$

Since $\xi \in \Gamma$, and $\xi_2 > 0$, it follows that $\frac{\xi_2}{\xi_1} < \epsilon$. Then

$$|\xi|^2 = \xi_1^2 + \xi_2^2 < \xi_1^2 + \epsilon^2\xi_1^2 = (1 + \epsilon^2)\xi_1^2; \ \frac{1}{\xi_1} < \frac{\sqrt{1+\epsilon^2}}{|\xi|}.$$

Thus,

$$m_\Theta < \frac{c_2}{c_1}\epsilon + \frac{(d_2-d_1)c_2}{{c_1}^{\frac{3}{2}}}\frac{(1+\epsilon^2)^{\frac{1}{4}}}{\sqrt{|\xi|}}.$$

Since $\tan\beta > \frac{c_2}{c_1}\epsilon$, it follows that for sufficiently large $|\xi|$, $m_\Theta < \tan\beta$. Thus $\Theta \in \Gamma_1$.

A similar analysis shows that the lower left corner of the rectangle Ψ_ξ is also in Γ_1. It follows that for sufficiently large $|\xi|$, $\mathcal{V}(a,\ \tau)\Omega \subset \Gamma_1$ for all $(a,\ \tau)$ in Δ_ξ.

This proves Lemma 2.

Proof of Lemma 3. The idea behind the proof is that, as $|\xi| \to \infty$ in Γ, the condition $(a,\ \tau) \in \Delta_\xi$ forces $a \to 0$, which concentrates the function $\zeta E_\tau T_b J_a h$ about the point $b \in Z$, where ϕ is zero.

Let $b \in Z, \xi \in \Gamma$, and let $(a,\tau) \in \Delta_\xi$. Since $u \in \mathcal{S}'(\mathbf{R}^2)$ and $\phi\overline{\zeta E_\tau T_b J_a h} \in \mathcal{S}(\mathbf{R}^2)$, it follows that

$$\begin{aligned}(\,L_{\,h}\phi u)(a,b,\tau,\zeta) &= \phi u[\overline{\zeta E_\tau T_b J_a h}]\\ &= u[\phi\overline{\zeta E_\tau T_b J_a h}] = \int_{\mathbf{R}^2}(-1)^{|\alpha|}g(x)D_x^a\,\phi\overline{\zeta E_\tau T_b J_a h}(x)dx\end{aligned}$$

for some polynomially bounded continuous function g and some multiindex α.

Because g is a polynomially bounded continuous function, $h \in \mathcal{S}(\mathbf{R}^2)$, each of the derivatives of ϕ is polynomially bounded, and $b \in Z$, there are constants K_1, K_2, and $L > 0$ where $B_L(b) \cap \operatorname{supp}\phi = \emptyset$, with L independent of b, such that for $N = 1, 2, \ldots$ there is a constant $D_N > 0$ such that

$$\begin{aligned}&|(L_h\phi u)(a,b,\tau,\zeta)|\\ &\le K_1 D_N \sum_{\beta\le\alpha}\binom{\alpha}{\beta}\sum_{\substack{\gamma\le\beta\\ \gamma_1=\beta_1}}\binom{\beta}{\gamma}\frac{|2\pi\tau|^{\beta_2-\gamma_2}}{|a|^{\frac{3}{2}}}\int_{\mathbf{R}^2\setminus B_L(b)}\frac{(1+|x|)^{K_2}}{(1+|M(a)^{-1}(x-b)|)^N}dx.\end{aligned}$$

Now note that if $\xi \in \Gamma$ and $|\xi|$ is sufficiently large, then $|a| < 1$ for $(a,\tau) \in \triangle_\xi$. In this case $\frac{1}{|a|}|x-b| \le |M(a)^{-1}(x-b)|$. Then

$$\begin{aligned}&\int_{\mathbf{R}^2\setminus B_L(b)}\frac{(1+|x|)^{K_2}}{(1+|M(a)^{-1}(x-b)|)^N}dx\\ &\le 2\pi|a|\sum_{\rho=0}^{K_2}\binom{K_2}{\rho}|b|^{K_2-\rho}\frac{1}{N-2-\rho}\quad\frac{1}{\left(1+\frac{L}{|a|}\right)^{N-2-\rho}}.\end{aligned}$$

Since for (a,τ) in $\triangle_\xi$,

$$\sqrt{\frac{c_1}{\xi_1}} \le |a| \le \sqrt{\frac{c_2}{\xi_1}}\quad\text{and}\quad|\tau| \le |\xi_2| + (d_2+|d_1|)\sqrt{\frac{\xi_1}{c_1}};$$

it follows that

$$|(L_h\phi u)(a,b,\tau,\zeta)|$$

$$\leq K_1 D_N \sum_{\beta\leq\alpha} \binom{\alpha}{\beta} \sum_{\substack{\gamma\leq\beta \\ \gamma_1=\beta_1}} \binom{\beta}{\gamma} |2\pi|^{\beta_2-\gamma_2+1} \left(|\xi_2| + (d_2+|d_1|)\sqrt{\frac{\xi_1}{c_1}}\right)^{\beta_2-\gamma_2}$$

$$\cdot \left(\sqrt{\frac{\xi_1}{c_1}}\right)^{\frac{1}{2}} \sum_{\rho=0}^{K_2} \binom{K_2}{\rho} |b|^{K_2-\rho} \frac{1}{N-2-\rho} \quad \frac{1}{\left(1+L\sqrt{\frac{\xi_1}{c_2}}\right)^{N-2-\rho}}$$

$$\to 0 \text{ as } |\xi| \to \infty \text{ in } \Gamma.$$

Because N may be chosen arbitrarily large, the decrease is rapid, and since L is independent of $b \in Z$, it follows that $(L_h \phi u)|_{(Z,\triangle_\xi)} \to 0$ rapidly as $|\xi| \to \infty$ in Γ.

This proves Lemma 3.

Proof of Lemma 4. Since $u \in \mathcal{E}'(\mathbf{R}^2)$ and $h \in \mathcal{S}(\mathbf{R}^2)$, it follows that

$$u[\zeta E_\tau T_b J_a h] = \sum_{\beta\leq\alpha} \int_{\mathbf{R}^2} g_\beta(x) D_x^\beta \zeta E_\tau T_b J_a h(x) dx$$

for some multiindex α and compactly supported continuous functions g_β. Then

$$\begin{aligned}
(L_h u)(a,b,\tau,\zeta) &= u[\overline{\zeta E_\tau T_b J_a h}] \\
&= \sum_{\beta\leq\alpha} \int_{\mathbf{R}^2} g_\beta(x) D_x^\beta \overline{\zeta E_\tau T_b J_a h(x)} dx \\
&= \sum_{\beta\leq\alpha} \langle g_\beta, D_x^\beta \zeta E_\tau T_b J_a h\rangle \\
&= \sum_{\beta\leq\alpha} \sum_{\substack{\gamma\leq\beta \\ \gamma_1=\beta_1}} \binom{\beta}{\gamma} (-1)^{|\gamma|} (-2\pi i\tau)^{\beta_2-\gamma_2} D_b^\gamma \langle g_\beta, \zeta E_\tau T_b J_a h\rangle \\
&= \sum_{\beta\leq\alpha} \sum_{\substack{\gamma\leq\beta \\ \gamma_1=\beta_1}} \binom{\beta}{\gamma} (-1)^{|\gamma|} (-2\pi i\tau)^{\beta_2-\gamma_2} D_b^\gamma (L_h g_\beta)(a,b,\tau,\zeta).
\end{aligned}$$

This proves Lemma 4.

A LYAPUNOV FUNCTION FOR TRIDIAGONAL COMPETITIVE-COOPERATIVE SYSTEMS*

BERNOLD FIEDLER† AND TOMÁŠ GEDEON‡

Abstract. We construct a Lyapunov function for tridiagonal competitive-cooperative systems. The same function is a Lyapunov function for Kolmogorov tridiagonal systems, which are defined on a closed positive orthant in $\mathbf{R}^n$. We show that all bounded orbits converge to the set of equilibria. Moreover, we show that there can be no heteroclinic cycles on the boundary of the first orthant, extending the results of H. I. Freedman and H. L. Smith [*Differential Equations Dynam. Systems*, 3 (1995), pp. 367–382].

1. Results.

We consider a system of differential equations

$$\begin{aligned} \dot{x}_1 &= f_1(x_1, x_2), \\ \dot{x}_i &= f_i(x_{i-1}, x_i, x_{i+1}), \qquad i = 2, \dots, n-1, \\ \dot{x}_n &= f_n(x_{n-1}, x_n), \end{aligned} \tag{1}$$

where functions f_i are defined on a nonempty open subset A of R^n. We assume that the f_i and their partial derivatives are continuous on A. We also assume that there are $\delta_i \in \{-1, +1\}$, such that

$$\delta_i \frac{\partial f_i}{\partial x_{i+1}} > 0, \quad \delta_i \frac{\partial f_{i+1}}{\partial x_i} > 0, \quad 1 \le i \le n-1.$$

This assumption implies that the Jacobi matrix $\partial f/\partial x$, corresponding to (1), is tridiagonal and sign symmetric in the sense that $\partial f_i/\partial x_{i+1}$ and $\partial f_{i+1}/\partial x_i$ have the same sign δ_i. If $\delta_i = -1$ for all i, then (1) is called *competitive*. If $\delta_i = 1$ for all i, then (1) is called *cooperative*. We introduce new variables, following Smith [S1]. We let $\bar{x}_i = \mu_i x_i$, $\mu_i \in \{\pm 1\}$, $1 \le i \le n$, with $\mu_1 = 1$, $\mu_i = \delta_{i-1}\mu_{i-1}$. Then the system (1) transforms into a new system of the same type with new

$$\bar{\delta}_i = \mu_i \mu_{i+1} \delta_i = \mu_i^2 \delta_i^2 = 1.$$

Therefore we can always assume, without loss of generality, that the competitive-cooperative system (1) is in fact cooperative and

$$\frac{\partial f_i}{\partial x_{i+1}} > 0, \quad \frac{\partial f_{i+1}}{\partial x_i} > 0, \quad 1 \le i \le n-1. \tag{H1}$$

Our goal in this paper is to construct a Lyapunov function for a class of equations (1). A Lyapunov function $V : \mathbf{R}^n \to \mathbf{R}$ for (1) is a real valued function which is nonincreasing along trajectories of (1) and is strictly decreasing along all nonequilibrium trajectories. We assume that the system (2) is *dissipative*. We spell out the precise form of the assumption below. We remark that this assumption implies that all trajectories of (2) eventually enter a compact region of phase space. By LaSalle's invariance principle (see Hale and Koçak [HK]) the existence of a Lyapunov function then implies that each trajectory converges to the set of equilibria. Our dissipativeness condition takes the form

$$f_i(x_{i-1}, x_i, x_{i+1})x_i < 0 \quad \text{for} \quad |x_i| \geq C, |x_{i\pm1}| \leq |x_i| \tag{H2}$$

and some large constant C.

It is easy to see that this assumption forces any trajectory to enter the box $\{x \in \mathbf{R}^n \mid |x_i| \leq C \text{ for all } i\}$ at some finite time and then remain there.

Our final assumption on the functions f_i is more technical. Observe that assumption (H1) implies that for any fixed x_i the set $z(f_i, x_i)$ of points (x_{i-1}, x_{i+1}) satisfying $f_i(x_{i-1}, x_i, x_{i+1}) = 0$ is a curve in the (x_{i-1}, x_{i+1})-plane. Furthermore $z(f_i, x_i)$ is monotone with respect to both x_{i-1} and x_{i+1}. The following assumption implies that for all x_i the curve $z(f_i, x_i)$ is unbounded in both x_{i-1} and x_{i+1} directions. Assume

$$\lim_{x_k \to \infty} f_i(x_{i-1}, x_i, x_{i+1}) > 0, \quad \lim_{x_k \to -\infty} f_i(x_{i-1}, x_i, x_{i+1}) < 0 \tag{H3}$$

for both $k = i - 1$ and $k = i + 1$ and all x_i, x_{i-1} and x_{i+1}.

We state the main theorem of this paper.

THEOREM 1.1. *The system* (1) *with assumptions* (H1), (H2), (H3) *admits a Lyapunov function.*

The system (1) with assumption (H1) is a *monotone dynamical system*. There is an extensive literature on monotone dynamical systems, starting with the work of Hirsch [Hi1, Hi2, Hi3, Hi4] for monotone semiflows. The results of Hirsch and later improvements by Matano [M], Smith and Thieme [ST1, ST2], and Poláčik [P] established that most orbits of a strongly order-preserving semiflow converge to the set of equilibria. For references on the theory of monotone semiflows see the recent monograph by Smith [S2].

For the system (1) more is known: Smilie [Sm] has shown that all trajectories converge to the set of equilibria. He used an integer-valued Lyapunov function (nodal properties) to prove his result. The main consequence of the existence of real valued Lyapunov function V for the system (1), namely that all trajectories of (1) converge to the set of equilibria, is not new and was proved by Smilie [Sm].

The importance of the existence of the Lyapunov function V is that it can be used in a more general setting. We now consider the class of *Kolmogorov* systems, which model an interaction of populations, where every population interacts only with "neighboring" populations. They have the form

$$\begin{aligned} \dot{x}_1 &= x_1 f_1(x_1, x_2), \\ \dot{x}_i &= x_i f_i(x_{i-1}, x_i, x_{i+1}), \\ \dot{x}_n &= x_n f_n(x_{n-1}, x_n) \end{aligned} \tag{2}$$

for $i = 2, \ldots, n-1$. We assume that the functions f_i satisfy (H1), (H2), and (H3). Since x_i's represent population densities we restrict ourselves to the closed positive orthant

$$\mathcal{O} := \{x \in \mathbf{R}^n \mid x_i \geq 0 \text{ for } i = 1, \ldots, n\}.$$

For specific biological systems modeled by (2), see Freedman and Smith [F-S] and the references herein.

The results of Smilie do not apply to the system (2) directly. The crucial assumption (H1) for the right-hand side of (2) holds only in the interior of the positive orthant. We also notice that $x_j(0) = 0$ implies $x_j(t) = 0$ for all t. Therefore every boundary hyperplane of the first orthant is invariant under (2). Furthermore, if we restrict the set of equations to such a boundary hyperplane, we obtain a decoupled system of the same type as (2). Consequently, all faces and subfaces of the boundary of the positive orthant are invariant under (2); the restriction of the system (2) to such a set is of the same type as the system (2) itself. The assumption (H1) is satisfied only in the interior of the positive orthant and by the previous argument in the interior of every face and subface of the boundary of the positive orthant.

The question arises whether all trajectories still converge to the set of equilibria in this case. The result is obviously true if the trajectory stays bounded away from the boundary of the region where it starts, which may be the positive orthant $\mathcal{O}$ itself, or a face or subface of the boundary. But in the context of population dynamics, the trajectories approaching the boundary of a given region are important, since they represent a situation whereby a certain population goes extinct.

This problem was studied by Freedman and Smith [F-S]. Under some nondegeneracy assumptions they were able to show that every bounded orbit converges either to an equilibrium, or to a cycle of equilibria on the boundary of $\mathcal{O}$. A *cycle of equilibria* is a nonempty finite set of equilibria $\{E_1, \ldots, E_n\}$ such that

$$E_1 \to E_2 \to \cdots \to E_n \to E_1.$$

Here we write $E_1 \to E_2$ if E_1 and E_2 are equilibria of (2), not necessarily distinct, such that there exists a solution $x \in \mathcal{O}$ with $\lim_{t\to-\infty} x(t) = E_1$ and $\lim_{t\to\infty} x(t) = E_2$. For illustration of such a boundary cycle of equilibria see Figure 1.

In every boundary component the flow is convergent to the set of equilibria, but the boundary components are assembled together in such a way that they produce a cycle of equilibria.

The Lyapunov function V constructed in Theorem 1.1 turns out to be a Lyapunov function for system (2). Furthermore, V is defined, continuous on the boundary of $\mathcal{O}$, and restricts to the Lyapunov function on every face and subface of the boundary of $\mathcal{O}$.

THEOREM 1.2. *Consider system* (2) *on the closed positive orthant* $\mathcal{O}$. *Assume that the functions* f_i *satisfy the assumptions* (H1), (H2), *and* (H3). *Then there is a Lyapunov function* $V : \mathcal{O} \to \mathbf{R}$, *which is strictly decreasing outside the set of equilibria.*

We can now rule out the existence of the cycles of equilibria on the boundary of $\mathcal{O}$.

COROLLARY 1.3. *Consider system* (2) *on the closed positive orthant* $\mathcal{O}$. *Assume that the functions* f_i *satisfy the assumptions* (H1), (H2), *and* (H3). *Then every bounded trajectory with initial data in the closed positive orthant* $\mathcal{O}$ *converges to the set of equilibria. If the set of equilibria is finite, every trajectory converges to a single equilibrium. Moreover, cycles of equilibria in* $\mathcal{O}$ *do not exist.*

The cycles of equilibria do not exist in the large class of Lotka–Voltera systems. We now briefly describe results of Fiedler and Gedeon [FG].

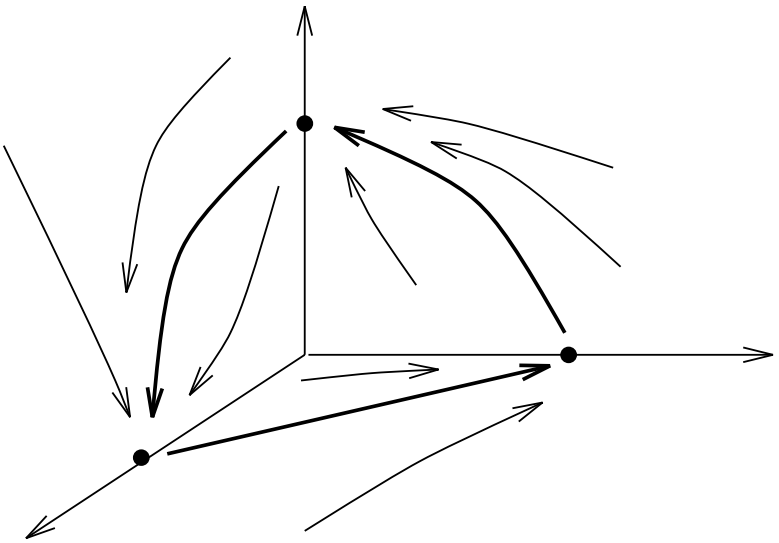

FIG. 1. *Heteroclinic cycle on the boundary of the positive orthant.*

Consider the system

$$\dot{x}_i = x_i \left(c_i - \sum_{j=1}^{n} \beta_{ij} f_j(x_j) \right) \tag{3}$$

on the positive orthant $\mathcal{O}$ in $\mathbf{R}^n$. If x_i describes the population size of a certain species, then the constants β_{ij} describe the interaction between the species. Let Υ be the undirected graph with n vertices, where the edge j is connected to the vertex i by the edge e_{ij} if and only if $\beta_{ij} \neq 0$. We assume $\beta_{ij}\beta_{ji} > 0$ for every edge e_{ij}. Therefore the definition of Υ makes sense.

Consider the system (3) and assume that $\frac{df_j}{dx_j} > 0$ for all j, that the interaction graph Υ is a tree, and that $\beta_{ij}\beta_{ji} > 0$ for every edge e_{ij}. Then, by the results of Fiedler and Gedeon [FG], every bounded trajectory of system (3) converges to the set of equilibria and boundary cycles of equilibria do not exist.

2. Proofs.

Proof of Theorem 1.1. Motivated by a somewhat analogous result of Matano [M] concerning parabolic partial differential equations with gradient dependence, we seek a Lyapunov function $V : \mathbf{R}^n \to \mathbf{R}$ of the form $V = -\sum_{i=1}^{n-1} g_i(x_i, x_{i+1})$. By differentiating and collecting terms we get

$$\dot{V} = -\sum_{i=1}^{n} \dot{x}_i(\partial_i g_i + \partial_i g_{i-1}),$$

where we used the notation $\partial_i := \frac{\partial}{\partial x_i}$. We also note that $\partial_1 g_0 = 0$ and $\partial_n g_n = 0$ in the expression for $\dot{V}$. Below, we will construct functions a_i such that

(a) $a_i f_i = \partial_i g_i + \partial_i g_{i-1}$ and $a_i > 0$ for $i = 1, \ldots, n$,

(b) $\partial_{i-1}(a_i f_i) = \partial_i(a_{i-1} f_{i-1})$ for $i = 2, \ldots, n$.

It follows from (a) that $a_i = a_i(x_{i-1}, x_i, x_{i+1})$ are functions of x_{i-1}, x_i, x_{i+1} for $i = 2, \ldots, n-1$, $a_1 = a_1(x_1, x_2)$, and $a_n = a_n(x_{n-1}, x_n)$. Property (a) also implies that

$$\begin{aligned}\dot{V} &= -\sum_i \dot{x}_i(\partial_i g_i + \partial_i g_{i-1}) \\ &= -\sum_i \dot{x}_i a_i f_i \\ &= -\sum_i a_i(\dot{x}_i)^2 \leq 0,\end{aligned}$$

since $a_i > 0$ for all i. Also $\dot{V}(x(t)) = 0$ if and only if $\dot{x}_i(t) = 0$ for all i. This implies that $\dot{V}(x(t)) = 0$ if and only if $x(t)$ is an equilibrium. Therefore V is a Lyapunov function.

We see that we have to construct functions a_i, $i = 1, \ldots, n$, which satisfy property (a).

Condition (b) is a consequence of (a) and the form of the function V. Indeed, (a) implies that

$$\partial_i(a_{i-1}f_{i-1}) = \partial_i\partial_{i-1}g_{i-1} + \partial_i\partial_{i-1}g_{i-2} = \partial_i\partial_{i-1}g_{i-1}$$

since $g_{i-2}(x_{i-2}, x_{i-1})$ does not depend on x_i. A similar computation leads to

$$\partial_{i-1}(a_i f_i) = \partial_i\partial_{i-1}g_{i-1}.$$

Therefore, if (a) is satisfied and g_i is a function of x_i and x_{i+1} only, then condition (b) must hold. In the inductive argument below we shall first construct functions $a_i > 0$ which satisfy (b), and then use (b) to construct functions g_i with property (a).

We construct the functions a_i, $i = 1, \ldots n$, by induction. The first step of the induction will be to construct functions a_1, g_0, and g_1 such that (a) and (b) are satisfied. We set $g_0 \equiv 0$ and $a_1 \equiv 1$. To determine $g_1(x_1, x_2)$ we set

$$\partial_1 g_1 := a_1 f_1 = f_1(x_1, x_2),$$

or more explicitly,

$$g_1(x_1, x_2) = \int_0^{x_1} f_1(\zeta_1, x_2) d\zeta_1.$$

This choice of a_1, g_0, and g_1 satisfies conditions (a) above. Observe that $\partial_2\partial_1 g_1(x_1, x_2)$ exists and is continuous. Condition (b) is vacuous for $i = 1$.

Having defined a_1, the condition (b) with $i = 2$ poses a restriction on a_2. The function a_2 must satisfy

$$\partial_1(a_2 f_2) = \partial_2(a_1 f_1).$$

Similarly, once the function a_{i-1} has been defined, the function a_i to be constructed in the next step of the induction must satisfy

$$\partial_{i-1}(a_i f_i) = \partial_i(a_{i-1} f_{i-1}).$$

With this in mind we define an auxiliary function

$$\gamma_1(x_1, x_2) := \partial_2(a_1 f_1).$$

Observe that $\partial_2(a_1 f_1) = \partial_2 f_1 > 0$, by assumption on function f_1, and so $\gamma_1 = \gamma_1(x_1, x_2) > 0$. So far, we have defined functions a_1, g_0, g_1 which satisfy (a), (b) for $i = 1$ and γ_1.

Now we proceed with the induction step. For technical reasons our induction hypothesis will not be statements (a) and (b) above but a slightly more complicated set of assumptions. We assume that we have constructed functions a_k, g_k, and γ_k, where $\gamma_k = \partial_{k+1}(a_k f_k)$ for $k = 1, \dots, i-1$ with the following properties:

(A1) $a_k > 0$ are continuous; $\partial_{k-1}(a_k f_k)$ and $\partial_{k+1}(a_k f_k)$ exist and are continuous.

(A2) $\partial_{k-1}(a_k f_k) = \partial_k(a_{k-1} f_{k-1})$.

(B) $a_k f_k = \partial_k g_k + \partial_k g_{k-1}$, $g_k = g_k(x_k, x_{k+1})$, and $\partial_{k+1}\partial_k g_k$ exists and is continuous.

(C) $\gamma_k(x_k, x_{k+1}) > 0$.

Observe that these conditions are satisfied for $k = 1$ by the above construction. Observe that (A2) is equivalent to (b), and (A1), (B) are equivalent to (a). Condition (C) is needed in the induction process.

Before we proceed with the induction step we introduce some notation. We denote $z(f_i) := \{x \mid f_i(x) = 0\}$ the zero set of the function f_i. In $\mathbf{R}^3$, spanned by coordinate axis x_{i-1}, x_i, x_{i+1}, the zero set $z(f_i)$ is a graph over the (x_{i-1}, x_i) plane. Indeed, the equation $f_i(x_{i-1}, x_i, x_{i+1}) = 0$ can be solved for

$$x_{i+1} = y_{i+1}(x_{i-1}, x_i),$$

since $\partial_{i+1} f_i > 0$. Similarly, since $\partial_{i-1} f_i > 0$, there is a function η_{i-1} with $x_{i-1} = \eta_{i-1}(x_i, x_{i+1})$ solving

$$f_i(\eta_{i-1}(x_i, x_{i+1}), x_i, x_{i-1}) = 0.$$

The assumption (H3) implies that both functions η_{i-1} and y_{i+1} are defined on the whole real line $\mathbf{R}$. We shall need this fact below in the construction of functions a_i. It is easy to see that $\partial_{i-1} y_{i+1}(x_i, x_{i-1}) < 0$ and

$$\partial_{i+1}\eta_{i-1}(x_i, x_{i+1}) < 0. \tag{4}$$

We now proceed with the induction step. We construct functions a_i, g_i and γ_i satisfying properties (A1)–(A2), (B) and (C) for $k := i$. The construction will be achieved in three steps. In the first step we will define a_i and verify properties (A1)–(A2). In the second step we will define g_i and show that (B) holds. The last step will be to check that $\gamma_i = \partial_{i+1}(a_i f_i)$ satisfies (C).

Step 1. *Construction of* a_i.

The function a_i must satisfy condition (A2) where the right-hand side $\partial_i(a_{i-1} f_{i-1})$ is the function γ_{i-1} already constructed in the previous step of the induction.

We first define a_i on the zero set $z(f_i)$ of f_i. On $z(f_i)$, which can be written as $x_{i+1} = y_{i+1}(x_{i-1}, x_i)$, the condition (A2) takes the form

$$\gamma_{i-1} = \partial_{i-1}(a_i f_i) = a_i(x_{i-1}, x_i, y_{i+1}(x_{i-1}, x_i)) \cdot \partial_{i-1} f_i(x_{i-1}, x_i, y_{i+1}(x_{i-1}, x_i)),$$

because $f_i = 0$. In order to satisfy (A2) we must therefore define the function a_i on the set $z(f_i)$ by the identity

$$a_i(x_{i-1}, x_i, y_{i+1}(x_{i-1}, x_i)) \cdot \partial_{i-1} f_i(x_{i-1}, x_i, y_{i+1}(x_{i-1}, x_i)) = \gamma_{i-1}(x_{i-1}, x_i). \tag{5}$$

To simplify notation we denote $\alpha_i(x_{i-1}, x_i) := a_i(x_{i-1}, x_i, y_{i+1}(x_{i-1}, x_i))$. Observe that

$$\alpha_i > 0 \tag{6}$$

since $\partial_{i-1} f_i > 0$ by assumption (H1) and $\gamma_{i-1} > 0$ by induction hypothesis.

Now we want to define a_i outside the zero set $z(f_i)$ of f_i. We set

$$a_i(x_{i-1}, x_i, x_{i+1}) = \frac{1}{f_i} \int_{\eta_{i-1}(x_i, x_{i+1})}^{x_{i-1}} \partial_{i-1} f_i(\zeta_{i-1}, x_i, y_{i+1}(\zeta_{i-1}, x_i)) \alpha_i(\zeta_{i-1}, x_i) d\zeta_{i-1}. \tag{7}$$

Observe that this definition makes sense only for those (x_{i-1}, x_i, x_{i+1}) for which $y_{i+1}(\zeta_{i-1}, x_i)$ and $\eta_{i-1}(x_i, x_{i+1})$ are defined. By assumption (H3), these functions are defined for all $(x_{i-1}, x_i, x_{i+1}) \in \mathbf{R}^3$. So the definition of a_i does make sense, and a_i is defined for all $(x_{i-1}, x_i, x_{i+1}) \in \mathbf{R}^3$.

We now check properties (A1) and (A2) for a_i. We show first that a_i is continuous and that $\partial_{i-1}(a_i f_i)$ and $\partial_{i+1}(a_i f_i)$ exist and are continuous. These properties obviously hold at points (x_{i-1}, x_i, x_{i+1}) which do not belong to the zero set $z(f_i)$ of the function f_i. The calculation for the points in the set $z(f_i)$ is straightforward, but tedious. In order not to disrupt the argument we postpone the proof to the Appendix.

Now we show that a_i is positive. By assumption $\partial_{i-1} f_i > 0$ and by (6) also $\alpha_i > 0$. Furthermore, $f_i = f_i(x_{i-1}, x_i, x_{i+1})$ is positive for $x_{i-1} > \eta_i(x_i, x_{i+1})$, and negative when $x_{i-1} < \eta_{i-1}(x_i, x_{i+1})$. In the first case the right-hand side of (7) is positive since all the entries are positive; in the second case $f_i < 0$ but since the order of integration changes, the right-hand side is still positive. For $x_{i-1} = \eta_i(x_i, x_{i+1})$ the function a_i is positive by (6). Therefore $a_i > 0$ for all $(x_{i-1}, x_i, x_{i+1}) \in \mathbf{R}^3$. Thus a_i satisfies (A1).

Now we check condition (A2) at an arbitrary point (x_{i-1}, x_i, x_{i+1}). For any point $(x_{i-1}, x_i, x_{i+1}) \notin z(f_i)$ we have

$$\begin{aligned} \partial_{i-1}(a_i f_i) &\overset{(7)}{=} \partial_{i-1} f_i(x_{i-1}, x_i, y_{i+1}(x_{i-1}, x_i)) \alpha_i(x_{i-1}, x_i) \\ &= a_i(x_{i-1}, x_i, y_{i+1}(x_{i-1}, x_i)) \partial_{i-1} f_i(x_{i-1}, x_i, y_{i+1}(x_{i-1}, x_i)) \\ &\overset{(5)}{=} \gamma_{i-1}(x_{i-1}, x_i) \\ &= \partial_i(a_{i-1} f_{i-1}), \end{aligned} \tag{8}$$

where the last equality is the definition of γ_{i-1}. Since $\partial_{i-1}(a_i f_i)$ and $\partial_{i+1}(a_i f_i)$ are continuous, (8) holds for all (x_{i-1}, x_i, x_{i+1}). This verifies (A2).

Therefore a_i, as defined in (5, 7) indeed satisfies (A1)–(A2).

Step 2. *Construction of* g_i. The goal in this step is to define the function g_i such that (B) holds. Condition (B) requires that $\partial_i g_i = a_i f_i - \partial_i g_{i-1}$. The function g_{i-1} is already constructed, by the induction hypothesis, and $a_i f_i$ has been constructed in Step 1. Our expression for $\partial_i g_i$ does not depend on x_{i-1} since

$$\begin{aligned} \partial_{i-1}(a_i f_i - \partial_i g_{i-1}) &= \partial_i(a_{i-1} f_{i-1}) - \partial_{i-1}\partial_i g_{i-1} \\ &= \partial_i(\partial_{i-1} g_{i-1} + \partial_{i-1} g_{i-2}) - \partial_{i-1}\partial_i g_{i-1} \\ &= \partial_{i-1}\partial_i g_{i-2}(x_{i-2}, x_{i-1}) = 0. \end{aligned}$$

In the first line, we used that $\partial_{i-1}(a_i f_i) = \partial_i(a_{i-1} f_{i-1})$, which is (A2) for $k = i$ and was verified in (8). The induction hypothesis (B) for $k = i - 1$ gives that $a_{i-1} f_{i-1} =$

$\partial_{i-1}g_{i-1} + \partial_{i-1}g_{i-2}$. Also $\partial_{i-1}\partial_i g_{i-1} = \partial_i\partial_{i-1}g_{i-1}$ follows from the continuity of $\partial_i\partial_{i-1}g_{i-1}$, which is guaranteed by induction hypothesis (B) for $k = i-1$.

Therefore we define

$$g_i = g_i(x_i, x_{i+1}) := \int_0^{x_i} ((a_i f_i)(x_{i-1}, \zeta_i, x_{i+1}) - \partial_i g_{i-1}(x_{i-1}, \zeta_i))d\zeta_i.$$

Since $\partial_{i+1}\partial_i g_i = \partial_{i+1}(a_i f_i)$ and $\partial_{i+1}(a_i f_i)$ is continuous by step 1, the condition (B) holds for $k = i$.

Step 3. $\gamma_i > 0$.

The remaining step in the induction is to show (C) for $\gamma_i := \partial_{i+1}(a_i f_i)$, i.e., that $\gamma_i > 0$.

We differentiate

$$\begin{aligned}\gamma_i = \partial_{i+1}(a_i f_i) &= \partial_{i+1} \int_{\eta_{i-1}(x_i, x_{i+1})}^{x_{i-1}} \partial_{i-1} f_i(\zeta_{i-1}, x_i, y_{i+1}(\zeta_{i-1}, x_i))\alpha_i(\zeta_{i-1}, x_i)d\zeta_{i-1} \\ &= -\partial_{i+1}\eta_{i-1}(x_i, x_{i+1}) \cdot \partial_{i-1} f_i(\eta_{i-1}(x_i, x_{i+1}), x_i, y_{i+1}(\eta_{i-1}, x_i))\alpha_i(\eta_{i-1}(x_i, x_{i+1}), x_i) \\ &= -\partial_{i+1}\eta_{i-1}(x_i, x_{i+1}) \cdot \partial_{i-1} f_i(\eta_{i-1}(x_i, x_{i+1}), x_i, x_{i+1})\alpha_i(\eta_{i-1}(x_i, x_{i+1}), x_i)\end{aligned}$$

since $x_{i+1} = y_{i+1}(\eta_{i-1}(x_i, x_{i+1}), x_i)$. We see that the function γ_i is a function of x_i and x_{i+1} only. Furthermore, since $-\partial_{i+1}\eta_{i-1} > 0$ by (4), $\partial_{i-1}f_i > 0$ by assumption (H1), and $\alpha_i > 0$ by (6), we see that

$$\gamma_i = \partial_{i+1}(a_i f_i) > 0.$$

This finishes the induction step and thus proves existence of the Lyapunov function V. □

Proof of Theorem 1.2. The Lyapunov function V constructed in Theorem 1.1 is also a Lyapunov function for the system (2) on the closed positive orthant $\mathcal{O}$. Indeed,

$$\begin{aligned}\dot V &= -\sum_i \dot x_i(\partial_i g_i + \partial_i g_{i-1}) \\ &= -\sum_i \dot x_i a_i f_i \\ &= -\sum_i a_i x_i (f_i)^2 \le 0\end{aligned}$$

since $a_i > 0$ and $x_i \ge 0$ in the positive orthant $\mathcal{O}$. The derivative $\dot V = 0$ if and only if $x_i(f_i)^2 = 0$ for all i. This is equivalent to $x_i f_i = 0$ for all i. Since $\dot x_i = x_i f_i$, we have $\dot V = 0$ if and only if $\dot x_i = 0$ for all i. This implies that $\dot V(x) = 0$ if and only if x is an equilibrium. Therefore V is a Lyapunov function for (2). □

Proof of Theorem 1.3. Observe that the Lyapunov function $V = -\sum g_i(x_i, x_{i+1})$ is defined on the closed positive orthant $\mathcal{O}$. Since we assume (H2) for the functions f_i in (2), we see immediately that $|x_i| > C$ for the maximal $|x_i|$ implies $\dot x_i < 0$. It follows that each trajectory enters the positively invariant box $Q := \{x \in \mathbf{R}^n \mid |x_i| \le C\}$ in finite time. Since the positive orthant $\mathcal{O}$ is invariant under (2), each trajectory starting in $\mathcal{O}$ enters the set $\mathcal{O} \cap Q$ in finite time. By the LaSalle's invariance principle each trajectory in $\mathcal{O} \cap Q$ converges to the set where $\dot V = 0$, which is the set of equilibria.

So there is no chain recurrent set in $\mathcal{O}$, apart from the set of equilibria. In particular, there are no cycles of equilibria in $\mathcal{O}$. □

Remark 2.1. We assume (H3) in the definition of the function a_i; it guarantees that we can define a_i for all points (x_{i-1}, x_i, x_{i+1}), since for each such point the values $\eta_{i-i}(x_i, x_{i+1})$ and $y_{i+1}(x_{i-1}, x_i)$ are defined. Suppose now that (H3) is violated and that for some fixed $x_i = x_i^*$ the zero set $z(f_i, x_i^*)$ of f_i with $x_i = x_i^*$ fixed is a curve which satisfies

$$\lim_{x_{i-1}\to-\infty} z(f_i, x_i^*) = a_i^-(x_i^*) > -\infty, \qquad \lim_{x_{i-1}\to\infty} z(f_i, x_i^*) = a_i^+(x_i^*) < \infty.$$

Then the function a_i can only be defined in points (x_{i-1}, x_i, x_{i+1}) for which $a_i^-(x_i^*) < x_{i+1} < a_i^+(x_i^*)$. We also observe that the absolute value $|a_i|$ grows without bounds as (x_{i-1}, x_i, x_{i+1}) approaches the boundary of this region. Similar restrictions occur if we assume that

$$\lim_{x_{i+1}\to-\infty} z(f_i, x_i^*) = a_i^-(x_i^*) > -\infty, \qquad \lim_{x_{i+1}\to\infty} z(f_i, x_i^*) = a_i^+(x_i^*) < \infty.$$

However, observe that we do not need to define the Lyapunov function on all of $\mathbf{R}^n$. It follows from the dissipativeness assumption (H2) that each trajectory enters the box $Q := \{x \in \mathbf{R}^n \mid |x_i| \le C\}$ in finite time. We need to define our Lyapunov function V and thus functions a_i only for $x \in Q$. Thus we can still construct the Lyapunov function V provided that $|a_i^+(x_i^*)| > C$ and $|a_i^-(x_i^*)| > C$ for all i, with C given in assumption (H2).

Appendix. We show that the function a_i is continuous and the partial derivatives $\partial_{i-1}(a_i f_i)$ and $\partial_{i+1}(a_i f_i)$ exist and are continuous.

For all $(x_{i-1}, x_i, x_{i+1}) \notin z(f_i)$ this follows from the definition of a_i. We hence consider $(x_{i-1}, x_i, x_{i+1}) \in z(f_i)$.

We first prove continuity of a_i. Write $x_{i-1} = \eta_{i-1}(x_i, x_{i+1}) + h$ and expand f_i with respect to h at the point $(\eta_{i-1}(x_i, x_{i+1}), x_i, x_{i+1}) \in z(f_i)$:

$$\begin{aligned} &f_i(\eta_{i-1}(x_i, x_{i+1}) + h, x_i, x_{i+1}) \\ &\qquad = h(\partial_{i-1} f_i(\eta_{i-1}(x_i, x_{i+1}), x_i, x_{i+1}) + \tau(h, x_i, x_{i+1})). \end{aligned} \tag{9}$$

Here the remainder $\tau(h, x_i, x_{i+1})$ is a continuous function with $\tau(0, x_i, x_{i+1}) = 0$.

The integral in definition (7) of a_i becomes

$$\int_{\eta_{i-1}(x_i,x_{i+1})}^{\eta_{i-1}(x_i,x_{i+1})+h} \partial_{i-1} f_{i-1}(\zeta_{i-1}, x_i, y_{i+1}(\zeta_{i-1}, x_i))\alpha_i(\zeta_{i-1}, x_i) d\zeta_{i-1},$$

for $h \neq 0$ with a (uniformly) continuous integrand. Indeed, α_i, which is the restriction of a_i to $z(f_i)$, is continuous by definition (5). From the standard integration theory, we immediately obtain

$$\begin{aligned} \lim_{h\to0, h\neq0} \quad & \frac{1}{h}\int_{\eta_{i-1}(x_i,x_{i+1})}^{\eta_{i-1}(x_i,x_{i+1})+h} \partial_{i-1} f_{i-1}(\zeta_{i-1}, x_i, y_{i+1}(\zeta_{i-1}, x_i))\alpha_i(\zeta_{i-1}, x_i) d\zeta_{i-1} \\ &= (a_i \partial_{i-1} f_i)(\eta_{i-1}(x_i, x_{i+1}), x_i, y_{i+1}(\eta_{i-1}, x_i)) \\ &= (a_i \partial_{i-1} f_i)(\eta_{i-1}(x_i, x_{i+1}), x_i, x_{i+1}). \end{aligned}$$

The limit is locally uniform with respect to x_i, x_{i+1} by continuity of all functions involved. Inserting the expansion (9) of f_i, we obtain

$$\lim_{h\to 0,h\neq 0} \quad \frac{1}{f_i}\int_{\eta_{i-1}(x_i,x_{i+1})}^{\eta_{i-1}(x_i,x_{i+1})+h} \partial_{i-1}f_{i-1}(\zeta_{i-1},x_i,x_{i+1})\alpha_i(\zeta_{i-1},x_i)d\zeta_{i-1}$$

$$= \lim_{h\to 0,h\neq 0} \frac{h\cdot(a_i\partial_{i-1}f_i)(\eta_{i-1}(x_i,x_{i+1}),x_i,x_{i+1})}{h\cdot(\partial_{i-1}f_i(\eta_{i-1}(x_i,x_{i+1}),x_i,x_{i+1})+\tau(h,x_i,x_{i+1}))}$$

$$= a_i(\eta_{i-1}(x_i,x_{i+1}),x_i,x_{i+1}),$$

locally uniformly with respect to x_i, x_{i+1}. This proves the continuity of a_i, defined by (5) and (7).

Now we show that the partial derivatives $\partial_{i-1}(a_if_i)$ and $\partial_{i+1}(a_if_i)$ exist and are continuous.

This is immediate from the integral representation (7) of a_if_i, which holds for all (x_{i-1},x_i,x_{i+1}); from continuity of the integrand, which does not contain x_{i+1} and x_{i-1}; from differentiability of η_{i-1}; and from the fundamental theorem of calculus.

Acknowledgments. T.G. wants to thank Mary Silber and Vivien Kirk for the useful discussion, which showed him the futility of the previous attempt to solve the problem.

LOGARITHMIC CONVEXITY AND THE "SLOW EVOLUTION" CONSTRAINT IN ILL-POSED INITIAL VALUE PROBLEMS*

ALFRED S. CARASSO†

Abstract. This paper examines a wide class of ill-posed initial value problems for partial differential equations, and surveys logarithmic convexity results leading to Hölder-continuous dependence on data for solutions satisfying prescribed bounds. The discussion includes analytic continuation in the unit disc, time-reversed parabolic equations in L^p spaces, the time-reversed Navier–Stokes equations, as well as a large class of nonlocal evolution equations that can be obtained by randomizing the time variable in abstract Cauchy problems. It is shown that in many cases, the resulting Hölder-continuity is too weak to permit useful continuation from imperfect data. However, considerable reduction in the growth of errors occurs, and continuation becomes feasible, for solutions satisfying the *slow evolution from the continuation boundary* constraint, previously introduced by the author.

Key words. ill-posed problems, analytic continuation, backwards in time continuation, logarithmic convexity, Hölder-continuity, parabolic equations, growing diffusion coefficients, non self-adjoint problems, Navier–Stokes equations, holomorphic semigroups, subordinated processes, slow evolution from continuation boundary, SECB constraint

1. Introduction.

The problem of reconstructing the past behavior of a system, given knowledge of its current state, is of interest to many branches of science. For evolution equations, such backwards in time continuation is typically ill-posed in the presence of dissipative terms. Other spatial continuation problems in elliptic or parabolic equations exhibit similar characteristics. This paper is concerned with the Hölder-continuous dependence on data that results when certain ill-posed continuation problems in partial differential equations are stabilized by prescribed bounds [14], [21].

Because the Hölder exponent must decay to zero as the continuation boundary is approached, there is an unavoidable growth of errors originating from imperfect data. In some cases, such errors may preclude continuation into a region of particular interest. The *slow evolution from the continuation boundary* (SECB) constraint introduced in [6], [7] is an a priori statement about the rate of change of the desired solution near the continuation boundary. This information supplements information provided by prescribed bounds on the solution. As a consequence, stronger stability estimates can be obtained for solutions satisfying the SECB constraint than is otherwise possible. This constraint was shown to be effective in controlling the growth of noise in certain *image deblurring* problems, in which backwards in time continuation in diffusion equations involving fractional Laplacians plays a key role. In these problems, the Hölder exponent decays *linearly* to zero.

The present self-contained paper deals with a much wider class of problems. We survey important classes of equations, including the Navier–Stokes equations, where logarithmic convexity inequalities can be shown to hold. Using the theory of holomorphic semigroups, we consider parabolic equations in L^p spaces, as well as a large class of nonparabolic problems, typically involving nonlocal differential operators, that can

†Mathematical and Computational Sciences Division, National Institute of Standards and Technology, Gaithersburg, MD 20899 (alfred@cam.nist.gov).

be constructed by *subordination* [8]. The resulting Hölder exponents are particularly instructive in their dependence on the continuation variable. Linear decay to zero is the exception, the behavior being generally sublinear, and rapid exponential decay is possible in some cases. In time-dependent problems, such Hölder exponents are indicative of the rate at which the evolution equation has forgotten the past, and hence, of the subsequent difficulty of reconstructing the past from imperfect knowledge of the present.

It is shown that the SECB constraint, when applicable, becomes progressively more significant the faster the Hölder exponent decays to zero. Considerable error reduction is possible in many cases. Indeed, continuation problems that were heretofore intractable may become amenable to numerical computation, provided their solutions satisfy an SECB constraint. The paper concludes with a simple, explicit example of backwards in time continuation in an evolution equation with exponentially decaying Hölder exponent.

The following problem is important in its own right and serves to motivate the subsequent discussion.

1.1. Analytic continuation in the unit disc. Let $\mathcal{A}$ be the class of complex-valued functions $u(z)$ that are continuous in the closed unit disc and holomorphic in its interior, and let

$$\| u(r) \|_\infty = \max_{0\le\theta\le 2\pi} |u(re^{i\theta})|. \tag{1}$$

Fix a with $0 < a < 1$, and consider the problem of determining $u(re^{i\theta})$ for $a < r < 1$ from approximate knowledge of $u(z)$ on the circle $r = a$. Hadamard's three-circle theorem asserts that $\log \| u(r) \|_\infty$ is a convex function of $\log r$ for $a \le r \le 1$. If

$$\omega(r) = \log r / \log a, \qquad 0 < a \le r \le 1, \tag{2}$$

then

$$\| u(r) \|_\infty \le \| u(1) \|_\infty^{1-\omega(r)} \| u(a) \|_\infty^{\omega(r)}, \qquad 0 < a \le r \le 1. \tag{3}$$

We have equality in (3) for $u(z) = z^n$. This convexity inequality is the basis for stabilizing the ill-posed continuation problem when noisy data are given on $r = a$. Restrict the class of admissible continuations to functions $u(z) \in \mathcal{A}$ satisfying a *prescribed* bound,

$$\| u(1) \|_\infty \le M. \tag{4}$$

Fix $\epsilon > 0$, $\epsilon \ll M$, and let data $f(\theta)$ be given on $r = a$ such that for some $u(z) \in \mathcal{A}$ satisfying (4), we have

$$\| u(a) - f \|_\infty \le \epsilon. \tag{5}$$

If now $u_1(z), u_2(z) \in \mathcal{A}$ are any two objects satisfying (4) and (5), we get from (3)

$$\| u_1(r) - u_2(r) \|_\infty \le 2M^{1-\omega(r)} \epsilon^{\omega(r)}, \qquad a \le r \le 1. \tag{6}$$

For fixed $r_0 < 1$, the difference between any two possible continuations at $r = r_0$ can be made arbitrarily small in the L^∞ norm by giving sufficiently accurate data at $r = a$, i.e., by making $\epsilon > 0$ *sufficiently small* in (5). On the other hand, no

matter how small one chooses ϵ in (5), the inequality (6) cannot ensure accurate results at the continuation boundary $r = 1$, since $\omega(1) = 0$. Indeed, with M given in (4), and $\epsilon > 0$ given in (5), consider continuing the function $u(z) \equiv M/2$ from data $f(\theta) = M(1 + a^n e^{in\theta})/2$ at $r = a$, where n is such that $a^n < 2\epsilon/M$. At $r = 1$, the continuation $v(z) = M(1+z^n)/2$ satisfies the prescribed bound, but approximates the desired continuation $u(z) \equiv M/2$ with a relative error of 100% in the L^∞ norm. The inequality (6) establishes Hölder-continuous dependence on the data only on compact subsets of the region where bounds are prescribed. This situation prevails in diverse classes of improperly posed problems in partial differential equations stabilized by a priori bounds. Use of such bounds, together with the analysis of the resulting continuity with respect to the data, was pioneered by Fritz John in a landmark paper [14].

A basic difficulty with the above Hölder-continuity is the following. In most applications, $\epsilon > 0$ is determined by the accuracy of the instrumentation used to acquire the data. While ϵ is usually small, it is *fixed* and *cannot* be made arbitrarily small. In such applications, the dependence of the Hölder exponent $\mu(t)$ on the continuation variable t plays a crucial role. In some cases, such as backwards in time continuation in the heat equation, we have $\mu(t) = t/T$, so that $\mu(t)$ decays linearly to zero as continuation progresses from $t = T > 0$ to the continuation boundary $t = 0$. More typically, μ is *sublinear* in the continuation variable. If μ decays too rapidly to zero, useful continuation becomes impossible, even in regions well away from the continuation boundary. This is the case in (2), for example, when $a > 0$ is small. In the case of evolution equations, as will be seen below, rapid decay of μ to zero can be brought about by various factors, including nonlinearity, non-self-adjointness, diffusion coefficients that grow with time, or adverse spectral properties in the spatial differential operator.

It develops that while prescribed bounds are necessary to stabilize ill-posed initial value problems, they are frequently insufficient to allow continuation far enough into the region of interest. Further a priori information must be provided for this purpose. In this paper we show that knowing the rate of change of the desired solution near the continuation boundary is *slow* can be very helpful.

2. Slow evolution from the continuation boundary (SECB). We consider linear or nonlinear continuation problems in a single variable t, $0 \le t \le T$, with continuation boundary at $t = 0$. In spatial continuation problems with radial symmetry, t is a radial coordinate, e.g., $t = 1 - r$ in (1). In applications involving continuation in the time variable, t is related to time. In an appropriate Banach space X with norm $\| \quad \|$, the continuation $u(t)$ is an X-valued function with norm $\| u(t) \|$ for fixed t. Let $u_1(t)$, $u_2(t)$, be any two continuations from the given data $f(x)$ at $t = T$, with $\| u_i(T) - f \| \le \epsilon$, and satisfying a prescribed bound, $\| u_i(0) \| \le M$ at $t = 0$. Here, ϵ, $M > 0$ are both known, and $\epsilon \ll M$. Let $w(t) = u_1(t) - u_2(t)$. We assume $w(t)$ satisfies a convexity inequality

$$\| w(t) \| \le \| w(0) \|^{1-\mu(t)} \| w(T) \|^{\mu(t)}, \qquad 0 \le t \le T \tag{7}$$

with known exponent $\mu(t)$, $0 \le \mu(t) \le 1$. For given K with $0 < K \ll M/\epsilon$, define μ^* by

$$\mu^* = \log\{M/(M - K\epsilon)\}/\log(M/\epsilon). \tag{8}$$

The SECB constraint is expressed as follows: *There exists a known small constant $K > 0$, and a known fixed $s > 0$, with $\mu(s) > \mu^*$, such that* $\| u(s) - u(0) \| \le K\epsilon$.

By continuity as $t \downarrow 0$, given any $\epsilon > 0$, there always exists a sufficiently small $s > 0$ such that the last inequality holds with a small K. However, the requirement that s be known and be such that $\mu(s) > \mu^*$, constitutes further a priori information about the continuation problem. It will turn out to be desirable that $\mu(s) \gg \mu^*$.

There are several sets of circumstances that can result in solutions satisfying SECB. As an example, consider linear parabolic initial value problems with time-independent coefficients, homogeneous boundary conditions, and no forcing term. If the coefficients are small and the initial values are not dominated by very high frequency components, the solution will evolve slowly from these data at the continuation boundary $t = 0$. This situation prevails in some important biomedical image deblurring problems, where the blurring kernel is a Gaussian distribution with small variance. In that case, the blurred image can be viewed as the solution at time $t = T > 0$, of an initial value problem for a diffusion equation with a small diffusivity, the data at $t = 0$ being the desired unblurred image. See [6], [7, Fig. 2]. Despite the small diffusivity, fine scale information that may be of vital significance typically cannot be discerned in the blurred image. Hence the need for deblurring. More generally, in parabolic problems with time-dependent coefficients, consider the case where the coefficients are initially small but grow with time. Again, the solution will evolve slowly from the initial values, while it may change rapidly at later times. See the example in section 8 below. Inhomogeneous boundary conditions provide another mechanism that can produce solutions satisfying SECB, even when the coefficients are not small. Thus, if a body in thermal equilibrium at $t = 0$ is subjected to a boundary heat flux $b(t)$, where, with $b(0) = 0$, $b(t)$ increases slowly in the interval $0 \le t \le T/4$; increases rapidly between $T/4$ and $T/2$; and decreases rapidly to zero between $T/2$ and $3T/4$, the solution at time T will differ considerably from its initial values, while evolving slowly near $t = 0$. Similar behavior can occur in the Navier–Stokes initial value problem. Consider flows in lid-driven cavities as in [20] and the references therein. If the velocity of the driving lid has a time dependence similar to that in the heat flux $b(t)$ above, the solution of the Navier–Stokes system at time $T > 0$ will differ substantially from its initial state, while having evolved slowly near $t = 0$. Examples of SECB may likewise be found in spatial continuation problems.[1]

LEMMA 1. *For $1 > \mu(s) > \mu^*$, let $\Gamma(K, s)$ be the unique root of the transcendental equation*

$$x = K + x^{1-\mu(s)}. \tag{9}$$

Then

$$\begin{aligned} &K + 1 < \Gamma < M/\epsilon, \\ &\{K/\mu(s)\} \le \Gamma \log \Gamma \le \{K/\mu(s)\}\{\Gamma/(\Gamma - K)\}, \\ &\Gamma \log \Gamma \approx K/\mu(s) \le \{\mu^*/\mu(s)\}(M/\epsilon) \log M/\epsilon, \qquad K \ll \Gamma. \end{aligned} \tag{10}$$

Moreover, if $K + 1 \le x_0 \le M/\epsilon$, the iteration $x_{n+1} = K + x_n^{1-\mu(s)}$ converges to Γ.

Proof. The curve $y = x$ intersects the curve $y = K + x^{1-\mu(s)}$ at a single point, Γ. From (8), we have $M/\epsilon = K + (M/\epsilon)^{1-\mu^*}$, so that M/ϵ is the root of (9) when

[1] In spatial continuation for the heat equation in the quarter plane, or *sideways heat equation* problem [10], large, rather than small, diffusivities near $x = 0$ are conducive to slow evolution from that boundary.

$\mu(s) = \mu^*$. The roots of (9) decrease monotonically as $\mu(s)$ increases. Therefore, $\Gamma < M/\epsilon$. Evidently, $\Gamma > 1$, which implies $\Gamma > K + 1$. Using the inequality $w \le \log\{1/(1-w)\} \le w/(1-w)$, $0 \le w < 1$, we get $K/\Gamma \le \mu(s)\log\Gamma \le K/(\Gamma - K)$. Thus, $\Gamma\log\Gamma \approx K/\mu(s)$ if $K \ll \Gamma$. Next, $K\epsilon/M \le \mu^*\log(M/\epsilon)$, which leads to the last inequality in (10). The last statement in Lemma 1 is a standard result called "fixed point iteration." □

THEOREM 1. *Let ϵ, M, K be given positive constants with $\epsilon < M$ and $K\epsilon < M$. Let X be a Banach space with norm $\| \ \|$, and let $f \in X$. Let $\mathcal{C}$ be a linear or nonlinear continuation problem from the data f for the X-valued function $u(t)$, $0 \le t \le T$, where $\| u(0) \| \le M$ and $\| u(T) - f \| \le \epsilon$. Let $\mathcal{C}$ be such that the difference $w(t)$ of any two possible continuations satisfies*

$$\| w(t) \| \le \| w(0) \|^{1-\mu(t)} \| w(T) \|^{\mu(t)}, \qquad 0 \le t \le T, \tag{11}$$

with known $\mu(t)$, $0 \le \mu(t) \le 1$. If the solutions of $\mathcal{C}$ also satisfy $\| u(s) - u(0) \| \le K\epsilon$ for some known $s > 0$ with $\mu(s) > \mu^*$, where μ^* is defined in (8), then

$$\| w(t) \| \le 2\Gamma^{1-\mu(t)}\epsilon, \qquad 0 \le t \le T, \tag{12}$$

where Γ is the constant defined in Lemma 1. Moreover, $\Gamma \ll M/\epsilon$ if $\mu^* \ll \mu(s)$.

Proof. From (11), the difference of any two continuations satisfies

$$\begin{aligned} &\| w(t) \| \le \Lambda^{1-\mu(t)}\delta^{\mu(t)}, \qquad 0 \le t \le T, \\ &\| w(s) - w(0) \| \le K\delta, \qquad s > 0, \quad \mu(s) > \mu^*, \end{aligned} \tag{13}$$

where $\Lambda = 2M$, $\delta = 2\epsilon$. From

$$\begin{aligned} \| w(t) \| &\le \| w(0) \|^{1-\mu(t)} \| w(T) \|^{\mu(t)} \\ &\le \{\| w(s) - w(0) \| + \| w(s) \|\}^{1-\mu(t)} \| w(T) \|^{\mu(t)}, \end{aligned} \tag{14}$$

together with (13), we get

$$\| w(s) \| \le \left\{K\delta + \Lambda^{1-\mu(s)}\delta^{\mu(s)}\right\}^{1-\mu(s)}\delta^{\mu(s)}. \tag{15}$$

The initial estimate for $w(s)$, $\| w^1(s) \| \le \Lambda^{1-\mu(s)}\delta^{\mu(s)}$, has been used in (14) to produce a new estimate, $\| w^2(s) \|$, given by (15). We may insert (15) back into (14) to produce a third estimate for $w(s)$, and so on. At the nth step of that iteration, we get $\| w^n(s) \| \le Z_n^{1-\mu(s)}\delta^{\mu(s)}$, where

$$Z_1 = \Lambda, \qquad Z_k/\delta = K + (Z_{k-1}/\delta)^{1-\mu(s)}, \qquad k > 1. \tag{16}$$

We have $Z_n \to \Gamma\delta$ as $n \uparrow \infty$, where Γ is defined in Lemma 1. Thus, $\| w(s) \| \le \Gamma^{1-\mu(s)}\delta$. Inserting this back into (14), and using (13), we get

$$\| w(t) \| \le 2\Gamma^{1-\mu(t)}\epsilon, \qquad 0 \le t \le T. \tag{17}$$

Finally, the last inequality in (10) shows that $\Gamma\log\Gamma \ll (M/\epsilon)\log(M/\epsilon)$ provided $\mu(s) \gg \mu^*$. □

To illustrate the SECB constraint, we return to analytic continuation in the unit disc, as discussed in the Introduction. Let $M = 4$, $\epsilon = 10^{-5}$, $a = 0.1$, and consider

continuing the function $u(z) = 1 + 0.1z$ from data $f(\theta) = 1 + 0.1ae^{i\theta} + 2a^6e^{6i\theta}$ at $r = a$. Let $v(z) = 1 + 0.1z + 2z^6$. Then,

$$\begin{aligned} &\| u(1) \|_\infty = 1.1 < M, && \| u(a) - f \|_\infty = 2 \times 10^{-6} < \epsilon, \\ &\| v(1) \|_\infty = 3.1 < M, && \| v(a) - f \|_\infty = 0 < \epsilon. \end{aligned} \tag{18}$$

Thus, both $u(z)$ and $v(z)$ satisfy the a priori constraints (4), (5). However, at $r = 3/4$, we find $\| u(3/4) - v(3/4) \|_\infty / \| u(3/4) \|_\infty = 33\%$, and $\| u(1) - v(1) \|_\infty / \| u(1) \|_\infty = 182\%$ at $r = 1$. These are unacceptable relative errors. Additional a priori information about $u(z)$ near the continuation boundary $r = 1$ can reduce this uncertainty. With $K = 12$ and $s = 0.001$, we have

$$\| u(1) - u(1 - s) \|_\infty = 0.1s \le K\epsilon, \tag{19}$$

while

$$\begin{aligned} \| v(1) - v(1 - s) \|_\infty &= \max_\theta |0.1se^{i\theta} + 2\{1 - (1 - s)^6\}e^{6i\theta}| \\ &= \max_\theta |10^{-4}e^{i\theta} + 1.197 \times 10^{-2}e^{6i\theta}| \\ &> 10^{-2} > K\epsilon. \end{aligned} \tag{20}$$

Therefore, the SECB constraint (19), with $s = 0.001$ and $K = 12$, eliminates $v(z)$ as a possible continuation. With $\omega(r)$ as in (2), let $\mu(t) = \omega(1 - t)$, $0 \le t \le 1 - a$. Since $\mu(s) = 4.345 \times 10^{-4}$, while $\mu^* = 2.326 \times 10^{-6}$, we have $\mu(s)/\mu^* = 187$, and $\Gamma \log \Gamma \approx K/\mu(s) = 27618$. This gives $\Gamma = 3397$ while $M/\epsilon = 400,000 = 118\Gamma$. Let $w(r, \theta)$ be the difference between any two possible continuations from data at $r = a = 0.1$ satisfying (4), (5), with $M = 4$ and $\epsilon = 10^{-5}$. Without the SECB constraint (19), we have $\| w(1) \|_\infty \le 2M = 8$. With the SECB constraint, we have $\| w(1) \|_\infty \le 2\ \Gamma\ \epsilon = 0.0679$.

Theorem 1 leads to the following corollary to the Hadamard three-circle theorem.

THEOREM 2 (corollary). *In the analytic continuation problem in the unit disc, let $u_1(z)$, $u_2(z)$ be as in (6), let $0 < s < 1 - a$, let $\omega(r)$ be as in (2), and let $\mu(s) = \omega(1 - s)$. If*

$$\| u_i(1) - u_i(1 - s) \|_\infty \le K\epsilon, \qquad i = 1, 2, \tag{21}$$

with known K, $0 < K < M/\epsilon$, and known s such that $\mu(s) > \mu^*$, where μ^* is defined in (8), then

$$\| u_1(r) - u_2(r) \|_\infty \le 2\Gamma^{1-\omega(r)}\epsilon, \qquad a \le r \le 1, \tag{22}$$

where $\Gamma < M/\epsilon$ is the constant in Lemma 1. Moreover, $\Gamma \ll M/\epsilon$ if $\omega(1 - s) \gg \mu^*$.

Remark 1. The SECB constraint does not imply differentiability of $u(1, \theta)$, as a function of θ, on the circle $r = 1$. More generally, at the continuation boundary $t = 0$, $u(t)$ need not be differentiable in its remaining variables in order to satisfy an SECB constraint. This point is emphasized in [6], [7, Fig. 2], and again in the example in section 8 below.

3. An approach to logarithmic convexity. The following method has been widely used to obtain continuous dependence inequalities in linear and nonlinear initial value problems, typically in a Hilbert space setting [2], [16], [17]. Let H be a

Hilbert space, and let $\mathcal{S}$ be an initial value problem for a system of partial differential equations, with solutions $u(t) \in H$ for each $t \in (0, T]$. Let $F(t)$ be a real-valued twice continuously differentiable function of t, defined on the set of solutions $u(t)$ of $\mathcal{S}$ and satisfying

$$\begin{aligned} &F(t) \geq 0, \qquad F(t) = 0 \Longleftrightarrow u(t) = 0, \qquad 0 \leq t \leq T, \\ &F(t)F''(t) - \{F'(t)\}^2 \geq -a_1\ F(t)F'(t) - a_2\ F^2(t), \qquad 0 < t < T, \end{aligned} \tag{23}$$

where a_1 and a_2 are constants. If $a_1 = a_2 = 0$ in (23), then

$$F(t) \leq \{F(0)\}^{(T-t)/T}\{F(T)\}^{t/T}, \qquad 0 \leq t \leq T. \tag{24}$$

More typically, $a_1 \neq 0$ in (23). In that case, let

$$m = -a_2/a_1, \qquad \mu(t) = \{e^{-a_1 t} - 1\}\{e^{-a_1 T} - 1\}^{-1}, \qquad 0 \leq t \leq T. \tag{25}$$

Then (see [2], [17])

$$e^{-mt}F(t) \leq \{F(0)\}^{1-\mu(t)}\{e^{-mT}F(T)\}^{\mu(t)}, \qquad 0 \leq t \leq T. \tag{26}$$

We now give two examples of the use of this technique in L^2, with $F(t) = \| u(t) \|^2$. Many other examples, and choices for $F(t)$, may be found in [2], [16], [24], and the references therein.

4. Self-adjoint parabolic problems with time-dependent coefficients. Let Ω be a bounded domain in R^n with sufficiently smooth boundary $\partial\Omega$. For $x \in R^n$ and $t \geq 0$, let $a(t; u, v)$ and $\dot{a}(t; u, v)$ be *symmetric* bilinear forms on $H_0^m(\Omega)$ given by

$$\begin{aligned} a(t; u, v) &= \sum_{|p|,|q| \leq m} \int_\Omega a_{pq}(x, t) D^q u \overline{D^p v} dx, \\ \dot{a}(t; u, v) &= \sum_{|p|,|q| \leq m} \int_\Omega \dot{a}_{pq}(x, t) D^q u \overline{D^p v} dx, \end{aligned} \tag{27}$$

where the coefficients a_{pq} depend smoothly on x and t, $\overline{a}_{pq} = a_{qp}$, and $\dot{a}_{pq}$ denotes $\partial a_{pq}/\partial t$. We assume $a(t; u, v)$ to be uniformly strongly coercive on $H_0^m(\Omega)$, i.e., there exists $\alpha > 0$, independent of t, such that

$$a(t; v, v) \geq \alpha \parallel v \parallel_m^2, \qquad v \in H_0^m(\Omega). \tag{28}$$

Both $a(t; u, v)$ and $\dot{a}(t, u, v)$ are continuous on $H_0^m(\Omega) \times H_0^m(\Omega)$, uniformly in t; i.e., there exist $\beta,\ \gamma > 0$, independent of t, such that

$$|a(t; u, v)| \leq \beta \parallel u \parallel_m \parallel v \parallel_m, \quad |\dot{a}(t; u, v)| \leq \gamma \parallel u \parallel_m \parallel v \parallel_m, \quad u, v \in H_0^m(\Omega). \tag{29}$$

The bilinear form $a(t, u, v)$ defines a positive self-adjoint operator $A(t)$ in $L^2(\Omega)$, [28], with domain $D_A = H^{2m}(\Omega) \cap H_0^m(\Omega)$ such that

$$\begin{aligned} &(A(t)v, v) = a(t : v, v), \qquad (\dot{A}(t)v, v) = \dot{a}(t; v, v), \qquad v \in D_A, \\ &|(\dot{A}(t)v, v)| \leq (\gamma/\alpha)(A(t)v, v), \qquad v \in D_A, \end{aligned} \tag{30}$$

where (,) denotes the scalar product in $L^2(\Omega)$. The operator $A(t)$ is the closed extension of the strongly elliptic symmetric differential operator

$$A(x,t,D)u = \sum_{|p|,|q|\le m} (-1)^{|p|} D^p(a_{pq}(x,t)D^q u), \qquad x \in \Omega, \quad t > 0, \tag{31}$$

with zero Dirichlet data on $\partial\Omega$. We distinguish two cases: a) the case where diffusion is constant or *decreases* with time and $(\dot{A}(t)v, v) \le 0$, and b) the case where diffusion *increases* at least some of the time and $(\dot{A}(t)v, v) \le \gamma \parallel v \parallel_m^2$. The theorem below is due to Agmon and Nirenberg [1].

THEOREM 3. *Let α and γ be the positive constants in* (28) *and* (29). *Let $u(t) \in L^2(\Omega)$ be a solution of $u_t = -A(t)u$, $t > 0$. If $(\dot{A}(t)v, v) \le 0$, $0 < t \le T$, let $\mu(t) = t/T$. If $(\dot{A}(t)v, v) \le \gamma \parallel v \parallel_m^2$, $0 < t \le T$, let $c = \gamma/\alpha$ and let $\mu(t) = \{e^{ct} - 1\}\{e^{cT} - 1\}^{-1}$. Then,*

$$\parallel u(t) \parallel \le \parallel u(0) \parallel^{1-\mu(t)} \parallel u(T) \parallel^{\mu(t)}, \qquad 0 \le t \le T. \tag{32}$$

Proof. With $F(t) = \parallel u(t) \parallel^2$, we have $F'(t) = -2(A(t)u, u)$, and

$$\begin{aligned} FF'' - \{F'\}^2 &= -2(\dot{A}(t)u, u)F + 4 \parallel A(t)u \parallel^2 \parallel u \parallel^2 - 4|(A(t)u, u)|^2 \\ &\ge -2(\dot{A}(t)u, u)F \end{aligned} \tag{33}$$

on using Schwarz's inequality. If $(\dot{A}(t)u, u) \le 0$, we have the case $a_1 = a_2 = 0$ in (23) and the result follows from (24). If $(\dot{A}(t)u, u) \le \gamma \parallel u \parallel_m^2$, we use (30) to obtain $-2(\dot{A}(t)u, u)F \ge (\gamma/\alpha)FF'$ in (33). This is the case $a_2 = 0$, $a_1 = -\gamma/\alpha$ in (23), and the result follows from (26) with $m = 0$. □

Evidently, growing diffusion coefficients can result in exponential decay in $\mu(t)$. In section 8 below, we study a simple explicit example where this is indeed the case. Applying Theorem 1 to the Agmon–Nirenberg result, we have the following corollary.

THEOREM 4 (corollary). *In Theorem* 3, *let positive constants ϵ, M, be given, with $\epsilon < M$. Let $f \in L^2(\Omega)$ be given data at time $T > 0$, and let $u_1(t)$, $u_2(t)$ be two solutions of $u_t = -A(t)u + g(t)$, $0 < t \le T$, such that $\parallel u_i(T) - f \parallel \le \epsilon$, and $\parallel u_i(0) \parallel \le M$, $i = 1, 2$. Let $w(t) = u_1(t) - u_2(t)$. Then, with $\mu(t)$ as in Theorem* 3,

$$\parallel w(t) \parallel \le 2M^{1-\mu(t)}\epsilon^{\mu(t)}, \qquad 0 \le t \le T. \tag{34}$$

If, in addition, $\parallel u_i(s) - u_i(0) \parallel \le K\epsilon$, $i = 1, 2$, with known K, $0 < K < M/\epsilon$, and known $s > 0$ such that $\mu(s) > \mu^*$, where μ^* is defined in (8), *then*

$$\parallel w(t) \parallel \le 2\Gamma^{1-\mu(t)}\epsilon, \qquad 0 \le t \le T, \tag{35}$$

where $\Gamma < M/\epsilon$ is the constant in Lemma 1. *Moreover, $\Gamma \ll M/\epsilon$ if $\mu(s) \gg \mu^*$.*

5. Navier–Stokes equations backwards in time. With $i = 1, 3$, and summation convention understood, consider the Navier–Stokes system in a bounded domain $\Omega \subset R^3$, with smooth boundary $\partial\Omega$,

$$\left.\begin{aligned} u_{i,t} &= \nu\Delta u_i - u_j u_{i,j} - \rho^{-1}p_{,i} + G_i(x,t) \\ u_{j,j} &= 0 \end{aligned}\right\} \qquad (x,t) \in \Omega \times (0,T], \tag{36}$$

$$u_i(x,T) = f_i(x), \quad x \in \Omega, \qquad u_i = g_i(x,t), \quad (x,t) \in \partial\Omega \times [0,T].$$

Here, differentiation is denoted by a comma, ν is the kinematic viscosity, ρ is the constant density, p the unknown pressure, $u_i(x,t)$ is the ith component of fluid velocity,

$G_i(x,t)$ is a prescribed body force per unit mass, and $g_i(x,t)$ are prescribed boundary values. In [18], Knops and Payne study the stability of reconstructing the solution of (36) on $[0,T)$, under small perturbations of the solution values $f_i(x)$ at some positive time T. Let P and Q be prescribed positive constants. A function $u_i(x,t)$ is said to belong to the set $\mathcal{P}$ provided

$$\sup_{\Omega\times[0,T]} u_i u_i \le P^2, \tag{37}$$

while it belongs to the set $\mathcal{Q}$ whenever

$$\sup_{\Omega\times[0,T]} \{u_i u_i + (u_{i,j}-u_{j,i})(u_{i,j}-u_{j,i}) + u_{i,t}u_{i,t}\} \le Q^2. \tag{38}$$

In [25], the same stability problem is studied under weaker constraints. Let $u_i^1(x,t)$ and $u_i^2(x,t)$ denote classical solutions of (36) corresponding to terminal data $f_i^1(x)$ and $f_i^2(x)$ at time $T>0$. Let $v_i(x,t)=(u_i^1-u_i^2)(x,t)$. Define the spatial L^2 norm of $v_i(x,t)$ at time t by

$$\| v(t) \| = \left\{ \int_\Omega v_i(x,t)v_i(x,t)dx \right\}^{1/2}. \tag{39}$$

Knops and Payne [18] show that if $u_i^1(x,t)\in\mathcal{P}$ and $u_i^2(x,t)\in\mathcal{Q}$, and if $F(t)=\| v(t) \|^2$,

$$\begin{aligned} F(t)F''(t)-\{F'(t)\}^2 &\ge 2\nu^{-1}(P^2+1)F(t)F'(t) - Q^2\{2\nu^{-2}(P^2+1)+1\}F^2(t) \\ &= -a_1F(t)F'(t)-a_2F^2(t). \end{aligned} \tag{40}$$

Hence, with

$$\begin{aligned} &c=-a_1=2\nu^{-1}(P^2+1), \\ &\mu(t)=(e^{ct}-1)(e^{cT}-1)^{-1}, \\ &w_i(x,t)=e^{-mt}v_i(x,t), \qquad m=-a_2/2a_1, \qquad 0\le t\le T, \end{aligned} \tag{41}$$

it follows from (40) and (26) that

$$\| w(t) \| \le \| w(0) \|^{1-\mu(t)} \| w(T) \|^{\mu(t)}, \qquad 0\le t\le T. \tag{42}$$

Applying Theorem 1 to the Knops–Payne result (42), we have the following corollary.

THEOREM 5 (corollary). *For the given positive ϵ, M, with $\epsilon<M$, let $w_i(x,t)$ in* (41) *satisfy* $\| w(0) \|\le M$, $\| w(T) \|\le\epsilon$, *and let $\mu(t)$ be as in* (41). *Then*

$$\| w(t) \| \le M^{1-\mu(t)}\epsilon^{\mu(t)}, \qquad 0\le t\le T. \tag{43}$$

If, in addition, $\| w(s)-w(0) \|\le K\epsilon$, *with known K, $0<K<M/\epsilon$, and known $s>0$ such that $\mu(s)>\mu^*\equiv\log\{M/(M-K\epsilon)\}/\log(M/\epsilon)$, then*

$$\| w(t) \| \le \Gamma^{1-\mu(t)}\epsilon, \qquad 0\le t\le T, \tag{44}$$

where $\Gamma<M/\epsilon$ is the unique root of $x-x^{1-\mu(s)}-K=0$. Moreover, $\Gamma\ll M/\epsilon$ if $\mu(s)\gg\mu^*$.

For large c, the rapid exponential decay of $\mu(t)$ as t decreases from $t = T$ makes it unlikely that the most general solutions satisfying the constraints (37) or (38) can be continued very far into the past. However, it may be possible to continue solutions that have evolved slowly near $t = 0$. Consider the following example. Let $P = 1,\ \nu = 10^{-1},\ T = 0.25,\ M = 20$, and $\epsilon = 10^{-6}$. Then, $c = 40$ and $\mu(t) = \{e^{40t} - 1\}\{e^{10} - 1\}^{-1},\ 0 \le t \le 0.25$. In particular, $\mu(T/2) = 6.693 \times 10^{-3}$. Consequently, (43) gives

$$\| w(T/2) \| \le 19.603 \times 0.911681 = 17.872 \tag{45}$$

On the other hand, suppose that the solutions to be reconstructed are known to have evolved slowly enough near $t = 0$ that with $s = 0.01T$ and $K = 10$, we have $\| w(s) - w(0) \| \le K\epsilon$. Then $\mu(s) = 4.775 \times 10^{-6}$, while $\mu^* = 2.974 \times 10^{-8}$. Thus, $\{\mu(s)/\mu^*\} = 160.55$. From $\Gamma \log \Gamma \approx K/\mu(s)$, we find $\Gamma \approx 173,600$ and $M/\epsilon = 115\Gamma$. From (44), we get

$$\| w(T/2) \| \le 160,134 \times 10^{-6} = 0.16. \tag{46}$$

Thus, the difference between any two solutions satisfying the SECB constraint is over one hundred times smaller at $t = T/2$ than it is in the more general case of (45).

6. Holomorphic semigroups and evolution equations. Let X be a complex Banach space, let A be a closed linear operator with domain D_A dense in X, and consider the evolution equation $u_t = -Au,\quad t > 0$, for the X-valued function $u(t)$. We assume that $-A$ generates a holomorphic semigroup e^{-tA} in an open sector of the complex t-plane, $\Sigma_\phi = \{\text{Re } t > 0,\ \ |\text{Arg } t| < \phi\}$, for some fixed $\phi,\ \ 0 < \phi \le \pi/2$. Moreover, for any $0 < \sigma < \phi,\ \ e^{-tA}$ is strongly continuous at $t = 0$ within $\Sigma_{\phi-\sigma}$, reduces to the identity operator at $t = 0$, and satisfies $\| e^{-tA} \| \le B_\sigma < \infty$ for $t \in \overline{\Sigma}_{\phi-\sigma}$. Thus, e^{-tA} is a bounded holomorphic semigroup as defined in [15].

Parabolic initial boundary value problems constitute the best-known area of application of holomorphic semigroups. We briefly sketch this connection below, and refer the reader to [12] and [28] for a complete treatment. Less well known are applications to a wide class of nonparabolic equations, typically involving nonlocal partial differential operators, that are obtained by "subordination" in well-posed Cauchy problems [4], [11], [8]. This class of problems, mentioned in section 6.1, is drawing increasing interest from physical scientists working in certain areas of fractal analysis.

Let Ω be a bounded domain in R^n with a sufficiently smooth boundary $\partial\Omega$. For $x \in R^n$, let $A(x, D) = \sum_{|\alpha| \le 2m} a_\alpha(x) D^\alpha$ be a linear partial differential operator with coefficients $a_\alpha(x)$ continuous in the closure of Ω. If $A(x, D)$ is strongly elliptic, and zero Dirichlet data are given on $\partial\Omega$, a closed linear operator A in $L^2(\Omega)$, with dense domain $D_A = H^{2m}(\Omega) \cap H_0^m(\Omega)$, can be defined by

$$(Au)(x) = A(x, D)u(x), \qquad u \in D_A. \tag{47}$$

Moreover, as shown in [12], [28], for some $k \ge 0$ the linear operator $-(A+kI)$ generates a bounded holomorphic semigroup in $L^2(\Omega)$. If $A(x, D)$ is a symmetric differential operator, then $A + kI$ is self-adjoint, and we may choose $\phi = \pi/2$ in Σ_ϕ.

More general boundary conditions can be handled and parabolic equations of order $2m$ can be considered in $L^p(\Omega),\ \ 1 \le p < \infty$. Let $H^{j,p}(\Omega)$ denote the Sobolev space of functions in $L^p(\Omega)$ whose weak derivatives of order less than or equal to j exist and belong to $L^p(\Omega)$. Let $\{B_j\}_{j=1}^m$ be m boundary operators of respective orders $m_j < 2m$, given by

$$B_j(x,D) = \sum_{|\alpha| \le m_j} b_\alpha^j(x) D^\alpha, \tag{48}$$

and consider the boundary value problem

$$\begin{aligned} &A(x,D)u = g, \qquad x \in \Omega, \\ &B_j(x,D)u = 0, \qquad x \in \partial\Omega, \quad 1 \le j \le m. \end{aligned} \tag{49}$$

A closed linear operator A with dense domain $D_A = H^{2m,p}(\Omega; \{B_j\})$, consisting of the closure in $H^{2m,p}(\Omega)$ of the set of functions $u \in C^{2m}(\overline{\Omega})$ that satisfy the boundary conditions in (49), can be defined via

$$(Au)(x) = A(x,D)u, \qquad u \in D_A. \tag{50}$$

If the system B_j is *normal*, and satisfies further *complementary* conditions, and if $A(x,D)$ is strongly elliptic, one obtains a *regular* elliptic boundary value problem, $(A, \{B_j\}, \Omega)$, such that for some $k \ge 0$, the linear operator $-(A + kI)$ generates a bounded holomorphic semigroup in $L^p(\Omega)$. See [12], [28].

6.1. Subordinated semigroups. Let $H(y)$ denote the Heaviside unit step function, and consider the family $p_y(t)$ given by

$$p_y(t) = \frac{tH(y)e^{-t^2/4y}}{\sqrt{4\pi y^3}}, \qquad t > 0. \tag{51}$$

For each fixed $t > 0$, $p_y(t)$ is a probability density function on $y \ge 0$, and $p_y(t)$ tends to the Dirac δ-function $\delta(y)$ as $t \downarrow 0$. Moreover, if $*$ denotes convolution with respect to y, then $p_y(t) * p_y(s) = p_y(t+s)$, for $s,\ t \ge 0$. The Laplace transform with respect to y of $p_y(t)$ is given by

$$\mathcal{L}\{p_y(t)\} \equiv \int_0^\infty e^{-yz} p_y(t)\,dy = e^{-t\sqrt{z}}, \qquad \text{Re } z > 0. \tag{52}$$

The "inverse Gaussian" family in (51) is just one example of an *infinitely divisible* family of probability density functions on the half-line $y \ge 0$, [11].

Let $T(t) = e^{-tA},\ t \ge 0$, be a uniformly bounded, not necessarily holomorphic, C_0 semigroup on a complex Banach space X. Using (51), one may construct a new C_0 semigroup $U(t)$ on X, with $\| U(t) \| \le \| T(t) \| \le B < \infty,\ \ t \ge 0$, by means of

$$U(0) = I, \quad U(t)g = \int_0^\infty p_y(t) T(y) g \; dy, \qquad t > 0, \quad g \in X. \tag{53}$$

Indeed, it turns out that $U(t) = e^{-tA^{1/2}}$ and that $U(t)$ can be extended to a *bounded holomorphic semigroup* in some sector Σ_ω.

The construction in (53) amounts to randomization of the time variable t in the original semigroup $T(t)$. A wide variety of infinitely divisible families $q_y(t)$ may be used in (53). The new semigroup $U(t)$ is said to be "subordinated" to $T(t)$ through the "directing process" $q_y(t)$ [11]. This concept originated in [4] and was subsequently refined into a functional calculus in [26], [23], and [3]. The observation that $U(t)$ is holomorphic whenever the directing process $q_y(t) = \mathcal{L}^{-1}\{e^{-tz^\alpha}\},\ \ 0 < \alpha < 1$, was made in [29]. In that case, $U(t) = e^{-tA^\alpha}$. Subordinated processes and fractional

differential operators are of interest in polymer science [9], while diffusion equations with fractional Laplacians play a role in image deblurring [6]. Further applications are discussed in [5, pp. 140–156] and [11].

An arbitrary infinitely divisible family $q_y(t)$ on $y \geq 0$ can be characterized in terms of its Laplace transform [11]. We have $\mathcal{L}\{q_y(t)\} = e^{-t\psi(z)},\ t \geq 0$, where the *exponent* $\psi(z)$ is holomorphic for Re $z > 0$ and continuous for Re $z \geq 0$, with Re $\psi(z) \geq 0$. Moreover, $\psi(0) = 0$, and $\psi'(x)$ is completely monotone for $x > 0$. In [8], the results of [29] are extended. A necessary and sufficient condition on $q_y(t)$ is given, in order that the subordinated semigroup $U(t) = e^{-t\psi(A)}$ be holomorphic on X, whenever $T(t)$ is C_0 and uniformly bounded on X. In addition, a *necessary* condition on the exponent $\psi(z)$ is obtained for that to be the case. In [13], a *sufficient* condition on $\psi(z)$ is given that ensures analyticity of $U(t)$. As a consequence of [29], [8], and [13], a rich class of exponents $\psi(z)$ is known, with the property that $-\psi(A)$ generates a bounded holomorphic semigroup on X whenever $-A$ generates a uniformly bounded C_0 semigroup on X. As one example, consider the symmetric hyperbolic system,

$$\begin{aligned} u_t &= \sum_{i=1}^{n} a_i(x) u_{x_i} + b(x)u, \qquad x \in R^n, t > 0, \\ u(x,0) &= f(x), \end{aligned} \tag{54}$$

where $u(x)$ is an N-component vector, $a_i(x),\ b(x)$ are $N \times N$ matrices with boundedly differentiable entries on R^n, and $a_i(x)$ is Hermitian. The differential operator on the right-hand side of (54) can be extended into a closed densely defined linear operator $-A$ in $L^2(R^n)^N$. As shown in [28], for some $k \geq 0,\ -(A+kI)$ generates a contraction semigroup on $L^2(R^n)^N$. It follows from [29], [8] that if

$$\psi_1(A) = (A + kI)^{\alpha},\ 0 < \alpha < 1, \qquad \psi_2(A) = \mathrm{Log}\{A + (k+1)I\}, \tag{55}$$

then each of $-\psi_1(A), -\psi_2(A)$, generates a holomorphic semigroup on $L^2(R^n)^N$. If $\{\alpha_n\}_{n=1}^{\infty}$ and $\{a_n\}_{n=1}^{\infty}$ are any two sequences satisfying $a_n \geq 0,\ \ a_1 > 0,\ \ 1 > \alpha_1 > \alpha_2 > \cdots > \alpha_n > \cdots > 0,\ \ \sum_{n=1}^{\infty} a_n/\alpha_n < \infty$, and if

$$\psi_3(A) = \sum_{n=1}^{\infty} a_n (A + kI)^{\alpha_n}, \tag{56}$$

it follows from [13] that $-\psi_3(A)$ generates a holomorphic semigroup on $L^2(R^n)^N$. None of the $\psi_i(A),\ i = 1, 3$, are elliptic operators when $-A$ is the differential operator on the right-hand side of (54). This shows that holomorphic semigroup theory encompasses a class of initial value problems in partial differential equations that is considerably wider than the class of parabolic problems.

7. Logarithmic convexity and holomorphic semigroups. In Banach space, approaches different from those used in sections 3–5 appear necessary to obtain logarithmic convexity inequalities. Following the basic work in [19], further convexity results were obtained in [1], [12], and [22]. Theorems 6 and 7 below are a reformulation of results originating with these authors.

For any $a \geq 0$, and $0 < \xi \leq 1$, let $S(a, \xi)$ be the set in the complex τ-plane given by

$$S(a,\xi) = \{\tau = t + is;\ \ t \geq a;\ \ |s| \leq (t-a)\tan(\pi\xi/2)\}. \tag{57}$$

Let $T > 0$. Then, $S(T,\xi) \subset S(0,\xi)$. Let $G(T,\xi) = S(0,\xi) \setminus S(T,\xi)$, and let Λ_L, Λ_R be, respectively, the left and right boundary arcs of $G(T,\xi)$. Let $\omega_\xi(t,s)$ be the unique bounded continuous function on $\overline{G}(T,\xi)$ which is harmonic in the interior of $G(T,\xi)$, equals zero on Λ_L, and equals one on Λ_R. Let $\mu_\xi(t) = \omega_\xi(t,0)$, $0 \le t \le T$.

LEMMA 2. *$\mu_1(t) = t/T$, and, if $0 < \xi < \eta \le 1$, $\mu_\xi(t) < \mu_\eta(t)$, $0 < t < T$.*

Proof. Let $H(\xi,\eta) = S(0,\eta) \setminus S(T,\xi)$. Then $G(T,\xi) \subset H(\xi,\eta)$, and $G(T,\eta) \subset H(\xi,\eta)$. Let Λ'_L be the left boundary arc of $H(\xi,\eta)$, and let Λ'_R be the right boundary arc of $G(T,\eta)$. Let $\tilde{\omega}(t,s)$ be the unique bounded continuous function on $\overline{H}(\xi,\eta)$ which is harmonic in the interior of $H(\xi,\eta)$, equals zero on Λ'_L, and equals one on Λ_R. The harmonic function $\tilde{\omega} - \omega_\xi$ in $G(T,\xi)$ has value zero on Λ_R, is nonnegative on Λ_L and hence must be strictly positive in the interior of $G(T,\xi)$. Therefore $\mu_\xi(t) < \tilde{\omega}(t,0)$, $0 < t < T$. A similar argument, applied to the harmonic function $\omega_\eta - \tilde{\omega}$ in $G(T,\eta)$, shows that $\mu_\eta(t) > \tilde{\omega}(t,0)$, $0 < t < T$. Finally, if $\xi = 1$, then $\overline{G}(T,1)$ is the vertical strip $0 \le \operatorname{Re}\tau \le T$, and $\omega_1(t,s) = t/T$. □

We now consider the evolution equation $u_t = -Au$, $t > 0$, in a complex Banach space X with norm $\| \quad \|$, under the assumption that $-A$ generates a bounded holomorphic semigroup in an open sector Σ_ϕ in the complex $\tau = t + is$ plane. With $0 < \alpha\pi/2 < \phi \le \pi/2$, let $S(0,\alpha)$, defined in (57), be a closed subsector of Σ_ϕ, and let $\| e^{-\tau A} \| \le B_\alpha < \infty$, $\tau \in S(0,\alpha)$. Introduce the equivalent norm $\| \quad \|_\alpha$ on X defined by

$$\| x \|_\alpha \equiv \sup_{\tau \in S(0,\alpha)} \| e^{-\tau A} x \|, \qquad x \in X. \tag{58}$$

Then, as is easily verified,

$$\| x \| \le \| x \|_\alpha \le B_\alpha \| x \|, \quad x \in X, \qquad \| e^{-\tau A} \|_\alpha \le 1, \quad \tau \in S(0,\alpha). \tag{59}$$

THEOREM 6. *Let X be a complex Banach space with norm $\| \quad \|$, let $u(t)$ be a solution of $u_t = -Au$, $0 < t \le T$, where $-A$ generates a bounded holomorphic semigroup on X. Then, with $\| \quad \|_\alpha$ as in (58) and $\mu_\alpha(t)$ as in Lemma 2,*

$$\| u(t) \|_\alpha \le \| u(0) \|_\alpha^{1-\mu_\alpha(t)} \| u(T) \|_\alpha^{\mu_\alpha(t)}, \qquad 0 \le t \le T, \tag{60}$$

and

$$\| u(t) \| \le B_\alpha \| u(0) \|^{1-\mu_\alpha(t)} \| u(T) \|^{\mu_\alpha(t)}, \qquad 0 \le t \le T. \tag{61}$$

Proof. Let l be a linear functional on X with $|l|_\alpha = 1$, where $| \ |_\alpha$ denotes the norm on X^* corresponding to the norm $\| \quad \|_\alpha$ on X. Let $h(\tau) = l(e^{-\tau A} u(0))$ for $\tau \in S(0,\alpha)$. We have that $h(\tau)$ is continuous and bounded on $S(0,\alpha)$, with $|h(\tau)| \le \| u(0) \|_\alpha$, and $h(\tau)$ is holomorphic in the interior of $S(0,\alpha)$. The same is true for $h(\tau)$ in $S(T,\alpha)$, with $|h(\tau)| \le \| u(T) \|_\alpha$. This follows from $e^{-\tau A} = e^{-(\tau - T)A} e^{-TA}$ for $\tau \in S(T,\alpha)$. Let $G(T,\alpha)$ and $\omega_\alpha(t,s)$ be as defined above, and consider the function $v(t,s)$ in $G(T,\alpha)$ where

$$v(t,s) = \log|h(\tau)| - \omega_\alpha(t,s) \log \| u(T) \|_\alpha + (\omega_\alpha(t,s) - 1) \log \| u(0) \|_\alpha . \tag{62}$$

The function $v(t,s)$ is upper semicontinuous and bounded above on $G(T,\alpha)$, subharmonic in the interior of $G(T,\alpha)$, and nonpositive on the left and right boundary arcs of $G(T,\alpha)$. Therefore $v(t,s) \le 0$ on $\overline{G}(T,\alpha)$. Using

$$\| u(\tau) \|_\alpha = \sup_{l \in X^*, \ |l|_\alpha = 1} |h(\tau)|, \tag{63}$$

we obtain

$$\| u(\tau) \|_\alpha \leq \| u(0) \|_\alpha^{1-\omega_\alpha(\tau)} \| u(T) \|_\alpha^{\omega_\alpha(\tau)}, \qquad \tau \in \overline{G}(T,\alpha), \tag{64}$$

which implies, on using (59),

$$\| u(\tau) \| \leq B_\alpha \, \| u(0) \|^{1-\omega_\alpha(\tau)} \| u(T) \|^{\omega_\alpha(\tau)}, \qquad \tau \in \overline{G}(T,\alpha). \tag{65}$$

Finally, (60), (61), follow from the above on putting $\tau = t$. □

Remark 2. The inequality (61) follows from (60) but not vice versa. From Lemma 2, we see that $\mu_\alpha(t)$ is sublinear in t, and this sublinearity becomes more severe as α becomes smaller. The choice of α depends on the spectrum of the spatial operator A. Since $-A$ generates a holomorphic semigroup in the open sector Σ_ϕ, the spectrum of A must be contained in the closed sector $Arg\,|z| \leq \beta = \pi/2 - \phi$ in the right half-plane. As β increases, ϕ, and hence α, must decrease. Theorem 6 does not yield the explicit dependence of $\mu_\alpha(t)$ on t, which is necessary for applying the SECB constraint. The next result is more useful in that regard.

THEOREM 7. *With $u(t)$ and α as in Theorem* 6, *let* $0 < \sigma < \alpha < 1$, *and let*

$$\begin{aligned} &\lambda = \inf_{0 \leq \theta \leq \pi/2} \{\cos\sigma\theta \, [1 - \tan\sigma\theta / \tan(\alpha\pi/2)] \, / (\cos\theta)^\sigma\}, \\ &\rho_\sigma(t) = (\lambda t/T)^{1/\sigma}, \qquad 0 \leq t \leq T. \end{aligned} \tag{66}$$

Then,

$$\| u(t) \|_\alpha \leq \| u(0) \|_\alpha^{1-\rho_\sigma(t)} \| u(T) \|_\alpha^{\rho_\sigma(t)}, \qquad 0 \leq t \leq T, \tag{67}$$

and

$$\| u(t) \| \leq B_\alpha \, \| u(0) \|^{1-\rho_\sigma(t)} \| u(T) \|^{\rho_\sigma(t)}, \qquad 0 \leq t \leq T. \tag{68}$$

Proof. Note that λ in (66) satisfies $0 < \lambda < 1$ and may be found graphically given α and σ. Let $Y > 0$, let l be a linear functional on X with $|l|_\alpha = 1$, and let $h(\tau) = l(e^{-\tau A} u(0))$ for $\tau \in S(0,\alpha)$. As in Theorem 6, $h(\tau)$ is continuous and bounded on $S(0,\alpha)$ (resp., $S(Y,\alpha)$) and holomorphic in its interior, with $|h(\tau)| \leq \| u(0) \|_\alpha$, (resp., $|h(\tau)| \leq \| u(Y) \|_\alpha$). Let $0 < \sigma < \alpha$, let V be the vertical strip $0 \leq \mathrm{Re}\ \tau \leq Y$, and consider the function $\psi(\tau) = h(\tau^\sigma)$ for $\tau \in V$. We have that $\psi(\tau)$ is continuous and bounded on V, holomorphic in its interior, with $|\psi(\tau)| \leq \| u(0) \|_\alpha$. A more precise estimate for $|\psi(\tau)|$ on the line $\mathrm{Re}\ \tau = Y$ will now be obtained. We first show that with λ as in (66),

$$\mathrm{Re}\ \tau = Y \Longrightarrow \tau^\sigma \in S(\lambda Y^\sigma, \alpha). \tag{69}$$

Indeed, with $\tau = Y + is = re^{i\theta}$, $0 \leq |\theta| < \pi/2$, we have $\tau^\sigma = r^\sigma(\cos\sigma\theta + i \, \sin\sigma\theta)$, and $Y = r\cos\theta$. Therefore, $\tau^\sigma \in S(\lambda Y^\sigma, \alpha)$ if and only if

$$r^\sigma |\sin\sigma\theta| \leq \{r^\sigma \cos\sigma\theta - \lambda(r\cos\theta)^\sigma\} \tan(\alpha\pi/2), \qquad 0 \leq |\theta| < \pi/2, \tag{70}$$

i.e., if and only if $\forall\ 0 \leq \theta < \pi/2$, we have

$$\lambda \leq \cos\sigma\theta \, \{1 - \tan\sigma\theta / \tan(\alpha\pi/2)\} \, / (\cos\theta)^\sigma. \tag{71}$$

But this is guaranteed from the definition of λ. It follows that

$$|\psi(\tau)| \leq \| u(0) \|_\alpha, \quad \text{Re } \tau = 0, \qquad |\psi(\tau)| \leq \| u(\lambda Y^\sigma) \|_\alpha, \quad \text{Re } \tau = Y. \tag{72}$$

We may now apply the "three lines theorem," [27, p. 244], to $\psi(\tau)$ in the strip V and conclude that

$$|\psi(y)| \leq \| u(0) \|_\alpha^{1-y/Y} \| u(\lambda Y^\sigma) \|_\alpha^{y/Y}, \qquad 0 \leq y \leq Y. \tag{73}$$

Using (63), we obtain

$$\| u(y^\sigma) \|_\alpha \leq \| u(0) \|_\alpha^{1-y/Y} \| u(\lambda Y^\sigma) \|_\alpha^{y/Y}, \qquad 0 \leq y \leq Y. \tag{74}$$

Putting $t = y^\sigma,\ T = \lambda Y^\sigma,\ \rho_\sigma(t) = (\lambda t/T)^{1/\sigma}$ in (74) gives

$$\| u(t) \|_\alpha \leq \| u(0) \|_\alpha^{1-\rho_\sigma(t)} \| u(T) \|_\alpha^{\rho_\sigma(t)}, \qquad 0 \leq t \leq T/\lambda. \tag{75}$$

Since $T/\lambda > T$, (75) implies (67) which implies (68). □

Remark 3. When X is a Hilbert space, $\rho_\sigma(t)$ in (66) may be viewed as expressing the penalty for non-self-adjointness in the spatial operator A. When A is self-adjoint, we have $\rho(t) = t/T$. If the spectrum of A leaves the nonnegative real axis and expands into the sector $Arg\ |z| \leq \pi/2 - \phi$, $\rho_\sigma(t)$ decays to zero faster than t/T, through the exponent $1/\sigma$. It is remarkable that (66) actually holds in any complex Banach space X. The next theorem summarizes the main results of this section.

THEOREM 8 (corollary). *Let X be a complex Banach space with norm $\| \quad \|$. Let $-A$ generate a holomorphic semigroup $e^{-\tau A}$ on X, satisfying $\| e^{-\tau A} \| \leq B_\alpha < \infty$, in a closed sector $|Arg\ \tau| \leq \alpha\pi/2$ of the complex $\tau = t + is$ plane, for suitable α with $0 < \alpha < 1$. Let $\| \quad \|_\alpha$ be the equivalent norm on X defined in* (58), (59). *Let $0 < \sigma < \alpha$, and let λ and $\rho_\sigma(t)$ be as in* (66). *For given ϵ, M, with $\epsilon < M$, let $f \in X$ be given data at time $T > 0$, and let $u_i(t)$, $i = 1, 2$, be two solutions of $u_t = -Au + g(t)$, $0 < t \leq T$, with $\| u_i(T) - f \| \leq \epsilon/B_\alpha$, and $\| u_i(0) \| \leq M/B_\alpha$. Finally, let $w(t) = u_1(t) - u_2(t)$. Then*

$$\| w(t) \| \leq \| w(t) \|_\alpha \leq 2M^{1-\rho_\sigma(t)} \epsilon^{\rho_\sigma(t)}, \qquad 0 \leq t \leq T. \tag{76}$$

If, in addition, $\| u_i(s) - u_i(0) \| \leq K\epsilon/B_\alpha$, $i = 1, 2$, with known K, $0 < K < M/\epsilon$, and known $s > 0$ such that $\rho_\sigma(s) > \mu^*$, where μ^* is defined in (8), *then*

$$\| w(t) \| \leq \| w(t) \|_\alpha \leq 2\Gamma^{1-\rho_\sigma(t)} \epsilon, \qquad 0 \leq t \leq T, \tag{77}$$

where $\Gamma < M/\epsilon$ is the unique root of $x - K - x^{1-\rho_\sigma(s)} = 0$. Moreover, $\Gamma \ll M/\epsilon$ if $\rho_\sigma(s) \gg \mu^*$.

Proof. From (59), we have $\| w(0) \|_\alpha \leq 2M$, $\| w(T) \|_\alpha \leq 2\epsilon$. Hence, (76) follows from (67). Likewise, $\| w(s) - w(0) \|_\alpha \leq 2K\epsilon$. Applying Theorem 1 with the $\| \quad \|_\alpha$ norm on X, we obtain (77) from (67). □

8. An example. In the Navier–Stokes equations, where the Hölder exponent $\mu(t)$ in (41) depends on $1/\nu$, it is not known whether or not there can be equality in the Knops–Payne inequality (42). However, the following example demonstrates that rapid exponential decay in $\mu(t)$ can be realized in quite simple problems. With positive constants $a,\ c,\ Q$, consider the 1-D parabolic initial value problem in $L^2(0, \pi)$,

$$\begin{aligned} &u_t = ae^{ct} u_{xx}, \qquad 0 < x < \pi, \quad t > 0, \\ &u(0, t) = u(\pi, t) = 0, \qquad t \geq 0, \\ &u(x, 0) = Q \sin mx, \qquad 0 \leq x \leq \pi. \end{aligned} \tag{78}$$

The unique solution of (78) is

$$u(x,t) = Q\ e^{-am^2(e^{ct}-1)/c}\ \sin mx, \qquad t \geq 0. \tag{79}$$

Moreover, $u(x,t)$ satisfies

$$\| u(t) \| = \| u(0) \|^{1-\mu(t)} \| u(T) \|^{\mu(t)}, \qquad 0 \leq t \leq T, \tag{80}$$

where $\mu(t) = \{e^{ct}-1\}\{e^{cT}-1\}^{-1}$ and $\|\ \ \|$ is the norm on $L^2(0,\pi)$. This shows that Theorem 3 is sharp. By choosing $c > 0$ sufficiently large in (78), we can expect to simulate some of the difficulties that would attend backwards in time continuation in the Navier–Stokes equations.

Let $a = 2 \times 10^{-5}$, let $c = 10$, and, for any positive integer m, let

$$g_m(t) = e^{-am^2(e^{ct}-1)/c}, \qquad t \geq 0. \tag{81}$$

Let $p = \sqrt{2/\pi}$. With $M = 10$, and $\epsilon = 2 \times 10^{-7}$, consider the initial data

$$u(x,0) = p\sqrt{(1-\epsilon^2)/2}\ M \sin 2x + p \sum_{n=1}^{\infty} b_{2n+1} \sin(2n+1)x, \tag{82}$$

where

$$\sum_{n=1}^{\infty} b_{2n+1}^2 = \epsilon^2 M^2/2, \qquad \sum_{n=1}^{\infty} n^q b_{2n+1}^2 = \infty \qquad \forall\ q > 0. \tag{83}$$

Thus, $u(x,0)$ is an L^2 function on $(0,\pi)$ which is not in $H^q(0,\pi)$ for any $q > 0$, and $\| u(0) \| = M/\sqrt{2}$. We may think of the second term in (82) as representing highly localized, nondifferentiable singularities that are superimposed onto the first term. With these initial data in (78), the unique solution is

$$u(x,t) = p\sqrt{(1-\epsilon^2)/2}\ M g_2(t)\ \sin 2x + p \sum_{n=1}^{\infty} b_{2n+1}\ g_{2n+1}(t)\ \sin(2n+1)x. \tag{84}$$

Given an a priori L^2 bound for $u(x,t)$ at $t = 0$, consider recovering the solution (84) on $0 \leq t < 1$, from approximate data $f(x)$ at $t = 1$, with $\| u(1) - f \| \leq \epsilon$. Let

$$\| u(0) \| \leq M = 10 \tag{85}$$

be this prescribed bound, and let the data $f(x)$ at $t = 1$ be given by

$$f(x) = u(x,1) + p(M/\sqrt{2})\ g_{20}(1)\ \sin 20x. \tag{86}$$

Then

$$\begin{aligned} &\| u(1) - f \| = (M/\sqrt{2}) g_{20}(1) = 1.574 \times 10^{-7} < \epsilon, \\ &\| u(1) - f \| \ / \ \| u(1) \| < g_{20}(1)\{\sqrt{1-\epsilon^2}\ g_2(1)\}^{-1} = 2.66 \times 10^{-8}. \end{aligned} \tag{87}$$

Evidently, the given data $f(x)$ approximates $u(x,1)$ extremely closely in both absolute and relative terms. However, if $v(x,t)$ is the function

$$v(x,t) = u(x,t) + p(M/\sqrt{2})\ g_{20}(t)\ \sin 20x, \qquad 0 \leq t \leq 1, \tag{88}$$

then $v(x,1) = f(x)$, $v(x,t)$ is a solution, and, since $\| v(0) \| = M$, $v(x,t)$ is an equally valid continuation. Noteworthy is the substantial qualitative difference between $u(x,t)$ and $v(x,t)$, which emerges as early as $t = 1/2$, as continuation unfolds backwards from $t = 1$. While $g_2(1) = 0.8384$ and $g_{20}(1) = 2.226 \times 10^{-8}$, we find $g_2(1/2) = 0.9988$ and $g_{20}(1/2) = 0.8888$. Consequently, while the primary component in $u(x,t)$ is the large amplitude $\sin 2x$ oscillation for $0 \le t \le 1$, the $\sin 2x$ and $\sin 20x$ terms have approximately *equal* amplitudes in $v(x,t)$, for $0 \le t \le 1/2$. Clearly, Hölder-continuous data dependence is simply too weak to distinguish $u(x,t)$ from $v(x,t)$ in this example, even though $\| u(1/2) - v(1/2) \| = 6.285$ is roughly the same size as $\| u(0 \|$.

We shall show that an SECB constraint can easily distinguish between $u(x,t)$ and $v(x,t)$, although neither function is differentiable in x at $t = 0$. Indeed, with $K = 35$ and $s = 0.01$, we find

$$\begin{aligned} \| u(s) - u(0) \|^2 &= (1-\epsilon^2)(M^2/2)(1-g_2(s))^2 + \sum_{n=1}^{\infty} b_{2n+1}^2 \, (1 - g_{2n+1}(s))^2, \\ &\le (1-\epsilon^2)(M^2/2)(1-g_2(s))^2 + \epsilon^2 M^2/2, \\ &= (6.115 \times 10^{-6})^2 < K^2 \, \epsilon^2. \end{aligned} \tag{89}$$

On the other hand, with $s = 0.01$,

$$\begin{aligned} \| v(s) - v(0) \|^2 &= \| u(s) - u(0) \|^2 + (M^2/2)(1 - g_{20}(s))^2, \\ &> (M^2/2)(1 - g_{20}(s))^2 = (5.949 \times 10^{-4})^2, \\ &> (2974)^2 \, \epsilon^2. \end{aligned} \tag{90}$$

Therefore, the SECB constraint

$$\| u(0.01) - u(0) \| \le 35 \, \epsilon \tag{91}$$

eliminates $v(x,t)$ in (88) as a possible continuation, while allowing $u(x,t)$ in (84). Here, $\mu(s)/\mu^* = 121$, $\Gamma = 554,235$, and $M/\epsilon = 90\Gamma$. It follows from Theorem 1 and (80) that if $u_1(x,t)$ is any other continuation satisfying (91), then $\| u(t) - u_1(t) \| \le 2\Gamma^{1-\mu(t)}\epsilon$, $0 \le t \le 1$. Hence, $\| u(1/2) - u_1(1/2) \| \le 0.203$, and $\| u(0) - u_1(0) \| \le 0.222$. Since $\| u(1/2) \| > \{(1-\epsilon^2)/2\}^{1/2} \, M g_2(1/2) = 7.063$, and $\| u(0) \| = 7.071$, the maximum L^2 relative errors in approximating $u(x,t)$ at $t = 1/2$ and at $t = 0$, are, respectively, 2.87% and 3.14%. Without the SECB constraint (91), these relative errors are, respectively, 251% and 283%.

RIEMANN PROBLEMS WITH A KINK*

HELGE HOLDEN† AND NILS HENRIK RISEBRO‡

Abstract. We study the Riemann problem for isothermal flow of a gas in a thin pipe with a kink in it. This is modeled by a 2×2 system of conservation laws with Dirac measure sink term concentrated at the location of the bends in the pipe. We show that the Riemann problem for this system of equations always has a unique solution, given an extra condition relating the speeds on both sides of the kink. Furthermore, we study the related problem where the flow is perturbed by a continuous addition of momentum at distinct points. Under certain conditions we show that this Riemann problem also has a unique solution.

Key words. Riemann problem, isothermal gas dynamics, nonlinear resonance

0. Introduction. We consider the flow of an isothermal gas in a (infinitely) long, thin pipe of constant cross section. If the walls of the pipe have no effect on the flow, and the pipe is straight, this can be modeled by the system of conservation laws [15, p. 56]

$$\rho_t + (\rho v)_x = 0, \qquad (\rho v)_t + (\rho v^2 + \rho)_x = 0. \tag{0.1}$$

Here, $\rho(x,t)$ denotes the density of the gas, and $v(x,t)$ the velocity. The position along the pipe is described by the coordinate x, and t denotes the time variable. These equations describe the conservation of mass and momentum, respectively.

We here discuss the isothermal case rather than the more general case of polytropic gas modeled by replacing the second equation in (0.1) by $(\rho v)_t + (\rho v^2 + \kappa\rho^\gamma)_x = 0$. This equation yields more unwieldy calculations, and thus we focus on the isothermal case here.

In this paper we discuss the situation where the pipe is not straight but has one or several kinks in it. In between these kinks the pipe is straight. Hence the pipe can be described by a polygonal curve, and we ignore gravity. As in the model without kinks, we let $\rho(x,t)$ denote the density of the gas, and $v(x,t)$ its velocity. We now let x be the arc-length parameter along the pipe, or rather the curve describing the pipe. Away from the kinks, conservation of mass and momentum is given by (0.1). It remains to determine the equations holding at the kinks.

Since the cross section of the pipe is assumed to be constant on each side of a kink, conservation of mass reads, as before,

$$\rho_t + (\rho v)_x = 0. \tag{0.2}$$

In general, we cannot assume that ρ and v are continuous at the location of the kink. Since a kink is always located at the same x, which for simplicity we assume to be at

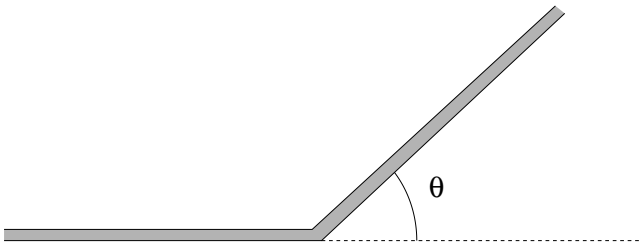

FIG. 1. *The kink.*

$x = 0$, discontinuities at kinks must satisfy a Rankine–Hugoniot condition where the speed of the discontinuity is zero. Hence, from (0.2) we obtain

$$0 = 0\,(\rho_l - \rho_r) = (\rho v)_l - (\rho v)_r,$$

where we have used the notation $f_{l,r} = \lim_{x \to 0^{\mp}} f(x)$. Therefore the product ρv is continuous across kinks. To derive the momentum balance, we again consider a kink located at $x = 0$; the angle of the kink is given by θ (see Figure 1). Since the velocity of the gas is assumed to be parallel to the pipe (except at the kinks), we have

$$\mathbf{v}_l = v_l(1, 0), \qquad \mathbf{v}_r = v_r(\cos\theta, \sin\theta).$$

Consequently, the change in momentum introduced by the kink is given by

$$\rho_r \mathbf{v}_r - \rho_l \mathbf{v}_l = \rho v(\cos\theta - 1, \sin\theta).$$

Therefore, the kink will act as a momentum sink, with a magnitude given by

$$|\rho_r \mathbf{v}_r - \rho_l \mathbf{v}_l| = \rho v \sqrt{2(1 - \cos\theta)}. \tag{0.3}$$

To compensate for the complicated and probably genuinely two-dimensional behavior at the kink, we introduce a multiplicative empirical factor $f \in [0, 1]$. This factor has dimension length(time)$^{-1}$ and is assumed to depend on the properties of the pipe and the gas. For simplicity, we will assume that the pipe is homogeneous, such that f is not dependent on location. Hence, we then arrive at the following model:

$$\begin{aligned} \rho_t + (\rho v)_x &= 0, \\ (\rho v)_t + \left(\rho v^2 + \rho\right)_x &= -f \sum_i k_i \delta_{x_i} \rho v, \end{aligned} \tag{0.4}$$

where δ_{x_i} is the Dirac measure located at the position x_i of the ith kink and k_i is given by the angle of this kink θ_i as

$$k_i = \sqrt{2\,(1 - \cos\theta_i)}.$$

In order to examine one simple consequence of the model (0.4), we imagine a closed piecewise linear pipe approximating a circle of radius r. Assume that we have n equally spaced kinks, each of an angle $\theta = 2\pi/n$. We are interested in what happens for large n; then

$$k_i = \sqrt{2(1 - \cos\,(2\pi/n))} \approx \frac{2\pi}{n}.$$

Also, the distance between adjacent kinks $\Delta x = x_i - x_{i-1} \approx r2\pi/n$. Therefore

$$\sum_i^n \rho v k_i \delta_{x_i} \approx \sum_i^n \rho v \frac{\Delta x}{r} \rightharpoonup \frac{\rho(x,t)v(x,t)}{r},$$

where $\rightharpoonup$ denotes weak convergence. Hence, for a smooth pipe, conservation of momentum is expressed by

$$(\rho v)_t + \left(\rho v^2 + \rho\right)_x = -\rho v f \kappa(x), \tag{0.5}$$

with $\kappa(x)$ denoting the curvature of the pipe at x and $f(x)$ the local empirical bending factor at x.

In our model (0.4) $k_i \in \langle 0, 2\rangle$. Mathematically, however, one can study the model for any value of k_i. For k_i nonnegative we find that (0.4) has a unique solution if k_i is less than 4. In our discussion we are mostly concerned with $k_i = \sqrt{2\,(1-\cos\theta_i)}$.

When one continuously *adds* momentum to the gas at distinct points x_i, we obtain the model (0.4) with k_i negative. The quantity $|fk_i|$ is proportional to the added momentum. For $k_i \geq 2(1-\sqrt{2})$ the equation has a unique solution with the appropriate entropy condition. This case is studied *mutatis mutandis* in section 3.

The model (0.4) also arises as a model for the boundary behavior in an important two-dimensional system of conservation laws. Consider the two-dimensional version of (0.1),

$$\begin{aligned} \rho_t + (\rho v)_x + (\rho u)_y &= 0, \\ (\rho v)_t + \left(\rho v^2 + \rho\right)_x + (\rho v u)_y &= 0, \\ (\rho u)_t + (\rho v u)_x + \left(\rho u^2 + \rho\right)_y &= 0. \end{aligned} \tag{0.6}$$

Here, v and u denote the velocity in the x and y direction, respectively. Let $p(x)$ denote the function

$$p(x) = \begin{cases} 0 & \text{for } x < 0, \\ x\tan\theta & \text{for } x \geq 0, \end{cases}$$

and let Ω denote the set

$$\{(x,y) \mid y > p(x)\}.$$

Then consider (0.6) in Ω with the boundary condition that the velocity is parallel to $\partial\Omega$ at $\partial\Omega$. This system models the isothermal flow across a ramp in two dimensions. If one imposes the initial condition

$$(\rho, u, v)(x,0) = \begin{cases} (\rho_l, u_l, v_l) & \text{for } x < 0, \\ (\rho_r, u_r, v_r) & \text{for } x \geq 0, \end{cases}$$

the solution along the boundary will be given by the solution of the Riemann problem considered here, (1.10). As an application, one could envision using the solution computed in this paper as input at the boundary in a numerical scheme for solving (0.6).

The model (0.5) is an example of a system of conservation laws with source, sometimes referred to as balance equations. The general form of such equations is

$$w_t + f(w)_x = g(x,w), \tag{0.7}$$

where $w = w(x,t)$ is in $\mathbb{R}^n$, and consequently f is a mapping $\mathbb{R}^n \to \mathbb{R}^n$ and g is a mapping $\mathbb{R} \times \mathbb{R}^n \to \mathbb{R}^n$. Balance equations of this form are used to model a variety of situations. One system of equations, which is somewhat related to the model presented here, is a quasi-one-dimensional model for gas flow in a variable area duct. This model reads

$$\begin{aligned} \rho_t + (\rho v)_x &= -\frac{a'(x)}{a(x)}\rho v, \\ (\rho v)_t + \left(\rho v^2 + p(v)\right)_x &= -\frac{a'(x)}{a(x)}\rho v^2, \\ (\rho E)_t + (\rho E v + p(v)v)_x &= -\frac{a'(x)}{a(x)}\left(\rho E v + p(v)v\right), \end{aligned} \tag{0.8}$$

where ρ and v are as before, and $p(v)$ denotes the pressure and E the total energy of the gas. The cross sectional area of the duct is denoted by $a(x)$. This model (0.8) has been analyzed by Liu in [4, 5, 7, 8]. A scalar version was analyzed by Greenberg et al. [3]. A discussion of multiple steady states in the context of one-dimensional transonic flow can be found in [1]. If the source term g is smooth and bounded, and if the eigenvalues of the Jacobian df are real, distinct, and different from zero, existence of a global (in t) solution was obtained in [4] by a generalization of Glimm's method, and uniqueness and stability were proved by Crasta and Piccoli [6] in the 2×2 case. A numerical method for such systems was analyzed by Glaister [2]. If, however, the eigenvalues may take the value zero, (0.7) is a so-called resonant hyperbolic system. This is the case for the system (0.8), as well as for the system discussed in this paper. Chen and Glimm [11] proved existence of global solutions of the system consisting of the first two equations in (0.8) with a smoothly varying cross section.

The wave structure for resonant hyperbolic systems may be surprisingly complicated; see Isaacson and Temple [12], as well as the above-mentioned works by Liu.

If the cross sectional area of the duct in (0.8) is piecewise constant, the source term becomes a point source similar to the source in (0.4). The Riemann problem for (0.8) with a piecewise constant a was analyzed by Marchesin and Paes-Leme in [9].

In addition, we mention that systems of equations exhibiting nonlinear resonance also occur in models of two- and three-phase flow in porous media; see [10] and [13].

1. The Riemann problem. We consider the following system of equations:

$$\begin{aligned} \rho_t + (\rho v)_x &= 0, \\ (\rho v)_t + \left(\rho v^2 + \rho\right)_x &= -\sum_i f_i k_i \delta_{x_i} \rho v, \\ \rho(x,0) = \rho_0(x), &\qquad v(x,0) = v_0(x), \end{aligned} \tag{1.1}$$

where the unknowns ρ and v are functions of x and t. The effects of the bends in the pipe are expressed by the term $k_i \delta_{x_i} \rho v$, where δ_{x_i} denotes the unit point mass located at x_i and k_i is given by

$$k_i = k(\theta_i) = \sqrt{2\left(1 - \cos\left(\theta_i\right)\right)}\,, \tag{1.2}$$

where θ_i is the angle of the bend located at x_i. Even in the absence of source terms, (1.1) generally develops discontinuities, so we seek weak solutions. By definition these

satisfy

(1.3)
$$\iint \rho\varphi_t + \rho v\varphi_x \, dxdt + \int \rho_0(x)\varphi(x,0)\, dx = 0,$$
$$\iint \rho v\varphi_t + \left(\rho v^2 + \rho\right)\varphi_x \, dxdt + \int \rho_0(x)v_0(x)\varphi(x,0)\, dx = \int \sum_i f_i k_i \varphi\left(x_i,t\right)\rho\left(x_i,t\right)v\left(x_i,t\right)\, dt.$$

If there are no source terms, (1.1) is a strictly hyperbolic conservation law, with eigenvalues

$$\lambda_1 = v - 1 \text{ and } \lambda_2 = v + 1. \tag{1.4}$$

The corresponding eigenvectors are

$$e_1 = (1, v-1) \text{ and } e_2 = (1, v+1). \tag{1.5}$$

When solving the Riemann problem we are interested in those states (ρ, v) that can be joined to a given state (ρ_0, v_0) by a simple wave, i.e., either a shock wave or a rarefaction wave. The shock waves satisfy the Lax entropy condition. For a definition of these concepts, see [14, 15]. Through each (ρ_0, v_0) there are two curves, $C_1(\rho_0, v_0)$ and $C_2(\rho_0, v_0)$, of such states. If (ρ, v) is on $C_1(\rho_0, v_0)$, then the initial value problem

$$\begin{gathered} \rho_t + (\rho v)_x = 0, \\ (\rho v)_t + \left(\rho v^2 + \rho\right)_x = 0, \\ \rho(x,0) = \begin{cases} \rho_0 & \text{for } x < 0, \\ \rho & \text{for } x > 0, \end{cases} \qquad v(x,0) = \begin{cases} v_0 & \text{for } x < 0, \\ v & \text{for } x > 0 \end{cases} \end{gathered} \tag{1.6}$$

is solved by a slow wave (also denoted as a one-wave). This wave is a (one-)shock wave if $\rho > \rho_0$ and a (one-)rarefaction wave if $\rho < \rho_0$. The curve C_1 is given by the following expression [15, pp. 71ff and p. 84f]:

$$C_1 \;:\; v_1(\rho; \rho_0, v_0) = \begin{cases} v_0 - \ln\left(\frac{\rho}{\rho_0}\right) & \text{for } \rho < \rho_0, \\ v_0 - \frac{\rho - \rho_0}{\sqrt{\rho\rho_0}} & \text{for } \rho > \rho_0. \end{cases} \tag{1.7}$$

Similarly, if (ρ, v) is on $C_2(\rho_0, v_0)$, then the initial value problem (1.6) is solved by either a two-shock wave or a two-rarefaction wave. The curve C_2 is given by [15, pp. 71ff and p. 84f]

$$C_2 \;:\; v_2(\rho; \rho_0, v_0) = \begin{cases} v_0 + \frac{\rho - \rho_0}{\sqrt{\rho\rho_0}} & \text{for } \rho < \rho_0, \\ v_0 + \ln\left(\frac{\rho}{\rho_0}\right) & \text{for } \rho > \rho_0, \end{cases} \tag{1.8}$$

with two-shock waves corresponding to $\rho < \rho_0$ and two-rarefaction waves corresponding to $\rho > \rho_0$. Whenever convenient we will denote the shock and rarefaction part of C_i by S_i and R_i, respectively. Furthermore, when we consider the *right state* R as fixed, we denote the corresponding wave curves by C_i^-, etc. Note that C_1

is given by a decreasing convex function of $v_1(\rho)$, such that $\lim_{\rho\to 0+} v_1 = \infty$ and $\lim_{\rho\to\infty} v_1 = -\infty$, and that C_2 is given by an increasing concave function $v_2(\rho)$, such that $\lim_{\rho\to 0+} v_2 = -\infty$ and $\lim_{\rho\to\infty} v_2 = -\infty$. If the source terms in (1.1) are absent, the unique solution of the Riemann problem is ensured.

The speed of shock waves is given by the Rankine–Hugoniot condition and may be computed from the first equation in (1.1):

$$s_j = \frac{\rho v_j - \rho_0 v_0}{\rho - \rho_0} = v_0 + (-1)^j \sqrt{\frac{\rho}{\rho_0}} = v_j + (-1)^j \sqrt{\frac{\rho_0}{\rho}}. \tag{1.9}$$

Note that both shock speeds and the speed of rarefaction waves can be both positive and negative. In our construction of the solution of the Riemann problem we will need certain points on the shock curves. If (ρ, v) is a given state, we denote the point on the shock curve that can be connected with a shock of zero speed by $Z(\rho, v)$. From expressions (1.7)–(1.9) we find that

$$Z(\rho, v) = \left(\rho v^2, \frac{1}{v}\right);$$

for one-shocks it is defined for $v \geq 1$, while for two-shocks it is defined for $v \in [-1, 0\rangle$. Furthermore, we will need the intersection of $C_1(L)$ and the line $v = -1$, and we denote by $\widehat{L}$ the unique point in $C_1(L) \cap \{v = -1\}$. In addition, we let $\widetilde{L}$ denote the unique intersection of $C_1(L)$ and the line $v = v_c^-$ (see (2.4)).

The Riemann problem for (1.1) is the initial value problem

$$\begin{gathered} \rho_t + (\rho v)_x = 0, \\ (\rho v)_t + \left(\rho v^2 + \rho\right)_x = -k\delta_0 \rho v, \\ \rho(x,0) = \begin{cases} \rho_L & \text{for } x < 0, \\ \rho_R & \text{for } x > 0, \end{cases} \qquad v(x,0) = \begin{cases} v_L & \text{for } x < 0, \\ v_R & \text{for } x > 0, \end{cases} \end{gathered} \tag{1.10}$$

where we have absorbed the empirical factor f in the geometric factor k. We study two distinct but related cases; k positive (where $\theta = \arccos(1-k^2/2)$ denotes the angle of the kink) and k negative. In both cases, $|k| \leq 2$. We seek self-similar solutions to (1.10); that is, $\rho = \rho\,(x/t)$ and $v = v\,(x/t)$. Away from the point $x = 0$, we can use the curves C_1 and C_2 to connect states (ρ, v). We label such connections C-waves. At the point $x = 0$, we will in general have a discontinuity. This discontinuity will satisfy the Rankine–Hugoniot conditions

$$[\![\rho v]\!] = 0, \qquad [\![\rho v^2 + \rho]\!] = -k\rho v, \tag{1.11}$$

where by $[\![\phi]\!]$ we denote the jump in ϕ, i.e., $[\![\phi]\!] = \phi_r - \phi_l$. (Recall that the momentum ρv is continuous across the kink.) Given (ρ_l, v_l), the last equation in (1.11) can be solved for v_r, giving

$$v_r := g_\pm\,(v_l) := \frac{1}{2v_l}\left(\alpha\,(v_l) \pm \sqrt{\alpha^2\,(v_l) - 4v_l^2}\right), \tag{1.12}$$

where

$$\alpha(v) = v^2 - kv + 1. \tag{1.13}$$

We can now use the first equation in (1.11) to calculate ρ_r,

$$\rho_r := \rho_l f_\pm(v_l) := \rho_l \frac{v_l}{g_\pm(v_l)}. \tag{1.14}$$

For any point (ρ_l, v_l) we therefore have two candidates for (ρ_r, v_r). In order to choose between these we impose the extra condition

$$\frac{dv_r}{dv_l} \geq 0; \tag{1.15}$$

an increase in velocity of the gas coming into the kink should result in an increase in outgoing velocity. We will use the same criterion for k negative. The choice (1.15) selects a branch of $g_\pm$ and hence of $f_\pm$. The remaining discussion will depend on the properties of this function determined by the sign of k.

2. The Riemann problem for flow through a kink. We will need detailed properties of the function $g_\pm$ which satisfies

$$vg^2 - \alpha(v)g + v = 0, \quad g = g_\pm, \tag{2.1}$$

and this implies that the solution satisfies

$$v = -g(-g(v)). \tag{2.2}$$

The two solutions fulfill

$$g_\pm(v) = g_\pm(1/v), \quad g_+(v)g_-(v) = 1. \tag{2.3}$$

Define

$$v_c^+ = -g_+(-1), \quad v_c^- = -g_-(-1). \tag{2.4}$$

We have that $v_c^- \leq 1 \leq v_c^+$, equality holding only if $k = 0$. The symmetry (2.2) implies that $g_\pm(v_c^\pm) = 1$. Furthermore,

$$\begin{aligned} &g'_+(v) \geq 0 \quad \text{for } v \leq -1 \text{ and for } v \geq v_c^+, \\ &g'_-(v) \geq 0 \quad \text{for } v \in \left[-1, v_c^-\right]. \end{aligned}$$

In Figure 2 below we show $g_\pm$ and $f_\pm$ for $k = 0.5$.

This means that for $v_l \in \langle -\infty, -1] \cup [v_c^+, \infty\rangle$, we choose the plus sign in (1.12) and (1.14), while for $v \in [-1, v_c^-]$, we choose the minus sign. There are no solutions in the region $\langle v_c^-, v_c^+\rangle$. In the figure this choice is indicated by solid lines. Therefore let the mapping K be given by

$$K(\rho, v) = \begin{cases} (\rho f_+(v), g_+(v)) & \text{for } v \leq -1 \text{ and for } v \geq v_c^+, \\ (\rho f_-(v), g_-(v)) & \text{for } v \in [-1, v_c^-]. \end{cases} \tag{2.5}$$

In the following we use the term "K-wave," meaning the mapping K. An important property of the K mapping is that it commutes with the stationary shocks.

LEMMA 2.1. *The K mapping commutes with Z, i.e., $Z(K(\rho, v)) = K(Z(\rho, v))$ whenever the two mappings are defined.*

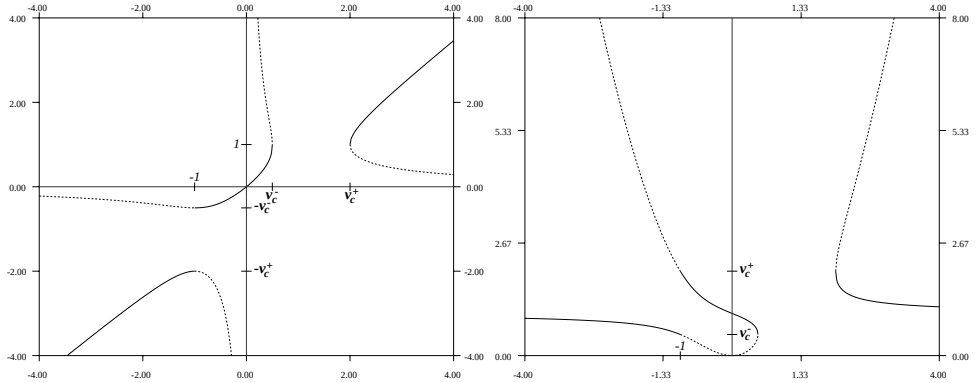

FIG. 2. *The functions $g_\pm$ (left) and $f_\pm$ (right) for $k = 0.5$.*

Proof. Let (ρ, v) be a point with $v \geq v_c^+$. We then compute

$$\begin{aligned} Z\left(K\left(\rho,v\right)\right) &= Z\left(\rho v g_+\left(v\right), g_-\left(v\right)\right) \\ &= \left(\rho v g_+\left(v\right) g_-^2\left(v\right), \frac{1}{g_-\left(v\right)}\right) \\ &= \left(\rho v g_-\left(v\right), g_+\left(v\right)\right) \end{aligned}$$

and

$$\begin{aligned} K\left(Z\left(\rho,v\right)\right) &= K\left(\rho v^2, \frac{1}{v}\right) \\ &= \left(\rho v^2 \frac{1}{v} g_-\left(\frac{1}{v}\right), g_+\left(\frac{1}{v}\right)\right) \\ &= \left(\rho v g_-\left(v\right), g_+\left(v\right)\right) \\ &= Z\left(K\left(\rho,v\right)\right). \end{aligned}$$

The case for fast waves is similar. ∎

So when solving the Riemann problem we have three waves at our disposal: C_1-waves, C_2-waves, and K-waves. The K-waves always have zero speed, and the C-waves can have both positive and negative speed. The solution has to contain a K-wave to bring us from one part of the pipe to the other. This means that a priori the solution may consist of up to five different waves: $C_1C_2KC_1C_2$. However, the following lemma limits this to four.

LEMMA 2.2. *The wave configuration $\ldots C_2KC_1 \ldots$ is impossible.*

Proof. The smallest speed of the right edge of any C_2-wave with a right state (ρ_l, v_l) is $v_l + 1$, and the largest speed of the left edge of a C_1-wave with a left state (ρ_r, v_r) is $v_l - 1$. Therefore we have the inequalities

$$v_l + 1 \leq 0 \leq v_r - 1,$$

which means that $v_l \leq -1$ and $v_r \geq 1$. Since ρv is constant across K-waves, there can be no K-wave connecting (ρ_l, v_l) and (ρ_r, v_r). ∎

Consequently, we are left with the four possible wave configurations to solve the Riemann problem:

$$C_1KC_1C_2, \;\; C_1KC_2, \; C_1C_2KC_2, \text{ and } KC_1C_2.$$

When solving the Riemann problem, we use the strategy that for each fixed left state $L = (\rho_L, v_L)$ we construct waves with increasing speed until we reach the right state R. In this way we partition the (ρ, v) plane into regions such that for each $R = (\rho_R, v_R)$ in a region, the wave structure of the solution is constant. Hence, we may have a $C_1C_2KC_2$ region, a C_1KC_2 region, etc. States to the left of the K-wave are denoted by l and states to the right are denoted by r.

It turns out that there are two cases: $v_L > v_c^+$ and $v_L \leq v_c^+$.

Case 1. $v_L > v_c^+$. Consider first a right state R near L. The waves in a neighborhood of L all have positive speed, and hence we have to start with a K-wave. Let $r_1 = (\rho_{r_1}, v_{r_1}) = K(L)$. Then $v_{r_1} \in [1, v_L]$. We now construct wave curves $C_1(r_1)$ and $C_2(r_1)$. For $r_2 \in R_1(r_1)$ wave speeds are all positive, and we may continue with a fast wave $C_2(r_2)$ to reach a right state R, viz. $R \in C_2(r_2)$. If, however, $r_2 \in C_1(r_1)$, the shock speed is positive only down to the point $Z(r_1)$, which by Lemma 2.1 equals $K(Z(L))$. Thus for each $r_2 = (\rho_{r_2}, v_{r_2})$ with $v_{r_2} \in [1/v_{r_1}, v_{r_1}]$, we may continue with a fast wave to a right state $R \in C_2(r_2)$. In this way we fill the region denoted by KC_1C_2 above the curve $C_2(K(Z(L)))$. To prove uniqueness, consider a right state R in this region. The Riemann problem with left state $K(L)$ and right state R has a unique solution by standard techniques, and hence the only alternative would be to start from the right with a K-wave to the state $K^{-1}(R)$, which, however, is in the region with only waves with positive speed and hence is impossible.

Consider now a point l_1 on $S_1(L)$ between $Z(L)$ and $\widehat{L}$. L connects to l_1 with a slow shock with negative speed. For each such state l_1, we may continue with a K-wave to a state $r_1 = K(l_1)$. At the state $\widehat{L}$ the K-map ceases to be continuous, and the wave structure will be different. Fast rarefaction waves from r_2 will all have positive speed and may be used in the construction to reach a right state $R \in R_2(r_2)$. For fast shock waves emanating from r_1 with positive v_{r_1}, the shock speed remains positive (the Z map is not defined), and hence R may be any point on $S_2(r_1)$. If, however, r_1 is between $v = 0$ and $v = -v_c^-$, the shocks on $C_2(r_1)$ have positive speed down to $Z(r_1)$, and only states R above this point can be reached with this wave structure. Let c denote the part of $S_1(L)$ between $v = 0$ and $v = -v_c^-$, and let $\kappa = K(c)$, and finally $\zeta = Z(K(c))$. We then find that the solution reads C_1KC_2 in the region bounded from above by $C_2(K(Z(L)))$ and bounded from below by ζ and $C_2(K(\widehat{L}))$, the two latter curves starting from $Z(K(\widehat{L}))$. To prove uniqueness we first define $\tilde{c}$ as the part of $C_1(L)$ between $Z(L)$ and $\widehat{L}$, and subsequently $\tilde{\kappa} = Z(\tilde{c})$. First we have to prove that the curve $\tilde{\kappa}$ is transversal to C_2 curves starting from $\tilde{\kappa}$. This is the content of Lemma A.1 in the appendix. Furthermore, let R be above ζ. The only alternative to the given solution would be to connect the states $K^{-1}(R)$ and R instead of using a fast shock. As K^{-1} is monotone in the v variable, $K^{-1}(R)$ will be above $K^{-1}(\zeta) = Z(c)$. But then the state $K^{-1}(R)$ can be reached only with shocks with positive speed, making it impossible to end with a K-wave.

Consider now a right state R in the region denoted C_1C_2K, i.e., below the curves ζ and $v = -v_c^+$. Let $l_2 = K^{-1}(R)$. Then $v_{l_2} \leq -1$. The curves $C_2^-(l_2)$ and $S_1(L)$ intersect uniquely at a point l_1. If l_2 (yes, l_2) is below $S_1(L)$, the states l_1 and l_2 will connect using a rarefaction wave with negative speed, as $v_{l_2} \leq -1$. If, on the other hand, l_2 is below $S_1(L)$, we will use a fast shock wave to connect l_1 with l_2. As R is below ζ and the map K^{-1} is monotone in the v variable, $l_2 = K^{-1}(R)$ also will be below $K^{-1}(\zeta) = Z(c)$ using Lemma 2.1, and the shock will have negative speed as required. In this way we solve the Riemann problem in the region C_1C_2K.

Finally, the region $C_1C_2KC_2$ is bounded from above by the curve $C_2(K(\widehat{L}))$ and

by the line $v = -v_c^+$ from below, both curves emanating from $Z(K(\widehat{L}))$. Let R be in this region. Assume R is such that $v_R \geq -v_c^-$. Then we let $r = (\rho_r, -v_c^-)$ be the unique point such that $R \in R_2(r)$, and subsequently $l_2 = K^{-1}(r) = (\rho_{l_2}, -1)$. There is a unique state l_1 on $S_1(L)$ such that $l_2 \in R_2(l_1)$. Thus the solution consists of the following waves: The left state L is connected to state l_1 using a slow shock wave (with negative speed), followed by a fast rarefaction wave (with nonpositive speed) up to the state l_2 on the line $v = -1$. This state is connected with a K-wave to the state r. Finally, we use a fast wave to connect to R. If R has v_R less than $-v_c^-$, we start by using a fast shock with positive speed from $r = (\rho_r, -v_c^-)$ down to R, i.e., $R \in S_2(r)$. The remaining part of the solution is the same. For the uniqueness question, consider first the case with $v_R > -v_c^-$. Any waves connecting to $K^{-1}(R)$ would have positive speed, which would make it impossible to connect $K^{-1}(R)$ and R with a stationary K-wave. If v_R is between $-v_c^+$ and $-v_c^-$, we cannot apply $K^{-1}(R)$, and all fast waves have negative speed in that region, making it impossible to construct a different solution.

Case 2. $v_L \leq v_c^+$. If $v_L \leq v_c^+$, we can connect to the state $l_1 = \widetilde{L}$ on the intersection $C_1(L) \cap \{v = v_c^-\}$ with a wave of nonpositive speed. (If $v_L < v_c^-$ the wave is a rarefaction wave, and if $v_L > v_c^-$ it will be a shock wave.) l_1 can be connected to the state $r_1 = K(l_1)$ with a K-wave. The slow rarefaction wave starting from r_1 will have nonnegative speed, and hence we may use fast waves from any point $r_2 \in R_1(r_1)$ to reach a right state $R \in C_2(r_2)$. In this way we fill the region above the curve $C_2(K(\widetilde{L}))$ with a solution of the form $C_1KC_1C_2$. The remaining part of the construction is similar to that of Case 1.

The curves separating the various regions are illustrated in Figures 3 (Case 1) and 4 (Case 2). An illustration of solution curves in all cases is given in Figure 5: the left column for Case 1 and the right column for Case 2.

Hence we have proven the following result.

THEOREM 2.3. *Let $0 \leq k < 2$. Then the Riemann problem*

$$\begin{gathered} \rho_t + (\rho v)_x = 0, \\ (\rho v)_t + \left(\rho v^2 + \rho\right)_x = -k\delta_0 \rho v, \\ \rho(x,0) = \begin{cases} \rho_L & \text{for } x < 0, \\ \rho_R & \text{for } x > 0, \end{cases} \qquad v(x,0) = \begin{cases} v_L & \text{for } x < 0, \\ v_R & \text{for } x > 0 \end{cases} \end{gathered} \tag{2.6}$$

has a unique solution in the class of combinations of Lax shocks, rarefaction waves, and K-waves for any left state (ρ_L, v_L) and right state (ρ_R, v_R) with positive densities ρ_L and ρ_R given by the above construction.

3. The Riemann problem for addition of momentum. The general structure of the argument is identical to that used in the case with k positive. However, the properties of the function $g_\pm$ and $f_\pm$ are different in the two cases (cf. Figure 2 and Figure 6), and a separate discussion is required. To keep the presentation short, we give the details only where they are different from those of the previous section. Define

$$v_c^\pm = g_\pm(1), \quad v_c^- \leq 1 \leq v_c^+.$$

The symmetry properties of $g_\pm$ imply that $g_\pm(-v_c^\pm) = -1$. Furthermore, we have that

$$\frac{dg_+(v)}{dv} \geq 0 \text{ for } v \in \langle -\infty, -v_c^+] \cup [1, \infty \rangle$$

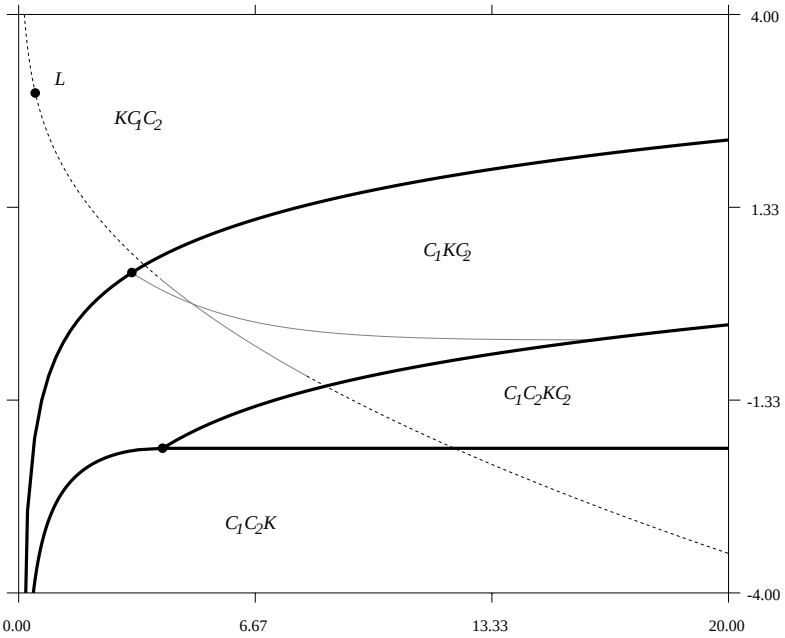

FIG. 3. *The solution to the Riemann problem where* $v_L \geq v_c^+$.

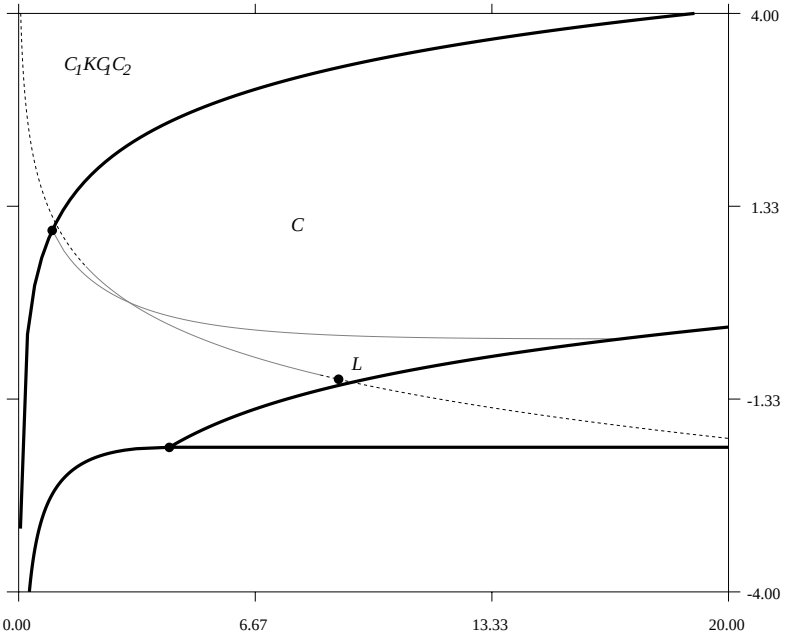

FIG. 4. *The solution to the Riemann problem where* $v_L \leq v_c^+$.

and

$$\frac{dg_-(v)}{dv} \geq 0 \text{ for } v \in [-v_c^+, 1],$$

and hence the K-wave reads

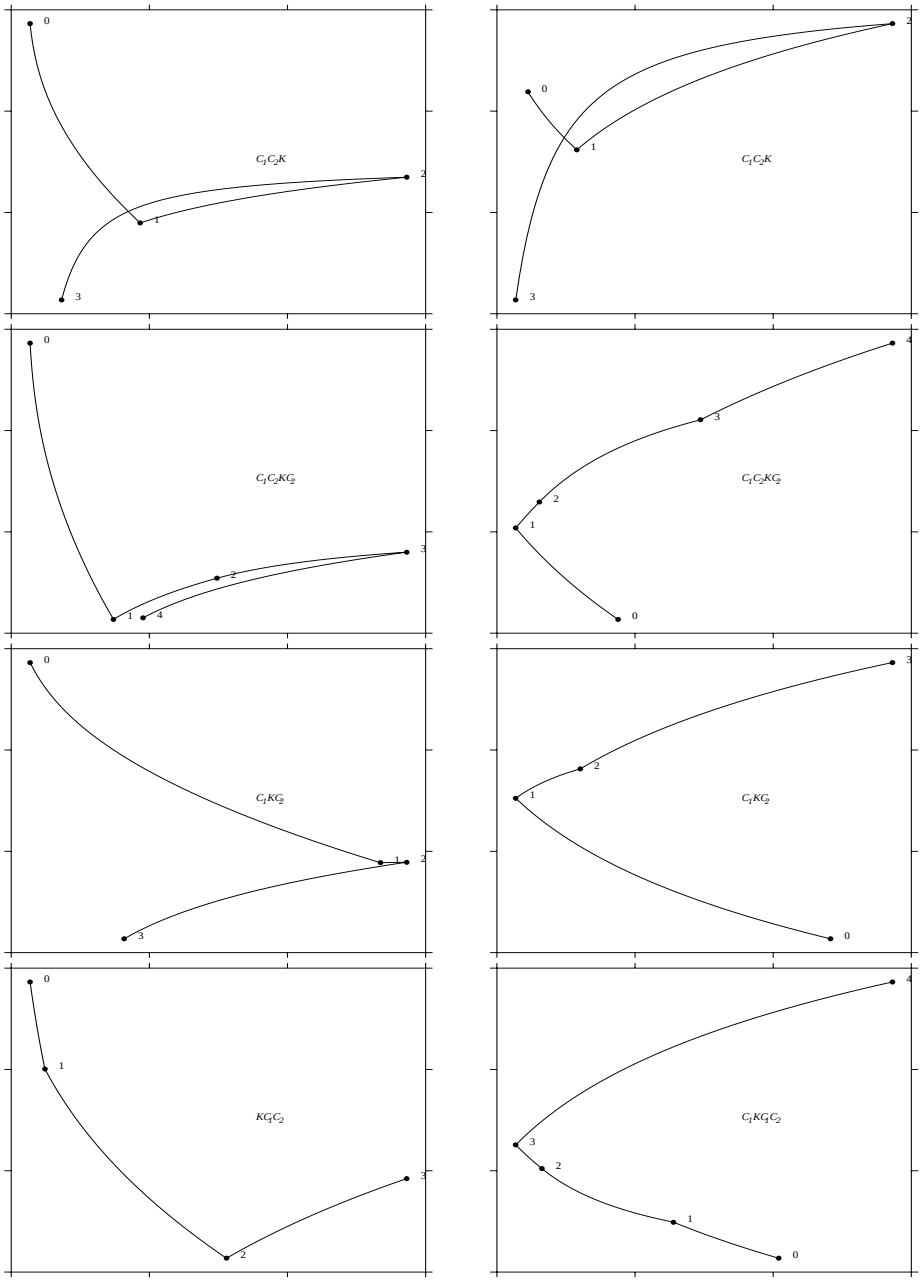

FIG. 5. *The solution in phase space in all subcases: $v_L \geq v_c^+$ right, $v_L \leq v_c^+$ left.*

$$K(\rho, v) = \begin{cases} (\rho f_+(v), g_+(v)) & \text{for } v \leq -v_c^+ \text{ and for } v \geq 1, \\ (\rho f_-(v), g_-(v)) & \text{for } v \in [-v_c^-, 1]. \end{cases} \tag{3.1}$$

The Z map (defined as before) and the K-map still commute, i.e., Lemma 2.1 remains valid. As designated points on the slow wave curve, it is convenient to define $\widehat{L}$ as the unique intersection of $C_1(L)$ and $\{v = -v_c^-\}$, and $\widetilde{L}$ as the unique intersection

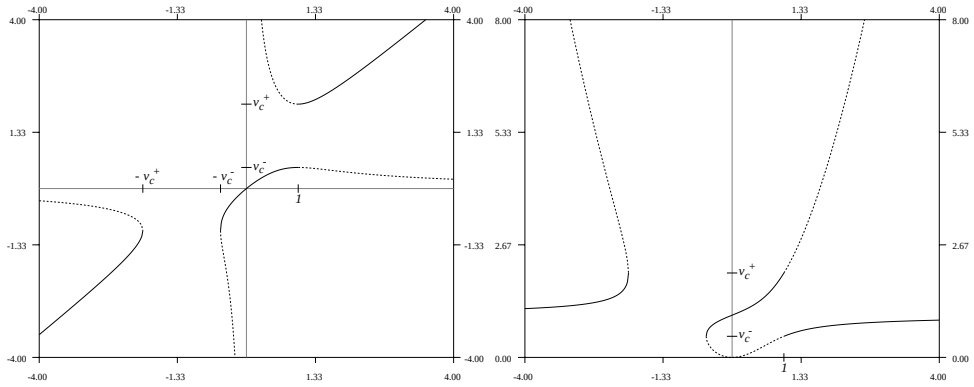

FIG. 6. *The functions* $g_\pm$ (*left*) *and* $f_\pm$ (*right*) *for* $k = -.5$.

between $C_1(L)$ and $\{v = 1\}$.

The general strategy for the construction of the solution of the Riemann problem is independent of the sign of k. Lemma 2.2 still reduces the number of possible wave combinations to four. As in the previous case, the analysis requires two distinct subcases; $v_L > 1$ and $v_L \leq 1$.

Case 1. $v_L > 1$. Waves in the neighborhood of L all have positive speed and we start with a K-wave to the state $r_1 = K(L)$. From the state r_1 we construct fast wave curves $C_1(r_1)$ and $C_2(r_1)$, which are all permissible except states on the slow shock below $Z(r_1) = K(Z(L))$. This results in a wave structure of the solution given by KC_1C_2 above the curve $C_2(K(Z(L)))$.

Now let l_1 be a state on $S_1(L)$ between $Z(L)$ and $\widehat{L}$. The left state L connects to l_1 with a shock with negative speed. We now employ the K-map to a state $r_1 = K(l_1)$. Fast rarefaction waves emanating from r_1 all have positive speed and can be used if the right state $R \in R_2(r_1)$. If v_{r_1} is positive, fast shocks on $S_2(r_1)$ will always have positive speed, while if $v_{r_1} \geq -1$ but negative, then the fast shocks will have positive speed only down to $Z(r_1)$. As before let c denote the part of $S_1(L)$ between $v = 0$ and $v = -v_c^-$, and $\kappa = K(c)$ and $\zeta = Z(\kappa)$. Then we obtain a solution with structure C_1KC_2 in the region bounded from above by $C_2(K(Z(L)))$ and below by ζ and $C_2(K(\widehat{L}))$ (starting from $Z(K(\widehat{L}))$). The question of uniqueness is more difficult in this case as we see that the curve $\tilde{\kappa} = K(\tilde{c})$, where $\tilde{c}$ is the part of $C_1(L)$ between $Z(L)$ and $\widehat{L}$, is in fact tangent to the curve $C_2(K(\widehat{L}))$. A proof that $\tilde{\kappa}$ is transversal to C_2 curves originating from $\tilde{\kappa}$ (except at $K(\widehat{L})$) is given in the appendix under the assumption that $k > 2(1 - \sqrt{2})$.

The construction of a solution with right state R in the region below ζ and $v = -1$ is similar to that in the case k positive.

Finally, let R be in the region bounded from above by $R_2(K(\widehat{L}))$ and from below by $v = -1$. Then there is a unique state r on $v = -1$ such that $R \in R_2(r)$, hence using only positive speeds. We have that r can be connected with K-wave from a state l_2 with $v_{l_2} = -v_c^+$. For each such state there is a unique state l_1 on $C_1(L)$ such that $l_2 \in C_2(l_1)$. This concludes the discussion of Case 1.

Case 2. $v_L \leq 1$. Because $v_L \leq 1$ we can use a one-rarefaction wave with non positive speed to reach the state $\widetilde{L}$ on the intersection of $C_1(L)$ and $v = 1$. When $v = 1$ we have two options for the map K, and denote $K^\pm(\rho, 1) = (\rho v_c^\mp, v_c^\pm)$. (For

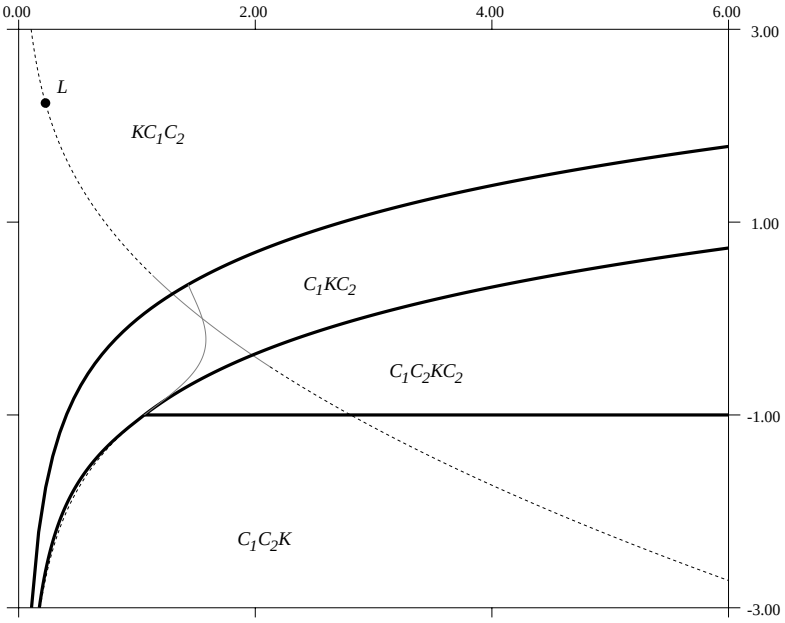

FIG. 7. *The solution of the Riemann problem for* $v_L > 1$.

the curve $\tilde{\kappa}$ we used the map K^-.) From the state $\widetilde{L}$ we use the K^+-map to the state $r_1 = K^+(\widetilde{L})$. We can now employ both slow and fast waves using $C_1(r_1)$ and $C_2(r_1)$. However, as in the case with k positive, we can use slow shocks only down to the point $Z(K^+(\widetilde{L}))$ which is equal to $K^-(\widetilde{L})$. Hence we obtain a solution structure of the form $C_1KC_1C_2$ in the region above $C_2(K^-(\widetilde{L}))$.

The remaining part of the construction equals that of Case 1.

We have proved the following theorem.

THEOREM 3.1. *Let* $0 \geq k > 2(1-\sqrt{2})$. *Then the Riemann problem*

$$\begin{gathered}\rho_t + (\rho v)_x = 0,\\ (\rho v)_t + \left(\rho v^2 + \rho\right)_x = -k\delta_0 \rho v,\\ \rho(x,0) = \begin{cases}\rho_L & \text{for } x<0,\\ \rho_R & \text{for } x>0,\end{cases} \qquad v(x,0) = \begin{cases}v_L & \text{for } x<0,\\ v_R & \text{for } x>0\end{cases}\end{gathered} \tag{3.2}$$

has a unique solution in the class of combinations of Lax shocks, rarefaction waves, and K-waves for any left state (ρ_L, v_L) *and right state* (ρ_R, v_R) *with positive densities* ρ_L *and* ρ_R *given by the above construction.*

See Figures 7 and 8 for an illustration of the various regions in Cases 1 and 2, respectively.

4. Conclusion. We have solved the Riemann problem for isothermal gas flow in a thin pipe through a sharp bend, a kink, modeled by a Dirac delta function located at the bend in the momentum equation. The equations then read

$$\rho_t + (\rho v)_x = 0, \quad (\rho v)_t + \left(\rho v^2 + \rho\right)_x = -k\delta_0 \rho v$$

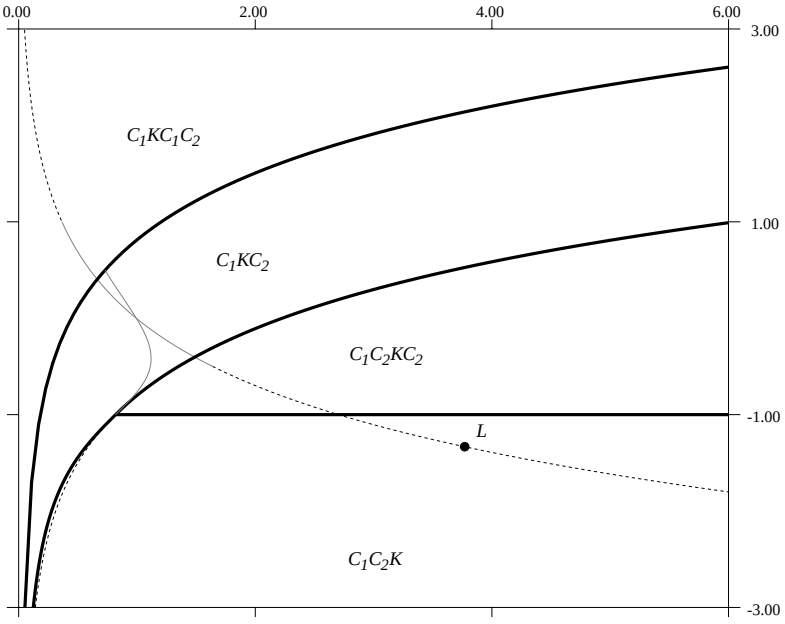

FIG. 8. *The solution of the Riemann problem for* $v_L < 1$.

with Riemann initial data. Here $k = \sqrt{2(1-\cos\theta)}$, where θ is the angle of the kink. By considering the case where k is positive, we model the case when momentum is added at an isolated point along the pipe. In both cases the Riemann problem has a unique solution.

Several important extensions are possible: First of all, the case of more general Cauchy initial data would be very interesting; i.e., both the source and the initial data are more general functions than those considered here. It is likely that the solution with Riemann initial data will play an important role, for instance, in building approximate solutions by Glimm's method or by front tracking.

Second, the extension to polytropic gas rather than isothermal gas would be quite interesting. In this case the algebraic manipulations are more complicated.

5. Appendix. In this appendix we prove that the curve $\tilde{\kappa}$ and C_2 curves starting from $\tilde{\kappa}$ are transversal. We first observe that for the C_2 curves originating on $\tilde{\kappa}$ we have that $d\tilde{\rho}/d\tilde{v} = \tilde{\rho}$, and hence it suffices to show that $d\tilde{\rho}/d\tilde{v}$ for the curve $\tilde{\kappa}$ is not equal to $\tilde{\rho}$. In the case k positive we show that indeed $d\tilde{\rho}/d\tilde{v}$ is negative, while in the case k is negative, the estimates have to be sharper as the curves are in fact tangent at the end point.

We start with the case when k is positive.

LEMMA A.1. *Assume that* $0 \le k \le 2$. *Let* $(\tilde{\rho}, \tilde{v})$ *be an arbitrary point on* $\tilde{\kappa}$. *Then*

$$\frac{d\tilde{\rho}}{d\tilde{v}} \le 0. \tag{A.1}$$

Proof. By the chain rule

$$\frac{d\tilde{\rho}}{d\tilde{v}} = \frac{\tilde{\rho}}{g_-'(v)}\left(\frac{\rho'}{\rho} + \frac{1}{v} - \frac{g_-'}{g_-}\right), \tag{A.2}$$

where we let the C_1 curve through (ρ_L, v_L) be parameterized by $(\rho(v), v)$. We have that $\rho'/\rho \le 0$, and the lemma will follow if

$$\frac{1}{v} - \frac{g_-'}{g_-} = \frac{g_- - g_-' v}{v g_- g_-'} \le 0. \tag{A.3}$$

The last inequality holds since g_-' satisfies the differential equation

$$g_-' = \frac{1 - v^2}{v\sqrt{\alpha^2 - 4v^2}} g_-, \tag{A.4}$$

which implies that $g_- - g_-' v \le 0$ as long as $k \le 4$. ∎

We now discuss the more complicated question of transversality of the $\tilde{\kappa}$ curve in the case with k negative.

LEMMA A.2. *Assume* $2(1-\sqrt{2}) < k < 0$. *Let* $(\tilde{\rho}, \tilde{v})$ *be an arbitrary point on* $\tilde{\kappa}$. *Then*

$$\frac{d\tilde{\rho}}{d\tilde{v}} < \tilde{\rho}, \tag{A.5}$$

except at the point $K(\widehat{L})$.

Proof. We parametrize the curve $\tilde{\kappa}$ using the parameter v running along the $C_1(L)$ curve, and hence write $\tilde{\rho} = \tilde{\rho}(\rho(v), v)$ and similarly for the other dependent variables.

We first compute

$$\begin{aligned}
\frac{d\tilde{\rho}}{d\tilde{v}} = \frac{\frac{d\tilde{\rho}}{dv}}{\frac{d\tilde{v}}{dv}} &= \frac{\frac{(\rho' v + \rho) g - \rho v g'}{g^2}}{g'} \\
&= \frac{1}{g'}\left(\frac{\rho' \rho v}{g\rho} + \frac{\rho v}{g v} - \frac{\rho v g'}{g g}\right) \\
&= \frac{\tilde{\rho}}{g'}\left(\frac{\rho'}{\rho} + \frac{1}{v} - \frac{g'}{g}\right).
\end{aligned} \tag{A.6}$$

What we aim to show is that

$$\frac{1}{v} + \frac{\rho'}{\rho} < \frac{g'}{g}(g+1), \tag{A.7}$$

except at the point $K(\widehat{L})$. From this it follows that $d\tilde{\rho}/d\tilde{v} < \tilde{\rho}$ away from the point $K(\widehat{L})$.

We have that

$$\frac{\rho'}{\rho} = \begin{cases} -1 & \text{for } \rho \le \rho_L, \\ -\frac{2\sqrt{\rho\rho_L}}{\rho + \rho_L} & \text{for } \rho > \rho_L. \end{cases}$$

We first show that $\tilde{\kappa}$ is never tangent to the C_2 curves for $v > 0$. Now we need the following lemma, the proof of which comes after this proof.

LEMMA A.3. *Let* $(\rho, v) = (\rho(v), v) \in C_1(L)$. *Then*

$$\frac{\rho'}{\rho} < \frac{-2v}{v^2+1} \tag{A.8}$$

for $0 < v < 1$.

With (A.7) in mind we introduce the reparametrization β by

$$\beta(u) = u - k + \frac{1}{u},$$
$$u = \frac{1}{2}\left(\gamma - \sqrt{\gamma^2 - 4}\right),$$

where $\gamma = \beta + k \geq 2$. The parameter β is in the interval $[2-k, \infty\rangle$. We have that $d\beta/dv = 1 - 1/v^2 < 0$, in this interval. Therefore, (A.7) will follow if

$$V(v) := \frac{\frac{1}{v} - \frac{2v}{v^2+1}}{1 - \frac{1}{v^2}} = \frac{-v}{v^2+1} = -\frac{1}{\gamma}$$

is greater than

$$H(v) := \frac{\frac{dg}{d\beta}}{g}(g+1) = -\frac{1}{2}\left(\sqrt{\frac{\beta+2}{\beta-2}} - 1\right).$$

Solving the equation $H = V$ for $\gamma = \tilde{\gamma}(k)$, we obtain

$$\tilde{\gamma}(k) = \frac{2+k}{k+1}. \tag{A.9}$$

Since $\gamma \geq 2$, and $\tilde{\gamma}(k) < 0$ for $k > -1$, we have that $H < V$ for all $k > -1$. This concludes the case $v > 0$.

For the (harder) case where $v < 0$, we use the crude estimate $\rho'/\rho < 0$ and wish to prove

$$\frac{1}{v} < \frac{g'}{g}(g+1). \tag{A.10}$$

Now we use the reparametrization

$$\beta = -v + k - \frac{1}{v},$$
$$v = -\frac{1}{2}\left(\gamma - \sqrt{\gamma^2 - 4}\right),$$

where $\gamma = \beta - k$. Now β is in the interval $[2, \infty\rangle$. We have that $d\beta/dv = 1/v^2 - 1 > 0$; consequently, (A.10) will follow if we can show that

$$V(v) := \frac{\frac{1}{v}}{\frac{1}{v^2} - 1} = \frac{v}{1 - v^2} = \frac{-1}{\sqrt{\gamma^2 - 4}}$$

is less than

$$H(v) := \frac{\frac{dg}{d\beta}}{g}(g+1) = \frac{1}{2}\left(\sqrt{\frac{\beta-2}{\beta+2}} - 1\right).$$

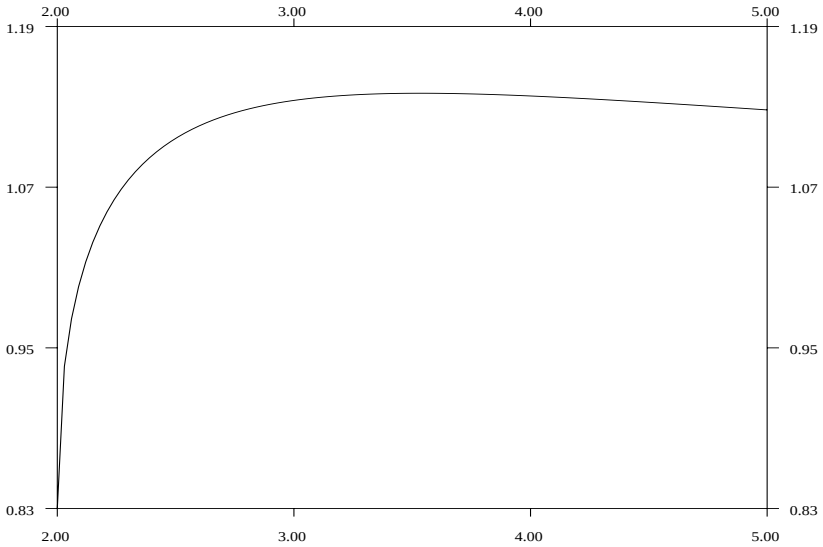

FIG. 9. *The function* $\tilde{k}(\beta)$.

In this case we can solve the equation $V = H$ for $k = \tilde{k}(\beta)$, obtaining

$$\tilde{k}(\beta) = -\beta + \sqrt{\frac{1}{2}(\beta+2)^2\left(\sqrt{\frac{\beta-2}{\beta+2}}+1\right) - (\beta-2)}\,.$$

For β in the interval $[2,\infty\rangle$, $\tilde{k}(\beta) \geq \tilde{k}(2) = 2(1-\sqrt{2})$; see Figure 9 below. Hence, for $k > 2(1-\sqrt{2})$, $V(v) < H(v)$. □

Proof of Lemma A.3. If (ρ, v) is on the rarefaction part of the C_1 curve, then $\rho'/\rho = -1$, and the lemma certainly holds. Assume therefore that (ρ, v) is on the shock part of the C_1 curve. Then it is below $Z(L) = (\rho_L v_L^2, 1/v_L)$, and hence $v \leq 1/v_L$. In this case we have that

$$\frac{\rho'}{\rho} = \frac{-2\sigma}{\sigma^2+1}, \tag{A.11}$$

where $\sigma(v) = \sqrt{\rho_0/\rho(v)}$. We see that $\sigma' \leq 1/2$, and $\sigma(1/v_L) = 1/v_L$, showing that $\sigma(v) > v$ for $v \leq 1/v_L$. The function $\phi(t) = -2t/(t^2+1)$ is monotonically decreasing for $|t| \leq 1$, and hence we infer that

$$\frac{\rho'}{\rho} < \frac{-2v}{v^2+1}. \qquad \square$$

RECOVERING ASYMPTOTICS OF COULOMB-LIKE POTENTIALS FROM FIXED ENERGY SCATTERING DATA*

M. S. JOSHI†

Abstract. Any compact smooth manifold, X, with boundary admits a Riemannian metric of the form $x^{-4}dx^2 + x^{-2}h'$ near the boundary with x a boundary defining function and h' restricting to a metric on the boundary. Melrose [*Spectral and scattering theory for the Laplacian on asymptotically Euclidean spaces*, in Spectral and Scattering Theory, M. Ikawa, ed., Marcel Dekker, New York, 1994] has associated a scattering matrix to such metrics and potentials in $xC^\infty(X)$. It is shown for potentials of the form $Ax + O(x^2)$ that this scattering matrix is a Fourier integral operator and that the asymptotics of such potentials can be recovered from the scattering matrix for various manifolds including Euclidean space.

1. Introduction. Our purpose in this article is to examine the microlocal properties of the scattering matrix at fixed energy associated to a class of potentials, which are similar to the Coulomb potential and show that the total symbols of these operators determine the asymptotics of these potentials. We shall work in the general context of a manifold with boundary equipped with a scattering metric which contains the important special case of Euclidean space. Our approach will be to extend the arguments of [3] and [5] to cover this more general case. In particular, we show that the scattering matrix at fixed energy is still a Fourier integral operator associated with geodesic flow at time π of order 0 but now with a classical symbol of imaginary order.

Recall, from [4], that a scattering metric on the manifold with boundary $(X, \partial X)$ is a metric which can be written in the form

$$g = \frac{dx^2}{x^4} + \frac{h}{x^2} \tag{1.1}$$

for some boundary defining function x, with h a symmetric tensor restricting to a positive definite form on $T(\partial X)$. (The choice of x is actually fixed up to $O(x^2)$ by g.) A long range potential is then a potential in the class $xC^\infty(X)$ and we shall define a Coulomb-like potential to be a long range potential of the form $Ax + O(x^2)$ for some $A \in \mathbb{R}$. Let Δ denote the Laplacian associated with g; then for each $f \in C^\infty(\partial X)$ and $\lambda \neq 0$ there is a unique eigenfunction u such that

$$(\Delta + V - \lambda^2)u = 0$$

of the form

$$e^{\frac{i\lambda}{x}} x^{\frac{n-1}{2} + i\alpha} f' + e^{\frac{-i\lambda}{x}} x^{\frac{n-1}{2} - i\alpha} f'',$$

where $\alpha = \frac{A}{2\lambda}$ with $f', f'' \in C^\infty(X)$, and such that the restriction of f' to the boundary is f. The scattering matrix associated with g and V is then defined to be the map

$$S(\lambda) : f \mapsto f'_{|\partial X}.$$

In the special case where $A = 0$, it is shown by Melrose and Zworski [5] that $S(\lambda)$ is a classical Fourier integral operator of order 0. The question of how to recover the asymptotics of V from the total symbol of $S(\lambda)$ in that case is addressed by Barreto and Joshi [3]. There, it is shown that given two potentials equal up to order k, the difference of the scattering matrices is order $1 - k$. The principal symbol of the difference of the associated scattering matrices was linearly determined by and determines weighted integrals of the lead term of the difference of the potentials along geodesics. It was also shown that a function could be recovered from these weighted integrals and thus that the asymptotics of a potential could be recovered from the scattering matrix.

Here we show that the analogous results hold when A is nonzero.

THEOREM 1.1. *Let $(X, \partial X, g)$ be manifold with boundary, with scattering metric g, and boundary defining function x. Let V be a Coulomb-like potential on $(X, \partial X)$ with lead term Ax; then the scattering matrix at energy λ associated with g and V is an elliptic, classical Fourier integral operator of order $-iA/\lambda$.*

Note that a classical Fourier integral operator of order $-iA/\lambda$ is of course a Fourier integral operator of order 0.

THEOREM 1.2. *Let $(X, \partial X, g, x)$ be as above. Let V_1, V_2 be Coulomb-like potentials on X such that*

$$V_1 - V_2 = x^k W + O(x^{k+1})$$

for $W \in C^\infty(\partial X)$; then if $S_j(\lambda)$ is the scattering matrix associated with V_j we have that $S_1(\lambda) - S_2(\lambda)$ is a classical Fourier integral operator of order $-iA/\lambda + 1 - k$ and the principal symbol of $S_1(\lambda) - S_2(\lambda)$ determines and is determined by

$$\int_0^\pi \sin(s)^{k-1} W(\gamma(s)) ds$$

for all geodesics γ of length π on ∂X.

The boundary ∂X has a natural Riemannian structure so the X-ray transform of a function on it is well defined. The x-ray transform is the operator on the space of functions on ∂X to the space of functions on the space of closed geodesics obtained by integrating along the geodesics. We recall that a manifold has an injectivity radius of at least R if the exponentiation map from the tangent space to the manifold is injective for vectors of size up to R. Then the same argument as in [3] is shown below.

THEOREM 1.3. *If $(X, \partial X)$ is such that the X-ray tranform on ∂X is injective, or the injectivity radius of ∂X is greater than π, or ∂X is a sphere not of radius $\frac{1}{k+1}$, $k > 0$, then if the Coulomb-like potentials V_1, V_2 have scattering matrices at some energy which are equal up to smoothing then $V_1 - V_2 = O(x^\infty)$.*

In particular, scattering data determine the asymptotics on Euclidean space as it is a special case, where the boundary is a sphere which is of radius 1.

The problem of recovering the short range part of a long range potential has been studied by Isozaki and Kitada [2] in the 2-body case and Enss and Weder [1] in the n-body case. They proved that the short range part is uniquely determined by the high energy limit of the scattering matrix.

It is known that one cannot recover Schwartz potentials, and examples of transparent potentials at fixed energy have been constructed by Regge [7], Newton [6], Sabatier [8], and others. Thus one would not expect to do better than the asymptotics in the long range case.

Vasy [9] has informed us of an alternative proof of Theorem 1.1, which avoids the necessity of using a symbol calculus and therefore does not prove Theorems 1.2 and 1.3.

2. Review of definition of scattering matrix. In this section, we review some work of Melrose [4] on how to define the scattering matrix of a Coulomb-like potential on a general manifold with boundary equipped with a scattering metric. Suppose that a boundary defining function x has been chosen and that $V = Ax + O(x^2)$. We work in a fixed product decomposition near the boundary. The Laplacian is then of the form

$$(x^2 D_x)^2 + ix(n-1)x^2 D_x + x^2 \Delta_{\partial X} + R,$$

where R is lower order at the boundary. Then

$$(\Delta + V - \lambda^2)(x^p e^{i\lambda/x} b(y)) = i\lambda(2p - n + 1 - iA/\lambda) x^{p+1} e^{i\lambda/x} b + O(x^{\Re p+1}).$$

Thus if we take $p = \frac{n-1}{2} + i\alpha$ with $\alpha = A/2\lambda$, the lead term vanishes and we can iteratively solve away the error terms and, applying the Borel lemma, obtain $f(x,y) \in C^\infty(X)$ such that $(\Delta + V - \lambda^2)(e^{i\lambda/x} x^p f(x,y))$ vanishes to infinite order at $x = 0$ and $f(0,y) = b(y)$. With this modification, the arguments in [4] are resolved and there is a unique eigenfunction of the form

$$e^{\frac{i\lambda}{x}} x^{\frac{n-1}{2} + i\alpha} f + e^{-\frac{i\lambda}{x}} x^{\frac{n-1}{2} - i\alpha} f'$$

with $f' \in C^\infty(X)$. The scattering matrix at energy λ is then the map

$$S(\lambda) : b \mapsto f'_{|\partial X}.$$

It is a unitary operator.

3. Review of Legendrian distributions. In this section, we review and rephrase the material we need from [4] and [5]. In this section, X is a compact manifold with boundary ∂X and g is a scattering metric on X with x a boundary defining function for ∂X such that g takes the form (1.1). Our account is necessarily brief and we refer the reader to [4] and [5] for more details.

There is a natural bundle over X called the scattering cotangent bundle, which is denoted ${}^{sc}T^*(X)$. This is the dual to the bundle of smooth, vector fields of bounded length with respect to some (and hence all) scattering metrics on X. The restriction of ${}^{sc}T^*(X)$ to ∂X is denoted ${}^{sc}T^*(X)_{|\partial X}$ and carries a natural contact structure. If y are local coordinates on ∂X and μ are the corresponding dual coordinates, then (y, μ, τ) form local coordinates on ${}^{sc}T^*(X)_{|\partial X}$, where τ is the coefficient of $\frac{dx}{x^2}$. We assume that a product decomposition close to the boundary has been chosen $X = \partial X \times \mathbb{R}_+$. If y are coordinates on ∂X, we then have coordinates $\partial X \times \mathbb{R}_+$ on X close to the boundary.

We omit the definition of scattering pseudodifferential operators as we need only consider differential operators; however, we note that a differential operator $P(x, y, xD_y, x^2 D_x)$ will be in $\Psi_{sc}^{m,k}(X, {}^{sc}\Omega^{1/2})$ if it is of order m and that the total

symbol as an operator in xD_y, x^2D_x vanishes to kth order at the boundary. The operator P then has a well-defined symbol at the boundary:

$$j(P) = x^k p_k + x^{k+1} p_{k+1},\ p_k, p_{k+1} \in C^\infty(\mathbb{R} \times T^*\partial X).$$

DEFINITION 3.1. *An intersecting pair with conic points is a subset, $\widetilde{W}$, of ${}^{sc}T^*(X)_{|\partial X}$, which is a union of the closure of a smooth Legendrian submanifold, W, and $W^\#$, a finite union of global sections of the form $W^\#(\lambda_j) = \{(y, 0, \lambda_j)\}$, containing $\overline{W} \setminus W$. We also require $\overline{W}$ to have an at most conic singularity at $\mu = 0$; that is, it is smooth if polar coordinates are introduced along $\overline{W} \setminus W$.*

The process of introducing polar coordinates along $\overline{W} \setminus W$ can be given an invariant meaning and is then called blow-up. We denote the blown-up manifold $\widehat{W}$.

The metric g induces a metric h on the nearby boundary. It is of the form

$$\tau^2 + h'(y, \mu) + xg'$$

as a function on ${}^{sc}T^*X$; we obtain h' from h via the isomorphism

$$\mu.\frac{dy}{x} \longmapsto \mu.dy.$$

EXAMPLE 3.1. *For each $y' \in \partial X$ and $0 \neq \lambda \in \mathbb{R}$, let $G_{y'}(\lambda)$ be equal to the set of (τ, y, μ), such that $\tau^2 + |\mu|^2 = \lambda^2, \mu \neq 0$, and, putting $\mu = |\mu|\hat{\mu}$,*

$$\begin{aligned} \tau &= |\lambda| \cos(s), \\ |\mu| &= |\lambda| \sin(s), \\ (y, \hat{\mu}) &= \exp(sH_{\frac{1}{2}h})(y', \hat{\mu}'), \end{aligned} \tag{3.1}$$

where $s \in (0, \pi)$, $(y', \hat{\mu}') \in T^*\partial X$, and $h(y', \hat{\mu}') = 1$. Then $G_{y'}(\lambda) \cup \{(\lambda, y, 0)\}$ is an intersecting pair with conic points. We denote this pair $\widetilde{G}(\lambda)$. This is the pair we are interested in this paper. The set $G^\sharp(\lambda) = \{(-\lambda, y, 0, y', 0)\}$ is also important in our construction. Note that $G^\sharp(\lambda)$ is the initial or incoming surface and that $G^\sharp(-\lambda)$ is the outgoing surface. Note that in the coordinates defined by (3.1)*, $G^\sharp(\lambda)$ is $s = \pi$ and $G^\sharp(-\lambda)$ is $s = 0$, when λ is positive.*

Associated with these intersecting pairs at each conic point is a unique homogeneous Lagrangian submanifold $\Lambda(\widetilde{W}, \lambda_i)$ of $T^*(\partial X)$. For the pair we are interested in, $\widetilde{G}(\lambda)$ this is precisely the relation of being π apart along a lifted geodesic (see Proposition 4 of [5]). For simplicity, we shall henceforth take λ to be positive, the λ negative case is similar (or could be deduced from the positive case).

Melrose and Zworski [5] associated any such intersecting pair with a class of smooth functions whose asymptotics on approach to the boundary are determined by symbols on the Legendrians. A symbol bundle over the smooth Legendrian $W(\lambda)$ in pair $\widetilde{W}$ can be defined and is denoted $\hat{E}^{m,p}$. The sections of this bundle are of the form

$$aS^{p-m}|dx|^{m-n/4}$$

with a a smooth section of $C^\infty(\hat{W}; \Omega_b^{\frac{1}{2}} \otimes M_{\hat{H}})$, S a defining function of the boundary of W, M the Maslov bundle, and $\Omega_b^{\frac{1}{2}}$ the $b-$half density bundle. For G above, one could take $S = \sin s$. Melrose and Zworski remove this singularity at the endpoints by rescaling, but for us it will be easier not to do so.

PROPOSITION 3.1. *If $\widetilde{W}(\lambda)$ is an intersecting pair with conic points then there is a class of smooth half-densities on X^o, denoted $I^{m,p}_{sc}(X,\widetilde{W})$, such that $\bigcap_{m,p} I^{m,p}_{sc}(X,\widetilde{W})$ is equal to the class of half-densities vanishing to infinite order at the boundary. There exists a symbol map*

$$\hat{\sigma}_{sc,m,p} : I^{m,p}_{sc}(X,\widetilde{W},{}^{sc}\Omega^{1/2}) \to C^\infty(\hat{W};\hat{E}^{m,p})$$

which gives a short exact sequence

$$0 \to I^{m+1,p}_{sc}(X,\widetilde{W},{}^{sc}\Omega^{1/2}) \to I^{m,p}_{sc}(X,\widetilde{W},{}^{sc}\Omega^{1/2}) \to C^\infty(\hat{W};\hat{E}^{m,p}) \to 0.$$

This is Proposition 12 from [5]. An important related fact we need to know is, how do Legendrian distributions map under scattering pseudodifferential operators? We recall Proposition 13 from [5].

PROPOSITION 3.2. *Suppose $P \in \Psi^{l,k}_{sc}(X,{}^{sc}\Omega^{1/2})$ has symbol $x^k p_k + x^{k+1}p_{k+1}$ with respect to a product decomposition of X near ∂X, and suppose that*

$$W \subset {}^{sc}T^*_{\partial X}(X)$$

is a smooth Legendre submanifold. Then for any $m \in \mathbb{R}$,

$$P : I^m_{sc}(X,W;{}^{sc}\Omega^{1/2}) \to I^{m+k}_{sc}(X,W;{}^{sc}\Omega^{1/2}), \tag{3.2}$$

$$\sigma_{sc,m+k}(Pu) = (p_{k|G})\sigma_{sc,m}(u) \otimes |dx|^k. \tag{3.3}$$

Furthermore, if p_k vanishes identically on W, then

$$P : I^m_{sc}(X,W;{}^{sc}\Omega^{1/2}) \to I^{m+k+1}_{sc}(X,W;{}^{sc}\Omega^{1/2})$$

and

$$\sigma_{sc,m+k+1}(Pu)$$
$$= \left(\frac{1}{i}\left(L_V + \left(\frac{1}{2}(k+1) + m - \frac{n}{4}\right)\frac{\partial p_k}{\partial \tau}\right) + p_{k+1|W}\right) a \otimes |dx|^{m+k+1-\frac{n}{4}},$$

where $\sigma_{sc,m}(u) = a \otimes |dx|^{m-\frac{n}{4}}$ and V is the rescaled Hamiltonian vector field associated with p_k.

We omit the definition of the rescaled Hamiltonian vector field but recall that for the pair G we are studying, it is equal to

$$2\lambda \sin s \frac{\partial}{\partial s}$$

in the semiglobal coordinates given by (3.1).

We also need two push-forward theorems, Propositions 16 and 17 from [5]. They relate the singularities of the scattering matrix to the asymptotics in small x of the Poisson operator. Given a product decomposition near the boundary, there is a natural pairing

$$B : C^{-\infty}(X,{}^{sc}\Omega^{1/2}) \times C^\infty(\partial X;{}^{sc}\Omega^{1/2}) \to C^{-\infty}([0,\epsilon),{}^{sc}\Omega^{1/2}), \tag{3.4}$$

$$B(u,f) = x^{\frac{n-1}{2}} \int_{\partial X} u(x,y)f(y). \tag{3.5}$$

PROPOSITION 3.3. *For any intersecting pair of Legendre submanifolds with conic points W, the partial pairing* (3.5) *gives a map*

$$B : I^{m,p}_{sc}(X, \widetilde{W}; {}^{sc}\Omega^{1/2}) \times C^\infty(\partial X; {}^{sc}\Omega^{1/2}) \mapsto \sum_j I^{p+\frac{n-1}{4}}([0,\epsilon), W'(\bar\tau_j; {}^{sc}\Omega^{1/2})),$$

where the $W'(\bar\tau_j) = \{(0, -\tau_j dx/x^2)\}$ are the Legendre submanifolds corresponding to the components of $W^\#$ and

$$B(u,f) = \sum_j e^{-i\bar\tau/x} x^{p+n/4} Q^0_{\bar\tau_j}(u,f) \left|\frac{dx}{x^2}\right|^{\frac12} + O(x^{p+n/4+1})$$

with

$$Q^0_{\bar\tau}(u) \in I^{p-m-\frac{n-1}{4}}_{phg}(\partial X, \Lambda(\widetilde{W}, \bar\tau)),$$

and the principal symbol of $Q^0_{\bar\tau}(u)$ determines and is determined by the lead singularity of the principal symbol of u on W on approach to $W'(\bar\tau_j)$.

When the Legendrian distribution is actually associated with a smooth Legendrian submanifold the push-forward becomes much simpler, and this simplifies the construction of the Poisson operator.

PROPOSITION 3.4. *If G is a smooth Legendre variety and $u \in I^m_{sc}(X, G'^{sc}\Omega^{1/2})$ near $\tau = \bar\tau$, then the distribution $Q^0_{\bar\tau}$ is a Dirac delta distribution.*

4. Construction of the Poisson operator. In this section, we apply the calculus reviewed in section 3 to construct the Poisson operator and prove Theorem 1.1. We shall refer heavily to [5, section 15], as our construction is a modification of the one there.

We assume a product decomposition of X close to the boundary has been chosen and is fixed throughout this section. We then have as in [5] that Δ, the intrinsic Laplacian acting on scattering half-densities on $X \times \partial X$, induces an operator

$$\Delta_X \in \mathrm{Diff}^2_{\mathrm{sc}}(X \times \partial X, {}^{sc}\Omega^{1/2}(X \times \partial X))$$

by

$$\Delta_X \left(u \left|\frac{dx}{x^2}\right|^{\frac12} \left|\frac{dy}{x^{n-1}}\right|^{\frac12} \left|\frac{dy'}{x^{n-1}}\right|^{\frac12} \right) = \Delta \left(u(.,y) \left|\frac{dx}{x^2}\right|^{\frac12} \left|\frac{dy}{x^{n-1}}\right|^{\frac12} \right) \left|\frac{dy'}{x^{n-1}}\right|^{\frac12},$$

where $(x, y; y')$ is a point in $X \times \partial X$. Throughout this section V will be a Coulomb-like potential, that is,

$$V = Ax + x^2 f, f \in C^\infty(X),$$

and α will be $\frac{A}{2\lambda}$.

We recall the following from [3].

LEMMA 4.1. *The symbol at the boundary of Δ_X is $p = p_0 + xp_1$ with p_1 equal to $-i(n-1)\tau + c$, where c is the derivative of the metric at the boundary and of the form $c(y,\mu,\tau) = \tau f(y,\mu) + g(y,\mu)$ with f linear in μ and g quadratic in μ.*

We also note the following lemma, which is important in our construction to show that the transport equations are solvable.

LEMMA 4.2. *If* $L \in I^{m,-\frac{1}{4}+i\alpha}(X \times \partial X, \tilde{G}(\lambda), {}^{sc}\Omega^{1/2})$ *is such that*

$$(\Delta_X - \lambda^2 + V)L \in I^{m+2,\frac{3}{4}+i\alpha}(X \times \partial X, \tilde{G}(\lambda), {}^{sc}\Omega^{1/2}),$$

then

$$(\Delta_X - \lambda^2 + V)L \in I^{m+2,\frac{7}{4}+i\alpha}(X \times \partial X, \tilde{G}(\lambda), {}^{sc}\Omega^{1/2}).$$

This is a modification of Lemma 15 from [5], and in fact, the $\alpha = 0$ case is essential to the construction there also.

Proof. The proof is no different from that of Lemma 15 in [5], the only difference being that in (15.17), there appears an extra term α, which is canceled by the lead term of the potential. □

PROPOSITION 4.1. *For any* $0 \neq \lambda \in \mathbb{R}$ *there exists*

$$K \in I^{m,p_1,p_2}(X \times \partial X, \tilde{G}(\lambda); {}^{sc}\Omega^{1/2}),$$

such that

$$(\Delta_X - \lambda^2 + V)K \in \mathcal{C}^\infty(X \times \partial X; {}^{sc}\Omega^{1/2})$$

and

$$Q^0_\lambda(K) = \mathrm{Id}$$

with

$$m = -\frac{2n-1}{4} + i\alpha,\ p_1 = -\frac{1}{4} + i\alpha,\ p_2 = -\frac{1}{4} - i\alpha,$$

and the principal symbol of K *on* G *is*

$$C \sin(s)^{\frac{n-1}{2} - i\alpha} \tan(s/2)^{-i\alpha} \frac{|ds|^{\frac{1}{2}} |dy|^{\frac{1}{2}} |d\hat{\mu}|^{\frac{1}{2}}}{(\sin s)^{\frac{1}{2}}} |dx|^{m - \frac{2n-1}{4}},$$

where $C(y, \hat{\mu})$ *is a nonzero smooth function.*

Note that in contrast to [5], we allow different orders on $G^\sharp(\lambda)$ and $G^\sharp(-\lambda)$.

Proof. As in [5], we first construct $K^b \in I^{m,p_2}(X \times \partial X, \tilde{G}(\lambda); {}^{sc}\Omega^{1/2})$ such that

$$(\Delta_X - \lambda^2 + V)K^b \in I^{\frac{3}{4} - i\alpha}_{sc}(X \times \partial X, G^\sharp(-\lambda)), \tag{4.1}$$

$$Q^0_\lambda(K^b) = \mathrm{Id}\,. \tag{4.2}$$

We construct K^b as an asymptotic sum of

$$K_j \in I^{-\frac{2n-1}{4} + j + i\alpha, -\frac{1}{4} - i\alpha}_{sc}(X \times \partial X, \tilde{G}(\lambda); {}^{sc}\Omega^{1/2}).$$

We would like

$$(\Delta_X - \lambda^2 + V)K_0 \in I^{-\frac{2n-1}{4} + i\alpha + 2, \frac{3}{4} - i\alpha}_{sc}(X \times \partial X, \tilde{G}(\lambda); {}^{sc}\Omega^{1/2})\ , \tag{4.3}$$

$$\sigma_0(Q^0_\lambda(K_0)) = \sigma_0(\mathrm{Id}); \tag{4.4}$$

then $(\Delta_X - \lambda^2 + V)K_0$ is automatically in

$$I_{sc}^{-\frac{2n-1}{4}+i\alpha+2,\frac{7}{4}-i\alpha}(X \times \partial X, \tilde{G}(\lambda); {}^{sc}\Omega^{1/2})$$

by Lemma 4.2. We also want

$$(\Delta_X - \lambda^2 + V)\left(\sum_{l=0}^{j-1} K_l\right) \in I_{sc}^{-\frac{2n-1}{4}+i\alpha+j+2,\frac{3}{4}-i\alpha}(X \times \partial X, \tilde{G}(\lambda); {}^{sc}\Omega^{1/2})$$

and this, of course, implies that it will also be an element of

$$I_{sc}^{-\frac{2n-1}{4}+i\alpha+j+2,\frac{7}{4}-i\alpha}(X \times \partial X, \tilde{G}(\lambda); {}^{sc}\Omega^{1/2}).$$

Now near $G \cap G^\sharp(\lambda)$, where G is smooth, we can as in [5] give an explicit construction, and it is then necessary only to have that the principal symbol of $Q_\lambda^0(K_0)$ is equal to 1 to ensure that $Q_\lambda^0(K^b) = \mathrm{Id}$. We look for K_j of the form

$$x^{j+i\alpha}e^{i\lambda\phi(y,y')/x}a_j(x,y,y',\lambda)v, a_j \in C^\infty(X \times \partial X)$$

with v a fixed scattering half-density and ϕ the cosine of the Riemannian distance from y to y. Let $a_j^{'}$ be the restriction of a_j to $x = 0$. Taking geodesic normal coordinates, y, about each y' the transport equations for $a_j^{'}$ is of the form

$$(y \cdot \partial_y + j)a_j^{'} + b_j a_j^{'} = c_j \in C^\infty(X \times \partial X)$$

near $y = 0$, where c_0 is identically zero and b_j vanishes quadratically at $y = 0$. Note that the extra power $x^{i\alpha}$ cancels with the extra term coming from the lead term of the potential. Thus, as in [5], the terms K_j exist sc-microlocally close to $G^\sharp(\lambda)$.

We now need to continue each K_j up to $G^\sharp(-\lambda)$; we do so by solving transport equations for the principal symbols and iteratively solving away the error.

Now the principal symbol of K_0, $\sigma_m(K_0)$ is of the form

$$b\frac{|ds|^{\frac{1}{2}}|dy|^{\frac{1}{2}}|d\hat{\mu}|^{\frac{1}{2}}}{(\sin s)^{\frac{1}{2}}}|dx|^{m-\frac{2n-1}{4}}.$$

On the lifted geodesic $\beta(s)$ the subprincipal term $c(\beta(s)) = 2\lambda\sin(s)d(\beta(s))$ for some smooth d. From Proposition 3.2, the transport equation for b is

$$\frac{2\lambda}{i}\left(\sin(s)\frac{d}{ds} + \left(\frac{1-n}{2} + i\alpha\right)\cos(s) + i\sin(s)d(\beta(s))\right)b + Ab = 0$$

with the final term being the contribution coming from the long range nature of the potential. Writing $\tilde{b} = (e^{i\int d(\beta(s'))ds'}\sin(s))^{\frac{1-n}{2}+i\alpha}b$, we thus have

$$\frac{d\tilde{b}}{ds} + i\frac{\alpha}{\sin(s)}\tilde{b} = 0$$

(using the fact that $\alpha = V/(2\lambda)$). Introducing an integrating factor, this becomes

$$\frac{d}{ds}\left[e^{i\alpha\int\frac{1}{\sin(s')}ds'}\tilde{b}\right] = 0.$$

This means that

$$\begin{aligned} b = &\ C\sin(s)^{\frac{n-1}{2}-i\alpha}e^{-i\alpha\int\frac{1}{\sin(s')}ds'}e^{-i\int d(\beta(s'))ds'} \\ = &\ C\sin(s)^{\frac{n-1}{2}-i\alpha}\tan(s/2)^{-i\alpha}e^{-i\int d(\beta(s'))ds'}. \end{aligned}$$

As $s\to\pi-$, that is, near $G^\sharp(\lambda)$, this has a singularity of the form $(\pi-s)^{\frac{n-1}{2}}$, and as $s\to 0+$, this has the form $s^{\frac{n-1}{2}-2i\alpha}$.

As the order on $G^\sharp(\lambda)$ is $p_1=-\frac{1}{4}+i\alpha$ and on $G^\sharp(-\lambda)$ is $p_2=-\frac{1}{4}-i\alpha$, the orders p_1-m and p_2-m are equal to the orders of singularities, and thus the solution of the transport equation is a legitimate symbol and we can construct K_0.

Now by Lemma 4.2,

$$(\Delta+V-\lambda^2)(K_0)\in I^{m+2,p_1+2,p_2+2}(X\times\partial X,\tilde{G};{}^{sc}\Omega^{1/2}),$$

and we look for

$$K_1\in I^{m+1,p_1,p_2}(X\times\partial X,\tilde{G};{}^{sc}\Omega^{1/2}),$$

such that

$$(\Delta+V-\lambda^2)(K_0+K_1)\in I^{m+3,p_1+1,p_2+1}(X\times\partial X,\tilde{G};{}^{sc}\Omega^{1/2}).$$

Now by Lemma 4.2, we have $I^{m+3,p_1+2,p_2+2}(X\times\partial X,\tilde{G};{}^{sc}\Omega^{1/2})$. Letting the principal symbol of K_1 be $b_1|dx|^{m+1-\frac{2n-1}{4}}$ times the trivializing density above, we obtain a transport equation; arguing as above, it becomes

$$\begin{aligned} &\sin(s)^{\frac{n-1}{2}+i\alpha}\tan(s/2)^{-i\alpha}e^{-i\int d(\beta(s'))ds'} \\ &\qquad \frac{d}{ds}e^{i\int d(\beta(s'))ds'}\left(\sin(s)^{\frac{1-n}{2}+1+i\alpha}\tan(s/2)^{i\alpha}b_1\right) \\ &\qquad\qquad = g(s)e^{-i\int d(\beta(s'))ds'}\sin(s)^{\frac{n-1}{2}-i\alpha}\tan(s/2)^{-i\alpha} \end{aligned}$$

with $g(s)$ a smooth function on $[0,\pi]$ (and depending smoothly on the suppressed parameters). Canceling, we obtain that

$$\frac{d}{ds}\left(e^{i\int d(\beta(s')ds'}\sin(s)^{\frac{1-n}{2}+1+i\alpha}\tan(s/2)^{i\alpha}b_1\right)=g(s),$$

which has a solution in the appropriate symbol class. The same argument, after appropriately shifting indices, constructs all the terms K_j.

Asymptotically summing, we obtain K^b such that

$$(\Delta+V-\lambda^2)K^b\in I^{7/4+i\alpha}(G^\sharp(\lambda))+I^{7/4-i\alpha}(G^\sharp(-\lambda)).$$

These errors can now be removed by an iterative construction of their Taylor series (cf. Lemma 16 of [5]), and we obtain K as desired. □

The remainder of the proof of Theorem 1.1 is identical to that of the main theorem in [5] and we therefore omit the details.

5. Recovering asymptotics of potentials. In this section, we prove Theorem 1.2 and recall from [3] the deduction of Theorem 1.3. Note that the lead term of the Coulomb-like potential is automatically determined by the order of the elliptic Fourier integral operator $S(\lambda)$. Thus we need consider only potentials which have the same lead term and thus which have Poisson operators with the same principal symbol.

Let V_1, V_2 be two Coulomb-like potentials with lead term A such that

$$V_1 - V_2 = x^k W + O(x^{k+1})$$

with $W \in C^\infty(\partial X)$. Letting P_1, P_2 be the associated Poisson operators at energy λ, we then have that

$$(\Delta - \lambda^2)P_j = -V_j P_j$$

and thus that

$$(\Delta - \lambda^2)(P_1 - P_2) = -V_1 P_1 + V_2 P_2 = -V_1(P_1 - P_2) + (V_2 - V_1)P_2.$$

Hence

$$(\Delta + V_1 - \lambda^2)(P_1 - P_2) = (V_2 - V_1)P_2.$$

We also have that

$$Q^0_{-\lambda}(P_1 - P_2) = \mathrm{Id} - \mathrm{Id} = 0.$$

Thus as in [3], we conclude that $P_1 - P_2$ is of order $-\frac{2n-1}{4} + i\alpha - k$ on G as the transport equations for the principal symbol at each level will be homogeneous with zero initial data and thus have zero solution. At the kth level, the equation becomes inhomogeneous, and we obtain the following transport equation, using Proposition 4.1 and Proposition 3.2:

$$\frac{2\lambda}{i}\left(\sin(s)\frac{d}{ds} + \left(\frac{1-n}{2} + k + i\alpha\right)\cos(s) + i\sin(s)d(\beta(s))\right)b + Ab$$
$$= CW(\gamma(s))e^{-i\int d(\beta(s'))ds'}\sin(s)^{\frac{n-1}{2}-i\alpha}\tan(s/2)^{-i\alpha},$$

where $b|dx|^{-\frac{2n-1}{2}+i\alpha+k}\frac{|ds|^{\frac{1}{2}}|dy|^{\frac{1}{2}}|d\hat{\mu}|^{\frac{1}{2}}}{(\sin s)^{\frac{1}{2}}}$ is the principal symbol of $P_1 - P_2$. Writing $\tilde{b} = e^{i\int d(\beta(s'))ds'}(\sin(s))^{\frac{1-n}{2}+k+i\alpha}b$, this becomes

$$\frac{d\tilde{b}}{ds} = \frac{i}{2\lambda}(\sin(s))^{k-1}W(\gamma(s)),$$

where $\gamma(s)$ is the geodesic in ∂X. Thus as in [3], on approach to $G^\sharp(-\lambda)$ the symbol will be $(\sin(s))^{\frac{n-1}{2}-k-i\alpha}\tan(\frac{s}{2})^{-i\alpha}e^{-i\int d(\beta(s'))ds'}$ times the weighted integral

$$\int_0^\pi (\sin(s))^{k-1}W(\gamma(s))ds$$

and thus from Proposition 3.3, the principal symbol of

$$S_1 - S_2 = Q^0_\lambda(P_1 - P_2)$$

will be a fixed elliptic factor times $\int_0^\pi(\sin(s))^{k-1}W(\gamma(s))ds$; the result follows. Note that the geodesic γ required to compute $\sigma_{1-k-2i\alpha}(S_1 - S_2)$ at a point (x,ξ) is just the geodesic, which when lifted, ends at (x,ξ).

Acknowledgments. I would like to thank Antonio Sa Barreto and Maciej Zworski for helpful conversations. This paper was prepared while participating in the microlocal methods programme at the Fields Institute in the fall of 1997, and I would like to thank the Fields Insititute and the progamme organizers for their hospitality.

ON THE ATTAINABLE EIGENVALUES OF THE LAPLACE OPERATOR*

DORIN BUCUR†, GIUSEPPE BUTTAZZO‡, AND ISABEL FIGUEIREDO§

Abstract. We consider the subset E of $\mathbb{R}^2$ of all points whose first and second components, respectively, coincide with the first and second eigenvalues of the Laplace operator $-\Delta$ with zero boundary conditions on domains of $\mathbb{R}^N$ with prescribed measure. We show that the set E is closed in $\mathbb{R}^2$.

1. Introduction.

Let $B \subseteq \mathbb{R}^N$ be a fixed ball and let $c > 0$ be a positive number. We denote by

$$\mathcal{A}_c(B) = \big\{ A \subseteq B : \quad A \quad \text{quasi open, } m(A) \le c \big\}$$

the family of all quasi-open subsets of B having Lebesgue measure less than or equal to c, and by $s : \mathcal{A}_c(B) \to \mathbb{R}^2$ the "spot" function defined by

$$s(A) = (\lambda_1(A), \lambda_2(A)),$$

where $\lambda_1(A), \lambda_2(A)$ are the first two eigenvalues (counted with their multiplicities) of the Laplace operator $-\Delta$ on the Sobolev space $H_0^1(A)$. Since we will always work with Sobolev functions it is convenient to consider domains which are quasi-open (that is, subsets of $\mathbb{R}^N$ of the form $\{u > 0\}$ where $u \in H^1(\mathbb{R}^N)$) instead of usual domains which are open subsets of $\mathbb{R}^N$. This choice is also justified by the relaxation theory of Dirichlet problems. In fact, the family of quasi-open sets is the largest class of domains contained in the closure of the family of open sets with respect to the γ-topology, on which Sobolev spaces H_0^1 are well defined.

The purpose of this paper is to prove that the range of s is closed in $\mathbb{R}^2$ if, for a given c, the ball B is large enough. This will immediately imply the existence of a solution for problems of the form

$$\min \Big\{ \Phi(\lambda_1(A), \lambda_2(A)) : \quad A \in \mathcal{A}_c(B) \Big\}$$

for a large class of cost functions Φ.

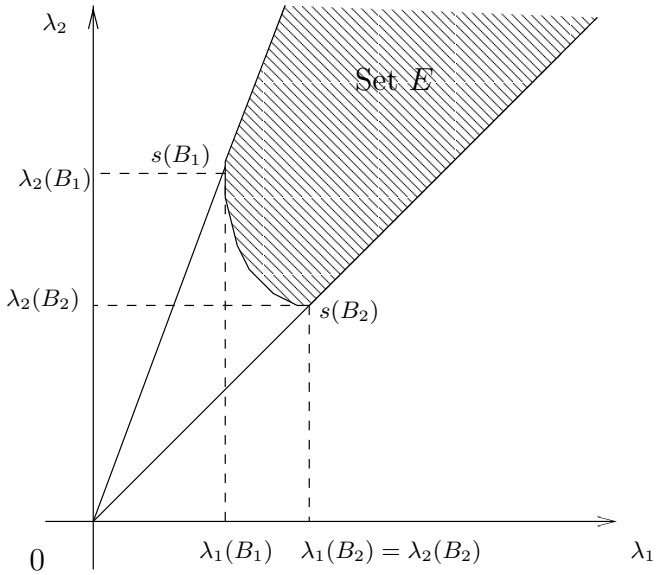

FIG. 1.

Let us denote by $E = s(\mathcal{A}_c(B))$ the image of s in $\mathbb{R}^2$. Some classical remarks already give an idea where the set E lies.

Denoting by B_1 the ball of mass c and by B_2 the union of two disjoint balls of mass $\frac{c}{2}$, classical arguments give that

- $\forall A \in \mathcal{A}_c(B), \quad \lambda_1(A) \geq \lambda_1(B_1)$ (proved by Faber [10] and Krahn [15], [16]);
- $\forall A \in \mathcal{A}_c(B), \quad \lambda_2(A) \geq \lambda_2(B_2) = \lambda_1(B_2)$ (we refer to Krahn [16]; see also [17] for a proof by P. Szegö);
- $\forall A \in \mathcal{A}_c(B), \quad \lambda_2(B_1)/\lambda_1(B_1) \geq \lambda_2(A)/\lambda_1(A) \geq 1$ (recently proved by Ashbaugh and Benguria (see [1]));
- the set E is conical with respect to the origin, that is $(tx, ty) \in E$ whenever $(x, y) \in E$ and $t \geq 1$ (by homothety of ratio $\frac{1}{\sqrt{t}}$).

For a numerical study of the set E in the case $N = 2$ we refer the interested reader to the paper by Wolf and Keller (see [18]), where the picture for E (see Figure 1) is obtained.

Unfortunately, we are not able to prove the convexity of the set E, which the picture above seems to show; this would imply the closure result quite straightforwardly. However, we can prove that E is convex horizontally and vertically, and this is enough to imply that it is closed (see Lemma 2.1).

In the paper we often use the definition of γ-convergence for sequences of domains and some of its properties; this definition, which we recall in section 2, was introduced by Dal Maso and Mosco (see [9]) and turned out to be a very powerful tool in several shape optimization problems (see Buttazzo and Dal Maso [7], [8]).

We conclude the paper with a section where some open problems are presented.

2. The main theorem and some preliminary results. Let $c > 0$ be given and let $B \subseteq \mathbb{R}^N$ be a ball containing two disjoint balls of mass $\frac{c}{2}$. We shall prove the following result.

THEOREM 2.1. *The set E is closed in $\mathbb{R}^2$.*

The proof of the theorem above is based on the following lemma.

LEMMA 2.1. *If the set E is convex on the vertical and horizontal directions, then E is closed in $\mathbb{R}^2$.*

Following this lemma it suffices to prove the convexity of E on vertical and horizontal directions. For this purpose, we shall split the proof in two steps:

Step 1. A is convex on horizontal lines; namely, if $A \in \mathcal{A}_c(B)$, then the segment joining $(\lambda_1(A), \lambda_2(A))$ to $(\lambda_2(A), \lambda_2(A))$ is contained in E.

Step 2. A is convex on vertical lines; namely, if $A \in \mathcal{A}_c(B)$, then the segment joining $(\lambda_1(A), \lambda_2(A))$ to $(\lambda_1(A), \frac{\lambda_2(B_1)}{\lambda_1(B_1)}\lambda_1(A))$ is contained in E.

The proofs of Lemma 2.1 and of Steps 1 and 2 will be given in section 3; we recall now classical notions and give some preliminary results.

The capacity of a set $E \subseteq B$ is defined by

$$cap(E) = \inf\left\{\int_B |\nabla u|^2, \quad u \in \mathcal{U}_E\right\},$$

where $\mathcal{U}_E$ is the class of all functions $u \in H_0^1(B)$ such that $u \geq 1$ almost everywhere (a.e.) in a neighborhood of E. We say that a property $p(x)$ holds quasi everywhere on E (q.e. on E) if the set of all points $x \in E$ for which $p(x)$ does not hold has capacity zero.

A subset $A \subseteq B$ is called quasi-open if for every $\epsilon > 0$ there exists an open subset G_ϵ of B such that $A \cup G_\epsilon$ is open and $cap(G_\epsilon) < \epsilon$. It easily can be seen that for any quasi-open set there exists a decreasing sequence $\{A_n\}_{n\in N}$ of open sets containing A such that $cap(A_n \setminus A) \to 0$. A function $f : B \mapsto \mathbb{R}$ is said to be quasi-continuous if for all $\epsilon > 0$ there exists an open set G_ϵ with $cap(G_\epsilon) < \epsilon$ such that f is continuous on $B \setminus G_\epsilon$ (see [13], [19]). For a quasi-open set A, the Sobolev space $H_0^1(A)$ is defined as

$$H_0^1(A) = \{u \in H_0^1(B) \ : \quad u = 0 \quad \text{q.e. on} \quad B \setminus A\}.$$

The fine topology on B is the coarsest topology making all superharmonic functions continuous. The relation between the quasi topology and the fine topology is studied in [12], [14].

For a quasi-open set $A \in \mathcal{A}_c(B)$, we denote by $\lambda_1(A)$, $\lambda_2(A)$ the first two eigenvalues (counted with their multiplicity) of the Laplace operator $-\Delta$ on $H_0^1(A)$. They are given by the classical formulae

$$\lambda_1(A) = \min_{\substack{\varphi\in H_0^1(A)\\ \varphi\neq 0}} \frac{\int_A |\nabla\varphi|^2 dx}{\int_A |\varphi|^2 dx},$$

$$\lambda_2(A) = \max_{\substack{\psi\in H_0^1(A)\\ \psi\neq 0}} \min_{\substack{\varphi\in H_0^1(A)\setminus\{0\}\\ \varphi\perp\psi}} \frac{\int_A |\nabla\varphi|^2 dx}{\int_A |\varphi|^2 dx}.$$

If we denote by φ_1, φ_2 the eigenfunctions corresponding to $\lambda_1(A)$ and $\lambda_2(A)$, then we have

$$\begin{aligned} &\varphi_1 \in H_0^1(A) \quad \text{and} \quad -\Delta\varphi_1 = \lambda_1(A)\varphi_1 \quad \text{in} \quad H_0^1(A),\\ &\varphi_2 \in H_0^1(A) \quad \text{and} \quad -\Delta\varphi_2 = \lambda_2(A)\varphi_2 \quad \text{in} \quad H_0^1(A). \end{aligned}$$

Generally, we shall use the notation $A_1 = \{\varphi_1 > 0\}$ and $A_2 = \{\varphi_2 \neq 0\}$, where we denote here by φ_1 and φ_2 the quasi-continuous representatives of the corresponding eigenfunctions. In order to establish the possible relations between A_1 and A_2 we shall give a lemma which is an extension of a classical result on open sets.

LEMMA 2.2. *If C_1, C_2 are two quasi-open sets with $cap(C_1 \cap C_2) = 0$ and $u \in H_0^1(C_1 \cup C_2)$, then $u_{|C_1} \in H_0^1(C_1)$ and $u_{|C_2} \in H_0^1(C_2)$.*

Proof. There exists a sequence of elements $u_n \in \mathcal{D}(C_1 \cup C_2)$ such that $u_n \to u$ strongly in $H_0^1(C_1 \cup C_2)$. (See [14] for the definition of $\mathcal{D}(C_1 \cup C_2)$.) Therefore it suffices to consider only elements of $\mathcal{D}(C_1 \cup C_2)$ since $u_{n|C_1} \to u_{|C_1}$ and $u_{n|C_2} \to u_{|C_2}$. Following Lemma 2.4 of [14], there exists a sequence of functions $g_k \to u$ strongly in $H_0^1(C_1 \cup C_2)$ and $g_k = g_k^1 + g_k^2$ where $g_k^1 \in H_0^1(C_1)$ and $g_k^2 \in H_0^1(C_2)$ since $\{C_1, C_2\}$ is a quasi covering of $C_1 \cup C_2$. Since $cap(C_1 \cap C_2) = 0$ the functions g_k^1 and g_k^2 are orthogonal in $L^2(B)$ and in $H_0^1(B)$; this implies that the sequences $\{g_k^1\}_k, \{g_k^2\}_k$ are bounded in both spaces. For subsequences still denoted with the same index we get $g_k^1 \rightharpoonup u^1$ weakly in $H_0^1(C_1)$ and $g_k^2 \rightharpoonup u^2$ weakly in $H_0^1(C_2)$. From the strong L^2 convergence we have $u^1 = u_{|C_1}$ and $u^2 = u_{|C_2}$, which concludes the proof. □

We can formulate now the following lemma.

LEMMA 2.3. *Let A be a quasi-open set such that $\lambda_1(A) < \lambda_2(A)$. Then the fine interior of A_1 is finely connected and there are two possibilities: either $A_2 \subseteq A_1$ or $cap(A_1 \cap A_2) = 0$ for a convenient second eigenfunction φ_2.*

Proof. If A is open the result is immediate. If A is quasi open, the proof is similar and based on the previous lemma and the following assertion (see [12]): any positive superharmonic function on a finely open and connected set is either strictly positive or equal to zero. Particularly, this will be the case of the first eigenfunction.

Indeed, if A_1 is not finely connected (we denoted here by A_1 its fine interior), then it can be decomposed in a union of disjoint finely connected components $\{C_i\}_{i\in I}$ and, since $\varphi_{1|C_i} \in H_0^1(C_i) \subseteq H_0^1(A)$, we have that

$$\forall i \in I \qquad \frac{\int_{C_i} |\nabla \varphi_{1|C_i}|^2 dx}{\int_{C_i} |\varphi_{1|C_i}|^2 dx} = \lambda_1(A).$$

Thus, if I contains at least two indices this would mean that $\lambda_1(A)$ is at least double since we have two independent eigenfunctions (defined by the restriction of φ_1 on each set). Therefore A_1 has only one finely connected component.

Suppose now that $cap(A_1 \cap A_2) \neq 0$. Decomposing $A_2 = \cup_{i\in I} C_i'$, C_i' being finely connected, then for any component for which $cap(A_1 \cap C_i') \neq 0$ we have $C_i' \subseteq A_1$; otherwise $C_i' \cup A_1$ would be finely connected and φ_1 could not vanish on $C_i' \setminus A_1$. Thus the finely connected components of A_2 are of two types, $C_i' \subseteq A_1$ and $cap(C_j' \cap A_1) = 0$. In this case we can see that $\varphi_{2|\cup C_i'}$ and $\varphi_{2|\cup C_j'}$ are both orthogonal to φ_1 and they are still second eigenfunctions. Then A_2 can be chosen as $\cup C_i'$ or $\cup C_j'$. □

In order to introduce the γ-convergence for a sequence $\{A_n\}_{n\in N}$ in $\mathcal{A}_c(B)$ we recall the Mosco conditions:

(M_1) $\forall \varphi \in H_0^1(A)$, $\exists \varphi_n \in H_0^1(A_n)$, such that $\varphi_n \to \varphi$ strongly in $H_0^1(B)$.

(M_2) $\forall \varphi_{n_k} \in H_0^1(A_{n_k})$, with $\varphi_{n_k} \rightharpoonup \varphi$ weakly in $H_0^1(B)$, we have $\varphi \in H_0^1(A)$.

It is said that A_n γ-converges to A if M_1 and M_2 hold simultaneously (see, for instance, [8]). It is said that A_n weakly γ-converges to A if $A = \{w > 0\}$ and $w_n \rightharpoonup w$ weakly in $H_0^1(B)$, where w_n are the solutions of

$$\begin{cases} -\Delta w_n = 1, \\ w_n \in H_0^1(A_n) \end{cases}$$

extended by zero on $B \setminus A_n$. It is known that the weak γ-convergence is sequentially compact on $\mathcal{A}_c(B)$ (see [5]).

An important tool that we shall use in the proof of Steps 1 and 2 is the continuous Steiner symmetrization (CSS) (see Brock [3], [4]). It is well known that the CSS of an open set keeps constant its measure and decreases the first Dirichlet eigenvalue of the Laplacian. Here, we are interested in the behavior of the second eigenvalue with respect to the CSS, which derives from the Mosco behavior of the associated Sobolev space (see [6]). Let's recall from [6] some useful results. Consider a measurable set A and a hyperplane $\mathcal{H} \subseteq \mathbb{R}^N$. For $t \in [0,1]$ denote by A^t the Steiner symmetrization of A at time t in the orthogonal direction to $\mathcal{H}$.

PROPOSITION 2.1. *If A is open, the mapping $t \mapsto A^t$ is γ-continuous from the left and M_1 continuous from the right.*

For a quasi-open set $A \in \mathcal{A}_c(B)$, the set A^t is defined in the following way: Consider a decreasing sequence of open sets $\{A_n\}_{n\in N}$ with $cap(A_n \setminus A) \to 0$ and $A \subseteq A_n \subseteq B$. For any $t \in [0,1]$ the set A_n^t is well defined and by monotonicity we define $A_n^t \supseteq A_{n+1}^t$. Then $\{A_n^t\}_{n\in N}$ is γ-convergent and

$$A^t = \gamma - \lim_{n\to\infty} A_n^t.$$

PROPOSITION 2.2. *If A is quasi-open, the mapping $t \mapsto A^t$ is M_2 continuous from the left and M_1 continuous from the right.*

In terms of eigenvalues, Proposition 2.2 gives the following corollary.

COROLLARY 2.1. *For every $A \in \mathcal{A}_c(B)$ and every positive integer i, the mappings $t \mapsto \lambda_i(A^t)$ are lower-semicontinuous on the left and upper-semicontinuous on the right.*

This result will permit us to prove that the second eigenvalue has a Darboux-like property, that is, if $t_1 < t_2$ and $\lambda_2(A^{t_1}) < \lambda_2(A^{t_2})$, then $\forall \lambda^* \in [\lambda_2(A^{t_1}), \lambda_2(A^{t_2})]$ there exists $t^* \in [t_1, t_2]$ such that $\lambda_2(A^{t*}) = \lambda^*$.

In the proof of Steps 1 and 2, the idea is to make a sequence of CSS to transform a given quasi-open set $A \in \mathcal{A}_c(B)$ into a ball. Here, one can see that the choice of B is important since if $A \in \mathcal{A}_c(B)$ for any hyperplane $\mathcal{H}$ we still have $A^t \in \mathcal{A}_c(B)$.

For a compact set $K \in \mathbb{R}^N$ it is known the existence of a sequence of hyperplanes $\{\mathcal{H}_n\}_{n\in N}$ such that, denoting $K_0 = K$ and K_n the symmetrization of K_{n-1} with respect to $\mathcal{H}_n$, we have $m(K_n \Delta K^{\#}) \to 0$ (generally by $C^{\#}$ we denote the closed ball of measure $m(C)$; see [2]). If the convergence in measure is replaced by the Hausdorff convergence, a similar type of result can be found in Federer (see [11]).

For quasi-open sets we can formulate the following.

PROPOSITION 2.3. *Let $A \in \mathcal{A}_c(B)$. There exists a sequence of Steiner symmetrizations of A, denoted $\{A_n\}_{n\in N}$, such that $m(A_n \setminus A^{\#}) \to 0$ for $n \to \infty$.*

Proof. This result appears to be weaker than the similar one for compact sets, but nevertheless it is still sufficient for the proof of Step 2.

Suppose first that A is open. Consider $K_1 \subset\subset A$ such that $m(A \setminus K_1) \leq \epsilon_1/2$. We make a finite number of Steiner symmetrizations given by the result of [2] for K_1 such that

$$m\Big((K_1)_{n_1} \Delta K_1^{\#}\Big) \leq \frac{\epsilon_1}{2}.$$

Then, by monotonicity,

$$m\Big(A_{n_1} \setminus A^{\#}\Big) \leq \frac{\epsilon_1}{2} + \frac{\epsilon_1}{2} = \epsilon_1.$$

Choosing now another set $K_2 \subset\subset A_{n_1}$ with $m(A_{n_1} \setminus K_2) \le \epsilon_2/2$ we continue the process and obtain

$$m\Big((K_2)_{n_2} \setminus K_2^{\#}\Big) \le \frac{\epsilon_2}{2},$$

and so on. Choosing a sequence $\epsilon_n \to 0$, we conclude the proof in the case of open sets.

If A is quasi-open, consider a sequence of open sets $\{C_r\}_{r\in N}$ such that

$$A \subseteq C_{r+1} \subseteq C_r \subseteq B$$

and $cap(C_r \setminus A) \to 0$. We apply the previous result for C_r and begin by making a finite number of symmetrizations to C_1 such that

$$m\Big((C_1)_{n_1} \setminus C_1^{\#}\Big) \le \epsilon_1.$$

Then $m(A_{n_1} \setminus C_1^{\#}) \le \epsilon_1$. Now making a finite number of symmetrizations for C_2 we get $m((C_2)_{n_2} \setminus C_2^{\#}) \le \epsilon_2$, and so on. Finally we get $m(A_n \setminus A^{\#}) \to 0$, since $m(C_n^{\#} \Delta A^{\#}) \to 0$. □

COROLLARY 2.2. *For every $A \in \mathcal{A}_c(B)$ there exists a sequence $\{A_n\}_{n\in N}$ of Steiner symmetrizations of A such that any weak γ-limit point of $\{A_n\}_{n\in N}$ is contained in $A^{\#}$.*

Proof. Indeed, from the previous proposition we have $m(A_n \setminus A^{\#}) \to 0$. If U is the weak γ-limit of $\{A_{n_k}\}$, then $w_{n_k} \rightharpoonup w$ weakly in $H_0^1(B)$ and $U = \{w > 0\}$. Since $m(A_n \setminus A^{\#}) \to 0$ and $w_{n_k} \to w$ in $L^2(B)$, we get $w = 0$ a.e. on $\mathbb{R}^N \setminus A^{\#}$, hence $w \in H_0^1(A^{\#})$, which means $U \subseteq A^{\#}$. □

COROLLARY 2.3. *For the sequence $\{A_n\}_{n\in N}$ given by Proposition 2.3 we have*

$$\lambda_2(A^{\#}) \le \liminf_{n\to\infty} \lambda_2(A_n).$$

3. Proof of the results. We proceed now with the proofs of Lemma 2.1 and of Steps 1 and 2. It is convenient to indicate by d_1 the half-line $\{ts(B_1) :\ t \ge 1\}$ and by d_2 the half-line $\{ts(B_2) :\ t \ge 1\} = \{(x,x) \in \mathbb{R}^2 :\ x \ge \lambda_1(B_2)\}$.

Proof of Lemma 2.1. Consider $(x,y) \in \bar{E}$. There exists a sequence of sets $\{A_n\}_{n\in N} \subseteq \mathcal{A}_c(B)$ such that $s(A_n) \to (x,y)$. From the weak γ-compactness of the set $\mathcal{A}_c(B)$ for a subsequence still denoted with the same indices, we can write $A_n \to A$ in the weak γ-sense. Then $A \in \mathcal{A}_c(B)$ and, since the eigenvalues of the Laplacian are weakly γ-lower-semicontinuous, we get $\lambda_1(A) \le \liminf_{n\to\infty} \lambda_1(A_n) = x$ and $\lambda_2(A) \le \liminf_{n\to\infty} \lambda_2(A_n) = y$. From the vertical convexity of E, the vertical segment joining $s(A)$ with the half-line d_1 is contained in E. If $y < \lambda_2(B_1)$, we can find the point $(\lambda_1(A), y)$ on this segment, and now using the horizontal convexity, the segment joining $(\lambda_1(A), y)$ to d_2 is in E. But this segment contains the point (x,y) since $\lambda_1(A) \le x$.

If $y \ge \lambda_2(B_1)$, then the horizontal convexity gives directly $(x,y) \in E$. □

We give now a general result which establishes the existence of a γ-continuous and decreasing homotopy between two quasi-open sets $A_1 \subseteq A_0$.

PROPOSITION 3.1. *Let $A_1 \subseteq A_0$ be two quasi-open sets. There exists a decreasing homotopy from A_0 to A_1 which is γ-continuous; namely, there exists a γ-continuous mapping $h : [0,1] \to \mathcal{A}(\mathbb{R}^N)$ such that for $t_1 < t_2$, $h(t_1) \supseteq h(t_2)$, and $h(0) = A_0$, $h(1) = A_1$.*

Proof. Denote by K a closed cube containing A_0. We shall divide the cube in 2^N equal closed cubes $K_0, \dots, K_{2^N-1}$; each cube K_i is analogously divided in 2^N closed cubes $K_{i0}, \dots, K_{i2^N-1}$, and so on. Then with each real number $t \in [0,1]$ written in the 2^N-basis by $0, \alpha_1, \alpha_2, \dots$ we associate the set

$$\Lambda_t = (A_0 \setminus F_t) \cup A_1,$$

where

$$F_t = \cup_{n=1}^{\infty} \cup_{i=0}^{\alpha_n - 1} K_{\alpha_1 \dots \alpha_{n-1} i}.$$

Remark first that Λ_t is quasi-open since F_t is quasi-closed. Indeed, let's denote by

$$F_{t,k} = \cup_{n=1}^{k} \cup_{i=0}^{\alpha_n - 1} K_{\alpha_1 \dots \alpha_{n-1} i}$$

the closed set consisting of the first k-blocks of F_t. Set also

$$\Lambda_{t,k} = (A_0 \setminus F_{t,k}) \cup A_1,$$

which is obviously quasi-open, and remark that

$$\cap_{k \geq 1} \Lambda_{t,k} = \Lambda_t.$$

Since $cap(\Lambda_{t,k} \setminus \Lambda_t) \to 0$ for $k \to \infty$ we get that Λ_t is quasi-open. Moreover, the mapping $t \to \Lambda_t$ is continuous in capacity. Indeed, fix $t \in [0,1]$ and consider $t_n \to t$. We have to distinguish two situations: either t has an infinite number of digits and is not finishing with $aa \dots aa \dots$, or t has a finite number of digits or finishes with $aa \dots aa \dots$ (a being the greatest digit in the basis 2^N, namely $a = 2^N - 1$). In the first case, if $t_n \to t$, then $\forall k \in \mathbb{N}\ \exists n_k \in \mathbb{N}$ such that $\forall n \geq n_k$, t_n, and t have the same first k digits. In this case

$$cap(A^t \Delta A^{t_n}) \leq cap(K_{\alpha_1 \dots \alpha_k}),$$

and we derive the continuity in capacity.

If t has a finite number of digits $t = 0.\alpha_1 \alpha_2 \dots \alpha_k$, then t written as

$$t = 0.\alpha_1 \alpha_2 \dots \alpha_k 0000 \dots$$

is identified with

$$t' = 0.\alpha_1 \alpha_2 \dots (\alpha_k - 1) aaaa \dots .$$

The difference between A^t and $A^{t'}$ is a point, hence of zero capacity. Consider $t_n \to t$. If $t_n \geq t$, the first k digits of t_n and t coincide for $n \geq n_k$. If $t_n < t$, then the first k digits of t_n and t' coincide for $n \geq n_k$ and the conclusion follows.

Since the mapping $t \mapsto \Lambda_t$ is obviously decreasing and γ-continuous, to achieve the proof it is enough to take

$$h(t) = \Lambda_t. \qquad \square$$

Proof of Step 1. Let $A \in \mathcal{A}_c(B)$. If there exists a subset A^* of A, such that $\lambda_1(A^*) = \lambda_2(A^*) = \lambda_2(A)$, then one can directly apply Proposition 3.1, and Step 1 is proved since there exists a decreasing and γ-continuous homotopy from A to A^*. Since

$\lambda_2(A) = \lambda_2(A^*)$, then by monotonicity $\lambda_2(\Lambda_t) = \lambda_2(A)$. Since the first eigenvalue is γ-continuous, for each $\alpha \in [\lambda_1(A), \lambda_2(A)]$ there exists some t_α such that $\lambda_1(\Lambda_{t_\alpha}) = \alpha$.

Let's prove now the existence of the set A^*. If $\lambda_1(A) = \lambda_2(A)$, there is nothing to prove. Hence we suppose $\lambda_1(A) < \lambda_2(A)$, and from what we have seen in the previous section we have two possibilities: either $A_2 = \{\varphi_2 \neq 0\} \subseteq \{\varphi_1 > 0\} = A_1$ (and in this case $A^* = A_2$) or $cap(A_1 \cap A_2) = 0$. Denoting by P_t the open half-space

$$P_t = \{(x_1, \dots, x_N) \in \mathbb{R}^N | t < x_1\},$$

there exists some $t_0 \in \mathbb{R}$ such that $\lambda_1(A_1 \cap P_{t_0}) = \lambda_2(A)$. Choosing

$$A^* = (A_1 \cap P_{t_0}) \cup A_2,$$

the conclusion follows. □

Proof of Step 2. Let's consider $A \in \mathcal{A}_c(B)$ and denote by $A^\#$ the closed ball of measure $m(A)$. The idea of proving the convexity in the vertical direction is to make a sequence of continuous Steiner symmetrizations transforming A such that $m(A_n \setminus A^\#) \to 0$ and to use the horizontal convexity. If $\lambda_2(A) \geq \lambda_2(A^\#)$, then the segment

$$\left\{ (\lambda_1(A), \gamma) \ : \quad \text{for} \quad \gamma \in \left[\lambda_2(A), \lambda_1(A) \frac{\lambda_2(B_1)}{\lambda_1(B_1)} \right] \right\}$$

is contained in E. This follows immediately from the convexity on the horizontal lines since all the half-line supported by d_1 and having B_1 as extreme point is in E.

So let's suppose $\lambda_2(A) < \lambda_2(A^\#)$ and choose $\alpha \in]\lambda_2(A), \lambda_2(A^\#)[$. We intend to prove that $(\lambda_1(A), \alpha) \in E$. We use Corollary 2.3 and we find a sequence of Steiner symmetrizations $\{A_n\}_{n \in N}$ such that $\liminf_{n \to \infty} \lambda_2(A_n) \geq \lambda_2(A^\#)$. In order to underline the evolution of the set A "toward" the ball, we say that the CSS from A_n to A_{n+1} is parametrized by $t \in [n, n+1]$ by simple translation of the interval $[0, 1]$. In this way we can define the set A^t for every $t \geq 0$, and the set A_n can also be written as A^n.

On the other hand, $\lambda_1(A_n) \leq \lambda_1(A)$. There exists some $n_0 \in N$ such that $\lambda_2(A_{n_0}) \geq \alpha$ and denote

$$t^* = \sup \Big\{ t \in [0, n_0] \ : \quad \lambda_2(A^t) \leq \alpha \Big\}.$$

From the upper-semicontinuity on the right we have $\lambda_2(A^{t^*}) \geq \alpha$ and from the lower-semicontinuity on the left we get $\lambda_2(A^{t^*}) \leq \alpha$ which give $\lambda_2(A^{t^*}) = \alpha$.

Using now the convexity on the horizontal lines, the segment joining $(\lambda_1(A^{t^*}), \alpha)$ with $(\alpha, \alpha) \in d_2$ is contained in E. However, since $\lambda_1(A^{t^*}) \leq \lambda_1(A)$, the point $(\lambda_1(A), \alpha)$ belongs to E. □

4. Further remarks. There are many other questions which can be raised. Is the set E convex? Is E still closed if the pair (λ_1, λ_2) is replaced by (λ_i, λ_j) or, more generally, if we consider the set

$$E_K = \Big\{ (\lambda_i(A))_{i \in K} : \quad A \in \mathcal{A}_c(B) \Big\},$$

where K is a given subset of positive integers? Are the sets A on the boundary of E smooth? If the ball B is replaced by an open set Ω, is the set $s(\mathcal{A}_c(\Omega))$ still closed? Or if the Laplace operator is replaced by

$$L = -\partial_i(a_{ij}\partial_j) + b_i\partial_i + c \ ?$$

Let's give a proposition which yields some information on the boundary of the set E. For a set $A \in \mathcal{A}_c(B)$ we shall denote

$$\mathcal{R}_{\inf}(A) = \{(x,y) \in \mathbb{R}^2 : x \le \lambda_1(A), y \le \lambda_2(A)\}.$$

PROPOSITION 4.1. *For every $A \in \mathcal{A}_c(B)$, there exists a set $\tilde{A} \in \mathcal{A}_c(B)$ which is either finely connected or two balls, such that $s(\tilde{A}) \in \mathcal{R}_{\inf}(A)$.*

Proof. Fix $A \in \mathcal{A}_c(B)$ and set $A_1 = \{\varphi_1 > 0\}$ and $A_2 = \{\varphi_2 \neq 0\}$. If $\lambda_1(A) = \lambda_2(A)$ the assertion is obvious since $s(A) \in d_2$. If $\lambda_1(A) < \lambda_2(A)$ there are two possibilities: if $A_2 \subseteq A_1$, then A_1 is finely connected and $s(A_1) \in \mathcal{R}_{\inf}(A)$; if $cap(A_2 \cap A_1) = 0$, we make the Schwarz rearrangements of A_1 and A_2 into the disjoint balls C_1 and C_2 and we get $s(C_1 \cup C_2) \in \mathcal{R}_{\inf}(A)$ and $C_1 \cup C_2 \in \mathcal{A}_c(B)$. □

This proposition means that any A whose $s(A)$ is on $\partial E \setminus (d_1 \cup d_2)$ is either finely connected or two balls. An open question is to study if these sets are simply connected.

To conclude, we remark that the result of this paper can be applied to prove the existence of solutions for some classes of shape optimization problems for which the shape functional is not monotone with respect with the set inclusion (see [8]). We can consider problems of the form

$$\min\Big\{\Phi(\lambda_1(A), \lambda_2(A)) : \quad A \in \mathcal{A}_c(B)\Big\}, \tag{4.1}$$

where $\Phi : E \to \overline{\mathbb{R}}$ is lower semicontinuous and goes to $+\infty$ at infinity. This is the case, for instance, of

$$\Phi(x,y) = (x-\alpha)^2 + (y-\beta)^2,$$

where (α, β) is any element in $\mathbb{R}^2$. Therefore by Theorem 2.1 the minimization problem (4.1) admits at least a solution.

Acknowledgments. The authors want to thank the Department of Mathematics of the University of Pisa, where this work was initiated, for the warm hospitality.

EXACT SOLUTIONS TO DEGENERATE CONSERVATION LAWS*

ROBIN YOUNG†

Abstract. We consider large variation solutions to systems of conservation laws, for which the Glimm–Lax theory of decay breaks down. We identify and isolate geometric nonlinearities which are distinct from the usual genuine nonlinearity of each wave field by describing some degenerate systems in which all nonlinearity is geometric and is manifested in the coupling of the different wave families. We then construct exact explicit solutions to these equations and examine properties of these solutions. We find a wide variety of phenomena, depending on the form of the nonlinearity. The most striking of these include strong nonlinear instability of solutions and nontrivial time-periodic solutions. We also find solutions which grow or decay exponentially and oscillating solutions which correspond to rotations by an irrational angle. These oscillating, periodic, and exponential solutions can all appear in a single system with small initial data, demonstrating sensitive dependence on initial conditions.

Key words. conservation laws, linear degeneracy, periodic solutions

1. Introduction.

We are interested in periodic solutions to systems of nonlinear conservation laws in one space dimension,

$$u_t + f(u)_x = 0,$$

where $u \in \mathbf{R}^N$ for $N \geq 3$. For these systems, the Glimm–Lax theory of decay breaks down due to geometric nonlinearities which are not present for systems of two equations.

The nonlinearity of the flux f is usually manifested as genuine nonlinearity: nonlinear wave-speeds lead to expansion of rarefactions and eventual shock formation. The appearance of shocks means that we must consider weak solutions, which are solutions of the integral conservation law

$$\int_0^\infty \int_{-\infty}^\infty (\psi_t u + \psi_x f(u))\, dx\, dt + \int_{-\infty}^\infty \psi(x,0) u_0(x)\, dx = 0,$$

where ψ is a smooth test function. After a shock forms, it interacts with rarefactions, leading to decay and loss of information. This is a stabilizing and time-irreversible effect. If the system consists of two equations, or if the total variation of the data is small, then this is the dominant phenomenon. Here the Glimm–Lax decay theory holds, and solutions decay like $1/t$ [2].

If the system consists of three or more equations and the total variation of the data is large, then a new nonlinear phenomenon emerges. This is a geometric nonlinear effect due to the coupling of the different wave families. This coupling is a

manifestation of the failure of the wave curves to form a coordinate system. The wave curves are composite rarefaction and shock curves and are approximately the integral curves of the eigenvector fields. The failure of these to commute is quantified by the Lie brackets

$$[r^j, r^k] = r^j \cdot \nabla r^k - r^k \cdot \nabla r^j = \sum \Lambda_i^{jk} r^i$$

of the eigenvectors. The *interaction coefficient* Λ_i^{jk} defined here represents the i-wave generated by the interaction of a j- and a k-wave, to leading order. These effects are quadratic and indeed yield all quadratic effects of interactions: when corrections for these terms are included, all errors become cubic [12].

These quadratic effects accumulate and become dominant when the total variation is large. Heuristically, this can be seen by counting waves and interactions: if all waves have strength $O(\epsilon)$ and there are approximately $O(V/\epsilon)$ waves, then there are $O(V^2/\epsilon^2)$ interactions. Thus the cumulative effect due to quadratic terms in interactions is $O(V^2)$, which does not vanish as the amplitude $\epsilon \to 0$. On the other hand, if these quadratic terms are not present, as is the case for two equations, the cumulative error becomes $O(V^2\epsilon)$ and can be controlled.

In this paper, we wish to investigate the consequences of these quadratic effects for solutions of large total variation, and in particular for data which is periodic. We study strictly hyperbolic systems in which there are no genuinely nonlinear fields, so that all the nonlinearity comes from the coupling of eigenvector fields. Specifically, we will assume that all wave-speeds, which are eigenvalues of the flux matrix $Df(u)$, are constant in a neighborhood. This assumption leads to simplifications which allow us to construct a class of exact weak solutions to the conservation law and study properties of these solutions. Since all fields are linearly degenerate, there are no shocks or rarefactions present, and all waves in our solutions are contact discontinuities. Moreover, the wave curves are then exactly the integrals of the eigenvector fields. We remark that in systems of two equations, the assumption of constant wave-speeds necessarily implies that the system be linear, as can be seen by rewriting the system in Riemann invariant coordinates.

The method of weakly nonlinear geometric optics has been used to predict a variety of new phenomena [9, 5, 6]. These include the strong nonlinear instability of solutions as well as the indefinite delay of shock formation. It is apparent from these simplified equations that the values of the interaction coefficients considered together are crucial to knowledge of the behavior of solutions. Thus we expect different behaviors depending on how many of these coefficients vanish and the positivity or negativity of others.

Not all of the interaction coefficients play an important role: with a careful normalization of the eigenvectors, all coefficients Λ_i^{ik} can be made to vanish at the origin [11]. Since the Lie bracket is antisymmetric, we thus need know only the values Λ_i^{jk}, where $j > k$ and both are distinct from i. Thus, for three equations we need only consider the triple $\{\Lambda_1, \Lambda_2, \Lambda_3\}$, where $\Lambda_1 = \Lambda_1^{32}$, etc. We shall see that different values for these triples lead to quite different qualitative behavior of solutions. This indicates that in order to make statements about the pointwise behavior of solutions, it will be necessary to make some assumptions about the systems and about the interaction coefficients in particular. Clearly, these assumptions should be based on physical principles.

The class of weak solutions which we study can be easily constructed due to the simplicity of the systems. We shall work with a 3×3 system for which the (constant)

wave-speeds are -1, 0, and 1. Our initial data is a piecewise constant with jumps at regular intervals. All waves are then contact discontinuities which propagate with speeds 0 or ± 1, and a repeating resonant interaction pattern develops. All interactions in this wave pattern are triple interactions and occur at the points of a regular lattice. In order to completely describe the solution, we need only keep track of the wave strengths. The problem thus reduces to a discrete problem, namely that of finding the wave strengths, which change only at points of interaction on the lattice.

We now describe some of the effects that appear for these systems depending on the choice of triples of interaction coefficients. The worst case of instability occurs when all three coefficients have the same sign: in this case a triple interaction may cause growth in each wave entering the interaction. Indeed, we shall set up a pattern in which each interaction has this magnification property, which has the effect of causing unbounded growth in amplitude of the solution in finite time. In this case, the wave strengths satisfy a Riccati-type difference equation,

$$\epsilon_{k+1} \approx \epsilon_k + \epsilon_k^2,$$

solutions of which explode in finite time. In fact, since our conservation law is completely linearly degenerate, the solutions can be scaled in such a way that the growth rate can be accurately controlled. We remark that the amplitudes do not actually become infinite, before which our methods break down, but become large relative to the initial amplitude. As a corollary, we find solutions which decay by a similar mechanism. We emphasize that this decay is not due to genuine nonlinearity and is the result of a different phenomenon. Indeed, all the solutions we consider are time-reversible, as may be expected from the lack of genuine nonlinearity.

This instability of solutions is the same phenomenon as that predicted by weakly nonlinear geometric optics in [5, 6]. However, here we are able to give an explicit description of the growth mechanism, as well as give accurate estimates of the rate of growth and the time of existence of solutions with sharp bounds on the total variation.

When considering realistic systems, physical assumptions lead to extra conditions on the interaction coefficients; the effects of various assumptions are described in [11]. The existence of a convex entropy function for which an additional conservation law can be derived is one such assumption and is equivalent to the assumption that we have a symmetric hyperbolic system. This symmetry leads to algebraic constraints on the interaction coefficients; for three equations, this is the relation

$$\frac{\Lambda_1}{\lambda_3 - \lambda_2} + \frac{\Lambda_2}{\lambda_3 - \lambda_1} + \frac{\Lambda_3}{\lambda_2 - \lambda_1} = 0.$$

In particular, this relation precludes the strong instability mentioned above, which requires that the Λ_i's have the same sign.

Another common constraint is the existence of a Riemann coordinate. This is a function whose gradient is a left eigenvector of the system, and implies that the corresponding interaction coefficient vanishes. This family can be thought of as being weakly decoupled from the system, in that it is not affected (to quadratic order) by the presence of waves of other families. We construct a class of degenerate systems of conservation laws with a 2-Riemann coordinateand study the variety of behaviors that can occur for these systems. In this class of examples, we are able to integrate the eigenvectors exactly and thus obtain exact formulæ for Riemann solutions and wave interactions. This in turn leads to a detailed description of the solutions constructed earlier. We remark that these solutions need not be small, and indeed the integrals of eigenvectors are globally defined.

Depending on the fluxes in these systems and on the initial data, our solutions exhibit qualitative differences. For a system with coefficients $\{1, 0, 1\}$, we find that we again obtain growing or decaying solutions, although in this case the rate of growth or decay is exponential. In particular, there is no finite time blowup in amplitude. Indeed, together with Blake Temple, the author has recently shown that solutions to systems of three conservation laws with one Riemann coordinate grow at most exponentially, so that this example shows that those results are sharp [10].

In [10], a new length scale was identified for solutions with large variation, which also determines the rate of growth of solutions. More precisely, a norm $\|u\|'_d$ is introduced which measures the variation of the solution over intervals of fixed size d, and the ratio $\rho = \|u\|'_d/d$ is seen to bound the rate of growth of the solutions. Indeed, the theorem in [10] states that if the sup-norm of the initial data is small, then solutions satisfy the bound

$$TV\big(u(\cdot,t)\big) \leq TV\big(u_0\big)\ \exp(k\rho t) + O(\epsilon),$$

where $k = 8\Lambda\lambda$ depends only on the flux. In this paper, we show that this bound is sharp; our solution satisfies

$$TV\big(u(\cdot,t)\big) \geq TV\big(u_0\big)\ \exp(\rho t),$$

so that the ratio again determines the rate of growth of solutions (we have $\Lambda = \lambda = 1$). Thus control of the d-norm leads to control of the time of existence of solutions.

When the coefficients are $\{1, 0, -1\}$, the behavior is very different. We may view this system as a completely linearly degenerate model for the equations of gas dynamics, as these are the coefficients for the Lagrange equations. In this case, we find that there are time-periodic solutions, as well as solutions which correspond to irrational rotations of the circle. These results indicate that there may be periodic solutions to the Euler equations, as well as other solutions which do not decay.

Although periodic solutions to 2×2 systems have been previously constructed [3, 4], those mechanisms for periodicity are different from the present case; indeed, those systems are genuinely nonlinear with trivial mode-mode interactions. In that case, the change in wave-speeds is exploited to piece together solutions consisting entirely of centered rarefaction waves.

These different types of solutions are not mutually exclusive; indeed, there are flux functions for which there are solutions which have exponential growth and decay, as well as periodic and irrationally oscillating solutions. The exact solutions can be described by a family of linear maps G_β of $\mathbf{R}^2$ parameterized by a number β, and with determinant 1. The dynamics of these maps are then determined by the eigenvalues, which may be real, corresponding to growth and decay, or complex, corresponding to rotations. As β varies, the map G_β may bifurcate, leading to the different phenomena we have described. Depending on the chosen flux, all of these phenomena may occur for one system. We remark that all of the initial data leading to these solutions may be chosen arbitrarily small in any periodic p-norm, showing sensitive dependence on initial data.

The paper is arranged as follows: in section 2, we recall the solution to the Riemann problem and the basic interaction estimate. In section 3, we construct the exact solutions which are to be analyzed. In section 4, we consider a specific system and find strongly unstable solutions. In section 5, we consider systems with a Riemann coordinateand describe in detail the exact solutions constructed above. Finally, in the appendix we show that the system used in section 4 exists; we were not able to write this system down explicitly.

2. Preliminaries. We briefly recall the construction of solutions to the Riemann problemand interactions of nonlinear waves. The Riemann problem is the problem obtained by taking Cauchy data consisting of two constant states, say u_L and u_R. It is solved by resolving the solution into constant states separated by N nonlinear waves, each wave corresponding to an eigenvalue of the flux matrix Df. These waves are either rarefactions or shocks when the field is genuinely nonlinear, $r^k \cdot \nabla \lambda_k > 0$, or contact discontinuities for a linearly degenerate field.

A k-rarefaction is a continuous expanding fan for which the state u_ϵ propagates along the characteristic given by $x/t = \lambda_k(u_\epsilon)$. Here the state u_ϵ lies on the integral curve of the eigenvector field $r^k(u)$ through the left state, that is, on the solution curve

$$\frac{du}{d\epsilon} = r^k(u), \quad \text{with} \quad u(0) = u_L.$$

This makes sense only if the wave-speed $\lambda_k(u_\epsilon)$ increases along this integral curve, which only accounts for positive values of the parameter ϵ. In order to pick up the other states to which u_L may be connected, we must consider discontinuous weak solutions, i.e., shocks. By considering the weak (integral) formulation of the conservation law, it is easy to see that discontinuities must satisfy the Rankine–Hugoniot relation

$$s(u_R - u_L) = f(u_R) - f(u_L),$$

where u_R and s are the right state and shock speed, respectively. This relation defines one curve in each family, tangent to the corresponding rarefaction curve. The entropy condition, which determines physically relevant shocks, selects that part of the curve along which λ_k decreases from left to right.

Combining the admissible parts of the shock and rarefaction curves, we complete the locus of states which can be connected to u_L by a (weak) nonlinear k-wave. It is well known that for a genuinely nonlinear field, the composite k-wave curve through a point is C^2 with discontinuous third derivative. The strength of a wave is given by the (signed) difference of a parameter which is increasing along the wave curve.

If the kth field is linearly degenerate, that is $r^k \cdot \nabla \lambda_k \equiv 0$ in a neighborhood, then the shock and rarefaction curves coincide, and the nonlinear wave is a jump discontinuity which propagates with speed $\lambda_k(u_L)$. In this case, the wave curve is exactly the integral curve of r^k and is as smooth as the flux. In particular, in our examples for which all eigenvalues are constant, and hence linearly degenerate, all nonlinear waves resolving Riemann problems are contacts which propagate with the constant speed λ_k. There are thus no nonlinear effects due to the expansion and compression of waves; rather, *all nonlinear effects come from interactions of waves of different families.*

Once we have constructed the wave curves, the general Riemann problem is solved by centering N nonlinear waves, one for each family, at the origin, and finding the correct intermediate states so that the extreme left and right states are those of the Riemann data. Note that we are using strict hyperbolicity here: since all waves are centered at the origin, these must appear in increasing order of wave-speed from left to right. This gives us a natural ordering of wave curves which must be taken into account when resolving wave interactions. Also, because the eigenvectors form a basis, the implicit function theorem yields a unique decomposition into waves and constant states [7].

The Riemann interaction problem is formulated as follows: suppose that the Riemann problems with data $\langle u_L, u_M\rangle$ and $\langle u_M, u_R\rangle$ are resolved into waves of known strength $\{\alpha_i\}$ and $\{\beta_i\}$, respectively. If the resulting Riemann problem with data $\langle u_L, u_R\rangle$ is resolved into waves $\{\epsilon_i\}$, the interaction problem is to estimate the wave strengths ϵ_i in terms of α_i and β_i. This problem has a satisfactory answer for weak waves, namely

$$\epsilon_i = \alpha_i + \beta_i + \sum_{j>k} \Lambda_i^{jk} \alpha_j \beta_k + O(SD). \tag{2.1}$$

Here the coefficients Λ_i^{jk} are the interaction coefficients determined by the Lie bracket, $[r^j, r^k] = \sum \Lambda_i^{jk} r^i$, while S is equivalent to the L^∞-norm of the solution and D is a quadratic error term measuring the error due to interactions [1, 12]. For our purposes, it is enough to note that $D = O(S^2)$, where S can be taken to be the maximum strength of interacting waves.

To interpret the estimate geometrically, we observe that the leading order effect of the interaction of a pair of waves from different families is simply the transposition of these waves, which is achieved by integrating along the wave curves in reversed order. The quadratic correction due to this reversal is then given by the Lie bracket of the vector fields, which yields the quadratic term in the estimate. We get the interaction estimate by including one bracket for each pair of transposed waves, namely α_j and β_k, where $j > k$, and separating these corrections into wave components. We remark that this interaction effect is determined by the geometry of the eigenvector fields, and is not related to the genuine nonlinearity of any individual wave family.

The interaction problem cannot in general be interpreted (locally) as the solution to a Riemann problem, except when all the pairwise interactions occur simultaneously. This can happen whenever a number of waves converge at a single point of space-time. In this case, a similar interaction estimate holds, and the continuation of the solution beyond the point of interaction is indeed an exact solution to the conservation law. In our examples, all waves are jump discontinuities, so we shall consider three waves in decreasing families converging to a single point, as in Figure 2.1, and refer to this as a triple interaction. Suppose the incident waves are γ, β, and α and these are, respectively, 3-, 2-, and 1-waves. After interaction, we resolve the solution into waves in increasing order of wave-speed. If waves are labeled as in the figure, then the outgoing wave strengths are given by

$$\begin{aligned} \alpha' &= \alpha + \Lambda_1^{32} \gamma\beta + O(S^3), \\ \beta' &= \beta + \Lambda_2^{31} \gamma\alpha + O(S^3), \quad \text{and} \\ \gamma' &= \gamma + \Lambda_3^{21} \beta\alpha + O(S^3), \end{aligned} \tag{2.2}$$

where $S = \max\{\alpha, \beta, \gamma\}$. Here we have normalized the eigenvectors so that all other interaction coefficients vanish at a point (see [11]). Figure 2.1 illustrates the interaction in two spaces, first by tracing the paths of the contacts ("characteristics") in space-time, and also by showing the constant states lying on the integral curves of eigenvectors in state space. Note that the characteristics are exactly as for a linear system, but the intermediate states are changing nonlinearly.

We shall use these triple interactions to build up periodic resonant solutions to our degenerate conservation laws, in which all interactions are of this type. These solutions will be piecewise constant, and we shall analyze them in some detail.

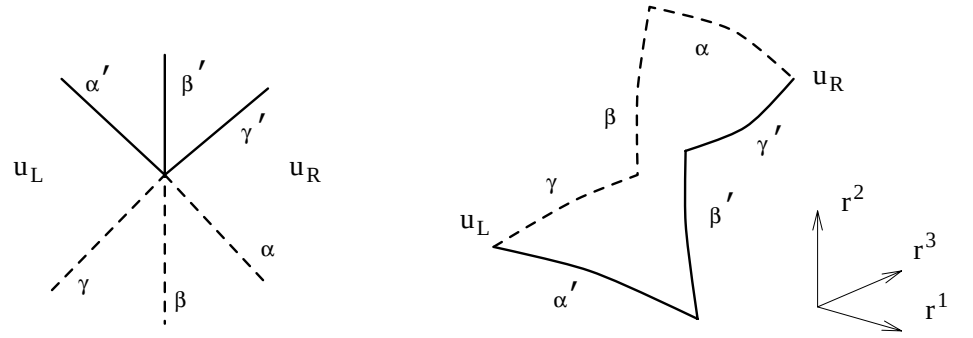

FIG. 2.1. *A triple interaction.*

3. Exact periodic solutions. We now construct exact solutions for certain Cauchy data for our degenerate conservation laws. Recall that these systems have constant wave-speeds, and the nonlinearity comes from the geometry of the eigenvector fields. We shall construct periodic solutions, although it is clear that these can be restricted to compact support. Our building blocks are the triple interactions constructed above.

In order to generate a repeating resonance pattern, we require that the ratio of differences of wave-speeds, $\frac{\lambda_3-\lambda_2}{\lambda_2-\lambda_1}$, be rational [5], and we shall take this to be unity. For simplicity, we assume that the eigenvalues of the conservation law are identically -1, 0, and 1. Thus all waves are contact discontinuities and propagate along straight line "characteristics" of slope 0 or ± 1 in space-time, and we set $\Delta t = \Delta x$. This is analogous to solutions of linear systems, for which singularities propagate along characteristics, $x = 0$ or $x = \pm t$, respectively. In our case, the singularities are jump discontinuities which, although they propagate at fixed speed, change strength after passing through each interaction.

We now set up a periodic resonant wave pattern. This is a local construction and all waves will be assumed to be weak, so that the solution is restricted to a neighborhood of state space, and Riemann problems can be solved. We start with a localized configuration of waves and extend this by periodicity. Referring to Figure 3.1, we choose a reference state, which we label 1. We then find state 2 on the 2-wave curve of 1, so that this 2-wave has strength δ_1, say. Choose another state 5, and connect this to state 6 by another 2-wave, say of strength δ_2. We now let Δx be a small positive number: our Cauchy data will be constant on intervals of length Δx. Indeed, we define the Cauchy data to take on the states 1, 2, 5, and 6 on consecutive intervals of length Δx, respectively, and extend this data periodically. We shall choose the states 1 and 5 and strengths δ_1 and δ_2 to obtain different types of behavior.

Once the Cauchy data has been prescribed, we can determine the solution as follows. Up to time $t = \Delta x$, we simply resolve the Riemann problems into constant states separated by waves, which by degeneracy are all contacts. By our choice of states, the Riemann problems $\langle 1, 2\rangle$ and $\langle 5, 6\rangle$ are resolved into a single 2-wave. Resolving the Riemann problems $\langle 6, 1\rangle$ and $\langle 2, 5\rangle$, we get three waves emanating from each point $x = 2k\Delta x$. At time $t = \Delta x$ triple interactions occur, and the solution is of the same form as the Cauchy data. Continuing in this way, a resonant periodic wave interaction pattern is formed. Figure 3.1 illustrates the resonance pattern by showing the characteristics and a projection of state space, where we integrate along the wave curves. We have labeled the constant states to show how they change, and

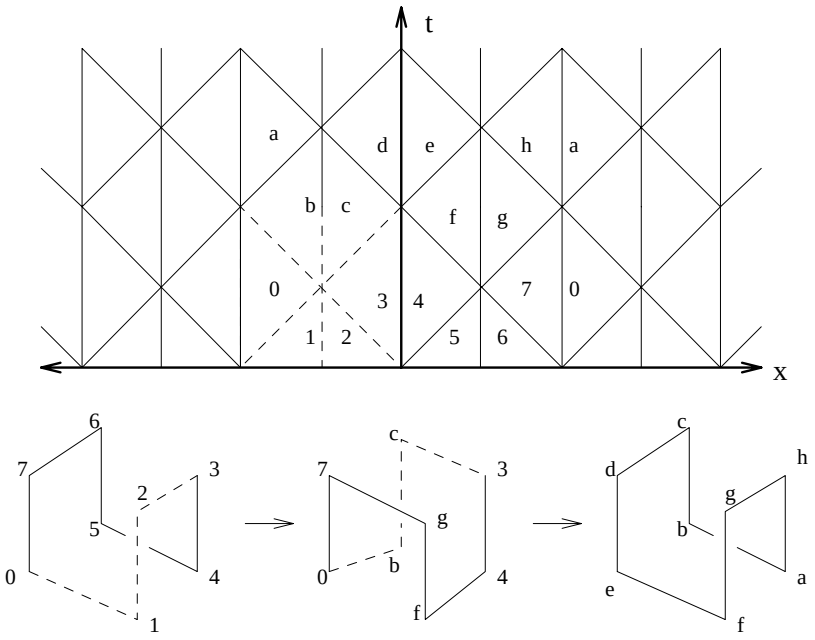

FIG. 3.1. *A resonant interaction pattern.*

the dashed lines show a single interaction.

It is clear that all interactions of waves are triple interactions, occurring exactly at the points $(x,t) = (k\Delta x, j\Delta x)$, for $j+k$ even. Moreover, the solution at each interaction time $t = j\Delta x$ is of the same form as the Cauchy data, and the wave pattern is repeated, although the intermediate states and wave strengths themselves change in time. This is to be contrasted with the usual behavior for nonlinear conservation laws, in which the wave patterns change and may become very complicated due to the expansion of rarefactions and formation of shock waves. We emphasize that we have constructed an exact solution to the degenerate conservation law and not an approximation.

At each fixed time, our solution is space-periodic with period $4\Delta x$ and takes on 8 (or 4) constant values. If these intermediate values are known, it is easy to write down the L^p-norm of the solution (as a $4\Delta x$-periodic function.) For example, labeling the states as in Figure 3.1, at time $t = 2\Delta x$ we have

$$\|u\|_p^p = |b|^p + |c|^p + |f|^p + |g|^p.$$

Similarly, by knowing the wave strengths at any time, we can estimate the L^p-norm of the solution. In fact, since the wave pattern and period of the solution do not change, a knowledge of the minimum and maximum wave strengths (the sup-norm) will allow us to deduce estimates for the other L^p-norms as well.

Temple and Young have introduced a norm, called the d-norm, which measures the local variation of the solution [10]. This norm is defined for fixed (small) d as

$$\|u\|_d' = \sup_a TV_{[a,a+d]}(u(\cdot)) \tag{3.1}$$

to be the maximum variation of a function $u(x)$ over intervals of length d. Clearly, if we set $d = 4\Delta x$, then for our examples the d-norm is just the total variation per

period of the solution. In [10], it was shown that the size of d and the corresponding value of the d-norm are critical in determining the growth of solutions.

Thus far we have set up the wave pattern without specifying the interaction coefficients or the exact Cauchy data. We shall choose the states 1 and 5 and wave strengths δ_1 and δ_2 to give different effects depending on the values of the interaction coefficients. We are primarily interested in two cases: all three interaction coefficients are positive and one coefficient vanishes.

Before proceeding with specific choices, we recall the interaction estimate (2.3):

$$\begin{aligned} \alpha' &= \alpha + \Lambda_1 \gamma\beta + O(S^3), \\ \beta' &= \beta + \Lambda_2 \gamma\alpha + O(S^3), \quad \text{and} \\ \gamma' &= \gamma + \Lambda_3 \beta\alpha + O(S^3), \end{aligned} \tag{3.2}$$

where α, β, and γ are 1-, 2-, and 3-waves, respectively, and $'$ refers to the outgoing wave, as in Figure 2.1. Assuming that $\Lambda_i \geq 0$ and ignoring cubic effects, we see that growth can occur in each family with a nonzero coefficient if the product $\alpha\beta\gamma$ is positive. That is, each outgoing wave will be of the same sign but have greater strength than the corresponding incident wave. We shall say that magnification occurs in the interaction. This product is positive if all three incident waves are positive, or if exactly two are negative. This gives us room to set up the resonance pattern so that each triple interaction yields magnification of wave strengths. Similarly, if the product $\alpha\beta\gamma$ is negative, then after interaction each wave is weaker but of the same sign, and we find resonant solutions which decay.

A careful check using Figure 3.1 reveals that if consecutive waves in each family alternate in sign, then the sign of the product of incident waves is the same at each lattice point. For example, with the notation of Figure 3.1, we take the 1-waves 23 and 67 to have opposite sign, and similarly the 2-waves 12, 34, 56, and 70 to alternate in sign, etc. Here 23 refers to the 1-wave between constant states 2 and 3, and so on. If this product of incident waves is positive we expect growth, and if it is negative we expect decay. In the following sections we shall examine the behavior of solutions for some specific values for the interaction coefficients.

4. Instability of solutions. We now make specific assumptions on the interaction coefficients and study the consequences of these assumptions. In this section we shall suppose that the interaction coefficients are all positive. The existence of a flux function which has constant wave-speeds and these coefficients is established in the appendix. The system can thus be described as follows: the wave-speeds are given by -1, 0, and 1, and the interaction coefficients Λ_i are positive. The following theorem holds for this system.

THEOREM 1. *There are solutions with initial data of bounded variation and arbitrarily small L^p-norm which grow arbitrarily in any finite time. More precisely, given positive constants τ, ϵ, and $K \gg 1$, there are some $t_e < \tau$ and weak solutions $u(x,t)$ defined for $t \in [0, t_e)$ satisfying*

$$\begin{gathered} \|u(\cdot,0)\|_\infty < \epsilon, \quad \|u(\cdot,0)\|_1 < \epsilon, \quad \textit{and} \\ 8/\Lambda_m \leq TV\big(u(\cdot,0)\big) \leq 10/\Lambda_m, \end{gathered}$$

where $0 < \Lambda_m < \min \Lambda_i$, while for some $t_b < t_e$, we have

$$\begin{aligned} \|u(\cdot,t_b)\|_\infty &> K \|u(\cdot,0)\|_\infty, \\ \|u(\cdot,t_b)\|_1 &> K \|u(\cdot,0)\|_1, \quad \textit{and} \\ TV\big(u(\cdot,t_b)\big) &> K\, TV\big(u(\cdot,0)\big). \end{aligned}$$

Similar statements hold for all other L^p-norms.

We note that although these solutions are highly unstable, they do not necessarily become infinite in finite time. That is, although the amplitudes can be arbitrarily magnified, our construction breaks down before solutions become infinite. Indeed, once the amplitude becomes large, the global structure of the wave curves becomes important and the Riemann problem is not necessarily well-posed. This is the same type of behavior seen in the constructions of geometric optics [5, 6].

It is remarkable that instability occurs for data which has total variation larger than $8/\Lambda_m$, when contrasted with the result of the author that solutions are stable as long as the initial total variation is less than $1/3\Lambda_M$, where $\Lambda_M = \max \Lambda_i$, and the sup-norm is small enough [12]. In this case, although a resonating pattern can be established and rapid growth may occur, there are not enough waves initially to preserve the resonance, so that the different families will separate, halting the growth process. In general, once the families separate, genuine nonlinearity takes over and solutions decay [8].

This behavior is clarified by the growth rate of solutions established in [10] and its relation to the d-norm defined there. The d-norm, given by (3.1), measures the "local" variation of the solution and provides a scale for the short-range effects of interactions, which do not cause growth in the solution. However, when the total variation is large, the long-range effects of interactions (namely those accumulating over multiple d-intervals) may dominate and cause instability. In our examples, the growth rate is a constant multiple of the ratio $\|u_0\|'_d/d$, which in turn determines the time of existence without explicit reference to the total variation and sup-norm. In particular, if we let $d \to 0$ faster than $\|u_0\|'_d$, then our solutions explode in arbitrarily short time. The following corollaries are evident from the proof of the theorem.

COROLLARY 1. *The d-norm determines the rate of growth and time of existence of solutions. That is, the amplitude $\eta(t)$ of the solution satisfies*

$$\eta(t) \geq \frac{\eta(0)}{1 - k\,\rho\,t},$$

where ρ is the ratio $\|u\|'_d/d$ and k is a constant depending only on the flux.

COROLLARY 2. *There are space-periodic solutions with arbitrarily small L^p-norms (measured over one period) which grow arbitrarily in finite time. That is, there are periodic solutions $u(x,t)$ satisfying*

$$\|u(\cdot,0)\|_p < \epsilon, \quad \textit{while} \quad \|u(\cdot,t_b)\|_p > K\,\|u(\cdot,0)\|_p$$

for each $1 \leq p \leq \infty$.

COROLLARY 3. *There are periodic solutions (to the same conservation law) defined for all time, which decay at the rate $1/(1+Kt)$, for any given constant K.*

Proof. We shall use the exact solutions constructed above and analyze changes in wave strengths after carefully choosing the initial data. In the notation of Figure 2.1, recall that we have the freedom to choose constant states which we labeled 1 and 5, and initial 2-wave strengths δ_1 and δ_2. We shall make these choices so that all waves have approximately the same strength, while waves in each family have alternating signs. Let $\eta > 0$ denote a small number to be determined, and fix state 1 inside a neighborhood of the origin. Let $\delta_1 = \delta_2 = \eta$, which determines states 2 and 6, once 5 has been chosen. We choose state 5 by setting the strengths of the waves 23, 34, and 45 to be η, $-\eta$ and $-\eta$, respectively. This fixes our initial data and implies that the waves 67, 70, and 01 have *approximate* strength $-\eta$, $-\eta$, and η, respectively. We now

find $\eta_0 \approx \eta$ so that all initial wave strengths are between η_0 and $5\eta_0/4$, where η_0 will be chosen later.

With these choices, we see that the product of strengths of waves entering each interaction of the lattice is positive, so that magnification occurs at each interaction. In order to see that unstable growth occurs, we now define η_q to be the minimum strength of all waves at time $t = 2q\,\Delta x+$, that is, after each wave has passed through at least q interactions. Then, assuming that the waves remain weak, for some positive $\Lambda' < \Lambda_m < \Lambda_i$, we have

$$\eta_{q+1} \geq \eta_q + \Lambda_m\,\eta_q^2 \geq \eta_q + \Lambda'\,\eta_q\,\eta_{q+1} \tag{4.1}$$

for each q. This is true by the interaction estimate (2.3), where we observe that the error $O(SD)$ is cubic in η_q, so that it is dominated by the quadratic part. Now, by comparison with the exact solution of the corresponding difference equation, we get

$$\eta_n \geq \frac{\eta_0}{1 - \Lambda'\,\eta_0\,n} \quad \text{for each } n. \tag{4.2}$$

We obtain solutions with compact support simply by cutting off the wave pattern for some $|x| > L$. Note that if we do this, resonance occurs in a region containing the set $\mathcal{S} = \{(x,t) | -L+t < x < L-t\}$. Our calculation of η_n remains valid as long as η_n measures the strength of waves contained in $\mathcal{S}$. We now estimate the norms for the solution by waves contained in $\mathcal{S}$. The sup-norm is measured by the maximum wave strength, and the total variation is measured by the sum of (absolute) wave strengths. We thus have

$$\begin{aligned} \eta_0 \leq \|u(.,0)\|_\infty \leq 5\eta_0/4 \quad &\text{and} \\ 4L\,\eta_0/\Delta x \leq TV\big(u(.,0)\big) \leq 5L\,\eta_0/\Delta x, & \end{aligned}$$

as there are four waves per interval of length $2\Delta x$. The L^1-norm is given by

$$\|u(.,0)\|_1 = 2L/4\Delta x \cdot \int_0^{4\Delta x} |u| \;\sim \eta_0 L.$$

Similarly, the norms at time $t < L$ satisfy

$$\begin{aligned} \|u(.,t)\|_\infty &\geq \eta_n, \\ TV\big(u(.,t)\big) &\geq 4(L-t)\,\eta_n/\Delta x, \quad \text{and} \\ \|u(.,t)\|_1 &\geq (L-t)\,\eta_n, \end{aligned}$$

where n is given by $n = [t/2\Delta x]$. Now, given any constant K, instability in all norms will follow as long as $\eta_n > \eta_0 \cdot 5KL/4(L-t)$, or by (4.2), if

$$\frac{1}{1 - \Lambda'\,\eta_0\,n} > \frac{5\,K\,L}{4\,(L-\tau)}, \tag{4.3}$$

while also $t < \tau < L$. Therefore we take $L > \tau$ and choose η_0 and Δx such that the relations

$$\Lambda'\,\eta_0\,n \to 1 \quad \text{and} \quad t \to \tau$$

are equivalent. This can be accomplished by defining $\rho = 2/\Lambda'\,\tau$ and setting $\eta_0 = \rho\,\Delta x$. We now choose Δx so small that (4.3) holds, while η_{n+2} remains small enough

that all estimates used above still hold. It is clear that the sup- and L^1-norms of the initial data can be made arbitrarily small, while the initial total variation is bounded below by $4L\rho > 8/\Lambda'$. Also, since the waves remain a fixed distance Δx apart while they grow in size, we have instability of the solution in all L^p-norms. Similar estimates hold for space-periodic solutions.

We can interpret our choice of the parameter ρ in terms of the d-norm as follows: with $d = 4\Delta x$ set to one period, we see that the d-norm satisfies

$$8\eta_0 \leq \|u(.,0)\|'_d \leq 10\eta_0$$

or equivalently the ratio

$$2\rho \leq \frac{\|u(.,0)\|'_d}{d} \leq 2.5\rho.$$

That is, our choice of ρ is just our choice of the ratio $\|u\|'_d/d$, which in turn determines the growth rate of solutions. Indeed, we can rewrite (4.2) as

$$\eta_n \geq \frac{\eta_0}{1 - \Lambda'\rho t/2},$$

and Λ' is a constant depending only on the flux.

The proof of the third corollary proceeds as above, except that we change the sign of the waves in one of the families in the initial data, say setting 45 to η. This makes all triple interactions lead to decay, so that the estimates will be reversed. Indeed, if χ_i denotes the maximum absolute wave strength, then we will get $\chi_{q+1} \leq \chi_q - \bar{\Lambda}\chi_{q+1}\chi_q$ for $\bar{\Lambda} \geq \Lambda_M$, so that

$$\chi_n \geq \frac{\chi_0}{1 + \bar{\Lambda}\,\chi_0\,n}.$$

We can now scale the initial data by taking $\chi_0 = \rho\Delta x$ with $\rho = 2K/\bar{\Lambda}$. We omit the details. □

The growth and decay of solutions is analogous to that of solutions of the equation $y' = y^2$ depending on the sign of the initial data. The extra freedom in choosing the rate of growth or decay is a consequence of total linear degeneracy: we are able to move the contacts closer together so that oscillations are more rapid without changing the basic wave pattern. In a genuinely nonlinear system, increasing the rate of oscillations in a fixed interval just leads to faster decay in each family as shock and rarefactions collide at a higher rate. We control the growth rate by choosing the d-norm, which in turn measures the scaling $\eta_0 \sim \Delta x$.

5. Time-periodic solutions. In realistic systems, there are usually extra constraints placed on the system by physical principles. One of the most common of these is to assume the existence of a Riemann coordinate. For these systems, solutions are more stable than the examples given above, and Temple and Young have recently shown that growth of solutions to 3×3 systems with a single Riemann coordinate can be at most exponential [10]. In this section we show that this theorem is sharp in the absence of other assumptions. The variety of qualitative phenomena present even when there is a Riemann coordinate suggests that further assumptions need to be made in order to determine specific properties of solutions.

A Riemann coordinate for the kth field is a function ρ whose gradient is orthogonal to all other eigenvectors: $r^j \cdot \nabla\rho = 0$ for each $j \neq k$. The existence of a Riemann

coordinate implies that the corresponding wave family decouples from the system and is equivalent to the vanishing of one of the interaction coefficients. The definition implies that $\nabla\rho$ is a kth left eigenvector, which in turn allows for a trivial row of the matrix $A = Df$ in some coordinate system, corresponding to a dimension reduction.

We shall consider three systems, with different flux coefficients, solutions of which exhibit different qualitative behavior. For definiteness we suppose that we have a 2-Riemann coordinate. The flux functions and their respective triples of interaction coefficients are given by

$$f_1(u,v,w) = \begin{pmatrix} we^{2v} \\ 0 \\ ue^{-2v} \end{pmatrix} \quad \text{with coefficients} \quad \{1,0,-1\}, \tag{5.1}$$

$$f_2(u,v,w) = \begin{pmatrix} w+2uv \\ 0 \\ u(1-4v^2)-2vw \end{pmatrix} \quad \text{with} \quad \{1,0,1\}, \quad \text{and} \tag{5.2}$$

$$f_3(u,v,w) = \begin{pmatrix} uv+we^{v} \\ 0 \\ u(1-v^2)e^{-v}-vw \end{pmatrix} \quad \text{with} \quad \left\{1-\frac{v}{2}, 0, \frac{-v}{2}\right\}. \tag{5.3}$$

We have the following theorem.

THEOREM 2. *For the system with flux f_1, there are space-periodic solutions of period π_x which are periodic in time with period $\pi_t = n\pi_x$ for integers n. These solutions are not stable under perturbations of the initial data, and we also have oscillating solutions corresponding to rotation by an irrational angle.*

For the system with flux f_2, there are periodic solutions which grow exponentially in those families not associated to the Riemann coordinate. Similarly, there are also solutions which decay exponentially in these families.

For the system with flux f_3, there are solutions exhibiting all of the above behaviors. That is, depending on the initial data, the solution may be exponentially growing or decaying, be periodic, or may oscillate as an irrational rotation.

These phenomena are local, in that the initial data may be arbitrarily small in any (periodic) L^p-norm. The growth of decay can be measured in these L^p-norms, while the oscillating solutions remain on an ellipse.

We remark that as in the previous examples, the linear degeneracy gives us the freedom to choose the rates at which these solutions decay or grow in time. We expect that if one weakens the hypothesis of degeneracy, it is still possible to get exponential growth of the solution, albeit not with an arbitrary rate. The variety of behaviors obtained for these simple examples again demonstrates the necessity of knowing exactly what the interaction coefficients are in order to make general statements about properties of solutions to conservation laws. We shall see that because of the simplicity of our examples, we do not require the solutions to be small, and indeed the solutions are globally defined.

Our analysis of system (5.2) shows that the result of [10] on stability of solutions is sharp: that result says that for data with small sup-norm, the total variation grows at most exponentially:

$$TV\big(\mathbf{u}(\cdot,t)\big) \le TV\big(\mathbf{u}_0\big)\ \exp(k\delta t/d) + O(\epsilon),$$

where $k = 8\Lambda\lambda$ (Λ and λ are the interaction coefficient and CFL number); δ is the d-norm of the Riemann coordinate; and ϵ is the amplitude of the initial data. Note that for (5.2), we have $\Lambda = \lambda = 1$.

COROLLARY 4. *The d-norm determines the growth rate of solutions to* 3×3 *systems with one Riemann coordinate. That is, there is a solution of* (5.2) *whose total variation satisfies*

$$TV\big(u(\cdot,t)\big) \geq TV\big(u_0\big)\ \exp(\delta t/d),$$

where $\delta = \|v_0\|'_d$ *is the d-norm of the Riemann coordinate* v*. A similiar statement holds for* w*. Here the vector* $\mathbf{u}_0 = (u_0, v_0, w_0)$ *is the initial data, and this can be taken to have arbitrarily small sup-norm.*

Proof. The proof is an exact calculation of the wave strengths for the exact periodic solutions constructed earlier. We shall consider a general case, substituting in the specific fluxes at the end.

By inspection, we see that the matrix

$$A = \begin{pmatrix} \sigma & C_1 & \tau \\ 0 & \nu & 0 \\ \frac{1-\sigma^2}{\tau} & C_2 & -\sigma \end{pmatrix}$$

has eigenvalues -1, ν, and 1, and left eigenvector $(0,1,0)$ corresponding to ν, which we take to be zero. With σ and τ yet to be chosen, we find C_1 and C_2 so that the rows become gradients. We compute the eigenvectors directly and the interaction coefficients according to the definition $\Lambda_i^{jk} = l_i \cdot [r^j, r^k]$. We then choose the functions σ and τ so that these take on the desired values.

It suffices to take σ and τ to be functions of v alone and choose C_1 and C_2 so that the rows of A are curl-free. For convenience we define the 2×2 matrix

$$\hat{A}(v) = \begin{pmatrix} \sigma(v) & \tau(v) \\ \frac{1-\sigma(v)^2}{\tau(v)} & -\sigma(v) \end{pmatrix},$$

and we take

$$\begin{pmatrix} C_1 \\ C_2 \end{pmatrix} = \begin{pmatrix} \sigma & \tau \\ \frac{1-\sigma^2}{\tau} & -\sigma \end{pmatrix}' \begin{pmatrix} u \\ w \end{pmatrix} = \hat{A}'(v) \begin{pmatrix} u \\ w \end{pmatrix}. \tag{5.4}$$

The full eigensystem of A is given by

$$\begin{array}{lccc} \lambda & -1 & 0 & 1 \\ r & \begin{pmatrix} \tau \\ 0 \\ -1-\sigma \end{pmatrix} & \begin{pmatrix} a \\ 1 \\ b \end{pmatrix} & \begin{pmatrix} \tau \\ 0 \\ 1-\sigma \end{pmatrix} \\ l & (\frac{1-\sigma}{2\tau} \ .. \ \frac{-1}{2}) & (0\ 1\ 0) & (\frac{\sigma+1}{2\tau} \ .. \ \frac{1}{2}) \end{array},$$

where a and b satisfy

$$\hat{A} \begin{pmatrix} a \\ b \end{pmatrix} + \begin{pmatrix} C_1 \\ C_2 \end{pmatrix} = 0, \tag{5.5}$$

and so, since $\hat{A}^{-1} = \hat{A}$ and by (5.4),

$$\begin{pmatrix} a \\ b \end{pmatrix} = -\hat{A}^{-1} \begin{pmatrix} C_1 \\ C_2 \end{pmatrix} = -\hat{A}(v)\ \hat{A}'(v) \begin{pmatrix} u \\ w \end{pmatrix}. \tag{5.6}$$

For this class of systems, we can integrate the wave curves and describe Riemann solutions and interactions explicitly, and thus find exact algebraic expressions for the solutions constructed in section 3. Since σ and τ are functions of v only, and this is the 2-Riemann coordinate, the 1- and 3-wave curves through $\{u_0, v_0, w_0\}$ are simply straight lines. If we define

$$\hat{r}^+(v) = \begin{pmatrix} \tau(v) \\ 1-\sigma(v) \end{pmatrix} \quad \text{and} \quad \hat{r}^-(v) = \begin{pmatrix} \tau(v) \\ -1-\sigma(v) \end{pmatrix}$$

to be the eigenvectors of $\hat{A}$ corresponding to the eigenvalues ± 1, then we can describe the 1- and 3-wave curves by

$$\begin{pmatrix} u \\ w \end{pmatrix} = \begin{pmatrix} u_0 \\ w_0 \end{pmatrix} + \epsilon \hat{r}^{\pm}(v_0) \quad \text{and} \quad v = v_0,$$

respectively, where ϵ is the wave strength. The 2-wave curve is found by noticing that we can use v as dependent variable and rewriting the system $u' = a$, $w' = b$. According to (5.4) and (5.5), the 2-wave curve satisfies

$$\frac{d}{dv}\left[\hat{A}(v)\begin{pmatrix} u \\ w \end{pmatrix}\right] = 0,$$

so the wave curve is given by

$$\hat{A}(v)\begin{pmatrix} u \\ w \end{pmatrix} = \hat{A}(v_0)\begin{pmatrix} u_0 \\ w_0 \end{pmatrix}$$

with wave strength $\epsilon = v - v_0$.

We can now write the complete solution to the Riemann problem: if states $\{u_L, v_L, w_L\}$ and $\{u_R, v_R, w_R\}$ are connected by 1-, 2-, and 3-waves α', β', and γ' respectively, then the wave strengths are determined by

$$\hat{A}(v_L)\left\{\begin{pmatrix} u_L \\ w_L \end{pmatrix} + \alpha' \hat{r}^-(v_L)\right\} = \hat{A}(v_R)\left\{\begin{pmatrix} u_R \\ w_R \end{pmatrix} - \gamma' \hat{r}^+(v_R)\right\} \tag{5.7}$$

and $\beta' = v_R - v_L$. The same expression can be used to find the right state once we are given a left state and wave strengths. Similarly, if $\{u_L, v_L, w_L\}$ and $\{u_R, v_R, w_R\}$ are connected by 3-, 2-, and 1-waves γ, β, and α, respectively, and converging at a point as in Figure 2.1, we get the expression

$$\hat{A}(v_L)\left\{\begin{pmatrix} u_L \\ w_L \end{pmatrix} + \gamma \hat{r}^+(v_L)\right\} = \hat{A}(v_R)\left\{\begin{pmatrix} u_R \\ w_R \end{pmatrix} - \alpha \hat{r}^-(v_R)\right\}.$$

Combining these expressions, we can describe the triple interaction depicted in Figure 2.1 by solving

$$\alpha' \hat{r}^-(v_L) - \gamma' \hat{r}^+(v_R) = \alpha \hat{r}^-(v_R) - \gamma \hat{r}^+(v_L) \quad \text{and} \quad \beta' = \beta, \tag{5.8}$$

where $v_R = v_L + \beta$. We stress that this is an exact formula, and it is also global; that is, it holds for incident waves of arbitrary strength.

We can compute the interaction coefficients directly: clearly $r^0 \cdot \nabla r^{\pm} = r^{\pm\prime}$, and from (5.6) we get

$$\hat{r}^{\pm} \cdot \nabla_{\{u,w\}} \begin{pmatrix} a \\ b \end{pmatrix} = -\hat{A}\, \hat{A}'\, \hat{r}^{\pm}.$$

Using these facts we get

$$\Lambda_1 = \frac{\tau\sigma' - (\sigma-1)\tau'}{2\tau}, \quad \Lambda_2 = 0 \quad \text{and} \quad \Lambda_3 = \frac{\tau\sigma' - (\sigma+1)\tau'}{2\tau}.$$

If we now choose $\sigma(v) = 0$ and $\tau(v) = e^{2v}$, we get flux f_1, while if $\tau(v) = 1$ and $\sigma(v) = 2v$, we get f_2. Flux f_3 is obtained by taking $\sigma(v) = v$ and $\tau(v) = e^v$. The corresponding interaction coefficients are then as in (5.1)–(5.3).

We now construct periodic initial data for the resonant pattern used previously and examine the behavior of these solutions. We shall consider only the simplest cases, but because the calculations are exact, it should be possible to treat more general cases.

Referring to Figure 3.1 and using the notation described earlier, we choose our initial data as follows. Fix state 1 and numbers α, β, and γ, which will refer to 1-, 2-, and 3-waves, respectively. As before, we choose the wave strengths 12, 23, 34, 45, and 56, which determine states 2 through 6, and resolve the Riemann problem $\langle 6, 1\rangle$ to determine the remaining wave strengths. If we define strengths 12, 23, 34, 45, and 56 to be β, α, $-\beta$, $-\gamma$, and β, respectively, then by a direct calculation using (5.7), we see that strengths 67, 70, and 01 are given *exactly* by $-\alpha$, $-\beta$, and γ, respectively. Moreover, we have that $v_4 = v_5 = v_0 = v_1$ and $v_2 = v_3 = v_6 = v_7 = v_1 + \beta$, where v_i is the v-component of state i, and these values do not change in time. This is to be expected from the "decoupled" equation $v_t = 0$ corresponding to the Riemann coordinate.

As a consequence of these observations, we see that we can describe the solution fully for all time with a knowledge of v_1 and v_2 and the strengths of the 1- and 3-waves in the solution at each time. In other words, once state 1 and strength β have been chosen, all we need to describe the system fully is a knowledge of the 1- and 3-wave strengths (corresponding to α and β) at each time. We shall use (5.8) to describe these changing wave strengths and choose different values for α, β, and γ to find solutions with different properties.

To this end, we let α_k denote the strength of the 1-wave in the solution (with the same sign as $\alpha = \alpha_0$) for time $k\Delta x < t < (k+1)\Delta x$ and define γ_k similarly. Then a representative triple interaction at time $(2k+1)\Delta x$ has waves γ_{2k}, β, and α_{2k} entering and α_{2k+1}, β, and γ_{2k+1} leaving, so that according to (5.8), we have

$$\alpha_{2k+1}\hat{r}^-(v_1) - \gamma_{2k+1}\hat{r}^+(v_2) = \alpha_{2k}\hat{r}^-(v_2) - \gamma_{2k}\hat{r}^+(v_1).$$

On the other hand, an interaction at time $2k\Delta x$ has waves $\pm\gamma_{2k+1}$, $-\beta$, and $\mp\alpha_{2k+1}$ entering, so that in this case, we get

$$\alpha_{2k+2}\hat{r}^-(v_2) + \gamma_{2k+2}\hat{r}^+(v_1) = \alpha_{2k+1}\hat{r}^-(v_1) + \gamma_{2k+1}\hat{r}^+(v_2).$$

We express the foregoing in matrix form as follows. We define

$$M = \begin{pmatrix} \hat{r}_1^- & \hat{r}_2^+ \end{pmatrix}, \quad N = \begin{pmatrix} \hat{r}_2^- & \hat{r}_1^+ \end{pmatrix}, \quad \text{and} \quad S = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

where the vectors $\hat{r}_i = \hat{r}(v_i)$ are viewed as columns. We then rewrite the above as

$$M\,S \begin{pmatrix} \alpha_{2k+1} \\ \gamma_{2k+1} \end{pmatrix} = N\,S \begin{pmatrix} \alpha_{2k} \\ \gamma_{2k} \end{pmatrix} \quad \text{and} \quad N \begin{pmatrix} \alpha_{2k+2} \\ \gamma_{2k+2} \end{pmatrix} = M \begin{pmatrix} \alpha_{2k+1} \\ \gamma_{2k+1} \end{pmatrix}.$$

This in turn yields

$$\begin{pmatrix} \alpha_{2k+2} \\ \gamma_{2k+2} \end{pmatrix} = G(v_1, v_2) \begin{pmatrix} \alpha_{2k} \\ \gamma_{2k} \end{pmatrix},$$

where the matrix $G(v_1, v_2)$ is given by

$$G(v_1, v_2) = N^{-1}\, M\, S\, M^{-1}\, N\, S. \tag{5.9}$$

The wave strengths α_{2k} and γ_{2k} are now easily calculated, namely

$$\begin{pmatrix} \alpha_{2k} \\ \gamma_{2k} \end{pmatrix} = G(v_1, v_2)^k \begin{pmatrix} \alpha \\ \gamma \end{pmatrix},$$

and α_{2k+1} and γ_{2k+1} are found similarly.

In order to complete the description of our solution to the conservation law, we calculate the powers of the matrix G. By inspection, G has determinant 1, so we can find the eigenvalues of G by a knowledge of its trace. Indeed, if $tr(G) = 2\mu$, then the eigenvalues are $\mu \pm \sqrt{\mu^2 - 1}$. Thus if $|\mu| < 1$, these are complex (with modulus 1), corresponding to oscillations, while if $|\mu| > 1$, they are real, corresponding to growth and decay.

As we have seen, the 2-wave strength β does not change with time, and the behavior of the solution to the conservation law is given by knowledge of the wave strengths α_k and γ_k. This can be regarded as a discrete dynamical system determined by the 2-parameter family of linear maps $G(v_1, v_2)$. With this point of view, we can study the stability and bifurcation properties of G. This in turn leads to statements about the stability or lack thereof for solutions to the conservation law.

We now restrict ourselves to the fluxes specified earlier, and describe the solutions. First, for the flux f_1, we had $\sigma(v) = 0$ and $\tau(v) = e^{2v}$, and we set $v_2 = v_1 + \beta$, so that $\tau(v_2) = e^{2\beta}\tau(v_1)$. After substituting and manipulating, we get

$$G(v_1, v_2) = \begin{pmatrix} \mathrm{sech}\beta & e^{-\beta}\tanh\beta \\ -e^{\beta}\tanh\beta & \mathrm{sech}\beta \end{pmatrix}^2.$$

The (complex) eigenvalues of G are $(\mathrm{sech}\beta \pm i\tanh\beta)^2$, with corresponding eigenvector given by $(\mp i, e^{\beta})^T$. We can now write down the values of α_{2k} and γ_{2k} explicitly: if we define the complex constant C by

$$\begin{pmatrix} \alpha \\ \gamma \end{pmatrix} = C \begin{pmatrix} -i \\ e^{\beta} \end{pmatrix} + C^* \begin{pmatrix} i \\ e^{\beta} \end{pmatrix},$$

then we have

$$\begin{pmatrix} \alpha_{2k} \\ \gamma_{2k} \end{pmatrix} = C(\mathrm{sech}\beta + i\tanh\beta)^{2k} \begin{pmatrix} -i \\ e^{\beta} \end{pmatrix} + C^*(\mathrm{sech}\beta - i\tanh\beta)^{2k} \begin{pmatrix} i \\ e^{\beta} \end{pmatrix}.$$

Depending on our choice of initial 2-wave strength β, there are two possibilities. First, if the eigenvalues are nth roots of unity, so $\mathrm{sech}\beta = \cos\frac{m\pi}{n}$, then $\alpha_{2n} = \alpha$ and $\gamma_{2n} = \gamma$, so that our solutions are periodic in time with period $4n\Delta x$. (There is an extra sign change in the waves.) On the other hand, if the eigenvalues are not roots of unity, there is a continuous transfer of energy between the two wave families and oscillation of wave strengths, but solutions are not time-periodic. Here we view G as a skewed

rotation of the $\alpha - \gamma$ plane, and the orbit of G is dense in an ellipse containing the point (α, γ). In other words, the origin is a nonhyperbolic fixed point for the map G. In particular, the periodic solutions are not stable under perturbations of the 2-wave strength β.

We now consider solutions of the conservation law with flux f_2, for which we took $\tau(v) = 1$ and $\sigma(v) = 2v$. Again we have $v_2 - v_1 = \beta$, and substituting these values into (5.9), we get

$$G(v_1, v_2) = \frac{1}{1-\beta^2} \begin{pmatrix} 1+\beta^2 & 2\beta \\ 2\beta & 1+\beta^2 \end{pmatrix}.$$

The eigenvalues of G are $\frac{1-\beta}{1+\beta}$ and $\frac{1+\beta}{1-\beta}$, with corresponding eigenvectors $(1,-1)^T$ and $(1,1)^T$, respectively. Since these eigenvalues are real, we have one growing mode and one decaying mode. For definiteness, suppose that $0 < \beta < 1$. Then choosing $\alpha = \gamma$ initially is the pure growth mode, and we have

$$\alpha_{2k} = \gamma_{2k} = \left(\frac{1+\beta}{1-\beta}\right)^k \alpha, \tag{5.10}$$

so that the 1- and 3-components of the solution grow exponentially in time. The other extreme is when $\gamma = -\alpha$, in which case we get exponential decay in the first and third families. In general, there will be a combination of growth and decay, but there will be some growth in L^p-norms of the solution to the conservation law, if the projection of the vector $(\alpha, \gamma)^T$ onto the growing mode is nonzero. This indicates that these solutions are more stable under perturbations than those above. In the $\alpha - \gamma$ plane, the origin is a hyperbolic fixed point of the map G corresponding to a saddle.

Since (5.10) gives an exact expression for the waves α_{2k} and γ_{2k}, we can calculate all norms of the solutions directly. Since there is one jump in v of size β per Δx, we take $d = \Delta x$ and we have $\|v\|'_d = \beta = \rho \Delta x$, where, as in section 4, ρ is a scaling parameter which determines the growth rate. In particular, we have for $t = 2k\Delta x$,

$$\begin{aligned} TV\big(u(\cdot,t)\big) &= TV\big(u_0\big) \left(\frac{1+\beta}{1-\beta}\right)^k \\ &= TV\big(u_0\big) \left(\frac{1+\rho\Delta x}{1-\rho\Delta x}\right)^{t/2\Delta x} \\ &\geq TV\big(u_0\big) \exp(\rho t), \end{aligned}$$

since $\frac{1+y}{1-y} \geq e^{2y}$ for $y \leq 1$, which proves the corollary. Indeed, since $\frac{1+y}{1-y} = e^{2y} + O(y^3)$, we can make the growth as close to $e^{\rho t}$ as we like.

For the flux f_3, similar calculations follow. We shall not carry out the tedious details but rather describe the general situation. The matrix $G(v_1, v_2)$ is viewed as a linear map on the $\alpha - \gamma$ plane. It has determinant 1, and the diagonal entries are equal and are given by $\mu = \frac{1}{2}\mathrm{tr}(G)$. As we noted earlier, the eigenvalues η and $1/\eta$ of G, which determine the dynamics of the map, are complex (with unit length) if $\mu^2 < 1$, and real otherwise. For $\tau(v) > 0$, an equivalent description is the following: defining

$$\Sigma(v_1, v_2) = \big(\sigma(v_2)\tau(v_1) - \sigma(v_1)\tau(v_2)\big)^2 - \big(\tau(v_2) - \tau(v_1)\big)^2,$$

we have complex eigenvalues for $\Sigma < 0$ and real eigenvalues for $\Sigma > 0$. As above, complex eigenvalues correspond to oscillations without growth, while real eigenvalues

correspond to growth and decay. Thus, each time Σ changes sign, we get a bifurcation from one type of behavior to another. In particular, for the flux f_3, we have $\sigma(v) = v$ and $\tau(v) = e^v$. Now fixing $v_1 = 0$ and $v_2 = \beta$, we get $\Sigma = \beta^2 - (e^\beta - 1)^2 = -\beta^3 + O(\beta^4)$, which changes sign as β passes through 0. Thus, for $\beta < 0$ we get growth and decay, while for $\beta > 0$ we get oscillations and periodic solutions. □

We remark that in all of the above examples, we obtain less interesting periodic solutions as follows. Referring again to Figure 3.1, we choose the initial 2-waves 12 and 56 to vanish, while choosing 34 and 70 to be β and $-\beta$, respectively, and choosing the 1- and 3-wave strengths as above. Calculations similar to the above then show that the solutions with these data are indeed periodic with period $d = 4\Delta x$, irrespective of the flux which is used.

Since these solutions are exact and global, they do not depend on the size of the initial data, and we can again scale the parameter Δx and the initial wave strengths to change the quantitative behavior of solution to get different values of d and the d-norm. Thus the rate at which the solution grows or decays, or the period of the solution, can be set according to our needs. These simple examples indicate that there is a wide variety of nonlinear phenomena associated with these simple equations. The author and Blake Temple have recently shown that for general systems with one Riemann coordinate, if the sup-norm of the data is small enough, then there can be at most exponential growth in the solution, with growth rate depending on d [10]. The examples presented here show that this result is sharp in the absence of further assumptions on the flux.

Appendix. Construction of the flux. We now describe the systems of degenerate conservation laws which satisfy the conditions used in earlier sections. Recall that the conservation law is given by

$$u_t + f(u)_x = 0,$$

where $u \in \mathbf{R}^3$ and $f : \mathcal{U} \to \mathbf{R}^3$ is a smooth vector valued function in an open neighborhood $\mathcal{U} \subset \mathbf{R}^3$. The hyperbolic wave-speeds are given by the (constant) eigenvalues λ_i of the matrix $A(u) = Df_u$, and the corresponding wave curves are the integrals of the right eigenvectors $r^i(u)$. The local nonlinear interactions of waves of different families are determined by the Lie algebra of eigenvector fields, quantified by the interaction coefficients

$$\Lambda_i \equiv \Lambda_i^{jk} = l_i \cdot [r^j, r^k], \quad \text{where} \quad i \neq j > k \neq i,$$

evaluated at the single point $\tilde{u} \in \mathcal{U}$, which we take to be the origin.

Our task is thus to find a matrix $A(u)$ with constant (distinct) eigenvalues and whose eigenvectors are such that the coefficients Λ_i^{jk} take on specified values at the origin. In addition, the matrix $A(u)$ should be the gradient of some vector function defined in a neighborhood of the origin. When there was a Riemann coordinate, we wrote down the system in closed form; if there is no Riemann coordinate we are not able to do this.

The eigenvalues λ_i of A are the roots of the characteristic polynomial $P_A(\lambda) = \det(A - \lambda I)$ of $A = [A_{ij}]$. The condition that the eigenvalues of $A(u)$ be constant in a neighborhood is thus equivalent to the statement that $P_A(\lambda)$ does not depend on u. In addition, we require that the curl of each row vanishes, so that each row of A is the gradient of a scalar function.

We reformulate the problem as a system of PDEs for the components $A_{ij}(u)$ with independent variables u_k, as follows. We shall consider a Cauchy problem, where

we take the Cauchy surface to be the plane $u_1 = 0$, and describe changes in the components A_{ij} of A in the (time-like) direction of u_1.

Since the characteristic polynomial $P_A(\lambda)$ is to be constant in the neighborhood, differentiating (each coefficient) with respect to u_1 must give zero. This gives three nonlinear equations, namely one for each coefficient of $P_A(\lambda)$. Since we have nine dependent variables, we need six more equations. These are obtained using the requirement that the rows of A be gradients, or curl-free. This is the condition that

$$\partial A_{ij}/\partial u_k = \partial A_{ik}/\partial u_j, \tag{A.1}$$

which is a nontrivial restriction for each $j \neq k$. We wish to describe changes in the time-like direction u_1, so we take as the remaining equations those obtained by letting $k = 1$ and $j = 2$ or 3, while i varies from 1 to 3. Thus our full system of equations is given by

$$\begin{aligned} &\partial P_A(\lambda)/\partial u_1 = 0 \quad \text{and} \\ &\partial A_{ij}/\partial u_1 = \partial A_{i1}/\partial u_j. \end{aligned} \tag{A.2}$$

If we choose analytic initial data, the Cauchy–Kowalewski theorem implies the existence and uniqueness of a local solution to this system. It remains to choose initial data on a noncharacteristic surface in such a way that the solution matrix $A = [A_{ij}]$ satisfies our requirements.

We take the Cauchy surface to be the plane $u_1 = 0$ and choose data A^0 satisfying the above conditions on the plane. That is, A^0 should have constant eigenvalues, while equations (A.1) hold in the plane $u_1 = 0$, when u_2 and u_3 vary. Uniqueness of solutions then implies that since $P_A(\lambda)$ is constant on the plane $u_1 = 0$ and satisfies $P_A(\lambda)_{u_1} = 0$, it is constant everywhere. Similarly, differentiating the linear equations in (A.2) gives

$$\frac{\partial^2 A_{i2}}{\partial u_3 \partial u_1} = \frac{\partial^2 A_{i1}}{\partial u_3 \partial u_2} = \frac{\partial^2 A_{i3}}{\partial u_2 \partial u_1}$$

for each i. Thus, again by uniqueness, if the Cauchy data satisfies (A.1) with $j = 2$ and $k = 3$, then this is satisfied throughout the neighborhood, and $A(u)$ is indeed a gradient.

It remains to choose appropriate Cauchy data $A^0(u_2, u_3)$ and calculate the interaction coefficients. We shall choose the second and third columns of A^0 to satisfy (A.1) and then choose the first column so that we get the correct characteristic polynomial. The interaction coefficients are given in terms of the gradient DA of A by the formula

$$\Lambda_i^{jk} = \frac{\lambda_j - \lambda_k}{(\lambda_j - \lambda_i)(\lambda_k - \lambda_i)} l_i \cdot DA(r^j) \cdot r^k, \tag{A.3}$$

so we calculate DA at the origin [11]. This amounts to finding all partial derivatives of the A_{ij} at the origin. These are found from (A.2) as follows. The quantities $\partial A_{ij}/\partial u_k$ can be immediately calculated for all i and j and for $k = 2$ and 3. The derivatives $\partial A_{ik}/\partial u_1$, for $k = 2$ and 3, are then equated with $\partial A_{i1}/\partial u_k$. Finally, $\partial A_{i1}/\partial u_1$ are obtained implicitly from the equation $P_A(\lambda)_{u_1} = 0$, by substituting in the previously found values for $\partial A_{ik}/\partial u_1$.

We carry out the details, assuming that the eigenvalues are -1, ν, and 1. Given some function $\psi(u_2, u_3)$ to be chosen later, define the matrix

$$A^0(u_2, u_3) = \begin{pmatrix} \alpha & 1 & 0 \\ \beta & 0 & 1 \\ \gamma & \psi_{u_2} & \psi_{u_3} \end{pmatrix},$$

where we must solve for α, β, and γ as functions of u_2 and u_3 so that the correct characteristic polynomial is realized. The coefficients of $P_{A^0}(\lambda)$ are easily seen to be $\alpha + \psi_{u_3}$, $\beta + \psi_{u_2} - \alpha\psi_{u_3}$, and $\gamma - \alpha\psi_{u_2} - \beta\alpha\psi_{u_3}$, respectively. It is now clear what α, β, and γ should be as functions of u_2 and u_3 to ensure a given constant characteristic polynomial on the plane $u_1 = 0$. If we make the further assumption that the first partial derivatives of ψ vanish at the origin, then it is easy to calculate the eigenvectors there. Indeed, we have

$$A^0(0,0) = \begin{pmatrix} \alpha_0 & 1 & 0 \\ \beta_0 & 0 & 1 \\ \gamma_0 & 0 & 0 \end{pmatrix} = \begin{pmatrix} \nu & 1 & 0 \\ 1 & 0 & 1 \\ -\nu & 0 & 0 \end{pmatrix},$$

whose eigenvectors are easily calculated.

To calculate DA at the origin, we differentiate the characteristic polynomial and evaluate at the origin, to get the system of three equations

$$\begin{aligned} A_{11,z} + A_{22,z} + A_{33,z} &= 0, \\ \alpha_0(A_{22,z} + A_{33,z}) - A_{21,z} - \beta_0 A_{12,z} - \gamma_0 A_{13,z} - A_{32,z} &= 0, \quad \text{and} \\ \gamma_0(A_{12,z} + A_{23,z}) + A_{31,z} - \alpha_0 A_{32,z} - \beta_0 A_{33,z} &= 0. \end{aligned} \tag{A.4}$$

We now take the dummy variable z to be u_2 and u_3 to get the derivatives of A_{i1} with respect to these; use symmetry; and finally take z to be u_1 to get the $\partial A_{i1}/\partial u_1$. Denoting $\partial A_{ij}/\partial u_k$ by $A_{ij,k}$ and $\psi_{u_j u_k}$ by ψ_{jk}, using (A.4) with $z = u_2$ and u_3 together with symmetry, we find

$$\begin{aligned} A_{12,1} &= A_{11,2} = -\psi_{23}, \\ A_{13,1} &= A_{11,3} = -\psi_{33}, \\ A_{22,1} &= A_{21,2} = \nu\psi_{23} - \psi_{22}, \\ A_{23,1} &= A_{21,3} = \nu\psi_{33} - \psi_{23}, \\ A_{32,1} &= A_{31,2} = \nu\psi_{22} + \psi_{23}, \quad \text{and} \\ A_{33,1} &= A_{31,3} = \nu\psi_{23} + \psi_{33}. \end{aligned}$$

Finally, we substitute these values back into (A.4) with $z = u_1$ to get

$$\begin{aligned} A_{11,1} &= \psi_{22} - 2\nu\psi_{23} - \psi_{33}, \\ A_{21,1} &= 2\nu^2\psi_{23} - 2\nu\psi_{22}, \quad \text{and} \\ A_{31,1} &= \nu^2\psi_{22} + (1+\nu^2)\psi_{33}. \end{aligned}$$

This determines completely the total derivative $DA(0,0,0)$ of A at the origin, and allows us to calculate the interaction coefficients. Note that (A.4) with $z = u_1$ determines $A_{i1,1}$ at the origin which, together with the linear equations in (A.2), shows that the Cauchy surface $u_1 = 0$ is noncharacteristic.

The eigenvectors at the origin are

$$\begin{aligned} r^1 &= (1 \quad -1-\nu \quad \nu)^T, \\ r^2 &= (1 \quad 0 \quad 1)^T, \qquad\qquad \text{and} \\ r^3 &= (1 \quad 1-\nu \quad -\nu)^T, \end{aligned}$$

respectively, and we take $\psi(u_2, u_3)$ to be quadratic with second derivatives

$$\begin{aligned} \psi_{22} &= \frac{2}{1-\nu^2} \pm \frac{1}{2}\nu^2, \\ \psi_{23} &= \frac{-2\nu}{1-\nu^2} \pm \frac{1}{2}\nu, \quad \text{and} \\ \psi_{33} &= \frac{2}{1-\nu^2} \pm \frac{1}{2}. \end{aligned}$$

Substituting all of the above into (A.3), we calculate the coefficients to be $\{1, \pm 1, 1\}$. Thus we have found a matrix $A(u)$ that satisfies the necessary conditions and that has these interaction coefficients.

SCATTERING OF ELECTROMAGNETIC WAVES BY ROUGH INTERFACES AND INHOMOGENEOUS LAYERS*

SIMON N. CHANDLER-WILDE† AND BO ZHANG‡

Abstract. We consider a two-dimensional problem of scattering of a time-harmonic electromagnetic plane wave by an infinite inhomogeneous conducting or dielectric layer at the interface between semi-infinite homogeneous dielectric half-spaces. The magnetic permeability is assumed to be a fixed positive constant. The material properties of the media are characterized completely by an index of refraction, which is a bounded measurable function in the layer and takes positive constant values above and below the layer, corresponding to the homogeneous dielectric media. In this paper, we examine only the transverse magnetic (TM) polarization case. A radiation condition appropriate for scattering by infinite rough surfaces is introduced, a generalization of the Rayleigh expansion condition for diffraction gratings. With the help of the radiation condition the problem is reformulated as an equivalent mixed system of boundary and domain integral equations, consisting of second-kind integral equations over the layer and interfaces within the layer. Assumptions on the variation of the index of refraction in the layer are then imposed which prove to be sufficient, together with the radiation condition, to prove uniqueness of solution and nonexistence of guided wave modes. Recent, general results on the solvability of systems of second kind integral equations on unbounded domains establish existence of solution and continuous dependence in a weighted norm of the solution on the given data. The results obtained apply to the case of scattering by a rough interface between two dielectric media and to many other practical configurations.

1. Introduction.

Consider a time harmonic electromagnetic plane wave incident on a layer of some inhomogeneous, isotropic, conducting, or dielectric material in $\mathbf{R}^3$. The media, above and below the layer, consist of some homogeneous dielectric materials. Adopting Cartesian axes $0x_1x_2x_3$, we assume throughout that the material is invariant in the x_3 direction. Thus, in effect, the problem geometry is two-dimensional. Further, we assume that the magnetic permeability is a fixed positive constant. The material properties of the media are then characterized completely by an index of refraction, dependent on the permittivity and conductivity, which is assumed to be a bounded measurable function in the layer and takes positive constant values above and below the layer. The scattering problem is to study the electromagnetic field distributions.

In this paper we formulate first the scattering problem as a boundary value problem for the reduced wave equation (Helmholtz equation), using a radiation condition recently introduced for problems of scattering by infinite one-dimensional rough surfaces and interfaces [4, 5, 7, 8, 9], which is a generalization of the usual radiation condition used in the study of plane wave diffraction by one-dimensional periodic gratings (see, e.g., [23, 1, 2, 4, 19, 20, 25]). Next, in section 3, we derive a novel

integral equation formulation of the problem, as a system of coupled second-kind domain and boundary integral equations, over the layer and over interfaces within the layer, and establish that this formulation is equivalent to the formulation as a boundary value problem. The radiation condition imposed does not rule out guided waves, localized in the inhomogeneous layer, which are thus solutions of the homogeneous boundary value problem and the homogeneous integral equation formulation. From section 4 onward we make restrictions on the variation of the index of refraction in the layer. Under these restrictions we establish, in section 4, an a priori inequality satisfied by any solution. Using this inequality, a key lemma from [8], and extensions of arguments in [7, 31], uniqueness results and hence conditions for the nonexistence of guided wave modes are established in section 5. In section 6, existence of solution is established by employing a novel form of Fredholm alternative based on general results on the solvability of systems of integral equations on unbounded domains in [10].

The assumptions we impose on the index of refraction from section 4 onward are satisfied in many practical cases. In particular, the results obtained apply to the case of scattering by a rough interface between two dielectric media and apply to scattering by a homogeneous layer having rough interfaces, with the media above and below, provided that the wavenumbers in the layer (k^*), and in the media above (k_+) and below (k_-), satisfy either that $\Im k^* > 0$ or that $\max(k_-, k_+) > k^*$. For a precise statement of the cases covered see section 2. Our conclusion that no guided waves exist if $\max(k_-, k_+) > k^*$ or $\Im k^* > 0$ is in agreement with explicit analytical calculations of guided wave modes for the case of plane interfaces between the layer and the media [24].

Integral equation methods have been used widely in the theoretical and numerical study of wave scattering by finite obstacles or local inhomogeneities (see, e.g., [12, 13] and the references quoted there). More recently they have been employed to study scattering by periodic structures [11, 17, 19, 20, 22] and by a nonstratified local inhomogeneity in a stratified medium [30]. Integral equation formulations have also been used extensively in computations of wave scattering by infinite one- and two-dimensional rough surfaces and interfaces (see, e.g., [26, 14, 21, 29] and the references quoted there), but little attention appears to have been paid in the literature to their mathematical justification (a recent exception is [15]).

This present paper is intended, in part, as a contribution to the mathematical analysis of rough surface scattering problems and of the well-posedness of their formulation as integral equations. It is related, in terms of results and methods of argument, to recent studies of scattering of a wave incident from a homogeneous half-space onto an inhomogeneous impedance plane [5]; of electromagnetic waves by a one-dimensional perfectly conducting rough surface [6, 8]; of electromagnetic waves by an inhomogeneous conducting or dielectric layer on a perfectly conducting plate [7]; and of acoustic waves by an inhomogeneous layer on a rigid plate [31]. In particular, the present study is closest to this last paper [31] in that the existence proof depends on the same novel results on the solvability of systems of weakly singular second-kind integral equations on unbounded domains. However, the whole space problem considered here requires a substantially more elaborate uniqueness proof and integral equation formulation, related to the presence of transmitted as well as reflected waves, in contrast to the half-plane problems considered in [5, 6, 8, 7, 31]. Moreover, in these latter papers integral equation formulations using half-plane Green's functions appear natural: as proposed here, the formulation of the whole-space problem as a system of integral

equations in overlapping half-planes, using half-plane Green's functions, is surprising but proves powerful in establishing uniqueness and existence results.

This paper can also be viewed as a generalization of the results of Bonnet-Bendhia and Starling [3] and Strycharz [25], who study plane wave scattering by an inhomogeneous *periodic* layer. In fact, our uniqueness results derive in part from those of Bonnet-Bendhia and Starling [3] and Strycharz [25], and include some of their results for a periodic layer as special cases; however, note that our results are obtained without an a priori assumption of quasi periodicity of the scattered field. We note also that our existence arguments, based on integral equation methods, differ from the variational methods used in [3] and [25] which appear restricted to the periodic case. We further point out that while integral equation-based existence proofs are common (and more straightforward) in the periodic, diffraction grating case (e.g., [19, 11]), they usually fail for a discrete set of combinations of grating period and angle of incidence at which the integral equation formulation is undefined. Our results show that, at least in the two-dimensional case, this problem can be avoided by use of a half-plane rather than a whole-space Green's function in the integral equation formulation. A finite element method for the case of plane wave scattering by an inhomogeneous periodic layer is analyzed in [1].

We remark that aside from the theoretical use to which the formulation is put in this paper, we anticipate that the novel integral equation formulation we derive in section 3 may also be of value for numerical computation. We point out that the integral operators in our formulation are exclusively of convolution type or are products of convolution and multiplication operators so that, after discretization, the matrix vector multiplications required in an iterative solution scheme can be performed efficiently using the FFT (see [27, pp. 109–111] and [28]). We further point out that, even for the simple case of a single interface between two dielectric media, for which a boundary integral equation formulation on the interface is usual (avoiding domain integrals), a recently successful numerical algorithm involves imbedding the one-dimensional boundary curve in a two-dimensional grid so that FFT techniques can be applied [29].

We conclude this section by introducing some notations used throughout. For $h \in \mathbf{R}$, define $\Gamma_h = \{x = (x_1, x_2) \in \mathbf{R}^2 | x_2 = h\}$ and $U_h = \{x \in \mathbf{R}^2 | x_2 > h\}$. Set $E_h^H = U_h \backslash \overline{U}_H$ for $H > h$, and write U, Γ, and E_H for U_0, Γ_0, and E_0^H, respectively. Define $D_A = \{x \in \mathbf{R}^2 | \, |x_1| < A\}$, $A > 0$, and $\Gamma_h(A) = \Gamma_h \cap D_A$, $E_h^H(A) = E_h^H \cap D_A$. For $G \subset \mathbf{R}^2$ let $BC(G)$ denote the space of bounded continuous functions defined on G. For $v \in C^1(\mathbf{R}^2)$ denote by $\partial_j v$, $j = 1, 2$, the derivative $\partial v(x)/\partial x_j$. Finally, for $A > 0$, $x \in \mathbf{R}^2$, let $B_A(x) = \{y \in \mathbf{R}^2 | \, |y - x| < A\}$.

2. The scattering problem and radiation conditions. Let us assume that $\mathbf{R}^3$ is filled with an inhomogeneous, isotropic, conducting, or dielectric medium of electric permittivity $\epsilon > 0$, magnetic permeability $\mu > 0$, and electric conductivity $\sigma \geq 0$. Suppose that the medium is nonmagnetic, i.e., the magnetic permeability μ is a fixed constant in $\mathbf{R}^3$, and suppose that the fields are source free. Then the electromagnetic wave propagation is governed by the time-harmonic Maxwell equations (time dependence $\exp(-i\omega t)$ with frequency $\omega > 0$)

$$\nabla \times E - i\omega\mu H = 0, \tag{2.1}$$

$$\nabla \times H + (i\omega\epsilon - \sigma)E = 0, \tag{2.2}$$

where E and H are the electric field and magnetic field, respectively. In this paper, it is assumed that the medium is invariant in the x_3 direction, i.e., $\epsilon = \epsilon(x)$ and $\sigma = \sigma(x)$

with $x = (x_1, x_2) \in \mathbf{R}^2$. Also, we restrict ourselves to the transverse magnetic (TM) polarization case; that is, the electric field E is assumed to point along the x_3 axis. Let $E = (0, 0, u)$, where $u = u(x)$ is a scalar function. Then it follows from the Maxwell equations (2.1)–(2.2) that u satisfies the reduced wave equation

$$\Delta u + k^2 u = 0 \quad \text{in} \quad \mathbf{R}^2, \tag{2.3}$$

where Δ is the Laplacian in $\mathbf{R}^2$ and $k^2 = \omega^2 \mu\epsilon[1 + i\sigma/(\omega\epsilon)]$ so that $\Im(k^2) \geq 0$.

Additionally we make the following assumptions on k throughout:

(A1) $k \in L_\infty(\mathbf{R}^2)$.

(A2) There are positive constants B, k_+, and k_- such that $k(x) = k_+$ for $x \in U_B$, $= k_-$ for $x \in \mathbf{R}^2 \backslash \overline{U}$.

These two assumptions are sufficient (together with the radiation conditions we introduce below) to derive, in section 3, an equivalent integral equation formulation of the problem. In sections 4 and 5 we address the question of uniqueness of solution which is related to the question of existence or otherwise of guided wave solutions of the homogeneous problem.

We remark that the radiation conditions we will impose will ensure that the scattered field does not contain a downward propagating component and that the transmitted wave does not contain an upward propagating component but (in common with the usual radiation condition for plane wave incidence on periodic gratings) will not rule out solutions of the homogeneous problem which are guided waves localized in the inhomogeneous layer. (See Theorem A.1 in the appendix, where a precise definition of a guided wave in this context is given.) Thus, to prove any uniqueness result, we will have to impose additional conditions (on k) which rule out guided waves. In other words (and more positively), any uniqueness proof will simultaneously establish conditions for the nonexistence of guided waves.

The additional requirements for our uniqueness proof (sections 4 and 5) and for proving the existence of solution (section 6) are that assumption (A3) is satisfied or that both assumptions (A4) and (A5) below are satisfied.

(A3) There exist constants $\lambda_1, \lambda_2, \eta$, and ρ, with $\lambda_1 > 0$, $1 > \lambda_2 > 0$ and $0 \leq \eta < \rho \leq B$ such that $\Im(k^2(x)) \geq \lambda_1$ for almost all $x \in E_\eta^\rho$, $\Im(k^2(x)) \geq \lambda_2 |k^2(x) - k_+^2|$ for almost all $x \in E_\eta^B$, and $\Im(k^2(x)) \geq \lambda_2 |k^2(x) - k_-^2|$ for almost all $x \in E_0^\rho$.

(A4) There exists $\beta \in \mathbf{R}$ such that $\Re(k^2(x))$ is monotonic nondecreasing in U_β and monotonic nonincreasing in $\mathbf{R}^2 \backslash U_\beta$ as x_2 increases: precisely, for all $h > 0$, where $e_2 = (0, 1)$, $\Re[k^2(x + e_2 h)] \geq \Re[k^2(x)]$ for almost all $x \in U_\beta$ and $\Re[k^2(x - e_2 h)] \geq \Re[k^2(x)]$ for almost all $x \in \mathbf{R}^2 \backslash \overline{U}_\beta$.

Let $\tilde{k}(x) = k_+$ for $x_2 \geq \beta$, $= k_-$ for $x_2 < \beta$. Then Assumption (A4) implies that $\Re[k^2(x)] \leq \tilde{k}^2(x)$ for almost all $x \in \mathbf{R}^2$.

(A5) There are constants λ_3, η, and ρ, with $\lambda_3 > 0$ and $0 \leq \eta < \rho \leq B$, such that $\Re[k^2(x)] \leq \tilde{k}^2(x) - \lambda_3$ for almost all $x \in E_\eta^\rho$.

We can write (A4) succinctly as

$$(x_2 - \beta)\partial_2(\Re(k^2)) \geq 0$$

in a distributional sense in $\mathbf{R}^2$ (cf. Bonnet-Bendhia and Starling [3, equation (3.34)] and [7]). If (A4) and (A5) hold with $\beta < \rho$, then it must be the case that $\Re[k^2(x)] \leq k_+^2 - \lambda_3$ for almost all $x \in E_\beta^\rho$, while if $\beta > \eta$, then $\Re[k^2(x)] \leq k_-^2 - \lambda_3$ for almost all $x \in E_\eta^\beta$.

To clarify the above assumptions we list some important practical cases in which they are satisfied:

(i) Suppose that $k_+ \neq k_-$ and, for some $f \in L_\infty(\mathbf{R})$, that $k(x) = k_+$, $x_2 > f(x_1)$, $= k_-$, $x_2 < f(x_1)$, and assume without loss of generality that $\epsilon \leq f(x_1) \leq B - \epsilon$ for some $\epsilon > 0$, $B > \epsilon$. Then (A1), (A2), (A4), (A5) are satisfied, with $0 = \beta = \eta$, $\rho = \epsilon$, if $k_- < k_+$, $B - \epsilon = \eta$, $B = \beta = \rho$, if $k_- > k_+$.

(ii) Suppose that $k^* > 0$ and, for some $f_+, f_- \in L_\infty(\mathbf{R})$, with $f_- \leq f_+$, that $k(x) = k_+$, $x_2 > f_+(x_1)$, $= k_-$, $x_2 < f_-(x_1)$, $= k^*$, $f_-(x_1) < x_2 < f_+(x_1)$. Suppose further without loss of generality that, for some $B > \epsilon > 0$, $\epsilon \leq f_-(x_1) \leq f_+(x_1) \leq B - \epsilon$, $x_1 \in \mathbf{R}$. Then assumptions (A1) and (A2) are satisfied and so are assumptions (A4) and (A5) in the following cases: (a) $k_- < k^* < k_+$ (set $\beta = \eta = 0$, $\rho = \epsilon$); (b) $k_- > k^* > k_+$ (set $\eta = B - \epsilon$, $\beta = \rho = B$); (c) $k^* < k_+$, $k^* < k_-$ provided, for some $0 < \eta < \rho < B$, $k(x) = k^*$, $x \in E_\eta^\rho$, and $\eta \leq \beta \leq \rho$.

(iii) Suppose that $\Im k^* > 0$ and that, for some $0 < \eta < \rho < B$, and disjoint open sets S_+, S, and S_-, with $\overline{S_+} \cup \overline{S} \cup \overline{S_+} = \mathbf{R}^2$ and $E_\eta^\rho \subset S$, $U_B \subset S_+$, and $\mathbf{R}^2 \setminus \overline{U} \subset S_-$,

$$k(x) = \begin{cases} k_+, & x \in S_+, \\ k^*, & x \in S, \\ k_-, & x \in S_-. \end{cases}$$

Then (A1)–(A3) are satisfied.

We mention one simple example not covered by the above assumptions. In the case $k \equiv k_+$ assumptions (A1), (A2), and (A4) are satisfied (with $k_- = k_+$), but assumption (A5) is not satisfied. Thus, the uniqueness results established in section 4 do not apply, and indeed, our problem as formulated will not have a unique solution in this case as is shown by the simple example $u(x) = \exp(\pm i k_+ x_1)$, which satisfies (2.3) with $k \equiv k_+$ and, by Remark 2.3 below, the radiation conditions (2.4) and (2.5).

Let $u^{\mathrm{i}}(x) = \exp(ik_+ x \cdot \alpha)$ be the time-harmonic incoming plane wave incident from U_B on the finite inhomogeneous layer E_B, where $x \in \mathbf{R}^2$, $\alpha = (\cos\theta, -\sin\theta) \in \mathbf{R}^2$, and $\theta \in (0, \pi)$ is the incident angle. We are interested in finding the total field u satisfying the reduced wave equation (2.3).

In order to determine the physical solution u, a radiation condition as x_2 tends to infinity has to be imposed on the scattered field $u^{\mathrm{s}} = u - u^{\mathrm{i}}$ in U_B; that is, the scattered field u^{s} should behave as an outgoing wave as $x_2 \to +\infty$. Similarly, the transmitted field u in $\mathbf{R}^2 \setminus U$ should behave as an outgoing wave as $x_2 \to -\infty$. The standard Sommerfeld radiation condition is not appropriate in this context as we cannot expect that the scattered and the transmitted fields will decay at infinity. We will use a radiation condition proposed in [5] and utilized recently in [7, 8] and [31], which we will usefully relate to the Sommerfeld radiation condition. To this end we introduce the following definitions.

DEFINITION 2.1. *Given a domain $G \subset \mathbf{R}^2$ and $k_* > 0$, call $v \in C^2(G) \cap L_\infty(G)$ a* radiating solution of the Helmholtz equation for wavenumber k_* in G *if $\Delta v + k_*^2 v = 0$ in G and*

$$v(x) = O(r^{-1/2}),$$
$$\frac{\partial v(x)}{\partial r} - ik_* v(x) = o(r^{-1/2}),$$

as $r = |x| \to \infty$, uniformly in $x/|x|$.

Let $\Phi(x, y; k_\pm)$ denote the free-space Green's function for $\Delta + k_\pm^2$; that is,

$$\Phi(x, y; k_\pm) = \frac{i}{4} H_0^{(1)}(k_\pm |x - y|), \qquad x, y \in \mathbf{R}^2, \qquad x \neq y,$$

with $H_0^{(1)}$ being the Hankel function of the first kind of order zero.

DEFINITION 2.2. *Given a domain $G \subset \mathbf{R}^2$, say that $v_+ : G \to \mathbf{C}$ satisfies the* upward propagating radiation condition (UPRC) for wavenumber k_+ *in G if, for some $H \in \mathbf{R}$ and $\phi_+ \in L_\infty(\Gamma_H)$, it holds that $U_H \subset G$ and*

$$v_+(x) = 2 \int_{\Gamma_H} \frac{\partial \Phi(x,y;k_+)}{\partial y_2} \phi_+(y) ds(y), \qquad x \in U_H; \tag{2.4}$$

and say that $v_- : G \to \mathbf{C}$ satisfies the downward propagating radiation condition (DPRC) for wavenumber k_- *in G if, for some $h \in \mathbf{R}$ and $\phi_- \in L_\infty(\Gamma_h)$, it holds that $\mathbf{R}^2 \backslash \overline{U}_h \subset G$ and*

$$v_-(x) = -2 \int_{\Gamma_h} \frac{\partial \Phi(x,y;k_-)}{\partial y_2} \phi_-(y) ds(y), \qquad x \in \mathbf{R}^2 \backslash \overline{U}_h. \tag{2.5}$$

Note that the existence of the integrals in (2.4) and (2.5) for arbitrary $\phi_+ \in L_\infty(\Gamma_H)$ and $\phi_- \in L_\infty(\Gamma_h)$ is ensured by the bound which follows from the asymptotic behavior of the Hankel function for small and large argument,

$$\left| \frac{\partial \Phi(x,y;k_\pm)}{\partial y_2} \right| \leq C|x_2 - y_2|(|x-y|^{-2} + |x-y|^{-3/2}), \quad x, y \in \mathbf{R}^2, \quad x \neq y, \tag{2.6}$$

which holds for some constant $C > 0$ dependent only on $k_\pm$.

The next lemma states properties of the upward propagating radiation condition needed later and, in particular, shows that, for $h \in \mathbf{R}$, a radiating solution for wavenumber k_* in U_h ($\mathbf{R}^2 \backslash \overline{U}_h$) satisfies the UPRC (DPRC) for wavenumber k_*. We first remark that the DPRC can be expressed, through reflection, in terms of the UPRC.

Remark 2.1. For $x = (x_1, x_2) \in \mathbf{R}^2$ let $x' = (x_1, -x_2)$, and for $G \subset \mathbf{R}^2$ let $G' = \{x' | x \in G\}$. Then $v_- : G \to \mathbf{C}$ satisfies the DPRC for wavenumber k_* in G if and only if $v_+ : G' \to \mathbf{C}$, given by $v_+(x) = v_-(x')$, $x \in G'$, satisfies the UPRC for wavenumber k_* in G'.

LEMMA 2.1 (see [7, Theorem 2.1]). *Given $H \in \mathbf{R}$ and $v : U_H \to \mathbf{C}$, the following statements are equivalent:*

(i) *$v \in C^2(U_H)$, $v \in L_\infty(U_H \backslash U_a)$ for all $a > H$, $\Delta v + k_+^2 v = 0$ in U_H, and v satisfies the UPRC for wavenumber k_+;*

(ii) *$v \in L_\infty(U_H \backslash U_a)$ for some $a > H$ and v satisfies* (2.4) *for each $h > H$ with $\phi = v|_{\Gamma_h}$;*

(iii) *$v \in C^2(U_H)$, $v \in L_\infty(U_H \backslash U_a)$ for all $a > H$, $\Delta v + k_+^2 v = 0$ in U_H, and for every $h > H$ and radiating solution in U_H, w, such that the restrictions of w and $\partial_2 w$ to Γ_h are in $L_1(\mathbf{R})$, it holds that*

$$\int_{\Gamma_h} \left(v \frac{\partial w}{\partial n} - w \frac{\partial v}{\partial n} \right) ds = 0. \tag{2.7}$$

From Lemma 2.1 and Remark 2.1 we can deduce corresponding characteristics of downward propagating solutions of the Helmholtz equation.

For convenience, we now state a local regularity estimate used throughout the paper.

LEMMA 2.2 (see [18, Theorem 3.9, Lemma 4.1]). *If for some $A > 0$ and $x \in \mathbf{R}^2$ it holds that $v \in L_\infty(B_A(x))$ and $\Delta v = f \in L_\infty(B_A(x))$ (in a distributional sense),*

then $v \in C^1(B_A(x))$ *and*

$$|\nabla v(y)| \le CA^{-1}(||v||_\infty + A^2||f||_\infty), \qquad y \in B_{A/2}(x),$$

where C *is an absolute constant.*

Remark 2.2. A consequence of Lemma 2.2 is that if $\Delta v + k^2 v = 0$ in some region G and $v \in L_\infty(G)$, $k \in L_\infty(G)$, then $v \in C^1(G)$ and ∇v is bounded in every compact subset of G. Further, if the sequence $(v_n) \subset L_\infty(G)$ is uniformly bounded, $\Delta v_n + k_*^2 v_n = 0$ in G for some $k_* \in \mathbf{C}$ and each n, and $v_n(x) \to v(x)$ uniformly on compact subsets of G, then $v \in C^2(G)$ and $\Delta v + k_*^2 v = 0$ in G.

Our problem of scattering of a time-harmonic plane wave by an inhomogeneous layer can now be formulated as the following boundary value problem.

Problem (P). Find $u \in C(\mathbf{R}^2)$ such that (i) u satisfies the reduced wave equation (2.3) in a distributional sense; (ii) u^s and u satisfy the UPRC and DPRC (2.4) and (2.5), respectively; and (iii) u is bounded in E^A_{-A} for every $A > 0$.

Remark 2.3. From (iii) and Lemma 2.2, it follows that $u \in C^1(\mathbf{R}^2) \cap C^2(U_B) \cap C^2(\mathbf{R}^2 \backslash \overline{U})$ and

$$\sup_{x \in E^A_{-A}} [|\nabla u(x)| + |u(x)|] < \infty \tag{2.8}$$

for every $A > 0$. Further, by (2.3) and standard local regularity results [18], we have that $u \in H^2_{\mathrm{loc}}(\mathbf{R}^2)$.

Remark 2.4. The radiation conditions (2.4) and (2.5) are generalizations of the standard radiation conditions for one-dimensional periodic gratings. Precisely, it was proven in [4] that if u^s has the usual representation as a Rayleigh expansion [2, 19, 20] in some U_τ, then it also satisfies (2.4) for all $h > \tau$ and thus satisfies the UPRC. As a consequence, any upward or horizontally propagating plane wave satisfies the UPRC and, by Remark 2.1, any downward or horizontally propagating plane wave satisfies the DPRC.

In what follows we are concerned with deriving an equivalent integral equation formulation of Problem (P) and with establishing unique solvability for Problem (P), employing integral equation methods.

3. An integral equation formulation. For $h \in \mathbf{R}$ let $y'_h = (y_1, 2h - y_2)$ be the image of y in Γ_h and define

$$G^\pm_h(x, y) = \Phi(x, y; k_\pm) - \Phi(x, y'_h; k_\pm), \qquad x, y \in \mathbf{R}^2, \qquad x \ne y.$$

Then $G^\pm_h$ is the Dirichlet Green's function for $\Delta + k^2_\pm$ in the half-planes U_h and $\mathbf{R}^2 \backslash \overline{U}_h$. It follows from [6, Lemma 3.1] that, for some constant C depending only on $k_\pm$ and h,

$$|G^\pm_h(x, y)|, \qquad |\nabla_x G^\pm_h(x, y)|, \qquad |\nabla_y G^\pm_h(x, y)| \le C \frac{(1 + x_2)(1 + y_2)}{|x - y|^{3/2}} \tag{3.1}$$

if $x, y \in U_h$ or $x, y \in \mathbf{R}^2 \backslash \overline{U}_h$ with $|x - y| \ge 1$. On the other hand, from asymptotic properties of the Hankel function it follows that

$$|G^\pm_h(x, y)| \le C\,(1 + |\log|x - y||)\,, \quad |\nabla_x G^\pm_h(x, y)|, \quad |\nabla_y G^\pm_h(x, y)| \le C|x - y|^{-1} \tag{3.2}$$

if $x, y \in U_h$ or $x, y \in \mathbf{R}^2 \backslash \overline{U}_h$ with $|x - y| \le 1$. It follows from (3.1) and (3.2) that, for $0 \le h \le B$,

$$|G^\pm_h(x, y)|, \qquad |\nabla_x G^\pm_h(x, y)|, \qquad |\nabla_y G^\pm_h(x, y)| \le C_b(1 + |x_1 - y_1|)^{-3/2} \tag{3.3}$$

if $y \in \overline{E}_h^B$, $x \in \Gamma_b$, with $b > B$, or if $y \in \overline{E}_0^h$, $x \in \Gamma_b$, with $b < 0$, where C_b depends only on b, B, h, and $k_\pm$.

Let u^{r} denote the upward propagating plane wave $u^{\mathrm{r}}(x) = -\exp(ik_+ x_c' \cdot \alpha)$, $x \in \mathbf{R}^2$.

THEOREM 3.1. *Let u be a solution of Problem* (P), *and let $0 \le c < d \le B$. Then we have*

$$u(x) = u^{\mathrm{i}}(x) + u^{\mathrm{r}}(x) + \int_{E_c^B} u(y)[k^2(y) - k_+^2]G_c^+(x,y)dy$$

$$+ \int_{\Gamma_c} u(y)\frac{\partial G_c^+(x,y)}{\partial y_2}ds(y), \qquad x \in U_c, \tag{3.4}$$

$$u(x) = \int_{E_0^d} u(y)[k^2(y) - k_-^2]G_d^-(x,y)dy$$

$$- \int_{\Gamma_d} u(y)\frac{\partial G_d^-(x,y)}{\partial y_2}ds(y), \qquad x \in \mathbf{R}^2 \backslash \overline{U}_d. \tag{3.5}$$

Remark 3.1. In view of (3.1) and (3.2), (A1), and the fact that $u \in BC(\overline{E_B})$, the integrals in (3.4) and (3.5) are well defined.

Proof. Take $x \in U_c$, choose $b > \max(x_2, B)$, $A > |x_1|$, and $\epsilon > 0$ sufficiently small and apply Green's second theorem to $G_c^+(x,\cdot)$ and u in the bounded region $E_c^b(A) \setminus \overline{B_\epsilon(x)}$, and then let $\epsilon \to 0$ to obtain that

$$u(x) = \int_{E_c^B(A)} u(y)[k^2(y) - k_+^2]G_c^+(x,y)dy$$

$$+ \int_{\partial(E_c^b(A))} \left[G_c^+(x,y)\frac{\partial u}{\partial n}(y) - u(y)\frac{\partial G_c^+(x,y)}{\partial n(y)} \right] ds(y). \tag{3.6}$$

Letting $A \to \infty$ in (3.6), in view of (3.1), we find that

$$u(x) = \int_{E_c^B} u(y)[k^2(y) - k_+^2]G_c^+(x,y)dy + \int_{\Gamma_c} u(y)\frac{\partial G_c^+(x,y)}{\partial y_2}ds(y) + I_b, \tag{3.7}$$

where

$$I_b = \int_{\Gamma_b} \left[G_c^+(x,y)\frac{\partial u}{\partial n}(y) - u(y)\frac{\partial G_c^+(x,y)}{\partial n(y)} \right] ds(y). \tag{3.8}$$

Now $v = u^{\mathrm{i}} + u^{\mathrm{r}}$ satisfies the Helmholtz equation $\Delta v + k_+^2 v = 0$ in U_c and the Dirichlet condition $v = 0$ on Γ_c, so that by the same argument used to derive (3.7), we can show that $v(x) = \tilde{I}_b$, where $\tilde{I}_b$ is given by (3.8) but with u replaced by v. It follows that

$$I_b = u^{\mathrm{i}}(x) + u^{\mathrm{r}}(x) + \int_{\Gamma_b} \left[G_c^+(x,y)\frac{\partial w}{\partial n}(y) - w(y)\frac{\partial G_c^+(x,y)}{\partial n(y)} \right] ds(y), \tag{3.9}$$

where $w = u^{\mathrm{s}} - u^{\mathrm{r}}$. Further, by Remark 2.4, u^{r} and thus w satisfies the UPRC. Also, $G_c^+(x,\cdot)$ is a radiating solution in U_τ for $\tau > \max(x_2, B)$ so that, in view of (3.1) and

the equivalence of (i) and (iii) in Lemma 2.1, the integral in (3.9) vanishes. Thus (3.4) follows.

Take $x \in \mathbf{R}^2\backslash\overline{U}_d$, and choose $a < \min(x_2, 0)$, $A > |x_1|$, and $\epsilon > 0$ sufficiently small. Then (3.5) can be derived similarly by applying Green's second theorem to $G_d^-(x,\cdot)$ and u in the bounded region $E_a^d(A) \setminus \overline{B_\epsilon(x)}$, letting $\epsilon \to 0$, $A \to \infty$, and finally utilizing the equivalence of (i) and (iii) in Lemma 2.1 and noting Remark 2.1. □

The next two lemmas state properties of volume and surface potentials of the type appearing in (3.4) and (3.5). Lemma 3.1(i) was proved as Lemma 3.1 in [7] while Lemma 3.2(i) was proved as Theorem 3.2 in [5]. In both lemmas the assertion (ii) is a consequence of (i) on noting Remark 2.1.

LEMMA 3.1. (i) *Define the* volume potential v_+ *with density* $\phi_+ \in L_\infty(E_c^B)$ *by*

$$v_+(x) = \int_{E_c^B} G_c^+(x,y)\phi_+(y)dy, \qquad x \in \overline{U}_c,$$

and extend the definition of ϕ_+ *to* U_c *by setting* $\phi_+(x) = 0$, $x \in U_B$. *Then* $v_+ \in C^1(\overline{U}_c) \cap L_\infty(E_c^b)$ *for* $b > c$, $v_+ = 0$ *on* Γ_c, $\Delta v_+ + k_+^2 v_+ = -\phi_+$ *in* U_c, *and* v_+ *satisfies the UPRC.*

(ii) *Define the* volume potential v_- *with density* $\phi_- \in L_\infty(E_0^d)$ *by*

$$v_-(x) = \int_{E_0^d} G_d^-(x,y)\phi_-(y)dy, \qquad x \in \mathbf{R}^2\backslash U_d,$$

and extend the definition of ϕ_- *to* $\mathbf{R}^2\backslash\overline{U}_d$ *by setting* $\phi_-(x) = 0$, $x \in \mathbf{R}^2\backslash U$. *Then* $v_- \in C^1(\mathbf{R}^2\backslash U_d) \cap L_\infty(E_a^d)$ *for* $a < d$, $v_- = 0$ *on* Γ_d, $\Delta v_- + k_-^2 v_- = -\phi_-$ *in* $\mathbf{R}^2\backslash\overline{U}_d$, *and* v_- *satisfies the DPRC.*

LEMMA 3.2. (i) *Define the* double layer potential D_+ *with density* $\psi_+ \in BC(\Gamma_c)$ *by*

$$D_+(x) = \int_{\Gamma_c} \frac{\partial G_c^+(x,y)}{\partial y_2}\psi_+(y)ds(y), \qquad x \in U_c.$$

Then $D_+ \in C(\overline{U}_c) \cap C^2(U_c) \cap L_\infty(E_c^b)$ *for* $b > c$, $D_+ = \psi_+$ *on* Γ_c, $\Delta D_+ + k_+^2 D_+ = 0$ *in* U_c, *and* D_+ *satisfies the UPRC.*

(ii) *Define the* double layer potential D_- *with density* $\psi_- \in BC(\Gamma_d)$ *by*

$$D_-(x) = \int_{\Gamma_d} \frac{\partial G_d^-(x,y)}{\partial y_2}\psi_-(y)ds(y), \qquad x \in \mathbf{R}^2\backslash\overline{U}_d.$$

Then $D_- \in C(\mathbf{R}^2\backslash U_d) \cap C^2(\mathbf{R}^2\backslash\overline{U}_d) \cap L_\infty(E_a^d)$ *for* $a < d$, $D_- = -\psi_-$ *on* Γ_d, $\Delta D_- + k_-^2 D_- = 0$ *in* $\mathbf{R}^2\backslash\overline{U}_d$, *and* D_- *satisfies the DPRC.*

As in Theorem 3.1, choose c and d so that $0 \le c < d \le B$ and let $\lambda = (k_+ c + k_- d)/(k_- + k_+)$ so that $k_-(d-\lambda) = k_+(\lambda - c)$. Suppose that u satisfies Problem (P) and let $\psi_1 = u|_{\overline{E}_\lambda^B}$, $\psi_2 = u|_{\overline{E}_0^\lambda}$, and $k^\pm = k^2 - k_\pm^2$. Then, by Theorem 3.1, $\psi_1 \in BC(\overline{E}_\lambda^B)$ and $\psi_2 \in BC(\overline{E}_0^\lambda)$ satisfy the pair of second-kind integral equations

$$\psi_1(x) = u^i(x) + u^r(x) + \int_{E_\lambda^B} \psi_1(y)k^+(y)G_c^+(x,y)dy + \int_{E_c^\lambda} \psi_2(y)k^+(y)G_c^+(x,y)dy$$

$$+\int_{\Gamma_c}\psi_2(y)\frac{\partial G_c^+(x,y)}{\partial y_2}ds(y),\qquad x\in\overline{E}_\lambda^B, \tag{3.10}$$

$$\psi_2(x)=\int_{E_0^\lambda}\psi_2(y)k^-(y)G_d^-(x,y)dy+\int_{E_\lambda^d}\psi_1(y)k^-(y)G_d^-(x,y)dy$$

$$-\int_{\Gamma_d}\psi_1(y)\frac{\partial G_d^-(x,y)}{\partial y_2}ds(y),\qquad x\in\overline{E}_0^\lambda. \tag{3.11}$$

Conversely, suppose now that $\psi_1\in BC(\overline{E}_\lambda^B)$ and $\psi_2\in BC(\overline{E}_0^\lambda)$ satisfy the integral equations (3.10) and (3.11) and define u as follows:

$$u(x)=u^{\mathrm{i}}(x)+u^{\mathrm{r}}(x)+\int_{E_\lambda^B}\psi_1(y)k^+(y)G_c^+(x,y)dy+\int_{E_c^\lambda}\psi_2(y)k^+(y)G_c^+(x,y)dy$$

$$+\int_{\Gamma_c}\psi_2(y)\frac{\partial G_c^+(x,y)}{\partial y_2}ds(y),\qquad x\in U_c, \tag{3.12}$$

$$u(x)=\lim_{y\to x,\ y\in U_c}u(y),\qquad x\in\Gamma_c, \tag{3.13}$$

$$u(x)=\int_{E_0^\lambda}\psi_2(y)k^-(y)G_d^-(x,y)dy+\int_{E_\lambda^d}\psi_1(y)k^-(y)G_d^-(x,y)dy$$

$$-\int_{\Gamma_d}\psi_1(y)\frac{\partial G_d^-(x,y)}{\partial y_2}ds(y),\qquad x\in\mathbf{R}^2\backslash\overline{U}_c. \tag{3.14}$$

Then it follows, provided $d-c$ is small enough, that u is a solution of Problem (P). To see this define v by

$$v(x)=\int_{E_0^\lambda}\psi_2(y)k^-(y)G_d^-(x,y)dy+\int_{E_\lambda^d}\psi_1(y)k^-(y)G_d^-(x,y)dy$$

$$-\int_{\Gamma_d}\psi_1(y)\frac{\partial G_d^-(x,y)}{\partial y_2}ds(y),\qquad x\in\mathbf{R}^2\backslash\overline{U}_d, \tag{3.15}$$

$$v(x)=\lim_{y\to x,\ y\in\mathbf{R}^2\backslash\overline{U}_d}v(y),\qquad x\in\Gamma_d. \tag{3.16}$$

Then, comparing (3.10) and (3.12), $\psi_1=u|_{\overline{E}_\lambda^B}$, and comparing (3.11) and (3.15), $\psi_2=v|_{\overline{E}_0^\lambda}$. Also, by Lemmas 3.1 and 3.2 applied to (3.12) and (3.15), $\psi_2=u$ on Γ_c and $\psi_1=v$ on Γ_d. Thus $u=v$ on Γ_c and Γ_d. Define $w=u-v$. Then it is clear from Lemmas 3.1 and 3.2 again, together with the above results, that (i) w is bounded in E_c^d and $w\in C(\overline{E}_c^d)\cap C^1(E_c^d)$; (ii) $\Delta w+\hat{k}^2w=0$ in E_c^d, where $\hat{k}(x)=k_-$, $x\in E_\lambda^d$, $=k_+$, $x\in E_c^\lambda$; (iii) $w=0$ on Γ_c and Γ_d. Now, consider the following eigenvalue problem: find $z\in C^1[c,d]\cap H^2(c,d)$, $\Lambda\in\mathbf{R}$, such that $-z''-qz=\Lambda z$ in (c,d) and $z(c)=z(d)=0$, where $q(x_2)=k_-$, $\lambda<x_2<d$, $=k_+$, $c<x_2<\lambda$. Provided this problem has only positive eigenvalues $\Lambda>0$, and this is the case if $(d-\lambda)k_-=(\lambda-c)k_+<\pi/2$, i.e., provided $2k_+k_-(d-c)<\pi(k_++k_-)$, then an elementary separation of variables argument establishes that $w\equiv0$ in E_c^d and hence $u\equiv v$ in E_c^d. It is now easy to see, by

further applications of Lemmas 3.1 and 3.2, that u, defined by (3.12)–(3.14), satisfies Problem (P). Thus we have the following equivalence theorem between Problem (P) and the integral equation problem (3.10) and (3.11).

THEOREM 3.2. *If $u \in C(\mathbf{R}^2)$ is a solution of Problem* (P), *then $\psi_1 := u|_{\overline{E}_\lambda^B}$ and $\psi_2 := u|_{\overline{E}_0^\lambda}$ satisfy the integral equations* (3.10) *and* (3.11). *Conversely, suppose that $\psi_1 \in BC(\overline{E}_\lambda^B)$ and $\psi_2 \in BC(\overline{E}_0^\lambda)$ satisfy the integral equations* (3.10) *and* (3.11) *and define u by* (3.12)–(3.14). *Then, provided $(d-\lambda)k_- = (\lambda - c)k_+$ and $2k_+k_-(d-c) < \pi(k_+ + k_-)$, u satisfies Problem* (P).

Remark 3.2. Let $(d-\lambda)k_- = (\lambda - c)k_+$ and $2k_+k_-(d-c) < \pi(k_+ + k_-)$. Then from Theorem 3.2 it follows that in order to prove the existence of a solution to Problem (P), it is enough to show that the pair of integral equations (3.10) and (3.11) has a solution. This will be done in section 6.

4. A basic inequality. In this section a basic inequality satisfied by solutions of (2.3) is established, which is a key step in the proof of the uniqueness theorem.

Suppose that $u \in C(\mathbf{R}^2)$ satisfies (2.3). Then, by Remark 2.3, $u \in C^1(\mathbf{R}^2) \cap H^2_{\mathrm{loc}}(\mathbf{R}^2)$. Let $\eta < c < d < \rho$ with η, ρ being as defined in assumptions (A3) or (A5) and define, for $t \in \mathbf{R}$ and $A > 0$,

$$J_A(t) = \Im \int_{\Gamma_t(A)} \overline{u}\partial_2 u ds, \qquad L_A(t) = \Re \int_{\Gamma_t(A)} \overline{u}\partial_2 u ds, \tag{4.1}$$

$$I_A^{\pm}(t) = \int_{\Gamma_t(A)} \{|\partial_2 u|^2 - |\partial_1 u|^2 + k_\pm^2 |u|^2\} ds, \tag{4.2}$$

$$K_A = \int_{E_\eta^B(A)} |u|^2 |k^2 - k_+^2| dx + \int_{E_0^\rho(A)} |u|^2 |k^2 - k_-^2| dx \tag{4.3}$$

$$+ \int_{\Gamma_c(A)} |u|^2 ds + \int_{\Gamma_d(A)} |u|^2 ds. \tag{4.4}$$

Let $a < 0 < B < b$, and for $t \in \mathbf{R}$, let $\gamma(t) = \{(t, x_2) | a \le x_2 \le b\}$.

THEOREM 4.1. *Assume that* (A3) *holds or that both* (A4) *and* (A5) *hold. Then, for some nonnegative constants C_j, $j = 1, 2, 3$, there holds*

$$\begin{aligned} K_A \le{}& C_1[(b-\beta)I_A^+(b) - (a-\beta)I_A^-(a)] + C_1[L_A(b) - L_A(a)] \\ &+ C_2[J_A(a) - J_A(b)] + C_3 R_1(A) + C_1 R_2(A), \end{aligned} \tag{4.5}$$

for all $A > 0$, where

$$R_1(A) = \left[\int_{\gamma(A)} + \int_{\gamma(-A)}\right] |\overline{u}\partial_1 u| ds$$

and

$$R_2(A) = \Re \left[\int_{\gamma(A)} - \int_{\gamma(-A)}\right] [2(x_2 - \beta)\partial_2 \overline{u}\partial_1 u + \overline{u}\partial_1 u] ds.$$

Proof. First we will deduce the inequality (4.5) in the case that (A3) holds.

Apply Green's first theorem to u and $\overline{u}$ in $E_a^b(A)$ and take the imaginary part of the result thus obtained to get that since $\Im(k^2(x)) = 0$ for $x_2 > B$ and $x_2 < 0$,

$$\int_{E_B(A)} \Im(k^2)|u|^2 dx + J_A(b) - J_A(a) \leq R_1(A). \tag{4.6}$$

Let $\theta \in C^2(\mathbf{R})$ be such that $0 \leq \theta(t) \leq 1$ for $t \in \mathbf{R}$, $\theta(t) = 1$ for $c \leq t \leq d$, and $\theta(t) = 0$ for $t \geq \rho$ and $t \leq \eta$. Then, by applying Green's first theorem to u and $\theta(x_2)\overline{u}$ in $E_B(A)$ and taking the real part of the result thus obtained, we obtain on integrating by parts that

$$\int_{E_B(A)} \theta(x_2)|\nabla u|^2 dx \leq \int_{E_B(A)} \left[\Re(k^2)\theta(x_2) + \frac{1}{2}\theta''(x_2)\right]|u|^2 dx + R_1(A),$$

which together with the definition of θ implies that

$$\int_{E_c^d(A)} |\nabla u|^2 dx \leq (\|k\|_\infty^2 + C) \int_{E_\eta^\rho(A)} |u|^2 dx + R_1(A), \tag{4.7}$$

for some constant $C > 0$ depending only on the choice of θ.

Now, for any $r, t \in \mathbf{R}$,

$$u((x_1, r)) - u((x_1, t)) = \int_t^r \partial_2 u(x) dx_2, \qquad x_1 \in \mathbf{R}, \tag{4.8}$$

so that using the Cauchy–Schwarz inequality,

$$|u((x_1, t))|^2 \leq 2|u((x_1, r))|^2 + 2(r - t) \int_t^r |\partial_2 u(x)|^2 dx_2, \qquad x_1 \in \mathbf{R}. \tag{4.9}$$

From (4.9) it follows that, for $R < T$, $r, t \in [R, T]$,

$$\int_{\Gamma_t(A)} |u|^2 ds \leq 2 \int_{\Gamma_r(A)} |u|^2 ds + 2(T - R) \int_{E_R^T(A)} |\partial_2 u|^2 dx \tag{4.10}$$

and hence that

$$(T - R) \int_{\Gamma_t(A)} |u|^2 ds \leq 2 \int_{E_R^T(A)} |u|^2 dx + 2(T - R)^2 \int_{E_R^T(A)} |\partial_2 u|^2 dx. \tag{4.11}$$

Thus, assuming that (A3) holds, the required inequality (4.5), with $C_1 = 0$, follows from (4.6), (4.7), and (4.11) with $R = c$, $T = d$, $t = c, d$.

Suppose now that (A4) and (A5) hold. Multiplying (2.3) by $2(x_2 - \beta)\partial_2\overline{u} + \overline{u}$, integrating over $E_a^b(A)$, and taking the real part, we obtain on noting that $\Im(k^2(x)) = 0$ for $x_2 > B$ and $x_2 < 0$,

$$2 \int_{E_a^b(A)} |\partial_2 u|^2 dx = \Re \int_{E_a^b(A)} \{2\nabla \cdot [(x_2 - \beta)\partial_2\overline{u}\nabla u] - \partial_2[(x_2 - \beta)|\nabla u|^2] + \nabla \cdot (\overline{u}\nabla u)\} dx$$

$$
\begin{aligned}
&+\int\limits_{E_a^b(A)} \Re(k^2)\partial_2[(x_2-\beta)|u|^2]dx + 2\int\limits_{E_B(A)} (x_2-\beta)\Im(k^2)\Im\{\overline{u}\partial_2 u\}dx \\
&= (b-\beta)\int\limits_{\Gamma_b(A)} (|\partial_2 u|^2 - |\partial_1 u|^2)ds - (a-\beta)\int\limits_{\Gamma_a(A)} (|\partial_2 u|^2 - |\partial_1 u|^2)ds \\
&+L_A(b) - L_A(a) + R_2(A) + \int\limits_{E_a^b(A)} \Re(k^2)\partial_2[(x_2-\beta)|u|^2]dx \\
&+2\int\limits_{E_B(A)} (x_2-\beta)\Im(k^2)\Im\{\overline{u}\partial_2 u\}dx. \qquad (4.12)
\end{aligned}
$$

Now, if $\Re(k^2) \in C^1(\mathbf{R}^2)$, then from (A4) we have that $(x_2-\beta)\partial_2(\Re(k^2)) \geq 0$, and integrating by parts, we obtain that

$$
\begin{aligned}
\int\limits_{E_a^b(A)} \Re(k^2)\partial_2[(x_2-\beta)|u|^2]dx &\leq (b-\beta)k_+^2 \int\limits_{\Gamma_b(A)} |u|^2 ds - (a-\beta)k_-^2 \int\limits_{\Gamma_a(A)} |u|^2 ds \\
&= \int\limits_{E_a^b(A)} \tilde{k}^2\partial_2[(x_2-\beta)|u|^2]dx. \qquad (4.13)
\end{aligned}
$$

Thus

$$
G_A \equiv \int\limits_{E_a^b(A)} [\tilde{k}^2 - \Re(k^2)]\partial_2[(x_2-\beta)|u|^2]dx \geq 0. \qquad (4.14)
$$

In the general case where $k \in L_\infty(\mathbf{R}^2)$, let $\phi(x) = \Re(k^2(x))$, $\psi(x) = (x_2-\beta)|u(x)|^2$, and for $h \in \mathbf{R}$, let $\phi_h(x) = \phi(x+he_2)$, $\psi_h(x) = \psi(x+he_2)$. Then, since $\phi(\psi_h - \psi) + \phi_h(\psi_h - \psi) = 2(\phi_h\psi_h - \phi\psi) - (\phi_h - \phi)(\psi + \psi_h)$, we have that for sufficiently small $h > 0$,

$$
\begin{aligned}
&\int\limits_{E_a^b(A)} \phi(\psi_h - \psi)dx + \int\limits_{E_{a+h}^{b+h}(A)} \phi(\psi - \psi_{-h})dx \\
&= 2\int\limits_{E_b^{b+h}(A)} \phi\psi dx - 2\int\limits_{E_a^{a+h}(A)} \phi\psi dx - \int\limits_{E_a^b(A)} (\phi_h - \phi)(\psi + \psi_h)dx. \qquad (4.15)
\end{aligned}
$$

By using (A4) the last term on the right-hand side of (4.15) can be estimated as follows. First, in the cases where $\beta \leq a$ and $\beta \geq b+h$, it is easy to see that

$$
I \equiv -\int\limits_{E_a^b(A)} (\phi_h - \phi)(\psi + \psi_h)dx \leq 0,
$$

while if $a < \beta < b+h$, then

$$
I \leq 2||k||_\infty^2 \int\limits_{E_{\beta-h}^{\beta}(A)} |\psi + \psi_h|dx \equiv I_h.
$$

Therefore, $I \le I_h$ in any case, and thus it follows from (4.15) that

$$\int\limits_{E_a^b(A)} \phi(\psi_h - \psi)dx + \int\limits_{E_{a+h}^{b+h}(A)} \phi(\psi - \psi_{-h})dx$$

$$\le 2k_+^2 \int\limits_{E_b^{b+h}(A)} \psi dx - 2k_-^2 \int\limits_{E_a^{a+h}(A)} \psi dx + I_h \tag{4.16}$$

on using (A2). Since $\psi \in C^1(\mathbf{R}^2)$ and $\psi = 0$ on Γ_β, dividing (4.16) by $2h$ and taking the limit $h \to 0$ we obtain that (4.13) and (4.14) hold in the general case.

It follows from (4.12) that

$$2\int\limits_{E_a^b(A)} |\partial_2 u|^2 dx + G_A = (b-\beta)I_A^+(b) - (a-\beta)I_A^-(a) + L_A(b) - L_A(a) + R_2(A)$$

$$+2\int\limits_{E_B(A)} (x_2 - \beta)\Im(k^2)\Im\{\overline{u}\partial_2 u\}dx. \tag{4.17}$$

Since $0 \le \Im(k^2) \le \|k\|_\infty^2$, the Cauchy–Schwarz inequality yields that

$$2\int\limits_{E_B(A)} (x_2 - \beta)\Im(k^2)\Im\{\overline{u}\partial_2 u\}dx \le \int\limits_{E_B(A)} |\partial_2 u|^2 dx + (B + |\beta|)^2\|k\|_\infty^2 \int\limits_{E_B(A)} \Im(k^2)|u|^2 dx.$$

(4.18)

Thus, it follows from (4.17), (4.18), and (4.6) that

$$\int\limits_{E_a^b(A)} |\partial_2 u|^2 dx + G_A \le (b-\beta)I_A^+(b) - (a-\beta)I_A^-(a) + L_A(b) - L_A(a) + R_2(A)$$

$$+(B + |\beta|)^2\|k\|_\infty^2[J_A(a) - J_A(b) + R_1(A)] \equiv F_A. \tag{4.19}$$

Now, from (4.19) and the fact that $G_A \ge 0$, it is seen that

$$\int\limits_{E_a^b(A)} |\partial_2 u|^2 dx \le F_A. \tag{4.20}$$

On the other hand, since $2|(x_2 - \beta)\Re(\overline{u}\partial_2 u)| \le |u|^2/2 + 2(b + |\beta|)^2|\partial_2 u|^2$ in E_a^b, we have

$$\partial_2[(x_2 - \beta)|u|^2] = |u|^2 + 2(x_2 - \beta)\Re(\overline{u}\partial_2 u) \ge |u|^2/2 - 2(b + |\beta|)^2|\partial_2 u|^2,$$

for $x \in E_a^b$, so that on noting that $\tilde{k}^2 \ge \Re(k^2)$ by (A4),

$$G_A \ge \frac{1}{2}\int\limits_{E_a^b(A)} [\tilde{k}^2 - \Re(k^2)]|u|^2 dx - 4(b + |\beta|)^2||k||_\infty^2 \int\limits_{E_a^b(A)} |\partial_2 u|^2 dx.$$

This, together with (4.19) and (4.20), implies that

$$\int\limits_{E_a^b(A)} [\tilde{k}^2 - \Re(k^2)]|u|^2 dx \le 2[1 + 4(b + |\beta|)^2||k||_\infty^2]F_A. \tag{4.21}$$

We now make use of (4.20) and (4.21) to derive the required inequality (4.5). First, using (4.9) and the fact that $\Re(k^2) \le \tilde{k}^2$ by (A4), we obtain (cf. (4.11)) that

$$\int_{E_c^d(A)} [\tilde{k}^2 - \Re(k^2)]|u((x_1, c))|^2 dx$$

$$\le 2 \int_{E_c^d(A)} [\tilde{k}^2 - \Re(k^2)]|u|^2 dx + 4(d-c)^2 ||k||_\infty^2 \int_{E_c^d(A)} |\partial_2 u|^2 dx. \tag{4.22}$$

Using (A4) and (A5) yields that

$$(d-c)\lambda_3 \int_{\Gamma_c(A)} |u|^2 ds \le 2 \int_{E_a^b(A)} [\tilde{k}^2 - \Re(k^2)]|u|^2 dx + 4B^2 ||k||_\infty^2 \int_{E_a^b(A)} |\partial_2 u|^2 dx. \tag{4.23}$$

From (4.10) with $R = a$, $T = b$, $r = c$, we obtain that

$$\int_{E_a^b(A)} |u|^2 dx \le 2(b-a) \int_{\Gamma_c(A)} |u|^2 ds + 2(b-a)^2 \int_{E_a^b(A)} |\partial_2 u|^2 dx. \tag{4.24}$$

Thus, utilizing (4.20) and (4.21) together with (4.23), (4.24), and (4.11), with $R = a$, $T = b$, $t = d$, it follows that K_A is bounded by a multiple of F_A. Thus the required result (4.5) holds with $C_2 = C_3$. □

5. Uniqueness of solution. In this section we establish the following uniqueness theorem for Problem (P).

THEOREM 5.1. *If* (A3) *holds or both* (A4) *and* (A5) *hold, then Problem* (P) *has at most one solution.*

We prove this theorem by showing that the homogeneous version of Problem (P) has only the trivial solution. Since guided waves are solutions of the homogeneous problem (see Definition A.1 and Theorem A.1 in the appendix), we have immediately the following corollary.

COROLLARY 5.1. *If* (A3) *holds or both* (A4) *and* (A5) *hold, then there are no guided wave solutions to the homogeneous problem.*

In the proof of Theorem 5.1 we utilize the following two lemmas, the first of which is a special case of Lemma A in [8].

LEMMA 5.1. *Suppose that* $F \in L_\infty(\mathbf{R})$ *and that, for some nonnegative constants* $C, \epsilon,$ *and* A_0,

$$\int_{-A}^{A} |F(t)|^2 dt \le C \int_{\mathbf{R}\setminus[-A,A]} G_A^2(t) dt + C \int_{-A}^{A} (G_\infty(t) - G_A(t)) G_\infty(t) dt + \epsilon, \quad A > A_0,$$

where, for $A_0 < A \le +\infty$,

$$G_A(s) = \int_{-A}^{A} (1 + |s-t|)^{-3/2} |F(t)| dt, \qquad s \in \mathbf{R}.$$

Then $F \in L_2(\mathbf{R})$ *and*

$$\int_{-\infty}^{+\infty} |F(t)|^2 dt \le \epsilon.$$

LEMMA 5.2. *If $\phi_+ \in L_2(\Gamma_H) \cap L_\infty(\Gamma_H)$, $\phi_- \in L_2(\Gamma_h) \cap L_\infty(\Gamma_h)$, and $v_\pm$ are defined by* (2.4) *and* (2.5), *respectively, then the restrictions of v_+, $\partial_1 v_+$, and $\partial_2 v_+$ to Γ_b are in $L_2(\Gamma_b) \cap BC(\Gamma_b)$ for $b > H$; the restrictions of v_-, $\partial_1 v_-$, and $\partial_2 v_-$ to Γ_a are in $L_2(\Gamma_a) \cap BC(\Gamma_a)$ for $a < h$; and*

$$\Im \int_{\Gamma_b} \overline{v}_+ \partial_2 v_+ ds \geq 0, \qquad \Re \int_{\Gamma_b} \overline{v}_+ \partial_2 v_+ ds \leq 0, \tag{5.1}$$

$$\int_{\Gamma_b} [|\partial_2 v_+|^2 - |\partial_1 v_+|^2 + k_+^2 |v_+|^2] ds \leq 2k_+ \Im \int_{\Gamma_b} \overline{v}_+ \partial_2 v_+ ds, \tag{5.2}$$

and

$$\Im \int_{\Gamma_a} \overline{v}_- \partial_2 v_- ds \leq 0, \qquad \Re \int_{\Gamma_a} \overline{v}_- \partial_2 v_- ds \geq 0, \tag{5.3}$$

$$\int_{\Gamma_a} [|\partial_2 v_-|^2 - |\partial_1 v_-|^2 + k_-^2 |v_-|^2] ds \leq -2k_- \Im \int_{\Gamma_a} \overline{v}_- \partial_2 v_- ds. \tag{5.4}$$

The statements in this lemma concerning v_+ were proved as in Lemma 6.1 in [7]. The statements regarding v_- follow from Remark 2.1.

Proof of Theorem 5.1. As in section 4, let $\eta < c < d < \rho$ and $a < 0$, $b > B$. Also for convenience choose a and b so that $b - \beta = \beta - a \equiv \omega > 0$.

Suppose that u_1 and u_2 are solutions of Problem (P). Then, by Remark 2.3, $u = u_1 - u_2 \in C^1(\mathbf{R}^2)$ and satisfies (2.3), the bound (2.8), the UPRC, and the DPRC. Also, by Theorem 3.1,

$$u(x) = \int_{E_c^B} u(y) k^+(y) G_c^+(x,y) dy + \int_{\Gamma_c} u(y) \frac{\partial G_c^+(x,y)}{\partial y_2} ds(y), \qquad x \in U_c, \tag{5.5}$$

$$u(x) = \int_{E_0^d} u(y) k^-(y) G_d^-(x,y) dy - \int_{\Gamma_d} u(y) \frac{\partial G_d^-(x,y)}{\partial y_2} ds(y), \qquad x \in \mathbf{R}^2 \backslash \overline{U}_d, \tag{5.6}$$

and by Theorem 4.1, for some constants $C_j \geq 0$, $j = 1, 2, 3$,

$$\begin{aligned} K_A \leq\ & C_1[\omega I_A^+(b) + \omega I_A^-(a) + L_A(b) - L_A(a) + R_2(A)] \\ & + C_2[J_A(a) - J_A(b)] + C_3 R_1(A), \end{aligned} \tag{5.7}$$

where J_A, $I_A^\pm$, L_A, and K_A are given by (4.1) and (4.2). Clearly, for $j = 1, 2$,

$$R_j(A) = O(1) \text{ as } A \to \infty, \tag{5.8}$$

and by (4.6),

$$J_A(b) - J_A(a) \leq R_1(A). \tag{5.9}$$

Now to make use of Lemma 5.1 and the bound (5.7), we define

$$v(x) = \int_{E_c^B(A)} u(y) k^+(y) G_c^+(x,y) dy + \int_{\Gamma_c(A)} u(y) \frac{\partial G_c^+(x,y)}{\partial y_2} ds(y), \quad x \in U_c, \tag{5.10}$$

$$v(x) = \int_{E_0^d(A)} u(y) k^-(y) G_d^-(x,y) dy - \int_{\Gamma_d(A)} u(y) \frac{\partial G_d^-(x,y)}{\partial y_2} ds(y), \quad x \in \mathbf{R}^2 \backslash \overline{U}_c. \tag{5.11}$$

Then, by (3.1)–(3.2), $v|_{\Gamma_B} \in L_2(\Gamma_B) \cap BC(\Gamma_B)$ and $v|_{\Gamma_0} \in L_2(\Gamma_0) \cap BC(\Gamma_0)$. Moreover, by Lemmas 3.1 and 3.2 and the equivalence of Lemmas 2.1(i)–(ii) and 2.2, v satisfies (2.4), with $h = B$ and $\phi_+ = v|_{\Gamma_B}$, and satisfies (2.5) with $h = 0$ and $\phi_- = v|_{\Gamma_0}$. For $t \in \mathbf{R}$ set,

$$J_A'(t) = \Im \int_{\Gamma_t(A)} \overline{v}\partial_2 v ds, \qquad J_A''(t) = \Im \int_{\Gamma_t} \overline{v}\partial_2 v ds,$$

$$I_A^{\pm\prime}(t) = \int_{\Gamma_t(A)} \{|\partial_2 v|^2 - |\partial_1 v|^2 + k_\pm^2 |v|^2\} ds, \quad I_A^{\pm\prime\prime} = \int_{\Gamma_t} \{|\partial_2 v|^2 - |\partial_1 v|^2 + k_\pm^2 |v|^2\} ds,$$

$$L_A'(t) = \Re \int_{\Gamma_t(A)} \overline{v}\partial_2 v ds, \qquad L_A''(t) = \Re \int_{\Gamma_t} \overline{v}\partial_2 v ds.$$

Then, by Lemma 5.2,

$$\begin{aligned} &J_A''(b) \geq 0, \qquad L_A''(b) \leq 0, \qquad I_A^{+\prime\prime}(b) \leq 2k_+ J_A''(b), \\ &J_A''(a) \leq 0, \qquad L_A''(a) \geq 0, \qquad I_A^{-\prime\prime}(a) \leq -2k_- J_A''(a). \end{aligned}$$

Hence, by the preceding and (5.7),

$$\begin{aligned} K_A \leq C_1 \{ &\omega [\ I_A^+(b) - I_A^{+''}(b)] + \omega [I_A^-(a) - I_A^{-''}(a)] + [L_A(b) - L_A''(b)] + [L_A''(a) - L_A(a)]\} \\ &+ [C_2 + 2C_1\omega(k_+ + k_-)]\{[J_A''(b) - J_A(b)] + [J_A(a) - J_A''(a)]\} \\ &+ [C_3 + 2C_1\omega(k_+ + k_-)] R_1(A) + C_1 R_2(A). \end{aligned} \tag{5.12}$$

Now note that

$$K_A = \int_{-A}^{A} |w(x_1)|^2 dx_1,$$

where

$$\begin{aligned} w(x_1) = \Big\{ &\int_\eta^B |u(x)|^2 |k^2(x) - k_+^2| dx_2 + \int_0^\rho |u(x)|^2 |k^2(x) - k_-^2| dx_2 \\ &+ |u(x_1, c)|^2 + |u(x_1, d)|^2 \Big\}^{1/2}, \qquad x_1 \in \mathbf{R}, \end{aligned}$$

and note that by (3.3) and the Cauchy–Schwarz inequality, for $x \in \Gamma_a,\ \Gamma_b$,

$$\begin{aligned} &|v(x)|, \qquad |\nabla v(x)| \leq C W_A(x_1), \\ &|u(x) - v(x)|, \qquad |\nabla u(x) - \nabla v(x)| \leq C(W_\infty(x_1) - W_A(x_1)), \end{aligned}$$

where C is a constant independent of A and, for $0 \leq A \leq +\infty$,

$$W_A(x_1) = \int_{-A}^{A} (1 + |x_1 - y_1|)^{-3/2} w(y_1) dy_1, \qquad x_1 \in \mathbf{R}.$$

It follows that

$$\begin{aligned} |I_A^{\pm\prime}(t) - I_A^{\pm\prime\prime}(t)|, \qquad &|J_A'(t) - J_A''(t)|, \qquad |L_A'(t) - L_A''(t)| \\ &\leq C \int_{\mathbf{R}\setminus[-A,A]} (W_A(x_1))^2 dx_1, \qquad (t = a, b), \end{aligned}$$

where C is a constant independent of A, and that

$$|I_A^{\pm}(t) - I_A^{\pm\prime}(t)|, \qquad |J_A(t) - J_A'(t)|, \qquad |L_A(t) - L_A'(t)|$$
$$\leq C \int_{-A}^{A} (W_\infty(x_1) - W_A(x_1)) W_\infty(x_1) dx_1, \qquad (t = a, b),$$

so that, from (5.12) for some constant $C_0 > 0$ and all $A > 0$,

$$K_A \leq C_0 \Big\{ \int_{\mathbf{R}\setminus[-A,A]} W_A^2(x_1) dx_1 + \int_{-A}^{A} (W_\infty(x_1) - W_A(x_1)) W_\infty(x_1) dx_1$$
$$+ |R_1(A)| + |R_2(A)| \Big\}. \tag{5.13}$$

Applying Lemma 5.1 to (5.13) we obtain that $w \in L_2(\mathbf{R})$, i.e., $u \in L_2(E_B) \cap L_2(\Gamma_c) \cap L_2(\Gamma_d)$ and, for all $A_0 > 0$,

$$\int_{E_B} |u|^2 dx + \int_{\Gamma_c} |u|^2 ds + \int_{\Gamma_d} |u|^2 ds = \int_{-\infty}^{+\infty} |w|^2$$
$$\leq C_0 \sup_{A > A_0} (|R_1(A)| + |R_2(A)|). \tag{5.14}$$

Since $u \in L_2(E_B) \cap L_2(\Gamma_c) \cap L_2(\Gamma_d)$, it follows from (5.5), (5.6), the bounds (3.1) and (3.2), and applications of Young's theorem that $u \in L_2(E_a^b)$ for any $a, b \in \mathbf{R}$ with $a < b$. Also, since $\nabla u \in BC(E_a^b)$ so that u is uniformly continuous in $\overline{E_a^b}$, it follows that $u(x) \to 0$ as $x_1 \to \infty$ uniformly in x_2 for $a \leq x_2 \leq b$ for any real numbers $a < b$. Also, noting Lemma 2.2, it follows that $R_j(A) \to 0$ as $A \to \infty$, $j = 1, 2$, and thus, from (5.14), that $u = 0$ in E_B and on $\Gamma_c \cup \Gamma_d$; and hence, from (5.5) and (5.6), that $u \equiv 0$ in $\mathbf{R}^2$. □

6. Existence of solution. In this section existence of a solution for Problem (P) will be established by making use of general results on the solvability of the system of second-kind integral equations

$$\psi_i = \phi_i + \sum_{j=1}^{N} K_{ij} \psi_j, \qquad i = 1, \ldots, N, \tag{6.1}$$

in which $\phi_i \in Y_i := BC(\overline{\Omega}_i)$ is assumed known, $\psi_i \in Y_i$ is to be determined, and $K_{ij} : Y_j \to Y_i$ is the integral operator defined by

$$K_{ij}\psi(x) = \int_{\Omega_j} k_{ij}(x, y) \psi(y) d\mu_j(y), \qquad x \in \overline{\Omega}_i, \tag{6.2}$$

$i, j = 1, \ldots, N$. Here Ω_j is an open subset of $\mathbf{R}^{n_j}$ ($n_j \geq 1$) and $d\mu_j$ is n_j-dimensional Lebesgue measure. The function $k_{ij} : \overline{\Omega}_i \times \Omega_j \to \mathbf{C}$ is assumed to take the form, for some $M \in \mathbf{N}$,

$$k_{ij}(x, y) = \sum_{m=1}^{M} k_{ij}^{(m)}(x, y) z_j^{(m)}(y),$$

where $z_j^{(m)} \in X_j := L_\infty(\Omega_j)$ and $k_{ij}^{(m)}(x,\cdot) \in L_1(\Omega_j)$ for every $x \in \overline{\Omega}_i$ $(i,j = 1,\dots,N,\ m = 1,\dots,M)$. We assume that the following conditions on $k_{ij}^{(m)}$ and Ω_j hold:

(C.1) $\sup_{x\in\overline{\Omega}_i} \int_{\Omega_j} |k_{ij}^{(m)}(x,y)|d\mu_j(y) < \infty$ and, for all $x \in \overline{\Omega}_i$,

$$\int_{\Omega_j} |k_{ij}^{(m)}(x,y) - k_{ij}^{(m)}(x',y)|d\mu_j(y) \to 0$$

as $x' \to x$ with $x' \in \overline{\Omega}_i$ $(i,j = 1,\dots,N,\ m = 1,\dots,M)$.

(C.2) For some $n_0 \le \min_j n_j$ and $i = 1,\dots,N$, there exists $a_j^{(i)} \in \mathbf{R}^{n_i}$, $j = 1,\dots,n_0$, and a bounded set $\omega_i \subset \Omega_i$ such that

(i) $\Omega_i = \bigcup_{P\in\mathbf{Z}^{n_0}} \omega_i^{(P)}$, where $\omega_i^{(P)} := \omega_i + \sum_{j=1}^{n_0} a_j^{(i)} p_j$, for $P = (p_1,\dots,p_{n_0}) \in \mathbf{Z}^{n_0}$;

(ii) $\omega_i^{(Q)} \cap \omega_i^{(P)} = \emptyset$ for $Q, P \in \mathbf{Z}^{n_0}$, $Q \ne P$;

(iii) $k_{ij}^{(m)}(x + a_l^{(i)}, y + a_l^{(j)}) = k_{ij}^{(m)}(x,y)$, $x \in \overline{\Omega}_i$, $y \in \Omega_j$, $i,j = 1,\dots,N$, $l = 1,\dots,n_0$,

$m = 1,\dots,M$.

Let X and Y denote the product spaces $X := \prod_{j=1}^N X_j$ and $Y := \prod_{j=1}^N Y_j \subset X$. Let $\phi = (\phi_1,\dots,\phi_N)^t$, $\psi = (\psi_1,\dots,\psi_N)^t \in Y$, where $(\cdot,\dots,\cdot)^t$ denotes the transpose of $(\cdot,\dots,\cdot)$. For $m = 1,\dots,M$, define the matrix operator $K^{(m)}$ on X by

$$K^{(m)} = \begin{pmatrix} K_{11}^{(m)} & \cdots & K_{1N}^{(m)} \\ & \ddots & \\ K_{N1}^{(m)} & \cdots & K_{NN}^{(m)} \end{pmatrix}, \tag{6.3}$$

where $K_{ij}^{(m)} : X_j \to X_i$ is the integral operator defined by (6.2) with K_{ij}, k_{ij} replaced by $K_{ij}^{(m)}$, $k_{ij}^{(m)}$. For $z = (z_1,\dots,z_N)^t \in X$ define $\hat{z}$ by

$$\hat{z} = \begin{pmatrix} z_1 & \cdots & 0 \\ & \ddots & \\ 0 & \cdots & z_N \end{pmatrix},$$

and for $m = 1,\dots,M$ and $z \in X$, define $K_z^{(m)} : Y \to Y$ by

$$K_z^{(m)}\psi = K^{(m)}(\hat{z}\psi), \qquad \psi \in Y. \tag{6.4}$$

For $w = (w^{(1)},\dots,w^{(M)}) \in X^M$ let K_w denote the matrix integral operator

$$K_w = \sum_{m=1}^M K_{w^{(m)}}^{(m)}. \tag{6.5}$$

Then (6.1) can be abbreviated as

$$\psi = \phi + K_z\psi, \tag{6.6}$$

where $z = (z^{(1)},\dots,z^{(M)})$ and $z^{(m)} = (z_1^{(m)},\dots,z_N^{(m)})^t$, $m = 1,\dots,M$.

For $j = 1, \dots, N$, $i = 1, \dots, n_0$, define the translation operator $T_{a_j^{(i)}} : X_j \to X_j$ by

$$T_{a_j^{(i)}} \psi(x) = \psi(x - a_j^{(i)}), \qquad x \in \Omega_j,$$

and for $a = (a_1, \dots, a_N) \in \tau := \{(a_l^{(1)}, \dots, a_l^{(N)})^t | l = 1, \dots, n_0\}$, define the matrix operator $T_a : X \to X$ by

$$T_a = \begin{pmatrix} T_{a_1} & & 0 \\ & \ddots & \\ 0 & & T_{a_N} \end{pmatrix}.$$

Then, by (C.2) (iii), $T_a K^{(m)} = K^{(m)} T_a$, $a \in \tau$, $m = 1, \dots, M$. Let $B(Y)$ denote the Banach space of bounded linear operators on Y and I the identity matrix operator on Y. The following results have been proved in [10], extending the results of [9] for single integral equations to systems of integral equations.

THEOREM 6.1. *Suppose that* (C.1) *and* (C.2) *are satisfied, that* $W \subset X^M$ *is weak* sequentially compact, that* $T_a W := \{(T_a z^{(1)}, \dots, T_a z^{(M)}) | (z^{(1)}, \dots, z^{(M)}) \in W\} = W$, $a \in \tau$, *and that* $I - K_z$ *is injective for all* $z \in W$. *Then* $(I - K_z)^{-1}$ *exists as an operator on the range space* $(I - K_z)Y$ *for all* $z \in W$ *and*

$$\sup_{z \in W} \|(I - K_z)^{-1}\| < \infty.$$

Also, if for every $z \in W$ *there exists a sequence* $(z_j) \subset W$ *such that* (z_j) *converges weak* to* z *in* X *and*

$$\text{for all } j, \qquad I - K_{z_j} \quad \text{injective} \Longrightarrow I - K_{z_j} \text{ surjective},$$

then $I - K_z$ *is surjective also for each* $z \in W$ *so that* $(I - K_z)^{-1} \in B(Y)$.

THEOREM 6.2. *If* (C.1) *and* (C.2) *are satisfied,* $z = ((z_1^{(1)}, \dots, z_N^{(1)})^t, \dots, (z_1^{(M)}, \dots, z_N^{(M)})^t) \in X^M$, *and for some constants* $\lambda_j^{(m)} \in \mathbf{C}$, $j = 1, \dots, N$, $m = 1, \dots, M$, *it holds that*

$$\text{ess sup}_{|x| \geq A, x \in \Omega_j} |z_j^{(m)}(x) - \lambda_j^{(m)}| \to 0$$

as $A \to \infty$, *then*

$$I - K_\lambda, \qquad I - K_z \text{ injective } \Rightarrow I - K_z \text{ surjective}, \qquad (I - K_z)^{-1} \in B(Y),$$

where $\lambda = ((\lambda_1^{(1)}, \dots, \lambda_N^{(1)})^t, \dots, (\lambda_1^{(M)}, \dots, \lambda_N^{(M)})^t)$.

To apply Theorems 6.1 and 6.2 to show the existence of a solution to Problem (P), we choose λ, c, and d so that $0 \leq c < d \leq B$, $k_-(d - \lambda) = k_+(\lambda - c)$, and $2(d - c)k_+k_- < \pi(k_+ + k_-)$. It then follows from Theorem 3.2 that Problem (P) and the integral equation problems (3.10) and (3.11) are equivalent.

Let $N = 4$, $n_0 = 1$, $\Omega_1 = E_\lambda^B \subset \mathbf{R}^2$, $\Omega_2 = E_0^\lambda \subset \mathbf{R}^2$, $\Omega_3 = \Omega_4 = \mathbf{R}$, $\omega_1 = \{x \in \Omega_1 | 0 \leq x_1 < B, \lambda < x_2 < B\}$, $\omega_2 = \{x \in \Omega_2 | 0 \leq x_1 < B, 0 < x_2 < \lambda\}$, $\omega_3 = \omega_4 = [0, B)$, $a_1^{(1)} = a_1^{(2)} = (B, 0)$, and $a_1^{(3)} = a_1^{(4)} = B$. Define $\tilde{y} := y$ and $\hat{y} := y$ for $y \in \mathbf{R}^2$ and $\tilde{y} := (y, c)$ and $\hat{y} := (y, d)$ for $y \in \mathbf{R}$. Let $\chi(t) = 1$, $t > 0$, $= 0$, $t < 0$, and let $M = 2$, $k_{ij}^{(1)}(x, y) = G_c^+(\hat{x}, y)\chi(y_2 - c)$ for all $x \in \Omega_i$, $y \in \Omega_j$,

$\hat{x} \neq y$, $i = 1, 3, j = 1, 2$, $k_{ij}^{(1)}(x, y) = G_d^-(\tilde{x}, y)\chi(d - y_2)$ for all $x \in \Omega_i$, $y \in \Omega_j$, $\tilde{x} \neq y$, $i = 2, 4, j = 1, 2$, $k_{i4}^{(1)}(x, y) = \partial G_c^+(\hat{x}, z)/\partial z_2|_{z=\tilde{y}}$ for all $x \in \Omega_i$, $y \in \Omega_4$, $i = 1, 3$, $k_{i3}^{(1)}(x, y) = \partial G_d^-(\tilde{x}, z)/\partial z_2|_{z=\hat{y}}$ for all $x \in \Omega_i$, $y \in \Omega_3$, $i = 2, 4$, $k_{ij}^{(1)}(x, y) = 0$ for all $x \in \Omega_i$, $y \in \Omega_j$, with $i = 1, 3, j = 3$, or $i = 2, 4, j = 4$. Let $k_{ij}^{(2)} = k_{ij}^{(1)}$, $i = 2, 4$, $j = 1, 2, = 0$, otherwise. Then conditions (C.1) and (C.2) are satisfied with these choices of $k_{ij}^{(m)}$ and Ω_j $(i, j = 1, 2, 3, 4, m = 1, 2)$. Set $w_j^{(1)}(y) = k^+(y)$ for $y \in \Omega_j$, $j = 1, 2$, $w_3^{(1)}(y) = -1$, $y \in \Omega_3$, $w_4^{(1)}(y) = 1$, $y \in \Omega_4$, and set $w^{(1)} = (w_1^{(1)}, \ldots, w_4^{(1)})^t$, $w^{(2)} = (k_+^2 - k_-^2)(1, 1, 0, 0)^t$. Then the integral equations (3.10) and (3.11) can be written as the 4×4 matrix system

$$(I - K_w)\psi = \phi, \qquad \psi = (\psi_1, \ldots, \psi_4)^t, \qquad \phi = (\phi_1, \ldots, \phi_4)^t \in Y, \tag{6.7}$$

where $w = (w^{(1)}, w^{(2)})$, K_w is defined by (6.5), (6.4), and (6.3), $\phi_2 = \phi_4 = 0$, $\phi_j(y) = u^i(\hat{y}) + u^r(\hat{y})$, $y \in \overline{\Omega}_j$, $j = 1, 3$, and $\psi_3, \psi_4 \in BC(\mathbf{R})$ are defined by $\psi_3(y) = \psi_2(\hat{y})$, $\psi_4(y) = \psi_1(\tilde{y})$, $y \in \mathbf{R}$.

THEOREM 6.3. *Assume that* (A3) *holds or that* (A4) *and* (A5) *hold and that* $k_-(d - \lambda) = k_+(\lambda - c)$ *and* $2(d - c)k_+k_- < \pi(k_+ + k_-)$. *Then* $(I - K_w)^{-1} \in B(Y)$ *so that the system of integral equations* (6.7) *has a unique solution* $\psi \in Y$. *Furthermore, for any* $L > 0$, *there is a constant* $C > 0$ *depending only on* L, $k_\pm$, c, d, η, ρ, B, λ_1, *and* λ_2, *in the case that* (A3) *is satisfied, or on* L, $k_\pm$, c, d, η, ρ, B, β, *and* λ_3, *in the case that* (A4) *and* (A5) *are satisfied such that, provided* $\|k\|_\infty \leq L$, $\|(I - K_w)^{-1}\| \leq C$ *so that* $\|\psi\| \leq C\|\phi\|$.

Proof. Theorem 6.3 is proved by means of Theorems 6.1 and 6.2. To this end, suppose without loss of generality that $L > k_\pm^2 + \lambda_1$ and set

$$\begin{aligned} Q = Q_3 := \{&\mu \in L_\infty(E_B) | \Im\mu \geq 0, \Im\mu(x) \geq \lambda_1, x \in E_\eta^\rho, \Im\mu(x) \geq \lambda_2 |\mu(x) - k_+^2|, \\ &x \in E_\eta^B, \Im\mu(x) \geq \lambda_2 |\mu(x) - k_-^2|, x \in E_0^\rho, ||\mu||_\infty \leq L^2\} \end{aligned}$$

in the case that (A3) is satisfied. In the case that (A4) and (A5) are satisfied suppose without loss of generality that $L^2 > k_\pm^2 + \lambda_3$ and set

$$\begin{aligned} Q = Q_4 := \{&\mu \in L_\infty(\mathbf{R}^2) | \Im\mu \geq 0, \mu(x) = k_+^2, x \in U_B, \mu(x) = k_-^2, x \in \mathbf{R}^2 \backslash \overline{U}, \\ &||\mu||_\infty \leq L^2, \text{ ess inf}_{x \in U_\beta} \Re[\mu(x + e_2 h) - \mu(x)] \geq 0, \\ &\text{ess inf}_{x \in \mathbf{R}^2 \backslash \overline{U}_\beta} \Re[\mu(x - e_2 h) - \mu(x)] \geq 0, \ h > 0, \\ &\text{ess inf}_{x \in E_\eta^\rho} \{\tilde{k}^2(x) - \Re[\mu(x)]\} \geq \lambda_3\}. \end{aligned}$$

Define $W^{(1)} \subset X$ by

$$W^{(1)} = \{(\mu|_{\Omega_1} - k_+^2, \ \mu|_{\Omega_2} - k_+^2, \ -1, \ 1)^t | \mu \in Q\}$$

and $W \subset X^2$ by

$$W = \{(w^{(1)}, \ (k_+^2 - k_-^2, \ k_+^2 - k_-^2, \ 0, \ 0)^t) | w^{(1)} \in W^{(1)}\}.$$

Then $T_a W = W$ for $a \in \tau = \{(a_1^{(1)}, \ldots, a_1^{(4)})\}$. Also, it follows easily from Theorems 3.2 and 5.1 that $I - K_z$ is injective for all $z \in W$.

Next, we show that W is weak$*$ sequentially compact. In view of the definition of W it is sufficient to show that $W^{(1)} \subset X$ is weak$*$ sequentially compact. Further,

in view of the definition of $W^{(1)}$, it is sufficient to show that Q is weak$*$ sequentially compact, where $Q = Q_3 \subset L_\infty(E_B)$ in the case that (A3) is satisfied and $Q = Q_4 \subset L_\infty(\mathbf{R}^2)$ in the case that (A4) and (A5) are satisfied.

Since Q is bounded it follows from the Alaoglu theorem [16, p. 60] that Q is weak$*$ sequentially compact if it is weak$*$ sequentially closed. In the case $Q = Q_3$, the fact that Q is weak$*$ sequentially closed follows from Lemma 2.13 in [9], since the sets $\{w \in \mathbf{C} | \, |w| \le L^2, \Im w \ge \lambda_1\}$ and $\{w \in \mathbf{C} | \, |w| \le L^2, \Im w \ge 0, \ \Im w \ge \lambda_2 |w - k_*^2|\}$, for $k_* = k_+$ and k_-, are compact and convex.

In the case $Q = Q_4$, in order to see that Q is weak$*$ sequentially compact consider a sequence $(\mu_j) \subset Q$. Since (μ_j) is bounded, it follows from the Alaoglu theorem [16, p. 60] that there is an element $\mu \in L_\infty(\mathbf{R}^2)$ and a subsequence of (μ_j), denoted simply by itself, such that (μ_j) converges weak$*$ to μ in $L_\infty(\mathbf{R}^2)$ and $\|\mu\|_\infty \le L^2$. Thus, for all $\xi \in L_1(\mathbf{R}^2)$,

$$\int_{\mathbf{R}^2} \mu_j \xi dx \to \int_{\mathbf{R}^2} \mu \xi dx, \tag{6.8}$$

as $j \to \infty$ and, in particular, (6.8) holds if ξ is the characteristic function of any bounded measurable subset of $\mathbf{R}^2$. This and the fact that $\mu_j \in Q$, $j = 1, 2, \ldots$, implies that $\Im \mu \ge 0$ in $\mathbf{R}^2$, $\mu(x) = k_+^2$ for $x \in U_B$, $\mu(x) = k_-^2$ for $x \in \mathbf{R}^2 \backslash \overline{U}$, ess $\inf_{x \in E_\eta^\rho} \{\tilde{k}^2(x) - \Re[\mu(x)]\} \ge \lambda_2$, and

$$\begin{aligned} \text{ess inf}_{x \in U_\beta} \, \Re[\mu(x + e_2 h) - \mu(x)] &\ge 0, \\ \text{ess inf}_{x \in \mathbf{R}^2 \backslash \overline{U}_\beta} \, \Re[\mu(x - e_2 h) - \mu(x)] &\ge 0 \end{aligned}$$

for all $h > 0$. Hence $\mu \in Q$ and (μ_j) converges weak$*$ to μ in Q. Thus Q is weak$*$ sequentially compact.

Finally, let $z = (z^{(1)}, z^{(2)}) \in W$. Then, for some $\mu \in Q$, $z^{(1)} = (\mu|_{\Omega_1} - k_+^2, \ \mu|_{\Omega_2} - k_+^2, \ -1, \ 1)^t$ and $z^{(2)} = (k_+^2 - k_-^2)(1, 1, 0, 0)^t$. For $j = 1, 2, \ldots$, set

$$\mu_j(x) = \begin{cases} \mu^*(x) & \text{for } |x_1| > j, \\ \mu(x) & \text{for } |x_1| \le j, \end{cases}$$

where $\mu^* \equiv i\lambda_1$ in the case that (A3) is satisfied, $\mu^* = k_+^2$ in U_B, $= k_-^2$ in $\mathbf{R}^2 \backslash \overline{U}$, $= \min(k_-^2, k_+^2) - \lambda_2$ in E_B, in the case that (A4) and (A5) are satisfied. Then $\mu^*, \mu_j \in Q$, and setting $z_j^{(1)} = (\mu_j|_{\Omega_1} - k_+^2, \ \mu_j|_{\Omega_2} - k_+^2, \ -1, \ 1)^t$ and $z_j = (z_j^{(1)}, z^{(2)})$, $j = 1, 2, \ldots$, it is easy to see that (z_j) converges weak$*$ to z. Define

$$\begin{aligned} z^* &= ((\mu^*|_{\Omega_1} - k_+^2, \ \mu^*|_{\Omega_2} - k_+^2, \ -1, \ 1)^t, z^{(2)}) \\ &= ((\lambda^*, \lambda^*, -1, 1)^t, (k_+^2 - k_-^2, k_+^2 - k_-^2, 0, 0)^t), \end{aligned}$$

where $\lambda^* \in \mathbf{C}$ is given by $\lambda^* = i\lambda_1 - k_+^2$ in the case that (A3) is satisfied and by $\lambda^* = \min(k_-^2, k_+^2) - \lambda_2 - k_+^2$ in the case that (A4) and (A5) are satisfied. Since $z^* \in W$ so that $I - K_{z^*}$ is injective, it follows from Theorem 6.2 that $I - K_{z_j}$ injective implies $I - K_{z_j}$ surjective, for $j = 1, 2, \ldots$.

All the assumptions in Theorem 6.1 have been verified so Theorem 6.3 follows from Theorem 6.1. ∎

THEOREM 6.4. *Assume that* (A3) *holds or that* (A4) *and* (A5) *hold. Then Problem* (P) *has exactly one solution. Further, for any* $L > 0$, *there exists a constant* $C > 0$ *depending only on* L, $k_\pm$, η, ρ, B, λ_1, *and* λ_2 *in the case that* (A3) *is satisfied, or*

on L, $k_\pm$, η, ρ, B, β, *and* λ_3 *in the case that* (A4) *and* (A5) *are satisfied such that, provided* $\|k\|_\infty \le L$,

$$|u(x)| \le C(1+|x_2|)^{1/2}, \qquad x \in \mathbf{R}^2. \tag{6.9}$$

Proof. The existence of a unique solution to Problem (P) follows from Theorems 3.1, 3.2, and 6.3. To derive the estimate (6.9) we note from the equivalence of (i) and (ii) in Lemma 2.1 that, for $h > B$,

$$u^{\mathrm{s}}(x) = 2\int_{\Gamma_h} \frac{\partial \Phi(x,y)}{\partial y_2} u^{\mathrm{s}}(y)\, ds(y), \qquad x \in U_h. \tag{6.10}$$

It follows from (2.6) and (6.10) (see [5]) that

$$|u^{\mathrm{s}}(x)| \le C(1+(x_2-B))^{1/2} \sup_{x\in\Gamma_B} |u(x)|, \qquad x \in U_B, \tag{6.11}$$

for some constant $C > 0$ dependent only on k_+, which together with Theorem 6.3 implies the estimate (6.9) for $x \in U$. The estimate (6.9) for $x \in \mathbf{R}^2 \backslash U$ can be proved similarly by using Lemma 2.2. ∎

Appendix: Guided waves. By a guided wave we mean a solution of the homogeneous problem which has its energy localized in or near the layer E_B. Precisely, for $a < b$, let $D(a,b) = \{x \in \mathbf{R}^2 | a < x_1 < b\}$. Then our definition is as follows.

Definition A.1. *Call* $v \in C^1(\mathbf{R}^2)$ *a* guided wave *if* $v \not\equiv 0$, v *satisfies* (2.3), v *is bounded in* E^h_{-h} *for every* $h > 0$,

$$\sup_{n\in\mathbf{Z}} \int_{D(n,n+1)} (|v|^2 + |\nabla v|^2)\, dx < \infty, \tag{A.1}$$

and

$$c_h := \sup_{n\in\mathbf{Z}} \int_{D(n,n+1)\backslash E^h_{-h}} (|v|^2 + |\nabla v|^2)\, dx \to 0 \tag{A.2}$$

as $h \to \infty$.

Remark A.1. In the case when the scatterer is a diffraction grating, i.e., k is periodic in the x_1-direction with some period L, it is usual to assume that v is correspondingly quasi periodic (i.e., that $v(x)\exp(-ik_+ \cos\theta\, x_1)$ is periodic). Then (A.1) and (A.2) reduce to the condition that

$$\int_{D(0,L)} (|v|^2 + |\nabla v|^2)\, dx < \infty,$$

i.e., that the energy is finite in a single period of the grating (cf. Bonnet-Bendhia and Starling [3]).

Remark A.2. Conditions (A.1) and (A.2) are satisfied if v decreases rapidly enough in the vertical direction, in particular, if for some constants $C > 0$ and $p > 1/2$,

$$|v(x)| \le C(1+|x_2|)^{-p}, \qquad x \in \mathbf{R}^2.$$

The following result follows from Theorem 8.1 in [7] and Remark 2.1.

Theorem A.1. *If* v *is a guided wave, then* v *satisfies the UPRC for wavenumber* k_+ *and the DPRC for wavenumber* k_-.

ON THE CLASSICAL SOLVABILITY OF THE STEFAN PROBLEM IN A VISCOUS INCOMPRESSIBLE FLUID FLOW*

YOSHIAKI KUSAKA† AND ATUSI TANI†

Abstract. This paper is devoted to the study of a solidification/melting process in the case where the fluid is flowing. Such a phenomenon is described by the Stefan problem with transport terms in the equation of the temperature distribution and the initial-boundary value problem for the incompressible Navier–Stokes equations. The existence of the classical solution is proved locally in time.

Key words. classical solvability, Stefan problem, viscous incompressible fluid

1. Introduction. This paper is devoted to the study of solidification/melting processes in the case where the fluid is flowing. Such phenomena have received attention only during past three decades in physics [4], [16], [23].

In contrast to the above, we have a long history of the study of phase change in stagnant media since Stefan's pioneering work in 1891. In these problems, the unknowns are the interface separating the liquid and the solid regions and the temperature distributions in both regions. An excellent survey is provided by Rubinstein [19], Yamaguti and Nogi [25], and Meĭrmanov [15]. Meĭrmanov [14] and Hanzawa [10], in particular, studied the time-dependent, multidimensional Stefan problem in the class of smooth functions by a regularization method and by the Nash–Moser implicit function theorem, respectively.

The classical solvability of the same problem for a convective motion in a viscous incompressible fluid flow was discussed by Bazaliĭ and Degtyarev [3]. Stimulated by their work, in this paper we consider the same problem in another situation.

The differences between our problem (1.1)–(1.6) below and that of Bazaliĭ and Degtyarev consist of two aspects:

1. Equations (1.1) and (1.2) are the same except for the right-hand side of (1.2), which is caused by Boussinesq approximation in [8].
2. Bazaliĭ and Degtyarev imposed the boundary condition $\boldsymbol{v} = 0$ on the interface. Instead we impose (1.3) on the interface since, in general, the densities of a liquid and a solid at the melting temperature are not equal; for example, the densities of water and ice at 0°C are 0.999 g/cm^3 and 0.917 g/cm^3 [7] and we assume that the melting or freezing processes proceed without cavity.

Now let us formulate our problem: find the interface Γ_t which separates the liquid and the solid phases, the temperature θ, and the fluid velocity $\boldsymbol{v} = (v_1, v_2, v_3)$ satisfying

$$\frac{\partial \boldsymbol{v}}{\partial t} + (\boldsymbol{v} \cdot \nabla)\boldsymbol{v} + \nabla p - \nu \Delta \boldsymbol{v} = \boldsymbol{f}(\theta), \quad \nabla \cdot \boldsymbol{v} = 0, \tag{1.1}$$

$$\frac{\partial\theta}{\partial t}+(\boldsymbol{v}\cdot\nabla)\theta-\frac{1}{\varrho C_p}\nabla\cdot(\kappa(\theta)\nabla\theta)=\frac{\nu}{2C_p}\sum_{i,k}\left(\frac{\partial v_i}{\partial x_k}+\frac{\partial v_k}{\partial x_i}\right)^2 \tag{1.2}$$

in $\bigcup_{0<t\le T}(\Omega_t\times\{t\})$, where Ω_t denotes the liquid region, ν and C_p mean kinetic viscosity and specific heat at constant pressure (assumed to be positive constants), and $\kappa(\theta)$ is heat conductivity. Equation (1.1) is known as the Navier–Stokes equations, and the right-hand side of (1.2) represents the heat generation due to viscosity.

We impose the following conditions on the interface $\bigcup_{0<t\le T}(\Gamma_t\times\{t\})$ (see, for example, [11]):

$$\boldsymbol{v}\cdot\boldsymbol{n}=\left(1-\frac{\varrho_e}{\varrho}\right)\mathcal{V},\quad 2\nu\Pi\,\mathbf{D}(\boldsymbol{v})\boldsymbol{n}=\Pi\left[\boldsymbol{v}(\boldsymbol{v}-\mathcal{V}\boldsymbol{n})^*\right]\boldsymbol{n}, \tag{1.3}$$

$$l\varrho_e\mathcal{V}=-\kappa(\theta)\nabla\theta\cdot\boldsymbol{n},\quad \theta=\theta_1. \tag{1.4}$$

Here ϱ and ϱ_e are positive constants representing the densities of liquid and solid, respectively; $\mathcal{V}$ is the normal velocity of the interface; l is a latent heat; $\mathbf{D}(\boldsymbol{v})$ is the velocity deformation tensor; Π is the projection operator to Γ_t; $\boldsymbol{n}$ is the unit normal vector to Γ_t pointing into the liquid region; θ_1 is the melting (solidification) temperature. The notation $\boldsymbol{a}^*$ is used for the transposed vector of $\boldsymbol{a}$. The conservation laws of mass and momentum imply $(1.3)^1$ and $(1.3)^2$, respectively, and (1.4) is the so-called Stefan condition which describes the conservation law of energy on the interface in the process of liquid-solid phase change.

Furthermore, in order to complete the problem, we need initial conditions and boundary conditions on the rigid boundary $\Sigma_T\equiv\Sigma\times(0,T)$:

$$\boldsymbol{v}=\boldsymbol{v}_0,\quad \theta=\theta_0\qquad\text{on}\quad \Omega\equiv\Omega_0, \tag{1.5}$$

$$\boldsymbol{v}=0,\quad \theta=\theta_2\qquad\text{on}\quad \Sigma_T. \tag{1.6}$$

Before stating our result, we introduce the function spaces used throughout this paper. Let D be a domain in $\mathbf{R}^3\times(0,T)$, l be a nonnegative integer, and $0<\alpha<1$. We denote by $C^{l+\alpha,\frac{l+\alpha}{2}}(D)$ the standard anisotropic Hölder space whose norm is $|\cdot|_D^{(l+\alpha,\frac{l+\alpha}{2})}$, and by $\tilde{C}^{3+\alpha,\frac{3+\alpha}{2}}(D)$ the function space

$$\left\{f\;\middle|\; f\in C^{3+\alpha,\frac{3+\alpha}{2}}(D),\frac{\partial f}{\partial t}\in C^{2+\alpha,\frac{2+\alpha}{2}}(D)\right\}$$

equipped with the norm

$$\|f\|_D^{(3+\alpha,\frac{3+\alpha}{2})}\equiv|f|_D^{(3+\alpha,\frac{3+\alpha}{2})}+\left|\frac{\partial f}{\partial t}\right|_D^{(2+\alpha,\frac{2+\alpha}{2})}.$$

We also define function spaces $C_0^{l+\alpha,\frac{l+\alpha}{2}}(D)$ and $\tilde{C}_0^{3+\alpha,\frac{3+\alpha}{2}}(D)$ as

$$\left\{f\in C^{l+\alpha,\frac{l+\alpha}{2}}(D)\;\middle|\;\left.\frac{\partial kf}{\partial tk}\right|_{t=0}=0\quad\text{for}\quad k=0,1,\dots,\left[\frac{l}{2}\right]\right\}$$

and

$$\left\{f\in\tilde{C}^{3+\alpha,\frac{3+\alpha}{2}}(D)\;\middle|\;\left.\frac{\partial kf}{\partial tk}\right|_{t=0}=0\quad\text{for}\quad k=0,1,2\right\},$$

respectively.

The following is our main result in this paper.

THEOREM 1.1. *Let T be an arbitrary positive real number and $0 < \alpha < 1$. Assume that*

$$\Gamma \equiv \Gamma_0 \in C^{3+\alpha}, \quad \Sigma \in C^{3+\alpha},$$

$$\boldsymbol{f} \in C^{1+\alpha}(0,\infty), \quad \kappa \in C^{2+\alpha}(0,\infty), \quad \boldsymbol{v}_0 \in C^{2+\alpha}(\overline{\Omega}),$$

$$\theta_0 \in C^{3+\alpha}(\overline{\Omega}), \quad \theta_1 \in C^{3+\alpha,\frac{3+\alpha}{2}}(\mathbf{R}^3 \times [0,T]), \quad \theta_2 \in C^{3+\alpha,\frac{3+\alpha}{2}}(\Sigma_T),$$

$$\kappa_0 \le \kappa(\theta) \le {\kappa_0}^{-1}, \quad \theta_2 \ge a_0, \quad |\boldsymbol{n} \cdot \nabla\theta_0|_{\Gamma_T}| \ge a_0$$

for some positive constants $\kappa_0 (< 1)$ and a_0. Moreover, we assume that the compatibility conditions up to order 1 hold. Then problem (1.1)–(1.6) has a solution

$$\Gamma_t \in \tilde{C}^{3+\alpha',\frac{3+\alpha'}{2}}, \quad \theta \in C^{3+\alpha',\frac{3+\alpha'}{2}}\left(\bigcup_{0\le t\le T_0}(\Omega_t \times \{t\})\right),$$

$$\boldsymbol{v} \in C^{2+\alpha',\frac{2+\alpha'}{2}}\left(\bigcup_{0\le t\le T_0}(\Omega_t \times \{t\})\right), \quad \nabla p \in C^{\alpha',\frac{\alpha'}{2}}\left(\bigcup_{0\le t\le T_0}(\Omega_t \times \{t\})\right)$$

for some $\alpha', 0 < \alpha' < \alpha$ and some $T_0, 0 < T_0 < T$.

2. Reduction of the problem. In this section, using the transformation due to Hanzawa [10] (see also [6]), we reduce problem (1.1)–(1.6) to that in a fixed domain. First we introduce the local coordinates $(\omega_1, \omega_2, \lambda)$ in a neighborhood of Γ, where $\omega = (\omega_1, \omega_2)$ denotes a point on the surface Γ, and a mapping x defined by $x(\omega, \lambda) = \omega + \boldsymbol{n}(\omega)\lambda$ from $\Gamma \times [-\gamma_0, \gamma_0]$ to $N_0 \subset \mathbf{R}^3$ with $\boldsymbol{n}(\omega)$ being the unit normal to Γ at ω directing into Ω. Here a positive number γ_0 is assumed to be chosen so small that the mapping x is regular and one to one. By $(\omega(x), \lambda(x))$ we denote the inverse mapping of x from N_0 to $\Gamma \times [-\gamma_0, \gamma_0]$.

Now let us assume that the interface $\Gamma_t, t \in [0,T]$ is represented by $x = \omega + \boldsymbol{n}(\omega)d(\omega,t)$ with a function $d(\omega,t)$ satisfying $d(\omega,0) = 0$. Certainly we get another representation of $\bigcup_{0\le t\le T}(\Gamma_t \times \{t\})$,

$$\bigcup_{0\le t\le T}(\Gamma_t \times \{t\}) = \left\{(x,t) \in N_0 \times [0,T] \;\middle|\; \Phi_d(x,t) = 0\right\},$$

for a function

$$\Phi_d(x,t) = \lambda(x) - d(\omega(x),t), \qquad (x,t) \in N_0 \times [0,T].$$

Accordingly, the Stefan condition can be written as

$$\frac{\partial \Phi_d}{\partial t} - c_0(\nabla\Phi_d \cdot \nabla\theta) = 0 \qquad \text{on} \qquad \bigcup_{0<t\le T}(\Gamma_t \times \{t\}),$$

where $c_0 = \kappa(\theta_1)/(l\varrho_e)$.

Next let X_T and Y_T be two coordinates (x_1, x_2, x_3, t) and (y_1, y_2, y_3, t) in $\mathbf{R}^3 \times [0, T]$ such that

$$x = (\omega(x), \lambda(x)), \qquad y = (\omega(y), \eta(y)),$$

$$\omega(x) = \omega(y), \quad \lambda(x) = \eta(y) + \chi(\eta(y))d(\omega(y), t) \qquad \text{if} \quad (x,t) \in N_0 \times [0,T],$$

$$\omega(x) = \omega(y), \quad \lambda(x) = \eta(y) \qquad \text{if} \quad (x,t) \in {N_0}^c \times [0,T],$$

where $\chi(\lambda) \in C^\infty(-\infty, +\infty)$ is a cut-off function satisfying

$$\chi(\lambda) = \begin{cases} 1 & \text{for} \quad |\lambda| \le \dfrac{\gamma_0}{4}, \\ 0 & \text{for} \quad |\lambda| \ge \dfrac{3\gamma_0}{4}, \end{cases} \qquad |\chi'(\lambda)| \le \frac{4}{3\gamma_0}.$$

Then we define a mapping $e_d : Y_T \to X_T$ by

$$e_d(y(\omega,\eta),t) = (x(\omega, \eta + \chi(\eta)d(\omega,t)), t) \qquad \text{for} \quad (x,t) \in N_0 \times [0,T],$$

$$e_d(y(\omega,\eta),t) = (x(\omega,\eta), t) \qquad \text{for} \quad (x,t) \in {N_0}^c \times [0,T].$$

It is obvious that $Q_T = \Omega \times [0,T]$ and $\Gamma_T = \Gamma \times [0,T]$ are transformed onto $\bigcup_{0\le t\le T}(\Omega_t \times \{t\})$ and $\bigcup_{0\le t\le T}(\Gamma_t \times \{t\})$, respectively, by e_d. Denoting simply by $\theta, \boldsymbol{v}$, and p the transformed functions $\theta \circ e_d, \boldsymbol{v} \circ e_d$, and $p \circ e_d$, respectively, we reduce problem (1.1)–(1.6) to that in the fixed domain Q_T in variables (y,t):

(2.1)
$$\begin{cases} \dfrac{\partial \boldsymbol{v}}{\partial t} + (\boldsymbol{h}_d \cdot \nabla)\boldsymbol{v} + (\boldsymbol{v} \cdot \nabla_d)\boldsymbol{v} - \nu {\nabla_d}^2 \boldsymbol{v} + \nabla_d p = \boldsymbol{f}(\theta), \quad \nabla_d \cdot \boldsymbol{v} = 0 \quad \text{in} \quad Q_T, \\ \boldsymbol{v}|_{t=0} = \boldsymbol{v}_0 \quad \text{on} \quad \bar{\Omega}, \\ \boldsymbol{v} \cdot \boldsymbol{n}_d = \left(1 - \dfrac{\varrho_e}{\varrho}\right)\mathcal{V}, \quad 2\nu \Pi_d \mathbf{D}_d(\boldsymbol{v})\boldsymbol{n}_d = \Pi_d[\boldsymbol{v}(\boldsymbol{v} - \mathcal{V}\boldsymbol{n}_d)^*]\boldsymbol{n}_d \quad \text{on} \quad \Gamma_T, \\ \boldsymbol{v} = 0 \quad \text{on} \quad \Sigma_T, \end{cases}$$

(2.2)
$$\begin{cases} \dfrac{\partial \theta}{\partial t} + (\boldsymbol{h}_d \cdot \nabla)\theta + (\boldsymbol{v} \cdot \nabla_d)\theta - \dfrac{1}{\varrho C_p}\nabla_d \cdot (\kappa(\theta)\nabla_d \theta) \\ \qquad = \dfrac{\nu}{2C_p} \displaystyle\sum_{i,k} \left(\sum_j \left\{ a^{kj} \frac{\partial v_i}{\partial y_j} + a^{ij} \frac{\partial v_k}{\partial y_j} \right\} \right)^2 \qquad \text{in} \quad Q_T, \\ \theta|_{t=0} = \theta_0 \qquad \text{on} \quad \bar{\Omega}, \\ \theta = \theta_1, \quad \dfrac{\partial d}{\partial t} + c_0(\nabla_d \Phi_d \cdot \nabla_d \theta) = 0 \quad \text{on} \quad \Gamma_T, \\ d(\omega, 0) = 0 \quad \text{on} \quad \Gamma, \\ \theta = \theta_2 \quad \text{on} \quad \Sigma_T. \end{cases}$$

Here we use the notation

$$\nabla_d = (E_d^*)^{-1}\nabla, \quad \boldsymbol{h}_d = \frac{\partial y}{\partial t} \circ e_d, \quad \boldsymbol{n}_d = \frac{\nabla_d \eta}{|\nabla_d \eta|}, \quad \mathbf{D}_d(\boldsymbol{v}) = \mathbf{D}(\boldsymbol{v}) \circ e_d, \quad \Pi_d g = \Pi g \circ e_d;$$

$E_d = (a_{ij})$ is the Jacobian matrix of the mapping from y to x, E_d^* is the transposed matrix of E_d, and a^{ij} is the (i,j)-component of $(E_d^*)^{-1}$.

It is obvious that there exist the extensions $\hat{\theta} \in C^{3+\alpha,\frac{3+\alpha}{2}}(Q_T)$, $\hat{d} \in C^{4+\alpha,\frac{4+\alpha}{2}}(\Gamma_T)$, $\hat{\boldsymbol{v}} \in C^{2+\alpha,\frac{2+\alpha}{2}}(Q_T)$, $\nabla\hat{p} \in C^{\alpha,\frac{\alpha}{2}}(Q_T)$ which satisfy the conditions

$$
\begin{cases}
\hat{\theta}(y,0) = \theta_0(y), \quad \dfrac{\partial\hat{\theta}}{\partial t}(y,0) = \theta^{(1)}(y), \\
\hat{d}(\omega,0) = 0, \quad \dfrac{\partial\hat{d}}{\partial t}(\omega,0) = d^{(1)}(\omega), \quad \dfrac{\partial^2\hat{d}}{\partial t^2}(\omega,0) = d^{(2)}(\omega), \\
\hat{\boldsymbol{v}}(y,0) = \boldsymbol{v}_0(y), \quad \dfrac{\partial\hat{\boldsymbol{v}}}{\partial t}(y,0) = \boldsymbol{v}^{(1)}(y), \\
\nabla\hat{p}(y,0) = -\boldsymbol{v}^{(1)}(y) - (\boldsymbol{v}_0(y)\cdot\nabla)\boldsymbol{v}_0(y) + \nu\nabla^2\boldsymbol{v}_0(y) + \boldsymbol{f}(\theta_0),
\end{cases}
$$

where $\theta^{(1)}, d^{(1)}, d^{(2)}$, and $\boldsymbol{v}^{(1)}$ are defined from the compatibility conditions of the equations and data in (2.1) and (2.2). It is clear that such extensions can be taken to satisfy the inequality

$$
|\hat{\theta}|_{Q_T}^{(3+\alpha,\frac{3+\alpha}{2})} + |\hat{d}|_{\Gamma_T}^{(4+\alpha,\frac{4+\alpha}{2})} + |\nabla\hat{p}|_{Q_T}^{(\alpha,\frac{\alpha}{2})} + |\hat{\boldsymbol{v}}|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})} \le C\left(|\theta_0|_{\bar{\Omega}}^{(3+\alpha)} + |\boldsymbol{v}_0|_{\bar{\Omega}}^{(2+\alpha)}\right)
$$

with a constant C being bounded as $T \to 0$.

Then by introducing the new functions $w \equiv \theta - \hat{\theta} - \chi\sigma\partial\hat{\theta}/\partial n, \sigma \equiv d - \hat{d}, \boldsymbol{u} \equiv \boldsymbol{v} - \hat{\boldsymbol{v}}$ and $\nabla q \equiv \nabla p - \nabla\hat{p}$, problems (2.1) and (2.2) can be written in the equivalent form

$$
\begin{cases}
\dfrac{\partial\boldsymbol{u}}{\partial t} - \nu\Delta\boldsymbol{u} + \nabla q = \boldsymbol{f}\left(w + \hat{\theta} + \chi\dfrac{\partial\hat{\theta}}{\partial n}\sigma\right) - \dfrac{\partial\hat{\boldsymbol{v}}}{\partial t} - \left(\boldsymbol{h}_{\sigma+\hat{d}}\cdot\nabla\right)(\boldsymbol{u}+\hat{\boldsymbol{v}}) \\
\qquad +\nu\left(\nabla_{\sigma+\hat{d}}^2 - \nabla^2\right)(\boldsymbol{u}+\hat{\boldsymbol{v}}) + \nu\Delta\hat{\boldsymbol{v}} - \left((\boldsymbol{u}+\hat{\boldsymbol{v}})\cdot\nabla_{\sigma+\hat{d}}\right)(\boldsymbol{u}+\hat{\boldsymbol{v}}) \\
\qquad -\nabla_{\sigma+\hat{d}}(q+\hat{p}) + \nabla q \equiv \mathcal{F}_1(\boldsymbol{u},\nabla q, w, \sigma) \quad \text{in} \quad Q_T, \\
\nabla\cdot\boldsymbol{u} = -\left(\nabla_{\sigma+\hat{d}} - \nabla\right)\cdot\boldsymbol{u} - \nabla_{\sigma+\hat{d}}\cdot\hat{\boldsymbol{v}} \equiv \mathcal{F}_2(\boldsymbol{u},\sigma) \quad \text{in} \quad Q_T, \\
\boldsymbol{u}\,\big|_{t=0} = 0 \quad \text{on} \quad \bar{\Omega}, \\
\boldsymbol{u}\cdot\boldsymbol{n} = -\boldsymbol{u}\cdot\left(\boldsymbol{n}_{\sigma+\hat{d}} - \boldsymbol{n}\right) - \hat{\boldsymbol{v}}\cdot\boldsymbol{n}_{\sigma+\hat{d}} + \left(1 - \dfrac{\varrho_e}{\varrho}\right)\left(\dfrac{\partial\sigma}{\partial t} + \dfrac{\partial\hat{d}}{\partial t}\right) \\
\qquad\qquad \equiv \mathcal{F}_3(\boldsymbol{u},\sigma) \quad \text{on} \quad \Gamma_T, \\
2\nu\Pi\mathbf{D}(\boldsymbol{u})\boldsymbol{n} = -\left(2\nu\Pi_{\sigma+\hat{d}}\mathbf{D}_{\sigma+\hat{d}}(\boldsymbol{u}+\hat{\boldsymbol{v}})\boldsymbol{n}_{\sigma+\hat{d}} - 2\nu\Pi\mathbf{D}(\boldsymbol{u}+\hat{\boldsymbol{v}})\boldsymbol{n}\right) \\
\qquad -2\nu\Pi\mathbf{D}(\hat{\boldsymbol{v}})\boldsymbol{n} + \Pi_{\sigma+\hat{d}}\left[(\boldsymbol{u}+\hat{\boldsymbol{v}})\left(\boldsymbol{u}+\hat{\boldsymbol{v}} - \dfrac{\partial}{\partial t}(\sigma+\hat{d})\boldsymbol{n}_{\sigma+\hat{d}}\right)^*\right]\boldsymbol{n}_{\sigma+\hat{d}} \\
\qquad\qquad \equiv \mathcal{F}_4(\boldsymbol{u},\sigma) \quad \text{on} \quad \Gamma_T, \\
\boldsymbol{u} = -\hat{\boldsymbol{v}} \quad \text{on} \quad \Sigma_T,
\end{cases}
\tag{2.3}
$$

$$
\begin{cases}
\dfrac{\partial w}{\partial t} - \dfrac{1}{\varrho C_p}\nabla\cdot(\kappa(\hat\theta)\nabla w) = -\dfrac{\partial}{\partial t}\left(\hat\theta + \chi\dfrac{\partial\hat\theta}{\partial n}\sigma\right) \\
\quad -(\boldsymbol{h}_{\sigma+\hat d}\cdot\nabla)\left(w+\hat\theta+\chi\dfrac{\partial\hat\theta}{\partial n}\sigma\right) - \left((\boldsymbol{u}+\hat{\boldsymbol{v}})\cdot\nabla_{\sigma+\hat d}\right)\left(w+\hat\theta+\chi\dfrac{\partial\hat\theta}{\partial n}\sigma\right) \\
\quad +\dfrac{1}{\varrho C_p}\nabla\cdot\left(\kappa(\hat\theta)\nabla\left(\hat\theta+\chi\dfrac{\partial\hat\theta}{\partial n}\sigma\right)\right) \\
\quad -\dfrac{1}{\varrho C_p}\nabla\cdot\left(\kappa(\hat\theta)\nabla\left(w+\hat\theta+\chi\dfrac{\partial\hat\theta}{\partial n}\sigma\right)\right) \\
\quad +\dfrac{1}{\varrho C_p}\nabla_{\sigma+\hat d}\cdot\left(\kappa\left(w+\hat\theta+\chi\dfrac{\partial\hat\theta}{\partial n}\sigma\right)\nabla_{\sigma+\hat d}\left(w+\hat\theta+\chi\dfrac{\partial\hat\theta}{\partial n}\sigma\right)\right) \\
\quad +\dfrac{\nu}{2C_p}\sum_{i,k}\left(\sum_j\left\{a^{kj}\dfrac{\partial(u_i+\hat v_i)}{\partial y_j}+a^{ij}\dfrac{\partial(u_k+\hat v_k)}{\partial y_j}\right\}\right)^2 \\
\qquad \equiv \mathcal{F}_5(\boldsymbol{u},w,\sigma) \quad \text{in} \quad Q_T, \\
w\,\big|_{t=0} = 0 \quad \text{on} \quad \bar\Omega, \\
w+\dfrac{\partial\hat\theta}{\partial n}\sigma = \theta_1-\hat\theta \quad \text{on} \quad \Gamma_T, \\
\dfrac{\partial\sigma}{\partial t}+c_0(\nabla\eta\cdot\nabla w) = -\dfrac{\partial\hat d}{\partial t} - c_0\left(\nabla_{\sigma+\hat d}\eta\cdot\nabla_{\sigma+\hat d}\left(w+\hat\theta+\chi\dfrac{\partial\hat\theta}{\partial n}\sigma\right)\right) \\
\quad +c_0\left(\nabla\eta\cdot\nabla\left(w+\hat\theta+\chi\dfrac{\partial\hat\theta}{\partial n}\sigma\right)\right) - c_0\left(\nabla\eta\cdot\nabla\left(\hat\theta+\chi\dfrac{\partial\hat\theta}{\partial n}\sigma\right)\right) \\
\qquad \equiv \mathcal{F}_6(w,\sigma) \quad \text{on} \quad \Gamma_T, \\
\sigma\,\big|_{t=0} = 0 \quad \text{on} \quad \Gamma, \\
w = \theta_2-\hat\theta \quad \text{on} \quad \Sigma_T.
\end{cases} \tag{2.4}
$$

3. Linear problems. In this section we consider the linear problems

$$
\begin{cases}
\dfrac{\partial\boldsymbol{u}}{\partial t} - \nu\Delta\boldsymbol{u} + \nabla p = \boldsymbol{F}_1, \quad \nabla\cdot\boldsymbol{u} = F_2 \qquad \text{in} \quad Q_T, \\
\boldsymbol{u}\,\big|_{t=0} = 0 \qquad \text{on} \quad \bar\Omega, \\
\boldsymbol{u}\cdot\boldsymbol{n} = F_3, \quad \Pi\mathbf{D}(\boldsymbol{u})\boldsymbol{n} = \boldsymbol{F}_4 \qquad \text{on} \quad \Gamma_T, \\
\boldsymbol{u} = \boldsymbol{G}_1 \qquad \text{on} \quad \Sigma_T,
\end{cases} \tag{3.1}
$$

$$
\begin{cases}
\dfrac{\partial w}{\partial t} - \dfrac{1}{\varrho C_p}\nabla\cdot(\kappa(\hat\theta)\nabla w) = F_5 \qquad \text{in} \quad Q_T, \\
w\,\big|_{t=0} = 0 \qquad \text{on} \quad \bar\Omega, \\
w+\dfrac{\partial\hat\theta}{\partial n}\sigma = F_6, \quad \dfrac{\partial\sigma}{\partial t}+c_0\dfrac{\partial w}{\partial n} = F_7 \qquad \text{on} \quad \Gamma_T, \\
w = G_2 \qquad \text{on} \quad \Sigma_T.
\end{cases} \tag{3.2}
$$

We will solve problems (3.1) and (3.2) separately. First we consider the following model problem in the half-space $D^3_\infty = R^3_+ \times (0,\infty)$, $R^3_+ = \{(z_1,z_2,z_3) \in \mathbf{R}^3 \mid z_3 > 0\}$.

$$\text{(3.3)} \qquad \begin{cases} \dfrac{\partial \boldsymbol{u}}{\partial t} - \nu\Delta \boldsymbol{u} + \nabla p = 0, \quad \nabla \cdot \boldsymbol{u} = 0 & \text{in} \quad D^3_\infty, \\ \boldsymbol{u}\,\big|_{t=0} = 0 \quad \text{on} \quad R^3_+, \\ \dfrac{\partial u_3}{\partial z_j} + \dfrac{\partial u_j}{\partial z_3} = b_j \quad (j=1,2), \quad u_3 = 0 & \text{on} \quad R^2_\infty, \end{cases}$$

where $b_j, j = 1,2$, are given functions defined on $R^2_\infty = \mathbf{R}^2 \times (0,\infty)$.

By means of Fourier transformation with respect to $z' = (z_1, z_2)$ and Laplace transformation with respect to t,

$$[\mathcal{F}f](\xi', z_3, s) \equiv \tilde{f}(\xi', z_3, s) = \int_0^\infty \mathrm{e}^{-st}dt \int_{\mathbf{R}^2} \mathrm{e}^{-iz'\cdot\xi'} f(z', z_3, t)dz',$$

the solution of the transformed problem of (3.3) can be represented as

$$\text{(3.4)} \qquad \begin{cases} \tilde{u}_j = \dfrac{e_0(z_3)}{r} + \dfrac{i\xi_j}{|\xi'|(r+|\xi'|)} \displaystyle\sum_{k=1,2} i\xi_k \tilde{b}_k \left(e_0(z_3) - e_1(z_3)\right), \quad j = 1,2, \\ \tilde{u}_3 = \dfrac{e_1(z_3)}{r+|\xi'|} \displaystyle\sum_{k=1,2} i\xi_k \tilde{b}_k, \quad \tilde{p} = -\dfrac{\nu}{|\xi'|} e_2(z_3) \displaystyle\sum_{k=1,2} i\xi_k \tilde{b}_k, \end{cases}$$

where

$$e_0(z_3) = e^{-rz_3}, \quad e_1(z_3) = \frac{e^{-rz_3} - e^{-|\xi'|z_3}}{r - |\xi'|}, \quad e_2(z_3) = e^{-|\xi'|z_3},$$

$$r^2 = \frac{s}{\nu} + \xi'^2, \quad s = a + i\xi_0, \quad \xi'^2 = \xi_1^2 + \xi_2^2 \quad \text{(see [24])}.$$

From (3.4) we can easily obtain

$$\text{(3.5)} \qquad |\boldsymbol{u}|^{(2+\alpha,\frac{2+\alpha}{2})}_{D^3_T} + |\nabla p|^{(\alpha,\frac{\alpha}{2})}_{D^3_T} \le C \sum_{k=1,2} |b_k|^{(1+\alpha,\frac{1+\alpha}{2})}_{R^2_T},$$

where $D^3_T = R^3_+ \times (0,T)$, $R^2_T = \mathbf{R}^2 \times (0,T)$.

Second we proceed to the nonhomogeneous problem

$$\text{(3.6)} \qquad \begin{cases} \dfrac{\partial \boldsymbol{u}}{\partial t} - \nu\Delta \boldsymbol{u} + \nabla p = \boldsymbol{f}, \quad \nabla \cdot \boldsymbol{u} = g & \text{in} \quad D^3_T, \\ \boldsymbol{u}\,\big|_{t=0} = 0 \quad \text{on} \quad R^3_+, \\ \dfrac{\partial u_3}{\partial z_j} + \dfrac{\partial u_j}{\partial z_3}\,\Big|_{z_3=0} = b_j \quad (j=1,2), \quad u_3\,\big|_{z_3=0} = b_3 & \text{on} \quad R^2_T. \end{cases}$$

It is obvious that the solution of problem (3.6) is given by

$$\boldsymbol{u} = \boldsymbol{u}' + \nabla\phi + \boldsymbol{u}'', \quad p = \pi - \frac{\partial \phi}{\partial t} + \nu\Delta\phi,$$

where $\boldsymbol{u}'$ is a solution to the Dirichlet problem of the heat equation

$$\begin{cases} \dfrac{\partial \boldsymbol{u}'}{\partial t} - \nu \Delta \boldsymbol{u}' = \boldsymbol{f} & \text{in} \quad D_T^3, \\ \boldsymbol{u}' \,\big|_{t=0} = 0, \quad \boldsymbol{u}' \,\big|_{z_3=0} = 0 & \text{on} \quad R_T^2; \end{cases} \tag{3.7}$$

ϕ is a solution of the Neumann problem of the elliptic equation with a parameter t

$$\begin{cases} \Delta \phi = g - \nabla \cdot \boldsymbol{u}' & \text{in} \quad R_+^3, \\ \dfrac{\partial \phi}{\partial z_3} \,\big|_{z_3=0} = b_3 & \text{on} \quad \mathbf{R}^2; \end{cases} \tag{3.8}$$

and $(\boldsymbol{u}'', \pi)$ is a solution of problem

$$\begin{cases} \dfrac{\partial \boldsymbol{u}''}{\partial t} - \nu \Delta \boldsymbol{u}'' + \nabla \pi = 0, \quad \nabla \cdot \boldsymbol{u}'' = 0 \quad \text{in} \quad D_T^3, \\ \boldsymbol{u}'' \,\big|_{t=0} = 0 \quad \text{on} \quad R_+^3, \\ \left(\dfrac{\partial u_3''}{\partial z_j} + \dfrac{\partial u_j''}{\partial z_3} \right) \big|_{z_3=0} = b_j - \dfrac{\partial u_3'}{\partial z_j} - \dfrac{\partial u_j'}{\partial z_3} - 2 \dfrac{\partial^2 \phi}{\partial z_3 \partial z_j} \,\big|_{z_3=0} \quad (j = 1, 2), \\ u_3'' \,\big|_{z_3=0} = 0 \quad \text{on} \quad R_T^2. \end{cases} \tag{3.9}$$

It is well known that problems (3.7) and (3.8) have solutions satisfying

$$|\boldsymbol{u}'|_{D_T^3}^{(2+\alpha, \frac{2+\alpha}{2})} \le C \, |\boldsymbol{f}|_{D_T^3}^{(\alpha, \frac{\alpha}{2})},$$

$$|\nabla \phi|_{R_+^3}^{(2+\alpha)} \le C \left(|g|_{R_+^3}^{(1+\alpha)} + |\boldsymbol{u}'|_{R_+^3}^{(2+\alpha)} + |b_3|_{\mathbf{R}^2}^{(2+\alpha)} \right).$$

With regard to problem (3.9), it follows from (3.5) that

$$\begin{aligned} &|\boldsymbol{u}''|_{D_T^3}^{(2+\alpha, \frac{2+\alpha}{2})} + |\nabla \pi|_{D_T^3}^{(\alpha, \frac{\alpha}{2})} \\ &\le C \left(\sum_{j=1,2} |b_j|_{R_T^2}^{(1+\alpha, \frac{1+\alpha}{2})} + |\boldsymbol{u}'|_{R_T^2}^{(2+\alpha, \frac{2+\alpha}{2})} + |\nabla \phi|_{R_T^2}^{(2+\alpha, \frac{2+\alpha}{2})} \right). \end{aligned}$$

Thus the solution of problem (3.6) is evaluated as follows:

$$|\boldsymbol{u}|_{D_T^3}^{(2+\alpha, \frac{2+\alpha}{2})} + |\nabla p|_{D_T^3}^{(\alpha, \frac{\alpha}{2})} \le C \left(|\boldsymbol{f}|_{D_T^3}^{(\alpha, \frac{\alpha}{2})} + |g|_{D_T^3}^{(1+\alpha, \frac{1+\alpha}{2})} + \sum_{j=1,2} |b_j|_{R_T^2}^{(1+\alpha, \frac{1+\alpha}{2})} \right).$$

Finally we solve problem (3.1) by a regularizer. Let $\{\omega^{(k)}\}$ and $\{\Omega^{(k)}\}$ be two systems of the coverings of $\bar{\Omega}$ constructed in the same way as in [12] and let λ be a positive constant determined later. For $k \in M_1$, $\omega^{(k)}$ and $\Omega^{(k)}$ are three-dimensional cubes included completely in Ω with common centers and with the length of their edges, in parallel directions of axes, equal to $\lambda/2$ and λ, respectively. For $k \in M_2, \omega^{(k)}$ and $\Omega^{(k)}$ have common parts with Σ which are defined in the local coordinates $\{z\}$ in the neighborhood of Σ as follows:

$$\omega^{(k)} = \Pi_x^z \left\{ |z_i| \le \frac{\lambda}{2} \quad (i = 1, 2), \quad 0 \le z_3 - F(z_1, z_2) \le \lambda \right\}$$

and

$$\Omega^{(k)} = \Pi_x^z \left\{ |z_i| \le \lambda \quad (i = 1, 2), \quad 0 \le z_3 - F(z_1, z_2) \le 2\lambda \right\},$$

respectively, where $z_3 = F(z_1, z_2)$ represents Σ and Π_x^z is the transformation from z to x. For $k \in M_3$, $\omega^{(k)}$ and $\Omega^{(k)}$, which are adjacent to Γ, are defined in the same way as $\omega^{(k)}$ and $\Omega^{(k)}$ for $k \in M_2$. Furthermore, we introduce the partitions of unity $\{\xi^{(k)}\}$ and $\{\eta^{(k)}\}$ subordinated to $\{\Omega^{(k)}\}$ and $\{\omega^{(k)}\}$ such that

$$\xi^{(k)}(x) = \begin{cases} 1 & \left(x \in \omega^{(k)}\right), \\ 0 & \left(x \in \Omega \backslash \Omega^{(k)}\right), \end{cases} \qquad 0 \le \xi^{(k)}(x) \le 1,$$

$$|D_x^\alpha \xi^{(k)}(x)| \le C\lambda^{-|\alpha|}, \quad \eta^{(k)}(x) = \frac{\xi^{(k)}(x)}{\sum_k \xi^{(k)}(x)^2}.$$

Then a regularizer $\mathcal{R}$ is defined by

$$\mathcal{R}H = \sum_{k \in M_1} \eta^{(k)}(\boldsymbol{u}_1^{(k)}, p_1^{(k)}) + \sum_{j=2,3} \sum_{k \in M_j} \eta^{(k)} \Pi_x^z (\boldsymbol{u}_j^{(k)}, p_j^{(k)}),$$

where $H = (\boldsymbol{F}_1, F_2, F_3, \boldsymbol{F}_4, \boldsymbol{G}_1)$. Here $(\boldsymbol{u}_1^{(k)}, p_1^{(k)})$ is a solution of the problem

$$\begin{cases} \dfrac{\partial \boldsymbol{u}_1^{(k)}}{\partial t} - \nu \Delta \boldsymbol{u}_1^{(k)} + \nabla p_1^{(k)} = \xi^{(k)} \boldsymbol{F}_1, \quad \nabla \cdot \boldsymbol{u}_1^{(k)} = \xi^{(k)} F_2 & \text{in} \quad R_T^3, \\ \boldsymbol{u}_1^{(k)} \big|_{t=0} = 0 & \text{on} \quad \mathbf{R}^3, \end{cases}$$

$(\boldsymbol{u}_2^{(k)}, p_2^{(k)})$ is a solution of the problem

$$\begin{cases} \dfrac{\partial \boldsymbol{u}_2^{(k)}}{\partial t} - \nu \Delta \boldsymbol{u}_2^{(k)} + \nabla p_2^{(k)} = \Pi_z^x \xi^{(k)} \boldsymbol{F}_1, \quad \nabla \cdot \boldsymbol{u}_2^{(k)} = \Pi_z^x \xi^{(k)} F_2 \quad \text{in} \quad D_T^3, \\ \boldsymbol{u}_2^{(k)} \big|_{t=0} = 0 \quad \text{on} \quad R_+^3, \\ \boldsymbol{u}_2^{(k)} \big|_{z_3=0} = \Pi_z^x \xi^{(k)} \boldsymbol{G}_1 \quad \text{on} \quad R_T^2, \end{cases}$$

and $(\boldsymbol{u}_3^{(k)}, p_3^{(k)})$ is a solution of the problem

$$\begin{cases} \dfrac{\partial \boldsymbol{u}_3^{(k)}}{\partial t} - \nu \Delta \boldsymbol{u}_3^{(k)} + \nabla p_3^{(k)} = \Pi_z^x \xi^{(k)} \boldsymbol{F}_1, \quad \nabla \cdot \boldsymbol{u}_3^{(k)} = \Pi_z^x \xi^{(k)} F_2 \quad \text{in} \quad D_T^3, \\ \boldsymbol{u}_3^{(k)} \big|_{t=0} = 0 \quad \text{on} \quad R_+^3, \\ u_{3,3}^{(k)} \big|_{z_3=0} = \Pi_z^x \xi^{(k)} F_3, \quad \dfrac{\partial u_{3,3}^{(k)}}{\partial z_j} + \dfrac{\partial u_{3,j}^{(k)}}{\partial z_3} \big|_{z_3=0} = \Pi_z^x \xi^{(k)} F_{4,j} \ \ (j = 1, 2) \quad \text{on} \quad R_T^2. \end{cases}$$

It is not difficult to see that $\mathcal{R}H = (\bar{\boldsymbol{v}}, \bar{q}), H = (\boldsymbol{F}_1, F_2, F_3, \boldsymbol{F}_4, \boldsymbol{G}_1)$ satisfies

$$\begin{cases} \dfrac{\partial \bar{\boldsymbol{v}}}{\partial t} - \nu \Delta \bar{\boldsymbol{v}} + \nabla \bar{q} = \boldsymbol{F}_1 - \mathcal{T}_1 H, \quad \nabla \cdot \bar{\boldsymbol{v}} = F_2 - \mathcal{T}_2 H \quad \text{in} \quad Q_T, \\ \bar{\boldsymbol{v}} \big|_{t=0} = 0 \quad \text{on} \quad \bar{\Omega}, \\ \bar{\boldsymbol{v}} \cdot \boldsymbol{n} = F_3 - \mathcal{T}_3 H, \quad \Pi \mathbf{D}(\bar{\boldsymbol{v}}) \boldsymbol{n} = \boldsymbol{F}_4 - \mathcal{T}_4 H \quad \text{on} \quad \Gamma_T, \\ \bar{\boldsymbol{v}} = \boldsymbol{G}_1 - \mathcal{S}_1 H \quad \text{on} \quad \Sigma_T, \end{cases}$$

where

$$
\begin{cases}
\mathcal{T}_1 H = -\nu \displaystyle\sum_{k\in M_1} \left\{\eta^{(k)}\Delta \boldsymbol{u}_1^{(k)} - \Delta(\eta^{(k)}\boldsymbol{u}_1^{(k)})\right\} \\
\qquad -\nu \displaystyle\sum_{j=2,3}\sum_{k\in M_j} \left\{\eta^{(k)}\Pi_x^z(\Delta - \overline{\nabla}^2)\boldsymbol{u}_j^{(k)} + \eta^{(k)}\Pi_x^z(\overline{\nabla}^2\boldsymbol{u}_j^{(k)}) - \Delta(\eta^{(k)}\Pi_x^z\boldsymbol{u}_j^{(k)})\right\} \\
\qquad + \displaystyle\sum_{k\in M_1} \left\{\eta^{(k)}\nabla p_1^{(k)} - \nabla(\eta^{(k)}p_1^{(k)})\right\} \\
\qquad + \displaystyle\sum_{j=2,3}\sum_{k\in M_j} \left\{\eta^{(k)}\Pi_x^z(\nabla - \overline{\nabla})p_j^{(k)} + \eta^{(k)}\Pi_x^z\overline{\nabla}p_j^{(k)} - \nabla(\eta^{(k)}\Pi_x^z p_j^{(k)})\right\}, \\
\mathcal{T}_2 H = \displaystyle\sum_{k\in M_1} \left\{\eta^{(k)}\nabla\cdot\boldsymbol{u}_1^{(k)} - \nabla\cdot(\eta^{(k)}\boldsymbol{u}_1^{(k)})\right\} \\
\qquad + \displaystyle\sum_{j=2,3}\sum_{k\in M_j} \left\{\eta^{(k)}\Pi_x^z(\nabla - \overline{\nabla})\cdot\boldsymbol{u}_j^{(k)} + \eta^{(k)}\Pi_x^z(\overline{\nabla}\cdot\boldsymbol{u}_j^{(k)}) - \nabla\cdot(\eta^{(k)}\Pi_x^z\boldsymbol{u}_j^{(k)})\right\}, \\
\mathcal{T}_3 H = \displaystyle\sum_{k\in M_3} \left\{\eta^{(k)}\Pi_x^z(\boldsymbol{u}_3^{(k)}\cdot\boldsymbol{n}_0) - (\eta^{(k)}\Pi_x^z\boldsymbol{u}_3^{(k)})\cdot\boldsymbol{n}\right\}, \\
\mathcal{T}_4 H = \displaystyle\sum_{k\in M_3} \left\{\eta^{(k)}\Pi_x^z\left(\Pi_0(\mathbf{D}(\boldsymbol{u}_3^{(k)}) - \overline{\mathbf{D}}(\boldsymbol{u}_3^{(k)}))\boldsymbol{n}_0\right)\right\} \\
\qquad + \displaystyle\sum_{k\in M_3} \left\{\eta^{(k)}\Pi_x^z\left(\Pi_0\overline{\mathbf{D}}(\boldsymbol{u}_3^{(k)})\boldsymbol{n}_0\right) - \Pi\mathbf{D}\left(\eta^{(k)}\Pi_x^z\boldsymbol{u}_3^{(k)}\right)\boldsymbol{n}\right\}, \\
\mathcal{S}_1 H = 0,
\end{cases}
$$

$\overline{\nabla} = {}^t(\partial x_i/\partial z_j)^{-1}\nabla$, $\overline{\mathbf{D}} = \Pi_z^x\mathbf{D}, \boldsymbol{n}_0 = {}^t(0,0,1)$, $\Pi_0\boldsymbol{g} = \boldsymbol{g} - (\boldsymbol{g}\cdot\boldsymbol{n}_0)\boldsymbol{n}_0$, and $\Pi\boldsymbol{g} = \boldsymbol{g} - (\boldsymbol{g}\cdot\boldsymbol{n})\boldsymbol{n}$. This means that $\mathcal{R}$ is an operator defined on the space

$$
\begin{aligned}
\mathcal{H} = {} & C_0^{\alpha,\frac{\alpha}{2}}(Q_T) \times C_0^{1+\alpha,\frac{1+\alpha}{2}}(Q_T) \\
& \times C_0^{2+\alpha,\frac{2+\alpha}{2}}(\Gamma_T) \times C_0^{1+\alpha,\frac{1+\alpha}{2}}(\Gamma_T) \times C_0^{2+\alpha,\frac{2+\alpha}{2}}(\Sigma_T)
\end{aligned}
$$

with the range $C_0^{2+\alpha,\frac{2+\alpha}{2}}(Q_T) \times C_0^{\alpha,\frac{\alpha}{2}}(Q_T)$.

We claim that the norm $\|\mathcal{T}\|$ of the operator $\mathcal{T} = (\mathcal{T}_1, \mathcal{T}_2, \mathcal{T}_3, \mathcal{T}_4, \mathcal{S}_1)$ on $\mathcal{H}$ is less than 1. Then we can find a solution of (3.1) in the form $\mathcal{R}(I-\mathcal{T})^{-1}H$. The proof of the contraction of $\mathcal{T}$ is not difficult. Indeed, for example, evaluating each term in $\mathcal{T}_1$, we have

$$
\begin{aligned}
\sup_k |\mathcal{T}_1 H|_{Q_T^{(k)}}^{(\alpha,\frac{\alpha}{2})} &\le C\left(\lambda + \frac{T^{\frac{1}{2}}}{\lambda} + \frac{T}{\lambda^2} + T^{\frac{\alpha}{2}}\right) \sup_k \left\{|\boldsymbol{u}^{(k)}|_{Q_T^{(k)}}^{(2+\alpha,\frac{2+\alpha}{2})} + |\nabla p^{(k)}|_{Q_T^{(k)}}^{(\alpha,\frac{\alpha}{2})}\right\} \\
&\le \frac{1}{2}\|H\|_{\mathcal{H}}, \quad Q_T^{(k)} = \Omega^{(k)} \times (0,T),
\end{aligned}
$$

for sufficiently small λ and T. In the same way similar estimates for $\mathcal{T}_j H, j = 2,3,4$ and $\mathcal{S}_1$ are derived. Hence we have the following theorem.

THEOREM 3.1. *Let us assume that*

$$
\boldsymbol{F}_1 \in C_0^{\alpha,\frac{\alpha}{2}}(Q_T), F_2 \in C_0^{1+\alpha,\frac{1+\alpha}{2}}(Q_T),
$$

$$
F_3 \in C_0^{2+\alpha,\frac{2+\alpha}{2}}(\Gamma_T), \boldsymbol{F}_4 \in C_0^{1+\alpha,\frac{1+\alpha}{2}}(\Gamma_T), \boldsymbol{G}_1 \in C_0^{2+\alpha,\frac{2+\alpha}{2}}(\Sigma_T).
$$

Then problem (3.1) *has a unique solution* $\boldsymbol{u} \in C_0^{2+\alpha,\frac{2+\alpha}{2}}(Q_T), \nabla q \in C_0^{\alpha,\frac{\alpha}{2}}(Q_T)$ *satisfying*

$$|\boldsymbol{u}|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})} + |\nabla q|_{Q_T}^{(\alpha,\frac{\alpha}{2})} \le C\left(|\boldsymbol{F}_1|_{Q_T}^{(\alpha,\frac{\alpha}{2})} + |F_2|_{Q_T}^{(1+\alpha,\frac{1+\alpha}{2})} + |F_3|_{\Gamma_T}^{(2+\alpha,\frac{2+\alpha}{2})} + |\boldsymbol{F}_4|_{\Gamma_T}^{(1+\alpha,\frac{1+\alpha}{2})} + |\boldsymbol{G}_1|_{\Sigma_T}^{(2+\alpha,\frac{2+\alpha}{2})}\right), \tag{3.10}$$

where a constant C *depends only on* $\boldsymbol{F}_1, F_2, F_3, \boldsymbol{F}_4, \boldsymbol{G}_1$, *and* T, *and remains bounded as* $T \to 0$.

Next we turn to problem (3.2). In the same way as above, first we treat the model problem

$$\begin{cases} \dfrac{\partial w'}{\partial t} - a\Delta w' = 0 \quad \text{in} \quad D_\infty^3, \\ w' \,\big|_{t=0} = 0 \quad \text{on} \quad R_+^3, \\ w' + b\sigma = 0 \quad \dfrac{\partial \sigma}{\partial t} + c\dfrac{\partial w'}{\partial z_3} = f \quad \text{on} \quad R_\infty^2, \end{cases} \tag{3.11}$$

where a, b, and c are positive constants, and f is a given function in $C_0^{2+\alpha,\frac{2+\alpha}{2}}(R_\infty^2)$ (see also [3]).

Making use of the Fourier–Laplace transformation, we obtain the explicit representation of the transformed unknowns

$$\tilde{w'} = -b\tilde{\sigma}\exp\left[-\left(\frac{s + a\xi'^2}{a}\right)^{1/2} z_3\right], \quad \tilde{\sigma} = \frac{\tilde{f}}{s + cb(a^{-1}s + \xi'^2)^{1/2}}. \tag{3.12}$$

Since the inverse Fourier–Laplace transformation of the symbol $(s+cb(a^{-1}s+\xi'^2)^{1/2})^{-1}$ is

$$\begin{aligned} K(z',t) &= \frac{a^{1/2}}{bc}\mathcal{F}^{-1}\left(\frac{1}{2\pi^{1/2}}\int_0^{\frac{bct}{a^{1/2}}} \tau\left(t - \frac{a^{1/2}\tau}{bc}\right)^{-3/2} \right. \\ &\qquad \left. \times \exp\left[-a\xi'^2\left(t - \frac{a^{1/2}\tau}{bc}\right) - \frac{\tau^2}{4(t - a^{1/2}\tau/bc)}\right] d\tau\right) \\ &= \frac{1}{4\pi^{1/2}}\frac{bc}{a^{3/2}}\int_0^t \tau(t-\tau)^{-5/2}\exp\left[-\frac{|z'|^2}{4a(t-\tau)} - \frac{c^2b^2\tau^2}{4a(t-\tau)}\right] d\tau \\ &= \frac{1}{4\pi^{1/2}}\frac{bc}{a^{3/2}}\int_0^t (t-\tau)\tau^{-5/2}\exp\left[-\frac{|z'|^2}{4a\tau} - \frac{c^2b^2(t-\tau)^2}{4a\tau}\right] d\tau, \end{aligned} \tag{3.13}$$

$\sigma(z',t)$ can be represented as

$$\sigma(z',t) = \int_0^t \int_{\mathbf{R}^2} K(z'-\xi', t-\tau) f(\xi',\tau) d\xi' d\tau.$$

From (3.13) it follows that

$$\left|D_t^r D_{z_1}^{s_1} D_{z_2}^{s_2} K(z',t)\right| \le C(t)\left(|z'|^2 + t^2\right)^{-1-(r+s_1+s_2)/2}.$$

Hence we have

$$\|\sigma\|_{R^2_\infty}^{(3+\alpha,\frac{3+\alpha}{2})} \le C\,|f|_{R^2_\infty}^{(2+\alpha,\frac{2+\alpha}{2})}. \tag{3.14}$$

On the other hand, in (3.11) w' can be considered as a solution of the Dirichlet problem of heat equation; we find the estimate for w' as

$$|w'|_{D^3_\infty}^{(3+\alpha,\frac{3+\alpha}{2})} \le Cb\,\|\sigma\|_{R^2_\infty}^{(3+\alpha,\frac{3+\alpha}{2})} \le C\,|f|_{R^2_\infty}^{(2+\alpha,\frac{2+\alpha}{2})}.$$

The nonhomogeneous case can be treated by adding the above w' to a solution w'' of the problem

$$\begin{cases} \dfrac{\partial w''}{\partial t} - a\Delta w'' = h \quad \text{in} \quad D^3_\infty, \\ w''\,\big|_{t=0} = 0 \quad \text{on} \quad R^3_+, \\ w'' = g \quad \text{on} \quad R^2_\infty. \end{cases}$$

Thus we have the following theorem.

THEOREM 3.2. *Let us assume*

$$F_5 \in C_0^{1+\alpha,\frac{1+\alpha}{2}}(Q_T),\ F_6 \in C_0^{3+\alpha,\frac{3+\alpha}{2}}(\Gamma_T),\ F_7 \in C_0^{2+\alpha,\frac{2+\alpha}{2}}(\Gamma_T),\ G_2 \in C_0^{3+\alpha,\frac{3+\alpha}{2}}(\Sigma_T).$$

Then problem (3.2) *has a unique solution* $w \in C_0^{3+\alpha,\frac{3+\alpha}{2}}(Q_T), \sigma \in \tilde{C}_0^{3+\alpha,\frac{3+\alpha}{2}}(\Gamma_T)$ *satisfying*

$$|w|_{Q_T}^{(3+\alpha,\frac{3+\alpha}{2})} + \|\sigma\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})} \tag{3.15}$$

$$\le C\left(|F_5|_{Q_T}^{(1+\alpha,\frac{1+\alpha}{2})} + |F_6|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})} + |F_7|_{\Gamma_T}^{(2+\alpha,\frac{2+\alpha}{2})} + |G_2|_{\Sigma_T}^{(3+\alpha,\frac{3+\alpha}{2})}\right),$$

where a constant C *depends only on* $F_j, j = 5, 6, 7, G_2$, *and* T *and remains bounded as* $T \to 0$.

Remark. Bazaliĭ and Degtyarev [3] derived the incorrect representation of the inverse Fourier–Laplace transformation of the symbol in (3.12); the correct formula is (3.13). However, the regularity of σ in the form of (3.14) can be obtained in the same way as their work.

4. Proof of Theorem 1.1. We begin with the estimates of $\mathcal{F}_j, j = 1, \dots, 6$ in (2.3) and (2.4).

LEMMA 4.1. *Let* $\sigma \in \tilde{C}_0^{3+\alpha,\frac{3+\alpha}{2}}(\Gamma_T)$, $w \in C_0^{3+\alpha,\frac{3+\alpha}{2}}(Q_T)$ *and* $0 < \alpha' < \alpha < 1$. *Then the following inequalities hold for any* $\boldsymbol{u}_1, \boldsymbol{u}_2 \in C_0^{2+\alpha,\frac{2+\alpha}{2}}(Q_T)$, $\nabla q_1, \nabla q_2 \in C_0^{\alpha,\frac{\alpha}{2}}(Q_T)$*:*

$$\begin{cases} |\mathcal{F}_1(\boldsymbol{u}_1, \nabla q_1, w, \sigma) - \mathcal{F}_1(\boldsymbol{u}_2, \nabla q_2, w, \sigma)|_{Q_T}^{(\alpha',\frac{\alpha'}{2})} \\ \qquad \le CT^{\frac{\alpha-\alpha'}{2}}\left(|\boldsymbol{u}_1 - \boldsymbol{u}_2|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})} + |\nabla q_1 - \nabla q_2|_{Q_T}^{(\alpha,\frac{\alpha}{2})}\right), \\ |\mathcal{F}_2(\boldsymbol{u}_1, \sigma) - \mathcal{F}_2(\boldsymbol{u}_2, \sigma)|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})} \le CT^{\frac{\alpha-\alpha'}{2}}\,|\boldsymbol{u}_1 - \boldsymbol{u}_2|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})}, \\ |\mathcal{F}_3(\boldsymbol{u}_1, \sigma) - \mathcal{F}_3(\boldsymbol{u}_2, \sigma)|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})} \le CT^{\frac{\alpha-\alpha'}{2}}\,|\boldsymbol{u}_1 - \boldsymbol{u}_2|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})}, \\ |\mathcal{F}_4(\boldsymbol{u}_1, \sigma) - \mathcal{F}_4(\boldsymbol{u}_2, \sigma)|_{\Gamma_T}^{(1+\alpha',\frac{1+\alpha'}{2})} \le CT^{\frac{\alpha-\alpha'}{2}}\,|\boldsymbol{u}_1 - \boldsymbol{u}_2|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})}. \end{cases} \tag{4.1}$$

Let $\boldsymbol{u} \in C_0^{2+\alpha,\frac{2+\alpha}{2}}(Q_T)$ *and* $\nabla q \in C_0^{\alpha,\frac{\alpha}{2}}(Q_T)$. *Then the following inequalities hold for any* $w_1, w_2 \in C_0^{3+\alpha,\frac{3+\alpha}{2}}(Q_T), \sigma_1, \sigma_2 \in \tilde{C}_0^{3+\alpha,\frac{3+\alpha}{2}}(\Gamma_T)$*:*

$$
\text{(4.2)}\quad \begin{cases}
|\mathcal{F}_1(\boldsymbol{u},\nabla q,w_1,\sigma_1)-\mathcal{F}_1(\boldsymbol{u},\nabla q,w_2,\sigma_2)|_{Q_T}^{(\alpha',\frac{1+\alpha'}{2})} \\
\qquad \le CT^{\frac{2+\alpha-\alpha'}{2}}\left(\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})}+|u_1-u_2|_{Q_T}^{(3+\alpha,\frac{3+\alpha}{2})}\right), \\
|\mathcal{F}_2(\boldsymbol{u},\sigma_1)-\mathcal{F}_2(\boldsymbol{u},\sigma_2)|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})} \le CT^{\frac{2+\alpha-\alpha'}{2}}\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})}, \\
|\mathcal{F}_3(\boldsymbol{u},\sigma_1)-\mathcal{F}_3(\boldsymbol{u},\sigma_2)|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})} \le CT^{\frac{\alpha-\alpha'}{2}}\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})}, \\
|\mathcal{F}_4(\boldsymbol{u},\sigma_1)-\mathcal{F}_4(\boldsymbol{u},\sigma_2)|_{\Gamma_T}^{(1+\alpha',\frac{1+\alpha'}{2})} \le CT^{\frac{1+\alpha-\alpha'}{2}}\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})}.
\end{cases}
$$

Here C*'s in* (4.1)–(4.2) *are constants depending on* $T, w, \sigma, \boldsymbol{u}, q$*, and bounded as* $T \to 0$.

Proof. Note that the definition of E_d implies

$$
\text{(4.3)}\quad \left|(E^*_{\sigma_1+\hat{d}})^{-1}-(E^*_{\sigma_2+\hat{d}})^{-1}\right|_{Q_T}^{(l+\alpha,\frac{l+\alpha}{2})} \le C\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(l+1+\alpha,\frac{l+1+\alpha}{2})}, \quad l=0,1,2.
$$

Then we have the following estimates:

$$
\begin{aligned}
&|\mathcal{F}_1(\boldsymbol{u}_1,\nabla q_1,w,\sigma)-\mathcal{F}_1(\boldsymbol{u}_2,\nabla q_2,w,\sigma)|_{Q_T}^{(\alpha',\frac{\alpha'}{2})} \\
&\quad=\Big|-(\boldsymbol{h}_{\sigma+\hat{d}}\cdot\nabla)(\boldsymbol{u}_1-\boldsymbol{u}_2)+\nu(\nabla^2_{\sigma+\hat{d}}-\nabla^2)(\boldsymbol{u}_1-\boldsymbol{u}_2) \\
&\qquad-\left((\boldsymbol{u}_1-\boldsymbol{u}_2)\cdot\nabla_{\sigma+\hat{d}}\right)(\boldsymbol{u}_1+\hat{\boldsymbol{v}})+\left((\boldsymbol{u}_2+\hat{\boldsymbol{v}})\cdot\nabla_{\sigma+\hat{d}}\right)(\boldsymbol{u}_1-\boldsymbol{u}_2) \\
&\qquad-(\nabla_{\sigma+\hat{d}}-\nabla)(q_1-q_2)\Big|_{Q_T}^{(\alpha',\frac{\alpha'}{2})} \\
&\quad\le C\left(|\boldsymbol{u}_1-\boldsymbol{u}_2|_{Q_T}^{(2+\alpha',\frac{2+\alpha'}{2})}+|\nabla q_1-\nabla q_2|_{Q_T}^{(\alpha',\frac{\alpha'}{2})}\right) \\
&\quad\le CT^{\frac{\alpha-\alpha'}{2}}\left(|\boldsymbol{u}_1-\boldsymbol{u}_2|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})}+|\nabla q_1-\nabla q_2|_{Q_T}^{(\alpha,\frac{\alpha}{2})}\right),
\end{aligned}
$$

$$
\begin{aligned}
|\mathcal{F}_2(\boldsymbol{u}_1,\sigma)-\mathcal{F}_2(\boldsymbol{u}_2,\sigma)|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})} &= \left|-(\nabla_{\sigma+\hat{d}}-\nabla)\cdot(\boldsymbol{u}_1-\boldsymbol{u}_2)\right|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})} \\
&\le C\,|\boldsymbol{u}_1-\boldsymbol{u}_2|_{Q_T}^{(2+\alpha',\frac{2+\alpha'}{2})} \\
&\le CT^{\frac{\alpha-\alpha'}{2}}\,|\boldsymbol{u}_1-\boldsymbol{u}_2|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})},
\end{aligned}
$$

$$
\begin{aligned}
|\mathcal{F}_3(\boldsymbol{u}_1,\sigma)-\mathcal{F}_3(\boldsymbol{u}_2,\sigma)|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})} &= \left|-(\boldsymbol{u}_1-\boldsymbol{u}_2)\cdot(\boldsymbol{n}_{\sigma+\hat{d}}-\boldsymbol{n})\right|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})} \\
&\le CT^{\frac{\alpha-\alpha'}{2}}\,|\boldsymbol{u}_1-\boldsymbol{u}_2|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})},
\end{aligned}
$$

$$
\begin{aligned}
&|\mathcal{F}_4(\boldsymbol{u}_1,\sigma)-\mathcal{F}_4(\boldsymbol{u}_2,\sigma)|_{\Gamma_T}^{(1+\alpha',\frac{1+\alpha'}{2})} \\
&\quad=\Big|-2\nu\Pi_{\sigma+\hat{d}}\mathbf{D}_{\sigma+\hat{d}}(\boldsymbol{u}_1-\boldsymbol{u}_2)\boldsymbol{n}_{\sigma+\hat{d}}+2\nu\Pi\mathbf{D}(\boldsymbol{u}_1-\boldsymbol{u}_2)\boldsymbol{n}
\end{aligned}
$$

$$
\begin{aligned}
&+\Pi_{\sigma+\hat{d}}\left[(\boldsymbol{u}_1-\boldsymbol{u}_2)\left(\boldsymbol{u}_1+\hat{\boldsymbol{v}}-\frac{\partial}{\partial t}(\sigma+\hat{d})\boldsymbol{n}_{\sigma+\hat{d}}\right)^*\right]\boldsymbol{n}_{\sigma+\hat{d}}\\
&+\Pi_{\sigma+\hat{d}}\left[(\boldsymbol{u}_2+\hat{\boldsymbol{v}})(\boldsymbol{u}_1-\boldsymbol{u}_2)^*\right]\boldsymbol{n}_{\sigma+\hat{d}}\Big|_{\Gamma_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\le C\,|\boldsymbol{u}_1-\boldsymbol{u}_2|_{Q_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\le CT^{\frac{\alpha-\alpha'}{2}}\,|\boldsymbol{u}_1-\boldsymbol{u}_2|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})}.
\end{aligned}
$$

Further we have the following estimates:

$$
\begin{aligned}
&|\mathcal{F}_1(\boldsymbol{u},\nabla q,w_1,\sigma_1)-\mathcal{F}_1(\boldsymbol{u},\nabla q,w_2,\sigma_2)|_{Q_T}^{(\alpha',\frac{\alpha'}{2})}\\
&\quad=\Bigg|\boldsymbol{f}\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)-\boldsymbol{f}\left(w_2+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_2\right)\\
&\qquad-\left((\boldsymbol{h}_{\sigma_1+\hat{d}}-\boldsymbol{h}_{\sigma_2+\hat{d}})\cdot\nabla\right)(\boldsymbol{u}+\hat{\boldsymbol{v}})+\nu\left(\nabla^2_{\sigma_1+\hat{d}}-\nabla^2_{\sigma_2+\hat{d}}\right)(\boldsymbol{u}+\hat{\boldsymbol{v}})\\
&\qquad-\left((\boldsymbol{u}+\hat{\boldsymbol{v}})\cdot(\nabla_{\sigma_1+\hat{d}}-\nabla_{\sigma_2+\hat{d}})\right)(\boldsymbol{u}+\hat{\boldsymbol{v}})-(\nabla_{\sigma_1+\hat{d}}-\nabla_{\sigma_2+\hat{d}})(q+\hat{p})\Bigg|_{Q_T}^{(\alpha',\frac{\alpha'}{2})}\\
&\quad\le C|D\boldsymbol{f}|^{(\alpha)}\left(|w_1-w_2|_{Q_T}^{(\alpha',\frac{\alpha'}{2})}+|\sigma_1-\sigma_2|_{Q_T}^{(\alpha',\frac{\alpha'}{2})}\right)\\
&\qquad+C\left|\left(E^*_{\sigma_1+\hat{d}}\right)^{-1}-\left(E^*_{\sigma_2+\hat{d}}\right)^{-1}\right|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\quad\le CT^{\frac{2+\alpha-\alpha'}{2}}\left(\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})}+|w_1-w_2|_{Q_T}^{(3+\alpha,\frac{3+\alpha}{2})}\right),
\end{aligned}
$$

$$
\begin{aligned}
&|\mathcal{F}_2(\boldsymbol{u},\sigma_1)-\mathcal{F}_2(\boldsymbol{u},\sigma_2)|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\quad=\left|-(\nabla_{\sigma_1+\hat{d}}-\nabla_{\sigma_2+\hat{d}})\cdot\boldsymbol{u}-(\nabla_{\sigma_1+\hat{d}}-\nabla_{\sigma_2+\hat{d}})\cdot\hat{\boldsymbol{v}}\right|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\quad\le C\left|\left(E^*_{\sigma_1+\hat{d}}\right)^{-1}-\left(E^*_{\sigma_2+\hat{d}}\right)^{-1}\right|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\quad\le CT^{\frac{2+\alpha-\alpha'}{2}}\,\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})},
\end{aligned}
$$

$$
\begin{aligned}
&|\mathcal{F}_3(\boldsymbol{u},\sigma_1)-\mathcal{F}_3(\boldsymbol{u},\sigma_2)|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\\
&\quad=\Bigg|-\boldsymbol{u}\cdot\left(\boldsymbol{n}_{\sigma_1+\hat{d}}-\boldsymbol{n}_{\sigma_2+\hat{d}}\right)-\hat{\boldsymbol{v}}\cdot\left(\boldsymbol{n}_{\sigma_1+\hat{d}}-\boldsymbol{n}_{\sigma_2+\hat{d}}\right)\\
&\qquad-\left(1-\frac{\varrho_e}{\varrho}\right)\left(\frac{\partial\sigma_1}{\partial t}-\frac{\partial\sigma_2}{\partial t}\right)\Bigg|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\\
&\quad\le C\left(\left|\boldsymbol{n}_{\sigma_1+\hat{d}}-\boldsymbol{n}_{\sigma_2+\hat{d}}\right|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}+\left|\frac{\partial\sigma_1}{\partial t}-\frac{\partial\sigma_2}{\partial t}\right|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\right)\\
&\quad\le C\left(\left|\left(E^*_{\sigma_1+\hat{d}}\right)^{-1}-\left(E^*_{\sigma_2+\hat{d}}\right)^{-1}\right|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}+\left|\frac{\partial\sigma_1}{\partial t}-\frac{\partial\sigma_2}{\partial t}\right|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\right)\\
&\quad\le CT^{\frac{\alpha-\alpha'}{2}}\,\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})},
\end{aligned}
$$

$$
\begin{aligned}
&|\mathcal{F}_4(\boldsymbol{u},\sigma_1)-\mathcal{F}_4(\boldsymbol{u},\sigma_2)|_{\Gamma_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\quad=\Bigg|-2\nu\Pi_{\sigma_1+\hat{d}}\mathbf{D}_{\sigma_1+\hat{d}}(\boldsymbol{u}+\hat{\boldsymbol{v}})\boldsymbol{n}_{\sigma_1+\hat{d}}+2\nu\Pi_{\sigma_2+\hat{d}}\mathbf{D}_{\sigma_2+\hat{d}}(\boldsymbol{u}+\hat{\boldsymbol{v}})\boldsymbol{n}_{\sigma_2+\hat{d}}\\
&\qquad+\Pi_{\sigma_1+\hat{d}}\left[(\boldsymbol{u}+\hat{\boldsymbol{v}})\left(\boldsymbol{u}+\hat{\boldsymbol{v}}-\frac{\partial}{\partial t}(\sigma_1+\hat{d})\boldsymbol{n}_{\sigma_1+\hat{d}}\right)^*\right]\boldsymbol{n}_{\sigma_1+\hat{d}}\\
&\qquad-\Pi_{\sigma_2+\hat{d}}\left[(\boldsymbol{u}+\hat{\boldsymbol{v}})\left(\boldsymbol{u}+\hat{\boldsymbol{v}}-\frac{\partial}{\partial t}(\sigma_2+\hat{d})\boldsymbol{n}_{\sigma_2+\hat{d}}\right)^*\right]\boldsymbol{n}_{\sigma_2+\hat{d}}\Bigg|_{\Gamma_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\quad\le C\left(\left|\left(E^*_{\sigma_1+\hat{d}}\right)^{-1}-\left(E^*_{\sigma_2+\hat{d}}\right)^{-1}\right|_{\Gamma_T}^{(1+\alpha',\frac{1+\alpha'}{2})}+\left|\frac{\partial\sigma_1}{\partial t}-\frac{\partial\sigma_2}{\partial t}\right|_{\Gamma_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\right)\\
&\quad\le CT^{\frac{1+\alpha-\alpha'}{2}}\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})}.
\end{aligned}
$$

Hence the proof is completed.

LEMMA 4.2. *Let $\boldsymbol{u}\in C_0^{2+\alpha,\frac{2+\alpha}{2}}(Q_T)$. Then the following inequalities hold for any $w_1,w_2\in C_0^{3+\alpha,\frac{3+\alpha}{2}}(Q_T)$, $\sigma_1,\sigma_2\in\tilde{C}_0^{3+\alpha,\frac{3+\alpha}{2}}(\Gamma_T)$:*

$$
\left\{\begin{aligned}
&|\mathcal{F}_5(\boldsymbol{u},w_1,\sigma_1)-\mathcal{F}_5(\boldsymbol{u},w_2,\sigma_2)|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\quad\le CT^{\frac{\alpha-\alpha'}{2}}\left(|u_1-u_2|_{Q_T}^{(3+\alpha,\frac{3+\alpha}{2})}+\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})}\right),\\
&|\mathcal{F}_6(w_1,\sigma_1)-\mathcal{F}_6(w_2,\sigma_2)|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\\
&\quad\le CT^{\frac{\alpha-\alpha'}{2}}\left(|w_1-w_2|_{Q_T}^{(3+\alpha,\frac{3+\alpha}{2})}+\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})}\right).
\end{aligned}\right.\tag{4.4}
$$

If $w\in C_0^{3+\alpha,\frac{3+\alpha}{2}}(Q_T),\sigma\in\tilde{C}_0^{3+\alpha,\frac{3+\alpha}{2}}(\Gamma_T)$, then the following inequality holds for any $\boldsymbol{u}_1,\boldsymbol{u}_2\in C_0^{2+\alpha,\frac{2+\alpha}{2}}(Q_T)$.

$$
|\mathcal{F}_5(\boldsymbol{u}_1,w,\sigma)-\mathcal{F}_5(\boldsymbol{u}_2,w,\sigma)|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\le CT^{\frac{1+\alpha-\alpha'}{2}}|\boldsymbol{u}_1-\boldsymbol{u}_2|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})}.\tag{4.5}
$$

Here C's in (4.4) *and* (4.5) *are constants depending on $T,w,\sigma,\boldsymbol{u},q$, and bounded as $T\to 0$.*

Proof. In the same way as in the proof of Lemma 4.1, we can prove (4.4) and (4.5). Here we give only the estimates of the most complicated terms in each of $\mathcal{F}_5$ and $\mathcal{F}_6$. For $(4.4)^1$,

$$
\begin{aligned}
&\Bigg|\nabla_{\sigma_1+\hat{d}}\cdot\left(\kappa\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)\nabla_{\sigma_1+\hat{d}}\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)\right)\\
&\qquad-\nabla_{\sigma_2+\hat{d}}\cdot\left(\kappa\left(w_2++\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_2\right)\nabla_{\sigma_2+\hat{d}}\left(w_2+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_2\right)\right)\Bigg|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\le\Bigg|\left(\nabla_{\sigma_1+\hat{d}}-\nabla_{\sigma_2+\hat{d}}\right)\cdot\left(\kappa\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)\right.\\
&\qquad\left.\nabla_{\sigma_1+\hat{d}}\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)\right)\Bigg|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}
\end{aligned}
$$

$$
\begin{aligned}
&+\left|\nabla_{\sigma_2+\hat{d}}\cdot\left(\left(\kappa\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)-\kappa\left(w_2+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_2\right)\right)\right.\right.\\
&\qquad\left.\left.\cdot\nabla_{\sigma_1+\hat{d}}\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)\right)\right|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&+\left|\nabla_{\sigma_2+\hat{d}}\cdot\left(\kappa\left(w_2+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_2\right)\right.\right.\\
&\qquad\left.\left.\cdot\left(\nabla_{\sigma_1+\hat{d}}-\nabla_{\sigma_2+\hat{d}}\right)\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)\right)\right|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&+\left|\nabla_{\sigma_2+\hat{d}}\cdot\left(\kappa\left(w_2+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_2\right)\right.\right.\\
&\qquad\left.\left.\cdot\nabla_{\sigma_2+\hat{d}}\left(w_1-w_2+\chi\frac{\partial\hat{\theta}}{\partial n}(\sigma_1-\sigma_2)\right)\right)\right|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\le C\left|\left(E^*_{\sigma_1+\hat{d}}\right)^{-1}-\left(E^*_{\sigma_2+\hat{d}}\right)^{-1}\right|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\quad+C\left|D^2\kappa\right|^{(\alpha)}\left|w_1-w_2+\chi\frac{\partial\hat{\theta}}{\partial n}(\sigma_1-\sigma_2)\right|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\quad+C\left|\left(E^*_{\sigma_1+\hat{d}}\right)^{-1}-\left(E^*_{\sigma_2+\hat{d}}\right)^{-1}\right|_{Q_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\\
&\quad+C\left|w_1-w_2+\chi\frac{\partial\hat{\theta}}{\partial n}(\sigma_1-\sigma_2)\right|_{Q_T}^{(3+\alpha',\frac{3+\alpha'}{2})}\\
&\le CT^{\frac{\alpha-\alpha'}{2}}\left(|w_1-w_2|_{Q_T}^{(3+\alpha,\frac{3+\alpha}{2})}+\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})}\right).
\end{aligned}
$$

For $(4.4)^2$,

$$
\begin{aligned}
&\left|\left(\nabla_{\sigma_1+\hat{d}}\eta\cdot\nabla_{\sigma_1+\hat{d}}\right)\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)\right.\\
&\qquad\left.-\left(\nabla_{\sigma_2+\hat{d}}\eta\cdot\nabla_{\sigma_2+\hat{d}}\right)\left(w_2+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_2\right)\right|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\\
&\le C\left|\left(\left(\nabla_{\sigma_1+\hat{d}}-\nabla_{\sigma_2+\hat{d}}\right)\eta\cdot\nabla_{\sigma_1+\hat{d}}\right)\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)\right|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\\
&\quad+C\left|\left(\nabla_{\sigma_2+\hat{d}}\eta\cdot\left(\nabla_{\sigma_1+\hat{d}}-\nabla_{\sigma_2+\hat{d}}\right)\right)\left(w_1+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma_1\right)\right|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}
\end{aligned}
$$

$$
\begin{aligned}
&+C\left|\left(\nabla_{\sigma_2+\hat{d}}\eta\cdot\nabla_{\sigma_2+\hat{d}}\right)\left(w_1-w_2+\chi\frac{\partial\hat{\theta}}{\partial n}(\sigma_1-\sigma_2)\right)\right|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\\
&\le C\left|\left(E^*_{\sigma_1+\hat{d}}\right)^{-1}-\left(E^*_{\sigma_2+\hat{d}}\right)^{-1}\right|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})}\\
&\quad+C\left|w_1-w_2+\chi\frac{\partial\hat{\theta}}{\partial n}(\sigma_1-\sigma_2)\right|_{\Gamma_T}^{(3+\alpha',\frac{3+\alpha'}{2})}\\
&\le CT^{\frac{\alpha-\alpha'}{2}}\left(|w_1-w_2|_{Q_T}^{(3+\alpha,\frac{3+\alpha}{2})}+\|\sigma_1-\sigma_2\|_{\Gamma_T}^{(3+\alpha,\frac{3+\alpha}{2})}\right).
\end{aligned}
$$

And for (4.5),

$$
\begin{aligned}
&\left|(\boldsymbol{u}_1\cdot\nabla_{\sigma+\hat{d}})\left(w+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma\right)-(\boldsymbol{u}_2\cdot\nabla_{\sigma+\hat{d}})\left(w+\hat{\theta}+\chi\frac{\partial\hat{\theta}}{\partial n}\sigma\right)\right|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\\
&\quad\le C\,|\boldsymbol{u}_1-\boldsymbol{u}_2|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})}\le CT^{\frac{1+\alpha-\alpha'}{2}}\,|\boldsymbol{u}_1-\boldsymbol{u}_2|_{Q_T}^{(2+\alpha,\frac{2+\alpha}{2})}.
\end{aligned}
$$

Hence the proof is completed.

Now we proceed to the proof of Theorem 1.1. Set

$$
X\equiv\left\{\begin{array}{l}(w,\sigma)\in C_0^{3+\alpha,\frac{3+\alpha}{2}}(Q_T)\times\tilde{C}_0^{3+\alpha,\frac{3+\alpha}{2}}(\Gamma_T)\;\big|\\[2ex] \|(w,\sigma)\|_X\equiv|w|_{Q_T}^{(3+\alpha',\frac{3+\alpha'}{2})}+\|\sigma\|_{\Gamma_T}^{(3+\alpha',\frac{3+\alpha}{2})}\le C\end{array}\right\},
$$

$$
Y\equiv\left\{\begin{array}{l}(\boldsymbol{u},\nabla q)\in C_0^{2+\alpha,\frac{2+\alpha}{2}}(Q_T)\times C_0^{\alpha,\frac{\alpha}{2}}(Q_T)\;\big|\\[2ex] \|(\boldsymbol{u},\nabla q)\|_Y\equiv|\boldsymbol{u}|_{Q_T}^{(2+\alpha',\frac{2+\alpha'}{2})}+|\nabla q|_{Q_T}^{(\alpha',\frac{\alpha'}{2})}\le C\end{array}\right\},
$$

where C is a positive constant. And let operators P and Q,

$$
P:((w_1,\sigma_1),(\boldsymbol{u}_1,\nabla q_1))\longmapsto((w_1,\sigma_1),(\boldsymbol{u}_2,\nabla q_2)),
$$

$$
Q:((w_1,\sigma_1),(\boldsymbol{u}_1,\nabla q_1))\longmapsto((w_2,\sigma_2),(\boldsymbol{u}_1,\nabla q_1)),
$$

assign the solution $(\boldsymbol{u}_2,\nabla q_2)$ of problem (2.3) and the solution (w_2,σ_2) of problem (2.4) for arbitrary given $((w_1,\sigma_1),(\boldsymbol{u}_1,\nabla q_1))$ in $X\times Y$, respectively. By using Lemmas 4.1 and 4.2, first it is easily seen that the operator $Q\circ P$ is continuous, i.e.,

$$
\begin{aligned}
&\|Q\circ P((w,\sigma),(\boldsymbol{u},\nabla q))-Q\circ P((w',\sigma'),(\boldsymbol{u}',\nabla q'))\|_{X\times Y}\\
&\quad\le C\|((w,\sigma),(\boldsymbol{u},\nabla q))-((w',\sigma'),(\boldsymbol{u}',\nabla q'))\|_{X\times Y}
\end{aligned}
$$

for arbitrary $((w,\sigma),(\boldsymbol{u},\nabla q)),((w',\sigma'),(\boldsymbol{u}',\nabla q'))$ in $X\times Y$, and some constant C.

Next for arbitrary $((w,\sigma),(\boldsymbol{u},\nabla q))$ in $X\times Y$ we have

$$
\begin{aligned}
&\|Q\circ P((w,\sigma),(\boldsymbol{u},\nabla q))\|_{X\times Y}\\
&\quad\le\|Q\circ P((w,\sigma),(\boldsymbol{u},\nabla q))-Q\circ P((0,0),(0,0))\|_{X\times Y}
\end{aligned}
$$

$$
\begin{aligned}
&+ \|Q \circ P((0,0),(0,0))\|_{X\times Y} \\
&\le C\,\|(w,\sigma),(\boldsymbol{u},\nabla q))\|_{X\times Y} \\
&+ |\mathcal{F}_1(0,0,0,0)|_{Q_T}^{(\alpha',\frac{\alpha'}{2})} + |\mathcal{F}_2(0,0)|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})} + |\mathcal{F}_3(0,0)|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})} \\
&+ |\mathcal{F}_4(0,0)|_{\Gamma_T}^{(1+\alpha',\frac{1+\alpha'}{2})} + |\mathcal{F}_5(0,0,0)|_{Q_T}^{(1+\alpha',\frac{1+\alpha'}{2})} + |\mathcal{F}_6(0,0)|_{\Gamma_T}^{(2+\alpha',\frac{2+\alpha'}{2})} \\
&\le C(T),
\end{aligned}
$$

where $C(T)$ is a constant which tends to 0 as $T \to 0$. Here we have used the fact that $((w,\sigma),(\boldsymbol{u},\nabla q))$ and $\mathcal{F}_i, i = 1,\dots,6$ are equal to zero at $t = 0$ in the higher-order classes. Hence $Q \circ P$ maps $X \times Y$ into itself for small T. Therefore Shauder's fixed point theorem yields the solution of problem (2.2).

A VERTICAL DIFFUSION MODEL FOR LAKES*

DIDIER BRESCH†, JÉRÔME LEMOINE†, AND JACQUES SIMON†

Abstract.
The motion of a fluid in a lake with small depth compared to width is investigated. We prove that when the depth goes to 0, the solution of the stationary Navier–Stokes equations with adherence at the bottom and traction by wind at the surface, once conveniently normalized, goes to a three-dimensional limit which is the solution of an incompressible model with vertical diffusion.

The limit velocity is given in terms of the vertical coordinate and of the limit pressure. This pressure, which depends only on the horizontal coordinates, is driven by a two-dimensional equation on the surface degenerating on the shore, which is solved in a weighted space. Thus, a three-dimensional approximation is obtained by a simple two-dimensional computation.

Key words. Navier–Stokes equations, thin domains, asymptotic analysis, hydrostatic

Introduction. *A simplified model for lakes.* The fluid occupies the following domain in $\mathbb{R}^3$

$$d = \{(x,z) : x \in \Gamma,\ -h(x) < z < 0\},$$

where Γ is an open bounded set in $\mathbb{R}^2$ (the horizontal section) and where the depth h is a positive continuous function on Γ, vanishing on $\partial\Gamma$. The boundary is $\partial d = f \cup s \cup \partial s$ (see Figure 1), where the bottom f, the surface s, and the shore ∂s are

$$f = \{(x,-h(x)) : x \in \Gamma\}, \quad s = \{(x,0) : x \in \Gamma\}, \quad \partial s = \partial f = \{(x,0) : x \in \partial\Gamma\}.$$

The horizontal velocity $v = (v_1, v_2)$, the vertical velocity w, and the pressure p satisfy the stationary Navier–Stokes equations in d, which may be written as

$$\begin{cases} -\nu(\Delta v + \partial_z^2 v) + kBv + k'we + (v\cdot\nabla)\,v + w\,\partial_z v + \nabla p = 0, \\ -\nu(\Delta w + \partial_z^2 w) - k'v_1 + (v\cdot\nabla)\,w + w\,\partial_z w + \partial_z p = 0, \\ \nabla\cdot v + \partial_z w = 0, \end{cases} \tag{1}$$

where $\nabla = (\partial/\partial x_1, \partial/\partial x_2)$, $\Delta = \partial^2/\partial x_1^2 + \partial^2/\partial x_2^2$, $\partial_z = \partial/\partial z$, $B(v_1,v_2) = (-v_2, v_1)$, $e = (1,0)$, $k = |\omega|\sin\theta$, $k' = |\omega|\cos\theta$, ω being the rotating velocity of the earth and θ the latitude, and $\nu > 0$. This system is completed by the adherence on the bottom and by the horizontal traction at the surface:

$$v = 0,\ w = 0 \text{ on } f, \quad \nu\partial_z v = g,\ w = 0 \text{ on } s, \tag{2}$$

where the force due to the wind $g = (g_1, g_2)$ is a given function on s.

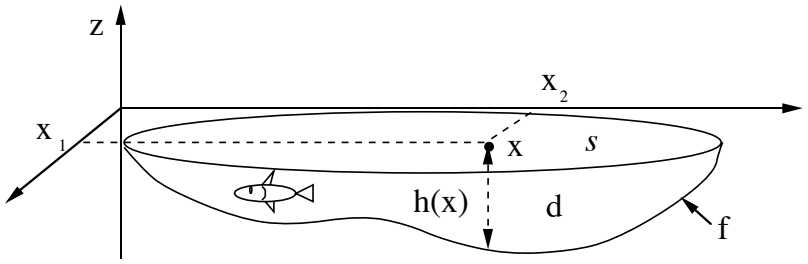

FIG. 1. *The domain occupied by the fluid.*

Asymptotic analysis. The aspect ratio ε of the domain, that is, the ratio of the height to the width, is assumed to be very small. Introducing a normalized depth H, we will investigate the behavior of the solution as

$$h^\varepsilon = \varepsilon H, \quad \varepsilon \to 0. \tag{3}$$

Denoting by $(u^\varepsilon, v^\varepsilon, w^\varepsilon)$ the solution of (1) and (2) and d^ε, s^ε, f^ε the domain, the surface, and the bottom associated with h^ε, we will prove that

$$\begin{cases} v^\varepsilon(x,z) \approx \dfrac{\varepsilon}{\nu}\left(\dfrac{1}{2}(r^2-1)H^2(x)\nabla\mathbf{P}(x) + (1-r)H(x)g(x)\right), \\ w^\varepsilon(x,z) \approx \dfrac{\varepsilon^2}{\nu}\nabla\cdot\left(\left(\dfrac{r^3}{6}-\dfrac{r}{2}\right)H^3(x)\nabla\mathbf{P}(x) + \left(r-\dfrac{r^2}{2}\right)H^2(x)g(x)\right), \\ p^\varepsilon(x,z) \approx \dfrac{1}{\varepsilon}\mathbf{P}(x), \end{cases} \tag{4}$$

where r is the relative depth in d^ε, which is given by $r = -z/(\varepsilon H(x))$ and thus

$$0 \le r \le 1, \quad r = 0 \text{ at the surface } s^\varepsilon, \quad r = 1 \text{ at the bottom } f^\varepsilon,$$

and where $\mathbf{P}$ is the solution (unique up to a constant) of the two-dimensional (2D) equation in Γ:

$$\nabla\cdot\left(\frac{1}{3}H^3\nabla\mathbf{P} - \frac{1}{2}H^2 g\right) = 0, \quad \left(\frac{1}{3}H^3\nabla\mathbf{P} - \frac{1}{2}H^2 g\right)\cdot n_{\partial\Gamma} = 0. \tag{5}$$

At first, we will prove (Theorem 4) that there exists a solution $(v^\varepsilon, w^\varepsilon, p^\varepsilon)$ of (1) and (2). Then we will prove (Theorem 7) that, after normalization, it converges to the solution of the incompressible model with vertical diffusion (10). Finally, we will prove (Theorem 10) that this solution is given by the right-hand side of (4) and by (5).

Interest of the results. We obtain three-dimensional (3D) information—vertical variations of the horizontal and vertical velocities—for the simple cost of a 2D computation. In addition, the approximation (4) is divergence free.

Numerical simulations [5] show that this approximation of the velocity gives a good feature of the driving by the wind at the surface, of the forward motion at the bottom, and of the horizontal and vertical deflection of the fluid by the submarine topography.

No regularity on the section $\partial\Gamma$ is assumed, excepted that d is star-shaped with respect to one point of s in Theorem 10, and we suppose only that the depth h is continuous on $\overline{\Gamma}$ and that the force g due to the wind satisfies $h^{1/2}g \in (L^2(\Gamma))^2$.

Comparison with previous results. For lubrication problems, a similar asymptotic analysis without Coriolis force has been done in [1], [2]. It gives a Reynolds equation on $\mathbf{P}$ similar to (5) but which does not degenerate on the shore, since the depth possesses a positive lower bound (the distance between pieces) which avoids the use of weighted spaces as here.

Many authors have studied nonstationary problems in thin domains with a constant depth (see [8], [12], and their references), which do not describe our problem, for which the topography is essential. The results presented in this paper have been announced in [6]. An outline of these results is listed here.

1. Formal calculations.

1.1. Notations. We distinguish the horizontal variables (2D) from the vertical ones (1D), which play a particular part: $x = (x_1, x_2)$ are the horizontal coordinates, z is the vertical one; $v = (v_1, v_2)$ is the horizontal component of the velocity, w its vertical component.

We denote by small letters the quantities in the varying domain: (x, z), the coordinates; h^ε, the depth; d^ε, the domain; f^ε, s^ε, its bottom and its surface; g, the force due to the wind; and $(v^\varepsilon, w^\varepsilon, p^\varepsilon)$, the velocity and the pressure.

We denote by capital letters the scaled quantities in the fixed domain after change of variable: (X, Z), the coordinates; H, the depth; D, the domain; F, S, its bottom and its surface; G, the force due to the wind; $(V^\varepsilon, W^\varepsilon, P^\varepsilon)$, the scaled velocity and pressure.

We denote in boldface the limits as $\varepsilon \to 0$: $(\mathbf{V}, \mathbf{W}, \mathbf{P})$, the limit of the scaled velocity and pressure.

1.2. Derivation of the vertical diffusion model. We use the scaling

$$x = X, \quad z = \varepsilon Z, \tag{6}$$

to get a fixed domain in $\mathbb{R}^3$,

$$D = \{(X, Z) : X \in \Gamma,\ -H(X) < Z < 0\},$$

with boundary $\partial D = F \cup S \cup \partial S$. Its bottom is $F = \{(X, -H(X)) : X \in \Gamma\}$; the surface $S = s$ and the shore $\partial S = \partial s$ are unchanged. The force due to the wind, $G = g$, is unchanged. The transported velocity and pressure are scaled to be of magnitude one. More precisely, $(V^\varepsilon, W^\varepsilon, P^\varepsilon)$ is defined by

$$v^\varepsilon(x, z) = \frac{\varepsilon}{\nu} V^\varepsilon(X, Z), \quad w^\varepsilon(x, z) = \frac{\varepsilon^2}{\nu} W^\varepsilon(X, Z), \quad p^\varepsilon(x, z) = \frac{1}{\varepsilon} P^\varepsilon(X, Z). \tag{7}$$

Equations (1) and (2) scaled with (6) and (7) yield

$$
(8)\quad \begin{cases} -\partial_Z^2 V^\varepsilon + \nabla P^\varepsilon + \dfrac{\varepsilon^2 k}{\nu} B V^\varepsilon - \varepsilon^2 \Delta V^\varepsilon + \dfrac{\varepsilon^3 k'}{\nu} W^\varepsilon e \\ \qquad\qquad + \dfrac{\varepsilon^3}{\nu^2}\Big((V^\varepsilon \cdot \nabla) V^\varepsilon + W^\varepsilon \, \partial_Z V^\varepsilon \Big) = 0, \\ \partial_Z P^\varepsilon - \dfrac{\varepsilon^3 k'}{\nu} V_1^\varepsilon - \varepsilon^2 \partial_Z^2 W^\varepsilon - \varepsilon^4 \Delta W^\varepsilon + \dfrac{\varepsilon^5}{\nu^2}\Big((V^\varepsilon \cdot \nabla) W^\varepsilon + W^\varepsilon \, \partial_Z W^\varepsilon \Big) = 0, \\ \nabla \cdot V^\varepsilon + \partial_Z W^\varepsilon = 0 \text{ in } D; \end{cases}
$$

$$
(9)\qquad V^\varepsilon = 0,\ W^\varepsilon = 0 \text{ on } F; \quad \partial_Z V^\varepsilon = G,\ W^\varepsilon = 0 \text{ on } S.
$$

The possible limit $(\mathbf{V}, \mathbf{W}, \mathbf{P})$ of $(V^\varepsilon, W^\varepsilon, P^\varepsilon)$ as $\varepsilon \to 0$ must satisfy

$$
(10)\qquad \begin{cases} -\partial_Z^2 \mathbf{V} + \nabla \mathbf{P} = 0, \quad \partial_Z \mathbf{P} = 0, \quad \nabla \cdot \mathbf{V} + \partial_Z \mathbf{W} = 0 \quad \text{in } D; \\ \mathbf{V} = 0, \mathbf{W} = 0 \text{ on } F; \quad \partial_Z \mathbf{V} = G, \mathbf{W} = 0 \text{ on } S. \end{cases}
$$

We will see (section 1.4) that some information on the shore ∂S has been lost here.

Remark. A limit model with isotropic diffusion, namely $-\nu(\partial_Z^2 + \Delta)\mathbf{V} + \nabla \mathbf{P} = 0$, is obtained if the viscosity is assumed to be conveniently anisotropic—that is, if $\nu \Delta v$ is replaced in (1) by $\varepsilon^{-2} \nu \Delta v$; see [4]. □

1.3. Solution of the vertical diffusion model. Let us solve (10) with respect to Z for a fixed X. The second equation gives $\mathbf{P} = \mathbf{P}(X)$. The first equation and the conditions $\mathbf{V}(-H) = 0$ and $\partial_Z \mathbf{V}(0) = G$ give

$$
(11)\qquad \mathbf{V} = \frac{1}{2}(Z^2 - H^2)\nabla \mathbf{P} + (Z + H) G.
$$

The third equation and the condition $\mathbf{W}(0) = 0$ yield $\mathbf{W} = \int_Z^0 \nabla \cdot \mathbf{V} = \nabla \cdot (\int_Z^0 \mathbf{V})$ whence

$$
(12)\qquad \mathbf{W} = \nabla \cdot \left(\left(\frac{Z H^2}{2} - \frac{Z^3}{6} \right) \nabla \mathbf{P} - \left(\frac{1}{2} Z^2 + H Z \right) G \right).
$$

It remains to take into account the condition $\mathbf{W}(-H) = 0$. Since we have $\mathbf{W}(-H) = \int_{-H}^0 \nabla \cdot \mathbf{V} = \nabla \cdot (\int_{-H}^0 \mathbf{V}) - \nabla H \cdot \mathbf{V}(-H)$ and $\mathbf{V}(-H) = 0$, it gives $\nabla \cdot (\int_{-H}^0 \mathbf{V}) = 0$, that is,

$$
(13)\qquad \nabla \cdot \left(\frac{1}{3} H^3 \nabla \mathbf{P} - \frac{1}{2} H^2 G \right) = 0 \quad \text{in } \Gamma.
$$

Therefore (10) is formally equivalent to (11)–(13).

This provides the right-hand sides of the announced approximations (4) and the equation on $\mathbf{P}$ included in (5). The limit condition announced in (5) is missing, however.

1.4. The lost condition. Equation (13) does not define a unique $\mathbf{P}$ since there is no boundary condition on $\partial\Gamma$.

This comes from the fact that the boundary conditions (9) are assigned only on F and S but not on the shore ∂S (recall that $\partial D = F \cup S \cup \partial S$). On the shore,

$V^\varepsilon = 0$, but this condition does not pass to the limit. Indeed $\mathbf{V} = 0$ on ∂S would give contradictory results in the expression (11), whether the shore is considered to be at the surface (i.e., $Z = 0$) or at the bottom (i.e., $Z = -H$, which is equal to 0 too!). Besides this contradiction, it would not give the true answer (see Theorem 10), which is the Neumann condition included in (5).

Thus, we have to use a weaker condition than $V^\varepsilon|_{\partial S} = 0$, but one which goes to the limit. The condition $V^\varepsilon \cdot n_{\partial S} = 0$ does not fit, for the same reasons. We will use the fact that the flux through the shore cancels. The total flux on the vertical passing through X is $\overline{V^\varepsilon}(X) = \int_{-H(X)}^{0} V^\varepsilon dZ$. On ∂S, it vanishes since H and V^ε do; thus $\overline{V^\varepsilon} \cdot n_{\partial\Gamma} = 0$, where $n_{\partial\Gamma}$ is the normal to $\partial\Gamma$ in $\mathbb{R}^2$ (that is the horizontal normal to ∂S). At the limit,

$$\overline{\mathbf{V}} \cdot n_{\partial\Gamma} = 0, \tag{14}$$

that is, due to (11),

$$\left(\frac{1}{3}H^3\nabla\mathbf{P} - \frac{1}{2}H^2G\right) \cdot n_{\partial\Gamma} = 0, \tag{15}$$

which is the Neumann condition included in (5). It closes (13), ensuring the existence and uniqueness of $\mathbf{P}$ in the weighted space $\mathbb{A}(\Gamma)$ defined by (58).

Remark. We cannot write (15) as $\frac{1}{3}H^3\partial\mathbf{P}/\partial n - \frac{1}{2}H^2G \cdot n = 0$ since $\partial\mathbf{P}/\partial n$ in general has no sense. If it had some sense, it would be a truism since $H = 0$ on $\partial\Gamma$. We will give a sense to the left-hand side of (15), that is, to the normal trace $\overline{\mathbf{V}} \cdot n_{\partial\Gamma}$, by using $\nabla \cdot \overline{\mathbf{V}} = 0$ (see Theorem 10). □

Remark. For lubrication problems, there is no such singularity on $\partial\Gamma$ because H does not vanish on it (see [2]). One can find, in some oceanic models, the introduction of the same hypothesis $H \geq H_0 > 0$ (see [10, pp. 17–18] and [11, p. 1016]). □

Remark. For Navier–Stokes equations, it is not necessary to give a condition on the shore ∂S since $V^\varepsilon = 0$ on the bottom F ensures that $V^\varepsilon = 0$ on ∂F. Indeed V^ε cannot possess a singularity on ∂S since $(V^\varepsilon, W^\varepsilon) \in (H^1(D))^3$. This is why (9) closes (8). On the contrary the vertical diffusion model (10) allows some singularities on ∂S as it is checked in the following 2D example. □

Example of singularity. Let us consider an infinite channel with a crossing wind: $\Gamma = (0,1) \times \mathbb{R}$, $H = H(X_1)$, $G = (1,0)$. Looking for a solution $\mathbf{V} = (\mathbf{V}_1(X_1), 0)$ of (10) we find, by (13), $\partial_1\mathbf{P} = \frac{3}{2}(1/H + c/H^3)$, where c is an arbitrary real number and, by (11),

$$\mathbf{V}_1 = \frac{1}{4}(3Z^2 + 4ZH + H^2)\frac{1}{H} + \frac{3}{4}(Z^2 - H^2)\frac{c}{H^3}.$$

The flux on each vertical is $\overline{\mathbf{V}}_1 = \int_{-H}^{0} \mathbf{V}_1\, dZ = c/2$, which is constant. If $c \geq 0$, the fluid moves from left to right; therefore, it goes in through the left shore and out through the right shore. This corresponds to a singularity on ∂S, excepted for $c = 0$, which is the only good solution satisfying the "lost condition" (14).

Nevertheless, even for $c \neq 0$, $\partial_Z\mathbf{V}_1$ lies in $L^2(D_1)$, where D_1 is the 2D section of the channel, when $H \geq |X_1(1 - X_1)|^\alpha$ for some $\alpha > 1/3$. □

2. Functional spaces.

2.1. The space $\mathbb{E}$. Throughout the paper, we suppose that

$$\Gamma \text{ is an open bounded subset of } \mathbb{R}^2, \tag{16}$$

$$h \in \mathcal{C}(\overline{\Gamma}),\ h > 0 \text{ in } \Gamma,\ h = 0 \text{ on } \partial\Gamma. \tag{17}$$

We denote

$$\begin{aligned} \mathcal{E}(d) = \{(v,w) \in (\mathcal{C}^\infty(\overline{d}))^2 \times \mathcal{C}^\infty(\overline{d}) :\ & \nabla \cdot v + \partial_z w = 0, \\ & (v,w) = 0 \text{ on a neighborhood of } f,\ w = 0 \text{ on } s\}. \end{aligned} \tag{18}$$

By definition,

$$\begin{cases} \mathbb{E}(d) \text{ is the closure of } \mathcal{E}(d) \text{ for the norm} \\ \|(v,w)\|_{\mathbb{E}(d)} = \displaystyle\left(\int_d |\nabla v|^2 + |\nabla w|^2 + |\partial_z v|^2 + |\partial_z w|^2 \, dxdz\right)^{1/2}. \end{cases}$$

Remark. In the definition (18) we suppose $w = 0$ only at the surface s and not in a neighborhood of s. This is a crucial point in the proof of Lemma 3.

If we suppose in (18) that $w = 0$ in a neighborhood of s, we should suppose then that the force due to the wind satisfies $\nabla \cdot g = 0$. Indeed in the neighborhood we would have $\nabla \cdot v = \nabla \cdot v + \partial_z w = 0$ and thus $\nabla \cdot \partial_z v = 0$; on the other hand, $\nu\, \partial_z v = g$ on s by (2), leading to the conclusion. ∎

LEMMA 1. *The embedding* $\mathbb{E}(d) \subset (H^1(d) \cap L^4(d))^3$ *holds and for any* $(v,w) \in \mathbb{E}(d)$,

$$\|(v,w)\|_{(L^2(d))^3} \le 2^{-1/2} h_{\max} \|\partial_z (v,w)\|_{(L^2(d))^3}, \tag{19}$$

$$\|(v,w)\|_{(L^4(d))^3} \le \gamma_d \|(\nabla, \partial_z)(v,w)\|_{(L^2(d))^9}, \tag{20}$$

where $\gamma_d = 2^{1/8} \beta^{3/4} (h_{\max})^{1/4}$, β *being defined by* (23). *It satisfies* $\beta \le 4$.

Moreover, (v,w) *has a trace in* $(H^{1/2}_{\mathrm{loc}}(s))^3$ *which belongs to* $(L^2(s))^3$ *and satisfies* $w_{|_s} = 0$, *and*

$$\int_s \frac{|v|^2}{h} dx \le \int_d |\partial_z v|^2 \, dxdz. \tag{21}$$

We denote $h_{\max} = \max\{h(x) : x \in \Gamma\}$, and we identify Γ with s to give a meaning to h (or to g) on s.

Remark. By definition, every element of $\mathbb{E}(d)$ is a distribution with derivatives in L^2. This single property does not imply that (v,w) belongs to L^2, or a fortiori to H^1, since d does not possess the cone property. (See the remark following Theorem 4.) ∎

Remark. To be in $\mathbb{E}(d)$ implies, in a weak sense, the condition $(v,w) = 0$ on the bottom f. This bottom is not regular enough (it is only the graph of a continuous function) to define the trace of (v,w) in a usual sense or even to define $L^2(f)$.

On the contrary, the trace on the surface is defined since s is a part of a plane. ∎

Proof of Lemma 1. It suffices to prove the inequalities for $(v,w) \in \mathcal{E}(d)$.

Inequality (19). We have $(v,w)(x,z) = \int_{-h(x)}^{z} \partial_z(v,w)(x,\zeta)\,d\zeta$; hence

$$|(v,w)(x,z)|^2 \le (z+h(x)) \int_{-h(x)}^{0} |\partial_z(v,w)(x,\zeta)|^2\,d\zeta,$$

and therefore

$$\int_{-h(x)}^{0} |(v,w)(x,z)|^2\,dz \le \frac{1}{2}(h(x))^2 \int_{-h(x)}^{0} |\partial_z(v,w)(x,z)|^2\,dz.$$

We conclude by bounding h and integrating with respect to x.

Inequality (20). With the help of Riesz's inequality, we have

$$\|(v,w)\|_{(L^4(d))^3} \le (\|(v,w)\|_{(L^2(d))^3})^{1/4} (\|(v,w)\|_{(L^6(d))^3})^{3/4}.$$

We conclude by bounding the right-hand side with (19) and

$$\|(v,w)\|_{(L^6(d))^3} \le 2^{1/3}\beta \|(\nabla,\partial_z)(v,w)\|_{(L^2(d))^9}. \tag{22}$$

This last inequality comes from the Sobolev–Gagliardo–Nirenberg inequality on $\mathbb{R}^3$ by extending (v,w) by 0 in the half space $\{(x,z) : z \le 0\}$, then by extending $\widetilde{v}$ by symetrization and $\widetilde{w}$ by antisymetrization on z in the whole space $\mathbb{R}^3$; that is, for $z \ge 0$,

$$\widetilde{v}(x,-z) = \widetilde{v}(x,z), \quad \widetilde{w}(x,-z) = -\widetilde{w}(w,z).$$

The function $(\widetilde{v},\widetilde{w})$ is Lipschitz continuous and has a compact support in $\mathbb{R}^3$, from which (see, for instance, [7, p. 162])

$$\|(\widetilde{v},\widetilde{w})\|_{(L^6(\mathbb{R}^3))^3} \le \beta \|(\nabla,\partial_z)(\widetilde{v},\widetilde{w})\|_{(L^2(\mathbb{R}^3))^9}, \tag{23}$$

which yields (22). The inequality $\beta \le 4$ is given in the note (2) on p. 162 of [7].

Inequality (21). We have $v(x,0) = \int_{-h(x)}^{0} \partial_z v(x,z)\,dz$; therefore

$$|v(x,0)|^2 \le h(x) \int_{-h(x)}^{0} |\partial_z v(x,z)|^2\,dz.$$

We conclude by dividing by $h(x)$ and integrating with respect to x. □

2.2. The space $\mathbb{F}$. By definition,

$$\mathbb{F}(d) \text{ is the closure of } \mathcal{E}(d) \text{ for the norm } \|(v,w)\|_{\mathbb{F}(d)} = \left(\int_d |\partial_z v|^2\,dxdz\right)^{1/2}. \tag{24}$$

LEMMA 2. *The space $\mathbb{F}(d)$ is a Hilbert space and*

$$\mathbb{E}(d) \subset \mathbb{F}(d) \subset (L^2(d))^2 \times H^{-1}(d).$$

For all $(v,w) \in \mathbb{F}(d)$

$$\|v\|_{(L^2(d))^2} \le \frac{1}{\sqrt{2}} h_{\max} \|\partial_z v\|_{(L^2(d))^2}, \tag{25}$$

$$\|w\|_{H^{-1}(d)} \le \frac{1}{2}(h_{\max})^2 \|\partial_z v\|_{(L^2(d))^2}, \tag{26}$$

$$\|\partial_z w\|_{H^{-1}(d)} \le \frac{1}{\sqrt{2}} h_{\max} \|\partial_z v\|_{(L^2(d))^2}, \tag{27}$$

and $v/h \in (L^2(d))^2$ *with*

$$\Big\|\frac{v}{h}\Big\|_{(L^2(d))^2} \leq \frac{1}{\sqrt{2}}\|\partial_z v\|_{(L^2(d))^2}. \tag{28}$$

Moreover, v *has a trace in* $(L^2(s))^2$ *which satisfies*

$$\int_s \frac{|v|^2}{h}\,dx \leq \int_d |\partial_z v|^2\,dxdz, \tag{29}$$

and w *has a trace in* $H^{-1}_{\rm loc}(s)$ *which is null.*

We denote

$$H^{-1}(d) = \left\{\varphi \in \mathcal{D}'(d) : \varphi = \varphi_0 + \frac{\partial \varphi_1}{\partial x_1} + \frac{\partial \varphi_2}{\partial x_2} + \frac{\partial \varphi_3}{\partial z},\ \varphi_j \in L^2(d) \text{ for } j \geq 0\right\},$$

this space being endowed with the norm

$$\|\varphi\|_{H^{-1}(d)} = \inf_{\{\varphi_j\}} \left(\int_d \varphi_0^2 + \cdots + \varphi_3^2\right)^{1/2}, \tag{30}$$

where the infimum is taken over all possible decompositions of φ.

Remark. The space $H^{-1}(d)$ is the dual space of $H^1_0(d)$ and its norm is equivalent to the dual norm, but these norms are not uniformly equivalent when d varies. ∎

Proof of Lemma 2. It suffices to prove the inequalities $\forall (v,w)$ in $\mathcal{E}(d)$.

Inequality (28). We have $v(x,z) = \int_{-h(x)}^{z} \partial_z v(x,\zeta)\,d\zeta$, which yields, as in the proof of (19),

$$\int_{-h(x)}^{0} |v(x,z)|^2\,dz \leq \frac{1}{2}(h(x))^2 \int_{-h(x)}^{0} |\partial_z v(x,z)|^2\,dz.$$

We conclude by dividing by $(h(x))^2$ and integrating with respect to x.

Inequality (25). It follows from (28) since $h(x) \leq h_{\max}$.

Inequality (27). We have $\partial_z w = -\nabla \cdot v$; therefore $\|\partial_z w\|_{H^{-1}(d)} \leq \|v\|_{(L^2(d))^2}$. We conclude with (25).

Inequality (26). Denoting by $\widehat{\ }$ the extension by 0 for $z \leq -h(x)$, we have

$$\begin{aligned} w(x,z) &= -\int_{-h(x)}^{z} (\nabla \cdot v)(x,\zeta)\,d\zeta \\ &= -\int_{-h_{\max}}^{z} (\nabla \cdot \widehat{v})(x,\zeta)\,d\zeta \\ &= (\nabla \cdot y)(x,z), \end{aligned}$$

where $y(x,z) = -\int_{-h_{\max}}^{z} \widehat{v}(x,\zeta)\,d\zeta = -\int_{-h(x)}^{z} v(x,\zeta)\,d\zeta$. We bound, as above,

$$\int_d |y(x,z)|^2\,dxdz \leq \frac{1}{2}(h_{\max})^2 \int_d |v(x,\zeta)|^2\,dxd\zeta;$$

therefore

$$\|w\|_{H^{-1}(d)} \leq \|y\|_{(L^2(d))^2} \leq \frac{1}{\sqrt{2}} h_{\max}\|v\|_{(L^2(d))^2},$$

which, together with (25), gives (26).

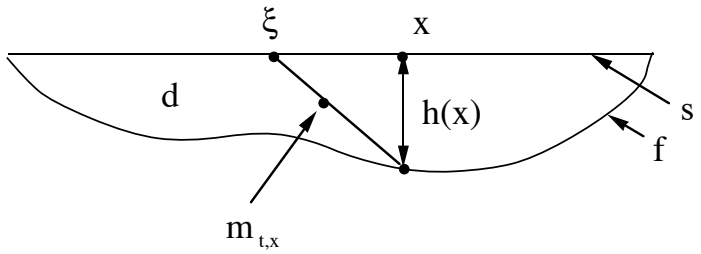

FIG. 2. *A star-shaped domain with respect to its surface.*

Traces. Given $(v,w) \in \mathbb{E}(d)$, $\Gamma'' \subset\subset \Gamma$, and $h'' = \min\{h(x) : x \in \Gamma''\}$, we have $\partial_z w = -\nabla \cdot v \in L^2((-h'',0); H^{-1}(\Gamma''))$. Hence $w \in \mathcal{C}([-h'',0]; H^{-1}(\Gamma''))$, which allows us to define its value for $z = 0$. We obtain a trace in $H^{-1}_{\rm loc}(s)$ by collecting traces in each Γ''.

Likewise, $\partial_z v \in L^2((-h'',0); (L^2(\Gamma''))^2)$ and therefore $v \in \mathcal{C}([-h'',0]; (L^2(\Gamma''))^2)$, which allows us to define the trace in $L^2_{\rm loc}(s)$ by recollection. The inequality (29) follows from (21). It shows that the trace belongs to $L^2(s)$. ∎

2.3. Approximation of $\mathbb{F}$ by smooth functions.

LEMMA 3. *We suppose that*

(31) $$d \text{ is star-shaped with respect to a point of } s.$$

Let $(v,w) \in (\mathcal{D}'(d))^3$ *be such that*

$$\text{(32)} \quad \begin{cases} \exists (\widetilde{v},\widetilde{w}) \in (L^2(\mathbb{R}^3_-))^2 \times \mathcal{D}'(\mathbb{R}^3_-), \quad \partial_z \widetilde{v} \in (L^2(\mathbb{R}^3_-))^2, \quad \nabla \cdot \widetilde{v} + \partial_z \widetilde{w} = 0, \\ (\widetilde{v},\widetilde{w}) = (v,w) \text{ in } d, \quad (\widetilde{v},\widetilde{w}) = 0 \text{ in } \mathbb{R}^3_- \setminus \overline{d}, \quad \widetilde{w} = 0 \text{ on } s. \end{cases}$$

Then $(v,w) \in \mathbb{F}(d)$.

We denote $\mathbb{R}^3_- = \{(x,z) : x \in \mathbb{R}^2, z < 0\}$.

Remark. The hypothesis (31) means (see Figure 2) that there exists $\xi \in \Gamma$ such that

$$m_{t,x} = (tx + (1-t)\xi, -t\,h(x)) \in d \quad \forall x \in \Gamma,\ \forall t \in (0,1).$$

It does not allow us to consider islands, because it implies that Γ is star-shaped with respect to ξ. It no longer allows us to consider two submarine valleys separated by a large plateau close to the surface. ∎

Remark. The trace of $\widetilde{w}$ on s is defined since $\partial_z \widetilde{w} = -\nabla \cdot \widetilde{v}$, which lies in $L^2(\mathbb{R}_-; H^{-1}(\mathbb{R}^2))$. ∎

Remark. The property (32) characterizes $\mathbb{F}(d)$. Indeed it is sufficient by Lemma 3 and it is necessary from the definitions (24) and (18) and from Lemma 2. ∎

Proof of Lemma 3. Let (v,w) satisfy (32). By definition (24) of $\mathbb{F}(d)$, it suffices to find a sequence in $\mathcal{E}(d)$ which is a Cauchy sequence for the norm $\|\partial_z v\|_{(L^2(d))^3}$ and which converges to (v,w) in $(\mathcal{D}'(d))^3$.

The condition (32) gives an extension $(\widetilde{v},\widetilde{w}) \in (L^2(\mathbb{R}^3_-))^2 \times \mathcal{C}(\mathbb{R}_-; H^{-1}(\mathbb{R}^2))$ such that $\widetilde{w} = 0$ for $z = 0$. Thus we define an extension $(\widetilde{v},\widetilde{w}) \in (L^2(\mathbb{R}^3))^2 \times \mathcal{C}(\mathbb{R}; H^{-1}(\mathbb{R}^2))$ in the whole space $\mathbb{R}^3$ by

$$(\widetilde{v},\widetilde{w})(x,z) = \big(\widetilde{v}(x,-z), -\widetilde{w}(x,-z)\big) \quad \text{if } z > 0.$$

By (31), d is star-shaped with respect to a point of s, which is chosen to be the origin. Given $\eta > 0$, we define

$$(v^\eta, w^\eta)(x,z) = (\widetilde{v},\widetilde{w})\big((1+\eta)x,(1+\eta)z\big).$$

Then, $\nabla \cdot v^\eta + \partial_z w^\eta = 0$ and support $(v^\eta, w^\eta) \subset \widetilde{d}$, where $\widetilde{d} = \{(x,z) :\ x \in \Gamma, |z| < h(x)\}$.

Let $\rho^\eta \in \mathcal{D}(\mathbb{R}^3)$ be a mollifier such that

$$\rho^\eta(x,z) = \rho^\eta(x,-z), \quad \int_{\mathbb{R}^3} \rho^\eta \, dxdz = 1, \quad \text{support } \rho^\eta + \text{support}\,(v^\eta, w^\eta) \subset \widetilde{d}.$$

By convolution, we obtain a function $(v^\eta \star \rho^\eta, w^\eta \star \rho^\eta)$ lying in $\mathcal{E}(d)$. Indeed, this function is $\mathcal{C}^\infty$ on $\overline{d}$, it satisfies $\nabla \cdot (v^\eta \star \rho^\eta) + \partial_z (w^\eta \star \rho^\eta) = 0$, it vanishes in a neighborhood of F, and $w^\eta \star \rho^\eta$ vanishes on s because $(w^\eta \star \rho^\eta)(x,0)$ is the integral on $\mathbb{R}^3$ of an antisymetric function with respect to z.

As $\eta \to 0$, we have $\partial_z(v^\eta \star \rho^\eta) \to \partial_z v$ in $(L^2(d))^2$; therefore $(v^\eta \star \rho^\eta, w^\eta \star \rho^\eta) \to (v,w)$ in $\mathbb{F}(d)$ and, by Lemma 2, in $(\mathcal{D}'(d))^3$. ∎

3. Solution of the Navier–Stokes equations. We define here a variational solution of the Navier–Stokes equations (1) and (2), for which we will pass to the limit for $\varepsilon \to 0$ further. Throughout this paper, we suppose that

$$h^{1/2} g \in (L^2(\Gamma))^2. \tag{33}$$

In order to recover a unique pressure, we introduce a nonempty bounded set

$$d' = \Gamma' \times (-h', 0), \quad \Gamma' \subset\subset \Gamma, \quad h' = \min_{x \in \Gamma'} h(x), \tag{34}$$

and we impose

$$\int_{d'} p \, dxdz = 0. \tag{35}$$

Now we are able to state the existence and uniqueness result.

THEOREM 4. *Suppose that* (16), (17), *and* (33) *are satisfied.*

(i) *There exists a solution* $(v,w) \in \mathbb{E}(d)$ *of the following:* $\forall (\varphi,\psi) \in \mathbb{E}(d)$,

$$\left\{ \begin{aligned} &\int_d \nu \left(\nabla v \cdot \nabla \varphi + \nabla w \cdot \nabla \psi + \partial_z v \cdot \partial_z \varphi + \partial_z w \, \partial_z \psi\right) + k'(w\,\varphi_1 - v_1\,\psi) \\ &\qquad + kv \times \varphi + (v \cdot \nabla + w\,\partial_z)\, v \cdot \varphi + (v \cdot \nabla + w\,\partial_z)\, w\,\psi \, dxdz = \int_s g \cdot \varphi \, dx. \end{aligned} \right. \tag{36}$$

(ii) *Every solution satisfies*

$$\int_d |\nabla v|^2 + |\nabla w|^2 + |\partial_z v|^2 + |\partial_z w|^2 \, dxdz \le \frac{1}{\nu^2} \int_\Gamma h\,|g|^2 \, dx. \tag{37}$$

(iii) *To every solution corresponds a unique pressure* $p \in L^2_{\text{loc}}(d)$ *such that the strong equation* (1) *is satisfied in the distribution sense and the condition* (35) *holds.*

It satisfies $\nabla p \in (H^{-1}(d))^2$, $\partial_z p \in H^{-1}(d)$ *and, for every Lipschitz set* d'' *included in* d,

$$\|\nabla p\|_{(H^{-1}(d))^2} + \|\partial_z p\|_{H^{-1}(d)} \le \left(1 + \frac{|\omega|}{\sqrt{2}\nu} h_{\max}\right) \|h^{1/2} g\|_{(L^2(\Gamma))^2} + \left(\frac{\gamma_d}{\nu} \|h^{1/2} g\|_{(L^2(\Gamma))^2}\right)^2$$

$$\|p\|_{L^2(d'')} \le c_{d,d',d''} \left(\left(1 + \frac{|\omega|}{\sqrt{2}\nu} h_{\max}\right) \|h^{1/2} g\|_{(L^2(\Gamma))^2} + \left(\frac{\gamma_d}{\nu} \|h^{1/2} g\|_{(L^2(\Gamma))^2}\right)^2\right).$$

(iv) *There is a unique solution* (v, w, p) *if*

$$\nu^2 > 2^{1/4}\beta^{3/2}(h_{\max})^{1/2}\|h^{1/2}g\|_{(L^2(\Gamma))^2}.$$

(v) *Assume in addition that* h *is Lipschitz continuous on* Γ *and* $g \in (H^1_{\mathrm{loc}}(\Gamma))^2$.

Then the boundary conditions (2) *are satisfied in the trace sense, and* (36) *is equivalent to* (1), (2), *and* $(v, w) \in \mathbb{E}(d)$.

We denote by $\times$ the vector product in $\mathbb{R}^2$; therefore $v \times \varphi = v_1\varphi_2 - v_2\varphi_1 = Bv \cdot \varphi$, and γ_d and β are defined in Lemma 1.

Remark. Without the assumptions of part (v), there is not enough regularity on $\partial_z v$ to define its trace on s and on the bottom f to define a trace on it.

Notice that the domain d does not necessarily possess the cone property, even if h is Lipschitz continuous. Indeed the cone property may fail on the shore ∂S, unless we assume in addition some regularity on $\partial\Gamma$ (the 2D cone property) and that the slope of the bottom does not cancel on the shore (for instance, in any point of $\partial\Gamma$, ∇h is continuous and does not vanish). We do not use such an assumption since, for real lakes, the slope may vanish on the shore and the cone condition may fail. □

Remark. The condition (35) defines a unique p if d, and therefore Γ, is connected. Otherwise, an open set d' must be introduced in each connected component of d, and (35) must be imposed on each d'. □

Remark. The regularity hypothesis (33) on g may be weakened in the interior of Γ: there exists a solution as soon as $g = g' + g''$ with g' satisfying (33) and $g'' \in (H^{-1/2}(\Gamma))^2$ with support included in Γ. Similarly, the results of part (v) probably hold for $g \in (H^{1/2}_{\mathrm{loc}}(\Gamma))^2$. □

Proof of Theorem 4. *Part* i. We will proceed by linearization and fixed point. In order to shorten, we denote

$$u = (v_1, v_2, w), \quad D = (\partial_{x_1}, \partial_{x_2}, \partial_z).$$

Linearization. Given $u' \in \mathbb{E}(d)$, the Lax–Milgram theorem gives the existence of a unique $u \in \mathbb{E}(d)$ such that for any $\mu \in \mathbb{E}(d)$,

$$\int_d \nu Du \cdot D\mu + \omega \times u \cdot \mu + (u' \cdot D)u \cdot \mu \, dxdz = \int_s g \cdot \varphi \, dx, \tag{38}$$

where $\varphi = (\mu_1, \mu_2)$, $\omega = (0, k', k)$, and $\omega \times u = (k'w - kv_2, kv_1, -k'v_1)$.

Indeed, the left-hand side defines a continuous bilinear form with respect to u and μ since, by (20), for any u', u and μ in $\mathbb{E}(d)$,

$$\left|\int_d (u' \cdot D)u \cdot \mu \, dxdz\right| \le (\gamma_d)^2 \|Du'\|_{(L^2(d))^9}\|Du\|_{(L^2(d))^9}\|D\mu\|_{(L^2(d))^9}.$$

This form is coercive since $\omega \times u \cdot u = 0$ and

$$\int_d (u' \cdot D)u \cdot u \, dxdz = 0. \tag{39}$$

To prove this last equation, it suffices to consider u' and u in $\mathcal{E}(d)$. Then, introducing

$d_{h_{\max}} = \Gamma \times (-h_{\max}, 0)$ and denoting by $\widetilde{u}$ the extension by 0 in $d_{h_{\max}} \setminus d$, we get

$$\begin{aligned}\int_d (u' \cdot D)u \cdot u \, dxdz &= \int_{d_{h_{\max}}} (\widetilde{u'} \cdot D)\, \widetilde{u} \cdot \widetilde{u} \, dxdz \\ &= \frac{1}{2} \int_{d_{h_{\max}}} D \cdot (\widetilde{u'}\, |\widetilde{u}|^2)\, dxdz \\ &= \frac{1}{2} \int_s w' \, |u|^2 \, dx \\ &= 0\end{aligned}$$

since $\widetilde{u'} \cdot n_{\partial d_{h_{\max}}} = w' = 0$ on s and $\widetilde{u'} = 0$ on the remainder of $\partial d_{h_{\max}}$. We used $D \cdot \widetilde{u'} = 0$, which follows from the definition of $\mathcal{E}(d)$.

On the other hand, the right-hand side of (38) defines a continuous linear form with respect to μ since, due to (21), we have for any $\mu \in \mathbb{E}(d)$,

$$\begin{aligned}\left| \int_s g \cdot \varphi \, dx \right| &\le \left(\int_s h \, |g|^2 \, dx \right)^{1/2} \left(\int_s \frac{|\varphi|^2}{h} \, dx \right)^{1/2} \\ &\le \|h^{1/2} g\|_{(L^2(\Gamma))^2} \|\partial_z \varphi\|_{(L^2(d))^2}.\end{aligned} \tag{40}$$

The space $\mathbb{E}(d)$ is a Hilbert space: it is a complete space by definition and separated by (20). Therefore the Lax–Milgram theorem ensures the existence and the uniqueness of u, and

$$\|Du\|_{(L^2(d))^9} \le \frac{1}{\nu} \|h^{1/2} g\|_{(L^2(\Gamma))^2}. \tag{41}$$

Fixed point. We denote

$$C = \left\{ u \in \mathbb{E}(d) : \|Du\|_{(L^2(d))^9} \le \frac{1}{\nu} \|h^{1/2} g\|_{(L^2(\Gamma))^2} \right\}.$$

It is a convex, nonempty, and compact set in $(L^4(d))^3$. Moreover, $u' \mapsto u$ maps C into itself by (41), and it is continuous from C (endowed with the norm $(L^4(d))^3$) into itself as we will see. Therefore Schauder's theorem gives the existence of a fixed point. This one satisfies (38) with $u' = u$, that is (36).

It remains to check the continuity. Let $\mathbf{u}'$ be another element of C and $\mathbf{u}$ be the corresponding solution of (38). For all $\mu \in \mathbb{E}(d)$ we have

$$\int_d \nu D(\mathbf{u} - u) \cdot D\mu + \omega \times (\mathbf{u} - u) \cdot \mu + (\mathbf{u}' \cdot D)\, (\mathbf{u} - u) \cdot \mu + \big((\mathbf{u}' - u') \cdot D\big)\, u \cdot \mu \, dxdz = 0.$$

For $\mu = \mathbf{u} - u$ we get, together with (39) and (20),

$$\begin{aligned}\nu \int_d |D(\mathbf{u} - u)|^2 \, dxdz &= - \int_d \big((\mathbf{u}' - u') \cdot D\big)\, u \cdot (\mathbf{u} - u) \, dxdz \\ &\le \gamma_d \, \|\mathbf{u}' - u'\|_{(L^4(d))^3} \|Du\|_{(L^2(d))^9} \|D(\mathbf{u} - u)\|_{(L^2(d))^9}.\end{aligned}$$

With the help of (41) and, once again, (20) we conclude that

$$\|\mathbf{u} - u\|_{(L^4(d))^3} \le \frac{1}{\nu^2} (\gamma_d)^2 \, \|h^{1/2} g\|_{(L^2(\Gamma))^2} \|\mathbf{u}' - u'\|_{(L^4(d))^3}. \tag{42}$$

Part ii. It suffices to choose $(\varphi,\psi)=(v,w)$ in (36) (which is (38) with $u'=u$) and to use (39) and (40) to obtain the announced estimate.

Part iii. Let us choose $(\varphi,\psi)=\mu\in(\mathcal{D}(d))^3$ such that $D\cdot\mu=0$. Then (36) gives

$$\langle -\nu D^2u+\omega\times u+(u\cdot D)u,\mu\rangle_{(\mathcal{D}'(d))^3\times(\mathcal{D}(d))^3}=0;$$

therefore de Rham's theorem (see, for instance, [13]) gives the existence of $p\in\mathcal{D}'(d)$ satisfying $-\nu D^2u+\omega\times u+(u\cdot D)u=-Dp$, that is, (1). This equation can be written, since $D\cdot u=0$, as

$$Dp=-\omega\times u+D\cdot(\nu Du-u\otimes u); \tag{43}$$

therefore, from the definition (30) of the norm in $H^{-1}(d)$ and (19), (20),

$$\begin{aligned}\|Dp\|_{(H^{-1}(d))^3}&\le\|\omega\times u\|_{(L^2(d))^3}+\|\nu Du-u\otimes u\|_{(L^2(d))^9}\\&\le|\omega|\frac{h_{\max}}{\sqrt{2}}\|Du\|_{(L^2(d))^9}+\nu\|Du\|_{(L^2(d))^9}+(\gamma_d\|Du\|_{(L^2(d))^9})^2,\end{aligned}$$

which, with (41), gives the announced estimates on ∇p and $\partial_z p$.

It follows (see, for instance, [14, Theorem 14], with $g=1_{d'}$) that p lies in $L^2(d'')$ for any Lipschitz set d'' included in d, with

$$\|p\|_{L^2(d'')}\le c_{d,d',d''}\left(\|Dp\|_{(H^{-1}(d))^3}+\left|\int_{d'}p\,dxdz\right|\right). \tag{44}$$

Since Dp is unique, p is unique up to a constant which is given by (35), then p is unique.

Part iv. The difference between two solutions u and $\mathbf{u}$ satisfies (42) with $u'=u$ and $\mathbf{u}'=\mathbf{u}$. Thus, it vanishes as soon as $(\gamma_d)^2\|h^{1/2}g\|_{(L^2(\Gamma))^2}<\nu^2$, which gives the announced condition due to the definition of γ_d given in Lemma 1.

Part v. Now $g\in(H^1_{\rm loc}(\Gamma))^2$; thus $u\in(H^2_{\rm loc}(d\cup s))^3$ and $p\in H^1_{\rm loc}(d\cup s)$. This regularity up to the surface may be proved by using either the translation method for the mixed formulation as in [9], the representation by Green's function as in [3], or the Agmon–Douglis–Nirenberg method as in [15, pp. 33–35]. (The reader is referred to these authors since this part of Theorem 4 is not used in the following.) Then, the following Green and Stokes's formulas hold for any $\mu=(\phi,\psi)$ in $\mathcal{E}(d)$, and therefore for any μ in $\mathbb{E}(d)$,

$$\int_d Du\cdot D\mu+D^2u\cdot\mu\,dxdz=\int_s\partial_z v\cdot\phi\,dx,\quad\int_d Dp\cdot\mu\,dxdz=0. \tag{45}$$

Substracting ν-times the first formula from (36) (that is, from (38) with $u'=u$) and adding the second formula, we get

$$\int_d\big(-\nu D^2u+\omega\times u+(u\cdot D)u+Dp\big)\cdot\mu\,dxdz=\int_s(g-\nu\partial_z)\cdot\varphi\,dx. \tag{46}$$

The left-hand side vanishes from (1), and since $\varphi_{|s}$ spans $(\mathcal{D}(s))^2$ this implies that $\nu\partial_z v=g$ on s.

On the other hand, here the bottom f is locally the graph of the Lipschitz function h, and then $(v,w)\in\mathbb{E}(d)$ gives $(v,w)=0$ on f in the trace sense. Finally, $w=0$ on s by Lemma 2; thus all the boundary conditions (2) are proven in the trace sense.

Conversely, if (1) and (2) hold, (46) holds and we get the variational equation (36) by using (45). □

4. Solution of the vertical diffusion model. We prove here the existence and uniqueness of a solution, and we give an equivalent variational formulation. Now we work in the transported domain D (one can choose $D = d_{\rm true}$). The hypotheses (17) and (33) are then equivalent to

$$H \in \mathcal{C}(\overline{\Gamma}),\ H > 0 \text{ in } \Gamma,\ H = 0 \text{ on } \partial\Gamma, \tag{47}$$

$$H^{1/2} G \in (L^2(\Gamma))^2. \tag{48}$$

THEOREM 5. *We suppose* (16), (47), *and* (48).

(i) *There exists a unique solution* $(\mathbf{V}, \mathbf{W}, \mathbf{P})$ *of*

$$\begin{cases} (\mathbf{V}, \mathbf{W}) \in \mathbb{F}(D), \quad \mathbf{P} \in H^1_{\rm loc}(\Gamma), \quad \displaystyle\int_{\Gamma'} \mathbf{P}\, dX = 0, \\ -\partial_Z^2 \mathbf{V} + \nabla \mathbf{P} = 0, \quad \partial_Z \mathbf{P} = 0, \quad \partial_Z \mathbf{V}_{|S} = G, \end{cases} \tag{49}$$

where Γ' *is given by* (34).

(ii) *The solution of* (49) *satisfies the following:* $\forall (\Phi, \Psi) \in \mathbb{F}(D)$,

$$\int_D \partial_Z \mathbf{V} \cdot \partial_Z \Phi \, dX dZ = \int_S G \cdot \Phi \, dX. \tag{50}$$

Conversely, if $(\mathbf{V}, \mathbf{W})$ *is the unique solution of* (50), *there exists a unique* $\mathbf{P}$ *such that* (49) *is satisfied.*

(iii) *The solution of* (49) *satisfies*

$$\int_D |\partial_Z \mathbf{V}|^2 \, dX dZ \le \int_\Gamma H |G|^2 \, dX.$$

The boundary conditions $\mathbf{W} = 0$ on S, $(\mathbf{V}, \mathbf{W}) = 0$ on F, and $(\int_{-H}^0 \mathbf{V}\, dZ) \cdot n_{\partial\Gamma} = 0$ announced in (10) and (14) are included in a weak sense in the condition $(\mathbf{V}, \mathbf{W}) \in \mathbb{F}(D)$. The traction condition has some sense according to the following result, which gives, in addition, a Green formula and the regularity of $\mathbf{P}$.

LEMMA 6. *Let* $\mathbf{V} \in (L^2(D))^2$ *and* $\mathbf{P} \in \mathcal{D}'(D)$ *be such that* $\partial_Z \mathbf{V} \in (L^2(D))^2$, $\partial_Z \mathbf{P} = 0$ *and* $-\partial_Z^2 \mathbf{V} + \nabla \mathbf{P} = 0$.

For all $\Gamma'' \subset\subset \Gamma$ *and for* $H'' = \min\{H(X) : X \in \Gamma''\}$, *such a function satisfies* $\mathbf{V} \in \mathcal{C}^\infty([-H'', 0]; (L^2(\Gamma''))^2)$, *which allows us to define a trace* $\partial_Z \mathbf{V} \in (L^2_{\rm loc}(\Gamma))^2$.

Moreover $\mathbf{P} \in H^1_{\rm loc}(\Gamma)$ *and the following holds:* $\forall\ (\Phi, \Psi) \in \mathcal{E}(D)$,

$$\int_D \partial_Z \mathbf{V} \cdot \partial_Z \Phi + \partial_Z^2 \mathbf{V} \cdot \Phi \, dX dZ = \int_S \partial_Z \mathbf{V} \cdot \Phi \, dX, \tag{51}$$

$$\int_D \nabla \mathbf{P} \cdot \Phi \, dX dZ = 0. \qquad \square \tag{52}$$

Proof of Lemma 6. *Regularity of* $\mathbf{V}$. The equation gives $\partial_Z^n \mathbf{V} = 0$ for any $n \ge 3$, which implies $\mathbf{V} \in C^\infty([-H'', 0]; (L^2(\Gamma''))^2)$ since $\mathbf{V} \in L^2([-H'', 0]; (L^2(\Gamma''))^2)$.

Regularity of $\mathbf{P}$. The equation gives $\nabla \mathbf{P} = \partial_Z^2 \mathbf{V} \in C([-H'', 0]; (L^2(\Gamma''))^2)$. Since $\nabla \mathbf{P}$ is independent on Z, it belongs to $(L^2(\Gamma''))^2$, and therefore $\mathbf{P} \in H^1_{\rm loc}(\Gamma)$.

Green formula. We cover Γ by a collection of cells Γ_i'' small enough to have $\Phi = 0$ if $X \in \Gamma_i''$, $Z \le -H_i''$. We have $\partial_Z \mathbf{V} \cdot \partial_Z \Phi + \partial_Z^2 \mathbf{V} \cdot \Phi = \partial_Z(\partial_Z \mathbf{V} \cdot \Phi)$ in $C([-H_i'', 0]; (L^2(\Gamma_i''))^2)$. Therefore, in $(L^2(\Gamma_i''))^2$,

$$\int_{-H_i''}^0 \partial_Z \mathbf{V} \cdot \partial_Z \Phi + \partial_Z^2 \mathbf{V} \cdot \Phi \, dZ = (\partial_Z \mathbf{V} \cdot \Phi)_{|Z=0}.$$

We deduce (51) by integrating with respect to X over Γ_i'' and summing with respect to i.

Proof of (52). The extension of Φ by 0 satisfies, for any fixed Z, $\Phi(\cdot, Z) \in (\mathcal{D}(\Gamma))^2$; thus

$$\int_\Gamma \nabla \mathbf{P}(X) \cdot \Phi(X,Z)\, dX = -\int_\Gamma \mathbf{P}(X)\, \nabla \cdot \Phi(X,Z)\, dX.$$

By definition of $\mathcal{E}(D)$, $\nabla \cdot \Phi = -\partial_Z \Psi$; therefore

$$\begin{aligned}\int_D \nabla \mathbf{P}(X) \cdot \Phi(X,Z)\, dX dZ &= \int_D \mathbf{P}(X)\, \partial_Z \Psi(X,Z)\, dX dZ \\ &= \int_\Gamma \mathbf{P}(X) \Big(\int_{-H(X)}^0 \partial_Z \Psi(X,Z)\, dZ \Big)\, dX,\end{aligned}$$

which cancels since $\Psi(X,0) = \Psi(X,-H(X))$. □

Proof of Theorem 5. *Variational solution.* The left-hand side of (50) defines a continuous bilinear form on $\mathbb{F}(D)$, which is coercive since $\int_D |\partial_Z \mathbf{V}|^2\, dX dZ = (\|(\mathbf{V},\mathbf{W})\|_{\mathbb{F}(D)})^2$. The right-hand side of (50) defines a continuous linear form according to (40). Then, the Lax–Milgram theorem gives the existence and uniqueness of a solution $(\mathbf{V},\mathbf{W}) \in \mathbb{F}(D)$ of (50).

Strong solution. Let us choose $(\Phi,\Psi) \in (\mathcal{D}(D))^3$ such that $\nabla \cdot \Phi + \partial_Z \Psi = 0$. Equation (50) yields

$$\langle (-\partial_Z^2 \mathbf{V}, 0), (\Phi,\Psi) \rangle_{(\mathcal{D}'(D))^3 \times (\mathcal{D}(D))^3} = 0;$$

therefore de Rham's theorem (see, for instance, [13]) gives the existence of $\mathbf{P} \in \mathcal{D}'(D)$ such that $(\nabla \mathbf{P}, \partial_Z \mathbf{P}) = (\partial_Z^2 \mathbf{V}, 0)$. Then, Lemma 6 gives $\mathbf{P} \in H^1_{\mathrm{loc}}(D)$. Since $\nabla \mathbf{P}$ is unique, $\mathbf{P}$ is unique up to a constant which is given by $\int_{\Gamma'} \mathbf{P}\, dX = 0$, and therefore $\mathbf{P}$ is unique.

Let us choose now $(\Phi,\Psi) \in \mathcal{E}(D)$. Substracting (50) from (51), one obtains

$$\int_S (\partial_Z \mathbf{V} - G) \cdot \Phi\, dX = \int_D \partial_Z^2 \mathbf{V} \cdot \Phi\, dX dZ.$$

The right-hand side equals $\int_D \nabla \mathbf{P} \cdot \Phi\, dX dZ$, which vanishes due to (52). Since $\Phi_{|S}$ spans $(\mathcal{D}(S))^2$, it follows that $\partial_Z \mathbf{V} = G$.

Converse assertion. Let us consider now a solution of (49) and $(\Phi,\Psi) \in \mathcal{E}(D)$. Since $\partial_Z^2 \mathbf{V} - \nabla \mathbf{P} = 0$,

$$\int_D \partial_Z \mathbf{V} \cdot \partial_Z \Phi\, dX dZ = \int_D \partial_Z \mathbf{V} \cdot \partial_Z \Phi + \partial_Z^2 \mathbf{V} \cdot \Phi - \nabla \mathbf{P} \cdot \Phi\, dX dZ.$$

According to (51) and (52), the right-hand side is equal to $\int_S \partial_Z \mathbf{V} \cdot \Phi\, dX$ and therefore, with the traction condition, to $\int_\Gamma G \cdot \Phi\, dX$ which gives (50). By continuity, this equation is satisfied for all (Φ,Ψ) in $\mathbb{F}(D)$. □

5. Convergence as $\varepsilon \to 0$. We prove here that the solution of the transported Navier–Stokes equations on the fixed domain D goes to the solution of the vertical diffusion model.

THEOREM 7. *Let* (3), (16), (47), *and* (48) *be satisfied.*

As $\varepsilon \to 0$, the image $(V^\varepsilon, W^\varepsilon, P^\varepsilon)$ by the scaling (6) *and* (7) *of the solution $(v^\varepsilon, w^\varepsilon, p^\varepsilon)$ defined by Theorem* 4 *goes to the solution $(\mathbf{V}, \mathbf{W}, \mathbf{P})$ of* (49) *in the following sense*:

$$(V^\varepsilon, W^\varepsilon, P^\varepsilon) \rightharpoonup (\mathbf{V}, \mathbf{W}, \mathbf{P}) \quad \text{in } (L^2(D))^2 \times H^{-1}(D) \times L^2_{\mathrm{loc}}(D) \text{ weak.}$$

Remark. From Theorem 4, $(v^\varepsilon, w^\varepsilon, p^\varepsilon)$, and therefore $(V^\varepsilon, W^\varepsilon, P^\varepsilon)$ is unique as soon as $\varepsilon < \nu^2/\big(2^{1/4}\beta^{3/2}(H_{\max})^{1/2}\|H^{1/2}G\|_{(L^2(\Gamma))^2}\big)$. ∎

Remark. For the limit problem, there is a "strong" formulation, namely (49), which is not the case for the initial problem (under the same hypothesis).

As we mentioned in the remark following Theorem 4, for the Navier–Stokes equations there is not enough regularity to define the trace of $\partial_Z V^\varepsilon$ on S. On the contrary, for the vertical diffusion model, this trace is defined at Lemma 6 with the help of the hydrostatic balance (that is, $\mathbf{P}$ independent on Z) which implies that $\partial_Z^2 \mathbf{V}$ is integrable with respect to Z. ∎

We will deduce Theorem 7 from the following properties, which are easy consequences of the results for a fixed ε.

PROPOSITION 8. *The image by the scaling* (3), (6), *and* (7) *of every solution $(v^\varepsilon, w^\varepsilon, p^\varepsilon)$ defined at Theorem* 4 *satisfies $(V^\varepsilon, W^\varepsilon) \in \mathbb{E}(D)$ and $\forall (\Phi, \Psi) \in \mathbb{E}(D)$,*

$$\left\{ \begin{aligned} &\int_D \partial_Z V^\varepsilon \cdot \partial_Z \Phi + \varepsilon^2 \nabla V^\varepsilon \cdot \nabla \Phi + \varepsilon^2 \partial_Z W^\varepsilon \partial_Z \Psi + \varepsilon^4 \nabla W^\varepsilon \cdot \nabla \Psi \\ &\quad + \frac{\varepsilon^3}{\nu^2}(V^\varepsilon \cdot \nabla + W^\varepsilon \partial_Z) V^\varepsilon \cdot \Phi + \frac{\varepsilon^5}{\nu^2}(V^\varepsilon \cdot \nabla + W^\varepsilon \partial_Z) W^\varepsilon \Psi \, dX dZ \\ &\quad + \frac{\varepsilon^2 k}{\nu} V^\varepsilon \times \Phi + \frac{\varepsilon^3 k'}{\nu}(W^\varepsilon \Phi_1 - V_1^\varepsilon \Psi) = \int_\Gamma G \cdot \Phi \, dX, \end{aligned} \right. \tag{53}$$

$$\int_D |\partial_Z V^\varepsilon|^2 + \varepsilon^2 |\nabla V^\varepsilon|^2 + \varepsilon^2 |\partial_Z W^\varepsilon|^2 + \varepsilon^4 |\nabla W^\varepsilon|^2 \, dX dZ \le \int_\Gamma H |G|^2 \, dX. \tag{54}$$

Moreover, it satisfies the strong equation (8), $P^\varepsilon \in L^2_{\mathrm{loc}}(D)$, *and, for* $\varepsilon \le 1$,

$$\|\nabla P^\varepsilon\|_{(H^{-1}(D))^2} \le \left(1 + \frac{\varepsilon^2 |\omega|}{\sqrt{2}\nu} H_{\max}\right) \|H^{1/2} G\|_{(L^2(\Gamma))^2} + \left(\frac{\gamma_D}{\nu} \|H^{1/2} G\|_{(L^2(\Gamma))^2}\right)^2 \tag{55}$$

$$\|\partial_Z P^\varepsilon\|_{H^{-1}(D)} \le \varepsilon \left(\left(1 + \frac{\varepsilon^2 |\omega|}{\sqrt{2}\nu} H_{\max}\right) \|H^{1/2} G\|_{(L^2(\Gamma))^2} + \left(\frac{\gamma_D}{\nu} \|H^{1/2} G\|_{(L^2(\Gamma))^2}\right)^2 \right) \tag{56}$$

$$\int_{D'} P^\varepsilon \, dX dZ = 0. \tag{57}$$

Here $D' = \Gamma' \times (-H', 0)$, Γ' is given by (34) *and $H' = \min\{H(X) : X \in \Gamma'\}$.*

Proof of Proposition 8. Equation (53) follows from (36) by observing that, if $(\varphi, \psi) \in \mathbb{E}(d_\varepsilon)$, an element $(\Phi, \Psi) \in \mathbb{E}(D)$ is defined by $\Phi(X, Z) = \varphi(x, z)$, $\Psi(X, Z) = \varepsilon \, \psi(x, z)$.

Inequality (54) follows from (37).

To get (55) and (56), we observe that, once scaled by (7), (43) may be written in the following form:

$$\left(\nabla, \frac{1}{\varepsilon}\partial_Z\right) P^\varepsilon = \varepsilon^2 \frac{\omega}{\nu} \times (V^\varepsilon, \varepsilon W^\varepsilon) + (\nabla, \partial_Z) \cdot \Big((\varepsilon^2 \nabla, \partial_Z)(V^\varepsilon, \varepsilon W^\varepsilon) - \frac{\varepsilon^3}{\nu^2} (V^\varepsilon, W^\varepsilon) \otimes (V^\varepsilon, \varepsilon W^\varepsilon) \Big);$$

therefore, with (30), (19), (20), and $\varepsilon \le 1$,

$$\left\| \left(\nabla, \frac{1}{\varepsilon}\partial_Z \right) P^\varepsilon \right\|_{(H^{-1}(D))^3} \le \varepsilon^2 \frac{|\omega|}{\nu} \|(V^\varepsilon, \varepsilon W^\varepsilon)\|_{(L^2(D))^3} + \|(\varepsilon^2\nabla, \partial_Z)(V^\varepsilon, \varepsilon W^\varepsilon)\|_{(L^2(D))^9} + \left(\frac{\varepsilon}{\nu} \|(V^\varepsilon, \varepsilon W^\varepsilon)\|_{(L^4(D))^9} \right)^2$$

$$\le \left(\frac{\varepsilon^2|\omega|}{\sqrt{2}\nu} H_{\max} + 1 \right) \|(\varepsilon\nabla, \partial_Z)(V^\varepsilon, \varepsilon W^\varepsilon)\|_{(L^2(D))^9} + \left(\frac{\gamma_D}{\nu} \|(\varepsilon\nabla, \partial_Z)(V^\varepsilon, \varepsilon W^\varepsilon)\|_{(L^2(D))^9} \right)^2,$$

which, due to (54), gives (55) and (56). ∎

Proof of Theorem 7. *Convergence of the velocity.* From (54), $(V^\varepsilon, W^\varepsilon)$ is bounded in $\mathbb{F}(D)$; therefore there exists a subsequence and $(\mathbf{V}, \mathbf{W})$ such that

$$(V^\varepsilon, W^\varepsilon) \rightharpoonup (\mathbf{V}, \mathbf{W}) \quad \text{in } \mathbb{F}(D) \text{ weak.}$$

Let us pass to the limit in (53) for $(\Phi, \Psi) \in \mathcal{E}(D)$. The weak convergence gives

$$\int_D \partial_Z V^\varepsilon \cdot \partial_Z \Phi \, dX dZ \to \int_D \partial_Z \mathbf{V} \cdot \partial_Z \Phi \, dX dZ.$$

The other terms in the left-hand side of (53) go to 0. Indeed, from (54), $\partial_Z V^\varepsilon$, $\varepsilon\nabla V^\varepsilon$, $\varepsilon\partial_Z W^\varepsilon$, and $\varepsilon^2\nabla W^\varepsilon$ are bounded in $(L^2(D))^n$ ($n = 1$, 2, or 4); thus V^ε and $\varepsilon W^\varepsilon$ are bounded in $(L^2(D))^n$ because of (19).

Therefore the limit $(\mathbf{V}, \mathbf{W})$ satisfies the variational equation (50) for any $(\Phi, \Psi) \in \mathcal{E}(D)$. By continuity, it satisfies this equation for any $(\Phi, \Psi) \in \mathbb{F}(D)$; thus, due to Theorem 5, it is unique. Therefore the whole sequence converges.

Convergence of the pressure. Its gradient $(\nabla P^\varepsilon, \partial_Z P^\varepsilon)$ is bounded in $(H^{-1}(D))^3$ because of (55) and (56). With (57) and (44), it results that P^ε is bounded in $L^2_{\text{loc}}(D)$. Then, there exists a subsequence and $\mathbf{P}$ such that

$$P^\varepsilon \rightharpoonup \mathbf{P} \quad \text{in } L^2_{\text{loc}}(D) \text{ weak.}$$

One can pass to the limit in the first equation of (8), the nonlinear term converging to 0 in $(L^1(D))^2$ since V^ε, $\varepsilon\nabla V^\varepsilon$, $\varepsilon W^\varepsilon$, and $\partial_Z V^\varepsilon$ are bounded in $(L^2(D))^n$ for some n. At the limit, $-\partial_Z^2 \mathbf{V} + \nabla \mathbf{P} = 0$.

From (56), $\partial_Z P^\varepsilon \to 0$; thus $\partial_Z \mathbf{P} = 0$. Finally, passing to the limit in (57), we obtain $\int_{D'} \mathbf{P} \, dX dZ = 0$. Due to Lemma 6, $\mathbf{P}$ satisfies (49), and due to Theorem 5 it is unique. Therefore the whole sequence converges, ending the proof of Theorem 7. ∎

6. Semiexplicit solution of the vertical diffusion model. Let us first give a variational solution $\mathbf{P} = \mathbf{P}(X)$ of the pressure equation. We denote

$$\mathbb{A}(\Gamma) = \left\{ \mathbf{P} \in L^2_{\text{loc}}(\Gamma) : H^{3/2}\nabla \mathbf{P} \in (L^2(\Gamma))^2, \int_{\Gamma'} \mathbf{P} \, dX = 0 \right\} \tag{58}$$

(recall that Γ' is not empty and $\Gamma' \subset\subset \Gamma$), a space which is endowed with the norm

$$\|\mathbf{P}\|_{\mathbb{A}(\Gamma)} = \left(\int_\Gamma H^3 |\nabla \mathbf{P}|^2 \, dX \right)^{1/2}.$$

Notice that $\mathbb{A}(\Gamma) \subset H^1_{\rm loc}(\Gamma)$.

PROPOSITION 9. *Let* (16), (47), *and* (48) *be satisfied. There exists a unique solution* $\mathbf{P} \in \mathbb{A}(\Gamma)$ *of the following*: $\forall\, \Xi \in \mathbb{A}(\Gamma)$,

$$\frac{1}{3}\int_\Gamma H^3 \nabla \mathbf{P} \cdot \nabla \Xi \, dX = \frac{1}{2}\int_\Gamma H^2 G \cdot \nabla \Xi \, dX. \tag{59}$$

It satisfies the strong equation (13) *and*

$$\frac{1}{9}\int_\Gamma H^3 |\nabla \mathbf{P}|^2 \, dX \le \frac{1}{4}\int_\Gamma H |G|^2 \, dX. \tag{60}$$

If Γ *is a Lipschitz set*, $\mathbf{P}$ *satisfies the boundary condition* (15) *in* $H^{-1/2}(\partial\Gamma)$.

The velocity is given explicitly in terms of Z and $\nabla \mathbf{P}(X)$ as follows.

THEOREM 10. *Let* (16), (31), (47), *and* (48) *be satisfied. Then*, $\mathbf{P}$ *being defined by* (59), *formulas* (11) *and* (12) *define the unique velocity* $(\mathbf{V}, \mathbf{W})$ *satisfying* (49).

Remark. The velocity is infinitely regular in the vertical direction. Indeed (49) gives $\partial_Z^2 \mathbf{V} = \nabla \mathbf{P}$, $\partial_Z^n \mathbf{V} = 0$ as soon as $n \ge 3$, and $\partial_Z \mathbf{W} = -\nabla \cdot \mathbf{V}$ gives $\partial_Z^n \mathbf{W} = 0$ as soon as $n \ge 4$. We recover this regularity in the explicit expressions (11) and (12). ∎

Remark. The hypothesis (31) is satisfied by d if and only if it is satisfied by D. ∎

Proof of Proposition 9. *Properties of the space* $\mathbb{A}(\Gamma)$. It is a separated space since, according to (44), for any $\Gamma'' \subset\subset \Gamma$, there exists $c_{\Gamma''}$ such that $\forall\, \mathbf{P} \in \mathbb{A}(\Gamma)$,

$$\left(\int_{\Gamma''} \mathbf{P}^2 \, dX\right)^{1/2} \le c_{\Gamma''} \|\mathbf{P}\|_{\mathbb{A}(\Gamma)}.$$

This inequality implies the completion; thus $\mathbb{A}(\Gamma)$ is a Hilbert space.

Solution of the variational equation (59). Its right-hand side is bounded by

$$\left|\int_\Gamma \frac{1}{2} H^2 G \cdot \nabla \Xi \, dX\right| \le \frac{1}{2}\left(\int_\Gamma H |G|^2 \, dX\right)^{1/2} \left(\int_\Gamma H^3 \, |\nabla \Xi|^2 \, dX\right)^{1/2};$$

therefore the Lax–Milgram theorem gives the existence of a unique solution $\mathbf{P} \in \mathbb{A}(\Gamma)$ of (59) and the inequality (60).

Verification of the strong equation (13). Let $\Xi \in \mathcal{D}(\Gamma)$. There exists a (unique) real number c such that $\Xi + c \in \mathbb{A}(\Gamma)$. Since $\nabla(\Xi + c) = \nabla \Xi$, (59) is satisfied by Ξ. This proves (13) in $\mathcal{D}'(\Gamma)$.

Verification of the boundary condition (15). The function $\overline{\mathbf{V}} = -\frac{1}{3} H^3 \nabla \mathbf{P} + \frac{1}{2} H^2 G$ belongs to $(L^2(\Gamma))^2$. It satisfies $\nabla \cdot \overline{\mathbf{V}} = 0$ because of (13). If Γ is a Lipschitz set, we can define $\overline{\mathbf{V}} \cdot n_{\partial\Gamma} \in H^{-1/2}(\partial\Gamma)$ by the following: $\forall \Xi \in H^1(\Gamma)$,

$$\langle \overline{\mathbf{V}} \cdot n_{\partial\Gamma}, \Xi \rangle_{H^{-1/2}(\partial\Gamma) \times H^{1/2}(\partial\Gamma)} = \int_\Gamma \overline{\mathbf{V}} \cdot \nabla \Xi \, dX.$$

The right-hand side is null because of (59) (it suffices to choose c such that $\Xi + c \in \mathbb{A}(\Gamma)$), which gives (15) in $H^{-1/2}(\Gamma)$. ∎

Proof of Theorem 10. Let $\mathbf{P}$ be defined by (59) and $(\mathbf{V}, \mathbf{W})$ be defined by (11) and (12).

Verification that $(\mathbf{V}, \mathbf{W}) \in \mathbb{F}(D)$. By Lemma 3, it suffices to find an extension $(\widetilde{\mathbf{V}}, \widetilde{\mathbf{W}})$ satisfying (32). Let us define

$$\begin{cases} \widetilde{\mathbf{V}} = \widehat{\mathbf{V}} = \frac{1}{2}\widehat{(Z^2 - H^2)\nabla\mathbf{P}} + \widehat{(Z+H)G}, \\ \widetilde{\mathbf{W}} = \nabla\cdot\left(\widehat{(\frac{1}{2}ZH^2 - \frac{1}{6}Z^3)\nabla\mathbf{P}} - \widehat{(\frac{1}{2}Z^2 + HZ)G}\right), \end{cases}$$

where $\widehat{\ }$ (and $\widehat{}$) denote the extension of functions by 0 outside D. Since $H^{3/2}\nabla\mathbf{P}$ and $H^{1/2}G$ lie in $(L^2(\Gamma))^2$ and $|Z| \le |H|$ in D, each of the extended functions lies in $(L^2(D))^2$ and therefore has an extension in $(L^2(\mathbb{R}^3_-))^2$.

The function $\widetilde{\mathbf{V}}$ coincides with $\mathbf{V}$ in D and it vanishes outside D. The distribution $\widetilde{\mathbf{W}}$ coincides with $\mathbf{W}$ in D and it vanishes outside D.

Let us verify that $\partial_Z\widetilde{\mathbf{V}} \in (L^2(\mathbb{R}^3_-))^2$. In the set $D_\infty = \Gamma \times (-\infty, 0)$, one has $\widetilde{\mathbf{V}} = \frac{1}{2}(\widetilde{Z}^2 - H^2)\nabla\mathbf{P} + (\widetilde{Z} + H)G$, where $\widetilde{Z} = \max\{Z, -H(X)\}$. The map $Z \mapsto \widetilde{Z}$ is differentiable into $L^q(D_\infty)$, $\forall q < \infty$, with $\partial_Z\widetilde{Z} = 1_D$. Since $\nabla\mathbf{P}$ and G belong to $(L^2_{\mathrm{loc}}(\Gamma))^2$, $Z \mapsto \widetilde{\mathbf{V}}$ is differentiable into $L^1_{\mathrm{loc}}(D_\infty)$ and

$$\partial_Z\widetilde{\mathbf{V}} = (Z\nabla\mathbf{P} + G)\,1_D.$$

Therefore

$$\begin{aligned} \left|\int_{D_\infty} |\partial_Z\widetilde{\mathbf{V}}|^2\,dX\,dZ\right| &\le \int_\Gamma dX \int_{-H(X)}^0 |Z\nabla\mathbf{P} + G|^2\,dZ \\ &\le \int_\Gamma \frac{2H^3}{3}|\nabla\mathbf{P}|^2 + 2H|G|^2\,dX, \end{aligned}$$

which is finite because of (60); thus $\partial_Z\widetilde{\mathbf{V}} \in (L^2(D_\infty))^2$. In $\mathbb{R}^3_- \setminus \overline{D}$, we have $\partial_Z\widetilde{\mathbf{V}} = 0$; therefore, by recollection of distributions ($\mathbb{R}^3_-$ is the union of the open sets D_∞ and $R^3_- \setminus \overline{D}$)

$$\partial_Z\widetilde{\mathbf{V}} \in (L^2(\mathbb{R}^3_-))^2.$$

On the other hand, in D_∞,

$$\begin{aligned} \partial_Z\widetilde{\mathbf{W}} &= \nabla\cdot\partial_Z\left(\left(\frac{1}{2}\widetilde{Z}H^2 - \frac{1}{6}\widetilde{Z}^3\right)\nabla\mathbf{P} - \left(\frac{1}{2}\widetilde{Z}^2 + H\widetilde{Z}\right)G\right) \\ &= -\nabla\cdot\left(\frac{1}{2}(\widetilde{Z}^2 - H^2)1_D\nabla\mathbf{P} + (\widetilde{Z} + H)1_D G\right) \\ &= -\nabla\cdot\widetilde{\mathbf{V}}. \end{aligned}$$

This equality is also true in $\mathbb{R}^3_- \setminus \overline{D}$ and therefore, by recollection, in the whole set $\mathbb{R}^3_-$.

Let us verify now the condition at the surface on $\widetilde{\mathbf{W}}$. Let $\Gamma'' \subset\subset \Gamma$ and $H'' = \inf\{H(X) : X \in \Gamma''\}$. In $\Gamma'' \times (-H'', 0)$ we have $\widetilde{Z} = Z$; therefore $\widetilde{\mathbf{W}} = \nabla\cdot Y$, where $Y(Z) = (\frac{1}{2}ZH^2 - \frac{1}{6}Z^3)\nabla\mathbf{P} - (\frac{1}{2}Z^2 + HZ)G$. Since $Y \in \mathcal{C}([-H'', 0]; (L^2(\Gamma''))^2)$ and $Y(0) = 0$, we have $\widetilde{\mathbf{W}} \in \mathcal{C}([-H'', 0]; H^{-1}(\Gamma''))$ and $\widetilde{\mathbf{W}} = 0$ on S. This ends the proof of (32).

Verification of the other properties. Differentiating (11) in the distribution sense, we obtain $\partial_Z^2 \mathbf{V} = \nabla \mathbf{P}$. On the other hand, by definition of $\mathbf{P}$, $\partial_Z \mathbf{P} = 0$ and $\int_{\Gamma'} \mathbf{P}\, dX = 0$. Finally, $\partial_Z \mathbf{V} = Z \nabla \mathbf{P} + G$, which is equal to G on S. Thus, (49) is proved. ∎

Remark. Any element of $L^2(D)$ has a unique extension in $L^2(\mathbb{R}^3_-)$ which vanishes outside $\overline{D}$. In $H^{-1}(\mathbb{R}^3_-)$ there is not uniqueness, since it may exist a "mass" on ∂D. This is the reason why we do not denote in the same manner the two extensions by 0 which are $\widehat{\ }$ (the unique extension in $L^2(\mathbb{R}^3_-)$) and $\widetilde{\ }$ (one of the possible extensions in $H^{-1}(\mathbb{R}^3_-)$). ∎

SELF-SIMILAR BLOW-UP AND HAUSDORFF DIMENSION ESTIMATES FOR A CLASS OF PARABOLIC FREE BOUNDARY PROBLEMS*

G. S. WEISS†

Abstract. We consider variational solutions of the quenching problem $\partial_t u - \Delta u = -u^\gamma \chi_{\{u>0\}}$ with exponent $\gamma \in (-\frac{1}{3}, 0)$ and solutions of the heat equation with Bernoulli-type condition on the free boundary which arises in combustion theory, $\partial_t v - \Delta v = 0$ in $\{v > 0\}$, $|\nabla v| = 1$ on $\partial\{v > 0\}$. We show that blow-up limits of u and v are backward self-similar solutions and use this to determine the Hausdorff dimension of the free boundaries $\partial\{u > 0\}$ and $\partial\{v > 0\}$.

Key words. free boundary, monotonicity formula, Hausdorff dimension estimate, characterization of blow-up limits, Bernoulli-type free boundary condition, quenching, combustion

1. Introduction.

In this paper we study the gradient flow in $L^2(\mathbf{R}^n)$ with respect to the energy

$$w \mapsto F(w) := \int_{\mathbf{R}^n} \left(|\nabla w|^2 \ + \ \lambda_+ \, \chi_{\{w>0\}} \, w^p \ + \ \lambda_- \, \chi_{\{w<0\}} \, (-w)^p \right), \tag{1.1}$$

where the exponent $p \in [0, 2)$, λ_+ and λ_- are real parameters, and χ_A denotes the characteristic function of the set A .

Depending on the choice of p, λ_+, and λ_- as well as initial data a solution u may exist or not. For certain sets of parameters the question of global existence, even in a weak sense, has not yet been answered, and for a large class of parameters uniqueness or even an ordering of solutions is unknown. Given a global weak solution in a sense to be specified, our objective is the study of sets of special relevance for this solution: for example, the "free boundary" $\partial\{u > 0\} \cup \partial\{u < 0\}$, the set of singular free boundary points, and the set of horizontal free boundary points in which the behavior in time is dominant. We are interested in the size in terms of the Hausdorff dimension of these sets as well as in regularity properties of the free boundary. Since differentiability of the solution, even directional differentiability, is not known in advance, *blow-up sequences*

$$u_k(t, x) := \frac{u(T + {\rho_k}^2 t, x_0 + \rho_k x)}{{\rho_k}^{\frac{2}{2-p}}},$$

defined with respect to a given point (T, x_0) and with respect to a given sequence $\rho_k \to 0$, prove to be very useful. The underlying reason for this is that blow-up sequences introduce the possibility of different subsequences converging to different "blow-up limits" and thereby allow—usually by indirect arguments—to obtain information on the solution's behavior at a free boundary point *without any knowledge of the free*

†Tokyo Institute of Technology, O-okayama 2-12-1, Meguro-ku, Tokyo, 152 Japan (gw@math.titech.ac.jp).

boundary's direction. Once the blow-up limits have been characterized, the size of the special sets mentioned above can usually be estimated by a standard dimension reduction procedure.

In section 3 we introduce a variational formulation for the parabolic equation associated with the energy (1.1) which involves the time-space first variation with respect to domain variations of the time-integrated energy. This formulation makes it possible to deal in an elegant way with the singular cases $p \in [0,1)$. Another advantage is that the class of nondegenerate variational solutions is closed with respect to convergence in $H^{1,2}$, a fact we exploit extensively in section 5 when estimating the Hausdorff dimension of the free boundary of variational solutions.

For these variational solutions we derive a monotonicity formula which allows us to characterize the blow-up limits of variational solutions as backward self-similar functions (section 4).

This we apply to the following two problems:

(1) The quenching problem with respect to exponent $\gamma \in (-\frac{1}{3}, 0)$ (see, for example, [Ph] and [Le]):

$$\begin{gathered} {u_1}^{1+\gamma} \in L^1((0,\infty)\times \mathbf{R}^n), \\ u_1(0,x) = u_1^0(x),\ 0 \le u_1^0 \in C_0^{2,\alpha}(\mathbf{R}^n), \\ \partial_t u_1 - \Delta u_1 = -{u_1}^{\gamma}\, \chi_{\{u_1>0\}} \text{ in } (0,\infty)\times\mathbf{R}^n \end{gathered}$$

and u_1 is a solution in the sense of distributions obtained by the regularization of Phillips [Ph] which arises in chemical engineering (see [Ph]).

(2) The heat equation with Bernoulli-type boundary condition on the free boundary,

$$\begin{gathered} u_2 \ge 0,\ \partial_t u_2 - \Delta u_2 = 0 \text{ in } ((0,\infty)\times\mathbf{R}^n)\cap\{u_2>0\}, \\ |\nabla u_2| = 1 \text{ on } ((0,\infty)\times\mathbf{R}^n)\cap\partial\{u_2>0\}, \end{gathered} \tag{1.2}$$

which has been introduced as a model for flame propagation in [CaVa]. Here u_2 denotes a variational solution as introduced in Definition 3.1.

We show that the blow-up limits of u_1 and u_2 are backward self-similar variational solutions. Then by a standard dimension reduction procedure it is possible to estimate the Hausdorff dimension of special sets which we carry out only for the case of free boundaries: the Hausdorff dimension (with respect to the parabolic metric) of $\partial\{u_i > 0\}$ $(i = 1, 2)$ does not exceed $n+1$ and this estimate is optimal (Theorem 5.2).

2. Notation. Considering functions $u \in H^{1,2}_{\mathrm{loc}}(\mathbf{R}^n)$, $v \in H^{1,2}_{\mathrm{loc}}((0,T)\times\mathbf{R}^n)$, $\phi \in H^{1,2}_{\mathrm{loc}}(\mathbf{R}^n;\mathbf{R}^n)$, and $\psi \in H^{1,2}_{\mathrm{loc}}((0,T)\times\mathbf{R}^n;\mathbf{R}^n)$, we denote by $\nabla u := (\partial_1 u, \dots, \partial_n u)$ and $\nabla v := (\partial_2 v, \dots, \partial_{n+1} v)$ the space gradient, by $\partial_t v := \partial_1 v$ the time derivative, by $\operatorname{div}\phi := \sum_{i=1}^n \partial_i \phi_i$ and $\operatorname{div}\psi := \sum_{i=2}^{n+1} \partial_i \psi_i$ the space divergences, by $\nabla_{t,x} v := (\partial_1 v, \dots, \partial_{n+1} v)$ the time-space gradient, by $\operatorname{div}_{t,x}\psi := \sum_{i=1}^{n+1} \partial_i \psi_i$ the time-space divergence, and by

$$D\phi := \begin{pmatrix} \partial_1\phi_1 & \dots & \partial_n\phi_1 \\ & \dots & \\ \partial_1\phi_n & \dots & \partial_n\phi_n \end{pmatrix} \quad \text{and } D\psi := \begin{pmatrix} \partial_2\psi_1 & \dots & \partial_{n+1}\psi_1 \\ & \dots & \\ \partial_2\psi_{n+1} & \dots & \partial_{n+1}\psi_{n+1} \end{pmatrix}$$

the space Jacobian.

Moreover let us denote by χ_A the characteristic function of the set A, by $x\cdot y$ the Euclidean inner product in $\mathbf{R}^n\times\mathbf{R}^n$, by $|x|$ the Euclidean norm in $\mathbf{R}^n$, by $B_r(x_0) :=$

$\{x \in \mathbf{R}^n |\ |x-x_0| < r\}$ the ball of center x_0 and radius r, by $Q_r(t_0,x_0) := (t_0-r^2, t_0+r^2)\times B_r(x_0)$ the cylinder of radius r and height $2r^2$, by $T_r^-(t_0) := (t_0-4r^2, t_0-r^2)\times\mathbf{R}^n$ the horizontal layer from t_0-4r^2 to t_0-r^2 , by $T_r^+(t_0) := (t_0+r^2, t_0+4r^2)\times\mathbf{R}^n$ the horizontal layer from t_0+r^2 to t_0+4r^2, and by

$$G_{(t_0,x_0)}(t,x) := 4\pi(t_0-t)\,|4\pi(t_0-t)|^{-\frac{n}{2}-1}\ \exp\left(-\frac{|x-x_0|^2}{4(t_0-t)}\right)$$

the backward heat kernel, defined in $((-\infty,t_0)\cup(t_0,+\infty))\times\mathbf{R}^n$.

Furthermore, by ν we will always refer to the outer normal on a given surface. Finally $\mathcal{L}^n$ shall denote the n-dimensional Lebesgue measure, $\mathcal{H}^s$ the s-dimensional Hausdorff measure, and $\mathbf{W}_p^{2,1}$ and $\mathbf{H}^{1,\frac{1}{2}}$ the parabolic Sobolev- and Hölder-spaces as defined in [LSU].

3. Notion of solution and monotonicity formula. We begin by introducing our notion of a variational solution of the equation

$$\begin{gathered}\partial_t u-\Delta u = -\tfrac{\lambda_+}{2}\,p\,u^{p-1}\,\chi_{\{u>0\}}\ +\ \tfrac{\lambda_-}{2}\,p\,(-u)^{p-1}\,\chi_{\{u<0\}}\\ \text{in the case } p\in(0,2) \text{ and}\\ \partial_t u-\Delta u = 0 \text{ in } \{u>0\}\cup\{u<0\}\ ,\\ |\nabla\max(u,0)|^2-|\nabla\min(u,0)|^2 = \lambda_+-\lambda_- \text{ on } \partial\{u>0\}\cup\partial\{u<0\}\\ \text{in the case } p=0,\end{gathered}\tag{3.1}$$

where λ_+,λ_- are parameters $\in\mathbf{R}$.

For $p\ge 1$, nonnegative λ_+,λ_-, and suitable initial data there exists a unique strong solution of (3.1) and the proofs to follow can be readily simplified in this case.

DEFINITION 3.1. *We define $u\in H^{1,2}((t_1,t_2)\times B_R(0))$ for any $R\in(0,\infty)$ to be a* variational solution of (3.1) *if u is continuous in $(t_1,t_2)\times\mathbf{R}^n$ and continuously differentiable in the set $((t_1,t_2)\times\mathbf{R}^n)\cap(\{u>0\}\cup\{u<0\})$ once in time direction and twice in space directions and*

$$\begin{aligned}0=I :=& \int_{t_1+\delta}^{t_2-\delta}\int_{\mathbf{R}^n}\Big[\Big(|\nabla u|^2\ +\ \lambda_+\,\chi_{\{u>0\}}\,u^p\ +\ \lambda_-\,\chi_{\{u<0\}}\,(-u)^p\Big)\ \operatorname{div}_{t,x}\psi\\ &-2\,\nabla_{t,x}u\,D\psi\,\nabla u\ -\ 2\,\partial_t u\,\nabla_{t,x}u\cdot\psi\Big]\\ &-\Big[\int_{\mathbf{R}^n}\Big(|\nabla u|^2\ +\ \lambda_+\,\chi_{\{u>0\}}\,u^p\ +\ \lambda_-\,\chi_{\{u<0\}}\,(-u)^p\Big)\,\psi_1\Big]_{t_1+\delta}^{t_2-\delta}\\ =&\int_{t_1+\delta}^{t_2-\delta}\int_{\mathbf{R}^n}\Big[\Big(|\nabla u|^2\ +\ \lambda_+\,\chi_{\{u>0\}}\,u^p\ +\ \lambda_-\,\chi_{\{u<0\}}\,(-u)^p\Big)\sum_{i=1}^{n+1}\partial_i\psi_i\\ &-2\sum_{j=2}^{n+1}\sum_{i=1}^{n+1}\partial_j u\,\partial_j\psi_i\,\partial_i u\ -\ 2\partial_t u\sum_{k=1}^{n+1}\partial_k u\,\psi_k\Big]\\ &-\int_{\mathbf{R}^n}\Big[\Big(|\nabla u|^2\ +\ \lambda_+\,\chi_{\{u>0\}}\,u^p\ +\ \lambda_-\,\chi_{\{u<0\}}\,(-u)^p\Big)\,\psi_1\Big]\ (t_2-\delta)\end{aligned}$$

$$+ \int_{\mathbf{R}^n} \left[\left(|\nabla u|^2 \, + \, \lambda_+ \, \chi_{\{u>0\}} \, u^p \, + \, \lambda_- \, \chi_{\{u<0\}} \, (-u)^p \right) \psi_1 \right] \, (t_1 + \delta)$$

for almost every (a.e.) small and positive δ *and any* $\psi \in C^1(\mathbf{R}^{n+1})$ *such that* supp $\psi(t) \subset\subset \mathbf{R}^n$ *for any* $t \in (t_1, t_2)$. *Notice that for given* u, I *is formally the first variation with respect to variations of the domain* in time and space *of the functional*

$$\mathbf{G}(u, v) := \int_{t_1+\delta}^{t_2-\delta} F(v(t)) \, dt \, + \, \int_{t_1+\delta}^{t_2-\delta} \int_{\mathbf{R}^n} 2 \, \partial_t u \, v,$$

i.e., $I = -\frac{d}{d\epsilon} \mathbf{G}(u, u((t, x) + \epsilon\psi(t, x)))|_{\epsilon=0}$.

The continuity and differentiability assumptions on u are necessary in that they cannot be deduced from the other assumptions in Definition 3.1 by regularity theory, but they are rather mild in the sense that they can be verified without effort in many of the examples (see section 5). Existence of variational solutions and the relation to other notions of weak solutions will be discussed along with applications in section 5.

In this section we are going to derive a monotonicity formula for variational solutions with respect to any $p \in (-\infty, 2)$. In the case of continuous variational solutions with respect to $p \in [0, 2)$ this monotonicity will hold in arbitrary points of $(t_1, t_2) \times \mathbf{R}^n$, and in the case of strong solutions with respect to $p < 0$ it will hold as long as the solution continues to exist. So we exclude the quenching problem with a critical exponent,

$$\partial_t u - \Delta u = -\frac{1}{u} \, \chi_{\{u>0\}}.$$

THEOREM 3.1 (monotonicity formula). *Suppose that* $t_1 \le T \le t_2$, *that* $x_0 \in \mathbf{R}^n$, *that*

$$\sup_{t \in (t_1, T-\delta) \cup (T+\delta, t_2)} \int_{\mathbf{R}^n} \exp\left(-\frac{|x - x_0|^2}{4(T-t)} \right) \left(|\nabla u|^2 \, + \, |u|^p \right) (t, x)$$

$$+ \int_{(t_1, T-\delta) \cup (T+\delta, t_2)} \int_{\mathbf{R}^n} \exp\left(-\frac{|x - x_0|^2}{4(T-t)} \right) \left((\partial_t u)^2 \, + \, u^2 \right) (t, x) \, dx \, dt \, < \, \infty$$

for any positive δ, *and that either* $p \in [0, 2)$, u *is in* $((t_1, T) \cup (T, t_2)) \times \mathbf{R}^n$ *a variational solution in the sense of Definition* 3.1, *and* λ_+, λ_- *are nonnegative constants in the case* $p \in (0, 1)$, *or that* $p < 0$, $u \in C^0(((t_1, T) \cup (T, t_2)) \times \mathbf{R}^n)$, $u(t, x) \neq 0$ *in* $((t_1, T) \cup (T, t_2)) \times \mathbf{R}^n$, *and that* u *is a solution of* (3.1) *in the sense of distributions.*

Then for $\alpha = \frac{2}{2-p}$ *and* T_r^- , T_r^+, *and* $G_{(T,x_0)}$ *as defined in section* 2 *the functions*

$$\Psi^-(r) := r^{-2(\alpha-1)-2} \int_{T_r^-(T)} \left(|\nabla u|^2 \, + \, \lambda_+ \, \chi_{\{u>0\}} \, u^p \, + \, \lambda_- \, \chi_{\{u<0\}} \, (-u)^p \right) G_{(T,x_0)}$$

$$- \, \frac{\alpha}{2} \, r^{-2\alpha} \int_{T_r^-(T)} \frac{1}{T-t} \, u^2 \, G_{(T,x_0)}$$

and

$$\Psi^+(r) := r^{-2(\alpha-1)-2} \int_{T_r^+(T)} \left(|\nabla u|^2 \, + \, \lambda_+ \, \chi_{\{u>0\}} \, u^p \, + \, \lambda_- \, \chi_{\{u<0\}} \, (-u)^p \right) G_{(T,x_0)}$$

$$-\frac{\alpha}{2}\, r^{-2\alpha} \int_{T_r^+(T)} \frac{1}{T-t}\, u^2\, G_{(T,x_0)}$$

are well defined in the interval $(0, \frac{\sqrt{T-t_1}}{2})$ *and* $(0, \frac{\sqrt{t_2-T}}{2})$, *respectively, and satisfy for any* $0 < \rho < \sigma < \frac{\sqrt{T-t_1}}{2}$ *and* $0 < \rho < \sigma < \frac{\sqrt{t_2-T}}{2}$, *respectively, the monotonicity formulae*

$$\Psi^-(\sigma) \;-\; \Psi^-(\rho)$$

$$= \int_\rho^\sigma r^{-2\alpha-1} \int_{T_r^-(T)} \frac{1}{T-t}\, \left(\nabla u \cdot (x-x_0) \;-\; 2(T-t)\partial_t u \;-\alpha\, u\right)^2\, G_{(T,x_0)}\, dr$$

$$\geq 0$$

and

$$\Psi^+(\sigma) \;-\; \Psi^+(\rho)$$

$$= \int_\rho^\sigma r^{-2\alpha-1} \int_{T_r^+(T)} \frac{1}{T-t}\, \left(\nabla u \cdot (x-x_0) \;-\; 2(T-t)\partial_t u \;-\alpha\, u\right)^2\, G_{(T,x_0)}\, dr$$

$$\geq 0.$$

Remark 3.1. The integrand on the right-hand side of the monotonicity formula with respect to $x_0 = 0$ and $T = 0$,

$$-\left(\frac{1}{t}\right) \left(\nabla_{t,x} u \cdot (2t, x) \;-\; \alpha\, u(t,x)\right)^2\, G_{(T,x_0)}(t,x),$$

is sort of a measure of the distance of u to a function being homogeneous of degree α on paths $\theta \mapsto (\theta^2 t, \theta x)$. Since such a function would be of class C^β for any $\beta < \alpha$ on paths $\theta \mapsto (\theta^2 t, \theta x)$ but in general not of class C^α we may speak of a *monotonicity formula of order* α.

In the special case $\lambda_+ = \lambda_- = 0$ we obtain a monotonicity formula of order α for solutions of the heat equation which coincides when extrapolated at $\alpha = 0$ with the well-known monotonicity formula for the evolution of harmonic maps (see, for example, the proof of Theorem 8.1 of [St]).

Also, for $p > 2$ the integrands in our monotonicity formula coincide if written in similarity variables with those of the energy identity derived by Giga and Kohn in the classical paper [GiKo] for smooth solutions of (3.1); however, for $p \in [0, 1)$ globally smooth solutions no longer exist, and this is where the variational solutions of Definition 3.1 enter the game. The technique in our proof is motivated by that of Allard in section 5 of [Al], where he proves Fleming's monotonicity formula for stationary rectifiable n-varifolds.

Proof of Theorem 3.1. We give a proof for the monotonicity of Ψ^-. In order to obtain a proof with respect to Ψ^+ it is then sufficient to replace in what follows the interval $(-4r^2, -r^2)$ by $(r^2, 4r^2)$. Applying a translation we may assume that

$x_0 = 0$ and $T = 0$. Omitting the index $(0,0)$ of $G_{(0,0)}$ and $T_r^-(0,0)$ and choosing $t_1 := -4r^2$, $t_2 := -r^2$, and, after approximation, $\psi(t,x) := (2t,x)\, G(t,x)\, \eta_\kappa(x)$ in Definition 3.1 where $\eta_\kappa \in H_0^{1,\infty}(\mathbf{R}^n)$ we get for a.e. $r \in (0, \frac{\sqrt{T-t_1}}{2})$ the identity

$$
\begin{aligned}
0 = \int_{T_r^-} \Bigg[& \Big(|\nabla u|^2 \,+\, \lambda_+ \,\chi_{\{u>0\}}\, u^p \,+\, \lambda_- \,\chi_{\{u<0\}}\, (-u)^p \Big) \Big(2G + 2t\,\partial_t G + \,\operatorname{div}(xG) \Big) \eta_\kappa \\
& - 2\,\eta_\kappa \sum_{j=2}^{n+1} \sum_{i=2}^{n+1} \partial_j u \;(\delta_{ji}\, G \,+\, \partial_j G\, x_i)\; \partial_i u \;-\; 2\eta_\kappa \sum_{j=2}^{n+1} \partial_j u\, \partial_j G\, 2t\, \partial_t u \\
& - 2\eta_\kappa \sum_{j=2}^{n+1} \partial_j u\, G\, x_j\, \partial_t u \;-\; 2\eta_\kappa\, (\partial_t u)^2\, 2t\, G \Bigg] \\
& - \int_{\mathbf{R}^n} \Big[2t\,\eta_\kappa \Big(|\nabla u|^2 \,+\, \lambda_+ \,\chi_{\{u>0\}}\, u^p \,+\, \lambda_- \,\chi_{\{u<0\}}\, (-u)^p \Big)\, G \Big] (-r^2) \\
& + \int_{\mathbf{R}^n} \Big[2t\,\eta_\kappa \Big(|\nabla u|^2 \,+\, \lambda_+ \,\chi_{\{u>0\}}\, u^p \,+\, \lambda_- \,\chi_{\{u<0\}}\, (-u)^p \Big)\, G \Big] (-4r^2) \\
& + \int_{T_r^-} \Big(|\nabla u|^2 \,+\, \lambda_+ \,\chi_{\{u>0\}}\, u^p \,+\, \lambda_- \,\chi_{\{u<0\}}\, (-u)^p \Big)\, \nabla \eta_\kappa \cdot x\, G \\
& - 2 \sum_{j=2}^{n+1} \sum_{i=2}^{n+1} \partial_j u\, \partial_j \eta_\kappa\, x_i\, \partial_i u\, G \;-\; 2 \sum_{j=2}^{n+1} \partial_j u\, \partial_j \eta_\kappa\, 2t\, \partial_t u\, G.
\end{aligned}
$$

Next, we derive the identity

$$
\begin{aligned}
(3.2) \int_{T_r^-} |\nabla u|^2\, G\, \eta_\kappa \;=\; - \int_{T_r^-} \Big[& u\, \eta_\kappa\, \nabla u \cdot \nabla G \,+\, \eta_\kappa\, G \Big(u\, \partial_t u \,+\, \frac{p}{2} (\lambda_+ \,\chi_{\{u>0\}}\, u^p \\
& + \lambda_- \,\chi_{\{u<0\}}\, (-u)^p) \Big) \Big] \;-\; \int_{T_r^-} u\, G\, \nabla u \cdot \nabla \eta_\kappa.
\end{aligned}
$$

First notice that $\max(u,\theta)$ is for small positive θ a subsolution of

$$
-\partial_t \max(u,\theta) \,+\, \Delta \max(u,\theta) - \frac{\lambda_+}{2}\, p\, \chi_{\{u>\theta\}}\, u^{p-1} \geq 0
$$

and that the nonnegative distribution

$$
-\partial_t \max(u,\theta) \,+\, \Delta \max(u,\theta) - \frac{\lambda_+}{2}\, p\, \chi_{\{u>\theta\}}\, u^{p-1}
$$

is a σ-finite σ-additive measure with support in $\partial\{u > \theta\}$. Since $\frac{\lambda_+}{2}\, p\, \chi_{\{u>\theta\}}\, u^{p-1} \to \frac{\lambda_+}{2} p \chi_{\{u>0\}} u^{p-1}$ in $L^1_{\mathrm{loc}}((t_1,t_2)\times\mathbf{R}^n)$ and $\partial_t \max(u,\theta) \to \partial_t \max(u,0)$ in $L^2_{\mathrm{loc}}((t_1,t_2)\times$

$\mathbf{R}^n$) as $\theta \searrow 0$, we obtain that $\Delta \max(u,\theta) \rightharpoonup \Delta \max(u,0)$ weakly-* in the space $(C^0(\overline{(t_1+\delta,t_2-\delta)\times B_R(0)}))^\star$ for each $\delta > 0$ as $\theta \searrow 0$ and that

$$\text{(3.3)} \quad \operatorname{supp}(-\partial_t \max(u,0) \,+\, \Delta \max(u,0) - \frac{\lambda_+}{2}\, p\, \chi_{\{u>0\}}\, u^{p-1}) \subset \partial\{u>0\}\,.$$

Considering mollified functions approximating $\max(u,0)$, we now see that

$$\int \nabla \max(u,0)\cdot\nabla\zeta \;=\; -\int \zeta \Delta \max(u,0)$$

for any $\zeta \in C^0(\overline{(t_1+\delta,t_2-\delta)\times B_R(0)}) \cap L^2((t_1+\delta,t_2-\delta); H_0^{1,2}(B_R(0)))$. An analogous formula holds for $-\min(u,0)$. Using this and (3.3) one can now easily derive the formula (3.2).

Now, multiplying the identity at the beginning of the proof by $-r^{-3-2(\alpha-1)}$, choosing $\eta_\kappa(x) := \min(1,\max(0,2-\kappa|x|))$ for small positive κ, and using the fact that $\nabla G = \frac{x\,G}{2t}$ and $\partial_t G \,+\, \Delta G = 0$ in $\{t<0\}\cup\{t>0\}$ we obtain

$$0 = r^{-3-2(\alpha-1)} \left[\int_{\mathbf{R}^n} 2t\,\eta_\kappa \left(|\nabla u|^2 \,+\, \lambda_+\,\chi_{\{u>0\}}\,u^p \,+\, \lambda_-\,\chi_{\{u<0\}}\,(-u)^p\right) G\right]_{-4r^2}^{-r^2}$$

$$+\,(-2(\alpha-1)-2)\,r^{-3-2(\alpha-1)} \int_{T_r^-} \eta_\kappa \left(|\nabla u|^2 \,+\, \lambda_+\,\chi_{\{u>0\}}\,u^p\right.$$

$$\left. +\,\lambda_-\,\chi_{\{u<0\}}\,(-u)^p\right) G \,+\, (2(\alpha-1)+2-2+2)\,r^{-3-2(\alpha-1)} \int_{T_r^-} \eta_\kappa\,|\nabla u|^2\,G$$

$$= r^{-3-2(\alpha-1)} \left[\int_{\mathbf{R}^n} 2t\, \eta_\kappa \,\left(|\nabla u|^2 \,+\, \lambda_+ \,\chi_{\{u>0\}}\, u^p \,+\, \lambda_- \,\chi_{\{u<0\}}\, (-u)^p\right)\, G\right]_{-4r^2}^{-r^2}$$

$$+ (-2(\alpha-1)-2)\, r^{-3-2(\alpha-1)} \int_{T_r^-} \eta_\kappa \left(|\nabla u|^2 \,+\, \lambda_+ \,\chi_{\{u>0\}}\, u^p\right.$$

$$\left. + \lambda_- \,\chi_{\{u<0\}}\, (-u)^p\right) G \,- r^{-2\alpha-1} \int_{T_r^-} \frac{\eta_\kappa G}{(-t)}\, (\nabla u\cdot x \,+\, 2t\, \partial_t u \,-\, \alpha\, u)^2$$

$$+ r^{-2\alpha-1} \int_{T_r^-} \eta_\kappa\, G \left(\frac{\alpha}{t}\, u\, \nabla u\cdot x \,+\, 2\alpha\, u\, \partial_t u \,-\, \frac{\alpha^2}{t}\, u^2\right) \,+\, o(1) \quad \text{as } \kappa\to 0.$$

Realizing finally that

$$r^{-2\alpha-1} \int_{T_r^-} \eta_\kappa\, G \left(\frac{\alpha}{t}\, u\, \nabla u\cdot x \,+\, 2\alpha\, u\, \partial_t u \,-\, \frac{\alpha^2}{t}\, u^2\right)$$

$$= \alpha \int_{T_1^-} \eta_\kappa(rx)\, \frac{G(t,x)}{t}\, r^{-\alpha}\, u(r^2 t, rx) \left(r^{-\alpha}\, (\nabla u)(r^2 t, rx)\cdot x\right.$$

$$\left. + r^{-\alpha+1}\, 2t\, (\partial_t u)(r^2 t, rx) \,-\, \alpha\, r^{-\alpha-1}\, u(r^2 t, rx)\right)$$

$$= o(1) \,+\, \partial_r \left(\frac{\alpha}{2} \int_{T_1^-} \left(\frac{u(r^2 t, rx)}{r^\alpha}\right)^2 \,\frac{G(t,x)}{t}\, \eta_\kappa(rx)\right)$$

$$= o(1) \,+\, \partial_r \left(-\frac{\alpha}{2} \int_{T_r^-} \left(\frac{u}{r^\alpha}\right)^2 \,\frac{G}{(-t)}\, \eta_\kappa\right) \quad \text{as } \kappa\to 0,$$

integrating the resulting identity from ρ to σ, using integration by parts, and letting $\kappa\to 0$ the theorem is proved. □

4. Characterization of blow-up limits. The result to be presented in this section is that assuming some regularity of the solution in "parabolic direction" $(2\theta t, x)$ on the path $\theta \mapsto (T+\theta^2 t, x_0+\theta x)$, it is possible to prove that the solution's derivatives at (T, x_0) in this direction vanish to a certain order; this implies, of course, that any blow-up limit at (T, x_0) is a self-similar solution. The required regularity takes the simple form of a growth estimate.

THEOREM 4.1. *Suppose that* $t_1 \le T \le t_2$, *that* $x_0 \in \mathbf{R}^n$, *that*

$$\sup_{t\in(t_1,T-\delta)\cup(T+\delta,t_2)} \int_{\mathbf{R}^n} \exp\left(-\frac{|x-x_0|^2}{4(T-t)}\right)\left(|\nabla u|^2 + |u|^p\right)(t)$$

$$+ \int_{(t_1,T-\delta)\cup(T+\delta,t_2)} \int_{\mathbf{R}^n} \exp\left(-\frac{|x-x_0|^2}{4(T-t)}\right)\left((\partial_t u)^2 + u^2\right) < \infty$$

for any positive δ, *that* $0 < \rho_k \to 0$ *as* $k \to \infty$, *and that either*

(i) $p \in [0,2)$, u *is in* $((t_1,T)\cup(T,t_2)) \times \mathbf{R}^n$ *a variational solution in the sense of Definition* 3.1 *and* λ_+, λ_- *are nonnegative constants in the case* $p \in (0,1)$ *or*

(ii) $p < 0$, $u \in C^0(((t_1,T)\cup(T,t_2)) \times \mathbf{R}^n)$, $u \neq 0$ *in* $((t_1,T)\cup(T,t_2)) \times \mathbf{R}^n$, *and* u *is a solution of* (3.1) *in the sense of distributions.*

Suppose furthermore that in either case the growth estimates

$$\sup_{r\in(0,\frac{\sqrt{T-t_1}}{4})} \max\left(r^{-2\alpha}\int_{T_r^-(T)} \frac{1}{T-t}\, u^2\, G_{(T,x_0)}\right.$$

$$- r^{-2(\alpha-1)-2}\int_{T_r^-(T)} \lambda_+\, \chi_{\{u>0\}}\, u^p\, G_{(T,x_0)},$$

$$\left. - r^{-2(\alpha-1)-2}\int_{T_r^-(T)} \lambda_-\chi_{\{u<0\}}(-u)^p G_{(T,x_0)}\right) < +\infty$$

and

$$\sup_{r\in(0,\frac{\sqrt{t_2-T}}{4})} \max\left(r^{-2\alpha}\int_{T_r^+(T)} \frac{1}{T-t}\, u^2\, G_{(T,x_0)},\ - r^{-2(\alpha-1)-2}\int_{T_r^+(T)} |\nabla u|^2\, G_{(T,x_0)}\right.,$$

$$- r^{-2(\alpha-1)-2}\int_{T_r^+(T)} \lambda_+\, \chi_{\{u>0\}}\, u^p\, G_{(T,x_0)}\,,$$

$$\left. - r^{-2(\alpha-1)-2}\int_{T_r^+(T)} \lambda_-\, \chi_{\{u<0\}}\, (-u)^p\, G_{(T,x_0)}\right) < +\infty$$

are satisfied. Then $\Psi^-(r) \searrow M^-(u,(T,x_0))$ *as* $r \searrow 0$ *provided that* $T > t_1$ *and* $\Psi^+(r) \searrow M^+(u,(T,x_0))$ *as* $r \searrow 0$ *provided that* $T < t_2$, *and for any* $D \subset\subset (((-\infty)\sqrt{T-t_1}, 0) \cup (0, ((+\infty)\sqrt{t_2-T}))) \times \mathbf{R}^n$ *and* $k \ge k(D)$ *the sequence*

$$u_k(t,x) := \frac{u(T+{\rho_k}^2 t, x_0+\rho_k x)}{{\rho_k}^\alpha}$$

is bounded in $H^{1,2}(D) \cap L^p(D)$ *and any weak* $H^{1,2}$*-limit* u_0 *with respect to a subsequence is a function homogeneous of degree* α *on paths* $\theta \mapsto (\theta^2 t, \theta x)$ *for* $\theta > 0$ *and* $(t,x) \in (((-\infty)\sqrt{T-t_1}, 0) \cup (0, ((+\infty)\sqrt{t_2 - T}))) \times \mathbf{R}^n$, *i.e.,*

$$u_0(\lambda^2 t, \lambda x) = \lambda^\alpha \, u_0(t,x) \quad \textit{for any } \lambda > 0$$

$$\textit{and for any } (t,x) \in (((-\infty)\sqrt{T-t_1}, 0) \cup (0, ((+\infty)\sqrt{t_2 - T}))) \times \mathbf{R}^n.$$

Proof. To avoid clumsy notation we give the proof only for the case $t_2 = T$. First we calculate for $0 < R < S < \infty$ (to be used later)

$$\Psi^-(\rho_k R) = R^{-2(\alpha-1)-2} \int_{T_R^-(0)} \left(|\nabla u_k|^2 + \lambda_+ \, \chi_{\{u_k > 0\}} \, {u_k}^p + \lambda_- \, \chi_{\{u_k < 0\}} \, (-u_k)^p \right) G_{(0,0)}$$

$$- \frac{\alpha}{2} \, R^{-2\alpha} \int_{T_R^-(0)} \frac{1}{(-t)} \, {u_k}^2 \, G_{(0,0)}.$$

Hence, using the assumed growth estimate, the monotonicity formula Theorem 3.1 yields that for $k \geq k(D)$ the sequences u_k and ∇u_k are bounded in $L^2(D)$ and u_k is bounded in $L^p(D)$.

Since Ψ^- is nondecreasing and bounded in $(0, r_0)$ for small positive r_0, we know that Ψ^- has a real right limit at 0. Consequently,

$$0 \leftarrow \Psi^-(\rho_k S) - \Psi^-(\rho_k R)$$

$$= \int_R^S r^{-2\alpha-1} \int_{T_r^-(0)} \frac{1}{(-t)} \, (\nabla u_k \cdot x \, + \, 2t \partial_t u_k \, - \alpha \, u_k)^2 \, G_{(0,0)} \, dr$$

as $k \to \infty$. Thus for $k \geq k(D)$ the sequence u_k is bounded in $H^{1,2}(D)$, and passing to a subsequence $k \to \infty$ such that $u_k \rightharpoonup u_0$ weakly in $H^{1,2}_{\mathrm{loc}}((-\infty, 0) \times \mathbf{R}^n)$ and using the lower semicontinuity of the L^2-norm with respect to weak convergence we obtain $\nabla u_0(t,x) \cdot x + 2t \partial_t u_0(t,x) - \alpha u_0(t,x) = 0$ a.e. in $(-\infty, 0) \times \mathbf{R}^n$. Now it is easily seen that u_0 is homogeneous of degree α on paths $\theta \mapsto (\theta^2 t, \theta x)$ for $\theta > 0$ and $(t,x) \in (-\infty, 0) \times \mathbf{R}^n$. □

5. Applications. In this section we will characterize the blow-up limits with respect to two one-phase problems, the quenching problem with exponent $\gamma \in (-\frac{1}{3}, 0)$ and the heat equation with a Bernoulli type boundary condition on the free boundary.

Before starting with these two equations let us briefly consider solutions of the heat equation with strong absorption, i.e., $\gamma \in [0,1), u \in L^{1+\gamma}((0,\infty) \times \mathbf{R}^n) \cap L^\infty((0,\infty) \times \mathbf{R}^n)$ satisfying $\partial_t u - \Delta u = -u^\gamma \chi_{\{u>0\}}$ in $(0,\infty) \times \mathbf{R}^n$, $u(0,x) = u^0(x)$ in the sense of distributions. Here we assume $0 \leq u^0 \in C_0^{2,\alpha}(\mathbf{R}^n)$ for some $\alpha \in (0,1)$ and $(u^0)^{-\gamma} \Delta u^0 \in L^\infty(\mathbf{R}^n)$.

This problem, in particular the solution's behavior at extinction points, has been extensively studied (see [FrHe] to cite one study). For issues not concentrating on the extinction angle see, for example, [Ca] and [ChWe].

Since we assume u to be bounded, the comparison principle holds and it follows immediately from L^p-estimates that the now unique $u \in \mathbf{W}^{2,1}_p((\frac{1}{R}, R) \times B_R(0))$ for

any $0 < R < \infty$ and $1 \le p < \infty$. Comparing u to $\max(0, (1-\gamma)(\frac{(\sup_{\mathbf{R}^n} u^0)^{1-\gamma}}{1-\gamma} - t))^{\frac{1}{1-\gamma}}$, we see that $u(t,x) = 0$ for $t \ge \frac{(\sup_{\mathbf{R}^n} u^0)^{1-\gamma}}{1-\gamma}$; furthermore, standard energy estimates imply that $\nabla u \in L^\infty((0,\infty); L^2(\mathbf{R}^n))$ and $\partial_t u \in L^2((0,\infty)\times\mathbf{R}^n)$. Thus,

$$\int_0^T \int_{\mathbf{R}^n} \left(|\nabla u|^2 \, + \, \frac{2}{1+\gamma} u^{1+\gamma} \, + \, 2\partial_t u \, u \right)$$

$$- \int_0^T \int_{\mathbf{R}^n} \left(|\nabla v|^2 \, + \, \frac{2}{1+\gamma} v^{1+\gamma} \, + \, 2\partial_t u \, v \right)$$

$$\le \int_0^T \int_{\mathbf{R}^n} \left(-|\nabla(u-v)|^2 \, + \, 2\nabla u \cdot \nabla(u-v) \, + \, 2u^\gamma \, (u-v) \, + \, 2\partial_t u \, (u-v) \right) \, \le \, 0$$

for any $v \in L^2((0,T); H^{1,2}_{\mathrm{loc}}(\mathbf{R}^n))$ such that $\mathrm{supp}(v-u)(t) \subset\subset B_R(0)$ for any $t \in (0,T)$. Consequently u satisfies the variational inequality

$\mathbf{G}(u,u) \le \mathbf{G}(u,v)$ for any such v and the $\mathbf{G}$ in Definition 3.1, and it follows that u is in $(0,\infty)\times\mathbf{R}^n$ a variational solution in the sense of Definition 3.1.

In order to be allowed to apply Theorem 4.1 in the past of any point $(T, x_0) \in \partial\{u > 0\} \cap ((0,\infty)\times\mathbf{R}^n)$, it is therefore sufficient to verify the growth estimate

$$\sup_{r \in (0, \frac{\sqrt{T}}{4})} r^{-\frac{4}{1-\gamma}} \int_{T_r^-(T)} \frac{1}{T-t} \, u^2 \, G_{(T,x_0)} \, < \, +\infty,$$

but this follows directly from the regularity estimate Theorem 3.1 derived in [ChWe],

$$\| u^{\frac{1-\gamma}{2}} \|_{\mathbf{H}^{1,\frac{1}{2}}((\delta,\frac{1}{\delta})\times B_{\frac{1}{\delta}}(0))} \, \le \, C(\delta), \tag{5.1}$$

and from the fact that $u \in L^\infty((0,\infty)\times\mathbf{R}^n)$. Therefore any blow-up limit of u must be a backward self-similar solution. Let us conclude this short observation with the remark that there exists a variety of such self-similar solutions; for example,

$$v_{k,\sigma}(t,x) := -\sigma \, t \, + \, (1-\sigma) \, \frac{1}{2k} \, \sum_{i=1}^k {x_i}^2 \quad \text{and}$$

$$w_\sigma(t,x) := \frac{1}{2} \, \max(0, x_1)^2$$

are for $t < 0$, $k \in \{1, \dots, n\}$, and $\sigma \in [0,1]$ self-similar solutions with respect to $\gamma = 0$. Notice that, of the stationary solutions ($\sigma = 0$), only the half-plane solution $\frac{1}{2} \, \max(0, x_1)^2$ has a regular free boundary.

We proceed to the quenching problem: Here we consider certain distributional solutions u of

$$\begin{gathered} u^{1+\gamma} \in L^1((0,\infty) \times \mathbf{R}^n), \; \partial_t u - \Delta u = -u^\gamma \, \chi_{\{u>0\}} \text{ in } (0,\infty)\times\mathbf{R}^n, \\ u(0,x) = u^0(x), \\ \gamma \in (-1,0) \text{ and } 0 \le u^0 \in C_0^{2,\alpha}(\mathbf{R}^n) \text{ for some } \alpha \in (0,1). \end{gathered} \tag{5.2}$$

Existence of a distributional solution u of (5.2) as well as optimal regularity in space has been shown by Phillips (see [Ph]) by way of a regularization of the equation in (5.2):

$$\text{for } f_\epsilon(z) := \begin{cases} 0, & z \le 0, \\ \frac{z}{\epsilon + z^{1-\gamma}}, & z > 0; \end{cases}$$

the equation $\partial_t v - \Delta v = -f_\epsilon(v)$ in $(0,\infty)\times\mathbf{R}^n$, $v(0,x) = u^0_\epsilon(x)$, $0 \le u^0_\epsilon \in C^\infty_0(\mathbf{R}^n)$, $u^0_\epsilon \to u^0$ in $C^{2,\alpha}(\mathbf{R}^n)$ as $\epsilon \to 0$ admits for positive ϵ a unique solution $0 \le u_\epsilon \in C^0_0([0,\infty)\times\mathbf{R}^n) \cap C^2((0,\infty)\times\mathbf{R}^n)$ such that

$$\nabla\left(u_\epsilon^{\frac{1-\gamma}{2}}\right) \text{ is bounded in } L^\infty((0,\infty)\times\mathbf{R}^n),$$

u_ϵ is bounded in $C^{0,\frac{1}{3n}}([0,\infty)\times\mathbf{R}^n)$, and as a subsequence $\epsilon \to 0$ the solutions u_ϵ converge in $C^0([0,\infty)\times\mathbf{R}^n)$ to a nonnegative solution u of (5.2) in the sense of distributions.

In order to verify the growth assumptions in Theorem 4.1 it is necessary to complete the optimal regularity of u in space by the optimal regularity estimate in time:

$$\|\partial_t(u^{1-\gamma})\|_{L^\infty((\delta,\frac{1}{\delta})\times B_{\frac{1}{\delta}}(0))} \;\le\; C(\delta).$$

For proof observe first that $u^{1-\gamma}$ satisfies the equation

$$\partial_t(u^{1-\gamma}) - \Delta(u^{1-\gamma}) = -\chi_{\{u^{1-\gamma}>0\}}\left((1-\gamma) - \frac{4\gamma}{1-\gamma}|\nabla(u^{\frac{1-\gamma}{2}})|^2\right)$$

in $(0,\infty)\times\mathbf{R}^n$ which may be written as

$$\partial_t w - \Delta w = -\chi_{\{w>0\}}\, g \text{ with } 0 \le w := u^{1-\gamma} \text{ and } g \in L^\infty((0,\infty)\times\mathbf{R}^n)\,.$$

LEMMA 5.1. *There exists a constant $C < \infty$ depending on $\|g\|_{L^\infty((0,\infty)\times\mathbf{R}^n)}$ and n such that any nonnegative solution $w \in L^1((0,\infty)\times\mathbf{R}^n)$ of $\partial_t w - \Delta w = -g\,\chi_{\{w>0\}}$ in $(0,\infty)\times\mathbf{R}^n$ satisfies for any $Q_{2r}(t_0,x_0) \subset (0,\infty)\times\mathbf{R}^n$ the estimate*

$$\sup_{P_r(t_0,x_0)} w \;\le\; C\,(w(t_0,x_0) \,+\, r^2)$$

(here $P_r(t_0,x_0) := \{(t,x) : 0 > t - t_0 > -r^2$ and $|x-x_0|^2 < t_0 - t\}$).

Proof. We observe that the function $w_r(t,x) := r^{-2}\, w(t_0 + r^2 t, x_0 + rx)$ satisfies in $Q_2(0) = (-4,4)\times B_2(0)$ the equation $\partial_t w_r - \Delta w_r = -g_r\,\chi_{\{w_r>0\}}$ where $g_r(t,x) := g(t_0 + r^2 t, x_0 + rx)$. Therefore we may apply Harnack's inequality to obtain a constant $C_1 < \infty$ depending only on n and $\|g\|_{L^\infty}$ such that

$$\sup_{(-1,-\frac{1}{2})\times B_1(0)} w_r \le C_1\,(w_r(0) \,+\, 1).$$

Scaling back yields

$$\sup_{P_r(t_0,x_0)} w \;\le\; C\,(w(t_0,x_0) \,+\, r^2). \qquad \square$$

LEMMA 5.2. *For the solution u from above and any positive δ there exists $C < \infty$ such that the function $w = u^{1-\gamma}$ satisfies*

$$\|\partial_t w\|_{L^\infty((\delta,\infty)\times\mathbf{R}^n)} \le C.$$

Proof. Suppose that there exists $(t_k, x_k) \in \{w > 0\} \cap ((\delta,\infty)\times\mathbf{R}^n)$ such that $|\partial_t w|(t_k,x_k) \to +\infty$ as $k \to \infty$: since $w \in C_0^0([0,\infty)\times\mathbf{R}^n)$ we conclude that $(t_k,x_k) \to (t_0,x_0)$ as a subsequence $k \to \infty$. Then we consider the sequence $w_k(t,x) := {\rho_k}^{-2} w(t_k + {\rho_k}^2 t, x_k + \rho_k x)$ where $\rho_k := w(t_k,x_k)^{\frac{1}{2}}$ can be assumed to go to 0 as $k \to \infty$. From Phillips' space gradient estimate we now know that $w_k(0,x) \le 2 + C_1|x|^2$ and Lemma 5.1 implies that $\sup_{P_1(0,x)} w_k \le C_2(2+|x|^2)$. Thus w_k is bounded in $L^\infty(Q_1^-(0))$ (where $Q_r^-(0) = (-r^2,0)\times B_r(0)$) and we infer from parabolic regularity theory that w_k is bounded in $C^{0,\beta}([-\frac{1}{2},0]\times\overline{B_{\frac{1}{2}}(0)})$ for $\beta \in (0,1)$. Consequently there is a subsequence $k \to \infty$ such that $w_k \to w_0$ in $C^0([-\frac{1}{2},0]\times\overline{B_1(0)})$, and the fact that $w_k(0) = 1$ implies that $w_k \ge c > 0$ in $\overline{Q_\kappa^-(0)}$ for some $\kappa > 0$ and large k of the subsequence.

But then $u_k(t,x) := {\rho_k}^{-\frac{2}{1-\gamma}} u(t_k + {\rho_k}^2 t, x_k + \rho_k x) \ge c^{\frac{1}{1-\gamma}} > 0$ in $\overline{Q_\kappa^-(0)}$ and u_k is bounded in $L^\infty(Q_1^-(0))$, and we obtain from regularity theory for the equation of u_k that u_k is for large k uniformly positive and bounded in $C^m(\overline{Q_{\frac{\kappa}{2}}^-(0)})$ for $m < \infty$, a contradiction to the assumption that $+\infty \leftarrow |\partial_t w|(t_k,x_k) = (1-\gamma)u^{-\gamma}(t_k,x_k)|\partial_t u(t_k,x_k)| = (1-\gamma){u_k}^{-\gamma}(0)|\partial_t u_k(0)|$. □

We may also state the corresponding nondegeneracy estimate.

LEMMA 5.3. *For the solution u from above and any $\delta > 0$ there exists $c > 0$ such that for any $(T,x_0) \in \overline{\{u>0\}}$ and any $Q_r^-(T,x_0) \subset ((\delta,\infty)\times\mathbf{R}^n)$ the estimate*

$$\sup_{Q_r^-(T,x_0)} u \ge c\, r^{\frac{2}{1-\gamma}}$$

holds.

Proof. Notice that it is sufficient to prove the existence of c depending only on n and γ such that the estimate is satisfied in points of $\{u > 0\}$. Since we have $\partial_t(u^{1-\gamma}) - \Delta(u^{1-\gamma}) \le -\chi_{\{u^{1-\gamma}>0\}}$, $w := u^{1-\gamma}$ is a subsolution of the parabolic obstacle problem.

As before we use scaled functions $w_r(t,x) := r^{-2} w(t_0 + r^2 t, x_0 + rx)$. Furthermore, we introduce a comparison function

$$v(t,x) := \frac{1}{4n}\,(|x|^2 - 2n\,t);$$

obviously v solves $\partial_t v - \Delta v = -1$ in $Q_1^-(0)$, and of course v is positive in $Q_1^-(0)$, it is positive on $(\{-1\}\times\overline{B_1(0)}) \cup ([-1,0]\times\partial B_1(0))$, and it vanishes in the point 0.

Now, if $w_r \le v$ on the *whole* parabolic boundary of $Q_1^-(0)$, then the comparison principle would imply $w_r \le v$ in $Q_1^-(0)$, a contradiction to the assumption $w_r(0) > 0$. Therefore there has to be a point on the parabolic boundary of $Q_1^-(0)$ in which $w_r > v$, and scaling back proves the statement of our proposition. □

Finally we have to verify that u is a variational solution in the sense of Definition 3.1. To this end, we confine ourselves to the case $\gamma \in (-\frac{1}{3},0)$ and start with another nondegeneracy estimate whose proof follows Lemma 7.3 of [ChWe].

LEMMA 5.4. *For the solution u from above and any $p \in (0, \frac{1-\gamma}{2})$ there exist $r_0 > 0$ and $C < \infty$ such that for any $(t_0, x_0) \in \partial\{u > 0\} \cap ((\delta, \infty) \times \mathbf{R}^n)$ and any $r \leq r_0$*

$$\int_{Q_r(t_0,x_0)\cap\{u>0\}} u^{-p} \;\leq\; C\, r^{n+2-\frac{2p}{1-\gamma}} \quad .$$

Proof. Let us define $w := u^{1-\gamma-p}$, which satisfies then in $\{u > 0\}$ the equation $\partial_t w - \Delta w = -(1-\gamma-p)u^{-p}\big(1-(\gamma+p)\frac{|\nabla u|^2}{u^{1+\gamma}}\big)$. Hence $\partial_t w - \Delta w \leq -(1-\gamma-p)u^{-p}\big(1-\frac{2(1+\eta)(\gamma+p)}{1+\gamma}\big) \leq -\kappa\, u^{-p} < 0$ in $Q_r(t_0,x_0)\cap\{u>0\}$ by Lemma 2 of [Ph], provided that η and r_0 have been chosen small enough. Furthermore we know from Lemma 2 of [Ph] that there exist constants C_1, C_2, C_3 such that $|\nabla w| \;\leq\; C_1\, u^{\frac{1+\gamma}{2}-\gamma-p} \;\leq\; C_2\, r^{1-\frac{2p}{1-\gamma}}$ and that $w \;\leq\; C_3\, r^{\frac{2(1-\gamma-p)}{1-\gamma}}$ in $Q_r(t_0,x_0)$.

Introducing now a C^∞-function ρ satisfying $\rho \geq 0$, $\rho' \geq 0$, $\rho'' \geq 0$ as well as $\rho(\tau) = \tau - 1$, $\tau \geq 2$ and $\rho(\tau) = 0$, $\tau \leq \frac{1}{2}$ and defining $\rho_\delta(\tau) := \delta\rho(\frac{\tau}{\delta})$ we obtain for $0 < \delta << \epsilon$

$$0 \leq \frac{1}{\epsilon}\int_{Q_r(t_0,x_0)} \nabla w \cdot \nabla \min(\epsilon, \rho_\delta(u)) \;=\; -\frac{1}{\epsilon}\int_{Q_r(t_0,x_0)\cap\{0<\rho_\delta(u)\leq\epsilon\}} \rho_\delta(u)\,\Delta w$$

$$-\int_{Q_r(t_0,x_0)\cap\{\rho_\delta(u)>\epsilon\}} \Delta w \;+\; \int_{t_0-r^2}^{t_0+r^2}\int_{\partial B_r(x_0)} \frac{\min(\epsilon,\rho_\delta(u))}{\epsilon}\,\nabla w\cdot\nu\, d\mathcal{H}^{n-1}.$$

Consequently

$$\kappa\int_{Q_r(t_0,x_0)\cap\{\rho_\delta(u)>\epsilon\}} u^{-p} \;\leq\; C_4\, r^{n+2-\frac{2p}{1-\gamma}} \;-\; \frac{\kappa}{\epsilon}\int_{Q_r(t_0,x_0)\cap\{0<\rho_\delta(u)\leq\epsilon\}} \rho_\delta(u)\, u^{-p}$$

$$-\frac{1}{\epsilon}\int_{Q_r(t_0,x_0)\cap\{0<\rho_\delta(u)\leq\epsilon\}} \rho_\delta(u)\,\partial_t w \;-\; \int_{Q_r(t_0,x_0)\cap\{\rho_\delta(u)>\epsilon\}} \partial_t w,$$

and letting $\delta \to 0$ we obtain

$$\kappa\int_{Q_r(t_0,x_0)\cap\{u>\epsilon\}} u^{-p} \;\leq\; C_4\, r^{n+2-\frac{2p}{1-\gamma}} - \frac{1}{\epsilon}\int_{Q_r(t_0,x_0)\cap\{0<u\leq\epsilon\}} u\,\partial_t w$$

$$-\int_{Q_r(t_0,x_0)\cap\{u>\epsilon\}} \partial_t w \;\leq\; C_4\, r^{n+2-\frac{2p}{1-\gamma}}$$

$$-\frac{1}{\epsilon}\int_{Q_r(t_0,x_0)} \frac{1-\gamma-p}{2-\gamma-p}\,\partial_t \min(\epsilon^{2-\gamma-p}, u^{2-\gamma-p})$$

$$+\int_{B_r(x_0)} \max(\epsilon^{1-\gamma-p}, w)(t_0-r^2) \;-\; \int_{B_r(x_0)} \max(\epsilon^{1-\gamma-p}, w)(t_0+r^2).$$

Integrating by parts in time and letting $\epsilon \to 0$ the lemma is proved. □

From Lemma 2 of [Ph] as well as Lemma 5.4 we obtain now that $u^\gamma|\partial_t u| \leq C u^{2\gamma}$ is locally contained in L^1 provided that $-2\gamma < \frac{1-\gamma}{2}$, which is the case since we assumed

$\gamma \in (-\frac{1}{3}, 0)$. We use this to prove that u is a variational solution in the sense of Definition 3.1: Since the variational formulation does not contain any discontinuous or singular term it is sufficient to prove that $u_\epsilon \to u$ strongly in $L^2((0,\infty); H^{1,2}(\mathbf{R}^n))$ and that $\partial_t u_\epsilon \to \partial_t u$ strongly in $L^2((0,\infty)\times\mathbf{R}^n)$. To this end we take u_ϵ and $\max(u,\delta)$ as test functions for the weak equation of u_ϵ and u, respectively, to obtain (after $\delta \to 0$) the convergence of the L^2-norm of ∇u_ϵ to that of ∇u, and we take $\partial_t u_\epsilon$ and $\partial_t u$ as test functions for the weak equation of u_ϵ and u, respectively, to obtain

$$\int_0^\infty \int_{\mathbf{R}^n} |\partial_t u_\epsilon|^2 \, - \, \frac{1}{2} \int_{\mathbf{R}^n} |\nabla u_\epsilon^0|^2 \, = \, \int_{\mathbf{R}^n} F_\epsilon(u_\epsilon^0)$$

$$\to \int_{\mathbf{R}^n} F_0(u^0) \, = \, \int_0^\infty \int_{\mathbf{R}^n} |\partial_t u|^2 \, - \, \frac{1}{2} \int_{\mathbf{R}^n} |\nabla u^0|^2$$

as the subsequence $\epsilon \to 0$; here $F_\epsilon(z) := \int_0^z f_\epsilon(s)\, ds$ and $F_0(z) := \int_0^z \max(s,0)^\gamma \, ds$. Since $\nabla_{t,x} u_\epsilon \rightharpoonup \nabla_{t,x} u$ weakly in $L^2((0,\infty)\times\mathbf{R}^n)$ it follows that $\nabla_{t,x} u_\epsilon \to \nabla_{t,x} u$ strongly in $L^2((0,\infty)\times\mathbf{R}^n)$ and that u is a variational solution in the sense of Definition 3.1.

As before, the estimates required in the assumptions of Theorem 4.1 follow from the regularity in time and space and from the fact that $u \in L^\infty((0,\infty)\times\mathbf{R}^n)$. Thus, supposing u to be a solution of (5.2) with respect to $\gamma \in (-\frac{1}{3}, 0)$ constructed by Phillips' regularization the blow-up limits are characterized as nontrivial self-similar variational solutions in $\mathbf{R}^{n+1} \cap \{t \le 0\}$ as follows.

For $(T, x_0) \in \partial\{u > 0\} \cap ((0,\infty)\times\mathbf{R}^n)$ and $0 < \rho_k \to 0$ as $k \to \infty$ we have for any open $D \subset\subset \mathbf{R}^{n+1}$ the following: the blow-up sequence

$$u_k(t,x) = \frac{u(T + \rho_k^2 t, x_0 + \rho_k x)}{\rho_k{}^{\frac{2}{1-\gamma}}} \tag{5.3}$$

is bounded in $C^{0,\frac{1}{2}}(\bar{D})$ and any pointwise limit u_0 with respect to a subsequence is a nontrivial nonnegative variational solution of (5.2) which is homogeneous of degree $\frac{2}{1-\gamma}$ on paths $\theta \mapsto (\theta^2 t, \theta x)$ for positive θ and $(t,x) \in \mathbf{R}^{n+1} \cap \{t \le 0\}$ and which preserves the regularity estimates in time and space.

That the blow-up limit is again a variational solution can be inferred from the fact that $u_k \to u_0$ strongly in $H^{1,2}(D)$, which can in turn be proved as before.

We proceed to the heat equation with Bernoulli-type condition on the free boundary which has been suggested in [CaVa] as a model for flame propagation. Here we consider variational solutions of

$$\begin{aligned} &u \ge 0\,,\ \partial_t u - \Delta u = 0 \text{ in } ((0,\infty)\times\mathbf{R}^n) \cap \{u > 0\}, \text{ and} \\ &\qquad |\nabla u| = 1 \text{ on } ((0,\infty)\times\mathbf{R}^n) \cap \partial\{u > 0\}. \end{aligned} \tag{5.4}$$

Since in general singularities appear in finite time there exists no global strong solution of (5.4). In [CaVa] Caffarelli and Vazquez introduce a notion of a weak solution for which they show existence in the case of an advancing flame ($\partial_t u \le 0$).

Here we use the notion of nondegenerate variational solutions in the sense of Definition 3.1 with respect to $p = \lambda_- = 0$. In this context, too, the question of existence with respect to general initial data remains unanswered: that a limit u of the solutions u_ϵ of the regularized equation in [CaVa] is a variational solution is in fact equivalent to the condition that no energy loss occurs in the limit, i.e.,

$$\limsup_{\epsilon\to 0} \int \left((\partial_t u_\epsilon)^2 \, + \, \chi_{\{u_\epsilon > 0\}}\right) \, \le \, \int \left((\partial_t u)^2 \, + \, \chi_{\{u > 0\}}\right)$$

(where $\epsilon \to 0$ is the subsequence with respect to u), which is very much like the situation in mean curvature flow or the Mullins–Sekerka equation—compare to [LuSt]. Notice that this may actually be used to construct numerical solutions since a sudden drop of the energy of the approximate solutions (as ϵ and the parameter h of the Galerkin approximation become small) can be registered numerically. Here we are going to show that no energy loss happens when passing to the blow-up limit of nondegenerate variational solutions, which means that the class of nondegenerate variational solutions is closed with respect to the blow-up process.

Concerning the subsequent nondegeneracy condition we like to point out that in the stationary case a nondegenerate variational solution can always be found, namely, a minimizer of the energy (compare to Lemma 3.4 of [AC] and Theorem 4.1 of [BCN]). In the nonvariational case, especially in the time-dependent case, however, the absence of a forcing term of order -1 makes for a severe difficulty: obviously any constant $> \epsilon$ solves the regularized equation in [CaVa] with respect to suitable initial data and violates the nondegeneracy of u_ϵ. Therefore a nondegeneracy assumption arises in a natural way when introducing weak solutions of the problem; compare to Definition 5.1 in [AC] for the stationary case.

THEOREM 5.1. *Let $u \in H^{1,\frac{1}{2}}((0,\infty)\times\mathbf{R}^n)$ be a variational solution of* (5.4)*, i.e., a nonnegative solution in the sense of Definition* 3.1 *with respect to $p = \lambda_- = 0$ and $\lambda_+ = 1$, and suppose that $(T, x_0) \in ((0,\infty)\times\mathbf{R}^n) \cap \partial\{u > 0\}$ and that $0 < \rho_k \to 0$ as $k \to \infty$. Then for any open $D \subset\subset \mathbf{R}^{n+1}$ the sequence*

$$u_k(t,x) = \frac{u(T+\rho_k^2 t, x_0 + \rho_k x)}{\rho_k}$$

is bounded in $C^{0,\frac{1}{2}}(\bar{D})$ and any pointwise limit u_0 with respect to a subsequence is a function $\in H^{1,\frac{1}{2}}_{\mathrm{loc}}((-\infty,\infty)\times\mathbf{R}^n)$ homogeneous of degree 1 on paths $\theta \mapsto (\theta^2 t, \theta x)$ for positive θ and $(t,x) \in \mathbf{R}^{n+1} \cap \{t \le 0\}$.

Moreover, if u satisfies the nondegeneracy condition that for any open $D \subset\subset (0,\infty)\times\mathbf{R}^n$ there exists $c > 0$ and $\delta > 0$ such that for any $Q_r(t,x) \subset D$ satisfying $r \le \delta$ the implication

$$\sup_{Q_r(t,x)} u \le c\, r \Rightarrow u = 0 \text{ in } Q_{\frac{r}{2}}(t,x) \tag{5.5}$$

holds, then any pointwise limit u_0 with respect to a subsequence is in $\mathbf{R}^{n+1} \cap \{t < 0\}$ a nondegenerate variational solution of (5.4).

Proof. The fact that $u \in H^{1,\frac{1}{2}}_{\mathrm{loc}}((0,\infty)\times\mathbf{R}^n)$ along with the sublinear growth in space imply that the growth estimates of Theorems 3.1 and 4.1 are satisfied in the past of any free boundary point $(T, x_0) \in (0,\infty)\times\mathbf{R}^n$. The point therefore is to show that u_0 is again a variational solution. To this end, we first prove that $\chi_{\{u_k>0\}} \to \chi_{\{u_0>0\}}$ a.e. in $\mathbf{R}^{n+1}$ as (having passed to an appropriate subsequence) $k \to \infty$.

First observe that $Q_{r_1}(t_1,x_1) \subset ((-\infty,+\infty)\times\mathbf{R}^n) \cap \{u_0 > 0\}$ and $Q_{r_2}(t_2,x_2) \subset\subset ((-\infty,+\infty)\times\mathbf{R}^n)\cap\{u_0 = 0\}$ imply by the uniform regularity and nondegeneracy of the sequence u_k that $u_k \ge c_1 > 0$ in $Q_{\frac{r_1}{2}}(t_1,x_1)$ and $u_k = 0$ in $Q_{\frac{r_2}{2}}(t_2,x_2)$ for large k. Thus $\chi_{\{u_k>0\}} = 1$ in $Q_{\frac{r_1}{2}}(t_1,x_1)$ and $\chi_{\{u_k>0\}} = 0$ in $Q_{\frac{r_2}{2}}(t_2,x_2)$ for large k and it is therefore sufficient to prove $\mathcal{L}^{n+1}(\partial\{u_0 > 0\}) = 0$ in order to verify the a.e. convergence of $\chi_{\{u_k>0\}}$. But this follows from the positive Lebesgue density of the set

$\{u_0 > 0\}$ in free boundary points. For any $D \subset\subset (-\infty,\infty)\times \mathbf{R}^n$, $(t,x) \in D \cap \partial\{u_0 > 0\}$, and $r \le \delta_1$, we have

$$\frac{\mathcal{L}^{n+1}(\{u_0>0\}\cap Q_r(t,x))}{\mathcal{L}^{n+1}(Q_r)} \ge c_2 > 0 : \tag{5.6}$$

since u_0 is again nondegenerate, there is $(t_3,x_3) \in Q_r(t,x)$ such that $u_0(t_3,x_3) \ge c\, r$. Therefore the fact that $u_0 \in \mathbf{H}^{1,\frac{1}{2}}(B_{2\delta}(D))$ implies that $u_0 > 0$ in $Q_{c_3 r}(t_3,x_3)$, where $c_3 \in (0,1)$ is a constant depending only on c as well as on the Hölder norm of u_0. Now, since $\mathcal{L}^{n+1}$-a.a. points in $(-\infty,+\infty)\times\mathbf{R}^n$ are Lebesgue-points with respect to $\chi_{\partial\{u_0>0\}}$ we know that

$$\frac{\mathcal{L}^{n+1}(\partial\{u_0>0\}\cap E_r(t,x))}{\mathcal{L}^{n+1}(E_r)} \to 1 \ \text{ as } r\to 0$$

for $\mathcal{L}^{n+1}$-a.a. points $(t,x) \in ((-\infty,+\infty)\times\mathbf{R}^n)\cap\partial\{u_0>0\}$ and $E_r(t,x) := (t-r,t+r)\times B_r(x)$. Considering such a point (t,x) and a subsequence $r\to 0$ such that $\frac{1}{2r} \in \mathbf{N}$ we may therefore decompose (up to a set of vanishing $\mathcal{L}^{n+1}$-measure) $E_r(t,x)$ into $\frac{1}{r}$ parabolic cylinders $Q_r(t_i,x_i)$ $(1 \le i \le \frac{1}{r})$ and conclude that $Q_{\frac{r}{2}}(t_i,x_i)\cap\partial\{u_0>0\} \neq \emptyset$ for at least $\frac{1}{2r}$ cylinders $Q_{\frac{r}{2}}(t_i,x_i)$ if r has been chosen small enough. With respect to those cylinders we may apply (5.6) to obtain

$$\frac{\mathcal{L}^{n+1}(\{u_0>0\}\cap Q_r(t_i,x_i))}{\mathcal{L}^{n+1}(Q_r)} \ge c(n)\, c_2 > 0.$$

Taking the sum with respect to the $\frac{1}{2r}$ cylinders we see that

$$\frac{\mathcal{L}^{n+1}(\{u_0>0\}\cap E_r(t,x))}{\mathcal{L}^{n+1}(E_r)} \ge \frac{1}{2}\, c(n)\, c_2 > 0$$

if r has been chosen small enough, a contradiction to

$$\frac{\mathcal{L}^{n+1}(\partial\{u_0>0\}\cap E_r(t,x))}{\mathcal{L}^{n+1}(E_r)} \to 1.$$

Thus we obtain a contradiction for $\mathcal{L}^{n+1}$-a.e. point $(t,x) \in ((-\infty,+\infty)\times\mathbf{R}^n)\cap\partial\{u_0>0\}$, proving that $\mathcal{L}^{n+1}(\partial\{u_0>0\}\cap((-\infty,+\infty)\times\mathbf{R}^n)) = 0$. Note that in the just-finished proof of the convergence $\chi_{\{u_k>0\}} \to \chi_{\{u_0>0\}}$ a.e. we did not make use of u_k being a blow-up sequence. The same remains true regarding the strong convergence of u_k to u_0 in $L^2_{\mathrm{loc}}((-\infty,\infty); H^{1,2}_{\mathrm{loc}}(\mathbf{R}^n))$: since u_k solves for given t_1,t_2 and large k the heat

equation in the open set $((t_1,t_2)\times\mathbf{R}^n)\cap\{u_k>0\}$, multiplication by $\eta\max(u_k-\delta,0)$ yields for $\delta>0$ and $\eta\in C_0^\infty(\mathbf{R}^n)$

$$\int_{t_1}^{t_2}\int_{\mathbf{R}^n} |\nabla\max(u_k-\delta,0)|^2\,\eta \;=\; \int_{t_1}^{t_2}\int_{\mathbf{R}^n} (-\partial_t u_k\ \max(u_k-\delta,0)\,\eta$$

$$-\max(u_k-\delta,0)\,\nabla u_k\cdot\nabla\eta \;=\; \int_{\mathbf{R}^n}\eta\left(\frac{1}{2}\max(u_k-\delta,0)^2(t_1)-\frac{1}{2}\max(u_k-\delta,0)^2(t_2)\right)$$

$$-\int_{t_1}^{t_2}\int_{\mathbf{R}^n}\max(u_k-\delta,0)\,\nabla u_k\cdot\nabla\eta\,,$$

and the analogous identity holds for u_0. Letting in both identities first $\delta \searrow 0$ and then the subsequence $k \to \infty$ we obtain

$$\int_{t_1}^{t_2} \int_{\mathbf{R}^n} |\nabla u_k|^2 \eta \;\to\; \int_{t_1}^{t_2} \int_{\mathbf{R}^n} |\nabla u_0|^2 \eta,$$

which, together with the weak convergence of u_k to u_0 in $L^2((t_1,t_2); H^{1,2}(B_R(0)))$ for $R \in (0,\infty)$, proves the strong convergence of u_k to u_0 in $L^2_{\mathrm{loc}}(H^{1,2}_{\mathrm{loc}})$. Next we use the monotonicity Theorem 3.1 to prove the strong convergence of $\partial_t u_k$ to $\partial_t u_0$ in $L^2_{\mathrm{loc}}(\mathbf{R}^{n+1} \cap \{t<0\})$ which will, incidentally, complete the proof of our theorem. For some $R, S \in (0,\infty)$ let E be any subset of $(-4R^2, -\frac{9}{4}R^2) \times B_S(0)$ such that E is $\mathcal{L}^{n+1}$-measurable. Then Theorem 3.1 implies that

$$\int_E (2t\,\partial_t u_k)^2 \;=\; \int_E (\nabla u_k \cdot x \;+\; 2t\partial_t u_k \;-\; u_k)^2$$

$$-\; \int_E (\nabla u_k \cdot x \;-\; u_k)^2 \;-\; \int_E 4t\partial_t u_k\,(\nabla u_k \cdot x \;-\; u_k)$$

$$\leq\; 2\,\|\nabla u_k \cdot x \;-\; u_k\|^2_{L^2(E)} \;+\; \frac{1}{2}\int_E (2t\,\partial_t u_k)^2$$

$$+\, C(n,R,S) \int_R^{\frac{3}{2}R} r^{-3} \int_{T_r^-(0)} \frac{1}{-t} (\nabla u_k \cdot x \;+\; 2t\partial_t u_k \;-\; u_k)^2\, G_{(0,0)}\, dr$$

$$\leq\; \frac{81\,R^4\,\epsilon}{32} \;+\; \frac{1}{2}\int_E (2t\,\partial_t u_k)^2$$

$$+\, C(n,R,S) \int_R^{\frac{3}{2}R} r^{-3} \int_{T_r^-(0)} \frac{1}{-t} (\nabla u_k \cdot x \;+\; 2t\partial_t u_k \;-\; u_k)^2\, G_{(0,0)}\, dr$$

provided that $\mathcal{L}^{n+1}(E) \leq \delta$. Since the third term on the right-hand side goes to 0 as $k \to \infty$, we obtain for any positive ϵ positive constants δ and $k_0 < \infty$ such that $\int_E (\partial_t u_k)^2 \;\leq\; \frac{\epsilon}{2}$ provided that $\mathcal{L}^{n+1}(E) \leq \delta$ and $k \geq k_0$. Last, we infer from the a.e. convergence $\partial_t u_k$ to $\partial_t u_0$, which can be proved exactly as the a.e. convergence of $\chi_{\{u_k>0\}}$ to $\chi_{\{u_0>0\}}$ (using the fact that $\mathcal{L}^{n+1}(\partial\{u_0 > 0\}) = 0$ as well as the nondegeneracy of u_k), that $\partial_t u_k \to \partial_t u_0$ in $L^2_{\mathrm{loc}}(\mathbf{R}^{n+1} \cap \{t<0\})$. □

Let us finally estimate the Hausdorff dimension of the free boundary of variational solutions of (5.2) and (5.4).

LEMMA 5.5. *Let u be either a variational solution of* (5.4) *satisfying the nondegeneracy* (5.5) *as well as the regularity $u \in \mathbf{H}^{1,\frac{1}{2}}((0,\infty)\times\mathbf{R}^n)$, or let u be a solution of* (5.2) *with respect to $\gamma \in (-\frac{1}{3}, 0)$ derived by Phillips' approximation. Then for any $(T, x_0) \in ((0,+\infty)\times\mathbf{R}^n) \cap \partial\{u > 0\}$, any sequence $0 < \rho_k \to 0$ and any open $D \subset\subset \mathbf{R}^{n+1}$ the blow-up sequence*

$$u_k(t,x) := \frac{u(T + {\rho_k}^2 t, x_0 + \rho_k x)}{{\rho_k}^{\frac{2}{1-\gamma}}}$$

(here $\gamma := -1$ in the case of a solution of (5.4)) is bounded in $C^{0,\frac{1}{2}}(\bar{D})$ and any pointwise limit u_0 with respect to a subsequence is a nontrivial variational solution in $\mathbf{R}^{n+1} \cap \{t < 0\}$ again satisfying the respective regularity and nondegeneracy and being homogeneous of degree $\frac{2}{1-\gamma}$ on paths $\theta \mapsto (\theta^2 t, \theta x)$ for positive θ and $(t,x) \in \mathbf{R}^{n+1} \cap \{t \le 0\}$. Furthermore for every compact set $K \subset \mathbf{R}^{n+1}$ and every open set $U \supset K \cap \partial\{u_0 > 0\}$ there exists $k_0 < \infty$ such that $\partial\{u_k > 0\} \cap K \subset U$ for $k \ge k_0$.

Note that the last statement is stronger than the one direction in the definition of the convergence in Hausdorff distance in that it holds for *any* open set U.

Proof. Except for the last statement everything follows directly from what was shown before. Now suppose that there exists $(t_k, x_k) \in \partial\{u_k > 0\} \cap (K - U)$. Then $(t_k, x_k) \to (\bar{t}, \bar{x}) \in (K-U) \cap \{u_0 = 0\}$ as a subsequence $k \to \infty$. Assuming now that $(\bar{t}, \bar{x})$ is an inner point of $\{u_0 = 0\}$ the uniform convergence of u_k to u_0 as well as the nondegeneracy of u_k yields a contradiction to the assumption that (t_k, x_k) is a free boundary point of u_k. □

Let us define with respect to the parabolic metric Hausdorff measures

$$\mathcal{H}_m^{\delta,par}(A) := \inf\left\{\sum_{j=1}^{\infty}(\text{pardiam } S_j)^m : A \subset \bigcup_{j=1}^{\infty} S_j \text{ , pardiam } S_j \le \delta\right\}$$

$$\text{and } \mathcal{H}_m^{par}(A) := \lim_{\delta \to 0} \mathcal{H}_m^{\delta,par}(A),$$

where $\delta \in (0, +\infty]$ and pardiam is the diameter in $\mathbf{R}^{n+1}$ with respect to the parabolic metric $\text{dist}((t,y),(s,x)) := \max(|x-y|, |s-t|^{\frac{1}{2}})$. We need three elementary properties of these parabolic Hausdorff measures of which the first as well as the third can be proved exactly as in Lemmas 11.2 and 11.5 of [Giu] and a proof of the second property (closely following Proposition 11.3 of [Giu]) is contained in the appendix:

(5.7) For every $A \subset \mathbf{R}^{n+1}$ the equivalence
$\mathcal{H}_m^{par}(A) = 0$ if and only if $\mathcal{H}_m^{\infty,par}(A) = 0$ holds.

(5.8) For every $n \ge 1$, $m > n$ and $A \subset \mathbf{R}^{n+1}$
$\limsup_{r \to 0} \frac{\mathcal{H}_m^{\infty,par}(A \cap \overline{Q_r^-(t,x)})}{r^m} \ge 1$ for $\mathcal{H}_m^{par}$-a.a. points $(t,x) \in A$.

(5.9) In the situation of Lemma 5.5 we have
$\mathcal{H}_m^{\infty,par}(K \cap \partial\{u_0 > 0\}) \ge \limsup_{k \to \infty} \mathcal{H}_m^{\infty,par}(K \cap \partial\{u_k > 0\})$,

where the limit superior is taken with respect to the subsequence chosen in Lemma 5.5.

Having listed the necessary tools we may now use the dimension reduction procedure. Suppose that $m > n+1$ and $\mathcal{H}_m^{par}(\partial\{u > 0\}) > 0$. Then in $\mathcal{H}_m^{par}$-a.a. points of $\partial\{u > 0\}$ we can use (5.8) as well as (5.9) to obtain a blow-up limit u_0 with the properties mentioned in Lemma 5.5, satisfying $\mathcal{H}_m^{\infty,par}(\partial\{u_0 > 0\} \cap \{t \le 0\}) > 0$. Therefore we find (by (5.7)) a point $(\bar{t}, \bar{x}) \in (\partial\{u_0 > 0\} \cap \{t \le 0\}) - \{(0,0)\}$ in which the density in (5.8) is estimated from below. Now any blow-up limit u_{00} with respect to $(\bar{t}, \bar{x})$ (and with respect to a subsequence such that the limit superior in (5.8) becomes a limit) again satisfies the properties of Lemma 5.5; in addition, we get from the homogeneity of u_0 as in Lemma 3.1 of [We] the following.

If $\bar{t} \neq 0$, then u_{00} has to be constant in time direction and we proceed with $\bar{u} := u_{00}|_{\{t=0\}}$, which in this case is a stationary variational solution satisfying $\mathcal{H}^{m-2}(\partial\{\bar{u} > 0\}) > 0$ as well as the properties of Lemma 5.5.

If $\bar{t} = 0$, then, applying a rotation in space, we may assume that u_{00} is constant in direction of the nth unit vector and proceed with $\bar{u} := u_{00}|_{\{x_n=0\}}$, which is then a variational solution in $(-\infty, +\infty) \times \mathbf{R}^{n-1}$ satisfying $\mathcal{H}^{par}_{m-1}(\partial\{\bar{u} > 0\} \cap \{t \leq 0\}) > 0$ as well as the properties of Lemma 5.5.

Repeating this n times either we obtain a stationary variational solution $u^\star : \mathbf{R} \to \mathbf{R}$ which is nontrivial, homogeneous of degree $\frac{2}{1-\gamma}$, has 0 as free boundary point, and satisfies $\mathcal{H}^{m-n-1}(\partial\{u^\star > 0\}) > 0$, or we obtain a space-independent variational solution $u_\star : (-\infty, 0) \to \mathbf{R}$ which is nontrivial, homogeneous of degree $\frac{1}{1-\gamma}$, has 0 as a free boundary point, and satisfies $\mathcal{H}^{\frac{m-n}{2}}(\partial\{u_\star > 0\} \cap \{t \leq 0\}) > 0$. Since both yield a contradiction if $m > n+1$ we proved the following theorem.

THEOREM 5.2. *Let u be either a variational solution of* (5.4) *in the sense of Definition* 3.1 *satisfying the nondegeneracy* (5.5) *as well as the regularity $u \in \mathbf{H}^{1,\frac{1}{2}}((0,\infty) \times \mathbf{R}^n)$ or a solution of* (5.2) *with respect to $\gamma \in (-\frac{1}{3}, 0)$ derived by Phillips' approximation. Then the parabolic Hausdorff dimension of $\partial\{u > 0\}$ does not exceed $n+1$.*

Considering the stationary solution $\max(x_n, 0)$ of (5.4) in $(0,\infty) \times \mathbf{R}^n$ it is obvious that the parabolic dimension $n+1$ in the estimate cannot be improved.

6. Appendix.

LEMMA 6.1. *If $\ell \geq 1$, $k > \ell$, and A is a subset of $\mathbf{R}^{\ell+1}$, then for $\mathcal{H}^{par}_k$-a.a. points $(t,x) \in A$ we have*

$$\limsup_{r \to 0} \frac{\mathcal{H}^{\infty,par}_k(A \cap \overline{Q^-_r(t,x)})}{r^k} \geq 1$$

(where $Q_r(t,x)$ is an $\ell+1$-dimensional cylinder).

Proof. Define $\zeta(S) := (\text{pardiam}(S))^k$ and, for positive τ, δ, and ϵ,

$$B(\mathcal{H}^{\delta,par}_k, \tau, \epsilon) := \{(t,x) \in A : \mathcal{H}^{\delta,par}_k(S^{t-} \cap A) \leq \tau\zeta(S)$$

for all sets $S \subset \mathbf{R}^{\ell+1}$ such that $S \ni (t,x)$ and $\text{pardiam}(S) < \epsilon\}$ (here $S^{t-} := \{(s,y) \in S : s \leq t\}$). Now suppose $S \subset \mathbf{R}^{\ell+1}$ to satisfy $\text{pardiam}(S) < \epsilon$. Defining $t := \sup\{\sigma : \{s = \sigma\} \cap S \cap B(\mathcal{H}^{\delta,par}_k, \tau, \epsilon) \neq \emptyset\}$ assume first that $\{\sigma = t\} \cap S \cap B(\mathcal{H}^{\delta,par}_k, \tau, \epsilon) = \emptyset$, in which case we obtain for $\theta \in (0, \min(\epsilon, \delta))$

$$\mathcal{H}^{\delta,par}_k(S \cap B(\mathcal{H}^{\delta,par}_k, \tau, \epsilon)) \leq \mathcal{H}^{\delta,par}_k(S^{(t-\theta^2)-} \cap B(\mathcal{H}^{\delta,par}_k, \tau, \epsilon))$$

$$+ \mathcal{H}^{\delta,par}_k((t-\theta^2, t) \times B_\epsilon(x)) \leq \tau\zeta(S) + C(\ell)\,\theta^k \left(\frac{\epsilon}{\theta}\right)^\ell = \tau\zeta(S) + o(1)$$

(as $\theta \to 0$) by the assumption $k - \ell > 0$.

In case there exists $(t,x) \in S \cap B(\mathcal{H}^{\delta,par}_k, \tau, \epsilon)$ we obtain by the definition of $B(\mathcal{H}^{\delta,par}_k, \tau, \epsilon)$ that

$$\mathcal{H}^{\delta,par}_k(S \cap B(\mathcal{H}^{\delta,par}_k, \tau, \epsilon)) \leq \tau\zeta(S).$$

The definition of $\mathcal{H}^{\epsilon,par}_k$ as well as the subadditivity of $\mathcal{H}^{\delta,par}_k$ therefore imply

$$\mathcal{H}^{\delta,par}_k(B(\mathcal{H}^{\delta,par}_k, \tau, \epsilon)) \leq \tau\mathcal{H}^{\epsilon,par}_k(B(\mathcal{H}^{\delta,par}_k, \tau, \epsilon)).$$

In particular, if $\delta < 1$,

$$\mathcal{H}_k^{\delta,par}(B(\mathcal{H}_k^{\delta,par}, 1-\delta, \delta)) \le (1-\delta)\, \mathcal{H}_k^{\delta,par}(B(\mathcal{H}_k^{\delta,par}, 1-\delta, \delta)) \ < \ \infty.$$

Hence $\mathcal{H}_k^{\delta,par}(B(\mathcal{H}_k^{\delta,par}, 1-\delta, \delta)) = 0$ and, by (5.7), $\mathcal{H}_k^{par}(B(\mathcal{H}_k^{\delta,par}, 1-\delta, \delta)) = 0$.

Now consider the set

$$C := \left\{ (t,x) \in A \ : \ \inf_{\epsilon>0} \sup \left\{ \frac{\mathcal{H}_k^{\infty,par}(A \cap S^{t-})}{\zeta(S)} \ : \ S \subset \mathbf{R}^{\ell+1} \text{ such that } \right.\right.$$

$$\left.\left. S \ni (t,x) \text{and pardiam}(S) < \epsilon \right\} \ < 1 \right\}$$

$$= \left\{ (t,x) \in A \ : \ \inf_{n \in \mathbf{N}} \sup \left\{ \frac{\mathcal{H}_k^{\infty,par}(A \cap S^{t-})}{\zeta(S)} \ : \ S \subset \mathbf{R}^{\ell+1} \text{ such that } \right.\right.$$

$$\left.\left. S \ni (t,x) \text{and pardiam}(S) < \frac{1}{n} \right\} \ < 1 \right\}.$$

If $(t,x) \in C$ we must have for some n

$$\sup \left\{ \frac{\mathcal{H}_k^{\infty,par}(A \cap S^{t-})}{\zeta(S)} \ : \ S \subset \mathbf{R}^{\ell+1} \text{ such that } \right.$$

$$\left. S \ni (t,x) \text{and pardiam}(S) < \frac{1}{n} \right\} \ < 1 - \frac{1}{n}.$$

Hence $(t,x) \in B(\mathcal{H}_k^{\infty,par}, 1-\frac{1}{n}, \frac{1}{n}))$, and since the definition of $\mathcal{H}_k^{\delta,par}$ implies $\mathcal{H}_k^{\delta,par}(\tilde{S} \cap A) = \mathcal{H}_k^{\infty,par}(\tilde{S} \cap A)$ for any $\tilde{S}$ such that pardiam$(\tilde{S}) < \delta$, we obtain $C \subset \bigcup_{n=1}^{\infty} B(\mathcal{H}_k^{\infty,par}, 1-\frac{1}{n}, \frac{1}{n})) \subset \bigcup_{n=1}^{\infty} B(\mathcal{H}_k^{\frac{1}{n},par}, 1-\frac{1}{n}, \frac{1}{n}))$. Consequently $\mathcal{H}_k^{par}(C) = 0$.

Finally, fixing $(t,x) \in A$, considering $S \ni (t,x)$, and setting $d := \text{pardiam}(S)$, we obviously have

$$\frac{\mathcal{H}_k^{\infty,par}(A \cap S^{t-})}{\zeta(S)} \ \le \ \frac{\mathcal{H}_k^{\infty,par}(A \cap \overline{Q_d^-(t,x)})}{d^k}.$$

Hence

$$\sup \left\{ \frac{\mathcal{H}_k^{\infty,par}(A \cap S^{t-})}{\zeta(S)} \ : \ S \subset \mathbf{R}^{\ell+1} \text{ such that } \right.$$

$$\left. S \ni (t,x) \text{ and pardiam}(S) < \delta \right\} \le \ \sup \left\{ \frac{\mathcal{H}_k^{\infty,par}(A \cap \overline{Q_d^-(t,x)})}{d^k} \ : \ d < \delta \right\}.$$

Thus the set $D := \{(t,x) \in A \ : \ \limsup_{r \to 0} \frac{\mathcal{H}_k^{\infty,par}(A \cap \overline{Q_d^-(t,x)})}{d^k} < 1\}$ must be contained in C and it follows that $\mathcal{H}_k^{par}(D) = 0$. □

Acknowledgments. The basic questions leading to this paper were asked during a one-week stay at Hokkaido University with Y. Giga, whom we thank for advice and numerous discussions. A vital literature hint was given by S. Müller. Many people, including S. Angenent, H. J. Choe, S. Luckhaus, and H. Matano, contributed helpful discussions.

APPROXIMATION OF THE STOKES DIRICHLET PROBLEM IN DOMAINS WITH CYLINDRICAL OUTLETS*

MARIA SPECOVIUS-NEUGEBAUER†

Abstract. Let $\Omega \subset \mathbf{R}^3$ be a domain with J cylindrical outlets to infinity and $u = (v, p)$ be a solution of the Dirichlet problem for the Stokes system with prescibed flux H_j through the jth outlet. Let $\{\Omega_R\}$ be the set of bounded domains defined by cutting each cylindrical outlet at the distance R from its origin. The problem investigated is how u can be approximated by solutions u^R of boundary problems which are defined on the bounded subdomain Ω_R. On the artificial boundary $\partial\Omega_R \backslash \partial\Omega$ a boundary condition $Bu^R = h$ has to be added. By a method similar to the Schwartz' alternating method, the asymptotic behavior (as R tends to infinity) for $u - u^R$ is investigated for different types of boundary conditions on the cut cross sections. The existence of solutions u^R that are regular up to the edges is shown while using a boundary operator usually related to free boundary problems. For exponentially decaying data asymptotically precise estimates are derived for the difference $u - u^R$; these results hold true for inhomogeneous boundary conditions on the lateral surface $\partial\Omega$ and nonvanishing divergence. For div $v = 0$ and homogeneous boundary conditions on $\partial\Omega$ the case of L^2-forces also is examined.

1. Preliminaries.

1.1. Introduction. Many problems in hydromechanics lead to the investigation of partial differential equations in unbounded domains. One example of such situations is the flow of a viscous fluid through a system of channels. The behavior of the velocity field v of the fluid particles and the pressure distribution p are often described by the nonlinear Navier–Stokes system. In this context the theory of the steady linear part, the so-called Stokes system

$$-\Delta v + \nabla p = f', \quad \text{div } v = f_{n+1} \quad \text{in } \Omega, \quad v = g \quad \text{on the boundary } \partial\Omega, \tag{1.1}$$

plays the fundamental role. Here $\Omega \subset \mathbf{R}^n$, $n \geq 2$, is an unbounded domain with several cylindrical outlets (see section 2 for the exact notations). The vector field f' is a given external force; f_{n+1} may be considered as a distribution of sources and sinks. To obtain unique solutions $u = (v, p)$ to the system (1.1), conditions at infinity have to be added. One possibility, which is also physically reasonable, is to prescribe the flux through each outlet; this condition will be used in the following. Although it is obvious that there exist no infinite volumes of liquid, problems in unbounded domains serve as models for practical problems. On the other hand, any sort of computational work can only be done on finite domains. One approach for overcoming the difficulties with unbounded domains is to truncate the domain, which leads to a problem on a bounded part $\Omega_R \subset \Omega$. For domains with cylindrical outlets, the easiest way to define Ω_R is to cut every outlet at the distance R from its origin. If we assume that the original problem is preserved on Ω_R and on $\partial\Omega_R \cap \partial\Omega$, at least an addititional

boundary condition

$$B^R u^R = h^R \tag{1.2}$$

has to be imposed on $\partial\Omega_R \backslash \partial\Omega$. Such conditions are usually called *artificial boundary conditions* (ABCs), and we refer to the problem on the bounded domain as an *approximation problem*.

During the last 20 years many efforts were made to create ABCs for various sorts of partial differential equations; we refer here to the survey articles [12, 53]. It is clear that the minimal requirements for the choice of ABCs are the following criteria:

(i) The approximation problem possesses a unique solution $u^R = (v^R, p^R)$.

(ii) On Ω_R the solution u^R is sufficiently close to the solution u of the original problem.

Of course, the best ABCs with respect to the second criterion are the so-called exact ABCs; this means $(u - u^R)|_{\Omega_R} = 0$. However, with the exception of some trivial, i.e., 1-dimensional cases, exact ABCs are *nonlocal*, which means the corresponding boundary operator is a pseudodifferential operator and can be derived in a simple form only for some particular geometries. In practical situations these boundary conditions also have to be approximated (see, e.g., [20, 21, 51, 16, 44] and especially the review articles [12, 53] and the papers cited there). Throughout this paper we deal with local ABCs. This means we investigate different types of boundary conditions in differential form on the artificial boundary $\partial\Omega_R \backslash \partial\Omega$, such that the problem on the truncated domain is elliptic in the sense of Agmon–Douglis–Nirenberg. These conditions are available for a very general class of data f and g not necessarily compactly supported. Local ABCs taking into account the asymptotic behavior of the solution to the Stokes system in an exterior 3-dimensional domain were proposed in [15, 8, 35]. For the Stokes problem in domains with outlets to infinity, a systematic study of local ABCs currently does not seem to exist.

Although the asymptotic behavior of $u - u^R$ is interesting by itself, independent of convergence, at least the application to computations requires a frame where the solution u (for the problem in the unbounded domain Ω) exists for appropriate data and is uniquely determined. Roughly speaking, solutions of boundary value problems in unbounded domains are not only determined by the right-hand sides of the differential equation system and the boundary values, conditions at infinity also have to be imposed.

Since Poincaré's inequality holds in domains with cylindrical outlets, it is clear that for $f \in H^{-1}(\Omega)^3$ (the space of all continuous linear functionals on $\overset{\circ}{H}{}^1(\Omega)^3$) there always exists a weak solution of the Stokes system (1.1) for $f_{n+1} = 0$ and $g = 0$. This means there is $v \in \overset{\circ}{H}{}^1(\Omega)^3$ with $(\nabla v, \nabla\varphi)_\Omega = (f, \varphi)_\Omega$ for all $\varphi \in C_0^\infty(\Omega)^3$ with $\operatorname{div} \varphi = 0$. However, using Gauss' theorem in bounded parts of Ω and Hölder's inequality, it is easy to see that this solution has zero flux through every outlet, which of course is physically nonrealistic. With the help of a *flux carrier* it is possible to construct solutions to the Stokes system (1.1) with prescribed flux H_j through each outlet, but with an unbounded Dirichlet integral, provided the total flux vanishes, i.e., $\sum H_j = 0$. This technique was introduced and applied to a very large class of domains by Ladyženskaja and Solonnikov [27].

A different approach was used by Nazarov and Pileckas in [36]. They applied the results for general elliptic systems in cylinders to derive existence, uniqueness, and asymptotic representations for the system (1.1) with exponentially dying data, where the flux carrier is the Poiseuille flow for large x. In this context they developed a

setting in which more general asymptotic conditions (than conditions on fluxes) can be posed at infinity. We use their results for the problem with prescribed fluxes.

To approximate these solutions we define a domain Ω_R by cutting the outlets at some distance from the origin. As already mentioned, it is reasonable to demand that the approximation problem has a unique solution converging to the solution $u = (v, p)$ of (1.1) with prescribed fluxes in some sense. Moreover, the approximating solution should preserve as much as possible from regularity properties of u. For domains with cylindrical outlets this is a problem insofar as the artificial boundary $\partial\Omega_R \backslash \partial\Omega$ and the cutted boundary $\partial\Omega \backslash \partial\Omega_R$ meet each other, usually in an edge. Even if the boundary of the truncated domain inherits the regularity of the boundary $\partial\Omega$ then the only reasonable situation, where the local H^l-regularity of (v, p) is preserved for arbitrary l, is the case $v|_{\partial\Omega} = 0$ and $v^R|_{\partial\Omega_R \backslash \partial\Omega} = 0$. In all other cases there normally appears a jump in the boundary conditions while using a "smooth" cutting of Ω, or edges in the domain Ω_R when doing sharp cuts. Both methods diminish the regularity properties of u^R. We will use the second approach and cut the outlets orthogonal to the axis of the cylinders. Then Ω_R has edges with an opening angle $\pi/2$, but we bend the data of the approximating problem smoothly to 0 before reaching the edge. We will see that it is possible to find approximating solutions which are C^∞ in the neighborhood of the cut, if the boundary condition is chosen properly.

The main results of the present paper are the following: using the method of matched asymptotic expansions, which is similar to the alternating method of Schwartz (see [50, Chapter IV, section 2]), the asymptotic behavior of $u - u^R$ is calculated for different classes of local ABCs on the artificial boundary (section 3). The existence of unique solutions to the approximation problem, together with regularity up to the edges, is proved for the approximation problem with an appropriate boundary condition on the artificial boundary (Theorem 4.2 and 4.4). In section 5 we derive a uniform estimate for solutions to the Stokes problem on the truncated domain. This estimate is the main tool to obtain an asymptotically precise estimate for $u|_{\Omega_R} - u^R$ as $R \to \infty$ in the case of exponentially decaying data (Theorem 6.1): the difference decays exponentially in $H^{l+1}(\Omega_R)^3 \times H^l(\Omega_R)$. Moreover, for L^2-data it can be shown at least that $\|v - v^R; H^2(\Omega_R)^3\| + \|\nabla(p - p^R); L^2(\Omega_R)^3\| \to 0$ as $R \to \infty$ (section 7).

1.2. Notations, characterization of the domain, basic function spaces, auxiliary results. We recall the notations of some basic function spaces. Let $\mathcal{G} \subset \mathbf{R}^3$ be an open set with closure $\overline{\mathcal{G}}$ and boundary $\partial\mathcal{G}$, which we assume at least to be Lipschitz; ν denotes the exterior normal vector on $\partial\mathcal{G}$. $C_0^\infty(\mathcal{G})$ denotes the set of all smooth functions with compact support in $\mathcal{G}$. For $l \in \mathbf{N}$, $C^l(\mathcal{G})$ is the space of l times continuously differentiable functions φ. We use the common multi-index terminology for partial derivatives: Let $\alpha \in \mathbf{N}_0^3$ with $|\alpha| = \sum_{i=1}^3 \alpha_i$, then $\partial_x^\alpha \varphi(x) = \partial^\alpha \varphi(x) = \frac{\partial^{\alpha_1}}{\partial x_1} \cdots \frac{\partial^{\alpha_3}}{\partial x_3} \varphi(x)$. In this context we mention that the notation $\partial\mathcal{G} \in C^l$ means: For each $x_0 \in \partial\mathcal{G}$ there exists a neighborhood $\mathcal{O}(x_0)$ and a C^l-diffeomorphism $\Phi : \mathcal{O} \to \mathcal{O}'$, such that $\Phi(\mathcal{O} \cap \partial\mathcal{G})$ is an open subset in $\mathbf{R}^{n-1}$. We indicate the L^2-scalar product on $\mathcal{G}$ and on $\partial\mathcal{G}$ by $(\,\cdot\,,\,\cdot\,)_\mathcal{G}$ and $(\,\cdot\,,\,\cdot\,)_{\partial\mathcal{G}}$, i.e., $(u, U)_\mathcal{G} = \int_\mathcal{G} u(x)\bar{U}(x)\,\mathrm{d}x$, $(u, U)_{\partial\mathcal{G}} = \int_{\partial\mathcal{G}} u(x)\bar{U}(x)\,\mathrm{d}o$, where $\mathrm{d}o$ is the 2-dimensional surface measure on $\partial\mathcal{G}$. We extend this notation to all measurable functions (vectorfields), where the integral is finite. We arrange the following convention: in calculations, vectors are always columns, otherwise we use the superscript $^\top$.

We use Sobolev spaces generated by L^2-norms, i.e., $H^l(\mathcal{G})$ is the space consisting of all functions $\varphi \in L^2(\mathcal{G})$ with $\nabla^m \varphi \in L^2(\mathcal{G})$; for all $0 \le m \le l$, ∇^m denotes the system of all (distributional) derivatives $\partial^\gamma \varphi$ of order m. As usual, we indicate the

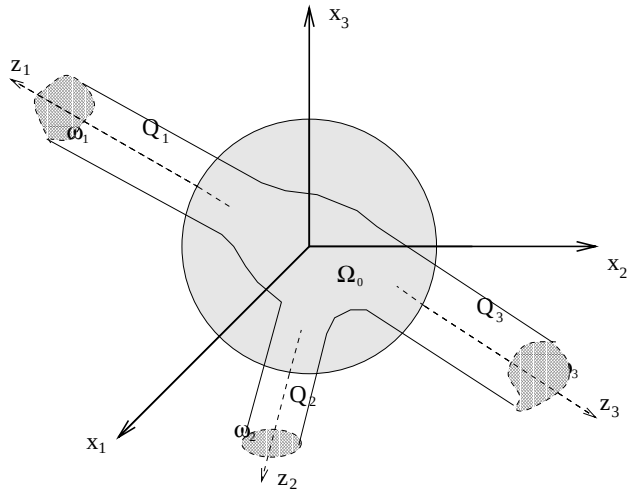

FIG. 1.

closure of $C_0^\infty(\mathcal{G})$ in $H^l(\mathcal{G})$ by $\overset{\circ}{H}{}^l(\Omega)$, the space with zero traces on the boundary. $\varphi \in H^l_{loc}(\mathcal{G})$ means $\varphi|_K \in H^l(K)$ for any bounded open subset of $\mathcal{G}$ with $\overline{K} \subset \mathcal{G}$. If $\mathcal{G}$ is unbounded, we define $H^l_{loc}(\overline{\mathcal{G}})$ in an analogous way ($H^l_{loc}(\overline{\mathcal{G}}) = H^l(\mathcal{G})$ if $\mathcal{G}$ is bounded).

We characterize the underlying domain Ω with J cylindrical outlets to infinity in the following way (see Fig. 1 for $J = 3$). We assume that $\partial\Omega$ is of class C^{l+2} for some $l \in \mathbf{N}$, $\Omega = \Omega_0 \cup Q_1 \cup \cdots \cup Q_J$, where Ω_0 is the intersection of Ω with a ball $B(0, R_0)$ of radius R_0 and $Q_j \cap Q_j = \emptyset$ for $i \neq j$. For each outlet Q_j we introduce a system of local coordinates $(y_j, z_j) \in \omega_j \times [1, \infty)$, where the cross section $\omega_j \subset \mathbf{R}^2$ is a smoothly surrounded bounded domain. Without loss of generality we may assume that $\omega_j \times [2, \infty) \cap \Omega_0 = \emptyset$. When considering a fixed outlet we omit the index j of the local coordinates if no confusion arises. To the cross section ω_j we also assign the cylinder $\Pi_j = \omega_j \times \mathbf{R}$ and the semicylinder $\Pi_j^- = \omega_j \times (-\infty, 0)$.

We recall the main results on existence and uniqueness for the problem (1.1) in the domain Ω. For simplicity assume for the moment that the domain under consideration is a cylinder $\Pi \equiv \omega \times \mathbf{R}$, where $\omega \subset \mathbf{R}^{n-1}$ is a bounded domain, and that the data are smooth and have compact support. We indicate the formal differential operator of the system (1.1) by S, but in order to obtain a formally self-adjoint system, we change div to $-$div , hence $Su = \binom{-\Delta v + \nabla p}{-\operatorname{div} u}$. Performing the complex Fourier transformation $\mathfrak{F}_{z \to \lambda}$ with respect to the variable z along the axis, the problem $S(\nabla_y, \partial_z)u = f$, $v|_{\partial\omega} = g$ turns into a family of problems on the cross section ω of the form

$$S(\nabla_y, i\lambda)U(y) = F(y), \quad y \in \omega; \qquad V(y) = G(y), \quad y \in \partial\omega. \tag{1.3}$$

We denote the associated operator pencil by $\mathfrak{S}(\lambda)$, i.e., $\mathfrak{S}(\lambda)$ is the family of mappings from $\mathcal{D}^l H(\omega) = H^{l+1}(\Omega)^3 \times H^l(\omega)$ to $\mathcal{R}^l(\omega) = H^{l-1}(\Omega)^3 \times H^l(\omega) \times H^{l+1/2}(\omega)^3$ related to the system (1.3). Suppose for $\beta \in \mathbf{R}$ that the line $\mathbf{R} + i\beta$ is free of eigenvalues of the operator pencil $\mathfrak{S}(\lambda)$, which means the problem (1.3) has a unique solution (v_λ, p_λ) for each $\lambda \in \mathbf{R} + i\beta$. Then the inverse Fourier transformation applied to the family (v_λ, p_λ) yields the solution (v, p) for the problem in the cylinder. Parseval's

identity provides

$$\int_{\mathbf{R}} e^{2\beta t}|w(t)|^2\,dt = \int_{\mathbf{R}+i\beta} |\hat{w}(\lambda)|^2\,d\lambda. \tag{1.4}$$

This relation is the motivation to formulate the problem in terms of spaces containing functions with certain exponential weights (for details see, e.g., [33, Chapter 3]).

On Π_j and Ω we define weighted Sobolev spaces in the following way.

DEFINITION 1.1. *Let $l \in \mathbf{N}_0$, $\beta \in \mathbf{R}$, and $\Pi = \omega \times \mathbf{R}$, where ω is a bounded domain in $\mathbf{R}^2$. For $u \in C_0^\infty(\overline{\Pi})$ we set*

$$\|u; W_\beta^l(\Pi)\| := \|ue^{\beta z}; H^l(\Pi)\|.$$

We define $W_\beta^l(\Pi)$ as the closure of $C_0^\infty(\overline{\Pi})$ in this norm.

To extend this definition to the domain Ω with cylindrical outlets we introduce a function $\mathfrak{z} \in C^\infty(\Omega)$ with $\mathfrak{z}(x) = 1$ for $x \in \Omega_0$ and $\mathfrak{z}(x) = z_j$ for $x \in Q_j$ and $z_j \geq 2$.

DEFINITION 1.2. *For l, β as above we define $W_\beta^l(\Omega)$ as the set of all $u \in H_{loc}^l(\Omega)$ such that*

$$\|u; W_\beta^l(\Omega)\| = \|u\, e^{\beta\mathfrak{z}}; H^l(\Omega)\| < \infty.$$

For $l \geq 1$, $\partial\Omega \in C^{l+1}$, we set $W_\beta^{l-1/2}(\partial\Omega) = \{u|_{\partial\Omega} : u \in W_\beta^l(\Omega)\}$ normed by

$$\|u; W_\beta^{l-1/2}(\partial\Omega)\| = \inf \|\tilde{u}; W_\beta^l(\Omega)\|,$$

where the infimum is taken over all $\tilde{u} \in W_\beta^l(\Omega)$ such that $\tilde{u}|_{\partial\Omega} = u$.

Remark. Here we have to observe that if $\Omega = \Pi$ is a cylinder, Definition 1.2 differs from Definition 1.1, when the cylinder Π is regarded as a domain with two outlets.

It is clear that $C_0^\infty(\overline{\Omega})$ is dense in $W_\beta^l(\Omega)$, since this is true for $H^l(\Omega)$ and the weight function $e^{\beta\mathfrak{z}(x)} \geq 1$ for all $x \in \Omega$. We have the obvious embedding $W_\beta^l(\Omega) \hookrightarrow W_{\bar{\beta}}^m(\Omega)$ for $l \geq m$, $\beta \geq \bar{\beta}$ (which is not true for $W_\beta^l(\Pi)$, of course!). Moreover, for $l > m$, $\beta > \bar{\beta}$, this embedding is compact (see the proof of [33, Proposition 4.1.1] and also [52, Lemma 5.4.1]).

We introduce the natural spaces for the data $f = (f', f_{n+1})$, g and the solution $u = (v, p)$ of the system (1.1). For $l \in \mathbf{N}$, let $\partial\Omega \in C^{l+2}$, $\beta \in \mathbf{R}$; we set

$$\begin{aligned} \mathcal{D}_\beta^l W(\Omega) &= W_\beta^{l+1}(\Omega)^3 \times W_\beta^l(\Omega), \\ \mathcal{R}_\beta^l W(\Omega, \partial\Omega) &= W_\beta^{l-1}(\Omega)^3 \times W_\beta^l(\Omega) \times W_\beta^{l+1/2}(\partial\Omega)^3. \end{aligned} \tag{1.5}$$

The mapping

$$\begin{aligned} \mathbb{S}_\beta : \mathcal{D}_\beta^l W(\Omega) &\to \mathcal{R}_\beta^l W(\Omega, \partial\Omega) \\ u &\mapsto (Su, v|_{\partial\Omega}) = (-\Delta v + \nabla p, -\operatorname{div} v, v|_{\partial\Omega}) \end{aligned} \tag{1.6}$$

defines a continuous linear operator. Moreover, the following Green's formula

$$(Su, U)_\Omega - (u, SU)_\Omega = (v, NU)_{\partial\Omega} - (Nu, V)_{\partial\Omega} \tag{1.7}$$

is valid for $u = (v, p) \in \mathcal{D}_\beta^l W(\Omega)$, $U = (V, P) \in \mathcal{D}_{-\beta}^l W(\Omega)$. Here Nu is the Neumann operator, $Nu = (-\nabla v \cdot \nu + p\nu)|_{\partial\Omega}$, ν is the exterior normal vector on $\partial\Omega$. The following results are well known (see [33, Chapter 5.8], [36]).

LEMMA 1.3. *Let $l \in \mathbf{N}$ and $\beta \in \mathbf{R}$. Then the following hold:*

(i) *The mapping* (1.6) *defines a Fredholm operator for all $\beta \in \mathbf{R}$ with the exception of a discrete countable subset $\mathcal{I} \subset \mathbf{R}$.*

(ii) *$0 \in \mathcal{I}$, and $\beta \notin \mathcal{I}$ implies $-\beta \notin \mathcal{I}$. If $\beta \notin \mathcal{I}$, then* $\ker \mathbb{S}_\beta = \operatorname{coker} \mathbb{S}_{-\beta}$ *(in the sense that the necessary conditions arising by Green's formula* (1.7) *are sufficient for the solvability of the system).*

We have $\beta \in \mathcal{I}$ iff the line $\operatorname{Im}\lambda = \beta$ is not free of eigenvalues of the associated elliptic pencils $\mathfrak{S}(\lambda)_j$ in $\Pi_j = \omega_j \times \mathbf{R}$, $j = 1, \dots, J$. This means that there exists λ with $\operatorname{Im}\lambda = \beta$, such that the homogeneous problem (1.3) (i.e., $F = 0$, $G = 0$) has a nontrivial solution on ω_j for at least one j. All eigenvalues give rise to special solutions $u_\lambda^{(k,m)}$ of the homogeneous Stokes system (1.1) in $\Pi_j = \omega_j \times \mathbf{R}$, which are called *exponential solutions of order k*. We have

$$u_\lambda^{(k,m)}(y,z) = e^{i\lambda z} \sum_{q=0}^{k} \frac{1}{q!}(iz)^q \varphi^{(k-q,m)}(y), \tag{1.8}$$

where the vectors $\{\varphi^{(l,m)}(y)\}_{l=1}^k$ form a Jordan chain corresponding to the eigenvalue λ, especially where $\varphi^{(0,m)}$ is a solution to $\mathfrak{S}(\lambda)\varphi^{(0,m)} = 0$ in ω_j. (The index m indicates that there is more than one eigenvector and associated Jordan chain in general.) We recall a further well-known result on the index of the operator $\mathbb{S}_\beta$ and the asymptotic representation of the solutions to (1.1). For this purpose we fix a system of cut-off functions with the properties $\operatorname{supp}\chi_j \subset Q_j$, $\chi_j(y_j, z_j) = \chi_j(z_j) = 1$ for $z_j > 2$ in the local coordinates of Q_j.

LEMMA 1.4 (see [33, Theorem 5.1.4]). *Let $\beta > \gamma$ such that both of the lines $\operatorname{Im}\lambda = \beta$ and $\operatorname{Im}\lambda = \gamma$ are free of eigenvalues of the elliptic pencils $\mathfrak{S}(\lambda)_j$, $j = 1, \dots, J$. Let $\{\lambda_{1,j}, \dots, \lambda_{\mu_j,j}\}$ be the set of eigenvalues of $\mathfrak{S}(\lambda)_j$ with $\beta < \operatorname{Im}\lambda < \gamma$ and $æ(\lambda)$ denote the total multiplicity of the eigenvalue λ. Then the following hold:*

$$\operatorname{Ind}\mathbb{S}_\beta - \operatorname{Ind}\mathbb{S}_\gamma = \sum_{j=1}^{J} \sum_{\mu=1}^{\mu_j} æ(\lambda_{\mu,j}). \tag{1.9}$$

If $(f,g) \in \mathcal{R}_\gamma^l W(\Omega)$, and $u \in \mathcal{D}_\beta^l W(\Omega)$ is a solution to (1.1)*, then u admits the following asymptotic representation as a sum of exponential solutions and $\tilde{u} \in \mathcal{D}_\beta^l W(\Omega)$,*

$$u = \sum_{j=1}^{J} \chi_j \sum_{\mu=1}^{\mu_j} \sum_{m,k} C_{\mu,m,k}(f,g) u_{\lambda_{\mu,j}}^{(k,m)}(y_j, z_j) + \tilde{u}. \tag{1.10}$$

Remark 1.5. Of course, these eigenvalues in general differ from outlet to outlet, but on the real line, $\lambda = 0$ is the only eigenvalue in every cylinder Π_j with corresponding Jordan chain of length 2 (see [36]); we repeat the calculations for the reader's convenience.

Let ω be one of the cross sections ω_j, $y = (y_1, y_2) \in \omega$. The system (1.3) for an eigenvector $\varphi^\top = (\varphi_1, \dots, \varphi_4) \in \mathcal{D}^l H(\omega)$ reads

$$-\Delta_y \varphi_k + \lambda^2 \varphi_k + \partial_k \varphi_4 = 0, \quad k = 1, 2, \tag{1.11}$$

$$-\Delta_y \varphi_3 + \lambda^2 \varphi_3 + i\lambda \varphi_4 = 0, \tag{1.12}$$

$$-\partial_1 \varphi_1 - \partial_2 \varphi_2 - i\lambda \varphi_3 = 0, \tag{1.13}$$

$$\varphi_1|_{\partial\omega} = \varphi_2|_{\partial\omega} = \varphi_3|_{\partial\omega} = 0. \tag{1.14}$$

We multiply the equations (1.11) and (1.12) scalarly in $L^2(\omega)$ by φ_k and φ_3, respectively. In summary, integrating by parts and exploiting (1.13) leads to $0 = \sum_{k=1}^3 \int_\omega (|\nabla_y \varphi_k|^2 + \lambda^2 |\varphi_k|^2)\,\mathrm{d}y$. For any $\lambda \in \mathbf{R}$ this leads, together with the boundary condition (1.14), to $\varphi_k = 0$ for $k = 1, 2, 3$. From (1.12) we obtain $\varphi_4 = 0$ for $\lambda \neq 0$, and $\varphi_4 = const$ for $\lambda = 0$. Hence $\lambda = 0$ is the only eigenvalue of $\mathfrak{S}(\lambda)$ on the real line with corresponding eigenvector $\varphi^{(0)} = (0, 0, 0, 1)^\top$. To calculate the corresponding Jordan chain, we recall the equation for the associated vectors:

$$\mathfrak{S}(0)\varphi^m = -\sum_{l=1}^{m} \frac{1}{l!} \frac{\mathrm{d}^l \mathfrak{S}}{\mathrm{d}\lambda^l}(0)\varphi^{(m-l)}, \quad m = 1, \ldots, \mathfrak{ae} - 1, \tag{1.15}$$

with $\mathfrak{ae}$ as in Lemma 1.4. Differentiating (1.11)–(1.13) with respect to λ, substituting $\lambda = 0$ and $\varphi^{(0)} = (0, 0, 0, 1)^\top$, elementary calculations lead to $\varphi^{(1)} = (0, 0, \frac{i}{2}\Psi, 0)$, where Ψ is a solution to the Dirichlet problem

$$-\Delta_y \Psi = 2 \text{ in } \omega, \qquad \Psi = 0 \text{ on } \partial\omega. \tag{1.16}$$

To see that there exists no associated vector $\varphi^{(2)}$ of order 2, let us assume the contrary. By (1.15), $\varphi^{(2)}$ is a solution to the problem

$$\begin{aligned} -\Delta_y \varphi_k^{(2)} + \frac{\partial}{\partial y_k}\varphi^{(2)} 2_4 &= -\varphi_k^{(0)} = 0, \quad k = 1, 2, \\ -\Delta_y \varphi_3^{(2)} &= -\varphi_3^{(0)} + i\varphi_4^{(1)} = 0, \\ -\frac{\partial}{\partial y_1}\varphi_1^{(2)} - \frac{\partial}{\partial y_2}\varphi_2^{(2)} &= i\varphi_3^{(1)} = -\frac{1}{2}\Psi \text{ in } \omega, \end{aligned} \tag{1.17}$$

$$\varphi_k^{(2)} = 0 \text{ on } \partial\omega, \quad k = 1, 2, 3. \tag{1.18}$$

We integrate (1.17) over ω. From the Gauss theorem and $\Delta\Psi = -2$ we obtain

$$0 = \int_\omega (\frac{\partial}{\partial y_1}\varphi_1^{(2)} + \frac{\partial}{\partial y_2}\varphi_2^{(2)})\,\mathrm{d}y = \frac{1}{2}\int_\omega \Psi\,\mathrm{d}y = -\frac{1}{4}\int \Psi\Delta\Psi\,\mathrm{d}y = -\frac{1}{4}\int_\omega |\nabla\Psi|^2\,\mathrm{d}y > 0,$$

which leads to a contradiction.

The eigenvector and the associated vector give rise to two polynomial (with respect to z) solutions of the homogeneous Stokes system in each cylinder Π_j. These are the *constant pressure solution* $u^{j0}(y, z)^\top = (0, 0, 0, 1)$, and the *Poiseuille flow* $u^{j1}(y, z)^\top = (0, 0, \varpi_j \Psi^{(j)}(y), -2\varpi_j z)$, where $\Psi^{(j)}$ is defined as in (1.16) with $\omega = \omega_j$, and $\varpi_j \in \mathbf{R}$ is chosen in such a way that

$$\int_{\omega_j} \varpi_j \Psi^{(j)}(y)\,\mathrm{d}y = 1, \tag{1.19}$$

i.e., u^{j1} carries the unit flux through the cylinder Π_j.

In the following we fix $l \geq 1$ and $\beta > 0$, $\beta^* > 0$ in such a way that the strips $0 < |\mathrm{Im}\,\lambda| < \beta^*$ are free of eigenvalues of the pencils $\mathfrak{S}(\lambda)_j$ for $j = 1, \ldots, J$, and $0 < \beta < \beta^*$. Since $\mathcal{D}_\beta^l W(\Omega) \subset H^2(\Omega)^3 \times H^1(\Omega)$, it follows from standard methods that the kernel of $\mathbb{S}_\beta$ is trivial, and thus, by Lemma 1.3, the operator $\mathbb{S}_{-\beta}$ is surjective. The index formula (1.9), Lemma 1.3, and Remark 1.5 lead to $\dim\ker\mathbb{S}_{-\beta} + \dim\mathrm{coker}\,\mathbb{S}_\beta = 2\dim\ker\mathbb{S}_{-\beta} = 2J$, hence $\dim\ker\mathbb{S}_{-\beta} = J$. Let $(f, g) \in \mathcal{R}_\beta^l$. We obtain a solution $u \in \mathcal{D}_\beta^l W(\Omega)$ of the system (1.1) iff

$$(f, U)_\Omega - (g, NU)_{\partial\Omega} = 0 \tag{1.20}$$

for all $U \in \ker \mathbb{S}_{-\beta}$. However, since $\mathcal{R}^l_\beta W(\Omega, \partial\Omega) \subset \mathcal{R}^l_{-\beta} W(\Omega, \partial\Omega)$, (1.1) always has a solution in $\mathcal{D}^l_{-\beta} W(\Omega)$ for every $(f, g) \in \mathcal{R}^l_\beta$. By (1.10) and Remark 1.5, we have the following asymptotic representation for u (see [36]):

$$u(x) = \sum_{j=1}^{J} \chi_j(x) \Big((a_j u^{j0}(x) + b_j u^{j1}(x) \Big) + \tilde{u}(x) \tag{1.21}$$

with coefficients $a_j, b_j \in \mathbb{C}$, $\tilde{u} \in \mathcal{D}^l_\beta W(\Omega)$. Here χ_j, $j = 1, \dots, J$, are the same cut-off functions as in Lemma 1.4. In order to simplify the presentation of calculations we adopt the following notations from [36]. We define $4 \times J-$matrices $\mathcal{U}^0$, $\mathcal{U}^1$, with columns $\chi_j u^{jh}$, $h = 0, 1$. For $c \in \mathbb{C}^J$ we have $\mathcal{U}^h \cdot c = \sum_j c_j \chi_j u^{jh}$. In this notation, (1.21) reads

$$u = \mathcal{U}^0 \cdot a + \mathcal{U}^1 \cdot b + \tilde{u}, \qquad a, b \in \mathbb{C}^J. \tag{1.22}$$

Hence we find the preimage $\mathbb{D}^l_{\pm\beta} W(\Omega)$ of $\mathcal{R}^l_\beta W(\Omega, \partial\Omega)$ in $\mathcal{D}^l_{-\beta} W(\Omega)$ as a space with detached asymptotics. Here the index $\pm\beta$ indicates that the space is related both to W^l_β, where the data are taken from, and to $W^l_{-\beta}$, where we look for the solutions. Precisely, we define (see [36])

$$\mathbb{D}^l_{\pm\beta} W(\Omega) = \{u \in \mathcal{D}^l_{-\beta} W(\Omega) : u \text{ fulfills (1.22)}\}.$$

The factor space $\mathbb{D}^l_{\pm\beta} W(\Omega)/\mathcal{D}^l_\beta W(\Omega)$ is isomorphic to $\mathbb{C}^{2J}$ and $\mathbb{D}^l_{\pm\beta} W(\Omega)$ is a Banach space provided with the norm

$$\|u; \mathbb{D}^l_{\pm\beta} W(\Omega)\| = \big(\|\tilde{u}; \mathcal{D}^l_\beta W(\Omega)\|^2 + |a|^2 + |b|^2 \big)^{1/2},$$

where $|\,.\,|$ means the Euclidean norm in $\mathbb{C}^J$. We denote the projections of u on the coefficients (a, b) in (1.22) by πu, i.e., $\pi u = (a, b) =: (\pi_0 u, \pi_1 u)$. By definition, the operator

$$\mathbb{S} : \mathbb{D}^l_{\pm\beta} W(\Omega) \ni u \mapsto (Su, v|_{\partial\Omega}) \in \mathcal{R}^l_\beta W(\Omega)$$

is surjective and $\ker \mathbb{S} = \ker \mathbb{S}_{-\beta}$; moreover, due to Lemma 1.3, $\dim \ker \mathbb{S} = J$. This means in particular that the coefficients a_j, b_j are not uniquely determined by the data. Namely, to the solution we may add $\eta \in \ker \mathbb{S}$, where η, of course, also has the form (1.22). Thus, to obtain unique solutions of the Stokes system in $\mathbb{D}^l_{\pm\beta} W(\Omega)$, additional asymptotic conditions have to be prescribed of the form

$$Bu = \mathbb{B} \cdot (\pi u) = \mathbb{B} \cdot \begin{pmatrix} a \\ b \end{pmatrix} = H \in \mathbb{C}^J, \tag{1.23}$$

where $\mathbb{B}$ is a suitable $J \times 2J$ matrix and $\binom{a}{b}$ is the column of coefficients in the asymptotic representation (1.21). It is self-evident that only special matrices $\mathbb{B}$ are reasonable, i.e., lead to Fredholm properties of the operator

$$(\mathbb{S}, B) : \mathbb{D}^l_{\pm\beta} W(\Omega) \to \mathcal{R}^l_\beta W(\Omega) \times \mathbb{C}^J.$$

We restrict ourselves in the following to the case $\mathbb{B} = (\mathbb{O}, \mathbb{I})$, where $\mathbb{I}$ is the $J \times J$ unit-matrix, and $\mathbb{O}$ is the matrix with all entries 0. This means we prescribe $b = H$. In the case $g = 0$, $f_4 = 0$ this is the problem with prescribed fluxes, i.e., $\int_{\omega_j} v \cdot \mathrm{e}_j \, \mathrm{d}y = H_j$,

where e_j is the unit vector in direction of the cylinder axis. The homogeneous problem $(\mathbb{S}, B) = 0$ has the nontrivial solution $u^\# = (0, 0, 0, 1)$ (see [33, Theorem 5.3]): If $b_j = 0$ in (1.21) then u is a solution to the homogeneous Dirichlet problem with $\nabla v \in L^2(\Omega)$; thus, $v = 0$ and $p=$ const. Now we use the following *generalized Green's formula* for $u = \binom{v}{p}, U = \binom{V}{P} \in \mathbb{D}^l_{\pm\beta} W(\Omega)$ (see [33, Section 5.8.1] and [36, Theorem 4.2]):

$$\begin{aligned}(Su, U)_\Omega - (u, SU)_\Omega + (Nu, V)_{\partial\Omega} - (v, NU)_{\partial\Omega} \\ = \langle \pi_0 u, \pi_1 U\rangle_J - \langle \pi_1 u, \pi_0 U\rangle_J,\end{aligned} \tag{1.24}$$

where $\langle\ ,\ \rangle_J$ is the scalar product in $\mathbb{C}^J$. Let $u \in \mathbb{D}^l_{\pm\beta} W(\Omega)$ be a solution to the Stokes problem $(\mathbb{S}, B)u = (f, g, H)$ with prescribed fluxes. Substituting u and $u^\#$ into (1.24) and using

$$\pi_1 u^\# = 0, \quad \pi_0 u^\# = E \quad \text{with } E = (1, 1, \dots, 1)^\top \in \mathbb{C}^J, \tag{1.25}$$

we obtain the necessary condition

$$\int_\Omega f_4 \,\mathrm{d}x + \int_{\partial\Omega} g \cdot n \,\mathrm{d}o = -\langle \pi_1 u, \pi_0 u^\#\rangle_J = -\sum_{j=1}^J H_j, \tag{1.26}$$

which means that the total flux has to vanish. In [36] it is shown that this condition is also sufficient to obtain a solution $u \in \mathbb{D}^l_{\pm\beta} W(\Omega)$, and this solution is uniquely determined up to a constant in pressure. We summarize this in the following theorem.

THEOREM 1.6 (Stokes system with prescribed fluxes). *Let $l \in \mathbf{N}$, $0 < \beta < \beta^*$, and β^* be defined as above. Then for every $(f, g, H) \in \mathcal{R}^l_\beta W(\Omega, \partial\Omega) \times \mathbb{C}^J$ fulfilling* (1.26) *there exists a solution $u = \binom{v}{p} \in \mathbb{D}^l_{\pm\beta} W(\Omega)$ of the Stokes problem*

$$Su = f \text{ in } \Omega, \quad v = g \text{ on } \partial\Omega, \quad \pi_1 u = H. \tag{1.27}$$

u is uniquely determined by the condition

$$\int_{G_0} p \,\mathrm{d}x = c, \tag{1.28}$$

where $G_0 \subset \Omega$ is an arbitrary nonvoid bounded subdomain and $c \in \mathbb{C}$ is an arbitrary but fixed constant. In this case u obeys the following estimate:

$$\|u; \mathbb{D}^l_{\pm\beta}(\Omega)\| \le C\Big(|H| + \|(f, g); \mathcal{R}^l_\beta W(\Omega, \partial\Omega)\|\Big), \tag{1.29}$$

where the constant C depends on G and on the normalization constant c for the pressure but does not depend on the data (f, g, H).

Remark 1.7. The normalization condition for the pressure is completely voluntary; p may be fixed by prescribing the value of any continuous linear functional Φ on $\mathbb{D}^l_{\pm\beta}(\Omega)$ with $\Phi(u^\#) \neq 0$. For example, for $E \in \mathbb{C}^J$ with $\sum E_j \neq 0$, we can fix p through $\langle E, \pi_0 u\rangle_J = c$.

Theorem 1.6 may also be applied to $(f, g) = (0, 0)$, which leads to a certain characterization of $\ker \mathbb{S}$ with prescribed fluxes. It is clear that linear independent vectors $H^1, \dots, H^k \in \mathbb{C}^J$ lead to linear independent solutions $\eta_1, \dots, \eta_k$ of

$$S\eta = 0 \text{ in } \Omega, \quad \eta = 0 \text{ on } \partial\Omega, \quad \pi_1 \eta = H^j, j = 1, \dots, k, \tag{1.30}$$

provided $\sum_{i=1}^{J} H_i^j = 0$. Let $E = (1, \dots, 1)^\top$ and

$$\mathbb{P} = (\mathcal{P}_1, \dots, \mathcal{P}_J) = \mathbb{I} - J^{-1} E \cdot E^\top, \qquad E \cdot E^\top = \begin{pmatrix} 1 & 1 & \dots & 1 \\ 1 & 1 & \dots & 1 \\ \dots & \dots & \dots & \dots \\ 1 & 1 & \dots & 1 \end{pmatrix}$$

denote the matrix associated with the projection P on $\mathbb{C}^J$ with $Pc = c - J^{-1}\langle c, E\rangle_J E$. Let η_j denote the solutions of (1.30) where $H^j = \mathcal{P}_j$ is the jth column of the matrix $\mathbb{P}$; this means η_j carries the flux $1 - 1/J$ through the outlet Q_j and the compensating flux is distributed equally through the other $J - 1$ outlets. By Theorem 1.6,

$$\eta_j = \mathcal{U}^1 \cdot \mathcal{P}_j + \mathcal{U}^0 \cdot \mathcal{Q}_j + \tilde{\eta}_j, \tag{1.31}$$

we can fix the vectors $\mathcal{Q}_j$ by $\langle \mathcal{Q}_j, E\rangle_J = 1$.

Then $\eta_1, \dots, \eta_J$ is a basis of $\ker \mathbb{S}$: It is clear that $\operatorname{rank} \mathbb{P} = \dim \operatorname{span}[\mathcal{P}_1, \dots, \mathcal{P}_j] = J-1$. Moreover, due to the special form of $\mathbb{P}$ any $J-1$ columns are linear independent; thus, any $J-1$ elements of $\{\eta_1, \dots, \eta_J\}$ are linear independent and may be completed by $u^\#$ to a basis of $\ker \mathbb{S}$. On the other hand, due to the choice of $\mathcal{Q}_j$, $j = 1, \dots, J$, we have $\sum_{j=1}^{J} \eta_j = u^\#$; thus, $\eta_1, \dots, \eta_j$ also form a basis of $\ker \mathbb{S}$.

We call the matrix $\mathcal{Q}_\Omega = (\mathcal{Q}_1, \dots, \mathcal{Q}_J)$ the *pressure distribution matrix.*

2. Formulation of the approximation problem. We want to approximate the solution of (1.27) by solutions u^R of Stokes problems on bounded subdomains. For $R > R_0$, we cut each outlet at $z_j = R$ and name the resulting domain Ω_R, i.e.,

$$\Omega_R = \{x \in \Omega_0\} \cup \bigcup_{j=1}^{J} \{x \in Q_j : z_j < R\}.$$

For the boundary $\partial\Omega_R$ we have $\partial\Omega_R = (\partial\Omega_R \cap \partial\Omega) \cup \bigcup_{j=1}^{J} \omega_j \times \{R\}$. We call $\partial\Omega(R)$ the intersection of $\partial\Omega_R$ with $\partial\Omega$, $\Gamma_{R,j} = \omega_j \times \{R\}$ the cross section at $z_j = R$, and $\Gamma_R = \bigcup_{j=1}^{J} \Gamma_{R,j}$; thus, $\partial\Omega_R = \partial\Omega(R) \cup \Gamma_R$. Furthermore, we denote the union of edges by $\partial\Gamma_R$. We define the approximation problem in the following way. We fix a system of cut-off functions $\chi_R(x)$ with $\chi_R(x) = 1$ on Ω_0; for each outlet Q_j, $\chi_R = \chi_R(z_j)$ in local coordinates, and

$$\chi_R(z_j) = 1 \text{ for } z_j \le R - 1, \quad \chi_R(z_j) = 0 \text{ for } z_j \ge R - \frac{1}{2}.$$

We look for $u^R = (v^R, p^R)$ as a solution of

$$Su^R = \chi_R f \text{ in } \Omega_R, \qquad v^R = \chi_R g \text{ on } \partial\Omega(R). \tag{2.1}$$

Then we have $Su^R = 0$ in a neighborhood of the edge. As we will see later, this will help us to increase the smoothness properties of the approximating solutions. We choose the boundary condition on the cut cross section $\Gamma_{R,j}$ in dependence of the main asymptotic term $u^{j1}H_j$, where, as before, H_j denotes the flux of the solution u through the outlet Q_j, and u^{j1} coincides with the Poiseuille flow for z_j large enough, i.e.,

$$B^R u^R = \mathcal{H}(H) \quad \text{on } \Gamma_R. \tag{2.2}$$

In the following section we investigate the formal asymptotic behavior of $u - u^R$ for the Dirichlet operator $Du^R = v^R$, for the Neumann boundary operator $Nu^R = \nabla v^R \cdot \nu - p\nu$, and for the operator $(Fu^R)^\top = (\tau_1^\top \cdot Tu^R \cdot \nu, \tau_2^\top \cdot Tu^R \cdot \nu, v^R \cdot \nu)$, where $T = \nabla v + (\nabla v)^\top - p\mathbb{I}$ is the stress tensor ($\mathbb{I}$ the unit matrix in $\mathbf{R}^3$) and τ_1, τ_2 are linear independent tangential vectors on the cross section. This means in local coordinates (y_j, z_j) we choose $\tau_1^\top = (1,0,0)$ and $\tau_2^\top = (0,1,0)$, while $\nu^\top = (0,0,1)$. F is a combination of the Dirichlet operator and a certain Neumann boundary operator, and is usually related to free boundary problems. We call this boundary operator the mixed boundary operator. While calculating the formal asymptotics we neglect the difficulties arising from the edge. We will prove the existence of u^R in suitable function spaces in section 4.

3. Formal asymptotics.

3.1. The general scheme. For the moment we assume that the boundary $\partial\Omega$ is smooth, the data (f, g) are smooth with compact support, and condition (1.26) holds for $H \in \mathbb{C}^J$. We choose R_0 large enough such that $\operatorname{supp} f \subset \Omega_{R_0}$ and $\operatorname{supp} g \subset \partial\Omega(R_0)$. With the transformation $\tilde{u} = u - \mathcal{U}^1 \cdot H$ we pass to the case of zero fluxes; hence, we may assume that $H = 0$ and

$$\int_\Omega f_4 \,\mathrm{d}x + \int_{\partial\Omega} g \,\mathrm{d}o = 0. \tag{3.1}$$

The condition at infinity changes to $\pi_1 u = 0$. By Theorem 1.6 we obtain a solution u of (1.1) and $\pi_1 u = 0$ which is unique under the condition (1.28). By (1.10) we attain in every fixed outlet Q_j for sufficiently large z the asymptotic expansion in exponential solutions of the homogeneous Stokes system

$$u(y,z) \simeq \sum_{\lambda_\mu} \sum_{k,m} c_\mu^{k,m}(f,g) u_{\lambda_\mu}^{(k,m)}(y,z), \tag{3.2}$$

where the sum is taken over all eigenvalues of the $\mathfrak{S}(\lambda)$, where $\operatorname{Im}\lambda \geq 0$, $u_{\lambda_\mu}^{(k,m)}(y,z)$ are the exponential solutions of order k belonging to the eigenvalue λ_k according to (1.8). If we order the eigenvalues according to the size of their imaginary parts β_k, then $\lambda_0 = 0$ and $c_0^{1,1} = 0$ due to the condition $\pi_1 u = 0$; moreover, $c_0^{0,1} = a_j$ according to (1.21). Let $R > R_0 + 1$ and u^R be a solution of the approximation problem. We suppose that u^R admits an asymptotic expansion into solutions of two-limit problems. We fix $x \in Q_j$, $x = (y,z)$ and put $\xi = (y,\zeta) = (y, z-R)$. Then

$$\begin{aligned} u^R(x) &= u^{(0)}(x) + \chi_j(z) U^{(0)}(\xi) + \mathcal{F}^{(1)}(R)\Big(u^{(1)}(x) + \chi_j(z) U^{(1)}(\xi)\Big) + \dots, \\ &\qquad |\mathcal{F}^{(1)}(R)| = O(e^{(-\beta_1 R)} R^{q_{max}}), \end{aligned} \tag{3.3}$$

where $u^{(0)}$ solves $Su^{(0)} = f$ in Ω, $v^{(0)}|_{\partial\Omega} = g$. q_{max} is determined by the maximal length of all Jordan chains belonging to the eigenvalues λ with $\operatorname{Im}\lambda = \beta_1$. $u^{(k)}$, $k = 1, 2, \dots$ are solutions of the *first limit problem*

$$Sw = \mathfrak{f} \quad \text{in } \Omega, \qquad w'|_{\partial\Omega} = 0. \tag{3.4}$$

$U^{(k)}$ are solutions of the *second limit problem*

$$\begin{aligned} &S_\xi W(\xi) = 0 \quad \text{in } \Pi_j^- = \omega_j \times (-\infty, 0), \quad W' = 0 \text{ on } \partial\omega_j \times (0,\infty) \\ &B_\xi W(\xi) = \mathcal{H} \text{ for } \zeta = 0 \end{aligned} \tag{3.5}$$

with suitable data $\mathfrak{f}$, $\mathcal{H}$. In both cases the superscript "$'$" indicates the velocity part of the solutions, i.e., the first three components.

We explain the main idea how to fix the first terms in (3.3) for the case $J = 1$, i.e., Ω has only one outlet. We choose $u^{(0)} \in \mathbb{D}^l_{\pm\beta} W(\Omega)$ as a solution to the Dirichlet problem (1.1) in Ω. By the transformation $\xi = (y, \zeta)$ with $\zeta = z - R$ we pass to R-independent coordinates and calculate the main asymptotic term of $B_\xi u^{(0)} = -\mathcal{H}^{(0)}$ for $\zeta = 0$ by means of (3.2) (where the first coefficients now need not vanish). We remove this term by putting $u^R = u^{(0)} + \chi(z)U^{(0)}(y, z - R) + \cdots$, where $U^{(0)}$ solves (3.5) with $\mathcal{H} = -\mathcal{H}^{(0)}$ and decays exponentially as $\zeta \to -\infty$. $\chi(z)$ is a cut-off function vanishing for $z > R_0$.

Here we use the fact that the assertions before Theorem 1.6 also hold for the problem (3.5) (see section 5 below). This means, in particular, that the solution of (3.5) can always be found in a class of functions growing exponentially to infinity with $\zeta \to -\infty$. If this growth is not too fast, then (up to multiplication with constants) there exists only one nontrivial solution to the homogeneous problem (3.5). Hence, to find $U^{(0)}$ which decays exponentially as $\zeta \to -\infty$, it is sufficient that $\mathcal{H}^{(0)}$ fulfills one compatibility condition arising from the corresponding Green's formula. This can be achieved by the correct choice of $u^{(0)}$.

It is clear that $v^{(0)} + \chi(z)V^{(0)}(y, z - R) = g$ on $\partial\Omega(R)$. We have

$$S(u^{(0)}(y, z) + \chi(z)U^{(0)})(y, z - R) = f + \tilde{f},$$

where $\tilde{f} = [S, \chi]U^{(0)}$ has a compact support. For $U^{(0)}$ we can again use the expansion (3.2), where the coefficients for $\lambda = 0$ now vanish. Using formula (1.8) for $u^{(k,m)}_{\lambda_\mu}$ gives

$$\tilde{f}(y, z) = e^{(i\lambda_1 R)} f^{(1)}(y, z, R) + O\Big(e^{-(\operatorname{Im}\lambda_2 + \varepsilon)}\Big),$$

and $f^{(1)}$ has the structure $f^{(1)}(y, z, R) = \sum_{q=1}^{q_{max}} R^q f^{(1,q)}(y, z)$. We remove these terms by solutions $u^{(1,q)}$ of (3.4) with $\mathfrak{f} = -f^{(1,q)}$, then calculate again the leading term of $B(u^{(0)} + \chi U^{(0)} + e^{i\lambda_1 R} \sum_q R^q u^{(1,q)})$ for $z = R$, and so on.

If $J > 1$, one has to take into account that $u^{(k)}$ influences all outlets, and the eigenvalues λ_μ for $\lambda \neq 0$ may be different in all outlets. Important for the behavior of $u - u^R$ is the choice of $u^{(0)}$ and the first step in the calculations, which can be done simultaneously in all outlets, since the first eigenvalue, $\lambda = 0$, is the same for all outlets.

3.2. The Dirichlet condition and the mixed boundary condition on the artificial boundary. Let f, g, and u be as in section 3.1. For sufficiently large R let $u^R = (v^R, p^R)$ be a solution to $Su^R = f$ in Ω_R, $v^R = g$ on $\partial\Omega(R)$, and $v^R = 0$ on Γ_R. We outline that u^R exists due to (3.1). We choose $u^{(0)} = u$. To calculate $v^{(0)}|_{z_j = R}$, we use (3.2) and apply the transformation $z = \zeta + R$ to the exponential solutions $u^{(k,m)}_\lambda(y, z)$. With (1.8) it follows that

$$u^{(k,m)}_\lambda(y, z) = e^{i\lambda R} \sum_{q=0}^{k} \frac{1}{q!} (iR)^q u^{(k-q,m)}_\lambda(y, \zeta).$$

For fixed j we obtain

$$v(y, R) = \sum_{\operatorname{Im}\lambda = \beta_1} e^{i\lambda R} \mathcal{M}^{(k,m)}_\lambda(f, g, R) v^{(k,m)}_\lambda(y, 0) + O(e^{(-\beta_2 + \varepsilon)R}).$$

Here the sum is taken over all eigenvalues of $\mathfrak{S}(\lambda)$ on the line $\operatorname{Im}\lambda = \beta_1$, $\beta_1 > 0$. Each $\mathcal{M}_\lambda^{(k,m)}(f,g,R)$ is a polynomial in R containing also the coefficients $c_\mu^{k,m}(f,g)$ of the representation (3.3). Each term in the sum has the form

$$Ce^{-\beta_1 R}\, e^{i\operatorname{Re}\lambda R} R^l v_\lambda^{k_l,m}(y,0) =: e^{-\beta_1 R} R^l \mathcal{H}^{(1,l)}(y) \tag{3.6}$$

with $\beta_1 = \operatorname{Im}\lambda > 0$. Applying the scheme of 3.1, we see that $U^{(0)} = 0$ in each outlet. Moreover, we find solutions $U^{(1,l)}$ to the second limit problem with $\mathcal{H} = \mathcal{H}^{(1,l)}$ decaying exponentially to 0 as $\zeta \to -\infty$: We recall that there exists only one nontrivial solution $U = \binom{V}{P}$ to the homogeneous problem (3.5) with

$$\sup_{\zeta\to-\infty} e^{\beta\zeta} U(y,\zeta) < \infty, \quad 0 < \beta < \beta^*.$$

Then it is clear that this solution $U = (0,0,0,1)^\top = u^\#$. Green's formula (1.7) in Π_j^- leads to the necessary condition

$$\int_{\omega_j} \mathrm{e}_z^\top \cdot H^{(1,l)}(y)\,\mathrm{d}y = 0, \tag{3.7}$$

where $\mathrm{e}_z = (0,0,1)^\top$ is the unit vector in z-direction. Replacing Ω in the same formula by $\omega_j \times [0,t]$, $u = u_\lambda^{(k,m)}$, $U = u^\#$ and passing with $t \to \infty$, we see $\int_{\omega_j} \mathrm{e}_z^\top v_\lambda^{(k,m)}(y,0)\,\mathrm{d}y = 0$ if $\operatorname{Im}\lambda > 0$; thus (3.7) holds.

Now we proceed as in section 3.1 and obtain the formal asymptotic error estimate

$$|u(x) - u^R(x)| = O(e^{-(\beta^*-\varepsilon)R}), \quad \varepsilon > 0 \text{ arbitrary},$$

if we keep in mind that β^* is the mimimum of all imaginary parts of the nonzero eigenvalues in all outlets.

For $Bu^R = Fu^R$ we have to observe the following Green's formula ($Tu = \nabla v + (\nabla v)^\top - p\mathbb{I}$):

$$\begin{aligned}&\int_{\Pi_j^-} S_1 u \cdot U\,\mathrm{d}x + \int_{-\infty}^0 \int_{\partial\omega_j} Tu\cdot\nu\cdot V\,\mathrm{d}o + \int_{\omega_j} Fu(y,0)\cdot F_0 U(y,0)\,\mathrm{d}y\\ &= \int_{\Pi_j^-} u\cdot S_1 U\,\mathrm{d}x + \int_{-\infty}^0 \int_{\partial\omega_j} TU\cdot\nu\cdot v\,\mathrm{d}o + \int_{\omega_j} F_0 u(y,0)\cdot FU(y,0)\,\mathrm{d}y\end{aligned} \tag{3.8}$$

with

$$S_1 u = \begin{pmatrix} -\Delta v - \nabla\operatorname{div} v + \nabla p \\ -\operatorname{div} v \end{pmatrix}, \quad F_0 u = (v_\tau, -\nu^\top \cdot Tu\cdot\nu).$$

The solution to the homogeneous second limit problem is again $u^\#$; thus Green's formula (3.8) leads to the same compatibility conditions, and we may use analogous calculations as for the Dirichlet operator.

3.3. The Neumann condition on the artificial boundary. Now let $u^R = \binom{v^R}{p^R}$ be a solution of

$$Su^R = f \text{ in } \Omega_R, \quad v^R = g \text{ on } \partial\Omega(R), \quad Nu^R = (\nabla v^R - p\mathbb{I})\cdot\nu = 0 \text{ on } \Gamma_R.$$

Let $j \in \{1, \dots, J\}$ and $x = (y, z) \in Q_j$ be fixed with $z > R_0$. If we put $u^{(0)} = u$, then to apply the scheme developed above, we use the expansion (3.2) and achieve

$$u(x) = \mathcal{U}^0 \cdot a + \sum_{\operatorname{Im}\lambda=\beta_1} e^{-\beta_1 z} \cdots + \cdots \tag{3.9}$$

with $a = (a_1, \dots, a_J) = \pi_0 u$. For $z = R$ this leads to

$$Nu(y, R) = \partial_z v(y, R) - p(y, R)\mathrm{e}_z = a_j + O(e^{-(\beta_1 - \varepsilon)R})$$

with some arbitrary small but in general positive ε. In order to remove the term a_j on $\Gamma_{R,j}$, $U^{(0)} = (V^{(1)}, P^{(1)})$ has to be a solution of (3.5) with

$$N_\xi U^{(0)}(\xi) = a_j \tag{3.10}$$

with $\xi = (y, z - R)$; (y, z) are the local coordinates in the outlet Q_j. If we choose $U^{(0)}(\xi) = u^{j0}(\xi)a_j$ in every outlet, then extending $\chi_j U^{(0)}$ by zero to $x \notin Q_j$ and substituting $\chi_j U^{(0)}$ into formula (3.3), we see that $u^{(1)}$ has to solve (3.4) with $\mathfrak{f} = \sum_j S(\chi_j U^{(0)})$. This gives $u^{(1)} = \mathcal{U}^0 \cdot a$ and we arrive again at the second limit problem with condition (3.10).

For this reason we have to find $U^{(0)}(\xi)$ in a class of functions where the velocity part $V^{(0)}$ and the pressure part $P^{(1)}$, together with all derivatives, exponentially die to 0 as $\zeta \to -\infty$, i.e.,

$$\sup_{\zeta<-1} e^{-\beta\zeta} |\partial^\alpha U^{(0)}(y, \zeta)| < \infty \qquad \text{for } 0 < \beta < \beta^*,$$

where β^* has the same meaning as in 1.3. Using Green's formula (1.7) in Π_j^-, we find that this implies

$$\int_{\omega_j(0)} NU^{(0)} \cdot V \, \mathrm{d}o = \int_{\omega_j} a_j V_3(y, 0) \, \mathrm{d}y = 0 \tag{3.11}$$

for any solution $U = (V, P)$ of

$$SU = 0 \text{ in } \Pi_j^-, \qquad V = 0 \text{ on } \partial\omega_j \times (-\infty, 0), \qquad NU = 0 \text{ for } \zeta = 0 \tag{3.12}$$

with $V \in H^2_{loc}(\overline{\Omega})$, $P \in H^1_{loc}(\overline{\Omega})$, and

$$\sup_{\zeta<-1} e^{\beta'\zeta} |\partial^\alpha V(y, \zeta)| < \infty \tag{3.13}$$

for some $\beta' < \beta$, $\alpha \in \mathbf{N}_0^3$. As already mentioned, up to multiplication with constants there exists only one nontrivial solution to (3.12) and (3.13), which is the Poiseuille flow in this case. From this result we see that only for $J = 1$, i.e., if the domain has only one outlet, can (3.11) be fulfilled through the change of the normalization condition (1.28) to $a_1 = 0$; whereas for $J \geq 2$, only $\sum_{j=1}^J a_j = 0$ is possible according to Remark 1.7. Thus we change $u^{(0)}$ to $u^{(0)} = u + \eta \cdot c$; $c = c(R) \in \mathbb{C}^J$ has to be chosen properly; $\eta(x)$ is the $4 \times J-$matrix with columns η_j, where η_j are the special solutions of the homogeneous Stokes problem defined in Remark 1.7. Using the representation (3.9) for u and (1.31) for η, we obtain

$$u^{(0)} = \mathcal{U}^1 \cdot \mathbb{P} \cdot c + \mathcal{U}^0 \cdot (a + \mathcal{Q}_\Omega \cdot c) + \tilde{u}, \tag{3.14}$$

where $\tilde{u}$ decays exponentially. To calculate the leading term of $Nu^{(0)}$ on Γ_R, we fix one outlet Q_j and rewrite (3.14) in ξ-coordinates, $\xi = (y, z - R)$; this gives

$$u^{(0)}(\xi) = \left[u^{j1}(\xi)(\mathbb{P}\cdot c)_j + u^{j0}\left(a_j + (\mathcal{Q}_\Omega \cdot c)_j - 2\varpi_j R(\mathbb{P}\cdot c)_j\right)\right] + \tilde{\tilde{u}}\,.$$

The term $-2\varpi_j R(\mathbb{P}\cdot c)_j$ appears because $u^{j1}(y,z) = u^{j1}(\xi) - 2\varpi_j(0,0,0,R)$. So the main discrepancy at $\xi = 0$ is produced by $N[\ldots]$, and we look for $U^{(0)}$ as a solution of (3.5) whereas the boundary condition (3.10) changes to

$$N_\xi U^{(0)}(\xi) = -N_\xi\left[u^{j1}(y,0)(\mathbb{P}\cdot c)_j + u^{j0}(a_j + (\mathcal{Q}_\Omega\cdot c)_j - 2\varpi_j R(\mathbb{P}\cdot c)_j)\right] =: \mathcal{H}^j_{(1)}(y).$$

The boundary operator annuls the first term on the right-hand side, hence $N_\xi u^{(0)}(\xi) = 0$ if $a_j + (\mathcal{Q}_\Omega\cdot c)_j - 2\varpi_j R(\mathbb{P}\cdot c)_j = 0$. This condition has to be accomplished in every outlet Q_j, so we arrive at a linear system for $c \in \mathbb{C}^J$:

$$-\mathcal{Q}_\Omega\cdot c + 2\varpi_j R\mathbb{P}\cdot c = a. \tag{3.15}$$

To show the solvability of this system, we substitute

$$c = \mathbb{P}\cdot c + c_E E \text{ with } c_E = J^{-1}\langle c, E\rangle_J, \quad E = (1,\ldots,1)^\top \tag{3.16}$$

into (3.15), remembering the choice of $\mathcal{Q}_j$; this leads to

$$-\mathcal{Q}_\Omega\cdot\mathbb{P}\cdot c - c_E E + 2\varpi_j R\mathbb{P}\cdot c = a. \tag{3.17}$$

We apply $\mathbb{P}$ to this system and obtain

$$-\mathbb{P}\cdot\mathcal{Q}_\Omega\cdot\mathbb{P}\cdot c + 2\varpi_j R\mathbb{P}\cdot c = \mathbb{P}a$$

because $\mathbb{P}^2 = \mathbb{P}$. Since $\mathbb{P}$ gives the identity on $\mathbb{P}\mathbb{C}^J$, this system is uniquely solvable in $\mathbb{P}\mathbb{C}^J$ for sufficiently large R. Now we multiply (3.17) scalar by E. Using the symmetry of $\mathcal{Q}_\Omega$ together with (3.16) we calculate $c_E = -J^{-1}\langle a, E\rangle_J$, and thus prove the unique solvability of (3.15).

We have

$$c_E = const, \quad \mathbb{P}c(R) = O(R^{-1}) \qquad \text{as } R\to\infty. \tag{3.18}$$

With this choice of c we find $U^{(0)}$ in each outlet such that

$$S\Big(\chi_j(z)U^{(0)}\Big)(y, z-R) = O(e^{-\beta_1 R}R^{q(j)})$$

and we proceed as indicated in section 3.1. As a result, we obtain

$$|u(x) - u^R(x)| = |\eta\cdot c(R)(x)| + O(e^{-(\beta^*-\varepsilon)R}) = O(1).$$

If the normalization condition $\langle a, E\rangle_J = 0$ is chosen, then the previous calculations lead to $c_E = 0$ and $|u - u^R(x)| = O(R^{-1})$.

4. Solution of the approximation problem. The aim of the following sections is to prove the existence of solutions u^R to the approximation problem and the error estimate for $u - u^R$ which justifies the formal asymptotic estimates rigorously. We carry out the proofs for the mixed boundary condition on the artificial boundary Γ_R, since this condition gives the best regularity properties of the approximating solutions (see Theorem 4.4 below).

For the approximation problem itself, it is possible to prove the existence of a solution $u^R \in \mathcal{D}^l H(\Omega_R) = H^{l+1}(\Omega_R)^3 \times H^l(\Omega_R)$ with comparably elementary methods. However, to obtain an error estimate for the difference $u - u^R$, it is necessary to prove the existence of solutions and uniform estimates for the problem

$$SU = f \text{ in } \Omega_R, \tag{4.1}$$

$$V = g \text{ on } \partial\Omega(R), \qquad FU = h \text{ on } \Gamma_R, \tag{4.2}$$

where (f, g, h) are general data in suitable function spaces. If we look for a solution $U \in H^2(\Omega_R)^3 \times H^1(\Omega_R)$ at least, then f_4, g, h have to fulfill the necessary condition arising from the Gauss theorem:

$$\int_{\Omega_R} f_4 \,\mathrm{d}x + \int_{\partial\Omega(R)} \nu^\top \cdot g \,\mathrm{d}o + \int_{\Gamma_R} \nu^\top \cdot h \,\mathrm{d}o = 0. \tag{4.3}$$

It is clear that if $u \in \mathbb{D}^l_{\pm\beta}(\Omega)$ is a solution to the Stokes problem with prescribed fluxes and $u^R \in \mathcal{D}^l H(\Omega_R)$ is a solution to the approximation problem, then the difference $U = u - u^R \in \mathcal{D}^l H(\Omega_R)$ fulfills (4.1), (4.2) with $f' \in H^{l-1}(\Omega_R)^3$, $f_4 \in H^l(\Omega_R)$, $g \in H^{l+1/2}(\partial\Omega(R))^3$, and $h \in H^{l-1/2}(\Gamma_R)^2 \times H^{l+1/2}(\Gamma_R)$. (The notation for h must be read in local coordinates of the outlet Q_j.) On the other hand, it is obvious that even for $l = 1$ we cannot obtain a solution $U \in \mathcal{D}^1 H(\Omega_R)$ of (4.1), (4.2) for arbitrary data $(f, g, h) \in \mathcal{R}^1 H(\Omega_R, \partial\Omega(R), \Gamma_R)$, even if (4.3) is satisfied. In a 3-dimensional domain the velocity part V of this solution would be continuous up to the boundary, and hence also on the edges of Ω_R, which would force additional compatibility conditions for the data. Thus, the general problem (4.1), (4.2) has to be treated in weighted spaces with weights $\sim \rho^\gamma$, where $\rho(x) = \mathrm{dist}(x, \partial\Gamma_R)$ in the vicinity of $\partial\Gamma_R$.

Since $\partial\Gamma_R$ is a disjoint union of 1-dimensional C^{l+2}-manifolds, we find $\varepsilon_0 > 0$ such that $\mathrm{dist}(x, \partial\Gamma_R)$ is of class C^{l+2} on $\mathcal{O}_{\varepsilon_0}(\Gamma_R) = \{x, \mathrm{dist}(x, \Gamma_R) < \varepsilon_0\}$. We choose a basic weight function $\rho \in C^{l+2}(\Omega_R)$ with $\rho(x) = \mathrm{dist}(x, \partial\Gamma_R)$ for $x \in \mathcal{O}_{\varepsilon_0} \cap \Omega_R$, and $\rho(x) = 1$ for $x \in \Omega_{R-2\varepsilon_0}$ and introduce spaces of Kondratiev's type on Ω_R.

Definition 4.1. *Let $l \in \mathbf{N}_0$, $\gamma \in \mathbf{R}$, $\varphi \in C_0^\infty(\overline{\Omega}_R \backslash \partial\Gamma_R)$. We set*

$$\|\varphi; V^l_\gamma(\Omega_R, \partial\Gamma_R)\| = \sum_{|\alpha| \le l} \left(\|\rho^{\gamma - l + |\alpha|} \partial^\alpha \varphi; L^2(\Omega_R)\|^2 \right)^{1/2} \tag{4.4}$$

and $V^l_\gamma(\Omega_R, \partial\Gamma_R)$ the closure of $C_0^\infty(\overline{\Omega}_R \backslash \partial\Gamma_R)$ in the norm (4.4).

By $V^{l-1/2}_\gamma(\partial\Omega(R), \partial\Gamma_R)$ and $V^{l-1/2}_\gamma(\Gamma_R, \partial\Gamma_R)$ we denote the spaces of traces on $\partial\Omega(R)$ and Γ_R. We define

$$\|\varphi; V^{l-1/2}_\gamma(M, \partial\Gamma_R)\| = \inf \|\tilde{\varphi}; V^l_\gamma(\Omega_R, \partial\Gamma_R)\|$$

for $M = \partial\Omega(R)$ and $M = \Gamma_R$, where the infimum is taken over all $\tilde{\varphi} \in V^l_\gamma(\Omega_R, \partial\Gamma_R)$ with $\tilde{\varphi}|_M = \varphi$.

$V^l_\gamma(\Omega_R, \partial\Gamma_R)$ coincides with the space of all functions

$$\{\varphi \in H^l_{loc}(\Omega_R); \|\varphi; V^l_\gamma(\Omega_R, \partial\Gamma_R)\| < \infty\}$$

and thus is a space of regular distributions on Ω_R. The trace space $V^{l-1/2}_\gamma(\Gamma_R, \partial\Gamma_R)$ is the union of the traces on the J cross sections $\Gamma_{R,j} = \Gamma_R \cap Q_j$, where the weight

$\rho(x) = \operatorname{dist}(x, \partial\omega_j \times \{R\})$ in the ε_0-neighborhood of $\partial\omega_j \times \{R\}$. Thus we denote the trace spaces on the cross section $\omega_j \times \{R\}$ by $V_\gamma^{l-1/2}(\omega_j(R), \partial\omega_j)$.

Analogous to the previous section we define the natural domain and range of the problem (4.1), (4.2),

$$\begin{aligned}
\mathcal{D}_\gamma^l V(\Omega_R) &= V_\gamma^{l+1}(\Omega_R, \partial\Gamma_R)^3 \times V_\gamma^l(\Omega_R, \partial\Gamma_R),\\
\mathcal{R}_\gamma^l V(\Omega_R) &= V_\gamma^{l-1}(\Omega_R, \partial\Gamma_R)^3 \times V_\gamma^l(\Omega_R, \partial\Gamma_R),\\
\mathcal{R}_\gamma^l V(\Omega_R, \partial\Omega(R), \Gamma_R) &= \mathcal{R}_\gamma^l V(\Omega_R) \times V_\gamma^{l+1/2}(\partial\Omega(R), \partial\Gamma_R)^3\\
&\quad \times \prod_{j=1}^J V_\gamma^{l-1/2}(\omega_j(R), \partial\omega_j)^2 \times V_\gamma^{l+1/2}(\omega_j(R), \partial\omega_j).
\end{aligned} \tag{4.5}$$

Then the operator

$$\begin{aligned}
(S, D, F) : \mathcal{D}_\gamma^l V(\Omega_R) &\to \mathcal{R}_\gamma^l V(\Omega_R, \partial\Omega(R), \Gamma_R),\\
u &\mapsto (Su, v|_{\partial\Omega(R)}, Fu|_{\Gamma_{R,j}}, j = 1, \dots, J)
\end{aligned} \tag{4.6}$$

defines a continuous linear operator. Here the notation

$$Fu|_{\Gamma_{R,j}} \in V_\gamma^{l-1/2}(\omega_j(R), \partial\omega_j(R))^2 \times V_\gamma^{l+1/2}(\omega_j(R), \partial\omega_j(R))$$

has to be understood in the local coordinates of Q_j:

$$\partial_{y_i} v_3 - \partial_z v_i \in V_\gamma^{l-1/2}(\omega_j(R), \partial\omega_j(R)) \text{ and } v_3 \in V_\gamma^{l+1/2}(\omega_j(R), \partial\omega_j(R)).$$

To derive Fredholm properties of the mapping (4.6) at least for γ in a certain bounded interval, we have to combine results from the general theory of elliptic systems in domains with smooth edges with results which are already known for the problem (4.1), (4.2).

THEOREM 4.2. *Let $l \in \mathbf{N}$, $\partial\Omega \in C^{l+2}$, $\gamma \in \mathbf{R}$. The operator (S, D, F) defined by (4.6) is Fredholm for $|\gamma - l| < 1$. For $(f, g, h) \in \mathcal{R}_\gamma^l V(\Omega_R, \partial\Omega(R), \Gamma_R)$ there exists a solution to the problem (4.1), (4.2) iff*

$$\int_{\Omega_R} f_4 \,\mathrm{d}x + \int_{\partial\Omega(R)} \nu^\top \cdot g \,\mathrm{d}o + \int_{\Gamma_R} \nu^\top \cdot h \,\mathrm{d}o = 0. \tag{4.7}$$

The solution is unique up to a constant in pressure and thus obeys the following estimate:

$$\|u; \mathcal{D}_\gamma^l V(\Omega_R)\| \le C\Big(\|(f, g, h); \mathcal{R}_\gamma^l V(\Omega_R, \partial\Omega(R), \Gamma_R)\| + \|p; L^2(G_0)\|\Big), \tag{4.8}$$

where G_0 is an arbitrary nonvoid subdomain of Ω_R and $C = C(R, \Omega, l)$ is a constant.

Proof. The domain Ω_R is a bounded domain with a smooth edge $\partial\Gamma_R$. This means for every $x_0 \in \partial\Gamma_R$ there exists a neighborhood $\mathcal{O}(x_0)$ and a C^{l+2}- diffeomorphism $\Phi : \mathcal{O} \to \mathcal{O}'(0)$ ($\mathcal{O}'(0)$ is a neighborhood of 0) such that $\Phi(\mathcal{O} \cap \Omega_R) = \mathcal{O}'(0) \cap \mathbb{D}$, $\mathbb{D} = d_{\pi/2} \times \mathbf{R}$ is an infinite wedge, $d_{\pi/2} = \{x = (r, \theta) \in \mathbf{R}^2 : 0 < r < \infty, 0 < \theta < \pi/2\}$. The treatise of the boundary value problem (4.1), (4.2) in Ω_R is connected to the analysis of the model problem in the wedge $\mathbb{D}$ which takes the following form:

$$Su(x) = f(x) \quad \text{for } x \in \mathbb{D} = d_{\pi/2} \times \mathbf{R}, \tag{4.9}$$

$$Du(x) = v(x) = g(x_2, x_3) \quad \text{for } x_1 = 0, \tag{4.10}$$

$$Fu = \left(\frac{\partial v_2}{\partial x_1} + \frac{\partial v_1}{\partial x_2}, -v_2, \frac{\partial v_3}{\partial x_2}\right)(x) = h(x_1, x_3) \quad \text{for } x_2 = 0. \tag{4.11}$$

We set $\Gamma^D = \{0\} \times \mathbf{R}^+ \times \mathbf{R}$, which corresponds to the lateral surface $\partial\Omega(R)$, and $\Gamma^F = \mathbf{R}^+ \times \{0\} \times \mathbf{R}$, which corresponds to the artificial boundary Γ_R. The union of edges, $\partial\Gamma_R$, corresponds to the infinite edge $M' = \{0\} \times \{0\} \times \mathbf{R}$.

In $\mathbb{D}$ let $\rho(x) = (x_1^2 + x_2^2)^{1/2}$, i.e., for all $x \in \mathbb{D}$, $\rho(x)$ is the distance of x to the edge M'; let $V_\gamma^l(\mathbb{D}, M')$ be defined as in Definition 4.1. We introduce the natural domain and range $\mathcal{D}_\gamma^l V(\mathbb{D})$ and $\mathcal{R}_\gamma^l V(\mathbb{D}, \Gamma^D, \Gamma^F)$ in an analogous way as in (4.5). Then the operator $(S, D, F) : \mathcal{D}_\gamma^l V(\mathbb{D}, M') \to \mathcal{R}_\gamma^l V(\mathbb{D}, \Gamma^D, \Gamma^F)$ defines an isomorphism for $|\gamma - l| < 1$. This was proved for $0 \le \gamma - l < 1$ in [49] and [32]. For $-1 < \gamma - l < 0$ it follows from Proposition 8.2.8 of [33] together with [49, pp. 353, 402] concerning the eigenvalues of the associated 2-dimensional problems in the angle $d_{\pi/2}$.

Theorem 8.3.1 in [33] now gives the Fredholm property of the mapping (4.6) for $|\gamma - l| < 1$. Moreover, from the proof of this theorem it follows that kernel and cokernel of (4.6) are independent of γ and l in this interval. Since $Su = f$ iff

$$S_1 u := (-\Delta v - \nabla \operatorname{div} v + \nabla p, -\operatorname{div} v) = (f' + \nabla f_4, f_4),$$

the same is valid for the operator

$$\mathbb{S}_\gamma^l : \mathcal{D}_\gamma^l V(\Omega_R) \ni u \to (S_1 u, v|_{\partial\Omega(R)}, Fu|_{\Gamma_R}) \in \mathcal{R}_\gamma^l V(\Omega_R, \partial\Omega(R), \Gamma_R).$$

The operator (S_1, D, F) is formally self-adjoint with respect to Green's formula

$$\begin{aligned} &(S_1 u, U)_{\Omega_R} + (v, N_1 U)_{\partial\Omega(R)} + (Fu, F_0 U)_{\Gamma_R} \\ &= (u, S_1 U)_{\Omega_R} + (N_1 u, V)_{\partial\Omega(R)} + (F_0 u, FU)_{\Gamma_R}, \end{aligned} \tag{4.12}$$

where $N_1 u = Tu \cdot \nu$ and, as in section 3.2, $(F_0 u)^\top = (v_\tau, -\nu^\top \cdot N_1 u)$. (4.12) is valid for $u \in \mathcal{D}_\gamma^l V(\Omega_R)$ and $U \in \mathcal{D}_{2l-\gamma}^l V(\Omega_R)$. (We note that for $|\gamma - l| < 1$ also $|(2l - \gamma) - l| < 1$ holds.) Therefore, Theorem 8.3.3 in [33] leads to $\operatorname{Ind} \mathbb{S}_\gamma^l = 0$, and it remains to calculate the kernel of $\mathbb{S}_\gamma^l$ for one exponent γ such that $|\gamma - l| < 1$, for example, for $\gamma = l$. We fix $u = (v, p) \in \mathcal{D}_l^l V(\Omega_R)$ such that $(S_1, D, F)u = (S, D, F)u = 0$. In this case we have $\nabla v \in L^2(\Omega_R)$ and $p \in L^2(\Omega_R)$. Since $v = 0$ on $\partial\Omega(R)$ we may apply Poincaré's inequality and obtain $v \in H^1(\Omega_R)$. Multiplying the equation $S_1 u = 0$ scalar (in $L^2(\Omega_R)$) by u, then using integration by parts and the boundary conditions, leads to $v = 0$ and $p = \text{const}$. Since the function $p \equiv 1$ is contained in V_γ^l for all γ with $\gamma - l > -1$, we have $\ker \mathbb{S}_\gamma^l = \{(0, 0, 0, c) : c \in \mathbf{R}\}$. Now the necessity of condition (4.7) follows from (4.12) and the sufficiency from $\operatorname{Ind} \mathbb{S}_\gamma^l = 0$. □

Remark 4.3. The other boundary conditions on the cut cross sections Γ_R mentioned in section 3 can be treated exactly along the same scheme; only the admissible intervals for the weight index γ are different.

We apply Theorem 4.2 to prove the existence of solutions to the approximation problem.

THEOREM 4.4. *Let $l \in \mathbf{N}$, $\partial\Omega \in C^{l+2}$, let $f \in H^{l-1}(\Omega)^3 \times H^l(\Omega)$, $g \in H^{l+1/2}(\partial\Omega)$, and $H \in \mathbb{C}^J$ be given such that $\int_\Omega |f_4| \, dx + \int_{\partial\Omega} |\nu \cdot g| \, do < \infty$, and the compatibility condition*

$$\int_\Omega f_4 \, dx + \int_{\partial\Omega} \nu^\top \cdot g \, do + \sum_{j=1}^J H_j = 0 \tag{4.13}$$

is fulfilled. Let $\{\chi_R\}_{R>1}$ be a system of cut-off functions with the following properties: $\chi_R(x) = \chi_R(z_j)$ in each outlet Q_j, $\chi_R(x) = 1$ for $x \in \Omega_0$ and for $x = (y_j, z_j)$

with $z_j < R-1$, *and* $\chi_R(y_j,z_j)=0$ *for* $z_j > R-1/2$. *Let* $\mathcal{U}^1$ *be defined as in section* 1.2, *i.e.,* $\mathcal{U}^1 = \binom{\mathcal{V}^1}{\mathcal{P}^1}$, $\mathcal{V}^1$ *is the* $3\times J$*-matrix with rows* $\chi_j v^{j1}$, $j=1,\dots,J$; $\mathcal{P}^1=(\chi_1 p^{j1},\dots,\chi_J p^{J1})$, *and* $u^{j1}=\binom{v^{j1}}{p^{j1}}$ *indicates the Poiseuille flow in the outlet* Qj.

Then there exists a unique solution $u^R=(v^R,p^R)$ *with* $v^R\in H^{l+1}(\Omega_R)^3$, $p^R\in H^l(\Omega_R)$ *to the approximation problem*

$$Su^R = \chi_R f \quad \text{in } \Omega_R \tag{4.14}$$

$$v^R = \chi_R g \quad \text{on } \partial\Omega(R) \tag{4.15}$$

$$Fu^R = F(\mathcal{U}^1\cdot(H+H_\infty)) \quad \text{on } \Gamma_R \tag{4.16}$$

$$\int_{G_0} p^R \,\mathrm{d}o = 0, \tag{4.17}$$

where $H_\infty^\top=(H_{\infty,1},\dots,H_{\infty,J})\in\mathbb{C}^J$ *with*

$$H_{\infty,j}=\int_{Q_j}(1-\chi_R)(z_j)f_4(y_j,z_j)\,\mathrm{d}y_j\,\mathrm{d}z_j+\int_{\partial Q_j}\nu^\top\cdot(1-\chi_R)(z_j)g(y_j,z_j)\,\mathrm{d}o,$$

and $G_0\subset\Omega_0$ *is a nonvoid subdomain such that* $G_0\cap Q_j=\emptyset$ *for* $j=1,\dots,J$.

Remark 4.5. The integrability conditions for f_4 and g look artificial, but they are fulfilled if the data meet the conditions of Theorem 1.6 or, trivially, if $f_4=0$ and $g=0$. Thus we can use this result to approximate the solution $u\in\mathbb{D}^l_{\pm\beta}W(\Omega)$ for exponentially dying data as well as for weak solutions with zero boundary values and $f=\binom{f'}{0}$.

Proof of Theorem 4.4. First of all, it is easy to see that $\chi_R f\in\mathcal{R}^l_\gamma V(\Omega_R)$, $\chi_R g\in V^{l+1/2}_\gamma(\partial\Omega(R))$ for all $\gamma\in\mathbf{R}$, since the support is separated from the edges $\partial\Gamma_R$. For the boundary values on Γ_R we have to use more subtle arguments, which are collected in the following lemma.

LEMMA 4.6. *Suppose* $w\in H^l(\Omega_R)$ *and* $w=0$ *on* $\partial\Omega(R)\cap\mathcal{O}$, *where* $\mathcal{O}$ *is a neighborhood of* $\partial\Gamma_R$. *Then* $w\in V^l_\gamma(\Omega_R)$ *for all* $\gamma-l\geq -1$.

Proof (see also [33, p. 31] for the 2-dimensional case). Because $V^l_{\bar\gamma}(\Omega_R)\supset V^l_\gamma(\Omega_R)$ for $\bar\gamma>\gamma$, it is sufficient to prove $w\in V^l_{l-1}(\Omega_R)$. Since $w\in H^l(\Omega_R)$ we have

$$\|\partial^\alpha w;V^0_{-1+|\alpha|}(\Omega_R)\|\leq C\sup_{x\in\mathcal{O}\cap\Omega_R}\rho(x)^{-1+|\alpha|}\|\partial^\alpha w;L^2(\Omega_R)\|<\infty$$

for all $1\leq|\alpha|\leq l$. It remains to show $w\in V^0_{-1}(\Omega_R)$. We choose a covering $\{\mathcal{O}_\mu\}_{\mu=1}^N$ of Ω_R such that $\bigcup_{\mu=1}^N\mathcal{O}_\mu$ covers the edges $\partial\Gamma_R$ and C^l-diffeomorphisms Φ_μ, such that $\Phi_\mu(\mathcal{O}_\mu)=\mathbb{D}\cap Z(T)$ for some $T>0$. Here $Z(T)=\{(x_2,x_2,x_3);x_1^2+x_2^2<T^2,-T<x_3<T\}$ is a circular cylinder. Moreover, we suppose $\Phi_\mu(\mathcal{O}_\mu\cap\partial\Omega(R))\subset\Gamma^D$ and $\Phi_\mu(\mathcal{O}_\mu\cap\Gamma_R)\subset\Gamma^F$ (see the notations in the proof of Theorem 4.2). Let χ_μ be a partition of unity subordinated to the covering $\{\mathcal{O}_\mu\}_\mu$. Then $w\in V^0_{-1}(\Omega_R)$ is equivalent to $\tilde w:=\chi_\mu w\circ\Phi_\mu^{-1}\in V^0_{-1}(\mathbb{D})$ for every μ. We have $\chi_\mu w\circ\Phi_\mu^{-1}\in H^1(\mathbb{D}\cap B(0,T))$, moreover, $\chi_\mu w\circ\Phi_\mu^{-1}=0$ on Γ^D. We use polar coordinates (ρ,θ) on $d_{\pi/2}$, then with Friedrichs' inequality we arrive at

$$\begin{aligned}\int_{\mathbb{D}\cap Z(T)}|\nabla\tilde w|^2\,\mathrm{d}x&\geq\int_0^T\int_0^T\int_0^{\pi/2}|\partial_\theta\tilde w|^2\rho^{-1}\,\mathrm{d}\theta\,\mathrm{d}\rho\,\mathrm{d}x_3\\&\geq\int_0^T\int_0^T\int_0^{\pi/2}|\tilde w|^2\rho^{-1}\,\mathrm{d}\theta\,\mathrm{d}\rho\,\mathrm{d}x_3=\int_{\mathbb{D}\cap Z(T)}|\tilde w|^2\rho^{-2}\,\mathrm{d}x,\end{aligned}$$

which proves the lemma. □

Using this result, we obtain $\mathcal{U}^1 \cdot A|_{\Omega_R} \in \mathcal{D}_l^l(\Omega_R)$ for every $A \in \mathbb{C}^J$; thus $F(\mathcal{U}^1 \cdot (H + H_\infty))$ is contained in the corresponding trace space. With Theorem 4.2 we obtain a solution $u \in \mathcal{D}_l^l V(\Omega_R)$ to the approximation problem; it is clear then that it is possible to fix the constant in pressure by condition (4.17).

It remains to verify the regularity property. From the definition of $\mathcal{D}_l^l V(\Omega_R)$ we know already that $u^R \in H^{l+1}(\Omega_{R-\varepsilon})^3 \times H^l(\Omega_{R-\varepsilon})$; moreover, $\nabla v^R \in L^2(\Omega_R)$ and $p^R \in L^2(\Omega_R)$. It remains to treat a neighborhood $\Omega_R \backslash \Omega_{R-\varepsilon}$ of the edges $\partial\Gamma_R$. Since $\nabla v^R \in L^2(\Omega_R)$ and $v^R|_{\partial\Omega(R)} = 0$ in a neighborhood of the edges, we can apply Poincaré's inequality on the cross sections ω_j and integrate with respect to z_j to see $v^R \in L^2(\Omega_R)$. Since the Poiseuille flow $\mathcal{U}^1 \cdot (H + H_\infty)$ is smooth, i.e., $\mathcal{U}^1 \cdot (H + H_\infty) \in \mathcal{D}^l H(\Omega_R)$, we prove the regularity of $U = u^R - \mathcal{U}^1 \cdot (H + H_\infty)$ in $\Omega_R \backslash \Omega_{R-\varepsilon}$.

We fix a single outlet Q_j with the cross section ω_j, together with the local coordinates (y, z) and $\varepsilon < 1/2$. Then $U = \binom{V}{P}$ fulfills

$$\begin{aligned} SU = 0 \text{ in } \omega_j \times (R-\varepsilon, R), \quad V = 0 \text{ on } \partial\omega_j \times (R-\varepsilon, R), \\ FU = 0 \quad \text{for } z = R. \end{aligned} \tag{4.18}$$

We use the transformation $z \to \zeta = z - R$. If we observe the representation of V in local coordinates, i.e., $V = V_1 \mathrm{e}_1 + V_2 \mathrm{e}_2 + V_3 \mathrm{e}_z$ where e_1, e_2 are the unit vectors in y_1, y_2-direction, and e_z in the direction of the cylinder axis, respectively, then (4.18) is equivalent to

$$SU(y, \zeta) = 0 \quad \text{for } (y, \zeta) \in \omega_j \times (-\varepsilon, 0), \tag{4.19}$$

$$V(y, \zeta) = 0 \quad \text{for } (y, \zeta) \in \partial\omega_j \times (-\varepsilon, 0) \tag{4.20}$$

together with the boundary condition on the cross section in local coordinates:

$$V_3(y, 0) = 0, \tag{4.21}$$

$$\partial_1 V_3(y, 0) + \partial_z V_1(y, 0) = \partial_z V_1(y, 0) = 0,$$

$$\partial_2 V_3(y, 0) + \partial_z V_2(y, 0) = \partial_z V_2(y, 0) = 0. \tag{4.22}$$

Now we extend U on $Q_\varepsilon = \omega_j \times (-\varepsilon, \varepsilon)$, namely V_1, V_2, and P even, i.e., $U_i(y, \zeta) = U_i(y, -\zeta)$, $i = 1, 2, 4$, and V_3 odd, i.e., $V_3(y, \zeta) = -V_3(y, -\zeta)$. Then $V(y, \zeta) = 0$ for $y \in \partial\omega_j$, $|\zeta| < \varepsilon$. It is clear that $U \in L^2(Q_\varepsilon)^4$ and $S(U)$ exists as a distribution (on Q_ε), which is regular on $Q_\varepsilon^- = \omega_j \times (-\varepsilon, 0)$ and on $Q_\varepsilon^+ = \omega_j \times (0, \varepsilon)$. We see $SU = 0$ on Q_ε^- and on Q_ε^+ by elementary calculations. We show that no additional terms appear on the cross section $\omega_j \times \{0\}$. For this purpose we choose (a real valued) $\varphi \in C_0^\infty(Q_\varepsilon)$; we denote by $-\langle \operatorname{div} V, \varphi \rangle_{Q_\varepsilon}$ the application of the distribution $-\operatorname{div} V$ on φ. By definition,

$$-\langle \operatorname{div} V, \varphi \rangle_{Q_\varepsilon} = (V, \nabla\varphi)_{Q_\varepsilon} = (V, \nabla\varphi)_{Q_\varepsilon^-} + (V, \nabla\varphi)_{Q_\varepsilon^+}.$$

To each integral we apply the Gauss theorem. Observing that $\varphi = 0$ on ∂Q_ε and $\lim_{\zeta \to 0^+} V_3(y, \zeta) = \lim_{\zeta \to 0^-} V_3(y, \zeta) = 0$ in the trace sense, we obtain

$$\begin{aligned} -\langle \operatorname{div} V, \varphi \rangle_{Q_\varepsilon} &= -\int_{Q_\varepsilon^-} \operatorname{div} V \varphi \, \mathrm{d}x + \int_{\omega_j} V_3(y, 0) \varphi(y, 0) \, \mathrm{d}y \\ &- \int_{Q_\varepsilon^+} \operatorname{div} V \varphi \, \mathrm{d}x + \int_{\omega_j} \lim_{\zeta \to 0^+} V_3(y, \zeta) \varphi(y, \zeta) \, \mathrm{d}y = 0; \end{aligned}$$

hence div $V = 0$ on Q_ε in the distributional sense. Since div $V = 0$, we can write $Su = -\text{div } TU$ with $TU = \nabla U + (\nabla U)^\top - P\mathbb{I}$, where $\mathbb{I}$ is the unit matrix in $\mathbf{R}^3$. Now we repeat the same procedure for $-\Delta V + \nabla P = -\text{div } TU$ and $\Phi \in C_0^\infty(Q_\varepsilon)^3$. Since div $TU = 0$ in Q_ε^- and Q_ε^+, the trace of $TU \cdot \mathrm{e}_z = \lim_{\zeta \to 0} TU(y,\zeta) \cdot \mathrm{e}_z$ exists for $\zeta > 0$ and $\zeta < 0$. Hence we can calculate

$$\begin{aligned} -\langle \text{div } TU, \Phi\rangle_{Q_\varepsilon} &= (TU, \nabla\Phi)_{Q_\varepsilon} \\ &= -(\text{div } TU, \Phi)_{Q_\varepsilon^-} + \int_{\omega_j} TU(y,0) \cdot \mathrm{e}_z \cdot \Phi(y,0)\,\mathrm{d}y \\ &\quad -(\text{div } TU, \Phi)_{Q_\varepsilon^+} - \int_{\omega_j} \lim_{\zeta \to 0^+} TU(y,\zeta) \cdot \mathrm{e}_z \cdot \Phi(y,\zeta)\,\mathrm{d}y. \end{aligned} \tag{4.23}$$

From the definition of $U(y,\zeta)$ for $\zeta > 0$ we obtain for the first two components of $TU \cdot \mathrm{e}_z$

$$\partial_{y_i} V_3(y,\zeta) + \partial_z V_i(y,\zeta) = -\partial_{y_i} V_3(y,-\zeta) - \partial_z V_i(y,-\zeta) \to 0 \text{ with } \zeta \to 0, i = 1,2,$$

by (4.21) and (4.22). For the third component we get for $\zeta > 0$

$$\mathrm{e}_z^\top \cdot TU(y,\zeta) \cdot \mathrm{e}_z = 2\partial_z V_3(y,\zeta) - P(y,\zeta) = 2\partial_z V_3(y,-\zeta) - P(y,-\zeta);$$

hence

$$\lim_{\zeta \to 0^+} \mathrm{e}_z^\top \cdot TU(y,\zeta) \cdot \mathrm{e}_z = \lim_{\zeta \to 0^-} \mathrm{e}_z^\top \cdot TU(y,\zeta) \cdot \mathrm{e}_z.$$

Therefore the $\int_{\omega_j} \dots$ cancel each other in (4.23), which leads to $-\langle \text{div } TU, \Phi\rangle_{Q_\varepsilon} = 0$. Thus we obtain $SU = 0$ in Q_ε and $V = 0$ on $\partial\omega_j \times (-\varepsilon, \varepsilon)$. We apply the results of [48] and [6] once more and obtain $U \in \mathcal{D}^l H(Q_{\varepsilon'})$ for all $\varepsilon' < \varepsilon$, which finishes the proof. □

5. Uniform estimates for the solutions in Ω_R. To derive an error estimate for $u - u^R$, we need uniform estimates for the solutions of the system

$$Su = 0 \text{ in } \Omega_R, \quad v = 0 \text{ on } \partial\Omega(R), \quad Fu = h \text{ on } \Gamma_R \tag{5.1}$$

for $u \in \mathcal{D}_l^l V(\Omega_R)$. We denote the space of traces of $\{Fu : u \in \mathcal{D}_l^l V(\Omega_R)\}$ by $\mathcal{R}_l^l V(\Gamma_R, \partial\Gamma_R)$. The main result of this section is the following theorem.

THEOREM 5.1. *Let $l \in \mathbf{N}$ and $h \in \mathcal{R}_l^l V(\Gamma_R, \partial\Gamma_R)$ be given with*

$$\int_{\Gamma_R} \nu^\top \cdot h\,\mathrm{d}o = 0. \tag{5.2}$$

Let $u = (v,p) \in \mathcal{D}_l^l V(\Omega_R)$ be the unique solution of (5.1) with $\int_{G_0} p\,\mathrm{d}x = 0$, where G_0 is chosen as in Theorem 4.4. Then the following holds:

$$\|u; \mathcal{D}_l^l V(\Omega_R)\| \le C\,R^2\,\|h; \mathcal{R}_l^l V(\Gamma_R, \partial\Gamma_R)\|, \tag{5.3}$$

where C is a constant independent of R.

Main idea of the proof. The main idea of the proof is the following: Let $X = \{u \in \mathcal{D}_l^l V(\Omega_R), Su = 0 \text{ in } \Omega_R, v = 0 \text{ on } \partial\Omega(R), \int_{G_0} p\,\mathrm{d}x = 0\}$. Then X is a closed linear subspace of $\mathcal{D}_l^l V(\Omega_R)$, and by Theorem 4.2, the operator

$$F : u \to Fu \in Y := \left\{ h \in \mathcal{R}_l^l V(\Gamma_R), \int_{G_R} \nu^\top \cdot h\,\mathrm{d}o = 0 \right\}$$

defines an isomorphism. To prove (5.3), we construct an "almost inverse operator," i.e., a continuous linear operator $\mathcal{A} : Y \to X$, such that $F\mathcal{A} = \mathbb{I} + \mathcal{F}$, where $\mathbb{I}$ is the identity on Y, $\mathcal{F}$ is small for large R, i.e., there exists $q < 1$ and $R_0 > 0$, such that

$$\|\mathcal{F} : Y \to Y\| < q \tag{5.4}$$

for all $R > R_0$. Moreover, we prove

$$\|\mathcal{A} : Y \to X\| \le CR^2, \tag{5.5}$$

where C is independent of R. Then $(\mathbb{I} + \mathcal{F})^{-1}$ exists as a Neumann series, and we obtain $F^{-1} = \mathcal{A}(\mathbb{I} + \mathcal{F})^{-1}$. Now (5.4) and (5.5) lead to (5.3).

For the construction of $\mathcal{A}$ we need existence and uniqueness results for the *second limit problem* in suitable function spaces. The second limit problem is the problem on the semicylinder formulated in the following form. Let $\omega \subset \mathbf{R}^2$ be a bounded domain with $\partial\omega \in C^{l+2}$. We set

$$\Pi^- = \omega \times (-\infty, 0), \quad x = (y, z) \text{ for } x \in \Pi^-, \quad \partial\Pi_{(-)} = \partial\omega \times (-\infty, 0).$$

By $\omega(z)$ and $\partial\omega(z)$ we denote the cross section and its boundary in $z \le 0$; in this notation $\partial\omega(0)$ is the edge of the semicylinder. On Π^- we consider the following boundary value problem:

$$Su = f \text{ in } \Pi^-, \quad v = g_0 \text{ on } \partial\Pi_{(-)}, \tag{5.6}$$

$$Fu = g_1 \text{ on } \omega \times \{0\}, \quad (Fu)^\top = (\mathrm{e}_1^\top \cdot Tu \cdot \mathrm{e}_z, \mathrm{e}_2^\top \cdot Tu \cdot \mathrm{e}_z, v_3). \tag{5.7}$$

As before, e_i denote the unit vectors in y_i-direction for $i = 1, 2$. The boundary of Π^- has two types of singularities: the edge $M = \partial\omega \times \{0\}$ and the cylindrical outlet to infinity. To treat the full asymptotic behavior in the vicinity of the edges and for $z \to -\infty$ we must use weighted spaces with different weights near $\partial\omega(0)$ and at $-\infty$.

We choose basic weight functions $\rho_1, \rho_2 \in C^{l+2}(\Pi^-)$ with the following properties: We define ρ_1 analogous to the weight ρ in section 3.2. $\rho_1(x) = \operatorname{dist}(x, \partial\omega(0))$ for $x \in \mathcal{O}_\varepsilon$, $\rho_1(y, z) = 1$ for $z < -2\varepsilon$, where ε is chosen small enough such that $\operatorname{dist}(x, \partial\omega(0))$ is a C^{l+2}-function on $\mathcal{O}_\varepsilon \cap \Pi^- = \{x \in \Pi^- : \operatorname{dist}(x, \partial\omega(0)) < \varepsilon\}$. We set $\rho_2(y, z) = \rho_2(z) = e^z$ for $z < -2$, $\rho_2(z) = 1$ for $-1 < z \le 0$. For $\gamma, \beta \in \mathbf{R}$, $l \in \mathbf{N}$, $\varphi \in C_0^\infty(\overline{\Pi}^- \setminus \partial\omega(0))$ we introduce the norm

$$\|\varphi; \mathbb{W}^l_{\gamma,\beta}(\Pi^-)\| = \sum_{|\alpha| \le l} \left(\|(\rho_1^{\gamma - l + |\alpha|} \rho_2^\beta \partial^\alpha \varphi; L^2(\Pi^-)\|^2 \right)^{1/2} \tag{5.8}$$

and $\mathbb{W}^l_{\gamma,\beta}(\Pi^-)$ as the closure of $C_0^\infty(\overline{\Pi}^- \setminus \partial\omega(0))$ in the norm (5.8). $\mathbb{W}^l_{\gamma,\beta}(\Pi^-)$ coincides with the space of all $\varphi \in H^l_{loc}(\Pi^-)$ such that $\|\varphi; \mathbb{W}^l_{\gamma,\beta}(\Pi^-)\| < \infty$. For $0 \le k \le l$, $\delta, \delta' \ge 0$, the space $\mathbb{W}^l_{\gamma,\beta}(\Pi^-)$ is continuously embedded into $\mathbb{W}^{l-k}_{\gamma-k+\delta,\beta+\delta'}(\Pi^-)$. For $k > 0$, $\delta, \delta' > 0$ this embedding is compact (see [52] for details).

The spaces of traces are defined in a natural way. Again we divide them into trace spaces on the lateral surface $\partial\Pi_{(-)}$ and on the cross section $\omega(0)$. We set $\mathbb{W}^{l-1/2}_{\gamma,\beta}(\partial\Pi_{(-)}) = \{\varphi|_{\partial\Pi_{(-)}} : \varphi \in \mathbb{W}^l_{\gamma,\beta}(\Pi^-)\}$ provided with the canonical norm $\|\varphi; \mathbb{W}^{l-1/2}_{\gamma,\beta}(\partial\Pi_{(-)})\| = \inf \|\tilde{\varphi}; \mathbb{W}^l_{\gamma,\beta}(\Pi^-)\|$, where the infimum is taken over all functions $\tilde{\varphi}$ with $\tilde{\varphi}|_{\partial\Pi_{(-)}} = \varphi$. On the cross section $\omega(0)$ the space of traces of $\mathbb{W}^l_{\gamma,\beta}(\Pi^-)$

coincides with $V_\gamma^{l-1/2}(\omega,\partial\omega)$, the trace space of $V_\gamma^l(\Pi^-,\partial\omega(0)) = \mathbb{W}_{\gamma,0}^l(\Pi^-)$ (where the exponential weight is equal to 1 everywhere). We define the natural domain and range of the problem (5.6), (5.7):

$$\begin{aligned}
\mathcal{D}_{\gamma,\beta}^l\mathbb{W}(\Pi^-) &= \mathbb{W}_{\gamma,\beta}^{l+1}(\Pi^-)^3 \times \mathbb{W}_{\gamma,\beta}^l(\Pi^-),\\
\mathcal{R}_{\gamma,\beta}^l\mathbb{W}(\Pi^-) &= \mathbb{W}_{\gamma,\beta}^{l-1}(\Pi^-)^3 \times \mathbb{W}_{\gamma,\beta}^l(\Pi^-),\\
\mathcal{R}_{\gamma,\beta}^l\mathbb{W}(\Pi^-,\partial\Pi_{(-)},\omega(0)) &= \mathcal{R}_{\gamma,\beta}^l\mathbb{W}(\Pi^-) \times \mathbb{W}_{\gamma,\beta}^{l+1/2}(\partial\Pi_{(-)})^3\\
&\quad \times V_\gamma^{l-1/2}(\omega(0),\partial\omega)^2 \times V_\gamma^{l+1/2}(\omega(0),\partial\omega).
\end{aligned}$$

Then the operator

$$\begin{aligned}
\mathbb{S}_{\gamma,\beta}^l : \mathcal{D}_{\gamma,\beta}^l\mathbb{W}(\Pi^-) &\to \mathcal{R}_{\gamma,\beta}^l\mathbb{W}(\Pi^-,\partial\Pi_{(-)},\omega(0))\\
u &\to (Su, Du|_{\partial\Pi_{(-)}}, Fu|_{\omega(0)})
\end{aligned} \tag{5.9}$$

defines a continuous linear operator. From the results of the previous sections it is evident for which exponents (5.9) can be expected to be Fredholm, namely, for $|\gamma - l| < 1$ and for all β such that the line $\operatorname{Im}\lambda = \beta$ is free of eigenvalues of the elliptic pencil belonging to the Dirichlet problem of the Stokes system in the cylinder $\Pi = \omega \times \mathbf{R}$, where ω is one of the cross sections ω_j. We formulate the special results we need in the following lemma.

LEMMA 5.2. *If $0 < \beta < \beta_*$, the Stokes problem* (5.6), (5.7) *has a solution $u \in \mathcal{D}_{l,\beta}^l\mathbb{W}(\Pi^-)$ for all $(f,g,h) \in \mathcal{R}_{l,-\beta}^l\mathbb{W}(\Pi^-,\partial\Pi_{(-)},\omega(0))$. This solution is uniquely determined up to a constant in the pressure and admits the asymptotic representation*

$$u = -Hu^{j1} + au^{\#} + \tilde{u}, \tag{5.10}$$

where $\tilde{u} \in \mathcal{D}_{l,-\beta}^l\mathbb{W}(\Pi^-)$ and

$$H = \int_{\Pi^-} f_4\,\mathrm{d}x + \int_{\partial\Pi_{(-)}} \nu^\top \cdot g\,\mathrm{d}o + \int_\omega h_3\,\mathrm{d}y.$$

The constant in pressure can be fixed, e.g., by the condition $\int_\omega p(y,-1)\,\mathrm{d}y = 0$. In this case the following estimate holds

$$|a| + \|\tilde{u}; \mathcal{D}_{l,-\beta}^l\mathbb{W}(\Pi^-)\| \le C\|(f,g,h); \mathcal{R}_{l,-\beta}^l\mathbb{W}(\Pi^-,\partial\Pi^-)\|. \tag{5.11}$$

Proof. Combining the results on the Stokes problem (1.1) in the straight cylinder $\Pi = \omega\times\mathbf{R}$ with the results in domains with smooth edges gives the Fredholm property of the mapping (5.9) if $|\gamma - l| < 1$ and the line $\operatorname{Im}\lambda = \beta$ is free of eigenvalues of the pencils $\mathfrak{S}(\lambda)$ associated to the Dirichlet problem (1.1) in the cylinder Π (see [33, Theorem 3.1.1, Theorem 8.1.1, and section 4.1.2]). From the results cited above, we obtain $\operatorname{Ind}\mathbb{S}_{l,\beta}^l - \operatorname{Ind}\mathbb{S}_{l,-\beta}^l = 2$ for $0 < \beta < \beta^*$. Moreover, if $(u^*,g^*,h^*) \in \ker\,(\mathbb{S}_{l,\beta}^l)^*$ (= kernel of the adjoint operator), then $u^* \in \ker\mathbb{S}_{l,-\beta}^l(\Pi^-)$, while $g^* = N_1u^*$ on $\partial\Pi_{(-)}$, $h^* = F_0u^*$ on $\omega(0)$.

If $0 < \beta < \beta^*$, then the operator $\mathbb{S}_{l,-\beta}^l$ is injective. Indeed, let $u \in \mathcal{D}_{l,-\beta}^l\mathbb{W}(\Pi^-)$ be a solution to the homogeneous problem (5.6), then $u \in H^{l+1}(\Pi^-)^3 \times H^l(\Pi^-)$. For $z \to -\infty$ this follows from the fact that the weight increases exponentially, in the neighborhood of the edge it follows from the mirror principle, as in the proof

of Theorem 4.4. Since $Su = 0$ iff $S_1 u = 0$ we can multiply the equation $S_1 u = 0$ scalar with u (in $L^2(\Pi^-)^4$) and integrate by parts. This gives $\nabla v + (\nabla v)^\top = 0$; hence, $v = A \times x + B$ with constant vectors A, $B \in \mathbb{C}$. The homogeneous boundary conditions lead to $u = 0$ then. Applying the results mentioned above gives the surjectivity of $\mathbb{S}^l_{l,\beta}$. Now elementary calulations together with the index formula lead to

$$\dim \ker \mathbb{S}^l_{l,\beta} = \dim \operatorname{coker} \mathbb{S}^l_{l,-\beta} = 1.$$

Then it is clear that $\ker \mathbb{S}^l_{l,\beta} = \{cu^\# : c \in \mathbb{C}\}$.

Now let $u \in \mathcal{D}^l_{l,\beta}\mathbb{W}(\Pi^-)$ be any solution to (5.6), (5.7) for given f, g, and h as above. Formula (1.21) (now for $J = 1$) ensures the existence of constants H and a, such that (5.10) holds. The cut-off function may be omitted in this case, since by Lemma 4.6, $u^{j1} \in \mathcal{D}^l_l V(\omega \times (-c_0, 0), \partial\omega(0))$ for any $c_0 < 0$, for $u^\#$ this is elementary. We apply the generalized Green's formula (1.24) to u and $U = u^\#$ and obtain (observing that $\pi_0(\,\cdot\,)$, $\pi_1(\,\cdot\,)$ consist of one component now)

$$\int_{\Pi^-} f_4 \,\mathrm{d}x + \int_{\partial\Pi_{(-)}} \nu^\top \cdot g \,\mathrm{d}o + \int_\omega h_3 \,\mathrm{d}y = \langle \pi_0 u, \pi_1 u^\# \rangle - \langle \pi_1 u, \pi_0 u^\# \rangle = H. \qquad \square$$

Proof of Theorem 5.1. We recall that $\Gamma_{R,j}$ denotes the cross section at $z_j = R$ in the outlet Q_j; we set $h_{(j)} = h|_{\Gamma_{R,j}}$. We define $H_j = \int_{\Gamma_{R,j}} \nu^\top \cdot h \,\mathrm{d}o$, this means in local coordinates of Q_j: $H_j = \int_{\omega_j} h_{(j),3}(y) \,\mathrm{d}y$, and we obtain

$$|H_j| \le C\|h; L^2(\Gamma_R)\| \le C\|h; \mathcal{R}^l_l V(\Gamma_R, \partial\Gamma_R)\|. \tag{5.12}$$

Now we fix β with $\beta < \beta^*$ arbitrary. Let $u_{(j)} \in \mathcal{D}^l_{l,\beta}(\Pi^-_j)$ be the unique solution of the problem

$$Su_{(j)} = 0 \text{ in } \Pi^-_j = \omega_j \times (-\infty, 0), \quad v_{(j)} = 0 \text{ on } \partial\omega_j \times (-\infty, 0), \tag{5.13}$$

$$Fu_{(j)} = h_{(j)} \text{ on } \omega_j(0), \quad \int_{\omega_j} p_{(j)}(y, -1) = 0. \tag{5.14}$$

According to (5.10), $u_{(j)}$ admits the representation $u_{(j)} = -H_j u^{j1} + a_j u^\# + \tilde{u}_{(j)}$ where, as before, u^{j1} is the Poiseuille flow in the cylinder Π_j and $u^\# = (0, 0, 0, 1)$ the constant pressure solution. The following estimate holds:

$$|a_j| + \|\tilde{u}_{(j)}; \mathcal{D}^l_{l,-\beta}\mathbb{W}(\Pi^-_j)\| \le C\|h_{(j)}; \mathcal{R}^l_l V(\omega_j, \partial\omega_j)\|. \tag{5.15}$$

Let χ_j denote the cut-off functions of section 1. For $x \in Q_j \cap \Omega_R$ the expression $\chi_j(z_j) u_{(j)}(y, z_j - R)$ is well defined and can be extended smoothly by 0 to the whole domain Ω_R. In this sense we set

$$u_\Pi = \sum_{j=1}^J \chi_j(z_j) u_{(j)}(y_j, z_j - R). \tag{5.16}$$

Recalling the notations of section 1, i.e.,

$$a = (a_1, \dots, a_J), \quad H = (H_1, \dots, H_J), \quad \mathcal{U}^h = (\chi_1 u^{1h}, \dots, \chi_J u^{Jh}),$$

$h = 0, 1$, where u^{j0} is the constant pressure solution and u^{j1} the Poiseuille flow in the outlet Q_j, then, with $\varpi = (\varpi_1, \dots, \varpi_J)$,

$$u_\Pi = -\mathcal{U}^1 \cdot H|_{\Omega_R} + \mathcal{U}^0 \cdot (a + 2R\, H\varpi)|_{\Omega_R} + \sum_{j=1}^J \chi_j(z_j) \tilde{u}_{(j)}(y_j, z_j - R). \tag{5.17}$$

The term $2R\,H\varpi = 2R(H_1\varpi_1, \dots, H_J\varpi_J)$ appears from the special structure of the Poiseuille flow. Then Su_Π has a compact support contained in $\bigcup_{j=1}^J \operatorname{supp} \nabla\chi_j \subset \Omega_0$; moreover, $v_\Pi = 0$ on $\partial\Omega(R)$ and $p_\Pi = 0$ on G_0 since $\operatorname{supp}\chi_j \cap G_0 = \emptyset$ for $j = 1, \dots, J$. We extend Su_Π smoothly by 0 to $f_\infty \in \mathcal{R}^l_\beta W(\Omega)$. The norm of f_∞ can be estimated by

$$\begin{aligned}\|f_\infty; \mathcal{R}^l_\beta W(\Omega)\| &\le C\|f_\infty; R^l H(\Omega_0)\| \\ &\le C\Big(|H|\,\|\mathcal{U}^1; \mathcal{D}^l H(\Omega_0)\| + |a + 2H\varpi R|\,\|\mathcal{U}^0; \mathcal{D}^l H(\Omega_0)\| \\ &\qquad + \sum_{j=1}^J \|\tilde{u}_{(j)}; \mathcal{D}^l H(\omega_j \times (-R, -R + R_0))\|\Big).\end{aligned}$$

The last term can be estimated by $e^{-\beta(R+R_0)}\|\tilde{u}_{(j)}; \mathcal{D}^l_{l,-\beta}\mathbb{W}(\Pi_j^-)\|$, thus decays exponentially, and with (5.12) and (5.15) it follows that

$$\|f_\infty; \mathcal{R}^l_\beta W(\Omega)\| \le CR\|h; Y\|. \tag{5.18}$$

Furthermore, we have $\int_\Omega f_{\infty,4}\,\mathrm{d}x = 0$: Since $v_\Pi = 0$ on $\partial\Omega(R)$ and $Fu_\Pi = h$ on Γ_R by construction, then Gauss' theorem gives, with (5.2),

$$\int_\Omega f_{\infty,4}\,\mathrm{d}x = -\int_{\Omega_R} \operatorname{div} u_\Pi\,\mathrm{d}x = -\int_{\partial\Omega_R} \nu^\top \cdot v_\Pi\,\mathrm{d}o = -\int_{\Gamma_R} \nu^\top \cdot h\,\mathrm{d}o = 0.$$

Thus, by Theorem 1.6, we obtain a unique solution $u_\infty \in \mathbb{D}^l_{\pm\beta}W(\Omega)$ of the problem $Su_\infty = f_\infty$ in Ω, $v_\infty = 0$ on $\partial\Omega$, $\pi_1 u_\infty = 0$, $\int_{G_0} p_\infty = 0$. u_∞ admits the representation

$$u_\infty = \mathcal{U}^0 \cdot a^* + \tilde{u}_\infty, \tag{5.19}$$

where

$$|a^*| + \|\tilde{u}_\infty; \mathcal{D}^l_\beta W(\Omega)\| \le C\|f_\infty; \mathcal{R}^l_\beta W(\Omega)\|. \tag{5.20}$$

Now we define

$$U = (V, P) = \mathcal{A}(h) = u_\Pi + u_\infty.$$

By construction it is clear that $SU = 0$ in Ω_R, $V = 0$ on $\partial\Omega(R)$, and $\int_{G_0} P\,\mathrm{d}x = 0$. Moreover, from Lemma 4.6 we have $u_\infty|_{\Omega_R} \in \mathcal{D}^l_l V(\Omega_R, \partial\Gamma_R)$; hence, $U \in X$ and $FU \in \mathcal{R}^l_l V(\Gamma_R, \partial\Gamma_R)$. As already mentioned in section 1, the solution u_∞ carries no flux through the outlets, which means

$$\int_{\Gamma_{R,j}} \nu^\top \cdot v_\infty\,\mathrm{d}o = 0$$

for $j = 1, \dots, J$; hence $\int_{\Gamma_R} \nu^\top \cdot FU\,\mathrm{d}o = 0$, which ensures $FU \in Y$. Since $F(\mathcal{U}^0 \cdot a^*) = 0$ on Γ_R, it follows $FU = Fu_\Pi + F\tilde{u}_\infty = h + \mathcal{F}(h)$.

Let $\mathcal{O}_\epsilon = \{x \in \Omega_R, \operatorname{dist}(x, \Gamma_R) < \epsilon\}$ be a neighborhood of Γ_R of constant size; then the trace theorem, together with (5.18) and (5.20), gives

$$\begin{aligned}\|\mathcal{F}(h); Y\| &\le \|\tilde{u}_\infty; \mathcal{D}^l_l V(\mathcal{O}_\epsilon, \partial\Gamma_R)\| \\ &\le Ce^{-\beta R}\|f_\infty; \mathcal{R}^l_\beta W(\Omega)\| \le Ce^{-\beta R}\,R\,\|h; Y\|,\end{aligned}$$

where C is a constant independent of R. Here we have to observe that by the definition of the norms in $W^l_\beta(\Omega)$ and Lemma 4.6

$$\|\tilde{u}_\infty; \mathcal{D}^l_l V(\mathcal{O}_\epsilon, \partial\Gamma_R)\| \le C\|\tilde{u}_\infty; \mathcal{D}^l H(\mathcal{O}_\epsilon)\| \le Ce^{-\beta R}\|\tilde{u}_\infty; \mathcal{D}^l_\beta W(\Omega)\|.$$

We remember that β can be chosen arbitrarily in the interval $(0, \beta^*)$. Now we fix R_* large enough, such that $Ce^{-\beta R_*}R_* \le q < 1$. Then for all $R > R_*$, it holds $\|\mathcal{F} : Y \to Y\| \le q$, and

$$(\mathbb{I} + \mathcal{F})^{-1} = \sum_{k=0}^{\infty}(-1)^k \mathcal{F}^k, \quad \|(\mathbb{I} + \mathcal{F})^{-1}\| \le \frac{1}{1+q}. \tag{5.21}$$

To estimate U, we first estimate u_Π with the help of the representation (5.17), estimate (5.15), and $E = (1, \dots, 1)^\top$:

$$\begin{aligned}
&\|u_\Pi; \mathcal{D}^l_l V(\Omega_R)\| \\
&\le C\Bigg(|H|\|\mathcal{U}^1 \cdot E; \mathcal{D}^l H(\Omega_R)\| + |a + 2H\varpi R|\|\mathcal{U}^0 \cdot E; \mathcal{D}^l H(\Omega_R)\| \\
&\qquad + \sum_{j=1}^{J} \|\tilde{u}_{(j)}; \mathcal{D}^l_l V(\omega_j \times (-R, 0))\|\Bigg) \\
&\le C\left(R^2|H| + R|a + 2H\varpi R| + \sum_{j=1}^{J} \|\tilde{u}_{(j)}; \mathcal{D}^l_{l,-\beta}\mathbb{W}(\Pi^-_j)\|\right);
\end{aligned}$$

hence

$$\|u_\Pi; \mathcal{D}^l_l V(\Omega_R)\| \le CR^2\|h; Y\|. \tag{5.22}$$

For u_∞ we calculate by means of (5.19), Lemma 4.6, (5.20), and (5.18):

$$\begin{aligned}
\|u_\infty; \mathcal{D}^l_l V(\Omega_R)\| &\le C\Big(|a^*|\,\|\mathcal{U}^0 \cdot E; \mathcal{D}^l_l V(\Omega_R)\| + \|\tilde{u}_\infty; \mathcal{D}^l_l V(\Omega_R)\|\Big) \\
&\le C\Big(|a^*|\,R\,\|f_\infty; \mathcal{R}^l_\beta W(\Omega)\|\Big) \\
&\le C\,R\,\|f_\infty; \mathcal{R}^l_\beta W(\Omega)\| \le C\,R^2\,\|h; Y\|.
\end{aligned} \tag{5.23}$$

Inequalities (5.21)–(5.23) lead to (5.3), and the theorem is proved. □

For the approximation of weak solutions with $L^2(\Omega)$-forces we need the following corollary.

COROLLARY 5.3. *Let $l \in \mathbf{N}$ and $h \in \mathcal{R}^l_l V(\Gamma_R, \partial\Gamma_R)$ be given with*

$$\int_{\Gamma_{R,j}} \nu^\top \cdot h \,\mathrm{d}o = 0 \quad \text{for } j = 1, \dots, J. \tag{5.24}$$

Let $u = \binom{v}{p} \in \mathcal{D}^l_l V(\Omega_R)$ be the unique solution of (5.1) with $\int_{G_0} p\,\mathrm{d}x = 0$. Then it holds that

$$\|v; V^{l+1}_l(\Omega_R, \partial\Gamma_R)^3\| + \|\nabla p, V^{l-1}_l(\Omega_R, \partial\Gamma_R)^3\| \le C\|h; \mathcal{R}^l_l V(\Gamma_R, \partial\Gamma_R)\|, \tag{5.25}$$

where C is a constant independent of R.

Proof. The corollary reflects the special case where $H_j = 0$, $j = 1, \dots, J$ in the proof of Theorem 5.1. Thus in the estimates of f_∞ and u_Π, all terms with H vanish, and we obtain

$$\|f_\infty; \mathcal{R}_l^l V(\Omega)\| \le C\|h; Y\| \tag{5.26}$$

instead of (5.18). If we observe that all terms with $\mathcal{U}^0$ influence only the estimates for the pressure; and moreover, $\nabla \mathcal{U}^0 = 0$ for $z_j > R_0$, $j = 1, \dots, J$, then it holds that

$$\|v_\Pi; V_l^{l+1}(\Omega_R, \partial\Gamma_R)\| + \|\nabla p_\Pi, V_l^{l-1}(\Omega, \partial\Gamma_R)\| \le C\|h; Y\| \tag{5.27}$$

instead of (5.22). Similarly, for u_∞ we obtain

$$\|v_\infty; V_l^{l+1}(\Omega, \partial\Gamma_R)^3\| + \|\nabla p_\infty; V_l^{l-1}(\Omega_R, \partial\Gamma_R)^3\| \le C\|h; Y\| \tag{5.28}$$

instead of (5.23). (5.25)–(5.28) lead to (5.24), which proves the assertion. □

6. The error estimate. With the result of the previous section we are now able to prove the error estimate for the approximation problem as it is defined in section 2. We recall the definition of the cut-off function χ_R. We assume that $\{\chi_R\}_R$ is a system of C^∞-functions in Ω with the properties $\chi_R \equiv 1$ on Ω_0; in Q_j we require $\chi_R(x) = \chi_R(z_j) = 1$ for $z_j < R - 1$, $\chi_R(z_j) = 0$ for $z_j > R - 1/2$.

THEOREM 6.1. *Let $l \in \mathbf{N}$, $\beta^* > \beta > 0$ meet the requirements of Theorem* 1.6, *$G_0 \subset \Omega_0$ be a nonvoid subdomain such that $G_o \cap \operatorname{supp} \chi_j = \emptyset$ for all j, and let $(f, g) \in \mathcal{R}_\beta^l W(\Omega, \partial\Omega)$, $H \in \mathbb{C}^J$ be given such that the flux condition*

$$\int_\Omega f_4 \,\mathrm{d}x + \int_{\partial\Omega} \nu^\top \cdot g \,\mathrm{d}o + \sum_{j=1}^J H_j = 0 \tag{6.1}$$

is fulfilled. Let $u \in \mathbb{D}_{\pm\beta}^l W(\Omega)$ be the unique solution of the Stokes problem with prescribed fluxes according to Theorem 1.6 *and $u^R \in \mathcal{D}^l H(\Omega_R)$ be the unique solution to the approximation problem*

$$\begin{aligned} Su^R = \chi_R f \text{ in } \Omega_R, \quad v^R = \chi_R g \text{ on } \partial\Omega(R), \\ Fu^R = F(\mathcal{U}^1 \cdot (H + H_\infty)) \text{ on } \Gamma_R, \quad \int_{G_0} p^R = 0, \end{aligned} \tag{6.2}$$

where $H_\infty \in \mathbb{C}^J$ with

$$H_{\infty,j} = \int_{Q_j} (1 - \chi_R) f_4 \,\mathrm{d}x + \int_{\partial Q_j} \nu^\top \cdot (1 - \chi_R) g \,\mathrm{d}o. \tag{6.3}$$

Then for every $\varepsilon > 0$ we obtain the error estimate:

$$\begin{aligned} \|u - u^R; \mathcal{D}^l H(\Omega_{R-1})\| &= \|u - u^R; H^{l+1}(\Omega_{R-1})^3 \times H^l(\Omega_{R-1})\| \\ &\le \|u - u^R; \mathcal{D}_l^l V(\Omega_R, \partial\Gamma_R)\| \\ &\le C\, e^{-(\beta-\varepsilon)R} \Big(|H| + \|(f, g); \mathcal{R}_\beta^l W(\Omega, \partial\Omega)\| \Big), \end{aligned} \tag{6.4}$$

where C is a constant independent of R and of the data.

Proof. From the flux condition (6.1) and the definition of H_∞ we obtain

$$\int_{\Omega_R} \chi_R f_4 \,\mathrm{d}x + \int_{\partial\Omega(R)} \nu^\top \cdot \chi_R g \,\mathrm{d}o + \int_{\Gamma_R} \nu^\top \cdot \mathcal{U}^1 \cdot (H + H_\infty) \,\mathrm{d}o = 0;$$

hence $u^R \in \mathcal{D}^l H(\Omega_R)$ exists due to Theorem 4.4.

According to (1.22), u has the representation

$$u = \mathcal{U}^1 \cdot H + \mathcal{U}^0 \cdot a + \tilde{u}, \tag{6.5}$$

with $\tilde{u} \in \mathcal{D}^l_\beta W(\Omega)$. Let u_∞ be the solution of

$$\begin{aligned} &Su_\infty = \chi_R f \text{ in } \Omega, \quad v_\infty = \chi_R g \text{ on } \partial\Omega, \\ &\pi_1 u_\infty = H + H_\infty, \quad \int_{G_0} p_\infty = 0. \end{aligned} \tag{6.6}$$

Again, with (1.22), we have the following representation for u_∞:

$$u_\infty = \mathcal{U}^1 \cdot (H + H_\infty) + \mathcal{U}^0 \cdot a_\infty + \tilde{u}_\infty. \tag{6.7}$$

The difference $U = u - u_\infty$ is the unique solution of the problem

$$SU = (1-\chi_R)f \text{ in } \Omega, \quad DU = (1-\chi_R)g \text{ on } \partial\Omega, \quad \pi_1 U = -H_\infty, \quad \int_{G_0} P \,\mathrm{d}x = 0.$$

Since $\operatorname{supp}(1-\chi_R)(f,g) \subset \{x \in \Omega : z_j > R-1, j = 1,\dots,J\}$, for every $\bar{\varepsilon}$ with $\beta > \bar{\varepsilon} > 0$, estimate (1.29) leads to

$$\begin{aligned} &|a - a_\infty| + \|\tilde{u} - \tilde{u}_\infty; \mathcal{D}^l_{\bar{\varepsilon}} W(\Omega)\| \\ &\le C\Big(\|(1-\chi_R)(f,g); \mathcal{R}^l_{\bar{\varepsilon}} W(\Omega, \partial\Omega)\| + |H_\infty|\Big) \\ &\le C\Big(e^{-(\beta-\bar{\varepsilon})R} \|(1-\chi_R)(f,g); \mathcal{R}^l_\beta W(\Omega, \partial\Omega)\| + |H_\infty|\Big). \end{aligned} \tag{6.8}$$

To estimate $|H_\infty|$ we apply the Cauchy–Schwarz inequality to

$$\begin{aligned} |H_{\infty,j}| &\le |\int_{Q_j} (1-\chi_R) f_4 \,\mathrm{d}x| + |\int_{\partial Q_j} \nu^\top \cdot (1-\chi_R) g \,\mathrm{d}o| \\ &\le \Big(\int_{Q_j} |1-\chi_R|^2 e^{-2\beta z} \,\mathrm{d}x\Big)^{1/2} \Big(\|f_4 e^{\beta z}; L^2(Q_j)\| + \|g e^{\beta z}; L^2(\partial\Omega)\|\Big) \\ &\le C\, e^{-\beta R} (\|(f,g); \mathcal{R}^l_\beta W(\Omega, \partial\Omega)\|. \end{aligned} \tag{6.9}$$

(6.8) and (6.9), together with Lemma 4.6, lead to

$$\begin{aligned} &\|U; \mathcal{D}^l H(\Omega_{R-1})\| \le \|U; \mathcal{D}^l_l V(\Omega_R)\| \\ &\le C(R^2 |H_\infty| + R|a - a_\infty| + \|\tilde{u} - \tilde{u}_\infty; \mathcal{D}^l_{\bar{\varepsilon}} W(\Omega)\|) \\ &\le C\, e^{-(\beta-\varepsilon)R} \|(f,g); \mathcal{R}^l_\beta W(\Omega, \partial\Omega)\|, \end{aligned} \tag{6.10}$$

where ε in dependence of $\bar{\varepsilon}$ can be chosen arbitrarily small. Now we rewrite the difference $u - u^R$ in Ω_R: $u - u^R = u - u_\infty + u_\infty - u^R$. Then $U^R = u_\infty - u^R \in \mathcal{D}^l_l V(\Omega_R, \partial\Gamma_R)$. Moreover, due to (6.2) and (6.7), U^R solves the problem

$$(SU^R, DU^R) = (0,0) \text{ in } (\Omega_R, \partial\Omega(R)), \text{ and } FU^R = F\tilde{u}_\infty \text{ on } \Gamma_R, \int_{G_0} P^R \,\mathrm{d}x = 0.$$

We apply Theorem 5.1 and gain

$$\begin{aligned}\|U^R;\mathcal{D}^l H(\Omega_{R-1})\| &\le C\|U^R;\mathcal{D}^l_l V(\Omega_R)\|\\ &\le CR^2\|F\tilde{u}_\infty;\mathcal{R}^l_l V(\Gamma_R,\partial\Gamma_R)\|\\ &\le CR^2\|\tilde{u}_\infty;\mathcal{D}^l_l V(\mathcal{O}_\epsilon(\Gamma_R),\partial\Gamma_R)\| \le Ce^{-\beta R}R^2\|\tilde{u}_\infty;\mathcal{D}^l_\beta W(\Omega)\|\\ &\le Ce^{-\beta R}R^2\Big(|H+H_\infty|+\|\chi_R(f,g);\mathcal{R}^l_\beta W(\Omega,\partial\Omega)\|\Big)\\ &\le C\,e^{-(\beta-\varepsilon)R}\Big(|H|+\|(f,g);\mathcal{R}^l_\beta W(\Omega,\partial\Omega)\|\Big),\end{aligned}$$

which, together with (6.10), proves the theorem. □

Remark 6.2. We outline that estimate (6.4) does *not* imply that $\|u^R;H^{l+1}(\Omega_R)^3\times H^l(\Omega_R)\|$ remains bounded as $R\to\infty$, of course.

The estimate (6.4) can also be proved with small modifications for $\|u-u^R;\mathcal{D}^l_{l,\bar\beta}\mathbb{W}(\Omega_R,\partial\Gamma_R)\|$ with $0<\bar\beta<\beta$. Here the $\mathcal{D}^l_{l,\bar\beta}V(\Omega_R,\partial\Gamma_R)$ means that the weight $\rho(x)$ for spaces $V^l_l(\Omega_R,\partial\Gamma_R)$ is multiplied by $e^{\bar\beta\mathfrak{z}}$. In this case we obtain

$$\|u-u^R;\mathcal{D}^l_{l,\bar\beta}V(\Omega_R,\partial\Gamma_R)\|\le Ce^{-(\beta-\bar\beta-\varepsilon)R}\Big(\|(f,g);\mathcal{R}^l_\beta W(\Omega,\partial\Omega)\|+|H|\Big).$$

7. Approximation for L^2-data. As already mentioned, it is possible to treat the problem

$$-\Delta v+\nabla p=f,\quad \operatorname{div} v=0\ \text{ in }\Omega,\quad v=0\text{ on }\partial\Omega \tag{7.1}$$

within the theory of H^l spaces, at least for v. Since p is unique up to a constant, we only obtain estimates for ∇p, of course. The following result is well known (see [40, p. 84]).

THEOREM 7.1 (weak solutions with zero fluxes). *Let $\Omega\subset\mathbf{R}^3$ be a domain with J cylindrical outlets as in the previous chapter and with $\partial\Omega$ of class C^{l+2} for some $l\in\mathbf{N}$. For every $f\in H^{l-1}(\Omega)^3$ there exists a unique solution $(v,\nabla p)$ of (7.1) with $\nabla v\in L^2(\Omega)$. The following estimate holds true:*

$$\|v;H^{l+1}(\Omega)^3\|+\|\nabla p;H^{l-1}(\Omega)^3\|\le C\|f;H^{l-1}(\Omega)^3\|, \tag{7.2}$$

where C is a constant independent of f.

By means of the divergence theorem, it is easy to see that the solutions of Theorem 7.1 produce no flux through the outlet Q_j. With the help of the Poiseuille flow u^{j1} we construct a flux carrier (a divergence-free vector field v_0 with zero trace), which drives a constant prescribed flux H_j through the outlet Q_j in the following way. Suppose v_0 is such a flux carrier; then for every $T>0$

$$\sum_{j=1}^J H_j=\int_{\Gamma_T}\nu^\top\cdot v_0\,\mathrm{d}o=\int_{\Omega_T}\operatorname{div} v_0\,\mathrm{d}x=0.$$

Therefore, $\sum_j H_j=0$ is a necessary (and physically sensible) condition. Let χ_j, $j=1,\dots,J$ be the cut-off functions as in Lemma 1.4, and u^{j1} the Poiseuille flow corresponding to the cylinder $\Pi_j=\omega_j\times\mathbf{R}$. Then $g_0=\operatorname{div}\sum_j(H_j\chi_j v^{j1})=\sum H_j(\nabla\chi_j)v^{j1}\in\overset{\circ}{H}{}^1(\Omega_{R_0})$ for a suitable $R_0>0$. Moreover,

$$\int_{\Omega_{R_0}}g_0\,\mathrm{d}x=\sum_j\int_{\omega_j}\mathrm{e}^\top_{z_j}\cdot v^{j1}(y_j,R_0)\,\mathrm{d}y_j=\sum_{j=1}^J H_j=0.$$

Hence, by using the result of [5] once more, we find $w_0 \in \overset{\circ}{H}{}^2(\Omega_{R_0})^3$ with div $w_0 = g_0$. We remember the notation $\mathcal{U}^1 = (\chi_1 u^{11}, \dots, \chi_J u^{J1})$, where the columns u^{j1} again denote the Poiseuille flow through the outlet Q_j. If we put

$$u_0 = \begin{pmatrix} v_0 \\ p_0 \end{pmatrix} = \mathcal{U}^1 \cdot H + \begin{pmatrix} w_0 \\ 0 \end{pmatrix}, \quad H = (H_1, \dots, H_J),$$

we obtain div $v_0 = 0$ in Ω, $v_0 = 0$ on $\partial\Omega$, and $-\Delta v_0 + \nabla p_0 = f_0 \in L^2(\Omega)^3$ with compact support in Ω_{R_0}. Moreover, from the construction of w_0, the following estimate follows:

$$\|f_0; L^2(\Omega)\| \le C \sum_j |H_j|. \tag{7.3}$$

We find a solution $u = u_0 + \tilde{u}$ to the problem (7.1) such that u has prescribed flux H_j through the outlet Q_j. If we apply Theorem 7.1 to the problem

$$-\Delta \tilde{v} + \nabla \tilde{p} = f - f_0, \quad \text{div } \tilde{v} = 0 \text{ in } \Omega, \quad \tilde{v} = 0 \text{ on } \partial\Omega, \tag{7.4}$$

we can formulate the following result.

COROLLARY 7.2. *Let $\Omega \subset \mathbf{R}^3$ be as in Theorem 7.1. For every $f \in L^2(\Omega)^3$, $H \in \mathbb{C}^J$ with $\sum_j H_j = 0$ we obtain a solution u to the problem (7.1) with flux H_j through Q_j in the form $u = u_0 + \tilde{u}$. Here $\tilde{u}$ is uniquely determined up to a constant in pressure and fulfills the following estimate:*

$$\|\tilde{v}, H^2(\Omega)^3\| + \|\nabla \tilde{p}; L^2(\Omega)^3\| \le C\Big(\|f; L^2(\Omega)^2\| + \sum_{j=1}^{J} |H_j|\Big). \tag{7.5}$$

The last result of this treatment concerns the approximation of the solutions obtained by Corollary 7.2.

THEOREM 7.3. *Let $\Omega \subset \mathbf{R}^3$ be a domain with J cylindrical outlets, $\partial\Omega \in C^3$. For $f \in L^2(\Omega)^3$, $H \in \mathbb{C}^j$ with $\sum_{j=1}^{J} H_j = 0$ let u be the solution of Corollary 7.2 to the problem (7.1) with flux H_j through Q_j. For $R > R_0$, let $u^R \in H^2(\Omega_R)^3 \times H^1(\Omega_R)$ be a solution to the approximation problem*

$$-\Delta v^R + \nabla p^R = f|_{\Omega_R}, \quad \text{div } v^R = 0 \text{ in } \Omega_R, \tag{7.6}$$

$$v^R = 0 \text{ on } \partial\Omega(R), \quad Fu^R = F(\mathcal{U}^1 \cdot H) \text{ on } \Gamma_R. \tag{7.7}$$

Then $\|v - v^R; H^2(\Omega_{R-\varepsilon})^3\| + \|\nabla p - \nabla p^R; L^2(\Omega_{R-\varepsilon})^3\| \to 0$ with $R \to \infty$ for every $\varepsilon > 0$.

Proof. The existence of u^R, uniquely determined up to a constant in pressure, was already proved in Theorem 4.2. Since $\sum_j H_j = 0$, it is not necessary now to introduce the "artificial" flux H_∞, as in Theorem 6.1. We apply Corollary 5.3 to $u - u^R$. By Corollary 7.2, $F(u - u^R) = F\tilde{u}$, the proof of Theorem 7.1 yields $\int_{\Gamma_{R,j}} \nu^\top \cdot F\tilde{u} = 0$ for $j = 1, \dots, J$. Therefore (5.24), the trace estimates, and Lemma 4.6 lead to

$$\begin{aligned} &\|v - v^R; H^2(\Omega_{R-\varepsilon})^3\| + \|\nabla p - \nabla p^R; L^2(\Omega_{R-\varepsilon})^3\| \\ &\le C\|F\tilde{u}; \mathcal{R}_1^1 V(\Gamma_R, \partial\Gamma_R)\| \\ &\le C\|\tilde{v}; \mathcal{D}_1^1 V(\Omega_R \backslash \Omega_{R-\varepsilon})\| \le \|\tilde{v}; H^2(\Omega_R \backslash \Omega_{R-\varepsilon})^3\|. \end{aligned}$$

Here we observe that the mixed boundary condition depends only on the velocity part, not on the pressure. Since $\tilde{v} \in H^2(\Omega_R)^3$, the right-hand side of the last inequality tends to 0, as $R \to \infty$, which proves the theorem. □

Remark 7.4. It is possible to formulate these results also in H^l-spaces for arbitrary $l \in \mathbf{N}$. Then in the formulation of the approximation problem, f has to be replaced by $\chi_R f$, like in Theorem 6.1. However, the corresponding results of Corollary 1.2 need a more detailed and technical discussion of the solution w_0 to the divergence equation; we therefore omit this part.

As already mentioned, without more specified assumptions on the decay properties of f, it is not possible to fix the order of convergence of $u - u^R$. But it is possible to refine the estimates after calculating how, for example, the property $f\mathfrak{z}^\gamma \in L^2(\Omega)^3$, $\gamma > 0$ influences the asymptotic behavior of u. This requires other tools than those explained in section 1.2 and will be done in a forthcoming paper.

Acknowledgment. The author is greatly indebted to Professor Sergueï Nazarov for many helpful discussions and advices.

ARBITRARILY SMOOTH ORTHOGONAL NONSEPARABLE WAVELETS IN $\mathbb{R}^2$*

EUGENE BELOGAY† AND YANG WANG†

Abstract. For each $r \in \mathbb{N}$, we construct a family of bivariate orthogonal wavelets with compact support that are nonseparable and have vanishing moments of order r or less. The starting point of the construction is a scaling function that satisfies a dilation equation with special coefficients and a special dilation matrix M: the coefficients are aligned along two adjacent rows, and $|\det(M)| = 2$. We prove that if $M^2 = \pm 2I$, e. g., $M = \left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$ or $M = \left(\begin{smallmatrix} 1 & 1 \\ 1 & -1 \end{smallmatrix}\right)$, then the smoothness of the wavelets improves asymptotically by $1 - \frac{1}{2}\log_2 3 \approx 0.2075$ when r is incremented by 1. Hence they can be made arbitrarily smooth by choosing r large enough.

Key words. nonseparable wavelets, smooth orthogonal scaling function, regularity

1. Introduction.

Since the introduction by Daubechies [7] of compactly supported orthogonal wavelet bases in $\mathbb{R}^1$ with arbitrarily high smoothness, various new wavelet bases (often with specially tailored properties) have been constructed and applied successfully in image processing, numerical computation, statistics, etc. Many of these applications, such as image compression, employ wavelet bases in $\mathbb{R}^2$. Virtually all of these bases are *separable*; that is, the bivariate basis functions are simply tensor products of univariate basis functions. A separable wavelet basis is easy to construct and simple to study, for it inherits features of the corresponding wavelet basis in $\mathbb{R}^1$, such as smoothness and support size. Separable wavelet transforms are easy to implement.

Nevertheless, separable bases have a number of drawbacks. Because they are so special, they have very little design freedom. Furthermore, separability imposes an unnecessary product structure on the plane, which is artificial for natural images. For example, the zero set of a separable scaling function contains horizontal and vertical lines. This "preferred directions" effect can create unpleasant artifacts that become obvious at high image compression ratios. Nonseparable wavelet bases offer the hope of a more isotropic analysis [6, 12, 15].

Despite the success in constructing univariate orthogonal and multivariate biorthogonal wavelet bases with arbitrarily high smoothness, a general theory of smooth multivariate orthogonal nonseparable wavelets is not currently available, and only a few such constructions have been published. Gröchenig and Madych [9] constructed several nonseparable Haar-type scaling functions in $\mathbb{R}^n$, which are discontinuous indicator functions of (often fractal-like) compact sets. Cohen and Daubechies [6] used the univariate construction [7] to produce nonseparable scaling functions with higher accuracy, which are not continuous, as proved by Villemoes [16]. Continuous nonseparable scaling functions were constructed by Kovačević and Vetterli [12], and recently by He and Lai [10], but none of these functions is differentiable.

In this paper we present a new family of arbitrarily smooth, orthogonal, nonseparable wavelet bases in $\mathbb{R}^2$. Our construction follows the standard multiresolution analysis (MRA) approach [8, 13, 14]: it focuses on a scaling function that solves a dilation (or refinement) equation with special coefficients and a special dilation matrix M with $|\det(M)| = 2$. Such dilation matrices make a popular "laboratory case," partly because the MRA involves only one wavelet [4, 6, 12, 15]. The wavelet is easy to construct from the scaling function and has the same smoothness, so we deal mainly with the scaling function.

The coefficients in the dilation equation, called scaling coefficients, determine the properties of the scaling function. To construct a scaling function usually means to find its scaling coefficients. We characterize completely the set of two-row scaling coefficients that produce nonseparable orthogonal scaling functions with arbitrarily high accuracy. We show that our construction can produce scaling functions of any desired smoothness for the special dilation matrix $\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$.

The paper is organized as follows. In section 2 we introduce some basic notions and assumptions and state our two main results: the first describes the scaling coefficients; the second determines the smoothness of the scaling function. In section 3 we formulate and solve the equations that the scaling coefficients must satisfy in order for the scaling function to be orthogonal and accurate. In section 4 we prove the smoothness result. In section 5 we plot some of the new scaling functions and explain how our results can be formulated for dilation matrices other than $\left(\begin{smallmatrix} 0 & 2 \\ 1 & 0 \end{smallmatrix}\right)$.

Note. After submitting this paper, the authors learned about related independent results by Ayache [1], who recently constructed arbitrarily smooth nonseparable orthogonal wavelets by perturbing the separable wavelets for dilation $\left(\begin{smallmatrix} 2 & 0 \\ 0 & 2 \end{smallmatrix}\right)$.

2. Preliminaries and main results. Let M be an expanding 2×2 matrix with integer entries such that $|\det(M)| = 2$. The key ingredients to an MRA with such a *dilation matrix* M are two functions: a *scaling function* ϕ and a *wavelet* ψ. The scaling function $\phi : \mathbb{R}^2 \to \mathbb{R}$ satisfies a *dilation equation* (*refinement equation*) of the form

$$\phi(\mathbf{x}) = 2 \sum_{\mathbf{n} \in \mathbb{Z}^2} c_{\mathbf{n}} \phi(M\mathbf{x} - \mathbf{n}), \qquad \text{where} \quad \sum_{\mathbf{n} \in \mathbb{Z}^2} c_{\mathbf{n}} = 1. \tag{2.1}$$

The numbers $c_{\mathbf{n}}$ are the *scaling coefficients* (*low-pass filter coefficients*) of $\phi(\mathbf{x})$. We assume that they are real and that $c_{\mathbf{n}} \neq 0$ for only finitely many $\mathbf{n} \in \mathbb{Z}^2$ (ensuring that $\phi(\mathbf{x})$ has compact support). A convenient way to work with the scaling coefficients as a whole is to consider the *coefficient mask* (z-*transform*)

$$C(z, w) := \sum_{(m,n) \in \mathbb{Z}^2} c_{(m,n)} z^m w^n, \quad \text{where } (z, w) \in \mathbb{C}^2.$$

Note that $C(1, 1) = 1$. The *symbol* (*frequency response*) of (2.1) is

$$m(\omega_1, \omega_2) := C(e^{i\omega_1}, e^{i\omega_2}).$$

Denote M^{T} by W. The mask is said to satisfy *Cohen's criterion* [16, p. 181] if there exists a compact fundamental domain Ω of the lattice $2\pi\mathbb{Z}^2$ with the property

$$m(W^{-j}\omega) \neq 0 \quad \text{for all } j \geq 1 \text{ and for all } \omega \in \Omega. \tag{2.2}$$

An important task in wavelet theory is to relate the properties of the scaling function $\phi(\mathbf{x})$ to the properties of the coefficient mask $C(z, w)$. Our goal is to find

coefficients in (2.1) that produce a scaling function with two important properties: orthogonality and accuracy.

A scaling function $\phi(\mathbf{x}) \in L^2(\mathbb{R}^2)$ is called *orthogonal* if the set of its lattice translates $\{\phi(\mathbf{x}-\mathbf{k}) : \mathbf{k} \in \mathbb{Z}^2\}$ is orthogonal. The following *orthogonal coefficients condition* is necessary for $\phi(\mathbf{x})$ to be orthogonal:

$$2\sum_{\mathbf{n}\in\mathbb{Z}^2} c_{\mathbf{n}} c_{\mathbf{n}+M\mathbf{k}} = \delta_{\mathbf{0},\,\mathbf{k}} \qquad \text{for all } \mathbf{k} \in \mathbb{Z}^2, \tag{2.3}$$

where $\delta_{\mathbf{m},\,\mathbf{k}}$ is the Kronecker symbol. The condition (2.3) becomes sufficient if, in addition, the scaling coefficients satisfy Cohen's criterion (2.2). The coefficient mask $C(z,w)$ is called *orthogonal* if (2.3) holds.

A scaling function $\phi(\mathbf{x})$ is said to have *accuracy* (*regularity*) r if the space of the infinite linear combinations of $\{\phi(\mathbf{x}-\mathbf{k}) : \mathbf{k} \in \mathbb{Z}^2\}$ contains all polynomials of degree $r-1$ or less. In this case the coefficient mask $C(z,w)$ is said to have accuracy r as well. (How the accuracy of ϕ relates to $C(z,w)$ is explained in the next section.) Accuracy is a desirable property in many applications; for example, in image processing it implies that the polynomial components of the filtered signal will not "leak" into the high-pass band, which improves compression.

In this paper we measure the smoothness of a real bivariate function ϕ by its Hölder exponent (there are alternative regularity measures, such as the Sobolev exponent). Let $s = m + \gamma$, where $0 \le \gamma < 1$ and m is a nonnegative integer. Then we say that $\phi(\mathbf{x}) \in C^s$ if for each partial derivative $D^\alpha\phi(\mathbf{x})$, where $\alpha = (\alpha_1, \alpha_2)$ and $\alpha_1 + \alpha_2 \le m$, there is a constant $c > 0$ such that $|D^\alpha\phi(\mathbf{x}) - D^\alpha\phi(\mathbf{y})| \le c|\mathbf{x}-\mathbf{y}|^\gamma$ for all $\mathbf{x}, \mathbf{y} \in \mathbb{R}^2$. If the Fourier transform $\widehat{\phi}(\omega)$ of $\phi(\mathbf{x})$ satisfies

$$|\widehat{\phi}(\omega)| \le c \cdot (1+|\omega_1|)^{-s-1-\epsilon}(1+|\omega_2|)^{-s-1-\epsilon}$$

for some constants $c > 0$ and $\epsilon > 0$, then $\phi(\mathbf{x}) \in C^s$. It is usually harder to estimate the smoothness of a scaling function than its accuracy.

The *autocorrelation* (*product filter*) of a real polynomial $F(z_1, z_2)$ is defined to be

$$\mathcal{P}_F(z_1, z_2) := F(z_1, z_2)F(z_1^{-1}, z_2^{-1}).$$

The polynomial F is called a *spectral factor* of $\mathcal{P}_F$. Note that $\mathcal{P}_F(e^{i\omega_1}, e^{i\omega_2}) = |F(e^{i\omega_1}, e^{i\omega_2})|^2$ and is therefore always real and nonnegative. Conversely, the Fèjer–Riesz theorem [7] ensures that every real-valued nonnegative univariate trigonometric polynomial $P(e^{i\omega_1})$ can be factored (nonuniquely) as $|F(e^{i\omega_1})|^2$. In most cases the spectral factor F can only be computed numerically. (Strang and Nguyen [15, p. 157] review several spectral factorization methods.)

Spectral factorization is a key technique in univariate orthogonal wavelet theory. Daubechies [7] constructed orthogonal univariate wavelets of arbitrarily high accuracy by deriving an analytic formula for the autocorrelation of the coefficient mask; the scaling coefficients themselves must be computed numerically. Theorem 2.1 is a similar result in a special bivariate setting.

The main difficulty in constructing bivariate nonseparable smooth wavelets is that some key univariate techniques, such as polynomial factorization, do not generalize to the bivariate case. The Fèjer–Riesz theorem is one of them: e.g., $2+\cos(\omega_1)+\cos(\omega_2)$ is real and nonnegative; yet it cannot be factored as $|F(e^{i\omega_1}, e^{i\omega_2})|^2$. One approach to nonseparable orthogonal wavelets is to solve the accuracy and orthogonality conditions for a specific arrangement of unknown scaling coefficients. Unfortunately, the resulting

system of linear and quadratic equations can only be solved (even numerically) when the number of coefficients is rather small. (Kovačević and Vetterli [12] placed the 8 nonzero coefficients in the $\bullet\!\!:\!\!:\!\!\bullet$ pattern; He and Lai [10] used a 4×4 mask.) Another approach to nonseparable wavelets, which we adopt here, is to study special cases of (2.1) and derive the scaling coefficients explicitly.

Our construction employs a special coefficient mask for a particular dilation matrix (generalizations are discussed in section 5). First, we fix the dilation matrix

$$M = \begin{pmatrix} 0 & 2 \\ 1 & 0 \end{pmatrix}.$$

The property $M^2 = 2I$ will be useful in the proof of Theorem 2.2. Next, we restrict the placement of the nonzero scaling coefficients in (2.1) to two adjacent rows in the first quadrant. That is, $\operatorname{supp} c := \{\mathbf{n} \in \mathbb{Z}^2 : c_{\mathbf{n}} \neq 0\} \subseteq \{0, \dots, N\} \times \{0, 1\}$ for some $N \in \mathbb{N}$. As a result, the coefficient mask has the form

$$C(z, w) = A(z) + wB(z), \tag{2.4}$$

where $A(z)$ and $B(z)$ are polynomials of one complex variable. The theorems below do not generalize easily to masks with more than two rows.

Observe that $A(1)+B(1) = C(1,1) = 1$, so it is impossible that $A(1) = B(1) = 0$. Therefore, we assume that $A(1) \neq 0$, for we can always achieve it by a suitable change of variables in (2.1), as explained at the end of section 3. Furthermore, we assume that $B(0) \neq 0$. Cohen and Daubechies [6] noted that if $B(z) \equiv 0$ (that is, if the scaling coefficients are aligned along a single horizontal line), then the scaling function is separable. A simple but important example of such a one-row mask is the *Haar coefficient mask*

$$H(z) := \frac{1}{2}(1 + z). \tag{2.5}$$

The corresponding separable scaling function is the indicator of the unit square.

Our first theorem gives the necessary conditions for a two-row coefficient mask to produce a nonseparable orthogonal scaling function of arbitrarily high accuracy. The proof is in section 3.
