BLOW-UP SOLUTIONS FOR A CLASS OF SEMILINEAR ELLIPTIC AND PARABOLIC EQUATIONS[*]

YIHONG DU[†] AND QINGGUANG HUANG[†]

Abstract. We study the asymptotic behavior of the solutions to the problem

$$\begin{cases} u_t - \Delta u &= au - b(x)u^p \quad \text{in} \quad (0,\infty)\times\Omega, \\ \alpha u_\nu + \beta u &= 0 \quad \text{on} \quad (0,\infty)\times\partial\Omega, \\ u(0,.) &= u_0 \quad \text{in} \quad \Omega, \end{cases}$$

where $p > 1$, $b(x) \geq 0$ is continuous and vanishes on the closure of a nontrivial subdomain Ω_0 of $\Omega \subset R^N$. This case can be regarded as a mixture of the well-understood logistic (when $b(x) > 0$ always) and Malthusian (when $b(x) \equiv 0$) models and has attracted much study in recent years. It follows from recent studies that the model behaves like the logistic model if the growth rate a of the species is less than some constant $a_0 > 0$ and it behaves differently from the logistic model once $a \geq a_0$. In this paper, we show that, when $a \geq a_0$, the model behaves like the Malthusian model on part of the domain (i.e., on Ω_0 where b vanishes) and it behaves like the logistic model on the remaining part of the domain. Our study shows that the boundary blow-up problem

$$-\Delta u = au - b(x)u^p \text{ in } \Omega\setminus\overline{\Omega}_0,\ \alpha u_\nu + \beta u = 0 \text{ on } \partial\Omega,\ \ u = \infty \text{ on } \partial\Omega_0$$

plays a key role in understanding the dynamics of our model and that the whole theory can be described by a nice bifurcation picture involving a branch of positive solutions at "infinity."

Key words. logistic equation, boundary blow-up

1. Introduction.

In this paper, we consider the semilinear elliptic equation

$$-\Delta u = au - b(x)u^p \text{ in } \Omega,\ \ Bu = 0 \text{ on } \partial\Omega \tag{1.1}$$

and the corresponding parabolic problem

$$\begin{cases} u_t - \Delta u &= au - b(x)u^p \quad \text{in} \quad (0,\infty)\times\Omega, \\ Bu &= 0 \quad \text{on} \quad (0,\infty)\times\partial\Omega, \\ u(0,.) &= u_0 \quad \text{in} \quad \Omega. \end{cases} \tag{1.2}$$

Here a is a real parameter, $b \geq 0$ is in $C^\mu(\bar{\Omega})$, and $p > 1$ is a constant; Ω is a $C^{2+\mu}$ bounded domain in R^N, $N \geq 2$, and the boundary condition is given by

$$Bu = \alpha u_\nu + \beta u,$$

where ν is the unit outward normal to $\partial\Omega$ and either $\alpha = 0, \beta = 1$ (which gives the Dirichlet boundary condition) or $\alpha = 1, \beta \geq 0$ is in $C^{1+\mu}(\partial\Omega)$ (which gives the Neumann or Robin boundary conditions).

Problems (1.1) and (1.2) are basic population models (see, e.g., [Hs]). Problem (1.1) is also related to some prescribed curvature problems in Riemannian geometry

(see, e.g., [Ou] and [KW]). We are interested only in positive solutions of (1.1) and (1.2) as these are the solutions which are interesting to us.

If $b(x) > 0 \ \forall \ x \in \overline{\Omega}$, then the equations are known as the logistic equations, and it is well known that (1.1) has a unique positive solution if and only if $a > \lambda_1(\Omega)$, where $\lambda_1(\Omega)$ denotes the first eigenvalue of

$$-\Delta u = \lambda u \text{ in } \Omega, \quad Bu = 0 \text{ on } \ \partial\Omega.$$

Moreover, $u \equiv 0$ attracts all the solutions of (1.2) with admissible nonnegative initial values if $a \leq \lambda_1(\Omega)$, while when $a > \lambda_1(\Omega)$, the unique positive solution of (1.1) attracts all the solutions of (1.2) with admissible nontrivial nonnegative initial values. That is, for any given admissible initial value $u_0 \geq 0$, $u_0 \not\equiv 0$, the unique solution $u(t, x)$ of (1.2) exists for all time $t > 0$, and as $t \to \infty$ it converges to 0 when $a \leq \lambda_1(\Omega)$ and it converges to the unique positive solution $u(x)$ of (1.1) when $a > \lambda_1(\Omega)$.

If $b(x) \equiv 0$, then the equations reduce to the linear Malthusian models with diffusion. It follows from elementary theory of linear parabolic equations (see, e.g., [Fr] or [LSU]) that, as $t \to \infty$, the solution $u(t, x)$ of (1.2) (with nontrivial nonnegative u_0) converges to 0 if $a < \lambda_1(\Omega)$ and it blows up at an exponential rate in t on the whole Ω if $a > \lambda_1(\Omega)$.

We are interested in the degenerate logistic case where $b \geq 0$, $b \not\equiv 0$, but the zero set of b is the closure of some suitably regular nonempty subdomain Ω_0:

$$\overline{\Omega}_0 = \{x \in \overline{\Omega} : b(x) = 0\}.$$

Hence the model becomes a mixture of the logistic and Malthusian models. The assumption that b vanishes on Ω_0 may be interpreted as Ω_0 being an ideal environment, so that the species on Ω_0 has almost no limitation for its population growth. We make this assumption from now on, and let $\lambda_1^D(\Omega_0)$ denote the first eigenvalue of the Dirichlet problem

$$-\Delta u = \lambda u, \quad u|_{\partial\Omega_0} = 0.$$

Under the above assumptions, the elliptic problem (1.1) was studied in [AT], [AG], [Da], [dP], [FKLM], and [Ou]; and [FKLM] also considered the corresponding parabolic problem (1.2). Their results can be summarized as follows (see, e.g., Theorems 3.5 and 3.7 of [FKLM]):

- Equation (1.1) has a positive solution if and only if $a \in (\lambda_1(\Omega), \lambda_1^D(\Omega_0))$. In this case (1.1) has a unique positive solution u_a, $a \to u_a$ is continuous as a map from $(\lambda_1(\Omega), \lambda_1^D(\Omega_0))$ to $C^{2+\mu}(\overline{\Omega})$, and $\|u_a\|_\infty \to \infty$ as $a \to \lambda_1^D(\Omega_0) - 0$.
- For $a \in (\lambda_1(\Omega), \lambda_1^D(\Omega_0))$, the unique positive solution u_a attracts all the solutions of (1.2) with admissible nontrivial nonnegative initial values.
- When $a \leq \lambda_1(\Omega)$, then $u \equiv 0$ attracts all the solutions of (1.2) with admissible nonnegative initial data.
- In the remaining case $a \geq \lambda_1^D(\Omega_0)$, any solution of (1.2) with admissible nontrivial nonnegative initial data blows up in the L^∞-norm as $t \to \infty$: $\lim_{t\to\infty} \|u(t, .)\|_\infty = \infty$.

We remark that $\lambda_1(\Omega) < \lambda_1^D(\Omega_0)$ always holds as $\lambda_1(\Omega) \leq \lambda_1^D(\Omega) < \lambda_1^D(\Omega_0)$.

Note that the above results imply that (1.2) behaves like the logistic model when $a < \lambda_1^D(\Omega_0)$ and it behaves differently from the logistic model when $a \geq \lambda_1^D(\Omega_0)$. It is natural to ask whether it behaves like the Malthusian model in the latter case. This question will be completely answered in this paper. It turns out that our model behaves like the Malthusian model only on part of the domain Ω (in fact, on Ω_0 where b vanishes), and on the rest of the domain, it behaves like the logistic model. Moreover, our results show that the whole theory can be explained by a nice bifurcation picture involving a branch of solutions at "infinity."

Let us now explain our main results in the following. Throughout the paper, we assume that $\overline{\Omega}_0 \subset\subset \Omega$ *is nonempty, connected, and with* $C^{2+\mu}$ *boundary.* The following problem will play an important role:

$$-\Delta u = au - b(x)u^p \text{ in } \Omega \setminus \overline{\Omega}_0,\ Bu = 0 \text{ on } \partial\Omega,\quad u = \infty \text{ on } \partial\Omega_0. \tag{1.3}$$

Here, as usual, $u = \infty$ on $\partial\Omega_0$ means that

$$u(x) \to \infty \text{ as } x \in \Omega \setminus \overline{\Omega}_0 \text{ and } d(x, \partial\Omega_0) \to 0.$$

Now we are ready to state our main results; for simplicity of statement, we have refrained from giving the most general form here.

THEOREM 1.1. (i) *For any* $a \in (-\infty, \infty)$, *problem* (1.3) *has a minimal positive solution* $\underline{U}_a$ *and a maximal positive solution* $\overline{U}_a$.

(ii) *If there exist positive constants* α *and* c *such that* $\lim_{d(x,\Omega_0)\to 0} b(x)/[d(x, \Omega_0)]^\alpha = c$, *then* (1.3) *has a unique positive solution.*

THEOREM 1.2. *Let* $a_0 = \lambda_1^D(\Omega_0)$. *Then*

(i) *for any fixed* $x \in \overline{\Omega}_0$, $u_a(x) \to \infty$ *as* $a \nearrow a_0$;

(ii) *for any fixed* $x \in \overline{\Omega} \setminus \overline{\Omega}_0$, $u_a(x) \to \underline{U}_{a_0}(x)$ *as* $a \nearrow a_0$.

THEOREM 1.3. *Let* $a \geq a_0 = \lambda_1^D(\Omega_0)$. *Then for any given admissible nontrivial nonnegative initial value* u_0, *the unique solution* $u(t, x)$ *of* (1.2) *satisfies*

(i) *for any fixed* $x \in \overline{\Omega}_0$, $u(t, x) \to \infty$ *as* $t \to \infty$;

(ii) *for any fixed* $x \in \overline{\Omega} \setminus \overline{\Omega}_0$, $\overline{\lim}_{t\to\infty} u(t, x) \leq \overline{U}_a(x)$; $\underline{\lim}_{t\to\infty} u(t, x) \geq \underline{U}_a(x)$;

(iii) *if* (1.3) *has a unique positive solution denoted as* U_a, *then for any fixed* $x \in \overline{\Omega} \setminus \overline{\Omega}_0$, $\lim_{t\to\infty} u(t, x) = U_a(x)$.

When the solution of (1.3) is unique (as in case (ii), Theorem 1.1), then the above results give the following nice bifurcation picture for (1.1) and (1.2):

Denote $\tilde{U}_a(x) = U_a(x)$ *when* $a \in \Omega \setminus \overline{\Omega}_0$ *and* $\tilde{U}_a(x) = \infty$ *when* $x \in \overline{\Omega}_0$; *and regard* $\tilde{U}_a$ *as a solution of* (1.1) *at "infinity." Then the unique positive solution branch*

$$\Sigma = \{(a, u_a) : \lambda_1(\Omega) < a < \lambda_1^D(\Omega_0)\}$$

bifurcates from the branch of trivial solutions

$$\Sigma_0 = \{(a, 0) : -\infty < a < \infty\}$$

at $a = \lambda_1(\Omega)$ *and it joins the branch of positive solutions at "infinity,"*

$$\Sigma_\infty = \{(a, \tilde{U}_a) : -\infty < a < \infty\},$$

at $a = \lambda_1^D(\Omega_0)$. *Moreover, when* $a \leq \lambda_1(\Omega)$, *the trivial solution on* Σ_0 *is globally attractive for* (1.2), *when* $\lambda_1(\Omega) < a < \lambda_1^D(\Omega_0)$, *the positive solution on* Σ *is globally attractive, and when* $a \geq \lambda_1^D(\Omega_0)$, *the solution at "infinity" on* Σ_∞ *is globally attractive.*

Remark 1.4. (i) Our results remain valid if $b(x)$ vanishes on the closure of a finite number of disjoint subdomains $\Omega_1, \ldots, \Omega_k$, all with $C^{2+\mu}$ boundary; the statements of our results being modified accordingly.

(ii) With a little more effort, our arguments (except the proofs of Theorem 2.8 and Proposition 4.4) can be carried out when Δ is replaced by a general self-adjoint second-order strongly elliptic operator and the term u^p replaced by a more general nonlinear function of the similar type.

(iii) Many difficulties in our arguments come from the fact that $b(x)$ vanishes on Ω_0 in a continuous fashion. If we allow $b(x)$ to be discontinuous on $\partial\Omega_0$ so that $b(x) \geq c_0 > 0$ on $\Omega \setminus \Omega_0$, then it is much easier to establish similar or better results (and with less regularity on $\partial\Omega_0$). For example, in this case, (1.3) has a unique positive solution (by a variant of [MV]). We suspect that the uniqueness result for (1.3) always holds.

(iv) Our techniques in this paper rely heavily on the assumption that $\Omega_0 \subset\subset \Omega$ and do not work for the case $\partial\Omega_0 \cap \partial\Omega \neq \emptyset$. This latter case is rather difficult and is discussed in [DG].

(v) As a by-product of our results, we find that the sufficient condition on the asymptotic behavior of the first eigenvalues given in [FKLM] is far from necessary. To be more specific, Theorem 2.4 of [FKLM] shows that

$$\lambda_1(-\Delta + q_k, \Omega) \to \lambda_1^D(\Omega_0)$$

if q_k is a sequence of increasing nonnegative functions in $C^\mu(\overline{\Omega})$ satisfying

$$q_k \equiv 0 \text{ on } \Omega_0, \quad q_k(x) \to \infty \text{ uniformly on any compact set } K \subset \overline{\Omega} \setminus \overline{\Omega}_0.$$

However, if we take $q_k(x) = b(x)u_{a_k}^{p-1}(x)$, where $a_k < a_0 = \lambda_1^D(\Omega_0)$ and $a_k \to a_0$, then by Theorem 3.6,

$$q_k(x) \to b(x)\underline{U}_{a_0}^{p-1}(x) < \infty \text{ uniformly on any compact set } K \subset \overline{\Omega} \setminus \overline{\Omega}_0,\ q_k \equiv 0 \text{ on } \Omega_0,$$

but we still have, from the equations for u_{a_k}, that

$$\lambda_1(-\Delta + q_k, \Omega) = a_k \to a_0 = \lambda_1^D(\Omega_0).$$

Finally, we would like to mention that if $b(x)$ changes sign on Ω, then it is known (see, e.g., [AT2] and [BCN]) that there exists $a^* > \lambda_1(\Omega)$ such that (1.1) has a positive solution if and only if

(i) $a < \lambda_1(\Omega)$ or

(ii) $a \in [\lambda_1(\Omega), a^*]$ and $\int_\Omega b(x)\phi(x) < 0$, where $\phi > 0$ is an eigenfunction corresponding to $\lambda_1(\Omega)$.

Some multiplicity results can also be found in [AT2].

The rest of the paper is organized as follows. Section 2 is devoted to the boundary blow-up problem (1.3), where we use various upper and lower solution arguments to prove the existence and uniqueness of positive solutions to (1.3). In section 3, we study the asymptotic behavior of the positive solution u_a of (1.1) as $a \nearrow a_0$. A crucial step here is to show that the solutions blow up on $\partial\Omega_0$. In section 4, we make use of the results obtained in the previous sections and discuss how the solution of (1.2) blows up as $t \to \infty$.

After this paper was submitted for publication, we learned of the works [GGLS] and [LS], where some related problems were discussed and interesting numerical simulations were presented. Our method in this paper can be used to improve some of the results on the blow-up behavior in [GGLS] and [LS]. More precisely, in [LS, Theorem 4.3] (see also [GGLS, Corollary 3.3]), through analysis on the first variation of the principal eigenvalues, it is proved that the stationary solution blows up on the boundary Γ of $\{b(x)>0\}$ as a approaches $\lambda_1^D(\{b(x)=0\})$, provided that

$$b(x)=o(d(x,\Gamma)) \text{ as } d(x,\Gamma)\to 0.$$

The method in section 3 of the present paper shows that the above condition is unnecessary.

2. The boundary blow-up problem (1.3). In this section, we study in detail problem (1.3). Boundary blow-up problems similar to (1.3) arise naturally from a number of different areas and have a long history. Considerable amounts of study have been attracted by such problems. We mention only [BM], [LM], [LN], and [MV]; many other works can be found from the references of these papers. One main difference, which posses technical difficulties, of our problem (1.3) from the previous ones is that our function $b(x)$ vanishes on $\partial\Omega_0$.

We start with an interesting comparison result which will be used frequently later (actually this result is a little more than enough for our later use).

LEMMA 2.1. *If $u_1,u_2\in C^2(\overline{\Omega}\setminus\overline{\Omega}_0)$ are both positive in $\Omega\setminus\overline{\Omega}_0$ and*

$$\Delta u_1+au_1-b(x)u_1^p\le 0\le \Delta u_2+au_2-b(x)u_2^p \textit{ in } \Omega\setminus\overline{\Omega}_0, \tag{2.1}$$

$$Bu_1\ge Bu_2 \textit{ on } \partial\Omega;\quad \overline{\lim}_{d(x,\partial\Omega_0)\to 0}(u_2-u_1)\le 0,$$

then $u_1\ge u_2$ on $\overline{\Omega}\setminus\overline{\Omega}_0$.

Proof. We shall use a variant of a method used in the proof of Lemma 1.1 in [MV] which goes back to [BBL].

We consider only the case that the boundary operator B in our problem is of Neumann or Robin type, as the Dirichlet case can be proved in exactly the same manner as in [MV]. Let w_1,w_2 be nonnegative C^2 functions on $\overline{\Omega}\setminus\Omega_0$ vanishing near $\partial\Omega_0$. Using (2.1) and applying integration by parts and subtraction we easily obtain

$$\begin{aligned}&-\int_{\tilde\Omega}[\nabla u_2\nabla w_2-\nabla u_1\nabla w_1]-\beta\int_{\partial\Omega}(u_2w_2-u_1w_1)\\ &\qquad\ge\int_{\tilde\Omega}b(x)(u_2^pw_2-u_1^pw_1)+a\int_{\tilde\Omega}(u_1w_1-u_2w_2),\end{aligned} \tag{2.2}$$

where $\tilde\Omega=\Omega\setminus\overline{\Omega}_0$.

Let $\epsilon_1>\epsilon_2>0$ and denote

$$v_i=(u_i+\epsilon_i)^{-1}[(u_2+\epsilon_2)^2-(u_1+\epsilon_1)^2]^+,\qquad i=1,2.$$

Since v_i can be approximated arbitrarily closely in the $W^{1,2}\cap L^\infty$ norm on $\overline{\Omega}\setminus\Omega_0$ by C^2 functions vanishing near $\partial\Omega_0$ (this is easily seen to be possible if, say, one extends v_i continuously across $\partial\Omega_0$ first and then uses mollifiers), we see that (2.2) holds when w_i is replaced by v_i. Denote

$$\Omega_+(\epsilon_1,\epsilon_2)=\{x\in\tilde\Omega: u_2(x)+\epsilon_2>u_1(x)+\epsilon_1\},$$

and note that the integrands of $\int_{\tilde\Omega}$ in (2.2) (with $w_i=v_i$) vanish outside this set. The first integral on the left-hand side of (2.2) equals

$$-\int_{\Omega_+(\epsilon_1,\epsilon_2)}\left(\left|\nabla u_2-\frac{u_2+\epsilon_2}{u_1+\epsilon_1}\nabla u_1\right|^2+\left|\nabla u_1-\frac{u_1+\epsilon_1}{u_2+\epsilon_2}\nabla u_2\right|^2\right),$$

which is nonpositive. On the other hand, as $0 < \epsilon_2 < \epsilon_1 \to 0$, the first term on the right-hand side of (2.2) converges to

$$\int_{\Omega_+(0,0)} b(x)(u_2^{p-1} - u_1^{p-1})(u_2^2 - u_1^2)$$

and the other two remaining terms in (2.2) converge to 0. Therefore we would have a contradiction unless $\Omega_+(0,0)$ has measure 0, i.e., $u_1 \geq u_2$ on $\tilde{\Omega}$. □

Remark 2.2. The conclusion of Lemma 2.1 holds under much weaker conditions; see, e.g., Lemma 1.1 in [MV], where Ω_0 is empty.

Lemma 2.3. *For any given positive function $\phi \in C^{2+\mu}(\partial\Omega_0)$ and $a \in (-\infty, \infty)$, the problem*

$$-\Delta u = au - b(x)u^p \text{ in } \Omega \setminus \overline{\Omega}_0;\ u|_{\partial\Omega_0} = \phi,\ Bu|_{\partial\Omega} = 0 \tag{2.3}$$

has a unique positive solution.

Proof. Let $a^* = \max\{\lambda_1(\Omega), a\}$. Then choose a smooth nonnegative function $b^*(x)$ such that $b^*(x) \leq b(x)$ on $\Omega \setminus \Omega_0$ and $\Omega_0^* \equiv \{x \in \overline{\Omega} : b^*(x) = 0\}$ has small volume so that $\lambda_1^D(\Omega_0^*) > a^*$. Then, by Theorem 2 of [Ou] (see also [AT], [dP], or [FKLM] for the Robin boundary conditions), there is a unique positive solution u^* for the problem

$$-\Delta u = a^*u - b^*(x)u^p, \quad Bu|_{\partial\Omega} = 0.$$

Choose a large constant $M > 1$ such that $Mu^* > \phi$ on $\partial\Omega_0$. Then it is easily checked that Mu^* is a supersolution to (2.3). Clearly $u \equiv 0$ is a subsolution to (2.3). Therefore, (2.3) has at least one positive solution (see, for example, [St]). By Lemma 2.1, there is at most one positive solution. Hence (2.3) has a unique positive solution. □

Theorem 2.4. *For any $a \in (-\infty, \infty)$,* (1.3) *has a minimal positive solution $\underline{U}_a$ and a maximal positive solution $\overline{U}_a$ in the sense that any positive solution u of* (1.3) *satisfies $\underline{U}_a(x) \leq u(x) \leq \overline{U}_a(x)$.*

Proof. Let $u_c(x)$ denote the unique positive solution of (2.3) with $\phi(x) \equiv c > 0$. We know from Lemma 2.1 that $c \to u_c(x)$ is increasing. If we can show that $u_c(x)$ is bounded from above by some function $V(x)$ which is uniformly bounded on all compact subsets of $\overline{\Omega} \setminus \overline{\Omega}_0$, then a simple regularity and compactness argument shows that $u_\infty(x) \equiv \lim_{c\to\infty} u_c(x)$ is a solution of (1.3). We now set out to find such a function V.

We can find a nonnegative function $b^*(x)$ in $C^2(\overline{\Omega} \setminus \Omega_0)$ such that

$$0 < b^*(x) \leq b(x) \quad \forall x \in \overline{\Omega} \setminus \overline{\Omega}_0.$$

Such a function is easy to construct for x bounded away from $\partial\Omega_0$. For x satisfying $0 < d(x, \Omega_0) < \delta$, where $\delta > 0$ is small such that $x \to d(x, \Omega_0)$ is C^2, we can define

$$b^*(x) = f(d(x, \Omega_0)), \quad \text{where } f(\eta) = \int_0^\eta \int_0^\xi [\min_{d(x,\Omega_0)\geq s} b(x)] ds d\xi.$$

We now fix a $c_0 > 0$ and define $V^*(x)$ such that

(i) $V^*(x) = u_{c_0}(x)$ for $x \in \overline{\Omega}$ and near $\partial\Omega$;

(ii) $V^*(x) = [b^*(x)]^\beta,\ \beta = 3/(1-p)$ for x satisfying $0 < d(x, \Omega_0) < \delta$;

(iii) V^* is C^2 and positive on $\overline{\Omega} \setminus \overline{\Omega}_0$.

We show that, for all large constant $M > 0$, $V(x) = MV^*(x)$ meets our requirement specified earlier.

Since

$$BV(x) = BMu_{c_0}(x) = 0 \ \forall x \in \partial\Omega \text{ and } \lim_{d(x,\Omega_0)\to 0}[u_c(x) - V(x)] = -\infty < 0,$$

by Lemma 2.1, we will have $u_c(x) \le V(x) \ \forall \ \ x \in \overline{\Omega} \setminus \overline{\Omega}_0$ if we can show that

$$-\Delta V \ge aV - b(x)V^p \quad \forall x \in \Omega \setminus \overline{\Omega}_0. \tag{2.4}$$

For x satisfying $0 < d(x, \Omega_0) < \delta$, a direct calculation gives

$$-\Delta V - aV + b(x)V^p$$

$$= -\beta M[b^*(x)]^{\beta-1}\Delta b^*(x) - \beta(\beta-1)M[b^*(x)]^{\beta-2}|\nabla b^*(x)|^2 - aM[b^*(x)]^{\beta} + M^p b(x)[b^*(x)]^{p\beta}$$

$$\ge M[b^*(x)]^{p\beta+1}\{-\beta b^*(x)\Delta b^*(x) - \beta(\beta-1)|\nabla b^*(x)|^2 - a[b^*(x)]^2 + M^{p-1}\} > 0$$

$\forall$ large $M > 0$. For $x \in \overline{\Omega}$ satisfying $d(x, \Omega_0) \ge \delta$,

$$-\Delta V - aV + b(x)V^p = M[-\Delta V^* - aV^* + b(x)M^{p-1}V^{*p}] \ge 0$$

$\forall$ large M. Hence (2.4) is always satisfied if M is large.

By Lemma 2.1, any solution u of (1.3) satisfies $u \ge u_c$ for every $c > 0$. Hence $\underline{U} \equiv \lim_{c\to\infty} u_c \le u$ and $\underline{U}$ is a minimal positive solution of (1.3).

To show the existence of a maximal solution for (1.3), we consider the problem

$$-\Delta u = au - b(x)u^p \text{ in } \Omega \setminus \overline{\Omega}_n, \quad u|_{\partial\Omega_n} = \infty, \ Bu|_{\partial\Omega} = 0,$$

where $\Omega_n \equiv \{x \in \Omega : d(x, \Omega_0) < 1/n\}$.

A similar but simpler (since $b(x) > 0$ on $\overline{\Omega}\setminus\Omega_n$) argument shows that this problem has a minimal positive solution u_n. Using Lemma 2.1, we see that for any positive solution u of (1.3), $u_n \ge u_{n+1} \ge u$ on $\Omega \setminus \overline{\Omega}_n$. Hence $\overline{U}(x) = \lim_{n\to\infty} u_n(x) \ge u(x)$. But one easily sees that $\overline{U}$ is a positive solution of (1.3). Hence it is a maximal positive solution. This finishes the proof of Theorem 2.4. □

Remark 2.5. To show the convergence of u_c as $c \to \infty$, we actually need to find only, for each open set O with $\overline{O} \subset \overline{\Omega} \setminus \overline{\Omega}_0$, a function V_O such that $V_O \ge u_c$ on O for all c. This is much easier to do and requires no regularity on $\partial\Omega_0$. In fact, in a number of places in this paper, our assumption on the regularity of the domain is more than necessary. Here we have kept the above longer proof because it shows that if $b(x)$ is C^2 near $\partial\Omega_0$, then $\underline{U}_a(x) \le M[b(x)]^{3/(1-p)}$ for x near $\partial\Omega_0$.

Next we discuss the uniqueness of the positive solutions of (1.3). The following result will be useful in our proof of the uniqueness result.

LEMMA 2.6. *Let $b^* \in C^{\mu}(\overline{\Omega})$ be such that $b^*(x) > 0 \ \forall x \in \overline{\Omega} \setminus \partial\Omega_0$. Then, for any $a \in (-\infty, \infty)$, the problem*

$$-\Delta u = au - b^*(x)u^p \ \textit{in } \Omega, \quad u|_{\partial\Omega} = \infty \tag{2.5}$$

has at least one positive solution.

Proof. Choose subdomains Ω_1 and Ω_2 such that

$$\overline{\Omega}_0 \subset\subset \Omega_1, \ \overline{\Omega}_1 \subset\subset \Omega_2, \ \overline{\Omega}_2 \subset\subset \Omega.$$

By [MV], the problem

$$-\Delta u = au - b^*(x)u^p \text{ in } \Omega \setminus \overline{\Omega}_1, \quad u|_{\partial\Omega} = \infty, \; u|_{\partial\Omega_1} = \infty$$

has a positive solution $u_1(x)$.

Let $a^* > \max\{a, \lambda_1(\Omega)\}$. Then the problem

$$-\Delta u = a^* u - b^*(x)u^p \text{ in } \Omega, \quad u|_{\partial\Omega} = 0$$

has a positive solution $u_2(x)$ (see, e.g., [dP]).

Now we define $u^* \in C^2(\overline{\Omega})$ such that

(i) $u^*(x) = u_1(x)$ for $x \in \Omega \setminus \Omega_2$;

(ii) $u^*(x) = u_2(x)$ for $x \in \Omega_1$;

(iii) $u^*(x) > 0$ on Ω.

Then it is easily checked that for all large constant $M > 0$, $U = Mu^*$ satisfies

$$-\Delta U(x) \geq aU(x) - b^*(x)U^p(x) \;\; \forall x \in \Omega.$$

A super- and subsolution argument, together with the use of Lemma 2.1, shows that the problem

$$-\Delta u = au - b^*(x)u^p \text{ in } \Omega, \quad u|_{\partial\Omega} = n$$

has a unique positive solution u_n and $u_n \leq u_{n+1} \leq U$ on Ω. Hence $u_\infty(x) \equiv \lim_{n\to\infty} u_n(x)$ exists and is a positive solution of (2.5). This finishes the proof of Lemma 2.6. □

Remark 2.7. It is easy to show that (2.5) has a unique positive solution (see [MV]). Lemma 2.6 generalizes earlier results of this type (see, e.g., [BM], [MV]), where $b^* > 0$ on the entire domain is required. One easily sees from the above proof how this result can be generalized to the case that b^* vanishes on the closure of a subdomain of Ω.

THEOREM 2.8. *Denote $d(x) = d(x, \Omega_0)$. Suppose there exist positive constants α and c such that*

$$\lim_{d(x)\to 0} b(x)/[d(x)]^\alpha = c.$$

Then for any $a \in (-\infty, \infty)$, problem (1.3) *has a unique positive solution U_a. Moreover,*

$$\lim_{d(x)\to 0} [d(x)]^{(\alpha+2)/(p-1)} U_a(x) = \Big(\frac{(2+\alpha)(1+\alpha+p)}{c(p-1)^2}\Big)^{1/(p-1)}.$$

Proof. Given any small $\epsilon > 0$, we fix a $\delta > 0$ small such that

(i) $d(x)$ is C^2 $\forall$ x satisfying $0 < d(x) < 2\delta$;

(ii) $|\frac{2+\alpha}{p-1}\Delta d(x)s - as^2| < \epsilon$ $\forall$ $s \in [0, 2\delta]$ and x satisfying $0 < d(x) < 2\delta$;

(iii) $(c-\epsilon)d(x)^\alpha \leq b(x) \leq (c+\epsilon)d(x)^\alpha$ $\forall$ x with $0 < d(x) < 2\delta$.

Denote $\beta = -\frac{2+\alpha}{p-1}$, and let

$$\underline{\xi} = \Big(\frac{\beta(\beta-1)-\epsilon}{c+\epsilon}\Big)^{1/(p-1)}, \quad \overline{\xi} = \Big(\frac{\beta(\beta-1)+\epsilon}{c-\epsilon}\Big)^{1/(p-1)}, \tag{2.6}$$

and for $\sigma \in (0, \delta)$, define

$$\underline{v}_\sigma = [d(x)+\sigma]^\beta \underline{\xi}, \quad \overline{v}_\sigma = [d(x)-\sigma]^\beta \overline{\xi}.$$

Since $|\nabla d(x)| \equiv 1$ and $b(x) \geq (c-\epsilon)[d(x)-\sigma]^\alpha$ when $\sigma < d(x) < 2\delta$, we easily obtain

$$-\Delta \overline{v}_\sigma - a\overline{v}_\sigma + b(x)(\overline{v}_\sigma)^p$$

$$= \overline{\xi}\Big\{-\beta[d(x)-\sigma]^{\beta-1}\Delta d(x) - \beta(\beta-1)[d(x)-\sigma]^{\beta-2} - a[d(x)-\sigma]^\beta + b(x)[d(x)-\sigma]^{\beta p}\overline{\xi}^{p-1}\Big\}$$

$$\geq \overline{\xi}[d(x)-\sigma]^{\beta-2}\Big\{-\beta\Delta d(x)[d(x)-\sigma] - a[d(x)-\sigma]^2 + \epsilon\Big\}$$

$$\geq 0 \quad \forall\ x \text{ satisfying } \sigma < d(x) < 2\delta.$$

Similarly, since $b(x) < (c+\epsilon)[d(x)+\sigma]^\alpha$ when $d(x)+\sigma < 2\delta$,

$$-\Delta \underline{v}_\sigma - a\underline{v}_\sigma + b(x)(\underline{v}_\sigma)^p$$

$$\leq \underline{\xi}[d(x)+\sigma]^{\beta-2}\Big\{-\beta\Delta d(x)[d(x)+\sigma] - a[d(x)+\sigma]^2 - \epsilon\Big\}$$

$$\leq 0 \quad \forall\ x \text{ satisfying } d(x)+\sigma < 2\delta.$$

Let w be the positive solution of (2.5) with Ω replaced by $\Omega_\delta \equiv \{x \in \Omega : d(x,\Omega_0) < \delta\}$ and $b^* \in C^\mu(\overline{\Omega_\delta})$ satisfying $b^*(x) = b(x)$ for $x \in \overline{\Omega_\delta} \setminus \Omega_0$ and $b^*(x) > 0$ for $x \in \Omega_0$.

Suppose that u is any positive solution of (1.3). Then one easily checks that $v = u + w$ satisfies

$$-\Delta v \geq av - b(x)v^p \quad \text{in } \Omega_\delta \setminus \overline{\Omega_0}.$$

Since

$$v|_{\partial\Omega_0} = \infty > \underline{v}_\sigma|_{\partial\Omega_0} \text{ and } v|_{\partial\Omega_\delta} = \infty > \underline{v}_\sigma|_{\partial\Omega_\delta},$$

by Lemma 2.1,

$$u + w \geq \underline{v}_\sigma \ \text{ on } \Omega_\delta \setminus \overline{\Omega}_0. \tag{2.7}$$

Similarly,

$$\overline{v}_\sigma + w \geq u \ \text{ on } \ \Omega_\delta \setminus \overline{\Omega}_\sigma. \tag{2.8}$$

Letting $\sigma \to 0$ in (2.7) and (2.8), we deduce

$$d(x)^\beta\overline{\xi} + 2w \geq u + w \geq d(x)^\beta\underline{\xi} \ \ \forall x \in \Omega_\delta \setminus \overline{\Omega}_0.$$

Since w is uniformly bounded on $\partial\Omega_0$, it follows that

$$\underline{\xi} \leq \underline{\lim}_{d(x)\to 0} d(x)^{-\beta}u(x) \leq \overline{\lim}_{d(x)\to 0} d(x)^{-\beta}u(x) \leq \overline{\xi}. \tag{2.9}$$

Recalling (2.6) and letting $\epsilon \to 0$ in (2.9), we obtain

$$\lim_{d(x)\to 0} d(x)^{-\beta}u(x) = \Big(\frac{\beta(\beta-1)}{c}\Big)^{1/(p-1)} = \Big(\frac{(2+\alpha)(1+\alpha+p)}{c(p-1)^2}\Big)^{1/(p-1)}. \tag{2.10}$$

Suppose now u_1 and u_2 are two positive solutions of (1.3). By (2.10), for any $\epsilon > 0$,

$$\lim_{d(x)\to 0}[u_1(x) - (1+\epsilon)u_2(x)] = -\infty, \lim_{d(x)\to 0}[u_2(x) - (1+\epsilon)u_1(x)] = -\infty.$$

Let us denote $w_i = (1+\epsilon)u_i$, $i = 1, 2$. Clearly,

$$-\Delta w_i \geq a w_i - b(x) w_i^p \text{ in } \Omega \setminus \overline{\Omega}_0, \quad B w_i = 0 \text{ on } \partial\Omega.$$

Hence we can use Lemma 2.1 to conclude that

$$u_1(x) \leq (1+\epsilon)u_2(x), \quad u_2(x) \leq (1+\epsilon)u_1(x) \quad \forall x \in \Omega \setminus \overline{\Omega}_0.$$

Letting $\epsilon \to 0$, we obtain $u_1 \equiv u_2$. This finishes the proof of Theorem 2.8. □

Remark 2.9. From the above proof, we easily see that if $b(x) > 0$ on $\overline{\Omega} \setminus \Omega_0$ and if the condition of Theorem 2.8 holds with $\alpha = 0$, then the uniqueness conclusion and the asymptotic formula near $\partial\Omega_0$ (with $\alpha = 0$) are also valid. In fact, it is easy to show by a simple variant of the techniques in [MV] that when $b(x) > 0$ on $\overline{\Omega} \setminus \Omega_0$, (1.3) always has a unique positive solution. We suspect that, even in our case where $b(x)$ vanishes on $\partial\Omega_0$, the condition $\lim_{d(x)\to 0} b(x)/[d(x)]^\alpha = c$ in Theorem 2.8 is unnecessary for uniqueness.

By using Lemma 2.1 and a simple compactness argument, we deduce easily the following result.

Corollary 2.10. *Suppose that* (1.3) *has a unique positive solution* U_a. *Then*

(i) $a \to U_a$ *is continuous as a map from* $(-\infty, \infty)$ *to* $C^{2+\mu}(K)$ *for any compact set* $K \subset \overline{\Omega} \setminus \overline{\Omega}_0$;

(ii) *for any fixed* $x \in \Omega \setminus \overline{\Omega}_0$, $a \to U_a(x)$ *is strictly increasing.*

3. Blow-up solutions of problem (1.1). In this section, we study the blow-up solutions of (1.1) as $a \to a_0$. It is well known that $a \to u_a(x)$ is strictly increasing for $a \in (\lambda_1(\Omega), a_0)$. Therefore, to study the behavior of $\lim_{a\to a_0} u_a(x)$, it suffices to study this limit when $a \to a_0$ is replaced by some sequence $a_n \to a_0$. To this end, we let

$$\Omega_n = \{x \in \Omega : d(x, \Omega_0) < 1/n\}.$$

Without loss of generality, we may assume that $\Omega_n \subset\subset \Omega$ for all $n \geq 1$. Let $a_n = \lambda_1^D(\Omega_n)$. Then we have

$$\lambda_1(\Omega) < a_n < a_0, \quad a_n \to a_0 \text{ as } n \to \infty.$$

We denote $u_n = u_{a_n}$, i.e.,

$$-\Delta u_n = a_n u_n - b(x) u_n^p \text{ in } \Omega, \quad B u_n = 0 \text{ on } \partial\Omega.$$

Lemma 3.1. $\lim_{n\to\infty} u_n(x) = \infty$ *uniformly for* x *in any compact set* $K \subset\subset \Omega_0$.

Proof. Let $\phi_0 \geq 0$ with $\|\phi_0\|_\infty = 1$ be the eigenfunction corresponding to $a_0 = \lambda_1^D(\Omega_0)$,

$$-\Delta\phi_0 = a_0\phi_0, \quad \phi_0|_{\partial\Omega_0} = 0,$$

and let

$$\alpha_0 = \inf_{x\in\Omega_0} u_1(x), \quad \beta_0 = \min_{x\in K} \phi_0(x).$$

Clearly,

$$\alpha_0 > 0,\ \beta_0 > 0,\quad u_n(x) \ge u_1(x) \ge \alpha_0\ \forall n \ge 1, x \in \Omega_0. \tag{3.1}$$

Given any large number $M > 0$, we can find a domain K^* satisfying $K \subset K^* \subset\subset \Omega_0$ such that

$$\phi_0(x) < \alpha_0\beta_0/(2M)\ \forall x \in \partial K^*. \tag{3.2}$$

By a standard interior regularity argument (see, e.g., the proof of Theorem 2.1 in [BNV]), $\phi_n \to \phi_0$ uniformly on K^*, where ϕ_n is given by

$$-\Delta\phi_n = a_n\phi_n,\quad \phi_n|_{\partial\Omega_n} = 0,\ \phi_n \ge 0,\ \|\phi_n\|_\infty = 1.$$

Thus, by (3.2) and the definition of β_0, ∀ large n,

$$(M/\beta_0)\phi_n(x) < \alpha_0\ \forall x \in \partial K^*;\quad (M/\beta_0)\phi_n(x) > M/2\ \forall x \in K. \tag{3.3}$$

Recall that $b(x) = 0$ on K^*. Hence u_n and $(M/\beta_0)\phi_n$ satisfy the same equation $-\Delta u = a_n u$. It now follows from (3.1) and (3.3) that $(M/\beta_0)\phi_n$ and u_n are, respectively, sub- and supersolutions of the problem

$$-\Delta u = a_n u \text{ in } K^*,\quad u|_{\partial K^*} = \alpha_0.$$

As $a_n < a_0 < \lambda_1^D(K^*)$, it follows from the maximum principle that ∀ large n,

$$u_n(x) \ge (M/\beta_0)\phi_n(x) \ge M/2\ \ \forall x \in K \subset K^*.$$

Since $M > 0$ is arbitrary, this shows $\lim_{n\to\infty} u_n(x) = \infty$ uniformly in K. □

Remark 3.2. Lemma 3.1 is related to Theorem 3 of [dP].

Since $\partial\Omega_0$ is $C^{2+\mu}$, it satisfies a uniform interior ball condition: There exists $R > 0$ such that for any $x \in \partial\Omega_0$, there is a ball B_x of radius R such that $B_x \subset \overline{\Omega}_0$ and $B_x \cap \partial\Omega_0 = \{x\}$.

Lemma 3.3. *Let $x_n \in \partial\Omega_0$ be such that*

$$u_n(x_n) = \min_{x\in\partial\Omega_0} u_n(x).$$

If $\{u_n(x_n)\}$ is bounded, then we can find a constant $\sigma > 0$ and a sequence $c_n \to \infty$ such that

$$u_n(x) \ge u_n(x_n) + c_n\psi(x) \quad \textit{whenever } R/2 \le |x - y_n| \le R, \tag{3.4}$$

where $\psi(x) = e^{-\sigma|x-y_n|^2} - e^{-\sigma R^2}$ and y_n is the center of the ball B_{x_n}.

Proof. A simple calculation gives

$$\Delta\psi + a_n\psi = (4\sigma^2|x - y_n|^2 - 2N\sigma + a_n)e^{-\sigma|x-y_n|^2} - a_n e^{-\sigma R^2}.$$

We can choose a large $\sigma > 0$ such that

$$-\Delta\psi(x) \le a_n\psi(x)\ \ \forall x \in B_{x_n} \setminus B_{R/2}(y_n),$$

where $B_{R/2}(y_n) = \{x \in R^N : |x - y_n| < R/2\}$.

Choose a compact set $K \subset\subset \Omega_0$ such that $K \supset \cup_{n=1}^{\infty} B_{R/2}(y_n)$. By Lemma 3.1 and the assumption that $\{u_n(x_n)\}$ is bounded, we can find a sequence $c_n \to \infty$ such that

$$u_n(x) \geq u_n(x_n) + c_n(e^{-\sigma R^2/4} - e^{-\sigma R^2}) \;\; \forall x \in B_{R/2}(y_n) \subset K.$$

On the other hand, since $a_n < a_0$, by the maximum principle, $u_n(x) \geq u_n(x_n)$ $\forall x \in \Omega_0$. In particular, $u_n(x) \geq u_n(x_n)$ on ∂B_{x_n}. Thus we see that u_n is a supersolution to the problem

$$\text{(3.5)} \qquad \begin{cases} -\Delta u = a_n u \text{ in } B_{x_n} \setminus \overline{B}_{R/2}(y_n), \\ u|_{\partial B_{x_n}} = u_n(x_n), \; u|_{\partial B_{R/2}(y_n)} = u_n(x_n) + c_n(e^{-\sigma R^2/4} - e^{-\sigma R^2}). \end{cases}$$

But clearly, $u_n(x_n) + c_n\psi(x)$ is a subsolution to (3.5). Hence, since $a_n < a_0 < \lambda_1^D(B_{x_n} \setminus \overline{B}_{R/2}(y_n))$, by the maximum principle,

$$u_n(x) \geq u_n(x_n) + c_n\psi(x) \;\; \text{whenever } R/2 \leq |x - y_n| \leq R,$$

as required. □

LEMMA 3.4. $\lim_{n\to\infty} u_n(x) = \infty$ *uniformly on* $\overline{\Omega}_0$.

Proof. By the maximum principle, it suffices to show that

$$u_n(x_n) = \min_{x\in\partial\Omega_0} u_n(x) \to \infty.$$

We argue indirectly. Suppose that this is not true. Then by passing to a subsequence, we may assume that $\{u_n(x_n)\}$ is bounded: $u_n(x_n) \leq C$ $\forall$ n.

Clearly, u_n is a supersolution to

$$\text{(3.6)} \qquad -\Delta u = a_n u - b(x)u^p \text{ in } \Omega \setminus \overline{\Omega}_0; u|_{\partial\Omega_0} = u_n(x_n), \; Bu|_{\partial\Omega} = 0.$$

By Lemma 2.3, (3.6) has a unique positive solution, which we denote as v_n. By Lemma 2.1, we deduce $u_n \geq v_n$ on $\Omega \setminus \Omega_0$. Replacing $u_n(x_n)$ in (3.6) by its upper bound C, we similarly obtain a unique positive solution V of (3.6) and by Lemma 2.1, $v_n \leq V$ on $\Omega\setminus\Omega_0$. In particular, $\|v_n\|_{L^\infty(\Omega\setminus\Omega_0)}$ is bounded. Then the L^p-estimates and the Sobolev imbedding theorems (see [GT]) imply that $\{v_n\}$ is bounded in $C^1(\overline{\Omega}\setminus\Omega_0)$. In particular, $|\nabla v_n(x_n)|$ is bounded. Since

$$u_n(x) \geq v_n(x) \;\; \forall x \in \Omega \setminus \Omega_0 \quad \text{and } u_n(x_n) = v_n(x_n),$$

we have

$$\partial u_n(x_n)/\partial\nu_n \leq \partial v_n(x_n)/\partial\nu_n \leq C_0$$

for some $C_0 > 0$, where $\nu_n = (y_n - x_n)/|y_n - x_n|$ and y_n is as in Lemma 3.3.

On the other hand, by Lemma 3.3,

$$\partial u_n(x_n)/\partial\nu_n \geq c_n\partial\psi(x_n)/\partial\nu_n = c_n[2\sigma Re^{-\sigma R^2}] \to \infty$$

as $n \to \infty$. This contradiction finishes the proof. □

LEMMA 3.5. *For any compact set* $K \subset \overline{\Omega}\setminus\overline{\Omega}_0$, $u_n \to U_{a_0}$ *in* $C^{2+\mu}(K)$ *as* $n \to \infty$.

Proof. By Lemma 2.1, $u_n \leq \underline{U}_{a_0}$ on $\Omega\setminus\overline{\Omega}_0$. Since $u_n(x) \leq u_{n+1}(x)$, $\lim_{n\to\infty} u_n(x) = u_\infty(x)$ exists. It follows that u_∞ satisfies (1.3) with $a = a_0$. Here the fact that

$u_\infty = \infty$ on $\partial\Omega_0$ follows from $u_n(x) \le u_{n+1}(x)$ and $u_n(x) \to \infty$ uniformly on $\partial\Omega_0$ by Lemma 3.4. By Theorem 2.4, we necessarily have $u_\infty = \underline{U}_{a_0}$.

Using Sobolev imbedding theorems and interior estimates, we easily see that $u_n \to \underline{U}_{a_0}$ in $C^{2+\mu}(K)$ as $n \to \infty$, for any compact set $K \subset \overline{\Omega} \setminus \overline{\Omega}_0$. □

From Lemmas 3.4 and 3.5, we obtain immediately the following result.

THEOREM 3.6. *Let $a_0 = \lambda_1^D(\Omega_0)$. Then*

(i) $u_a \to \infty$ *uniformly on* $\overline{\Omega}_0$ *as* $a \nearrow a_0$;

(ii) $u_a \to \underline{U}_{a_0}$ *in* $C^{2+\mu}(K)$, *as* $a \nearrow a_0$, *for any compact set* $K \subset \overline{\Omega} \setminus \overline{\Omega}_0$.

Clearly, Theorem 1.2 is a weaker version of Theorem 3.6.

4. Blow-up solutions of problem (1.2).

In this section, we study how the solutions of (1.2) with admissible nontrivial nonnegative initial values blow up as $t \to \infty$ when $a \ge a_0 = \lambda_1^D(\Omega_0)$.

Denote $X = C(\overline{\Omega})$ and $X^+ = \{u \in X : u \ge 0 \ \ \forall x \in \Omega\}$.

LEMMA 4.1. *Suppose $a \ge a_0$ and $u_0 \in X^+ \setminus \{0\}$. Then the unique solution $u(t,x)$ of* (1.2) *satisfies*

$$\lim_{t\to\infty} u(t,x) = \infty \qquad \textit{uniformly for } \ x \in \overline{\Omega}_0.$$

Proof. For $\epsilon > 0$ small, let $u_\epsilon(t,x)$ be the unique solution to the problem

$$\left\{\begin{array}{ll} u_t - \Delta u = (a_0-\epsilon)u - b(x)u^p, & (t,x) \in (0,\infty)\times\Omega, \\ Bu = 0, & (t,x) \in (0,\infty)\times\partial\Omega, \\ u(0,x) = u_0(x), & x \in \Omega. \end{array}\right. \tag{4.1}$$

Since $a > a_0 - \epsilon$, clearly, $u(t,x)$ is a supersolution of (4.1) and hence

$$u(t,x) \ge u_\epsilon(t,x) \ \ \forall (t,x) \in [0,\infty)\times\Omega.$$

For any given $M > 0$, by Lemma 3.4, we can find $\epsilon_0 > 0$ such that the unique positive solution $u_{a_0-\epsilon_0}(x)$ of

$$-\Delta u = (a_0-\epsilon_0)u - b(x)u^p \ \text{ in } \Omega, \quad Bu|_{\partial\Omega} = 0$$

satisfies $u_{a_0-\epsilon_0}(x) > M \ \forall\, x \in \overline{\Omega}_0$. But it is well known that $u_{\epsilon_0}(t,x) \to u_{a_0-\epsilon_0}(x)$ as $t \to \infty$ in the $L^\infty(\Omega)$ norm. Hence $\min_{x\in\overline{\Omega}_0} u(t,x) \ge M \ \forall$ large t. This implies that $u(t,x) \to \infty$ as $t \to \infty$ uniformly for $x \in \overline{\Omega}_0$. □

LEMMA 4.2. *Suppose $a \ge a_0$ and $u_0 \in X^+ \setminus \{0\}$. Then the unique solution $u(t,x)$ of* (1.2) *satisfies*

(i) $\underline{\lim}_{t\to\infty} u(t,x) \ge \underline{U}_a(x)$ *and* $\overline{\lim}_{t\to\infty} u(t,x) \le \overline{U}_a(x) \ \ \forall x \in \overline{\Omega} \setminus \overline{\Omega}_0$;

(ii) *if* (1.3) *has a unique positive solution denoted as U_a, then* $\lim_{t\to\infty} u(t,\cdot) = U_a$ *in $C^{2+\mu}(K)$ for any compact set $K \subset \overline{\Omega} \setminus \overline{\Omega}_0$.*

Proof. Let us denote the unique positive solution of (2.3) with $\phi \equiv c > 0$ by u_c. We first show that for any $v_0 \in C(\overline{\Omega} \setminus \Omega_0)$ with $v_0 \ge 0$, $v_0 \not\equiv 0$, the unique solution $v(t,x)$ of

$$\left\{\begin{array}{ll} v_t - \Delta v = av - b(x)v^p, & (t,x) \in (0,\infty)\times[\Omega\setminus\overline{\Omega}_0], \\ v(t,x) = c, & (t,x) \in (0,\infty)\times\partial\Omega_0, \\ Bv(t,x) = 0, & (t,x) \in (0,\infty)\times\partial\Omega, \\ v(0,x) = v_0(x), & x \in \Omega\setminus\overline{\Omega}_0 \end{array}\right. \tag{4.2}$$

satisfies

$$v(t,x) \to u_c(x) \text{ as } t \to \infty \ \text{ uniformly for } x \in \overline{\Omega} \setminus \Omega_0.$$

Indeed, for any constant $M > 1$, Mu_c is a supersolution of (2.3). Choose $M > 1$ large such that $Mu_c(x) > v(1,x)$ on $\Omega \setminus \Omega_0$ (note this is possible by the strong maximum principle), and let $\underline{v}(t,x)$ denote the unique solution of (4.2) with $v(0,x) \equiv 0$, and let $\overline{v}(t,x)$ denote the unique solution of (4.2) with $v(0,x) \equiv Mu_c(x)$. Then $\underline{v}(t+1,x) \le v(t+1,x) \le \overline{v}(t,x)$. But since u_c is the only steady-state solution of (4.2), we have $\underline{v}(t,x) \to u_c(x)$ and $\overline{v}(t,x) \to u_c(x)$ as $t \to \infty$ uniformly for $x \in \overline{\Omega} \setminus \Omega_0$ (see, e.g., [Ma] or [Sa]). Hence $v(t,x) \to u_c(x)$ as $t \to \infty$ uniformly for $x \in \overline{\Omega} \setminus \Omega_0$.

By Lemma 2.1 and the properties of $\underline{U}_a$, for any $c > 0$, $u_c \le \underline{U}_a$ and $c \to u_c(x)$ is increasing. It then follows easily from the equation of u_c that $u_c \to \underline{U}_a$ as $c \to \infty$ in $C^{2+\mu}(K)$ for any compact set $K \subset \overline{\Omega} \setminus \overline{\Omega}_0$.

For any give $\epsilon > 0$, let $c_0 > 0$ be chosen such that

$$u_{c_0}(x) > \underline{U}_a(x) - \epsilon/2 \ \ \forall x \in K. \tag{4.3}$$

By Lemma 4.1 we can find $T > 0$ such that the unique solution of (1.2) with initial value $u_0 \in X^+ \setminus \{0\}$ satisfies $u(t,x) > c_0$ for $t \ge T$ and $x \in \partial\Omega_0$. Therefore, $u(T+t,x)$ is a supersolution of (4.2) with $c = c_0$ and $v_0(x) = u(T,x)$. Hence, $u(t,x) \ge u_{c_0}(x) - \epsilon/2$ for all large t and $x \in \overline{\Omega} \setminus \overline{\Omega}_0$. Using (4.3), we see that $\forall$ large t,

$$u(t,x) \ge \underline{U}_a(x) - \epsilon \ \ \forall x \in K. \tag{4.4}$$

This implies that

$$\underline{\lim}_{t\to\infty} u(t,x) \ge \underline{U}_a(x) \ \forall x \in \overline{\Omega} \setminus \overline{\Omega}_0. \tag{4.5}$$

Choose a large constant $M > 1$ such that $M\underline{U}_a(x) > u(1,x)$ for all $x \in \overline{\Omega} \setminus \overline{\Omega}_0$ (note this is possible in the Dirichlet boundary condition case since $\underline{U}_a(x) \ge u_{a'}(x)$ near $\partial\Omega$, where $a' \in (\lambda_1(\Omega), \lambda_1^D(\Omega_0))$ and $\partial u_{a'}/\partial\nu < 0$ on $\partial\Omega$). An application of the parabolic maximum principle shows that

$$u(t,x) \le M\underline{U}_a(x) \ \ \forall t > 1, x \in \overline{\Omega} \setminus \overline{\Omega}_0. \tag{4.6}$$

Now consider (4.2) with Ω_0 replaced by Ω_n, where $\Omega_n = \{x \in \Omega : d(x,\Omega_0) < 1/n\}$. We may assume that $\overline{\Omega}_n \subset\subset \Omega \ \forall \ n \ge 1$. Then, for any fixed n, as before, every solution $v_{n,c}(t,x)$ of (4.2) (with Ω_0 replaced by Ω_n) converges to the unique steady-state solution, which we denote as $v^*_{n,c}(x)$. By the parabolic maximum principle and (4.6), $\forall$ large c, $u(t,x) \le v_{n,c}(t,x)$ for $(t,x) \in (0,\infty) \times \overline{\Omega} \backslash \Omega_n$, provided $v_0(x) = u(0,x)$. Thus

$$\overline{\lim}_{t\to\infty} u(t,x) \le v^*_{n,c}(x) \ \ \forall x \in \overline{\Omega} \setminus \Omega_n. \tag{4.7}$$

By the proof of Theorem 2.4, as $c \to \infty$, $v^*_{n,c}(x) \to v^*_{n,\infty}(x)$, which is the minimal positive solution of (1.3) with Ω_0 replaced by Ω_n, and as $n \to \infty$, $v^*_{n,\infty}(x) \to \overline{U}_a(x)$, the maximal solution of (1.3). Therefore, by (4.7),

$$\overline{\lim}_{t\to\infty} u(t,x) \le \overline{U}_a(x) \ \ \forall x \in \overline{\Omega} \setminus \overline{\Omega}_0. \tag{4.8}$$

If (1.3) has a unique positive solution U_a, then by (4.5) and (4.8), we necessarily have

$$\lim_{t\to\infty} u(t,x) = U_a(x) \ \ \forall x \in \overline{\Omega} \setminus \overline{\Omega}_0.$$

Moreover, if $\{t_n\}$ is any sequence of positive numbers satisfying $t_n \to \infty$ as $n \to \infty$, then it follows from (4.6) that $\{u_\infty(t_k, .) : k \geq 1\}$ is bounded in $C(K)$. By regularity, it is compact in $C^{2+\mu}(K)$. Hence we can find a subsequence of $\{t_k\}$, still denoted by $\{t_k\}$, and some C^2 function u_∞ such that

$$u_\infty(t_k, .) \to u_\infty \text{ in } C^{2+\mu}(K).$$

But we must have $u_\infty = U_a$ by our previous discussions. This implies that $\lim_{t\to\infty} u(t, .) = U_a$ in the $C^{2+\mu}(K)$ norm. The proof of Lemma 4.2 is now complete. □

Thus we have the following result which implies Theorem 1.3.

Theorem 4.3. *Suppose $a \geq a_0 = \lambda_1^D(\Omega_0)$ and $u_0 \in X^+ \setminus \{0\}$. Then the unique solution $u(t, x)$ of* (1.2) *satisfies*

(i) $\lim_{t\to\infty} u(t, x) = \infty$ *uniformly for* $x \in \overline{\Omega}_0$.

(ii) $\underline{\lim}_{t\to\infty} u(t, x) \geq \underline{U}_a(x)$ *and* $\overline{\lim}_{t\to\infty} u(t, x) \leq \overline{U}_a(x)$ $\forall x \in \overline{\Omega} \setminus \overline{\Omega}_0$;

(iii) *if* (1.3) *has a unique positive solution denoted as U_a, then* $\lim_{t\to\infty} u(t, .) = U_a$ *in $C^{2+\mu}(K)$ for any compact set $K \subset \overline{\Omega} \setminus \overline{\Omega}_0$.*

As we are able to show that (1.3) has a unique positive solution only if certain conditions on $b(x)$ are satisfied (see Theorem 2.8), it is of some interest to see whether conclusion (ii) in Theorem 4.3 can be improved. We suspect that $\lim_{t\to\infty} u(t, x) = \underline{U}_a(x)$, but again, can only prove this under some conditions on $b(x)$.

Proposition 4.4. *Let us denote $d(x) = d(x, \Omega_0)$. If there exist constants $\alpha \geq 0, c_1 > 0$, $c_2 > 0$ and $\hat{\alpha} \in (\alpha, \alpha + 2)$ such that*

$$c_1 d(x)^{\hat{\alpha}} \leq b(x) \leq c_2 d(x)^\alpha \ \forall \ x \text{ near } \ \partial\Omega_0, \tag{4.9}$$

then for $a \geq a_0$ and $u_0 \in X^+ \setminus \{0\}$, the unique solution $u(t, x)$ of (1.2) *satisfies* $\lim_{t\to\infty} u(t, .) = \underline{U}_a$ *in $C^{2+\mu}(K)$ for any compact set $K \subset \overline{\Omega} \setminus \overline{\Omega}_0$.*

Proof. To make the ideas more transparent, we divide the proof into two steps.

Step 1. The conclusion holds under the condition

$$\underline{\lim}_{d(x)\to 0} b(x)[\underline{U}_a(x)]^{p-1} > a/p. \tag{4.10}$$

We first show that there exists some large positive constant C such that

$$u(t, x) - \underline{U}_a(x) \leq C \ \forall (t, x) \in (0, \infty) \times \overline{\Omega} \setminus \overline{\Omega}_0. \tag{4.11}$$

If this is not true, then we can find (t_n, x_n) satisfying

$$u(t_n, x_n) - \underline{U}_a(x_n) = \max\{u(t, x) - \underline{U}_a(x) : 0 \leq t \leq n, \, x \in \overline{\Omega} \setminus \overline{\Omega}_0\} \to \infty,$$

as $n \to \infty$. By (4.6) and the fact that $\underline{U}_a(x)$ blows up at $\partial\Omega_0$, one easily sees that

$$x_n \in \Omega \setminus \overline{\Omega}_0, \quad d(x_n) \to 0. \tag{4.12}$$

We now look at the equation satisfied by $u(t, x) - \underline{U}_a(x)$:

$$\frac{\partial}{\partial t}(u - \underline{U}_a) - \Delta(u - \underline{U}_a) = \Big\{a - pb(x)\big[\theta u^{p-1} + (1 - \theta)\underline{U}_a^{p-1}\big]\Big\}(u - \underline{U}_a), \tag{4.13}$$

where $\theta = \theta(t, x) \in (0, 1)$. At $(t, x) = (t_n, x_n)$, because of (4.12), the left side of (4.13) is nonnegative. However, using (4.10), we see that the right side of (4.13) at $(t, x) = (t_n, x_n)$ is negative! This contradiction proves (4.11).

Given any small $\epsilon > 0$, denote $\Omega_\epsilon = \{x \in \Omega : d(x, \Omega_0) < \epsilon\}$. By (4.11), we know that

$$u(t,x) \le (1+\delta(\epsilon))\underline{U}_a(x) \quad \forall t \ge 0, x \in \partial\Omega_\epsilon, \tag{4.14}$$

where $\delta(\epsilon) > 0$ and converges to 0 as $\epsilon \to 0$. Let $v_\epsilon(t,x)$ denote the unique solution of

$$\begin{cases} v_t - \Delta v = av - b(x)v^p, & (t,x) \in (0,\infty) \times [\Omega \setminus \overline{\Omega}_\epsilon], \\ v(t,x) = (1+\delta(\epsilon))\underline{U}_a(x), & (t,x) \in (0,\infty) \times \partial\Omega_\epsilon, \\ Bv(t,x) = 0, & (t,x) \in (0,\infty) \times \partial\Omega, \\ v(0,x) = M\underline{U}_a(x), & x \in \Omega \setminus \overline{\Omega}_\epsilon. \end{cases} \tag{4.15}$$

Then using (4.6), (4.14), and the parabolic maximum principle, we obtain

$$u(t+1,x) \le v_\epsilon(t,x) \quad \forall t \ge 0, x \in \overline{\Omega} \setminus \overline{\Omega}_\epsilon. \tag{4.16}$$

By Lemma 2.3, problem (4.15) has a unique steady-state solution which we denote as $u_\epsilon(x)$. It follows that $v_\epsilon(t,x) \to u_\epsilon(x)$ as $t \to \infty$. Using Lemma 2.1, we easily deduce $u_\epsilon(x) \le (1+\delta(\epsilon))\underline{U}_a(x)$. Therefore, from (4.16), we have

$$\overline{\lim}_{t\to\infty} u(t,x) \le (1+\delta(\epsilon))\underline{U}_a(x) \quad \forall x \in \overline{\Omega} \setminus \overline{\Omega}_\epsilon.$$

Letting $\epsilon \to 0$, we finally obtain

$$\overline{\lim}_{t\to\infty} u(t,x) \le \underline{U}_a(x) \quad \forall x \in \overline{\Omega} \setminus \overline{\Omega}_0.$$

This combined with conclusion (ii) of Theorem 4.3 gives

$$\lim_{t\to\infty} u(t,x) = \underline{U}_a(x) \quad \forall x \in \overline{\Omega} \setminus \overline{\Omega}_0.$$

As in the proof of Lemma 4.2, it follows then from the regularity of solutions that $\lim_{t\to\infty} u(t,.) = \underline{U}_a$ in $C^{2+\mu}(K)$ for any compact set $K \subset \overline{\Omega} \setminus \overline{\Omega}_0$.

Step 2. Condition (4.9) implies (4.10).

By (4.9), we can find $c_2' > c_2$ and $c_1' \in (0, c_1)$ such that

$$c_1' d(x)^{\hat{\alpha}} \le b(x) \le c_2' d(x)^\alpha \ \forall x \in \overline{\Omega} \setminus \Omega_0.$$

Hence, one easily sees that $\underline{U}_a(x)$ is a supersolution to (1.3) with $b(x)$ replaced by $c_2' d(x)^\alpha$, whose unique positive solution (guaranteed by Theorem 2.8 and Remark 2.9) we denote as $v(x)$. Considering that $v(x)$ can be obtained as the limit of the solutions of problem (2.3) with $\phi \equiv n \to \infty$ and $b(x) = c_2' d(x)^\alpha$, one sees easily by Lemma 2.1 that $\underline{U}_a(x) \ge v(x)$. By Theorem 2.8 and Remark 2.9,

$$\lim_{d(x)\to 0} d(x)^{\alpha+2} v(x)^{p-1} = c_0 > 0.$$

Hence,

$$\underline{\lim}_{d(x)\to 0} b(x)[\underline{U}_a(x)]^{p-1} \ge \lim_{d(x)\to 0} c_1' d(x)^{\hat{\alpha}} v(x)^{p-1} = +\infty > a/p.$$

The proof is complete. □

Finally we give some estimates on the blow-up rate of the solutions of (1.2).

Theorem 4.5. *Let $a \geq a_0$ and $u_0 \in X^+ \setminus \{0\}$. Then for any given small $\epsilon > 0$, there exists a constant $M_\epsilon > 0$ such that the unique solution $u(t,x)$ of* (1.2) *satisfies*

$$u(t,x) \leq M_\epsilon e^{(a-a_0+\epsilon)t} \quad \forall \quad x \in \overline{\Omega}_0 \quad \text{and } \forall \text{ large } t;$$

for any $x \in \Omega_0$ and any positive constant M, it holds

$$u(t,x) \geq M e^{(a-a_0)t} \quad \forall \text{ large } t.$$

Proof. For any given $\epsilon > 0$, define

$$v(t,x) = e^{(a_0-\epsilon-a)t}u(t,x),$$

where $u(t,x)$ is the unique solution of (1.2). A simple calculation shows

$$v_t - \Delta v \leq (a_0 - \epsilon)v - b(x)v^p.$$

Clearly, $Bv|_{\partial\Omega} = 0$ and $v(0,x) = u(0,x)$. Hence v is a subsolution of (1.2) with a replaced by $a_0 - \epsilon$. It follows from the parabolic maximum principle that

$$v(t,x) \leq u_\epsilon(t,x) \quad \forall (t,x) \in (0,\infty) \times \Omega.$$

Here $u_\epsilon(t,x)$ denotes the positive solution of (1.2) with a replaced by $a_0 - \epsilon$. It is well known that $u_\epsilon(t,x) \to u_{a_0-\epsilon}(x)$ uniformly on $\overline{\Omega}$. Hence if we define M_ϵ by

$$M_\epsilon = (1+\epsilon) \max_{x \in \overline{\Omega}} u_{a_0-\epsilon}(x),$$

then $v(t,x) \leq M_\epsilon$ $\forall$ large t and $x \in \overline{\Omega}_0$. That is,

$$u(t,x) \leq M_\epsilon e^{(a-a_0+\epsilon)t} \quad \forall \quad x \in \overline{\Omega}_0 \quad \text{and } \forall \text{ large } t.$$

Next we let $\phi_0(x) \geq 0$ with $\|\phi_0\|_{L^\infty(\Omega_0)} = 1$ be the eigenfunction for the problem

$$-\Delta\phi = a_0\phi, \quad \phi|_{\partial\Omega_0} = 0.$$

Then for any positive constant M', $v(t,x) = M'e^{(a-a_0)t}\phi_0(x)$ satisfies

$$v_t - \Delta v = av \text{ in } \Omega_0, \quad v|_{\partial\Omega_0} = 0.$$

By Lemma 4.1, there exists $T > 0$ such that $u(T,x) > M'\phi_0(x)$ on $\overline{\Omega}_0$. Hence by the parabolic maximim principle, $v(t,x) \leq u(T+t,x)$ for all $t > 0$ and $x \in \Omega_0$. Now for any given $x \in \Omega_0$ and $M > 0$, choose M' such that $M'e^{-(a-a_0)T}\phi_0(x) = M$; then

$$u(t,x) \geq M e^{(a-a_0)t} \quad \forall \text{ large } t.$$

This finishes the proof of Theorem 4.5. □

A SOBOLEV SPACE THEORY OF SPDEs WITH CONSTANT COEFFICIENTS IN A HALF SPACE[*]

N. V. KRYLOV[†] AND S. V. LOTOTSKY[‡]

Abstract. Equations of the form $du = (a^{ij}u_{x^ix^j} + D_if^i)\,dt + \sum_k(\sigma^{ik}u_{x^i} + g^k)\,dw_t^k$ are considered for $t > 0$ and $x \in \mathbb{R}^d_+$. The unique solvability of these equations is proved in weighted Sobolev spaces with fractional positive or negative derivatives, summable to the power $p \in [2,\infty)$.

Key words. stochastic partial differential equations, Sobolev spaces with weights

AMS subject classifications. 60H15, 35R60

Introduction. The main goal of this article is to extend the results of [6] to multidimensional cases. We are dealing with the equation

$$du = (a^{ij}u_{x^ix^j} + f^i_{x^i})\,dt + (\sigma^{ik}u_{x^i} + g^k)\,dw_t^k$$

given for $t \geq 0$ and $x \in \mathbb{R}^d_+ := \{x = (x^1, x') : x^1 > 0, x' \in \mathbb{R}^{d-1}\}$. Here w_t^k are independent one-dimensional Wiener processes, i and j run from 1 to d, k runs through $\{1, 2, \dots\}$ with the summation convention being enforced, and f^i and g^k are some given functions of (ω, t, x) defined for $i = 1, \dots, d$ and $k \geq 1$. The functions a^{ij} and σ^{ik} are assumed to depend only on ω and t, and in this sense we consider equations with "constant" coefficients. Without loss of generality we also assume that $a^{ij} = a^{ji}$.

As in [6], let us mention that such equations with a finite number of the processes w_t^k appear, for instance, in nonlinear filtering problems for partially observable diffusions (see [8]). Considering infinitely many w_t^k turns out to be instrumental in treating equations for measure valued processes, for instance, driven by space-time white noise (see [3] or [4]).

Our main goal is to prove the solvability of such equations in spaces similar to Sobolev spaces, in which derivatives are understood as generalized functions, the number of derivatives may be fractional or negative, and underlying power of summability is $p \in [2,\infty)$.

The motivation for this goal is explained in detail in [3] or [4], where an L_p-theory is developed for the equations in the whole space. We mention only that if $p = 2$, the theory was developed long ago and an account of it can be found, for instance, in [8]. The case of equations in domains is also treated in [8]. However, the solvability is proved only in spaces W_2^1 of functions having one generalized derivative in x square summable in (ω, t, x). It turns out that going to better smoothness of solutions is not possible in spaces W_2^n and one needs to consider Sobolev spaces with weights, allowing derivatives to blow up near the boundary. The theory of solvability in Hilbert spaces like W_2^n with weights is developed in [1] and [7], where n is an integer. Here we show

what happens if one takes a fractional or negative number of derivatives and replaces 2 with any $p \geq 2$. By the way, according to [2], it is not possible to take $p < 2$ when a stochastic term is present in the equation.

One of the main difficulties in developing the theory presented below was finding the right spaces where to look for solutions. In the one-dimensional case $\mathbb{R}^d_+ = \mathbb{R}_+$ they have been found in [6]. It turns out that there are many multidimensional counterparts of spaces from [6]. The one which looks the most natural is to apply weights only to derivatives with respect to x^1. Indeed, why should we allow the derivatives with respect to tangential variables blow up near $x^1 = 0$? The equation is translation invariant with respect to x', isn't it? However, in such spaces it is impossible to solve equations with variable coefficients in smooth domains unless the coefficients not only are smooth with respect to x but also behave in a very restrictive way as x approaches the boundary. And, of course, considering equations with constant coefficients in half spaces aims at equations with variable coefficients in smooth domains.

This shows that one cannot just imitate the original definition of Sobolev spaces with weights $H^\gamma_{p,\theta}$ from [6]. However, it turns out that one can very naturally generalize to the multidimensional case an equivalent definition, looking much more complex, which is discovered in [6] and stated there as Theorem 1.11 (see Definition 1.1 below).

This article is organized as follows. In section 1 we present some definitions and facts from [5] on the basis of which, in section 2, we introduce the stochastic Banach spaces in which we are going to solve our equations. Our main result is given and proved in section 3. One auxiliary result used in section 3 is proved in section 4.

We finish the introduction with some notation. Everywhere, apart from section 1, we assume that $p \in [2, \infty)$. By $C^n_0(D)$ we denote the set of all n times continuously differentiable (real-valued) functions with compact support belonging to D. We denote

$$D_i = \partial/\partial x^i, \quad Du = u_x = (D_1 u, \dots, D_d u).$$

For a multi-index $\alpha = (\alpha_1, \dots, \alpha_d)$, where α_i's are nonnegative integers, denote

$$D^\alpha = D_1^{\alpha_1} \cdots D_d^{\alpha_d}, \quad |\alpha| = \alpha_1 + \dots + \alpha_d.$$

By $H^\gamma_p = H^\gamma_p(\mathbb{R}^d)$ we denote the space of Bessel potentials ($= (1-\Delta)^{-\gamma/2} L_p$) with norm $|| \cdot ||_{\gamma,p}$ (see [9]). For $\gamma = 0$, we have $H^0_p = L_p$ and we denote $|| \cdot ||_p = || \cdot ||_{0,p}$.

Any function given on $\mathbb{R}_+ := \mathbb{R}^1_+$ is also considered as a function on $\mathbb{R}^d_+$ independent of x'. Define M^α as the operator of multiplying by $(x^1)^\alpha$, $M = M^1$.

Finally, by $\mathcal{D}(R^d_+)$ we denote the space of all distributions on $\mathbb{R}^d_+$ that is of continuous linear functionals on $C^\infty_0(\mathbb{R}^d_+)$.

1. Sobolev spaces with weights.

Here we collect some definitions and facts from [5].

DEFINITION 1.1. *Take and fix a nonnegative function $\zeta \in C^\infty_0(\mathbb{R}_+)$ such that*

$$\sum_{n=-\infty}^{\infty} \zeta^p(e^{x-n}) \geq 1 \quad \textit{for all} \;\; x \in \mathbb{R}. \tag{1.1}$$

For $\gamma, \theta \in \mathbb{R}$, and $p \in (1, \infty)$ let $H^\gamma_{p,\theta}$ be the set of all distributions u on $\mathbb{R}^d_+$ such that

$$||u||^p_{\gamma,p,\theta} := \sum_{n=-\infty}^{\infty} e^{n\theta} ||u(e^n \cdot)\zeta||^p_{\gamma,p} = \sum_{n=-\infty}^{\infty} e^{n\theta} ||(1-\Delta)^{\gamma/2}(u(e^n \cdot)\zeta)||^p_p < \infty. \tag{1.2}$$

Denote $L_{p,\theta} = H^0_{p,\theta}$.

In the same way, for any separable Banach space X, *we introduce the spaces* $H^\gamma_{p,\theta}(X)$ *of* X*-valued functions by replacing* $(1-\Delta)^{\gamma/2}(u(e^n \cdot)\zeta)$ *in* (1.2) *with* $|(1-\Delta)^{\gamma/2}(u(e^n \cdot)\zeta)|_X$.

LEMMA 1.2. (i) *The spaces* $H^\gamma_{p,\theta}$ *are Banach spaces and the space* $C_0^\infty(\mathbb{R}^d_+)$ *is dense in* $H^\gamma_{p,\theta}$.

(ii) *For different* ζ *satisfying* (1.1), *we get the same spaces* $H^\gamma_{p,\theta}$ *with equivalent norms. Furthermore, if* $\eta \in C_0^\infty(\mathbb{R}^d_+)$, *then for any* $u \in \mathcal{D}(\mathbb{R}^d_+)$ *and* γ, θ, p *we have*

$$\sum_{n=-\infty}^{\infty} e^{n\theta} ||u(e^n \cdot)\eta||^p_{\gamma,p} \leq N \sum_{n=-\infty}^{\infty} e^{n\theta} ||u(e^n \cdot)\zeta||^p_{\gamma,p},$$

where N *depends only on* γ, θ, p, η, d *(and* ζ*).*

(iii) *Let* $\alpha \in \mathbb{R}$. *We have* $u \in H^\gamma_{p,\theta}$ *if and only if* $u = M^\alpha v$ *with* $v \in H^\gamma_{p,\theta+\alpha p}$. *Hence,*

$$M^\alpha H^\gamma_{p,\theta+\alpha p} = H^\gamma_{p,\theta}.$$

In addition,

$$||u||_{\gamma,p,\theta} \leq N||M^{-\alpha}u||_{\gamma,p,\theta+\alpha p} \leq N||u||_{\gamma,p,\theta},$$

where N *are independent of* u.

(iv) *The space* $L_{p,\theta}$ *coincides with the space of functions summable to the power* p *over* $\mathbb{R}^d_+$ *with respect to the measure* $(x^1)^{\theta-d}\,dx$.

(v) *If* γ *is a nonnegative integer, then the space* $H^\gamma_{p,\theta}$ *is*

$$\{u : u, x^1 u_x, \dots, (x^1)^{|\alpha|} D^\alpha u \in L_{p,\theta} \quad \textit{for all} \ \ \alpha : |\alpha| \leq \gamma\}$$

with a natural norm.

The spaces $H^\gamma_{p,\theta}$ are introduced and studied in [5] for all $\theta \in \mathbb{R}$. However, below in this article we always suppose that $d-1 < \theta < p+d-1$. For this range of θ, the following results, again borrowed from [5], are true.

LEMMA 1.3. *Let* $d-1 < \theta < p+d-1$.

(i) *The following conditions are equivalent:*

(a) $u \in H^\gamma_{p,\theta}$,

(b) $u \in H^{\gamma-1}_{p,\theta}$ *and* $Mu_x \in H^{\gamma-1}_{p,\theta}$,

(c) $u \in H^{\gamma-1}_{p,\theta}$ *and* $(Mu)_x \in H^{\gamma-1}_{p,\theta}$.

In addition, under either of these three conditions for some constants $N = N(\gamma, p, \theta, d)$ *we have*

$$||u||_{\gamma,p,\theta} \leq N||Mu_x||_{\gamma-1,p,\theta} \leq N||u||_{\gamma,p,\theta},$$

$$||u||_{\gamma,p,\theta} \leq N||(Mu)_x||_{\gamma-1,p,\theta} \leq N||u||_{\gamma,p,\theta}.$$

(ii) *We have* $M^{-1}u \in H^\gamma_{p,\theta}$ *if and only if*

$$u_x \in H^{\gamma-1}_{p,\theta} \quad \textit{and} \quad M^{-1}u \in \bigcup_\mu H^\mu_{p,\theta}.$$

Moreover, there exist constants $N = N(d, \gamma, \mu, \theta, p)$ such that, for any $\mu \le \gamma$ and $M^{-1}u \in H^{\gamma}_{p,\theta}$, we have

$$||M^{-1}u||_{\gamma,p,\theta} \le N||u_x||_{\gamma-1,p,\theta} \le N||M^{-1}u||_{\gamma,p,\theta}.$$

(iii) *The operator $\mathcal{L} := M^2\Delta + 2MD_1$ is a bounded operator from $H^{\gamma}_{p,\theta}$ onto $H^{\gamma-2}_{p,\theta}$ and its inverse is also bounded.*

(iv) *There is a bounded operator*

$$Q : u \in H^{\gamma}_{p,\theta} \to Qu = (Q_1 u, \dots, Q_d u) \in (H^{\gamma+1}_{p,\theta})^d$$

such that, for any $u \in H^{\gamma}_{p,\theta}$, we have $u = MD_iQ_iu$.

2. Stochastic Banach spaces on $\mathbb{R}^d_+$. Let $(\Omega, \mathcal{F}, P)$ be a complete probability space, $(\mathcal{F}_t, t \ge 0)$ be an increasing filtration of σ-fields $\mathcal{F}_t \subset \mathcal{F}$ containing all P-null subsets of Ω, and $\mathcal{P}$ be the predictable σ-field generated by $(\mathcal{F}_t, t \ge 0)$. Let $\{w^k_t; k = 1, 2, \dots\}$ be a family of independent one-dimensional $\mathcal{F}_t$-adapted Wiener processes defined on $(\Omega, \mathcal{F}, P)$. We are going to use the Banach spaces $\mathbb{H}^{\gamma}_p(\tau)$, $\mathbb{H}^{\gamma}_p(\tau, l_2)$, and $\mathcal{H}^{\gamma}_p(\tau)$ introduced in [3] or [4].

Throughout the remaining part of the paper we assume that

$$d - 1 < \theta < p + d - 1.$$

DEFINITION 2.1. *Let τ be a stopping time and f and g^k, $k = 1, 2, \dots$, be $\mathcal{D}(\mathbb{R}^d_+)$-valued $\mathcal{P}$-measurable functions defined on $(\!(0, \tau]\!]$. We write $f \in \mathbb{H}^{\gamma}_{p,\theta}(\tau)$ and $g \in \mathbb{H}^{\gamma}_{p,\theta}(\tau, l_2)$ if and only if $f \in L_p((\!(0, \tau]\!]; H^{\gamma}_{p,\theta})$ and $g \in L_p((\!(0, \tau]\!]; H^{\gamma}_{p,\theta}(l_2))$, respectively. We also denote*

$$\mathbb{H}^{\gamma}_{p,\theta} = \mathbb{H}^{\gamma}_{p,\theta}(\infty), \quad \mathbb{H}^{\gamma}_{p,\theta}(l_2) = \mathbb{H}^{\gamma}_{p,\theta}(\infty, l_2), \quad \mathbb{L}_{\dots}\dots = \mathbb{H}^0_{\dots}\dots.$$

In the case $f \in \mathbb{H}^{\gamma}_{p,\theta}(\tau)$ and $g \in \mathbb{H}^{\gamma+1}_{p,\theta}(\tau, l_2)$ we write $(f, g) \in \mathcal{F}^{\gamma}_{p,\theta}(\tau)$ and define

$$||f||_{\mathbb{H}^{\gamma}_{p,\theta}(\tau)} = E\int_0^{\tau} ||f(t)||^p_{\gamma,p,\theta}\,dt, \quad ||g||_{\mathbb{H}^{\gamma}_{p,\theta}(\tau,l_2)} = E\int_0^{\tau} ||g(t)||^p_{H^{\gamma}_{p,\theta}(l_2)}\,dt,$$

$$||(f,g)||_{\mathcal{F}^{\gamma}_{p,\theta}(\tau)} = ||f||_{\mathbb{H}^{\gamma}_{p,\theta}(\tau)} + ||g||_{\mathbb{H}^{\gamma+1}_{p,\theta}(\tau,l_2)}.$$

Finally, we introduce spaces of initial data. We write $u_0 \in U^{\gamma}_{p,\theta}$ if and only if $M^{2/p-1}u(0,\cdot) \in L_p(\Omega, \mathcal{F}_0, H^{\gamma-2/p}_{p,\theta})$ (or by Lemma 1.2, part (iii)*, if and only if $u(0,\cdot) \in L_p(\Omega, \mathcal{F}_0, H^{\gamma-2/p}_{p,\theta+2-p})$) and denote*

$$||u(0,\cdot)||^p_{U^{\gamma}_{p,\theta}} = E||M^{2/p-1}u(0,\cdot)||^p_{\gamma-2/p,p,\theta}.$$

DEFINITION 2.2. *For a $\mathcal{D}(\mathbb{R}^d_+)$-valued function u defined on $\Omega \times ([0,\tau] \cap [0,\infty))$ with $u(0,\cdot) \in U^{\gamma}_{p,\theta}$, we write $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ if and only if $M^{-1}u \in \mathbb{H}^{\gamma}_{p,\theta}(\tau)$ and there exists $(f, g) \in \mathcal{F}^{\gamma-2}_{p,\theta}(\tau)$ such that, for any $\phi \in C^{\infty}_0(\mathbb{R}^d_+)$, with probability one, we have*

$$(u(t,\cdot), \phi) = (u(0,\cdot), \phi) + \int_0^t (M^{-1}f(s,\cdot), \phi)\,ds + \sum_{k=1}^{\infty}\int_0^t (g^k(s,\cdot), \phi)\,dw^k_s \tag{2.1}$$

for all $t \in [0,\tau] \cap [0,\infty)$. *In this situation we also write* $M^{-1}f = \tilde{\mathbb{D}}u$, $g = \tilde{\mathbb{S}}u$,

$$du = M^{-1}f\,dt + g^k\,dw_t^k$$

and we define $\mathfrak{H}^\gamma_{p,\theta,0}(\tau) = \mathfrak{H}^\gamma_{p,\theta}(\tau) \cap \{u: \ u(0,\cdot) = 0\}$,

$$||u||^p_{\mathfrak{H}^\gamma_{p,\theta}(\tau)} = ||u_x||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau)} + ||(f,g)||^p_{\mathcal{F}^{\gamma-2}_{p,\theta}(\tau)} + ||u(0,\cdot)||^p_{U^\gamma_{p,\theta}}. \tag{2.2}$$

As always, we drop τ *in* $\mathfrak{H}^\gamma_{p,\theta}(\tau)$ *and* $\mathcal{F}^\gamma_{p,\theta}(\tau)$ *if* $\tau = \infty$.

Remark 2.3. If $u \in \mathfrak{H}^\gamma_{p,\theta}(\tau)$ and $\phi(x) = \phi(x^1)$ with $\phi \in C_0^\infty(\mathbb{R}_+)$, then ϕu lies in $\mathcal{H}^\gamma_p(\tau)$. By Theorem 2.7 of [4] this implies that if $u \in \mathfrak{H}^\gamma_{p,\theta}(\tau)$ and $||u||_{\mathfrak{H}^\gamma_{p,\theta}(\tau)} = 0$, then u is indistinguishable from zero.

Of course, we identify elements of $\mathfrak{H}^\gamma_{p,\theta}(\tau)$ which are indistinguishable.

Remark 2.4 (cf. Remark 2.3 in [4]). Given $u \in \mathfrak{H}^\gamma_{p,\theta}(\tau)$, there exists only one couple of functions f and g in Definition 2.2. Therefore, the notations $M^{-1}f = \tilde{\mathbb{D}}u$, $g = \tilde{\mathbb{S}}u$, and (2.2) make sense.

It is also worth noting that the last series in (2.1) converges uniformly in t on each interval $[0, \tau \wedge T]$, $T \in (0,\infty)$, in probability.

Remark 2.5. It follows from Lemma 1.3 part (ii) that the condition $M^{-1}u \in \mathbb{H}^\gamma_{p,\theta}(\tau)$ can be replaced with

$$M^{-1}u \in \bigcup_\mu \bigcap_{T>0} \mathbb{H}^\mu_{p,\theta}(\tau \wedge T) \quad \text{and} \quad u_x \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau).$$

Also in (2.2), replacing the norm $||u_x||_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau)}$ with $||M^{-1}u||_{\mathbb{H}^\gamma_{p,\theta}(\tau)}$ leads to an equivalent norm.

Remark 2.6. In the same way as in Remark 2.6 of [6] one proves that the spaces $\mathfrak{H}^\gamma_{p,\theta}(\tau)$ and $\mathfrak{H}^\gamma_{p,\theta,0}(\tau)$ are Banach spaces.

Remark 2.7. The term $M^{-1}f$ in (2.1) can be replaced with D_if^i for $f^i := Q_if \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau)$, $i = 1,\dots,d$ (see Lemma 1.3), and the norm $||f||_{\mathbb{H}^{\gamma-2}_{p,\theta}(\tau)}$ (participating in (2.2)) with $\sum_i ||f^i||_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau)}$, the latter leading to an equivalent norm.

Remark 2.8. If $u \in \mathfrak{H}^\gamma_{p,\theta}(\tau)$, then $MD_iu \in \mathfrak{H}^{\gamma-1}_{p,\theta}(\tau)$ for $i = 1,\dots d$, and

$$||MDu||_{\mathfrak{H}^{\gamma-1}_{p,\theta}(\tau)} \le N(\gamma,\theta,p,d)||u||_{\mathfrak{H}^\gamma_{p,\theta}(\tau)}.$$

Indeed, by Lemma 1.3, $M^{-1}(MD_iu) = D_iu \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau)$ and by Remark 2.7, $du = D_jf^j\,dt + g^k\,dw_t^k$ with $f^j \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau)$ and $g \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau, l_2)$, so that

$$d(MD_iu) = M^{-1}M^2D_iD_jf^j\,dt + MD_ig^k\,dw_t^k,$$

where $M^2D_iD_jf^j = MD_iMD_jf^j - \delta^{1i}MD_jf^j$. By Lemma 1.3

$$||M^2D_iD_jf^j||_{\mathbb{H}^{\gamma-3}_{p,\theta}(\tau)} \le N\sum_j ||f^j||_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau)} \le N||f||_{\mathbb{H}^{\gamma-2}_{p,\theta}(\tau)},$$

$$||MD_ig||_{\mathbb{H}^{\gamma-2}_{p,\theta}(\tau,l_2)} \le N||g||_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau,l_2)},$$

$$\begin{aligned}&||M^{2/p-1}MD_iu(0,\cdot)||_{\gamma-1-2/p,p,\theta}\\ &\quad = ||MD_i(M^{2/p-1}u(0,\cdot)) - \delta^{1i}(2/p-1)M^{2/p-1}u(0,\cdot)||_{\gamma-1-2/p,p,\theta}\\ &\quad \le N||M^{2/p-1}u(0,\cdot)||_{\gamma-2/p,p,\theta}.\end{aligned}$$

THEOREM 2.9. *For any nonnegative integer $n \geq \gamma$, the set*

$$\mathfrak{H}^n_{p,\theta}(\tau) \bigcap \bigcup_{k=1}^{\infty} \bigcap_{T \in (0,\infty)} L_p(\Omega, C([0, \tau \wedge T], C^n_0(G_k))), \tag{2.3}$$

where $G_k = (1/k, k) \times \{|x'| < k\}$, is everywhere dense in $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$.

Proof. Corollary 1.20 of [5] states that there exists a sequence of functions $\eta_k \in C^{\infty}_0(\mathbb{R}_+)$ vanishing near zero and infinity and such that, for any $u \in H^{\gamma}_{p,\theta}$, we have

$$||\eta_k u||_{\gamma,p,\theta} \leq N||u||_{\gamma,p,\theta}, \quad ||\eta_k u - u||_{\gamma,p,\theta} \to 0$$

as $k \to \infty$, where N is independent of k and u. Obviously, if $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$, then $\eta_k u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ and by Remark 2.5 and the above result of [5] we get that $\eta_k u \to u$ in $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$.

To prove the theorem it remains to show only that any $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$, vanishing outside some G_k, can be approximated by elements of set (2.3). To do this, notice that for such u its $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$-norm is equivalent to $\mathcal{H}^{\gamma}_p(\tau)$-norm. Next, take a function $\xi \in C^{\infty}_0(\mathbb{R}^d_+)$ with unit integral and for $\varepsilon > 0$ define $\xi_{\varepsilon}(x) = \varepsilon^{-d}\xi(x/\varepsilon)$, $u^{(\varepsilon)}(t,x) := \xi_{\varepsilon}(x) * u(t,x)$. It is easy to check that for ε small enough (for instance, such that $u^{(\varepsilon)}$ vanishes when x^1 is close to zero or infinity), we have $u^{(\varepsilon)} \in \mathfrak{H}^n_{p,\theta}(\tau)$ and $u^{(\varepsilon)} \in \mathcal{H}^n_p(\tau)$ for all n. In addition, by well-known properties of mollified functions, $u^{(\varepsilon)}$ converge to u in $\mathcal{H}^{\gamma}_p(\tau)$- and $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$-norm as $\varepsilon \downarrow 0$. Of course, $u^{(\varepsilon)}(t,x)$ is infinitely differentiable with respect to x.

Finally, since $u \in \mathcal{H}^{\gamma}_p(\tau)$, by Theorems 7.1 and 7.2 of [4] we have

$$u \in L_p(\Omega, C([0, \tau \wedge T], H^{\gamma-1}_p)). \tag{2.4}$$

In addition, by Sobolev's embedding theorems and by properties of mollifiers, for any $v \in H^{\gamma-1}_p$ and multi-index α with $|\alpha| = n$,

$$|D^{\alpha} v^{(\varepsilon)}| \leq N||v^{(\varepsilon)}||_{d+n,p} \leq N\varepsilon^{-\kappa}||v||_{\gamma-1,p},$$

where N and κ are independent of v (and ε). This and (2.4) show that

$$u^{(\varepsilon)} \in L_p(\Omega, C([0, \tau \wedge T], C^n_0(\mathbb{R}^d_+))).$$

The theorem is proved.

By repeating the proof of Theorem 2.9 with obvious changes we obtain one more useful result.

THEOREM 2.10. *The statement of Theorem 2.9 remains true if we replace $\mathfrak{H}^n_{p,\theta}(\tau)$ and $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ with $\mathbb{H}^n_{p,\theta}(\tau)$ and $\mathbb{H}^{\gamma}_{p,\theta}(\tau)$, respectively, or with $\mathbb{H}^n_{p,\theta}(\tau, l_2)$ and $\mathbb{H}^{\gamma}_{p,\theta}(\tau, l_2)$, respectively.*

As in the one-dimensional case (cf. [6]), the following embedding theorem presents certain interest.

THEOREM 2.11. *Let $T \in (0,\infty)$ be a constant and let $\tau \leq T$. Then for any function $u \in \mathfrak{H}^{\gamma}_{p,\theta,0}(\tau)$, we have*

$$E \sup_{t \leq \tau} ||u(t,\cdot)||^p_{\gamma-1,p,\theta} \leq N(p,d,\theta,\gamma) T^{(p-2)/2} ||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)}. \tag{2.5}$$

To prove this theorem we use the following fact which is similar to Remark 2.2 of [3] or Remark 4.11 of [4]. Its proof can be obtained just by repeating the proof of Lemma 2.12 of [6] and is omitted.

LEMMA 2.12. *Let $T \in (0,\infty)$ be a constant and let $\tau \leq T$. Let $u \in \mathcal{H}^{\gamma}_{p,0}(\tau)$ and $du = f\,dt + g^k\,dw^k_t$. Then for any constant $c > 0$,*

$$E\sup_{t\leq\tau}||u_x(t,\cdot)||^p_{\gamma-2,p} \leq N(p,d)T^{(p-2)/2}(c||u_{xx}||^p_{\mathbb{H}^{\gamma-2}_p(\tau)} + c^{-1}||f||^p_{\mathbb{H}^{\gamma-2}_p(\tau)} + ||g_x||^p_{\mathbb{H}^{\gamma-2}_p(\tau,l_2)}).$$

Proof of Theorem 2.11. We proceed as in the proof of Theorem 2.11 of [6]. We have

$$E\sup_{t\leq\tau}||u(t,\cdot)||^p_{\gamma-1,p,\theta} \leq \sum_{n=-\infty}^{\infty} e^{n\theta}E\sup_{t\leq\tau}||u(t,e^n\,\cdot)\zeta||^p_{\gamma-1,p}. \tag{2.6}$$

Define $u_n(t,x) := \zeta(x)u(t,e^nx)$ and notice that, since the support of $\zeta(x)u(t,e^nx)$ is not larger than the one of $\zeta(x)$, we have (see, for instance, Remark 1.12 of [5])

$$||u_n(t,\cdot)||_{\gamma-1,p} \leq N||u_{nx}(t,\cdot)||_{\gamma-2,p}. \tag{2.7}$$

To estimate the right-hand side of (2.7), assume that $du = M^{-1}f\,dt + g^k\,dw^k_t$. Then

$$du_n(t,x) = f_n(t,x)\,dt + g_n(t,x)\,dw^k_t,$$

where $f_n(t,x) = (M^{-1}\zeta)(x)e^{-n}f(t,e^nx)$, $g_n(t,x) = \zeta(x)g(t,e^nx)$. By Lemma 2.12 with $c = e^{-np}$,

$$E\sup_{t\leq\tau}||u_{nx}(t,\cdot)||^p_{\gamma-2,p} \leq NT^{(p-2)/2}(e^{-np}||u_{nxx}||^p_{\mathbb{H}^{\gamma-2}_p(\tau)}$$

$$+e^{np}||f_n||^p_{\mathbb{H}^{\gamma-2}_p(\tau)} + ||g_{nx}||^p_{\mathbb{H}^{\gamma-2}_p(\tau,l_2)}). \tag{2.8}$$

Furthermore, $||g_{nx}||_{H^{\gamma-2}_p(l_2)} \leq ||g_n||_{H^{\gamma-1}_p(l_2)}$ and

$$\sum_{n=-\infty}^{\infty} e^{n\theta}||g_n||^p_{\mathbb{H}^{\gamma-1}_p(\tau,l_2)} = ||g||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau,l_2)} \leq N||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)}.$$

Also,

$$\sum_{n=-\infty}^{\infty} e^{n(\theta+p)}||f_n||^p_{\mathbb{H}^{\gamma-2}_p(\tau)} = \sum_{n=-\infty}^{\infty} e^{n\theta}||f(\cdot,e^n\,\cdot)M^{-1}\zeta||^p_{\mathbb{H}^{\gamma-2}_p(\tau)}$$

$$\leq N||f||^p_{\mathbb{H}^{\gamma-2}_{p,\theta}(\tau)} \leq N||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)},$$

$$\sum_{n=-\infty}^{\infty} e^{n(\theta-p)}||u_{nxx}||^p_{\mathbb{H}^{\gamma-2}_p(\tau)} \leq \sum_{n=-\infty}^{\infty} e^{n(\theta-p)}||u_n||^p_{\mathbb{H}^{\gamma}_p(\tau)}$$

$$= \sum_{n=-\infty}^{\infty} e^{n(\theta-p)} ||(M^{-1}u)(\cdot, e^n \cdot)M\zeta||^p_{\mathbb{H}^\gamma_p(\tau)}$$

$$\leq N||M^{-1}u||^p_{\mathbb{H}^\gamma_{p,\theta}(\tau)} \leq N||u||^p_{\mathfrak{H}^\gamma_{p,\theta}(\tau)}.$$

By combining this with (2.8) and (2.6) we get (2.5). The theorem is proved.

As always the main role is played by the spaces $\mathfrak{H}^\gamma_{p,\theta,0}(\tau)$ of functions with zero as an initial condition. In connection with this it is worth noting that while constructing our theory we could replace

$$||u(0,\cdot)||^p_{U^\gamma_{p,\theta}} := E||M^{2/p-1}u(0,\cdot)||^p_{H^{\gamma-2/p}_{p,\theta}} \tag{2.9}$$

with

$$\inf\{||v_x||_{\mathbb{H}^{\gamma-1}_{p,\theta}} + ||\tilde{\mathbb{D}}v||_{\mathbb{H}^{\gamma-2}_{p,\theta}} + ||\tilde{\mathbb{S}}v||_{\mathbb{H}^{\gamma-1}_{p,\theta}} : u - v \in \mathfrak{H}^\gamma_{p,\theta,0}\}.$$

Such an axiomatic approach to defining a norm of $u(0,\cdot)$ yields, of course, the solvability results for the widest possible class of initial data, namely, for those which are extendible at least in some way for $t > 0$. However, in applications we often want to know how to describe "admissible" initial data by knowing only their analytic properties.

A partial answer to this question is given in the following theorem, which also shows why we use the norm given by (2.9). For the only case, which we need, $\gamma = 2$, the proof of this theorem can be obtained in the same way as Theorem 2.13 of [6]. For arbitrary γ and parabolic operators with coefficients depending only on time instead of Δ this theorem is proved in [5].

THEOREM 2.13. *If $\gamma \in \mathbb{R}$, $d-1 < \theta < p+d-1$, and $1 < p < \infty$, then, for every u_0 satisfying $u_0 \in U^\gamma_{p,\theta}$, in the space $\mathfrak{H}^\gamma_{p,\theta}$ there exists a unique solution of the heat equation $du = \Delta u\, dt$ with initial data $u(0,\cdot) = u_0$. Moreover,*

$$||u||_{\mathfrak{H}^\gamma_{p,\theta}} \leq N(d,\gamma,p,\gamma)||u_0||_{U^\gamma_{p,\theta}}.$$

3. SPDEs with constant coefficients in $\mathbb{R}^d_+$. Take a stopping time τ. On $[(0,\tau]] \cap (0,\infty)] \times \mathbb{R}^d_+$ we will be dealing with the following equation:

$$du = (a^{ij}u_{x^ix^j} + M^{-1}f)\, dt + (\sigma^{ik}u_{x^i} + g^k)\, dw^k_t \tag{3.1}$$

with initial condition $u|_{t=0} = u_0$, where u_0 is a $\mathcal{D}(\mathbb{R}^d_+)$-valued, $\mathcal{F}_0$-measurable random variable, f and g^k are $\mathcal{D}(\mathbb{R}^d_+)$-valued $\mathcal{P}$-measurable functions, a^{ij} and σ^{ik} are real-valued $\mathcal{P}$-measurable functions, u is an unknown $\mathcal{D}(\mathbb{R}^d_+)$-valued function, and the equation is understood in the sense of distributions as follows. We say that u is a solution of (3.1) with initial data u_0 if for any test function $\phi \in C^\infty_0(\mathbb{R}^d_+)$ we have

$$\begin{aligned}(u(t\wedge\tau,\cdot),\phi) &= (u_0,\phi)\\ &+ \int_0^{t\wedge\tau} \big[\sum_{i,j=1}^d a^{ij}(s)(u(s,\cdot),\phi_{x^ix^j}) + (f(s,\cdot),M^{-1}\phi)\big]\, ds\\ &+ \sum_{k=1}^\infty \int_0^{t\wedge\tau} \big[-\sum_{i=1}^d \sigma^{ik}(s)(u(s,\cdot),\phi_{x^i}) + (g^k(s,\cdot),\phi)\big]\, dw^k_s \qquad (3.2)\end{aligned}$$

for all $t > 0$ with probability one, where all integrals are assumed to have sense and the last series is assumed to converge uniformly on each interval of time $[0, T]$ in probability, where T is any finite constant.

Remark 3.1. If a function u belongs to $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$, then it satisfies (3.1) with

$$f = M\left(\tilde{\mathbb{D}}u - a^{ij}D_iD_ju\right), \tag{3.3}$$

$$g^k = \tilde{\mathbb{S}}^k u - \sigma^{ik}D_iu.$$

In addition (see Lemma 1.3), we have $f \in \mathbb{H}^{\gamma-2}_{p,\theta}(\tau)$ and $g \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau, l_2)$. Below we show that under additional assumptions on θ, a, and σ the mapping $u \to (f, g)$ is onto.

Assumption 3.2. There exist constants $\delta_0, \delta_1 \in (0, 1]$ such that, for every (ω, t) and every $\xi \in \mathbb{R}^d$,

$$\delta_0|\xi|^2 \le \delta_1 a^{ij}(t)\xi^i\xi^j \le \bar{a}^{ij}\xi^i\xi^j \le a^{ij}(t)\xi^i\xi^j \le \delta_0^{-1}|\xi|^2,$$

where

$$\bar{a}^{ij} := a^{ij}(t) - \alpha^{ij}(t), \quad \alpha^{ij}(t) = \tfrac{1}{2}\sigma^{ik}(t)\sigma^{jk}(t).$$

Here is our main result.

THEOREM 3.3. *Let $d - 1 < \theta < p + d - 1$, $2 \le p < \infty$, $\gamma \in \mathbb{R}$, $f \in \mathbb{H}^{\gamma-2}_{p,\theta}(\tau)$, $g \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau, l_2)$, and $u_0 \in U^{\gamma}_{p,\theta}$. Assume that*

$$d - 1 + p\big[1 - \frac{1}{p(1-\delta_1) + \delta_1}\big] < \theta < d - 1 + p. \tag{3.4}$$

Then (3.1) *or equivalently* (3.3) *with initial data u_0 has a unique solution in $\mathfrak{H}^{\gamma}_{p,\theta}(\tau)$. In addition, for this solution it holds that*

$$||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)} \le N\big(||f||^p_{\mathbb{H}^{\gamma-2}_{p,\theta}(\tau)} + ||g||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau,l_2)} + ||u_0||^p_{U^{\gamma}_{p,\theta}}\big), \tag{3.5}$$

where $N = N(\gamma, \theta, p, d, \delta_0, \delta_1)$.

Remark 3.4. By Remark 2.7, one gets a statement equivalent to Theorem 3.3 if one replaces $M^{-1}f$ in (3.1) with D_if^i for certain $f^i \in \mathbb{H}^{\gamma-1}_{p,\theta}(\tau)$ and replaces $||f||^p_{\mathbb{H}^{\gamma-2}_{p,\theta}(\tau)}$ in (3.5) with $\sum_i ||f^i||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau)}$.

Remark 3.5. If $\sigma \equiv 0$, then one can take $\delta_1 = 1$ and (3.4) becomes $d - 1 < \theta < d - 1 + p$. Furthermore, it is easy to see that, for any σ, condition (3.4) is satisfied if $d - 2 + p \le \theta < d - 1 + p$.

Remark 3.6. It is worth noting that if $\theta \ge p + d - 1$ or $\theta \le d - 1$, then the statement of Theorem 3.3 is false even in the case of the heat equation. This can be shown by simple examples.

The proof of this theorem is based on two lemmas, the first of which we prove in section 4.

LEMMA 3.7. *Theorem* 3.3 *holds if $\gamma = 2$.*

LEMMA 3.8. *Let the assumptions of Theorem* 3.3 *be satisfied and let $\mu \le \gamma$. Let $\theta_1 \in \mathbb{R}$ and let $u \in \mathfrak{H}^{\mu}_{p,\theta_1}(\tau)$ be a solution of* (3.1) *with initial condition u_0. Assume that $M^{-1}u \in \mathbb{H}^{\mu}_{p,\theta}(\tau)$. Then $u \in \mathfrak{H}^{\gamma}_{p,\theta}(\tau)$ and*

$$||u||^p_{\mathfrak{H}^{\gamma}_{p,\theta}(\tau)} \le N\big(||f||^p_{\mathbb{H}^{\gamma-2}_{p,\theta}(\tau)} + ||g||^p_{\mathbb{H}^{\gamma-1}_{p,\theta}(\tau,l_2)} + ||u_x||^p_{\mathbb{H}^{\mu-1}_{p,\theta}(\tau)} + ||u_0||^p_{U^{\gamma}_{p,\theta}}\big),$$

where $N = N(d, \gamma, \mu, \theta, p)$.

One can prove this lemma by repeating almost word for word the proof of Lemma 3.5 of [6]. The only noticeable difference is that the equations in [6] are written in the form

$$du = (au_{xx} + f_x)\,dt + (\sigma^k u_x + g^k)\,dw^k_t,$$

where we have f_x instead of $M^{-1}f$. But by Remark 3.4 we also can rewrite (3.1) with $D_i f^i$ in place of $M^{-1}f$.

Proof of Theorem 3.3. As in the proof of Theorem 3.2 of [6] we may assume that $\tau = \infty$. In the case $\gamma \geq 2$ the proof is achieved on the basis of Lemma 3.8 by repeating the proof of Theorem 3.2 of [6]. In the case $\gamma < 2$ we need only some minor adjustments which we present for completeness.

Denote by $\mathcal{R}$ the operator which maps (f, g, u_0) with $f \in \mathbb{H}^{\gamma-2}_{p,\theta}$, $g \in \mathbb{H}^{\gamma-1}_{p,\theta}(l_2)$, and $u_0 \in U^{\gamma}_{p,\theta}$ into the solution $u \in \mathfrak{H}^{\gamma}_{p,\theta}$ of (3.1) with initial data u_0. Thus far we know that $\mathcal{R}$ is well defined in spaces $\mathbb{H}^{\gamma-2}_{p,\theta} \times \mathbb{H}^{\gamma-1}_{p,\theta}(l_2) \times U^{\gamma}_{p,\theta}$ for $\gamma \geq 2$. We want to show that one can also define $\mathcal{R}$ for $\gamma < 0$.

First, let $2 > \gamma \geq 1$. Observe that by Lemma 1.3, part (iii),

$$(\mathcal{L}^{-1}f, \mathcal{L}^{-1}g, M^{1-2/p}\mathcal{L}^{-1}M^{2/p-1}u_0) \in \mathbb{H}^{\gamma}_{p,\theta} \times \mathbb{H}^{\gamma+1}_{p,\theta}(l_2) \times U^{\gamma+2}_{p,\theta}.$$

Since $\gamma > 0$, by what we know in the case $\gamma \geq 2$, the function

$$v = \mathcal{R}(\mathcal{L}^{-1}f, \mathcal{L}^{-1}g, M^{1-2/p}\mathcal{L}^{-1}M^{2/p-1}u_0)$$

is well defined and belongs to $\mathfrak{H}^{\gamma+2}_{p,\theta}$.

Define

$$\tilde{u} = \mathcal{L}v.$$

By Remark 2.8, we have $\tilde{u} \in \mathfrak{H}^{\gamma}_{p,\theta}$. Furthermore, by definition v satisfies

$$dv = (a^{ij}v_{x^ix^j} + M^{-1}\mathcal{L}^{-1}f)\,dt + (\sigma^{ik}v_{x^i} + \mathcal{L}^{-1}g^k)\,dw^k_t.$$

We apply $\mathcal{L}$ to both parts of this equality, or in other words, we substitute $\mathcal{L}^*\phi$ in place of ϕ in (3.2), where $\mathcal{L}^*$ is the formal adjoint to $\mathcal{L}$. Then we get

$$d\tilde{u} = (a^{ij}\tilde{u}_{x^ix^j} + M^{-1}f + M^{-1}\bar{f})\,dt + (\sigma^{ik}\tilde{u}_{x^i} + g^k + \bar{g}^k)\,dw^k_t,$$

$$\tilde{u}(0, \cdot) = u_0 + \bar{u}_0,$$

where

$$\bar{f} = M\mathcal{L}a^{ij}v_{x^ix^j} - Ma^{ij}(\mathcal{L}v)_{x^ix^j} + M\mathcal{L}M^{-1}\mathcal{L}^{-1}f - f,$$

$$\bar{g}^k = \mathcal{L}\sigma^{ik}v_{x^i} - \sigma^{ik}(\mathcal{L}v)_{x^i}, \quad \bar{u}_0 = \mathcal{L}M^{1-2/p}\mathcal{L}^{-1}M^{2/p-1}u_0 - u_0.$$

Next, we use

$$\mathcal{L}D_i\phi = D_i\mathcal{L}\phi - 2\delta^{i1}M^{-1}(\mathcal{L} - MD_1)\phi,$$

$$\mathcal{L}M^{-1}\phi = M^{-1}\mathcal{L}\phi - 2D_1\phi.$$

Then we find that

$$\bar{f} = -2a^{i1}MD_iM^{-1}(\mathcal{L} - MD_1)v - 2a^{1j}(\mathcal{L} - MD_1)D_jv - 2MD_1\mathcal{L}^{-1}f,$$

$$\bar{g}^k = -2\sigma^{1k}M^{-1}(\mathcal{L} - MD_1)v,$$

$$M^{2/p-1}\bar{u}_0 = (2 - 4/p)MD_1\mathcal{L}^{-1}M^{2/p-1}u_0 + c\mathcal{L}^{-1}M^{2/p-1}u_0,$$

where c is a constant. As above

$$(\mathcal{L} - MD_1)v \in \mathfrak{H}^\gamma_{p,\theta}, \quad M^{-1}(\mathcal{L} - MD_1)v \in \mathbb{H}^\gamma_{p,\theta}, \quad Dv \in \mathbb{H}^{\gamma+1}_{p,\theta},$$

$$M^{2/p-1}\bar{u}_0 \in L_p(\Omega, \mathcal{F}_0, H^{\gamma+1-2/p}_{p,\theta}).$$

It follows that

$$(\bar{f}, \bar{g}, \bar{u}_0) \in \mathbb{H}^{\gamma-1}_{p,\theta} \times \mathbb{H}^\gamma_{p,\theta}(l_2) \times U^{\gamma+1}_{p,\theta}. \tag{3.6}$$

Since $\gamma \geq 1$, it follows from (3.6) that the function $\bar{u} := \mathcal{R}(\bar{f}, \bar{g}, \bar{u}_0)$ is well defined, belongs to $\mathfrak{H}^{\gamma+1}_{p,\theta}$, and the function $u = \tilde{u} - \bar{u}$ is of class $\mathfrak{H}^\gamma_{p,\theta}$ and solves (3.1). For thus constructed u, estimate (3.5) follows from the explicit representation and known estimates for $\mathcal{R}$, $\mathcal{L}$, MD.

By repeating the above argument, we consider the case $1 > \gamma \geq 0$, this time using the fact that $\gamma + 1 \geq 1$ and relying upon the result for $\gamma \geq 1$. One can continue in the same way and it remains to prove only the uniqueness of solutions in $\mathfrak{H}^\gamma_{p,\theta}$.

It suffices to consider the case $f = 0, g = 0, u_0 = 0$ (and $\gamma < 2$). In this case any solution $u \in \mathfrak{H}^\gamma_{p,\theta,0}$ also belongs to $\mathfrak{H}^2_{p,\theta,0}$ by Lemma 3.8 and its uniqueness follows from Lemma 3.7.

The theorem is thus proved.

Remark 3.9. From the above derivation of Theorem 3.3 from Lemma 3.7 it is seen that for *any* fixed $\gamma, p, \theta, a, \sigma$ satisfying the conditions of Theorem 3.3, if the assertion of Theorem 3.3 holds for these $\gamma, p, \theta, a, \sigma$, then it holds for any $\gamma \in \mathbb{R}$ with the same p, θ, a, σ.

4. Proof of Lemma 3.7. By Remarks 2.7, we may concentrate on the following form of (3.1):

$$\begin{aligned} du(t,x) = (a^{ij}(t)u_{x^ix^j}(t,x) + D_if^i(t,x))dt \\ + (\sigma^{ik}(t)u_{x^i}(t,x) + g^k(t,x))dw^k(t). \end{aligned} \tag{4.1}$$

Next, notice that by Theorem 2.13 there is a function $\bar{u} \in \mathfrak{H}^2_{p,\theta}$ such that, $\bar{u}|_{t=0} = u_0$, $\partial\bar{u}/\partial t = D_i\bar{f}^i$ with $\bar{f} \in \mathbb{H}^1_{p,\theta}$, and appropriate estimates of $||\bar{u}_x||_{\mathbb{H}^1_{p,\theta}}$ and $||\bar{f}||_{\mathbb{H}^1_{p,\theta}}$ through $||u_0||_{U^2_{p,\theta}}$ hold. This implies that in the equation

$$du = (a^{ij}u_{x^ix^j} + (a^{ij}\bar{u}_{x^j} + f^i - \bar{f}^i)_{x^i})\,dt + (\sigma^{ik}u_{x^i} + (\sigma^{ik}\bar{u}_{x^i} + g^k))\,dw^k_t$$

we have $a^{ij}\bar{u}_{x^j} + f^i - \bar{f}^i \in \mathbb{H}^1_{p,\theta}(\tau)$ and $\sigma^{i\cdot}\bar{u}_{x^i} + g \in \mathbb{H}^1_{p,\theta}(\tau, l_2)$. Also, obviously if we can solve the above equation in $\mathfrak{H}^2_{p,\theta,0}(\tau)$, then by adding to the solution the function

$\bar{u}$ we get a solution of (4.1) with initial data u_0. Therefore, in the proof of Lemma 3.7 without loss of generality, we may and will confine ourselves only to the case $u_0 \equiv 0$.

Finally, obviously we may assume that $\tau \leq T$, where the constant $T < \infty$, and we start by proving the following a priori estimate.

LEMMA 4.1. *Assume that there exists a constant $\delta_2 > 0$ such that*

$$(p-1)(d+p-1-\theta)\bar{a}^{11} - p(d+p-2-\theta)a^{11} \geq \delta_2 \tag{4.2}$$

for all ω and t. Then for any $u \in \mathfrak{H}^2_{p,\theta,0}(\tau)$,

$$||M^{-1}u||_{\mathbb{L}_{p,\theta}(\tau)} \leq N(||M(\tilde{\mathbb{D}} - a^{ij}D_iD_j)u||_{\mathbb{L}_{p,\theta}(\tau)} + ||(\tilde{\mathbb{S}} - \sigma^{i\cdot}D_i)u||_{\mathbb{L}_{p,\theta}(\tau,l_2)}), \tag{4.3}$$

where N depends only on $\delta_0, \delta_2, d,$ and p.

Proof. For any γ the operators $M\tilde{\mathbb{D}}$ and $\tilde{\mathbb{S}}$ are obviously continuous on $\mathfrak{H}^\gamma_{p,\theta}(\tau)$ with values in $\mathbb{H}^{\gamma-2}_{p,\theta}(\tau)$ and $\mathbb{H}^{\gamma-1}_{p,\theta}(\tau, l_2)$, respectively. By Remark 2.5 the same is true for $M^{-1} : \mathfrak{H}^\gamma_{p,\theta}(\tau) \to \mathbb{H}^\gamma_{p,\theta}(\tau)$. By Definition 2.2 and Lemma 1.3 the operators

$$MD_iD_j : \mathfrak{H}^\gamma_{p,\theta}(\tau) \to \mathbb{H}^{\gamma-2}_{p,\theta}(\tau), \quad \sigma^{ik}D_i : \mathfrak{H}^\gamma_{p,\theta}(\tau) \to \mathbb{H}^{\gamma-1}_{p,\theta}(\tau, l_2)$$

are bounded. By Theorem 2.9, it follows that we need to prove only (4.3) for functions u belonging to set (2.3) with sufficiently large n.

Take such a function u and define f and g according to (3.3). By Sobolev's embedding theorem, if n is large, then f and g are continuous in x, have compact supports in x, and

$$E\int_0^\tau \sup_x |f(t,x)|^p\,dt < \infty, \quad E\int_0^\tau \sup_x |g(t,x)|^p_{l_2}\,dt < \infty.$$

It follows easily that u satisfies (3.1) pointwise, that is, for almost any ω for all $x \in \mathbb{R}^d_+$ and $t \in [0, \tau]$.

Next we define $c = 2 + \theta - d - p$, apply Itô's formula to $(x^1)^c|u(t,x)|^p$, and find almost surely for all $x \in \mathbb{R}^d_+$

$$(x^1)^c|u(\tau,x)|^p = \int_0^\tau \Bigg[p(x^1)^c|u|^{p-2}ua^{ij}u_{x^ix^j}$$

$$+p(x^1)^{c-1}|u|^{p-2}uf + \tfrac{1}{2}p(p-1)(x^1)^c|u|^{p-2}\sum_k(\sigma^{ik}u_{x^i} + g^k)^2\Bigg]\,ds$$

$$+\int_0^\tau p(x^1)^c|u|^{p-2}u(\sigma^{ik}u_{x^i} + g^k)\,dw^k_s. \tag{4.4}$$

We take expectations of both parts of this equality, noticing that

$$E\left[\int_0^\tau |u|^{2p-2}\sum_k |\sigma^{ik}u_{x^i} + g^k|^2\,ds\right]^{1/2} \tag{4.5}$$

$$\leq NTE\sup_{s\leq\tau}|u|^{p-1}|u_x| + NE\sup_{s\leq\tau}|u|^{p-1}\left[\int_0^\tau |g|^2_{l_2}\right]^{1/2}.$$

Here, for instance, by Hölder's inequality the last expectation is less than

$$\big(E\sup_{s\leq\tau}|u|^p\big)^{(p-1)/p}\left(T^{(p-2)/2}E\int_0^\tau |g|_{l_2}^p\,ds\right)^{1/p}<\infty.$$

Therefore, the left-hand side of (4.5) is finite and the stochastic integral will disappear after taking expectations in (4.4). After this we integrate with respect to x over $\mathbb{R}^d_+$. By the way, owing to the fact that x-supports of all functions u, f, and g belong to some G_k and the fact that even the pth power of sup's over x of these functions are integrable over $(0,\tau]\!]$, we see that all integrals converge absolutely. Hence, by using Fubini's theorem and integrating by parts, we get from (4.4) that

$$0\leq E\int_0^\tau\int_{\mathbb{R}^d_+}\big[-p(p-1)(x^1)^c|u|^{p-2}\bar{a}^{ij}u_{x^i}u_{x^j}$$

$$-c(x^1)^{c-1}a^{i1}(|u|^p)_{x^i}+p(p-1)(x^1)^c|u|^{p-2}g^k\sigma^{ik}u_{x^i}$$

$$+p(x^1)^{c-1}|u|^{p-1}|f|+\tfrac{1}{2}p(p-1)(x^1)^c|u|^{p-2}|g|_{l_2}^2\big]\,dxdt.$$

Next, we use Young's inequality to get relations like

$$(x^1)^{c-1}|u|^{p-1}|f|\leq\varepsilon(x^1)^{\theta-d}|u/x^1|^p+N(x^1)^{\theta-d}|f|^p,$$

$$g^k\sigma^{ik}u_{x^i}\leq N|g|_{l_2}|u_x|\leq\varepsilon\bar{a}^{ij}u_{x^i}u_{x^j}+N|g|_{l_2}^2,$$

where $\varepsilon>0$ is arbitrary and N depends only on ε, δ_0, and p. Then we get

$$0\leq E\int_0^\tau\int_{\mathbb{R}^d_+}\big[(\varepsilon-p(p-1))(x^1)^c|u|^{p-2}\bar{a}^{ij}u_{x^i}u_{x^j}$$

$$+(\varepsilon+c(c-1))a^{11}(x^1)^{\theta-d}|u/x^1|^p+N(x^1)^{\theta-d}|f|^p+N(x^1)^{\theta-d}|g|_{l_2}^p\big]\,dxdt.$$

By Corollary 6.2 of [5] for any t

$$\int_{\mathbb{R}^d_+}(x^1)^c|u|^{p-2}\bar{a}^{ij}u_{x^i}u_{x^j}\geq\bar{a}^{11}(1-c)^2p^{-2}\int_{\mathbb{R}^d_+}(x^1)^{\theta-d}|u/x^1|^p\,dx.$$

Hence,

$$E\int_0^\tau\{\bar{a}^{11}[p(p-1)-\varepsilon](1-c)^2p^{-2}+a^{11}[c(1-c)-\varepsilon]\}||M^{-1}u||_{0,p,\theta}^p\,dt$$

$$\leq N(||f||^p_{\mathbb{L}_{p,\theta}(\tau)}+||g||^p_{\mathbb{L}_{p,\theta}(\tau,l_2)}).$$

It remains only to observe that for ε small enough from (4.2) we get that

$$\bar{a}^{11}[p(p-1)-\varepsilon](1-c)^2p^{-2}+a^{11}[c(1-c)-\varepsilon]$$

$$\geq -(1-c)p^{-1}\delta_2/2 + \bar{a}^{11}(p-1)(1-c)^2p^{-1} + a^{11}c(1-c)$$

$$= -(1-c)p^{-1}\delta_2/2 + (1-c)p^{-1}[(p-1)(d+p-1-\theta)\bar{a}^{11} - p(d+p-2-\theta)a^{11}]$$

$$\geq (1-c)p^{-1}\delta_2/2.$$

The lemma is proved.

We divide the remaining part of the proof of Lemma 3.7 into the following subcases:

(1) $\sigma \equiv 0$;

(2) general case.

4.1. Case $\boldsymbol{\sigma \equiv 0}$. Observe that in this case $\bar{a} = a$ and (4.2) becomes

$$a^{11}(\theta - d + 1) \geq \delta_2,$$

which is satisfied for δ_2 sufficiently small because we always assume that $\theta > d-1$ (and, for that matter, $\theta < p+d-1$). Therefore, estimate (4.3) holds. Of course, this estimate implies uniqueness.

To prove existence again use (4.3) and proceed as in the proof of Lemma 4.2 of [6] or Lemma 5.7 of [5]. Since this can be done in quite a straightforward way, we give only a sketch.

First, bearing in mind the a priori estimate and the method of continuity, we see that it suffices to consider the case $a^{ij} = \delta^{ij}$. Furthermore, owing to Theorem 2.10 and Lemma 4.1 we may and will additionally assume that

$$f \in L_p(\Omega, C((0,\tau], C_0^n(G_k))), \quad g \in L_p(\Omega, C((0,\tau], C_0^n(G_k))).$$

Continue f and g across $x^1 = 0$ so that f becomes an even smooth function and g an odd smooth function of x^1. By Theorem 3.2 of [3] or Theorem 5.1 of [4] there exists a unique solution $u \in \mathcal{H}_p^n(\tau)$ of (3.1) considered in the whole $\mathbb{R}^d$ with zero initial condition. If n is large enough, u is smooth with respect to x and satisfies (3.1) pointwise. From the uniqueness, it follows that $u(t,x) = 0$ for $x^1 = 0$. Next use the fact that the functions f and g have compact support and that outside this support u satisfies the deterministic equation $du = \Delta u\,dt$. Then as in the proof of Lemma 4.2 of [6] we derive that $u \in \mathfrak{H}^2_{p,\theta,0}(\tau)$. Using Lemma 3.8 with $\gamma = 2$ and $\mu = 0$ and Lemma 4.1 we conclude that u belongs to $\mathfrak{H}^2_{p,\theta,0}(\tau)$, satisfies (3.1), and estimate (3.5) holds for $\gamma = 2$ and $u_0 = 0$. This proves Lemma 3.7 in our first particular case.

4.2. General case. The left inequality in (3.4) means that

$$\delta_1(p-1)(d+p-1-\theta) > p(d+p-2-\theta),$$

which by virtue of Assumption 3.2 implies (4.2) with

$$\delta_2 = \delta_0[\delta_1(p-1)(d+p-1-\theta) - p(d+p-2-\theta)] > 0.$$

Therefore, a priori estimate (4.3) holds. Using Lemma 3.8 with $\gamma = 2$ and $\mu = 0$, we get that estimate (3.5) holds for $\gamma = 2$ and $u_0 = 0$. In particular, we get the uniqueness.

Furthermore, the same estimate with the same constant N holds if we take $\lambda\sigma^{ik}$ instead of σ^{ik} if $|\lambda| \leq 1$. Now to get the result in our present case from the case $\sigma \equiv 0$ it remains only to use the method of continuity (cf., for instance, the end of the proof of Theorem 5.1 of [4]).

CONTINUOUS DEPENDENCE IN CONSERVATION LAWS WITH PHASE TRANSITIONS*

RINALDO M. COLOMBO[†] AND ANDREA CORLI[‡]

Abstract. This paper is concerned with systems of 2×2 conservation laws

$$(\star) \qquad \partial_t u + \partial_x [f(u)] = 0, \qquad t \geq 0\,,\ x \in \mathbf{R}\,,\ u \in \mathbf{R}^2,$$

developing phase transitions, as happens in models related to elastodynamics or to van der Waals fluids, for instance.

In the present paper, a definition of Ψ-admissible solution to $(\star)$ is given which comprises the various definitions in the current literature. Furthermore, the Ψ-admissible Riemann semigroup (ΨRS) generated by $(\star)$ is introduced and constructed by means of a wave-front tracking algorithm. Uniqueness and continuous dependence for Ψ-admissible solutions to $(\star)$ thus follow.

Key words. conservation laws, phase boundaries

1. Introduction.

This paper is concerned with phase transitions in systems of 2×2 conservation laws

$$\partial_t u + \partial_x [f(u)] = 0, \tag{1.1}$$

where $t \geq 0$, $x \in \mathbf{R}$, $u \in \Omega$, and $\Omega \subset \mathbf{R}^2$. The smooth flow function $f\colon \Omega \mapsto \mathbf{R}^2$ is strictly hyperbolic. We assume that Ω is the union of two disjoint open sets Ω_1 and Ω_2 which we refer to as *phases*. The eigenvalues of Df are assumed to be either genuinely nonlinear or linearly degenerate in each phase. By *phase transition* we mean a jump in a solution to (1.1) whose states on the two sides of the discontinuity belong to different phases.

Phase transitions model abrupt changes in some physical property of the system under consideration. A well-known example comes from elastodynamics, where $u = (v, w)$ and $f(u) = (-\sigma(w), -v)$. Here v is the particle speed, w is the strain, and σ is a nonmonotone stress-strain function. In recent years many authors dealt with this model; we quote for brevity only [11], [1], [14], [13]. Another model developing phase boundaries is the system of van der Waals fluids, as considered in [18], [19], [8]. We refer the reader to the survey paper [21] and to [23] for other physical accounts.

The introduction of phase transitions in (1.1) may be necessary in order to solve the Riemann problem

$$\begin{cases} \partial_t u + \partial_x [f(u)] = 0, \\ u(0, x) = u_o(x), \end{cases} \qquad \text{where} \qquad u_o(x) = \begin{cases} u^\flat & \text{if } x < 0, \\ u^\sharp & \text{if } x > 0 \end{cases} \tag{1.2}$$

with $u^\flat, u^\sharp$ in the same phase but not necessarily close. It may well happen that no physically acceptable solution to (1.2) exists, unless a middle state $u^\natural$ is chosen in the other phase. From a mathematical point of view, the Lax shock-rarefaction curves may have no intersection in the phase which contains $u^\flat$ and $u^\sharp$. Nonetheless, a physically acceptable solution can be defined by introducing two phase boundaries between $u^\flat$ and $u^\sharp$.

We shall consider only *subsonic* phase transitions, which means that the absolute value of the speed of the discontinuity is lower than the absolute value of the characteristic speeds. An important feature of this case is that the Rankine–Hugoniot conditions turn out to be insufficient to uniquely determine a solution to (1.2) and a further *admissibility* condition, expressed by a function Ψ, is required.

From our point of view, we are not interested in the particular admissibility condition that is added, provided it satisfies some minimal regularity and stability assumptions. We consider it to be a *physical* problem to select the most suitable admissibility condition for every single specific application of (1.1). We remark, however, that our procedures apply to both the kinetic approach of elastodynamics [1] and the visco-capillarity approach [18], [19], [8] of van der Waals' model.

The main result of this paper is the construction of a Ψ-admissible Riemann semigroup (ΨRS) whose orbits are solutions to

$$\begin{cases} \partial_t u + \partial_x \left[f(u) \right] = 0, \\ u(0,x) = \underline{u}(x) + \tilde{u}(x), \end{cases} \tag{1.3}$$

where $\tilde{u}$ is assumed to have suitably small total variation. $\underline{u}$ is the solution to (1.2) evaluated at some nonnegative time, with $u^\flat$, $u^\sharp$ in the same or in different phases. For example, the case $\underline{u} = u_o$ is acceptable.

The main tool is a modification of the wave-front tracking algorithm as developed in [4], [5] for the construction of a standard Riemann semigroup (SRS). We refer to [3] for a review of the SRS theory.

The above results depend on a *stability* and a *strong nonresonance* condition on the unperturbed problem (1.2). The former was first stated in [6]; the latter resembles what is done in [5]. A notable difference with respect to [5] is the addition of a condition to single out the solutions to the Riemann problems, as we mentioned above; moreover, the generic interaction of a wave against a phase boundary leads to a configuration entirely different from the case considered therein.

Due to the result in this paper, the whole recent theory of SRSs [3] and *viscosity solutions* [2] can be extended to systems of the form (1.1) that develop phase boundaries. We recall only that by means of the definition of viscosity solutions the trajectories of the SRS are characterized in terms of integral inequalities relying solely on (1.1). Furthermore, by introducing a condition analogous to (A3) in [5], it is possible to uniquely characterize the solution constructed here, thus providing an *existence and uniqueness* theorem for viscosity solution to (1.1) satisfying (A3) and developing admissible phase boundary.

The paper is organized as follows. In section 2 we collect some basic facts, give precise definitions, and state our main result. The main theorem is applied in section 3 to the problem of elastodynamics and to a model of a van der Waals gas. Section 4 contains the statements of a number of propositions, which are proved in the last section 5.

2. Notations and main results. Let Ω be the union of two disjoint open subsets Ω_1, Ω_2 of $\mathbf{R}^2$; Ω_1 and Ω_2 are called *phases*. Throughout this paper we assume that $f\colon \Omega \mapsto \mathbf{R}^2$ is a smooth function and that its Jacobian matrix $A(u) = Df(u)$ is strictly hyperbolic in all Ω; this means that $A(u)$ has two real and distinct eigenvalues $\lambda_1(u)$, $\lambda_2(u)$ for every $u \in \Omega$. By eventually applying a linear change of coordinates, we assume that

$$(2.1) \qquad -\lambda^{\max} < \lambda_1(u) < -\lambda^{\min} < 0 < \lambda^{\min} < \lambda_2(u) < \lambda^{\max} \qquad \text{for all } u \in \Omega$$

for two fixed constants $\lambda^{\min}$, $\lambda^{\max}$. We denote by $r_1(u)$, $r_2(u)$ the eigenvectors associated to the eigenvalues $\lambda_1(u)$, $\lambda_2(u)$. Each characteristic family is locally either linearly degenerate or genuinely nonlinear, i.e., we assume that

$$\text{either} \quad \nabla\lambda_i(u) \cdot r_i(u) = 0 \quad \text{or} \quad \nabla\lambda_i(u) \cdot r_i(u) > 0 \quad \text{for all } u \in \mathcal{U}^\flat$$

and similarly for $\mathcal{U}^\natural$ and $\mathcal{U}^\sharp$. Here $\mathcal{U}^\flat$, $\mathcal{U}^\natural$, and $\mathcal{U}^\sharp$ are subsets of Ω which are going to be specified in the following.

The fact that Ω is the disjoint union of two open sets has important consequences on the solutions of the Riemann problem (1.2). First, if $u^\flat$ and $u^\sharp$ belong to different phases, no Lax [12] solution can be defined. But even if $u^\flat$ and $u^\sharp$ both belong to the same phase Ω_j, then again the Lax solution may not exist. In fact, the shock-rarefaction curves through $u^\flat$, $u^\sharp$ may have no intersection inside Ω_j. In these cases, *phase boundaries* arise.

More precisely, let $u\colon [0, +\infty[\times \mathbf{R} \mapsto \Omega$ be a weak solution to (1.1) such that $u(t, \cdot) \in BV$ for all t. A Lipschitz continuous curve $x = \Lambda(t)$ is a *phase boundary* for u if for almost every t the traces

$$u^l(t) = \lim_{x \to \Lambda(t)-} u(t,x) \qquad \text{and} \qquad u^r(t) = \lim_{x \to \Lambda(t)+} u(t,x)$$

are in two different phases. When this happens, the Rankine–Hugoniot condition

$$(2.2) \qquad \dot\Lambda \cdot \left(u^l - u^r\right) = f(u^l) - f(u^r)$$

must be satisfied for a.e. t in order to have a weak solution. By eliminating $\dot\Lambda$ in (2.2), the Rankine–Hugoniot equations reduce to the scalar condition

$$(2.3) \qquad \Phi_{RH}(u^l, u^r) = 0$$

for a suitable smooth function Φ_{RH}.

In the rest of this paper, we consider only *subsonic* phase boundaries, i.e., we assume that

$$(2.4) \qquad \left|\dot\Lambda\right| < \lambda^{\min} .$$

The choice (2.4) is motivated by the fact that phase boundaries satisfying $\left|\dot\Lambda\right| > \lambda^{\max}$ can be treated as overcompressive shocks [16], but this situation does not seem physically relevant; see [11]. In the intermediate *supersonic* case $\lambda_i(u^l) < \dot\Lambda < \lambda_i(u^r)$ (or $\lambda_i(u^r) < \dot\Lambda < \lambda_i(u^l)$), Lax shock inequalities are satisfied and phase boundaries behave as large shocks and can be treated exactly as in [5]. For sonic phase boundaries, we refer to [7].

It is possible to define a solution to the Riemann problem (1.2) relying solely on (2.3). However, in the subsonic case (2.4) the requirement (2.3) alone does not single out a unique solution. It is thus necessary to impose a further constraint on the states on the sides of the discontinuity, say,

$$\Psi(u^l, u^r) = 0, \tag{2.5}$$

where $\Psi\colon (\Omega_1 \times \Omega_2) \cup (\Omega_2 \times \Omega_1) \to \mathbf{R}$ is a smooth function. The conditions (2.3) and (2.5) allow us to single out a unique solution to (1.2). We shall consider only Ψ-*admissible* phase boundaries, i.e., those whose side states satisfy (2.3) and (2.5). We stress that our condition depends on the particular choice of Ψ.

From a physical point of view, the choice of the function Ψ is usually related to some kind of entropy dissipation, as in the examples developed in section 3. Let us point out that the case of an admissibility function Ψ depending solely on the speed of the phase boundary is contained in our framework, since the jump conditions (2.3) allow us to express $\dot{\Lambda}$ by means of u^l and u^r.

Under assumption (2.4) and having imposed condition (2.5), it is natural to give the following definition.

Definition 2.1. *We call Ψ-admissible solution to the Riemann problem* (1.2) *under the admissibility condition* (2.5)

(i) *the usual Lax solution as long as it exists;*

(ii) *the solution consisting of a Lax wave of the first family, a Ψ-admissible phase boundary, and a Lax wave of the second family, whenever $u^\flat$ and $u^\sharp$ belong to different phases;*

(iii) *the solution consisting of a Lax wave of the first family, two Ψ-admissible phase boundaries, and a Lax wave of the second family, whenever $u^\flat$ and $u^\sharp$ belong to the same phase but a Lax solution does not exist.*

For notational simplicity, we introduce the function $\Phi\colon (\Omega_1 \times \Omega_2) \cup (\Omega_2 \times \Omega_1) \to \mathbf{R}^2$ by

$$\Phi(u^l, u^r) = \begin{bmatrix} \Phi_{RH}(u^l, u^r) \\ \Psi(u^l, u^r) \end{bmatrix} .$$

Denote by $D_1\Phi$ (resp., $D_2\Phi$) the 2×2 Jacobian of Φ with respect to the first (resp., second) argument. It is useful to consider the following situations separately:

(1) $\Phi(u^\flat, u^\sharp) = 0$, so that (1.2) is solved by a subsonic phase boundary and no other waves;

(2) $\Phi(u^\flat, u^\natural) = 0$ and $\Phi(u^\natural, u^\sharp) = 0$ for some middle state $u^\natural$, so that (1.2) is solved by two subsonic phase boundaries and no other waves.

We emphasize that we do not take into account in this paper the phenomenon of *nucleation*, i.e., the initiation of two phase boundaries at a certain time from data in the same phase (see [1], [13]). To prevent nucleation we shall make some assumptions in order that the solutions to (1.3) have the same number of phase boundaries of (1.2), which is, according to the previous situations, either one or two.

In case (1), we say that the phase boundary separating $u^\flat$ from $u^\sharp$ is *stable* when

$$\det\Big(D_1\Phi(u^\flat, u^\sharp) r_1(u^\flat),\ D_2\Phi(u^\flat, u^\sharp) r_2(u^\sharp)\Big) \neq 0. \tag{2.6}$$

This condition ensures the unique solvability in the sense of Definition 2.1, part (ii), of all Riemann problems with data sufficiently near to $u^\flat$, $u^\sharp$ by the implicit function theorem. Similarly, in case (2), we assume that

$$\det\Big(D_1\Phi(u^\flat, u^\natural) r_1(u^\flat),\ D_2\Phi(u^\flat, u^\natural) r_2(u^\natural)\Big) \neq 0, \tag{2.7}$$

$$\det\Big(D_1\Phi(u^\natural, u^\sharp) r_1(u^\natural),\ D_2\Phi(u^\natural, u^\sharp) r_2(u^\sharp)\Big) \neq 0. \tag{2.8}$$

The conditions above imply the solvability of small perturbations of the Riemann problems with data $(u^\flat, u^\natural)$ and $(u^\natural, u^\sharp)$. Due to Definition 2.1, we need a further global condition ensuring that no small perturbation of the Riemann problem with data $(u^\flat, u^\sharp)$ may be solved without the introduction of two phase boundaries. Let $\mathcal{R}_1^\flat$ be the set of points that can be to the right of a wave of the first family exiting $u^\flat$. Similarly, let $\mathcal{L}_2^\sharp$ be the set of all those points that can be on the left of a wave of the second family entering $u^\sharp$. We require that

$$\inf_{u \in \mathcal{R}_1^\flat, w \in \mathcal{L}_2^\sharp} d\,(u, w) > \rho > 0\ . \tag{2.9}$$

We remark that without (2.9), the $\mathbf{L}^1$-continuous dependence on the initial data may be lost. Indeed, assume for simplicity that there exists a

$$u^* \in \mathcal{R}_1^\flat \cap \mathcal{L}_2^\sharp\ .$$

Choose now a positive a. Then, problem (1.1) with initial data

$$u_a(x) = \begin{cases} u^\flat & \text{if } x < -a, \\ u^\natural & \text{if } x \in [-a, a], \\ u^\sharp & \text{if } x > a \end{cases}$$

has a unique solution u_a containing two phase boundaries, due to (2.7) and (2.8). For all $a > 0$, the qualitative properties of the solution remain unchanged. However, due to Definition 2.1, at $a = 0$ the solution corresponding to u_0 contains no phase boundaries, but only a Lax wave of the first family joining $u^\flat$ to u^* and a Lax wave of the second family joining u^* to $u^\sharp$.

In case (2), a damping condition as in [5] is necessary to ensure that small perturbations of (1.2) still have a global solution. In order to state this condition, let us denote by $\Lambda^\flat$, $\Lambda^\sharp$ the propagation speeds of the phase boundaries, with $\Lambda^\flat, \Lambda^\sharp \in \mathbf{R}$. Consider the case of a small wave σ hitting one of the phase boundaries. From the interaction, a reflected wave and a transmitted wave arise. A first-order analysis shows that these arising waves are bounded by $|\sigma|$ times suitable reflection and transmission coefficients, respectively. These coefficients are given by

$$\Big(D_1\Phi r_1(u^\flat),\ -D_2\Phi r_2(u^\natural)\Big)^{-1}\Big(-D_2\Phi r_1(u^\flat),\ D_1\Phi r_2(u^\natural)\Big) = \begin{pmatrix} T_{\natural\flat} & R_\flat \\ R^\flat_\natural & T_{\flat\natural} \end{pmatrix}, \tag{2.10}$$

$$\Big(D_1\Phi r_1(u^\natural),\ -D_2\Phi r_2(u^\sharp)\Big)^{-1}\Big(-D_2\Phi r_1(u^\natural),\ D_1\Phi r_2(u^\sharp)\Big) = \begin{pmatrix} T_{\sharp\natural} & R^\sharp_\natural \\ R_\sharp & T_{\natural\sharp} \end{pmatrix}, \tag{2.11}$$

where for simplicity we omitted the arguments $(u^\flat, u^\natural)$ in the first line and $(u^\natural, u^\sharp)$ in the second one. Then let us define

$$\Theta^\flat = -\frac{\lambda_2(w^\natural) - \Lambda^\flat}{\Lambda^\flat - \lambda_1(w^\natural)}, \qquad \Theta^\sharp = -\frac{\lambda_1(w^\natural) - \Lambda^\sharp}{\Lambda^\sharp - \lambda_2(w^\natural)}.$$

Due to (2.4), both $\Theta^\flat$ and $\Theta^\sharp$ are negative numbers and, under condition (2.4), we have

$$\Theta^\flat \Theta^\sharp > 1. \tag{2.12}$$

We say that the *strong nonresonance* condition holds if

$$\left|R^\flat_\natural \Theta^\flat\right| \cdot \left|R^\sharp_\natural \Theta^\sharp\right| < 1 \tag{2.13}$$

with $R^\flat_\natural$ as in (2.10) and $R^\sharp_\natural$ as in (2.11). On one hand, this condition provides the Lipschitz-continuous dependence in $\mathbf{L}^1$ from the initial data of the solutions to (1.3); see [5]. On the other hand, it implies

$$\left|R^\flat_\natural\right| \cdot \left|R^\sharp_\natural\right| < 1 \tag{2.14}$$

because of (2.12). Formula (2.14) is the usual *nonresonance* condition (see [17], [5]) which says, roughly speaking, that the strength of a small wave diminishes after two reflections against the phase boundaries.

Let us remark that the stability conditions (2.7)–(2.8) together with the assumption

$$R^\flat_\natural \cdot R^\sharp_\natural \neq 1 \tag{2.15}$$

imply the stability of the solution to the Riemann problem (1.2) in case (iii) of Definition 2.1. In fact, by (2.10) and (2.11),

$$R^\flat_\natural = -\frac{\det T_1(u^\flat, u^\natural)}{\det S(u^\flat, u^\natural)}, \qquad R^\sharp_\natural = -\frac{\det T_2(u^\natural, u^\sharp)}{\det S(u^\natural, u^\sharp)},$$

where T_1, T_2, and S are the 2×2 matrices

$$\begin{aligned} T_i(u^l, u^r) &= \Big(D_1\Phi(u^l, u^r) r_i(u^l),\ D_2\Phi(u^l, u^r) r_i(u^r)\Big), \qquad i = 1, 2, \\ S(u^l, u^r) &= \Big(D_1\Phi(u^l, u^r) r_1(u^l),\ -D_2\Phi(u^l, u^r) r_2(u^r)\Big) . \end{aligned}$$

The stability of the solution to (1.2) in case (iii) of Definition 2.1 is equivalent to the applicability of the implicit function theorem to

$$\left\{ \begin{array}{l} \Phi\big(\phi_1(u^\flat, \sigma_1), u^\natural\big) = 0, \\ \Phi\big(u^\natural, \tilde{\phi}_2(u^\sharp, \sigma_2)\big) = 0 \end{array} \right.$$

in the unknowns σ_1, $u^\natural$, and σ_2. Here, ϕ_i (resp., $\tilde{\phi}_i$) is the shock-rarefaction curve from left to right (resp., right to left). The above requires the 4×4 matrix

$$\left(\begin{array}{ccc} D_1\Phi(u^\flat, u^\natural) r_1(u^\flat) & D_2\Phi(u^\flat, u^\natural) & 0 \\ 0 & D_1\Phi(u^\natural, u^\sharp) & D_2\Phi(u^\natural, u^\sharp) r_2(u^\sharp) \end{array} \right)$$

to be nonsingular, which in turn is equivalent to the nonsingularity of

$$\left(\begin{array}{cccc} D_1\Phi(u^\flat, u^\natural) r_1(u^\flat) & D_2\Phi(u^\flat, u^\natural) r_1(u^\natural) & D_2\Phi(u^\flat, u^\natural) r_2(u^\natural) & 0 \\ 0 & D_1\Phi(u^\natural, u^\sharp) r_1(u^\natural) & D_1\Phi(u^\natural, u^\sharp) r_2(u^\natural) & D_2\Phi(u^\natural, u^\sharp) r_2(u^\sharp) \end{array} \right).$$

A quick calculation shows that the determinant of the latter matrix is

$$\det T_1(u^\flat, u^\natural) \det T_2(u^\natural, u^\sharp) - \det S(u^\flat, u^\natural) \det S(u^\natural, u^\sharp),$$

which is nonzero iff (2.15) holds. This proves our remark.

The following definition of ΨRS is an adaptation of [2]; similar to [5], we introduce the set $\mathcal{M}$ of smooth increasing diffeomorphisms $\mathbf{R} \mapsto \mathbf{R}$. Assume that system (1.2) admits a solution $\underline{u}$, either in case (1) or in case (2).

Definition 2.2. *A Ψ-admissible Riemann semigroup (ΨRS) generated by* (1.2) *is a map $S\colon [0, +\infty[\times \mathcal{D} \mapsto \mathcal{D}$ satisfying the following:*

(i) *there exists a positive δ such that the closed invariant domain $\mathcal{D} \subset L^1_{loc}(\mathbf{R})$ contains the set of functions $u\colon \mathbf{R} \mapsto \Omega$, such that there exists $\mu \in \mathcal{M}$:*

$$\|u(\cdot) - \underline{u}(1, \mu(\cdot))\|_{\mathbf{L}^1} < \infty, \quad \mathrm{TV}\left\{u(\cdot) - \underline{u}(1, \mu(\cdot))\right\} \leq \delta; \tag{2.16}$$

(ii) $S_0 u = u$ *and* $S_{t''} \circ S_{t'}(u) = S_{t'+t''} u$;

(iii) *there exists a positive L such that*

$$\left\| S_{t''} u'' - S_{t'} u' \right\|_{\mathbf{L}^1} \leq L \cdot \left(\|u'' - u'\|_{\mathbf{L}^1} + |t'' - t'| \right);$$

(iv) *every trajectory $t \mapsto S_t u$ yields a Ψ-admissible weak solution to* (1.1) *with initial data u*;

(v) *if $u \in \mathcal{D}$ is piecewise constant, then for t small $S_t u$ coincides with the glueing of the Ψ-admissible solutions of Definition* 2.1.

Note that in case (2) the initial data u_o at (1.2) belongs to $\mathcal{D}$ but it does not belong to the set defined through (2.16). Moreover, the initial data satisfying (2.16) are more general than the ones considered at (1.3).

Our main result is the existence of such a ΨRS, which we accomplish by means of a *constructive* procedure.

Theorem 2.3. *Consider system* (1.1)*. Assume that it is strictly hyperbolic with each characteristic field either linearly degenerate or genuinely nonlinear. Let the admissibility condition* (2.5) *be given.*

In case (1)*, fix $u^\flat$ and $u^\sharp$ such that the solution to* (1.2) *contains a subsonic* (2.4) *and stable* (2.6) *phase boundary.*

In case (2)*, fix $u^\flat$, $u^\natural$, and $u^\sharp$ satisfying* (2.9) *and such that the solution to* (1.2) *contains two subsonic* (2.4)*, stable* (2.7)*–*(2.8)*, and strongly nonresonant* (2.13) *phase boundaries with middle state $u^\natural$.*

Then, there exists a ΨRS generated by (1.2)*.*

We remark here that the whole construction is *local* in the space of conserved quantities. Thus the above assumption on the linear degeneracy or genuine nonlinearity of the characteristic families is sufficient when satisfied in suitable neighborhoods of $u^\flat$, $u^\natural$, and $u^\sharp$.

3. Examples.

In this section we give two examples: the first coming from elastodynamics and the latter from van der Waals fluids.

In the case of elastodynamics we write $u = (v, w)$, where v is the particle velocity and w the strain; the flow function is $f(v, w) = (-\sigma(w), -v)$, defined on $\Omega = \mathbf{R} \times (]-1, w_M[\cup]w_m, +\infty[)$, with $w_M < w_m$. The system (1.1) becomes

$$\begin{cases} \partial_t v - \partial_x [\sigma(w)] = 0, \\ \partial_t w - \partial_x v = 0. \end{cases} \tag{3.1}$$

The function σ is the stress-strain function. We assume that it has a maximum point w_M and a minimum point w_m; see Figure 3.1. Moreover, with a little abuse of notation, we let

$$\Omega_1 =]-1, w_M[, \quad \Omega_2 =]w_m, +\infty[$$

and we assume also that

$$\sigma' > 0 \text{ in } \Omega_1 \cup \Omega_2 \qquad \text{and} \qquad \sigma'' < 0 \text{ in } \Omega_1, \quad \sigma'' > 0 \text{ in } \Omega_2; \tag{3.2}$$

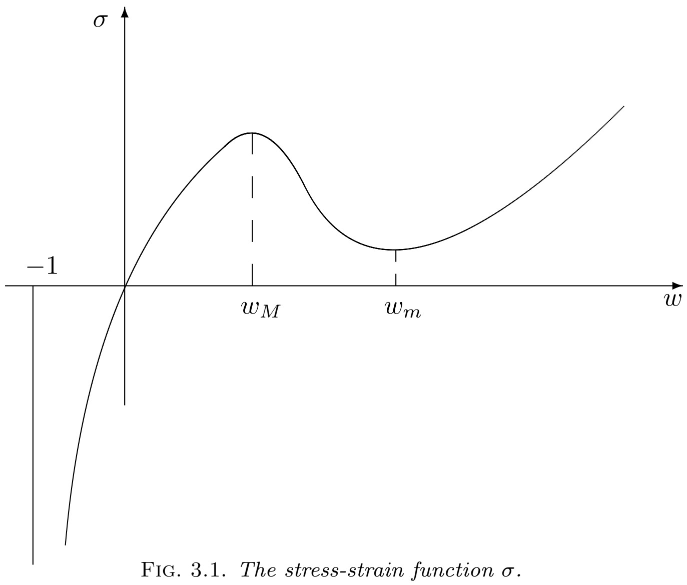

FIG. 3.1. *The stress-strain function* σ.

the behavior of σ'' in the middle zone $[w_M, w_m]$ is not relevant. In what follows, we shall always limit w to the phases Ω_1 or Ω_2, where the system is strictly hyperbolic and genuinely nonlinear. We introduce the sound speed

$$c(w) = \sqrt{\sigma'(w)}$$

so that the characteristic speeds of (3.1) are

$$\lambda_1(w) = -c(w) \quad \text{and} \quad \lambda_2(w) = c(w).$$

Let us remark that, from a physical point of view, both evolution from the first (hard) phase to the second (soft) one and vice versa are possible: an example of the first case is given by the cold drawing of polyethylene, while an example of the second case is the hardening of polybutene (see [23]). Moreover, the assumption of concavity of σ in the first phase and convexity in the second one is made only for simplicity; for some materials, different situations are possible and can be considered within the present construction.

We consider the Riemann problem for (3.1) with initial data

$$u_o(x) = \begin{cases} u^\flat = (v^\flat, w^\flat) & \text{if } x < 0, \\ u^\sharp = (v^\sharp, w^\sharp) & \text{if } x > 0. \end{cases} \tag{3.3}$$

Due to the nonmonotonicity of the stress-strain function σ, the Lax shock-rarefaction curves through $(v^\flat, w^\flat)$ and $(v^\sharp, w^\sharp)$ may have no intersection even if both $w^\flat$ and $w^\sharp$ both belong to the same hyperbolic phase. In fact, straightforward computations show that the Lax solution to (3.1) and (3.3) exists precisely in the following situations:

$$v^\sharp - v^\flat < \int_{w^\flat}^{w_M} c(w)dw + \int_{w^\sharp}^{w_M} c(w)dw \quad \text{if} \quad w^\flat, w^\sharp \in \Omega_1, \tag{3.4}$$

$$v^\flat - v^\sharp < \int_{w_m}^{w^\flat} c(w)dw + \int_{w_m}^{w^\sharp} c(w)dw \quad \text{if} \quad w^\flat, w^\sharp \in \Omega_2\ . \tag{3.5}$$

Condition (2.9) becomes

$$\begin{aligned} v^\sharp - v^\flat &> \int_{w^\flat}^{w_M} c(w)dw + \int_{w^\sharp}^{w_M} c(w)dw + \rho \quad \text{if} \quad w^\flat, w^\sharp \in \Omega_1, \\ v^\flat - v^\sharp &> \int_{w_m}^{w^\flat} c(w)dw + \int_{w_m}^{w^\sharp} c(w)dw + \rho \quad \text{if} \quad w^\flat, w^\sharp \in \Omega_2 \ . \end{aligned}$$

If $\int_{-1}^{w_M} c(w)dw < +\infty$, then the above inequalities follow from

$$\left\| u^\sharp - u^\flat \right\| > C \cdot \rho \ . \tag{3.6}$$

On the contrary, if $\int_{-1}^{w_M} c(w)dw = +\infty$, then no assumption of the type (3.6) implies (2.9).

Consider now a phase boundary with speed Λ, with right and left states $u^r = (v^r, w^r)$, $u^l = (v^l, w^l)$, respectively. From the Rankine–Hugoniot conditions (2.2), it follows that

$$\Lambda = \zeta \cdot \sqrt{\frac{\sigma(w^r) - \sigma(w^l)}{w^r - w^l}}, \tag{3.7}$$

where

$$\zeta = -\zeta_v \cdot \zeta_w, \quad \zeta_v = \operatorname{sign}(v^r - v^l), \quad \zeta_w = \operatorname{sign}(w^r - w^l) \tag{3.8}$$

(and $\operatorname{sign} 0 = 0$). We consider now admissibility and stability of the phase boundaries. In the kinetic approach proposed by [1] the choice for the function Ψ is

$$\begin{aligned} &\Psi(u^l, u^r) \\ &= \frac{\sigma(w^r) + \sigma(w^l)}{2}(w^r - w^l) - \int_{w^l}^{w^r} \sigma(w)\, dw + \zeta_w \phi \left(-\zeta_v \sqrt{\frac{\sigma(w^r) - \sigma(w^l)}{w^r - w^l}} \right), \end{aligned} \tag{3.9}$$

where ϕ is a given constitutive function and ζ_v, ζ_w are defined in (3.8).

If u^l, u^r are the side states of a nonstationary phase boundary, then the vanishing of the function Ψ prescribes the amount of physical entropy dissipated by the phase boundary.

The function ϕ above, as chosen in [1], is singular when $\Lambda = 0$. For this reason the case of a stationary phase boundary needs to be ruled out. With a different (smooth) choice of ϕ, the construction developed in section 2 can be applied also to the case of stationary phase boundaries.

In the case (3.9), the stability condition (2.6) reads (see [6])

$$\phi' \left(-\zeta_v \sqrt{\frac{\sigma(w^\sharp) - \sigma(w^\flat)}{w^\sharp - w^\flat}} \right) \neq - \frac{\dfrac{\sigma(w^\sharp) - \sigma(w^\flat)}{w^\sharp - w^\flat} + c(w^\flat)c(w^\sharp)}{c(w^\flat) + c(w^\sharp)} \, (w^\sharp - w^\flat)^2.$$

The above inequality is satisfied whenever ϕ is increasing, which is physically acceptable.

Let us consider now the case of two phase boundaries, having speeds $\Lambda^\flat$ and $\Lambda^\sharp$, with $\Lambda^\flat, \Lambda^\sharp \in \mathbf{R}$ and $\Lambda^\flat < \Lambda^\sharp$, with the same notations of Case 2 of the previous section; we look for an explicit condition for strong nonresonance. It comes out that

$$\text{(3.10)}\ R^\flat_\natural = -\frac{1}{\Theta^\flat}\frac{c(w^\natural)c(w^\flat) - (\Lambda^\flat)^2 + h^\flat\big(c(w^\natural) - c(w^\flat)\big)}{c(w^\natural)c(w^\flat) + (\Lambda^\flat)^2 + h^\flat\big(c(w^\natural) + c(w^\flat)\big)} \quad \text{for} \quad h^\flat = \frac{\phi'(\zeta^\flat_w \Lambda^\flat)}{(w^\natural - w^\flat)^2},$$

$$\text{(3.11)}\ R^\sharp_\natural = -\frac{1}{\Theta^\sharp}\frac{c(w^\natural)c(w^\sharp) - (\Lambda^\sharp)^2 + h^\sharp\big(c(w^\natural) - c(w^\sharp)\big)}{c(w^\natural)c(w^\sharp) + (\Lambda^\sharp)^2 + h^\sharp\big(c(w^\natural) + c(w^\sharp)\big)} \quad \text{for} \quad h^\sharp = \frac{\phi'(\zeta^\sharp_w \Lambda^\sharp)}{(w^\sharp - w^\natural)^2},$$

where

$$\Theta^\flat = \frac{\Lambda^\flat - c(w^\natural)}{\Lambda^\flat + c(w^\natural)}, \qquad \Theta^\sharp = \frac{\Lambda^\sharp + c(w^\natural)}{\Lambda^\sharp - c(w^\natural)}.$$

We already remarked in section 2 that $\Theta^\flat$ and $\Theta^\sharp$ are negative numbers and that (2.12) holds. Let us point out that, differently from [5], we have $\Theta^\flat < -1$ iff $\Lambda^\flat < 0$ and $\Theta^\sharp < -1$ iff $\Lambda^\sharp > 0$; the condition $\Lambda^\flat < 0 < \Lambda^\sharp$ is always satisfied in the case of a trilinear stress-strain function σ (see [1, p. 137]). What is more important here is that from (3.10) and (3.11) we see that the strong nonresonance condition (2.13) holds if the constitutive function ϕ is increasing.

We briefly note here that the approach developed in section 2 applies also to the case of those materials for which $\sigma'' < 0$ also in Ω_2. Indeed, in this case, simply substitute (3.5) with

$$v^\flat - v^\sharp < \sqrt{(\sigma(w^\sharp) - \sigma(w_m))\,(w^\sharp - w_m)} + \sqrt{\big(\sigma(w^\flat) - \sigma(w_m)\big)\,(w^\flat - w_m)};$$

here, $w^\flat$, $w^\sharp$ both belong to Ω_2. Similarly, condition (2.9) becomes

$$v^\flat - v^\sharp > \sqrt{(\sigma(w^\sharp) - \sigma(w_m))\,(w^\sharp - w_m)} + \sqrt{\big(\sigma(w^\flat) - \sigma(w_m)\big)\,(w^\flat - w_m)} + \rho.$$

The case $\sigma'' > 0$ in Ω_1 can be considered similarly.

With suitable choices of f, Ω_1, and Ω_2, the construction presented in this paper includes also the trilinear material, as considered in [13]. In this context, Definition 2.1 reduces to the one given therein. Moreover, see [21] for a simple cubic model of σ.

Our second example is the one-dimensional isothermal model for a van der Waals fluid:

$$\text{(3.12)} \qquad \begin{cases} \partial_t v + \partial_x\,[p(w)] = 0, \\ \partial_t w - \partial_x v = 0. \end{cases}$$

Here $u = (v, w)$, with v being the particle velocity and w the specific volume. The pressure p is a smooth positive function defined in $]0, +\infty[$, with a minimum point w_m and a maximum point $w_M > w_m$, $p(w_m) < p(w_M)$. The liquid phase is $\Omega_1 =]w_0, w_m[$ while the vapor phase is $\Omega_2 =]w_M, +\infty[$ and we assume

$$\text{(3.13)} \qquad p' < 0 \text{ in } \Omega_1 \cup \Omega_2, \qquad p'' > 0 \text{ in } \Omega_1,$$

as in Figure 3.2.

A key difference between this example and the previous one is the following. As shown in Figure 3.2, the pressure has an inflection point in Ω_2, which makes each of

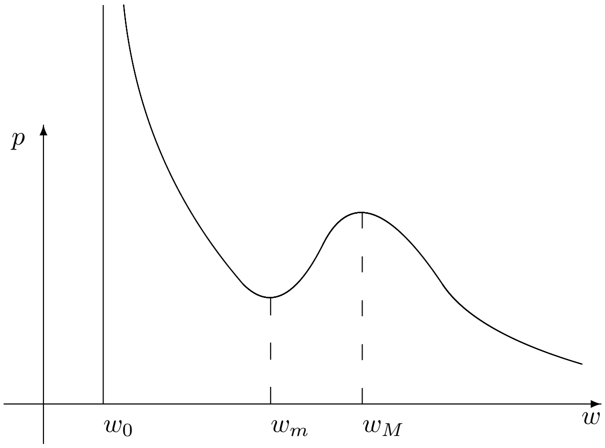

FIG. 3.2. *The pression p as a function of the specific volume w.*

the characteristic families neither globally linearly degenerate nor globally genuinely nonlinear. However, thanks to its *local* nature, the present construction still applies, provided that none of the points $u^\flat$, $u^\natural$, $u^\sharp$ coincides with the inflection point. We point out that in this case the sets $\mathcal{R}_1^\flat$ and $\mathcal{L}_2^\sharp$ in (2.9) are the *mixed curves* introduced by T.-P. Liu in [15, Section 2]. These curves generalize the usual Lax shock-rarefaction curves enabling the construction of a solution to Riemann problems with nongenuinely nonlinear characteristic families.

The formal calculations are omitted, since they are entirely analogous to what has been shown above. Let us emphasize, however, that the present construction can be applied also to the admissibility condition obtained in terms of the viscosity-capillarity criterium (see [18], [19], [8], [9], and [21, formula (5.26)] for the explicit admissibility condition) as well as to the so-called "normal growth" condition (see [22, formulas (3.6) and (4.11)]).

4. The algorithm. Following [4], all the construction below essentially relies on a suitable approximation of the solution to Riemann problems with data in Ω. As long as the solution to (1.2) does not develop any phase boundary, the results in [4] apply.

Consider now Cases 1 and 2. In Case 1, we construct two sets of Riemann coordinates, defined on neighborhoods $\mathcal{U}^\flat$, $\mathcal{U}^\sharp$ of $u^\flat$, $u^\sharp$. In Case 2, we introduce Riemann coordinates on disjoint neighborhoods $\mathcal{U}^\flat$, $\mathcal{U}^\natural$, and $\mathcal{U}^\sharp$ of $u^\flat$, $u^\natural$, and $u^\sharp$, which is possible due to (2.9). The local Riemann coordinates are denoted by v. Whenever necessary, the functions defined on $\mathcal{U}^\flat$, $(\mathcal{U}^\natural, \mathcal{U}^\sharp)$ will be bounded uniformly on $\mathcal{U}^\flat$, $(\mathcal{U}^\natural, \mathcal{U}^\sharp)$.

We define now the approximate solutions to the Riemann problems when the initial data belong to the previous neighborhoods.

In a given set of Riemann coordinates, the i-rarefaction curve ϕ_i^+ and the i-shock curve ϕ_i^- through point v can now be parametrized by means of the arc-length σ, for σ in a suitable neighborhood of 0, as

$$\begin{cases} \phi_1^+(v,\sigma) = (v_1+\sigma, v_2), \\ \phi_2^+(v,\sigma) = (v_1, v_2+\sigma), \end{cases} \qquad \begin{cases} \phi_1^-(v,\sigma) = (v_1+\sigma, v_2+\hat{\phi}_2(v,\sigma)\sigma^3), \\ \phi_2^-(v,\sigma) = (v_1+\hat{\phi}_1(v,\sigma)\sigma^3, v_2+\sigma) \end{cases}$$

for suitable smooth functions $\hat{\phi}_1, \hat{\phi}_2$. The juxtaposition of ϕ_i^+ and ϕ_i^- is the ith shock-rarefaction curve through v. Choose any $\mathbf{C}^\infty$ function $\varphi: \mathbf{R} \mapsto \mathbf{R}$ such that

$$\begin{cases} \varphi(s) = 1 & \text{if } s \le -2, \\ \varphi'(s) \in [-2, 0] & \text{if } s \in [-2, -1], \\ \varphi(s) = 0 & \text{if } s \ge -1, \end{cases}$$

and, for a fixed $\varepsilon > 0$, approximate the i-shock-rarefaction curve as follows:

$$\psi_i^\varepsilon(v, \sigma) = \varphi\left(\sigma/\sqrt{\varepsilon}\right) \cdot \phi_i^-(v, \sigma) + \left(1 - \varphi\left(\sigma/\sqrt{\varepsilon}\right)\right) \cdot \phi_i^+(v, \sigma), \quad i = 1, 2. \tag{4.1}$$

Let now a left and a right state u^l, u^r are given, with Riemann coordinates $v^l = (v_1^l, v_2^l)$ and $v^r = (v_1^r, v_2^r)$. There are two different situations.

A first possibility is that u^l, u^r both belong to the domain of the same chart (hence also to the same phase) and that the solution to the Riemann problem (1.1) with data

$$\bar{u}(x) = \begin{cases} u^l & \text{if } x < 0, \\ u^r & \text{if } x > 0 \end{cases} \tag{4.2}$$

attains values in the same phase. An ε-approximate solution to (1.1)–(4.2) is constructed as follows. First, by the implicit function theorem, we determine unique values σ_1 and σ_2 and a middle state v^m such that

$$v^r = \psi_2^\varepsilon\left(v^m, \sigma_2\right), \qquad v^m = \psi_1^\varepsilon\left(v^l, \sigma_1\right).$$

If $\sigma_1 \ge 0$, we connect the states v^l, v^m with a discrete rarefaction wave by the following procedure. Let the integers h, k be such that

$$h\varepsilon \le v_1^l < (h+1)\varepsilon, \qquad k\varepsilon \le v_1^m < (k+1)\varepsilon$$

and define the states

$$\omega_1^j = (j\varepsilon, v_2^l), \qquad \hat{\omega}_1^j = \left(\frac{2j+1}{2}\varepsilon, v_2^l\right) \qquad \text{for } j = h, \dots, k.$$

Then the ε-approximate solution in the quadrant $\{t \ge 0,\ x \le 0\}$ is the discrete rarefaction fan:

$$v^\varepsilon(t, x) = \begin{cases} v^l & \text{if } x < \lambda_1(\hat{\omega}_1^h)\, t, \\ \omega_1^j & \text{if } \lambda_1(\hat{\omega}_1^{j-1})\, t < x < \lambda_1(\hat{\omega}_1^j)\, t, \qquad j = h+1, \dots, k, \\ v^m & \text{if } \lambda_1(\hat{\omega}_1^k) < x \le 0. \end{cases} \tag{4.3}$$

If $\sigma_1 < 0$, the states v^l and v^m are connected by a single discontinuity:

$$v^\varepsilon(t, x) = \begin{cases} v^l & \text{if } x < \lambda_1^\varphi(v^l, \sigma_1)\, t, \\ v^m & \text{if } \lambda_1^\varphi(v^l, \sigma_1)\, t < x \le 0. \end{cases} \tag{4.4}$$

The speed λ_1^φ of the discontinuity is defined here as

$$\lambda_1^\varphi(v^l, \sigma_1) = \varphi(\sigma_1/\sqrt{\varepsilon}) \cdot \lambda_1^s(v^l, \sigma_1) + \left(1 - \varphi(\sigma_1/\sqrt{\varepsilon})\right) \cdot \lambda_1^r(v^l, \sigma_1),$$

with

$$\lambda_1^s(v^l, \sigma_1) = \lambda_1\left(v^l, \phi_1^-(v^l, \sigma_1)\right),$$

$$\lambda_1^r(v^l, \sigma_1) = \sum_{j=h}^{k} \frac{\operatorname{meas}\left([j\varepsilon, (j+1)\varepsilon] \cup [v_1^m, v_1^l]\right)}{|\sigma_1|}\ \lambda_1(\hat{\omega}_1^j)\ .$$

Observe that as soon as $\sigma_1 \leq -2\sqrt{\varepsilon}$ the function v^ε in (4.4) is an exact solution to the Rankine–Hugoniot equations, a shock wave. For this reason, we shall call briefly shock waves every funtion v^ε as defined in (4.4).

The construction of the ε-approximate solution on the quadrant where $x \geq 0$ is entirely similar, repeating the above construction with waves of the second family. We refer the reader to [4] for details.

A second eventuality is that u^l, u^r belong to different phases; in this case the Riemann problem is solved with the introduction of a small 1-wave, a *single exact* phase boundary, and a small 2-wave. This is possible by the implicit funtion theorem and the stability condition (2.6).

We pass now to a piecewise constant initial condition $\bar{u}$ belonging to some suitable domain. An ε-approximate piecewise constant solution to the Cauchy problem with initial data $\bar{u}$ is constructed as follows. At the initial time $\tau_0 = 0$ we solve the Riemann problems determined by the jumps in $\bar{u}$ applying the algorithm previously described. This yields a piecewise constant approximate solution $u = u^\varepsilon(t, x)$ defined up to the time $\tau_1 > 0$, where the first set of wave-front interactions takes place. We then solve these new Riemann problems by again applying the above algorithm. The solution is prolonged up to the time τ_2 where the second set of interactions takes place and so on.

The domain $\mathcal{D}^\varepsilon_\delta$ of the approximate semigroup in the two Cases 1 and 2 is defined as follows. We are concerned only with piecewise constant functions $u = u(x)$ of the form

$$u = u^\flat \cdot \chi_{]-\infty, x_1]} + \sum_{\alpha=1}^{n-1} u^\alpha \cdot \chi_{]x_\alpha, x_{\alpha+1}]} + u^\sharp \cdot \chi_{]x_n, +\infty[} \; . \tag{4.5}$$

Whenever $u^{\alpha-1}$, u^α belong to the same chart (and hence to the same phase), a suitable choice of neighborhoods $B\big(u^\flat, \delta_o\big) \subset \mathcal{U}^\flat$, $B\big(u^\natural, \delta_o\big) \subset \mathcal{U}^\natural$, and $B\big(u^\sharp, \delta_o\big) \subset \mathcal{U}^\sharp$ ensures that the Riemann problem determined by the jump at x_α is uniquely solved by the above algorithm in terms of waves with sizes $\sigma_{1,\alpha}$, $\sigma_{2,\alpha}$. Recalling (4.1), this means

$$v^\alpha = \psi_2^\varepsilon \left(\psi_1^\varepsilon(v^{\alpha-1}, \sigma_{1,\alpha}), \sigma_{2,\alpha} \right), \tag{4.6}$$

where $v^{\alpha-1}$, v^α stand for the Riemann coordinates of $u^{\alpha-1}$, u^α.

Case 1. Assume $\mathcal{U}^\flat \subseteq \Omega_1$ and $\mathcal{U}^\sharp \subseteq \Omega_2$. For all functions u of the form (4.5)–(4.6) satisfying

$$u^1, \ldots, u^{\alpha^\flat} \in B\Big(u^\flat, \delta_o\Big) \qquad \text{and} \qquad u^{\alpha^\flat+1}, \ldots, u^n \in B\big(u^\sharp, \delta_o\big), \tag{4.7}$$

define $\mathcal{A}^\flat$ as the set of pairs of waves $\sigma_{i,\alpha}$, $\sigma_{j,\beta}$, that are approaching (see [20]), with $\alpha, \beta \leq \alpha^\flat$; the set $\mathcal{A}^\sharp$ is defined similarly $(\alpha, \beta \geq \alpha^\flat + 1)$. Then we introduce the linear functionals and the interaction potentials as

$$\begin{aligned} V^\flat &= \sum_{\alpha=1}^{\alpha^\flat} |\sigma_{1,\alpha}| + K_2 \sum_{\alpha=\alpha^\flat+1}^{n} |\sigma_{2,\alpha}|, \qquad & V^\sharp &= K_1 \sum_{\alpha=1}^{\alpha^\flat} |\sigma_{1,\alpha}| + \sum_{\alpha=\alpha^\flat+1}^{n} |\sigma_{2,\alpha}|, \\ Q^\flat &= \sum_{\mathcal{A}^\flat} |\sigma_{i,\alpha}\sigma_{j,\beta}|, & Q^\sharp &= \sum_{\mathcal{A}^\sharp} |\sigma_{i,\alpha}\sigma_{j,\beta}| \end{aligned} \tag{4.8}$$

and finally

$$\Upsilon^\flat = V^\flat + Q^\flat, \quad \Upsilon^\sharp = V^\sharp + Q^\sharp, \tag{4.9}$$

$$\Upsilon = \Upsilon^\flat + \Upsilon^\sharp. \tag{4.10}$$

For the sake of simplicity, we omitted the dependence on u. Note the introduction of the weights K_i on the waves eventually impinging the phase boundary. Below it is proved that the domain

$$\mathcal{D}^{\varepsilon}_{\delta} = \{u \text{ as in (4.5)–(4.6)–(4.7)};\ \Upsilon(u) \leq \delta\} \tag{4.11}$$

is positively invariant with respect to system (1.1).

Case 2. Similar to above, assume $\mathcal{U}^{\flat} \subseteq \Omega_1$, $\mathcal{U}^{\natural} \subseteq \Omega_2$, and $\mathcal{U}^{\sharp} \subseteq \Omega_1$. Moreover, for all functions of the form (4.5)–(4.6) satisfying

$$\begin{aligned} &u^1, \ldots, u^{\alpha^{\flat}} \in B\big(u^{\flat}, \delta_o\big),\\ &u^{\alpha^{\flat}+1}, \ldots, u^{\alpha^{\sharp}-1} \in B\big(u^{\natural}, \delta_o\big),\\ &u^{\alpha^{\sharp}}, \ldots, u^{n} \in B\big(u^{\sharp}, \delta_o\big), \end{aligned} \tag{4.12}$$

with $\alpha^{\flat} + 1 < \alpha^{\sharp} - 1$ (so that u attains values in both phases), introduce

$$\begin{aligned} &V^{\flat} = \sum_{i=1}^{2} \sum_{\alpha=1}^{\alpha^{\flat}} K_i^{\flat} |\sigma_{i,\alpha}|, \quad V^{\natural} = \sum_{i=1}^{2} \sum_{\alpha=\alpha^{\flat}+1}^{\alpha^{\sharp}-1} K_i^{\natural} |\sigma_{i,\alpha}|, \quad V^{\sharp} = \sum_{i=1}^{2} \sum_{\alpha=\alpha^{\sharp}}^{n} K_i^{\sharp} |\sigma_{i,\alpha}|,\\ &Q^{\flat} = \sum_{\mathcal{A}^{\flat}} |\sigma_{i,\alpha}\sigma_{j,\beta}|, \qquad Q^{\natural} = \sum_{\mathcal{A}^{\natural}} |\sigma_{i,\alpha}\sigma_{j,\beta}|, \qquad Q^{\sharp} = \sum_{\mathcal{A}^{\sharp}} |\sigma_{i,\alpha}\sigma_{j,\beta}| \end{aligned} \tag{4.13}$$

and then

$$\Upsilon^{\flat} = V^{\flat} + Q^{\flat}, \qquad \Upsilon^{\natural} = V^{\natural} + Q^{\natural}, \qquad \Upsilon^{\sharp} = V^{\sharp} + Q^{\sharp},$$

$$\Upsilon = \Upsilon^{\flat} + \Upsilon^{\natural} + \Upsilon^{\sharp} + \frac{1}{K_3} \left\| v^{\alpha^{\flat}+1} - v^{\natural} \right\|. \tag{4.14}$$

At last we define

$$\mathcal{D}^{\varepsilon}_{\delta} = \{u \text{ as in (4.5)–(4.6)–(4.12)};\ \Upsilon(u) \leq \delta\}\,. \tag{4.15}$$

The various constants K_i, $K_i^{\flat}$, $K_i^{\natural}$, $K_i^{\sharp}$ in (4.8), (4.13), and (4.14) will be defined later. They all depend on f and Φ_S.

PROPOSITION 4.1. *Let the Riemann problem* (1.2) *satisfy the stability assumption* (2.6) *in Case* 1, *the stability assumptions* (2.7), (2.8), *and the nonresonance condition* (2.14) *in Case* 2. *Then there exists* $\delta > 0$, *and suitable constants in the definitions* (4.8), (4.13), *and* (4.14), *independent of* ε *such that, for any* $\bar{u} \in \mathcal{D}^{\varepsilon}_{\delta}$, *the wave-front tracking algorithm constructs a unique approximate solution* $u^{\varepsilon} \colon [0, +\infty[\times \mathbf{R} \mapsto \mathbf{R}^2$ *of*

$$\begin{cases} \partial_t u + \partial_x \left[f(u)\right] = 0,\\ u(0,x) = \bar{u}(x) \end{cases} \tag{4.16}$$

with the following properties:

(i) $u^{\varepsilon}(t,\cdot) \in \mathcal{D}^{\varepsilon}_{\delta}$ *for all* $t \geq 0$;

(ii) *the function* $t \mapsto \Upsilon\left(u^{\varepsilon}(t,\cdot)\right)$ *is nonincreasing*;

(iii) *any strip* $[0,T] \times \mathbf{R}$ *contains finitely many interaction points of* u^{ε};

(iv) $\mathrm{TV}\left(u^{\varepsilon}(t,\cdot)\right)$ *is uniformly bounded*;

(v) u^{ε} *is* Ψ*-admissible.*

Here $\mathcal{D}^\varepsilon_\delta$ is defined by (4.11) *in Case* 1 *and by* (4.15) *in Case* 2*.*

In both cases, to denote this unique, globally defined, ε-approximate solution, we use the semigroup notation

$$u^\varepsilon(t,\cdot) = S^\varepsilon_t \bar{u}. \tag{4.17}$$

As in [4], the rest of the proof works toward an estimate independent from ε of the Lipschitz constant for S^ε, in the $\mathbf{L}^1$ norm. The basic technique is to shift the locations of the jumps of the initial data $\bar{u}$ at constant rates and then to estimate the shift rates of the jumps of the solution $u^\varepsilon(t,\cdot)$, at any fixed $t > 0$. First we introduce the shifts and the notion of pseudopolygonal.

Definition 4.2. *Let $]a,b[$ be an open interval. An elementary path is a map $\gamma\colon]a,b[\mapsto \mathbf{L}^1_{loc}(\mathbf{R})$ of the form*

$$\gamma(\theta) = \sum_{\alpha=1}^{N} u^\alpha \cdot \chi_{]x^\theta_{\alpha-1},\, x^\theta_\alpha[}, \qquad x^\theta_\alpha = x_\alpha + \xi_\alpha \theta, \tag{4.18}$$

with $x^\theta_{\alpha-1} < x^\theta_\alpha$ for all $\theta \in]a,b[$ and $\alpha = 1,\ldots,N$; the constants ξ_α are called shift rates.

Definition 4.3. *A continuous map $\gamma\colon [a,b] \mapsto \mathbf{L}^1_{loc}(\mathbf{R})$is called a pseudopolygonal if there exist countably many disjoint open intervals $J_h \subset [a,b]$ such that*

(i) *the restriction of γ to each J_h is an elementary path;*

(ii) *the set $[a,b] \setminus \bigcup_{h\geq 1} J_h$ is countable.*

Exactly as in [4], one can prove the following proposition.

Proposition 4.4. *Let $\gamma_o\colon [a,b] \mapsto \mathcal{D}^\varepsilon_\delta$ be a pseudopolygonal. Then, for all $\tau > 0$, the path*

$$\gamma_\tau = S^\varepsilon_\tau \circ \gamma_o$$

is also a pseudopolygonal. Indeed, there exist countably many open intervals J_h such that $[a,b] \setminus \bigcup J_h$ is countable and the wave-front configuration of the solution $u^\theta = S^\varepsilon_\tau \circ \gamma_o(\theta)$ on $[0,\tau] \times \mathbf{R}$ remains the same as θ ranges in each J_h.

Below, we move towards a definition of length of pseudopolygonals by first defining the length of elementary paths. The latter, in turn, depends on a suitable functional Υ_ξ which we define below.

Case 1. For all u in $\mathcal{D}^\varepsilon_\delta$ defined as in (4.11), let

$$\begin{aligned} V^\flat_\xi &= \sum_{i=1}^{2} \sum_{\alpha=1}^{\alpha^\flat} p^\flat_{i,\alpha} |\sigma_{i,\alpha} \xi_{i,\alpha}|, & Q^\flat_\xi &= \sum_{\mathcal{A}^\flat} |\sigma_{i,\alpha}\sigma_{j,\beta}| \left(p^\flat_{i,\alpha} |\xi_{i,\alpha}| + p^\flat_{j,\beta} |\xi_{j,\beta}| \right), \\ V^\sharp_\xi &= \sum_{i=1}^{2} \sum_{\alpha=\alpha^\flat+1}^{n} p^\sharp_{i,\alpha} |\sigma_{i,\alpha} \xi_{i,\alpha}|, & Q^\sharp_\xi &= \sum_{\mathcal{A}^\sharp} |\sigma_{i,\alpha}\sigma_{j,\beta}| \left(p^\sharp_{i,\alpha} |\xi_{i,\alpha}| + p^\sharp_{j,\beta} |\xi_{j,\beta}| \right). \end{aligned} \tag{4.19}$$

Then we define

$$\Upsilon^\flat_\xi = V^\flat_\xi (1 + Q^\flat) + K^\flat Q^\flat_\xi, \qquad \Upsilon^\sharp_\xi = V^\sharp_\xi (1 + Q^\sharp) + K^\sharp Q^\sharp_\xi \tag{4.20}$$

with $Q^\flat$ and $Q^\sharp$ defined as in (4.8) and finally

$$\Upsilon_\xi = \left(\Upsilon^\flat_\xi + \Upsilon^\sharp_\xi + \left|\hat{\xi}\right| \right) e^{\mathcal{K}\Upsilon}. \tag{4.21}$$

Above, $\hat{\xi}$ is the shift speed of the phase boundary. The constants $p^\flat_{i,\alpha}$, $p^\sharp_{i,\alpha}$, $K^\flat$, $K^\sharp$, and $\mathcal{K}$ are specified in section 5.

Case 2. For all u in $\mathcal{D}^\varepsilon_\delta$ as defined in (4.15), let

$$\begin{aligned} V^\flat_\xi &= \sum_{i=1}^{2} \sum_{\alpha=1}^{\alpha^\flat} p^\flat_{i,\alpha} |\sigma_{i,\alpha} \xi_{i,\alpha}|, & Q^\flat_\xi &= \sum_{\mathcal{A}^\flat} |\sigma_{i,\alpha}\sigma_{j,\beta}| \left(p^\flat_{i,\alpha}|\xi_{i,\alpha}| + p^\flat_{j,\beta}|\xi_{j,\beta}|\right), \\ V^\natural_\xi &= \sum_{i=1}^{2} \sum_{\alpha=\alpha^\flat+1}^{\alpha^\sharp-1} p^\natural_{i,\alpha} |\sigma_{i,\alpha} \xi_{i,\alpha}|, & Q^\natural_\xi &= \sum_{\mathcal{A}^\natural} |\sigma_{i,\alpha}\sigma_{j,\beta}| \left(p^\natural_{i,\alpha}|\xi_{i,\alpha}| + p^\natural_{j,\beta}|\xi_{j,\beta}|\right), \\ V^\sharp_\xi &= \sum_{i=1}^{2} \sum_{\alpha=\alpha^\sharp+1}^{n} p^\sharp_{i,\alpha} |\sigma_{i,\alpha} \xi_{i,\alpha}|, & Q^\sharp_\xi &= \sum_{\mathcal{A}^\sharp} |\sigma_{i,\alpha}\sigma_{j,\beta}| \left(p^\sharp_{i,\alpha}|\xi_{i,\alpha}| + p^\sharp_{j,\beta}|\xi_{j,\beta}|\right); \end{aligned} \tag{4.22}$$

then

$$\begin{aligned} \Upsilon^\flat_\xi &= V^\flat_\xi (1 + Q^\flat) + K^\flat Q^\flat_\xi, \\ \Upsilon^\natural_\xi &= V^\natural_\xi (1 + Q^\natural) + K^\natural Q^\natural_\xi, \\ \Upsilon^\sharp_\xi &= V^\sharp_\xi (1 + Q^\sharp) + K^\sharp Q^\sharp_\xi, \end{aligned} \tag{4.23}$$

and, finally,

$$\Upsilon_\xi = \left(\Upsilon^\flat_\xi + \Upsilon^\natural_\xi + \Upsilon^\sharp_\xi + H\left(\left|\hat{\xi}^\flat\right| + \left|\hat{\xi}^\sharp\right|\right)\right) e^{\mathcal{K}\Upsilon}; \tag{4.24}$$

$\hat{\xi}^\flat$ and $\hat{\xi}^\sharp$ are the shift speeds of the phase boundaries. Also in this case the constants $p^\flat_{i,\alpha}$, $p^\natural_{i,\alpha}$, $p^\sharp_{i,\alpha}$, $K^\flat$, $K^\natural$, $K^\sharp$, H, and $\mathcal{K}$ are given in section 5.

By means of Υ_ξ we can now define the weighted length of a polygonal and the weighted distance between two piecewise constant functions. Note that if γ is an elementary path, then the function $\theta \mapsto \Upsilon_\xi(\gamma(\theta))$ is constant.

DEFINITION 4.5. *For a fixed $\varepsilon > 0$ the weighted length of the elementary path γ in* (4.18) *is*

$$\|\gamma\| \doteq (b - a) \cdot \Upsilon_\xi(\gamma).$$

DEFINITION 4.6. *The weighted length of a pseudopolygonal is the sum of the weighted lengths of its elementary paths. For any two piecewise constant functions $u, w \in \mathcal{D}^\varepsilon_\delta$, their weighted distance is*

$$d_\varepsilon(u, w) \doteq \inf\left\{\|\gamma\|;\ \gamma\colon [0,1] \mapsto \mathcal{D}^\varepsilon_\delta \textit{ is a pseudopolygonal joining } u \textit{ with } w\right\}. \tag{4.25}$$

Below, we prove that the function

$$t \mapsto d_\varepsilon\left(S^\varepsilon_t u, S^\varepsilon_t u\right)$$

is nonincreasing for all $u, w \in \mathcal{D}^\varepsilon_\delta$. This, together with the equivalence of d_ε with the $\mathbf{L}^1$ distance, implies that the semigroup S^ε is uniformly Lipschitz continuous with respect to the $\mathbf{L}^1$ distance.

PROPOSITION 4.7. *Let the Riemann problem* (1.2) *satisfy the assumptions of Theorem* 2.3. *In both Cases* 1 *and* 2, *there exist $\delta > 0$ and positive constants in the above definitions of Υ_ξ, independent of ε, such that if γ_o is a pseudopolygonal,* *then the weighted length* $\|\gamma_\tau\|$ *of the pseudopolygonal* $\gamma_\tau = S^\varepsilon_\tau \circ \gamma_o$ *is a nonincreasing function of time.*

PROPOSITION 4.8. *For any* $\delta > 0$, *there exists some* $\delta' \in \,]0, \delta]$ *such that any two functions* u, u' *in* $\mathcal{D}^\varepsilon_{\delta'}$ *can be joined by a pseudopolygonal entirely contained in* $\mathcal{D}^\varepsilon_\delta$. *Moreover, the weighted length of this pseudopolygonal is uniformly equivalent with respect to* ε *to the usual distance* $\|u - u'\|_{\mathbf{L}^1}$.

PROPOSITION 4.9. *Let the Riemann problem* (1.2) *satisfy the assumptions of Theorem* 2.3. *Then there exists a positive* δ, *independent of* ε, *such that the semigroup*

$$S^\varepsilon\colon [0, +\infty[\, \times \mathcal{D}^\varepsilon_\delta \mapsto \mathcal{D}^\varepsilon_\delta$$

defined by (4.17) *is uniformly Lipschitz continuous with respect to the* $\mathbf{L}^1$ *distance, with a Lipschitz constant independent of* ε.

As in [4], to complete the proof of Theorem 2.3, we now consider a sequence of semigroups S^{ε_n} with $\lim_{n\to+\infty} \varepsilon_n = 0$ and construct the limit semigroup. More precisely, we fix $\delta > 0$ according to Proposition 4.9 and define the closed domain

$$\mathcal{D} = \{\bar{u}\colon \exists \bar{u}_n \to \bar{u}, \quad \bar{u}_n \in \mathcal{D}^\varepsilon_\delta \quad \text{for all } n\}. \tag{4.26}$$

For $\bar{u} \in \mathcal{D}$ and $t \geq 0$, we then define

$$S_t \bar{u} = \lim_{n\to+\infty} S^{\varepsilon_n}_t \bar{u}_n, \tag{4.27}$$

where $\bar{u}_n \in \mathcal{D}^{\varepsilon_n}_\delta$ is any sequence approaching $\bar{u}$ in $\mathbf{L}^1$. We conclude by proving the following proposition.

PROPOSITION 4.10. *The closed domain* $\mathcal{D}$ *in* (4.26) *and the semigroup* S *in* (4.27) *are well defined and satisfy* (i)–(v) *of Definition* 2.2 *for suitable constants* $L, \delta > 0$.

Let us point out that an important point in the previous proposition consists in proving that the Ψ-admissibility is conserved in the limit.

5. Technical proofs.

In this section we collect those technical parts that differ significantly from [4]. Indeed, the present construction of the semigroup differs from the one therein in the proofs that the amounts Υ and Υ_ξ are nonincreasing when an interaction involving a phase boundary takes place (Propositions 4.1, part (ii), and 4.7). Once this is known, the same inductive (resp., perturbation) technique used in [4] to prove that Υ (resp., Υ_ξ) is nonincreasing still applies. Then we give a proof of Proposition 4.8 on the basis of an analogous result in [5]. For what concerns Proposition 4.10, we prove the Ψ-admissibility of the orbits of the semigroup and refer the reader to [4] for the missing parts.

Propositions 4.4 and 4.9 are proved as in [4].

Aiming at the proof of Proposition 4.1 we recall the basic interaction estimates.

First, we give the basic estimates for two small interacting waves, the case of many interacting waves is covered as in [4, Lemma 5]. Here and in all that follows, σ_i^+ denotes the total size of outgoing i-waves; see (4.3).

With reference to the notation in Figure 5.1(i), if two waves σ_1^-, σ_2^- of different families interact, then

$$\left|\sigma_1^+ - \sigma_1^-\right| + \left|\sigma_2^+ - \sigma_2^-\right| \leq C \cdot \left|\sigma_1^- \sigma_2^-\right| \left(\left|\sigma_1^-\right| + \left|\sigma_2^-\right|\right). \tag{5.1}$$

In this section, by C we denote a suitably large positive constant. In the case of two waves σ', σ'' both belonging to the first family (see Figure 5.1(ii)), we have

$$\left|\sigma_1^+ - (\sigma' + \sigma'')\right| + \left|\sigma_2^+\right| \leq C \cdot |\sigma'\sigma''| \left(|\sigma'| + |\sigma''|\right). \tag{5.2}$$

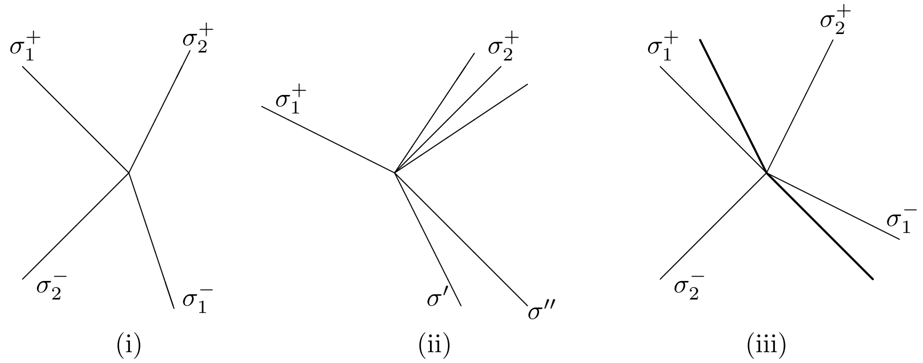

FIG. 5.1. *Interaction of small waves of different families* (i)*, of the same family* (ii)*, and of small waves with the phase boundary* (iii)*.*

The case of waves both belonging to the second family is entirely similar.

Moreover, we shall consider in detail interactions involving a phase boundary having, say, a left state in Ω_1 and a right state in Ω_2, with the notation as in Figure 5.1(iii).

In Case 1, using the notation in Figure 5.1(iii), the basic estimates related to interactions involving the phase boundary are

$$|\sigma_1^+| \le C\left(|\sigma_1^-| + |\sigma_2^-|\right), \qquad |\sigma_2^+| \le C\left(|\sigma_1^-| + |\sigma_2^-|\right). \tag{5.3}$$

In Case 2, slightly more precise estimates are necessary:

$$|\sigma_1^+| \le C\left(|\sigma_1^-| + |\sigma_2^-|\right), \qquad |\sigma_2^+| \le (1 + C\delta)\left|R_\natural^\flat\right||\sigma_1^-| + C|\sigma_2^-|. \tag{5.4}$$

An entirely similar convention is followed in case (2.11).

Let τ be a time at which an interaction occurs. We use the notation

$$F^+ = F(\tau+), \qquad F^- = F(\tau-), \qquad \text{and} \qquad \Delta F = F^+ - F^-,$$

where F can be V, Q, Υ, V_ξ, Q_ξ, or Υ_ξ. In general, the signs $+$ (resp., $-$) are attached to quantities related to waves exiting (resp., entering) an interaction.

Proof of Proposition 4.1. Below, we prove that Υ decreases strictly whenever a simple interaction takes place, in both Cases 1 and 2.

Case 1. We choose first

$$K_1 = K_2 = 1 + 2C$$

and a sufficiently small δ so that (5.5) and (5.6) hold.

(1) Two small waves of different families interact in the left phase.

We denote the waves as in Figure 5.1(i); by (5.1) we have

$$\begin{aligned}\Delta\Upsilon = \Delta\Upsilon^\flat &\le |\sigma_1^+| + K_2|\sigma_2^+| - |\sigma_1^-| - K_2|\sigma_2^-| - |\sigma_1^-\sigma_2^-| \\ &\qquad\qquad + \left(|\sigma_1^+ - \sigma_1^-| + |\sigma_2^+ - \sigma_2^-|\right)V^\flat \\ &\le \left[C(1 + K_2 + \delta)\left(|\sigma_1^-| + |\sigma_2^-|\right) - 1\right]\cdot|\sigma_1^-\sigma_2^-| \\ &< 0\end{aligned} \tag{5.5}$$

provided δ is sufficiently small.

(2) Two small waves of a same family interact in the left phase.

As in Figure 5.1(ii), σ' and σ'' belong to the first family (the other case is analogous). Then, by (5.2)

$$\begin{aligned}\Delta\Upsilon = \Delta\Upsilon^\flat &\le \left|\sigma_1^+\right| + K_2\left|\sigma_2^+\right| - |\sigma'| - |\sigma''| - |\sigma'\sigma''| + \left(\left|\sigma_1^+ - (\sigma' + \sigma'')\right| + \left|\sigma_2^+\right|\right) V^\flat \\ &\le \left[C\left(1 + K_2 + \delta\right)\left(|\sigma'| + |\sigma''|\right) - 1\right] \cdot |\sigma'\sigma''| \qquad (5.6) \\ &< 0\end{aligned}$$

provided δ is sufficiently small. The interaction of small waves in the right phase is completely analogous; hence it is omitted.

(3) Two small waves interact with the phase boundary.

The following estimates rely on a first-order argument. Thus we can consider interactions of, possibly, several waves hitting the phase boundary on both sides. Call σ_i^- the total size of the waves of the ith family impinging the phase boundary; then

$$\begin{aligned}\Delta\Upsilon &\le \left|\sigma_1^+\right| + \left|\sigma_2^+\right| + \left|\sigma_1^+\right|V^\flat + \left|\sigma_2^+\right|V^\sharp - K_2\left|\sigma_2^-\right| - K_1\left|\sigma_1^-\right| \\ &\le \left[C(1+\delta) - K_1\right]\left|\sigma_1^-\right| + \left[C(1+\delta) - K_2\right]\left|\sigma_2^-\right| \\ &\le -\left(\left|\sigma_1^-\right| + \left|\sigma_2^-\right|\right) \qquad (5.7)\end{aligned}$$

due to the choice of K_i. The proof of Proposition 4.1 in Case 1 is concluded.

Case 2. We choose the weights in (4.13) in the following way. First

$$K_1^\flat = 1 \quad \text{and} \quad K_2^\sharp = 1.$$

Because of (2.14) we can choose $K_1^\natural$ and $K_2^\natural$ such that

$$\begin{aligned}&K_1^\natural - (1 + C\delta)\left|R_\natural^\flat\right|K_2^\natural > 2C + (1 + C\delta)\left|R_\natural^\flat\right| + 2, \\ &K_2^\natural - (1 + C\delta)\left|R_\natural^\sharp\right|K_1^\natural > 2C + (1 + C\delta)\left|R_\natural^\sharp\right| + 2\ .\end{aligned} \qquad (5.8)$$

Next select $K_2^\flat$, $K_1^\sharp$ sufficiently large so that estimates analogous to the ones in Case 1, subcase 3, still hold and moreover

$$K_2^\flat > C(K_2^\natural + 3) + 2 \quad \text{and} \quad K_1^\sharp > C(K_1^\natural + 3) + 2\,. \qquad (5.9)$$

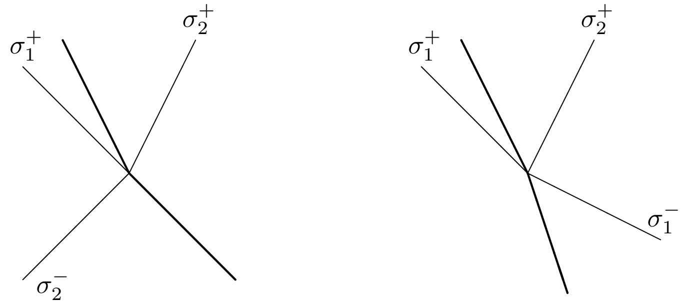
Let small waves of strengths σ_1^- and σ_2^- impinge on the leftmost phase boundary; see Figure 5.1(iii). Let v_r^-, v_r^+ be the states in $\mathcal{U}^\natural$ just on the right of the phase boundary, respectively, before and after the interaction. A simple first-order argument shows that there exists a constant C such that

$$\|v_r^+ - v_r^-\| \le C\left(\left|\sigma_1^-\right| + \left|\sigma_2^-\right|\right); \qquad (5.10)$$

let K_3 in (4.14) be such that $K_3 \ge C$.

We consider in detail only the case of Figure 5.1(iii), since the interactions against the other phase boundary are treated entirely similarly, while those interactions far from the phase boundaries can be tackled as in Case 1. From (5.4) we have

$$\begin{aligned}\Delta\Upsilon^\flat &\le K_1^\flat\left|\sigma_1^+\right| - K_2^\flat\left|\sigma_2^-\right| + \left|\sigma_1^+\right|V^{\flat-} \\ &\le \left(C(K_1^\flat + \delta) - K_2^\flat\right)\left|\sigma_2^-\right| + C(K_1^\flat + \delta)\left|\sigma_1^-\right|, \\ \Delta\Upsilon^\natural &\le K_2^\natural\left|\sigma_2^+\right| - K_1^\natural\left|\sigma_1^-\right| + \left|\sigma_2^+\right|V^{\natural-} \\ &\le \left((1 + C\delta)\left|R_\natural^\flat\right|(K_2^\natural + \delta) - K_1^\natural\right)\left|\sigma_1^-\right| + C(K_2^\natural + \delta)\left|\sigma_2^-\right|.\end{aligned}$$



(i) (ii)

FIG. 5.2. *Interactions of waves (thin lines) with the phase boundary (thick line).*

Then by (5.8), (5.9), and (5.10) we deduce

$$\begin{aligned}\Delta\Upsilon &\le \Big((1+C\delta)\Big|R^\flat_\natural\Big|(K_2^\natural+\delta)+C(K_1^\flat+\delta)-K_1^\natural\Big)\left|\sigma_1^-\right| \\ &\quad+\Big(C(K_1^\flat+\delta)+C(K_2^\natural+\delta)-K_2^\flat\Big)\left|\sigma_2^-\right| \\ &\quad+\left(\left|\sigma_1^-\right|+\left|\sigma_2^-\right|\right) \\ &\le -\left(\left|\sigma_1^-\right|+\left|\sigma_2^-\right|\right) \qquad (5.11)\end{aligned}$$

due to (5.9) and to the choice of K_3. This accounts for Case 2; the proof of Proposition 4.1 is therefore complete. □

We note that applying the usual compactness argument based on Helly's theorem to the result of the above Proposition 4.1 we have the usual Glimm's theorem on the global existence of weak solutions to (1.1).

Preliminarily to the proof Proposition 4.7, we collect below the basic interaction estimates for shifting waves; see [4]. It goes without saying that ξ_i^+ (resp., ξ_i^-, ξ', etc.) are the shift speeds of σ_i^+ (resp., σ_i^-, σ', etc.); see Figures 5.1(i) and 5.1(ii).

$$\begin{aligned}&\sum_\alpha\left|\sigma_{1,\alpha}^+\xi_{1,\alpha}^+\right|-\left|\sigma_1^-\xi_1^-\right|+\sum_\alpha\left|\sigma_{2,\alpha}^+\xi_{2,\alpha}^+\right|-\left|\sigma_2^-\xi_2^-\right| \\ &\qquad\le C\cdot\left|\sigma_1^-\sigma_2^-\right|\cdot\left(\left|\xi_1^-\right|+\left|\xi_2^-\right|\right), \qquad (5.12)\end{aligned}$$

$$\left|\sigma_1^+\xi_1^+\right|-\left(\left|\sigma' xi'\right|+\left|\sigma'' xi''\right|\right)+\sum_\alpha\left|\sigma_{2,\alpha}^+\xi_{2,\alpha}^+\right|\le C\cdot\left|\sigma'\sigma''\right|\cdot\left(\left|\xi'\right|+\left|\xi''\right|\right). \qquad (5.13)$$

We refer to [4, Lemmas 21, 22] for a proof.

In Case 1, refer to Figures 5.2(i) and 5.2(ii) and denote by $\hat\xi^-$, $\hat\xi^+$ the shift speeds of the phase boundaries before and after the interaction.

A first-order analysis similar to the one in [5] yields

$$\left|\hat\xi^+-\hat\xi^-\right|\le C\cdot\left|\sigma_i^-\right|\left(\left|\xi_i^-\right|+\left|\hat\xi^-\right|\right), \qquad (5.14)$$

$$\sum_\alpha\left|\sigma_{1,\alpha}^+\xi_{1,\alpha}^+\right|\le C\cdot\left|\sigma_i^-\right|\left(\left|\xi_i^-\right|+\left|\hat\xi^-\right|\right), \qquad (5.15)$$

$$\sum_\alpha\left|\sigma_{2,\alpha}^+\xi_{2,\alpha}^+\right|\le C\cdot\left|\sigma_i^-\right|\left(\left|\xi_i^-\right|+\left|\hat\xi^-\right|\right) \qquad (5.16)$$

for $i=1,2$.

In Case 2, we make use of the same estimates, but we denote the shift speeds of the two phase boundaries by $\xi^\flat$ and $\xi^\sharp$. Moreover, (see (5.20) in [5])

$$\sum_\alpha \left|\sigma_{2,\alpha}^+ \xi_{2,\alpha}^+\right| \leq (1+C\delta)\left|R^\flat_\natural \Theta^\flat\right| \left|\sigma_1^- \xi_1^-\right| + C\cdot\left|\sigma_1^-\right|\left|\xi^{\flat -}\right|, \tag{5.17}$$

$$\sum_\alpha \left|\sigma_{1,\alpha}^+ \xi_{1,\alpha}^+\right| \leq (1+C\delta)\left|R^\sharp_\natural \Theta^\sharp\right| \left|\sigma_2^- \xi_2^-\right| + C\cdot\left|\sigma_2^-\right|\left|\xi^{\sharp -}\right|. \tag{5.18}$$

Proof of Proposition 4.7. We denote the quantities related to interacting waves as above; see Figures 5.1(i), 5.1(ii), 5.1(iii), 5.2(i), and 5.2(ii). Noninteracting waves are labeled $\sigma_{j,\beta}$. We denote, moreover, by $\mathcal{A}_{i,\alpha}$ the set of waves approaching $\sigma_{i,\alpha}$.

Case 1. First, the choice of the weights; referring to formula (4.19) we take

$$\begin{aligned} p^\flat_{1,\alpha} &= 1 + \varepsilon_o \operatorname{sign} \sigma_{1,\alpha}, & p^\flat_{2,\alpha} &= K(1 + \varepsilon_o \operatorname{sign} \sigma_{2,\alpha}), \\ p^\sharp_{1,\alpha} &= K(1 + \varepsilon_o \operatorname{sign} \sigma_{1,\alpha}), & p^\sharp_{2,\alpha} &= 1 + \varepsilon_o \operatorname{sign} \sigma_{2,\alpha}. \end{aligned}$$

Choose the various constants in the definition (4.19), (4.20), and (4.21) of Υ in the following order: K, $K^\flat$, $K^\sharp$, and $\mathcal{K}$ sufficiently large; ε_o and δ sufficiently small. A possible choice is

$$K = 1 + 24C, \qquad K^\flat = K^\sharp = 1 + 8CK, \qquad \mathcal{K} = 1 + 2C(1 + K + KK^\flat), \qquad \varepsilon_o < \frac{1}{3}$$

with $\delta < \frac{4}{(KK^\flat)^2}$.

(1) Interaction between small waves of different families.

Assume that the interaction takes place in the leftmost phase. Compute first

$$\begin{aligned} \Delta V^\flat_\xi &= \sum_{i,\alpha} p^{\flat +}_{i,\alpha} \left|\sigma^+_{i,\alpha}\xi^+_{i,\alpha}\right| - \sum_i p^{\flat -}_i \left|\sigma^-_i \xi^-_i\right| \\ &\leq CK(1+\varepsilon_o)\left|\sigma_1^-\sigma_2^-\right| \left(\left|\xi_1^-\right| + \left|\xi_2^-\right|\right) \end{aligned}$$

since $p^{\flat +}_{i,\alpha} = p^{\flat -}_i$ for every α and i. Moreover,

$$\begin{aligned} \Delta Q^\flat_\xi = &\sum_{i,\alpha} \sum_{(j,\beta)\in\mathcal{A}^{\flat +}_{i,\alpha}} \left|\sigma^+_{i,\alpha}\sigma_{j,\beta}\right| \left(p^{\flat +}_{i,\alpha}\left|\xi^+_{i,\alpha}\right| + p^\flat_{j,\beta}\left|\xi_\beta\right|\right) \\ &- \sum_i \sum_{(j,\beta)\in\mathcal{A}^{\flat -}_i} \left|\sigma^-_i\sigma_{j,\beta}\right| \left(p^{\flat -}_i\left|\xi^-_i\right| + p^\flat_{j,\beta}\left|\xi_\beta\right|\right) - \left|\sigma_1^-\sigma_2^-\right| \sum_i p^{\flat -}_i \left|\xi^-_i\right| \\ \leq &\sum_i p^{\flat -}_i \left|\sum_\alpha \left|\sigma^+_{i,\alpha}\xi^+_{i,\alpha}\right| - \left|\sigma^-_i\xi^-_i\right|\right| V^{\flat -} \\ &+ \sum_i p^{\flat -}_i \left|\sum_\alpha \left|\sigma^+_{i,\alpha}\right| - \left|\sigma^-_i\right|\right| V^{\flat -}_\xi - \frac{2}{3}\left|\sigma_1^-\sigma_2^-\right| \left(\left|\xi_1^-\right| + \left|\xi_2^-\right|\right) \\ \leq &\, CK(1+\varepsilon_o)\left|\sigma_1^-\sigma_2^-\right| \left(\left|\xi_1^-\right| + \left|\xi_2^-\right|\right)\delta \\ &+ C\left|\sigma_1^-\sigma_2^-\right| \left(\left|\sigma_1^-\right| + \left|\sigma_2^-\right|\right) V^{\flat -}_\xi - \frac{2}{3}\left|\sigma_1^-\sigma_2^-\right| \left(\left|\xi_1^-\right| + \left|\xi_2^-\right|\right) \\ \leq &\, CK\left|\sigma_1^-\sigma_2^-\right| \left(\left|\sigma_1^-\right| + \left|\sigma_2^-\right|\right) V^{\flat -}_\xi - \frac{1}{2}\left|\sigma_1^-\sigma_2^-\right| \left(\left|\xi_1^-\right| + \left|\xi_2^-\right|\right). \end{aligned}$$

At last

$$\Delta Q^\flat \leq -\frac{1}{2}\left|\sigma_1^- \sigma_2^-\right| \ .$$

The above estimates are valid under the choices above of the weights and for δ sufficiently small. From the previous estimates, it follows that

$$\begin{aligned}
\Delta \Upsilon_\xi^\flat &= \Delta V_\xi^\flat + K^\flat \Delta Q_\xi^\flat + Q^{\flat+} \Delta V_\xi^\flat + V_\xi^{\flat-} \Delta Q^\flat \\
&\leq \left(CK(1+\varepsilon_o)(1+\delta) - \frac{1}{2}K^\flat \right) \left|\sigma_1^- \sigma_2^-\right| \left(\left|\xi_1^-\right| + \left|\xi_2^-\right| \right) \\
&\qquad + \left(CK^\flat K\delta - \frac{1}{2} \right) \left|\sigma_1^- \sigma_2^-\right| V_\xi^{\flat-} \\
&\leq 0 \ .
\end{aligned} \tag{5.19}$$

By Proposition 4.1 we obtain

$$\Delta \Upsilon_\xi \leq \Delta \Upsilon_\xi^\flat e^{K\Upsilon^-} \leq 0.$$

Analogous estimates hold for interactions of waves of different families in the rightmost phase.

(2) Interaction between two shocks of the same family.

Again, assume that the interaction takes place on the leftmost phase. Similar to the previous case we find

$$\Delta V_\xi^\flat \leq CK(1+\varepsilon_o)|\sigma'\sigma''| \left(|\xi'| + |\xi''|\right),$$

while

$$\begin{aligned}
\Delta Q_\xi^\flat = &\sum_{(j,\beta)\in\mathcal{A}_1^{\flat+}} \left|\sigma_1^+ \sigma_{j,\beta}\right| \left(p_1^{\flat+} \left|\xi_1^+\right| + p_{j,\beta}^\flat |\xi_\beta| \right) \\
&+ \sum_\alpha \sum_{(j,\beta)\in\mathcal{A}_{2,\alpha}^{\flat+}} \left|\sigma_{2,\alpha}^+ \sigma_{j,\beta}\right| \left(p_{2,\alpha}^{\flat+} \left|\xi_{2,\alpha}^+\right| + p_{j,\beta}^\flat |\xi_\beta| \right) \\
&- \sum_{(j,\beta)\in\mathcal{A}'} |\sigma' \sigma_{j,\beta}| \left(p'|\xi'| + p_{j,\beta}^\flat |\xi_\beta| \right) - \sum_{(j,\beta)\in\mathcal{A}''} |\sigma'' \sigma_{j,\beta}| \left(p''|\xi''| + p_{j,\beta}^\flat |\xi_\beta| \right) \\
&-|\sigma'\sigma''| \left(p'|\xi'| + p''|\xi''| \right) \\
\leq &\, K \left((1-\varepsilon_o) \left| \left|\sigma_1^+ \xi_1^+\right| - |\sigma'\xi'| - |\sigma''\xi''| \right| + (1+\varepsilon_o) \sum_\alpha \left|\sigma_{2,\alpha}^+ \xi_{2,\alpha}^+\right| \right) V^{\flat-} \\
&+K \left((1-\varepsilon_o) \left|\sigma_1^+ - (\sigma' + \sigma'')\right| + (1+\varepsilon_o) \sum_\alpha \left|\sigma_{2,\alpha}^+\right| \right) V_\xi^{\flat-} \\
&-\frac{2}{3}|\sigma'\sigma''| \left(|\xi'| + |\xi''|\right) \\
\leq &\, CK(1+\varepsilon_o)|\sigma'\sigma''| \left(|\xi'| + |\xi''|\right) V^{\flat-} + CK|\sigma'\sigma''| \left(|\sigma'| + |\sigma''|\right) V_\xi^{\flat-} \\
&-\frac{2}{3}|\sigma'\sigma''| \left(|\xi'| + |\xi''|\right) \\
\leq &\, CK|\sigma'\sigma''| \left(|\sigma'| + |\sigma''|\right) V_\xi^{\flat-} - \frac{1}{2}|\sigma'\sigma''| \left(|\xi'| + |\xi''|\right).
\end{aligned}$$

Since

$$\Delta Q^\flat \leq -\frac{1}{2}|\sigma'\sigma''|,$$

in this case the proof is completed exactly as in Step 1.

(3) Interaction between two small waves of the same family but of different sign.

Assume that $\sigma' > 0$, $\sigma'' < 0$ and that both belong to the first family, the other situations being similar. Observe that in this case one must have $\sigma_1^+ \leq 0$, otherwise the two incoming wave-fronts would have exactly the same speed. We have

$$\begin{aligned}\Delta V_\xi^\flat &\leq K(1-\varepsilon_o)\left|\sigma_1^+\xi_1^+\right| + \sum_\alpha p_{2,\alpha}^+\left|\sigma_{2,\alpha}^+\xi_{2,\alpha}^+\right| - (1+\varepsilon_o)|\sigma'\xi'| - (1-\varepsilon_o)|\sigma''\xi''|\\ &\leq CK(1+\varepsilon_o)|\sigma'\sigma''|\left(|\xi'|+|\xi''|\right) - 2\varepsilon_o|\sigma'\xi'|\ .\end{aligned}$$

For the interaction potential, we find

$$\begin{aligned}\Delta Q_\xi^\flat = & \sum_{(j,\beta)\in\mathcal{A}_1^{\flat+}} \left(\left|\sigma_1^+\sigma_{j,\beta}\right|\left(p_1^{\flat+}\left|\xi_1^+\right| + p_{j,\beta}^\flat|\xi_\beta|\right)\right)\\ & + \sum_\alpha \sum_{(j,\beta)\in\mathcal{A}_{2,\alpha}^{\flat+}} \left(\left|\sigma_{2,\alpha}^+\sigma_{j,\beta}\right|\left(p_{2,\alpha}^{\flat+}\left|\xi_{2,\alpha}^+\right| + p_{j,\beta}^\flat|\xi_\beta|\right)\right)\\ & - \sum_{(j,\beta)\in\mathcal{A}'} \left(\left|\sigma'\sigma_{j,\beta}\right|\left(p'|\xi'| + p_{j,\beta}^\flat|\xi_\beta|\right)\right)\\ & - \sum_{(j,\beta)\in\mathcal{A}''} \left(\left|\sigma''\sigma_{j,\beta}\right|\left(p''|\xi''| + p_{j,\beta}^\flat|\xi_\beta|\right)\right) - |\sigma'\sigma''|\left(p'|\xi'|+p''|\xi''|\right)\\ \leq & K\left((1-\varepsilon_o)\left|\left|\sigma_1^+\xi_1^+\right| - |\sigma''\xi''|\right| + (1+\varepsilon_o)\sum_\alpha\left|\sigma_{2,\alpha}^+\xi_{2,\alpha}^+\right|\right)V^{\flat-}\\ & + K(1+\varepsilon_o)\sum_\alpha\left|\sigma_{2,\alpha}^+\right|V_\xi^{\flat-} - \frac{2}{3}|\sigma'\sigma''|\left(|\xi'|+|\xi''|\right)\\ \leq & CK|\sigma'\sigma''|\left(|\xi'|+|\xi''|\right)V^{\flat-} + K|\sigma'\xi'|V^{\flat-} + CK|\sigma'\sigma''|\left(|\sigma'|+|\sigma''|\right)V_\xi^{\flat-}\\ & - \frac{2}{3}|\sigma'\sigma''|\left(|\xi'|+|\xi''|\right)\\ \leq & CK|\sigma'\sigma''|\left(|\sigma'|+|\sigma''|\right)V_\xi^{\flat-} + K|\sigma'\xi'|V^{\flat-} - \frac{1}{2}|\sigma'\sigma''|\left(|\xi'|+|\xi''|\right).\end{aligned}$$

Since the inequality $\Delta Q^\flat \leq -|\sigma'\sigma''|/2$ still holds, using (5.19), we have

$$\begin{aligned}\Delta\Upsilon_\xi^\flat \leq & \left(CK(1+\varepsilon_o)(1+\delta) - \frac{1}{2}K^\flat\right)|\sigma'\sigma''|\left(|\xi'|+|\xi''|\right)\\ & + \left(CKK^\flat\delta - \frac{1}{2}\right)|\sigma'\sigma''|V_\xi^{\flat-} + \left(KK^\flat\delta - 2\varepsilon_o\right)|\sigma'\xi'|\\ \leq & \ 0,\end{aligned}\tag{5.20}$$

so that $\Delta\Upsilon_\xi \leq 0$ for δ sufficiently small.

(4) Interaction between the phase boundary and a small wave.

We consider the case of a 2-wave hitting the phase boundary from the left, the other case being similar (see Figure 5.2(ii)). By (5.15) and (5.3) we deduce

$$\Delta V_\xi^\flat = \sum_\alpha p_{1,\alpha}^{\flat+}\left|\sigma_{1,\alpha}^+\xi_{1,\alpha}^+\right| - p_2^{\flat-}\left|\sigma_2^-\xi_2^-\right|$$

$$
\begin{aligned}
&\le \left(C(1+\varepsilon_o) - K(1-\varepsilon_o)\right) |\sigma_2^- \xi_2^-| + 2C|\sigma_2^-||\hat{\xi}^-| \\
&\le \left(2C - \frac{1}{2}K\right) |\sigma_2^- \xi_2^-| + 2C|\sigma_2^-|\left|\hat{\xi}^-\right|,
\end{aligned}
$$

where we used the above choice of K.

$$
\begin{aligned}
\Delta Q_\xi^\flat &= \sum_\alpha \sum_{(j,\beta)\in\mathcal{A}_{1,\alpha}^{\flat+}} |\sigma_{1,\alpha}^+ \sigma_{j,\beta}| \left(p_{1,\alpha}^{\flat+}|\xi_{1,\alpha}^+| + p_{j,\beta}^\flat |\xi_{j,\beta}|\right) \\
&\le \sum_\alpha \sum_{(j,\beta)\in\mathcal{A}_{1,\alpha}^{\flat+}} p_{1,\alpha}^{\flat+}|\sigma_{1,\alpha}^+ \sigma_{j,\beta}||\xi_{1,\alpha}^+| + \sum_\alpha \sum_{(j,\beta)\in\mathcal{A}_{1,\alpha}^{\flat+}} p_{j,\beta}^\flat |\sigma_{1,\alpha}^+ \sigma_{j,\beta}||\xi_{j,\beta}| \\
&\le 2C|\sigma_2^-|\left(|\xi_2^-| + |\hat{\xi}^-|\right) V^{\flat-} + 2CK|\sigma_2^-|V_\xi^{\flat-}\ , \\
\Delta Q^\flat &= \sum_\alpha \sum_{(j,\beta)\in\mathcal{A}_{1,\alpha}^{\flat+}} |\sigma_{1,\alpha}^+ \sigma_{j,\beta}| \\
&\le C|\sigma_2^-|V^{\flat-}\ .
\end{aligned}
$$

By (5.19) it follows that

$$
\begin{aligned}
\Delta \Upsilon_\xi^\flat \le &\left(2C(1+2\delta) - \frac{1}{2}K\right) |\sigma_2^- \xi_2^-| + 2C(1+2\delta)|\sigma_2^-|\left|\hat{\xi}^-\right| \\
&+2C(1+K)\left|\sigma_2^-\right|V_\xi^{\flat-}\ . \qquad (5.21)
\end{aligned}
$$

We now consider the terms referring to the right of the phase boundary. By (5.16) and (5.3) we have

$$
\begin{aligned}
\Delta V_\xi^\sharp &= \sum_\alpha p_{2,\alpha}^{\sharp+} |\sigma_{2,\alpha}^+ \xi_{2,\alpha}^+| \\
&\le 2C|\sigma_2^-|\left(|\xi_2^-| + |\hat{\xi}^-|\right), \\
\Delta Q_\xi^\sharp &= \sum_\alpha \sum_{(j,\beta)\in\mathcal{A}_{2,\alpha}^{\sharp+}} |\sigma_{2,\alpha}^+ \sigma_{j,\beta}| \left(p_{2,\alpha}^{\sharp+}|\xi_{2,\alpha}^+| + p_{j,\beta}^\sharp |\xi_{j,\beta}|\right) \\
&\le 2CK|\sigma_2^-|\left(|\xi_2^-| + |\hat{\xi}^-|\right) V^{\sharp-} + CK|\sigma_2^-|V_\xi^{\sharp-}\ , \\
\Delta Q^\sharp &= \sum_\alpha \sum_{(j,\beta)\in\mathcal{A}_{2,\alpha}^{\sharp+}} |\sigma_{2,\alpha}^+ \sigma_{j,\beta}| \\
&\le C|\sigma_2^-|V^{\sharp-}\ .
\end{aligned}
$$

Therefore,

$$
\Delta \Upsilon_\xi^\sharp \le 2C\left(1 + (1+KK^\sharp)\delta\right)|\sigma_2^-|\left(|\xi_2^-| + |\hat{\xi}^-|\right) + C(\delta + KK^\sharp)|\sigma_2^-|V_\xi^{\sharp-}\ . \qquad (5.22)
$$

From the inequalities (5.21), (5.22), (5.14), and (5.11), it follows finally that

$$
\begin{aligned}
\Delta \Upsilon_\xi &= \left(\Delta \Upsilon_\xi^\flat + \Delta \Upsilon_\xi^\sharp + \Delta|\hat{\xi}|\right) e^{\mathcal{K}\Upsilon^+} + \left(\Upsilon_\xi^{\flat-} + \Upsilon_\xi^{\sharp-} + |\hat{\xi}^-|\right)\left(e^{\mathcal{K}\Upsilon^+} - e^{\mathcal{K}\Upsilon^-}\right) \\
&\le \left(\Delta \Upsilon_\xi^\flat + \Delta \Upsilon_\xi^\sharp + \Delta|\hat{\xi}| - \mathcal{K}|\Delta\Upsilon|\left(\Upsilon_\xi^{\flat-} + \Upsilon_\xi^{\sharp-} + |\hat{\xi}^-|\right)\right) e^{\mathcal{K}\Upsilon^+} \\
&\le \Big[\left(2C(3 + 3\delta + KK^\sharp\delta) - \frac{1}{2}K\right)|\sigma_2^- \xi_2^-|
\end{aligned}
$$

$$
\begin{aligned}
&\quad + \left(2C(3+3\delta+KK^\sharp\delta)-\mathcal{K}\right)\left|\sigma_2^-\right|\left|\hat{\xi}^-\right| \\
&\quad + \left(2C(1+K)-\mathcal{K}\right)\left|\sigma_2^-\right|V_\xi^{\flat -} + \left(C(\delta+KK^\sharp)-\mathcal{K}\right)\left|\sigma_2^-\right|V_\xi^{\sharp -}\Big]e^{\mathcal{K}\Upsilon^+} \\
&\leq 0
\end{aligned}
$$

by the above choices of the weights. The proposition is proved in Case 1.

Case 2. Let us choose the weights in (4.22) and (4.24). Define

$$
\begin{aligned}
p_{1,\alpha}^\flat &= 1+\varepsilon_o \operatorname{sign}\sigma_{1,\alpha}, \qquad & p_{2,\alpha}^\flat &= K_2^\flat(1+\varepsilon_o \operatorname{sign}\sigma_{2,\alpha}), \\
p_{i,\alpha}^\natural &= K_i^\natural(1+\varepsilon_o \operatorname{sign}\sigma_{1,\alpha}), & & \\
p_{1,\alpha}^\sharp &= K_1^\sharp(1+\varepsilon_o \operatorname{sign}\sigma_{1,\alpha}), & p_{2,\alpha}^\sharp &= 1+\varepsilon_o \operatorname{sign}\sigma_{2,\alpha}.
\end{aligned}
$$

Choose first $K_1^\natural$ and $K_2^\natural$ such that

$$((1+\varepsilon_o)(1+C\delta))\left|R_\natural^\flat\Theta^\flat\right|\cdot K_2^\natural-(1-\varepsilon_o)K_1^\natural < 3(1+\varepsilon_o)C, \tag{5.23}$$

$$((1+\varepsilon_o)(1+C\delta))\left|R_\natural^\sharp\Theta^\sharp\right|\cdot K_1^\natural-(1-\varepsilon_o)K_2^\natural < 3(1+\varepsilon_o)C, \tag{5.24}$$

which is possible provided $\varepsilon_o = \sqrt{\delta}$ and δ sufficiently small, thanks to the strong nonresonance condition (2.13). The other weights are chosen similarly to the previous case, i.e., in the order $K_2^\flat = K_1^\sharp$, $K^\flat$, $K^\natural$, $K^\sharp$, and $\mathcal{K}$. As usual, choose finally a suitably small δ.

The estimates in this case differ from the previous ones only in the interaction of a wave coming from the middle phase against a phase boundary. We now consider only this interaction in detail.

$$
\begin{aligned}
\Delta\Upsilon_\xi^\flat &= C(1+\varepsilon_o)\left(1+\delta+K^\flat\delta\right)\left|\sigma_1^-\right|\left(\left|\xi_1^-\right|+\left|\xi^{\flat -}\right|\right)+C(\delta+K^\flat)\left|\sigma_1^-\right|V_\xi^{\flat -}, \\
\Delta\Upsilon_\xi^\natural &= \left((1+\varepsilon_o)(1+C\delta)\left|R_\natural^\flat\Theta^\flat\right|K_2^\natural-(1-\varepsilon_o)K_1^\natural\right)\left|\sigma_1^-\xi_1^-\right| \\
&\qquad +C(1+\varepsilon_o)K_2^\natural\left|\sigma_1^-\right|\left|\xi^{\flat -}\right|+(1+C\delta)R_\natural^\flat K_2^\natural\left|\sigma_1^-\right|V_\xi^{\natural -}, \\
\Delta\Upsilon_\xi &\leq \left(\Delta\Upsilon_\xi^\flat+\Delta\Upsilon_\xi^\natural+\Delta\left|\xi^\flat\right|-\mathcal{K}\left|\sigma_1^-\right|V_\xi^{\flat -}-\mathcal{K}\left|\sigma_1^-\right|V_\xi^{\natural -}-\mathcal{K}\left|\sigma_1^-\right|\left|\xi^{\flat -}\right|\right)e^{\mathcal{K}\Upsilon^+} \\
&\leq \left(C(1+\varepsilon_o)\left(1+\delta+K^\flat\delta\right)+C+(1+\varepsilon_o)(1+C\delta)\left|R_\natural^\flat\Theta^\flat\right|K_2^\natural-(1-\varepsilon_o)K_1^\natural\right) \\
&\qquad \times\left|\sigma_1^-\xi_1^-\right| \\
&\qquad +\left(C(1+\varepsilon_o)\left(1+\delta+K^\flat\delta\right)+C(1+\varepsilon_o)K_2^\natural+C-\mathcal{K}\right)\left|\sigma_1^-\right|\left|\xi^{\flat -}\right| \\
&\qquad +\left(C(\delta+K^\flat)-\mathcal{K}\right)\left|\sigma_1^-\right|V_\xi^{\flat -}+\left(1+C\delta R_\natural^\flat K_2^\natural-\mathcal{K}\right)\left|\sigma_1^-\right|V_\xi^{\natural -} \\
&\leq 0.
\end{aligned}
$$

This concludes the proof of Proposition 4.7. □

Proof of Proposition 4.8. Let $u', u'' \in \mathcal{D}_{\delta'}^\varepsilon$ be given, with $\delta' > 0$ small. We consider only case (2), since case (1) is simpler.

For $i = 1, 2$, call x_i', x_i'' the positions of the phase boundaries in u' and u'', respectively. One can then connect u' with u'' in such a way that each intermediate state u^θ contains exactly two large phase boundaries. For example, assume $x_1' < x_1'' <$

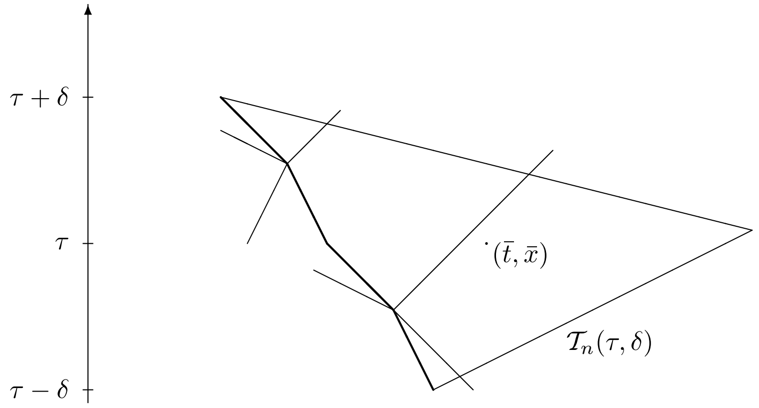


FIG. 5.3. *The set $\mathcal{T}_n(\tau,\delta)$.*

$x'_2 < x''_2$, the other cases being entirely similar. We first define the path $\gamma_1\colon [x'_2, x''_2] \mapsto \mathcal{D}^{\varepsilon}_{\delta}$,

$$\gamma_1(\theta) = u' \cdot \chi_{]-\infty,x'_2]\cup]\theta\ \ ,\infty+[} + u'' \cdot \chi_{]x'_2,\theta]}$$

joining u' with the intermediate function

$$w(x) = \begin{cases} u'(x) & \text{if } x \in\ ]-\infty, x'_2] \cup]x''_2, \infty[, \\ u''(x) & \text{if } x \in\ ]x'_2, x''_2]. \end{cases}$$

We then connect w with u'' by setting

$$\gamma_2(\theta) = u'' \cdot \chi_{]-\infty,\theta]} + w \cdot \chi_{]\theta,+\infty[}\,.$$

The concatenation of γ_1 and γ_2 yields the desired path. □

Proof of Proposition 4.10. As we announced in section 4 we give only the proof of the Ψ-admissibility of the solutions.

Fix a positive sequence $\{\varepsilon_n\colon n \in \mathbf{N}\}$ converging to 0. For all n, let u_n be the ε_n-approximate solution constructed by the algorithm. Call $x = \Lambda_n(t)$ the equation of the leftmost approximate phase boundary in u_n; the other cases are completely analogous.

Then choose a positive τ. For all n and positive δ, define $\mathcal{T}_n(\tau,\delta)$ as the following region of the (t,x)-plane (see Figure 5.3):

$$\begin{aligned} &\mathcal{T}_n(\tau,\delta) \\ &= \left\{ (t,x) \in [0,+\infty[\, \times \mathbf{R}\colon \left\{ \begin{array}{l} t \in]\tau-\delta, \tau+\delta[, \\ x < \Lambda_n(\tau-\delta) + \lambda^{\min} \cdot (t-(\tau-\delta)), \\ x < \Lambda_n(\tau+\delta) - \lambda^{\min} \cdot (t-(\tau+\delta)), \\ x > \Lambda_n(t) \end{array} \right. \right\}. \end{aligned} \tag{5.25}$$

Due to the subsonic hypothesis (2.4), $\mathcal{T}_n(\tau,\delta)$ is bounded. Moreover, note that by (2.1), 1-waves may exit $\mathcal{T}_n(\tau,\delta)$ only by crossing the phase boundary, while they may enter $\mathcal{T}_n(\tau,\delta)$ only through the bottom right side. Similarly, 2-waves may enter $\mathcal{T}_n(\tau,\delta)$ only by crossing the phase boundary, while they may exit $\mathcal{T}_n(\tau,\delta)$ only crossing the top right side. Due to (iii) in Proposition 4.1 there is only a finite number (depending on n) of such exiting or entering waves. Clearly, we can have creation or cancellation of both 1- and 2-waves inside $\mathcal{T}_n(\tau,\delta)$. Let us call $\mathcal{T}(\tau,\delta)$ the region analogous to (5.25) but constructed with reference to the exact phase boundary $x = \Lambda(t)$.

The following lemma is crucial; it is analogous to the celebrated Lemma 3.4 of [10] but we emphasize that its proof is much easier, as a consequence of the wave-front tracking scheme.

LEMMA 5.1. *For all but countably many τ and eventually passing to a subsequence of the approximate solutions, the following holds: for every $\varepsilon > 0$, there exists $\delta = \delta(\varepsilon,\tau)$ such that for every $(t,x) \in \mathcal{T}(\tau,\delta)$ and for all n large*

$$|u_n(t,x) - u_n\left(\tau,\Lambda_n(\tau)+\right)| < \varepsilon\ .$$

Proof. Let $\Upsilon_n(t) = \Upsilon^{\varepsilon_n}\left(u_n(t,\cdot)\right)$. By Helly's theorem, eventually passing to a subsequence we define for all $t \geq 0$

$$\tilde{\Upsilon}(t) = \lim_{n\to+\infty} \Upsilon_n(t).$$

Fix $\varepsilon > 0$ so small that for all the future constants C the estimate $C\varepsilon < 1$ holds. For every τ apart from a finite set of times (dependent on ε), there exists a positive δ such that

$$\left|\tilde{\Upsilon}(\tau+\delta+) - \tilde{\Upsilon}(\tau-\delta-)\right| < \varepsilon^6\ .$$

In Case 2 we eventually further restrict δ to ensure that the other phase boundary does not intersect $\mathcal{T}(\tau,\delta)$.

Then there exists a positive sequence $\{\delta_n : n \in \mathbf{N}\}$ such that δ_n increases, $\delta_n \to \delta$, and

$$|\Upsilon_n(\tau+\delta_n+) - \Upsilon_n(\tau-\delta_n-)| < \varepsilon^5 \tag{5.26}$$

for n sufficiently large. Choose an arbitrary $(\bar{t},\bar{x}) \in \mathcal{T}(\tau,\delta)$ and consider n sufficiently large in order that $(\bar{t},\bar{x}) \in \mathcal{T}_n(\tau,\delta_n)$ and (5.26) holds.

To compute $|u_n(\bar{t},\bar{x}) - u_n\left(\tau,\Lambda_n(\tau)+\right)|$, first draw the horizontal line segment $\mathcal{S}_n$ joining $(\bar{t},\bar{x})$ with the approximate phase boundary $x = \Lambda_n(t)$. Then, using the triangle inequality and the known estimate on $\Delta\Upsilon_n$

$$\begin{aligned}
&|u_n(\bar{t},\bar{x}) - u_n\left(\tau,\Lambda_n(\tau)+\right)| \\
&\leq |u_n(\bar{t},\bar{x}) - u_n\left(\bar{t},\Lambda_n(\bar{t})+\right)| + |u_n\left(\bar{t},\Lambda_n(\bar{t})+\right) - u_n\left(\tau,\Lambda_n(\tau)+\right)| \\
&\leq \mathrm{TV}\left(u_n\left(\bar{t},x\right) : x \in [\Lambda_n(\bar{t}),\bar{x}]\right) \\
&\quad + \mathrm{TV}\left(u_n\left(t,\Lambda_n(t)+\right) : t \in [\tau-\delta_n,\tau+\delta_n]\right) \\
&\leq C \sum_{\alpha:\,\sigma_{i,\alpha}\text{crosses } \mathcal{S}_n} |\sigma_{i,\alpha}| + C|\Upsilon_n(\tau+\delta_n+) - \Upsilon_n(\tau-\delta_n-)| \\
&\leq C \sum_{\alpha:\,\sigma_{i,\alpha}\text{crosses } \mathcal{S}_n} |\sigma_{i,\alpha}| + \varepsilon^4.
\end{aligned}$$

The rest of the proof aims at bounding from above the total quantity of waves crossing $\mathcal{S}_n$ and will be achieved by the following two claims.

Claim 1. For all large n, the total size of 1-waves exiting $\mathcal{T}_n(\tau,\delta_n)$ and the total size of 2–waves entering $\mathcal{T}_n(\tau,\delta_n)$ are both lower than ε^4.

Assume that $\sigma_{1,\alpha}^+$ exits $\mathcal{T}_n(\tau,\delta_n)$ at some time $t_\alpha \in [\tau-\delta_n, \tau+\delta_n]$. By (5.3) and (5.7) or (5.11) in Case 2

$$\sum_\alpha |\sigma_{1,\alpha}^+| \le C \sum_\alpha \left(|\sigma_{1,\alpha}^-| + |\sigma_{2,\alpha}^-|\right) \le C \sum_\alpha |\Delta \Upsilon_n(t_\alpha)| \le C\varepsilon^5 \le \varepsilon^4$$

by (5.26) and the decreasing of Υ_n. Here $\sigma_{1,\alpha}^-$, $\sigma_{2,\alpha}^-$ are the waves hitting the phase boundary.

The case of 2-waves is entirely analogous.

Claim 2. For all large n, the total size of 1- and 2-waves crossing $\mathcal{S}_n$ is smaller than ε^3.

As above, let $\sigma_{1,\alpha}$ for $\alpha = 1,\ldots,$ be the size of the 1-waves crossing $\mathcal{S}_n$. By eventually prolonging $\sigma_{1,\alpha}$ as a null wave, we can assume that $\sigma_{1,\alpha}$ exits $\mathcal{T}_n(\tau,\delta_n)$ through the phase boundary at some time $t_\alpha \in [\tau-\delta_n,\tau+\delta_n]$. By (4.10) in [5] (which generalizes to the case of many colliding waves our estimates (5.1) and (5.2)), by the definitions (4.8)–(4.10) or (4.13)–(4.14), by the interaction estimates (5.5) and (5.6), and by the previous Claim 1

$$\begin{aligned}\sum_{\alpha\colon \sigma_{1,\alpha} \text{crosses } \mathcal{S}_n} |\sigma_{1,\alpha}| &\le \sum_\alpha |\sigma_{1,\alpha}(t_\alpha+)| + \sum_{\substack{t_h \text{ interaction time}\\ \bar t \le t_h < t_\alpha}} |\Delta Q(t_h)| \\ &\le \varepsilon^4 + C \sum_{\substack{t_h \text{ interaction time}\\ \bar t \le t_h < t_\alpha}} |\Delta \Upsilon_n(t_h)| \\ &\le \varepsilon^4 + C\cdot |\Upsilon_n(\tau+\delta+) - \Upsilon_n(\tau-\delta-)| \\ &\le \varepsilon^3\end{aligned}$$

for a suitable constant C, where Q stands for $Q^\sharp$ in Case 1 and for $Q^\natural$ in Case 2.

For 2-waves the proof is entirely symmetric, the only difference being that now waves are prolonged as null waves backwards.

The lemma is therefore proved. □

The admissibility of the solutions follows from this lemma, since we have, arguing as in [10],

$$\lim_{n\to+\infty} u_n\big(t,\Lambda_n(t)+\big) = u\big(t,\Lambda(t)+\big).$$

This concludes the proof of Proposition 4.10. □

ON THE ROLE OF MEAN CURVATURE IN SOME SINGULARLY PERTURBED NEUMANN PROBLEMS[*]

MANUEL DEL PINO[†], PATRICIO L. FELMER[†], AND JUNCHENG WEI[‡]

Abstract. We construct solutions exhibiting a single spike-layer shape around some point of the boundary as $\varepsilon \to 0$ for the problem

$$\begin{cases} \varepsilon^2 \triangle u - u + u^p = 0 \quad \text{in } \Omega, \\ u > 0 \quad \text{in } \Omega, \\ \frac{\partial u}{\partial \nu} = 0 \quad \text{on } \partial\Omega, \end{cases} \tag{0.1}$$

where Ω is a bounded domain with smooth boundary in R^N, $p > 1$, and $p < \frac{N+2}{N-2}$ if $N \geq 3$. Our main result states that given a *topologically nontrivial critical point* of the mean curvature function of $\partial\Omega$, for instance, a possibly degenerate local maximum, local minimum, or saddle point, there is a solution with a single local maximum, which is located at the boundary and approaches this point as $\varepsilon \to 0$ while vanishing asymptotically elsewhere.

Key words. spike layer, singular perturbations, Neumann problems

1. Introduction.

In this paper, we are concerned with the following singularly perturbed problem:

$$\begin{cases} \varepsilon^2 \Delta u - u + u^p = 0 \quad \text{in } \Omega, \\ u > 0 \quad \text{in } \Omega, \\ \dfrac{\partial u}{\partial v} = 0 \quad \text{on } \partial\Omega, \end{cases} \tag{1.1}$$

where $\Omega \subset R^N$ is a smooth, not necessarily bounded domain; $\varepsilon > 0$; and $1 < p < (N+2)/(N-2)$ if $N \geq 3$ and $p > 2$ if $N = 2$.

Equation (1.1) arises from various applications. For instance, it can be regarded as that satisfied by stationary solutions for the Keller–Segal system in chemotaxis (see [14], [17], [19]) and the Gierer–Meinhardt system in biological pattern formation (see [12], [21]).

In [17], Lin, Ni, and Takagi first studied the problem of existence of least-energy solutions. Subsequently, Ni and Takagi in [19] and [21] showed that the least-energy solution u_ε has a unique local maximum point P_ε, which is located on $\partial\Omega$. Moreover, $u_\varepsilon \to 0$ in $C^1_{loc}(\overline{\Omega}\backslash P_\varepsilon)$ and $u_\varepsilon(P_\varepsilon) \to \alpha > 0$ as $\varepsilon \to 0$. Such a family of solutions is usually called a *boundary spike-layer*. Moreover, they are able to locate the spike by establishing that P_ε approaches the *most curved* part of $\partial\Omega$, namely, $H(P_\varepsilon) \to$

$\max_{P\in\partial\Omega} H(P)$, where H is the mean curvature. Later Wei studied general boundary spike solutions in [23] and showed that for any solution with single peak P_ε on $\partial\Omega$, $\nabla_{\tau_{P_\varepsilon}} H(P_\varepsilon) \to 0$, where $\nabla_{\tau_{P_\varepsilon}}$ denote the tangential gradient at $P_\varepsilon \in \partial\Omega$. On the other hand, if $P_0 \in \partial\Omega$, $\nabla_{\tau_{P_0}} H(P_0) = 0$ and the matrix $(\nabla^2_{\tau_{P_0}} H(P_0))$ is nonsingular, then there exists for ε sufficiently small, solution u_ε of (1.1) with a single peak approaching P_0. The degenerate case was left open.

In [21], Ni and Takagi constructed boundary spike solutions in the case when Ω is axially symmetric. Gui [10] has studied the case when $H(P)$ has a possibly degenerate local maximum at P_0, also constructing multiple-peak solutions at given local maximum points of $H(P)$. In the single peak case, the result in [10] states that for any set $\Lambda \subset \partial\Omega$, open relative to $\partial\Omega$, such that

$$\max_{P\in\Lambda} H(P) > \max_{P\in\partial\Lambda} H(P) \tag{1.2}$$

there exists a family of solutions with a single global maximum point which approaches a local maximum point of $H(P)$ in Λ.

In this paper, we will show that a spike-layer family indeed exists concentrating at any *topologically nontrivial critical point-region*, a variational linking notion first introduced in [5] in the framework of concentration phenomena in nonlinear Schrödinger equations.

This notion includes, for instance, the case of local maxima or local minima of the mean curvature of the boundary, in the same sense as in (1.2), and also that of a possibly degenerate *saddle-point*. More precisely, we can consider a local situation on a set $\Lambda \subset \partial\Omega$ where a change of topology of the level sets of $H(P)$ occurs. If c is the level at which this change takes place in a sense to be made precise below, then a boundary-spike family of solutions exists, with maxima $P_\varepsilon \in \Lambda$ so that $H(P_\varepsilon) \to c$.

Since we do not want to restrict ourselves to the case of a homogeneous nonlinearity, we will consider the more general semilinear Neumann problem

$$\begin{cases} \varepsilon^2 \Delta u - u + f(u) = 0 \quad \text{in } \Omega, \\ u > 0 \quad \text{in } \Omega, \\ \dfrac{\partial u}{\partial v} = 0 \quad \text{on } \partial\Omega, \end{cases} \tag{1.3}$$

where ε is a small positive number. $f : R \to R$ satisfies the conditions (f1)–(f5) below:

(f1) $f \in C^1(R)$, $f(t) \equiv 0$ for $t \leq 0$, and $f(t) \to +\infty$ as $t \to +\infty$.

(f2) For $t \geq 0$, f admits the decomposition in $C^1(R)$

$$f(t) = f_1(t) - f_2(t),$$

where (i) $f_1(t) \geq 0$, $f_2(t) \geq 0$ with $f_1(0) = f_1'(0) = f_2(0) = f_2'(0) = 0$; and (ii) there is a $q \geq 1$ such that $\frac{f_1(t)}{t^q}$ is nondecreasing in $t > 0$, where as $\frac{f_2(t)}{t^q}$ is nonincreasing in $t > 0$.

(f3) $|f'(t)| \leq a_1 + a_2 t^{p-1}$ for some positive constants a_1, a_2 and $1 < p < (\frac{N+2}{N-2})_+$.

(f4) There exists $\eta \in (0, \frac{1}{2})$ such that $F(t) \leq \eta t f(t)$, $t \geq 0$, where $F(t) = \int_0^t f(s)ds$.

To state the last condition, as in [20], we consider the problem in the whole space

$$\begin{cases} \Delta w - w + f(w) = 0, w > 0 \text{ in } R^N, \\ w(0) = \max\limits_{x\in R^N} w(x) \text{ and } w(x) \to 0 \text{ as } |x| \to +\infty. \end{cases} \tag{1.4}$$

It is well known that (1.4) has a solution w, and w is radial and unique (see [13], [4], [15]). The last condition is stated in (f5).

(f5) $L = \Delta - 1 + f'(w)$ is invertible over $H^2_r(R^N) = \{u \in H^2 : u(x) = u(|x|)\}$.

We note that the function

$$f(t) = t^p - at^q \text{ for } t \geq 0, 1 < q < p$$

with p subcritical and $a \geq 0$ satisfies all the assumptions (see [20]).

Let $H(P)$ be the mean curvature function at $P \in \partial\Omega$. In what follows, we state precisely our assumption on Ω and H. We assume that Ω is a smooth, not necessarily bounded domain in R^N, and that there is an open and bounded set $\Lambda \subset \partial\Omega$ with smooth boundary $\partial\Lambda$ and closed subsets of Λ, B, B_0 such that B is connected and $B_0 \subset B$. Let Γ be the class of all continuous functions $\phi : B \to \Lambda$ with the property that $\phi(y) = y$ for all $y \in B_0$. Assume that the max-min value

$$c = \sup_{\phi \in \Gamma} \min_{y \in B} H(\phi(y)) \tag{1.5}$$

is well defined and additionally that

(H1)

$$\min_{y \in B_0} H(y) > c.$$

(H2) For all $y \in \partial\Lambda$ such that $H(y) = c$, there exists a direction $\hat{T}$, tangent to $\partial\Lambda$ at y so that

$$\nabla H(y) \cdot \hat{T} \neq 0.$$

Note that $\partial\Lambda \subset \partial\Omega$ is an $(N-2)$-dimensional set.

Standard deformation arguments show that these assumptions ensure that the max-min value c is a critical value for $H(P)$ in Λ, which is topologically nontrivial (therefore, our results cover that of [10] in the single peak case). In fact, assumption (H2) "seals" Λ so that the local linking structure described indeed provides critical points at the level c in Λ, possibly admitting full degeneracy.

It is not hard to check that all these assumptions are satisfied in a general local maximum, local minimum, or saddle-point situation, not necessarily nondegenerate or isolated. Our main result asserts that there is a family of solutions to problem (1.1) concentrating around a critical point at the level c of H in Λ.

THEOREM 1.1. *Suppose f satisfies* (f1)–(f5) *and the mean curvature function H satisfied* (H1) *and* (H2). *Then there exists $\varepsilon_0 > 0$ such that when $\varepsilon \leq \varepsilon_0$, problem* (1.3) *has a solution u_ε with the property that*

(i) *u_ε has exactly one local maximum point x_ε and $x_\varepsilon \in \Lambda$;*

(ii) $\lim_{\varepsilon \to 0} H(x_\varepsilon) = c$;

(iii) $\lim_{\varepsilon \to 0} u_\varepsilon(x_\varepsilon + \varepsilon x) = w(x)$ *and there exist positive constants c, δ such that*

$$0 < u_\varepsilon(x) \leq c \, \exp\left(-\frac{\delta|x - x_\varepsilon|}{\varepsilon}\right), \quad x \in \overline{\Omega}.$$

Here w is the unique solution of (1.4).

The proof of this result makes use of ideas developed in [20] and [23] and a variational scheme similar to that in [5], where it is constructed as a bound state for the *semiclassical Schrödinger equation*

$$\varepsilon^2 \Delta u - V(x)u + u^p = 0 \quad \text{in} \quad R^N,$$

exhibiting concentration near topologically nontrivial critical points of $V(x)$; see also the work of the authors in [9]. Related results in this direction can be found in [6] and [7].

We have recently learned that Li [16] has considered, in the case of a bounded domain, a different notion of *nontriviality* not variational in nature. This notion is implied by our assumptions (H1)–(H2) in case the curvature is C^1. Thus, in case $f(s) = u^p$, with p superlinear and subcritical, and for a bounded domain, our result is a consequence of the results in [16]. However, Li's method, relying on a finite-dimensional Lyapunov–Schmidt reduction, is very different from ours.

On the other hand, our method is also applicable to obtain partial localization results even in case H is not C^1.

Finally, we remark that when $p = \frac{N+2}{N-2}$, problem (1.1) has been studied in [1], [2], [3], [11], [18], and [22], among others.

The rest of this paper will be devoted to the proof of Theorem 1.1. In section 2, we define a modified functional which satisfies the Palais–Smale (P.S.) condition and, roughly speaking, permits us to restrict ourselves to what happens in Λ. We then define a min-max value and by using assumption (H1) we prove that there is a critical point for the modified functional with this value. In section 3 by using assumption (H2) we prove that the critical point so found is actually a critical point of the original functional and we conclude the proof of Theorem 1.1.

2. Preliminary results and set-up of a min-max scheme. In this section, we first define a modified functional and state some preliminary results. We then set up a variational scheme and obtain a critical point for the modified functional.

Let $f : R \to R$ satisfying (f1)–(f5). We first define an "energy" functional

$$I_\varepsilon(u) = \frac{1}{2}\int_\Omega \varepsilon^2|\nabla u|^2 + u^2 - \int_\Omega F(u),$$

where $u \in H^1(\Omega)$, $F(u) = \int_0^u f(s)ds$.

As in [5], we now define a modification of this functional which satisfies the P.S. condition and for which we find a critical point via an appropriate min-max scheme.

Let $\mu = \frac{1}{\eta}$, where η is defined by (f4). Let $R > \frac{\mu}{\mu-2}$. Let $a > 0$ be the value at which $f(a)/a = 1/R$. Set

$$\bar{f}(s) = \begin{cases} f(s) & \text{if } s \le a, \\ \dfrac{1}{R}s & \text{if } s > a. \end{cases}$$

The following technical lemma is stated in [10] and can be proved by using local coordinate systems for $\partial\Lambda$.

<u>Lemma 2.1</u>. *There exists a subdomain $\partial\Omega_0 \subset \Omega$ such that $\partial\Omega_0 \cap \partial\Omega = \overline{\Lambda}$ and $\partial\Omega_0^+ := \overline{\partial\Omega_0 \backslash \partial\Omega}$ is smooth and orthogonal to $\partial\Omega$ at $\partial\Lambda$.*

We now define

$$g(\cdot, s) = \chi_{\Omega_0} f(s) + (1-\chi_{\Omega_0})\bar{f}(s) \quad \text{and} \quad G(x,\xi) = \int_0^\xi g(x,\tau)d\tau,$$

where χ_{Ω_0} denotes the characteristic function of Ω_0.

First we note that g is a Carathéodory function. In addition one can check that (f1)–(f4) implies that g satisfies the following conditions:

(g1) $g(x,t) = 0$ for $t \leq 0$ and $g(x,t) \to \infty$ as $t \to \infty$.
(g2) $g(x,t) = o(t)$ near $t = 0$ uniformly in $x \in \Omega$.
(g3) $g(x,t) = O(t^p)$ as $t \to \infty$ for $1 < p < \frac{N+2}{N-2}$ if $N \geq 3$ and no restriction on p if $N = 1, 2$.
(g4) (i) $G(x,t) \leq \mu g(x,t)t \quad \forall x \in \Omega_0, t > 0$

and

(ii) $2G(x,t) \leq g(x,t)t \leq \frac{1}{R}t^2 \quad \forall t \in R^+, x \notin \Omega_0$.

Consider the modified functional

$$J_\varepsilon(u) = \frac{1}{2}\int_\Omega \varepsilon^2|\nabla u|^2 + \frac{1}{2}\int_\Omega u^2 - \int_\Omega G(x,u), \qquad u \in H^1(\Omega),$$

whose critical points correspond to solutions of the equation

$$\begin{cases} \varepsilon^2\Delta u - u + g(u,x) = 0 \quad \text{in } \Omega, \\ \dfrac{\partial u}{\partial v} = 0 \quad \text{on } \partial\Omega. \end{cases} \tag{2.1}$$

As in [5], J_ε satisfies the P.S. condition whether Ω is bounded or not. We observe that a solution to (2.1) which satisfies that $u \leq a$ on $\overline{\Omega}\backslash\Omega_0$ will also be a solution of (1.3). We will define a min-max quantity for J_ε which will yield a solution to (2.1) which turns out to be a solution for (1.3) and thus will be the solution announced by Theorem 1.1.

To this end, we consider the solution manifold of (2.1) defined as

$$M_\varepsilon = \left\{ u \in H^1(\Omega)\backslash\{0\} | \int_\Omega (\varepsilon^2|\nabla u|^2 + u^2) = \int_\Omega g(x,u)u \right\}. \tag{2.2}$$

All nonzero critical points of J_ε of course lie on M_ε. Reciprocally, it is standard to check that critical points of J_ε constrained to this manifold are critical points of J_ε on $H^1(\Omega)$.

Let w be the unique solution of (1.4) and let us consider its energy

$$I(w) = \frac{1}{2}\int_{R^N} (|\nabla w|^2 + w^2) - \int_{R^N} F(w). \tag{2.3}$$

For $P \in \partial\Omega$, we define w_ε^P as

$$w_\varepsilon^P = t_{\varepsilon,P}\, w\left(\frac{x-P}{\varepsilon}\right) \in M_\varepsilon,$$

with $t_{\varepsilon,P} > 0$. Let us consider the center of mass of a function $u \in L^2(\Omega)$ defined as

$$\beta(u) = \frac{\int_{\Omega_0} xu^2 dx}{\int_\Omega u^2 dx}. \tag{2.4}$$

For $P \in B$, it is easy to see that $\beta(w_\varepsilon^P) = P + O(\varepsilon)$. Hence, there exists a continuous function $\tau_\varepsilon(P)$ such that $\tau_\varepsilon(P) = P + O(\varepsilon)$ and $\beta(w_\varepsilon^{\tau_\varepsilon(P)}) = P$ for $P \in B$. We now define

$$w_{\varepsilon,P} = w_\varepsilon^{\tau_\varepsilon(P)}.$$

Hence we have $\beta(w_{\varepsilon,P}) = P \; \forall \; P \in B$, and by similar arguments as in Proposition 3.2 in [19] we find that, $\forall \; P \in B$,

$$J_\varepsilon(w_{\varepsilon,P}) = \varepsilon^N \left\{ \frac{1}{2} I(w) - \gamma\varepsilon(N-1)H(P) + o(\varepsilon) \right\}, \tag{2.5}$$

where

$$\gamma := \frac{1}{N+1} \int_{R^N_+} w'(y)^2 y_N dy. \tag{2.6}$$

We now consider the class Γ_ε of all continuous maps $\varphi : B \to M_\varepsilon$ such that

$$\varphi(y) = w_{\varepsilon,y} \qquad \forall y \in B_0,$$

and we define the min-max value S_ε as follows:

$$S_\varepsilon = \inf_{\varphi \in \Gamma_\varepsilon} \sup_{y \in B} J_\varepsilon(\varphi(y)). \tag{2.7}$$

We note that

$$S_\varepsilon \geq \sup_{y \in B_0} J_\varepsilon(w_{\varepsilon,y}) \tag{2.8}$$

and

$$S_\varepsilon = \inf_{\varphi \in \Gamma_\varepsilon} \sup_{y \in B} J_\varepsilon(\varphi(y)) \leq \sup_{y \in B} J_\varepsilon(w_{\varepsilon,y}). \tag{2.9}$$

Hence by (2.5), (2.8), and (2.9), we have

$$\lim_{\varepsilon \to 0} \varepsilon^{-N} S_\varepsilon = \frac{1}{2} I(w). \tag{2.10}$$

The following is the key result of this section. It implies that S_ε is a critical value for J_ε.

LEMMA 2.2. *For ε sufficiently small, we have*

$$S_\varepsilon > \sup_{y \in B_0} J_\varepsilon(w_{\varepsilon,y}). \tag{2.11}$$

In the rest of this section, we prove Lemma 2.2. To this end we will first prove a version of a result of Ni and Takagi for the modified functional J_ε (see Proposition 2.1 in [20]).

LEMMA 2.3. *Let $\Omega_1 \subset \overline{\Omega}$ be a subdomain such that $\partial\Omega_1 \cap \partial\Omega = \Lambda_1$ is open relative to $\partial\Omega$ and $\partial\Omega_1^+ := \overline{\partial\Omega_1 \backslash \partial\Omega}$ is smooth and orthogonal to $\partial\Omega$ at $\partial\Lambda_1$. We define*

$$g_{\Omega_1}(x,u) = \chi_{\Omega_1} f(u) + (1 - \chi_{\Omega_1})\bar{f}(u), \qquad G_{\Omega_1}(x,u) = \int_0^u g_{\Omega_1}(x,s) ds,$$

and

$$J_{\varepsilon,\Omega_1}(u) = \frac{1}{2} \int_\Omega \varepsilon^2 |\nabla u|^2 + \frac{1}{2} \int_\Omega u^2 - \int_\Omega G_{\Omega_1}(x,u).$$

Suppose that u_ε is a solution of

$$\begin{cases} \varepsilon^2 \Delta u - u + g_{\Omega_1}(x,u) = 0 \ \textit{in} \ \Omega, \\ u > 0 \ \textit{in} \ \Omega, \\ \dfrac{\partial u}{\partial v} = 0 \ \textit{on} \ \partial\Omega, \end{cases} \tag{2.12}$$

such that

$$\varepsilon^{-N} J_{\varepsilon,\Omega_1}(u_\varepsilon) \to \frac{1}{2} I(w). \tag{2.13}$$

Then we have

$$J_{\varepsilon,\Omega_1}(u_\varepsilon) = \varepsilon^N \left\{ \frac{1}{2} I(w) - \gamma\varepsilon(N-1)H(x_\varepsilon) + o(\varepsilon) \right\}, \tag{2.14}$$

where $x_\varepsilon \in \partial\Omega_1 \cap \partial\Omega$ is the maximum point of u_ε and γ is defined by (2.6). In particular,

$$J_{\varepsilon,\Omega_1}(u_\varepsilon) \geq \varepsilon^N \left\{ \frac{1}{2} I(w) - \varepsilon\gamma \max_{x\in\partial\Omega_1\cap\partial\Omega} (N-1)H(x) + o(\varepsilon) \right\}. \tag{2.15}$$

Before going into the proof of Lemma 2.3 we state and prove a corollary that will be useful later.

COROLLARY 2.1. *Let $\varepsilon = \varepsilon_k \to 0$ and $u_\varepsilon \in M_{\varepsilon,\Omega_1}$ be a family of functions such that*

$$\limsup_{\varepsilon\to 0} \varepsilon^{-N} J_{\varepsilon,\Omega_1}(u_\varepsilon) \leq \frac{1}{2} I(w), \tag{2.16}$$

where

$$M_{\varepsilon,\Omega_1} = \left\{ u \in H^1(\Omega)\backslash\{0\} | \int_\Omega (\varepsilon^2|\nabla u|^2 + u^2) = \int_\Omega g_{\Omega_1}(x,u)u \right\}.$$

Let $x_\varepsilon = \beta(u_\varepsilon)$ be the center of mass of u_ε; then $x_\varepsilon \to \partial\Omega$, and if $\bar{x}$ is an accumulation point of $\{x_\varepsilon\}$, the following estimate holds:

$$J_{\varepsilon,\Omega_1}(u_\varepsilon) \geq \varepsilon^N \left\{ \frac{1}{2} I(w) - \gamma\varepsilon(N-1)H(\bar{x}) + o(\varepsilon) \right\}. \tag{2.17}$$

Proof. Passing to a subsequence we can assume that $x_\varepsilon \to \bar{x}$. Let us consider the modified center of mass defined as

$$\bar{\beta}(u) = \frac{\int_{B_\delta(\bar{x})} xu^2}{\varepsilon^N \int_{R^N} w^2}.$$

Given $\delta > 0$ we then have that

$$\bar{\beta}(u_\varepsilon) \in B_\delta(\bar{x}) \tag{2.18}$$

$\forall$ small ε. In fact, using a concentration-compactness-type argument similar to the one given in Lemma 1.1 in [5], we find $R > 0$, a subsequence $\varepsilon \to 0$, and $y_\varepsilon \in \Omega_\varepsilon = \varepsilon^{-1}\Omega$ such that

$$\int_{B_R(y_\varepsilon)} v_\varepsilon^2 \geq \sigma > 0,$$

where $v_\varepsilon(x) = v_\varepsilon(\varepsilon x)$.

Let us assume first that $dist(y_\varepsilon, \partial\Omega_\varepsilon) \to \infty$. Since v_ε is bounded in $H^1(\Omega_\varepsilon)$, given $\delta > 0$ there exists $r > 0$ such that

$$\int_{B_{r+1}(0)\setminus B_r(0)} |\nabla u_\varepsilon|^2 + u_\varepsilon^2 \leq \delta.$$

Then we choose an appropriate cut-off function ψ so that $\psi = 1$ on $B_r(0)$ and $\psi = 0$ on $B_{r+1}(0)$ and we find

$$u_\varepsilon = \psi u_\varepsilon + (1-\psi)u_\varepsilon = w_\varepsilon + v_\varepsilon.$$

If we choose δ small enough, we find that for both v_ε and w_ε we can find t_ε^1, t_ε^2 very close to 1 so that $\tilde{w}_\varepsilon = t_\varepsilon^1 w_\varepsilon$ and $\tilde{v}_\varepsilon = t_\varepsilon^2 v_\varepsilon$ are in M_{ε,Ω_1}. But this implies that lim inf $J_{\varepsilon,\Omega_1}(u_\varepsilon) \geq I(w)$, contradicting the hypothesis.

Therefore, we must have that $dist(y_\varepsilon, \partial\Omega_\varepsilon) \leq C$. We can assume that $y_\varepsilon \in \partial\Omega_\varepsilon$. By the argument given above, taking a sequence $\delta_n \to 0$ and using (2.16) we find a subsequence $u_\varepsilon = v_\varepsilon + w_\varepsilon$ with $w_\varepsilon \to 0$.

Finally, using the minimizing character of this sequence u_ε and Ekeland's variational principle we find that $u_\varepsilon(x_\varepsilon + \varepsilon y)$ converges in H^1-sense to a least energy critical point w of the limiting functional I given in (2.3) in the half space. We certainly have that $x_\varepsilon + \varepsilon y_\varepsilon \to x \in \partial\Omega$, thus proving (2.18).

Then we have

$$J_{\varepsilon,\Omega_1}(u_\varepsilon) \geq \inf\{J_{\varepsilon,\Omega_1}(u) \mid u \in M_{\varepsilon,\Omega_1},\ \bar{\beta}(u) \in B_\delta(\bar{x})\}.$$

Since the functional J_{ε,Ω_1} satisfies the P.S. condition, it follows that the latter number is attained at some function $\bar{u}_\varepsilon \in H^1(\Omega)$. Working out a first variation with test functions supported outside $B_\delta(\bar{x})$, we see that $\bar{u}_\varepsilon$ satisfies the equation

$$\varepsilon^2\Delta\bar{u}_\varepsilon - \bar{u}_\varepsilon + g_{\Omega_1}(x, \bar{u}_\varepsilon) = 0 \text{ in } \Omega\setminus B_\delta(\bar{x}).$$

Again, if we set $v_\varepsilon(y) = \bar{u}_\varepsilon(\bar{x}_\varepsilon + \varepsilon y)$ with $\bar{x}_\varepsilon = \beta(\bar{u}_\varepsilon)$, then v_ε converges in the H^1-sense to w in the half space. In particular, elliptic estimates applied to the above equation imply that $\bar{u}_\varepsilon$ goes to zero uniformly, away from the ball $B_\delta(\bar{x})$. Thus we have that

$$J_{\varepsilon,\Omega_1}(\bar{u}_\varepsilon) = J_{\varepsilon,\Omega_1\cap B_{2\delta}(\bar{x})}(\bar{u}_\varepsilon)$$

and also $\bar{u}_\varepsilon \in M_{\varepsilon,\Omega_1\cap B_{2\delta}(\bar{x})}$. Let us consider a set Ω_δ so that $\Omega_1 \cap B_{2\delta}(\bar{x}) \subset \Omega_\delta \subset \Omega_1 \cap B_{3\delta}(\bar{x})$, satisfying the hypotheses of Lemma 2.3. Then we obtain

$$J_{\varepsilon,\Omega_1}(\bar{u}_\varepsilon) \geq \inf_{u \in M_{\varepsilon,\Omega_\delta}} J_{\varepsilon,\Omega_\delta}(u).$$

However the latter number can be estimated from below using Lemma 2.3. Doing so we have

$$J_{\varepsilon,\Omega_1}(\bar{u}_\varepsilon) \geq \varepsilon^N \left\{\frac{1}{2}I(w) - \varepsilon\gamma \max_{x\in\partial\Omega_\delta\cap\partial\Omega}(N-1)H(x) + o(\varepsilon)\right\}.$$

To obtain (2.17), we first use the continuity of H to choose δ and then we choose ε small enough, according to (2.15). This finishes the proof. $\square$

Now we will give a proof of Lemma 2.3. We start with some preliminaries.

Proof of Lemma 2.3. Since u_ε satisfies (2.12) and $\varepsilon^{-N} J_{\varepsilon,\Omega_1}(u_\varepsilon)$ is bounded, u_ε converges locally in the H^1 sense to a solution of the limiting equation. Then a concentration-compactness argument gives that $\|\tilde{u}_\varepsilon - w\|_{H^1(\Omega_{\varepsilon,z_\varepsilon})} \to 0$ for some $z_\varepsilon \in \overline{\Omega}$, where

$$\Omega_{\varepsilon,P} = \{y | \varepsilon y + P \in \overline{\Omega}\}, \qquad P \in \overline{\Omega},$$

and $\tilde{u}_\varepsilon(y) = u_\varepsilon(\varepsilon y + z_\varepsilon)$. Moreover, because of (2.13) we have that $\frac{d(z_\varepsilon,\partial\Omega)}{\varepsilon} \leq C$ and $z_\varepsilon \in \Omega_1$ (otherwise, the energy of u_ε will be at least of the order of $\varepsilon^N I(w)$; see Lemma 1.1 in [5]). Observe that u_ε satisfies

$$\varepsilon^2 \Delta u_\varepsilon - u_\varepsilon + f(u_\varepsilon) + h_\varepsilon = 0, \tag{2.19}$$

where $h_\varepsilon = (1 - \chi_{\Omega_1})(\bar{f}(u_\varepsilon) - f(u_\varepsilon))$. Hence $h_\varepsilon = o(1)$ uniformly and $\tilde{u}_\varepsilon \to w$ in a C^1_{loc} sense. Furthermore, there exist constants α, $\beta > 0$ such that

$$\tilde{u}_\varepsilon(y) \leq \alpha \ \exp(-\beta|y|).$$

Next, an argument given in [19] shows that u_ε has only one local maximum point x_ε and $x_\varepsilon \in \partial\Omega_1 \cap \partial\Omega$.

We now consider two cases. Let $b > 0$ so that $w(b) = a$.

Case 1. If lim $\inf_{\varepsilon\to 0} d(x_\varepsilon, \partial\Omega_1^+)/\varepsilon > b$, then u_ε satisfies

$$\varepsilon^2 \Delta u_\varepsilon - u_\varepsilon + f(u_\varepsilon) = 0,$$

and then, by Proposition 2.1 in [20], we have that

$$J_{\varepsilon,\Omega_1}(u_\varepsilon) = \varepsilon^N \left\{ \frac{1}{2} I(w) - \gamma\varepsilon(N-1)H(x_\varepsilon) + o(\varepsilon) \right\},$$

finishing the proof of the lemma.

Case 2. lim $\inf_{\varepsilon\to 0} d(x_\varepsilon, \partial\Omega_1^+)/\varepsilon \leq b$. We see first that we can assume that lim $\inf_{\varepsilon\to 0} d(x_\varepsilon, \partial\Omega_1^+)/\varepsilon = b$ since the contrary, together with the convergence of $\tilde{u}_\varepsilon$ to w, implies a contradiction with (2.13).

To prove the lemma in this case we need some work. We next consider some notation. Let $\bar{x}_\varepsilon \in \partial\Omega_1^+$ be such that $d(x_\varepsilon, \partial\Omega_1^+) = |x_\varepsilon - \bar{x}_\varepsilon|$. Then since $\partial\Omega_1^+$ is orthogonal to $\partial\Omega$ at Λ_1, we have that the projection of $\bar{x}_\varepsilon$ onto $\partial\Lambda_1$, which we call $\bar{x}_\varepsilon^p$, satisfies

$$\frac{|x_\varepsilon - \bar{x}_\varepsilon^p|}{\varepsilon} \to b \qquad \text{and} \qquad \frac{|\bar{x}_\varepsilon - \bar{x}_\varepsilon^p|}{\varepsilon} \to 0. \tag{2.20}$$

Without loss of generality, we can assume that $\nu_{x_\varepsilon} = -e_N$, where ν_{x_ε} denotes the exterior normal at x_ε and that $\bar{x}_\varepsilon = d(x_\varepsilon, \partial\Omega_1^+)e_1^\varepsilon$, where $e_1^\varepsilon \to e_1$ as $\varepsilon \to 0$.

Set $x = x_\varepsilon + \varepsilon y$, $\Omega_\varepsilon = \{y : x_\varepsilon + \varepsilon y \in \Omega\}$. For notational convenience in the rest of the paper, given a function $p : \Omega \to R$, we denote by $\tilde{p}$ the function defined on Ω_ε as $\tilde{p}(y) = p(x)$. We observe that support of the function $\tilde{h}_\varepsilon$ is contained in $B_{\delta_\varepsilon}((\bar{x}_\varepsilon - x_\varepsilon)/\varepsilon) \cap \overline{\Omega}_\varepsilon$, where $\delta_\varepsilon \to 0$. This fact follows from the uniform convergence of $\tilde{u}_\varepsilon$ to w and the exponential decay of w at infinity.

Now we will study the asymptotic behavior of u_ε. First we define the function ϕ_ε as

$$u_\varepsilon(x) = w_\varepsilon(x) + \varepsilon\phi_\varepsilon, \qquad x \in \Omega, \tag{2.21}$$

where $w_\varepsilon(x) = w(\frac{x-x_\varepsilon}{\varepsilon})$. It is our goal to study the behavior of the function ϕ_ε. The next lemma provides an important estimate.

LEMMA 2.4. *For ε sufficiently small, we have*

$$\|\tilde{h}_\varepsilon\|_{L^1(\Omega_\varepsilon)} \leq o(\varepsilon). \tag{2.22}$$

Proof. We multiply the equation satisfied by $\tilde{u}_\varepsilon$ (see (2.19)) by $\frac{\partial \tilde{u}_\varepsilon}{\partial y_1}$ and integrate by parts to obtain

$$\int_{\Omega_\varepsilon} \tilde{h}_\varepsilon \frac{\partial \tilde{u}_\varepsilon}{\partial y_1} = \int_{\partial\Omega_\varepsilon} \left\{ F(\tilde{u}_\varepsilon) - \frac{1}{2}\tilde{u}_\varepsilon^2 \right\} \nu_1 dy,$$

where ν_1 is the first component of the normal vector. To estimate the right-hand side of the above equality we give a local representation of the boundary near the origin and find that $\nu_1 = \varepsilon \sum_{i=1}^{N-1} \alpha_i y_i + O(\varepsilon^2)$. On the other hand, from the radial symmetry of w we have that

$$\int_{\partial R^N_+} \left\{ F(w) - \frac{1}{2} w^2 \right\} y_i dy = 0 \qquad \text{for} \quad i = 1, \ldots, N-1. \tag{2.23}$$

Then

$$\int_{\partial\Omega_\varepsilon} \left\{ F(\tilde{u}_\varepsilon) - \frac{1}{2}\tilde{u}_\varepsilon^2 \right\} \nu_1 dy = o(\varepsilon). \tag{2.24}$$

To finish we observe that since $\text{supp}(\tilde{h}_\varepsilon) \subset B_{2\delta_\varepsilon}(be_1)$, for small ε, we have that $\frac{\partial \tilde{u}_\varepsilon}{\partial u_1} \to \frac{\partial w}{\partial y_1}(be_1) \neq 0$ for all $y \in \text{supp}(\tilde{h})$ and hence

$$\int_{\Omega_\varepsilon} \tilde{h}_\varepsilon = o(\varepsilon),$$

proving (2.22). □

Next we study the behavior of the function $\tilde{\phi}_\varepsilon$. We see that $\tilde{\phi}_\varepsilon$ satisfies the equation

$$\begin{cases} \Delta\tilde{\phi}_\varepsilon - (1 + d_\varepsilon)\tilde{\phi}_\varepsilon + f'(w)\tilde{\phi}_\varepsilon + \dfrac{\tilde{h}_\varepsilon}{\varepsilon} = 0 \text{ in } \Omega_\varepsilon, \\ \dfrac{\partial\tilde{\phi}_\varepsilon}{\partial\nu} = -\dfrac{1}{\varepsilon}\dfrac{\partial w}{\partial \nu} \text{ on } \partial\Omega_\varepsilon, \end{cases} \tag{2.25}$$

where

$$d_\varepsilon = \frac{1}{\varepsilon\tilde{\phi}_\varepsilon}(f(\tilde{u}_\varepsilon) - f(w)) - f'(w).$$

We observe that $d_\varepsilon \to 0$ uniformly and we note that $\tilde{w}_\varepsilon = w$.

A local representation of Ω near x_ε is considered next. There is $R > 0$ and a neighborhood N_ε of x_ε so that $(y', y_N) \in N_\varepsilon \cap \Omega$ if and only if $y_N > \rho_\varepsilon(y')$,

$y' \in B(0,R)$, $\rho_\varepsilon(0) = x_\varepsilon$, and $\nabla\rho_\varepsilon(0) = 0$. We observe that if $x_\varepsilon \to x_0$ as $\varepsilon \to 0$, then $\rho_\varepsilon \to \rho$ in C^3 uniformly, where ρ is a local representation of the boundary centered at x_0.

Now we get an asymptotic formula for the normal derivative of w. We find, for $y \in B(0, \frac{R}{\varepsilon})$, that

$$\frac{\partial w}{\partial \nu}(y, \tilde{\rho}_\varepsilon(y)) = \frac{\varepsilon w'(|y|)}{2|y|}(\rho_\varepsilon)_{ij} y_i y_j + o(\varepsilon), \tag{2.26}$$

where $(\rho_\varepsilon)_{ij}$ denotes the partial derivatives of ρ_ε at 0. Here and in what follows we use the Einstein convention for summations.

In studying the behavior of $\tilde{\phi}_\varepsilon$ we need the limiting equation

$$\begin{cases} \Delta\phi - \phi + f'(w)\phi = 0 \text{ in } R^N_+, \\ \dfrac{\partial\hat{\phi}}{\partial y_N} = -\dfrac{w'(|y|)}{2|y|}\rho_{ij} y_i y_j \quad \text{on } \partial R^N_+. \end{cases} \tag{2.27}$$

We have the following lemma.

Lemma 2.5. *There is $1 < q < N/(N-1)$ so that $\|\tilde{\phi}_\varepsilon\|_{L^q(\Omega_\varepsilon)}$ is bounded and there are constants α, β, $R_0 > 0$ so that*

$$|\tilde{\phi}_\varepsilon(y)| \le \alpha \ \exp(-\beta|y|) \qquad \textit{for} \quad |y| > R_0. \tag{2.28}$$

Moreover,

$$\|\tilde{\phi}_\varepsilon - \tilde{\phi}_0\|_{L^q(\Omega_\varepsilon)} \to 0, \tag{2.29}$$

where $\tilde{\phi}_0 \in H^1(R^N_+)$ is the solution to (2.27).

Proof. Let us assume that $\|\tilde{\phi}_\varepsilon\|_{L^q(\Omega_\varepsilon)}$ is not bounded and define the function $\hat{\phi}_\varepsilon = \tilde{\phi}_\varepsilon / \|\tilde{\phi}_\varepsilon\|_{L^q(\Omega)_\varepsilon)}$. Then $\hat{\phi}_\varepsilon$ satisfies

$$\begin{cases} \Delta\hat{\phi}_\varepsilon - (1+d_\varepsilon)\hat{\phi}_\varepsilon + f'(w)\hat{\phi}_\varepsilon + \hat{h}_\varepsilon = 0 \text{ in } \Omega_\varepsilon, \\ \dfrac{\partial\hat{\phi}_\varepsilon}{\partial\nu} = n_\varepsilon \text{ on } \partial\Omega_\varepsilon, \end{cases} \tag{2.30}$$

where $\hat{h}_\varepsilon = \tilde{h}_\varepsilon / \varepsilon \|\tilde{\phi}_\varepsilon\|_{L^q(\Omega_\varepsilon)} \to 0$ in the L^1 sense and

$$n_\varepsilon = -\frac{1}{\varepsilon}\frac{\partial w}{\partial\nu} / \|\tilde{\phi}_\varepsilon\|_{L^q(\Omega_\varepsilon)}.$$

We observe that $n_\varepsilon \to 0$ uniformly and that it satisfies an estimate of the form

$$|n_\varepsilon(y)| \le \alpha_\varepsilon \ \exp(-\bar{\beta}|y|) \qquad \text{for} \quad y \in \partial\Omega_\varepsilon \tag{2.31}$$

for some constants α_ε, $\bar{\beta} > 0$, and $\alpha_\varepsilon \to 0$.

We recall that $\text{supp}(\tilde{h}_\varepsilon) \subset B_{2\delta_\varepsilon}(be_1)$, with $\delta_\varepsilon \to 0$. Thus, standard elliptic estimates and comparison arguments, using the facts just mentioned and that $\|\hat{h}_\varepsilon\|_{L^q(\Omega_\varepsilon)}$ is bounded, yield the existence of constants R_0, α, $\beta > 0$ such that

$$|\hat{\phi}_\varepsilon(y)| \le \alpha \ \exp(-\beta|y|) \qquad \text{for} \quad |y| > R_0. \tag{2.32}$$

Since $\|\Delta\hat{\phi}_\varepsilon\|_{L^1(\Omega_\varepsilon)} \le C$, a well-known elliptic estimate yields that

$$\|\hat{\phi}_\varepsilon\|_{W^{1,q}(\Omega_\varepsilon \cap B_{R_0}(0))} \le C_{R_0}. \tag{2.33}$$

By the boundedness of $\hat{\phi}_\varepsilon$ in L^q we have that for a subsequence $\hat{\phi}_\varepsilon \rightharpoonup \hat{\phi}$ weakly in L^q. Now, (2.32) and (2.33) implies that this convergence is strong in L^q, in particular, $\hat{\phi} \ne 0$. Moreover, $\hat{\phi} \in W^{1,q}(R^N_+)$, it satisfies

$$\begin{cases} \Delta\hat{\phi} - \hat{\phi} + f'(w)\hat{\phi} = 0 \text{ in } R^N_+, \\ \dfrac{\partial \hat{\phi}}{\partial y_N} = 0 \text{ on } \partial R^N_+ \end{cases} \tag{2.34}$$

and

$$|\hat{\phi}(y)| \le \alpha\ \exp(-\beta|y|) \qquad \text{for} \quad |y| \quad \text{large}. \tag{2.35}$$

We observe that $\nabla w(0) = 0$ and that $\nabla u_\varepsilon(x_\varepsilon) = 0$; then $\nabla\hat{\phi}_\varepsilon(0) \to \nabla\hat{\phi}(0) = 0$. Thus hypothesis (f5) and the argument given in the proof of Lemma 4.6 of Ni and Takagi [20] imply that $\hat{\phi} \equiv 0$, which is a contradiction.

Next we can give a similar argument to obtain that the family $\tilde{\phi}_\varepsilon$ satisfies (2.28) and that, if $\tilde{\phi}_0$ is the solution of (2.27), then

$$\|\tilde{\phi}_\varepsilon - \tilde{\phi}_0\|_{L^q(\Omega_\varepsilon)} \to 0, \tag{2.36}$$

finishing the proof of Lemma 2.5. □

Proof of Lemma 2.3 (*finished*). We have

$$\begin{aligned} \varepsilon^{-N} J_{\varepsilon,\Omega_1}(u_\varepsilon) &= \int_{\Omega_\varepsilon} \frac{1}{2}(|\nabla \tilde{u}_\varepsilon|^2 + \tilde{u}_\varepsilon^2) - F(\tilde{u}_\varepsilon) - F(\tilde{u}_\varepsilon) + \int_{\Omega_\varepsilon \setminus \Omega_{1\varepsilon}} \bar{F}(\tilde{u}_\varepsilon) - F(\tilde{u}_\varepsilon). \\ &= I_1 + I_2 \end{aligned}$$

We first estimate integral I_2. It follows from hypothesis (f5) and Lemma 2.4 that

$$\begin{aligned} |I_2| &= \int_{\Omega_\varepsilon} (1 - \chi_{\Omega_{1\varepsilon}})(F(\tilde{u}_\varepsilon) - \bar{F}(\tilde{u}_\varepsilon)) \\ &= \int_{\Omega_\varepsilon} (1 - \chi_{\Omega_{1\varepsilon}}) \int_0^{\tilde{u}_\varepsilon} (f(s) - \bar{f}(s))ds \\ &\le \int_{\Omega_\varepsilon} (1 - \chi_{\Omega_{1\varepsilon}}) \frac{f(\tilde{u}_\varepsilon) - \bar{f}(\tilde{u}_\varepsilon)}{\tilde{u}_\varepsilon} \frac{\tilde{u}_\varepsilon^2}{2} = o(\varepsilon). \end{aligned} \tag{2.37}$$

Next we study I_1; for that purpose, we write

$$\begin{aligned} I_1 &= \int_{\Omega_\varepsilon} \frac{1}{2}(|\nabla w|^2 + w^2) - F(w) + \\ &+ \varepsilon \int_{\Omega_\varepsilon} \{\nabla w \cdot \nabla\tilde{\phi}_\varepsilon + w\tilde{\phi}_\varepsilon - f(w)\tilde{\phi}_\varepsilon\} + E_\varepsilon = I_1' + I_2' + E_\varepsilon. \end{aligned} \tag{2.38}$$

A direct computation using the properties of w yields

$$I_1' = \frac{1}{2} I(w) - \gamma\varepsilon(N-1)H(x_\varepsilon) + o(\varepsilon). \tag{2.39}$$

Using integration by parts and the equation satisfied by w we find

$$I_2' = \varepsilon \int_{\partial\Omega_\varepsilon} \frac{\partial w}{\partial \nu} \tilde{\phi}_\varepsilon = o(\varepsilon), \tag{2.40}$$

where the last equality follows from (2.26) and the fact that $\varepsilon\tilde{\phi}_\varepsilon \to 0$ uniformly. Finally we consider E_ε: using Taylor expansion we have

$$E_\varepsilon = \varepsilon^2 \left\{ \int_0^1 (1-t) \left(\int_{\Omega_\varepsilon} |\nabla \tilde{\phi}_\varepsilon|^2 + \tilde{\phi}_\varepsilon^2 - f'(w + t\varepsilon\tilde{\phi}_\varepsilon)\tilde{\phi}_\varepsilon^2 \right) dt \right\}. \tag{2.41}$$

For a given large R, we obtain

$$\begin{aligned} \varepsilon \int_{\Omega_\varepsilon} |\nabla \tilde{\phi}_\varepsilon|^2 = {} & \varepsilon \int_{\Omega_\varepsilon \cap B_R(0)} |\nabla \tilde{\phi}_\varepsilon|^2 + \varepsilon \int_{\partial(\Omega_\varepsilon \cap B_R(0))} \nabla \tilde{\phi}_\varepsilon \cdot \nu \tilde{\phi}_\varepsilon \\ & - \varepsilon \int_{\Omega_\varepsilon \cap B_R(0)^c} \Delta \tilde{\phi}_\varepsilon \tilde{\phi}_\varepsilon. \end{aligned} \tag{2.42}$$

The first and second term on the right-hand side above go to zero because $\varepsilon\tilde{\phi}_\varepsilon \to 0$ in C^1_{loc} and $\tilde{\phi}_\varepsilon \in W^{1,q}_{loc}(\Omega_\varepsilon)$. Next, using the equation for $\tilde{\phi}_\varepsilon$ and (2.28) we find that the third term also converges to 0, so we conclude that

$$\varepsilon \int_{\Omega_\varepsilon} |\nabla \tilde{\phi}_\varepsilon|^2 = o(1). \tag{2.43}$$

Using similar arguments we treat the other terms appearing in (2.41). Thus we finally obtain that $E_\varepsilon = o(\varepsilon)$, finishing the proof. □

Proof of Lemma 2.2. Suppose (2.11) is not true; then

$$S_\varepsilon = \sup_{y \in B_0} J_\varepsilon(w_{\varepsilon,y}). \tag{2.44}$$

Hence

$$\begin{aligned} S_\varepsilon &= \varepsilon^N \left\{ \frac{1}{2} I(w) - \gamma\varepsilon \min_{y \in B_0} (N-1) H(y) + o(\varepsilon) \right\} \\ &\leq \varepsilon^N \left\{ \frac{1}{2} I(w) - \gamma\varepsilon(c+\delta) + o(\varepsilon) \right\}, \end{aligned}$$

where $c+\delta \leq \min_{y\in B_0} H(y)$ for some $\delta > 0$ (by assumption (H1)). Then, by definition of S_ε there exists $\varphi_\varepsilon \in \Gamma_\varepsilon$ such that

$$J_\varepsilon(\varphi_\varepsilon(y)) \leq \varepsilon^N \left\{ \frac{1}{2} I(w) - \gamma\varepsilon \left(c + \frac{\delta}{2} \right) + o(\varepsilon) \right\} \quad \forall\, y \in B. \tag{2.45}$$

Take a sequence $\varepsilon_n \to 0$ and denote $\varphi_{\varepsilon_n} = \varphi_n$. Let Λ^+ be a small fixed neighborhood of Λ and $\pi : \Lambda^+ \to \Lambda$ a continuous map which equals the identity on Λ. Define $\phi_n(y) = \pi(\beta(\varphi_n(y)))$ for $y \in B$, where β is the center of mass defined in (2.4). We claim that for large n we have

$$\beta(\varphi_n(y)) \in \Lambda^+ \quad \text{and} \quad H(\phi_n(y)) \geq c + \frac{\delta}{4} \quad \forall\, y \in B. \tag{2.46}$$

This immediately yields the desired contradiction. In fact, since $\varphi_n(y) = w_{\varepsilon_n,y}$ for $y \in B_0$, it follows that $\phi_n(y) = y$ for $y \in B_0$. Hence $\phi_n \in \Gamma$ and by definition of c, we have

$$c \geq \min_{y\in B} H(\phi_n(y)), \tag{2.47}$$

which is impossible in view of (2.46).

We now prove (2.46). The fact that $\beta(\varphi_n(y)) \in \Lambda^+$ is obtained by slightly modifying the arguments in [5, Lemma 1.1]. Thus, we just need to prove the second statement in (2.46). Suppose it is not true; then there exists $y_n \in B$ such that

$$H(\phi_n(y_n)) \leq c + \frac{\delta}{4}.$$

We can assume that $\phi_n(y_n) \to x_0 \in \bar{\Lambda}$ and then $H(x_0) \leq c + \frac{\delta}{4}$.

Next we apply Corollary 2.1 to the family of functions $u_n = \varphi_n(y_n)$ and obtain that

$$J_\varepsilon(u_n) \geq \varepsilon_n^N \left\{ \frac{1}{2} I(w) - \gamma\varepsilon \left(c + \frac{\delta}{4} \right) + o(\varepsilon) \right\}. \tag{2.48}$$

Comparing (2.45) and (2.48) we get a contradiction and thus Lemma 2.2 is proved. □

By Lemma 2.2, we have by a standard deformation argument the main result of this section, namely, the following proposition.

PROPOSITION 2.6. *The number defined by* (2.8) *is a critical value of* J_ε. *That is, there is a solution* $u_\varepsilon \in H^1$ *to* (2.1) *such that* $J_\varepsilon(u_\varepsilon) = S_\varepsilon$ $\forall$ ε *sufficiently small.*

3. Proof of Theorem 1.1. In this section, we show that the solution u_ε to (2.1) constructed in Proposition 2.6 is a solution of (1.3). The key step is the following proposition.

PROPOSITION 3.1. *If* m_ε *is given by* $m_\varepsilon = \max_{x\in\partial\Omega_0} u_\varepsilon(x)$, *then*

$$\lim_{\varepsilon\to 0} m_\varepsilon = 0. \tag{3.1}$$

Before we prove the above proposition, we need the following lemma.

LEMMA 3.2. *Let* x_ε *be the maximum point of* u_ε; *then we have*

$$\lim_{\varepsilon\to 0} H(x_\varepsilon) \to c,$$

where c *is the max-min value defined in* (1.5).

Proof. By Lemma 2.3, we have

$$J_\varepsilon(u_\varepsilon) = \varepsilon^N \left\{ \frac{1}{2} I(w) - \gamma\varepsilon(N-1)H(x_\varepsilon) + o(\varepsilon) \right\} \tag{3.2}$$

and then

$$\limsup_{\varepsilon\to 0} H(x_\varepsilon) \leq c. \tag{3.3}$$

In fact, assuming the contrary we have $H(x_\varepsilon) \geq c + \frac{\delta}{2}$ for ε and δ small and then we have a similar situation as in (2.45), so that following the arguments given from there we get a contradiction.

On the other hand, let $\delta > 0$ and $\phi_0 \in \Gamma$ be such that

$$\min_{y \in B} H(\phi_0(y)) \geq c - \delta.$$

Then, by (2.5) and the definition of $S_\varepsilon = J_\varepsilon(u_\varepsilon)$, we have

$$\begin{aligned} J_\varepsilon(u_\varepsilon) &\leq \sup_{y \in B} J_\varepsilon(w_{\varepsilon,\phi_0(y)}) \\ &\leq \varepsilon^n \left\{ \frac{1}{2} I(w) - \varepsilon\gamma(N-1) \min_{y \in B} H(\phi_0(y)) + o(\varepsilon) \right\} \\ &\leq \varepsilon^n \left\{ \frac{1}{2} I(w) - \varepsilon\gamma(N-1)(c - \delta) + o(\varepsilon) \right\}. \end{aligned} \tag{3.4}$$

From here and (3.2) we obtain

$$H(x_\varepsilon) \geq c - \delta + o(1).$$

Since δ is arbitrary using (3.3) we then conclude with the proof. □

We are now in a position to prove Proposition 3.1.

Proof of Proposition 3.1. Suppose, on the contrary, that $m_\varepsilon \geq \delta > 0$. Then let $u_\varepsilon(x_\varepsilon) = \max_{x \in \bar{\Omega}} u_\varepsilon(x)$. Then $x_\varepsilon \in \overline{\Lambda}$, $\frac{d(x_\varepsilon, \partial\Lambda)}{\varepsilon} \to b > 0$, and $w(b) = a$, and by Lemma 3.2 $H(x_\varepsilon) \to c$ as $\varepsilon \to 0$. We recall that the function $\tilde{u}_\varepsilon$ satisfies

$$\begin{cases} \Delta\tilde{u}_\varepsilon - \tilde{u}_\varepsilon + f(\tilde{u}_\varepsilon) + \tilde{h}_\varepsilon = 0 \text{ in } \Omega_\varepsilon, \\ \dfrac{\partial \tilde{u}_\varepsilon}{\partial \nu} = 0 \text{ on } \partial\Omega_\varepsilon. \end{cases} \tag{3.5}$$

Let $\hat{T}_\varepsilon$ be a direction, tangent to Λ_ε at $\bar{x}_\varepsilon^p$. We assume that $\hat{T}_\varepsilon$ converges to $\hat{T}_0$ and we observe that $\hat{T}_0 \perp e_N$, with the notational convention given in the proof of Lemma 2.3. Next we multiply (3.5) by $\nabla\tilde{u}_\varepsilon \cdot \hat{T}_\varepsilon$ and we integrate by parts to obtain

$$\int_{\partial\Omega_\varepsilon} \left\{ \frac{|\nabla\tilde{u}_\varepsilon|^2}{2} + \frac{\tilde{u}_\varepsilon^2}{2} - F(\tilde{u}_\varepsilon) \right\} \hat{T}_\varepsilon \cdot \nu = \int_{\Omega_\varepsilon} \tilde{h}_\varepsilon \frac{\partial \tilde{u}_\varepsilon}{\partial \hat{T}_\varepsilon}. \tag{3.6}$$

Using the asymptotic expansion (2.21), integrating by parts again, and using the equation for w we obtain that

$$\begin{aligned} \int_{\partial\Omega_\varepsilon} \frac{\partial w}{\partial \nu} \frac{\partial w}{\partial \hat{T}_\varepsilon} + \varepsilon \int_{\partial\Omega_\varepsilon} \int_0^1 \left\{ \nabla\tilde{u}_\varepsilon(t) \cdot \nabla\tilde{\phi}_\varepsilon + \tilde{u}_\varepsilon(t)\tilde{\phi}_\varepsilon - f(\tilde{u}_\varepsilon(t))\tilde{\phi}_\varepsilon \right\} \hat{T}_\varepsilon \cdot \nu \, dt \\ = \int_{\Omega_\varepsilon} \tilde{h}_\varepsilon \frac{\partial \tilde{u}_\varepsilon}{\partial \hat{T}_\varepsilon}, \end{aligned} \tag{3.7}$$

where $\tilde{u}_\varepsilon(t) = w + t\varepsilon\tilde{\phi}_\varepsilon$. For later reference, we write $I_1 + I_2 = I_3$ above. We first claim that by slightly modifying $\hat{T}_\varepsilon$ we can get $I_3 = 0$. In fact, the normal vector ν near the origin, in a ball of fixed radius $R_0 > 0$, has the form

$$\nu = 0(1 + O(\varepsilon))e_N + \varepsilon \sum_{i=1}^{N-1} \vec{\alpha}_i y_i + o(\varepsilon). \tag{3.8}$$

Thus, taking into account that the support of $\tilde{h}_\varepsilon$ shrinks to a point, that $\tilde{h}_\varepsilon \geq 0$, and that $\tilde{u}_\varepsilon$ converges to w, we perturb $\hat{T}_\varepsilon$ so that $\hat{T}_\varepsilon \perp e_N$ and $I_3 = 0$, and still keep that $\hat{T}_\varepsilon \to \hat{T}_0$.

Next we consider I_2. We observe that

$$\int_{\partial R^N_+} \left\{ \nabla w \cdot \nabla \tilde{\phi}_0 + w\tilde{\phi}_0 - f(w)\tilde{\phi}_0 \right\} y_i = 0, \tag{3.9}$$

since the function $\tilde{\phi}_0$, the solution of (2.27), is even on the boundary and so is w. From here, and taking into account (3.8), (2.28), and the convergence of $\tilde{\phi}_\varepsilon$ to ϕ_0 in $W^{1,q}_{loc}(\Omega_\varepsilon)$, we find that $I_2 = o(\varepsilon^2)$ and thus

$$\int_{\partial\Omega_\varepsilon} \frac{\partial w}{\partial \nu} \frac{\partial w}{\partial \hat{T}_\varepsilon} = o(\varepsilon^2). \tag{3.10}$$

Now we turn to study this last term. For this purpose, we obtain an expansion for derivatives of w near the origin and on the boundary of Ω_ε. A direct calculation, using Taylor expansion of the function w and the local representation the boundary, with the notation given in section 2, gives

$$w_\ell(y, \tilde{\rho}_\varepsilon(y)) = w_\ell(y, 0) + O(\varepsilon^2), \qquad 1 \leq \ell \leq N-1, \tag{3.11}$$

and

$$\frac{\partial u}{\partial \nu}(y, \tilde{\rho}_\varepsilon(y)) = \frac{\varepsilon}{2} \frac{w'}{|y|} (\rho_\varepsilon)_{ij} y_i y_j + \frac{\varepsilon^2}{3} \frac{w'}{|y|} (\rho_\varepsilon)_{ijk} y_i y_j y_k + o(\varepsilon^2). \tag{3.12}$$

Using evenness-oddness properties of these functions, we see that

$$\int_{\partial R^N_+} w_\ell(y, 0) \frac{w'}{|y|} \rho_{ij} y_i y_j = 0,$$

and then, computing the integral on $\partial\Omega_\varepsilon$, we see that for any $R > 0$ we have

$$\int_{\partial\Omega_\varepsilon \cap B(0,R)} w_i(y, 0) \frac{w'}{|y|} (\rho_\varepsilon)_{ij} y_i y_j = O(\varepsilon^2).$$

We also see that

$$\int_{\partial R^N_+} w_\ell(y, 0) \frac{w'}{|y|} \rho_{ijk} y_i y_j y_k = K \rho_{ii\ell}, \tag{3.13}$$

where K is a nonzero constant. Then we conclude that

$$\frac{1}{\varepsilon^2} I_1 = \rho_{ii\ell} \hat{T}^\ell_0 + o(1). \tag{3.14}$$

From here and (3.10), taking the limit as $\varepsilon \to 0$ we find that

$$\nabla H(\bar{x}) \cdot \hat{T}_0 = 0 \tag{3.15}$$

and this contradicts hypothesis (H2). □

Finally we prove Theorem 1.1.

Proof of Theorem 1.1. By (3.1), we have that

$$u_\varepsilon(x) < a \quad \forall\ x \in \partial\Omega_0.$$

Hence u_ε satisfies (1.3) since $f(u_\varepsilon) = \bar{f}(u_\varepsilon)$ for $x \notin \Omega_0$. Since $\varepsilon^{-N} J_\varepsilon(u_\varepsilon) \to \frac{1}{2} I(w)$, by [19] or [23], we have that u_ε has only one local maximum point x_ε and $x_\varepsilon \in \Lambda$. By Lemma 3.2, $\lim_{\varepsilon \to 0} H(x_\varepsilon) = c$. The rest of the proof follows from [19] and [20]. □

Acknowledgments. The authors would like to thank the referees for carefully reading the manuscript. They pointed out several misprints and suggested some changes that made the text clearer. In particular, we thank them for the suggestion that simplified our hypotheses (H1)–(H2).

EXISTENCE OF NONPLANAR SOLUTIONS OF A SIMPLE MODEL OF PREMIXED BUNSEN FLAMES*

ALEXIS BONNET† AND FRANÇOIS HAMEL‡

Abstract. This work deals with the existence of solutions of a reaction-diffusion equation in the plane $\mathbb{R}^2$. The problem, whose unknowns are the real c and the function u, is the following:

$$(P) \qquad \begin{cases} \Delta u - c\dfrac{\partial u}{\partial y} + f(u) = 0 & \text{in } \mathbb{R}^2, \\ \forall \vec{k} \in \mathcal{C}(-\vec{e}_2, \alpha), & u(\lambda\vec{k}) \underset{\lambda\to+\infty}{\longrightarrow} 0, \\ \forall \vec{k} \in \mathcal{C}(\vec{e}_2, \pi-\alpha), & u(\lambda\vec{k}) \underset{\lambda\to+\infty}{\longrightarrow} 1, \end{cases}$$

where $0 < \alpha \leq \pi/2$ is given, $\vec{e}_2 = (-1, 0)$, and, for any angle ϕ and any unit vector $\vec{e}$, $\mathcal{C}(\vec{e}, \phi)$ denotes the open half-cone with angle ϕ around the vector $\vec{e}$. The given function f is of the "ignition temperature" type. In this paper, we show the existence of a solution (c, u) of (P) and we give an explicit formula that relates the speed c and the angle α.

1. Introduction.

Bunsen flames are usually made of two flames: a diffusion flame and a premixed flame (see Figure 1 and the papers by Buckmaster and Ludford [11], Joulin [23], Liñan [27], and Sivashinsky [31], [32]). In this paper, we focus on the study of the premixed Bunsen flame. Roughly speaking, the hot products of the chemical reactions are located above the flame and the fresh gaseous mixture (fuel and oxidant) is located below (see Figure 1). For the sake of simplicity, we can assume that a global chemical reaction takes place in the gaseous mixture:

$$\mathcal{R}: \qquad \text{Fuel} \quad + O_2 \quad \rightarrow \quad \text{Products.}$$

The isotherms (level sets of the temperature) of the premixed Bunsen flame are conical in shape and, far away from the axis of symmetry, the flame is almost planar. The underlying subsonic mass flow goes upward from the fresh zone to the burnt gases with a uniform vertical velocity c.

In this paper, we deal with the stationary states of premixed flames that are invariant by translation in one of the directions orthogonal to the flow. Consequently, the mathematical problem only involves two variables (x, y) (see Figure 1). This situation occurs with Bunsen burners that have a thin rectangular cross section.

Under some additional physical conditions that correspond to the classical thermodiffusive model (see Berestycki and Larrouturou [4], Buckmaster and Ludford [11], Matkowsky and Sivashinsky [29]), the temperature $u(x, y)$, normalized in such a way

that $u \simeq 0$ in the fresh zone and $u \simeq 1$ in the hot zone far from the reaction sheet, solves the following reaction-diffusion equation in $\mathbb{R}^2 = \{(x,y),\ x \in \mathbb{R},\ y \in \mathbb{R}\}$:

$$\Delta u - c\frac{\partial u}{\partial y} + f(u) = 0 \ \text{ in } \mathbb{R}^2, \tag{1.1}$$

with the following limiting conditions at infinity:

$$\forall \vec{k} \in \mathcal{C}(-\vec{e}_2, \alpha), \qquad u(\lambda\vec{k}) \underset{\lambda \to +\infty}{\longrightarrow} 0, \tag{1.2}$$

$$\forall \vec{k} \in \mathcal{C}(\vec{e}_2, \pi - \alpha), \qquad u(\lambda\vec{k}) \underset{\lambda \to +\infty}{\longrightarrow} 1, \tag{1.3}$$

where α is a given angle such that $0 < \alpha \leq \pi/2$. The vector $\vec{e}_2 = (0,1)$ is the unit vector in the direction $[Oy)$ and, for any unit vector $\vec{e}$ and any angle $\phi \in (0,\pi)$, $\mathcal{C}(\vec{e},\phi)$ denotes the open half-cone with aperture ϕ in the direction $\vec{e}$: $\mathcal{C}(\vec{e},\phi) = \{\vec{k} \in \mathbb{R}^2,\ \vec{k}\cdot\vec{e} > \|\vec{k}\|\ \|\vec{e}\| \cos\phi\}$. We also set $\mathcal{C}(z,\vec{e},\phi) = z + \mathcal{C}(\vec{e},\phi)$ for any point $z = (x,y) \in \mathbb{R}^2$.

The unknowns of this problem (1.1)–(1.3) are both the real c, which is like a nonlinear eigenvalue, and the function u, $0 < u < 1$, of class C^2 in $\mathbb{R}^2$. We shed light here on the fact that looking for the speed c, the angle α being known, is equivalent to looking for the angle α, the speed c being known, as is the case in experiments (see the comments after Theorem 1.2 below).

The function $1 - u$ also represents the relative concentration of the reactant. In (1.1), the terms Δu, $c\frac{\partial u}{\partial y}$, and $f(u)$ are, respectively, the diffusion, transport, and source terms. The source term $f(u)$, which may take into account the Arrhénius law and the mass action law, is given and Lipschitz continuous in $[0,1]$. Furthermore, one assumes that it is of the "ignition temperature" type:

$$\text{(1.4)}\ \exists\theta \in (0,1) \text{ such that } f \equiv 0 \text{ on } [0,\theta] \cup \{1\}, \quad f > 0 \text{ on } (\theta,1) \text{ and } f'(1) < 0.$$

For mathematical convenience, we extend f by 0 outside the interval $[0,1]$. The temperature θ is an ignition temperature, below which no chemical reaction happens.

In the one-dimensional case, the problem is reduced to

$$\begin{cases} u'' - c_0 u' + f(u) = 0, \\ u(-\infty) = 0,\ u(+\infty) = 1. \end{cases} \tag{1.5}$$

There have been many works devoted to the solutions of (1.5). We refer to the pioneering articles of Kolmogorov, Petrovsky, and Piskunov [26] for biological models, Zeldovich and Frank-Kamenetskii [37] for planar flames, as well as other papers by Aronson and Weinberger [2], Fife [14], Fife and McLeod [15], and Kanel' [24]. The main result is the following: if the function f fulfils (1.4), then there exist a unique real c_0 and a unique function $U(\xi)$ (up to translation with respect to ξ) which are solutions of (1.5). The real c_0 is positive and the function U is increasing in ξ. We may suppose that $U(0) = \theta$.

In more recent papers, multidimensional curved flames in infinite cylinders $\Sigma = \mathbb{R}\times\omega = \{(x_1, y),\, x_1 \in \mathbb{R},\, y \in \omega\}$, with smooth cross sections ω, have been investigated. In this case, the temperature $u(x, y)$ solves the equations

$$\left\{\begin{array}{rll} \Delta u - (c + \alpha(y))\dfrac{\partial u}{\partial x_1} + f(u) & = 0 & \text{in } \Sigma, \\ u(-\infty, \cdot) = 0,\ u(+\infty, \cdot) & = 1, & \\ \dfrac{\partial u}{\partial \nu} & = 0 & \text{on } \partial\Sigma, \end{array}\right. \tag{1.6}$$

where ν is the outward unit normal to $\partial\omega$ and $\alpha(y)$ is the x_1-component of the given underlying flow (see Berestycki and Larrouturou [5]; Berestycki, Larrouturou, and Lions [6]; Berestycki and Nirenberg [9]; Vega [33]; Volpert and Volpert [34]; and Xin [36] under periodic conditions). If $\alpha(y) = \alpha_0$ does not depend on y, it is known that (1.6) has a unique solution and that it is planar; namely, it depends only on the longitudinal variable x_1. If the function $y \mapsto \alpha(y)$ is not constant, the solution of (1.6) still exists and is unique, but it is not planar anymore (such solutions correspond to curved flames). Nonplanar flames may also be observed in infinite cylinders under different physical conditions: Glangetas and Roquejoffre [18] and Margolis and Sivashinsky [28] proved that if the single partial differential equation in (1.6) was replaced with a system of two reaction-diffusion equations, then a bifurcation toward nonplanar flames might occur.

Let us now come back to the question of the existence of solutions (c, u) of the problem (1.1)–(1.3). If $\alpha = \pi/2$, the couple (c_0, U) is obviously a solution. The question of the existence of solutions if $\alpha < \pi/2$ has so far remained open. In this paper, we show the existence of a speed c and of a nonplanar—if $\alpha < \pi/2$—function u defined in $\mathbb{R}^2$, which are solutions of (1.1)–(1.3). As a consequence, nonplanar flames exist for the model (1.1)–(1.3) although this model involves only one reaction-diffusion equation (and not two such equations) and although the underlying flow is uniform.

In this paper, we prove two main theorems. The first one states the existence of a solution (c, u) of (1.1)–(1.3) for any angle $0 < \alpha \le \pi/2$. The second one deals with the question of the speed c's uniqueness.

Theorem 1.1. *Let f fulfill* (1.4) *("ignition temperature" profile). For any $\alpha \in (0, \pi/2]$, there exists a solution (c, u) of* (1.1)–(1.3)*, namely,*

$$\left\{\begin{array}{lrl} & \Delta u - c\dfrac{\partial u}{\partial y} + f(u) = & 0 \quad \textit{in } \mathbb{R}^2, \\ \forall \vec{k} \in \mathcal{C}(-\vec{e}_2, \alpha), & u(\lambda\vec{k}) \underset{\lambda\to+\infty}{\longrightarrow} & 0, \\ \forall \vec{k} \in \mathcal{C}(\vec{e}_2, \pi - \alpha), & u(\lambda\vec{k}) \underset{\lambda\to+\infty}{\longrightarrow} & 1, \end{array}\right.$$

such that

$$c = \frac{c_0}{\sin\alpha}. \tag{1.7}$$

Furthermore, $0 < u < 1$, u *is symmetric with respect to the variable* x, *and* u *is decreasing in any direction* $\vec{k} \in \mathcal{C}(-\vec{e}_2, \alpha)$. *The following limiting conditions, which are stronger than* (1.2)–(1.3), *also hold:*

$$u(\lambda \vec{k}') \to 0 \quad \text{as } \lambda \to +\infty \text{ and } \vec{k}' \to \vec{k} \in \mathcal{C}(-\vec{e}_2, \alpha), \tag{1.8}$$

$$u(\lambda \vec{k}') \to 1 \quad \text{as } \lambda \to +\infty \text{ and } \vec{k}' \to \vec{k} \in \mathcal{C}(\vec{e}_2, \pi - \alpha). \tag{1.9}$$

Finally, for each $\lambda \in (0,1)$, *the level set* $\{(x,y),\ u(x,y) = \lambda\}$ *is a curve* $\{y = \varphi_\lambda(x), x \in \mathbb{R}\}$ *and it has two asymptotic directions that are directed by the vectors* $(\pm \sin\alpha, -\cos\alpha)$. *If* $x_n \to -\infty$, *then the functions* $u_n(x,y) = u(x + x_n, y + \varphi_\lambda(x_n))$ *converge locally to the planar function* $U(y \sin\alpha - x\cos\alpha + U^{-1}(\lambda))$.

THEOREM 1.2. *Let* f *fulfill* (1.4) *and* α *be an angle in* $(0, \pi/2]$. *If* (c,u) *is a solution of* (1.1) *and* (1.8)–(1.9), *then*

$$c = \frac{c_0}{\sin\alpha}.$$

We can see that the speed $c = c_0/\sin\alpha$ of the nonplanar flame (for $\alpha < \pi/2$) is greater than the speed c_0 of the planar flame. Furthermore, the angle α is all the smaller as the speed c is larger. That is physically meaningful since the curvature of the flame increases with the speed of the fuel flow. It is worth noticing that the formula (1.7) has been known for a long time and had been formally derived from the planar behavior of the flame, far away from its center, along the directions $(\pm \sin\alpha, -\cos\alpha)$. This formula had been used in experiments to find the planar speed c_0: indeed, the vertical speed c of the gases at the exit of the Bunsen burner being known, one can measure the angle α and the one-dimensional speed c_0 is then given by the formula $c_0 = c \sin\alpha$ (see [31], Williams [35]).

Hence, the results of Theorems 1.1 and 1.2 are not surprising. Nevertheless, they are the first rigorous analysis of the conical premixed Bunsen flames.

REMARK 1.3. *From Theorem* 1.1, *there is a continuum of solutions* $(c_0/\sin\alpha, u)$ *solving* (1.1) *and satisfying the simple asymptotic limits* $u(x, -\infty) = 0$ *and* $u(x, +\infty) = 1$ *for all* $x \in \mathbb{R}$. *This is in contrast with problem* (1.6) *mentioned above. However, if the limits* $u(x,-\infty) = 0$ *and* $u(x, +\infty) = 1$ *are uniform with respect to* $x \in \mathbb{R}$, *then* (c_0, U) *will be the unique solution of* (1.1) *up to translation in the variables* (x, y) *for* U *(see Hamel and Monneau* [21]*).*

Open questions.

(1) For each fixed angle $\alpha \in]0, \pi/2]$, do all the solutions u of (1.1)–(1.3) have the same profile? What kind of a priori monotonicity or symmetry properties do they fulfill? Are they stable for the evolution problem $\partial_t u = \Delta u - c\partial_y u + f(u)$? Answers to some of those questions are given in [21].

(2) Is there any solution (c,u) to (1.1)–(1.3) if $\alpha > \pi/2$? The answer is no and is given in [21].

(3) Is there any solution (c,u) to the free boundary problem equivalent to (1.1)–(1.3) and obtained in the limit of "high activation energies"? The answer is yes (see Hamel and Monneau [22]).

(4) Are there three-dimensional flames and, if so, are they necessarily invariant by rotation?

Structure of the paper. Section 2 is devoted to solving problems that are similar to (1.1)–(1.3) but are set in finite rectangles $[-a, a] \times [-a \cot\gamma_a, a \cot\gamma_a]$ where

γ_a is an angle close to α. For those problems, some a priori estimates about the speeds c_a and the functions u_a are established. A technical lemma, which is proved in the Appendix (section 5), is devoted to determining the behavior of the functions u_a near the corners of the rectangles. In section 3, we pass to the limit $a \to \infty$ in the whole plane and we determine the shape of the level sets of the limit function u by resorting to arguments of the "sliding method" type. In section 4, we prove Theorem 1.2.

REMARK 1.4. *The proof of Theorem* 1.1*, which is detailed in the next sections, actually allows us to get an independent result about the following problem set in an infinite strip* $\Sigma = \{(x,y) \in (-L,L) \times \mathbb{R}\}$ *with oblique Neumann boundary conditions:*

$$\begin{cases} \Delta u - c\partial_y u + f(u) = & 0 \text{ in } \Sigma, \\ \forall y \in \mathbb{R}, \quad \partial_\tau u(-L,y) = \partial_{\tilde{\tau}} u(L,y) = & 0, \\ u(\cdot,-\infty) = 0, \ u(\cdot,+\infty) = & 1, \end{cases} \tag{1.10}$$

where $\tau = (-\sin\alpha, -\cos\alpha)$ *and* $\tilde{\tau} = (\sin\alpha, -\cos\alpha)$*. Namely, with the same method as for Theorem* 1.1*, it follows that there exists a solution* (c,u) *to* (1.10) *such that the function* u *is nondecreasing in each direction* $\rho \in \overline{\mathcal{C}(\vec{e}_2,\alpha)}$*.*

2. Solving equivalent problems in finite rectangles. Let us set any real $a > 1/\alpha^2$ and $\gamma_a = \alpha - 1/\sqrt{a}$. The angle γ_a is such that $0 < \gamma_a < \alpha$, $\gamma_a \to \alpha$ and $a(\cot\gamma_a - \cot\alpha) \to +\infty$ as $a \to +\infty$. Let Σ_a be the bounded and open rectangle $\Sigma_a = (-a,a)\times(-a\cot\gamma_a, a\cot\gamma_a)$. Call $\tau = (-\sin\alpha, -\cos\alpha)$ and $\tilde{\tau} = (\sin\alpha, -\cos\alpha)$ (see Figure 2). When there is no confusion, γ_a is often replaced with γ.

In this section, we focus on the questions of the existence and the uniqueness as well as on a priori estimates of the solutions (c_a, u_a) to the following problem:

$$\begin{cases} \Delta u_a - c_a\partial_y u_a + f(u_a) = & 0 \text{ in } \Sigma_a, \\ \forall x \in [-a,a], \quad u_a(x,-a\cot\gamma_a) = 0, \ u_a(x,a\cot\gamma_a) = & 1, \\ \forall y \in (-a\cot\gamma_a, a\cot\gamma_a), \quad \dfrac{\partial u_a}{\partial\tau}(-a,y) = \dfrac{\partial u_a}{\partial\tilde{\tau}}(a,y) = & 0 \end{cases} \tag{2.1}$$

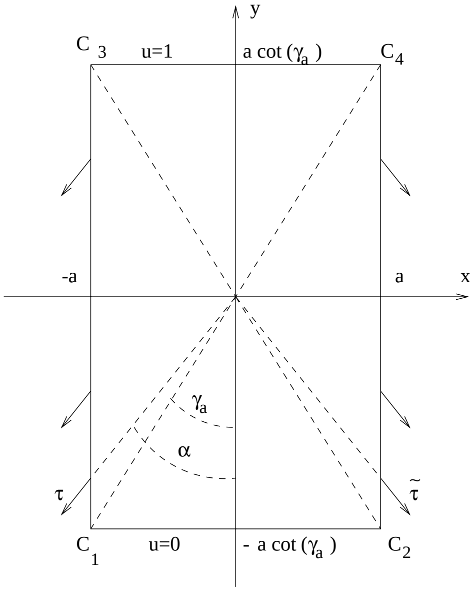

FIG. 2. *The rectangle* Σ_a*.*

under the following normalization condition:

$$\max_{\substack{y=-\cot\alpha\ \ |x| \\ -a\le x\le a}} u_a(x,y)=\theta. \tag{2.2}$$

2.1. Existence of solutions of (2.1)–(2.2) and a priori bounds for the speeds c_a.

2.1.1. On the solutions u_c of (2.1). Let c be any fixed real. Let us call $(C_i)_{1\le i\le 4}$ the four corners of Σ_a: $C_1=(-a,-a\cot\gamma)$, $C_2=(a,-a\cot\gamma)$, $C_3=(-a,a\cot\gamma)$, $C_4=(a,a\cot\gamma)$ (see Figure 2) and set $\tilde{\Sigma}_a=\overline{\Sigma_a}\setminus\cup_{i=1}^{4}\{C_i\}$.

Now consider the following Dirichlet–Neumann problem:

$$\left\{\begin{array}{r}\Delta u-c\partial_y u+f(u)=0\qquad\text{in }\Sigma_a,\\ \forall x\in[-a,a],\quad u(x,-a\cot\gamma)=0,\ u(x,a\cot\gamma)=1,\\ \forall y\in(-a\cot\gamma,a\cot\gamma),\quad \partial_\tau u(-a,y)=\partial_{\tilde{\tau}}u(a,y)=0.\end{array}\right. \tag{2.3}$$

This problem is the same as (2.1), but the speed c is given in (2.3) and only the function u is unknown. The following three lemmas are similar to some of the results in a paper by Berestycki and Nirenberg [7]. The proofs, which will be used several times in the sequel, are written for the sake of completeness.

LEMMA 2.1. *For each speed $c\in\mathbb{R}$, we have that problem* (2.3) *has a solution u_c in $\cap_{p>1}W^{2,p}_{loc}(\tilde{\Sigma}_a)\cap\ C(\overline{\Sigma_a})$, where $C(\overline{\Sigma_a})$ is the space of all continuous functions in $\overline{\Sigma_a}$.*

Proof. Let $(\Sigma_{a,\varepsilon})_{\varepsilon>0}$ be a sequence of bounded and smooth domains such that, for each $\varepsilon>0$,

$$\Sigma_a\setminus\bigcup_{i=1}^{4}B(C_i,\varepsilon)\ \subset\ \Sigma_{a,\varepsilon}\ \subset\ \Sigma_a,$$

where $B(C_i,\varepsilon)$ denotes the open ball centered on the point C_i with radius ε. Let $\varepsilon>0$ be small enough. Consider a smooth vector field $\rho_\varepsilon(x,y)$ defined on $\partial\Sigma_{a,\varepsilon}$ such that $\rho_\varepsilon\cdot\nu_\varepsilon\ge 0$ on $\partial\Sigma_{a,\varepsilon}$ (where ν_ε is the outward unit normal to $\partial\Sigma_{a,\varepsilon}$) $\rho_\varepsilon=\tau$ on $\{-a\}\times(-a\cot\gamma\ +\varepsilon,a\cot\gamma\ -\varepsilon)$, $\rho_\varepsilon=\tilde{\tau}$ on $\{a\}\times(-a\cot\gamma\ +\varepsilon,a\cot\gamma\ -\varepsilon)$, and $\rho_\varepsilon=\vec{0}$ on $(-a+\varepsilon,a-\varepsilon)\times\{\pm a\cot\gamma\}$. Let $\sigma_{0,\varepsilon}(x,y)$ be a smooth nonnegative function defined on $\partial\Sigma_{a,\varepsilon}$ such that $\sigma_{0,\varepsilon}=1$ on $\partial\Sigma_{a,\varepsilon}\cap\{y\le -a\cot\gamma\ +\varepsilon\}$ and $\sigma_{0,\varepsilon}=0$ on $\partial\Sigma_{a,\varepsilon}\cap\{y\ge -a\cot\gamma\ +2\varepsilon\}$. Last, let $\sigma_{1,\varepsilon}$ be a smooth nonnegative function defined on $\partial\Sigma_{a,\varepsilon}$ such that $\sigma_{1,\varepsilon}=1$ on $\partial\Sigma_{a,\varepsilon}\cap\{y\ge a\cot\gamma\ -\varepsilon\}$ and $\sigma_{1,\varepsilon}=0$ on $\partial\Sigma_{a,\varepsilon}\cap\{y\le a\cot\gamma\ -2\varepsilon\}$. For each $\varepsilon>0$ small enough, the problem

$$\left\{\begin{array}{r}\Delta u_\varepsilon-c\partial_y u_\varepsilon+f(u_\varepsilon)=0\quad\text{in }\Sigma_{a,\varepsilon},\\ \rho_\varepsilon\cdot\nabla u+\sigma_{0,\varepsilon}u+\sigma_{1,\varepsilon}(u-1)=0\quad\text{on }\partial\Sigma_{a,\varepsilon}\end{array}\right.$$

has a solution u_ε such that $0\le u_\varepsilon\le 1$ since 0 and 1, respectively, are sub- and supersolutions (see Berestycki and Nirenberg [7]).

From the standard elliptic estimates up to the boundary (Agmon, Douglis, and Nirenberg [1]; Gilbarg and Trudinger [17]), up to extraction of some subsequence, the functions u_ε approach a function $u_c\in\bigcap\limits_{p>1}W^{2,p}_{loc}(\tilde{\Sigma}_a)\ \cap\ C_{loc}(\tilde{\Sigma}_a)$ as $\varepsilon\to 0$. The function u_c is a solution of

$$\left\{\begin{array}{r}\Delta u_c-c\partial_y u_c+f(u_c)=0\qquad\text{in }\Sigma_a,\\ \forall x\in(-a,a),\quad u_c(x,-a\cot\gamma)=0,\ u_c(x,a\cot\gamma)=1,\\ \forall y\in(-a\cot\gamma,a\cot\gamma),\quad \partial_\tau u_c(-a,y)=\partial_{\tilde{\tau}}u_c(a,y)=0.\end{array}\right. \tag{2.4}$$

Furthermore, we claim that, for each $i \in \{1, \dots, 4\}$, there exists a function $\overline{v}_i$ defined in a neighborhood V_i of the corner C_i such that $\overline{v}_i(C_i) = 0$ and, for all $\varepsilon > 0$ small enough,

$$\begin{array}{lrl} \text{if } i = 1 \text{ or } 2, & u_\varepsilon(x,y) & \leq \overline{v}_i(x,y) \\ \text{if } i = 3 \text{ or } 4, & 1 - u_\varepsilon(x,y) & \leq \overline{v}_i(x,y) \end{array} \quad \text{in } V_i \cap \overline{\Sigma_{a,\varepsilon}}. \tag{2.5}$$

The proof of this fact is temporarily postponed and will be given in Remark 5.2 in section 5.

As a consequence, the function u_c can be extended by continuity at the four corners C_i of Σ_a. In other words, $u_c \in \cap_{p>1} W^{2,p}_{loc}(\tilde{\Sigma}_a) \cap C(\overline{\Sigma_a})$. From the strong maximum principle and the Hopf lemma, it also follows that $0 < u_c < 1$ in $[-a,a] \times (-a\cot\gamma, a\cot\gamma)$. □

Lemma 2.2. *The function u_c is increasing in y and it is the unique solution of (2.3) in $\cap_{p>1} W^{2,p}_{loc}(\tilde{\Sigma}_a) \cap C(\overline{\Sigma_a})$. Furthermore, if f is of class C^1, then $\partial_y u_c > 0$ in $\tilde{\Sigma}_a$.*

Proof. It is based on the sliding method (see [7]). Let u be any solution of (2.3) in $\cap_{p>1} W^{2,p}_{loc}(\tilde{\Sigma}_a) \cap C(\overline{\Sigma_a})$. For any $\lambda \in (0, 2a\cot\gamma)$, let v^λ be the function defined by $v^\lambda(x,y) = u(x, y-\lambda) - u(x,y)$ in the set

$$\Sigma^\lambda_a = (-a,a) \times (-a\cot\gamma + \lambda, a\cot\gamma). \tag{2.6}$$

Since u is uniformly continuous on the compact set $\overline{\Sigma_a}$ and since $u(\cdot, -a\cot\gamma) = 0$, $u(\cdot, a\cot\gamma) = 1$, there exists $\varepsilon > 0$ small enough such that v^λ is negative in $\overline{\Sigma^\lambda_a}$ for all λ in $[2a\cot\gamma - \varepsilon, 2a\cot\gamma)$.

Let us now decrease λ. Suppose that there exists $\lambda^* > 0$ such that $v^\lambda < 0$ in $\overline{\Sigma^\lambda_a}$ for all $\lambda \in (\lambda^*, 2a\cot\gamma)$ and $v^{\lambda^*} \leq 0$ in $\overline{\Sigma^{\lambda^*}_a}$ with equality somewhere at a point $(\overline{x}, \overline{y}) \in \overline{\Sigma^{\lambda^*}_a}$. Since $0 < u < 1$ in $[-a,a] \times (-a\cot\gamma, a\cot\gamma)$, the function v^{λ^*} is negative at the "bottom" $[-a,a] \times \{-a\cot\gamma + \lambda^*\}$ of the boundary of $\Sigma^{\lambda^*}_a$. Similarly, the function v^{λ^*} is negative at the "top" $[-a,a] \times \{a\cot\gamma\}$ of the boundary of $\Sigma^{\lambda^*}_a$. We also have $\partial_\tau v^{\lambda^*}(-a,y) = \partial_{\tilde{\tau}} v^{\lambda^*}(a,y) = 0$ for all $y \in (-a\cot\gamma + \lambda^*, a\cot\gamma)$. The nonpositive function v^{λ^*} satisfies the elliptic equation

$$\Delta v^{\lambda^*} - c\partial_y v^{\lambda^*} + c(x,y) v^{\lambda^*} = 0 \quad \text{in } \Sigma^{\lambda^*}_a,$$

where the function $c(x,y)$ is bounded in $\Sigma^{\lambda^*}_a$ because of the Lipschitz continuity of f. Since $v^{\lambda^*}(\overline{x}, \overline{y}) = 0$ at a point $(\overline{x}, \overline{y}) \in \overline{\Sigma^{\lambda^*}_a}$, we then conclude from the strong maximum principle (if $-a < \overline{x} < a$) or from the Hopf lemma (if $\overline{x} = \pm a$) that $v^{\lambda^*} \equiv 0$ in $\overline{\Sigma^{\lambda^*}_a}$. That is ruled out by the boundary conditions on $[-a,a] \times \{-a\cot\gamma + \lambda^*, a\cot\gamma\}$.

Hence, there is no such $\lambda^* > 0$. We finally conclude that

$$\forall 0 < \lambda < 2a\cot\gamma, \quad u^\lambda(x,y) = u(x, y-\lambda) < u(x,y) \ \text{ in } \overline{\Sigma^\lambda_a}.$$

This yields that for any $x \in [-a,a]$, the function $y \mapsto u(x,y)$ is strictly increasing with respect to $y \in [-a\cot\gamma, a\cot\gamma]$.

If f is of class C^1, we can differentiate the equation satisfied by u. From the strong maximum principle and the Hopf lemma, it follows that $\partial_y u > 0$ in $\tilde{\Sigma}_a$.

The second part of Lemma 2.2, namely, the uniqueness of the solution u_c of (2.3) in $\cap_{p>1} W^{2,p}_{loc}(\tilde{\Sigma}_a) \cap C(\overline{\Sigma_a})$, could be proved in the same way. Indeed, if there were two solutions u_c and u'_c, we would find as above that $u_c(x, y-\lambda) < u'_c(x,y)$ in $\overline{\Sigma^\lambda_a}$ for all $\lambda \in (0, 2a\cot\gamma)$, whence $u_c \le u'_c$ in $\overline{\Sigma_a}$. Changing u_c and u'_c, we have $u'_c \le u_c$ and finally $u_c = u'_c$. □

Corollary 2.3. *For each c, the function u_c is symmetric with respect to x.*

Proof. Indeed, if u_c denotes the unique solution of (2.3), the function $\tilde{u}(x,y) = u_c(-x,y)$ is also a solution. By uniqueness, we have $\tilde{u} = u_c$. □

Lemma 2.4. *The functions u_c are decreasing and continuous, with respect to c, in the spaces $W^{2,p}_{loc}(\tilde{\Sigma}_a) \cap C(\overline{\Sigma_a})$ in the following sense: if $c < c'$, then $u_c > u_{c'}$ in $[-a,a] \times (-a\cot\gamma, a\cot\gamma)$ and if $c \to c_0$, then $u_c \to u_{c_0}$ in $\cap_{p>1} W^{2,p}_{loc}(\tilde{\Sigma}_a) \cap C(\overline{\Sigma_a})$.*

Proof. Choose any c and c' such that $c < c'$. We have to prove that $u_c > u_{c'}$ in $[-a,a] \times (-a\cot\gamma, a\cot\gamma)$. For each $0 < \lambda < 2a\cot\gamma$, we define the function $v^\lambda(x,y) = u_{c'}(x, y-\lambda) - u_c(x,y)$ in Σ_a^λ (see definition (2.6)).

If λ is close enough to $2a\cot\gamma$, we have $v^\lambda < 0$ in $\overline{\Sigma_a^\lambda}$ thanks to the boundary conditions fulfilled by u_c and $u_{c'}$. Let us now suppose that there exists $\lambda^* > 0$ such that $v^\lambda < 0$ in $\overline{\Sigma_a^\lambda}$ for all $\lambda \in (\lambda^*, 2a\cot\gamma)$ and $v^{\lambda^*} \le 0$ with equality somewhere in $\overline{\Sigma_a^{\lambda^*}}$. The function v^{λ^*} satisfies

$$(2.7) \qquad \begin{cases} \Delta v^{\lambda^*} - c\partial_y v^{\lambda^*} + c(x,y)v^{\lambda^*} & = (c'-c)\partial_y u_{c'}(x, y-\lambda^*) \ \text{ in } \Sigma_a^{\lambda^*}, \\ \quad \partial_\tau v^{\lambda^*}(-a,y) = \partial_{\tilde{\tau}} v^{\lambda^*} & = 0 \quad \forall y \in (-a\cot\gamma + \lambda^*, a\cot\gamma) \end{cases}$$

for a bounded function $c(x,y)$. On the one hand, since $c < c'$ and $\partial_y u_{c'} \ge 0$ (from the first part of Lemma 2.2), it follows from the strong maximum principle and the Hopf lemma that $v^{\lambda^*} \equiv 0$ in $\overline{\Sigma_a^{\lambda^*}}$. On the other hand, since $0 < u_c, u_{c'} < 1$ in $[-a,a] \times (-a\cot\gamma, a\cot\gamma)$, we have $v^{\lambda^*} < 0$ on $[-a,a] \times \{-a\cot\gamma + \lambda^*, a\cot\gamma\}$. That eventually leads to a contradiction.

Hence, for all $\lambda \in (0, 2a\cot\gamma)$, we have

$$v^\lambda = u_{c'}(x, y-\lambda) - u_c(x,y) < 0 \text{ in } \overline{\Sigma_a^\lambda}.$$

Then, $u_c \ge u_{c'}$ in $\overline{\Sigma_a}$. Since $v^0 = u_{c'} - u_c$ satisfies equation (2.7), the strong maximum principle and the Hopf lemma yield that $u_c > u_{c'}$ in $[-a,a] \times (-a\cot\gamma, a\cot\gamma)$.

Now, consider a sequence (c_n) such that $c_n \to c_0 \in \mathbb{R}$ as $n \to +\infty$. From the standard elliptic estimates up to the boundary, and up to extraction of some subsequence, the functions u_{c_n} approach a function $\tilde{u}_{c_0} \in \cap_{p>1} W^{2,p}_{loc}(\tilde{\Sigma}_a) \cap C_{loc}(\tilde{\Sigma}_a)$. The function $\tilde{u}_{c_0}$ is a solution of (2.4) with the speed c_0. Furthermore, for each $i \in \{1, \ldots, 4\}$, there exists a function $\overline{v}_i$ defined in a neighborhood V_i of the corner C_i, such that $\overline{v}_i(C_i) = 0$ and, for n large enough,

$$(2.8) \qquad \begin{array}{llll} \text{if } i = 1 \text{ or } 2, & u_{c_n}(x,y) & \le \overline{v}_i(x,y) & \multirow{2}{*}{} \\ \text{if } i = 3 \text{ or } 4, & 1 - u_{c_n}(x,y) & \le \overline{v}_i(x,y) & \end{array} \quad \text{in } V_i \cap \overline{\Sigma_a}$$

(see Remark 5.2). Hence, the function $\tilde{u}_{c_0}$ can be extended by continuity at the four corners C_i. As a consequence, $\tilde{u}_{c_0} = u_{c_0}$. Furthermore, since the functions u_{c_n} approach u_{c_0} in any compact subset of $\tilde{\Sigma}_a$, the above estimates around the four corners C_i also imply that u_{c_n} approach u_{c_0} uniformly in $\overline{\Sigma_a}$. Finally, since the limit function u_{c_0} is unique, it follows that the whole sequence (u_{c_n}) approaches u_{c_0} as $n \to +\infty$. □

2.1.2. Estimating the speeds.

In this subsection, we aim at establishing some a priori estimates for the speeds c_a of the possible solutions (c_a, u_a) of (2.1)–(2.2).

We first need some preliminary results about the speeds of some one-dimensional traveling fronts. Remember that the function f has been extended by 0 outside $[0,1]$.

Let $f'_-(1) = \lim_{t\to 1,\ t<1} \frac{f(t)}{t-1}$. For each $0 < \eta < \min(1-\theta, |f'_-(1)|)$, let f_η be a C^1 function in $[0,1]$, fulfilling (1.4) with the ignition temperature $\theta + \eta$, such that $f'_\eta(1) = f'_-(1) + \eta$, $f - \eta \le f_\eta \le f$ in $[0,1]$, and $f_\eta < f$ in $(\theta, 1)$. As for f, we also extend f_η by 0 outside $[0,1]$. From the results in [2], [9], [15] and [24], there exists a unique real c_0^η and a unique function u_η solving

$$\left\{\begin{array}{rl} u''_\eta - c_0^\eta u'_\eta + f_\eta(u_\eta) = 0 & \text{in } \mathbb{R}, \\ u_\eta(-\infty) = -\eta,\ u_\eta(0) = \theta,\ u_\eta(+\infty) = 1. & \end{array}\right.$$

Moreover, $u'_\eta > 0$ in $\mathbb{R}$. With the same arguments as in the paper by Berestycki and Nirenberg [9], it also follows that $c_0^\eta \overset{\le}{\to} c_0$ as $\eta \to 0$ (remember that c_0 is the unique speed for which (1.5) has a solution).

LEMMA 2.5. *Under the above notation, there exists a real $a_1(\eta) > 0$ such that if $a \ge a_1(\eta)$ and if $c < c_0^\eta/\sin\alpha$, then $\theta < \max_{\substack{y=-\cot\alpha\ |x| \\ |x|\le a}} u_c$.*

Proof. Assume that c is such that $c < c_0^\eta/\sin\alpha$. Let u_c be the solution of (2.3) and set $v(x,y) = u_\eta(\cos\alpha\ x + \sin\alpha\ y)$ in Σ_a. We want to prove that if a is large enough, then this function v is a subsolution of problem (2.3).

We have

$$\begin{array}{rl} \Delta v - c\partial_y v + f(v) & = u''_\eta - c\sin\alpha\ u'_\eta + f(u_\eta) \\ & = (c_0^\eta - c\sin\alpha)u'_\eta(\cos\alpha\ x + \sin\alpha\ y) + f(u_\eta) - f_\eta(u_\eta) \\ & > 0 \ \text{ in } \Sigma_a \end{array}$$

since $c < c_0^\eta/\sin\alpha$, $u'_\eta > 0$, and $f \ge f_\eta$. Furthermore, for all $y \in (-a\cot\gamma_a, a\cot\gamma_a)$, we can see that

$$\partial_\tau v(-a,y) = -2\sin\alpha\cos\alpha\ u'_\eta(-a\cos\alpha + \sin\alpha\ y) \le 0$$

and that $\partial_{\tilde\tau} v(a,y) = 0$. At the "top"of the boundary of Σ_a, we have $v(x, a\cot\gamma_a) < 1$ for all $x \in [-a,a]$. At the "bottom" of the boundary of Σ_a, the function v is equal to

$$v(x, -a\cot\gamma_a) = u_\eta(\cos\alpha\ x - a\cot\gamma_a\ \sin\alpha).$$

Since $|x| \le a$, it follows that

$$\cos\alpha\ x - a\cot\gamma_a\sin\alpha \le (\cos\alpha - \cot\gamma_a\sin\alpha)\ a \to -\infty \text{ as } a \to +\infty$$

since $\gamma_a = \alpha - 1/\sqrt{a}$ for $a > 1/\alpha^2$. On the other hand, the function u_η is increasing and $u_\eta(\xi) \to -\eta$ as $\xi \to -\infty$. Consequently, there exists a real $a_1(\eta)$ such that

$$(a \ge a_1(\eta)) \implies (\forall x \in [-a,a],\ v(x, -a\cot\gamma) < 0).$$

Hence, if $c < c_0^\eta/\sin\alpha$ and if $a \ge a_1(\eta)$, the function v is a subsolution of problem (2.3). Remember now that the function u_c is a solution of (2.3). As in the proof of the monotonicity result in Lemma 2.2, we can compare the functions v and u_c by using a sliding method. We would find that $v < u_c$ in Σ_a. This yields that $v(0,0) = \theta < u_c(0,0)$, whence $\theta < \max_{\substack{y=-\cot\alpha\ |x| \\ |x|\le a}} u_c$. That completes the proof of Lemma 2.5. □

The next lemma states that if the speed c is large enough, then the solution u_c of (2.3) will be below θ on the set $\{y = -\cot\alpha\ |x|,\ |x| \le a\}$. Before doing that, we need a few auxiliary notation. For any $\varepsilon \in (0,\theta)$, let f^ε be a C^1 function in

$[0,1+\varepsilon]$ such that $f^\varepsilon \equiv 0$ in $(-\infty,\theta-\varepsilon]\cup[1+\varepsilon,+\infty)$, $f^\varepsilon > 0$ in $(\theta-\varepsilon,1+\varepsilon)$, $(f^\varepsilon)'_-(1+\varepsilon) := \lim_{t\to 1+\varepsilon,\ t<1+\varepsilon} \frac{f^\varepsilon(t)}{t-1-\varepsilon}$ exists and is negative. In other words, f^ε fulfills the assertion (1.4) on the interval $[0,1+\varepsilon]$ with the ignition temperature $\theta-\varepsilon$. Moreover, one assumes that $f \le f^\varepsilon \le f+\varepsilon$ in $\mathbb{R}$ and $f < f^\varepsilon$ in $[\theta,1]$. From the results in [2], [9], [15] and [24], there exists a unique real $\tilde c_0^\varepsilon$ and a unique function u^ε defined in $\mathbb{R}$ such that

$$\left\{\begin{array}{ll} (u^\varepsilon)'' - \tilde c_0^\varepsilon (u^\varepsilon)' + f^\varepsilon(u^\varepsilon) & = 0 \text{ in } \mathbb{R}, \\ u^\varepsilon(-\infty)=0,\ u^\varepsilon(0)=\theta,\ u^\varepsilon(+\infty) & = 1+\varepsilon. \end{array}\right.$$

Moreover, one has $(u^\varepsilon)' > 0$ in $\mathbb{R}$ and $\tilde c_0^\varepsilon \overset{>}{\to} c_0$ as $\varepsilon \to 0$ (see [9]).

LEMMA 2.6. *There exists a real $a_2(\varepsilon)$ such that if $a \ge a_2(\varepsilon)$ and if $c > \tilde c_0^\varepsilon/\sin^2\alpha$, then $\theta > \max_{\substack{y=-\cot\alpha\ |x| \\ |x|\le a}} u_c$.*

Proof. Let c be a real such that $c > \tilde c_0^\varepsilon/\sin^2\alpha$. Let us set

$$\beta = \frac{3\cot\alpha}{2(c-\tilde c_0^\varepsilon/\sin^2\alpha)}$$

and choose $a > \beta$. Let us call φ the function defined in $\mathbb{R}$ by

$$\left\{\begin{array}{ll} \varphi(x) = \dfrac{\cot\alpha}{8\beta^3}x^4 - \dfrac{3\cot\alpha}{4\beta}x^2 & \text{if } |x|\le\beta, \\ \varphi(x) = -|x|\cot\alpha + \dfrac{3}{8}\beta\cot\alpha & \text{if } \beta\le|x|\le a. \end{array}\right.$$

It is easy to see that the function φ is concave, is of class C^2 in $\mathbb{R}$, and that $|\varphi'(x)| \le \cot\alpha$, $|\varphi''(x)| \le c - \tilde c_0^\varepsilon/\sin^2\alpha$.

Let us now define the function $v(x,y) = u^\varepsilon(y-\varphi(x))$ in Σ_a and check that this function v is a supersolution of (2.3) for a large enough. We have

$$\partial_y v = (u^\varepsilon)'(y-\varphi(x))$$

and $$\Delta v = (1+\varphi'(x)^2)(u^\varepsilon)''(y-\varphi(x)) - \varphi''(x)(u^\varepsilon)'(y-\varphi(x)).$$

Hence,

$$\begin{array}{ll} \Delta v - c\partial_y v + f(v) & = (1+\varphi'(x)^2)(u^\varepsilon)''(y-\varphi(x)) \\ & \quad -(c+\varphi''(x))(u^\varepsilon)'(y-\varphi(x)) + f(u^\varepsilon(y-\varphi(x))) \\ & = [\tilde c_0^\varepsilon(1+\varphi'(x)^2) - c - \varphi''(x)]\ (u^\varepsilon)'(y-\varphi(x)) \\ & \quad -\varphi'(x)^2 f^\varepsilon(u^\varepsilon(y-\varphi(x))) \\ & \quad +f(u^\varepsilon(y-\varphi(x))) - f^\varepsilon(u^\varepsilon(y-\varphi(x))). \end{array}$$

On the one hand, we know that $(u^\varepsilon)' > 0$ and that $0 \le f \le f^\varepsilon$. On the other hand, in view of the definition of φ, we infer that

$$\forall x \in \mathbb{R}, \quad \tilde c_0^\varepsilon(1+\varphi'(x)^2) - c - \varphi''(x) \le 0.$$

It follows that

$$\Delta v - c\partial_y v + f(v) \le 0 \ \text{ in } \Sigma_a.$$

Furthermore, one has, for all $y \in (-a\cot\gamma_a, a\cot\gamma_a)$,

$$\begin{array}{ll} \partial_\tau v(-a,y) & = (\sin\alpha\ \varphi'(-a) - \cos\alpha)\ (u^\varepsilon)'(y-\varphi(-a)) \\ & = 0 \end{array}$$

since $\varphi'(-a) = \cot\alpha$. Similarly, $\partial_{\tilde{\tau}} v(a,y) = 0$ for all $y \in (-a\cot\gamma_a, a\cot\gamma_a)$.

At the "bottom" of the boundary of Σ_a, one has $v(x, -a\cot\gamma_a) \geq 0$ for all $x \in [-a,a]$. At the "top" of the boundary of Σ_a, $v(x, a\cot\gamma_a) = u^\varepsilon(a\cot\gamma_a - \varphi(x))$ for all $x \in [-a,a]$ and

$$\forall x \in [-a,a], \quad |\varphi(x)| \leq a\cot\alpha - \frac{3}{8}\beta\cot\alpha \leq a\cot\alpha.$$

Since $(\cot\gamma_a - \cot\alpha)a \to +\infty$ as $a \to +\infty$ and since $u^\varepsilon(+\infty) = 1+\varepsilon$, it then follows that there exists a real $a_2(\varepsilon) > \beta$ such that if $a \geq a_2(\varepsilon)$ then $v(x, a\cot\gamma_a) > 1$ for all $x \in [-a,a]$.

Let us now choose $a \geq a_2(\varepsilon)$. The function v is a supersolution of problem (2.3). With the same arguments as in Lemma 2.2, we finally conclude that $v > u_c$ in $[-a,a] \times (-a\cot\gamma_a, a\cot\gamma_a)$. In particular, $u_c < v$ in $\{y = -|x|\cot\alpha,\ |x| \leq a\}$ since $0 < \gamma_a < \alpha$. As a consequence,

$$\max_{\substack{y=-\cot\alpha\ |x| \\ |x|\leq a}} u_c < \max_{\substack{y=-\cot\alpha\ |x| \\ |x|\leq a}} v \ = \ \max_{|x|\leq a} u^\varepsilon(-\cot\alpha\ |x| - \varphi(x)) = u_\varepsilon(0) = \theta. \qquad \Box$$

We complete this section with the following proposition.

Proposition 2.7. *If ε and $\eta > 0$ are small enough, then there is a real $a_0(\eta,\varepsilon) \geq A_0$ such that, for any $a \geq a_0(\eta,\varepsilon)$, problem* (2.1)–(2.2) *has a unique solution (c_a, u_a). Furthermore, one has*

$$c_0^\eta/\sin\alpha \leq c_a \leq \tilde{c}_0^\varepsilon/\sin^2\alpha.$$

Proof. Proposition 2.7 is an immediate consequence of Lemmas 2.4, 2.5, and 2.6. Indeed, let us choose $\varepsilon > 0$ and $\eta > 0$ small enough and take $a_0(\eta,\varepsilon) = \max\,(a_1(\eta), a_2(\varepsilon))$: for $a \geq a_0(\eta,\varepsilon)$, if $c < c_0^\eta/\sin\alpha$, then $\max_{\substack{y=-\cot\alpha\ |x| \\ |x|\leq a}} u_c > \theta$ from Lemma 2.5 and if $c > \tilde{c}_0^\varepsilon/\sin^2\alpha$, then $\max_{\substack{y=-\cot\alpha\ |x| \\ |x|\leq a}} u_c < \theta$ from Lemma 2.6. From Lemma 2.4, the functions u_c are continuously increasing with respect to c. Hence, problem (2.1)–(2.2) has a unique solution (c_a, u_a) and $c_0^\eta/\sin\alpha \leq c_a \leq \tilde{c}_0^\varepsilon/\sin^2\alpha$. $\Box$

2.2. Monotonicity properties of the solutions u_a. From Proposition 2.7, we assume from now on that a is large enough ($a \geq a(\eta_0, \varepsilon_0)$, where $\eta_0 > 0$, $\varepsilon_0 > 0$ are small enough) such that (2.1)–(2.2) has a unique solution (c_a, u_a). When there is no ambiguity, we call this solution (c,u). Set $\Sigma_a^- = (-a,0) \times (-a\cot\gamma_a, a\cot\gamma_a)$ and $\Sigma_a^+ = (0,a) \times (-a\cot\gamma_a, a\cot\gamma_a)$. Remember that C_i $(i = 1,\ldots,4)$ are the four corners of the rectangle Σ_a.

Proposition 2.8. *For a large enough, the unique solution (c_a, u_a) of* (2.1)–(2.2) *is such that*

(i) *for any $\rho = (\cos\beta, \sin\beta)$ with $\pi/2 - \alpha \leq \beta \leq \pi$, one has $\partial_\rho u \geq 0$ in $\overline{\Sigma_a^-} \setminus \{C_1, C_3\}$;*

(ii) *for any $\rho = (\cos\beta, \sin\beta)$ with $0 \leq \beta \leq \pi/2 + \alpha$, one has $\partial_\rho u \geq 0$ in $\overline{\Sigma_a^+} \setminus \{C_2, C_4\}$.*

From this proposition we immediately get the following corollary.

Corollary 2.9. (i) *The function u is nonincreasing with respect to x in $\overline{\Sigma_a^-}$ and nondecreasing with respect to x in $\overline{\Sigma_a^+}$.*

(ii) *For any nonzero vector $\rho \in \overline{\mathcal{C}(\vec{e}_2, \alpha)}$, one has*

$$\partial_\rho u \geq 0 \quad \text{in} \quad \tilde{\Sigma}_a = \overline{\Sigma_a} \backslash \{C_1, C_2, C_3, C_4\}.$$

Proof of Proposition 2.8. By symmetry with respect to x and by continuity, it is sufficient to prove that $\partial_\rho u \geq 0$ in Σ_a^- for any vector $\rho = (\cos\beta, \sin\beta)$ such that $\pi/2 - \alpha < \beta < \pi$. Let ρ be such a vector.

Let us temporarily consider the case where the function f is of class C^1 in $[0,1]$. Let $z = (x,y)$ be the generic notation for the points of $\overline{\Sigma_a}$. For $\varepsilon > 0$ small enough, we are going to compare the functions $u(z)$ and $u(z+\varepsilon\rho)$ in the rectangular domain $R_\varepsilon = \overline{\Sigma_a^- \cap (\Sigma_a^- - \varepsilon\rho)}$ (see Figure 3).

Let us first show that

$$u(z) < u(z+\varepsilon\rho) \quad \text{on } \partial R_\varepsilon \tag{2.9}$$

for ε small enough. Indeed, consider first the "top" and "bottom" boundaries of R_ε. Set $\vec{e}_1 = (1,0)$. If $\rho \cdot \vec{e}_1 > 0$ (as drawn in Figure 3), then those parts of ∂R_ε are $[-a, -\varepsilon\rho\cdot\vec{e}_1] \times \{-a\cot\gamma\}$ and $[-a, -\varepsilon\rho\cdot\vec{e}_1] \times \{a\cot\gamma - \varepsilon\rho\cdot\vec{e}_2\}$. Since $\rho\cdot\vec{e}_2 > 0$, inequality (2.9) is satisfied there because $u = 0$ (resp., $u = 1$) on $[-a,a] \times \{-a\cot\gamma\}$ (resp., $[-a,a] \times \{a\cot\gamma\}$) and because $0 < u < 1$ in $[-a,a] \times (-a\cot\gamma, a\cot\gamma)$. The other case $\rho\cdot\vec{e}_1 \geq 0$ can be treated similarly.

On the other hand, on $\{0\} \times [-a\cot\gamma, a\cot\gamma]$, we have $\partial_y u > 0$ from Lemma 2.2 (remember that f is assumed here to be of class C^1) and $\partial_x u = 0$ since u is symmetric with respect to x (from Corollary 2.3). Hence, $\partial_\rho u > 0$ on the compact set $\{0\} \times [-a\cot\gamma, a\cot\gamma]$. Since the function $\partial_\rho u$ is uniformly continuous in a neighborhood of $\{0\} \times [-a\cot\gamma, a\cot\gamma]$, it follows from the finite increment theorem that there exists

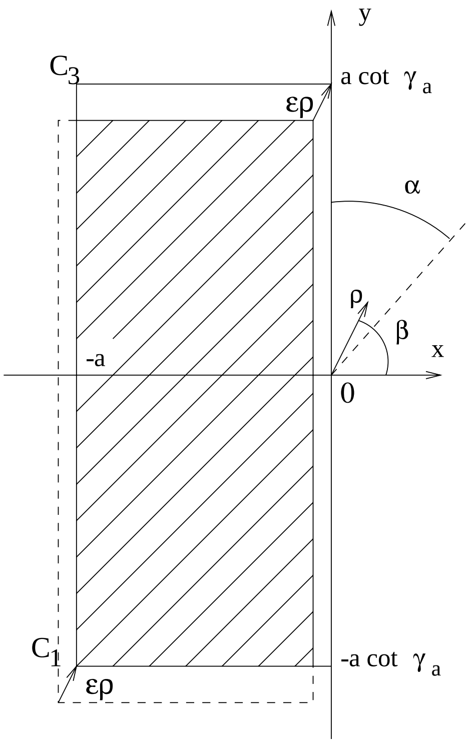

FIG. 3. *The rectangle R_ε.*

a real $\tilde{\varepsilon} > 0$ such that, if $0 < \varepsilon < \tilde{\varepsilon}$, then (2.9) is true on the right-hand side boundary of R_ε, namely, $\{-\varepsilon\rho \cdot \vec{e}_1\} \times [-a\cot\gamma, a\cot\gamma - \varepsilon\rho\cdot\vec{e}_2]$ if $\rho\cdot\vec{e}_1 \geq 0$ (as in Figure 3) or $\{0\} \times [-a\cot\gamma, a\cot\gamma - \varepsilon\rho\cdot\vec{e}_2]$ if $\rho\cdot\vec{e}_1 \leq 0$.

We now have to deal with the behavior of the function u on the left-hand boundary of R_ε and especially around the corners C_1 and C_3. We shall use the following lemma (notice that in this lemma the function f does not need to be of class C^1 in $[0,1]$).

LEMMA 2.10. *For each $i = 1$ or 3, there exist a neighborhood V_i of C_i and a real $\varepsilon_i > 0$ such that*

$$\left(0 < \varepsilon < \varepsilon_i \text{ and } z,\ z + \varepsilon\rho\ \in V_i \cap \overline{\Sigma_a}\right) \implies (u(z) < u(z + \varepsilon\rho)).$$

This technical lemma is proved in section 5.

End of the proof of Proposition 2.8. For any point $z = (-a, y_0)$ on the left-hand boundary $\{-a\} \times (-a\cot\gamma, a\cot\gamma)$ of Σ_a, we have $\partial_\tau u = 0$ and $\partial_y u > 0$ from Lemma 2.2. Since $\tau = (-\sin\alpha, -\cos\alpha)$ and $\rho = (\cos\beta, \sin\beta)$ with $\pi/2 - \alpha < \beta < \pi$, it follows that $\partial_\rho u > 0$. Since u is of class C^1 near the point z, there exists a neighborhood V_z of z such that $\partial_\rho u(x,y) > 0$ for any $(x,y) \in V_z \cap \overline{\Sigma_a}$. Hence, from the finite increment theorem, there exists a real $\varepsilon_z > 0$ such that if $0 < \varepsilon < \varepsilon_z$ and if the point $z + \varepsilon\rho$ is in $\overline{V_z} \cap \overline{\Sigma_a}$, then

$$u(z) < u(z + \varepsilon\rho).$$

Without any restriction, the neighborhoods V_1 and V_3 of C_1 and C_3, which are given in Lemma 2.10, can be replaced with two open balls $B(C_i, \delta_i)$ centered on the points C_i and with radii δ_i ($i = 1$ or 3). Since $\{-a\} \times [-a\cot\gamma + \delta_1, a\cot\gamma - \delta_3]$ is a compact set, there exists a real $\overline{\varepsilon} > 0$ such that, if $0 < \varepsilon < \overline{\varepsilon}$, if $z = (x,y)$ where $y \in [-a\cot\gamma + \delta_1, a\cot\gamma - \delta_3]$, and $x = -a$ in the case $\rho\cdot\vec{e}_1 \geq 0$ (resp., $x = -a - \varepsilon\rho\cdot\vec{e}_1$ in the case $\rho\cdot\vec{e}_1 < 0$), then $z,\ z + \varepsilon\rho \in R_\varepsilon$ and

$$u(z) < u(z + \varepsilon\rho).$$

From Lemma 2.10, we conclude that, if $0 < \varepsilon < \min(\varepsilon_1, \varepsilon_3, \overline{\varepsilon})$, then (2.9) is true on the left-hand boundary of R_ε, namely, on $\{-a - \varepsilon\rho\cdot\vec{e}_1\} \times [-a\cot\gamma, a\cot\gamma - \varepsilon\rho\cdot\vec{e}_2]$ or $\{-a\} \times [-a\cot\gamma, a\cot\gamma - \varepsilon\rho\cdot\vec{e}_2]$ according to the sign of $\rho\cdot\vec{e}_1$.

Finally, we set $\varepsilon_0 = \min(\tilde{\varepsilon}, \varepsilon_1, \varepsilon_3, \overline{\varepsilon})$ (remember that $\tilde{\varepsilon}$ has been defined just before Lemma 2.10). For any $\varepsilon \in (0, \varepsilon_0)$ and for any $z \in \partial R_\varepsilon$, the points z and $z + \varepsilon\rho$ are in $\overline{\Sigma_a}$ and we have $u(z) < u(z + \varepsilon\rho)$. Next, as in the proof of Lemma 2.2, that is to say by using a sliding method along the direction $\vec{e}_2$ and the fact that u is increasing with respect to y, we find that

$$u(z) < u(z + \varepsilon\rho) \text{ in } R_\varepsilon.$$

This completes the proof of Proposition 2.8 in the case where the function f is of class C^1 in $[0,1]$.

If f is not of class C^1 in $[0,1]$, we can however approximate it by a sequence of functions f_n of class C^1 which are such that $\|f'_n\|_{L^\infty([0,1])} \leq C$, $\|f - f_n\|_{L^\infty([0,1])} \to 0$ as $n \to +\infty$ and which satisfy (1.4) with ignition temperature $\theta_n \to \theta$ as $n \to +\infty$. Under the notation of Lemmas 2.5 and 2.6, there exist two positive reals ε_1 and η_1 such that, for n large enough, we have $f_{\eta_1} \leq f_n \leq f^{\varepsilon_1}$, whence $f_{\eta_1} \leq f \leq f^{\varepsilon_1}$ by taking the limit $n \to +\infty$. Thus, as in the proof of Proposition 2.7, for n large enough and for $a \geq \max(a_1(\eta_1), a_2(\varepsilon_1))$, we get that there exists a unique solution (c_n, u_n) of

(2.1)–(2.2) with the source term f_n as well as a unique solution (c_a, u_a) of (2.1)–(2.2) with the source term f. Furthermore, one has $c_0^{\eta_1}/\sin\alpha \le c_n \le \tilde{c}_0^{\varepsilon_1}/\sin^2\alpha$.

Choose any $a \ge \max(a_1(\eta_1), a_2(\varepsilon_1))$. First of all, up to extraction of some subsequence, we can assume that $c_n \to \tilde{c} \in \mathbb{R}$. From the standard elliptic estimates up to the boundary, we can extract a subsequence $u_{n'}$ which approaches a solution u of (2.4) with the speed $\tilde{c}$ in the spaces $W^{2,p}_{loc}(\tilde{\Sigma}_a) \cap C_{loc}(\tilde{\Sigma}_a)$. Furthermore, for each $i \in \{1,\ldots,4\}$, there exists a function $\overline{v}_i$ defined in a neighborhood V_i of the corner C_i such that $\overline{v}_i(C_i) = 0$ and, for all n' large enough,

$$\begin{array}{lrl} \text{if } i = 1 \text{ or } 2, & u_{n'}(x,y) & \le \overline{v}_i(x,y) \\ \text{if } i = 3 \text{ or } 4, & 1 - u_{n'}(x,y) & \le \overline{v}_i(x,y) \end{array} \quad \text{in } V_i \cap \overline{\Sigma_a} \tag{2.10}$$

(see Remark 5.2). As a consequence, the function $\tilde{u}$ can be extended by continuity at the four corners C_i. Hence, $\tilde{u}$ is the unique solution of (2.3) with the speed $\tilde{c}$. On the other hand, by passage to the limit $n' \to \infty$, the statements of Proposition 2.8 hold good for the function $\tilde{u}$. In particular, it follows that $\tilde{u}$ fulfills (2.2). Finally, from Lemma 2.4, we conclude that $(\tilde{c}, \tilde{u}) = (c_a, u_a)$. This completes the proof of Proposition 2.8. □

3. Passage to the limit in the whole plane. In the previous section, we proved the existence and the uniqueness of a solution (c_a, u_a) to problem (2.1)–(2.2) for a large enough. Moreover, we found several a priori bounds for the speeds c_a as well as a priori monotonicity properties for the functions u_a. We are now going to pass to the limit $a \to \infty$.

PROPOSITION 3.1. *There exists a sequence $a_n \to \infty$, a real c, and a function u such that $c_{a_n} \to c$ in $\mathbb{R}$ and $u_{a_n} \to u$ in $W^{2,p}_{loc}(\mathbb{R}^2)$ for all $p > 1$. Furthermore, the real c is such that*

$$\frac{c_0}{\sin\alpha} \le c \le \frac{c_0}{\sin^2\alpha}$$

and the function u satisfies

$$\Delta u - c\partial_y u + f(u) = 0 \textit{ in } \mathbb{R}^2, \tag{3.1}$$

$$0 < u < 1 \textit{ in } \mathbb{R}^2,$$

$$\forall (x,y) \in \mathbb{R}^2, \quad u(x,y) = u(-x,y),$$

$$\max_{\substack{y \le -\cot\alpha\ |x| \\ x \in \mathbb{R}}} u = u(0,0) = \theta, \tag{3.2}$$

$$\begin{cases} \forall \rho = (\cos\beta, \sin\beta) \textit{ such that } \pi/2 - \alpha \le \beta \le \pi, & \partial_\rho u(x,y) \ge 0 \textit{ if } x \le 0, \\ \forall \rho = (\cos\beta, \sin\beta) \textit{ such that } 0 \le \beta \le \pi/2 + \alpha, & \partial_\rho u(x,y) \ge 0 \textit{ if } x \ge 0. \end{cases} \tag{3.3}$$

COROLLARY 3.2. *For all $\rho = (\cos\beta, \sin\beta)$ with $\pi/2 - \alpha \le \beta \le \pi/2 + \alpha$, one has*

$$\partial_\rho u \ge 0 \quad \textit{in } \mathbb{R}^2.$$

Proof of Proposition 3.1. Under the notation of Proposition 2.7, choose $\varepsilon = \eta = 1/n$ where the integer n is large enough and set $a_n = a_0(1/n, 1/n)$. For n large enough, problem (2.1)–(2.2) has a unique solution (c_n, u_n) in Σ_{a_n} and one has $c_0^{1/n}/\sin\alpha \le c_n \le \tilde{c}_0^{1/n}/\sin^2\alpha$.

From the results of [9], we have $c_0^{1/n}$ and $\tilde{c}_0^{1/n} \to c_0$ as $n \to \infty$. Hence there exists a subsequence, that is still called (c_n), such that $c_n \to c \in [c_0/\sin\alpha, c_0/\sin^2\alpha]$. For any compact set K of $\mathbb{R}^2$, from the standard elliptic estimates, the sequence (u_{a_n}) is bounded in $W^{2,p}(K)$ (for a_n large enough such that $\overline{\Sigma_{a_n}} \subset \overset{o}{K}$). Hence, from the diagonal extraction process, there exists a subsequence that is still called (u_{a_n}) and a function u such that $u_{a_n} \to u$ in $W^{2,p}_{loc}(\mathbb{R}^2)$ for all $p > 1$. The function u satisfies (3.1). From the Sobolev injections and since f is Lipschitz continuous, the function u is in $C^{2,\mu}_{loc}(\mathbb{R}^2)$ for all $0 \le \mu < 1$.

Since $u(0,0) = \lim\ u_n(0,0) = \theta$ and since $0 \le u \le 1$, the strong maximum principle implies that $0 < u < 1$ in $\mathbb{R}^2$. The symmetry of u with respect to x derives from the symmetry of u_n. The assertions (3.3) come from Proposition 2.8. Together with (2.2), they yield the normalization condition (3.2). □

3.1. Exponential decay properties. For any $z = (x,y) \in \mathbb{R}^2$, let us define

$$T_z = (-|x|,|x|) \times (-\infty, y) \ \cup\ \mathcal{C}((x,y), -\vec{e}_2, \alpha) \ \cup\ \mathcal{C}((-x,y), -\vec{e}_2, \alpha).$$

Proposition 3.3. *Let x_0 be in $\mathbb{R}$.*

(i) *There exists a real $y_0 \in [-|x_0| \cot\alpha, 0]$ such that $u(x_0,y_0) = \theta$.*

(ii) *Set $z_0 = (x_0,y_0)$. The following exponential decay holds in $\overline{T_{z_0}}$:*

$$\forall z = (x,y) \in \overline{T_{z_0}}, \quad u(z) \ \ \le 2\theta e^{-c\sin\alpha\cos\alpha\ |x_0|}\cosh(c\sin\alpha\cos\alpha\ x)e^{c\sin^2\alpha\ (y-y_0)} + \theta e^{c(y-y_0)}. \tag{3.4}$$

(iii) *A similar estimate is true in $\overline{\mathcal{C}(z_0, -\vec{e}_2, \alpha)}$. Namely, for all $\pi/2 - \alpha \le \varphi \le \pi/2 + \alpha$ and $\rho = (\cos\varphi, -\sin\varphi)$, we have*

$$\forall \lambda \ge 0, \quad u(z_0 + \lambda\rho) \le 2\theta\cosh(c\lambda\sin\alpha\cos\alpha\cos\varphi)\ e^{-c\lambda\sin^2\alpha\sin\varphi}. \tag{3.5}$$

Remark 3.4. *By taking $z_0 = (0,0)$ and $\vec{k} \in \mathcal{C}(-\vec{e}_2, \alpha)$ in* (3.5)*, it follows that the function u fulfills* (1.2) *and* (1.8).

Corollary 3.5. *The function u is increasing in y.*

Proof. From Corollary 3.2, we know that $u(x,y)$ is nondecreasing in y. Suppose that $u(x_0,y_0) = u(x_0,y_0')$ where $x_0 \in \mathbb{R}$ and $y_0 < y_0'$. It follows that u is equal to a constant u_0 in $\overline{\mathcal{C}((x_0,y_0), \vec{e}_2, \alpha)} \cap \overline{\mathcal{C}((x_0,y_0'), -\vec{e}_2, \alpha)}$. This constant u_0 is then a zero of the function f. Since $0 < u < 1$ in $\mathbb{R}^2$ and $f > 0$ on $(\theta, 1)$, we get $u_0 \in (0, \theta]$. The monotonicity properties imply that $u \le u_0$ in the cone $\mathcal{C} = \mathcal{C}((x_0,y_0'), -\vec{e}_2, \alpha)$ and that the function u satisfies

$$\Delta u - c\partial_y u = 0 \ \text{ in } \mathcal{C}.$$

In $\mathcal{C}$, the function u reaches its maximum u_0 at an interior point, for instance, $(x_0, (y_0 + y_0')/2)$. From the strong maximum principle, u is then equal to u_0 in $\overline{\mathcal{C}}$. This is impossible because $u(x_0,y) \to 0$ as $y \to -\infty$ from inequality (3.5). □

Proof of Proposition 3.3. From the symmetry of u with respect to x, we may suppose that $x_0 \ge 0$. Let now $a > x_0$. By Proposition 2.8, we have $u_a(x_0, 0) \ge \theta$ and $u_a(x_0, -x_0\cot\alpha) \le \theta$. Since u_a is continuous, there exists a real y_a in $[-x_0\cot\alpha, 0]$ such that $u_a(x_0,y_a) = \theta$. Since the y_a are bounded and since the functions u_a approach u in $C^1_{loc}(\mathbb{R}^2)$ (for a certain sequence $a \to +\infty$), then there exists a real y_0 in $[-x_0\cot\alpha, 0]$ such that $y_a \to y_0$ (for a sequence $a \to \infty$) and $u(x_0,y_0) = \theta$. This yields the assertion (i) of Proposition 3.3.

Let $z_0 = (x_0,y_0)$. Let us now consider the open trapezium D_a whose vertices are the four points $C_1 = (-a, -a\cot\gamma_a)$, $S_1 = (-x_0, y_a)$, $S_2 = (x_0, y_a)$, and $C_2 =$

$(a, -a\cot\gamma_a)$. The angles between $-\vec{e_2}$ and each side $[S_1, C_1]$ and $[S_2, C_2]$ are equal and, since $y_a \geq -x_0\cot\alpha \geq -x_0\cot\gamma_a$, they are not larger than γ_a and, a fortiori, they are less than α. Hence, from Proposition 2.8 we have

$$u_a \leq \theta \ \text{ in } \overline{D_a}$$

and

$$\Delta u_a - c_a\partial_y u_a = 0 \ \text{ in } D_a.$$

We are now going to compare u_a with the sum of three exponential functions in D_a. Choose any point $z_1 = (x_1, y_1)$ in the open set T_{z_0}. Since $y_a \to y_0$ and $\gamma_a \to \alpha$, there exists a positive real a_0 such that $z_1 \in D_a$ for all $a \geq a_0$. Let c' be a real in $(0, c\sin\alpha)$ − notice that this is possible since $\sin\alpha > 0$ and $c\sin\alpha \geq c_0 > 0$. Let us set $r_a = 1/\sqrt{(a\cot\gamma_a + y_a)^2 + (-a+x_0)^2}$ and define

$$w_a(x,y) = f_1(x,y) + f_2(x,y) + f_3(x,y),$$

where

$$\begin{cases} f_1(x,y) & = \theta e^{-c'r_a((a\cot\gamma_a+y_a)(x+x_0)+(x_0-a)(y-y_a))}, \\ f_2(x,y) & = \theta e^{-c'r_a(-(a\cot\gamma_a+y_a)(x-x_0)+(x_0-a)(y-y_a))}, \\ f_3(x,y) & = \theta e^{c'/\sin\alpha\ (y-y_a)}. \end{cases}$$

In particular, we have $w_a \geq \theta \geq u_a$ on ∂D_a. Moreover, a straightforward calculation gives

$$\Delta w_a - c_a\partial_y w_a = c'(c' - c_a r_a(a - x_0))(f_1 + f_2) + \frac{c'}{\sin^2\alpha}\ (c' - c_a\sin\alpha)f_3.$$

Since $c' > 0$ and since $c_a \to c > c'/\sin\alpha$, $\ r_a(a - x_0) \to \sin\alpha$ as $a \to \infty$, it follows that

$$\Delta w_a - c_a\partial_y w_a < 0 \ \text{ in } D_a$$

for a large enough. From the maximum principle, we deduce that $u_a < w_a$ in D_a. By passing to the limit $a \to \infty$, we obtain

$$\begin{aligned} u(x_1,y_1) \ & \leq \theta e^{-c'[\cos\alpha(x_1+x_0)-\sin\alpha(y_1-y_0)]} \\ & \quad + \theta e^{-c'[-\cos\alpha(x_1-x_0)-\sin\alpha(y_1-y_0)]} + \theta e^{c'/\sin\alpha\ (y_1-y_0)}. \end{aligned}$$

Since this is true for any $c' < c\sin\alpha$, we can pass to the limit $c' \to c\sin\alpha$ and we get

$$u(x_1,y_1) \leq 2\theta\cosh(c\sin\alpha\cos\alpha\ x_1)\ e^{c\sin^2\alpha\ (y_1-y_0) - c\sin\alpha\cos\alpha\ x_0} + \theta e^{c(y_1-y_0)}.$$

This can be extended by continuity in $\overline{T_{z_0}}$. This gives assertion (ii) of Proposition 3.3.

In the same way, we could prove that for any $x_0 \geq 0$,

$$u(x,y) \leq 2\theta\cosh(c\sin\alpha\cos\alpha\ (x - x_0))e^{c\sin^2\alpha(y-y_0)} \ \text{ in } \overline{\mathcal{C}(z_0, -\vec{e_2}, \alpha)}$$

by comparing the function u_a with the sum of two suitable exponential functions in the triangles whose vertices are $S_1 = (-a + 2x_0, -a\cot\gamma_a)$, $S_2 = (x_0, y_0)$, and $S_3 = (a, -a\cot\gamma_a)$. This corresponds to assertion (iii) of Proposition 3.3. The case $x_0 \leq 0$ can be treated by symmetry. □

3.2. Estimating the speed c: Proof of formula (1.7). Consider now a sequence $x_n \to -\infty$ and, for any x_n, let y_n be the unique real such that $u(x_n, y_n) = \theta$. One has $x_n \cot \alpha \leq y_n \leq 0$. Move the origin at the point (x_n, y_n) and consider the functions

$$v_n(x,y) = u(x + x_n, y + y_n) \text{ in } \mathbb{R}^2.$$

From the standard elliptic estimates and the Sobolev injections, the functions v_n are bounded in $W^{2,p}_{loc}(\mathbb{R}^2)$ for all $1 < p < \infty$ and approach, up to extraction of some subsequence, a function $v \in \bigcap_{p>1} W^{2,p}_{loc}(\mathbb{R}^2)$, such that

$$\begin{cases} \Delta v - c\partial_y v + f(v) = 0 & \text{in } \mathbb{R}^2, \\ v(0,0) = \theta. \end{cases} \tag{3.6}$$

The function v has the following monotonicity properties.

LEMMA 3.6. *For any $\rho = (\cos\varphi, -\sin\varphi)$ such that $0 \leq \varphi \leq \pi/2 + \alpha$, one has the following:*

(i) *the function v is nonincreasing in the direction ρ;*

(ii) *it also holds that*

$$\forall \lambda \geq 0, \quad v(\lambda\rho) \leq \theta e^{-c\lambda \sin\alpha \cos(\alpha - \varphi)} + \theta e^{-c\lambda \sin\varphi}. \tag{3.7}$$

Proof. Let ρ be as in the lemma above. Let $z = (x,y)$ be any point in $\mathbb{R}^2$ and let $\lambda > 0$. Consider both points z and $z + \lambda\rho$. Since $x_n \to -\infty$, we have $x + x_n \leq 0$ and $x + x_n + \lambda\cos\varphi \leq 0$ for n large enough. From (3.3), we have, for n large enough,

$$v_n(z) = u(x + x_n, y + y_n) \geq u(x + x_n + \lambda\cos\varphi, y + y_n - \lambda\sin\varphi) = v_n(z + \lambda\rho).$$

By taking the limit $n \to \infty$, it follows that $v(z) \geq v(z + \lambda\rho)$. This gives the assertion (i).

Consider the set

$$T_n = (-|x_n|, |x_n|) \times (-\infty, y_n) \ \cup \ \mathcal{C}((x_n, y_n), -\vec{e}_2, \alpha) \ \cup \ \mathcal{C}((-x_n, y_n), -\vec{e}_2, \alpha).$$

Under the notation of section 3.1, we have $T_n = T_{z_n = (x_n, y_n)}$. Since $x_n \to -\infty$, the points $(x_n, y_n) + \lambda\rho$ are in $\overline{T_n}$ for n large enough. Hence, inequality (3.4) implies that

$$\begin{aligned} v_n(\lambda\rho) \quad &\leq 2\theta e^{-c|x_n| \sin\alpha\cos\alpha} \cosh(c \sin\alpha \cos\alpha \ (x_n + \lambda\cos\varphi)) e^{-c\lambda \sin^2\alpha \sin\varphi} \\ &+ \theta e^{-c\lambda\sin\varphi}. \end{aligned}$$

Since $x_n \to -\infty$, we obtain at the limit $n \to \infty$

$$v(\lambda\rho) \leq \theta e^{-c\lambda \sin\alpha\cos\alpha\cos\varphi} e^{-c\lambda\sin^2\alpha\sin\varphi} + \theta e^{-c\lambda\sin\varphi}.$$

This completes the proof of Lemma 3.6. □

PROPOSITION 3.7. *The speed c is equal to $c_0/\sin\alpha$.*

Proof. From (1.7), we already know that $c_0/\sin\alpha \leq c \leq c_0/\sin^2\alpha$. Let us suppose that $c > c_0/\sin\alpha$.

First step: Construction of a supersolution. As in the proof of Lemma 2.6, we use the same functions $f^\varepsilon \geq f$ such that $f^\varepsilon \equiv 0$ on $[0, \theta - \varepsilon] \cup \{1 + \varepsilon\}$, $f^\varepsilon > 0$ on

$(\theta-\varepsilon,1+\varepsilon)$, and $f^\varepsilon\to f$ as $\varepsilon\to 0$ uniformly in $[0,1]$. For each $\varepsilon>0$, there exists a unique solution $(\overline{c}_0^\varepsilon,U^\varepsilon)$ of

$$\left\{\begin{array}{rl} (U^\varepsilon)''-\overline{c}_0^\varepsilon(U^\varepsilon)'+f^\varepsilon(U^\varepsilon) & =0 \qquad \text{in } \mathbb{R},\\ U^\varepsilon(-\infty)=\varepsilon,\ U^\varepsilon(0)=\theta,\ U^\varepsilon(+\infty) & =1+\varepsilon. \end{array}\right. \tag{3.8}$$

From the results in [9], we have $\overline{c}_0^\varepsilon\to c_0$ as $\varepsilon\to 0$. Now choose $\varepsilon>0$ such that

$$c>\overline{c}_0^\varepsilon/\sin\alpha$$

and denote by U the function U^ε.

Let us consider the new variables

$$X=y\cos\alpha+x\sin\alpha \quad\text{ and }\quad Y=y\sin\alpha-x\cos\alpha.$$

The variables (X,Y) are obtained from (x,y) by a rotation of angle $\pi/2-\alpha$ around the origin.

We are looking for a supersolution of (3.6) of the type

$$w(x,y)=U(Y-\phi(X)).$$

For such a function w, we have

$$\Delta w-c\partial_y w+f(w)=A(X)U'(Y-\phi(X))+f(U)-f_\varepsilon(U)-\phi'^2 f_\varepsilon(U), \tag{3.9}$$

where

$$A(X)=\overline{c}_0^\varepsilon(1+\phi'^2)-\phi''-c(\sin\alpha-\cos\alpha\ \phi').$$

Since $f_\varepsilon\geq f\geq 0$ and $U'>0$, in order to make the right-hand side of (3.9) nonpositive, it is sufficient to choose a function ϕ in such a way that $A(X)\leq 0$. Let ϕ be defined by

$$\phi(X)=-\frac{1}{c\sin\alpha}\ln(e^{-c\sin\alpha\tan\beta\ X}+e^{c\sin\alpha\cot(\alpha-\beta)X}),$$

where $\beta>0$ shall be chosen later. Set $\delta=\cot(\alpha-\beta)+\tan\beta$. It is easy to check that

$$A(X)=\frac{1}{(1+e^{c\sin\alpha\delta X})^2}\left[B(\beta)e^{2c\sin\alpha\delta X}+C(\beta)e^{c\sin\alpha\delta X}+D(\beta)\right],$$

where

$$\left\{\begin{array}{rcl} B(\beta) & = & \overline{c}_0^\varepsilon-c\sin\alpha-c\cos\alpha\cot(\alpha-\beta)+\overline{c}_0^\varepsilon\cot^2(\alpha-\beta),\\ C(\beta) & = & 2(\overline{c}_0^\varepsilon-c\sin\alpha)-c\cos\alpha\cot(\alpha-\beta)\\ & & +c\cos\alpha\tan\beta-2\overline{c}_0^\varepsilon\tan\beta\cot(\alpha-\beta)+c\sin\alpha\ \delta^2,\\ D(\beta) & = & \overline{c}_0^\varepsilon-c\sin\alpha+c\cos\alpha\tan\beta+\overline{c}_0^\varepsilon\tan^2\beta. \end{array}\right.$$

As $\beta\to 0$, we have $B(\beta)\to\overline{c}_0^\varepsilon/\sin^2\alpha-c/\sin\alpha<0$, $C(\beta)\to 2(\overline{c}_0^\varepsilon-c\sin\alpha)<0$, and $D(\beta)\to\overline{c}_0^\varepsilon-c\sin\alpha<0$. Hence, we can choose $\beta\in(0,\alpha)$ small enough such that $B(\beta)$, $C(\beta)$, $D(\beta)<0$.

Let β be chosen as above. The function $w(x,y)$ is then a supersolution of (3.6) in the sense that

$$\Delta w-c\partial_y w+f(w)<0\ \text{ in } \mathbb{R}^2. \tag{3.10}$$

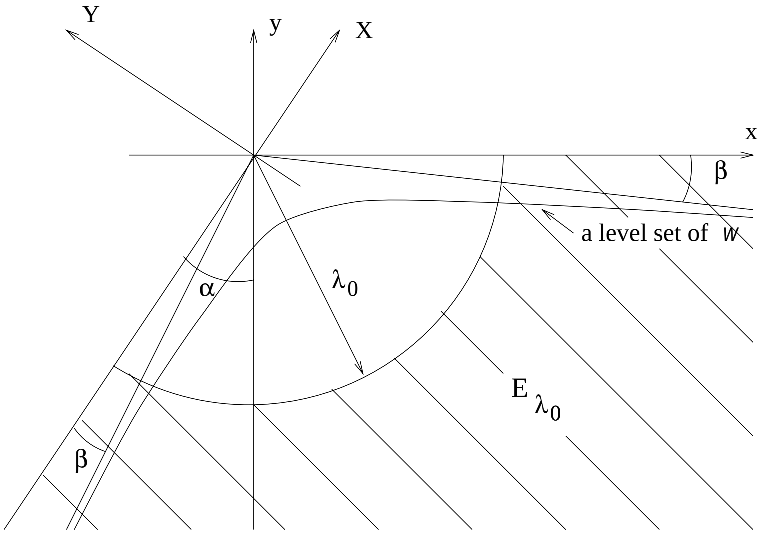

FIG. 4. *The set E_{λ_0}.*

Second step: Initialization of a sliding method. For any λ_0, we set

$$E_{\lambda_0} = \{z = (\lambda\cos\varphi, -\lambda\sin\varphi) \in \mathbb{R}^2,\ 0 \le \varphi \le \pi/2 + \alpha,\ \lambda \ge \lambda_0\} \tag{3.11}$$

(see Figure 4).

LEMMA 3.8. *There exists $\lambda_0 > 0$ such that*

$$w > v \quad in\ E_{\lambda_0}.$$

Proof. Assume that the previous conclusion is not true. There exist then two sequences $0 \le \lambda_n \to +\infty$ and $z_n = (x_n, y_n) = (\lambda_n\cos\varphi_n,\ -\lambda_n\sin\varphi_n) \in E_{\lambda_n}$ such that $w(z_n) \le v(z_n)$.

Set $X_n = y_n\cos\alpha + x_n\sin\alpha = \lambda_n\sin(\alpha - \varphi_n)$ and $Y_n = y_n\sin\alpha - x_n\cos\alpha = -\lambda_n\cos(\alpha - \varphi_n)$. From (3.6) and Lemma 3.6 (i), it follows that $v \le \theta$ in E_{λ_0} and a fortiori in E_{λ_n} for n large enough. Hence, $w(z_n) = U(Y_n - \phi(X_n)) \le \theta$. Since U is increasing and $U(0) = \theta$, we get that $Y_n - \phi(X_n) \le 0$. On the other hand, from equation (3.8) satisfied by U, we have

$$\forall \xi \le 0, \quad U(\xi) = \varepsilon + (\theta - \varepsilon)e^{\overline{c}_0^\varepsilon \xi}.$$

Hence,

$$w(z_n) = U(Y_n - \phi(X_n)) = \varepsilon + (\theta - \varepsilon)e^{\overline{c}_0^\varepsilon (Y_n - \phi(X_n))} \le v(z_n). \tag{3.12}$$

Since $\varphi_n \in [0, \pi/2 + \alpha]$, up to extraction of some subsequence, the following two cases occur.

(i) $\varphi_n \to \varphi \in]0, \pi/2 + \alpha[$. In this case, inequality (3.7) implies that $v(z_n) \to 0$ as $n \to +\infty$, whereas the left-hand side of (3.12) is greater than the positive constant ε. Case (i) is then impossible.

(ii) $\varphi_n \to 0$ or $\pi/2 + \alpha$. Since $\beta > 0$ and since each level set of the function $Y - \phi(X)$ has two asymptotes directed by the vectors $\rho_1 = (\cos\beta, -\sin\beta)$ and $\rho_2 =$

$(\cos(\pi/2+\alpha-\beta), -\sin(\pi/2+\alpha-\beta))$, the distance between the points z_n and the half-lines $\mathbb{R}_+\rho_1$, $\mathbb{R}_+\rho_2$ necessarily approaches $+\infty$. This finally yields that $Y_n - \phi(X_n) \to +\infty$, whence $w(z_n) \to 1+\varepsilon$ as $n \to \infty$. This is ruled out by the inequality $w(z_n) \le v(z_n) < 1$.

This completes the proof of Lemma 3.8. □

Third step: The sliding method. We are now going to slide w in the Y-direction and compare it with the function v. For all $\tau \in \mathbb{R}$, we set

$$w_\tau(x,y) = U(\tau + Y - \phi(X)).$$

From Lemma 3.8, there exists a real λ_0 such that $w > v$ in E_{λ_0}, whence $w_\tau > v$ in E_{λ_0} for any $\tau \ge 0$ (remember that U is increasing).

The level set $\{Y - \phi(X) = 1+\varepsilon/2\}$ of w has two asymptotes directed by the vectors $(\cos\beta, -\sin\beta)$ and $(\cos(\pi/2+\alpha-\beta), -\sin(\pi/2+\alpha-\beta))$. Owing to the definition of E_{λ_0} and since $0<\beta$, there exists a real $\tau > 0$ such that the shifted level set $\{Y+\tau-\phi(X) = 1+\varepsilon/2\}$ in the direction Y is included in E_{λ_0}.

We now claim that

$$w_\tau > v \text{ in } \mathbb{R}^2.$$

Indeed, we already know that this is true in E_{λ_0}. But in $\mathbb{R}^2\backslash E_{\lambda_0}$, we have $w_\tau(x,y) = U(\tau+Y-\phi(X)) \ge 1+\varepsilon/2$ from the definition of τ. Hence,

$$w_\tau(x,y) \ge 1+\varepsilon/2 > v(x,y) \ \text{ in } \mathbb{R}^2\backslash E_{\lambda_0}.$$

Let us now slide w in the Y-direction. In other words, let us decrease τ and call

$$\tau^* = \inf\,\{\tau \in \mathbb{R},\ w_\tau > v \text{ in } \mathbb{R}^2\}.$$

This real is finite because $w_\tau(0,0) \to U(-\infty) = \varepsilon < \theta$ as $\tau \to -\infty$ and $v(0,0) = \theta$. Since U is increasing, we have $w_\tau > v$ for all $\tau > \tau^*$. By continuity, we find that

$$w_{\tau^*} \ge v \text{ in } \mathbb{R}^2.$$

Since the function w_{τ^*} satisfies (3.10), the nonnegative function $z = w_{\tau^*} - v$ is such that

$$\Delta z - c\partial_y z + c(x,y)z \le 0 \ \text{ in } \mathbb{R}^2$$

for some bounded function $c(x,y)$. From the strong maximum principle, one of the following two situations occurs:

(i) $w_{\tau^*} \equiv v$ in $\mathbb{R}^2$,

(ii) $w_{\tau^*} > v$ in $\mathbb{R}^2$.

Case (i) cannot occur since $w_{\tau^*} \to 1+\varepsilon$ as $Y \to +\infty$, whereas $v < 1$ in $\mathbb{R}^2$. If case (ii) occurs, let us consider an increasing sequence $\tau_n \to \tau^*$. For each n, owing to the definition of τ^*, there exists a point $(x_n,y_n) \in \mathbb{R}^2$ such that $w_{\tau_n}(x_n,y_n) \le v(x_n,y_n)$. The points (x_n,y_n) cannot be bounded; otherwise there would exist a point $(\overline{x},\overline{y}) \in \mathbb{R}^2$ such that $w_{\tau^*}(\overline{x},\overline{y}) \le v(\overline{x},\overline{y})$. The latter is impossible because of assumption (ii). Now, as in Lemma 3.8, there exists a real $\tilde{\lambda}_0$ such that $w_{\tau_0} > v$ in $E_{\tilde{\lambda}_0}$. Since the sequence (τ_n) is increasing, we have $w_{\tau_n} > v$ in $E_{\tilde{\lambda}_0}$. This implies that $(x_n,y_n) \notin E_{\tilde{\lambda}_0}$. On the other hand, since $0<\beta$ and since any level set of the function $Y-\phi(X)$ has two asymptotes directed by the vectors $\rho_1 = (\cos\beta, -\sin\beta)$ and $\rho_2 = (\cos(\pi/2+\alpha-\beta), -\sin(\pi/2+\alpha-\beta))$, it follows that $w_{\tau_n}(x_n,y_n) \to 1+\varepsilon$ as $n \to \infty$. This is impossible since $w_{\tau_n}(x_n,y_n) \le v(x_n,y_n) < 1$.

Finally, the assertion $c > c_0/\sin\alpha$ was impossible. Hence, $c = c_0/\sin\alpha$. This completes the proof of Proposition 3.7. □

3.3. Convergence of the function u to a planar wave far away from the axis of symmetry. The case $\alpha = \pi/2$ is treated separately. Indeed, in this case, from the uniqueness result in Lemma 2.2, the functions u_a only depend on y and they solve $u_a'' - c_a u_a' + f(u_a) = 0$, $u_a(-a\cot\gamma_a) = 0$, $u_a(0) = \theta$, and $u_a(a\cot\gamma_a) = 1$. From the construction given in [9], those functions u_a approach the solution $U(y)$ of (1.5) as $a \to +\infty$. This immediately yields the asymptotic limit (1.3) as well as the last assertion of Theorem 1.1.

In the case where $\alpha < \pi/2$, as in section 3.2, we again consider the function v, obtained as the limit of the functions $v_n(x,y) = u(x + x_n, y + y_n)$, where $x_n \to -\infty$ and $u(x_n, y_n) = \theta$. We know that the function v is nonincreasing in each direction $\rho = (\cos\varphi, -\sin\varphi)$ such that $0 \le \varphi \le \pi/2 + \alpha$. Furthermore, v has an exponential decay in the set $\{\lambda(\cos\varphi, -\sin\varphi),\ \lambda \ge 0, 0 \le \varphi \le \pi/2 + \alpha\}$ of the type (3.7).

Our goal is to prove that v is actually equal to the planar wave $U(Y) = U(y\sin\alpha - x\cos\alpha)$. We divide the proof into four main steps.

First step: Construction of a supersolution. We still use the variables $X = y\cos\alpha + x\sin\alpha$ and $Y = y\sin\alpha - x\cos\alpha$. In the previous section, we considered a supersolution of (3.6) of the type $w(x,y) = U^\varepsilon(Y - \phi(X))$, which had two asymptotes directed by the two vectors $\rho_1 = (\cos\beta, -\sin\beta)$ and $\rho_2 = (\cos(\pi/2+\alpha-\beta), -\sin(\pi/2+\alpha-\beta))$ ($\beta > 0$ was a small angle).

Now, consider the function w defined by

$$w(x,y) = U(Y - \phi(X)),$$

where U is the unique solution of (1.5) such that $U(0) = \theta$ and where

$$\phi(X) = -\frac{1}{c_0}\ln(1 + e^{c_0\cot\alpha\ X}).$$

Since $c = c_0/\sin\alpha$, we have

$$\Delta w - c\partial_y w + f(w) = -\phi'(X)^2 f(U(Y - \phi(X))) \le\not\equiv 0 \ \text{ in } \mathbb{R}^2. \tag{3.13}$$

Second step: Initialization of a sliding method. Let $h(X)$ be the function defined as follows:

$$h(X) = \begin{cases} 0 & \text{if } X \le 0, \\ -X\cot\alpha & \text{if } X \ge 0. \end{cases}$$

Set $E_0 = \{\lambda(\cos\varphi, -\sin\varphi),\ \lambda \ge 0, 0 \le \varphi \le \pi/2 + \alpha\} = \{Y \le h(X)\}$ (this definition is the same as (3.11)). We claim that

$$w \ge v \ \text{ in } E_0. \tag{3.14}$$

Indeed, let $(x,y) = (\lambda\cos\varphi, -\lambda\sin\varphi) \in E_0$ with $\lambda \ge 0$ and $0 \le \varphi \le \pi/2 + \alpha$. We have $X = \lambda\sin(\alpha - \varphi)$, $Y = -\lambda\cos(\alpha - \varphi)$, and

$$w(x,y) = U(-\lambda\cos(\alpha - \varphi) - \phi(\lambda\sin(\alpha - \varphi))).$$

From Lemma 3.6 (i) and since $v(0,0) = \theta$, one has $v \le \theta$ in E_0. Hence, inequality (3.14) is immediately satisfied if $w \ge \theta$. Consider now the case where $w(x,y) \le \theta$. Since $U(\xi) = \theta e^{c_0\xi}$ for $\xi \le 0$, it follows that

$$\begin{aligned} w(x,y) &= U(-\lambda\cos(\alpha - \varphi) - \phi(\lambda\sin(\alpha - \varphi))) \\ &= \theta e^{c_0(-\lambda\cos(\alpha-\varphi) + \frac{1}{c_0}\ln(1+e^{c_0\lambda\cot\alpha\sin(\alpha-\varphi)}))} \\ &= \theta(e^{-c\lambda\sin\alpha\cos(\alpha-\varphi)} + e^{-c\lambda\sin\varphi}) \\ &\ge v(x,y) \quad \text{by (3.7).} \end{aligned}$$

For any $\tau \in \mathbb{R}$, we set $w_\tau(x,y) = U(\tau + Y - \phi(X))$. Since U is increasing, we have

$$\forall \tau \geq 0, \quad w_\tau \geq v \ \text{ in } E_0. \tag{3.15}$$

On the half-line $\{Y = 0, X \leq 0\}$ of ∂E_0, we have $Y - \phi(X) = -\phi(X) \geq 0$. On the other half-line $\{Y = -\cot\alpha\ X, X \geq 0\}$ of ∂E_0, we have $Y - \phi(X) = -\cot\alpha\ X + 1/c_0 \ln(1 + e^{c_0 \cot\alpha\ X}) \geq 0$. Thus $w_\tau \geq U(\tau)$ on ∂E_0.

Since $f'_-(1) = \lim_{t\to 1,\ t<1} \frac{f(t)-f(1)}{t-1} < 0$ and $f \equiv 0$ on $[1, \infty[$, there exists a real $\varepsilon \in (0, 1-\theta)$ such that

$$(\ t \leq s \in [1-\varepsilon, 1]\ ) \implies \left(\ f(s) - f(t) \leq \frac{f'_-(1)}{2}\ (s-t) \leq 0\ \right). \tag{3.16}$$

Since U is increasing and approaches 1 at $+\infty$, there exists a real $\tau_1 \geq 0$ such that

$$\forall \tau \geq \tau_1, \quad w_\tau \geq 1 - \varepsilon \text{ on } \partial E_0. \tag{3.17}$$

Since the function w increases with respect to Y, we finally conclude from the definition of E_0 that

$$\forall \tau \geq \tau_1, \quad w_\tau \geq 1 - \varepsilon \ \text{ in } \mathbb{R}^2 \backslash E_0.$$

Lemma 3.9. *For all $\tau \geq \tau_1$, $w_\tau \geq v$ in $\mathbb{R}^2$.*

Proof. Choose any $\tau \geq \tau_1$. By (3.15) and since $\tau_1 \geq 0$, we already know that $w_\tau \geq v$ in E_0.

Let $\tilde{\Omega}_+$ be the open set $\tilde{\Omega}_+ = \mathbb{R}^2 \backslash E_0\ \cap\ \{w_\tau < v\}$. In order to prove Lemma 3.9, the only thing we still need to prove is that $\tilde{\Omega}_+$ is empty. Set $z = w_\tau - v$. From (3.6) and (3.13) we have

$$\Delta z - c\partial_y z \leq f(v) - f(w_\tau) \ \text{ in } \mathbb{R}^2.$$

In $\tilde{\Omega}_+$, the function v satisfies $1 \geq v > w_\tau \geq 1 - \varepsilon$ from (3.17). From the choice of ε (see (3.16)), we finally get

$$\Delta z - c\partial_y z + f'_-(1)/2\ z \leq 0 \ \text{ in } \tilde{\Omega}_+. \tag{3.18}$$

If $\tilde{\Omega}_+$ is not empty, define $-\delta = \inf_{\tilde{\Omega}_+} z$ (we have $-\varepsilon \leq -\delta < 0$) and consider a sequence $(x_n, y_n) \in \tilde{\Omega}_+$ such that $z(x_n, y_n) \to -\delta$ as $n \to \infty$. From the standard elliptic estimates, ∇z is bounded in $\mathbb{R}^2$. There exists then a real $r > 0$ such that the open ball $B((x_n, y_n), r)$ lies in $\tilde{\Omega}_+$ for n large enough. The functions $z_n(x,y) = z(x + x_n, y + y_n)$ approach, up to extraction of some subsequence, a function $\tilde{z}$ defined at least in $B((0,0), r)$. This function $\tilde{z}$ reaches its minimum $-\delta < 0$ at the point $(0,0)$ and it satisfies (3.18) in $B((0,0), r)$. This is clearly impossible since $f'_-(1) < 0$. Hence, $\tilde{\Omega}_+ = \emptyset$ and $w_\tau \geq v$ in $\mathbb{R}^2$ for all $\tau \geq \tau_1$. □

Third step: Sliding method. We now decrease τ and we are going to prove the following lemma.

Lemma 3.10. *There exist two reals τ^*, $\overline{Y}$ and a sequence of points (x_n, y_n) such that the coordinates (X_n, Y_n) satisfy $X_n \to -\infty$, $Y_n \to \overline{Y}$, and*

$$v_n(x,y) = v(x + x_n, y + y_n) \ \to \ U(\tau^* + \overline{Y} + Y) \ \textit{as } n \to \infty$$

in the spaces $W^{2,p}_{loc}(\mathbb{R}^2)$ *for all* $p > 1$.

Proof. Call

$$\mathcal{E} = \{\tau,\ w_\tau \geq v \text{ in } \mathbb{R}^2\}.$$

The set $\mathcal{E}$ is not empty from Lemma 3.9. Let us define

$$\tau^* = \inf\ \mathcal{E}.$$

The real τ^* is finite since $w_\tau(x, y) \to 0$ as $\tau \to -\infty$ for any $(x, y) \in \mathbb{R}^2$. By continuity with respect to τ, we have

$$w_{\tau^*} \geq v.$$

Since the function w_{τ^*} is a strict supersolution of (3.1) in the sense that it satisfies (3.13), the strong maximum principle yields that $w_{\tau^*} > v$ in $\mathbb{R}^2$.

Remember that ε satisfies (3.16). Owing to the definition of w, there exists a real $A \geq 0$ such that

$$w_{\tau^*} \geq 1 - \varepsilon/2 \ \text{ on } \{Y = h(X) + A\}. \tag{3.19}$$

Let us set $\Omega_+ = \{Y \geq h(X) + A\}$ and $\Omega_- = E_0 = \{Y \leq h(X)\}$. By (3.6) and Lemma 3.6, we have already seen that $v \leq \theta$ in Ω_-. Last, let $\mathcal{B} = \{h(X) < Y < h(X) + A\} = \mathbb{R}^2 \backslash (\Omega_+ \cup \Omega_-)$ (see Figure 5).

Comparison of $w_{\tau^*-\delta}$ *and* v *on* $\partial\Omega_+$. Since the function w is Lipschitz continuous and fulfills (3.19), we have $w_{\tau^*-\delta} \geq 1 - \varepsilon$ on $\partial\Omega_+ = \{Y = h(X) + A\}$ if $\delta \in (0, \delta_0)$ for δ_0 small enough. Two cases may occur:

(i) There exists $\delta_1 \in (0, \delta_0)$ such that $w_{\tau^*-\delta_1} > v$ on $\partial\Omega_+$.

(ii) For n large enough, there exists a point $(x_n, y_n) \in \partial\Omega_+$ such that

$$w_{\tau^*-1/n}(x_n, y_n) \leq v(x_n, y_n). \tag{3.20}$$

Study of case (i). In this case, we argue as in the proof of Lemma 3.9 and conclude that $w_{\tau^*-\delta_1} \geq v$ in Ω_+. As a consequence, for all $\delta \in [0, \delta_1]$, one has $w_{\tau^*-\delta} \geq v$ in Ω_+.

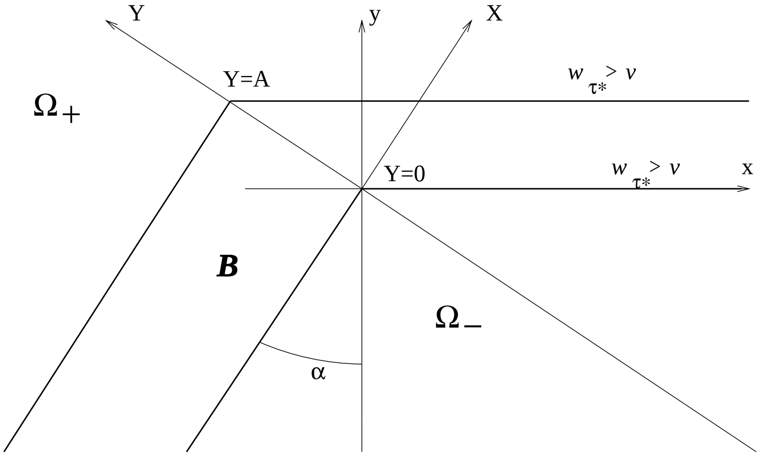

FIG. 5. *The sets* Ω_+, Ω_-, *and* $\mathcal{B}$.

Study of case (ii). In this case, the points (x_n, y_n) cannot be bounded; otherwise there exists a point $(\overline{x}, \overline{y}) \in \partial\Omega_+$ such that $w_{\tau^*}(\overline{x}, \overline{y}) = v(\overline{x}, \overline{y})$. But we have already seen that $w_{\tau^*} > v$ in $\mathbb{R}^2$. Hence one of the following situations occurs:

(ii)(a) There exists a subsequence of (x_n, y_n) such that $X_n \to -\infty$, and $Y_n = A$. We set

$$\begin{cases} w_n(x,y) &= w_{\tau^*}(x + x_n, y + y_n) \quad \text{in } \mathbb{R}^2, \\ v_n(x,y) &= v(x + x_n, y + y_n) \quad \text{in } \mathbb{R}^2. \end{cases}$$

Up to extraction of some subsequence, the functions v_n approach a solution v_∞ of (1.1) and the functions w_n approach the function $w_\infty = U(\tau^* + A + Y)$ in the spaces $W^{2,p}_{loc}(\mathbb{R}^2)$. At the limit $n \to +\infty$, we get

$$w_\infty \geq v_\infty \text{ in } \mathbb{R}^2. \tag{3.21}$$

Since the function w_τ has bounded derivatives, we conclude from (3.20) and (3.21) that $w_\infty(0,0) = v_\infty(0,0)$. Now, both functions v_∞ and w_∞ solve (1.1). From the strong maximum principle, we conclude that

$$v_\infty \equiv w_\infty = U(\tau^* + A + Y).$$

That gives the conclusion of Lemma 3.10.

(ii)(b) There exists a subsequence of (x_n, y_n) such that $x_n \to +\infty$, $y_n = A \sin\alpha$. We again normalize the functions w_{τ^*} and v as in case (ii)(a). Under the same notation as in case (ii)(a), we have $w_\infty = U((1/\sin\alpha)\ (y + A\sin\alpha) + \tau^*) \geq v_\infty$ and $w_\infty(0,0) = v_\infty(0,0)$. On the other hand, the function w_∞ is a solution of

$$\Delta w_\infty - c\partial_y w_\infty + f(w_\infty) = (1 - 1/\sin^2\alpha)\ f(U((1/\sin\alpha)\ (y + A\sin\alpha) + \tau^*)).$$

Since $\alpha < \pi/2$, the function w_∞ is then a strict supersolution of (1.1), whereas v_∞ is a solution. This is ruled out by the strong maximum principle.

As a conclusion of this part, only the cases (i) or (ii)(a) may occur and case (ii)(a) leads to the conclusion of Lemma 3.10.

Comparison of $w_{\tau^*-\delta}$ *and* v *on* $\partial\Omega_-$. As above, only two cases may occur:

(i′) There exists $\delta_2 \in (0, \delta_0)$ such that $w_{\tau^*-\delta_2} > v$ on $\partial\Omega_-$.

(ii′) For n large enough, there exists $(x_n, y_n) \in \partial\Omega_-$ such that

$$w_{\tau^*-1/n}(x_n, y_n) \leq v(x_n, y_n).$$

If case (i′) occurs, then, for any $0 \leq \delta \leq \delta_2$, we have $w_{\tau^*-\delta} > v$ on $\partial\Omega_-$. Since $f \equiv 0$ on $[0, \theta]$ and $v \leq \theta$ in Ω_-, with the same method as in the proof of Lemma 3.9, we would actually find that $w_{\tau^*-\delta} \geq v$ in Ω_- for all $0 \leq \delta \leq \delta_2$.

If case (ii′) occurs, we can argue word by word as in case (ii) above. That leads to the conclusion of Lemma 3.10.

Completion of the proof of Lemma 3.10. To complete the proof, the only thing left to consider is the case where both (i) and (i′) occur. Set $\delta_3 = \min(\delta_1, \delta_2)$. Thus

$$\forall \delta \in [0, \delta_3], \quad w_{\tau^*-\delta} \geq v \ \text{ in } \Omega_+ \cup \Omega_-. \tag{3.22}$$

From the definition of τ^*, for any $n \geq 1$, there exists a point (x_n, y_n) such that

$$w_{\tau^*-1/n}(x_n, y_n) < v(x_n, y_n).$$

By (3.22), the points (x_n, y_n) are in $\mathcal{B}$ for n large enough. Consequently, up to extraction of a subsequence, one of the following situations occurs:

(i,i′)(a) $X_n \to -\infty$, $Y_n \to \overline{Y} \in [0, A]$.

(i,i′)(b) $x_n \to +\infty$, $y_n \to \overline{y} \in [0, A \sin\alpha]$. The latter can be treated in the same way as the case (ii)(b) above: it is ruled out by the strong maximum principle.

Hence, only case (i,i′)(a) may occur and, as in the case (ii)(a), we get the conclusion of Lemma 3.10. □

Fourth step: Proving the planar behavior of u far away from the axis of symmetry. We are going to use here the (X, Y) coordinates. Fix a point $(X, Y) \in \mathbb{R}^2$. With the notation of Lemma 3.10, we have $X \geq X_n$ for n large enough. Since v is nondecreasing in the direction X, it follows that

$$v(X, Y) \geq v(X_n, Y) = v_n(0, Y - Y_n)$$

for n large enough. Since $Y_n \to \overline{Y}$ and since v has bounded derivatives, we conclude from Lemma 3.10 that

$$v(X_n, Y) \to U(\tau^* + Y) \text{ as } n \to \infty,$$

whence

$$v(X, Y) \geq U(\tau^* + Y).$$

On the other hand, from the definition of τ^*, we have

$$v(X, Y) \leq U(\tau^* + Y - \phi(X)).$$

By summarizing the previous results, it follows that

$$U(\tau^* + Y) \leq v(X, Y) \leq U(\tau^* + Y - \phi(X)) \text{ in } \mathbb{R}^2. \tag{3.23}$$

Now, for any $X_0 \geq 0$, consider the function

$$w^{X_0}(x, y) = U(Y - \phi(X - X_0)).$$

We could compare the functions w^{X_0} and v by arguing in the same way as above. First, the function w^{X_0} satisfies (3.13). Second, instead of (3.14), it is easy to check that

$$\forall \tau \geq X_0 \cot\alpha, \quad w_\tau^{X_0} := U(\tau + Y - \phi(X - X_0)) \geq v \text{ in } E_0.$$

Furthermore, we have $Y - \phi(X - X_0) \geq -X_0 \cot\alpha$ on ∂E_0. Hence, there exists a real $\tau_1' \geq 0$ that we can choose greater than $X_0 \cot\alpha$ such that

$$\forall \tau \geq \tau_1', \quad w_\tau^{X_0} \geq 1 - \varepsilon \text{ on } \partial E_0$$

with the same ε as in (3.16). As in Lemma 3.9, it follows that

$$\forall \tau \geq \tau_1', \quad w_\tau^{X_0} \geq v \text{ in } \mathbb{R}^2.$$

Lemma 3.10 can be applied to the function w^{X_0}. As for (3.23), we get the existence of a real $\tilde{\tau}^*$ such that

$$U(\tilde{\tau}^* + Y) \leq v(X, Y) \leq U(\tilde{\tau}^* + Y - \phi(X - X_0)) \text{ in } \mathbb{R}^2. \tag{3.24}$$

By taking the limit $X \to -\infty$ in (3.23) and (3.24) and by using the monotonicity of U, we conclude that $\widetilde{\tau^*} = \tau^*$.

As a consequence, for all $X_0 \geq 0$, we have

$$U(\tau^* + Y) \leq v(X, Y) \leq U(\tau^* + Y - \phi(X - X_0)) \ \text{ in } \mathbb{R}^2.$$

We pass to the limit $X_0 \to +\infty$ and obtain

$$U(\tau^* + Y) \leq v(X, Y) \leq U(\tau^* + Y) \ \text{ in } \mathbb{R}^2.$$

Since $v(0, 0) = U(0) = \theta$, it follows that $\tau^* = 0$. In other words, the function v is actually nothing but the planar function $U(Y)$. Last, the function v, which is the limit of a subsequence of the functions $v_n(x, y) = u(x + x_n, y + y_n)$, does not depend on the sequence $x_n \to -\infty$. We conclude that the whole sequence (u_n) approaches the function $U(Y)$.

So far, we have proved that, for any $x \in \mathbb{R}$, there existed a unique real $y = \varphi_\theta(x)$ such that $u(x, y) = \theta$. Furthermore, for any sequence $x_n \to -\infty$, the functions $u_n(x, y) = u(x + x_n, y + \varphi_\theta(x_n))$ approach the planar function $U(Y) = U(y \sin\alpha - x \cos\alpha)$.

Let $\lambda \in (0, 1)$. We shall now prove that the level set $\{(x, y),\ u(x, y) = \lambda\}$ is a curve $\{y = \varphi_\lambda(x),\ x \in \mathbb{R}\}$.

First of all, the function u is increasing with respect to y. For each $x \in \mathbb{R}$, set $\psi(x) = \lim_{y \to +\infty} u(x, y)$. In the set $\Omega = \mathbb{R} \times (0, 1)$, let us define the functions

$$\tilde{u}_n(x, y) = u(x, y + n) \ \text{ in } \Omega.$$

They still satisfy (3.1). From the standard elliptic estimates, those functions $\tilde{u}_n$ approach, up to extraction of some subsequence, a function u_∞ that is a solution of

$$\Delta u_\infty - c\partial_y u_\infty + f(u_\infty) = 0 \ \text{ in } \Omega.$$

But this function $v_\infty(x, y)$ is actually identically equal to the function $\psi(x)$. Hence, ψ fulfills

$$\psi'' + f(\psi) = 0 \ \text{ in } \mathbb{R}.$$

On the other hand, for any $y \in \mathbb{R}$, the function $x \mapsto u(x, y)$ is symmetric, nonincreasing in x for $x \leq 0$, and nondecreasing for $x \geq 0$. The same property holds well for the limit function ψ. Thus, 0 is a minimum point of ψ; whence $\psi''(0) \geq 0$. Furthermore, $\psi''(0) = -f(\psi(0)) \leq 0$. Hence, $\psi''(0) = f(\psi(0)) = 0$. In other words, $\psi(0)$ is a zero of the function f. Since $\psi(0) > u(0, 0) = \theta$ and since f is positive on $(\theta, 1)$, we conclude that $\psi(0) = 1$ and finally that $\psi \equiv 1$.

Hence, for any $x \in \mathbb{R}$, $u(x, y) \to 1$ as $y \to +\infty$. Furthermore, $u(x, y) \to 0$ as $y \to -\infty$ from (3.5) applied in $z_0 = (0, 0)$. Since u is continuous and increasing in y, we conclude that there exists a unique $y = \varphi_\lambda(x)$ such that $u(x, \varphi_\lambda(x)) = \lambda$.

Let (x_n) be a sequence such that $x_n \to -\infty$ as $n \to \infty$ and let K be the compact set

$$K = \{(X, Y) \in \mathbb{R}^2,\ |X| \leq 2 \cot\alpha\ |U^{-1}(\lambda)|,\ |Y| \leq 2|U^{-1}(\lambda)|\}.$$

We know that the functions $u_n(x, y) = u(x + x_n, y + \varphi_\theta(x_n))$ approach the function $U(Y) = U(y \sin\alpha - x \cos\alpha)$ uniformly in K. For any $\varepsilon > 0$, there exists an integer n_0 such that if $n \geq n_0$, then

$$u_n(0, (1/\sin\alpha)\ U^{-1}(\lambda) - \varepsilon) < \lambda \ \text{ and } \ u_n(0, (1/\sin\alpha)\ U^{-1}(\lambda) + \varepsilon) > \lambda.$$

Hence, for $n \geq n_0$, one has

$$\varphi_\theta(x_n) + (1/\sin\alpha)\ U^{-1}(\lambda) - \varepsilon \leq \varphi_\lambda(x_n) \leq \varphi_\theta(x_n) + (1/\sin\alpha)\ U^{-1}(\lambda) + \varepsilon.$$

It then follows that

$$\varphi_\lambda(x_n) - \varphi_\theta(x_n) \to (1/\sin\alpha)\ U^{-1}(\lambda) \text{ as } n \to \infty.$$

Since this limit does not depend on the sequence $x_n \to -\infty$, we conclude that, for any $\lambda, \lambda' \in (0,1)$,

$$\varphi_\lambda(x) - \varphi_{\lambda'}(x) \to (1/\sin\alpha)\ (U^{-1}(\lambda) - U^{-1}(\lambda')) \text{ as } x \to -\infty.$$

The same limit also holds as $x \to +\infty$ by symmetry.

In particular, that implies that the functions $\tilde{u}_n(x,y) = u(x + x_n, y + \varphi_\lambda(x_n))$ approach the function $U(Y + U^{-1}(\lambda))$ in $W^{2,p}_{loc}(\mathbb{R}^2)$.

3.4. Asymptotic directions for the level sets of *u*. Let $\vec{k}$ be a vector in the open cone $\mathcal{C}(\vec{e_2}, \pi - \alpha)$. We are going to prove that the function u fulfills the limiting condition (1.3), namely, that $u(\lambda\vec{k}) \to 1$ as $\lambda \to +\infty$. By symmetry with respect to x and since $u(0,y) \to 1$ as $y \to +\infty$, it is enough to treat the case of a vector $\vec{k}$ such that $\vec{k} \cdot \vec{e}_1 < 0$. We can write $\vec{k} = (-\sin\beta, -\cos\beta)$ with $\alpha < \beta < \pi$ (β is the angle between $\vec{k}$ and $-\vec{e}_2$ if one goes clockwise).

Let $0 < \varepsilon < 1$. We shall show that, for λ large enough, we have

$$u(\lambda\vec{k}) \geq 1 - \varepsilon.$$

Consider the compact $K = [-1,1] \times [-2\cot\alpha, 2\cot\alpha]$ and the functions

$$u_n(x,y) = u(x - n, y + \varphi_{1-\varepsilon/2}(-n)).$$

From the previous sections, these functions u_n converge uniformly in K to the function $U(y\sin\alpha - x\cos\alpha + U^{-1}(1 - \varepsilon/2))$.

Let S be the segment between the points $(0,0)$ and $(-1, -\cot\alpha)$. The functions u_n converge uniformly to $1 - \varepsilon/2$ on S. Since u is increasing in y, we deduce that there exists n_0 large enough such that

$$(3.25)\ \forall n \geq n_0, \quad \forall x \in [-n-1, -n], \quad \varphi_{1-\varepsilon}(x) \leq \varphi_{1-\varepsilon/2}(-n) + \cot\alpha\ (x + n).$$

Similarly, since $\alpha < \beta < \pi$ and since U is increasing, the sequence $(u_n(-1, -\cot((\alpha + \beta)/2)))$ approaches $1 - \eta$, as $n \to \infty$, with $0 < \eta < \varepsilon/2$. Hence, there exists $n_0' \geq n_0$ such that

$$\forall n \geq n_0', \quad \varphi_{1-\varepsilon/2}(-n-1) \leq \varphi_{1-\varepsilon/2}(-n) - \cot((\alpha+\beta)/2).$$

With an immediate induction, we get that

$$(3.26) \qquad \forall n \geq n_0', \quad \varphi_{1-\varepsilon/2}(-n) \leq \varphi_{1-\varepsilon/2}(-n_0') - \cot((\alpha+\beta)/2)(n - n_0').$$

Putting together (3.25) and (3.26), we have, for all $n \geq n_0'$ and for all $x \in [-n-1, -n]$,

$$\varphi_{1-\varepsilon}(x) \leq \varphi_{1-\varepsilon/2}(-n_0') + \cot\alpha\ (x + n) - \cot((\alpha+\beta)/2)\ (n - n_0').$$

Since $\cot\alpha \geq \cot((\alpha+\beta)/2)$ and since $x+n \leq 0$ in the previous inequality, we get

$$\forall x \leq -n_0', \quad \varphi_{1-\varepsilon}(x) \leq \varphi_{1-\varepsilon/2}(-n_0') + \cot((\alpha+\beta)/2)\ (x+n_0').$$

By putting $x = -\lambda\sin\beta$ in the last inequality, and since $\beta > \alpha$, we conclude that, for λ large enough,

$$\varphi_{1-\varepsilon}(-\lambda\sin\beta) \leq -\lambda\cos\beta.$$

Remember that $\vec{k} = (-\sin\beta, -\cos\beta)$ and that u is increasing with respect to y. It follows that $u(\lambda\vec{k}) \geq 1-\varepsilon$ for λ large enough. That implies the required formula (1.3).

Since (1.3) is true for any $\vec{k} \in \mathcal{C}(\vec{e}_2, \pi-\alpha)$ and since u is increasing with respect to y, the stronger limit (1.9) also holds.

Furthermore, for any $\rho \in \mathcal{C}(-\vec{e}_2, \alpha)$, we already know that u is nonincreasing in the direction ρ. Hence, for any $\tau > 0$, the function $z = u((x,y)+\tau\rho) - u(x,y)$ is nonpositive and it satisfies a linear elliptic equation of the type $\Delta z - c\partial_z + c(x,y)z = 0$ in $\mathbb{R}^2$ where $c(x,y)$ is a bounded function. Since $u(\lambda\rho) \to 0$ (resp., 1) as $\lambda \to +\infty$ (resp., $\lambda \to -\infty$), the function z cannot be identically 0. The strong maximum principle implies then that $z > 0$ in $\mathbb{R}^2$. In other words, the function u is decreasing in the direction ρ.

Last, the limiting conditions (1.2) and (1.3) imply that each level set $\{y = \varphi_\lambda(x),\ x \in \mathbb{R}\} = \{u = \lambda\}$ of the function u has two asymptotic directions that are directed by the vectors $(\pm\sin\alpha, -\cos\alpha)$.

4. Uniqueness of the speed *c*. In sections 2 and 3, we have proved the existence of a solution (c,u) of (1.1)–(1.3), (1.8)–(1.9) with the speed $c = c_0/\sin\alpha$ for any angle $\alpha \in (0, \pi/2]$.

Choose an angle $\alpha \in (0,\pi/2]$ and let (c,u) be a solution of (1.1)–(1.3), (1.8)–(1.9). First of all, since f is extended by 0 outside $[0,1]$, the strong maximum principle implies that $0 < u < 1$ in $\mathbb{R}^2$. We shall now prove the equality $c = c_0/\sin\alpha$. We divide the proof into three main steps.

(1) Let us consider the case where $0 < \alpha < \pi/2$ and let us suppose that $c < c_0/\sin\alpha$. For $\varepsilon > 0$ small enough, let f_ε be the function defined in $[-\varepsilon, 1-\varepsilon]$ by

$$f_\varepsilon(s) = \begin{cases} f(s) & \text{on } [-\varepsilon, 1-2\varepsilon], \\ \min\ (f(s), (1-\varepsilon-s)/\varepsilon\ f(1-2\varepsilon)) & \text{on } [1-2\varepsilon, 1-\varepsilon]. \end{cases}$$

Furthermore, we extend the functions f_ε by 0 outside $[-\varepsilon, 1-\varepsilon]$. For $\varepsilon > 0$ small enough, f_ε is Lipschitz continuous in $[-\varepsilon, 1-\varepsilon]$, $(f_\varepsilon)'_-(1-\varepsilon) := \lim_{t\to 1-\varepsilon,\ t<1-\varepsilon} \frac{f_\varepsilon(t)}{t-1+\varepsilon}$ exists and is negative, and f_ε fulfills (1.4) on $[-\varepsilon, 1-\varepsilon]$ with the ignition temperature θ. Moreover, we have $f_\varepsilon \leq f$ and the functions f_ε approach f uniformly in $[0,1]$ as $\varepsilon \to 0$. From the results in [2], [9], [15], [24], there exists a unique couple $(c_\varepsilon, u_\varepsilon)$ satisfying

$$\text{(4.1)} \qquad \begin{cases} u_\varepsilon'' - c_\varepsilon u_\varepsilon' + f_\varepsilon(u_\varepsilon) &= 0 \quad \text{in } \mathbb{R}, \\ u_\varepsilon(-\infty) = -\varepsilon,\ u_\varepsilon(0) = \theta,\ u_\varepsilon(+\infty) &= 1-\varepsilon. \end{cases}$$

Furthermore, we have $c_\varepsilon \leq c_0$ and $c_\varepsilon \to c_0$ as $\varepsilon \to 0$ [9].

Since $c < c_0/\sin\alpha$ and $0 < \alpha < \pi/2$, there exist a real $\varepsilon > 0$ small enough and an angle α' such that $0 < \alpha < \alpha' < \pi/2$ and $c < c_\varepsilon/\sin\alpha' < c_0/\sin\alpha$. Set

$$v(x,y) = u_\varepsilon(y\sin\alpha' - x\cos\alpha').$$

Let us first check that v is a subsolution of (1.1). Indeed,

$$\begin{aligned}\Delta v - c\partial_y v + f(v) &= u_\varepsilon'' - c\ \sin\alpha'\ u_\varepsilon' + f(u_\varepsilon)\\ &= (c_\varepsilon - c\sin\alpha')u_\varepsilon' + f(u_\varepsilon) - f_\varepsilon(u_\varepsilon) > 0 \text{ in } \mathbb{R}^2\end{aligned} \tag{4.2}$$

since $c_\varepsilon > c\ \sin\alpha'$, $u_\varepsilon' > 0$, and $f \geq f_\varepsilon$.

We now claim that there exists $\tau \geq 0$ such that

$$v(x, y-\tau) < u(x,y) \text{ in } \mathbb{R}^2. \tag{4.3}$$

If not, then for any $n \in \mathbb{N}$, there exists a point $(x_n, y_n) \in \mathbb{R}^2$ such that

$$v(x_n, y_n - n) = u_\varepsilon(\sin\alpha'\ (y_n - n) - \cos\alpha'\ x_n)\ \geq\ u(x_n, y_n). \tag{4.4}$$

The points (x_n, y_n) are not bounded; otherwise the left-hand side of (4.4) approaches $-\varepsilon$, whereas the right-hand side is nonnegative. Write $(x_n, y_n) = \lambda_n(\sin\varphi_n, -\cos\varphi_n)$ with $-\pi < \varphi_n \leq \pi$: φ_n is the angle between (x_n, y_n) and the vector $-\vec{e}_2$ if one goes counterclockwise. We have $\lambda_n \to +\infty$. We can assume, up to extraction, that the sequence (φ_n) approaches $\varphi \in [-\pi, \pi]$ as $n \to +\infty$.

If $-\alpha' < \varphi < \pi - \alpha'$, then

$$v(x_n, y_n - n) = u_\varepsilon(-\lambda_n \sin(\alpha' + \varphi_n) - n\sin\alpha') \to -\varepsilon \text{ as } n \to \infty.$$

This is ruled out by (4.4) since $u > 0$.

In the other case, one has $-\pi \leq \varphi \leq -\alpha'$ or $\pi - \alpha' \leq \varphi \leq \pi$. In particular, $\varphi \in [-\pi, -\alpha) \cup (\alpha, \pi]$. The limiting condition (1.9) implies that $u(x_n, y_n) \to 1$ as $n \to \infty$. This contradicts (4.4) because $u_\varepsilon \leq 1 - \varepsilon$.

As a consequence, (4.3) is true. Next, decrease τ and define

$$\tau^* = \inf\{\tau \in \mathbb{R},\ v(x, y-\tau) < u(x,y) \text{ in } \mathbb{R}^2\}.$$

This real τ^* is finite because there are some points (x, y) where $u(x,y) < 1 - \varepsilon$ and $v(x, y-\tau) \to 1 - \varepsilon$ as $\tau \to -\infty$. For each $n \in \mathbb{N}^*$, there exists a point (x^n, y^n) such that

$$v(x^n, y^n - \tau^* + 1/n) = u_\varepsilon(\sin\alpha'\ (y^n - \tau^* + 1/n) - \cos\alpha'\ x^n) \geq u(x^n, y^n).$$

With the same arguments as above, we claim that the points (x^n, y^n) are bounded. Hence there exists a point $(\overline{x}, \overline{y}) \in \mathbb{R}^2$ such that $v(\overline{x}, \overline{y} - \tau^*) \geq u(\overline{x}, \overline{y})$. Moreover, owing to the definition of τ^*, we have $v(x, y-\tau^*) \leq u(x,y)$ in $\mathbb{R}^2$. The function $z(x,y) = v(x, y-\tau^*) - u(x,y)$ is nonpositive and reaches 0 somewhere in $\mathbb{R}^2$. Furthermore, from (1.1) and (4.2), it satisfies $\Delta z - c\partial_y z + f(v(x, y-\tau^*)) - f(u) \geq 0$ in $\mathbb{R}^2$. This implies that

$$\Delta z - c\partial_y z + c(x,y) z \geq 0$$

for a bounded function $c(x,y)$. The strong maximum principle yields that $z \equiv 0$ in $\mathbb{R}^2$; i.e., $v(x, y-\tau^*) = u_\varepsilon(\sin\alpha'\ (y - \tau^*) - \cos\alpha'\ x) \equiv u(x,y)$ in $\mathbb{R}^2$. This is impossible because $u_\varepsilon \leq 1 - \varepsilon$ and $\sup_{\mathbb{R}^2} u = 1$.

Eventually, that shows that if $0 < \alpha < \pi/2$, then $c \geq c_0/\ \sin\alpha$.

(2) In this part, we deal with the case $\alpha = \pi/2$, which has not been treated in part 1. Indeed, the sliding method used in part 1 no longer works for the limiting case $\alpha = \pi/2$.

Suppose that $c < c_0$. With the same notation as in part 1, there exists a real $\varepsilon > 0$, small enough and fixed, such that $c < c_\varepsilon$, where $(c_\varepsilon, u_\varepsilon)$ is the solution of (4.1). For some reals η, $\kappa > 0$ that will be chosen later, consider the function $v(x, y) = u_\varepsilon(y - \varphi(x))$, where $\varphi(x) = \sqrt{\eta^2 x^2 + \kappa^2}$.

Let us check that this function v is a subsolution of (1.1) if $\eta > 0$ and $\kappa > 0$ are suitably chosen. We have

$$\begin{aligned}\Delta v - c\partial_y v + f(v) &= (1 + \varphi'(x)^2)u_\varepsilon'' - \varphi''(x)u_\varepsilon' - cu_\varepsilon' + f(u_\varepsilon)\\ &= \varphi'(x)^2 u_\varepsilon'' + (c_\varepsilon - c - \varphi''(x))u_\varepsilon' + f(u_\varepsilon) - f_\varepsilon(u_\varepsilon).\end{aligned}$$

On the one hand, we have $f \geq f_\varepsilon$. On the other hand, since u_ε fulfills (4.1), it is well known that u_ε admits the following asymptotic behavior as $x_1 \to \pm\infty$: $u_\varepsilon(x_1) = -\varepsilon + (\theta + \varepsilon)e^{c_\varepsilon x_1}$ if $x_1 \leq 0$ and $u_\varepsilon(x_1) = 1 - \varepsilon - \alpha e^{\lambda' x_1} + o(e^{\lambda x_1})$, $u_\varepsilon'(x_1) = -\alpha\lambda e^{\lambda' x_1} + o(e^{\lambda x_1})$ as $x_1 \to +\infty$, where $\lambda = \frac{c_\varepsilon - \sqrt{c_\varepsilon^2 - 4(f_\varepsilon)'_-(1-\varepsilon)}}{2} < 0$. Furthermore, we have $u_\varepsilon'' = c_\varepsilon u_\varepsilon' - f_\varepsilon(u_\varepsilon)$ and $u_\varepsilon' > 0$ in $\mathbb{R}$. Finally, there exists a constant $C > 0$ such that $|u_\varepsilon''| \leq Cu_\varepsilon'$ in $\mathbb{R}$. Remember now that $c_\varepsilon > c$. In order to have $\Delta v - c\partial_y v + f(v) \geq 0$ in $\mathbb{R}^2$, it is then sufficient to choose the function ϕ such that $|\varphi'^2|$ and $|\varphi''|$ are small enough. We have $|\varphi'^2| \leq \eta^2$ and $|\varphi''| \leq \eta^2/\kappa$. Hence, we can choose $\eta > 0$ and $\kappa > 0$ such that

$$\Delta v - c\partial_y v + f(v) \geq 0 \quad \text{in } \mathbb{R}^2.$$

To sum up, the function v is a subsolution of (1.1) and each of its level sets has two asymptotes directed by the vectors $(\pm 1, \arctan \eta)$.

We can now argue as in part 1: formula (4.3) is still true if τ is large enough. As in part 1, we can decrease τ, we can define τ^*, and we get a contradiction thanks to the maximum principle.

This eventually proves that if $\alpha = \pi/2$, then $c \geq c_0$.

(3) Choose now any angle $\alpha \in (0, \pi/2]$. We still have to prove that $c \leq c_0/\sin\alpha$. Suppose on the contrary that $c > c_0/\ \sin\alpha$. Let us consider some functions f^ε on $[\varepsilon, 1+\varepsilon]$ such that $f^\varepsilon = f$ on $[\varepsilon, 1-\varepsilon]$, $f^\varepsilon > 0$ on $(\theta, 1+\varepsilon)$, $f^\varepsilon(1+\varepsilon) = 0$, $(f^\varepsilon)'(1+\varepsilon)$ exists and is negative, $f^\varepsilon \geq f$ and $\|f^\varepsilon - f\|_\infty \to 0$ as $\varepsilon \to 0$. In particular, the function f^ε is of the ignition temperature type on the interval $[\varepsilon, 1+\varepsilon]$. For each $\varepsilon > 0$ small enough, there exists a unique couple $(c^\varepsilon, u^\varepsilon)$ fulfilling

$$\left\{\begin{aligned} u^{\varepsilon\prime\prime} - c^\varepsilon u^{\varepsilon\prime} + f^\varepsilon(u^\varepsilon) &= 0 \quad \text{in } \mathbb{R},\\ u^\varepsilon(-\infty) = \varepsilon,\ u^\varepsilon(0) = \theta,\ u^\varepsilon(+\infty) &= 1+\varepsilon.\end{aligned}\right.$$

Furthermore, $c^\varepsilon > c_0$ and $c^\varepsilon \to c_0$ as $\varepsilon \to 0$ (see [9]).

Choose α' and $\varepsilon > 0$ such that $0 < \alpha' < \alpha \leq \pi/2$ and $c > c^\varepsilon/\sin\alpha' > c_0/\ \sin\alpha$. From Theorem 1.1 applied to the function f^ε, there exists a solution $v(x, y)$ of

$$\left\{\begin{array}{ll} & \Delta v - c^\varepsilon/\sin\alpha'\ \partial_y v + f^\varepsilon(v) = 0 \ \text{ in } \mathbb{R}^2,\\ v(\lambda\vec{k}') \to \varepsilon & \text{as } \lambda \to +\infty \text{ and } \vec{k}' \to \vec{k} \in \mathcal{C}(-\vec{e}_2, \alpha'),\\ v(\lambda\vec{k}') \to 1+\varepsilon & \text{as } \lambda \to +\infty \text{ and } \vec{k}' \to \vec{k} \in \mathcal{C}(\vec{e}_2, \pi - \alpha').\end{array}\right.$$

Moreover, $\partial_y v \geq 0$. The function v is a supersolution of (1.1) in the sense that

$$\Delta v - c\partial_y v + f(v) = (c^\varepsilon/\sin\alpha' - c)\partial_y v + f(v) - f^\varepsilon(v) \leq 0 \ \text{ in } \mathbb{R}^2$$

since $c > c^\varepsilon/\sin\alpha'$, $\partial_y v \geq 0$, and $f \leq f^\varepsilon$.

We now claim that there exists $\tau \geq 0$ such that

$$v(x, y + \tau) > u(x, y) \text{ in } \mathbb{R}^2.$$

Otherwise, for each $n \in \mathbb{N}$, there exists a point $(x^n, y^n) \in \mathbb{R}^2$ such that $v(x^n, y^n + n) \leq u(x^n, y^n)$. As in part 1, by dealing successively with the cases where the sequence (x_n, y_n) is bounded or unbounded, we would get a contradiction.

Now, let us set

$$\tau^* = \inf \{\tau \in \mathbb{R},\ v(x, y + \tau) > u(x, y) \text{ in } \mathbb{R}^2\}.$$

As above, τ^* is finite and $v(x, y + \tau^*) \geq u(x, y)$ in $\mathbb{R}^2$ with equality somewhere. This is ruled out by the strong maximum principle.

Finally, it is always true that $c \leq c_0/\ \sin\alpha$. Together with parts 1 and 2, this inequality completes the proof of Theorem 1.2.

5. Appendix: Proof of Lemma 2.10. In this section, we actually deal with a more general situation than in Lemma 2.10. Let u be a bounded and positive function defined in the set

$$V = \{(x, y) \in \mathbb{R}^2, x > 0, y > 0, \sqrt{x^2 + y^2} < \delta\}$$

for a certain $\delta > 0$. We assume that the function u belongs to $W^{2,p}_{loc}(\overline{V}\backslash\{(0,0)\})$ for all $1 < p < \infty$ and that it is continuous in $\overline{V}$. We also suppose that that function v satisfies the following equations:

$$\left\{ \begin{aligned} \Delta u - c\partial_y u + f(u) &= 0 \quad \text{in } V, \\ u(x, 0) &= 0 \quad \text{for } 0 \leq x \leq \delta, \\ \partial_\tau u(0, y) &= 0 \quad \text{for } 0 < y \leq \delta, \end{aligned} \right. \tag{5.1}$$

where $\tau = (-\sin\alpha, -\cos\alpha)$. The given function f is Lipschitz continuous. Furthermore, $f(0) = 0$ and $f'_+(0) = \lim_{t\to 0,\ t>0} \frac{f(t)-f(0)}{t}$ exists.

Set $O = (0, 0)$. Choose any vector $\rho = (\cos\beta, \sin\beta)$ with $\pi/2 - \alpha < \beta < \pi$. We are going to determine the asymptotic behavior of u and ∇u in the neighborhood of the corner O. That behavior will imply the existence of a neighborhood $\tilde{V}$ of O and of a real $\varepsilon_1 > 0$ such that if $0 < \varepsilon \leq \varepsilon_1$ and if z, $z + \varepsilon\rho \in \tilde{V} \cap \overline{V}$, then $u(z) < u(z + \varepsilon\rho)$.

Before doing that, we briefly mention some papers and results that have been devoted to similar problems in the literature. In many works (see, e.g., Bernardi and Maday [10], Grisvard [19], Maz'ja and Plamenevskii [30]), the *linear* elliptic problem

$$\begin{gathered} Lu = f \text{ in } G, \\ Bu = g \text{ on } \partial G\backslash\{K\} \end{gathered} \tag{5.2}$$

has been investigated under the assumption that G is a subdomain of the plane $\mathbb{R}^2$ and that the boundary ∂G of G is Lipschitz continuous everywhere and smooth except at a corner K, say, $K = O$. Assume that L is an elliptic operator and B is a smooth linear function depending on the traces of u or ∇u on $\partial G\backslash\{K\}$. The function u belongs to some Sobolev spaces with weights but u, or its derivatives, may be singular at the point K. The general result is the following: in a neighborhood of the point $K = O$, the function u can be written as

$$u(r, \theta) = \sum_{k\geq 1} c_k r^{\alpha_k} \sum_{h=0}^{k} (-\ln r)^h \varphi_{k,h}(\theta), \tag{5.3}$$

where (r, θ) is the usual polar coordinate and where the complex numbers α_k have nondecreasing real parts. Thanks to the change of variables $r = e^t$ (see Kondrat'ev [25]), equation (5.2) becomes

$$\tilde{L}u = \tilde{f}$$

in a set containing an infinite strip of the type $(-\infty, \alpha] \times (0, \beta)$. The terms r^{α_k} become $e^{\alpha_k t}$ and the numbers α_k are given in terms of the eigenvalues of an operator L_0 depending on θ and on the principal part of L at the corner K.

In particular, for the Dirichlet problem

$$\begin{aligned} \Delta u = f \quad & \text{in } G = \{r > 0,\ 0 < \theta < \omega\}, \\ u = 0 \quad & \text{on } \partial G \backslash \{K\}, \end{aligned}$$

where $f \in W^{m,p}(G)$, it is known that, in a neighborhood of K, the function u is equal to

$$u(r, \theta) = \sum_{\pi/\omega \leq k\pi/\omega < m+2-2/p} c_k r^{k\pi/\omega} \left\{ \begin{array}{l} \sin(k\pi\theta/\omega) \\ \text{or } (\ln r)\sin(k\pi\theta/\omega) + \theta\cos(k\pi\theta/\omega) \end{array} \right. + \ u_R,$$

where $u_R \in W^{m+2,p}(G)$ (see Geymonat and Grisvard [16], Grisvard [19], [20], or Dauge [13] for a three-dimensional situation).

Let us now come back to the elliptic problem (5.1) that is set in the domain V with the corner O. The boundary conditions on ∂V are of the Dirichlet and oblique-Neumann type. But, unlike the problems mentioned above, we have to deal with a *semilinear* problem. Then, we cannot a priori hope for an infinite asymptotic development of the type (5.3) for u. Nevertheless, we only need to know what u and its derivatives are equivalent to in the neighborhood of O.

In [9], [8], Berestycki and Nirenberg have emphasized the semilinear problem

$$\begin{aligned} Lu + f(x_1, u) = 0,\ u > 0 \quad & \text{in } \Sigma_- = \{(x_1, y),\ x_1 < 0,\ y \in \omega\}, \\ \partial_\nu u = 0 \quad & \text{on } (-\infty, 0) \times \partial\omega, \end{aligned}$$

where ω is a smooth domain with unit outward normal ν. If $u \to 0$ as $x_1 \to -\infty$ and if $|f(x_1, u)| = O(u^{1+\delta})$ as $u \to 0$ for a certain $\delta > 0$, then the nonlinear term $f(x_1, u)$ only makes small perturbations with respect to Δu. The asymptotic behavior of u as $x_1 \to -\infty$ is given in [8], [9].

If we come back to (5.1) and if we make the change of variables $r = e^t$, we can see that u fulfills

$$\Delta u - c\sin\theta \varepsilon^t \partial_t u - c\cos\theta\ e^t \partial_\theta u + e^{2t} f(u) = 0 \text{ in } (-\infty, \ln\delta) \times (0, \pi/2)$$

with Dirichlet and oblique-Neumann boundary conditions:

$$\begin{aligned} u = 0 \quad & \text{on } \{\theta = 0\}, \\ -\cos\alpha\ \partial_t u + \sin\alpha\ \partial_\theta u = 0 \quad & \text{on } \{\theta = \pi/2\}. \end{aligned}$$

To conclude this discussion, the semilinear problem (5.1) with mixed boundary conditions does not seem to have been treated so far in the literature. Hence, for the sake of completeness, we give a detailed proof of Lemma 5.1.

LEMMA 5.1. *Let $\gamma = (2/\pi)\ \alpha$. There exists a real $\lambda > 0$ such that*

$$\left\{ \begin{array}{rl} u - \lambda r^\gamma \sin(\gamma\theta) & = o(r^\gamma) \\ \nabla u - \lambda \nabla(r^\gamma \sin(\gamma\theta)) & = o(r^{\gamma-1}) \end{array} \right. \quad \textit{as } r \overset{>}{\to} 0.$$

Proof of Lemma 2.10. Consider the behavior of u near the corner C_1 of Σ_a and call (r,θ) the polar coordinates with respect to the point C_1. From Lemma 5.1, one has

$$\nabla u \cdot \rho - \lambda \nabla(r^\gamma \sin(\gamma\theta)) \cdot \rho = o(r^{\gamma-1}) \quad \text{as } r \to 0. \tag{5.4}$$

Remember that $\rho = (\cos\beta, \sin\beta)$ with $\pi/2 - \alpha < \beta < \pi$. Thus,

$$\nabla(r^\gamma \sin(\gamma\theta)) \cdot \rho = \gamma r^{\gamma-1} \sin((\gamma-1)\theta + \beta).$$

For any point $z = (r,\theta) \in V$, we have

$$0 < \alpha - \pi/2 + \beta \leq (\gamma-1)\theta + \beta \leq \beta < \pi.$$

As a consequence, there exists a real $\eta > 0$ such that

$$r^{-(\gamma-1)}\ \nabla(r^\gamma \sin(\gamma\theta)) \cdot \rho \geq \eta > 0.$$

From (5.4), it follows then that $\partial_\rho u > 0$ in a neighborhood V_1 of C_1. As far as the behavior of the function u near the corner C_1 of Σ_a is concerned, Lemma 2.10 is then a consequence of the finite increment theorem.

The other corner C_3 can be treated similarly. Indeed, after setting the origin in C_3 and making the change of variables $y \to -y$, $\tilde{u}(x,y) = u(x,-y)$, we find that

$$\left\{ \begin{array}{ll} (1-\tilde{u}) - \lambda r^\gamma \sin(\gamma\theta) & = o(r^\gamma) \\ -\nabla\tilde{u} - \lambda\nabla(r^\gamma \sin(\gamma\theta)) & = o(r^{\gamma-1}) \end{array} \right. \quad \text{as } r \overset{>}{\to} 0,$$

where $\gamma = (2/\pi)\ (\pi - \alpha)$ and where λ is a positive real. The same calculations as above yield that, for any $\rho = (\cos\beta, \sin\beta)$ with $\pi/2 - \alpha < \beta < \pi$, the function u is such that $\partial_\rho u > 0$ in a neighborhood V_3 of C_3. Notice that, unlike the situation around the point C_1, the function $\partial_\rho u$ is bounded near C_3 since $\gamma \geq 1$. □

Proof of Lemma 5.1. Remember first that $V = \{0 < r < \delta,\ 0 < \theta < \pi/2\}$. We choose to work with the (r,θ) coordinates. Notice that everything works similarly with the coordinates (t,θ), where $r = e^t$. The following proof, similar to the one in [8], is divided into six main steps for the sake of clarity.

Step 1. Set $\gamma = (2/\pi)\ \alpha$; notice that $\gamma \in (0,1]$. Let v be the function

$$v(r,\theta) = r^\gamma \sin(\gamma\theta) \quad \text{for } (r,\theta) \in (0,\delta] \times [0,\pi/2]$$

and $v(O) = 0$. It is easy to check that

$$\left\{ \begin{array}{rl} \Delta v = 0 & \text{in } V, \\ \partial_\tau v(0,y) = 0 & \text{if } 0 < y < \delta, \end{array} \right.$$

where $\tau = (-\sin\alpha, -\cos\alpha)$. Moreover, $v(x,0) = 0$ for all $0 \leq x \leq \delta$ and $v(x,y) > 0$ if $y > 0$.

Step 2. We now want to construct two sub- and supersolutions $\underline{v}$ and $\overline{v}$ such that

$$\left\{ \begin{array}{rl} \Delta\underline{v} - c\partial_y \underline{v} + f(\underline{v}) \geq 0 & \text{in } V_0, \\ \underline{v}(x,0) \leq 0 & \text{if } 0 \leq x < \delta_0, \\ \partial_\tau \underline{v}(0,y) < 0 & \text{if } 0 < y < \delta_0, \end{array} \right. \tag{5.5}$$

$$\text{(5.6)}\qquad \begin{cases} \Delta\overline{v} - c\partial_y\overline{v} + f(\overline{v}) \le 0 & \text{in } V_0, \\ \overline{v}(x,0) \ge 0 & \text{if } 0 \le x < \delta_0, \\ \partial_\tau\overline{v}(0,y) > 0 & \text{if } 0 < y < \delta_0, \end{cases}$$

in a small enough neighborhood V_0 of O of the type $V_0 = V \cap B(0,\delta_0)$, where the real $\delta_0 \in (0,\delta]$ will be chosen later.

Consider the functions

$$\begin{cases} \underline{g}(\theta) & = 1 - \cos(\underline{\beta}\theta) + \underline{A}\sin(\underline{\beta}\theta), \\ \overline{g}(\theta) & = -1 + \cos(\overline{\beta}\theta) + \overline{A}\sin(\overline{\beta}\theta), \end{cases}$$

and

$$\begin{cases} \underline{v} & = r^\gamma\sin(\gamma\theta) + r^{\underline{\beta}}\underline{g}(\theta), \\ \overline{v} & = r^\gamma\sin(\gamma\theta) + r^{\overline{\beta}}\overline{g}(\theta), \end{cases}$$

where $\underline{\beta}$ and $\overline{\beta}$ are two fixed reals, different from 1 and such that $\gamma < \underline{\beta}, \overline{\beta} < \gamma + 1$. The reals $\underline{A}$ and $\overline{A}$ will be chosen later. A straightforward computation gives

$$\begin{aligned} L\underline{v} := \;& \Delta\underline{v} - c\partial_y\underline{v} + f(\underline{v}) \\ = \;& \underline{\beta}^2 r^{\underline{\beta}-2} - c\gamma r^{\gamma-1}\cos((\gamma-1)\theta) \\ & -c\underline{\beta}r^{\underline{\beta}-1}[\sin\theta + \sin((\underline{\beta}-1)\theta) + \underline{A}\cos((\underline{\beta}-1)\theta)] + f(\underline{v}). \end{aligned}$$

Since $\underline{\beta} < \gamma + 1$ and $|f(t)| \le M|t|$ for all t (with $M = \|f\|_{Lip} = \sup_{x,y\in[0,1],\ x\neq y} \frac{|f(x)-f(y)|}{|x-y|}$), it follows that there exists a real $\delta_1 \in (0,\delta]$ that depends only on α, $\underline{\beta}$, M, and $\underline{A}$ such that $L(\kappa\underline{v}) > 0$ in $V \cap B(O,\delta_1)$ for any $\kappa > 0$. On the other hand,

$$\forall 0 < y < \delta, \quad \partial_\tau\underline{v}(0,y) = \underline{\beta}r^{\underline{\beta}-1}[2\sin(\alpha - \underline{\beta}\pi/4)\sin(\underline{\beta}\pi/4) + \underline{A}\sin(\alpha - \underline{\beta}\pi/2)].$$

Since $(2/\pi)\,\alpha < \underline{\beta} < (2/\pi)\,\alpha + 1$, we can then choose a real $\underline{A}$ large enough, depending on α and $\underline{\beta}$, such that $\partial_\tau\underline{v}(0,y) < 0$ for all $0 < y < \delta_1$. Furthermore, we have $\underline{v}(x,y) = 0$ if $y = 0$ and $0 \le x < \delta_1$. We then conclude that $\underline{v}$ satisfies (5.5) in $V \cap B(O,\delta_1)$.

Similarly, we can prove that there exists a real $\delta_2 \in (0,\delta]$ such that $\overline{v}$ satisfies (5.6) in $V \cap B(O,\delta_2)$. Eventually, by defining $\delta_0 = \min(\delta_1,\delta_2)$, it follows that $\underline{v}$ (resp., $\overline{v}$) satisfies (5.5) (resp., (5.6)) in $V_0 = V \cap B(0,\delta_0)$.

Step 3. Even if it means decreasing $\delta_0 > 0$, we can assume that $\underline{v}$ and $\overline{v}$ are positive in $\overline{V_0} \cap \{y > 0\}$. Indeed, this is possible because $\gamma < \underline{\beta}, \overline{\beta}$, because $\sin(\gamma\theta) > 0$ for $0 < \theta < \pi/2$ and because both functions $\underline{g}(\theta)/\sin(\gamma\theta)$ and $\overline{g}(\theta)/\sin(\gamma\theta)$ are bounded in the interval $\{0 \le \theta \le \pi/2\}$. On the other hand, we define a function

$$\varphi(x,y) = 2e^{\cos\alpha\ +\ \sin\alpha} - e^{1/\delta_0(\cos\alpha\ x\ -\ \sin\alpha\ y\ +\ \sin\alpha\ \delta_0)} \ \text{ in } V_0.$$

We observe that the function φ is positive in $\overline{V_0}$ and $\partial_\tau\varphi(0,y) = 0$ for all $0 < y < \delta_0$. Furthermore, we have

$$\Delta\varphi - c\partial_y\varphi + \|f\|_{Lip}\varphi \le -1/\delta_0^2 + 1/\delta_0\ |c|\sin\alpha\ e^{\cos\alpha+\sin\alpha} + 2\|f\|_{Lip}e^{\cos\alpha+\sin\alpha}.$$

Even if it means decreasing again $\delta_0 > 0$, we may also assume that

$$\Delta\varphi - c\partial_y\varphi + \|f\|_{Lip}\varphi < 0 \ \text{ in}V_0.$$

Since u is positive in V_0 and satisfies (5.1), the maximum principle and the Hopf lemma yield that $u(x,y) > 0$ as soon as $y > 0$ and that $\partial_y u(x,0) > 0$ for all $x > 0$. Similarly, $\partial_y \overline{v}(x,0) > 0$ for all $x > 0$. Finally, there exist two reals ν, $\mu > 0$ such that

$$\forall (x,y) \in V \cap \{x^2+y^2=\delta_0^2\}, \quad \mu \underline{v}(x,y) < u(x,y) < \nu \overline{v}(x,y). \tag{5.7}$$

Let us now show that this last inequality (5.7) is actually true in the whole set V_0. Remember that u solves (5.1) and that $\mu \underline{v}$ satisfies inequality (5.5). Hence, the function $w = u - \mu \underline{v}$ satisfies

$$\tilde{L}w := \Delta w - c\partial_y w + c(x,y)w \le 0 \ \text{ in } V_0,$$

where $c(x,y)$ is a bounded function in V_0 such that $\|c\|_\infty \le \|f\|_{Lip}$. Set $g = w/\varphi$. One has

$$Mg := \Delta g + 2\frac{\nabla \varphi}{\varphi} \cdot \nabla g - c\partial_y g \le -\frac{g}{\varphi}(\Delta\varphi - c\partial_y\varphi + c(x,y)\varphi) = -\frac{g}{\varphi}\tilde{L}\varphi.$$

In view of the properties fulfilled by φ, it follows that

$$\tilde{L}\varphi \le \Delta\varphi - c\partial_y\varphi + \|f\|_{Lip}\varphi < 0 \ \text{ in } V_0.$$

If the set $\Omega_- = \{(x,y) \in V_0,\ g(x,y) < 0\}$ is not empty, we get that $Mg < 0$ in Ω_-. Since g is continuous in $\overline{V_0}$ (the function φ is positive and continuous in the compact set $\overline{V_0}$), let z_0 be a point in $\overline{\Omega_-}$ where g reaches its minimal value. If $z_0 \in V_0$, then $\nabla g(z_0) = 0$ and $\Delta g(z_0) \ge 0$. That is impossible because $Mg(z_0) < 0$. Now, since $w \ge 0$ on $\partial V_0 \cap (\{y=0\} \cup \{x^2+y^2=\delta_0^2\})$, it follows that $z_0 = (0,y_0)$ with $0 < y_0 < \delta_0$. Furthermore, since $\partial_\tau \underline{v}(0,y_0) < 0$, we have $\partial_\tau w(z_0) = \partial_\tau u(z_0) - \mu\partial_\tau \underline{v}(z_0) > 0$ and

$$0 < \partial_\tau w(z_0) = g(z_0)\partial_\tau\varphi(z_0) + \varphi(z_0)\partial_\tau g(z_0).$$

The function φ is such that $\partial_\tau \varphi(z_0) = 0$ and $\varphi(z_0) > 0$. Hence, $\partial_\tau g(z_0) > 0$. The latter is ruled out by the Hopf lemma.

Finally, we have $\Omega_- = \emptyset$, whence $w \ge 0$; i.e., $\mu\underline{v} \le u$ in V_0 and even $\mu\underline{v} < u$ in V_0 from the strong maximum principle. Similarly, we infer that $u < \nu\overline{v}$ in V_0.

So far, we have shown that

$$\mu\underline{v} < u < \nu\overline{v} \ \text{ in } V_0 = \{x > 0,\ y > 0,\ r < \delta_0\}.$$

Step 4. Let us now replace the variables (x,y) with $(\varepsilon x, \varepsilon y)$. Set $W_\varepsilon = \{(x,y) \in \mathbb{R}^2,\ (\varepsilon x, \varepsilon y) \in V_0\}$ and $u_\varepsilon(x,y) = \varepsilon^{-\gamma}u(\varepsilon x, \varepsilon y)$ for $(x,y) \in W_\varepsilon$. From the definitions of $\overline{v}$ and $\underline{v}$, we have

$$\mu\ (v + \varepsilon^{\underline{\beta}-\gamma} r^{\underline{\beta}} \underline{g}(\theta)) < u_\varepsilon(x,y) < \nu\ (v + \varepsilon^{\overline{\beta}-\gamma} r^{\overline{\beta}} \overline{g}(\theta)) \ \text{ in } W_\varepsilon, \tag{5.8}$$

where $r = \sqrt{x^2+y^2}$. Let Π be the positive quadrant

$$\Pi = \{x > 0, y > 0\}.$$

Since $\gamma < \underline{\beta}, \overline{\beta}$, the left and the right sides of the inequality (5.8) uniformly approach μv and νv in any compact set $K \subset \overline{\Pi}$ as $\varepsilon \to 0$.

Furthermore, we have

$$\begin{cases} \Delta u_\varepsilon - \varepsilon c \partial_y u_\varepsilon & = -\varepsilon^{2-\gamma} f(u(\varepsilon x, \varepsilon y)) & \text{in } W_\varepsilon, \\ u_\varepsilon(x,0) & = 0 & \text{for all } 0 \le x < \delta_0/\varepsilon, \\ \partial_\tau u_\varepsilon(0,y) & = 0 & \text{for all } 0 < y < \delta_0/\varepsilon. \end{cases}$$

Since $\gamma < 2$ and $f(u)$ is bounded in $\overline{V_0}$, the right side of the equation fulfilled by u_ε approaches 0 uniformly in any compact set $K \subset \overline{\Pi}$. The functions u_ε are defined in such a compact set K for ε small enough and they are also uniformly bounded in K from (5.8). Moreover, from the standard elliptic estimates up to the boundary, the functions (u_ε) are then bounded in $W^{2,p}(K)$ for any compact set $K \subset \overline{\Pi}\backslash\{O\}$ and for any $1 < p < \infty$. By a diagonal extraction process, it follows that there exists a continuous function u_0 defined in $\overline{\Pi}\backslash\{O\}$ such that, up to extraction of some subsequence, $u_\varepsilon \to u_0$ in $C^{1,\delta}_{loc}(\overline{\Pi}\backslash\{O\})$ for any $\delta \in (0,1)$. The function u_0 fulfills

$$\left\{\begin{aligned} \Delta u_0 &= 0 && \text{in } \Pi,\\ u_0(x,0) &= 0 && \text{for all } x > 0,\\ \partial_\tau u_0(0,y) &= 0 && \text{for all } y > 0.\end{aligned}\right. \tag{5.9}$$

Moreover, $\mu v \le u_0 \le \nu v$ in $\overline{\Pi}\backslash\{O\}$. In particular, the latter implies that the function u_0 can be extended by continuity at the point $O = (0,0)$ by setting $u_0(0,0) = 0$. Hence,

$$\mu v \le u_0 \le \nu v \ \text{ in } \overline{\Pi}.$$

From (5.8), for any $\eta > 0$, there exists $\delta' > 0$ such that $|u_\varepsilon| \le \eta$ in $\{(x,y) \in \overline{\Pi},\ \sqrt{x^2+y^2} \le \delta'\}$. It follows that, up to extraction of some subsequence, the functions u_ε also approach u_0 uniformly in any compact set $K \subset \overline{\Pi}$.

Step 5. We now aim at proving that $u_0 = \lambda v$ for a certain λ such that $\mu \le \lambda \le \nu$. Define $\overline{\mu}$ and $\overline{\nu}$ by $\overline{\mu} = \sup\{\mu,\ \mu v \le u_0 \text{ in } \overline{\Pi}\}$ and $\overline{\nu} = \inf\{\nu,\ u_0 \le \nu v \text{ in } \overline{\Pi}\}$. We have $\overline{\mu} v \le u_0 \le \overline{\nu} v$ in $\overline{\Pi}$ and $\overline{\mu} \le \overline{\nu} \in \mathbb{R}$.

Let us now suppose that $\overline{\mu} < \overline{\nu}$. The strong maximum principle then yields that $\overline{\mu} v < u_0 < \overline{\nu} v$ in Π. For every $R > 0$, let us call $C(R) = \{(x,y) \in \overline{\Pi},\ x^2+y^2 = R^2\}$ and $B(R) = \{(x,y) \in \overline{\Pi},\ x^2+y^2 \le R^2\}$. Choose any $R > 0$. On $C(R)$, we have $v > 0$ and $\overline{\mu} \le u_0/v \le \overline{\nu}$. There exists then a subset $\Gamma \subset C(R)$ such that $|\Gamma|/|C(R)| \ge 1/2$ ($|\Gamma|$ is the length of Γ) and one of the following assertions occurs:

$$\text{(i)}\quad \frac{\overline{\mu}+\overline{\nu}}{2} \le \frac{u_0}{v} \ \text{ on } \Gamma, \quad \text{i.e.,}\ \ u_0 - \overline{\mu} v \ge \frac{\overline{\nu}-\overline{\mu}}{2} v,$$

$$\text{(ii)}\quad \frac{u_0}{v} \le \frac{\overline{\mu}+\overline{\nu}}{2} \ \text{ on } \Gamma, \quad \text{i.e.,}\ \ \overline{\nu} v - u_0 \ge \frac{\overline{\nu}-\overline{\mu}}{2} v.$$

Suppose that case (i) occurs. Since $u_0 - \overline{\mu} v > 0$ in Π, since both u_0 and v fulfill (5.9), and since (5.9) is invariant by stretching the variables, a straightforward application of the Harnack inequality up to the boundary leads to the existence of a real $\varepsilon > 0$, which does not depend on R, such that

$$u_0 - \overline{\mu} v \ge \varepsilon v \ \text{ on } C(R/2)$$

(see also Berestycki, Caffarelli, and Nirenberg [3] and Caffarelli [12] for related problems). Hence, as in Step 3, we get

$$u_0 - \overline{\mu} v \ge \varepsilon v \ \text{ in } B(R/2).$$

Since (i) or (ii) occurs for each $R > 0$, we may suppose, say, that there is a sequence $R_n \to +\infty$ such that (i) occurs for each R_n. As a consequence, $u_0 - \overline{\mu} v \ge \varepsilon v$ in $B(R_n/2)$, whence

$$u_0 - \overline{\mu} v \ge \varepsilon v \ \text{ in } \overline{\Pi}.$$

That is ruled out by the definition of $\overline{\mu}$.

We conclude that $\overline{\mu} = \overline{\nu} =: \lambda$, that is to say that $u_0 \equiv \lambda v$ in $\overline{\Pi}$.

Step 6. Conclusion: we have to prove that

$$u - \lambda r^{\gamma}\sin(\gamma\theta) = o(r^{\gamma}) \ \text{ as } r \overset{>}{\to} 0, \tag{5.10}$$

$$\nabla u - \lambda\nabla(r^{\gamma}\sin(\gamma\theta)) = o(r^{\gamma-1}) \ \text{ as } r \overset{>}{\to} 0. \tag{5.11}$$

Let K be the compact defined by $K = \{(x,y) \in \overline{\Pi}, 1 \leq \sqrt{x^2+y^2} \leq 2\}$ and let η be any positive number. We know that $u_\varepsilon \to \lambda v$ as $\varepsilon \to 0$, uniformly in K. Hence, there exists a real $\varepsilon_0 \in (0,1)$ such that: $\forall 0 < \varepsilon \leq \varepsilon_0$, $\forall (x,y) \in K$, $|u_\varepsilon - \lambda v| \leq \eta$. Owing to the definitions of the function u_ε and v, we get

$$\forall (x,y) \in K,\ \forall \varepsilon \leq \varepsilon_0, \quad |u(\varepsilon x, \varepsilon y) - \lambda(\varepsilon r)^{\gamma}\sin(\gamma\theta)| \leq \eta\varepsilon^{\gamma} \leq \eta(\varepsilon r)^{\gamma}.$$

In other words, for each $(x,y) \in \overline{\Pi}$ such that $0 < r = \sqrt{x^2+y^2} \leq 2\varepsilon_0$, we have $|u(x,y) - \lambda r^{\gamma}\sin(\gamma\theta)| \leq \eta r^{\gamma}$. Since $\eta > 0$ was arbitrary, we have thus shown the formula (5.10).

Assertion (5.11) can be proved with the same arguments as above. That completes the proof of Lemma 5.1. □

Remark 5.2. Let $\overline{v}$ be defined as in Step 2 by

$$\overline{v} = r^{\gamma}\sin(\gamma\theta) + r^{\overline{\beta}}\overline{g}(\theta),$$

where $\overline{g}(\theta) = -1 + \cos(\overline{\beta}\theta) + \overline{A}\sin(\overline{\beta}\theta)$ and where (r,θ) are the polar coordinates with respect to the corner $C_1 = (-a, -a\cot\gamma)$ of Σ_a. We choose $\overline{A}$ such that (5.6) holds in $V_0 = \{x > 0,\ y > 0,\ 0 < r < \delta_0\}$ for some δ_0 small enough. In particular, for $\varepsilon \in (0,\delta_0)$, we have $\partial_\tau \overline{v} = \nabla\overline{v}\cdot\tau > 0$ at the point $(-a, -a\cot\gamma+\varepsilon)$. Hence, under the notation of Lemma 2.1, one can require that the vector field ρ_ε fulfill $\rho_\varepsilon = \tau$ on $\{-a\}\times(-a\cot\gamma+\varepsilon, -a\cot\gamma+\delta_0)$ and $\rho_\varepsilon\cdot\nabla\overline{v} \geq 0$ on $\partial\Sigma_{a,\varepsilon}\cap B(C_1,\delta_0)$. For instance, choose a function $\eta(x,y)$ defined on $\partial\Sigma_{a,\varepsilon}\cap B(C_1,\delta_0)$ such that $0 \leq \eta \leq 1$, $\eta = 1$ on $\{-a\}\times(-a\cot\gamma+\varepsilon, -a\cot\gamma+\delta_0)$, $\eta = 0$ on $\partial\Sigma_{a,\varepsilon}\cap\{x > -a+\varepsilon^2\}$ (for $\varepsilon > 0$ small enough). Next, take $\rho_\varepsilon(x,y) = \eta(x,y)\tau$ on $\partial\Sigma_{a,\varepsilon}\cap B(C_1,\delta_0)$. Finally, the function $\overline{v}$ fulfills

$$\rho_\varepsilon\cdot\nabla\overline{v} + \sigma_{0,\varepsilon}\overline{v} \geq 0 \ \text{ on } \partial\Sigma_{a,\varepsilon}\cap B(C_1,\delta_0),$$

whereas the function u_ε fulfills

$$\rho_\varepsilon\cdot\nabla u_\varepsilon + \sigma_{0,\varepsilon}u_\varepsilon = 0 \ \text{ on } \partial\Sigma_{a,\varepsilon}\cap B(C_1,\delta_0)$$

(remember that $\sigma_{1,\varepsilon} = 0$ on $\partial\Sigma_{a,\varepsilon}\cap B(C_1,\delta_0)$ for $\varepsilon > 0$ and $\delta_0 > 0$ small enough).

Furthermore, since $\partial_y u_\varepsilon(-a+\delta_0, -a\cot\gamma) \to \partial_y u_c(-a+\delta_0, -a\cot\gamma) < +\infty$ as $\varepsilon \to 0$ and $u_\varepsilon \leq 1$ in $\overline{\Sigma_{a,\varepsilon}}$, there exists then a constant $\nu > 0$ such that, as in Step 3,

$$\forall (x,y) \in \overline{\Sigma_{a,\varepsilon}}\cap\{r = \delta_0\}, \quad u_\varepsilon(x,y) \leq \nu\overline{v}(x,y)$$

for all $\varepsilon > 0$ small enough. Next, we choose the same function φ as in Step 3. In particular, in view of the choice of ρ_ε, we have $\rho_\varepsilon\cdot\nabla\varphi = 0$ and $\rho_\varepsilon\cdot\nu_\varepsilon \geq 0$ on $\partial\Sigma_{a,\varepsilon}\cap B(C_1,\delta_0)$ for $\varepsilon > 0$ small enough (ν_ε is the outward unit normal to $\partial\Sigma_{a,\varepsilon}$). As in Step 3, it follows then that if the function $g = \frac{w}{\varphi} := \frac{\nu\overline{v}-u_\varepsilon}{\varphi}$ reaches a negative minimal value at a point z_0 in $\overline{\Sigma_{a,\varepsilon}} \cap \overline{B(C_1, \delta_0)}$, then $z_0 = (x_0, y_0)$ lies necessarily on $\partial\Sigma_{a,\varepsilon} \cap B(C_1, \delta_0)$. At the point z_0, one has $\rho_\varepsilon \cdot \nabla w + \sigma_{0,\varepsilon} w \geq 0$, whence

$$g(z_0)\ \rho_\varepsilon(z_0) \cdot \nabla\varphi(z_0) + \varphi(z_0)\ \rho_\varepsilon(z_0) \cdot \nabla g(z_0) + \sigma_{0,\varepsilon}(z_0) g(z_0) \varphi(z_0) \geq 0. \tag{5.12}$$

The first term of (5.12) is equal to 0 because $\rho_\varepsilon \cdot \nabla\varphi = 0$. The second and third terms are nonpositive because $\varphi > 0$, $\rho_\varepsilon \cdot \nabla g \leq 0$ (from the Hopf lemma), $g(z_0) < 0$, and $\sigma_{0,\varepsilon} \geq 0$. Furthermore, if $y_0 \geq -a \cot\gamma + \varepsilon$, then $\rho_\varepsilon(z_0) = \tau$ whence $\rho_\varepsilon(z_0) \cdot \nabla g(z_0) < 0$, and if $y_0 \leq -a \cot\gamma + \varepsilon$, then $\sigma_{0,\varepsilon}(z_0) = 1$. Hence, all the three terms of (5.12) are nonpositive and at least one is negative. This is impossible.

We conclude that

$$u_\varepsilon(x, y) \leq \nu \overline{v}(x, y) \quad \text{in } \overline{\Sigma_{a,\varepsilon}} \cap \overline{B(C_1, \delta_0)}$$

for all $\varepsilon > 0$ small enough. This gives the required estimate (2.5) around the point C_1. The other corners C_2, C_3, C_4 can be treated similarly.

The proofs of the estimates (2.8) and (2.10) resort to the same arguments. As far as (2.8) is concerned, the function $\overline{v}$ can be chosen as in Step 2 such that (5.6) is true for each c_n because the reals c_n are bounded. As far as (2.10) is concerned, the function $\overline{v}$ can be chosen as in Step 2 such that (5.6) is true for each f_n because the norms $\|f_n\|_{Lip}$ are bounded.

Acknowledgments. We are grateful to Prof. P. Clavin for suggesting this subject and to Prof. J.-M. Roquejoffre for useful remarks.

EXISTENCE AND NONEXISTENCE OF SOLUTIONS OF NONLINEAR NEUMANN PROBLEMS[*]

STANISLAV I. POHOZAEV[†] AND ALBERTO TESEI[‡]

Abstract. Existence theorems for nonnegative solutions to a class of nonlinear Neumann problems are proved. Nonexistence results are also discussed, depending either on absorption or on first-order terms. The proofs make use of a direct variational approach.

Key words. Neumann problems, problems of indefinite type, variational methods, fibering method, nonnegative solutions, existence of solutions

1. Introduction.

In this paper we study the existence of nonnegative solutions to the nonlinear Neumann problem

$$\text{(1.1)}\qquad \begin{cases} -\Delta_p u = (\nabla\psi(x), \nabla u) \mid \nabla u \mid^{p-2} + a(x)u^{q-1} + b(x)u^{s-1} & \text{in } \Omega, \\ \\ \mid \nabla u \mid^{p-2} \dfrac{\partial u}{\partial \nu} = 0 & \text{on } \partial\Omega. \end{cases}$$

Here $\Omega \subseteq \mathbb{R}^n$ is a connected bounded domain with $C^{1,\alpha}$ boundary; by ν we denote the outer normal at any point $x \in \partial\Omega$. We also set

$$\Delta_p u \equiv \operatorname{div}(\mid \nabla u \mid^{p-2} \nabla u)$$

for $p > 1$ and

$$(\nabla\psi, \nabla u) \equiv \sum_{i=1}^{n} \frac{\partial \psi}{\partial x_i} \frac{\partial u}{\partial x_i}.$$

The functions a, b are continuous in $\bar{\Omega}$, while (ψ is differentiable) $\nabla\psi$ is bounded and uniformly continuous in Ω. An essential feature of the problem is that the function a changes sign (namely, the problem is of indefinite type; see [9]); instead, the function b is assumed to be nonpositive. Concerning the exponents q, s we shall always make the following hypothesis:

$$(\mathrm{H}_0)\qquad 1 < q < p^*, \qquad 1 < s < p^*,$$

where

$$p^* := \begin{cases} \frac{np}{n-p} & \text{if } p < n, \\ \\ \infty & \text{otherwise.} \end{cases}$$

Problem (1.1) is suggested by some mathematical models of the applied sciences (e.g., see [1], [12]); besides, in several respects it generalizes other problems previously dealt with in the literature. In particular, if $p = 2$, $\psi =$ constant, and $b \equiv 0$, it reads

$$\begin{cases} -\Delta u = a(x)\, u^{q-1} & \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu} = 0 & \text{on } \partial\Omega. \end{cases}$$

This was investigated in [2] in the case $1 < q < 2$, respectively, and in [3] in the case $2 < q < 2^*$. In both cases the following conditions,

$$(\mathrm{H}_1) \qquad a_+ := \max\{a, 0\} \not\equiv 0,$$

$$(1.2) \qquad \int_\Omega a\, dx < 0$$

are necessary and sufficient for the existence of positive solutions.

As already mentioned, we retain (H$_1$) in the present investigation. As for the latter condition, recasting (1.1) in the equivalent form

$$(1.3) \qquad \begin{cases} -\mathrm{div}\,(\rho(x) \mid \nabla u \mid^{p-2} \nabla u) = \rho(x)a(x)u^{q-1} + \rho(x)b(x)u^{s-1} & \text{in } \Omega, \\ \mid \nabla u \mid^{p-2} \dfrac{\partial u}{\partial \nu} = 0 & \text{on } \partial\Omega, \end{cases}$$

where $\rho := e^\psi$, suggests the more general assumption

$$(\mathrm{H}_2) \qquad \int_\Omega \rho\, a\, dx < 0.$$

In the following we always assume (H$_0$)–(H$_2$) and moreover

$$(\mathrm{H}_3) \qquad b \leq 0 \quad \text{in } \Omega.$$

When $b \equiv 0$ the following theorem holds, which generalizes previous existence results in [2], [3].

Theorem 1.1. *Let assumptions* (H$_0$)–(H$_2$) *be satisfied; let $b \equiv 0$. Then there exists a nontrivial nonnegative solution $u \in L^\infty(\Omega)$ of problem* (1.1). *Moreover, $u \in C^{1,\beta}(\bar{\Omega})$ for some $\beta > 0$.*

Under the more general assumption (H$_3$) the relationship between the exponents p, q, and s plays an essential role. If either

$$(\mathrm{A}) \qquad q > \max\{p, s\}$$

or

$$(\mathrm{B}) \qquad q < \min\{p, s\},$$

the following result applies.

Theorem 1.2. *Let either* (A) *or* (B) *hold and assumptions* (H$_0$)–(H$_3$) *be satisfied. Then there exists a nontrivial nonnegative solution $u \in L^\infty(\Omega)$ of problem* (1.1). *Moreover, $u \in C^{1,\beta}(\bar{\Omega})$ for some $\beta > 0$.*

The remaining cases, namely,

$$s < q < p, \tag{C}$$

$$p < q < s, \tag{D}$$

are more cumbersome. Assuming that

$$\operatorname{supp} a_+ \setminus \operatorname{supp} b \quad \text{has nonempty interior,} \tag{H$_4$}$$

for case (C), the following can be proved.

THEOREM 1.3. *Let* (C) *hold and assumptions* (H_0)–(H_4) *be satisfied. Then there exists a nontrivial nonnegative solution $u \in L^\infty(\Omega)$ of problem* (1.1). *Moreover, $u \in C^{1,\beta}(\bar{\Omega})$ for some $\beta > 0$.*

To deal with case (D) we shall use the following assumption:

$$b(x) \leq -b_0 < 0 \quad \text{for any x} \in \Omega. \tag{H$_5$}$$

(Observe that conditions (H_4) and (H_5) exclude each other.) In the following statement, by saying that "*a_+ is large with respect to b*," we mean that condition (H_6) below (see section 2) is satisfied.

THEOREM 1.4. *Let* (D) *hold and assumptions* (H_0)–(H_2) *and* (H_5) *be satisfied. Assume that a_+ is large with respect to b. Then there exists a nontrivial nonnegative solution $u \in L^\infty(\Omega)$ of problem* (1.1). *Moreover, $u \in C^{1,\beta}(\bar{\Omega})$ for some $\beta > 0$.*

According to the above theorem, in case (D) a nontrivial, nonnegative solution exists if the source term $a_+(x)u^{q-1}$ prevails over the absorption term $b(x)u^{s-1}$. In the opposite case such a solution does not exist, as the following result shows. By saying that "*b is large with respect to a_+*," we mean that condition (H_7) (see section 4) is satisfied.

THEOREM 1.5. *Let* (D) *hold and assumptions* (H_0)–(H_2) *and* (H_5) *be satisfied. Assume that b is large with respect to a_+. Then the only nonnegative solution of problem* (1.1) *is trivial.*

Observe that the above nonexistence result depends (for fixed functions a, ρ) on the magnitude of the absorption coefficient b. A different nonexistence result, which depends only on the first-order term, can be pointed out. If $b \equiv 0$ and $q > 2$, condition (H_2) is necessary for the existence of a nontrivial, nonnegative solution to (1.1) (see Proposition 4.1). Suppose that condition (1.2) is satisfied, while (H_2) is not. In this case nontrivial, nonnegative solutions of (1.1) (with $b \equiv 0$, $q > 2$) exist if $\psi =$ constant by Theorem 1.1, yet they do not exist for general ψ. Similar nonexistence phenomena due to the effect of first-order terms are known for Dirichlet boundary value problems and for free boundary problems (see [4], [5]).

The proofs of the above results make use of direct variational arguments introduced in [13], [14], [15] (see also [8]); an outline is given in section 2 for convenience of the reader.

2. Mathematical framework and results. Let X be a real Banach space with norm $\|\cdot\|$; let f and H be real-valued functionals defined in X. Let f, H be continuously differentiable in $X \setminus \{0\}$; suppose that $H(0) = 0$ and

$$\langle H'(v), v\rangle \neq 0 \tag{2.1}$$

for any v such that

$$H(v) = 1. \tag{2.2}$$

Here H' denotes the derivative of H and $\langle \cdot, \cdot \rangle$ denotes the pairing between X and its dual space.

We associate with f a functional F setting

$$F(r, v) := f(rv) \tag{2.3}$$

for any $r \in \mathbb{R}$ and $v \in X$.

Proposition 2.1. *Let (r, v) be a conditionally critical point of F under condition (2.2) such that $r \neq 0$. Then $u := rv$ is a nonzero critical point of the functional f.*

Proof. According to the rule of Lagrange multipliers, there exist λ, $\mu \in \mathbb{R}$ such that $\lambda^2 + \mu^2 > 0$ and

$$\lambda F_v(r, v) = \mu H'(v), \tag{2.4}$$

$$\lambda F_r(r, v) = 0. \tag{2.5}$$

Here F_r, F_v denote the partial derivatives of F. By the definition (2.3) of F we have

$$rF_r(r, v) = \langle F_v(r, v), v \rangle \tag{2.6}$$

and

$$f'(u) = \frac{1}{r} F_v \left(r, \frac{u}{r} \right). \tag{2.7}$$

Since $\langle H'(v), v \rangle \neq 0$ by assumption, we obtain $\lambda \neq 0$, $\mu = 0$. Then the conclusion follows. □

Suppose that in some open subset $E \subseteq X \setminus \{0\}$ a real-valued, continuously differentiable functional $r = r(v)$ is defined, such that $r(v) \neq 0$ and

$$F_r(r(v), v) = 0 \tag{2.8}$$

for any $v \in E$ such that condition (2.2) is satisfied. Define a functional $\tilde{f}(v)$ setting

$$\tilde{f}(v) := F(r(v), v). \tag{2.9}$$

Proposition 2.2. *Let v be a conditionally extremum point of $\tilde{f}(v)$ under condition (2.2). Then $u := r(v)v$ is a nonzero critical point of the functional f.*

Proof. If $r = r(v)$, equality (2.8) and the definition of $\tilde{f}$ ensure that (r, v) is a conditionally critical point of F under condition (2.2). Then the conclusion follows by Proposition 2.1. □

The previous results suggest the following approach to investigating critical points of the functional f. First we study the equation

$$F_r(r, v) = 0, \tag{2.10}$$

referred to as the *bifurcation equation*. Suppose that for any v in some open subset $E \subseteq X \setminus \{0\}$ there exists a root $r = r(v) \neq 0$ of (2.10); let $r \in C^1(E)$. Then the *reduced functional* $\tilde{f}$ given by (2.9) is defined and is of class C^1 in E; following Proposition

2.2, we maximize (or minimize) $\tilde{f}$ under the constraint $H(v) = 1$, where H is some suitable functional.

Let us investigate problem (1.3) using the previous considerations. We shall work in the Sobolev space $X = W^{1,p}(\Omega)(1 < p < \infty)$ endowed with the norm

$$|u|_X := \left\{ \int_\Omega \rho\, |u|^p \, dx + \int_\Omega \rho\, |\nabla u|^p \, dx \right\}^{1/p} .$$

Since ρ is bounded away from zero in Ω, this norm is equivalent to the usual one. The functional f associated with (1.3) is

$$f(u) = -\frac{1}{p} \int_\Omega \rho\, |\nabla u|^p \, dx + \frac{1}{q} \int_\Omega \rho\, a\, |u|^q \, dx + \frac{1}{s} \int_\Omega \rho\, b\, |u|^s \, dx.$$

The functional (2.3) and the bifurcation equation (2.10) read in the present case

$$F(r, v) = -\frac{|r|^p}{p} \int_\Omega \rho\, |\nabla v|^p \, dx + \frac{|r|^q}{q} A(v) - \frac{|r|^s}{s} B(v),$$

respectively,

$$F_r(r, v) = A(v)|r|^{q-2}r - B(v)|r|^{s-2}r - \int_\Omega \rho\, |\nabla v|^p \, dx\, |r|^{p-2}r = 0; \tag{2.11}$$

here

$$A(v) := \int_\Omega \rho\, a\, |v|^q \, dx,$$

$$B(v) := \int_\Omega \rho\, |b|\, |v|^s \, dx,$$

and use of the assumption (H_3) has been made.

For $r \neq 0$ the bifurcation equation (2.11) is equivalent to

$$\phi(r, v) = \int_\Omega \rho\, |\nabla v|^p \, dx,$$

where

$$\phi(r, v) := A(v)|r|^{q-p} - B(v)|r|^{s-p}. \tag{2.12}$$

Set

$$E := \{v \in X \mid A(v) > 0\}; \tag{2.13}$$

observe that by assumption (H_1) the set E is nonempty.

It is apparent from (2.12) that, if $b \equiv 0$ in Ω, for any $v \in E$ the bifurcation equation has a unique positive root, namely,

$$r(v) = \left\{ \frac{\int_\Omega \rho\, |\nabla v|^p \, dx}{A(v)} \right\}^{1/(q-p)} .$$

Then the reduced functional reads

$$\tilde{f}(v) = \left(\frac{1}{q} - \frac{1}{p}\right) \left\{ \frac{[\int_\Omega \rho\,|\nabla v|^p\,dx]^q}{[A(v)]^p} \right\}^{1/(q-p)} . \tag{2.14}$$

In the following we always choose the functional H as follows:

$$H(v) := \int_\Omega \rho\,|\nabla v|^p\,dx.$$

Concerning the variational problem

$$\max_{v \in E} \tilde{f}(v) \quad \text{under the condition} \quad \int_\Omega \rho\,|\nabla v|^p\,dx = 1, \tag{2.15}$$

the following result will be proved.

Proposition 2.3. *Let assumptions* (H$_0$)–(H$_2$) *be satisfied; let $b \equiv 0$. Then the maximum in* (2.15) *(where $\tilde{f}$ is the functional* (2.14)*) is achieved at some function $\bar{v} \geq 0$, $\bar{v} \not\equiv 0$ in Ω.*

Theorem 1.1 is an immediate consequence of the above proposition. Similarly, Theorems 1.2–1.4 follow easily from Propositions 2.4–2.6 below.

If $b \not\equiv 0$ and either (A) or (B) holds, the bifurcation equation has a unique positive root $r = r(v)$ for any $v \in E$ (see (2.12)). Moreover, for any $v \in E$ the quantity

$$\langle f''(r(v)v)v, v\rangle = F_{rr}(r(v), v)$$

$$= (q-p) \int_\Omega \rho\,|\nabla v|^p\,dx\,|r(v)|^{p-2} + (q-s)B(v)\,|r(v)|^{s-2}$$

is strictly positive if (A) holds or negative if (B) holds; hence $r \in C^1(E)$. The reduced functional

$$\tilde{f}(v) = \left(\frac{1}{q} - \frac{1}{p}\right) \int_\Omega \rho\,|\nabla v|^p\,dx\,|r(v)|^p + \left(\frac{1}{q} - \frac{1}{s}\right) B(v)\,|r(v)|^s$$

$$= \left(\frac{1}{q} - \frac{1}{p}\right) A(v)\,|r(v)|^q - \left(\frac{1}{s} - \frac{1}{p}\right) B(v)\,|r(v)|^s \tag{2.16}$$

is defined for any $v \in E$; the following result will be proved.

Proposition 2.4. *Let assumptions* (H$_0$)–(H$_3$) *be satisfied; moreover, let either* (A) *or* (B) *hold. Then the maximum in* (2.15) *(where $\tilde{f}$ is the functional* (2.16)*) is achieved at some function $\bar{v} \geq 0$, $\bar{v} \not\equiv 0$ in Ω.*

Concerning case (C), it is easily seen from (2.12) that a nontrivial solution $r(v)$ of the bifurcation equation exists for any $v \in E$ such that $B(v) = 0$, yet need not exist if $B(v) > 0$. In the latter case the function $\phi(\cdot, v)$ has a unique positive maximum point, namely,

$$r_*(v) := \left\{ \frac{p-s}{p-q}\,\frac{B(v)}{A(v)} \right\}^{1/(q-s)} . \tag{2.17}$$

Moreover,

$$\phi(r_*(v), v) = \left\{ \frac{[A(v)]^{p-s}}{\gamma_0 [B(v)]^{p-q}} \right\}^{1/(q-s)} ,$$

where

$$\gamma_0 := \frac{(p-s)^{p-s}}{(q-s)^{q-s}(p-q)^{p-q}}. \tag{2.18}$$

Define

$$E_0 := \left\{ v \in E \mid [A(v)]^{p-s} > \gamma_0 \, [B(v)]^{p-q} \left[\int_\Omega \rho \, |\nabla v|^p \, dx \right]^{q-s} \right\}.$$

Observe that $E_0 \neq \emptyset$ by assumption (H_4); in fact, for any $v \neq 0$ such that

$$\operatorname{supp} v \subseteq (\operatorname{supp} a_+ \setminus \operatorname{supp} b)^o$$

we have $A(v) > 0$, $B(v) = 0$.

For any $v \in E_0$ the bifurcation equation has one positive root if $B(v) = 0$ or two, say,

$$r_-(v) < r_*(v) < r_+(v),$$

if $B(v) > 0$. In both cases we denote by $r(v)$ the maximal positive root. Observe that the quantity $F_{rr}(r(v), v)$ is strictly negative; hence $r \in C^1(E_0)$; in fact,

$$F_{rr}(r(v), v) = -(p-q)A(v) \, |r(v)|^{q-2} \quad \text{if } B(v) = 0$$

or

$$F_{rr}(r(v), v) = -(p-q)A(v) \, |r(v)|^{s-2}[|r(v)|^{q-s} - |r_*(v)|^{q-s}] \quad \text{if } B(v) > 0.$$

Since the reduced functional (2.16) is defined for any $v \in E_0$, the variational problem

$$\max_{v \in E_0} \tilde{f}(v) \quad \text{under the condition} \quad \int_\Omega \rho \, |\nabla v|^p \, dx = 1 \tag{2.19}$$

can be investigated. The following proposition holds.

Proposition 2.5. *Let assumptions* (H_0)–(H_4) *be satisfied; let* (C) *hold. Then the maximum in* (2.19) *is achieved at some function* $\bar{v} \geq 0$, $\bar{v} \not\equiv 0$ *in* Ω.

Finally, let us discuss case (D) under assumption (H_5); observe that this assumption implies $B(v) > 0$ whenever $A(v) > 0$. Instead of the set E_0 considered in case (C), now define

$$E_1 := \left\{ v \in E \mid [A(v)]^{s-p} > \gamma_1 \, [B(v)]^{q-p} \left[\int_\Omega \rho \, |\nabla v|^p \, dx \right]^{s-q} \right\},$$

where

$$\gamma_1 := \frac{(s-p)^{s-p}}{(s-q)^{s-q} \, (q-p)^{q-p}}. \tag{2.20}$$

If $E_1 \neq \emptyset$, for any $v \in E_1$ there exist two positive solutions of the bifurcation equation. In such a case we denote again by $r(v)$ the maximal positive root and consider the reduced functional (2.16) for $v \in E_1$.

To ensure that the set E_1 be nonempty, we find it convenient to introduce its subset

$$E_2 := \left\{ v \in E \mid [A(v)]^{s-p} > \gamma_2 \, [B(v)]^{q-p} \left[\int_\Omega \rho \, |\nabla v|^p \, dx \right]^{s-q} \right\},$$

where

$$\gamma_2 := \frac{q^{s-p}}{p^{s-q} \, s^{q-p}} \, \gamma_1.$$

It is easily checked that $\gamma_2 > \gamma_1$; thus $E_2 \subseteq E_1$ as asserted. We shall assume that

$$(\mathrm{H}_6) \qquad E_2 \text{ is nonempty.}$$

It is easily proven that for any $v \in E_2$ the functional $F(\cdot, v)$ has two positive zeros. Hence it has a (local) minimum point and a maximum point, which are the minimal, respectively, the maximal positive root of the bifurcation equation. It follows that

$$\tilde{f}(v) = F(r(v), v) = \max_{r>0} F(r, v) > 0$$

for any $v \in E_2$.

Concerning the problem

$$(2.21) \qquad \max_{v \in E_1} \; \tilde{f}(v) \quad \text{under the condition} \quad \int_\Omega \rho \, |\nabla v|^p \, dx = 1,$$

the following result will be proved.

PROPOSITION 2.6. *Let assumptions* (H$_0$)–(H$_2$) *and* (H$_5$)–(H$_6$) *be satisfied; let* (D) *hold. Then the maximum in* (2.21) *is achieved at some function* $\bar{v} \geq 0$, $\bar{v} \not\equiv 0$ *in* Ω.

In connection with assumption (H$_6$) and the statement of Theorem 1.4, observe that the inequality

$$[A(v)]^{s-p} > \gamma_2 \, [B(v)]^{q-p} \left[\int_\Omega \rho \, |\nabla v|^p \, dx \right]^{s-q}$$

is satisfied for some $v \in E$ if the positive part a_+ is sufficiently large with respect to b (for instance, it suffices to replace a_+ by λa_+, $\lambda > 0$ large enough).

3. Proofs of existence. Set

$$S := \left\{ v \in X | \int_\Omega \rho \, |\nabla v|^p \, dx = 1 \right\}.$$

Let us prove the following lemma.

LEMMA 3.1. *Let assumptions* (H$_0$)–(H$_2$) *be satisfied. Then the set*

$$E \cap S = \left\{ v \in X | A(v) > 0, \int_\Omega \rho \, |\nabla v|^p \, dx = 1 \right\}$$

is bounded in X.

Proof. By absurd, let $\{v_n\} \subseteq E \cap S$ be such that

$$\int_\Omega \rho \, |v_n|^p \, dx + \int_\Omega \rho \, |\nabla v_n|^p \, dx \longrightarrow \infty$$

as $n \to \infty$. For any $n \in \mathbb{N}$ set

$$v_n = t_n + w_n,$$

where

$$t_n := \frac{1}{\|\rho\|_1} \int_\Omega \rho v_n dx,$$

$$w_n := v_n - t_n.$$

Since

$$\int_\Omega \rho \, |\nabla w_n|^p \, dx = \int_\Omega \rho \, |\nabla v_n|^p \, dx = 1$$

and

$$\int_\Omega \rho \, w_n \, dx = 0,$$

by embedding results there exists $C > 0$ such that

$$|w_n|_X \leq C \quad \text{for any } n \in \mathbb{N}.$$

This implies that $|t_n| \to \infty$; moreover, since by assumption (H_0) the space X is compactly embedded in $L^q(\Omega)$, we may assume that $\{w_n\}$ converges strongly in the latter space. Then we have

$$\int_\Omega \rho \, a \, |v_n|^q \, dx = |t_n|^q \int_\Omega \rho \, a \left| 1 + \frac{w_n}{t_n} \right|^q \, dx \longrightarrow -\infty$$

as $n \to \infty$ by assumption (H_2). This contradicts the definition of E; hence the conclusion follows. □

Let us prove Proposition 2.4. The proof of Proposition 2.3 is similar, yet simpler by the homogeneity of the reduced functional (2.14); hence it is omitted.

Proof of Proposition 2.4. Set

$$M := \sup\{\tilde{f}(v) \mid v \in E \cap S\}, \tag{3.1}$$

where $\tilde{f}$ is the reduced functional (2.16). It is easily seen that $M \in (-\infty, 0]$ if (A) holds or $M \in (0, \infty)$ if (B) is satisfied. Let $\{v_n\} \subseteq E \cap S$ be a maximizing sequence. Due to Lemma 3.1, we can assume that $\{v_n\}$ converges weakly in X to some $\bar{v}$; by assumption (H_0), it follows that $v_n \to \bar{v}$ both in $L^q(\Omega)$ and in $L^s(\Omega)$. Let us prove that $\bar{v} \in E \cap S$.

(i) Since $\{v_n\} \subseteq E \cap S$, from the bifurcation equation we obtain

$$A(v_n)|r(v_n)|^{q-p} \geq 1 \quad \text{for any } n \in \mathbb{N}. \tag{3.2}$$

On the other hand, since $v_n \to \bar{v}$ in $L^q(\Omega)$, there holds

$$A(v_n) \to A(\bar{v}) \quad \text{as } n \to \infty.$$

By absurd, let $A(\bar{v}) = 0$. If (A) holds, let us rewrite (3.2) as follows:

$$|r(v_n)| \geq [A(v_n)]^{-1/(q-p)};$$

then we conclude that $|r(v_n)| \to \infty$. Since by (2.16)

$$\tilde{f}(v_n) \le \left(\frac{1}{q} - \frac{1}{p}\right) |r(v_n)|^p,$$

this implies that $\tilde{f}(v_n) \to -\infty$, which is impossible. If (B) holds, we can recast (3.2) in the following form,

$$A(v_n) \ge |r(v_n)|^{p-q}, \tag{3.3}$$

thus obtaining that $|r(v_n)| \to 0$. Since $B(v_n) \to B(\bar{v}) < \infty$, this implies that $\tilde{f}(v_n) \to 0$, contradicting the inequality $M > 0$. Then $A(\bar{v}) > 0$, i.e., $\bar{v} \in E$.

(ii) By the weak convergence of $\{v_n\}$ in X there holds

$$\int_\Omega \rho\, |\nabla \bar{v}|^p \, dx \le 1.$$

Since $A(\bar{v}) > 0$, by (H_2) we also have

$$\int_\Omega \rho\, |\nabla \bar{v}|^p \, dx > 0.$$

If the first inequality were strict, we could find $t > 1$ such that

$$\int_\Omega \rho |\nabla (t\bar{v})|^p dx = 1;$$

hence $t\bar{v} \in E \cap S$. The root $r = r(t\bar{v})$ of the bifurcation equation satisfies the equality

$$A(t\bar{v})\, |r(t\bar{v})|^{q-p} - B(t\bar{v})\, |r(t\bar{v})|^{s-p} = 1. \tag{3.4}$$

Since

$$A(t\bar{v}) = t^q\, A(\bar{v}),$$

$$B(t\bar{v}) = t^s\, B(\bar{v}),$$

this gives

$$A(\bar{v})\, |tr(t\bar{v})|^{q-p} - B(\bar{v})\, |tr(t\bar{v})|^{s-p} = t^{-p} < 1. \tag{3.5}$$

On the other hand, it is easily seen that the sequence $\{r(v_n)\}$ is bounded. In fact, in case (B) this follows from inequality (3.3). Concerning (A), rewrite the bifurcation equation for $v = v_n$ as

$$|r(v_n)|^{q-p} \{A(v_n) - B(v_n) |r(v_n)|^{s-q}\} = 1.$$

Since $A(v_n) \to A(\bar{v}) > 0$ and $\{B(v_n)\}$ is converging, for any diverging subsequence of $\{r(v_n)\}$ the left-hand side of the above equality would diverge, which is impossible. Since $\{r(v_n)\}$ is bounded, some subsequence is converging; then its limit, say, $\bar{r}$, satisfies the equality

$$A(\bar{v})\, |\bar{r}|^{q-p} - B(\bar{v})\, |\bar{r}|^{s-p} = 1. \tag{3.6}$$

Comparing (3.5) and (3.6) immediately gives

$$tr(t\bar{v}) < \bar{r}$$

if (A) holds, respectively,

$$tr(t\bar{v}) > \bar{r}$$

if (B) is satisfied. Then an elementary investigation of the function

$$\psi(\xi) := \left(\frac{1}{q} - \frac{1}{p}\right) A(\bar{v})\, \xi^q - \left(\frac{1}{s} - \frac{1}{p}\right) B(\bar{v})\, \xi^s \qquad (\xi > 0) \tag{3.7}$$

proves that in both cases

$$\tilde{f}(t\bar{v}) = \psi(t|r(t\bar{v})|) > \psi(\bar{r}) = M, \tag{3.8}$$

which is absurd. It follows that $\bar{v} \in S$; thus the claim is proved. Since the equality (3.4) holds with $t = 1$, we get $r(\bar{v}) = \bar{r}$ (see (3.6)); thus $M = \tilde{f}(\bar{v})$. Then the conclusion follows. □

Let us now consider case (C).

Proof of Proposition 2.5. Set

$$M := \sup\{\tilde{f}(v) \mid v \in E_0 \cap S\}.$$

Observe that $M > 0$ by assumption (H_4); in fact, for any $v \not\equiv 0$ with

$$\operatorname{supp} v \subseteq (\operatorname{supp} a_+ \setminus \operatorname{supp} b)^o$$

there holds

$$\tilde{f}(v) = \left(\frac{1}{q} - \frac{1}{p}\right) A(v)\, |r(v)|^q > 0.$$

Since $E_0 \cap S \subseteq E \cap S$ is bounded in X (see Lemma 3.1), any maximizing sequence $\{v_n\} \subseteq E_0 \cap S$ converges to some $\bar{v} \in X$ as in the proof of Proposition 2.4. Let us prove that $\bar{v} \in E_0 \cap S$.

To this purpose, observe first that the sequence $\{r(v_n)\}$ is bounded. In fact, for any diverging subsequence the right-hand side of the equality

$$A(v_n)\, |r(v_n)|^{q-p} - B(v_n)\, |r(v_n)|^{s-p} = 1 \tag{3.9}$$

would be infinitesimal, which is impossible.

(i) Let us show that $A(\bar{v}) > 0$. Since $\{r(v_n)\}$ is bounded, some subsequence (again denoted $\{r(v_n)\}$) converges to a limit $\bar{r}$. If $A(\bar{v}) = 0$, we have

$$M = \lim_{n\to\infty} \tilde{f}(v_n) = \left(\frac{1}{p} - \frac{1}{s}\right) B(\bar{v}) |\bar{r}|^s \leq 0,$$

which is absurd since $M > 0$.

(ii) Let us prove that the strict inequality in the definition of the set E_0 is satisfied at $v = \bar{v}$. This follows by (i) if $B(\bar{v}) = 0$. In any case there holds

$$[A(\bar{v})]^{p-s} \geq \gamma_0\, [B(\bar{v})]^{p-q} \left[\int_\Omega \rho\, |\nabla \bar{v}|^p\, dx\right]^{q-s}.$$

Suppose that $B(\bar{v}) > 0$ and the equality sign holds in the above relation. This means that the maximum of the function $\phi(\cdot, \bar{v})$ equals $\int_\Omega \rho\, |\nabla \bar{v}|^p\, dx$ (see section 2); hence

$$r(\bar{v}) = r_*(\bar{v}).$$

On the other hand, it follows easily from (3.9) that $\bar{r} := \lim_{n\to\infty} |r(v_n)|$ is strictly positive. Passing to the limit in the same equation as $n \to \infty$ we find

$$A(\bar{v})\, |\bar{r}|^{q-p} - B(\bar{v})\, |\bar{r}|^{s-p} = 1 \geq \int_\Omega \rho\, |\nabla \bar{v}|^p\, dx, \tag{3.10}$$

whence

$$\bar{r} = r(\bar{v}) = r_*(\bar{v}).$$

Then we obtain

$$M = \lim_{n\to\infty} \tilde{f}(v_n)$$

$$= \left(\frac{1}{q} - \frac{1}{p}\right) A(\bar{v})\, r^*(\bar{v})^q + \left(\frac{1}{p} - \frac{1}{s}\right) B(v)\, r^*(\bar{v})^s$$

$$= \frac{1}{p}\left(\frac{1}{q} - \frac{1}{s}\right)\left\{\frac{[(p-s)B(\bar{v})]^q}{[(p-q)A(\bar{v})]^s}\right\}^{1/(q-s)} < 0,$$

which is absurd. Hence the claim follows.

(iii) It is easily checked that, if

$$\int_\Omega \rho\, |\nabla \bar{v}|^p\, dx < 1,$$

we can find $t > 1$ such that $t\bar{v} \in E_0 \cap S$. As in the proof of Proposition 2.4 this gives inequality (3.5). Moreover, observe that

$$r_*(\bar{v}) = t\frac{1}{t} r_*(\bar{v}) = t r_*(t\bar{v}) < t r(t\bar{v});$$

similarly,

$$r_*(\bar{v}) < \bar{r}.$$

Thus comparing (3.5) and (3.10) we find

$$\bar{r} < t r(t\bar{v}),$$

whence the claim follows as in the proof of Proposition 2.4. Since $\bar{v} \in E_0 \cap S$ and $\bar{r} = r(\bar{v})$, we have $M = \tilde{f}(\bar{v})$. Then the conclusion follows. □

Let us now prove Proposition 2.6.

Proof of Proposition 2.6. Set

$$M := \sup\{\tilde{f}(v) \mid v \in E_1 \cap S\};$$

observe that $M > 0$ by assumption (H$_6$), since $\tilde{f} > 0$ for any $v \in E_2$ (see section 2). Let $\{v_n\} \subseteq E_1 \cap S \subseteq E \cap S$ be a maximizing sequence, which converges to $\bar{v} \in X$ as in the proof of Proposition 2.4. The conclusion will follow if we prove that $\bar{v} \in E_1 \cap S$.

(i) Let us first show that $A(\bar{v}) > 0$. Since $\{v_n\} \subseteq E_1 \cap S$, for any $n \in N$ we have

$$\gamma_1 \, [B(v_n)]^{q-p} < [A(v_n)]^{s-p}$$

$$\le \left(\frac{\|a\|_\infty}{b_0} \right)^{s-p} (\|b\|_\infty \|\rho\|_1)^{(s-p)(s-q)/s} [B(v_n)]^{(s-p)q/s}. \tag{3.11}$$

Taking the limit as $n \to \infty$ gives

$$B(\bar{v}) \ge \frac{\gamma_1^{s/[p(s-q)]}}{(\|b\|_\infty \|\rho\|_1)^{(s-p)/p}} \left(\frac{b_0}{\|a\|_\infty} \right)^{[s(s-p)]/[p(s-q)]} > 0.$$

On the other hand, from the first inequality in (3.11) we obtain

$$A(\bar{v}) \ge \gamma_1^{1/(s-p)} [B(\bar{v})]^{(q-p)/(s-p)};$$

hence the claim follows.

(ii) It is easily seen that

$$[A(\bar{v})]^{s-p} \ge \gamma_1 [B(\bar{v})]^{q-p} \left[\int_\Omega \rho \, |\nabla \bar{v}|^p \, dx \right]^{s-q}.$$

To exclude the equality in the above relation we can use the same argument as in part (ii) of the proof of Proposition 2.4, provided that the sequence $\{r(v_n)\}$ is bounded. This follows easily from the bifurcation equation

$$|r(v_n)|^{s-p} \{A(v_n) |r(v_n)|^{q-s} - B(v_n)\} = 1,$$

since $B(v_n) \to B(\bar{v}) > 0$ by (i) above. Hence the claim follows.

(iii) To prove that $\int_\Omega \rho |\nabla \bar{v}|^p dx = 1$ we can use the same argument as in the proof of Proposition 2.4; we omit the details. The proof is complete. □

Proof of Theorem 1.1. Due to Proposition 2.3, there exists a conditionally extremum point $\bar{v} \ge 0$, $\bar{v} \ne 0$ of the reduced functional $\tilde{f}$ in the set E. According to Proposition 2.2 $u := r(\bar{v})\bar{v}$ is a nonzero critical point of the functional f, hence a nontrivial, nonnegative solution of problem (1.1). A standard bootstrap argument (see [7]) shows that $u \in L^\infty(\Omega)$; then the asserted regularity of u follows by [10] (see also [6], [16], [11]). Hence we have the conclusion. □

Theorems 1.2–1.4 follow similarly by Propositions 2.1 and 2.4–2.6; the details are omitted.

4. Nonexistence results. Let us briefly discuss the nonexistence results mentioned in section 1.

Proof of Theorem 1.5. Since the set $E \cap S$ is bounded in X (see Lemma 3.1), by assumptions (H$_0$) and (H$_2$) there exists $M_0 > 0$ (depending on a, ρ) such that

$$\int_\Omega \rho |v|^s dx \le M_0 \quad \text{for any } v \in E \cap S. \tag{4.1}$$

We shall prove the following statement: let

$$\|a_+\|_\infty^{s-p} \, \|\rho\|_1^{(s-p)(s-q)/s} \, M_0^{p(s-q)/s} < \gamma_1 b_0^{q-p}, \tag{H$_7$}$$

the constant γ_1 being defined in (2.20). Then the inequality

$$[A(v)]^{s-p} < \gamma_1 \, [B(v)]^{q-p} \left[\int_\Omega \rho \, |\nabla v|^p \, dx \right]^{s-q} \tag{4.2}$$

holds for any $v \in E$.

The above statement implies that the only solution of the bifurcation equation is trivial; thus the conclusion follows.

(i) Let us prove first the above statement for $v \in E \cap S$. Since

$$A(v) \leq \|a_+\|_\infty \, \|\rho\|_1^{(s-q)/s} \left(\int_\Omega \rho \, |v|^s \, dx \right)^{q/s},$$

$$B(v) \geq b_0 \int_\Omega \rho |v|^s dx,$$

the inequality (4.2) holds if

$$\|a_+\|_\infty^{s-p} \, \|\rho\|_1^{(s-p)(s-q)/s} \left(\int_\Omega \rho \, |v|^s \, dx \right)^{[p(s-q)]/s} < \gamma_1 b_0^{q-p}.$$

Due to (4.1), the latter inequality is satisfied if (H$_7$) holds. Then the conclusion will follow in this case.

(ii) By absurd, let $v \in E$ satisfy

$$[A(v)]^{s-p} \geq \gamma_1 [B(v)]^{q-p} \left[\int_\Omega \rho \, |\nabla v|^p \, dx \right]^{s-q}. \tag{4.3}$$

Recall that by (H$_2$)

$$\int_\Omega \rho \, |\nabla v|^p \, dx > 0;$$

then there exists $t > 0$ such that $tv \in E \cap S$. It is easily checked that (4.3) implies

$$[A(tv)]^{s-p} \geq \gamma_1 \, [B(tv)]^{q-p},$$

thus contradicting (i) above. This completes the proof. □

Let us finally prove the following result.

Proposition 4.1. *Let $b \equiv 0$; let $u \geq 0$, $u \neq 0$ be a solution of problem* (1.1). *Then*

$$\int_{\operatorname{supp} u} \rho \, a \, dx < 0.$$

Proof. Following [2] we set for any $\epsilon > 0$

$$h_\epsilon(s) := \int_0^s \frac{dt}{(t+\epsilon)^{(q-1)/(p-1)}}.$$

Then by (1.1) with $b \equiv 0$ the function $h_\epsilon(u(x))$ satisfies the problem

$$-\text{div} \left(\rho(x) \mid \nabla[h_\epsilon(u)] \mid^{p-2} \nabla[h_\epsilon(u)] \right)$$

$$= \rho(x)a(x)\left(\frac{u}{u+\epsilon}\right)^{q-1} + (q-1)\rho(x)\frac{|\nabla u|^p}{(u+\epsilon)^q} \quad \text{in } \Omega,$$

$$|\nabla[h_\epsilon(u)]|^{p-2}\,\frac{\partial[h_\epsilon(u)]}{\partial\nu} = \left(\frac{1}{u+\epsilon}\right)^{q-1} |\nabla u|^{p-2}\,\frac{\partial u}{\partial \nu} = 0 \quad \text{on } \partial\Omega.$$

Hence

$$\int_\Omega \rho\, a \left(\frac{u}{u+\epsilon}\right)^{q-1} dx = -(q-1)\int_\Omega \rho\,\frac{|\nabla u|^p}{(u+\epsilon)^q}\,dx < 0.$$

Letting $\epsilon \to 0$ we obtain

$$\int_{\operatorname{supp} u} \rho\, a\, dx \leq 0.$$

As in [2] it is proved that the above inequality is strict; then the conclusion follows. □

BOUNDS ON THE DISPERSION OF VORTICITY IN 2D INCOMPRESSIBLE, INVISCID FLOWS WITH A PRIORI UNBOUNDED VELOCITY[*]

J. HOUNIE[†], M. C. LOPES FILHO[‡], and H. J. NUSSENZVEIG LOPES[‡]

Abstract. We consider approximate solution sequences of the 2D incompressible Euler equations obtained by mollifying compactly supported initial vorticities in L^p, $1 \leq p \leq 2$, or bounded measures in H^{-1}_{loc} and exactly solving the equations. For these solution sequences we obtain uniform estimates on the evolution of the mass of vorticity and on the measure of the support of vorticity outside a ball of radius R. If the initial vorticity is in L^p, $1 \leq p \leq 2$, these uniform estimates imply certain a priori estimates for weak solutions which are weak limits of these approximations. In the case of nonnegative vorticities, we obtain results that extend, in a natural way, the cubic-root growth of the diameter of the support of vorticity proved first by C. Marchioro for bounded initial vorticities [*Comm. Math. Phys.*, 164 (1994), pp. 507–524] and extended by two of the authors to initial vorticities in L^p, $p > 2$.

Introduction. The main object of this work is the behavior of weak solutions of the 2D Euler equations, modeling the flow of incompressible, inviscid ideal fluids in two space dimensions. We will be concerned with flows of fluids that are assumed to fully occupy the 2D Euclidean plane, with velocity vanishing at infinity. We write the initial value problem in the form of the *vorticity equation*:

$$\begin{cases} \omega_t + u \cdot \nabla \omega = 0 \ \text{ in } \mathbb{R}^2 \times (0,\infty), \\ \text{div } u = 0 \ \text{ in } \mathbb{R}^2 \times [0,\infty), \\ \text{curl } u = \omega \ \text{ in } \mathbb{R}^2 \times [0,\infty), \\ \omega(x,0) = \omega_0(x) \ \text{ on } \mathbb{R}^2 \times \{t=0\}. \end{cases} \tag{0.1}$$

The velocity can be eliminated from the vorticity equation by means of the Biot–Savart law:

$$u(x,t) = (K * \omega(\cdot,t))(x) \equiv \frac{1}{2\pi} \int_{\mathbb{R}^2} \frac{(x-y)^\perp}{|x-y|^2} \omega(y,t) dy.$$

The usual strategy to obtain existence of weak solutions to the problem (0.1) is to consider a suitable approximate problem, for which existence of solutions is known, and then to obtain enough estimates to pass to the limit in the weak form of the equations. The standard approximation schemes used in the literature are the following: smoothing out initial data, the vanishing viscosity limit of the Navier–Stokes equations, and desingularized vortex methods. In this work we are specifically

concerned with weak solutions obtained by exactly solving (0.1) with smoothed-out initial data. If the initial vorticity ω_0 is a function in $L^p(\mathbb{R}^2)$, $1 < p < \infty$, with compact support, the existence of a weak solution obtained as the weak limit of a sequence of approximate solutions (produced by mollifying initial data) was first proved by DiPerna and Majda in [4]. For nonnegative initial vorticities in the space of bounded Radon measures with compact support, $\mathcal{BM}_c(\mathbb{R}^2)$, and in $H^{-1}_{\mathrm{loc}}(\mathbb{R}^2)$ a corresponding existence result was proved by Delort in [2]. Vecchi and Wu in [13] extended Delort's proof to initial vorticities of compact support in $L^1(\mathbb{R}^2) \cap H^{-1}_{\mathrm{loc}}(\mathbb{R}^2)$, without sign restrictions. Uniqueness, in these cases, is an outstanding open problem, as is existence for arbitrary bounded Radon measures of compact support in $H^{-1}_{\mathrm{loc}}(\mathbb{R}^2)$. Following DiPerna and Majda, we will refer to initial vorticities in $\mathcal{BM}(\mathbb{R}^2) \cap H^{-1}_{\mathrm{loc}}(\mathbb{R}^2)$ as vortex sheet initial data, which we will abbreviate with the acronym VSID. For bounded initial vorticities, then both existence and uniqueness of weak solutions were obtained by Yudovich in [14].

Little is known regarding the qualitative behavior of weak solutions of (0.1). The general problem we will focus on is the following: How fast can a fluid particle be displaced from its initial position and how is this displacement affected by the regularity of the subjacent flow? If the initial vorticity lies in the space $L^p_c(\mathbb{R}^2)$ (the space of compactly supported functions in L^p), $p > 2$, it is well known that the corresponding velocity field is bounded a priori. This means that the trajectory of almost all fluid particles is contained in a space-time cone centered at their initial positions and with aperture bounded by global conserved quantities of the flow. Since vorticity is constant along particle trajectories, this implies that the support of vorticity remains compact and its diameter grows at most linearly in time. For nonnegative bounded vorticities Marchioro [10] showed that the growth of the displacement from the initial position is at most of the order of the cubic-root of time, so that the space-time cone above can be substituted with a space-time cubic parabola. This result captures the trend that flows with single-signed vorticity have of rotating, rather than spreading particles. The result was extended by two of the authors in [9] to nonnegative initial vorticities in $L^p_c(\mathbb{R}^2)$, $p > 2$. However, the estimate on the aperture of the cubic parabola obtained is lost when $p \to 2^+$.

If the initial vorticity is in $L^p_c(\mathbb{R}^2)$, $1 \leq p \leq 2$, or in $\mathcal{BM}_c(\mathbb{R}^2) \cap H^{-1}_{\mathrm{loc}}(\mathbb{R}^2)$, it is not known whether the flow preserves the compactness of the support of vorticity. This problem was the initial motivation for the present work. The results we obtain here address the rate of dispersion of vorticity (or, equivalently, of material domains) in time. We will prove that the pictures obtained for more regular flows, i.e., linear cones in space-time for general vorticities and cubic parabolas for nonnegative vorticities, remain substantially true for even the most irregular cases. More precisely, we will show that, for any approximate solution sequence, given an initial disk in the plane and any $\varepsilon > 0$, there exists an aperture for a space-time cone (and for a cubic parabola in the case of nonnegative vorticity), uniform in the sequence, for which the set of particles in the initial disk whose trajectories leave the cone (respectively, the cubic parabola) has Lebesgue measure less than ε.

The remainder of this paper is organized in three sections: the first on flows without sign restriction on the vorticity, the second on flows with nonnegative vorticity, and the third containing extensions and conclusions. In the first one, we obtain estimates resembling Chebyshev inequalities for the Lagrangian maps that are applicable to any linear transport equation with a divergence-free smooth velocity field bounded in $L^q(\mathbb{R}^2)$. These results can be better understood in the context of the transport theory by vector fields with Sobolev space regularity by DiPerna and Lions [3]. In the specific context of the 2D vorticity equation, we also obtain a result of the same nature in the physically relevant situation where the velocity is only $L^2_{\mathrm{loc}}(\mathbb{R}^2)$. The second section begins with a simplified proof of an exponential decay estimate on the mass of vorticity near infinity due to Marchioro (this is the heart of the proof of Theorem 2.1 in [10]). We apply Marchioro's result and the Chebyshev inequalities obtained in the first section to get results on the smallness of the mass and of the Lebesgue measure of the support of vorticity outside a suitable cubic parabola. All our results are proved for a smooth approximate solution sequence generated by regularizing initial data, with estimates independent of the regularization parameter.

Some remarks regarding notation are in order. We denote by $B(p;R)$ the open ball centered at p with radius R in the plane. The Lebesgue measure of the set E is denoted by $|E|$ and the complement of E is denoted by E^c. If $z = (z_1, z_2)$ is a point in the plane, then $z^\perp = (-z_2, z_1)$. We denote the Lebesgue conjugate exponent of p by $p' = p/(p-1)$. Finally, we will use supp ω to denote the support of the function ω.

1. Chebyshev inequalities. We begin with a result which applies to a general flow by a divergence-free, time-dependent vector field u. Consider a bounded, divergence-free, smooth vector field $u : \mathbb{R}^n \times [0,T] \to \mathbb{R}^n$.

Let $X = X(\alpha, t)$ denote an orbit associated with the flow by u:

$$\begin{cases} \dfrac{dX}{dt} = u(X,t), \ 0 < t < T, \\ \\ X(\alpha, 0) = \alpha \in \mathbb{R}^n. \end{cases}$$

We use $X(D,t) \equiv \{X(\alpha,t) \mid \alpha \in D\}$ to denote the flow of a set $D \subseteq \mathbb{R}^n$ under the vector field u. We often refer to the family of diffeomorphisms $\alpha \mapsto X(\alpha,t)$ as Lagrangian maps.

The first result of this section will be referred to as the *filtering theorem.*

THEOREM 1.1. *Let* $0 < R_1 < R_2$ *and define the annulus* $A = \{x \in \mathbb{R}^n \mid R_1 < |x| < R_2\}$, $\Sigma(R_1, R_2, t) \equiv \{\alpha \in B(0;R_1) \mid |X(\alpha,t)| > R_2\}$ *and let* $q \geq 1$. *Then*

$$|\Sigma(R_1,R_2,t)| \leq \left(\frac{t \sup\limits_{0 \leq t \leq T} \|u(\cdot,t)\|_{L^q(A)}}{R_2 - R_1} \right)^q .$$

Proof. Fix $t > 0$. In this proof we will abbreviate $\Sigma(R_1, R_2, t)$ by Σ. Let us introduce the material cylinder $\mathcal{C}$ defined by

$$\mathcal{C} \equiv \bigcup_{0 \leq s \leq t} X(\Sigma, s).$$

The proof consists of integrating and estimating the radial component of velocity on the set $(A \times [0,t]) \cap \mathcal{C}$. Let $\chi_A = \chi_A(x)$ denote the characteristic function of the annulus A. Then, by incompressibility we have

$$\int_{\mathcal{C}} \chi_A(x) u(x,s) \cdot \frac{x}{|x|} dx ds = \int_0^t \int_\Sigma \chi_A(X(\alpha,s)) \frac{d|X(\alpha,s)|}{ds} d\alpha ds.$$

Claim. For any $\alpha \in \Sigma$, we have

$$\int_0^t \chi_A(X(\alpha,s)) \frac{d|X(\alpha,s)|}{ds} ds = R_2 - R_1. \tag{1.1}$$

To see that, consider $\Gamma \equiv \{0 < s < t \mid X(\alpha, s) \in A\}$. Since Γ is open, it can be written as a countable union of disjoint open intervals:

$$\Gamma = \bigcup_{i=1}^{\infty} (a_i, b_i).$$

Therefore,

$$\int_0^t \chi_A(X(\alpha,s)) \frac{d|X(\alpha,s)|}{ds} ds = \sum_{i=1}^{\infty} \int_{a_i}^{b_i} \frac{d|X(\alpha,s)|}{ds} ds$$

$$= \sum_{i=1}^{\infty} \left(|X(\alpha,b_i)| - |X(\alpha,a_i)|\right).$$

By the continuity of the trajectories $X(\alpha,\cdot)$, each of these numbers $|X(\alpha,b_i)|$ and $|X(\alpha,a_i)|$ is either R_1 or R_2. The curve $s \mapsto X(\alpha,s)$ has finite total length, and hence the summation above has a finite number of nonzero terms, which correspond precisely to the time intervals during which the curve completely traverses the annulus. Since $|X(\alpha,0)| = |\alpha| < R_1$ and $|X(\alpha,t)| > R_2$,

$$\sum_{i=1}^{\infty} \left(|X(\alpha,b_i)| - |X(\alpha,a_i)|\right) = R_2 - R_1,$$

and the claim is proved. $\square$

Hence, in view of (1.1),

$$\int_{\mathcal{C}} \chi_A(x) u(x,s) \cdot \frac{x}{|x|} dx ds = (R_2 - R_1)|\Sigma|. \tag{1.2}$$

On the other hand, we also have

$$\int_{\mathcal{C}} \chi_A(x) u(x,s) \cdot \frac{x}{|x|} dx ds \leq \int_0^t \int_{X(\Sigma,s)} |\chi_A(x) u(x,s)| dx ds$$

$$\leq \int_0^t \|\chi_A(\cdot) u(\cdot,s)\|_{L^q(X(\Sigma,s))} |\Sigma|^{(q-1)/q} ds$$

$$\leq t \sup_{0 \leq s \leq t} \|u(\cdot,s)\|_{L^q(A)} |\Sigma|^{(q-1)/q}.$$

Putting together the identity (1.2) and the inequality above we obtain the estimate we wished. $\square$

This result can be understood in the context of the linear transport theory developed by DiPerna and Lions in [3]. What we achieve is control over the local transport in terms of weak local control over the transporting vector fields that can be applied in situations where the flow is very singular. A theorem of this nature can also be proved for vector fields with bounded divergence, which is the context of [3]. However, in this work we are interested in the incompressible situation.

In [3], DiPerna and Lions observed that if the vector field $u \in L^q(\mathbb{R}^n) \cap W^{1,1}_{\text{loc}}(\mathbb{R}^n)$ has bounded divergence, then the Lagrangian maps are $L^q_{\text{loc}}(\mathbb{R}^n)$. Let $X(\cdot, t)$ be the unique renormalized flow associated with u, with $X(\cdot, t) \in L^q_{\text{loc}}(\mathbb{R}^n)$. In order to compare the estimate in Theorem 1.1 with results obtained by DiPerna and Lions, first recall the classical Chebyshev inequality, which states that if $\Omega \subset \mathbb{R}^n$ and if f in $L^q(\Omega)$, then for any $\lambda > 0$,

$$|\{x \in \Omega : |f(x)| > \lambda\}| \leq \frac{\|f\|^q_{L^q(\Omega)}}{\lambda^q}.$$

Note that we have

$$|\{\alpha \in B(0; R_1) \mid |X(\alpha, t)| > R_2\}| \leq |\{\alpha \in B(0; R_1) \mid |X(\alpha, t) - \alpha| > R_2 - R_1\}|$$

$$\leq \frac{\|X(\alpha, t) - \alpha\|^q_{L^q(B(0;R_1))}}{(R_2 - R_1)^q} = (1.1),$$

where the last inequality follows from the Chebyshev inequality applied to $X(\alpha, t) - \alpha \in L^q(B(0, R_1))$,

$$(1.1) = \frac{\| \int_0^t u(X(\alpha, s), s) ds\|^q_{L^q(B(0;R_1))}}{(R_2 - R_1)^q} \leq \frac{t^q \sup_{0 \leq s \leq t} \|u(\cdot, s)\|^q_{L^q(\mathbb{R}^n)}}{(R_2 - R_1)^q},$$

where the final inequality was deduced from the generalized Minkowski inequality; see [12]. The estimate in Theorem 1.1 is a generalization of this conclusion mainly because our estimate is local, in the sense that it depends only on the L^q-norm of u in the annulus A and not on a global L^q bound.

In the next result we single out a special case of the filtering theorem, which is more in the nature of a Chebyshev inequality for the Lagrangian maps, and which will be useful in the applications to 2D incompressible flow. Once again, we assume that the flow u is smooth.

Corollary 1.2. *Let $S_0 \subseteq B(0; R_0)$ and $t > 0$. Then, for every $R > R_0$, we have*

$$|X(S_0, t) \cap B(0; R)^c| \leq \left(\frac{t \sup\limits_{0 \leq s \leq t} \|u(\cdot, s)\|_{L^q(\mathbb{R}^n)}}{R - R_0} \right)^q.$$

Proof. Since

$$|X(S_0, t) \cap B(0; R)^c| = |\{X(\alpha, t) \mid \alpha \in S_0 \text{ and } |X(\alpha, t)| > R\}|,$$

we have, by incompressibility, that this is equal to

$$|\{\alpha \in S_0 \mid |X(\alpha, t)| > R\}| \leq |\Sigma(R_0, R, t)|,$$

and the result follows from Theorem 1.1. □

This estimate applies to incompressible flows of ideal fluids in a number of instances. First, the case $q = 2$ applies to n-dimensional incompressible flows as long as the flow exists and the initial data has globally bounded kinetic energy. In the remainder of this article we will develop applications to 2D Euler flows.

For any $1 \leq p \leq \infty$, the L^p-norm of vorticity is a conserved quantity as long as the flow is smooth. We first assume that $\omega_0 \in L^p_c$, and we are interested in the cases $1 < p \leq 2$. Our concern is the propagation of the support of vorticity, which is a material domain. In order to apply Corollary 1.2, we need to know the appropriate a priori estimate for velocity. This is given in the next result, which is an analogue of the Sobolev embedding $W^{1,p} \hookrightarrow L^{p^*}$, with $p^* = 2p/(2-p)$.

PROPOSITION 1.3. *If $\omega \in L^p(\mathbb{R}^2)$, for some $1 < p < 2$, then $u = K * \omega \in L^{p^*}(\mathbb{R}^2)$, where p^* is the critical Sobolev exponent introduced above. Moreover, we have the estimate*

$$\|u\|_{L^{p^*}} \leq \frac{C}{\sqrt{2-p}} \|\omega\|_{L^p},$$

for some $C = C(p)$, which blows up as $p \to 1$ and remains bounded as $p \to 2$.

Proof. Let I_1 be the first-order Riesz potential, so that, for f in the Schwarz space $\mathcal{S}(\mathbb{R}^n)$

$$\widehat{(I_1 f)}(\xi) = \frac{\widehat{f}(\xi)}{2\pi|\xi|}.$$

We consider also the Riesz transforms R_j in $\mathbb{R}^2$, $j = 1, 2$ so that, for a function $f \in \mathcal{S}(\mathbb{R}^n)$

$$\widehat{(R_j f)}(\xi) = i \frac{\xi_j \widehat{f}(\xi)}{|\xi|},$$

where $i = \sqrt{-1}$ and $\xi = (\xi_1, \xi_2)$.

The Riesz transforms are bounded in $L^q(\mathbb{R}^2)$, for any $1 < q < \infty$ with the operator norm continuous with respect to q, blowing up as $q \to 1$; see [12]. By the Hardy–Littlewood–Sobolev theorem, the Riesz potential maps $L^p(\mathbb{R}^2)$ continuously into $L^{p^*}(\mathbb{R}^2)$.

We observe that the Biot–Savart law can be rewritten (up to a constant factor) as

$$u = I_1 R^{\perp} \omega,$$

where $R^{\perp} = (-R_2, R_1)$.

To see this, we first note that $I_1 R^{\perp}$ maps L^p continuously into L^{p^*}. For a function in $f \in \mathcal{S}(\mathbb{R}^2)$ we have that $I_1 R^{\perp} f = K_1 * f$, where $K_1 \in \mathcal{S}'(\mathbb{R}^2)$ is such that its Fourier transform is $\widehat{K_1} = i\xi^{\perp}/(2\pi|\xi|^2)$, for $\xi \neq 0$.

Let ω be a vorticity in the Schwarz space $\mathcal{S}(\mathbb{R}^2)$, and consider both $u_1 = K_1 * \omega$ and $u_2 = K * \omega$. We will show they are the same. Observe that u_1 and u_2 are tempered distributions. The vector field u_2 is the unique solution to the elliptic system:

$$\begin{cases} \operatorname{div} u = 0, \\ \operatorname{curl} u = \omega, \\ |u| \to 0 \text{ as } |x| \to \infty. \end{cases}$$

We can pass the Fourier transform on the system above, and invert the resulting linear system for $\xi \neq 0$, to find that the Fourier transforms of u_1 and u_2 coincide. In particular, by varying ω, one may conclude that $\widehat{K} = \widehat{K_1}$, for $\xi \neq 0$, which then implies, by Theorem 3.2.3 of [5] (since $\widehat{K}$ and $\widehat{K_1}$ are homogeneous of degree $-1 > -2$), that $K_1 = K$ and hence that $u_1 = u_2$.

The proposition is proved, except for the asymptotic behavior, as $p \to 2$ of the operator norm of I_1.

To prove the asymptotic estimate, we begin by following the proof of Proposition 3.1.2 in [1], which gives a pointwise estimate of $I_1 f$ for $f \in L^p(\mathbb{R}^2)$ in terms of the maximal function $M|f|$. Tracking the constants, one arrives at the following estimate:

$$|I_1 f|(x) \leq C \left[2\pi + (2\pi)^{(p-1)/p} \left(\frac{p-1}{2-p} \right)^{(p-1)/p} \right] \|f\|_{L^p(\mathbb{R}^2)}^{p/2} (M|f|(x))^{p/p^*}.$$

Using the Hardy–Littlewood maximal theorem, this implies that

$$\|I_1 f\|_{L^{p^*}(\mathbb{R}^2)} \leq A_p \|f\|_{L^p(\mathbb{R}^2)},$$

with $A_p = C[2\pi + (2\pi)^{(p-1)/p}(\frac{p-1}{2-p})^{(p-1)/p}]$. Since $1 < p < 2$, A_p can be bounded from above by $C/\sqrt{2-p}$. □

Estimates for the propagation of support of vorticity can now be proved as a further corollary of Theorem 1.1 and Proposition 1.3.

COROLLARY 1.4. *Assume that ω_0 is a smooth function such that* supp $(\omega_0) \subseteq B(0; R_0)$. *If $1 < p < 2$, then there exists $C_p > 0$ such that, for any $R > R_0$,*

$$|\text{supp } \omega(\cdot, t) \cap B(0; R)^c| \leq \left(\frac{C_p \, t \, \|\omega_0\|_{L^p}}{R - R_0} \right)^{p^*}.$$

In addition, there exist constants $C > 0$ and $\eta > 0$ such that if $t/(R - R_0) < \eta$, then

$$|\text{supp } \omega(\cdot, t) \cap B(0; R)^c| \leq |\text{supp } \omega_0| \exp \left(-C \frac{(R - R_0)^2}{t^2 \|\omega_0\|_{L^2}^2} \right).$$

Proof. The first part is a trivial consequence of Corollary 1.2 and Proposition 1.3 together with the fact that the support of vorticity is a material domain: supp $\omega(\cdot, t) = X(\text{supp } \omega_0, t)$.

We now consider the second part. We use the fact that a compactly supported function in L^2 is also in L^p for any $p < 2$. More precisely, we have

$$\|\omega_0\|_{L^p} \leq |\text{supp } \omega_0|^{1/p^*} \|\omega_0\|_{L^2}.$$

Hence, from Proposition 1.3, we know that

$$|\text{supp } \omega(\cdot, t) \cap B(0; R)^c| \leq |\text{supp } \omega_0| \left(\frac{Ct\|\omega_0\|_{L^2}}{R - R_0} \right)^{p^*},$$

for any $1 < p < 2$. We optimize the estimate above in p. Since we are interested only in the behavior for p near 2, we restrict ourselves to searching for minima in the range $7/4 < p < 2$. We find that if

$$\frac{t}{R - R_0} < \frac{1}{2C\|\omega_0\|_{L^2}} e^{-7/16} \equiv \eta,$$

then there exists another constant $\widetilde{C} > 0$ such that

$$|\text{supp } \omega(\cdot, t) \cap B(0; R)^c| \leq |\text{supp } \omega_0| \exp \left(-\widetilde{C} \frac{(R - R_0)^2}{t^2 \|\omega_0\|_{L^2}^2} \right)$$

as we wanted. □

The critical estimate in terms of the L^2-norm obtained above can be understood as a Trudinger–Moser inequality for the Lagrangian maps. The proof we presented is a variation on the standard proofs in this context.

If the initial vorticity has compact support and it belongs to $L^1(\mathbb{R}^2)$ or it is a bounded Radon measure in $H^{-1}_{\text{loc}}(\mathbb{R}^2)$, that is, VSID, then the associated velocity belongs to $L^2_{\text{loc}}(\mathbb{R}^2)$ for each fixed time. It is well known that velocity belongs to $L^2(\mathbb{R}^2)$ only if the vorticity has vanishing integral over all of $\mathbb{R}^2$. Consequently, for initial vorticities of compact support in $L^1(\mathbb{R}^2)$ or VSID, with integral zero, we also have an estimate, valid for smooth approximate solution sequences, of the form

$$|\text{supp } \omega(\cdot,t) \cap B(0;R)^c| \leq \left(\frac{t\|u_0\|_{L^2}}{R-R_0}\right)^2.$$

However, flows with locally bounded kinetic energy are of physical interest. Furthermore, the only rigorous existence result for weak solutions with VSID requires that the initial vorticities have a distinguished sign. We can still prove an estimate for the Lebesgue measure of the support of vorticity lying outside a ball of radius R in this setting.

THEOREM 1.5. *Let ω_0 be a smooth function and let $T > 0$. Assume the support of ω_0 is contained in the ball $B(0;R_0)$. Then there exists a constant $C = C(T,R_0) > 0$ such that for all $R > R_0$ and $0 \leq t \leq T$ we have*

$$|\text{supp } \omega(\cdot,t) \cap B(0;R)^c| \leq C\left(\frac{t}{R-R_0}\right)^2.$$

Proof. Fix $R > R_0$ and $0 \leq t \leq T$. Recall

$$\Sigma = \Sigma(R_0,R,t) \equiv \{\alpha \in B(0;R_0) \mid |X(\alpha,t)| > R\}.$$

Observe that

$$|\text{supp } \omega(\cdot,t) \cap B(0;R)^c| \leq |\Sigma|.$$

Hence, it is enough to estimate $|\Sigma|$. We have

$$|\Sigma| \leq \frac{1}{R^2}\int_\Sigma |X(\alpha,t)|^2 d\alpha$$

$$\leq \frac{2}{R^2}\left(\int_\Sigma |X(\alpha,t)-\alpha|^2 d\alpha + \int_\Sigma |\alpha|^2 d\alpha\right)$$

$$\equiv \frac{2}{R^2}(\mathcal{I}_1 + \mathcal{I}_2).$$

Note that $X(\alpha,t) - \alpha = \int_0^t u(X(\alpha,s),s)ds$. We will need to make use of the DiPerna–Majda decomposition of an L^2_{loc} velocity (see [4]). To do this, choose a circularly symmetric, smooth, and compactly supported function $\bar{\omega} = \bar{\omega}(|x|)$ such that $\int_{\mathbb{R}^2} \bar{\omega}(|x|)dx = \int_{\mathbb{R}^2} \omega_0(x)dx$. Let $\bar{u} \equiv K * \bar{\omega}(|\cdot|)$. The stationary velocity field $\bar{u}$ is smooth and decays as $1/|x|$, as $|x| \to \infty$. Let $\check{\omega}(x,s) \equiv \omega(x,s) - \bar{\omega}(|x|)$ and $\check{u} \equiv K * \check{\omega}$. It was shown in [4] that

$$\|\check{u}\|^2_{L^2(\mathbb{R}^2)} \leq K(T) = \|\check{u}(\cdot,0)\|^2_{L^2(\mathbb{R}^2)} e^{cT}.$$

Let $\alpha \in \Sigma$. Using the decomposition $u = \bar{u} + \check{u}$ we have

$$|X(\alpha,t) - \alpha|^2 \leq \left(\int_0^t |\bar{u}(X(\alpha,s))| ds + \int_0^t |\check{u}(X(\alpha,s),s)| ds \right)^2$$

$$\leq \frac{Ct^2}{R^2} + Ct \int_0^t |\check{u}(X(\alpha,s),s)|^2 ds.$$

We can now estimate $\mathcal{I}_1$:

$$\mathcal{I}_1 \leq \frac{Ct^2}{R^2}|\Sigma| + Ct \int_0^t \int_\Sigma |\check{u}(X(\alpha,s),s)|^2 d\alpha ds$$

$$\leq \frac{Ct^2}{R^2} + Ct^2 K(T).$$

In order to estimate $\mathcal{I}_2$ note that if $\alpha \in \Sigma$, then

$$|X(\alpha,t) - \alpha| \geq R - R_0 \geq \frac{|\alpha|(R - R_0)}{R_0}.$$

Therefore,

$$|\alpha| \leq \frac{R_0}{R - R_0} |X(\alpha,t) - \alpha|.$$

We hence obtain

$$\mathcal{I}_2 \leq \left(\frac{R_0}{R - R_0} \right)^2 \mathcal{I}_1 \leq \left(\frac{R_0}{R - R_0} \right)^2 \left(\frac{Ct^2}{R^2} + Ct^2 K(T) \right).$$

Collecting these estimates, we finally get

$$|\Sigma| \leq \frac{2}{R^2} \left(\frac{Ct^2}{R^2} + Ct^2 K(T) \right) \left(1 + \left(\frac{R_0}{R - R_0} \right)^2 \right)$$

$$\leq \frac{Ct^2}{(R - R_0)^2},$$

since, at the same time, $R > R_0$ and $R > R - R_0$. □

There is one essential difference between this result and that of Corollary 1.4, which is the exponential growth of the constant C in T, while the constant in Corollary 1.4 did not depend on T.

For flows with no restrictions on the sign of vorticity, there is a well-known trend for paired eddies with vorticities of opposite sign to move off to infinity with constant speed. Since more than one such pair of eddies may be present in a given flow, with different average speeds, one expects that in some situations the diameter of the support of vorticity may grow linearly in time. We offer an explicit example from vortex dynamics to illustrate this behavior.

We consider the point-vortex evolution of four vortices, with initial configuration occupying the four vertices of the rectangle $[-a_0, a_0] \times [-b_0, b_0]$, with vorticity strength $+\omega$ at (a_0, b_0) and $(-a_0, -b_0)$ and with vorticity strength $-\omega$ at $(a_0, -b_0)$ and $(-a_0, b_0)$. This configuration is called a *vortex quadrupole*. The evolution preserves the quadrupole structure and is determined by a 2×2 system of ordinary differential equations for $(a(t), b(t))$, which is the position of the point vortex in the first quadrant. (In fact, by the reflexion method, the evolution of a vortex quadrupole is precisely the evolution of a single vortex in the first quadrant, regarded as a domain with boundary.) This 2×2 system is explicitly integrable, and the solution is given by the formulas

$$a(t) = \sqrt{\frac{1}{2}\left(q(t)^2 + 4k^2 + q(t)\sqrt{q(t)^2 + 4k^2}\right)},$$

$$b(t) = \frac{ka(t)}{\sqrt{a(t)^2 - k^2}},$$

where

$$c_0 = \sqrt{a_0^2 + b_0^2}, \quad k = a_0 b_0 / c_0, \quad q(t) = \frac{\omega t}{4\pi k} - \frac{b_0^2 - a_0^2}{c_0}.$$

From these formulas it can be seen that the diameter of the support of vorticity grows linearly in time.

Since this article was first distributed in preprint form, a continuous version of this example was obtained by Iftimie, Sideris, and Gamblin in [6].

2. Flows with vorticity of distinguished sign. In this section we will concentrate on 2D flows with nonnegative vorticity. Our objective is to derive results for flows with a priori unbounded velocity that capture the $\mathcal{O}(t^{1/3})$ growth on the diameter of the support of vorticity proved by Marchioro in [10] for bounded vorticities.

Our results rely heavily on an exponential decay estimate on the mass of vorticity far from the center of motion. Although originally proved for flows with bounded vorticities in [10], this estimate actually applies, with negligible changes in the original proof, to very singular vorticities such as weak solutions of (0.1) with VSID, obtained as limits of approximate solution sequences generated by regularizing initial data. This exponential decay estimate was derived by Marchioro in the course of proving Theorem 2.1 in [10] and has never been stated as an independent result. We will do so here and we will offer a simplified proof, in part for the sake of completeness, in which we avoid the use of dyadic decompositions. We note that an even simpler and more elegant proof of Marchioro's exponential decay estimate has been derived independently by Iftimie and Sideris [7].

We begin with an elementary technical lemma and then proceed to Marchioro's result.

Lemma 2.1. *Let $\phi = \phi(r) \geq 0$ be a function such that*

$$\int_0^\infty \phi(r) r^2 dr \equiv L < \infty.$$

Let $0 < \lambda < 1$ *and* $a > 0$. *Then*

$$\int_0^{\lambda a} \frac{r}{a(a-r)} \phi(r) r dr \leq \frac{L}{a^2(1-\lambda)^2}.$$

Proof. Set $F(r) = \int_r^{\lambda a} \phi(s) s ds$. Then

$$\int_0^{\lambda a} \frac{r}{a(a-r)} \phi(r) r dr = -\int_0^{\lambda a} \frac{r}{a(a-r)} F'(r) dr = \int_0^{\lambda a} \frac{1}{(a-r)^2} F(r) dr$$

$$\leq \frac{1}{a^2(1-\lambda)^2} \int_0^{\lambda a} F(r) dr \leq \frac{1}{a^2(1-\lambda)^2} \int_0^{\lambda a} \int_r^{\lambda a} \phi(s) s ds dr$$

$$= \frac{1}{a^2(1-\lambda)^2} \int_0^{\lambda a} \phi(s) s^2 ds \leq \frac{L}{a^2(1-\lambda)^2}$$

as we wanted. □

THEOREM 2.2 (see Marchioro [10]). *Let* ω_0 *be a smooth nonnegative function with support contained in* $B(0; R_0)$. *Let* $\omega = \omega(x,t)$ *be the unique smooth solution of the vorticity equation* (0.1) *with initial vorticity* ω_0. *For* $R > 0$ *define*

$$m_t(R) \equiv \int_{|x|>R} \omega(x,t) dx. \tag{2.1}$$

Then there exists a constant $C > 0$, *depending only on* $\int_{\mathbb{R}^2} \omega_0(x) dx$, *on the moment of inertia* $\int_{\mathbb{R}^2} |x|^2 \omega_0(x) dx$ *and on* R_0, *such that for any* $n \in \mathbb{N}$ *and any* $R > 0$ *satisfying* $nR_0 < R \leq (n+1)R_0$, *we have*

$$m_t(R + R_0) \leq \left(\frac{Ct}{(R-R_0)^3} \right)^n.$$

Proof. Let $W = W(r)$ be a nondecreasing smooth function such that $W(r) = 0$, if $r \leq R_0$ and $W(r) = 1$ if $r \geq 2R_0$. Let $R > R_0$. Set $\varphi = \varphi(y) \equiv W(|y| - (R - R_0))$ for $y \in \mathbb{R}^2$. Clearly, if $|y| > R_0 + R$ or $|y| < R$, φ is constant, and hence its first derivatives vanish. We will need the fact that the second derivatives of φ are uniformly bounded, independently of $R \geq R_0$. Indeed,

$$\frac{\partial^2 \varphi}{\partial y_i \partial y_j} = W''(|y| - (R - R_0)) \frac{y_i y_j}{|y|^2} + W'(|y| - (R - R_0)) \left(\frac{\delta_{ij}}{|y|} - \frac{y_i y_j}{|y|^3} \right).$$

Therefore, this second derivative vanishes outside $R < |y| < R + R_0$ and is bounded by $C(1 + 1/R) < C(1 + 1/R_0)$.

Following Marchioro, we introduce the smoothed-out version of $m_t(R)$:

$$\tilde{m}_t(R) = \int_{\mathbb{R}^2} \varphi(y) \omega(y,t) dy.$$

Then

$$\frac{d}{dt} \tilde{m}_t(R) = \int_{\mathbb{R}^2} \varphi(y) \omega_t(y,t) dy = \int_{\mathbb{R}^2} \nabla \varphi(y) u(y,t) \omega(y,t) dy$$

$$= \frac{1}{2}\int_{\mathbb{R}^2}\int_{\mathbb{R}^2} (\nabla\varphi(y) - \nabla\varphi(z))\, K(y-z)\omega(y,t)\omega(z,t)dydz.$$

We divide $\mathbb{R}^2$ into three regions: $O_1 = B(0, R/2)$, $O_2 = \{R/2 \le |x| < R\}$, and $O_3 = \{|x| \ge R\}$, and divide $\mathbb{R}^2 \times \mathbb{R}^2$ into the nine disjoint regions $O_{ij} = O_i \times O_j$. We first observe that

$$\int_{O_{ij}} (\nabla\varphi(y) - \nabla\varphi(z))\, K(y-z)\omega(y,t)\omega(z,t)dydz = 0$$

if both i and j are at most 2.

We begin by estimating the integral on O_{13}:

$$\frac{1}{2}\int_{O_{13}} (\nabla\varphi(y) - \nabla\varphi(z))\, K(y-z)\omega(y,t)\omega(z,t)dydz$$

$$= -\frac{1}{2}\int_{|y|<R/2}\int_{|z|\ge R} W'(|z| - (R-R_0))\frac{z}{|z|}K(y-z)\omega(y,t)\omega(z,t)dydz$$

$$\le C\left(\sup_{|z|\ge R}\left|\int_{|y|<R/2}\frac{z}{|z|}K(y-z)\omega(y,t)dy\right|\right)\int_{|z|\ge R}\omega(z,t)dz.$$

We will now make use of Lemma 2.1. Let $\phi(r,t) \equiv \int_0^{2\pi}\omega(r(\cos\theta,\sin\theta),t)d\theta$. Then,

$$\int_0^\infty \phi(r,t)r^2dr = \int_{\mathbb{R}^2}|x|\omega(x,t)dx \le \frac{1}{2}\int_{\mathbb{R}^2}(1+|x|^2)\omega(x,t)dx$$

$$= C\int_{\mathbb{R}^2}(1+|x|^2)\omega_0(x)dx \equiv L.$$

Note that, for $|z| \ge R$, we have

$$\left|\int_{|y|<R/2}\frac{z}{|z|}K(y-z)\omega(y,t)dy\right| \tag{2.2}$$

$$= \left|\int_{|y|<R/2}\frac{y}{|z|}\frac{(y-z)^\perp}{2\pi|y-z|^2}\omega(y,t)dy\right| \le \int_{|y|<|z|/2}\frac{|y|}{|z|(|z|-|y|)}\omega(y,t)dy$$

$$= \int_0^{|z|/2}\frac{r}{|z|(|z|-r)}\phi(r,t)rdr \le \frac{4L}{|z|^2} \tag{2.3}$$

using Lemma 2.1 with $a = |z|$ and $\lambda = 1/2$.

We conclude the estimate on O_{13} obtaining

$$\frac{1}{2}\int_{O_{13}} (\nabla\varphi(y) - \nabla\varphi(z))\, K(y-z)\omega(y,t)\omega(z,t)dydz \le C\frac{m_t(R)}{R^2}.$$

Similarly, on O_{31}

$$\frac{1}{2}\int_{O_{31}} \left(\nabla\varphi(y) - \nabla\varphi(z)\right) K(y-z)\omega(y,t)\omega(z,t)dydz \leq C\frac{m_t(R)}{R^2}.$$

Next observe that since the moment of inertia is conserved, $m_t(r) \leq C/r^2$. We now estimate the integral on $O_{23} \cup O_{33}$. We have

$$\frac{1}{2}\int_{O_{23}\cup O_{33}} \left(\nabla\varphi(y) - \nabla\varphi(z)\right) K(y-z)\omega(y,t)\omega(z,t)dydz$$

$$\leq C\left(\sup_{y,z\in\mathbb{R}^2} |(\nabla\varphi(y) - \nabla\varphi(z))K(y-z)|\right)\int_{|y|\geq R/2}\omega(y,t)dy\int_{|z|\geq R}\omega(z,t)dz$$

$$\leq C\frac{m_t(R)}{R^2},$$

similarly for $O_{32} \cup O_{33}$. Finally, observe that

$$\frac{1}{2}\int_{O_{33}} \left(\nabla\varphi(y) - \nabla\varphi(z)\right) K(y-z)\omega(y,t)\omega(z,t)dydz$$

$$\leq C(m_t(R))^2 \leq C\frac{m_t(R)}{R^2},$$

since the second derivatives of φ are bounded.

We have therefore shown that

$$\frac{d}{dt}\tilde{m}_t(R) \leq C\frac{m_t(R)}{R^2},$$

that is,

$$\tilde{m}_t(R) \leq \frac{C}{R^2}\int_0^t m_s(R)ds,$$

since $\tilde{m}_0(R) = 0$. Now we repeat the backwards induction argument of Marchioro.

Note that

$$\tilde{m}_t(R) \leq m_t(R) \leq \tilde{m}_t(R - R_0).$$

We now fix $n \in \mathbb{N}$ and R such that $nR_0 < R \leq (n+1)R_0$. By iterating backwards in time and in R we get

$$\tilde{m}_t(R) \leq \frac{C^n}{\prod_{i=0}^{n-1}(R - iR_0)^2}\int_0^t\int_0^{s_1}\dots\int_0^{s_{n-1}} m_{s_n}(R-(n-1)R_0)ds_n\dots ds_2 ds_1$$

$$\leq \frac{C^n t^n}{(n!)^3} \leq \frac{C^n t^n e^{3n}}{n^{3n}} \equiv \left(\frac{Ct}{n^3}\right)^n \leq \left(\frac{Ct}{(R-R_0)^3}\right)^n.$$

Since $\tilde{m}_t(R) \geq m_t(R + R_0)$, the conclusion follows. □

The result above offers no control on the mass of vorticity contained in the annulus $\{R_0 \leq |x| \leq 2R_0\}$. The proof could be modified, by suitably changing the definition of W, so that this absence of control would occur only on the annulus $\{R_0 \leq |x| \leq R_0 + \varepsilon\}$, with ε arbitrary. However, the constant C would blow up as $\varepsilon \to 0$. To obtain uniform control over the mass of vorticity outside a ball of radius $R_0 + \varepsilon$, we need to use the Chebyshev-type inequalities proved in the first section.

The following results are extensions of the statement of Theorem 2.1 in [10] to much more singular flows. We will continue using the notation $m_t(R)$ as in (2.1).

PROPOSITION 2.3. *Let ω_0 be a smooth nonnegative function, with support contained in $B(0; R_0)$. Let $1 < p \leq 2$ and $\|\omega_0\|_{L^p(\mathbb{R}^2)} \leq K$. Then, for every $\delta > 0$, there exists $b = b(K, \delta) > 0$ such that for any $t > 0$*

$$m_t((R_0^3 + bt)^{1/3}) < \delta.$$

Proof. Fix $0 < \delta < 1$. We start with the trivial observation that, for any $R > R_0$,

$$m_t(R) \leq \|\omega_0\|_{L^p} \left|\text{supp } \omega(\cdot, t) \cap B(0; R)^c\right|^{1/p'}.$$

From this and from Corollary 1.4 it follows that there exists $b_1 = b_1(K, \delta) > 0$ such that $m_t(R_0 + b_1 t) < \delta$ for all $t > 0$.

From Theorem 2.2, there exists $b_2 = b_2(K, \delta) > 0$ such that $m_t(2R_0 + (b_2 t)^{1/3}) < \delta$, again for every $t > 0$.

It is easy to see that one can choose $b = b(K, \delta)$ such that

$$\min\left\{R_0 + b_1 t, 2R_0 + (b_2 t)^{1/3}\right\} \leq (R_0^3 + bt)^{1/3},$$

and this concludes the proof. □

A similar result is still true in L^1; however, the constant b obtained does not depend uniformly on the L^1-norm of vorticity.

PROPOSITION 2.4. *Let $\{\omega_0^\varepsilon\}$ be a uniformly integrable family of nonnegative smooth functions, with support contained in $B(0; R_0)$. Then, for every $\delta > 0$, there exists $b = b(\delta)$ such that for any ε*

$$\int_{|x| > (R_0^3 + bt)^{1/3}} \omega^\varepsilon(x, t)\,dx < \delta.$$

Proof. Fix $\delta > 0$. By the definition of uniform integrability, there exists $\eta > 0$ such that for any $E \subseteq \mathbb{R}^2$, with $|E| < \eta$ and for any ε,

$$\int_E \omega_0^\varepsilon(\alpha)\,d\alpha < \delta.$$

Recall, from the proof of Theorem 1.5, that

$$|\Sigma(R_0, R, t)| = |\{\alpha \in B(0; R_0) \mid |X^\varepsilon(\alpha, t)| > R\}| \leq C \frac{t^2}{(R - R_0)^2},$$

where X^ε is the trajectory associated with the velocity field induced by ω^ε. Note from the proof of Theorem 1.5 that C does not depend on ε.

It is then possible to choose b_1 such that $|\Sigma(R_0, R_0 + b_1 t, t)| < \eta$. Next note that

$$\int_{|x| > R_0 + b_1 t} \omega^\varepsilon(x, t)\,dx = \int_{\Sigma(R_0, R_0 + b_1 t, t)} \omega_0^\varepsilon(\alpha)\,d\alpha < \delta.$$

The remainder of the argument follows precisely as in the proof of Proposition 2.3. □

Let $\omega_0 \in L^1_c(\mathbb{R}^2)$ be nonnegative. Consider any weak solution ω, obtained by mollifying the initial data ω_0, in such a way as to keep the support of the regularized vorticities inside $B(0;R_0)$. Such a weak solution was first shown to exist by Delort in [2]. Then Proposition 2.4 implies that, for any $\delta > 0$, there exists b such that $m_t((R_0^3 + bt)^{1/3}) < \delta$. Of course, Proposition 2.3 implies the same estimate for weak solutions obtained by regularizing initial vorticities in $L^p_c(\mathbb{R}^2)$. The subtle difference is that, for $1 < p \leq 2$, b depends on ω_0 through its L^p-norm. The dependence of b on ω_0 in the L^1 case is more delicate. (It depends on the modulus of continuity of ω_0, regarded as a measure.)

For ω_0 a nonnegative, compactly supported bounded measure in $H^1_{\text{loc}}(\mathbb{R}^2)$, we cannot prove a result of this nature for the approximate solution sequences obtained by mollifying ω_0. Theorem 2.2 remains valid in this situation, enabling the choice of b_2. However, we have no tools to choose b_1, i.e., to estimate the mass of vorticity outside $B(0;R)$, with R close to R_0. Proposition 2.4 cannot be used since, by the Dunford–Pettis theorem, regularizing ω_0 does not produce a uniformly integrable sequence. The best result we can obtain along these lines retains the asymptotic behavior as $t \to \infty$. It is a trivial consequence of Theorem 2.2 that, for every $\delta > 0$, there exists $b > 0$ such that

$$m_t(2R_0 + (bt)^{1/3}) < \delta.$$

In a sense, the results above, controlling the dispersion of the mass of vorticity, are unsatisfactory. We set out to study how much the fluid particles can get displaced by irregular fluid flow, and the control on the dispersion of the mass of vorticity, at first glance, does not give information in that respect. The next two results address this issue more precisely, demonstrating that the control on the dispersion of the mass of vorticity achieved so far, plus the techniques and results of the first section, do indeed control the dispersion of material domains in general. We cast the results in terms of the measure of the set of vorticity-bearing particles flung far from their initial positions by the flow, a very particular material domain, but this restriction is not essential. We prove two results: one showing precisely how the control on the dispersion of the mass of vorticity implies control on particle trajectories and the second one, giving a less precise, but more elegant description, in which we bring out explicitly the cubic parabola behavior of the dispersion discovered by Marchioro.

Theorem 2.5. *Let ω_0 be a nonnegative smooth function, with support contained in $B(0;R_0)$. Suppose that $\|\omega_0\|_{L^1(\mathbb{R}^2)} \leq K$. Then there exist $C_1 = C_1(K,R_0) > 0$ and $C_2 = C_2(K,R_0) > 0$ such that if $R > 2R_0$ and $0 < t < C_2R^3$, then*

$$|\text{supp }\omega(\cdot,t) \cap B(0;R)^c| \leq \frac{C_1 t R^3}{C_2R^3 - t} m_t(R/4).$$

Proof. Fix $R > 2R_0$ and $t > 0$. Let $\Sigma(R/2,R,t) \equiv \{\alpha \in B(0;R/2) \mid |X(\alpha,t)| > R\}$, which we abbreviate Σ_R. Then, $|\text{supp }\omega(\cdot,t) \cap B(0;R)^c| \leq |\Sigma_R|$.

We intend to estimate the velocity in the annulus $A_R \equiv \{R/2 < |x| < R\}$. We decompose the velocity $u = K * \omega(\cdot,s)$, for $0 \leq s \leq t$, into a near-field and a far-field velocity in the following way:

$$u^N(x,s) = \int_{|y|>R/4} K(x-y)\omega(y,s)dy; \quad u^F = u - u^N.$$

Consider the cylinder $\mathcal{C}$, defined by $\mathcal{C} \equiv \bigcup_{0\le s\le t} X(\Sigma_R, s)$. Next, observe that

$$\int_{\mathcal{C}} \chi_{A_R}(x)u^N(x,s)\cdot\frac{x}{|x|}dxds$$

$$= \int_{\mathcal{C}} \chi_{A_R}(x)u(x,s)\cdot\frac{x}{|x|}dxds - \int_{\mathcal{C}} \chi_{A_R}(x)u^F(x,s)\cdot\frac{x}{|x|}dxds$$

$$\geq (R - R/2)|\Sigma_R| - t|\Sigma_R| \sup_{(x,s)\in\mathcal{C}} \left| u^F(x,s)\cdot\frac{x}{|x|}\chi_{A_R}(x)\right|$$

$$\geq \frac{R}{2}|\Sigma_R| - t|\Sigma_R|\frac{C}{R^2} = \left(\frac{R}{2} - \frac{Ct}{R^2}\right)|\Sigma_R|,$$

where the latter inequality follows from the same reasoning as in (2.2)–(2.3), with $C = C(K, R_0)$, and the former inequality is a consequence of (1.1). On the other hand, using Hölder's inequality we have

$$\int_{\mathcal{C}} \chi_{A_R}(x)u^N(x,s)\cdot\frac{x}{|x|}dxds \leq t \sup_{0\le s\le t} \|u^N(\cdot,s)\|_{L^1(A_R)}$$

$$\leq \widetilde{C}t \sup_{0\le s\le t} \int_{|y|>R/4} \omega(y,s) \int_{A_R} \frac{1}{|x-y|}dxdy$$

$$\leq \widetilde{C}tRm_t(R/4),$$

since, due to the monotonicity of $1/r$, the integral of $|x|^{-1}$ on any set of measure $3\pi R^2/4$ is maximized by taking the integrating set to be the ball with this measure centered at 0, and hence it is bounded by $\sqrt{3}\pi R$. Taking $C_2 = (2C)^{-1}$, $C_1 = \widetilde{C}/C$, and assuming that $t < C_2R^3$ we obtain the desired conclusion. □

Proposition 2.6. *Let ω_0 be a nonnegative smooth function with support contained in $B(0;R_0)$. Suppose that $\|\omega_0\|_{L^1(\mathbb{R}^2)} \leq K$. Then for every $\delta > 0$, there exists $b = b(K, R_0, \delta) > 0$ such that for every $t > 0$*

$$|\text{supp } \omega(\cdot,t) \cap B(0;(R_0^3 + bt)^{1/3})^c| < \delta.$$

Proof. The proof follows the reasoning of the proofs of Propositions 2.3 and 2.4, but it is more intricate.

We begin by choosing $b_1 > 0$ such that for $0 \leq t \leq 1$

$$|\text{supp } \omega(\cdot,t) \cap B(0;R_0 + b_1t)^c| < \delta.$$

This is done using Theorem 1.5, with $T = 1$.

Next we choose $b_2 > 0$ such that for $t \geq 1$

$$|\text{supp } \omega(\cdot,t) \cap B(0;8R_0 + (b_2t)^{1/3})^c| < \delta.$$

This is accomplished using Theorems 2.5 and 2.2, as we shall describe below.

Denote $R(t) = 8R_0 + (b_2 t)^{1/3}$ for some b_2 to be determined.

First we choose b_2 large enough so as to guarantee that, for some $C_3 > 0$, we have $t < t + C_3 < C_2(R(t))^3$, where C_2 comes from Theorem 2.5. Next, we invoke the estimate on $m_t(R(t)/4)$, given by Theorem 2.2, together with Theorem 2.5. After a number of straightforward estimates, we observe it is enough to find b_2 large enough, so that

$$C_4 b_2 (1 + t^2) \left(\frac{C_5}{b_2} \right)^{C_6 (b_2 t)^{1/3}} < \delta$$

for certain constants C_4, C_5, and C_6. Then it is enough to note that if b_2 is large enough, the left-hand side of the inequality above is monotone decreasing as a function of t and its value at $t = 1$ converges to zero as $b_2 \to \infty$.

Finally, it is easy to see that we can choose b so that

$$\begin{aligned} R_0 + b_1 t &\leq (R_0^3 + bt)^{1/3}, && 0 \leq t \leq 1, \\ 8R_0 + (b_2 t)^{1/3} &\leq (R_0^3 + bt)^{1/3}, && 1 \leq t < \infty. \end{aligned}$$

This concludes the proof. □

3. Concluding remarks. We have proved several results concerning the amount of vorticity near infinity, arising from flow with compactly supported initial vorticity, explicitly formulated as uniform estimates on approximate solution sequences. Let us now consider a weak solution u of the incompressible 2D Euler equations, obtained as the weak limit of an approximate solution sequence u^ε. Let $\omega =$ curl u, $\omega^\varepsilon =$ curl u^ε. We restrict ourselves to approximate solution sequences obtained by mollifying the initial data and exactly solving the equations.

First we assume that $\omega_0 = \omega(\cdot, 0) \in L^p_c(\mathbb{R}^2)$, $1 \leq p \leq 2$. If $p = 1$, we have to assume in addition that $u_0 = u(\cdot, 0) \in L^2_{\text{loc}}(\mathbb{R}^2)$. The estimates obtained in Proposition 2.6 for nonnegative vorticities, in Corollary 1.4 for vorticities without sign restriction and $p > 1$, and in Theorem 1.5 if $p = 1$, which are all estimates on the size of the support of vorticity near infinity do not extend in any obvious way to the weak limit, because the measure of the support of an L^p function is not even weakly lower semicontinuous. These uniform estimates on the size of the support of vorticity imply estimates on the pth power integral of vorticity near infinity, which remain valid for the weak limit because the pth power integral is a weakly lower semicontinuous functional over L^p.

Let us be more precise. We will detail the argument in the case of a nonnegative initial vorticity $\omega_0 \in L^p_c(\mathbb{R}^2)$, $1 \leq p \leq 2$, supported in $B(0; R_0)$. We begin by observing that the mollified initial data ω_0^ε is uniformly pth power integrable, by the Dunford–Pettis theorem, since $|\omega_0^\varepsilon|^p$ converges strongly in L^1 to $|\omega_0|^p$. This means that, for every $\eta > 0$, there exists $\delta > 0$, independent of ε, such that

$$\int_E |\omega_0^\varepsilon|^p dx \leq \eta,$$

for any measurable set E with Lebesgue measure less than δ. Fix $\eta > 0$ and consider the corresponding δ. We use Proposition 2.6 to obtain $b > 0$, depending only on $\|\omega_0\|_{L^1}$, on R_0, and on δ such that

$$|\text{supp } \omega^\varepsilon(\cdot, t) \cap B(0; (R_0^3 + bt)^{1/3})^c| < \delta.$$

Hence, if E^ε is the backwards flow through u^ε of supp $\omega^\varepsilon(\cdot,t)\cap B(0;(R_0^3+bt)^{1/3})^c$, then

$$\int_{|x|>(R_0^3+bt)^{1/3}} |\omega^\varepsilon|^p(x,t)dx = \int_{E^\varepsilon} \omega_0^\varepsilon(x)dx \leq \eta,$$

since $|E^\varepsilon|<\delta$. Clearly, by the weak lower semicontinuity,

$$\int_{|x|>(R_0^3+bt)^{1/3}} |\omega|^p(x,t)dx \leq \eta.$$

Analogous results for vorticity without sign restrictions follow from Corollary 1.4 and Theorem 1.5 in the same manner.

For VSID, the only result obtained that extends, in the sense above, to an estimate on the weak limits is Theorem 2.2, again because the total variation of measures is weak-$*$ lower semicontinuous.

We have mentioned that there is no obvious way to pass the weak limit in the estimates on the size of the support of vorticity near infinity. We will show now that if $\omega_0\in L^p_c(\mathbb{R}^2)$, $1<p\leq 2$, then we can produce an estimate on the size of the support near infinity of any weak solution obtained as a weak limit of smooth approximants generated by mollifying initial data.

THEOREM 3.1. *Let $\omega_0\in L^p_c(\mathbb{R}^2)$, $1<p\leq 2$, and let u be a weak solution of the 2D Euler equations, obtained as the weak limit of an approximate solution sequence $\{u^\varepsilon\}$, obtained by mollifying the initial data. Let $\omega^\varepsilon=$ curl u^ε. Then, for almost every $t>0$ and every $R>0$*

$$|\text{supp }\omega(\cdot,t)\cap B(0;R)^c| \leq \limsup_{\varepsilon\to 0} |\text{supp }\omega^\varepsilon(\cdot,t)\cap B(0;R)^c|.$$

Proof. Fix $T>0$ and let $R_0>0$ be such that $B(0;R_0)$ contains the support of ω_0^ε for every ε.

We begin by observing that $\omega=\text{curl }u$ is the unique renormalized solution of the linear transport equation:

$$\begin{cases} f_t+u\cdot\nabla f=0, \\ f(x,0)=\omega_0, \end{cases} \tag{3.1}$$

as defined by DiPerna and Lions; see [3].

To see this, first note that the restriction to $p>1$ is needed to ensure that $u\in L^1([0,T];W^{1,1}_{\text{loc}}(\mathbb{R}^2))$. Of course, div $u=0$. We also have that

$$\frac{u}{1+|x|}\in L^1([0,T];L^2(\mathbb{R}^2))+L^1([0,T];L^\infty(\mathbb{R}^2)). \tag{3.2}$$

(See Remark 1.1 and Section 1.C of [4].) In order to show that ω is a renormalized solution of (3.1), we will make use of the uniqueness result, Theorem II.3, and the stability result, Theorem II.4, in [3]. Both of these results require u as above except that $u/(1+|x|)$ has to belong to $L^1([0,T];L^1(\mathbb{R}^2))+L^1([0,T];L^\infty(\mathbb{R}^2))$. However, it is easy to see that one can substitute this condition with (3.2) and still prove uniqueness and stability.

Next we check the hypothesis of the stability result. We know that ω is the weak-$*$ limit in $L^\infty([0,T];L^p(R^2))$ of the sequence $\{\omega^\varepsilon\}$, which is a smooth solution (and hence a renormalized solution) of (3.1) with u replaced by u^ε and ω_0 replaced by ω_0^ε. Additionally, the initial data ω_0^ε converge strongly to ω_0 in L^p. Therefore, by Theorem II.4 of [3], ω is the unique renormalized solution of (3.1).

Let X^ε be the Lagrangian map associated with the flow u^ε and X be the unique renormalized Lagrangian map associated with u, by Theorem III.2 of [3]. Then, by a time-dependent version of the stability of Lagrangian maps, Corollary III.1 in [3], we conclude that $X^\varepsilon \to X$ locally uniformly in time and locally in measure in space. Therefore, for every $\eta > 0$, there exists ε_0 independent of $t \in [0,T]$ such that for $\varepsilon < \varepsilon_0$,

$$|\{\alpha \in B(0;R_0) | |X^\varepsilon(\alpha,t) - X(\alpha,t)| > \eta\}| \leq \eta.$$

Fix $\eta > 0$ and choose $\varepsilon_0 = \varepsilon_0(\eta)$ as above. Let $R > 0$. Then, for any $\varepsilon < \varepsilon_0$, we have that

$$\begin{aligned} |\{\alpha \in B(0;R_0) | |X(\alpha,t)| > R\}| &\leq |\{\alpha \in B(0;R_0) | |X^\varepsilon(\alpha,t) - X(\alpha,t)| > \eta\}| \\ &\quad + |\{\alpha \in B(0;R_0) | |X^\varepsilon(\alpha,t)| > R-\eta\}| \\ &\leq \eta + |\{\alpha \in B(0;R_0) | |X^\varepsilon(\alpha,t)| > R-\eta\}| \\ \leq \eta + |\{\alpha \in B(0;R_0) | R-\eta < |X^\varepsilon(\alpha,t)| &\leq R\}| + |\{\alpha \in B(0;R_0) | |X^\varepsilon(\alpha,t)| > R\}| \\ &\leq \eta + (2\pi R\eta - \eta^2) + |\{\alpha \in B(0;R_0) | |X^\varepsilon(\alpha,t)| > R\}|, \end{aligned}$$

where the last inequality follows from the fact that X^ε is area-preserving. Therefore, taking $\limsup_{\eta\to 0}$, we have

$$|\{\alpha \in B(0;R_0) | |X(\alpha,t)| > R\}| \leq \limsup_{\varepsilon\to 0} |\{\alpha \in B(0;R_0) | |X^\varepsilon(\alpha,t)| > R\}|,$$

since we may assume that $\varepsilon_0(\eta) \to 0$ as $\eta \to 0$.

We conclude by observing that the renormalized Lagrangian map X is area-preserving and $\omega(X(\alpha,t),t) = \omega_0(\alpha)$ (see Theorem III.2 in [3]); hence

$$|\{\alpha \in B(0;R_0) | |X(\alpha,t)| > R\}| = |\text{supp } \omega(\cdot,t) \cap B(0;R)^c|. \qquad \square$$

Let u be a weak solution of the incompressible 2D Euler equations with vorticity $\omega = \text{curl } u \in L^\infty([0,T];L^p(\mathbb{R}^2))$, $p > 1$. It was mentioned in the proof of Theorem 4.1 in [8] that ω is the unique renormalized solution of the vorticity equation, regarded as a linear transport equation. We included an outline of the proof of this fact for the sake of completeness. Of course, given Theorem 3.1 above, the uniform estimates derived in Corollary 1.4 and in Proposition 2.6 remain valid for the weak solution, if the initial vorticity belongs to L^p_c, $p > 1$.

One natural question at this point is how close these estimates are to being optimal. In this respect, we do not have anything to add to the comments made by Marchioro in [10] and we refer the reader to the discussion contained there. We are left with no answer to the question we started with, i.e., whether the support of vorticity remains compact as time evolves. We can say only that the knowledge developed here does not appear to be enough to answer this question.

Finally, we note that since this article was first distributed in preprint form, a significant improvement of Marchioro's cubic-root estimate was obtained by Serfati; see [11]. A similar, if slightly weaker improvement was obtained independently by Iftimie and Sideris in [6]. By using the conservation of the center of vorticity, they observe that Marchioro's space-time cubic-root parabola can almost be improved to a fourth-root parabola. It would be possible to rewrite section 2 of our work reflecting these improvements, in a straightforward manner.

A NECESSARY AND SUFFICIENT CONDITION FOR PALAIS–SMALE CONDITIONS[*]

KUAN-JU CHEN[†] AND HWAI-CHIUAN WANG[†]

Abstract. In this paper we prove the following assertions: (1) $\alpha_I = \alpha_M = \alpha_\Gamma = \alpha_{\Gamma'}$; (2) let $\Omega_0 = \Omega_1 \cup \Omega_2$, where $\Omega_1 \cap \Omega_2$ is bounded, and let $\alpha_i = \alpha(\Omega_i)$ be the index of J in Ω_i for $i = 0, 1, 2$. J satisfies the $(PS)_{\alpha_0}$-condition if and only if the inequality $\alpha_0 < \min\{\alpha_1, \alpha_2\}$ holds; (3) the union of a solvable domain and an unsolvable domain may be solvable and the union of two unsolvable domains may be solvable.

Key words. Palais–Smale condition, solvable domain

1. Introduction.

The study of Esteban–Lions domains is the cornerstone and the starting point for understanding the existence of solutions of equations in unbounded domains. In this paper, we examine the existence of solutions in perturbed Esteban–Lions domains.

Let $N \geq 2$ and $2 < p < 2^*$, where $2^* = \frac{2N}{N-2}$ for $N \geq 3$, $2^* = \infty$ for $N = 2$. Consider the semilinear elliptic equation

$$\begin{cases} -\Delta u + u = |u|^{p-2}u \quad \text{in} \quad \Omega, \\ \quad u \in H_0^1(\Omega), \end{cases} \tag{1.1}$$

where Ω is a domain in $\boldsymbol{R}^N$ and $H_0^1(\Omega)$ is the Sobolev space in Ω. It is well known that (1.1) in a bounded domain or in the whole space $\boldsymbol{R}^N$ admits a positive solution, but the same equation in an Esteban–Lions domain does not admit any solution. The Esteban–Lions domain is defined as follows.

DEFINITION 1.1. *We say that a proper unbounded domain Ω in $\boldsymbol{R}^N$ is an Esteban–Lions domain if there is $\chi \in \boldsymbol{R}^N$, $||\chi|| = 1$ such that $n(x)\cdot\chi \geq 0$, $n(x)\cdot\chi \not\equiv 0$ on $\partial\Omega$, where $n(x)$ denotes the unit outward normal to $\partial\Omega$ at the point x.*

Let the potential operators $a : H_0^1(\Omega) \to \boldsymbol{R}$, $b : H_0^1(\Omega) \to \boldsymbol{R}$, and the energy functional $J : H_0^1(\Omega) \to \boldsymbol{R}$ be given by

$$a(u) = \int_\Omega \left(|\nabla u|^2 + u^2\right),$$
$$b(u) = \int_\Omega |u|^p,$$
$$J(u) = \frac{1}{2}a(u) - \frac{1}{p}b(u).$$

In the following definitions, we simply denote Palais–Smale by (PS).

DEFINITION 1.2.

(1) *For $\beta \in \boldsymbol{R}$, a sequence $\{u_n\} \subset H_0^1(\Omega)$ is a $(PS)_\beta$-sequence for J if $J(u_n) \to \beta$ and $J'(u_n) \to 0$ strongly as $n \to \infty$;*

[†] Department of Mathematics, National Tsing Hua University, Hsinchu, 300, Taiwan, Republic of China (d837201@math.nthu.edu.tw, hwang@math.nthu.edu.tw).

(2) *$\beta \in \boldsymbol{R}$ is a $(PS)_\beta$-value for J if there is a $(PS)_\beta$-sequence for J;*

(3) *J satisfies the $(PS)_\beta$-condition if every $(PS)_\beta$-sequence for J contains a convergent subsequence;*

(4) *J satisfies the (PS) condition if, for every $\beta \in \boldsymbol{R}$, every $(PS)_\beta$-sequence for J contains a convergent subsequence.*

Note that J is of class $C^{1,1}$ (see Rabinowitz [9, Proposition B.10]) and J clearly satisfies the mountain pass hypothesis: there are r, $\delta > 0$ and $e \in H_0^1(\Omega)$, such that $e \notin \overline{B(0,r)}$, $J(e) = 0$, $J(u) \geq \delta > 0$ for $u \in \partial B(0,r)$.

Let

$$\begin{aligned}
&I = \inf\{a(u) \mid b(u) = 1\};\\
&\alpha_I = (\tfrac{1}{2} - \tfrac{1}{p}) I^{p/(p-2)};\\
&\mathbf{M} = \left\{u \in H_0^1(\Omega) \backslash \{0\} \mid a(u) = b(u)\right\};\\
&\alpha_M = \inf_{v \in M} J(v);\\
&\Gamma = \left\{g \in C([0,1], H_0^1(\Omega)) \mid g(0) = 0, g(1) = e\right\}, \text{ where } J(e) = 0;\\
&\alpha_\Gamma = \inf_{g \in \Gamma} \max_{t \in [0,1]} J(g(t));\\
&\Gamma' = \left\{K \subset H_0^1(\Omega) \,|K \text{ is closed, connected, and } 0,\ e \in K\right\};\\
&\alpha_{\Gamma'} = \inf_{K \in \Gamma'} \max_{u \in K} J(u).
\end{aligned}$$

Next we assert the following theorem.

Theorem A. $\alpha_I = \alpha_M = \alpha_\Gamma = \alpha_{\Gamma'}$.

For convenience we state the following definition.

Definition 1.3.

(1) *We say that $\alpha(\Omega) = \alpha_I$ is the index of the energy functional J in Ω;*

(2) *We say that a solution u of equation* (1.1) *is a ground state solution if $J(u) = \alpha(\Omega)$, and is a higher energy solution if $J(u) > \alpha(\Omega)$.*

Remark 1.

(1) *If the Nehari minimization problem α_M or the minimax problem α_Γ admits a solution u, then u must be a ground state solution. If J satisfies the $(PS)_{\alpha(\Omega)}$-condition, then the Nehari minimization problem α_M and the minimax problem α_Γ admit a ground state solution.*

(2) *Applying Theorem* A, *we prove that α_Γ is independent of the choice of e.*

(3) *Rabinowitz* [9, *p.* 19] *asked whether $\alpha_\Gamma = \alpha_{\Gamma'}$. We answer his question for our special energy functional J.*

(4) *Theorem* A *simplifies many calculations.*

Let $\Omega_0 = \Omega_1 \cup \Omega_2$, where $\Omega_1 \cap \Omega_2$ is bounded,

$$\mathbf{M}_i = \left\{u \in H_0^1(\Omega_i) \backslash \{0\} \mid a(u) = b(u)\right\},$$

and $\alpha_i = \alpha(\Omega_i)$ be the index of J in Ω_i for $i = 0, 1, 2$.

In this article, we will study the existence of positive solutions of (1.1) in a proper unbounded domain Ω. In fact, we give a necessary and sufficient condition in Ω, in which J satisfies the $(\mathrm{PS})_{\alpha(\Omega)}$-condition as follows.

Theorem B. *J satisfies the $(PS)_{\alpha_0}$-condition if and only if the inequality $\alpha_0 < \min\{\alpha_1, \alpha_2\}$ holds. In particular, if the inequality $\alpha_0 < \min\{\alpha_1, \alpha_2\}$ holds, then there is a solution u_0 of* (1.1) *in Ω_0.*

In section 4, Theorem B is applied to prove that the union of a solvable domain and an unsolvable domain may be solvable. We also assert that the union of two unsolvable domains may be solvable. Here we need another definition.

DEFINITION 1.4. *We say that Ω is solvable if there exists a positive solution of* (1.1) *in Ω; otherwise, Ω is unsolvable.*

2. Palais–Smale values. In this section, we study the set of all $(\mathrm{PS})_\beta$-values for J.

Let $\{u_n\} \subset H_0^1(\Omega)$ be a $(\mathrm{PS})_\beta$-sequence for J; then clearly $\beta \geq 0$ and $\{u_n\}$ is bounded in $H_0^1(\Omega)$. Let $\mathbf{F}$ be the set of all $(\mathrm{PS})_\beta$-values for J, where $\beta > 0$.

Moreover, the three important numbers α_I, α_M, and α_Γ are in $\mathbf{F}$.

LEMMA 2.1. *α_I, α_M, and α_Γ are (PS)-values for J.*

Proof. Lien–Tzeng–Wang [7] proved that α_I is a $(\mathrm{PS})_{\alpha_I}$-value for J. Using two different methods, the Ekeland variational principle and the deformation lemma, Brezis–Nirenberg [2] prove that α_Γ is a $(\mathrm{PS})_{\alpha_\Gamma}$-value for J.

Using the Ekeland variational principle, Stuart [11, Lemma 3.4] asserted that there is a $(\mathrm{PS})_{\alpha_M}$-sequence as well as a minimizing sequence for α_M in $H_0^1(\Omega)$. We generalize his result and prove that every minimizing sequence for α_M is a $(\mathrm{PS})_{\alpha_M}$-sequence for J as follows.

Let $\{u_n\} \subset \mathbf{M}$ be a minimizing sequence for $J : a(u_n) = b(u_n)$ for all $n = 1, 2, 3, \ldots$ and $J(u_n) = (\frac{1}{2} - \frac{1}{p})a(u_n) = \alpha_M + o(1)$ as $n \to \infty$. Then

$$a(u_n) = \frac{2p}{p-2}\alpha_M + o(1) \text{ as } n \to \infty. \tag{2.1}$$

For $n = 1, 2, \ldots$, denote

$$f_n(\varphi) = \int_\Omega |u_n|^{p-2} u_n \varphi, \quad \varphi \in H_0^1(\Omega).$$

Let $\phi \in H_0^1(\Omega)$ and $||\phi||_{H^1} = 1$; there exists $s > 0$ such that $||s\phi||_{H^1}^2 = ||s\phi||_p^p$. We conclude that $s = ||\phi||_p^{\frac{-p}{p-2}}$ and

$$\alpha_M \leq \left(\frac{1}{2} - \frac{1}{p}\right) ||s\phi||_{H^1}^2 = \frac{p-2}{2p} s^2 = \frac{p-2}{2p} ||\phi||_p^{\frac{-2p}{p-2}}.$$

Therefore $||\phi||_p \leq (\frac{2p}{p-2}\alpha_M)^{\frac{2-p}{2p}}$ and

$$\begin{aligned} |f_n(\phi)| &= \left| \int_\Omega |u_n|^{p-2} u_n \phi \right| \leq \left(\int_\Omega |u_n|^p \right)^{\frac{p-1}{p}} \left(\int_\Omega |\phi|^p \right)^{\frac{1}{p}} \\ &\leq \left(\frac{2p}{p-2}\alpha_M \right)^{\frac{p-1}{p}} \left(\frac{2p}{p-2}\alpha_M \right)^{\frac{2-p}{2p}} + o(1) = \left(\frac{2p}{p-2}\alpha_M \right)^{\frac{1}{2}} + o(1) \text{ as } n \to \infty. \end{aligned}$$

We have

$$||f_n||_{H^{-1}} \leq \left(\frac{2p}{p-2}\alpha_M \right)^{\frac{1}{2}} + o(1) \text{ as } n \to \infty. \tag{2.2}$$

Furthermore,

$$f_n\left(\frac{u_n}{\|u_n\|_{H^1}} \right) = \frac{b(u_n)}{a(u_n)^{1/2}} = b(u_n)^{1/2} = \left(\frac{2p}{p-2}\alpha_M \right)^{\frac{1}{2}} + o(1) \text{ as } n \to \infty. \tag{2.3}$$

By (2.2) and (2.3) we conclude that

$$\|f_n\|_{H^{-1}} = \left(\frac{2p}{p-2}\alpha_M\right)^{\frac{1}{2}} + o(1) \text{ as } n \to \infty. \tag{2.4}$$

By the Riesz representation theorem, for each n there is $w_n \in H_0^1(\Omega)$ such that, for each $\varphi \in H_0^1(\Omega)$,

$$f_n(\varphi) = \langle w_n, \varphi\rangle = \int_\Omega (\nabla w_n \cdot \nabla\varphi + w_n\varphi),$$

$$||w_n||_{H^1} = ||f_n||_{H^{-1}} = \left(\frac{2p}{p-2}\alpha_M\right)^{\frac{1}{2}} + o(1) \text{ as } n \to \infty. \tag{2.5}$$

We conclude that

$$\langle w_n, u_n\rangle = f_n(u_n) = \int_\Omega |u_n|^p = \frac{2p}{p-2}\alpha_M + o(1) \text{ as } n \to \infty. \tag{2.6}$$

By (2.1), (2.5), and (2.6) we obtain

$$\begin{aligned} \|u_n - w_n\|_{H^1}^2 &= \|u_n\|_{H^1}^2 - 2\langle u_n, w_n\rangle + \|w_n\|_{H^1}^2 \\ &= \frac{2p}{p-2}\alpha_M - 2\frac{2p}{p-2}\alpha_M + \frac{2p}{p-2}\alpha_M + o(1) \\ &= o(1) \text{ as } n \to \infty. \end{aligned}$$

For $\varphi \in H_0^1(\Omega)$, $||\varphi||_{H^1} = 1$, we have

$$\begin{aligned} \langle J'(u_n), \varphi\rangle &= \int_\Omega (\nabla u_n \cdot \nabla\varphi + u_n\varphi) - \int_\Omega |u_n|^{p-2}u_n\varphi \\ &= \langle u_n, \varphi\rangle - \langle w_n, \varphi\rangle = \langle u_n - w_n, \varphi\rangle, \end{aligned}$$

so

$$|\langle J'(u_n), \varphi\rangle| \le ||u_n - w_n||_{H^1}.$$

We conclude that

$$J'(u_n) = o(1) \text{ strongly in } H^{-1}(\Omega) \text{ as } n \to \infty. \qquad \square$$

In order to study the number β in $\mathbf{F}$, we study the Nehari manifold $\mathbf{M}$ through the unit sphere $\mathbf{S}$ and the zero energy manifold $\mathbf{Z}$ defined by

$$\begin{aligned} &\mathbf{S} = \left\{u \in H_0^1(\Omega) \,|\, \|u\|_{H^1} = 1\right\}, \\ &\mathbf{Z} = \left\{u \in H_0^1(\Omega) \setminus \{0\} \,\middle|\, \tfrac{1}{2}a(u) = \tfrac{1}{p}b(u)\right\}. \end{aligned}$$

Note that $\mathbf{M}$ contains every solution of (1.1). We claim that $\mathbf{M}$ and $\mathbf{Z}$ are $C^{1,1}$ isomorphic to the unit sphere $\mathbf{S}$. In fact, for $\lambda \ge 0$, $u \in \mathbf{S}$, let

$$h_u(\lambda) = J(\lambda u) = \frac{1}{2}\lambda^2 a(u) - \frac{1}{p}\lambda^p b(u).$$

Then

$$\begin{cases} h_u'(\lambda) = \lambda a(u) - \lambda^{p-1} b(u), \\ h_u''(\lambda) = a(u) - (p-1)\lambda^{p-2} b(u). \end{cases}$$

From these properties we can take uniquely r_u, s_u, and $t_u \in \boldsymbol{R}_+$ such that $0 < r_u < s_u < t_u$, $s_u u \in \mathbf{M}$, $t_u u \in \mathbf{Z}$, and

$$0 = h_u''(r_u) = h_u'(s_u) = h_u(t_u).$$

Let $m : \mathbf{S} \to \mathbf{M}$ and $z : \mathbf{S} \to \mathbf{Z}$ be given by $m(u) = s_u u$ and $z(u) = t_u u$. We apply the implicit function theorem and the Sobolev imbedding theorem to obtain the following.

Lemma 2.2.

(1) *m is bijective and of $C^{1,1}$. Moreover $\mathbf{M}$ is path-connected and there exists a constant $c > 0$ such that, for $u \in \mathbf{M}$, $||u||_{H^1} \geq c$ and $J(u) \geq c$;*

(2) *z is bijective and of $C^{1,1}$. Moreover $\mathbf{Z}$ is path-connected and there exists a constant $c' > 0$ such that, for $u \in \mathbf{Z}$, $||u||_{H^1} \geq c'$.*

In the following two lemmas, we assert that every number $\beta > 0$ in $\mathbf{F}$ admits several interesting properties.

Lemma 2.3. *Let $\{u_n\} \subset H_0^1(\Omega)$ be a $(PS)_\beta$-sequence for J with $\beta > 0$. Then there is a sequence $\{s_n\}$ in $\boldsymbol{R}_+$ such that $\{s_n u_n\} \subset \mathbf{M}$ and $J(s_n u_n) = \beta + o(1)$ as $n \to \infty$.*

Proof. By Lemma 2.2(1), there is a sequence $\{s_n\}$ in $\boldsymbol{R}_+$ such that $\{s_n u_n\} \subset \mathbf{M}$ and $h_n'(s_n) = 0$ for each n. Thus $s_n a(u_n) = s_n^{p-1} b(u_n)$ for each n. That $a(u_n) = b(u_n)+o(1)$ as $n \to \infty$ implies $s_n = 1+o(1)$ as $n \to \infty$. Therefore $|J(u_n) - J(s_n u_n)| = o(1)$ as $n \to \infty$, or $J(s_n u_n) = \beta + o(1)$ as $n \to \infty$. □

Lemma 2.4. *Let β be in* $\mathbf{F}$. *Then* (1) *$\beta \geq \alpha_I$;* (2) *$\beta \geq \alpha_M$;* (3) *$\beta \geq \alpha_\Gamma$.*

Proof. Let $\{u_n\} \subset H_0^1(\Omega)$ be a $(PS)_\beta$-sequence for J with $\beta > 0$: that is,

$$\begin{cases} \frac{1}{2} a(u_n) - \frac{1}{p} b(u_n) = \beta + o(1) \text{ as } n \to \infty, \\ a(u_n) - b(u_n) = o(1) \text{ as } n \to \infty. \end{cases}$$

Then $\{u_n\}$ is bounded in $H_0^1(\Omega)$ and $(\frac{1}{2} - \frac{1}{p}) a(u_n) = \beta + o(1)$ as $n \to \infty$.

(1) Let $w_n = u_n (b(u_n))^{-1/p}$, then $b(w_n) = 1$ and $a(w_n) = a(u_n) b(u_n)^{-2/p} \geq I$. Thus $a(u_n) \geq I^{p/(p-2)} + o(1)$ as $n \to \infty$, or $\beta \geq (\frac{1}{2} - \frac{1}{p}) I^{p/(p-2)} = \alpha_I$.

(2) By Lemma 2.3, there is a sequence $\{s_n\}$ in $\boldsymbol{R}_+$ such that $\{s_n u_n\} \subset \mathbf{M}$ and $J(s_n u_n) = \beta + o(1)$ as $n \to \infty$. Therefore $\beta \geq \alpha_M$.

(3) By Lemma 2.3, there is a sequence $\{s_n\}$ in $\boldsymbol{R}_+$ such that $\{s_n u_n\} \subset \mathbf{M}$ and $J(s_n u_n) = \beta + o(1)$ as $n \to \infty$. By Lemma 2.2 (2) there is a sequence $\{t_n\}$ in $\boldsymbol{R}_+$ such that $\{t_n u_n\}$ in $\mathbf{Z}$. Since the manifold $\mathbf{Z}$ is path-connected, there is a path η_n in $\mathbf{Z}$ which connects $t_n u_n$ to e. Let γ_n' be the line segment connecting 0 and $t_n u_n$ and the path $\gamma_n = \gamma_n' \cup \eta_n$. We obtain

$$\alpha_\Gamma \leq \max_{0 \leq t \leq 1} J(\gamma_n(t)) = J(s_n u_n) = \beta + o(1) \text{ as } n \to \infty.$$

Thus $\beta \geq \alpha_\Gamma$. □

By Lemmas 2.1 and 2.4, we have the following theorem.

Theorem 2.5. $\alpha_I = \alpha_M = \alpha_\Gamma$.

Theorem 2.5 has the following two corollaries.

Corollary 2.6. *The minimax number α_Γ is independent of the choice of $e \in \mathbf{Z}$.*

Corollary 2.7. $\alpha_{\Gamma} = \alpha_{\Gamma'}$.

Proof. Since $\Gamma \subset \Gamma'$, we have $\alpha_{\Gamma} \geq \alpha_{\Gamma'}$.

We claim that $K \cap \mathbf{M} \neq \emptyset$ for each $K \in \Gamma'$. If not, let $K \in \Gamma'$ satisfying $K \cap \mathbf{M} = \emptyset$. Let $K_1 = \{u \in K \backslash \{0\} \mid u \in (0, s_u u)\} \cup \{0\}$ and $K_2 = \{u \in K \mid u \in (s_u u, \infty)\}$. Then K_1 and K_2 are nonempty and relatively closed in K, $K_1 \cap K_2 = \emptyset$ and $K_1 \cup K_2 = K$. This contradicts that K is connected.

Assume that $\alpha_{\Gamma} > \alpha_{\Gamma'}$. By Theorem 2.5, $\alpha(\Omega) = \alpha_{\Gamma}$, there exists $K \in \Gamma'$ such that

$$\max_{u \in K} J(u) < \inf_{u \in \mathbf{M}} J(u).$$

Let $u_0 \in K \cap \mathbf{M}$; then we have

$$J(u_0) \leq \max_{u \in K} J(u) < \inf_{u \in \mathbf{M}} J(u) \leq J(u_0),$$

a contradiction. Therefore $\alpha_{\Gamma} = \alpha_{\Gamma'}$. □

We conclude that the numbers α_I, α_M, α_{Γ}, and $\alpha_{\Gamma'}$ are the same and call any one of them the index $\alpha(\Omega)$ of J in Ω. Thus $\alpha(\Omega) \in \mathbf{F}$ and $\mathbf{F} \subset [\alpha(\Omega), \infty)$. In order to understand more about the index $\alpha(\Omega)$, we give the following definition.

Definition 2.8. *Let $\Omega_1 \subset \Omega_2$ be two unbounded domains in $\boldsymbol{R}^N$. We say Ω_2 is a translation-union domain of Ω_1 if there are, for $i = 1, 2, \ldots, l$, $\tau_i \in \boldsymbol{R}^N$ with $\|\tau_i\| = 1$, and sequences $\{r_n^i\}$ of positive numbers, with $r_n^i \to \infty$ as $n \to \infty$ such that*

$$\Omega_2 = \cup_{i=1}^{l} \cup_{n=1}^{\infty} (\Omega_1 + r_n^i \tau_i).$$

Example 2.9.

(1) *Let $\Omega \subset \boldsymbol{R}^N$ be a ball-up domain: that is to say, that for any $r > 0$ there exists $x \in \Omega$ such that $B(x; r) \subset \Omega$. Then $\boldsymbol{R}^N$ is a translation-union domain of Ω.*

(2) *Given $r > 0$, $s \in \boldsymbol{R}$, let*

$$\begin{aligned}
&A^r = \{(x_1, x_2, \ldots, x_N) \in \boldsymbol{R}^N \mid x_1^2 + \cdots + x_{N-1}^2 < r^2\};\\
&A_s^r = \{(x_1, x_2, \ldots, x_N) \in \boldsymbol{R}^N \mid x_1^2 + \cdots + x_{N-1}^2 < r^2, x_N > s\};\\
&A^r \backslash \omega, \text{ where } \omega \subset A^r \text{ is a bounded domain;}\\
&D^r = \{(x_1, x_2, \ldots, x_N) \in \boldsymbol{R}^N \mid x_2^2 + \cdots + x_N^2 < r^2\};\\
&D_s^r = \{(x_1, x_2, \ldots, x_N) \in \boldsymbol{R}^N \mid x_2^2 + \cdots + x_N^2 < r^2, x_1 > s\};\\
&D^r \backslash \omega, \text{ where } \omega \subset D^r \text{ is a bounded domain.}
\end{aligned}$$

Then A^r is a translation-union domain of A_s^r and of $A^r \backslash \omega$; D^r is a translation-union domain of D_s^r and of $D^r \backslash \omega$; and $A^r \cup D^r$ is a translation-union domain of $A_s^r \cup D_s^r$ and of $(A^r \backslash \omega) \cup (D^r \backslash \omega)$.

We have the following important properties.

Proposition 2.10.

(1) *Let $\Omega_1 \subsetneq \Omega_2$ and $J : H_0^1(\Omega_2) \to \boldsymbol{R}$ the energy functional. If J satisfies the $(PS)_{\alpha_1}$-condition or in particular α_1 is a critical value, then $\alpha_2 < \alpha_1$.*

(2) *Let Ω_2 be a translation-union domain of Ω_1. Then $\alpha(\Omega_1) = \alpha(\Omega_2)$, J does not satisfy the $(PS)_{\alpha_1}$-condition, and the only possible solutions of* (1.1) *in Ω_1 are higher energy solutions.*

Proof.

(1) $\Omega_1 \subset \Omega_2$, so $\alpha_2 \leq \alpha_1$. Suppose that J satisfies the $(\mathrm{PS})_{\alpha_1}$-condition; then there exists $u_0 \in \mathbf{M}_1$ such that $u_0 \geq 0$ and $J(u_0) = \alpha_1$. To the contrary, assume $\alpha_2 = \alpha_1$; then $J(u_0) = \alpha_2 = \inf_{u \in \mathbf{M}_2} J(u)$. It is known that every minimizer of the problem $\alpha_2 = \inf_{u \in \mathbf{M}_2} J(u)$ is a critical point of J. Therefore u_0 solves (1.1) in Ω_2. By the maximum principle, $u_0 > 0$ in Ω_2. This contradicts $u_0 \in H_0^1(\Omega_1)$. Therefore $\alpha_2 < \alpha_1$.

(2) $\Omega_1 \subset \Omega_2$, so $\alpha_2 \leq \alpha_1$. Let $\{u_n\} \subset H_0^1(\Omega_2)$ be a minimizing sequence of α_2 :

$$\begin{aligned} J(u_n) &= \alpha_2 + o(1) \text{ as } n \to \infty, \\ a(u_n) &= b(u_n) \text{ for } n = 1, 2, \ldots. \end{aligned}$$

By the definition of translation-union domain, $\Omega_2 = \cup_{i=1}^{l} \cup_{n=1}^{\infty} (\Omega_1 + r_n^i \tau_i)$, it suffices to prove the case $l = 1$. Let $F^n \subset \Omega_1 + r_n \tau$ be a bounded domain, $F^n \nearrow \Omega_2$ as $n \to \infty$ and O_n a bounded and open set in Ω_1 satisfying $F^n - r_n\tau \subset\subset O_n$. Define

$$v_n(x) = \begin{cases} u_n(x + r_n\tau) & \text{if } x \in F^n - r_n\tau, \\ 0 & \text{if } x \notin O_n. \end{cases}$$

Then

$$\begin{aligned} &v_n(x) \in H_0^1(\Omega_1), \\ &a(u_n) = a(v_n) + o(1) \text{ as } n \to \infty, \\ &b(u_n) = b(v_n) + o(1) \text{ as } n \to \infty. \end{aligned}$$

By Lemma 2.2(1), there exists $s_n > 0$ such that $a(s_n v_n) = b(s_n v_n)$, or $s_n = 1 + o(1)$ as $n \to \infty$. $J(s_n v_n) = (\frac{1}{2} - \frac{1}{p}) a(s_n v_n) = (\frac{1}{2} - \frac{1}{p}) s_n^2 a(v_n) = \alpha_2 + o(1)$ as $n \to \infty$. Therefore $\alpha_1 \leq \alpha_2$. We conclude that $\alpha_1 = \alpha_2$. Then we apply the first part to conclude that J does not satisfy the $(\mathrm{PS})_{\alpha_1}$-condition. As in the first part, if u is a ground state solution of (1.1) in Ω_1, then by the maximum principle, u is a positive solution in Ω_2. This contradicts $u \in H_0^1(\Omega_1)$. Therefore the only possible solutions of (1.1) in Ω_1 are higher energy solutions. □

There are some relative properties.

Lemma 2.11.

(1) *There is a ground state solution of* (1.1) *in the infinite strip A^r;*

(2) *Let $\Omega = A^r \backslash \omega$, where $\omega \subset A^r$ is a bounded domain. Then the only possible positive solutions of* (1.1) *in Ω are higher energy solutions;*

(3) *Let $\Omega = A^r \backslash \omega$, where $\omega \subset A^r$ is small and regular. Then there is a positive solution u of* (1.1) *in Ω;*

(4) *There is a $(PS)_\beta$-value β for J such that $\beta > \alpha(\Omega)$.*

Proof.

(1) See Lien–Tzeng–Wang [7, Example 4.3] for the proof.

(2) The proof is by Proposition 2.9(2).

(3) See Hsu–Wang [5, p. 1002] for the proof.

(4) Let u and Ω be as in (3). Set $\beta = J(u)$ and $u_n = u$ for each n to conclude the proof. □

To get further information on the distributions of $\mathbf{F}$, we need the following two important results.

Proposition 2.12. *The only positive solutions of* (1.1) *in $\boldsymbol{R}^N$ are ground state solutions. Moreover the infimum $\alpha(\boldsymbol{R}^N)$ is achieved by a unique positive regular* *ground state solution* $\bar{u} \in H^1(\boldsymbol{R}^N)$ *of* (1.1) *such that* $\bar{u}$ *is spherically symmetric about some point* x_0 *in* $\boldsymbol{R}^N$, $\bar{u}'(r) < 0$ *for* $r = |x - x_0|$, *and*

$$\lim_{r\to\infty} r^{\frac{N-1}{2}} e^r \bar{u}(r) = \gamma > 0,$$
$$\lim_{r\to\infty} r^{\frac{N-1}{2}} e^r \bar{u}'(r) = -\gamma.$$

Proof. See Gidas–Ni–Nirenberg [4] and Kwong [6]. □

LEMMA 2.13 (decomposition lemma). *Let* $\{u_n\} \subset H_0^1(\Omega)$ *be a* $(PS)_\beta$*-sequence for* J. *Then there is a subsequence* $\{u_n\}$, *integer* $l \geq 0$, l *sequences* $\{x_n^i\}_{n=1}^\infty$ *in* $\boldsymbol{R}^N$, $i = 1, \ldots, l$, *function* $\tilde{u}$, *and* w_i *for* $1 \leq i \leq l$ *such that*

$$\begin{aligned}
&-\triangle\tilde{u} + \tilde{u} = |\tilde{u}|^{p-2}\tilde{u} \text{ in } \Omega, \quad \tilde{u} \in H_0^1(\Omega),\\
&-\triangle w_i + w_i = |w_i|^{p-2} w_i \text{ in } \boldsymbol{R}^N, \quad w_i \in H^1(\boldsymbol{R}^N),\\
&u_n = \tilde{u} + \textstyle\sum_{i=1}^l w_i(\cdot - x_n^i) + \mathrm{o}(1) \text{ strongly in } H^1(\boldsymbol{R}^N) \text{ as } n \to \infty,\\
&J(u_n) = J(\tilde{u}) + \textstyle\sum_{i=1}^l J^\infty(w_i) + \mathrm{o}(1) \text{ as } n \to \infty,\\
&|x_n^i| \to \infty, \quad |x_n^i - x_n^j| \to \infty \quad \text{for} \quad 1 \leq i \neq j \leq l, \text{ as } n \to \infty
\end{aligned}$$

where $J^\infty(u) = \frac{1}{2}\int_{\boldsymbol{R}^N}(|\nabla u|^2 + u^2) - \frac{1}{p}\int_{\boldsymbol{R}^N}|u|^p$ *for* $u \in H^1(\boldsymbol{R}^N)$. *In addition, if* $u_n \geq 0$, *then* $\tilde{u} \geq 0$, $w_i > 0$ *for all* $1 \leq i \leq m$, *and each* w_i *can be chosen to be the unique solution* $\overline{u}$ *in Proposition* 2.11.

Proof. See Lions [8], Struwe [10, p. 169], and Lien–Tzeng–Wang [7, Theorem 4.1] for the proof. □

Now we apply Proposition 2.11 and Lemma 2.12 to get the following.

PROPOSITION 2.14. *If* $\beta \in \mathbf{F}$, *then* $\beta = J(u) + m\alpha(\boldsymbol{R}^N)$, *where* u *is a solution of* (1.1) *in* Ω *and* $m = 0, 1, 2, \ldots$.

3. Palais–Smale conditions. In this section, in terms of the index $\alpha(\Omega)$, we give a necessary and sufficient condition for the energy functional J to satisfy the $(\mathrm{PS})_{\alpha(\Omega)}$-condition.

Let $\Omega_0 = \Omega_1 \cup \Omega_2$, where $\Omega_1 \cap \Omega_2$ is bounded, and $\alpha_i = \alpha(\Omega_i)$ be the index of J in Ω_i for $i = 0, 1, 2$. Since $H_0^1(\Omega_i) \subset H_0^1(\Omega_0)$ and $\mathbf{M}_i \subset \mathbf{M}_0$ for $i = 1, 2$, we have $\alpha_0 \leq \min\{\alpha_1, \alpha_2\}$, and the following theorem.

THEOREM 3.1. *The energy functional* J *satisfies the* $(PS)_{\alpha_0}$*-condition if and only if the inequality* $\alpha_0 < \min\{\alpha_1, \alpha_2\}$ *holds. In particular, if the inequality* $\alpha_0 < \min\{\alpha_1, \alpha_2\}$ *holds, then there is a ground state solution* u_0 *of* (1.1) *in* Ω_0.

Proof. The sufficient condition is proven as follows: Suppose that $\alpha_0 < \min\{\alpha_1, \alpha_2\}$. Let $\{u_n\} \subset H_0^1(\Omega_0)$ such that

$$\begin{aligned}
J(u_n) &= \alpha_0 + \mathrm{o}(1) \text{ as } n \to \infty,\\
J'(u_n) &= \mathrm{o}(1) \text{ as } n \to \infty.
\end{aligned}$$

Then

$$\begin{aligned}
\mathrm{o}(1) &= \langle J'(u_n), u_n\rangle = a(u_n) - b(u_n) \text{ as } n \to \infty,\\
\alpha_0 + \mathrm{o}(1) &= J(u_n) = \left(\frac{1}{2} - \frac{1}{p}\right) a(u_n) + \mathrm{o}(1) \text{ as } n \to \infty.
\end{aligned}$$

Thus we have

$$a(u_n) = b(u_n) + o(1) = \frac{2p}{p-2}\alpha_0 + o(1) \text{ as } n \to \infty.$$

We claim that for each subsequence of $\{u_n\}$ still denoted by $\{u_n\}$, there are $r > 0$, $b > 0$ such that for $Q_r = \Omega_0 \cap B(0, r)$,

$$\int_{Q_r} |u_n|^p \geq b. \tag{3.1}$$

If not, there are $\{r_n\}$, $r_n \to \infty$ and a subsequence $\{u_n\}$ such that for $Q_n = \Omega_0 \cap B(0, r_n)$,

$$\int_{Q_n} |u_n|^p = \mathrm{o}(1) \text{ as } n \to \infty. \tag{3.2}$$

Let $\xi \in C_c^\infty([0, \infty))$ such that

$$0 \leq \xi \leq 1, \quad \xi(t) = \begin{cases} 0 & \text{for } t \in [0, 1], \\ 1 & \text{for } t \in [2, \infty). \end{cases}$$

Let $\xi_n(x) = \xi(\frac{2|x|}{r_n})$ and $w_n = \xi_n^2 u_n$. Since $\{w_n\}$ is bounded in $H_0^1(\Omega_0)$,

$$\begin{aligned} o(1) &= \langle J'(u_n), w_n \rangle \\ &= \int_{\Omega_0} (\xi_n^2 |\nabla u_n|^2 + 2\xi_n u_n \nabla \xi_n \cdot \nabla u_n + \xi_n^2 u_n^2) - \int_{\Omega_0} \xi_n^2 |u_n|^p \text{ as } n \to \infty. \end{aligned}$$

Note that $|\nabla \xi_n(x)| \leq \frac{c}{r_n}$ and (3.2), so

$$\int_{\Omega_0} \xi_n u_n \nabla \xi_n \cdot \nabla u_n = \mathrm{o}(1) \text{ as n} \to \infty,$$

and

$$\int_{\Omega_0} \xi_n^q |u_n|^p = \int_{\Omega_0} |u_n|^p + \mathrm{o}(1) = \frac{2p}{p-2}\alpha_0 + o(1) \text{ as } n \to \infty \text{ for } q > 0. \tag{3.3}$$

We conclude that

$$\int_{\Omega_0} \xi_n^2 (|\nabla u_n|^2 + u_n^2) = \mathrm{o}(1) \text{ as } n \to \infty. \tag{3.4}$$

Let $v_n = \xi_n u_n$. By (3.3) and (3.4),

$$\begin{aligned} J(v_n) &= \frac{1}{2} \int_{\Omega_0} (|\nabla v_n|^2 + v_n^2) - \frac{1}{p} \int_{\Omega_0} |v_n|^p \\ &= \frac{1}{2} \int_{\Omega_0} (|\nabla \xi_n|^2 u_n^2 + \xi_n^2 (|\nabla u_n|^2 + u_n^2) - 2\xi_n u_n \nabla \xi_n \cdot \nabla u_n) \\ &\quad - \frac{1}{p} \int_{\Omega_0} {\xi_n}^p |u_n|^p \\ &= \frac{1}{2} \frac{2p}{p-2}\alpha_0 - \frac{1}{p} \frac{2p}{p-2}\alpha_0 + o(1) \\ &= \alpha_0 + o(1) \text{ as } n \to \infty. \end{aligned}$$

As in the same line of the proof of Lemma 2.1, because $\alpha_0 = \alpha_M$, we have $J'(v_n) = \mathrm{o}(1)$ as $n \to \infty$. Since $\Omega_1 \cap \Omega_2$ is bounded for large n, $v_n = 0$ in $\overline{\Omega_1 \cap \Omega_2}$ and $v_n = v_n^1 + v_n^2$, where $v_n^i \in H_0^1(\Omega_i)$, $i = 1, 2$,

$$v_n^i(x) = \begin{cases} v_n(x) & \text{if } x \in \Omega_i \\ 0 & \text{otherwise} \end{cases} \quad \text{for } i = 1, 2.$$

We obtain

$$J'(v_n^i) = \mathrm{o}(1) \text{ as } n \to \infty \quad \text{for } i = 1, 2.$$

Assume

$$J(v_n^i) = c_i + \mathrm{o}(1) \text{ as } n \to \infty \quad \text{for } i = 1, 2,$$

$$J'(v_n^i) = \mathrm{o}(1) \text{ as } n \to \infty \quad \text{for } i = 1, 2,$$

where $c_1 + c_2 = \alpha_0$. Since c_1 and c_2 are (PS)-values, they are nonnegative. At least one of c_1, c_2 is positive, say $c_1 > 0$. By Lemma 2.4, $c_1 \geq \alpha_1$; thus $\alpha_0 \geq c_1 \geq \alpha_1$. This contradicts $\alpha_0 < \min\{\alpha_1, \alpha_2\}$. Therefore there are $r > 0$, $b > 0$ and for each subsequence $\{u_n\}$ such that for $Q_r = \Omega_0 \cap B(0, r)$,

$$\int_{Q_r} |u_n|^p \geq b.$$

Since $\{u_n\}$ is bounded in $H_0^1(\Omega_0)$, there exists a subsequence $\{u_n\}$ such that

$$u_n \rightharpoonup u_0$$

weakly in $H_0^1(\Omega_0)$, a.e. in Ω_0, and strongly in $L^p_{loc}(\Omega_0)$. Then u_0 is a nonnegative solution of (1.1) in Ω_0. By the fact that $\int_{Q_r} |u_n|^p \geq b$ for each n and by the compact embedding theorem, we have

$$\int_{Q_r} |u_0|^p \geq b.$$

Thus $u_0 \not\equiv 0$. By the maximum principle, u_0 is a positive solution of (1.1) in Ω_0. Thus $u_0 \in M_0$ and

$$J(u_0) \geq \inf_{u \in M_0} J(u) = \alpha_0.$$

Let $p_n = u_n - u_0$; then $\{p_n\}$ is a Palais–Smale sequence for J:

$$\begin{aligned} &J(p_n) = J(u_n) - J(u_0) + \mathrm{o}(1) = \alpha_0 - J(u_0) + \mathrm{o}(1) \text{ as } n \to \infty, \\ &J'(p_n) = \mathrm{o}(1) \text{ as } n \to \infty. \end{aligned}$$

Since $\alpha_0 \geq J(u_0)$, $\alpha_0 = J(u_0)$. Now

$$\mathrm{o}(1) = J(p_n) = \left(\frac{1}{2} - \frac{1}{p}\right) ||p_n||^2_{H^1} + \mathrm{o}(1) \text{ as } n \to \infty.$$

Thus

$$||p_n||^2_{H^1} = \mathrm{o}(1) \text{ as } n \to \infty$$

or

$$u_n \to u_0 \text{ strongly in } H_0^1(\Omega_0) \text{ as } n \to \infty.$$

We conclude that J satisfies the $(\mathrm{PS})_{\alpha_0}$-condition.

The necessary condition is proven as follows: Suppose that $\alpha_0 = \min\{\alpha_1, \alpha_2\}$. Without loss of generality, let $\alpha_0 = \alpha_1$ and $\Omega_1 \subsetneq \Omega_0$. We claim that J does not satisfy the $(\mathrm{PS})_{\alpha_0}$-condition. In fact, suppose on the contrary, J satisfies the $(\mathrm{PS})_{\alpha_0}$-condition in Ω_0. Then we claim that J satisfies the $(\mathrm{PS})_{\alpha_0}$-condition in Ω_1. In fact, let $\{u_n\} \subset H_0^1(\Omega_1)$ satisfy $J(u_n) \to \alpha_1$ and $J'(u_n) \to 0$. There is a subsequence $\{u_n\}$ and $u \in H_0^1(\Omega_0)$ satisfying $u_n \to u$ strongly in $H_0^1(\Omega_0)$; that is to say $u_n \to u$ strongly in $H_0^1(\Omega_1)$. Therefore $J|_{H_0^1(\Omega_1)}$ satisfies the $(\mathrm{PS})_{\alpha_1}$-condition. By Proposition 2.9 (1), $\alpha_0 < \alpha_1$. This is a contradiction. $\square$

4. Solvable and unsolvable domains. In this section, we apply the results in section 3 to solve (1.1) in an unbounded domain Ω.

Esteban–Lions [3, Theorem I.1] proved the following.

Proposition 4.1. *Equation* (1.1) *in an Esteban–Lions domain* Ω *does not admit any nontrivial solution. In particular,* (1.1) *in either* $\boldsymbol{R}_+^N$, *or* A_s^r, *or* D_s^r *does not admit any nontrivial solution.*

We need the following results whose proofs are routine.

Lemma 4.2. *Let* $B_r = \{x \in \boldsymbol{R}^N | \; ||x|| < r\}$, *O be a bounded domain containing* 0 *in* $\boldsymbol{R}^m$, $m \geq 1$, $\Omega = O \times \boldsymbol{R}$, *and* $D_r = r\Omega = \{rx \,|x \in \Omega\}$, $r > 0$. *Then*

(1) $\lim_{r\to\infty} \alpha(B_r) = \alpha(\boldsymbol{R}^N)$;

(2) $\lim_{r\to 0+} \alpha(B_r) = \infty$;

(3) $\lim_{r\to\infty} \alpha(D_r) = \alpha(\boldsymbol{R}^N)$;

(4) $\lim_{r\to 0+} \alpha(D_r) = \infty$.

It is clear that $\alpha(A^r) \leq \alpha(A_s^r)$, $\alpha(D^r) \leq \alpha(D_s^r)$, where $\alpha(A^r)$ and $\alpha(D^r)$ admit minimizers. By Proposition 2.9(2), we obtain the following lemma.

Lemma 4.3. $\alpha(A^r) = \alpha(A_s^r)$ *and* $\alpha(D^r) = \alpha(D_s^r)$ *for any* $s \in \boldsymbol{R}$.

Note that $B_t = \{x \in \boldsymbol{R}^N \mid ||x|| < t\}$ is solvable, but A_0^r is unsolvable since it is an Esteban–Lions domain. However, their union $\Omega_t = B_t \cup A_0^r$, for a fixed r, is solvable.

Theorem 4.4. *There exists* $t_0 > 0$ *such that if* $t \geq t_0$, *then* Ω_t *is solvable.*

Proof. Note that $\alpha(A^r) = \alpha(A_0^r)$. Since $A^r \subsetneq \boldsymbol{R}^N$ is solvable, by Proposition 2.9(1), $\alpha(A_0^r) > \alpha(\boldsymbol{R}^N)$. By Lemma 4.2(1), there exists $t_0 > 0$ such that if $t \geq t_0$, then $\alpha(A_0^r) > \alpha(B_t) > \alpha(\Omega_t)$. Then by Theorem 3.1, Ω_t is solvable. $\square$

Let r, t be the fixed positive numbers, $s \in \boldsymbol{R}$, $x_0 = (0, \ldots, r)$, $\Omega_s = B_t(x_0) \cup D_{-s}^r$, and $D_{-s,s}^r = \{(x_1, x_2, \ldots, x_N) \in \boldsymbol{R}^N \mid x_2^2 + \cdots + x_N^2 < r^2,\ s > x_1 > -s\}$. Then we have the following theorem.

Theorem 4.5. *There exists* $s_0 > r$ *such that if* $s \geq s_0$, *then* Ω_s *is solvable.*

Proof. Since D^r is solvable, we have $\alpha(B_t(x_0) \cup D^r) < \alpha(D^r)$. Similar to Lemma 4.2(1) we obtain $\lim_{s\to\infty} \alpha(B_t(x_0) \cup D_{-s,s}^r) = \alpha(B_t(x_0) \cup D^r)$, so there exists $s_0 > r$ such that if $s \geq s_0$, then $\alpha(B_t(x_0) \cup D_{-s}^r) \leq \alpha(B_t(x_0) \cup D_{-s,s}^r) < \alpha(D^r) = \alpha(D_{-s}^r)$. Since $B_t(x_0)$ is solvable, we have $\alpha(B_t(x_0) \cup D_{-s}^r) < \alpha(B_t(x_0))$. Then by Theorem 3.1, Ω_s is solvable. $\square$

$A_{-\rho}^r$ and D_{-s}^r are Esteban–Lions domains, so they are unsolvable. However, their union is solvable.

Theorem 4.6. *Let* $t < r$ *be fixed. There exists* $s_0 > r$ *such that if* $s \geq s_0$ *and* $\Omega_\rho = A_{-\rho}^r \cup D_{-s}^r$, *then for* $\rho > 0$, Ω_ρ *is solvable.*

Proof. Let s be as in Theorem 4.5, and for $\rho > 0$, $\Omega_\rho = A_{-\rho}^r \cup (B_t(x_0) \cup D_{-s}^r)$. By Theorem 4.5, $B_t(x_0) \cup D_{-s}^r$ is solvable; thus $\alpha(\Omega_\rho) < \alpha(B_t(x_0) \cup D_{-s}^r)$. Note that $\alpha(B_t(x_0) \cup D_{-s}^r) \leq \alpha(D_{-s}^r) = \alpha(A_{-\rho}^r)$, or $\alpha(\Omega_\rho) < \alpha(A_{-\rho}^r)$. Then by Theorem 3.1, for $\rho > 0$, Ω_ρ is solvable. $\square$

GLOBAL EXISTENCE OF STEADY SUPERSONIC POTENTIAL FLOW PAST A CURVED WEDGE WITH A PIECEWISE SMOOTH BOUNDARY[*]

YONGQIAN ZHANG[†]

Abstract. In this paper we use a modified Glimm scheme to construct a global weak solution to the steady supersonic potential flow past a two-dimensional wedge with a piecewise smooth boundary, small vertex angle, and small total variation of the tangent angle along each side.

Key words. supersonic, wedge, piecewise smooth

AMS subject classifications. 35L65, 76N15

PII. S0036141097331056

1. Introduction.

The problem of steady supersonic flow past a wedge with a smooth boundary has been extensively studied by many authors (for instance, see [1, 2, 3, 6, 9, 11, 14] and references therein). The simple case in which both sides are straight was solved in the book [3] by the shock polar. In [9, 14], applying the theory of quasi-linear hyperbolic systems, Li and Schaeffer give the local existence of steady supersonic flow past the two-dimensional curved wedge with the vertex angle less than the critical value. In [1] Chen extended this result to the case of three-dimensional wedge. Recently Chen established the global existence and asymptotic behavior of steady supersonic flow past a convex combined wedge by making use of hodograph transformation (see [2]).

In this paper we study the potential flow past a two-dimensional wedge with a piecewise smooth boundary. Here, as usual, we consider the case of irrotational and polytropic gas in which the pressure p and the density ρ are related by $p = p(\rho) = A\rho^\gamma$, where A is some positive constant and $\gamma > 1$ is an adiabatic exponent. For simplicity, we study the problem for the half of the wedge, that is, we consider the problem

$$(1.1)\qquad \begin{cases} (\rho u)_x + (\rho v)_y = 0, & \\ v_x - u_y = 0 & \text{in} \quad \Omega \cap \{x > 0\}, \\ (u, v)\cdot \overrightarrow{n} = 0 & \text{on} \quad \partial\Omega, \\ (u, v)|_{x<0} = (q_\infty, 0), & \end{cases}$$

under the following assumptions.

(A1) The Bernoulli relation holds as follows:

$$(1.2)\ \rho = A^{-\frac{1}{\gamma-1}} \left(\frac{\gamma+1}{2\gamma} c_*^2 - \frac{\gamma-1}{2\gamma} q^2 \right)^{\frac{1}{\gamma-1}} = A^{\frac{-1}{\gamma-1}} \left[\frac{\gamma-1}{2\gamma} (q_*^2 - q^2) \right]^{\frac{1}{\gamma-1}}$$

with the constant $q_* = \sqrt{\frac{\gamma+1}{\gamma-1}} c_*$. Here c_* is the critical speed, $q = \sqrt{u^2 + v^2}$, $\gamma > 1$ is the adiabatic exponent, $A > 0$ is some constant.

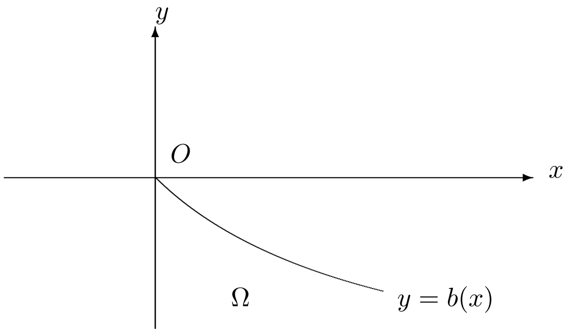

Fig. 1.1.

(A2) The velocity of incoming flow q_∞ is a constant and $q_\infty > c_*$.

(A3) There exists $b \in C[0, +\infty)$ with $b(x) < 0$ for $x > 0$ and $b(0) = 0$ such that $\Omega = \{(x, y)|x \le 0, y < 0\} \cup \{(x, y)|y < b(x), x > 0\}$. In addition there exists a set of points $\{x_k\}_{k=1}^{l} \subseteq (0, +\infty)$ such that $b \in C^\infty[x_{k-1}, x_k]$ for $1 \le k \le l$ and b is affine in $[x_l, +\infty)$. Here $\overrightarrow{n}$ is the outer normal to $\partial\Omega \backslash \{(x_k, b(x_k)), 0 \le k \le l\}$, $x_0 = 0$ (see Figure 1.1).

In [2, 3] the function $y = b(x)$ was assumed to be convex or straight. In this study, we set a rather general assumption on the function $y = b(x)$, that is, there is no special assumption on the shape of the curve $y = b(x)$ except the requirement on the total curvature of the curve. New shock may issue from some place away from the wedge surface; also more complicated boundary interactions may occur (see [3, 5]). To overcome these difficulties we modify the Glimm scheme to handle the initial-boundary value problem. In this paper, under suitable conditions, we shall construct the global weak solution that satisfies $(u, v) = (q_\infty, 0)$ near the line set $\{(x, y)|x = 0, y < 0\}$ and solve the problem (1.1) in the following sense as in [7]:

$$
\begin{aligned}
&\int_{\Omega \cap \{x>0\}} \rho u \phi_{1x} + \rho v \phi_{1y} = \int_{-\infty}^{+\infty} \rho_\infty q_\infty \phi_1(0, y) dy, \\
&\int_{\Omega \cap \{x>0\}} v \phi_{2x} - u \phi_{2y} = 0
\end{aligned}
\tag{1.3}
$$

$\forall \phi_1 \in C_c^\infty(R^2), \phi_2 \in C_c^\infty(\Omega)$ (see [3, 7, 11]). Here $\rho_\infty = \rho(q_\infty, 0)$ is given by (1.2).

The remaining parts of the paper are organized in the following way. In section 2 we first rewrite the equations in the equivalent form and prove that these two systems admit the equivalent entropy conditions. Then by the well-known results of the conservation laws we parameterize the wave curves, i.e., the shock polar and epicycloid in the supersonic region according to the entropy conditions. In section 3 we apply the results in section 2 to establish the existence of solutions to a class of mixed problems and the estimates on the interactions and reflections of waves and the flows past a corner. In section 4 we first approximate the boundary by a collection of straight line segments and modify the Glimm scheme in each approximate domain. In each domain we get the approximate solution and define the Glimm functional analogous to that used in [12, 13] (see also [4, 10]), which is supplemented by additional terms needed to take more complicated boundary interactions into account. The desired decrease of the functional is obtained provided that the top angle and the total curvature of the boundary are sufficiently small. In section 5 we extend the

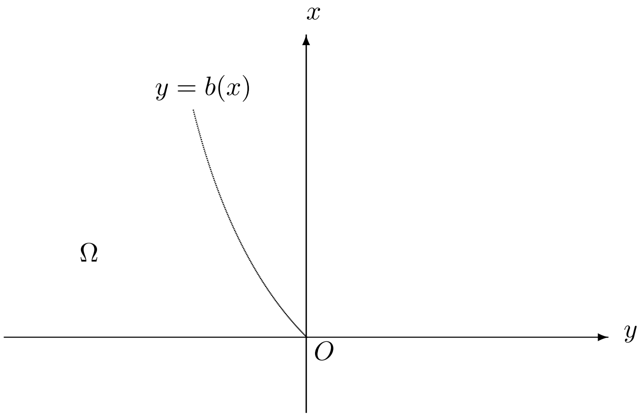

Fig. 2.1.

approximate solutions to the whole domain and prove the compactness of approximate solutions, then obtain the global solution by the convergence of the approximate solutions. Our main results are also stated in section 5.

2. Entropy condition. First we give some notations that will be used throughout the paper. As usual, we view the x-direction as the vertical direction and the y-direction as the horizontal direction and we still use the notation (a, b) to denote the point whose x-coordinate is a and y-coordinate is b (see Figure 2.1).

We recall some basic results about the system. This system is genuinely nonlinear and hyperbolic if the x-direction is regarded as the time direction. It is obvious that the system possesses two distinct characteristics, $\lambda_1 = \frac{uv - c\sqrt{u^2+v^2-c^2}}{u^2-c^2}$, $\lambda_2 = \frac{uv + c\sqrt{u^2+v^2-c^2}}{u^2-c^2}$ and two right eigenvectors $r_j(u, v) = e_j(u, v)\binom{-\lambda_j}{1}$ $(j = 1, 2)$ and $\lambda_1 < 0 < \lambda_2$ near the point $(q_\infty, 0)$. Here $e_j(u, v)$ $(j = 1, 2)$ are smooth functions near the point $(q_\infty, 0)$ which satisfy

$$r_j \cdot \nabla\lambda_j = 1 \tag{2.1}$$

$(j = 1, 2)$ near the point $(q_\infty, 0)$. Moreover we have the following.

Lemma 2.1. *There hold*

$$e_j(u, v) > 0 \tag{2.2}$$

$(j = 1, 2)$ *for any state* (u, v) *near* $(q_\infty, 0)$.

Proof. We prove only the lemma for $j = 2$.

Differentiating the Bernoulli relation $\frac{c^2}{\gamma-1} + \frac{q^2}{2} =$ constant with respect to u and v, we get

$$(c^2)_u|_{(q_\infty,0)} = -(\gamma - 1)q_\infty,$$
$$(c^2)_v|_{(q_\infty,0)} = 0;$$

then

$$\lambda_{2u}|_{(q_\infty,0)} = -\frac{(\gamma-1)q_\infty}{2c_\infty\sqrt{q_\infty^2 - c_\infty^2}} - \frac{(\gamma+1)q_\infty c_\infty}{2\sqrt{(q_\infty^2 - c_\infty^2)^3}} < 0$$

and

$$\lambda_{2v}|_{(q_\infty,0)} = \frac{q_\infty}{q_\infty^2 - c_\infty^2} > 0.$$

Thus it follows

$$\nabla_{(u,v)}\lambda_2 \cdot (-\lambda_2, 1)|_{(q_\infty,0)} > 0.$$

This implies that $e_2 > 0$ near the point $(q_\infty, 0)$. In the same way we can also prove that $e_1 > 0$ near the point $(q_\infty, 0)$. □

Let $R_2(u_0, v_0)$ and $S_2(u_0, v_0)$ (or $R_1(u_0, v_0)$ and $S_1(u_0, v_0)$, resp.) represent, respectively, the epicycloid and shock polar in the supersonic region with respect to λ_2-characteristic field (or λ_1-characteristic field, resp.) passing through (u_0, v_0), $q = \sqrt{u^2 + v^2}$ and denote

$$\begin{aligned} R_2^+(u_0, v_0) &= \{(u, v) \in R_2(u_0, v_0) | q \le q_0.\}, \\ S_2^-(u_0, v_0) &= \{(u, v) \in S_2(u_0, v_0) | q \ge q_0.\}, \\ R_1^+(u_0, v_0) &= \{(u, v) \in R_1(u_0, v_0) | q \ge q_0.\}, \\ S_1^-(u_0, v_0) &= \{(u, v) \in S_1(u_0, v_0) | q \le q_0.\} \end{aligned} \tag{2.3}$$

(see Figure 2.2) and

$$T_j(u_0, v_0) = R_j^+(u_0, v_0) \cup S_j^-(u_0, v_0), \quad j = 1, 2. \tag{2.4}$$

The $T_j(u_0, v_0)$ $(j = 1, 2)$ gives the physically admissible solution with (u_0, v_0) as the left state (see [3, 7]). In addition, from the rotation invariance of the equation and the Hugoniot locus, we have the following lemma.

LEMMA 2.2. *There exists a $\delta_1 > 0$ such that the following holds for all points (u_0, v_0) belonging to the neighborhood of $(q_\infty, 0)$, $O_{\delta_1}((q_\infty, 0))$:*

$$\begin{aligned} R_2^+(u_0, v_0) &= \{(u, v) \in R_2(u_0, v_0) | u \le u_0, v \ge v_0.\}, \\ S_2^-(u_0, v_0) &= \{(u, v) \in S_2(u_0, v_0) | u \ge u_0, v \le v_0.\}, \\ R_1^+(u_0, v_0) &= \{(u, v) \in R_1(u_0, v_0) | u \ge u_0, v \ge v_0.\}, \\ S_1^-(u_0, v_0) &= \{(u, v) \in S_1(u_0, v_0) | u \le u_0, v \le v_0.\}. \end{aligned} \tag{2.5}$$

Set

$$\Psi : \begin{cases} m = \rho u, \\ \quad w = v \end{cases} \tag{2.6}$$

and $W = \binom{m}{w}$, $U = \binom{u}{v}$, $D = \{U \in R^2 | u > c_*, q < q_*\}$.

LEMMA 2.3. *$\Psi : D \longmapsto \Psi(D)$ is a smooth diffeomorphism.*

Proof. A simple calculation shows that

$$m_u = A^{-\frac{1}{\gamma-1}} \left(\frac{\gamma+1}{2\gamma}c_*^2 - \frac{\gamma-1}{2\gamma}q^2\right)^{\frac{2-\gamma}{\gamma-1}} \left(\frac{\gamma+1}{2\gamma}c_*^2 - \frac{\gamma+1}{2\gamma}u^2 - \frac{\gamma-1}{2\gamma}v^2\right) < 0$$

$\forall (u, v) \in D$. This proves the lemma. □

Thus the system can be written in the new coordinates as

$$W_x + H(W)_y = 0, \tag{2.7}$$

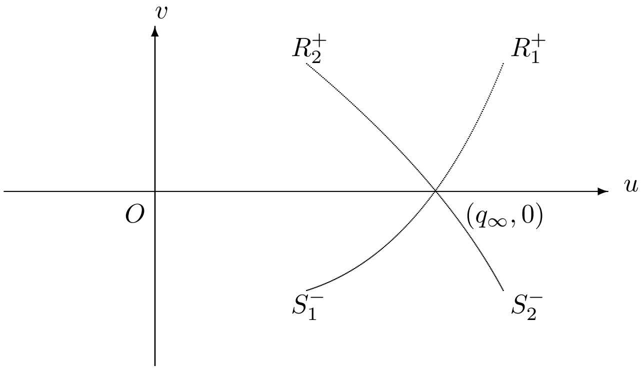

FIG. 2.2. *Wave curves in the case* $u_0 = q_\infty, v_0 = 0$.

where $W = \Psi(u, v)$.

Obviously this new system is also genuinely nonlinear and hyperbolic with respect to the x-direction.

PROPOSITION 2.4. *There is a* $\delta_2 > 0$ *such that the following assertions hold for any state* (u_0, v_0) *near* $U_\infty = (q_\infty, 0)$:

$$\begin{aligned}
&R_j^+(u_0, v_0) \cap O_{\delta_2}(U_\infty) \\
&= \{(u, v) \in R_j(u_0, v_0) | \lambda_j(u, v) \geq \lambda_j(u_0, v_0)\} \cap O_{\delta_2}(U_\infty), \\
&S_j^-(u_0, v_0) \cap O_{\delta_2}(U_\infty) \\
&= \{(u, v) \in S_j(u_0, v_0) | \lambda_j(u, v) \leq \lambda_j(u_0, v_0)\} \cap O_{\delta_2}(U_\infty), \\
&j = 1, 2.
\end{aligned} \tag{2.8}$$

Proof. It suffices to prove the lemma in the case $u_0 = q_\infty$, $v_0 = 0$. First we prove the lemma for S_2^-.

Noticing that S_2 is also the shock curve for the new system, we can parametize S_2 by ϵ with $\frac{dW}{d\epsilon}|_{\epsilon=0} = \tilde{r}_2(W)$ according to Lax [8], where $\tilde{r}_2(W) = \nabla\Psi \cdot r_2|_{U=\Psi^{-1}(W)}$; then the following holds along $S_2(q_\infty, 0)$ by Lemma 2.1:

$$\begin{cases} \dfrac{du}{d\epsilon}\Big|_{\epsilon=0} = -\lambda_2(q_\infty, 0)e_2(q_\infty, 0) < 0, \\ \dfrac{dv}{d\epsilon}\Big|_{\epsilon=0} = e_2(q_\infty, 0) > 0. \end{cases}$$

Therefore it follows that near $\epsilon = 0$

$$\begin{aligned} u(\epsilon) &> u(0) = q_\infty, \\ v(\epsilon) &< v(0) = 0 \end{aligned}$$

holds if and only if $\epsilon < 0$ holds.

Also from (2.1) it follows that near $\epsilon = 0$

$$\lambda_2(u(\epsilon), v(\epsilon)) < \lambda_2(u(0), v(0)) = \lambda_2(q_\infty, 0)$$

holds if and only if $\epsilon < 0$.

This proves the result for $S_2^-(q_\infty, 0)$. The general case for S_2^- follows by the argument of continuity.

The result for S_1^- and $R_{1,2}^+$ can be proved in the same way. □

Equation (2.8) implies that the system in (1.1) and the system (2.7) admit the same entropy condition, that is, they are equivalent in the weak sense. Therefore we can parameterize these waves easily as follows: for any state $W_l \in \Psi(O_{\delta(1)}(U_\infty))$, where $\delta(1) = \min(\delta_1, \delta_2)$, let $L_j(W_l)$ $(j = 1, 2)$ be the curves of Lax (see [8]) parameterized by $\epsilon_j \mapsto \tilde{\Phi}_j(\epsilon_j, W_l)$ with $\tilde{\Phi}_j \in C^2$ and

$$\begin{aligned} &\tilde{\Phi}_j|_{\epsilon_j=0} = W_l, \\ &\frac{\partial \tilde{\Phi}_j}{\partial \epsilon_j}\Big|_{\epsilon_j=0} = \tilde{r}_j(W_l). \end{aligned} \tag{2.9}$$

Here $\tilde{r}_j(W) = \nabla\Psi \cdot r_j|_{U=\Psi^{-1}(W)}$ $(j = 1, 2)$.

By Lemma 2.2 and Proposition 2.4 it's obvious that L_j is constituted by $\Psi(S_j^-)$ and $\Psi(R_j^+)$ $(j = 1, 2)$, and we call the waves given by T_j or $\Psi(T_j)$ the elementary waves or j-wave throughout the paper. Moreover, it follows that $\epsilon_j > 0$ along $\Psi(R_j^+)$ while $\epsilon_j < 0$ along $\Psi(S_j^-)$ $(j = 1, 2)$.

Denote

$$\begin{aligned} &\tilde{\Phi}(\epsilon_2, \epsilon_1, W_l) = \tilde{\Phi}_2(\epsilon_2, \tilde{\Phi}_1(\epsilon_1, W_l)), \\ &\Phi_j = \Psi^{-1} \cdot \tilde{\Phi}_j, \quad j = 1, 2, \end{aligned} \tag{2.10}$$

and

$$\Phi(\epsilon_2, \epsilon_1, (u_l, v_l)) = \Phi_2(\epsilon_2, \Psi \cdot \Phi_1(\epsilon_1, \Psi(u_l, v_l))); \tag{2.11}$$

then we have the following lemma.

Lemma 2.5. *For any pair of states $U_r = \binom{u_r}{v_r}$ and $U_l = \binom{u_l}{v_l}$ close to $U_\infty = \binom{q_\infty}{0}$ in the supersonic region, the system*

$$\begin{cases} W_x + H(W)_y = 0, \\ W|_{x=0} = \begin{cases} W_r, y > 0, \\ W_l, y < 0 \end{cases} \end{cases} \tag{2.12}$$

admits the unique admissible solution constituted by two elementary waves. In addition it owns the representation $(u_r, v_r) = \Phi(\beta, \alpha, (u_l, v_l))$ with

$$\begin{aligned} &\Phi|_{\alpha=\beta=0} = (u_l, v_l), \\ &\frac{\partial \Phi}{\partial \alpha}\Big|_{\alpha=\beta=0} = r_1(u_l, v_l), \end{aligned} \tag{2.13}$$

and

$$\frac{\partial \Phi}{\partial \beta}\Big|_{\alpha=\beta=0} = r_2(u_l, v_l), \tag{2.14}$$

where $W = \binom{\rho u}{v}$.

This lemma can be derived by Lemma 2.2, Proposition 2.4, and the results in the [8]. It will lead to the estimates given in the next section.

For simplicity, we shall use the notation $\{U_l, U_r\} = (\alpha, \beta)$ to denote that $U_r = \Phi(\beta, \alpha, U_l)$ throughout the paper. It is obvious that $\alpha > 0$ along R_1^+ and $\beta > 0$ along R_2^+ while $\alpha < 0$ along S_1^- and $\beta < 0$ along S_2^-.

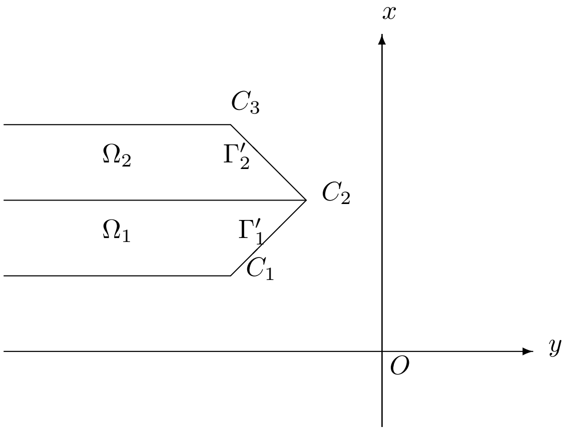

Fig. 3.1.

3. Basic estimates on the nonlinear waves. In this section we shall give the estimates on the interactions and reflections of waves and the flow past the corners. First, by the standard result (see [4, 10]), we have the interaction estimates in the interior as follows.

Lemma 3.1. *If U_l, U_m, and U_r are three states near U_∞, with $\{U_l, U_m\} = \alpha = (\alpha_1, \alpha_2)$, $\{U_m, U_r\} = \beta$, and $\{U_l, U_r\} = \gamma$, then*

$$\gamma_k = \alpha_k + \beta_k + O(1)\Delta'(\alpha, \beta). \tag{3.1}$$

Here $k = 1, 2$ and $\Delta'(\alpha, \beta) = \sum |\alpha_i||\beta_j|$, where the sum is over all pairs for which the ith wave from α and the jth wave from β are approaching; $O(1)$ depends only on the system and U_∞.

Let $C_k = (a_k, b_k)$ $(k = 1, 2, 3)$ with $a_{k+1} > a_k > 0$ $(k = 1, 2)$ (see Figure 3.1) and

$$\begin{aligned}
&\omega = \arctan\frac{b_3 - b_2}{a_3 - a_2} - \arctan\frac{b_2 - b_1}{a_2 - a_1},\\
&\omega_0 = \arctan\frac{b_2 - b_1}{a_2 - a_1},\\
&\Omega_k = \left\{(x, y)|a_k \le x \le a_{k+1}, y < \frac{b_{k+1} - b_k}{a_{k+1} - a_k}(x - a_k) + b_k\right\},\\
&\Gamma'_k = \left\{(x, y)|a_k < x < a_{k+1}, y = \frac{b_{k+1} - b_k}{a_{k+1} - a_k}(x - a_k) + b_k\right\},\\
&\overrightarrow{n_k} = (b_{k+1} - b_k, a_k - a_{k+1}).
\end{aligned}$$

Set

$$\Delta(a, b) = \begin{cases} 0 & \text{if} \quad a \ge 0 \text{ and } \quad b \ge 0,\\ |a||b| & \quad \text{otherwise,}\end{cases}$$

and let H be a neighborhood of U_∞ satisfying $\bar{H} \subset D$ and is compact.

Consider the following mixed problem:

$$\begin{cases} W_x + H(W)_y = 0 & \text{in} \quad \Omega_2,\\ W|_{x=a_2} = W_2, & \\ (u, v) \cdot \vec{n}_2 = 0 & \text{on} \quad \Gamma'_2, \end{cases} \tag{3.2}$$

where $W = \Psi(u, v)$.

LEMMA 3.2. *There exist $\delta_3 > 0$ and $\delta_3' > 0$, $\delta_4 > 0$ with $\delta_4 < \min_H |\arctan \lambda_{1,2}|$ such that if $|U_\infty - U_0| < \delta_3$, $|\omega_0| + |\omega| < \delta_4$ with $U_0 \cdot \overrightarrow{n_1} = 0$, then there exist a unique $\epsilon \in (-\delta_3', \delta_3')$ and a constant state U_2 with $\{U_0, U_2\} = (\epsilon, 0)$ such that the mixed problem (3.2) in Ω_2 with the initial data $W_2 = \Psi(U_0)$ admits a unique admissible solution W constituted by a 1-wave of which the strength is ϵ and $W = \Psi(U_2)$ in some neighborhood of Γ_2'. Moreover,*

$$\epsilon = K_1\omega + O(1)|\omega|^2 \tag{3.3}$$

with $K_1 > c_0 > 0$, where c_0 and the bounds of K_1 and $O(1)$ depend only on the system, U_∞, and $\min_H |\lambda_{1,2}|$.

Proof. It suffices to solve the following equation for the given ω_0, ω, and U_0:

$$\Phi(0, \epsilon, U_0) \cdot (-\sin(\omega_0 + \omega), \cos(\omega_0 + \omega)) = 0. \tag{3.4}$$

Since $\Phi(0, 0, U_\infty) \cdot (0, 1) = 0$ and by Lemma 2.1,

$$\frac{\partial}{\partial \epsilon}[\Phi(0, \epsilon, U_0) \cdot (-\sin(\omega_0 + \omega), \cos(\omega_0 + \omega))] = r_1(q_\infty, 0) \cdot (0, 1) > 0 \tag{3.5}$$

for $\epsilon = \omega = 0$, $\omega_0 = 0$, and $U_0 = U_\infty$, we can get the unique C^2-function $\epsilon = \epsilon(\omega_0 + \omega, U_0)$ which solves the above equation in some neighborhood of $\epsilon = \omega = \omega_0 = 0$ and $U_0 = U_\infty$ by the theorem of implicit function.

Moreover, by assumptions we have

$$\Phi(0, 0, U_0) \cdot (-\sin\omega_0, \cos\omega_0) = 0 \tag{3.6}$$

and this implies $\epsilon(\omega_0, U_0) = 0$. Thus the result follows by the Taylor formula. □

This lemma deals only with the case of the paralleling flow past the corner with small turning angle. To take account of more complicated boundary interaction, including the reflection of waves, we need the following proposition.

PROPOSITION 3.3. *There exist $\delta_i > 0$ $(i = 5, 6)$ and $\delta_5' > 0$ with $\delta_6 < \min_H |\arctan \lambda_{1,2}|$ such that if U_l, U_m, and U_r are three states in the supersonic region with $|U_\infty - U_r| < \delta_5$, $|U_l - U_\infty| < \delta_5$, $|U_m - U_\infty| < \delta_5$, and $|\omega_0| + |\omega| < \delta_6$ and satisfy that $\{U_l, U_m\} = (0, \alpha)$, $\{U_m, U_r\} = (\gamma, 0)$, and $U_r \cdot \overrightarrow{n_1} = 0$, then there exist a unique $\epsilon \in (-\delta_5', \delta_5')$ and a constant state U_2 with $\{U_l, U_2\} = (\epsilon, 0)$ such that the mixed problem (3.2) in Ω_2 with the initial data $W_2 = \Psi(U_l)$ admits a unique admissible solution W constituted by a 1-wave of which the strength is ϵ and $W = \Psi(U_2)$ in some neighborhood of Γ_2'. Moreover,*

$$\epsilon = \gamma + K_3\alpha + K_4\omega + O(1)\{|\alpha||\gamma| + |\alpha||\omega| + \Delta(\gamma, \omega) + |\alpha|^2 + |\omega|^2\} \tag{3.7}$$

holds with $K_3 > 0$ and $K_4 > 0$ and the bounds of K_3, K_4, and $O(1)$ depend only on the system U_∞ and $\min_H |\arctan \lambda_{1,2}|$.

Proof. It suffices to solve the following equations:

$$\begin{aligned} &\Phi(0, \epsilon, U_l) \cdot (-\sin(\omega + \omega_0), \cos(\omega + \omega_0)) \\ &= \Phi(0, \beta, \Phi(0, \gamma, \Phi(\alpha, 0, U_l))) \cdot (-\sin(\omega + \omega_0), \cos(\omega + \omega_0)) \\ &= 0 \end{aligned} \tag{3.8}$$

for the given α, γ, ω, and ω_0 and U_l.

To find the solution (ϵ, β) to the equations, we should carry out the following three steps.

First, noticing $U_r \cdot \vec{n}_1 = 0$, by Lemma 3.2 we can get the unique C^2-function $\beta = \beta(\omega + \omega_0, \Phi(0, \gamma, U_m))$ which solves the equation

$$\Phi(0, \beta, \Phi(0, \gamma, U_m)) \cdot (-\sin(\omega + \omega_0), \cos(\omega + \omega_0)) = 0 \tag{3.9}$$

in the neighborhood of $\beta = \omega_0 = \omega = \gamma = 0$ and $U_m = U_\infty$ and

$$\beta = K_1 \omega + O(1)|\omega|^2, \tag{3.10}$$

with $K_1 > C_0 > 0$.

Also by Lemma 3.1 we can find the unique C^2-function $\epsilon' = \epsilon'(\beta', \gamma, U_m)$ which solves the following equation in some neighborhood of $\epsilon' = \beta = \gamma = 0$ and $U_m = U_\infty$:

$$\Phi(0, \epsilon', U_m) = \Phi(0, \beta', \Phi(0, \gamma, U_m)) \tag{3.11}$$

with

$$\epsilon' = \beta' + \gamma + O(1)\Delta(\beta', \gamma). \tag{3.12}$$

The third step is to solve the following equation:

$$\begin{aligned} &\Phi(0, \epsilon, U_l) \cdot (-\sin(\omega + \omega_0), \cos(\omega + \omega_0)) \\ &= \Phi(0, \epsilon'', \Phi(\alpha, 0, U_l)) \cdot (-\sin(\omega + \omega_0), \cos(\omega + \omega_0)) \end{aligned} \tag{3.13}$$

for the given $\epsilon'', \alpha, \omega, \omega_0$, and U_l.

In the same way as in the proof of Lemma 3.2 we can also get the unique C^2-function $\epsilon = \epsilon(\epsilon'', \alpha, \omega + \omega_0, U_l)$ which solves (3.13) in some neighborhood of $\epsilon = \epsilon'' = \alpha = \omega = \omega_0 = 0$ and $U_l = U_\infty$.

Throughout the paper we omit the U_l in $\epsilon = \epsilon(\epsilon'', \alpha, \omega + \omega_0, U_l)$. It is obvious that

$$\epsilon = I_1 + I_2 + I_3 + I_4 + \epsilon(0, 0, \omega_0), \tag{3.14}$$

where

$$\begin{aligned} I_1 &= \epsilon(\epsilon'', \alpha, \omega + \omega_0) - \epsilon(\epsilon'', 0, \omega + \omega_0) - \epsilon(0, \alpha, \omega + \omega_0) + \epsilon(0, 0, \omega + \omega_0), \\ I_2 &= \epsilon(\epsilon'', 0, \omega + \omega_0), \\ I_3 &= \epsilon(0, \alpha, \omega + \omega_0) - \epsilon(0, 0, \omega + \omega_0) - \epsilon(0, \alpha, \omega_0) + \epsilon(0, 0, \omega_0), \end{aligned}$$

and

$$I_4 = \epsilon(0, \alpha, \omega_0);$$

then we have by the Taylor formula and Lemma 2.1 that

$$\begin{aligned} I_1 &= \mathrm{O}(1)|\epsilon''||\alpha|, \\ I_3 &= \mathrm{O}(1)|\omega||\alpha|, \\ I_4 &= K_3\alpha + \mathrm{O}(1)|\alpha|^2, \end{aligned} \tag{3.15}$$

with $K_3 > 0$. Moreover, it follows by uniqueness that

$$\begin{aligned} &I_2 = \epsilon'', \\ &\epsilon(0, 0, \omega_0) = 0. \end{aligned} \tag{3.16}$$

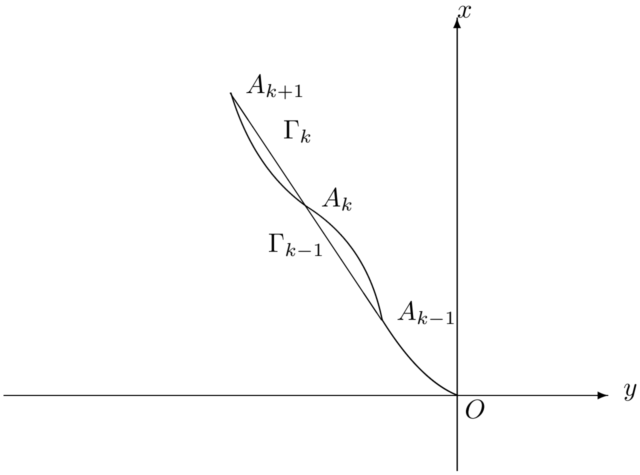

FIG. 4.1.

Hence

$$\epsilon = \epsilon'' + K_3\alpha + O(1)(|\epsilon''||\alpha| + |\omega||\alpha| + |\alpha|^2). \tag{3.17}$$

Let $U_m = \Phi(\alpha, 0, U_l)$, $\epsilon' = \epsilon''$, and $\beta = \beta'$; then by (3.9), (3.11), and (3.13) and noticing

$$\frac{\partial}{\partial\epsilon}\Phi(0, \epsilon, U_l) \cdot (-\sin(\omega + \omega_0), \cos(\omega + \omega_0)) \neq 0 \tag{3.18}$$

for $\epsilon = \omega = \omega_0 = 0$ and $U_l = U_\infty$ we can find the unique ϵ which solves (3.8) in some neighborhood of $\epsilon = \beta = \omega_0 = \omega = \gamma = 0$ and $U_l = U_m = U_r = U_\infty$. In addition, the desired estimates follow from (3.10), (3.12), and (3.17).

The proof is complete. □

4. Glimm scheme. In this section we shall use a modified Glimm scheme to obtain the approximate solution in the approximate domain $\Omega_{\Delta x}$ which will be defined. Without loss of generality we assume that b is smooth and let $y_k = b(k\Delta x)$; we then choose the points $\{A_k = (k\Delta x, y_k)\}_{k=0}^{+\infty}$ in the $\Gamma = \{(x, y)|y = b(x), x \geq 0\}$ and denote

$$\begin{aligned}
&\omega(A_k) = \arctan\frac{y_{k+1} - y_k}{\Delta x} - \arctan\frac{y_k - y_{k-1}}{\Delta x}, \quad k \geq 1,\\
&\omega(A_0) = \arctan\frac{y_1 - y_0}{\Delta x},\\
&\Gamma_k = \{(x, y)|k\Delta x < x < (k + 1)\Delta x, y = b(x, k, \Delta x)\},
\end{aligned}$$

and $\vec{n}_k$ is the outer normal to Γ_k,

$$\Omega_{\Delta x} = \cup_{k\geq 0}\{(x, y)|k\Delta x \leq x < (k + 1)\Delta x, y < b(x, k, \Delta x)\},$$

where $b(x, k, \Delta x) = y_k + \frac{y_{k+1}-y_k}{\Delta x}(x - k\Delta x)$ (see Figure 4.1).

Let $B = \{U \in D||U - U_\infty| < \delta(2)\} \subset H$ and Δy satisfy that $\frac{\Delta y - m\Delta x}{\Delta x} = 2\sup\{|\lambda_{1,2}(z)|, z \in B\}$, where $\delta(2)$ is a constant specialized to meet the requirement of propositions and lemmas in sections 2 and 3, $m = \sup_{k>0}\{\frac{|y_k - y_{k-1}|}{\Delta x}\}$.

Choose mesh points $\{(k\Delta x, a_{k,n})\}_{k\geq 0, -\infty<n<+\infty}$ in R^2 with

$$a_{k,n} = (2n+1+\theta_k)\Delta y + y_k \tag{4.1}$$

and θ_k is randomly chosen in $(-1,1)$. We connect the mesh point $(k\Delta x, a_{k,n})$ by two line segments to the two mesh points, $((k-1)\Delta x, a_{k-1,n-1})$ and $((k-1)\Delta x, a_{k-1,n})$ if $\theta_k \leq 0$, or connect mesh point $(k\Delta x, a_{k,n})$ by two line segments to the two mesh points $((k-1)\Delta x, a_{k-1,n})$ and $((k-1)\Delta x, a_{k-1,n+1})$ if $\theta_k > 0$.

Definition 4.1. *A mesh curve is defined to be an unbounded piecewise linear and space-like curve which is composed of these segments.*

Then each mesh curve I divides the R^2 into I^+ part and I^- part, the I^- part being the one containing $\{x=0\}$. As in [15] we also partially order the mesh curves by saying $I_1 > I_2$ if every point of the mesh curve I_1 is on either I_2 or contained in I_2^+, and call J an immediate successor to I if $J > I$ and every mesh point of J except one is on I.

Now we can define the difference scheme in $\Omega_{\Delta x}$, that is, define the global approximate solution $\tilde{U} = \tilde{U}(x,y)$ in $\Omega_{\Delta x}$. This can be done by carrying out the following steps inductively.

Assume that the approximate solution $\tilde{U}$ has been constructed for $0 \leq x < k\Delta x$ with $\tilde{U}|_{x=0} = U_\infty$ and $\tilde{U}(x,y) = U_j(x,y)$ for $(x,y) \in \{(j-1)\Delta x \leq x < j\Delta x\} \cap \Omega_{\Delta x}$ $(0 \leq j \leq k-1)$, we will define the approximate solution $\tilde{U} = U_k = \Psi^{-1}(W_k)$ in $\{k\Delta x \leq x < (k+1)\Delta x\}$ by solving the following problems.

First we have to solve the following Riemann problem:

$$\begin{cases} (W_k)_x + H(W_k)_y = 0, \\ W_k|_{x=k\Delta x} = W_k^0 \end{cases} \tag{4.2}$$

in each rhombus $T_{k,n}$ whose vertices are $(k\Delta x, (2n-1)\Delta y + y_k)$ $(k\Delta x, (2n+1)\Delta y + y_k)$, $((k+1)\Delta x, (2n-1)\Delta y + y_{k+1})$, $((k+1)\Delta x, (2n+1)\Delta y + y_{k+1})$. Here $n \leq -1$, $W_k^0 = \Psi(U_k^0)$ and

$$U_k^0(y) = U_{k-1}(k\Delta x-, a_{k,n}), \quad y \in (y_k + 2n\Delta y, y_k + 2(n+1)\Delta y).$$

If the problem (4.2) is solvable, define $\tilde{U} = \Psi^{-1}(W_k)$ in $T_{k,n}$ $(n \leq -1)$.

Set

$$U_{k,n} = U_{k-1}(k\Delta x-, a_{k,n}), \quad n \leq -1; \tag{4.3}$$

then by Lemma 3.1 we have that if $W_k^0 \in \Psi(B)$ for $n \leq -1$, the problem (4.2) admits a unique admissible solution and there exist uniquely $\epsilon_{k,n,1}$ and $\epsilon_{k,n,2}$ such that

$$U_{k,n} = \Phi(\epsilon_{k,n,2}, \epsilon_{k,n,1}, U_{k,n-1}). \tag{4.4}$$

Second, to define $\tilde{U}$ in rhombus $T_{k,0}$ whose vertices are $((k+1)\Delta x, y_{k+1})$, $((k+1)\Delta x, \Delta y + y_{k+1})$, $(k\Delta x, \Delta y + y_k)$, and $(k\Delta x, y_k)$, we solve the following mixed problem:

$$\begin{cases} (W_k)_x + H(W_k)_y = 0, \\ W_k|_{x=k\Delta x} = W_k^0, \\ (u_k, v_k)\cdot \overrightarrow{n_k}\,|_{\Gamma_k} = 0 \end{cases} \tag{4.5}$$

in rhombus $T_{k,0}$. If this problem is solvable, then define $\tilde{U} = \Psi^{-1}(W_k)$.

By Lemma 3.2, if $W_k^0 \in \Psi(B)$ and the turning angle is small enough, this problem admits a unique admissible solution; moreover, we can find out a unique $\epsilon_{k,0,1}$ and a constant state $U_{k,0}$ such that

$$U_{k,0} = \Phi(0, \epsilon_{k,0,1}, U_{k,-1}) \tag{4.6}$$

and

$$U_{k,0} \cdot \overrightarrow{n_k}\,|_{\Gamma_k} = 0, \tag{4.7}$$

$$W_k = \Psi(U_{k,0}) \quad \text{in some neighborhood of} \quad \Gamma_k. \tag{4.8}$$

By these solutions we can get the global approximate solution defined in $\Omega_{\Delta x}$. From the discussion above we have the following lemma.

LEMMA 4.2. *For each $k \geq 0$ there exists an $n(k) < 0$ such that*

$$U_{k,n} = U_\infty \quad \forall n < n(k). \tag{4.9}$$

LEMMA 4.3. *If $\{U_l, U_r\} = (\alpha, \beta)$, $U_l, U_r \in B$, then*

$$|U_l - U_r| \leq s(|\alpha| + |\beta|). \tag{4.10}$$

Here $s = \max\{|\frac{\partial}{\partial\alpha}\Phi(\beta,\alpha,U)|, |\frac{\partial}{\partial\beta}\Phi(\beta,\alpha,U)||U \in \bar{H}, |\beta| + |\alpha| \leq \delta_4'\}$.

Throughout the paper we define $U_k(k\Delta x, a_{k,n}) = U_{k,0}$ if $n \geq 0$ for simplification. Then it is obvious that $\epsilon_{k,n,1} = \epsilon_{k,n,2} = 0$ for $n \geq 0$ and $k \geq 0$.

Next we can define the Glimm functional for the approximate solution in $\Omega_{\Delta x}$.

Denote by $U_{\Delta x,\theta}$ the approximate solution constructed above and $W_{\Delta x,\theta} = \Psi(U_{\Delta x,\theta})$, where $\theta = \{\theta_0, \theta_1, \ldots, \theta_k, \ldots\}$. For any mesh curve J, let Ω_J be the set of A_k that lies in J^+, that is,

$$\Omega_J = \{A_k | A_k \in J^+ \cap \partial\Omega_{\Delta x}, A_k = (k\Delta x, y_k)\};$$

denote by α_j (or β_j etc.) the jth wave from α (or β etc.) and by α_j^J (or β_j^J) the strength of α_j (β_j, resp.) wave crossing J ($j = 1, 2$), and denote $K_0 = \sup_B\{K_1, K_2, K_3, K_4\}$ and $K = 8K_0$.

DEFINITION 4.4.

$$\begin{aligned}
L_j(J) &= \sum\{|\alpha_j^J|, \quad \alpha = (\alpha_1, \alpha_2), \alpha_j \textit{ crosses } J\}, \quad j = 1, 2,\\
L_0(J) &= \sum\{|\omega(A)|, \quad A \in \Omega_J\},\\
Q_2(J) &= \sum\{\Delta(\alpha_2^J, \beta_2^J), \quad \alpha_2, \beta_2 \textit{ cross } J \textit{ and } \alpha \textit{ lies to the left of } \beta\},\\
Q_1(J) &= \sum\{\Delta(\alpha_1^J, \beta_1^J), \textit{ both of } \alpha_1, \beta_1 \textit{ cross } J \textit{ and } \alpha \textit{ lies to the left of } \beta\},\\
Q'(J) &= \sum\{|\alpha_2^J||\beta_1^J|, \quad \alpha, \beta \textit{ cross } J, \alpha \textit{ lies to the left of } \beta\},\\
Q''(J) &= \sum\{\Delta(\alpha_1^J, \beta_2^J), \alpha, \beta \textit{ cross } J, \alpha \textit{ lies to the left of } \beta\}\\
&\quad + \sum\{\Delta(\alpha_1^J, \alpha_2^J), \quad \alpha \textit{ crosses } J\},\\
Q_0(J) &= |L_2(J)|^2
\end{aligned}$$

and

$$\begin{aligned} D_2(J) &= \sum\{|\alpha_2^J||\omega(A)|, \quad \alpha_2 \textit{ crosses } J, A \in \Omega_J\} \\ &= L_2(J)L_0(J), \\ D_1(J) &= \sum\{\Delta(\alpha_1^J, \omega(A)), \quad \alpha \textit{ crosses } J, A \in \Omega_J\}, \\ D_0(J) &= \sum\{|\omega(A)|^2, \quad A \in \Omega_J\}, \\ D'(J) &= \sum\{\Delta(\omega(A), \omega(A')), \quad A, A' \in \Omega_J, A \neq A'\}. \end{aligned}$$

Definition 4.5.

$$\begin{aligned} Q(J) &= K^2Q_2(J) + 2KQ'(J) + KQ''(J) + Q_1(J) + K^2Q_0(J), \\ D(J) &= K^2D_2(J) + KD_1(J) + KD_0(J) + K^2D'(J), \\ L(J) &= KL_2(J) + L_1(J) + KL_0(J), \\ F(J) &= L(J) + c\{Q(J) + D(J)\}. \end{aligned}$$

Let $\delta(3) = \min(\delta_4, \delta_6)$ and $\delta(4) = \min(\frac{\delta(2)}{2s}, \frac{\delta_3'}{2}, \frac{\delta_5'}{2})$; then we have the following lemma.

Theorem 4.6. *Let I and J be two mesh curves satisfying $J > I$, and suppose that $|\omega(A_0)| + L_0(x = 0) < \delta(3)$ and I is contained in the domain of definition of $U_{\Delta x,\theta}$ with $U_{\Delta x,\theta}|_I \in B$. There exist constants $c > 0$ and $\delta_7 > 0$ independent of I and J such that if $L(I) < \delta_7$ then J is also contained in the domain of definition of $U_{\Delta x,\theta}$ with $U_{\Delta x,\theta}|_J \in B$ and*

$$F(J) \leq F(I). \tag{4.11}$$

Proof. We first assume J is an immediate successor to I and assume that J and I differ by a single diamond that either lies entirely in the interior of $\Omega_{\Delta x}$ or intersects the boundary of $\Omega_{\Delta x}$.

Case 1. If I and J differ by a single diamond that lies entirely in $\Omega_{\Delta x}$, then $\Omega_I = \Omega_J$. The proof can be carried out in the same way as in [13, 15] by Lemma 3.1. Namely, we can find suitable constants $\delta' \in (0, \delta(4))$ and $c' > 0$ independent of I and J such that if $c \geq c'$ and $L(I) \leq \min(\delta', \frac{1}{(K^2+K+1)c})$, then

$$\begin{aligned} &F(J) \leq F(I), \\ &F(J) \leq L(I) + c(K^2 + K + 1)L(I)^2 \leq 2L(I). \end{aligned}$$

Thus $L(J) \leq \frac{\delta(2)}{s}$ and this implies $U_{\Delta x,\theta}|_J \in B$ by Lemmas 4.2 and 4.3.

Case 2. If I and J differ by a single diamond Λ that intersects the boundary of $\Omega_{\Delta x}$, then Ω_I and Ω_J differ by a single angle ω, that is, $\Omega_I = \Omega_J \cup \{\omega\}$.

Let $I = I_0 \cup I'$ and $J = I_0 \cup J'$ with $J' = \{\epsilon_1\}$; here ϵ_1 is a 1-wave of which the strength crossing J' is ϵ_1. Denote $I_{(2)}$ (or $I_{(1)}$, resp.) the set of 2-waves (or 1-waves, resp.) crossing I. The notations $I_{0,(j)}$, $I'_{(j)}$, $J_{(j)}$, and $J'_{(j)}$ $(j = 1, 2)$ are defined in the same way. In the next notation, without confusion, we shall use $\alpha_j \in I_{*,(j)}$ to denote one j-wave from α of which the strength crossing I_* is α_j.

Define

$$\begin{aligned} Q_1(I_{0,(1)}, \epsilon_1) &= \sum\{\Delta(\beta_1, \epsilon_1), \beta_1 \in I_{0,(1)}\}, \\ Q''(I_{0,(1)}, \alpha_2) &= \sum\{\Delta(\beta_1, \alpha_2), \beta_1 \in I_{0,(1)}\}, \end{aligned}$$

and

$$D_1(I_{0,(1)},\omega)=\sum\{\Delta(\beta_1,\omega),\beta_1\in I_{0,(1)}\}.$$

Now we can carry out the proof. This case is divided into three subcases, for which only the proofs are given.

Subcase (i): If $I'_{(1)}=\{\gamma_1\}$, $I'_{(2)}=\{\alpha_2\}$, α_2 lies to the left of γ_1, then we have

$$\begin{aligned}
&L_2(J)=L_2(I)-|\alpha_2|,\\
&L_0(J)=L_0(I)-|\omega|,\\
&Q_2(J)\le Q_2(I),\\
&Q''(J)=Q''(I_0)=Q''(I)-Q''(I_{0,(1)},\alpha_2),\\
&Q_0(J)=Q_0(I)-|\alpha_2|^2-2|\alpha_2|L_2(I_0),\\
&D_2(J)=D_2(I)-|\alpha_2|L_0(I)-|\omega|L_2(I_0),\\
&D_0(J)=D_0(I)-|\omega|^2,\\
&D'(J)=D'(I)-\sum_{\omega'\in\Omega_J}\Delta(\omega,\omega');
\end{aligned}\tag{4.12}$$

moreover, by Proposition 3.3,

$$\begin{aligned}
L_1(J)\le{}& L_1(I)+K|\alpha_2|+K|\omega|\\
&+\mathrm{O}(1)\{|\alpha_2||\gamma_1|+|\alpha_2||\omega|+\Delta(\gamma_1,\omega)+|\alpha_2|^2+|\omega|^2\},
\end{aligned}\tag{4.13}$$

$$\begin{aligned}
Q_1(J)&=Q_1(I_0)+Q_1(I_{0,(1)},\epsilon_1)\\
&\le Q_1(I)+KQ''(I_{0,(1)},\alpha_2)+KD_1(I_{0,(1)},\omega)\\
&\quad+\mathrm{O}(1)L_1(I_0)\{|\alpha_2||\gamma_1|+|\alpha_2||\omega|+\Delta(\gamma_1,\omega)+|\alpha_2|^2+|\omega|^2\},
\end{aligned}\tag{4.14}$$

$$\begin{aligned}
Q'(J)&=Q'(I_0)+Q'(I_{0,(2)},\epsilon_1)\\
&\le Q'(I)-|\alpha_2||\gamma_1|+K_0|\alpha_2|L_2(I_0)+K_0|\omega|L_2(I_0)\\
&\quad+\mathrm{O}(1)L_2(I_0)\{|\alpha_2||\gamma_1|+|\alpha_2||\omega|+\Delta(\gamma_1,\omega)+|\alpha_2|^2+|\omega|^2\},
\end{aligned}\tag{4.15}$$

and

$$\begin{aligned}
D_1(J)\le{}& D_1(I)+K|\alpha_2|L_0(I)-K|\alpha_2||\omega|-D_1(I_{0,(1)},\omega)\\
&-\Delta(\gamma_1,\omega)+K\sum_{\omega'\in\Omega_J}\Delta(\omega,\omega')\\
&+\mathrm{O}(1)L_0(J)\{|\alpha_2||\gamma_1|+|\alpha_2||\omega|+\Delta(\gamma_1,\omega)+|\alpha_2|^2+|\omega|^2\}.
\end{aligned}\tag{4.16}$$

Thus by (4.12), (4.13), and Definition 4.5 we have the estimate of the linear part,

$$\begin{aligned}
L(J)\le{}& L(I)\\
&+\mathrm{O}(1)K(K+1)\{|\alpha_2||\gamma_1|+|\alpha_2||\omega|+\Delta(\gamma_1,\omega)+|\alpha_2|^2+|\omega|^2\},
\end{aligned}\tag{4.17}$$

and we can get the following estimates of quadratic terms by (4.12), (4.14), (4.15), (4.16), and Definition 4.5:

$$\begin{aligned}
Q(J)\le{}& Q(I)-2K|\gamma_1||\alpha_2|-K^2|\alpha_2|^2\\
&+2K_0K|\omega|L_2(I_0)+KD_1(I_{0,(1)},\omega)\\
&+\mathrm{O}(1)L(I)\{|\alpha_2||\gamma_1|+|\alpha_2||\omega|+\Delta(\gamma_1,\omega)+|\alpha_2|^2+|\omega|^2\}
\end{aligned}\tag{4.18}$$

and

$$\begin{aligned}D(J) \le D(I) &- K^2|\alpha_2||\omega| - K\Delta(\gamma_1,\omega)\\ &- K^2|\omega|L_2(I_0) - K|\omega|^2 - KD_1(I_{0,(1)},\omega)\\ &+ \mathrm{O}(1)L(I)\{|\alpha_2||\gamma_1| + |\alpha_2||\omega| + \Delta(\gamma_1,\omega) + |\alpha_2|^2 + |\omega|^2\};\end{aligned} \tag{4.19}$$

then it follows that

$$\begin{aligned}F(J) \le F(I) &+ (\mathrm{O}(1)L(I)c + \mathrm{O}(1) - (\min(K^2,K))c)\\ &\cdot \{|\alpha_2||\gamma_1| + |\alpha_2||\omega| + \Delta(\gamma_1,\omega) + |\alpha_2|^2 + |\omega|^2\}.\end{aligned} \tag{4.20}$$

Thus we can choose suitable constants $\delta'' \in (0,\delta(4))$ and $c'' > 0$ independent of I and J such that if $c \ge c''$ and $L(I) \le \min(\delta'', \frac{1}{(K^2+K+1)c})$, then

$$\begin{aligned}&F(J) \le F(I),\\ &F(J) \le L(I) + c(K^2+K+1)L(I)^2 \le 2L(I)\end{aligned}$$

and the second inequality implies $U_{\Delta x,\theta}|_J \in B$. This proves subcase (i). There are still two more subcases.

Subcase (ii): If no wave enters Λ, then the same result follows by Lemma 3.2.

Subcase (iii): If there is only a 1-wave entering Λ, the result can be proved in the same way as above by Lemma 3.2 and Proposition 3.3.

Therefore we get the desired result for the case that J is an immediate successor to I. Thus, for the general case, we can pass from I to J by immediate successors, where at each stage F are monotonic nonincreasing and $L \le \min(\delta', \delta'', \frac{1}{(K^2+K+1)c})$ for $c \ge \max(c', c'')$ and where $U_{\Delta x,\theta}$ can be defined and $U_{\Delta x,\theta} \in B$. This proves the desired result. □

Let

$$\omega(0) = \arctan(b'(0)),$$

$$\omega(x_k) = \arctan(b'(x_k+)) - \arctan(b'(x_k-)),$$

and

$$\tau(x) = \frac{b''(x)}{1+(b'(x))^2};$$

then as a corollary of Theorem 4.6 we have the following theorem.

Theorem 4.7. *There exists a* $\delta_0' > 0$ *such that if*

$$|\omega(0)| + \sum_{k=1}^{l}\left(\int_{x_{k-1}}^{x_k} |\tau(x)|dx + |\omega(x_k)|\right) < \delta_0',$$

then there exists a constant $\delta_0'' > 0$ *depending on the function* $b(x)$ *and* δ_0' *such that if* $0 < \Delta x \le \delta_0''$, *then* $U_{\Delta x,\theta}$ *can be defined in* $\Omega_{\Delta x}$ *and Theorem* 4.6 *holds. In addition* $\bigvee_{-\infty}^{y_k}(U_{\Delta x,\theta}(k\Delta x-,\cdot)) \le 3s\delta_0'$ *for any* $k > 0$. *Here the constant* s *is given in Lemma* 4.3 *and* $\bigvee_a^b(w)$ *denotes the total variation of* w *on* $[a,b]$.

5. Convergence of the approximate solution. By (4.8) and (4.9) we can extend $U_{\Delta x,\theta}$ by the constant $U_{k,0}$ continuously across the boundary to the whole strip $\{k\Delta x < x < (k+1)\Delta x\}$ for every $k \geq 0$.

Let the line $\{x = a\}$ intersect $\cup_{k\geq 0}\bar{\Gamma}_k = \cup\{A_{k-1}A_k, k \geq 1\}$ at the point $(a, p_a^{\Delta x})$ for $a > 0$, $y_{n,k} = (2n+1)\Delta x + y_k$, then we have the following lemma.

Lemma 5.1. *The inequality*

$$\int_{-\infty}^{0} |U_{\Delta x,\theta}(x+h, y+p_{x+h}^{\Delta x}) - U_{\Delta x,\theta}(x, y+p_x^{\Delta x})|dy \leq c|h| \tag{5.1}$$

holds for any $h > 0$ and $x > 0$, where the constant c is independent of Δx, θ, and h.

Proof. First by the solution to Riemann problem given in [8], if $k\Delta x \leq x < x + h \leq (k+1)\Delta x$ and $n \leq -1$, we can get

$$\begin{aligned}&\int_{y_{n,k}}^{y_{n+1,k}} |U_{\Delta x,\theta}(x+h, y+p_{x+h}^{\Delta x}) - U_{\Delta x,\theta}(x, y+p_x^{\Delta x})|dy \\ &\qquad \leq c''' \left[\bigvee_{y_{n,k}}^{y_{n+1,k}} (U_{\Delta x,\theta}((k+1)\Delta x-, \cdot))\right] |h|;\end{aligned} \tag{5.2}$$

moreover, by the solution to the mixed problem given in Proposition 3.3,

$$\begin{aligned}&\int_{y_{0,k}}^{y_k} |U_{\Delta x,\theta}(x+h, y+p_{x+h}^{\Delta x}) - U_{\Delta x,\theta}(x, y+p_x^{\Delta x})|dy \\ &\qquad \leq c''' \left[\bigvee_{y_{0,k}}^{y_k} (U_{\Delta x,\theta}((k+1)\Delta x-, \cdot))\right] |h|.\end{aligned} \tag{5.3}$$

Here c''' is a universal constant independent of Δx, θ, and h.

After doing the summation over (5.2) and (5.3), we obtain the estimate by Theorem 4.7.

The general case can be derived by summation over the estimates in each semistrip of $\{k\Delta x \leq x \leq (k+1)\Delta x\}$ and the CFL condition. The proof is complete. □

Lemma 5.2. *If $w \in BV(R^1)$, then*

$$\int_a^b |w(t+h) - w(t)|dt \leq 6 \left[\bigvee_{-\infty}^{+\infty} (w) + |w|_{L^\infty}\right] |h|. \tag{5.4}$$

Proof. It suffices to prove the lemma for $h \geq 0$. Let $g(t) = \bigvee_{-\infty}^{t}(w) - w(t)$ and $f(t) = \bigvee_{-\infty}^{t}(w)$; then $g(t)$ and $f(t)$ are monotonically nondecreasing. Thus we have

$$\begin{aligned}\int_a^b |w(t+h) - w(t)|dt &\leq \int_a^b (f(t+h) + g(t+h))dt - \int_a^b (f(t) + g(t))dt \\ &= \left(-\int_a^{a+h} + \int_b^{b+h}\right)(f(t) + g(t))dt.\end{aligned}$$

This implies (5.4). □

Lemma 5.3. *There holds $|p_{a+h}^{\Delta x} - p_a^{\Delta x}| \leq c|h|$ for any $a \geq 0$ and $h \geq 0$. Here $c = \sup\{|b'(x+)||x \geq 0\}$.*

This result can be derived by direct caculation.

By these lemmas and Lemma 4.2 and Theorem 4.7 we can get the following.

PROPOSITION 5.4. *If $|h|+|l|\le 1$, $D\subseteq\Omega$ is compact, then*

$$\int\int_{D\cap\overline{\Omega}_{\Delta x}}|U_{\Delta x,\theta}(x+h,y+l)-U_{\Delta x,\theta}(x,y)|dxdy\le c(|h|+|l|) \tag{5.5}$$

with the constant c independent of Δx, θ, h, and l.

Set

$$J(\theta,\Delta x,\phi)=\sum_{k=1}^{+\infty}\int_{-\infty}^{0}\phi(k\Delta x,y+y_k)\cdot[U_{\Delta x,\theta}]|_{x=k\Delta x}dy \tag{5.6}$$

with $\phi=(\phi_1,\phi_2)\in C_c^\infty(R^2,R^2)$. Carrying out the same step as in Smoller [15], we have the following proposition.

PROPOSITION 5.5. *There is a null set $N\subset\prod_{k=0}^{+\infty}[-1,1]$ and a sequence $\Delta x_i\xrightarrow[i\longrightarrow+\infty]{}0$, and a $U\in L^1_{loc}(\Omega)\cap L^\infty(\Omega)$ with $U|_{x\le0}=(q_\infty,0)$ such that $J(\theta,\Delta x_i,\phi)\xrightarrow[i\longrightarrow+\infty]{}0$ and $U_{\Delta x_i,\theta}\xrightarrow[i\longrightarrow+\infty]{}U$ strongly in $L^1_{loc}(\Omega\cap\{x\ge0\})$ for any $\theta\in(\prod_{k=0}^{+\infty}[-1,1])\backslash N$ and $\phi_1,\phi_2\in C_c^\infty(R^2)$.*

Now we can establish the global existence.

THEOREM 5.6. *Under the assumptions* (A1), (A2), *and* (A3), *there exists a $\delta_0>0$ such that if $|\omega(0)|+\sum_{k=1}^{l}(\int_{x_{k-1}}^{x_k}|\tau(x)|dx+|\omega(x_k)|)<\delta_0$, the problem* (1.1) *admits a global weak solution in Ω.*

Proof. Choose $\delta_0'>0$ and $\delta_0''>0$ such that Theorem 4.7 holds and let $W=\Psi(U)$ and $U_{\Delta x,\theta}=(u_{\Delta x,\theta},v_{\Delta x,\theta})$ be the approximate solution constructed above.

For any $\phi_2\in C_c^\infty(\Omega)$, there exists a $\delta_0'''\in(0,\delta_0'')$ such that if $\Delta x<\delta_0'''$, then

$$\text{supp}\phi_2\cap\partial\Omega_{\Delta x}=\emptyset. \tag{5.7}$$

So doing the calculation in each rhombus for $\phi_1\in C_c^\infty(R^2)$ and $\phi_2\in C_c^\infty(\Omega)$ and $\Delta x<\delta_0'''$ we have

$$\int_{\Omega_{\Delta x}}W_{\Delta x,\theta}\cdot\phi_x+H(W_{\Delta x,\theta})\phi_y+J(\Delta x,\theta,\phi)=\int_{-\infty}^{0}\rho_\infty q_\infty\phi_1(0,y)dy, \tag{5.8}$$

where $\phi=(\phi_1,\phi_2)$.

Since $|u_{\Delta x,\theta}|\le M$ and $|v_{\Delta x,\theta}|\le M$ for some M by Theorem 4.7 and Lemma 4.2 and

$$\text{mes}(\text{supp}\phi_1\cap\{(\Omega\backslash\Omega_{\Delta x})\cup(\Omega_{\Delta x}\backslash\Omega)\}\cap\{x\ge0\})\xrightarrow[\Delta x\longrightarrow0]{}0,$$

we have

$$\begin{aligned}&\left|\int_{\Omega^+}(W_{\Delta x,\theta}\phi_x+H(W_{\Delta x,\theta})\phi_y)-\int_{\Omega_{\Delta x}}(W_{\Delta x,\theta}\phi_x+H(W_{\Delta x,\theta})\phi_y)\right|\\&\quad\le\int_{(\Omega_{\Delta x}\backslash\Omega^+)\cup(\Omega^+\backslash\Omega_{\Delta x})}|W_{\Delta x,\theta}||\phi_x|+|H(W_{\Delta x,\theta})||\phi_y|\xrightarrow[\Delta x\longrightarrow0]{}0,\end{aligned} \tag{5.9}$$

where $\Omega^+=\Omega\cap\{x\ge0\}$.

Moreover, according to Propositions 5.4 and 5.5, we can find sequences $\Delta x_i \longrightarrow 0$, $\theta \in N$, and U such that $U_{\Delta x_i,\theta} \longrightarrow U$ strongly in L^1_{loc} as $\Delta x_i \longrightarrow 0$ and $J(\theta, \Delta x_i, \phi) \xrightarrow[i \longrightarrow +\infty]{} 0$. Then from (5.8), (5.9), and the discussion in section 4 it follows that U is a weak solution to (1.1) in Ω.

The proof is complete. □

Remark 5.7. In the same way we can also construct a global solution U_+ in Ω_+. Here Ω_+ denote the subdomain of $\{y > 0\}$ that is outside the right half of the wedge. Denote

$$U = \begin{cases} U_+(x, y), & (x, y) \in \Omega_+, \\ U_-(x, y), & (x, y) \in \Omega, \end{cases}$$

and from the structure of the solution we know that U is the desired solution.

Acknowledgment. The author thanks referees for helpful and encouraging comments.

WAVELETS ON MANIFOLDS I: CONSTRUCTION AND DOMAIN DECOMPOSITION*

WOLFGANG DAHMEN† AND REINHOLD SCHNEIDER‡

Abstract. The potential of wavelets as a discretization tool for the numerical treatment of operator equations hinges on the validity of norm equivalences for Besov or Sobolev spaces in terms of weighted sequence norms of wavelet expansion coefficients and on certain cancellation properties. These features are crucial for the construction of optimal preconditioners, for matrix compression based on sparse representations of functions and operators as well as for the design and analysis of adaptive solvers. However, for realistic domain geometries the relevant properties of wavelet bases could so far only be realized to a limited extent. This paper is concerned with concepts that aim at expanding the applicability of wavelet schemes in this sense. The central issue is to construct wavelet bases with the desired properties on manifolds which can be represented as the disjoint union of smooth parametric images of the standard cube. The approach considered here is conceptually different though from others working in a similar setting. The present construction of wavelets is closely intertwined with a suitable characterization of function spaces over such a manifold in terms of product spaces, where each factor is a corresponding local function space subject to certain boundary conditions. Wavelet bases for each factor can be obtained as parametric liftings from bases on the standard cube satisfying appropriate boundary conditions. The use of such bases for the discretization of operator equations leads in a natural way to a conceptually new domain decomposition method. It is shown to exhibit the same favorable convergence properties for a wide range of elliptic operator equations covering, in particular, also operators of nonpositive order. In this paper we address all three issues, namely, the characterization of function spaces which is intimately intertwined with the construction of the wavelets, their relevance with regard to matrix compression and preconditioning as well as the domain decomposition aspect.

Key words. topological isomorphisms, Sobolev spaces on manifolds, norm equivalences, complementary boundary conditions, biorthogonal wavelet bases, domain decomposition, boundary integral equations

1. Introduction.

1.1. Motivation and perspectives.

Thus far wavelet concepts have unfolded their full computational efficiency mainly when dealing with problems defined on the full Euclidean space or the torus. This is to a great extent due to the fact that in this setting wavelets as discretization tools exhibit some remarkable features.

(I) Wavelet expansions induce *isomorphisms* between *function* and *sequence* spaces [39], that is, certain *Sobolev or Besov norms* of functions are equivalent to weighted *sequence norms* for the coefficients in their wavelet expansions. Specifically, denoting for $s \in \mathbb{R}$ by H^s a scale of Sobolev spaces (possibly incorporating homogeneous boundary conditions), such norm equivalences

have the form

$$c\|\{2^{js}d_{j,k}\}_{j,k}\|_{\ell_2} \leq \|\sum_{j,k} d_{j,k}\psi_{j,k}\|_{H^s} \leq C\|\{2^{js}d_{j,k}\}_{j,k}\|_{\ell_2} \tag{1.1.1}$$

for some range of s.

(II) The wavelets have *cancellation* properties that are usually expressed in terms of *vanishing polynomial moments.*

(I) has immediate important consequences for *preconditioning* systems stemming from elliptic operator equations [19, 17, 32] of positive or even nonnegative order depending on the range of the norm equivalences. In particular, when dealing with operators of negative order, it is important to realize the validity of such norm equivalences as well as for *negative* Sobolev indices $s < 0$ in (1.1.1) in which case the space H^s is understood to be the *dual* of H^{-s}. This latter case has to be treated with some care which we will briefly explain now because this will identify more specific requirements on the wavelet bases.

On the one hand, recall that when $s < 0$, (1.1.1) is proved by establishing an analogous relation for H^{-s} and a *dual* basis $\{\tilde{\psi}_{j,k}\}_{j,k}$. More precisely, suppose that the $\psi_{j,k}$ and $\tilde{\psi}_{j,k}$ are *biorthogonal* with respect to some L_2 inner product $(\cdot,\cdot)$ and that $g := \sum_{j,k} d_{j,k}\psi_{j,k}$ is an element of L_2. Then for (1.1.1) to hold, g has to be identified with a *functional* in H^s. In principle, this can be done through *any* L_2 inner product $\langle\cdot,\cdot\rangle$ by $g(v) := \langle g, v\rangle$ provided that the inner products $(\cdot,\cdot)$ and $\langle\cdot,\cdot\rangle$ are s-equivalent. By this we mean that the Riesz map $R : L_2 \to L_2$ defined by $(\cdot,\cdot) = \langle R\cdot,\cdot\rangle$ not only is an automorphism on L_2 but also extends to one on H^s, i.e., $\|g\|_{H^s}$ and $\|Rg\|_{H^s}$ are equivalent for $g \in L_2$.

On the other hand, the relevance of (1.1.1) for preconditioning stiffness matrices of an operator $\mathcal{L}$ with respect to the wavelet basis hinges on its *H^s-ellipticity.* Specifically, when $\langle\mathcal{L}v, v\rangle$ is equivalent to $\|v\|_{H^s}^2$ for some L_2 inner product $\langle\cdot,\cdot\rangle$, this in turn *determines* how to embed L_2 into H^s for $s < 0$, namely, (up to s-equivalence) through the particular inner product $\langle\cdot,\cdot\rangle$ appearing in the variational formulation of the operator equation [16, 19]. In summary, in order to draw conclusions on preconditioning, it is therefore important to construct biorthogonal wavelet bases not with respect to *any convenient* inner product but to one that is compatible with the underlying variational problem. Since this involves usually the standard L_2 inner product, this is the primary choice considered in this paper.

(II) entails that functions which are smooth except on lower dimensional manifolds have *nearly sparse* wavelet representations. By this we mean that only relatively few coefficients are needed to approximate such a function with desired accuracy. Moreover, applying this principle to the (singular) kernels of a wide class of integral or pseudodifferential operators leads to nearly sparse matrix representations of such operators [5]. This provides the basis for matrix compression schemes whose analysis relies again on (I) and (II). The norm equivalences allow one to transform the continuous problem into a discrete problem that is well posed in the Euclidean metric. In fact, one can show that given the right interplay between the range of norm equivalences and the order of vanishing moments one can, in principle, design efficient solvers which produce approximate solutions with *asymptotically optimal accuracy* at the expense of computational and storage cost that stays *proportional* to the problem size [19, 20, 23, 45].

Again the combination of (I) and (II) (respectively, the consequences with regard to matrix compression) also provides the basis for a rigorous analysis of *adaptive schemes* for elliptic equations. In fact, the analysis of refinement strategies based on *a* *posteriori error estimates* for residuals exploit both (I) and (II) [13, 11]. In particular, convergence in the energy norm can be proved without a priori assumptions on the solution like those commonly needed in a finite element context [6].

Moreover, *nonlinear approximation* is an important theoretical concept related to adaptive approximation. The accuracy that can be achieved by so-called *best N-term approximation* can be characterized in terms of the membership of the approximand to a certain *Besov space* [25]. It is again important to characterize such spaces in terms of discrete norm equivalences.

These facts have motivated various attempts to exploit this potential for the numerical treatment of operator equations. However, the above-mentioned strong implications of wavelet discretizations are valid only under the *assumption* that (I) and (II) hold with appropriate choices of parameters. Unfortunately, as indicated before, so far these properties are conveniently realized within the desired range only when the underlying domain is the full Euclidean space or, via *periodization*, the torus. For more general domain geometries, the construction of appropriate wavelet bases may become prohibitively difficult and expensive.

1.2. Construction principles. Several strategies for dealing with complex domain geometries have been explored in the literature; see [16] for a brief survey and further references. One possible approach is offered by *embedding* techniques. For instance, one can extend the problem to some larger simple domain and enforce the actual boundary conditions by appending them with the aid of Langrange multipliers [36] or correct them by solving a boundary integral equation [3]. However, in both cases a multiresolution setting on the boundary, that is, on a closed manifold, would be highly desirable. This in turn cannot be treated by an embedding strategy.

However, the results in [10, 18] indicate that at least for the *interval*, and hence via tensor products for the unit n-cube, wavelet bases with all the required properties are within reach retaining nearly the full efficiency of wavelet discretizations in the classical setting. It is then fairly straightforward to go one step further. Suppose that $\Omega = \kappa(\square)$, where $\square := (0,1)^n$ and κ is a smooth regular *parametric* mapping. Wavelet bases on $\square$ can then easily be *lifted* to bases on Ω retaining the main driving mechanisms (I) and (II) (see, e.g., [21]). This in turn suggests for us to next consider domains that are *disjoint unions of smooth parametric images* of the standard n-cube $\square$ which will be the setting to be dealt with in this paper.

In fact, in many cases the domain on which the operator equation is defined can be naturally decomposed into a union of simpler domains. For instance, when the domain is a *closed surface*, on which a boundary integral equation is defined, standard CAD packages provide (approximate) representations of such surfaces as a disjoint union of *parametric images* of a standard parameter domain such as the unit square. The individual parametric *patches* are then smoothly joined up to a certain degree of regularity. This means that there exist local reparametrizations for neighboring patches so that the corresponding piecewise defined mapping has a certain number of continuous derivatives; see section 2.1. But this paradigm does not apply only to closed surfaces but also to *bounded domains* (with boundary) in Euclidean space. This is essentially the same point of view as taken in connection with *domain decomposition methods.* Thus a suitable mathematical framework covering all these cases is to view the domain as a (smooth or at least piecewise smooth) *manifold* Γ represented as the union of the disjoint images of some parameter domain. In many cases such as the closed surfaces arising in CAD or domains in CFD the parameter domain can be chosen to be a *cube.*

1.3. Previous approaches and main obstructions. In summary, as pointed out above, the construction of wavelets on manifolds in the above sense has to be intimately connected with the topology of function spaces such as Sobolev and Besov spaces defined on these manifolds. While it is known how to construct suitable bases on each individual patch the problem remains to form from such individual components bases on the *global* manifold which still satisfy (I) and (II). For Sobolev spaces of moderate regularity indices there is no problem. In fact, it is well known that

$$H^s(\Gamma) \asymp \prod_{i=1}^{N} H^s(\Gamma_i), \quad s \in (-1/2, 1/2). \tag{1.3.1}$$

Unfortunately, this is no longer true for $|s| \geq 1/2$. Thus beforehand it is not so clear how to deal with the above task. A natural first idea is to construct a global basis by somehow stitching wavelets defined on the individual patches together so as to realize a certain degree of global smoothness. This idea has been pursued first for special cases in [34, 35] and later in greater generality and in larger range concerning (I) in [21]; see also [7, 12] for slightly different subsequent approaches. However, this concept turns out to have principal limitations. First it requires a *global* parametric representation of the manifold because the wavelets living on more than one parametric patch tie the parametrizations of corresponding adjacent patches together and prohibit local reparametrizations. Hence, aside from expected enormous technical difficulties, a global regularity of a piecewise defined parametrization of higher degree than continuity can only be realized for domains that are topologically equivalent to domains in Euclidean space. Second, in all the above-mentioned cases, pairs of biorthogonal wavelet bases are constructed where biorthogonality is realized with respect to a *modified* L_2-inner product which generally involves *discontinuous* weight functions. Therefore the corresponding Riesz map relating the modified inner product to the standard one (which is simply multiplication by the weight function and hence symmetric) does not take H^s into H^s for $s \geq 1/2$ and, therefore, by duality, neither for $s \leq -1/2$. Hence, on account of the above discussion of (I), whenever ellipticity of the operator is based on using the standard inner product in the variational formulation of the operator equation, relations like (1.1.1) can in this setting be exploited only for preconditioning when $s > -1/2$ which excludes, for instance, the single layer potential operator.

For a restricted class of manifolds including the important case of piecewise affine surfaces with triangular facets, the finite element based wavelets constructed in [24] are indeed biorthogonal bases with respect to the canonical L_2-inner product. This covers the range $|s| \leq 1$, respectively, $|s| \leq 3/2$ for domains in Euclidean space with regard to (I). Moreover, in principle, cancellation properties of any desired order can be realized in this setting, however, at the expense of having explicit local dual bases available.

1.4. Main objectives. The objective of this paper is the construction of biorthogonal wavelet bases with the following properties:

(i) Biorthogonality is realized with respect to some *given* L_2-inner product which in absence of further information will be the canonical one. Both primal and dual wavelets have compact support whose size scales in the usual way.

(ii) The construction applies to manifolds of essentially arbitrary topology.

(iii) Properties (I) and (II) can be realized for *any* range permitted by the regularity of the manifold. In particular, (II) holds in a *patchwise* sense.

Our approach is conceptually different from all the other above mentioned ones. The construction of wavelets will be intimately intertwined with a suitable characterization of function spaces on manifolds. One noteworthy consequence is that a *global* parametric representation of the manifold is never needed so that topology dependent regularity constraints do not arise. We will briefly comment now on these issues.

The basic difficulty is that function spaces on manifolds are usually defined in terms of *open coverings* and associated charts [1], not in terms of *partitions* of the manifold. However, in principle, characterizations of Sobolev and Besov spaces on compact C^∞-manifolds Γ (with or without boundary) of the latter sort have been established in [9]. These results provide the main foundation for the present investigation. The key there is to establish *topological isomorphisms*

$$T : H^s(\Gamma) \to \prod_{i=1}^{N} H^s(\Gamma_i)^\uparrow \tag{1.4.1}$$

between the *global* function space on Γ and a *product* space whose components $H^s(\Gamma_i)^\uparrow$ are corresponding local function spaces defined on the (smooth) patches Γ_i but subject to certain *boundary conditions*. Moreover, in [9] unconditional bases for the individual component spaces were constructed which, with the aid of the previously mentioned isomorphism, lead to discrete norms for the global space. It is important to note that the range of s for which (1.4.1) holds is limited only by the regularity of the manifold.

In full recognition of the fundamental importance of the results in [9] one should note though that the main emphasis has been the *existence* of unconditional bases for function spaces on compact C^∞-manifolds. The existence and structure of the isomorphisms as well as the construction of bases is embedded in a rather involved development. For instance, due to lack of locality and concrete transformation devices which are typical and essential for wavelet schemes, the bases constructed in [9] as well as several constructive ingredients do not yet seem to be practically feasible.

Therefore we will take up the basic concept from [9] here again. Trying first to isolate the relevant ingredients from [9], we realized that, on the one hand, the exposition would be hardly accessible without a complete understanding of [9] and, on the other hand, several crucial deviations from [9] that are necessary from a practical point of view, would not be well founded. Of course, in the above mentioned context one has to deal with less smooth manifolds covering the case of piecewise smooth but globally Lipschitz manifolds.

Thus a first objective of this paper is to rederive topological isomorphisms of the form (1.4.1) in a way that clearly isolates the essential ingredients in a possibly constructive fashion in order to facilitate their adaptation to the computational needs of the concrete problem at hand. A necessary essential prerequisite turns out to be the clear identification of conditions *solely* imposed on certain extension operators so that the rest becomes completely constructive offering clear strategies for further problem dependent modifications. The construction of *scale-dependent* completely *localized* extensions based on suitable local biorthogonal wavelet bases for the parameter domain is one essential distinction of the present approach from the treatment of the desired topological isomorphisms in [9].

The second objective is to reveal the implications of these concepts with regard to the numerical treatment of operator equations. Again appropriate pairs of biorthogonal wavelet bases on the parameter domain play a pivotal role. Together with (1.4.1) they give rise to wavelet bases on the manifold which have optimal localization properties and satisfy requirements (I) and (II) above for any desired range of regularity (permitted by the manifold) and any desired order of cancellation properties. The main consequences for issues like preconditioning and matrix compression will be indicated along with some computational aspects, especially in the context of boundary integral equations. An important point is to reinterpret (1.4.1) as a *domain decomposition method* which appears to differ from those studied in the literature so far and whose convergence properties based on the preceding analysis is now well understood also for operators with global Schwartz kernel.

1.5. Organization of material. Section 2 is devoted to the construction of the isomorphisms T from (1.4.1) which is based on certain projections P_i onto the component spaces. In contrast to [9] we begin with a concrete recursive definition of these projections based on certain *extension* operators from the patches Γ_i to certain neighborhoods. It will be seen that the topological properties of T are completely determined by the topological properties of these extensions and their adjoints.

In section 3 we construct wavelet bases on the manifold which satisfy (I) and (II) for any desired range of regularity permitted by the manifold. We know from [19] that the efficient treatment of boundary integral equations by wavelet schemes requires the option of choosing the order of vanishing moments *higher* than the order of accuracy of the trial spaces. Therefore we employ the concept of *biorthogonal bases* rather than *orthonormal* ones. On account of (1.4.1), the construction of wavelets on the manifold reduces to constructing wavelet bases for the individual component spaces $H^s(\Gamma_i)^{\uparrow}$. Due to the smoothness of the parametric mappings onto each patch Γ_i this can easily be achieved by *lifting* corresponding wavelet bases defined on the unit cube $\square$. At this point we can resort to the results in [22], where exactly those wavelet bases with the right *complementary boundary conditions on the primal and dual side* have been constructed.

Recall that aside from these bases for the component spaces the second ingredient, which the practical feasibility of the approach is ultimately based upon, are suitable extension operators. Therefore special attention will be paid to the realization of appropriate extension operators. Deviating from the developments in [9] we show in section 4 how the multiscale bases on $\square$ can be used to construct *scale-dependent* extension operators that will be seen to significantly improve the efficiency of wavelet schemes for operator equations.

The discretization of operator equations is briefly addressed in section 5. Roughly speaking, (1.4.1) allows one to reformulate a given linear operator equation on Γ as an $N \times N$ *system* of operator equations on the product space. Moreover, when the original operator is self-adjoint and positive definite, the system can be solved iteratively in the spirit of *Schwarz iterations.* In fact, the convergence rate can then be shown to be independent of the discretizations in the individual product spaces provided appropriate wavelet bases are employed. This framework covers differential as well as integral operators. As far as we know this extends the present state of the art for domain decomposition in connection with integral operators significantly. Moreover, due to the validity of (I) and (II), the understanding of adaptive techniques [13, 11] can be fully exploited in this setting. The formulation as a Schwarz iteration has another important practical consequence. For instance, when the operator under consideration only has a global Schwartz kernel, one can choose the extensions in a way that for actual computations the wavelets on Γ *never* have to be determined explicitly. *All* computations refer to problems defined on $\square$ and thus involve wavelet bases defined on $\square$. Moreover, parallel techniques suggest themselves in a natural way.

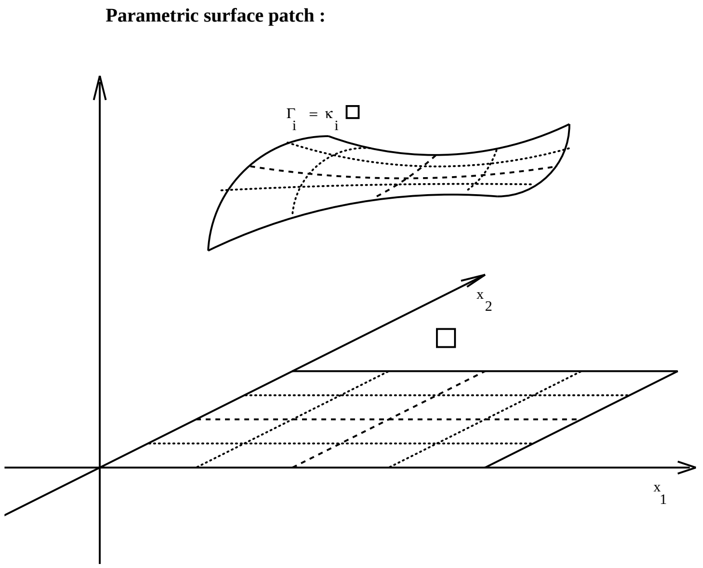

FIG. 1. *Local parametrization.*

2. Function spaces on manifolds.

2.1. Piecewise parametric representations of manifolds. In practical applications, surfaces or manifolds are usually *parametrically* piecewise defined. More precisely, denoting by

$$\square = (0,1)^n,$$

the standard parameter domain, we will assume that

$$\overline{\Gamma}_i = \bigcup_{i=1}^{N} \overline{\Gamma}_i, \quad \Gamma_i = \kappa_i(\square), \quad i = 1, \dots, N, \tag{2.1.1}$$

where

$$\Gamma_i \cap \Gamma_j = \emptyset, \quad i \neq j,$$

and the $\kappa_i : \mathbb{R}^n \to \mathbb{R}^{n'}$, $n \leq n'$ are smooth *regular* parametrizations; see Figure 1. In particular, this means that the induced Lebesgue measures $|\partial\kappa_i(x)|dx = d\mu(\kappa_i(x))$ satisfy

$$c_1 \leq |\partial\kappa_i(x)| \leq c_2, \quad x \in \square \tag{2.1.2}$$

for some positive finite constants c_1, c_2. In most practical situations the regularity of the individual parametric mappings exceeds the global regularity of the manifold. In all currently available surface modeling schemes the κ_i are polynomial or rational mappings of low degree; see, e.g., [31]. The partition of Γ into the patches Γ_i is always supposed to be *conforming*. That is, $\overline{\Gamma}_i \cap \overline{\Gamma}_l$ is either empty or the full parametric image of some lower dimensional face of $\square$ under κ_i and κ_l; see Figure 2.

Moreover we will always assume that Γ is (globally) $C^{m,1}$ for some $m \in \mathbb{N}_0$, $\mathbb{N}_0 := \{0, 1, 2, \dots\}$. Thus Γ coincides locally with the graph of an m times differentiable function with Lipschitz continuous mth order derivatives. It is important to

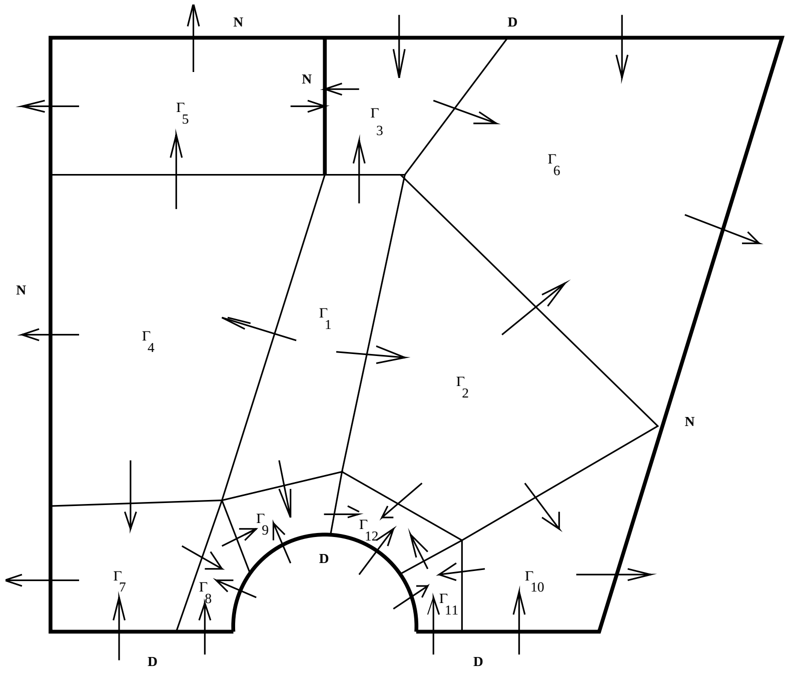

FIG. 2. *Domain with boundary conditions.*

note that in contrast to [12, 7, 21] the individual parmetrizations κ_i are fairly independent of each other. In fact, the factors in the product space on the right-hand side of (1.4.1) are invariant under regular reparametrizations of the patches Γ_i. Therefore each mapping κ_i should rather be viewed as a *representative* of the equivalence class of all parametrizations of Γ_i which are related to κ_i through a $C^{m,1}$-regular reparametrization. The freedom of choosing suitable local reparametrizations will be essential for overcoming topological constraints. Only later in section 4.1 one way of realizing certain extension operators will require a mild local interrelation of the parametrizations of neighboring patches. Roughly speaking, what matters then is the ability of forming for every Γ_i through suitable reparametrizations a piecewise defined $C^{m,1}$-homeomorhic mapping from a neighborhood of $\square$ in $\mathbb{R}^n$ onto a neighborhood of Γ_i; see section 4.1 for more details.

One should also note, however, that the above assumptions are to provide at this point primarily a conceptually convenient basis for the following theoretical developments. In typical practical situations Γ is usually not *given* in the above way but one rather has to *construct* (or approximate) Γ by properly stitching together individual parametric patches in such a way that a certain desired global smoothness is realized. Whenever the patch complex corresponds to a Cartesian grid structure one can employ parametric mappings based on tensor products of univariate sufficiently smooth splines. Of course, in general one encounters *singular vertices*, which means that at such a vertex a number of cubical patches meet that is different from 2^n. It is then much less obvious how to find a piecewise defined parametrization for the union of these patches such that each component of the parametric mapping is $C^{m,1}$. For a general treatment of this question as well as for concrete constructions we refer, for instance, to [30, 27, 31].

The construction of patch complexes such that suitable reparametrizations of some of the patches form local piecewise defined componentwise smooth parametric representations of parts of the surface is a central theme in computer aided geometric design (CAGD) and we will draw upon the techniques developed in this community. This has been primarily developed for surfaces ($n = 2$) which corresponds to the most relevant case with regard to boundary integral equations. Concrete practicable schemes for modeling $C^{m,1}$-surfaces of *arbitrary topology* are by now known for $m = 0, 1, 2$. (Although it is in principle clear how to proceed for higher degrees of smoothness as well.) Typical mild provisions (not imposing any topological constraints) are that singular vertices are sufficiently separated in the patch complex which can always be achieved by dyadic subdivisions of a complex that might initially not meet this requirement; see [31, 42, 44].

2.2. Parametric lifting. We will always assume that Γ is endowed with the induced Lebesgue measure $d\mu$ and $L_0(\Gamma)$ denotes the space of measurable functions on Γ equipped with the topology of convergence in measure on compact sets. By $\langle\cdot,\cdot\rangle_\Gamma$, or more generally, for $\Gamma' \subset \Gamma$, by

$$\langle u, v\rangle_{\Gamma'} = \int\limits_{\Gamma'} u(x)v(x)\,\mathrm{d}\mu(x)$$

we will denote the corresponding L_2-inner product on Γ, Γ', respectively.

We will be concerned with function spaces $\mathcal{F}(\Gamma') \subset L_0(\Gamma')$, $\Gamma' \subset \Gamma$, of the form $\mathcal{F}(\Gamma') = H^s(\Gamma')$ or $\mathcal{F}(\Gamma') = B^s_q(L_p(\Gamma'))$, where $H^s(\Gamma')$, $B^s_q(L_p(\Gamma'))$ denote Sobolev and Besov spaces on Γ', respectively. Here the regularity index s for which these spaces are canonically defined depends on the regularity of the domain Γ'. In particular, under the above assumptions of Γ we have

$$0 \le s \le m + 1 \quad \text{for} \quad m \in \mathbb{N}_0; \tag{2.2.1}$$

see, e.g., [29]. Let s_Γ denote the supremum of all admissible regularity indices. Throughout the following $s < s_\Gamma$ will be fixed in connection with the interpretation of $\mathcal{F}$. The *duals* of $\mathcal{F}(\Gamma')$ (with respect to the duality pairing $\langle\cdot,\cdot\rangle_{\Gamma'}$) will be denoted by $\mathcal{F}^*(\Gamma')$.

The spaces $\mathcal{F}(\Gamma')$ are usually defined via an atlas and partition of unity by lifting corresponding spaces defined on open domains in $\mathbb{R}^n$ [1, 29]; see, e.g., [4, 26] for the definition of these spaces on domains in $\mathbb{R}^n$.

When $\Gamma' = \Gamma_i$, the situation is particularly simple. We record the following observations for later use. To this end, we will briefly write $a \lesssim b$ to express that a can be bounded by a constant multiple of b uniformly with respect to any parameters on which a and b may depend. Moreover, $a \sim b$ means that $a \lesssim b$ and $b \lesssim a$.

Remark 2.2.1. *Let*

$$g_i := |\partial\kappa_i(\kappa_i^{-1}(\cdot))|. \tag{2.2.2}$$

Then setting

$$(u, v)_i := \langle u \circ \kappa_i, v \circ \kappa_i\rangle_\Box, \tag{2.2.3}$$

one has

$$(g_i u, v)_i = \langle u, v\rangle_{\Gamma_i} = \langle|\partial\kappa_i| u \circ \kappa_i, v \circ \kappa_i\rangle_\Box. \tag{2.2.4}$$

By (2.1.2), one has

$$c_1 \leq g_i(x) \leq c_2, \quad x \in \Gamma_i, \tag{2.2.5}$$

so that

$$(v,v)_i \sim \langle v,v\rangle_{\Gamma_i}, \quad v \in L_2(\Gamma_i). \tag{2.2.6}$$

REMARK 2.2.2. *The bilinear form*

$$(u,v) := \sum_{i=1}^{N} (u,v)_i \tag{2.2.7}$$

defines a scalar product for $L_2(\Gamma)$ *such that*

$$\|\cdot\|_{L_2(\Gamma)} \sim (\cdot,\cdot)^{1/2}. \tag{2.2.8}$$

Hence any Riesz basis in $L_2(\Gamma)$ *has a dual with respect to* $(\cdot,\cdot)$ *which also belongs to* $L_2(\Gamma)$.

For any $\Gamma' \subset \Gamma$, the space $\mathcal{F}(\Gamma')$ is defined as the *quotient space* normed by

$$\|g\|_{\mathcal{F}(\Gamma')} := \inf_{f \in \mathcal{F}(\Gamma), f|_{\Gamma'} = g} \|f\|_{\mathcal{F}(\Gamma)}. \tag{2.2.9}$$

We will make use of the following familiar fact; see, e.g., [29].

REMARK 2.2.3. *Assume that* w *is any smooth function on* Γ' *satisfying* (2.2.5). *Then*

$$\|f\|_{\mathcal{F}} \sim \|wf\|_{\mathcal{F}}, \quad f \in \mathcal{F}$$

for any $\mathcal{F}$ *of the form* $\mathcal{F}(\Gamma')$, $\Gamma' \subseteq \Gamma$.

REMARK 2.2.4. *Suppose that* $\mathcal{U}$ *denotes any closed subspace of* $\mathcal{F}$. *Then for any regular parametrization* κ_i *of* Γ_i *one has*

$$\mathcal{U}(\Box) = \{v \circ \kappa_i : v \in \mathcal{U}(\Gamma_i)\} \tag{2.2.10}$$

and

$$\|v\|_{\mathcal{U}(\Gamma_i)} \sim \|v \circ \kappa_i\|_{\mathcal{U}(\Box)}, \quad v \in \mathcal{U}(\Gamma_i). \tag{2.2.11}$$

Of course, regular reparametrizations in (2.2.10) *affect only the constants in* (2.2.11) *and thus give rise to equivalent norms.*

As mentioned before, our objective is to construct topological isomorphisms of the form

$$T : \mathcal{F}(\Gamma) \to \prod_{i=1}^{N} \mathcal{F}(\Gamma_i)^{\uparrow}, \tag{2.2.12}$$

where $\mathcal{F}(\Gamma_i)^{\uparrow}$ are certain closed subspaces of $\mathcal{F}(\Gamma_i)$ which, according to Remark 2.2.4, can be fully described by subspaces of $\mathcal{F}(\Box)$. The superscript $\uparrow$ will be seen to indicate certain boundary conditions as detailed in the next section.

2.3. Numbering of patches and orientation of faces. The construction of T from (2.2.12) involves an appropriate numbering of the patches Γ_i. To construct this numbering it is useful to view the patches as vertices of a graph $\mathcal{G}$. The set of edges $\mathcal{E}$ is identified with the $(n-1)$ faces shared by adjacent patches Γ', Γ''. Any two patches having an $(n-1)$ face in common are called neighbors.

We will construct now a numbering of the vertices of $\mathcal{G}$, and based on this, an *orientation* for $\mathcal{E}$. The numbering for $\mathcal{G}$ will be defined recursively as follows. Pick any patch in $\mathcal{G}$, call it Γ_1, and define

$$\mathcal{G}_1 = \{\Gamma_1\}. \tag{2.3.1}$$

Next form a layer of *level* 2 around $\mathcal{G}_1$ by setting

$$\mathcal{G}_2 = \left\{\Gamma' \in \mathcal{G} \setminus \mathcal{G}_1 \,:\, \overline{\Gamma}_1 \cap \overline{\Gamma}' \in \mathcal{E}\right\}. \tag{2.3.2}$$

We will fix some ordering of $\mathcal{G}_2$ by setting

$$\mathcal{G}_2 = \{\Gamma_{1,i} \,:\, i = 1, \dots, \#\mathcal{G}_2\}. \tag{2.3.3}$$

Suppose now we have constructed subsets $\mathcal{G}_1, \dots, \mathcal{G}_{\ell-1}$ for some $\ell \geq 2$, where $\mathcal{G}_j$ contains all neighbors of the elements in $\mathcal{G}_{j-1} \setminus \mathcal{G}_{j-2}$. Then set

$$\mathcal{G}_\ell = \left\{\Gamma' \in \mathcal{G} \setminus \{\mathcal{G}_1 \cup \dots \cup \mathcal{G}_{\ell-1}\} \,:\, \overline{\Gamma}' \cap \overline{\Gamma}'' \in \mathcal{E},\, \Gamma'' \in \mathcal{G}_{\ell-1}\right\}. \tag{2.3.4}$$

Again assuming that the elements of $\mathcal{G}_{\ell-1}$ are indexed as $\Gamma_{\mathbf{a}}$ by some multi-integer $\mathbf{a} \in \mathbb{N}^{\ell-1}$ we set

$$\mathcal{G}_\ell = \{\Gamma_{\mathbf{a},i} \,:\, \Gamma_{\mathbf{a}} \in \mathcal{G}_{\ell-1},\, \Gamma_{\mathbf{a},i} \text{ a neighbor of } \Gamma_{\mathbf{a}}\}. \tag{2.3.5}$$

Obviously, there exists $L \in \mathbb{N}$ such that $\mathcal{G} = \mathcal{G}_1 \cup \dots \cup \mathcal{G}_L$. Now suppose that we have fixed for each ℓ a total ordering for the elements $\Gamma_{\mathbf{a}}$, $\mathbf{a} \in \mathbb{N}^\ell$, in $\mathcal{G}_\ell$ denoted by $\prec$. For any $\mathbf{a}$, we fix an ordering for the neighbors $\Gamma_{\mathbf{a},i}$, $i = 1, \dots, n_{\mathbf{a}}$ and extend $\prec$ in a lexicographical fashion by

$$(\mathbf{a}, i) \prec (\mathbf{a}', i') \quad \text{iff} \quad \begin{cases} \mathbf{a} \prec \mathbf{a}', & i, i' \text{ arbitrary}, \\ \mathbf{a} = \mathbf{a}', & i < i'. \end{cases} \tag{2.3.6}$$

Obviously this establishes a total ordering in $\mathcal{G}_{\ell+1}$ which immediately extends to a total ordering in $\mathcal{G}$ by

$$\mathbf{a} < \mathbf{a}' \text{ iff } \begin{cases} \ell(\mathbf{a}) < \ell(\mathbf{a}') \text{ or} \\ \ell(\mathbf{a}) = \ell(\mathbf{a}') \text{ and } \mathbf{a} \prec \mathbf{a}', \end{cases} \tag{2.3.7}$$

where $\ell(\mathbf{a})$ is the level ℓ so that $\Gamma_{\mathbf{a}} \in \mathcal{G}_\ell$.

In the following the numbering $(\Gamma_i)_{i=1}^N$ will always be assumed to stem from the above ordering, i.e.,

$$i < j \;\text{ iff }\; \mathbf{a}(i) < \mathbf{a}'(j) \tag{2.3.8}$$

in the sense of (2.3.7).

Each edge $\overline{\Gamma}_i \cap \overline{\Gamma}_l$ in $\mathcal{E}$ will be indexed as $e_{i,l}$ iff $i < l$ which induces an orientation in $\mathcal{E}$. The oriented set of edges will be denoted by $\mathcal{E}^\uparrow$. One may picture this by

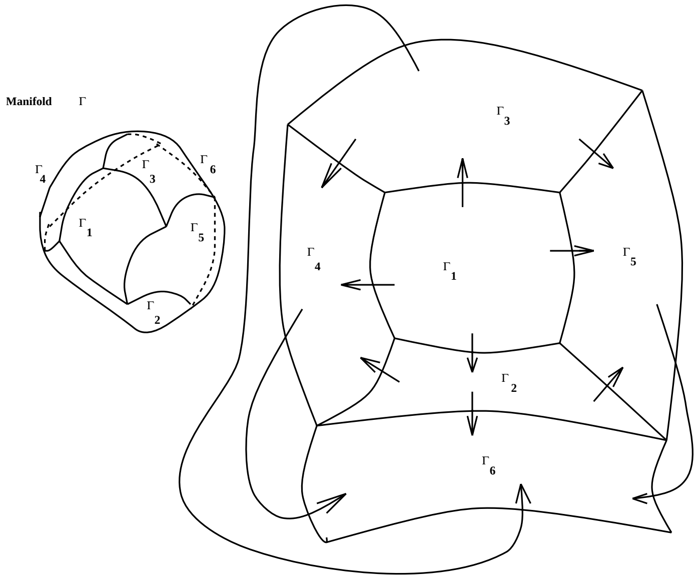

FIG. 3. *Manifold and orientation of patch boundaries.*

associating with $e_{i,l} \in \mathcal{E}^{\uparrow}$ an arrow pointing from the patch Γ_i into the patch Γ_l across the common face; see Figure 3 indicating the decomposition of a closed spherelike surface. The corresponding oriented graph will be denoted by $\mathcal{G}^{\uparrow}$.

The purpose of the above construction is to divide the $(n-1)$ faces of the patches Γ_i into at most two groups, namely, *inflow* or *outflow* faces depending on the orientation. Accordingly, we denote by $\partial^{\uparrow}\Gamma_i$ the *outflow boundary* of the patch Γ_i, i.e.,

$$\partial^{\uparrow}\Gamma_i = \bigcup_l \left\{ e_{i,l} \in \mathcal{E}^{\uparrow} \right\}, \tag{2.3.9}$$

as indicated in Figure 4.

When Γ has a boundary there exist some $(n-1)$ faces which are not yet included in $\mathcal{E}$. We will assign arrows to these boundary faces depending on the type of *boundary conditions* that may be imposed there. If a patch boundary is part of the boundary of Γ, where *homogeneous Dirichlet conditions* are imposed, this edge becomes an inflow boundary while *Neumann boundary conditions* correspond to outflow boundaries; see Figure 2, where respective boundary segments are flagged with D and N for Dirichlet and Neumann conditions, respectively. The rationale behind this will become clear from the subsequent discussion.

We will have to consider *extensions* across the outflow boundary. Accordingly, we need to define an appropriate set of *outflow neighbors*

$$\mathcal{N}_i^{\uparrow} := \left\{ \Gamma_j \in \mathcal{G}^{\uparrow} \,:\, j > i,\, \overline{\Gamma}_j \cap (\text{rel int } \partial^{\uparrow}\Gamma_i) \neq \emptyset \right\}, \tag{2.3.10}$$

which consists of those patches whose boundary intersects the relative interior of the outflow boundary of Γ_i. In complete analogy we define the *inflow boundary*

$$\partial^{\downarrow}\Gamma_i = \bigcup \left\{ e_{\ell,i} \in \mathcal{E}^{\uparrow} \right\} \tag{2.3.11}$$

and its set of neighbors $\mathcal{N}_i^{\downarrow}$

$$\mathcal{N}_i^{\downarrow} = \left\{ \Gamma_\ell \in \mathcal{G}^{\uparrow} \,:\, \ell < i,\, \overline{\Gamma}_j \cap (\text{rel int } \partial^{\downarrow}\Gamma_i) \neq \emptyset \right\}. \tag{2.3.12}$$

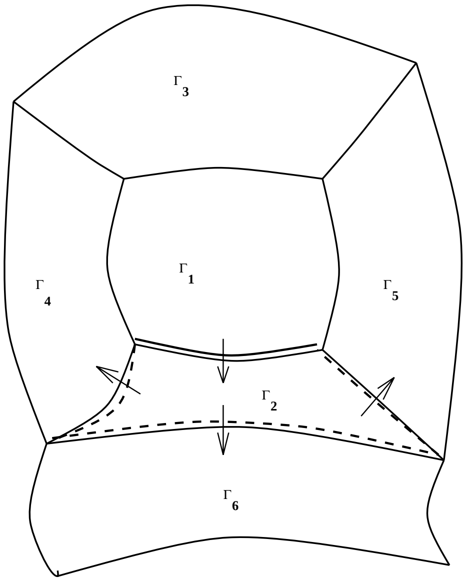

FIG. 4. *Inflow and outflow boundaries.*

With each Γ_i we associate next the open set $\Gamma_i^{\uparrow}$ defined as

$$\Gamma_i^{\uparrow} := \operatorname{int}\left(\overline{\Gamma}_i \bigcup \left\{\overline{\Gamma}' : \Gamma' \in \mathcal{N}_i^{\uparrow}\right\}\right). \tag{2.3.13}$$

Note that (2.3.13) implies that

$$\text{rel int } \partial^{\uparrow}\Gamma_i \subset \Gamma_i^{\uparrow} \tag{2.3.14}$$

and

$$\Gamma_\ell \cap \Gamma_i^{\uparrow} = \emptyset \text{ for } \ell < i. \tag{2.3.15}$$

We will sometimes have to refer to the set of all *upflow successors* $\mathcal{G}_i^{\uparrow}$ or *downflow predecessors* $\mathcal{G}_i^{\downarrow}$ of Γ_i given by

$$\mathcal{G}_i^{\uparrow} := \{\Gamma_j : j \geq i\}, \quad \mathcal{G}_i^{\downarrow} := \{\Gamma_j : j \leq i\} \tag{2.3.16}$$

and their respective associated open domains

$$\Gamma_i^{\uparrow\uparrow} := \operatorname{int} \bigcup \left\{\overline{\Gamma}' : \Gamma' \in \mathcal{G}_i^{\uparrow}\right\}, \quad \Gamma_i^{\downarrow\downarrow} := \operatorname{int} \bigcup \left\{\overline{\Gamma}' : \Gamma' \in \mathcal{G}_i^{\downarrow}\right\}. \tag{2.3.17}$$

Hence aside from the list of parametric mappings the information that will ultimately be needed for the characterization of function spaces on Γ and for the subsequent construction of wavelets are the neighborhood relations encoded by $\mathcal{G}^{\uparrow}$.

2.4. A family of projections. The component spaces on the right-hand side of (2.2.12) will ultimately be identified as ranges of certain projectors. In contrast to [9] we will give an explicit (yet recursive) definition of these projectors and verify then their relevant properties.

To this end, let for $\Gamma' \subset \Gamma$ the characteristic function of Γ' be denoted by $\chi_{\Gamma'}$, i.e., $\chi_{\Gamma'}(x) = 1, x \in \Gamma'$ and $\chi_{\Gamma'}(x) = 0, x \notin \Gamma'$. Thus for any $v \in L_0(\Gamma)$, the expression $\chi_{\Gamma'} v$ means that v is first restricted to Γ' and then extended by zero to $\Gamma \backslash \Gamma'$. Likewise, with a slight abuse of notation we will also write $\chi_{\Gamma'} v$ to mean the trivial extension by zero of $v \in L_0(\Gamma')$ to all of Γ even though v may have been a priorily defined only on Γ'. The restriction of v to Γ' will be denoted by $v\,|_{\Gamma'}$.

The main ingredient for the construction of the above mentioned projections will be linear *extension* operators E_i from $L_0(\Gamma_i)$ to $L_0(\Gamma_i^{\uparrow})$, i.e.,

$$(E_i v)\,|_{\Gamma_i} = v\,|_{\Gamma_i}, \tag{2.4.1}$$

whose particular properties will be specified later.

Given such E_i we define next a family $\mathcal{P}^{\uparrow}$ of mappings P_i from $L_0(\Gamma)$ into $L_0(\Gamma)$ associated with the flow $\mathcal{G}^{\uparrow}$. For $i = 1$, let

$$P_1 v := \chi_{\Gamma_1^{\uparrow}} E_1\,(v\,|_{\Gamma_1}) \tag{2.4.2}$$

as well as

$$P_i v := \chi_{\Gamma_i^{\uparrow}} E_i \left(\left(v - \sum_{j<i} P_j v \right) |_{\Gamma_i} \right), \quad i = 2, \dots, N. \tag{2.4.3}$$

In the following we will use the form (2.4.3) also for $i = 1$, where, of course, it is understood that the sum $\sum_{j<i} P_j v$ is then vacuous and thus ignored. Clearly, each P_i depends only on a few predecessors, namely, by (2.3.15), one has

$$P_i v = \chi_{\Gamma_i^{\uparrow}} E_i \left(\left(v - \sum_{\Gamma_j \in \mathcal{N}_i^{\downarrow}} P_j v \right) |_{\Gamma_i} \right). \tag{2.4.4}$$

Of course, by definition (2.4.3), one has

$$\operatorname{supp} P_i v \subseteq \overline{\Gamma_i^{\uparrow}}. \tag{2.4.5}$$

The adjoints of the operators E_i, P_i are denoted by E_i^*, P_i^*, respectively. More precisely, one has for any $u, v \in L_2(\Gamma)$

$$\langle E_i v, w \rangle_{\Gamma_i^{\uparrow}} = \langle v, E_i^* w \rangle_{\Gamma_i}, \quad \langle P_j u, v \rangle_{\Gamma} = \langle u, P_j^* v \rangle_{\Gamma},$$

which, of course, indicates that E_i^* is a *restriction* operator.

THEOREM 2.1. *Let $\mathcal{P}^{\uparrow}$ be defined as above. The mappings*

$$Tv := ((P_i v)\,|_{\Gamma_i})_{i=1}^N, \qquad Vv := ((P_i^* v)\,|_{\Gamma_i})_{i=1}^N \tag{2.4.6}$$

are linear isomorphisms from $L_0(\Gamma)$ onto $\prod_{j=1}^N L_0(\Gamma_i)$ whose inverses are given by

$$S(v_i)_{i=1}^N = \sum_{i=1}^N P_i \chi_{\Gamma_i} v_i, \qquad U(v_i)_{i=1}^N = \sum_{i=1}^N P_i^* \chi_{\Gamma_i} v_i, \tag{2.4.7}$$

respectively.

Proof. The proof hinges on the properties of the P_i listed in the two subsequent propositions. While the development in [9] aimed at proving the existence of projectors P_i with these properties it remains to verify here that the P_i defined in (2.4.3) indeed have these properties.

PROPOSITION 2.4.1. *The P_i defined above have the following properties:*

(i) *One has*

$$P_iP_j = \delta_{i,j}P_i, \quad 1 \leq i,\, j \leq N. \tag{2.4.8}$$

(ii) *For any $v \in L_0(\Gamma)$, one has*

$$v = \sum_{j=1}^{N} P_j v. \tag{2.4.9}$$

(iii) *One has*

$$\chi_{\Gamma_i} P_j v = P_i \chi_{\Gamma_j} v = 0, \quad 1 \leq i < j \leq N. \tag{2.4.10}$$

Since these verifications are elementary but after all helpful to keep the present approach self-contained, they will be deferred to Appendix A.

We will have to deal with the adjoints P_i^* as well. To this end, note that

$$\langle P_i v, w\rangle_\Gamma = \left\langle \left(v - \sum_{j<i} P_j v\right) |_{\Gamma_i}, E_i^*(w\,|_{\Gamma_i^\uparrow})\right\rangle_\Gamma = \left\langle v - \sum_{j<i} P_j v, \chi_{\Gamma_i} E_i^*(w\,|_{\Gamma_i^\uparrow})\right\rangle_\Gamma,$$

i.e.,

$$P_i^* w = \left(I - \sum_{j<i} P_j^*\right) \chi_{\Gamma_i} E_i^*(w\,|_{\Gamma_i^\uparrow}). \tag{2.4.11}$$

It is now easy to establish the following analogous statements for the adjoints.

Proposition 2.4.2. *The adjoints P_i^* have analogous properties, i.e.,*

$$P_i^* P_j^* = \delta_{i,j} P_i^*, \tag{2.4.12}$$

$$v = \sum_{j=1}^{N} P_j^* v, \tag{2.4.13}$$

and

$$\chi_{\Gamma_i} P_j^* v = P_i^* \chi_{\Gamma_j} v = 0, \quad 1 \leq j < i \leq N. \tag{2.4.14}$$

Proof. Relations (2.4.12) and (2.4.13) follow immediately from (2.4.8) and (2.4.9) by duality. Likewise, by (2.4.10), one has for $j < i$

$$0 = \left\langle \chi_{\Gamma_j} P_i v, w\right\rangle_\Gamma = \left\langle v, P_i^* \chi_{\Gamma_j} w\right\rangle_\Gamma$$

and also

$$0 = \langle P_j \chi_{\Gamma_i} v, w\rangle_\Gamma = \left\langle v, \chi_{\Gamma_i} P_j^* w\right\rangle_\Gamma. \qquad \square$$

Thanks to properties established in Propositions 2.4.1 and 2.4.2 the proof of Theorem 2.1 is essentially the same as in [9]. For the convenience of the reader and since the result is of central importance, we sketch the argument. By definition of T and S one obtains

$$S(Tv) = \sum_{i=1}^{N} P_i \chi_{\Gamma_i}(P_i v)\,|_{\Gamma_i} = \sum_{i=1}^{N} P_i \chi_{\Gamma_i} P_i v. \tag{2.4.15}$$

By (2.4.8), one has

$$P_i v = P_i^2 v = P_i \left(\sum_{j=1}^{N} \chi_{\Gamma_j} \right) P_i v = P_i \left(\sum_{j=1}^{i} \chi_{\Gamma_j} \right) P_i v = P_i \chi_{\Gamma_i} P_i, \tag{2.4.16}$$

where we have used (2.4.10) in the last two steps. Combining (2.4.16) with (2.4.15) and bearing (2.4.9) in mind yields

$$S(Tv) = \sum_{i=1}^{N} P_i v = v,$$

which proves that $T^{-1} = S$.

As for the remaining part of the claim, one can use the same arguments based on Proposition 2.4.2. Alternatively, one can exploit that obviously

$$U = T^*, \quad V = S^*. \tag{2.4.17}$$

Thus, by the previous argument

$$V = S^* = (T^{-1})^* = (T^*)^{-1} = U^{-1},$$

which completes the proof of Theorem 2.1. □

2.5. Topological isomorphisms. The properties of the mappings T, V and their inverses are so far purely algebraic. We will show next that their *topological* properties are completely determined by the continuity properties of the extension operators E_i which will be described next.

To this end, let us first fix some notation and conventions that will be used throughout the remainder of the paper. As above $\mathcal{F}$ will always stand for a Besov function space of the type $\mathcal{F} = B_q^s(L_p)$, $s > 0$ ($s \geq 0$ when $p = q = 2$), where s is bounded from above by some s_Γ depending on Γ; see, e.g., [4, 26, 46] for the precise definition of these Besov spaces. Occasionally we will refer to the specific regularity index by writing $\mathcal{F}_s$ or $\mathcal{F}_\tau$ for $\tau \leq s$. Throughout the following $s \leq s_\Gamma$ will be fixed describing the range in which subsequent topological properties will be considered. For us it is important that $B_2^s(L_2) = H_2^s =: H^s$, i.e., for $p = q = 2$ the Besov space coincides with the standard Sobolev space relative to the L_2 up to norm equivalence.

Many of the results will actually hold for $p, q \in (0, \infty]$. When duality enters one often has to restrict the discussion to $p, q \geq 1$. In this context, given $\mathcal{F} = B_q^\tau(L_p)$, the corresponding scale of spaces $\tilde{\mathcal{F}}_\tau = B_{q'}^\tau(L_{p'})$ with *adjoint* indices p', q' satisfying $\frac{1}{p} + \frac{1}{p'} = \frac{1}{q} + \frac{1}{q'} = 1$ comes into play.

Moreover, the Besov spaces are *interpolation spaces* with respect to real interpolation [4, 46],

$$\mathcal{F}_\tau = (H_p^t, L_p)_{\tau/t,q} = (\mathcal{F}_s, \mathcal{F}_r)_{\theta,q}, \quad \tau = \theta s + (1-\theta) r, \tag{2.5.1}$$

where H_p^t denotes the usual Sobolev (respectively, Bessel potential) spaces with respect to L_p; see, e.g., [4, 46].

Recall that by definition

$$\|v\|_{\mathcal{F}(\Gamma')} \lesssim \|v\|_{\mathcal{F}(\Gamma'')} \tag{2.5.2}$$

holds for any domains $\Gamma' \subseteq \Gamma'' \subseteq \Gamma$. Now define the spaces

$$\mathcal{F}(\Gamma_i)^{\uparrow} \quad (\mathcal{F}(\Gamma_i)^{\downarrow}) := \left\{ v \in \mathcal{F}(\Gamma_i) \,:\, \chi_{\Gamma_i} v \in \mathcal{F}(\Gamma_i^{\uparrow}) \quad (\mathcal{F}(\Gamma_i^{\downarrow})) \right\}, \tag{2.5.3}$$

endowed with the norms

$$\|v\|_{\mathcal{F}(\Gamma_i)^{\uparrow}} := \|\chi_{\Gamma_i} v\|_{\mathcal{F}(\Gamma_i^{\uparrow})}\,, \qquad \|v\|_{\mathcal{F}(\Gamma_i)^{\downarrow}} := \|\chi_{\Gamma_i} v\|_{\mathcal{F}(\Gamma_i^{\downarrow})}\,. \tag{2.5.4}$$

Suppose that $v \in \mathcal{F}(\Gamma_i^{\uparrow})$ is the strong limit of a sequence $v_l \in \mathcal{F}(\Gamma_i)^{\uparrow}$. Since for every C^∞-function φ with compact support in $\Gamma_i^{\uparrow} \setminus \Gamma_i$ one has

$$|\langle v, \varphi\rangle_{\Gamma_i^{\uparrow}}| = |\langle v - v_l, \varphi\rangle_{\Gamma_i^{\uparrow}}| \le \|v - v_l\|_{\mathcal{F}(\Gamma_i^{\uparrow})} \|\varphi\|_{\mathcal{F}^*(\Gamma_i^{\uparrow})} \to 0,$$

we see that $\chi_{\Gamma_i} v = v$ which confirms the following fact.

REMARK 2.5.1. *$\mathcal{F}(\Gamma_i)^{\uparrow}$, $\mathcal{F}(\Gamma_i)^{\downarrow}$ are closed subspaces of $\mathcal{F}(\Gamma_i)$ with respect to the norms defined in* (2.5.4).

Since $\mathcal{F}(\Gamma_i)^{\uparrow}$ consists of exactly those elements in $\mathcal{F}(\Gamma_i)$ whose trivial extension by zero across the outflow boundary $\partial^{\uparrow}\Gamma_i$ belongs to the corresponding space $\mathcal{F}(\Gamma_i^{\uparrow})$ for the extended domain, the elements in $\mathcal{F}(\Gamma_i)^{\uparrow}$ are characterized by the fact that their trace vanishes on the outflow boundary $\partial^{\uparrow}\Gamma_i$ in a certain sense. More precisely, although we will not make explicit use of it, we recall the following fact; see, e.g., [46, Section 2.10.2, Theorem 1] or [29, Theorem 1.4.5.2].

REMARK 2.5.2. *$\mathcal{F}_\tau(\Gamma_i)^{\uparrow}$ agrees with the closure in $\|\cdot\|_{\mathcal{F}_\tau(\Gamma_i)}$ of all smooth functions whose support is contained in $\overline{\Gamma}_i$ but does not intersect $\partial^{\uparrow}\Gamma_i$ provided that $\tau + 1/p$ is* not an integer. *The same holds for $\mathcal{F}(\Gamma_i)^{\downarrow}$ relative to the reverse flow. Moreover one has*

$$\|\cdot\|_{\mathcal{F}_\tau(\Gamma_i)^{\uparrow}} = \|\cdot\|_{\mathcal{F}_\tau(\Gamma_i)^{\downarrow}} = \|\cdot\|_{\mathcal{F}_\tau(\Gamma_i)} \quad \textit{if} \;\; \tau + 1/p \notin \mathbb{N}. \tag{2.5.5}$$

Throughout the remaining part of this section we will assume the following properties of the extension operators E_i:

ASSUMPTION A.

- *Localness*:

$$\chi_{\Gamma_i^{\uparrow}} E_i v \in \mathcal{F}(\Gamma_i^{\uparrow\uparrow}), \quad v \in \mathcal{F}(\Gamma_i), \;\; i = 1, \dots, N. \tag{2.5.6}$$

- *Continuity of E_i*:

$$\|E_i v\|_{\mathcal{F}(\Gamma_i^{\uparrow})^{\downarrow}} \lesssim \|v\|_{\mathcal{F}(\Gamma_i)^{\downarrow}}\,, \quad v \in \mathcal{F}(\Gamma_i)^{\downarrow}, \;\; i = 1, \dots, N. \tag{2.5.7}$$

- *Continuity of E_i^**:

$$\|E_i^* v\|_{\tilde{\mathcal{F}}(\Gamma_i)^{\uparrow}} \lesssim \|v\|_{\tilde{\mathcal{F}}(\Gamma_i^{\uparrow})}\,, \quad v \in \tilde{\mathcal{F}}(\Gamma_i^{\uparrow}), \;\; i = 1, \dots, N. \tag{2.5.8}$$

One could actually require *different* regularity parameters $s', \tilde{s}'$ in (2.5.7) and (2.5.8), respectively, which will naturally come up in section 4.3 below. Since this will not be essential for the subsequent analysis, we dispense here with this complication of notation.

Remark 2.5.3. *We will always assume that Assumption A holds, in particular, for the L_p-norm corresponding to $\mathcal{F} = \mathcal{F}_s$. The spaces $\mathcal{F}(\Gamma_i)^{\uparrow}$ are also* stable *under interpolation*

$$\mathcal{F}_\tau(\Gamma_i)^{\uparrow} = (\mathcal{F}_s(\Gamma_i)^{\uparrow}, L_p)_{\tau/s,q} \tag{2.5.9}$$

(and likewise for $\uparrow$ replaced by $\downarrow$), see, e.g., [38], *so that Assumption A will actually hold for the full range between* 0 *and* s.

Next we will comment on the dual spaces for spaces of the type $\mathcal{F}(\Gamma_i)^{\uparrow}$.

Remark 2.5.4. *Suppose that $\Gamma' \subset \Gamma$. Then $w \in \mathcal{F}^*(\Gamma')$, the dual of $\mathcal{F}(\Gamma')$ (the space of bounded linear functionals on $\mathcal{F}(\Gamma')$), iff $\chi_{\Gamma'} w \in \mathcal{F}^*(\Gamma)$ and*

$$\|\chi_{\Gamma'} w\|_{\mathcal{F}^*(\Gamma)} \sim \|w\|_{\mathcal{F}^*(\Gamma')}. \tag{2.5.10}$$

Now consider the closed subspace

$$\mathcal{F}_i := \{v \in \mathcal{F}(\Gamma) : \chi_{\Gamma_i^{\uparrow\uparrow}} v \in \mathcal{F}(\Gamma)\}, \quad \|v\|_{\mathcal{F}_i} := \|\chi_{\Gamma_i^{\uparrow\uparrow}} v\|_{\mathcal{F}(\Gamma)}$$

of $\mathcal{F}(\Gamma)$, consisting of those elements in $\mathcal{F}(\Gamma_i^{\uparrow\uparrow})$ whose trivial extension by zero belongs to $\mathcal{F}(\Gamma)$. The same reasoning as above yields the following fact.

Remark 2.5.5. $w \in \big(\mathcal{F}(\Gamma_i)^{\downarrow}\big)^*$ *iff* $\chi_{\Gamma_i} w \in \mathcal{F}_i^*$ *and*

$$\|\chi_{\Gamma_i} w\|_{\mathcal{F}_i^*} \sim \|w\|_{(\mathcal{F}(\Gamma_i)^{\downarrow})^*}. \tag{2.5.11}$$

Thus $\big(\mathcal{F}(\Gamma_i)^{\downarrow}\big)^*$ consists of those functionals whose trivial extension by zero *only* in the outflow direction remains continuous. In this sense it is justified to set

$$\big(\mathcal{F}(\Gamma_i)^{\downarrow}\big)^* = \mathcal{F}^*(\Gamma_i)^{\uparrow}, \quad \big(\mathcal{F}(\Gamma_i)^{\uparrow}\big)^* = \mathcal{F}^*(\Gamma_i)^{\downarrow}. \tag{2.5.12}$$

We are now ready to state the first main result in this section.

Theorem 2.2. *Under the assumptions* (2.5.7) *and* (2.5.8) *the projectors P_j defined by* (2.4.2) *and* (2.4.3) *satisfy*

$$\begin{aligned} (P_i \chi_{\Gamma_i^{\uparrow\uparrow}} v)\,|_{\Gamma_i} &= v\,|_{\Gamma_i} \quad \forall \;\; v \in \mathcal{F}(\Gamma), \;\; v\,|_{\Gamma_i} \in \mathcal{F}(\Gamma_i)^{\downarrow}, \\ (P_i^* \chi_{\Gamma_i^{\downarrow\downarrow}} v)\,|_{\Gamma_i} &= v\,|_{\Gamma_i} \quad \forall \;\; v \in \tilde{\mathcal{F}}(\Gamma), \;\; v\,|_{\Gamma_i} \in \tilde{\mathcal{F}}(\Gamma_i)^{\uparrow}, \end{aligned} \tag{2.5.13}$$

and their restriction to Γ_i induces topological isomorphisms from $P_i(\mathcal{F}(\Gamma))$, $P_i^*(\tilde{\mathcal{F}}(\Gamma))$ onto $\mathcal{F}(\Gamma_i)^{\downarrow}$, $\tilde{\mathcal{F}}(\Gamma_i)^{\uparrow}$, respectively, i.e.,

$$(P_i(\mathcal{F}(\Gamma)))\,|_{\Gamma_i} = \mathcal{F}(\Gamma_i)^{\downarrow}, \quad (P_i^*(\tilde{\mathcal{F}}(\Gamma)))\,|_{\Gamma_i} = \tilde{\mathcal{F}}(\Gamma_i)^{\uparrow}, \tag{2.5.14}$$

where

$$\|(P_i v)\,|_{\Gamma_i}\|_{\mathcal{F}(\Gamma_i)^{\downarrow}} \;\lesssim\; \|v\|_{\mathcal{F}(\Gamma)}\,, \quad \|(P_i^* v)\,|_{\Gamma_i}\|_{\tilde{\mathcal{F}}(\Gamma_i)^{\uparrow}} \;\lesssim\; \|v\|_{\tilde{\mathcal{F}}(\Gamma)}\,. \tag{2.5.15}$$

Moreover, the P_i as well as their adjoints P_i^* are continuous in $\mathcal{F}(\Gamma)$, $\tilde{\mathcal{F}}(\Gamma)$, respectively, i.e., one has

$$\|P_i v\|_{\mathcal{F}(\Gamma)} \lesssim \|v\|_{\mathcal{F}(\Gamma)}, \quad v \in \mathcal{F}(\Gamma), \quad \|P_i^* v\|_{\tilde{\mathcal{F}}(\Gamma)} \lesssim \|v\|_{\tilde{\mathcal{F}}(\Gamma)}, \quad v \in \tilde{\mathcal{F}}(\Gamma). \tag{2.5.16}$$

An analogous result has been already established in [9]. However, since for the anticipated applications it will be important to apply the above characterizations with the particular projectors P_j defined in (2.4.3) and since in this form they do not seem to be readily identified with the corresponding quantities occurring in [9], we will include a self-contained proof which will be deferred to Appendix B.

By Theorem 2.2, the mappings T and V from (2.4.6) and (2.4.7) actually induce now mappings

$$T : \mathcal{F}(\Gamma) \to \Pi\mathcal{F}^{\downarrow} := \prod_{i=1}^{N} \mathcal{F}(\Gamma_i)^{\downarrow}, \quad V : \tilde{\mathcal{F}}(\Gamma) \to \Pi\tilde{\mathcal{F}}^{\uparrow} := \prod_{i=1}^{N} \tilde{\mathcal{F}}(\Gamma_i)^{\uparrow},$$

which will turn out to be *topological isomorphisms.* The main result of this section reads as follows.

THEOREM 2.3. *One has*

$$\mathcal{F}(\Gamma) \cong \prod_{i=1}^{N} \mathcal{F}(\Gamma_i)^{\downarrow}, \quad \tilde{\mathcal{F}}(\Gamma) \cong \prod_{i=1}^{N} \tilde{\mathcal{F}}(\Gamma_i)^{\uparrow},$$

and defining

$$|||v|||_{\mathcal{F}^{\downarrow}} := \left(\sum_{i=1}^{N} \|(P_i v)\ |_{\Gamma_i}\|^2_{\mathcal{F}(\Gamma_i)^{\downarrow}} \right)^{\frac{1}{2}}, \quad |||v|||_{\tilde{\mathcal{F}}^{\uparrow}} := \left(\sum_{i=1}^{N} \|(P_i^* v)\ |_{\Gamma_i}\|^2_{\tilde{\mathcal{F}}(\Gamma_i)^{\uparrow}} \right)^{\frac{1}{2}}, \tag{2.5.17}$$

the norms $\|\cdot\|_{\tilde{\mathcal{F}}(\Gamma)}$, $\|\cdot\|_{\mathcal{F}(\Gamma)}$ and $|||\cdot|||_{\tilde{\mathcal{F}}^{\uparrow}}$, $|||\cdot|||_{\mathcal{F}^{\downarrow}}$, respectively, are equivalent, i.e.,

$$\|v\|_{\tilde{\mathcal{F}}(\Gamma)} \sim |||v|||_{\tilde{\mathcal{F}}^{\uparrow}}, \quad v \in \tilde{\mathcal{F}}(\Gamma), \qquad \|v\|_{\mathcal{F}(\Gamma)} \sim |||v|||_{\mathcal{F}^{\downarrow}}, \quad v \in \mathcal{F}(\Gamma). \tag{2.5.18}$$

Moreover, V and T extend to isomorphisms from $\mathcal{F}^*(\Gamma)$, $\tilde{\mathcal{F}}^*(\Gamma)$ onto the spaces $\Pi\mathcal{F}^*_{\uparrow} := \prod_{i=1}^{N} \mathcal{F}^*(\Gamma_i)^{\uparrow}$ and $\Pi\tilde{\mathcal{F}}^*_{\downarrow} := \prod_{i=1}^{N} \tilde{\mathcal{F}}^*(\Gamma_i)^{\downarrow}$, respectively, and

$$\|v\|_{\tilde{\mathcal{F}}^*(\Gamma)} \sim \left(\sum_{j=1}^{N} \left\|(P_j v)\ |_{\Gamma_j}\right\|^2_{\tilde{\mathcal{F}}^*(\Gamma_j)^{\downarrow}} \right)^{\frac{1}{2}}, \quad \|v\|_{\mathcal{F}^*(\Gamma)} \sim \left(\sum_{j=1}^{N} \left\|(P_j^* v)\ |_{\Gamma_j}\right\|^2_{\mathcal{F}^*(\Gamma_j)^{\uparrow}} \right)^{\frac{1}{2}}. \tag{2.5.19}$$

Proof. With Theorem 2.2 and the other prerequisites at hand the proof follows exactly the reasoning of [9]. In fact, the availability of algebraic inverses combined with the open mapping theorem yields (2.5.18). As for the dual spaces, the first part of the theorem ensures that $V : \tilde{\mathcal{F}}(\Gamma) \to \Pi\tilde{\mathcal{F}}^{\uparrow}$ and hence $V^* : (\Pi\tilde{\mathcal{F}}^{\uparrow})^* \to \tilde{\mathcal{F}}^*(\Gamma)$ are isomorphisms. By denseness of the involved spaces in their dual versions and noting that $U = V^{-1}$ the mapping U^* extends to an isomorphism from $\tilde{\mathcal{F}}^*(\Gamma)$ onto $(\Pi\tilde{\mathcal{F}}^{\uparrow})^* = \Pi\tilde{\mathcal{F}}^*_{\downarrow}$, where we have used (2.5.12) in the last step. The reasoning for $v = S^*$ is analogous. The assertion follows now from (2.4.17). □

In view of Theorems 2.2 and 2.3, the construction of wavelet bases on Γ satisfying (I) in section 1.1 amounts to the following two tasks:

(a) The construction of wavelet bases for the component spaces $\tilde{\mathcal{F}}(\Gamma_i)^\uparrow$ or $\mathcal{F}(\Gamma_i)^\downarrow$ with respective properties (I).

(b) The (practical) realization of extension operators E_i satisfying Assumption A.

We will first address (a) which incidentally will be crucial for dealing with (b) as well.

3. Discrete norm equivalences. We adhere to the above notation and recall that the parametric mappings κ_i will always be assumed to be regular parametrizations of any degree of smoothness required at each instance.

Our goal is to establish isomorphisms from $\mathcal{F}(\Gamma)$ and $\tilde{\mathcal{F}}(\Gamma)$ onto *sequence spaces* which consist of expansion sequences of the elements of $\mathcal{F}(\Gamma)$ and $\tilde{\mathcal{F}}(\Gamma)$ with respect to certain wavelet bases. In principle, such isomorphisms have been already constructed in [9]. However, the present construction differs from that in [9] in several respects. The main point here is that the underlying bases are completely *local* and that the involved extension operators in (2.4.6) affect *only* basis functions *near* the patch boundaries.

The desired norm equivalences will be based on Theorem 2.3. Thus one has to identify first suitable bases for the component spaces $\mathcal{F}(\Gamma_i)^\downarrow$, $\tilde{\mathcal{F}}(\Gamma_i)^\uparrow$. Due to the regularity of the mappings κ_i these spaces can be essentially identified with corresponding smoothness spaces over the parameter domain $\Box$. Thus the construction will be divided into the following steps:

(i) Employ suitable biorthogonal wavelet bases over $\Box$ which give rise there to discrete norm equivalences for the pull backs of the spaces $\mathcal{F}(\Gamma_i)^\downarrow$ and their duals $\mathcal{F}^*(\Gamma_i)^\uparrow$.

(ii) Lift these bases parametrically to the patches Γ_i and verify the validity of corresponding norm equivalences.

(iii) Use Theorem 2.3 to construct bases on Γ along with corresponding isomorphisms.

We emphasize already at this point that the construction of bases on Γ is primarily a conceptual issue. Actual computations will be seen later to involve only bases of the component spaces $\tilde{\mathcal{F}}(\Gamma_i)^\uparrow, \mathcal{F}(\Gamma_i)^\downarrow$ or better yet bases on the parameter domain $\Box$.

3.1. Wavelet bases on $\Box$. Wavelet bases on $\Box = (0,1)^n$ are conveniently constructed with the aid of *tensor products* of wavelet bases on $[0,1]$. The essential property of such pairs of biorthogonal wavelet bases on $[0,1]$ will be seen to be certain *complementary boundary conditions*. Such bases have been constructed in [22] and this section is devoted to briefly summarizing the relevant properties needed in the subsequent development.

To this end, we will consistently use the following notation:

$$\Psi = \{\psi_\lambda : \lambda \in \nabla\}, \quad \tilde{\Psi} = \{\tilde{\psi}_\lambda : \lambda \in \nabla\}$$

will always denote a pair of biorthogonal wavelet bases (relative to some inner product to be specified at each instance). The indices $\lambda \in \nabla$ are to encode the level $|\lambda|$ of resolution of ψ_λ (typically representing a mesh size of order $2^{-|\lambda|}$) as well as the location and type of the wavelet ψ_λ. For instance, the wavelets ψ_λ supported in the interior of the respective domain will have the form $\psi_\lambda = 2^{jn/2}\psi_e(2^j \cdot -k)$ with $e \in \{0,1\}^n \setminus \{\mathbf{0}\}$, $k \in \mathbb{Z}^n$, i.e., $\lambda = 2^{-j}(k + \frac{e}{2})$. By $\Psi_j = \{\psi_\lambda : |\lambda| = j\}$ we mean all wavelets in Ψ on level j. There will always be some coarsest level $j_0 \in \mathbb{N}$ for which in addition to the complement basis Ψ_{j_0} we also need a basis $\Phi_{j_0} = \{\phi_\lambda : \lambda \in \Delta_+\}$ whose elements are of *scaling function type* (adapted to the domain) containing polynomials up to some fixed order d (degree $d-1$). Thus the whole index set ∇ is split into $\nabla = \Delta_+ \cup \nabla_-$, where Δ_+ refers to the coarse level (polynomial) part and ∇_- represents the “true” wavelets. Such bases will be considered for various domains Ω such as $\square$, Γ_i, Γ which will be indicated by corresponding superscripts. Likewise, the reference of index sets to respective bases will be indicated by superscripts. For instance, ∇^i refers to a basis on Γ_i.

Furthermore, we will consistently make use of the following conventions. Any collection Φ of functions will be viewed as a (column) vector whose components are the elements of Φ with respect to some fixed but unspecified order. Thus

$$\mathbf{c}^T\Phi = \sum_{\phi\in\Phi} c_\phi \phi$$

denotes corresponding linear combinations where coefficient vectors are kept in boldface. Likewise given any dual form $\langle\cdot,\cdot\rangle$

$$\langle\Phi,\Theta\rangle = (\langle\phi,\theta\rangle)_{\phi\in\Phi,\theta\in\Theta}$$

is a matrix. In particular, for any function v the expressions $\langle v,\Phi\rangle$, $\langle\Phi,v\rangle$ are row and column vectors, respectively. By $\mathbf{I}$ we will denote the identity matrix whose dimensionality will always be clear from the context.

According to the nature of the spaces $\tilde{\mathcal{F}}(\Gamma_i)^{\uparrow}$ and $\mathcal{F}(\Gamma_i)^{\downarrow}$, we have to deal with analogous spaces on $\square$ whose elements admit zero extensions across all possible unions of facets of $\square$. To organize this we follow essentially the notation in [9] and describe first how to extend the cube $\square$ across such faces in order to define suitable preimages of the sets $\Gamma_i^{\uparrow}$, $\Gamma_i^{\downarrow}$. To this end, consider first the univariate case and let for $Z \subseteq \{0,1\}$

$$[0,1]_Z := \begin{cases} [0,1] & \text{if } Z=\emptyset, \\ [-1,1] & \text{if } Z=\{0\}, \\ [0,2] & \text{if } Z=\{1\}, \\ [-1,2] & \text{if } Z=\{0,1\}. \end{cases} \tag{3.1.1}$$

For $n>1$, we simply set $\mathbf{Z} = Z_1\times\cdots\times Z_n \subseteq \{0,1\}^n$ and define

$$\square_{\mathbf{Z}} = [0,1]_{Z_1}\times\cdots\times[0,1]_{Z_n}. \tag{3.1.2}$$

Then

$$\partial_{\mathbf{Z}}\square := \bigcup_{\ell=1}^{n} [0,1]^{\ell-1}\times Z_\ell\times[0,1]^{n-\ell} \tag{3.1.3}$$

is the union of those faces of $\square$ across which $\square$ has been extended to $\square_{\mathbf{Z}}$. We will consistently use the notation

$$\tilde{Z} := \{0,1\}\setminus Z, \qquad \tilde{\mathbf{Z}} := \{0,1\}^n\setminus\mathbf{Z}, \tag{3.1.4}$$

so that

$$\partial_{\tilde{\mathbf{Z}}}\square = \partial\square\setminus\partial_{\mathbf{Z}}\square, \tag{3.1.5}$$

where as usual $\partial\square$ denotes the boundary of $\square$. In complete analogy to (2.5.3) we define the spaces

$$\mathcal{F}_\tau(\square)_{\mathbf{Z}} := \{v\in\mathcal{F}_\tau(\square) : \chi_\square v\in\mathcal{F}_\tau(\square_{\mathbf{Z}})\},$$

endowed with the norm

$$\|v\|_{\mathcal{F}_\tau(\Box)_{\mathbf{Z}}} := \|\chi_\Box v\|_{\mathcal{F}_\tau(\Box_{\mathbf{Z}})}. \tag{3.1.6}$$

Throughout the rest of this section we will make use of the fact that for any pair of regularity parameters $\gamma = \gamma(p) > 0$, $\tilde{\gamma} = \tilde{\gamma}(p') > 0$ and for each choice of $\mathbf{Z}$ certain pairs of *biorthogonal wavelet bases*

$$\Psi^{\mathbf{Z}} = \{\psi_\lambda^{\mathbf{Z}} : \lambda \in \nabla^{\mathbf{Z}}\}, \quad \tilde{\Psi}^{\tilde{\mathbf{Z}}} = \{\tilde{\psi}_\lambda^{\tilde{\mathbf{Z}}} : \lambda \in \nabla^{\mathbf{Z}}\}$$

(identifying their respective index sets) on $\Box$ have been constructed in [22] which will be said to have *type* $\mathbf{Z}, \tilde{\mathbf{Z}}$, respectively, such that for $d, \tilde{d} \in \mathbb{N}$, $d + \tilde{d} \in 2\mathbb{N}$, sufficiently large, the following properties hold; see Theorem 3.2.1 in [22].

Properties B.

(i) *The collections* $\Psi^{\mathbf{Z}}, \tilde{\Psi}^{\tilde{\mathbf{Z}}}$ *are biorthogonal, i.e.,*

$$\langle \Psi^{\mathbf{Z}}, \tilde{\Psi}^{\tilde{\mathbf{Z}}} \rangle_\Box = \mathbf{I}. \tag{3.1.7}$$

Moreover, one has

$$\Psi^{\mathbf{Z}} \subset \mathcal{F}_\tau(\Box) \quad \textit{for} \quad \tau < \gamma, \quad \tilde{\Psi}^{\tilde{\mathbf{Z}}} \subset \tilde{\mathcal{F}}_\tau(\Box) \quad \textit{for} \quad \tau < \tilde{\gamma}. \tag{3.1.8}$$

In addition, the primal and dual wavelets satisfy certain (complementary) homogeneous boundary conditions *in the following sense. For some fixed* $0 < s' < \gamma$, $0 < \tilde{s}' < \tilde{\gamma}$ *one has*

$$\Psi^{\mathbf{Z}} \subset \mathcal{F}_\tau(\Box)_{\mathbf{Z}}, \quad \tau \leq s', \quad \tilde{\Psi}^{\tilde{\mathbf{Z}}} \subset \tilde{\mathcal{F}}_\tau(\Box)_{\tilde{\mathbf{Z}}}, \quad \tau \leq \tilde{s}'. \tag{3.1.9}$$

(ii) *The bases* $\Psi^{\mathbf{Z}}$, $\tilde{\Psi}^{\tilde{\mathbf{Z}}}$ *are local, i.e., for* $\Omega_\lambda^\Box := \operatorname{supp} \psi_\lambda^{\mathbf{Z}}$, $\tilde{\Omega}_\lambda^\Box := \operatorname{supp} \tilde{\psi}_\lambda^{\tilde{\mathbf{Z}}}$ *one has*

$$\operatorname{diam} \Omega_\lambda^\Box, \quad \operatorname{diam} \tilde{\Omega}_\lambda^\Box \sim 2^{-|\lambda|}. \tag{3.1.10}$$

(iii) *For* $s', \tilde{s}'$ *as above one has*

$$\Pi_d(\Box) \cap \mathcal{F}_{s'}(\Box)_{\mathbf{Z}} \subset \operatorname{span}\{\psi_\lambda^{\mathbf{Z}} : \lambda \in \Delta_+^{\mathbf{Z}}\},$$

and

$$\Pi_{\tilde{d}}(\Box) \cap \tilde{\mathcal{F}}_{\tilde{s}'}(\Box)_{\tilde{\mathbf{Z}}} \subset \operatorname{span}\{\tilde{\psi}_\lambda^{\tilde{\mathbf{Z}}} : \lambda \in \Delta_+^{\mathbf{Z}}\},$$

where $\Pi_d(\Omega)$ *denotes the space of all polynomials of order* d *on* Ω. *Moreover, for some* $a > 0$ *and any* $\Omega \subset \Box$ *with* $\operatorname{dist}(\partial_{\mathbf{Z}}\Box, \partial\Omega) > a2^{-j}$ *one has*

$$\Pi_d(\Omega) \subseteq \operatorname{span}\{\psi_\lambda^{\mathbf{Z}} : \lambda \in \nabla^{\mathbf{Z}}, |\lambda| < j\} =: S_{j,\mathbf{Z}}.$$

Likewise, when $\operatorname{dist}(\partial_{\tilde{\mathbf{Z}}}\Box, \partial\Omega) > a2^{-j}$ *one has*

$$\Pi_{\tilde{d}}(\Omega) \subseteq \operatorname{span}\{\tilde{\psi}_\lambda^{\tilde{\mathbf{Z}}} : \lambda \in \nabla^{\mathbf{Z}}, |\lambda| < j\} =: \tilde{S}_{j,\tilde{\mathbf{Z}}},$$

that is, away from the part of the boundary marked by $\mathbf{Z}$, $\tilde{\mathbf{Z}}$, *the primal and dual multiresolution spaces contain polynomials up to order* $d, \tilde{d}$, *respectively.*

(iv) *There exists* $\Lambda_{\mathbf{Z}}^\emptyset \subset \nabla^{\mathbf{Z}}$ *such that*

- $\nu \in \nabla^{\mathbf{Z}} \setminus \Lambda_{\mathbf{Z}}^\emptyset$ *implies that* $\operatorname{dist}(\partial_{\mathbf{Z}}\Box, \Omega_\nu^\Box) \lesssim 2^{-|\nu|}$.

- *The collection* $\{\psi_\nu^{\mathbf{Z}} : \nu \in \Lambda_{\mathbf{Z}}^{\emptyset}\}$ *can be extended to a collection* $\Psi^{\emptyset}$ *of type* $\mathbf{Z} = \emptyset$ *(having, therefore, by* (iii)*, full polynomial exactness of order* d *on all of* $\square$*). Moreover, the corresponding biorthogonal collection* $\tilde{\Psi}^{\{0,1\}^n}$ *contains* $\{\tilde{\psi}_\nu^{\tilde{\mathbf{Z}}} : \nu \in \Lambda_{\mathbf{Z}}^{\emptyset}\}$ *and belongs to* $\tilde{\mathcal{F}}_{\tilde{s}'}(\square)_{\{0,1\}^n}$*.*

Likewise, there exists $\Lambda_{\mathbf{Z}}^{\{0,1\}^n} \subset \nabla^{\mathbf{Z}}$ *such that*

- $\nu \in \nabla^{\mathbf{Z}} \setminus \Lambda_{\mathbf{Z}}^{\{0,1\}^n}$ *implies that* $\operatorname{dist}(\partial_{\tilde{\mathbf{Z}}}\square, \Omega_\nu^{\square}) \lesssim 2^{-|\nu|}$*.*
- *The collection* $\{\psi_\nu^{\mathbf{Z}} : \nu \in \Lambda_{\mathbf{Z}}^{\{0,1\}^n}\}$ *can be extended to a collection* $\Psi^{\{0,1\}^n}$ *of type* $\mathbf{Z} = \{0,1\}^n$*. Moreover, the corresponding biorthogonal collection* $\tilde{\Psi}^{\emptyset}$ *contains* $\{\tilde{\psi}_\nu^{\tilde{\mathbf{Z}}} : \nu \in \Lambda_{\mathbf{Z}}^{\{0,1\}^n}\}$ *and reproduces all polynomials in* $\Pi_{\tilde{d}}$ *on* $\square$*.*

All wavelet bases are local in the sense of (3.1.10)*.*

In particular, (iii) implies the *moment conditions*

$$\langle P, \psi_\lambda^{\mathbf{Z}}\rangle = 0,\ \ P \in \Pi_{\tilde{d}}(\square)\cap\tilde{\mathcal{F}}_{\tilde{s}'}(\square)_{\tilde{\mathbf{Z}}},\ \ \langle P, \tilde{\psi}_\lambda^{\tilde{\mathbf{Z}}}\rangle = 0,\ \ P \in \Pi_d(\square)\cap\mathcal{F}_{s'}(\square)_{\mathbf{Z}},\ \ \text{for } \lambda \in \nabla_-^{\mathbf{Z}}. \tag{3.1.11}$$

Moreover, (iv) says that away from the boundary of $\square$ the wavelets of *all* types $\mathbf{Z}$ can actually be arranged to *coincide* and that the adaptation of boundary conditions on level j affects only a margin of width 2^{-j}, which will turn out to have important implications.

Since the wavelets will ultimately be transported to the manifold Γ, we may assume without loss of generality that throughout the remainder of the paper

$$s', \tilde{s}' \le s < s_\Gamma. \tag{3.1.12}$$

In addition to the above structural properties pertaining mainly to *localization* and (local) polynomial exactness we will make essential use of the following *topological* properties from Theorems 3.3.1 and 3.4.1 in [22]. To this end, since we have to deal with spaces for which the regularity is not tied to the order of boundary conditions, consider

$$\mathcal{F}_{\tau,s'}(\square)_{\mathbf{Z}} := \begin{cases} \mathcal{F}_\tau(\square)_{\mathbf{Z}} & \text{for} \quad \tau \le s', \\ \mathcal{F}_{s'}(\square)_{\mathbf{Z}} \cap \mathcal{F}_\tau(\square) & \text{for} \quad s' < \tau < d, \\ H_p^d(\square) \cap \mathcal{F}_{s'}(\square)_{\mathbf{Z}} & \text{for} \quad \tau = d. \end{cases} \tag{3.1.13}$$

The spaces $\tilde{\mathcal{F}}_{\tau,\tilde{s}'}(\square)_{\tilde{\mathbf{Z}}}$ are defined analogously with $d, p, s, \mathbf{Z}$ replaced by $\tilde{d}, p', \tilde{s}', \tilde{\mathbf{Z}}$, respectively.

Properties C.

(i) *The following Jackson inequalities hold for the multiresolution spaces* $S_{j,\mathbf{Z}}, \tilde{S}_{j,\tilde{\mathbf{Z}}}$ *defined in Properties B* (iii)*. One has*

$$\inf_{v_j \in S_{j,\mathbf{Z}}} \|v - v_j\|_{\mathcal{F}_{t,s'}(\square)_{\mathbf{Z}}} \lesssim 2^{-j(\tau - t)}\|v\|_{\mathcal{F}_{\tau,s'}(\square)_{\mathbf{Z}}}, \quad v \in \mathcal{F}_{\tau,s'}(\square)_{\mathbf{Z}}, \tag{3.1.14}$$

for $t < \gamma,\ t \le \tau \le d$*, and*

$$\inf_{v_j \in \tilde{S}_{j,\tilde{\mathbf{Z}}}} \|v - v_j\|_{\tilde{\mathcal{F}}_{t,\tilde{s}'}(\square)_{\tilde{\mathbf{Z}}}} \lesssim 2^{-j(\tau - t)}\|v\|_{\tilde{\mathcal{F}}_{\tau,\tilde{s}'}(\square)_{\tilde{\mathbf{Z}}}}, \quad v \in \tilde{\mathcal{F}}_{\tau,\tilde{s}'}(\square)_{\tilde{\mathbf{Z}}}, \tag{3.1.15}$$

for $t \le \tilde{\gamma},\ t \le \tau \le \tilde{d}$*. Furthermore the following inverse estimates are valid*

$$\begin{aligned} \|v_j\|_{\mathcal{F}_{\tau,s'}(\square)_{\mathbf{Z}}} &\lesssim 2^{j\tau}\|v_j\|_{L_p(\square)}, \quad v_j \in S_{j,\mathbf{Z}}, \\ \|v_j\|_{\tilde{\mathcal{F}}_{\tau,\tilde{s}'}(\square)_{\tilde{\mathbf{Z}}}} &\lesssim 2^{j\tau}\|v_j\|_{L_{p'}(\square)}, \quad v_j \in \tilde{S}_{j,\tilde{\mathbf{Z}}}. \end{aligned} \tag{3.1.16}$$

(ii) *For* $\mathcal{F} = B^\tau_q(L_p)$ *as above,* $0 < \tau \le s'$ *and* $\frac{1}{p} + \frac{1}{p'} = \frac{1}{q} + \frac{1}{q'} = 1$ *one has*

$$\|v\|_{\mathcal{F}(\Box)_{\mathbf{Z}}} \sim \left(\sum_{j=j_0}^{\infty} \left\{ 2^{j(\frac{n}{2} - \frac{n}{p} + \tau)} \|\langle v, \tilde{\Psi}_j^{\tilde{\mathbf{Z}}} \rangle_\Box \|_{\ell_p} \right\}^q \right)^{1/q} ,$$

$$\|v\|_{\mathcal{F}^*(\Box)_{\tilde{\mathbf{Z}}}} \sim \left(\sum_{j=j_0}^{\infty} \left\{ 2^{j(\frac{n}{2} - \frac{n}{p'} - \tau)} \|\langle v, \Psi_j^{\mathbf{Z}} \rangle_\Box \|_{\ell_{p'}} \right\}^{q'} \right)^{1/q'} . \tag{3.1.17}$$

Again analogous relations hold with interchanged roles of $\Psi^{\mathbf{Z}}, \mathbf{Z}, s'$ *and* $\tilde{\Psi}^{\tilde{\mathbf{Z}}}, \tilde{\mathbf{Z}}, \tilde{s}'$.

We will also have to make special use later of the following extreme cases of (3.1.17) which are perhaps worth being stated separately.

Remark 3.1.1. *For* $\mathcal{F}_\tau$ *as above the basis* $\Psi^{\{0,1\}^n}$ *in Properties B* (iv) *give rise to the relations*

$$\|\chi_\Box v\|_{\mathcal{F}_\tau(\mathbb{R}^n)} \sim \left(\sum_{j=j_0}^{\infty} \left\{ 2^{j(\frac{n}{2} - \frac{n}{p} + \tau)} \|\langle v, \tilde{\Psi}_j^{\emptyset} \rangle_\Box \|_{\ell_p} \right\}^q \right)^{1/q} , \quad 0 < \tau \le s' \tag{3.1.18}$$

as well as

$$\|v\|_{\tilde{\mathcal{F}}_\tau(\Box)} \sim \left(\sum_{j=j_0}^{\infty} \left\{ 2^{j(\frac{n}{2} - \frac{n}{p'} + \tau)} \|\langle v, \Psi_j^{\{0,1\}^n} \rangle_\Box \|_{\ell_{p'}} \right\}^q \right)^{1/q} , \quad 0 < \tau \le \tilde{s}'. \tag{3.1.19}$$

Remark 3.1.2. *We also remark that the validity of the first relation in* (3.1.17) *extends to the quasi-Banach spaces obtained for* $p < 1$ *which is important in the context of* nonlinear approximation [22, 26].

3.2. Wavelets on Γ_i. In order to relate the above setting on $\Box$ to the spaces $\mathcal{F}(\Gamma_i)^{\downarrow}$ we will associate with each patch Γ_i a set $\mathbf{Z}^{(i)} \subset \{0,1\}^n$ determined by the flow. In fact, the component sets $Z_\ell^{(i)}$ in $\mathbf{Z}^{(i)} = Z_1^{(i)} \times \cdots \times Z_n^{(i)}$ are characterized by

$$\kappa_i^{-1}\left(\partial^{\downarrow}\Gamma_i\right) = \bigcup_{\ell=1}^{n} [0,1]^{\ell-1} \times Z_\ell^{(i)} \times [0,1]^{n-\ell} \tag{3.2.1}$$

(where $Z_\ell^{(i)}$ could, of course, be empty); see (3.1.3). In other words, $\mathbf{Z}^{(i)}$ encodes the preimage of the inflow boundary $\partial^{\downarrow}\Gamma_i$. Accordingly, $\tilde{\mathbf{Z}}^{(i)} := \{0,1\}^n \setminus \mathbf{Z}^{(i)}$ determines the preimage of the outflow boundary $\partial^{\uparrow}\Gamma_i$ of Γ_i.

Due to the assumed regularity of the mappings κ_i the local smoothness spaces on Γ_i can be characterized by corresponding pull-backs to the parameter domain $\Box$. An immediate consequence of Remark 2.2.4 can be formulated as follows.

Remark 3.2.1. *For* $\mathbf{Z}^{(i)}$ *defined by* (3.2.1) *and any regular smooth parametrization* κ_i *of* Γ_i *one has*

$$\mathcal{F}(\Box)_{\mathbf{Z}^{(i)}} = \{v \circ \kappa_i : v \in \mathcal{F}(\Gamma_i)^{\downarrow}\} \tag{3.2.2}$$

and

$$\|v\|_{\mathcal{F}(\Gamma_i)^{\downarrow}} \sim \|v \circ \kappa_i\|_{\mathcal{F}(\Box)_{\mathbf{Z}^{(i)}}}, \quad v \in \mathcal{F}(\Gamma_i)^{\downarrow}. \tag{3.2.3}$$

Completely analogous relations hold for $\mathcal{F}, \downarrow$ *replaced by* $\tilde{\mathcal{F}}, \uparrow$.

Setting $\Phi \circ \kappa_i := \{\phi \circ \kappa_i : \phi \in \Phi\}$ and defining the push-forwards onto the patches Γ_i

$$\Psi^{\Gamma_i,\downarrow} := \Psi^{\mathbf{Z}^{(i)}} \circ \kappa_i^{-1}, \quad \tilde{\Psi}^{\Gamma_i,\uparrow} := \tilde{\Psi}^{\tilde{\mathbf{Z}}^{(i)}} \circ \kappa_i^{-1}, \tag{3.2.4}$$

we immediately infer from the definition of $(\cdot,\cdot)_i$ and (3.1.7) that these collections are biorthogonal, i.e.,

$$(\Psi^{\Gamma_i,\downarrow}, \tilde{\Psi}^{\Gamma_i,\uparrow})_i = \langle \Psi^{\mathbf{Z}^{(i)}}, \tilde{\Psi}^{\tilde{\mathbf{Z}}^{(i)}} \rangle_{\Box} = \mathbf{I}. \tag{3.2.5}$$

Moreover, it follows from Remark 3.2.1 and (3.1.8) that

$$\Psi^{\Gamma_i,\downarrow} \subset \mathcal{F}_{s'}(\Gamma_i)^{\downarrow}, \quad \tilde{\Psi}^{\Gamma_i,\uparrow} \subset \tilde{\mathcal{F}}_{\tilde{s}'}(\Gamma_i)^{\uparrow}. \tag{3.2.6}$$

We can now lift the relations (3.1.17) to the patches Γ_i. Since by (2.2.3) and (3.2.4),

$$(v, \tilde{\Psi}^{\Gamma_i,\uparrow})_i = \langle v \circ \kappa_i, \tilde{\Psi}^{\tilde{\mathbf{Z}}^{(i)}} \rangle_{\Box}, \quad (v, \Psi^{\Gamma_i,\downarrow})_i = \langle v \circ \kappa_i, \Psi^{\mathbf{Z}^{(i)}} \rangle_{\Box}, \tag{3.2.7}$$

the relation (3.2.3) combined with (3.1.17) provides for $\mathcal{F} = B_q^\tau(L_p)$ (and the respective range of $\tau \le s'$)

$$\begin{aligned} \|v\|_{\mathcal{F}(\Gamma_i)^{\downarrow}} &\sim \left(\sum_{j=j_0}^{\infty} \left\{ 2^{j(\frac{n}{2} - \frac{n}{p} + \tau)} \|(v, \tilde{\Psi}_j^{\Gamma_i,\uparrow})_i\|_{\ell_p} \right\}^q \right)^{1/q}, \quad v \in \mathcal{F}(\Gamma_i)^{\downarrow}, \\ \|v\|_{\mathcal{F}^*(\Gamma_i)^{\uparrow}} &\sim \left(\sum_{j=j_0}^{\infty} \left\{ 2^{j(\frac{n}{2} - \frac{n}{p'} - \tau)} \|(v, \Psi_j^{\Gamma_i,\downarrow})_i\|_{\ell_{p'}} \right\}^{q'} \right)^{1/q'}, \quad v \in \mathcal{F}^*(\Gamma_i)^{\uparrow}. \end{aligned} \tag{3.2.8}$$

Here we have used that, due to the smoothness of the κ_i, the Riesz maps interrelating the inner products $(\cdot,\cdot)_i$ and $\langle \cdot,\cdot \rangle_{\Gamma_i}$ are automorphisms for all the spaces $\mathcal{F}$ under consideration.

REMARK 3.2.2. *Analogous relations hold, of course, when $\mathcal{F}(\Gamma_i)^{\downarrow}$, $\tilde{\Psi}_j^{\Gamma_i,\uparrow}$ in the first relation of* (3.2.8) *are replaced by $\tilde{\mathcal{F}}(\Gamma_i)^{\uparrow}$, $\Psi_j^{\Gamma_i,\downarrow}$, respectively. Likewise $\mathcal{F}^*(\Gamma_i)^{\uparrow}$, $\Psi_j^{\Gamma_i,\downarrow}$ in the second relation of* (3.2.8) *can be replaced by $\tilde{\mathcal{F}}^*(\Gamma_i)^{\downarrow}$, $\tilde{\Psi}_j^{\Gamma_i,\uparrow}$ and s' is replaced by $\tilde{s}'$, respectively.*

3.3. Wavelets on Γ. It is now straightforward to assemble bases on Γ. To this end, consider the inner product

$$\langle \cdot,\cdot \rangle_{\Pi} := \sum_{i=1}^{N} \langle \cdot,\cdot \rangle_{\Gamma_i} \tag{3.3.1}$$

on the product space $\prod_{i=1}^{N} L_2(\Gamma_i)$. Let T, V, S, U denote the mappings from (2.4.6) and (2.4.7). Employing in the following the abbreviation

$$\nabla^i := \nabla^{\mathbf{Z}^{(i)}}, \quad i = 1, \ldots, N,$$

for the index sets of the bases $\Psi^{\mathbf{Z}^{(i)}}, \tilde{\Psi}^{\tilde{\mathbf{Z}}^{(i)}}$, we set

$$\begin{aligned} &\psi_\lambda^\Gamma := P_i \chi_{\Gamma_i} \psi_\nu^{\Gamma_i,\downarrow}, \quad \lambda := (i,\nu),\ \nu \in \nabla^i,\ i = 1,\dots,N, \\ &\tilde{\psi}_\lambda^\Gamma := P_i^* \chi_{\Gamma_i} g_i^{-1} \tilde{\psi}_\nu^{\Gamma_i,\uparrow}, \quad \lambda := (i,\nu),\ \nu \in \nabla^i,\ i = 1,\dots,N, \end{aligned} \tag{3.3.2}$$

where g_i is defined by (2.2.2). Note that these relations can be further simplified. In fact, by (3.2.6), (2.5.13), and the definition (2.4.3) of the P_i, one has

$$\psi_\lambda^\Gamma = \chi_{\Gamma_i^\uparrow} E_i \psi_\nu^{\Gamma_i,\downarrow}, \quad \lambda = (i,\nu) \in \nabla^\Gamma. \tag{3.3.3}$$

Setting

$$\nabla^\Gamma := \bigcup_{i=1}^N (\{i\} \times \nabla^i)$$

(and analogously for the components Δ_+, ∇_-) the collections

$$\Psi^\Gamma := \{\psi_\lambda^\Gamma : \lambda \in \nabla^\Gamma\}, \quad \tilde{\Psi}^\Gamma := \{\tilde{\psi}_\lambda^\Gamma : \lambda \in \nabla^\Gamma\} \tag{3.3.4}$$

are natural candidates for wavelets on Γ.

To see this, we may identify, in view of (3.2.6), each $\psi_\nu^{\Gamma_i,\downarrow}, \nu \in \nabla^i$, with an element $\mathbf{v}_\nu^{i,\downarrow} \in \Pi\mathcal{F}^\downarrow$, obtained by setting all other components to zero. Analogously define $\mathbf{v}_\nu^{\Gamma_i,\uparrow}$ with $\psi_\nu^{\Gamma_i,\downarrow}$ replaced by $g_i^{-1}\tilde{\psi}_\nu^{\Gamma_i,\uparrow}$. By (2.4.7), this means that

$$\psi_\lambda^\Gamma = S\mathbf{v}_\nu^{i,\downarrow}, \quad \tilde{\psi}_\lambda^\Gamma = U\mathbf{v}_\nu^{i,\uparrow}, \quad \lambda = (i,\nu) \in \nabla^\Gamma; \tag{3.3.5}$$

in brief

$$\Psi^\Gamma = S\{\Psi^{\Gamma_i,\downarrow}\}_{i=1}^N, \quad \tilde{\Psi}^\Gamma = U\{g_i^{-1}\tilde{\Psi}^{\Gamma_i,\uparrow}\}_{i=1}^N. \tag{3.3.6}$$

The following observation confirms that the collections Ψ^Γ and $\tilde{\Psi}^\Gamma$ are reasonable candidates for wavelet bases on Γ.

THEOREM 3.1. *Suppose that Properties B hold for the wavelet bases on* $\Box$. *Then the collections* $\Psi^\Gamma, \tilde{\Psi}^\Gamma$ *defined by* (3.3.6) *are biorthogonal with respect to the canonical inner product on* Γ

$$\langle \Psi^\Gamma, \tilde{\Psi}^\Gamma \rangle_\Gamma = \mathbf{I}. \tag{3.3.7}$$

Proof. By (3.3.2), we obtain for $\lambda = (i,\nu), \lambda' = (l,\mu)$

$$\langle \psi_\lambda^\Gamma, \tilde{\psi}_{\lambda'}^\Gamma \rangle_\Gamma = \langle S\mathbf{v}_\nu^{i,\downarrow}, U\mathbf{v}_\mu^{l,\uparrow} \rangle_\Gamma = \langle \mathbf{v}_\nu^{i,\downarrow}, S^*U\mathbf{v}_\mu^{l,\uparrow} \rangle_\Pi.$$

In view of (2.4.17) and the fact that $P_i^* P_l^* = \delta_{i,l} P_i^*$, the right-hand side becomes

$$\langle \mathbf{v}_\nu^{i,\downarrow}, S^*U\mathbf{v}_\mu^{l,\uparrow} \rangle_\Pi = \delta_{i,l} \langle \psi_\nu^{\Gamma_i,\downarrow}, P_i^*(\chi_{\Gamma_i} g_l^{-1} \tilde{\psi}_\mu^{\Gamma_l,\uparrow}) \rangle_{\Gamma_i},$$

where we have used (2.4.7). Since, by Theorem 2.2, $(P_i^* \chi_{\Gamma_i^{\downarrow\downarrow}} v) \mid_{\Gamma_i} = v \mid_{\Gamma_i}$ for $v \mid_{\Gamma_i} \in \tilde{\mathcal{F}}(\Gamma_i)^\uparrow$, we conclude

$$\langle \psi_\lambda^\Gamma, \tilde{\psi}_{\lambda'}^\Gamma \rangle_\Gamma = \delta_{i,l} \langle \psi_\nu^{\Gamma_i,\downarrow}, g_l^{-1} \tilde{\psi}_\mu^{\Gamma_l,\uparrow} \rangle_{\Gamma_i} = \delta_{i,l} \delta_{\nu,\mu},$$

where we have first used (2.2.4) to switch from $\langle\cdot,\cdot\rangle_{\Gamma_i}$ to $(\cdot,\cdot)_i$ and then employed (3.1.7). This confirms biorthogonality (3.3.7). □

A closer look at the above construction principle (3.3.2) reveals that one can similarly realize biorthogonality relative to some modified inner product which could, for instance, be required from a particular variational formulation of an operator equation. In absence of any such specification we focus here on the standard inner product as opposed to one that depends on the construction of the wavelet bases as, e.g., in [7, 12, 21].

REMARK 3.3.1. *Recall that the wavelets on Γ_i have been defined for* any *regular parametrization of Γ_i. Their construction is in this sense completely local and* independent *of the neighboring patches. The global regularity of the manifold enters the construction of the wavelets on Γ only through the extension operators in* (3.3.3). *Only the application of these extension operators (or their adjoints) will require smoothly joining locally (re)parametrizations of neighboring patches; see sections* 4, 5 *below.*

3.4. Approximation and inverse properties, norm equivalences. We are now ready to discuss the stability properties of the bases $\Psi^\Gamma, \tilde{\Psi}^\Gamma$ on Γ. The first step is to know how accurately one can approximate by elements of the spaces

$$S_j := \operatorname{span}\{\psi_\lambda^\Gamma : \lambda \in \nabla,\ |\lambda| < j\}, \quad \tilde{S}_j := \operatorname{span}\{\tilde{\psi}_\lambda^\Gamma : \lambda \in \nabla,\ |\lambda| < j\}. \tag{3.4.1}$$

THEOREM 3.2. *Under the above assumptions one has for any $0 \le \tau \le s'$*

$$\inf_{v_j \in S_j} \|v - v_j\|_{\mathcal{F}_\tau(\Gamma)} \lesssim 2^{-j(s-\tau)} \|v\|_{\mathcal{F}_s(\Gamma)}, \quad v \in \mathcal{F}_s(\Gamma), \tag{3.4.2}$$

and similarly for $0 \le \tau \le \tilde{s}'$

$$\inf_{v_j \in \tilde{S}_j} \|v - v_j\|_{\tilde{\mathcal{F}}_\tau(\Gamma)} \lesssim 2^{-j(s-\tau)} \|v\|_{\tilde{\mathcal{F}}_s(\Gamma)}, \quad v \in \tilde{\mathcal{F}}_s(\Gamma). \tag{3.4.3}$$

Moreover, when $\mathcal{F}_{s'} = H^{s'} = B_2^{s'}(L_2)$ assume that for a given $v \in \mathcal{F}_s(\Gamma)$ the components v^i of $Tv = \{v^i\}_{i=1}^N$, respectively, of $Vv = \{v^i\}_{i=1}^N$, are smooth. Then one has

$$\inf_{v_j \in V_j} \|v - v_j\|_{L_2(\Gamma)} \lesssim 2^{-mj} \left(\sum_{i=1}^N \|v^i\|_{H^m(\Gamma)} \right) \tag{3.4.4}$$

with $m = d, \tilde{d}$, when $V_j = S_j, \tilde{S}_j$, respectively.

Proof. Recall from (3.3.2) that any $v_j = \sum_{\lambda \in \nabla^\Gamma, |\lambda| < j} d_\lambda \psi_\lambda^\Gamma$ has the form $v_j = \sum_{i=1}^N \sum_{\nu \in \nabla^i, |\nu| < j} d_{i,\nu} P_i \chi_{\Gamma_i} \psi_\nu^{\Gamma_i,\downarrow}$. Moreover, since by Theorem 2.1, (2.4.7), $v = STv = \sum_{l=1}^N P_l \chi_{\Gamma_l} v^l$ one readily infers from (2.4.8) and (2.5.13) that $(P_i v)\,|_{\Gamma_i} = v^i$. Thus Proposition 2.4.1 (i) yields

$$(P_i(v - v_j))\,|_{\Gamma_i} = v^i - \sum_{\nu \in \nabla^i, |\nu| < j} d_{i,\nu} \psi_\nu^{\Gamma_i,\downarrow}.$$

Therefore, one obtains by Theorem 2.3 for $0 \le \tau \le s' < s_\Gamma$

$$\inf_{v_j \in S_j} \|v - v_j\|_{\mathcal{F}_\tau(\Gamma)}^2 \lesssim \sum_{i=1}^N \inf_{d_{i,\nu}} \|v^i - \sum_{\nu \in \nabla^i, |\nu| < j} d_{i,\nu} \psi_\nu^{\Gamma_i,\downarrow}\|_{\mathcal{F}_\tau(\Gamma_i)^\downarrow}. \tag{3.4.5}$$

From Properties C (i), (3.1.14), and Remark 2.2.4, we infer that

$$\begin{aligned}\inf_{d_{i,\nu}} \|v^i - \sum_{\nu\in\nabla^i,|\nu|<j} d_{i,\nu}\psi_\nu^{\Gamma_i,\downarrow}\|_{\mathcal{F}_\tau(\Gamma_i)^\downarrow} &\lesssim \inf_{d_{i,\nu}} \|v^i\circ\kappa_i - \sum_{\nu\in\nabla^i,|\nu|<j} d_{i,\nu}\psi_\nu^{\mathbf{Z}^{(i)}}\|_{\mathcal{F}_\tau(\Box)_{\mathbf{Z}^{(i)}}}\\ &\lesssim 2^{-j(s-\tau)}\|v^i\circ\kappa_i\|_{\mathcal{F}_s(\Box)_{\mathbf{Z}^{(i)}}}\\ &\lesssim 2^{-j(s-\tau)}\|v^i\mid_{\Gamma_i}\|_{\mathcal{F}_s(\Gamma_i)^\downarrow}.\end{aligned}$$

Combining this with (3.4.5) and invoking Theorem 2.3 yields (3.4.2) for $s' \geq \tau \geq 0$ and $V_j = S_j$.

Let us establish now the estimates for the dual multiresolution spaces $\tilde{S}_j$. Since $g_i^{-1}\tilde{\psi}_\nu^{\Gamma_i,\uparrow} \in \tilde{\mathcal{F}}_\tau(\Gamma_i)^\uparrow$ for $\tau \leq \tilde{s}' < s_\Gamma$ the second relation of (2.5.13) in Theorem 2.2 implies that $(P_i^*\chi_{\Gamma_i}g_i^{-1}\tilde{\psi}_\nu^{\Gamma_i,\uparrow})\mid_{\Gamma_i}= g_i^{-1}\tilde{\psi}_\nu^{\Gamma_i,\uparrow}$, we conclude as above (this time using Proposition 2.4.2) that

$$\inf_{v_j\in\tilde{S}_j} \|v-\tilde{v}_j\|^2_{\mathcal{F}_\tau(\Gamma)} \lesssim \sum_{i=1}^N \inf_{d_{i,\nu}} \|(P_i^*v)\mid_{\Gamma_i} - \sum_{\nu\in\nabla^i,|\nu|<j} d_{i,\nu}g_i^{-1}\tilde{\psi}_\nu^{\Gamma_i,\uparrow}\|^2_{\tilde{\mathcal{F}}_\tau(\Gamma_i)^\uparrow}.$$

Thus it remains to estimate $\|g_i^{-1}(g_iv^i - \sum_{\nu\in\nabla^i,|\nu|<j} d_{i,\nu}\tilde{\psi}_\nu^{\Gamma_i,\uparrow})\|_{\tilde{\mathcal{F}}_\tau(\Gamma_i)^\uparrow}$ which, in view of (3.1.15), proceeds exactly as above. This confirms (3.4.3) for $s \geq \tau \geq 0$.

The rest of the assertion follows again from (3.1.14) applied to the pull-back of

$$\inf_{d_{i,\nu}} \|v^i - \sum_{\nu\in\nabla^i,|\nu|<j} d_{i,\nu}\psi_\nu^{\Gamma_i,\downarrow}\|_{\mathcal{F}_\tau(\Gamma_i)^\downarrow} \lesssim 2^{-j(d-\tau)}\|v^i\|_{\mathcal{F}_{d,s'}(\Gamma_i)},$$

where $\mathcal{F}_{d,s'}(\Gamma_i)$ is the push-forward of $\mathcal{F}_{d,s'}(\Box)_{\mathbf{Z}^{(i)}} = H^d(\Box)\cap\mathcal{F}_{s'}(\Box)_{\mathbf{Z}^{(i)}}$. □

Remark 3.4.1. *When Γ had a boundary, one could have incorporated homogeneous Dirichlet boundary conditions on all or part of the boundary composed of a union of patch boundaries. It is obvious from the above proof that analogous estimates persist to hold as long as the approximands satisfy corresponding boundary conditions. Details are left to the reader.*

There is the following counterpart to estimates of the type (3.4.2).

Remark 3.4.2. *One has*

$$\|v_j\|_{\mathcal{F}_{\tau,s'}(\Gamma)} \lesssim 2^{\tau j}\|v_j\|_{L_p(\Gamma)}, \quad v_j \in S_j,\ 0\leq\tau<\min\{s_\Gamma,\gamma\}. \tag{3.4.6}$$

An analogous estimate holds for the spaces $\tilde{S}_j$ with $\mathcal{F}, p, s', \gamma$, replaced by $\tilde{\mathcal{F}}, p', \tilde{s}', \tilde{\gamma}$.

Proof. Properties C (i) (3.1.16) ensures that

$$\|v_j\|_{\mathcal{F}_{\tau,s'}(\Box)_{\mathbf{Z}^{(i)}}} \lesssim 2^{\tau j}\|v_j\|_{L_p(\Box)}, \quad v_j \in S_{j,\mathbf{Z}^{(i)}}\ \forall\ 0\leq\tau\leq\gamma. \tag{3.4.7}$$

Analogous estimates for the spaces $\mathcal{F}_\tau(\Gamma_i)^\downarrow$ follow immediately from Remark 3.2.1. Now one can invoke Theorem 2.3 to confirm (3.4.6). □

Because of its importance we consider first the special case $\mathcal{F}_\tau = H^\tau$, i.e., $p = q = 2$. Combining Theorem 3.2 with Remark 3.4.2 we can apply Corollary 5.2 in [14] to conclude the following Sobolev norm equivalences for a *whole regularity range* which play a key role in wavelet concepts for the numerical solution of operator equations; see section 5.

THEOREM 3.3. *Under the above assumptions one has for any $v \in H^\tau(\Gamma)$*

$$\|v\|_{H^\tau(\Gamma)} \sim \left(\sum_{\lambda \in \nabla^\Gamma} 2^{2\tau|\lambda|} |\langle v, \tilde{\psi}_\lambda^\Gamma \rangle_\Gamma|^2 \right)^{1/2}, \quad \tau \in [-\tilde{s}', s']; \tag{3.4.8}$$

see (3.1.12), *where for $\tau < 0$ we mean as usual $H^\tau(\Gamma) = (H^{-\tau}(\Gamma))^*$. An analogous relation holds with $\tilde{\psi}_\lambda^\Gamma$ replaced by ψ_λ^Γ and reversed end points of the interval describing the range of validity. In particular, $\Psi^\Gamma, \tilde{\Psi}^\Gamma$ are Riesz bases for $L_2(\Gamma)$.*

Again we could have formulated analogous relations for Sobolev spaces $H^s_{0,D}(\Gamma)$ satisfying homogeneous Dirichlet boundary conditions on some part D of the boundary of Γ.

REMARK 3.4.3. *In the case $p = 2 = q$, i.e., $\mathcal{F}_s = H^s$ it is important to estimate the error in dual norms; see* [19]. *In particular, we have for $-\sigma \leq \tau \leq \sigma$*

$$\inf_{v_j \in V_j} \|v - v_j\|_{H^\tau(\Gamma)} \lesssim 2^{-j(s-\tau)} \|v\|_{H^s(\Gamma)}, \quad v \in H^s(\Gamma), \tag{3.4.9}$$

where $\sigma = s' < \gamma, \tilde{s}' < \tilde{\gamma}$ for $V_j = S_j, \tilde{S}_j$, respectively.

Proof. As usual one can use duality for the case $\tau < 0$. In fact, let

$$Q_j v := \sum_{\lambda \in \nabla^\Gamma} \langle v, \tilde{\psi}_\lambda^\Gamma \rangle_\Gamma \psi_\lambda^\Gamma, \quad Q_j^* v := \sum_{\lambda \in \nabla^\Gamma} \langle v, \psi_\lambda^\Gamma \rangle_\Gamma \tilde{\psi}_\lambda^\Gamma,$$

and observe that, due to the uniform boundedness of the Q_j, Q_j^* in $H^\tau(\Gamma)$, $0 \leq \tau \leq s', \tilde{s}'$, which follows from Theorem 3.3,

$$\|v - Q_j v\|_{H^\tau(\Gamma)} \lesssim \inf_{v_j \in S_j} \|v - v_j\|_{H^\tau(\Gamma)}, \quad \|v - Q_j^* v\|_{H^\tau(\Gamma)} \lesssim \inf_{\tilde{v}_j \in \tilde{S}_j} \|v - \tilde{v}_j\|_{H^\tau(\Gamma)}.$$

Now suppose that $0 < \tau \leq s$ and note that

$$\begin{aligned} \|v - Q_j v\|_{H^{-\tau}(\Gamma)} &= \sup_{\|w\|_{H^\tau(\Gamma)}=1} \langle Q_j v - v, w \rangle_\Gamma = \sup_{\|w\|_{H^\tau(\Gamma)}=1} \langle (Q_j - I)^2 v, w \rangle_\Gamma \\ &= \sup_{\|w\|_{H^\tau(\Gamma)}=1} \langle Q_j v - v, Q_j^* w - w \rangle_\Gamma \\ &\leq \sup_{\|w\|_{H^\tau(\Gamma)}=1} \|Q_j v - v\|_{L_2(\Gamma)} \|w - Q_j^* w\|_{L_2(\Gamma)} \\ &\lesssim \sup_{\|w\|_{H^\tau(\Gamma)}=1} \left(2^{-j\tau} \|w\|_{H^\tau(\Gamma)} 2^{-js} \|v\|_{H^s(\Gamma)} \right), \end{aligned}$$

where we have used the previously established estimates for positive Sobolev indices. The reasoning for $\tilde{S}_j$ is completely analogous. □

We conclude this section with similar norm equivalences for the general case of Besov spaces $\mathcal{F}_\tau = B^\tau_q(L_p)$. This time we combine the local relations (3.2.8) with Theorem 2.3 to derive similar relations for Γ.

THEOREM 3.4. *One has for $\mathcal{F} = B^\tau_q(L_p)$ and $\frac{1}{p} + \frac{1}{p'} = \frac{1}{q} + \frac{1}{q'} = 1$, $0 < \tau \leq s'$,*

$$\|v\|_{\mathcal{F}(\Gamma)} \sim \left(\sum_{j=j_0}^\infty \left\{ 2^{j(\frac{n}{2} - \frac{n}{p} + \tau)} \|\langle v, \tilde{\Psi}_j^\Gamma \rangle_\Gamma\|_{\ell_p} \right\}^q \right)^{1/q}, \quad v \in \mathcal{F}(\Gamma), \tag{3.4.10}$$

and

$$\text{(3.4.11)}\quad \|v\|_{\mathcal{F}^*(\Gamma)} \sim \left(\sum_{j=j_0}^{\infty}\left\{2^{j(\frac{d}{2}-\frac{d}{p'}-\tau)}\|\langle v,\Psi_j^{\Gamma}\rangle_{\Gamma}\|_{\ell_{p'}}\right\}^{q'}\right)^{1/q'}, \qquad v\in\mathcal{F}^*(\Gamma).$$

Analogous relations hold when interchanging the roles of Ψ^{Γ}, s' *and* $\tilde{\Psi}^{\Gamma}, \tilde{s}'$.

Proof. By Theorem 2.3, we have

$$\text{(3.4.12)}\qquad \|v\|_{\mathcal{F}(\Gamma)} \sim \left(\sum_{i=1}^{N}\|(P_i v)\,|_{\Gamma_i}\,\|^q_{\mathcal{F}(\Gamma_i)^{\downarrow}}\right)^{1/q}.$$

Invoking (3.2.8), one obtains

$$\text{(3.4.13)}\qquad \|(P_i v)\,|_{\Gamma_i}\,\|^q_{\mathcal{F}(\Gamma_i)^{\downarrow}} \sim \sum_{j=j_0}^{\infty}\left\{2^{j(\frac{n}{2}-\frac{n}{p}+\tau)}\|(P_i v,\tilde{\Psi}_j^{\Gamma_i,\uparrow})_i\|_{\ell_p}\right\}^q.$$

Since again, by (2.2.4) and (3.3.2), analogous reasoning to the above yields

$$\text{(3.4.14)}\qquad \begin{aligned}(P_i v,\tilde{\psi}_{\nu}^{\Gamma_i,\uparrow})_i &= \langle P_i v, g_i^{-1}\tilde{\psi}_{\nu}^{\Gamma_i,\uparrow}\rangle_{\Gamma_i} = \langle P_i v, \chi_{\Gamma_i} g_i^{-1}\tilde{\psi}_{\nu}^{\Gamma_i,\uparrow}\rangle_{\Gamma}\\ &= \langle v, P_i^*\chi_{\Gamma_i} g_i^{-1}\tilde{\psi}_{\nu}^{\Gamma_i,\uparrow}\rangle_{\Gamma} = \langle v,\tilde{\psi}^{\Gamma}_{(i,\nu)}\rangle_{\Gamma},\end{aligned}$$

and combining (3.4.12), (3.4.13), and (3.4.14) provides (3.4.10). The equivalence relation (3.4.11) follows by analogous arguments based on (2.5.19) in Theorem 2.3 and again in (3.2.8). □

Note that we could have recovered Theorem 3.3 from Theorem 3.4 combined with an interpolation and duality argument; see [14]. Accordingly, we would get for $\tau = 0$ a norm equivalence for $B^0_q(L_p(\Gamma))$ which differs from L_p when $p \neq 2$.

REMARK 3.4.4. *Again if one dispenses with duality relations, the validity of equivalences of the type* (3.4.10) *(for positive regularity index τ) extends to $p < 1$ which follows from Remark* 3.1.2 *and a corresponding version of the first relation in* (2.5.17) *of Theorem* 2.3.

4. Extensions. The above construction and, in particular, its *practicality* hinges on the identification of suitable extension operators. This section is devoted to this issue. We will depart from the development in [9] by interrelating the construction of extension operators directly with the wavelet bases on □. This will result in *scale-dependent* extensions. First we need a few preparations.

4.1. Lifted extensions. In view of the preceding development it is natural to construct extensions in the parameter domain and then lift them to the manifold. To this end, we adhere to the notation in section 3.1 and recall the meaning of $\square_{\tilde{\mathbf{Z}}^{(i)}}$ from (3.2.1) and (3.1.2). At this point we have to interrelate the parametrizations of the patches Γ_i with the global smoothness of the manifold. For every patch Γ_i this will concern only κ_i and the parametrizations of *neighboring* patches. In particular, at *no point* will our approach ever require any specific *global* parametric representation of Γ. We will address this issue in two steps. First we identify the conceptually relevant property which holds in full generality, then we formulate a more specified version which is desirable from a practical point of view. Since the validity of this latter property has been verified for various concrete constructions only for $n \leq 2$, we prefer to state it separately.

Property G. *There exists a neighborhood $\diamond \subset \mathbb{R}^n$ of $\square$, i.e.,* $\operatorname{dist}(\partial\square, \partial\diamond) \geq a > 0$, *such that for each $i = 1, \dots, N$ one can find a neighborhood $\hat{\Gamma}_i$ of Γ_i in the above sense and a parametric mapping $\hat{\kappa}_i$ such that*

$$\hat{\kappa}_i(\diamond) = \hat{\Gamma}_i, \quad \hat{\kappa}_i, \hat{\kappa}_i^{-1} \in C^{m,1}, \quad \hat{\kappa}_i|_{\square} = \kappa_i. \tag{4.1.1}$$

In brief, each κ_i can be extended to a $C^{m,1}$-homeomorphism to some open neighborhood of Γ_i.

We emphasize first that Property G entails *no* constraints on the topology of Γ. In fact, recall that our smoothness assumption on Γ means that there exists a covering $\mathcal{C}$ of Γ of neighborhoods Γ' which are $C^{m,1}$-homeomorphic images of neigborhoods in $\mathbb{R}^n$. Since Γ is compact, one can subdivide the patch complex $\{\Gamma_i\}$ finiteley many times, e.g., by dyadic subdivisions of the parameter domain $\square$, such that the closure of each of the resulting cubical patches on Γ is fully contained in some neighborhood in $\mathcal{C}$. Thus, independently of the topology of Γ, there exists a $C^{m,1}$ parametrization of a neighborhood of each patch in the (subdivided) complex as stated in Property G.

Of course, this argument is not very practical. A little more effort shows that extensibility in the sense of (4.1.1) can be confirmed without subdividing the patch complex. A constructive argument can be based on building first a $C^{m,1}$-extension of a given κ_i which takes a neigborhood of $\square$ into a $C^{m,1}$ parametric extension of Γ_i staying close to Γ. A suitable "smooth correction" yields then a $C^{m,1}$ parametric representation of a neighborhood of Γ_i in Γ. While Property G is important for theoretical reasons it is not quite satisfactory from a practical point of view so that we dispense here with going into more details of the argument.

A practical counterpart to Property G that in the framework of [31, 42, 44] is realized for *arbitrary topology* can now be formulated as follows.

Property G′. *For any $i \in \{1, \dots, N\}$, let*

$$\hat{\Gamma}_i := \bigcup \{\overline{\Gamma}_l : \overline{\Gamma}_l \cap \overline{\Gamma}_i \neq \emptyset\}$$

denote the union of all patches whose closure intersects the closure of Γ_i. If $\hat{\Gamma}_i$ is topologically equivalent to a domain in $\mathbb{R}^n$, then there exists a neighborhood $\diamond \subset \mathbb{R}^n$ of $\square$ and a parametric mapping $\hat{\kappa}_i$ such that

$$\hat{\kappa}_i(\diamond) = \hat{\Gamma}_i, \quad \hat{\kappa}_i \hat{\kappa}_i^{-1} \in C^{m,1}, \quad \hat{\kappa}_i|_{\Gamma_i} = \kappa_i. \tag{4.1.2}$$

Moreover, $\diamond$ is a disjoint union of subdomains of the form $\rho_l(\square)$, ($\rho_i(\square) = \square$) such that

$$\hat{\kappa}_i(\rho_l(\square)) = \Gamma_l, \tag{4.1.3}$$

i.e., the restriction of $\hat{\kappa}_i$ to $\rho_l(\square)$ is a regular reparametrization of κ_l.

Of course, the assumption that $\hat{\Gamma}_i$ is topologically equivalent to a domain in $\mathbb{R}^n$ is no serious restriction and can always be enforced by one subdivision step (which may be needed for separating singular vertices anyway, recall the discussion in section 2.1). We will therefore assume throughout the following that this holds for each $\hat{\Gamma}_i$.

For simplicity, assume now the validity of Property G′ in the general case. First recall that $\square_{\tilde{\mathbf{Z}}^{(i)}}$, $\Gamma_i^{\uparrow}$ are subsets of $\diamond$ and $\hat{\Gamma}_i$, respectively. Therefore let $\kappa_i^{\uparrow}$ denote the restriction of $\hat{\kappa}_i$ to $\square_{\tilde{\mathbf{Z}}^{(i)}}$, i.e.,

$$\kappa_i^{\uparrow}(\square_{\tilde{\mathbf{Z}}^{(i)}}) = \Gamma_i^{\uparrow}, \quad \kappa_i^{\uparrow}\Big|_{\square} = \kappa_i. \tag{4.1.4}$$

We could also work with Property G in which case $\Gamma_i^\uparrow$ has to be replaced by a suitable subset that still contains the relative interior of the outflow boundary (employing reparametrizations one does not have to restrict the domain $\square_{\tilde{\mathbf{Z}}^{(i)}}$). Of course, the smoothness of $\kappa_i^\uparrow$ (and analogously of $\kappa_i^\downarrow$) is now limited by the global smoothness of Γ.

Note that each mapping $\kappa_i : \square \to \Gamma_i$ (and likewise $\kappa_i^\uparrow$) induces a mapping $\kappa_i^* : \mathcal{F}(\Gamma_i) \to \mathcal{F}(\square)$ by

$$(\kappa_i^* v)(y) = v(\kappa_i(y)), \quad y \in \square. \tag{4.1.5}$$

Now suppose that $A_{\tilde{\mathbf{Z}}^{(i)}}$ is an extension from $\mathcal{F}(\square)$ into $\mathcal{F}(\square_{\tilde{\mathbf{Z}}^{(i)}})$ satisfying (2.5.7) and (2.5.8) and define

$$E_i = (\kappa_i^\uparrow)^{*\,-1} A_{\tilde{\mathbf{Z}}^{(i)}} \kappa_i^*, \quad i = 1, \ldots, N. \tag{4.1.6}$$

It is not hard to verify that then the E_i also satisfy (2.5.7) and (2.5.8).

Straightforward calculations show that when E_i is defined by (4.1.6) then the adjoints E_i^* are given by

$$E_i^* = (\kappa_i^{-1})^* \left(|\partial \kappa_i|^{-1} A^*_{\tilde{\mathbf{Z}}^{(i)}} (|\partial \kappa_i^\uparrow| (\kappa_i^\uparrow)^* \right). \tag{4.1.7}$$

It will be instructive to consider now the following concrete type of extensions used in [9] which will serve as *one possible* building block.

4.2. Hestenes extensions. Since all the domains appearing in the above construction are cubes, hyperrectangles, and their parametric images, it is natural to employ tensor products of extension operators for the unit interval. Following [9], suitable versions of Hestenes extensions appear to be a possible choice which will be pointed out first since it may be used as a starting point for subsequent modifications to be explained in more detail later. To this end, choose for some $l \in \mathbb{N}$ real numbers β_i such that

$$-2 \le \beta_1 < \cdots < \beta_l \le -\frac{1}{2}$$

and assume that $\eta \in C^\infty(\mathbb{R})$ satisfies

$$\eta(x) = \begin{cases} 1, & x \in \left[-\frac{1}{4}, \frac{1}{4}\right], \\ 0, & x \notin (-\frac{1}{2}, \frac{1}{2}). \end{cases} \tag{4.2.1}$$

Of course, the support of the cut-off function η could be chosen to be much smaller. The present choice refers for simplicity to Property G′ which is relevant for practical applications. Adaptations to Property G are straightforward and left to the reader. Now define

$$\begin{aligned} (A_Z f)(x) := {}& \chi_{[0,1]}(x) f(x) + \chi_{[-1,0] \cap [0,1]_Z}(x) \sum_{j=1}^{l} \alpha_j (\eta f)(\beta_j x) \\ & + \chi_{[1,2] \cap [0,1]_Z}(x) \sum_{j=1}^{l} \alpha_j \eta(\beta_j(x-1)) f(1 + \beta_j(x-1)), \end{aligned} \tag{4.2.2}$$

where the numbers $\alpha_j, j = 1, \dots l$, satisfy for $l \geq 2m+2$

$$\sum_{j=1}^{l} \alpha_j \beta_j^k = 1, \quad k = -m-1, \dots, m. \tag{4.2.3}$$

Hence, whenever $0 \in \tilde{Z}$, one has

$$\left(\frac{\mathrm{d}}{\mathrm{d}x}\right)^k (A_Z f)(x)\Big|_{x=0^-} = \sum_{j=1}^{l} \alpha_j \beta_j^k f^{(k)}(0) = f^{(k)}(0), \quad k = 0, \dots, m, \tag{4.2.4}$$

and, when $1 \in \tilde{Z}$,

$$\left(\frac{\mathrm{d}}{\mathrm{d}x}\right)^k (A_Z f)(x)\Big|_{x=1^+} = \sum_{j=1}^{l} \alpha_j \beta_j^k f^{(k)}(1) = f^{(k)}(1), \quad k = 0, \dots, m. \tag{4.2.5}$$

Here we have also used that for $2 \geq x \geq 1$ one has $\beta_j x \leq -\frac{1}{2}$, $j = 1, \dots, l$, so that, by (4.2.1), $\eta(\beta_j x) = 0$, $x \geq 1$. Likewise, when $x \leq 0$ one has $\beta_j(x-1) \geq \frac{1}{2}$, $j = 1, \dots, l$, so that $\eta(\beta_j(x-1)) = 0$ for $x \leq 0$.

Next note that

$$\begin{aligned}
\int\limits_{\mathbb{R}} (A_Z f)(x) g(x)\,\mathrm{d}x &= \int\limits_{[0,1]_Z} (A_Z f)(x) g(x)\,\mathrm{d}x \\
&= \int\limits_0^1 f(x) g(x)\,\mathrm{d}x + \int\limits_{[-1,0]\cap[0,1]_Z} \sum_{j=1}^{l} \alpha_j \eta(\beta_j x) f(\beta_j x) g(x)\,\mathrm{d}x \\
&\quad + \int\limits_{[1,2]\cap[0,1]_Z} \sum_{j=1}^{l} \alpha_j \eta(\beta_j(x-1)) f(1+\beta_j(x-1)) g(x)\,\mathrm{d}x.
\end{aligned}$$

Straightforward computation reveals that then

$$\begin{aligned}
(A_Z^* g)(x) &= \chi_{[0,1]}(x) g(x) \\
&\qquad -\chi_{[-1,0]\cap[0,1]_Z}(x-1) \sum_{j=1}^{l} \beta_j^{-1} \alpha_j \eta(x) g(\beta_j^{-1} x) \\
&\qquad -\chi_{[1,2]\cap[0,1]_Z}(1+x) \sum_{j=1}^{l} \beta_j^{-1} \alpha_j \eta(x-1) g(1+\beta_j^{-1}(x-1)).
\end{aligned} \tag{4.2.6}$$

Here we have used the choice of the support of the cut-off function η.

As before, the choice of the α_j, $j = 1, \dots, l$, ensures that when $0 \in Z$, resp., $1 \in Z$,

$$\left(\frac{\mathrm{d}}{\mathrm{d}x}\right)^\ell (A_Z^* g)(0) = 0, \quad \left(\frac{\mathrm{d}}{\mathrm{d}x}\right)^\ell (A_Z^* g)(1) = 0, \quad \ell = 0, \dots, m. \tag{4.2.7}$$

The next step is to form tensor products of these operators. To this end, let for $Z_\ell \subseteq \{0,1\}$, $\ell = 1, \dots, n$,

$$\mathbf{Z} := Z_1 \times \cdots \times Z_n$$

and define

$$A_{\mathbf{Z}} f = (A_{Z_1} \otimes \cdots \otimes A_{Z_n})\, f. \tag{4.2.8}$$

Here we set

$$(A_{Z_i} f)(x_1, \ldots, x_n) = (A_{Z_i} f(x_1, \ldots, x_{i-1}, \cdot, x_{i+1}, \ldots, x_n))(x_i)$$

and for $i \le n$

$$\begin{aligned} &((A_{Z_i} \otimes \cdots \otimes A_{Z_1})\, f)\, (x_1, \ldots, x_n) \\ &\quad = \big(A_{Z_i} \left((A_{Z_{i-1}} \otimes \cdots \otimes A_{Z_1})\, f\right) (x_1, \ldots, x_{i-1}, \cdot, x_{i+1}, \ldots, x_n)\big)\, (x_i). \end{aligned} \tag{4.2.9}$$

One can verify that for any permutation π of $\{1, \ldots, n\}$

$$A_{Z_1} \otimes \cdots \otimes A_{Z_n} = A_{Z_{\pi(1)}} \otimes \cdots \otimes A_{Z_{\pi(n)}}. \tag{4.2.10}$$

It remains to *lift* these extension operators to the manifold Γ as described in section 4.1. Recall from Property G that when Γ is a $C^{m,1}$-surface κ_i then $\kappa_i^{\uparrow}$ and its inverse can be chosen to be $C^{m,1}$, so that by construction, $\hat{E}_i$ defined by (4.1.6) in combination with the Hestenes extension (4.2.8) satisfies

$$\hat{E}_i v \in C^{m,1}(\Gamma_i^{\uparrow}) \text{ if } v \in C^{m,1}(\Gamma_i). \tag{4.2.11}$$

Note that for applications in connection with boundary integral equations the case $m = 0$ is of particular interest so that $l = 2$ in (4.2.2) suffices.

4.3. Scale-dependent modifications. From a practical point of view the above Hestenes extensions still have certain drawbacks. To explain this suppose that f is smooth and has support strictly contained in $(0, 1/4)$, say. Thus the trivial extension of f to $\mathbb{R}$ by zero would satisfy (4.2.5). However, it is clear that A_Z defined by (4.2.2) may very well differ from zero outside $(0, 1)$. Therefore, even though by Proposition 2.4.1 (ii) and (2.5.14) in Theorem 2.2,

$$\chi_{\Gamma_i} (P_i v) \,|_{\Gamma_i} = \chi_{\Gamma_i} v \in \mathcal{F}(\Gamma) \quad \text{for} \;\; v \in \mathcal{F}(\Gamma_i)^{\downarrow} \cap \mathcal{F}(\Gamma_i)^{\uparrow}, \tag{4.3.1}$$

the above property of the extensions E_i may cause that

$$P_i v \,|_{\Gamma \setminus \Gamma_i} \not\equiv 0, \tag{4.3.2}$$

i.e., $P_i v$ may differ from $\chi_{\Gamma_i} v$ on $\Gamma_i^{\uparrow}$ and hence on all of Γ.

In this section we will point out how to construct modified extension operators which do not suffer from this deficiency. To this end, we will assume throughout this section that $\hat{E}_i$ are *some* (initial) extension operators satisfying Assumption A (2.5.7), (2.5.8) (for instance, Hestenes extensions of the type discussed in section 4.2).

The next result says that one can always construct extensions also satisfying Assumption A in such a way that those wavelets which do not interfere with the outflow boundary are extended outside Γ_i by zero. To this end, recall from Properties B (iv) the sets

$$\Lambda_i^{\uparrow} := \Lambda_{\mathbf{Z}^{(i)}}^{\{0,1\}^n}, \tag{4.3.3}$$

where as before $\mathbf{Z}^{(i)}$ is related to Γ_i by (3.2.1).

Theorem 4.1. *Let $\mathcal{F} = \mathcal{F}_{s'}$. For $\hat{E}_i$ satisfying* (2.5.7), (2.5.8) *let*

$$E_i v := \sum_{\nu \in \nabla^i \setminus \Lambda_i^{\uparrow}} (v, \tilde{\psi}_\nu^{\Gamma_i,\uparrow})_i \hat{E}_i \psi_\nu^{\Gamma_i,\downarrow} + \sum_{\nu \in \Lambda_i^{\uparrow}} (v, \tilde{\psi}_\nu^{\Gamma_i,\uparrow})_i \chi_{\Gamma_i} \psi_\nu^{\Gamma_i,\downarrow}. \tag{4.3.4}$$

Then one has

$$\|E_i v\|_{\mathcal{F}(\Gamma_i^{\uparrow})^{\downarrow}} \lesssim \|v\|_{\mathcal{F}(\Gamma_i)^{\downarrow}}, \quad v \in \mathcal{F}(\Gamma_i)^{\downarrow}. \tag{4.3.5}$$

Moreover, the corresponding adjoints E_i^* satisfy (2.5.8) *now for $\tau \le \tilde{s}'$, i.e., the new extensions E_i also satisfy Assumption A.*

Proof. One immediately infers from (3.2.6) and the definition of $\Lambda_i^{\uparrow}$ that for any $v \in \mathcal{F}(\Gamma_i)^{\downarrow}$

$$v_0 := \sum_{\nu \in \Lambda_i^{\uparrow}} (v, \tilde{\psi}_\nu^{\Gamma_i,\uparrow})_i \chi_{\Gamma_i} \psi_\nu^{\Gamma_i,\downarrow} \in \mathcal{F}(\Gamma_i)^{\downarrow} \cap \mathcal{F}(\Gamma_i)^{\uparrow}.$$

By construction, one has $E_i v_0 = \chi_{\Gamma_i} v_0$ and

$$E_i(v - v_0) = \hat{E}_i(v - v_0), \tag{4.3.6}$$

so that we have

$$\|E_i v_0\|_{\mathcal{F}(\Gamma_i^{\uparrow})^{\downarrow}} = \|v_0\|_{\mathcal{F}(\Gamma_i)^{\uparrow\downarrow}}.$$

By Properties B (iv) and the definition of $\Lambda_i^{\uparrow}$, we can employ Remark 3.1.1 and (3.1.18) to estimate $\|v_0\|_{\mathcal{F}(\Gamma_i)^{\uparrow\downarrow}}$ by the discrete norm relative to $\Psi^{\{0,1\}^n}$. Since the summands appearing in this expression are a subset of the terms occurring in the discrete norm (3.2.8) of v expanded with respect to $\Psi^{\Gamma_i,\downarrow}$, we have

$$\|v_0\|_{\mathcal{F}(\Gamma_i)^{\uparrow\downarrow}} \lesssim \|v\|_{\mathcal{F}(\Gamma_i)^{\downarrow}}. \tag{4.3.7}$$

Furthermore, by Assumptions A (2.5.7) and (4.3.6),

$$\|E_i(v - v_0)\|_{\mathcal{F}(\Gamma_i^{\uparrow})^{\downarrow}} = \|\hat{E}_i(v - v_0)\|_{\mathcal{F}(\Gamma_i^{\uparrow})^{\downarrow}} \lesssim \|v\|_{\mathcal{F}(\Gamma_i)^{\downarrow}} + \|v_0\|_{\mathcal{F}(\Gamma_i)^{\downarrow}}.$$

Since $\|v_0\|_{\mathcal{F}(\Gamma_i)^{\downarrow}} \lesssim \|v_0\|_{\mathcal{F}(\Gamma_i)^{\downarrow,\uparrow}}$ we can invoke (4.3.7) again to conclude finally by (4.3.4),

$$\begin{aligned} \|E_i v\|_{\mathcal{F}(\Gamma_i^{\uparrow})^{\downarrow}} &\le \|E_i(v - v_0)\|_{\mathcal{F}(\Gamma_i^{\uparrow})^{\downarrow}} + \|E_i v_0\|_{\mathcal{F}(\Gamma_i^{\uparrow})^{\downarrow}} \\ &\lesssim \|v\|_{\mathcal{F}(\Gamma_i)^{\downarrow}} + 2\|v_0\|_{\mathcal{F}(\Gamma_i)^{\downarrow}} \lesssim \|v\|_{\mathcal{F}(\Gamma_i)^{\downarrow}}, \end{aligned}$$

which confirms (4.3.5).

As for the rest of the claim, note that for $w \in \tilde{\mathcal{F}}_{\tilde{s}'}(\Gamma_i^{\uparrow})$

$$\begin{aligned} \langle E_i v, w \rangle_{\Gamma_i^{\uparrow}} &= \sum_{\nu \in \nabla^i \setminus \Lambda_i^{\uparrow}} (v, \tilde{\psi}_\nu^{\Gamma_i,\uparrow})_i \langle \hat{E}_i \psi_\nu^{\Gamma_i,\downarrow}, w \rangle_{\Gamma_i^{\uparrow}} + \sum_{\nu \in \Lambda_i^{\uparrow}} (v, \tilde{\psi}_\nu^{\Gamma_i,\uparrow})_i \langle \psi_\nu^{\Gamma_i,\downarrow}, w \rangle_{\Gamma_i} \\ &= \left(v, \sum_{\nu \in \nabla^i \setminus \Lambda_i^{\uparrow}} \langle \hat{E}_i^* w, \psi_\nu^{\Gamma_i,\downarrow} \rangle_{\Gamma_i} \tilde{\psi}_\nu^{\Gamma_i,\uparrow} + \sum_{\nu \in \Lambda_i^{\uparrow}} \langle w, \psi_\nu^{\Gamma_i,\downarrow} \rangle_{\Gamma_i} \tilde{\psi}_\nu^{\Gamma_i,\uparrow} \right)_i \\ &= \left\langle v, g_i^{-1} \left\{ \sum_{\nu \in \nabla^i \setminus \Lambda_i^{\uparrow}} (g_i \hat{E}_i^* w, \psi_\nu^{\Gamma_i,\downarrow})_i \tilde{\psi}_\nu^{\Gamma_i,\uparrow} + \sum_{\nu \in \Lambda_i^{\uparrow}} (g_i w, \psi_\nu^{\Gamma_i,\downarrow})_i \tilde{\psi}_\nu^{\Gamma_i,\uparrow} \right\} \right\rangle_{\Gamma_i}, \end{aligned}$$

i.e.,

$$E_i^* w \;=\; g_i^{-1}\left\{\sum_{\nu\in\nabla^i\setminus\Lambda_i^{\uparrow}} (g_i\hat{E}_i^* w, \psi_\nu^{\Gamma_i,\downarrow})_i\tilde{\psi}_\nu^{\Gamma_i,\uparrow} + \sum_{\nu\in\Lambda_i^{\uparrow}} (g_i w, \psi_\nu^{\Gamma_i,\downarrow})_i\tilde{\psi}_\nu^{\Gamma_i,\uparrow}\right\}$$

$$=: w_1 + w_0. \tag{4.3.8}$$

By assumption (2.5.8) on $\hat{E}_i$, one has $\hat{E}_i^* w \in \tilde{\mathcal{F}}(\Gamma_i)^{\uparrow}$ since $\tilde{s}' \leq s$; see (3.1.12). By the obvious analog to (3.2.8) and Assumption A (2.5.8), one has

$$\|g_i w_1\|_{\tilde{\mathcal{F}}_{\tilde{s}'}(\Gamma_i)^{\uparrow}} \;\lesssim\; \|g_i\hat{E}_i^* w\|_{\tilde{\mathcal{F}}_{\tilde{s}'}(\Gamma_i)^{\uparrow}} \;\lesssim\; \|w\|_{\tilde{\mathcal{F}}(\Gamma_i^{\uparrow})}. \tag{4.3.9}$$

By Remark 3.2.2 and the definition of $\Lambda_i^{\uparrow}$ in Properties B (iv), $\|w_0\|_{\tilde{\mathcal{F}}(\Gamma_i)^{\uparrow}}$ can be estimated by a discrete norm analogous to the first relation in (3.2.8). This discrete norm involves a subset of coefficients of w expanded with respect to the basis $\tilde{\Psi}^{\emptyset}$. Thus by (3.1.19) in Remark 3.1.1, this, in turn, can be estimated by $\|w\|_{\tilde{\mathcal{F}}(\Gamma_i)} \leq \|w\|_{\tilde{\mathcal{F}}(\Gamma_i^{\uparrow})}$ which together with (4.3.9) confirms (2.5.8) and finishes the proof. □

Corollary 4.3.1. *Let P_i be defined by* (2.4.2) *and* (2.4.3) *with respect to the E_i defined by* (4.3.4)*. Then*

$$P_i\left(\chi_{\Gamma_i}\psi_\nu^{\Gamma_i,\downarrow}\right) = \chi_{\Gamma_i}\psi_\nu^{\Gamma_i,\downarrow},\quad \nu\in\Lambda_i^{\uparrow},\quad P_i\left(\psi_\nu^{\Gamma_i,\downarrow}\right) = \hat{E}_i\psi_\nu^{\Gamma_i,\downarrow},\quad \nu\in\nabla^i\setminus\Lambda_i^{\uparrow}. \tag{4.3.10}$$

Proof. The relations (4.3.10) follow from Theorem 2.2 (see (2.5.13)), (2.4.3), and the definition (4.3.4). □

We conclude this section by quantifying the locality of the extensions E_i expressed in (2.5.6). We will require throughout the paper that

$$\operatorname{diam}(\operatorname{supp} E_i v) \;\lesssim\; \operatorname{diam}(\operatorname{supp} v) \tag{4.3.11}$$

holds. This is obviously the case for the Hestenes extensions as well as for the scale-dependent extensions based on *any* extension satisfying (4.3.11). As a consequence, we have, in view of (3.1.10), that

$$\operatorname{diam}(\operatorname{supp}\psi_\lambda^{\Gamma}),\ \operatorname{diam}(\operatorname{supp}\tilde{\psi}_\lambda^{\Gamma}) \;\lesssim\; 2^{-|\lambda|}. \tag{4.3.12}$$

5. Discretization of operators.

This section is devoted to a brief outline of some practical consequences of the foregoing constructions. More details will be given in [23] in the context of a more specified class of boundary integral operators.

5.1. A global point of view.

Suppose throughout the rest of the paper that $t \in \mathbb{R}$ satisfies $|t| \leq s < s_\Gamma$ so that $\mathcal{F}(\Gamma) = H^t(\Gamma)$ is well defined. When $t < 0$ the space $H^t(\Gamma)$ is to be understood as $(H^{-t}(\Gamma))^*$ (which agrees with the conventional notation when Γ has no boundary). Let $\mathcal{L} : H^t(\Gamma) \to H^{-t}(\Gamma)$ be a linear boundedly invertible operator, i.e.,

$$\|\mathcal{L}v\|_{H^{-t}(\Gamma)} \sim \|v\|_{H^t(\Gamma)},\quad v \in H^t(\Gamma). \tag{5.1.1}$$

Therefore for any $f \in H^{-t}(\Gamma)$ the equation

$$\mathcal{L}u = f \tag{5.1.2}$$

has a unique solution $u \in H^t(\Gamma)$. This covers a large class of (not necessarily symmetric) *elliptic* integral as well as differential equations (see, e.g., [16, 45]).

We wish to study Galerkin discretizations of (5.1.2) involving the above bases $\Psi^\Gamma, \tilde{\Psi}^\Gamma$. To describe this, let us denote for $\Lambda \subset \nabla^\Gamma$ by

$$\Psi^\Gamma_\Lambda := \{\psi^\Gamma_\lambda : \lambda \in \Lambda\}, \quad \tilde{\Psi}^\Gamma_\Lambda := \{\tilde{\psi}^\Gamma_\lambda : \lambda \in \Lambda\}$$

finite subsets of the wavelet bases $\Psi, \tilde{\Psi}$ determined by the index set $\Lambda \subset \nabla$. Furthermore, for any (at most countable) collection $\Phi \subset L_2(\Gamma)$ let

$$S(\Phi) := \operatorname{clos}_{L_2}(\operatorname{span}(\Phi)).$$

Our objective is to find $u_\Lambda \in S(\Psi^\Gamma_\Lambda)$ such that

$$\langle \mathcal{L} u_\Lambda, v\rangle_\Gamma = \langle f, v\rangle_\Gamma, \quad v \in S(\Psi^\Gamma_\Lambda) \tag{5.1.3}$$

with the ansatz $u_\Lambda = \mathbf{d}^T_\Lambda \Psi^\Gamma_\Lambda$; this is equivalent to the discrete system

$$\langle \mathcal{L}\Psi^\Gamma_\Lambda, \Psi^\Gamma_\Lambda\rangle^T_\Gamma \mathbf{d}_\Lambda = \langle f, \Psi^\Gamma_\Lambda\rangle^T_\Gamma. \tag{5.1.4}$$

We will always assume that the Galerkin scheme is *stable* and explain next what this means in the present context. Associating with the pair $\Psi^\Gamma, \tilde{\Psi}^\Gamma$ the projectors

$$Q_\Lambda v := \langle v, \tilde{\Psi}^\Gamma_\Lambda\rangle_\Gamma \Psi^\Gamma_\Lambda, \quad Q^*_\Lambda v := \langle v, \Psi^\Gamma_\Lambda\rangle_\Gamma \tilde{\Psi}^\Gamma_\Lambda,$$

(which are adjoints of each other) stability means that

$$\|Q^*_\Lambda \mathcal{L} v\|_{H^{-t}(\Gamma)} \sim \|v\|_{H^t(\Gamma)}, \quad v \in S(\Psi^\Gamma_\Lambda),\ \#\Lambda \to \infty. \tag{5.1.5}$$

Of course, when $\mathcal{L}$ satisfies (5.1.1) and is self-adjoint, respectively, *strongly elliptic*, (5.1.5) is trivially satisfied. For sufficient conditions when $\mathcal{L}$ is a pseudodifferential operator, see, e.g., [19] and the literature cited there.

5.2. Preconditioning. As before we will assume in the following that Assumption A holds for $\mathcal{F} = H^s$, $|t| \le s < s_\Gamma$. The relations in Theorem 3.3 then read

$$\|v\|_{H^t(\Gamma)} \sim \|\langle v, \tilde{\Psi}^\Gamma\rangle_\Gamma \mathbf{D}^t\|_{\ell_2(\nabla^\Gamma)}, \quad \|v\|_{H^{-t}(\Gamma)} \sim \|\langle v, \Psi^\Gamma\rangle_\Gamma \mathbf{D}^{-t}\|_{\ell_2(\nabla^\Gamma)}, \tag{5.2.1}$$

where

$$\mathbf{D}^t := (2^{t|\lambda|}\delta_{\lambda,\lambda'})_{\lambda,\lambda' \in \nabla^\Gamma}.$$

Recall that analogous relations hold for the roles of Ψ and $\tilde{\Psi}$ interchanged. By $\mathbf{D}^s_\Lambda$ we denote the principal sections of $\mathbf{D}^s$ determined by Λ. It is well known that the norm equivalences (5.2.1) together with the stability of the Galerkin scheme implies the following fact [19, 16].

THEOREM 5.1. *Under the above assumptions one has*

$$\operatorname{cond}_2\left(\mathbf{D}^{-t}_\Lambda \langle \mathcal{L}\Psi^\Gamma_\Lambda, \Psi^\Gamma_\Lambda\rangle_\Gamma \mathbf{D}^{-t}_\Lambda\right) = \mathcal{O}(1), \quad \#\Lambda \to \infty, \tag{5.2.2}$$

where $\operatorname{cond}_2(\mathbf{B}) := \|\mathbf{B}\|\|\mathbf{B}^{-1}\|$ *denotes the spectral condition number of the matrix* $\mathbf{B}$.

Thus diagonal scalings of stiffness matrices relative to the above wavelet bases produce well-conditioned system matrices so that *iterative solvers* have a chance to work with asymptotically optimal efficiency; see [16].

5.3. Computation of stiffness matrices. Let us briefly indicate next what it means concretely to compute the stiffness matrices

$$\mathbf{A}_\Lambda := \langle \mathcal{L}\Psi^\Gamma_\Lambda, \Psi^\Gamma_\Lambda \rangle^T_\Gamma.$$

Throughout this section we will assume that the projections P_i are defined with respect to the localized extensions (4.3.4) constructed in section 4.3. Let $\lambda = (i, \nu), \lambda' = (l, \mu) \in \nabla^\Gamma$. It is instructive to see first how an inner product with a wavelet reduces to an inner product over $\Box$. Of course, when $\nu \in \Lambda^\uparrow_i$ (see (4.3.3)) one simply obtains, in view of (3.3.3) and the fact that E_i reduces in this case to multiplication with χ_{Γ_i},

$$\langle v, \psi^\Gamma_\lambda \rangle_\Gamma = \langle v, \psi^{\Gamma_i,\downarrow}_\nu \rangle_{\Gamma_i} = \langle |\partial\kappa_i| v \circ \kappa_i, \psi^{\mathbf{Z}^{(i)}}_\nu \rangle_\Box, \tag{5.3.1}$$

where we have used (2.2.4) in the last step. When $\nu \notin \Lambda^\uparrow_i$ so that $E_i \psi^{\Gamma_i,\downarrow}_\nu$ reaches into $\Gamma^\uparrow_i \setminus \Gamma_i$ a natural option is to compute each contribution of the involved patches according to

$$\begin{aligned}\langle v, \psi^\Gamma_\lambda \rangle_\Gamma &= \langle v, \psi^{\Gamma_i,\downarrow}_\nu \rangle_{\Gamma_i} + \sum_{\Gamma_l \subset \Gamma^\uparrow_i \setminus \Gamma_i} \langle v, E_i \psi^{\Gamma_i,\downarrow}_\nu \rangle_{\Gamma_l} \\ &= \langle |\partial\kappa_i| v \circ \kappa_i, \psi^{\mathbf{Z}^{(i)}}_\nu \rangle_\Box + \sum_{\Gamma_l \subset \Gamma^\uparrow_i \setminus \Gamma_i} \langle |\partial\kappa_l| v \circ \kappa_l, (E_i \psi^{\Gamma_i,\downarrow}_\nu) \circ \kappa_l \rangle_\Box. \end{aligned} \tag{5.3.2}$$

Suppose now that the extensions are defined by lifting (4.1.6). Note that the patches $\Gamma_l \subset \Gamma^\uparrow_i$ induce a partition of $\Box_{\tilde{\mathbf{Z}}^{(i)}}$ consisting of the patches $\rho_{i,l}(\Box)$, $\Gamma_l \subset \Gamma^\uparrow_i \setminus \Gamma_i$, so that $\Gamma_l = \kappa^\uparrow_i \circ \rho_{i,l}(\Box)$, i.e., $\kappa_l = \kappa^\uparrow_i \circ \rho_{i,l}$. Using these relations and substituting (4.1.6), (5.3.2) becomes

$$\begin{aligned}\langle v, \psi^\Gamma_\lambda \rangle_\Gamma = {} & \langle |\partial\kappa_i| v \circ \kappa_i, \psi^{\mathbf{Z}^{(i)}}_\nu \rangle_\Box \\ & + \sum_{\Gamma_l \subset \Gamma^\uparrow_i \setminus \Gamma_i} \langle |\partial\kappa_l| v \circ \kappa_l, (A_{\tilde{\mathbf{Z}}^{(i)}} \psi^{\mathbf{Z}^{(i)}}_\nu) \circ \rho_{i,l} \rangle_\Box. \end{aligned} \tag{5.3.3}$$

An alternative is to use the adjoints to obtain via (2.2.4) and (3.3.3)

$$\begin{aligned}\langle v, \psi^\Gamma_\lambda \rangle_\Gamma &= \langle v, \chi_{\Gamma^\uparrow_i} E_i \psi^{\Gamma_i,\downarrow}_\lambda \rangle_\Gamma = \langle E^*_i(v\,|_{\Gamma^\uparrow_i}), \psi^{\Gamma_i,\downarrow}_\nu \rangle_{\Gamma_i} \\ &= \langle |\partial\kappa_i| \kappa^*_i \left(E^*_i (v\,|_{\Gamma^\uparrow_i}) \right), \psi^{\mathbf{Z}^{(i)}}_\nu \rangle_\Box = \langle A^*_{\tilde{\mathbf{Z}}^{(i)}} \left(|\partial\kappa^\uparrow_i| v \circ \kappa^\uparrow_i \right), \psi^{\mathbf{Z}^{(i)}}_\nu \rangle_\Box, \end{aligned} \tag{5.3.4}$$

where we have used (4.1.7).

Which option is preferable depends on the particular nature of the extensions and, since we are particularly interested in the entries of stiffness matrices which means that the above expressions have to be applied to $v = \mathcal{L}\psi^\Gamma_{\lambda'}$, also on the nature of $\mathcal{L}$.

Let us briefly discuss here the case

$$\mathcal{L}v = \int_\Gamma K(\cdot, y) v(y) ds_y. \tag{5.3.5}$$

Substituting $v = \mathcal{L}\psi^\Gamma_\lambda$ in (5.3.4) yields the following relations.

REMARK 5.3.1. *Under the above hypotheses one has for $\lambda = (i, \nu)$, $\lambda' = (l, \mu)$*

$$\langle \mathcal{L}\psi^\Gamma_{\lambda'}, \psi^\Gamma_\lambda \rangle_\Gamma = \int_\Box \int_\Box L_{l,i}(x, y) \psi^{\mathbf{Z}^{(l)}}_\mu (y) \psi^{\mathbf{Z}^{(i)}}_\nu (x) dx dy, \tag{5.3.6}$$

where the kernel $L_{l,i}$ *has the following form:*

$$L_{l,i}(x,y) = \begin{cases} |\partial\kappa_i(x)||\partial\kappa_l(y)|K(\kappa_i(x),\kappa_l(y)), \\ \qquad \nu\in\Lambda_i^{\uparrow}, \mu\in\Lambda_l^{\uparrow}; \\ (A^*_{\tilde{\mathbf{Z}}^{(i)}}\otimes I)\left(|\partial\kappa_i^{\uparrow}(x)||\partial\kappa_l(y)|\,K(\kappa_i^{\uparrow}(x),\kappa_l(y))\right), \\ \qquad \nu\in\nabla^i\setminus\Lambda_i^{\uparrow}, \mu\in\Lambda_l^{\uparrow}; \\ (I\otimes A^*_{\tilde{\mathbf{Z}}^{(l)}})\left(|\partial\kappa_i(x)||\partial\kappa_l^{\uparrow}(y)|\,K(\kappa_i(x),\kappa_l^{\uparrow}(y))\right), \\ \qquad \nu\in\Lambda_i^{\uparrow}, \mu\in\nabla^l\setminus\Lambda_l^{\uparrow}; \\ (A^*_{\tilde{\mathbf{Z}}^{(i)}}\otimes A^*_{\tilde{\mathbf{Z}}^{(l)}})\left(|\partial\kappa_i^{\uparrow}(x)||\partial\kappa_l^{\uparrow}(y)|\,K(\kappa_i^{\uparrow}(x),\kappa_l^{\uparrow}(y))\right), \\ \qquad \mu\in\nabla^l\setminus\Lambda_l^{\uparrow}, \nu\in\nabla^i\setminus\Lambda_i^{\uparrow}. \end{cases} \tag{5.3.7}$$

Clearly the smoothness of the modified kernel and consequently the compressibility of corresponding stiffness matrices depend on the regularity of the extended parametrization $\kappa_i^{\uparrow}$, recall Property G.

5.4. Matrix compression. Suppose now that the kernel K in (5.3.5) is smooth everywhere except for $x=y$ and satisfies the estimates

$$|\partial_x^{\alpha}\partial_y^{\beta}K(x,y)| \lesssim \operatorname{dist}(x,y)^{-(n+2t+|\alpha|+|\beta|)} \tag{5.4.1}$$

for any $\alpha,\beta\in\mathbb{N}_0^d$ such that $n+2t+|\alpha|+|\beta|>0$ with constants depending on α,β; see, e.g., [16, 19, 45] for the background of such estimates. The representation (5.3.7) has the following important consequence with regard to *matrix compression.*

THEOREM 5.2. *Let* Ω_λ *denote the support of* ψ_λ^{Γ}. *Under the above hypotheses one has the estimates*

$$2^{-(|\lambda'|+|\lambda|)t}|\langle\mathcal{L}\psi_{\lambda'}^{\Gamma},\psi_\lambda^{\Gamma}\rangle_\Gamma| \lesssim \frac{2^{-||\lambda|-|\lambda'||\sigma}}{(1+2^{\min(|\lambda|,|\lambda'|)}\operatorname{dist}(\Omega_\lambda,\Omega_{\lambda'}))^{n+2\tilde{d}+2t}}, \tag{5.4.2}$$

provided that when $2^{\min(|\lambda|,|\lambda'|)}\operatorname{dist}(\Omega_\lambda,\Omega_{\lambda'})\gtrsim 1$ *the kernel* $L_{l,i}(x,y)$ *has bounded* $\tilde{d}$*th order derivatives in* x *and* y *on* $\operatorname{supp}(\psi_\nu^{\mathbf{Z}^{(i)}})\times\operatorname{supp}(\psi_\mu^{\mathbf{Z}^{(l)}})$, $\lambda=(i,\nu)$, $\lambda'=(l,\mu)$. *Here* $\tilde{d}$ *is the integer from Properties B* (iii) *and* $\sigma>\frac{d}{2}$ *depends on the regularity of the wavelets.*

Proof. We sketch only the argument and refer to [23] for a detailed discussion of inequalities of the above type. Recall from (3.1.11) that

$$\langle P,\psi_\lambda^{\mathbf{Z}^{(i)}}\rangle_\square = 0 \quad \forall\ P\in\Pi_{\tilde{d}}(\square)\cap\mathcal{F}(\square)_{\tilde{\mathbf{Z}}^{(i)}},\ \lambda\in\nabla_-^{\mathbf{Z}^{(i)}}. \tag{5.4.3}$$

This, in turn, is easily seen to imply that

$$|\langle f,\psi_\lambda^{\mathbf{Z}^{(i)}}\rangle_\square| \lesssim 2^{-|\lambda|(\tilde{d}+\frac{n}{2})}\|f\|_{H_\infty^{\tilde{d}}(\Omega_\lambda^\square)}, \quad \lambda\in\nabla_-^{\mathbf{Z}^{(i)}}, \tag{5.4.4}$$

whenever

$$f\in\tilde{\mathcal{F}}(\square)_{\tilde{\mathbf{Z}}^{(i)}}\cap C^{\tilde{d}}(\overline{\Omega}_\lambda^\square). \tag{5.4.5}$$

Whenever the extensions are sufficiently smooth the kernel $L_{l,i}(\cdot,y)$ belongs for every y as a function of x, due to the action of the restriction $A^*_{\tilde{\mathbf{Z}}^{(i)}}$, to the space $\tilde{\mathcal{F}}(\square)_{\tilde{\mathbf{Z}}^{(i)}}$, which by the above remarks provides an estimate of type (5.4.4). Applying (5.4.4) successively with respect to each variable x and y one deduces for $\operatorname{dist}(\Omega_\lambda, \Omega_{\lambda'}) \gtrsim 2^{-|\lambda'|}$ where $|\lambda'| \leq |\lambda|$ the estimate

$$|\langle \mathcal{L}\psi^{\Gamma}_{\lambda'}, \psi^{\Gamma}_{\lambda}\rangle_{\Gamma}| \lesssim \frac{2^{-(|\lambda|+|\lambda'|)(n/2+\tilde{d})}}{(\operatorname{dist}(\Omega_\lambda, \Omega_{\lambda'}))^{n+2\tilde{d}+2t}};$$

see [21, 24] for details on the last step. Using a Cauchy–Schwarz argument for the remaining cases (see [13]) one finally obtains (5.4.2). □

Recall that, due to the boundary conditions of the wavelet bases on □, the moment conditions in (5.4.3) are *constrained.* However, we stress that, on account of (5.3.7) and the properties of the E_i, E_i^*, the modified kernels satisfy exactly the right constraints so that in smooth regions the cancellation properties hold *patchwise* with maximum order which distinguishes the present concept from those based on gluing neighboring bases directly [7, 22].

5.5. Domain decomposition. The above discussion already indicates that actual computations are essentially reduced to the unit cube □. It is then natural to extend this conceptually to the solution process which is the somewhat different point of view to be briefly discussed next. Obviously, (5.1.2) is equivalent to

$$V\mathcal{L}S(Tu) = Vf,$$

where T, S, V are defined by (2.4.6) and (2.4.7). Thus setting

$$\Pi_\downarrow := \prod_{i=1}^{M} H^s(\Gamma_i)^\downarrow, \quad \Pi_\uparrow^* := \prod_{i=1}^{M} H^{-s}(\Gamma_i)^\uparrow,$$

one has

$$\mathcal{L}_\Pi := V\mathcal{L}S : \Pi_\downarrow \to \Pi_\uparrow^*, \quad \mathbf{f} := Vf \in \Pi_\uparrow^*, \tag{5.5.1}$$

and we wish to find for every $\mathbf{f} \in \Pi_\uparrow^*$ the unique $\mathbf{u} \in \Pi_\downarrow$ such that

$$\mathcal{L}_\Pi \mathbf{u} = \mathbf{f}. \tag{5.5.2}$$

Of course, given $\mathbf{u}$ satisfying (5.5.2), $u = S\mathbf{u}$ solves (5.1.2). One easily confirms that

$$\mathcal{L}_\Pi = (\mathcal{L}_{i,l})_{i,l=1}^{M}, \quad \mathcal{L}_{i,l}w := (P_i^* \mathcal{L} P_l \chi_{\Gamma_l} w)\,|_{\Gamma_i}\,.$$

Moreover, recalling from (3.3.1) the inner product

$$\langle \{v_i\}, \{u_i\}\rangle_\Pi := \sum_{i=1}^{M} \langle v_i, u_i\rangle_{\Gamma_i}$$

on the product space, one has by definition

$$\langle \mathcal{L}_\Pi\{u_i\}, \{v_i\}\rangle_\Pi = \langle \mathcal{L}u, v\rangle_\Gamma, \quad \{u_i\} = Tu.$$

The weak formulation $\langle \mathcal{L}_\Pi \mathbf{u}, \mathbf{v}\rangle_\Pi = \langle \mathbf{f}, \mathbf{v}\rangle_\Pi$, $\mathbf{v} \in \Pi_\downarrow$, of (5.5.2) takes the form

$$\sum_{l=1}^{N} \left\langle \sum_{i=1}^{N} \mathcal{L}_{l,i} u_i - f_l, v_l \right\rangle_{\Gamma_l} = 0, \quad \mathbf{v} = \{v_i\}_{i=1}^{N} \in \Pi_\downarrow. \tag{5.5.3}$$

A natural idea is to solve (5.5.3) iteratively. The simplest version is a Jacobi-type scheme yielding $\mathbf{u}^n$ by

$$\mathcal{L}_{i,i}u_i^{n+1} = f_i - \sum_{l\neq i}\mathcal{L}_{i,l}u_l^n, \quad i=1,\dots,N. \tag{5.5.4}$$

Let us briefly discuss now the convergence properties of the iteration (5.5.4) (or a corresponding relaxation version). First note that the ellipticity (5.1.1) combined with Theorem 2.3 yield

$$\|\mathcal{L}_\Pi \mathbf{v}\|_{\Pi_\uparrow^*} \sim \|\mathbf{v}\|_{\Pi_\downarrow}, \quad \mathbf{v}\in\Pi_\downarrow.$$

Specifically, when $\mathcal{L}$ is self-adjoint and positive definite this means

$$\|\mathbf{v}\|_{\Pi_\downarrow}^2 \sim \langle\mathcal{L}_\Pi\mathbf{v},\mathbf{v}\rangle_\Pi, \quad \mathbf{v}\in\Pi_\downarrow.$$

which, in particular, implies that

$$\|\mathcal{L}_{i,i}v\|_{H^{-t}(\Gamma_i)^\uparrow} \sim \|v\|_{H^t(\Gamma_i)^\downarrow}, \quad i=1,\dots,N. \tag{5.5.5}$$

Hence, the *local problems*

$$\mathcal{L}_{i,i}u_i = g_i, \quad i=1,\dots,N, \tag{5.5.6}$$

on □ are elliptic. Of course, the obvious analog to Theorem 5.1, which holds on account of norm equivalences of the type (3.1.17) on □ (for $\mathcal{F}=H^t$), ensures that these local problems (5.5.6) can, in turn, be solved iteratively with asymptotically optimal complexity.

Remark 5.5.1. *Thus we see that the stability properties of the local wavelet bases combined with Theorem* 2.3 *lead to* stable splittings *in the sense of* [41] *which means that convergence is guaranteed for a controlled number of outer and inner iterations. We emphasize that this is true* regardless *of whether $\mathcal{L}$ is a (local) differential operator or a (global) singular integral operator as long as* (5.1.1) *holds. Roughly speaking, the localization properties of wavelet bases makes differential and integral operators equally tractable by domain decomposition schemes. In combination with the compression estimates in section* 5.4 *this is expected to give rise to numerical schemes by which the problem can be solved within the accuracy admitted by the discretization error at an expense of CPU and storage that remains proportional to the problem size while in addition parallel techniques are naturally incorporated. Details will be given in* [23].

We also remark that the global discretization discussed in section 5.1 as well as the local problems (5.5.6) satisfy all assumptions required in [13] for the analysis of *adaptive* strategies. In particular, the above domain decomposition concept offers a natural marriage between parallel techniques and adaptive strategies based on the wavelet bases $\Psi^{\Gamma_i,\downarrow}\subset H^t(\Gamma_i)^\downarrow$ applied independently to each local problem.

Appendix A: Proof of Proposition 2.4.1.

ad (i):. First consider the case $i<j$. Since by (2.3.15) $\Gamma_i\cap\Gamma_j^\uparrow=\emptyset$, we infer from (2.4.2) for $i=1$ and (2.4.5) that

$$P_1P_jv = \chi_{\Gamma_1^\uparrow}E_1\left((P_jv)\,|_{\Gamma_1}\right) = \chi_{\Gamma_1^\uparrow}E_1(0)=0.$$

Suppose that (2.4.8) holds for $l<i<j$. Again by (2.3.15), the definition (2.4.3) and (2.4.5) the induction assumption gives

$$P_iP_jv = \chi_{\Gamma_i^\uparrow}E_i\left(\left(P_jv-\sum_{l<i}P_lP_jv\right)|_{\Gamma_i}\right) = \chi_{\Gamma_i^\uparrow}E_i\left((P_jv)\,|_{\Gamma_i}\right)=0,$$

which confirms that

$$P_iP_j = 0, \quad i < j. \tag{5.5.7}$$

To prove the rest of (2.4.8) we use (2.4.2) to conclude first that

$$P_1^2 v = \chi_{\Gamma_1^\uparrow} E_1 \left((\chi_{\Gamma_1^\uparrow} E_1(v\,|_{\Gamma_1}))\,|_{\Gamma_1} \right) = \chi_{\Gamma_1^\uparrow} E_1\,(v\,|_{\Gamma_1}) = P_1 v, \tag{5.5.8}$$

while for $i > 1$, in view of (5.5.8),

$$P_iP_1v = \chi_{\Gamma_i^\uparrow} E_i \left(\left(P_1v - \sum_{j<i} P_jP_1v \right) |_{\Gamma_i} \right) = \chi_{\Gamma_i^\uparrow} E_i \left(\left(- \sum_{1<j<i} P_jP_1v \right) |_{\Gamma_i} \right). \tag{5.5.9}$$

Thus when $i = 2$ the right-most term in (5.5.9) is vacuous so that $P_2P_1v = 0$ while induction based on (5.5.9) easily yields

$$P_iP_1 = 0, \quad i > 1. \tag{5.5.10}$$

In view of (5.5.8) and (5.5.10), we may assume now that

$$P_jP_\ell = \delta_{j,\ell}P_j, \quad j < i,\ \ell \le j \tag{5.5.11}$$

and

$$P_iP_r = 0, \quad r < \ell. \tag{5.5.12}$$

To advance the induction assumptions let us verify first that $P_i^2 = P_i$. To this end, note first that in analogy to (5.5.8)

$$\chi_{\Gamma_i^\uparrow} E_i \left((\chi_{\Gamma_i^\uparrow} E_i(w\,|_{\Gamma_i}))\,|_{\Gamma_i} \right) = \chi_{\Gamma_i^\uparrow} E_i(w\,|_{\Gamma_i}). \tag{5.5.13}$$

Now (5.5.7) yields

$$\begin{aligned} P_i^2 v &= \chi_{\Gamma_i^\uparrow} E_i \left(\left(P_iv - \sum_{j<i} P_jP_iv \right) |_{\Gamma_i} \right) = \chi_{\Gamma_i^\uparrow} E_i((P_iv)\,|_{\Gamma_i}) \\ &= \chi_{\Gamma_i^\uparrow} E_i \left(\chi_{\Gamma_i^\uparrow} E_i \left(\left(v - \sum_{j<i} P_jv \right) |_{\Gamma_i} \right) |_{\Gamma_i} \right) = \chi_{\Gamma_i^\uparrow} E_i \left(\left(v - \sum_{j<i} P_jv \right) |_{\Gamma_i} \right) = P_iv, \end{aligned}$$

where we have used (5.5.13) in the second but last step. Furthermore, by (5.5.7) and (5.5.11),

$$\begin{aligned} P_iP_\ell v &= \chi_{\Gamma_i^\uparrow} E_i \left(\left(P_\ell v - \sum_{j<i} P_jP_\ell v \right) |_{\Gamma_i} \right) = \chi_{\Gamma_i^\uparrow} E_i \left(\left(P_\ell v - P_\ell v - \sum_{j=\ell+1}^{i-1} P_jP_\ell v \right) |_{\Gamma_i} \right) \\ &= \chi_{\Gamma_i^\uparrow} E_i(0) = 0, \quad \text{for} \quad \ell < i, \end{aligned}$$

which advances the induction and proves (i).

ad (ii):. Let $h := v - \sum_{j=1}^{N} P_j v$. By (2.4.8) one has

$$P_i h = P_i v - \sum_{j=1}^{N} P_i P_j v = P_i v - P_i v = 0,$$

$i = 1, \ldots, N$. Thus

$$0 = P_i h = \chi_{\Gamma_i^{\uparrow}} E_i \left(\left(h - \sum_{j<i} P_j h \right) |_{\Gamma_i} \right) = \chi_{\Gamma_i^{\uparrow}} E_i \left(h \,|_{\Gamma_i} \right)$$

implies $h = 0$ which confirms (ii).

ad (iii):. The first relation in (2.4.10) is an immediate consequence of (2.3.15) and the definition of P_i. Likewise for $j > i$, it is clear that

$$P_1 \chi_{\Gamma_j} v = \chi_{\Gamma_1^{\uparrow}} E_1 \left((\chi_{\Gamma_j} v) \,|_{\Gamma_1} \right) = \chi_{\Gamma_1^{\uparrow}} E_1(0) = 0,$$

and assuming that $P_\ell \chi_{\Gamma_j} v = 0$, $\ell < i < j$, one has

$$P_i(\chi_{\Gamma_j} v) = \chi_{\Gamma_i^{\uparrow}} E_i \left(\left(\chi_{\Gamma_j} v - \sum_{\ell<i} P_\ell \chi_{\Gamma_j} v \right) |_{\Gamma_i} \right) = \chi_{\Gamma_i^{\uparrow}} E_i \left((\chi_{\Gamma_j} v) \,|_{\Gamma_i} \right) = \chi_{\Gamma_i^{\uparrow}} E_i(0) = 0,$$

which proves (iii) and finishes the proof of the proposition. □

Appendix B: Proof of Theorem 2.2. If $v \,|_{\Gamma_i} \in \mathcal{F}(\Gamma_i)^{\downarrow}$, then $\hat{v} := \chi_{\Gamma_i^{\uparrow\uparrow}} v = \sum_{l=i}^{N} \chi_{\Gamma_l} v \in \mathcal{F}(\Gamma)$. By (2.4.9), one has

$$\begin{aligned} \hat{v} \,|_{\Gamma_i} &= \left(\sum_{j=1}^{N} P_j \hat{v} \right) |_{\Gamma_i} = \left(\sum_{j=1}^{N} \chi_{\Gamma_i} P_j \hat{v} \right) |_{\Gamma_i} = \left(\sum_{j=1}^{i} P_j \hat{v} \right) |_{\Gamma_i} \\ &= \left(\sum_{j=1}^{i} \sum_{l=i}^{N} P_j \chi_{\Gamma_l} v \right) |_{\Gamma_i} = \left(P_i \sum_{l=i}^{N} \chi_{\Gamma_l} v \right) |_{\Gamma_i} = (P_i \hat{v}) \,|_{\Gamma_i}, \end{aligned}$$

which proves the first relation in (2.5.13). Employing (2.4.13) and (2.4.14), the argument for the second relation in (2.5.13) is completely analogous.

By definition (2.4.2) and Assumption A (2.5.7), we know that

$$\begin{aligned} \|P_1 v\|_{\mathcal{F}(\Gamma_1)^{\uparrow}} &= \|E_1(v \,|_{\Gamma_1})\|_{\mathcal{F}(\Gamma_1^{\uparrow})} = \|E_1(v \,|_{\Gamma_1})\|_{\mathcal{F}(\Gamma_1^{\uparrow})^{\downarrow}} \\ &\lesssim \|v\|_{\mathcal{F}(\Gamma_1)^{\downarrow}} = \|v\|_{\mathcal{F}(\Gamma_1)} \leq \|v\|_{\mathcal{F}(\Gamma)}, \end{aligned}$$

where we have used several times that Γ_1 has no inflow boundary. This confirms the first relations in (2.5.16) and (2.5.15) for $i = 1$. Now suppose that the first relations in (2.5.15) and (2.5.16) have been verified for $1 \leq \ell < i$. Thus

$$h_i := \left(v - \sum_{j<i} P_j v \right) \in \mathcal{F}(\Gamma)$$

and for any $\ell < i$ one has by (2.4.9) and (2.4.10),

$$\begin{aligned} \chi_{\Gamma_\ell} h_i &= \sum_{r=1}^{N} \chi_{\Gamma_\ell} P_r h_i = \sum_{r=1}^{\ell} \chi_{\Gamma_\ell} P_r h_i \\ &= \sum_{r=1}^{\ell} \chi_{\Gamma_\ell} \left(P_r v - \sum_{j<i} P_r P_j v \right) = \sum_{r=1}^{\ell} \chi_{\Gamma_\ell} (P_r v - P_r v) = 0, \end{aligned} \tag{5.5.14}$$

where we have used (2.4.8) of Proposition 2.4.1 in the last step. Moreover, since $h_i = \chi_{\Gamma_i^{\uparrow\uparrow}} h_i$, (2.5.13) and (2.4.8) yield

$$h_i = P_i h_i = P_i v \in \mathcal{F}(\Gamma). \tag{5.5.15}$$

Therefore (5.5.14) also says that $(P_i v) \mid_{\Gamma_i} \in \mathcal{F}(\Gamma_i)^{\downarrow}$ which confirms together with (2.5.13) the first relation in (2.5.14).

Thus, by (2.5.7),

$$\begin{aligned} \|P_i v\|_{\mathcal{F}(\Gamma)} &= \|\chi_{\Gamma_i^{\uparrow}} E_i(h_i \mid_{\Gamma_i})\|_{\mathcal{F}(\Gamma)} = \|E_i(h_i \mid_{\Gamma_i})\|_{\mathcal{F}(\Gamma_i^{\uparrow})^{\downarrow}} \\ &\lesssim \|h_i \mid_{\Gamma_i} \|_{\mathcal{F}(\Gamma_i)^{\downarrow}} \leq \|h_i\|_{\mathcal{F}(\Gamma)} \leq \|v - \sum_{j<i} P_j v\|_{\mathcal{F}(\Gamma)} \\ &\leq \|v\|_{\mathcal{F}(\Gamma)} + \sum_{j<i} \|P_j v\|_{\mathcal{F}(\Gamma)} \lesssim \|v\|_{\mathcal{F}(\Gamma)}, \end{aligned}$$

which, by induction, confirms the first relation in (2.5.16) $\forall i = 1, \dots N$. Since by definition,

$$\|(P_i v) \mid_{\Gamma_i} \|_{\mathcal{F}(\Gamma_i)^{\downarrow}} = \|P_i v\|_{\mathcal{F}(\Gamma_i^{\downarrow})} \leq \|P_i v\|_{\mathcal{F}(\Gamma)};$$

also the first relation in (2.5.15) and hence all claims concerning the projectors P_i have been verified.

As for the adjoints P_i^*, we have by (2.4.11), (2.4.13), and (2.4.14),

$$P_i^* w = \left(I - \sum_{j<i} P_j^* \right) \chi_{\Gamma_i} E_i^*(w \mid_{\Gamma_i^{\uparrow}}) = \sum_{j=i}^{N} P_j^* \chi_{\Gamma_i} E_i^*(w \mid_{\Gamma_i^{\uparrow}}) = P_i^* \chi_{\Gamma_i} E_i^*(w \mid_{\Gamma_i^{\uparrow}}). \tag{5.5.16}$$

For $r \geq i$ one obtains by (2.4.14), that $\chi_{\Gamma_r} P_j^* = 0$ whenever $j < i$, so that for w replaced for simplicity by $w \mid_{\Gamma_i^{\uparrow}}$

$$\chi_{\Gamma_r} \sum_{j<i} P_j^* \chi_{\Gamma_i} E_i^* w = 0, \quad r \geq i. \tag{5.5.17}$$

Hence we infer from (2.4.14) and (5.5.16) that

$$\chi_{\Gamma_r} P_i^* w = 0, \quad r > i, \quad \chi_{\Gamma_i} P_i^* w = \chi_{\Gamma_i} E_i^* w, \tag{5.5.18}$$

which, by (2.5.8), means that

$$P_i^* w \in \tilde{\mathcal{F}}(\Gamma_i)^{\uparrow} \tag{5.5.19}$$

and

$$\|(P_i^* w)\,|_{\Gamma_i^{\uparrow\uparrow}}\,\|_{\tilde{\mathcal{F}}(\Gamma_i^{\uparrow\uparrow})} \;\lesssim\; \|w\,|_{\Gamma_i^{\uparrow\uparrow}}\,\|_{\tilde{\mathcal{F}}(\Gamma_i^{\uparrow\uparrow})}. \tag{5.5.20}$$

Therefore

$$\|(P_i^* v)\,|_{\Gamma_i}\|_{\tilde{\mathcal{F}}(\Gamma_i)^\uparrow} \;\lesssim\; \|v\|_{\tilde{\mathcal{F}}(\Gamma_i^\uparrow)}, \quad v \in \tilde{\mathcal{F}}(\Gamma_i^\uparrow),\; i = 1, \ldots, N, \tag{5.5.21}$$

whence the second parts of (2.5.14) and (2.5.15) follow.

It remains to verify the second part of (2.5.16). It suffices to show that the P_i are bounded in $\tilde{\mathcal{F}}^*(\Gamma)$. To this end note first that it follows from (2.5.8) that

$$\|E_i w\|_{\tilde{\mathcal{F}}^*(\Gamma_i^\uparrow)} \;\lesssim\; \|w\|_{\tilde{\mathcal{F}}^*(\Gamma_i)^\downarrow}, \quad w \in \tilde{\mathcal{F}}^*(\Gamma_i)^\downarrow. \tag{5.5.22}$$

In fact,

$$\begin{aligned}
\|E_i w\|_{\tilde{\mathcal{F}}^*(\Gamma_i^\uparrow)} &= \sup_{\|v\|_{\tilde{\mathcal{F}}(\Gamma_i^\uparrow)}=1} |\langle E_i w, v\rangle_{\Gamma_i^\uparrow}| = \sup_{\|v\|_{\tilde{\mathcal{F}}(\Gamma_i^\uparrow)}=1} |\langle w, E_i^* v\rangle_{\Gamma_i}| \\
&\le \sup_{\|v\|_{\tilde{\mathcal{F}}(\Gamma_i^\uparrow)}=1} \|w\|_{\tilde{\mathcal{F}}^*(\Gamma_i)^\downarrow} \|E_i^* v\|_{\tilde{\mathcal{F}}(\Gamma_i)^\uparrow} \\
&\lesssim \sup_{\|v\|_{\tilde{\mathcal{F}}(\Gamma_i^\uparrow)}=1} \|w\|_{\tilde{\mathcal{F}}^*(\Gamma_i)^\downarrow} \|v\|_{\mathcal{F}(\tilde{\Gamma}_i^\uparrow)},
\end{aligned}$$

where we have used (2.5.8) in the last step. Now for $i = 1$ the boundedness of P_i in $\tilde{\mathcal{F}}^*(\Gamma)$ follows immediately from the definition and (5.5.22). Suppose that the P_j are bounded in $\tilde{\mathcal{F}}^*(\Gamma)$ for $1 \le j < i$. Thus for $v \in \tilde{\mathcal{F}}^*(\Gamma)$ the distribution $h_i = (v - \sum_{j<i} P_j v)$ belongs to $\tilde{\mathcal{F}}^*(\Gamma)$ and $\|h_i\|_{\tilde{\mathcal{F}}^*(\Gamma)} \lesssim \|v\|_{\tilde{\mathcal{F}}^*(\Gamma)}$. From the beginning of the proof we know that $\chi_{\Gamma_l} h_i = 0$ for $l < i$ so that $\chi_{\Gamma_i^{\uparrow\uparrow}} h_i \in \tilde{\mathcal{F}}^*(\Gamma)$. The assertion follows then by (2.5.7) as before. □

STABILITY OF RELATIVE EQUILIBRIA IN THE PROBLEM OF $N+1$ VORTICES*

H. E. CABRAL[†] AND D. S. SCHMIDT[‡]

Abstract. The stability of a regular polygon configuration of N vortices with a central vortex is investigated. When the strength of the central vortex has a value within a certain interval, it is shown that the configuration is locally Liapunov stable. When the stability of the configuration changes, new configurations bifurcate. Although the $N+1$ body problem of celestial mechanics looks similar, it has been shown there that the change of stability and the bifurcation of new configurations occur for different values of the central mass.

Ever since the Adams Prize essay of Thomson, *A Treatise on the Motion of Vortex Rings*, it was known that the stability of the heptagon could not be decided by the linear terms. With methods from fluid mechanics G. J. Mertz had shown in 1978 that the heptagon is stable. By normalizing the Hamiltonian function we can show that except for rotational symmetry the heptagon is locally Liapunov stable.

Key words. vortices, spectral stability, relative equilibria

1. Introduction.

The problem of vortices in an ideal fluid was discussed by J. J. Thomson [13] in his essay for the Adams Prize of 1882. He placed N vortices of equal strength at the vertices of a regular polygon. In a uniformly rotating coordinate system he found that the configuration could be stable for $N \leq 6$ but was unstable for $N \geq 8$. Many papers have extended the work of Thomson since then. Some of the more recent papers include those by G. Morikawa and E. Swenson [9], who studied the motion of geostrophic vortices, and H. Aref [1], who investigated a row of vortices and showed its relationship to the polygon configuration. The question, what happens with a heptagon, is addressed, for example, in [2] and [6].

Maxwell [5] used in his essay for the Adams Prize of 1856 regular polygon configurations for the $N+1$ body problem of celestial mechanics to explain the rings of Saturn. Many papers have been written on that subject, including [7], where bifurcations of relative equilibria in the $N+1$ body problem and $N+1$ vortex problem were studied as a purely algebraic problem without worrying about stability. Moeckel [8] studied carefully the spectral stability of Maxwell's polygon configurations. After this the second author used canonical transformations in [12] in order to explain how bifurcations and changes in stability are related. The current paper is an extension of the above methods to the vortex problem.

By using the methods developed for the problem of celestial mechanics, we are able to derive the results for the polygon configuration of N equal vortices in a straightforward manner. Extending the methods to the polygon configuration with a central vortex of strength κ, that is, the $N+1$ vortex problem, we obtain the results of Thomson and others in a unified way. Actually we can show more, that is, for a

bounded range of κ the $N+1$ vortex configuration is not only linearly stable, but it is also locally stable in the sense of Liapunov. For seven bodies this interval of stability starts when $\kappa = 0$. This explains the special nature of the heptagon. By normalizing the Hamiltonian function through fourth-order terms we show that the heptagon of Thomson is also locally Liapunov stable.

Since the $N+1$ vortex problem has only $N+1$ degrees of freedom versus $2(N+1)$ for the problem in celestial mechanics, the calculations are simpler. Furthermore, polygon configuration have a lot of symmetries, which make these calculations feasible. In addition to this a Taylor series expansion for the logarithmic potential of the vortex problem can be found with the help of analytic functions, which makes it much easier to compute than the one for the Newtonian potential.

It is for this reason that we have repeated the calculations of [12] and [7], not only to work on a different problem but with the hope that the results of this paper can be used later to get some additional insight into the corresponding problem of celestial mechanics.

We consider the planar flow of an ideal incompressible fluid, which is not constrained by any boundaries. For any positively oriented, closed path, circulation is defined by

$$\Gamma = \oint v_s ds,$$

where v_s represents the component of velocity along an element of the path of length ds. The strength of the vortices enclosed by this path is then given by

$$\kappa = \frac{\oint v_s ds}{Area}.$$

Let $N+1$ vortices be located at $q_j = (x_j, y_j)$ with vortex strength κ_j for $j = 0, \dots, N$. Kirchhoff [3] derived the equations of motion for these vortices in the framework of Hamiltonian mechanics and these equations are

$$\kappa_j \dot{x}_j = \frac{\partial U}{\partial y_j},$$
$$\kappa_j \dot{y}_j = -\frac{\partial U}{\partial x_j},$$

with the Hamiltonian function

$$U = -\sum_{i<j} \kappa_i \kappa_j \log\left((x_i - x_j)^2 + (y_i - y_j)^2\right)^{\frac{1}{2}}. \tag{1.1}$$

The potential function of celestial mechanics has a similar form. Therefore, we call U the logarithmic potential function and hope that it will not be confused with the velocity potential in the theory of incompressible potential flow.

With the column vector $q = (x_0, \dots, x_N, y_0, \dots, y_N)^T$, the diagonal matrix $\mathbf{M} = \mathrm{diag}(\kappa_0, \dots, \kappa_N, \kappa_0, \dots, \kappa_N)$, and the standard symplectic matrix

$$\mathbf{J} = \begin{pmatrix} 0 & \mathbf{I} \\ -\mathbf{I} & 0 \end{pmatrix},$$

the above equation can also be written in vector form

$$\mathbf{M}\dot{q} = \mathbf{J}\,\nabla U. \tag{1.2}$$

A relative equilibrium is a configuration of vortices, which becomes stationary in a rotating coordinate system. Let $Q \in \mathcal{R}^{2(N+1)}$ be the coordinates, which rotate uniformly with angular velocity ν around the origin, so that the coordinate transformation is given by

$$q = \mathrm{e}^{\nu \mathbf{J} t} Q.$$

The equations of motion are then

$$\mathbf{M}\dot{Q} = \mathbf{J}(-\nu \mathbf{M} Q + \nabla U(Q)). \tag{1.3}$$

A stationary solution Q_0 satisfies

$$0 = -\nu \mathbf{M} Q_0 + \nabla U(Q_0).$$

Form the scalar product of the above equation with Q_0 to find for the value of ν

$$\nu = \frac{Q_0^T \nabla U(Q_0)}{Q_0^T \mathbf{M} Q_0}. \tag{1.4}$$

Since

$$U(\lambda Q) = -\log \lambda \sum \kappa_i \kappa_j + U(Q), \qquad \lambda > 0,$$

differentiating with respect to λ and setting $\lambda = 1$, we get

$$Q^T \cdot \nabla U(Q) = -\sum_{i<j} \kappa_i \kappa_j,$$

which lets us find a simpler expression for the numerator in (1.4). For the $N+1$ body problem of celestial mechanics, the denominator of (1.4) would be related to the moment of inertia. We will use the same notation and write

$$I(Q_0) = \frac{1}{2} Q_0^T \mathbf{M} Q_0 = \frac{1}{2} \sum_{j=0}^{N} \kappa_j (x_{0,j}^2 + y_{0,j}^2).$$

The angular velocity for the uniformly rotating coordinate system is then

$$\nu = \frac{-\sum_{i<j} \kappa_i \kappa_j}{2I(Q_0)}.$$

The derivation above demonstrates the similarity of the problem of $N+1$ vortices with the $N+1$ problem of celestial mechanics. Of these two problems the vortex problem is actually simpler since the position coordinates x_j and y_j are already conjugate to each other. In a strict sense (1.2) is not a Hamiltonian differential equation; nevertheless, most results in Hamiltonian mechanics can be carried over, as one can consider a nonstandard symplectic structure (see [4] or [10]). Thus it is not surprising that the computations for the spectral stability of relative equilibria in the $N+1$ body problem (see [8], [12]) can also be repeated for the vortex problem. What is surprising is that the results are more degenerate than those in celestial mechanics.

In the next section we give the conditions for spectral stability of relative equilibrium and mention the problems of a ring of vortices and the ring with a central vortex. These two problems will be discussed in the following sections. We then vary the strength κ of the central vortex and show in the last section that the change of stability occurs at those values of κ where new relative equilibria bifurcate. The final section reports on our calculations when $N = 7$; that is, we demonstrate that the heptagon configuration is locally Liapunov stable.

2. Spectral stability. In order to determine the stability of the relative equilibrium Q_0 of (1.3) we look at solutions nearby and set

$$Q = Q_0 + Z,$$

so that (1.3) becomes

$$\mathbf{M}\dot{Z} = \mathbf{J}\nabla V(Z), \tag{2.1}$$

where

$$V(Z) = -\frac{\nu}{2}(Q_0 + Z)^T\mathbf{M}(Q_0 + Z) + U(Q_0 + Z). \tag{2.2}$$

Since Q_0 is a stationary point, $\nabla V(0) = -\nu\mathbf{M}Q_0 + \nabla U(Q_0) = 0$. With $D^2V(0) = -\nu\mathbf{M} + D^2U_0$, where D^2U_0 stands for the Hessian of U evaluated at Q_0, the linearized form of (2.1) is

$$\mathbf{M}\dot{Z} = \mathbf{J}(-\nu\mathbf{M} + D^2U_0)Z. \tag{2.3}$$

Solutions of the form $Z = \mathrm{e}^{\lambda t}\zeta$ exist when the matrix

$$\lambda\mathbf{J} - \nu\mathbf{I} + \mathbf{M}^{-1}D^2U_0 \tag{2.4}$$

is singular.

Definition 2.1. *A relative equilibrium solution Q_0 of* (1.3) *is spectrally stable if all roots λ of*

$$\left|\lambda\mathbf{J} - \nu\mathbf{I} + \mathbf{M}^{-1}D^2U_0\right| = 0 \tag{2.5}$$

are purely imaginary.

Remark. In order for the relative equilibrium to be linearly stable, we require, in addition, that all elementary divisors have simple roots; that is, the system (2.3) can be diagonalized completely.

The problem to be considered is a ring of N identical vortices at the vertices of a regular N-gon with an additional vortex at the origin. Let $\omega = \mathrm{e}^{2\pi\sqrt{-1}/N}$ be the Nth root of unity. The position of the jth vortex is then ω^j for $j = 0, \ldots, N-1$ and its strength is κ_0. The strength of the vortex at the origin will be κ_N. We write therefore for the potential function (1.1)

$$U = \kappa_0^2 U_1 + \kappa_0\kappa_N U_2,$$

where the two functions are given by

$$U_1 = -\sum_{0\le i<j<N} \log|Q_i - Q_j| = -\frac{1}{2}\sum_{i=0}^{N-1}\sum_{j=1}^{N-1} \log|Q_i - Q_{i+j}| \tag{2.6}$$

with the index $i + j$ to be taken mod$N$ and

$$U_2 = -\sum_{j=0}^{N-1} \log|Q_j - Q_N|. \tag{2.7}$$

If in (2.4) we scale λ and ν by κ_0, then only the ratio of the strength of the two vortices κ_N/κ_0 is of significance. Thus without loss of generality we can set $\kappa_0 = 1$

and write κ instead of κ_N for the strength of the vortex at the origin. The potential function to be considered is therefore

$$U = U_1 + \kappa U_2. \tag{2.8}$$

The moment of inertia for the above configuration is then $I(Q_0) = N/2$, and its rate of rotation is

$$\nu = -\frac{N-1}{2} - \kappa. \tag{2.9}$$

3. Expansion of the Hamiltonian function U_1. Consider first the case of a ring where the N vortices form a regular N-gon. Since $\kappa = 0$, we can ignore here the $(N+1)$st coordinate and consider the problem in $\mathcal{R}^{2N}$. We will use a transformation which brings $D^2U_1(Q_0)$ into a normal form. The transformation has been used in a nonsymplectic form by Palmore [11] and others. In complex notation the transformation is $Z = \mathbf{W}z$ or

$$Q = Q_0 + \mathbf{W}z \tag{3.1}$$

with

$$\mathbf{W} = \frac{1}{\sqrt{N}} \begin{pmatrix} 1 & 1 & \cdots & 1 \\ 1 & \omega & \cdots & \omega^{N-1} \\ \vdots & \vdots & & \vdots \\ 1 & \omega^{N-1} & \cdots & \omega^{(N-1)^2} \end{pmatrix}. \tag{3.2}$$

The matrix $\mathbf{W}$ is unitary and therefore defines a symplectic transformation in $\mathcal{R}^{2N}$. This is seen when we keep the correspondence of the complex-valued ω with the 2×2 real submatrices

$$\begin{pmatrix} \cos 2\pi/N & -\sin 2\pi/N \\ \sin 2\pi/N & \cos 2\pi/N \end{pmatrix}$$

in mind. Since $\mathbf{M}$ is an identity matrix, the transformed differential equation (2.3) is

$$\dot{z} = (-\nu\mathbf{J} + \mathbf{J}\mathbf{W}^T D^2 U_1 \mathbf{W})z,$$

where $\mathbf{W}^T$ stands for the transpose of the $2N \times 2N$ matrix $\mathbf{W}$ written in its real form. The only task, albeit a tedious one, is the transformation of the Hessian. We accomplish it by computing partial derivatives of $U_1(Q_0 + \mathbf{W}z)$ and evaluating them at $z = 0$. This job is simplified by staying with complex notation as long as possible.

Consider first a function $f(z) = \log \phi(z)$ of the complex variable $z = x + \sqrt{-1}y$. The partial derivatives of the function $g(x, y) = \log|\phi|$ can be obtained from the real part of the derivative with respect to z of the analytical function $f(z)$ since

$$\log \phi = \log|\phi| + \sqrt{-1}\arg\phi. \tag{3.3}$$

Therefore, write $z_k = x_k + \sqrt{-1}y_k$ for $k = 0, 1, \ldots, N-1$. From (3.2) we have

$$Q_j = \omega^j + \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} \omega^{jk} z_k$$

and we can write

$$\begin{aligned} Q_i - Q_{i+j} &= \omega^i - \omega^{i+j} + \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} (\omega^{ik} - \omega^{(i+j)k}) z_k \\ &= \omega^i \left(d_j + \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} d_{jk} \omega^{i(k-1)} z_k \right), \end{aligned}$$

where we have set

$$d_j = 1 - \omega^j \tag{3.4}$$

so that $|d_j| = 2 \sin \pi j/N$. Since $|\omega| = 1$ for ϕ in (3.3) use

$$\phi = (Q_i - Q_{i+j})\omega^{-i} = d_j + \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} d_{jk} \omega^{i(k-1)} z_k$$

so that

$$\frac{\partial \phi}{\partial z_k} = \frac{d_{jk}}{\sqrt{N}} \omega^{i(k-1)}. \tag{3.5}$$

For $f = \log \phi$, we then find

$$\begin{aligned} \frac{\partial f}{\partial z_r} &= \frac{1}{\phi} \frac{\partial \phi}{\partial z_r}, \\ \frac{\partial^2 f}{\partial z_r \partial z_s} &= \frac{-1}{\phi^2} \frac{\partial \phi}{\partial z_r} \frac{\partial \phi}{\partial z_s}, \\ \frac{\partial^3 f}{\partial z_r \partial z_s \partial z_t} &= \frac{2}{\phi^3} \frac{\partial \phi}{\partial z_r} \frac{\partial \phi}{\partial z_s} \frac{\partial \phi}{\partial z_t}, \end{aligned}$$

and so on. At $z = 0$ we have $\phi(0) = d_j$ and the partial derivatives are therefore

$$\begin{aligned} \frac{\partial f}{\partial z_r} &= \frac{1}{\sqrt{N}} \omega^{i(r-1)} \frac{d_{jr}}{d_j}, \\ \frac{\partial^2 f}{\partial z_r \partial z_s} &= \frac{-1}{N} \omega^{i(r+s-2)} \frac{d_{jr} d_{js}}{d_j^2}, \\ \frac{\partial^3 f}{\partial z_r \partial z_s \partial z_t} &= \frac{2}{N\sqrt{N}} \omega^{i(r+s+t-3)} \frac{d_{jr} d_{js} d_{jt}}{d_j^3}, \\ \frac{\partial^4 f}{\partial z_r \partial z_s \partial z_t \partial z_u} &= \frac{-6}{N^2} \omega^{i(r+s+t+u-4)} \frac{d_{jr} d_{js} d_{jt} d_{ju}}{d_j^4}, \end{aligned}$$

and so on. We then obtain, for example, the second-order partial derivatives of $g = \log |\phi|$ to be

$$\frac{\partial^2 g}{\partial x_r \partial x_s} = -\frac{1}{N} \mathrm{Re} \left(\omega^{i(r+s-2)} \frac{d_{jr} d_{js}}{d_j^2} \right).$$

Similarly, we find

$$\frac{\partial^2 g}{\partial y_r \partial x_s} = \frac{1}{N} \mathrm{Im} \left(\omega^{i(r+s-2)} \frac{d_{jr} d_{js}}{d_j^2} \right) \quad \text{and} \quad \frac{\partial^2 g}{\partial y_r \partial y_s} = -\frac{\partial^2 g}{\partial x_r \partial x_s}.$$

Since ω is the Nth root of unity,

$$\sum_{i=0}^{N-1} \omega^{i(r+s-2)} = \begin{cases} N & \text{for} \quad r+s=2 \bmod N, \\ 0 & \text{otherwise,} \end{cases}$$

so that

$$\frac{\partial^2 U_1}{\partial x_r \partial x_s} = -\frac{1}{2}\sum_{i=0}^{N-1}\sum_{j=1}^{N-1} \frac{\partial^2 g}{\partial x_r \partial x_s} = \frac{1}{2}\sum_{j=1}^{N-1} \mathrm{Re}\left(\frac{d_{jr} d_{js}}{d_j^2}\right)$$

for $r+s=2 \bmod N$ and zero otherwise. On the other hand,

$$\sum_{j=1}^{N-1} \frac{d_{jr} d_{js}}{d_j^2} = \sum_{j=1}^{N-1} \frac{(1-\omega^{jr})(1-\omega^{js})}{(1-\omega^j)^2};$$

hence, this sum is zero if $r=0$ or $s=0$, while in the other cases it is equal to

$$\sum_{j=1}^{N-1} (1+\omega^j+\cdots+\omega^{j(r-1)})(1+\omega^j+\cdots+\omega^{j(s-1)}).$$

Since

$$\sum_{j=1}^{N-1} \omega^{jm} = -1 \quad \text{if} \quad m \neq 0 \bmod N,$$

and denoting by $k(r,s)$ the number of pairs (ρ,σ) such that $\rho+\sigma=0 \bmod N$, with $0 \le \rho < r$ and $0 \le \sigma < s$, we see that this sum is equal to

$$k(r,s)(N-1)-(rs-k(r,s)) = N\ k(r,s)-rs.$$

We readily see that there are only two cases, one being $r=s=1$ with $k(1,1)=1$ and the other $r+s=N+2$ when r or s is greater than 1, which gives $k(r,s)=2$. Thus,

$$\frac{\partial^2 U_1}{\partial x_1^2} = -\frac{\partial^2 U_1}{\partial y_1^2} = \frac{N-1}{2}, \tag{3.6}$$

and, for $r+s=2 \bmod N$, $rs \neq 0$,

$$\frac{\partial^2 U_1}{\partial x_r \partial x_s} = -\frac{\partial^2 U_1}{\partial y_r \partial y_s} = \frac{2N-rs}{2}, \tag{3.7}$$

while the derivatives are zero in all the other cases.

By summing up the terms for the third-order partial derivatives we will see, as before, that most of them cancel out and we are left, for $r+s+t=3 \bmod N$, with the expression

$$\frac{\partial^3 U_1}{\partial x_r \partial x_s \partial x_t} = \frac{-1}{\sqrt{N}}\mathrm{Re}\left(\sum_{j=1}^{N-1} \frac{d_{jr} d_{js} d_{jt}}{d_j^3}\right),$$

and this derivative is zero if $r+s+t \neq 3 \bmod N$ or if $rst = 0$. Similarly, we find that

$$\frac{\partial^3 U_1}{\partial y_r \partial y_s \partial x_t} = -\frac{\partial^3 U_1}{\partial x_r \partial x_s \partial x_t},$$

while the third-order derivatives involving one or three y's are zero.

Denoting by $k(r,s,t)$ the number of triplets (ρ, σ, τ) such that $\rho+\sigma+\tau = 0 \bmod N$ when $0 \leq \rho < r$, $0 \leq \sigma < s$, $0 \leq \tau < t$, we find that

$$\frac{\partial^3 U_1}{\partial x_r \partial x_s \partial x_t} = -\frac{1}{\sqrt{N}}(N\ k(r,s,t) - rst).$$

We find similar expressions for the fourth-order partial derivatives of U_1, for instance,

$$\frac{\partial^4 U_1}{\partial x_r \partial x_s \partial x_t \partial x_u} = \frac{3}{N}\mathrm{Re}\left(\sum_{j=1}^{N-1} \frac{d_{jr} d_{js} d_{jt} d_{ju}}{d_j^4}\right) \quad \text{if} \quad r+s+t+u = 4 \bmod N.$$

We compute

$$\frac{\partial^4 U_1}{\partial x_r \partial x_s \partial x_t \partial x_u} = -\frac{\partial^4 U_1}{\partial x_r \partial x_s \partial y_t \partial y_u} = \frac{\partial^4 U_1}{\partial y_r \partial y_s \partial y_t \partial y_u} = \frac{3}{N}(N\ k(r,s,t,u) - rstu)$$

if $r+s+t+u = 4 \bmod N$, $rstu \neq 0$. The remaining partial derivatives are all equal to zero.

4. Stability polynomial for a ring of vortices. Let us call the nonzero second-order derivatives of U_1 in (3.7) $c_r = \frac{1}{2}(2N - rs)$, which holds when $r+s = 2+N$ so that

$$c_r = -\frac{1}{2}(r-2)(N-r) \tag{4.1}$$

for $r = 2, 3, \ldots$. For $r = 1$, the above formula gives also the correct value of (3.6) so that (4.1) is valid for all cases. For reference we list in Table 4.1 the values of c_r for 3 to 12 vortices. Actually only about half of the values are listed, as the remaining ones are found via symmetry from $c_r = c_{N+2-r}$.

Table 4.1
Values of c_r given by (4.1) *for N vortices.*

N	c_1	c_2	c_3	c_4	c_5	c_6	c_7
3	1.0	0.0					
4	1.5	0.0	−0.5				
5	2.0	0.0	−1.0				
6	2.5	0.0	−1.5	−2.0			
7	3.0	0.0	−2.0	−3.0			
8	3.5	0.0	−2.5	−4.0	−4.5		
9	4.0	0.0	−3.0	−5.0	−6.0		
10	4.5	0.0	−3.5	−6.0	−7.5	−8.0	
11	5.0	0.0	−4.0	−7.0	−9.0	−10.0	
12	5.5	0.0	−4.5	−8.0	−10.5	−12.0	−12.5

Hence we have the matrix

$$\mathbf{C} = \left(\frac{\partial^2 U_1}{\partial x_r \partial x_s}\right) = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & c_1 & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cdots & 0 & c_3 \\ 0 & 0 & 0 & 0 & 0 & \cdots & c_4 & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & 0 & c_4 & \cdots & 0 & 0 \\ 0 & 0 & 0 & c_3 & 0 & \cdots & 0 & 0 \end{pmatrix}.$$

The matrix (2.4) has thus the block form

$$\begin{pmatrix} -\nu\mathbf{I} + \mathbf{C} & \lambda\mathbf{I} \\ -\lambda\mathbf{I} & -\nu\mathbf{I} - \mathbf{C} \end{pmatrix} \tag{4.2}$$

with $\mathbf{I}$ an $N \times N$ identity matrix. Due to the special nature of $\mathbf{C}$ the determinant of (4.2) decomposes into the product of 2×2 and 4×4 subdeterminants, which is easily seen by shuffling rows and columns. These cases will be referred to by the index r of the coefficient in the matrix $\mathbf{C}$ and discussed now as follows.

Cases $r = 0$ and $r = 2$.

$$\begin{vmatrix} -\nu & \lambda \\ -\lambda & -\nu \end{vmatrix} = \lambda^2 + \nu^2 = 0.$$

It gives rise to two pairs of trivial solutions $\lambda = \pm \mathrm{i}\nu$, which have to be expected due to the existence of four integrals.

Case $r = 1$.

$$\begin{vmatrix} -\nu + c_1 & \lambda \\ -\lambda & -\nu - c_1 \end{vmatrix} = \lambda^2 + \nu^2 - c_1^2 = \lambda^2 = 0.$$

This pair of zero roots is related to the fact that the relative equilibria are circular solutions in an inertial coordinate system and that among all solutions the circular ones are isolated. The remaining cases give the nontrivial ones.

Cases $r > 2$, $s = N + 2 - r$, and $c_r = c_s$.

$$\begin{vmatrix} -\nu & c_r & \lambda & 0 \\ c_r & -\nu & 0 & \lambda \\ -\lambda & 0 & -\nu & -c_r \\ 0 & -\lambda & -c_r & -\nu \end{vmatrix} = (\lambda^2 + \nu^2 - c_r^2)^2 = 0$$

has the real double roots $\lambda = \pm\sqrt{c_r^2 - \nu^2}$. At these values the corresponding 4×4 matrix has rank two, and therefore the system can be diagonalized completely. Finally when N is even, the following determinant has to be considered.

Case $r = s = \frac{N+2}{2}$.

$$\begin{vmatrix} -\nu + c_r & \lambda \\ -\lambda & -\nu - c_r \end{vmatrix} = \lambda^2 + \nu^2 - c_r^2 = 0,$$

which gives the simple pair of real roots $\lambda = \pm\sqrt{c_r^2 - \nu^2}$.

Since $c_r^2 - \nu^2 = c_r^2 - c_1^2 = \{(r-2)(N-r) + (N-1)\}\{(r-2)(N-r) - (N-1)\}/4$, we determine from this formula or by inspecting Table 4.1 the number of different characteristic exponents. Table 4.2 gives these numbers with the trivial characteristic exponents included in the count. As already discovered by Thomson the ring with 7 vortices is somewhat degenerate, and we will get back to this case later on.

Table 4.2
Number of roots of the stability polynomial for a ring with N vortices.

N	Negative	Positive	Zero	Imaginary
3	0	0	2	4
4	0	0	2	6
5	0	0	2	8
6	0	0	2	10
7	0	0	6	8
≥ 8	$N-5$	$N-5$	2	8

5. Stability of a ring with a central vortex. When we include a central vortex we have to use the function (2.8) and have to work in $\mathcal{R}^{2N+2}$. We can use the results of the previous section but have to add to it the contributions of the potential function U_2 given in (2.7). As an intermediate step we first determine for $0 \leq j \leq N-1$ the partial derivatives of $f = \log \phi$ at $z = 0$, where

$$\phi = (Q_j - Q_N)\omega^{-j} = 1 + \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} \omega^{j(k-1)} z_k - \omega^{-j} z_N$$

with the new coordinate $Q_N = z_N$. The derivatives of first order are

$$\frac{\partial f}{\partial z_r} = \begin{cases} \dfrac{1}{\sqrt{N}} \omega^{j(r-1)}, & 0 \leq r \leq N-1, \\ -\omega^{-j}, & r = N, \end{cases}$$

and of the second order

$$\frac{\partial^2 f}{\partial z_r \partial z_s} = \begin{cases} -\dfrac{1}{N} \omega^{j(r+s-2)}, & 0 \leq r, s \leq N-1, \\ \dfrac{1}{\sqrt{N}} \omega^{j(r-2)}, & 0 \leq r \leq N-1, \quad s = N, \\ -\omega^{-2j}, & r = s = N. \end{cases}$$

By summing over j from 0 through $N-1$, we have that the only nonzero terms left are

$$\frac{\partial^2 U_2}{\partial x_r \partial x_s} = \begin{cases} 1 & \text{for } r + s = 2 \bmod N, \\ -\sqrt{N} & \text{for } r = 2 \text{ and } s = N, \text{ or } r = N \text{ and } s = 2, \\ 0 & \text{otherwise.} \end{cases}$$

The matrix (2.4) has again the form given in (4.2) with $\mathbf{I}$ now an $(N+1) \times (N+1)$ identity matrix, $\nu = -c_1 - \kappa$, and after the multiplication with $\mathbf{M}^{-1}$ the matrix $\mathbf{C}$ is replaced by

$$\mathbf{C} = \begin{pmatrix} 0 & 0 & \kappa & 0 & \cdots & 0 & 0 \\ 0 & c_1 + \kappa & 0 & 0 & \cdots & 0 & 0 \\ \kappa & 0 & 0 & 0 & \cdots & 0 & -\kappa\sqrt{N} \\ 0 & 0 & 0 & 0 & \cdots & c_3 + \kappa & 0 \\ \vdots & \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & c_3 + \kappa & \cdots & 0 & 0 \\ 0 & 0 & -\sqrt{N} & 0 & \cdots & 0 & 0 \end{pmatrix}.$$

The splitting of (4.2) into subdeterminants still occurs. For rows $r = 0, 2$, and N we obtain the following subdeterminant:

$$\begin{vmatrix} -\nu & \kappa & 0 & \lambda & 0 & 0 \\ \kappa & -\nu & -\kappa\sqrt{N} & 0 & \lambda & 0 \\ 0 & -\sqrt{N} & -\nu & 0 & 0 & \lambda \\ -\lambda & 0 & 0 & -\nu & -\kappa & 0 \\ 0 & -\lambda & 0 & -\kappa & -\nu & \kappa\sqrt{N} \\ 0 & 0 & -\lambda & 0 & \sqrt{N} & -\nu \end{vmatrix} = 0.$$

For block matrices the following is easily verified:

$$\begin{vmatrix} \mathbf{A} & \lambda\mathbf{I} \\ -\lambda\mathbf{I} & \mathbf{B} \end{vmatrix} = \left|\lambda^2\mathbf{I} + \mathbf{AB}\right|,$$

so that for the determinant above we find

$$\begin{vmatrix} \lambda^2+\nu^2-\kappa^2 & 0 & \kappa^2\sqrt{N} \\ 0 & \lambda^2+\nu^2-\kappa^2-\kappa N & 0 \\ \kappa\sqrt{N} & 0 & \lambda^2+\nu^2-\kappa N \end{vmatrix}$$

$$= (\lambda^2+\nu^2)(\lambda^2+\nu^2-\kappa^2-\kappa N)^2 = 0.$$

The first factor gives the trivial exponents, whereas the second factor gives the repeated characteristic exponents

$$\lambda = \pm\sqrt{\kappa - (N-1)^2/4}.$$

Thus a change in stability occurs when

$$\kappa = \left(\frac{N-1}{2}\right)^2, \tag{5.1}$$

with the configuration becoming less stable as κ increases. The case of $r = 1$ leads to a determinant of the form

$$\begin{vmatrix} -2\nu & \lambda \\ -\lambda & 0 \end{vmatrix} = 0,$$

so that it again gives the repeated zeros. The general case $r > 2$ gives with $\nu = -c_1 - \kappa$ the 4×4 submatrix

$$\begin{pmatrix} c_1+\kappa & c_r+\kappa & \lambda & 0 \\ c_r+\kappa & c_1+\kappa & 0 & \lambda \\ -\lambda & 0 & c_1+\kappa & -c_r-\kappa \\ 0 & -\lambda & -c_r-\kappa & c_1+\kappa \end{pmatrix} \tag{5.2}$$

whose determinant could be evaluated as above. Instead we use an additional symplectic transformation; that is, we perform the rotation

$$\begin{pmatrix} x_r \\ x_s \end{pmatrix} \leftarrow \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}\begin{pmatrix} x_r \\ x_s \end{pmatrix}, \qquad \begin{pmatrix} y_r \\ y_s \end{pmatrix} \leftarrow \frac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}\begin{pmatrix} y_r \\ y_s \end{pmatrix}.$$

The matrix (5.2) then becomes and reads

$$\begin{pmatrix} c_1 - c_r & 0 & \lambda & 0 \\ 0 & c_1 + c_r + 2\kappa & 0 & \lambda \\ -\lambda & 0 & c_1 + c_r + 2\kappa & 0 \\ 0 & -\lambda & 0 & c_1 - c_r \end{pmatrix}$$

from where we obtain the repeated characteristic exponents

$$\lambda = \pm\sqrt{(c_r - c_1)(2\kappa + c_r + c_1)}. \tag{5.3}$$

A change of stability occurs when

$$\kappa = -\frac{c_r + c_1}{2} \tag{5.4}$$

with the configuration becoming more stable as κ increases. Finally we consider the case when N is even and a 2×2 subdeterminant occurs for $r = s = (N+2)/2$:

$$\begin{vmatrix} c_1 + c_r + 2\kappa & \lambda \\ -\lambda & c_1 - c_r \end{vmatrix} = 0.$$

It gives rise to characteristic exponents that have the same form as in (5.3), except that they are now simple.

A change of stability occurs at values of κ given in (5.1) and (5.4). Since these values do not depend only on r but also on N, we denote them by

$$\kappa(r, N) = \begin{cases} -\dfrac{c_r + c_1}{2} & \text{for } 2 < r \le (N+2)/2, \\ \left(\dfrac{N-1}{2}\right)^2 & \text{for } r = 2. \end{cases} \tag{5.5}$$

The ordering of the values where the stability of the $N+1$ vortex configuration changes is

$$-0.5 = \kappa(3, N) < \kappa(4, N) < \cdots < \kappa\left(\left\lfloor \frac{N+2}{2} \right\rfloor, N\right) < \kappa(2, N) = (N-1)^2/4.$$

Values for the $\kappa(r, N)$ are listed in this order in Table 5.1. Also listed under $\kappa_{v=0}$ is the value of κ, where the rate of rotation ν of the coordinate system is zero.

Table 5.1
Critical values for $\kappa(r, N)$ for a ring with a central vortex.

N	$\kappa_{\nu=0}$	$\kappa(3,N)$	$\kappa(4,N)$	$\kappa(5,N)$	$\kappa(6,N)$	$\kappa(7,N)$	$\kappa(2,N)$
3	−1.0						1.00
4	−1.5	−0.5					2.25
5	−2.0	−0.5					4.00
6	−2.5	−0.5	−0.25				6.25
7	−3.0	−0.5	0.00				9.00
8	−3.5	−0.5	0.25	0.50			12.25
9	−4.0	−0.5	0.50	1.00			16.00
10	−4.5	−0.5	0.75	1.50	1.75		20.25
11	−5.0	−0.5	1.00	2.00	2.50		25.00
12	−5.5	−0.5	1.25	2.50	3.25	3.50	30.25

Furthermore, (5.3) shows that the configuration becomes more stable as κ passes through one of the values $\kappa(r, N)$ for $r > 2$, since we have $c_r - c_1 < 0$. On the other hand (5.1) shows that we lose stability when $\kappa > \kappa(2, N)$. This contradicts the claim made in [6] that a very strong central vortex could make the configuration stable. This happens in the $N + 1$ body problem of celestial mechanics with a large mass of the central body when $N > 7$. For the $N + 1$ vortex configuration, spectral stability can occur only for values for the central vortex in the interval $\kappa(\lfloor (N + 2)/2 \rfloor, N) \leq \kappa \leq \kappa(2, N)$. We can prove even more in Theorem 5.1.

THEOREM 5.1. *The $N + 1$ vortex configuration with the central vortex of size κ is Liapunov stable for*
$(N^2 - 8N + 8)/16 < \kappa < (N - 1)^2/4$ *when N is even, and*
$(N^2 - 8N + 7)/16 < \kappa < (N - 1)^2/4$ *when N is odd.*

Proof. The values on the left-hand side of the above inequalities are those of $\kappa(\lfloor (N+2)/2 \rfloor)$ and on the right-hand side those of $\kappa(2, N)$. As was shown above only in this interval are all nontrivial roots of the characteristic polynomial purely imaginary. We will now show that in this interval the quadratic part of the Hamiltonian is positive definite and can serve as a Liapunov function.

After a sequence of symplectic transformations, including the rotation mentioned above, the original system of equations (1.2) was transformed to represent the motion near the equilibrium by

$$\mathbf{M}\dot{z} = \mathbf{J}\nabla H(z)$$

with the column vector $z = (x, y)^T$ in $\mathcal{R}^{2(N+1)}$. The Hamiltonian $H(z)$ starts with the second-order terms:

$$H_2(z) = \frac{1}{2}(x^T \mathbf{A} x + y^T \mathbf{B} y).$$

Since the matrices $\mathbf{A}$ and $\mathbf{B}$ are mostly diagonal, we will not display them but write down the Hamiltonian with the components as they were used in the discussion of the different cases

$$\begin{aligned} H_2(z) = \frac{1}{2}\,[x_0, x_2, x_N] & \begin{bmatrix} c_1 + \kappa & \kappa & 0 \\ \kappa & c_1 + \kappa & -\kappa\sqrt{N} \\ 0 & -\sqrt{N} & c_1 + \kappa \end{bmatrix} \begin{bmatrix} x_0 \\ x_2 \\ x_N \end{bmatrix} + (c_1 + \kappa)x_1^2 \\ & + \frac{c_1 + c_3 + 2\kappa}{2} x_3^2 + \frac{c_1 + c_4 + 2\kappa}{2} x_4^2 + \cdots + \frac{c_1 - c_4}{2} x_{N-2}^2 + \frac{c_1 - c_3}{2} x_{N-1}^2 \\ & + \frac{1}{2}\,[y_0, y_2, y_N] \begin{bmatrix} c_1 + \kappa & -\kappa & 0 \\ -\kappa & c_1 + \kappa & \kappa\sqrt{N} \\ 0 & \sqrt{N} & c_1 + \kappa \end{bmatrix} \begin{bmatrix} y_0 \\ y_2 \\ y_N \end{bmatrix} \\ & + \frac{c_1 - c_3}{2} y_3^2 + \frac{c_1 - c_4}{2} y_4^2 + \cdots + \frac{c_1 + c_4 + 2\kappa}{2} y_{N-2}^2 + \frac{c_1 + c_3 + 2\kappa}{2} y_{N-1}^2. \end{aligned}$$

In the given interval for κ all coefficients of the quadratic terms are positive. It remains to show that the two quadratic forms are also positive definite. The reason why these matrices are not diagonalized and left as they are has to do with the fact that a transformation matrix has also to commute with $\mathbf{M}$. Nevertheless, their three eigenvalues are easily computed and they are

$$c_1 + \kappa, \qquad c_1 + \kappa + \sqrt{\kappa(\kappa + N)}, \qquad c_1 + \kappa - \sqrt{\kappa(\kappa + N)}. \tag{5.6}$$

For $0 < \kappa < (N-1)^2$ only the sign of the last eigenvalue is questionable. With $c_1 = (N-1)/2$ consider therefore the function

$$\lambda(\kappa) = (N-1)/2 + \kappa - \sqrt{\kappa(\kappa+N)}.$$

With

$$\lambda'(\kappa) = 1 - \frac{2\kappa + N}{2\sqrt{\kappa(\kappa+N)}} < 0 \qquad \text{for} \quad \kappa > 0$$

and $\lambda(0) > 0$ we look for a positive root of $\lambda(\kappa) = 0$ by squaring

$$(N-1)/2 + \kappa = \sqrt{\kappa(\kappa+N)}.$$

We find this value to be $\kappa = (N-1)^2/4 = c_1^2$, which coincides with the upper limit of the interval under consideration.

For $N < 7$ the given intervals for κ allow negative values for the central vortex. These intervals are

$$\begin{aligned}
N &= 3, \quad -1.0 < \kappa < 1.00, \quad c_1 = 1.0,\\
N &= 4, \quad -0.5 < \kappa < 2.25, \quad c_1 = 1.5,\\
N &= 5, \quad -0.5 < \kappa < 4.00, \quad c_1 = 2.0,\\
N &= 6, \quad -0.25 < \kappa < 6.25, \quad c_1 = 2.5,
\end{aligned}$$

with the value of c_1 listed in each case. Since the real part of the eigenvalues (5.6) are positive, it follows that the quadratic forms are positive definite.

6. Degenerate relative equilibria. Relative equilibria are characterized as the extrema of the potential function U under the condition that the moment of inertia is kept constant. In [7] it was shown that degenerate relative equilibria lead to new configurations. Since the discussion in that paper is somewhat terse and its notation different, we will repeat the arguments here.

A configuration is called degenerate if it is not isolated in a reduced space. The configurations discussed so far are not isolated in a trivial manner, since we can move the center of vorticity by a finite amount and find another one. We could also rotate the configuration around its center by a finite angle. In order to remove these trivial degeneracies one has to work in a quotient space that removes these actions. Keeping the center of vorticity at the origin gives in our coordinates

$$z_0 = -\frac{\kappa}{\sqrt{N}} z_N.$$

The rotation is removed by requiring that z_1 is real; i.e., $y_1 = 0$. The moment of inertia of the unperturbed N-gon is $N/2$, and keeping it fixed leads to the equation

$$0 = 2\sqrt{N} x_1 + x_1^2 + \sum_{k=2}^{N-1} (x_k^2 + y_k^2) + \frac{\kappa}{N}(N+\kappa)(x_N^2 + y_N^2).$$

By the implicit function theorem this equation can be solved to give

$$x_1 = x_1(x_2, \ldots, x_N, y_2, \ldots, y_N)$$

near the origin. All of its first-order and most of its second-order partial derivatives are zero with the exception of

$$\frac{\partial^2 x_1}{\partial x_r^2} = \frac{\partial^2 x_1}{\partial y_r^2} = -\frac{1}{\sqrt{N}} \qquad \text{for} \quad 2 \le r \le N-1$$

and

$$\frac{\partial^2 x_1}{\partial x_N^2} = \frac{\partial^2 x_1}{\partial y_N^2} = -\frac{\kappa}{\sqrt{N}}\left(1 + \frac{\kappa}{N}\right).$$

If $\tilde{U}$ is the restriction of U given by these formulas, that is,

$$\tilde{U}(x_2, \dots, y_N) = U\left(-\frac{\kappa x_N}{\sqrt{N}}, x_1, x_2, \dots, x_N, -\frac{\kappa y_N}{\sqrt{N}}, 0, y_2, \dots, y_N\right),$$

then to compute its Hessian at $z = 0$, we also need that for $z = 0$,

$$\frac{\partial U}{\partial x_r} = \frac{\partial U}{\partial y_r} = \begin{cases} -\sqrt{N}\nu & \text{for } r = 1, \\ 0 & \text{otherwise.} \end{cases}$$

The Hessian is found to be of the form

$$D^2\tilde{U}(Q_0) = \begin{pmatrix} \mathbf{B} + \mathbf{C} & \mathbf{0} \\ \mathbf{0} & \mathbf{B} - \mathbf{C} \end{pmatrix}$$

with

$$\mathbf{B} + \mathbf{C} = \begin{pmatrix} c_1 + \kappa & 0 & \cdots & 0 & -\frac{\kappa}{\sqrt{N}}(N+\kappa) \\ 0 & c_1 + \kappa & \cdots & c_3 + \kappa & 0 \\ \vdots & \vdots & & \vdots & \vdots \\ 0 & c_3 + \kappa & \cdots & c_1 + \kappa & 0 \\ -\frac{\kappa}{\sqrt{N}}(N+\kappa) & 0 & \cdots & 0 & \frac{\kappa}{N}(c_1+\kappa)(N+\kappa) \end{pmatrix}.$$

Since $\mathbf{B} - \mathbf{C}$ has the same form with the cross diagonal terms having the opposite sign, it suffices to investigate where the above matrix is singular and with it the Hessian of $\tilde{U}$. The determinant decomposes nicely into 2×2 subdeterminants plus into a single term in case the two diagonals cross when N is even. These subdeterminants are zero exactly at those values of κ given in (5.5) where the stability changes. The following theorem now follows easily.

THEOREM 6.1. *The Hessian of the reduced potential function $\tilde{U}$ is degenerate when the spectral stability of the ring with a central vortex changes, that is, for $\kappa = \kappa(r, N)$ with $2 \le r \le (N+2)/2$. The ordering of these critical values is*

$$-0.5 = \kappa(3, N) < \kappa(4, N) < \cdots < \kappa(2, N) = (N-1)^2/4.$$

Whenever κ is varied and passes through one of the critical values $\kappa(r, N)$ two pairs of exponents come from the imaginary axis, meet at the origin, and then one pair moves to the positive real axis, the other pair to the negative axis. The only exception is the case $r = (N+2)/2$ when N is even, where we have just one pair moving from the imaginary to the real axis.

Despite the similarities between the Newtonian potential and the logarithmic potential in the vortex problem, the results concerning the stability and bifurcation from a regular polygon configuration are different. In the Newtonian case the change in stability and the bifurcation occur for different values of the central mass. For the rotating vortices, these phenomena happen at the same value for the central vortex. It makes this problem more degenerate, but it also allowed the complete analysis of the spectral stability of regular polygon configurations, except in the case of the heptagon, which will be considered next.

7. The stability of the Thomson heptagon. For the heptagon configuration of Thomson, that is, for $N = 7$ with no central vortex, we now carry out the expansion of the Hamiltonian function as it was outlined in section 3. With the notation of that section we have

$$k(1,1) = 1, \qquad k(3,6) = k(4,5) = k(4,5) = k(6,3) = 2,$$

and for the quadratic part of U_1 we have

$$U_1^{(2)} = \frac{1}{2}\mathrm{Re}\left(\sum_{r+s=2 \bmod 7} \frac{7k(r,s) - rs}{2} z_r z_s \right),$$

so that

$$U_1^{(2)} = \frac{1}{2}\mathrm{Re}\left(3z_1^2 - 4z_3z_6 - 6z_4z_5\right).$$

In real variables, $z_j = x_j + \sqrt{-1}\; y_j$, $j = 1, \dots, 6$, we have then

$$U_1^{(2)} = \frac{1}{2}\left(3(x_1^2 - y_1^2) - 4(x_3x_6 - y_3y_6) - 6(x_4x_5 - y_4y_5)\right).$$

For the cubic terms, we notice that the values of $k(r,s,t)$ are given by $k(1,1,1) = 1$, $k(r,s,t) = 2$ if $r + s + t = 10$ and $k(r,s,t) = 26$ if $r + s + t = 17$. Then we find that for the homogeneous cubic part of U_1,

$$U_1^{(3)} = \frac{-1}{\sqrt{7}}\mathrm{Re}\left(z_1^3 - 4z_1z_3z_6 - 6z_1z_4z_5 - 5z_2^2z_6 - 16z_2z_3z_5 - 9z_2z_4^2 - 11z_3^2z_4 + z_5z_6^2\right).$$

For the fourth-degree terms, we first compute $k(r,s,t,u)$ (recall that $rstu \neq 0$): $k(1,1,1,1) = 1$, and when $r + s + t + u = 11$,

$$\begin{aligned} k(1,1,3,6) &= k(1,1,4,5) = k(1,2,2,6) = k(1,2,3,5) = k(1,2,4,4) \\ &= k(1,3,3,4) = k(2,2,2,5) = k(2,2,3,4) = k(2,3,3,3) = 2, \end{aligned}$$

while for $r + s + t + u = 18$ we have the possibilities

$$\begin{array}{lll} k(1,5,6,6) = 26, & k(2,4,6,6) = 42, & k(2,5,5,6) = 44, \\ k(3,3,6,6) = 48, & k(3,4,5,6) = 54, & k(3,5,5,5) = 57, \\ k(4,4,4,6) = 58, & k(4,4,5,5) = 62, & \end{array}$$

and these values are the same for $k(r,s,t,u)$ under a permutation of (r,s,t,u).

Then, for the coefficients of $C_{rstu} = C_{x_rx_sx_tx_u} = C_{y_ry_sy_ty_u} = -C_{x_rx_sy_ty_u}$ of the Taylor expansion of U_1, we have

$$C_{rstu} = \frac{3}{7}(7\;k(r,s,t,u) - rstu).$$

We find that

$$\begin{aligned}U_1^{(4)} = \frac{3}{7}\mathrm{Re}\biggl(&\frac{1}{4}z_1^4 - 2z_1^2z_3z_6 - 3z_1^2z_4z_5 - 5z_1z_2^2z_6 - 16z_1z_2z_3z_5 - 9z_1z_2z_4^2\\ &-11z_1z_3^2z_4 + z_1z_5z_6^2 - \frac{13}{3}z_2^3z_5 - 17z_2^2z_3z_4 - \frac{20}{3}z_2z_3^3 + 3z_2z_4z_6^2 + 4z_2z_5^2z_6\\ &+3z_3^2z_6^2 + 18z_3z_4z_5z_6 + 4z_3z_5^3 + \frac{11}{3}z_4^3z_6 + \frac{17}{2}z_4^2z_5^2\biggr).\end{aligned}$$

The complex variables $z_j = x_j + \sqrt{-1}y_j$ were useful for finding the expansion, but for the system of Hamiltonian differential equations we have to use the position variables x_j and the momenta y_j for $j = 0, 1, \ldots, 6$. After adding the terms, due to the rotation with $\nu = -3$, the Hamiltonian function (2.1) reads

$$V = \frac{3}{2}\sum_{j=0}^{6}(x_j^2 + y_j^2) + U_1^{(2)} + U_1^{(3)} + U_1^{(4)} + \cdots.$$

Since x_0 and y_0 occur only in the sum and setting $x_0 = y_0 = 0$ corresponds to fixing the center of vorticity at the origin, we can ignore these two variables from now on. The quadratic terms for the heptagon are therefore

$$\begin{aligned}V_2 = {}& 3x_1^2 + \frac{3}{2}(x_2^2 + y_2^2)\\ &+\frac{3}{2}x_3^2 - 2x_3x_6 + \frac{3}{2}x_6^2 + \frac{3}{2}x_4^2 - 3x_4x_5 + \frac{3}{2}x_5^2\\ &+\frac{3}{2}y_3^2 + 2y_3y_6 + \frac{3}{2}y_6^2 + \frac{3}{2}y_4^2 + 3y_4y_5 + \frac{3}{2}y_5^2.\end{aligned}$$

The quadratic terms can be simplified further by the rotation used already with (5.2) to give

$$V_2 = 3x_1^2 + \frac{3}{2}(x_2^2 + y_2^2) + \frac{5}{2}x_3^2 + 3x_4^2 + \frac{1}{2}x_6^2 + \frac{1}{2}y_3^2 + 3y_5^2 + \frac{5}{2}y_6^2.$$

In order to normalize the higher-order terms of the Hamiltonian function the linearized system should be in diagonal form as much as possible and we need one more symplectic transformation to complex-valued position and momenta variables given by

$$\begin{aligned}
x_1 &= \xi_1, & y_1 &= i\eta_1,\\
x_2 &= \tfrac{1}{\sqrt{2}}(\xi_2 + \eta_2), & y_2 &= \tfrac{i}{\sqrt{2}}(-\xi_2 + \eta_2),\\
x_3 &= \tfrac{1}{\sqrt{2\sqrt{5}}}(\xi_3 + \eta_3), & y_3 &= i\sqrt{\tfrac{\sqrt{5}}{2}}(-\xi_3 + \eta_3),\\
x_4 &= \xi_4, & y_4 &= i\eta_4,\\
x_5 &= \xi_5, & y_5 &= i\eta_5,\\
x_6 &= \sqrt{\tfrac{\sqrt{5}}{2}}(\xi_6 + \eta_6), & y_6 &= \tfrac{i}{\sqrt{2\sqrt{5}}}(-\xi_6 + \eta_6).
\end{aligned}$$

All momenta were changed so that the transformation is symplectic with multiplier $\sqrt{-1}$. The resulting Hamiltonian function is then written in a form so that the Lie transformation of Deprit can be applied:

$$H = -i\left(H_0 + H_1 + \frac{1}{2!}H_2 + \frac{1}{3!}H_3 + \cdots\right), \tag{7.1}$$

where H_k consists of homogeneous polynomials of degree $k+2$. The quadratic terms are given by

$$H_0 = 3\xi_1^2 + 3\xi_2\eta_2 + \sqrt{5}\xi_3\eta_3 + 3\xi_4^2 - 3\eta_5^2 + \sqrt{5}\xi_6\eta_6.$$

The higher-order terms have to be subjected to the same sequence of transformations. It results in 110 nonzero terms of degree three in H_1 and 595 of these of degree four in H_2. The Lie transformation lets us eliminate all terms that are in the range of the operator

$$\begin{aligned}
L_W H_0 &= \sum_{j=1}^{6} \frac{\partial H_0}{\partial \xi_j}\frac{\partial W}{\partial \eta_j} - \frac{\partial H_0}{\partial \eta_j}\frac{\partial W}{\partial \xi_j} \\
&= 6\left(\xi_1\frac{\partial W}{\partial \eta_1} + \xi_4\frac{\partial W}{\partial \eta_4} + \eta_5\frac{\partial W}{\partial \xi_5}\right) + 3\left(\eta_2\frac{\partial W}{\partial \eta_2} - \xi_2\frac{\partial W}{\partial \xi_2}\right) \\
&\quad + \sqrt{5}\left(\eta_3\frac{\partial W}{\partial \eta_3} - \xi_3\frac{\partial W}{\partial \xi_3} + \eta_6\frac{\partial W}{\partial \eta_6} - \xi_6\frac{\partial W}{\partial \xi_6}\right).
\end{aligned}$$

Due to the degeneracy of the problems with respect to the variables with indices one, four, and five, and due to the resonance between the variables with indices three and six, the complement of the range of the above operator is fairly large. The second author used his program called POLYPACK for the efficient manipulation of polynomials in several variables to carry out this normalization by machine. The calculations were performed with the coefficients stored as floating point numbers. After having obtained the answer, the computations were then checked in part with the help of *Mathematica*.

Without going into the details of these computations, the results were that at order three the following four terms were left over in the complex form of H_1:

$$H_1 = 2\sqrt{10/7}\left[(-\xi_3\eta_3 + \xi_6\eta_6)\xi_5 + (\xi_6\eta_3 - \xi_3\eta_6)\eta_4\right].$$

At the next order there were 46 nonzero terms left over, and there are too many to be listed here. Since the main purpose of the normalization is to investigate the stability of the origin, we will use polar variables where appropriate and return to the real variables in the other cases:

$$\begin{aligned}
&\xi_j = r_j e^{i\phi_j}, \quad && \eta_j = r_j e^{-i\phi_j} \quad && \text{for } j = 2, 3, \text{ and } 6, \\
&\xi_j = x_j, && \eta_j = iy_j && \text{for } j = 1, 4, \text{ and } 5.
\end{aligned}$$

The quadratic part of the Hamiltonian for the heptagon is then

$$H_0 = 3x_1^2 + 3r_2^2 + \sqrt{5}(r_3^2 + r_6^2) + 3x_4^2 + 3y_5^2.$$

The function is obviously indefinite as far as the variables y_1, y_4, and x_5 are concerned. The third-order terms in the normal form are then

$$H_1 = \sqrt{10/7}\left[2x_5(r_6^2 - r_3^2) - y_4 r_3 r_6 \sin(\phi_6 - \phi_3)\right].$$

They do not exclude Liapunov stability of the origin since they are dominated by the quadratic terms $\sqrt{5}(r_3^2 + r_6^2)$ near the origin. Therefore, we have to look at terms of degree four in the normalized H_2. All terms containing a factor r_2^2, r_3^2, or r_6^2 are of no interest since they cannot change the positive definiteness of the Hamiltonian near the origin. The terms in the normalized $H_2/2!$, which do not meet that criteria, are

$$\frac{9}{4}(x_5^2 + y_4^2)^2 - 17(x_4 x_5 + y_4 y_5)^2.$$

Another term with $x_5 y_4(x_4 x_5 + y_4 y_5)$ could have appeared in the normal form, but due to the symmetry of our problem its coefficient turns out to be zero. Since the coefficient of the first term, that is, of $(x_5^2 + y_4^2)^2$, is positive, we cannot make the Hamiltonian negative by choosing any values of x_5 and y_4 near zero. The coefficient of the second term is negative, but it cannot make the entire Hamiltonian negative near the origin, since each of its terms is dominated by the quadratic terms $3x_4^2 + 3y_5^2$ in H_0. No information is available with respect to the variable y_1, and we have to expect that the Hamiltonian remains indefinite in that direction. Actually this could have been predicted since fixing y_1 selects one of the relative equilibria from the rotational symmetry. Except for the extensive numerical computations by machine we have thus shown the following theorem.

THEOREM 7.1. *Except for the rotational symmetry the Thomson heptagon is locally Liapunov stable.*

The result corresponds to the one of Mertz in [6], which was obtained by a completely different method. It also agrees with what is observed when a careful numerical integration of the problem is performed. It differs from the results in [2], which predicted instability with the appearance of third-order terms in the normalized Hamiltonian function. To be precise the normalization for the heptagon is not given in that paper, and the statement about instability concerns a Hamiltonian whose quadratic part can be diagonalized. As shown above the appearance of terms of third degree in the Hamiltonian does not necessarily destroy the local stability of the origin. The effect of the third-order terms on the global stability is, of course, another issue.

A COMPREHENSIVE MATHEMATICAL MODEL FOR A MULTISPECIES FLOW THROUGH GROUND COFFEE[*]

A. FASANO[†] AND F. TALAMUCCI[†]

Abstract. A model of filtration in a multispecies porous medium with mechanical and chemical interaction between the flow and the porous matrix is presented. The species removed by the medium are transported either as solids or as solutes. The accumulation of the migrating particles in proximity of the outflow surface gives rise to the growth of a compact layer, with high hydraulic resistance.

The corresponding mathematical problem is a free boundary problem for parabolic and hyperbolic partial differential equations. Existence and uniqueness globally in time are proved.

Key words. nonstandard filtration processes in porous media, systems of PDEs in a free boundary domain, convection and diffusion

1. The physical problem.

This paper is in the framework of a research which was promoted years ago by illycaffè s.p.a. (Trieste, Italy) aimed at describing the extremely complex set of phenomena taking place during the filtration of water through ground coffee in the espresso-coffee machine. For a review of the main results previously obtained on the espresso-coffee problem and other related models, see [6]. The studies performed so far have pointed out various aspects of the process, whose analysis has been carried out separately due to the relevant difficulties of the corresponding mathematical models. The present paper is the conclusive effort in providing a comprehensive description of the process, taking into account mechanical and chemical interactions between the flow and the porous matrix.

Our aim is to combine the model presented in [9] for the removal and transport of a single family of particles building up a low conductivity compact layer, and the models of [8], [13], in which several species are transported by the flow (either as solutes or as solid particles) but are allowed to leave the system. At the same time we try to keep the model as close as possible to reality, removing some simplifying assumptions introduced in previous investigations (see, e.g., the choice of a uniform and constant porosity in [9]).

Here we will not deal with the first stage of the process, in which the initially dry medium is penetrated by water. We recall however that invasion problems have been considered rather extensively in this context [7], [10], [4]. In addition we remark that in this paper we allow for nonuniform distribution of the removable species at the time $t = 0$ (a nontrivial extension of [9]), so that the initial conditions could be those determined at the end of the invasion process. One feature of [8] not incorporated here is the deformability of the porous matrix, since there is very little hope to obtain any experimental information on it. However, this would not represent a

major complication from a mathematical point of view. More could be done in the field on nonisothermal flows, in the spirit of the studies performed in [1], [2] for flow processes in the manufacturing of composite materials.

Let us come to the description of our paper.

We are going to formulate a mathematical model for a process of multispecies flow through a saturated porous medium occupying a layer of given thickness. A positive pressure is imposed at the inflow surface and during the filtration through the pores some components of the layer are removed by the action of the flow. The main features of the model are the following:

(i) The flow is able to extract mass in various ways from the porous matrix. The removed components are both sufficiently fine solid particles, which are transported convectively by the flow (and eventually accumulated in a compactlayer), and substances which may also diffuse in the liquid (typically as solutes).

(ii) The porosity is affected by the removal process, but here we neglect additional effects such as mechanical compression of the porous matrix by the flow.

(iii) The removal rate depends on the concentration of the particles still bound to the porous matrix and on the liquid flux intensity.

(iv) The hydraulic permeability in the part of the layer where the removal process takes place depends on the concentration of each species and on the porosity, while it is much lower and constant in the compact layer.

(v) The fine particles do not leave the system but they accumulate in the vicinity of the outflow surface, giving rise to a compact layer, whose structure depends on the history of the flow.

(vi) Effects of gravity and interdiffusion can be neglected.

In sections 2 and 3 we will introduce the mathematical model corresponding to (i)–(vi). Under the hypotheses listed in section 4 we will show existence and uniqueness for the solution of the mathematical problem, provided that the dependence of the removal rate on the particle's concentrations and on the liquid flux (cf. point (iii)) is sufficiently mild. Finally, in section 6 we will discuss some qualitative properties of the solution.

2. The equations governing the displacement of each species.

The model we are going to present may look exceedingly complicated because of the large number of quantities involved and the complexity of the phenomena taking place simultaneously. Nevertheless, as we shall see, it is not too difficult to find a way through it, although the existence proof is necessarily technical, since the basic unknowns are just the overall volumetric velocity (as a function of time and space) and the thickness of the compact layer. All the other quantities can be calculated using these two unknowns as input.

Different from previous attempts, based on heuristic simplifications, and therefore of limited applicability, here we set up a completely rigorous model. In such a way, not only do we have a reliable description of the whole process, but we also provide a basis for the analysis of all physical situations involving flows through porous media with movable or soluble components.

First, we define the concentrations of the various components entering the process.

As in [13], we denote by b_i and m_i the concentration of the i-species, $i = 1, \dots, n$, (mass per unit volume of the total system) when it is bound to the porous matrix and when it is moving, respectively.

After defining $\rho_i^{(\ell)}$, $\ell = b, m$, as the densities of each species (i.e., mass per unit volume of that component), we find it convenient to introduce also the specific volumes of the species in the system:

$$\begin{cases} \theta_i = b_i/\rho_i^{(b)}, & i = 1, \dots, n, \\ \eta_i = m_i/\rho_i^{(m)}, & i = 1, \dots, n, \\ \eta_w = m_w/\rho_w & \text{water.} \end{cases} \tag{2.1}$$

We introduce the following distinction among the components:

- $b_i, i = 1, \dots, k < n$, refers to fine solid particles bound to the porous matrix (typical diameters $1 - 10\,\mu$);
- $m_i, i = 1, \dots, k < n$, are the concentrations of the particles moving in the flow;
- $b_i, i = k + 1, \dots, n$, refers to substances in the porous matrix which once removed are dissolved in the fluid as solutes or as droplets;
- $m_i, i = k + 1, \dots, n$, refers to dissolved substances.

Let us denote by V_i and V_w the molecular velocities of the species m_i and of the water, respectively.

We define the following quantities:

$$\varepsilon = \eta_{(s)} + \eta_w \quad \text{porosity}, \qquad \eta_{(s)} = \sum_{i=k+1}^{n} \eta_i, \tag{2.2}$$

$$q = \eta_w V_w + \sum_{i=k+1}^{n} \eta_i V_i \quad \text{volumetric compound velocity.} \tag{2.3}$$

The meaning of (2.2) is that since the medium is constantly saturated, the pore volume is entirely occupied by the fluid and the partition between the volume fractions of water (η_w) and solutes ($\eta_{(s)}$) is emphasized. The necessity of introducing (2.3) comes from the fact that q is precisely the quantity which obeys Darcy's law (see (3.3)). We also define the cumulative volume fractions

$$\eta_{(p)} = \sum_{i=1}^{k} \eta_i, \quad \theta_{(p)} = \sum_{i=1}^{k} \theta_i, \quad \theta_{(s)} = \sum_{i=k+1}^{n} \theta_i, \tag{2.4}$$

and $\theta_0 = \theta_0(x)$ as the volume fraction (with respect to the unit volume of the total system) of the rigid porous skeleton. The part of unit volume complementary to (2.2) and occupied by solid components is partitioned as follows:

$$1 - \varepsilon = \eta_{(p)} + \theta_0 + \theta_{(s)} + \theta_{(p)}, \tag{2.5}$$

where we see the contribution of the nondeformable matrix (θ_0) of the solid moving ($\eta_{(p)}$) or movable ($\theta_{(p)}$) particles and of the soluble substances at the solid state ($\theta_{(s)}$).

As in [13], we start from the conservation laws of each species:

$$\frac{\partial m_i}{\partial t} + \frac{\partial}{\partial x}(m_i V_i) = -\frac{\partial b_i}{\partial t}, \ i = 1, \dots, n, \tag{2.6}$$

$$\frac{\partial m_w}{\partial t} + \frac{\partial}{\partial x}(m_w V_w) = 0. \tag{2.7}$$

The boundary $s(t)$, whose position is unknown a priori, separates the region $0 < x < s(t)$, where the removal process occurs, from the region $s(t) < x < 1$, where the particles accumulate, forming the compact layer.

Arguing in the same way as in [12], we see that the mass balances at the boundary $s(t)$, obtained by integration of (2.6) and (2.7) are

$$[[m_i + b_i]]\,\dot{s}(t) - [[m_i V_i]] = 0, \quad i = 1, \dots, n, \tag{2.8}$$

$$[[m_w]]\,\dot{s}(t) - [[m_w V_w]] = 0, \tag{2.9}$$

where $[[\chi]]$ (here and throughout the paper) denotes the jump of χ at $s(t)$:

$$[[\chi]] = \lim_{x \to s(t)^+} \chi(x,t) - \lim_{x \to s(t)^-} \chi(x,t). \tag{2.10}$$

Denoting by

$$V = q/\varepsilon$$

the average velocity of the liquid and assuming (cf. [6], [13]) that

$$V_i = \alpha_i V, \quad 0 < \alpha_i \le 1,\ i = 1, \dots, k, \tag{2.11}$$

where α_i are slowing factors due to the shocks, we get from (2.8)

$$[[m_i + b_i]]\,\dot{s}(t) - \alpha_i \left[\left[\frac{q}{\varepsilon} m_i\right]\right] = 0,\ i = 1, \dots, k. \tag{2.12}$$

On the other hand, for the dissolved species $i = k+1, \dots, n$ and for water we introduce the molecular diffusive flux with respect to the average (i.e., over all species) velocity $V = q/\varepsilon$:

$$J_i = \frac{m_i}{\varepsilon}(V_i - V),\ i = k+1, \dots, n, \quad J_w = \frac{m_w}{\varepsilon}(V_w - V). \tag{2.13}$$

The diffusive flux (2.13) is related to the concentration of the species in the liquid in the following way (cf., e.g., [5]):

$$J_i = -D_i \nabla(m_i/\varepsilon), \quad i = k+1, \dots, n, \tag{2.14}$$

where D_i are the diffusion coefficients and m_i/ε represents concentrations in the flow. In (2.14) interdiffusion is neglected, according to assumption (vi) of section 1.

From (2.13) and (2.14) we obtain the following expression for the partial mass fluxes $m_i V_i$:

$$m_i V_i = m_i V - \varepsilon D_i \frac{\partial}{\partial x}\left(\frac{m_i}{\varepsilon}\right),\ i = k+1, \dots, n. \tag{2.15}$$

The concentration of the i-species, $i = k+1, \dots, n$, in the flowing liquid and the concentration b_i, $i = k+1, \dots, n$, are supposed to be continuous across the boundary s:

$$\left[\left[\frac{m_i(s(t),t)}{\varepsilon(s(t),t)}\right]\right] = [[b_i(s(t),t)]] = 0,\ i = k+1, \dots, n. \tag{2.16}$$

It is worth noticing that by summing up (2.8), $i = k+1, \dots, n$, and (2.9) and recalling (2.1)–(2.3) and (2.16) we get the following condition at $s = s(t)$:

$$[[\varepsilon]]\,\dot{s}(t) = [[q]]\,. \tag{2.17}$$

(If ε jumps, q has to jump in order to preserve saturation.) Concerning the migrating particles, if we assume, as it appears quite natural, that the solid particles are no longer mobile in the compact layer, i.e.,

$$m_i(s(t)^+, t) = 0, \quad i = 1, \dots, k, \tag{2.18}$$

then mass balances (2.12) become

$$\begin{aligned} &\{b_i(s(t)^+, t) - \big(m_i(s(t)^-, t) + (b_i(s(t)^-, t))\big)\}\dot{s}(t) \\ &= -\alpha_i \frac{q(s(t), t)}{\varepsilon(s(t), t)} m_i(s(t)^-, t), \ i = 1, \dots, k. \end{aligned} \tag{2.19}$$

Let us denote now by M_i, $i = 1, \dots, k$, the concentration of the i-species in the compact layer $s(t) < x \leq 1$.

If (2.18) holds throughout the compact layer (i.e., $M_i = b_i$ in $s(t) < x < 1$, $i = 1, \dots, k$), we obviously have

$$\frac{\partial M_i}{\partial t}(x, t) = 0, \quad i = 1, \dots, k, \ s(t) < x < 1, \tag{2.20}$$

but the functions $M_i(x)$ are not known. The structure of the compact layer, corresponding to a sequence $M_1, \dots, M_k$ depends on the history of the process, since it depends on the incoming flux of particles.

In order to model the formation of the compact layer, a constraint f for the concentrations M_i must be assigned, defining a *packing configuration*

$$f(M_1, \dots, M_k) = 0, \tag{2.21}$$

f being a C^1 function such that $\partial f / \partial M_i > 0$, $i = 1, \dots, k$.

Since in (2.19) we identify M_i with $b_i(s(t)^+, t)$, $i = 1, \dots, k$, from (2.21), we get

$$f\left(-\frac{1}{\dot{s}}\alpha_1 \frac{q}{\varepsilon} m_1^- + m_1^- + b_1^-, \cdots, -\frac{1}{\dot{s}}\alpha_k \frac{q}{\varepsilon} m_k^- + m_k^- + b_k^-\right) = 0, \tag{2.22}$$

where r^- stands for $r(s(t)^-, t)$. The solvability of (2.22) with respect to $\dot{s}$ is guaranteed by the condition

$$\frac{q}{\varepsilon} \sum_{i=1}^{k} \alpha_i m_i^- \frac{\partial f}{\partial M_i} \neq 0. \tag{2.23}$$

A simple but reasonable way to prescribe the packing configuration (2.21) is the following, which refers to the specific volumes of the species:

$$\sum_{i=1}^{k} \frac{M_i}{\rho_i} = \Theta, \tag{2.24}$$

where ρ_i is the density of M_i and Θ is a known quantity. Equation (2.24) shows that the layer is compact when the incoming particles occupy the maximum specific volume at their disposal, represented by Θ.

If only one species of fine particles is present (i.e., $k = 1$), condition (2.24) implies the knowledge of the particle concentration in the compact layer, as in [9].

3. The complete mathematical model. The removal process (species $i = 1, \ldots, k$) occurs only in the region $D_T = \{(x,t) : 0 < x < s(t),\ 0 < t < T\}$. On the other hand, the extraction process (species $i = k+1, \ldots, n$) may take place also in the compact layer $R_T = \{(x,t) : s(t) < x < 1,\ 0 < t < T\}$. The governing equations, which will be noted just below (together with the new symbols introduced), are

$$\frac{\partial m_i}{\partial t} + \frac{\partial}{\partial x}\left(\alpha_i m_i \frac{q}{\varepsilon}\right) = -\frac{\partial b_i}{\partial t},\ i = 1, \ldots, k,\ (x,t) \in D_T, \tag{3.1}$$

$$\begin{aligned}&\frac{\partial m_i}{\partial t} + \frac{\partial}{\partial x}\left(-D_i \varepsilon \frac{\partial}{\partial x}\frac{m_i}{\varepsilon}\right) + \frac{\partial}{\partial x}\left(m_i \frac{q}{\varepsilon}\right) = -\frac{\partial b_i}{\partial t},\\ &i = k+1, \ldots, n \quad (x,t) \in D_T \cup R_T,\end{aligned} \tag{3.2}$$

$$q = -K(b, m, \varepsilon)\frac{\partial p}{\partial x}, \quad (x,t) \in D_T \cup R_T, \tag{3.3}$$

$$\frac{\partial b_i}{\partial t} = -F_i(q,b)G_i[b_i - \beta_i(q,b)]^+, \quad i = 1, \ldots, k, \quad (x,t) \in D_T, \tag{3.4}$$

$$\frac{\partial b_i}{\partial t} = -H_i(q,b), \quad i = k+1, \ldots, n, \quad (x,t) \in D_T \cup R_T, \tag{3.5}$$

$$\frac{\partial \varepsilon}{\partial t} + \frac{\partial q}{\partial x} = -\frac{\partial}{\partial t}\theta_{(s)}, \quad (x,t) \in D_T \cup R_T, \tag{3.6}$$

$$\frac{\partial q}{\partial x} + \frac{\partial}{\partial x}\sum_{i=1}^{k}\left(\alpha_i \eta_i \frac{q}{\varepsilon}\right) = 0, \quad (x,t) \in D_T \cup R_T, \tag{3.7}$$

together with the initial and boundary conditions

$$m_i(x,0) = m_{i,0}(x), \quad i = 1, \ldots, n, \quad x \in [0,1], \tag{3.8}$$

$$\varepsilon(x,0) = \varepsilon_0(x), \quad x \in [0,1], \tag{3.9}$$

$$b_i(x,0) = b_{i,0}(x), \quad i = 1, \ldots, n, \quad x \in [0,1], \tag{3.10}$$

$$m_i(0,t) = 0, \quad i = 1, \ldots, k, \quad 0 \le t \le T, \tag{3.11}$$

$$\begin{aligned}&D_i \varepsilon(0,t)\frac{\partial m_i}{\partial x}(0,t) = \frac{q(0,t)m_i(0,t)}{\varepsilon(0,t)},\\ &i = k+1, \ldots, n,\ 0 < t < T,\end{aligned} \tag{3.12}$$

$$[[p]] = 0, \quad x = s(t), \tag{3.13}$$

$$\left[\left[\frac{m_i}{\varepsilon}\right]\right] = 0, \quad x = s(t), \quad i = k+1, \ldots, n, \tag{3.14}$$

$$\left[\left[D_i \varepsilon \frac{\partial}{\partial x}\frac{m_i}{\varepsilon}\right]\right] = 0, \quad x = s(t), \quad i = k+1, \ldots, n, \tag{3.15}$$

$$\big(\Theta - (\eta_{(p)} + \theta_{(p)})\big)\,\dot{s} = -\frac{q}{\varepsilon}\sum_{i=1}^{k}\alpha_i \eta_i, \quad x = s(t), 0 \le t \le T, \tag{3.16}$$

$$\frac{\partial}{\partial x}\frac{m_i}{\varepsilon}(1,t) = 0, \quad i = k+1, \ldots, n, \tag{3.17}$$

$$p(0,t) = p_0(t) > 0, \quad p(1,t) = 0, \quad 0 \le t \le T, \tag{3.18}$$

$$s(0) = 1. \tag{3.19}$$

The unknown quantities for (3.1)–(3.19) are the concentrations $b_i(x,t)$, $m_i(x,t)$, $i = 1, \ldots, n$ (or the specific volumes θ_i, η_i, $i = 1, \ldots, n$; see (2.1)), the liquid flux $q(x,t)$, the porosity $\varepsilon(x,t)$, the liquid pressure $p(x,t)$, and the free boundary $s(t)$.

Equations (3.1) and (3.2) are the mass balances (2.6) according to assumption (i) of section 1 with the specification of V_i (see (2.11) and (2.15)). Equation (3.3) gives the liquid flux q (see definition (2.3)), while (3.4) and (3.5) regulate the release of particles or substances from the porous matrix (see [6] and [8] for a more detailed explanation of the physical model). The functions $\beta_i(q, b)$ are threshold concentrations for the removal of the species $i = 1, \dots, k$ (fine particles). As pointed out in [9] they play a crucial role in explaining some qualitative features of the process.

In (3.3)–(3.5) by b and m we mean the vectors $(b_1, \dots, b_n)$ and $(m_1, \dots, m_n)$, respectively. We will also consider (3.4) and (3.5) in terms of volumetric contents by introducing the functions $\hat{\Phi}_i = \Phi_i/\rho_i(q, \rho_1\theta_1, \dots, \rho_n\theta_n)$ and $\hat{H}_i$ defined analogously and by considering the removal laws

$$\frac{\partial \theta_i}{\partial t} = -\hat{\Phi}_i(q, \theta), \quad i = 1, \dots, k, \tag{3.20}$$

$$\frac{\partial \theta_i}{\partial t} = -\hat{H}_i(q, \theta), \quad i = k+1, \dots, n. \tag{3.21}$$

The global conservation laws (3.6) and (3.7) have been introduced in [13], under the hypothesis (which will be assumed true from now on) $\rho_i^{(b)} = \rho_i^{(m)} = \rho_i, i = 1, \dots, n$. Equation (3.6), which expresses incompressibility and saturation of the system, is obtained by replacing in (2.7) (divided by ρ_w) the quantities η_w and $\eta_w V_w$ deduced from (2.2) and (2.3), respectively, and by taking into account (2.6) for $i = k+1, \dots, n$. There is an easy way of reading (3.6): the divergence of the flux must compensate the possible unbalance between the pore volume created by dissolution and the volume previously occupied in the solid matrix by the dissolved substances (the two extremes being $\varepsilon + \theta_{(s)} =$ constant, or $\partial\theta_{(s)}/\partial t$ negligible in comparison to $\partial\varepsilon/\partial t$, which is the approach used in [9]).

Equation (3.7) comes from summing up (2.6) (divided by ρ_i), for $i = 1, \dots, n$ and (2.7) (divided by ρ_w). The terms containing the time-derivatives eliminate by virtue of (2.2) and (2.5), and using (2.3) gives the final form (3.7). The balance (3.7) states that the global volumetric flux of all the moving components (water and species η_i, $i = 1, \dots, n$) is constant at each time t.

In writing (3.12) we assume that the velocity of the i-species, $i = k+1, \dots, n$ vanishes at $x = 0$ (cf. (2.15)). Equation (3.14) is (2.16), while (3.15) comes from (2.8), (2.15), (2.16), and (2.17) and expresses the continuity of the diffusive flux of each species at the interface. By condition (3.17) we assume that the effect of diffusion is negligible at the outflow surface $x = 1$. Finally, the free boundary condition (3.16) is obtained by assuming the configuration constraint (2.24) and by summing up (2.19) with respect to i.

Note that the function $\theta_0(x)$, which gives the volume fraction of the porous skeleton (cfr. (2.5)), can be calculated by means of (3.8)–(3.10):

$$\theta_0(x) = 1 - (\varepsilon_0(x) + \eta_{(k),0}(x) + \theta_{(k),0}(x) + \eta_{(s)_0}(x)). \tag{3.22}$$

Obviously, the initial given functions appearing on the right-hand side of (3.22) are physically consistent only if $0 < \theta_0(x) < 1$.

We conclude this section by remarking that the water volume fraction η_w and the water velocity V_w can be computed a posteriori by means of (2.2), (2.3), and (2.11) once problem (3.1)–(3.19) has been solved.

4. List of assumptions. We assume that $K(b, m, \varepsilon)$, $F_i(q, b)$, $G_i(\eta)$, $\beta_i(q, b)$, $i = 1, \dots, k$, $H_i(q, b)$, $i = k+1, \dots, n$, are C^1-functions of their respective arguments and each first derivative is Lipschitz continuous. The given functions $\varepsilon_0(x)$, $m_{i,0}(x)$, $b_{i,0}(x)$, $i = 1, \dots, n$, and $p_0(t)$ are assumed to be C^1 with respect to their argument with bounded derivatives. Moreover, we will assume that there exist positive constants K_m, K_M, p_0^m, p_0^M, and m_0 such that

$$0 < K_m \le K(b, m, \varepsilon) \le K_M \quad \forall\, b, m, \varepsilon, \tag{4.1}$$

$$0 < p_0^m \le p_0(t) \le p_0^M, \quad t \ge 0. \tag{4.2}$$

The initial distribution of the various species must satisfy

$$m_{i,0}(x) \not\equiv 0, \quad b_{i,0}(x) \not\equiv 0, \quad x \in [0,1], \tag{4.3}$$

$$\eta_{(k),0}(x) + \theta_{(k),0}(x) < \Theta < 1 - (\theta_0(x) + {\theta_{(s)}}_0(x)), \quad x \in [0,1]. \tag{4.4}$$

Moreover, for simplicity we take the compatibility conditions

$$m_{i,0}(0) = 0, \quad i = 1, \dots, k. \tag{4.5}$$

Remark 4.1. Combining (4.4) with (2.5) and recalling (3.22) we get the following restriction for the initial data:

$$1 - \big(\Theta + \theta_0(x) + {\theta_{(s)}}_0(x)\big) < \varepsilon_0(x) < 1 - \theta_0(x), \quad x \in [0,1]. \tag{4.6}$$

We set

$$\begin{cases} \varepsilon_0^m = \min\limits_{x\in[0,1]} \big(1 - (\Theta + \theta_0(x) + {\theta_{(s)}}_0(x))\big)\,, \\ \varepsilon_0^M = \max\limits_{x\in[0,1]} (1 - \theta_0(x)) \end{cases} \tag{4.7}$$

(note that $0 < \varepsilon_0^m < \varepsilon_0^M < 1$). From (4.6) and (4.7), we deduce

$$0 < \varepsilon_0^m < \varepsilon_0(x) < \varepsilon_0^M < 1, \quad x \in [0,1]. \tag{4.8}$$

The functions introduced in the removal laws (3.4) and (3.5) have the properties

$$F_i(q, b_1, \dots, b_n) \ge 0,\ i = 1, \dots, k \quad \forall q \ge 0, 0 \le b_j \le b_{j,0},\ 1 \le j \le n, \tag{4.9}$$

$$\begin{aligned} &H_i(q, b_1, \dots, b_n) \ge 0,\ i = k+1, \dots, n \quad \forall q \ge 0, 0 \le b_j \le b_{j,0},\ 1 \le j \le n, \\ &H_i(q, 0, \dots, 0) = 0,\ i = k+1, \dots, n \quad \forall q \ge 0, \end{aligned} \tag{4.10}$$

$$\frac{\partial \beta_i}{\partial q}(q, b_1, \dots, n) \le 0,\ i = 1, \dots, k \quad \forall q \ge 0, 0 \le b_j \le b_{j,0},\ 1 \le j \le n. \tag{4.11}$$

Moreover, setting

$$\Phi = \sum_{i=1}^{k} \Phi_i = \sum_{i=1}^{k} F_i G_i, \quad H = \sum_{i=k+1}^{n} H_i \tag{4.12}$$

and defining the norm

$$\|\Psi\| = \sup_{q \ge 0, 0 \le b_i \le b_{i,0}} |\Psi(q, b)|, \tag{4.13}$$

we assume that

$$\|\Phi\| < \infty, \quad \|H\| < \infty. \tag{4.14}$$

For a function $g(\cdot)$, $\|g\|$ will denote the sup-norm. For a vector $v(t) = (v_1(t), \dots, v_n(t))$, we define

$$\|v\|_T = \max_{1\le i\le n} \sup_{0\le t\le T} |v_i(t)|. \tag{4.15}$$

We will denote by L_g^z the Lipschitz constant of the function g with respect to the variable z. (In the case $z = x$ we write simply L_g.) In particular, defining the vector

$$S = (S_1, \dots, S_n) = (\Phi_1, \dots, \Phi_k, H_{k+1}, \dots, H_n) \tag{4.16}$$

we will assume that positive constant values $L^q_{S_i}$, $L^b_{S_i}$, $L^q_{S_{i_q}}$, $L^b_{S_{i_{b_j}}}$, $i, j = 1, \dots, n$, exist such that

$$\begin{aligned}
&|S_i(q_1, b) - S_i(q_2, b)| \le L^q_{S_i}|q_1 - q_2|,\\
&|S_i(q, b^{(1)}) - S_i(q, b^{(2)})| \le L^b_{S_i} \max_{1\le j\le n} |b_j^{(1)} - b_j^{(2)}|,\\
&\left|\frac{\partial S_i}{\partial q}(q_1, b) - \frac{\partial S_i}{\partial q}(q_2, b)\right| \le L^q_{S_{i_q}}|q_1 - q_2|,\\
&\left|\frac{\partial S_i(q, b^{(1)})}{\partial b_j} - \frac{\partial S_i(q, b^{(2)})}{\partial b_j}\right| \le L^b_{S_{i_{b_j}}} \max_{1\le r\le n} |b_r^{(1)} - b_r^{(2)}|,
\end{aligned} \tag{4.17}$$

where q, q_1, q_2 are nonnegative real numbers and b, $b^{(1)}$, $b^{(2)}$ are vectors in $\mathbb{R}^n$ whose components belong to the intervals $[0, b_{j,0}]$, $j = 1, \dots, n$.

We introduce also the vector $\hat S$ defined as (cf. (3.20) and (3.21))

$$\hat S = (\hat S_1, \dots, \hat S_n) = (\hat\Phi_1, \dots, \hat\Phi_k, \hat H_{k+1}, \dots, \hat H_n). \tag{4.18}$$

We will denote by $L^q_{\hat S_i}$, $L^\theta_{\hat S_i}$, $L^q_{\hat S_i q}$, ${L_{\hat S_i \theta_j}}^\theta$, $i, j = 1, \dots, n$, the Lipschitz constant of $\hat S_i$, $\partial \hat S_i/\partial q$, $\partial \hat S_i/\partial \theta_j$ defined in the same way as in (4.17).

5. Existence and uniqueness of the solution. We will show the existence of solutions of (3.1)–(3.19) basing our proof on the Schauder's fixed point theorem. Our first aim is to calculate the volumetric flux for $t = 0$.

5.1. Determination of $q(x, 0)$. Let us integrate (3.3) with respect to x:

$$\int_0^{s(t)} \frac{q(\xi, t)}{K(b(\xi, t), m(\xi, t), \varepsilon(\xi, t))} d\xi = p_0(t) - p(s(t)^-, t). \tag{5.1}$$

We notice that the liquid flux in the compact layer is a function of time only as it can be deduced from (3.7). It will be denoted by $q_c(t)$. In the compact layer we have $q_c(t)(1 - s(t))/K_0 = p(s(t)^+, t)$ (see assumption (iv) of section 1, (2.20), and (3.18)), where K_0 is the hydraulic conductivity.

According to (3.13), we have

$$\int_0^{s(t)} \frac{q(\xi, t)}{K(b(\xi, t), m(\xi, t), \varepsilon(\xi, t))} d\xi = p_0(t) - (1 - s(t))\,\frac{q_c(t)}{K_0}. \tag{5.2}$$

Define now

$$l(x, t) = \frac{\displaystyle\sum_{i=1}^{k} \alpha_i \eta_i(x, t)}{\varepsilon(x, t)}, \quad l_0(x) = l(x, 0). \tag{5.3}$$

Equation (3.7) yields

$$q(x,t) = f(t)\frac{1}{1+l(x,t)}, \quad 0 \le x \le s(t), \tag{5.4}$$

where $f(t) = q(0,t)$ (owing to (3.11)). Assuming that the functions we are using have the regularity requested by the following computations and evaluating (5.4) and (5.2) for $t = 0$, we find

$$q_0(x) = q(x,0) = Q_0\frac{1}{1+l_0(x)}, \quad 0 \le x \le 1, \tag{5.5}$$

where Q_0 is the known constant

$$Q_0 = \frac{p_0(0)}{\displaystyle\int_0^1 \frac{1}{1+l_0(\xi)}\frac{1}{K(b_0(\xi), m_0(\xi), \varepsilon_0(\xi))}d\xi}.$$

Owing to (2.5), (2.16), and (3.16), we have

$$[[\varepsilon]]\,\dot{s} = ((\eta_{(p)} + \theta_{(p)})|_{(s(t)^-,t)} - \Theta)\dot{s} = (ql)|_{(s(t)^-,t)}\,. \tag{5.6}$$

Hence, from (2.17) we get

$$q_c(t) = q(s(t)^-,t)\left(1 + l(s(t)^-,t)\right). \tag{5.7}$$

By combining (5.2) with (5.4) and by taking into account (5.7), we get the following expression for $f(t)$:

$$f(t) = q(0,t) = \frac{p_0(t)}{\displaystyle\int_0^{s(t)} \frac{1}{1+l(\xi,t)}\frac{1}{K(\xi,t)}d\xi + \frac{1-s(t)}{K_0}}, \tag{5.8}$$

where we abridged $K(b(\xi,t), m(\xi,t), \varepsilon(\xi,t))$ by $K(\xi,t)$. Note that both $K(\xi,t)$ and $l(\xi,t)$ are still unknown.

5.2. The fixed point procedure. For the sake of simplicity, we will discuss the case $\alpha_i = 1$, $i = 1,\dots,k$, observing that the general case $\alpha_i < 1$ can be treated with slight modifications.

We start with the following remark. Assume that a pair $(q(x,t), s(t))$ is known to solve the problem. Then, all the other quantities can be computed. Indeed, the species $b_i(x,t)$ are calculated by integrating (3.4) and (3.5); then, $\varepsilon(x,t)$ can be found by means of (3.6). Moreover, the functions m_i, $i = 1,\dots,n$ are computed by means of (3.1) and (3.2). (We will discuss this point with more details in subsection 5.4.) Finally, $p(x,t)$ is found by integrating (3.3).

This argument can be summarized in the following points:

- fix a pair (q,s) in a suitable space;
- solve the problem (3.1)–(3.6), (3.8)–(3.15), (3.17), and (3.18) for (b,m,ε,p) with special adjustments for (3.1) and (3.2), as it will be discussed in detail in subsection 5.4;
- define a new guess $(\tilde{q},\tilde{s})$ in such a way that if it happens that $\tilde{q} = q$, $\tilde{s} = s$, then (3.7) and (3.16) are satisfied.

Such a procedure is performed in the next subsections.

5.3. Auxiliary estimates. Let us consider the set

$$
\begin{aligned}
&\mathcal{E}_T(u_1, u_2, A_y, A_t, M_y, M_t, s_0, A_s, M_s)\\
&= \big\{(u(y,t), s(t)) \mid u \in C^{1,1}(\bar{B}_T),\\
&u(y,0) = q_0(y),\ 0 \le y \le 1, 0 < u_1 \le u(y,t) \le u_2,\\
&\left|\frac{\partial u}{\partial y}(y,t)\right| \le A_y,\ \left|\frac{\partial u}{\partial t}(y,t)\right| \le A_t,\ (y,t) \in \bar{B}_T,\\
&\left|\frac{\partial}{\partial y}u(y_1,t) - \frac{\partial}{\partial y}u(y_2,t)\right| \le M_y\,|y_1 - y_2|\ \forall\, y_1, y_2 \in [0,1],\\
&\left|\frac{\partial}{\partial t}u(y_1,t) - \frac{\partial}{\partial t}u(y_2,t)\right| \le M_t\,|y_1 - y_2|\ \forall\, y_1, y_2 \in [0,1],\\
&s \in C^1[0,T], s(0) = 1, \quad 0 < s_0 \le s(t) \le 1,\\
&-A_s \le \dot{s}(t) \le 0, \quad 0 \le t \le 1,\\
&|\dot{s}(t_1) - \dot{s}(t_2)| \le M_s\,|t_1 - t_2| \quad \forall\, t_1, t_2 \in [0,T]\big\},
\end{aligned}
\tag{5.9}
$$

where $B_T = (0,1) \times (0,T)$ and $u_1 > 0$, $u_2 > u_1$, A_y , A_t, M_y, M_t, s_0, A_s, and M_s are positive constant values to be specified later.

For a pair $(u,s) \in \mathcal{E}_T$, we set

$$
q(x,t) = u\left(\frac{x}{s(t)}, t\right), \quad (x,t) \in \bar{D}_T.
\tag{5.10}
$$

Once problem (3.1)–(3.6), (3.8)–(3.15), (3.17), and (3.18) is solved, we can introduce the mapping $\mathcal{F}$ on $\mathcal{E}_T$ defined as $\mathcal{F}(u,s) = (\tilde{u}, \tilde{s})$, where

$$
\tilde{u}(y,t) = f(t)\frac{1}{1 + l(s(t)y, t)}, \quad (y,t) \in B_T,
\tag{5.11}
$$

$$
\tilde{s}(t) = 1 - \int_0^t \frac{l(s(\tau),\tau)q(s(\tau),\tau)}{\Theta - \big(\eta_{(p)}(s(\tau),\tau) + \theta_{(p)}(s(\tau),\tau)\big)}\,d\tau, \quad t \in [0,T]
\tag{5.12}
$$

inspired by (5.4) (i.e., (3.7)) and (3.16), respectively. In (5.11) the function $f(t)$ is calculated by using (5.8) and $l = \eta_{(p)}/\varepsilon$ (cfr. (5.3)).

Once $(\tilde{u}, \tilde{s})$ is calculated, the new guess $\tilde{q}$ for problem (3.1)–(3.6), (3.8)–(3.15), (3.17), and (3.18) is $\tilde{q}(x,t) = \tilde{u}(x/\tilde{s}(t), t)$ defined in the domain $\{(x,t) : x \in [0, \tilde{s}(t)],\ t \in [0,T]\}$. It is easily checked that if $(\bar{u}, \bar{s})$ is a fixed point of $\mathcal{F}$ in $\mathcal{E}_T$, then $\bar{q} = \bar{u}(x/\bar{s}, t)$ and $\bar{s}$ fulfills (3.7) and (3.16).

PROPOSITION 5.1. *Let* $(u,s) \in \mathcal{E}_T$, $A_y < s_0\varepsilon_0^m/T$ (*see* (4.8)), *with* T *arbitrarily fixed, and set*

$$
\begin{cases}
\epsilon_1 = \varepsilon_0^m - A_y T/s_0,\\
\epsilon_2 = \varepsilon_0^M + \varepsilon_0^m + \|\theta_0^{(k)}\|,\\
C_1 = \|\eta_{(k),0}\|/\varepsilon_0^m + \|\hat{\Phi}\| u_2/\epsilon_1, \quad K_{min} = \min\{K_0, K_m\}
\end{cases}
\tag{5.13}
$$

(see (3.20) *for the definition of* $\hat{\Phi}$*). Then, for* $(x,t) \in D_T$,

$$
0 < \epsilon_1 < \varepsilon(x,t) < \epsilon_2,
\tag{5.14}
$$

$$
0 \le l(x,t) \le C_1,
\tag{5.15}
$$

$$
0 < K_{min} p_0^m \le f(t) \le K_M p_0^M (1 + C_1).
\tag{5.16}
$$

Proof. Inequalities (5.14) follow immediately from the hypotheses and from (3.6), (4.10), and (3.21). As to (5.15), we notice that the function l defined by (5.3) satisfies the following equation in D_T:

$$\begin{cases} \varepsilon \dfrac{\partial l}{\partial t} + q \dfrac{\partial l}{\partial x} = l \dfrac{\partial \theta_{(s)}}{\partial t} - \dfrac{\partial \theta_{(p)}}{\partial t}, \\ l(x,0) = l_0(x) = \dfrac{\eta_{(k),0}(x)}{\varepsilon_0(x)}, \quad l(0,t) = 0. \end{cases} \tag{5.17}$$

Equation (5.17) is obtained by differentiating formally $\eta_{(p)}/\varepsilon$ and by taking into account (3.6) and

$$\frac{\partial \eta_{(p)}}{\partial t} = -\frac{\partial (lq)}{\partial x} - \frac{\partial \theta_{(p)}}{\partial t}, \tag{5.18}$$

which is the sum of (3.1) with respect to i, $i = 1, \dots, k$. The initial and boundary conditions in (5.17) come from (3.8), (3.9), and (3.11).

If we denote by Γ any of the characteristic curves of (5.17), it is easy to see that the slope $d\Gamma(t)\ /dt = q(\Gamma(t),t)\ /\varepsilon(\Gamma(t),t)$ is uniformly bounded by

$$0 < \frac{u_1}{\epsilon_2} \le \frac{d}{dt}\Gamma(t) \le \frac{u_2}{\epsilon_1}. \tag{5.19}$$

The starting points in D_T for the curves Γ are either the points $(x_0, 0)$, with $x_0 \in (0,1)$, and the points $(0, t_0)$, with $t_0 \ge 0$. Correspondingly, the initial value $l(\Gamma(t_0), t_0)$ is $l_0(x)$, $x \in [0,1)$, if $t_0 = 0$ or 0 if $t_0 > 0$. The estimate (5.15) is a consequence of (4.9), (4.10), and (5.19). Finally, the bounds (5.16) for f (see (5.8)) follow from (4.1), (4.2), (4.9), (4.10), and (5.15). □

PROPOSITION 5.2. *If $(u,s) \in \mathcal{E}_T$, then the functions l, $\partial l/\partial x$, and $\partial l/\partial t$ are Lipschitz continuous with respect to x in $\bar{D}_T$.*

Proof. By virtue of the Gronwall's lemma (cf., e.g., [3, Lemma 8.4.1]) and of assumption (4.17), we get

$$\|\theta(x',t) - \theta(x'',t)\|_T \le L_\theta |x' - x''|, \quad L_\theta = L_1 e^{L_2 T} \tag{5.20}$$

with $L_1 = \max_{1\le i\le n} L_{\theta_{i,0}} + \max_{1\le i \le n} L^q_{\hat{S}_i} A_y T/s_0$, $L_2 = \max_{1\le i\le n} L^\theta_{\hat{S}_i}$.

At this point, it is useful to remark that q/ε is Lipschitz continuous with respect to x with constant

$$L_{q/\varepsilon} = \frac{1}{\epsilon_1^2}\left(\epsilon_2 \frac{A_y}{s_0} + u_2 \left(L_{\varepsilon_0 + \theta_0^{(k)}} + \frac{1}{s_0^2} M_y T\right)\right). \tag{5.21}$$

In order to prove the Lipschitz continuity of l, we consider the two characteristic curves Γ_1 and Γ_2 passing through (x',t) and (x'',t), respectively. Recalling (5.20), we easily find

$$|l(x',t) - l(x'',t)| \le \omega\lambda |x' - x''|, \quad t_0 \le \tau \le t, \tag{5.22}$$

where t_0 is the max between the initial times of Γ_1 and Γ_2,

$$\omega = e^{L_{q/\varepsilon} T}, \quad \lambda = \left(T\left(\frac{A_y}{s_0}\tilde{L}_1 + \tilde{L}_2 L_\theta\right) + L_{l_0}\right), \tag{5.23}$$

and $\tilde{L}_1$, $\tilde{L}_2$ depend only on $\|\Phi\|$, $\max_{0\le x\le 1} l_0(x)$, $L^q_{\hat{H}_i} + \sum_{i=1}^k$, $L^q_{\hat{\Phi}_i}$, $L^\theta_{\hat{H}_i} + \sum_{i=1}^k$, $L^\theta_{\hat{\Phi}_i}$ (cf. also (4.17)).

It is worth noticing that (5.22) with (5.17) provides the following bounds for the derivatives of l:

$$\left|\frac{\partial l}{\partial x}\right| \le \omega\lambda, \qquad \left|\frac{\partial l}{\partial t}\right| \le \frac{1}{\epsilon_1}\left(u_2\omega\lambda + \max\{C_1\|\hat{\Phi}\|, \|\hat{H}\|\}\right). \tag{5.24}$$

The Lipschitz continuity of $\partial l/\partial t$, with respect to x can be established arguing in the same way as before. We first remark that $l_t = \partial l/\partial t$ satisfies the following equation along the characteristic curves:

$$\begin{aligned}&\varepsilon(\Gamma(t),t)\frac{\partial}{\partial t}l_t(\Gamma(t),t) + q(\Gamma(t),t)\frac{\partial}{\partial x}l_t(\Gamma(t),t)\\ &= w_1(\Gamma(t),t)l_t(\Gamma(t),t) + w_2(\Gamma(t),t),\end{aligned} \tag{5.25}$$

where

$$w_1 = -\frac{\partial\varepsilon}{\partial t} - \frac{\varepsilon}{q}\frac{\partial q}{\partial t} \quad w_2 = \frac{1}{q}\frac{\partial q}{\partial t}(l\hat{H} - \hat{\Phi}) - \left(l\frac{\partial\hat{H}}{\partial t} - \frac{\partial\hat{\Phi}}{\partial t}\right). \tag{5.26}$$

It can be seen that the Lipschitz constant L_{l_t} is such that

$$L_{l_t} \le \omega\left\{L_{l_t(x,0)} + L_{w_2})e^{\bar{w}_1 T} + (\bar{l}_{t,0} + T\bar{w}_2)L_{w_1}T\right\}, \tag{5.27}$$

where $\bar{w}_i = \max_{(x,t)\in\bar{D}_T}|w_i(x,t)|$, $\bar{l}_{t,0} = \max_{0\le x\le 1}|l_t(x,0)|$. (Note that $l_t(x,0)$ is a known function obtained from (5.17), (3.8), (3.9), (3.4), and (3.5).) It is not difficult to realize that $\bar{w}_i$, $i = 1,2$, does not depend on M_y, M_t.

In order to stress the dependence of $L_{w_i}, i = 1,2$ on M_y, M_t we write the following formula, which can be obtained after some calculations by recalling (3.6) and (5.21):

$$\begin{cases}L_{w_1} \le \alpha_1 M_y + \beta_1 M_t + \gamma_1,\\ L_{w_2} \le \alpha_2 M_y + \beta_2 M_t + \gamma_2 + \delta_2\omega.\end{cases} \tag{5.28}$$

Although we avoid writing, for the sake of simplicity, the lengthy expressions of the coefficients α_i, β_i, γ_i, $i = 1,2,3$, and δ_2, it is important to remark that they depend only on A_y, A_t, A_s, s_0, u_1, u_2, T, L_{l_0}, $L_{l_t(x,0)}$ and on the Lipschitz constants appearing in (4.17).

Owing to (5.28), we finally write

$$L_{l_t} \le \omega(\alpha_3 M_y + \beta_3 M_y + \gamma_3 + \delta_3\omega) \tag{5.29}$$

with

$$\begin{cases}\alpha_3 = \alpha_1 T(L_{l_0} + T\bar{w}_2) + \alpha_2 T e^{\bar{w}_1 T},\\ \beta_3 = \beta_1 T(L_{l_0} + T\bar{w}_2) + \beta_2 T e^{\bar{w}_1 T},\\ \gamma_3 = L_{l_t(x,0)}e^{\bar{w}_1 T} + \gamma_1 T(L_{l_0} + T\bar{w}_2) + \gamma_2 T e^{\bar{w}_1 T},\\ \delta_3 = \delta_2 T e^{\bar{w}_1 T}.\end{cases} \tag{5.30}$$

Note that the values defined in (5.30) do not depend on M_y, M_t.

We conclude the proof of this lemma by remarking that the Lipschitz continuity of $\partial l/\partial x$ with respect to x comes directly from (5.17):

$$L_{l_x} \leq \left(\frac{\epsilon_1}{u_1}\right)^2 \max_{(x,t)\in\bar{D}_t} |l_t(x,t)| + \frac{\epsilon_2}{u_1} L_{l_t} + \lambda \frac{\|\hat{H}\|}{u_1}\omega + \frac{1}{u_1}\left\{C_1 L_{\theta_{(s)_t}} + L_{\theta_{(p)_t}} + \frac{A_y}{s_0 u_1}\left(C_1\|\hat{H}\| + \|\hat{\Phi}\|\right)\right\}, \tag{5.31}$$

where $|l_t|$ is estimated by means of (5.24). □

5.4. Determination of the concentrations. In order to calculate $f(t)$ by means of (5.8), it is necessary to find the concentration of each species separately, because of the dependence of f on θ_i, η_i, $i = 1, \ldots, n$, through the hydraulic conductivity K.

Problem (3.1), (3.8), and (3.11) involves the x-derivative of q/ε, which does not necessarily exist, since (see (3.6)) ε may not be differentiable with respect to x. Hence, we formally consider the following equation, which comes from (3.7) and (5.4) and is of course applicable to the solution of the original problem only:

$$\frac{\partial \varepsilon}{\partial x} = \varepsilon\left(\frac{1}{q}\frac{\partial q}{\partial x} + \frac{1}{\varepsilon + \eta_{(p)}}\frac{\partial}{\partial x}(\varepsilon + \eta_{(p)})\right). \tag{5.32}$$

If we recall (2.5), we can replace the x-derivative of $\varepsilon + \eta_{(p)}$ on the right-hand side by $-\theta_0'(x)$ $-\partial/\partial x(\theta_{(p)}$ $+\theta_{(s)})$, which is computed by introducing the vector

$$\zeta = \frac{\partial}{\partial x}(\theta_1, \ldots, \theta_n)$$

and by solving the ODEs

$$\begin{cases} \dfrac{\partial \zeta_i}{\partial t} = -\dfrac{\partial \hat{S}_i}{\partial q}\dfrac{\partial q}{\partial x} - \nabla_\theta \hat{S}_i \cdot \zeta & \text{for } i = 1, \ldots, n, \\ \zeta(x,0) = \zeta_0(x) = (\theta_1'(x), \ldots, \theta_n'(x)). \end{cases} \tag{5.33}$$

Having in mind (5.32), we modify (3.1) replacing $\partial/\partial x(q/\varepsilon)$ by the x-derivative of a function E such that

$$\frac{\partial E}{\partial x} = \frac{1}{\varepsilon + \eta_{(p)}}\frac{q}{\varepsilon}\left(\zeta_0 + \sum_{i=1}^n \zeta_i\right). \tag{5.34}$$

The Lipschitz continuity of ζ_i (hence that of $\partial E/\partial x$) can be easily checked by examining (5.33). Thus, for the components $i = 1, \ldots, k$ we consider the following modified problem, to be solved in the given domain $D_T = \{(x,t) : 0 < x < s(t),\ 0 < t < T\}$ together with (3.8) and (3.11):

$$\frac{\partial \eta_i}{\partial t} + \alpha_i \eta_i \frac{\partial E}{\partial x} + \alpha_i \frac{q}{\varepsilon}\frac{\partial \eta_i}{\partial x} = -\frac{\partial \theta_i}{\partial t}, \quad i = 1, \ldots, k. \tag{5.35}$$

As for the remaining species $i = k+1, \ldots, n$, we define

$$c_i = \frac{m_i}{\varepsilon}, \quad i = k+1, \ldots, n,$$

as the concentration of the i-component in the solute. Owing to (3.2) and (3.6), we see that in the original problem c_i must satisfy the following equation in $D_T \cup R_T$:

$$\begin{aligned}\varepsilon\frac{\partial c_i}{\partial t} + \frac{\partial}{\partial x}\left(-\varepsilon D_i \frac{\partial c_i}{\partial x}\right) + q\frac{\partial c_i}{\partial x}\\ -c_i\frac{\partial \theta_{(s)}}{\partial t} = H_i,\ i = k+1, \dots, n.\end{aligned} \tag{5.36}$$

Actually, here too we use a modified equation, replacing $\partial\varepsilon/\partial x$ with

$$\frac{\varepsilon}{q}\left(\frac{\partial q}{\partial x} - \varepsilon\frac{\partial E}{\partial x}\right).$$

The modified equation replacing (5.36) is therefore

$$\begin{aligned}\varepsilon\frac{\partial c_i}{\partial t} + \varepsilon\frac{\partial}{\partial x}\left(-D_i\frac{\partial c_i}{\partial x}\right) + \left(q - D_i\frac{\varepsilon}{q}\left(\frac{\partial q}{\partial x} - \varepsilon\frac{\partial E}{\partial x}\right)\right)\frac{\partial c_i}{\partial x}\\ -c_i\frac{\partial \theta_{(s)}}{\partial t} = H_i, \quad i = k+1, \dots, n.\end{aligned} \tag{5.37}$$

The initial and boundary conditions associated to (5.36) come from (3.8), (3.9), (3.14), (3.15), and (3.17), namely,

$$c_i(x,0) = m_{i,0}(x)/\varepsilon_0(x), \quad i = k+1, \dots, n, \tag{5.38}$$

$$[[c_i]] = 0, \quad x = s(t) \quad i = k+1, \dots, n, \tag{5.39}$$

$$\left[\left[\varepsilon D_i\frac{\partial c_i}{\partial x}\right]\right] = 0 \quad x = s(t), \quad i = k+1, \dots, n, \tag{5.40}$$

$$\frac{\partial c_i}{\partial x}(1,t) = 0, \quad 0 < t < T, \quad i = k+1, \dots, n. \tag{5.41}$$

Existence for the diffraction problem (5.37)–(5.41) is guaranteed by Theorem 13.1, page 227, of [11].

5.5. The property $\mathcal{F}(\mathcal{E}_T) \subseteq \mathcal{E}_T$. In order to simplify the mathematical presentation, it can be assumed that the dependence of K on m_i occurs through q (i.e., $K = K(q,b,\varepsilon)$). Even if we are going to make such an assumption, it must be said that it plays a very marginal role in the proof of the proposition we are going to show.

PROPOSITION 5.3. *There exists at least one set of positive values* $\{T, u_1, u_2 > u_1,\ A_y,\ A_t,\ M_y,\ M_t,\ s_0,\ A_s, M_s\}$ *so that, if* $(u,s) \in \mathcal{E}_T(u_1, u_2,\ A_y, A_t, M_y,\ M_t, s_0, A_s, M_s)$*, then* $(\tilde u, \tilde s) \in \mathcal{E}_T$*, provided that* (*see* (5.13) *for the definition of* C_1)

(i)

$$\epsilon_2 C_1 + \|\theta_{(k),0}\| < \Theta; \tag{5.42}$$

(ii)

$$\frac{\|\hat\Phi\|}{\epsilon_1}K_M p_0^M < 1, \quad p_0^M(1+C_1)^2\left|\frac{\partial K}{\partial q}\right| < 1; \tag{5.43}$$

(iii) *the Lipschitz constants with respect to* x *of the given functions* ε_0*,* $\eta_{(k),0}$*,* $\eta_0^{(k)}$*,* ε_0'*,* $\eta_{(k),0}'$*, and the Lipschitz constants* $L^q_{\hat S_i}$*,* $L^\theta_{\hat S_i}$*,* $i = 1, \dots, n$*, of the removal functions are small enough, in the sense that will be specified more precisely through the proof of the proposition.*

Proof. It is easy to check that $\tilde{u}(y,0) = u(y,0) = q_0(y)$, $0 \leq y \leq 1$, where q_0 is given by (5.5). From (5.11), (5.15), and (5.16) we see that

$$\frac{1}{1+C_1} K_m p_0^m \leq \tilde{u}(x,t) \leq K_M p_0^M (1+C_1). \tag{5.44}$$

Recalling (5.13) and owing to the first inequality in (5.43), it is possible to find u_2 sufficiently large so that $K_M p_0^M\ (1+C_1) \leq u_2$. On the other hand, it is sufficient to take $u_1 = (1+C_1)^{-1}(K_m p_0^m)$ in order to have $\tilde{u}$ bounded within the interval $[u_1, u_2]$. From (5.15), (5.14), and (4.10) we see that

$$1 \geq \tilde{s} \geq 1 - \frac{K_M p_0^M C_1 (1+C_1) T}{\Theta - (\epsilon_2 C_1 + \sup\limits_{0 \leq x \leq 1} \theta_{(k),0}(x))}. \tag{5.45}$$

By virtue of (5.42) and taking T sufficiently small, we see that the boundary $\tilde{s}$ is uniformly bounded by a constant $s_0 > 0$.

If we calculate explicitly the y-derivative of $\tilde{u}$ and we recall (5.16) and (5.24), we can easily realize that

$$\left|\frac{\partial \tilde{u}}{\partial y}\right| \leq (1+C_1) K_M p_0^M \omega \lambda. \tag{5.46}$$

Recalling (5.23), it can be seen that two values A_{y_1} and A_{y_2}, $0 < A_{y_1} < A_{y_2}$ can be found such that the right-hand side of (5.46) is smaller than A_y for $A_y \in [A_{y_1}, A_{y_2}]$, provided that $\tilde{L}_1$ and $\tilde{L}_2$ are taken sufficiently small. Note that $\tilde{L}_1$ and $\tilde{L}_2$ depend only on the quantities mentioned in assumption (iii) of the statement of the present proposition. It is useful to observe that A_{y_1} tends to zero if $\tilde{L}_1$ and $\tilde{L}_2$ tend to vanish.

As to the t-derivative of $\tilde{u}$, we have from (5.24) and (5.46)

$$\left|\frac{\partial \tilde{u}}{\partial t}\right| \leq \max_{0 \leq t \leq T} |\dot{f}(t)| + (1+C_1) K_M p_0^M \left(\omega\lambda \left(A_s + \frac{u_2}{\epsilon_1} \right) + \frac{1}{\epsilon_1} \max\{C_1 \|\hat{\Phi}\|, \|\hat{H}\|\} \right). \tag{5.47}$$

Recalling (5.13) and (5.22), we see that the second term on the right-hand side of (5.47) is independent of A_t. On the other hand, when we calculate $\dot{f}$ explicitly, it is easy to find a bound for it of the type $c_1 A_t + c_2$, where c_1 is exactly the left-hand side of (5.43), the second inequality, and c_2 is independent of A_t. Hence, $c_1 < 1$ entails that $|\partial\tilde{u}/\partial t| \leq A_t$ for $A_t > c_2(1-c_1)^{-1}$.

We now pass evaluating the Lipschitz constants $L_{\tilde{u}_y}$ and $L_{\tilde{u}_t}$ with respect to y of the derivatives of $\tilde{u}$. We find (cf. (5.22), (5.27), (5.31), and (5.24))

$$L_{\tilde{u}_y} \leq K_M p_0^M (1+C_1)^2 \left((1+C_1) L_{l_x} + 2\omega^2\lambda^2 \right), \tag{5.48}$$

$$\begin{aligned} L_{\tilde{u}_t} \leq \max_{0 \leq t \leq T} \|\dot{f}\| + K_M p_0^M (1+C_1)^2 [(1+C_1)(L_{l_x} A_s + L_{l_t}) \\ + 2\omega\lambda \left(\omega\lambda A_s + \frac{1}{\epsilon_1}(u_2 \omega\lambda + C_1 \|\hat{\Phi}\| + \|\hat{H}\|) \right)]. \end{aligned} \tag{5.49}$$

We first remark that $\max_{0 \leq t \leq T} |\dot{f}|$ can be expressed in the form $\gamma_f + \delta_f \omega$, where γ_f and δ_f depend also on the norm of $|\partial K/\partial q|$, $|\partial K/\partial \varepsilon|$, $|\dot{p}_0|$, but not on M_y, M_t.

Imposing that the right-hand sides of (5.48) and (5.49) are not greater than M_y and M_t, respectively, and taking account of the estimates (5.29) and (5.31), we arrive at the following system of inequalities:

$$\begin{cases} (\mu_1\omega+\mu_2)M_y+\mu_3\omega M_t+\mu_4\omega^2+\mu_5\omega\le M_y,\\ A_s\left((\mu_1\omega+\mu_2)M_y+\mu_3\omega M_t\right)+\mu_6\omega^2+(\mu_7+\delta_f)\omega+\gamma_f\le M_t, \end{cases} \tag{5.50}$$

where (see also (5.30))

$$\begin{cases} \mu_1=(1+C_1)\nu_0\left(\dfrac{\epsilon_2}{u_1}\alpha_3+\dfrac{\epsilon_1 r_2}{u_1^2}\lambda\right),\\ \mu_2=(1+C_1)\nu_0\dfrac{1}{\epsilon_1u_1^2s_0^2}(C_1\|\hat{\Phi}\|+\|\hat{H}\|)T,\\ \mu_3=\nu_0\dfrac{\epsilon_2}{u_1}\beta_3,\\ \mu_4=\nu_0\left\{\left[(1+C_1)\dfrac{\epsilon_2}{u_1}\delta_3\right]+2\dfrac{\epsilon_2}{\epsilon_1u_2}\lambda^2\right\},\\ \mu_5=\dfrac{\nu_0}{u_1}\left\{(1+C_1)\left[\gamma_3\epsilon_2u_1+\lambda\|\hat{H}\|+\dfrac{u_2\epsilon_1r_1\lambda}{u_1}\right]\right.\\ \qquad\qquad\left.+2\lambda\left(\left(1+\dfrac{\epsilon_2}{\epsilon_1}\right)(C_1\|\hat{\Phi}\|+\|\hat{H}\|)\right)\right\} \end{cases} \tag{5.51}$$

and

$$\begin{cases} \nu_0=K_Mp_0^M(1+C_1)^2,\\ r_1=\dfrac{1}{\epsilon_1^2}\left(\epsilon_2\dfrac{A_y}{s_0}+u_2L_{\varepsilon_0+\theta_0^{(k)}}\right)T,\\ r_2=\dfrac{u_2}{\epsilon_1^2s_0^2}T^2. \end{cases} \tag{5.52}$$

The coefficient μ_6 (resp., μ_7) is similar to μ_4 (resp., μ_5), with the only difference being that A_s multiplies the term in square brackets. We recall that ω depends on M_y through $L_{q/\varepsilon}$ (cf. (5.21) and (5.23)), namely,

$$\omega=e^{r_1+r_2M_y}.$$

Now, fix any $Y>1$. Owing to (5.51) and (5.52) (see also (5.30) for the definition of α_3), we easily realize that a positive value T_0 can be found such that

$$e^{r_1(T)}<Y<\frac{1-\mu_1(T)}{\mu_2(T)} \tag{5.53}$$

for any $T\in(0,T_0]$. Second, we define

$$Z=3\left(\delta_fe^{r_1(T_0)+r_2(T_0)Y}+\gamma_f\right) \tag{5.54}$$

(we recall that γ_f and δ_f have been introduced just above (5.49)) and we pass to solve the first inequality in (5.50) setting $M_t=Z$. We find it convenient to write such an inequality in the following form:

$$\begin{cases} \phi_1(\omega,T) \ge \phi_2(\omega,T), \\ \phi_1(\omega,T) = \dfrac{\ln\omega - r_1}{r_2}, \\ \phi_2(\omega,T) = \dfrac{(\mu_3 M_t + \mu_5)\omega + \mu_4\omega^2}{1-\mu_1\omega-\mu_2}. \end{cases} \tag{5.55}$$

The dependence of ϕ_1 and ϕ_2 on T is through the coefficients μ_i, $i=1,\dots,5$, and r_1, r_2. It can be seen, by simply examining the functions ϕ_1 and ϕ_2 and the coefficients defined in (5.51) and (5.52), that two positive values $T_1 \le T_0$ and $\omega_0 > e^{r_1(T_0)}$ can be found such that (5.55) is satisfied for $0 < T \le T_1$ and $\omega_0 \le \omega \le Y$.

On the other hand, we rewrite the second inequality in (5.50) as

$$\begin{cases} Z \ge \phi_3(\omega,T) + \phi_4(\omega,T), \\ \phi_3(\omega,T) = \dfrac{A_s(\mu_1\omega+\mu_2)\phi_1(\omega,T) + \mu_6\omega^2 + \mu_7\omega}{1 - A_s\mu_3\omega}, \\ \phi_4(\omega,T) = \dfrac{\delta_f\omega + \gamma_f}{1 - A_s\mu_3\omega}. \end{cases} \tag{5.56}$$

Note that $\phi_3(\omega,T) \le \phi_3(Y,T)$ for $\omega \in [\omega_0, Y]$. Recalling also (5.30) and (5.51), we see that it is possible to find a positive $T_2 \le T_1$ so that

$$1 - A_s\mu_3 \ge \frac{1}{2}, \quad \phi_3(Y,T) \le \frac{1}{3}Z.$$

Since $\phi_4(\omega,T) \le \frac{2}{3}Z$ (see (5.54)) for $T \in (0,T_2]$ and $\omega \in [\omega_0, Y]$, we conclude that (5.56) (hence (5.50) with $M_t = Z$) holds for T and ω belonging to the same intervals.

By definition (5.12) and estimate (5.15) we immediately see that the boundary velocity $\dot{\tilde{s}}$ is uniformly bounded as follows:

$$-\frac{u_2 C_1}{\Theta - (\epsilon_2 C_1 + \|\theta_{(k),0}\|)} \le \dot{\tilde{s}}(t) \le 0. \tag{5.57}$$

Hence, it is sufficient to take $A_s \ge u_2 C_1 \; (\Theta - (\epsilon_2 C_1 + \; \|\theta_{(k),0})\|)^{-1}$ in order to have a uniform bound for $\dot{\tilde{s}}(t)$. Note that $A_s > 0$ because of (5.42).

Finally, we discuss the Lipschitz continuity of $\dot{\tilde{s}}$. We take $0 \le t_1 < t_2$ and we consider the point $(\Gamma_2(t_1), t_1)$, where Γ_2 is the characteristic curve passing by $(\tilde{s}(t_2), t_2)$. Calling

$$\sigma(t) = \frac{l(\Gamma_2(t),t)q(\Gamma_2(t),t)}{\Theta - (\eta_{(p)}(s(t),t) + \theta_{(p)}(s(t),t))},$$

we see that

$$\begin{aligned} &|\dot{\tilde{s}}(t_1) - \dot{\tilde{s}}(t_2)| \le |\dot{\tilde{s}}(t_1) - \sigma(t_1)| + |\sigma(t_1) - \dot{\tilde{s}}(t_2)| \\ &\le \frac{1}{(A_y T)^2}\left((\Theta + C_1 u_2 L_{\eta_{(p)}+\theta_{(p)}})|\Gamma_2(t_1) - \tilde{s}(t_1)|\right. \\ &+\Theta\left|(lq)|_{(\Gamma_2(t_1),t_1)} - (lq)|_{(\Gamma_2(t_1),t_1)}\right| \\ &\left.+C_1 u_2\left|(\eta_{(p)} + \theta_{(p)})|_{(\Gamma_2(t_1),t_1)} - (\eta_{(p)} + \theta_{(p)})|_{(\Gamma_2(t_2),t_2)}\right|\right). \end{aligned} \tag{5.58}$$

By virtue of (5.19) we easily get

$$|\tilde{s}(t_1) - \Gamma_2(t_1)| \leq \left(A_s + \frac{u_2}{\epsilon_1}\right)|t_1 - t_2|. \tag{5.59}$$

On the other hand, the functions q, l, $\eta_{(p)}$, and $\theta_{(p)}$ are easily estimated along a characteristic curve. Eventually, the right-hand side of (5.58) is bounded by a term of the type $C_2|t_1 - t_2|$, with C_2 independent of M_s. □

5.6. The main result. We start by the following local result. Second, it will be extended globally in time (see Proposition 5.5).

PROPOSITION 5.4. *Under the same hypotheses as in Propositions* 5.1 *and* 5.3*, $\mathcal{F}$ has at exactly one fixed point in $\mathcal{E}_T$, for some $T > 0$.*

Proof. Concerning existence, we make use of the Schauder's fixed point theorem. It is easily checked that the set $\mathcal{E}_T$ is bounded, closed, and convex. By virtue of Proposition 5.3, there exists $T > 0$ so that $\mathcal{F}(\mathcal{E}_T) \subseteq \mathcal{E}_T$. As to the continuity of $\mathcal{F}$, we take two points (u_1, s_1), $(u_2, s_2) \in \mathcal{E}_T$ and the two groups of calculated functions $(\varepsilon_1, \theta_1^{(1)}, \ldots, \theta_n^{(1)}, \eta_1^{(1)}, \ldots, \eta_n^{(1)})$, $(\varepsilon_2, \theta_1^{(2)}, \ldots, \theta_n^{(2)}, \eta_1^{(2)}, \ldots, \eta_n^{(2)})$. If $\|u_1 - u_2\|_{C^{1,1}}$ $+\|s_1 - s_2\|_{C^1}$ is sufficiently small, it is not difficult to see that $|\varepsilon_1 - \varepsilon_2|$, $\|\theta^{(1)} - \theta^{(2)}\|_T$, and $\|\eta^{(1)} - \eta^{(2)}\|_T$ are arbitrarily small (of course, we have to restrict x in $[0, \min_{i=1,2} s_i(t)$, for each $t \in [0, T])$. The same property is true for the derivatives of u with respect to y and t and for the t-derivative of s. Eventually, it can be obtained that $\|\tilde{u}_1 - \tilde{u}_2\|_{C^{1,1}}$ $+\|\tilde{s}_1 - \tilde{s}_2\|_{C^1} \to 0$ for $\|u_1 - u_2\|_{C^{1,1}}$ and $\|s_1 - s_2\|_{C^1}$ tending to zero.

Finally, the precompactness of $\mathcal{F}(\mathcal{E}_T)$ follows from what was proved in Propositions 5.2 and 5.3 and from observing that $\partial\tilde{u}/\partial t$ is Lipschitz continuous also with respect to t. Indeed, for any pair (y, t_1), (y, t_2), $0 \leq t_1 < t_2$, $0 \leq y \leq 1$, we consider the points $P_1 \equiv (s(t_1)y, t_1)$, $P_2 \equiv (s(t_2)y, t_2)$ and $P_3 \equiv (\Gamma_2(t_1), t_1)$ with Γ_2 characteristic curve passing by P_2. By examining (5.25), it can be seen that $l_t(\Gamma_2(t), t)$ (hence l_x) is Lipschitz continuous with respect to t along the characteristic $\widehat{P_2P_3}$. On the other hand, the Lipschitz continuity (with respect to y) along the horizontal segment $\overline{P_1P_3}$ has been already proved. Moreover, for any $y \in [0, 1]$, $0 \leq t_1 < t_2$ we have (cf. (5.19))

$$|y - y'| \leq \frac{u_2}{s_0\epsilon_1}|t_1 - t_2|, \quad y' = \Gamma_2(t_1).$$

As to uniqueness, we observe that the mapping is a contraction if T is chosen sufficiently small. By means of an iteration argument, we can extend uniqueness with no limitation in time. This concludes the proof of Proposition 5.4. □

We now define

$$\beta = \frac{\|\hat{\Phi}\|K_M p_0^M}{\varepsilon_0^m}, \quad \epsilon_2 = \varepsilon_0^M + \varepsilon_0^m + \|\theta_0^{(k)}\|, \tag{5.60}$$

where the norm is the sup-norm and we take $\bar{C}_1$ as any constant such that

$$\frac{\dfrac{\|\eta_{(p),0}\|}{\varepsilon_0^m} + \beta}{1 - \beta} < C_1 < \frac{\|\theta_{(p,0)}\|}{\epsilon_2}.$$

PROPOSITION 5.5. *Under assumptions*

(i) *a* $\beta < 1$, $\frac{\epsilon_2/\varepsilon_0^m}{1-\beta}\|\eta_{(p),0}\| + \|\theta_{(k),0}\| + \epsilon_2\frac{1}{1-\beta} < \Theta$,

(ii) *a* $p_0^M(1+\bar{C}_1)^2|\frac{\partial K}{\partial q}| < 1$,

and assumption (iii) *of Proposition* 5.3*, system* (3.1)–(3.19) *has exactly one solution for any* $t \geq 0$.

Proof. It is immediate to see that if (i) part a and (ii) part a hold, then a positive T can be found such that assumptions (i) and (ii) of Proposition 5.3 are fulfilled.

We also remark the following important property of the solution found by means of Proposition 5.4. By integrating (3.1) in the domain D_t, $0 < t \leq T$, by using the Gauss–Green formula, and by taking into account of the boundary condition (3.16) we get the following balance:

$$\begin{aligned}(5.61)\qquad &\int_0^{s(t)} (\eta_{(p)}(x,t) + \theta_{(p)}(x,t))dx + \Theta(1-s(t))\\ &= \int_0^1 (\eta_{(k),0}(x) + \theta_{(k),0}(x))dx.\end{aligned}$$

The physical meaning of (5.61) is evident: the initial concentration of the i-species, $i = 1, \dots, k$, is partitioned between the porous medium and the compact layer. When the first term in the left-hand side of (5.61) vanishes, we get the minimum possible value s_{min} for the boundary $s(t)$:

$$(5.62)\qquad s_{min} = 1 - \frac{\bar{m}_0}{\Theta}, \quad \bar{m}_0 = \int_0^1 (\eta_{(k),0} + \theta_{(k),0})dx.$$

In (5.62) $\bar{m}_0$ is the initial volume occupied by the particles. Note that $0 < s_{min} < 1$, by virtue of (4.3).

An important consequence of (5.61) is that s is bounded by a quantity depending only on the data of the problem and independently of T. A second property of the solution is

$$(5.63)\qquad \eta_{(p)} + \theta_{(p)} < \Theta, \quad (x,t) \in D_T.$$

Inequality (5.63) follows immediately from (5.15), (5.14), (4.9), and (5.42) and will be commented in the following section.

Assume now that $\eta_{(p)}(x,T) \not\equiv 0$, $x \in [0, s(T)]$. (Otherwise, the removal process stops, as will be stated more precisely in subsection 6.1.) Using (2.5) (note that this equation is a consequence of (3.1), (3.6), (3.7), and (3.22)) and taking into account (5.63) and the fact that $\theta_{(p)}$ and $\theta_{(s)}$ are decreasing functions with respect to t, we can estimate the porosity at the time $t = T$ as follows:

$$\begin{aligned}(5.64)\qquad & 1 - (\Theta + \theta_0(x) + {\theta_{(s)}}_0(x)) < \varepsilon(x,T)\\ (5.65)\qquad & < 1 - \theta_0(x), \quad x \in [0, s(T)].\end{aligned}$$

We remark that $s(T) > 0$ owing to (5.62). Recalling (4.7) and (4.8), we see that

$$(5.66)\qquad \varepsilon_0^m < \varepsilon(x,T) < \varepsilon_0^M, \quad x \in [0, s(T)].$$

Let us consider now the interval $[T, 2T]$. Arguing as in Proposition 5.1, we see that $l(x,t)$ is bounded by the same constant C_1 for $T \leq t \leq 2T$. (Note that ϵ_1 and ϵ_2 have the same value as for $t \in [0,T]$, by virtue of (5.66).) This in turn implies that assumptions (i)–(iii) are still valid for $t = T$, so that the result stated in Proposition 5.4 still holds for $t \in [T, 2T]$. Iterating the procedure, we get existence and uniqueness globally in time. □

6. Qualitative properties of the solution.

Let us define

$$D = \{(x,t) : 0 < x < s(t), t > 0\}.$$

We start by commenting (5.63), which prevents the formation of new compact layers in the region D. First, we remark that condition (5.42), which is fundamental in order to get (5.63), is more restrictive than the first inequality in (4.4), since it can be written in the following form (cf. (5.13)):

$$\left(1 + \frac{\varepsilon_0^M + \|\theta_0^{(k)}\|}{\varepsilon_0^m}\right) \|\eta_{(k),0}\| + \|\theta_{(k),0}\| \tag{6.1}$$

$$+ \left(\varepsilon_0^m + \varepsilon_0^M + \|\eta_{(s)_0}\|\right) \|\hat{\Phi}\| \frac{u_2}{\epsilon_1} < \Theta. \tag{6.2}$$

It is worth noticing that (6.1) is a condition either on the initial distribution of particles $\theta_{(k),0}$, $\eta_{(k),0}$ or on the removal rate of the particles $\|\hat{\Phi}\|$.

If a uniform distribution of m_i, b_i, $i = 1, \ldots, k$, is assumed for $t = 0$ (as in [6, part 1]), where the case $k = 1$ is discussed), a condition like $\eta_{(k),0} + \theta_{(k),0} < \Theta$ is sufficient in order to guarantee (5.63) for $t > 0$. However, in the present case it is not difficult to exhibit nonuniform initial distributions of m_i and b_i (even if $k = 1$) such that $\eta_{(p)} + \theta_{(p)} = \Theta$ for some point in D. In such a case, a new compact layer will develop.

6.1. Growth of the compact layer.

We start by remarking that, by virtue of (4.8), (4.2), and (5.5), we have that $\dot{s}(t) = 0$ if and only if $\eta_{(p)}(s(t), t) = 0$.

We now introduce the set

$$\mathcal{S} = \{(x,t) \in D \mid b_i(x,t) \le \beta_i(q,b),\ i = 1, \ldots, k\}, \tag{6.3}$$

where β_i are the functions appearing in (4.9). Furthermore, we set $\mathcal{R} = D/\mathcal{S}$.

Proposition 6.1. *If a characteristic curve* Γ *with* $t_0 > 0$ *is such that* $\Gamma \subset \mathcal{S}$, *then* $\dot{s}(\tau) = 0$, *where* τ *is the time when the curve* Γ *intersects the boundary* s.

Proof. It is a consequence of the following formula, which comes from integrating along a characteristic curve Γ:

$$\begin{aligned} l(\Gamma(t), t) = {} & l(\Gamma(t_0), t_0) e^{-\int_{t_0}^t \hat{H}(q(\Gamma(\tau),\tau),\theta(\Gamma(\tau),\tau))d\tau} \\ & + \int_{t_0}^t \hat{\Phi}(q(\Gamma(\tau),\tau),\theta(\Gamma(\tau),\tau)) e^{-\int_\tau^t \hat{H}(q(\Gamma(\sigma),\sigma),\theta(\Gamma(\sigma),\sigma))d\sigma} d\tau. \end{aligned} \tag{6.4}$$

The first term in the right-hand side of (6.4) is zero, since $\Gamma(t_0) = 0$; moreover, the second term (due to the removal of particles) vanishes owing to (cfr. (3.20). Note that τ is certainly finite, because of (5.19). ☐

A further consequence of (6.4) is that if $\Gamma \bigcap \mathcal{R} \neq \emptyset$, then $\dot{s}(\tau) < 0$, with τ defined as above. The profile of the characteristic curves and of the free boundary $s(t)$ is sketched in Figure 6.1.

We consider now the region $\mathcal{S}_1 = \bigcup_{\Gamma \in \mathcal{S}} \Gamma \subseteq D$. Since $\eta_{(p)} = 0$, $\theta_{(p)}$ is constant in that region, from Proposition 6.1, (3.7), and (5.18)

$$\frac{\partial q}{\partial x}(x,t) = 0, \quad \dot{s}(t) = 0, \quad (x,t) \in \mathcal{S}_1. \tag{6.5}$$

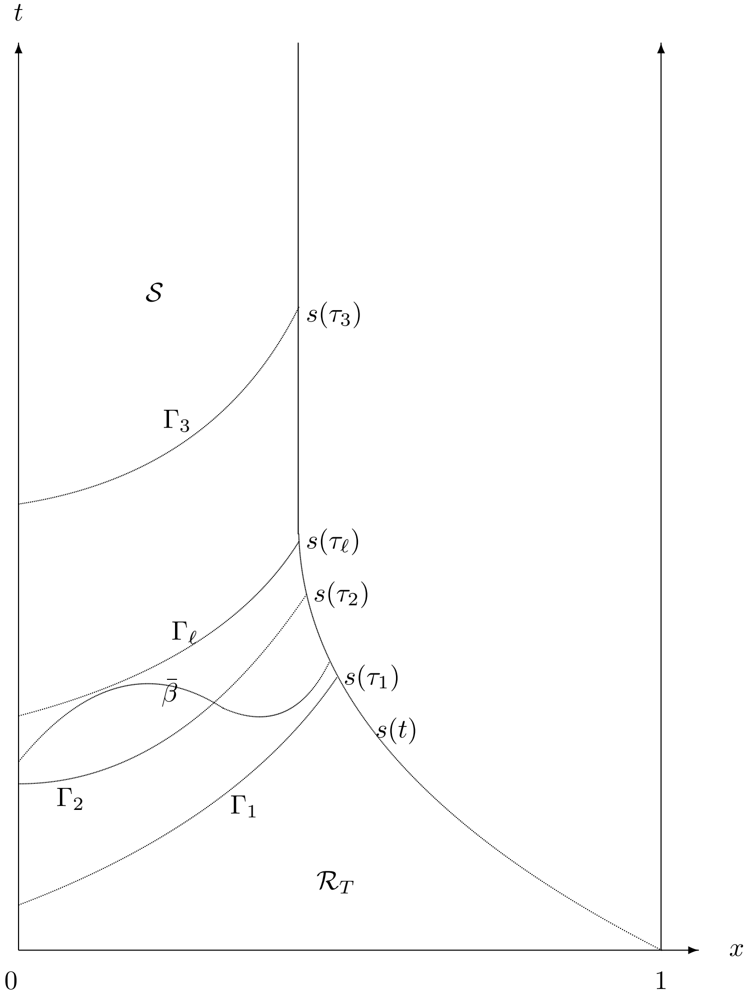

FIG. 6.1. *The characteristic curves Γ_1 and Γ_2 are totally or partially contained in $\mathcal{R}$; hence $\dot{s}(\tau_1)$ and $\dot{s}(\tau_2)$ are negative; Γ_3 is contained in $\mathcal{S}$; hence $\dot{s}(\tau_3) = 0$. The curve $\bar{\beta}$ separates $\mathcal{S}$ from $\mathcal{R}$, while the curve Γ_ℓ is the lower boundary of the region $\mathcal{S}_1$. For $t \geq \tau_\ell$, we have $\dot{s}(t) = 0$.*

The value of s in $\mathcal{S}_1$ is obtained by solving the equation (cf. (5.8))

$$q_c(t)\left(\frac{1-s}{K_0} + \int_0^s \frac{1}{K(\xi,t)}d\xi\right) = p_0(t). \tag{6.6}$$

Notice that $K(\xi, t)$ changes with respect to t in $\mathcal{S}_1$ only if ε varies. Moreover,

$$\frac{\partial K}{\partial t} = -\frac{\partial K}{\partial \varepsilon}\frac{\partial \theta_{(s)}}{\partial t}, \quad (x,t) \in \mathcal{S}_1. \tag{6.7}$$

Equation (6.7) comes from (3.6) and (6.5). Owing to (6.7), (6.6) and recalling (4.10), (4.11) we can conclude that

- if $\partial K/\partial \varepsilon \geq 0$, then the water flux $q_c(t)$ increases (and also q because of (6.5)) if $p_0(t)$ increases and the removal process may restart ($\dot{s} < 0$);

- if $\partial K/\partial\varepsilon \le 0$ and $p_0(t)$ does not increase, then $q_c(t)$ is a nonincreasing function and the removal process cannot occur again.

If we neglect the dependence of K on ε, we have simply that $q_c(t)$ increases if and only if $p_0(t)$ increases; thus, only in that case the removal process can occur a second time.

Owing to (5.62), the limit of $s(t)$ for t tending to ∞ is a positive value not smaller than s_{min}.

ANALYSIS AND CONSTRUCTION OF OPTIMAL MULTIVARIATE BIORTHOGONAL WAVELETS WITH COMPACT SUPPORT[*]

BIN HAN[†]

Abstract. In applications, it is well known that high smoothness, small support, and high vanishing moments are the three most important properties of a biorthogonal wavelet. In this paper, we shall investigate the mutual relations among these three properties. A characterization of $L_p\,(1 \le p \le \infty)$ smoothness of multivariate refinable functions is presented. It is well known that there is a close relation between a fundamental refinable function and a biorthogonal wavelet. We shall demonstrate that any fundamental refinable function, whose mask is supported on $[1-2r, 2r-1]^s$ for some positive integer r and satisfies the sum rules of optimal order $2r$, has L_p smoothness not exceeding that of the univariate fundamental refinable function with the mask b_r. Here the sequence b_r on $\mathbb{Z}$ is the unique univariate interpolatory refinement mask which is supported on $[1-2r, 2r-1]$ and satisfies the sum rules of order $2r$. Based on a similar idea, we shall prove that any orthogonal scaling function, whose mask is supported on $[0, 2r-1]^s$ for some positive integer r and satisfies the sum rules of optimal order r, has L_p smoothness not exceeding that of the univariate Daubechies orthogonal scaling function whose mask is supported on $[0, 2r-1]$. We also demonstrate that a similar result holds true for biorthogonal wavelets. Examples are provided to illustrate the general theory. Finally, a general CBC (cosets by cosets) algorithm is presented to construct all the dual refinement masks of any given interpolatory refinement mask with the dual masks satisfying arbitrary order of sum rules. Thus, for any scaling function which is fundamental, this algorithm can be employed to generate a dual scaling function with arbitrary approximation order. This CBC algorithm can be easily implemented. As a particular application of the general CBC algorithm, a TCBC (triangle cosets by cosets) algorithm is proposed. For any positive integer k and any interpolatory refinement mask a such that a is symmetric about all the coordinate axes, such a TCBC algorithm provides us with a dual mask of a such that the dual mask satisfies the sum rules of order $2k$ and is also symmetric about all the coordinate axes. As an application of this TCBC algorithm, a family of optimal bivariate biorthogonal wavelets is presented with the scaling function being a spline function.

1. Introduction.

Based on the work [25, 26], the present paper deals with the analysis and construction of multivariate biorthogonal wavelets with some desired properties. It is well known that in various applications high smoothness, small support, and high vanishing moments are the three most important properties of a (bi)orthogonal wavelet. On the other hand, there is no C^∞ (bi)orthogonal wavelet with compact support. In this paper, we shall investigate the mutual relations among these three properties.

Compactly supported (bi)orthogonal wavelets on the real line have been found to be very useful in applications such as signal processing and image compression; for examples, see [1, 16, 36, 37]. In [10], Cohen, Daubechies, and Feauveau proposed a general way of constructing univariate biorthogonal wavelets. Although the tensor product (bi)orthogonal wavelets provide a family of multivariate (bi)orthogonal

wavelets to deal with problems in high dimensions in applications, it has its own advantages and disadvantages. Therefore, as noted in many papers [5, 9, 12, 24, 27, 37, 42] and references cited there, it is of interest in its own right to construct nontensor product (bi)orthogonal wavelets in the high dimensions. In the current literature, there are many papers on constructing multivariate biorthogonal wavelets, especially bivariate biorthogonal wavelets. To mention only a few here, see [9, 12, 24, 27, 37, 42] and references therein. Bivariate compactly supported quincunx biorthogonal wavelets were constructed by Cohen and Daubechies in [9]. In [42], a family of bivariate biorthogonal wavelets with the scaling function being a box spline was given by Riemenschneider and Shen.

Usually, a biorthogonal wavelet is derived from a multiresolution analysis generated by a pair consisting of a scaling function and its dual scaling function. The construction of wavelets in the multivariate setting is more challenging than its univariate counterpart; see [3, 10, 16, 24, 27, 33, 35, 38, 42] and references therein on construction of (bi)orthogonal wavelets from a multiresolution analysis. To obtain a biorthogonal wavelet, we have to find two refinable functions with some desired properties. A function ϕ is said to be *refinable* if it satisfies the following refinement equation:

$$\phi = \sum_{\beta\in\mathbb{Z}^s} a(\beta)\phi(2\cdot-\beta), \tag{1.1}$$

where a is a finitely supported sequence on $\mathbb{Z}^s$, called the *refinement mask*. If a satisfies $\sum_{\beta\in\mathbb{Z}^s} a(\beta) = 2^s$, then it is known (see [4]) that there exists a unique compactly supported distribution ϕ satisfying the refinement equation (1.1) subject to the condition $\widehat{\phi}(0) = 1$. This distribution is said to be the *normalized solution* of the refinement equation (1.1). Throughout this paper we shall use ϕ_a to denote the normalized solution of the refinement equation (1.1) with the mask a.

The concepts of linear independence and approximation order of a function play an important role in the study of biorthogonal wavelets. The shifts of a compactly supported function $\phi : \mathbb{R}^s \to \mathbb{C}$ are said to be *linearly independent* if for any $z \in \mathbb{C}^s$, there exists a multi-integer β in $\mathbb{Z}^s$ such that $\widehat{\phi}(z+2\pi\beta) \neq 0$. If for any $\xi \in \mathbb{R}^s$, there exists a multi-integer β in $\mathbb{Z}^s$ such that $\widehat{\phi}(\xi+2\pi\beta) \neq 0$, then the shifts of ϕ are said to be *stable*. See [34] for discussion on linear independence and stability.

By $\ell(\mathbb{Z}^s)$ we denote the linear space of all sequences on $\mathbb{Z}^s$. For a compactly supported function ϕ in $L_p(\mathbb{R}^s)$ $(1 \le p \le \infty)$, we define

$$S(\phi) := \left\{ \sum_{\alpha\in\mathbb{Z}^s} \phi(\cdot-\alpha)b(\alpha) \;:\; b \in \ell(\mathbb{Z}^s) \right\}$$

and call it the shift-invariant space generated by ϕ. For $h > 0$, the scaled space S^h is defined by $S^h := \{f(\cdot/h) \;:\; f \in S(\phi)\}$. For a positive integer k, we say that $S(\phi)$ provides *approximation order k* if for each sufficiently smooth function f in $L_p(\mathbb{R}^s)$, there exists a positive constant C such that

$$\inf_{g\in S^h} \|f-g\|_p \le Ch^k \qquad \forall\, h > 0.$$

The general procedure of constructing a biorthogonal wavelet is the following. First, find a refinable function ϕ in $L_2(\mathbb{R}^s)$ such that ϕ satisfies the refinement equation (1.1) with a finitely supported refinement mask a and the shifts of ϕ are linearly independent; such a function ϕ is called a *scaling function.* The next step is to find a refinable function ϕ^d in $L_2(\mathbb{R}^s)$ such that ϕ^d satisfies

$$\phi^d = \sum_{\beta\in\mathbb{Z}^s} a^d(\beta)\phi^d(2\cdot-\beta), \tag{1.2}$$

where a^d is a finitely supported sequence on $\mathbb{Z}^s$ and ϕ^d satisfies the following biorthogonal relation

$$\int_{\mathbb{R}^s} \overline{\phi(t-\alpha)}\phi^d(t)\,dt = \delta(\alpha) \qquad \forall\,\alpha\in\mathbb{Z}^s, \tag{1.3}$$

where $\delta(0)=1$ and $\delta(\alpha)=0\ \forall\,\alpha\in\mathbb{Z}^s\backslash\{0\}$. This function ϕ^d is called a *dual scaling function* of ϕ. If ϕ is the dual scaling function of itself, ϕ is called an *orthogonal scaling function.* Finally, a biorthogonal wavelet is derived from the above ϕ, ϕ^d, a, and a^d. The reader is referred to [5, 6, 7, 10, 16, 24, 27, 33, 35, 38, 42] for detail on the construction of a biorthogonal wavelet from a pair consisting of a scaling function and its dual scaling function. It is well known that the smoothness of the scaling function and its dual scaling function will determine the smoothness of their derived wavelets, and the approximation orders of the scaling function and its dual scaling function will determine the vanishing moments of their derived wavelets. For more detail on (bi)orthogonal wavelets, the reader is referred to [3, 5, 6, 7, 9, 10, 12, 13, 14, 16, 24, 27, 33, 35, 37, 42, 44] and references therein.

By Ω we denote the set of the vertices of the unit cube $[0,1]^s$. For a positive integer k, we say that a sequence a on $\mathbb{Z}^s$ satisfies the *sum rules* of order k if

$$\sum_{\beta\in\mathbb{Z}^s} a(2\beta+\varepsilon)p(2\beta+\varepsilon) = \sum_{\beta\in\mathbb{Z}^s} a(2\beta)p(2\beta) \qquad \forall\,\varepsilon\in\Omega,\ p\in\Pi_{k-1}, \tag{1.4}$$

where Π_{k-1} is the set of polynomials with total degree less than k. Let a function ϕ be a refinable function with a mask a. It was proved by Jia in [30, 31] that if the shifts of ϕ are stable, then $S(\phi)$ provides approximation order k if and only if the mask a satisfies the sum rules of order k. Therefore, it is evident that $S(\phi)$ (or $S(\phi^d)$) provides approximation order k if and only if the mask a (or a^d) satisfies the sum rules of order k.

Now it is natural to ask the following question: Given a scaling function with compact support, does a dual scaling function with compact support exist? As noted by Lemarié–Rieusset [39], the answer is yes at least in the univariate case. More precisely, given a scaling function with compact support, a dual scaling function always exists with compact support and arbitrarily high smoothness. Therefore, it is valuable to ask that for a scaling function, if we fix the size of the support of a dual scaling function, then what is the highest approximation order and the highest smoothness of a dual scaling function that we can expect? Based on our previous work on interpolatory subdivision schemes [25, 26], we shall answer the above question in this paper.

Here is an outline of this paper. In section 2, given a scaling function, we shall study the relation between the approximation order of its dual scaling function and the support of its dual scaling function. In section 3, a characterization of L_p smoothness of a multivariate refinable function is given. In section 4, we shall prove that any orthogonal scaling function, whose mask is supported on $[0,2r-1]^s$ ($r\in\mathbb{N}$) and satisfies the sum rules of optimal order r, has L_p smoothness not exceeding that of the univariate Daubechies orthogonal scaling function whose mask is supported on $[0, 2r-1]$. An example will be provided to illustrate our result. In section 5, we first study the optimal L_p smoothness of a fundamental refinable function if its mask is supported on $[1-2r, 2r-1]^s$ and satisfies the sum rules of optimal order $2r$. Next, for any given scaling function, we shall study the optimal smoothness of a dual scaling function if its support is fixed and it attains the optimal approximation order. Finally, in section 6, a general CBC (cosets by cosets) algorithm is presented to generate all the dual masks of a given interpolatory refinement mask. This algorithm can be easily implemented. In particular, as an application of this general construction, we shall propose a TCBC (triangle cosets by cosets) algorithm such that for any bivariate interpolatory mask which is symmetric about the two coordinate axes, we can construct a family of dual masks with arbitrary order of sum rules and symmetry about the two coordinate axes. At the end of this paper, a family of optimal bivariate biorthogonal wavelets is constructed from a spline scaling function.

2. Optimal approximation order of a dual scaling function. In this section, we shall first introduce some notation. For a given scaling function, we shall study the relation between the approximation order of a dual scaling function and the support of a dual scaling function.

In order to solve the refinement equation (1.1), we start with an initial function ϕ_0 given by

$$\phi_0(x_1, \dots, x_s) := \prod_{j=1}^{s} \chi(x_j), \qquad (x_1, \dots, x_s) \in \mathbb{R}^s,$$

where χ is the univariate hat function defined by

$$\chi(x) := \max\{1 - |x|, 0\}, \qquad x \in \mathbb{R}.$$

Then we employ the iteration scheme $Q_a^n \phi_0$, $n = 0, 1, 2, \dots$, where Q_a is the bounded linear operator on $L_p(\mathbb{R}^s)$ $(1 \le p \le \infty)$ given by

$$Q_a f := \sum_{\beta \in \mathbb{Z}^s} a(\beta) f(2 \cdot - \beta), \qquad f \in L_p(\mathbb{R}^s). \tag{2.1}$$

This iteration scheme is called a *subdivision scheme* or a *cascade algorithm* associated with the mask a (see [4, 17]). For any p such that $1 \le p \le \infty$, we say that the subdivision scheme associated with a mask a converges in the L_p norm if there exists a function f in $L_p(\mathbb{R}^s)$ such that $\lim_{n\to\infty} \|Q_a^n \phi_0 - f\|_p = 0$. If this is the case, then the limit function f must be the normalized solution of the refinement equation (1.1) with the refinement mask a.

Before proceeding further, we introduce some notation. By $\ell(\mathbb{Z}^s)$ we denote the space of all sequences on $\mathbb{Z}^s$ and by $\ell_0(\mathbb{Z}^s)$ the linear space of all finitely supported sequences on $\mathbb{Z}^s$. By δ we denote the element given by $\delta(0) = 1$ and $\delta(\beta) = 0$ $\forall\, \beta \in \mathbb{Z}^s \backslash \{0\}$. For $j = 1, \dots, s$, let e_j be the jth coordinate unit vector. The difference operator ∇_j on $\ell(\mathbb{Z}^s)$ is defined by $\nabla_j \lambda := \lambda - \lambda(\cdot - e_j)$, $\lambda \in \ell(\mathbb{Z}^s)$.

The *subdivision operator* associated with a mask a is defined by

$$S_a \lambda(\alpha) := \sum_{\beta \in \mathbb{Z}^s} a(\alpha - 2\beta) \lambda(\beta), \qquad \alpha \in \mathbb{Z}^s, \tag{2.2}$$

where $\lambda \in \ell_0(\mathbb{Z}^s)$. It was proved in [25] that the subdivision scheme associated with a mask a converges in the L_p norm if and only if

$$\lim_{n\to\infty} \max\big\{ \|\nabla_j S_a^n \delta\|_p^{1/n} \ : \ j = 1, \ldots, s \big\} < 2^{s/p}.$$

It is well known that there is a close relation between biorthogonal wavelets and fundamental refinable functions. A function ϕ is said to be *fundamental* if ϕ is continuous, $\phi(0) = 1$, and $\phi(\alpha) = 0 \ \forall\, \alpha \in \mathbb{Z}^s\backslash\{0\}$. If ϕ is a fundamental refinable function with a mask a, then it is necessary that

$$a(0) = 1 \quad \text{and} \quad a(2\beta) = 0 \qquad \forall\, \beta \in \mathbb{Z}^s\backslash\{0\}.$$

A mask that satisfies the above condition is called an *interpolatory refinement mask*.

The following fact is well known (see [8, 16, 40]) and reveals the relation between a biorthogonal wavelet and a fundamental refinable function.

LEMMA 2.1. *Let a function ϕ be a scaling function with a mask a and let ϕ^d be a dual scaling function of ϕ with a mask a^d. Define*

$$\Phi(x) := \int_{\mathbb{R}^s} \overline{\phi(t-x)}\phi^d(t)\, dt, \qquad x \in \mathbb{R}^s, \tag{2.3}$$

and

$$b(\alpha) := 2^{-s} \sum_{\beta\in\mathbb{Z}^s} \overline{a(\beta-\alpha)} a^d(\beta), \qquad \alpha \in \mathbb{Z}^s. \tag{2.4}$$

Then the function Φ is a fundamental refinable function satisfying the refinement equation (1.1) *with the interpolatory mask b. In other words, the mask a and a^d satisfy the following well-known discrete biorthogonal relation:*

$$\sum_{\beta\in\mathbb{Z}^s} \overline{a(\beta-2\alpha)}\, a^d(\beta) = 2^s\delta(\alpha) \qquad \forall\, \alpha \in \mathbb{Z}^s. \tag{2.5}$$

Conversely, if the masks a and a^d satisfy the above discrete biorthogonal relation (2.5) *and the subdivision schemes associated with a and a^d converge in the L_2 norm, respectively, then the functions ϕ and ϕ^d lie in $L_2(\mathbb{R}^s)$ and satisfy the biorthogonal relation* (1.3) *where the functions ϕ and ϕ^d are the normalized solutions of the refinement equations* (1.1) *with the masks a and a^d, respectively. Therefore, the function ϕ is a scaling function and ϕ^d is a dual scaling function of ϕ.*

If two sequences a and a^d on $\mathbb{Z}^s$ satisfy the discrete biorthogonal relation (2.5), then the mask a^d is called a *dual mask* of the mask a. Throughout this paper, we shall use the following notation:

$$\mathbb{T}^s := \{\, (z_1, \ldots, z_s) \in \mathbb{C}^s \ : \ |z_1| = \cdots = |z_s| = 1 \,\}.$$

For any sequence λ in $\ell_0(\mathbb{Z}^s)$, its *symbol* $\widetilde{\lambda}$ is given by

$$\widetilde{\lambda}(z) := \sum_{\beta\in\mathbb{Z}^s} \lambda(\beta) z^\beta, \qquad z \in \mathbb{T}^s. \tag{2.6}$$

By Lemma 2.1, we have $\widehat{\Phi}(\xi) = \overline{\widehat{\phi}(\xi)}\widehat{\phi^d}(\xi), \xi \in \mathbb{R}^s$ and $\widetilde{b}(z) = 2^{-s}\overline{\widetilde{a}(z)}\widetilde{a^d}(z), z \in \mathbb{T}^s$. The following result was proved in [26] and will be needed later.

THEOREM 2.2 (see [26, Theorems 2.1 and 2.2]). *Suppose that a is an interpolatory mask supported on $\mathbb{Z}^s \cap \Pi_{j=1}^s[-L_j, H_j]$ for some nonnegative integers L_j and H_j. If the mask a satisfies the sum rules of order k, then*

$$k \le \min_{1\le j\le s} \left(\left\lfloor \frac{L_j+1}{2} \right\rfloor + \left\lfloor \frac{H_j+1}{2} \right\rfloor \right),$$

where $\lfloor\cdot\rfloor$ is the floor function. Moreover, when $s = 1$, there exists a unique interpolatory refinement mask supported on $[-L_1, H_1]$ and satisfying the sum rules of order $\lfloor \frac{L_1+1}{2} \rfloor + \lfloor \frac{H_1+1}{2} \rfloor$.

By the above theorem, in the univariate case ($s = 1$), there is a unique interpolatory mask supported on $[1-2r, 2r-1]$ and satisfying the sum rules of order $2r$. This is the same interpolatory mask as given by Deslauriers and Dubuc in [18], and will be denoted by b_r throughout this paper. In the multivariate case ($s > 1$), such interpolatory masks are not unique. Let t_r be the sequence on $\mathbb{Z}^s$ given by

$$t_r(\alpha_1, \dots, \alpha_s) := b_r(\alpha_1) \cdots b_r(\alpha_s), \qquad (\alpha_1, \dots, \alpha_s) \in \mathbb{Z}^s. \tag{2.7}$$

Then t_r is a tensor product interpolatory refinement mask supported on $[1-2r, 2r-1]^s$ and it satisfies the sum rules of the optimal order $2r$.

Based on the above results, we have the following theorem.

THEOREM 2.3. *Let ϕ be a scaling function with its refinement mask a supported on $\Pi_{j=1}^s[-l_j, h_j]$ for some nonnegative integers l_j and h_j, and let ϕ^d be its dual scaling function with its mask a^d supported on $\Pi_{j=1}^s[-L_j, H_j]$ for some nonnegative integers L_j and H_j. Suppose that a satisfies the sum rules of order k; then a^d can satisfy the sum rules of order at most*

$$\min_{1\le j\le s} \left(\left\lfloor \frac{h_j+L_j+1}{2} \right\rfloor + \left\lfloor \frac{l_j+H_j+1}{2} \right\rfloor \right) - k,$$

where $\lfloor\cdot\rfloor$ is the floor function.

Proof. Let b be the sequence defined in (2.4). Then by Lemma 2.1, b is an interpolatory mask and b is supported on $\Pi_{j=1}^s[-h_j - L_j, l_j + H_j]$. From Theorem 2.2, we see that b can satisfy the sum rules of order at most $\min_{1\le j\le s} \left(\lfloor \frac{h_j+L_j+1}{2} \rfloor + \lfloor \frac{l_j+H_j+1}{2} \rfloor \right)$. To complete the proof, it suffices to prove that if the mask a^d satisfies the sum rules of order $\widetilde{k}$, then b will satisfy the sum rules of order at least $k + \widetilde{k}$. Denote

$$\mathbb{Z}_+^s := \{ (\alpha_1, \dots, \alpha_s) \in \mathbb{Z}^s \ : \ \alpha_j \ge 0 \quad \forall\, j = 1, \dots, s \},$$

and $|\mu| := \mu_1 + \cdots + \mu_s$ for $\mu = (\mu_1, \dots, \mu_s) \in \mathbb{Z}_+^s$ and $\alpha^\mu := \alpha_1^{\mu_1} \cdots \alpha_s^{\mu_s}$ for $\alpha = (\alpha_1, \dots, \alpha_s) \in \mathbb{Z}^s$. Thus, by the definition of the sum rules given in (1.4), it suffices to prove that

$$\sum_{\alpha\in\mathbb{Z}^s} b(2\alpha+\varepsilon)(2\alpha+\varepsilon)^\mu = \sum_{\alpha\in\mathbb{Z}^s} b(2\alpha)(2\alpha)^\mu \qquad \forall\, \mu \in \mathbb{Z}_+^s,\, |\mu| < k + \widetilde{k},\, \varepsilon \in \Omega.$$

By the definition of the sequence b given in (2.4), we can rewrite the above equality as follows: for any $\varepsilon \in \Omega$ and $\mu \in \mathbb{Z}_+^s$ such that $|\mu| < k + \widetilde{k}$,

$$\sum_{\alpha\in\mathbb{Z}^s} \sum_{\beta\in\mathbb{Z}^s} \overline{a(\beta - 2\alpha - \varepsilon)} a^d(\beta)(2\alpha+\varepsilon)^\mu = \sum_{\alpha\in\mathbb{Z}^s} \sum_{\beta\in\mathbb{Z}^s} \overline{a(\beta - 2\alpha)} a^d(\beta)(2\alpha)^\mu.$$

Therefore, it suffices to prove that the left side of the above equality

$$C_\varepsilon := \sum_{\varepsilon' \in \Omega} \sum_{\alpha \in \mathbb{Z}^s} \sum_{\beta \in \mathbb{Z}^s} \overline{a(2\beta + \varepsilon' - 2\alpha - \varepsilon)} a^d(2\beta + \varepsilon')(2\alpha + \varepsilon)^\mu$$

does not depend on ε for any $\mu \in \mathbb{Z}_+^s$ such that $|\mu| < k + \widetilde{k}$. On the other hand,

$$\begin{aligned}(2\alpha + \varepsilon)^\mu &= \big((2\beta + \varepsilon') - (2\beta + \varepsilon' - 2\alpha - \varepsilon)\big)^\mu \\ &= \sum_{0 \le \nu \le \mu} (-1)^{|\nu|} \frac{\mu!}{\nu!(\mu - \nu)!} (2\beta + \varepsilon' - 2\alpha - \varepsilon)^\nu (2\beta + \varepsilon')^{\mu - \nu},\end{aligned}$$

where $\mu! := \mu_1! \cdots \mu_s!$ for $\mu = (\mu_1, \ldots, \mu_s)$ and $\nu \le \mu$ if and only if $\nu_j \le \mu_j \ \forall\, j = 1, \ldots, s$. Thus, C_ε can be rewritten as

$$\begin{aligned}C_\varepsilon = \sum_{0 \le \nu \le \mu} (-1)^{|\nu|} \frac{\mu!}{\nu!(\mu - \nu)!} &\sum_{\beta \in \mathbb{Z}^s} \sum_{\varepsilon' \in \Omega} \sum_{\alpha \in \mathbb{Z}^s} \\ &\overline{a(2\beta + \varepsilon' - 2\alpha - \varepsilon)} (2\beta + \varepsilon' - 2\alpha - \varepsilon)^\nu a^d(2\beta + \varepsilon')(2\beta + \varepsilon')^{\mu - \nu}.\end{aligned}$$

Therefore, it suffices to demonstrate that for any $\nu \in \mathbb{Z}_+^s$ such that $0 \le \nu \le \mu$,

$$C_{\varepsilon,\nu} := \sum_{\varepsilon' \in \Omega} \sum_{\alpha \in \mathbb{Z}^s} \overline{a(2\alpha + \varepsilon' - \varepsilon)} (2\alpha + \varepsilon' - \varepsilon)^\nu \sum_{\beta \in \mathbb{Z}^s} a^d(2\beta + \varepsilon')(2\beta + \varepsilon')^{\mu - \nu}$$

does not depend on ε. Note that $|\mu - \nu| + |\nu| = |\mu| < k + \widetilde{k}$ implies that either $|\mu - \nu| < k$ or $|\nu| < \widetilde{k}$. If $|\nu| < k$, then $\sum_{\alpha \in \mathbb{Z}^s} a(2\alpha + \varepsilon' - \varepsilon)(2\alpha + \varepsilon' - \varepsilon)^\nu$ does not depend on both ε and ε' since the sequence a satisfies the sum rules of order k. Hence, for any ν in $\mathbb{Z}_+^s$ such that $|\nu| < k$, we have

$$C_{\varepsilon,\nu} = \overline{\sum_{\alpha \in \mathbb{Z}^s} a(2\alpha)(2\alpha)^\nu} \sum_{\beta \in \mathbb{Z}^s} a^d(\beta)\beta^{\mu - \nu}$$

does not depend on ε. Similarly, if $|\mu - \nu| < \widetilde{k}$, then $\sum_{\beta \in \mathbb{Z}^s} a^d(2\beta + \varepsilon')(2\beta + \varepsilon')^{\mu - \nu}$ does not depend on ε' since the sequence a^d satisfies the sum rules of order $\widetilde{k}$. Therefore,

$$C_{\varepsilon,\nu} = \sum_{\beta \in \mathbb{Z}^s} a^d(2\beta)(2\beta)^{\mu - \nu} \overline{\sum_{\alpha \in \mathbb{Z}^s} a(\alpha)\alpha^\nu}$$

does not depend on ε which completes the proof. □

From the proof of Theorem 2.3, it is straightforward to obtain the following result.

Corollary 2.4. *If a function ϕ in $L_2(\mathbb{R}^s)$ is an orthogonal scaling function with its mask a supported on $[0, r]^s$ for some positive integer r, then the mask a can satisfy the sum rules of order at most $\lfloor \frac{r+1}{2} \rfloor$. Therefore, $S(\phi)$ can provide approximation order at most $\lfloor \frac{r+1}{2} \rfloor$.*

3. Characterization of L_p smoothness of a refinable function. In this section, we will study the smoothness of a refinable function in the multivariate setting. Many results on the analysis of L_2 smoothness of a refinable function both in the univariate case and in the multivariate case are obtained in the current literature. To mention only a few here, see [11, 17, 23, 29, 41, 43, 45] and references therein. For $s = 1$, the characterization of L_p smoothness was given by Villemoes in [45].

In this section, based on a result of Ditzian [19, 20], we present a simple proof to characterize the L_p smoothness of a multivariate refinable function. Jia will discuss the L_p smoothness of a refinable function with an arbitrary dilation matrix in a forthcoming paper [32].

We shall use the generalized Lipschitz space to measure smoothness of a given function. For any vector y in $\mathbb{R}^s$, the *difference operator* ∇_y on $L_p(\mathbb{R}^s)$ is defined to be

$$\nabla_y f = f - f(\cdot - y), \qquad f \in L_p(\mathbb{R}^s).$$

Let k be a positive integer. The kth *modulus of smoothness* of a function f in $L_p(\mathbb{R}^s)$ is defined by

$$\omega_k(f,h)_p := \sup_{|y|\le h} \|\nabla_y^k f\|_p, \qquad h > 0.$$

For $\nu > 0$, let k be an integer greater than ν. The *generalized Lipschitz space* $Lip^*\big(\nu, L_p(\mathbb{R}^s)\big)$ consists of those functions f in $L_p(\mathbb{R}^s)$ for which

$$\omega_k(f,h)_p \le Ch^\nu \qquad \forall\, h > 0, \tag{3.1}$$

where C is a constant independent of h, or in other words, $\omega_k(f,h)_p = O(h^\nu)$.

The L_p smoothness of a function $f \in L_p(\mathbb{R}^s)$ in the L_p norm sense is described by its L_p *critical exponent* $\nu_p(f)$ defined by

$$\nu_p(f) := \sup\left\{ \nu \ : \ f \in Lip^*\big(\nu, L_p(\mathbb{R}^s)\big) \right\}. \tag{3.2}$$

In the following, we will characterize the L_p $(1 \le p \le \infty)$ smoothness of a refinable function in multidimensional spaces. To do this, we need the following result on moduli of smoothness, which is based on a result of Ditzian in [19, 20].

Theorem 3.1. *Let f be a function in $L_p(\mathbb{R}^s)$ and ν be a positive real number. Then f belongs to the space $Lip^*\big(\nu, L_p(\mathbb{R}^s)\big)$ if and only if for an integer k greater than ν, there exists a positive constant C such that*

$$\max\{\, \|\nabla_{2^{-n}e_i}^k f\|_p \ : \ i = 1,\ldots,s \,\} \le C2^{-n\nu} \qquad \forall n \in \mathbb{N}, \tag{3.3}$$

where e_i is the ith coordinate unit vector.

Proof. Necessity: If f belongs to $Lip^*\big(\nu, L_p(\mathbb{R}^s)\big)$, then by the definition of the Lipschitz space $Lip^*\big(\nu, L_p(\mathbb{R}^s)\big)$, there exists a positive constant C such that

$$\|\nabla_{2^{-n}e_i}^k f\|_p \le \omega_k(f, 2^{-n}) \le C2^{-n\nu} \qquad \forall\, 1 \le i \le s, n \in \mathbb{N}.$$

Hence inequality (3.3) holds true.

Sufficiency: If inequality (3.3) holds true, then we can demonstrate that there exists a positive constant C_1 such that

$$\|\nabla_{he_i}^k f\|_p \le C_1 h^\nu \qquad \forall\, 1 \le i \le s, h > 0. \tag{3.4}$$

Let g be a simple function such that $\|g\|_q = 1$, where $1/p + 1/q = 1$. Define

$$F(x) := f * g(x) = \int_{\mathbb{R}^s} f(x-t)g(t)\,dt, \qquad x \in \mathbb{R}^s.$$

Then the function F is continuous and bounded. Note that the inequality (3.3) implies that for any $i = 1, \ldots, s$,

$$\|\nabla^k_{2^{-n}e_i} F\|_\infty = \|(\nabla^k_{2^{-n}e_i} f) * g\|_\infty \le \|\nabla^k_{2^{-n}e_i} f\|_p \|g\|_q \le C 2^{-n\nu} \qquad \forall\, n \in \mathbb{N}.$$

Therefore, in particular, we have

$$|\nabla^k_{2^{-n}e_i} F(te_i)| \le C 2^{-n\nu} \qquad \forall\, t \in \mathbb{R}, n \in \mathbb{N}.$$

By a result of Boman [2, Theorem 1] and Ditzian [20], there exists a positive constant C_1 depending only on k and C (independent of g) such that

$$|\nabla^k_{he_i} F(te_i)| \le C_1 h^\nu \qquad \forall\, t \in \mathbb{R},\, h > 0. \tag{3.5}$$

Note that $\nabla^k_{he_i} F(0) = (\nabla^k_{he_i} f) * g(0)$. It follows from the above inequality (3.5) that for any simple function g with $\|g\|_q = 1$, we have that for any $i = 1, \ldots, s$,

$$\left| \int_{\mathbb{R}^s} \left(\nabla^k_{he_i} f\right)(-x) g(x)\, dx \right| = |(\nabla^k_{he_i} f) * g(0)| = |\nabla^k_{he_i} F(0)| \le C_1 h^\nu \quad \forall\, h > 0.$$

This yields

$$\|\nabla^k_{he_i} f\|_p = \sup_{\|g\|_q = 1} \left| \int_{\mathbb{R}^s} \left(\nabla^k_{he_i} f\right)(-x) g(x)\, dx \right| \le C_1 h^\nu \qquad \forall\, 1 \le i \le s, h > 0.$$

Therefore, inequality (3.4) is verified. By inequality (3.4) and a result of Ditzian [19, Corollary 5.2, and also cf. Theorem 5.1], it is straightforward to see that the function f belongs to the function space $Lip^*\big(\nu, L_p(\mathbb{R}^s)\big)$. ◻

Remark 3.2. In fact, the result in Corollary 5.2 of Ditzian [19] is a Marchaud-type inequality which says that to characterize the kth modulus of smoothness of a function in $L_p(\mathbb{R}^s)$ in the L_p norm sense, the information of the kth modulus of smoothness in s independent directions is enough. More precisely, for any vector y in $\mathbb{R}^s$, we denote $\omega_k(f, h, y)_p := \sup_{|t| \le h} \|\nabla^k_{ty} f\|_p$, $h > 0$. Let $y_i, i = 1, \ldots, s$ be s linearly independent vectors in $\mathbb{R}^s$. Then for any $\nu > 0$ and an integer $k > \nu$, $\omega_k(f, h)_p = O(h^\nu)$ if and only if $\omega_k(f, h, y_i)_p = O(h^\nu)$ $\forall\, i = 1, \ldots, s$. Therefore, in Theorem 3.1, the vectors $e_i, i = 1, \ldots, s$ can be replaced by vectors $y_i, i = 1, \ldots, s$ provided that $y_i, i = 1, \ldots, s$ are linearly independent vectors in $\mathbb{R}^s$. For more detail on the above result, the reader is referred to the works of Boman [2] and Ditzian [19, 20].

Based on the above result, the following theorem gives us a characterization of the critical exponent $\nu_p(\phi)$ of a refinable function ϕ in $L_p(\mathbb{R}^s)$ in terms of its mask provided that the shifts of the refinable function ϕ are stable.

THEOREM 3.3. *Let a function ϕ in $L_p(\mathbb{R}^s)$ $(1 \le p \le \infty)$ be the normalized solution of the refinement equation* (1.1) *with a finitely supported refinement mask a on $\mathbb{Z}^s$ such that $\sum_{\beta \in \mathbb{Z}^s} a(\beta) = 2^s$. For any nonnegative integer k, let*

$$\sigma_{k,p}(a) := \lim_{n \to \infty} \max\{\, \|\nabla^k_i S^n_a \delta\|_p^{1/n} \;:\; i = 1, \ldots, s \,\}.$$

Then

$$\min\{\, k,\ \nu_p(\phi)\,\} \ge s/p - \log_2 \sigma_{k,p}(a). \tag{3.6}$$

In addition, if the shifts of ϕ are stable, then

$$\min\{\, k, \nu_p(\phi)\,\} = s/p - \log_2 \sigma_{k,p}(a). \tag{3.7}$$

More generally, let $Y := \{\, y_i \in \mathbb{Z}^s \;:\; i = 1, \ldots, s \,\}$ be a set of s linearly independent vectors. Define

$$\sigma_{k,p,Y}(a) := \lim_{n\to\infty} \max\{\, \|\nabla^k_{y_i} S^n_a \delta\|_p^{1/n} \;:\; i = 1, \ldots, s \,\}.$$

Then the above results still hold true if $\sigma_{k,p}(a)$ is replaced with $\sigma_{k,p,Y}(a)$.

Proof. By the definition of $\sigma_{k,p}(a)$, for any real number r such that $r > \sigma_{k,p}(a)$, there exists a positive constant C_r such that

$$\max\{\, \|\nabla^k_i\, S^n_a \delta\|_p \;:\; i = 1, \ldots, s \,\} \le C_r r^n \qquad \forall\, n \in \mathbb{N}. \tag{3.8}$$

By induction and the definition of the subdivision operator defined in (2.2), we observe that

$$\nabla^k_{2^{-n}e_i} \phi = \sum_{\beta\in\mathbb{Z}^s} \nabla^k_i S^n_a \delta(\beta)\phi(2^n \cdot -\beta), \qquad i = 1, \ldots, s. \tag{3.9}$$

Since the function ϕ in $L_p(\mathbb{R}^s)$ is compactly supported, from (3.9), there exists a positive constant C_1 depending only on ϕ such that

$$\|\nabla^k_{2^{-n}e_i}\, \phi\|_p \le C_1 2^{-ns/p} \|\nabla^k_i\, S^n_a \delta\|_p \qquad \forall\, n \in \mathbb{N}, i = 1, \ldots, s.$$

Therefore, it follows from inequality (3.8) that

$$\|\nabla^k_{2^{-n}e_i}\, \phi\|_p \le C_1 C_r 2^{-ns/p} r^n \qquad \forall\, n \in \mathbb{N}, i = 1, \ldots, s. \tag{3.10}$$

On the other hand, by induction, we observe $\sigma_{k,p}(a) \ge 2^{s/p-k}$ since $\sum_{\beta\in\mathbb{Z}^s} a(\beta) = 2^s$. Therefore, the inequality $k \ge s/p - \log_2 \sigma_{k,p}(a)$ holds true for any nonnegative integer k. Since $r > \sigma_{k,p}(a)$, we deduce that $k \ge s/p - \log_2 \sigma_{k,p}(a) > s/p - \log_2 r$. By Theorem 3.1, it follows from inequality (3.10) that $\phi \in Lip^*\big(s/p - \log_2 r, L_p(\mathbb{R}^s)\big)$ for any r such that $r > \sigma_{k,p}(a)$. Thus in conclusion, we have

$$\min\{\, k, \nu_p(\phi) \,\} \ge s/p - \log_2 \sigma_{k,p}(a).$$

If the shifts of the function ϕ are stable, to prove (3.7), it suffices to prove that $\min\{k, \nu_p(\phi)\} \le s/p - \log_2 \sigma_{k,p}(a)$, equivalently, it suffices to prove that

$$\sigma_{k,p}(a) \le 2^{s/p-\nu} \qquad \forall\, 0 < \nu < \min\{\, k,\, \nu_p(\phi) \,\}.$$

Since the shifts of the function ϕ are stable and ϕ lies in $L_p(\mathbb{R}^s)$, from (3.9), there exists a positive constant C_2 depending only on the function ϕ such that

$$\|\nabla^k_i\, S^n_a \delta\|_p \le C_2 2^{ns/p} \|\nabla^k_{2^{-n}e_i}\, \phi\|_p \qquad \forall\, n \in \mathbb{N},\, i = 1, \ldots, s.$$

Since $\phi \in Lip^*\big(\nu, L_p(\mathbb{R}^s)\big)$ and $k > \nu$, by Theorem 3.1, we have

$$\max_{1\le i\le s}\{\, \|\nabla^k_i\, S^n_a \delta\|_p \,\} \le C_2 2^{ns/p} \max_{1\le i\le s}\{\, \|\nabla^k_{2^{-n}e_i}\, \phi\|_p \,\} \le C_2 C 2^{n(s/p-\nu)} \qquad \forall\, n \in \mathbb{N}.$$

Therefore, the inequality $\sigma_{k,p}(a) \le 2^{s/p-\nu}$ holds true, as desired. The last assertion of this theorem follows directly from Remark 3.2. □

Remark 3.4. If the shifts of the function ϕ are stable and its mask a satisfies the sum rules of order k but not $k + 1$, then $\nu_p(\phi) \le k$ (see [4, 30]) and therefore, by

Theorem 3.3, $\nu_p(\phi) = s/p - \log_2 \sigma_{k,p}(a)$. Another remark about the above theorem is that by carefully choosing the set Y, the equality in (3.6) may hold even when the shifts of the function are not stable. For example, let

$$\phi(x) = \max\{1 - |x|/2,\, 0\}, \qquad x \in \mathbb{R}.$$

Then the function ϕ is a refinable function with its mask a given by its symbol $\widetilde{a}(z) := 1 + (z^{-2} + z^2)/2$. It is a known fact that the shifts of ϕ are *not* stable and $\nu_p(\phi) = 1 + 1/p$ for any p such that $1 \le p \le \infty$. On the other hand, choose $y = 2$. It is not difficult to verify that $\sigma_{2,p,y}(a) := \lim_{n\to\infty} \|\nabla_y^2 S_a^n \delta\|_p^{1/n} = 1/2$. Therefore, we still have $\nu_p(\phi) = 1/p - \log_2 \sigma_{2,p,y}(a) = 1/p + 1$ for any p such that $1 \le p \le \infty$. In passing, we mention that $\sigma_{k,2}(a)$ can be obtained by finding the spectral radius of a finite matrix by [25, Theorem 4.1]. If $\sigma_{k,p}(a) < 2^{s/p}$ for some positive integer k, then $\sigma_{1,p}(a) < 2^{s/p}$ and therefore, by [25, Theorem 3.2] the subdivision scheme associated with the mask a converges in the L_p norm and $\phi_a \in L_p(\mathbb{R}^s)$.

Finally, in this section, we prove the following result which will be needed later.

THEOREM 3.5. *Suppose that a function ϕ is a fundamental real-valued function on the real line and ϕ satisfies the refinement equation* (1.1) *with an interpolatory refinement mask a supported on* $[-3, 3]$. *Then the inequality $\nu_\infty(\phi) \le 2$ holds true and therefore, $\phi \notin C^2(\mathbb{R})$.*

Proof. We use proof by contradiction to verify our claim. Suppose $\nu_\infty(\phi) > 2$. Then a must satisfy the sum rules of order at least 3 (see [4, 30]). By a simple calculation, it is not difficult to see that the symbol $\widetilde{a}(z)$ can be written as

$$\widetilde{a}(z) = z^{-3}\,(1+z)^3\,\widetilde{c}(z) \quad \text{with} \quad \widetilde{c}(z) := t - 3\,t\,z + (3/8 + 3t)\,z^2 - (1/8 + t)\,z^3,$$

for some $t \in \mathbb{R}$. By [28, Theorem 3.2] or [26, Theorem 3.1], we observe that

$$\sigma_{3,\infty}(a) = \sigma_{0,\infty}(c) = \lim_{n\to\infty} \big(\max\big\{\|B_1 \cdots B_n\| \;:\; B_1, \ldots, B_n \in \{A_0, A_1\}\big\}\big)^{1/n},$$

where A_0 and A_1 are matrices given by

$$A_0 := \begin{pmatrix} t & 3/8 + 3\,t & 0 \\ 0 & -3\,t & -1/8 - t \\ 0 & t & 3/8 + 3\,t \end{pmatrix}$$

and

$$A_1 := \begin{pmatrix} -3\,t & -1/8 - t & 0 \\ t & 3/8 + 3\,t & 0 \\ 0 & -3\,t & -1/8 - t \end{pmatrix}.$$

Therefore, it is evident that

$$\sigma_{3,\infty}(a) = \sigma_{0,\infty}(c) \ge \lim_{n\to\infty} \|A_0^n\|^{1/n} =: \rho(A_0),$$

where $\rho(A_0)$ is the spectral radius of A_0. By a simple calculation again, we see that $\lambda = 3/16 + \sqrt{(3/8)^2 + 4(t + 8t^2)}/2$ is an eigenvalue of A_0. Note that

$$\lambda = 3/16 + \sqrt{1/256 + 8(t + 1/16)^2} \ge 1/4 \qquad \forall\, t \in \mathbb{R}.$$

This yields

$$\sigma_{3,\infty}(a) = \sigma_{0,\infty}(c) \ge \rho(A_0) \ge 1/4.$$

Since the function ϕ is a fundamental function, the shifts of ϕ are stable. By Theorem 3.3, we have

$$\min\{\,3,\,\nu_\infty(\phi)\,\} = -\log_2 \sigma_{3,\infty}(a) \le -\log_2(1/4) = 2.$$

This is a contradiction to our assumption $\nu_\infty(\phi) > 2$. Hence, the inequality $\nu_\infty(\phi) \le 2$ holds true. This completes our proof. □

4. Optimal orthogonal wavelets in the multivariate setting. In [15], Daubechies first constructed a family of compactly supported orthogonal scaling functions on the real line, namely, ϕ_{D_r} $(r \in \mathbb{N})$, where ϕ_{D_r} satisfies the refinement equation (1.1) with the mask D_r supported on $[0, 2r-1]$. It is observed (see [40]) that D_r satisfies the sum rules of order r and $\overline{\widetilde{D_r}(z)}\widetilde{D_r}(z) = 2\widetilde{b}_r(z)$ for any z in $\mathbb{T}$, where b_r is the unique univariate interpolatory mask which is supported on $[1-2r, 2r-1]$ and satisfies the sum rules of order $2r$. Therefore, by Corollary 2.4, the mask D_r attains the sum rules of optimal order r. In the multivariate setting, due to the lack of the Riesz factorization theorem, it is much more difficult to construct multivariate orthogonal scaling functions than to construct univariate ones. In the current literature, there are few examples of nontensor product multivariate orthogonal scaling functions.

Before proceeding further, we need the following two lemmas.

LEMMA 4.1. *Let a sequence a on $\mathbb{Z}^s$ be an interpolatory mask supported on $[1-2r, 2r-1]^s$ for some positive integer r. Define a new sequence a_1 on $\mathbb{Z}$ as follows:*

$$a_1(k) = 2^{1-s} \sum_{\alpha_2 \in \mathbb{Z}} \cdots \sum_{\alpha_s \in \mathbb{Z}} a(k, \alpha_2, \ldots, \alpha_s), \qquad k \in \mathbb{Z}. \tag{4.1}$$

If the mask a satisfies the sum rules of order at least $2r-1$, then a_1 is a univariate interpolatory refinement mask satisfying the sum rules of order $2r-1$. Moreover, if the mask a satisfies the sum rules of order $2r$, then the mask a_1 must be the mask b_r, the unique interpolatory refinement mask which is supported on $[1-2r, 2r-1]$ and satisfies the sum rules of order $2r$.

Proof. By the definition of sum rules given in (1.4), it is easily seen that the sequence a_1 satisfies the same order of sum rules as the sequence a does. Hence, to complete the proof, it suffices to prove that a_1 is a univariate interpolatory refinement mask. Namely, we have to prove that $a_1(2k) = 0\ \forall\, k \in \mathbb{Z}\backslash\{0\}$. To this end, it suffices to prove that for any ε in Ω such that $\varepsilon = (0, \varepsilon_2, \ldots, \varepsilon_s)$,

$$\sum_{\alpha_2 \in \mathbb{Z}} \cdots \sum_{\alpha_s \in \mathbb{Z}} a(2k, 2\alpha_2 + \varepsilon_2, \ldots, 2\alpha_s + \varepsilon_s) = 0 \qquad \forall\, k \in \mathbb{Z}\backslash\{0\}. \tag{4.2}$$

Let b be a sequence on $\mathbb{Z}$ given by

$$b(k) := \sum_{\alpha_2 \in \mathbb{Z}} \cdots \sum_{\alpha_s \in \mathbb{Z}} a(2k, 2\alpha_2 + \varepsilon_2, \ldots, 2\alpha_s + \varepsilon_s), \qquad k \in \mathbb{Z}.$$

It is evident that b is supported on $[1-r, r-1]$ since a is supported on $[1-2r, 2r-1]^s$. Note that the mask a is an interpolatory refinement mask which satisfies the sum rules of order $2r-1$. By the definition of sum rules given in (1.4), for any integer j such that $0 \le j < 2r-1$, we deduce that

$$\sum_{k \in \mathbb{Z}} b(k)(2k)^j = \sum_{k \in \mathbb{Z}} \sum_{\alpha_2 \in \mathbb{Z}} \cdots \sum_{\alpha_s \in \mathbb{Z}} a(2k, 2\alpha_2 + \varepsilon_2, \ldots, 2\alpha_s + \varepsilon_s)(2k)^j = \delta(j).$$

This gives us

$$\sum_{k=1-r}^{r-1} b(k)k^j = \delta(j), \qquad 0 \le j < 2r-1. \tag{4.3}$$

This linear system has $2r-1$ unknowns $b(1-r), \dots, b(r-1)$ and $2r-1$ equations and its coefficient matrix is a Vandermonde matrix. Hence, it has a unique solution. It is easily seen that $b(j) = \delta(j)$, $j = 1-r, \dots, r-1$, is a solution to the above linear system. This verifies (4.2), thereby completing the proof. □

LEMMA 4.2. *Let a function ϕ in $L_p(\mathbb{R}^s)$ $(1 \le p \le \infty)$ be the normalized solution of the refinement equation* (1.1) *with a finitely supported refinement mask a on $\mathbb{Z}^s$. Let the sequence a_1 be given by* (4.1) *and ϕ_{a_1} be the normalized solution of the refinement equation* (1.1) *with the refinement mask a_1. Suppose that the shifts of ϕ are stable. Then the subdivision scheme associated with the mask a_1 converges in the L_p norm and $\nu_p(\phi) \le \nu_p(\phi_{a_1})$.*

Proof. In the following, we shall prove that for any nonnegative integer k, there exists a positive constant C such that

$$\|\nabla_1^k S_{a_1}^n \delta\|_p \le C 2^{n(1-s)/p} \|\nabla_1^k S_a^n \delta\|_p \qquad \forall\, n \in \mathbb{N}. \tag{4.4}$$

From the definition of the subdivision operator given in (2.2), we observe that $\widetilde{S_a^n\delta}(z) = \prod_{j=0}^{n-1} \widetilde{a}(z^{2^j})$ for any z in $\mathbb{T}^s$. Therefore, we deduce $\widetilde{S_{a_1}^n\delta}(z) = 2^{(1-s)n}\widetilde{S_a^n\delta}(z,1,\dots,1)$ for any z in $\mathbb{T}$ since $\widetilde{a_1}(z) = 2^{1-s}\widetilde{a}(z,1,\dots,1)$ and $\widetilde{S_{a_1}^n\delta}(z) = \prod_{j=0}^{n-1}\widetilde{a_1}(z^{2^j})$ for any z in $\mathbb{T}$. That is,

$$S_{a_1}^n\delta(j) = 2^{(1-s)n} \sum_{\beta_2\in\mathbb{Z}} \cdots \sum_{\beta_s\in\mathbb{Z}} S_a^n\delta(j,\beta_2,\dots,\beta_s) \qquad \forall\, j \in \mathbb{Z},\ n \in \mathbb{N}. \tag{4.5}$$

Since $\nabla_1\lambda(\beta) = \lambda(\beta) - \lambda(\beta - e_1)$, $\lambda \in \ell_0(\mathbb{Z}^s)$, where e_1 is the first coordinate unit vector, we have

$$\begin{aligned}\nabla_1^k S_{a_1}^n\delta(j) &= 2^{(1-s)n}\nabla_1^k \sum_{\beta_2\in\mathbb{Z}} \cdots \sum_{\beta_s\in\mathbb{Z}} S_a^n\delta(j,\beta_2,\dots,\beta_s)\\ &= 2^{(1-s)n} \sum_{\beta_2\in\mathbb{Z}} \cdots \sum_{\beta_s\in\mathbb{Z}} \nabla_1^k S_a^n\delta(j,\beta_2,\dots,\beta_s).\end{aligned}$$

Since the mask a is finitely supported, there exists a positive integer r such that $\operatorname{supp} a \subseteq [-r,r]^s$. It is easily seen that $\operatorname{supp} S_a^n\delta \subseteq [-2^n r, 2^n r]$. Therefore, the above equality can be rewritten as

$$\nabla_1^k S_{a_1}^n\delta(j) = 2^{(1-s)n} \sum_{\beta_2=-2^n r}^{2^n r} \cdots \sum_{\beta_s=-2^n r}^{2^n r} \nabla_1^k S_a^n\delta(j,\beta_2,\dots,\beta_s), \qquad j \in \mathbb{Z}.$$

Applying the Hölder inequality to the above sum, we obtain

$$\begin{aligned}|\nabla_1^k S_{a_1}^n\,\delta(j)|^p &\le 2^{n(1-s)p}(2^{n+1}r+1)^{(s-1)p/q} \sum_{\beta_2\in\mathbb{Z}} \cdots \sum_{\beta_s\in\mathbb{Z}} |\nabla_1^k\, S_a^n\,\delta(j,\beta_2,\dots,\beta_s)|^p\\ &\le C_1 2^{n(1-s)} \sum_{\beta_2\in\mathbb{Z}} \cdots \sum_{\beta_s\in\mathbb{Z}} |\nabla_1^k\, S_a^n\,\delta(j,\beta_2,\dots,\beta_s)|^p,\end{aligned}$$

where $1/p + 1/q = 1$ and $C_1 = (2r+1)^{(s-1)p/q}$. It follows from the above inequality that

$$\|\nabla_1^k S_{a_1}^n \delta\|_p \le C_1^{1/p} 2^{n(1-s)/p} \|\nabla_1^k S_a^n \delta\|_p \qquad \forall\, n \in \mathbb{N}.$$

Therefore, the inequality (4.4) holds true. Since the shifts of ϕ are stable and ϕ lies in $L_p(\mathbb{R}^s)$, the subdivision scheme associated with the mask a converges in the L_p norm. That is, by [25, Theorem 3.2], it is equivalent to

$$\lim_{n\to\infty} \max\{\, \|\nabla_i S_a^n \delta\|_p^{1/n} \;:\; i = 1, \dots, s \,\} < 2^{s/p}.$$

The reader is referred to [25] for a detailed discussion on the convergence of a subdivision scheme in the L_p norm. Taking $k = 1$ in (4.4), we get

$$\lim_{n\to\infty} \|\nabla_1 S_{a_1}^n \delta\|_p^{1/n} \le 2^{(1-s)/p} \lim_{n\to\infty} \max\{\, \|\nabla_i S_a^n \delta\|_p^{1/n} \;:\; i = 1, \dots, s \,\} < 2^{1/p}.$$

Hence, the subdivision scheme associated with the mask a_1 converges in the L_p norm. In particular, we have $\phi_{a_1} \in L_p(\mathbb{R})$.

Note that $\sigma_{k,p}(a_1) := \lim_{n\to\infty} \|\nabla_1^k S_{a_1}^n \delta\|_p^{1/n}$ and

$$\sigma_{k,p}(a) := \lim_{n\to\infty} \max\{\, \|\nabla_i^k S_a^n \delta\|_p^{1/n} \;:\; i = 1, \dots, s \,\} \ge \lim_{n\to\infty} \|\nabla_1^k S_a^n \delta\|_p^{1/n}.$$

Hence, the inequality (4.4) gives rise to

$$\sigma_{k,p}(a_1) \le 2^{(1-s)/p} \sigma_{k,p}(a) \qquad \forall\, k \in \mathbb{N} \cup \{0\}.$$

Let k be a positive integer greater than $\nu_p(\phi)$. It follows from Theorem 3.3 that

$$\nu_p(\phi_{a_1}) \ge 1/p - \log_2 \sigma_{k,p}(a_1) \ge s/p - \log_2 \sigma_{k,p}(a) = \nu_p(\phi),$$

as desired. □

Combining the above lemmas and Theorem 3.5, we have the following result.

COROLLARY 4.3. *Suppose that a function ϕ is a fundamental real-valued function and satisfies the refinement equation* (1.1) *with an interpolatory refinement mask a supported on $[-3, 3]^s$. Then the inequality $\nu_\infty(\phi) \le 2$ holds true and therefore, ϕ does not belong to $C^2(\mathbb{R}^s)$.*

Proof. Let the sequence a_1 on $\mathbb{Z}$ be given in (4.1). Suppose that $\nu_\infty(\phi) > 2$. Then the mask a must satisfy the sum rules of order at least 3. Therefore, it follows from Lemma 4.1 that a_1 is an interpolatory mask. Let ϕ_{a_1} be the normalized solution of (1.1) with the mask a_1. Then by Lemma 4.2, the subdivision scheme associated with a_1 converges in the L_∞ norm which implies that the function ϕ_{a_1} is a fundamental function. From Lemma 4.2, we also have $\nu_\infty(\phi) \le \nu_\infty(\phi_{a_1})$. It follows from Theorem 3.5 that $\nu_\infty(\phi) \le \nu_\infty(\phi_{a_1}) \le 2$. This is a contradiction to our assumption $\nu_\infty(\phi) > 2$. Therefore, the inequality $\nu_\infty(\phi) \le 2$ holds true. □

Corollary 4.3 says that there is no C^2 fundamental refinable function supported on $[-3, 3]^s$. This result also implies that if a function ϕ is an orthogonal scaling function supported on $[0, 3]^s$, then $\nu_2(\phi) \le 1$ and therefore, $\phi \notin C^1(\mathbb{R}^s)$.

Let ϕ be an orthogonal scaling function with its mask supported on $[0, 2r - 1]^s$ for some positive integer r. From Corollary 2.4, we see that $S(\phi)$ can provide approximation order at most r. For this case, we shall study the upper bound of the critical exponent $\nu_p(\phi)$ for any p such that $1 \le p \le \infty$. Based on the above lemmas and Theorem 3.3, we have the following result on orthogonal scaling functions.

THEOREM 4.4. *Suppose that a function ϕ in $L_2(\mathbb{R}^s)$ is an orthogonal scaling function with its refinement mask a supported on $[0, 2r-1]^s \cap \mathbb{Z}^s$ for some positive integer r. Define a new sequence a_1 on $\mathbb{Z}$ as follows:*

$$a_1(k) := 2^{1-s} \sum_{\beta_2 \in \mathbb{Z}} \cdots \sum_{\beta_s \in \mathbb{Z}} a(k, \beta_2, \ldots, \beta_s), \qquad k \in \mathbb{Z}.$$

Let ϕ_{a_1} be the normalized solution of the refinement equation (1.1) *with the mask a_1. If the mask a satisfies the sum rules of optimal order r, then the function ϕ_{a_1} is an orthogonal scaling function with the mask a_1 satisfying*

$$\overline{\widetilde{a_1}(z)}\, \widetilde{a_1}(z) = 2\widetilde{b}_r(z), \qquad z \in \mathbb{T}.$$

If, in addition, the function ϕ belongs to $L_p(\mathbb{R}^s)$ for some p such that $1 \le p \le \infty$, then

$$\nu_p(\phi) \le \nu_p(\phi_{a_1}).$$

In particular,

$$\nu_2(\phi) \le \nu_2(\phi_{D_r}) \quad \textit{and} \quad \nu_2(\phi_{a_1}) = \nu_2(\phi_{D_r}) = \nu_\infty(\phi_{b_r})/2,$$

where ϕ_{D_r} is the Daubechies orthogonal scaling function with its mask D_r supported on $[0, 2r-1]$, and ϕ_{b_r} is the Deslauriers and Dubuc fundamental refinable function with its mask b_r supported on $[1-2r, 2r-1]$.

Proof. Let a sequence b on $\mathbb{Z}^s$ be given by its symbol

$$\widetilde{b}(z) := 2^{-s}\overline{\widetilde{a}(z)}\widetilde{a}(z), \qquad z \in \mathbb{T}^s.$$

By Lemma 2.1, the sequence b is an interpolatory refinement mask since ϕ is an orthogonal scaling function. Since the mask a satisfies the sum rules of order r, by the proof of Theorem 2.3, we see that the sequence b must satisfy the sum rules of order at least $2r$. Define a new sequence c on $\mathbb{Z}$ as in (4.1) by

$$c(k) = 2^{1-s} \sum_{\beta_2 \in \mathbb{Z}} \cdots \sum_{\beta_s \in \mathbb{Z}} b(k, \beta_2, \ldots, \beta_s), \qquad k \in \mathbb{Z}.$$

By Lemma 4.1, the sequence c must be the mask b_r since the sequence b is supported on $[1-2r, 2r-1]^s$ and satisfies the sum rules of order $2r$. Note that $\widetilde{c}(z) = 2^{1-s}\widetilde{b}(z, 1, \ldots, 1)$ and $\widetilde{a_1}(z) = 2^{1-s}\widetilde{a}(z, 1, \ldots, 1)$ for any $z \in \mathbb{T}$. Therefore,

$$\overline{\widetilde{a_1}(z)}\widetilde{a_1}(z) = 2^{2-s}\widetilde{b}(z, 1, \ldots, 1) = 2\widetilde{c}(z) = 2\widetilde{b}_r(z) \qquad \forall\, z \in \mathbb{T}.$$

Thus, the mask a_1 is the dual mask of itself for $s = 1$. By Lemma 4.2, the subdivision scheme associated with the mask a_1 converges in the L_2 norm since the function ϕ is a scaling function. Hence, the function ϕ_{a_1} is an orthogonal scaling function by Lemma 2.1. If ϕ lies in $L_p(\mathbb{R}^s)$ for some p such that $1 \le p \le \infty$, then by Lemma 4.2, we have $\nu_p(\phi) \le \nu_p(\phi_{a_1})$. Note that $\overline{\widetilde{a_1}(z)}\widetilde{a_1}(z) = 2\widetilde{b}_r(z)$ implies that $\nu_2(\phi_{a_1}) = \nu_\infty(\phi_{b_r})/2$. Since $\overline{\widetilde{D_r}(z)}\widetilde{D_r}(z) = 2b_r(z)$ for any z in $\mathbb{T}$,

$$\nu_2(\phi) \le \nu_2(\phi_{a_1}) = \nu_\infty(\phi_{b_r})/2 = \nu_2(\phi_{D_r}),$$

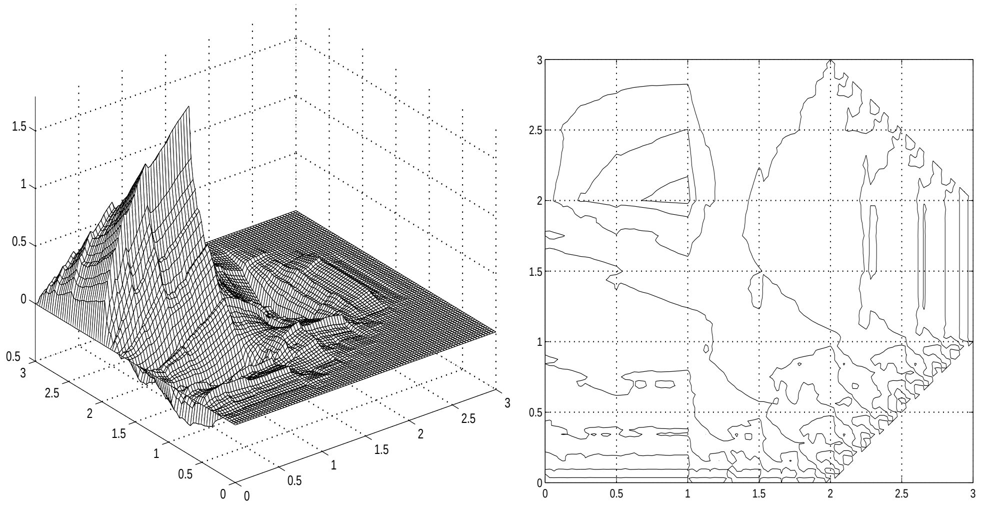

FIG. 4.1. *The graph and contour of the orthogonal scaling function ϕ_a in Example* 4.5.

which completes the proof. □

In the following, we give an example to demonstrate that when $s > 1$, such optimal orthogonal scaling functions are not unique.

Example 4.5. The mask a is supported on $[0,3]^2$ and is given by

$$\begin{pmatrix} -\frac{3}{8} - \frac{\sqrt{-10+6\sqrt{3}}}{8} + \frac{\sqrt{3}}{8} & \frac{1}{4} - \frac{\sqrt{3}}{4} & \frac{5}{8} - \frac{3\sqrt{3}}{8} + \frac{\sqrt{-10+6\sqrt{3}}}{8} & 0 \\ -\frac{1}{8} + \frac{\sqrt{3}}{8} + \frac{\sqrt{-10+6\sqrt{3}}}{8} & \frac{1}{2} & \frac{7}{8} - \frac{3\sqrt{3}}{8} - \frac{\sqrt{-10+6\sqrt{3}}}{8} & \frac{1}{4} - \frac{\sqrt{3}}{4} \\ \frac{5}{8} + \frac{\sqrt{3}}{8} + \frac{\sqrt{-10+6\sqrt{3}}}{8} & \frac{1}{2} + \frac{\sqrt{3}}{2} & \frac{1}{8} - \frac{\sqrt{-10+6\sqrt{3}}}{8} + \frac{\sqrt{3}}{8} & \frac{1}{4} - \frac{\sqrt{3}}{4} \\ \frac{3}{8} + \frac{\sqrt{3}}{8} - \frac{\sqrt{-10+6\sqrt{3}}}{8} & \frac{1}{4} + \frac{\sqrt{3}}{4} & -\frac{1}{8} + \frac{\sqrt{3}}{8} + \frac{\sqrt{-10+6\sqrt{3}}}{8} & 0 \end{pmatrix}.$$

Then the function ϕ_a is an orthogonal scaling function and the mask a satisfies the sum rules of order 2. Moreover, by calculation, we have $\nu_2(\phi_a) = 1$. Combining Theorem 4.4 and Corollary 4.3, we see that for any orthogonal scaling ϕ with its mask supported on $[0,3]^s$, the inequality $\nu_2(\phi) \le 1$ holds true. Therefore, the function ϕ_a is an optimal orthogonal scaling function in the L_2 norm sense. The graph and contour of ϕ_a are presented in Figure 4.1.

5. Optimal multivariate biorthogonal wavelets. In this section, we will demonstrate a result similar to Theorem 4.4 for the biorthogonal wavelets. Since there is a close relation between a biorthogonal wavelet and a fundamental refinable function, let us first prove the following result on fundamental refinable functions.

THEOREM 5.1. *Let ϕ be a fundamental refinable function with a finitely supported interpolatory mask a. Suppose that a is supported on $[1-2r, 2r-1]^s$ for some positive integer r and the mask a satisfies the sum rules of order $2r-1$. Let a sequence a_1 on $\mathbb{Z}$ be given by* (4.1) *and let ϕ_{a_1} be the normalized solution of the refinement equation* (1.1) *with the mask a_1. Then the function ϕ_{a_1} is a fundamental function and*

$$\nu_p(\phi) \le \nu_p(\phi_{a_1}) \qquad \forall\, 1 \le p \le \infty.$$

Moreover, if the mask a satisfies the sum rules of order $2r$, then

$$\nu_p(\phi) \le \nu_p(\phi_{b_r}) \qquad \forall\, 1 \le p \le \infty.$$

In other words, the inequality $\nu_p(\phi) \le \nu_p(\phi_{t_r})$ holds true, where t_r is the tensor product interpolatory mask given in (2.7).

Proof. By Lemma 4.1, we see that the mask a_1 is an interpolatory refinement mask. Since the function ϕ is fundamental, the shifts of ϕ are stable. By Lemma 4.2, the subdivision scheme associated with the mask a_1 converges in the L_p norm for any p such that $1 \le p \le \infty$. Hence ϕ_{a_1}, the normalized solution of the refinement equation (1.1) with the interpolatory refinement mask a_1, is continuous and therefore fundamental. It follows from Lemma 4.2 that $\nu_p(\phi) \le \nu_p(\phi_{a_1})$ for any $1 \le p \le \infty$.

If the mask a satisfies the sum rules of order $2r$, by Lemma 4.1, then the sequence a_1 must be the mask b_r. Hence, by Lemma 4.2, $\nu_p(\phi) \le \nu_p(\phi_{b_r})$ for any p such that $1 \le p \le \infty$. □

The reader is referred to [18, 21, 22, 26, 40, 41] on interpolatory subdivision schemes. In particular, a general construction of bivariate interpolatory masks g_r ($r \in \mathbb{N}$) was reported by Han and Jia in [26] with each mask g_r supported on $[1-2r, 2r-1]^2$, satisfying the optimal sum rules of order $2r$ and $\nu_2(\phi_{g_r}) = \nu_2(\phi_{b_r})$ at least for $r = 1, \ldots, 12$. Recall that by ϕ_a we denote the normalized solution of the refinement equation (1.1) with a mask a.

A similar result to Theorem 4.4 for a biorthogonal wavelet is the following.

THEOREM 5.2. *Let a function ϕ in $L_2(\mathbb{R}^s)$ be a scaling function with a refinement mask a and a function ϕ^d in $L_2(\mathbb{R}^s)$ be a dual scaling function of ϕ with a refinement mask a^d. Define two new sequences a_1 and a_1^d on $\mathbb{Z}$ as follows:*

$$a_1(k) = 2^{1-s} \sum_{\beta_2 \in \mathbb{Z}} \cdots \sum_{\beta_s \in \mathbb{Z}} a(k, \beta_2, \ldots, \beta_s), \qquad k \in \mathbb{Z},$$

and

$$a_1^d(k) = 2^{1-s} \sum_{\beta_2 \in \mathbb{Z}} \cdots \sum_{\beta_s \in \mathbb{Z}} a^d(k, \beta_2, \ldots, \beta_s), \qquad k \in \mathbb{Z}.$$

By ϕ_{a_1} and $\phi_{a_1^d}$ we denote the normalized solutions of the refinement equation (1.1) *with the masks a_1 and a_1^d, respectively. Let a sequence b on $\mathbb{Z}^s$ be given as in* (2.4) *by*

$$b(\alpha) := 2^{-s} \sum_{\beta \in \mathbb{Z}^s} \overline{a(\beta - \alpha)}\, a^d(\beta), \qquad \alpha \in \mathbb{Z}^s. \tag{5.1}$$

Suppose that the sequence b is supported on $[1-2k, 2k-1]^s \cap \mathbb{Z}^s$ for some positive integer k and b satisfies the sum rules of order $2k-1$. Then the function ϕ_{a_1} is a univariate scaling function with $\phi_{a_1^d}$ being a dual scaling function of ϕ_{a_1}. If ϕ belongs to $L_p(\mathbb{R}^s)$ and ϕ^d belongs to $L_q(\mathbb{R}^s)$ for some p, q such that $1 \le p, q \le \infty$, then $\phi_{a_1} \in L_p(\mathbb{R})$, $\phi_{a_1^d} \in L_q(\mathbb{R})$ and

$$\nu_p(\phi) \le \nu_p(\phi_{a_1}) \quad \textit{and} \quad \nu_q(\phi^d) \le \nu_q(\phi_{a_1^d}). \tag{5.2}$$

In particular, if the sequence b satisfies the sum rules of order $2k$, then

$$\overline{\widetilde{a_1}(z)}\widetilde{a_1^d}(z) = 2\widetilde{b_k}(z), \qquad z \in \mathbb{T}, \quad \textit{and} \quad \nu_q(\phi^d) \le \nu_r(\phi_{b_k}) - \nu_p(\phi),$$

where $1/r = 1/p + 1/q - 1$ *and* b_k *is the unique interpolatory mask which is supported on* $[1-2k, 2k-1]$ *and satisfies the sum rules of order* $2k$.

Proof. By Lemma 2.1, it is easily seen that the sequence b is an interpolatory mask. Let c be a sequence on $\mathbb{Z}$ given by

$$c(k) = 2^{1-s} \sum_{\beta_2 \in \mathbb{Z}} \cdots \sum_{\beta_s \in \mathbb{Z}} b(k, \beta_2, \ldots, \beta_s), \qquad k \in \mathbb{Z}.$$

It follows from Lemma 4.1 that the sequence c is an interpolatory mask since the sequence b is supported on $[1-2k, 2k-1]^s$ and satisfies the sum rules of order $2k-1$. Observe that $\widetilde{c}(z) = 2^{1-s}\widetilde{b}(z, 1, \ldots, 1)$, $\widetilde{a_1}(z) = 2^{1-s}\widetilde{a}(z, 1, \ldots, 1)$, and $\widetilde{a_1^d}(z) = 2^{1-s}\widetilde{a^d}(z, 1, \ldots, 1)$ for any z in $\mathbb{T}$. It is easy to see that

$$\overline{\widetilde{a_1}(z)}\widetilde{a_1^d}(z) = 2^{2-2s}\overline{\widetilde{a}(z, 1, \ldots, 1)}\widetilde{a^d}(z, 1, \ldots, 1) = 2\widetilde{c}(z), \qquad z \in \mathbb{T}. \tag{5.3}$$

Therefore, the masks a_1 and a_1^d must satisfy the discrete biorthogonal relation (2.5) with $s = 1$ since the sequence c is an interpolatory mask. Since both ϕ and ϕ^d belong to $L_2(\mathbb{R}^s)$ and their shifts are stable, by Lemma 4.2, the subdivision schemes associated with the masks a_1 and a_1^d converge in the L_2 norm, respectively. Thus, by Lemma 2.1, the function ϕ_{a_1} is a scaling function with $\phi_{a_1^d}$ being a dual scaling function of ϕ_{a_1}. The inequality (5.2) follows directly from Lemma 4.2.

If the sequence b satisfies the sum rules of order $2k$, by Lemma 4.1, the mask c in (5.3) must be the mask b_k. Note that $\widetilde{\nabla^{k_1} S_{a_1}^n \delta}(z) = (1-z)^{k_1}\Pi_{j=0}^{n-1}\widetilde{a_1}(z^{2^j})$. Therefore, it follows from (5.3) that for any positive integers k_1 and k_2, it is easy to verify that

$$2^n \widetilde{\nabla^{k_1+k_2} S_{b_k}^n \delta}(z) = \overline{\widetilde{\nabla^{k_1} S_{a_1}^n \delta}(z)}\widetilde{\nabla^{k_2} S_{a_1^d}^n \delta}(z), \qquad z \in \mathbb{T}.$$

Therefore, by applying Young's inequality to the above equation, we have

$$2^n \|\nabla^{k_1+k_2} S_{b_k}^n \delta\|_r \leq \|\nabla^{k_1} S_{a_1}^n \delta\|_p \|\nabla^{k_2} S_{a_1^d}^n \delta\|_q \qquad \forall\, n \in \mathbb{N},$$

where $1/r = 1/p + 1/q - 1$. This yields

$$2\sigma_{k_1+k_2,r}(b_k) \leq \sigma_{k_1,p}(a_1)\sigma_{k_2,q}(a_1^d) \qquad \forall\ k_1, k_2 \in \mathbb{N}.$$

By Theorem 3.3, we have $\nu_r(\phi_{b_k}) \geq \nu_p(\phi_{a_1}) + \nu_q(\phi_{a_1^d})$. Since $\nu_p(\phi) \leq \nu_p(\phi_{a_1})$ and $\nu_q(\phi^d) \leq \nu_q(\phi_{a_1^d})$, we conclude that $\nu_r(\phi_{b_k}) \geq \nu_p(\phi_a) + \nu_q(\phi_{a^d})$. □

COROLLARY 5.3. *Let* ϕ *be a scaling function with a refinement mask* a *supported on* $[-l, l]^s$ *for some positive integer* l *and* ϕ^d *be a dual scaling function with a refinement mask* a^d *supported on* $[1+l-2k, 2k-l-1]^s$ *for some positive integer* k. *Let the sequence* b *be given in* (5.1). *Suppose that the mask* a *satisfies the sum rules of order* m. *Then the mask* a^d *can satisfy the sum rules of order at most* $2k-m$. *Moreover, if the mask* a^d *satisfies the sum rules of order* $2k-m-1$ (*or* $2k-m$), *then the sequence* b *can satisfy the sum rules of order at least* $2k-1$ (*or* $2k$) *and the corresponding results in Theorem* 5.2 *hold true.*

Proof. This is a direct consequence of Theorems 2.3 and 5.2. □

Let us consider an example. Let ϕ be a refinable box spline function with its mask a given by its symbol

$$\widetilde{a}(z) = 2^{-s}\Pi_{j=1}^{s}(z_j^{-1} + 2 + z_j), \qquad z \in \mathbb{T}^s,$$

or

$$\widetilde{a}(z) = 2^{-1}(1 + z_1^{-1} \cdots z_s^{-1})\Pi_{j=1}^{s}(1 + z_j), \qquad z \in \mathbb{T}^s.$$

It is easy to verify that ϕ is a fundamental function with $\nu_1(\phi) = 2$, its mask a is supported on $[-1, 1]^s$, and a satisfies the sum rules of order 2. Thus, the function ϕ is a scaling function. Then Corollaries 4.3 and 5.3 imply that if a function ϕ^d is a dual scaling function of the scaling function ϕ with its mask supported on $[-2, 2]^s$, then the function ϕ^d cannot be continuous. For any dual scaling function ϕ^d of the scaling function ϕ with its mask a^d supported on $[2 - 2r, 2r - 2]^s$ for some positive integer r, by Theorem 2.3, the mask a^d can satisfy the sum rules of order at most $2r - 2$. If a^d satisfies the sum rules of order $2r - 2$, by Corollary 5.3, then we have

$$\nu_2(\phi^d) \le \nu_2(\phi_{b_r}) - \nu_1(\phi) = \nu_2(\phi_{b_r}) - 2.$$

When $s = 2$, in the next section, we shall construct a family of dual scaling functions $\phi_{\mathcal{H}_r}$ $(r \in \mathbb{N})$ of the bivariate hat function ϕ such that the dual mask $\mathcal{H}_r$ is supported on $[2-2r, 2r-2]^2$ and satisfies the sum rules of order $2r-2$. In addition, the equality $\nu_2(\phi_{\mathcal{H}_r}) = \nu_2(\phi_{b_r}) - 2$ holds true at least for $r = 3, \ldots, 12$ and each mask $\mathcal{H}_r$ is symmetric about the two coordinate axes, and the lines $x_1 = x_2$ and $x_1 = -x_2$.

6. Construction of multivariate biorthogonal wavelets. In this section, we shall present a general method to construct multivariate biorthogonal wavelets. More precisely, for any scaling function ϕ with an interpolatory refinement mask a, a general CBC algorithm is given to produce all the dual masks of the mask a. As an application of this general theory, for any bivariate fundamental mask a which is symmetric about the two coordinate axes, we construct a family of dual masks of a which satisfy any desired order of sum rules and are also symmetric about the two coordinate axes. Based on this construction, a family of optimal bivariate biorthogonal wavelets is presented. Such biorthogonal wavelets have full symmetry (i.e., they are symmetric about the x_1-axis, x_2-axis, and the lines $x_1 = x_2$ and $x_1 = -x_2$), have the optimal order of sum rules, the optimal L_2 smoothness order, and relatively small support of the dual masks.

Before proceeding further, we introduce some notation. Recall that

$$\mathbb{Z}_+^s := \{\, (\alpha_1, \ldots, \alpha_s) \in \mathbb{Z}^s \;:\; \alpha_i \ge 0 \quad \forall\, i = 1, \ldots, s \,\}.$$

For any $\mu = (\mu_1, \ldots, \mu_s) \in \mathbb{Z}^s$, we denote $|\mu| := |\mu_1| + \cdots + |\mu_s|$ and $\mu! := \mu_1! \cdots \mu_s!$ if $\mu \in \mathbb{Z}_+^s$. For any $\mu = (\mu_1, \ldots, \mu_s), \nu = (\nu_1, \ldots, \nu_s) \in \mathbb{Z}^s$, by $\nu \le \mu$ we mean $\nu_i \le \mu_i$ $\forall\, i = 1, \ldots, s$, and by $\nu < \mu$ we mean $\nu \le \mu$ and $\nu \ne \mu$.

Throughout this section, for any $\nu \in \mathbb{Z}_+^s$, by p_ν we denote the monomial $(\cdot)^\nu$ and

$$\langle \lambda, p_\nu \rangle := \sum_{\alpha \in \mathbb{Z}^s} \lambda(\alpha) p_\nu(\alpha) = \sum_{\alpha \in \mathbb{Z}^s} \lambda(\alpha)\alpha^\nu, \qquad \lambda \in \ell_0(\mathbb{Z}^s).$$

THEOREM 6.1. *Let a sequence a on $\mathbb{Z}^s$ satisfy $\sum_{\beta \in \mathbb{Z}^s} a(\beta) = 2^s$. Suppose that a sequence a^d on $\mathbb{Z}^s$ is a dual mask of a that satisfies the following discrete biorthogonal relation:*

$$\sum_{\beta \in \mathbb{Z}^s} \overline{a(\beta - 2\alpha)} a^d(\beta) = 2^s \delta(\alpha) \qquad \forall\, \alpha \in \mathbb{Z}^s. \tag{6.1}$$

If the sequence a^d satisfies the sum rules of order k for some positive integer k, then for any $\mu \in \mathbb{Z}_+^s$ such that $|\mu| < k$, the value $h_\mu := 2^{-s}\langle a^d, p_\mu\rangle$ is uniquely determined by the sequence a. More precisely, h_μ is given by the following recursive relation:

$$h_\mu = \delta(\mu) - 2^{-s} \sum_{0 \le \nu < \mu} (-1)^{|\mu-\nu|} \frac{\mu!}{\nu!(\mu-\nu)!} \overline{\langle a, p_{\mu-\nu}\rangle}\, h_\nu, \qquad |\mu| < k, \mu \in \mathbb{Z}_+^s. \tag{6.2}$$

Proof. Recall that Ω is the set of the vertices of the unit cube $[0,1]^s$. By the definition of the sum rules (1.4), we observe that the sequence a^d satisfies the sum rules of order k if and only if

$$\sum_{\beta \in \mathbb{Z}^s} a^d(2\beta+\varepsilon)(2\beta+\varepsilon)^\nu = 2^{-s}\langle a^d,\, p_\nu\rangle = h_\nu \qquad \forall\, \varepsilon \in \Omega,\ |\nu| < k,\ \nu \in \mathbb{Z}_+^s. \tag{6.3}$$

From (6.1), we get for any $\mu \in \mathbb{Z}_+^s$,

$$\begin{aligned} 2^s\delta(\mu) &= \sum_{\alpha \in \mathbb{Z}^s} \sum_{\beta \in \mathbb{Z}^s} \overline{a(\beta - 2\alpha)} a^d(\beta)(2\alpha)^\mu \\ &= \sum_{\varepsilon \in \Omega} \sum_{\alpha \in \mathbb{Z}^s} \sum_{\beta \in \mathbb{Z}^s} \overline{a(2\beta+\varepsilon-2\alpha)} a^d(2\beta+\varepsilon)(2\alpha)^\mu. \end{aligned}$$

On the other hand, we have

$$(2\alpha)^\mu = \big((2\beta+\varepsilon) - (2\beta+\varepsilon-2\alpha)\big)^\mu = \sum_{0 \le \nu \le \mu} c_{\nu,\mu}(2\beta+\varepsilon-2\alpha)^{\mu-\nu}(2\beta+\varepsilon)^\nu,$$

where $c_{\nu,\mu} := (-1)^{|\mu-\nu|}\mu!/(\nu!(\mu-\nu)!)$ and recall that by $\nu \le \mu$ we mean $\nu_i \le \mu_i$ $\forall\, i = 1, \dots, s$. Hence, for any $\mu \in \mathbb{Z}_+^s$, we deduce that

$$\begin{aligned} &2^s\delta(\mu) \\ &\quad = \sum_{0 \le \nu \le \mu} c_{\nu,\mu} \sum_{\varepsilon \in \Omega} \sum_{\alpha \in \mathbb{Z}^s} \sum_{\beta \in \mathbb{Z}^s} \overline{a(2\beta+\varepsilon-2\alpha)}(2\beta+\varepsilon-2\alpha)^{\mu-\nu} a^d(2\beta+\varepsilon)(2\beta+\varepsilon)^\nu \\ &\quad = \sum_{0 \le \nu \le \mu} c_{\nu,\mu} \sum_{\varepsilon \in \Omega} \sum_{\alpha \in \mathbb{Z}^s} \overline{a(2\alpha+\varepsilon)}(2\alpha+\varepsilon)^{\mu-\nu} \sum_{\beta \in \mathbb{Z}^s} a^d(2\beta+\varepsilon)(2\beta+\varepsilon)^\nu. \end{aligned}$$

Since $\sum_{\beta \in \mathbb{Z}^s} a(\beta) = 2^s$, we have $\langle a,\, p_0\rangle = 2^s$. Note that $c_{\mu,\mu} = 1$ for any $\mu \in \mathbb{Z}_+^s$. From (6.3), we conclude that

$$\begin{aligned} 2^s\delta(\mu) &= \sum_{0 \le \nu \le \mu} c_{\nu,\mu} \sum_{\varepsilon \in \Omega} \sum_{\alpha \in \mathbb{Z}^s} \overline{a(2\alpha+\varepsilon)}(2\alpha+\varepsilon)^{\mu-\nu}\, h_\nu \\ &= \sum_{0 \le \nu \le \mu} c_{\nu,\mu} \overline{\langle a,\, p_{\mu-\nu}\rangle}\, h_\nu = 2^s h_\mu + \sum_{0 \le \nu < \mu} c_{\nu,\mu} \overline{\langle a,\, p_{\mu-\nu}\rangle}\, h_\nu \end{aligned}$$

from which (6.2) can be easily derived. □

By definition, the value $\langle a^d,\, p_\mu\rangle$ in Theorem 6.1 is totally determined by the sequence a^d. But Theorem 6.1 says that if the sequence a^d is a dual mask of the mask a and the sequence a^d satisfies the sum rules of order k, then for any $\mu \in \mathbb{Z}_+^s$ such that $|\mu| < k$, the value $\langle a^d,\, p_\mu\rangle$ is uniquely determined by the sequence a instead of the sequence a^d. Therefore, by the above Theorem 6.1, if a sequence a on $\mathbb{Z}^s$ satisfies $\sum_{\beta \in \mathbb{Z}^s} a(\beta) = 2^s$, then we can define a sequence h^a on $\mathbb{Z}_+^s$ as follows:

$$h^a(\mu) = \delta(\mu) - 2^{-s} \sum_{0 \le \nu < \mu} (-1)^{|\mu-\nu|} \frac{\mu!}{\nu!(\mu-\nu)!} \overline{\langle a, p_{\mu-\nu}\rangle}\, h^a(\nu), \qquad \mu \in \mathbb{Z}_+^s. \tag{6.4}$$

An important consequence of Theorem 6.1 is that it allows us to propose a general method to construct a dual mask satisfying the sum rules of arbitrary order for any given interpolatory refinement mask. Since, in the following method, we obtain the dual masks a^d by constructing each coset $a^d(2\beta+\varepsilon), \beta \in \mathbb{Z}^s$ separately, we call this method the CBC algorithm.

CBC ALGORITHM.

(1) *Given a sequence a on $\mathbb{Z}^s$ such that a satisfies the following conditions:*

$$(6.5) \quad \sum_{\beta\in\mathbb{Z}^s} a(\beta) = 2^s, \quad a(0)=1, \quad \textit{and} \quad a(2\beta)=0 \qquad \forall\, \beta \in \mathbb{Z}^s\backslash\{0\};$$

(2) *let k be any fixed positive integer;*

(3) *calculate $h^a(\mu)$ as in (6.4) for $\mu \in \mathbb{Z}_+^s$ such that $|\mu| < k$;*

(4) *let Ω be the set of vertices of $[0,1]^s$. For each $\varepsilon \in \Omega\backslash\{0\}$, choose an appropriate subset E_ε of $\mathbb{Z}^s$ such that the following linear system*

$$(6.6) \qquad \sum_{\beta\in E_\varepsilon} b_{\varepsilon,\beta}(2\beta+\varepsilon)^\mu = h^a(\mu), \qquad \mu\in\mathbb{Z}_+^s,\ |\mu|<k$$

has at least one solution for $\{b_{\varepsilon,\beta} \,:\, \beta \in E_\varepsilon\}$;

(5) *construct the mask a^d coset by coset as follows: for each $\varepsilon \in \Omega\backslash\{0\}$,*

$$a^d(2\beta+\varepsilon) = b_{\varepsilon,\beta},\ \beta\in E_\varepsilon \quad \textit{and} \quad a^d(2\beta+\varepsilon)=0, \quad \beta\in\mathbb{Z}^s\backslash E_\varepsilon$$

and

$$(6.7) \quad a^d(2\beta) = 2^s\delta(\beta) - \sum_{\varepsilon\in\Omega\backslash\{0\}}\sum_{\alpha\in\mathbb{Z}^s} \overline{a(2\alpha-2\beta+\varepsilon)}\, a^d(2\alpha+\varepsilon),\ \beta\in\mathbb{Z}^s;$$

(6) *then the mask a^d is a dual mask of the given interpolatory mask a and satisfies the sum rules of order k.*

Proof. It is easy to verify that if the sequence a is an interpolatory mask, then the dual relation (6.1) is equivalent to (6.7). Therefore, the mask a^d is a dual mask of the given mask a. On the other hand, (6.6) can be rewritten as

$$(6.8) \qquad \sum_{\beta\in\mathbb{Z}^s} a^d(2\beta+\varepsilon)(2\beta+\varepsilon)^\mu = h^a(\mu), \qquad \varepsilon\in\Omega\backslash\{0\},\ |\mu|<k,\ \mu\in\mathbb{Z}_+^s.$$

By the definition of sum rules, to verify that the sequence a^d satisfies the sum rules of order k, it suffices to demonstrate that

$$(6.9) \qquad \sum_{\beta\in\mathbb{Z}^s} a^d(2\beta)(2\beta)^\mu = h^a(\mu) \qquad \forall\,|\mu|<k,\ \mu\in\mathbb{Z}_+^s.$$

As in the proof of Theorem 6.1, from (6.7), we have

$$\begin{aligned}&\sum_{\beta\in\mathbb{Z}^s} a^d(2\beta)(2\beta)^\mu\\ &= 2^s\delta(\mu) - \sum_{0\le\nu\le\mu} c_{\nu,\mu} \sum_{\varepsilon\in\Omega\backslash\{0\}}\sum_{\alpha\in\mathbb{Z}^s} \overline{a(2\alpha+\varepsilon)}(2\alpha+\varepsilon)^{\mu-\nu} \sum_{\beta\in\mathbb{Z}^s} a^d(2\beta+\varepsilon)(2\beta+\varepsilon)^\nu,\end{aligned}$$

where $c_{\nu,\mu} := (-1)^{|\mu-\nu|}\mu!/(\nu!(\mu-\nu)!)$. Since the sequence a is an interpolatory mask, it is easily seen that

$$\sum_{\varepsilon\in\Omega\backslash\{0\}}\sum_{\alpha\in\mathbb{Z}^s}\overline{a(2\alpha+\varepsilon)}(2\alpha+\varepsilon)^{\mu-\nu} = \overline{\langle a,\ p_{\mu-\nu}\rangle} - \delta(\mu-\nu).$$

Therefore, it follows from (6.8) that for any $\mu \in \mathbb{Z}_+^s$ such that $|\mu| < k$,

$$\begin{aligned}\sum_{\beta\in\mathbb{Z}^s} a^d(2\beta)(2\beta)^\mu &= 2^s\delta(\mu) - \sum_{0\le\nu\le\mu} c_{\nu,\mu}\left(\overline{\langle a,\ p_{\mu-\nu}\rangle} - \delta(\mu-\nu)\right) h^a(\nu)\\ &= (1-2^s)h^a(\mu) + 2^s\delta(\mu) - \sum_{0\le\nu<\mu} c_{\nu,\mu}\overline{\langle a,\ p_{\mu-\nu}\rangle}\, h^a(\nu)\\ &= h^a(\mu),\end{aligned}$$

where in the last equality we used (6.4) for $h^a(\mu)$. This completes the proof. □

It is evident that the above CBC algorithm can produce all the dual masks for any given interpolatory mask. In general, if the set E_ε is large enough, the equation in step (4) must have at least one solution. We point out that based on Theorem 6.1, the CBC algorithm can be generalized to the general case. In a forthcoming paper, we shall propose a similar CBC algorithm such that for any given scaling function with a mask a, we can construct a dual mask of the mask a which can satisfy the sum rules of arbitrary order. Based on the work [26], here we present a concrete way to implement the above general CBC algorithm in the bivariate case. By $\#E$ we denote the cardinality of a set E. Let us cite a result from [26].

LEMMA 6.2 (see [26, Lemma 4.1]). *Let $l_1,\dots,l_r$ be distinct parallel lines in $\mathbb{R}^2$ and let E be a subset of $l_1\cup\cdots\cup l_r$ such that $\#(E\cap l_j) = j$ for each $j = 1,\dots,r$. Suppose p is a polynomial in two variables of (total) degree at most $r-1$. If p vanishes on E, then p vanishes everywhere. Consequently, the square matrix $(t_1^{\nu_1}t_2^{\nu_2})_{(t_1,t_2)\in E, 0\le\nu_1+\nu_2\le r-1}$ is nonsingular.*

Now for any bivariate interpolatory mask a which is symmetric about the two coordinate axes, the following algorithm provides us with a method to construct a dual mask which satisfies the sum rules of arbitrary order.

TCBC ALGORITHM.

(1) *Let a bivariate mask a satisfy $\sum_{\beta\in\mathbb{Z}^2} a(\beta) = 4, a(0) = 1,$ and $a(2\beta) = 0$ $\forall\, \beta \in \mathbb{Z}^2\backslash\{0\}$ with symmetry about the two coordinate axes, i.e.,*

$$a(\beta_1,\beta_2) = a(-\beta_1,\beta_2) = a(\beta_1,-\beta_2) = a(-\beta_1,-\beta_2); \tag{6.10}$$

(2) *let k be any fixed positive integer;*

(3) *calculate $h^a(2\mu)$ as in (6.4) for $\mu \in \mathbb{Z}_+^2$ such that $|\mu| < k$;*

(4) *let the set $E := \{(\beta_1,\beta_2) \in \mathbb{Z}^2\ :\ \beta_1 \ge 0,\ \beta_2 \ge 0$ and $\beta_1+\beta_2 < k\}$;*

(5) *let $\Omega' := \{(1,0),(0,1),(1,1)\}$. For each $\varepsilon \in \Omega'$, there is a unique solution for $\{b_{\varepsilon,\beta}, \beta \in E\}$ to the following linear system:*

$$\sum_{\beta\in E} b_{\varepsilon,\beta}(2\beta+\varepsilon)^{2\mu} = h^a(2\mu)/4, \qquad |\mu| < k, \mu \in \mathbb{Z}_+^2;$$

(6) *for each $(\varepsilon_1,\varepsilon_2) \in \Omega'$, set $a^d(2\beta_1+\varepsilon_1, 2\beta_2+\varepsilon_2) = 0\ \forall\,(\beta_1,\beta_2) \in \mathbb{Z}_+^2\backslash E$, and for any $(\beta_1,\beta_2) \in E$,*

$$a^d(2\beta_1+\varepsilon_1, 2\beta_2+\varepsilon_2) = \big(1+\delta(2\beta_1+\varepsilon_1)\big)\big(1+\delta(2\beta_2+\varepsilon_2)\big)b_{(\varepsilon_1,\varepsilon_2),(\beta_1,\beta_2)};$$

(7) *for each* $\varepsilon \in \Omega'$*, complete each coset* $a(2\beta+\varepsilon), \beta \in \mathbb{Z}^2$*, by symmetry as in* (6.10) *and set*

$$a^d(2\beta) := 4\delta(\beta) - \sum_{\varepsilon\in\Omega'} \sum_{\alpha\in\mathbb{Z}^2} \overline{a(2\alpha-2\beta+\varepsilon)}a^d(2\alpha+\varepsilon), \quad \beta \in \mathbb{Z}^2;$$

(8) *then the mask* a^d *is a dual mask of the given mask* a*, satisfies the sum rules of order* $2k$*, and it is symmetric about the two coordinate axes.*

The above algorithm is called the TCBC algorithm since we choose a special triangle subset E of $\mathbb{Z}^2$ it. The existence and uniqueness of the solution in step (5) of the TCBC algorithm are guaranteed by Lemma 6.2. The claim that the mask a^d satisfies the sum rules of order $2k$ follows from the fact that if the sequence a is symmetric about the two coordinate axes, then $\langle a, p_{(\nu_1,\nu_2)}\rangle = 0$ for any $(\nu_1,\nu_2) \in \mathbb{Z}_+^2$ with either ν_1 or ν_2 being an odd integer. We mention that if, in the TCBC algorithm, the mask a is also symmetric about the lines $x_1 = x_2$ and $x_1 = -x_2$, then the resulting dual mask also has such properties. For this case, in step (5) of the TCBC algorithm, we need to deal only with the coset of a^d at $2\beta+\varepsilon, \beta \in \mathbb{Z}^2$, for $\varepsilon \in \{(1,0),(1,1)\}$. The coset of the mask a^d at $2\beta+(0,1), \beta\in\mathbb{Z}^2$, is obtained by symmetry.

Let us illustrate the above general theory by giving an example. Let φ_h be the bivariate hat function with its mask a_h supported on $[-1,1]^2 \cap \mathbb{Z}^2$ and given by

$$\begin{pmatrix} 1/4 & 1/2 & 1/4 \\ 1/2 & 1 & 1/2 \\ 1/4 & 1/2 & 1/4 \end{pmatrix}. \tag{6.11}$$

An easy calculation gives us

$$\langle a, p_{(\mu_1,\mu_2)}\rangle = \begin{cases} \big(1+\delta(\mu_1)\big)\big(1+\delta(\mu_2)\big), & (\mu_1,\mu_2) \in 2\mathbb{Z}_+^2; \\ 0 & \text{otherwise.} \end{cases}$$

Let H_r denote the dual mask of the mask a_h derived by the TCBC algorithm such that H_r satisfies the sum rules of order $2r-2$.

From the TCBC algorithm, it is easily seen that

$$\operatorname{supp} H_r \subseteq \{\, (\beta_1,\beta_2) \in \mathbb{Z}^2 \;:\; |\beta_1| \le 2r-2,\, |\beta_2| \le 2r-2,\, |\beta_1|+|\beta_2| \le 2r \,\}$$

and it is symmetric about the x_1-axis, x_2-axis, and the lines $x_1 = x_2$ and $x_1 = -x_2$.

Let us give an example of the dual mask H_r for $r = 3$ in the following.

Example 6.3. The mask H_3 is supported on $[-4,4]^2$ and is given by

$$\begin{pmatrix}
0 & 0 & \frac{3}{256} & 0 & \frac{9}{128} & 0 & \frac{3}{256} & 0 & 0 \\
0 & 0 & 0 & -\frac{3}{64} & -\frac{3}{32} & -\frac{3}{64} & 0 & 0 & 0 \\
\frac{3}{256} & 0 & -\frac{1}{32} & -\frac{1}{32} & -\frac{51}{128} & -\frac{1}{32} & -\frac{1}{32} & 0 & \frac{3}{256} \\
0 & -\frac{3}{64} & -\frac{1}{32} & \frac{11}{32} & \frac{21}{32} & \frac{11}{32} & -\frac{1}{32} & -\frac{3}{64} & 0 \\
\frac{9}{128} & -\frac{3}{32} & -\frac{51}{128} & \frac{21}{32} & \frac{75}{32} & \frac{21}{32} & -\frac{51}{128} & -\frac{3}{32} & \frac{9}{128} \\
0 & -\frac{3}{64} & -\frac{1}{32} & \frac{11}{32} & \frac{21}{32} & \frac{11}{32} & -\frac{1}{32} & -\frac{3}{64} & 0 \\
\frac{3}{256} & 0 & -\frac{1}{32} & -\frac{1}{32} & -\frac{51}{128} & -\frac{1}{32} & -\frac{1}{32} & 0 & \frac{3}{256} \\
0 & 0 & 0 & -\frac{3}{64} & -\frac{3}{32} & -\frac{3}{64} & 0 & 0 & 0 \\
0 & 0 & \frac{3}{256} & 0 & \frac{9}{128} & 0 & \frac{3}{256} & 0 & 0
\end{pmatrix}.$$

It is a dual mask of the mask a_h and satisfies the sum rules of order 4. By calculation, we have $\nu_2(\phi_{H_3}) \approx 0.42927$. Therefore, by Theorem 2.3 and Corollary 5.3, the dual scaling function ϕ_{H_3} attains the optimal sum rules but does not attain the optimal L_2 smoothness order since $\nu_2(\phi_{H_3}) < \nu_2(\phi_{b_3}) - \nu_1(\varphi_h) \approx 1.17513$.

In the rest of this section, we shall modify the above TCBC algorithm to construct a new family of optimal biorthogonal wavelets by shrinking the support of each H_r. Since the mask a_h has full symmetry, we need to deal only with $\varepsilon \in \{(1,0),(1,1)\}$ in step (5) of the TCBC algorithm. The only part we need to modify in the TCBC algorithm is steps (5) and (6). All the other steps are the same. Throughout the rest of this section, the mask a in the TCBC algorithm is assumed to be a_h given in (6.11).

Let the set E be given in step (4) of the TCBC algorithm and let $b_\beta, \beta \in E$, be the unique solution of the following linear system:

$$\sum_{\beta\in E} b_\beta\big(2\beta+(1,1)\big)^{2\mu} = h^a(2\mu)/4, \qquad |\mu|<k, \mu\in\mathbb{Z}_+^2.$$

Set $a^d(2\beta+(1,1)) = b_\beta, \beta \in E$, and $a^d(2\beta+(1,1)) = 0, \beta \in \mathbb{Z}_+^2\backslash E$. Take F to be the following set:

$$F := \{\,(\beta_1,\beta_2)\in\mathbb{Z}_+^2 \ :\ \beta_1+\beta_2 = k \quad\text{and}\quad \beta_2>0\,\}.$$

Now we set $a^d(2\beta+(1,0)) = 0$ for any $\beta \in \mathbb{Z}_+^2\backslash(E\cup F)$ and

$$a^d(2\beta_1+1,2\beta_2) = \big(1+\delta(\beta_2)\big)c_{(\beta_1,\beta_2)}, \qquad (\beta_1,\beta_2)\in E\cup F,$$

with some yet-to-be-determined parameters $c_\beta, \beta \in E\cup F$.

This extra freedom $c_\beta, \beta \in F$, given by F will be used to reduce the support of the mask a^d at the coset $(0,0)$ constructed in step (7) of the TCBC algorithm. More precisely, we try to adjust the coefficients of H_{k-1} on the set $\{(\beta_1,\beta_2)\in\mathbb{Z}^2 : \beta_1+\beta_2 = 2k-2\}$ to be zero. By using symmetry, after a simple calculation, it is easily seen that this restriction is equivalent to the following linear system:

$$c_{(\beta_1,\beta_2)} + c_{(\beta_2-1,\beta_1+1)} + b_{(\beta_1,\beta_2-1)}/2 = 0 \qquad \forall\,(\beta_1,\beta_2)\in F.$$

By simply setting $c_{(\beta_1,\beta_2)} = 0$ for any $(\beta_1,\beta_2)\in F$ such that $k/2 \le \beta_1 < k$, the above linear system has a unique solution $c_\beta, \beta \in F$. Now the following linear system:

$$\sum_{\beta\in E} c_\beta\big(2\beta+(1,0)\big)^{2\mu} = h^a(2\mu)/4 - \sum_{\beta\in F} c_\beta\big(2\beta+(1,0)\big)^{2\mu}, \qquad |\mu|<k, \mu\in\mathbb{Z}_+^2,$$

has a unique solution for $c_\beta, \beta \in E$, by Lemma 6.2.

Set $a^d(2\beta_1,2\beta_2+1) = a^d(2\beta_2+1,2\beta_1), (\beta_1,\beta_2)\in\mathbb{Z}_+^2$. By the TCBC algorithm, we have a dual mask a^d of the mask a_h such that a^d satisfies the sum rules of order $2k$. We shall use $\mathcal{H}_r$ to denote the dual mask of the mask a_h derived from the above modified TCBC algorithm such that $\mathcal{H}_r$ satisfies the sum rules of order $2r-2$. For each positive integer r, by G_r we denote the following set:

$$G_r := \{(\alpha_1,\alpha_2)\in\mathbb{Z}^2 \ :\ |\alpha_1|+|\alpha_2| = 2r-1 \text{ and either } |\alpha_1| \text{ or } |\alpha_2| \\ \text{is an even number less than } r-1\}.$$

To sum up and restate the above construction of the dual masks $\mathcal{H}_r$ of the mask a_h, we have the following theorem.

Theorem 6.4. *Let r be a positive integer greater than two. Then there exists a unique refinement mask $\mathcal{H}_r$ satisfying the following conditions:*

(1) *$\mathcal{H}_r$ is supported on*

$$\big\{ (\alpha_1, \alpha_2) \in \mathbb{Z}^2 \ : \ |\alpha_1| + |\alpha_2| \le 2r-1, \ \max\{ |\alpha_1|, |\alpha_2| \} \le 2r-2 \big\} \backslash G_r;$$

(2) *$\mathcal{H}_r$ is symmetric about the two coordinate axes, the lines $x_1 = x_2, x_1 = -x_2$;*
(3) *$\mathcal{H}_r$ satisfies the sum rules of order $2r-2$;*
(4) *$\mathcal{H}_r$ and a_h (the mask a_h is given in (6.11)) satisfy the dual relation (6.1).*

Remark 6.5. The set G_r appears strange. The reason is that, in our modified TCBC algorithm, we set $c_{(\beta_1,\beta_2)} = 0$ for any $(\beta_1, \beta_2) \in F$ such that $(r-1)/2 \le \beta_1 < r-1$. Note that both H_r and $\mathcal{H}_r$ are symmetric about the x_1-axis, x_2-axis, and the lines $x_1 = x_2$ and $x_1 = -x_2$. Let a be a multivariate interpolatory mask such that a satisfies the sum rules of order k. For any positive integer r, by convolution, it is easy to obtain a new interpolatory mask b such that $\widetilde{b}(z) = \big(\widetilde{a}(z)\big)^r \widetilde{c_r}(z)$, $z \in \mathbb{T}^s$, where $\widetilde{c_r}(z)$ can be explicitly expressed by using $\widetilde{a}(z)$. Such an interpolatory mask b satisfies the sum rules of order rk by Theorem 2.2. See Proposition 3.7 in Han [24] for a detailed discussion on construction of biorthogonal wavelets using this convolution method. Such a method was further discussed by Ji, Riemenschneider, and Shen [27]. The TCBC algorithm proposed in this paper can be generalized to the general case, and it has many advantages over the convolution method. We shall illustrate the advantages of our CBC and TCBC algorithms over the convolution method and other known methods in the literature on construction of biorthogonal wavelets elsewhere.

Let us provide detail in the following for the masks $\mathcal{H}_3$ and $\mathcal{H}_4$.

Example 6.6. The mask $\mathcal{H}_3$ is supported on $[-4,4]^2$ and is given by

$$\begin{pmatrix}
0 & 0 & 0 & \frac{3}{128} & \frac{3}{64} & \frac{3}{128} & 0 & 0 & 0 \\
0 & 0 & 0 & -\frac{3}{64} & -\frac{3}{32} & -\frac{3}{64} & 0 & 0 & 0 \\
0 & 0 & \frac{1}{16} & -\frac{1}{8} & -\frac{3}{8} & -\frac{1}{8} & \frac{1}{16} & 0 & 0 \\
\frac{3}{128} & -\frac{3}{64} & -\frac{1}{8} & \frac{11}{32} & \frac{51}{64} & \frac{11}{32} & -\frac{1}{8} & -\frac{3}{64} & \frac{3}{128} \\
\frac{3}{64} & -\frac{3}{32} & -\frac{3}{8} & \frac{51}{64} & \frac{33}{16} & \frac{51}{64} & -\frac{3}{8} & -\frac{3}{32} & \frac{3}{64} \\
\frac{3}{128} & -\frac{3}{64} & -\frac{1}{8} & \frac{11}{32} & \frac{51}{64} & \frac{11}{32} & -\frac{1}{8} & -\frac{3}{64} & \frac{3}{128} \\
0 & 0 & \frac{1}{16} & -\frac{1}{8} & -\frac{3}{8} & -\frac{1}{8} & \frac{1}{16} & 0 & 0 \\
0 & 0 & 0 & -\frac{3}{64} & -\frac{3}{32} & -\frac{3}{64} & 0 & 0 & 0 \\
0 & 0 & 0 & \frac{3}{128} & \frac{3}{64} & \frac{3}{128} & 0 & 0 & 0
\end{pmatrix}.$$

Then the mask $\mathcal{H}_3$ satisfies the sum rules of order 4 and $\phi_{\mathcal{H}_3}$ is a dual scaling function of φ_h with $\nu_2(\phi_{\mathcal{H}_3}) \approx 1.17513$. Thus, the function $\phi_{\mathcal{H}_3}$ is an optimal dual scaling function of the function φ_h in the L_2 norm sense since $\nu_2(\phi_{\mathcal{H}_3}) \approx \nu_2(\phi_{b_3}) - \nu_1(\varphi_h)$.

The graphs and contours of the scaling function φ_h and the dual scaling function $\phi_{\mathcal{H}_3}$ with their associated wavelets are given in Figures 6.2–6.4.

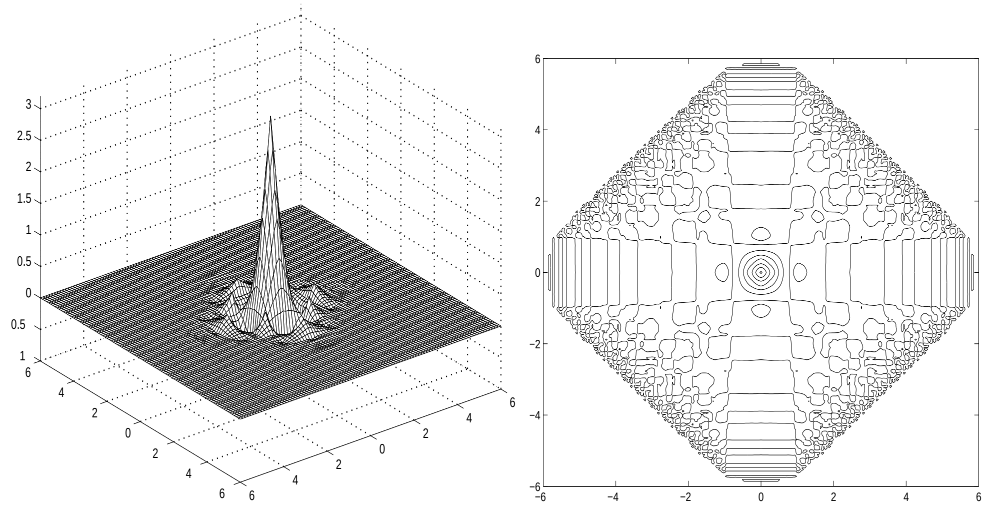

FIG. 6.1. *The graph and contour of the function* $\phi_{\mathcal{H}_4}$.

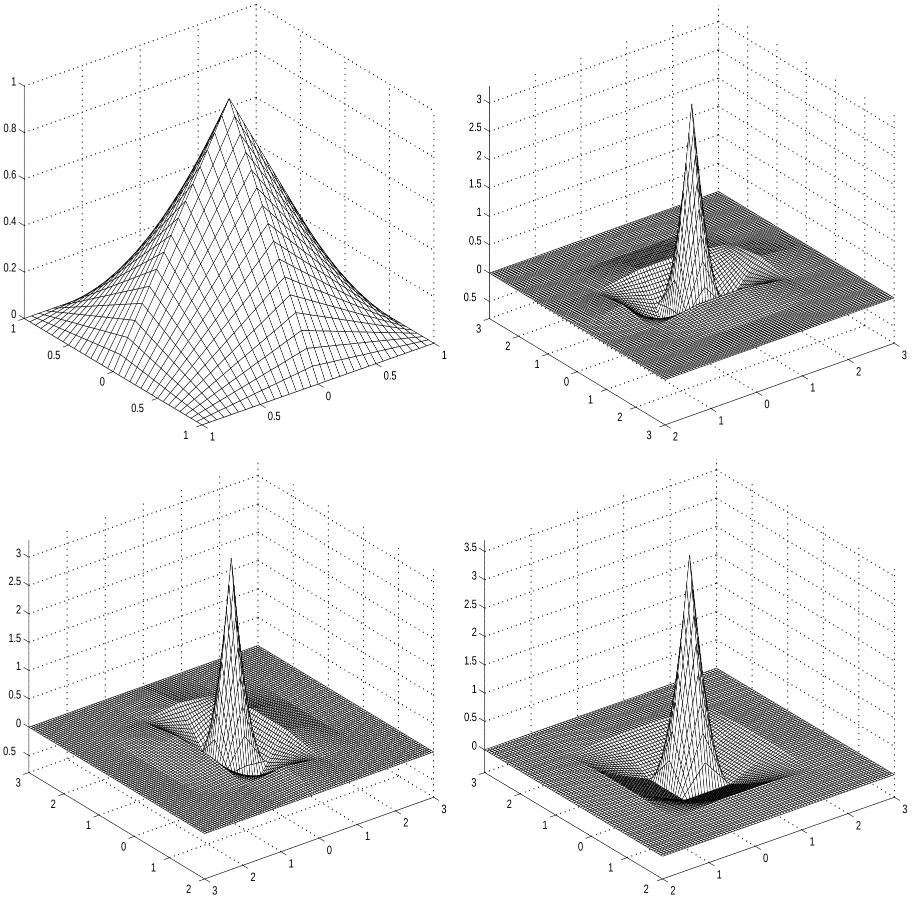

FIG. 6.2. (a) *is the scaling function* φ_h *and* (b), (c), *and* (d) *are the associated three wavelets* ψ_1, ψ_2, *and* ψ_3 *in Example* 6.6.

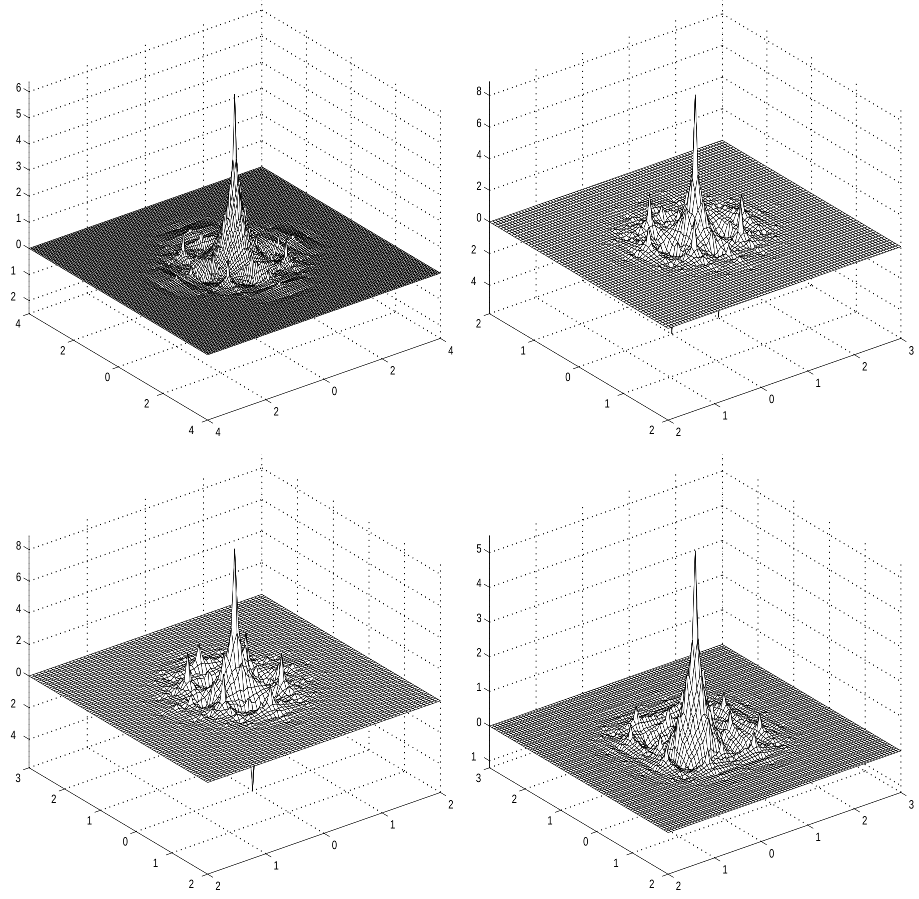

FIG. 6.3. (a) *is the dual scaling function* $\phi_{\mathcal{H}_3}$ *and* (b), (c), *and* (d) *are the associated three dual wavelets* ψ_1^d, ψ_2^d, *and* ψ_3^d *in Example* 6.6.

Example 6.7. The mask $\mathcal{H}_4$ is supported on $[-6,6]^2$ and the part of $\mathcal{H}_4$ in the first quadrant is supported on $[0,6]^2$ and is given by

$$\begin{pmatrix}
-\frac{5}{512} & -\frac{5}{1024} & 0 & 0 & 0 & 0 & 0 \\
\frac{5}{256} & \frac{5}{512} & 0 & 0 & 0 & 0 & 0 \\
\frac{83}{1024} & \frac{145}{4096} & -\frac{15}{2048} & -\frac{9}{4096} & 0 & 0 & 0 \\
-\frac{363}{2048} & -\frac{87}{1024} & \frac{15}{1024} & \frac{9}{1024} & -\frac{9}{4096} & 0 & 0 \\
-\frac{359}{1024} & -\frac{69}{512} & \frac{1}{16} & \frac{15}{1024} & -\frac{15}{2048} & 0 & 0 \\
\frac{1723}{2048} & \frac{401}{1024} & -\frac{69}{512} & -\frac{87}{1024} & \frac{145}{4096} & \frac{5}{512} & -\frac{5}{1024} \\
\frac{493}{256} & \frac{1723}{2048} & -\frac{359}{1024} & -\frac{363}{2048} & \frac{83}{1024} & \frac{5}{256} & -\frac{5}{512}
\end{pmatrix}$$

with the number $\frac{493}{256}$ at the bottom-left as $\mathcal{H}_4(0,0)$. Since $\mathcal{H}_4$ is symmetric about the coordinate axes, other parts of $\mathcal{H}_4$ are obtained by symmetry as in (6.10). By calculation, we have $\nu_2(\phi_{\mathcal{H}_4}) \approx 1.79313$ and the mask $\mathcal{H}_4$ satisfies the sum rules of order 6. Thus, the function $\phi_{\mathcal{H}_4}$ is an optimal dual scaling function of φ_h in the L_2

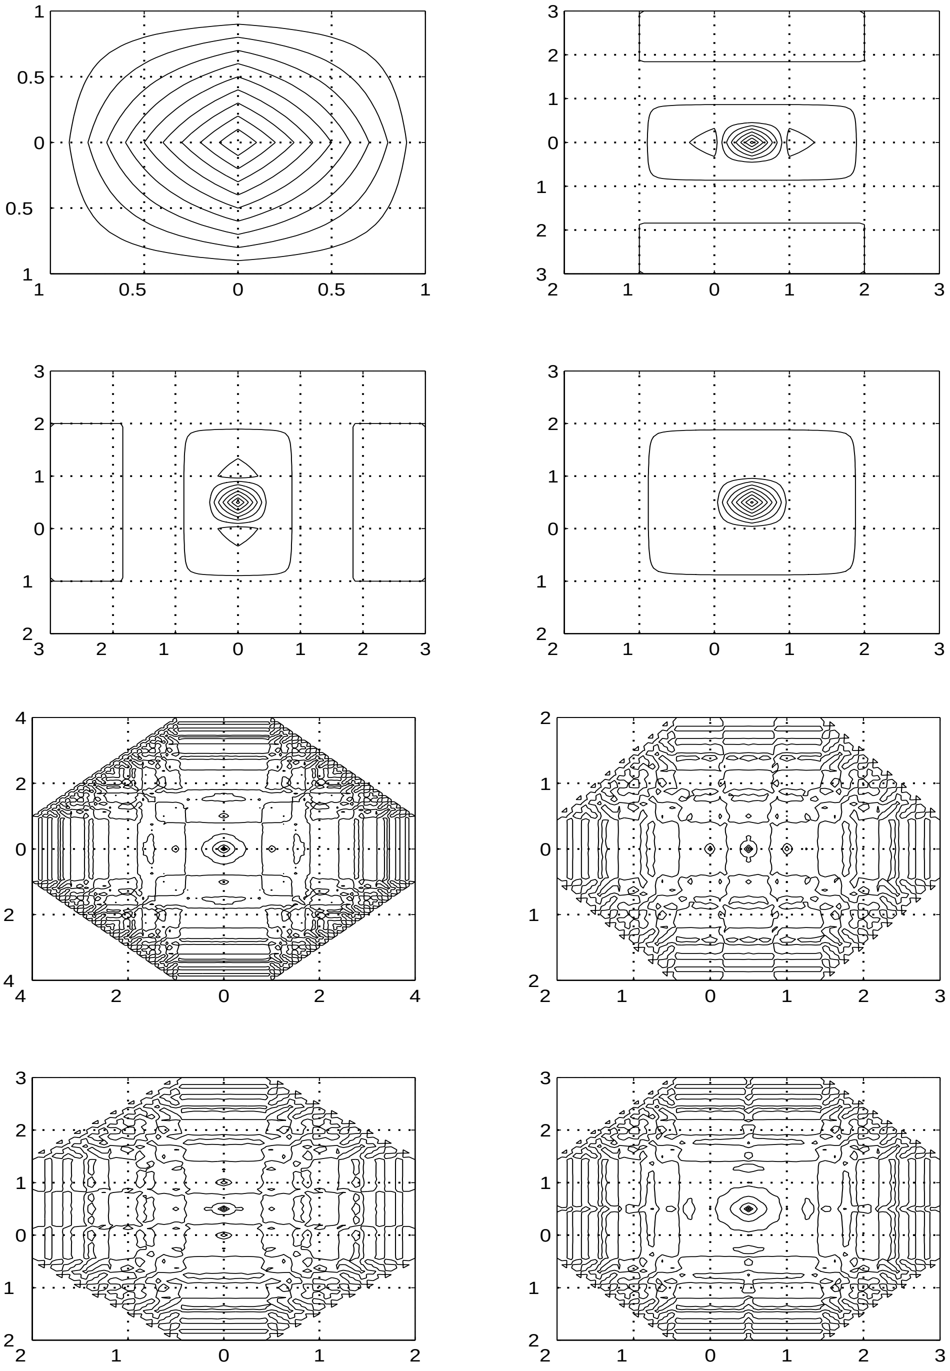

Fig. 6.4. *The contours of the scaling function* φ_h*, its dual scaling function* $\phi_{\mathcal{H}_3}$*, and the associated wavelets and dual wavelets in Example* 6.6.

Table 6.1

r	$\nu_2(\phi_{b_r})$	$\nu_2(\phi_{a^d_{t_r}})$	$\nu_2(\phi_{H_r})$	$\nu_2(\phi_{\mathcal{H}_r})$	$N(a^d_{t_r})$	$N(H_r)$	$N(\mathcal{H}_r)$
3	3.17513	1.17513	0.42927	1.17513	81	49	49
4	3.79313	1.79313	0.98084	1.79313	169	97	101
5	4.34408	2.34408	1.46708	2.34408	289	161	161
6	4.86202	2.86202	1.90387	2.86202	441	241	245
7	5.36283	3.36283	2.30033	3.36283	625	337	337
8	5.85293	3.85293	2.66264	3.85293	841	449	453
9	6.33524	4.33524	2.99578	4.33524	1089	577	577
10	6.81144	4.81144	3.30381	4.81144	1369	721	725
11	7.28260	5.28260	3.58991	5.28260	1681	881	881
12	7.74953	5.74953	3.85672	5.74953	2025	1057	1061

norm sense since $\nu_2(\phi_{\mathcal{H}_4}) \approx \nu_2(\phi_{b_4}) - \nu_1(\varphi_h)$. The graph and contour of $\phi_{\mathcal{H}_4}$ are presented in Figure 6.1.

Recall that by b_r we denote the interpolatory refinement mask supported on $[1-2r, 2r-1]$ as constructed by Deslauriers and Dubuc in [18]. By $\phi_{a^d_{t_r}}$ we denote the tensor product dual scaling function of φ_h with its mask $a^d_{t_r}$ satisfying

$$\overline{\widetilde{a_h}(z_1,z_2)}\widetilde{a^d_{t_r}}(z_1,z_2) = \overline{\widetilde{b_r}(z_1)}\widetilde{b_r}(z_2), \qquad (z_1,z_2) \in \mathbb{T}^2.$$

Let the masks H_r and $\mathcal{H}_r$ be the dual masks constructed by the TCBC algorithm and the modified TCBC algorithm, respectively, such that both H_r and $\mathcal{H}_r$ satisfy the sum rules of order $2r-2$. In the following, we use $N(a)$ to denote the number of nonzero coefficients in the refinement mask a. The values of $\nu_2(\phi_{b_r})$ are taken from [23]. Table 6.1 shows that for $r = 3, \ldots, 12$, the function $\phi_{\mathcal{H}_r}$ is an optimal dual scaling function of φ_h in the L_2 norm sense.

Acknowledgments. The author is indebted to Professor Rong-Qing Jia for his advice and comments on this paper and to Professor Zeev Ditzian for providing his reprints and sharing his ideas.

THE INFLUENCE OF LATERAL BOUNDARY CONDITIONS ON THE ASYMPTOTICS IN THIN ELASTIC PLATES*

MONIQUE DAUGE†, ISABELLE GRUAIS†, AND ANDREAS RÖSSLE‡

Abstract. Here we investigate the limits and the boundary layers of the three-dimensional displacement in thin elastic plates as the thickness tends to zero in each of the eight main types of lateral boundary conditions on their edges: hard and soft clamped, hard and soft simple support, friction conditions, sliding edge, and free plates. Relying on construction algorithms [M. Dauge and I. Gruais, *Asymptotic Anal.*, 13 (1996), pp. 167–197], we establish an asymptotics of the displacement combining inner and outer expansions. We describe the two first terms in the outer expansion: these are Kirchhoff–Love displacements satisfying prescribed boundary conditions that we exhibit. We also study the first boundary layer term: when the transverse component is clamped, it has generically nonzero transverse and normal components, whereas when the transverse component is free, the first boundary layer term is of bending type and has only its nonzero in-plane tangential component.

Key words. thin plates, linear elasticity, singular perturbation, boundary layer, asymptotic expansion

1. Introduction.

The problem of thin elastic plate bending in linearized elastostatics has been addressed for more than 150 years (the first correct model was presented in a paper by Kirchhoff [18] published in 1850). But due to the singular perturbation nature of the problem as the thickness of the plate tends to zero, it is not quite straightforward to perform a rigorous mathematical analysis of characteristic fields and tensors, solutions of the three-dimensional equations. However, the knowledge of accurate asymptotics allows first an evaluation of the validity of mechanical models, and second, the construction of simplified and performing numerical models.

In the case when the plate is clamped along its lateral boundary, the situation is now well-known, at least theoretically: The comparison between three-dimensional and two-dimensional models was first performed by the construction of infinite *formal* asymptotic expansions; see Friedrichs and Dressler [15], Gol'denveizer [16], Gregory and Wan [17]. Shortly before, Morgenstern [21] was indeed the first to prove that the Kirchhoff model [18] is the correct asymptotic limit of the three-dimensional model when the thickness approaches zero in the hard clamped, hard simply supported and free plate situations by using the Prager–Synge hypercircle theorem [29]. Next, rigorous error estimates between the three-dimensional solution and its limit were proved by Shoikhet [31] and by Ciarlet and Destuynder [5, 13, 3]. Further terms were exhibited by Nazarov and Zorin [24], and the whole asymptotic expansion was constructed in [8, 9].

The research of this author was supported by a grant of the German National Science Foundation (DFG, graduate collegium "GKKS – Modelling and discretization methods in continua and fluids").

Different types of lateral boundary conditions are of interest: let us quote the soft clamped plate where the tangential in-plane component of the displacement is free, the hard simply supported plate where its normal component is free, the soft simply supported plate where both above components of the displacement are free, and also the totally free plate. These cases were investigated by Arnold and Falk [1], where an asymptotics for the Reissner–Mindlin plate was constructed, and by Chen [2], where error bounds between the three-dimensional solution and its limit were evaluated.

In this paper, we prove the validity of an infinite asymptotic expansion of the displacement with optimal error estimates in H^1, L^2, and energy norms. Such an expansion can be differentiated and provides corresponding results for the stress and the strain tensors; see [7] for the clamped case. As in [24] and [8, 9], this asymptotics includes, simultaneously,

- an outer part containing displacements only depending on the in-plane variables x_* and on the scaled transverse variable x_3;
- an inner part containing exponentially decaying profiles (boundary layer terms), depending on two scaled variables (x_3 and $t = r/\varepsilon$, where r is the distance to the lateral boundary).

As material law, we choose to remain in the framework of homogeneous, isotropic materials, which allows us to uncouple the boundary layer terms $\boldsymbol{\varphi}$ into two parts:

- the horizontal tangential component φ_s governed by the Laplace equation,
- the two other components φ_t and φ_3 governed by the bidimensional Lamé equations, whose solutions can themselves be uncoupled in membrane and bending modes, i.e., possessing parity properties with respect to the transverse variable: the former having an even φ_t and an odd φ_3 and the latter having converse properties.

Thus, conditions ensuring the exponential decay at infinity of solutions of the above problems can be made explicit, resulting in simple coupling formulas between the inner and outer parts of the expansion. These coupling formulas lead to the determination of boundary conditions for the limit membrane and bending problems.

The first boundary layer terms bring the quantitative limitation of accuracy of bidimensional models. In the clamped and simple support cases, we find a strong boundary layer term with generically nonzero membrane and bending parts, whereas in the frictional and free cases, we find a first boundary layer term which has the bending type and only the in-plane tangential component nonzero, and moreover, the subprincipal term in the outer part of the expansion is a Kirchhoff–Love displacement as usual, but with zero membrane part. Thus if the right-hand side has the membrane type, the solution of the three-dimensional Lamé equations for the free plate converges to the usual limit Kirchhoff–Love displacement with improved accuracy.

This paper contains twelve sections: in section 1 we introduce the elasticity problems and in section 2 we present our results in the form of several tables. In section 3 we give as an algorithm the construction rules for the outer part of the Ansatz, while in section 4 we formulate the boundary value problems on a half-strip governing the boundary layer profiles $\boldsymbol{\varphi}$, and in section 5 we give the conditions on the data ensuring the existence of exponentially decreasing solutions to these problems. The five next sections are devoted to each of the eight types of lateral boundary conditions with more emphasis on five of them: hard and soft clamped, hard simple support, sliding edge and free plates. In section 11, we prove error estimates between the three-dimensional solution and any truncated series from the asymptotic expansion, and analyze the regularity of the different terms in the asymptotics: whereas the outer expansion terms are smooth if the data are so, the profiles have singularities along the edges of the plate. We conclude in section 12 with considerations about relative errors between the three-dimensional solution and a limited two-dimensional solution, which has to be carefully chosen according to what we wish to approximate (the displacement in H^1 norm, or the strain in L^2 norm).

2. Lateral boundary conditions. We aim to study the behavior of the displacement field $\boldsymbol{u}^\varepsilon$ in a family of thin elastic three-dimensional plates Ω^ε as the thickness parameter ε tends to zero. The plates Ω^ε are constituted of a homogeneous, isotropic material with Lamé constants and μ, and are defined as follows:

$$\Omega^\varepsilon = \omega \times (-\varepsilon, +\varepsilon) \quad \text{with } \ \omega \subset \mathbb{R}^2 \ \text{ a regular domain and } \varepsilon > 0\,.$$

Let $\Gamma^\varepsilon_\pm$ be their upper and lower faces $\omega \times \{\pm\varepsilon\}$ and Γ^ε_0 be their lateral faces $\partial\omega \times (-\varepsilon, +\varepsilon)$.

2.1. Cartesian, scaled, and local coordinates. Let $\tilde{x} = (x_1,\, x_2,\, \tilde{x}_3)$ be the Cartesian coordinates in the plates Ω^ε. We will often denote by x_* the in-plane coordinates $(x_1,\, x_2) \in \omega$ and by α or β the indices in $\{1, 2\}$ corresponding to the in-plane variables. The dilatation along the vertical axis ($x_3 = \varepsilon^{-1}\,\tilde{x}_3$) transforms Ω^ε into the fixed reference configuration $\Omega = \omega \times (-1, +1)$:

$$\tilde{x} = (x_*,\, \tilde{x}_3) \in \Omega^\varepsilon = \omega \times (-\varepsilon, +\varepsilon) \longmapsto x = (x_*,\, x_3) \in \Omega = \omega \times (-1, +1). \tag{2.1}$$

We also have to introduce in-plane local coordinates (r, s) in a neighborhood of the boundary $\partial\omega$. Let $\boldsymbol{n}$ be the inner unit normal to $\partial\omega$ and $\boldsymbol{\tau}$ be the tangent unit vector field to $\partial\omega$ such that the basis $(\boldsymbol{\tau}, \boldsymbol{n})$ is direct in each point of $\partial\omega$. Denote by s a curvilinear abscissa (arc length) along $\partial\omega$ oriented according to $\boldsymbol{\tau}$. Let $\mathbb{S} \sim \partial\omega$ be the set of the values of s:

$$\mathbb{S} \ni s \longmapsto \boldsymbol{\gamma}(s) \in \partial\omega.$$

For a point $x_* \in \mathbb{R}^2$, let $r = r(x_*)$ be its signed distance to $\partial\omega$ oriented along $\boldsymbol{n}$; i.e., r is this distance if $x_* \in \omega$ and r is minus this distance if $x_* \notin \omega$. If $|r|$ is small enough, there exists a unique point $x^0_* \in \partial\omega$ such that $|r| = \operatorname{dist}(x_*, x^0_*)$ and we define $s = s(x_*)$ as the curvilinear abscissa of x^0_*. Thus, we have a tubular neighborhood of $\partial\omega$ which is diffeomorphic to $(-r^0, r^0) \times \mathbb{S}$ via the change of variables $x_* \mapsto (r, s)$. And, in this tubular neighborhood, the partial derivatives ∂_r and ∂_s are well defined (and, of course, commute with each other).

We extend the vector fields $\boldsymbol{n}$ and $\boldsymbol{\tau}$ from $\mathbb{S}$ to $(-r^0, r^0) \times \mathbb{S}$ by

$$\forall r \in (-r^0, r^0), \quad \forall s \in \mathbb{S}, \qquad \boldsymbol{n}(r, s) = \boldsymbol{n}(s) \quad \text{and} \quad \boldsymbol{\tau}(r, s) = \boldsymbol{\tau}(s).$$

We have

$$\boldsymbol{n} = \begin{pmatrix} n_1 \\ n_2 \end{pmatrix} \quad \text{and} \quad \boldsymbol{\tau} = \begin{pmatrix} n_2 \\ -n_1 \end{pmatrix}.$$

Moreover, with $R = R(s)$ the curvature radius of $\partial\omega$ at s from inside ω and $\kappa = \frac{1}{R}$ the curvature, there holds (the last identities are Frenet's relations)

$$\partial_r \boldsymbol{n} = 0, \quad \partial_r \boldsymbol{\tau} = 0 \quad \text{and} \quad \partial_s \boldsymbol{n} = -\,\kappa\,\boldsymbol{\tau}, \quad \partial_s \boldsymbol{\tau} = \,\kappa\,\boldsymbol{n}.$$

Thus, relying on the relation $x_* = \boldsymbol{\gamma}(s) + r\,\boldsymbol{n}(s)$, we obtain

$$\partial_r = n_1\partial_1 + n_2\partial_2 \quad \text{and} \quad \partial_s = (1 - \kappa\, r)(n_2\partial_1 - n_1\partial_2). \tag{2.2}$$

Of course $\partial_n = \partial_r$.

Table 1
Lateral boundary conditions.

ⓘ	Type	Dirichlet	Neumann	$A_{\textcircled{\scriptsize i}}$	$B_{\textcircled{\scriptsize i}}$
①	hard clamped	$\boldsymbol{u}=0,$		$\{n,s,3\}$	
②	soft clamped	$u_n,\ u_3=0,$	$T_s=0$	$\{n,3\}$	$\{s\}$
③	hard simply supported	$u_s,\ u_3=0,$	$T_n=0$	$\{s,3\}$	$\{n\}$
④	soft simply supported	$u_3=0,$	$T_n,\ T_s=0$	$\{3\}$	$\{n,s\}$
⑤	frictional I	$u_n,\ u_s=0,$	$T_3=0$	$\{n,s\}$	$\{3\}$
⑥	sliding edge	$u_n=0,$	$T_s,\ T_3=0$	$\{n\}$	$\{s,3\}$
⑦	frictional II	$u_s=0,$	$T_n,\ T_3=0$	$\{s\}$	$\{n,3\}$
⑧	free		$\boldsymbol{T}=0$		$\{n,s,3\}$

2.2. Cartesian, scaled, and local tensors. The displacement and traction tensors in Ω^ε are denoted $\boldsymbol{u}^\varepsilon$ and $\boldsymbol{T}^\varepsilon$ and their Cartesian components are $(u_1^\varepsilon, u_2^\varepsilon, u_3^\varepsilon)$ and $(T_1^\varepsilon, T_2^\varepsilon, T_3^\varepsilon)$. As $\boldsymbol{u}$ is covariant, it is naturally transformed by the scaling (2.1) into $\boldsymbol{u}(\varepsilon)$ according to

$$u_\alpha(\varepsilon)(x) = u_\alpha^\varepsilon(\tilde{x}),\ \alpha=1,2, \qquad u_3(\varepsilon)(x) = \varepsilon\, u_3^\varepsilon(\tilde{x}), \tag{2.3}$$

whereas $\boldsymbol{T}$, which is contravariant, is transformed according the same laws as the volume force field $\boldsymbol{f}^\varepsilon$: by the scaling (2.1) $\boldsymbol{f}^\varepsilon$ is transformed into $\boldsymbol{f}(\varepsilon)$

$$f_\alpha(\varepsilon)(x) = f_\alpha^\varepsilon(\tilde{x}),\ \alpha=1,2, \qquad f_3(\varepsilon)(x) = \varepsilon^{-1} f_3^\varepsilon(\tilde{x}). \tag{2.4}$$

In the tubular neighborhood $(-r^0, r^0)\times\mathbb{S}$, in view of (2.2) we can introduce the in-plane normal and tangential components of $\boldsymbol{u}$ and $\boldsymbol{T}$ by

$$u_n = n_1u_1 + n_2u_2 \quad\text{and}\quad u_s = (1-\kappa\, r)(n_2u_1 - n_1u_2), \tag{2.5a}$$

$$T_n = n_1T_1 + n_2T_2 \quad\text{and}\quad T_s = (1-\kappa\, r)^{-1}(n_2T_1 - n_1T_2). \tag{2.5b}$$

2.3. The equations of elasticity. As standard, let $e(\boldsymbol{u})$ denote the linearized strain tensor $e_{ij}(\boldsymbol{u}) = \frac{1}{2}\left(\partial_i u_j + \partial_j u_i\right)$ associated with the displacement $\boldsymbol{u}$. Then the stress tensor $\sigma(\boldsymbol{u})$ is given by Hooke's law $\sigma(\boldsymbol{u}) = A\, e(\boldsymbol{u})$, where the rigidity matrix $A = (A_{ijkl})$ of the material is given by $A_{ijkl} = \lambda\,\delta_{ij}\delta_{kl} + \mu(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk})$. The inward traction field at a point on the boundary is $\boldsymbol{T}$ defined as $\sigma(\boldsymbol{u})\,\boldsymbol{n}$, where $\boldsymbol{n}$ is the unit interior normal to the boundary.

We make the assumption that the boundary conditions on the upper and lower faces $\Gamma_\pm^\varepsilon$ of the plate are of traction type. On the lateral face Γ_0^ε we are going to consider the eight "canonical" choices of boundary conditions which will be denoted by ⓘ, where $\mathbf{i} = 1,\dots,8$. Indeed, on the lateral boundary Γ_0^ε we can distinguish three natural components in the displacements or the tractions: normal, horizontal tangential, and vertical, and we obtain eight "canonical" lateral boundary conditions, according to how we choose to prescribe the displacement or the traction for each component.

On Γ_0^ε, we recall that the normal component of $\boldsymbol{u}$ is $u_n = u_1n_1 + u_2n_2$, its horizontal tangential component is $u_s = u_1n_2 - u_2n_1$, and its vertical component is u_3. Similar notations apply to $\boldsymbol{T}$. Each boundary condition ⓘ corresponds to two complementary sets of indices $A_{\textcircled{\scriptsize i}}$ and $B_{\textcircled{\scriptsize i}}$, where $A_{\textcircled{\scriptsize i}}$ is attached to the Dirichlet conditions of $\textcircled{i}$; i.e., $u_a = 0$ for each index $a \in A_{\textcircled{i}}$: these are the *stable* conditions. The Neumann conditions are $T_b = 0$ for each index $b \in B_{\textcircled{i}}$ and appear as *natural* conditions.

To each boundary condition $\textcircled{i}$ is associated the space of displacements $V_{\textcircled{i}}(\Omega^\varepsilon)$ of the $\boldsymbol{v} \in H^1(\Omega^\varepsilon)^3$ such that $v_a = 0$ for all $a \in A_{\textcircled{i}}$, and the space $\mathcal{R}_{\textcircled{i}}$ of the rigid motions satisfying the Dirichlet conditions of $V_{\textcircled{i}}$. Then, the variational formulation of the problem consists of finding

$$(2.6)\quad \begin{cases} \boldsymbol{u}^\varepsilon \in V_{\textcircled{i}}(\Omega^\varepsilon) \\ \forall\, \boldsymbol{v} \in V_{\textcircled{i}}(\Omega^\varepsilon), \quad \displaystyle\int_{\Omega^\varepsilon} A\, e(\boldsymbol{u}^\varepsilon) : e(\boldsymbol{v}) = \int_{\Omega^\varepsilon} \boldsymbol{f}^\varepsilon \cdot \boldsymbol{v} \, + \int_{\Gamma_+^\varepsilon} \boldsymbol{g}^{\varepsilon,+} \cdot \boldsymbol{v} \, - \int_{\Gamma_-^\varepsilon} \boldsymbol{g}^{\varepsilon,-} \cdot \boldsymbol{v}, \end{cases}$$

where $\boldsymbol{f}^\varepsilon$ represents the volume force and $\boldsymbol{g}^{\varepsilon,\pm}$ the prescribed horizontal tractions. If the right-hand side satisfies the correct compatibility condition (orthogonality to all $\boldsymbol{v} \in \mathcal{R}_{\textcircled{i}}(\Omega^\varepsilon)$), then there exists a unique solution to (2.6) satisfying the orthogonality conditions $\int_{\Omega^\varepsilon} \boldsymbol{u}^\varepsilon \cdot \boldsymbol{v} = 0$ for all $\boldsymbol{v} \in \mathcal{R}_{\textcircled{i}}(\Omega^\varepsilon)$.

After the scaling (2.3), an asymptotic expansion of $\boldsymbol{u}(\varepsilon)$ makes sense if the scaled data have comparable behaviors as ε is varying. To this aim, we make the assumption on the right-hand sides that they are given by profiles in x_3, namely,

$$(2.7\text{a})\qquad f^\varepsilon_\alpha(\tilde{x}) = f_\alpha(x),\ \alpha = 1,2, \qquad \varepsilon^{-1} f^\varepsilon_3(\tilde{x}) = f_3(x),$$

$$(2.7\text{b})\qquad \varepsilon^{-1} g^{\varepsilon,\pm}_\alpha(\tilde{x}) = g^{\pm}_\alpha(x_*),\ \alpha = 1,2, \qquad \varepsilon^{-2} g^{\varepsilon,\pm}_3(\tilde{x}) = g^{\pm}_3(x_*);$$

compare with (2.4) for the homogeneities. To simplify, we assume that the profiles $\boldsymbol{f}$ and $\boldsymbol{g}^\pm$ are regular up to the boundary, i.e., $\boldsymbol{f} \in \mathcal{C}^\infty(\overline{\Omega})^3$ and $\boldsymbol{g}^\pm \in \mathcal{C}^\infty(\overline{\omega})^3$.

After scaling (2.3) and assumption (2.7), problem (2.6) is transformed into a new boundary value problem on Ω, where now the operators depend on the small parameter ε: The variational formulation of the problem for the scaled displacement $\boldsymbol{u}(\varepsilon)$ consists of finding

$$(2.8)\quad \begin{cases} \boldsymbol{u}(\varepsilon) \in V_{\textcircled{i}}(\Omega), \\ \forall\, \boldsymbol{v} \in V_{\textcircled{i}}(\Omega), \quad \displaystyle\int_{\Omega} A\, \theta(\varepsilon)(\boldsymbol{u}(\varepsilon)) : \theta(\varepsilon)(\boldsymbol{v}) = \int_{\Omega} \boldsymbol{f} \cdot \boldsymbol{v} \, + \int_{\Gamma_+} \boldsymbol{g}^{+} \cdot \boldsymbol{v} \, - \int_{\Gamma_-} \boldsymbol{g}^{-} \cdot \boldsymbol{v}, \end{cases}$$

where $V_{\textcircled{i}}(\Omega)$ is the space of the geometrically admissible displacements $\boldsymbol{v} \in H^1(\Omega)^3$ associated with the problem with lateral boundary conditions $\textcircled{i}$, and $\theta(\varepsilon)(\boldsymbol{v})$ denotes the scaled linearized strain tensor defined by

$$(2.9)\quad \theta_{\alpha\beta}(\varepsilon)(\boldsymbol{v}) := e_{\alpha\beta}(\boldsymbol{v})\,, \quad \theta_{\alpha 3}(\varepsilon)(\boldsymbol{v}) := \varepsilon^{-1}\, e_{\alpha 3}(\boldsymbol{v})\,, \quad \theta_{33}(\varepsilon)(\boldsymbol{v}) := \varepsilon^{-2}\, e_{33}(\boldsymbol{v})$$

for $\alpha, \beta = 1, 2$; note that there holds $\theta(\varepsilon)(\boldsymbol{u}(\varepsilon)) = e(\boldsymbol{u}^\varepsilon)$.

Denoting by $\mathcal{R}_{\textcircled{i}}(\Omega)$ the space of rigid motions satisfying the Dirichlet conditions of $V_{\textcircled{i}}(\Omega)$, the compatibility condition becomes

$$(2.10)\qquad \forall\, \boldsymbol{v} \in \mathcal{R}_{\textcircled{i}}(\Omega), \quad \int_{\Omega} \boldsymbol{f} \cdot \boldsymbol{v} \, + \int_{\Gamma_+} \boldsymbol{g}^{+} \cdot \boldsymbol{v} \, - \int_{\Gamma_-} \boldsymbol{g}^{-} \cdot \boldsymbol{v} = 0$$

and $\boldsymbol{u}(\varepsilon)$ satisfies the orthogonality condition

$$(2.11)\qquad \forall\, \boldsymbol{v} \in \mathcal{R}_{\textcircled{i}}(\Omega), \quad \int_{\Omega} \boldsymbol{u}(\varepsilon)\, \cdot\, \boldsymbol{v} = 0\,.$$

Problem (2.8) can be written in the boundary value problem form (2.12a)–(2.14) on Ω as follows. To formulate it, we use the repeated index convention. Moreover, $\boldsymbol{u}_*$ is a condensed notation for (u_1, u_2), $\operatorname{div}_* \boldsymbol{u}_*$ denotes $\partial_1 u_1 + \partial_2 u_2$, and Δ_* denotes the horizontal Laplacian $\partial_{11} + \partial_{22}$. The in-plane components, indexed by $\alpha = 1, 2$, and the vertical component of the interior equations in Ω are

$$2\mu\, \partial_3 e_{\alpha 3}(\boldsymbol{u}) + \lambda\, \partial_{\alpha 3} u_3 + \varepsilon^2 \big((\lambda + \mu)\partial_\alpha \operatorname{div}_* \boldsymbol{u}_* + \mu\, \Delta_* u_\alpha\big) = -\varepsilon^2 f_\alpha, \tag{2.12a}$$

$$(\lambda + 2\mu)\partial_{33} u_3 + \varepsilon^2 \big(\lambda\, \partial_3 \operatorname{div}_* \boldsymbol{u}_* + 2\mu\, \partial_\beta e_{\beta 3}(\boldsymbol{u})\big) = -\varepsilon^4 f_3. \tag{2.12b}$$

The boundary conditions on the horizontal sides $\Gamma_\pm := \{x_3 = \pm 1\} \cap \partial\Omega$ are

$$2\mu\, e_{\alpha 3}(\boldsymbol{u}) = \varepsilon^2 g_\alpha^{\pm}\,, \qquad \alpha = 1, 2, \tag{2.13a}$$

$$(\lambda + 2\mu)\partial_3 u_3 + \varepsilon^2\, \lambda \operatorname{div}_* \boldsymbol{u}_* = \varepsilon^4 g_3^{\pm}\,. \tag{2.13b}$$

The boundary conditions on the lateral side $\Gamma_0 = \partial\omega \times (-1, 1)$ can be written as

$$u_a = 0, \quad \forall a \in A_{\textcircled{i}} \qquad \text{and} \qquad T_b = 0, \quad \forall b \in B_{\textcircled{i}}. \tag{2.14}$$

The normal, tangential horizontal, and vertical components of the traction $\boldsymbol{T} = \boldsymbol{T}(\varepsilon)$ on Γ_0 are given by, respectively,

$$T_n(\varepsilon) = \lambda\, \partial_3 u_3(\varepsilon) + \varepsilon^2 \big(\lambda \operatorname{div}_* \boldsymbol{u}_*(\varepsilon) + 2\mu\, \partial_n u_n(\varepsilon)\big), \tag{2.15a}$$

$$T_s(\varepsilon) = \varepsilon^2 \mu\big(\partial_s u_n(\varepsilon) + \partial_n u_s(\varepsilon) + 2\kappa\, u_s(\varepsilon)\big), \tag{2.15b}$$

$$T_3(\varepsilon) = \mu\big(\partial_n u_3(\varepsilon) + \partial_3 u_n(\varepsilon)\big). \tag{2.15c}$$

3. Description of results.

We first state the common features of the asymptotics of the scaled displacement $\boldsymbol{u}(\varepsilon)$ and next deduce the asymptotics of the displacement $\boldsymbol{u}^\varepsilon$ in the thin plates. Then we describe the first terms of the asymptotics in each of the eight lateral boundary conditions.

3.1. Common features.

Just as in the well-known situation of the clamped plate, the scaled displacement $\boldsymbol{u}(\varepsilon)$ tends in Ω to a Kirchhoff–Love displacement. Let us recall the following definition.

Definition 3.1. *A displacement $\boldsymbol{u}$ in Ω is called a* Kirchhoff–Love displacement *if there exist a displacement $\boldsymbol{\zeta}_* = (\zeta_1, \zeta_2)$ in the mean surface ω and a function ζ_3 on ω such that*

$$\boldsymbol{u} = (\zeta_1 - x_3 \partial_1 \zeta_3,\ \zeta_2 - x_3 \partial_2 \zeta_3,\ \zeta_3).$$

The function $\boldsymbol{\zeta} := (\boldsymbol{\zeta}_*, \zeta_3)$ is called the generator *of $\boldsymbol{u}$, and the descaled displacement associated with $\boldsymbol{u}$ in Ω^ε has exactly the same form with x_3 replaced by $\tilde{x}_3$. Then*

$$\boldsymbol{u}_{\mathrm{KL,b}} = (-x_3 \partial_1 \zeta_3, -x_3 \partial_2 \zeta_3,\ \zeta_3) \quad \textit{and} \quad \boldsymbol{u}_{\mathrm{KL,m}} = (\zeta_1, \zeta_2, 0) \tag{3.1}$$

are respectively the bending and membrane parts of $\boldsymbol{u}$.

The asymptotics of $\boldsymbol{u}(\varepsilon)$ contains three types of terms for $k \geq 0$:

- $\boldsymbol{u}_{\mathrm{KL}}^k$: Kirchhoff–Love displacements with 'generating functions' $\boldsymbol{\zeta}^k = (\boldsymbol{\zeta}_*^k, \zeta_3^k)$, i.e., $\boldsymbol{u}_{\mathrm{KL}}^k(x) = \big(\boldsymbol{\zeta}_*^k(x_*) - x_3 \nabla_* \zeta_3^k(x_*), \zeta_3^k(x_*)\big)$,
- $\boldsymbol{v}^k$: displacements with zero mean value: $\forall x_* \in \overline{\omega}$, $\int_{-1}^{+1} \boldsymbol{v}^k(x_*, x_3)\, dx_3 = 0$,
- $\boldsymbol{w}^k$: exponentially decreasing profiles as $t \to +\infty$

and can be written as

$$\boldsymbol{u}(\varepsilon)(x) \simeq \boldsymbol{u}^0_{\mathrm{KL}} + \varepsilon \boldsymbol{u}^1\left(x, \frac{r}{\varepsilon}\right) + \cdots + \varepsilon^k \boldsymbol{u}^k\left(x, \frac{r}{\varepsilon}\right) + \cdots, \tag{3.2}$$

where

$$\begin{array}{rclll} \boldsymbol{u}^1(x,t) & = & \boldsymbol{u}^1_{\mathrm{KL}} \phantom{+ \boldsymbol{v}^k} + \chi(r)\,\boldsymbol{w}^1(t,s,x_3) & \text{with} & w^1_3 = 0, \\ \boldsymbol{u}^k(x,t) & = & \boldsymbol{u}^k_{\mathrm{KL}} + \boldsymbol{v}^k + \chi(r)\,\boldsymbol{w}^k(t,s,x_3) & \text{for} & k \geq 2\,, \end{array} \tag{3.3}$$

with χ a cut-off function equal to 1 in a neighborhood of $\partial\omega$.

Theorem 3.2. *Let $\boldsymbol{u}(\varepsilon)$ be the unique solution of problem* (2.8) *satisfying the mean value conditions* (2.11). *Then there exist Kirchhoff–Love generators $\boldsymbol{\zeta}^k$ for $k \geq 0$, displacements with zero mean value $\boldsymbol{v}^k$ for $k \geq 2$, and profiles $\boldsymbol{w}^k$ for $k \geq 1$ such that there holds $\forall N \geq 0$*

$$\left\| \boldsymbol{u}(\varepsilon)(x) - \boldsymbol{u}^0_{\mathrm{KL}}(x) - \sum_{k=1}^{N} \varepsilon^k \boldsymbol{u}^k\ \left(x, \frac{r}{\varepsilon}\right) \right\| H^1(\Omega)^3 \leq C\,\varepsilon^{N+1/2} \tag{3.4}$$

with $\boldsymbol{u}^k(x, \frac{r}{\varepsilon})$ given in (3.3).

Let us point out that the "physical" displacement $\boldsymbol{u}^\varepsilon$ expands like $\boldsymbol{u}(\varepsilon)$ in the following way in the sense of asymptotic expansions:

$$\begin{aligned} \boldsymbol{u}^\varepsilon \simeq \boldsymbol{u}^0_{\mathrm{KL,b}} + \tilde{\boldsymbol{u}}^0_{\mathrm{KL,m}} + \tilde{\boldsymbol{u}}^0_{\mathrm{KL,b}} + \varepsilon(\tilde{\boldsymbol{u}}^1_{\mathrm{KL,m}} + \tilde{\boldsymbol{u}}^1_{\mathrm{KL,b}} + \tilde{\boldsymbol{v}}^1 + \boldsymbol{\varphi}^1) + \cdots \\ + \varepsilon^k(\tilde{\boldsymbol{u}}^k_{\mathrm{KL,m}} + \tilde{\boldsymbol{u}}^k_{\mathrm{KL,b}} + \tilde{\boldsymbol{v}}^k + \boldsymbol{\varphi}^k) + \cdots, \end{aligned} \tag{3.5}$$

where

- $\tilde{\boldsymbol{u}}^k_{\mathrm{KL,b}}$ and $\tilde{\boldsymbol{u}}^k_{\mathrm{KL,m}}$ are the bending and membrane parts on Ω^ε of the Kirchhoff–Love displacement with generator $\boldsymbol{\zeta}^k$;
- $\tilde{\boldsymbol{v}}^k = \tilde{\boldsymbol{v}}^k(x_*, \frac{\tilde{x}_3}{\varepsilon})$, i.e., does not depend on ε in the scaled domain Ω;
- $\boldsymbol{\varphi}^k = \boldsymbol{\varphi}^k(\frac{r}{\varepsilon}, s, \frac{\tilde{x}_3}{\varepsilon})$ is a boundary layer profile.

The links with expansion (3.2) on the thin plates are simply provided by the following relations:

$$\left\{ \begin{array}{l} \tilde{\boldsymbol{u}}^k_{\mathrm{KL,b}}(\tilde{x}) = \boldsymbol{u}^k_{\mathrm{KL,b}}(x), \quad \tilde{\boldsymbol{u}}^k_{\mathrm{KL,m}}(\tilde{x}) = \boldsymbol{u}^k_{\mathrm{KL,m}}(x), \\ \tilde{\boldsymbol{v}}^k = (\boldsymbol{v}^k_*, v^{k+1}_3), \quad \text{and} \quad \boldsymbol{\varphi}^k = (\boldsymbol{w}^k_*, w^{k+1}_3)\,. \end{array} \right. \tag{3.6}$$

In Table 8, we will give the formulas linking the displacements $\mathbf{v}^k$ to the Kirchhoff–Love generators. These formulas do not depend on the nature of the lateral boundary conditions. In particular, the first non-Kirchhoff displacement $\tilde{\boldsymbol{v}}^1 = (\mathbf{0}, v^2_3)$ is completely determined by $\boldsymbol{\zeta}^0$, *cf* Destuynder [14] for a similar formula:

$$\tilde{\boldsymbol{v}}^1(x_*, x_3) = \frac{\lambda}{6(\lambda + 2\mu)}\Big(0,\ 0,\ -6x_3 \operatorname{div}_* \boldsymbol{\zeta}^0_* + (3x_3^2 - 1)\,\Delta_* \zeta^0_3\Big). \tag{3.7}$$

3.2. Specific features: The Kirchhoff–Love generators. The generators $\boldsymbol{\zeta}^k_*$ and ζ^k_3 of the above Kirchhoff displacements are solutions of membrane and bending equations, respectively, with boundary conditions on $\partial\omega$. Let us first write down these membrane and bending operators together with the associated Dirichlet and Neumann conditions. Then we describe the boundary operators and data associated with the generators.

3.2.1. Membrane. The bilinear form associated with the membrane operator L^{m} (plane stress model)

$$L^{\mathrm{m}}\boldsymbol{\zeta}_* = \mu\,\boldsymbol{\Delta}_*\boldsymbol{\zeta}_* + (\tilde\lambda+\mu)\nabla_*\operatorname{div}_*\boldsymbol{\zeta}_* \tag{3.8}$$

is $\int_\omega \tilde\lambda\, e_{\alpha\alpha}(\boldsymbol{\zeta}_*)\; e_{\beta\beta}(\boldsymbol{\eta}_*) + 2\mu\, e_{\alpha\beta}(\boldsymbol{\zeta}_*)\; e_{\alpha\beta}(\boldsymbol{\eta}_*)$ with the homogenized Lamé coefficient

$$\tilde\lambda = \frac{2\lambda\mu}{\lambda+2\mu}\,. \tag{3.9}$$

In normal and tangential components (cf. (2.5a))

$$\zeta_n = n_1\zeta_1 + n_2\zeta_2 \quad\text{and}\quad \zeta_s = (1-\kappa\, r)(n_2\zeta_1 - n_1\zeta_2),$$

the Dirichlet traces are simply (ζ_n, ζ_s) on $\partial\omega$, and the Neumann traces are

$$T^{\mathrm{m}}_n(\boldsymbol{\zeta}_*) = \tilde\lambda\operatorname{div}_*\boldsymbol{\zeta}_* + 2\mu\,\partial_n\zeta_n, \tag{3.10a}$$

$$T^{\mathrm{m}}_s(\boldsymbol{\zeta}_*) = \mu(\partial_s\zeta_n + \partial_n\zeta_s + 2\kappa\,\zeta_s), \tag{3.10b}$$

where ∂_n and ∂_s are defined in (2.2).

3.2.2. Bending. The bilinear form associated with the bending operator L^{b},

$$L^{\mathrm{b}}\zeta_3 = (\tilde\lambda+2\mu)\Delta^2_*\zeta_3 \tag{3.11}$$

is $\int_\omega \tilde\lambda\,\partial_{\alpha\alpha}\zeta_3\;\partial_{\beta\beta}\eta_3 + 2\mu\,\partial_{\alpha\beta}\zeta_3\;\partial_{\alpha\beta}\eta_3$. Its Dirichlet traces are ζ_3 and $\partial_n\zeta_3$ on $\partial\omega$, whereas the Neumann traces are

$$M_n(\zeta_3) = \tilde\lambda\,\Delta_*\zeta_3 + 2\mu\,\partial_{nn}\zeta_3, \tag{3.12a}$$

$$N_n(\zeta_3) = (\tilde\lambda+2\mu)\partial_n\Delta_*\zeta_3 + 2\mu\,\partial_s(\partial_n+\kappa)\partial_s\zeta_3. \tag{3.12b}$$

The mechanical interpretation of these boundary operators is that M_n corresponds to the “Kirchhoff bending moment” and N_n corresponds to the “Kirchhoff shear force” on the lateral side of the plate (up to constants only depending on λ and μ).

3.2.3. Boundary value problems for the Kirchhoff–Love generators. The $\boldsymbol{\zeta}^k_*$ and ζ^k_3 are solutions of equations of the type

$$L^{\mathrm{m}}(\boldsymbol{\zeta}^k_*) = \boldsymbol{R}^k_{\mathrm{m}} \quad\text{in } \omega, \qquad \gamma^{\mathrm{m},1}(\boldsymbol{\zeta}^k_*) = \gamma^k_{\mathrm{m},1}, \;\text{ and }\; \gamma^{\mathrm{m},2}(\boldsymbol{\zeta}^k_*) = \gamma^k_{\mathrm{m},2} \quad\text{on } \partial\omega, \tag{3.13a}$$

$$L^{\mathrm{b}}(\zeta^k_3) = R^k_{\mathrm{b}} \quad\text{in } \omega, \qquad \gamma^{\mathrm{b},1}(\zeta^k_3) = \gamma^k_{\mathrm{b},1}, \;\text{ and }\; \gamma^{\mathrm{b},2}(\zeta^k_3) = \gamma^k_{\mathrm{b},2} \quad\text{on } \partial\omega, \tag{3.13b}$$

(see Table 8 for expressions of the right-hand sides $\boldsymbol{R}^k_{\mathrm{m}}$ and R^k_{b}) where the boundary operators $\gamma^{\mathrm{m},j}$ and $\gamma^{\mathrm{b},j}$, $j=1,2$, depend on the nature of lateral boundary conditions according to Table 2.

3.2.4. Boundary data for $\boldsymbol{\zeta}^0$. For conditions ①–④, the boundary data $\gamma^0_{\mathrm{m},j}$ and $\gamma^0_{\mathrm{b},j}$, $j=1,2$, are all zero, whereas for conditions ⑤–⑧, only the membrane boundary data $\gamma^0_{\mathrm{m},j}$, $j=1,2$, are always zero.

In the cases ⑤ and ⑦, we assume for simplicity that ω is simply connected. Then $\gamma^0_{\mathrm{b},1}$, which is the trace of ζ^0_3 on $\partial\omega$, is a prescribed constant (so that ζ^0_3 has a zero mean value in accordance with the orthogonality condition (2.11)) which is given by the scalar product of R^0_{b} versus the solution of a typical problem of type (3.13b). The other boundary data $\gamma^0_{\mathrm{b},2}$ is zero.

Table 2
Boundary operators for the Kirchhoff–Love generators.

	Membrane part		Bending part	
	$\gamma^{\mathrm{m},1}(\boldsymbol{\zeta}_*)$	$\gamma^{\mathrm{m},2}(\boldsymbol{\zeta}_*)$	$\gamma^{\mathrm{b},1}(\zeta_3)$	$\gamma^{\mathrm{b},2}(\zeta_3)$
①	ζ_n	ζ_s	ζ_3	$\partial_n\zeta_3$
②	ζ_n	$T^{\mathrm{m}}_s(\boldsymbol{\zeta}_*)$	ζ_3	$\partial_n\zeta_3$
③	$T^{\mathrm{m}}_n(\boldsymbol{\zeta}_*)$	ζ_s	ζ_3	$M_n(\zeta_3)$
④	$T^{\mathrm{m}}_n(\boldsymbol{\zeta}_*)$	$T^{\mathrm{m}}_s(\boldsymbol{\zeta}_*)$	ζ_3	$M_n(\zeta_3)$
⑤	ζ_n	ζ_s	ζ_3	$\partial_n\zeta_3$
⑥	ζ_n	$T^{\mathrm{m}}_s(\boldsymbol{\zeta}_*)$	$\partial_n\zeta_3$	$N_n(\zeta_3)$
⑦	$T^{\mathrm{m}}_n(\boldsymbol{\zeta}_*)$	ζ_s	ζ_3	$M_n(\zeta_3)$
⑧	$T^{\mathrm{m}}_n(\boldsymbol{\zeta}_*)$	$T^{\mathrm{m}}_s(\boldsymbol{\zeta}_*)$	$M_n(\zeta_3)$	$N_n(\zeta_3)$

Table 3
Boundary data for $\boldsymbol{\zeta}^1$.

	Membrane part		Bending part	
	$\gamma^1_{\mathrm{m},1}$	$\gamma^1_{\mathrm{m},2}$	$\gamma^1_{\mathrm{b},1}$	$\gamma^1_{\mathrm{b},2}$
①	$c_1^{\textcircled{1}}\,\mathrm{div}_*\,\boldsymbol{\zeta}^0_*$	0	0	$c_4^{\textcircled{1}}\,\Delta_*\zeta^0_3$
②	$c_1^{\textcircled{2}}\,\mathrm{div}_*\,\boldsymbol{\zeta}^0_*$	$c_2^{\textcircled{2}}\,\partial_s\,\mathrm{div}_*\,\boldsymbol{\zeta}^0_*$	0	$c_4^{\textcircled{2}}\,\Delta_*\zeta^0_3$
③	$c_1^{\textcircled{3}}\,\kappa^2\,\zeta^0_n$	0	0	$c_4^{\textcircled{3}}\,\kappa^2\,\partial_n\zeta^0_3$
④	$c_1^{\textcircled{4}}\,\kappa\,\mathrm{div}_*\,\boldsymbol{\zeta}^0_*$	$c_2^{\textcircled{4}}\,\partial_s\,\mathrm{div}_*\,\boldsymbol{\zeta}^0_*$	0	$(c_4^{\textcircled{4}}\,\kappa^2 + c_5^{\textcircled{4}}\,\partial_{ss})\,\partial_n\zeta^0_3$

In the cases ⑥ and ⑧ the boundary condition related to $\gamma^{\mathrm{b},2} = N_n$ is given by

$$N_n(\zeta^0_3) = \frac{3}{2}\left(\int_{-1}^{+1} x_3\, f_n\, dx_3 + g^+_n + g^-_n\right)\bigg|_{\partial\omega}\,. \tag{3.14}$$

The mechanical interpretation of the right-hand side in this relation reads that this expression has the dimension of a moment and can be understood as a prescribed moment on the lateral side of the plate, generated by f_n, g^+_n and g^-_n. Obviously, this right-hand side is zero, if the supports of the data f_n and $g^{\pm}_n$ avoid $\overline{\Gamma}_0$ and $\partial\omega$, respectively. The other boundary data $\gamma^0_{\mathrm{b},1}$ is zero.

3.2.5. Boundary data for $\boldsymbol{\zeta}^1$. For conditions ①–④, all the boundary data for $\boldsymbol{\zeta}^1$ are special traces of $\boldsymbol{\zeta}^0$, according to Table 3 (we recall that κ is the curvature of $\partial\omega$).

Here, the constants $c_j^{\textcircled{i}}$ depend only on λ and μ and come from typical boundary layer profiles.

In contrast to the four "clamped" lateral conditions, for the four "free" lateral conditions ⑤–⑧ the boundary conditions related to the membrane part $\boldsymbol{\zeta}^1_*$ are all zero, which combined with the fact that the interior right-hand side $\boldsymbol{R}^1_{\mathrm{m}}$ is zero, yields that $\boldsymbol{\zeta}^1_*$ is itself zero.

TABLE 4
Boundary data for ζ_3^1.

	$\gamma^1_{\mathrm{b},1}$	$\gamma^1_{\mathrm{b},2}$
⑤	$\Lambda^{\textcircled{5}}$	0
⑥	0	$P^{\textcircled{6}}(\zeta_3^0) + \kappa K^{\textcircled{6}}\Big(f_n, g_n^{\pm}\Big)$
⑦	$\Lambda^{\textcircled{7}}$	$c_4^{\textcircled{7}}\, L$
⑧	$c_3^{\textcircled{8}}\, \partial_s(\partial_n+\kappa)\partial_s\zeta_3^0$	$P^{\textcircled{8}}(\zeta_3^0) + \kappa K^{\textcircled{8}}\Big(f_n, g_n^{\pm}\Big)$

TABLE 5
Typical boundary layer profiles.

Components	$\bar{\boldsymbol{\varphi}}^{\mathrm{m}}$	$\bar{\boldsymbol{\varphi}}^{\mathrm{b}}$	$\bar{\boldsymbol{\varphi}}^{\mathrm{s}}$
Normal	even	odd	0
Horizontal tangential	0	0	odd
Vertical	odd	even	0

The traces of ζ_3^1 are generically not zero: in cases ⑤ and ⑦ (and if ω is simply connected) all traces can be expressed with the help of the function

$$L(s) = \left[-\frac{2}{3}(\tilde{\lambda}+2\mu)\partial_n\Delta_*\,\zeta_3^0 + \int_{-1}^{+1} x_3\, f_n\, dx_3 + g_n^+ + g_n^-\right]\Bigg|_{\partial\omega} . \tag{3.15}$$

In cases ⑥ and ⑧ the prescribed values of the traces involve more complicated operators. We write the boundary data for ζ_3^1 in a condensed form in Table 4.

Here $\Lambda^{\textcircled{5}}$ and $\Lambda^{\textcircled{7}}$ are special double primitives of L on $\partial\omega$. $P^{\textcircled{6}}$ is a linear combination of $\partial_s\kappa^2\partial_s$, $(\kappa\partial_s)^2$ and $\kappa\partial_n\Delta_*$, $P^{\textcircled{8}}$ of $\kappa\partial_n\Delta_*$, $\partial_s(\kappa(\partial_n{+}\kappa))\partial_s$, and $\kappa\partial_s(\partial_n{+}\kappa)\partial_s$. Finally, $K^{\textcircled{6}}$ and $K^{\textcircled{8}}$ are operators preserving the support with respect to the in-plane variables.

3.3. Specific features: The first boundary layer profile. For conditions ①–④, the first boundary layer profile $\boldsymbol{\varphi}^1$ can be described as a sum of three terms in tensor product form in the variables s and (t, x_3) with $t = \frac{r}{\varepsilon}$:

$$\boldsymbol{\varphi}^1 = \ell^{\mathrm{m}}(s)\,\bar{\boldsymbol{\varphi}}^{\mathrm{m}}(t,x_3) + \ell^{\mathrm{b}}(s)\,\bar{\boldsymbol{\varphi}}^{\mathrm{b}}(t,x_3) + \ell^{\mathrm{s}}(s)\,\bar{\boldsymbol{\varphi}}^{\mathrm{s}}(t,x_3) . \tag{3.16}$$

Here $\bar{\boldsymbol{\varphi}}^{\mathrm{m}}$, $\bar{\boldsymbol{\varphi}}^{\mathrm{b}}$, and $\bar{\boldsymbol{\varphi}}^{\mathrm{s}}$ are typical profiles only depending on the Lamé constants and whose components have special parities with respect to x_3: $\bar{\boldsymbol{\varphi}}^{\mathrm{m}}$ is a membrane displacement whereas $\bar{\boldsymbol{\varphi}}^{\mathrm{b}}$ and $\bar{\boldsymbol{\varphi}}^{\mathrm{s}}$ are bending displacements; moreover, some of their components are zero, which is summarized in Table 5.

The functions ℓ are given as traces of $\boldsymbol{\zeta}^0$ along the boundary $\partial\omega$ according to Table 6.

Again in contrast to the four "clamped" lateral conditions, the normal and transverse components of the first boundary layer profile $\boldsymbol{\varphi}^1$ are always zero in the cases ⑤–⑧. Only the in-plane tangential component φ_s^1 is generically nonzero, and it is odd with respect to x_3. This means that $\boldsymbol{\varphi}^1$ is a bending displacement.

Table 6
Lateral traces coming up in the first boundary layer profile.

Case	ℓ^{m}	ℓ^{b}	ℓ^{s}
① and ②	$\mathrm{div}_* \, \zeta^0_*$	$\Delta_* \zeta^0_3$	0
③	$\kappa \, \zeta^0_n$	$\kappa \, \partial_n \zeta^0_3$	0
④	$\mathrm{div}_* \, \zeta^0_*$	$\kappa \, \partial_n \zeta^0_3$	$\partial_s(\partial_n \zeta^0_3)$

Table 7
The first boundary layer profile.

Case	ℓ^{s}	$\bar\varphi^{\mathrm{s}}$
⑤	$\partial_s \zeta^0_3$	$\bar\varphi^{\mathrm{s}}_{\mathrm{Dir}}$
⑥	$\kappa \partial_s \zeta^0_3$	$\bar\varphi^{\mathrm{s}}_{\mathrm{Neu}}$
⑦	$\partial_s \zeta^0_3$	$\bar\varphi^{\mathrm{s}}_{\mathrm{Dir}}$
⑧	$(\partial_n + \kappa) \partial_s \zeta^0_3$	$\bar\varphi^{\mathrm{s}}_{\mathrm{Neu}}$

The component φ^1_s can be written in tensor product form $\ell^{\mathrm{s}}(s)\, \bar\varphi^{\mathrm{s}}(t, x_3)$ according to Table 7.

Here $\bar\varphi^{\mathrm{s}}_{\mathrm{Dir}}$ and $\bar\varphi^{\mathrm{s}}_{\mathrm{Neu}}$ are solutions on the half strip $\mathbb{R}^+ \times (-1, 1)$ of special boundary problems for the Laplace operator; see Lemmas 6.5 and 6.7.

Note the presence of κ in front of the traces for the hard simple support case ③ and for the sliding edge case ⑥ (compare also with [2] and [27], respectively): due to the possibility of reflecting the solution across any flat part of the boundary, the existence of boundary layer terms is linked to nonzero curvature.

4. Inner–outer expansion Ansatz.

4.1. The Ansatz. The determination of the asymptotics (3.2) can be split into two steps. The first one consists of finding *all* suitable power series

$$\underline{\boldsymbol{u}}(\varepsilon)(x) \simeq \underline{\boldsymbol{u}}^0(x) + \varepsilon \underline{\boldsymbol{u}}^1(x) + \cdots + \varepsilon^k \underline{\boldsymbol{u}}^k(x) + \cdots \tag{4.1}$$

which solve in the sense of asymptotic expansions the interior equations (2.12a) in Ω and conditions (2.13a) of traction on the horizontal sides $\Gamma_\pm$. We refer to Maz'ya, Nazarov and Plamenevskii [19, Chap. 15] for general developments relating to the structure of expansion (4.1).

We will see in what follows that all the terms in the suitable series (4.1) are strictly determined *except* the elliptic traces of the Kirchhoff–Love generators $\boldsymbol{\zeta}^k$. The second step, which we will initiate in the next section, consists of finding the profiles $\boldsymbol{w}^k$ so that $\sum_k \varepsilon^k \boldsymbol{w}^k(r\varepsilon^{-1}, s, x_3)$ solves RefPb in Ω with zero volume force, conditions (2.13a) of zero traction, and so that the lateral boundary conditions (2.14) are satisfied by the complete Ansatz. The outcome will be that the existence of *exponentially decaying* profiles is subordinated to the determination of the remaining degrees of freedom in the series (4.1).

4.2. The algorithms of the outer expansion part. This section is devoted to the construction of the most general power series (4.1) solving (2.12a)–(2.13a). Let us introduce the two operators A and B which associate with a displacement $\boldsymbol{u}$ in Ω, a volume force in Ω, and tractions on the horizontal sides on $\Gamma_\pm$ according to

$$A\boldsymbol{u} = \Big(2\mu\,\partial_3 e_{\alpha 3}(\boldsymbol{u}) + \lambda\,\partial_{\alpha 3}u_3,\ (\lambda+2\mu)\partial_{33}u_3\ ;\ 2\mu\, e_{\alpha 3}(\boldsymbol{u})\big|_{\Gamma_\pm},\ (\lambda+2\mu)\partial_3 u_3\big|_{\Gamma_\pm}\Big),$$

$$B\boldsymbol{u} = \Big((\lambda+\mu)\partial_\alpha \mathrm{div}_*\boldsymbol{u}_* + \mu\,\Delta_* u_\alpha,\ \lambda\,\partial_3\,\mathrm{div}_*\boldsymbol{u}_* + 2\mu\,\partial_\beta e_{\beta 3}(\boldsymbol{u})\,;\ 0\big|_{\Gamma_\pm},\ \lambda\,\mathrm{div}_*\boldsymbol{u}_*\big|_{\Gamma_\pm}\Big),$$

the first group of arguments being the in-plane volume forces, the second, the transverse volume force, and similarly for the tractions. Solving (2.12a)–(2.13a) by a power series (4.1) is equivalent to solving the system of equations

$$\tag{4.2} \begin{cases} A\underline{\boldsymbol{u}}^k &= \ 0 \qquad\qquad\qquad \text{for } k=0,1,\\ A\underline{\boldsymbol{u}}^2 + B\underline{\boldsymbol{u}}^0 &= \ \Big(-f_\alpha\ ,\ 0\ ;\ \overset{\pm}{g_\alpha}\big|_{\Gamma_\pm}\ ,\ 0\big|_{\Gamma_\pm}\Big),\\ A\underline{\boldsymbol{u}}^4 + B\underline{\boldsymbol{u}}^2 &= \ \Big(0\ ,\ -f_3\ ;\ 0\big|_{\Gamma_\pm}\ ,\ \overset{\pm}{g_3}\big|_{\Gamma_\pm}\Big),\\ A\underline{\boldsymbol{u}}^k + B\underline{\boldsymbol{u}}^{k-2} &= \ 0 \qquad\qquad\qquad \text{for } k=3 \text{ and } k\ge 5. \end{cases}$$

It is well known that the solutions of the problem $A\underline{\boldsymbol{u}} = 0$ are the Kirchhoff–Love displacements. Thus $\underline{\boldsymbol{u}}^0 = \boldsymbol{u}^0_{\mathrm{KL}}$ and $\underline{\boldsymbol{u}}^1 = \boldsymbol{u}^1_{\mathrm{KL}}$, with generators $\boldsymbol{\zeta}^0$ and $\boldsymbol{\zeta}^1$.

In order to solve the series of equations of *odd order* $A\underline{\boldsymbol{u}}^k + B\underline{\boldsymbol{u}}^{k-2} = 0$, let us introduce the operator V.

DEFINITION 4.1. *The operator* $V : \boldsymbol{\zeta} \mapsto V\boldsymbol{\zeta}$ *is defined from* $\mathcal{C}^\infty(\overline{\omega})^3$ *into* $\mathcal{C}^\infty(\overline{\Omega})^3$ *by*

$$\tag{4.3} \begin{aligned} (V\boldsymbol{\zeta})_\alpha &= \bar p_2\,\partial_\alpha\,\mathrm{div}_*\,\boldsymbol{\zeta}_* + \bar p_3\,\partial_\alpha\Delta_*\zeta_3,\\ (V\boldsymbol{\zeta})_3 &= \bar p_1\ \mathrm{div}_*\,\boldsymbol{\zeta}_* + \bar p_2\,\Delta_*\zeta_3 \end{aligned}$$

with $\bar p_j$ *for* $j=1,2,3$ *the polynomials in the variable* x_3 *of degrees* j *defined as*

$$\tag{4.4} \begin{aligned} \bar p_1(x_3) = -\,\frac{\tilde\lambda}{2\mu}\,x_3, \qquad \bar p_2(x_3) = \frac{\tilde\lambda}{4\mu}\,\Big(x_3^2 - \frac{1}{3}\Big),\\ \bar p_3(x_3) = \frac{1}{12\mu}\,\big((\tilde\lambda+4\mu)\,x_3^3 - (5\tilde\lambda+12\mu)\,x_3\big). \end{aligned}$$

Here $\tilde\lambda$ *still denotes the "homogenized" Lamé coefficient* $2\lambda\mu(\lambda+2\mu)^{-1}$.

With L^{m} the membrane operator (3.8), direct computations yield the following lemma.

LEMMA 4.2. *Let* $\boldsymbol{\zeta}$ *belong to* $\mathcal{C}^\infty(\overline{\omega})^3$ *and let* $\boldsymbol{u}_{\mathrm{KL}}$ *be the associated Kirchhoff–Love displacement. Then the field* $V\boldsymbol{\zeta}$ *is the unique solution with zero mean values on each fiber* $x_*\times(-1,1)$ *of the problem*

$$\tag{4.5} A(V\boldsymbol{\zeta}) + B(\boldsymbol{u}_{\mathrm{KL}}) = \Big(L^{\mathrm{m}}\boldsymbol{\zeta}_*\ ,\ 0\ ;\ 0\big|_{\Gamma_\pm}\ ,\ 0\big|_{\Gamma_\pm}\Big).$$

Then, if $L^{\mathrm{m}}\boldsymbol{\zeta}^1_* = 0$, we can take $\underline{\boldsymbol{u}}^3 = \boldsymbol{u}^3_{\mathrm{KL}} + V\boldsymbol{\zeta}^1$. In order to proceed, we remark that each component of $B(V\boldsymbol{\zeta})$ can be split into two parts, both of them being the product of a polynomial in x_3 and of $\Delta_*\,\mathrm{div}_*\,\boldsymbol{\zeta}_*$ or $\Delta_*^2\zeta_3$, or a derivative of these expressions. With the bending operator (3.11) we easily obtain that if $L^{\mathrm{m}}\boldsymbol{\zeta}_*$ and $L^{\mathrm{b}}\zeta_3$ are zero, then $B(V\boldsymbol{\zeta})$ is zero, too. Thus, the odd part of the outer Ansatz is solved, since we obtain by an induction argument the following proposition.

Proposition 4.3. *For any $k = 1, 3, 5, \ldots$ let $\boldsymbol{\zeta}^k$ be such that $L^{\mathrm{m}}\boldsymbol{\zeta}^k_* = 0$ and $L^{\mathrm{b}}\zeta^k_3 = 0$. Then, setting for $k = 3, 5, \ldots$*

$$\underline{\boldsymbol{u}}^k = \boldsymbol{u}^k_{\mathrm{KL}} + V\boldsymbol{\zeta}^{k-2}\,,$$

we obtain all the solutions of the odd order equations in system (4.2).

Let us consider now the equations of *even* order. The operator A is block triangular and its diagonal is made of ordinary Neumann problems on the interval $(-1, 1)$. So actually, in order to have solvability for these problems, compatibility conditions are required on the right-hand sides. Conversely, if the problems are solvable, the solutions are uniquely determined if we require that they have a mean value zero on each fiber $x_* \times (-1, 1)$ with $x_* \in \overline{\omega}$.

With $\underline{\boldsymbol{u}}^0 = \boldsymbol{u}^0_{\mathrm{KL}}$, we will find $\underline{\boldsymbol{u}}^2$ being of the form $\boldsymbol{u}^2_{\mathrm{KL}} + V\boldsymbol{\zeta}^0 + G(\boldsymbol{f}, \boldsymbol{g}^{\pm})$, where G is another solution operator. But prior to this, we need two sorts of primitives of an integrable function u on the interval $(-1, +1)$.

Notation 4.4. *Let us introduce the following:*

- *the primitive of u with zero mean value on* $(-1, +1)$

$$\oint^{x_3} u\, dy_3 \;:=\; \int_{-1}^{x_3} u(y_3)\, dy_3 - \frac{1}{2}\int_{-1}^{+1}\int_{-1}^{z_3} u(y_3)\, dy_3\, dz_3;$$

- *the primitive of u which vanishes in -1 and 1 if u has a zero mean value on $(-1, +1)$ and which is even, respectively, odd, if u is odd, respectively, even*

$$\fint^{y_3} u\, dz_3 \;:=\; \frac{1}{2}\left(\int_{-1}^{y_3} u(z_3)\, dz_3 - \int_{y_3}^{+1} u(z_3)\, dz_3\right).$$

Definition 4.5. *The operator $G : (\boldsymbol{f}, \boldsymbol{g}^{\pm}) \mapsto G(\boldsymbol{f}, \boldsymbol{g}^{\pm})$ is defined from $\mathcal{C}^\infty(\overline{\Omega})^3 \times \mathcal{C}^\infty(\overline{\omega})^6$ into $\mathcal{C}^\infty(\overline{\Omega})^3$ by*

$$\begin{cases} (G(\boldsymbol{f}, \boldsymbol{g}^{\pm}))_3 &=& 0, \\ (G(\boldsymbol{f}, \boldsymbol{g}^{\pm}))_\alpha &=& \dfrac{1}{2\mu}\displaystyle\oint^{x_3}\left[-2\fint^{y_3} f_\alpha \;+\; \left(g^+_\alpha - g^-_\alpha + \int_{-1}^{+1} f_\alpha\right) y_3 + g^+_\alpha + g^-_\alpha\right] dy_3\,. \end{cases}$$

The reason for the introduction of G is as follows.

Lemma 4.6. *For any $(\boldsymbol{f}, \boldsymbol{g}^{\pm}) \in \mathcal{C}^\infty(\overline{\Omega})^3 \times \mathcal{C}^\infty(\overline{\omega})^6$, $G(\boldsymbol{f}, \boldsymbol{g}^{\pm})$ is the unique solution with zero mean values on each fiber $x_* \times (-1, 1)$ of the problem*

$$A\big(G(\boldsymbol{f}, \boldsymbol{g}^{\pm})\big) = \left(-f_\alpha + \frac{1}{2}\left[\int_{-1}^{+1} f_\alpha\, dx_3 + g^+_\alpha - g^-_\alpha\right]\;,\; 0\;;\; g^{\pm}_\alpha\big|_{\Gamma_\pm}\;,\; 0\big|_{\Gamma_\pm}\right).$$

Now, we can see that if we set

$$\boldsymbol{R}^0_{\mathrm{m}}(x_*) = -\frac{1}{2}\left[\int_{-1}^{+1} \boldsymbol{f}_*(x_*, x_3)\, dx_3 + \boldsymbol{g}^+_*(x_*) - \boldsymbol{g}^-_*(x_*)\right] \tag{4.6}$$

for any $\boldsymbol{\zeta}^0_*$ satisfying the membrane equation $L^{\mathrm{m}}(\boldsymbol{\zeta}^0_*) = \boldsymbol{R}^0_{\mathrm{m}}$, the displacement $\underline{\boldsymbol{u}}^2 = \boldsymbol{u}^2_{\mathrm{KL}} + V\boldsymbol{\zeta}^0 + G(\boldsymbol{f}, \boldsymbol{g}^{\pm})$ solves the equation of order $k = 2$ of system (4.2). We denote by $\boldsymbol{v}^2 = V\boldsymbol{\zeta}^0 + G$ its part with zero mean values on each fiber $x_* \times (-1, 1)$.

In order to go further in solving the even part of the Ansatz, we are going to introduce a residual operator $F = (F_*, F_3)$ and a new solution operator W.

Definition 4.7. (i) *The operator* $F : \boldsymbol{v} \mapsto F\boldsymbol{v} = (F_*\boldsymbol{v}, F_3\boldsymbol{v})$ *is defined from* $\mathcal{C}^\infty(\overline{\Omega})^3$ *into* $\mathcal{C}^\infty(\overline{\omega})^3$ *by*

$$\left\{\begin{array}{rcl} F_3\boldsymbol{v} &=& \mu \displaystyle\int_{-1}^{+1} \partial_\beta e_{\beta 3}(\boldsymbol{v})\, dy_3\,, \\ F_\alpha\boldsymbol{v} &=& \dfrac{\tilde\lambda}{2} \displaystyle\int_{-1}^{+1} \fint^{y_3} \partial_{\alpha\beta} e_{\beta 3}(\boldsymbol{v})\, dz_3\, dy_3\,. \end{array}\right.$$

(ii) *The operator* $W : \boldsymbol{v} \mapsto W\boldsymbol{v}$ *is defined from* $\mathcal{C}^\infty(\overline{\Omega})^3$ *into itself by*

$$\left\{\begin{array}{rcl} W_3\boldsymbol{v} &=& -\displaystyle\oint^{x_3} \Big(\frac{\tilde\lambda}{2\mu}\operatorname{div}_* \boldsymbol{v}_* + \frac{\tilde\lambda}{\lambda}\fint^{y_3} \partial_\beta e_{\beta 3}(\boldsymbol{v})\Big) dy_3, \\ W_\alpha\boldsymbol{v} &=& -\displaystyle\oint^{x_3} \Big(\partial_\alpha W_3\boldsymbol{v} + \fint^{y_3}\Big(\frac{\lambda}{\mu}\,\partial_{\alpha 3} W_3\boldsymbol{v} + \frac{\lambda+\mu}{\mu}\,\partial_\alpha \operatorname{div}_* \boldsymbol{v}_* + \Delta_* v_\alpha\Big)\Big) dy_3. \end{array}\right.$$

With these operators, we can prove the following lemma.

Lemma 4.8. *Let* $\boldsymbol{v}$ *in* $\mathcal{C}^\infty(\overline{\Omega})^3$ *be a displacement field with zero mean values on each fiber* $x_* \times (-1, 1)$, $x_* \in \overline{\omega}$. *Then* $W\boldsymbol{v}$ *has also zero mean values on each fiber* $x_* \times (-1, 1)$ *and solves the problem*

$$A(W\boldsymbol{v}) + B(\boldsymbol{v}) = \Big(0\ ,\ 0\ ;\ \pm F_*(\boldsymbol{v})\big|_{\Gamma_\pm}\ ,\ \mp F_3(\boldsymbol{v})\big|_{\Gamma_\pm}\Big).$$

Now, it is natural to search for $\underline{\boldsymbol{u}}^4$ with the form $\boldsymbol{u}^4_{\mathrm{KL}} + V\boldsymbol{\zeta}^2 + W(V\boldsymbol{\zeta}^0 + G) + H$. In view of Lemmas 4.2 and 4.8, with such an Ansatz, H has to solve the problem

$$AH = \Big(-L^{\mathrm{m}}(\boldsymbol{\zeta}^2_*)\ ,\ -f_3\ ;\ \mp F_*(V\boldsymbol{\zeta}^0 + G)\big|_{\Gamma_\pm}\ ,\ g_3^\pm \pm F_3(V\boldsymbol{\zeta}^0 + G)\big|_{\Gamma_\pm}\Big). \tag{4.7}$$

Thus, it is important to have more information about $F(V\boldsymbol{\zeta}^0 + G)$. It is not difficult to check, as seen below.

Lemma 4.9. *For all* $\boldsymbol{\zeta}$ *in* $\mathcal{C}^\infty(\overline{\omega})^3$ *we have*

$$F_*(V\boldsymbol{\zeta}) = 0 \qquad \textit{and} \qquad F_3(V\boldsymbol{\zeta}) = -\tfrac{1}{3}L^{\mathrm{b}}\zeta_3\,.$$

Moreover, we have

$$F_3(G) = \frac{1}{2}\operatorname{div}_* \Big[\int_{-1}^{+1} x_3\, \boldsymbol{f}_*\, dx_3 + \boldsymbol{g}_*^+ + \boldsymbol{g}_*^-\Big]\,. \tag{4.8}$$

Then there holds the following lemma.

Lemma 4.10. *Let* R^0_{b} *be defined as*

$$R^0_{\mathrm{b}} = \frac{3}{2}\Big[\int_{-1}^{+1} f_3\, dx_3 + g_3^+ - g_3^- + \operatorname{div}_*\Big(\int_{-1}^{+1} x_3\, \boldsymbol{f}_*\, dx_3 + \boldsymbol{g}_*^+ + \boldsymbol{g}_*^-\Big)\Big] \tag{4.9}$$

and $\boldsymbol{R}^2_{\mathrm{m}}$ *be defined as*

$$\boldsymbol{R}^2_{\mathrm{m}} = F_*(G) - \frac{\tilde\lambda}{4\mu}\nabla_*\Big[\int_{-1}^{+1} x_3\, f_3\, dx_3 + g_3^+ + g_3^-\Big]\,. \tag{4.10}$$

TABLE 8
Algorithm formulas.

k	$\underline{\boldsymbol{u}}^k$	$\boldsymbol{v}^k$	$\boldsymbol{y}^{k-2}$	$\boldsymbol{R}^k_{\mathrm{m}}$	R^k_{b}
0	$\boldsymbol{u}^0_{\mathrm{KL}}$	—	—	$\boldsymbol{R}^0_{\mathrm{m}}$	R^0_{b}
2	$\boldsymbol{u}^2_{\mathrm{KL}}+\boldsymbol{v}^2$	$V\boldsymbol{\zeta}^0+\boldsymbol{y}^0$	G	$\boldsymbol{R}^2_{\mathrm{m}}$	$3F_3(W\boldsymbol{v}^2+H)$
4	$\boldsymbol{u}^4_{\mathrm{KL}}+\boldsymbol{v}^4$	$V\boldsymbol{\zeta}^2+\boldsymbol{y}^2$	$W\boldsymbol{v}^2+H$	$F_*\boldsymbol{v}^4$	$3F_3(W\boldsymbol{v}^4+Y\boldsymbol{\zeta}^4_*)$
$2\ell{+}2$	$\boldsymbol{u}^{2\ell+2}_{\mathrm{KL}}+\boldsymbol{v}^{2\ell+2}$	$V\boldsymbol{\zeta}^{2\ell}+\boldsymbol{y}^{2\ell}$	$W\boldsymbol{v}^{2\ell}+Y\boldsymbol{\zeta}^{2\ell}_*$	$F_*\boldsymbol{v}^{2\ell+2}$	$3F_3(W\boldsymbol{v}^{2\ell+2}{+}Y\boldsymbol{\zeta}^{2\ell+2}_*)$
1	$\boldsymbol{u}^1_{\mathrm{KL}}$	—	—	0	0
$2\ell{+}1$	$\boldsymbol{u}^{2\ell+1}_{\mathrm{KL}}+\boldsymbol{v}^{2\ell+1}$	$V\boldsymbol{\zeta}^{2\ell-1}$	—	0	0

If there hold $L^{\mathrm{b}}(\zeta^0_3)=R^0_{\mathrm{b}}$ *and* $L^{\mathrm{m}}(\boldsymbol{\zeta}^2_*)=\boldsymbol{R}^2_{\mathrm{m}}$, *then* (4.7) *admits a unique solution* $H=H(\boldsymbol{f},\boldsymbol{g}^{\pm})$ *with zero mean values on each fiber* $x_*\times(-1,1)$ *which is given by*

$$\left\{\begin{array}{lcl} H_3 &=& \dfrac{1}{2(\lambda+2\mu)}\displaystyle\oint^{x_3}\Big[\Big(-2\,{-}\!\!\!\!\!\!\int^{y_3} f_3\Big)+g^+_3+g^-_3\Big]dy_3, \\ H_\alpha &=& -\displaystyle\oint^{x_3}\Big[\partial_\alpha H_3+\frac{1}{\mu}\,y_3\,F_*(G)+\frac{\lambda}{\mu}\,{-}\!\!\!\!\!\!\int^{y_3}\Big\{\partial_{\alpha3}H_3-\frac{1}{2}\int_{-1}^{+1}\partial_{\alpha3}H_3\,dz_3\Big\}\Big]dy_3\,. \end{array}\right.$$

Thus, we have found $\underline{\boldsymbol{u}}^4$ as $\boldsymbol{u}^4_{\mathrm{KL}}+\boldsymbol{v}^4$, where $\boldsymbol{v}^4$ has zero mean values on each fiber $x_*\times(-1,1)$: $\boldsymbol{v}^4$ is given by $V\boldsymbol{\zeta}^2+W(V\boldsymbol{\zeta}^0+G)+H=V\boldsymbol{\zeta}^2+W\boldsymbol{v}^2+H$.

Next, we search for a $\underline{\boldsymbol{u}}^6$ with the form $\boldsymbol{u}^6_{\mathrm{KL}}+V\boldsymbol{\zeta}^4+W\boldsymbol{v}^4+Y$. In view of Lemmas 4.2 and 4.8, with such an Ansatz, Y has to solve the problem

$$AY=\Big(-L^{\mathrm{m}}(\boldsymbol{\zeta}^4_*)\;,\;0\;;\;\mp F_*(\boldsymbol{v}^4)\big|_{\Gamma_\pm}\;,\;\pm F_3(\boldsymbol{v}^4)\big|_{\Gamma_\pm}\Big). \tag{4.11}$$

This problem is solvable if (i) $F_3(\boldsymbol{v}^4)$ is zero, which holds true if $L^{\mathrm{b}}\zeta^2_3=3F_3(W\boldsymbol{v}^2{+}H)$, (ii) $L^{\mathrm{m}}(\boldsymbol{\zeta}^4_*)=F_*(\boldsymbol{v}^4)$, compare Lemma 4.10.

Then $Y=Y(\boldsymbol{\zeta}^4_*)$ solves (4.11), with the solution operator Y defined as follows.

DEFINITION 4.11. *For* $\boldsymbol{\zeta}_*\in\mathcal{C}^\infty(\overline{\omega})^2$, $Y=Y(\boldsymbol{\zeta}_*)$ *is defined as*

$$Y_3=0\quad\textit{and}\quad Y_*=-2\,\tilde{\lambda}^{-1}\,\bar{p}_2\,L^{\mathrm{m}}(\boldsymbol{\zeta}_*)\,.$$

From now on, the solution of (4.2) is self-similar. Summarizing, we obtain by induction that every expansion (4.1) solving (2.12a)–(2.13a) can be described according to Table 8, where G and H are a condensed notation for $G(\boldsymbol{f},\boldsymbol{g}^{\pm})$ and $H(\boldsymbol{f},\boldsymbol{g}^{\pm})$, respectively, and $\boldsymbol{R}^k_{\mathrm{m}}$ and R^k_{b} are the prescribed values for $L^{\mathrm{m}}(\boldsymbol{\zeta}^k_*)$ and $L^{\mathrm{b}}(\zeta^k_3)$, respectively (note that $\boldsymbol{R}^0_{\mathrm{m}}$, $\boldsymbol{R}^2_{\mathrm{m}}$, and R^0_{b} are defined in (4.6), (4.10), and (4.9)).

Here the even order terms and the odd order ones are independent from each other. We will see later on that they are connected by the lateral boundary conditions via the boundary layer terms. We emphasize that each term $\underline{\boldsymbol{u}}^k$ in the algorithm is the sum of two terms $\underline{\boldsymbol{u}}^k=\boldsymbol{u}^k_{\mathrm{KL}}+\boldsymbol{v}^k$ with $\boldsymbol{u}^k_{\mathrm{KL}}$ representing the general solution of homogeneous Neumann problems for ordinary differential equations over each fiber $x_*\times(-1,1)$ and $\boldsymbol{v}^k$ being particular solutions of inhomogeneous ordinary Neumann problems across the thickness with mean value zero.

4.3. Formulas for the determined part of the displacements. The formulas in Table 8 giving the $\boldsymbol{v}^k$ yield in a straightforward way that

$$\begin{aligned} \boldsymbol{v}^{2k+1} &= V\boldsymbol{\zeta}^{2k-1}\,, \\ \boldsymbol{v}^{2k+2} &= \sum_{\ell=0}^{k} W^\ell\circ V\boldsymbol{\zeta}^{2(k-\ell)} + \sum_{\ell=0}^{k-2} W^\ell\circ Y\boldsymbol{\zeta}_*^{2(k-\ell)} \\ &\quad + W^k\circ G(\boldsymbol{f},\boldsymbol{g}^\pm) + W^{k-1}\circ H(\boldsymbol{f},\boldsymbol{g}^\pm) \end{aligned} \tag{4.12}$$

with the convention that $W^{-1}=0$ and $W^0=\mathrm{Id}$.

Using the definitions of V and W, we can prove the following.

LEMMA 4.12. *For $\ell=0,1,\ldots,$ we have the following formulas for the iterates $W^\ell\circ V$:*

$$\begin{aligned} (W^\ell\circ V\boldsymbol{\zeta})_\alpha &= \bar r_{2\ell+2}\,\partial_\alpha\Delta_*^\ell\operatorname{div}_*\boldsymbol{\zeta}_* + \bar r_{2\ell+3}\,\partial_\alpha\Delta_*^{\ell+1}\zeta_3, \\ (W^\ell\circ V\boldsymbol{\zeta})_3 &= \bar q_{2\ell+1}\,\Delta_*^\ell\operatorname{div}_*\boldsymbol{\zeta}_* + \bar q_{2\ell+2}\,\Delta_*^{\ell+1}\zeta_3 \end{aligned} \tag{4.13}$$

with $\bar q_j$, $\bar r_j$ the polynomials in the variable x_3 of degrees j and of parities j defined recursively as

$$\bar q_1=\bar p_1,\quad \bar q_2=\bar p_2,\quad \bar r_2=\bar p_2,\quad \bar r_3=\bar p_3,$$

with $\bar p_j$ for $j=1,2,3$, the polynomials defined in (4.4)*, and*

$$\begin{aligned} \bar q_j(x_3) &= -\oint^{x_3}\Big(\frac{\tilde\lambda}{2\mu}\bar r_{j-1} + \frac{\tilde\lambda}{2\lambda}\fint^{y_3}(\bar q_{j-2}+\bar r'_{j-1})\Big)dy_3 && \textit{for } j\ge 3, \\ \bar r_j(x_3) &= -\oint^{x_3}\Big(\bar q_{j-1} + \fint^{y_3}\Big(\frac{\lambda}{\mu}\,\bar q'_{j-1} + \frac{\lambda+2\mu}{\mu}\,\bar r_{j-2}\Big)\Big)dy_3, && \textit{for } j\ge 4. \end{aligned} \tag{4.14}$$

Similarly, using the definition of Y, we are able to show the following lemma.

LEMMA 4.13. *For $\ell=0,1,\ldots,$ we have the following formulas for the iterates $W^\ell\circ Y$:*

$$\begin{aligned} (W^\ell\circ Y\boldsymbol{\zeta}_*)_\alpha &= \bar s_{2\ell+2}\,\partial_\alpha\Delta_*^\ell\operatorname{div}_*\boldsymbol{\zeta}_* + \bar t_{2\ell+2}\,\Delta_*^{\ell+1}\zeta_\alpha, \\ (W^\ell\circ Y\boldsymbol{\zeta}_*)_3 &= \bar s_{2\ell+1}\,\Delta_*^\ell\operatorname{div}_*\boldsymbol{\zeta}_* \end{aligned} \tag{4.15}$$

with $\bar s_j$ and $\bar t_j$ the polynomials in the variable x_3 of degrees j and of parities j defined recursively as

$$\bar s_1=0,\quad \bar s_2=-\,\frac{\lambda+2\mu}{\lambda}\,\bar p_2\quad \textit{and}\quad \bar t_2=-\,\frac{3\lambda+2\mu}{\lambda}\,\bar p_2$$

with $\bar p_2$ given in (4.4)*, and for $\ell\ge 1$*

$$\begin{aligned} \bar s_{2\ell+1}(x_3) &= -\oint^{x_3}\Big(\frac{\tilde\lambda}{2\mu}(\bar s_{2\ell}+\bar t_{2\ell}) + \frac{\tilde\lambda}{2\lambda}\fint^{y_3}(\bar s_{2\ell-1}+\bar s'_{2\ell}+\bar t'_{2\ell})\Big)dy_3, \\ \bar s_{2\ell+2}(x_3) &= -\oint^{x_3}\Big(\bar s_{2\ell+1} + \fint^{y_3}\Big(\frac{\lambda}{\mu}\,\bar s'_{2\ell+1} + \frac{\lambda+\mu}{\mu}\,(\bar s_{2\ell}+\bar t_{2\ell}) + \bar s_{2\ell}\Big)\Big)dy_3, \\ \bar t_{2\ell+2}(x_3) &= -\oint^{x_3}\Big(\fint^{y_3}\bar t_{2\ell}\Big)dy_3. \end{aligned} \tag{4.16}$$

Condensing $G(\boldsymbol{f}, \boldsymbol{g}^{\pm})$ into G and $H(\boldsymbol{f}, \boldsymbol{g}^{\pm})$ into H, we obtain the following formulas for the first $\boldsymbol{v}^k$ (k even):

$$\begin{aligned} v_\alpha^2 &= \bar{p}_2\, \partial_\alpha \operatorname{div}_* \boldsymbol{\zeta}_*^0 + \bar{p}_3\, \partial_\alpha \Delta_* \zeta_3^0 + G_\alpha, \\ v_3^2 &= \bar{p}_1 \operatorname{div}_* \boldsymbol{\zeta}_*^0 + \bar{p}_2\, \Delta_* \zeta_3^0\,, \end{aligned} \tag{4.17}$$

$$\begin{aligned} v_\alpha^4 &= \bar{p}_2\, \partial_\alpha \operatorname{div}_* \boldsymbol{\zeta}_*^2 + \bar{p}_3\, \partial_\alpha \Delta_* \zeta_3^2 + \bar{r}_4\, \partial_\alpha \Delta_* \operatorname{div}_* \boldsymbol{\zeta}_*^0 + \bar{r}_5\, \partial_\alpha \Delta_*^2 \zeta_3^0 + (WG + H)_\alpha, \\ v_3^4 &= \bar{p}_1 \operatorname{div}_* \boldsymbol{\zeta}_*^2 + \bar{p}_2\, \Delta_* \zeta_3^2 + \bar{q}_3\, \Delta_* \operatorname{div}_* \boldsymbol{\zeta}_*^0 + \bar{q}_4\, \Delta_*^2 \zeta_3^0 + (WG + H)_3\,. \end{aligned} \tag{4.18}$$

5. The principles of construction of the inner expansion part.

After the construction of the most general power series (4.1) solving (2.12a)–(2.13a), we see that the only remaining degrees of freedom can be given by traces of the Kirchhoff–Love generators $\boldsymbol{\zeta}^k$. As will be investigated for each case in particular, complementing traces of the Kirchhoff–Love generators $\boldsymbol{\zeta}^k$ can be determined along with the computation of the boundary layer terms $\boldsymbol{w}^k$.

The boundary layer Ansatz, namely $\sum_{k\geq 1} \varepsilon^k \boldsymbol{w}^k$, must satisfy the equations (2.12a) inside Ω with vanishing right-hand side and the boundary conditions (2.13a) of zero traction on the horizontal faces of Ω, and must compensate for the lateral boundary conditions of the power series $\sum_{k\geq 0} \varepsilon^k \underline{\boldsymbol{u}}^k$ so that the lateral boundary conditions (2.14) are fulfilled. We present in this section some common features of all problems.

5.1. The equations of the inner expansion.

5.1.1. Lateral boundary conditions. In order to obtain the relations which have to be satisfied by the inner part of the expansion, we evaluate the boundary conditions for a displacement $\boldsymbol{u}$ of the form

$$\boldsymbol{u}(\varepsilon)(x) = \underline{\boldsymbol{u}}(x) + (\boldsymbol{\varphi}_*, \varepsilon\varphi_3)\Big(\frac{r}{\varepsilon}, s, x_3\Big), \tag{5.1}$$

where $\underline{\boldsymbol{u}} = \sum_{k\geq 0} \varepsilon^k \underline{\boldsymbol{u}}^k$ and $\boldsymbol{\varphi} = \sum_{k\geq 1} \varepsilon^k \boldsymbol{\varphi}^k$. The form of the boundary layer term $(\boldsymbol{\varphi}_*, \varepsilon\varphi_3)$ is related to the covariant nature of displacements: indeed we return with $\boldsymbol{\varphi}$ to the homogeneity of the original unknown $\boldsymbol{u}^\varepsilon$. We denote by φ_t the normal component of $\boldsymbol{\varphi}$.

For $\boldsymbol{u}$ of the form (5.1), the formulas for the lateral Dirichlet conditions are obvious, and the lateral Neumann conditions can be written with the help of the following boundary operators acting on the profiles $\boldsymbol{\varphi}$:

$$\begin{aligned} T_t^{(0)}(\boldsymbol{\varphi}) &= \lambda\, \partial_3 \varphi_3 + (\lambda + 2\mu)\partial_t \varphi_t, & T_t^{(1)}(\boldsymbol{\varphi}) &= \lambda(\partial_s \varphi_s - \tfrac{1}{R}\, \varphi_t), \\ T_s^{(0)}(\boldsymbol{\varphi}) &= \mu\, \partial_t \varphi_s, & T_s^{(1)}(\boldsymbol{\varphi}) &= \mu(\partial_s \varphi_t + \tfrac{2}{R}\, \varphi_s), \\ T_3^{(0)}(\boldsymbol{\varphi}) &= \mu(\partial_t \varphi_3 + \partial_3 \varphi_t). \end{aligned} \tag{5.2}$$

Thus, we can write the components of the lateral traction (cf. (2.15a)) as

$$T_n(\varepsilon) = \varepsilon\, T_t^{(0)}(\boldsymbol{\varphi}) + \varepsilon^2 T_t^{(1)}(\boldsymbol{\varphi}) + \lambda\, \partial_3\, \underline{u}_3 + \varepsilon^2\big(\lambda \operatorname{div}_* \underline{\boldsymbol{u}}_* + 2\mu\, \partial_n \underline{u}_n\big), \tag{5.3a}$$

$$T_s(\varepsilon) = \varepsilon\, T_s^{(0)}(\boldsymbol{\varphi}) + \varepsilon^2 T_s^{(1)}(\boldsymbol{\varphi}) + \varepsilon^2 \mu\big(\partial_s \underline{u}_n + \partial_n \underline{u}_s + \tfrac{2}{R}\, \underline{u}_s\big), \tag{5.3b}$$

$$T_3(\varepsilon) = T_3^{(0)}(\boldsymbol{\varphi}) + \mu(\partial_n \underline{u}_3 + \partial_3 \underline{u}_n). \tag{5.3c}$$

5.1.2. Interior equations. In variables (t, s, x_3) and unknowns

$$\boldsymbol{\varphi} = (\varphi_t, \varphi_s, \varphi_3) \sim \Big(\boldsymbol{w}_*, \frac{1}{\varepsilon}\, w_3\Big),$$

the interior equations (2.12a) for $\boldsymbol{w}$ have the form

$$\mathcal{B}(\varepsilon\,;\, t, s\,;\, \partial_t, \partial_s, \partial_3)\boldsymbol{\varphi} = 0,$$

where the three components $\mathcal{B}(\varepsilon)_t$, $\mathcal{B}(\varepsilon)_s$, and $\mathcal{B}(\varepsilon)_3$ of $\mathcal{B}(\varepsilon)$ can be written as polynomials of degree 2 in ε with coefficients involving partial derivative operators of degree ≤ 2 combined with integer powers of $R = R(s)$ and of $\frac{1}{\rho}$ with

$$\rho = R(s) - r = R(s) - \varepsilon t$$

which is the curvature radius in s of the curve $\{x_* \in \omega,\ \operatorname{dist}(x_*, \partial\omega) = r\}$. The thorough expression of $\mathcal{B}(\varepsilon)$ can be found in [11, section 3]. A Taylor expansion at $t = 0$ of $\rho^{-1} = (R - \varepsilon t)^{-1}$ yields an asymptotic expansion of $\mathcal{B}$ in a power series of ε:

$$\mathcal{B} \sim \mathcal{B}^{(0)} + \varepsilon\mathcal{B}^{(1)} + \cdots \varepsilon^k \mathcal{B}^{(k)} + \cdots, \tag{5.4}$$

where the $\mathcal{B}^{(k)}(t, s\,;\, \partial_t, \partial_s, \partial_3)$ are partial differential systems of order 2 with polynomial coefficients in t independent from ε. Here follow the expressions for $\mathcal{B}^{(0)}$ and $\mathcal{B}^{(1)}$:

$$\begin{aligned}
(\mathcal{B}^{(0)}\boldsymbol{\varphi})_t &= \mu\big(\partial_{tt}\varphi_t + \partial_{33}\varphi_t\big) + (\lambda+\mu)\,\partial_t\big(\partial_t\varphi_t + \partial_3\varphi_3\big),\\
(\mathcal{B}^{(0)}\boldsymbol{\varphi})_s &= \mu\big(\partial_{tt}\varphi_s + \partial_{33}\varphi_s\big),\\
(\mathcal{B}^{(0)}\boldsymbol{\varphi})_3 &= \mu\,\big(\partial_{tt}\varphi_3 + \partial_{33}\varphi_3\big) + (\lambda+\mu)\,\partial_3\big(\partial_t\varphi_t + \partial_3\varphi_3\big)
\end{aligned} \tag{5.5}$$

and, with the curvature $\kappa = \frac{1}{R}$,

$$\begin{aligned}
(\mathcal{B}^{(1)}\boldsymbol{\varphi})_t &= -\mu\,\kappa\,\partial_t\varphi_t + (\lambda+\mu)\,\partial_t\big(-\kappa\,\varphi_t + \partial_s\varphi_s\big),\\
(\mathcal{B}^{(1)}\boldsymbol{\varphi})_s &= \mu\,\kappa\big(\partial_{tt}(t\varphi_s) + \partial_{33}(t\varphi_s)\big) - \mu\,\kappa\,\partial_t\varphi_s + (\lambda+\mu)\,\partial_s\big(\partial_t\varphi_t + \partial_3\varphi_3\big),\\
(\mathcal{B}^{(1)}\boldsymbol{\varphi})_3 &= -\mu\,\kappa\,\partial_t\varphi_3 + (\lambda+\mu)\,\partial_3\big(-\kappa\,\varphi_t + \partial_s\varphi_s\big).
\end{aligned} \tag{5.6}$$

Thus, the interior equation $\mathcal{B}(\varepsilon)\boldsymbol{\varphi} = 0$ can be written as

$$\mathcal{B}^{(0)}\boldsymbol{\varphi} + \varepsilon\mathcal{B}^{(1)}\boldsymbol{\varphi} + \cdots \varepsilon^k\mathcal{B}^{(k)}\boldsymbol{\varphi} + \cdots \sim 0. \tag{5.7}$$

5.1.3. Horizontal boundary conditions. The boundary conditions on the horizontal sides $x_3 = \pm 1$ are (cf. (2.13a))

$$\mu(\partial_3\varphi_t + \partial_t\varphi_3) = 0, \tag{5.8a}$$

$$\mu\partial_3\varphi_s + \varepsilon\,\mu\,\partial_s\varphi_3 = 0, \tag{5.8b}$$

$$(\lambda + 2\mu)\partial_3\varphi_3 + \lambda\,\partial_t\varphi_t + \varepsilon\,\lambda\bigg(-\tfrac{1}{\rho}\varphi_t + \tfrac{R}{\rho}\partial_s\Big(\tfrac{R}{\rho}\varphi_s\Big)\bigg) = 0. \tag{5.8c}$$

Similarly to the interior equations, we can develop the horizontal boundary conditions $\mathcal{G}$ (5.8a) in powers of ε:

$$\mathcal{G} \sim \mathcal{G}^{(0)} + \varepsilon\mathcal{G}^{(1)} + \cdots \varepsilon^k\mathcal{G}^{(k)} + \cdots, \tag{5.9}$$

where the $\mathcal{G}^{(k)}(t, s\,;\partial_t, \partial_s, \partial_3)$ are partial differential systems of order 1 with polynomial coefficients in t. The expressions for $\mathcal{G}^{(0)}$ and $\mathcal{G}^{(1)}$ are

$$(5.10)\quad \begin{array}{lcllcl} (\mathcal{G}^{(0)}\boldsymbol{\varphi})_t &=& \mu(\partial_3\varphi_t + \partial_t\varphi_3), & (\mathcal{G}^{(1)}\boldsymbol{\varphi})_t &=& 0, \\ (\mathcal{G}^{(0)}\boldsymbol{\varphi})_s &=& \mu\partial_3\varphi_s, & (\mathcal{G}^{(1)}\boldsymbol{\varphi})_s &=& \mu\partial_s\varphi_3, \\ (\mathcal{G}^{(0)}\boldsymbol{\varphi})_3 &=& (\lambda+2\mu)\partial_3\varphi_3 + \lambda\,\partial_t\varphi_t, & (\mathcal{G}^{(1)}\boldsymbol{\varphi})_3 &=& \lambda(-\kappa\,\varphi_t + \partial_s\varphi_s). \end{array}$$

Thus, the horizontal boundary conditions $\mathcal{G}(\varepsilon)\boldsymbol{\varphi} = 0$ can be written as

$$(5.11)\qquad \mathcal{G}^{(0)}\boldsymbol{\varphi} + \varepsilon\mathcal{G}^{(1)}\boldsymbol{\varphi} + \cdots \varepsilon^k\mathcal{G}^{(k)}\boldsymbol{\varphi} + \cdots \sim 0.$$

5.2. The recursive equations. Assuming that $\sum_k \varepsilon^k \underline{\boldsymbol{u}}^k$ already fulfills the relations in Table 8, we determine now the equations satisfied by the profiles $\boldsymbol{\varphi}^k$ and the remaining conditions satisfied by the displacements $\underline{\boldsymbol{u}}^k$ so that

$$(5.12)\qquad \sum_{k\,\geq\,0} \varepsilon^k \underline{\boldsymbol{u}}^k + \sum_{k\,\geq\,1} \varepsilon^k (\boldsymbol{\varphi}_*^k, \varepsilon\varphi_3^k)$$

satisfies equations (2.12a)–(2.14).

5.2.1. Interior equations. Equation (5.7) yields that

$$(5.13)\qquad \forall k \geq 0, \qquad \sum_{\ell=0}^{k} \mathcal{B}^{(\ell)}\boldsymbol{\varphi}^{k-\ell} = 0,$$

which guarantees (2.12a) for the whole expansion (5.12).

5.2.2. Horizontal boundary conditions. Equation (5.11) yields that

$$(5.14)\qquad \forall k \geq 0, \qquad \sum_{\ell=0}^{k} \mathcal{G}^{(\ell)}\boldsymbol{\varphi}^{k-\ell} = 0,$$

which guarantees (2.13a) for the whole expansion (5.12).

5.2.3. Lateral Dirichlet boundary conditions. Let $\sum_k \varepsilon^k D_n^k$, $\sum_k \varepsilon^k D_s^k$, and $\sum_k \varepsilon^k D_3^k$ be the normal, tangential, and vertical components of the lateral Dirichlet traces of the series (5.12). The lateral Dirichlet boundary conditions then read

$$(5.15)\quad \forall k \geq 0, \qquad D_n^k = 0 \text{ if } n \in A, \quad D_s^k = 0 \text{ if } s \in A, \quad D_3^k = 0 \text{ if } 3 \in A,$$

which immediately yields the Dirichlet conditions for the whole expansion (5.12).

For the terms D^k, we have

$$(5.16)\qquad D_n^0 = \underline{u}_n^0, \quad D_s^0 = \underline{u}_s^0, \quad D_3^0 = \underline{u}_3^0, \quad D_3^1 = \underline{u}_3^1,$$

and for $k \geq 1$

$$(5.17a)\qquad D_n^k = \varphi_t^k + \underline{u}_n^k,$$

$$(5.17b)\qquad D_s^k = \varphi_s^k + \underline{u}_s^k,$$

$$(5.17c)\qquad D_3^{k+1} = \varphi_3^k + \underline{u}_3^{k+1}\,.$$

5.2.4. Lateral Neumann boundary conditions. Let $\sum_k \varepsilon^k T_n^k$, $\sum_k \varepsilon^k T_s^k$, and $\sum_k \varepsilon^k T_3^k$ be the normal, tangential, and vertical components of the lateral Neumann traces of the series (5.12). The lateral Neumann boundary conditions then read

$$\forall k \geq 0, \qquad T_n^k = 0 \text{ if } n \in B, \quad T_s^k = 0 \text{ if } s \in B, \quad T_3^k = 0 \text{ if } 3 \in B, \tag{5.18}$$

which immediately yields the Neumann conditions for the whole expansion (5.12).

Let us evaluate the terms T^k. To that aim, we rely on the following formulas for $\underline{\boldsymbol{u}}^k$, cf. Table 8. Either $\underline{\boldsymbol{u}}^k = \boldsymbol{u}^k_{\mathrm{KL}} + \boldsymbol{v}^k$, i.e.,

$$\underline{u}_n^k = \zeta_n^k - x_3\,\partial_n \zeta_3^k + v_n^k, \tag{5.19a}$$

$$\underline{u}_s^k = \zeta_s^k - x_3\,\partial_s \zeta_3^k + v_s^k, \tag{5.19b}$$

$$\underline{u}_3^k = \zeta_3^k + v_3^k, \tag{5.19c}$$

or $\underline{\boldsymbol{u}}^k = \boldsymbol{u}^k_{\mathrm{KL}} + V\boldsymbol{\zeta}^{k-2} + \boldsymbol{y}^{k-2}$, i.e.,

$$\underline{u}_n^k = \zeta_n^k - x_3\,\partial_n \zeta_3^k + \bar{p}_2\,\partial_n \operatorname{div}_* \boldsymbol{\zeta}_*^{k-2} + \bar{p}_3\,\partial_n \Delta_* \zeta_3^{k-2} + \boldsymbol{y}_n^{k-2}, \tag{5.20a}$$

$$\underline{u}_s^k = \zeta_s^k - x_3\,\partial_s \zeta_3^k + \bar{p}_2\,\partial_s \operatorname{div}_* \boldsymbol{\zeta}_*^{k-2} + \bar{p}_3\,\partial_s \Delta_* \zeta_3^{k-2} + \boldsymbol{y}_s^{k-2}, \tag{5.20b}$$

$$\underline{u}_3^k = \zeta_3^k + \bar{p}_1\, \operatorname{div}_* \boldsymbol{\zeta}_*^{k-2} + \bar{p}_2\,\Delta_* \zeta_3^{k-2} + \boldsymbol{y}_3^{k-2}, \tag{5.20c}$$

where $\bar{p}_1$, $\bar{p}_2$, $\bar{p}_3$ are introduced in (4.4).

Thus, we find

$$T_n^0 = 0, \quad T_n^1 = 0, \quad T_s^0 = 0, \quad T_s^1 = 0, \quad T_3^0 = 0, \tag{5.21}$$

and for $k \geq 1$ (cf. (3.10a), (3.12a), (5.2))

$$\begin{aligned} {}^{k+1}_{n} = {} & T_t^{(0)}(\boldsymbol{\varphi}^k) + T_t^{(1)}(\boldsymbol{\varphi}^{k-1}) + T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^{k-1}) - x_3\, M_n(\zeta_3^{k-1}) \\ & + \lambda\,\partial_3\, \boldsymbol{y}_3^{k-1} + \lambda \operatorname{div}_* \boldsymbol{v}_*^{k-1} + 2\mu\,\partial_n v_n^{k-1}, \end{aligned} \tag{5.22a}$$

$$\begin{aligned} T_s^{k+1} = {} & T_s^{(0)}(\boldsymbol{\varphi}^k) + T_s^{(1)}(\boldsymbol{\varphi}^{k-1}) + T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^{k-1}) - 2\mu x_3\,(\partial_n + \tfrac{1}{R})\partial_s \zeta_3^{k-1} \\ & + \mu\big(\partial_s v_n^{k-1} + \partial_n v_s^{k-1} + \tfrac{2}{R}\, v_s^{k-1}\big), \end{aligned} \tag{5.22b}$$

$$\begin{aligned} T_3^k = {} & T_3^{(0)}(\boldsymbol{\varphi}^k) + \mu(\bar{p}_2 + \bar{p}_3')\,\partial_n \Delta_* \zeta_3^{k-2} \\ & + \mu(\partial_n \boldsymbol{y}_3^{k-2} + \partial_3 \boldsymbol{y}_n^{k-2}). \end{aligned} \tag{5.22c}$$

5.3. Solving the inner expansion. According to the calculations of the previous subsection, to solve the problem with the Ansatz (5.12), it remains to find a sequence of profiles $(\boldsymbol{\varphi}^k)_k$ and a sequence of Kirchhoff–Love generators $(\boldsymbol{\zeta}^k)_k$ such that (5.13), (5.14), (5.15), and (5.18) hold.

Let us consider now the profiles $\boldsymbol{\varphi}^k$ for $k \geq 1$ as main unknowns. In view of (5.13), (5.14), (5.17a), and (5.22), we see that the sequence of problems satisfied by the $\boldsymbol{\varphi}^k$ can be written in a recursive way: for each $k \geq 1$ the profile $\boldsymbol{\varphi}^k$ has to solve the equation

$$\mathcal{B}_{\textcircled{\scriptsize i}}(\boldsymbol{\varphi}^k) = (\mathfrak{f}^k; \mathfrak{g}^k; \mathfrak{h}^k), \tag{5.23}$$

where

- $\mathcal{B}_{\textcircled{i}}$ is the operator $\mathcal{B}^{(0)}$ inside the domain, the traction operator $\mathcal{G}^{(0)}$ on the horizontal sides, the Dirichlet traces on the lateral side for $a \in A_{\textcircled{i}}$ and the Neumann traces on the lateral side for $b \in B_{\textcircled{i}}$,
- $\mathfrak{f}^k$ and $\mathfrak{g}^k$ are the following functions of the previous profiles

$$\mathfrak{f}^k = -\sum_{\ell=1}^{k} \mathcal{B}^{(\ell)} \boldsymbol{\varphi}^{k-\ell} \quad \text{and} \quad \mathfrak{g}^k = -\sum_{\ell=1}^{k} \mathcal{G}^{(\ell)} \boldsymbol{\varphi}^{k-\ell}, \tag{5.24}$$

so that (5.13)–(5.14) is solved, and $\mathfrak{h}^k$ involves previous profiles as well as certain traces of the Kirchhoff–Love generators, according to (5.15)–(5.22).

An important point is now to note that neither $\mathcal{B}^{(0)}$, nor $\mathcal{G}^{(0)}$, nor the lateral trace operators of $\mathcal{B}_{\textcircled{i}}$ contain any derivative with respect to the tangential variable s. Thus, (5.23) can be solved in the variables $t \in \mathbb{R}^+$ and $x_3 \in (-1,1)$, the role of s being only that of a parameter. So we introduce the half-strip

$$\Sigma^+ = \big\{(t, x_3); \quad 0 < t, \quad -1 < x_3 < 1\big\}. \tag{5.25}$$

Its boundary has two horizontal parts $\gamma_\pm = \mathbb{R}^+ \times \{x_3 = \pm 1\}$ and a lateral part

$$\gamma_0 = \big\{(t, x_3); \quad t = 0, \quad -1 < x_3 < 1\big\}. \tag{5.26}$$

Thus, we have

$$\mathcal{B}_{\textcircled{i}}(\boldsymbol{\varphi}) = (\mathfrak{f}; \mathfrak{g}; \mathfrak{h}) \quad \Longleftrightarrow \quad \left\{ \begin{array}{rcll} \mathcal{B}^{(0)}(\boldsymbol{\varphi}) & = & \mathfrak{f}, & \text{in } \Sigma^+, \\ \mathcal{G}^{(0)}(\boldsymbol{\varphi}) & = & \mathfrak{g}, & \text{on } \gamma_\pm, \\ \varphi_a & = & \mathfrak{h}_a, & \text{on } \gamma_0, \quad \forall a \in A_{\textcircled{i}}, \\ T_b^{(0)}(\boldsymbol{\varphi}) & = & \mathfrak{h}_b, & \text{on } \gamma_0, \quad \forall b \in B_{\textcircled{i}}. \end{array} \right. \tag{5.27}$$

Essential is the possibility of finding *exponentially decreasing* solutions when $\mathfrak{f}$ and $\mathfrak{g}$ have the same property. This is what we start to investigate in the next section.

6. Exponentially decaying profiles in a half-strip.

6.1. General principles. The properties of the operators $\mathcal{B}_{\textcircled{i}}$ are closely linked to those of the corresponding operator $\underline{\mathcal{B}}$ on the full strip $\Sigma := \mathbb{R} \times (-1,1)$, defined as $\underline{\mathcal{B}}(\boldsymbol{\varphi}) = (\mathfrak{f}; \mathfrak{g})$ with $\mathfrak{f} = \mathcal{B}^{(0)}(\boldsymbol{\varphi})$ in Σ and $\mathfrak{g} = \mathcal{G}^{(0)}(\boldsymbol{\varphi})$ on $\mathbb{R} \times \{x_3 = \pm 1\}$; see also Nazarov and Plamenevskii [23, Chap. 5].

Let $\mathcal{P}$ be the space of polynomial displacements $\boldsymbol{Z}$ satisfying $\underline{\mathcal{B}}(\boldsymbol{Z}) = 0$. Computations like those of Mielke in [20] yield that $\mathcal{P}$ has eight dimensions and that a basis of $\mathcal{P}$ is given by the following polynomial displacements $\boldsymbol{Z}^{[1]}, \dots, \boldsymbol{Z}^{[8]}$

$$\boldsymbol{Z}^{[1]} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \qquad \boldsymbol{Z}^{[2]} = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \qquad \boldsymbol{Z}^{[3]} = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \qquad \boldsymbol{Z}^{[4]} = \begin{pmatrix} -x_3 \\ 0 \\ t \end{pmatrix},$$

$$\boldsymbol{Z}^{[5]} = \begin{pmatrix} t \\ 0 \\ \bar{p}_1 \end{pmatrix}, \qquad \boldsymbol{Z}^{[6]} = \begin{pmatrix} 0 \\ t \\ 0 \end{pmatrix}, \qquad \boldsymbol{Z}^{[7]} = \begin{pmatrix} -2tx_3 \\ 0 \\ t^2 + 2\bar{p}_2 \end{pmatrix},$$

$$\boldsymbol{Z}^{[8]} = \begin{pmatrix} -3t^2 x_3 + 6\bar{p}_3 \\ 0 \\ t^3 + 6t\bar{p}_2 \end{pmatrix},$$

where $\bar{p}_1(x_3)$, $\bar{p}_2(x_3)$, $\bar{p}_3(x_3)$ are the polynomials previously introduced in (4.4).

Let us introduce weighted spaces H^m_η on the half-strip Σ^+: for $\eta > 0$, their elements are exponentially decreasing as $t \to \infty$.

Definition 6.1. *Let $\eta \in \mathbb{R}$. For $m \geq 0$ let $H^m_\eta(\Sigma^+)$ be the space of functions v such that $e^{\eta t} v$ belongs to $H^m(\Sigma^+)$. We also denote $H^0_\eta(\Sigma^+)$ by $L^2_\eta(\Sigma^+)$. Similar definitions hold for $\mathbb{R}^+$.*

Like in [9, Lemmas 4.10 and 4.11], we have, with η_0 the smallest exponent arising from the Papkovich–Fadle eigenfunctions, compare Papkovich [26] for early reference and Gregory and Wan [17]:

Lemma 6.2. *Let η, $0 < \eta < \eta_0$. Let $\mathfrak{f}$ belong to $L^2_\eta(\Sigma^+)^3$ and $\mathfrak{g}$ belong to $L^2_\eta(\mathbb{R}^+)^6$, let $\mathfrak{h}_a$ belong to $H^{1/2}(\gamma_0)$ for each $a \in A_{\textcircled{i}}$, and $\mathfrak{h}_b$ belong to $H^{-1/2}(\gamma_0)$ for each $b \in B_{\textcircled{i}}$. Then there exist $\boldsymbol{\varphi} \in H^1_\eta(\Sigma^+)^3$ and $\boldsymbol{Z} \in \mathcal{P}$ so that*

$$\mathcal{B}_{\textcircled{i}}(\boldsymbol{\varphi} + \boldsymbol{Z}) = (\mathfrak{f}; \mathfrak{g}; \mathfrak{h}). \tag{6.1}$$

But the solution given by Lemma 6.2 is not unique. Let $\mathcal{T}_{\textcircled{i}}$ denote the space of the polynomial displacements $\boldsymbol{Z}$ such that there exists $\boldsymbol{\varphi} = \boldsymbol{\varphi}(\boldsymbol{Z}) \in H^1_\eta(\Sigma^+)^3$ satisfying

$$\mathcal{B}_{\textcircled{i}}(\boldsymbol{Z} + \boldsymbol{\varphi}(\boldsymbol{Z})) = 0.$$

Like in [9, Proposition 4.12], we can prove that the dimension of $\mathcal{T}_{\textcircled{i}}$ is 4. Thus $\mathcal{P}$ can be split in the direct sum of two four-dimensional spaces $\mathcal{Z}_{\textcircled{i}}$ and $\mathcal{T}_{\textcircled{i}}$, and we have as a corollary the following lemma.

Lemma 6.3. *Let $\mathfrak{f}$, $\mathfrak{g}$, and $\mathfrak{h}$ be as in Lemma* 6.2. *Then there exist $\boldsymbol{\varphi}$* unique *in $H^1_\eta(\Sigma^+)^3$ and $\boldsymbol{Z}$* unique *in the four-dimensional space $\mathcal{Z}_{\textcircled{i}}$ so that* (6.1) *holds.*

At this stage, the conclusion is that we have a defect number equal to four for the solution of the sequence of the above equations (5.23) by exponentially decreasing displacements $\boldsymbol{\varphi}^k$ for each $s \in \partial\omega$. But four traces on $\partial\omega$ are still available, allowing us to modify $\mathfrak{h}^k$. Note that this is coherent with the principle of "matching asymptotics," according to which the behavior at infinity of the profiles is transformed into a function of the primitive variable x (which is a Kirchhoff–Love displacement).

6.2. The operators acting on profiles. We can immediately see that the operators $\mathcal{B}_{\textcircled{i}}$ act separately on the couple of components (φ_t, φ_3) that we denote $\boldsymbol{\varphi}_\natural$ and on φ_s. The elasticity operator with the Lamé constants λ and μ acts on $\boldsymbol{\varphi}_\natural$, and the Laplace operatoron φ_s.

The interior elasticity operator in Σ^+ is

$$\mathcal{B}^{(0)}_\natural : \ \boldsymbol{\varphi}_\natural \quad \longmapsto \quad \mathfrak{f}_\natural \ = \ \mu(\partial_{tt} + \partial_{33}) \begin{pmatrix} \varphi_t \\ \varphi_3 \end{pmatrix} + (\lambda + \mu) \begin{pmatrix} \partial_t \\ \partial_3 \end{pmatrix} (\partial_t \varphi_t + \partial_3 \varphi_3), \tag{6.2}$$

its horizontal boundary conditions $\mathcal{G}^{(0)}$ (5.10) on $\gamma_\pm$ are

$$\mathcal{G}^{(0)}_\natural : \ \boldsymbol{\varphi}_\natural \quad \longmapsto \quad \mathfrak{g}_\natural \ = \ \begin{pmatrix} \mu(\partial_3 \varphi_t + \partial_t \varphi_3) \\ (\lambda + 2\mu)\partial_3 \varphi_3 + \lambda\, \partial_t \varphi_t \end{pmatrix}, \tag{6.3}$$

and the lateral boundary conditions are either Dirichlet's or Neumann's acting on the traction $\boldsymbol{T}^{(0)}_\natural = (T^{(0)}_t, T^{(0)}_3)$; cf. (5.25).

Let us introduce the four elasticity operators that we need. For each of them $\mathfrak{f}_\natural = \mathcal{B}^{(0)}_\natural(\boldsymbol{\varphi}_\natural)$ and $\mathfrak{g}_\natural = \mathcal{G}^{(0)}_\natural(\boldsymbol{\varphi}_\natural)$. Only differs the definition of the lateral trace $\mathfrak{h}_\natural$:

- $E_{\rm Dir}$: $\boldsymbol{\varphi}_\natural \mapsto (\mathfrak{f}_\natural;\mathfrak{g}_\natural;\mathfrak{h}_\natural)$ with $\mathfrak{h}_\natural$ the trace of $\boldsymbol{\varphi}_\natural$ on γ_0,
- $E_{\rm Mix1}$: $\boldsymbol{\varphi}_\natural \mapsto (\mathfrak{f}_\natural;\mathfrak{g}_\natural;\mathfrak{h}_\natural)$ with $\mathfrak{h}_\natural$ the trace of $\big(T^{(0)}_t(\boldsymbol{\varphi}_\natural),\varphi_3\big)$ on γ_0,
- $E_{\rm Mix2}$: $\boldsymbol{\varphi}_\natural \mapsto (\mathfrak{f}_\natural;\mathfrak{g}_\natural;\mathfrak{h}_\natural)$ with $\mathfrak{h}_\natural$ the trace of $\big(\varphi_t, T^{(0)}_3(\boldsymbol{\varphi}_\natural)\big)$ on γ_0,
- $E_{\rm Free}$: $\boldsymbol{\varphi}_\natural \mapsto (\mathfrak{f}_\natural;\mathfrak{g}_\natural;\mathfrak{h}_\natural)$ with $\mathfrak{h}_\natural$ the trace of $\boldsymbol{T}^{(0)}_\natural(\boldsymbol{\varphi}_\natural)$ on γ_0,

whereas the Laplace operators are defined as

- $L_{\rm Dir}$: $\varphi_s \mapsto (\mathfrak{f}_s;\mathfrak{g}_s;\mathfrak{h}_s)$ with $\mathfrak{f}_s = \mu\Delta\varphi_s$, $\mathfrak{g}_s = \mu\partial_3\varphi_s$ and $\mathfrak{h}_s = \varphi_s$ on γ_0,
- $L_{\rm Neu}$: $\varphi_s \mapsto (\mathfrak{f}_s;\mathfrak{g}_s;\mathfrak{h}_s)$ with $\mathfrak{f}_s = \mu\Delta\varphi_s$, $\mathfrak{g}_s = \mu\partial_3\varphi_s$ and $\mathfrak{h}_s = \mu\partial_t\varphi_s$ on γ_0.

Then we have the splittings

$$\mathcal{B}_{\textcircled{1}} = E_{\rm Dir}\oplus L_{\rm Dir}, \quad \mathcal{B}_{\textcircled{2}} = E_{\rm Dir}\oplus L_{\rm Neu}, \quad \mathcal{B}_{\textcircled{3}} = E_{\rm Mix1}\oplus L_{\rm Dir}, \quad \mathcal{B}_{\textcircled{4}} = E_{\rm Mix1}\oplus L_{\rm Neu},$$
$$\mathcal{B}_{\textcircled{5}} = E_{\rm Mix2}\oplus L_{\rm Dir}, \quad \mathcal{B}_{\textcircled{6}} = E_{\rm Mix2}\oplus L_{\rm Neu}, \quad \mathcal{B}_{\textcircled{7}} = E_{\rm Free}\oplus L_{\rm Dir}, \quad \mathcal{B}_{\textcircled{8}} = E_{\rm Free}\oplus L_{\rm Neu}.$$

6.3. The Laplacian on the half-strip. The Neumann problem on the full strip Σ has a polynomial kernel of dimension 2 generated by 1 and t, corresponding to the elements $\boldsymbol{Z}^{[2]}$ and $\boldsymbol{Z}^{[6]}$ of the space $\mathcal{P}$ introduced at the beginning of the section.

6.3.1. Operator protect $\boldsymbol{L_{\rm Dir}}$. The polynomial kernel of this problem is the function t and by integration by parts of $t\,\Delta(\varphi+\delta)$ on rectangles $\Sigma_L = (0,L)\times(-1,1)$ with $L\to+\infty$, we easily prove the following proposition.

Proposition 6.4. *For $\eta>0$, let $f\in L^2_\eta(\Sigma^+)$, $g^\pm \in L^2_\eta(\mathbb{R}^+)^2$, and $h\in H^{1/2}(\gamma_0)$. If, moreover, $\eta<\pi/2$, then the problem*

$$L_{\rm Dir}(\psi) = \Big(f; g^\pm; h\Big)$$

has a unique solution $\psi = \varphi+\delta$ in $H^1_\eta(\Sigma^+)\oplus\operatorname{span}\{1\}$ with $\varphi\in H^1_\eta(\Sigma^+)$ and

$$\text{(6.4)}\ \ \delta = \frac{1}{2\mu}\left(-\int_{\Sigma^+} t\,f(t,x_3)\,dt\,dx_3 + \int_{\mathbb{R}^+} t\big(g^+(t)-g^-(t)\big)\,dt + \mu\int_{-1}^{+1} h(x_3)\,dx_3\right).$$

Later on we will use as a model profile the exponentially decaying solution $\bar\varphi^{\rm s}_{\rm Dir}$ of a special problem involving $L_{\rm Dir}$.

Lemma 6.5. *Let $\bar\varphi^{\rm s}_{\rm Dir}\in H^1_\eta(\Sigma^+)$ be the exponentially decaying solution of the problem*

$$L_{\rm Dir}(\bar\varphi^{\rm s}_{\rm Dir}) = (0;0;x_3)\,;$$

then it holds

$$\int_0^\infty \bar\varphi^{\rm s}_{\rm Dir}(t,1)\,dt > 0.$$

Proof. The function $\bar\varphi^{\rm s}_{\rm Dir}$ is an odd function with respect to x_3. Hence $\bar\varphi^{\rm s}_{\rm Dir}(t,0) = 0$ for $t\in\mathbb{R}^+$. Moreover, as $\bar\varphi^{\rm s}_{\rm Dir}$ is harmonic, it can be reflected by parity at the line $x_3=1$ according to the reflection principle of Schwarz for harmonic functions. Thus, we obtain a function $\tilde\varphi$, which is still harmonic, but now in $\widetilde{\Sigma}^+ = \mathbb{R}^+\times(0,2)$. Hence $\tilde\varphi$ satisfies the Dirichlet problem $\Delta\,\tilde\varphi = 0$ in $\widetilde{\Sigma}^+$ and $\tilde\varphi = \tilde\Phi$ on $\partial\widetilde{\Sigma}^+$ with $\Phi(t,x_3)=0$ for $x_3 = 0$, 2, and any t and $\Phi(0,x_3) = x_3$ for $0<x_3\le 1$ and $\Phi(0,x_3) = 2-x_3$ for $1\le x_3<2$. From the maximum principle for harmonic functions it follows $\tilde\varphi>0$ in $\widetilde{\Sigma}^+$, hence the assertion. $\square$

6.3.2. Operator $\boldsymbol{L}_{\mathbf{Neu}}$. The polynomial kernel of this problem is the function 1 and there holds the following proposition similarly.

Proposition 6.6. *For $\eta > 0$, let $f \in L^2_\eta(\Sigma^+)$, $g^\pm \in L^2_\eta(\mathbb{R}^+)^2$, and $h \in H^{-1/2}(\gamma_0)$. If, moreover, $\eta < \pi/2$, then the problem*

$$L_{\mathrm{Neu}}(\psi) = \Big(f; g^\pm; h\Big)$$

has a unique solution $\psi = \varphi + \delta\, t$ in $H^1_\eta(\Sigma^+) \oplus \mathrm{span}\{t\}$ with $\varphi \in H^1_\eta(\Sigma^+)$ and

$$(6.5)\quad \delta = \frac{1}{2\mu}\left(\int_{\Sigma^+} f(t,x_3)\,dt\,dx_3 - \int_{\mathbb{R}^+}\big(g^+(t) - g^-(t)\big)\,dt + \int_{-1}^{+1} h(x_3)\,dx_3\right).$$

We introduce the solution $\bar\varphi^{\mathrm{s}}_{\mathrm{Neu}}$ similarly as above, and using the second Green formula for the product $x_3\,\Delta\bar\varphi^{\mathrm{s}}_{\mathrm{Neu}}(t,x_3)$ on Σ_+ we prove the following lemma.

Lemma 6.7. *Let $\bar\varphi^{\mathrm{s}}_{\mathrm{Neu}} \in H^1_\eta(\Sigma^+)$ be the exponentially decaying solution of the problem*

$$L_{\mathrm{Neu}}(\bar\varphi^{\mathrm{s}}_{\mathrm{Neu}}) = (0; 0; 2\mu x_3)\,;$$

then it holds

$$\int_0^\infty \bar\varphi^{\mathrm{s}}_{\mathrm{Neu}}(t,1)\,dt = -\frac{2}{3}\,.$$

6.4. Elasticity on the half-strip. The problem (6.2)–(6.3) on the full strip has a polynomial kernel of dimension six generated by $\boldsymbol{Z}^{[1]}_\natural, \boldsymbol{Z}^{[3]}_\natural, \boldsymbol{Z}^{[4]}_\natural, \boldsymbol{Z}^{[5]}_\natural, \boldsymbol{Z}^{[7]}_\natural, \boldsymbol{Z}^{[8]}_\natural$, where the two components of $\boldsymbol{Z}^{[j]}_\natural$ are the first and third ones of $\boldsymbol{Z}^{[j]}$. In particular a basis of the two-dimensional rigid motions is given by

$$\boldsymbol{Z}^{[1]}_\natural = \begin{pmatrix}1\\0\end{pmatrix}, \qquad \boldsymbol{Z}^{[3]}_\natural = \begin{pmatrix}0\\1\end{pmatrix}, \qquad \boldsymbol{Z}^{[4]}_\natural = \begin{pmatrix}-x_3\\t\end{pmatrix}.$$

6.4.1. Operator $\boldsymbol{E}_{\mathbf{Dir}}$. From [9, Proposition 4.12], we obtain the following proposition.

Proposition 6.8. *For $\eta > 0$, let $\mathfrak{f}_\natural \in L^2_\eta(\Sigma^+)^2$, $\mathfrak{g}^\pm_\natural \in L^2_\eta(\mathbb{R}^+)^4$, and $\mathfrak{h}_\natural \in H^{1/2}(\gamma_0)^2$. If, moreover, $\eta < \eta_0$, then the problem*

$$E_{\mathrm{Dir}}(\boldsymbol{\psi}) = \Big(\mathfrak{f}_\natural; \mathfrak{g}^\pm_\natural; \mathfrak{h}_\natural\Big)$$

has a unique solution in $H^1_\eta(\Sigma^+)^2 \oplus \mathrm{span}\,\{\boldsymbol{Z}^{[1]}_\natural, \boldsymbol{Z}^{[3]}_\natural, \boldsymbol{Z}^{[4]}_\natural\}$.

6.4.2. Other operators. Concerning the other operators E_{Mix1}, E_{Mix2}, and E_{Free}, and in contrast to the case of E_{Dir}, they have a polynomial kernel generated by some of the $\boldsymbol{Z}^{[j]}_\natural$. Relying on the following duality relations (6.7) satisfied by the $\boldsymbol{Z}^{[j]}$, formulas for the coefficients in the asymptotics at infinity of the solutions can be obtained from integrations by parts.

Lemma 6.9. *Let $\boldsymbol{T}^{(0)}$ denote the lateral inward traction operator $(T_t^{(0)}, T_s^{(0)}, T_3^{(0)})$; cf.* (5.2). *With σ the permutation*

$$\begin{aligned}
&\sigma(1)=5, \quad \sigma(2)=6, \quad \sigma(3)=8, \quad \sigma(4)=7,\\
&\sigma(5)=1, \quad \sigma(6)=2, \quad \sigma(7)=4, \quad \sigma(8)=3,
\end{aligned}$$

the antisymmetrized flux, which can be defined for any $L \in \mathbb{R}$ by

$$\underline{\Phi}\Big(\boldsymbol{Z}^{[i]}, \boldsymbol{Z}^{[j]}\Big) := \int_{-1}^{+1} \Big(\boldsymbol{T}^{(0)}\Big(\boldsymbol{Z}^{[i]}\Big)\cdot \boldsymbol{Z}^{[j]} - \boldsymbol{T}^{(0)}\Big(\boldsymbol{Z}^{[j]}\Big)\cdot \boldsymbol{Z}^{[i]}\Big)(L, x_3)\, dx_3 \tag{6.6}$$

is independent of L (compare [9, *Lemma* 3.1]) *and satisfies, for $i, j \in \{1, \ldots, 8\}$*

$$\underline{\Phi}\Big(\boldsymbol{Z}^{[i]}, \boldsymbol{Z}^{[j]}\Big) = \bar\gamma_i\, \delta_{j\sigma(i)}, \tag{6.7}$$

with $\bar\gamma_i$ a nonzero real number.

For $i = 2, 6$ we find again the simple relations on which rely Propositions 6.4 and 6.6. For the remaining values of i, the relations (6.7) apply to the bidimensional displacements $\boldsymbol{Z}_\natural^{[i]}$. Relying on (6.7) and integration by parts, we are able to present formulas for the coefficients in the asymptotics at infinity of the solutions to the problems concerning the operators E_{Mix1}, E_{Mix2}, and E_{Free}.

Proposition 6.10. *For $\eta > 0$, let $\mathfrak{f}_\natural \in L^2_\eta(\Sigma^+)^2$, $\mathfrak{g}_\natural^{\pm} \in L^2_\eta(\mathbb{R}^+)^4$, $\mathfrak{h}_t \in H^{-1/2}(\gamma_0)$, and $\mathfrak{h}_3 \in H^{1/2}(\gamma_0)$. If, moreover, $\eta < \eta_0$, then the problem*

$$E_{\mathrm{Mix1}}(\boldsymbol{\psi}) = \Big(\mathfrak{f}_\natural; \mathfrak{g}_\natural^{\pm}; \mathfrak{h}_\natural\Big)$$

has a unique solution $\boldsymbol{\psi} = \boldsymbol{\varphi} + \delta_3 \boldsymbol{Z}_\natural^{[3]} + \delta_5 \boldsymbol{Z}_\natural^{[5]} + \delta_7 \boldsymbol{Z}_\natural^{[7]}$ with $\boldsymbol{\varphi} \in H^1_\eta(\Sigma^+)^2$ and

$$\bar\gamma_5 \delta_5 = \int_{\Sigma^+} f_t - \int_{\mathbb{R}^+} (g_t^+ - g_t^-) + \int_{-1}^{+1} \mathfrak{h}_t\,, \tag{6.8a}$$

$$\bar\gamma_7 \delta_7 = \int_{\Sigma^+} (-x_3 f_t + t f_3) + \int_{\mathbb{R}^+} \Big(g_t^+ + g_t^- - t(g_3^+ - g_3^-)\Big) - \int_{-1}^{+1} x_3 \mathfrak{h}_t\,, \tag{6.8b}$$

(6.8c)

$$\bar\gamma_3 \delta_3 = \int_{\Sigma^+} \mathfrak{f}_\natural \cdot \boldsymbol{Z}_\natural^{[8]} - \int_{\mathbb{R}^+} \Big(\mathfrak{g}^+ \cdot \boldsymbol{Z}_\natural^{[8]}\big|_{\gamma^+} - \mathfrak{g}^- \cdot \boldsymbol{Z}_\natural^{[8]}\big|_{\gamma^-}\Big) + 6\int_{-1}^{+1} \bar p_3\, \mathfrak{h}_t - \mu(\bar p_2 + \bar p_3')\mathfrak{h}_3\,.$$

Proposition 6.11. *For $\eta > 0$, let $\mathfrak{f}_\natural \in L^2_\eta(\Sigma^+)^2$, $\mathfrak{g}_\natural^{\pm} \in L^2_\eta(\mathbb{R}^+)^4$, $\mathfrak{h}_t \in H^{1/2}(\gamma_0)$, and $\mathfrak{h}_3 \in H^{-1/2}(\gamma_0)$. If, moreover, $\eta < \eta_0$, then the problem*

$$E_{\mathrm{Mix2}}(\boldsymbol{\psi}) = \Big(\mathfrak{f}_\natural; \mathfrak{g}_\natural^{\pm}; \mathfrak{h}_\natural\Big)$$

has a unique solution $\boldsymbol{\psi} = \boldsymbol{\varphi} + \delta_1 \boldsymbol{Z}_\natural^{[1]} + \delta_4 \boldsymbol{Z}_\natural^{[4]} + \delta_8 \boldsymbol{Z}_\natural^{[8]}$ with $\boldsymbol{\varphi} \in H^1_\eta(\Sigma^+)^2$ and

$$\bar\gamma_8 \delta_8 = \int_{\Sigma^+} f_3 - \int_{\mathbb{R}^+} (g_3^+ - g_3^-) + \int_{-1}^{+1} \mathfrak{h}_3\,, \tag{6.9a}$$

$$\bar\gamma_1\delta_1 = \int_{\Sigma^+} tf_t - \int_{\mathbb{R}^+} t(g_t^+ - g_t^-) - \int_{-1}^{+1} (\tilde\lambda+2\mu)\mathfrak{h}_t - \frac{\tilde\lambda}{2\mu}\Big(\int_{\Sigma^+} x_3 f_3 - \int_{\mathbb{R}^+}(g_3^+ + g_3^-) + \int_{-1}^{+1} x_3\mathfrak{h}_3\Big)\,,$$

(6.9b)

$$\text{(6.9c)}\quad \bar\gamma_4\delta_4 = \int_{\Sigma^+} \mathfrak{f}_\natural\cdot \boldsymbol{Z}_\natural^{[7]} - \int_{\mathbb{R}^+}\Big(\mathfrak{g}^+\cdot\boldsymbol{Z}_\natural^{[7]} - \mathfrak{g}^-\cdot\boldsymbol{Z}_\natural^{[7]}\Big) + 2\int_{-1}^{+1}\Big(\bar p_2\mathfrak{h}_3 + (\tilde\lambda+2\mu)x_3\mathfrak{h}_t\Big)\,.$$

Proposition 6.12. *For $\eta > 0$, let $\mathfrak{f}_\natural \in L^2_\eta(\Sigma^+)^2$, $\mathfrak{g}^{\pm}_\natural \in L^2_\eta(\mathbb{R}^+)^4$, and $\mathfrak{h}_\natural \in H^{-1/2}(\gamma_0)^2$. If, moreover, $\eta < \eta_0$, then the problem*

$$E_{\text{Free}}(\boldsymbol{\psi}) = \Big(\mathfrak{f}_\natural; \overset{\pm}{\mathfrak{g}}_\natural; \mathfrak{h}_\natural\Big)$$

has a unique solution $\boldsymbol{\psi} = \boldsymbol{\varphi} + \delta_5\boldsymbol{Z}_\natural^{[5]} + \delta_7\boldsymbol{Z}_\natural^{[7]} + \delta_8\boldsymbol{Z}_\natural^{[8]}$ with $\boldsymbol{\varphi}\in H^1_\eta(\Sigma^+)^2$ and

$$\text{(6.10a)}\qquad \bar\gamma_5\delta_5 = \int_{\Sigma^+} f_t - \int_{\mathbb{R}^+}(g_t^+ - g_t^-) + \int_{-1}^{+1}\mathfrak{h}_t\,,$$

$$\text{(6.10b)}\qquad \bar\gamma_8\delta_8 = \int_{\Sigma^+} f_3 - \int_{\mathbb{R}^+}(g_3^+ - g_3^-) + \int_{-1}^{+1}\mathfrak{h}_3\,,$$

$$\text{(6.10c)}\quad \bar\gamma_7\delta_7 = \int_{\Sigma^+}(-x_3 f_t + tf_3) + \int_{\mathbb{R}^+}\big(g_t^+ + g_t^- - t(g_3^+ - g_3^-)\big) - \int_{-1}^{+1} x_3\mathfrak{h}_t\,.$$

7. Clamped plates.

7.1. Hard clamped plates: The first terms in the asymptotics. In [19, Chap. 16], Maz'ya, Nazarov, and Plamenevskii prove estimates like (3.4) for isotropic clamped plates and in [8, 9] the analog of Theorem 3.2 is proved for monoclinic clamped plates.

Here we will show how the formulas relating to lateral boundary condition ① in Tables 2, 3, 5, and 6 can be derived.

From (5.16) it follows that the boundary operators for the generators are the Dirichlet ones and that the four traces of $\boldsymbol{\zeta}^0$ are zero. We find again a fact known for long; cf. [5, 13] for early reference.

Let us investigate $\boldsymbol{\zeta}^1$ and $\boldsymbol{\varphi}^1$ simultaneously. Condition (5.15) for $k=1$ yields that $\zeta_3^1 = 0$, $\varphi_n^1 + \zeta_n^1 - x_3\partial_n\zeta_3^1 = 0$ and $\varphi_s^1 + \zeta_s^1 - x_3\partial_s\zeta_3^1 = 0$ on Γ_0. Moreover, condition (5.15) for $k=2$ with (5.17c) yields that $\varphi_3^1 + \zeta_3^2 + v_3^2 = 0$ on Γ_0.

Thus, the first profile $\boldsymbol{\varphi}^1(s) : (t,x_3)\mapsto\boldsymbol{\varphi}^1(t,s,x_3)$ has to solve for all $s\in\partial\omega$ (cf. (5.23)), the equation $\mathcal{B}_{①}(\boldsymbol{\varphi}^1(s)) = (0;0;\mathfrak{h}^1(s))$ with the trace $\mathfrak{h}^1(s)$ equal to

$$\mathfrak{h}_n^1(s) = -(\zeta_n^1 - x_3\partial_n\zeta_3^1)(s),\quad \mathfrak{h}_s^1(s) = -(\zeta_s^1 - x_3\partial_s\zeta_3^1)(s),\quad \mathfrak{h}_3^1(s) = -(\zeta_3^2 + v_3^2)(s).$$

Note that the unknowns are the profile $\boldsymbol{\varphi}^1$ and the traces of ζ_n^1, ζ_s^1, $\partial_n\zeta_3^1$, and ζ_3^2.

Since $\mathcal{B}_{①}$ splits into the direct sum $E_{\text{Dir}}\oplus L_{\text{Dir}}$, for each $s\in\partial\omega$ (fixed now, thus omitted),

- φ_s^1 is the solution of the Poisson problem

$$\text{(7.1)}\qquad L_{\text{Dir}}(\varphi_s^1) = (0;0;\mathfrak{h}_s^1),$$

- the couple $\boldsymbol{\varphi}^1_\natural$ is the solution of the elasticity system

$$E_{\mathrm{Dir}}(\boldsymbol{\varphi}^1_\natural) = (0; 0; \mathfrak{h}^1_\natural). \tag{7.2}$$

We have to find the conditions on $\boldsymbol{\zeta}^1$ so that (7.1) and (7.2) admit exponentially decreasing solutions.

Concerning the Poisson problem, Proposition 6.4 yields that (7.1) admits an exponentially decreasing solution if the coefficient (6.4) is zero, i.e., if $\int_{-1}^{+1} \mathfrak{h}^1_s = 0$. With the above expression of $\mathfrak{h}^1_s$, this yields that $\zeta^1_s = 0$ on $\partial\omega$. Since we already found that $\zeta^1_3 = 0$ on $\partial\omega$, we obtain that $\mathfrak{h}^1_s \equiv 0$, thus $\varphi^1_s = 0$.

Concerning the Lamé problem, Proposition 6.8 yields a solution for (7.2) in $H^1_\eta(\Sigma^+)^2 \oplus \mathrm{span}\{\boldsymbol{Z}^{[1]}_\natural, \boldsymbol{Z}^{[3]}_\natural, \boldsymbol{Z}^{[4]}_\natural\}$. We first recall that (cf. (4.3)–(4.4))

$$v^2_3(x_*, x_3) = \bar{p}_1(x_3)\ \mathrm{div}_*\, \boldsymbol{\zeta}^0_*(x_*) + \bar{p}_2(x_3)\ \Delta_* \zeta^0_3(x_*)\,. \tag{7.3}$$

Let $\bar{\boldsymbol{\psi}}^{\mathrm{m}}_\natural$ be the solution in $H^1_\eta(\Sigma^+)^2 \oplus \mathrm{span}\{\boldsymbol{Z}^{[1]}_\natural, \boldsymbol{Z}^{[3]}_\natural, \boldsymbol{Z}^{[4]}_\natural\}$ of

$$E_{\mathrm{Dir}}(\bar{\boldsymbol{\psi}}^{\mathrm{m}}_\natural) = (0; 0; 0, -\bar{p}_1). \tag{7.4}$$

Since the right-hand side of (7.4) has the parities of a membrane mode (the first component is even and the second odd with respect to x_3), the symmetries of the isotropic elasticity system yield that $\bar{\psi}^{\mathrm{m}}_t$ is even and $\bar{\psi}^{\mathrm{m}}_3$ odd. Thus the asymptotic behavior as $t \to \infty$ has the same parities: only $\boldsymbol{Z}^{[1]}_\natural$ is convenient.

Hence there exists a unique coefficient $c^{\textcircled{1}}_1$ such that $\bar{\boldsymbol{\psi}}^{\mathrm{m}}_\natural$ splits into

$$\bar{\boldsymbol{\psi}}^{\mathrm{m}}_\natural = \bar{\boldsymbol{\varphi}}^{\mathrm{m}}_\natural + c^{\textcircled{1}}_1 \boldsymbol{Z}^{[1]}_\natural \quad \text{with } \bar{\boldsymbol{\varphi}}^{\mathrm{m}}_\natural \text{ exponentially decreasing.} \tag{7.5}$$

Similarly, let $\bar{\boldsymbol{\psi}}^{\mathrm{b}}_\natural$ be the solution in $H^1_\eta(\Sigma^+)^2 \oplus \mathrm{span}\{\boldsymbol{Z}^{[1]}_\natural, \boldsymbol{Z}^{[3]}_\natural, \boldsymbol{Z}^{[4]}_\natural\}$ of

$$E_{\mathrm{Dir}}(\bar{\boldsymbol{\psi}}^{\mathrm{b}}_\natural) = (0; 0; 0, -\bar{p}_2). \tag{7.6}$$

Since the right-hand side of (7.6) has the parities of a bending mode, the symmetries of the problem yield that $\bar{\psi}^{\mathrm{b}}_t$ is odd and $\bar{\psi}^{\mathrm{b}}_3$ even with respect to x_3. Thus only $\boldsymbol{Z}^{[3]}_\natural$ and $\boldsymbol{Z}^{[4]}_\natural$ are present in the asymptotics at infinity of $\bar{\boldsymbol{\psi}}^{\mathrm{b}}_\natural$.

Hence there exist unique coefficients $c^{\textcircled{1}}_3$ and $c^{\textcircled{1}}_4$ such that $\bar{\boldsymbol{\psi}}^{\mathrm{b}}_\natural$ splits into

$$\bar{\boldsymbol{\psi}}^{\mathrm{b}}_\natural = \bar{\boldsymbol{\varphi}}^{\mathrm{b}}_\natural + c^{\textcircled{1}}_3 \boldsymbol{Z}^{[3]}_\natural + c^{\textcircled{1}}_4 \boldsymbol{Z}^{[4]}_\natural \quad \text{with } \bar{\boldsymbol{\varphi}}^{\mathrm{b}}_\natural \text{ exponentially decreasing.} \tag{7.7}$$

Then $\boldsymbol{\psi}^1_\natural$, defined as

$$\boldsymbol{\psi}^1_\natural(t, s, x_3) = \mathrm{div}_*\, \boldsymbol{\zeta}^0_*(s)\ \bar{\boldsymbol{\psi}}^{\mathrm{m}}_\natural(t, x_3) + \Delta_* \zeta^0_3(s)\ \bar{\boldsymbol{\psi}}^{\mathrm{b}}_\natural(t, x_3),$$

is the solution for each $s \in \partial\omega$ of (cf. (7.3), (7.4), and (7.6))

$$E_{\mathrm{Dir}}(\boldsymbol{\psi}^1_\natural) = (0; 0; 0, -v^2_3). \tag{7.8}$$

Thus, if we have for each $s \in \partial\omega$, (cf. (7.5) and (7.7))

$$\begin{pmatrix} \zeta^1_n(s) - x_3 \partial_n \zeta^1_3(s) \\ \zeta^2_3(s) \end{pmatrix} \quad = \quad \mathrm{div}_*\, \boldsymbol{\zeta}^0_*(s)\ c^{\textcircled{1}}_1 \boldsymbol{Z}^{[1]}_\natural\,\big|_{\gamma_0} + \Delta_* \zeta^0_3(s) \left(c^{\textcircled{1}}_3 \boldsymbol{Z}^{[3]}_\natural + c^{\textcircled{1}}_4 \boldsymbol{Z}^{[4]}_\natural \right)\big|_{\gamma_0}\,,$$

i.e.,

$$\begin{pmatrix} \zeta_n^1(s) - x_3\partial_n\zeta_3^1(s) \\ \zeta_3^2(s) \end{pmatrix} = \begin{pmatrix} \operatorname{div}_* \boldsymbol{\zeta}_*^0(s)\, c_1^{\textcircled{1}} - x_3\Delta_*\zeta_3^0(s)\, c_4^{\textcircled{1}} \\ \Delta_*\zeta_3^0(s)\, c_3^{\textcircled{1}} \end{pmatrix}, \tag{7.9}$$

then $\boldsymbol{\varphi}_\natural^1$ defined as

$$\boldsymbol{\varphi}_\natural^1(t,s,x_3) = \operatorname{div}_* \boldsymbol{\zeta}_*^0(s)\, \bar{\boldsymbol{\varphi}}_\natural^{\mathrm{m}}(t,x_3) + \Delta_*\zeta_3^0(s)\, \bar{\boldsymbol{\varphi}}_\natural^{\mathrm{b}}(t,x_3) \tag{7.10}$$

is the solution of $E_{\mathrm{Dir}}(\boldsymbol{\varphi}_\natural^1(s)) = (0;0;\mathfrak{h}_\natural^1(s))$; see (7.2). Thus we have obtained all the results relating to $\boldsymbol{\zeta}^1$ and $\boldsymbol{\varphi}^1$.

7.2. The nonzero coupling constants. There holds the following lemma.

LEMMA 7.1. *The coefficients $c_1^{\textcircled{1}}$ and $c_4^{\textcircled{1}}$ are nonzero.*

Let us prove first that $c_4^{\textcircled{1}}$ is not zero. Let us denote by $\boldsymbol{Z}_\natural$ the polynomial displacement $\frac{1}{2}\boldsymbol{Z}_\natural^{[7]}$. Thus $\boldsymbol{Z}_\natural$ satisfies

$$E_{\mathrm{Dir}}(\boldsymbol{Z}_\natural) = (0;0;0,\bar{p}_2). \tag{7.11}$$

So, (7.11) joined with (7.6)–(7.7) yields that

$$\boldsymbol{K} := \boldsymbol{Z}_\natural + \bar{\boldsymbol{\varphi}}_\natural^{\mathrm{b}} + c_3^{\textcircled{1}}\boldsymbol{Z}_\natural^{[3]} + c_4^{\textcircled{1}}\boldsymbol{Z}_\natural^{[4]} \quad \in \quad \ker E_{\mathrm{Dir}}\,.$$

The proof proceeds by computation about the "flux" (cf. (6.6)):

$$\Phi_{t=t_0}(\boldsymbol{u}\,|\,\boldsymbol{v}) := \int_{-1}^{+1} \boldsymbol{T}_\natural^{(0)}(\boldsymbol{u})(t_0,x_3)\cdot\boldsymbol{v}(t_0,x_3)\,dx_3\,. \tag{7.12}$$

We have

$$\boldsymbol{T}_\natural^{(0)}(\boldsymbol{Z}_\natural) = \begin{pmatrix} -4\,\frac{\mu(\lambda+\mu)}{\lambda+2\mu}\,x_3 \\ 0 \end{pmatrix}.$$

Thus,

$$\Phi_{t=0}\Big(\boldsymbol{Z}_\natural\,|\,c_3^{\textcircled{1}}\boldsymbol{Z}_\natural^{[3]} + c_4^{\textcircled{1}}\boldsymbol{Z}_\natural^{[4]}\Big) = \frac{8}{3}\,\frac{\mu(\lambda+\mu)}{\lambda+2\mu}\,c_4^{\textcircled{1}}. \tag{7.13}$$

We are going to prove that (cf. (7.7))

$$\Phi_{t=0}\Big(\boldsymbol{Z}_\natural\,|\,c_3^{\textcircled{1}}\boldsymbol{Z}_\natural^{[3]} + c_4^{\textcircled{1}}\boldsymbol{Z}_\natural^{[4]}\Big) = \Phi_{t=0}\Big(\boldsymbol{K}\,|\,c_3^{\textcircled{1}}\boldsymbol{Z}_\natural^{[3]} + c_4^{\textcircled{1}}\boldsymbol{Z}_\natural^{[4]} + \bar{\boldsymbol{\varphi}}_\natural^{\mathrm{b}}\Big) \tag{7.14}$$

and that

$$\Phi_{t=0}\Big(\boldsymbol{K}\,|\,c_3^{\textcircled{1}}\boldsymbol{Z}_\natural^{[3]} + c_4^{\textcircled{1}}\boldsymbol{Z}_\natural^{[4]} + \bar{\boldsymbol{\varphi}}_\natural^{\mathrm{b}}\Big) > 0. \tag{7.15}$$

The fact that $c_4^{\textcircled{1}} > 0$ is clearly a consequence of (7.13)–(7.15).

In order to prove (7.14) and (7.15), we abbreviate the notations by

$$c_3^{\textcircled{1}}\boldsymbol{Z}_\natural^{[3]} + c_4^{\textcircled{1}}\boldsymbol{Z}_\natural^{[4]} := \boldsymbol{R} \quad \text{and} \quad \boldsymbol{\varphi} := \bar{\boldsymbol{\varphi}}_\natural^{\mathrm{b}}\,.$$

Proof of (7.14). We want to prove that $\Phi_{t=0}(\boldsymbol{Z}_\natural \,|\, \boldsymbol{R}) = \Phi_{t=0}(\boldsymbol{K} \,|\, \boldsymbol{R} + \boldsymbol{\varphi})$. Indeed, integrating by parts on the rectangle $\Sigma_L = (0, L) \times (-1, 1)$ we obtain

$$\begin{aligned}
&\int_{-1}^{+1} \Big[\boldsymbol{T}_\natural^{(0)}(\boldsymbol{K}) \cdot (\boldsymbol{R} + \boldsymbol{\varphi}) - \boldsymbol{K} \cdot \boldsymbol{T}_\natural^{(0)}(\boldsymbol{R} + \boldsymbol{\varphi})\Big]\,(0, x_3)\, dx_3 \\
&\quad - \int_{-1}^{+1} \Big[\boldsymbol{T}_\natural^{(0)}(\boldsymbol{K}) \cdot (\boldsymbol{R} + \boldsymbol{\varphi}) - \boldsymbol{K} \cdot \boldsymbol{T}_\natural^{(0)}(\boldsymbol{R} + \boldsymbol{\varphi})\Big]\,(L, x_3)\, dx_3 \\
&\qquad\qquad = \int_0^L \Big[\mathcal{G}_\natural^{(0)}(\boldsymbol{K}) \cdot (\boldsymbol{R} + \boldsymbol{\varphi}) - \boldsymbol{K} \cdot \mathcal{G}_\natural^{(0)}(\boldsymbol{R} + \boldsymbol{\varphi})\Big]\,(t, 1)\, dt \\
&\qquad\qquad\quad - \int_0^L \Big[\mathcal{G}_\natural^{(0)}(\boldsymbol{K}) \cdot (\boldsymbol{R} + \boldsymbol{\varphi}) - \boldsymbol{K} \cdot \mathcal{G}_\natural^{(0)}(\boldsymbol{R} + \boldsymbol{\varphi})\Big]\,(t, -1)\, dt \\
&\qquad\qquad\qquad\qquad - \int_{\Sigma_L} \mathcal{B}_\natural^{(0)}(\boldsymbol{K}) \cdot (\boldsymbol{R} + \boldsymbol{\varphi}) - \boldsymbol{K} \cdot \mathcal{B}_\natural^{(0)}(\boldsymbol{R} + \boldsymbol{\varphi})\,.
\end{aligned}$$

As $\mathcal{B}_\natural^{(0)}(\boldsymbol{K}) = \mathcal{B}_\natural^{(0)}(\boldsymbol{Z}_\natural) = 0$ and $\mathcal{G}_\natural^{(0)}(\boldsymbol{K}) = \mathcal{G}_\natural^{(0)}(\boldsymbol{Z}_\natural) = 0$, the above right-hand side is zero. Therefore

$$\Phi_{t=0}(\boldsymbol{K} \,|\, \boldsymbol{R} + \boldsymbol{\varphi}) = \Phi_{t=L}(\boldsymbol{K} \,|\, \boldsymbol{R} + \boldsymbol{\varphi}) - \int_{-1}^{+1} \boldsymbol{K}(L, x_3) \cdot \boldsymbol{T}_\natural^{(0)}(\boldsymbol{R} + \boldsymbol{\varphi})(L, x_3)\; dx_3.$$

Since $\boldsymbol{T}_\natural^{(0)}(\boldsymbol{R}) = 0$ ($\boldsymbol{R}$ is a rigid displacement) and since $\boldsymbol{\varphi}$ is exponentially decreasing, we deduce from the identity above that, for all $0 < \eta < \eta_0$

$$\Phi_{t=0}(\boldsymbol{K} \,|\, \boldsymbol{R} + \boldsymbol{\varphi}) = \Phi_{t=L}(\boldsymbol{Z}_\natural \,|\, \boldsymbol{R}) + \mathcal{O}(e^{-\eta L}).$$

But for all L, we have the conservation of the flux against rigid displacements

$$\Phi_{t=L}(\boldsymbol{Z}_\natural \,|\, \boldsymbol{R}) = \Phi_{t=0}(\boldsymbol{Z}_\natural \,|\, \boldsymbol{R}),$$

whence the result. □

Proof of (7.15). We want to prove that $\Phi_{t=0}(\boldsymbol{K} \,|\, \boldsymbol{R}{+}\boldsymbol{\varphi}) > 0$. To see it, notice that, since $\boldsymbol{Z}_\natural\big|_{t=0} = -(\boldsymbol{R}{+}\boldsymbol{\varphi})\big|_{t=0}$ and since we easily check the equality $\Phi_{t=0}(\boldsymbol{Z}_\natural \,|\, \boldsymbol{Z}_\natural) = 0$, we have

$$\begin{aligned}
\Phi_{t=0}(\boldsymbol{K} \,|\, \boldsymbol{R} + \boldsymbol{\varphi}) \;&=\; \Phi_{t=0}(\boldsymbol{Z}_\natural \,|\, \boldsymbol{R} + \boldsymbol{\varphi}) + \Phi_{t=0}(\boldsymbol{R} + \boldsymbol{\varphi} \,|\, \boldsymbol{R} + \boldsymbol{\varphi}), \\
&=\; -\Phi_{t=0}(\boldsymbol{Z}_\natural \,|\, \boldsymbol{Z}_\natural) + \Phi_{t=0}(\boldsymbol{\varphi} \,|\, \boldsymbol{R} + \boldsymbol{\varphi}), \\
&=\; \Phi_{t=L}(\boldsymbol{\varphi} \,|\, \boldsymbol{R} + \boldsymbol{\varphi}) + \int_{\Sigma_L} A\, e(\partial_t, \partial_3)(\boldsymbol{\varphi}) : e(\partial_t, \partial_3)(\boldsymbol{R} + \boldsymbol{\varphi}), \\
&=\; \int_{\Sigma_L} A\, e(\partial_t, \partial_3)(\boldsymbol{\varphi}) : e(\partial_t, \partial_3)(\boldsymbol{\varphi}) + \mathcal{O}(e^{-\eta L}).
\end{aligned}$$

Since $\boldsymbol{Z}_\natural + \boldsymbol{R}$ is clearly not zero on $\{t = 0\}$, then $\boldsymbol{\varphi} \not\equiv 0$. The result follows from the positivity of the elasticity matrix A. □

The positivity of $c_1^{\textcircled{1}}$ can be proved analogously to that of $c_4^{\textcircled{1}}$, taking into account that $\boldsymbol{Z}_\natural^{[5]}$ satisfies problem $E_{\mathrm{Dir}}(\boldsymbol{Z}_\natural^{[5]}) = (0; 0; 0, \bar{p}_1)$, thus

$$\boldsymbol{K}^{\mathrm{m}} := \boldsymbol{Z}_\natural^{[5]} + \bar{\boldsymbol{\varphi}}_\natural^{\mathrm{m}} + c_1^{\textcircled{1}} \boldsymbol{Z}_\natural^{[1]} \quad \in \quad \ker E_{\mathrm{Dir}}$$

and that, moreover, there hold

$$\boldsymbol{T}_\natural^{(0)}\Big(\boldsymbol{Z}_\natural^{[5]}\Big) = \begin{pmatrix} 4\, \frac{\mu(\lambda+\mu)}{\lambda+2\mu} \\ 0 \end{pmatrix} \quad \text{and} \quad \Phi_{t=0}\Big(\boldsymbol{Z}_\natural^{[5]} \,|\, c_1^{\textcircled{1}} \boldsymbol{Z}_\natural^{[1]}\Big) = \frac{8\mu(\lambda + \mu)}{\lambda + 2\mu}\; c_1^{\textcircled{1}}\,.$$

7.3. Soft clamped plates: The first terms in the asymptotics. We now have to take care of the space $\mathcal{R}_{\textcircled{2}}$, which is the space of rigid motions $\boldsymbol{v}$ satisfying the soft clamped plate conditions, i.e., v_n and $v_3 = 0$ on the lateral boundary Γ_0. If the mean surface ω is not a disk or an annulus, $\mathcal{R}_{\textcircled{2}}$ is reduced to $\{0\}$. If ω is a disk or an annulus that we may suppose is centered in 0, $\mathcal{R}_{\textcircled{2}}$ is one-dimensional, generated by the in-plane rotation $(x_2, -x_1, 0)$ and the orthogonality condition (2.11), ensuring uniqueness can be transcribed in Ω into $\int_\Omega \boldsymbol{u}_*(\varepsilon) \cdot (x_2, -x_1)^\top = 0$.

Thus, in this situation, the compatibility conditions on ω for the membrane problems (3.13a) has to be checked and the coherence with the orthogonality condition (2.11) has to be realized by an orthogonality condition for the $\boldsymbol{\zeta}_*^k$ in ω. We refer to [11, section 6] for details.

The behavior of the boundary layer terms is very similar to the hard clamped case because the boundary conditions involving the components $\boldsymbol{\varphi}_\natural$ are Dirichlet as in ①; the only change concerns the lateral component φ_s, which is uncoupled from the previous ones and subject now to lateral Neumann conditions instead of Dirichlet.

7.3.1. The traces of $\boldsymbol{\zeta}^0$. Solving recursively equations (5.13)–(5.14), (5.15), and (5.18), we find first the Dirichlet traces at the order zero: $\zeta_n^0 - x_3\partial_n\zeta_3^0$ and ζ_3^0 are zero on $\partial\omega$. Thus, the Dirichlet conditions concerning $\boldsymbol{\zeta}^0$ are obtained.

The terms T_s^0 and T_s^1 are always zero. Next, condition $T_s^2 = 0$ yields (cf. (5.22b))

$$T_s^{(0)}(\boldsymbol{\varphi}^1) = -T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) + 2\mu x_3 \left(\partial_n + \tfrac{1}{R}\right)\partial_s\zeta_3^0.$$

Taking account of the already known Dirichlet conditions for ζ_3^0, we obtain that φ_s^1 solves the Laplace–Neumann problem on the half-strip:

$$L_{\mathrm{Neu}}(\varphi_s^1) = (0; 0; -T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^0)). \tag{7.16}$$

Since, for each fixed $s \in \partial\omega$, $T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^0)$ is a constant, Proposition 6.6 yields that the only exponentially decreasing solution is $\varphi_s^1 \equiv 0$ obtained with $T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) = 0$ on $\partial\omega$. Then $\boldsymbol{\zeta}^0$ satisfies zero boundary conditions according to Table 2.

7.3.2. The traces of $\boldsymbol{\zeta}^1$. The equations (5.15) for $k = 1$ and for $k = 2$ yield the same condition as in case ① for the trace of ζ_3^1 which must vanish, and the same equations (7.2) linking the couple $\boldsymbol{\varphi}_\natural^1$ and the traces of ζ_n^1, $\partial_n\zeta_3^1$, ζ_3^2. Thus, the result concerning these traces is the same for the hard and soft clamped situations.

As a consequence the coefficients $c_1^{\textcircled{2}}$ and $c_4^{\textcircled{2}}$ are equal to their homologues $c_1^{\textcircled{1}}$ and $c_4^{\textcircled{1}}$ for the hard clamped plate.

Concerning the tangential component, the condition $T_s^3 = 0$ yields (cf. (5.22b))

$$T_s^{(0)}(\boldsymbol{\varphi}^2) = -T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^1) + 2\mu x_3 \left(\partial_n + \tfrac{1}{R}\right)\partial_s\zeta_3^1 - T_s^{(1)}(\boldsymbol{\varphi}^1).$$

Taking into account the already known trace condition $\zeta_3^1 = 0$, (5.23) leads to the following Neumann problem for the lateral part φ_s^2:

$$L_{\mathrm{Neu}}(\varphi_s^2) = \Big(-(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1)_s\,; -(\mathcal{G}^{(1)}\boldsymbol{\varphi}^1)_s\,; - T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^1) + 2\mu x_3\partial_{sn}\zeta_3^1 - T_s^{(1)}(\boldsymbol{\varphi}^1)\Big). \tag{7.17}$$

Proposition 6.6 yields that φ_s^2 is exponentially decreasing if and only if

$$
\begin{aligned}
T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^1) = -\frac{1}{2}\Bigg(\int_{\Sigma_+} (\mathcal{B}^{(1)}\boldsymbol{\varphi}^1)_s(t,x_3)\,dt\,dx_3 \\
- \int_{\mathbb{R}_+}\Big((\mathcal{G}^{(1)}\boldsymbol{\varphi}^1)_s(t,1) - (\mathcal{G}^{(1)}\boldsymbol{\varphi}^1)_s(t,-1)\Big)\,dt \\
+ \int_{-1}^{+1} T_s^{(1)}(\boldsymbol{\varphi}^1)(0,x_3) - 2\mu x_3 \partial_{sn}\zeta_3^1(0)\,dx_3\Bigg).
\end{aligned}
\tag{7.18}
$$

Since $\varphi_s^1 = 0$, the terms involved in (7.18) reduce to

$$
(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1)_s = (\lambda+\mu)\partial_s(\partial_t\varphi_t^1 + \partial_3\varphi_3^1), \quad (\mathcal{G}^{(1)}\boldsymbol{\varphi}^1)_s = \mu\,\partial_s\varphi_3^1, \quad T_s^{(1)}(\boldsymbol{\varphi}^1) = \mu\,\partial_s\varphi_t^1.
$$

Since only the *even* terms in x_3 contribute to the integrals in (7.18), we see that we have only to take into consideration the membrane part of $\boldsymbol{\varphi}_\natural^1$, which is equal to $\operatorname{div}_*\boldsymbol{\zeta}_*^0(s)\;\bar{\boldsymbol{\varphi}}_\natural^{\mathrm{m}}(t,x_3)$, cf. (7.10). Thus $T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^1) = c_2^{\textcircled{2}}\,\partial_s \operatorname{div}_*\boldsymbol{\zeta}_*^0$, with $-\frac{2}{\mu}\,c_2^{\textcircled{2}}$ equal to

$$
\frac{\lambda+\mu}{\mu}\int_{\Sigma_+}(\partial_t\bar\varphi_t^{\mathrm{m}} + \partial_3\bar\varphi_3^{\mathrm{m}})\,dt\,dx_3 - \int_{\mathbb{R}_+}\Big(\bar\varphi_3^{\mathrm{m}}(t,1) - \bar\varphi_3^{\mathrm{m}}(t,-1)\Big)\,dt + \int_{-1}^{+1}\bar\varphi_t^{\mathrm{m}}(0,x_3)\,dx_3.
$$

Formulas of Table 3 concerning case $\textcircled{2}$ are completely proved.

7.3.3. Recursivity. It can be proved like in [8], cf. [11, section 6].

8. Simply supported plates. The space of rigid motions $\mathcal{R}_{\textcircled{3}}$ is reduced to $\{0\}$, whereas $\mathcal{R}_{\textcircled{4}}$ is three-dimensional and spanned by the in-plane rigid motions. Here we only present the analysis for the hard simply supported plate. The main feature of the analysis of the soft simply supported plate is the treatment of compatibility conditions: we refer to [11, section 8] for this.

8.1. Hard simple support: The traces of $\boldsymbol{\zeta}^0$. According to (5.15), $D_3^0 = 0$ yields $\zeta_3^0 = 0$ on $\partial\omega$; then $D_s^0 = 0$ is equivalent to $\zeta_s^0 = 0$ on $\partial\omega$. Next, $D_3^1 = 0$ yields $\zeta_3^1 = 0$ on $\partial\omega$, and $D_s^1 = 0$ provides the equation $L_{\mathrm{Dir}}(\varphi_s^1) = (0;0;-\zeta_s^1)$. Then Proposition 6.4 yields that the only exponentially decreasing solution is $\varphi_s^1 \equiv 0$, obtained with $\zeta_s^1 = 0$ on $\partial\omega$.

Conditions $T_n^2 = 0$ (cf. (5.22b)) and $D_3^2 = 0$ yield that $\boldsymbol{\varphi}_\natural^1$ has to solve

$$
E_{\mathrm{Mix1}}(\boldsymbol{\varphi}_\natural^1) = \Big(0;\;0;\;-T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) + x_3\,M_n(\zeta_3^0),\;-(\zeta_3^2 + v_3^2)\Big).
\tag{8.1}
$$

With formulas (6.8) we can compute the three coefficients δ_3, δ_5, and δ_7, and determine conditions on $T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^0)$, $M_n(\zeta_3^0)$, and ζ_3^2 so that these three coefficients are zero, ensuring that $\boldsymbol{\varphi}_\natural^1$ is exponentially decaying. We have

$$
\bar\gamma_5\,\delta_5 = \int_{-1}^{+1} -T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) + x_3\,M_n(\zeta_3^0)\,dx_3,
\tag{8.2a}
$$

$$
\bar\gamma_7\,\delta_7 = \int_{-1}^{+1} x_3\,T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) - x_3^2\,M_n(\zeta_3^0)\,dx_3,
\tag{8.2b}
$$

$$
\bar\gamma_3\,\delta_3 = \int_{-1}^{+1} 6\bar p_3(-T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) + x_3\,M_n(\zeta_3^0)) + 6\mu(\bar p_2 + \bar p_3{}')(\zeta_3^2 + v_3^2)\,dx_3.
\tag{8.2c}
$$

With (8.2a) and (8.2b), the conditions $\delta_5 = 0$ and $\delta_7 = 0$ give immediately that $T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) = 0$ and $M_n(\zeta_3^0) = 0$ on $\partial\omega$, respectively. Then with the formula $v_3^2 = \bar{p}_1 \operatorname{div}_* \boldsymbol{\zeta}_*^0 + \bar{p}_2 \Delta_* \zeta_3^0$ we can compute from (8.2c)

$$\bar{\gamma}_3\, \delta_3 = -4(\tilde{\lambda} + 2\mu)\Big(\zeta_3^2 - \frac{\tilde{\lambda}}{30\mu}\, \Delta_* \zeta_3^0\Big),$$

whence the relation $30\mu\, \zeta_3^2 = \tilde{\lambda}\, \Delta_* \zeta_3^0$ on $\partial\omega$ ensuring the existence of a unique exponentially decreasing profile solution of (8.1).

But we have on $\partial\omega$

$$T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*) = (\tilde{\lambda} + 2\mu) \operatorname{div}_* \boldsymbol{\zeta}_* + 2\mu(\kappa\, \zeta_n - \partial_s \zeta_s), \tag{8.3a}$$

$$M_n(\zeta_3) = (\tilde{\lambda} + 2\mu)\Delta_* \zeta_3 + 2\mu(\kappa\, \partial_n \zeta_3 - \partial_{ss} \zeta_3). \tag{8.3b}$$

Since ζ_s^0 and ζ_3^0 are zero on $\partial\omega$, then $\partial_s \zeta_s^0$ and $\partial_{ss}\zeta_3^0$ are also zero and since $T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) = 0$ and $M_n(\zeta_3^0) = 0$ we deduce from (8.3a) the relations

$$\operatorname{div}_* \boldsymbol{\zeta}_*^0 = -\frac{2\mu}{\tilde{\lambda} + 2\mu}\, \kappa\, \zeta_n^0 \quad \text{and} \quad \Delta_* \zeta_3^0 = -\frac{2\mu}{\tilde{\lambda} + 2\mu}\, \kappa\, \partial_n \zeta_3^0. \tag{8.4}$$

Therefore, with $\bar{\boldsymbol{\varphi}}_\natural^{\mathrm{m}}$ the solution of $E_{\mathrm{Mix1}}(\bar{\boldsymbol{\varphi}}_\natural^{\mathrm{m}}) = \big(0;\ 0;\ 0,\ \frac{2\mu}{\tilde{\lambda}+2\mu}\, \bar{p}_1\big)$, and with $\bar{\boldsymbol{\varphi}}_\natural^{\mathrm{b}}$ the solution of $E_{\mathrm{Mix1}}(\bar{\boldsymbol{\varphi}}_\natural^{\mathrm{b}}) = \big(0;\ 0;\ 0,\ \frac{2\mu}{\tilde{\lambda}+2\mu}\, (\frac{\tilde{\lambda}}{30\mu} + \bar{p}_2)\big)$, we obtain the expression in Table 6 of the first boundary layer term.

8.2. The traces of $\boldsymbol{\zeta}^1$. The next relations are deduced from $T_n^3 = 0$ and $D_3^3 = 0$: $\boldsymbol{\varphi}_\natural^2$ has to solve

$$-E_{\mathrm{Mix1}}(\boldsymbol{\varphi}_\natural^2) = \Big(\big(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1\big)_\natural\ ;\ \big(\mathcal{G}^{(1)}\boldsymbol{\varphi}^1\big)_\natural\ ;\ T_t^{(1)}(\boldsymbol{\varphi}^1) + T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^1) - x_3\, M_n(\zeta_3^1),\ \zeta_3^3 + v_3^3\Big).$$

Since $\varphi_s^1 = 0$, the terms in the right-hand side reduce to

$$\big(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1\big)_t = -(\lambda + 2\mu)\, \kappa\, \partial_t \varphi_t^1, \quad \big(\mathcal{G}^{(1)}\boldsymbol{\varphi}^1\big)_t = 0, \quad T_t^{(1)}(\boldsymbol{\varphi}^1) = -\lambda\, \kappa\, \varphi_t^1.$$

The cancellation of the coefficients δ_5, δ_7, and δ_3 (cf. (8.2a)) is ensured by relations determining $T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^1)$, $M_n(\zeta_3^1)$, and ζ_3^3. In particular, we have

$$\begin{aligned} T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^1) = -\frac{1}{2}\Bigg(&\int_{\Sigma_+} \big(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1\big)_t(t, x_3)\, dt\, dx_3 \\ &- \int_{\mathbb{R}_+} \Big(\big(\mathcal{G}^{(1)}\boldsymbol{\varphi}^1\big)_t(t, 1) - \big(\mathcal{G}^{(1)}\boldsymbol{\varphi}^1\big)_t(t, -1)\Big)\, dt \\ &+ \int_{-1}^{+1} T_t^{(1)}(\boldsymbol{\varphi}^1)(0, x_3) - x_3 M_n(\zeta_3^1)(0)\, dx_3\Bigg). \end{aligned}$$

Combining with the already known expression for $\boldsymbol{\varphi}^1$, we obtain the formula of Table 3 for $T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^1)$. The trace $M_n(\zeta_3^1)$ is determined similarly.

9. Sliding edge. Lateral condition $\textcircled{6}$ is the other one, with $\textcircled{3}$, which allows a reflexion across the boundary in any region $\mathcal{V}$ where it is flat. If the support of the data avoids $\mathcal{V}$, there are *no boundary layer* terms and $\boldsymbol{u}(\varepsilon)$ can be expanded in a power series in $\mathcal{V}$. In the special case when ω is a rectangle (in principle forbidden here!) and the support of the data avoids the lateral boundary, the solution can be extended outside Ω in both in-plane directions into a periodic solution in $\mathbb{R}^2 \times I$: this link is indicated by Paumier in [27], where the periodic boundary conditions are addressed.

If the midplane of the plate ω is not a disk or an annulus, then the space $\mathcal{R}_{⑥}$ is one-dimensional and spanned by the vertical translation $(0,0,1)$. But if ω is a disk or an annulus that we may suppose is centered in 0, then $\mathcal{R}_{⑥}$ is two-dimensional, generated by the vertical translation $(0,0,1)$ and the in-plane rotation $(x_2, -x_1, 0)$. Here we will only treat the generic case.

9.1. The traces of $\boldsymbol{\zeta}^0$. As the Dirichlet trace D_n^0 is zero, we have $\zeta_n^0 = 0$ and $\partial_n \zeta_3^0 = 0$ on $\partial\omega$. We deduce the problem for $\boldsymbol{\varphi}_\natural^1$ from $D_n^1 = 0$ and $T_3^1 = 0$:

$$E_{\text{Mix2}}(\boldsymbol{\varphi}_\natural^1) = (0; 0; -\zeta_n^1 + x_3 \partial_n \zeta_3^1, 0)\,.$$

Proposition 6.11 then yields the conditions $\zeta_n^1 = 0$ and $\partial_n \zeta_3^1 = 0$ on $\partial\omega$ and thus $\boldsymbol{\varphi}_\natural^1 \equiv 0$.

The condition $T_s^2 = 0$ yields that φ_s^1 has to satisfy

$$L_{\text{Neu}}(\varphi_s^1) = (0; 0; -T_s^{\text{m}}(\boldsymbol{\zeta}_*^0) + 2\mu x_3 (\partial_n + \kappa)\partial_s \zeta_3^0)\,. \tag{9.1}$$

Proposition 6.6 yields that $T_s^{\text{m}}(\boldsymbol{\zeta}_*^0) = 0$ on $\partial\omega$. Combining with $\partial_n \zeta_3^0 = 0$ on $\partial\omega$, this solution is given by (cf. Lemma 6.7)

$$\varphi_s^1 = \kappa\, \partial_s \zeta_3^0(s)\, \bar{\varphi}_{\text{Neu}}^{\text{s}}(t, x_3). \tag{9.2}$$

With $T_s^3 = 0$ we obtain that φ_s^2 has to satisfy

$$L_{\text{Neu}}(\varphi_s^2) = \Big(-(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1)_s\,;\; -(\mathcal{G}^{(1)}\boldsymbol{\varphi}^1)_s\,;\; \mathfrak{h}_s \Big)\,, \tag{9.3}$$

where the terms in the right-hand side are given by, since $\boldsymbol{\varphi}_\natural^1 = 0$,

$$(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1)_s = \mu\kappa \Big(\partial_{tt}(t\,\varphi_s^1) + \partial_{33}(t\,\varphi_s^1) - \partial_t \varphi_s^1 \Big)\,, \quad (\mathcal{G}^{(1)}\boldsymbol{\varphi}^1)_s = 0,$$
$$\mathfrak{h}_s = -\Big(2\mu\kappa\varphi_s^1 + T_s^{\text{m}}(\boldsymbol{\zeta}_*^1) - 2\mu x_3 (\partial_n + \kappa)\partial_s \zeta_3^1 \Big)\,.$$

With the help of Proposition 6.6 and the fact that φ_s^1 is odd with respect to x_3, we deduce that $T_s^{\text{m}}(\boldsymbol{\zeta}_*^1) = 0$ on $\partial\omega$. Taking into account relation (9.2) and the already known condition $\partial_n \zeta_3^1 = 0$ on $\partial\omega$, this solution is given by

$$\varphi_s^2 = -\kappa^2 \partial_s \zeta_3^0\, \bar{\psi}_{\text{Neu}}^{\text{s}} + \kappa\, \partial_s \zeta_3^1\, \bar{\varphi}_{\text{Neu}}^{\text{s}}\,, \tag{9.4}$$

where $\bar{\psi}_{\text{Neu}}^{\text{s}}$ is the (odd) exponentially decreasing solution of

$$L_{\text{Neu}}(\bar{\psi}_{\text{Neu}}^{\text{s}}) = \mu \Big(\Delta(t\, \bar{\varphi}_{\text{Neu}}^{\text{s}}) - \partial_t \bar{\varphi}_{\text{Neu}}^{\text{s}}\,;\; 0\,;\; 2\bar{\varphi}_{\text{Neu}}^{\text{s}} \Big). \tag{9.5}$$

Conditions $D_n^2 = 0$ and $T_3^2 = 0$ lead to the following problem for $\boldsymbol{\varphi}_\natural^2$:

$$E_{\text{Mix2}}(\boldsymbol{\varphi}_\natural^2) = \Big(-(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1)_\natural\,;\; -(\mathcal{G}^{(1)}\boldsymbol{\varphi}^1)_\natural\,;\; \mathfrak{h}_t\,,\; \mathfrak{h}_3 \Big)\,, \tag{9.6}$$

where the terms in the right-hand side are given by

$$\text{(9.7a)}\qquad (\mathcal{B}^{(1)}\boldsymbol{\varphi}^1)_t = (\lambda+\mu)\,\partial_t\partial_s\varphi^1_s\,, \qquad (\mathcal{G}^{(1)}\boldsymbol{\varphi}^1)_t = 0,$$

$$\text{(9.7b)}\qquad (\mathcal{B}^{(1)}\boldsymbol{\varphi}^1)_3 = (\lambda+\mu)\,\partial_3\partial_s\varphi^1_s, \qquad (\mathcal{G}^{(1)}\boldsymbol{\varphi}^1)_3 = \lambda\,\partial_s\varphi^1_s,$$

$$\text{(9.7c)}\qquad \mathfrak{h}_t = -\left(\zeta^2_n - x_3\partial_n\zeta^2_3 + \bar p_2\,\partial_n\operatorname{div}_*\boldsymbol{\zeta}^0_* + \bar p_3\,\partial_n\Delta_*\zeta^0_3 + (G(\boldsymbol{f},\boldsymbol{g}^\pm))_n\right),$$

$$\text{(9.7d)}\qquad \mathfrak{h}_3 = -\mu\left((\bar p_2 + \bar p_3')\,\partial_n\Delta_*\zeta^0_3 + \partial_3(G(\boldsymbol{f},\boldsymbol{g}^\pm))_n\right)\,.$$

Combining with (9.2), the condition $\delta_8 = 0$ from Proposition 6.11 yields

$$2\mu\partial_s(\partial_n+\kappa)\partial_s\zeta^0_3\int_{\mathbb{R}^+}\bar\varphi^{\mathrm{s}}_{\mathrm{Neu}}(t,1)\,dt = \int_{-1}^{+1}\mathfrak{h}_3\,dx_3\,.$$

Using the expressions of G_n (cf. Definition 4.5) and of $\bar p_2$ and $\bar p_3$ (cf. (4.4)), we derive

$$\int_{-1}^{+1}\mathfrak{h}_3\,dx_3 = -\left[-\frac{2}{3}(\tilde\lambda+2\mu)\partial_n\Delta_*\,\zeta^0_3 + \int_{-1}^{+1}x_3\,f_n\,dx_3 + g^+_n + g^-_n\right]\Bigg|_{\partial\omega}.$$

Then Lemma 6.7 yields

$$\frac{2}{3}\underbrace{\left((\tilde\lambda+2\mu)\partial_n\Delta_*\,\zeta^0_3 + 2\mu\partial_s(\partial_n+\kappa)\partial_s\zeta^0_3\right)}_{=\,N_n(\zeta^0_3)} = \left(\int_{-1}^{+1}x_3\,f_n\,dx_3 + g^+_n + g^-_n\right)\Bigg|_{\partial\omega},$$

hence the condition $N_n(\zeta^0_3) = \frac{3}{2}\int_{-1}^{+1}x_3\,f_n\,dx_3 + g^+_n + g^-_n$ on $\partial\omega$. Then the compatibility condition for the solvability of problem (3.13b) for ζ^0_3 reads

$$\text{(9.8)}\qquad \int_\omega R^0_{\mathrm{b}}(x_*)\,dx_* - \int_{\partial\omega}\frac{3}{2}\Big(\int_{-1}^{+1}x_3\,f_n\,dx_3 + g^+_n + g^-_n\Big)(0,s)\,ds = 0\,.$$

With the help of the divergence theorem and formula (4.9), we can rewrite (9.8) as

$$\frac{3}{2}\int_\omega\left\{\int_{-1}^{+1}f_3\,dx_3 + g^+_3 - g^-_3\right\}dx_* = 0\,,$$

which is nothing else than the compatibility condition (2.10), whence (9.8).

9.2. The traces of $\boldsymbol{\zeta}^1$. The only remaining boundary condition is that for $N_n(\zeta^1_3)$. Therefore we only consider the problem for $\boldsymbol{\varphi}^3_\natural$, which is deduced from $D^3_n = 0$ and $T^3_3 = 0$ and reads

$$E_{\mathrm{Mix2}}(\boldsymbol{\varphi}^3_\natural) = \Big(-(\mathcal{B}^{(1)}\boldsymbol{\varphi}^2)_\natural - (\mathcal{B}^{(2)}\boldsymbol{\varphi}^1)_\natural\,;\; -(\mathcal{G}^{(1)}\boldsymbol{\varphi}^2)_\natural - (\mathcal{G}^{(2)}\boldsymbol{\varphi}^1)_\natural\,;\; \mathfrak{h}_t\,,\;\mathfrak{h}_3\Big)\,.$$

The boundary condition prescribing $N_n(\zeta^1_3)$ is then found by the cancellation of the coefficient δ_8 (6.9a). For this, we need an expression for $\boldsymbol{\varphi}^2_\natural$, which is derived from the cancellation of the constants δ_1 and δ_4 (6.9b)–(6.9c) relating to problem (9.6). The details can be found in [12, section 5].

Let us check the compatibility condition for ζ^1_3. Setting $\boldsymbol{\varphi} = \boldsymbol{\varphi}^1 + \varepsilon\boldsymbol{\varphi}^2$, we have by construction

$$\text{(9.9)}\qquad \begin{aligned} N_n(\zeta^0_3+\varepsilon\zeta^1_3) = \frac{3}{2}\Big(&\int_{\Sigma^+}\mathfrak{f}_3(\varepsilon) - \int_{\mathbb{R}^+}\Big(\mathfrak{g}^+_3(\varepsilon) - \mathfrak{g}^-_3(\varepsilon)\Big) + \int_{-1}^{+1}\mathfrak{h}_3(\varepsilon)\Big) \\ &+ 2\mu\,\partial_s(\partial_n+\kappa)\partial_s(\zeta^0_3+\varepsilon\zeta^1_3), \end{aligned}$$

TABLE 9
Auxiliary problems.

⑤	$\operatorname{mes}(\omega)\, L^{\mathrm{b}}(\eta_\omega) = 1 \quad \text{in } \omega$	$\eta_\omega = 0 \;\text{ and }\; \partial_n \eta_\omega = 0 \quad \text{on } \partial\omega$
⑦	$\operatorname{mes}(\omega)\, L^{\mathrm{b}}(\xi_\omega) = 1 \quad \text{in } \omega$	$\xi_\omega = 0 \;\text{ and }\; M_n(\xi_\omega) = 0 \quad \text{on } \partial\omega$

TABLE 10
Boundary conditions.

⑤	$\zeta_3^1 = c_3^{\textcircled{5}} \Big(\oint_{\partial\omega} \oint_{\partial\omega} L - \int_{\partial\omega} \Big(\oint_{\partial\omega} \oint_{\partial\omega} L \Big) N_n(\eta_\omega) \Big)$	$\partial_n \zeta_3^1 = 0$
⑦	$\zeta_3^1 = c_3^{\textcircled{7}} \Big(\oint_{\partial\omega} \oint_{\partial\omega} L + 2\mu \int_{\partial\omega} L\, \partial_n \xi_\omega \; - \int_{\partial\omega} \Big(\oint_{\partial\omega} \oint_{\partial\omega} L \Big) N_n(\xi_\omega) \Big)$	$M_n(\zeta_3^1) = c_4^{\textcircled{7}}\, L$

where

$$\mathfrak{f}(\varepsilon) = \mathcal{B}\boldsymbol{\varphi} + \mathcal{O}(\varepsilon^2), \qquad \mathfrak{g}(\varepsilon) = \mathcal{G}\boldsymbol{\varphi} + \mathcal{O}(\varepsilon^2), \qquad \mathfrak{h}(\varepsilon) = \boldsymbol{T}\boldsymbol{\varphi} + \mathcal{O}(\varepsilon^2).$$

With $\boldsymbol{w}(\tilde{x}) = \chi(r)\, \boldsymbol{\varphi}(\frac{r}{\varepsilon}, s, \frac{\tilde{x}_3}{\varepsilon})$ on Ω^ε and integrating (9.9) along $\partial\omega$, we obtain for any rigid motion $\boldsymbol{v} = (0, 0, a)$ in $\mathcal{R}_{\textcircled{6}}$

$$\int_{\partial\omega} N_n(\zeta_3^0 + \varepsilon\zeta_3^1)\, v_3 = -\frac{3}{2} \int_{\Omega^\varepsilon} Ae(\boldsymbol{w}) : e(\boldsymbol{v}) + \mathcal{O}(\varepsilon^2) = \mathcal{O}(\varepsilon^2),$$

where we have used $\int_{\partial\omega} \partial_s(\partial_n + \kappa)\partial_s(\zeta_3^0 + \varepsilon\zeta_3^1)\, ds = 0$. The desired compatibility condition then follows.

10. Friction conditions. We only give a few precisions about the traces of the first Kirchhoff–Love generators $\boldsymbol{\zeta}^0$ and $\boldsymbol{\zeta}^1$ for conditions ⑤ and ⑦, referring to [12, sections 4 and 6] for the proofs, which make use in particular of Lemma 6.5.

The membrane boundary operators $\gamma^{\mathrm{m},j}$, $j = 1, 2$, are Dirichlet's in both cases and the corresponding traces $\gamma^0_{\mathrm{m},j}$ and $\gamma^1_{\mathrm{m},j}$ are zero.

The spaces of rigid motions $\mathcal{R}_{\textcircled{5}}$ and $\mathcal{R}_{\textcircled{7}}$ are one-dimensional and both are generated by the vertical translation $(0, 0, 1)$. As a consequence, the first terms ζ_3^0 and ζ_3^1 have to satisfy the zero mean value condition on ω. The bending boundary operators $\gamma^{\mathrm{b},j}$, $j = 1, 2$, are Dirichlet's for ⑤, and the trace operator on $\partial\omega$ and M_n for ⑦. Thus the corresponding problems (3.13b) are uniquely solvable. The way out is that the boundary conditions issued from the solution of the Ansatz include $\partial_s \zeta_3 = 0$ on $\partial\omega$. Thus the trace of ζ_3 can be fixed to any constant (we assume here for simplicity that $\partial\omega$ is connected), which can be chosen such that $\int_\omega \zeta_3 = 0$. The formula for this constant relies on the introduction of the solutions η_ω and ξ_ω of the auxiliary problems (Table 9).

NOTATION 10.1. *If L is an integrable function on $\partial\omega$ such that $\int_{\partial\omega} L = 0$, then we denote by $\oint_{\partial\omega} L$ the unique primitive of L along $\partial\omega$ with zero mean value on $\partial\omega$ (that is, $\int_{\partial\omega} \oint L\, ds = 0$). The second primitive $\oint_{\partial\omega} \oint_{\partial\omega} L$ then makes sense.*

For condition ⑤, $\partial_n \zeta_3^0 = 0$ and ζ_3^0 is equal to the constant $-\int_\omega R_{\mathrm{b}}^0 \eta_\omega$ on $\partial\omega$, whereas for condition ⑦, $M_n(\zeta_3^0) = 0$ and ζ_3^0 is equal to the constant $-\int_\omega R_{\mathrm{b}}^0\, \xi_\omega$ on $\partial\omega$. Finally, the boundary conditions for ζ_3^1 are displayed in Table 10, with L given in (3.15).

11. Free. The space $\mathcal{R}_{⑧}$ is six-dimensional and spanned by all rigid motions. We are only going to explain how the traces of $\boldsymbol{\zeta}^0$ can be determined by our method and refer to [12, section 7] for the traces of $\boldsymbol{\zeta}^1$. The nonhomogeneity of the boundary condition $N_n(\zeta_3^0)$ is known; see Ciarlet [4, Theorem 1.7.2].

From the conditions $T_3^1 = 0$ and $T_n^2 = 0$, we obtain for $\boldsymbol{\varphi}_\natural^1$

$$E_{\mathrm{Free}}(\boldsymbol{\varphi}_\natural^1) = (0; 0; -T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) + x_3 M_n(\zeta_3^0), 0)\,. \tag{11.1}$$

From the cancellation of the constants δ_5 and δ_7 in Proposition 6.12, the conditions $T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) = 0$ and $M_n(\zeta_3^0) = 0$ on $\partial\omega$ are obtained. Thus $\boldsymbol{\varphi}_\natural^1 \equiv 0$.

The condition $T_s^2 = 0$ yields that φ_s^1 has to satisfy problem (9.1). Thus $T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^0) = 0$ on $\partial\omega$ and φ_s^1 is then given by (cf. Lemma 6.7)

$$\varphi_s^1 = (\partial_n + \kappa)\partial_s\zeta_3^0(s)\,\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}\,. \tag{11.2}$$

With $T_s^3 = 0$ we obtain that φ_s^2 has to satisfy problem (9.3), hence the condition $T_s^{\mathrm{m}}(\boldsymbol{\zeta}_*^1) = 0$ on $\partial\omega$ ensures the existence of an exponentially decaying profile. Taking into account the relation (11.2), this solution is given by

$$\varphi_s^2 = -\kappa(\partial_n + \kappa)\partial_s\zeta_3^0\,\bar\psi_{\mathrm{Neu}}^{\mathrm{s}} + (\partial_n + \kappa)\partial_s\zeta_3^1\,\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}\,, \tag{11.3}$$

where $\bar\psi_{\mathrm{Neu}}^{\mathrm{s}}$ is the solution of problem (9.5).

The conditions $T_3^2 = 0$ and $T_n^3 = 0$ lead to the following problem for $\boldsymbol{\varphi}_\natural^2$:

$$E_{\mathrm{Free}}(\boldsymbol{\varphi}_\natural^2) = \Big(-\big(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1\big)_\natural\,;\ -\big(\mathcal{G}^{(1)}\boldsymbol{\varphi}^1\big)_\natural\,;\ \mathfrak{h}_t\,,\ \mathfrak{h}_3\Big)\,, \tag{11.4}$$

where the terms in the right-hand side of (11.4) are given by

$$\big(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1\big)_t = (\lambda+\mu)\,\partial_t\partial_s\varphi_s^1\,,\ \big(\mathcal{G}^{(1)}\boldsymbol{\varphi}^1\big)_t = 0\,,\ \mathfrak{h}_t = -\big(\lambda\partial_s\varphi_s^1 + T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^1) - x_3 M_n(\zeta_3^1)\big)\,,$$

whereas $\big(\mathcal{B}^{(1)}\boldsymbol{\varphi}^1\big)_3$ and $\big(\mathcal{G}^{(1)}\boldsymbol{\varphi}^1\big)_3$ are still given by (9.7b) and $\mathfrak{h}_3$ by (9.7d). Thus, the cancellation of the constants δ_5, δ_7, and δ_8 from Proposition 6.12 is required. The cancellation of δ_5 leads to the boundary condition $T_n^{\mathrm{m}}(\boldsymbol{\zeta}_*^1) = 0$ on $\partial\omega$. Inserting the expressions involved, the condition $\delta_7 = 0$ reads

$$\begin{aligned}\Bigg[(\lambda+\mu)\int_{\Sigma^+}(x_3\,\partial_t\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}} - t\,\partial_3\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}})\,dt\,dx_3 + \lambda\int_0^\infty t\,(\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}(1,t) - \bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}(1,t))\,dt\\ + \lambda\int_{-1}^{+1} x_3\,\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}(0,x_3)\,dx_3\Bigg]\,\partial_s(\partial_n+\kappa)\partial_s\zeta_3^0 - \int_{-1}^{+1} x_3^2\,M_n(\zeta_3^1)\,dx_3 = 0\,.\end{aligned}$$

As the boundary layer term $\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}$ is odd, the above condition becomes

$$\frac{2}{3}\,M_n(\zeta_3^1) = \partial_s(\partial_n+\kappa)\partial_s\zeta_3^0\left[-\mu\int_{-1}^{+1} x_3\,\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}(0,x_3)\,dx_3 - 2\mu\int_0^\infty t\ \bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}(1,t)\,dt\right].$$

Applying the second Green formula for Laplace to the functions $\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}(t,x_3)$ and $w(t,x_3) = t\,x_3$ yields the relation

$$2\int_0^\infty t\,\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}(t,1)\,dt = \int_{-1}^{+1} x_3\,\bar\varphi_{\mathrm{Neu}}^{\mathrm{s}}(0,x_3)\,dx_3\,.$$

Thus $M_n(\zeta_3^1) = c_3^{\textcircled{8}} \partial_s(\partial_n + \kappa)\partial_s \zeta_3^0$ on $\partial\omega$ with $c_3^{\textcircled{8}} = -3\mu \int_{-1}^{+1} x_3\, \bar\varphi^{\mathrm{s}}_{\mathrm{Neu}}(0, x_3)\, dx_3$.

The evaluation of the condition $\delta_8 = 0$ has been already done in section 8.1, which yields in exactly the same way, formula (3.14) for the trace $N_n(\zeta_3^0)$.

Now let us check the compatibility conditions ensuring the existence of the generator $\boldsymbol{\zeta}^0$. Concerning $\boldsymbol{\zeta}_*^0$, we have to show that the membrane right-hand side $\boldsymbol{R}_{\mathrm{m}}^0$ of the limit problem is orthogonal to each of the two-dimensional rigid motions $(1,0)$, $(0,1)$, and $(x_2, -x_1)$, since we have homogeneous traction boundary conditions in the problem for $\boldsymbol{\zeta}_*^0$. These orthogonality conditions are clearly a consequence of the expression of the right-hand side $\boldsymbol{R}_{\mathrm{m}}^0$ and of the three-dimensional compatibility conditions (2.10) for in-plane rigid motions.

The compatibility conditions for ζ_3^0 remains to be checked. They are related to the kernel of L^{b} with boundary conditions M_n and N_n, i.e., to the functions 1, x_1, and x_2. It has been already shown in section 8.1 that the condition (9.8) relating to the element 1 of the kernel is fulfilled. Now let us check the condition for x_1, namely,

$$\int_\omega x_1\, R_{\mathrm{b}}^0(x_*)\, dx_* - \frac{3}{2} \int_{\partial\omega} x_1 \left(\int_{-1}^{+1} x_3\, f_n\, dx_3 + g_n^+ + g_n^- \right)(0, s)\, ds = 0\ .$$

With the help of the divergence theorem we can rewrite it as

$$\frac{3}{2} \left\{ \int_\Omega (x_1\, f_3 - x_3\, f_1)\, dx_3\, dx_* + \int_\omega \left\{ x_1\, (g_3^+ - g_3^-) - (g_1^+ + g_1^-) \right\}\, dx_* \right\} = 0\,,$$

which coincides with a compatibility condition (2.10) for the three-dimensional problem. Of course, the condition for x_2 can be proved analogously.

12. Error estimates. We provide in this section estimates in H^1 and L^2 norms.

12.1. In $\boldsymbol{H^1}$ norm. In this section we prove Theorem 3.2, which yields an optimal estimation of the error between the scaled displacement $\boldsymbol{u}(\varepsilon)$ and the Ansatz of order N. This extends the results obtained in [8, section 5] for the hard clamped situation to the eight "canonical" boundary conditions on the lateral side. The proof relies on energy estimates and on a very simple argument consisting in pushing the development a few terms further.

We define the space $\mathcal{V}_{\textcircled{i}}(\Omega)$ as the subspace of the admissible displacements $\boldsymbol{u}$ in $V_{\textcircled{i}}(\Omega)$ which are orthogonal for the L^2 product to all the rigid motions $\boldsymbol{v} \in \mathcal{R}_{\textcircled{i}}(\Omega)$. Thus $\boldsymbol{u}(\varepsilon)$ belongs to $\mathcal{V}_{\textcircled{i}}(\Omega)$. Combining Korn's inequality without boundary conditions and the infinitesimal rigid displacement lemma we obtain a Korn inequality with boundary conditions for arbitrary $\boldsymbol{u} \in \mathcal{V}_{\textcircled{i}}(\Omega)$; compare [25] and [4], which reads in terms of the scaled linearized strain tensor $\theta(\varepsilon)$,

$$\left(\int_\Omega A\theta(\varepsilon)(\boldsymbol{u}) : \theta(\varepsilon)(\boldsymbol{u}) \right)^{1/2} \geq C^* \|\theta(\varepsilon)(\boldsymbol{u})\|_{L^2(\Omega)^9} \geq C \|\boldsymbol{u}\|_{H^1(\Omega)}\,. \tag{12.1}$$

Defining the remainder at the order N of the asymptotics of $\boldsymbol{u}(\varepsilon)$ by $\overline{U}^N(\varepsilon) := \boldsymbol{u}(\varepsilon) - U^N(\varepsilon)$, where $U^N(\varepsilon)$ denotes the asymptotic expansion of order N, namely,

$$U^N(\varepsilon) \;=\; \underbrace{\sum_{k=0}^{N} \varepsilon^k\, \underline{\boldsymbol{u}}^k}_{=:\, V^N(\varepsilon)} \;+\; \chi(r) \underbrace{\sum_{k=1}^{N} \varepsilon^k\, \boldsymbol{w}^k \left(\frac{r}{\varepsilon}, s, x_3 \right)}_{=:\, W^N(\varepsilon)} \tag{12.2}$$

with $\underline{\boldsymbol{u}}^k := \boldsymbol{u}^k_{\mathrm{KL}} + \boldsymbol{v}^k$; compare section 3.1 for notations, we only need to establish an a priori estimate for $\overline{U}^N(\varepsilon)$ in the norm of the space $H^1(\Omega)^3$.

Therefore, we split $U^N(\varepsilon)$ into its natural parts $U^N(\varepsilon) = V^N(\varepsilon) + \chi(r)\, W^N(\varepsilon)$. Considering carefully the construction algorithm, in particular the derivation of the boundary layer terms, we observe that for any $N \in \mathbb{N}$, $U^N(\varepsilon)$ belongs to the space $\mathcal{V}_{\textcircled{i}}(\Omega)$. Thus, we have

$$\forall N \in \mathbb{N}\,, \quad \overline{U}^N(\varepsilon) \in \mathcal{V}_{\textcircled{i}}(\Omega)$$

and the variational form of the problem for $\overline{U}^N(\varepsilon)$ can be written down, where we split the deviation to the true solution into an error generated by $V^N(\varepsilon)$ and an error coming from $W^N(\varepsilon)$; compare [8, (5.8)–(5.11)]. For the choice $\boldsymbol{v} = \overline{U}^N(\varepsilon)$ of the test function in the variational formulation of the problem for $\overline{U}^N(\varepsilon)$, we obtain as one side of the resulting equation the energy associated to the remainder, namely,

$$\int_\Omega A\,\theta(\varepsilon)(\overline{U}^N(\varepsilon)) \,:\, \theta(\varepsilon)(\overline{U}^N(\varepsilon))\,.$$

Korn's inequality (12.1) and the coercivity of the operator of elasticity then provides the following rough estimate

$$\|\overline{U}^N(\varepsilon)\|_{H^1(\Omega)^3} \le C\varepsilon^{N-3}$$

exactly in the same manner as in the proof of Lemma 5.3 in [8]. This estimate reads for $\|\overline{U}^{N+4}(\varepsilon)\|_{H^1(\Omega)^3} \le C\varepsilon^{N+1}$ at the rank $N+4$, whence

$$\begin{aligned}(12.3)\quad &\left\|\boldsymbol{u}(\varepsilon)(x) - \boldsymbol{u}^0_{\mathrm{KL}}(x) - \sum_{k=1}^{N} \varepsilon^k \boldsymbol{u}^k\left(x, \frac{r}{\varepsilon}\right)\right\| H^1(\Omega)^3 \\ &\qquad \le C\,\varepsilon^{N+1} + \sum_{k=N+1}^{N+4} \varepsilon^k \left(\|\underline{\boldsymbol{u}}^k\| H^1(\Omega)^3 + \left\|\chi(r)\boldsymbol{w}^k\left(\frac{r}{\varepsilon}, s, x_3\right)\right\| H^1(\Omega)^3 \right)\,.\end{aligned}$$

With the help of the following H^1-estimates of each term in the asymptotics

$$(12.4)\qquad \|\underline{\boldsymbol{u}}^k\|_{H^1(\Omega)^3} \le C \quad\text{and}\quad \left\|\chi(r)\boldsymbol{w}^k\left(\frac{r}{\varepsilon}, s, x_3\right)\right\| H^1(\Omega)^3 \le C\varepsilon^{-1/2}\,,$$

the estimate (3.4) directly follows from (12.3).

12.2. In other norms. The L^2-estimates of each term corresponding to (12.4)

$$(12.5)\qquad \|\underline{\boldsymbol{u}}^k\|_{L^2(\Omega)^3} \le C \quad\text{and}\quad \left\|\chi(r)\boldsymbol{w}^k\left(\frac{r}{\varepsilon}, s, x_3\right)\right\| L^2(\Omega)^3 \le C\varepsilon^{1/2}$$

lead in a straightforward way to the following estimates in L^2 norm:

$$(12.6)\qquad \left\|\boldsymbol{u}(\varepsilon) - \sum_{k=0}^{N} \varepsilon^k\, \underline{\boldsymbol{u}}^k - \chi(r) \sum_{k=1}^{N} \varepsilon^k\, \boldsymbol{w}^k\left(\frac{r}{\varepsilon}, s, x_3\right)\right\| L^2(\Omega)^3 \le C\,\varepsilon^{N+1}\,.$$

The question of estimates in higher norms, H^2 for instance, is also considered in [9] for the clamped case. Such estimates require a splitting of the solution and of terms in the asymptotics, since in general the H^2 regularity is not attained. The situation is similar for all lateral conditions. Let us just emphasize that all the terms in the outer expansion are smooth, but also that the singularities along the edges $\partial\omega \times \{\pm 1\}$ of the plate are concentrated in the inner expansion: the model profiles are all nonsmooth, with a regularity between $H^{3/2}$ and H^3. For example, $\bar{\varphi}^{\rm s}_{\rm Dir}$ is almost H^2 and $\bar{\varphi}^{\rm s}_{\rm Neu}$ is almost H^3, whereas the profiles $\bar{\boldsymbol{\varphi}}^{\rm m}_{{\rm Dir},\natural}$ and $\bar{\boldsymbol{\varphi}}^{\rm b}_{{\rm Dir},\natural}$ occurring in the clamped plates have less regularity, cf. [10].

13. Conclusions. Coming back to the family of thin domains Ω^ε, we will briefly address the question of the determination of a limit solution and of the evaluation of the relative error between this limit and the three-dimensional solution. The correct answer depends on the norm in which the error is evaluated and on the type of the loading.

13.1. $\boldsymbol{H^1}$ norm. We have first to evaluate the behavior of the $H^1(\Omega^\varepsilon)$ norm denoted by $\|\cdot\|_{H1}$ of each of the four types of components of series (3.5), namely, $\tilde{\boldsymbol{u}}^k_{\rm KL,b}$, $\tilde{\boldsymbol{u}}^k_{\rm KL,m}$, $\tilde{\boldsymbol{v}}^k$, and $\boldsymbol{\varphi}^k$. We find

$$\|\tilde{\boldsymbol{u}}^k_{\rm KL,b}\|_{H1} = \mathcal{O}(\varepsilon^{-1/2}), \qquad \|\tilde{\boldsymbol{u}}^k_{\rm KL,m}\|_{H1} = \mathcal{O}(\varepsilon^{1/2}),$$

$$\|\tilde{\boldsymbol{v}}^k\|_{H1} = \mathcal{O}(\varepsilon^{-1/2}), \qquad \|\boldsymbol{\varphi}^k\|_{H1} = \mathcal{O}(1).$$

In the case of a bending load such that $R^0_{\rm b}$ (cf. (4.9)) is nonzero, we have

$$\frac{\|\boldsymbol{u}^\varepsilon - \tilde{\boldsymbol{u}}^0_{\rm KL,b}\|_{H1}}{\|\boldsymbol{u}^\varepsilon\|_{H1}} \le C\,\varepsilon \tag{13.1}$$

and this estimate is sharp for any lateral boundary condition, since the main contribution to the error comes from $\tilde{\boldsymbol{v}}^1$, which is equal to $(0, 0, \bar{p}_2(x_3)\,\Delta_*\zeta^0_3)$; indeed, since we assumed that $R^0_{\rm b}$ is nonzero, $\Delta^2_*\zeta^0_3$ is nonzero, and $\tilde{\boldsymbol{v}}^1 \not\equiv 0$.

In the case of a membrane load such that $\boldsymbol{R}^0_{\rm m}$ (cf. (4.6)) is nonzero, we have to include $\tilde{\boldsymbol{v}}^1$ in the limit solution to have a convergence: we set

$$\boldsymbol{u}^{\rm lim}_{\rm m} = \tilde{\boldsymbol{u}}^0_{\rm KL,m} + \varepsilon\tilde{\boldsymbol{v}}^1 = (\zeta^0_*,\ \bar{p}_1(\tilde{x}_3)\,{\rm div}_*\,\zeta^0_*). \tag{13.2}$$

Then

$$\frac{\|\boldsymbol{u}^\varepsilon - \boldsymbol{u}^{\rm lim}_{\rm m}\|_{H1}}{\|\boldsymbol{u}^\varepsilon\|_{H1}} \le C\,\varepsilon^{1/2}, \quad \text{in cases ①–④}, \tag{13.3}$$

this estimate being generically optimal, in the sense that it is sharp when $\boldsymbol{\varphi}^1$ is nonzero, i.e., when ${\rm div}_*\,\zeta^0_*$ is nonzero on $\partial\omega$ in cases ①, ②, and ④, and when $\kappa\zeta^0_n$ is nonzero on $\partial\omega$ in cases ③. On the other hand,

$$\frac{\|\boldsymbol{u}^\varepsilon - \boldsymbol{u}^{\rm lim}_{\rm m}\|_{H1}}{\|\boldsymbol{u}^\varepsilon\|_{H1}} \le C\,\varepsilon, \quad \text{in cases ⑤–⑧}, \tag{13.4}$$

this estimate being generically optimal too, in the sense that it is sharp when $\tilde{\boldsymbol{v}}^2$ is nonzero, i.e., when ${\rm div}_*\,\zeta^0_* \not\equiv 0$; compare also with [22] for a special membrane loading on a free plate.

13.2. Energy norm. We now set $\|\boldsymbol{u}\|_E = \left(\int_{\Omega^\varepsilon} Ae(\boldsymbol{u}) : e(\boldsymbol{u})\right)^{1/2}$. The energy of the four types of terms in the series (3.5) has the same behavior as their H^1 norm *except* the one concerning $\tilde{\boldsymbol{u}}^k_{\mathrm{KL,b}}$, whose energy is one order smaller:

$$\|\tilde{\boldsymbol{u}}^k_{\mathrm{KL,b}}\|_E = \mathcal{O}(\varepsilon^{1/2}).$$

We obtain exactly the same conclusions if we use this energy, or the L^2 norm of the strain tensor, or the complementary energy. We have to include the polynomial terms up to the order 2 to obtain a convergence: we set $\boldsymbol{u}^{\mathrm{lim}}_{\mathrm{m}}$ as above in (13.2) and moreover

$$\boldsymbol{u}^{\mathrm{lim}}_{\mathrm{b}} = \tilde{\boldsymbol{u}}^0_{\mathrm{KL,b}} + \varepsilon\tilde{\boldsymbol{v}}^1 = (-x_3\nabla_*\zeta^0_3,\ \varepsilon^{-1}\zeta^0_3 + \varepsilon\bar{p}_2(x_3)\,\Delta_*\zeta^0_3); \tag{13.5}$$

cf. [28] and [30] in this context.

In the case of a bending load such that R^0_{b} is nonzero, we have

$$\frac{\|\boldsymbol{u}^\varepsilon - \boldsymbol{u}^{\mathrm{lim}}_{\mathrm{b}}\|_E}{\|\boldsymbol{u}^\varepsilon\|_E} \le C\,\varepsilon^{1/2}, \tag{13.6}$$

this estimate being generically optimal, in the sense that it is sharp when $\boldsymbol{\varphi}^1$ is nonzero, i.e., when ℓ^{b} is nonzero on $\partial\omega$ in cases ①–④ (cf. Table 6) and when ℓ^{s} is nonzero on $\partial\omega$ in cases ⑤–⑧ (cf. Table 7).

In the case of a membrane load such that $\boldsymbol{R}^0_{\mathrm{m}}$ is nonzero, we have exactly the same behavior as with the H^1 norm; see (13.3) and (13.4). In particular, the condition for the optimality of the estimates is visibly sharp, which brings a conclusion to the work [2].

The observation of the first terms in the asymptotics also sheds light on the order of magnitude of the answer of the plate under the loading. The maximal answer rate (of order ε^{-2}) is obtained with a bending load such that R^0_{b} is nonzero and corresponds to the flexural nature of plates. In contrast, the membrane (or stretching) answer is of order 1 when $\boldsymbol{R}^0_{\mathrm{m}}$ is nonzero. Moreover, there are very many other types of loading (bending or membrane) whose answer rate is much lower; see [6].

ON TRANSITIONS TO STATIONARY STATES IN A MAXWELL–LANDAU–LIFSCHITZ–GILBERT SYSTEM[*]

PATRICK JOLY[†], ALEXANDER KOMECH[‡], AND OLIVIER VACUS[§]

Abstract. In this paper we consider Maxwell's equations together with a dissipative nonlinear magnetic law, the Landau–Lifschitz–Gilbert equation, and we study long-time asymptotics of solutions in the 1D case in an infinite domain of propagation. We prove long-time convergence to zero of the electromagnetic field in a Fréchet topology defined by local energy seminorms: this corresponds to the local energy decay. We then introduce the set of stationary states for the Landau–Lifschitz–Gilbert equation and prove that it corresponds to the attractor set for the distribution of magnetization whose presence is one of the characteristics of ferromagnetic media.

Key words. Maxwell's equations, Landau–Lifchitz–Gilbert law, local energy decay, Liapunov theory, long-time asymptotics

AMS subject classifications. 15A15, 15A09, 15A23

1. Introduction.

Ferromagnetic materials possess a spontaneous magnetization whose interaction with the magnetic field provides to this type of medium interesting absorbing properties with respect to electromagnetic waves. That is why the use of such materials as absorbing coatings for scatterers is of real importance for stealth technology. The present paper is a contribution to the mathematical theory of electromagnetic scattering by such objects. One of the main characteristics of ferromagnetic materials lies in the fact that their constitutive law, namely, the relationship between the magnetic field H and the magnetization M, is nonlinear and nonlocal with respect to time. This equation is the Landau–Lifschitz–Gilbert (LLG) equation that can be written pointwise in the form

$$\dot{M} \;=\; \gamma H_T \times M + \frac{\alpha}{|M|} M \times \dot{M}, \tag{1.1}$$

where H_T is the total magnetic field defined as

$$H_T \;=\; H + H_s + H_a(M), \tag{1.2}$$

with each of these contributions being defined as

$$\left\{ \begin{array}{lll} H & & \text{is the magnetic field;} \\ H_s \;=\; H_s(\mathbf{x}) & & \text{is an exterior static field (given);} \\ H_a(M) \;=\; -K\;P(M) & & \text{is a field of anisotropy.} \end{array} \right. \tag{1.3}$$

In (1.3), $\mathbf{x} = (x, y, z)$ denotes the space variable, t denoting time; K denotes a positive coefficient, constant in time but that may depend on $\mathbf{x}$; and $P(M)$ is the orthogonal

projection in $\mathbb{R}^3$ on the plane orthogonal to some unit vector $\mathbf{p}$, called the easy axis (this direction, which is linked to the crystallic structure of the material, may also depend on $\mathbf{x}$):

$$P(M) = M - (p \cdot M)p\ . \tag{1.4}$$

Let us mention that in (1.1), γ, the gyromagnetic factor, is a universal constant while α, the damping factor, is a phenomenologic coefficient which depends on $\mathbf{x}$. Therefore, for our applications, a propagation medium will be determined by H_s, α, K, as function of $\mathbf{x}$ (and by the initial distribution of magnetization M_0; see (1.7)).

Here we are interested in the coupling of (1.1) with Maxwell's equations in some domain Ω (typically an exterior domain, if one thinks of applications to scattering problems) with boundary $\Gamma = \partial\Omega$. We assume that space and time variables are scaled in such a way that the constants γ, ε_0 (the electric permittivity) and μ_0 (the magnetic permeability) can be taken equal to 1. One then has to solve

$$\left\{\begin{array}{l} \dot{E}(\mathbf{x},t) - \text{curl } H(\mathbf{x},t) = 0, \\ \dot{H}(\mathbf{x},t) + \text{curl } E(\mathbf{x},t) + \dot{M}(\mathbf{x},t) = 0, \\ \dot{M}(\mathbf{x},t) = H_T(\mathbf{x},t) \times M(\mathbf{x},t) + \dfrac{\alpha}{|M(\mathbf{x},t)|} M(\mathbf{x},t) \times \dot{M}(\mathbf{x},t), \end{array}\right. \qquad \mathbf{x} \in \Omega,\ t > 0, \tag{1.5}$$

with a perfectly conducting boundary condition on Γ with unit normal vector n

$$E \times n\ |_\Gamma =\ 0, \tag{1.6}$$

and initial conditions on $\mathbb{R}_-$:

$$E(\mathbf{x}, t=0)\ =\ E_0(\mathbf{x}),\ H(\mathbf{x}, t=0)\ =\ H_0(\mathbf{x}),\ M(\mathbf{x}, t=0)\ =\ M_0(\mathbf{x}). \tag{1.7}$$

From a mathematical point of view, even the existence and uniqueness result for system (1.5) appears to be a very difficult question (see [4], [5]). Another natural question that we wish to address here is the following: Is it possible to describe the asymptotic behavior of the solution of system (1.9) for large time? In the case of linear materials, the answer to this question has been known for a long time (see [9], [10], [11]): the electric and magnetic fields tend locally to 0. This result is known as the local energy decay. A more subtle question is an estimate of the rate of decay; this question is closely related to the geometry of the obstacle [18].

In the case of nonlinear media, there are much fewer results in that direction (see [16], [17]). Our goal in this paper is to establish a result analogous to the local energy decay in a simplified 1*D model problem.* More precisely we assume that all the unknowns are functions of only one space variable x (i.e., we consider the propagation of plane waves). The curl operator is then defined by

$$\text{curl } H(x,t) = \left(0, -\frac{\partial H_z}{\partial x}, \frac{\partial H_y}{\partial x}\right),\ \text{curl } E(x,t) = \left(0, -\frac{\partial E_z}{\partial x}, \frac{\partial E_y}{\partial x}\right). \tag{1.8}$$

We assume that the propagation medium is the half-space $x < 0$ and apply the perfectly conducting boundary condition at $x = 0$ ($e_x = (1,0,0)$):

$$E \times e_x\ =\ 0.$$

We also assume that the support of the initial magnetization M_0, which defines the ferromagnetic layer (see 2.6), is compact:

$$\text{supp } M_0\ \subset\ ]-a, 0].$$

Then, by a principle of reflection (or image principle), the analysis of (1.5), (1.6), and (1.7) can be reduced to the analysis of the pure Cauchy problem on the whole line:

$$\left\{\begin{array}{l} \dot{E}(x,t) - \text{curl } H(x,t) = 0, \\ \dot{H}(x,t) + \text{curl } E(x,t) + \dot{M}(x,t) = 0, \\ \dot{M}(x,t) = H_T(x,t) \times M(x,t) + \dfrac{\alpha}{|M(x,t)|} M(x,t) \times \dot{M}(x,t), \end{array}\right. \qquad x \in \mathbb{R},\ t > 0, \tag{1.9}$$

provided that the new initial data M_0, E_0, H_0 are appropriate extensions of the original ones:

$$\left\{\begin{array}{lcl} M_0(-x) & = & M_0(x), \\ E_0(-x) & = & \Pi_\perp\, E_0(x), \\ H_0(-x) & = & \Pi_{\|}\, H_0(x), \end{array}\right. \tag{1.10}$$

where the operators $\Pi_\perp$ and $\Pi_{\|}$ are defined for any field $A(A_x, A_y, A_z)$ by

$$\left|\begin{array}{lcl} \Pi_\perp(A_x, A_y, A_z) & = & (A_x, -A_y, -A_z), \\ \Pi_{\|}(A_x, A_y, A_z) & = & (-A_x, A_y, A_z). \end{array}\right. \tag{1.11}$$

Remark 1.1. Concerning the longitudinal components, equations (1.9) imply

$$\begin{array}{c} E_x(x,t) = E_x^0(x), \\ H_x(x,t) + M_x(x,t) = H_x^0(x) + M_x^0(x). \end{array} \tag{1.12}$$

We see here that the component E_x is constant in time, while convergence results on M_x yield results on H_x.

The outline of this article is as follows. In section 2, after having recalled some known results about weak and strong solutions of the 1D scattering problem, we state the main results of the paper, namely, Theorems A and A$'$ for the local energy decay (respectively, for weak and strong solutions) and Theorem B on long-time asymptotics of the magnetization M. Sections 3 and 4 are, respectively, devoted to the proof of Theorems A and A$'$. In section 5, we give some intermediate results about the LLG equation seen as an ordinary differential equation; these results are preparatory for section 6, in which we prove Theorem B. Finally, section 7 is devoted to some additional remarks and comments.

2. Statement of the main results.

2.1. Overview of known results in the 1D case. As we said above, existence and uniqueness results for system (1.9) are very difficult in dimension 3. In the case of the 1D model, the problem is easier and can be handled via a fixed point theorem. Let us summarize the main existence and uniqueness results from [7].

We introduce the phase space V for the system (1.9). Let $L^p = [L^p(\mathbb{R})]^3$ for $1 \le p \le \infty$, $L^{2,\infty}$ be the Banach space $L^2 \cap L^\infty$ with the norm

$$\|M\|_{L^{2,\infty}} = \|M\|_{L^2} + \|M\|_{L^\infty}, \tag{2.1}$$

and let $H(\text{curl})$ denote the Hilbert space $\{u \in L^2 \,/\, \text{curl } u \in L^2\}$ with the norm

$$\|u\|_{\text{curl}}^2 = \|\text{curl } u\|_{L^2}^2 + \|u\|_{L^2}^2. \tag{2.2}$$

Definition 2.1. *Let V be the Banach space*

$$V \;=\; \Big\{(E, H, M) \in H(\text{curl}) \times H(\text{curl}) \times L^{2,\infty};\ H_x \in L^\infty(\mathbb{R})\Big\}$$

equipped with the norm

$$\|(E,H,M)\|_V = \|E\|_{\text{curl}} + \|H\|_{\text{curl}} + \|M\|_{L^{2,\infty}} + \|H_x\|_{L^\infty(\mathbb{R})}. \tag{2.3}$$

Remark 2.2. The x component H_x of the magnetic field plays a particular role because of the particular form of the curl operator in the 1D case.

Definition 2.3. *A function* $Y(t) = (E(x,t), H(x,t), M(x,t)) \in C^0(0,\infty;V)$ *is a global strong solution to the system* (1.9) *if*

$$(E,H) \in C^1(0,\infty;L^2) \cap C^0(0,\infty;H^1) \text{ and } M \in C^1(0,\infty;L^{2,\infty}) \cap C^2(0,\infty;L^2) \tag{2.4}$$

and all equations in (1.9) *hold in the sense of distributions.*

One then shows the following theorem.

Theorem 2.4. *Let the following assumptions hold:*

$$\begin{cases} \bullet\ \alpha(x), K(x) \in L^\infty(\mathbb{R}),\ p(x) \in L^\infty; \\ \bullet\ H_s(x) \in L^{2,\infty}, \\ \bullet\ (E^0(x), H^0(x), M^0(x)) \in V. \end{cases} \tag{2.5}$$

Then the Cauchy problem (1.9) *admits a unique global strong solution* (E,H,M)*, which, moreover, satisfies*

$$|M(x,t)| = |M_0(x)| \quad a.e.\ x \in \mathbb{R}\ \forall t \geq 0, \tag{2.6}$$

$$\frac{d}{dt}\mathcal{E}(E,H,M) + \int_{\mathbb{R}} \frac{\alpha}{|M|} \left|\dot{M}\right|^2 dx = 0, \tag{2.7}$$

where $\mathcal{E}(E,H,M)$ *denotes the electromagnetic energy defined by*

$$\mathcal{E}(E,H,M) = \frac{1}{2}\int_{\mathbb{R}} \left[|E|^2 + |H|^2 + K|P(M)|^2 + |H_s - M|^2\right] dx\,. \tag{2.8}$$

Remark 2.5. For any strong solution, the electromagnetic energy is a function of class C^1 with respect to time.

One has to make precise the sense of the integral of $\frac{\alpha}{|M|}|\dot{M}|^2$. In fact, from the LLG equation, we have

$$\dot{M}(t) - \alpha\frac{M}{|M|} \times \dot{M}(t) = \gamma H_T(M(t)) \times M(t);$$

hence we deduce, via Pythagoras's theorem, that

$$(1+\alpha^2)\,|\dot{M}(t)|^2 = \gamma^2\,|H_T(M) \times M|^2\,. \tag{2.9}$$

This observation leads to the following definition.

Definition 2.6. *For the strong solution* (E,H,M) *to system* (1.9)*, we set*

$$\frac{\alpha}{|M|}\left|\dot{M}\right|^2 = \gamma^2 \frac{\alpha}{1+\alpha^2}\frac{|H_T \times M|^2}{|M|}, \tag{2.10}$$

which is finite since the function $M \mapsto \frac{|H_T \times M|^2}{|M|}$ *can be continuously extended by* 0 *for* $M = 0$. *We have the estimate*

$$\int_{\mathbb{R}} \frac{\alpha}{|M|}\left|\dot{M}\right|^2 dx \leq \gamma^2 \int_{\mathbb{R}} \frac{\alpha}{1+\alpha^2}|M||H_T|^2\,dx \tag{2.11}$$

which makes sense since one easily checks that $M \in (L^\infty)^3$ *and* $H_T \in (L^2)^3$ *for any time.*

Proof. See [7] for a complete proof. We just explain below how to obtain the two estimates of Theorem 2.4. Concerning (2.6), the product of the LLG equation with M shows that $M \cdot \dot{M} = 0$; we deduce that

$$|M(x,t)| \;=\; |M_0(x)|, \quad \text{a.e. } x \in \mathbb{R} \;\, \forall t \geq 0.$$

For (2.7), from Maxwell's equations we get

$$\left\{ \begin{array}{lcl} \dot{E} \cdot E - \mathrm{curl} H \cdot E &=& 0, \\ \dot{H} \cdot H + \mathrm{curl} E \cdot H &=& -\dot{M} \cdot H. \end{array} \right. \tag{2.12}$$

Summing these two equalities and integrating over $\mathbb{R}$ leads, after integration by parts, to the following identity:

$$\frac{d}{dt} \left\{ \frac{1}{2} \int_{\mathbb{R}} \left(|E|^2 + |H|^2 \right) \, dx \right\} \;=\; - \int_{\mathbb{R}} \dot{M} \cdot H \, dx. \tag{2.13}$$

We now use the LLG equation:

$$\dot{M} \;=\; \gamma H_T \times M + \frac{\alpha}{|M|} M \times \dot{M}. \tag{2.14}$$

Taking the scalar product with H_T, and using the notation $(\cdot,\cdot,\cdot)$ for the mixed product in $\mathbb{R}^3$, we get

$$\dot{M} \cdot H_T = \frac{\alpha}{|M|} \left(M, \dot{M}, H_T \right).$$

Taking the scalar product of the LLG equation by $\dot{M}$ gives

$$\left| \dot{M} \right|^2 = \gamma \left(\dot{M}, H_T, M \right).$$

Therefore, eliminating the mixed product gives

$$\dot{M} \cdot H_T = \frac{\alpha}{\gamma |M|} \left| \dot{M} \right|^2. \tag{2.15}$$

(The meaning of the right-hand side of this expression has to be understood in the sense we made precise in Definition 2.6.) Now, by definition of H_T, we have

$$\dot{M} \cdot H_T = \dot{M} \cdot H - K P\left(M\right) \cdot P\left(\dot{M}\right) + H_s \cdot \dot{M}.$$

Using the fact that $|M(x,t)| = |M_0(x)|$, we note that

$$\left\{ \begin{array}{l} H_s \cdot \dot{M} = -\dfrac{1}{2} \dfrac{\partial}{\partial t} |H_s - M|^2, \\ -K P\left(M\right) \cdot P\left(\dot{M}\right) = -\dfrac{1}{2} \dfrac{\partial}{\partial t} \left[K |P(M)|^2 \right]. \end{array} \right. \tag{2.16}$$

Therefore, we have

$$\dot{M} \cdot H_T = \dot{M} \cdot H - \frac{1}{2} \frac{\partial}{\partial t} \left[|H_s - M|^2 + K |P(M)|^2 \right]; \tag{2.17}$$

that is to say, using (2.15),

$$-\dot{M}\cdot H = -\frac{\alpha}{\gamma|M|}\left|\dot{M}\right|^2 - \frac{1}{2}\frac{\partial}{\partial t}\left[|H_s - M|^2 + K|P(M)|^2\right]. \tag{2.18}$$

Plugging (2.18) into (2.13) leads to the energy identity

$$\frac{d}{dt}\left\{\frac{1}{2}\int_{\mathbb{R}}\left(|E|^2 + |H|^2 + |H_s - M|^2 + K|P(M)|^2\right)dx\right\} \tag{2.19}$$
$$+\frac{1}{\gamma}\int_{\mathbb{R}}\frac{\alpha}{|M|}\left|\dot{M}\right|^2 dx = 0. \qquad \square$$

Thanks to a priori estimates (2.6) and (2.7), one is also able to obtain a theorem for weak solutions (i.e., less regular solutions) under weaker assumptions on the initial data; see the following definition.

DEFINITION 2.7. *A function* $Y(t) = (E(x,t), H(x,t), M(x,t)) \in C^0(0,\infty;V)$ *is a global weak solution to the system* (1.9) *if and only if*

(i) $M \in C^1(0,\infty;L^{2,\infty})$;

(ii) *for any* $(\varphi,\psi) \in V \times V$ *where* V *is the space of test fields*

$$V = \left\{\varphi \in C^1(H(\mathrm{curl}))\ /\ \mathrm{supp}\ (\varphi)\ \textit{is compact}\right\},$$

$$\left\{\begin{array}{rcl} \displaystyle\iint(\dot{\varphi}\cdot E + \mathrm{curl}\ \varphi\cdot H)\ dxdt & = & \displaystyle -\int E_0\cdot\varphi(\cdot,0)dx, \\ \displaystyle\iint(\dot{\psi}\cdot H - \mathrm{curl}\ \psi\cdot E)\ dxdt & = & \displaystyle -\int H_0\cdot\psi(\cdot,0)dx\ -\ \iint\dot{M}\cdot\psi\ dxdt; \end{array}\right.$$

(iii) *for almost every* $(x,t) \in \mathbb{R}\times\mathbb{R}^+$,

$$\left\{\begin{array}{l} \dot{M}(x,t) = H_T(x,t)\times M(x,t) + \dfrac{\alpha}{|M(x,t)|}M(x,t)\times\dot{M}(x,t), \\ M(x,0) = M_0(x). \end{array}\right.$$

THEOREM 2.8. *Assume that*

$$(E_0, H_0, M_0)\ \in\ (L^2)^3\times(L^2)^3\times(L^{2,\infty})^3;$$

then system (1.9) *admits a unique global weak solution which satisfies*

$$\int_0^\infty\int_{\mathbb{R}}\frac{\alpha}{|M|}|\dot{M}|^2\,dx\,dt\ <\ +\infty. \tag{2.20}$$

Moreover, a.e. $x \in \mathbb{R}$, $t \mapsto M(x,t)$ *belongs to* $C^0(\mathbb{R})$.

Remark 2.9. From (2.20) and Fubini's theorem, we deduce that

$$\text{a.e. } x \in \mathbb{R}, \quad \frac{|\dot{M}(x,t)|^2}{|M_0(x)|} \in L^1(\mathbb{R}).$$

Therefore, function $t \mapsto M(x,t)$ is in $H^1(\mathbb{R}_+) \subset C^0(\mathbb{R}_+)$.

2.2. Main results of the paper. Our first main theorem concerns the convergence to 0 in Fréchet topology of the transverse components of the electromagnetic fields. In the following, we denote the transverse components $E_{\|}(x,t) = (E_y(x,t), E_z(x,t))$, $H_{\|}(x,t) = (H_y(x,t), H_z(x,t))$, and so on.

THEOREM A. *Let all assumptions* (2.5) *hold. Assume, moreover, that*

$$M_0(x) \ = \ 0 \quad \textit{for } |x| > a \tag{2.21}$$

and

$$\exists\, \alpha_* > 0 \textit{ such that } \ \alpha(x) \geq \alpha^*, \ \textit{a.e.} \quad x \in [-a;a]. \tag{2.22}$$

Then, for the global solution to the Cauchy problem (1.9):

(i) *For almost every* $x \in \mathbb{R}$

$$\int_0^\infty (|E_{\|}(x,t)|^2 + |H_{\|}(x,t)|^2)dt < \infty. \tag{2.23}$$

(ii) *For every* $R > 0$

$$\int_{|x|<R} (|E_{\|}(x,t)|^2 + |H_{\|}(x,t)|^2)dx \to 0 \textit{ as } t \to \infty. \tag{2.24}$$

Our second result is a variant of Theorem A. We prove that, provided additional regularity assumptions on the initial data, we have convergence to zero of the transverse electromagnetic field, not only in the local energy norm, but also uniformly in any compact set.

THEOREM A′. *Let the assumptions of Theorem* A *hold (in particular* $(E_0, H_0) \in (H(\text{curl}))^2$. *Then*

$$\lim_{t\to+\infty} \int_{-a}^{a} |\dot{M}(x,t)|^2 dx = 0, \tag{2.25}$$

and, for every $R > 0$,

$$\lim_{t\to+\infty} \int_{-R}^{R} \left(\left| \frac{\partial E_{\|}}{\partial x}(x,t) \right|^2 + \left| \frac{\partial H_{\|}}{\partial x}(x,t) \right|^2 \right) dx = 0, \tag{2.26}$$

$$\lim_{t\to+\infty} \sup_{|x|\leq R} \Big\{ |E_{\|}(x,t)| + |H_{\|}(x,t)| \Big\} = 0. \tag{2.27}$$

Our other results concern the asymptotic behavior of the magnetization $M(x,t)$ (and thus of the longitudinal magnetic field). We first need to introduce a nondegeneracy assumption. Let us define

$$\tilde{H}_T(x,M) \ = \ H_s + K(p \cdot M)p - (e_x \cdot M)e_x, \tag{2.28}$$

where the dependence of $\tilde{H}_T(x,M)$ with respect to x appears in the dependence of H_s, K, and p. We introduce the assumption, for any x in $\mathbb{R}$,

$$(\mathcal{H}_x) \ : \ (\forall M \in \mathbb{R}^3, \ \exists\, \lambda(x,M) \in \mathbb{R}, \ \tilde{H}_T(M) = \lambda(x,M)e_x\,) \ \Rightarrow \ (\forall M \in \mathbb{R}^3, \ \lambda(x,M) \neq 0\,).$$

Remark 2.10. Assumption $(\mathcal{H}_x)$ is not satisfied if and only if the following two properties are satisfied:

(i) H_s and p are collinear to e_x ;
(ii) there exists $M \in \mathbb{R}^3$ such that $(H_s + (K-1)M) \cdot e_x \ = \ 0$.
For any x, we introduce the set

$$\mathcal{Z}(x, M_0) \ = \ \Big\{ M \in \mathbb{R}^3 \text{ such that } \tilde{H}_T(x, M) \times M = 0 \text{ and } |M| = |M_0(x)| \Big\}.$$

This set will be identified in section 5 as the set of stationary states of some unperturbed LLG equation at point x that are possible limits for $M(x,t)$ with the initial data $M_0(x)$. It will be proved to be a finite set containing between two and six elements (see Theorem 5.2).

Our first result for M concerns weak solutions.

Theorem B. *Let the assumptions of Theorem* A *be satisfied. Assume that* $(\mathcal{H}_x)$ *holds almost everywhere in* x. *Then*

$$M(x,t) \to \mathcal{Z}(x, M_0) \ \textit{as}\ t \to \infty \ \textit{for a.e.}\ x \in \mathbb{R}. \tag{2.29}$$

Remark 2.11. With the set $\mathcal{Z}(x, M_0)$ being discrete, (2.29) means that for a.e. x, there exists $M_\infty \in \mathcal{Z}(x, M_0)$ such that

$$M(x,t) \to M_\infty \text{ as } t \to \infty.$$

In other words,

$$\mathcal{M} \ = \ \{\, M \in L^\infty([-a,a]) \,/\, \text{for a.e. } x \in [-a,a],\ M(x) \ = \ M_\infty \in \mathcal{Z}(x, M_0) \,\}$$

is an infinite-dimensional attractor for $M(x,t)$.

Our last result is a variant of Theorem B for strong solutions.

Corollary 2.12. *Let the assumptions of Theorem* A′ *be satisfied. Assume that* $(\mathcal{H}_x)$ *holds everywhere. For every* x, *there exists* $M_\infty(x) \in \mathcal{Z}(x, M_0)$ *such that*

$$\lim_{t\to\infty} |M(x,t) - M_\infty(x)| \ = \ 0. \tag{2.30}$$

Remark 2.13. We show with Theorem A′ that the transverse magnetic field $H_\parallel$ converges in time to 0 uniformly in space. It must be emphasized that this property is not strong enough to ensure that the convergence of the magnetization M is also uniform in space. Section 7 will be devoted to a counterexample and some comments about this assertion.

3. Proof of Theorem A: L^2 bounds of the transverse electromagnetic field for weak solutions. The first two equations of (1.9) read

$$\begin{cases} \dot{E}_x = 0, & \dot{E}_y + \dfrac{\partial H_z}{\partial x} = 0, & \dot{E}_z - \dfrac{\partial H_y}{\partial x} = 0, \\[2ex] \dot{H}_x + \dot{M}_x = 0, & \dot{H}_y - \dfrac{\partial E_z}{\partial x} + \dot{M}_y = 0, & \dot{H}_z + \dfrac{\partial E_y}{\partial x} + \dot{M}_z = 0. \end{cases} \tag{3.1}$$

We easily deduce that

$$\begin{cases} L_+(E_y + H_z) & = - & \dot{M}_z, \\ L_-(E_y - H_z) & = & \dot{M}_z, \\ L_+(E_z - H_y) & = & \dot{M}_y, \\ L_-(E_z + H_y) & = - & \dot{M}_y, \end{cases} \tag{3.2}$$

where we have introduced the two transport operators $L_\pm = \frac{\partial}{\partial t} \pm \frac{\partial}{\partial x}$. Considering $\dot{M}$ as known, we can solve explicitly (3.1) using the method of characteristics. After some algebraic manipulations, we end up with the following formulas:

$$(3.3)\quad \left\{ \begin{aligned} E_\|(x,t) &= \tfrac{1}{2}\{E_\|^0(x+t) + E_\|^0(x-t)\} + \tfrac{J}{2}\{H_\|^0(x+t) - H_\|^0(x-t)\} \\ &\quad - \tfrac{J}{2}\left\{\int_{\Gamma_+(x,t)} \dot{M}_\|(y,s)d\sigma - \int_{\Gamma_-(x,t)} \dot{M}_\|(y,s)d\sigma\right\}, \\ H_\|(x,t) &= \tfrac{1}{2}\{H_\|^0(x+t) + H_\|^0(x-t)\} - \tfrac{J}{2}\{E_\|^0(x+t) - E_\|^0(x-t)\} \\ &\quad - \left\{\int_{\Gamma_+(x,t)} \dot{M}_\|(y,s)d\sigma + \int_{\Gamma_-(x,t)} \dot{M}_\|(y,s)d\sigma\right\}, \end{aligned} \right.$$

where

$$J = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix},$$

$\Gamma_\pm(x,t)$ is the curve $\Gamma_\pm(x,t) = (x,t) - D_\pm$, with $D_\pm = \{(x,t)/x \pm t = 0\}$ (see Figure 3.1), and σ is the curvilinear abscissa along $\Gamma_\pm(x,t)$. Therefore, introducing

$$F(x,t) = \begin{pmatrix} E_\|(x,t) \\ H_\|(x,t) \end{pmatrix},$$

we get (note that $d\sigma = \sqrt{2}dy$, $\|J\| = 1$, and $|\dot{M}_\|| \le |\dot{M}|$)

$$(3.4)\qquad |F(x,t)| \le \frac{\sqrt{2}}{2}\int_{\Gamma^a(x,t)} |\dot{M}(y,s)|dy + \frac{1}{2}\{|F^0(x+t)| + |F^0(x-t)|\}$$

with $\Gamma^a(x,t) = \{(y,s) \in \Gamma_+(x,t) \cup \Gamma_-(x,t) :\ |y| < a\}$ (see Figure 3.1).

Then, the Cauchy–Schwarz inequality yields the estimate ($\int_{\Gamma^a(x,t)} dy = 2a$)

$$(3.5)\quad |F(x,t)| \le \sqrt{a}\left(\int_{\Gamma^a(x,t)} |\dot{M}(y,s)|^2 dy\right)^{\frac{1}{2}} + \frac{1}{2}\{|F^0(x+t)| + |F^0(x-t)|\}.$$

Integrating this inequality between 0 and T, and noticing that

$$K(x,T) \equiv \bigcup_{t=0}^{T} \Gamma^a(x,t)$$

is such that $K(x,T) \subset [-a,a] \times [0,T]$, we get the estimate

$$\int_0^T |F(x,t)|^2 dt \ \le\ 2a\int_0^T \left(\int_{|y|<a} |\dot{M}(y,s)|^2 dy\right) ds \ +\ \frac{1}{2}\sum_\pm \int_0^T |F^0(x \pm t)|^2 dt,$$

which yields, after integrating over $[-a,a]$,

$$\left|\ \begin{aligned} \int_0^T \int_{-a}^{a} |F(x,t)|^2 dxdt \quad &\le \quad 4a^2 \int_0^T \left(\int_{|y|<a} |\dot{M}(y,s)|^2 dy\right) ds \\ &\quad + \quad \frac{1}{2}\sum_\pm \int_0^T \int_{-a}^{a} |F^0(x \pm t)|^2 dt. \end{aligned}\right.$$

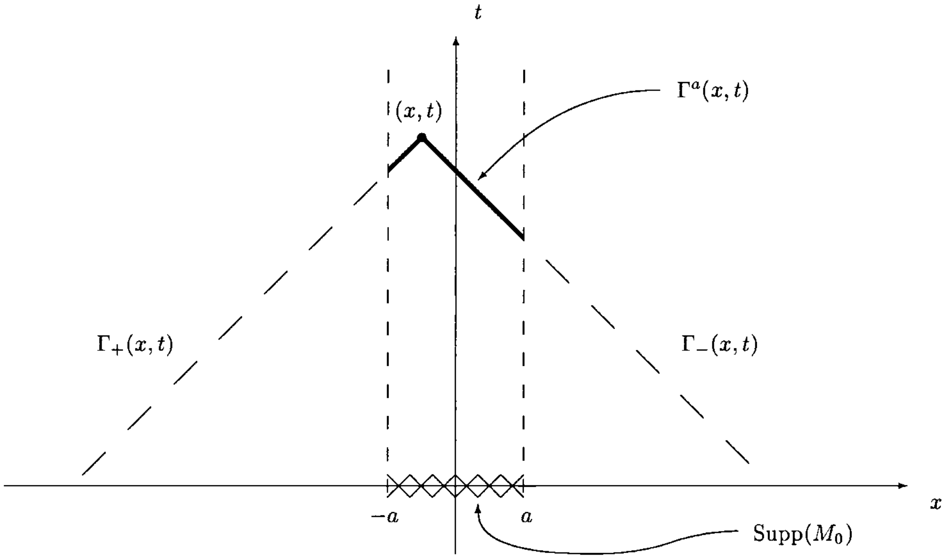

FIG. 3.1. *Characteristic lines and the 1D layer.*

Writing $|\dot M|^2 = \frac{|M|}{\alpha}\cdot\frac{\alpha|\dot M|^2}{|M|}$ and using the conservation of the norm of M and the assumption (2.22) about the damping function $\alpha(x)$, we get

$$\left|\begin{aligned}\int_0^T\int_{-a}^a |F(x,t)|^2 dxdt \;&\le\; \frac{4a^2}{\alpha_*}\|M_0\|_\infty\int_0^T\left(\int_{|y|<a}\frac{\alpha}{|M|}|\dot M(y,s)|^2dy\right)ds\\ &+\;\frac12\sum_{\pm}\int_0^T\int_{-a}^a|F^0(x\pm t)|^2dt.\end{aligned}\right. \tag{3.6}$$

Therefore, (2.5) and (2.20) imply (2.23). Besides, (3.4) can be rewritten as

$$\left|\begin{aligned}|F(x,t)| \;\le\; \frac{\sqrt2}{2}\int_{\Gamma_a^+(x,t)}|\dot M(y,s)|\,ds \;&+\; \frac{\sqrt2}{2}\int_{\Gamma_a^-(x,t)}|\dot M(y,s)|\,ds\\ &+\;\frac12\left\{|F^0(x+t)|\,+\,|F^0(x-t)|\right\},\end{aligned}\right.$$

where $\Gamma_a^+ = \Gamma_+\cap\Gamma^a$ and $\Gamma_a^- = \Gamma_-\cap\Gamma^a$. This yields, via the Cauchy–Schwarz inequality,

$$\left|\begin{aligned}|F(x,t)| \;\le\; \frac{\sqrt{2a}}{2}\left(\int_{\Gamma_a^+(x,t)}|\dot M(y,s)|^2ds\right)^{\frac12} \;&+\; \frac{\sqrt{2a}}{2}\left(\int_{\Gamma_a^-(x,t)}|\dot M(y,s)|^2ds\right)^{\frac12}\\ &+\;\frac12\left(|F^0(x+t)|+|F^0(x-t)|\right).\end{aligned}\right.$$

Therefore

$$\left|\begin{aligned}|F(x,t)|^2 \;\le\; 2a\left(\int_{\Gamma_a^+(x,t)}|\dot M(y,s)|^2ds \;+\; \int_{\Gamma_a^-(x,t)}|\dot M(y,s)|^2ds\right)&\\ +\;|F^0(x+t)|^2+|F^0(x-t)|^2.&\end{aligned}\right. \tag{3.7}$$

After having remarked that, for $t > R + a$,

$$\bigcup_{x=-R}^{R} \Gamma_a^{\pm}(x,t) \subset [-a,a] \times [t-(R+a), t],$$

we obtain

$$(3.8) \quad \left| \begin{array}{rcl} \displaystyle\int_{-R}^{R} |F(x,t)|^2 dx & \leq & \displaystyle 4a \int_{t-(R+a)}^{t} \int_{-a}^{a} |\dot{M}(y,s)|^2 dyds \\ & & \displaystyle + \int_{-R}^{R} \left(|F^0(x+t)|^2 + |F^0(x-t)|^2 \right) dx \end{array} \right.$$

which leads to

$$(3.9) \quad \left| \begin{array}{rcl} \displaystyle\int_{-R}^{R} |F(x,t)|^2 dx & \leq & \displaystyle \frac{4a\|M_0\|_\infty}{\alpha_*} \int_{t-(R+a)}^{t} \int_{-a}^{a} \frac{\alpha}{|M|} |\dot{M}(y,s)|^2 dyds \\ & & \displaystyle + \int_{-R-t}^{R-t} |F^0(x)|^2 dx + \int_{-R+t}^{R+t} |F^0(x)|^2 dx. \end{array} \right.$$

By (2.5) and (2.7),

$$\int_{-\infty}^{+\infty} |F^0(x)|^2 dx < +\infty \quad \text{and} \quad \int_0^{\infty} \int_{-a}^{a} \frac{\alpha}{|M|} |\dot{M}|^2 dyds < +\infty.$$

Therefore, (3.9) implies (2.24). This concludes the proof. □

4. Proof of Theorem A′: Uniform bounds of the transverse electromagnetic field for strong solutions.

The proof of Theorem A′ relies on a technical lemma.

LEMMA 4.1. *The solution of the system satisfies*

$$(4.1) \qquad \int_0^{\infty} \int_{-a}^{a} \frac{\alpha}{|M_0(x)|} |\ddot{M}(x,t)|^2 dxdt < \infty.$$

Proof. We give a proof which supposes that the electromagnetic field (E, H) is slightly more regular in time than local strong solutions. However, all the forthcoming assumptions can be justified using the method of differential quotients (see [7] for details).

Nevertheless, our proof remains rather long and will be divided into four steps.

Step 1: *Estimates using the characteristics.* In what follows, we keep the notation of the proof of Theorem A. In particular, we set

$$(4.2) \qquad F(x,t) = \begin{bmatrix} E_{\|}(x,t) \\ H_{\|}(x,t) \end{bmatrix} \in \mathbb{R}^4.$$

First, we note that if we differentiate the system with respect to time, thanks to the linearity of Maxwell's equations, the relationship between $\ddot{M}$ and $\dot{E}$, $\dot{H}$ is exactly the same as the one between $\dot{M}$ and E, H. Therefore, reproducing the computations in the proof of Theorem A leads to the estimate

$$(4.3) \quad |\dot{F}(x,t)| \leq \sqrt{a} \left(\int_{\Gamma^a(x,t)} |\ddot{M}(y,s)| dy \right)^{\frac{1}{2}} + \frac{1}{2} \Big\{ |\dot{F}^0(x+t)| + |\dot{F}^0(x-t)| \Big\}.$$

Then, proceeding as in the proof of Theorem A, we easily get

$$\left|\begin{aligned} \int_0^T \int_{-a}^a |\dot F(x,t)|^2 dxdt \quad &\le \quad \frac{4a^2}{\alpha_*}\|M_0\|_\infty \int_0^T \left(\int_{|y|<a} \frac{\alpha}{|M|}|\ddot M(y,s)|^2 dy\right) ds \\ &+ \quad \frac{1}{2}\sum_{\pm}\int_0^T \int_{-a}^a |\dot F^0(x\pm t)|^2 dt. \end{aligned}\right. \tag{4.4}$$

Step 2: *Energy-like estimates.* We start from the linear Maxwell's equations after time derivation:

$$\left\{\begin{aligned} &\ddot E - \operatorname{curl} \dot H = 0, \\ &\ddot H + \operatorname{curl} \dot E = -\ddot M. \end{aligned}\right. \tag{4.5}$$

We multiply the first equation of (4.5) by $\dot E$, the second by $\dot H$, and add the two resulting equations. After integration over x, we easily get, using Green's formula and the fact that M is supported in $[-a,a]\times\mathbb{R}^+$,

$$\frac{d}{dt}\left(\frac{1}{2}\int (|\dot E|^2 + |\dot H|^2)dx\right) + \int_{-a}^a \dot H \ddot M dx = 0. \tag{4.6}$$

Now, we differentiate in time the LLG equation which leads to

$$\ddot M = \dot H \times M + K(p\cdot\dot M)p\times M + H_T \times \dot M + \frac{\alpha}{|M|} M \times \ddot M, \tag{4.7}$$

using the fact that $|M|$ is constant in time. Multiplying (4.7) successively by $\dot H$ and $\ddot M$ gives

$$\left|\begin{aligned} \ddot M \cdot \dot H \quad &= \quad K(p\cdot\dot M)(p, M\dot M) + (H_T, \dot M, \dot H) + \frac{\alpha}{|M|}(M, \ddot M, \dot H), \\ |\ddot M|^2 \quad &= \quad (\dot H, M, \ddot M) + K(p\cdot \dot M)(p, M, \ddot M) + (H_T, \dot M, \ddot M). \end{aligned}\right. \tag{4.8}$$

By an adequate linear combination of these two equalities, we eliminate the mixed product $(\dot H, M, \ddot M)$. This leads to

$$\ddot M \cdot \dot H = \frac{\alpha}{|M|}|\ddot M|^2 + (H_T, \dot M, \dot H) - \frac{\alpha}{|M|}(H_T, \dot M, \ddot M) \tag{4.9}$$

that we plug into (4.6) to obtain

$$\frac{d}{dt}\left[\frac{1}{2}\int (|\dot H|^2 + |\dot E|^2)dx\right] + \int_{-a}^a \frac{\alpha}{|M|}|\ddot M|^2 dx \ = \ \int_{-a}^a \left\{\frac{\alpha}{|M|}(H_T, \dot M, \ddot M) - (H_T, \dot M, \dot H)\right\} dx. \tag{4.10}$$

Let us use the bounds

$$\left|\begin{aligned} &|(H_T, \dot M, \ddot M)| \le \frac{1}{2}|\ddot M|^2 + \frac{1}{2}|H_T|^2|\dot M|^2, \\ &|(H_T, \dot M, \dot H)| \le \varepsilon |\dot H|^2 + \frac{1}{4\varepsilon}|H_T|^2|\dot M|^2, \end{aligned}\right.$$

where ε is an arbitrary strictly positive real number. We then obtain

$$\left| \begin{aligned} &\frac{d}{dt}\left(\frac{1}{2}\int(|\dot{H}|^2+|\dot{E}|^2)dx\right)+\frac{1}{2}\int_{-a}^{a}\frac{\alpha}{|M|}|\ddot{M}|^2dx \\ &\qquad\qquad \le \varepsilon\int_{-a}^{a}|\dot{H}|^2dx+\int_{-a}^{a}\left(\frac{\alpha}{2|M|}+\frac{1}{4\varepsilon}\right)|H_T|^2|\dot{M}|^2dx, \end{aligned}\right.$$

which we can integrate between 0 and T, to obtain

$$\tag{4.11} \left| \begin{aligned} &\frac{1}{2}\int(|\dot{H}(x,T)|^2+|\dot{E}(x,T)|^2)dx+\frac{1}{2}\int_{-a}^{a}\int_0^T\frac{\alpha}{|M|}|\ddot{M}|^2dxdt \\ &\quad \le \frac{1}{2}\int(|\dot{H}(x,0)|^2+|\dot{E}(x,0)|^2)dx+\varepsilon\int_{-a}^{a}\int_0^T|\dot{H}|^2dxdt \\ &\qquad +\int_{-a}^{a}\int_0^T\left(\frac{\alpha}{2|M|}+\frac{1}{4\varepsilon}\right)|H_T|^2|\dot{M}|^2dxdt. \end{aligned}\right.$$

Step 3: *Combination of the two estimates.* We use (1.12) in Remark 1.1 to write

$$\int_{-a}^{a}\int_0^T|\dot{H}|^2dxdt \ \le\ \int_{-a}^{a}\int_0^T|\dot{F}|^2dxdt\ +\ \int_{-a}^{a}\int_0^T|\dot{M}_x|^2dxdt.$$

We thus obtain, using (4.4) in (4.11),

$$\left| \begin{aligned} &\frac{1}{2}\int(|\dot{H}(x,T)|^2+|\dot{E}(x,T)|^2)dx+\frac{1}{2}\int_{-a}^{a}\int_0^T\left(1-\frac{8\varepsilon a^2}{\alpha_*}\|M_0\|_\infty\right)\frac{\alpha}{|M|}|\ddot{M}|^2dxdt \\ &\quad \le \frac{1}{2}\int(|\dot{H}(x,0)|^2+|\dot{E}(x,0)|^2)dx+\frac{\varepsilon}{2}\sum_{\pm}\int_{-a}^{a}\int_0^T|\dot{F}^0(x\pm t)|^2dxdt \\ &\qquad +\int_{-a}^{a}\int_0^T\left(\frac{\alpha}{2|M|}+\frac{1}{4\varepsilon}\right)|H_T|^2|\dot{M}|^2dxdt+\varepsilon\int_{-a}^{a}\int_0^T|\dot{M}_x|^2dxdt. \end{aligned}\right.$$

We observe that

$$\int_{-a}^{a}\int_0^T|\dot{F}^0(x\pm t)|^2dxdt\le 2a\int(|\dot{H}(x,0)|^2+|\dot{E}(x,0)|^2)dx$$

and we choose ε such that

$$\tag{4.12} 1-\frac{8\varepsilon a^2}{\alpha_*}\|M_0\|_\infty=\frac{1}{2}.$$

Finally, if we set

$$\tag{4.13} C_0=\frac{1}{2}+2a\varepsilon,\quad C_2=\frac{1}{2}+\frac{\|M_0\|_\infty}{4\varepsilon\alpha_*},\quad C_1=\varepsilon\frac{\|M_0\|_\infty}{\alpha_*},$$

we obtain

$$\tag{4.14} \left| \begin{aligned} &\frac{1}{2}\int(|\dot{H}(x,T)|^2+|\dot{E}(x,T)|^2)dx+\frac{1}{4}\int_{-a}^{a}\int_0^T\frac{\alpha}{|M|}|\ddot{M}|^2dxdt \\ &\le C_0\int(|\dot{H}(x,0)|^2+|\dot{E}(x,0)|^2)dx+C_1\int_{-a}^{a}\int_0^T\frac{\alpha}{|M|}|\dot{M}|^2dxdt \\ &\qquad +C_2\int_{-a}^{a}\int_0^T\frac{\alpha}{|M|}|H_T|^2|\dot{M}|^2dxdt. \end{aligned}\right.$$

From (2.20), we already know that

$$\int_{-a}^{a}\int_{0}^{T}\frac{\alpha}{|M|}|\dot{M}|^2 dxdt < +\infty$$

while, because of the regularity assumptions on the initial data, one can see that

$$\int |\dot{E}(x,0)|^2 dx \;=\; \int |\text{curl } H_0|^2 dx < +\infty. \tag{4.15}$$

Conversely,

$$\int |\dot{H}(x,0)|^2 dx \;\le\; 2\int |\text{curl } E_0|^2 dx \;+\; 2\int |\dot{M}(x,0)|^2 dx, \tag{4.16}$$

and from the LLG equation one deduces that

$$|\dot{M}(x,0)|^2 = \frac{1}{1+\alpha^2}|H_T(x,0)|^2|M(x,0)|^2.$$

Therefore, setting $H_T^0(x) = H_T(x,0)$, we have

$$\int |\dot{M}(x,0)|^2 dx \le \|M_0\|_{L^\infty}^2 \|H_T^0\|_{L^2}^2 \tag{4.17}$$

which is finite since, under the conditions on the data of the problem

$$H_T^0 = H_0 - KP(M_0) + H_s \;\in\; L^2, \tag{4.18}$$

we can conclude that

$$\int |\dot{H}(x,0)|^2 dx \le 2\|\text{curl } E_0\|_{L^2}^2 + 2\|M_0\|_{L^\infty}^2\|H_T^0\|_{L^2}^2. \tag{4.19}$$

Finally, if C denotes a constant which depends only on M_0, E_0, H_0, α_*, K, H_s, and a, we can write

$$\left|\begin{aligned} &\frac{1}{2}\int(|\dot{H}(x,T)|^2 + |\dot{E}(x,T)|^2)dx + \frac{1}{4}\int_0^T\int_{-a}^{a}\frac{\alpha}{|M|}|\ddot{M}|^2 dxdt \\ &\qquad\qquad \le C + C_2\int_0^T\int_{-a}^{a}\frac{\alpha}{|M|}|\dot{M}|^2|H_T|^2 dxdt. \end{aligned}\right. \tag{4.20}$$

Step 4: *A Gronwall-type estimate.* From the definition of H_T, we easily get the following bound for $|H_T|^2$:

$$|H_T|^2 \le 3(1+\|K\|_\infty^2)\left[|H_s|^2 + |M|^2 + |H|^2\right]$$

that implies, since $H_x = -M_x$,

$$|H_T|^2 \le 3(1+\|K\|_\infty^2)(|H_s|^2 + 2|M|^2) + 3(1+\|K\|_\infty^2)|H_\parallel|^2. \tag{4.21}$$

Using the interpolation inequality

$$\|H_\parallel\|_{L^\infty}^2 \;\le\; \|H_\parallel\|_{L^2}\left\|\frac{\partial H_\parallel}{\partial x}\right\|_{L^2},$$

we can write

$$\|H_T\|^2_{L^\infty} \;\le\; 3(1+\|K\|^2_\infty)(\|H_s\|^2_{L^\infty}+2\|M_0\|^2_{L^\infty}) + 3(1+\|K\|^2_\infty)\|H_\|\|_{L^2}\left\|\frac{\partial H_\|}{\partial x}\right\|_{L^2}. \tag{4.22}$$

As we already know from Theorem 2.4 that $\|H_\|\|_{L^2}$ remains bounded, from (4.20) and (4.22), we can write

$$\left|\begin{array}{l} \displaystyle\frac{1}{2}\int(|\dot H(x,T)|^2+|\dot E(x,T)|^2)dx + \frac{1}{4}\int_0^T\int_{-a}^a \frac{\alpha}{|M|}|\ddot M|^2 dxdt \\ \displaystyle\qquad\qquad\qquad \le C\left(1+\int_0^T\left(\int_{-a}^a \frac{\alpha}{|M|}|\dot M|^2dx\right)\left\|\frac{\partial H_\|}{\partial x}\right\|_{L^2}dt\right), \end{array}\right. \tag{4.23}$$

where C denotes a new positive constant depending only on the data of the problem. Finally, using Maxwell's equations, we observe that

$$\left\|\frac{\partial H_\|}{\partial x}\right\|_{L^2} = \left\|\dot E_\|\right\|_{L^2}. \tag{4.24}$$

Therefore, if we set

$$\left\{\begin{array}{rcl} G(t) &=& \displaystyle\int(|\dot H(x,t)|^2+|\dot E(x,t)|^2)dx, \\ m(t) &=& \displaystyle\int_{-a}^a \frac{\alpha}{|M|}|\dot M|^2dx, \end{array}\right. \tag{4.25}$$

we deduce from (4.23), using that $\int_0^\infty\int_{-a}^a \frac{\alpha}{|M|}|\dot M|^2dxdt < +\infty$, the inequality ($C$ denoting another constant)

$$G(t) \;\le\; C\left(1+\int_0^t m(s)G(s)^{\frac{1}{2}}ds\right)$$

with $m \in L^1(0,+\infty)$. Therefore, using an appropriate generalization of Gronwall's lemma, we get

$$G(t) \le \left(C^{\frac{1}{2}} + C\int_0^t m(s)ds\right)^2. \tag{4.26}$$

As $m \in L^1(0,+\infty)$, this shows that $G(t)$ remains bounded in time. Moreover, from (4.23) we also deduce

$$\int_0^T\int_{-a}^a \frac{\alpha}{|M|}|\ddot M|^2dxdt \le C\left(1+\int_0^T G(s)^{\frac{1}{2}}m(s)ds\right). \tag{4.27}$$

Setting $G^* = \sup_{t\ge 0} G(t)$, we thus obtain

$$\int_0^T\int_{-a}^a \frac{\alpha}{|M|}|\ddot M|^2dxdt \le C\left(1+(G^*)^{\frac{1}{2}}\|m\|_{L^1}\right) \tag{4.28}$$

which concludes the proof of the lemma. □

Proof of Theorem A$'$. First, note that the inequalities

$$\left|\begin{array}{l} \displaystyle\int_{-a}^{a} |\dot M(x,t)|^2 dx \leq \frac{\|M_0\|_{L^\infty}}{\alpha_*} \int_{-a}^{a} \frac{\alpha}{|M|} |\dot M|^2 dx, \\ \displaystyle\int_{-a}^{a} |\ddot M(x,t)|^2 dx \leq \frac{\|M_0\|_{L^\infty}}{\alpha_*} \int_{-a}^{a} \frac{\alpha}{|M|} |\ddot M|^2 dx, \end{array}\right.$$

joined to the results of Theorem A and Lemma 4.1, imply

$$\int_0^\infty \int_{-a}^{a} \left(|\dot M|^2 + |\ddot M|^2 \right) dxdt < +\infty;$$

that is to say,

$$\dot M \in H^1\left(\mathbb{R}^+, L^2(-a,a)\right), \tag{4.29}$$

which implies

$$\lim_{t\to+\infty} \int_{-a}^{a} |\dot M(x,t)|^2 dx = 0. \tag{4.30}$$

Now, let us return to the formula

$$|\dot F(x,t)| \leq \frac{\sqrt{2}}{2} \int_{\Gamma_a(x,t)} |\ddot M(y,s)| dy + \frac{1}{2} \left\{ |\dot F^0(x+t)| + |\dot F^0(x-t)| \right\}.$$

By the same manipulations as in the proof of Theorem A (cf. the method we used to obtain (3.9)), we get

$$\left|\begin{array}{l} \displaystyle\int_{-R}^{R} |\dot F(x,t)|^2 dx \leq \frac{4a\|M_0\|_\infty}{\alpha_*} \int_{t-(R+a)}^{t} \int_{-a}^{a} \frac{\alpha}{|M|} |\ddot M(y,s)|^2 dyds \\ \displaystyle\qquad\qquad + \int_{-R-t}^{R-t} |\dot F^0(x)| dx + \int_{-R+t}^{R+t} |\dot F^0(x)| dx. \end{array}\right. \tag{4.31}$$

Since $\int_{-\infty}^{+\infty} |\dot F^0(x)|^2 dx < +\infty$ and $\int_0^\infty \int_{-a}^{a} \frac{\alpha}{|M|} |\ddot M|^2 dyds < +\infty$ (cf. Lemma 2.1), (4.31) implies that

$$\lim_{R\to+\infty} \int_{-R}^{R} \left(\left|\dot E_\parallel\right|^2 + \left|\dot H_\parallel\right|^2 \right) dx = 0. \tag{4.32}$$

Now, using Maxwell's equations we have

$$\left|\begin{array}{l} \displaystyle\int_{-R}^{R} \left|\frac{\partial E_\parallel}{\partial x}\right|^2 dx = \int_{-R}^{R} \left|\dot H_\parallel\right|^2 dx, \\ \displaystyle\int_{-R}^{R} \left|\frac{\partial H_\parallel}{\partial x}\right|^2 dx \leq 2 \int_{-R}^{R} \left|\dot E_\parallel\right|^2 dx + 2 \int_{-a}^{a} |\dot M|^2 dx \end{array}\right. \tag{4.33}$$

which, taking into account (4.30) and (4.32), lead to (2.26). Thanks to Theorem A, (2.27) is then a consequence of (2.26), since $H^1(-R,R) \subset L^\infty(-R,R)$. This concludes the proof of the theorem. □

5. Transitions to stationary states in the LLG equation. This section must be seen as an introduction to the second part of the paper, which is devoted to long-time asymptotics of the magnetization M.

5.1. Stationary states in the LLG equation. We consider the solutions to the following nonlinear evolution equation that we shall call the unperturbed LLG equation at point x:

$$\left\{ \begin{array}{l} \dot{M}(x,t) = \tilde{H}_T(x, M(x,t)) \times M(x,t) + \dfrac{\alpha}{|M(x,t)|} M(x,t) \times \dot{M}(x,t), , \\ M(x, t=0) = M_0(x), \end{array} \right. \tag{5.1}$$

where $\tilde{H}_T(x, M(x,t))$ has been defined by (2.28).

Remark 5.1. One can easily check that the first equation of (5.1) can be rewritten as

$$\dot{M}(x,t) = L(x, M(x,t)), \tag{5.2}$$

where we have defined

$$L(x,M) \;=\; \frac{1}{1+\alpha^2} \left[\tilde{H}_T(x,M) \times M + \frac{\alpha}{|M|} M \times \Big(\tilde{H}_T(x,M) \times M \Big) \right]. \tag{5.3}$$

We now introduce the set $\mathcal{S}(x)$ of the stationary states for (5.1) as

$$\mathcal{S}(x) \;=\; \Big\{ M_0 \in \mathbb{R}^3 / \dot{M}(x,t) \;=\; 0 \quad \forall t > 0 \Big\}. \tag{5.4}$$

The main property of this set is that its intersection with any sphere $\Sigma(R)$ is a discrete set. (See Figure 5.1).

Theorem 5.2. *Let $R > 0$. Under assumption ($\mathcal{H}_x$) (see section* 2.2*), the intersection of $\mathcal{S}(x)$ with the sphere $\Sigma(R)$ with center at the origin and of radius R is a set which contains at least two elements and at most six.*

This result is of interest because (see (2.9))

$$|\dot{M}| \;=\; 0 \quad \Leftrightarrow \quad |\tilde{H}_T(x,M) \times M| \;=\; 0.$$

This shows that, for the set $\mathcal{Z}(x, M_0)$ defined in section2.2,

$$\mathcal{Z}(x, M_0) \;=\; \mathcal{S}(x) \cap \Sigma(|M_0(x)|),$$

and we have the following corollary.

Corollary 5.3. *The set $\mathcal{Z}(x, M_0)$ is a discrete set which contains at least two elements and at most six.*

Proof. We give a geometrical proof of Theorem 5.2: we characterize $\mathcal{S}(x)$ in every possible case. Toward this end, let us consider

$$\tilde{H}_T(x,M) \times M \;=\; 0. \tag{5.5}$$

This equality leads to two different problems depending on whether or not H_s is equal to 0.

Case 1. $H_s = 0$. If M belongs to $\mathcal{S}(x)$, we deduce from (5.5) that

$$\exists\, \lambda \in \mathbb{R}, \quad K\,(p \cdot M)p \,-\, (e_x \cdot M)e_x \;=\; \lambda M, \tag{5.6}$$

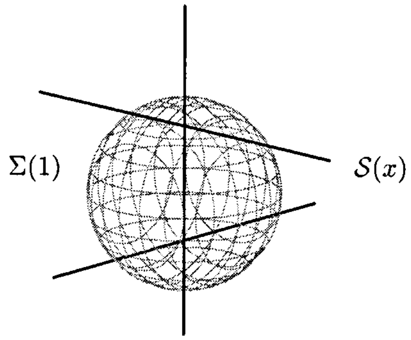

FIG. 5.1. *The unit sphere and the set $\mathcal{S}(x)$ with six intersection points ($H_s = 0.5\,e_z$, $K = 0.7$, $p = e_y$).*

which corresponds to a simple eigenvalue problem. Assumption $(\mathcal{H}_x)$ ensures that p and e_x are not collinear and that $K \neq 0$. Thus the operator defined by $M \mapsto K(p \cdot M)p - (e_x \cdot M)e_x$ is a real symmetric operator A; in the basis $(e_x, p, e_x \times p)$, we have

$$A \;=\; \begin{bmatrix} -1 & -(e_x \cdot p) & 0 \\ K(e_x \cdot p) & K & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

The operator A has three distinct real eigenvalues: one is zero, and the other ones have opposite signs (as $K\left[(e_x \cdot p)^2 - 1\right] < 0$). Thus there exist three different eigendirections, (e_i) and $\mathcal{S}(x)$ is made up of three lines passing through the center of the $\Sigma(R)$. There are exactly six stationary states such that $|M_0| = R$, namely $M_0 = Re_i$, $i = 1, \ldots, 3$.

Case 2. $H_s \neq 0$. Let us denote $u = e_x$, $v = p$, and $w = H_s/|H_s|$. We shall distinguish three cases:

- *Case* 2.1 (*general case, see Figure* 5.2): $(u, v, w) \neq 0$.

  In the basis $\{u, v, w\}$, we denote M by $(x, y, z)^t$. Equality (5.5) then reads

  $$(\,|H_s|\,w \;+\; Ky\,v \;-\; x\,u\,) \times (\,x\,u \;+\; y\,v \;+\; z\,w\,) \;=\; 0,$$

  which yields

  $$|H_s|x\; w{\times}u + |H_s|y\; w{\times}v + Kxy\; v{\times}u + Kyz\; v{\times}w - xy\; u{\times}v - xz\; u{\times}w \;=\; 0.$$

  As $\{u \times v, u \times w, v \times w\}$ is also a basis of $\mathbb{R}^3$, we deduce that

  $$\text{(5.7)} \qquad \left\{ \begin{array}{rcl} x\,(|H_s| + z) & = & 0, \\ y\,(|H_s| - Kz) & = & 0, \\ x\,y\,(K+1) & = & 0. \end{array} \right.$$

  This shows that $\mathcal{S}(x)$ is made up of two or three lines: $d_1 = \{x = 0, y = 0\}$, $d_2 = \{y = 0, z = -|H_s|\}$ and, if $K \neq 0$, $d_3 = \{x = 0, z = |H_s|/K\}$. We deduce that the intersection between $\mathcal{S}(x)$ and a sphere of radius R has at least two points (because the line d_1 passes through the point $(0, 0, 0)$) and at most six points. All the values between 2 and 6 are possible, depending on R and on the distance of the lines d_2 and d_3 from the point $(0, 0, 0)$.

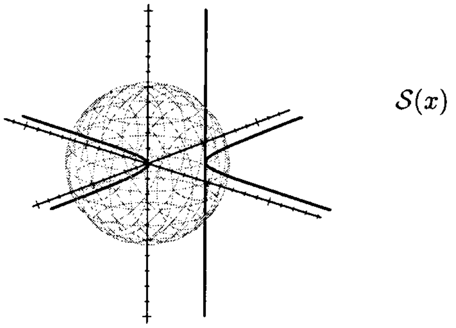

FIG. 5.2. *The unit sphere and the set $\mathcal{S}(x)$ with six intersection points ($H_s = 0.5\,(e_x + p)$, $K = 0.5$, $p = e_y$).*

- *Case* 2.2: $(u, v, w) = 0$, $(u, v, u \times v) \neq 0$.
  In the basis $\{u, v, u \times v\}$, we denote M by $(x, y, z)^t$ and H_s by $(h_u, h_v, 0)^t$. The computations now lead to

$$(5.8)\qquad \left\{\begin{array}{ccc} x\,(h_v + Ky) \;-\; y\,(h_u + x) & = & 0, \\ z\,(h_v + Ky) & = & 0, \\ z\,(h_u - x) & = & 0. \end{array}\right.$$

  In this case, the set $\mathcal{S}(x)$ is made up of a hyperbola ($\{z = 0, (K+1)xy + h_v x - h_u y = 0\}$) and, if $K \neq 0$, a line ($\{x = h_u, y = -h_v/K\}$). As one of the branches of the hyperbola passes through the point $(0, 0, 0)$, the conclusions are exactly the same as in the previous case.
- *Case* 2.3: u, v, and w are collinear.
  In the canonical basis $\{e_x, e_y, e_z\}$, we have $p = e_x$, $H_s = |H_s| e_x$, and $M = (x, y, z)^t$. The computations now lead to

$$(5.9)\qquad \left\{\begin{array}{ccc} y\,(|H_s| + Ky - x) & = & 0, \\ z\,(|H_s| + Ky - x) & = & 0. \end{array}\right.$$

  As

$$(\mathcal{H}_x) \quad \Leftrightarrow \quad (|H_s| + Ky - x) \;\neq\; 0,$$

  the set $\mathcal{S}(x)$ reduces in this case to the line $\{y = 0, z = 0\}$, and there are always exactly two intersection points. □

5.2. Free transitions to stationary states. In this section we still consider the unperturbed case (i.e., $H_\parallel = 0$). It is indeed easy to show in this case the convergence of $M(x, t)$ to some element of $\mathcal{Z}(x, M_0)$. It is also possible to see which of these positions are stable and which are not (see Remark 5.6).

THEOREM 5.4. *Let $\mathcal{Z}(x, M_0)$ be defined as in section* 2.2. *The solution to system* (5.1) *satisfies*

$$\exists\, M_\infty(x) \in \mathcal{Z}(x, M_0) \quad \textit{such that} \quad \lim_{t\to\infty} M(x, t) \;=\; M_\infty(x).$$

Proof. Note that

$$(5.10)\qquad \tilde{H}_T(x, M(x,t)) \;=\; H_s(x) + K(p \cdot M(x,t))p - (e_x \cdot M(x,t))e_x$$

can also be defined as

$$\tilde{H}_T(x, M(x,t)) \;=\; (\nabla_M V)\,(x, M(x,t)), \tag{5.11}$$

where we define

$$V(x,M) \;=\; H_s(x)\cdot M(x,t) - \frac{1}{2}(e_x \cdot M(x,t))^2 - \frac{1}{2}|P(M)|^2 \quad \forall x \in \mathbb{R},\ \forall M \in \mathbb{R}^3.$$

For this reason, we have

$$\tilde{H}_T(x, M(x,t)) \cdot \dot{M}(x,t) \;=\; \frac{d}{dt}V(x, M(x,t)). \tag{5.12}$$

Additionally, we deduce from (5.2) that

$$\tilde{H}_T(x, M(x,t)) \cdot \dot{M}(x,t) \;=\; \frac{\alpha}{1+\alpha^2}\,\frac{1}{|M|}\left|\tilde{H}_T(x, M(x,t)) \times M(x,t)\right|^2. \tag{5.13}$$

Thus

$$\frac{d}{dt}V(x, M(x,t)) \;=\; g(x, M(x,t)), \tag{5.14}$$

where

$$g(x,M) \;=\; \frac{\alpha}{1+\alpha^2}\,\frac{1}{|M|}\left|\tilde{H}_T(x,M) \times M\right|^2 \quad \forall x \in \mathbb{R},\ \forall M \in \mathbb{R}^3. \tag{5.15}$$

The main properties of this function g are, respectively,

(i) $g(x,M) \;\geq\; 0$;

(ii) $(\,g(x,M) = 0 \text{ and } |M| = |M_0(x)|\,) \;\Leftrightarrow\; (M \in \mathcal{Z}(x, M_0))\,$;

(iii) $g(x,M) \;=\; \frac{\alpha}{1+\alpha^2}\,\frac{1}{|M|}\,|\nabla_M V(x,M) \times M|^2$.

Therefore, (5.14) means that the function $M \to V(x,M)$ is a strict anti-Liapunov function for the system (5.1). Classical results on dynamic systems then ensure the convergence to these stationary states (see, for instance, [6]). □

Remark 5.5. Property (iii) of function g means, in particular, that the set of extremal points of $V(x,M)$ on the sphere is included in $\mathcal{Z}(x, M_0)$.

Moreover, in the general case ($(e_x, p, H_s) \neq 0$), it can be shown that, if $M \in \mathcal{Z}(x, M_0)$ is neither a maximum nor a minimum for V, then it is a saddlepoint for V (it cannot be a local extremum).

As an illustration of these results and Theorem 5.2, we represent below two trajectories of the vector $M(t)$ on the sphere of radius $|M_0| = 1$ (see Figure 5.3). These trajectories have been computed numerically and correspond to the following data: ($H_s = 2\,e_z$, $K = 0$) and ($H_s = 0.5\,e_z$, $K = 0.7$, $p = e_y$), respectively. One can check that the first case corresponds to two stationary states on the sphere while the second one corresponds to six states (all are indicated by bold arrows). The initial position, indicated by a bold dot, is the same in both cases.

Remark 5.6. Although it is not the main objective of this paper, one could complete the analysis by results on the stability of the stationary points. Let us first recall the following definition.

Definition 5.7. *A stationary state M_∞ is stable for the trajectory $M(x,t)$ if and only if*

$$\exists\, \mathcal{V}(M_\infty)\ \forall M_0 \in \mathcal{V}(M_\infty), \quad \lim_{t\to\infty} M(x,t) \;=\; M_\infty, \tag{5.16}$$

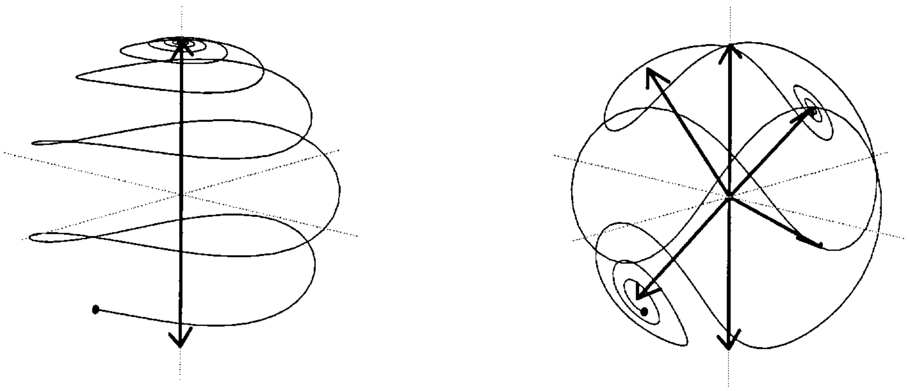

FIG. 5.3. *Trajectories of $M(t)$ with two and six stationary states.*

where $\mathcal{V}(M_\infty)$ is a neighborhood of M_∞ and $M(x,t)$ is the solution to (5.1) *associated with the initial data M_0. (Otherwise, M_∞ is said to be unstable.)*

Two results can now be pointed out:

1. In the general case $((e_x, p, H_s) \neq 0)$, one can show that only the points $M_\infty \in \mathcal{Z}(x, M_0)$, such that

$$V(M_\infty) \;=\; \max_{M \in S} V,$$

are stable stationary states, while the others are unstable.

2. This is not necessarily true when $(e_x, p, H_s) = 0$.

6. Proof of Theorem B: Attraction of M for weak solutions. Using the notation of section 5, one can check that the LLG equation of (1.5) can be rewritten (see Remark 5.1) in the form

$$\dot{M}(x,t) \;=\; L(x, M(x,t)) + R(x,t), \tag{6.1}$$

where

$$R(x,t) = \frac{1}{1+\alpha^2}\left[H_\parallel(x,t) \times M(x,t) + \frac{\alpha}{|M|} M(x,t) \times \big(H_\parallel(x,t) \times M(x,t)\big)\right]. \tag{6.2}$$

By the definition of V and g (see section 5, proof of Theorem 5.4), one easily shows that

$$\frac{d}{dt} V(x, M(x,t)) = g(x, M(x,t)) + r(x,t), \;\; t > 0, \tag{6.3}$$

where

$$r(x,t) \;=\; -\tilde{H}_T(x, M(x,t)) \cdot R(x,t) + \frac{\alpha}{1+\alpha^2} \frac{1}{|M|} \left|H_\parallel(x,t) \times M(x,t)\right|^2. \tag{6.4}$$

As a consequence of Theorem A and (2.6), we see that $R(x,M)$ satisfies

$$\int_0^\infty |R(x, M(x,t), H_\parallel(x,t))|^2 dt \;<\; \infty \text{ for a.e. } x \in \mathbb{R}. \tag{6.5}$$

and thus

$$\int_0^\infty |r(x, M(x,t), H_\|(x,t))|dt \; < \; \infty \text{ for a.e. } x \in \mathbb{R}. \tag{6.6}$$

Let us fix an $x \in \mathbb{R}$ such that (6.1)–(6.6) hold. For this reason we shall write $M(t)$, $R(t)$, and $r(t)$ instead of $M(x,t)$, $R(x,t)$, and $r(x,t)$, respectively, and similarly $g(M)$ and $V(M)$ instead of $g(x,M)$ and $V(x,M)$. By Theorem 2.8, we know that all these functions are, almost everywhere in x, continuous functions of time. In the following, we shall consider such an x. We shall also write $\mathcal{Z}$ instead of $\mathcal{Z}(x, M_0)$ and denote by S the sphere of radius $|M_0(x)|$.

The first step of the proof is the convergence of $V(M(t))$. Let $V(\mathcal{Z}) = \{V_0, V_1, \ldots, V_N\}$ with $V_0 < V_1 < \cdots < V_N$ (In particular, by Remark 5.5 V_0 is the minimum of V on S and V_N is the maximum). Let us introduce

$$V^+ = \limsup_{t\to\infty} V(M(t)) \in]V_i, V_{i+1}] \quad \text{for some } i. \tag{6.7}$$

Lemma 6.1. *Let V_{i+1} be defined by* (6.7). *Then we necessarily have*

$$V(M(t)) \to V_{i+1} \textit{ as } t \to \infty. \tag{6.8}$$

Proof. We prove (6.8) by contradiction. Let us assume to the contrary that

$$V^- \; = \; \liminf_{t\to\infty} \; V(M(t)) \; < \; V_{i+1}.$$

Using also (6.7), we deduce that there exists $\varepsilon > 0$ and $V^0 \in \mathbb{R}$ such that

$$\max(V^-, V_i + \varepsilon) < V^0 < \min(V^+, V_{i+1} - \varepsilon). \tag{6.9}$$

Therefore, by continuity of $V(M(t))$ there exists a sequence $t_k \to \infty$ such that

$$V(M(t_k)) = V^0. \tag{6.10}$$

If we prove that, for sufficiently large T and $t > T$,

$$V(M(t)) \; \geq \; V_{i+1} - \varepsilon, \tag{6.11}$$

we will get a contradiction to (6.10) since $t_k \to \infty$ and $V^0 < V_{i+1} - \varepsilon$. To prove (6.11), first note that the properties of g imply the existence of some $\delta > 0$ such that

$$V(M) \in \left[V_i + \frac{\varepsilon}{2}, V_{i+1} - \frac{\varepsilon}{2}\right] \; \Rightarrow \; g(M) \geq \delta. \tag{6.12}$$

Let us introduce for each k the set

$$\mathcal{E}_k = \left\{ t > t_k : \; V(M(\tau)) \in \left[V_i + \frac{\varepsilon}{2}, V_{i+1} - \frac{\varepsilon}{2}\right] \text{ for } t_k < \tau < t \right\}, \tag{6.13}$$

It is easy to see that by construction $\mathcal{E}_k$ is connected and that, taking into account (6.9) and (6.10) as well as the continuity of $V(M(t))$, it is not empty. One can also prove that this set is bounded. Indeed, let $\tau \in \mathcal{E}_k$; integrating (6.3) between t_k and τ, we get

$$V(M(\tau)) - V(M(t_k)) \; = \; \int_{t_k}^{\tau} g(M(s))ds + \int_{t_k}^{\tau} r(s)ds. \tag{6.14}$$

By definition of $\mathcal{E}_k$, we have

$$\forall\, t_k < s < \tau, \quad V(M(s)) \in \left[V_i + \frac{\varepsilon}{2}, V_{i+1} - \frac{\varepsilon}{2}\right].$$

Therefore, using (6.14) and (6.12), we get

$$V(M(\tau)) - V(M(t_k)) \;\geq\; \delta(\tau - t_k) - I_k, \tag{6.15}$$

and thus,

$$\tau \;\leq\; t_k + \frac{1}{\delta}\left(\max_{M\in S} V(M) - \min_{M\in S} V(M) + I_k\right), \tag{6.16}$$

where

$$I_k \;=\; \int_{t_k}^{\infty} |r(s)| ds. \tag{6.17}$$

Therefore $\mathcal{E}_k$ is bounded by

$$t_k + \frac{1}{\delta}\left(\max_{M\in S} V(M) - \min_{M\in S} V(M) + I_k\right). \tag{6.18}$$

Now, let us introduce

$$\tau_k = \sup \mathcal{E}_k < +\infty. \tag{6.19}$$

By continuity, $V(M(\tau_k))$ is equal to $V_i + \frac{\varepsilon}{2}$ or $V_{i+1} - \frac{\varepsilon}{2}$. Let us show that $V(M(\tau_k)) = V_{i+1} - \frac{\varepsilon}{2}$ at least for k large enough. Indeed, from (6.14), we deduce in particular that (g is positive and we take $\tau = \tau_k$)

$$V(M(\tau_k)) - V(M(t_k)) \;\geq\; -I_k. \tag{6.20}$$

I_k tends to 0 when k tends to $+\infty$ because of (6.6). Thus, there exists $\bar{k} = \bar{k}(\varepsilon)$ such that, for $k \geq \bar{k}$,

$$V(M(\tau_k)) - V(M(t_k)) \;\geq\; -\frac{\varepsilon}{2} \text{ for } t_k < \tau < \tau_k. \tag{6.21}$$

Therefore

$$V(M(\tau_k)) \geq V(M(t_k)) - \frac{\varepsilon}{2} = V^0 - \frac{\varepsilon}{2} > V_i + \frac{\varepsilon}{2}.$$

This proves that (see Figure 6.1)

$$k \geq \bar{k} \Rightarrow V(M(\tau_k)) = V_{i+1} - \frac{\varepsilon}{2}.$$

Now, we introduce the set

$$\mathcal{F}_k \;=\; \left\{t \geq \tau_k \,:\, V(M(\tau)) \geq V_{i+1} - \frac{\varepsilon}{2} \text{ for } \tau_k \leq \tau \leq t\right\}. \tag{6.22}$$

Equations (6.9) and (6.10) ensure that $\mathcal{F}_k$ is bounded for every k. Let us set

$$\theta_k = \max \mathcal{F}_k. \tag{6.23}$$

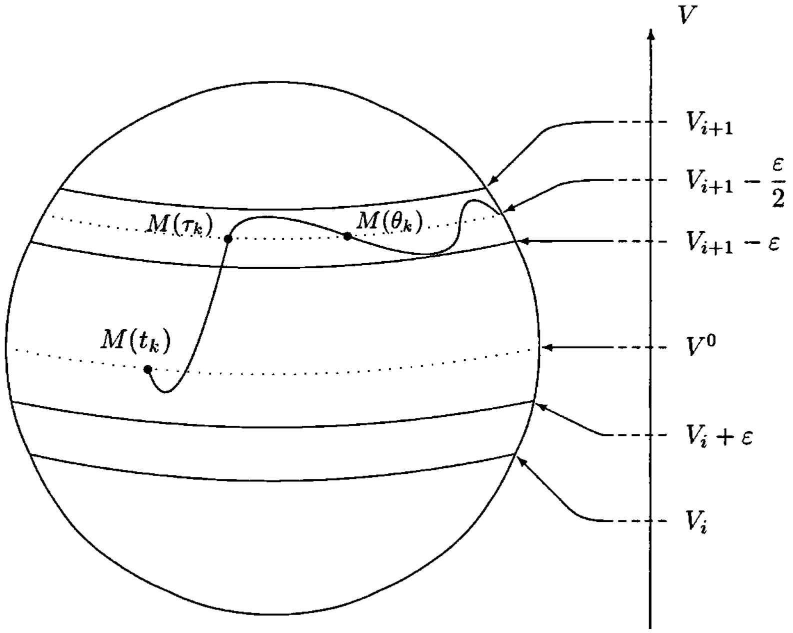

FIG. 6.1. *Behavior of a Liapunov function.*

By definition of $\mathcal{F}_k$ and continuity of $V(M(t))$, we have

$$V(M(\theta_k)) = V_{i+1} - \frac{\varepsilon}{2}. \tag{6.24}$$

Integrating (6.3) between θ_k and $t > \theta_k$ and using once again the positivity of g, we get, for $k \geq \overline{k}$,

$$\forall\, t > \theta_k \quad V(M(k)) - V_{i+1} + \frac{\varepsilon}{2} \geq -I_k \geq -\frac{\varepsilon}{2} \tag{6.25}$$

which proves (6.11) with $T = \theta_{\overline{k}}$. □

Now to prove Theorem B, let us assume by contradiction that the conclusion is not true. This means that there exists $\rho > 0$ and a strictly increasing sequence $t_k \to \infty$ such that (see Figure 6.2)

$$\operatorname{dist}(M(t_k), \mathcal{Z}) \;\geq\; \rho. \tag{6.26}$$

We are going to prove that this contradicts Lemma 6.1.

First, using the properties of g, we know that there exists $\delta > 0$ such that

$$\operatorname{dist}(M(t_k), \mathcal{Z}) \;\geq\; \frac{\rho}{2} \;\Rightarrow\; g(M) \geq \delta. \tag{6.27}$$

By continuity of $M(t)$ and by (6.26), we know that the set

$$\mathcal{G}_k \;=\; \left\{ t > t_k \,/\, \tau \in]t_k, t[\Rightarrow \operatorname{dist}(M(\tau), \mathcal{Z}) \;\geq\; \frac{\rho}{2} \right\}$$

is not empty. Let us check that, for k large enough,

$$]t_k, t_k + T] \subset \mathcal{G}_k \;\text{ where }\; T \;=\; C\rho, C > 0. \tag{6.28}$$

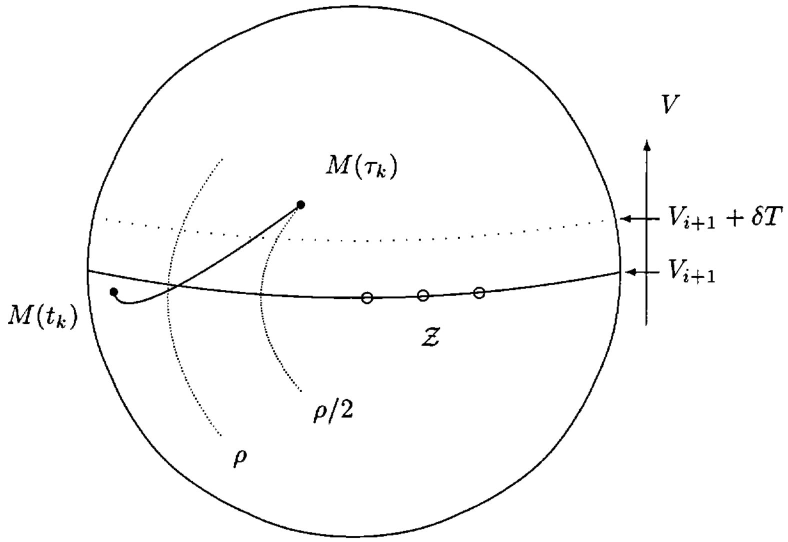

FIG. 6.2

Let $\tau_k = \sup \mathcal{G}_k$. As the case $\tau_k = +\infty$ is obvious ($]t_k, t_k+T] \subset]t_k, +\infty[$), let us assume that $\tau_k < +\infty$. By continuity, $\operatorname{dist}(M(\tau_k), \mathcal{Z}) = \rho/2$, and using (6.26),

$$|M(t_k) - M(\tau_k)| \geq \frac{\rho}{2}. \tag{6.29}$$

Conversely, integrating (6.1) between t_k and τ_k and using (6.5) and the Cauchy–Schwarz inequality, we get

$$|M(\tau_k) - M(t_k)| = \left| \int_{t_k}^{\tau_k} L(M(s))ds + \int_{t_k}^{\tau_k} R(s)ds \right| \leq \omega(\tau - t_k) + J_k(\tau_k - t_k)^{\frac{1}{2}}, \tag{6.30}$$

where $\omega > 0$, and

$$J_k^2 = \int_{t_k}^{\infty} |R(s)|^2 ds. \tag{6.31}$$

Regrouping (6.29) and (6.30), we get, using Young's inequality,

$$\frac{\rho}{2} \leq \omega(\tau_k - t_k) + J_k(\tau_k - t_k)^{\frac{1}{2}} \leq 2\omega(\tau_k - t_k) + \frac{J_k^2}{2\omega}. \tag{6.32}$$

As J_k^2 tends to 0 when $k \to \infty$, we have, for $k \geq \tilde{k}$, $J_k^2/2\omega < \rho/4$. Therefore,

$$k \geq \tilde{k} \Rightarrow \frac{\rho}{4} \leq 2\omega(\tau_k - t_k) \Rightarrow (\tau_k - t_k) \geq CT. \tag{6.33}$$

Now, integrating (6.3) between t_k and $t_k + T$, we get

$$V(M(t_k+T)) - V(M(t_k)) = \int_{t_k}^{t_k+T} g(M(s))ds + \int_{t_k}^{t_k+T} r(s)ds. \tag{6.34}$$

By (6.26)–(6.28), $g(M(s)) \geq \delta$ for $s \in [t_k, t_k + T]$ and $k \geq \tilde{k}$. Therefore,

$$V(M(t_k + T)) - V(M(t_k)) \ \geq \ \delta T \ - \ I_k, \tag{6.35}$$

where $I_k = \int_{t_k}^{+\infty} |r(s)| ds$ tends to 0 when $k \to +\infty$. Therefore, for k large enough,

$$V(M(t_k + T)) - V(M(t_k)) \ \geq \ \frac{\delta T}{2} \tag{6.36}$$

which of course contradicts Lemma 6.1. □

7. On the attraction of M for strong solutions. In this last section, the assumptions are those of Theorem A′. First, note that the proof of Corollary 2.12 is obvious: indeed, the proof given in the previous section for weak solutions also applies to strong solutions and ensures the convergence of $M(x, t)$ for every $x \in \mathbb{R}$.

One could think that the uniform convergence to 0 of the transverse field $H_{\|}(x, t)$ would yield that the convergence of the magnetization distribution $M(x, t)$ to $M_\infty(x, t)$ is itself uniform. In fact, such a result is not obvious at all, and may not be true. More precisely, we are going to prove, with the help of a suitable counterexample, that it is not possible to prove the uniform convergence of $M(x, t)$ with the only assumption that the convergence of $H_{\|}(x, t)$ is uniform.

To construct this counterexample, we denote by S the unit sphere, set $M_\infty = e_z = (0, 0, 1)^t$, and $M_{-\infty} = -M_\infty$. We shall need two simple lemmas which apply to the evolution equation

$$\begin{cases} \dot{M}(t) = \tilde{H}_T(M(t)) \times M(t) + \dfrac{\alpha}{|M(t)|} M(t) \times \dot{M}(t), \\ M(t = 0) = M_0 \in S, \end{cases} \tag{7.1}$$

where $\tilde{H}_T(M(t)) = -(M(t) \cdot e_x)e_x + 2e_z + H_{\|}(t)$, which corresponds to $H_s = 2e_z$ and $K = 0$. In such a case, one easily verifies that

$$\mathcal{Z} \ = \ \{ M_\infty, M_{-\infty} \} .$$

LEMMA 7.1. *Assuming that $H_{\|}(t) = 0$, for any solution $M(t)$ to system* (7.1), *and for all $M_0 \in S$, we have*

$$(M_0 \neq M_{-\infty}) \Rightarrow \Big(V(M_0) \ > \ V_{\min} = V(M_{-\infty}) \text{ and } \lim_{t \to \infty} M(t) \ = \ M_\infty \Big) , \tag{7.2}$$

where

$$\forall M \in S, \quad V(M) \ = \ 2M \cdot e_z - \frac{1}{2} |M \cdot e_x|^2.$$

Remark 7.2. This result means that M_∞ can be a limit state if and only if $M_0 = M_{-\infty}$, in which case the solution is stationary.

Proof. It is easy to check that

$$\max_{M \in S} V(M) \ = \ V_{\max} \ = \ V(M_\infty),$$

and

$$\min_{M \in S} V(M) \ = \ V_{\min} \ = \ (V(M_{-\infty})).$$

This is true as soon as $|H_s| > 1$ (see section 4). Moreover, for the same reason, V admits no other critical point on S. The lemma is then a direct consequence of the fact that V is a strict anti-Liapunov function for the system (7.1). □

LEMMA 7.3. *Let $\varepsilon \in]0,1]$, and let us assume that $H_{\|}(t) = \varepsilon e_y$ and $M_0 = M_{-\infty}$. Then, for all $T > 0$, the solution to system* (7.1) *on* $[0,T]$ *is such that*

$$V(M(T)) \; < \; V_{\min} \; = \; V(M_{-\infty})$$

where V is as defined in Lemma 7.1.

Proof. In this case, the total magnetic field is

$$\tilde{H}_T(M) = -(M(t) \cdot e_x)e_x + 2e_z + \varepsilon e_y.$$

The associated strict anti-Liapunov function is

$$\forall M \in S, \; V'(M) \; = \; -\frac{1}{2}|M \cdot e_x|^2 + 2M \cdot e_z + \varepsilon M \cdot e_y, \tag{7.3}$$

which is such that

$$\min_{M \in S} V'(M) \; = \; V'_{\min} \; = \; V'(M_{-\infty}) \; = \; V(M_{-\infty}),$$

where V has been defined in Lemma 7.1, and

$$\max_{M \in S} V'(M) \; = \; V'_{\max} \; = \; V'(M_{\infty}) \; = \; V(M_{\infty}).$$

Thus,

$$V'(M(T)) \; > \; V'_{\min} \; = \; V(M_{\infty}). \tag{7.4}$$

Let us define

$$\mathcal{C}' \; = \; \{M \in S \setminus V'(M) \; = \; V'(M(T))\} \tag{7.5}$$

and

$$V_T \; = \; \min_{M \in \mathcal{C}'} V(M). \tag{7.6}$$

As $V'_{\min} = V_{\min}$ is reached in M_{∞} only, we see that

$$(\, V_T = V_{\min} \,) \implies (\, V'(M(T)) = V'_{\min} \,)\,, \tag{7.7}$$

which is not true; whence the result, since

$$V'(M(T)) \; \geq \; V_T \; > \; V_{\min}. \qquad \square \tag{7.8}$$

We can now state the following theorem.

THEOREM 7.4. *Let $\Omega = [0,1]$ be a ferromagnetic layer defined by the initial distribution*

$$M_0(x) \; = \; M_{-\infty} \quad \forall x \in [0,1],$$

$H_s = 2e_z$, and $K = 0$. Let us consider a transverse magnetic field defined by

$$\left| \begin{array}{lcll} H_{\|}(x,t) & = & 0 & \forall x \notin [0,1]\,, \\ & = & 0 & \forall t \notin \left[\dfrac{1}{x}, \dfrac{2}{x}\right], \\ & = & x & \forall t \in \left[\dfrac{1}{x}, \dfrac{2}{x}\right]. \end{array} \right.$$

Then, $H_{\|}(x,t)$ *converges uniformly to* 0 *when* t *goes to* $+\infty$; *however,*

(i) $\lim_{t\to\infty} M(0,t) \;=\; M_{-\infty}$*;*

(ii) $\forall x \in]0,1]$*,* $\lim_{t\to\infty} M(x,t) \;=\; M_{\infty}$*;*

(iii) $\forall \varepsilon \in [0,2[\; \forall T > 0$*,* $\exists\, x \in]0,1]$*,* $\exists\, t > T$ *such that*

$$\left| M(x,t) - \lim_{t\to\infty} M(x,t) \right| \;=\; |\, M(x,t) - M_\infty \,| \;=\; 2 \;> \varepsilon.$$

Proof. First of all, it is easy to see that

$$\sup_{x\in\,]0,1]} H_{\|}(x,t) \;=\; \frac{2}{t} \tag{7.9}$$

which ensures that the convergence of $H_{\|}$ to 0 in time is uniform in space.

Concerning the three assertions of the theorem, result (i) is clear since $H_{\|}(0,t) = 0$ for all $t \geq 0$. For (ii) and (iii), let us consider $\varepsilon \in [0,2[$ and $T > 0$. We choose $x \in]0,1]$ such that $1/x > T$. Then, on the one hand,

$$\forall t \in [0,T], \quad H_{\|}(x,t) = 0 \;\text{ and } M(x,t) \;=\; M_{-\infty}. \tag{7.10}$$

On the other hand, by Lemma 7.3,

$$V\left(M\left(x, t = \frac{2}{x}\right)\right) \;>\; V_{\min} \tag{7.11}$$

and thus, by Lemma 7.1,

$$\lim_{t\to\infty} M(x,t) \;=\; M_\infty \qquad \square \tag{7.12}$$

Remark 7.5. The previous example is only a counterexample to the fact that the uniform convergence of M could be proven by using uniform convergence of $H_{\|}$. It is not a counterexample to the uniform convergence of M: indeed, it is not a solution of the coupled Maxwell–LLG system.

Remark 7.6. One might also believe that $M(t)$ always converges to a stable stationary state. This is not so obvious, and may not be true. In fact, one can show that a "perturbation" $H_{\|}(x,t)$—that is to say, a function C^1 in time vanishing to 0 with $t \to \infty$— can lead the magnetization M from a stable position to an unstable one. Let us consider

$$\left\{ \begin{array}{l} \dot\mu(t) = -\,\mu(t) \times (H_T(\mu(t)) \times \mu(t)), \\ \mu(t=0) = \mu_0 \in S, \end{array} \right. \tag{7.13}$$

where $H_T(\mu) = -(\mu \cdot e_x)e_x + 2e_z$. The solution to this problem is such that

$$\forall \mu_0 \neq M_\infty, \quad \lim_{t\to\infty} \mu(t) \;=\; M_{-\infty}, \tag{7.14}$$

because $V(\mu)$ is a strict anti-Liapunov function for (7.13). Let us now define the function $h(t)$ as

$$h(t) \;=\; \frac{1}{1+\alpha^2} H_T(\mu(t)) \times \mu(t) - \frac{1+\alpha+\alpha^2}{1+\alpha^2}\mu(t) \times (H_T(\mu(t)) \times \mu(t)). \tag{7.15}$$

This function is such that

(i) $h(t) \in C^1(\mathbb{R})$ because $\mu(t) \in C^1(\mathbb{R})$;

(ii) $h(t) \to 0$ when $t \to \infty$ because $\mu(t) \times H_T(\mu(t)) \to 0$ when $t \to \infty$;

(iii) additionally, computations lead to

$$(H_T(\mu(t)) + h(t)) \times \mu(t) + \alpha\mu(t) \times [(H_T(\mu(t)) + h(t)) \times \mu(t)] = \\ -\ \mu(t) \times (H_T(\mu(t)) \times \mu(t)).$$

In other words, function $\mu(t)$, the solution to problem (7.13), is also the solution to problem (7.1) with the perturbation $H_{\|}(t) = h(t)$.

ON THE SOLUTION OF A LINEAR HOMOGENEOUS DIFFERENCE EQUATION WITH VARIABLE COEFFICIENTS[*]

RANJAN K. MALLIK[†]

Abstract. A closed form solution of a linear homogenous difference equation of order N with variable coefficients is presented for $N \geq 3$. From it, the solution for the special case of an equation with constant coefficients is also obtained.

Key words. Nth order linear homogeneous difference equation, linear recurrence, variable coefficients, closed form solution

AMS subject classification. 39A10

1. Introduction.

Linear homogeneous difference equations or linear homogeneous recurrences play a significant role in the mathematical models of systems which we come across in various areas of science and engineering. Closed form solutions of linear recurrences with constant coefficients are known, and the recurrences have a nice and complete theory. That is no longer the case when the coefficients vary with the index [1]. For equations with variable coefficients, the closed form solution of the first order equation is known [2, 3, 4]. However, for homogeneous equations of order N greater than one, if $N-1$ linearly independent solutions are known, then any other linearly independent solution can be obtained in closed form in terms of the known solutions using the Casoratian (Wronskian in discrete domain) [2, 3, 5, 6]. For a second order linear homogeneous difference equation with variable coefficients, the closed form solution in terms of coefficients has been presented in [7, 8]. The solution of the Nth order linear difference equation with variable coefficients has also been represented in terms of determinants of submatrices of a single solution matrix [9]. But, in the available open literature, there are no general closed form expressions in terms of coefficients for the complete solution of linear homogeneous difference equations with varying coefficients when the order is N, except for cases when the coefficients have some special properties [1]. This paper presents *a complete closed form solution in terms of coefficients* of a linear homogeneous difference equation of order N with variable coefficients when $N \geq 3$.

We begin with some definitions and examine some properties based on the definitions. Let $\mathbf{N}$ denote the set of natural numbers. For any given $N \in \mathbf{N}$, $N \geq 3$, and for all $n \in \mathbf{N}$, define a function $f : \mathbf{N} \to \mathbf{N}$ as

$$f(n) \triangleq \begin{cases} (N-1)\lfloor \frac{n}{N} \rfloor + 1 & \text{if } n \text{ is divisible by } N, \\ (N-1)\lfloor \frac{n}{N} \rfloor + N - 1 & \text{if } n \text{ is not divisible by } N, \end{cases} \tag{1.1}$$

where $\lfloor \frac{n}{N} \rfloor$ is the largest natural number which is less than or equal to $\frac{n}{N}$. For all ascending q-tuples $(k_1, \ldots, k_q)$ of natural numbers, where $q \geq 2$ and $k_1 < \cdots < k_q$,

[†] Department of Electrical Engineering, Indian Institute of Technology, Delhi, Hauz Khas, New Delhi 110016, India (rkmallik@ee.iitd.ernet.in).

define a function $\mathbf{g}_q : \mathbf{N}^q \to \mathbf{N}^q$ as

$$
\begin{array}{l}
\mathbf{g}_q(k_1, \ldots, k_q) \triangleq (l_1, \ldots, l_q)\,, \\
\text{such that} \\
l_1 = 2, \ \text{ and} \\
\text{for } m = 2, \ldots, q, \\
l_m = \begin{cases} 1 + l_{m-1} & \text{if } k_m - k_{m-1} = 1, \\ 2 & \text{if } k_m - k_{m-1} \geq 2. \end{cases}
\end{array}
\tag{1.2}
$$

For example, $\mathbf{g}_2(3,4) = (2,3)$, $\mathbf{g}_2(3,5) = \mathbf{g}_2(3,6) = (2,2)$, $\mathbf{g}_3(3,4,5) = (2,3,4)$, $\mathbf{g}_3(4,5,7) = (2,3,2)$, $\mathbf{g}_4(3,4,6,7) = (2,3,2,3)$, $\mathbf{g}_4(3,5,6,7) = (2,2,3,4)$. Thus the function $\mathbf{g}_q$ keeps track of the strings of consecutive numbers in $(k_1, \ldots, k_q)$.

Let a set $S_q(L,U)$, where $q, L, U \in \mathbf{N}$, be defined as the set of all q-tuples with elements from $\{L, L+1, \ldots, U\}$ arranged in ascending order in which no N consecutive elements are present, that is,

$$
\begin{array}{lll}
(1.3\text{a}) & S_q(L,U) \triangleq \{L, L+1, \ldots, U\} & \text{if } \ U \geq L \ \text{ and } \ q = 1 \\
(1.3\text{b}) & \quad\quad\quad \triangleq \left\{ {\scriptstyle (k_1,\ldots,k_q)\,:\, L \leq k_1 < \cdots < k_q \leq U} \right\} & \text{if } \ U \geq L + q - 1, \ \ q = 2, \ldots, N-1 \\
& \quad\quad\quad \triangleq \left\{ {\scriptstyle (k_1,\ldots,k_q)\,:\, L \leq k_1 < \cdots < k_q \leq U;\ \ k_m - k_{m-N+1} \geq N \ \text{ for } \ m = N, \ldots, q} \right\} & \\
(1.3\text{c}) & \quad\quad\quad\quad \text{if } \ U \geq L + N \ \text{ and } \ N \leq q \leq f(U-L) & \\
(1.3\text{d}) & \quad\quad\quad \triangleq \emptyset \quad \text{otherwise.} &
\end{array}
$$

Also, let a set $T_q(L,U)$ be defined as

$$
T_q(L,U) \triangleq \left\{ {\scriptstyle ([k_1,l_1],\ldots,[k_q,l_q])\,:\,(k_1,\ldots,k_q) \in S_q(L,U);\ \ (l_1,\ldots,l_q) \in \mathbf{g}_q(k_1,\ldots,k_q)} \right\}, \tag{1.4}
$$

where functions f and $\mathbf{g}_q$ are defined in (1.1) and (1.2), respectively.

Proposition 1. *For $U \geq L+1$, $2 \leq q \leq f(U-L+N)$,*

$$
\begin{aligned}
S_q(L, U+N) = S_q(L, U+N-1) & \\
& \cup \left\{ {\scriptstyle (k_1,\ldots,k_q)\,:\,(k_1,\ldots,k_{q-1}) \in S_{q-1}(L,U+N-2);\ \ k_q = U+N} \right\} \\
& \cup \left\{ {\scriptstyle (k_1,\ldots,k_q)\,:\,(k_1,\ldots,k_{q-2}) \in S_{q-2}(L,U+N-3);\ \ k_{q-1} = U+N-1,\ \ k_q = U+N} \right\} \\
& \cup \cdots \\
& \cup \left\{ {\scriptstyle (k_1,\ldots,k_q)\,:\,(k_1,\ldots,k_{q-N+1}) \in S_{q-N+1}(L,U);\ \ k_{q-N+2} = U+2,\ldots,k_q = U+N} \right\} \\
= S_q(L, U+N-1) \cup & \\
& \left[\bigcup_{r=1}^{N-1} \left\{ {\scriptstyle (k_1,\ldots,k_q)\,:\,(k_1,\ldots,k_{q-r}) \in S_{q-r}(L,U+N-r-1);\ \ k_{q-p} = U+N-p,\ p=0,\ldots,r-1} \right\} \right].
\end{aligned}
\tag{1.5}
$$

Proof. From the definition of $S_q(L,U)$, $S_q(L,U+N)$ can be expressed as a disjoint union of $\mathcal{S}_r$, $r = 0, \ldots, N-1$, where $\mathcal{S}_r$ is the set of q-tuples $(k_1, \ldots, k_q) \in S_q(L, U+N)$ such that $k_{q-r} \leq U + N - r - 1$, and

$$
k_{q-r+1} = U + N - r + 1,\ k_{q-r+2} = U + N - r + 2,\ \ldots,\ k_q = U + N.
$$

Note that

$$\mathcal{S}_r = \left\{ (k_1,\ldots,k_{q-r},U+N-r+1,\ldots,U+N) : (k_1,\ldots,k_{q-r}) \in S_{q-r}(L,U+N-r-1) \right\},$$

so the proposition immediately follows. □

PROPOSITION 2. *For $U \geq L+1$, $2 \leq q \leq f(U-L+N)$,*

$$\begin{aligned} T_q(L,U+N) = T_q(L,U+N-1) \cup \\ \left[\bigcup_{r=1}^{N-1} \left\{ ([k_1,l_1],\ldots,[k_q,l_q]) : ([k_1,l_1],\ldots,[k_{q-r},l_{q-r}]) \in T_{q-r}(L,U+N-r-1); \right. \right. \\ \left. \left. [k_{q-p},l_{q-p}] = [U+N-p,r+1-p],\ p=0,\ldots,r-1 \right\} \right]. \end{aligned} \tag{1.6}$$

Proof. From Proposition 1 and the definition of $T_q(L,U)$ in (1.4), we obtain (1.6). □

2. Solution of the difference equation. Consider the Nth order linear homogeneous difference equation ($N \geq 3$)

$$y_{n+N} = a_{n,1}\,y_{n+N-1} + a_{n,2}\,y_{n+N-2} + a_{n,3}\,y_{n+N-3} + \cdots + a_{n,N}\,y_n\,, \quad n \geq 1, \tag{2.1}$$

with integral index n, variable complex coefficients $a_{n,1},\ldots,a_{n,N}$, and complex initial values $y_1,\ldots,y_N$.

Since our basic objective is to obtain the solution in terms of relations between the coefficient indices directly or indirectly, we approach the problem by *transforming* the original difference equation into another difference equation with new coefficients expressed in terms of the original coefficients. The transformed difference equation is then solved in closed form in terms of the new coefficients.

We begin by defining a quantity $\gamma_{i,j}$ for $i \geq 2$, $j \geq 2$ as

$$\gamma_{i,j} \triangleq \begin{cases} \frac{a_{i,j}}{a_{i-1,j-1}a_{i,1}} & \text{if } j = 2,\ldots,N, \\ 0 & \text{if } j \geq N+1. \end{cases} \tag{2.2}$$

It is clear that the solution of difference equation (2.1) with initial values $y_1,\ldots,y_N$ can also be written as

$$\begin{aligned} y_i &= c_{i-N,1}\,y_N + c_{i-N,2}\,y_{N-1} + c_{i-N,3}\,y_{N-2} + \cdots + c_{i-N,N}\,y_1 \\ &= \sum_{j=1}^{N} c_{i-N,j}\,y_{N+1-j}\,, \quad i \geq 1, \end{aligned} \tag{2.3}$$

with

$$\begin{bmatrix} c_{0,1} & c_{0,2} & \cdots & c_{0,N} \\ c_{-1,1} & c_{-1,2} & \cdots & c_{-1,N} \\ \vdots & \vdots & & \vdots \\ c_{-(N-1),1} & c_{-(N-1),2} & \cdots & c_{-(N-1),N} \end{bmatrix} = \mathbf{I}_N\,, \tag{2.4}$$

$\mathbf{I}_N$ being the $N \times N$ identity matrix, where

$$c_{i,j} = a_{i,1}c_{i-1,j} + a_{i,2}c_{i-2,j} + a_{i,3}c_{i-3,j} + \cdots + a_{i,N}c_{i-N,j}\,, \quad i \geq 1,\ j = 1, \ldots, N, \tag{2.5}$$

i.e., $y_i = c_{i-N,j}$, $j = 1, \ldots, N$ are N solutions of difference equation (2.1) for $i \geq 1$.

Equation (2.5) can be rewritten as

$$\begin{aligned} c_{1,j} &= a_{1,j} && \text{for } \ j = 1, \ldots, N, \\ c_{i,j} &= \sum_{l=1}^{i-1} a_{i,l}c_{i-l,j} \ + \ a_{i,i+j-1} && \text{for } \ 2 \leq i \leq N+1-j, \ \ j = 1, \ldots, N-1 \\ &= \sum_{l=1}^{i-1} a_{i,l}c_{i-l,j} && \text{for } \ N+2-j \leq i \leq N, \ \ j = 2, \ldots, N \\ &= \sum_{l=1}^{N} a_{i,l}c_{i-l,j} && \text{for } \ \ i \geq N+1, \ \ j = 1, \ldots, N. \end{aligned} \tag{2.6}$$

Next, we define, for $j = 1, \ldots, N$,

$$\begin{aligned} d_{1,j} &\triangleq \tfrac{c_{1,j}}{a_{1,j}}\,, \\ d_{i,j} &\triangleq \tfrac{c_{i,j}}{a_{1,j}a_{2,1}\ldots a_{i,1}} \quad \text{for } \ i \geq 2. \end{aligned} \tag{2.7}$$

Using (2.7) and the definition of $\gamma_{i,j}$ in (2.2), we obtain, from (2.6),

$$\begin{aligned} d_{1,j} &= 1\,, \\ d_{2,j} &= d_{1,j} + \gamma_{2,j+1} \\ &= 1 + \gamma_{2,j+1}\,, \\ d_{i,j} &= d_{i-1,j} \ + \ \sum_{l=2}^{i-1} d_{i-l,j}\left[\prod_{p=2}^{l} \gamma_{i-l+p,p}\right] \ + \ \prod_{p=2}^{i} \gamma_{p,j+p-1} \quad \text{for } \ 3 \leq i \leq N \\ &= d_{i-1,j} \ + \ \sum_{l=2}^{N} d_{i-l,j}\left[\prod_{p=2}^{l} \gamma_{i-l+p,p}\right] \quad \text{for } \ i \geq N+1, \end{aligned} \tag{2.8}$$

where $j = 1, \ldots, N$.

It is clear from (2.8) that, for $j = 1, \ldots, N$, $i \geq 1$, the quantity $d_{i,j}$ can be expressed as

$$d_{i,j} = \phi_1(i) \ + \ \sum_{m=2}^{N} \phi_m(i)\left[\prod_{p=2}^{m} \gamma_{p,j+p-1}\right]\,, \tag{2.9}$$

where

$$\phi_1(1) = 1, \quad \phi_2(1) = \cdots = \phi_N(1) = 0, \\ \phi_1(2) = \phi_2(2) = 1, \quad \phi_3(2) = \cdots = \phi_N(2) = 0, \tag{2.10a}$$

$$\phi_m(i) = \phi_m(i-1) \ + \sum_{l=2}^{\min(i-1,N)} \phi_m(i-l) \left[\prod_{p=2}^{l} \gamma_{i-l+p,p}\right] \quad \text{for } \ i \geq 3, \tag{2.10b}$$

where $m = 1, \dots, N$. The *transformed difference equation* is given by (2.10b). Equation (2.10) also implies that

$$\begin{aligned}&\phi_1(1) = \phi_1(2) = 1, \quad \phi_1(3) = 1 + \gamma_{3,2}, \\ &\phi_m(i) = 0, \ \ 1 \leq i \leq m-1, \quad \phi_m(m) = \phi_m(m+1) = 1, \quad \phi_m(m+2) = 1 + \gamma_{m+2,2} \\ &\text{for } \ m = 2, \dots, N.\end{aligned} \tag{2.11}$$

The closed form solution of the transformed difference equation can be expressed in terms of $\gamma_{i,j}$s with their indices related by the set $T_q(L,U)$ defined in (1.4), as is given by the following proposition.

PROPOSITION 3. *For $m = 1, \dots, N$, $i \geq m+3$,*

$$\phi_m(i) \ = \ 1 \ + \sum_{k=m+2}^{i} \gamma_{k,2} \ + \sum_{q=2}^{q_{max}(i-m)} \ \sum_{([k_1,l_1],\dots,[k_q,l_q]) \in T_q(m+2,i)} (\gamma_{k_1,l_1} \cdots \gamma_{k_q,l_q}), \tag{2.12}$$

where f is defined in (1.1), *$T_q(L,U)$ in* (1.4), *$\gamma_{i,j}$ in* (2.2), *and*

$$q_{max}(i-m) = \begin{cases} i-m-1 & \textit{if} \ \ 3 \leq i-m \leq N-1, \\ f(i-m-2) & \textit{if} \ \ i-m \geq N. \end{cases} \tag{2.13}$$

Proof. From (2.10b) and (2.11), we obtain, for $m = 1, \dots, N$ (substituting $i = m+n$),

$$\phi_m(m+n) = \phi_m(m+n-1) \ + \sum_{r=2}^{\min(n,N)} \phi_m(m+n-r) \left[\prod_{p=2}^{r} \gamma_{m+n-r+p,p}\right] \\ \text{for } \ n \geq 3. \tag{2.14}$$

Using (2.10b) and (2.11), we get

$$\phi_m(m+3) = 1 + (\gamma_{m+2,2} + \gamma_{m+3,2}) + \gamma_{m+2,2}\gamma_{m+3,3}\,, \tag{2.15}$$

which satisfies (2.12) for all $N \geq 3$. Note that $q_{\max}(i-m) = 2$ when $i - m = 3$.

For $n \geq 4$, let (2.12) be valid for $\phi_m(m+n-1), \phi_m(m+n-2), \dots, \phi_m(m+3)$.

Then, applying (2.14), we obtain

$$\begin{aligned}\phi_m(m+n) \;=\; 1 \;&+\; \sum_{k=2}^{n-1}\gamma_{m+k,2} \\ &+ \sum_{q=2}^{q_{\max}(n-1)} \sum_{([k_1,l_1],\ldots,[k_q,l_q])\in T_q(2,n-1)} (\gamma_{m+k_1,l_1}\cdots\gamma_{m+k_q,l_q}) \\ &+ \sum_{r=2}^{\min(n,N)} (\gamma_{m+n-r+2,2}\cdots\gamma_{m+n,r}) \\ &+ \sum_{r=2}^{\min(n,N)} \sum_{k=2}^{n-r}\gamma_{m+k,2}(\gamma_{m+n-r+2,2}\cdots\gamma_{m+n,r}) \\ &+ \sum_{r=2}^{\min(n,N)} \sum_{q=r+1}^{q_{\max}(n-r)+r-1} \\ &\times \sum_{([k_1,l_1],\ldots,[k_{q-r+1},l_{q-r+1}])\in T_{q-r+1}(2,n-r)} (\gamma_{m+k_1,l_1}\cdots\gamma_{m+k_{q-r+1},l_{q-r+1}})(\gamma_{m+n-r+2,2}\cdots\gamma_{m+n,r})\,.\end{aligned}\tag{2.16}$$

Substituting $U = n - N$, $L = 2$ in (1.6), we get, for $2 \leq q \leq f(n-2)$,

$$\begin{aligned}&T_q(2,n) = T_q(2,n-1) \cup \\ &\left[\bigcup_{r=2}^{N} \{([k_1,l_1],\ldots,[k_q,l_q]) : ([k_1,l_1],\ldots,[k_{q-r+1},l_{q-r+1}])\in T_{q-r+1}(2,n-r); \right. \\ &\left. [k_{q-p},l_{q-p}]=[n-p,r-p],\ p=0,\ldots,r-2\}\right].\end{aligned}\tag{2.17}$$

Combining the q-product terms in (2.16) using (2.17) gives (2.12) when $i = m + n$. By mathematical induction, (2.12) is valid for all $i \geq m + 3$. □

From (2.3), (2.7), (2.9), and (2.2), we conclude that the *closed form solution* (in terms of the variable coefficients) of difference equation (2.1) with initial values $y_1, \ldots, y_N$, $N \geq 3$, is given by

$$y_{i+N} = c_{i,1}\,y_N + c_{i,2}\,y_{N-1} + c_{i,3}\,y_{N-2} + \cdots + c_{i,N}\,y_1 = \sum_{j=1}^{N} c_{i,j}\,y_{N+1-j}\,, \quad i \geq 1,\tag{2.18}$$

where

$$\begin{aligned}c_{1,j} &= a_{1,j}d_{1,j} = a_{1,j}\,, \quad j = 1,\ldots,N, \\ c_{i,j} &= a_{1,j}a_{2,1}\ldots a_{i,1}d_{i,j}\,, \quad j = 1,\ldots,N,\;\; i \geq 2,\end{aligned}\tag{2.19}$$

such that, for $j = 1, \ldots, N$, $i \geq 1$,

$$d_{i,j} = \phi_1(i) \;+\; \sum_{m=2}^{N} \phi_m(i)\left[\prod_{p=2}^{m}\gamma_{p,j+p-1}\right],\tag{2.20}$$

where $\gamma_{i,j}$ is defined in (2.2), and $\phi_m(i)$, $m = 1, \ldots, N$, are given by (2.11) and Proposition 3.

3. An example. Consider the case when $N = 3$ in difference equation (2.1). The initial values are y_1, y_2, y_3. Suppose we want to obtain an expression for y_6 in terms of the coefficients $a_{i,j}$, $j = 1, 2, 3$, $i = 1, 2, 3$. To start with, we find $\gamma_{i,j}$s and $\phi_m(i)$s. Equation (2.2) gives

$$\begin{aligned} \gamma_{2,2} &= \frac{a_{2,2}}{a_{1,1}a_{2,1}}\,, \quad \gamma_{3,2} = \frac{a_{3,2}}{a_{2,1}a_{3,1}}\,, \\ \gamma_{2,3} &= \frac{a_{2,3}}{a_{1,2}a_{2,1}}\,, \quad \gamma_{3,3} = \frac{a_{3,3}}{a_{2,2}a_{3,1}}\,, \end{aligned} \tag{3.1}$$

and, from (2.11), we get

$$\begin{array}{lll} \phi_1(1) = 1, & \phi_2(1) = 0, & \phi_3(1) = 0, \\ \phi_1(2) = 1, & \phi_2(2) = 1, & \phi_3(2) = 0, \\ \phi_1(3) = 1 + \gamma_{3,2}, & \phi_2(3) = 1, & \phi_3(3) = 1. \end{array} \tag{3.2}$$

Next, from (2.20) and (3.2), we obtain

$$\begin{aligned} d_{3,1} &= \phi_1(3) + \phi_2(3)\gamma_{2,2} + \phi_3(3)\gamma_{2,2}\gamma_{3,3} \\ &= 1 + \gamma_{3,2} + \gamma_{2,2} + \gamma_{2,2}\gamma_{3,3}\,, \\ d_{3,2} &= \phi_1(3) + \phi_2(3)\gamma_{2,3} \\ &= 1 + \gamma_{3,2} + \gamma_{2,3}\,, \\ d_{3,3} &= \phi_1(3) \\ &= 1 + \gamma_{3,2}\,. \end{aligned} \tag{3.3}$$

In addition, (2.19), (3.3), and (3.1) give

$$\begin{aligned} c_{3,1} &= a_{1,1}a_{2,1}a_{3,1}d_{3,1} = a_{1,1}a_{2,1}a_{3,1} + a_{1,1}a_{3,2} + a_{3,1}a_{2,2} + a_{3,3}\,, \\ c_{3,2} &= a_{1,2}a_{2,1}a_{3,1}d_{3,2} = a_{1,2}a_{2,1}a_{3,1} + a_{1,2}a_{3,2} + a_{3,1}a_{2,3}\,, \\ c_{3,3} &= a_{1,3}a_{2,1}a_{3,1}d_{3,3} = a_{1,3}a_{2,1}a_{3,1} + a_{1,3}a_{3,2}\,. \end{aligned} \tag{3.4}$$

Finally, (2.18) implies that

$$y_6 = c_{3,1}\, y_3 + c_{3,2}\, y_2 + c_{3,3}\, y_1\,, \tag{3.5}$$

where $c_{3,1}$, $c_{3,2}$ and $c_{3,3}$ are given by (3.4). This is the desired result, and it agrees with what is obtained by direct substitution.

4. Difference equation with constant coefficients. Consider the difference equation (2.1) with initial values $y_1, \ldots, y_N$, in which $a_{n,j} = a_j$ for all $i \geq 1$, $j = 1, \ldots, N$, i.e.,

$$y_{n+N} = a_1\, y_{n+N-1} + a_2\, y_{n+N-2} + a_3\, y_{n+N-3} + \cdots + a_N\, y_n\,, \quad n \geq 1. \tag{4.1}$$

As in (2.2), define

$$\gamma_j \triangleq \begin{cases} \frac{a_j}{a_{j-1}a_1} & \text{if } j = 2, \ldots, N, \\ 0 & \text{if } j \geq N+1. \end{cases} \tag{4.2}$$

The solution of difference equation (4.1) with initial values $y_1, \ldots, y_N$ is then given by (see (2.18), (2.19), (2.20))

$$y_{i+N} = c_{i,1}\, y_N + c_{i,2}\, y_{N-1} + c_{i,3}\, y_{N-2} + \cdots + c_{i,N}\, y_1\,, \quad i \geq 1, \tag{4.3}$$

where

$$c_{i,j} = a_j (a_1)^{i-1} d_{i,j}\,, \quad j = 1, \ldots, N, \;\; i \geq 1, \tag{4.4}$$

such that, for $j = 1, \ldots, N$, $i \geq 1$,

$$d_{i,j} = \phi_1(i) \; + \; \sum_{m=2}^{N} \phi_m(i) \left[\prod_{p=2}^{m} \gamma_{j+p-1} \right], \tag{4.5}$$

where, from (2.11) and (2.10),

$$\begin{aligned}
&\phi_1(1) = \phi_1(2) = 1, \quad \phi_1(3) = 1 + \gamma_2, \\
&\phi_m(i) = 0, \;\; 1 \leq i \leq m-1, \quad \phi_m(m) = \phi_m(m+1) = 1, \quad \phi_m(m+2) = 1 + \gamma_2 \\
&\text{for } \; m = 2, \ldots, N,
\end{aligned} \tag{4.6a}$$

$$\phi_m(i) = \phi_m(i-1) \; + \sum_{l=2}^{\min(i-1,N)} \phi_m(i-l) \left[\prod_{p=2}^{l} \gamma_p \right] \quad \text{for } \; i \geq 3. \tag{4.6b}$$

It is clear from (4.6) that

$$\phi_m(i) = \phi_1(i - (m-1)) \quad \text{for } \; m = 1, \ldots, N. \tag{4.7}$$

The condition $\phi_m(0) = 0$ satisfies the relation (4.6b). Let the generating function $\Phi_m(u)$ of $\phi_m(i)$ be defined as

$$\Phi_m(u) \triangleq \sum_{i=0}^{\infty} \phi_m(i) u^i\,. \tag{4.8}$$

Then, from (4.6) and (4.7), we obtain

$$\Phi_m(u) = \frac{u^m}{1 - u - \sum_{l=2}^{N} (\gamma_2 \ldots \gamma_l) u^l}\,. \tag{4.9}$$

Equation (4.2) gives

$$\gamma_2 \cdots \gamma_l = \frac{a_l}{a_1^l}\,, \quad l = 2, \ldots, N. \tag{4.10}$$

Expressing $\Phi_m(u)$ as a formal power series and using the multinomial expansion formula for each term of the series, we get, from (4.9) and (4.10),

$$\Phi_m(u) = u^m \sum_{q=0}^{\infty} \sum_{\substack{(k_1, \ldots, k_N) \\ k_1, \ldots, k_N \geq 0 \\ k_1 + k_2 + \cdots + k_N = q}} \binom{q}{k_1, \ldots, k_N} \left[\prod_{l=1}^{N} a_l^{k_l} \right] \left(\frac{u}{a_1} \right)^{k_1 + 2k_2 + \cdots + N k_N}. \tag{4.11}$$

Substituting $i-m = k_1 + 2k_2 + \cdots + Nk_N$ in (4.11), and using (4.8), we obtain

$$\phi_m(i) = \frac{1}{a_1^{i-m}} \sum_{\substack{(k_1,\ldots,k_N) \\ k_1,\ldots,k_N \geq 0 \\ k_1+2k_2+\cdots+Nk_N=i-m}} \begin{pmatrix} k_1+k_2+\cdots+k_N \\ k_1,\ldots,k_N \end{pmatrix} \left[\prod_{l=1}^{N} a_l^{k_l}\right], \tag{4.12}$$

for $i \geq m$. Note that $\phi_m(i) = 0$ for $0 \leq i \leq m-1$.

Now, (4.2) gives

$$\prod_{p=2}^{m} \gamma_{j+p-1} = \begin{cases} \frac{a_{j+m-1}}{a_j a_1^{m-1}} & \text{if } j+m-1 = 2,\ldots,N, \\ 0 & \text{if } j+m-1 \geq N+1, \end{cases} \tag{4.13}$$

which, along with (4.4) and (4.5), implies

$$c_{i,j} = \sum_{m=1}^{N+1-j} a_{j+m-1} a_1^{i-m} \phi_m(i)\,. \tag{4.14}$$

Substituting (4.12) in (4.14), we get

$$c_{i,j} = \sum_{m=j}^{N} \left\{ \sum_{\substack{(k_1,\ldots,k_N) \\ k_1,\ldots,k_N \geq 0 \\ k_1+2k_2+\cdots+Nk_N=i-m+j-1}} \begin{pmatrix} k_1+k_2+\cdots+k_N \\ k_1,\ldots,k_N \end{pmatrix} \left[\prod_{l=1}^{N} a_l^{k_l}\right] \right\} a_m\,. \tag{4.15}$$

After replacing k_m+1 by k_m in (4.15), the equation can be rewritten as

$$c_{i,j} = \sum_{\substack{(k_1,\ldots,k_N) \\ k_1,\ldots,k_N \geq 0 \\ k_1+2k_2+\cdots+Nk_N=i+j-1}} \frac{k_j+k_{j+1}+\cdots+k_N}{k_1+k_2+\cdots+k_N} \begin{pmatrix} k_1+k_2+\cdots+k_N \\ k_1,\ldots,k_N \end{pmatrix} \left[\prod_{l=1}^{N} a_l^{k_l}\right], \tag{4.16}$$

for $i \geq 1$, $j = 1,\ldots,N$. Therefore the solution of difference equation (4.1) with initial values $y_1,\ldots,y_N$ is given by (4.3) and (4.16). This is a closed form solution in terms of the coefficients $a_1,\ldots,a_N$ and does not require evaluation of the roots of the characteristic polynomial.

If the difference equation (4.1) is written in vector form as

$$\begin{bmatrix} y_{n+N} \\ y_{n+N-1} \\ \vdots \\ y_{n+1} \end{bmatrix} = \begin{bmatrix} a_1 & a_2 & a_3 & \cdots & a_{N-1} & a_N \\ 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 1 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & 0 \end{bmatrix} \begin{bmatrix} y_{n+N-1} \\ y_{n+N-2} \\ \vdots \\ y_n \end{bmatrix}, \quad n \geq 1, \tag{4.17}$$

where the $N \times N$ matrix on the right hand side of (4.17) is the *companion matrix*, and the initial value vector is $[y_N, y_{N-1}, \ldots, y_1]^T$, then the solution of (4.17) can also be obtained in terms of the powers of the companion matrix, that is,

$$\begin{bmatrix} y_{i+N} \\ y_{i+N-1} \\ \vdots \\ y_{i+1} \end{bmatrix} = \begin{bmatrix} a_1 & a_2 & a_3 & \cdots & a_{N-1} & a_N \\ 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 1 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & 0 \end{bmatrix}^i \begin{bmatrix} y_N \\ y_{N-1} \\ \vdots \\ y_1 \end{bmatrix}, \quad i \geq 1. \tag{4.18}$$

Comparing (4.18) with (4.3) and (2.4), we get

$$\begin{aligned} &\begin{bmatrix} a_1 & a_2 & a_3 & \cdots & a_{N-1} & a_N \\ 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 1 & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & & \vdots & \vdots \\ 0 & 0 & 0 & \cdots & 1 & 0 \end{bmatrix}^i \\ &\qquad = \begin{bmatrix} c_{i,1} & c_{i,2} & \cdots & c_{i,N-1} & c_{i,N} \\ c_{i-1,1} & c_{i-1,2} & \cdots & c_{i-1,N-1} & c_{i-1,N} \\ \vdots & \vdots & & \vdots & \vdots \\ c_{i-N+1,1} & c_{i-N+1,2} & \cdots & c_{i-N+1,N-1} & c_{i-N+1,N} \end{bmatrix} \end{aligned} \tag{4.19}$$

for $i \geq 0$.

Equation (4.19) implies that (4.16) and (2.4) give the expressions for the entries of any nonnegative power of the companion matrix in terms of the coefficients $a_1, \ldots, a_N$. The result is consistent with the expression for the combinatorial power of the companion matrix presented in Theorem 3.1 of [10], which has been proved by using a digraph to represent a matrix.

5. Conclusion. The closed form solution of the Nth order difference equation ($N \geq 3$) presented here makes use of combinatorial properties of the indices of the coefficients in an indirect manner. By substituting $N = 3$ and forcing the coefficient $a_{n,N}$ of the last term of (2.1) to zero, we can obtain the solution of the second order equation. The solution for the special case of the equation with constant coefficients gives a method of obtaining the nonnegative powers of the companion matrix.

Acknowledgment. The author expresses his gratitude to the anonymous referees for their constructive comments.

1. Introduction.

We will prove a persistence theorem for attracting invariant tori for systems subjected to rapidly oscillating perturbations. The singular nature of these perturbations prevents the direct application of the standard persistence results for normally hyperbolic invariant manifolds. However, as we will illustrate in this paper, the theory of normally hyperbolic invariant manifolds, *when combined with an appropriate continuation method,* does apply.

Systems with rapidly oscillating perturbations arise naturally when a priori stable systems are periodically forced. In fact, partial averaging (perhaps to some high order) at a resonant torus together with a rescaling to slow time produces a system with a rapidly oscillating perturbation. For example, systems of this type are obtained in the dissipative periodically forced oscillator models introduced in [2].

We will consider the existence of invariant tori for a smooth family of differential equations of the form

$$\dot{x} = f(x, \epsilon) + \epsilon g(x, t, \epsilon),$$

where g is a periodic function of the independent variable. For systems of this type, the behavior of the subsystem

$$\dot{x} = f(x, \epsilon)$$

at $\epsilon = 0$ is important. If this subsystem has a normally hyperbolic invariant manifold at $\epsilon = 0$, then the persistence of this manifold into the full system is a result of the general persistence theorems of Fenichel [3] and Hirsch, Pugh, and Shub [7]. However, in many applications, either there is an invariant manifold at $\epsilon = 0$ that is not normally hyperbolic or the system is singular at $\epsilon = 0$. For example, the first situation will arise when a periodically forced oscillator is averaged at a resonance. In these cases,

a change of coordinates and a rescaling of the independent variable often yields an equivalent family, for $\epsilon \neq 0$, of the form

$$y' = F(y) + \epsilon G(y, \tau/\epsilon, \epsilon) \tag{1.1}$$

with new independent variable τ. While the subsystem

$$y' = F(y) \tag{1.2}$$

of the family (1.1) in these new coordinates no longer depends on the perturbation parameter, and is therefore regular, the singular nature of the perturbation is reflected in system (1.1) by rapid oscillations of the perturbation term in the slow time.

If the subsystem (1.2) has a normally hyperbolic invariant torus, then a small C^1 perturbation will also have a normally hyperbolic invariant torus by the general persistence theorems mentioned above. However, in the full system (1.1), the perturbation is not defined at $\epsilon = 0$. Also, we note that the perturbation is not C^1 small. In fact, the partial derivative with respect to τ can be large relative to ϵ. Thus, the usual persistence theory does not apply directly. To overcome this difficulty we will use the idea introduced by Kopell [8] of embedding the system into an auxiliary family given by

$$y' = F(y) + \delta G(y, \tau/\epsilon, \epsilon). \tag{1.3}$$

If $\epsilon > 0$ is fixed and $\delta > 0$ is sufficiently small, then, by the usual persistence theory, the system (1.3) has a normally hyperbolic invariant manifold. We will show that if $\epsilon > 0$ is sufficiently small, then this normally hyperbolic invariant manifold can be continued in this family to $\delta = \epsilon$.

The plan of the paper is as follows. In section 2, a description of the origin of the model system that we will study is given. In section 3 we discuss some previous work by Kopell [8] on the continuation problem for system (1.3). A conceptual gap in this work will be described. Also, we will present the general method for continuation that is used in this paper. The statement of our main theorem on the existence of invariant tori is in section 4, and the remaining sections of the paper are devoted to its proof.

2. A periodically perturbed oscillator. In this section we will briefly describe the origin of the explicit perturbation problem that we will study; see [2] for more details.

Consider a periodically perturbed planar oscillator given by

$$\dot{u} = f(u) + \epsilon g(u, t), \tag{2.1}$$

where, for each $u \in \mathbb{R}^2$, the function $t \mapsto g(u, t)$ is $2\pi/\Omega$ periodic and ϵ is a small parameter. Let us assume that the unperturbed system

$$\dot{u} = f(u) \tag{2.2}$$

is Hamiltonian and it has a regular period annulus $\mathcal{A}$, that is, an annulus consisting entirely of periodic orbits such that the associated period function is regular. Also, for each point ζ in the domain of definition of the system (2.1), let $t \mapsto u(t, \zeta, \epsilon)$ denote the solution of (2.1) with the initial condition $u(0, \zeta, \epsilon) = \zeta$.

A periodic orbit Γ in $\mathcal{A}$ with period T is called resonant if there are relatively prime positive integers m and n such that

$$m\frac{2\pi}{\Omega} = nT. \tag{2.3}$$

If Γ is a resonant periodic orbit and $p \in \Gamma$, then the associated (subharmonic) Melnikov function is given by

$$M^{m:n}(\phi) := \int_0^{m2\pi/\Omega} f(u(t,p,0)) \wedge g(u(t,p,0), t-\phi)\, dt. \tag{2.4}$$

From a geometric point of view, the sign of the Melnikov function on a resonant orbit determines the "drift direction" for perturbed orbits. If, for example, the Melnikov function has a fixed sign, then perturbed orbits drift away from the vicinity of the resonant orbit in a direction determined by this sign; while if the Melnikov function has a simple zero, then there is a nearby perturbed periodic orbit; see [5], [9], [11].

If the Melnikov function vanishes identically on a resonant orbit, then a reasonable expectation is that the corresponding unperturbed torus in the phase cylinder, corresponding to the unperturbed resonant orbit, persists under the perturbation. If the perturbation is dissipative, then the perturbed invariant torus is an attractor. The presence of this attractor is often one of the dominant features of the global dynamics: perturbed orbits are entrained to this torus. Thus, the existence of invariant tori is an important consideration in the analysis of the global dynamics of the system. However, as we will see, the proof of the existence of an attracting invariant torus in this context requires additional hypotheses as well as a delicate perturbation analysis.

To study the dynamics of differential (2.1) near a resonant periodic orbit, it is convenient to consider the system in action angle coordinates. In fact, there is a smooth change of coordinates in a neighborhood of the resonant orbit such that the differential (2.1), in the new coordinates (I, ϑ), has the form

$$\dot{I} = \epsilon F(I,\vartheta,t), \quad \dot{\vartheta} = \omega(I) + \epsilon G(I,\vartheta,t), \tag{2.5}$$

where both F and G are 2π periodic in ϑ and $2\pi m/\Omega$ periodic in t. In these coordinates, the resonant orbit is given by $\{(I,\vartheta) : I = I_0\}$, where

$$m\frac{2\pi}{\Omega} = n\frac{2\pi}{\omega(I_0)}. \tag{2.6}$$

A "normal form" for system (2.5) with $\epsilon > 0$ at the resonant orbit is obtained by using the coordinate transformation

$$I = I_0 + \sqrt{\epsilon}\,\ell, \qquad \vartheta = \omega(I_0)t + \sigma,$$

followed by the Taylor expansion of the resulting vector field to third order in powers of $\sqrt{\epsilon}$. The transformed system

$$\begin{aligned}
\dot{\ell} =& \sqrt{\epsilon}\, F(I_0, \omega(I_0)t+\sigma, t) + \epsilon F_I(I_0, \omega(I_0)t+\sigma, t)\ell \\
&+ \epsilon^{3/2} F_{II}(I_0, \omega(I_0)t+\sigma, t)\ell^2 + O(\epsilon^2), \\
\dot{\sigma} =& \sqrt{\epsilon}\, \omega'(I_0)\ell + \epsilon\Big(G(I_0, \omega(I_0)t+\sigma, t) + \frac{1}{2}\omega''(I_0)\ell^2\Big) \\
&+ \epsilon^{3/2}\Big(G_I(I_0, \omega(I_0)t+\sigma, t)\ell + \frac{1}{6}\omega'''(I_0)\ell^3\Big) + O(\epsilon^2)
\end{aligned} \tag{2.7}$$

is in the "time periodic standard form," the correct form for averaging. Under the assumption that the Melnikov function vanishes on the resonant orbit, that is, the average of F in the new coordinates vanishes, there is an averaging transformation (slightly more general than the transformation used in [2] where the average of G is also assumed to vanish) such that the averaged system has the abstract form

$$\begin{aligned}\dot{\ell} &= \mu^2 p(\sigma)\ell + \mu^3\big(q(\sigma)\ell^2 + r(\sigma)\big) + \mu^4 \widehat{R}(\ell,\sigma,t,\mu),\\ \dot{\sigma} &= \mu\lambda\ell + \mu^2(\nu\ell^2 + g(\sigma)) + \mu^3\widehat{S}(\ell,\sigma,t,\mu),\end{aligned} \tag{2.8}$$

where p, q, r, and g are 2π periodic functions, λ, μ, and ν are real numbers, and both of the functions $\widehat{R}$ and $\widehat{S}$ are 2π periodic in σ and $2\pi/\Omega$ periodic in t. In fact, all of the functions appearing in the system (2.8) are identifiable in terms of the original vector field. Also, the new small parameter is defined by $\mu := \sqrt{\epsilon}$.

Let us rewrite system (2.8) as the autonomous system

$$\begin{aligned}\dot{\ell} &= \mu^2 p(\sigma)\ell + \mu^3\big(q(\sigma)\ell^2 + r(\sigma)\big) + \mu^4 \widehat{R}(\ell,\sigma,\varphi,\mu),\\ \dot{\sigma} &= \mu\lambda\ell + \mu^2(\nu\ell^2 + g(\sigma)) + \mu^3\widehat{S}(\ell,\sigma,\varphi,\mu),\\ \dot{\varphi} &= 1,\end{aligned} \tag{2.9}$$

where φ is a new angular variable modulo $2\pi m/\Omega$. Also, let us assume that the family is class C^∞. We will seek an invariant torus for system (2.9) as the graph of a periodic function $(\sigma,\varphi) \mapsto h(\sigma,\varphi)$; that is, h is 2π periodic in σ and $2\pi m/\Omega$ periodic in φ.

The Lyapunov–Perron method is used in [2] to prove the following theorem.

THEOREM 2.1. *Consider the differential* (2.9) *and define*

$$M := \min_{0\le\sigma\le 2\pi} |p(\sigma)| > 0.$$

If $g(\sigma) \equiv 0$, $\lambda \neq 0$,

$$5M > \operatorname{Lip}(p), \qquad M^2 \ge 6|\lambda|\|r\|_{0,1}, \tag{2.10}$$

and μ *is sufficiently small, then there is a periodic function* $h \in C^{0,1}$ *(supremum + Lipschitz norm) such that its graph* $\{(\ell,\sigma,t) : \ell = h(\sigma,t)\}$ *is an invariant torus for* (2.9).

Here, M is a measure of the minimum "normal contraction rate" and the inequality $M^2 \ge 6|\lambda|\|r\|_{0,1}$ is a sufficient condition to preclude "roll up" of the invariant manifold at a sink; see the example in [2, p. 63]. The inequality $5M > \operatorname{Lip}(p)$ does not seem to have a geometric interpretation; rather it arises from the technical estimates in the proof.

We note that Robinson and Murdock in [10] prove the existence of invariant tori for a differential equation similar to system (2.9). Their result concerns the continuation of certain nonresonant unperturbed tori in analytic systems.

3. Normal hyperbolicity and continuation. In this section we recall the definition of normal hyperbolicity and discuss the basic idea, introduced by Kopell [8], that we will use to continue invariant manifolds. While our continuation method applies to normally hyperbolic invariant manifolds with expanding and contracting normal directions, in this paper we discuss only the case of normally hyperbolic invariant manifolds with no unstable normal directions. In particular, when we use the phrase "normally hyperbolic" we will use it in this restricted sense.

Let us consider a smooth differential equation

$$\dot{x} = F(x), \qquad x \in \mathbb{R}^n$$

with flow ϕ^t that has an overflowing invariant manifold $\overline{M} = M \cup \partial M$. Also, let TM denote the tangent bundle of M, and, with respect to the usual inner product on $\mathbb{R}^n$, let N denote the bundle normal to TM over M. Then,

$$T_M\mathbb{R}^n = TM \oplus N,$$

and there is a natural orthogonal projection $\Pi : T_M\mathbb{R}^n \to N$. Recall that in this context (see [3]) there are operators

$$\begin{aligned} &A_t(p) := D\phi^{-t}(p)|_{T_pM} : T_pM \to T_{\phi^{-t}(p)}M, \\ &B_t(p) := \Pi_p D\phi^t(\phi^{-t}(p))|_{N_{\phi^{-t}(p)}} : N_{\phi^{-t}(p)} \to N_p, \end{aligned} \tag{3.1}$$

and Lyapunov-type numbers, introduced in [3], are assigned to each point $p \in M$ as follows:

$$\nu(p) := \limsup_{t\to\infty} \|B_t(p)\|^{1/t}, \qquad \sigma(p) := \limsup_{t\to\infty} \frac{\ln \|A_t(p)\|}{-\ln \|B_t(p)\|}. \tag{3.2}$$

The number $\nu(p)$ measures the "exponential of the normal contraction rate" while $\sigma(p)$ compares the normal and tangential contraction rates. Both of these numbers are constant on orbits. Moreover, the Lyapunov-type numbers of an orbit are dominated by the supremum of the Lyapunov-type numbers on its α-limit set. Thus, to prove that M is normally hyperbolic, it suffices to compute the type numbers on the limit sets of the flow that are contained in M. A basic persistence result of Fenichel [3] states that if for all $p \in M$, we have $\nu(p) < 1$ and $\sigma(p) < 1/k$ for some positive integer k, then the manifold M persists under small C^1 perturbations by C^k vector fields. Moreover, the perturbed manifold is C^k. Let us mention that M, with the hypotheses of Fenichel's theorem is called k-normally hyperbolic. We will also use an equivalent formulation of k-normal hyperbolicity introduced by Hirsch, Pugh, and Shub [7]. A specialization of their definition to our perturbation problem is given below in display (8.11).

The persistence results just mentioned are widely applicable. However, in the perturbation problem (1.1) mentioned in the introduction, the existence of an invariant manifold cannot be obtained by a direct application of these persistence results due to the singular nature of the perturbation terms. Also, in the setting of the auxiliary family (1.3), the persistence result does not guarantee the existence of an invariant manifold up to $\delta = \epsilon$. On the other hand, in combination with an appropriate continuation method, the full strength of the persistence theory can be exploited to study perturbation problems of this type.

The idea of the continuation method is simple. To describe it, let us consider the smooth family E^ϵ of differential equations

$$\dot{x} = f(x, \epsilon). \tag{3.3}$$

Suppose that E^0 has a k-normally hyperbolic invariant manifold $M(0)$, and we wish to know if there is a corresponding family $M(\epsilon)$ of k-normally hyperbolic invariant manifolds that can be continued to some preassigned value of ϵ, say, $\epsilon = 1$. In this case, we can proceed in the following manner: Define A to be the set of all ϵ in the unit interval such that, for all $\epsilon' \in [0, \epsilon]$, the corresponding system $E^{\epsilon'}$ has a k-normally hyperbolic invariant manifold $M(\epsilon')$, and then prove that A is nonempty, open, and closed. Because $M(0)$ is a k-normally hyperbolic invariant manifold for E^0, A is not empty. The fact that A is open follows from the general persistence theory. Thus, all that remains is to show that A is closed; that is, if ϵ_* is the supremum of A, then $\epsilon_* \in A$. This can be accomplished in two steps: Prove that the system E^{ϵ_*} has a C^1 invariant manifold; then, prove that this invariant manifold is k-normally hyperbolic. Since we have a family of k-normally hyperbolic invariant manifolds $M(\epsilon)$ defined for $\epsilon' \in [0, \epsilon_*)$, the first step can be proved by showing that these manifolds are realized as graphs of an equicontinuous family of C^1 functions. The C^k smoothness of the limit manifold is obtained as a consequence of the second step which can be proved by checking the definition of k-normal hyperbolicity.

Let us consider a general family of the form

$$\dot{x} = f(x, \epsilon) + \epsilon g(x, \epsilon),$$

where, for some $\delta_0 > 0$, the system $\dot{x} = f(x, \delta)$ has a normally hyperbolic invariant manifold for $0 < \delta \leq \delta_0$. Kopell [8] studies a model equation that can be viewed as a special case of this family. To apply the general continuation method just described, she introduces an auxiliary family, which in our more general context would be

$$\dot{x} = f(x, \delta) + \epsilon g(x, \epsilon).$$

For this auxiliary system, if $\delta \in (0, \delta_0)$, then there is some $\epsilon(\delta) > 0$ such that, for $0 \leq \epsilon < \epsilon(\delta)$, the corresponding member of the auxiliary family has a normally hyperbolic invariant manifold $M(\delta, \epsilon)$. The idea is to fix some $\delta > 0$ sufficiently small so that continuation of normally hyperbolic invariant manifolds relative to the parameter ϵ can be carried out all the way to $\epsilon = \delta$. If this continuation is possible, then the member of the original family corresponding to $\epsilon = \delta$ has an invariant manifold.

In [8] (see also Wiggins [12, pp. 168–170]), a continuation theorem is stated for a family of the type described above, but of a more special form. However, the strategy of the proof of this theorem contains a gap. To describe the gap it is not necessary to consider the precise form of the equations or the hypotheses of the theorem. Rather, we will explain the problem in a general framework. Indeed, let us consider the parameter space of a family of differential equations and the subspace $\mathcal{N}$ corresponding to family members with a normally hyperbolic invariant manifold. Suppose that a path in $\mathcal{N}$ approaches the boundary of $\mathcal{N}$. Also, consider the supremum of each of the Lyapunov-type numbers ν and σ taken individually over the orbits of each normally hyperbolic invariant manifold in a continuous family. It is perhaps natural to suspect that the limit of at least one of these suprema converges to the number 1 as the path approaches the boundary. In other words, one might assume that the normal hyperbolicity is lost at the boundary only in this manner. However, this is not always the case. In fact, there may be paths for which the corresponding continuous family of normally hyperbolic invariant manifolds has both Lyapunov-type numbers uniformly bounded below one but the family of invariant manifolds does not converge to a C^1 manifold. Thus, in a continuation argument, it is required to prove that smooth invariant manifolds exist over the entire continuation interval and that all these manifolds are normally hyperbolic. The following example clearly shows why both requirements must be satisfied.

Consider a planar system

$$\dot{x} = f(x)$$

with a homoclinic loop at a hyperbolic saddle p whose eigenvalues α and β are such that $\alpha+\beta < 0$. In particular, the loop will be stable from the inside and the divergence of the vector field f at p is negative. Now add a one parameter family of perturbations $g(x,\epsilon)$ so that for $-1 < \epsilon < 0$ there is a limit cycle $\Gamma(\epsilon)$ that limits on the loop as ϵ approaches zero from the left and such that there is no limit cycle for $\epsilon > 0$. If we view $\Gamma(\epsilon)$ as an invariant manifold, then the corresponding Lyapunov-type number $\sigma(\epsilon)$ is identically zero. Also, the Lyapunov-type number $\nu(\epsilon)$ of $\Gamma(\epsilon)$ is exactly its Floquet multiplier; that is,

$$\nu(\epsilon) = e^{\frac{1}{T(\epsilon)}\int_0^{T(\epsilon)} \operatorname{div} f(\gamma(t,\epsilon))\, dt},$$

where $t \mapsto \gamma(t,\epsilon)$ is a periodic solution corresponding to the limit cycle and $T(\epsilon)$ is its period. Since the periodic solution spends most of its time near the hyperbolic saddle point, the Lyapunov-type number $\nu(\epsilon)$ approaches $e^{\alpha+\beta}$ as $\epsilon \to 0^-$. In particular, both Lyapunov-type numbers are bounded above by some number that is strictly less than one. But, the limit of the hyperbolic limit cycles is the nonsmooth homoclinic loop. Thus, in general, it is not enough to obtain uniform estimates on the Lyapunov-type numbers to ensure that a family of normally hyperbolic invariant manifolds can be continued.

4. Statement of main result. In this section we will state the continuation theorem that will be proved in this paper.

To obtain an invariant manifold for system (2.9) using a perturbation argument, it is useful to have an unperturbed system with an invariant manifold. As given, system (2.9), even after rescaling time, is degenerate in the limit as μ approaches zero. To remedy this problem, we will change coordinates and also rescale time so as to obtain a suitable perturbation problem.

Let us suppose that $\mu \neq 0$. Introduce new coordinates $\ell = \mu\hat{\rho}$, $\tau = \mu^2\varphi$, and a slow time $s = \mu^2 t$, and note that system (2.9) is equivalent to the system

$$\begin{aligned} \hat{\rho}' &= p(\sigma)\hat{\rho} + r(\sigma) + \mu^2 q(\sigma)\hat{\rho}^2 + \mu\widehat{R}(\mu\hat{\rho},\sigma,\tau/\mu^2,\mu),\\ \sigma' &= \lambda\hat{\rho} + g(\sigma) + \mu^2\nu\hat{\rho}^2 + \mu\widehat{S}(\mu\hat{\rho},\sigma,\tau/\mu^2,\mu),\\ \tau' &= 1, \end{aligned} \tag{4.1}$$

where the symbol “ $'$ ” denotes differentiation with respect to s. Let us also use the new coordinate $\rho := \lambda\hat{\rho} + g(\sigma)$ to express system (4.1) in the form

$$\begin{aligned} \rho' &= \Delta(\sigma)\rho + \Lambda(\sigma) + \mu R(\rho,\sigma,\tau/\mu^2,\mu),\\ \sigma' &= \rho + \mu S(\rho,\sigma,\tau/\mu^2,\mu),\\ \tau' &= 1, \end{aligned} \tag{4.2}$$

where

$$\Lambda(\sigma) := \lambda r(\sigma) - p(\sigma)g(\sigma), \qquad \Delta(\sigma) := p(\sigma) + g'(\sigma), \tag{4.3}$$

and the functions R and S are 2π periodic in σ and $2\pi m\mu^2/\Omega$ periodic in τ.

Let us write $\sigma \in \mathbb{S}^1$ to indicate that σ is an angular variable in the interval $0 \leq \sigma \leq 2\pi$ with the end points identified. Also, we will use the following hypothesis.

Hypothesis 1. *For each $\sigma \in \mathbb{S}^1$, $\Lambda(\sigma) \neq 0$ and $\Delta(\sigma) < 0$.*

Theorem 4.1. *If $k \geq 2$ is an integer, Hypothesis* 1 *holds, and $|\mu| > 0$ is sufficiently small, then system* (4.2) *has a k-normally hyperbolic invariant torus.*

We note that the k-normal hyperbolicity of the invariant torus in the conclusion of Theorem 4.1 implies that the invariant torus is C^k; see [7]. Also, as an immediate corollary of Theorem 4.1—just reverse the direction of time—the same conclusion holds under the assumption that, for each $\sigma \in \mathbb{S}^1$, $\Lambda(\sigma) \neq 0$ and $\Delta(\sigma) > 0$. Also, if we assume that $g(\sigma) \equiv 0$, as in Theorem 2.1 and if we assume that r has no zeros as in Hypothesis 1, then Theorem 4.1 is a generalization of Theorem 2.1. Indeed, the inequalities required in Theorem 2.1 are all replaced by the requirement that p has no zeros.

Finally, we mention that Theorem 4.1 is not valid if Hypothesis 1 is modified to allow the function Λ to have zeros. In fact, to obtain an analogue of Theorem 4.1 in case Λ has zeros, additional restrictions must be imposed. The formulation of the "right" hypotheses needed to prove an analogue of Theorem 4.1 in this case remains an interesting open problem.

The main idea of our proof of Theorem 4.1 is to view system (4.2) as a perturbation of the system

$$\begin{aligned} \rho' &= \Delta(\sigma)\rho + \Lambda(\sigma), \\ \sigma' &= \rho, \\ \tau' &= 1 \end{aligned} \tag{4.4}$$

and to show that the unperturbed system (4.4) has a normally hyperbolic invariant torus that continues to an invariant torus for system (4.2). We also note that the invariant torus for system (4.4) is the suspension of a normally hyperbolic invariant (simple closed) curve for the system

$$\begin{aligned} \rho' &= \Delta(\sigma)\rho + \Lambda(\sigma), \\ \sigma' &= \rho. \end{aligned} \tag{4.5}$$

5. Existence of an invariant curve. In this section we will prove that the unperturbed system (4.5) has a normally hyperbolic invariant curve. More precisely, we have the following theorem.

Theorem 5.1. *If Hypothesis* 1 *holds, then the system* (4.5) *has a C^∞ normally hyperbolic invariant simple closed curve given as the graph of a C^∞ function of the angular variable.*

There are several ways to prove Theorem 5.1. For example, a positively invariant annulus can be constructed, and the existence of a limit cycle can be proved using the Poincaré–Bendixson theorem. While the proof given below is more involved, it serves to illustrate the continuation technique that will be used in our proof of the existence of an invariant torus for system (4.1).

Our idea is to find a family of systems that includes system (4.5), to find a member of the family that has a normally hyperbolic invariant manifold, and then to continue this manifold through the family to the system (4.5).

Let us consider the family

$$\begin{aligned} \rho' &= \Delta(\sigma)\rho + \epsilon\Lambda(\sigma), \\ \sigma' &= \rho. \end{aligned} \tag{5.1}$$

We will use the next obvious lemma.

Lemma 5.2. *If Hypothesis* 1 *holds and* $\epsilon > 0$*, then system* (5.1) *has no rest point.*

Theorem 5.1 is an immediate consequence of the following lemma.

Lemma 5.3. *If Hypothesis* 1 *holds for system* (4.5)*, then system* (5.1) *has a* C^∞ *normally hyperbolic invariant curve that is given as the graph of a* C^∞ *function of the angular variable for all* $\epsilon \in [0, 1]$.

Proof. By Hypothesis 1, the function Λ does not vanish. Without loss of generality, we will assume that $\Lambda(\sigma) > 0$ for all σ. Also, by Hypothesis 1, the curve given by $\{(\rho, \sigma) : \rho = 0\}$ is a normally hyperbolic invariant manifold for the member of the family (5.1) at $\epsilon = 0$. Following the strategy discussed in section 3 let us consider the set A of all ϵ in the closed unit interval such that for all $\epsilon' \in [0, \epsilon]$ the corresponding member of the family (5.1) has a normally hyperbolic invariant closed curve γ^ϵ given as the graph of a C^∞ function h^ϵ of the angular variable. We will show that A is nonempty, open, and closed. This implies $A = [0, 1]$.

Because the invariant curve given by $\{(\rho, \sigma) : \rho = 0\}$ is normally hyperbolic for the family member at $\epsilon = 0$, we have that $0 \in A$ and therefore A is not empty. The fact that A is open follows from the persistence results for normally hyperbolic invariant manifolds. Let us define $\epsilon_* = \sup A$. To complete the proof we will show that $\epsilon_* \in A$; that is, A is closed.

Consider the family of curves

$$\Gamma(\kappa) := \{(\rho, \sigma) \in \mathbb{R}^2 : \rho - \kappa\Lambda(\sigma) = 0\},$$

where $\kappa \in \mathbb{R}$. Note that the curve $\Gamma(\kappa)$ is the graph of a periodic function of the angular variable. Thus, it separates the phase cylinder given by $(\rho, \sigma) \in \mathbb{R} \times \mathbb{S}^1$. Moreover, on $\Gamma(\kappa)$, by a straightforward computation, it follows that the dot product of the gradient of the function $(\rho, \sigma) \mapsto \rho - \kappa\Lambda(\sigma)$ and the vector field corresponding to the differential equation E^ϵ is given by

$$\left(-\kappa^2\Lambda'(\sigma) + \kappa\Delta(\sigma) + \epsilon\right)\Lambda(\sigma). \tag{5.2}$$

For $\epsilon \in [\epsilon_*/2, \epsilon_*)$, there exists $\kappa_0 > 0$ such that the coefficient of $\Lambda(\sigma)$ in (5.2) with $\kappa = \kappa_0$ is positive for all σ. Hence, the vector field corresponding to E^ϵ is transverse to the curve $\Gamma(\kappa_0)$. Because the function Λ is positive, it follows that γ^ϵ lies above the curve $\Gamma(\kappa_0)$; that is, $h^\epsilon(\sigma) > \kappa_0\Lambda(\sigma)$. Similarly, if $\nu \in \mathbb{R}$ is sufficiently large, then γ^ϵ lies below the curve $\{(\rho, \sigma) : \rho = \nu\}$. In particular, the set of functions $\mathcal{S} := \{h^\epsilon : \epsilon \in [\epsilon_*/2, \epsilon_*)\}$ is uniformly bounded.

Using the invariance, the function h^ϵ satisfies the differential equation

$$h^\epsilon_\sigma(\sigma) = \Delta(\sigma) + \epsilon\frac{\Lambda(\sigma)}{h^\epsilon(\sigma)}. \tag{5.3}$$

Thus, we have that $|h^\epsilon_\sigma| \leq |\Delta(\sigma)| + \epsilon_*/\kappa_0$ uniformly for $\epsilon \in [\epsilon_*/2, \epsilon_*)$, and, as a result, the set $\mathcal{S}$ is equicontinuous in the C^0 norm. By Arzela's theorem, there is a subsequence that converges to a continuous function h^{ϵ_*}.

We claim that the graph of h^{ϵ_*} is an invariant set for E^{ϵ_*}. To prove the claim, let $s \mapsto (\rho^\epsilon(s, q), \sigma^\epsilon(s, q))$ denote the solution of E^ϵ such that $\sigma^\epsilon(0, q) = q$ and $\rho^\epsilon(0, q) = h^\epsilon(q)$, and let us suppose that h^{ϵ_n} converges to h^{ϵ_*}. If $s \in \mathbb{R}$, then, using the continuity of the flow with respect to parameters, we have that $\sigma^{\epsilon_n}(s, q) \to \sigma^{\epsilon_*}(s, q)$ and $\rho^{\epsilon_n}(s, q) \to \rho^{\epsilon_*}(s, q)$. By passing to the limit as $n \to \infty$ in the identity

$\rho^{\epsilon_n}(s,q) = h^{\epsilon_n}(\sigma^{\epsilon_n}(s,q))$, we have $\rho^{\epsilon_*}(s,q) = h^{\epsilon_*}(\sigma^{\epsilon_*}(s,q))$. Thus, it follows that the graph of h^{ϵ_*} is an invariant set for E^{ϵ_*}. Because this invariant set is a single orbit of the differential equation, it is C^∞. Moreover, because the function Δ is everywhere negative, this invariant set is normally hyperbolic—it is a hyperbolic limit cycle. □

6. An a priori estimate for perturbed manifolds. The following proposition, which perhaps has independent interest, will play a key role in our proof of Theorem 4.1. While the statement of this proposition is natural, we do not know if it appears in the literature. Thus, we will give a complete proof in the appendix.

PROPOSITION 6.1. *Consider a smooth planar vector field*

$$x' = f(x) \tag{6.1}$$

with a periodic solution $t \mapsto x(t,p)$ of period ω corresponding to the periodic orbit Γ. If Γ is hyperbolic and asymptotically stable, that is,

$$b := \int_0^\omega \operatorname{tr} Df(x(t,p))\,dt < 0,$$

then there exist a neighborhood N of Γ and a constant $C > 0$ such that for every smooth function $g : N \to \mathbb{R}^2$ for which the differential equation

$$x' = f(x) + g(x) \tag{6.2}$$

has an invariant set $\bar{\Gamma} \subset N$, we have the following a priori estimate:

$$\sup\{d(x,\Gamma) : x \in \bar{\Gamma}\} \le C\|g\|_{C^0},$$

where $\|g\|_{C^0}$ is the supremum norm over N and d denotes the usual distance between sets.

PROPOSITION 6.2. *Consider a planar differential equation*

$$x' = f(x)$$

with a hyperbolic limit cycle Γ of period $T > 0$, and let τ be an angular variable modulo T. If Γ is asymptotically stable, then there is a neighborhood $N \subset \mathbb{R}^2 \times \mathbb{R}$ of the corresponding invariant torus M for the system

$$x' = f(x), \qquad \tau' = 1$$

and a constant $C > 0$ such that for every smooth function $g : N \to \mathbb{R}^2$, with $g(x, \tau + T) = g(x,\tau)$ for each $x \in \mathbb{R}^2$ and all $\tau \in \mathbb{R}$, and for which the system

$$x' = f(x) + g(x,\tau), \qquad \tau' = 1$$

has an invariant set $\bar{M} \subset N$, we have the a priori estimate

$$\sup\{d(x,M) : x \in \bar{M}\} \le C\|g\|_{C^0}.$$

7. Existence of invariant tori. In this section we will state our result on the existence of an invariant torus for the systems (2.9) and (4.2) as well as the main lemmas that we will use to prove it. In fact, we will prove the existence of invariant tori for systems of the more general form

$$\begin{aligned} \rho' &= f(\rho,\sigma) + \mu R(\rho,\sigma,\tau/\mu^2,\mu),\\ \sigma' &= g(\rho,\sigma) + \mu S(\rho,\sigma,\tau/\mu^2,\mu),\\ \tau' &= 1, \end{aligned} \tag{7.1}$$

where $|\mu| > 0$, where f, g, R, and S (redefined for this section) are all C^r functions that are 2π-periodic functions of the angular variable σ, and where the functions $t \mapsto R(\rho,\sigma,t,\mu)$ and $t \mapsto S(\rho,\sigma,t,\mu)$ are $2\pi m/\Omega$-periodic. For system (7.1), we view τ as an angular variable modulo $2\pi m\mu^2/\Omega$ and we let s denote the independent variable. Note that the slow time system (4.1) equivalent to system (2.9) is a special case of the differential (7.1). For a general discussion of integral manifolds for nonautonomous systems, see [1], [6].

To state our main result for system (7.1), let us consider the corresponding unperturbed system

$$\rho' = f(\rho,\sigma), \qquad \sigma' = g(\rho,\sigma), \tag{7.2}$$

and the following hypothesis.

HYPOTHESIS 2. *System* (7.2) *has an attracting hyperbolic limit cycle* Γ *that is the graph of a function of the angular variable* σ*.*

THEOREM 7.1. *If k is an integer such that $2 \le k \le r$ and the system* (7.2) *satisfies Hypothesis* 2*, then, for sufficiently small* $|\mu| > 0$*, system* (7.1) *has a k-normally hyperbolic invariant manifold that is the graph of a function of the angular variables σ and τ.*

The proof of Theorem 7.1 is given in the remaining sections of this paper using the lemmas that are stated below. Let us note at this point that it suffices to prove Theorem 7.1 for the case $\mu > 0$. The result for $\mu < 0$ follows from the first case by redefining the functions R and S in an obvious manner. Thus, we will consider only the case $\mu > 0$.

Let us consider the auxiliary family $E^{\epsilon,\mu}$ given by

$$\begin{aligned} \rho' &= f(\rho,\sigma) + \epsilon R(\rho,\sigma,\tau/\mu^2,\mu),\\ \sigma' &= g(\rho,\sigma) + \epsilon S(\rho,\sigma,\tau/\mu^2,\mu),\\ \tau' &= 1. \end{aligned} \tag{7.3}$$

Note that, by our assumption, the suspended system

$$\begin{aligned} \rho' &= f(\rho,\sigma),\\ \sigma' &= g(\rho,\sigma),\\ \tau' &= 1, \end{aligned} \tag{7.4}$$

where τ is viewed as a new angular variable modulo $2\pi m\mu^2/\Omega$, has a normally hyperbolic torus that is a graph over the two angular variables σ and τ. For our analysis we will consider the torus as a submanifold of the phase cylinder $\mathcal{C}$ given by $(\rho,\sigma,\tau) \in \mathbb{R}^3$, where σ and τ are viewed as the angular variables defined above. Topologically, $\mathcal{C}$ is the product of the real line with a two-dimensional torus.

For each $\mu > 0$, let us denote by A^μ the maximal interval with left endpoint at $\epsilon = 0$ such that the system $E^{\epsilon,\mu}$ has a k-normally hyperbolic invariant manifold, $k \geq 2$, as defined in [7]; see also display (8.11), given as the graph of a C^k function of the angular variables. Using the continuation strategy outlined in section 3, let us note that, for each $\mu > 0$, the set A^μ contains a nonempty relatively open interval with left endpoint $\epsilon = 0$. Moreover, if $\epsilon \in A^\mu$, then, by the general persistence results for normally hyperbolic invariant manifolds, there is an open interval containing ϵ that is contained in A^μ. Thus, Theorem 7.1 is an immediate consequence of the following proposition.

PROPOSITION 7.2. *Suppose that $\mu > 0$ and A^μ is the maximal interval with left endpoint at $\epsilon = 0$ such that the system $E^{\epsilon,\mu}$ has a k-normally hyperbolic invariant manifold, $k \geq 2$, that is the graph of a C^k function of the angular variables. If $\mu > 0$ is sufficiently small and if $\epsilon_* \leq \mu$ is the least upper bound of a relatively open interval with left endpoint $\epsilon = 0$ in A^μ, then $\epsilon_* \in A^\mu$.*

Proposition 7.2 is a consequence of the following three lemmas.

LEMMA 7.3. *With the hypotheses and notation of Proposition* 7.2*, the system $E^{\epsilon_*,\mu}$ has an invariant manifold $M(\epsilon_*, \mu)$ given as the graph of a C^1 function of the angular variables.*

LEMMA 7.4. *If $M(\epsilon_*, \mu)$ is the invariant manifold in Lemma* 7.3*, then it has an invariant normal bundle.*

LEMMA 7.5. *If $M(\epsilon_*, \mu)$ is the invariant manifold in Lemma* 7.3*, then $M(\epsilon_*, \mu)$ is k-normally hyperbolic. In particular, $M(\epsilon_*, \mu)$ is C^k and $\epsilon_* \in A^\mu$.*

8. Notation and preliminary results.

Lemmas (7.3)–(7.5) will be proved in the following sections. In this section we will define new notation and obtain some preliminary results that will be used in all three proofs. For the remainder of this section let us assume that $\mu > 0$ and $\epsilon \geq 0$ are fixed, and that system (7.3) has a normally hyperbolic invariant torus $M := M(\epsilon, \mu)$ given as the graph of the C^1 function h^ϵ of the angular variables.

8.1. Normal splitting and variational solutions.

The general results for normally hyperbolic invariant manifolds give the existence of an invariant splitting of $T_M\mathcal{C}$, the tangent bundle of the phase cylinder $\mathcal{C}$ restricted to this normally hyperbolic invariant torus, as a direct sum of the tangent bundle of the invariant torus M and an invariant normal bundle.

For notational convenience, let us define new functions

$$\begin{aligned} F(\rho, \sigma, \tau, \mu, \epsilon) &:= f(\rho, \sigma) + \epsilon R(\rho, \sigma, \tau/\mu^2, \mu), \\ G(\rho, \sigma, \tau, \mu, \epsilon) &:= g(\rho, \sigma) + \epsilon S(\rho, \sigma, \tau/\mu^2, \mu), \end{aligned} \tag{8.1}$$

and let us suppose that the invariant torus $M(\epsilon, \mu)$ is given as the graph of the function $(\sigma, \tau) \mapsto h^\epsilon(\sigma, \tau)$.

The vector field

$$\mathcal{X}_1^\epsilon(\sigma, \tau) := \begin{pmatrix} F(h^\epsilon(\sigma, \tau), \sigma, \tau, \mu, \epsilon) \\ G(h^\epsilon(\sigma, \tau), \sigma, \tau, \mu, \epsilon) \\ 1 \end{pmatrix} \tag{8.2}$$

is clearly tangent to $M(\epsilon, \mu)$. Also, as is easily seen by computing the tangents to each curve on $M(\epsilon,\mu)$ given by $\sigma \mapsto (h^\epsilon(\sigma,\tau),\sigma,\tau)$ for some fixed τ, the vector field

$$\mathcal{X}_2^\epsilon(\sigma,\tau) := \begin{pmatrix} h_\sigma^\epsilon(\sigma,\tau) \\ 1 \\ 0 \end{pmatrix} \tag{8.3}$$

is tangent to $M(\epsilon,\mu)$. Moreover, if $\xi = (h^\epsilon(\sigma,\tau),\sigma,\tau)$, then $\mathcal{X}_1^\epsilon(\sigma,\tau)$ and $\mathcal{X}_2^\epsilon(\sigma,\tau)$ span the corresponding fiber $T_\xi M(\epsilon,\mu)$ of the tangent bundle of $M(\epsilon,\mu)$.

To determine the contraction rates for the flow on the invariant torus $M(\epsilon,\mu)$, we must consider the solutions of the first variational equation for the system (7.3). If

$$s \mapsto \gamma^\epsilon(s,q) := (h^\epsilon(\sigma^\epsilon(s,q),\tau(s)),\sigma^\epsilon(s,q),\tau(s)) \tag{8.4}$$

is the solution of the system (7.3) with $\gamma^\epsilon(0,q) = (h^\epsilon(q,0),q,0)$, then the variational equation along the solution $s \mapsto \gamma^\epsilon(s,q)$ is given by

$$\begin{pmatrix} u' \\ v' \\ w' \end{pmatrix} \begin{pmatrix} F_\rho & F_\sigma & F_\tau \\ G_\rho & G_\sigma & G_\tau \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} u \\ v \\ w \end{pmatrix}, \tag{8.5}$$

where the argument of each function in the system matrix is given by

$$(h^\epsilon(\sigma^\epsilon(s,q),\tau(s)),\sigma^\epsilon(s,q),\tau(s),\mu,\epsilon). \tag{8.6}$$

Proposition 8.1. *The variational* (8.5) *along the solution* (8.4) *on the invariant torus* $M(\epsilon,\mu)$ *has two independent solutions given by*

$$X_1(s) := \mathcal{X}_1^\epsilon(\gamma^\epsilon(s,q)), \qquad X_2(s) := y^\epsilon(s,q)\mathcal{X}_2^\epsilon(\gamma^\epsilon(s,q)), \tag{8.7}$$

where

$$y^\epsilon(t,q) := \exp\left(\int_0^t (G_\rho h_\sigma^\epsilon + G_\sigma)\,ds\right) \tag{8.8}$$

and the argument of F and G is given in display (8.6)*. Moreover, $X_1(s)$ and $X_2(s)$ span the tangent space of the invariant torus at each point along the solution* (8.4)*.*

Proof. The solution $X_1(s)$ is just the evaluation of the vector field corresponding to the base differential (7.3) along one of its integral curves. Thus, as is well known, it is a solution of the variational equation.

To obtain the second solution, let us recall that the invariant torus is given as a graph over the angular variables. In particular, the differential equation expressed in the corresponding local coordinates—the projection $(\rho,\sigma,\tau) \mapsto (\sigma,\tau)$ restricted to the graph is the coordinate map—is given by

$$\sigma' = G(h^\epsilon(\sigma,\tau),\sigma,\tau,\mu,\epsilon), \quad \tau' = 1.$$

The corresponding variational equation has the form

$$v' = (G_\rho h_\sigma^\epsilon + G_\sigma)v + (G_\rho h_\tau^\epsilon + G_\tau)w, \quad w' = 0.$$

One of its solutions is given by

$$s \mapsto (v(s),w(s)) = (y^\epsilon(s,q),0).$$

As $\rho = h^\epsilon(\sigma,\tau)$ on the invariant torus, the corresponding solution of the variational equation in the original coordinates is given by $y^\epsilon(s,q)\mathcal{X}_2^\epsilon(\gamma^\epsilon(s,q))$—substitute the general base solution into the local coordinate representation and then differentiate with respect to the initial condition.

In view of the fact that $\mathcal{X}_1^\epsilon$ and $\mathcal{X}_2^\epsilon$ are independent at each point of the manifold, and by virtue of the fact that y^ϵ is a positive function, the two solutions $X_1(s)$ and $X_2(s)$ are independent at each point along the solution γ^ϵ. □

Let $\Phi^\epsilon(s)$ denote the principal fundamental matrix solution of the variational equation (8.5) at $s = 0$. By the general theory of normally hyperbolic invariant manifolds, there is a normal bundle over the invariant torus M that is invariant under $\Phi^\epsilon(s)$. Because, M has codimension one, the fiber dimension of the normal bundle is one. Also, let us consider the family of cylinders given by

$$\mathcal{L}^s := \{(\rho,\sigma,\tau) : \tau = s\},$$

and note that $\mathcal{L} := \cup\{\mathcal{L}^s : s \in \mathbb{R}\}$ is a foliation of the phase cylinder that is invariant under the flow of system (7.3). Thus, it follows that $\mathcal{L}$ is also invariant for the variational equation, or equivalently, it is invariant under $\Phi^\epsilon(s)$. Because of the invariance of this foliation and the normal hyperbolicity, the fiber of the invariant normal bundle must be tangent to the leaf of this foliation that passes through the base point of the fiber. Also, the normal bundle of the embedded torus is trivial. Thus, it has a continuous nonzero section $\mathcal{X}_0^\epsilon$. Let us define

$$X_0(s) := \mathcal{X}_0^\epsilon(\gamma^\epsilon(s,q)), \tag{8.9}$$

where γ^ϵ is the solution defined in display (8.4). We remark here that the invariant normal bundle is required only to be continuous. In fact, in general it is not smooth.

To determine the growth rates required for the normal hyperbolicity, let us define

$$\lambda_1(s) := \frac{|X_1(s)|}{|X_1(0)|}, \quad \lambda_2(s) := \frac{|X_2(s)|}{|X_2(0)|}, \quad \lambda_3(s) := \frac{|\Phi^\epsilon(s)X_0(0)|}{|X_0(0)|}. \tag{8.10}$$

If k is a positive integer, then the invariant torus $M(\epsilon,\mu)$ is k-normally hyperbolic, as defined in [7], provided that there are numbers $\beta > 0$ and $c > 0$ independent of the choice of the solution on $M(\epsilon,\mu)$ such that the following conditions are satisfied for $s \geq 0$:

$$\lambda_3(s) \leq ce^{-\beta s}, \quad \frac{\lambda_3(s)}{\lambda_1^k(s)} \leq ce^{-\beta s}, \quad \frac{\lambda_3(s)}{\lambda_2^k(s)} \leq ce^{-\beta s}. \tag{8.11}$$

8.2. A formula for $\boldsymbol{\lambda_3(s)}$. The vector function $s \mapsto X_2(s)$ defined in display (8.7) is a solution of the system (8.5). Define

$$X_2^\perp(s) := \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} X_2(s),$$

and note that there are smooth functions $s \mapsto a(s)$ and $s \mapsto b(s)$ such that

$$\Phi^\epsilon(s)X_2^\perp(0) = a(s)X_2(s) + b(s)X_2^\perp(s).$$

Moreover, it is not difficult to compute the following formulas:

$$\begin{aligned} b(s) &= \frac{|X_2(0)|^2}{|X_2(s)|^2} \exp\left(\int_0^s \operatorname{tr} B(t)\,dt\right),\\ a'(s) &= \frac{b(s)}{|X_2(s)|^2}(\langle B(s)X_2(s), X_2^{\perp}(s)\rangle + \langle B(s)X_2^{\perp}(s), X_2(s)\rangle),\\ a(0) &= 0, \end{aligned} \tag{8.12}$$

where $B(s)$ is the system matrix of the linear system (8.5).

By the above remarks, the vector $X_0(s)$ is in the span of the linearly independent vectors $X_2(s)$ and $X_2^{\perp}(s)$. Thus, by an appropriate choice of the nonzero normal bundle section $\mathcal{X}_0^{\epsilon}$, there is a smooth function $s \mapsto \alpha(s)$ such that

$$X_0(s) = \alpha(s)X_2(s) + X_2^{\perp}(s) \tag{8.13}$$

and a smooth function $s \mapsto \lambda(s)$ such that

$$\Phi^{\epsilon}(s)X_0(0) = \lambda(s)X_0(s). \tag{8.14}$$

By substitution of the identity (8.13) into (8.14) and by using the independence of X_2 and $X_2^{\perp}$, it follows that $\lambda(s)\alpha(s) = \alpha(0) + a(s)$ and $\lambda(s) = b(s)$. Hence, using the definition given in display (8.10), and the formulas obtained in this section, we have the following equalities:

$$\begin{aligned} \lambda_3(s) = \lambda(s)\frac{|X_0(s)|}{|X_0(0)|} &= \left(\frac{|X_2(0)|^2}{|X_2(s)|^2} \exp\left(\int_0^s \operatorname{tr} B(t)\,dt\right)\right) \frac{(\alpha^2(s)+1)^{1/2}|X_2(s)|}{(\alpha^2(0)+1)^{1/2}|X_2(0)|}\\ &= \frac{|X_2(0)|}{|X_2(s)|}\left(\frac{\alpha^2(s)+1}{\alpha^2(0)+1}\right)^{1/2} \exp\left(\int_0^s \operatorname{tr} B(t)\,dt\right). \end{aligned} \tag{8.15}$$

8.3. Derivative estimates. Under the assumptions that $\mu > 0$ and the unperturbed system (7.2) have a normally hyperbolic invariant manifold given as a graph of a function of the angular variables, we know that $E^{\epsilon,\mu}$, for sufficiently small $\epsilon > 0$, has a normally hyperbolic invariant manifold given as the graph of a function h^{ϵ} of the angular variables. In this section, we will determine some a priori estimates on the size of the derivatives of h^{ϵ}. We will first state and prove two lemmas. The first reduces the main estimate from the vector to the scalar case, while the second lemma gives certain properties of an operator equation for one of the derivatives that must be estimated.

8.3.1. A reduction lemma. The next lemma shows that it suffices to estimate the partial derivative h_{σ} on a Poincaré section.

LEMMA 8.2. *Suppose that $\mu > 0$ and $\epsilon_* > 0$ and that $E^{\epsilon,\mu}$ has an invariant manifold given as the graph of the function h^{ϵ} of the angular variables for $0 \le \epsilon < \epsilon_* \le \mu$. If there is a constant $C_1 > 0$ such that, for all angles σ and τ, the following estimates hold:*

$$|h^{\epsilon}(\sigma,\tau) - h^0(\sigma,\tau)| < C_1\epsilon, \qquad |h^{\epsilon}_{\sigma}(\sigma,0) - h^0_{\sigma}(\sigma,0)| < C_1\epsilon,$$

then for μ sufficiently small there is a constant $C_2 > 0$ such that

$$|h^{\epsilon}_{\sigma}(\sigma,\tau) - h^0_{\sigma}(\sigma,\tau)| < C_2\epsilon.$$

Proof. Let us suppose first that $\dot{x} = F(x, \epsilon)$ is a smooth family of differential equations. If x^ϵ and x^0 are solutions of the members of this family corresponding to their superscripts, then by an application of Gronwall's inequality there is a constant $K > 0$ such that

$$|x^\epsilon(t) - x^0(t)| < K e^{K|t|}(|x^\epsilon(0) - x^0(0)| + \epsilon|t|). \tag{8.16}$$

Let $s \mapsto \phi(s, (\rho, \sigma, \tau), \epsilon)$ be the solution of the system $E^{\epsilon,\mu}$ with the initial condition $\phi(0, (\rho, \sigma, \tau), \epsilon) = (\rho, \sigma, \tau)$, and note that the solution γ^ϵ defined in display (8.4) is given by $\gamma^\epsilon(s, q) = \phi(s, (h^\epsilon(q, 0), q, 0), \epsilon)$. For each pair of angles p and τ with $0 \le \tau < 2\pi m\mu^2/\Omega$, there is a unique angle q^ϵ defined by the equation

$$(h^\epsilon(q^\epsilon, 0), q^\epsilon, 0) = \phi(-\tau, (h^\epsilon(p, \tau), p, \tau), \epsilon). \tag{8.17}$$

By an application of the inequality (8.16) to the family of solutions (8.17), if μ is sufficiently small, then there is a constant $K_1 > 0$, that does not depend on the choice of τ, such that

$$\begin{aligned} |h^\epsilon(q^\epsilon, 0) - h^0(q^0, 0)| + |q^\epsilon - q^0| &\le K_1(|h^\epsilon(p, \tau) - h^0(p, \tau)| + \epsilon) \\ &\le K_1(C_1 + 1)\epsilon. \end{aligned} \tag{8.18}$$

In particular, there is a constant $K_2 > 0$ such that

$$|q^\epsilon - q^0| \le K_2\epsilon. \tag{8.19}$$

By inverting the flow in (8.17), we have that $\gamma^\epsilon(\tau, q^\epsilon) = (h^\epsilon(p, \tau), p, \tau)$. Using an obvious modification of the notation as well as the result of Proposition 8.1, let us consider the first variational equation for $E^{\epsilon,\mu}$ along the solution $s \mapsto \gamma^\epsilon(s, q^\epsilon)$ and the solution of this variational equation that is given by

$$X_2^\epsilon(s, q^\epsilon) = y^\epsilon(s, q^\epsilon) \begin{pmatrix} h_\sigma^\epsilon(\sigma^\epsilon(s, q^\epsilon), \tau(s)) \\ 1 \\ 0 \end{pmatrix}.$$

Note that its initial condition and its value at $s = \tau$ are given by

$$X_2^\epsilon(0, q^\epsilon) = \begin{pmatrix} h_\sigma^\epsilon(q^\epsilon, 0) \\ 1 \\ 0 \end{pmatrix}, \qquad X_2^\epsilon(\tau, q^\epsilon) = y^\epsilon(\tau, q^\epsilon) \begin{pmatrix} h_\sigma^\epsilon(p, \tau) \\ 1 \\ 0 \end{pmatrix}.$$

By an application of the inequality (8.16) to this family of solutions of the variational equation, if μ is sufficiently small, then there is a constant $K_2 > 0$ such that

$$\begin{aligned} |y^\epsilon(\tau, q^\epsilon)h_\sigma^\epsilon(p, \tau) &- y^0(\tau, q^0)h_\sigma^0(p, \tau)| + |y^\epsilon(\tau, q^\epsilon) - y^0(\tau, q^0)| \\ &\le K_2(|h_\sigma^\epsilon(q^\epsilon, 0) - h_\sigma^0(q^0, 0)| + \epsilon) \\ &\le K_2(|h_\sigma^\epsilon(q^\epsilon, 0) - h_\sigma^0(q^\epsilon, 0)| + |h_\sigma^0(q^\epsilon, 0) - h_\sigma^0(q^0, 0)| + \epsilon). \end{aligned}$$

Moreover, by the hypothesis of the lemma, by inequality (8.19), and by the fact that h_σ^0 is Lipschitz, we have that there is a constant $K_3 > 0$ such that

$$|y^\epsilon(\tau, q^\epsilon)h_\sigma^\epsilon(p, \tau) - y^0(\tau, q^0)h_\sigma^0(p, \tau)| + |y^\epsilon(\tau, q^\epsilon) - y^0(\tau, q^0)| \le K_3\epsilon. \tag{8.20}$$

In particular, both summands on the left-hand side of the last inequality are bounded above by $K_3\epsilon$.

By a reverse triangle law estimate starting with the fact that the quantity

$$|(y^\epsilon(\tau,q^\epsilon)h^\epsilon_\sigma(p,\tau)-y^\epsilon(\tau,q^\epsilon)h^0_\sigma(p,\tau))-(y^0(\tau,q^0)h^0_\sigma(p,\tau)-y^\epsilon(\tau,q^\epsilon)h^0_\sigma(p,\tau))|$$

is bounded above by $K_3\epsilon$, by the inequality (8.20), and the fact that h^0_σ is uniformly bounded, we find that there is a constant $K_4>0$ such that

$$|y^\epsilon(\tau,q^\epsilon)||h^\epsilon_\sigma(p,\tau)-h^0_\sigma(p,\tau)|\le K_3\epsilon+|h^0_\sigma(p,\tau)||y^\epsilon(\tau,q^\epsilon)-y^0(\tau,q^0)|\le K_4\epsilon. \tag{8.21}$$

By a second reverse triangle law estimate, we have that

$$|y^\epsilon(\tau,q^\epsilon)|=|y^0(\tau,q^0)+(y^\epsilon(\tau,q^\epsilon)-y^0(\tau,q^0))|\ge|y^0(\tau,q^0)|-K_3\mu.$$

Also, if we take $\mu>0$ sufficiently small, then there is a constant $K_5>0$ such that $|y^\epsilon(\tau,q^\epsilon)|>K_5$. The result follows from this fact and the inequality (8.21). □

8.3.2. The estimates. Some of the most important estimates that are required for the proof of our main result are given in the next lemma.

LEMMA 8.3. *Suppose Hypothesis* 2 *holds for the unperturbed system* (7.2). *There is a number* $\mu>0$ *and a constant* $C>0$ *such that if* ϵ_* *is as in Proposition* 7.2, *then*

$$|h^\epsilon-h^0|_{C^0}<C\epsilon,\quad |h^\epsilon_\sigma-h^0_\sigma|_{C^0}\le C\epsilon,\quad |h^\epsilon_\tau|_{C^0}\le C\epsilon$$

for $0\le\epsilon<\epsilon_*$.

Proof. We will show that, if $\mu>0$ is sufficiently small, then there is a constant $C>0$ such that $|h^\epsilon_\sigma-h^0_\sigma|_{C^0}\le C\epsilon$. By Lemma 8.2, it suffices to find a constant $C>0$ such that, for all $q\in\mathbb{S}^1$,

$$|h^\epsilon_\sigma(q,0)-h^0_\sigma(q,0)|\le C\epsilon.$$

To prove this inequality, let us recall Proposition 8.1, and note that the function given by $s\mapsto(h^\epsilon_\sigma(\sigma^\epsilon(s,q),\tau(s))y^\epsilon(s,q),y^\epsilon(s,q))$ is a solution of the "subsystem" of system (8.5) given by

$$\begin{aligned}u'&=(f_\rho+\epsilon R_\rho)u+(f_\sigma+\epsilon R_\sigma)v,\\ v'&=(g_\rho+\epsilon S_\rho)u+(g_\sigma+\epsilon S_\sigma)v.\end{aligned}\tag{8.22}$$

If $\Psi^\epsilon(s,q):=(\psi^\epsilon_{ij}(s,q))_{2\times2}$ is the principal fundamental matrix solution of (8.22) at $s=0$, then

$$\begin{pmatrix}h^\epsilon_\sigma(\sigma^\epsilon(s,q),\tau(s))y^\epsilon(s,q)\\ y^\epsilon(s,q)\end{pmatrix}=\Psi^\epsilon(s,q)\begin{pmatrix}h^\epsilon_\sigma(q,0)\\ 1\end{pmatrix}.$$

Therefore, we have

$$h^\epsilon_\sigma(\sigma^\epsilon(s,q),\tau(s))=\frac{\psi^\epsilon_{11}(s,q)h^\epsilon_\sigma(q,0)+\psi^\epsilon_{12}(s,q)}{\psi^\epsilon_{21}(s,q)h^\epsilon_\sigma(q,0)+\psi^\epsilon_{22}(s,q)}.\tag{8.23}$$

Because the second angular argument τ will often be set to $\tau=0$, in the remainder of the proof we will suppress the second argument in expressions involving the functions h^ϵ and their partial derivatives whenever $\epsilon>0$ and the second angular argument is set to $\tau=0$. In addition, the function h^0 is constant with respect to τ;

thus we will always suppress its second angular argument and write h^0 as a function of the first angular variable only.

If $s \mapsto (\rho(s), \sigma(s))$ is a solution of the unperturbed system

$$\rho' = f(\rho, \sigma), \qquad \sigma' = g(\rho, \sigma),$$

then the vector function

$$s \mapsto (f(h^0(\sigma), \sigma), g(h^0(\sigma), \sigma))$$

is a solution of the corresponding variational equation (8.22) with $\epsilon = 0$. Using the fact that $\rho(s) = h^0(\sigma(s))$ on the invariant manifold, and differentiating with respect to s, we find that

$$f(h^0(\sigma(s)), \sigma(s)) = h^0_\sigma(\sigma(s))g(h^0(\sigma(s)), \sigma(s)).$$

Thus, the function $s \mapsto (h^0_\sigma(\sigma(s))g(h^0(\sigma(s)), \sigma(s)), g(h^0(\sigma(s)), \sigma(s)))$ is a solution of the variational equation. Using the fundamental matrix solution Ψ^ϵ defined after display (8.22), we find that

$$\psi^0_{21}(s,q)h^0_\sigma(q) + \psi^0_{22}(s,q) = \frac{g(h^0(\sigma(s,q)), \sigma(s,q))}{g(h^0(q), \sigma(q))}.$$

In view of the hypothesis that σ' does not vanish, there is a number $M_0 > 0$ such that $|\psi^0_{21}(s,q)h^0_\sigma(q) + \psi^0_{22}(s,q)| \geq M_0$ for every $s \in \mathbb{R}$ and $q \in \mathbb{S}^1$.

By hypothesis, the unperturbed normally hyperbolic invariant manifold for $E^{0,\mu}$ is the suspension of an attracting hyperbolic limit cycle. In particular, the characteristic multiplier of the limit cycle is negative. Using the fact that the determinant of the fundamental matrix solution of the variational equation is proportional to the exponential of the integral of the divergence of the vector field evaluated along the limit cycle, it follows that there is some $T_0 > 0$ such that, for $t \geq T_0$, we have the inequality $\det \Psi^0(t,q) \leq (1/4)M_0^2$. If, in addition, $0 < \mu^2 < \Omega/(2\pi m)$, then there is a positive integer n such that $T_0 \leq 2\pi m n\mu^2/\Omega < T_0 + 1$. For definiteness, let $n = n(\mu)$ denote the smallest such integer, and define

$$T := T(\mu) = 2\pi m n \mu^2/\Omega. \tag{8.24}$$

While T will vary as $\mu > 0$ is made sufficiently small so that new requirements are satisfied, the final value of T is an integer multiple of the period of the perturbation terms in the corresponding differential equation $E^{\epsilon,\mu}$, the value of T is bounded above and below, and T approaches T_0 as μ decreases toward zero.

If we set $s = T$ in (8.23), then

$$h^\epsilon_\sigma(p) = \frac{\psi^\epsilon_{11}(T,q^\epsilon)h^\epsilon_\sigma(q^\epsilon) + \psi^\epsilon_{12}(T,q^\epsilon)}{\psi^\epsilon_{21}(T,q^\epsilon)h^\epsilon_\sigma(q^\epsilon) + \psi^\epsilon_{22}(T,q^\epsilon)}, \tag{8.25}$$

where q^ϵ is defined by the relation

$$p = \sigma^\epsilon(T, q^\epsilon). \tag{8.26}$$

Choose a bounded neighborhood N of the graph of h^0 and the corresponding constant $C_0 > 0$ as in Proposition 6.2. Also, choose $r_0 > 0$ so small that if $|h^\epsilon - h^0|_{C^0} < r_0$, then the graph of h^ϵ is in N, and note that

$$K := \sup\left\{|R(\rho, \sigma, \tau/\mu^2, \mu)| + |S(\rho, \sigma, \tau/\mu^2, \mu)| : (\rho, \sigma, \tau) \in N,\ 0 < \mu^2 < \frac{\Omega}{2\pi m}\right\}$$

is finite—the functions R and S are the perturbation terms of the system $E^{\epsilon,\mu}$ in display (7.3).

Choose $r > 0$ sufficiently small so that, for $T_0 \leq T < T_0 + 1$,

$$|d_{21}\xi + d_{22}| > \frac{2}{3}M_0, \qquad |\det D - \det \Psi^0(T, q)| < \frac{1}{8}M_0^2 \tag{8.27}$$

whenever ξ, a real number, D, a 2×2 real matrix, and $q \in \mathbb{S}^1$ are such that

$$|\xi - h^0_\sigma(q)| < r, \qquad |D - \Psi^0(T, q)| < r.$$

The existence of r with the required properties follows from the continuity of the map $(u, v, w) \mapsto |uv + w|$, the continuity of the determinant function, and the compactness of $\mathbb{S}^1$.

If we choose $\mu > 0$ so small that $0 < \mu^2 < \Omega/2\pi m$ and $C_0 K\mu < r_0$, then, by Proposition 6.2,

$$|h^\epsilon - h^0|_{C^0} < C_0 K\epsilon \tag{8.28}$$

as long as $|h^\epsilon - h^0|_{C^0} < r_0$. Thus, we have that the inequality (8.28) holds for $0 \leq \epsilon < \epsilon_*$. Also, by an application of the Gronwall estimate (8.16) applied to the solutions $\gamma^\epsilon(-s, p)$ and $\gamma^0(-s, p)$ defined in display (8.4), we find that there is a constant $C_1 > 0$ such that

$$|h^\epsilon(q^\epsilon) - h^0(q^0)| + |q^\epsilon - q^0| \leq C_1(|h^\epsilon(p) - h^0(p)| + \epsilon).$$

In view of the estimate in display (8.28), we conclude that there is a constant $C_2 > 0$ such that $|q^\epsilon - q^0| \leq C_2\epsilon$. By an application of the estimate (8.16) to the solutions $s \mapsto \Psi^\epsilon(s, q^\epsilon)$ and $s \mapsto \Psi^0(s, q^0)$ of the variational equation, we have, for some $C_3 > 0$, the inequality

$$|\Psi^\epsilon(T, q^\epsilon) - \Psi^0(T, q^0)| \leq C_3(|q^\epsilon - q| + \epsilon).$$

To obtain the estimates in the statement of the lemma, we will first prove the following claim.

Claim. There exists a constant $C > 0$ such that, for $0 \leq \epsilon < \epsilon_*$, if $|h^\epsilon_\sigma - h^0_\sigma|_{C^0} \leq r$, then $|h^\epsilon_\sigma - h^0_\sigma|_{C^0} \leq C\epsilon$.

Proof of claim. Fix $p \in \mathbb{S}^1$, and let q^ϵ be as in (8.26). Using this notation and the identity (8.25), we have

$$\begin{aligned}|h^\epsilon_\sigma(p) - h^0_\sigma(p)| \leq{}& \left|\frac{\psi^\epsilon_{11}(T, q^\epsilon)h^\epsilon_\sigma(q^\epsilon) + \psi^\epsilon_{12}(T, q^\epsilon)}{\psi^\epsilon_{21}(T, q^\epsilon)h^\epsilon_\sigma(q^\epsilon) + \psi^\epsilon_{22}(T, q^\epsilon)} - \frac{\psi^\epsilon_{11}(T, q^\epsilon)h^0_\sigma(q^\epsilon) + \psi^\epsilon_{12}(T, q^\epsilon)}{\psi^\epsilon_{21}(T, q^\epsilon)h^0_\sigma(q^\epsilon) + \psi^\epsilon_{22}(T, q^\epsilon)}\right| \\ &+ \left|\frac{\psi^\epsilon_{11}(T, q^\epsilon)h^0_\sigma(q^\epsilon) + \psi^\epsilon_{12}(T, q^\epsilon)}{\psi^\epsilon_{21}(T, q^\epsilon)h^0_\sigma(q^\epsilon) + \psi^\epsilon_{22}(T, q^\epsilon)} - \frac{\psi^0_{11}(T, q^0)h^0_\sigma(q^0) + \psi^0_{12}(T, q^0)}{\psi^0_{21}(T, q^0)h^0_\sigma(q^0) + \psi^0_{22}(T, q^0)}\right| \\ :={}& I + II.\end{aligned}$$

To estimate the quantities I and II, let us consider, for real numbers ξ and 2×2 matrices $D = (d_{ij})$, the function $u : \mathbb{R} \times \mathbb{R}^4 \to \mathbb{R}$ defined by

$$u(\xi, D) = \frac{d_{11}\xi + d_{12}}{d_{21}\xi + d_{22}}.$$

Using this function, we have

$$\begin{aligned} I &= |u(y, \Psi^\epsilon(T, q^\epsilon)) - u(x, \Psi^\epsilon(T, q^\epsilon))|, \\ II &= |u(x, \Psi^\epsilon(T, q^\epsilon)) - u(z, \Psi^0(T, q^0))|, \end{aligned}$$

where $x := h^0_\sigma(q^\epsilon)$, $y := h^\epsilon_\sigma(q^\epsilon)$, and $z := h^0_\sigma(q)$.

To estimate I, apply the mean value theorem to the function $\xi \mapsto u(\xi, D)$ and use the fact that

$$u_\xi(\xi, D) = \frac{\det D}{d_{21}\xi + d_{22}}$$

to obtain the inequality

$$I \le \left|\frac{\det \Psi^\epsilon(T, q^\epsilon)}{\psi^\epsilon_{21}(T, q^\epsilon)\xi + \psi^\epsilon_{22}(T, q^\epsilon)}\right| |h^\epsilon_\sigma(q^\epsilon) - h^0_\sigma(q^\epsilon)|$$

for some ξ between $h^\epsilon_\sigma(q^\epsilon)$ and $h^0_\sigma(q^\epsilon)$. Let us note that $|\xi - h^0_\sigma(q^\epsilon)| < r$. Also, if $\mu > 0$ is sufficiently small, then $|\Psi^\epsilon(T, q^\epsilon) - \Psi^0(T, q^0)|_{C^0} < r$. Thus, if we use the inequalities (8.27) together with a triangle law estimate for the term containing the determinant, then we find that $I \le \lambda |h^\epsilon_\sigma - h^0_\sigma|_{C^0}$ for $\lambda = 27/32 < 1$.

To estimate II, let us note that the function u is Lipschitz on the set

$$\{(\xi, D) : \xi = h^0_\sigma(q),\ D = \Psi^\epsilon(T, q),\ q \in \mathbb{S}^1,\ 0 \le \epsilon < \epsilon^*\}.$$

In particular, there is a constant $L_1 > 0$ such that

$$II \le L_1(|h^0_\sigma(q^\epsilon) - h^0_\sigma(q^0)| + |\Psi^\epsilon(T, q^\epsilon) - \Psi^0(T, q^0)|).$$

Using the fact that h^0 is Lipschitz on $\mathbb{S}^1$, we conclude that there exist constants $L > 0$ and $C_4 > 0$ such that

$$II \le L(|q^\epsilon - q^0| + |\Psi^\epsilon(T, q^\epsilon) - \Psi^0(T, q^0)|) \le C_4\epsilon.$$

Thus,

$$|h^\epsilon_\sigma(p) - h^0_\sigma(p)| \le C_4\epsilon + \lambda|h^\epsilon_\sigma(q) - h^0_\sigma(q)| \le C_4\epsilon + \lambda|h^\epsilon_\sigma - h^0_\sigma|_{C^0},$$

and, as a result,

$$|h^\epsilon_\sigma - h^0_\sigma|_{C^0} \le \frac{C_4}{1-\lambda}\epsilon.$$

This completes the proof of the claim.

In addition to the restrictions on the size of μ already made, let us also require that $\mu < r/C$, where C is the constant appearing in the claim. Define

$$\epsilon_0 = \sup\{\epsilon' : 0 \le \epsilon' < \epsilon_*,\ |h^\epsilon_\sigma - h^0_\sigma|_{C^0} \le r \text{ for } \epsilon \in [0, \epsilon']\}.$$

We will show that $\epsilon_0 = \epsilon_*$. Suppose not, then $\epsilon_0 < \epsilon_*$. For $\epsilon < \epsilon_0$, $|h^\epsilon_\sigma - h^0_\sigma|_{C^0} \le r$ and, hence, $|h^\epsilon_\sigma - h^0_\sigma|_{C^0} \le C\epsilon$ by the claim. Since $\epsilon_0 < \epsilon_*$, the graph of h^{ϵ_0} is normally hyperbolic by the definition of ϵ_*. Passing to the limit as $\epsilon \to \epsilon_0$, we have $|h^{\epsilon_0}_\sigma - h^0_\sigma|_{C^0} \le C\epsilon_0 < r$. This contradicts the fact that ϵ_0 is the supremum; hence $\epsilon_0 = \epsilon_*$. Now, by the claim, we conclude that $|h^\epsilon_\sigma - h^0_\sigma|_{C^0} \le C\epsilon$ for $0 \le \epsilon < \epsilon_*$.

Let us now estimate h^ϵ_τ. Note first that the invariance of the graph of the function h^ϵ is equivalent to the identities

$$\begin{aligned} h^\epsilon_\sigma \sigma' + h^\epsilon_\tau &= f(h^\epsilon, \sigma) + \epsilon R(h^\epsilon, \sigma, \tau/\mu^2, \mu), \\ \sigma' &= g(h^\epsilon, \sigma) + \epsilon S(h^\epsilon, \sigma, \tau/\mu^2, \mu). \end{aligned} \tag{8.29}$$

If we suppose that $h^\epsilon(\sigma, \tau) = h^0(\sigma) + \epsilon H(\sigma, \tau, \epsilon)$ and substitute this expression into the relation (8.29), then we obtain the equation

$$\begin{aligned} &(g(h^0 + \epsilon H, \sigma) + \epsilon S(h^0 + \epsilon H, \sigma, \tau/\mu^2, \mu))H_\sigma + H_\tau \\ &\qquad = \frac{1}{\epsilon}(f(h^0 + \epsilon H, \sigma) - h^0_\sigma g(h^0 + \epsilon H, \sigma)) - h^0_\sigma S + R. \end{aligned}$$

Finally, using the estimate

$$|H_\sigma|_{C^0} = \frac{1}{\epsilon}|h^\epsilon_\sigma - h^0_\sigma|_{C^0} \le C_1$$

and the relation $f(h^0, \sigma) = h^0_\sigma g(h^0, \sigma)$, we conclude that there is a constant $C > 0$, that is independent of ϵ, such that $|H_\tau|_{C^0} \le C$; that is, $|h^\epsilon_\tau|_{C^0} \le C\epsilon$. □

Let us note that we will eventually have to verify estimates as in display (8.11). As a step in this direction, let us first consider λ_3 and note, from the formula (8.15), that the growth estimate requires an asymptotic estimate of the norm of $X_2(s)$. By the definition of $X_2(s)$, it is clear that this norm estimate is determined by the behavior of the function $s \mapsto y^\epsilon(s, q)$ defined in display (8.8). To determine this behavior, we must estimate the integral

$$\int_0^s (G_\rho h^\epsilon_\sigma + G_\sigma)\, dt. \tag{8.30}$$

The precise integral estimate that we will require is the content of the next lemma.

Lemma 8.4. *If, for all $s \ge 0$, the function $s \mapsto G(h^\epsilon(\sigma(s), \tau(s)), \sigma(s), \tau(s), \epsilon)$ has no zeros, and if $\mu > 0$ is sufficiently small, then there is a constant $C > 0$ such that*

$$y^\epsilon(s, q) = \exp\left(\int_0^s (G_\rho h^\epsilon_\sigma + G_\sigma)\, dt\right) \ge e^{-C} e^{-C\epsilon s}.$$

Proof. Note that

$$\begin{aligned} \frac{d}{ds} \ln |G(h^\epsilon(\sigma(s), \tau(s)), \sigma(s), \tau(s), \epsilon)| &= \frac{1}{G}(G_\rho h^\epsilon_\sigma \sigma' + G_\rho h^\epsilon_\tau + G_\sigma \sigma' + G_\tau) \\ &= G_\rho h^\epsilon_\sigma + G_\sigma + \frac{G_\rho h^\epsilon_\tau}{G} + \frac{G_\tau}{G}. \end{aligned}$$

After integration over the interval $[0, s]$ and a rearrangement, we obtain the identity

$$\begin{aligned} \int_0^s (G_\rho h^\epsilon_\sigma + G_\sigma)\, dt = \ln \Big| &\frac{G(h^\epsilon(\sigma(s), \tau(s)), \sigma(s), \tau(s), \epsilon)}{G(h^\epsilon(\sigma(0), \tau(0)), \sigma(0), \tau(0), \epsilon)} \Big| \\ &- \int_0^s \frac{G_\rho h^\epsilon_\tau}{G}\, dt - \int_0^s \frac{G_\tau}{G}\, dt. \end{aligned} \tag{8.31}$$

Recall the definition (8.1) of G, and note that

$$\frac{d}{ds}\Big(\frac{S}{G}\Big) = \frac{S_\rho h^\epsilon_\sigma \sigma' + S_\rho h^\epsilon_\tau + S_\sigma \sigma' + \frac{1}{\mu^2} S_\tau}{G} \\ - \frac{S(G_\rho h^\epsilon_\sigma \sigma' + G_\rho h^\epsilon_\tau + G_\sigma \sigma' + \frac{\epsilon}{\mu^2} S_\tau)}{G^2}.$$

Using this identity and an easy computation, we find that

$$\begin{aligned}\int_0^s \frac{G_\tau}{G}\,dt &= \frac{\epsilon}{\mu^2}\int_0^s \frac{S_\tau}{G}\,dt \\ &= \epsilon\Big(\frac{S(h^\epsilon(\sigma(s),\tau(s)),\sigma(s),\tau(s),\epsilon)}{G(h^\epsilon(\sigma(s),\tau(s)),\sigma(s),\tau(s),\epsilon)} - \frac{S(h^\epsilon(\sigma(0),\tau(0)),\sigma(0),\tau(0),\epsilon)}{G(h^\epsilon(\sigma(0),\tau(0)),\sigma(0),\tau(0),\epsilon)}\Big) \\ &\quad - \epsilon\int_0^s \frac{S_\rho h^\epsilon_\sigma G + S_\rho h^\epsilon_\tau + S_\sigma G}{G}\,dt \\ &\quad + \epsilon\int_0^s \frac{S G_\rho h^\epsilon_\sigma G + S G_\rho h^\epsilon_\tau + S G_\sigma G}{G^2}\,dt + \frac{\epsilon^2}{\mu^2}\int_0^s \frac{S S_\tau}{G^2}\,d\tau.\end{aligned}\tag{8.32}$$

Note that, because their integrands are bounded, all terms except the last one on the right-hand side of the final equality of display (8.32) are $O(\epsilon)$. To estimate the last term, let us differentiate the function S^2/G^2 with respect to s, and rearrange the resulting identity, to obtain the following expression:

$$\frac{S S_\tau}{G^2} = \frac{\mu^2}{2}\frac{d}{ds}\Big(\frac{S^2}{G^2}\Big) - \mu^2 S\frac{S_\rho h^\epsilon_\sigma G + S_\rho h^\epsilon_\tau + S_\sigma G}{G^2} \\ + \mu^2 S^2 \frac{G_\rho h^\epsilon_\sigma G + G_\rho h^\epsilon_\tau + G_\sigma G}{G^3} + \epsilon S^2 \frac{S_\tau}{G^3}.$$

If we integrate both sides of the last identity over the interval $[0, s]$, then all the integrands are bounded. In view of this fact and the inequality $\epsilon \le \mu$, it follows that

$$\frac{\epsilon^2}{\mu^2}\int_0^s \frac{S S_\tau}{G^2}\,dt = sO(\epsilon).$$

To estimate the term

$$\int_0^s \frac{G_\rho h^\epsilon_\tau}{G}\,dt$$

that appears in the expression (8.31) for the integral

$$\int_0^s (G_\rho h^\epsilon_\sigma + G_\sigma)\,dt,$$

use the inequality $|h^\epsilon_\tau|_{C^0} \le C\epsilon$ obtained in Lemma 8.3.

In summary, we have $|\int_0^s (G_\rho h^\epsilon_\sigma + G_\sigma)\,dt| \le C_1 + C_2\epsilon s$ for some constants $C_1 > 0$ and $C_2 > 0$ both independent of ϵ. □

LEMMA 8.5. *With the hypotheses of Lemma* 8.3, *if* $\mu > 0$ *is sufficiently small, then there is a constant* $C > 0$ *such that* $|h^\epsilon_{\sigma\sigma}|_{C^0} \le C$.

Proof. The proof of the lemma is similar to the proof of Lemma 8.3.

Recall that h^ϵ_σ satisfies the "fixed point equation" in display (8.23), and choose $\mu > 0$ sufficiently small so that $T(\mu)$ is as in the proof of Lemma 8.3. If we set $p = \sigma(T, q^\epsilon)$ and $s = T$, then we have the identity

$$h^\epsilon_\sigma(p) = \frac{\psi^\epsilon_{11}(T, q^\epsilon) h^\epsilon_\sigma(q^\epsilon) + \psi^\epsilon_{12}(T, q^\epsilon)}{\psi^\epsilon_{21}(T, q^\epsilon) h^\epsilon_\sigma(q^\epsilon) + \psi^\epsilon_{22}(T, q^\epsilon)}. \tag{8.33}$$

By a direct computation of the derivative of both sides of (8.33) with respect to p, we obtain

$$\begin{aligned} h^\epsilon_{\sigma\sigma}(p) = \frac{\frac{dq^\epsilon}{dp}}{(\psi^\epsilon_{21} h^\epsilon_\sigma(q^\epsilon) + \psi^\epsilon_{22})^2} \Bigg(& \left(\psi^\epsilon_{21} \frac{d}{dq} \psi^\epsilon_{11} - \psi^\epsilon_{11} \frac{d}{dq} \psi^\epsilon_{21}\right) (h^\epsilon_\sigma(q^\epsilon))^2 \\ & + \left(\psi^\epsilon_{22} \frac{d}{dq} \psi^\epsilon_{11} - \psi^\epsilon_{12} \frac{d}{dq} \psi^\epsilon_{21} + \psi^\epsilon_{21} \frac{d}{dq} \psi^\epsilon_{12} - \psi^\epsilon_{11} \frac{d}{dq} \psi^\epsilon_{22}\right) h^\epsilon_\sigma(q^\epsilon) \\ & + (\psi^\epsilon_{11} \psi^\epsilon_{22} - \psi^\epsilon_{12} \psi^\epsilon_{21}) h^\epsilon_{\sigma\sigma}(q^\epsilon) + \psi^\epsilon_{22} \frac{d}{dq} \psi^\epsilon_{12} \ - \psi^\epsilon_{12} \frac{d}{dq} \psi^\epsilon_{22} \Bigg), \end{aligned} \tag{8.34}$$

where the functions ψ^ϵ_{ij}, $i, j = 1, 2$, on the right-hand side of the equality are evaluated at (T, q^ϵ).

Using the identity $p = \sigma^\epsilon(T, q^\epsilon)$ and differentiating with respect to p, we have that $dq^\epsilon/dp = 1/\sigma^\epsilon_q(T, q^\epsilon)$. Moreover, using the solution (8.4) and Proposition 8.1, it is not difficult to see that $\sigma^\epsilon_q(T, q) = y^\epsilon(T, q)$, where, y^ϵ is defined in Proposition 8.1. If $\mu > 0$ is sufficiently small so that h^ϵ_σ is sufficiently close to h^0_σ, the matrix $\Psi^\epsilon(T, \cdot)$ is sufficiently close to $\Psi^0(T_0, \cdot)$, and the partial derivative Ψ^ϵ_q is uniformly bounded, then, for all q and all $T = T(\mu)$, we have

$$|\det \Psi^\epsilon(T, q)| < \frac{1}{4} M_0^2, \qquad |(\psi^\epsilon_{21}(T, q) h^\epsilon_\sigma(q) + \psi^\epsilon_{22}(T, q))^2| > \frac{1}{3} M_0,$$

where $M_0 > 0$ is the constant appearing in Lemma 8.3. Thus, using Lemma 8.4, the absolute value of the coefficient

$$\frac{\frac{dq^\epsilon}{dp}}{(\psi^\epsilon_{21} h^\epsilon_\sigma(q^\epsilon) + \psi^\epsilon_{22})^2} (\psi^\epsilon_{11} \psi^\epsilon_{22} - \psi^\epsilon_{12} \psi^\epsilon_{21}) \tag{8.35}$$

will be uniformly bounded less than one.

To estimate the supremum of $h_{\sigma\sigma}$, we proceed in the following order: We take the absolute value of each side of (8.34), apply the triangle law to the right-hand side, take the supremum of the right-hand side over q^ϵ, take the supremum of the left-hand side over p, move the term containing the norm of $h_{\sigma\sigma}$ on the right-hand side to the left-hand side, collect terms, and then divide both sides by the coefficient of the norm of $h_{\sigma\sigma}$. This coefficient is not zero because of the uniform bound on the absolute value of the quantity in display (8.35). Thus, we obtain a uniform bound on the norm of $h_{\sigma\sigma}$. □

9. Proof of Lemma 7.3. If $\mu > 0$ is chosen as in Lemma 8.3 and $\epsilon_* > 0$ is such that, for $0 \le \epsilon < \epsilon_*$, the system $E^{\epsilon,\mu}$ has a k-normally hyperbolic invariant manifold, $k \ge 2$, that is the graph of a C^k function h^ϵ of the angular variables, then, by Lemmas 8.3 and 8.5, the subset $\mathcal{S} := \{h^\epsilon : 0 \le \epsilon < \epsilon_*\}$ in the space of C^2 functions of the angular variables is uniformly bounded. As a result, the set $\mathcal{S}$ is equicontinuous in the C^1 norm. By Arzela's theorem, if we choose a sequence of real numbers increasing to the limit ϵ_*, then we can extract a subsequence $\{\epsilon_k\}$ such that the corresponding sequence $\{h^{\epsilon_k}\}$ converges to a C^1 function h^{ϵ_*}. An easy argument, as in Lemma 5.3, shows that the graph of h^{ϵ_*} is invariant under the flow of $E^{\epsilon_*,\mu}$, as required.

10. Proof of Lemma 7.4. If $\mu > 0$ is chosen as in Lemma 8.3, the number $\epsilon_* > 0$ is such that, for $0 \leq \epsilon < \epsilon_*$, the system $E^{\epsilon,\mu}$ has a k-normally hyperbolic invariant manifold that is the graph of a C^k function h^ϵ of the angular variables, and if $E^{\epsilon_*,\mu}$ has a C^1 invariant manifold $M(\epsilon_*, \mu)$ given as the graph of the function h^{ϵ_*} of the angular variables, then we must show that $M(\epsilon_*, \mu)$ has a continuous invariant normal bundle.

It suffices to construct a normal bundle over the curve

$$q \mapsto (h^{\epsilon_*}(q, 0), q, 0) \tag{10.1}$$

that is invariant with respect to some iterate of the stroboscopic linearized Poincaré map; that is, the map given by moving a point on the slice $\{(\rho, \sigma, \tau) : \tau = 0\}$ forward by the flow to time $2\pi m\mu^2/\Omega$. To prove this reduction, note that the linearized Poincaré map is two-dimensional at each point and that the tangent line to the invariant torus is invariant under the map. Also, for a two-dimensional linear map with an invariant line, if an iterate of the map has two distinct invariant lines, then so does the map. Finally, if there is a normal bundle over the curve, then a normal bundle over the torus is constructed by moving the vectors in the given normal bundle forward by the linearized flow.

We will construct a normal bundle over the curve (10.1). For this, let us consider the function space

$$\Gamma := \{\alpha : \mathbb{S}^1 \to \mathbb{R} : \alpha \in C^0\}.$$

Also, for $\alpha \in \Gamma$, let us define a vector at the point $(h^{\epsilon_*}(q, 0), q, 0)$ as follows:

$$X_0(q) := \alpha(q)X_2(q) + X_2(q)^\perp,$$

where $X_2(q) := \mathcal{X}_2(h^{\epsilon_*}(q, 0), q, 0)$. We will show that there is some choice for $\alpha \in \Gamma$ so that X_0 generates an invariant normal bundle over the curve (10.1).

If n is an integer, $T := 2\pi mn\mu^2/\Omega$, and $p = \sigma^{\epsilon_*}(T, q)$, then X_0 generates an invariant bundle if and only if

$$\lambda^{\epsilon_*}(T, q)X_0(p) = (\alpha(q) + a^{\epsilon_*}(T, q))X_2(p) + b^{\epsilon_*}(T, q)X_2(p)^\perp, \tag{10.2}$$

where λ^{ϵ_*}, a^{ϵ_*}, and b^{ϵ_*} are defined in subsection 8.2 for the system corresponding to ϵ_*. Using these definitions, we find that (10.2) holds if and only if

$$\alpha(p) = \frac{\alpha(q) + a^{\epsilon_*}(T, q)}{b^{\epsilon_*}(T, q)}.$$

Define $T < 0$ analogous to the definition in display (8.24) with the property that, for $0 \leq \epsilon < \epsilon_*$, there is some η such that

$$b^\epsilon(T) := \sup\{b^\epsilon(T, q) : q \in \mathbb{S}^1\} > \eta > 1.$$

Passing to the limit as ϵ approaches ϵ_* from below and using the fact that h^ϵ converges to h^{ϵ_*}, we find that

$$b^{\epsilon_*}(T) := \sup\{b^{\epsilon_*}(T, q) : q \in \mathbb{S}^1\} \geq \eta > 1.$$

Also, let us define $\Lambda : \Gamma \to \Gamma$ by

$$(\Lambda\alpha)(p) = \frac{\alpha(q) + a^{\epsilon_*}(T,q)}{b^{\epsilon_*}(T,q)}.$$

A fixed point of Λ corresponds to the desired invariant normal bundle. But, by a simple computation, we have the inequality

$$|(\Lambda\alpha_2)(p) - (\Lambda\alpha_1)(p)| \le \frac{1}{\eta}|\alpha_2(q) - \alpha_1(q)|.$$

Thus, Λ is a contraction on the complete metric space Γ and Λ has a unique fixed point, as required.

11. Proof of Lemma 7.5. We will show that the C^1 invariant manifold given as the graph of the function h^{ϵ_*} is k-normally hyperbolic under the assumption that this manifold has an invariant normal splitting. For this, we must verify the inequalities given in display (8.11).

Consider $\lambda_3(s)$, and recall formula (8.15). Let us suppose that a bounded neighborhood N as in Proposition 6.2 is chosen, the invariant tori are given by the graphs of the functions h^ϵ of the angular variables, and $\mu > 0$ is sufficiently small so that the invariant manifold given by h^{ϵ_*} is in N. Then, by Lemma 8.3, the functions h^ϵ satisfy the inequality

$$|h^\epsilon - h^0| < C\epsilon \tag{11.1}$$

for $0 \le \epsilon \le \epsilon_*$.

Let $s \to \gamma^{\epsilon_*}(s,q,\tau) = (h^{\epsilon_*}(\sigma^{\epsilon_*}(s,q,\tau), s+\tau), \sigma^{\epsilon_*}(s,q,\tau), s+\tau)$ be the solution of (7.3) corresponding to ϵ_* with the initial condition $(h^{\epsilon_*}(q,\tau), q, \tau)$, let B be the system matrix of the linearization of system (7.3) along the solution γ^ϵ, and note that

$$\operatorname{tr} B(\gamma^{\epsilon_*}(t,q,\tau)) = f_\rho + g_\sigma + \epsilon(R_\rho + S_\sigma).$$

Let ω be the minimal period of the periodic solution of the unperturbed system (7.2), let $(\bar{q}, \bar{\tau})$ be an arbitrary choice of the angular variables, and define

$$b := \int_0^\omega \operatorname{tr} B(\gamma^0(s,\bar{q},\bar{\tau}))\, ds.$$

The quantity b is a Floquet exponent of the periodic orbit that is independent of the choice of the angular variables. By an application of Gronwall's inequality (8.16), there is a constant $C_1 > 0$ such that, for $0 \le s \le \omega$,

$$|\gamma^{\epsilon_*}(s,\bar{q},\bar{\tau}) - \gamma^0(s,\bar{q},\bar{\tau})| \le C_1\epsilon_*.$$

Hence, there is a constant $C_2 > 0$ such that

$$|\operatorname{tr} B(\gamma^{\epsilon_*}(s,\bar{q},\bar{\tau})) - \operatorname{tr} B(\gamma^0(s,\bar{q},\bar{\tau}))| \le C_2\epsilon_*$$

and

$$\int_0^\omega \operatorname{tr} B(\gamma^{\epsilon_*}(s,\bar{q},\bar{\tau}))\, ds \le \int_0^\omega \operatorname{tr} B(\gamma^0(s,\bar{q},\bar{\tau}))\, ds + C_2\epsilon_*\omega = b + C_2\epsilon_*\omega.$$

An arbitrary $s \geq 0$ can be expressed in the form $s = \ell\omega + r$ with $0 \leq r < \omega$. Also, for $k = 1, 2, \dots, \ell$, let us define

$$q_k := \sigma^{\epsilon_*}(k\omega, q, \tau), \quad \tau_k := k\omega + \tau.$$

There are constants $C_3 > 0$ and $C_4 > 0$ such that

$$\begin{aligned}\int_0^s \operatorname{tr} B(\gamma^{\epsilon_*}(t, q, \tau))\, dt =& \sum_{k=0}^{\ell-1} \int_{k\omega}^{(k+1)\omega} \operatorname{tr} B(\gamma^{\epsilon_*}(t, q, \tau))\, dt \\ &+ \int_{\ell\omega}^{\ell\omega + r} \operatorname{tr} B(\gamma^{\epsilon_*}(t, q, \tau))\, dt \\ =& \sum_{k=0}^{\ell-1} \int_0^{\omega} \operatorname{tr} B(\gamma^{\epsilon_*}(t, q_k, \tau_k))\, dt \\ &+ \int_0^{r} \operatorname{tr} B(\gamma^{\epsilon_*}(t, q_\ell, \tau_\ell))\, dt \\ \leq& \ell(b + C_2\epsilon_*\omega) + C_3 \leq \left(\frac{b}{\omega} + C_2\epsilon_*\right) s + C_4.\end{aligned}$$

By Proposition 8.1 and Lemma 8.4, there are constants $C_5 > 0$ and $C_6 > 0$ such that

$$|X_2(s)| \geq C_6 e^{-\mu C_5 s}. \tag{11.2}$$

Also, by Lemma 7.4, the function α corresponding to the normal splitting at ϵ_* is bounded as a periodic function over the invariant manifold.

Taking the above estimates into account and using formula (8.15), there is a constant $c > 0$ such that $\lambda_3(s) \leq ce^{(\frac{b}{\omega} + c\mu)s}$. If, in addition, $\mu > 0$ is sufficiently small, then $-\beta := \frac{b}{\omega} + c\mu < 0$, and we have the desired estimate:

$$\lambda_3(s) \leq ce^{-\beta s} \tag{11.3}$$

for all $s \geq 0$.

The function $|X_1(s)|$ is uniformly bounded below, in fact $|X_1(s)| \geq 1$. Thus, if k is a positive integer, then using the estimate (11.3), there is some $c_1 > 0$ such that

$$\frac{\lambda_3(s)}{\lambda_1^k(s)} \leq c_1 e^{-\beta s}.$$

Using the estimates (11.2) and (11.3), we have that

$$\frac{\lambda_3(s)}{\lambda_1^k(s)} \leq \frac{c_1}{C_6^k} e^{-s(\beta - \mu k c_1)}.$$

Thus, if $\mu > 0$ is sufficiently small, there are constants $c_2 > 0$ and $\beta_1 > 0$ such that

$$\frac{\lambda_3(s)}{\lambda_2^k(s)} \leq c_2 e^{-\beta_1 s}.$$

Finally, using the general smoothness result in [7], it follows that the C^1 manifold given as the graph of h^{ϵ_*} with invariant splitting and with the hyperbolic estimates just proved is in fact a C^k manifold, as required.

12. Appendix.

In this appendix we will prove Propositions 6.1 and 6.2.

Proof of Proposition 6.1. We will construct a family of C^1 curves S_r^+ and S_r^-, $r \in (0,1]$ for system (6.1) such that the following properties are satisfied:

(i) The curves S_r^+ and S_r^- lie in the exterior and interior domains separated by Γ, respectively, and S_r^+ (resp., S_r^-) together with Γ encloses an annulus.

(ii) The curves S_r^+ and S_r^- are transverse to the vector field f.

(iii) There is a constant $C_0 > 0$ that is independent of r such that $\sup\{d(x,\Gamma) : x \in S_r^\pm\} \le C_0 r$.

(iv) If $C_f^\pm(r) := \min_{x\in S_r^\pm}\{\langle f(x), n(x)\rangle\}$, where $n(x)$ is the inward (resp., outward) unit normal vector to S_r^+ (resp., S_r^-) at $x \in S_r^\pm$ and the angle brackets denote the usual inner product, then $C_f^\pm(r) \ge C_1 r$ for some constant $C_1 > 0$ independent of r.

Let us assume for the moment that the above construction is possible and use it to complete the proof of the proposition.

For this, let $N \subset \mathbb{R}^2$ be the annulus such that $\partial N = S_1^+ \cup S_1^-$. If $\|g\|_{C^0}$ is small enough, then there exists an $r_0 \in (0,1]$ such that $\|g\|_{C^0} = C_1 r_0$. Using this fact, we have, for $r > r_0$ and $x \in S_r^\pm$, that

$$\langle f(x) + g(x), n(x)\rangle \ge C_f^\pm(r) - \|g\|_{C^0} \ge C_1 r - C_1 r_0 > 0.$$

Thus, for $r > r_0$, the set $S_r^+ \cup S_r^-$ encloses a positively invariant annulus for the system (6.2) in $\mathbb{R}^2$. It follows that $\bar\Gamma$ is contained in this domain, and, by the estimates given in (iii) and (iv), that $d(x,\Gamma) \le C_0 r_0 = \frac{C_0}{C_1}\|g\|_{C^0}$ for every $x \in \bar\Gamma$, as required.

The proof will be completed by constructing a family of curves that satisfies properties (i)–(iv).

The constructions and the verifications of properties (i)–(iv) for the families S_r^+ and S_r^- are similar. We will give the proof for S_r^+ only. Also, in the arguments to follow we will suppress the superscript "+."

Step 1. Construction of S_r.

Since the periodic solution Γ is asymptotically stable, there exists a neighborhood of Γ, contained in the stable manifold of Γ, with an invariant foliation with respect to the system (6.1) whose leaves are curves. Let $M^s(p)$ denote the leaf through the point $p \in \Gamma$. Also, let $t \mapsto x(t,\xi)$ denote the solution of the differential equation (6.1) with $x(0,\xi) = \xi$, and let $\Phi(t,\xi)$ denote the principal fundamental matrix solution at $t = 0$ of the linearized system along this solution.

Fix a point $q_1 \in M^s(p)$ that lies in the exterior domain separated by Γ, and let $q_0 := x(\omega, q_1)$ be the point where the solution through q_1 first returns to $M^s(p)$. Choose a smooth function $q : [0,1] \to M^s(p) \subset \mathbb{R}^2$ such that the derivative of q, including the left-hand and right-hand derivatives at the end points of its domain, does not vanish, and with the additional properties that $q(0) = q_0$, $q(1) = q_1$, and

$$\dot q(0^+) = \Phi(\omega, q_1)\dot q(1^-). \tag{12.1}$$

The last requirement can be met because, by the invariance of the foliation,

$$\Phi(\omega, q_1) T_{q_1} M^s(p) = T_{q_0} M^s(p).$$

Let $t : [0,1] \to [0,\omega]$ be the linear transformation given by $t(\lambda) = \lambda\omega$, and consider the curve S defined parametrically by $\lambda \mapsto x(t(\lambda), q(\lambda))$. Let us note that S is closed. Indeed, since $t(0) = 0$ and $t(1) = \omega$, we have that $x(t(0), q(0)) = x(t(1), q(1)) = q_0$.

For each $\lambda \in (0,1)$, define $T(\lambda)$ to be the tangent vector to S at the point $x(t(\lambda),q(\lambda))$ given by

$$\begin{aligned} T(\lambda) &= \frac{d}{ds}x(t(s),q(s))\big|_{s=\lambda} = \omega\dot{x}(t(\lambda),q(\lambda)) + x_\xi(t(\lambda),q(\lambda))\dot{q}(\lambda) \\ &= \omega f(x(t(\lambda),q(\lambda))) + \Phi(t(\lambda),q(\lambda))\dot{q}(\lambda). \end{aligned} \tag{12.2}$$

To check that S is a C^1 curve, it suffices to show that $T(0^+) = T(1^-)$. But, this equality follows from the identities (12.1) and (12.2).

Let ϕ^s denote the flow associated with the system (6.1). The family of curves S_r, for $r \in (0,1]$, is defined as follows: $S_r := \phi^s(S)$, where $s = (\omega/b)\ln r$.

Step 2. Verification of properties (i)–(iv) for S_r.

Property (i) is obvious from the construction.

To check property (ii), we will show first that the curve S is transverse to the vector field given by f. Because the vector $\dot{q}(\lambda)$ is tangent to $M^s(p)$ at $q(\lambda)$, this vector is not parallel to the vector $f(q(\lambda))$. Using the fact that

$$\Phi(t(\lambda),q(\lambda))f(q(\lambda)) = f(x(t(\lambda),q(\lambda))),$$

it follows that the vectors $\Phi(t(\lambda),q(\lambda))\dot{q}(\lambda)$ and $f(x(t(\lambda),q(\lambda)))$ are independent at $x(t(\lambda),q(\lambda))$. In view of this fact and the formula (12.2) for the vector $T(\lambda)$ tangent to S, it is clear that f is everywhere transverse to S.

Next, for each point $Q \in S_r$, there exists a point $P \in S$ such that $\phi^s(P) = Q$. Therefore, $T_QS_r = D\phi^s(P)T_PS$ and $f(Q) = D\phi^s(P)f(P)$. Since T_PS is transverse to $f(P)$, we have that T_QS_r is transverse to $f(Q)$. This proves property (ii).

For the proof of property (iii), let us note that, due to the hyperbolicity of the orbit Γ, there exists some $C_0 > 0$ such that, for each point $x_0 \in N$, we have $d(\phi^s(x_0),\Gamma) \le C_0e^{bs/\omega}$. Hence, for each $Q \in S_r$, if we take the point $P \in S$ such that $\phi^s(P) = Q$, then

$$d(Q,\Gamma) = d(\phi^s(P),\Gamma) \le C_0e^{\frac{bs}{\omega}} = C_0r,$$

and the constant C_0 depends only on the "size" of the neighborhood N.

Finally, let us prove property (iv). To this end, note that for each point $Q \in S_r$, there is a corresponding point $P \in S$ such that $Q = \phi^s(P)$ and some λ such that $P = x(t(\lambda),q(\lambda))$. Also, with an abuse of notation, let $T(Q)$ denote the vector in T_QS_r given by $T(Q) = D\phi^s(P)T(\lambda)$, and define $n(Q)$ to be the inward unit normal vector to S_r at Q.

Using the easily verified identity $\langle f(Q),n(Q)\rangle|T(Q)| = |f(Q)\times T(Q)|$, let us note that if $r \in (0,1]$, then

$$C_f^+(r) = \min_{Q\in S_r}\left\{\frac{|f(Q)\times T(Q)|}{|T(Q)|}\right\}.$$

Also, recall formula (12.2), and note that

$$\begin{aligned} T(Q) = D\phi^s(P)T(\lambda) &= \omega\Phi(s,P)f(P) + \Phi(s,P)\Phi(t(\lambda),q(\lambda))\dot{q}(\lambda) \\ &= \omega f(Q) + \Phi(s+t(\lambda),q(\lambda))\dot{q}(\lambda). \end{aligned}$$

Moreover, we have that $|f(Q)\times T(Q)| = |f(Q)\times\Phi(s+t(\lambda),q(\lambda))\dot{q}(\lambda)|$.

By an initial choice of the point q_1 sufficiently close to $p \in M^s(p)$, there is a number $K \geq 1$ such that

$$\frac{1}{K}\exp\left(\int_0^{s+t(\lambda)} \operatorname{tr} A(\tau)\, d\tau\right) \leq |\Phi(s+t(\lambda), q(\lambda))\dot{q}(\lambda)| \leq K\exp\left(\int_0^{s+t(\lambda)} \operatorname{tr} A(\tau)\, d\tau\right),$$

where $A(t) = Df(x(t,p))$.

Let $v(Q)$ denote the unit tangent vector at Q to the stable fiber through Q. Because $\Phi(s+t(\lambda), q(\lambda))\dot{q}(\lambda)$ is tangent to the stable fiber through Q, we have that

$$\begin{aligned}|f(Q) \times T(Q)| &= |f(Q) \times \Phi(s+t(\lambda), q(\lambda))\dot{q}(\lambda)|\\ &\geq \frac{1}{K}|f(Q) \times v(Q)| \exp\left(\int_0^{s+t(\lambda)} \operatorname{tr} A(\tau)\, d\tau\right),\end{aligned}$$

and there is a constant $C_2 > 0$ such that

$$\begin{aligned}|T(Q)| &\leq \omega|f(Q)| + |\Phi(s+t(\lambda), q(\lambda))\dot{q}(\lambda)|\\ &\leq \omega|f(Q)| + K\exp\left(\int_0^{s+t(\lambda)} \operatorname{tr} A(\tau)\, d\tau\right)\\ &\leq \omega|f(Q)| + C_2.\end{aligned}$$

Therefore, using the above estimates and the fact that the quantities $|f|$ and $|f(Q) \times v(Q)|$ are bounded below over N, there is a constant $C_3 > 0$ such that

$$\begin{aligned}\frac{|f(Q) \times T(Q)|}{|T(Q)|} &\geq \frac{|f(Q) \times v(Q)|}{K(\omega|f(Q)| + C_2)} \exp\left(\int_0^{s+t(\lambda)} \operatorname{tr} A(\tau)\, d\tau\right)\\ &\geq C_3 \exp\left(\int_0^{s} \operatorname{tr} A(\tau)\, d\tau\right).\end{aligned}$$

If m is a nonnegative integer and $0 \leq \lambda < \omega$ is such that $s = m\omega + \lambda$, then there are constants $C_1 > 0$ and $C_4 > 0$ such that

$$\begin{aligned}C_3 \exp\left(\int_0^{s} \operatorname{tr} A(\tau)\, d\tau\right) &= C_3 \exp\left(\int_0^{m\omega+\lambda} \operatorname{tr} A(\tau)\, d\tau\right)\\ &\geq C_4 \exp\left(\int_0^{m\omega} \operatorname{tr} A(\tau)\, d\tau\right)\\ &= C_4 e^{bm} = C_4 e^{\frac{bs-b\lambda}{\omega}} \geq C_1 r.\end{aligned}$$

Thus, we have proved that $C_f(r) \geq C_1 r$. □

Proof of Proposition 6.2. If the families of curves S_r^+ and S_r^- are "suspended" to tori in the space $\mathbb{R}^2 \times \mathbb{R}$, then the corresponding tori can be shown to satisfy conditions analogous to the conditions (i)–(iv) that are defined in the proof of Proposition 6.1. The verification of each condition is essentially identical to the corresponding proof in Proposition 6.1; we omit the details. □

Acknowledgments. Finally, we thank the referees for carefully reading the original version of this paper. Their comments led to many improvements.

DIRECTIONAL AND TIME-SCALE WAVELET ANALYSIS[*]

ROB A. ZUIDWIJK[†]

Abstract. Combined use of the X-ray (Radon) transform and the wavelet transform has proved to be useful in application areas such as diagnostic medicine and seismology. The wavelet X-ray transform performs one-dimensional wavelet transforms along lines in $\mathbb{R}^n$ which are parameterized in the same fashion as for the X-ray transform. The reconstruction formula for this transform gives rise to a continuous family of elementary projections. These projections provide the building blocks of a directional wavelet analysis of functions in several variables. Discrete wavelet X-ray transforms are described which make use of wavelet orthonormal bases and, more generally, of biorthogonal systems of wavelet Riesz bases. Some attention is given to approximation results which involve wavelet X-ray analysis in several directions.

Key words. wavelet X-ray transform, wavelet transform, X-ray transform, Radon transform, windowed Radon transform, local Radon transform, reconstruction formula, wavelet orthonormal basis, biorthogonal wavelet expansion, wavelet frame

1. Introduction and preliminaries.

The wavelet transform and the X-ray transform (or Radon transform) and their discretizations have received considerable attention in the mathematical literature. Moreover, the two transforms have proved to be very useful as a tool to handle a variety of engineering problems. See references [Chu, Dau, Hol, Mey, RV] for the wavelet transform and [Dea, Nat, Sol, SSW] for the X-ray transform.

A combined use of the two transforms has also proved to be useful. Among the application areas are seismology and diagnostic medicine. Indeed, localized inversion of the Radon transform using wavelets [BW, OD] can be applied in diagnostic medicine to reduce the radiation exposure when X-rays of only a small area in a local region of tissue are required. This technique can also be applied to cross-borehole tomography in seismic exploration; see [DL].

On the other hand, the Radon transform has been applied extensively in reflection seismology. If one models the earth's subsurface as a stratified medium, then the Radon transform can be used to transform seismic data in such a way that arriving wavefronts with distinct propagating velocities are separated. In this context, the Radon transform is referred to as a *slant stack* [Rob].

We shall now shortly describe the aforementioned integral transforms. The *X-ray transform*

$$Pf(\theta, x) = \int_{\mathbb{R}} f(x + t\theta)\, dt$$

integrates a function f on $\mathbb{R}^n$ along an affine line $x+\mathbb{R}\theta$, where $x \in \mathbb{R}^n$ is perpendicular to the direction θ. Observe that (θ, x), where θ is a vector on the unit sphere $S^{n-1} = \{y \in \mathbb{R}^n \mid \|y\| = 1\}$ and x a vector orthogonal to θ, parameterize all lines in $\mathbb{R}^n$. In

particular, the distance of the line $x + \mathbb{R}\theta$ to the origin is given by $\|x\|$. The relevance of the X-ray transform to diagnostic medicine can be understood as follows. The attenuation of X-ray beams (along lines in $\mathbb{R}^2$ or $\mathbb{R}^3$) passing through a medium with density f is modeled by the integral of the density function along these lines. It is the aim of computerized tomography to reconstruct the density function from these attenuation data, i.e., from the X-ray transformed function [SSW, Nat].

The *continuous wavelet transform*

$$W_g f(b,a) = \int_{\mathbb{R}} f(t) \frac{1}{\sqrt{a}} \overline{g\left(\frac{t-b}{a}\right)}\, dt, \quad b \in \mathbb{R}, \quad a > 0,$$

which puts a function f to its wavelet coefficients $W_g f(b,a)$, is often considered as an alternative for the windowed Fourier transform in the time-frequency analysis of transient signals; e.g., see [Mey, RV, Wal]. The transform actually computes inner products of f with respect to translated and dilated versions of one and the same function g, which is referred to as the wavelet. Usually, the function g satisfies an admissibility condition to ensure that the function f can be reconstructed from its wavelet coefficients $W_g f$; details are given in section 2.

In [FKV, FKV2], it has been argued that the Radon transform (as a slant stack) and the wavelet transform (as a time-frequency analysis tool) have complementary useful features to remove noise from seismic reflection data. For this reason, the two transforms are applied in a cascaded fashion. This work motivated the definition of a transformation which combines the properties of the wavelet and the X-ray transform. Indeed, we consider the *wavelet X-ray transform*

$$P_g f(\theta, x, b, a) = \int_{\mathbb{R}} f(x + t\theta) \frac{1}{\sqrt{a}} \overline{g\left(\frac{t-b}{a}\right)}\, dt.$$

This transform computes one-dimensional wavelet transforms along lines in $\mathbb{R}^n$ which are parameterized in the same fashion as for the X-ray transform.

Starting from the reconstruction formulas for the wavelet X-ray transform given in section 3, it will be shown in section 4 that a function $f \in L^2(\mathbb{R}^n)$ can be analyzed into elementary projections $G_{\theta,b,a} f \in L^2(\mathbb{R}^n)$ which are parameterized by direction $\theta \in S^{n-1}$, position (or time) $b \in \mathbb{R}$, and scale $a > 0$. In other words, a directional wavelet analysis is performed on functions in several variables.

An alternative approach towards directional wavelet analysis in two or more dimensions uses a continuous wavelet transform on functions in two or more variables incorporating rotation, translation, and dilation [AM]. In this case, wavelets in two or more variables are not only translated and dilated but also rotated.

The wavelet X-ray transform originates from [KS], where it was called the windowed Radon transform. In that paper, the theory continues into the direction of the analytic signal transform. Reconstruction formulas for the wavelet X-ray transform given there (see also [Tak]) are improved in this paper; see Theorem 3.2.

Further, as a localized Radon transform, the wavelet X-ray transform has been used to detect linear events in radar images [WD].

The setup of this paper reads as follows. In sections 2 and 3, respectively, the continuous wavelet transform and the continuous wavelet X-ray transform are discussed briefly. In section 4, the notion of an elementary projection $G_{\theta,b,a} f$ of a function $f \in L^2(\mathbb{R}^n)$ is introduced. It is shown that the operators $G_{\theta,b,a} : L^2(\mathbb{R}^n) \to L^2(\mathbb{R}^n)$ form a continuous family of projection operators; see Theorem 4.6.

In section 5, the continuous wavelet X-ray transform is discretized using an orthonormal basis of wavelets in $L^2(\mathbb{R})$. It is shown in Theorem 5.5 that any function $f \in L^2(\mathbb{R})$ can be written as a series of elementary projections with fixed direction $\theta \in S^{n-1}$. Therefore, each function can be approximated with arbitrary precision by a finite sum of elementary projections. Proposition 5.7 shows that the use of several directions improves the performance of the approximation; see Lemma 5.8. In section 6, the discretization of the wavelet X-ray transform is carried out using biorthogonal systems of Riesz bases. Part of the results there are proved for frame systems.

Some remarks on notation in this paper are in order. The inner product and induced norm on an infinite-dimensional Hilbert space H are denoted by $\langle\cdot,\cdot\rangle_H$ and $\|\cdot\|_H$. The inner product and the Euclidian norm on $\mathbb{R}^n$, however, are indicated by $\langle\cdot,\cdot\rangle$ and $\|\cdot\|$, respectively. It should not lead to confusion that the (spectral) norm of a linear operator $A : H_1 \to H_2$ between Hilbert spaces is also indicated by $\|A\|$. Further, we write $\ker A = \{x \in H_1 \mid Ax = 0\}$ and $\operatorname{ran} A = \{Ax \mid x \in H_1\}$. The open upper half-plane is denoted by $\mathbb{H} = \{(x, y) \in \mathbb{R}^2 \mid y > 0\}$ and the unit sphere in $\mathbb{R}^n$ is denoted by $S^{n-1} = \{z \in \mathbb{R}^n \mid \|z\| = 1\}$. We shall denote the measure $db\, a^{-2}da$ on the open upper half-plane by $d\mu(b, a)$.

In the last part of this section, some preliminary material concerning Riesz bases and frames will be presented; for more information, we refer to [You] and to relevant parts in the wavelet literature; see, for example, [CR, Chu, Dau, Hol]. Recall that a *Riesz basis* in a Hilbert space H is a sequence of vectors $(x_k)_{k=1}^{\infty}$ with closed linear span equal to H and with constants $0 < A \le B$ such that the following holds: for each finite sequence $(a_k)_{k=1}^{N}$, we have

$$A\sum_{k=1}^{N}|a_k|^2 \le \left\|\sum_{k=1}^{N} a_k x_k\right\|_H^2 \le B\sum_{k=1}^{N}|a_k|^2.$$

If the constants A, B are chosen optimally, then they are referred to as the *Riesz bounds* of $(x_k)_{k=1}^{\infty}$. We shall consider Riesz bases $(x_k)_{k=1}^{\infty}$ and $(\widetilde{x}_k)_{k=1}^{\infty}$ which satisfy the *biorthogonality condition*

$$\langle x_k, \widetilde{x}_l\rangle_H = \begin{cases} 1, & k = l, \\ 0, & k \ne l. \end{cases} \tag{1.1}$$

Let $(x_k)_{k=1}^{\infty}$ be a Riesz basis in a Hilbert space H with Riesz bounds A, B. There exists a unique Riesz basis $(\widetilde{x}_k)_{k=1}^{\infty}$ in H such that the biorthogonality condition (1.1) is satisfied. Moreover, the Riesz bounds of $(\widetilde{x}_k)_{k=1}^{\infty}$ are given by $\widetilde{A} = B^{-1}, \widetilde{B} = A^{-1}$.

A *frame* $(x_k)_{k=1}^{\infty}$ in a Hilbert space H is a sequence of vectors with constants $0 < A \le B$ such that for all $y \in H$, we get

$$A\|y\|_H^2 \le \sum_{k=1}^{\infty}|\langle y, x_k\rangle_H|^2 \le B\|y\|_H^2.$$

If the constants A, B are chosen optimally, then they are called the *frame bounds* of $(x_k)_{k=1}^{\infty}$. Observe that if $y \perp x_k$ for all $k \in \mathbb{Z}^+$, then $y = 0$. This implies that the closed linear span of the frame vectors is the whole Hilbert space H. However, the frame vectors need not be linearly independent. We also mention that each Riesz basis is a frame. In general, a biorthogonality condition for frames does not make sense because of lack of linear independence. Nevertheless, expansions with frames are possible using a so-called dual frame. Indeed, consider the operator $F : H \to \ell^2(\mathbb{Z}^+)$, given by

$$Fy = (\langle y, x_k \rangle_H)_{k=1}^{\infty}, \quad y \in H.$$

By construction, F is a bounded operator on H. Its adjoint $F^* : \ell^2(\mathbb{Z}^+) \to H$ is given by

$$F^*(a_k)_{k=1}^{\infty} = \sum_{k=1}^{\infty} a_k x_k, \quad \sum_{k=1}^{\infty} |a_k|^2 < \infty.$$

The operator $F^*F : H \to H$, called the *frame operator*, is a positive boundedly invertible operator; in fact, $A \cdot I_H \le F^*F \le B \cdot I_H$. Define $\widetilde{x}_k = (F^*F)^{-1}x_k$ for $k \in \mathbb{Z}^+$. It turns out that the sequence of vectors $(\widetilde{x}_k)_{k=1}^{\infty}$ is a frame, and it is called the *dual frame* of $(x_k)_{k=1}^{\infty}$. By construction,

$$y = \sum_{k=1}^{\infty} \langle y, \widetilde{x}_k \rangle_H x_k = \sum_{k=1}^{\infty} \langle y, x_k \rangle_H \widetilde{x}_k, \quad y \in H.$$

The frame $(\widetilde{x}_k)_{k=1}^{\infty}$ has frame bounds $\widetilde{A} = B^{-1}$ and $\widetilde{B} = A^{-1}$.

2. Continuous wavelet transform. In this section, we discuss the continuous wavelet transform. We shall consider the general case when the analyzing wavelet need not equal the reconstructing wavelet. Results in this section are without proof. The proofs can be found in, e.g., [Hol, Koo]. For $f, g \in L^2(\mathbb{R})$, consider the expression

$$W_g f(b,a) = \int_{\mathbb{R}} f(t) \overline{\frac{1}{\sqrt{a}} g\left(\frac{t-b}{a}\right)} \, dt, \quad (b,a) \in \mathbb{H},$$

where $\mathbb{H} = \{(b,a) \in \mathbb{R}^2 \mid a > 0\}$ denotes the open upper half-plane. We shall refer to W_g as the *continuous wavelet transform.* The function g plays the role of the *analyzing wavelet* and will be accompanied by a *reconstructing wavelet* $h \in L^2(\mathbb{R})$. The pair of wavelets g, h normally satisfies an admissibility condition which will be specified later. Introducing the shorthand notation

$$g_{b,a}(t) = \frac{1}{\sqrt{a}} g\left(\frac{t-b}{a}\right), \quad g_a(t) = g_{0,a}(t), \quad t \in \mathbb{R}, \quad (b,a) \in \mathbb{H},$$

we get $W_g f(b,a) = \langle f, g_{b,a} \rangle_{L^2(\mathbb{R})}$. Observe that $g_{b,a}$ represents a dilated and translated version of the function g, which is normalized in such a way that $\|g_{b,a}\|_{L^2(\mathbb{R})} = \|g\|_{L^2(\mathbb{R})}$. The Fourier transform $f \mapsto \widehat{f}$, given by

$$\widehat{f}(\omega) = \frac{1}{\sqrt{2\pi}} \int_{\mathbb{R}} f(x) e^{-i\omega x} \, dx,$$

is a unitary operator on $L^2(\mathbb{R})$. In the following theorem, which states Parseval's formula for the continuous wavelet transform, the pair of wavelets $g, h \in L^2(\mathbb{R})$ should satisfy the following *admissibility condition*: the expression

$$c_{g,h} = \int_0^{\infty} \frac{\overline{\widehat{g}(a\omega)} \widehat{h}(a\omega)}{a} \, da$$

must assume a nonzero value and should be constant for almost all $\omega \in \mathbb{R}$. A pair of wavelets $g, h \in L^2(\mathbb{R})$ which satisfies this admissibility condition will be called an *admissible pair of wavelets*. A wavelet $g \in L^2(\mathbb{R})$ is called an *admissible wavelet* if the pair g, g is an admissible pair of wavelets.

THEOREM 2.1 (Parseval's formula). *Let $g, h \in L^2(\mathbb{R})$ be an admissible pair of wavelets; then for $f, k \in L^2(\mathbb{R})$, one gets*

$$\langle W_g f, W_h k\rangle_{L^2(\mathbb{H})} = c_{g,h} \cdot \langle f, k\rangle_{L^2(\mathbb{R})}.$$

We now proceed with a reconstruction formula for the continuous wavelet transform. Observe that, in this theorem, we require the admissible pair of wavelets to consist of wavelets which are admissible themselves.

THEOREM 2.2 (reconstruction formula). *Let $g, h \in L^2(\mathbb{R})$ be an admissible pair of admissible wavelets, and assume that $f \in L^2(\mathbb{R})$. Then*

$$f = \frac{1}{c_{g,h}} \int_{\mathbb{H}} W_g f(b,a) h_{b,a}(\cdot)\, d\mu(b,a).$$

The integral converges in the norm of $L^2(\mathbb{R})$.

3. Continuous wavelet X-ray transform. We shall now consider a transform acting on square integrable functions on $\mathbb{R}^n$. This transform actually performs one-dimensional wavelet transforms (see the preceding section) along lines in $\mathbb{R}^n$. These lines are parameterized in the same fashion as for the usual X-ray transform (see [Nat, Sol]), i.e., by means of the vector bundle on the unit sphere

$$\mathcal{T} = \{(\theta, x) \mid \theta \in S^{n-1}, x \in \theta^\perp\}.$$

Here $\theta^\perp$ denotes the orthogonal complement of $\theta \in S^{n-1}$ in $\mathbb{R}^n$. Let $g \in L^2(\mathbb{R})$, $f \in L^2(\mathbb{R}^n)$, and define

$$P_g f(\theta, x, b, a) = \int_{\mathbb{R}} f(x + t\theta)\overline{g_{b,a}(t)}\, dt, \quad (\theta, x) \in \mathcal{T}, \quad (b,a) \in \mathbb{H}.$$

The transform P_g will be called the *continuous wavelet X-ray transform.* If we fix $\theta \in S^{n-1}$, we shall write

$$P_{g,\theta} f(x, b, a) = P_g(\theta, x, b, a), \qquad x \in \theta^\perp,\ (b,a) \in \mathbb{H}.$$

We shall also formulate results in terms of this transform, i.e., for the wavelet X-ray transform with fixed direction $\theta \in S^{n-1}$. In the next theorem, we derive Parseval's formulas for the wavelet X-ray transforms. The proofs of the following two theorems can be found in [Zui, Zui2] for the case when $g = h$. For completeness, we shall give an outline of the proof of Theorem 3.2.

THEOREM 3.1 (Parseval's formulas). *Let $g, h \in L^2(\mathbb{R})$ be an admissible pair of admissible wavelets and assume that $f, k \in L^2(\mathbb{R}^n)$. Then*

$$\langle P_g f, P_h k\rangle_{L^2(\mathcal{T}\times\mathbb{H})} = c_{g,h} \cdot |S^{n-1}| \cdot \langle f, k\rangle_{L^2(\mathbb{R}^n)}.$$

Moreover, for fixed $\theta \in S^{n-1}$, we get

$$\langle P_{g,\theta} f, P_{h,\theta} k\rangle_{L^2(\theta^\perp\times\mathbb{H})} = c_{g,h} \cdot \langle f, k\rangle_{L^2(\mathbb{R}^n)}.$$

THEOREM 3.2. *Let $g, h \in L^2(\mathbb{R})$ be an admissible pair of admissible wavelets; then for any $f \in L^2(\mathbb{R}^n)$, one gets*

$$f = \frac{1}{c_{g,h} \cdot |S^{n-1}|} \int_{S^{n-1}} \int_{\mathbb{H}} P_g f(\theta, E_\theta \cdot, b, a) h_{b,a}(\langle \cdot, \theta \rangle) \, d\mu(b,a) \, d\theta, \tag{3.1}$$

where $E_\theta = I - \langle \cdot, \theta \rangle \theta$ denotes the orthoprojector onto $\theta^\perp \subseteq \mathbb{R}^n$. Moreover, for $\theta \in S^{n-1}$ fixed,

$$f = \frac{1}{c_{g,h}} \int_{\mathbb{H}} P_{g,\theta} f(E_\theta \cdot, b, a) h_{b,a}(\langle \cdot, \theta \rangle) \, d\mu(b,a). \tag{3.2}$$

Both integrals converge in $L^2(\mathbb{R}^n)$.

Proof. We will prove (3.2). In the main part of the proof we will replace $P_{g,\theta} f$ by an arbitrary $\Sigma \in L^2(\theta^\perp \times \mathbb{H})$. Let $(K_m)_{m=1}^\infty$ denote an increasing sequence of compact subsets in the open upper half-plane such that $\bigcup_{m=1}^\infty K_m = \mathbb{H}$. For fixed $m \in \mathbb{Z}^+$, consider the expression

$$\mathcal{I}_m = \frac{1}{c_{g,h}} \int_{K_m} \Sigma(E_\theta \cdot, b, a) h_{b,a}(\langle \cdot, \theta \rangle) \, d\mu(b,a).$$

First, one needs to show that $\mathcal{I}_m \in L^2(\mathbb{R}^n)$. This follows from

$$\int_{\mathbb{R}^n} |\mathcal{I}_m(y)|^2 \, dy = \int_{\theta^\perp} \int_{\mathbb{R}} \frac{1}{|c_{g,h}|^2} \left| \int_{K_m} \Sigma(x,b,a) h_{b,a}(t) \, d\mu(b,a) \right|^2 dt \, dx$$

$$\leq \frac{\mu(K_m)}{|c_{g,h}|^2} \|h\|^2_{L^2(\mathbb{R})} \int_{\theta^\perp} \int_{K_m} |\Sigma(x,b,a)|^2 \, d\mu(b,a) \, dx \leq \frac{\mu(K_m)}{|c_{g,h}|^2} \|h\|^2_{L^2(\mathbb{R})} \|\Sigma\|^2_{L^2(\theta^\perp \times \mathbb{H})}.$$

Convergence of the sequence $(\mathcal{I}_m)_{m=1}^\infty$ in $L^2(\mathbb{R}^n)$ follows from the following estimate. Let $p < q$ be positive integers and $k \in L^2(\mathbb{R}^n)$; then application of Fubini's theorem gives

$$\left| \langle \mathcal{I}_q - \mathcal{I}_p, k \rangle_{L^2(\mathbb{R}^n)} \right| = \left| \frac{1}{c_{g,h}} \int_{K_q \setminus K_p} \int_{\theta^\perp} \Sigma(x,b,a) \overline{P_{h,\theta} k(x,b,a)} \, dx \, d\mu(b,a) \right|$$

$$\leq \frac{\sqrt{c_{h,h}}}{|c_{g,h}|} \cdot \sqrt{\int_{K_q \setminus K_p} \int_{\theta^\perp} |\Sigma(x,b,a)|^2 \, dx \, d\mu(b,a)} \cdot \|k\|_{L^2(\mathbb{R}^n)} \to 0$$

as $p, q \to \infty$. Finally, after the substitution $\Sigma = P_{g,\theta} f$, we get

$$\lim_{m \to \infty} \langle \mathcal{I}_m, k \rangle_{L^2(\mathbb{R}^n)} = \lim_{m \to \infty} \frac{1}{c_{g,h}} \langle P_{g,\theta} f, P_{h,\theta} k \rangle_{L^2(\theta^\perp \times K_m)} = \langle f, k \rangle_{L^2(\mathbb{R}^n)}.$$

This proves (3.2). Formula (3.1) now follows trivially. □

In the remainder of this paper, we shall fix $\theta \in S^{n-1}$ in many places, but we will always use $P_g(\theta, x, b, a)$ instead of $P_{g,\theta}(b,a)$.

4. Elementary projections. In this section, we assume that $g, h \in L^2(\mathbb{R})$ is an admissible pair of admissible wavelets. The normalization $\langle g, h\rangle_{L^2(\mathbb{R}^n)} = 1$ is required for the statement in Lemma 4.1. This lemma shows that the integrands in the right-hand sides of (3.1) and (3.2) give rise to the definition of projections on $L^2(\mathbb{R}^n)$.

LEMMA 4.1. *The linear mapping $G_{\theta,b,a} : L^2(\mathbb{R}^n) \to L^2(\mathbb{R}^n)$ given by*

$$G_{\theta,b,a}f(y) = P_g f(\theta, E_\theta y, b, a)\, h_{b,a}(\langle y, \theta\rangle), \quad y \in \mathbb{R}^n, \tag{4.1}$$

is a projection with norm $\|G_{\theta,b,a}\| = \|g\|_{L^2(\mathbb{R})} \cdot \|h\|_{L^2(\mathbb{R})}$.

We shall call $G_{\theta,b,a}$ an *elementary projection* for each direction $\theta \in S^{n-1}$ and each translation-dilation pair $(b, a) \in \mathbb{H}$. Observe that the projection $G_{\theta,b,a}$ is an orthoprojector if and only if $g = h$.

Proof. We first prove that $G_{\theta,b,a}$ is a bounded operator. Indeed,

$$\|G_{\theta,b,a}f\|^2_{L^2(\mathbb{R}^n)} = \int_{\theta^\perp}\int_{\mathbb{R}} |P_g f(\theta, x, b, a)|^2 |h_{b,a}(t)|^2\, dt\, dx$$

$$= \|h\|^2_{L^2(\mathbb{R})} \cdot \int_{\theta^\perp} |P_g f(\theta, x, b, a)|^2\, dx \le \|g\|^2_{L^2(\mathbb{R})} \cdot \|h\|^2_{L^2(\mathbb{R})} \cdot \|f\|^2_{L^2(\mathbb{R}^n)}.$$

We claim that $\|G_{\theta,b,a}\| = \|g\|_{L^2(\mathbb{R})} \cdot \|h\|_{L^2(\mathbb{R})}$. This can be seen by considering $f = \rho(E_\theta \cdot) g_{b,a}(\langle \cdot, \theta\rangle)$ for some $\rho \in L^2(\theta^\perp)$. It is rather straightforward to verify that $G_{\theta,b,a}$ is idempotent, i.e., $G_{\theta,b,a} = G^2_{\theta,b,a}$. □

The following lemmas will be used to prove Theorem 4.6. We omit their straightforward proofs.

LEMMA 4.2. *Let $A : \mathbb{R}^n \to \mathbb{R}^n$ be an invertible linear mapping; then $D_A : L^2(\mathbb{R}^n) \to L^2(\mathbb{R}^n)$, defined by $D_A f = \sqrt{|\det A|} f(A\cdot)$, is unitary. Moreover, if $f \in L^2(\mathbb{R}^n)$, then $D_A f \to f$ as $A \to I_n$.*

LEMMA 4.3. *For $h \in \mathbb{R}^n$, the linear operator $T_h : L^2(\mathbb{R}^n) \to L^2(\mathbb{R}^n)$ given by $T_h f = f(\cdot + h)$ is unitary. Moreover, for each $f \in L^2(\mathbb{R}^n)$, we get $T_h f \to f$ as $h \to 0$.*

LEMMA 4.4. *Let $U : \mathbb{R}^n \to \mathbb{R}^n$ be an orthogonal linear mapping. Then*

$$G_{U\theta,b,a} = D_U^{-1} G_{\theta,b,a} D_U.$$

LEMMA 4.5. *Given $(b, a) \in \mathbb{H}$ and $\theta \in S^{n-1}$, we get*

$$G_{\theta,0,1} = D_{aI_n} T_{b\theta} G_{\theta,b,a} T_{b\theta}^{-1} D_{aI_n}^{-1}.$$

We shall prove in Theorem 4.6 that the elementary projections $G_{\theta,b,a}$ depend continuously on the parameters $\theta \in S^{n-1}$ and $(b, a) \in \mathbb{H}$ in the following sense: fix $f \in L^2(\mathbb{R}^n)$; then $G_{\varphi,\beta,\alpha}f \to G_{\theta,b,a}f$ whenever $\varphi \to \theta$ and $(\beta, \alpha) \to (b, a)$.

THEOREM 4.6. *Fix $f \in L^2(\mathbb{R}^n)$; then*

$$G_{\varphi,\beta,\alpha}f \to G_{\theta,b,a}f$$

in $L^2(\mathbb{R}^n)$ whenever $\varphi \to \theta$ and $(\beta, \alpha) \to (b, a)$ in the topologies of $\mathbb{R}^n$ and $\mathbb{H}$, respectively.

Proof. By Lemma 4.5, we may and do assume that $(b, a) = (0, 1)$. Moreover, let U be a rotation in $\mathbb{R}^n$ such that $U\theta = \varphi$ and $\|I_n - U\| = \|\theta - \varphi\|$.

Write $V = D_{\alpha I_n} T_{\beta\theta} D_U$. By Lemmas 4.4 and 4.5,

$$G_{\varphi,\beta,\alpha}f - G_{\theta,0,1}f = (I - V)G_{\varphi,\beta,\alpha}f - G_{\theta,0,1}(I - V)f.$$

Therefore,

$$\|G_{\varphi,\beta,\alpha}f - G_{\theta,0,1}f\|_{L^2(\mathbb{R}^n)} \leq \|(I-V)G_{\varphi,\beta,\alpha}f\|_{L^2(\mathbb{R}^n)} + \|(I-V)f\|_{L^2(\mathbb{R}^n)}.$$

Given $F \in L^2(\mathbb{R}^n)$, we get $(I-V)F = (I-D_{\alpha I_n})F + D_{\alpha I_n}(I-T_{\beta\theta})F + D_{\alpha I_n}T_{\beta\theta}(I-D_U)F$; so

$$\|(I-V)F\|_{L^2(\mathbb{R}^n)} \leq \|(I-D_{\alpha I_n})F\|_{L^2(\mathbb{R}^n)} + \|(I-T_{\beta\theta})F\|_{L^2(\mathbb{R}^n)} + \|(I-D_U)F\|_{L^2(\mathbb{R}^n)} \to 0$$

as $\beta \to 0$, $\alpha \to 1$, and $U \to I_n$, by Lemmas 4.2 and 4.3. This proves the theorem. □

5. Discrete wavelet X-ray transform: Orthonormal case. In this section, we study a discretization of the wavelet X-ray transform, based on the existence of wavelet orthonormal bases. We will assume that for the wavelet $g \in L^2(\mathbb{R}^n)$, there exists a countable set $K \in \mathbb{H}$ such that $(g_{b,a})_{(b,a)\in K}$ defines an orthonormal basis in $L^2(\mathbb{R})$. As an example of such a basis, we mention the case when $K = \{(k2^j, 2^j) \mid k, j \in \mathbb{Z}\}$ and where g is a Daubechies wavelet of a certain order [Dau, Dau2]. Other examples are Battle–Lemarié wavelets and Meyer wavelets; see [CR] and [Dau]. We shall consider the previous results on elementary projections for the special case when $g = h$, i.e., the case when $G_{\theta,b,a}$ is an orthogonal projection. In the next section, the general case will be dealt with. To avoid confusion, we shall write $G^o_{\theta,b,a}$ in the particular case when $g = h$, i.e.,

$$G^o_{\theta,b,a}f = P_g f(\theta, E_\theta\cdot, b, a)g_{b,a}(\langle\cdot,\theta\rangle), \quad \theta \in S^{n-1}, \quad (b,a) \in \mathbb{H}. \tag{5.1}$$

LEMMA 5.1. *The elementary projections $G^o_{\theta,b,a}$ for $\theta \in S^{n-1}$ fixed and $(b,a) \in K$ are mutually disjoint, i.e., $G^o_{\theta,b,a}G^o_{\theta,\beta,\alpha} = O$ whenever $(b,a) \neq (\beta,\alpha)$. In particular, if $K_0 \subseteq K$ is a finite subset, then*

$$G^o_{\theta,K_0} = \sum_{(b,a)\in K_0} G^o_{\theta,b,a}$$

is also an orthogonal projection.

Proof. Indeed, if we consider products of the projections $G^o_{\theta,b,a}$, then, for $f \in L^2(\mathbb{R}^n)$, we get

$$G^o_{\theta,b,a}G^o_{\theta,\beta,\alpha}f(y) = \int_{\mathbb{R}}\int_{\mathbb{R}} f(E_\theta y + s\theta)\overline{g_{\beta,\alpha}(s)}\ \overline{g_{b,a}(t)}g_{\beta,\alpha}(t)\,ds\,dt\ g_{b,a}(\langle y,\theta\rangle)$$

$$= \langle g_{\beta,\alpha}, g_{b,a}\rangle_{L^2(\mathbb{R})}P_g f(\theta, E_\theta y, \beta, \alpha)\ g_{b,a}(\langle y,\theta\rangle) = 0$$

whenever $(b,a) \neq (\beta,\alpha)$. The orthogonal projections are therefore mutually disjoint and the lemma follows immediately. □

We will show in Theorem 5.5 that functions in $L^2(\mathbb{R}^n)$ can be expanded in terms of elementary projections. The theorem will be proved using a number of elementary results which we will discuss first. We state the following lemma.

LEMMA 5.2. *Let $\{P_\nu\}_{\nu=1}^\infty$ be an increasing sequence of orthogonal projections on a Hilbert space H, i.e., $P_\mu P_\nu = P_\nu P_\mu = P_\mu$ for $\mu \leq \nu$. Then the following statements are equivalent:*

(1) *$P_\nu x \to x$ for all $x \in H$.*

(2) *$\bigcup_{\nu=1}^\infty \operatorname{ran} P_\nu \subseteq H$ dense.*

(3) *$\bigcap_{\nu=1}^\infty \ker P_\nu = (0)$.*

Next, we will construct an orthonormal basis in $L^2(\mathbb{R}^n)$ using products of elementary projections. If $\theta \perp \varphi$, then

$$G^o_{\theta,b,a} G^o_{\varphi,\beta,\alpha} f(y) = \int_{\mathbb{R}} \int_{\mathbb{R}} f(E_\varphi E_\theta y + t\theta + s\varphi) \overline{g_{\beta,\alpha}(s)}\, \overline{g_{b,a}(t)}\, ds\, dt\, g_{\beta,\alpha}(\langle y, \varphi\rangle) g_{b,a}(\langle y, \theta\rangle).$$

Observe that $E_\theta E_\varphi = E_\varphi E_\theta$ is the orthoprojector onto the $(n-2)$-dimensional subspace $\{\theta, \varphi\}^\perp$. Moreover, it is immediate that the orthoprojectors $G^o_{\theta,b,a}$ and $G^o_{\varphi,\beta,\alpha}$ commute. The following two lemmas are direct consequences of these facts. The lemmas describe the so-called *separable wavelet analysis* which has been the first approach towards wavelet analysis of functions in several variables; see for example [Dau].

LEMMA 5.3. *Let $\theta_1, \dots, \theta_n \in S^{n-1}$ be mutually orthogonal unit vectors, and let $(b_j, a_j) \in \mathbb{H}$ for $j = 1, \dots, n$. Write*

$$\underline{\theta} = (\theta_1, \dots, \theta_n), \quad \underline{b,a} = ((b_1, a_1), \dots, (b_n, a_n)).$$

Next, define $F_{\underline{\theta,b,a}} = \prod_{j=1}^n g_{b_j,a_j}(\langle \cdot, \theta_j\rangle)$ and $G^o_{\underline{\theta,b,a}} = \prod_{j=1}^n G^o_{\theta_j,b_j,a_j}$. Then $F_{\underline{\theta,b,a}} \in L^2(\mathbb{R}^n)$, $\|F_{\underline{\theta,b,a}}\|_{L^2(\mathbb{R}^n)} = 1$, and $G^o_{\underline{\theta,b,a}} f = \langle f, F_{\underline{\theta,b,a}}\rangle_{L^2(\mathbb{R}^n)}\, F_{\underline{\theta,b,a}}$. In particular, the operator $G^o_{\underline{\theta,b,a}}$ is an orthogonal projector of rank one.

LEMMA 5.4. *Let $K \subseteq \mathbb{H}$ be a countable subset and let $g \in L^2(\mathbb{R})$ be a wavelet, such that $\{g_{b,a}\}_{(b,a)\in K}$ is an orthonormal basis of $L^2(\mathbb{R})$. If $\theta_1, \dots, \theta_n \in S^{n-1}$ are fixed mutually orthogonal unit vectors, then $\{F_{\underline{\theta,b,a}}\}_{\underline{b,a}\in K^n}$ is an orthonormal basis of $L^2(\mathbb{R}^n)$. In particular, if $f \in L^2(\mathbb{R}^n)$, then*

$$f = \sum_{\underline{b,a}\in K^n} \langle f, F_{\underline{\theta,b,a}}\rangle_{L^2(\mathbb{R}^n)}\, F_{\underline{\theta,b,a}}$$

and

$$\|f\|^2_{L^2(\mathbb{R}^n)} = \sum_{\underline{b,a}\in K^n} |\langle f, F_{\underline{\theta,b,a}}\rangle_{L^2(\mathbb{R}^n)}|^2.$$

We are now ready to prove the following result.

THEOREM 5.5. *If $f \in L^2(\mathbb{R}^n)$ and $\theta \in S^{n-1}$, then*

$$f = \sum_{(b,a)\in K} G^o_{\theta,b,a} f$$

converges in $L^2(\mathbb{R}^n)$. In particular,

$$\|f\|^2_{L^2(\mathbb{R}^n)} = \sum_{(b,a)\in K} \|G^o_{\theta,b,a} f\|^2_{L^2(\mathbb{R}^n)}.$$

Proof. By Lemma 5.2, it suffices to prove that $\bigcap_{(b,a)\in K} \ker\ G^o_{\theta,b,a} = (0)$. Indeed, let $(K_\nu)_{\nu=1}^\infty$ be an increasing sequence of finite subsets in K such that $\bigcup_{\nu=1}^\infty K_\nu = K$. If $P_\nu = \sum_{(b,a)\in K_\nu} G^o_{\theta,b,a}$, then $(P_\nu)_{\nu=1}^\infty$ is an increasing sequence of orthogonal projections on $L^2(\mathbb{R}^n)$. We now prove that $\bigcap_{\nu=1}^\infty \ker\ P_\nu = (0)$. Assume that $f \in \ker\ G^o_{\theta,b,a}$ for all $(b,a) \in K$. This means that for each $(b,a) \in K$,

$$G^o_{\theta,b,a} f(x + t\theta) = P_g f(\theta, x, b, a)\, g_{b,a}(t) = 0$$

for almost all $(x,t) \in \theta^\perp \times \mathbb{R}$. In particular, $P_g f(\theta, x, b, a) = 0$ for almost all $x \in \theta^\perp$. Let $\theta, \theta_2, \ldots, \theta_n$ be an orthonormal basis in $\mathbb{R}^n$ and write $\underline{\theta} = (\theta, \theta_2, \ldots, \theta_n)$. Then by Lemma 5.4,

$$f = \sum_{\underline{(b,a)} \in K^n} \langle f, F_{\underline{\theta,b,a}} \rangle_{L^2(\mathbb{R}^n)} \, F_{\underline{\theta,b,a}}.$$

On the other hand, for arbitrary $\underline{(b,a)} \in K^n$,

$$\langle f, F_{\underline{\theta,b,a}} \rangle_{L^2(\mathbb{R}^n)} = \int_{\mathbb{R}^n} f(\langle y, \theta\rangle \theta + \langle y, \theta_2\rangle \theta_2 + \cdots + \langle y, \theta_n \rangle \theta_n)$$

$$\times \, \overline{g_{b_1,a_1}(\langle y, \theta\rangle)} \, \overline{g_{b_2,a_2}(\langle y, \theta_2\rangle)} \cdots \overline{g_{b_n,a_n}(\langle y, \theta_n\rangle)} \, dy$$

$$= \int_{\theta^\perp} \int_{\mathbb{R}} f(x + t\theta) \overline{g_{b_1,a_1}(t)} \, dt \; \overline{g_{b_2,a_2}(\langle x, \theta_2\rangle)} \cdots \overline{g_{b_n,a_n}(\langle x, \theta_n\rangle)} \, dx.$$

The inner integral satisfies

$$\int_{\mathbb{R}} f(x + t\theta) \overline{g_{b_1,a_1}(t)} \, dt = P_g f(\theta, x, b_1, a_1) = 0$$

for almost all $x \in \theta^\perp$, and we arrive at $\langle f, F_{\underline{\theta,b,a}} \rangle_{L^2(\mathbb{R}^n)} = 0$. Since $\underline{(b,a)} \in K^n$ was arbitrary, we get $f = 0$. This proves the theorem. □

Let $(K_\nu)_{\nu=1}^\infty$ be an increasing sequence of finite sets such that $K_\nu \uparrow K$. We state the following corollary to Theorem 5.5.

COROLLARY 5.6. *Let $f \in L^2(\mathbb{R}^n)$; then $G^o_{\theta,K_\nu} f \to f$ in $L^2(\mathbb{R}^n)$ as $K_\nu \uparrow K$.*

Proof. Observe that, by Theorem 5.5,

$$\|G^o_{\theta,K_\nu} f - f\|^2_{L^2(\mathbb{R}^n)} = \sum_{(b,a) \in K/K_\nu} \|G^o_{\theta,b,a} f\|^2_{L^2(\mathbb{R}^n)} \to 0, \quad K_\nu \uparrow K. \qquad □$$

So far, we have fixed $\theta \in S^{n-1}$. Next, we will take averages over orthogonal projections corresponding to a finite number of distinct unit vectors. The idea is that averaging over approximations from several directions will improve the approximation result. Proposition 5.7 shows that this is the case in a certain sense to be explained below. Indeed, let $\Theta \subseteq S^{n-1}$ be a finite set of unit vectors and define for a fixed finite subset $K_0 \subseteq K$,

$$T^o_{\Theta,K_0} = \frac{1}{|\Theta|} \sum_{\theta \in \Theta} G^o_{\theta,K_0}, \tag{5.2}$$

where $|\Theta|$ denotes the number of elements in Θ. In order to understand the relevance of the following result, define an *approximation of the identity* as a sequence of operators $\{T_n\}_{n=1}^\infty$ on a Hilbert space H such that $T_n x \to x$ as $n \to \infty$ for all $x \in H$. Observe that for fixed n, the subspace ker T_n contains elements which are not approximated by T_n. The performance of the approximation of the identity $\{T_n\}_{n=1}^\infty$ is therefore measured by the null spaces of the operators in the sequence. The smaller these subspaces are, the better one may expect the performance to be. Proposition 5.7 states that the null space of the average T^o_{Θ,K_0} is contained in all of the null spaces of the orthoprojectors G^o_{θ,K_0}, $\theta \in \Theta$.

Proposition 5.7. *Let* $\Theta = \{\theta_1, \ldots, \theta_N\} \subseteq S^{n-1}$ *denote a finite set of directions,* $K_0 \subseteq K$ *finite, and define* T^o_{Θ,K_0} *as in* (5.2). *Then*

$$\ker\ T^o_{\Theta,K_0} = \bigcap_{j=1}^{N} \ker\ G^o_{\theta_j,K_0}.$$

The proposition is a consequence of the following rather general statement.

Lemma 5.8. *If* $P_1, \ldots, P_N$ *are orthogonal projections on a Hilbert space* H, *and if* $\alpha_1, \ldots, \alpha_N$ *are strictly positive numbers, and* $T = \sum_{j=1}^{N} \alpha_j P_j$, *then* $\ker\ T = \bigcap_{j=1}^{N} \ker\ P_j$.

Proof. If $x \in \bigcap_{j=1}^{N} \ker\ P_j$, then obviously $Tx = 0$. On the other hand, if $Tx = 0$, then

$$0 = \langle Tx, x\rangle_H = \sum_{j=1}^{N} \alpha_j \langle P_j x, x\rangle_H = \sum_{j=1}^{N} \alpha_j \|P_j x\|_H^2,$$

and hence $P_j x = 0$ for $j = 1, \ldots, N$. This proves the lemma. □

The self-adjoint operator T^o_{Θ,K_0} given by (5.2) need not be an orthogonal projection. Although we have described its kernel (and thereby its range), it is somewhat cumbersome to identify functions in $\ker\ T^o_{\Theta,K_0}$. It would help if we could identify the orthogonal projection onto this subspace. An approximation of this projector can be obtained using the Kacmarz method, as in [HS] for the X-ray transform.

6. Discrete wavelet X-ray transform: General case. We now study the general case in which $g \neq h$. The discretizations of the wavelet X-ray transform are now based on the existence of biorthogonal pairs of Riesz bases. Indeed, we will assume that g, h are a pair of wavelets for which there exists a countable subset $K \subseteq \mathbb{H}$ such that $(g_{b,a})_{(b,a)\in K}$ and $(h_{b,a})_{(b,a)\in K}$ are Riesz bases in $L^2(\mathbb{R})$ with Riesz bounds A_g, B_g and A_h, B_h, respectively. Moreover, we assume that the biorthogonality condition

$$\langle g_{b,a}, h_{\beta,\alpha}\rangle_{L^2(\mathbb{R})} = \begin{cases} 1, & (b,a) = (\beta,\alpha), \\ 0, & (b,a) \neq (\beta,\alpha), \end{cases}$$

holds. From the discussion on Riesz systems in the introduction, it follows that $A_g B_h = A_h B_g = 1$. Examples of biorthogonal pairs of Riesz bases are given in, for example, [Dau, CDF, CR]. These examples are all based on the countable set $K = \{(k2^j, 2^j) \mid k, j \in \mathbb{Z}\}$. In principle, orthonormal bases are to be preferred over biorthogonal systems of Riesz bases, as they allow for simpler implementation. On the other hand, the relaxed conditions on biorthogonal systems allow for a wider choice of wavelets, e.g., splines of higher order; see [Chu, CDF, CR].

In the general case when $g \neq h$, the elementary projections need not be orthogonal. The analogue to Theorem 5.5 in the general case reads as follows. Theorem 6.1 and Corollary 6.2 will be proved under the weaker condition that $(g_{b,a})_{(b,a)\in K}$ and $(h_{b,a})_{(b,a)\in K}$ are dual frames in $L^2(\mathbb{R})$. The frame bounds of $(g_{b,a})_{(b,a)\in K}$ are A_g, B_g; therefore the frame bounds of $(h_{b,a})_{(b,a)\in K}$ are given by $A_h = B_g^{-1}$ and $B_h = A_g^{-1}$; see the description of frames in the introduction. We recall the definition of an elementary projection from section 4:

$$G_{\theta,b,a} f = \int_{\mathbb{R}} f(E_\theta \cdot + t\theta)\overline{g_{b,a}(t)}\, dt\, h_{b,a}(\langle \cdot, \theta\rangle), \quad (b,a) \in K.$$

THEOREM 6.1. *Assume that $(g_{b,a})_{(b,a)\in K}$ and $(h_{b,a})_{(b,a)\in K}$ are dual frames in $L^2(\mathbb{R})$. If $f \in L^2(\mathbb{R}^n)$, then*

$$f = \sum_{(b,a)\in K} G_{\theta,b,a} f.$$

The series converges in $L^2(\mathbb{R}^n)$. Moreover, we find that

$$\frac{A_h}{\|h\|^2_{L^2(\mathbb{R})}} \sum_{(b,a)\in K} \|G_{\theta,b,a} f\|^2_{L^2(\mathbb{R}^n)} \leq \|f\|^2_{L^2(\mathbb{R}^n)} \leq \frac{B_h}{\|h\|^2_{L^2(\mathbb{R})}} \sum_{(b,a)\in K} \|G_{\theta,b,a} f\|^2_{L^2(\mathbb{R}^n)}.$$

Proof. If $f \in L^2(\mathbb{R}^n)$, observe that $f(x+t\theta) = \sum_{(b,a)\in K} \langle f(x+\cdot\theta), g_{b,a}\rangle_{L^2(\mathbb{R})} h_{b,a}(t)$ for almost all $x \in \theta^\perp$ and $t \in \mathbb{R}$. Since $(g_{b,a})_{(b,a)\in K}$ is a frame with Riesz bounds A_g, B_g, we get

$$A_g \|f(x+\cdot\theta)\|^2_{L^2(\mathbb{R})} \leq \sum_{(b,a)\in K} |\langle f(x+\cdot\theta), g_{b,a}\rangle_{L^2(\mathbb{R})}|^2 \leq B_g \|f(x+\cdot\theta)\|^2_{L^2(\mathbb{R})}.$$

Observe that

$$\|G_{\theta,b,a} f\|^2_{L^2(\mathbb{R}^n)} = \int_{\mathbb{R}^n} |P_g f(\theta, E_\theta y, b, a)|^2 |h_{b,a}(\langle y, \theta\rangle)|^2 \, dy$$

$$= \int_{\theta^\perp} |P_g f(\theta, x, b, a)|^2 \, dx \, \cdot \|h\|^2_{L^2(\mathbb{R})} = \int_{\theta^\perp} |\langle f(x+\cdot\theta), g_{b,a}\rangle_{L^2(\mathbb{R})}|^2 \, dx \, \cdot \|h\|^2_{L^2(\mathbb{R})}.$$

By Fubini's theorem, we get

$$\sum_{(b,a)\in K} \|G_{\theta,b,a} f\|^2_{L^2(\mathbb{R}^n)} = \int_{\theta^\perp} \sum_{(b,a)\in K} |\langle f(x+\cdot\theta), g_{b,a}\rangle_{L^2(\mathbb{R})}|^2 \, dx \, \cdot \|h\|^2_{L^2(\mathbb{R})}.$$

The theorem can now be proved using the equality

$$\|f\|^2_{L^2(\mathbb{R}^n)} = \int_{\theta^\perp} \|f(x+\cdot\theta)\|^2_{L^2(\mathbb{R})} \, dx. \qquad \square$$

We mention the following corollary without proof.

COROLLARY 6.2. *Let $(K_\nu)_{\nu=1}^\infty$ be an increasing sequence of finite sets in K such that $K_\nu \uparrow K$. If $f \in L^2(\mathbb{R}^n)$, then $G_{\theta,K_\nu} f \to f$ in $L^2(\mathbb{R}^n)$ as $K_\nu \uparrow K$.*

Next, we study null spaces of sums of elementary projections. From now on, we assume that $(g_{b,a})_{(b,a)\in K}$ and $(h_{b,a})_{(b,a)\in K}$ form a biorthogonal system of Riesz bases. We will use the results that were obtained for orthogonal elementary projections in the preceding section to deal with the general case. In order to do this, choose a wavelet ψ such that $(\psi_{b,a})_{(b,a)\in K}$ is an orthonormal basis in $L^2(\mathbb{R})$. Assume that $\|\psi\|_{L^2(\mathbb{R})} = 1$. We shall write

$$G^o_{\theta,b,a} f = P_\psi f(\theta, E_\theta \cdot, b, a) \psi_{b,a}(\langle \cdot, \theta\rangle).$$

Define the operator $S_{\theta,h}$ on $L^2(\mathbb{R}^n)$ by

$$S_{\theta,h} f = \sum_{(b,a)\in K} P_\psi f(\theta, E_\theta \cdot, b, a) h_{b,a}(\langle \cdot, \theta\rangle). \tag{6.1}$$

For each $\rho \in L^2(\theta^\perp)$, $S_{\theta,h}$ maps $f = \rho(E_\theta \cdot)\psi_{b,a}(\langle \cdot, \theta \rangle)$ to $S_{\theta,h} f = \rho(E_\theta \cdot) h_{b,a}(\langle \cdot, \theta \rangle)$. In this manner, $S_{\theta,h}$ is a lifted version of the boundedly invertible mapping on $L^2(\mathbb{R})$ which maps $(\psi_{b,a})_{(b,a)\in K}$ onto $(h_{b,a})_{(b,a)\in K}$. We now prove that $S_{\theta,h}$ itself is indeed a boundedly invertible operator on $L^2(\mathbb{R}^n)$.

LEMMA 6.3. *The operator $S_{\theta,h}$ defined in* (6.1) *is boundedly invertible on $L^2(\mathbb{R}^n)$. Its inverse is given by*

$$S_{\theta,h}^{-1} f = \sum_{(b,a)\in K} P_g f(\theta, E_\theta \cdot, b, a)\psi_{b,a}(\langle \cdot, \theta \rangle),$$

and the adjoint of $S_{\theta,h}$ reads

$$S_{\theta,h}^{*} f = \sum_{(b,a)\in K} P_h f(\theta, E_\theta \cdot, b, a)\psi_{b,a}(\langle \cdot, \theta \rangle).$$

Observe that $S_{\theta,h}^{-1} = S_{\theta,g}^{*}$. Moreover, $\|S_{\theta,h}\| = B_h^{1/2}$ and $\|S_{\theta,h}^{-1}\| = A_h^{-1/2}$.

Proof. We first prove that $S_{\theta,h}$ is bounded on $L^2(\mathbb{R}^n)$. Let $f \in L^2(\mathbb{R}^n)$; then

$$\|S_{\theta,h} f\|_{L^2(\mathbb{R}^n)}^2 = \left\| \sum_{(b,a)\in K} P_\psi f(\theta, E_\theta \cdot, b, a) h_{b,a}(\langle \cdot, \theta, \rangle) \right\|_{L^2(\mathbb{R}^n)}^2$$

$$\leq B_h \sum_{(b,a)\in K} \|P_\psi f(\theta, E_\theta \cdot, b, a)\|_{L^2(\theta^\perp)}^2 = B_h \sum_{(b,a)\in K} \|G_{\theta,b,a}^{o} f\|_{L^2(\mathbb{R}^n)}^2 = B_h \|f\|_{L^2(\mathbb{R}^n)}^2.$$

In order to prove that the norm of $S_{\theta,h}$ equals $B_h^{1/2}$, let $\varepsilon > 0$ and let $(c_{(b,a)})_{(b,a)\in K} \in \ell^2(K)$ such that

$$\left\| \sum_{(b,a)\in K} c_{(b,a)} h_{b,a} \right\|_{L^2(\mathbb{R})}^2 > (B_h - \varepsilon) \sum |c_{(b,a)}|^2.$$

Let $\rho \in L^2(\theta^\perp)$ with unit norm, and let $f = \sum_{(b,a)\in K} c_{(b,a)} \rho(E_\theta \cdot)\psi_{b,a}(\langle \cdot, \theta \rangle)$. It is now easy to verify that

$$\frac{\|S_{\theta,h} f\|_{L^2(\mathbb{R}^n)}^2}{\|f\|_{L^2(\mathbb{R}^n)}^2} \geq B_h - \varepsilon.$$

In the same fashion, it can be shown that $\|S_{\theta,g}^{*}\| = A_h^{-1/2}$. Using Theorem 6.1, one proves that $S_{\theta,g}^{*} S_{\theta,h} = S_{\theta,h} S_{\theta,g}^{*} = I$. □

We state the following lemma without proof.

LEMMA 6.4.

$$S_{\theta,h}^{-1} G_{\theta,b,a} S_{\theta,h} = G_{\theta,b,a}^{o}.$$

The following results are obtained easily now.

LEMMA 6.5.

$$\ker G_{\theta,b,a} = S_{\theta,h} \ker G_{\theta,b,a}^{o}.$$

Corollary 6.6. *Define* $G_{\theta,K_0} = \sum_{(b,a)\in K_0} G_{\theta,b,a}$*; then*

$$\ker G_{\theta,K_0} = \bigcap_{(b,a)\in K_0} \ker G_{\theta,b,a}.$$

As in the previous section, we shall study the approximation of functions by averaging over approximations from several directions. In analogy to (5.2), we define the operator

$$T_{\Theta,K_0} = \frac{1}{|\Theta|} \sum_{\theta\in\Theta} G^*_{\theta,K_0} G_{\theta,K_0}, \tag{6.2}$$

where both $\Theta \subset S^{n-1}$ and $K_0 \subset K$ are finite subsets. Observe that if G_{θ,K_0} is an orthogonal projection, then $G^*_{\theta,K_0} G_{\theta,K_0} = G_{\theta,K_0}$; therefore the definition of T_{θ,K_0} here is consistent with the one given in (5.2). The proof of the following proposition is achieved along the same lines as the proof of Proposition 5.7.

Proposition 6.7. *Let* $\Theta = \{\theta_1, \ldots, \theta_N\} \subseteq S^{n-1}$ *denote a finite set of directions,* $K_0 \subseteq K$ *finite, and define* T_{Θ,K_0} *as in* (6.2)*. Then*

$$\ker\ T_{\Theta,K_0} = \bigcap_{j=1}^{N} \ker\ G_{\theta_j,K_0}.$$

It is not known to the author whether a result as in the Proposition 6.7 holds true for an operator of the form

$$\widetilde{T}_{\Theta,K_0} = \frac{1}{|\Theta|} \sum_{\theta\in\Theta} G_{\theta,K_0}.$$

Observe that Lemma 5.8 does not hold for sums of not necessarily orthogonal projections.

A GEOMETRIC APPROACH TO SINGULARLY PERTURBED NONLOCAL REACTION-DIFFUSION EQUATIONS*

AMITABHA BOSE†

Abstract. In the context of a microwave heating problem, a geometric method to construct a spatially localized, 1-pulse steady-state solution of a singularly perturbed, nonlocal reaction-diffusion equation is introduced. The 1-pulse is shown to lie in the transverse intersection of relevant invariant manifolds. The transverse intersection encodes a consistency condition that all solutions of nonlocal equations must satisfy. An oscillation theorem for eigenfunctions of nonlocal operators is established. The theorem is used to prove that the linear operator associated with the 1-pulse solution possesses an exponentially small principal eigenvalue. The existence and instability of n-pulse solutions is also proved. A further application of the theory to the Gierer–Meinhardt equations is provided.

Key words. nonlocal reaction-diffusion equation, geometric singular perturbation theory, transversality, metastability, eigenvalues

1. Introduction.

This paper is concerned with establishing a geometric method to analyze singularly perturbed, nonlocal reaction-diffusion equations. Such equations arise in microwave heating applications [18], activator-inhibitor chemical systems [20], thermistor [19], and ballast resistor problems [3], among other places. Nonlocal equations also are of interest because a higher-dimensional system can often be recast into a lower-dimensional nonlocal system [5, 7, 9, 14]. Existence of stationary solutions for scalar nonlocal equations has been considered by [3, 7, 9, 18, 19]. Stability of solutions for scalar nonlocal equations has been studied by [1, 3, 5, 10, 11, 12, 14].

Various methods for showing existence of solutions to nonlocal, boundary value problems have been employed. In [3, 9], it is shown that a homogeneous steady-state solution becomes unstable and a certain bifurcation occurs, thereby yielding a new steady-state or time-periodic solution. Lacey uses Picard iteration to show that nonhomogeneous steady-state solutions exist for equations modeling thermistors [19]. These methods establish the existence of solutions, but are not constructive in the sense that they give little information about the structure of solutions and where they lie in an appropriate phase space. Alternatively, asymptotic methods can be used to formally construct solutions [18]. However, asymptotic analysis does not actually yield a proof that a solution exists, and without a proof, one cannot be certain that what is constructed by formal asymptotics actually corresponds to the asymptotics of the true solution. Indeed, there are examples in the literature in which what appear to be asymptotic approximations of solutions are derived, but in fact there are no true solutions nearby at all. In the spirit of the approach that we shall take, Doelman and Rottschäfer [7] have studied a nonlocal reduction of the Ginzburg–Landau equations from a geometric point of view. The main purpose of their work is to compare a nonlocal model to a singularly perturbed one to determine whether the former is a

good approximant of the latter. As a result, their nonlocal equations do not involve singular perturbations.

In this paper, in the context of a microwave heating problem, it is shown how to use geometric singular perturbation theory to construct spatially localized 1-pulse solutions for a nonlocal boundary value problem. A 1-pulse solution contains one spatially localized local maxima. This solution is shown to lie in the transverse intersection of relevant invariant manifolds. Two manifolds intersect transversely, if at a point of intersection, the tangent spaces of these manifolds span the ambient space. Solutions to nonlocal equations must satisfy a so-called consistency condition, which we discuss in detail below. An important byproduct of this work is the development of a geometric method to determine which trajectories in phase space satisfy the consistency condition. We show how to replace the scalar nonlocal boundary value problem with a higher-dimensional local boundary value problem in which the consistency constraint has been embedded.

Transversality is obtained as a direct result of the higher dimensionality. In fact, our analysis shows that transversality implies satisfaction of the consistency condition. Furthermore, since transversality of manifolds implies local uniqueness of intersections, we also obtain local uniqueness of the 1-pulse solution. This means that in a neighborhood of phase space of a 1-pulse solution, there are no other steady-state solutions. We also prove the existence of spatially localized n-pulse solutions.

Freitas [10, 11, 12] has obtained extensive results on the stability of scalar nonlocal reaction-diffusion equations. He shows how to locate the spectrum of a nonlocal linear operator by seeing how the spectrum of a related local operator changes under perturbations. Here, we locate the spectrum of a nonlocal version of a standard Sturm–Liouville operator. We show that the 1-pulse is metastable in that the nonlocal operator possesses an exponentially small principal eigenvalue. For $n \geq 2$, the n-pulses are unstable. The primary tool we employ is an oscillation theorem found in Bose and Kriegsmann [1]. Using Freitas' results, we show that this theorem holds under more general circumstances than those found in [1].

The equation of interest arises in microwave heating applications. A spatially localized hot spot forms in a thin ceramic fiber when it is microwave heated in a highly resonant, single mode cavity. The spot forms along the axis of the sample and begins to propagate [21]. In most cases the spot eventually becomes stationary, thereby leaving a localized region of the fiber at a dramatically higher temperature than the rest. Kriegsmann [18] derives the following nonlocal reaction-diffusion equation to model this phenomena:

$$U_t = \epsilon^2 U_{xx} + \frac{pf(U)}{1 + c^2(\int_0^1 f(U)\ dx)^2} - h(U), \tag{1.1}$$

$$U_x(0,t) = U_x(1,t) = 0.$$

Here $0 \leq x \leq 1$, U corresponds to the dimensionless temperature along the fiber and is assumed to be nonnegative; p is the dimensionless power which is proportional to the square of the amplitude of the mode which excites the cavity; and c lumps several physical parameters together. The function $h(U)$ models heat loss at the surface of the fiber due to convection and radiation and satisfies $h(0) = 0$, $h'(U) > 0$. The function $f(U)$ represents the effective electrical conductivity of a low-loss ceramic, such as alumina, and satisfies $f(0) = 1$, $f'(U) > 0$ and $f(U)$ grows faster than $h(U)$

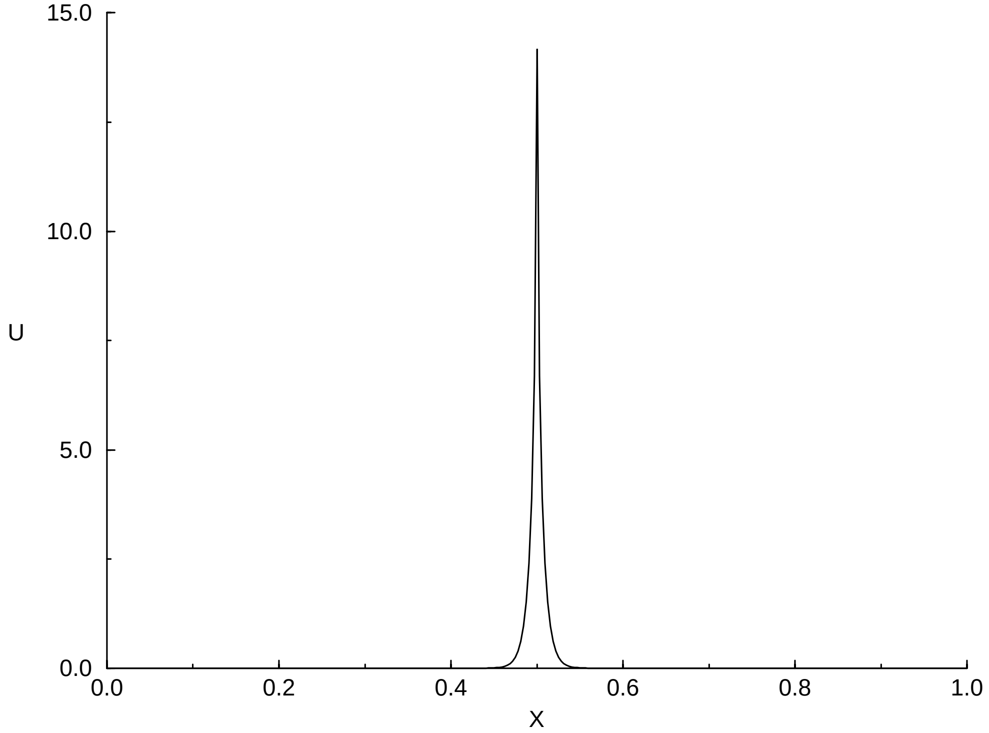

FIG. 1.1. *Kriegsmann's* 1*-pulse solution with* $\epsilon = 0.01$*,* $p = 1.0$*,* $c = 0.01$*,* $\beta = 0.01$*,* $c_1 = 1.0$*.*

for sufficiently large values of U. Both f and h are assumed to be sufficiently smooth. The nonlocal term models the detuning effect the heated fiber has upon the cavity. The diffusion constant ϵ is the aspect ratio of the fiber and in practice is much less than one, thereby making (1.1) singularly perturbed.

In [18], Kriegsmann chooses $f(U) = e^{c_1 U}$, $c_1 > 0$ and $h(U) = 2(U+\beta[(U+1)^4-1])$, $\beta \ll 1$. There, he formally constructs a localized, 1-pulse, steady-state solution ($U_t = 0$) using matched asymptotic expansions (see Figure 1.1). Kriegsmann shows that for ϵ sufficiently small, the 1-pulse possesses the following characteristics:

(C1) The solution is symmetric about $x = 1/2$.

(C2) It is nearly constant and close to zero valued on most of $[0, 1]$.

(C3) On a small interior layer centered around $x = 1/2$, the solution attains a maximum value that tends to ∞ as $\epsilon \to 0$. The value of the nonlocal integral term also tends to ∞ in this limit.

Recently, Bose and Kriegsmann [1] proved that this solution is metastable. The solution is, in fact, unstable, but perturbations of the solution decay to the solution or a translate of it, which then persists for exponentially long amounts of time.

In this paper, we study (1.1) with $f(U) = 1 + U^2$ and $h(U) = 2U$. Our choice of these functions is motivated by the fact that they are the simplest functions for which solutions of (1.1) retain the qualitative features of those found in [18]. Moreover, this choice simplifies the analysis so as to focus on the geometric approach. See Remark 3.6 for a discussion on the effect of including $O(\beta)$ terms in the function $h(U)$. To construct a steady-state 1-pulse solution of (1.1), we study the following boundary value problem:

$$\epsilon^2 U_{xx} + \frac{p(1+U^2)}{1+c^2(\int_0^1 1+U^2\ dx)^2} - 2U = 0, \tag{1.2}$$

$$U_x(0) = U_x(1) = 0.$$

Let $I = \int_0^1 U^2\ dx$. Replacing $\int_0^1 1+U^2\ dx$ by $1+I$, we note that the value I is determined by the solution itself. Thus a solution of (1.2) must satisfy the *consistency condition*

$$I_\star = \int_0^1 U^2(x, I_\star)\ dx. \tag{1.3}$$

The prescribed value $I_\star$ must be the value that is determined by computing the integral of U^2 along a trajectory of (1.2). This motivates the introduction of an auxiliary variable $V(x) = \int_0^x U^2\ dx$.

We recast (1.2) as the following system of first-order equations, where $' = d/dx$:

$$\begin{aligned} \epsilon U' &= W, & V' &= U^2, \\ \epsilon W' &= 2U - \tfrac{p(1+U^2)}{1+c^2(1+I)^2}, & I' &= 0. \end{aligned} \tag{1.4}$$

Note that $V(1) = \int_0^1 U^2\ dx$. This formulation, in a very natural way, recasts (1.2)–(1.3) into the boundary value problem (1.4), subject to the boundary conditions

$$\begin{aligned} (U, W, V, I) &= (U(0), 0, 0, I_\star) \text{ at } x = 0, \\ (U, W, V, I) &= (U(1), 0, I_\star, I_\star) \text{ at } x = 1. \end{aligned} \tag{1.5}$$

The new consistency condition is $V(1) = I_\star$. The analysis will show that $I_\star$ is unique, as a priori, this is not obvious. The values of $U(0)$ and $U(1)$ will also need to be determined. Since $\int_0^1 1+U^2\ dx = 1+I$ is simply a number, by phase plane considerations, any pulse solution of (1.4)–(1.5) will necessarily be symmetric about $x = 1/2$. Thus $U(0) = U(1)$. Also, the trivial equation $I' = 0$ in (1.4) is necessary, as the unique value $I_\star$ will be determined by transversality with respect to I.

We employ geometric singular perturbation theory to construct a 1-pulse solution of (1.4)–(1.5) [8, 15]. This theory involves finding solutions to sets of reduced equations obtained by formally setting $\epsilon = 0$ in appropriately scaled versions of (1.4). These solutions are then pieced together to form a singular solution. If the singular solution lies in certain manifolds which satisfy relevant transversality conditions, then an actual solution for $\epsilon \ll 1$ is obtained. Transverse intersections persist under perturbation which allows the $\epsilon = 0$ results to be extended to ϵ small. The first theorem that we prove is the following.

THEOREM 1.1. (a) *For ϵ sufficiently small, there exists a locally unique, symmetric* 1*-pulse solution U_1 of* (1.4)–(1.5)*. The maximum value U_{max} of this solution and the unique value $I_\star$ of the nonlocal term are given by*

$$U_{max} = 3c^2 I_\star^2/p + O(\epsilon), \qquad I_\star = \left(\frac{p^2}{12\sqrt{2}c^4\epsilon}\right)^{1/3} + O(\epsilon).$$

(b) *Let ϵ_1 be sufficiently small such that a symmetric* 1*-pulse solution exists as in* (a)*. Then for $\epsilon = \epsilon_1/n$, there exists a symmetric n-pulse solution U_n of* (1.4)–(1.5).

Stability of these solutions with respect to arbitrary perturbations is an important property for any physically realizable solution. For nonlocal equations of the type under consideration, Chafee [3] has shown that linear stability implies asymptotic stability. If a solution is asymptotically stable, then arbitrary perturbations of the solution decay in an appropriate function space. The main result to be proved here is that the 1-pulse solution is metastable, as is the case for the 1-pulse constructed in [18] and analyzed in [1].

THEOREM 1.2. (a) *The* 1*-pulse solution* U_1 *is a metastable solution of* (1.1). (b) *For* $n \geq 2$*,* n*-pulse solutions* U_n *are unstable solutions of* (1.1) *with principal eigenvalue bounded away from the origin as* $\epsilon \to 0$*.*

We now give an outline of the paper. Due to criterion (C3) of Kriegsmann's solution, it turns out that (1.4) is not the correctly scaled version of the equations with which to work. In section 2, we rescale (1.4) to obtain the correct set of equations, together with relevant sets of reduced equations. In section 3, we construct a singular 1-pulse solution and show that it perturbs to yield an actual 1-pulse solution for ϵ sufficiently small. We also obtain n-pulse solutions using a simple rescaling argument. In section 4, we prove Theorem 1.2 concerning the stability of solutions. Section 5 contains numerical simulations of the full time-dependent equations. The numerically obtained values for U_{max} and $I_\star$ are shown to agree closely with the theoretically predicted ones. In section 6, we give a second application of our theory to a special limit of the Gierer–Meinhardt equations [13] which describe biological pattern formation. In this limit, the system of two reaction-diffusion equations can be reduced to a scalar nonlocal reaction-diffusion equation of the type considered above. A brief discussion concludes the paper.

2. The singular solution.

2.1. Scalings. The asymptotic analysis of Kriegsmann [18] shows that the maximum value of the 1-pulse solution of (1.1) tends to infinity as ϵ tends to 0. Moreover, the value of the nonlocal term I also tends to infinity in this limit. Numerical simulations of (1.1), with either set of nonlinearities discussed above, show that the main contribution to the nonlocal term occurs on the small interior layer around $x = 1/2$. A set of outer and inner equations associated with (1.4) can naively be derived in an attempt to capture this behavior. An outer set of equations is found simply by setting $\epsilon = 0$ in (1.4). An inner set of equations is obtained by rescaling the spatial variable x in a neighborhood of $1/2$ by using $\xi = (x - 1/2)/\epsilon$ and then setting $\epsilon = 0$ in the ensuing equations. The problem with this scaling is that $dV/d\xi = 0$. Thus there would be no contribution to the nonlocal integral term over the inner solution.

Following ideas similar to those found in [6], we rescale both the spatial and dependent variables in (1.4). Let $u = \epsilon^a U$, $w = \epsilon^a W$, $v = \epsilon^b V$, $Z = \epsilon^b I$, and $\xi = (x - 1/2)/\epsilon$. We use a capital Z for the new scaling of I to emphasize that transversality occurs with respect to this parameter. It is clear why U and W need to be scaled by the same power of ϵ. That V and I also need to be scaled by equal powers of ϵ follows from the fact that the consistency condition requires $V(1) = I$. Introducing these scalings in (1.4) with $\dot{} = d/d\xi$ yields

$$
\begin{aligned}
&\dot{u} = w, && \dot{v} = \epsilon^{b+1-2a} u^2, \\
&\dot{w} = 2u - p\, \tfrac{\epsilon^{a+2b} + \epsilon^{2b-a} u^2}{\epsilon^{2b} + c^2(\epsilon^b + Z)^2}\ , && \dot{Z} = 0, \\
&\dot{Z} = 0. &&
\end{aligned}
\tag{2.1}
$$

We require that all nonconstant terms in (2.1) be $O(1)$. We do this in order to make sure that both the linear (u) and the nonlinear (u^2) terms in the w component of the vector field are $O(1)$ so that the fast subsystem possesses a homoclinic orbit. Doing so implies $2b = a$ and $2a = b + 1$. Thus $a = 2/3$ and $b = 1/3$. Next, scale back to the x-variable, introduce $y = x$, and append the equation $dx/dy = 1$ to allow the invariant manifolds, defined below, to explicitly contain a spatial component. The set of equations then becomes

$$\begin{aligned} \epsilon du/dy &= w, & dZ/dy &= 0, \\ \epsilon dw/dy &= 2u - p\tfrac{\epsilon^{4/3}+u^2}{\epsilon^{2/3}+c^2(\epsilon^{1/3}+Z)^2}, & dx/dy &= 1, \\ \epsilon dv/dy &= u^2. \end{aligned} \tag{2.2}$$

In these new scalings, the consistency condition (1.3) becomes

$$\epsilon Z_\star = \int_0^1 u^2(y, Z_\star)\ dy. \tag{2.3}$$

The boundary conditions (1.5) transform to

$$\begin{aligned} (u, w, v, Z, x) &= (u(0), 0, 0, Z_\star, 0), \\ (u, w, v, Z, x) &= (u(1), 0, Z_\star, Z_\star, 1). \end{aligned} \tag{2.4}$$

In terms of these boundary conditions, the consistency condition is also recognized as $v(1) = Z_\star$. As before the symmetry of the 1-pulse implies $u(0) = u(1)$, and these values along with $Z_\star$ will need to be determined by the analysis.

2.2. Solutions to reduced equations and singular solutions. The inner and outer sets of equations associated with (2.2) are now easy to obtain. To derive the outer equations, set $\epsilon = 0$ in (2.2):

$$\begin{aligned} 0 &= w, & dZ/dy &= 0, \\ 0 &= 2u - p\tfrac{u^2}{c^2Z^2}, & dx/dy &= 1, \\ 0 &= u^2. \end{aligned} \tag{2.5}$$

To obtain the inner inequations which incorporate the symmetry of the 1-pulse, condition (C1), we rescale (2.2) in a neighborhood of $y = 1/2$ using $\xi = (y - 1/2)/\epsilon$, and set $\epsilon = 0$:

$$\begin{aligned} \dot{u} &= w, & \dot{Z} &= 0, \\ \dot{w} &= 2u - p\ \tfrac{u^2}{c^2Z^2}\ , & \dot{x} &= 0, \\ \dot{v} &= u^2. \end{aligned} \tag{2.6}$$

Solutions to (2.5) are easily found as both u and w are forced to be zero by the vector field. The values of v and Z, however, are unspecified, but constant for the outer equations. Solutions to the outer equations capture the behavior described in condition (C2). Solutions to (2.6) are also easily obtained. Note that the u and w equations are decoupled from the v equation and that Z acts as a parameter in these equations. For each value of Z, the $u - w$ equations are Hamiltonian with critical points $(0, 0)$ and $(2c^2Z^2/p, 0)$. The origin is a saddle point and the other critical point is a center. The $u - w$ phase plane is shown in Figure 2.1. The value of v along an

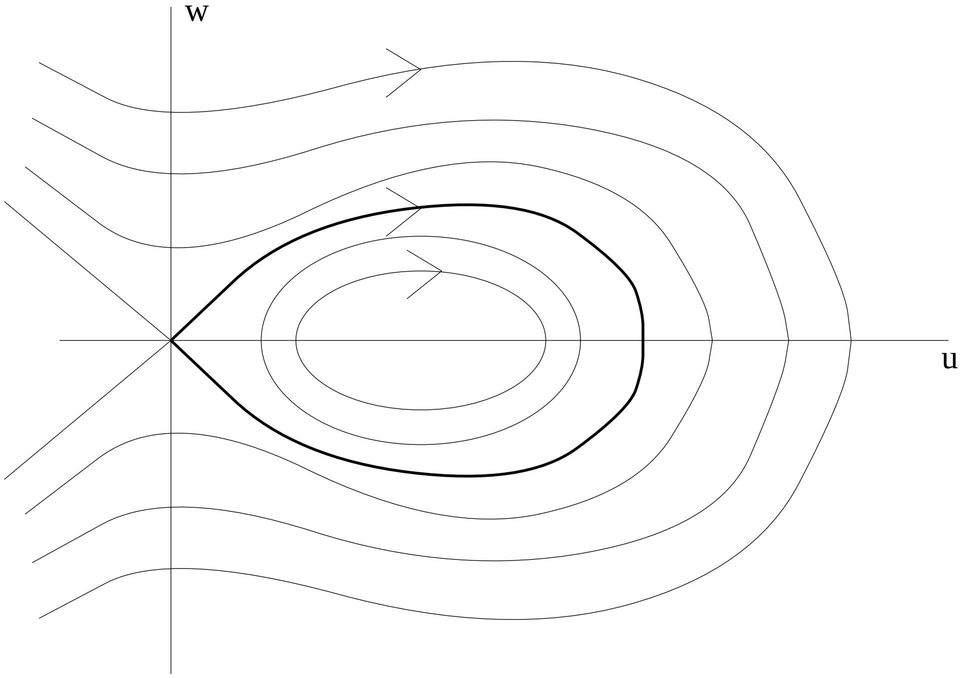

FIG. 2.1. *The phase plane for the $u - w$ equations of* (2.6). *The homoclinic solution is the darker curve.*

inner solution is determined by integrating u^2 along a trajectory in the $u - w$ phase plane. The homoclinic solution of the inner equations (2.6) captures the behavior described in (C3).

The singular solution can now be constructed. By definition, $v(0) = 0$. Thus at $y = 0$, only Z is unspecified. Since Z can vary, there exists a one-parameter family of singular solutions. We describe one particular member of this family. Fix $Z > 0$. The first piece of the singular trajectory is a solution of (2.5) that connects $(0, 0, 0, Z, 0)$ to $(0, 0, 0, Z, 1/2)$ in (u, w, v, Z, x) space. The second piece is the solution of (2.6) that connects $(0, 0, 0, Z, 1/2)$ at $\xi = -\infty$ to $(0, 0, v, Z, 1/2)$ at $\xi = \infty$. In the u and w components, this singular piece corresponds to the homoclinic orbit pictured in Figure 2.1. Since the value of v at $\xi = -\infty$ is different than at $\xi = +\infty$, the inner piece is actually a heteroclinic orbit in the full five-dimensional phase space. The third and final piece of the singular trajectory is a solution of (2.5) from $(0, 0, v, Z, 1/2)$ to $(0, 0, v, Z, 1)$.

With these scalings, the consistency condition (2.3) reduces to a particularly simple form. In the outer equations (2.5), $u = 0$. Thus, the outer solutions contribute nothing to the integral. The $\epsilon = 0$ value of $Z_\star$, denoted by Z_0, is determined solely by the inner equations and is given by

$$Z_0 = \int_{-\infty}^{\infty} u^2(\xi, Z_0)\, d\xi. \tag{2.7}$$

3. Invariant manifolds and transversality. We now pick out a unique singular solution which satisfies (2.7) from the one-parameter family of singular 1-pulse solutions. We then extend the analysis to ϵ small. To do both, we recast the above analysis into the language of invariant manifolds. Our analysis relies on the seminal work of Fenichel [8] on the persistence of invariant manifolds. See Jones [15] and the references therein for a thorough exposition of the theory and some of its applications.

Following Tin, Kopell, and Jones [22], we define manifolds of points which, respectively, satisfy the boundary conditions (2.4) at $y = 0$ and 1. We then flow the $y = 0$ boundary manifold forward to determine whether it intersects the boundary manifold at $y = 1$. Denote the flows of (2.5) and (2.6) as the outer and inner flows, respectively. These flows are used to track the evolution of the $y = 0$ boundary manifold over different pieces of the singular solution.

The $y = 0$ boundary manifold is defined by

$$B_0 = \{(u, w, v, Z, x) : u = w = v = x = 0\}.$$

Thus B_0 is a one-dimensional curve consisting solely of different Z values along which u, w, v, and x are restricted to 0. At $y = 1$, we define two different boundary manifolds. First, let

$$B_R = \{(u, w, v, Z, x) : u = w = 0, x = 1\}.$$

The manifold B_R is two-dimensional as both v and Z are free and by definition positive. It contains no information about the consistency condition. Enforcing $v(1) = Z$ restricts B_R to the following one-dimensional submanifold:

$$B_1 = \{(u, w, v, Z, x) : u = w = 0, v = Z, x = 1\}.$$

At $y = 1/2$, the jump off and touch down curves are defined. These are curves along which the outer and inner flows must match. The jump off curve is

$$J_0 = \{(u, w, v, Z, x) : u = w = v = 0, x = 1/2\}$$

and the touch down curve is

$$T_0 = \left\{(u, w, v, Z, x) : u = w = 0, v = \int_{-\infty}^{\infty} u^2(\xi, Z)\, d\xi, x = 1/2\right\}.$$

The touch down curve is determined by flowing J_0 forward under the inner flow. In particular, it contains no information about the consistency condition. In the next subsection, we will define an analogous curve T_c which will encode the consistency condition.

Denote by $B_0 \cdot y$ the two-dimensional manifold formed by flowing B_0 forward. Note that $J_0 = B_0 \cdot y|_{y=1/2^-}$, so the outer flow transversely intersects the jump off curve on the slow manifold. This is essential for the perturbation result later for ϵ small. Now use the inner flow to follow $J_0 = B_0 \cdot 1/2^-$. For each point on J_0, there exists a homoclinic solution of the inner $u - w$ equations (2.6). As mentioned earlier, considering the full set of inner equations in a five-dimensional phase space, this is actually a heteroclinic solution in that the values of v and Z on the jump off curve J_0 and touch down curve T_0 are dramatically different; see Figure 3.1. Thus the inner flow defines a two-dimensional (sheet) manifold of heteroclinic orbits, which connects J_0 to T_0. Therefore T_0 is also one-dimensional. Lastly, flow T_0 forward to $y = 1$ using the outer flow to obtain $T_0 \cdot 1$. The curve $T_0 \cdot 1$ is the image of B_0 flowed under the appropriate outer and inner equations. Thus we define $B_0 \cdot 1 = T_0 \cdot 1$. By

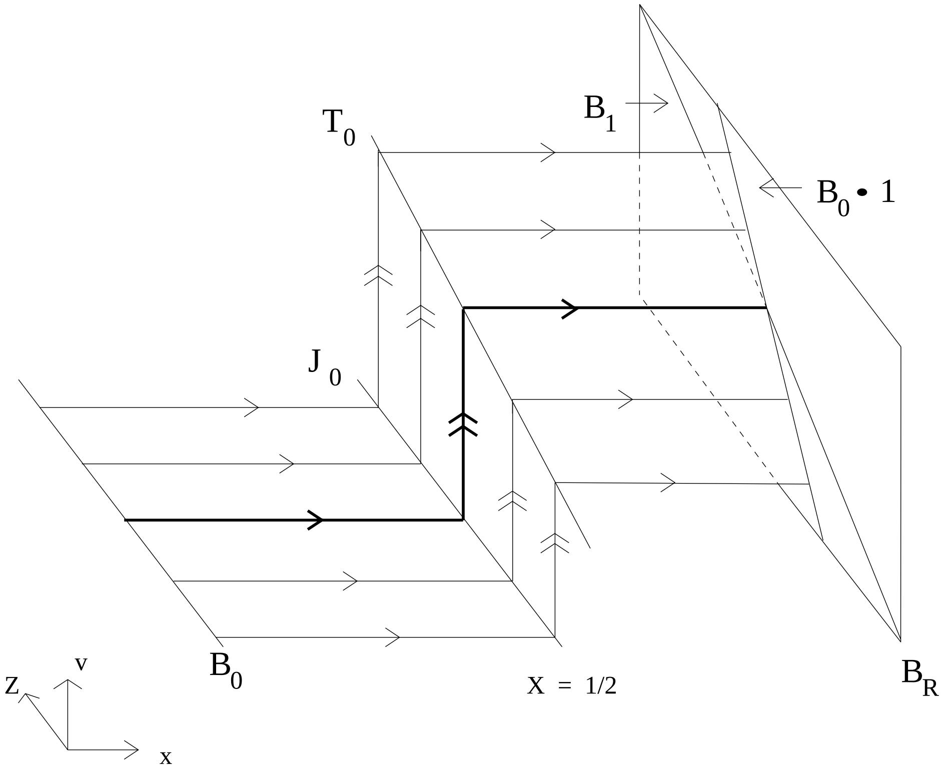

FIG. 3.1. *A graphical representation of the singular manifolds, curves, and flows, projected into (v, Z, x) space. The darker curve depicts the unique singular solution that satisfies the consistency condition.*

construction, $B_0 \cdot 1 \cap B_R \neq \emptyset$. If there is a singular 1-pulse solution, then it must satisfy the following geometric version of (2.7):

$$B_0 \cdot 1 \cap B_1 \neq \emptyset. \tag{3.1}$$

Further, if $B_0 \cdot 1$ transversely intersects B_1 in $\mathbf{R^2}$, then there exists a unique singular 1-pulse solution which satisfies (2.7). The following lemma establishes the transversality.

LEMMA 3.1. *The curve T_0 transversely intersects the line $v = Z$ at a unique point in (Z, v) space.*

Proof. It is easy to verify that

$$u(\xi) = \frac{3c^2 Z^2}{p} \operatorname{sech}^2 \frac{\xi}{\sqrt{2}}, \quad w(\xi) = \dot{u} \tag{3.2}$$

solves the $u - w$ equations of (2.6). Let $v(Z)$ be defined by the first equation of (3.3), below. It is easily checked that

$$v(Z) = \int_{-\infty}^{+\infty} u^2(\xi, Z)\, d\xi = \tfrac{12\sqrt{2}c^4 Z^4}{p^2}. \tag{3.3}$$

The graph of (3.3) is exactly T_0 projected onto (Z, v) space; see Figure 3.2. Note that it intersects the line $v = Z$ at exactly one point. This intersection value is calculated

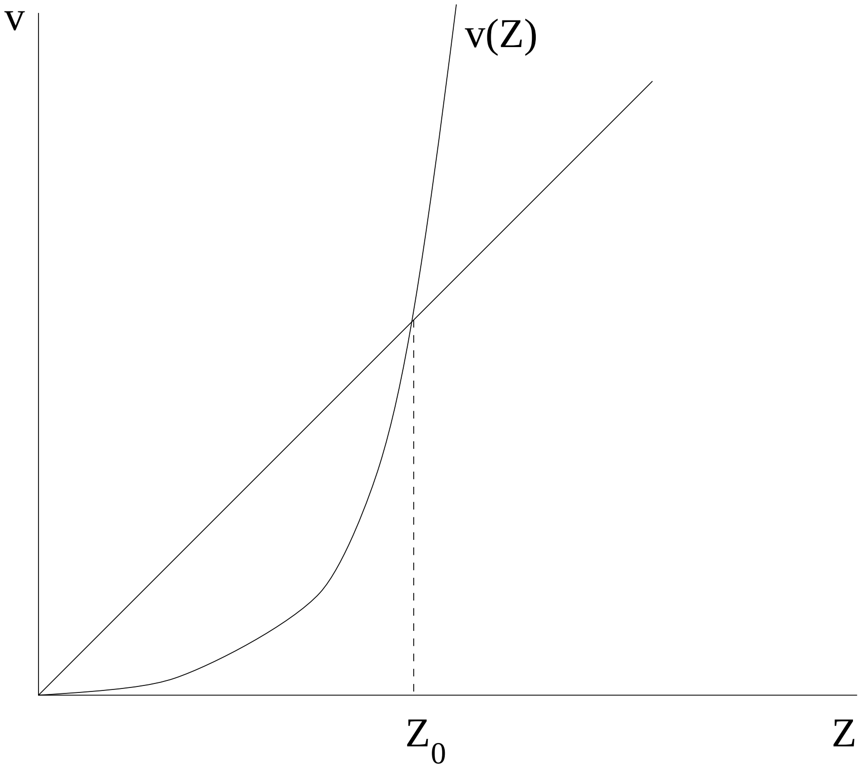

FIG. 3.2. *The transverse intersection of $v(Z)$ and $v = Z$ in (Z, v) space.*

by solving $Z_0 = v(Z_0)$, which yields

$$Z_0 = \left(\frac{p^2}{12\sqrt{2}c^4} \right)^{1/3}. \tag{3.4}$$

Therefore (3.4) determines the unique value Z_0 that satisfies (2.7). Transversality follows since the slope of T_0 at the point Z_0 is not equal to one, which is the slope of $v = Z$. □

Remark 3.2. While we use the closed form of $u(\xi)$ to obtain transversality, it will be clear from the estimates for the Gierer–Meinhardt equations in section 6 that the transversality can be obtained in the absence of a closed form solution.

Lemma 3.1 is sufficient to prove that $B_0 \cdot 1$ transversely intersects B_1, the restriction of B_R to the line $v = Z$. Since v changes only along the inner solution, in the (Z, v) plane, the curves T_0 and $B_0 \cdot 1$ are identical. Thus transversality follows from the lemma and is stated in the following corollary.

COROLLARY 3.3. *The curve $B_0 \cdot 1$ transversely intersects B_1 at $v = Z_0$ in (Z, v) space.*

3.1. The argument for $0 < \epsilon \ll 1$. A region of an invariant manifold M_0 is normally hyperbolic if all of the eigenvalues corresponding to eigenvectors normal to the manifold are bounded away from the imaginary axis. Fenichel [8] showed that a normally hyperbolic invariant manifold persists under perturbations. Moreover, the perturbed manifold M_ϵ is $O(\epsilon)$ close to M_0 and also retains this hyperbolic structure.

Finally he showed that the flow on M_ϵ is $O(\epsilon)$. For any Z, recall that $(u, w) = (0, 0)$ is a saddle point for the inner flow and that u and w are restricted to these values on B_0 and B_1. It follows then that the boundary manifolds B_0 and B_1 are normally hyperbolic. Therefore, they perturb to nearby manifolds B_0^ϵ and B_1^ϵ. We need to show that the forward evolution of B_0^ϵ transversely intersects B_1^ϵ at $x = 1$. Instead of making the calculation at $x = 1$, it is more convenient to check this intersection at some intermediate value $x = a$ by flowing B_1^ϵ backwards in space. We will assume that $x = a$ is in some sufficiently small deleted neighborhood of $x = 1/2$.

We need one more critical result concerning the singular flows. Figure 3.1 gives a picture of how the singular flows evolve, but it is deceptive in that it does not fully reveal the transversality that exists in the equations. Indeed, in Figure 3.1, it appears that there is no transversality due to the inner equations. While it is certainly true that the manifold leaving J_0 does not transversely intersect the manifold approaching T_0, we are not actually interested in T_0.

Instead, flow B_1 backwards to $x = 1/2$ under the outer flow. Define a new consistency curve by

$$T_c = \{(u, w, v, Z, x) : u = w = 0, v = Z, x = 1/2\}.$$

Consider once again the inner equations (2.5). Let $W^u(J_0)$ denote the two-dimensional center-unstable manifold of J_0 composed of the union of the one-dimensional unstable manifolds of the critical point $(0, 0)$ over different values of Z. Similarly, let $W^s(T_c)$ denote the two-dimensional center-stable manifold of T_c. Both of these manifolds exist since $(0, 0)$ is a hyperbolic critical point. Note that $W^u(J_0) \to T_0$ as $\xi \to \infty$, and that T_c projected into (Z, v) space is the line $v = Z$. The following is a corollary of Lemma 3.1 and Corollary 3.3.

COROLLARY 3.4. *The manifold $W^u(J_0)$ transversely intersects $W^s(T_c)$ in (u,w,Z) space at $Z = Z_0$.*

The corollary shows that the inner flow induces a transverse intersection of *the* manifolds needed to actually construct the 1-pulse solution. This transversality encodes the consistency condition. Finally, for later use, let $M_0 = \cup_{y\in[0,1/2]} B_0 \cdot y$ and $\mathcal{M}_0 = \cup_{y\in[1/2,1]} T_c \cdot y$, under the outer flow (2.5).

Tin, Kopell, and Jones [22] give conditions for general boundary value problems for which the existence of a singular solution implies the existence of an actual solution for ϵ small. Consistent with the major simplifications offered by geometric singular perturbation theory, these conditions are on the $\epsilon = 0$ singular manifolds. Thus the verification of these conditions occurs in lower-dimensional reduced settings. Tin, Kopell, and Jones' work is based on the exchange lemma of Jones and Kopell [16], which itself relies on Fenichel's invariant manifold theory. The hypotheses (H1)–(H3) below, which provide sufficient conditions to prove the existence of an actual solution for ϵ sufficiently small, are all based on transversality at $\epsilon = 0$ [22]. Stated in notation adapted for this paper, they are the following:

(H1) The outer flow on M_0 transversely intersects J_0.

(H2) $W^u(J_0)$ transversely intersects $W^s(T_c)$ in (u, w, Z) space.

(H3) The outer flow on $\mathcal{M}_0$ transversely intersects T_c.

For our situation, (H1) and (H3) are trivial to verify as can be seen in Figure 3.1. Note that these transversality calculations need to be verified in only a two-dimensional ambient space. Hypothesis (H2) follows directly from Corollary 3.4. Although the ambient space for this intersection is three-dimensional, the needed calculation occurs in a two-dimensional space.

Tin, Kopell, and Jones' results imply the existence of an actual solution for ϵ sufficiently small for the following reason. Let $\mathcal{B}_0^\epsilon$ and $\mathcal{B}_1^\epsilon$ denote the manifolds obtained by flowing B_0^ϵ forward and B_1^ϵ backward under (2.2), respectively. The perturbed manifold $\mathcal{B}_0^\epsilon$ is $O(\epsilon)$ close to M_0, up to a neighborhood of $x = 1/2$. Similarly $\mathcal{B}_1^\epsilon$ is $O(\epsilon)$ close to $\mathcal{M}_0$. Based on the exchange lemma [16], Tin, Kopell, and Jones show that when $\mathcal{B}_0^\epsilon$ and $\mathcal{B}_1^\epsilon$ veer away from these outer manifolds, they are $C^1 - O(\epsilon)$ close to $W^u(J_0)$ and $W^s(T_c)$, respectively. Thus not only are the perturbed manifolds $O(\epsilon)$ close to relevant singular manifolds, so are their tangent spaces. Since transversality is determined by the behavior of tangent spaces, the C^1 closeness is important. Therefore, since $W^u(J_0)$ and $W^s(T_c)$ intersect transversely at Z_0 independent of ϵ, the $C^1 - O(\epsilon)$ closeness of the perturbed manifolds $\mathcal{B}_0^\epsilon$ and $\mathcal{B}_1^\epsilon$ to these manifolds implies that they also intersect transversely for some $Z_\star$ $O(\epsilon)$ close to Z_0.

Therefore, we have shown that $B_0^\epsilon \cdot 1$ transversely intersects B_1^ϵ for ϵ sufficiently small. In $\mathbf{R}^2$, the unique point of intersection of these two curves determines $Z_\star$. This value of $Z_\star$ determines $I_\star$ which is then used in (1.2) to obtain $U_1(x)$. The value of $U_1(0) = U_1(1)$ can then be found. To determine U_{max}, we use the Hamiltonian associated with the inner equations (2.6):

$$H(u,w) = w^2/2 - u^2 + \frac{pu^3}{3c^2Z_0^2}. \tag{3.5}$$

Since the value of H is conserved along trajectories, and, in particular, along the homoclinic of Figure 2.1, we can solve $H(0,0) = H(u_{max}, 0)$. This yields $u_{max} = 3c^2Z_0^2/p$. Finally, rescaling (u, v, w, Z) back to the original (U, W, V, I) variables and using Fenichel [8], the values U_{max} and $I_\star$ stated in Theorem 1.1 are obtained.

Remark 3.5. The geometric argument presented above fails to uniquely pick out the point at which the 1-pulse is centered. Indeed, it is only by using symmetry of the 1-pulse solution that we define the inner equations at $x = 1/2$ and not at some other point in the domain. See Ward [23] for a thorough discussion on this indeterminacy. As he shows, the metastability of solutions is a direct consequence of it.

Remark 3.6. In (1.2), we have not included the $O(\beta)$ terms which actually appear in Kriegsmann's model [18]. The geometric results presented here can be extended to the case where these terms are included in the vector field provided that β is $O(\epsilon^{2+\alpha})$, $\alpha > 0$. The reason why this restriction is needed is precisely because of characteristic (C3) of Kriegsmann's solution. On the interior layer, $U \to \infty$. Thus the included quartic U^4 would be the dominant term of the rescaled equations (2.1) unless β is $O(\epsilon^{2+\alpha})$. As a result, the existence and transverse intersection of $B_0^\epsilon \cdot 1$ with B_1^ϵ persists provided β is small enough.

3.2. Existence of n-pulse solutions. Equation (1.2) also admits n-pulse solutions for small values of ϵ. These solutions contain n equal, local maxima and are also symmetric about $x = 1/2$. A similar geometric argument as above could be given to construct these solutions. Instead, we present a simple rescaling argument which exploits the symmetry requirements of the solutions.[1]

Denote the symmetric 1-pulse solution by $\Phi_1(x)$. This solution satisfies

$$\epsilon^2 \Phi_{1_{xx}} + \frac{pf(\Phi_1)}{1 + c^2(\int_0^1 f(\Phi_1)\,dx)^2} - h(\Phi_1) = 0,$$

[1] I thank Gregory Kriegsmann for suggesting the rescaling argument to me.

$$\Phi_1'(0) = \Phi_1'(1) = 0.$$

Next define

$$\Phi_2(x) = \begin{cases} \Phi_1(x), & 0 < x < 1, \\ \Phi_1(x-1), & 1 < x < 2. \end{cases}$$

Then $\Phi_2(2x)$ satisfies

$$\frac{\epsilon^2}{4}\Phi_{2_{xx}} + \frac{pf(\Phi_2)}{1 + c^2(\int_0^1 f(\Phi_2)\, dx)^2} - h(\Phi_2) = 0,$$

$$\Phi_2'(0) = \Phi_2'(1) = 0.$$

Thus

$$\Phi_2(2x) = \begin{cases} \Phi_1(2x), & 0 < x < 1/2, \\ \Phi_1(2x-1), & 1/2 < x < 1, \end{cases}$$

and $\Phi_2(2x)$ has two local maximum at $x = 1/4$ and $x = 3/4$. Thus $\Phi_2(2x)$ is a symmetric 2-pulse solution of (1.2) which has been obtained by reflecting and rescaling the 1-pulse solution $\Phi_1(x)$. The diffusion constant is half that of the corresponding 1-pulse solution. Now continue the process to obtain a symmetric 4-pulse solution and so on. It is seen that a symmetric $\Phi_{2^m}(2^m x)$ solution exists which satisfies (1.2).

There is nothing special about base 2. In fact, defining

$$\Phi_3(x) = \begin{cases} \Phi_1(x), & 0 < x < 1, \\ \Phi_1(x-1), & 1 < x < 2, \\ \Phi_1(x-2), & 2 < x < 3, \end{cases}$$

we see that $\Phi_3(3x)$ satisfies (1.2) and is a symmetric 3-pulse solution. Continuing in this fashion, it is easy to obtain a symmetric n-pulse solution for any value of n.

In closing, we do not obtain local uniqueness of these solutions by this rescaling method. However, in the next section, we show that any n-pulse solutions for $n \geq 2$ are unstable, so this lack of information concerning local uniqueness is not so important.

4. Stability. In this section, we prove Theorem 1.2. In particular, we show that the 1-pulse solution constructed above is metastable, with its principal eigenvalue being exponentially small in ϵ. The n-pulse solutions, however, are unstable, with principal eigenvalues bounded away from the origin as $\epsilon \to 0$.

Our analysis relies on two key ingredients. The first is an oscillation theorem for the nonlocal eigenfunctions and their corresponding eigenvalues. This theorem is similar to the one found in Bose and Kriegsmann [1], but is established here under more general conditions. We need a different argument to prove it due to the choice of $f(u)$. The second ingredient will be an analysis of Ward [23], which shows the existence of an exponentially small eigenvalue for equations of the type that we consider.

The oscillation theorem that we prove below is quite general. It holds for a large class of nonlinearities, provided that the underlying pulse solution is symmetric about the midpoint of the domain of interest. In particular, the theorem also holds outside of the singular perturbation parameter regime. However, using the oscillation theorem to prove the metastability of the 1-pulse uses the singular structure in two important ways. First, it is needed to establish the existence of an exponentially small eigenvalue. Second, it is used to rule out the existence of an eigenfunction of strictly one sign. For local equations, it is well known that pulse solutions have O(1) with respect to ϵ unstable principal eigenvalues. The corresponding eigenfunction, after normalization, is strictly positive. Using our oscillation theorem and information about the structure of solutions as $\epsilon \to 0$, we show that no such eigenfunction can exist for the nonlocal problem. Thus, the nonlocal term can be viewed as stabilizing an unstable solution of the local problem.

In the standard manner, assume $U(x,t) = U_1(x) + \phi(x)e^{-\lambda t}$ and linearize (1.1) about U_1 to obtain the following nonlocal eigenvalue problem:

$$\epsilon^2\phi'' + (A(x)+\lambda)\phi = B(x)\int_0^1 C(x)\phi\,dx, \tag{4.1}$$

$$\phi'(0) = \phi'(1) = 0, \tag{4.2}$$

where

$$A(x) = -2 + \frac{2pU_1}{1+c^2(1+I_\star)^2},\ B(x) = \frac{2pc^2(1+I_\star)(1+U_1^2)}{(1+c^2(1+I_\star)^2)^2},\ C(x) = \ 2U_1. \tag{4.3}$$

Let L_1 be the linear operator associated with (4.1), which is given by

$$L_1\phi = -\epsilon^2\phi'' - A(x)\phi + B(x)\int_0^1 C(x)\phi\ dx. \tag{4.4}$$

Denote the spectrum of L_1 by $\sigma(L_1)$. If $Re\ \sigma(L_1) > 0$, then U_1 will be an asymptotically stable solution of (1.1) [3]. In [1], $f(u) = e^{c_1 u}$ which implies that L$_1$ is self-adjoint. Now, since $f(u) = 1+u^2$, L_1 is not a self-adjoint operator. Thus there is no a priori guarantee that the eigenvalues of L_1 are real. We show below that due to the symmetry of U_1, the eigenvalues of L_1 must in fact be real.

The spectrum of L_1 can be related to the eigenvalues of the following Sturm–Liouville equation:

$$\epsilon^2\psi'' + (A(x)+\nu)\psi = 0, \tag{4.5}$$

$$\psi'(0) = \psi'(1) = 0. \tag{4.6}$$

Denote by L_0 the corresponding linear operator. For L_0, there exists a sequence of eigenvalues $\{\nu_n\}$ such that $\nu_0 < \nu_1 < \nu_2 \dots$ and corresponding eigenfunctions $\{\psi_n\}$ such that each eigenfunction has exactly n interior zeros [4]. Due to the fact that U_1 is symmetric about $x = 1/2$, it turns out that the eigenfunctions $\{\psi_n\}$ break up into two subsets: $\{\psi_{2n}\}$ which are even about $x = 1/2$ and $\{\psi_{2n+1}\}$ which are odd about $x = 1/2$. This occurs because $A(x)$, $B(x)$, and $C(x)$ all must be even about $x = 1/2$. As a result, note that

$$\int_0^1 C(x)\psi_{2n+1}\ dx = 0. \tag{4.7}$$

Therefore the odd local eigenpairs $(\nu_{2n+1}, \psi_{2n+1})$ also turn out to be nonlocal eigenpairs. This observation forms the basis for the following oscillation theorem for the nonlocal eigenvalues and eigenfunctions.

Oscillation Theorem. *Let λ be a nonlocal eigenvalue of L_1 with corresponding eigenfunction ϕ. For $n \geq 1$,*

(a) *$\lambda = \nu_{2n-1}$ if and only if $\phi = \psi_{2n-1}$ has $2n - 1$ interior zeros.*

(b) *$\nu_{2n-1} < \lambda < \nu_{2n+1}$ if and only if ϕ has $2n$ interior zeros.*

(c) *Every interval (ν_{2n-1}, ν_{2n+1}) contains exactly one nonlocal eigenvalue except possibly one such interval which may contain at most two nonlocal eigenvalues.*

Remark 4.1. The oscillation theorem, along with Lemma 4.2 below, gives a complete description of $\sigma(L_1)$. Moreover, as will be apparent from the proof, the exact forms of the nonlinearities $f(u)$ and $h(u)$ are never used. As a result, the oscillation theorem holds quite generally.

Proof. Part (a) of the theorem is obvious. Part (b) is proved by Bose and Kriegsmann in [1]. To prove part (c), we need a different argument than in [1]. There, because $f(u) = e^{c_1 u}$, we were able to explicitly show that in the interval (ν_{2n-2}, ν_{2n}), there exists exactly one nonlocal eigenvalue. In the present situation, we have no information about the interval (ν_{2n-2}, ν_{2n}). We show, however, that the symmetry of U_1 forces part (c) to hold.

We need the following result.

Lemma 4.2. *The eigenvalues of L_1 are strictly real.*

Proof. Following Freitas [10], we introduce the parameter δ to define

$$L_\delta \phi = L_0 \phi + \delta B(x) \int_0^1 C(x)\phi \, dx. \tag{4.8}$$

Note that $\delta = 1$ yields L_1 as defined in (4.4) and $\delta = 0$ yields L_0. Freitas shows that the eigenvalues $\lambda(\delta)$ of L_δ vary continuously with δ. If $\lambda \in \sigma(L_\delta)$ for all δ, then Freitas calls the eigenvalue a fixed eigenvalue, otherwise the eigenvalue is a moving eigenvalue. Generically, as δ is varied from zero, some of the eigenvalues $\lambda(\delta)$ begin to move along the real axis. Freitas shows that eigenvalues cannot suddenly appear or disappear as δ is varied. Moreover, he shows that the only way complex conjugate eigenvalues can be created is if for some value of δ, two moving eigenvalues collide while traveling in opposite directions. Then for some nonzero δ interval, perhaps semi-infinite, they remain complex. Finally, Freitas shows that moving eigenvalues which are traveling in the same direction cannot cross over one another. We see here that the odd subscripted eigenvalues $\lambda_{2n+1}(\delta) = \nu_{2n+1}$ are fixed eigenvalues and that the even ones $\lambda_{2n}(\delta)$, where $\lambda_{2n}(0) = \nu_{2n}$, are moving eigenvalues.

In [1], the Prüfer transformation, $\tan \epsilon\phi'/\phi$, is used to show that for $\delta = 1$, there must exist a (moving) nonlocal eigenvalue in every subinterval (ν_{2n-1}, ν_{2n+1}). That same argument actually shows that this must be true for all δ. This observation is sufficient to rule out the existence of complex conjugate eigenvalues. We argue by contradiction. Suppose that there exists $\hat{\delta}$ at which $\lambda_0(\hat{\delta})$ and $\lambda_2(\hat{\delta})$ collide and become complex. Then since there must exist a real nonlocal eigenvalue in (ν_1, ν_3), it follows that $\lambda_4(\hat{\delta}) \in (\nu_1, \nu_3)$. In particular, there exists $\delta_4 < \hat{\delta}$ such that $\lambda_4(\delta_4) = \nu_3$. Since for any value of δ, (ν_3, ν_5) must also contain a real nonlocal eigenvalue, it follows that $\lambda_6(\delta_4) \in (\nu_3, \nu_5)$. Thus there exists a $\delta_6 < \delta_4 < \hat{\delta}$ such that $\lambda_6(\delta_6) = \nu_5$. Continuing by induction, there exists a monotone decreasing sequence $\{\delta_{2n}\}$ such that $\lambda(\delta_{2n}) = \nu_{2n-1}$ for $n \geq 2$.

The sequence $\{\delta_{2n}\}$ denotes the "crossing times" at which a moving eigenvalue crosses over the fixed eigenvalue immediately to its left. Since the sequence $\{\delta_{2n}\}$ is monotone decreasing, let us assume that $\lim_{n\to\infty} \delta_{2n} = \delta^\star$, where $\delta^\star \geq 0$. If $\delta^\star < 0$, then we are done. At $\delta = \delta^\star$, no moving eigenvalues can have crossed fixed ones.

But for $\delta = \delta^\star + \alpha$, where $\alpha > 0$ but arbitrarily small, an *infinite* number of moving eigenvalues must have crossed over fixed ones. The following lemma, which is a direct consequence of Proposition 3.8 in Freitas [10], shows that this situation cannot occur.

LEMMA 4.3. *For any fixed $\delta > 0$, only a finite number of moving eigenvalues can have crossed fixed ones.*

Proof. We sketch the proof here. The details of the proof can be found in Freitas [10]. Let $\eta \in \rho(L_0)$, where ρ is the resolvent set of L_0. Let $R(\eta, L_0)$ denote the resolvent of L_0. Using a general result of Kato [17], Freitas shows that if $\delta \int_0^1 B(x)\phi_{2n}\, dx \int_0^1 C(x)\phi_{2n}\, dx \cdot ||R(\eta, L_0)|| < 1$, then $\eta \in \rho(L_\delta)$. Moreover, again using Kato, he shows that $||R(\eta, L_0)|| = (\text{dist}(\eta, \sigma(L_0)))^{-1}$. Therefore if

$$\delta \int_0^1 B(x)\phi_{2n}\, dx \int_0^1 C(x)\phi_{2n}\, dx < \text{dist}(\eta, \sigma(L_0)), \tag{4.9}$$

then $\eta \in \rho(L_\delta)$, i.e., $\eta \notin \sigma(L_\delta)$. Freitas shows that since $\nu_{2n+1} - \nu_{2n} \to \infty$ as $n \to \infty$, the $\text{dist}(\eta, \sigma(L_0))$ can be made arbitrarily large for sufficiently large n. Since $B(x)$ and $C(x)$ are functions associated with the linearization about U_1 and are independent of n and since ϕ_{2n} is increasingly oscillatory as $n \to \infty$, $\int_0^1 B(x)\phi_{2n}\, dx \int_0^1 C(x)\phi_{2n}\, dx$ is bounded as $n \to \infty$. Thus, for any fixed value of δ, if n is sufficiently large, (4.9) holds. This means that if δ is fixed, if n is sufficiently large, and if $\text{Re}\ \eta \in (\nu_{2n-1}, \nu_{2n})$, then $\lambda_{2n}(\delta) > \text{Re}\ \eta$. Therefore only a finite number of moving eigenvalues can have crossed fixed ones. □

Lemma 4.3 stands in direct contradiction to the construction of our sequence $\{\delta_{2n}\}$. Recall, that the existence of such a sequence is a necessary condition for complex conjugate eigenvalues to exist. Thus, we conclude that no complex eigenvalues can exist for $\delta > 0$ and, in particular, for $\delta = 1$. □

Using Lemma 4.2, we can now prove part (c) of the oscillation theorem. From the proof of Lemma 4.2, a moving eigenvalue $\lambda_{2n}(\delta)$ can only cross over the fixed eigenvalue ν_{2n+1} that lies immediately to its right. Moreover, for all δ every interval (ν_{2n-1}, ν_{2n+1}) must contain at least one nonlocal eigenvalue. Thus if $\lambda_0(\delta) < \nu_1$ for all δ, then for $n \geq 1$, every interval (ν_{2n-1}, ν_{2n+1}) must contain exactly one nonlocal eigenvalue. Next suppose $\lambda_0(1)$ and $\lambda_2(1)$ are both in (ν_1, ν_3), then for $n \geq 2$, (ν_{2n-1}, ν_{2n+1}) contains exactly one nonlocal eigenvalue. If (ν_3, ν_5) contains two nonlocal eigenvalues, then for $n \geq 3$, (ν_{2n-1}, ν_{2n+1}) contains exactly one nonlocal eigenvalue. It also implies that $\lambda_2(1)$ and $\lambda_4(1)$ are elements of (ν_3, ν_5). The eigenvalue $\lambda_0(1)$ must remain in (ν_1, ν_3). Continuing in this manner, we see that at most one interval (ν_{2n-1}, ν_{2n+1}) contains two nonlocal eigenvalues. □

See [1] for further remarks concerning the oscillation theorem.

4.1. Analysis for the 1-pulse U_1.

The specific analysis to prove the metastability of the 1-pulse is very similar to that in Bose and Kriegsmann [1]. We sketch only the results.

LEMMA 4.4. *The nonlocal eigenvalue $\lambda_1 = \nu_1 < 0$ but is exponentially small in ϵ. Moreover, it is the principal eigenvalue of L_1.*

Proof. Consider (4.1) with Dirichlet boundary conditions. The derivative of the 1-pulse, $\zeta = U_1'$, is an eigenfunction of this equation with a corresponding eigenvalue of zero. Thus ζ satisfies

$$\epsilon^2 \zeta'' + A(x)\zeta = 0, \tag{4.10}$$

$$\zeta(0) = \zeta(1) = 0. \tag{4.11}$$

Next, consider (4.1) for the eigenpair (ϕ_1, λ_1). A standard trick is to multiply (4.1) by ζ, (4.10) by ϕ_1, subtract the two ensuing equations, and then integrate by parts. Doing so yields that λ_1 is $O(\epsilon^2 U_1''(1))$ and negative; see [1] for specifics. Ward [23] shows that $\epsilon^2 U_1''(1)$ is $O(e^{-a/\epsilon})$, with $a > 0$, for the class of pulse like solutions under consideration here. See [23] for a detailed derivation of this result. Thus λ_1 is exponentially small in ϵ.

We next show that L_1 has no eigenfunction of strictly one sign. Thus, part (b) of the oscillation theorem will imply that λ_1 is the principal eigenvalue. We argue by contradiction. Assume that there exists $\phi_0 > 0$ for all $x \in [0,1]$ which satisfies (4.1–4.2). Let λ_0 be its associated eigenvalue. Let $J = \int_0^1 2U_1\phi_0 \, dx$. Note that $J > 0$. Integrating (4.1) on $[0,1]$ yields

$$(\lambda_0 - 2)\int_0^1 \phi_0 \, dx + \frac{pJ}{1 + c^2(1+I_\star)^2} = \frac{2pc^2 J(1+I_\star)^2}{(1+c^2(1+I_\star)^2)^2}. \tag{4.12}$$

Rearranging and factoring common terms yields

$$(\lambda_0 - 2)\int_0^1 \phi_0 \, dx = \frac{pJ}{(1+c^2(1+I_\star)^2)^2}\left[c^2(1+I_\star)^2 - 1\right]. \tag{4.13}$$

From Theorem 1.1, we know that $I_\star \to \infty$ as $\epsilon \to 0$. Thus for ϵ sufficiently small, the right-hand side of (4.13) is strictly positive. Since $\int_0^1 \phi_0 \, dx > 0$ by assumption, this implies $\lambda_0 > 2$. This however contradicts part (b) of the oscillation theorem as λ_0 cannot by greater than ν_1. Thus there is no eigenfunction of strictly one sign. □

4.2. Analysis for the n-pulse solutions U_n. The eigenvalue equation for the n-pulse is identical to (4.1) except that U_1 is replaced by U_n. Recall that the n-pulse solutions were generated using the symmetry of the 1-pulse. As a result, information about the principal eigenvalue for the linearization around these pulses can be obtained from the 1-pulse. Assume first that $n = 2$. The analysis for $n \geq 3$ is identical to this case. As shown in [1], it turns out that λ_1 is $O(\epsilon^2 U_1''(1/2))$. Notice the difference between this relationship and that for the 1-pulse presented above. Since $U_1(1/2) = U_{max}$, by (1.2),

$$\epsilon^2 U_1''(1/2) = 2U_{max} - \frac{p(1+U_{max}^2)}{1+c^2(1+I_\star)^2}. \tag{4.14}$$

Using the estimates from Theorem 1.1, we obtain

$$\epsilon^2 U_1''(1/2) = \frac{3c^2 I_\star^2}{p}\left(2 - \frac{3c^2 I_\star^2}{1+c^2(1+I_\star)^2}\right). \tag{4.15}$$

As ϵ tends to zero, the term in parentheses tends to negative one, while the factor multiplying this tends to infinity. Thus the right-hand side tends to negative infinity. Therefore $\lambda_1 \to -\infty$ as $\epsilon \to 0$. This shows that the principal eigenvalue of the 2-pulse (and analogously the n-pulses) is unstable and bounded away from the origin for ϵ sufficiently small.

5. Numerical simulations. In this section we present a few numerical simulations. We solved the time dependent equation (1.1) using an implicit Crank–Nicholson scheme as in [1, 18]. For all simulations we ran the code for around 20,000 time steps, which corresponds to about 12 seconds. To create a 1-pulse solution, we evolved an

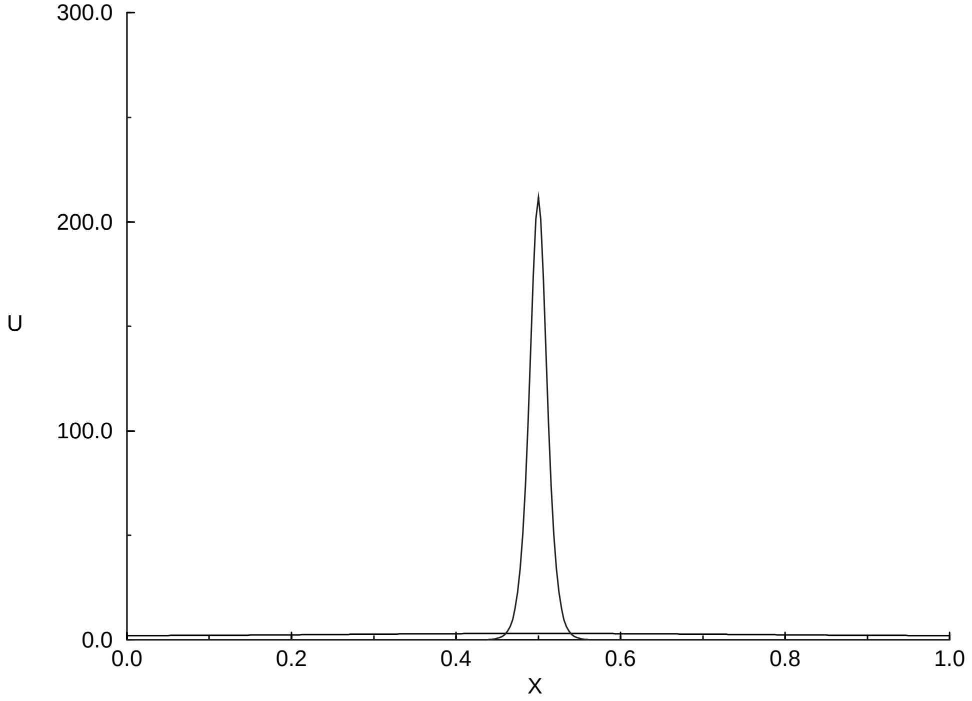

FIG. 5.1. *The* 1*-pulse solution with* $\epsilon = 0.01$*,* $p = 1.0$*,* $c = 0.01$*.*

initial condition that had one small local maxima at $x = 1/2$; see Figure 5.1. To test whether our analytic predictions of U_{max} and $I_\star$ are reasonable, we ran the code with several different choices of p and c and a few different values of ϵ and numerically calculated these values. In Table 5.1, we show results for $p = 1.0$. Different values for ϵ and c are presented. Kriegsmann [18] uses $\epsilon = 0.01$ and $c = 0.01$ in his simulations, which are both physically relevant parameter values. As can be seen, the numerical values agree closely with the theoretical predictions, thus implying a consistency between our numerical and analytic results.

TABLE 5.1
A comparison of analytically predicted and numerically calculated values of U_{max} *and* $I_\star$*.*

ϵ	c	Numerical value of U_{max}	Analytic value of U_{max}	Numerical value of $I_\star$	Analytic value of $I_\star$
0.01	0.01	211.77	210.85	831.41	838.37
0.03	0.01	100.32	101.37	568.52	581.29
0.01	0.1	43.96	45.42	36.89	38.9

Given such close agreement, we further pursued the ramifications of the metastability of the 1-pulse by evolving different initial conditions. Figure 5.2 shows the evolution of a symmetric 2-bump perturbation of a homogeneous solution for $\epsilon = 0.01$. We show only the initial condition and the ensuing 1-pulse. Notice that it is not centered at the midpoint of the domain, so it is not a steady-state solution. When we let the code run for much longer times, the 1-pulse remained fixed. This is a manifestation of the metastability of the solution. This non–steady-state 1-pulse is moving exponentially slowly towards one of the boundaries. We do not know why the pulse

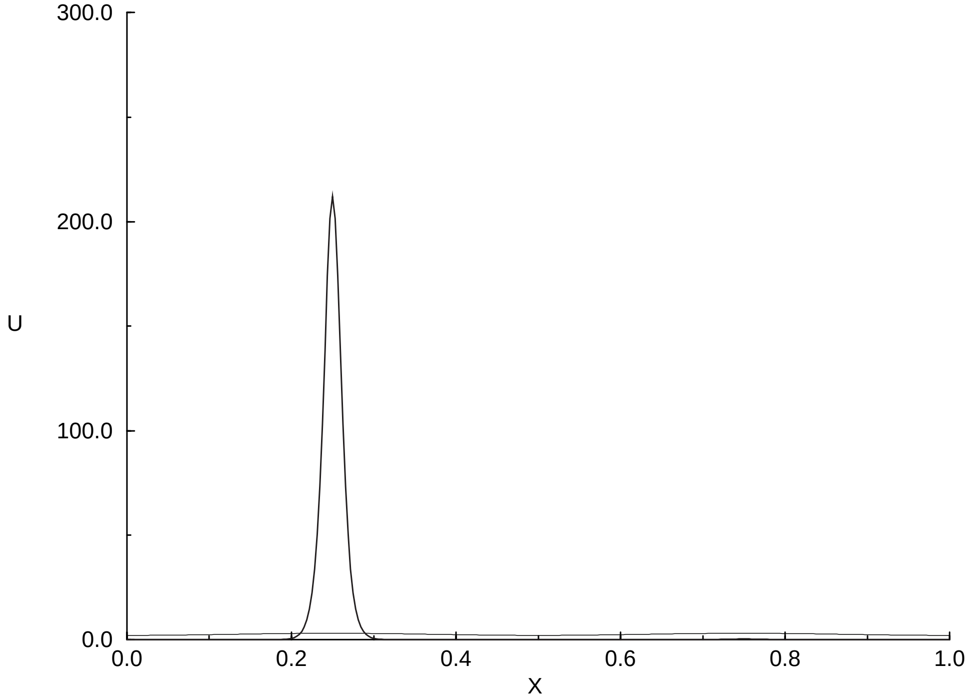

FIG. 5.2. *An exponentially slowly moving* 1*-pulse with* $\epsilon = 0.01$*,* $p = 1.0$*,* $c = 0.01$*.*

forms at $x = 1/4$ and not at $x = 3/4$. Using other initial conditions, we can generate a pulse at any location in the domain (simulations not shown). The exponentially small eigenvalue introduces a near translational invariance, so this is not surprising. Incidentally, it is possible to obtain a 1-pulse centered at $x = 1/2$ by providing an initial condition with a sufficiently large local maximum at $x = 1/2$. These results are consistent with [1].

Finally, using the rescaling argument in section 3.2, we can obtain so-called 1/2-pulse steady-state solutions. These solutions are close to zero valued on most of $(0, 1)$, but contain a layer near one of the boundaries where the value of U grows inversely to some power of ϵ. We call them 1/2-pulses since they look like the 1-pulse solution over the interval $[0, 1/2]$ (or alternatively, $[1/2, 1]$). We also observed such solutions numerically, which leads us to believe that they are stable solutions. We do not, however, pursue their stability here.

6. Application to the Gierer–Meinhardt equations.

The Gierer–Meinhardt equations [13] arise in biological pattern formation. They fall in the general class of activator-inhibitor systems. They can be written in nondimensional form in one spatial dimension as

$$U_t = \epsilon^2 U_{xx} - U + \frac{U^p}{H^q}, \tag{6.1}$$

$$\tau H_t = D_H H_{xx} - \mu H + \frac{U^m}{H^s}, \tag{6.2}$$

$$U_x(0,t) = U_x(1,t) = 0,\ H_x(0,t) = H_x(1,t) = 0. \tag{6.3}$$

The variable U represents the activator concentration and H represents the inhibitor concentration. Here $p > 1$, $q, m > 0$, and $s \geq 0$. These equations were studied numerically in [13] and localized pulses were observed. Recently, Iron and Ward [14] used numerical and asymptotic techniques to demonstrate the metastability of the observed 1-pulse solution of a nonlocal reduction of (6.1) for $x \in \Omega$, where Ω is a closed subset of $\mathbf{R^N}$. They derived a nonlocal reaction-diffusion equation which was valid in the limit as $\tau \to 0$ and $D_H \to \infty$. They did not rigorously construct solutions nor prove their stability. Here, for $x \in [0, 1]$ we derive a slightly different scaled version of the nonlocal equation that appears in [14] and then construct a 1-pulse solution. As before n-pulses can be obtained by the rescaling argument. Moreover, the metastability analysis will be exactly as in section 4.

As $D_H \to \infty$, H becomes spatially homogeneous. We then integrate (6.2) from zero to one and set $\tau = 0$ to obtain the following algebraic equation:

$$\mu H^{s+1} = \int_0^1 U^m \, dx. \tag{6.4}$$

Setting $\mu = 1$, for convenience, we obtain the following scalar nonlocal reaction-diffusion equation:

$$U_t = \epsilon^2 U_{xx} - U + \frac{U^p}{(\int_0^1 U^m \, dx)^{q/(s+1)}}, \tag{6.5}$$

$$U_x(0, t) = U_x(1, t) = 0.$$

Iron and Ward first scale the system (6.1–6.2) to reflect that the height of the pulse goes to infinity as ϵ tends to zero. They then integrate (6.2). The difference is that they have a factor of $(1/\epsilon)^{q/(s+1)}$ multiplying the nonlocal term.

As before, we rewrite (6.5) as a system of first-order equations using $I = \int_0^1 U^m \, dx$ and the auxiliary variable $V(x) = \int_0^x U^m \, dx$. Set $n = q/(s + 1)$.

$$\begin{aligned} \epsilon U' &= W, & V' &= U^m, \\ \epsilon W' &= U - \tfrac{U^p}{I^n}, & I' &= 0. \end{aligned} \tag{6.6}$$

Introducing the scalings $u = \epsilon^a U$, $w = \epsilon^a W$, $v = \epsilon^b V$, and $Z = \epsilon^b I$ as before and balancing terms yields the following values for a and b:

$$a = \frac{q}{qm - p(s + 1)}, \qquad b = \frac{p(s + 1)}{qm - p(s + 1)}.$$

Thus we require $qm > p(s + 1)$, which is consistent with [13, 14]. This yields

$$\begin{aligned} \epsilon u' &= w, & \epsilon v' &= u^m, \\ \epsilon w' &= u - \tfrac{u^p}{Z^n}, & Z' &= 0. \end{aligned} \tag{6.7}$$

If we rescale in a neighborhood of $x = 1/2$ using $\xi = (x - 1/2)/\epsilon$, then the ensuing system has one saddle point and one center point as before. Similarly, there exists a homoclinic solution connecting the saddle to itself. Using the change of variable $y = x$ and appending $dx/dy = 1$, the boundary manifolds, jump off, and touch down curves are defined exactly as before. Consistency is again checked on the inner equations.

As before, the outer flow transversely intersects J_0 and T_c, so (H1) and (H3) are satisfied. To verify (H2), we must check transversality of $B_0 \cdot 1$ with B_1. We use the inner equations associated with (6.7) which are

$$\begin{aligned} \dot{u} &= w, & \dot{v} &= u^m, \\ \dot{w} &= u - \tfrac{u^p}{Z^n}, & \dot{Z} &= 0. \end{aligned} \tag{6.8}$$

The first two equations have Hamiltonian given by

$$H(u,w) = w^2/2 - u^2/2 + \frac{u^{p+1}}{(p+1)Z^n}. \tag{6.9}$$

The maximum value of u is given by $u_{max} = ((p+1)Z^n/2)^{1/(p-1)}$. Recall that the curve $v(Z) = \int_{-\infty}^{\infty} u^m(\xi, Z)\, d\xi$ is the projection of the touch down curve T_0 on the (Z, v) plane. We must show that this curve transversely intersects the line $v = Z$. To do this we obtain estimates for $\int_{-\infty}^{\infty} u^m\, d\xi$ for $Z \ll 1$ and $Z \gg 1$ and use the intermediate value theorem.

Recall that the homoclinic solution of the first two equations of (6.8) corresponds to the pulse. The value of the Hamiltonian on this solution is 0. Using (6.9), the integral of interest can be rewritten as

$$\int_{-\infty}^{\infty} u^m\, d\xi = 2\int_0^{u_{max}} \frac{u^{m-1}}{(1 - \frac{2u^{p-1}}{(p+1)Z^n})^{1/2}}\, du. \tag{6.10}$$

Moreover,

$$\begin{aligned} \int_0^{u_{max}} \frac{u^{m-1}}{\left(1 - \frac{2u^{p-1}}{(p+1)Z^n}\right)^{1/2}}\, du &> \int_0^{u_{max}} u^{m-1}\, du \\ &= \frac{1}{m}\left(\tfrac{(p+1)Z^n}{2}\right)^{m/(p-1)}. \end{aligned} \tag{6.11}$$

It is easily seen that if $Z \gg 1$, then the right-hand side of the above inequality is greater than Z, since $nm/(p-1) = qm/(p-1)(s+1) > qm/p(s+1) > 1$, by assumption.

Depending on the choices of the parameters m, p, q, and s there are many ways to obtain an upper bound for $\int_{-\infty}^{\infty} u^m\, d\xi$. We assume that $n > 1$ and $p \le m+1$ in the following. Note that $Z < 1$ implies that u_{max} and thus u are less than one. Then

$$\begin{aligned} \int_0^{u_{max}} \frac{u^{m-1}}{\left(1 - \frac{2u^{p-1}}{(p+1)Z^n}\right)^{1/2}}\, du &< \int_0^{u_{max}} \frac{u^{p-2}}{\left(1 - \frac{2u^{p-1}}{(p+1)Z^n}\right)^{1/2}}\, du \\ &= \tfrac{(p+1)Z^n}{(p-1)}. \end{aligned} \tag{6.12}$$

Clearly, if $Z \ll 1$, then the right-hand side of (6.12) is less than Z. For different choices of the parameters m, p, q, and s, other estimates such as (6.12) can be obtained, but we do not pursue them here.

Combining the appropriate estimates above, it is seen that if $Z \ll 1$, then $\int_{-\infty}^{\infty} u^m\, d\xi < Z$, and if $Z \gg 1$, then $\int_{-\infty}^{\infty} u^m\, d\xi > Z$. Thus by the intermediate value theorem, there exists at least one value of Z_0 for which $\int_{-\infty}^{\infty} u^m(\xi, Z_0)\, d\xi = Z_0$. This value is unique as can be inferred from the above estimates. Specifically, for the particular choices $m = p - 1$ and $m = 2p - 2$, it is easy to check by direct integration that $v(Z)$ is $O(Z^n)$ and $O(Z^{2n})$, respectively. For any choice of $m > 2p - 2$, the function $v(Z)$ can be obtained by using a suitable number of integration by parts and eventually reducing to the calculation of an integral of the form (6.10) where $p - 1 \leq m \leq 2p - 2$. In each integration by parts, the boundary terms disappear and an additional factor of Z^n is introduced. By rewriting the relevant integral as the sum of two integrals for the cases $u < 1$ and $u > 1$, if necessary, and using the results obtained from the special cases $m = p-1$ or $m = 2p-2$, we can obtain a lower bound for $v(Z)$ which is at least $O(Z^n)$. This result holds for all $m \geq p - 1$, which is the parameter regime of interest. Since $n > 1$, this clearly shows that $V(Z)$ is not linear in Z. This establishes transversality of T_0 with the line $v = Z$.

The stability analysis for this 1-pulse solution is analogous to what we presented in section 4. The nonexistence of a positive eigenfunction can be established under the further restriction that $p \leq m$. We leave the details to the interested reader. Also, time-dependent simulations of (6.5) using different choices of the parameters, produced metastable 1-pulses as in section 5.

Finally, Iron and Ward [14] discuss the metastability of the 1-pulse in higher spatial dimensions. Moreover, they derive an equation of motion for the metastable pulse and discuss how it interacts with the boundary in which it is enclosed. We refer the interested reader to their work.

7. Discussion. In this paper, we have developed a systematic geometric method to construct spatially localized pulse like solutions for singularly perturbed nonlocal boundary value problems. While we have not stated a general theorem concerning the construction of solutions, it is clear that the procedure outlined above is applicable to a large variety of scalar nonlocal equations. Moreover, the analysis presented above is not restricted to singularly perturbed equations or to the construction of pulse-like solutions. These methods can also be used to construct front-type (heteroclinic) solutions.

We showed how to recast the scalar nonlocal problem as a higher-dimensional local problem. The geometric framework provided above can also extend to higher-dimensional nonlocal systems. In higher dimensions, the jump off and touch down curves may become surfaces, but the abstract description using manifolds accounts easily for this possibility. One aspect of the present low-dimensional analysis that will remain in the higher-dimensional setting will be the transversality of two one-dimensional curves in a two-dimensional ambient space needed to establish the consistency condition (1.3). No matter what the dimensionality of the full system is, this two-dimensional problem will always persist. Thus one of the challenges of any nonlocal analysis is to recast the system into a form where this consistency condition becomes apparent.

A general oscillation theorem was also presented. A sufficient condition for which this theorem holds is the symmetry of the underlying pulse solution. We note, however, that this condition is a very natural one to impose since any steady-state pulse solution of (1.1) must necessarily by symmetric. Modifications of the oscillation theorem should also hold in circumstances where the operator L_1 has an infinite number of fixed eigenvalues. It is hard to give a general example where this may occur, but such a situation may arise when the underlying solution is not strictly of one sign.

We have also proved the metastability of the 1-pulse solution and the instability of n-pulse solutions. As discussed in [1], this type of metastability is qualitatively different than the metastability found in, say, Carr and Pego [2]. There, the authors construct metastable solutions that contain an arbitrarily high number of interior layers. These layers consist of heteroclinic, and not homoclinic, solutions to the appropriate set of inner equations. They show that each interior layer contributes an exponentially small eigenvalue. In our work, we have shown that additional localized pulses contribute $O(1)$ unstable eigenvalues. The nonlocal term can be viewed as being strong enough to remove at most one local unstable eigenvalue.

Finally, the applications considered in this paper are of interest in their own right. Because of the time scales of physical interest, metastability is tantamount to stability. Thus metastability of the 1-pulse of the microwave heating model due to Kriegsmann [18] suggests that localized heating of ceramic materials can be achieved in a stable and reliable manner. The nonlinearities chosen for the present study yield maximum heating rates that are too high and beyond the melting point of the fiber. However, for the nonlinearities used in [1, 18], physically acceptable maximal heating rates are obtained. Other nonlocal models arising in different microwave heating applications are the focus of further research.

Acknowledgment. I offer my most sincere thanks to my colleague Gregory Kriegsmann for introducing me to microwave heating problems and nonlocal equations. This paper is a result of countless discussions that I have had with him on the topic. I also thank him for his unwavering support and encouragement.

NONEXISTENCE OF STAR-SUPPORTED SPLINE BASES[*]

PETER ALFELD[†] AND LARRY L. SCHUMAKER[‡]

Abstract. We consider polynomial spline spaces $\mathcal{S}_d^r(\triangle)$ of degree d and smoothness r defined on triangulations. It is known that for $d \geq 3r+2$, $\mathcal{S}_d^r(\triangle)$ possesses a basis of *star-supported* splines, i.e., splines whose supports are at most the set of triangles surrounding a vertex. Here we extend the theory by showing that for all $d \leq 3r+1$, there exist triangulations for which no such bases exist.

Key words. multivariate splines, piecewise polynomial functions, triangulations

AMS subject classifications. 41A63, 41A15, 65D07

1. Introduction.

Given a regular triangulation $\triangle$, let

$$\mathcal{S}_d^r(\triangle) := \{s \in C^r(\Omega) : \; s|_T \in \mathcal{P}_d \text{ for all triangles } T \in \triangle\},$$

where $\mathcal{P}_d$ is the space of polynomials of degree d and Ω is the union of the triangles in $\triangle$. Such spline spaces have been heavily studied; cf., e.g., [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [12], [13], [14], and references therein.

Of particular interest for applications are spline spaces that possess a basis where every spline is supported only on the star of a vertex. (The star of a vertex is the set of triangles sharing that vertex.) Using such bases in applications leads to sparse linear systems. We call such splines *star-supported*. In [1] they are referred to as *minimally supported*, while in [8] they are called *vertex splines.* It is easy to see that for all $d \geq 1$, the spaces $\mathcal{S}_d^0(\triangle)$ have star-supported bases. In addition, for $r \geq 1$, it is known [9], [10] that the spaces $\mathcal{S}_d^r(\triangle)$ possess bases of star-supported splines for all $d \geq 3r+2$. The following complement to this result is the main result of this paper.

THEOREM 1. *Suppose $r \geq 1$ and $d \leq 3r+1$. Then there are triangulations $\triangle$ for which $\mathcal{S}_d^r(\triangle)$ does not have a star-supported basis.*

Our proof of this theorem is based on showing that there exist triangulations such that the number of linearly independent star-supported splines in the space $\mathcal{S}_d^r(\triangle)$ is less than the dimension of the space. Clearly, it suffices to work with an upper bound on the number of linearly independent star-supported splines and a lower bound on the dimension.

Concerning the dimension of $\mathcal{S}_d^r(\triangle)$, as shown in [13],

$$\begin{aligned}\dim \mathcal{S}_d^r(\triangle) \geq & V_B(d^2+d-2rd+r^2-r)/2 + V_I(d^2-3rd+2r^2) \\ & + 3rd - d^2 - 3r(r-1)/2 + 1 + \sigma,\end{aligned} \tag{1}$$

where V_B and V_I are the number of *boundary vertices* and *interior vertices* of $\triangle$,

respectively, and

$$\sigma = \sum_{v \in \mathcal{V}_I} \sigma_v, \qquad \sigma_v = \sum_{j=1}^{d-r} (r + j + 1 - je_v)_+ . \tag{2}$$

Here $\mathcal{V}_I$ is the set of interior vertices, and e_v is the number of edges of *different slopes* attached to the vertex v.

To help simplify the proof, we shall work with *uniform type*-I *triangulations.* Such a triangulation is obtained by starting with a rectangular grid, which we may assume is generated by the lines $x_i = i/L$ and $y_j = j/L$ for $i, j = 0, \ldots, L$, and then drawing in all diagonals in the northeasterly direction. For a uniform type-I triangulation, the number of edges attached to each interior vertex v is six, and the number of edges with different slopes is three. Thus,

$$\sigma_v = \sum_{j=1}^{d-r} (r + 1 - 2j)_+ \qquad \text{for all } v \in \mathcal{V}_I. \tag{3}$$

Moreover, for this type of triangulation, the number of interior vertices is significantly larger than the number of boundary vertices when L is large, and the term involving V_I dominates in (1). In view of this, to prove Theorem 1 it suffices to establish the following theorem.

Theorem 2. *Let $\triangle_H$ be the triangulation formed by the six triangles surrounding a typical interior vertex v of a type*-I *triangulation. Suppose $r \geq 1$ and $d \leq 3r + 1$, and let*

$$\mathcal{V}_d^r(\triangle_H) = \{s \in \mathcal{S}_d^r(\triangle_H) : s \textit{ vanishes up to order } r \textit{ on the boundary of } \triangle_H\} .$$

Then

$$\dim \mathcal{V}_d^r(\triangle_H) < N_{r,d}(v) := d^2 - 3rd + 2r^2 + \sigma_v. \tag{4}$$

Theorem 2 (and thus also Theorem 1) is trivial in the case $d \leq r$ since in this case $\mathcal{S}_d^r(\triangle) \equiv \mathcal{P}_d$, and clearly there are no star-supported splines in the space. We give a proof of Theorem 2 for $r + 1 \leq d \leq 2r$ in section 2 and for $2r + 1 \leq d \leq 3r + 1$ in section 4.

Throughout the paper we assume familiarity with the Bernstein–Bézier machinery as used, e.g, in [1], [2], [3], [4], [5], [6], [7], [8], [9], [10]. In particular, given a vertex v of $\triangle$, we recall that the *jth ring $\mathcal{R}_j(v)$ around v* is the set of domain points at a distance j from v, while the *jth disk $\mathcal{D}_j(v)$ around v* is the set of domain points at a distance of at most j from v. For each domain point P, we write $\lambda_P s$ for the associated coefficient of a spline s. We recall that a subset Γ of the domain points associated with a spline space $\mathcal{S}$ is called a *determining set* for $\mathcal{S}$ provided that the identically zero spline is the only spline $s \in \mathcal{S}$ whose coefficients $\lambda_P s$ are zero for all $P \in \Gamma$. We also recall that if Γ is a determining set, then $\dim \mathcal{S} \leq \#\Gamma$.

We conclude this section with an example to illustrate the basic ideas. Figure 1 shows the B-net of a typical spline in the space$\mathcal{V}_4^1(\triangle_H)$. Coefficients marked with dots on the outermost two rings must be zero because we require function values and first derivatives of a spline in $\mathcal{V}_4^1(\triangle_H)$ to vanish on the boundary of $\triangle_H$. We can identify the points in rings $\mathcal{R}_0(v), \ldots, \mathcal{R}_2(v)$ with the B-net of a spline in $S_2^1(\triangle_H)$. The subset

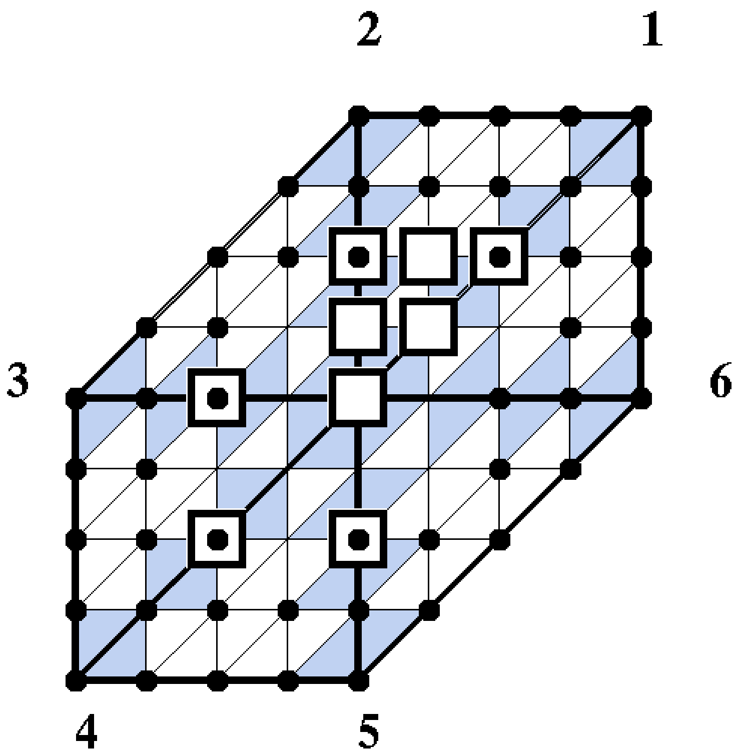

FIG. 1. *A determining set for* $\mathcal{V}_4^1(\triangle_H)$.

of points which are marked with a box in the figure form a minimal determining set for $\mathcal{S}_2^1(\triangle_H)$. This follows from the general theory of minimal determining sets for spline spaces on vertex stars given in [14] but can also easily be verified directly. For a spline $s \in \mathcal{V}_4^1(\triangle_H)$, not all of these coefficients can be set independently, since the smoothness conditions coupled with the boundary conditions imply that certain coefficients in the second ring must be automatically zero. In particular, the C^1 conditions indicated by the quadrilaterals in Figure 1 force the coefficients in the centers of the interior edges to vanish. We see that five coefficients associated with points in the minimal determining set of $\mathcal{S}_2^1(\triangle_H)$ must vanish. These are marked with boxes containing dots. Thus the dimension of $\mathcal{V}_4^1(\triangle_H)$ cannot exceed the number of remaining empty boxes, which is 4. Since $N_{1,4} = 6$, this establishes Theorem 2 in this case.

2. Proof of Theorem 1 for $r + 1 \leq d \leq 2r$. Given an interior vertex v of a triangulation, let $\triangle_v$ be the triangulation consisting of the triangles which make up star(v). Let

$$(5) \qquad \mathcal{V}_d^r(\triangle_v) = \{s \in \mathcal{S}_d^r(\triangle_v) : s \text{ vanishes up to order } r \text{ on the boundary of } \triangle_v\}.$$

In this section we show that for $r + 1 \leq d \leq 2r$, $\mathcal{V}_d^r(\triangle_v)$ is trivial in the sense that it contains only the zero function. Applying this to an interior vertex v of a type-I triangulation $\triangle_I$ and noting that $N_{r,d}$ is positive, this implies Theorem 2 and thus also Theorem 1 in this case. We have the following slightly more precise result.

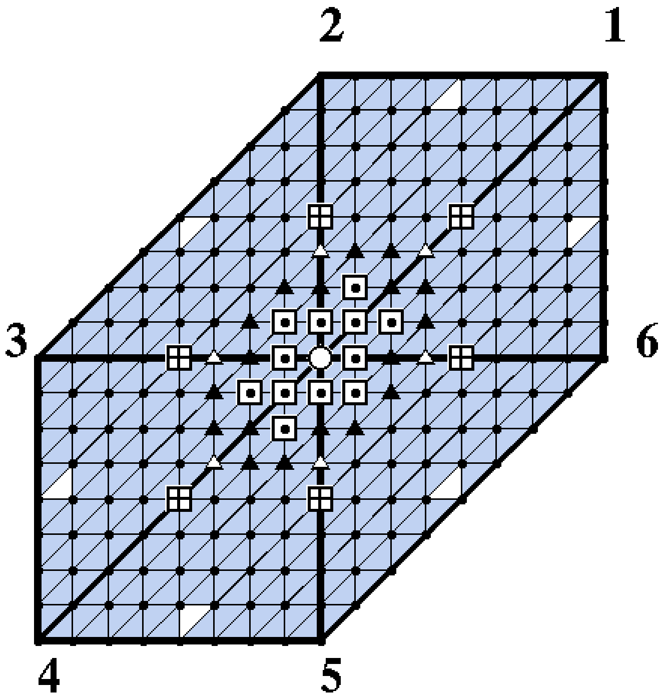

FIG. 2. *Theorem 3 for* $\mathcal{V}_8^4(\triangle_H)$.

THEOREM 3. $\mathcal{V}_d^r(\triangle_v) \equiv \{0\}$ *for all* $d \le 2r$ *if* r *is even and for all* $d \le 2r+1$ *if* r *is odd.*

Proof. Consider first the case $r = 2m$. Suppose $v_1, \ldots, v_n$ are the vertices connected to v, and let $s \in \mathcal{V}_d^r(\triangle_v)$. Then by the boundary conditions, all coefficients of s associated with domain points on the rings $\mathcal{R}_{d-r}(v), \ldots, \mathcal{R}_d(v)$ are zero. Let $w_i^{(1)} = (rv + (d-r)v_i)/d$ for $i = 1, \ldots, n$. Applying Lemma 4 below to the rings $\mathcal{R}_j(w_1^{(1)}), \ldots, \mathcal{R}_j(w_n^{(1)})$ for $j = 1, \ldots, m$ shows that all coefficients of s are zero for domain points on these rings. Then all of the coefficients associated with points on the ring $\mathcal{R}_{d-r-1}(v)$ are zero if and only if $d \le 2r$. Now the process can be repeated based on the points $w_i^{(2)} = ((r+1)v + (d-r-1)v_i$, $i = 1, \ldots, n$. Repeating this process a total of $d - r - 1$ times, we find that all of the coefficients of s are zero.

The case $r = 2m+1$ is similar. In the first step we apply Lemma 4 to the rings $\mathcal{R}_j(w_1^{(1)}), \ldots, \mathcal{R}_j(w_n^{(1)})$ for $j = 1, \ldots, m+1$. Then all coefficients associated with the ring $\mathcal{R}_{d-r+1}(v)$ are zero if and only if $d \le 2r+1$. We then repeat as before. $\square$

Figure 2 illustrates Theorem 3 for $\mathcal{V}_8^4(\triangle_H)$. The points $w_i^{(1)}$ alluded to in the proof are marked with a plus sign in a box. The boundary conditions imply that the coefficients associated with points on $\mathcal{R}_4(v)$ are zero. Then carrying out the first step of the proof, we see that the coefficients associated with the rings $\mathcal{R}_1(w_i^{(1)})$ and $\mathcal{R}_2(w_i^{(1)})$ are zero. These are marked with open triangles and with filled triangles, respectively. In the second step of the proof we get the coefficients in the rings $\mathcal{R}_2(w_i^{(2)})$ to be zero—these are marked as boxes containing a dot. Finally, in the

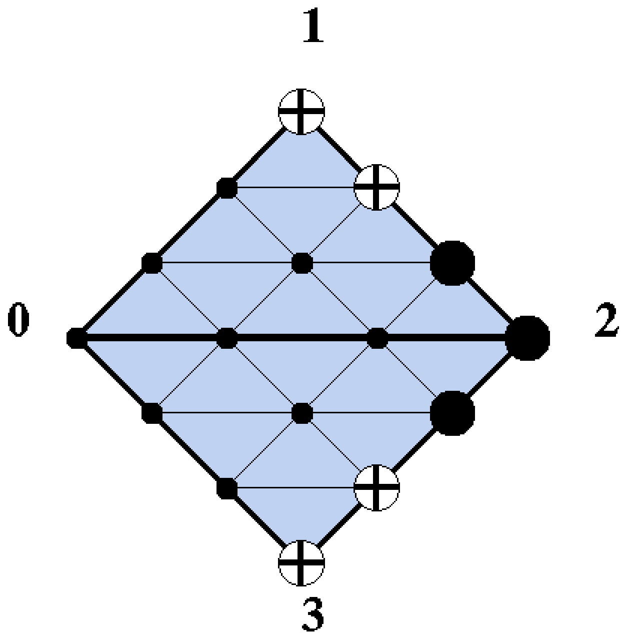

FIG. 3. *Use of Lemma* 4 *for* $j = k = d = 3$ *and* $q = 2$.

third step, we find that the coefficient associated with the point at v (marked with an open circle) is also zero.

The following restatement of Lemma 3.3 of [10] was used in the proof of Theorem 3 and will also be used again later.

LEMMA 4. *Let* $T^{[1]} = \langle v_0, v_1, v_2 \rangle$ *and* $T^{[2]} = \langle v_0, v_2, v_3 \rangle$ *be two triangles sharing the common edge* $e := \langle v_0, v_2 \rangle$. *Suppose* p_1, p_2 *are polynomials of degree* d *on* $T^{[1]}, T^{[2]}$ *which join together with* C^k *smoothness across the edge* e *for some* $0 \le k \le d$. *Given* $k \le j \le d$, *suppose that all coefficients of* p_1 *and* p_2 *in the set* $\mathcal{D}_{j-1}(v_0)$ *are zero, and define*

$$\begin{aligned} c_i &= c^{[1]}_{d-j,i,j-i}, \\ c_{-i} &= c^{[2]}_{d-j,j-i,i}, \end{aligned} \qquad i = 0, \ldots, j.$$

Suppose that

$$c_i = c_{-i} = 0 \quad \text{for } i = k - q + 1, \ldots, k$$

for some q *with* $m = k - 2q \ge -1$. *Suppose in addition that*

$$c_i = 0 \quad \text{for } i = 0, \ldots, m \quad \text{if } m \ge 0.$$

Then $c_i = c_{-i} = 0$ *for all* $i = 0, \ldots, k$.

Figure 3 illustrates Lemma 4 in the case $j = k = d = 3$ and $q = 2$. Here we are assuming that the coefficients associated with the small dots are all zero and that the four coefficients associated with the points marked with a plus sign are also zero. Then the lemma asserts that the three points associated with the large dots must be zero.

3. Constructing minimal determining sets on cells. Let $\triangle_v$ be a triangulation which is obtained by connecting a vertex v to boundary vertices $v_1, \ldots, v_n$. Such a triangulation is called a *cell.* For $\ell = 1, \ldots, n$, let $T^{[\ell]}$ be the triangle with vertices $v, v_\ell, v_{\ell+1}$, where for convenience we identify $v_{n+1} := v_1$. We denote the Bézier points in triangle $T^{[\ell]}$ by $P^{[\ell]}_{ijk}$. We now establish the following modification of Theorem 3.3 in [14].

THEOREM 5. *Let Γ_0 be the set of all Bézier domain points in the triangle $T^{[1]}$. Suppose $\mu_{n-e+1} < \cdots < \mu_n = n+1$ are such that the associated edges are pairwise noncollinear, and let $\mu_1 < \cdots < \mu_{n-e}$ be a complementary set so that $M = \{\mu_1, \ldots, \mu_n\} = \{2, \ldots, n+1\}$. For each $j = 1, \ldots, d-r$, let Γ_j be the first $nj - (r+j+1) + (r+j+1-je)_+$ points in the ordered set*

$$\{P^{[\mu_1]}_{d-j-r,0,j+r}, \ldots, P^{[\mu_1]}_{d-j-r,j-1,r+1}, \ldots, P^{[\mu_n]}_{d-j-r,0,j+r}, \ldots, P^{[\mu_n]}_{d-j-r,j-1,r+1}\}, \tag{6}$$

and let

$$\Gamma = \Gamma_0 \cup \bigcup_{j=1}^{d-r} \Gamma_j.$$

Then the set Γ is a determining set for $\mathcal{S}^r_d(\triangle_v)$.

Proof. This theorem differs from Theorem 3.3 of [14] inasmuch as the points in each group of 6 are written in reverse order. The proof of this version is nearly identical to the original one. Suppose s is a spline in $\mathcal{S}^r_d(\triangle_v)$ such that the coefficients $\lambda_P s$ corresponding to points $P \in \Gamma$ are all zero. We claim that this implies $s \equiv 0$, and thus Γ is a determining set for $\mathcal{S}^r_d(\triangle_v)$. To see this involves examining the rank of a certain block diagonal matrix A; cf. Lemma 2.1 of [14]. Here the submatrix B_j appearing in the proof of Theorem 2.2 in [14] involves different columns in the last block and now corresponds to a Hermite–Birkhoff interpolation problem of the type described in Lemma 6 below. □

LEMMA 6. *Let $\theta_1 < \cdots < \theta_{l+1}$ and let $0 < k < m$ be integers. Then the Hermite–Birkhoff interpolation problem of finding a polynomial p of degree $n := lm + k - 1$ satisfying*

$$\begin{aligned} p^{(j-1)}(\theta_i) &= r_{ij}, \qquad j = 1, \ldots, m, \qquad i = 1, \ldots, l, \\ p^{(m-j)}(\theta_{l+1}) &= r_{l+1,m-j}, \qquad j = 1, \ldots, k, \end{aligned} \tag{7}$$

is poised, i.e., there exists a unique solution for every choice of the data r_{ij}.

Proof. It suffices to show that the homogeneous problem admits only the solution $p \equiv 0$. Suppose p satisfies 7 with 0 data. Then by Rolle's theorem, we conclude that $q := p^{(m-k)}$ has a k-tuple zero at each θ_i, $i = 1, \ldots, l$, $m-k$ zeros in each interval (θ_i, θ_{i+1}), $i = 1, \ldots, l-1$, and an additional k-tuple zero at θ_{l+1}. Thus q has a total of $lk + (l-1)(m-k) + k = n - (m-k) + 1$ zeros, counting multiplicities. But q is a polynomial of degree $n - (m-k)$, and hence q must be identically zero. Integrating $m-k$ times and using the fact that $p^{(j-1)}(\theta_1) = 0$ for $j = 1, \ldots, m$, we conclude that $p \equiv 0$. □

We will apply Theorem 5 to the hexagonal triangulation $\triangle_H$ where $n = 6$ and $e = 3$. In this case we take $M = \{2, 3, 4, 5, 6, 1\}$.

TABLE 1
Number of points in Γ.

Ring	$T^{[1]}$	$T^{[2]}, T^{[3]}, T^{[4]}$	$r = 2m$	$r = 2m + 1$
$\mathcal{R}_0(v)$	1	0	0	0

$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
$\mathcal{R}_{2r}(v)$	$2r + 1$	r	$2m - 1$	$2m$

4. Proof of Theorem 1 for $2r + 1 \le d \le 3r + 1$. Throughout this section we assume that

$$d = 2r + k + 1 \tag{8}$$

with $0 \le k \le r$. Suppose v is an interior vertex of a uniform type-I triangulation, and as before, let $\triangle_H$ be the hexagonal triangulation corresponding to star(v). To prove Theorem 2 (and thus also Theorem 1), we need to show that the dimension of $\mathcal{V}_d^r(\triangle_H)$ is bounded by the number $N_{r,d}$ in (4). First, we observe that for this range of d,

$$\sigma_v = \begin{cases} m^2 & \text{if } r = 2m, \\ m^2 + m & \text{if } r = 2m + 1, \end{cases} \tag{9}$$

and thus

$$N_{r,d} = \begin{cases} (k + m + 1)^2, & r = 2m, \\ (k + m + 1)(k + m + 2), & r = 2m + 1. \end{cases} \tag{10}$$

To get an upper bound on $\dim \mathcal{V}_d^r(\triangle_H)$, we proceed as in the example $\mathcal{V}_4^1(\triangle_H)$ discussed in the introduction. We need to find a set Γ which determines $\mathcal{S}_d^r(\triangle_H)$ on $\mathcal{D}_{d-r-1}$ and then examine which of these points can be dropped in view of the interaction of the smoothness conditions with the boundary conditions. Note that $d - r - 1 = r + k$.

To find a set Γ which determines $\mathcal{S}_d^r(\triangle_H)$ on $\mathcal{D}_{d-r-1}$, we identify the domain points of a spline $s \in \mathcal{S}_d^r(\triangle_H)$ lying in $\mathcal{D}_{d-r-1}$ with the domain points of a spline in $\mathcal{S}_{d-r-1}^r(\triangle_H)$ and then apply Theorem 5. We can choose Γ one ring at a time. The rows marked $\mathcal{R}_i(v)$ in Table 1 give the number of points on the rings $\mathcal{R}_0(v), \dots, \mathcal{R}_{r+k}$. For each ring $\mathcal{R}_i(v)$, Γ includes all of the points on that ring in triangle $T^{[1]}$. The number of such points is $i + 1$ and is listed in the second column of the table. In addition, for each $i = r + 1, \dots, r + k$, Γ also includes the last $i - r$ points on $\mathcal{R}_i(v)$ in the triangles $T^{[2]}, T^{[3]}, T^{[4]}$. The numbers of these points are shown in the third column of the table. If $r = 2m$, Γ also includes the last $2(i - m) - 1$ points on $\mathcal{R}_{r+i}(v)$ in the triangles $T^{[5]}$ for $i = m + 1, \dots, k$. These points are shown in the fourth column of the table. Finally, if $r = 2m + 1$, Γ also includes the last $2(i - m - 1)$ points on $\mathcal{R}_{r+i}(v)$ in the triangles $T^{[5]}$ for $i = m + 2, \dots, k$. These points are shown in the fifth column of the table.

We now show how to select a subset $\widetilde{\Gamma}$ of Γ which is a determining set for $\mathcal{V}_d^r(\triangle_H)$. Since the cardinality of $\widetilde{\Gamma}$ is an upper bound on $\dim \mathcal{V}_d^r(\triangle_H)$, our proof of Theorem 2 will be complete if we show that $\#\widetilde{\Gamma} < N_{r,d}$. There are two cases.

Case 1 $(r = 2m)$. For each $i = 1, \dots, m$, let

$$\Gamma_{i,1} := \{\text{the } 2i \text{ domain points in } \mathcal{R}_{r+k-m+i}(v) \cap T^{[1]} \text{ closest to edge } \langle v, v_1\rangle\},$$

and set

$$\Gamma_{i,j} := \{\text{the } 2i \text{ domain points in } \mathcal{R}_{r+k-m+i}(v) \cap T^{[j-1]} \text{ closest to edge } \langle v, v_j\rangle\}$$

for $j = 2, \dots, 6$. Define

$$\widetilde{\Gamma} := \Gamma \setminus \bigcup_{i=1}^{m} \bigcup_{j=1}^{6} \Gamma_{i,j}.$$

Note that the sets $\Gamma_{i,j}$ may contain some points which are not contained in Γ. To see that $\widetilde{\Gamma}$ is a determining set for $\mathcal{V}_d^r(\triangle_H)$, suppose s is a spline in this space with $\lambda_P s = 0$ for all $P \in \widetilde{\Gamma}$. Then since none of the points of Γ in the rings $\mathcal{R}_0(v), \dots, \mathcal{R}_{r+k-m}(v)$ have been removed, all coefficients of s corresponding to points on these rings are zero. Now combining this with the fact that all coefficients of s on the rings $\mathcal{R}_{r+k+1}(v), \dots, \mathcal{R}_d(v)$ are zero, Lemma 4 implies that all coefficients corresponding to the remaining points in $\Gamma \setminus \widetilde{\Gamma}$ are zero. Then $s \equiv 0$, and we have shown that $\widetilde{\Gamma}$ is a determining set.

We now compute the cardinality of $\widetilde{\Gamma}$. The number of points in $\widetilde{\Gamma}$ on the rings $\mathcal{R}_0(v), \dots, \mathcal{R}_{m+k}(v)$ and lying in triangle $T^{[1]}$ is

$$\kappa_1 := \sum_{i=1}^{m+k+1} i = \binom{m+k+2}{2}.$$

The number of points in $\widetilde{\Gamma}$ on rings $\mathcal{R}_{r+1}(v), \dots, \mathcal{R}_{m+k}(v)$ outside of $T^{[1]}$ is given by

$$\kappa_2 := 3 \sum_{i=r+1}^{m+k} (i - r) = \frac{3(k-m+1)(k-m)_+}{2}.$$

We get the factor 3 since such points occur in each of the triangles $T^{[i]}$ for $i = 2, 3, 4$. Now the number of points in $\widetilde{\Gamma}$ lying in triangle $T^{[1]}$ and on the rings $\mathcal{R}_{m+k+1}(v), \dots, \mathcal{R}_{r+k}(v)$ is given by

$$\kappa_3 := \sum_{i=1}^{m} [m+k+i+1-4i]_+ = \sum_{i=1}^{m} [m+k+1-3i]_+ \le \frac{(m+k)(m+k-1)}{6}.$$

Finally, we count the number of points in $\widetilde{\Gamma}$ which lie outside the triangle $T^{[1]}$ and on the rings $\mathcal{R}_{m+k+1}(v), \dots, \mathcal{R}_{r+k}(v)$. There are no such points near the edge $\langle v, v_6\rangle$. Using the values in the fourth column of Table 1, we get

$$\kappa_4 := 3 \sum_{i=1}^{m} [m+k+i-r-2i]_+ = 3 \sum_{i=1}^{m} [k-m-i]_+ = \frac{3(k-m)(k-m-1)_+}{2}.$$

It follows that $n_{r,d} := \kappa_1 + \kappa_2 + \kappa_3 + \kappa_4$ is an upper bound on the cardinality of $\widetilde{\Gamma}$, and

$$n_{r,d} \le \begin{cases} (2k^2 + 4km + 4k + 2m^2 + 4m + 3)/3 & \text{if } 0 \le k \le m, \\ (11k^2 - 14km + 4k + 11m^2 + 4m + 3)/3 & \text{if } m \le k \le 2m. \end{cases}$$

We claim that $n_{r,d} < N_{r,d}$ for all choices of k and m. To see this, note that $\delta(k) := N_{r,d} - n_{r,d}$ is a quadratic polynomial on each of the intervals $[0, m]$ and $[m, 2m]$. Simple calculus shows that both pieces are positive on their domains.

Case 2 ($r = 2m + 1$). This case is very similar to Case 1. For each $i = 0, \dots, m$, let

$$\Gamma_{i,1} := \{\text{the } 2i + 1 \text{ domain points in } \mathcal{R}_{r+k-m+i}(v) \cap T^{[1]} \text{ closest to edge } \langle v, v_1 \rangle\},$$

and set

$$\Gamma_{i,j} := \{\text{the } 2i + 1 \text{ domain points in } \mathcal{R}_{r+k-m+i}(v) \cap T^{[j-1]} \text{ closest to } \langle v, v_j \rangle\}$$

for $j = 2, \dots, 6$. Define

$$\widetilde{\Gamma} := \Gamma \setminus \bigcup_{i=0}^{m} \bigcup_{j=1}^{6} \Gamma_{i,j}.$$

If $s \in \mathcal{V}_d^r(\triangle_H)$ and $\lambda_P s = 0$ for all $P \in \widetilde{\Gamma}$, then all coefficients corresponding to points on the rings $\mathcal{R}_0(v), \dots, \mathcal{R}_{r+k-m-1}(v)$ and $\mathcal{R}_{r+k+1}(v), \dots, \mathcal{R}_d(v)$ are zero. Then Lemma 4 implies that all coefficients corresponding to the remaining points in $\Gamma \setminus \widetilde{\Gamma}$ are zero. Then $s \equiv 0$, and we have shown that $\widetilde{\Gamma}$ is a determining set.

To compute the cardinality of $\widetilde{\Gamma}$, first we note that κ_1 is the same as in Case 1. Now

$$\kappa_2 := 3 \sum_{i=r+1}^{m+k} (i - r) = \frac{3(k - m - 1)(k - m)_+}{2},$$

$$\kappa_3 := \sum_{i=0}^{m} [m + k + i + 2 - 2(2i + 1)]_+ = \sum_{i=0}^{m} [m + k - 3i]_+ \le \frac{(k + m)^2 + 3(k + m) + 2}{6},$$

and

$$\kappa_4 := 3 \sum_{i=0}^{m} [m + k + i - r + 1 - (2i + 1)]_+ = 3 \sum_{i=0}^{m} [k - m - i]_+ = \frac{3(k - m)(k - m - 1)_+}{2}.$$

This leads to

$$n_{r,d} \le \begin{cases} (2k^2 + 4km + 6k + 2m^2 + 6m + 4)/3 & \text{if } 0 \le k \le m, \\ (11k^2 - 14km - 3k + 11m^2 + 15m + 4)/3 & \text{if } m \le k \le 2m + 1. \end{cases}$$

As in the first case, the difference $\delta(k) := N_{r,d} - n_{r,d}$ is a positive quadratic polynomial on each of the intervals $[0, m]$ and $[m, 2m + 1]$. This completes the proof.

Figure 4 illustrates the choice of $\widetilde{\Gamma}$ for the spaces $\mathcal{V}_7^2(\triangle_H)$ and $\mathcal{V}_{10}^3(\triangle_H)$. The boxes represent points in the set Γ, and the boxes containing dots represent points in the set $\Gamma \setminus \widetilde{\Gamma}$. The numbers of linearly independent splines in $\mathcal{V}_7^2(\triangle_H)$ and $\mathcal{V}_{10}^3(\triangle_H)$, respectively, are bounded by the numbers of empty boxes. The numbers are 14 and 26, respectively (see also Table 2 below).

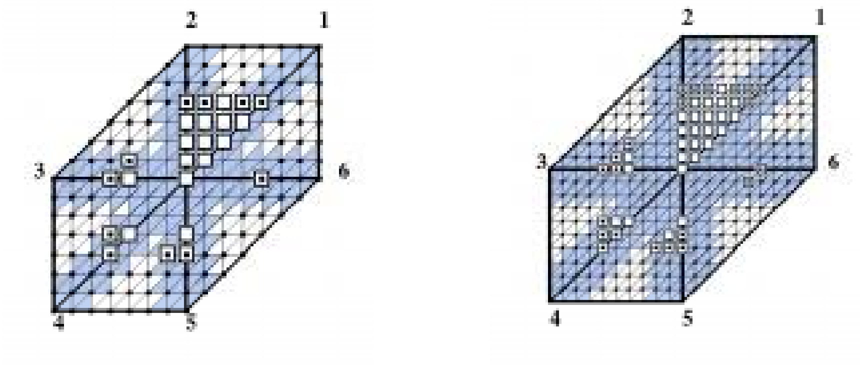

Fig. 4. *Determining sets for* $\mathcal{V}_7^2(\triangle_H)$ *and* $\mathcal{V}_{10}^3(\triangle_H)$.

5. Remarks.

Remark 7. It is known (cf. [5], [6]) that for $d \le 3r+1$ the spline spaces $\mathcal{S}_d^r(\triangle)$ do not have full approximation power on type-I triangulations. This implies that such spaces do not have stable local bases. However, it does not imply the nonexistence of star-supported bases which might be unstable. What we have shown here is that for this range of d, on such triangulations $\mathcal{S}_d^r(\triangle)$ does not possess any basis of star-supported splines, let alone a stable one.

Remark 8. For $d \ge 3r+2$, the spaces $\mathcal{S}_d^r(\triangle)$ have full approximation power, as can be shown by the construction of stable local bases and an associated quasiinterpolant; see [7], [11]. These spaces also have star-supported bases, as was shown in [3]. On the other hand, they do not seem to have stable star-supported bases.

Remark 9. To give an idea of the tightness of our upper bounds on the dimensions of the spaces $\mathcal{V}_d^r(\triangle_H)$, we have used the algebra package REDUCE to compute the dimensions for the case $d = 3r+1$ for $r = 1, \ldots, 10$. The results are displayed in Table 2 which lists the true dimension $D_r := \dim \mathcal{V}_{3r+1}^r(\triangle_H)$, the value of our upper bound on $n_r := n_{r,3r+1}$, and the value of the coefficient $N_r := N_{r,3r+1}$ defined in (4).

Remark 10. As explained in the introduction, to simplify the analysis, we have worked on uniform type-I triangulations $\triangle_I$ generated by $L-1$ interior lines in each direction on a unit square, and we have ignored the number of star-supported splines supported on the stars of boundary vertices. It is not difficult to include such splines in the counts. For example, it is easy to see that for $S_4^1(\triangle_I)$, the total number of star-supported splines is bounded by $4L^2+16L+4$, while the dimension of the space is $6L^2 + 12L + 3$. Thus, we see that $S_4^1(\triangle_I)$ does not admit a star-supported spline basis for any $L \geq 3$. Similarly, for $S_7^2(\triangle_I)$, the total number of star-supported splines is bounded by $14L^2 + 40L + 8$, while the dimension of the space is $16L^2 + 28L + 7$. Thus, we see that $S_7^2(\triangle_I)$ does not admit a star-supported spline basis for any $L \geq 7$.

Remark 11. The problem of computing the exact number of star-supported splines in $\mathcal{S}_d^r(\triangle)$ which are associated with an interior vertex v of Δ is currently under study. The case $r = 1$ is considered in [8].

Remark 12. The figures for this paper were generated using a Java applet which can be found at http://www.math.utah.edu/∼alfeld/MDS/.

ON THE INITIAL-VALUE PROBLEM IN THE LIFSHITZ–SLYOZOV–WAGNER THEORY OF OSTWALD RIPENING*

BARBARA NIETHAMMER† AND ROBERT L. PEGO‡

Abstract. The Lifshitz–Slyozov–Wagner (LSW) theory of Ostwald ripening concerns the time evolution of the size distribution of a dilute system of particles that evolve by diffusional mass transfer with a common mean field. We prove global existence, uniqueness, and continuous dependence on initial data for measure-valued solutions with compact support in particle size. These results are established with respect to a natural topology on the space of size distributions, one given by the Wasserstein metric which measures the smallest maximum volume change required to rearrange one distribution into another.

Key words. Ostwald ripening, mean-field model, measure-valued solutions, Wasserstein metric

1. Introduction.

The classical theory of Ostwald ripening, formulated by Lifshitz and Slyozov [6] and Wagner [15], concerns the evolution of the size distribution of a large number of small particles of one phase embedded in a matrix of another phase. Particles are assumed to be widely separated spheres that evolve by diffusional mass transfer with a common mean field. In the late stages of the phase transformation, diffusion is quasi-steady and the particle growth rate is determined by the mass flux at the particle boundary. The mass flux is proportional to the gradient of a potential that is harmonic, is proportional to curvature on the particle boundaries, and is close to constant in the mean field between particles.

In appropriate units, it is found that any particle radius $R(t)$ evolves according to

$$\frac{dR}{dt} = V(R, R_c(t)) := \frac{a}{R^2}\left(\frac{R}{R_c(t)} - 1\right), \tag{1.1}$$

where a is a constant and the critical radius $R_c(t)$ is the same for all particles. The value of $R_c(t)$ is determined from conservation of mass. If mass changes in the diffusion field can be neglected, the particle volume is conserved and one finds that the critical radius equals the average radius of currently existing particles. Particles with radius larger than $R_c(t)$ are growing, and particles with smaller radius shrink and can disappear in finite time.

Classically, the size distribution of particles is described by a particle radius distribution $n(t, R)$. This is a normalized number density that we may scale so that $\int_0^R n(t, r)\, dr$ is the number of (currently existing) particles with radius less than R, divided by the number N of initially existing particles. The number of particles with

size between $R_1(t)$ and $R_2(t)$ for any two solutions of (1.1) is conserved, so $n(t,R)$ should satisfy the conservation law

$$\partial_t n + \partial_R(Vn) = 0, \tag{1.2}$$

where the critical radius is given by

$$R_c(t) = \int_0^\infty Rn(t,R)\,dR \bigg/ \int_0^\infty n(t,R)\,dR\,. \tag{1.3}$$

The initial number density $n_0(R) = n(0,R)$ satisfies $\int_0^\infty n_0(R)\,dR = 1$ in this normalization.

A large literature on Ostwald ripening has developed over the past several decades in the metallurgical and physical communities. For an introduction to the problem and an overview of the literature we refer to the review articles of Voorhees [13, 14]. More recently the subject has been taken up by mathematicians. Penrose [10] found that the Lifshitz–Slyozov–Wagner (LSW) evolution law formally governs large-time dynamics in the Becker–Döring clustering equations. The LSW law is derived rigorously in [7] from the Mullins–Sekerka free boundary problem by homogenization methods. The proof suggests that the law is valid only if the electrostatic capacity of the particles is small. In this work the free boundary is restricted to spherical balls, an approach which is justified by a stability analysis in [1]. The works [2, 8, 12] address the large-time asymptotic behavior of the particle size distribution, which is a major point of interest in the theory of Ostwald ripening. The LSW theory predicted asymptotically self-similar behavior, but quantitative agreement with experiment proved elusive.

Our aim in this paper is to develop a satisfactory theory of well-posedness for the initial value problem for the particle size distribution. From the physical point of view, it is reasonable to suppose that a positive fraction of the particles can have the same radius, in which case the size distribution contains one or more Dirac deltas. Mathematically, the ideal is to allow the initial data $n_0(R)\,dR$ to be an arbitrary probability measure such that the total volume $\int_0^\infty \frac{4}{3}\pi R^3 n_0(R)\,dR$ is finite.

It will be convenient to work with particle volume v instead of radius R, and to work with a cumulative number distribution function φ instead of the number density n. We say that

(1.4) φ is the fraction of (initially existing) particles with volume $\geq v$.

As a function of volume v at time t, $\varphi(t,v)$ is a monotonically decreasing function which is left continuous at jumps with $\varphi(t,0) = 1$, and $\int_0^\infty \varphi(t,v)\,dv$ (the total volume) is independent of time. The particle volume distribution, defined by $f(t,v)\,dv = -d\varphi(t,v)$ for each fixed t, is formally related to n via $f(t,v)\,dv = n(t,R)\,dR$.

We normalize the time scale by the factor $4\pi a$ and let $\theta(t) = (4\pi R_c(t)^3/3)^{-1/3}$, so that the volume $v(t)$ of any existing particle should satisfy

$$\frac{dv}{dt} = \Lambda(v,\theta(t)) := v^{1/3}\theta(t) - 1. \tag{1.5}$$

If $v(t)$ is a positive solution of (1.5) on some time interval, then $\varphi(t,v(t))$ should remain constant. This means $\varphi(t,v)$ should be a solution of the hyperbolic equation

$$\partial_t\varphi + \Lambda(v,\theta(t))\partial_v\varphi = 0, \tag{1.6}$$

whose characteristics satisfy (1.5). The value of $\theta(t)$ is obtained from φ in terms of Riemann–Stieltjes integrals by

$$\theta(t) = \int_{0^+}^{\infty} d\varphi(t,v) \Big/ \int_0^{\infty} v^{1/3}\, d\varphi(t,v)\,. \tag{1.7}$$

The numerator is -1 times the quantity $\varphi_0(t) := \lim_{v\to 0}\varphi(t,v)$, which is the fraction of initially existing particles that still exist at time t.

It turns out to be even better to regard the volume v as a function of the fraction φ, $0 \le \varphi \le 1$. We take the map $\varphi \mapsto v(t,\varphi)$ to be right continuous and decreasing with $v(t,1) = 0$. Mathematically, given $\varphi(t,v)$ we obtain $v(t,\varphi)$ via the prescription

$$v(t,x) = \sup\{y \mid \varphi(t,y) > x\} \quad \text{for } 0 \le x < 1 = \max\varphi. \tag{1.8}$$

This is most easily understood when the size distribution corresponds to a finite number of particles. If we list the particle volumes in decreasing order, $v_0(t) \ge \cdots \ge v_{N-1}(t)$, then $v(t,\varphi) = v_j$ for $\varphi \in [j/N,(j+1)/N)$. We shall call $\varphi \mapsto v(t,\varphi)$ a *volume ordering* for the system at time t.

For technical simplicity we shall assume that the particle volumes in the system are bounded. This seems reasonable physically and corresponds to assuming that the particle volume distribution has compact support in v. We then introduce function spaces as follows. Let $rcd([0,1])$ be the set of functions $v : [0,1] \to \mathbb{R}$ that are right continuous, are decreasing, and satisfy $v(1) = 0$. (To be precise, we say v is *decreasing* if $v(x_1) \le v(x_2)$ whenever $x_1 \ge x_2$, and similarly for *increasing*. A decreasing function need not be strictly decreasing.) The set $rcd([0,1])$ is contained in the space $bdd([0,1])$ of real-valued bounded functions on $[0,1]$, equipped with the sup norm $\|v\| = \sup_\varphi |v(\varphi)|$. $rcd([0,1])$ is a complete metric space in the induced topology.

If X is a Banach space and $I \subset \mathbb{R}$ is an interval, then $C(I,X)$ is the space of continuous X-valued functions on I, and $L^\infty_{\text{loc}}(I)$ is the space of equivalence classes of measurable functions locally bounded on I, where two functions are considered equivalent if they agree almost everywhere.

Our main results are the following.

Theorem 1.1 (global existence and uniqueness). *Let $v_0 \in rcd([0,1])$. Then there exist unique functions $\theta \in L^\infty_{\text{loc}}(0,\infty)$ and $v \in C([0,\infty), rcd([0,1]))$, such that*

$$\int_0^1 v(t,\varphi)\, d\varphi = \int_0^1 v_0(\varphi)\, d\varphi$$

for all $t \ge 0$ and

$$v(t,\varphi) = v_0(\varphi) + \int_0^t (v(s,\varphi)^{1/3}\theta(s) - 1)\, ds$$

for all (t,φ) such that $v(t,\varphi) > 0$.

Theorem 1.2 (continuous dependence on initial data). *Given positive constants T and C_0, there exists a positive constant C such that, if (v_1,θ_1) and (v_2,θ_2) are two solutions with the properties stated for (v,θ) in Theorem 1.1, and if $\max(v_1(0,0), v_2(0,0)) \le C_0$, then*

$$\sup_{0\le t\le T} \|v_1(t,\cdot) - v_2(t,\cdot)\| \le C\|v_1(0,\cdot) - v_2(0,\cdot)\|.$$

Consequently the map $v_0 \mapsto v$ is locally Lipschitz from $rcd([0,1])$ into $C([0,\infty), rcd([0,1]))$.

Our strategy to prove these results at the same time justifies a method of numerical approximation for the problem that has a direct physical interpretation. We first consider solutions that are piecewise constant, taking a finite number of values $v_0(t) > \cdots > v_{N-1}(t)$ as is the case for a finite number of particles. We show that these solutions are determined on a succession of time intervals by solving finite systems of coupled ordinary differential equations with a number of components that decreases as the smallest particles vanish. Once we prove the continuity estimate in Theorem 1.2 (at first for initial data near to each other), uniqueness is immediate and existence for general initial data in $rcd([0,1])$ follows by an approximation argument.

The solutions constructed in Theorem 1.1 correspond to measure-valued weak solutions of the evolution equation

$$\partial_t f + \partial_v(\Lambda(v,\theta(t))f) = 0 \tag{1.9}$$

for the particle volume distribution. This means that at each time t, the formal expression $f(t,v)\,dv$ corresponds to a probability measure ν_t having compact support in $[0,\infty)$, the set of volumes. The notion of distance used in Theorem 1.2 has an interpretation as a natural metric on the space $\mathcal{P}_0$ of such probability measures. This metric measures the smallest "maximum volume change" required to rearrange one volume distribution into another. Mathematically it is the L^∞ Wasserstein metric [4, 11], which we denote by d_∞. In section 3 we shall establish the relationship between $v(t,\varphi)$ and ν_t and deduce the following result as a corollary of Theorems 1.1 and 1.2.

THEOREM 1.3. *Let $\mathcal{P}_0$ denote the set of probability measures on $[0,\infty)$ of compact support, with topology given by d_∞, the L^∞ Wasserstein metric. Given $\nu_0 \in \mathcal{P}_0$, there exist a unique $\theta \in L^\infty_{\rm loc}(0,\infty)$ and a unique map $t \mapsto \nu_t$ that is locally Lipschitz from $[0,\infty)$ into $\mathcal{P}_0$, such that (θ,ν) is a volume-conserving weak solution of (1.9), in the sense that*

$$\int_0^\infty v\,d\nu_t(v) = \int_0^\infty v\,d\nu_0(v)$$

for all $t \geq 0$ and

$$\int_0^\infty \int_0^\infty \big(\partial_t\zeta(t,v) + \Lambda(v,\theta(t))\partial_v\zeta(t,v)\big)d\nu_t(v)\,dt = 0$$

for all smooth $\zeta : (0,\infty)\times(0,\infty) \to \mathbb{R}$ with compact support.

Furthermore, given any $T > 0$, $C_0 > 0$, there exists $C > 0$ such that, if two such weak solutions $(\theta_1,\nu^{(1)})$, $(\theta_2,\nu^{(2)})$ are given, such that the supports of $\nu_0^{(1)}$ and $\nu_0^{(2)}$ are contained in $[0,C_0]$, then

$$\sup_{0\leq t\leq T} d_\infty(\nu_t^{(1)},\nu_t^{(2)}) \leq C\,d_\infty(\nu_0^{(1)},\nu_0^{(2)}).$$

It is arguably natural from the physical point of view to measure distance between volume distributions by using the Wasserstein distance as is done here. (In this we were partly motivated by the works [9, 5] that employ Wasserstein distance in connection with parabolic partial differential equations.) A physically reasonable notion of distance should reflect in a plausible way the effect of small perturbations of the system on size distributions. In late-stage Ostwald ripening one imagines that the nucleation or destruction of large particles is unlikely. Thus the topology should not make it "easy" to change the number of large particles. It is plausible, rather, that small perturbations to the system would involve small changes to particle volumes. These notions are captured here by the use of the sup norm distance between volume orderings, and this is equivalent to using the L^∞ Wasserstein metric to compare volume distributions.

In section 4 we briefly treat a related, but simpler, case that arises in LSW theory, in which mass variations in the diffusion field are not neglected. In this case it is not total particle volume that is conserved in time but rather a quantity of the form

$$a\theta(t) + \int_0^1 v(t,\varphi)\,d\varphi,$$

where $a > 0$ is constant. The evolution of particle volumes is still given by (1.5), but θ is now determined directly from the conserved quantity.

2. A priori estimates and well-posedness.

In order to prove the a priori estimate stated in Theorem 1.2, we need a pair of lemmas that yield strengthened variants of Gronwall's inequality.

LEMMA 2.1. *Suppose $G : [0,T] \to \mathbb{R}$ is increasing with $G(0) = 0$, $K \geq 0$ is a constant, and $f : [0,T] \to \mathbb{R}$ is continuous and satisfies*

$$0 \leq f(t) \leq K + \int_{0^+}^t f(s)\,dG(s), \quad 0 \leq t \leq T.$$

Then $f(t) \leq Ke^{G(t)}$ for $0 \leq t \leq T$.

Proof. Let

$$U(t) = K + \int_{0^+}^t f(s)\,dG(s);$$

then $U(0) = K$ and U is increasing. To prove the lemma it suffices to show that $e^{-G}U \leq K$. Let $\{t_j\}_{j=0}^n$ be a partition of $[0,T]$ and define

$$\Delta t = \sup_{1\leq j\leq n}(t_j - t_{j-1}), \quad \epsilon(\Delta t) = \sup_{|t-s|\leq\Delta t}|f(t) - f(s)|.$$

Put $U_j = U(t_j)$, $G_j = G(t_j)$. Then

$$\begin{aligned}
e^{-G_{j+1}}U_{j+1} - e^{-G_j}U_j &= e^{-G_{j+1}}(U_{j+1} - U_j) - U_j(e^{-G_j} - e^{-G_{j+1}})\\
&= e^{-G_{j+1}}\left(\int_{t_j}^{t_{j+1}} f(s)\,dG(s) - U_j\left(e^{G_{j+1}-G_j} - 1\right)\right)\\
&\leq e^{-G_{j+1}}\left(f(t_j) + \epsilon(\Delta t) - U_j\right)(G_{j+1} - G_j)\\
&\leq \epsilon(\Delta t)(G_{j+1} - G_j),
\end{aligned}$$

where we used that $e^x - 1 \geq x$ for all x and $f(t_j) \leq U_j$. Summing, we find that $e^{-G_j}U_j \leq K + \epsilon(\Delta t)G_j$ for all j. Since the partition is arbitrary, $\epsilon(\Delta t)$ can be made arbitrarily small and the result follows. ◻

LEMMA 2.2. *Suppose $G : [0,T] \to \mathbb{R}$ is increasing, and $f : [0,T] \to \mathbb{R}$ is continuous, nonnegative, and increasing. Then as long as $0 \leq t + f(t) \leq T$ we have*

$$\int_0^t (G(s + f(s)) - G(s))\,ds \leq \int_0^{f(0)} (G(f(0)) - G(s))\,ds + \int_0^t f(s)\,d\tilde{G}(s),$$

where $\tilde{G}(s) = G(s + f(s))$.

Proof. Let Q denote the quantity on the right-hand side of the desired inequality. Observe that since G is increasing, we have that

$$Q + \int_t^{t+f(t)} (G(s + f(s)) - G(s))ds \geq Q + \int_t^{t+f(t)} \tilde{G}(s)\, ds - G(t + f(t))f(t).$$

Since $G(t + f(t)) = \tilde{G}(t)$, after integrating by parts in the Riemann–Stieltjes integral and canceling boundary terms we find that the last right-hand side equals

$$\begin{aligned} & -\int_0^{f(0)} G(s)\, ds - \int_0^t \tilde{G}(s)\, df(s) + \int_t^{t+f(t)} \tilde{G}(s)\, ds \\ &= -\int_0^{f(0)} G(s)\, ds - \int_0^t \tilde{G}(s)\, d(s + f(s)) + \int_0^{t+f(t)} \tilde{G}(s)\, ds \\ &= \int_0^{t+f(t)} (G(s + f(s)) - G(s))\ ds. \end{aligned}$$

Canceling the part of the integral from t to $t + f(t)$ finishes the proof. □

Next we establish some basic properties of solutions of the initial value problem as described in Theorem 1.2. Fixing $T > 0$, we shall consider $t \in [0, T]$. Let $\theta \in L^\infty(0, T)$ be positive and let $v \in C([0, T], rcd([0, 1]))$ be such that

$$\int_0^1 v(t, \varphi)\, d\varphi = \int_0^1 v(0, \varphi)\, d\varphi \tag{2.1}$$

for all t and

$$v(t, \varphi) = v(0, \varphi) + \int_0^t (v(s, \varphi)^{1/3}\theta(s) - 1)\, ds \tag{2.2}$$

whenever $v(t, \varphi) > 0$. By scaling, we may assume $\int_0^1 v(t, \varphi)\, d\varphi = 1$ for all $t \in [0, T]$.

From (2.2) it follows that $t \mapsto v(t, \varphi)$ is Lipschitz and satisfies

$$\frac{\partial v}{\partial t} = v^{1/3}\theta(t) - 1 \tag{2.3}$$

for almost every t in any interval where $v > 0$. Since $v^{1/3}\theta - 1 \leq -\frac{1}{2}$ for $v < \varepsilon_0$ where

$$\varepsilon_0^{-1} = 8 \operatorname*{ess\,sup}_{0 \leq t \leq T} \theta(t),$$

it follows easily that if $v(t_0, \varphi) = 0$, then $v(t, \varphi) = 0$ for all $t \geq t_0$.

We define $\bar{v}(t) = v(t, 0) = \max_\varphi v(t, \varphi)$ and with the notation $a \wedge b = \min(a, b)$ we define

$$\begin{aligned} \bar{t}(\varphi) &= \inf\{t \in [0, T] \mid v(t, \varphi) = 0\} \wedge T, \\ \bar{\varphi}(t) &= \sup\{\varphi \in [0, 1] \mid v(t, \varphi) > 0\}. \end{aligned}$$

The functions $\bar{t}$ and $\bar{\varphi}$ are decreasing functions, and $\bar{\varphi}(t) > 0$ for all t, since $v(t, \cdot)$ can never vanish identically by volume conservation. We call $\bar{t}(\varphi)$ the *vanishing time* for $v(t, \varphi)$ at φ if $\bar{t}(\varphi) < T$ (but note that $\bar{t}(\varphi) = T$ if $v(T, \varphi) > 0$).

Lemma 2.3. *For almost every $t \in [0,T]$ we have*

$$0 < \theta(t) = \frac{\bar\varphi(t)}{\displaystyle\int_0^1 v(t,\varphi)^{1/3}\,d\varphi} \le \bar v(t)^{2/3} \le (e^t \bar v(0))^{2/3}.$$

Proof. Evaluate (2.2) at $\min(t,\bar t(\varphi))$ and integrate over $\varphi \in [0,1]$. Changing the order of integration and using the fact that $v(\bar t(\varphi),\varphi) = 0$ if $\bar t(\varphi) < t$, we obtain

$$\begin{aligned} 0 &= \int_0^{\bar\varphi(t)} v(t,\varphi)\,d\varphi - \int_0^1 v(0,\varphi)\,d\varphi \\ &= \int_0^1 \int_0^{\min(t,\bar t(\varphi))} (v(s,\varphi)^{1/3}\theta(s) - 1)\,ds\,d\varphi \\ &= \int_0^t \int_0^{\bar\varphi(s)} (v(s,\varphi)^{1/3}\theta(s) - 1)\,d\varphi\,ds. \end{aligned}$$

Since t is arbitrary the formula for $\theta(t)$ follows. To get the inequalities, we use that $\bar\varphi(t) \le 1$ and $\int_0^1 v^{1/3}\,d\varphi \ge \bar v(t)^{-2/3}\int_0^1 v\,d\varphi$. Then since $d\bar v/dt \le \bar v^{1/3}\theta \le \bar v$ we find

$$\bar v(t) \le e^t \bar v(0). \qquad \square \tag{2.4}$$

Lemma 2.4. *Whenever $v(t_1,\varphi) < \varepsilon_0$, we have $\partial v/\partial t < -\frac{1}{2}$ for almost every $t \in [t_1, \bar t(\varphi)]$ and*

$$\frac{1}{2}(\bar t(\varphi) - t) \le v(t,\varphi) < \varepsilon_0 - \frac{1}{2}(t - t_1)$$

for all $t \in [t_1, \bar t(\varphi)]$.

Proof. $v < \varepsilon_0$ implies $v^{1/3}\theta - 1 < -\frac{1}{2}$ almost everywhere, and the results follow easily. $\square$

Corollary 2.5. *There is a constant $C = C(T, C_0)$ such that*

$$\int_0^{\bar t(\varphi)} v(t,\varphi)^{-2/3}\,dt \le C$$

for all $\varphi \in [0,1]$. Furthermore, the function β given by

$$\beta(t) = \int_0^{\bar\varphi(t)} v(t,\varphi)^{-2/3}\,d\varphi$$

is finite for almost every $t \in [0,T]$ and $\int_0^T \beta(t)\,dt \le C$.

Proof. The first assertion follows directly from the estimates of the preceding lemma. The second follows from Fubini's theorem. $\square$

Our plan now is first to prove a restricted version of Theorem 1.2 for two solutions that are initially close together. This restricted result will suffice to establish the existence and uniqueness theorem, after which the results of Theorem 1.2 without restriction can be proved.

Proposition 2.6. *Given $T > 0$, $C_0 > 0$, there exist $C > 0$ and $\delta > 0$ such that the bound asserted in Theorem 1.2 holds under the additional assumption that*

$$\|v_1(0,\cdot) - v_2(0,\cdot)\| \le \delta.$$

To start the proof of this restricted version of Theorem 1.2, we suppose that $T, C_0 > 0$ are given and put

$$\varepsilon_1 = (8e^T C_0)^{-1}.$$

We suppose that (θ_1, v_1) and $(\theta_2, v_2) \in L^\infty(0,T) \times C([0,T], rcd([0,1]))$ are two solutions of (2.1) and (2.2) such that $\max(v_1(0,0), v_2(0,0)) \le C_0$. We define

$$M(t) = \sup_{0\le s\le t} \|v_1(s,\cdot) - v_2(s,\cdot)\|$$

and assume that $M(0) < \varepsilon_1$.

Lemma 2.7. *There is a constant $C_1 = C_1(T, C_0)$ such that for $0 \le t \le T$ we have*

$$M(t) \le C_1 \left(M(0) + \int_0^t |\theta_1(s) - \theta_2(s)|\, ds \right).$$

Proof. Fix $\varphi \in [0,1]$. We suppose that $\bar t_1(\varphi) \ge \bar t_2(\varphi)$ without loss of generality. For $t \in [0, \bar t_2(\varphi)]$ we may write

$$\begin{aligned} v_1(t,\varphi) - v_2(t,\varphi) = v_1(0,\varphi) - v_2(0,\varphi) &+ \int_0^t v_2(s,\varphi)^{1/3}(\theta_1(s) - \theta_2(s))\, ds \\ &+ \int_0^t \theta_1(s)(v_1(s,\varphi)^{1/3} - v_2(s,\varphi)^{1/3})\, ds. \end{aligned}$$

Using the bounds above for θ_1 and v_2, and the fact that $|a-b| \le |a^3 - b^3|/a^2$ whenever $a, b > 0$, with $C_* = (e^T C_0)^{1/3}$, we obtain the estimate

$$\begin{aligned} |v_1(t,\varphi) - v_2(t,\varphi)| \le |v_1(0,\varphi) - v_2(0,\varphi)| &+ C_* \int_0^t |\theta_1(s) - \theta_2(s)|\, ds \\ &+ C_*^2 \int_0^t v_1(s,\varphi)^{-2/3} |v_1(s,\varphi) - v_2(s,\varphi)|\, ds. \end{aligned} \tag{2.5}$$

For $t \in [\bar t_2(\varphi), \bar t_1(\varphi)]$, we have $v_2(t,\varphi) = 0$ and may write

$$v_1(t,\varphi) \le v_1(\bar t_2(\varphi), \varphi) + C_*^2 \int_{\bar t_2(\varphi)}^t v_1(s,\varphi)^{1/3}\, d\varphi.$$

Using (2.5) with $t = \bar t_2(\varphi)$ to estimate $v_1(\bar t_2(\varphi), \varphi)$, we find that (2.5) is valid for all $t \in [0, \bar t_1(\varphi)]$. Gronwall's inequality then yields that

$$\begin{aligned} &\exp\left(-C_*^2 \int_0^t v_1(s,\varphi)^{-2/3} ds \right) |v_1(t,\varphi) - v_2(t,\varphi)| \\ &\quad \le |v_1(0,\varphi) - v_2(0,\varphi)| + C_* \int_0^t |\theta_1(s) - \theta_2(s)|\, ds. \end{aligned}$$

Using Corollary 2.5 completes the proof. ∎

Lemma 2.8. *Suppose $M(t) \le \varepsilon_1$ for $0 \le t \le \tau$. Then*

$$|\bar\varphi_1(t) - \bar\varphi_2(t)| \le \bar\varphi_1(t) - \bar\varphi_1(t + 2M(t)) + \bar\varphi_2(t) - \bar\varphi_2(t + 2M(t))$$

as long as $t + 2M(t) \le \tau$.

Proof. Fixing t, by relabeling we can assume $\bar\varphi_1(t) \le \bar\varphi_2(t)$. For $\varphi \in [\bar\varphi_1(t), \bar\varphi_2(t)]$, $s \in [t, \tau]$ we have $v_1(s,\varphi) = 0$ and $v_2(s,\varphi) \le M(s) \le \varepsilon_1$ by assumption. By Lemma 2.4, for $s \le \bar t_2(\varphi)$ we have $\partial v_2/\partial t \le -\frac{1}{2}$ and therefore $\bar t_2(\varphi) \le \min(t + 2M(t), T)$. Hence $\bar\varphi_2(t + 2M(t)) \le \bar\varphi_1(t)$, and the result follows. □

LEMMA 2.9. *There is a constant* $C_2 = C_2(T, C_0)$ *and an increasing function* $H : [0,T] \to \mathbb{R}$ *depending on* v_1 *and* v_2*, satisfying* $H(0) = 0$ *and* $H(T) \le C_2$*, such that if* $M(t) \le \varepsilon_1$ *for* $0 \le t \le \tau$*, then*

$$\int_0^t |\theta_1(s) - \theta_2(s)|\, ds \le C_2 M(0) + \int_{0^+}^t M(s)\, dH(s)$$

as long as $t + 2M(t) \le \tau$.

Proof. Using that $\int v_j^{1/3} d\varphi \ge \bar v_j^{-2/3} \ge C_*^{-2}$, from the formula for $\theta(t)$ we obtain that

$$|\theta_1(t) - \theta_2(t)| \le C_*^2 |\bar\varphi_1(t) - \bar\varphi_2(t)| + C_*^4 \int_0^1 |v_1^{1/3} - v_2^{1/3}|\, d\varphi.$$

Let $\varphi_+(t) = \max(\bar\varphi_1(t), \bar\varphi_2(t))$; then for $\varphi < \varphi_+$ we have

$$|v_1^{1/3} - v_2^{1/3}| \le \frac{|v_1 - v_2|}{v_1^{2/3} + v_2^{2/3}}.$$

Note that from Corollary 2.5, it follows that with $t_+(\varphi) = \max(\bar t_1(\varphi), \bar t_2(\varphi))$ we have

$$\int_0^{t_+(\varphi)} \frac{1}{v_1^{2/3} + v_2^{2/3}} dt \le C(T, C_0).$$

By Fubini's theorem it follows that the function defined by

$$h_0(t) = \int_0^{\varphi_+(t)} \frac{1}{v_1^{2/3} + v_2^{2/3}} d\varphi$$

is finite for a.e. t and is integrable with $\int_0^T h_0(t)\, dt \le C(T, C_0)$. Then we have

$$\int_0^1 |v_1^{1/3} - v_2^{1/3}|\, d\varphi \le M(t) h_0(t) \tag{2.6}$$

for a.e. $t \in [0,T]$.

Next, for $j = 1$ and 2 we invoke Lemma 2.2 with $G(t) = -\bar\varphi_j(t)$, $f(t) = 2M(t)$, and conclude that as long as $t + 2M(t) \le \tau$, then

$$\int_0^t \bar\varphi_j(s) - \bar\varphi_j(s + 2M(s))\, ds \le 2M(0) + \int_{0^+}^t 2M(s)\, dH_j(s),$$

where $H_j(t) = -\bar\varphi_j(t + 2M(t)) + \bar\varphi_j(2M(0))$. Evidently H_j satisfies $H_j(t) \le 1$ for all t.

Putting these estimates together with the result of Lemma 2.8, we find that

$$\int_0^t |\theta_1(s) - \theta_2(s)|\, ds \le 4C_*^2 M(0) + \int_{0^+}^t M(s)\, dH(s),$$

where

$$H(t) = 2C_*^2(H_1(t) + H_2(t)) + C_*^4 \int_0^t h_0(s)\, ds.$$

The desired result follows. □

The proof of Proposition 2.6 uses a continuation argument based on the estimates above together with the estimate

$$M(\tau) - M(t) \le 2C_*^3(\tau - t) \tag{2.7}$$

whenever $0 \le t \le \tau \le T$, which follows from $|\partial v/\partial t| \le C_*^3$. Since M is increasing, we can find $\tilde{T} \le T$ such that $\tilde{T} + 2M(\tilde{T}) = T$. With $\tau = t + 2M(t)$, inequality (2.7) yields

$$M(t + 2M(t)) \le M(t)(1 + 4C_*^3) \tag{2.8}$$

whenever $t \le \tilde{T}$. Now let

$$\Omega = \{t \in [0, \tilde{T}] \mid M(t + 2M(t)) \le \varepsilon_1\}.$$

If $M(0) \le \delta_0 := \varepsilon_1/(1 + 4C_*^3)$, then $0 \in \Omega$ so Ω is nonempty, and clearly Ω is closed. We claim Ω is open in $[0, \tilde{T}]$ if $M(0)$ is sufficiently small.

Given any $t_1 \in \Omega$ we can apply Lemmas 2.7 and 2.9 to deduce that

$$M(t) \le C_1(1 + C_2)M(0) + C_1 \int_{0^+}^t M(s)\, dH(s) \tag{2.9}$$

for $0 \le t \le t_1$. Then Lemma 2.1 implies

$$M(t) \le C_3 M(0) \tag{2.10}$$

for $0 \le t \le t_1$, where $C_3(T, C_0) = \exp(C_1C_2)C_1(1 + C_2)$. Using (2.8) we infer that $M(t_1 + 2M(t_1)) \le C_4 M(0)$ with $C_4 = C_3(1 + 4C_*^3)$. Provided we assume

$$M(0) \le \delta_1 := \frac{1}{2}\frac{\varepsilon_1}{C_4},$$

it follows that $M(t_1 + 2M(t_1)) < \varepsilon_1$, and since M is continuous, Ω is open in $[0, \tilde{T}]$.

Consequently we have $\tilde{T} \in \Omega$. Putting $t_1 = \tilde{T}$, this means we have $M(T) \le \varepsilon_1$ and $M(T) \le C_4 M(0)$ if $M(0) \le \delta_1$. This finishes the proof of Proposition 2.6.

Proof of Theorem 1.1. Uniqueness follows immediately from Proposition 2.6. To prove existence for arbitrary $v_0 \in rcd([0,1])$, by Proposition 2.6 and Lemma 2.3 it evidently suffices to prove global existence for v_0 in a dense set of $rcd([0,1])$. Solutions in general are constructed by passing to the limit in $C([0,T], rcd([0,1]))$ for every $T > 0$.

Lemma 2.10. *The set of functions in* $rcd([0,1])$ *that take a finite number of values is dense in* $rcd([0,1])$.

Proof. Let $v_0 \in rcd([0,1])$ and let $\varepsilon > 0$. Let $y_j = \frac{1}{2}\varepsilon j$ for $j = 0, 1, \ldots,$ and let

$$v_\varepsilon(\varphi) = \min\{y_j \mid y_j \ge v_0(\varphi)\}$$

for $\varphi \in [0,1]$. It is easy to see that v_ε has a finite number of values, that $v_\varepsilon \in rcd([0,1])$, and $\|v_\varepsilon - v_0\| < \varepsilon$. This proves the lemma. □

Suppose, then, that $v_0 \in rcd([0,1])$ takes a finite number of values $y_0 > \cdots > y_N = 0$. Then with $\varphi_j = \inf\{\varphi \mid v_0(\varphi) = y_j\}$, we have $0 = \varphi_0 < \cdots < \varphi_N \leq 1$ and $v_0(\varphi) = y_j$ for $\varphi \in [\varphi_j, \varphi_{j+1})$, $j = 0, \dots, N-1$. We start to construct a solution by solving the system of ordinary differential equations

$$w_j'(t) = w_j(t)^{1/3}\Theta(t) - 1, \qquad j = 0, \dots, N-1, \tag{2.11}$$

with

$$\Theta(t) = \varphi_N \Bigg/ \sum_{j=0}^{N-1} w_j(t)^{1/3}(\varphi_{j+1} - \varphi_j) \tag{2.12}$$

and $w_j(0) = y_j$, on a maximal interval $[0, t_N)$ in which $\min w_j(t) > 0$. The solution is smooth and $w_j(t) > w_{j+1}(t)$ by backward uniqueness for the equation $w' = w^{1/3}\Theta - 1$. The quantity

$$\sum_{j=0}^{N-1} w_j(t)(\varphi_{j+1} - \varphi_j)$$

is conserved in time. Without loss of generality we can assume this quantity is 1.

We can estimate $\Theta(t) \leq w_0(t)^{2/3}$ so $w_0' \leq w_0$ and hence $w_0(t) \leq e^t y_0$. If $t_N < \infty$, then it follows that the smallest component vanishes, i.e., $w_{N-1}(t_N^-) = \lim_{t \nearrow t_N} w_{N-1}(t) = 0$.

For $t \in [0, t_N)$ we define $v(t, \varphi) = w_j(t)$ for $\varphi \in [\varphi_j, \varphi_{j+1})$, $j = 0, \dots, N-1$, and let $\theta = \Theta$. This yields a solution of (2.2) and (2.1) for $t \in [0, t_N)$. As $t \to t_N$ from below, the limits $v(t_N^-, \varphi)$ and $\theta(t_N^-)$ exist. The solution can then be reinitialized at time t_N with one less component (N replaced by $N-1$). After some finite number of such steps the solution must exist globally.

Thus, for $v_0 \in rcd([0,1])$ with a finite number of values, a global solution exists. Theorem 1.1 follows.

Proof of Theorem 1.2. The additional restriction imposed in Proposition 2.6 can be removed now by considering convex combinations of initial data. Given T, C_0, v_1, and v_2 as stated, let $C > 0$, $\delta > 0$ be as given by Proposition 2.6, and let $M_0 = \|v_1(0,\cdot) - v_2(0,\cdot)\|$. Fix an integer $n > M_0/\delta$, and for $j = 0, 1, \dots, n$ let

$$x_j(\varphi) = \left(1 - \frac{j}{n}\right) v_1(0,\varphi) + \left(\frac{j}{n}\right) v_2(0,\varphi)$$

for $\varphi \in [0,1]$. Then $x_j \in rcd([0,1])$, $x_j(0) \leq C_0$ for all j and $\|x_{j+1} - x_j\| = M_0/n < \delta$. By the existence theorem there exist corresponding solutions $v = \tilde{v}_j$ to (2.1)–(2.2) with $\tilde{v}_j(0,\cdot) = x_j$, and by Proposition 2.6 we have

$$\sup_{0 \leq t \leq T} \|\tilde{v}_{j+1}(t,\cdot) - \tilde{v}_j(t,\cdot)\| \leq C\|x_{j+1} - x_j\| = CM_0/n.$$

Since $v_1 - v_2 = \sum_{j=0}^{n-1}(\tilde{v}_{j+1} - \tilde{v}_j)$, using the triangle inequality we find that

$$\sup_{0 \leq t \leq T} \|v_1(t,\cdot) - v_2(t,\cdot)\| \leq CM_0,$$

as desired.

3. Measure-valued solutions. Our aim here is to describe a precise correspondence between the solutions $v(t,\varphi)$ of Theorem 1.1 and measure-valued weak solutions ν_t of (1.9) and to show that the metric $\|v_1 - v_2\|$ on $rcd([0,1])$ corresponds to the L^∞ Wasserstein metric on the space $\mathcal{P}_0$ of (Borel) probability measures on $[0,\infty)$ with compact support. Theorem 1.3 then follows as a corollary of Theorems 1.1 and 1.2.

We begin with a technical lemma on generalized inverses of increasing functions.

Lemma 3.1. *Suppose $b > 0$ and $w : [0,b] \to \mathbb{R}$ is a left continuous increasing function with $w(0) = 0$. Let $b^\dagger = w(b)$ and define $w^\dagger : [0,b^\dagger] \to \mathbb{R}$ by*

$$w^\dagger(y) = \begin{cases} \sup\{x \mid w(x) < y\}, & 0 < y \le b^\dagger, \\ 0, & y = 0. \end{cases}$$

Then $w^\dagger$ is left continuous and increasing and, moreover,

$$w^{\dagger\dagger} = w.$$

Proof. Clearly $w^\dagger$ is increasing. Given $y \in (0,b^\dagger]$ and $\varepsilon > 0$, put $\bar{x} = w^\dagger(y)$ and $2\delta = y - w(\bar{x} - \varepsilon)$. Then $\delta > 0$ and $w(\bar{x} - \varepsilon) < y - \delta$; hence $\bar{x} - \varepsilon < w^\dagger(y - \delta) \le \bar{x}$. It follows $w^\dagger$ is left continuous.

To show $w^{\dagger\dagger} = w$, it suffices to show that for $0 < x < b$,

$$w(x - \varepsilon) \le w^{\dagger\dagger}(x) \le w(x + \varepsilon)$$

for all sufficiently small $\varepsilon > 0$. Let $\bar{y} = w^{\dagger\dagger}(x) = \sup\{y \mid w^\dagger(y) < x\}$. Then for all $\varepsilon_0 > 0$, $w^\dagger(\bar{y}+\varepsilon_0) \ge x$; hence for any small $\varepsilon > 0$ we have $w(x-\varepsilon) < \bar{y}+\varepsilon_0$. Therefore $w(x - \varepsilon) \le \bar{y}$.

For the reverse inequality there are two cases. If $\bar{x} = w^\dagger(\bar{y}) < x$, then for small $\varepsilon > 0$ we have

$$\bar{y} \le w(\bar{x} + \varepsilon) \le w(x + \varepsilon). \tag{3.1}$$

Otherwise $\bar{x} \ge x$, and since w is left continuous, $\bar{x} = x$. In this case, (3.1) again holds. This finishes the proof. □

If w is continuous and strictly increasing, then $w^\dagger$ is the inverse function of w.

Given a probability measure ν with compact support $[0,\bar{v}] \subset [0,\infty)$, we associate the distribution function $F_\nu : [0,\infty) \to [0,1]$ given by

$$F_\nu(x) = \begin{cases} \nu([0,x)), & x > 0, \\ 0, & x = 0. \end{cases} \tag{3.2}$$

F_ν is left continuous and increasing, and F_ν determines ν (that is, the values of F_ν determine the values of ν on all Borel sets). We associate a decreasing function $v = \hat{v}(\nu)$ to ν via $v(x) = F_\nu^\dagger(1-x)$ for $x \in [0,1]$. (Here, $F_\nu^\dagger$ is the generalized inverse of the restriction of F_ν to $[0,\bar{v}+1]$.) That is,

$$v(x) = \begin{cases} \sup\{y \mid F_\nu(y) < 1 - x\}, & 0 \le x < 1, \\ 0, & x = 1. \end{cases} \tag{3.3}$$

With the notation $Rv(x) = v(1-x)$ we have $\hat{v}(\nu) = R(F_\nu^\dagger)$. The first part of Lemma 3.1 implies $\hat{v}(\nu) \in rcd([0,1])$; thus the map $\hat{v} : \mathcal{P}_0 \to rcd([0,1])$. (Recall $\mathcal{P}_0$ is the set of probability measures on $[0,\infty)$ with compact support.)

The inverse map to $\hat{v}$ is given as follows. If $v \in rcd([0,1])$ we let $F = (Rv)^\dagger$ on $[0, v(0)]$ and put $F(x) = 1$ for $x > v(0)$. Then F is increasing and left continuous and determines a (Borel) probability measure ν for which $F = F_\nu$. For later use we note that for any continuous $f : (0,\infty) \to \mathbb{R}$ with compact support, we have

$$\int_0^1 f(v(x))\,dx = \int_0^1 f(F^\dagger(x))\,dx = \int_0^\infty f(y)\,dF(y) = \int_0^\infty f(y)\,d\nu(y). \tag{3.4}$$

This follows from [3, 2.5.18(3)], for example. The identity function $y \mapsto y$ can be approximated uniformly on compact sets in $[0,\infty)$ by such functions f, hence

$$\int_0^1 v(x)\,dx = \int_0^\infty y\,d\nu(y). \tag{3.5}$$

We let $\hat{\nu}(v) = \nu$, so $\hat{\nu} : rcd([0,1]) \to \mathcal{P}_0$. Lemma 3.1 implies that we have the following.

Lemma 3.2. *$\hat{v}$ and $\hat{\nu}$ are inverse maps: $\hat{v}(\hat{\nu}(v)) = v$ for all $v \in rcd([0,1])$ and $\hat{\nu}(\hat{v}(\nu)) = \nu$ for all $\nu \in \mathcal{P}_0$.*

We now recall from [4] that the L^p Wasserstein metric can be defined on $\mathcal{P}_0$ as follows. Given ν_1 and ν_2 in $\mathcal{P}_0$, let $D(\nu_1,\nu_2)$ be the set of probability measures μ on $[0,\infty) \times [0,\infty)$ with marginal distributions ν_1 and ν_2, that is, for all continuous $\zeta : [0,\infty) \to \mathbb{R}$,

$$\int_0^\infty \int_0^\infty \zeta(x)\,d\mu(x,y) = \int_0^\infty \zeta(x)\,d\nu_1(x)$$

and

$$\int_0^\infty \int_0^\infty \zeta(y)\,d\mu(x,y) = \int_0^\infty \zeta(y)\,d\nu_2(y).$$

If $1 \le p < \infty$, then the L^p Wasserstein metric is defined by

$$d_p(\nu_1,\nu_2) = \left(\inf_{\mu \in D(\nu_1,\nu_2)} \int |x-y|^p\,d\mu(x,y) \right)^{1/p}.$$

The L^∞ Wasserstein metric is defined by

$$d_\infty(\nu_1,\nu_2) = \inf_{\mu \in D(\nu_1,\nu_2)} \mu\text{-ess sup}|x-y|.$$

The measures μ represent ways to "rearrange mass" from one distribution into the other, and the L^p Wasserstein metrics measure the least costly way to do this according to the notion of cost indicated.

Lemma 3.3. *Given ν_1, $\nu_2 \in \mathcal{P}_0$, let $v_1 = \hat{v}(\nu_1)$, $v_2 = \hat{v}(\nu_2)$. Then for $1 \le p < \infty$ we have*

$$d_p(\nu_1,\nu_2) = \left(\int_0^1 |v_1(\varphi) - v_2(\varphi)|^p\,d\varphi \right)^{1/p},$$

and

$$d_\infty(\nu_1,\nu_2) = \|v_1 - v_2\|.$$

Proof. The assertion for $1 \le p < \infty$ follows from [11, pp. 28–30, Corollary 7.3.6], which yields that

$$d_p(\nu_1, \nu_2) = \left(\int_0^1 |F^\dagger_{\nu_1}(\varphi) - F^\dagger_{\nu_2}(\varphi)|^p \, d\varphi \right)^{1/p}.$$

Then Proposition 3 of [4] asserts that $\lim_{p\to\infty} d_p(\nu_1, \nu_2) = d_\infty(\nu_1, \nu_2)$. Since v_1 and v_2 are right continuous, it follows

$$\begin{aligned} d_\infty(\nu_1, \nu_2) &= \lim_{p\to\infty} \left(\int_0^1 |v_1(\varphi) - v_2(\varphi)|^p \, d\varphi \right)^{1/p} \\ &= \operatorname*{ess\,sup}_{[0,1]} |v_1(\varphi) - v_2(\varphi)| = \sup_{[0,1]} |v_1(\varphi) - v_2(\varphi)|. \qquad \square \end{aligned}$$

Corollary 3.4. *Let $\mathcal{P}_0$ have the topology induced by d_∞. Then $\mathcal{P}_0$ is complete, and the map $\hat{v} : \mathcal{P}_0 \to rcd([0, 1])$ is an isometric isomorphism of complete metric spaces.*

The completeness of $\mathcal{P}_0$ with respect to the metric d_∞ was established in [4].

The correspondence between volume orderings $v \in rcd([0, 1])$ and volume distributions $\nu \in \mathcal{P}_0$ has been established. Now we seek to show that this correspondence maps solutions to weak solutions and vice versa.

Proposition 3.5. *Let $\theta \in L^\infty_{\text{loc}}(0, \infty)$, $v \in C([0, \infty),\ rcd([0, 1]))$ be a solution of* (2.2)*. For each $t \ge 0$, let $\nu_t = \hat{\nu}(v(t, \cdot))$. Then $\nu : [0, \infty) \to \mathcal{P}_0$ is locally Lipschitz, and ν is a weak solution of* (1.9)*.*

Proof. From (2.2) we have that $v : [0, \infty) \to rcd([0, 1])$ is locally Lipschitz; therefore $\nu : [0, \infty) \to \mathcal{P}_0$ is locally Lipschitz by Corollary 3.4.

Let $\zeta : (0, \infty) \times (0, \infty) \to \mathbb{R}$ be smooth with compact support. Then for all $\varphi \in [0, 1]$, $t \mapsto \zeta(t, v(t, \varphi))$ is Lipschitz continuous and we have

$$\begin{aligned} 0 &= \int_0^\infty \frac{d}{dt} \zeta(t, v(t, \varphi)) \, dt \\ &= \int_0^\infty \partial_t \zeta(t, v(t, \varphi)) + \Lambda(v(t, \varphi), \theta(t)) \partial_v \zeta(t, v(t, \varphi)) \, dt. \end{aligned}$$

Let $F(t, \cdot) = (Rv(t, \cdot))^\dagger$ and let $\varphi(t, \cdot) = 1 - F(t, \cdot)$. We integrate over $\varphi \in [0, 1]$, use Fubini's theorem, and change variables using (3.4). We obtain

$$\begin{aligned} 0 &= -\int_0^\infty \int_0^\infty \left(\partial_t \zeta(t, v) + \Lambda(v, \theta(t)) \partial_v \zeta(t, v) \right) \, d\varphi(t, v) \, dt \\ &= \int_0^\infty \int_0^\infty \left(\partial_t \zeta(t, v) + \Lambda(v, \theta(t)) \partial_v \zeta(t, v) \right) \, d\nu_t(v) \, dt. \end{aligned}$$

Thus (θ, ν) is a weak solution in the sense of Theorem 1.3, as claimed. $\square$

Proposition 3.6. *Suppose that $\theta \in L^\infty_{\text{loc}}(0, \infty)$ and $\nu : [0, \infty) \to \mathcal{P}_0$ is locally Lipschitz, and ν is a weak solution of* (1.9)*. Let $v(t, \cdot) = \hat{v}(\nu_t)$ for each $t \ge 0$. Then v is a solution of* (2.2)*.*

Proof. Given θ and v as described, the map $v : [0, \infty) \to rcd([0, 1])$ is locally Lipschitz. We consider test functions ζ of the form

$$\zeta(t, v) = \xi(t) \eta(v), \tag{3.6}$$

where the functions ξ, $\eta : \mathbb{R} \to \mathbb{R}$ are smooth with compact support in $(0, \infty)$. Using this form together with the fact that (θ, ν) form a weak solution to (1.9), and using the change of variables from (3.4) as previously, we find that

$$0 = \int_0^\infty \int_0^1 \xi'(t)\eta(v(t,\varphi)) + \xi(t)\eta'(v(t,\varphi))\Lambda(v(t,\varphi),\theta(t))\, d\varphi\, dt.$$

Using Fubini's theorem and integrating by parts in time, this gives

$$0 = \int_0^1 \int_0^\infty \xi(t)\tilde{\eta}(v(t,\varphi))(\Lambda(v(t,\varphi),\theta(t)) - \partial_t v(t,\varphi))\, dt\, d\varphi, \tag{3.7}$$

where $\tilde{\eta} = \eta'$. This formula is justified since for each $\varphi \in [0, 1]$, $v(\cdot, \varphi)$ is Lipschitz, hence differentiable almost everywhere. We note that since v is bounded on compact sets, $\tilde{\eta}$ can be chosen to agree on the range of v with an arbitrary smooth function with compact support in $(0, \infty)$. We do this and drop the tilde. Furthermore, we note that by Lebesgue's dominated convergence theorem, (3.7) remains valid for any ξ with compact support in $(0, \infty)$ that is the bounded pointwise limit $\xi = \lim_{n\to\infty} \xi_n$ of a sequence of smooth ξ_n with compact support in $(0, \infty)$, and similarly for η. For the moment it will suffice to consider ξ, $\eta \in C_c(\mathbb{R}^+)$, the set of continuous functions on $(0, \infty)$ with compact support.

For what follows, we take some care regarding joint measurability in (t, φ) and sets of measure zero. We fix a representative $\tilde{\theta}$ in the equivalence class θ, then drop the tilde. $\partial_t v(t, \varphi)$ need not exist at every point, but (3.7) also holds if $\partial_t v$ is replaced by the upper derivative $\overline{\partial}_t v$ or the lower derivative $\underline{\partial}_t v$, defined by

$$\overline{\partial}_t v(t,\varphi) = \lim_{\varepsilon\to 0} \sup_{0<|h|<\varepsilon} \delta^h v(t,\varphi), \quad \underline{\partial}_t v(t,\varphi) = \lim_{\varepsilon\to 0} \inf_{0<|h|<\varepsilon} \delta^h v(t,\varphi),$$

where

$$\delta^h v(t,\varphi) = \frac{v(t+h,\varphi) - v(t,\varphi)}{h}.$$

Since v is locally Lipschitz in t uniformly in φ, $\overline{\partial}_t v$ and $\underline{\partial}_t v$ are bounded on compact sets, and $\underline{\partial}_t v \le \overline{\partial}_t v$.

LEMMA 3.7. *As maps from* $(0, \infty) \times [0, 1] \to \mathbb{R}$, $\overline{\partial}_t v$ *and* $\underline{\partial}_t v$ *are Borel measurable. Moreover,* $\overline{\partial}_t v = \underline{\partial}_t v$ *almost everywhere in* $(0, \infty) \times [0, 1]$.

Proof. Since v is continuous in t uniformly in φ and is right continuous and decreasing in φ, v is lower semicontinuous, hence Borel. Suppose $0 < t_1 < t_2 < \infty$; then for $0 < |h| < t_1$ the map $\delta^h v$ is Borel on $[t_1, t_2] \times [0, 1]$. Let $\{h_j\}$ be a dense sequence in $(-1, 0) \cup (0, 1)$. Since the maximum of two Borel functions is Borel and pointwise limits of sequences of Borel functions are Borel, and pointwise we have

$$\sup_{0<|h|<\varepsilon} \delta^h v(t,\varphi) = \sup_{|h_j|<\varepsilon} \delta^{h_j} v(t,\varphi) = \lim_{k\to\infty} \max_{\substack{j\le k\\ |h_j|<\varepsilon}} \delta^{h_j} v(t,\varphi),$$

by taking ε to zero along a sequence it follows that $\overline{\partial}_t v$ is Borel on $[t_1, t_2] \times [0, 1]$, hence on $(0, \infty) \times [0, 1]$. A similar argument applies for $\underline{\partial}_t v$.

Now we have that the set $Z = \{(t, \varphi) \mid (\overline{\partial}_t v - \underline{\partial}_t v)(t, \varphi) > 0\}$ is a Borel set. We know that for each φ, $v(\cdot, \varphi)$ is differentiable almost everywhere, so $(\overline{\partial}_t v - \underline{\partial}_t v)(t, \varphi) = 0$ for almost every $t > 0$. Fubini's theorem now implies that Z has Lebesgue measure zero in $(0, \infty) \times [0, 1]$. □

Returning to (3.7), we can now apply Fubini's theorem and deduce that for almost every t, $(\overline{\partial}_t v - \underline{\partial}_t v)(t,\varphi) = 0$ for almost every φ, and with

$$J_\eta(t) = \int_0^1 \eta(v(t,\varphi))(\Lambda(v(t,\varphi),\theta(t)) - \overline{\partial}_t v(t,\varphi))\,d\varphi,$$

we have that for any $\eta \in C_c(\mathbb{R}^+)$, $\int_0^\infty \xi(t)J_\eta(t)\,dt = 0$ for all $\xi \in C_c(\mathbb{R}^+)$. Therefore, given η there is a set $\Omega_\eta \subset (0,\infty)$ of full measure (meaning the complement has measure zero), such that $J_\eta(t) = 0$ for all $t \in \Omega_\eta$.

The set $C_c(\mathbb{R}^+)$ is separable, so if we do this for a dense sequence $\{\eta_n\}$ we find there is a set $\Omega \subset \cap\Omega_{\eta_n}$ of full measure in $(0,\infty)$ such that for $t \in \Omega$, $J_{\eta_n}(t) = 0$ for all n. Since any $\eta \in C_c(\mathbb{R}^+)$ can be approximated uniformly by a subsequence of $\{\eta_n\}$, we infer the following.

Lemma 3.8. *There is a set $\Omega \subset (0,\infty)$ of full measure, such that for all $t \in \Omega$, $\partial_t v(t,\varphi)$ exists for almost every $\varphi \in [0,1]$ and $J_\eta(t) = 0$ for all $\eta \in C_c(\mathbb{R}^+)$.*

Lemma 3.9. *Let $t \in \Omega$, and suppose $v(t,x) = v(t,y)$, where $0 \le x < y \le 1$. Then $\partial_t v(t,\varphi)$ exists for all $\varphi \in (x,y)$ and is constant on this interval.*

The proof of this lemma is straightforward, using the facts that $v(t,\cdot)$ is decreasing for every t and $\partial_t v(t,\varphi)$ exists for almost every φ.

Lemma 3.10. *Let $t \in \Omega$, and let $\bar\varphi(t) = \sup\{\varphi \mid v(t,\varphi) > 0\}$. Then*

$$\Lambda(v(t,\varphi),\theta(t)) - \partial_t v(t,\varphi) = 0$$

for almost all $\varphi \in [0,\bar\varphi(t))$.

Proof. We thank B. Kirchheim for the main idea of the following proof. Since t is fixed, we suppress indicating dependence on t, and we let $g(\varphi) = \Lambda(v(t,\varphi),\theta(t)) - \overline{\partial}_t v(t,\varphi)$. We know g is measurable and bounded. $\varphi \mapsto v(\varphi)$ is decreasing, so if $0 \le y$ is in the range of v, either the preimage $v^{-1}(y)$ is a singleton or an interval of nonzero width. There can be only a countable set of y of the latter type. Let Δ be the (countable) set of endpoints of such intervals. For x, $y \in [0,1] \setminus \Delta$, we know that $v(x) = v(y)$ implies $\overline{\partial}_t v(x) = \overline{\partial}_t v(y)$, and so $g(x) = g(y)$.

Given any $\varepsilon > 0$, let $A_\varepsilon = [0,\bar\varphi(t)) \cap \{x \in [0,1] \mid g(x) > \varepsilon\} \setminus \Delta$. Then A_ε is measurable, and we claim the measure of A_ε is zero for any $\varepsilon > 0$. Suppose not, so $|A_\varepsilon| = 2\delta > 0$ for some $\varepsilon > 0$. By Lusin's theorem, there is a compact $K \subset A_\varepsilon$ such that $|K| \ge \delta$ and $v|_K$ is continuous. Then $v(K)$ is compact and is contained in $(0,\infty)$ since v is positive at each point of $[0,\bar\varphi(t))$.

Apply Lemma 3.8 with $\eta(\varphi) = \eta_n(\varphi) = \max\{0, 1 - n\,\mathrm{dist}(\varphi, v(K))\}$ for $n = 1,2,\ldots$. Then η_n has compact support in $(0,\infty)$ for n sufficiently large and converges boundedly pointwise to the characteristic function $\chi_{v(K)}$. It follows that

$$0 = \int_0^1 \chi_{v(K)}(v(\varphi))g(\varphi)\,d\varphi.$$

Now if $v(x) \in v(K)$, then $v(x) = v(y)$ for some $y \in K$, and either $g(x) = g(y) > \varepsilon$ or $x \in \Delta$. It follows that

$$\int_0^1 \chi_{v(K)}(v(\varphi))g(\varphi)\,d\varphi \ge \varepsilon|K| > 0,$$

yielding a contradiction. Hence $|A_\varepsilon| = 0$ for any $\varepsilon > 0$. A similar argument applies for $\{x \mid g(x) < -\varepsilon\}$, and we then deduce that $g(\varphi) = 0$ for almost every $\varphi \in [0,\bar\varphi(t))$. This proves the Lemma. □

Note that for $t \in \Omega$ and $\varphi \in (\bar{\varphi}(t), 1]$ we have that $v(t,\varphi) = 0$, and $\partial_t v(t,\varphi) = 0$.

Since $(t,\varphi) \mapsto v(t,\varphi)$ is right continuous in φ and locally Lipschitz in t uniformly in φ, the set $Q = \{(t,\varphi) \mid v(t,\varphi) > 0\}$ is open in $(0,\infty) \times [0,1]$. Define

$$g(t,\varphi) = \Lambda(v(t,\varphi), \theta(t)) - \overline{\partial}_t v(t,\varphi);$$

then g is measurable on $(0,\infty) \times [0,1]$ and by Lemma 3.10 we have

$$\int_0^\infty \int_0^1 \chi_Q |g| \, d\varphi \, dt = 0.$$

By Fubini's theorem, we have $\chi_Q g = 0$ a.e. Hence there exists a set S of full measure in $[0,1]$ such that if $\varphi \in S$, then $(\chi_Q g)(t,\varphi) = 0$ for almost every t, and $t \mapsto v(t,\varphi)$ is differentiable almost everywhere.

Lemma 3.11. *If $\varphi \in S$ and $v(t,\varphi) > 0$, then $v(s,\varphi) > 0$ for all $s \in [0,t]$ and*

$$v(t,\varphi) = v(0,\varphi) + \int_0^t \Lambda(v(s,\varphi), \theta(s)) \, ds. \tag{3.8}$$

Proof. For any $t_1 \in (0,t)$, if $v(s,\varphi) > 0$ for all $s \in [t_1, t]$, then since $s \mapsto v(s,\varphi)$ is differentiable and $g(s,\varphi) = 0$ a.e. in $[t_1,t]$, we have

$$v(t,\varphi) = v(t_1,\varphi) + \int_{t_1}^t \Lambda(v(s,\varphi), \theta(s)) \, ds.$$

We claim that the set $\{t_1 \in [0,t) \mid v(s,\varphi) > 0 \text{ for all } s \in [t_1,t]\}$ has the infimum $t_* = 0$. Note that the set is nonempty by the continuity of $s \mapsto v(s,\varphi)$. Suppose the infimum t_* is positive. Then $v(t_*,\varphi) = 0 < v(s,\varphi)$ for $s \in (t_*,t]$. We know that $\theta(s)$ is bounded for $s \in [0,t]$, so for some sufficiently small $h > 0$ it follows that $\Lambda(v(s,\varphi),\theta(s)) < -1/2$ for $t_* < s < t_* + h$. Then we have

$$0 < v(t_* + h, \varphi) = 0 + \int_{t_*}^{t_*+h} \Lambda(v(s,\varphi), \theta(s)) \, ds < -h/2,$$

a contradiction. Hence our claim holds: $v(s,F) > 0$ for all $s \in [0,t]$, and the formula asserted in the lemma follows. ◻

Now we can finish the proof of Proposition 3.6. Suppose $t > 0$, $\varphi \in [0,1]$ are arbitrary and $v(t,\varphi) > 0$. Since $v(t,\cdot)$ is right continuous and decreasing, there exists a sequence of numbers $\varphi_n \in S$ such that $\varphi_n > \varphi$, $\varphi_n \to \varphi$ as $n \to \infty$ and $v(t,\varphi_n) > 0$. Using Lemma 3.11 it follows that $v(s,\varphi) > 0$ for all $s \in [0,t]$ and

$$\begin{aligned} &v(t,\varphi) - v(0,\varphi) - \int_0^t \Lambda(v(s,\varphi),\theta(s)) \, ds \\ &\quad = \lim_{n\to\infty} \left(v(t,\varphi_n) - v(0,\varphi_n) - \int_0^t \Lambda(v(s,\varphi_n),\theta(s)) \, ds \right) = 0. \end{aligned}$$

This completes the proof of Proposition 3.6. ◻

The results asserted in Theorem 1.3 now follow directly from Theorems 1.1 and 1.2, with the help of Propositions 3.5 and 3.6, Corollary 3.4, and (3.5).

4. A different conserved quantity. In the theory of Ostwald ripening, one also encounters an alternative to the condition that the total particle volume is conserved in time. If mass in the diffusion field is taken into account, one finds that a quantity of the form

$$Q = a\theta(t) + \int_0^1 v(t,\varphi)\, d\varphi \tag{4.1}$$

is conserved instead, where $a > 0$ is a constant. $\theta(t)$ need no longer be positive.

In terms of the theory developed in this paper, the constraint (4.1) is simpler to deal with than the constraint of constant volume. One has the bound

$$\theta(t) \le Q/a,$$

and when comparing two solutions of (2.2), one can use the arguments of Lemma 2.7 and replace the use of Lemma 2.9 by the simpler estimate

$$|\theta_1(t) - \theta_2(t)| \le a^{-1}\|v_1(t,\cdot) - v_2(t,\cdot)\| + a^{-1}|Q_1 - Q_2|. \tag{4.2}$$

From the standard Gronwall's inequality, one easily deduces the a priori estimate asserted in the following result. The existence and uniqueness proofs are the same as in section 2.

THEOREM 4.1. *Let $v_0 \in rcd([0,1])$, $Q \in \mathbb{R}$. Then there exists a unique function $v \in C([0,\infty), rcd([0,1]))$ such that, with $\theta(t)$ determined by* (4.1), *we have*

$$v(t,\varphi) = v_0(\varphi) + \int_0^t (v(s,\varphi)^{1/3}\theta(s) - 1)\, ds$$

whenever $v(t,\varphi) > 0$.

Given $T > 0$, $C_0 > 0$, there exists a positive constant C such that, given two solutions as above which also satisfy $\max(Q_1,Q_2) \le C_0$, *then*

$$\sup_{0\le t\le T} \|v_1(t,\cdot) - v_2(t,\cdot)\| \le C\left(\|v_1(0,\cdot) - v_2(0,\cdot)\| + |Q_1 - Q_2|\right).$$

Using the correspondence $v(t,\cdot) \mapsto \nu_t = \hat{\nu}(v(t,\cdot))$ and its inverse as in section 3, from Propositions 3.5 and 3.6 one may deduce directly the following corollary of Theorem 4.1.

THEOREM 4.2. *Given $\nu_0 \in \mathcal{P}_0$, $Q \in \mathbb{R}$, there exists a unique map $t \mapsto \nu_t$ that is locally Lipschitz from $[0,\infty)$ into $\mathcal{P}_0$ such that, with $\theta(t)$ determined by the relation*

$$Q = a\theta(t) + \int_0^\infty v\, d\nu_t(v),$$

we have

$$\int_0^\infty \int_0^\infty \partial_t\zeta(t,v) + \Lambda(v,\theta(t))\partial_v\zeta(t,v)\ d\nu_t(v)\, dt = 0$$

for all smooth $\zeta : (0,\infty)\times(0,\infty) \to \mathbb{R}$ with compact support.

Given any $T > 0$, $C_0 > 0$, there exists $C > 0$ such that, if two such weak solutions $\nu^{(1)}$, $\nu^{(2)}$ are given, which satisfy $\max(Q_1,Q_2) \le C_0$, *then*

$$\sup_{0\le t\le T} d_\infty(\nu_t^{(1)}, \nu_t^{(2)}) \le C\left(d_\infty(\nu_0^{(1)}, \nu_0^{(2)}) + |Q_1 - Q_2|\right).$$

GLOBAL SMALL AMPLITUDE SOLUTIONS OF NONLINEAR HYPERBOLIC SYSTEMS WITH A CRITICAL EXPONENT UNDER THE NULL CONDITION*

AKIRA HOSHIGA† AND HIDEO KUBO‡

Dedicated to Professor Rentaro Agemi on the occasion of his 60th birthday.

Abstract. This paper deals with the Cauchy problems of nonlinear hyperbolic systems in two space dimensions with small data. We assume that the propagation speeds differ from each other and that nonlinearities are cubic. Then it will be shown that if the nonlinearities satisfy the *null condition*, there exists a global smooth solution. To prove this kind of claim, one usually makes use of the generalized differential operators Ω_{ij}, S, and L_i, which will be introduced in section 1. But it is difficult to adopt the operators $L_i = x_i\partial_t + t\partial_{x_i}$ to our problem, because they do not commute with the d'Alembertian whose propagation speed is not equal to one. We succeed in taking L_i away from the proof of our theorem. One can apply our method to a scalar equation; hence L_i are needless in this kind of argument.

Key words. null condition, different speeds, a unique global smooth solution

1. Introduction and statement of main result.

We consider the initial value problem for

$$\square_i u^i \equiv \partial_t^2 u^i - c_i^2 \Delta u^i = F^i(\partial u, \partial^2 u) \quad \text{in } \mathbf{R}^n \times (0,\infty), \tag{1.1}$$

$$u^i(x,0) = \varepsilon f^i(x), \quad \partial_t u^i(x,0) = \varepsilon g^i(x) \quad \text{in } \mathbf{R}^n, \tag{1.2}$$

where $i = 1,\dots,m$, $n = 2,3,c_i$ are positive constants and $\varepsilon > 0$ is a small parameter. Besides, $F^i \in C^\infty(\mathbf{R}^{(n+1)m} \times \mathbf{R}^{(n+1)^2 m})$ and f^i, $g^i \in C_0^\infty(\mathbf{R}^n)$. We also denoted $u = (u^1,\dots,u^m)$, $\partial = (\partial_t, \partial_1, \dots, \partial_n)$ with $\partial_t = \partial/\partial t$, $\partial_j = \partial/\partial x_j$ and $\partial^2 u$ stands for the second derivatives of u. As for F^i, we assume

$$F^i(\partial u, \partial^2 u) = \sum_{l=1}^{m} \sum_{\gamma,\delta=0}^{n} H_{il}^{\gamma\delta}(\partial u)\partial_\gamma\partial_\delta u^l + K_i(\partial u), \tag{1.3}$$

where $H_{il}^{\gamma\delta}$ and $K_i \in C^\infty(\mathbf{R}^{(n+1)m})$ satisfy

$$H_{il}^{\gamma\delta}(\partial u) = O(|\partial u|^{p-1}), \quad K_i(\partial u) = O(|\partial u|^p) \quad \text{near } \partial u = 0. \tag{1.4}$$

Here p is an integer with $p > 1$. In order to derive an energy estimate we further assume

$$H_{il}^{\gamma\delta}(\partial u) = H_{li}^{\gamma\delta}(\partial u) = H_{il}^{\delta\gamma}(\partial u). \tag{1.5}$$

Although our interest lies in the case where the system (1.1) has different propagation speeds, we start with a review of known results for the case where $m = 1$ or the system (1.1) has same propagation speeds. Indeed, such cases have been studied extensively. Set $p_c = (n+1)/(n-1)$. If $p > p_c$, then the problem (1.1) and (1.2) has a smooth global solution for sufficiently small ε. Moreover, if $p = p_c$, then the problem (1.1) and (1.2) admits an "almost" global solution for small initial data. (See F. John and S. Klainerman [12], S. Klainerman [16], and M. Kovalyov [19], for instance). On the other hand, if $1 < p \le p_c$, then the problem (1.1) and (1.2) does not admit global solutions in general. (See R. Agemi [1], S. Alinhac [3], L. Hörmander [7], A. Hoshiga [9], and F. John [10].) Therefore, we shall call the number p_c the critical exponent in the following.

In the critical case $p = p_c$, the following interesting result is known. If the nonlinearity has a special form, a global solution of (1.1) and (1.2) exists, instead of an almost global solution. (See D. Christodoulou [4], P. Godin [6], A. Hoshiga [8], F. John [11], S. Katayama [13], and S. Klainerman [17], for instance.) We shall call the restriction on the nonlinearlities *null condition*, according to S. Klainerman [15]. We will restrict ourselves to the case where $n = 2$ and $p = p_c = 3$. Then, when $c_1 = \cdots = c_m = 1$, the null condition is stated as follows: For any $i, j, k, l = 1, \ldots, m$,

$$(1.6) \qquad \sum_{\alpha,\beta,\gamma=0}^{2} A_{ijkl}^{\alpha\beta\gamma} X_\alpha X_\beta X_\gamma = 0 \quad \text{and} \quad \sum_{\alpha,\beta,\gamma,\delta=0}^{2} D_{ijkl}^{\alpha\beta\gamma\delta} X_\alpha X_\beta X_\gamma X_\delta = 0$$

hold on the hypersurface $(X_0)^2 - c_i^2\{(X_1)^2 + (X_2)^2\} = 0$, where we have set

$$(1.7) \ A_{ijkl}^{\alpha\beta\gamma} \equiv \left. \frac{\partial^3 K_i(\partial u)}{\partial(\partial_\alpha u^j)\partial(\partial_\beta u^k)\partial(\partial_\gamma u^l)} \right|_{\partial u=0} \quad \text{and} \quad D_{ijkl}^{\alpha\beta\gamma\delta} \equiv \left. \frac{\partial^2 H_{il}^{\gamma\delta}(\partial u)}{\partial(\partial_\alpha u^j)\partial(\partial_\beta u^k)} \right|_{\partial u=0}.$$

A role of the null condition is closely connected to the following vector fields which generate a Lie algebra with respect to the usual commutator of linear operators:

$$(1.8) \qquad \partial_t, \partial_1, \partial_2, \quad S = t\partial_t + r\partial_r, \quad \Omega = x_1\partial_2 - x_2\partial_1,$$

and

$$L_i = x_i\partial_t + t\partial_i \quad (i = 1, 2),$$

where $r = |x|$. In fact, we may write

$$(1.9) \qquad \partial_i = -\omega_i\partial_t + \frac{1}{t}L_i + \frac{\omega_i}{t+r}S - \sum_{j=1}^{2} \frac{r\omega_i\omega_j}{t(t+r)}L_j \quad (i = 1, 2),$$

where $\omega_i = x_i/|x|$. (See [11].) In the leading terms of F^i, replacing ∂_i with (1.9) and using the null condition (1.6), we get

$$(1.10) \ |\Gamma^a F^i(\partial u, \partial^2 u)| \le \frac{C}{t} \sum_{|b+c+d| \le |a|+1} |\Gamma^b u||\Gamma^c \partial u||\Gamma^d \partial u| + \text{ (higher order terms)},$$

which gives us an additional decaying factor t^{-1}. This is a crucial point to treat the critical nonlinearity.

We now turn our attention to the case where $m \ge 2$ and the propagation speeds are different from each other when $n = 2$ and $p = 3$. M. Kovalyov proved the existence of the global solution of (1.1) and (1.2) in [20] under the assumption that for each $i(=1,\ldots,m)$, $A^{\alpha\beta\gamma}_{ijjj}=0$ for any $\alpha,\beta,\gamma=0,1,2$, $j=1,\ldots,m$ and $H^{\gamma\delta}_{il}(\partial u)\equiv 0$ for any $\gamma,\delta=0,1,2$, $l=1,\ldots,m$. In [2], R. Agemi and K. Yokoyama had the same result under the weaker assumption that for each $i(=1,\ldots,m)$, $A^{\alpha\beta\gamma}_{iiii}=0$ for any $\alpha,\beta,\gamma=0,1,2$ and $D^{\alpha\beta\gamma\delta}_{iiii}=0$ for any $\alpha,\beta,\gamma,\delta=0,1,2$. Here we have used the notation in (1.7). These results imply that when the propagation speeds are distinct, the global solution of (1.1) and (1.2) exists even if the nonlinearities do not satisfy (1.6). In this paper, we would like to show more generally that when the propagation speeds are distinct, (1.1) and (1.2) has a global solution under the following condition: For each $i=1,\ldots,m$,

$$\sum_{\alpha,\beta,\gamma=0}^{2} A^{\alpha\beta\gamma}_{iiii}X_\alpha X_\beta X_\gamma=0 \quad\text{and}\quad \sum_{\alpha,\beta,\gamma,\delta=0}^{2} D^{\alpha\beta\gamma\delta}_{iiii}X_\alpha X_\beta X_\gamma X_\delta=0 \tag{1.11}$$

hold on the hypersurface $(X_0)^2-c_i^2\{(X_1)^2+(X_2)^2\}=0$. Having the condition (1.11) in mind, we shall rewrite F^i in the following form:

$$F^i(\partial u,\partial^2 u)=N^i(\partial u^i,\partial^2 u^i)+R^i(\partial u,\partial^2 u)+G^i(\partial u,\partial^2 u), \tag{1.12}$$

where

$$\begin{aligned} N^i(\partial u^i,\partial^2 u^i)&=\sum_{\alpha,\beta,\gamma,\delta=0}^{2} D^{\alpha\beta\gamma\delta}_{iiii}\partial_\alpha u^i\partial_\beta u^i\partial_\gamma\partial_\delta u^i+\sum_{\alpha,\beta,\gamma=0}^{2} A^{\alpha\beta\gamma}_{iiii}\partial_\alpha u^i\partial_\beta u^i\partial_\gamma u^i,\\ R^i(\partial u,\partial^2 u)&=\sum_{j,k,l=1}^{m}\sum_{\alpha,\beta,\gamma,\delta=0}^{2} E^{\alpha\beta\gamma\delta}_{ijkl}\partial_\alpha u^j\partial_\beta u^k\partial_\gamma\partial_\delta u^l\\ &\quad+\sum_{j,k,l=1}^{m}\sum_{\alpha,\beta,\gamma=0}^{2} B^{\alpha\beta\gamma}_{ijkl}\partial_\alpha u^j\partial_\beta u^k\partial_\gamma u^l, \end{aligned}$$

and

$$G^i(\partial u,\partial^2 u)=\sum_{l=1}^{m}\sum_{\gamma,\delta=0}^{2} H_{il}(\partial u)\partial_\gamma\partial_\delta u^l+M_i(\partial u).$$

Here $E^{\alpha\beta\gamma\delta}_{ijkl}$ and $B^{\alpha\beta\gamma}_{ijkl}$ are defined by

$$\begin{aligned} E^{\alpha\beta\gamma\delta}_{ijkl}&=\begin{cases} D^{\alpha\beta\gamma\delta}_{ijkl} & (j,k,l)\neq(i,i,i),\\ 0 & (j,k,l)=(i,i,i),\end{cases}\\ B^{\alpha\beta\gamma}_{ijkl}&=\begin{cases} A^{\alpha\beta\gamma}_{ijkl} & (j,k,l)\neq(i,i,i),\\ 0 & (j,k,l)=(i,i,i).\end{cases} \end{aligned} \tag{1.13}$$

Also, we assume H_{il} and $M_i\in C^\infty(\mathbf{R}^{3m})$ satisfy

$$H_{il}(\partial u)=O(|\partial u|^3),\quad M_i(\partial u)=O(|\partial u|^4)\quad\text{near } \partial u=0.$$

By (1.11), N^i has the usual null-form for a scalar wave equation. Its concrete form will be proposed in section 3. We shall call N^i the null-form, while R^i is the resonance-form.

Now we state our main theorem.

THEOREM 1.1. *Let $n = 2$ and $c_i \neq c_j$ if $i \neq j$. Suppose that* (1.12), (1.5), *and* (1.11) *hold. Then there exists a positive constant ε_0 such that the initial value problem* (1.1) *and* (1.2) *has a unique C^∞-solution in $\mathbf{R}^2 \times [0,\infty)$ for $0 < \varepsilon \leq \varepsilon_0$.*

Remark 1. We would like to mention here the key idea of the proof of Theorem 1.1. Compared with the case where the system (1.1) has common propagation speeds, a treatment of the null-form is much more complicated when the speeds are different. The difficulty comes from the simple fact that L_j does not commute with $\Box_i$ if $c_i \neq 1$. Therefore, it seems difficult to adopt the operator L_j (or some modification of them) for the system (1.1) with different propagation speeds. Our main idea in this paper is to use the operator S effectively. More precisely, in order to obtain a variant of (1.10) without using L_j, we shall use the following relation instead of (1.9):

$$\partial_t = -c_i\partial_r + \frac{c_i t - r}{t}\partial_r + \frac{1}{t}S \tag{1.14}$$

and

$$\nabla = \frac{x}{r}\partial_r - \frac{x^\perp}{r^2}\Omega, \tag{1.15}$$

where $\nabla = (\partial_1, \partial_2)$ and $x^\perp = (x_2, -x_1)$. Since we need an additional decaying factor only in the region near the characteristic lay, we rewrite (1.14) as

$$\partial_t = -c_i\partial_r - \frac{\delta(r,t)}{\sqrt{t}}\partial_r + \frac{1}{t}S \quad \text{for } |c_i t - r| \leq \sqrt{t}, \tag{1.16}$$

where $-1 \leq \delta(r,t) \leq 1$. This is a key point in our argument. (For the details, see section 3 below). Moreover, this approach also works when either $m = 1$ or $c_1 = \cdots = c_m$ holds.

Remark 2. The other attempts to argue within the framework of $(\partial_\alpha, \Omega, S)$ were also done by S. Klainerman and T. Sideris [18] and by T. Sideris [23]. They studied the nonlinear elastic waves with the critical exponent. They used the operator S in order to extract a decaying factor from the elastic wave operator. However, their method requires that the nonlinearity has a divergence structure. Unfortunately, we can not apply their method to our case due to the lack of such a structure. Hence, following [19], [20], and [2], we make use of L^∞-weighted estimates derived by estimating the fundamental solution of the wave operator $\partial_t^2 - \Delta$, pointwisely. (See also section 4 below.)

2. Notations. In this section we collect some notations which will be used in the following discussion. Without loss of generality, we may assume

$$c_1 > c_2 > \cdots > c_m. \tag{2.1}$$

We denote the vector fields introduced in (1.8) by Γ_i as follows:

$$\Gamma = (\Gamma_0, \Gamma_1, \ldots, \Gamma_4) = (\partial, \Omega, S),$$

where

$$\partial = (\partial_0, \partial_1, \partial_2), \quad \partial_0 = \partial_t, \quad \Omega = x_1\partial_2 - x_2\partial_1, \quad \text{and} \quad S = t\partial_t + r\partial_r.$$

We can easily verify the following commutator relations:

$$[\Gamma_\sigma, \Box_i] = -2\delta_{4\sigma}\Box_i \quad \text{for} \quad \sigma = 0, \dots, 4, i = 1, \dots, m \tag{2.2}$$

and

$$\begin{aligned} &[\partial_\alpha, \partial_\beta] = 0 \quad (\alpha, \beta = 0, 1, 2), \quad [\Omega, \partial_0] = 0, \quad [\Omega, \partial_1] = -\partial_2, \quad [\Omega, \partial_2] = \partial_1, \\ &[S, \partial_\alpha] = -\partial_\alpha \quad (\alpha = 0, 1, 2), \quad [S, \Omega] = -\Omega. \end{aligned} \tag{2.3}$$

Here $[,]$ denotes the usual commutator of linear operators and $\delta_{\alpha\beta}$ is Kronecker's delta.

Next we define several norms for a vector valued function $u(x,t)$:

$$\begin{aligned} |u(t)|_k &= \sum_{|a|\le k} \sum_{i=1}^m \|\Gamma^a u^i(\cdot, t)\|_{L^\infty}, \\ [u(t)]_k &= \sum_{|a|\le k} \sum_{i=1}^m \|w_i(|\cdot|, t)\Gamma^a u^i(\cdot, t)\|_{L^\infty}, \\ \|u(t)\|_k &= \sum_{|a|\le k} \sum_{i=1}^m \|\Gamma^a u^i(\cdot, t)\|_{L^2}, \end{aligned}$$

where k is a nonnegative integer, $a = (a_0, \dots, a_4)$ is a multi-index, $\Gamma^a = \Gamma_0^{a_0} \cdots \Gamma_4^{a_4}$, and $|a| = a_0 + \cdots + a_4$. In addition, w_i is the following weight function associated with the ith component of u:

$$w_i(r,t) = (1+r)^{\frac{1}{2}-\gamma}(1+t+r)^\gamma(1+|c_it-r|)^{\frac{1}{2}} \quad \text{for } r \ge 0, t \ge 0,$$

where $1/4 < \gamma < 1/2$. Moreover, we also use

$$|u|_{k,T} = \sup_{0<t<T} |u(t)|_k, \quad [u]_{k,T} = \sup_{0<t<T} [u(t)]_k, \quad \|u\|_{k,T} = \sup_{0<t<T} \|u(t)\|_k.$$

Next we split the region $(0,\infty) \times (0,\infty)$ for each $i (i = 1, \dots, m)$ as follows:

$$\tilde{\Lambda}_i = \left\{(r,t) \in (0,\infty) \times (0,\infty) : \frac{1}{3}\left(2 + \frac{c_i}{c_{i-1}}\right) r \le c_i t \le \frac{1}{3}\left(2 + \frac{c_i}{c_{i+1}}\right) r \ \text{ and } \ r \ge 1\right\}$$

and $\tilde{\Lambda}_i^c = ((0,\infty) \times (0,\infty)) \setminus \tilde{\Lambda}_i$, where we have set $c_0 = 4c_1$ and $c_{m+1} = c_m/4$. Because of (2.1), this definition is meaningful. In particular, we have

$$\tilde{\Lambda}_i \cap \tilde{\Lambda}_l = \emptyset \quad \text{if } i \ne l. \tag{2.4}$$

Using the fact that $1+r$ is equivalent to $1+t+r$ for $(r,t) \in \tilde{\Lambda}_i$, while, so is $1+|c_it-r|$ for $(r,t) \in \tilde{\Lambda}_i^c$, we easily see that

$$w_i(r,t) \ge C(1+t+r)^{\frac{1}{2}} \quad \text{for } (r,t) \in (0,\infty) \times (0,\infty) \tag{2.5}$$

and that if $\gamma > 1/4$,

$$w_i(r,t) \ge C(1+t+r)^{\frac{3}{4}} \quad \text{for } (r,t) \in \tilde{\Lambda}_i^c. \tag{2.6}$$

We conclude this section by showing an important property of the weight function based on the following other decomposition of $(0,\infty)\times(0,\infty)$ for each $i(i=1,\dots,m)$:

$$\Lambda_i=\{(r,t)\in(0,\infty)\times(0,\infty):|c_it-r|\le\sqrt{t}\}$$

and $\Lambda_i^c=((0,\infty)\times(0,\infty))\setminus\Lambda_i$.

Proposition 2.1. *Let $1/4<\gamma<1/2$ and $i=1,2,\dots,m$. Then we have*

$$w_i(r,t)\ge C(1+t)^{\frac{3}{4}}\quad \textit{for } (r,t)\in\Lambda_i^c, \tag{2.7}$$

$$w_i(r,t)\le C(1+t)^{\frac{3}{4}}\quad \textit{for } (r,t)\in\Lambda_i. \tag{2.8}$$

Proof. First we shall show (2.7). If $(r,t)\in\tilde{\Lambda}_i^c\cap\Lambda_i^c$, we have

$$w_i(r,t)\ge C(1+t+r)^{\gamma+\frac{1}{2}}\ge C(1+t+r)^{\frac{3}{4}}$$

for $\gamma>1/4$. If $(r,t)\in\tilde{\Lambda}_i\cap\Lambda_i^c$, we have

$$w_i(r,t)\ge C(1+t+r)^{\frac{1}{2}}(1+\sqrt{t})^{\frac{1}{2}}\ge C(1+t)^{\frac{3}{4}}.$$

We thus obtain (2.7).

Next we shall show (2.8). Note that

$$\frac{c_it}{2}\le r\le 2c_it\quad\text{for } (r,t)\in\Lambda_i\quad\text{with } t\ge\frac{4}{c_i^2}. \tag{2.9}$$

Therefore, we get

$$w_i(r,t)\le C(1+t)^{\frac{1}{2}}(1+\sqrt{t})^{\frac{1}{2}}\le C(1+t)^{\frac{3}{4}}$$

for such (r,t). On the other hand, if $(r,t)\in\Lambda_i$ and $0\le t\le 4/c_i^2$, r is also bounded by some uniform constant, hence (2.8) follows. This completes the proof. □

3. An estimate for the null-form. By (1.11), one can write N^i defined in (1.12) as linear combinations of the following:

$$\begin{aligned}
N_1^i&=((\partial_0u^i)^2-c_i^2|\nabla u^i|^2)\partial_\alpha\partial_\beta u^i,\\
N_2^i&=\partial_\alpha u^i\partial_\beta((\partial_0u^i)^2-c_i^2|\nabla u^i|^2),\\
N_3^i&=\partial_\alpha u^i\partial_\beta u^i\Box_i u^i,\\
N_4^i&=\partial_\alpha u^i(\partial_\beta u^i\partial_\gamma\partial_\delta u^i-\partial_\gamma u^i\partial_\beta\partial_\delta u^i),\\
N_5^i&=\partial_\alpha u^i((\partial_0u^i)^2-c_i^2|\nabla u^i|^2)
\end{aligned}$$

for $\alpha,\beta,\gamma,\delta=0,1,2$. As we have already discussed in introduction, we shall extract an additional decaying factor from the null-form, by making use of their special form together with the identity (1.16). This is a crucial point in our argument.

Proposition 3.1. *It holds that for $i=1,\dots,m$*

$$|\Gamma^aN^i(\partial u^i,\partial^2u^i)|\le\frac{C}{\sqrt{1+t}}\Phi_a^i+\frac{C}{\sqrt{1+t}}\Theta_a^i\quad \textit{in } \Lambda_i, \tag{3.1}$$

where we have set

$$\Phi_a^i=\sum_{|b+c+d|\le|a|+1}|\partial\Gamma^bu^i||\partial\Gamma^cu^i||\partial\Gamma^du^i|,$$

$$\Theta_a^i=\sum_{\substack{|b+c+d|\le|a|+2\\|b|,|c|,|d|\le|a|+1}}|\Gamma^bu^i||\partial\Gamma^cu^i||\partial\Gamma^du^i|.$$

Proof. It is evident that (3.1) holds for $0 \le t \le \max\{1, 4/c_i^2\}$. Therefore, we shall assume $t \ge \max\{1, 4/c_i^2\}$ in the following. For simplicity, we omit the upper index i of u^i during the proof.

First, we consider the case $N^i = N_1^i$. If we set

$$Q_1(u,v) = \partial_0 u \partial_0 v - c_i^2 \nabla u \cdot \nabla v,$$

then we may write

$$\Gamma^a N_1^i = \sum_{a'+d'=a} \binom{a}{a'} \Gamma^{a'}(Q_1(u,u))\Gamma^{d'}(\partial_\alpha \partial_\beta u). \tag{3.2}$$

By the commutator relations (2.3), we obtain

$$\Gamma Q_1(u,v) = Q_1(\Gamma u, v) + Q_1(u, \Gamma v) - 2\delta_{4\sigma} Q_1(u,v) \quad \text{for } \sigma = 0, \dots, 4.$$

Therefore, we have

$$\Gamma^{a'} Q_1(u,u) = \sum_{b+c \le a'} C_{b,c}^{a'} Q_1(\Gamma^b u, \Gamma^c u). \tag{3.3}$$

By (3.2), (3.3), and $t \ge \max\{1, 4/c_i^2\}$, it suffices to show

$$|Q_1(u,v)| \le \frac{C}{\sqrt{t}} |\partial u||\partial v| + \frac{C}{t}(|\Gamma u||\partial v| + |\partial u||\Gamma v|). \tag{3.4}$$

Setting

$$\tilde{Q}_1(u,v) = \partial_0 u \partial_0 v - c_i^2 \partial_r u \partial_r v$$

and using the formula

$$\nabla = \frac{x}{r}\partial_r - \frac{x^\perp}{r^2}\Omega, \qquad x^\perp = (x_2, -x_1), \tag{3.5}$$

we get

$$Q_1(u,v) = \tilde{Q}_1(u,v) + \frac{c_i^2}{r^2}\Omega u \, \Omega v;$$

hence

$$|Q_1(u,v)| \le |\tilde{Q}_1(u,v)| + \frac{C}{r}|\partial u||\Omega v|, \tag{3.6}$$

where we used the fact that $|\Omega u|/r \le C|\partial u|$.

If we introduce operators $S_i^\pm = \partial_t \pm c_i \partial_r$, then a simple computation yields

$$2\tilde{Q}_1(u,v) = S_i^+ u S_i^- v + S_i^- u S_i^+ v.$$

Moreover, by the formula

$$S_i^+ = \partial_t + c_i \partial_r = -\frac{\delta(r,t)}{\sqrt{t}}\partial_r + \frac{1}{t}S \quad \text{with } -1 \le \delta(r,t) \le 1 \quad \text{in } \Lambda_i, \tag{3.7}$$

we obtain

$$|\tilde{Q}_1(u,v)| \le \frac{C}{\sqrt{t}}|\partial u||\partial v| + \frac{C}{t}(|Su||\partial v| + |\partial u||Sv|) \quad \text{in} \quad \Lambda_i. \tag{3.8}$$

Thus (3.6), (3.8), and (2.9) imply (3.4).

Second, from the above argument, we immediately obtain (3.1) for the case $N^i = N_2^i$ and $N^i = N_5^i$, because of the fact that

$$N_2^i = 2Q_1(\partial_\beta u, u)\partial_\alpha u \quad \text{and} \quad N_5^i = Q_1(u,u)\partial_\alpha u.$$

Third, we consider the case $N^i = N_3^i$. It follows from (2.2) that

$$\Gamma^a \Box_i u = \sum_{b\le a} C_b \Box_i \Gamma^b u \quad \text{and} \quad \Box_i \Gamma^a u = \sum_{b \le a} C_b' \Gamma^b \Box_i u, \tag{3.9}$$

where C_b and C_b' are some constants. By (3.7), (2.9), $t \ge \max\{1, 4/c_i^2\}$, and the identity

$$\Box_i u = S_i^+ S_i^- u - \frac{c_i^2}{r^2}\Omega^2 u,$$

we obtain

$$|\Box_i u| \le \frac{C}{\sqrt{t}}|\partial^2 u| + \frac{C}{t}|\Gamma \partial u|. \tag{3.10}$$

Hence, by the first identity in (3.9) and (3.10) we have (3.1) for the case $N^i = N_3^i$.

Finally, we consider the case $N^i = N_4^i$. Using a notation

$$Q_{\alpha\beta}(u,v) = \partial_\alpha u \partial_\beta v - \partial_\beta u \partial_\alpha v, \quad \alpha, \beta = 0,1,2,$$

we can write

$$N_4^i = Q_{\beta\gamma}(u, \partial_\delta u)\partial_\alpha u.$$

Note that $Q_{\beta\alpha} = -Q_{\alpha\beta}$. Moreover, it follows from (2.3) that

$$\begin{aligned}
\partial_\eta Q_{\alpha\beta}(u,v) &= Q_{\alpha\beta}(\partial_\eta u, v) + Q_{\alpha\beta}(u, \partial_\eta v), \quad \eta = 0,1,2,\\
S Q_{\alpha\beta}(u,v) &= Q_{\alpha\beta}(Su, v) + Q_{\alpha\beta}(u, Sv) - 2Q_{\alpha\beta}(u,v),\\
\Omega Q_{01}(u,v) &= Q_{01}(\Omega u, v) + Q_{01}(u, \Omega v) - Q_{02}(u,v),\\
\Omega Q_{02}(u,v) &= Q_{02}(\Omega u, v) + Q_{02}(u, \Omega v) + Q_{01}(u,v),\\
\Omega Q_{12}(u,v) &= Q_{12}(\Omega u, v) + Q_{12}(u, \Omega v).
\end{aligned}$$

Therefore we have

$$\Gamma^a Q_{\alpha\beta}(u,v) = \sum_{\gamma,\delta=0}^{2} \sum_{b+c\le a} C_{bc}^{\gamma\delta} Q_{\gamma\delta}(\Gamma^b u, \Gamma^c v). \tag{3.11}$$

On the other hand, by (2.9), (3.5), and the formula

$$\partial_t = -\frac{r}{t}\partial_r + \frac{1}{t}S,$$

we have

$$|Q_{\alpha\beta}(u,v)| \le \frac{C}{t}(|\partial u||\Gamma v| + |\Gamma u||\partial v|). \tag{3.12}$$

Combining (3.11) and (3.12), we have (3.1) for the case $N^i = N_4^i$. This completes the proof of Proposition 3.1. ∎

4. Weighted L^∞-estimates. The aim of this section is to establish weighted L^∞-estimates of a solution $u = (u^1, \dots, u^m)$ of (1.1) and (1.2) such that $u^i \in C^\infty(\mathbf{R}^2 \times [0, T))$ and satisfies

$$[\partial u]_{k,t} \le \delta_1 \quad \text{for } 0 \le t < T, \tag{4.1}$$

where k is a nonnegative integer and $\delta_1 (0 < \delta_1 < 1)$ is a real number independent of $T > 0$. A main result of this section is the following proposition.

PROPOSITION 4.1. *Suppose that* $u = (u^1, \dots, u^m)$ *is the solution of* (1.1) *and* (1.2) *and that* (1.12) *holds. Then we have for* $(|x|, t) \in \Lambda_i^c$ *with* $t < T$ *and* $|a| \le N$

$$|w_i(|x|, t)\Gamma^a \partial u^i(x, t)| \le C_N \left(\varepsilon + [\partial u]^2_{[\frac{N+2}{2}],t} \|\partial u\|_{N+4,t}\right), \tag{4.2}$$

provided (4.1) *with* $k = [(N + 2)/2]$ *holds. Moreover, if* (1.11), (1.12), *and* (4.1) *with* $k = [(N + 4)/2]$ *hold, we have for* $(x, t) \in \mathbf{R}^2 \times [0, T)$ *and* $|a| \le N$

$$|w_i(|x|, t)\Gamma^a \partial u^i(x, t)| \le C_N \left(\varepsilon + (\varepsilon + [\partial u]^2_{[\frac{N+4}{2}],t})\|\partial u\|_{N+6,t}\right). \tag{4.3}$$

Here we take δ_1 *to be sufficiently small positive number and* C_N *denotes a positive constant independent of* T *and* δ_1.

By (3.9) and (1.1), $\Gamma^a \partial^b u^i(x, t)$ satisfies

$$\Box_i \Gamma^a \partial^b u^i(x, t) = \tilde{F}^i(\partial u, \partial^2 u) \quad \text{in } \mathbf{R}^2 \times (0, T), \tag{4.4}$$

where we have set $\tilde{F}^i(\partial u, \partial^2 u) = \sum_{d \le a} C_{a,b} \partial^b \Gamma^d F^i(\partial u, \partial^2 u)$ and a, b, and d are multi-indices. Moreover, the initial values of $\Gamma^a \partial^b u^i(x, t)$ are determined by ε, f^j, and g^j $(j = 1, \dots, m)$ by using (1.1). For instance, when $a = 0$ and $\partial^b = \partial_t$, we have

$$(\partial_t u^i)(x, 0) = \varepsilon g^i(x), \quad (\partial_t^2 u^i)(x, 0) = \varepsilon c_i^2 \Delta f^i(x) + F^i(\partial u, \partial^2 u)(x, 0).$$

We can solve the second equation with respect to $(\partial_t^2 u^i)(x, 0)$ if δ_1 is sufficiently small.

Based on this, we decompose $\Gamma^a \partial^b u(x, t)$ as follows:

$$\Gamma^a \partial^b u(x, t) = u_0(x, t) + u_1(x, t) \quad \text{with} \quad u_0 = (u_0^1, \dots, u_0^m), u_1 = (u_1^1, \dots, u_1^m), \tag{4.5}$$

where u_1^i is a solution to $\Box_i u_1^i = \tilde{F}^i(\partial u, \partial^2 u)$ with the zero initial data, while u_0^i is a solution to $\Box_i u_0^i = 0$ and $u_0^i(x, 0) = (\Gamma^a \partial^b u)(x, 0)$, $\partial_t u_0^i(x, 0) = (\partial_t \Gamma^a \partial^b u)(x, 0)$. Since $f^j(x)$, $g^j(x) \in C_0^\infty(\mathbf{R}^2)$, the initial values of u_0^i also belong to $C_0^\infty(\mathbf{R}^2)$. Therefore, when $|a| + |b| \le N$, we have

$$|u_0^i(x, t)| \le M_N \varepsilon (1 + t + r)^{-\frac{1}{2}} (1 + |c_i t - r|)^{-\frac{1}{2}} \quad \text{for} \quad (x, t) \in \mathbf{R}^2 \times [0, \infty), \tag{4.6}$$

where M_N depends on L^1-norms of f^j, g^j and their finite times derivatives. (See Lemma 1 in R. T. Glassey [5] and also Lemma 4 in [19] and [21].)

Therefore, we need to estimate only u_1^i. We may assume $c_i = 1$ without loss of generality. In the following, we shall consider the solution to an inhomogeneous wave equation $(\partial_t^2 - \Delta)u = \partial^b F$ with the zero initial data. When $F \in C^\infty(\mathbf{R}^2 \times [0, T))$, we have

$$u(x, t) = \frac{1}{2\pi} \int_{|x-y| \le t} \frac{\partial^b F(y, s)}{\sqrt{t^2 - |x - y|^2}} dy. \tag{4.7}$$

Switching to polar coordinates as $x = (r\cos\theta, r\sin\theta)$ and $y = (\lambda\cos(\theta+\psi), \lambda\sin(\theta+\psi))$ as in section 2 in [19], we have

$$\begin{aligned}u(x,t) = {} & \frac{1}{2\pi}\iint_{D'} \lambda d\lambda ds \int_{-\varphi}^{\varphi} \partial^b F(\lambda\xi, s) K_1 d\psi \\ & +\frac{1}{2\pi} H(t-r) \iint_{D''} \lambda d\lambda ds \int_{-\pi}^{\pi} \partial^b F(\lambda\xi, s) K_1 d\psi,\end{aligned} \tag{4.8}$$

where H is the Heaviside function and we have set

$$\begin{aligned}\xi &= (\cos(\theta+\psi), \sin(\theta+\psi)),\\ K_1 &= K_1(\lambda, s, \psi; r, t) = \{(t-s)^2 - r^2 - \lambda^2 + 2r\lambda\cos\psi\}^{-\frac{1}{2}},\\ \varphi &= \varphi(\lambda, s; r, t) = \arccos\left[\frac{r^2+\lambda^2-(t-s)^2}{2r\lambda}\right] \quad \text{for } (\lambda, s) \in D'.\end{aligned}$$

Moreover, the domains D' and D'' are defined as follows:

$$\begin{aligned}D' &= \{(\lambda, s) \in (0,\infty)\times(0,\infty) : 0 < s < t, \lambda_- < \lambda < \lambda_+\},\\ D'' &= \{(\lambda, s) \in (0,\infty)\times(0,\infty) : 0 < s < t-r, 0 < \lambda < \lambda_-\},\end{aligned}$$

where

$$\lambda_- = |t-s-r|, \quad \lambda_+ = t-s+r. \tag{4.9}$$

The key point to get such estimates as in Proposition 4.1 is to integrate by parts with respect to λ and s. Following [19] and [2], we shall sketch this process briefly. To begin with, we split the regions of integration D' and D'' into subregions as follows:

$$\begin{aligned}& D' = \mathit{blue} \cup \mathit{white}, \quad D'' = \mathit{black} \cup \mathit{red},\\ & \mathit{blue} = \{(s,\lambda) \in D' : \lambda_- < \lambda \le \lambda_- + \delta \text{ or } \lambda_+ - \delta \le \lambda < \lambda_+\},\\ & \mathit{black} = \{(s,\lambda) \in D' : \lambda_- - \tilde{\delta} \le \lambda < \lambda_- \text{ or } 0 < \lambda \le \tilde{\delta}\},\end{aligned} \tag{4.10}$$

where we have set $\delta = \min\{r, 1/2\}$ and $\tilde{\delta} = \min\{(t-r)/2, 1/2\}$. Notice that *white* is empty if $0 < r \le 1/2$ and that *red* is empty if $0 < t-r \le 1$.

Let $\partial^b = \partial_\alpha$ $(\alpha = 0, 1, 2)$ in (4.8). Then, according to the above decompositions, we have

$$\begin{aligned}2\pi u(x,t) = {} & \iint_{blue} \lambda d\lambda ds \int_{-\varphi}^{\varphi} (\partial_\alpha F)(\lambda\xi, s) K_1 d\psi \\ & + H\left(r - \frac{1}{2}\right) \sum_{j=0}^{1} \iint_{white} \lambda d\lambda ds \int_0^1 (\partial_\alpha F)(\lambda\Xi_j, s) K_2 d\tau \\ & + H(t-r) \iint_{black} \lambda d\lambda ds \int_{-\pi}^{\pi} (\partial_\alpha F)(\lambda\xi, s) K_1 d\psi \\ & + H(t-r-1) \iint_{red} \lambda d\lambda ds \int_{-\pi}^{\pi} (\partial_\alpha F)(\lambda\xi, s) K_1 d\psi,\end{aligned} \tag{4.11}$$

where we have changed the variable as $\psi = \Psi$ in the second term and set

$$\begin{aligned}\Psi &= \Psi(\lambda, s, \tau; r, t) = \arccos[1 - (1-\cos\varphi)\tau],\\ \Xi_j &= \Xi_j(\lambda, s, \tau; r, t) = (\cos(\theta + (-1)^j\Psi), \sin(\theta + (-1)^j\Psi)),\\ K_2 &= K_2(\lambda, s, \tau; r, t) = \{2r\lambda\tau(1-\tau)(2-(1-\cos\varphi)\tau)\}^{-\frac{1}{2}}.\end{aligned}$$

Carrying out the integration by parts in the second and fourth terms, we get the following proposition.

Proposition 4.2. *Let $u(x,t)$ be the solution to $(\partial_t^2-\Delta)u=\partial_\alpha F$ with the zero initial data. If $F\in C^\infty(\mathbf{R}^2\times[0,T))$, then $|u(t,x)|$ is dominated by the following:*

$$
\begin{aligned}
I_1(F)(x,t)&=\iint_{blue}\lambda d\lambda ds\int_{-\varphi}^{\varphi}|(\partial_\alpha F)(\lambda\xi,s)|K_1d\psi,\\
I_2(F)(x,t)&=\int_{\partial(white)}\lambda d\sigma\int_0^1|F(\lambda\Xi_j,s)|K_2d\tau,\\
I_3(F)(x,t)&=\iint_{white}d\lambda ds\int_0^1\{|F(\lambda\Xi_j,s)|+|(\Omega F)(\lambda\Xi_j,s)|\}K_2d\tau,\\
I_4(F)(x,t)&=\iint_{white}\lambda d\lambda ds\int_0^1|F(\lambda\Xi_j,s)|\{|\partial_sK_2|+|\partial_\lambda K_2|\}d\tau,\\
I_5(F)(x,t)&=\iint_{white}\lambda d\lambda ds\int_0^1|(\Omega F)(\lambda\Xi_j,s)|K_2\{|\partial_s\Psi|+|\partial_\lambda\Psi|\}d\tau,\\
J_1(F)(x,t)&=\iint_{black}\lambda d\lambda ds\int_{-\pi}^{\pi}|(\partial_\alpha F)(\lambda\xi,s)|K_1d\psi,\\
J_2(F)(x,t)&=\int_{\partial(red)}\lambda d\sigma\int_{-\pi}^{\pi}|F(\lambda\xi,s)|K_1d\psi,\\
J_3(F)(x,t)&=\iint_{red}d\lambda ds\int_{-\pi}^{\pi}\{|F(\lambda\xi,s)|+|(\Omega F)(\lambda\xi,s)|\}K_1d\psi,\\
J_4(F)(x,t)&=\iint_{red}\lambda d\lambda ds\int_{-\pi}^{\pi}|F(\lambda\xi,s)|\{|\partial_sK_1|+|\partial_\lambda K_1|\}d\psi.
\end{aligned}
$$

Proof. It is easy to see that the first and second terms in (4.11) are dominated by $I_1(F)$ and $J_1(F)$, respectively. Since

$$
(\nabla F)(\lambda\xi,s)=\xi\partial_\lambda(F(\lambda\xi,s))-\frac{\xi^\perp}{\lambda}(\Omega F)(\lambda\xi,s),\quad \xi^\perp=\sin(\theta+\psi),-\cos(\theta+\psi)),
$$

we find that the fourth term in (4.11) is dominated by $J_j(F)$ $(j=2,3,4)$ by integration by parts.

To deal with the second term in (4.11), we use the following identities:

$$
\begin{aligned}
&(\partial_sF)(\lambda\Xi_j,s)=\partial_s(F(\lambda\Xi_j,s))-(-1)^j\partial_s\Psi(\Omega F)(\lambda\Xi_j,s),\\
&\quad(\nabla F)(\lambda\Xi_j,s)=\Xi_j(\partial_\lambda(F(\lambda\Xi_j,s))-(-1)^j\partial_\lambda\Psi(\Omega F)(\lambda\Xi_j,s))-\frac{\Xi_j^\perp}{\lambda}(\Omega F)(\lambda\Xi_j,s),
\end{aligned}
$$

where $\Xi_j^\perp=(\sin(\theta+(-1)^j\Psi),-\cos(\theta+(-1)^j\Psi))$. Again by integration by parts, we find that the second term is dominated by $I_j(F)$ $(j=2,\dots,5)$. The proof is complete. □

We shall use the following estimates of K_1 and K_2. For the proof, see Proposition 2.1 in [19] and also Proposition 5.3 in [2].

Lemma 4.1. *It holds that for $(\lambda,s)\in D'$*

$$
(4.12)\quad \int_{-\varphi}^{\varphi}K_1d\psi=2\int_0^1K_2d\tau\le\frac{C}{(r\lambda)^{\frac12}}\log\left[2+\frac{r\lambda}{(\lambda-\lambda_-)(\lambda_++\lambda)}H(t-s-r)\right],
$$

$$\int_0^1 \{|\partial_s K_2| + |\partial_\lambda K_2|\} d\tau \le \frac{C}{(r\lambda)^{\frac{1}{2}}(\lambda + s + r - t)}, \tag{4.13}$$

$$\int_0^1 K_2\{|\partial_s \Psi| + |\partial_\lambda \Psi|\} d\tau \le \frac{C(r+\lambda)}{\{r\lambda(\lambda^2 - \lambda_-^2)(\lambda_+^2 - \lambda^2)\}^{\frac{1}{2}}} \tag{4.14}$$

and that for $(\lambda, s) \in D''$

$$\int_{-\pi}^{\pi} K_1 d\psi \le C\{(\lambda + \lambda_-)(\lambda_+ - \lambda)\}^{-\frac{1}{2}} \log\left[2 + \frac{r\lambda}{(\lambda_- - \lambda)(\lambda_+ + \lambda)}\right], \tag{4.15}$$

$$\int_{-\pi}^{\pi} \{|\partial_s K_1| + |\partial_\lambda K_1|\} d\psi \le \frac{C}{(\lambda_- - \lambda)\{(\lambda + \lambda_-)(\lambda_+ - \lambda)\}^{\frac{1}{2}}}. \tag{4.16}$$

Now we are in a position to derive a new weighted $L^\infty - L^\infty$ estimate for the solution ∂u of (1.1) and (1.2). We introduce the following weight functions:

$$\frac{1}{\overline{w}_i(r,t)} = \frac{1}{(1+r)^{1-2\gamma}(1+t+r)^{1+2\gamma}} + \sum_{j \ne i} \frac{1}{(1+t+r)(1+|c_j t - r|)} + \frac{1}{(1+t+r)^{1+\mu}(1+|c_i t - r|)^{1-\mu}} \tag{4.17}$$

and

$$\frac{1}{\tilde{w}(r,t)} = \frac{1}{(1+r)^{1-2\gamma}(1+t+r)^{1+2\gamma}} + \sum_{j=1}^{m} \frac{1}{(1+t+r)(1+|c_j t - r|)}, \tag{4.18}$$

where $1/4 < \gamma < 1/2$ and $0 < \mu < 1$.

Proposition 4.3. *Let* u_1^i *be the solution to* $(\partial_t^2 - \Delta)u_1^i = \partial_\alpha F^i(\partial u, \partial^2 u)$ *with the zero initial data. Here* u *is a solution of* (1.1) *and* (1.2).

(i) *Let* $(r,t) \in \tilde{\Lambda}_i^c$ *with* $r = |x|$ *and* $t < T$. *Assume that* $w(r,t)$ *satisfies*

$$0 < \frac{1}{w(r,t)} \le \frac{C}{\tilde{w}(r,t)}. \tag{4.19}$$

Then we have

$$w_i(r,t)|u_1^i(x,t)| \le CM_{0,1}, \tag{4.20}$$

where we have set for a nonnegative integer k

$$M_{0,k} = \sum_{|a| \le k} \sup_{0<s<t} \sup_{y \in \mathbf{R}^2} \||y|^{\frac{1}{2}} w(|y|, s)\Gamma^a F^i(y,s)|.$$

(ii) *Let* $(x,t) \in \mathbf{R}^2 \times [0,T)$. *Assume* $\eta_j(r,t)$ $(j = 1,2)$ *satisfy*

$$0 < \frac{1}{\eta_1(r,t)} \le \frac{C}{\overline{w}_i(r,t)}, \quad 0 < \frac{1}{\eta_2(r,t)} \le \frac{C}{\tilde{w}(r,t)}. \tag{4.21}$$

Then we have

$$w_i(r,t)|u_1^i(x,t)| \le C(M_{1,1} + M_{2,1} + M_{3,1}), \tag{4.22}$$

where we have set for a positive integer k

$$\begin{aligned}
M_{1,k} &= \sum_{|a|\le k} \sup_{0<s<t} \sup_{y\in\mathbf{R}^2} \| y|^{\frac12}\eta_1(|y|,s)\Gamma^a(R^i(y,s)+G^i(y,s))|,\\
M_{2,k} &= \sum_{|a|\le k} \sup_{0<s<t} \sup_{y\in\mathbf{R}^2} \| y|^{\frac12}\eta_2(|y|,s)\Gamma^a N^i(y,s)|,\\
M_{3,k} &= \sum_{|a|\le k} \sup_{(|y|,s)\in\Lambda_i, s<t} \| y|^{\frac12}\eta_2(|y|,s)(1+s)^{\frac12}\Gamma^a N^i(y,s)|.
\end{aligned}$$

Here, we have divided the function F^i into three parts: G^i, R^i, and N^i as in (1.12).

Proof. Employing Proposition 4.2, we find that $|u_1^i(t,x)|$ is dominated by $I_j(F^i)$ $(j=1,\dots,5)$ and $J_j(F^i)$ $(j=1,\dots,4)$. □

In the proof of Proposition 5.4 in [2], the following estimates are shown. Strictly speaking, they proved only the former part of Lemma 4.2 below. However, following their proof, we find that the assumption (4.19) is sufficient to derive (4.24) with $j=3,4$ and (4.25).

Lemma 4.2. *Set*

$$\begin{aligned}
I_1' &= \iint_{blue} \frac{\lambda^{\frac12}}{w(\lambda,s)} d\lambda ds \int_{-\varphi}^{\varphi} K_1 d\psi,\\
I_2' &= \int_{\partial(white)} \frac{\lambda^{\frac12}}{w(\lambda,s)} d\sigma \int_0^1 K_2 d\tau,\\
I_3' &= \iint_{white} \frac{1}{\lambda^{\frac12}w(\lambda,s)} d\lambda ds \int_0^1 K_2 d\tau,\\
I_4' &= \iint_{white} \frac{\lambda^{\frac12}}{w(\lambda,s)} d\lambda ds \int_0^1 \{|\partial_s K_2|+|\partial_\lambda K_2|\} d\tau,\\
I_5' &= \iint_{white} \frac{\lambda^{\frac12}}{w(\lambda,s)} d\lambda ds \int_0^1 K_2\{|\partial_s \Psi|+|\partial_\lambda \Psi|\} d\tau,\\
I_1'' &= \iint_{black} \frac{\lambda^{\frac12}}{w(\lambda,s)} d\lambda ds \int_{-\pi}^{\pi} K_1 d\psi,\\
I_2'' &= \int_{\partial(red)} \frac{\lambda^{\frac12}}{w(\lambda,s)} d\sigma \int_{-\pi}^{\pi} K_1 d\psi,\\
I_3'' &= \iint_{red} \frac{1}{\lambda^{\frac12}w(\lambda,s)} d\lambda ds \int_{-\pi}^{\pi} K_1 d\psi,\\
I_4'' &= \iint_{red} \frac{\lambda^{\frac12}}{w(\lambda,s)} d\lambda ds \int_{-\pi}^{\pi} \{|\partial_s K_1|+|\partial_\lambda K_1|\} d\psi.
\end{aligned}$$

Assume $w(r,t)$ satisfies

$$0<\frac{1}{w(r,t)} \le \frac{C}{\overline{w}_i(r,t)}. \tag{4.23}$$

Then we have for $(x,t)\in\mathbf{R}^2\times(0,\infty)$

$$w_i(r,t)I_j' \le C, \tag{4.24}$$

$$w_i(r,t)I_j'' \le C. \tag{4.25}$$

Moreover, (4.24) *with* $j = 3, 4$ *and* (4.25) *are still true, if* $w(r,t)$ *satisfies* (4.19).

First, we shall show the statement (i) in Proposition 4.3. By the definition of $M_{0,1}$, (4.19), and Lemma 4.2, we get for $(x,t) \in \mathbf{R}^2 \times (0,\infty)$

$$w_i(r,t)I_j(F^i)(x,t) \le CM_{0,1} \quad \text{for } j = 3, 4,$$
$$w_i(r,t)J_j(F^i)(x,t) \le CM_{0,1} \quad \text{for } j = 1, \dots, 4.$$

Therefore, our task becomes to prove

$$w_i(r,t)I_j(F^i)(x,t) \le CM_{0,1} \quad \text{for } j = 1, 2, 5, \tag{4.26}$$

provided (4.19) and $(r,t) \in \tilde{\Lambda}_i^c$. Since the treatment of $I_2(F^i)$ is similar to that of $I_1(F^i)$, we shall deal with only $I_1(F^i)$ and $I_5(F^i)$. If we set

$$\frac{1}{\xi(\lambda,s)} = \frac{1}{(1+s+\lambda)(1+|s-\lambda|)}, \tag{4.27}$$

then we have from (4.17) and (4.18)

$$\frac{1}{\tilde{w}(\lambda,s)} \le \frac{1}{\overline{w}_i(\lambda,s)} + \frac{1}{\xi(\lambda,s)}. \tag{4.28}$$

Hence, using (4.24) with $j = 1, 5$, (4.12), and (4.14), we have

$$I_j(F^i)(x,t) \le CM_{0,1}(\{w_i(r,t)\}^{-1} + \tilde{I}_j(\xi)) \quad \text{for } j = 1, 5,$$

where we have set

$$\tilde{I}_1(w) = \frac{1}{r^{\frac{1}{2}}} \iint_{blue} \frac{1}{w(\lambda,s)} \log\left[2 + \frac{r\lambda}{(\lambda-\lambda_-)(\lambda_+ + \lambda)} H(t-s-r)\right] d\lambda ds, \tag{4.29}$$

$$\tilde{I}_5(w) = \frac{1}{r^{\frac{1}{2}}} \iint_{white} \frac{1}{w(\lambda,s)} \frac{r+\lambda}{\{(\lambda^2-\lambda_-^2)(\lambda_+^2-\lambda^2)\}^{\frac{1}{2}}} d\lambda ds. \tag{4.30}$$

In the following, we shall prove for $(r,t) \in \tilde{\Lambda}_i^c$

$$\tilde{I}_j(\xi) \le \frac{C}{(1+r)^{\frac{1}{2}}(1+t+r)^{\frac{1}{2}+\gamma}} \quad \text{for } j = 1, 5. \tag{4.31}$$

First we consider $\tilde{I}_1(\xi)$. It follows from (5.33) and (5.34) in [2] that for $0 \le s \le t$

$$\int_{\lambda_-}^{\lambda_-+\delta} \log\left[2 + \frac{r\lambda}{(\lambda-\lambda_-)(\lambda_+ + \lambda)} H(t-s-r)\right] d\lambda \le C\delta, \tag{4.32}$$

$$\int_{\lambda_+-\delta}^{\lambda_+} \log\left[2 + \frac{r\lambda}{(\lambda-\lambda_-)(\lambda_+ + \lambda)} H(t-s-r)\right] d\lambda \le C\delta^{\frac{1}{2}} \log[2+|t-r|]. \tag{4.33}$$

Therefore we have

$$\begin{aligned}\tilde{I}_1(\xi) &\le \frac{C\delta^{\frac{1}{2}}}{r^{\frac{1}{2}}} \log[2+|t-r|] \left\{\int_0^t \frac{1}{\xi(\lambda_-,s)} ds + \int_0^t \frac{1}{\xi(\lambda_+,s)} ds\right\} \\ &\le \frac{C\log[2+|t-r|]}{(1+r)^{\frac{1}{2}}(1+t+r)} \left\{\int_0^t \frac{1}{1+|2s-t+r|} ds + \int_0^t \frac{1}{1+|2s-t-r|} ds\right\}\end{aligned}$$

because $\delta r^{-1} \le C(1+r)^{-1}$ and $1+|t-r|$ is equivalent to $1+t+r$ for $(r,t) \in \tilde{\Lambda}_i^c$. Since $\gamma < 1/2$, we thus obtain (4.31) for $j=1$.

Next we consider $\tilde{I}_5(\xi)$. Notice that $\delta = 1/2$ if the domain *white* is not empty, hence r is equivalent to $1+r$. Moreover, since

$$\lambda \pm \lambda_- \ge \delta, \quad \lambda \pm \lambda_- \ge \delta \quad \text{for } (\lambda, s) \in \ \textit{white},$$

we have

$$\begin{aligned}\tilde{I}_5(\xi) \le \frac{C}{(1+r)^{\frac{1}{2}}} \iint_{D'} & \frac{1}{\xi(\lambda,s)} \\ & \times \frac{r+\lambda}{\{(\lambda-\lambda_-+1)(\lambda+\lambda_-+1)(\lambda_+-\lambda+1)(\lambda_++\lambda+1)\}^{\frac{1}{2}}} d\lambda ds.\end{aligned}$$

Note that

$$\begin{aligned}&\frac{r+\lambda}{\{(\lambda-\lambda_-+1)(\lambda+\lambda_-+1)(\lambda_+-\lambda+1)(\lambda_++\lambda+1)\}^{\frac{1}{2}}} \\ &\le \frac{2}{(\lambda-\lambda_-+1)^{\frac{1}{2}}} \left\{ \frac{1}{(\lambda+\lambda_-+1)^{\frac{1}{2}}} + \frac{1}{(\lambda_+-\lambda+1)^{\frac{1}{2}}} \right\},\end{aligned}$$

which follows from

$$\begin{aligned}&\lambda_+ + \lambda \ge \max\{r, \lambda\}, \\ &\lambda_+ - \lambda \ge \max\{r, \lambda\} \quad \text{for } \lambda \le \frac{\lambda_+ - \lambda_-}{2}, \\ &\lambda + \lambda_- \ge \max\{r, \lambda\} \quad \text{for } \lambda \ge \frac{\lambda_+ - \lambda_-}{2}.\end{aligned}$$

Therefore we have

$$\begin{aligned}(1+r)^{\frac{1}{2}} \tilde{I}_5(\xi) \le C \iint_{D'} & \frac{1}{\xi(\lambda,s)} \frac{1}{\{(\lambda-t+s+r+1)(\lambda+t-s-r+1)\}^{\frac{1}{2}}} d\lambda ds \\ +C \iint_{D'} & \frac{1}{\xi(\lambda,s)} \frac{1}{\{(\lambda-t+s+r+1)(t-s+r-\lambda+1)\}^{\frac{1}{2}}} d\lambda ds \\ +C \iint_{D'} & \frac{1}{\xi(\lambda,s)} \frac{1}{\{(\lambda+t-s-r+1)(t-s+r-\lambda+1)\}^{\frac{1}{2}}} d\lambda ds.\end{aligned} \tag{4.34}$$

We shall show in the following that the right-hand side of (4.34) is dominated by $C(1+t+r)^{-\gamma-1/2}$. Since

$$1+s+\lambda \ge 1+|t-r| \quad \text{for } (\lambda, s) \in D', \tag{4.35}$$

the second term is dominated by

$$\begin{aligned}&\frac{C}{1+|t-r|} \iint_{D'} \frac{1}{1+|s-\lambda|} \left\{ \frac{1}{\lambda+s-t+r+1} + \frac{1}{t+r-s-\lambda+1} \right\} d\lambda ds \\ &\le \frac{C}{2(1+t+r)} \int_{|t-r|}^{t+r} \left\{ \frac{1}{\alpha-t+r+1} + \frac{1}{t+r-\alpha+1} \right\} d\alpha \int_{-\alpha}^{t-r} \frac{1}{1+|\beta|} d\beta,\end{aligned}$$

where we have changed the variables as

$$\alpha = s+\lambda, \quad \beta = s-\lambda. \tag{4.36}$$

Since the double integral is dominated by $C\{\log(1+t+r)\}^2$, we get the desired estimate.

To treat the first and third terms, we divide the domain D' into two parts:

$$D_- = \left\{(\lambda,s) \in D' : |\lambda - s| \le \frac{1}{2}|t-r|\right\}, \quad D_-^c = white \setminus D_-. \tag{4.37}$$

Since D_- is empty if $0 < t \le r$, we have

$$\lambda + t - s - r \ge \frac{1}{2}|t-r| \quad \text{for } (\lambda,s) \in D_-. \tag{4.38}$$

On the other hand, we have

$$1 + |s-\lambda| \ge \frac{1}{2}(1+|t-r|) \quad \text{for } (\lambda,s) \in D_-^c. \tag{4.39}$$

Using these estimates together with (4.35) and changing the variables as (4.36), we find that the first term is majored by

$$\begin{aligned}
&\frac{C}{1+|t-r|}\left\{\iint_{D'} \frac{1}{(1+s+\lambda)^{\frac{1}{2}}(1+|s-\lambda|)(\lambda+s-t+r+1)^{\frac{1}{2}}}d\lambda ds\right. \\
&\quad \left. + \iint_{D'} \frac{1}{(1+s+\lambda)}\left\{\frac{1}{\lambda-t+s+r+1} + \frac{1}{\lambda+t-s-r+1}\right\}d\lambda ds\right\} \\
&\le \frac{C}{1+t+r}\left\{\int_{|t-r|}^{t+r}\left\{\frac{1}{1+\alpha} + \frac{1}{\alpha-t+r+1}\right\}d\alpha \int_{-\alpha}^{t-r}\frac{1}{1+|\beta|}d\beta\right. \\
&\quad + \int_{|t-r|}^{t+r}\frac{1}{(1+\alpha)}\frac{1}{\alpha-t+r+1}d\alpha\int_{-\alpha}^{t-r}d\beta \\
&\quad \left. + \int_{|t-r|}^{t+r}\frac{1}{(1+\alpha)}d\alpha\int_{-\alpha}^{t-r}\frac{1}{-\beta+t-r+1}d\beta\right\},
\end{aligned}$$

which yields the desired estimate. Since the third term is dealt with similarly, we omit the details. This completes the proof of (4.26).

Second, we shall show the statement (ii). By (4.21), we have for $|a| \le 1$

$$|\Gamma^a F^i(y,s)| \le \frac{M_{1,1}+M_{2,1}}{\lambda^{\frac{1}{2}}\tilde{w}(\lambda,s)}.$$

Therefore, by Lemma 4.2, we get for $(x,t) \in \mathbf{R}^2 \times (0,\infty)$

$$\begin{aligned}
w_i(r,t)I_j(F^i)(x,t) &\le C(M_{1,1}+M_{2,1}) \quad \text{for } j = 3,4, \\
w_i(r,t)J_j(F^i)(x,t) &\le C(M_{1,1}+M_{2,1}) \quad \text{for } j = 1,\dots,4.
\end{aligned}$$

Moreover, similarly to (4.26), we get for $(|x|,t) \in \tilde{\Lambda}_i^c$

$$w_i(r,t)I_j(F^i)(x,t) \le C(M_{1,1}+M_{2,1}) \quad \text{for } j = 1,2,5.$$

Thus it suffices to prove

$$w_i(r,t)I_j(F^i)(x,t) \le C(M_{1,1}+M_{2,1}+M_{3,1}) \quad \text{for } j = 1,2,5, \tag{4.40}$$

provided (4.21) and $(r,t)\in\tilde{\Lambda}_i$.

Having (3.1) in mind, we introduce a characteristic function of Λ_i denoted by $\chi(\lambda,s)$. Then we may write

$$\Gamma^a F^i=\Gamma^a(R^i+G^i)+(1-\chi)\Gamma^a N^i+\chi\Gamma^a N^i$$

and find from (4.28) and the definition of $M_{i,1}$ given in (4.22) that

$$|\Gamma^a F^i(y,s)|\le C(M_{1,1}+M_{2,1}+M_{3,1})\lambda^{-\frac{1}{2}}\left(\frac{1}{\bar{w}_i(\lambda,s)}+\frac{1-\chi(\lambda,s)}{\xi(\lambda,s)}+\frac{\chi(\lambda,s)}{\xi(\lambda,s)(1+s)^{\frac{1}{2}}}\right)$$

for $|a|\le 1$. Therefore, using (4.24), we have for $j=1,5$

$$I_j(F^i)(r,t)\le C(M_{1,1}+M_{2,1}+M_{3,1})(\{w_i(r,t)\}^{-1}+\tilde{I}_j(\tilde{\xi})), \tag{4.41}$$

where $\tilde{I}_j$ is defined in (4.29), (4.30) and we have set

$$\frac{1}{\tilde{\xi}(\lambda,s)}=\frac{1-\chi(\lambda,s)}{\xi(\lambda,s)}+\frac{\chi(\lambda,s)}{\xi(\lambda,s)(1+s)^{\frac{1}{2}}}.$$

In the following, we shall show for $(r,t)\in\tilde{\Lambda}_i$ and $j=1,5$

$$\tilde{I}_j(\tilde{\xi})\le\frac{C}{(1+r)^{\frac{1}{2}}(1+|t-r|)^{\frac{1}{2}}} \tag{4.42}$$

because $1+r$ is equivalent to $1+t+r$ for $(r,t)\in\tilde{\Lambda}_i$.

First we consider $\tilde{I}_1(\tilde{\xi})$. Using (4.32) and (4.33), we have

$$\tilde{I}_1(\tilde{\xi})\le\frac{C\log[2+|t-r|]}{(1+r)^{\frac{1}{2}}}\left\{\int_0^t\frac{1}{\tilde{\xi}(\lambda_-,s)}ds+\int_0^t\frac{1}{\tilde{\xi}(\lambda_+,s)}ds\right\},$$

because $\delta r^{-1}\le C(1+r)^{-1}$. Since

$$(1+|s-\lambda|)^{\frac{1}{4}}\ge(1+s)^{\frac{1}{8}}\quad\text{for }(\lambda,s)\in\operatorname{supp}\{1-\chi\}, \tag{4.43}$$

we have from (4.27)

$$\frac{1}{\tilde{\xi}(\lambda,s)}\le\frac{2}{(1+s+\lambda)^{\frac{3}{4}}(1+|s-\lambda|)^{\frac{3}{4}}(1+s)^{\frac{3}{8}}}.$$

Therefore, we get

$$\begin{aligned}(1+r)^{\frac{1}{2}}\tilde{I}_1(\tilde{\xi})\le{}&\frac{C\log[2+|t-r|]}{(1+|t-r|)^{\frac{3}{4}}}\\&\times\left\{\int_0^t\frac{1}{(1+|2s-t+r|)^{\frac{3}{4}}(1+s)^{\frac{3}{8}}}ds+\int_0^t\frac{1}{(1+|2s-t-r|)^{\frac{3}{4}}(1+s)^{\frac{3}{8}}}ds\right\},\end{aligned}$$

which yields (4.42) for $j=1$.

Next we consider $\tilde{I}_5(\tilde{\xi})$. From (4.34), we have

$$\begin{aligned}(1+r)^{\frac{1}{2}}\tilde{I}_5(\tilde{\xi})\le{}&C\iint_{D'}\frac{1}{\tilde{\xi}(\lambda,s)}\frac{1}{\{(\lambda-t+s+r+1)(\lambda+t-s-r+1)\}^{\frac{1}{2}}}d\lambda ds\\&+C\iint_{D'}\frac{1}{\tilde{\xi}(\lambda,s)}\frac{1}{\{(\lambda-t+s+r+1)(t-s+r-\lambda+1)\}^{\frac{1}{2}}}d\lambda ds\\&+C\iint_{D'}\frac{1}{\tilde{\xi}(\lambda,s)}\frac{1}{\{(\lambda+t-s-r+1)(t-s+r-\lambda+1)\}^{\frac{1}{2}}}d\lambda ds.\end{aligned} \tag{4.44}$$

We shall show that the right-hand side is dominated by $C(1+|t-r|)^{-1/2}$. Using (4.27) and (4.35), we have

$$\begin{aligned}\frac{1}{\tilde{\xi}(\lambda,s)} &\le \frac{2}{\xi(\lambda,s)}\\ &\le \frac{2}{(1+|t-r|)^{\frac12}(1+s+\lambda)^{\frac14}(1+|s-\lambda|)^{\frac54}}.\end{aligned}$$

Therefore, the second term is majored by $C(1+|t-r|)^{-1/2}$ times

$$\begin{aligned}&\iint_{D'} \frac{1}{(1+s+\lambda)^{\frac14}(1+|s-\lambda|)^{\frac54}}\left\{\frac{1}{\lambda+s-t+r+1}+\frac{1}{t+r-s-\lambda+1}\right\}d\lambda ds\\ &\le C\int_{|t-r|}^{t+r}\left\{\frac{1}{(1+\alpha)^{\frac54}}+\frac{1}{(\alpha-t+r+1)^{\frac54}}+\frac{1}{(t+r-\alpha+1)^{\frac54}}\right\}d\alpha\int_{-\alpha}^{t-r}\frac{1}{(1+|\beta|)^{\frac54}}d\beta,\end{aligned}$$

which yields the desired estimate.

Next we deal with the first term, by dividing the domain D' as in (4.37). Using (4.38) and (4.39), we find that the first term is majored by $C(1+|t-r|)^{-1/2}$ times

$$\begin{aligned}&\iint_{D'}\frac{1}{\xi(\lambda,s)}\frac{1}{(\lambda+s-t+r+1)^{\frac12}}d\lambda ds\\ &+\iint_{D'}\frac{(1+|s-\lambda|)^{\frac12}}{\xi(\lambda,s)}\frac{1}{\lambda+s-t+r+1}d\lambda ds\\ &+\iint_{D'}\frac{(1+|s-\lambda|)^{\frac12}}{\tilde{\xi}(\lambda,s)}\frac{1}{\lambda-s+t-r+1}d\lambda ds.\end{aligned}$$

Analogous to the above calculation, we see that the first and second terms are bounded by some constant. Since we have by (4.43)

$$\frac{(1+|s-\lambda|)^{\frac12}}{\tilde{\xi}(\lambda,s)} \le \frac{2}{(1+s)^{\frac98}(1+|s-\lambda|)^{\frac14}},$$

the third term is dominated by

$$\int_0^\infty \frac{ds}{(1+s)^{\frac98}}\int_{-\infty}^{\infty}\left\{\frac{1}{(1+|s-\lambda|)^{\frac54}}+\frac{1}{(\lambda-s+t-r+1)^{\frac54}}\right\}d\lambda \le C;$$

hence we obtain the desired estimate of the first term in the right-hand side of (4.44). Since the third term in the right-hand side of (4.44) is dealt with similarly, we omit the details. This completes the proof of the proposition.

In our analysis, we need an upper bound of not only ∂u^i but also u^i itself.

PROPOSITION 4.4. *Let u_1^i be the solution to $(\partial_t^2-\Delta)u_1^i = F^i(\partial u, \partial^2 u)$ with the zero initial data. Here u is a solution to* (1.1) *and* (1.2). *Let $0 \le \mu < 1/2$. Assume that $w(r,t)$ satisfies* (4.19). *Then we have for $(|x|,t) \in \tilde{\Lambda}_i$ with $t<T$*

$$(1+t+r)^{\mu}|u_1^i(x,t)| \le CM_{0,0}, \tag{4.45}$$

where $M_{0,0}$ is defined in (4.20).

Proof. It follows from (4.8) with $b = 0$, (4.12), (4.15), and (4.19) that

$$|u_1^i(x,t)| \le CM_{0,0}(P_1 + P_2), \tag{4.46}$$

where we have set

$$P_1 = \frac{1}{r^{\frac{1}{2}}} \iint_{D'} \frac{1}{\tilde{w}(\lambda, s)} \log \left[2 + \frac{r\lambda}{(\lambda - \lambda_-)(\lambda_+ + \lambda)} H(t - s - r) \right] d\lambda ds$$

and

$$P_2 = H(t - r) \iint_{D''} \frac{\lambda^{\frac{1}{2}}}{\tilde{w}(\lambda, s)\{(\lambda + \lambda_-)(\lambda_+ - \lambda)\}^{\frac{1}{2}}} \log \left[2 + \frac{r\lambda}{(\lambda_- - \lambda)(\lambda_+ + \lambda)} \right] d\lambda ds.$$

Since t is equivalent to r for $(r,t) \in \tilde{\Lambda}_i$, it suffices to show

$$P_j \le C(1 + r)^{-\mu} \quad \text{for } j = 1, 2. \tag{4.47}$$

First, we treat P_1. We split the domain D' into *blue* and *white* defined by (4.10). According to this decomposition, we shall write $P_1 = P_{1,blue} + P_{1,white}$. By (4.32) and (4.33), we have

$$\begin{aligned} P_{1,blue} &\le \frac{C\delta^{\frac{1}{2}}}{r^{\frac{1}{2}}} \log[2 + |t - r|] \left\{ \int_0^t \frac{1}{\tilde{w}(\lambda_-, s)} ds + \int_0^t \frac{1}{\tilde{w}(\lambda_+, s)} ds \right\} \\ &\le \frac{C \log[2 + |t - r|]}{(1 + r)^{\frac{1}{2}}} \int_0^t \frac{1}{1 + s} ds \\ &\le \frac{C}{(1 + r)^{\mu}} \end{aligned}$$

for $0 \le \mu < 1/2$ because $1 + r$ is equivalent to $1 + t + r$ for $(r,t) \in \tilde{\Lambda}_i$.

On the other hand, we have for $(\lambda, s) \in$ *white* with $0 \le s \le t - r$

$$\frac{r\lambda}{(\lambda - \lambda_-)(\lambda_+ + \lambda)} \le \frac{\lambda}{\lambda - \lambda_-} \le 1 + 2\lambda_- \le 1 + 2(t - r)$$

because $\delta = 1/2$, if *white* is not empty. Therefore we have

$$\begin{aligned} (1 + r)^{\frac{1}{2}} P_{1,white} &\le C \log[2 + |t - r|] \iint_{D'} \frac{1}{\tilde{w}(\lambda, s)} d\lambda ds \\ &\le C \log[2 + |t - r|] \int_0^t \frac{ds}{1 + s} \int_0^{t+r} \left\{ \frac{1}{1 + \lambda} + \sum_{j=1}^m \frac{1}{1 + |c_j s - \lambda|} \right\} d\lambda; \end{aligned}$$

hence $P_{1,blue} \le C(1 + r)^{-\mu}$ for $0 \le \mu < 1/2$. We thus get (4.47) for $j = 1$.

Second, we deal with P_2. Notice that $\tilde{w}(\lambda, s)$ is equivalent to $\tilde{w}(\lambda_-, s)$ for $\lambda_- - 1 \le \lambda \le \lambda_-$ and that $(\lambda_+ - \lambda)^{1/2} \le (1 + r)^{1/2}$ for $0 < \lambda \le \lambda_- - 1$ and $0 \le s \le t - r$. Moreover, we have for $0 < \lambda \le \lambda_- - 1$ and $0 \le s \le t - r$

$$\frac{r\lambda}{(\lambda_- - \lambda)(\lambda_+ + \lambda)} \le \frac{\lambda}{\lambda_- - \lambda} \le -1 + \lambda_- \le t - r.$$

Splitting the integral into two parts, we have

$$\begin{aligned}P_2 \le\ & CH(t-r-1)(1+r)^{-\frac{1}{2}}\log[2+|t-r|]\iint_{D''}\frac{1}{\tilde{w}(\lambda,s)}d\lambda ds\\ &+CH(t-r)\int_0^{t-r}\frac{1}{\tilde{w}(\lambda_-,s)}ds\int_{(\lambda_- -1)_+}^{\lambda_-}\frac{\lambda^{\frac{1}{2}}}{\{(\lambda+\lambda_-)(\lambda_+-\lambda)\}^{\frac{1}{2}}}\\ &\times\log\left[2+\frac{r\lambda}{(\lambda_- -\lambda)(\lambda_+ +\lambda)}\right]d\lambda.\end{aligned}$$

Notice that

$$\int_{(\lambda_- -1)_+}^{\lambda_-}\frac{\lambda^{\frac{1}{2}}}{\{(\lambda+\lambda_-)(\lambda_+-\lambda)\}^{\frac{1}{2}}}\log\left[2+\frac{r\lambda}{(\lambda_- -\lambda)(\lambda_+ +\lambda)}\right]d\lambda \le C\frac{\log[2+|t-r|]}{(1+r)^{\frac{1}{2}}}.$$

(For the proof, see (5.73) in [2].) Therefore we have

$$(4.48)\qquad (1+r)^{\frac{1}{2}}P_2 \le C\log[2+|t-r|]\left\{\iint_{D''}\frac{1}{\tilde{w}(\lambda,s)}d\lambda ds+\int_0^{t-r}\frac{ds}{1+s}\right\},$$

which implies (4.47) for $j=2$. This completes the proof. □

LEMMA 4.3. *Let F^i satisfy* (1.12) *and u be smooth function satisfying* (4.1) *with $k=[(N+1)/2]$. If we set*

$$(4.49)\qquad \frac{1}{w(\lambda,s)}=\sum_{j,k=1}^{m}\frac{1}{(w_jw_k)(\lambda,s)}\qquad \textit{for } \lambda>0, s>0,$$

then we have

$$(4.50)\qquad M_{0,N}\le C_N[\partial u]^2_{[\frac{N+1}{2}],t}\|\partial u\|_{N+3,t}.$$

Moreover, if we set

$$(4.51)\qquad \frac{1}{w(\lambda,s)}=\sum_{j,k,l=1}^{m}\frac{\lambda^{\frac{1}{2}}}{(w_jw_kw_l)(\lambda,s)}\ \textit{for } \lambda>0, s>0,$$

then we have

$$(4.52)\qquad M_{0,[\frac{N+1}{2}]}\le C_N[\partial u]^3_{[\frac{N+1}{2}]+1,t}.$$

Here $M_{0,N}$ is defined in (4.20).

Proof. First, we shall show (4.52). Since (4.1) with $k=[(N+1)/2]$ implies

$$(4.53)\ \sum_{j=1}^{m}\sum_{|a|\le[(N+1)/2]}|\Gamma^a\partial u^j(y,s)|\le[\partial u]_{[\frac{N+1}{2}],T}<1\quad \text{for } 0\le s\le t<T, y\in\mathbf{R}^2,$$

by (1.12) we have for $|a|\le[(N+1)/2]$

$$|\Gamma^aF^i(y,s)|\le C\sum_{j,k,l=1}^{m}\frac{1}{(w_jw_kw_l)(\lambda,s)}[\partial u(s)]^3_{[\frac{N+1}{2}]+1}$$

with $\lambda = |y|$. By (4.51), we therefore get (4.52).

Second, we shall prove (4.50). It follows that for $|a| \le N$

$$|\Gamma^a F^i(y,s)| \le C \sum_{j,k,l=1}^m \frac{1}{(w_j w_k)(\lambda,s)} [\partial u(s)]^2_{[\frac{N+1}{2}]} \sum_{|b|\le|a|+1} |\Gamma^b \partial u^l(y,s)|.$$

We now use an imbedding theorem concerning the invariant norm

$$|x|^{\frac{1}{2}}|f(x)| \le \sum_{|a|\le 2} \|\Gamma^a f\|_{L^2} \quad \text{for } x \in \mathbf{R}^2. \tag{4.54}$$

(For the proof, see, e.g., Lemma 6 in [19].) Applying this and using (4.49), we obtain (4.50). The proof is complete. □

COROLLARY 4.1. *Let $u = (u^1, \dots, u^m)$ be the solution of* (1.1) *and* (1.2) *and let F^i satisfy* (1.12). *Let $0 \le \mu < 1/2$. Then we have for $(|x|,t) \in \Lambda_i$ with $t < T$*

$$(1+t+r)^\mu |\Gamma^a u^i(x,t)| \le C_N \left(\varepsilon + [\partial u]^2_{[\frac{N+1}{2}],t} \|\partial u\|_{N+3,t} \right) \quad \textit{for } |a| \le N, \tag{4.55}$$

$$(1+t+r)^\mu |\Gamma^a u^i(x,t)| \le C_N \left(\varepsilon + [\partial u]^3_{[\frac{N+1}{2}],t} \right) \quad \textit{for } |a| \le [(N+1)/2], \tag{4.56}$$

provided (4.1) *with $k = [(N+1)/2]$ holds.*

Proof. Using the decomposition (4.5) with $b = 0$ and the estimates (4.6) and (4.45), we have

$$(1+t+r)^\mu |\Gamma^a u^i(x,t)| \le M_N \varepsilon + C_N M_{0,|a|}, \tag{4.57}$$

where $M_{0,|a|}$ is defined in (4.20), if $w(r,t)$ satisfies (4.19). Note that both (4.51) and (4.49) satisfy (4.19). Applying Lemma 4.3, we obtain (4.55) and (4.56). This completes the proof. □

End of the proof of Proposition 4.1. First we shall show (4.2). Using the decomposition (4.5) with $|b| = 1$ and the estimates (4.6) and (4.20), we have

$$w_i(r,t)|\Gamma^a \partial u^i(x,t)| \le M_N \varepsilon + C_N M_{0,|a|+1} \quad \text{for } (|x|,t) \in \tilde{\Lambda}_i^c \text{ with } t < T \tag{4.58}$$

if $w(r,t)$ satisfies (4.19). Using (4.50) with N replaced by $N+1$, we obtain (4.2).

Next we shall show (4.3). Similarly, it follows from (4.6) and (4.22) that for $|a| \le N$

$$w_i(r,t)|\Gamma^a \partial u^i(x,t)| \le M_N \varepsilon + C_N (M_{1,N+1} + M_{2,N+1} + M_{3,N+1}) \tag{4.59}$$

if $\eta_i(r,t)$ $(i = 1,2)$ satisfies (4.21).

First, we shall show

$$M_{1,N+1} \le C\left(\varepsilon + [\partial u]^2_{[\frac{N+4}{2}],t} \|\partial u\|_{N+6,t} \right). \tag{4.60}$$

If we set

$$\frac{1}{\eta_1(\lambda,s)} = \sum_{j,k,l=1}^m \frac{1}{(w_j w_k w_l)(\lambda,s)} + \sum_{(j,k)\ne(i,i)} \frac{1}{(w_j w_k)(\lambda,s)} + \frac{1-\tilde{\chi}(\lambda,s)}{\{w_i(\lambda,s)\}^2}, \tag{4.61}$$

then $\eta_1(r,t)$ satisfies the first condition in (4.21). Here $\tilde{\chi}$ is the characteristic function of $\tilde{\Lambda}_i$. In what follows, we always assume $|a| \leq N+1$. By (1.12) and (4.1) with $k = [(N+2)/2]$, we have

$$(4.62)\ |\Gamma^a G^i(y,s)| \leq C \sum_{j,k,l=1}^{m} \frac{1}{(w_j w_k w_l)(\lambda,s)} [\partial u(s)]^3_{\left[\frac{|a|+1}{2}\right]} \sum_{|b|\leq|a|+1} |\Gamma^b \partial u^l(y,s)|.$$

Using (4.54), we get

$$|\lambda^{\frac{1}{2}} \eta_1(\lambda,s) \Gamma^a G^i(y,s)| \leq C [\partial u(s)]^2_{\left[\frac{N+2}{2}\right]} \|\partial u(s)\|_{N+4}. \tag{4.63}$$

As for the resonance-form R^i, we find from (1.13) that there is at least one index among j, k, and l which does not coincide with i. Therefore, by (1.12) we have

$$\begin{aligned} |\Gamma^a R^i(y,s)| \leq{}& C \sum_{(j,k)\neq(i,i)} \sum_{l=1}^{m} \frac{1}{(w_j w_k)(\lambda,s)} [\partial u(s)]^2_{\left[\frac{|a|+1}{2}\right]} \sum_{|b|\leq|a|+1} |\Gamma^b \partial u^l(y,s)| \\ &+ C \sum_{\substack{(j,k)=(i,i)\\ l\neq i}} \frac{1-\tilde{\chi}(\lambda,s)}{\{w_i(\lambda,s)\}^2} [\partial u(s)]^2_{\left[\frac{|a|+1}{2}\right]} \sum_{|b|\leq|a|+1} |\Gamma^b \partial u^l(y,s)| \\ &+ C \sum_{\substack{(j,k)=(i,i)\\ l\neq i}} \frac{1}{(w_i w_l)(\lambda,s)} \frac{[\partial u(s)]^2_{\left[\frac{|a|+1}{2}\right]}}{w_i(\lambda,s)} \sum_{|b|\leq|a|+1} |(\tilde{\chi} w_l)(\lambda,s) \Gamma^b \partial u^l(y,s)|. \end{aligned} \tag{4.64}$$

By (4.61) and (4.54), we find that the first and second terms are dominated by

$$C\lambda^{-\frac{1}{2}} \{\eta_1(\lambda,s)\}^{-1} [\partial u(s)]^2_{\left[\frac{N+2}{2}\right]} \|\partial u(s)\|_{N+4}. \tag{4.65}$$

On the other hand, by (4.61), (4.1) with $k = [(N+2)/2]$, and $w_i(\lambda,s) \geq \lambda^{1/2}$, the third term is dominated by

$$C\lambda^{-\frac{1}{2}} \{\eta_1(\lambda,s)\}^{-1} \sum_{|b|\leq N+2} |(\tilde{\chi} w_l)(\lambda,s) \Gamma^b \partial u^l(y,s)|. \tag{4.66}$$

Moreover, since $\tilde{\Lambda}_i \subset \tilde{\Lambda}_l^c$ by (2.4), we get from (4.2),

$$|(\tilde{\chi} w_l)(\lambda,s) \Gamma^b \partial u^l(y,s)| \leq C_N \left(\varepsilon + [\partial u]^2_{\left[\frac{N+4}{2}\right],t} \|\partial u\|_{N+6,t} \right)$$

for $|b| \leq N+2$. We thus find that the third term is dominated by

$$C\lambda^{-\frac{1}{2}} \{\eta_1(\lambda,s)\}^{-1} \left(\varepsilon + [\partial u]^2_{\left[\frac{N+4}{2}\right],t} \|\partial u\|_{N+6,t} \right); \tag{4.67}$$

hence, together with (4.65), we get

$$|\lambda^{\frac{1}{2}} \eta_1(\lambda,s) \Gamma^a R^i(y,s)| \leq C \left(\varepsilon + [\partial u]^2_{\left[\frac{N+4}{2}\right],t} \|\partial u\|_{N+6,t} \right). \tag{4.68}$$

Combining (4.63) and (4.68), we finally get (4.60).

Second, we consider $M_{2,N+1}$. Taking $\eta_2(r,t) = w_i(r,t)^2$, we easily see that $\eta_2(r,t)$ satisfies the second condition of (4.21) and that

$$M_{2,N+1} \leq C[\partial u]^2_{[\frac{N+2}{2}],t} \|\partial u\|_{N+4,t}. \tag{4.69}$$

Third, we consider $M_{3,N+1}$ by taking $\eta_2(r,t) = w_i(r,t)^2$. By (3.1) we have

$$(1+s)^{\frac{1}{2}} |\Gamma^a N^i(y,s)| \leq C(\Phi^i_a + (1+s)^{-\frac{1}{2}} \Theta^i_a)$$

for $(|y|, s) \in \Lambda_i$. Therefore, we obtain

$$\begin{aligned} |\lambda^{\frac{1}{2}} \eta_2(\lambda,s)(1+s)^{\frac{1}{2}} \Gamma^a N^i(y,s)| &\leq C \sum_{|b+c+d| \leq |a|+1} |\lambda^{\frac{1}{2}} \eta_2(\lambda,s) |\partial \Gamma^b u^i \| \partial \Gamma^c u^i \| \partial \Gamma^d u^i \| \\ &+C \sum_{\substack{|b+c+d| \leq |a|+2 \\ |b|,|c|,|d| \leq |a|+1}} |\lambda^{\frac{1}{2}} \eta_2(\lambda,s)(1+s)^{-\frac{1}{2}} |\Gamma^b u^i \| \partial \Gamma^c u^i \| \partial \Gamma^d u^i \|. \end{aligned} \tag{4.70}$$

We easily see that the first term is dominated by $C[\partial u(s)]^2_{[(N+2)/2]} \|\partial u(s)\|_{N+4}$.

To treat the second term, we divide the argument into two cases. First we assume $|b| \geq [(N+2)/2]$. Since $1+\lambda$ is equivalent to $1+s$ for $(\lambda, s) \in \Lambda_i$ by (2.9), we have

$$\begin{aligned} &|\lambda^{\frac{1}{2}} \eta_2(\lambda,s)(1+s)^{-\frac{1}{2}} |\Gamma^b u^i \| \partial \Gamma^c u^i \| \partial \Gamma^d u^i \| \\ &\leq C[\partial u(s)]^2_{[\frac{N+2}{2}]} |\Gamma^b u^i(y,s)| \\ &\leq C\left(M_N \varepsilon + [\partial u]^2_{[\frac{N+4}{2}],s} \|\partial u\|_{N+6,s} \right), \end{aligned}$$

where we have used (4.1) with $k = [(N+4)/2]$ and (4.55) with $\mu = 0$ and N replaced by $N+3$.

Next we assume $|b| \leq [(N+2)/2]$. In this case, we have

$$\begin{aligned} &|\lambda^{\frac{1}{2}} \eta_2(\lambda,s)(1+s)^{-\frac{1}{2}} |\Gamma^b u^i \| \partial \Gamma^c u^i \| \partial \Gamma^d u^i \| \\ &\leq C \|\partial u(s)\|_{N+4} [\partial u(s)]_{[\frac{N+2}{2}]} |w_i(\lambda,s)(1+s)^{-\frac{1}{2}} |\Gamma^b u^i(\lambda,s)\| \\ &\leq C(1+s)^{\frac{1}{4}-\mu} \|\partial u(s)\|_{N+4} \left(\varepsilon + [\partial u]^3_{[\frac{N+2}{2}]+1,s} \right), \end{aligned}$$

where we have used (4.54), (2.8), (4.1) with $k = [(N+4)/2]$, and (4.56). Taking μ such that $\mu > 1/4$, we obtain

$$M_{3,N+1} \leq C\left((1 + \|\partial u\|_{N+4,t})\varepsilon + [\partial u]^2_{[\frac{N+4}{2}],t} \|\partial u\|_{N+6,t} \right). \tag{4.71}$$

Combining (4.60), (4.69), and (4.71) with (4.59), we obtain (4.3). This completes the proof. □

5. Proof of Theorem 1.1. By the existence and the uniqueness of the local smooth solution of (1.1) and (1.2) (see, e.g., S. Klainerman [14]), it is enough to establish a uniform a priori estimate of $[\partial u(t)]_N$ for some large integer N. To deal with the L^2-norm in the right-hand side of (4.3), we need the following.

Proposition 5.1. *Let $u^i \in C^\infty(\mathbf{R}^2 \times [0,T))$ be a solution of* (1.1) *and* (1.2). *Suppose that* (1.5) *holds. Then there exists a sufficiently small $\delta_1 > 0$ independent* *of T and a constant $C_N > 0$ independent of T and δ_1 such that the following energy estimate holds for $0 \le t < T$:*

$$\|\partial u(t)\|_N \le C_N \|\partial u(0)\|_N (1+t)^{C_N [\partial u]^2_{[\frac{N+1}{2}],t}}, \tag{5.1}$$

provided (4.1) *with $k = [(N+1)/2]$ holds.*

Proposition 5.2. *Let $u^i \in C^\infty(\mathbf{R}^2 \times [0,T))$ be a solution of* (1.1) *and* (1.2). *Also let $0 < \delta_1 < 1$ in* (4.1). *Suppose that* (1.11) *holds. Then there exists a constant $C_N > 0$ independent of T and δ_1 such that the following energy estimate holds for $0 \le t < T$:*

$$\begin{aligned} \|\partial u(t)\|_N^2 \le C_N^2 \Big\{ & \|\partial u(0)\|_N^2 \\ & + \int_0^t (1+s)^{-\frac{5}{4}} ([\partial u(s)]^2_{N+1} + \langle u(s)\rangle^2_{N+1}) \|\partial u(s)\|^2_{N+1} ds \Big\}, \end{aligned} \tag{5.2}$$

provided (4.1) *with $k = [(N+1)/2]$ holds. Here we have set*

$$\langle u(s)\rangle_k = \sum_{i=1}^m \sum_{|a|\le k} \sup_{\{x\in \mathbf{R}^2 : (x,s)\in \Lambda_i\}} |\Gamma^a u^i(x,s)|.$$

Proof of Proposition 5.1. If we set

$$L_i v = \Box_i v^i - \sum_{l=1}^m \sum_{\gamma,\delta=0}^2 H_{il}^{\gamma\delta}(\partial u)\partial_\gamma \partial_\delta v^l - K_i(\partial u) \quad \text{for} \quad v = (v^1, \dots, v^m), \tag{5.3}$$

we have an identity

$$\begin{aligned} \frac{d}{dt}\int_{\mathbf{R}^2} \Big\{ & (\partial_t v^i)^2 + c_i^2 |\nabla v^i|^2 - \sum_{l=1}^m H_{il}^{00}(\partial u)\partial_t v^i \partial_t v^l \\ & + \sum_{p,q=1}^2 H_{il}^{pq}(\partial u)\partial_p v^i \partial_q v^q \Big\} dx = \int_{\mathbf{R}^2} J_i(v) dx, \end{aligned} \tag{5.4}$$

where

$$\begin{aligned} J_i(v) = {} & 2L_i v \partial_t v^i - \sum_{l=1}^m (\partial_t H_{il}^{00}(\partial u))\partial_t v^i \partial_t v^l + 2\sum_{l=1}^m \sum_{p=1}^2 (\partial_p H_{il}^{p0}(\partial u))\partial_t v^i \partial_t v^l \\ & -2 \sum_{l=1}^m \sum_{p,q=1}^2 (\partial_p H_{il}^{pq}(\partial u))\partial_q v^i \partial_t v^l \\ & + \sum_{l=1}^m \sum_{p,q=1}^2 (\partial_t H_{il}^{pq}(\partial u))\partial_p v^i \partial_q v^l + 2K_i(\partial u)\partial_t v^i. \end{aligned}$$

Here we have used (1.5) and the divergence theorem. By (1.12), we have

$$|H_{il}^{\gamma\delta}(\partial u)| < \frac{1}{2m}\min\{1, c_m^2\}$$

if we take δ_1 in (4.1) to be sufficiently small. Therefore, (5.4) yields

$$\|\partial v(t)\|_0^2 \leq C\left(\|\partial v(0)\|_0^2 + \sum_{i=1}^{m}\int_0^t ds\int_{\mathbf{R}^2}|J_i(v)|dx\right). \tag{5.5}$$

Hence, if we take $v = \Gamma^a u (|a| \leq N)$ in (5.5), we have

$$\|\partial u(t)\|_N^2 \leq C\left(\|\partial u(0)\|_N^2 + \sum_{i=1}^{m}\sum_{|a|\leq N}\int_0^t ds\int_{\mathbf{R}^2}|J_i(\Gamma^a u)|dx\right). \tag{5.6}$$

Furthermore, it follows from (1.12), (4.1), and the Leibniz rule that

$$\int_{\mathbf{R}^2}|J_i(\Gamma^a u)|dx \leq C|\partial u(s)|^2_{[\frac{N+1}{2}]}\|\partial u(s)\|_N^2. \tag{5.7}$$

Thus, combining (5.6) and (5.7) and using Gronwall's inequality, we have

$$\|\partial u(t)\|_N \leq C_N\|\partial u(0)\|_N \exp\left(\int_0^t C_N|\partial u(s)|^2_{[\frac{N+1}{2}]}ds\right), \tag{5.8}$$

which yields (5.1), due to (2.5). This completes the proof. □

Proof of Proposition 5.2. Multiplying $\partial_t\Gamma^a u^i$ by (3.9) and integrating it over $\mathbf{R}^2 \times [0,t]$, we have

$$\|\partial u^i(t)\|_N^2 \leq \|\partial u^i(0)\|_N^2 + C_N\sum_{|b|\leq|a|\leq N}\int_0^t\int_{\mathbf{R}^2}|\Gamma^b(F^i(\partial u, \partial^2 u))\partial_t\Gamma^a u^i|dxds. \tag{5.9}$$

We divide the function F^i into three parts: G^i, R^i, and N^i as in (1.12).

First, we derive the estimate for the higher-order term G^i. Using (2.5) and (4.1) with $k = [(N+1)/2]$, we have

$$|\Gamma^b G^i(x,s)| \leq C_N(1+s)^{-\frac{3}{2}}[\partial u(s)]^3_{[\frac{N+1}{2}]}\sum_{j=1}^{m}\sum_{|c|\leq|b|+1}|\partial\Gamma^c u^j(x,s)|, \tag{5.10}$$

which yields

$$\int_{\mathbf{R}^2}|\Gamma^b(G^i(x,s))\partial_t\Gamma^a u^i|dx \leq C_N(1+s)^{-\frac{3}{2}}[\partial u(s)]^3_{[\frac{N+1}{2}]}\|\partial u(s)\|_{N+1}^2. \tag{5.11}$$

Second, we consider the resonance-form R^i. Without loss of generality, we may assume $l \neq i$ by (1.13). We now use the "resonance" property by the aid of (2.5), (2.6), and (2.4), namely,

$$\frac{1}{(w_l w_i)(|x|,s)} \leq \frac{C}{(1+s)^{\frac{5}{4}}}. \tag{5.12}$$

Using this estimate, we get

$$\begin{aligned}|\Gamma^b(R^i(x,s))\partial_t\Gamma^a u^i| &\leq C_N\sum_{j,k,=1}^{m}\sum_{l\neq i}\sum_{|c+d+e|\leq|b|+1}|\Gamma^c(\partial u^j)\Gamma^d(\partial u^k)\Gamma^e(\partial u^l)\partial_t\Gamma^a u^i|\\ &\leq C_N\sum_{j,k=1}^{m}\sum_{|c+d|\leq|b|+1}(1+s)^{-\frac{5}{4}}[\partial u(s)]^2_{N+1}|\Gamma^c(\partial u^j)\Gamma^d(\partial u^k)|,\end{aligned}$$

which yields

$$\int_{\mathbf{R}^2} |\Gamma^b(R^i(x,s))\partial_t\Gamma^a u^i| dx \le C_N(1+s)^{-\frac{5}{4}}[\partial u(s)]^2_{N+1}\|\partial u(s)\|^2_{N+1}. \tag{5.13}$$

Finally, we treat the null-form N^i. When $(x,s) \in \Lambda_i^c$, we find from (2.7) that

$$|\Gamma^b(N^i(x,s))| \le C_N(1+s)^{-\frac{3}{2}}[\partial u(s)]^2_{[\frac{N+1}{2}]} \sum_{|c|\le|b|+1} |\partial\Gamma^c u^i(x,s)|.$$

When $(x,s) \in \Lambda_i$, it follows from Proposition 3.1 and (2.5) that

$$\begin{aligned}|\Gamma^b(N^i(x,s))| &\le C_N((1+s)^{-\frac{1}{2}}\Phi^i_b + (1+s)^{-1}\Theta^i_b)\\ &\le C_N(1+s)^{-\frac{3}{2}}([\partial u(s)]^2_{N+1} + [\partial u(s)]_{N+1}\langle u(s)\rangle_{N+1}) \sum_{|c|\le|b|+1} |\partial\Gamma^c u^i(x,s)|.\end{aligned}$$

Therefore, we get

$$\begin{aligned}&\int_{\mathbf{R}^2} |\Gamma^b(N^i(x,s))\partial_t\Gamma^a u^i| dx\\ &\le \|\Gamma^b(N^i(s))\|_0 \|\partial u(s)\|_{N+1}\\ &\le C_N(1+s)^{-\frac{3}{2}}([\partial u(s)]^2_{N+1} + \langle u(s)\rangle^2_{N+1})\|\partial u(s)\|^2_{N+1}.\end{aligned} \tag{5.14}$$

Combining (5.11), (5.13), and (5.14) with (5.9), we obtain (5.2). The proof is complete. □

Corollary 5.1. *Let* $u^i \in C^\infty(\mathbf{R}^2 \times [0,T))$ *be a solution of* (1.1) *and* (1.2). *Suppose that* (1.5) *and* (1.11) *hold. Then there exist a sufficiently small* $\delta_1 > 0$ *independent of* T *and a constant* $C_N > 0$ *independent of* T *and* δ_1 *such that the following holds for* $0 \le t < T$:

$$\|\partial u(t)\|^2_{N+6} \le C_N^2\varepsilon^2 \left\{1 + \int_0^t (1+s)^{-\frac{5}{4}+4C_N[\partial u]^2_{[\frac{N+14}{2}],s}} ds\right\}, \tag{5.15}$$

provided (4.1) *with* $k = [(N+14)/2]$ *holds and* $0 < \varepsilon \le 1$.

Proof. It follows from (4.3) and (5.1) that for $0 \le s \le t$

$$[\partial u(s)]_{N+7} \le C_N(\varepsilon + (\varepsilon + \delta_1^2)\|\partial u\|_{N+13,s}) \tag{5.16}$$

and

$$\|\partial u\|_{N+13,s} \le C_N\varepsilon(1+s)^{C_N[\partial u]^2_{[\frac{N+14}{2}],s}} \tag{5.17}$$

because $\|\partial u(0)\|_{N+13} \le C_N\varepsilon$ for sufficiently small δ_1. Therefore, we have

$$[\partial u(s)]_{N+7} \le C_N(1+\varepsilon+\delta_1^2)\varepsilon(1+s)^{C_N[\partial u]^2_{[\frac{N+14}{2}],s}}. \tag{5.18}$$

Moreover, $\langle u(s)\rangle_{N+7}$ has the same estimate as $[\partial u(s)]_{N+7}$, because of (4.55). Now (5.15) follows from (5.2) and (5.18) together with (5.17). The proof is complete. □

End of the proof of Theorem 1.1. As we stated at the beginning of the present section, what we need to prove Theorem 1.1 is an a priori estimate for $[\partial u(t)]_N$. We fix an integer N satisfying $N \ge 13$, which guarantees $[(N+14)/2] \le N$. We take a positive constant B_N such that $B_N \geq 2\tilde{C}_N$ and $B_N \geq M_N$, where M_N is the constant in (4.6) and $\tilde{C}_N$ is the constant larger than C_N appearing in (4.3) and (5.15). We also take ε_1 such that

$$0 < \varepsilon_1 \leq 1 \quad \text{and} \quad 3B_N\varepsilon_1 \leq \delta_1, \tag{5.19}$$

where δ_1 is the smallest one taken in Proposition 4.1 and Corollary 5.1. Moreover, set

$$\begin{aligned} T_\varepsilon = \sup\{T > 0 :\ &\text{(1.1) and (1.2) have a solution } u^i \text{ in } C^\infty(\mathbf{R}^2 \times [0, T)) \\ &\text{and } [\partial u]_{N,T} \leq 3B_N\varepsilon \text{ holds}\}. \end{aligned} \tag{5.20}$$

We can see that $T_\varepsilon > 0$, because of the existence of a local solution, the continuity of $[\partial u]_{N,t}$, and (4.5). Then, for each ε satisfying $0 < \varepsilon \leq \varepsilon_1$, we have $u^i \in C^\infty(\mathbf{R}^2 \times [0, T_\varepsilon))$ and

$$[\partial u]_{[\frac{N+14}{2}],T_\varepsilon} \leq [\partial u]_{N,T_\varepsilon} \leq \delta_1,$$

which imply that (4.3) and (5.15) hold. In particular, we have for $0 \leq t < T_\varepsilon$

$$\|\partial u(t)\|_{N+6} \leq \tilde{C}_N\varepsilon \left\{1 + \int_0^t (1+s)^{-\frac{5}{4}+4\tilde{C}_N[\partial u]_{[\frac{N+14}{2}],s}} ds\right\}^{\frac{1}{2}}. \tag{5.21}$$

Now, we take ε_0 to be

$$0 < \varepsilon_0 \leq \varepsilon_1, \quad 3\tilde{C}_N\varepsilon_0 \leq 1, \quad \text{and} \quad 12\tilde{C}_N B_N\varepsilon_0 \leq \frac{1}{8}, \tag{5.22}$$

and fix an ε in $[0, \varepsilon_0)$ in the following. Then, by (5.21), (5.20), and (5.22), we have for $0 \leq t < T_\varepsilon$

$$\begin{aligned} \|\partial u(t)\|_{N+6} &\leq \tilde{C}_N\varepsilon \left(1 + \int_0^t (1+s)^{-\frac{9}{8}} ds\right)^{\frac{1}{2}} \\ &\leq 1. \end{aligned}$$

Substituting this into (4.3) and using (5.20), we have

$$[\partial u]_{N,T_\varepsilon} \leq \tilde{C}_N \left(2\varepsilon + 3B_N\varepsilon[\partial u]_{[\frac{N+4}{2}],T_\varepsilon}\right).$$

Hence, by $B_N \geq 2\tilde{C}_N$ and (5.22), we have

$$[\partial u]_{N,T_\varepsilon} \leq 2B_N\varepsilon. \tag{5.23}$$

By the blowup criterion (see, e.g., [22, Theorem 2.2, p. 31]), we see that if $T_\varepsilon < +\infty$, we must have $\lim_{t\to T_\varepsilon - 0}[\partial u]_{N,T} = 3B_N\varepsilon$, which contradicts (5.23). Therefore, we have $T_\varepsilon = +\infty$. This completes the proof of Theorem 1.1. □

GLOBAL ASYMPTOTIC STABILITY OF TRAVELING WAVES IN DELAYED REACTION-DIFFUSION EQUATIONS*

HAL L. SMITH† AND XIAO-QIANG ZHAO†

Abstract. The existence and comparison theorem of solutions is first established for the quasi-monotone delayed reaction-diffusion equations on R by appealing to the theory of abstract functional differential equations. The global asymptotic stability, Liapunov stability, and uniqueness of traveling wave solutions are then proved by the elementary super- and subsolution comparison and squeezing methods.

Key words. delayed reaction-diffusion equations, comparison principle, super- and subsolutions, traveling waves

1. Introduction.

Traveling wave solutions have been widely studied for nonlinear reaction-diffusion equations modeling a variety of physical and biological phenomena (see, e.g., [3], [11], monograph [16], and references therein). More recently, Chen [1] studied the existence, uniqueness, and global asymptotic stability of traveling wave solutions in nonlocal evolution equations with bistable nonlinearities. A basic assumption in [1] is the comparison principle. Shen [12] investigated these problems for traveling wave solutions in temporally almost periodic reaction-diffusion equations with bistable nonlinearities. In [9], Ogiwara and Matano discussed the monotonicity and stability of pseudotraveling wave solutions in temporally or spatially periodic media as an application of their general theory on stable equilibria in order-preserving systems in the presence of symmetry.

Recently, great attention has also been paid to reaction-diffusion equations with time delays (see, e.g., [15], [7], [8], [4], monograph [17], and references therein). Most of the known results in this direction are about the existence, comparison, monotonicity, bifurcations, and asymptotic behavior of solutions to delayed reaction-diffusion equations on a bounded spatial domain. Schaaf [13] first studied traveling wave solutions for some delayed reaction-diffusion equations and, in particular, proved the existence of monotone traveling wave solutions and uniqueness of wave speeds for the delayed reaction-diffusion equations with quasi-monotone and bistable nonlinearities by a phase plane analysis method. In [18], Zou and Wu obtained the existence of traveling waves in some delayed reaction-diffusion systems via the monotone iteration method. As a consequence of the delayed reaction term, the study of uniqueness and global asymptotic stability of traveling wave solutions becomes relatively more difficult. This paper is devoted to the study of global asymptotic stability with phase shift, Liapunov stability, and uniqueness up to translation of traveling wave solutions in delayed reaction-diffusion equations with quasi-monotone and bistable nonlinearities. The first key point is to establish a refined comparison principle for this class of delayed reaction-diffusion equations defined on the whole real line R. We do this by appealing to the theory of abstract functional differential equations developed in [7]

and properties of the analytic semigroup generated by the one-dimensional Laplacian operator on the Banach space of all bounded and uniformly continuous functions on R. In order to prove global asymptotic stability of monotone traveling wave solutions, we have borrowed a "squeezing" technique introduced in [1], which is similar in spirit to a "contracting rectangles" approach developed in [8] for quasi-monotone delayed reaction-diffusion systems on a bounded spatial domain. The Liapunov stability of monotone traveling waves and the uniqueness of traveling waves are then proved by using an elementary super- and subsolution comparison method and the established global asymptotic stability of monotone traveling waves.

We note that the recent publication [9] contains results related to ours on traveling wave solutions for delayed reaction-diffusion equations. These authors show that monotone traveling waves are *locally* asymptotically stable with phase shift. By contrast, our results allow replacing locally with *globally and exponentially* in their result and are based on more elementary methods.

The organization of this paper is as follows. In section 2, we establish an existence and comparison theorem for quasi-monotone delayed reaction-diffusion equations on R (Theorem 2.2). For use in the next section, we also prove three technical lemmas about the construction of super- and subsolutions and the derivative of profiles of monotone traveling wave solutions (Lemmas 2.3, 2.4, and 2.5). In section 3, we first prove two lemmas about the iteration and ultimate estimation of solutions (Lemmas 3.1 and 3.2); then we establish the global exponential stability with phase shift of monotone traveling wave solutions (Theorem 3.3), Liapunov stability, and uniqueness up to translation of traveling wave solutions (Theorem 3.4).

2. Existence and comparison of solutions.

Consider delayed reaction-diffusion equations

$$\begin{cases} \dfrac{\partial u}{\partial t} &= d\Delta u + f(u(x,t), u(x,t-\tau)), \quad x \in R, t > 0, \\ u(x,s) &= \varphi(x,s), \quad x \in R, s \in [-\tau, 0], \end{cases} \tag{2.1}$$

where $d > 0$, $\tau \geq 0$, and Δ is the Laplacian operator on R. We will impose the following conditions on $f(\cdot,\cdot)$.

(H1) $f \in C^1(I^2, R)$ for some open interval $I \subset R$ with $[0,1] \subset I$; $\partial_2 f(u,v) \geq 0$, for $(u,v) \in I^2$.

(H2) $f(0,0) = f(1,1) = 0$, $\partial_1 f(0,0) + \partial_2 f(0,0) < 0$, and $\partial_1 f(1,1) + \partial_2 f(1,1) < 0$.

Let $X = BUC(R,R)$ be the Banach space of all bounded and uniformly continuous functions from R into R with the usual supremum norm. Let $X^+ = \{\varphi \in X; \varphi(x) \geq 0, x \in R\}$. It is easy to see that X^+ is a closed cone of X and its induced partial ordering makes X into a Banach lattice. By [2, Theorem 1.5], it then follows that the X-realization $d\Delta_X$ of $d\Delta$ generates a strongly continuous analytic semigroup $T(t)$ on X and $T(t)X^+ \subset X^+$, $t \geq 0$. Moreover, by the explicit expression of solutions of the heat equation

$$\begin{cases} \dfrac{\partial u}{\partial t} &= d\Delta u, \quad x \in R, t > 0, \\ u(x,0) &= \varphi(x), \quad x \in R, \end{cases} \tag{2.2}$$

we have

$$T(t)\varphi(x) = \frac{1}{\sqrt{4\pi dt}} \int_{-\infty}^{\infty} \exp\left(-\frac{(x-y)^2}{4dt}\right) \varphi(y)dy, \qquad x \in R, \quad t > 0, \quad \varphi_{(\cdot)} \in X. \tag{2.3}$$

Let $f_0(\cdot) : I \to R$ be defined by $f_0(u) = f(u, u)$, $u \in I$. By the continuity of f_0 and condition (H2), it then easily follows that there exist δ_0, a^-, $a^+ \in (0, 1)$ with $[-\delta_0, 1 + \delta_0] \subset I$ and $a^- \leq a^+$ such that $f_0(\cdot) : [-\delta_0, 1 + \delta_0] \to R$ satisfies

$$\begin{aligned} & f_0(0) = f_0(a^-) = f_0(a^+) = f_0(1) = 0, \\ & f_0(u) > 0 \quad \text{for } u \in [-\delta_0, 0) \cup (a^+, 1), \\ & \text{and } f_0(u) < 0 \quad \text{for } u \in (0, a^-) \cup (1, 1 + \delta_0]. \end{aligned} \tag{2.4}$$

Let $L_i = \max\{|\partial_i f(u, v)|; -\delta_0 \leq u, v \leq 1 + \delta_0\}$, $i = 1, 2$, and define

$$\theta(J, t) = \frac{1}{\sqrt{4\pi dt}} \exp\left(-L_1 t - \frac{(J + 1)^2}{4dt}\right), \quad J \geq 0,\ t > 0.$$

Clearly, $\theta \in C([0, \infty) \times (0, \infty), R)$.

Let $C = C([-\tau, 0], X)$ be the Banach space of continuous functions from $[-\tau, 0]$ into X with the supremum norm, and let $C^+ = \{\varphi \in C; \varphi(s) \in X^+, s \in [-\tau, 0]\}$. Then C^+ is a positive cone of C. For convenience, we identify an element $\varphi \in C$ as a function from $R \times [-\tau, 0]$ into R defined by $\varphi(x, s) = (\varphi(s))(x)$. For any continuous function $w(\cdot) : [-\tau, b) \to X$, $b > 0$, we define $w_t \in C$, $t \in [0, b)$, by $w_t(s) = w(t + s)$, $s \in [-\tau, 0]$. It is then easy to see that $t \mapsto w_t$ is a continuous function from $[0, b)$ to C. For any $\varphi \in [-\delta_0, 1 + \delta_0]_C = \{\varphi \in C; \varphi(x, s) \in [-\delta_0, 1 + \delta_0], x \in R, s \in [-\tau, 0]\}$, define $F(\varphi)(x) = f(\varphi(x, 0), \varphi(x, -\tau))$, $x \in R$. By the global Lipschitz continuity of $f(\cdot, \cdot)$ on $[-\delta_0, 1 + \delta_0]^2$, we can verify that $F(\varphi) \in X$ and $F : [-\delta_0, 1 + \delta_0]_C \to X$ is globally Lipschitz continuous.

Definition 2.1. *A continuous function $v : [-\tau, b) \to X$, $b > 0$, is called a supersolution (subsolution) of* (2.1) *on* $[0, b)$ *if*

$$v(t) \geq (\leq) T(t - s)v(s) + \int_s^t T(t - r)F(v_r)dr \tag{2.5}$$

for all $0 \leq s < t < b$. If v is both a supersolution and a subsolution on $[0, b)$*, then we call it a mild solution of* (2.1).

Remark 2.1. *Assume that there is a $v \in BUC(R \times [-\tau, b], R)$, $b > 0$, such that v is C^2 in $x \in R$, C^1 in $t \in (0, b)$, and*

$$\frac{\partial v}{\partial t} \geq (\leq) d\Delta v + f(v(x, t), v(x, t - \tau)), \quad x \in R, t \in (0, b). \tag{2.6}$$

Then, by the positivity of the linear semigroup $T(t) : X \to X$, it easily follows that (2.5) *holds. Hence v is a supersolution (subsolution) of* (2.1) *on* $[0, b)$.

Now we are in a position to establish the following existence and comparison theorem for (2.1).

Theorem 2.2. *Assume that* (H1) *and* (H2) *hold. Then for any $\varphi \in [-\delta_0, 1+\delta_0]_C$,* (2.1) *has a unique mild solution $u(x, t, \varphi)$ on $[0, \infty)$ and $u(x, t, \varphi)$ is a classical solution to* (2.1) *for $(x, t) \in R \times (\tau, \infty)$. Furthermore, for any pair of supersolution $u(x, t)$ and subsolution $w(x, t)$ of* (2.1) *on $[0, \infty)$ with $-\delta_0 \leq u(x, t)$, $w(x, t) \leq 1 + \delta_0$, $x \in R$, $t \in [-\tau, \infty)$, and $u(x, s) \geq w(x, s)$, $x \in R$, $s \in [-\tau, 0]$, there holds $u(x, t) \geq w(x, t)$ for $x \in R$, $t \geq 0$, and*

$$u(x, t) - w(x, t) \geq \theta(J, t - t_0) \int_z^{z+1} (u(y, t_0) - w(y, t_0))dy$$

for any $J \geq 0$*,* x *and* $z \in R$ *with* $|x - z| \leq J$*, and* $t > t_0 \geq 0$*.*

Proof. Under an abstract setting in [7], a mild solution of (2.1) is a solution to its associated integral equation

$$\begin{cases} u(t) = T(t)\varphi(0) + \int_0^t T(t-r)F(u_r)dr, & t > 0, \\ u_0 = \varphi \in [-\delta_0, 1+\delta_0]_C. \end{cases} \tag{2.7}$$

By the choice of δ_0 in (2.4), we have $f(1+\delta_0, 1+\delta_0) < 0$ and $f(-\delta_0, -\delta_0) > 0$. Clearly, $v^+ = 1 + \delta_0$ and $v^- = -\delta_0$ are an ordered pair of super- and subsolutions of (2.1) on $[0, \infty)$. As aforementioned, $F : [-\delta_0, 1+\delta_0]_C \to X$ is globally Lipschitz continuous. We further claim that F is quasi-monotone on $[-\delta_0, 1+\delta_0]_C$ in the sense that

$$\lim_{h \to 0^+} \frac{1}{h} \operatorname{dist}(\psi(0) - \varphi(0) + h[F(\psi) - F(\varphi)]; X^+) = 0 \tag{2.8}$$

$$\text{for all } \psi, \varphi \in [-\delta_0, 1+\delta_0]_C \text{ with } \psi \geq \varphi.$$

Indeed it follows from condition (H1) that

$$\begin{aligned} F(\psi) - F(\varphi) &= f(\psi(\cdot, 0), \psi(\cdot, -\tau)) - f(\varphi(\cdot, 0), \varphi(\cdot, -\tau)) \\ &\geq f(\psi(\cdot, 0), \varphi(\cdot, -\tau)) - f(\varphi(\cdot, 0), \varphi(\cdot, -\tau)) \\ &\geq -L_1(\psi(0) - \varphi(0)) \quad \text{in } X, \end{aligned} \tag{2.9}$$

and hence, for any $h > 0$ satisfying $hL_1 < 1$,

$$\psi(0) - \varphi(0) + h[F(\psi) - F(\varphi)] \geq (1 - L_1 h)(\psi(0) - \varphi(0)) \geq 0 \quad \text{in } X.$$

Then the existence and uniqueness of $u(x, t, \varphi)$ follows from [7, Corollary 5] with $S(t, s) = T(t, s) = T(t - s)$, $t \geq s \geq 0$, and $B(t, \varphi) \equiv F(\varphi)$. Moreover, by a semigroup theory argument given in the proof of [7, Theorem 1], it follows that $u(x, t, \varphi)$ is a classical solution for $t > \tau$.

For simplicity, let $\psi(x, s) = u(x, s)$, $\varphi(x, s) = w(x, s)$, $x \in R$, $s \in [-\tau, 0]$. Then $\psi, \varphi \in [-\delta_0, 1+\delta_0]_C$ with $\psi \geq \varphi$ in C. Again by [7, Corollary 5], we have

$$1 + \delta_0 \geq u(x, t, \psi) \geq u(x, t, \varphi) \geq -\delta_0, \quad x \in R, t \geq 0. \tag{2.10}$$

By applying [7, Corollary 5] with $v^+(x, t) = 1 + \delta_0$ and $v^-(x, t) = w(x, t)$, $v^+(x, t) = u(x, t)$ and $v^-(x, t) = -\delta_0$, respectively, we get

$$w(x, t) \leq u(x, t, \varphi) \leq 1 + \delta_0, \quad x \in R, t \geq 0 \tag{2.11}$$

and

$$-\delta_0 \leq u(x, t, \psi) \leq u(x, t), \quad x \in R, t \geq 0. \tag{2.12}$$

Combining (2.10)–(2.12), we have $u(x, t) \geq w(x, t)$ for all $x \in R$ and $t \geq 0$.

It remains to prove the last inequality in the theorem. Let $v(x, t) = u(x, t) - w(x, t)$, $x \in R$, $t \in [-\tau, \infty)$. Then $v(x, t) \geq 0$, $x \in R$, $t \in [-\tau, \infty)$. Clearly, $u_t, w_t \in [-\delta_0, 1+\delta_0]_C$ with $u_t \geq w_t$ in C for all $t \geq 0$. For any given $t_0 \geq 0$, by Definition 2.1 and (2.9), it then follows that, for all $t \geq t_0$,

$$\begin{aligned} v(t) &\geq T(t - t_0)v(t_0) + \int_{t_0}^t T(t - r)(F(u_r) - F(w_r))dr \\ &\geq T(t - t_0)v(t_0) - L_1 \int_{t_0}^t T(t - r)v(r)dr. \end{aligned} \tag{2.13}$$

Let

$$z(t) = e^{-L_1(t-t_0)}T(t-t_0)v(t_0), \quad t \geq t_0.$$

Then $z(t)$ satisfies

$$z(t) = T(t-t_0)z(t_0) - L_1 \int_{t_0}^{t} T(t-r)z(r)dr, \quad t \geq t_0. \tag{2.14}$$

By [7, Proposition 3] with $v^- \equiv z(t)$, $v^+ = +\infty$, $S(t,s) = S^-(t,s) = T(t,s) = T(t-s)$, $t \geq s \geq 0$, and $B(t,\varphi) \equiv B^-(t,\varphi) \equiv -L_1\varphi(0)$, we have $v(t) \geq z(t)$ for all $t \geq t_0$. Thus it follows that

$$u(t) - w(t) \geq e^{-L_1(t-t_0)}T(t-t_0)(u(t_0) - w(t_0)), \quad t \geq t_0. \tag{2.15}$$

Combining (2.3), (2.15), and the definition of $\theta \in C([0,\infty) \times (0,\infty), R)$, we then have

$$u(x,t) - w(x,t) \geq \theta(J, t-t_0) \int_{z}^{z+1} (u(y,t_0) - w(y,t_0))dy \tag{2.16}$$

for all $x \in R$ with $|x - z| \leq J$ and $t > t_0 \geq 0$.

This completes the proof. □

For delayed reaction-diffusion equation (2.1), we are interested in its traveling wave solutions which connect two equilibria 0 and 1. Without loss of generality, throughout this paper, by a traveling wave we refer to a solution of the form of $u(x,t) = U(x-ct)$, $x \in R$, $t \in R$, with the property that

$$\lim_{\xi \to \infty} U(\xi) = 1, \qquad \lim_{\xi \to -\infty} U(\xi) = 0, \tag{2.17}$$

where $U(\xi)$ is a function on R and c is a constant real number. As usual, $|c|$ is called the wave speed and U the profile of the wave front. Moreover, we say a traveling wave $U(x-ct)$ is a monotone if $U(\cdot) : R \to R$ is a strictly increasing function.

LEMMA 2.3. *Assume that* (H1) *and* (H2) *hold and let* $U(x-ct)$ *be a monotone traveling wave solution. Then there exist three positive numbers* β_0 *(which is independent of* U*),* σ_0*, and* $\bar{\delta}$ *such that for any* $\delta \in (0, \bar{\delta}]$ *and every* $\xi_0 \in R$*, the functions* w^+ *and* w^- *defined by*

$$w^{\pm}(x,t) := U(x - ct + \xi_0 \pm \sigma_0\delta[1 - e^{-\beta_0 t}]) \pm \delta e^{-\beta_0 t}$$

are a supersolution and a subsolution of (2.1) *on* $[0,\infty)$*, respectively.*

Proof. Clearly, $0 < U(\xi) < 1$, and hence, $0 < U(x-ct) < 1$, $x \in R$, $t \in R$. By Theorem 2.2 and monotonicity of $U(\cdot)$, it follows that $U(\cdot) \in C^1(R)$ and $U'(\xi) > 0$, $\xi \in R$. Since

$$\lim_{(u,v,\beta)\to(0,0,0)} (\partial_1 f(u,v) + e^{\beta\tau}\partial_2 f(u,v) + \beta) = \partial_1 f(0,0) + \partial_2 f(0,0) < 0$$

and

$$\lim_{(u,v,\beta)\to(1,1,0)} (\partial_1 f(u,v) + e^{\beta\tau}\partial_2 f(u,v) + \beta) = \partial_1 f(1,1) + \partial_2 f(1,1) < 0,$$

we can fix $\beta_0 > 0$ and $\delta^* \in (0, \delta_0)$ such that

$$\partial_1 f(u,v) + e^{\beta_0\tau}\partial_2 f(u,v) < -\beta_0 \text{ for all } (u,v) \in [-\delta^*, \delta^*]^2 \cup [1-\delta^*, 1+\delta^*]^2. \tag{2.18}$$

Let $c_0 = \tau|c| + (e^{\beta_0\tau} - 1)$. By (2.17), there exists $M_0 = M_0(U, \beta_0, \delta^*) > 0$ such that

$$\begin{aligned} &U(\xi) \geq 1 - \frac{\delta^*}{2} \quad \text{for all } \xi \geq M_0 - c_0, \\ &U(\xi) \leq \frac{\delta^*}{2} \quad \text{for all } \xi \leq -M_0 + c_0. \end{aligned} \tag{2.19}$$

Take

$$\begin{aligned} c_1 = c_1(\beta_0, \delta^*) &= \max\{|\partial_1 f(u,v)|; (u,v) \in [-\delta^*, 1+\delta^*]^2\} \\ &+ e^{\beta_0\tau} \max\{|\partial_2 f(u,v)|; (u,v) \in [-\delta^*, 1+\delta^*]^2\}, \end{aligned}$$

$m_0 = m_0(U, \beta_0, \delta^*) = \min\{U'(\xi); |\xi| \leq M_0\} > 0$, and define

$$\sigma_0 = \sigma_0(U, \beta_0, \delta^*) = \frac{\beta_0 + c_1}{m_0\beta_0} > 0, \quad \bar{\delta} = \bar{\delta}(U, \beta_0, \delta^*) = \min\{\frac{1}{\sigma_0}, \frac{\delta^*}{2} \cdot e^{-\beta_0\tau}\} > 0.$$

We prove only $w^+(x,t)$ is a supersolution of (2.1) since the proof for $w^-(x,t)$ is analogous. By a translation, we can assume that $\xi_0 = 0$. For any given $\delta \in (0, \bar{\delta}]$, let $\xi(t) = x - ct + \sigma_0\delta[1 - e^{-\beta_0 t}]$. It then follows that $\xi(t) + c\tau \geq \xi(t-\tau)$ and $|\xi(t-\tau) - \xi(t)| = |c\tau + \sigma_0\delta e^{-\beta_0 t}[1 - e^{\beta_0\tau}]| \leq c_0$ for all $t \geq 0$. Since $U(x - ct)$ is a solution of (2.1), we have

$$dU''(\xi) + cU'(\xi) + f(U(\xi), U(\xi + c\tau)) = 0, \xi \in R. \tag{2.20}$$

Notice that $U'(\xi) > 0$ and $\partial_2 f(\cdot,\cdot) \geq 0$. It then follows that, for any $t \geq 0$,

$$\begin{aligned} &\frac{\partial w^+(x,t)}{\partial t} - d\Delta w^+(x,t) - f(w^+(x,t), w^+(x,t-\tau)) \\ &= U'(\xi(t))(-c + \sigma_0\delta\beta_0 e^{-\beta_0 t}) - \beta_0\delta e^{-\beta_0 t} \\ &\quad -dU''(\xi(t)) - f(U(\xi(t)) + \delta e^{-\beta_0 t}, U(\xi(t-\tau)) + \delta e^{-\beta_0(t-\tau)}) \\ &= (U'(\xi(t))\sigma_0\beta_0 - \beta_0)\delta e^{-\beta_0 t} + f(U(\xi(t)), U(\xi(t) + (c\tau))) \\ &\quad -f(U(\xi(t)) + \delta e^{-\beta_0 t}, U(\xi(t-\tau) + \delta e^{-\beta_0(t-\tau)}) \\ &\geq (U'(\xi(t))\sigma_0\beta_0 - \beta_0)\delta e^{-\beta_0 t} + f(U(\xi(t)), U(\xi(t-\tau))) \\ &\quad -f(U(\xi(t)) + \delta e^{-\beta_0 t}, U(\xi(t-\tau)) + \delta e^{-\beta_0(t-\tau)}) \\ &= \delta e^{-\beta_0 t}\Big[U'(\xi(t))\sigma_0\beta_0 - \beta_0 - \int_0^1 \big(\partial_1 f(U(\xi(t)) + s\delta e^{-\beta_0 t}, U(\xi(t-\tau)) \\ &\quad + s\delta e^{-\beta_0(t-\tau)}) + e^{\beta_0\tau}\partial_2 f(U(\xi(t)) + s\delta e^{-\beta_0 t}, U(\xi(t-\tau)) + s\delta e^{-\beta_0(t-\tau)})\big)ds\Big]. \end{aligned} \tag{2.21}$$

We distinguish among three cases.

Case (i) $|\xi(t)| \leq M_0$: By the choice of M_0 and c_1, the absolute value of the integral in (2.21) is less than or equal to c_1. Then, by the choice of σ_0, we have

$$\begin{aligned} &\frac{\partial w^+(x,t)}{\partial t} - d\Delta w^+(x,t) - f(w^+(x,t), w^+(x,t-\tau)) \\ &\geq [m_0\sigma_0\beta_0 - \beta_0 - c_1] \cdot \delta e^{-\beta_0 t} = 0. \end{aligned} \tag{2.22}$$

Case (ii) $\xi(t) \geq M_0$: Clearly, $\xi(t-\tau) = \xi(t) + \xi(t-\tau) - \xi(t) \geq M_0 - c_0$. Then, by (2.19), $1 - \frac{\delta^*}{2} \leq U(\xi(t))$, $U(\xi(t-\tau)) \leq 1$. Thus we have

$$1 - \frac{\delta^*}{2} \leq U(\xi(t)) + \delta e^{-\beta_0 t} \leq 1 + \frac{\delta^*}{2}$$

and

$$1 - \frac{\delta^*}{2} \le U(\xi(t-\tau)) + \delta e^{-\beta_0(t-\tau)} \le 1 + \delta e^{\beta_0\tau} \cdot e^{-\beta_0 t} \le 1 + \frac{\delta^*}{2}.$$

Therefore, by (2.21) and (2.18), it follows that

$$\begin{aligned} &\frac{\partial w^+(x,t)}{\partial t} - d\Delta w^+(x,t) - f(w^+(x,t), w^+(x,t-\tau)) \\ &\ge [U'(\xi(t))\sigma_0\beta_0 - \beta_0 - (-\beta_0)]\delta e^{-\beta_0 t} \ge 0. \end{aligned} \tag{2.23}$$

Case (iii) $\xi(t) \le -M_0$: Clearly, $\xi(t-\tau) \le \xi(t) + \xi(t-\tau) - \xi(t) \le -M_0 + c_0$. Then, again by (2.19), $0 \le U(\xi(t)),\ U(\xi(t-\tau)) \le \frac{\delta^*}{2}$, and hence,

$$0 \le U(\xi(t)) + \delta e^{-\beta_0 t} \le \frac{\delta^*}{2} + \delta e^{-\beta_0 t} \le \delta^*$$

and

$$0 \le U(\xi(t-\tau)) + \delta e^{-\beta_0(t-\tau)} \le \frac{\delta^*}{2} + \delta e^{\beta_0\tau} \cdot e^{-\beta_0 t} \le \delta^*.$$

Again (2.23) follows from (2.21) and (2.18).
Combining cases (i)–(iii), we have

$$\frac{\partial w^+}{\partial t} - d\Delta w^+ - f(w^+(x,t), w^+(x,t-\tau)) \ge 0, \quad x \in R,\ t \ge 0. \tag{2.24}$$

This completes the proof. □

Let $\bar{\delta}_0 = \min\{\frac{a^-}{2}, \frac{1-a^+}{2}, \delta_0\}$, and let $\zeta(\cdot) \in C^\infty(R)$ be a fixed function with the following properties:

$$\begin{aligned} &\zeta(s) = 0 \quad \text{if } s \le 0; \qquad \zeta(s) = 1 \quad \text{if } s \ge 4; \\ &0 < \zeta'(s) < 1; \qquad |\zeta''(s)| \le 1 \quad \text{if } s \in (0,4). \end{aligned} \tag{2.25}$$

Then we have the following result.

Lemma 2.4. *Assume that* (H1) *and* (H2) *hold. Then, for any* $\delta \in (0, \bar{\delta}_0]$, *there exist two positive numbers* $\epsilon = \epsilon(\delta)$ *and* $C = C(\delta)$ *such that, for every* $\xi \in R$, *the functions* v^+ *and* v^- *defined by*

$$\begin{aligned} v^+(x,t) &:= (1+\delta) - [1 - (a^- - 2\delta)e^{-\epsilon t}]\zeta(-\epsilon(x - \xi + Ct)), \\ v^-(x,t) &:= -\delta + [1 - (1 - a^+ - 2\delta)e^{-\epsilon t}]\zeta(\epsilon(x - \xi - Ct)) \end{aligned}$$

are a supersolution and a subsolution of (2.1) *on* $[0,\infty)$, *respectively.*

Proof. By a translation, we can assume $\xi = 0$. Given $\delta \in (0, \bar{\delta}_0]$, we define

$$\begin{aligned} m_1 &= m_1(\delta) = \max\{\partial_2 f(u,v); (u,v) \in [-\delta, 1-\delta]^2\} \ge 0, \\ m_2 &= m_2(\delta) = \min\left\{\zeta'(s); \frac{\delta}{2} \le \zeta(s) \le 1 - \frac{\delta}{2}\right\} > 0. \end{aligned}$$

Then there exists an $\epsilon = \epsilon(\delta) > 0$ such that

$$(1 - a^+)e^{\epsilon\tau} < 1, \tag{2.26}$$

$$-\min\left\{f_0(u); u \in \left[-\delta, -\frac{\delta}{2}\right]\right\} + (\epsilon + \tau m_1 \epsilon + d\epsilon^2) < 0, \tag{2.27}$$

and

$$-\min\left\{f_0(u); u \in \left[a^+ + \frac{\delta}{2}, 1-\delta\right]\right\} + (\epsilon + \tau m_1 \epsilon + d\epsilon^2) < 0. \tag{2.28}$$

We further choose $C = C(\delta) > 0$ such that

$$-C\epsilon a^+ m_2 + \max\{|f_0(u)|; u \in [-\delta, 1-\delta]\} + (\epsilon + \tau m_1 \epsilon + d\epsilon^2) < 0. \tag{2.29}$$

By a direct computation and (2.26), it follows that for all $t \geq -\tau$,

$$\begin{aligned}\frac{\partial v^-(x,t)}{\partial t} &= -C\epsilon[1-(1-a^+-2\delta)e^{-\epsilon t}]\zeta'(\epsilon(x-Ct)) \\ &\quad +\epsilon(1-a^+-2\delta)\cdot\zeta(\epsilon(x-Ct))e^{-\epsilon t} \\ &\leq -C\epsilon[1-(1-a^+)e^{\epsilon\tau}]\zeta'(\epsilon(x-Ct)) + \epsilon(1-a^+)\zeta(\epsilon(x-Ct))e^{\epsilon\tau} \\ &\leq \epsilon. \end{aligned} \tag{2.30}$$

It is easy to see that $v^-(x,t) \in [-\delta, 1-\delta]$ for all $x \in R$ and $t \geq -\tau$. Therefore we have that for all $t \geq 0$,

$$\begin{aligned} f(v^-(x,t), v^-(x,t-\tau)) &= f_0(v^-(x,t)) + [f(v^-(x,t), v^-(x,t-\tau)) \\ &\quad -f(v^-(x,t), v^-(x,t))] \\ &= f_0(v^-(x,t)) + \partial_2 f(v^-(x,t), v^*(x,t))(v^-(x,t-\tau) \\ &\quad -v^-(x,t)) \\ &= f_0(v^-(x,t)) + \partial_2 f_2(v^-(x,t), v^*(x,t))\frac{\partial v^-(x,t^*)}{\partial t}\cdot \\ &\quad ((t-\tau)-t) \\ &\geq f_0(v^-(x,t)) - \tau\epsilon m_1, \end{aligned} \tag{2.31}$$

where $v^*(x,t)$ is between $v^-(x,t)$ and $v^-(x,t-\tau)$, $t^* \in [t-\tau, t]$, and hence, $t^* \geq -\tau$. It then follows that

$$\begin{aligned} &\frac{\partial v^-(x,t)}{\partial t} - d\Delta v^-(x,t) - f(v^-(x,t), v^-(x,t-\tau)) \\ &\quad = -C\epsilon[1-(1-a^+-2\delta)e^{-\epsilon t}]\zeta'(\epsilon(x-Ct) + \epsilon(1-a^+-2\delta)\zeta(\epsilon(x-Ct))\cdot \\ &\quad e^{-\epsilon t} - d[1-(1-a^+-2\delta)e^{-\epsilon t}]\zeta''(\epsilon(x-Ct))\epsilon^2 - f(v^-(x,t), v^-(x,t-\tau)) \\ &\quad \leq -C\epsilon a^+\zeta'(\epsilon(x-Ct)) + \epsilon + d\epsilon^2 - f_0(v^-(x,t) - \tau\epsilon m_1) \\ &\quad = -C\epsilon a^+\zeta'(\epsilon(x-Ct)) - f_0(v^-(x,t)) + (\epsilon + \tau\epsilon m_1 + d\epsilon^2). \end{aligned} \tag{2.32}$$

We distinguish among three cases.

Case (i) $\zeta(\epsilon(x-Ct)) < \frac{\delta}{2}$: Clearly, $v^-(x,t) \in \left[-\delta, -\frac{\delta}{2}\right]$ for all $x \in R$ and $t \geq 0$. By (2.32) and (2.27), it follows that

$$\begin{aligned} &\tfrac{\partial v^-}{\partial t} - d_0\Delta v^- - f(v^-(x,t), v^-(x,t-\tau)) \\ &\quad \leq -\min\left\{f_0(u); u \in \left[-\delta, -\tfrac{\delta}{2}\right]\right\} \\ &\qquad +(\epsilon + \tau\epsilon m_1 + d\epsilon^2) < 0. \end{aligned}$$

Case (ii) $\zeta(\epsilon(x-Ct)) > 1-\frac{\delta}{2}$: It then follows that

$$\begin{aligned}1-\delta \geq v^-(x,t) &\geq -\delta + \left(1-\frac{\delta}{2}\right)[1-(1-a^+-2\delta)]\\ &= a^+ + \frac{\delta}{2}[2-(2\delta+a^+)]\\ &\geq a^+ + \frac{\delta}{2}. \qquad (2.33)\end{aligned}$$

Therefore, by (2.32) and (2.28), we have

$$\begin{array}{l}\frac{\partial v^-}{\partial t} - d\Delta v^- - f(v^-(x,t), v^-(x,t-\tau))\\ \leq -\min\left\{f_0(u); u\in\left[a^+ + \frac{\delta}{2}, 1-\delta\right]\right\}\\ \quad +(\epsilon+\tau\epsilon m_1 + d\epsilon^2) < 0.\end{array}$$

Case (iii) $\zeta(\epsilon(x-Ct)) \in \left[\frac{\delta}{2}, 1-\frac{\delta}{2}\right]$: By (2.32) and (2.29), we have

$$\begin{aligned}\frac{\partial v^-}{\partial t} - d_0\Delta v^- - f(v^-(x,t), v^-(x,t-\tau)) \leq{}& -C\epsilon a^+ m_2 + \max\{|f_0(u)|;\\ & u\in[-\delta, 1-\delta]\}\\ & +(\epsilon+\tau\epsilon m_1 + d\epsilon^2) < 0.\end{aligned}$$

Combining cases (i)–(iii), we have

$$\frac{\partial v^-}{\partial t} - d\Delta v^- - f(v^-(x,t), v^-(x,t-\tau)) \leq 0, \quad x\in R, \quad t\geq 0.$$

Then $v^-(x,t)$ is a subsolution of (2.1) on $[0,\infty)$. In a similar way, we can prove $v^+(x,t)$ is a supersolution of (2.1) on $[0,\infty)$.

This completes the proof. □

REMARK 2.2. *It is easy to see $v^+(x,t)$ and $v^-(x,t)$ in Lemma 2.4 have the following properties:*

(P1) *$v^+(x,t) = 1+\delta$ for all $x\geq \xi + C\tau$ and $t\in[-\tau,0]$; $v^+(x,t)\geq a^- - \delta$ for all $x\in R$ and $t\in[-\tau,0]$; $v^+(x,t)\leq \delta + (a-2\delta)e^{-\epsilon t}$ for all $x\leq \xi - Ct - 4\epsilon^{-1}$ and $t\in[0,\infty)$.*

(P2) *$v^-(x,t) = -\delta$ for all $x\leq \xi - C\tau$ and $t\in[-\tau,0]$; $v^-(x,t)\leq a^+ + \delta$ for all $x\in R$ and $t\in[-\tau,0]$; $v^-(x,t)\geq 1-\delta-(1-a^+-2\delta)e^{-\epsilon t}$ for all $x\geq \xi + Ct + 4\epsilon^{-1}$ and $t\in[0,\infty)$.*

LEMMA 2.5. *For any traveling wave solution $U(x-ct)$ of (2.1) with $0\leq U(\xi)\leq 1, \xi\in R$, there holds $\lim_{\xi\to\pm\infty} U'(\xi) = 0$.*

Proof. We prove only $\lim_{\xi\to+\infty} U'(\xi) = 0$ since $\lim_{\xi\to-\infty} U'(\xi) = 0$ follows by the transformation $V(\xi) = U(-\xi)$. By Theorem 2.2, $U(\cdot)\in C^2(R)$ and $U(\xi)$ satisfy (2.20). In the case where $c=0$, (2.20) implies that $U''(\cdot)$ is bounded on R, and hence, $U'(\cdot)$ is uniformly continuous on R. Then, by (2.17) and the Barbalat lemma (see, e.g., [5]), $\lim_{\xi\to+\infty} U'(\xi) = 0$. In the case where $c\neq 0$, we first claim that $\lim_{\xi\to+\infty} U'(\xi)$ exists. Assume that, by contradiction, $\liminf_{\xi\to+\infty} U'(\xi) < \limsup_{\xi\to+\infty} U'(\xi)$. Then, by the fluctuation lemma (see [6]), there are two sequences $\{\xi_n\}_{n=1}^\infty$ and $\{s_n\}_{n=1}^\infty$ with $\xi_n\to+\infty$ and $s_n\to+\infty$ as $n\to+\infty$ such that

$$\lim_{n\to+\infty} U'(\xi_n) = \limsup_{\xi\to+\infty} U'(\xi), \quad U''(\xi_n) = 0, \quad n\geq 1$$

and

$$\lim_{n\to+\infty} U'(s_n) = \liminf_{\xi\to+\infty} U'(\xi), \quad U''(s_n) = 0, \quad n \geq 1.$$

Since $\lim_{\xi\to+\infty} U(\xi) = 1$ and $f(1,1) = 0$, letting $n \to +\infty$ in (2.20) with ξ replaced by ξ_n and s_n, respectively, we get that $\limsup_{\xi\to+\infty} U'(\xi) = 0 = \liminf_{\xi\to+\infty} U'(\xi)$, which is a contradiction to our assumption. Let $\lim_{\xi\to+\infty} U'(\xi) = L$. Since $U(n+1) - U(n) = U'(t_n)$, where $t_n \in [n, n+1]$, letting $n \to \infty$, we have $L = 1 - 1 = 0$.

This completes the proof. □

3. Stability and uniqueness of traveling waves. In this section we will discuss the global asymptotic stability with shift and stability of monotone traveling waves and uniqueness of traveling waves. To prove our main results, we need the following two lemmas.

Let $U(x-ct)$ be a monotone traveling wave solution of (2.1). In view of Lemma 2.3, we define the following two functions:

$$\begin{gathered} w^{\pm}(x,t,\eta,\delta) = U(x - ct + \eta \pm \sigma_0\delta(1 - e^{-\beta_0 t})) \pm \delta e^{-\beta_0 t}, \\ x \in R, \quad t \in [-\tau, \infty), \quad \eta \in R, \text{ and } \delta \in [0, \infty), \end{gathered}$$

where σ_0, β_0 are as in Lemma 2.3. By the proof of Lemma 2.3 we can choose $\beta_0 > 0$ as small as we wish. Then we assume that β_0 has been chosen such that $3e^{\beta_0\tau} < 4$ throughout this section.

LEMMA 3.1. *Let $U(x-ct)$ be a monotone traveling wave solution of* (2.1). *Then there exists a positive number ϵ^* such that, if $u(x,t)$ is a solution of* (2.1) *on* $[0,\infty)$ *with $0 \leq u(x,t) \leq 1$ for $x \in R$ and $t \in [0,\infty)$, and for some $\xi \in R$, $h > 0$, $0 < \delta < \min\left(\bar{\delta}, \frac{1}{\sigma_0}\right)$ and $T \geq 0$, there holds*

$$\begin{gathered} w_0^-(x, -cT + \xi, \delta)(s) \leq u_T(x)(s) \leq w_0^+(x, -cT + \xi + h, \delta)(s), \\ s \in [-\tau, 0], x \in R; \end{gathered}$$

then for every $t \geq T + \tau + 1$, there exist $\hat{\xi}(t), \hat{\delta}(t)$, and $\hat{h}(t)$ such that

$$\begin{gathered} w_0^-(x, -ct + \hat{\xi}(t), \hat{\delta}(t))(s) \leq u_t(x)(s) \leq w_0^+(x, -ct + \hat{\xi}(t) + \hat{h}(t), \hat{\delta}(t))(s), \\ s \in [-\tau, 0], \quad x \in R, \end{gathered}$$

with $\hat{\xi}(t), \hat{\delta}(t)$, and $\hat{h}(t)$ satisfying

$$\hat{\xi}(t) \in [\xi - \sigma_0\delta - 2\sigma_0(\delta + \epsilon^* \min(h,1))e^{\beta_0\tau}, \xi + h + \sigma_0\delta],$$

$$\hat{\delta}(t) = (\delta e^{-\beta_0} + \epsilon^* \min(1,h))e^{-\beta_0(t-(T+\tau+1))},$$

$$\hat{h}(t) \in [0, h + (3e^{\beta_0\tau} - 4)\sigma_0\epsilon^* \min(h,1) + 3e^{\beta_0\tau}\sigma_0\delta].$$

Proof. By Lemma 2.3, $w^+(x,t,-cT+\xi+h,\delta)$ and $w^-(x,t,-cT+\xi,\delta)$ are super- and subsolutions of (2.1), respectively. Clearly, $v(x,t) = u(x,T+t)$, $t \geq 0$, is also a solution of (2.1) with $v_0(x)(s) = u_T(x)(s)$, $s \in [-\tau, 0]$, $x \in R$. Then, by Theorem 2.2, there holds

$$\begin{gathered} w^-(x,t,-cT+\xi,\delta) \leq u(x,T+t) \leq w^+(x,t,-cT+\xi+h,\delta), \\ x \in R, t \geq 0. \end{gathered} \tag{3.1}$$

That is,

$$\begin{aligned} &U(x-c(T+t)+\xi-\sigma_0\delta(1-e^{-\beta_0 t}))-\delta e^{-\beta_0 t}\\ &\quad \leq u(x,T+t)\\ &\quad \leq U(x-c(T+t)+\xi+h+\sigma_0\delta(1-e^{-\beta_0 t}))\\ &\qquad +\delta e^{-\beta_0 t}, \quad x\in R, t\geq 0. \end{aligned} \tag{3.2}$$

Let $z=cT-\xi$. Again by Theorem 2.2, we have that for any $J\geq 0$, all $x\in R$ with $|x-z|\leq J$ and all $t>0$,

$$\begin{aligned} &u(x,T+t)-w^-(x,t,-cT+\xi,\delta)\\ &\quad\geq \theta(J,t)\int_z^{z+1}(u(y,T)-w^-(y,0,-cT+\xi,\delta))dy\\ &\quad=\theta(J,t)\int_z^{z+1}[u(y,T)-(U(y-cT+\xi)-\delta)]dy\\ &\quad=\theta(J,t)\left[\int_z^{z+1}(u(y,T)-U(y-cT+\xi))dy+\delta\right]. \end{aligned} \tag{3.3}$$

By Lemma 2.5, $\lim_{|\eta|\to\infty}U'(\eta)=0$. Then we can fix a positive number M such that $U'(\eta)\leq\frac{1}{2\sigma_0}$ for all $|\eta|\geq M$. Let $J=M+|c|(1+\tau)+1$, $\bar{h}=\min(1,h)$ and

$$\epsilon_1=\frac{1}{2}\min\{U'(x);|x|\leq 2\}>0.$$

Then

$$\int_z^{z+1}[U(y-cT+\xi+\bar{h})-U(y-cT+\xi)]dy=\int_0^1(U(y+\bar{h})-U(y))dy\geq 2\epsilon_1\bar{h},$$

and hence, at least one of the following is true:

(i) $\int_z^{z+1}[u(y,T)-U(y-cT+\xi)]dy\geq\epsilon_1\bar{h}$;

(ii) $\int_z^{z+1}[U(y-cT+\xi+\bar{h})-u(y,T)]dy\geq\epsilon_1\bar{h}$.

In what follows, we consider only the case (i). The case (ii) is similar and thus omitted. For any $s\in[-\tau,0]$, $|x-z|\leq J$, letting $t=1+\tau+s\geq 1$ in (3.3), we have

$$\begin{aligned} u(x,T+1+\tau+s)\geq{}& U(x-z-c(1+\tau+s)-\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)}))\\ &-\delta e^{-\beta_0(1+\tau+s)}+\theta_0(J)\epsilon_1\bar{h}, \end{aligned} \tag{3.4}$$

where $\theta_0(J)=\min_{s\in[-\tau,0]}\theta(J,1+\tau+s)$. Let

$$\begin{aligned} J_1&=J+|c|(1+\tau)+3,\\ \epsilon^*&=\min\left\{\min_{|x|\leq J_1}\frac{\theta_0(J)\epsilon_1}{2\sigma_0U'(x)},\frac{1}{3\sigma_0}\right\}. \end{aligned}$$

By the mean value theorem, it then follows that for all $|x-z|\leq J$, $s\in[-\tau,0]$,

$$\begin{aligned} &U(x-z-c(1+\tau+s)+2\sigma_0\epsilon^*\bar{h}-\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)}))\\ &-U(x-z-c(1+\tau+s)-\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)}))\\ &=U'(\eta_1)2\sigma_0\epsilon^*\bar{h}\leq\theta_0(J)\epsilon_1\bar{h}, \end{aligned} \tag{3.5}$$

and hence,

$$\begin{aligned} u(x,T+1+\tau+s) \geq\ & U(x-c(T+1+\tau+s)+\xi+2\sigma_0\epsilon^*\bar{h} \\ & -\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)}))-\delta e^{-\beta_0(1+\tau+s)}. \end{aligned} \tag{3.6}$$

By the choice of M and J and by the mean value theorem, it then follows that for all $|x-z|\geq J$, $s\in[-\tau,0]$,

$$\begin{aligned} & U(x-c(T+1+\tau+s)+\xi-\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)})) \\ & -U(x-c(T+1+\tau+s)+2\sigma_0\epsilon^*\bar{h}+\xi-\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)})) \\ & = U'(\eta_2)(-2\sigma_0\epsilon^*\bar{h}) \geq -\epsilon^*\bar{h}. \end{aligned} \tag{3.7}$$

That is, for all $|x-z|\geq J$, $s\in[-\tau,0]$,

$$\begin{aligned} & U(x-c(T+1+\tau+s)+\xi-\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)})) \\ & \quad \geq U(x-c(T+1+\tau+s)+\xi+2\sigma_0\epsilon^*\bar{h} \\ & \qquad -\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)}))-\epsilon^*\bar{h}, \end{aligned} \tag{3.8}$$

and hence, by (3.2) with $t=1+\tau+s$, we have

$$\begin{aligned} u(x,T+1+\tau+s) \geq\ & U(x-c(T+1+\tau+s)+\xi+2\sigma_0\epsilon^*\bar{h} \\ & -\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)})) \\ & -\epsilon^*\bar{h}-\delta e^{-\beta_0(1+\tau+s)} \end{aligned} \tag{3.9}$$

for all $|x-z|\geq J,\quad s\in[-\tau,0]$. By (3.6) and (3.9), it follows that for all $x\in R$, $x\in[-\tau,0]$,

$$\begin{aligned} u(x,T+1+\tau+s) \geq\ & U(x-c(T+1+\tau+s)+\xi+2\sigma_0\epsilon^*\bar{h} \\ & -\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)})) \\ & -\delta e^{-\beta_0(1+\tau+s)}-\epsilon^*\bar{h}, \end{aligned} \tag{3.10}$$

and hence,

$$\begin{aligned} u_{T+1+\tau}(x)(s) \geq\ & U(x-cs+[-c(T+1+\tau)+\xi+2\sigma_0\epsilon^*\bar{h} \\ & -\sigma_0\delta(1-e^{-\beta_0(1+\tau+s)})+\sigma_0(\delta e^{-\beta_0}+\epsilon^*\bar{h})(1-e^{-\beta_0 s}) \\ & -\sigma_0(\delta e^{-\beta_0}+\epsilon^*\bar{h})(1-e^{-\beta_0 s})])-(\delta e^{-\beta_0}+\epsilon^*\bar{h})e^{-\beta_0 s} \\ \geq\ & U(x-cs+(-c(T+1+\tau)+\xi+2\sigma_0\epsilon^*\bar{h}+\bar{\xi}) \\ & -\sigma_0(\delta e^{-\beta_0}+\epsilon^*\bar{h})(1-e^{-\beta_0 s})) \\ & -(\delta e^{-\beta_0}+\epsilon^*\bar{h})e^{-\beta_0 s}, \end{aligned} \tag{3.11}$$

where

$$\bar{\xi} = -\sigma_0\delta+\sigma_0(\delta e^{-\beta_0}+\epsilon^*\bar{h})(1-e^{\beta_0\tau}). \tag{3.12}$$

Then

$$u_{T+1+\tau}(x)(s) \geq w_0^-(x,\eta,\delta e^{-\beta_0}+\epsilon^*\bar{h})(s), \quad x\in R, s\in[-\tau,0], \tag{3.13}$$

where $\eta=-c(T+1+\tau)+\xi+2\sigma_0\epsilon^*\bar{h}+\bar{\xi}$. Again, by Theorem 2.2,

$$u_{T+1+\tau+t'}(x)(s) \geq w_{t'}^-(x,\eta,\delta e^{-\beta_0}+\epsilon^*\bar{h})(s) \quad \text{for all } t'\geq 0, s\in[-\tau,0]. \tag{3.14}$$

Then for any $t \geq T + 1 + \tau$, setting $t' = t - (T + 1 + \tau)$ in (3.14), we have

$$\begin{aligned} u_t(x)(s) &\geq w^-_{t-(T+1+\tau)}(x, \eta, \delta e^{-\beta_0} + \epsilon^* \bar{h})(s) \\ &= U(x - cs - ct + c(T + 1 + \tau) + \eta - \sigma_0(\delta e^{-\beta_0} + \epsilon^* \bar{h}) \cdot \\ &\quad (1 - e^{-\beta_0(t-(T+1+\tau))} \cdot e^{-\beta_0 s})) \\ &\quad -(\delta e^{-\beta_0} + \epsilon^* \bar{h}) e^{-\beta_0(t-(T+1+\tau))} \cdot e^{-\beta_0 s} \\ &\geq U(x - cs - ct + c(T + 1 + \tau) + \eta - \sigma_0(\delta e^{-\beta_0} + \epsilon^* \bar{h}) \cdot 1 \\ &\quad +\sigma_0 \hat{\delta}(t)(1 - e^{-\beta_0 s}) - \sigma_0 \hat{\delta}(t)(1 - e^{-\beta_0 s})) - \hat{\delta}(t) e^{-\beta_0 s} \\ &\geq U(x - cs - ct + c(T + 1 + \tau) + \eta - \sigma_0(\delta e^{-\beta_0} + \epsilon^* \bar{h}) \\ &\quad +\sigma_0 \hat{\delta}(t)(1 - e^{\beta_0 \tau})] - \sigma_0 \hat{\delta}(t)(1 - e^{-\beta_0 s})) - \hat{\delta}(t) \cdot e^{-\beta_0 s}, \end{aligned} \tag{3.15}$$

where $\hat{\delta}(t) = (\delta e^{-\beta_0} + \epsilon^* \bar{h}) \cdot e^{-\beta_0(t-(T+1+\tau))}$. By the monotonicity of $U(\cdot)$, the choice of η and (3.12), it then follows that

$$u_t(x)(s) \geq w^-_0(x, -ct + \hat{\xi}(t), \hat{\delta}(t))(s), \quad s \in [-\tau, 0], x \in R, \tag{3.16}$$

where

$$\begin{aligned} \hat{\xi}(t) &= \xi + 2\sigma_0 \epsilon^* \bar{h} + [-\sigma_0 \delta + \sigma_0(\delta e^{-\beta_0} + \epsilon^* \bar{h})(1 - e^{\beta_0 \tau})] \\ &\quad -\sigma_0(\delta e^{-\beta_0} + \epsilon^* \bar{h}) + \sigma_0 \hat{\delta}(t)(1 - e^{\beta_0 \tau}) \\ &= \xi + 2\sigma_0 \epsilon^* \bar{h} - \sigma_0 \delta - \sigma_0(\delta e^{-\beta_0} + \epsilon^* \bar{h}) e^{\beta_0 \tau} \\ &\quad +\sigma_0 \hat{\delta}(t) - \sigma_0 \hat{\delta}(t) e^{\beta_0 \tau}. \end{aligned}$$

Therefore it follows that

$$\begin{aligned} \hat{\xi}(t) &\geq \xi - \sigma_0 \delta - \sigma_0(\delta e^{-\beta_0} + \epsilon^* \bar{h}) e^{\beta_0 \tau} - \sigma_0 \hat{\delta}(t) e^{\beta_0 \tau} \\ &\geq \xi - \sigma_0 \delta - 2\sigma_0(\delta e^{-\beta_0} + \epsilon^* \bar{h}) e^{\beta_0 \tau} \\ &\geq \xi - \sigma_0 \delta - 2\sigma_0(\delta + \epsilon^* \bar{h}) e^{\beta_0 \tau}, \end{aligned} \tag{3.17}$$

and, by the choice of ϵ^*,

$$\begin{aligned} \hat{\xi}(t) &\leq \xi + 2\sigma_0 \epsilon^* \bar{h} + \sigma_0(\delta e^{-\beta_0} + \epsilon^* \bar{h}) \\ &\leq \xi + 3\sigma_0 \epsilon^* \bar{h} + \sigma_0 \delta \\ &\leq \xi + h + \sigma_0 \delta. \end{aligned} \tag{3.18}$$

For any $t \geq T$, by the inequality of the right-hand side of (3.2), we have

$$u(x, t) \leq U(x - ct + \xi + h + \sigma_0 \delta(1 - e^{-\beta_0(t-T)})) + \delta e^{-\beta_0(t-T)}. \tag{3.19}$$

It then follows that, for all $t \geq T + 1 + \tau$,

$$\begin{aligned} u_t(x)(s) = u(x, t + s) \leq U(x &- c(t + s) + \xi + h \\ &+\sigma_0 \delta(1 - e^{-\beta_0(t+s-T)})) + \delta e^{-\beta_0(t+s-T)}, \\ &s \in [-\tau, 0], x \in R. \end{aligned} \tag{3.20}$$

Therefore for all $t \geq T + 1 + \tau$,

$$\begin{aligned} u_t(x)(s) &\leq U(x - cs - ct + \xi + h + \sigma_0 \delta(1 - e^{-\beta_0(t+s-T)})) + \hat{\delta}(t) e^{-\beta_0 s} \\ &= U(x - cs - ct + \xi + h + \sigma_0 \delta(1 - e^{-\beta_0(t-T)} \cdot e^{-\beta_0 s}) \\ &\quad -\sigma_0 \hat{\delta}(t)(1 - e^{-\beta_0 s}) + \sigma_0 \hat{\delta}(t)(1 - e^{-\beta_0 s})) + \hat{\delta}(t) e^{-\beta_0 s} \\ &\leq U(x - cs - ct + \xi + h + \sigma_0 \delta - \sigma_0 \hat{\delta}(t)(1 - e^{\beta_0 \tau}) \\ &\quad +\sigma_0 \hat{\delta}(t)(1 - e^{-\beta_0 s})) + \hat{\delta}(t) e^{-\beta_0 s}, \quad s \in [-\tau, 0], x \in R. \end{aligned} \tag{3.21}$$

It then follows that for all $t \geq T + 1 + \tau$,

$$u_t(x)(s) \leq w_0^+(x, -ct + \hat{\xi}(t) + \hat{h}(t), \hat{\delta}(t))(s), \quad s \in [-\tau, 0], x \in R, \tag{3.22}$$

where

$$\begin{aligned}\hat{h}(t) &= \xi + h + \sigma_0\delta - \sigma_0\hat{\delta}(t)(1 - e^{\beta_0\tau}) - \hat{\xi}(t)\\ &= h - 2\sigma_0\epsilon^*\bar{h} + 2\sigma_0\delta + 2\sigma_0\hat{\delta}(t)(e^{\beta_0\tau} - 1)\\ &\quad +\sigma_0(\delta e^{-\beta_0} + \epsilon^*\bar{h})e^{\beta_0\tau}.\end{aligned}\tag{3.23}$$

Notice that we have used the expression of $\hat{\xi}(t)$ in getting the second equality of (3.23). By the choice of ϵ^*, we have $h - 2\sigma_0\epsilon^*\bar{h} \geq h - 2\sigma_0\epsilon^* h = (1 - 2\sigma_0\epsilon^*)h > 0$, and hence,

$$\begin{aligned}0 < \hat{h}(t) &\leq h - 2\sigma_0\epsilon^*\bar{h} + 2\sigma_0\delta + 2\sigma_0(\delta e^{-\beta_0} + \epsilon^*\bar{h}) \cdot (e^{\beta_0\tau} - 1)\\ &\quad +\sigma_0(\delta e^{-\beta_0} + \epsilon^*\bar{h})e^{\beta_0\tau}\\ &\leq h - 2\sigma_0\epsilon^*\bar{h} + 2\sigma_0\delta + \sigma_0(\delta e^{-\beta_0} + \epsilon^*\bar{h}) \cdot (3e^{\beta_0\tau} - 2)\\ &\leq h - 2\sigma_0\epsilon^*\bar{h} + 2\sigma_0\delta + \sigma_0(\delta + \epsilon^*\bar{h})(3e^{\beta_0\tau} - 2)\\ &= h + (3e^{\beta_0\tau} - 4)\sigma_0\epsilon^*\bar{h} + 3e^{\beta_0\tau} \cdot \sigma_0\delta.\end{aligned}\tag{3.24}$$

Combining (3.16) and (3.22), now we complete the proof. □

LEMMA 3.2. *Let $U(x - ct)$ be a monotone traveling wave solution of* (2.1)*, and let $\varphi \in [0, 1]_C$ be such that*

$$\liminf_{x\to\infty} \min_{s\in[-\tau,0]} \varphi(x, s) > a^+, \quad \limsup_{x\to-\infty} \max_{s\in[-\tau,0]} \varphi(x, s) < a^-.$$

Then, for any $\delta > 0$, there exist $T = T(\varphi, \delta) > 0$, $\xi = \xi(\varphi, \delta) \in R$, and $h = h(\varphi, \delta) > 0$ such that

$$\begin{gathered}w_0^-(x, -cT + \xi, \delta)(s) \leq u_T(x, \varphi)(s) \leq w_0^+(x, -cT + \xi + h, \delta)(s),\\ s \in [-\tau, 0], x \in R.\end{gathered}$$

Proof. By Theorem 2.2, $u(x, t, \varphi)$ exists globally on $[0, \infty)$ and $0 \leq u(x, t, \varphi) \leq 1$, $x \in R$, $t \geq 0$. For any $\delta > 0$, we choose a $0 < \delta_1 = \delta_1(\delta, \varphi) < \min(\delta, \bar{\delta}_0)$ such that

$$\liminf_{x\to\infty} \min_{s\in[-\tau,0]} \varphi(x, s) > a^+ + \delta_1,$$

$$\limsup_{x\to-\infty} \max_{s\in[-\tau,0]} \varphi(x, s) < a^- - \delta_1.$$

Then there exists $M = M(\varphi, \delta_1) > 0$ such that

$$\begin{aligned}&\varphi(x, s) \leq a^- - \delta_1 \quad \text{for all } x \leq -M \text{ and } s \in [-\tau, 0],\\ &\varphi(x, s) \geq a^+ + \delta_1 \quad \text{for all } x \geq M \text{ and } s \in [-\tau, 0].\end{aligned}\tag{3.25}$$

Let $\epsilon = \epsilon(\delta_1)$ and $C = C(\delta_1)$ be defined in Lemma 2.4 with δ replaced by δ_1. Define $\xi^+ = -M - C\tau$ and $\xi^- = M + C\tau$, and let $v^\pm(x, t)$ be defined in Lemma 2.4 with $\xi = \xi^\pm$, respectively. By (3.25) and Remark 2.2, it follows that for all $s \in [-\tau, 0]$,

$$\begin{aligned}&\varphi(x, s) \leq a^- - \delta_1 \leq v^+(x, s) &&\text{for } x \leq -M,\\ &\varphi(x, s) \leq 1 < 1 + \delta_1 = v^+(x, s) &&\text{for } x \geq \xi^+ + C\tau = -M\end{aligned}$$

and

$$\begin{aligned}&\varphi(x,s) \geq a^{+} + \delta_1 \geq v^{-}(x,s) \quad \text{for } x \geq M,\\ &\varphi(x,s) \geq 0 > -\delta_1 = v^{-}(x,s) \quad \text{for } x \leq \xi^{-} - C\tau = M.\end{aligned}$$

Then we have

$$v^{-}(x,s) \leq \varphi(x,s) \leq v^{+}(x,s), \quad x \in R, s \in [-\tau, 0]. \tag{3.26}$$

By Lemma 2.4 and Theorem 2.2, it follows that

$$v^{-}(x,t) \leq u(x,t,\varphi) \leq v^{+}(x,t), \quad x \in R, t \geq 0. \tag{3.27}$$

Since $\delta_1 < \delta$, we choose a sufficiently large positive number $T > \tau$ such that, for all $t \geq T - \tau$,

$$\delta_1 + (a^{-} - 2\delta_1)e^{-\epsilon t} < \delta \quad \text{and } 1 - \delta_1 - (1 - a^{+} - 2\delta_1)e^{-\epsilon t} > 1 - \delta,$$

and hence, again by Remark 2.2,

$$u(x,t,\varphi) \leq v^{+}(x,t) < \delta \quad \text{for } x \leq \xi^{+} - Ct - 4\epsilon^{-1} \tag{3.28}$$

and

$$u(x,t,\varphi) \geq v^{-}(x,t) > 1 - \delta \quad \text{for } x \geq \xi^{-} + Ct + 4\epsilon^{-1}. \tag{3.29}$$

Let $x^{-} = \xi^{+} - CT - 4\epsilon^{-1}$ and $x^{+} = \xi^{-} + CT + 4\epsilon^{-1}$. By (3.28) and (3.29), it follows that for any $t \in [T - \tau, T]$,

$$\begin{aligned}&u(x,t,\varphi) < \delta \quad \text{for } x \leq x^{-}\\ &u(x,t,\varphi) > 1 - \delta \quad \text{for } x \geq x^{+}.\end{aligned} \tag{3.30}$$

By (2.17), there exists a sufficiently large positive number H such that $\frac{H}{2} > x^{+}$, $-\frac{H}{2} < x^{-}$, and

$$U(x) + \delta > 1 \quad \text{for all } x \geq \frac{H}{2} \quad \text{and } U(x) - \delta < 0 \quad \text{for all } x \leq -\frac{H}{2}. \tag{3.31}$$

Combining (3.30), (3.31), and the fact that $0 \leq U(x) \leq 1$ and $0 \leq u(x,t,\varphi) \leq 1$ for all $x \in R$ and $t \in [0, \infty)$, we then have

$$U(-H+x) - \delta \leq u(x,t,\varphi) \leq U(H+x) + \delta \quad \text{for all } x \in R \quad \text{and } t \in [T-\tau, T]. \tag{3.32}$$

Let $\xi_0 = -H + cT$, $h_0 = 2H > 0$. Then (3.32) implies that

$$U(x - cT + \xi_0) - \delta \leq u_T(x,\varphi)(s) \leq U(x - cT + \xi_0 + h_0) + \delta, \quad s \in [-\tau, 0], \quad x \in R. \tag{3.33}$$

Let $\xi = \xi_0 + \sigma_0\delta(1 - e^{\beta_0\tau}) - |c|\tau$ and $h = h_0 - 2\sigma_0\delta(1 - e^{\beta_0\tau}) + 2|c|\tau > 0$. Then by (3.33), we have that for any $s \in [-\tau, 0]$ and $x \in R$,

$$\begin{aligned}&w_0^{-}(x, -cT + \xi, \delta)(s)\\ &\quad = U(x - cs - cT + \xi - \sigma_0\delta(1 - e^{-\beta_0 s})) - \delta e^{-\beta_0 s}\\ &\quad \leq U(x + |c|\tau - cT + \xi - \sigma_0\delta(1 - e^{\beta_0\tau})) - \delta\\ &\quad = U(x - cT + \xi_0) - \delta \leq u_T(x,\varphi)(x)\end{aligned}$$

and

$$\begin{aligned}&w_0^+(x, -cT + \xi + h, \delta)(s)\\ &\quad = U(x - cs - cT + \xi + h + \sigma_0\delta(1 - e^{-\beta_0 s})) + \delta e^{-\beta_0 s}\\ &\quad \geq U(x - |c|\tau - cT + \xi + h + \sigma_0\delta(1 - e^{\beta_0\tau})) + \delta\\ &\quad = U(x - cT + \xi_0 + h_0) + \delta \geq u_T(x, \varphi)(s).\end{aligned}$$

It then follows that

$$w_0^-(x, -cT + \xi, \delta)(s) \leq u_T(x, \varphi)(s) \leq w_0^+(x, -cT + \xi + h, \delta)(s).$$

This completes the proof. □

Now we are in a position to prove the main results in this section.

THEOREM 3.3. *Assume that* (2.1) *has a monotone traveling wave solution* $U(x - ct)$. *Then* $U(x - ct)$ *is globally asymptotically stable with phase shift in the sense that there exists* $k > 0$ *such that for any* $\varphi \in [0, 1]_C$ *with*

$$\liminf_{x\to\infty} \min_{s\in[-\tau,0]} \varphi(x, s) > a^+, \quad \limsup_{x\to-\infty} \max_{s\in[-\tau,0]} \varphi(x, s) < a^-;$$

the solution $u(x, t, \varphi)$ *of* (2.1) *satisfies*

$$|u(x, t, \varphi) - U(x - ct + \xi)| \leq Ke^{-kt}, \quad x \in R, t \geq 0$$

for some $K = K(\varphi) > 0$ *and* $\xi = \xi(\varphi) \in R$.

Proof. Let β_0, σ_0, $\bar{\delta}$ be as in Lemma 2.3 with β_0 chosen such that $3e^{\beta_0\tau} < 4$, and then let ϵ^* be as in Lemma 3.1 with ϵ^* chosen such that $(4 - 3e^{\beta_0\tau})\sigma_0 \cdot \epsilon^* < 1$. We further choose a $0 < \delta^* < \min(\frac{\delta_0}{2}, \bar{\delta}, \frac{1}{\sigma_0})$ such that

$$1 > k^* := (4 - 3e^{\beta_0\tau})\sigma_0\epsilon^* - 3e^{\beta_0\tau}\sigma_0\delta^* > 0,$$

and then fix a $t^* \geq \tau + 1$ such that

$$e^{-\beta_0(t^*-\tau-1)}(1 + \epsilon^*/\delta^*) < 1 - k^*.$$

We first prove the following two claims.

Claim 1. There exist $T^* = T^*(\varphi) > 0$, $\xi^* = \xi^*(\varphi) \in R$ such that

$$\begin{aligned}&w_0^-(x, -cT^* + \xi^*, \delta^*)(s) \leq u_{T^*}(x, \varphi)(s) \leq w_0^+(x, -cT^* + \xi^* + 1, \delta^*)(s),\\ &\qquad\qquad s \in [-\tau, 0], x \in R.\end{aligned} \tag{3.34}$$

Indeed, by Lemma 3.2, there exist $T = T(\varphi) > 0$, $\xi = \xi(\varphi) \in R$, and $h = h(\varphi) > 0$ such that

$$w_0^-(x, -cT + \xi, \delta^*)(s) \leq u_T(x, \varphi)(s) \leq w_0^+(x, -cT + \xi + h, \delta^*)(s), \tag{3.35}$$

$$s \in [-\tau, 0], \quad x \in R.$$

If $h \leq 1$, (3.34) follows immediately from the monotonicity of $U(\cdot)$. Then we assume that $h > 1$ and let

$$N = \max\{m; m \text{ is a nonnegative integer and } mk^* < h\}.$$

Since $0 < k^* < 1$ and $h > 1$, we have $N \geq 1$, $Nk^* < h \leq (N+1)k^*$, and hence, $0 < h - Nk^* \leq (N+1)k^* - Nk^* = k^* < 1$. Clearly, $\bar{h} := \min(1, h) = 1$. By (3.35), Lemma 3.1 and the choice of t^* and k^*, it then follows that

$$\begin{aligned} w_0^-(x, -c(T+t^*) + \hat{\xi}(T+t^*), \hat{\delta}(T+t^*))(s) &\leq u_{T+t^*}(x, \varphi)(s) \\ &\leq w_0^+(x, -c(T+t^*) + \hat{\xi}(T+t^*) \\ &\quad + \hat{h}(T+t^*), \hat{\delta}(T+t^*))(s), \\ &\quad\ s \in [-\tau, 0], x \in R, \end{aligned} \tag{3.36}$$

where

$$\begin{aligned} &\hat{\xi}(T+t^*) \in [\xi - \sigma_0\delta^* - 2\sigma_0(\delta^* + \epsilon^*)e^{\beta_0\tau}, \xi + h + \sigma_0\delta^*], \\ &\hat{\delta}(T+t^*) = (\delta^* e^{-\beta_0} + \epsilon^*)e^{-\beta_0(t^*-\tau-1)} \leq (1-k^*)\delta^* < \delta^*, \\ &0 \leq \hat{h}(T+t^*) \leq h + (3e^{\beta_0\tau} - 4)\sigma_0\epsilon^* + 3e^{\beta_0\tau}\sigma_0\delta^* = h - k^*. \end{aligned}$$

Repeating the same process N times, we have that (3.36), with $T + t^*$ replaced by $T + Nt^*$, holds for some $\hat{\xi} \in R$, $0 < \hat{\delta} \leq \delta^*$, and $0 \leq \hat{h} \leq h - Nk^* < 1$. Let $T^* = T + Nt^*$, $\xi^* = \hat{\xi}$. Again, by the monotonicity of $U(\cdot)$, (3.34) then follows.

Claim 2. Let $p = 2\sigma_0\delta^* + 2\sigma_0(\delta^* + \epsilon^*)e^{\beta_0\tau} + 1$, $T_m = T^* + mt^*$, $\delta_m^* = (1-k^*)^m\delta^*$, and $h_m = (1-k^*)^m$, $m \geq 0$. Then there exists a sequence $\{\xi_m\}_{m=0}^{\infty} \subset R$ with $\xi_0 = \xi^*$ such that

$$|\xi_{m+1} - \xi_m| \leq ph_m, \quad m \geq 0 \tag{3.37}$$

and

$$\begin{aligned} w_0^-(x, -cT_m + \xi_m, \delta_m^*)(s) &\leq u_{T_m}(x, \varphi)(s) \\ &\leq w_0^+(x, -cT_m + \xi_m + h_m, \delta_m^*)(s), \\ &\quad\ s \in [-\tau, 0], \quad x \in R, m \geq 0. \end{aligned} \tag{3.38}$$

In fact, Claim 1 implies that (3.38) holds for $m = 0$. Now suppose that (3.38) holds for some $m = l \geq 0$. By Lemma 3.1 with $T = T_l$, $\xi = \xi_l$, $h = h_l$, $\delta = \delta_l^*$, and $t = T_l + t^* = T_{l+1}$ (since $t^* \geq \tau + 1$), we then have

$$w_0^-(x, -cT_{l+1} + \hat{\xi}, \hat{\delta})(s) \leq u_{T_{l+1}}(x, \varphi)(s) \leq w_0^+(x, -cT_{l+1} + \hat{\xi} + \hat{h}, \hat{\delta})(s), \tag{3.39}$$

$$s \in [-\tau, 0], \quad x \in R,$$

where

$$\begin{aligned} \hat{\xi} &\in [\xi_l - \sigma_0\delta_l^* - 2\sigma_0(\delta_l^* + \epsilon^* h_l)e^{\beta_0\tau},\ \xi_l + h_l + \sigma_0\delta_l^*], \\ \hat{\delta} &= (\delta_l e^{-\beta_0} + \epsilon^* h_l)e^{-\beta_0(T_{l+1} - T_l - \tau - 1)} \\ &\quad \leq (1-k^*)^l \cdot \delta^* \left[\left(1 + \frac{\epsilon^*}{\delta^*}\right) e^{-\beta_0(t^*-\tau-1)}\right] \\ &\quad \leq (1-k^*)^l \cdot \delta^*(1-k^*) = \delta_{l+1}^*, \\ \hat{h} &\leq h_l - (4 - 3e^{\beta_0\tau})\sigma_0\epsilon^* h_l + 3e^{\beta_0\cdot\tau}\sigma_0\ \delta_l \\ &\quad = (1-k^*)^l \cdot [1 - (4 - 3e^{\beta_0\tau})\sigma_0\epsilon^* + 3e^{\beta_0\tau}\sigma_0\delta^*] \\ &\quad = (1-k^*)^{l+1} = h_{l+1}. \end{aligned}$$

We choose $\xi_{l+1} = \hat{\xi}$. Then

$$|\xi_{l+1} - \xi_l| \leq |\xi_l + h_l + \sigma_0\delta_l^* - (\xi_l - \sigma_0\delta_l^* - 2\sigma_0(\delta_l^* + \epsilon^* h_l) \cdot e^{\beta_0\tau})| = p \cdot h_l.$$

It then follows that (3.37) holds for $m = l$ and (3.38) holds for $m = l+1$. By induction, (3.37) and (3.38) hold for all $m \geq 0$.

For each $m \geq 0$, by (3.38) and Theorem 2.2, it follows that for all $t \geq T_m$, $x \in R$,

$$\begin{aligned} &U(x - ct + \xi_m - \sigma_0\delta_m^*(1 - e^{-\beta_0(t-T_m)})) - \delta_m^* e^{-\beta_0(t-T_m)} \leq u(x, t, \varphi) \\ &\leq U(x - ct + \xi_m + h_m + \sigma_0\delta_m^*(1 - e^{-\beta_0(t-T_m)})) + \delta_m^* e^{-\beta_0(t-T_m)}. \end{aligned} \tag{3.40}$$

For any $t \geq T^*$, let $m = [\frac{t-T^*}{t^*}] \geq 0$ be the largest integer not greater than $\frac{t-T^*}{t^*}$, and define $\delta(t) = \delta_m^*$, $\xi(t) = \xi_m - \sigma_0\delta_m^*$, and $h(t) = h_m + 2\sigma_0\delta_m^*$; then we have $T_m = T^* + mt^* \leq t < T^* + (m+1)t^* = T_{m+1}$. By (3.40), it follows that for all $t \geq T^*$, $x \in R$,

$$U(x - ct + \xi(t)) - \delta(t) \leq u(x, t, \varphi) \leq U(x - ct + \xi(t) + h(t)) + \delta(t). \tag{3.41}$$

Moreover, we have

$$\delta(t) = \delta_m^* = [1 - k^*]^m \delta^* \leq \delta^* \exp\left\{\left(\frac{t - T^*}{t^*} - 1\right)\ln(1 - k^*)\right\}, \quad t \geq T^*, \tag{3.42}$$

$$\begin{aligned} h(t) = h_m + 2\sigma_0\delta_m^* &= (1 + 2\sigma_0\delta^*)(1 - k^*)^m \\ &\leq (1 + 2\sigma_0\delta^*)\exp\left\{\left(\frac{t - T^*}{t^*} - 1\right)\ln(1 - k^*)\right\}, \quad t \geq T^*, \end{aligned} \tag{3.43}$$

and for any $r \geq t \geq T^*$, by (3.37),

$$\begin{aligned} |\xi(r) - \xi(t)| &= |\xi_m - \sigma_0\delta_m^* - (\xi_n - \sigma_0\delta_n^*)| \\ &\leq |\xi_m - \xi_n| + \sigma_0\delta_m^* + \sigma_0\delta_n^* \\ &\leq \sum_{l=n}^{m-1} |\xi_{l+1} - \xi_l| + 2\sigma_0\delta_n^* \\ &\leq \sum_{l=n}^{m-1} p \cdot h_l + 2\sigma_0\delta_n^* \\ &\leq \frac{ph_n}{1 - (1 - k^*)} + 2\sigma_0\delta_n^* \\ &= q \cdot \delta(t), \end{aligned} \tag{3.44}$$

where $m = \left[\frac{r-T^*}{t^*}\right] \geq n = \left[\frac{t-T^*}{t^*}\right]$ and $q = \frac{p}{k^*\delta^*} + 2\sigma_0$. Clearly, (3.44) implies that $\xi(\infty) = \lim_{t\to\infty} \xi(t)$ exists and

$$|\xi(\infty) - \xi(t)| \leq q\delta(t), \quad t \geq T^*.$$

Then

$$|\xi(t) - \xi(\infty)| \leq q \cdot \delta^* \exp\left\{\left(\frac{t - T^*}{t^*} - 1\right)\ln(1 - k^*)\right\}, \quad t \geq T^*. \tag{3.45}$$

Therefore, by defining $k = -\frac{1}{t^*}\ln(1-k^*) > 0$ and combining (3.41), (3.42), (3.43), and (3.45), we obtain the assertion of the theorem.

This completes the proof. □

THEOREM 3.4. *Every monotone traveling wave solution of* (2.1) *is Liapunov stable. If* (2.1) *has a monotone traveling wave solution $U(x-ct)$, then the traveling wave solutions of* (2.1) *are unique up to a translation in the sense that for any traveling wave solution $\bar{U}(x-\bar{c}t)$ with $0 \le \bar{U}(\xi) \le 1$, $\xi \in R$, we have $\bar{c} = c$ and $\bar{U}(\cdot) = U(\xi_0 + \cdot)$ for some $\xi_0 = \xi_0(\bar{U}) \in R$.*

Proof. Let $U(x-ct)$ be a monotone traveling wave solution of (2.1). By the uniform continuity of $U(\cdot)$ on R, it follows that for any $\epsilon > 0$, there exists a $\delta_1 = \delta_1(\epsilon) > 0$ such that for all $|y| \le \delta_1$,

$$|U(x-ct+y) - U(x-ct)| < \frac{\epsilon}{2}, \quad x \in R, t \ge 0. \tag{3.46}$$

We then further choose a $\delta = \delta(\epsilon) > 0$ such that $\delta < \min(\frac{\epsilon}{2}, \frac{\delta_1 \cdot e^{-\beta_0\tau}}{\sigma_0}, \bar{\delta})$, where β_0, σ_0, and $\bar{\delta}$ are as in Lemma 2.3. For any $\varphi \in C([-\tau,0],X)$ with $|\varphi(x,s) - U(x-cs)| < \delta$ for $s \in [-\tau,0]$ and $x \in R$, we have

$$\begin{aligned} &U(x-cs+\sigma_0\delta(1-e^{\beta_0\tau}) - \sigma_0\delta(1-e^{-\beta_0 s})) - \delta e^{-\beta_0 s} \\ &\quad \le \varphi(x,s) \le U(x-cs+\sigma_0\delta(e^{\beta_0\tau}-1) \\ &\qquad +\sigma_0\delta(1-e^{-\beta_0 s})) + \delta e^{-\beta_0 s}, \quad s \in [-\tau,0], x \in R. \end{aligned} \tag{3.47}$$

By Lemma 2.3 and Theorem 2.2, it then follows that

$$\begin{aligned} &U(x-ct+\sigma_0\delta(1-e^{\beta_0\tau}) - \sigma_0\delta(1-e^{-\beta_0 t})) - \delta e^{-\beta_0 t} \le u(x,t,\varphi) \\ &\quad \le U(x-ct+\sigma_0\delta(e^{\beta_0\tau}-1) + \sigma_0\delta(1-e^{-\beta_0 t})) \\ &\qquad +\delta e^{-\beta_0 t}, x \in R, t \ge 0. \end{aligned} \tag{3.48}$$

By the choice of $\delta = \delta(\epsilon)$, we have that for all $t \ge 0$,

$$\begin{aligned} |\sigma_0\delta(1-e^{\beta_0\tau}) - \sigma_0\delta(1-e^{-\beta_0 t})| &\le \sigma_0\delta(e^{\beta_0\tau}-1) + \sigma_0\delta(1-e^{-\beta_0 t}) \\ &\le \sigma_0\delta e^{\beta_0\tau} < \delta_1(\epsilon) \end{aligned}$$

and

$$|\sigma_0\delta(e^{\beta_0\tau}-1) + \sigma_0\delta(1-e^{-\beta_0 t})| \le \sigma_0\delta e^{\beta_0\tau} < \delta_1(\epsilon).$$

Then, by (3.46) and (3.48), it follows that $U(x-ct) - \epsilon \le u(x,t,\varphi) \le U(x-ct) + \epsilon$, $x \in R$, $t \ge 0$. That is, $|u(x,t,\varphi) - U(x-ct)| < \epsilon$, $x \in R$, $t \ge 0$. Therefore $U(x-ct)$ is Liapunov stable.

To prove the uniqueness, we let $U(x-ct)$ be the given monotone traveling wave solution, and let $\bar{U}(x-\bar{c}t)$ be any traveling wave solution of (2.1) with $0 \le \bar{U} \le 1$ on R. Since $\lim_{x\to\infty}\bar{U}(x-\bar{c}s) = 1$ and $\lim_{x\to-\infty}\bar{U}(x-\bar{c}s) = 0$ uniformly for $s \in [-\tau,0]$, we have

$$\begin{aligned} &\liminf_{x\to\infty} \min_{s\in[-\tau,0]} \bar{U}(x-\bar{c}s) > a^+ \quad \text{and} \\ &\limsup_{x\to-\infty} \max_{s\in[-\tau,0]} \bar{U}(x-\bar{c}s) < a^-. \end{aligned} \tag{3.49}$$

Then, by Theorem 3.3, there exists $K_0 = K_0(\bar{U}) > 0$ and $\xi_0 = \xi_0(\bar{U}) \in R$ such that

$$|\bar{U}(x-\bar{c}t) - U(x-ct+\xi_0)| \le K_0 e^{-kt}, \quad x \in R, \quad t \ge 0. \tag{3.50}$$

Let $\bar{\xi} \in R$ be such that $0 < \bar{U}(\bar{\xi}) < 1$, and define $L(\bar{\xi}) := \{(x,t); x \in R, t \geq 0, x - \bar{c}t = \bar{\xi}\}$. By (3.50), it then follows that

$$U(\bar{\xi} + \xi_0 + (\bar{c} - c)t) - K_0 e^{-kt} \leq \bar{U}(\bar{\xi}) \leq U(\bar{\xi} + \xi_0 + (\bar{c} - c)t) + K_0 e^{-kt} \quad \text{for all } (x,t) \in L(\bar{\xi}). \tag{3.51}$$

Since $U(\infty) = 1$ and $U(-\infty) = 0$, letting $t \to \infty$ in (3.51), we obtain that $\bar{c} \leq c$ from the first inequality and that $\bar{c} \geq c$ from the second inequality. Then $\bar{c} = c$. For any $\xi \in R$, again by (3.50), we then have

$$|\bar{U}(\xi) - U(\xi + \xi_0)| \leq K_0 e^{-kt} \quad \text{for all } (x,t) \in L(\xi). \tag{3.52}$$

Therefore, letting $t \to \infty$ in (3.52), we get $\bar{U}(\xi) = U(\xi + \xi_0)$ for all $\xi \in R$, that is, $\bar{U}(\cdot) = U(\xi_0 + \cdot)$.

This completes the proof. □

Remark 3.1. *For the typical Huxley nonlinearity*

$$f(u,v) = \begin{cases} u(1-u)(v-a) & \textit{for } 0 \leq u \leq 1, v \in R, \\ u(1-u)(u-a) & \textit{otherwise}, \end{cases}$$

with $0 < a < 1$, *let* $\hat{f} : I^2 \to R$ *be a smooth extension of* $f : [0,1]^2 \to R$ *such that* (H1) *and* (H2) *hold for* $\hat{f}$. *Clearly,* [7, Corollary 5] *implies that* $[0,1]_C$ *is positively invariant for* (2.1) *with* f *replaced by* $\hat{f}$. *It then follows that Theorems* 3.3 *and* 3.4 *hold for* (2.1) *with the Huxley nonlinearity.*

Remark 3.2. *With some additional assumptions on* $f(\cdot,\cdot)$, *Schaaf* [13] *proved the existence of the monotone traveling wave solution of* (2.1) *and uniqueness of the wave speeds. By Theorems* 3.3 *and* 3.4 *we further conclude that this monotone traveling wave solution is globally and exponentially asymptotically stable with phase shift, that all traveling waves are unique up to translation, and that every traveling wave solution is Liapunov stable.*

Acknowledgment. The authors would like to thank Professor H. Matano for valuable discussions during his visit to the Arizona State University.

QUALITATIVE BEHAVIOR OF SOLUTIONS OF CHEMOTACTIC DIFFUSION SYSTEMS: EFFECTS OF MOTILITY AND CHEMOTAXIS AND DYNAMICS*

XUEFENG WANG†

Abstract. Chemotaxis is the oriented movement of cells in response to the concentration gradient of chemical substances in their environment. We consider the situation of a single bacterial population which responds chemotactically to a nutrient diffusing from an adjacent phase not accessible to the bacteria. The concentration and density of the substrate and cells (resp.) satisfy a quasi-linear parabolic system with nonlinear boundary condition. Our first set of results addresses the effects of two important biological parameters $\lambda > 0$ and $\chi > 0$ on the steady states, where λ measures the (random) motility of bacteria and χ the magnitude of chemotactic response (or sensitivity) to the chemical. Our second set of results concerns the global boundedness of time-dependent solutions and stability issues of trivial and nontrivial steady states with small amplitudes.

Key words. chemotaxis, motility, monotonicity, Helly's theorem, concentration, blowup, bifurcation, existence and uniqueness, global boundedness, stability, decay rates, Moser–Alikakos iteration

1. Introduction and description of main results.

Chemotaxis is the oriented movement of cells in response to the concentration gradient of chemical substances in their environment. Motility, on the other hand, refers to the random diffusivity of cells. It is known that chemotaxis and motility can affect not only the distribution but also the growth of cells. Sometimes they can even be a decisive advantage for a species of cells in its competition for a limited resource with another species of less chemotactic or more motile cells which has even superior growth kinetics [LAK], [PW].

Keller and Segal [KS] seem to have been the first to propose mathematical models for chemotaxis. To illustrate the general idea in modeling chemotaxis, we consider a species of cells which responds chemotactically to a chemical. Let $u(x, t)$ and $v(x, t)$ be the concentration and density of the chemical and cells, respectively. If the chemical is diffusive, then by Fick's law the random diffusive flux is given by $-D_1\nabla u$, where $D_1 > 0$ is assumed to be a constant. The cell flux is assumed to be the combination of the random diffusive flux and chemotactic flux, with the latter parallel to ∇u, so the cell flux takes the form $-D_2\nabla v + \chi v\phi'(u)\nabla u$, where $D_2 > 0$ and χ are constants, and $\phi'(u) > 0$. D_2 is the *motility* of cells and measures the ability of cells to diffuse randomly; χ (positive if the chemical is an attractant and negative if it is a repellent) is called the *chemotaxis coefficient* and measures the magnitude of response of cells to the chemical. $\phi(u)$ is called the *sensitivity function*. We need the factor $\phi'(u)$ in the chemotaxis flux to reflect the fact that the sensitivity of cells to the chemical may vary at different levels of chemical concentration.

Now by the law of conservation of mass, we are led to the following quasi-linear

system

$$\begin{cases} u_t = D_1 \Delta u + h(u,v), \\ v_t = \nabla \cdot (D_2 \nabla v - \chi v \nabla \phi(u)) + k(u,v), \end{cases} \tag{1.1}$$

where $h(u,v)$ is the creation-degradation rate of the chemical and $k(u,v)$ is the birth-death rate of cells.

Physiologists are interested in the effects of cell motility and chemotaxis on the population growth. To elucidate such effects, Lauffenburger, Aris, and Keller [LAK] investigated the situation of a single bacterial population in a one-dimensional medium with finite length, with growth limited by a nutrient diffusing from an adjacent phase not accessible to the bacteria. Their mathematical model is the following (nondimensionalized form):

$$\begin{cases} u_t = u_{xx} - f(u)v, \ 0 \le x \le 1, \ t > 0, \\ v_t = (\lambda v_x - \chi v(\phi(u))_x)_x + (kf(u) - \theta)v, \\ u_x(0) = 0, \ u_x(1) = h(1 - u(1)), \\ \lambda v_x - \chi v(\phi(u))_x = 0 \quad \text{at} \quad x = 0, 1. \end{cases} \tag{1.2}$$

Here λ, χ, k, θ, and h are positive constants except that χ is allowed to equal zero; u is the concentration of the nutrient and v the density of the bacteria; $f(u)$ is the consumption rate of the nutrient per cell; the term $(kf(u) - \theta)v$ in the v-equation represents that the bacteria have a *Malthusian* (or exponential) growth with $kf(u)$ and θ measuring the birth and death rate of cells. The boundary condition for u at $x = 1$ reflects the assumption that the flux of u at $x = 1$ is proportional to the difference of chemical concentration on two sides of the point $x = 1$ with h being the proportionality constant. The boundary condition for v says that there is no flux for the cells at the boundary.

From biological and technical considerations, we require f and ϕ satisfying

$$\begin{gathered} f(0) = 0, \ f'(u) > 0, \quad \text{and} \quad \phi'(u) > 0 \quad \text{for} \quad u \in [0, \infty), \\ f \in C^3([0,\infty)) \quad \text{and} \quad \phi \in C^5([0,\infty)). \end{gathered} \tag{1.3}$$

Typical choices for f and ϕ are $f(u) = au/(b+u)$, $\phi(u) = u$, $\phi(u) = \log(c+u)$, $\phi(u) = u/(1+cu)$, etc. In [LAK], $\phi(u)$ is taken to be u.

Numerical simulations on *steady states* of (1.2) (with $\phi(u) = u$, χ proportional to λ) led the authors of [LAK] to the following interesting observations.

(C1) Random motility λ may lead to decreased population (at least in nonchemotactic case $\chi = 0$).

(C2) Chemotaxis coefficient χ acts to increase population size.

These are the primary motivations of the current paper. We shall

(i) study the effects of large or small λ or χ on positive steady states of (1.2);

(ii) do so when the bacteria have a different growth type (logistic growth, which was not considered in [LAK]);

(iii) study the important related dynamical issues, such as stability of steady states and boundedness of global solutions.

The results obtained do lead to new phenomena and new understandings beyond (C1), (C2), and the numerical simulations in [LAK], though (C1) and (C2) are not "proved" completely.

Before describing our main results, we mention that in [Z] (which to our knowledge is the only previous rigorous work on (1.2)), Zeng proved that (i) if $\theta \ge kf(1)$, the only steady state of (1.2) is the trivial one: $(u, v) = (1, 0)$; (ii) if $0 < \theta < kf(1)$, then (1.2) has a positive steady state (u, v); (iii) any positive steady state (u, v) of (1.2) satisfies $0 < u < 1$, $u' > 0$, and $v' > 0$. (In [Z], $\phi(u) = u$ is assumed; but the arguments there go through for general ϕ satisfying (1.3).)

In this paper, concerning positive steady states of (1.2), we obtain what can be roughly described as follows.

(R1) Small motility λ and large chemotaxis coefficient χ (when compared to λ, that is, χ is large and λ/χ is small) have the same effect on the distribution and the total population of the bacteria: v concentrates and is approximately an δ-function at the boundary point $x = 1$; moreover, the total population of bacteria $\int_0^1 v(x)dx$ is close to $kh(1-c)/\theta$, u is close to c, where c is the constant in $(0, 1)$ such that $kf(c) = \theta$.

(R2) Small motility λ and large chemotaxis coefficient χ (when compared to λ) act to increase the total population of bacteria: $\int_0^1 v(x)dx$ is maximized in the limit $\lambda \to 0$ or $\lambda/\chi \to 0$ and $\chi \to \infty$.

(R3) When both λ and χ are large and λ is at least at the order of χ, v no longer concentrates at $x = 1$; in the limit, both u and v converge in $C^1[0, 1]$ norm to functions which, in the case $\lambda/\chi \to \infty$, can be uniquely determined.

(For the precise statements of the results described above, see Theorem 2.1.)

(R1) and (R3) were not observed numerically or by the formal arguments in [LAK] or in any other places, to the best of our knowledge. According to (C1) and (C2), the functions

$$\lambda \to \int_0^1 v_\lambda(x)dx, \quad \chi \to \int_0^1 v_\chi(x)dx \tag{1.4}$$

(subscripts indicating the dependence of v on the parameters, *not* partial derivatives) should be monotone decreasing and increasing (resp.), at least when χ is proportional to λ. It seems that this kind of question has not been rigorously studied for the classical reaction-diffusion systems (nonchemotactic). In fact, for many of them, even the uniqueness or multiplicity problem has largely remained open. For our system (1.2) with $\chi = 0$, the uniqueness of positive steady state was pointed out by Yuan Lou and later by Junping Shi. If $\chi > 0$, we are unable to prove that the functions in (1.4) are single-valued.

We have seen from (R1) that for small λ or large χ (compared to λ), the bacteria concentrate in a small neighborhood of the boundary point $x = 1$, which is a "fertile zone", because the nutrient diffuses into the medium through $x = 1$. This should promote the growth of bacteria if they have a Malthusian growth, as assumed in the model (1.2). This may not promote the growth of bacteria if their growth type is logistic, that is, if large density of bacteria leads to negative growth due to overcrowding.

Motivated by this, we propose the following model which is a slight modification of (1.2).

$$\begin{cases} u_t = u_{xx} - f(u)v, \ 0 \le x \le 1, \ t > 0, \\ v_t = (\lambda v_x - \chi v(\phi(u))_x)_x + (kf(u) - \theta - \beta v)v, \\ u_x(0) = 0, \ u_x(1) = h(1 - u(1)), \\ \lambda v_x - \chi v(\phi(u))_x = 0 \ \text{ at } \ x = 0, 1, \end{cases} \tag{1.5}$$

where β is a positive constant. At the constant level of the chemical concentration u, the bacteria have logistic growth.

We shall show that as in the Malthusian case, (1.5) has a positive steady state if and only if $0 < \theta < kf(1)$ (see Theorem 3.1). Our results on qualitative behavior of positive steady states can be described as follows.

(R4) In sharp contrast to the Malthusian case, large chemotaxis coefficient χ (compared to λ) is *detrimental* to the growth of bacteria: u is close to 1 throughout the interval $[0, 1]$, v concentrates at the boundary point, but the total population $\int_0^1 v(x)dx$ is close to zero.

(R5) If $\chi/\sqrt{\lambda}$ remains bounded as $\lambda \to 0$, then v does not concentrate at point $x = 1$ and $\liminf_{\lambda \to 0} \int_0^1 v_\lambda(x)dx > 0$; these are true if χ is only bounded as $\lambda \to 0$, in the special case $\phi(u) = u$.

(R6) The conclusion in (R3) holds in the logisitc case (1.5).

See Theorem 3.3 for precise statements. Notice that in the logisitc case, small motility λ and large chemotaxis coefficient χ no longer have the same effect on v and the total population $\int_0^1 v(x)dx$, in contrast to the Malthusian case. We conjecture that in the logisitc case, small motility λ is also detrimental to the total population $\int_0^1 v(x)dx$, that is, in the limit $\lambda \to 0$, $\int_0^1 v_\lambda(x)dx$ is minimized (assuming that χ remains bounded).

We remark that the purpose of the logistic kinetics we use here is not to prevent the blowup (in finite time or infinite time) of v (concentration) or $\int_0^1 v(x,t)dx$ (total population) because both remain bounded as $t \to \infty$ even in the Malthusian case (see (R7)). Instead, it is used to model the inhibition on growth due to the competition for the nutrient among cells at locations of aggregation.

All of the above results concern the behavior of positive steady states of (1.2) and (1.5). On the dynamical issues for (1.5) ($\beta = 0$ allowed so that the Malthusian case is included), we have the following.

(R7) (1.5) has a unique bounded global (in time) solution.

(R8) When $\theta \geq kf(1)$, the trivial steady state $(1, 0)$ is globally asymptotically stable; when $0 < \theta < kf(1)$, it is unstable.

(R9) For θ less than but close to $kf(1)$, the positive steady state of (1.5) is unique and asymptotically stable. See Theorems 4.8, 5.1, and 5.2 for precise statements.

Recall that (1.5) has a positive steady state if and only if $0 < \theta < kf(1)$. We conjecture that for the full parameter range $\theta \in (0, kf(1))$, the positive steady state of (1.5) is unique and globally asymptotically stable. If this is true, it would imply that the behavior of the positive steady state represents that of the time-dependent solution for large time. The results (R7)–(R9) support this conjecture. It has been an outstanding open problem for many classical (nonchemotactic) diffusion systems to obtain uniqueness and stability of steady states for the full range of parameters. For our problems, we have one more significant difficulty to overcome: the nonlinear boundary condition for v. Indeed, in obtaining even the stability in (R9) for θ close to $kf(1)$ by using the bifurcation method, we cannot directly apply the standard result of Crandall–Rabinowitz because the linearized differential operators have varying domains, due to the nonlinear boundary condition.

The paper is organized as follows. We study (i) the behavior of steady states in the Malthusian case in section 2; (ii) existence and behavior of steady states in the logisitc case in section 3; (iii) global existence and boundedness of time-dependent solutions in section 4; (iv) stability of steady states in section 5.

We remind the reader that we assume the condition (1.3) throughout this paper.

2. Behavior of steady states in Malthusian case. We first write down the system satisfied by steady states of (1.2):

$$\begin{cases} u'' = f(u)v, \ x \in [0,1], \\ (\lambda v' - \chi v(\phi(u)')') + (kf(u) - \theta)v = 0, \\ u'(0) = 0, \ u'(1) = h(1 - u(1)), \\ \lambda v' - \chi v(\phi(u))' = 0 \ \text{ at } \ x = 0, 1. \end{cases} \tag{2.1}$$

Recall [Z] that (2.1) has a positive steady state if and only if $0 < \theta < kf(1)$. We shall assume this throughout this section.

The purpose of this section is to prove the following theorem.

THEOREM 2.1. *Let* (u_i, v_i) *be positive solutions of* (2.1) *with* $(\lambda, \chi) = (\lambda_i, \chi_i)$.

(i) *If* $\lambda_i \to 0$, *then* $u_i \to$ *constant* c *uniformly on* $[0,1]$, *where* $kf(c) = \theta$, v_i *concentrates and blows up at* $x = 1$, *i.e.,* v_i *converges to zero uniformly outside any left neighborhood of* $x = 1$ *and* $v_i(1) \to \infty$; *moreover, the total population of bacteria* $\int_0^1 v_i(x) \to kh(1-c)/\theta$. *(Thus* v_i *converges to a constant multiple of the* δ*-function centered at* $x = 1$.*)*

(ii) *If* $\lambda_i/\chi_i \to 0$ *as* $\chi_i \to \infty$ *or as* $\lambda_i \to \infty$ *(so* χ_i *is relatively large), then the conclusion in* (i) *is true.*

(iii) *Suppose that* $\lim_{\lambda_i \to \infty} \lambda_i/\chi_i = a$ *exists and* $a \in (0, \infty]$. *Then after passing to a subsequence,* $u_i(x) \to u_\infty(x)$, $v_i(x) \to v_\infty(x)$ *in* $C^1([0,1])$, *where* u_∞ *and* v_∞ *satisfy*

$$\begin{cases} u''_\infty = f(u_\infty)v_\infty, \ u_\infty > 0, \ v_\infty > 0, \ x \in [0,1], \\ u'_\infty(0) = 0, \ u'_\infty(1) = h(1 - u_\infty(1)), \\ \textit{constraint: } \int_0^1 (kf(u_\infty(x)) - \theta)v_\infty dx = 0. \end{cases} \tag{2.2}$$

Moreover, if $a = \infty$, *then* v_∞ *is a constant, and* (u_∞, v_∞) *is uniquely determined by* (2.2) *and hence the whole sequence* (u_i, v_i) *converges to* (u_∞, v_∞); *if* a *is finite, then* $v_\infty = (\text{const}M)\exp(\phi(u_\infty)/a)$.

Proof of (i). *Step* 1. By integrating both sides of the v-equation in (2.1), we see

$$\int_0^1 (kf(u_i(x)) - \theta)v_i(x)dx = 0. \tag{2.3}$$

Step 2. We show that for any $x \in [0,1)$, $\limsup_{i\to\infty} v_i(x) < \infty$.

If this is not true, then there exists $x_0 \in [0,1)$ and a sequence $i \to \infty$ such that $\lim_{i\to\infty} v_i(x_0) = \infty$. Since $u''_i > 0$ and by the boundary condition on u_i, we have $0 \le u'_i(x) \le u'_i(1) < h$ for $x \in [0,1]$. Then by virtue of the Azela–Ascoli theorem, we obtain that, after passing to a subsequence,

$$u_i(x) \to u_0(x) \ \text{ uniformly on } \ [0,1] \ \text{ as } \ i \to \infty. \tag{2.4}$$

On the other hand, by integrating the u-equation, we obtain

$$\begin{aligned} h > u'_i(1) - u'_i(0) &= \int_0^1 f(u_i(x))v_i(x)dx \\ &\ge \int_{x_0}^1 f(u_i(x))v_i(x)dx \ge \int_{x_0}^1 f(u_i(x))v_i(x_0)dx \end{aligned}$$

(recall v_i is increasing on $[0,1]$), which in turn implies $h \ge \int_{x_0}^1 f(u_0(x))\infty\, dx$ by Fatou's lemma. Thus $u_0 \equiv 0$ on $[0,1]$. But this and (2.4) imply that the integral in (2.3) is negative for i large enough; thus, we have a contradiction!

Step 3. By Step 2, the monotonicity of v_i and Helly's theorem, we have that after passing to yet another subsequence,

$$v_i(x) \to \text{some } v_0(x) \text{ pointwise on } [0,1) \text{ as } i \to \infty, \tag{2.5}$$

where v_0 is, of course, nondecreasing on $[0,1)$. Since the case when χ_i becomes unbounded as $\lambda_i \to 0$ can be covered by part (ii) of Theorem 2.1, here we assume that χ_i remains bounded as $\lambda_i \to 0$. After passing to a subsequence, we assume $\chi_i \to$ some $\chi_0 \geq 0$. We claim

$$\int_0^x (kf(u_0(y)) - \theta)v_0(y)dy = \chi_0 v_0(x)u_0'(x)\phi'(u_0(x)) \text{ almost everywhere (a.e.) on } [0,1). \tag{2.6}$$

To see this, we integrate the v-equation in (2.1) over the interval $[0,x]$ to obtain

$$\lambda_i v_i'(x) - \chi_i v_i(x)u_i'(x)\phi'(u_i(x)) + F_i(x) = 0, \; x \in [0,1], \tag{2.7}$$

where $F_i(x) = \int_0^x (kf(u_i(y)) - \theta)v_i(y)dy$. Observe that by Step 2 and Lebesgue's dominated convergence theorem, we have that $F_i(x) \to F_0(x) \equiv \int_0^x (kf(u_0(y)) - \theta)v_0(y)dy$ pointwise on $[0,1)$ as $i \to \infty$. Integrating (2.7) from 0 to x and sending λ_i to 0, we have

$$\int_0^x [-\chi_0 v_0(y)u_0'(y)\phi'(u_0(y)) + F_0(y)]dy = 0, \; x \in [0,1).$$

Now (2.6) follows.

Step 4. We show $v_0 \equiv 0$ on $[0,1)$ and $u_0 \equiv$ const c with $kf(c) = \theta$. There are two cases to consider.

Case 1. $\chi_0 = 0$. In light of (2.6), we have

$$(kf(u_0(x)) - \theta)v_0(x) = 0, \text{ a.e. on } (0,1). \tag{2.8}$$

If $v_0 \not\equiv 0$ on $[0,1)$, then there exists $x_0 \in [0,1)$ such that $v_0(x) > 0$ for $x \in [x_0,1)$. Then (2.8) implies that $kf(u_0(x)) = \theta$, i.e., $u_0 \equiv c$ on $[x_0,1]$. On the other hand, by integrating the u-equation, it is easy to see

$$u_0'(x) = \int_0^x f(u_0(y))v_0(y)dy, \; x \in [0,1). \tag{2.9}$$

Now since u_0 is a constant on $[x_0,1]$, $\int_0^x f(u_0(y))v_0(y)dy \equiv 0$ and hence $v_0 \equiv 0$ on $[0,1)$, contradicting the assumption that $v_0(x) > 0$ for $x \in [x_0,1)$. Thus $v_0 \equiv 0$ on $[0,1)$ and by (2.9), u_0 is a constant.

By (2.3), $f(u_i(1)) > \theta/k$. Thus $f(u_0) \geq \theta/k$. If $f(u_0) > \theta/k$, then the integral in (2.3) is negative for small enough λ_i, which is impossible. Therefore $kf(u_0) = \theta$. Step 4 is finished in the case where $\chi_0 = 0$.

Case 2. $\chi_0 > 0$. If we can show $v_0 \equiv 0$ on $[0,1)$, then the rest of the arguments are exactly the same as in Case 1. Suppose there exists $x_0 \in [0,1)$ such that $v_0 > 0$ on $[x_0,1)$. We want to show that $u_0' \equiv 0$ on $[x_0,1)$. Otherwise, there exists $x_1 \in (x_0,1)$ such that $u_0'(x_1) > 0$. Then by (2.6), we have $\int_0^{x_1} (kf(u_0(y)) - \theta)v_0(y)dy > 0$; hence, $kf(u_0(x_1)) > \theta$. Therefore, $kf(u_i(x)) - \theta > 0$ for $x \in [x_1,1)$ and large enough i. Consequently, for such i, $\int_{x_1}^1 (kf(u_i(y)) - \theta)v_i(y)dy > 0$. Now observe

$$\begin{aligned} 0 = \lim_{i\to\infty} \int_0^1 (kf(u_i(y)) - \theta)v_i(y)dy &= \lim_{i\to\infty} \left(\int_0^{x_1} + \int_{x_1}^1 \right) (kf(u_i(y)) - \theta)v_i(y)dy \\ \geq \lim_{i\to\infty} \int_0^{x_1} (kf(u_i(y)) - \theta)v_i(y)dy &= \int_0^{x_1} (kf(u_0(y)) - \theta)v_0(y)dy > 0; \end{aligned}$$

we have a contradiction! We have shown that $u_0' \equiv 0$ on $[x_0, 1)$ under the assumption that $v_0 > 0$ on $[x_0, 1)$. Now as in Case 1, we are led to a contradiction.

Step 5. We now only need to show $\int_0^1 v_i(x)dx \to kh(1-c)/\theta$. By (2.3),

$$\theta \lim_{i\to\infty} \int_0^1 v_i(y)dy = k \lim_{i\to\infty} \int_0^1 f(u_i(y))v_i(y)dy = k \lim_{i\to\infty} (u_i'(1) - u_i'(0))$$
$$= kh \lim_{i\to\infty} (1 - u_i(1)) = kh(1-c).$$

This completes the proof of (i) of Theorem 2.1.

Proof of (ii) *of Theorem* 2.1. The proof is basically the same as that for part (i). The revisions needed are to replace (2.6) by

$$v_0(x)u_0'(x)\phi'(u_0(x)) = 0, \ x \in [0, 1), \tag{2.10}$$

then to change the proof in Step 4 slightly. To show (2.10), we divide both sides of (2.7) by χ_i and then send χ_i or λ_i to infinity. Combining (2.9) with (2.10), we immediately see that $v_0 \equiv 0$ and $u_0 \equiv$ constant on $[0, 1)$. Now using the arguments in Step 4, we have $u_0 \equiv c$ on $[0, 1]$. (ii) of Theorem 2.1 is proved.

Before proving part (iii) of Theorem 2.1, we prove the following.

LEMMA 2.2. *If λ is bounded away from* 0 *and if χ/λ is bounded, then v is bounded on* $[0, 1]$. *Here λ and χ are allowed to vary, dependently or independently on each other.*

Proof. From (2.7) (dropping the subscripts), we have

$$v'(x) - \frac{\chi u'(x)}{\lambda} v(x)\phi'(u(x)) \le \theta \int_0^1 v(x)dx/\lambda.$$

By (2.3) and the u-equation in (2.1), $\theta \int_0^1 v(x)dx = ku'(1) \le hk$. Using this and the fact that $u'(x) \le u'(1) \le h$, we see that

$$v'(x) - \frac{\chi h}{\lambda} v(x)\|\phi'\|_{L^\infty} \le hk/\lambda.$$

From this it follows that

$$v(x) \le v(0)e^{\frac{\chi h\|\phi'\|_{L^\infty}}{\lambda}x} + \frac{k}{\chi\|\phi'\|_{L^\infty}}(e^{\frac{\chi h\|\phi'\|_{L^\infty}}{\lambda}x} - 1), \ x \in [0, 1],$$

where the second term should be understood as equal to its limit when $\chi = 0$. On the other hand, as argued in the proof of (i) of Theorem 2.1, $v(0)$ must remain bounded. Thus v remains bounded on $[0, 1]$. Lemma 2.2 is proved.

Proof of (iii) *of Theorem* 2.1. We shall consider only the case $\chi_i \to \infty$ with $\lambda_i/\chi_i \to \infty$. The other case can be handled in the same way.

By the u-equation in (2.1) and Lemma 2.2, u_i'' is bounded on $[0, 1]$. Thus by the Azela–Ascoli theorem, $u_i \to$ some u_∞ in $C^1([0, 1])$, as $i \to \infty$, after passing to a subsequence. From (2.7) and Lemma 2.2, we easily see that $v_i' \to 0$ uniformly on $[0, 1]$ as $i \to \infty$. This implies that after passing to a subsequence, $v_i \to$ const v_∞ in $C^1([0, 1])$ as $i \to \infty$. We now show that $v_\infty > 0$. Otherwise, $u_\infty' \equiv 0$ on $[0, 1]$ (see (2.9)) and then $u_\infty \equiv 1$ on $[0, 1]$. Then for i large, the integral in (2.3) is positive (recall $0 < \theta < kf(1)$). Impossible.

It is easy to see that (u_∞, v_∞) satisfies (2.2). To show the uniqueness of (u_∞, v_∞), we first observe that by the comparison principle, for a fixed $v_\infty \ge 0$, (2.2) without the constraint has at most one solution u_∞ (here we need the assumption $f'(u) > 0$). Thus it suffices to show that v_∞ is unique. By the comparison principle again, we have that u_∞ is monotonically decreasing with respect to constant v_∞. Thus there exists at most one $v_\infty > 0$ such that $\int_0^1 kf(u_\infty(x))dx = \theta$, i.e., the constraint in (2.2) is satisfied.

Remark 2.3. Simple calculations below show that in the cases considered in (i) and (ii) of Theorem 2.1, $\int_0^1 v(x)dx$ is maximized in the limit $\lambda \to 0$. By (2.3), we have $\int_0^1 v(x)dx = \frac{k}{\theta}\int_0^1 f(u(x))v(x)dx = \frac{k}{\theta}u'(1) = \frac{kh}{\theta}(1-u(1))$. By (2.3) again, $u(1) > c$. Thus $\lim_{\lambda\to 0}\int_0^1 v(x)dx = \frac{kh}{\theta}(1-c) > \int_0^1 v(x)dx$. The same is true when $\chi \to \infty$ and $\lambda/\chi \to 0$.

3. Positive steady states in the logistic case.

3.1. Existence. The steady states of (1.5) satisfy

$$\begin{cases} u'' = f(u)v, \\ \lambda v'' - \chi(v\phi'(u)u')' + (kf(u) - \theta - \beta v)v = 0, \\ u'(0) = 0,\ u'(1) = h(1-u(1)), \\ \lambda v' - \chi v\phi'(u)u' = 0 \quad \text{at} \quad x = 0, 1, \end{cases} \tag{3.1}$$

where $\beta > 0$ is a constant.

Theorem 3.1. (i) *For $\theta \geq kf(1)$,* (3.1) *has no positive solutions.*

(ii) *For $0 < \theta < kf(1)$,* (3.1) *has a positive solution.*

(iii) *For θ less than but close to $kf(1)$, the positive solution of* (3.1) *is unique.*

The proof of (i) is easy. To prove (ii), we can use either the decoupling method combined with bifurcation techniques (as in [Z] for (3.1) with $\beta = 0$), or the bifurcation method directly applied to the system (as developed in [BB] for another system). We choose the second approach, which also prepares results and notation for our stability analysis in section 5. The proof is, in spirit, similar to that in [Z] and will be only sketched here.

The following can be easily observed by inspecting (3.1) and is useful in proving (i).

Lemma 3.2. *If (u, v) is a positive solution of* (3.1), *then $u(x) < 1$ for $0 \leq x \leq 1$ and $u'(x) > 0$ for $0 < x \leq 1$.*

Proof of (i) *of Theorem* 3.1. Integrating the v-equation in (3.1) and using the boundary condition, we have

$$\int_0^1 (kf(u) - \theta - \beta v)v\, dx = 0. \tag{3.2}$$

If $\theta \geq kf(1)$ and v is positive, then the integrand is strictly negative because $u < 1$ and $f'(u) > 0$.

Proof of (ii) *of Theorem* 3.1. We first convert (3.1) into a bifurcation problem with $\mu \equiv kf(1) - \theta$ as a parameter. Let $w = 1 - u$. Then (3.1) is transformed into

$$\begin{cases} -w'' = f(1-w)v, \\ \lambda v'' + \chi(v\phi'(1-w))'w' - \chi v\phi'(1-w)f(1-w)v + (kf(1-w) - \theta - \beta v)v = 0, \\ w'(0) = 0 = w'(1) + hw(1), \\ \lambda v' + \chi v\phi'(1-w)w' = 0 \quad \text{at} \quad x = 0, 1. \end{cases} \tag{3.3}$$

We seek a positive solution (w, v) of (3.3) with $1 - w > 0$. For technical reasons, we need to extend f and ϕ on $\mathbb{R}$. By the regularity assumption (1.3) for f and ϕ, we can extend them on the whole real line so that f and ϕ have the same regularity on $\mathbb{R}$ as in (1.3). This extension will not affect the set of positive solutions of (3.3) with $w < 1$.

Observe that (3.3) is equivalent to the following functional equation:

$$\begin{pmatrix} w \\ v \end{pmatrix} = \begin{pmatrix} 0 & f(1)K_1 \\ 0 & K_2 \end{pmatrix} \begin{pmatrix} w \\ v \end{pmatrix} + \mu \begin{pmatrix} 0 & 0 \\ 0 & K_2 \end{pmatrix} \begin{pmatrix} w \\ v \end{pmatrix} + \begin{pmatrix} R_1(w,v) \\ R_2(w,v) \end{pmatrix}, \tag{3.4}$$

where K_1 is the inverse of $-\frac{d^2}{dx^2}$ with the w-boundary condition in (3.3), K_2 is the inverse of $-\lambda\frac{d^2}{dx^2}+1$ with the homogeneous Neumann boundary condition, $R_1(w,v) = K_1[(f(1-w)-f(1))v]$, $B(w,v) = -w'(1)v(1)\phi'(1-w(1))[\chi x^2/2\lambda - K_2(-\chi+\chi x^2/2\lambda)]$,

$$R_2(w,v) = K_2[\chi(v\phi'(1-w))'w' - \chi v\phi'(1-w)f(1-w)v + (kf(1-w)-kf(1)-\beta v)v] + B(w,v).$$

By the elliptic regularity theory, the linear operators K_1 and K_2 map $C^\alpha([0,1])$ into $X \equiv C^{\alpha+1}([0,1])$ and are compact. Denote by K the first matrix in (3.4), by L the second matrix, and by $R(w,v)$ the R_1, R_2 vector. Then (3.4) can be rewritten as

$$(I - K - \mu L)\begin{pmatrix} w \\ v \end{pmatrix} - R(w,v) = 0, \ (w,v) \in X \times X. \tag{3.5}$$

Denote the left-hand side of (3.5) by $F(\mu,(w,v))$. Obviously $F(\mu,(0,0)) = 0$. We show that a local bifurcation occurs at $(\mu,(w,v)) = (0,(0,0))$ by using the Crandall–Rabinowitz bifurcation theorem (see Lemma 1.1 in [CR]). To this end, we need to show (details omitted)

(a) $F : \mathbb{R} \times X \times X \to X \times X$ is C^2 smooth;

(b) $\dim N(F_{(w,v)}(0,(0,0))) = 1 = \operatorname{codim} R(F_{(w,v)}(0,(0,0)))$;

(c) $F_{\mu(w,v)}(0,(0,0))(\bar{w}_0,\bar{v}_0) \notin R(F_{(w,v)}(0,(0,0)))$, where $(\bar{w}_0,\bar{v}_0) = (K_1 f(1), 1)$ spans $N(F_{(w,v)}(0,(0,0)))$.

Now let Z be any complement of span $\binom{\bar{w}_0}{\bar{v}_0}$ in $X \times X$. Then by the Crandall–Rabinowitz theorem, there exist a positive ε and C^1 smooth functions $\mu : (-\varepsilon,\varepsilon) \to \mathbb{R}$, $\binom{\psi_1}{\psi_2} : (-\varepsilon,\varepsilon) \to Z$ such that $\mu(0) = 0$, $\psi_1(0) = 0 = \psi_2(0)$, and $F(\mu(s),(w(s),v(s))) = 0$, where $w(s) = s\bar{w}_0 + s\psi_1(s)$, $v(s) = s\bar{v}_0 + s\psi_2(s)$, $s \in (-\varepsilon,\varepsilon)$. Moreover, all solutions $(\lambda,(w,v))$ of $F = 0$ near $(0,(0,0))$ are either on $(w,v) = 0$ or on the curve $(\mu(s),(w(s),v(s)))$, $s \in (-\varepsilon,\varepsilon)$. Notice that for $s > 0$ small, $w(s)$ and $v(s)$ are positive functions (of x) on $[0,1]$ because so are $\bar{w}_0$ and $\bar{v}_0$.

Let S be the closure of the set of solutions $(\mu,(w,v)) \in \mathbb{R} \times X \times X$ of $F = 0$ with $(w,v) \neq (0,0)$. Let C be the maximal subcontinuum of S passing through $(0,(0,0))$. Let C^+ be the maximal subcontinuum of the closure of $C - \{(\mu(s),(w(s),v(s))) \mid -\varepsilon < s < 0\}$ which meets $(0,(0,0))$. Then by combining the reflection argument in [R, Theorem 1.27] and [BB, Theorem 3.2] we have that C^+ either meets "infinity" or meets $(\widehat{\mu},(0,0))$ where $\widehat{\mu} \neq 0$ and $I - K - \widehat{\mu}L$ is not invertible, or C^+ contains a pair of points $(\mu,(w,v))$ and $(\mu,-(w,v))$. We proceed to show $C^+ \backslash \{(0,(0,0))\} \subset \mathbb{R} \times X^+ \times X^+$, where X^+ is the positive cone of X consisting of functions positive on $[0,1]$. We omit the details.

Now we see that C^+ cannot possibly satisfy either of the last two alternatives mentioned above and hence C^+ meets "infinity."

By an argument similar to the one for $C^+ \backslash \{(0,(0,0))\} \subset \mathbb{R} \times X^+ \times X^+$, we can show that if $(\mu,(w,v)) \in C^+ \backslash \{(0,(0,0))\}$, then $w < 1$; and by integrating both sides of v-equation in (3.1) on $[0,1]$, we see $\mu > 0$ (thus the bifurcation curve "turns to the right" at $(0,(0,0))$).

We now show that the projection of $C^+\backslash\{(0,(0,0))\}$ onto the μ-axis contains the interval $(0, kf(1))$. It is sufficient to obtain an a priori bound for (w, v) if $(\mu, (w, v))$ in $\mathbb{R} \times X^+ \times X^+$ is a solution of $F = 0$ and if $\mu \in (0, kf(1))$. We proceed to obtain such a bound for v first. By (3.2), we have

$$\beta \int_0^1 v^2 dx < \mu \int_0^1 v\, dx < kf(1) \left(\int_0^1 v^2 dx \right)^{1/2}, \tag{3.6}$$

and hence

$$\int_0^1 v(x) dx \leq \left(\int_0^1 v^2 dx \right)^{1/2} < \frac{kf(1)}{\beta}. \tag{3.7}$$

Now integrating the v-equation in (3.1) from 0 to x, and using (3.7), we obtain

$$\lambda v'(x) + \chi \phi'(1-w) w' v = g(x), \ x \in [0,1],$$

where $|g|$ is bounded by a constant depending only on k and β. It follows that

$$v(x) = e^{\frac{\chi}{\lambda}\phi(1-w(x))}(v(0)e^{-\chi\phi(1-w(0))/\lambda} + \frac{1}{\lambda}\int_0^x g(x) e^{-\chi\phi(1-w(x))/\lambda} dx). \tag{3.8}$$

Thus if $v(0)$ remains bounded for $\mu \in (0, kf(1))$, so does $\|v\|_{L^\infty}$ (recall $0 < w < 1$). If $v(0)$ does not remain bounded for $\mu \in (0, kf(1))$, then there exists a sequence $(\mu_n, (w_n, v_n)) \in (0, kf(1)) \times X^+ \times X^+$ which are solutions of $F = 0$, with $\mu_n \to \mu_0 \in [0, kf(1)]$ and $v_n(0) \to \infty$. Then by (3.8), $v_n(x) \to \infty$ uniformly on $[0,1]$. This would contradict (3.2) for n large. Thus $\|v\|_{L^\infty}$ is bounded for $\mu \in (0, kf(1))$. Hence by (3.3), $\|w\|_{C^2}$ is bounded and consequently so is $\|v\|_{C^2}$ for $\mu \in (0, kf(1))$.

We have so far shown that for $\mu \in (0, kf(1))$, (3.3) always has a positive solution (w, v) with $w < 1$. Part (ii) of Theorem 3.1 is proved.

Proof of (iii) *of Theorem* 3.1. We use the notation in the above proof. We claim that as $\theta \to kf(1)$ from the left, that is, as $\mu \to 0^+$, $\|(w, v)\| \to 0$. Suppose otherwise; then there exists sequence $(\mu_n, (w_n, v_n)) \subset \mathbb{R}^+ \times X^+ \times X^+$ which are solutions of (3.5), with $\mu_n \to 0^+$ and $\|(w_n, v_n)\|$ bounded away from 0. By the last part of the above proof, $\|(w_n, v_n)\|_X$ is bounded. Then the compactness of K, L, and R implies that (w_n, v_n) has a subsequence converging to some nonzero (w_∞, v_∞), which satisfies (3.5) and hence (3.3) with $\theta = kf(1)$. By (3.2), this is impossible. The claim is proved.

Now by Step 2 in the proof of (ii), for θ less than but close to $kf(1)$, i.e., for μ positive but small, $(\mu, (w, v))$ is on the curve $(\mu(s), (w(s, \cdot), v(s, \cdot)))$, $0 < s < \varepsilon$. If we can show $\mu'(0) \neq 0$, then the desired uniqueness follows. By (3.2), we have

$$\mu(s) \int_0^1 v(s,x) dx = \int_0^1 k(f(1) - f(1 - w(s,x))) v(s,x) dx + \beta \int_0^1 v^2(s,x) dx.$$

Dividing both sides by s^2 and sending $s \to 0$, we obtain

$$\mu'(0) \int_0^1 \bar{v}_0 dx = \int_0^1 k \bar{v}_0 f'(1) \bar{w}_0 dx + \beta \int_0^1 \bar{v}_0^2 dx.$$

Recall $\bar{w}_0 = K_1 f(1)$ (which is positive) and $\bar{v}_0 = 1$. Thus $\mu'(0) > 0$. This completes the proof of (iii).

3.2. Behavior of positive steady states. The main result in this subsection is the following.

THEOREM 3.3. *Suppose* $0 < \theta < kf(1)$. *Let* (u_i, v_i) *be positive solutions of* (3.1) *with* $(\lambda, \chi) = (\lambda_i, \chi_i)$. *In* (i) *and* (ii) *below we assume* $\lim_{\chi_i \to \infty} \lambda_i/\chi_i = a \in [0, \infty]$ *exists.*

(i) *If* $a = 0$, *then* $u_i \to 1$ *in* $C^1([0,1])$, $v_i \to 0$ *uniformly outside any fixed neighborhood of* $x = 1$, $\int_0^1 v_i(x)dx \to 0$. *Moreover, for i large the maximum of* v_i *is achieved at* $x = 1$ *and* $v_i(1) \not\to 0$.

(ii) *If* $0 < a \leq \infty$, *then the conclusion in* (iii) *of Theorem* 2.1 *holds with the constraint in* (2.2) *replaced by*

$$\int_0^1 (kf(u_\infty) - \theta - \beta v_\infty)v_\infty dx = 0.$$

(iii) *Suppose that* $\lambda_i \to 0$ *and* $\chi_i/\sqrt{\lambda_i}$ *remains bounded. Then* $u_i \to u_0$ *in* $C^1([0,1])$, $v_i \to v_0$ *pointwise in* $[0,1)$, *where* u_0 *is the unique positive solution of*

$$\begin{cases} u_0''(x) = f(u_0)(kf(u_0) - \theta)/\beta, \ x \in (0,1), \\ u_0'(0) = 0, \ u_0'(1) = h(1 - u_0(1)), \end{cases} \tag{3.9}$$

satisfying $kf(u_0) - \theta \geq 0$, *and* $v_0 = (kf(u_0) - \theta)/\beta$ *is positive on* $[0,1]$ *(and hence* $\liminf_{i\to\infty} \int_0^1 v_i(x)dx > 0$*).*

(iv) *Suppose* $\phi(u) = u$. *If* $\chi_i \to 0$, $\lambda_i \to 0$ *as* $i \to \infty$, *then the conclusion in* (iii) *holds; moreover, the convergence* $v_i \to v_0$ *is uniform outside any fixed neighborhood of* $x = 1$. *If* $\chi_i \to$ *some positive constant* χ_0 *and* $\lambda_i \to 0$, *then after passing to a subsequence* $u_i \to u_0$ *in* $C^1([0,1])$, $v_i \to v_0$ *uniformly outside any fixed neighborhood of* $x = 1$, $v_i(1) \to \infty$, *where* v_0 *is a positive function continuous on* $[0,1]$, $kf(u_0) > \theta + \beta v_0$ *on* $[0,1)$.

REMARK 3.4. The boundedness condition for $\chi/\sqrt{\lambda}$ in (iii), we suspect, is only a technical one. We tend to believe that the condition $\chi \to 0$ as $\lambda \to 0$ is sufficient, as in the case $\phi(u) = u$. The difficulty arises when we do not know if v is monotone increasing for general ϕ.

Before we start the proof of the above theorem, we make some preliminary observations.

LEMMA 3.5. *Let* (u, v) *be a positive solution of* (3.1). *Then we have*

(i) $(\int_0^1 v^2(x)dx)^{1/2} \leq kf(1)/\beta$.

(ii) *Let* x_0 *be a local maximum of* v *in* $[0,1)$. *Then*

$$v(x_0) \leq \begin{cases} (kf(1) + \chi h^2 \|\phi''\|_{L^\infty([0,1])})/\beta; \\ k/(\chi \min_{[0,1]} \phi'(u)). \end{cases}$$

(iii) *If* χ/λ *is bounded, then* $v(1)$ *is bounded.*

Proof. (i) follows easily from integrating the v-equation of (3.1) over the interval $[0,1]$.

To show (ii), observe that v satisfies

$$\lambda v'' - \chi\phi''(u)(u')^2 v - \chi\phi'(u)v^2 f(u) - \chi\phi'(u)u'v' + (kf(u) - \theta - \beta v)v = 0. \tag{3.10}$$

At x_0, $v'' \leq 0$ and $v' = 0$ (if $x_0 = 0$, we first extend u and v evenly and we have that u and v are C^2 smooth on $[-1,1]$). Therefore,

$$v(x_0) < (kf(u(x_0)) - \chi\phi''(u(x_0))(u'(x_0))^2)/\beta.$$

This and the fact that $0 < u < 1,\ 0 < u' \le u'(1) < h$ imply the first inequality in (ii).

On the other hand, from the v-equation in (3.1), we deduce

$$\lambda v'(x) - \chi\phi'(u)u'v(x) + \int_0^x (kf(u) - \theta - \beta v)v = 0, \tag{3.11}$$

$$\chi\phi'(u(x_0))u'(x_0)v(x_0) < k\int_0^{x_0} f(u)v = ku'(x_0).$$

Whence

$$v(x_0) < k/(\chi \min_{[0,1]} \phi'(u)). \tag{3.12}$$

To show (iii), assume $kf(1) - \theta - \beta v(1) < 0$. Since $kf(u(x)) - \theta - \beta v(x)$ must change sign on $[0,1]$, there exists $b \in (0,1)$ such that $kf(u(x)) - \theta - \beta v(x)$ is negative on $(b,1]$, equal to zero at $x = b$. Then on $(b,1)$, $(\lambda v' - \chi\phi'(u)u'v)' > 0$, and by the boundary condition at $x = 1$, $\lambda v' - \chi\phi'(u)u'v < 0$. So on $(b,1]$, $(v\exp(-\phi(u)\chi/\lambda))' < 0$ and hence

$$v(x) < e^{\frac{\chi}{\lambda}(\phi(u(x)) - \phi(u(b)))}v(b),\ x \in (b,1].$$

Since $v(b) = (kf(u(b)) - \theta)/\beta$, we see that $v(1)$ remains bounded.

Proof of (i) *of Theorem* 3.3. By (i) of Lemma 3.5 and the u-equation in (3.1), $\{u_i\}$ and $\{u_i'\}$ are equicontinuous on $[0,1]$. So after passing to a subsequence $\chi_n \to \infty$,

$$u_i \to \text{some } u_\infty \text{ in } C^1([0,1]). \tag{3.13}$$

There are two cases to consider.

Case 1. Each v_i is monotone increasing on $[0,1]$. Then as in the proof of Theorem 2.1, by Helly's theorem, after passing to another subsequence, we have $v_i \to v_\infty$ pointwise on $[0,1)$. Similarly as in the proof of (ii) of Theorem 2.1, we have $u_\infty'(x)v_\infty(x) = 0$ for $x \in [0,1)$. Combining this with

$$u_\infty'(x) = \int_0^x f(u_\infty(s))v_\infty(s)ds,\ x \in [0,1), \tag{3.14}$$

we have $u_\infty' \equiv 0$ and hence $u_\infty \equiv 1$, $v_\infty \equiv 0$ on $[0,1)$.

Case 2. There exists a subsequence of v_i (still denoted by itself) such that each v_i is not monotone increasing (not monotone decreasing either because of the boundary condition at $x = 1$). Let y_i be the largest local maximum point of v_i in $[0,1)$ and let z_i be the next local minimum point.

Subcase 1. $y_i \to 1$ as $i \to \infty$. In this case, (3.12) implies that $v_i \to 0$ in $C^0_{\text{loc}}([0,1))$. Then from (3.14) we have $u_\infty' \equiv 0$ and hence $u_\infty \equiv 1$ on $[0,1]$.

Subcase 2. $y_i \to$ some $y_\infty \in [0,1)$, $z_i \to z_\infty \in [y_\infty, 1)$ as $i \to \infty$. Again, (3.12) implies $v_i \to 0$ in $C^0_{\text{loc}}([0,y_\infty))$. On the other hand, since v_i is monotone increasing on $[z_i,1]$, we can use the arguments in Case 1 to show $v_i \to 0$ in $C^0_{\text{loc}}((z_\infty,1))$. Now it is clear that $v_i \to 0$ in $C^0_{\text{loc}}([0,1))$ and $u_\infty \equiv 1$.

We have shown that $u_i \to 1$ in $C^1([0,1])$ and $v_i \to 0$ in $C^0_{\text{loc}}([0,1))$ (without passing to a subsequence). This and (i) of Lemma 3.5 imply $\int_0^1 v_i(x)dx \to 0$. Moreover, by (3.2), it is easy to see that for large i the maximum of v_i is no less than

$(kf(1)-\theta)/2\beta$. Then in view of (3.12), the maximum must be achieved at $x=1$ for large i. Therefore we also have $v_i(1) \not\to 0$.

Proof of (ii) *and* (iii) *of Theorem* 3.3. The proof is similar to that for the corresponding parts of Theorem 2.1 ((iii) and (iv)). We just need to note that the boundedness of v needed for our present situation is guaranteed by (ii) and (iii) of Lemma 3.5.

Proof of (iv) *of Theorem* 3.3. As in the proof of part (i), after passing to a subsequence, $u_i \to$ some u_0 in $C^1([0,1])$. We want to show that along this sequence,

$$v_i \to v_0 \equiv (kf(u_0)-\theta)/\beta \text{ pointwise on } [0,1). \tag{3.15}$$

This will be done by showing that for any $x_0 \in [0,1)$, after passing to yet another subsequence, $v_i(x_0) \to v_0(x_0)$. To this end, define $\bar{u}_i(x) = u_i(\sqrt{\lambda_i}x + x_0)$, $\bar{v}_i(x) = v_i(\sqrt{\lambda_i}x + x_0)$, $x \in ([0,1]-x_0)/\sqrt{\lambda_i}$. We assume $x_0 > 0$—the case $x_0 = 0$ can be handled by first making the even extension of u_i and v_i. $\bar{v}_i$ satisfies on $([0,1]-x_0)/\sqrt{\lambda_i}$,

$$\begin{aligned} &\bar{v}_i'' - \frac{\chi_i}{\sqrt{\lambda_i}}\phi'(\bar{u}_i)u_i'(\sqrt{\lambda_i}x+x_0)\bar{v}_i' - \chi_i\phi''(\bar{u}_i)\bar{v}_i(u_i')^2(\sqrt{\lambda_i}x+x_0) \\ &\quad - \chi_i\phi'(\bar{u}_i)f(\bar{u}_i)\bar{v}_i^2 + (kf(\bar{u}_i)-\theta-\beta\bar{v}_i)\bar{v}_i = 0. \end{aligned} \tag{3.16}$$

Claim 1. For any $a \in (0,1)$, v_i remains bounded on $[0,a]$ as $\lambda_i \to 0$. To see this, we observe that by (ii) of Lemma 3.5, the claim is true in any of the following cases: (i) the maximum of v_i on $[0,a]$ is achieved in $[0,a)$; (ii) the maximum is achieved at $x=a$ which is also a local maximum of v_i; (iii) v_i has a local maximum in $(a,1)$ with the function value greater than $v_i(a)$. Thus the only case left to consider is the one in which v_i is increasing on $[a,1]$ and $v_i(a)$ is unbounded. In this case the L^2-norm of v_i is unbounded, contradicting (i) of Lemma 3.5. Claim 1 is proved.

By Claim 1, $\bar{v}_i$ remains bounded on an interval of the form $(-\delta,\delta)/\sqrt{\lambda_i}$, which expands to the whole real line as $\lambda_i \to 0$. Applying the interior L^2-estimates of elliptic equations to (3.16), we have that for any fixed $M > 0$, $\|\bar{v}_i\|_{H^2(-M,M)}$ is bounded. Since $H^2(-M,M) \hookrightarrow C^1([-M,M])$, we see from (3.16) that $\|\bar{v}_i\|_{C^2([-M,M])}$ is bounded. Now differentiating (3.16), we have that $\|\bar{v}_i\|_{C^3([-M,M])}$ is also bounded. By a diagonalization argument and the Azela–Ascoli theorem, we obtain that after passing to a subsequence, $\bar{v}_i \to$ some $\bar{v}_0$ in $C^2_{\text{loc}}(\mathbb{R})$ as $\lambda_i \to 0$. Since $\chi_i/\sqrt{\lambda_i}$ is bounded, we can extract another sequence $\lambda_i \to 0$ such that $\chi_i/\sqrt{\lambda_i} \to a \geq 0$. Now sending $\lambda_i \to 0$ in (3.16), we are led to

$$\bar{v}_0'' - a\phi'(u_0(x_0))u_0'(x_0)\bar{v}_0' + (kf(u_0(x_0))-\theta-\beta\bar{v}_0)\bar{v}_0 = 0,\ x \in (-\infty,\infty), \tag{3.17}$$

where $\bar{v}_0 \geq 0$ is bounded on $(-\infty,\infty)$ because of Claim 1. We want to show $\bar{v}_0 \equiv (kf(u_0(x_0))-\theta)/\beta$.

Claim 2. $u_0(x) > c$ for $x \in [0,1]$, where $kf(c) = \theta$. We first prove $u_0 \geq c$. Suppose this is not true. Then there exists $x_0 \in (0,1]$ such that $u_0(x) < c$ for $0 \leq x < x_0$ and $u_0(x_0) = c$ or $x_0 = 1$. Since v_i is bounded in $L^2([0,1])$, after passing to a subsequence, $v_i \to$ some $\widetilde{v}_0$ weakly in $L^2([0,1])$ as $i \to \infty$. Obviously $\widetilde{v}_0 \geq 0$. For any $\varphi \in C_0^\infty((0,1))$, we have

$$\lambda_i \int_0^1 v_i\varphi'' + \chi_i \int_0^1 \phi'(u_i)u_i'v_i\varphi' + \int_0^1 (kf(u_i)-\theta-\beta v_i)v_i\varphi = 0.$$

Sending $\lambda_i \to 0$, we have $\lim_{i\to\infty}\int_0^1 (kf(u_i)-\theta-\beta v_i)v_i\varphi = 0$. Take $\varphi \geq 0$. Define space $L^2_\varphi(0,1)$ with the inner product $(g,h) = \int_0^1 gh\varphi dx$. Then in $L^2_\varphi(0,1)$, $v_i \to \widetilde{v}_0$

weakly and hence $\|\widetilde{v}_0\|^2_{L^2_\varphi(0,1)} \leq \liminf_{i\to\infty} \|v_i\|^2_{L^2_\varphi(0,1)}$. Now

$$\begin{aligned}\int_0^1 (kf(u_0)-\theta)\widetilde{v}_0\varphi &= \lim_{i\to\infty}\int_0^1 (kf(u_i)-\theta)v_i\varphi, \\ &= \beta\lim_{i\to\infty}\int_0^1 v_i^2\varphi \geq \beta\int_0^1 \widetilde{v}_0^2\varphi,\end{aligned}$$

i.e., $\int_0^1 (kf(u_0)-\theta-\beta\widetilde{v}_0)\widetilde{v}_0\varphi \geq 0$. Therefore,

$$(kf(u_0)-\theta-\beta\widetilde{v}_0)\widetilde{v}_0 \geq 0 \ \text{ a.e. on } \ (0,1). \tag{3.18}$$

Since $kf(u_0)-\theta<0$ on $[0,x_0)$, $\widetilde{v}_0 \equiv 0$ a.e. on $(0,x_0)$. Because

$$u_0'(x) = \int_0^x f(u_0(s))\widetilde{v}_0(s)ds, \ x\in[0,1], \tag{3.19}$$

$u_0' \equiv 0$ on $[0,x_0]$. Thus $u_0 \equiv \text{const} < c$ on $[0,x_0]$ and hence $x_0 = 1$. This contradicts $u_0'(1) = h(1-u_0(1))$.

We have shown $u_0 \geq c$ on $[0,1]$ and combining this with (3.18), we have $\widetilde{v}_0 \leq (kf(u_0)-\theta)/\beta$ a.e. on $(0,1)$. Now (3.19) yields

$$u_0'(x) \leq \int_0^x f(u_0(x))(kf(u_0)-\theta)/\beta\, dx, \ x\in[0,1].$$

Define $w(x) = u_0(x) - c$. Then $w \geq 0$, is nondecreasing on $[0,1]$, and satisfies for some positive function $c(x)$ the following:

$$w'(x) \leq \int_0^x c(s)w(s)ds \leq w(x)\int_0^x c(s)ds.$$

It follows from this that if $w(0) = 0$, then $w \equiv 0$ on $[0,1]$, which would contradict $u_0'(1) = h(1-u_0(1))$. Thus $w(x) \geq w(0) > 0$ for $x \in [0,1]$. Claim 2 is proved.

Claim 3. $\bar{v}_0(x) > 0$ for $x \in \mathbb{R}$. If $\bar{v}_0 = 0$ somewhere, then by the strong maximum principle $\bar{v}_0 \equiv 0$. Then the minimum of v_i on $[0,1]$ shrinks to zero as $i \to \infty$. At a minimum point $\bar{x}_0$ of v_i, $v_i' = 0$ and $v_i'' \geq 0$. Then by (3.10), we have that at $\bar{x}_0$,

$$kf(u_i) - \theta - \beta v_i - \chi_i\phi''(u_i)(u_i')^2 - \chi_i\phi'(u_i)f(u_i)v_i \leq 0,$$

i.e.,

$$\frac{kf(u_i) - \chi_i\phi''(u_i)(u_i')^2 - \theta}{\beta + \chi_i\phi'(u_i)f(u_i)} \leq v_i.$$

Thus $kf(u_0(0)) - \theta \leq 0$, contradicting Claim 2. Claim 3 is proved.

Claim 4. $I(x) \equiv kf(u_0(x_0)) - \theta - \beta\bar{v}_0(x) \geq 0$ on $\mathbb{R}$. Suppose $I(x) < 0$ on an interval (r,s). Then (3.17) implies (writing $b = a\phi'(u_0(x_0))u_0'(x_0)$),

$$\bar{v}_0'' - b\bar{v}_0' > 0, \ \text{ i.e., } \ (e^{-bx}\bar{v}_0')' > 0 \ \text{ on } \ (r,s).$$

If there exists $x_0 \in (r,s)$ such that $\bar{v}_0'(x_0) \geq 0$, then $\bar{v}_0' > 0$ on (x_0,s). This implies that $I < 0$ on (x_0,∞) which in return implies $\bar{v}_0' > 0$ on (x_0,∞). Now we see that $\bar{v}_0'' > \text{const} > 0$ on (x_0,∞) which contradicts the boundedness of $\bar{v}_0$. If $\bar{v}_0'(x_0) < 0$, we would be led to a similar contradiction again. Claim 4 is proved.

Claim 5. $I(x) \leq 0$ on $\mathbb{R}$. Suppose $I > 0$ on an interval (r, s). Then $(e^{-bx}\bar{v}_0')' < 0$ on (r, s). If there exists $x_0 \in (r, s)$ such that $\bar{v}_0'(x_0) \geq 0$, then $\bar{v}_0' > 0$ on (r, x_0). Hence $I > 0$, $\bar{v}_0' > 0$ on $(-\infty, x_0)$. Then $\lim_{x\to-\infty} \bar{v}_0(x) = 0$, which implies that $\min_{[0,1]} v_i \to 0$ as $i \to \infty$. As in Claim 3, this is impossible. If $\bar{v}_0'(x_0) < 0$, we will be led to a similar contradiction again.

We have shown $\bar{v}_0 \equiv (kf(u_0(x_0)) - \theta)/\beta$ and hence (3.15). By the equation $u_i'(x) = \int_0^x f(u_i(s))v_i(s)ds$, Lebesgue's dominated theorem, and Claim 1, we have

$$u_0'(x) = \int_0^x f(u_0(s))(kf(u_0(s)) - \theta)/\beta\, ds, \ x \in [0, 1).$$

Therefore u_0 satisfies (3.9). By the comparison principle, (3.9) has at most one solution satisfying $kf(u_0) - \theta \geq 0$, i.e., $u_0 \geq c$ on $[0, 1]$. Thus, without passing to a subsequence, $u_i \to u_0$ in $C^1([0, 1])$ and $v_i \to v_0$ pointwise on $[0, 1)$ as $i \to \infty$. The proof of (iv) is complete.

Proof of (v) *of Theorem* 3.3. We first show that in the current case $\phi(u) = u$, v is strictly increasing on $[0, 1]$. Otherwise, there exist a and b in $[0, 1)$ with $a < b$ such that $v(a) \geq v(b)$ and $v(a)$ and $v(b)$ are local maximum and local minimum, respectively. Then by inspecting (3.10) ($\phi'' = 0$), we have

$$kf(u(a)) - \theta - \beta v(a) - \chi f(u(a))v(a) \geq 0 \geq kf(u(b)) - \theta - \beta v(b) - \chi f(u(b))v(b).$$

Thus

$$\frac{kf(u(a)) - \theta}{\beta + \chi f(u(a))} \geq v(a) \geq v(b) \geq \frac{kf(u(b)) - \theta}{\beta + \chi f(u(b))}.$$

This is impossible because $u(a) < u(b)$ and hence $f(u(a)) < f(u(b))$. We have shown that v is strictly increasing on $[0, 1]$. Now as before, after passing to a subsequence, $v_i \to v_0$ pointwise on $[0, 1)$, $u_i \to u_0$ in $C^1([0, 1])$ as $i \to \infty$.

We first consider the case $\chi_i \to 0$ as $\lambda_i \to 0$. As in the proof of (i) of Theorem 2.1, we have $(kf(u_0) - \theta - \beta v_0)v_0 = 0$ a.e. in $(0, 1)$. By exactly the same arguments in Claim 2 of the proof of (iv), $kf(u_0(x)) - \theta > 0$, $x \in [0, 1]$. This and the arguments in Claim 3 imply $v_0 > 0$. Thus $kf(u_0) - \theta - \beta v_0 = 0$ a.e. on $(0, 1)$. Since both u_0 and v_0 are nondecreasing and u_0 is continuous, the above equation must hold everywhere in $[0, 1)$. In particular, v_0 is continuous on $[0, 1)$. Now it is easy to prove that the convergence $v_i \to v_0$ is uniform outside any fixed neighborhood of $x = 1$. It is also easy to see that u_0 satisfies (3.9) (with $kf(u_0) - \theta = \beta v_0 > 0$). Since u_0 is unique, we have $u_i \to u_0$ in $C^1([0, 1])$, $v_i \to v_0 \equiv (kf(u_0) - \theta)/\beta$ uniformly outside any neighborhood of $x = 1$, without passing to a subsequence.

Now we consider the case when $\chi_i \to \chi_0 > 0$ as $\lambda_i \to 0$. By using the arguments that lead to (2.6), we have

$$\chi_0 u_0'(x)v_0(x) = \int_0^x (kf(u_0(s)) - \theta - \beta v_0(s))v_0(s)ds, \text{ a.e. in } (0, 1). \tag{3.20}$$

From this, we see that $u_0(x) > c$, i.e., $kf(u_0(x)) - \theta > 0$ for $x \in [0, 1)$. Then as can be seen as follows, $v_0(0) > 0$ and hence $v_0 > 0$ on $[0, 1)$. Suppose $v_0(0) = 0$. Since $v_i''(0) \geq 0$ and $v_i'(0) = 0$, by (3.10) we have $kf(u_i(0)) - \theta - \beta v_i(0) - \chi_i f(u_i(0))v_i(0) \leq 0$. Sending $i \to \infty$, we obtain $kf(u_0(0)) - \theta \leq 0$. We have a contradiction. Now $u_0'(x) = \int_0^x f(u_0(s))v_0(s)ds > 0$ for $x \in (0, 1]$. Then (3.20) implies that v_0 is continuous on $(0, 1)$. If we define v_0 at $x = 0, 1$ by the one-sided limits, v_0 is actually continuous on

$[0,1]$ with $v_0 > 0$. Then u_0'' exists on $[0,1]$ and $u_0''(x) = f(u_0(x))v_0(x) > 0$ for $x \in [0,1]$. Now it follows from (3.20) that $(kf(u_0(x)) - \theta - \beta v_0(x))v_0(x) > 0$, $x \in [0,1]$. Thus $kf(u_0) > \theta + \beta v_0$ on $[0,1]$.

Since v_0 is continuous, the convergence $v_i \to v_0$ is uniform outside any neighborhood of $x = 1$. At last, we show $v_i(1) \to \infty$ (this does not contradict $v_0(1) < \infty$). For any $\delta \in (0,1)$, we write

$$\beta \int_0^\delta v_i^2(x)dx = \int_0^1 (kf(u_i(x)) - \theta)v_i(x)dx - \beta \int_\delta^1 v_i^2(x)dx.$$

Sending $i \to \infty$, by Lebesgue's dominated convergence theorem, we have

$$\beta \int_0^\delta v_0^2(x)dx = \int_0^1 (kf(u_0(x)) - \theta)v_0(x)dx - \beta \lim_{i\to\infty} \int_\delta^1 v_i^2(x)dx.$$

Now

$$\begin{aligned}\beta \lim_{\delta\to 1}\lim_{i\to\infty} \int_\delta^1 v_i^2(x)dx &= \int_0^1 (kf(u_0(x)) - \theta)v_0(x)dx - \beta \int_0^1 v_0^2(x)dx \\ &= \int_0^1 (kf(u_0(x)) - \theta - \beta v_0(x))v_0(x)dx > 0.\end{aligned}$$

Thus $v_i(1) \to \infty$ as $i \to \infty$. The proof of Theorem 3.3 is complete.

4. Time-dependent solutions. In this section, we study the global existence and boundedness of solutions of (1.5) ($\beta = 0$ allowed and hence the Malthusian case included). Some estimates proved in the process will be useful in the study of the stability of the trivial steady state $(1,0)$ in the next section.

The local existence and uniqueness of the solution of (1.5) with the initial condition

$$u(x,0) = u_0(x),\ v(x,0) = v_0(x) \tag{4.1}$$

follow from [Am 1, Am 2].

THEOREM 4.1 (local existence). *Extend f and ϕ so that*

$$f \in C^3(\mathbb{R}) \quad \textit{and} \quad \phi \in C^5(\mathbb{R}).$$

(i) *For any u_0, $v_0 \in H^1(0,1)$, there exists a unique maximal solution $(u(x,t), v(x,t))$ defined on $[0,1] \times [0, T_{(u_0,v_0)})$ with $0 < T_{(u_0,v_0)} \le \infty$ such that*

$$\begin{gathered}(u(\cdot,t), v(\cdot,t)) \in C([0,T_{(u_0,v_0)}),\ H^1(0,1) \times H^1(0,1)),\\ (u,v) \in C^{2+2\epsilon,1+\epsilon}_{\text{loc}}([0,1] \times (0, T_{(u_0,v_0)}))\end{gathered}$$

for any $0 < \epsilon < \frac{1}{4}$.

(ii) *Let $\varphi(t,(u_0,v_0))$ be the unique solution described above. Then φ is a $C^{0,1}$-map from $\{(t,(u,v)) \mid (u,v) \in H^1(0,1) \times H^1(0,1),\ 0 < t < T_{(u,v)}\}$ to $H^1(0,1) \times H^1(0,1)$.*

(iii) *If $\|(u,v)(\cdot,t)\|_{L^\infty(0,1)}$ is bounded for $t \in [\delta, T_{(u_0,v_0)})$, δ small, then $T_{(u_0,v_0)} = \infty$, i.e., (u,v) is global in time. Furthermore, $(u,v) \in C^\rho([\delta,\infty),\ C^{2(1-\sigma)}[0,1] \times C^{2(1-\sigma)}[0,1])$ for any $0 \le \rho \le \sigma \le 1$.*

Proof. Let $w = 1 - u$. Then (1.5) is written as follows:

$$\begin{cases} \binom{w}{v}_t = \Big[A(w,v)\binom{w}{v}_x\Big]_x + \binom{f(1-w)v}{(kf(1-w)-\theta-\beta v)v}, \\ A(w,v)\binom{w}{v}_x + H(x)\binom{w}{v} = 0 \ \text{ at } \ x = 0, 1, \end{cases} \tag{4.2}$$

where

$$A(w,v) = \begin{pmatrix} 1 & 0 \\ \chi\phi'(1-w)v & \lambda \end{pmatrix}, \ H(x) = \begin{pmatrix} hx & 0 \\ 0 & 0 \end{pmatrix}.$$

Since the eigenvalues of A are positive, (4.2) is "normally parabolic" [Am 1]. Then (i) and (ii) follow from [Am 1, Theorems 7.3 and 9.3]. (iii) follows from [Am 2, Theorem 5.2] because (4.2) is a "triangular system."

PROPOSITION 4.2 (positivity). *Suppose in Theorem* 4.1, $1 \ge u_0 \ge 0$, $v_0 > 0$ *on* $[0,1]$. *Then* $1 > u > 0$ *and* $v > 0$ *on* $[0,1] \times [0,T)$, $T = T_{(u_0,v_0)}$.

REMARK 4.3. Later we shall handle the case $v_0 \ge 0$ (see the discussion preceding Theorem 4.8).

Proof. Since $(u(\cdot,t), v(\cdot,t)) \in C([0,T), H^1(0,1) \times H^1(0,1)) \subset C([0,T), C[0,1] \times C[0,1])$, if $v > 0$ on $[0,1] \times [0,T)$ is untrue, then there exists $(x_0,t_0) \in [0,1] \times (0,T)$ such that $v(x_0,t_0) = 0$, $v(x,t) > 0$ for $(x,t) \in [0,1] \times [0,t_0)$. v obviously satisfies

$$\begin{cases} v_t = \lambda v_{xx} + b(x,t)v_x + c(x,t)v, \ (x,t) \in [0,1] \times (0,T), \\ \lambda v_x = d(x,t)v \ \text{ at } \ x = 0, 1, \end{cases} \tag{4.3}$$

where b, c, and $d(x,t)$ are continuous on $[0,1] \times (0,T)$. If $x_0 \in (0,1)$, then by the strong maximum principle, $v \equiv 0$ on $[0,1] \times [0,t_0]$, which is impossible. On the other hand, if x_0 is either 0 or 1, then by the boundary condition in (4.3), $v_x(x_0,t_0) = 0$. This also is impossible by the Hopf boundary point lemma. We have thus shown $v > 0$ on $[0,1] \times [0,T)$. Now observe that $\underline{u} \equiv 0$ and $\bar{u} \equiv 1$ are strict lower and upper solutions of the u-equation with the boundary condition in (1.5), because $v > 0$. By the comparison principle, $0 < u < 1$ on $[0,1] \times (0,T)$. Proposition 4.2 is proved.

We now proceed to establish the L^∞-bound of v under the condition on the initial value (u_0,v_0) as in Proposition 4.2. Then in light of (iii) of Theorem 4.1, the global existence of the solution of (1.5) and (4.1) follows. The L^∞-bound of v will be obtained through series of lemmas.

LEMMA 4.4. *Suppose* (u_0,v_0) *satisfies the condition in Theorem* 4.1 *and Proposition* 4.2. *Let* (u,v) *be the unique (positive) solution of* (1.5) *and* (4.1). *Then*

$$\int_0^1 v(x,t)dx \le \int_0^1 (v_0(x) + ku_0(x))dx + k(h+\theta)/\theta, \ 0 \le t < T, \tag{4.4}$$

where $T = T_{(u_0,v_0)}$.

Proof. Let $\bar{u}(t) = \int_0^1 u(x,t)dx$, $\bar{v}(t) = \int_0^1 v(x,t)dx$. Integrating (1.5) on $[0,1]$, we have that for $0 < t < T$,

$$\begin{aligned} \bar{u}'(t) &= -\int_0^1 f(u)v\,dx + h(1 - u(1,t)) \le -\int_0^1 f(u)v\,dx + h, \\ \bar{v}'(t) &\le k\int_0^1 f(u)v\,dx - \theta\bar{v}(t) \le kh - k\bar{u}'(t) - \theta\bar{v}(t), \\ &\le -k\bar{u}'(t) - \theta(\bar{v}(t) + k\bar{u}(t)) + kh + \theta k. \end{aligned}$$

Thus

$$\bar{v}(t) + k\bar{u}(t) \leq e^{-\theta t}(\bar{v}(0) + k\bar{u}(0)) + (kh + \theta k)(1 - e^{-\theta t})/\theta.$$

This completes the proof of Lemma 4.4.

LEMMA 4.5. *Under the condition on (u_0, v_0) in Lemma 4.4 for any small $\delta > 0$, we have*

$$\int_0^1 v^2(x,t)dx \leq 2\int_0^1 v^2(x,\delta)dx + \mu, \ \ \delta \leq t < T,$$

where $T = T(u_0, v_0)$ and μ is a positive constant depending on all the constants in (1.5), *f, ϕ, v_0, and $\|u(x,\delta)\|_{H^2(0,1)}$.*

Proof. We shall use "energy estimates" to get the L^2-bound for v. But because of the chemotactic flux term in the v-equation, we first need to estimate the L^2-norm of u_x.

For $2 > p > 1$, let $X = L^p(0,1)$, $\Delta = \frac{d^2}{dx^2}$ with domain $D(\Delta) = W^{2,p}(0,1) \cap \{u'(0) = 0 = u'(1) + hu(1)\}$. Then Δ generates a linear analytic semigroup $e^{t\Delta}$ on the Banach space X. Since the spectrum of Δ lies on the negative real line, away from 0, $\|e^{t\Delta}\| \leq ce^{-at}$ for $t \geq 0$ and for some positive constant a [H, Thm. 1.3.4]. Also, the fractional space $X^\alpha \hookrightarrow H^1(0,1)$ if $\alpha > (\frac{1}{2} + \frac{1}{p})/2$ [H, Thm. 1.6.1]. We take p close to 1 so α can be taken close to 3/4. By [H, Thm. 1.4.3], $\|e^{t\Delta}\|_\alpha \leq C_\alpha t^{-\alpha}e^{-at}$. Let $w = 1 - u$; then w is the classical solution of

$$\begin{cases} w_t = w_{xx} + f(u)v, \ \ x \in [0,1], \ \ \delta \leq t < T, \\ w_x(0,t) = 0 = w_x(1,t) + hw(1,t), \\ w(x,\delta) = 1 - u(x,\delta). \end{cases} \tag{4.5}$$

Therefore w satisfies the following variation of constants formula:

$$w(\cdot,t) = e^{(t-\delta)\Delta}(1 - u(\cdot,\delta)) + \int_\delta^t e^{(t-s)\Delta}f(u(\cdot,s))v(\cdot,s)ds, \ \ \delta \leq t < T.$$

Now for $\delta \leq t < T$,

$$\begin{aligned} \|u_x(\cdot,t)\|_{L^2(0,1)} &\leq \|w(\cdot,t)\|_{H^1(0,1)} \leq \|w(\cdot,t)\|_{X^\alpha} \\ &\leq \|e^{(t-\delta)\Delta}(1 - u(\cdot,\delta))\|_{X^\alpha} + \int_\delta^t \|e^{(t-s)\Delta}f(u(\cdot,s))v(\cdot,s)\|_{X^\alpha}ds \\ &\leq ce^{-a(t-\delta)}\|1 - u(\cdot,\delta)\|_{X^\alpha} \\ &\quad + \int_\delta^t c_\alpha(t-s)^{-\alpha}e^{-a(t-s)}\|f(u(\cdot,s))v(\cdot,s)\|_X ds. \end{aligned}$$

By the Hölder's inequality,

$$\|v(\cdot,s)\|_X = \|v(\cdot,s)\|_{L^p(0,1)} \leq (\bar{v}(s))^{\frac{2-p}{p}} \left(\int_0^1 v^2(x,s)dx\right)^{\frac{p-1}{p}}.$$

Let $K(t) = \max_{\delta \leq s \leq t} \int_0^1 v^2(x,s)dx$. The above estimates together with Lemma 4.4 imply that for $\delta \leq t < T$,

$$\|u_x(\cdot,t)\|_{L^2(0,1)} \leq c_1 + c_2(K(t))^{\frac{p-1}{p}}, \tag{4.6}$$

where c_1 depends on $\|u(\cdot,\delta)\|_{H^2(0,1)}$, and c_2 on f, v_0, k, h, and θ.

In the following, we use these inequalities:

$$a^r b^{1-r} \le ra + (1-r)b \quad \text{(Young's inequality)}, \tag{4.7}$$

$$\|v\|_{L^\infty(0,1)} \le c\left(\bar{v} + \bar{v}^{1/3}\left(\int_0^1 v_x^2 dx\right)^{1/3}\right), \tag{4.8}$$

$$\int_0^1 v^2 dx \le \varepsilon \int_0^1 v_x^2 dx + (c\varepsilon^{-1/2} + 1)\bar{v}^2 \tag{4.9}$$

(Garliardo–Ladyzenskaya–Nirenberg inequality).

(For (4.8) and (4.9), see [LSU, Thm. 2.2 and Remark 2.1].)

We now multiply v to the v-equation in (1.5) and integrate by parts on $[0,1]$. We obtain that for $\delta \le t < T$,

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\int_0^1 v^2(x,t)dx \\
&\quad \le -\int_0^1 (\lambda v_x - \chi\phi'(u)u_x v)v_x dx + \int_0^1 kf(u)v^2 dx \\
&\quad \le -\lambda\int_0^1 v_x^2 dx + \chi\int_0^1 (\phi'(u)v)u_x v_x dx + kf(1)\int_0^1 v^2 dx \\
&\quad \overset{(4.8)}{\le} -\lambda\int_0^1 v_x^2 dx + c_3\left(\bar{v} + \bar{v}^{1/3}\left(\int_0^1 v_x^2\right)^{1/3}\right)\left(\int_0^1 u_x^2 dx\right)^{1/2}\left(\int_0^1 v_x^2 dx\right)^{1/2} \\
&\qquad\quad + kf(1)\int_0^1 v^2 dx, \\
&\quad \overset{(4.7)}{\le} -\lambda\int_0^1 v_x^2 dx + \frac{\lambda}{4}\int_0^1 v_x^2 dx + \frac{1}{\lambda}c_3^2\bar{v}^2\int_0^1 u_x^2 dx \\
&\qquad\quad + c_3\bar{v}^{1/3}\left(\int_0^1 u_x^2 dx\right)^{1/2}\left(\int_0^1 v_x^2 dx\right)^{5/6} + kf(1)\int_0^1 v^2 dx, \\
&\quad \overset{(4.7)}{\le} \frac{-3\lambda}{4}\int_0^1 v_x^2 dx + \frac{c_3^2\bar{v}^2}{\lambda}\int_0^1 u_x^2 dx + \frac{\lambda}{4}\int_0^1 v_x^2 dx \\
&\qquad\quad + c_4\bar{v}^2\left(\int_0^1 u_x^2 dx\right)^3 + kf(1)\int_0^1 v^2 dx, \\
&\quad \le -\frac{\lambda}{2}\int_0^1 v_x^2 dx + c_5\bar{v}^2 + c_5\bar{v}^2\left(\int_0^1 u_x^2 dx\right)^3 + kf(1)\int_0^1 v^2 dx, \\
&\quad \overset{(4.9)}{\le} -\frac{\lambda}{2\varepsilon}\left(\int_0^1 v^2 dx - (c\varepsilon^{-1/2} + 1)\bar{v}^2\right) + c_5\bar{v}^2 + c_5\bar{v}^2\left(\int_0^1 u_x^2 dx\right)^3 \\
&\qquad\quad + kf(1)\int_0^1 v^2 dx, \\
&\quad = \left(kf(1) - \frac{\lambda}{2\varepsilon}\right)\int_0^1 v^2 dx + c_6\bar{v}^2 + c_5\bar{v}^2\left(\int_0^1 u_x^2 dx\right)^3.
\end{aligned}$$

Taking $\varepsilon = \lambda/(3kf(1))$ and using (4.6), we have

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_0^1 v^2(x,t)dx &\le \frac{-kf(1)}{2}\int_0^1 v^2dx + c_6\bar{v}^2 + c_5\bar{v}^2(c_1 + c_2(K(t))^{(p-1)/p})^6,\\ &\le \frac{-kf(1)}{2}\int_0^1 v^2dx + c_7\bar{v}^2 + c_8\bar{v}^2(K(t))^{6(p-1)/p},\end{aligned}$$

for which it follows that for $\delta \le t < T$,

$$\int_0^1 v^2(x,t)dx \le \int_0^1 v^2(x,\delta)dx + c_9(1 + (K(t))^{6(p-1)/p}).$$

Thus

$$K(t) \le \int_0^1 v^2(x,\delta)dx + c_9(1 + (K(t))^{6(p-1)/p}).$$

Now we take $p > 1$ but close to 1 such that $6(p-1)/p < 1$. Lemma 4.5 follows.

Lemma 4.6. *Let the initial value (u_0, v_0) be as in Lemma 4.4. Then*

$$\|u_x(\cdot,t)\|_{L^\infty(0,1)} \le L,\ \ \delta \le t < T,$$

where the constant L depends on the items that μ in Lemma 4.5 also depends on, plus the L^2-norm of $v(x,\delta)$.

Proof. Take $p = 2$ at the beginning of the proof of Lemma 4.5. Then $X^\alpha \hookrightarrow C^\nu[0,1]$, where ν is any number in $(0, 2\alpha - \frac{1}{2})$. Take $\alpha = 7/8$ so ν can be taken to be 1. Since $w = 1 - u$ satisfies the variation of constants formula below (4.5),

$$\begin{aligned}\|u'\|_{C[0,1]} &\le \|w(\cdot,t)\|_{X^\alpha}\\ &\le ce^{-a(t-\delta)}\|1 - u(\cdot,\delta)\|_{X^\alpha} + \int_\delta^t c_\alpha(t-s)^{-\alpha}e^{-a(t-s)}\|f(u(\cdot,s))v(\cdot,s)\|_X ds,\\ &\overset{\text{(Lemma 4.5)}}{\le} ce^{-a(t-\delta)}\|1 - u(\cdot,\delta)\|_{X^\alpha}\\ &\qquad + \left(2\int_0^1 v^2(x,\delta)dx + \mu\right) f(1)c_\alpha \int_\delta^t (t-s)^{-\alpha}e^{-a(t-s)}ds,\end{aligned}$$

for $\delta \le t < T$. This completes the proof of Lemma 4.6.

Lemma 4.7. *Let the initial value (u_0, v_0) be as in Lemma 4.4. Then $\|v(\cdot,t)\|_{L^\infty} \le c$, $\delta \le t < T$, where constant c depends on all items that L in Lemma 4.6 also depends on, plus $\|v(\cdot,\delta)\|_{L^\infty(0,1)}$.*

Proof. We use the Moser–Alikakos iteration [A]. For $s \ge 2$, multiplying the v-equation in (1.5) by v^{s-1} and integrating on $[0,1]$ by parts, we have

$$\begin{aligned}\frac{1}{s}\frac{d}{dt}\int_0^1 v^s(x,t)dx &\le -\lambda(s-1)\int_0^1 v_x^2 v^{s-2}dx + (s-1)\chi\int_0^1 \phi'(u)u_x v^{s-1}v_x dx\\ &\qquad + kf(1)\int_0^1 v^s dx,\\ &\overset{\text{(Lemma 4.6)}}{\le} \frac{-4\lambda(s-1)}{s^2}\int_0^1 (v^{s/2})_x^2 dx + c_1\int_0^1 v^{s/2}|(v^{s/2})_x|dx\\ &\qquad + kf(1)\int_0^1 v^s dx.\end{aligned}$$

Thus

$$\begin{aligned}
\frac{d}{dt}\int_0^1 v^s(x,t)dx &\le \frac{-4\lambda(s-1)}{s}\int_0^1 (v^{s/2})_x^2 dx + c_1 s\left(\int_0^1 v^s dx\right)^{1/2}\left(\int_0^1 (v^{s/2})_x^2 dx\right)^{1/2}\\
&\qquad + kf(1)s\int_0^1 v^s dx,\\
&\le -2\lambda\int_0^1 (v^{s/2})_x^2 dx + \lambda\int_0^1 (v^{s/2})_x^2 dx + \frac{c_1^2 s^2}{4\lambda}\int_0^1 v^s dx\\
&\qquad + kf(1)s\int_0^1 v^s dx,\\
&\le -\lambda\int_0^1 (v^{s/2})_x^2 dx + c_2 s^2\int_0^1 v^s dx,\\
&\overset{(4.9)}{\le} -\lambda\left(\frac{1}{\varepsilon}\int_0^1 v^s dx - \frac{(c_3\varepsilon^{-1/2}+1)}{\varepsilon}\left(\int_0^1 v^{s/2}dx\right)^2\right) + c_2 s^2\int_0^1 v^s dx,\\
&\le -c_2 s^2\int_0^1 v^s dx + c_4 s^3\left(\int_0^1 v^{s/2}dx\right)^2 \quad \left(\text{taking } \varepsilon = \frac{\lambda}{2c_2 s^2}\right).
\end{aligned}$$

From this, we have that for $\delta \le t < T$,

$$\frac{d}{dt}\left(e^{c_2 s^2 t}\int_0^1 v^s(x,t)dx\right) \le c_4 s^3 e^{c_2 s^2 t}\sup_{\delta\le t<T}\left(\int_0^1 v^{s/2}(x,t)dx\right)^2,$$

$$\int_0^1 v^s(x,t)dx \le \|v(\cdot,\delta)\|_{L^\infty(0,1)}^s + c_5 s\sup_{\delta\le t<T}\left(\int_0^1 v^{s/2}(x,t)dx\right)^2. \tag{4.10}$$

Let $M(s) = \max(\|v(\cdot,\delta)\|_{L^\infty(0,1)},\ \sup_{\delta\le t<T}(\int_0^1 v^s(x,t)dx)^{1/s})$. Then (4.10) implies

$$M(s) \le (c_6 s)^{1/s} M(s/2) \quad\text{for}\quad s \ge 2. \tag{4.11}$$

Taking $s = 2^k,\ k = 1, 2, \ldots$, we obtain

$$\begin{aligned}
M(2^k) &\le c_6^{\frac{1}{2^k}} 2^{\frac{k}{2^k}} M(2^{k-1}),\\
&\le c_6^{\frac{1}{2^k}+\cdots+1} 2^{\frac{k}{2^k}+\cdots+\frac{1}{2}} M(1).
\end{aligned}$$

Sending $k \to \infty$, we have that for $\delta \le t < T$,

$$\begin{aligned}
\|v(\cdot,t)\|_{L^\infty(0,1)} &\le \lim_{k\to\infty} M(2^k),\\
&\le c_7 M(1).
\end{aligned}$$

This completes the proof of Lemma 4.7.

Now, by (iii) of Theorem 4.1, the solution (u,v) of (1.5) and (4.1) is global in t, provided that (u_0, v_0) satisfies the conditions in Theorem 4.1 and Proposition 4.2, i.e., u_0, $v_0 \in H^1(0,1)$, $1 \ge u_0 \ge 0$, $v_0 > 0$ on $[0,1]$. We point out that we can actually allow $v_0 \ge 0, \not\equiv 0$ on $[0,1]$. To see this, we take a sequence v_{0n} in $H^1(0,1)$ with $v_{0n} > 0$ on $[0,1]$ and $v_{0n} \to v_0$ in $H^1(0,1)$. Let (u_n, v_n) be the global positive solutions of

(1.5) and (4.1) (with v_0 replaced by v_{0n}). Then by (ii) of Theorem 4.1, for $x \in [0,1]$, $0 \le t < T_{(u_0,v_0)}$, $(u_n(x,t), v_n(x,t)) \to (u(x,t), v(x,t))$. Thus $1 \ge u \ge 0$, $v \ge 0$. By the strong maximum principle and the Hopf boundary point lemma, $1 > u > 0$, $v > 0$ on $[0,1] \times (0, T_{(u_0,v_0)})$. Note that the condition $1 \ge u_0 \ge 0$, $v_0 > 0$ was required in Lemmas 4.4–4.7 only for the reason of ensuring $1 > u > 0$, $v > 0$. Thus in the present situation, Lemmas 4.4–4.7 still apply and hence $T(u_0, v_0) = \infty$.

We have thus shown the main result of this section.

Theorem 4.8 (global existence and boundedness). *For any $u_0, v_0 \in H^1(0,1)$ satisfying $1 \ge u_0 \ge 0$, $v_0 \ge 0$, $\not\equiv 0$ on $[0,1]$, (1.5) and (4.1) have a unique positive global solution (u,v) such that*

(i) $(u(\cdot,t), v(\cdot,t)) \in C([0,\infty),\ H^1(0,1) \times H^1(0,1))$, $(u,v) \in C^{2+2\varepsilon,1+\varepsilon}_{\text{loc}}([0,1] \times [0,\infty))$;

(ii) $0 < u < 1$, $v > 0$ *and is bounded on* $[0,1] \times [0,\infty)$.

5. Stability and instability of steady states. The first result of this section deals with the stability of the trivial steady state $(u,v) = (1,0)$ of (1.5) (again $\beta = 0$ is allowed so that both Malthusian and logisitc cases are included).

Theorem 5.1. (i) *Suppose $kf(1) \le \theta$. Then in L^∞-topology $(u,v) = (1,0)$ attracts every positive solution of* (1.5) *whose initial value $(u(x,0), v(x,0)) = (u_0(x), v_0(x))$ satisfies the condition in Theorem* 4.8. *Furthermore, if $kf(1) < \theta$, then $\|v(\cdot,t)\|_{L^\infty} \le C\ \exp((kf(1)-\theta)t)$, $\|1-u(\cdot,t)\|_{L^\infty} \le C\ \exp(-\min(a, \theta - kf(1))t)$, $t \ge 0$, where a is any number less than the first eigenvalue α of $-d^2/dx^2$ with the boundary condition $u'(0) = 0 = u'(1) + hu(1)$; if $kf(1) = \theta$ and $\beta > 0$, then $\|v(\cdot,t)\|_{L^\infty} \le \frac{C}{\beta t+1}$, $\|1-u(\cdot,t)\|_{L^\infty} \le \frac{C}{\beta t+1}$, $t \ge 0$.*

(ii) *Suppose $kf(1) > \theta$. Then $(u,v) = (1,0)$ is unstable in the L^∞-topology.*

Proof of (i). Consider first the case $kf(1) < \theta$. Let $z = e^{(\theta - kf(1))t} v$. Then

$$(5.1)\qquad \begin{cases} z_t \le (\lambda z_x - \chi\phi'(u) u_x z)_x, \\ \lambda z_x - \chi\phi'(u) u_x z = 0 \ \text{ at } \ x = 0,1, \\ z(x,0) = v_0(x). \end{cases}$$

Integrating (5.1) on $[0,1]$, we see that

$$\int_0^1 z(x,t)dx \le \int_0^1 v_0(x)dx,\ t \ge 0.$$

This and the proof of Lemma 4.7 imply that $\|z(\cdot,t)\|_{L^\infty} \le \text{const } C$, i.e., $\|v(\cdot,t)\|_{L^\infty} \le C\ \exp((kf(1)-\theta)t)$, $t \ge 0$. We now use the comparison principle to obtain a decay rate for $\|1-u(\cdot,t)\|_{L^\infty}$. Observe $1-u$ is a subsolution of

$$(5.2)\qquad \begin{cases} w_t = w_{xx} + C\ \exp((kf(1)-\theta)t), \\ w_x(0,t) = 0 = w_x(1,t) + hw(1,t), \\ w(x,0) = 1 - u_0(x). \end{cases}$$

Define $\bar{w}(x,t) = K\psi(x)e^{-\min(a,\theta-kf(1))t}$, where $K > 0$ is a constant, ψ is a first eigenfunction of $-d^2/dx^2$ with the boundary condition $u'(0) = 0 = u'(1) + hu(1)$. Since $\psi(x) > 0$ on $[0,1]$, we see for a large enough K, $\bar{w}$ is a supersolution of (5.2). By the comparison principle, $0 \le 1 - u(x,t) \le \bar{w}(x,t)$, $x \in [0,1]$, $t \ge 0$. Hence $\|1-u(\cdot,t)\|_{L^\infty} \le C\ \exp(-\min(a, \theta - kf(1))t)$, $t \ge 0$.

Now we consider the case $kf(1) = \theta$, $\beta > 0$. Integrating the v-equation in (1.5) gives

$$\bar{v}'(t) \le -\beta \int_0^1 v^2(x,t)dx \le -\beta\bar{v}^2(t),\ t \ge 0.$$

So

$$\bar{v}(t) \leq \frac{C}{\beta t + 1},\ t \geq 0. \tag{5.3}$$

Let $z(x,t) = (\beta t + 1)v(x,t)$. Then

$$\begin{cases} z_t \leq (\lambda z_x - \chi\phi'(u)u_x z)_x + \beta z, \\ \lambda z_x - \chi\phi'(u)u_x z = 0 \text{ at } \ x = 0, 1, \\ z(x,0) = v_0(x). \end{cases} \tag{5.4}$$

Again, (5.3) and the proof of Lemma 4.7 imply that $\|z(\cdot,t)\|_{L^\infty} \leq \text{const } C$, i.e., $\|v(\cdot,t)\|_{L^\infty} \leq C/(\beta t + 1),\ t \geq 0$. By a comparison argument as above, we also have $\|1 - u(\cdot,t)\|_{L^\infty} \leq C/(\beta t + 1)$, $t \geq 0$.

Next, we consider the case $kf(1) = \theta$, $\beta = 0$. Integrating the v-equation in (1.5) and using the fact that $kf(u) - \theta = kf(u) - kf(1) \leq -k \min_{\eta\in[0,1]} f'(\eta)\ (1-u)$, we have

$$\bar{v}'(t) \leq -C \int_0^1 (1 - u(x,t))v(x,t)dx,\ t \geq 0. \tag{5.5}$$

Because of the global boundedness of v, we have

$$\int^\infty \int_0^1 (1 - u(x,t))v(x,t)dx\, dt < \infty. \tag{5.6}$$

Let $w = 1 - u$. By the u-equation in (1.5), we obtain

$$\frac{1}{2}\frac{d}{dt}\int_0^1 w^2(x,t)dx \leq -hw^2(1,t) - \int_0^1 w_x^2(x,t)dx + C\int_0^1 w(x,t)v(x,t)dx.$$

This and (5.6) imply

$$\int^\infty w^2(1,t)dt < \infty,\ \int^\infty \int_0^1 w_x^2(x,t)dx\, dt < \infty. \tag{5.7}$$

By the second part of (iii) of Theorem 4.1, $w(1,t)$ and $\int_0^1 w_x^2(x,t)dx$ are uniformly continuous on $[0,\infty)$ and hence by (5.7), $w(1,t) \to 0$ and $\int_0^1 w_x^2(x,t)dx \to 0$ as $t \to \infty$. Now

$$|w(x,t) - w(1,t)| \leq \int_0^1 |w_x(x,t)|dx \leq \left(\int_0^1 w_x^2(x,t)dx\right)^{1/2} \to 0$$

as $t \to 0$. Thus $\|1 - u(\cdot,t)\|_{L^\infty} \to 0$ as $t \to \infty$.

We proceed to show $\|v(\cdot,t)\|_{L^\infty} \to 0$ as $t \to \infty$. Since $\bar{v}'(t) + k\bar{u}'(t) = kh(1 - u(1,t)) - \theta\bar{v}(t)$ and since $\bar{v}(t)$ is decreasing (see (5.5)), $\bar{v}(t) \to 0$ as $t \to \infty$. By the v-equation in (1.5) again,

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\int_0^1 v^2(x,t)dx &\leq -\lambda\int_0^1 v_x^2(x,t)dx + \chi\int_0^1 \phi'(u)u_x v v_x dx \\ &\leq -\frac{\lambda}{2}\int_0^1 v_x^2(x,t)dx + C\int_0^1 u_x^2(x,t)dx.\end{aligned}$$

Then the global boundedness of v and (5.7) imply

$$\int^{\infty}\int_0^1 v_x^2(x,t)dx\,dt<\infty. \tag{5.8}$$

By the second part of (iii) of Theorem 4.1 again, $\int_0^1 v_x^2(x,t)dx$ is uniformly continuous on $[0,\infty)$ and hence by (5.8), we have $\int_0^1 v_x^2(x,t)dx\to 0$ as $t\to\infty$. Now

$$|v(x,t)-\bar{v}(t)|\leq\left(\int_0^1 v_x^2(x,t)dx\right)^{1/2}\to 0,$$

and thus $\|v(\cdot,t)\|_{L^\infty}\to 0$ as $t\to\infty$.

Proof of (ii) *of Theorem* 5.1. Let N_δ be the neighborhood of the trivial steady state $(1,0)$ consisting of (u,v) such that $\|1-u\|_{L^\infty}+\|v\|_{L^\infty}<\delta$. We want to show that for a small $\delta>0$, the solution $(u(\cdot,t),v(\cdot,t))$ of (1.5) always leaves N_δ in finite time no matter how close the initial value (u_0,v_0) is to $(1,0)$ (assuming (u_0,v_0) satisfies the condition in Theorem 4.8). If this is not true, then for a small $\delta>0$,

$$kf(u(x,t))-\theta-\beta v(x,t)\geq(kf(1)-\theta)/2,\ x\in[0,1],\ t\geq 0.$$

Thus by integrating the v-equation in (1.5), we have

$$\frac{d}{dt}\int_0^1 v(x,t)dx\geq\frac{(kf(1)-\theta)}{2}\int_0^1 v(x,t)dx,\ t\geq 0.$$

This obviously makes it impossible for $(u(\cdot,t),v(\cdot,t))$ to stay in N_δ forever. This completes the proof of Theorem 5.1.

Next we wish to establish the asymptotic stability of the positive steady states of (1.5) (again $\beta=0$ is allowed) when θ less than but close to $kf(1)$. By the proof of Theorem 3.1, (1.5) has a unique positive steady state $(u(s,x),v(s,x))$, $0<s<\varepsilon$, such that $kf(1)-\theta=\mu(s)$, $u(s,\cdot)=1-s(K_1f(1)+\psi_1(s))$, $v(s,\cdot)=s(1+\psi_2(s))$. Recall that $\mu(0)=0<\mu'(0)$, $\psi_1(0)=\psi_2(0)=0$.

THEOREM 5.2. *For θ less than but close to $kf(1)$, the unique positive solution of* (1.5) *($\beta=0$ allowed) is exponentially asymptotically stable in the $H^1(0,1)$ topology.*

Proof. Linearize (1.5) at $(u(s,\cdot),v(s,\cdot))$. By the principle of the linearized stability ([S, Thm. 8.6], [D, Thm. 5.2]), we only need to show the negativeness of the real part of the eigenvalues η of the linearized elliptic problem

$$\begin{cases} u''-f'(u(s,\cdot))v(s,\cdot)u-f(u(s,\cdot))v=\eta u,\\ [\lambda v'-\chi\phi''(u(s,\cdot))u'(s,\cdot)v(s,\cdot)u-\chi\phi'(u(s,\cdot))v(s,\cdot)u'\\ \qquad -\chi\phi'(u(s,\cdot))u'(s,\cdot)v]'+(kf(u(s,\cdot))-kf(1)-\beta v(s,\cdot))v\\ \qquad +(kf'(u(s,\cdot))u-\beta v)v(s,\cdot)+\mu(s)v=\eta v,\\ u'(0)=0=u'(1)+hu(1),\\ \lambda v'-\chi\phi''(u(s,x))u'(s,x)v(s,x)u-\chi\phi'(u(s,x))v(s,x)u'\\ \qquad -\chi\phi'(u(s,x))u'(s,x)v=0\quad\text{at}\quad x=0,1. \end{cases} \tag{5.9}$$

Multiplying u^* and v^* (the conjugates of u and v) to the u-equation and v-equation in (5.9), respectively, then integrating by parts, we see that (a) the real part of the eigenvalues is bounded above uniformly with respect to small $s>0$; (b) the imaginary part of the eigenvalues in any fixed vertical strip on the plane is bounded uniformly with respect to small $s > 0$.

Then since the set of the eigenvalues is discrete, there is an eigenvalue, denoted by $\eta(s)$, whose real part is the largest. We wish to show $\operatorname{Re}\eta(s) < 0$ for all small $s > 0$. Suppose otherwise; then $\operatorname{Re}\eta(s) \geq 0$ along a subsequence $s \to 0$. Now by the above discussion, $\eta(s)$ is bounded and hence we can assume $\eta(s) \to \eta_0$ as $s \to 0$, where $\operatorname{Re}\eta_0 \geq 0$.

We claim $\eta_0 = 0$. Denote the eigenvector corresponding to $\eta(s)$ by $(\widetilde{u}(s,\cdot), \widetilde{v}(s,\cdot))$ which is normalized: $\|\widetilde{u}(s,\cdot)\|^2_{L^2(0,1)} + \|\widetilde{v}(s,\cdot)\|^2_{L^2(0,1)} = 1$. By the elliptic regularity theory, after passing to a subsequence, $(\widetilde{u}(s), \widetilde{v}(s)) \to (\widetilde{u}_0, \widetilde{v}_0)$ in $C^2([0,1])$ as $s \to 0$. $(\widetilde{u}_0, \widetilde{v}_0)$ is nonzero and satisfies

$$\begin{cases} \widetilde{u}_0'' - f(1)\widetilde{v}_0 = \eta_0 \widetilde{u}_0, \\ \lambda \widetilde{v}_0'' = \eta_0 \widetilde{v}_0, \\ \widetilde{u}_0'(0) = 0 = \widetilde{u}_0'(1) + h\widetilde{u}_0(1), \\ \widetilde{v}_0'(0) = 0 = \widetilde{v}_0'(1). \end{cases}$$

Thus $\eta_0 = 0$ and $(\widetilde{u}_0, \widetilde{v}_0) = (-K_1 f(1), 1)/(1 + \|K_1 f(1)\|^2_{L^2})$.

We now renormalize $(\widetilde{u}(s), \widetilde{v}(s))$ so that it converges to $(-K_1 f(1), 1)$ in $C^2([0,1])$ as $s \to 0$. Since $\int_0^1 (kf(u(s,x)) - kf(1) - \beta v(s,x) + \mu(s))v(s,x)dx = 0$, we have ("$\bullet$" meaning differentiation in s-variable),

$$\begin{aligned} &\int_0^1 (kf'(u(s,x))\overset{\bullet}{u}(s,x) - \beta \overset{\bullet}{v}(s,x) + \mu'(s))v(s,x)dx \\ &\qquad + \int_0^1 (kf(u(s,x)) - kf(1) - \beta v(s,x) + \mu(s))\overset{\bullet}{v}(s,x)dx = 0. \end{aligned} \tag{5.10}$$

Integrating the v-equation in (5.9) (with $\eta = \eta(s)$, $(u,v) = (\widetilde{u}(s), \widetilde{v}(s))$, we have

$$\begin{aligned} &\int_0^1 (kf'(u(s,x))\widetilde{u}(s,x) - \beta \widetilde{v}(s,x))v(s,x)dx \\ &\qquad + \int_0^1 (kf(u(s,x)) - kf(1) + \mu(s) - \beta v(s,x))\widetilde{v}(s,x)dx \\ &= \eta(s) \int_0^1 \widetilde{v}(s,x)dx. \end{aligned} \tag{5.11}$$

Comparing (5.11) with (5.10), we have

$$\eta(s)(1 + o(1)) = o(s) - \mu'(s)s(1 + o(1)) = s(-\mu'(0) + o(1)).$$

Since $\mu'(0) > 0$, $\operatorname{Re}\eta(s) < 0$ for small $s > 0$, contradicting our assumption $\operatorname{Re}\eta(s) \geq 0$. Theorem 5.2 is proved.

STOPPING TIMES AND LOCAL CONVERGENCE FOR SPLINE WAVELET EXPANSIONS[*]

RICHARD F. GUNDY[†] AND KAZAROS KAZARIAN[‡]

Abstract. A local convergence theorem for spline wavelet expansions is proved. This theorem relates the finiteness of the quadratic variation of the expansion with the local convergence of the expansion on sets of positive measure. A stability property of these expansions is one of the key points in the proof.

Key words. wavelets, stopping times, martingales

1. Introduction.

The principal purpose of this paper is to prove a local convergence theorem for spline wavelet expansions, using a combination of techniques from martingale theory and wavelet analysis. In particular, we show that the notion of a stopping time may be adapted to these wavelet expansions.

The Haar functions are the point of departure for this discussion. The Haar series may be viewed as the sequence of partial sums of orthogonal elements from the multiresolution analysis generated by the dilations and translations of $\chi_{[0,1]}(x)$, the indicator function of the unit interval. On the other hand, this sequence of partial sums forms a martingale with respect to the filtration of σ-fields generated by the (dyadic) dilations and (integer) translations of $\chi_{[0,1]}$. This coincidence is unique: no other multiresolution analysis generates martingales in a similar fashion. The following theorem concerning Haar functions is proved by martingale methods [3] (see also [5]).

THEOREM A. *Let $f = (f_0, f_1, \ldots)$ be the sequence of partial sums of a Haar series on $[0,1]$. Then the following sets are equivalent, i.e., they differ by at most a set of Lebesgue measure zero:*

$$A = \{x : f^*(x) := \sup_n |f_n(x)| < \infty\};$$

$$B = \left\{ x : S^2(f)(x) := \sum_0^\infty (f_n(x) - f_{n-1}(x))^2 < \infty \right\};$$

$$C = \{x : \limsup f_n(x) = \liminf f_n(x)\}.$$

This theorem is not true for other martingales, in general. Some additional stability condition must be assumed. The goal of this paper is to extend this local convergence theorem for a class of wavelet expansions satisfying a stability condition. This class includes the series arising from polynomial spline wavelets. The precise statement of the theorem, together with the stability condition, is given below.

2. Notation. We will use a *multiresolution analysis* $V = \{V_j; -\infty < j < \infty\}$ generated by a compactly supported, continuous (pre)scale function $\phi(x)$. That is, we require that ϕ have a nonzero integral, that it satisfy a dilation equation of the form

$$\phi(x) = \sum_{k=0}^{N} p_k \phi(2x - k), \tag{a}$$

and that

$$\sum a_n^2 \cong \left\| \sum a_k \phi(x-k) \right\|_2^2 \tag{b}$$

(the translates of ϕ are a Riesz basis). Linear combinations of the translates of ϕ form a subspace of $L^2(\mathbf{R})$; the L^2-closure of this subspace is denoted by V_0. Dyadic dilations of functions in V_0 form a closed subspace of $L^2(\mathbf{R})$, denoted by V_j ($f(\cdot) \in V_j$ iff $f(2^{-j}\,\cdot) \in V_0$). If $V_j \subset V_{j+1}$ for all integers j it then follows that the increasing sequence of subspaces $\{V_j\}$ exhausts $L^2(\mathbf{R})$ (see [6, Chapter 2, p. 48]). Let P_j be the orthogonal projection operator from L^2 onto V_j.

A special case of a multiresolution analysis of this type is the one generated by $\phi(x) = \chi_{[0,1]}(x)$. In this case, the projections P_j are conditional expectations, and a sequence $P_j(f)(x)$ forms a martingale. To distinguish this special case, we use D_0 to denote the set of *all* linear combinations of translates $\chi_{[0,1]}(\cdot - k)$, $k \in \mathbf{Z}$, and $D = \{D_j; -\infty < j < \infty\}$ to denote the set of 2^j-dilates of elements of $D_0 : D_j = \{f : f(2^{-j}x) \in D_0\}$. A *stopping time* $\tau(x)$ is a function with values in $\mathbf{Z}_+ \cup \{\infty\}$, such that the indicator function of $\{x : \tau(x) = j\}$ belongs to D_j.

3. Prewavelets with compact support. In this paper we assume that ϕ is supported in the interval $[0, N]$. This implies the existence of a prewavelet ψ having compact support. By this, we mean a function $\psi \in V_0$ such that $\psi(2x - 2k)$, $k \in \mathbf{Z}$, is a Riesz basis in the orthogonal complement of V_0 in V_1, usually written as W_0. The function $\psi(2\,\cdot)$ is necessarily of the form

$$\psi(2x) = \sum_{-N+1}^{2N-1} c_k \phi(2x - k),$$

and since $\psi(2\,\cdot) \in W_0$, we have

$$\int \phi(x)\bar{\psi}(2x)dx = \sum_{-N+1}^{2N-1} \bar{c}_k \int \phi(x)\overline{\phi(2x-k)}dx = 0.$$

If we set

$$e_k = \int \phi(x)\overline{\phi(2x-k)}dx,$$

one solution to this equation is given by $c_k = (-1)^k \bar{e}_{1-k}$; the products $\bar{c}_k e_k$ and $\bar{c}_{1-k} e_{1-k}$ have opposite signs and equal magnitudes and so cancel in pairs. The function $\psi(2x)$ is compactly supported on the interval $[-N+1, 3N-1]$ since $e_k \equiv 0$ if $k \notin [-N+1, 2N-1]$. It turns out that, with this choice, the translates $\psi(2x - 2k)$, $k \in \mathbf{Z}$, form a Riesz basis for W_0 (see [6]). (We pause here to note that our notation is slightly different from the usual custom, where $\psi(x)$ is taken to be a function in W_0, whose translates $\psi(x-k)$, $k \in \mathbf{Z}$, form a Riesz basis. Our notation seems to us to make the exposition run more smoothly.) We shall also use the notions of dual prescale function and dual prewavelet (see Chui [2, Chapter 5, p. 170]). The dual prescale function $\tilde{\phi}$ is a function that belongs to V_0 and satisfies

$$\int \phi(x-k)\overline{\tilde{\phi}(x)}dx = \delta_0(k).$$

The dual prewavelet satisfies $\tilde{\psi}(2x) \in W_0$:

$$\int \psi(2x-2k)\overline{\tilde{\psi}(2x)}dx = \delta_0(k).$$

We now impose an additional stability condition on the prescale function ϕ.

Condition (M-Z). Given any measurable subset $E \subseteq [0,1]$, of measure greater than $\delta > 0$, and any sequence a_k, $k = -N+1, \ldots, 0$, we have

$$\sum_{k=-N+1}^{0} |a_k| \le c(\delta) \sup_{x\in E} \left| \sum_{k=-N+1}^{0} a_k \phi(x-k) \right|,$$

where $c(\delta)$ depends on δ but is otherwise independent of E.

Remarks. Since ϕ is assumed to be bounded, the inequality may be reversed at the expense of another constant. That is,

$$c^{-1}(\delta) \sum_{k=-N+1}^{0} |a_k| \le \sup_{x\in E} \left| \sum_{k=-N+1}^{0} a_k \phi(x-k) \right| \le c \sum_{k=-N+1}^{0} |a_k|.$$

This "two-norm" condition is in the same spirit as a stability condition suggested by Marcinkiewicz and Zygmund in their study of convergence of series of independent random variables [8]. Their stability condition was introduced in a conditional form in [4] to prove a generalization of Theorem A. This conditional stability condition is the basis for the results in [1].

The Haar scale function $\chi_{[0,1]}(x)$ satisfies Condition (M-Z) in a vacuous way. On the other hand, if we take the N-fold convolution of $\chi_{[0,1]}$ with itself, we obtain a prescale function ϕ for the multiresolution analysis of polynomial splines of degree $N-1$. The translates $\phi(x-k)$, $k = -N+1, \ldots, 0$, are linearly independent polynomials on $[0,1]$. Given $E \subseteq [0,1]$ of measure greater than $\delta > 0$, we can find $x_1, \ldots, x_N$, $x_i \in E$, such that

$$\min_{i,j} |x_i - x_j| = O_N(\delta).$$

Now write

$$\sum_{-N+1}^{0} a_k \phi(x-k) = \sum_{k=0}^{N-1} b_k x^k$$

and compute the coefficients b_k by using Cramer's rule on the Vandermonde determinant at the points $x_1, \ldots, x_N$. This gives an estimate for the b-sequence:

$$\sum_{k=0}^{N-1} |b_k| \le c(\delta) \sup_{x\in E} \left| \sum_{k=-N+1}^{0} a_k \phi(x-k) \right|,$$

and consequently, the same estimate for the a-sequence:

$$\sum_{k=-N+1}^{0} |a_k| \leq c'(\delta) \sup \left| \sum_{k=-N+1}^{0} a_k \phi(x-k) \right| .$$

Results. The principal result is as follows.

THEOREM B. *Suppose that ϕ is a prescale function that satisfies Condition* (M-Z). *Suppose that $f = (f_{j-1}, f_j, \ldots)$ is a sequence of functions such that*

$$P_j(f_{j+1}) = f_j$$

for every $j \in \mathbf{Z}$. Then the following sets are equal almost everywhere (a.e.):

$$A = \left\{ x : f^*(x) := \sup_j |f_j(x)| < \infty \right\};$$

$$B = \left\{ x : S^2(f)(x) = \sum_{j=-\infty}^{\infty} (f_j(x) - f_{j-1}(x))^2 < \infty \right\};$$

$$C = \left\{ x : \overline{\lim} f_j(x) = \underline{\lim} f_j(x) < \infty \right\}.$$

(That is, the Lebesgue measure of the sets $A \triangle B, A \triangle C, C \triangle B$ vanishes.)

Proof. Before giving the details of the proof, let us outline the strategy. It is enough to prove the theorem with the sets A, B, C restricted to any interval of unit length. Therefore, we assume that A, B, and C are subsets of the unit interval. Given $\epsilon > 0$, we may also assume that the measure of any one of these sets is greater than $1 - \epsilon$. Both of these assumptions amount to an appropriate choice of an origin for the dilation scale. Since $f_0 \in L^2(\mathbf{R})$, we have

$$\sup_{j \leq 0} |f_j(x)| < \infty;$$

$$\sum_{j \leq 0} (f_j(x) - f_{j-1}(x))^2 < \infty.$$

(See [6].) Therefore, we restrict attention to $f_j(x)$, $x \in [0,1]$, and $j \geq 0$. □

The basic idea of the proof is to introduce a (dyadic) stopping time $\tau = \tau_\lambda$ with the property that $\{\tau(x) = \infty\}$ (essentially) coincides with the set A_λ (or B_λ) where $f^*(x) \leq \lambda$ (or $S(f) < \lambda$). Furthermore, the stopping time should be such that the stopped sequence $f_{\tau(\cdot) \wedge j}(\cdot)$ is uniformly bounded in $L^2(\mathbf{R})$. *If it were true* that the projections P_j commute with the stopping time, i.e.,

$$P_j(f_{\tau \wedge (j+1)}) = f_{\tau \wedge j},$$

then the sequence $f^\tau = (f_{\tau \wedge 1}, f_{\tau \wedge 2}, \ldots)$ would satisfy

$$S^2(f)(x) = S^2(f^\tau)(x)$$

on $\{x : \tau(x) = \infty\}$. This would imply that $A_\lambda \subseteq B$ since

$$\|S(f^\tau)\|_2 = \sup_j \|f_{\tau \wedge j}\|_2 < \infty.$$

The commutation hypothesis (that P_j commute with all dyadic stopping times) is equivalent to assuming that the P_j are dyadic conditional expectations. In this case, the sequence f_j is forced to be a martingale. Since those sequences we deal with here are not martingales, we cannot prove the theorem in this way. Nevertheless, the strategy may be rescued from obvious failure. The proof is carried out by an inductive procedure that involves a number of details. In order to clarify the description, we proceed in steps.

Step 1. We now prove that $A \subseteq B$, assuming that $A \subseteq [0,1]$ and that $\text{meas}(A) > 1-\epsilon$. Here $\epsilon > 0$ is assumed to be small, subject to constraints that will become clear as the discussion unfolds. Since $f_0(x)$ is restricted to the unit interval, we may write

$$f_0(x) = \sum_{j=-N+1}^{0} a_j \phi(x-j).$$

Choose $\lambda > 0$ and define

$$A_\lambda^c := \left\{ x : \sup_{j \geq 0} |f_j(x)| > \lambda \right\}.$$

Then A_λ^c satisfies $A_\lambda^c \supset A^c$, and if λ is large enough, we will have

$$\text{meas}(A_\lambda^c) \leq 2\epsilon.$$

We construct a covering of A_λ^c by dyadic intervals, defined by means of a stopping time $\gamma(x)$ relative to the dyadic multiresolution analysis D. This stopping time will be modified by subsequent considerations before we are finished.

Step 2. We wish to project the characteristic function of the set A_λ^c onto the space D_j; let g_j be this projection. The function g_j is just the average of the characteristic function of A_λ^c over each dyadic interval of length 2^{-j}. The sequence g_j, $j \geq 0$, is a dyadic martingale. Define

$$\gamma(x) = \inf \{ j : g_j(x) \geq 1/2 \}, \quad \text{where } \gamma(x) = \infty \text{ if this set is empty.}$$

By Doob's maximal inequality, applied to the sequence g_j, $j \geq 0$, we have

$$\text{meas}\{x : \gamma(x) < \infty\} \leq 2 \ \text{meas}(A_\lambda^c) \leq 4\epsilon.$$

The stopping time $\gamma(x)$ determines a family of disjoint subintervals of $[0,1]$ defined by $\{x : \gamma(x) = j\}$. These intervals are unions of dyadic intervals of length 2^{-j}. A connected union of maximal length is called a component of $\{x : \gamma(x) = j\}$.

Step 3. Starting with level $n_1 = \inf_x \gamma(x)$, the components of $\{x : \gamma(x) = n_1\}$ are divided into three classes: The first class consists of all components of length less than $N \cdot 2^{-n_1}$. The second class consists of all components of length greater than or equal to $N \cdot 2^{-n_1}$ but less than $8N \cdot 2^{-n_1}$. The third class consists of components of length greater than or equal to $8 \cdot N \cdot 2^{-n_1}$. We modify the intervals of the second class by extending them, to the right, by a union of dyadic intervals such that the total length of the enlarged interval (the component plus the added intervals) equals $8N \cdot 2^{-n_1}$. The entire set of intervals obtained in this way may again be divided into two components: (a) short components of length less than $N \cdot 2^{-n_1}$ and (b) the remaining components of length greater than or equal to $8N \cdot 2^{-n_1}$. We modify the stopping time $\gamma(x)$ to obtain another one, $\tau(x)$, in the following ways: (a) $\tau(x) = n_1$

for points in any component containing the point $x = 0$ or $x = 1$ if such a component exists. (b) $\tau(x) = n_1$ for points in the long components (of length greater than or equal to $8 \cdot N2^{-n_1}$). (c) On the remaining points, $\tau(x) > n_1$ and will be defined by the inductive process. To recapitulate, we have enlarged the set $\{x : \gamma(x) = n_1\}$ to obtain a new set of components. The measure of the enlarged set is no greater than nine times the measure of the components of $\{x : \gamma(x) = n_1\}$ of intermediate length. The stopping time $\tau(x) = n_1$ on the "long" components and on the components, if they exist, containing $x = 0$ or $x = 1$. The "short" components of the enlarged set are those that do not contain $x = 0$ or $x = 1$ and whose length does not exceed $N \cdot 2^{-n_1}$.

Step 4. We now continue the induction as follows: Consider the set of short components, just cited, together with the set $\{x : \gamma(x) = n_1 + 1\}$. We combine the short components of the set $\{x : \gamma(x) = n_1\}$ and those components of the set $\{x : \gamma(x) = n_1 + 1\}$ that do not belong to the set $\{x : \tau(x) = n_1\}$. The union of these two sets is a collection of dyadic intervals of length $2^{-(n_1+1)}$. The components of this set are sorted into three categories as before: those of length less than $N \cdot 2^{-(n_1+1)}$, those of intermediate length, from $N \cdot 2^{-(n_1+1)}$ to $8N \cdot 2^{-(n_1+1)}$, and those of length greater than or equal to $8N \cdot 2^{-(n_1+1)}$. The components of intermediate length are enlarged so that they have length exactly $8N \cdot 2^{-(n_1+1)}$. (This enlargement is made simply by adjoining adjacent dyadic intervals, of length $2^{-(n_1+1)}$, to the right of the component in question. The new component may overlap some of the set $\{x : \tau(x) = n_1\}$, as well as other components of $\{x : \gamma(x) \leq n_1 + 1\}$ not contained in $\{x : \tau(x) = n_1\}$.) We now combine the short, enlarged, and long components of this set *together with* the components of the set $\{x : \tau(x) = n_1\}$. Since the components of $\{x : \tau(x) = n_1\}$ are all longer than $8N \cdot 2^{-n_1}$, the *components of the combined set* are either longer than or equal to $8 \cdot N \cdot 2^{-(n_1+1)}$ or shorter than $N \cdot 2^{-(n_1+1)}$.

We now define $\tau(x) = n_1 + 1$ for points x in a long component of the combined set if $\tau(x)$ has not been previously defined. We also define $\tau(x) = n_1 + 1$ if x is in a component (long or short) that contains 0 or 1 and $\tau(x)$ has not been previously defined. Thus, the only components that remain are short and isolated; that is, they are of length less than $N \cdot 2^{-(n_1+1)}$ and lie in the interior of the *complement* of the long components and contain neither 0 nor 1.

Step 5. The passage from n_1 to n_1+1 is indicative of the induction procedure. At the nth stage, the set $\{x : \tau(x) = n\}$ has been defined. The short components defined by the procedure are of length less than $N \cdot 2^{-n}$ and lie in the interior of the unit interval, separated from the long components by a distance of at least 2^{-n}. These short components are a part of the set $\{x : \gamma(x) \leq n\}$.

The short components are combined with that part of the set $\{x : \gamma(x) = n + 1\}$ that remains in the complement of $\{x : \tau(x) \leq n\}$ and are treated as in Step 3 to define the set $\{x : \tau(x) = n + 1\}$.

Step 6. We now make a penultimate adjustment in the definition of $\tau(x)$. At each stage, if the set $\{x : \tau(x) = n\}$ produces complementary intervals belonging to the complement of $\{x : \tau(x) \leq n\}$ that are of length less than $8N \cdot 2^{-n}$, we adjoin them to the set $\{x : \tau(x) = n\}$. (That is, we define $\tau(x) = n$ on these intervals also.) This addition will take place only if new points were added to the set $\{x : \tau(x) < n\}$ by additional stopping. A fixed component of $\{x : \tau(x) = n\}$ can have at most two "small" complementary contiguous intervals, and the components of $\{x : \tau(x) = n\}$ are at least of length 2^{-n}. Therefore, this addition multiplies the measure of $\{x : \tau(x) = n\}$ by a factor no greater than $16N$.

Step 7. It remains for us to estimate the measure of the set $\{x : \tau(x) < \infty\}$. First of all, let us observe that $\tau(x)$ satisfies

$$\gamma(x) \leq \tau(x) \leq \gamma(x) + \log_2 N$$

since any component of $\{x : \gamma(x) = n\}$ must be "long" or "intermediate" if the scale is 2^{-m}, where $N \cdot 2^{-m} \leq 2^{-n}$. Finally, the enlargement procedure has been done in such a way that

$$\operatorname{meas}\{x : \tau(x) < \infty\} \leq 9 \operatorname{meas}\{x : \gamma(x) < \infty\} = O(\epsilon).$$

Step 8. Now let us give a preliminary definition of the stopped sequence $\tilde{f}^{\tau}_j$. As we pointed out above, the straightforward approach, where $\tilde{f}^{\tau}_j(x) := f_{j\wedge\tau(x)}(x)$, is not suitable. However, this procedure may be modified as follows: The sequence $f_0, f_1, \ldots, f_{n_1-1}$ is not altered. For the index n_1, we consider the intervals that are *complementary* to $\{x : \tau(x) = n_1\}$, that is, the set $\{x : \tau(x) > n_1\}$. A typical complementary interval (in $\{x : \tau(x) > n_1\}$) consists of a union of dyadic intervals of length 2^{-n_1}. Each of these dyadic intervals may be classified by the stopping time γ: on a given interval of length 2^{-n_1}, $\gamma(\cdot) \equiv n_1$ or $\gamma(\cdot) > n_1$. By construction, the extreme left and right dyadic intervals (of the entire complementary interval) are of the latter type, where $\gamma(\cdot) > n_1$. The dyadic intervals in the interior may be of either type. However, the short components of $\{x : \gamma(x) = n_1\}$ are of length less than $N \cdot 2^{-n_1}$. The complementary interval may, of course, contain many such components, separated from each other by dyadic intervals where $\gamma(\cdot) > n_1$. Finally, the complementary interval contains neither endpoint $x = 0$ nor $x = 1$.

On a fixed complementary interval the function $f_{n_1}(x)$ may be represented as a finite sum $\tilde{f}^{\tau}_{n_1}$,

$$\tilde{f}^{\tau}_{n_1}(x) := \sum_{k=\ell}^{r} a_k \phi(2^{n_1}x - k).$$

Here we assume that the complementary interval has left endpoint $(\ell + N - 1) \cdot 2^{-n_1}$ and right endpoint $(r + 1) \cdot 2^{-n_1}$, so that the above is the shortest representation of $f_{n_1}(x)$ on the interval. The sum does not necessarily give the value of $f_{n_1}(x)$ outside the complementary interval, nor are we assured that the difference

$$\begin{aligned} \tilde{d}^{\tau}_{n_1}(x) &= \tilde{f}^{\tau}_{n_1}(x) - \tilde{f}_{n_1-1}(x) \\ &\quad (= \tilde{f}^{\tau}_{n_1}(x) - f_{n_1-1}(x)) \end{aligned}$$

belongs to the space W_{n_1-1}. However, we can assert that

$$\max_{k \leq n_1} |\tilde{f}^{\tau}_k(x)| \leq O(\lambda)$$

for all $x \in \mathbf{R}$. This is true because of Condition (M-Z). The argument is as follows: For $\tilde{f}^{\tau}_k = f_k$, $k < n_1$, on *every* dyadic interval of length 2^{-k}, the (closed) subset of points $\{x : \sup_{j\geq 0} |f_j(x)| \leq \lambda\}$ contained in the dyadic interval has a proportion that is less than $1/2$. Condition (M-Z) then guarantees that

$$|f_k(x)| = O(\lambda)$$

uniformly in the dyadic interval. (See the Remarks after the statement of Condition (M-Z).) The argument for $\tilde{f}^{\tau}_{n_1}$ ($= f_{n_1}$ on the complementary interval) is similar but a bit more complicated. The function $|\tilde{f}^{\tau}_{n_1}(x)| = O(\lambda)$ on any interval where $\gamma(x) > n_1$ for the reason just stated. On the stretches (short components) of length less than $N \cdot 2^{-n_1}$, where $\gamma(x) = n_1$, we cannot apply this argument directly. However, the values of $\tilde{f}^{\tau}_{n_1}(\cdot)$ in this stretch are majorized by a constant times the sum of the moduli of all coefficients a_k that enter into the representation

$$\tilde{f}^{\tau}_{n_1}(x) = \sum_{k=\ell}^{r} a_k \phi(2^{n_1}x - k)$$

on this stretch. Because the stretch is short, the translates $\{k\}$ specific to this stretch also appear in the representation of the function $\tilde{f}^{\tau}$ on the dyadic intervals of length 2^{-n_1}, I_0, and I_1, that bound the stretch. (Some translates are associated with I_0, some are associated with I_1.) On each interval I_i, $i = 0, 1$, we know that $\gamma(\cdot) > n_1$, so that $|\tilde{f}^{\tau}_{n_1}(x)| = O(\lambda)$ on these intervals. By Condition (M-Z), the sum of the moduli of the corresponding coefficients is of the same order. On the stretch, $|\tilde{f}^{\tau}_{n_1}(x)|$ is also majorized, up to a constant, by the sum of all of these coefficients. Therefore, we may conclude that $|\tilde{f}^{\tau}_{n_1}(x)| = O(\lambda)$ on the entire complementary interval. The constants depend only on N, the bound on $|\phi(x)|$, and the constants from Condition (M-Z).

Outside the complementary interval, we claim that $\tilde{f}^{\tau}_{n_1}(x)$ satisfies the same estimate. In fact, the support of any sum

$$\tilde{f}^{\tau}_{n_1}(x) = \sum_{k=\ell}^{r} a_k \phi(2^{n_1}x - k)$$

contained in an interval consisting of the complementary interval, together with two intervals, to the left and right, of the complementary interval. Since $\phi(2^{n_1}x)$ has support on $[0, N \cdot 2^{-n_1}]$, the additional intervals are at most of length $(N-1)2^{-n_1}$. However, we know that the intervals where $\tau(x) = n_1$ are of length at least $8N \cdot 2^{-n_1}$, so the supports of the sums defining $\tilde{f}^{\tau}_{n_1}$ are disjoint. Since $|\tilde{f}_{n_1}(x)| = O(\lambda)$ on each complementary interval, Condition (M-Z) implies that this estimate holds on the entire support. Therefore, $|\tilde{d}^{\tau}_{n_1}| = O(\lambda)$ also.

Step 9. As noted above, the difference

$$\tilde{d}^{\tau}_{n_1}(x) = \tilde{f}^{\tau}_{n_1}(x) - \tilde{f}^{\tau}_{n_1-1}(x)$$

belongs to V_{n_1}, but not necessarily to W_{n_1-1}, the orthogonal complement of V_{n_1-1} in V_{n_1}, even though it represents d_{n_1} on each complementary interval. To remedy this, our strategy will be to obtain an expression for the difference $\tilde{d}^{\tau}_{n_1}(x)$ in terms of the prewavelets $\psi(2^{n_1}x - 2k)$ and to estimate the magnitude of the new representation. The stopping time τ will be altered again to obtain another stopping time ρ, such that the measure of $\{x : \rho(x) < \infty\}$ is larger than that of $\{x : \tau(x) < \infty\}$ by a fixed multiple. With this stopping time, the difference $f^{\rho}_{n_1} - f^{\rho}_{n_1-1}$ will be contained in W_{n_1-1}. The procedure will then be carried out for $n \geq n_1$, and we will be able to estimate the quantity $\sup_n \|f^{\rho}_n\|_2$.

On each complementary interval, $\tilde{d}^{\tau}_{n_1}(x)$ has a representation

$$\tilde{d}^{\tau}_{n_1}(x) = \sum_{k=\ell}^{r} e_k \phi(2^{n_1}x - k)$$

with possibly different ℓ, r. The supports of these sums are disjoint for the reasons cited above. Each sum composing $\tilde{d}^{\tau}_{n_1}$ may be restricted to a function that belongs to W_{n_1-1}. In fact, the original difference

$$\begin{aligned} d_{n_1}(x) &= f_{n_1}(x) - f_{n_1-1}(x) \\ &= \sum_s b_{2s}\psi(2^{n_1}x - 2s) \end{aligned}$$

belongs to W_{n_1-1} by assumption. We define $d_n^\tau(x)$ as the sum

$$d^\tau_{n_1}(x) = \sum_m b_{2m}\psi(2^{n_1}x - 2m),$$

where the indicated sum is taken over indices $2m$, $\ell + N - 1 \leq 2m \leq r - (2N-1)$. With this definition, $d^\tau_{n_1}$ belongs to W_{n_1-1} and its support is contained in the support of $\tilde{d}^\tau_{n_1}$.

(a) Since each complementary interval is at least of length $8N\cdot 2^{-n_1}$ $(r-\ell \geq 9N-1)$ and the support of $\psi(2^{n_1}x)$ is contained in an interval of length $(4N-2)2^{-n_1}$, the sums are nonempty.

(b) Furthermore, the supports of the various sums corresponding to disjoint complementary intervals are disjoint, because of the support remark above.

(c) The coefficients $|b_{2m}| = O(\lambda)$. In fact,

$$b_{2m} = \int d^\tau_{n_1}(x)\overline{\tilde{\psi}(2^{n_1}x - 2m)}dx,$$

where $\tilde{\psi}(2^{n_1}x - 2m)$ is the dual wavelet, acting as a linear functional of $W_{n_1-1} \subset V_{n_1}$. As a function on V_{n_1}, $\tilde{\psi}(2^{n_1}x - 2m)$ may be expressed as a linear combination of translates of the dual prescale function $\tilde{\phi}$. To estimate b_{2m}, it is enough to restrict the translates $\tilde{\phi}(2^{n_1}x - k)$ to those indices k such that $\phi(2^{n_1}x - k)$ is contained in the support of $\psi(2^{n_1}x - 2m)$. There are at most $3N-1$ such translates, and we have

$$\begin{aligned} |e_k| &= \left| \int d^\tau_{n_1}(x)\tilde{\phi}(2^{n_1}x - k)dx \right| \\ &= O(\lambda). \end{aligned}$$

Therefore, $|b_{2m}| = O(\lambda)$ also, since b_{2m} is a linear combination of at most $3N-1$ coefficients e_k.

(d) We recall that, on a fixed complementary interval,

$$\tilde{d}^\tau_{n_1}(x) = \sum_{k=\ell}^{r} e_k\phi(2^{n_1}x - k)$$

represents the difference $f^\tau_{n_1} - f^\tau_{n_1-1}$ on the complementary interval, but not necessarily outside this interval, where $\tilde{d}^\tau_{n_1}(x)$ has its support. The total support of $\sum_{k=\ell}^{r} e_k\phi(2^{n_1}x - k)$ consists of two intervals of length $(N-1)2^{-n_1}$, to the left and right of the complementary interval. Because the representation of

$$d^\tau_{n_1}(x) = \sum b_{2m}\psi(2^{n_1}x - 2m)$$

involves the function $\psi(2^{n_1}x)$, whose support is an interval of length $(4N-2)2^{-n_1}$, we need $(2N-1)$ translates to represent a function on intervals of length $2\cdot 2^{-n_1}$.

On the other hand, in order to obtain the estimate $|b_{2m}| = O(\lambda)$ we are only allowed translates $2m \leq r - (2N-1)$. All of this means that the sum

$$d^\tau_{n_1}(x) = \sum_{k=\ell}^{r} b_{2m}\psi(2^{n_1}x - 2m)$$

represents $d_{n_1}(x)$ for all x in the complementary interval except possibly at the two extremes of the interval: we must exclude intervals no longer than $(3N)2^{-n_1}$ on the left and an interval of length $(2N)2^{-n_1}$ on the right. The measure of the exceptional points $\{x : d^\tau_{n_1}(x) \neq d_{n_1}(x)\}$ is the sum of contributions from each complementary interval. Each such contribution is at most $5N \cdot 2^{-n_1}$, and as such, the total measure of the exceptional set is less than at most $5N$ times the measure of $\{x : \tau(x) = n_1\}$. We use these exceptional intervals to define a modification ρ of the stopping time τ. Each component of $\{x : \tau(x) = n_1\}$ is expanded to include an interval of length $(3N)2^{-n_1}$ on the right (the left extreme of the complementary interval) and an interval of length $(2N) \cdot 2^{-n_1}$ on the left (the right extreme of the complementary interval). Since each complementary interval is of length at least $(8N)2^{-n_1}$, we have diminished, but not eliminated, any complementary interval. The expanded component becomes a component of $\{x : \rho(x) = n_1\}$.

Step 10. We repeat this procedure for each $n > n_1$. On each component of the set $\{x : \tau(x) > n\}$, the analysis made in Steps 7, 8, and 9 may be applied. The functions $\tilde{f}^\tau_n(x)$ and $d^\tau_n(x)$ satisfy the same estimates. That is, $|\tilde{f}^\tau_n(x)| = O(\lambda)$ and $|d^\tau_n(x)| = O(\lambda)$.

Now let us write

$$f^\tau_n(x) = f_0(x) + \sum_{k=1}^{n} d^\tau_k(x).$$

The functions $d^\tau_n(x) = d_n(x)$ except on a set of measure comparable to the measure of the set $\{x : \tau(x) \leq n\}$. We prove this by induction, as follows: For $n = n_1$, we have shown that $d^\tau_{n_1}(x) = d_{n_1}(x)$ except on the set $\{x : \rho(x) = n_1\}$. Now fix a complementary interval of the set $\{x : \tau(x) = n_1\}$ (which contains a complementary interval of $\{x : \rho(x) = n_1\}$). There are two cases to consider: (i) The set $\{x : \tau(x) = n_1 + 1\}$ does not intersect the fixed complementary interval. (ii) The set $\{x : \tau(x) = n_1 + 1\}$ does intersect, creating a smaller complementary interval (or intervals).

In case (i), the difference $d^\tau_{n_1+1}(x) = d_{n_1+1}(x)$ except on intervals of length $(3N)2^{-(n_1+1)}$ and $(2N)2^{-(n_1+1)}$ on the left and right extremes of the complementary interval. However, these exceptional intervals are already contained in the complement of $\{x : \rho(x) = n_1\}$, so that no adjustment is needed in this case. The same is true for any $n > n_1$ as long as the set $\{x : \tau(x) = n\}$ does not intersect the complementary interval of $\{x : \tau(x) = n_1\}$. In other words, $d^\tau_n(x) = d_n(x)$ except on the set $\{x : \rho(x) = n_1\} \cap \{x : \tau(x) > n\}$.

In case (ii), the set $\{x : \tau(x) = n_1 + 1\}$ intersects the complementary interval of $\{x : \tau(x) = n_1\}$, creating a complementary interval (or intervals) to the set $\{x : \tau(x) \leq n_1 + 1\}$. In this case, we expand the components of $\{x : \tau(x) = n_1 + 1\}$ on the left and right by $(2N)2^{-(n_1+1)}$ and $(3N)2^{-(n_1+1)}$, respectively, if these components disconnect the complementary interval of $\{x : \tau(x) = n_1\}$. If the component of $\{x : \tau(x) = n_1 + 1\}$ does not disconnect (e.g., it falls, for example, at the right end of the complementary interval) we expand unilaterally (on the left, in the example).

This expansion process creates a new set of exceptional points $\{x : \rho(x) = n_1 + 1\}$, whose measure is comparable to the measure of $\{x : \tau(x) = n_1 + 1\}$.

We continue this process for all $n > n_1$, and so define the stopping time ρ.

Step 11. Now we stop the sequence f_n^τ, $n \geq 0$, using the stopping time ρ in the same way as in Step 8. At the level n, the complementary intervals of $\{x : \rho(x) \leq n\}$ are isolated and for each interval we define

$$f_n^\rho(x) = \sum_{s=\ell}^{r} b_{2s}\psi(2^n x - 2s).$$

As in Step 8 we take the shortest sum, so that $f_n^\rho(x) = f_n(x)$ on the complementary interval. The coefficients b_{2s} are, of course, the same as those in the expansion of d_n^τ. The new differences are denoted d_n^ρ.

We may now estimate the $\sup_n \|f_n^\rho\|_2$ as follows: On the set $\{x : \rho(x) = \infty\} \subset \{x : \tau(x) = \infty\}$,

$$(f^\rho)^*(x) = (\tilde{f}^\tau)^*(x) = O(\lambda),$$

as indicated in Step 10.

Therefore it remains for us to estimate $(f^\rho)^*(x)$ on the set $\{x : \rho(x) < \infty\}$. This set is a union of disjoint sets $\{x : \rho(x) = n\}$, $n = n_1, n_1 + 1, \ldots$; we estimate $(f^\rho)^*$ on each of these sets. Each set $\{x : \rho(x) = n\}$ is itself a union of components I_n^j, each of which is at least of length 2^{-n}. (Recall that a component of $\{x : \rho(x) = n\}$ contains a component of $\{x : \tau(x) = n\}$ of length less than $N \cdot 2^{-n}$ that is either contiguous with a component of $\{x : \tau(x) \leq n - 1\}$, of length greater than $8 \cdot N \cdot 2^{-(n-1)}$, or is an "endpoint interval," one that contains zero or one. Since we are restricting attention to $[0, 1]$, the endpoint components may be considered to have infinite length. Otherwise, any component of $\{x : \tau(x) = n\}$ (and $\{x : \rho(x) = n\}$) has length greater than or equal to $8 \cdot N \cdot 2^{-n}$.) By construction,

$$\max_{k<n} |f_k^\rho(x)| = O(\lambda),$$

so that it is necessary to estimate the magnitude of sums

$$\left|\sum_{k=n}^{m} d_k^\rho(x)\right|, \qquad m = n, n+1, \ldots,$$

on a fixed component of $\{x : \rho(x) = n\}$. Each of the differences

$$\left|d_{n+k}^\rho\right| = O(\lambda), \qquad k = 0, 1, \ldots.$$

Now consider that part of the support of d_{n+k}^ρ that lies in the component I_n^j of $\{x : \rho(x) = n\}$ under examination.

(a) If $k > 4\log_2 N$ (so that $N \cdot 2^{-(n+k)} < 2^{-n}$), then that part of the support of d_{n+k}^ρ that intersects the component interval I_n^j, is contained in at most two disjoint intervals, each of length $N \cdot 2^{-(n+k)}$, lying at either end of the component interval I_n^j. Thus, the supports of d_{n+k}^ρ form a decreasing sequence of sets within each component of $\{x : \rho(x) = n\}$. Therefore, we may majorize

$$\sum_{k>\log_2 4N} \left|d_{n+k}^\rho(x)\right|$$

in terms of the relative distance function $\Delta_n^j(x)$, defined on each component I_n^j of $\{x : \rho(x) = n\}$: Let $|I_n^j|$ be the length of I_n^j and

$$\frac{\Delta_n^j(x) = \text{distance } (x, \text{ complement of } I_n^j)}{|I_n^j|.}$$

The above considerations lead us to the estimate

$$\sum_{k>\log_2 4N} |d_{n+k}^{\tau}(x)| = O(\lambda)|\log_2 \Delta_n^j(x)|$$

for $x \in I_n^j$.

(b) If $k \leq \log_2 4N$, the best estimate is simply

$$|d_{n+k}^{\rho}(x)| = O(\lambda).$$

With these estimates, we may estimate $\|(f^\rho)^*\|_2$ as follows: On each component I_n^j,

$$\begin{aligned}|(f^\rho)^*(x)|^2 &\leq O(\lambda^2) + \left(\sum_{k\geq n} |d_k^\rho(x)|\right)^2 \\ &\leq O(\lambda^2)\left[1 + \log_2^2(N) + \log_2^2 \Delta_n^j(x)\right].\end{aligned}$$

Therefore

$$\int_{I_n^j} |(f^\rho)^*(x)|^2\, dx = O(\lambda^2)|I_n^j| + O(\lambda^2)\int_{I_n^j} \log_2^2 \Delta_n^j(x) dx.$$

The last integral is estimated by the quantity

$$\left(\int_0^1 \log_2^2 |x|^{-1} dx\right)|I_n^j|.$$

If we sum these estimates over j and n, we obtain

$$\begin{aligned}\int |(f^\rho)^*(x)|^2 dx &= \int_{\{\rho(x)<\infty\}} + \int_{\{\rho(x)=\infty\}} |(f^\rho)^*(x)|^2 \\ &= O(\lambda^2).\end{aligned}$$

Step 12. The stopped sequence $f_n^\rho(x)$, $n \geq 0$, agrees with the original sequence $f_n(x)$, $n \geq 0$ except for points in a set of measure comparable to the measure of $\{x : \rho(x) < \infty\}$. This set has small measure (less than $O(\epsilon)$). Furthermore, the estimate given in the previous step shows that $\|(f^\rho)^*\|_2 = O(\lambda)$, and f_n^ρ, $n \geq 0$, satisfies the property $P_n f_{n+1}^\rho = f_n^\rho$. Therefore

$$\begin{aligned}\|S(f^\rho)\|_2 &= \sup_n \|f_n^\rho\|_2 \\ &\leq \|(f^\rho)^*\|_2 \\ &= O(\lambda).\end{aligned}$$

Since $S(f^\tau)(x) = S(f)(x)$ on the set where $f_n^\rho(x) \equiv f_n(x)$, $n = 0, 1, \ldots$, we may conclude that meas$(B\setminus A) = O(\epsilon)$. Furthermore, it is known that L^2-bounded wavelet expansions converge a.e. in this context (see [7]), so that meas$(B \setminus A) = 0$.

Step 13. The entire procedure may be repeated using B as the initial set. The conclusion of this argument is meas$(A \setminus B) = 0$, and the proof of Theorem B is now complete. □

STABILITY PROPERTIES FOR A COMPACTLY SUPPORTED PRESCALE FUNCTION[*]

V. DOBRIĆ[†], R. F. GUNDY[‡], AND P. HITCZENKO[§]

Abstract. We show that if ϕ is a continuous, minimally supported prescale function, then its translates are linearly independent on any set of positive measure in the unit interval. This generalizes results of Y. Meyer and P. G. Lemarié.

This result implies that a stability condition, introduced by Gundy and Kazarian for the study of local convergence of spline wavelet expansions, is satisfied for all expansions arising from multiresolution analyses generated by such prescale functions ϕ.

Key words. wavelets, linear independence, local convergence

1. Introduction.

In [7], P. G. Lemarié proved that if a multiresolution analysis contains a compactly supported function, then it contains a minimal (pre)scale function. More specifically, there exists a function ϕ of compact support such that

(1) the integer translates, $\phi(\cdot - k),\ k \in \mathbf{Z}$, are a Riesz basis for the space V_0;

(2) every function in V_0 that is compactly supported may be written as a finite linear combination of translates of ϕ.

(Throughout this paper, we will use the term "scale function" to mean the above, although some authors refer to this as "prescale function.") The most basic examples of minimal scale functions of this type are the B-splines and the compactly supported scale functions constructed by I. Daubechies [1]. An important property of these minimal-scale functions was first proved by Y. Meyer [10] for Daubechies' functions and subsequently stated by Lemarié [7] in the general case: *The translates of ϕ, restricted to the unit interval, form a linearly independent set.*

The purpose of this paper is to prove the following stronger version of the above for a minimal scale function ϕ that is continuous on the unit interval: the translates of ϕ are linearly independent over any subset of positive measure contained in the unit interval. The stronger version is of interest because it may be used to obtain a local convergence theorem for multiresolution analyses with continuous minimal scale functions. The first version of this type of local convergence theorem was proved by Gundy and Kazarian [4] for a class of wavelet expansions that includes the spline wavelets. Their theorem assumed a stability condition (condition (M-Z) of [4]). It turns out that this stability condition is, in fact, a property of all multiresolution analyses with continuous minimal scale functions, as a consequence of the above strong linear independence of these functions.

2. Notation. We suppose that a multiresolution analysis is given. That is, we have a sequence of subspaces of $L^2(\mathbf{R})$, V_j, $j \in \mathbf{Z}$, such that $V_j \subset V_{j+1}$, and $f(\cdot) \in V_j$ iff $f(2^{-j}\cdot) \in V_0$. Furthermore, we are given a function $\phi \in V_0$ such that the integer translates $\phi(\cdot - k)$ form a Riesz basis for V_0: any function $f(\cdot) \in V_0$ has a representation

$$f(x) = \sum a_k \phi(x-k)$$

with

$$\sum a_k^2 \cong \|f\|_2^2, \quad \text{i.e.,} \quad c\sum a_k^2 \leq \|f\|_2^2 \leq C \sum a_k^2, \quad 0 < c < C.$$

If ϕ has a nonzero integral, then it follows that the increasing sequence of subspaces exhausts $L^2(\mathbf{R})$ (see [5, Chapter 2]). Let P_j be the orthogonal projection operator from L^2 onto V_j.

Now we impose another restriction on the multiresolution analysis. We require that the space V_0 contains a nontrivial continuous function that is compactly supported. With this additional assumption, the techniques of Lemarié [7] may be used to show that there exists a minimally supported, real-valued, continuous function $\phi \in V_0$ such that every compactly supported function in V_0 admits a representation as a finite linear combination of integer translates of ϕ. If we agree to normalize ϕ by setting its integral equal to one, then ϕ is unique, up to integer translates. (Our class of multiresolution analyses does include the spline wavelets, the compactly supported Daubechies wavelets, and those obtained from these classes by integration, as indicated in Lemarié [7].)

3. Linear independence of translates. In this section, we state the theorem on linear independence.

THEOREM 1. *Let ϕ be a continuous, minimal (pre)scale function supported on the interval* $[0, N]$. *Then the translates* $\phi(\cdot + k)$, $k = 0, \ldots, N-1$, *are linearly independent over any set of positive measure of the unit interval.*

Remarks. As we noted above, this line of investigation was initiated by Y. Meyer [10] and pursued by P. G. Lemarié in [7]. These authors treated the case where the "set of positive measure" was the entire unit interval. Lemarié and Malgouyres [8] gave another simplified proof that showed that the translates were linearly independent on any subinterval of the unit interval. Finally, Lemarié [7] showed that this property characterizes minimal scale functions. Those authors made no continuity assumptions.

Proof. We give a proof by contradiction as follows: If the translates are linearly dependent over a set of positive measure, we show that they are dependent over a set of measure one in the unit interval. Since the function ϕ is continuous, this means that the translates of ϕ are dependent over the unit interval itself, thus contradicting the theorem of Meyer.

Throughout the proof, we will use matrices $\mathbf{P}_0$ and $\mathbf{P}_1$. To define these matrices, let us write the dilation equation for ϕ as

$$\phi(x/2) = \sum_{k=0}^{N} p_k \phi(x-k) \qquad \text{with } p_0, p_N \neq 0.$$

With this notation, let us define the $(N-1)\times(N-1)$ matrix $\mathbf{P}$ whose first row consists of the vector of odd numbered coefficients, p_{2k+1}, followed by the appropriate number of zeros to give the vector $N-1$ components. The second row of $\mathbf{P}$ is defined in the same way, using the even numbered coefficients, p_{2k}, followed by the appropriate number of zeros. Third and fourth rows are obtained from the first two rows by a cyclic permutation of the indices: each entry is shifted to the right, with the final entry, a zero, moving to first position. This procedure is continued until $N-1$ rows are obtained. (Thus if $N=2k$, the second row will contain the $k+1$ entries $p_0, p_2, \ldots, p_{2k}$ followed by $k-2$ zeros. The last row will contain $k-1$ zeros followed by the k coefficients $p_1, p_3, \ldots, p_{2k-1}$. If $N=2k+1$, then the last row of the matrix consists of $k-1$ zeros, followed by the $k+1$ entries $p_0, p_2, \ldots, p_{2k}$.) Now define the two $N \times N$ matrices

$$\mathbf{P}_0 = \begin{pmatrix} p_0 & \mathbf{p}_t \\ 0 & \mathbf{P} \end{pmatrix} \qquad \text{and} \qquad \mathbf{P}_1 = \begin{pmatrix} \mathbf{P} & 0 \\ \mathbf{p}_b & p_N \end{pmatrix},$$

where $\mathbf{p}_t$ is the $N-1$ vector consisting of the even numbered p_k, starting with p_2, followed by the appropriate number of zeros; $\mathbf{p}_b$ consists of zeros followed by the coefficients p_k where k has the same parity as N, where the final entry of the vector $\mathbf{p}_b$ is the coefficient p_{N-2}.

The roles of $\mathbf{P}_0$ and $\mathbf{P}_1$ are as follows. Consider a general linear combination of translates $\sum c_k \phi(x+k)$. If we take into account fact that ϕ is supported on $[0,N]$ and restrict attention to $x \in [0,1]$, this sum is, in fact, finite and may be expressed as $\sum_{k=0}^{N-1} c_k \phi(x+k)$. If we apply the dilation equation to express each $\phi(\cdot + k)$ in terms of a sum of translates of $\phi(2\cdot)$, the resulting double sum is a certain linear combination of translates of $\phi(2x)$ and $\phi(2x-1)$, depending on whether x is in $[0, \frac{1}{2}]$ or in $[\frac{1}{2}, 1]$. The coefficients of this linear combination are given by the matrices $\mathbf{P}_0$ or $\mathbf{P}_1$, acting on the vector $\mathbf{c} = (c_0, \ldots, c_{N-1})$. (These matrices are implicit in the reconstruction-decomposition schemes in the wavelet literature and appear explicitly in the 3×3 case in Daubechies [2, section 7.2].) Let $\mathbf{\Phi}(x) = \big(\phi(x), \phi(x+1), \ldots, \phi(x+N-1)\big)^t$ for $x \in [0,1]$, and let $\epsilon_k(x)$, $k = 1, 2, \ldots$, be the digits in the binary expansion of x. That is, $x = \sum \epsilon_k / 2^k$, with $\epsilon_k = 0$ or 1, $k \geq 1$. Let T be the plus-one shift on the ϵ-sequence: $T : (\epsilon_1, \epsilon_2, \ldots) \to (\epsilon_2, \epsilon_3, \ldots)$. We write $Tx = \sum_{k=1}^{\infty} \epsilon_{k+1}/2^k$. We summarize the above in the following lemma.

Lemma 1. *For* $\mathbf{c} = (c_0, c_1, \ldots, c_{N-1})$ *we have*

$$\mathbf{c} \circ \mathbf{\Phi}(x) = (\mathbf{P}_{\epsilon_1} \mathbf{c}^t) \circ \mathbf{\Phi}(Tx).$$

More generally, for any m,

$$\mathbf{c} \circ \mathbf{\Phi}(x) = (\mathbf{P}_{\epsilon_1} \cdots \mathbf{P}_{\epsilon_m} \mathbf{c}^t) \circ \mathbf{\Phi}(T^m x).$$

Proof. Recall that the support of $\phi(\cdot + m)$ is the interval $[-m, -m+N]$. For $x \in [0,1]$,

$$\begin{aligned} \mathbf{c} \circ \mathbf{\Phi}(x) &= \sum_{k=0}^{N-1} c_k \phi(x+k) = \sum_k c_k \bigg(\sum_j p_j \phi\big(2(x+k)-j\big) \bigg) \\ &= \sum_m \bigg(\sum_k c_k p_{2k-m} \bigg) \phi(2x+m) = \sum_m \bigg(\sum_k c_k p_{2k-m} \bigg) \phi(Tx + \epsilon_1 + m). \end{aligned}$$

The inner sum is taken over all k with the provision that $p_{2k-m} = 0$ if $2k-m$ is not one of the integers $0, 1, \ldots, N$. The outer sum with index m changes according to whether $0 < 2x \leq 1$ or $1 < 2x \leq 2$, due to the support condition mentioned above. In the first case, when $\epsilon_1 = 0$, we have $0 \leq m \leq N-1$; in the second case, when $\epsilon_1 = 1$,

$0 \le m+1 \le N-1$. Thus, the transformation takes two forms, with matrices $\mathbf{P}_0$ and $\mathbf{P}_1$. The rest of Lemma 1 is easily proved by induction.

Fix $\mathbf{c} = (c_0, \ldots, c_{N-1})$ and let $K_{\mathbf{c}} = \{x : \mathbf{c} \circ \mathbf{\Phi}(x) = 0\}$. The continuity of $\mathbf{\Phi}(x)$ implies that $K_{\mathbf{c}}$ is closed. From now on, we assume that $\mathbf{c} \neq 0$ and that $K_{\mathbf{c}}$ has positive measure in $[0,1]$; we seek to contradict Meyer–Lemarié theorem [10], [7]. There are two cases to consider. □

Case 1. There exists a finite sequence $\mathbf{P}_{\epsilon_k}$, $k = 1, \ldots, m$, such that $\mathbf{P}_{\epsilon_1} \cdots \mathbf{P}_{\epsilon_m} \mathbf{c}^t = 0$. If this is the case, we have our contradiction since $\mathbf{c} \circ \mathbf{\Phi} \equiv 0$ on the dyadic interval

$$\{x : \epsilon_1(x) = \epsilon_1, \ldots, \epsilon_m(x) = \epsilon_m\}.$$

Case 2. The vector $\mathbf{c}$ is such that $\mathbf{P}_{\epsilon_1} \cdots \mathbf{P}_{\epsilon_m} \mathbf{c}^t \neq 0$ for every finite sequence $\epsilon_1, \ldots, \epsilon_m$. In this case, we say that $\mathbf{c}$ is a "never zero" vector.

Lemma 2. *Let* $\mathbf{c}$ *be a never zero vector. Then, for every* η, $0 < \eta < 1$, *there exists a never zero vector* $\mathbf{b}$ *such that* $m(K_{\mathbf{b}}) > 1 - \eta$.

Proof. Since $K_{\mathbf{c}}$ has positive measure, we can find a dyadic interval $I_j = \{x : \epsilon_1(x) = \epsilon_1, \ldots, \epsilon_j(x) = \epsilon_j\}$ such that $m(K_{\mathbf{c}} \cap I_j)/2^{-j} > 1 - \eta$. This is a consequence of the fact that every Lebesgue measurable set may be approximated by a finite union of dyadic intervals. Set $\mathbf{b} = \mathbf{P}_{\epsilon_1} \cdots \mathbf{P}_{\epsilon_j} \mathbf{c}^t$. Then $T^j(K_{\mathbf{c}} \cap I_j) \subseteq K_{\mathbf{b}}$ by Lemma 1. The set $K_{\mathbf{b}}$ has measure greater than $1 - \eta$ since $m\big(\{x : x = T^j y \text{ for some } y \in I_j\}\big) = 1$. This proves Lemma 2. □

Now set

$$\mathcal{A}_{\mathbf{c}} = \left\{ \mathbf{a} \in \mathbb{R}^N : \mathbf{a} = \frac{\mathbf{b}}{\|\mathbf{b}\|_2} \text{ for some } \mathbf{b} = \mathbf{P}_{\epsilon_1} \cdots \mathbf{P}_{\epsilon_j} \mathbf{c}, \quad j \in \mathbf{Z} \right\}.$$

By Lemma 2, we have

$$\sup_{\mathbf{a} \in \mathcal{A}_{\mathbf{c}}} m(K_{\mathbf{a}}) = 1.$$

Now we claim that there is an $\mathbf{a} \in \mathbf{R}^N$ with $\|\mathbf{a}\|_2 = 1$ such that $m(K_{\mathbf{a}}) = 1$. To this end, we topologize the class $\mathcal{K}$ of all nonempty compact subsets of $[0,1]$ with the Hausdorff metric ρ:

$$\rho(A,B) = \sup_{x \in [0,1]} |d(x,A) - d(x,B)|,$$

where $d(x,D) = \inf\{|x-y| : y \in D\}$. This metric is equivalent to

$$\sigma(A,B) = \inf\{\epsilon > 0, A \subset V_\epsilon(B) \text{ and } B \subset V_\epsilon(A)\},$$

where $V_\epsilon(D) = \{z \in [0,1] : d(z,D) < \epsilon\}$. It is known that $(\mathcal{K}, \rho)$ is a compact metric space. A complete discussion of these facts may be found in Kornum [6, section 6.2].

Let $\{K_{\mathbf{a}_n}\}$ be a sequence of sets in $\mathcal{K}$ such that $m(K_{\mathbf{a}_n})$ tends to one. From this sequence we may extract a convergent subsequence $\{K_{\mathbf{a}_{n_k}}\}$ with limit K. Since $\|\mathbf{a}_{n_k}\|_2 = 1$, we may extract a convergent subsequence of $\mathbf{a}_{n_k}$, call it $\{\mathbf{a}_n\}$, so that finally, we obtain sequences $K_{\mathbf{a}_n} \to K$ and $\mathbf{a}_n \to \mathbf{a}$. Since $E \to m(E)$ is an uppersemicontinuous function on $(\mathcal{K}, \rho)$, that is if $E_n \to E$ then $\overline{\lim} m(E_n) \le m(E)$, it follows that $m(K) = 1$. Second, we claim that $K \subset K_{\mathbf{a}}$. Since $K_{\mathbf{a}_n} \to K$, we have

$$\sup_{y \in [0,1]} |d(y,K) - d(y, K_{\mathbf{a}_n})| \to 0.$$

Therefore, if $x \in K$, $d(x, K_{\mathbf{a}_n}) \to 0$. Choose $x_n \in K_{\mathbf{a}_n}$ so that $|x - x_n| = d(x, K_{\mathbf{a}_n})$. Then, by the Cauchy–Schwarz inequality and the definition of $K_{\mathbf{a}}$,

$$\begin{aligned} |\mathbf{a} \circ \Phi(x)| &\le |(\mathbf{a} - \mathbf{a}_n) \circ \mathbf{\Phi}(x)| + |\mathbf{a}_n \circ (\mathbf{\Phi}(x) - \mathbf{\Phi}(x_n))| + |\mathbf{a}_n \circ \mathbf{\Phi}(x_n)| \\ &\le \|\mathbf{a} - \mathbf{a}_n\|_2 \cdot \|\mathbf{\Phi}(x)\|_2 + \|\mathbf{\Phi}(x) - \mathbf{\Phi}(x_n)\|_2. \end{aligned}$$

Since both terms on the right tend to zero, we have the inclusion $K \subset K_{\mathbf{a}}$. Therefore, $m(K_{\mathbf{a}}) = 1$. □

4. Local convergence of wavelet expansions. In [3], the following local convergence theorem is proved for Haar series, using martingale methods.

Theorem A. *Let $\{f_j\}$ be a sequence of functions such that*

(a) *$f_j \in V_j$ where $\{V_j\}$ is the Haar multiresolution analysis;*

(b) *$P_j(f_{j+1})(x) = f_j(x)$ for $j \ge 0$.*

Set $f(x) = (f_0(x), f_1(x), \dots)$ and let $S(f)(x) = \left(\sum (f_{j+1}(x) - f_j(x))^2 + f_0^2(x)\right)^{1/2}$; $f^*(x) = \sup_j |f_j(x)|$. Then, the following sets are equivalent almost everywhere (a.e.):

(a) *$\{x : \lim_{j\to\infty} f_j(x)$ exists and is finite$\}$;*

(b) *$\{x : S(f)(x) < +\infty\}$;*

(c) *$\{x : f^*(x) < \infty\}$.*

Gundy and Kazarian [4] extended this local convergence theorem to the class of multiresolution analyses arising from the basic splines. In fact, the proof did not appear to use properties specific to the spline family. The basic stability condition essential to the proof is a two-norm condition, reminiscent of a condition first proposed by Marcinkiewicz and Zygmund [9] in their study of series of independent random variables. This condition, called condition (M-Z), is as follows: Let ϕ be a compactly supported scale function, supported on $[0, N]$. We suppose that, for every δ, $0 < \delta < 1$, there exist constants B_δ and C_δ such that for every measurable subset $E \subset [0, 1]$ of measure greater than δ and any sequence a_k; $k = 0, 1, \dots, N-1$, we have

$$\begin{aligned} C_\delta \sum_{k=0}^{N-1} |a_k| &\le \sup_{x\in E} \left| \sum_{k=0}^{N-1} a_k \phi(x+k) \right| \\ &\le B_\delta \sum_{k=0}^{N-1} |a_k|. \end{aligned}$$

The constants B_δ, C_δ depend only on ϕ and δ. The condition holds for the class of B-spline scale functions, as pointed out in [4]. However, the scope of the condition was not known and was left as an open problem in [4]. The following proposition we label as a corollary of Theorem 1.

Corollary 1. *Let $\{V_j\}$ be a multiresolution analysis such that V_0 contains a continuous function of compact support. Then the minimal scale function ϕ satisfies condition* (M-Z).

Before proving the corollary, we state the following theorem, in which we use the definitions in Theorem A.

Theorem 2 (Theorem B of [4]). *Let $\{V_j\}$ be a multiresolution analysis that contains a continuous function of compact support. Then the following sets are equivalent a.e.:*

(a) *$\{x : \lim_{j\to\infty} f_j(x)$ exists and is finite$\}$;*

(b) *$\{x : S(f)(x) < +\infty\}$;*

(c) *$\{x : f^*(x) < \infty\}$.*

Proof of Corollary 1. Notice that B_δ may be taken to be $\|\phi\|_\infty$. Since ϕ is continuous on $[0,1]$, the issue is to show the existence of C_δ that is uniform over all sets $E \subset [0,1]$ of measure greater than δ. First, observe that, since the translates of ϕ are linearly independent over E (Theorem 1), there is a constant $C(E) > 0$, such that

$$C(E) \sum_{k=0}^{N-1} |a_k| \leq \sup_{x\in E} \left| \sum_{k=0}^{N-1} a_k \phi(x+k) \right|.$$

This follows from the fact that the right-hand side defines a norm on $\mathbf{R}^N$: the linear independence of the translates of ϕ on the set E guarantees that the right-hand side is strictly positive on $\mathbf{R}^N \setminus \{0\}$. Since the left-hand side is also a norm, the existence of a constant is assured by the equivalence of norms on finite dimensional spaces. Now we must show that

$$\inf\{C(E) : m(E) \geq \delta\} > 0.$$

It is enough to show this for closed sets. To this end, we show that $C : (\mathcal{K}, \rho) \to \mathbf{R}$ defined by

$$C(E) = \inf_{\mathbf{a}\neq 0} \sup_{x\in E} \frac{|\mathbf{a} \circ \mathbf{\Phi}(x)|}{\|\mathbf{a}\|_1}$$

is a continuous function. Let $\epsilon > 0$ be given, and let $\{A_n\}$ be a sequence of sets converging to A in $\mathcal{K}$. The function $\mathbf{\Phi}$ is uniformly continuous on $[0,1]$; that is,

$$\|\mathbf{\Phi}(x) - \mathbf{\Phi}(y)\|_2 \leq \epsilon$$

whenever $|x-y| \leq \eta(\epsilon)$. Let n_0 be an integer such that

$$A_n \subset V_\eta(A) \qquad \text{and} \qquad A \subset V_\eta(A_n)$$

for all $n \geq n_0$. Notice that

$$C(A) \leq C(\overline{V_\eta(A_n)}),$$

and that, by continuity, there exists $x = x(n, \eta, \mathbf{a}) \in \overline{V_\eta(A_n)}$ such that

$$C(\overline{V_\eta(A_n)}) = \inf_{\mathbf{a}\neq 0} \frac{|\mathbf{a} \circ \mathbf{\Phi}(x)|}{\|\mathbf{a}\|_1}.$$

Choose $y = y(n, \eta, \mathbf{a}) \in A_n$ so that $|x-y| \leq \eta(\epsilon)$. Then

$$\begin{aligned} C(\overline{V_\eta(A_n)}) &\leq \inf_{\mathbf{a}\neq 0} \left(\frac{\|\mathbf{a}\|_2}{\|\mathbf{a}\|_1} \|\mathbf{\Phi}(x) - \mathbf{\Phi}(y)\|_2 + \frac{|\mathbf{a} \circ \mathbf{\Phi}(y)|}{\|\mathbf{a}\|_1} \right) \\ &\leq \inf_{\mathbf{a}\neq 0} \left(\frac{\|\mathbf{a}\|_2}{\|\mathbf{a}\|_1} \epsilon + \sup_{y\in A_n} \frac{|\mathbf{a} \circ \mathbf{\Phi}(y)|}{\|\mathbf{a}\|_1} \right) \\ &\leq \inf_{\mathbf{a}\neq 0} \left(\epsilon + \sup_{y\in A_n} \frac{|\mathbf{a} \circ \mathbf{\Phi}(y)|}{\|\mathbf{a}\|_1} \right) \\ &= \epsilon + C(A_n). \end{aligned}$$

If we reverse the roles of A_n and A in the above argument, we see that $C(A_n) \leq C(A) + \epsilon$. Thus, C is continuous on $\mathcal{K}$.

The collection $\{E \in \mathcal{K} : m(E) \geq \delta\}$ is a closed set in $\mathcal{K}$ since $m(\cdot)$ is uppersemicontinuous on $(\mathcal{K}, \rho)$. Therefore, by continuity of C, there exists an $E_0 \in \mathcal{K}$, $m(E_0) \geq \delta$ such that $C(E_0) \leq C(E)$ for all $E \in \mathcal{K}$ with $m(E) \geq \delta$. Now, by the compactness of the unit sphere in ℓ_1^N, there exists an $\mathbf{a}$ such that

$$C(E_0) = \sup_{x \in E_0} \frac{|\mathbf{a} \circ \mathbf{\Phi}(x)|}{\|\mathbf{a}\|_1}.$$

By Theorem 1, $C(E_0) > 0$. □

5. Concluding remarks. The quadratic variation functional $S(f)$ of Theorem 2 is invariant under changes of scale functions ϕ for V_0 and ψ for V_1: $S(f)$ is defined from the sequence of projections $\{P_j\}$ without specific reference to the choice of scale function. However, $S(f)$ is an "incomplete" square function in the sense that if the prewavelet family $\{\psi(2^j \cdot -k)\}$ is orthogonalized in k to obtain a family $\{\tilde{\psi}(2^j \cdot -k)\}$ that is orthonormal in both variables $j, k \in \mathbf{Z}$, then one could consider a quadratic variation functional $\mathbf{S}(f)(x) = \left(\sum_{j,k}(a_{j,k}\tilde{\psi}(2^j x - k))^2\right)^{1/2}$. If we have a multiresolution analysis that admits a compactly supported, continuous orthonormal family $\{\tilde{\psi}(2^j \cdot -k)\}$, then one can show that $S(f)$ and $\mathbf{S}(f)$ are finite on the same set, up to a set of measure zero. The proof of this fact follows the same lines as the proof in [4]. Since the details are given there, we will not repeat them here.

ASYMPTOTIC BEHAVIOR OF NONLINEAR ELLIPTIC SYSTEMS ON VARYING DOMAINS*

JUAN CASADO DIAZ† AND ADRIANA GARRONI‡

Abstract. We consider a monotone operator of the form $Au = -\mathrm{div}(a(x, Du))$, with $\Omega \subseteq \mathbf{R}^n$ and $a : \Omega \times \mathbf{M}^{M\times N} \to \mathbf{M}^{M\times N}$, acting on $W_0^{1,p}(\Omega, \mathbf{R}^M)$. For every sequence (Ω_h) of open subsets of Ω and for every $f \in W^{-1,p'}(\Omega, \mathbf{R}^M)$, $1/p+1/p' = 1$, we study the asymptotic behavior, as $h \to +\infty$, of the solutions $u_h \in W_0^1(\Omega_h, \mathbf{R}^M)$ of the systems $Au_h = f$ in $W^{-1,p'}(\Omega_h, \mathbf{R}^M)$, and we determine the general form of the limit problem.

1. Introduction.

In this paper we study the asymptotic behavior of the solutions of elliptic nonlinear systems, of M equations and N variables, on varying domains with Dirichlet boundary conditions. Namely, let Ω be a bounded open subset of $\mathbf{R}^N$ and let $1 < p < +\infty$. We regard A as a vector monotone operator defined from $W^{1,p}(\Omega, \mathbf{R}^M)$ to $W^{-1,p'}(\Omega, \mathbf{R}^M)$, mapping $u \in W^{1,p}(\Omega, \mathbf{R}^M)$ in $Au = -\mathrm{div}\big(a(x, Du)\big) \in W^{-1,p'}(\Omega, \mathbf{R}^M)$. The function $a\colon \Omega \times \mathbf{M}^{M\times N} \mapsto \mathbf{M}^{M\times N}$ is a Carathéodory function which satisfies the standard assumptions of strong monotonicity and Hölder continuity (see conditions (i)–(iv) in section 5). Given an arbitrary sequence of open subsets Ω_n of Ω and given an arbitrary $f \in W^{-1,p'}(\Omega, \mathbf{R}^M)$, we consider the solutions u_n of the following systems with Dirichlet boundary condition

$$u_n \in W_0^{1,p}(\Omega_n, \mathbf{R}^M)\,, \qquad Au_n = f \quad \text{in } \Omega_n. \tag{1.1}$$

We set $u_n = 0$ in $\Omega \setminus \Omega_n$ and regard the sequence (u_n) as a sequence in $W_0^{1,p}(\Omega, \mathbf{R}^M)$. Our results describe the asymptotic behavior of (u_n) as $n \to \infty$ and characterize the limit function as the solution of a variational "limit problem."

The main result of this paper is given by the following compactness theorem.

Theorem 1.1. *Let Ω_n be an arbitrary sequence of open subsets of Ω. Then there exist a subsequence of Ω_n, still denoted by Ω_n, a measure μ in the class $\mathcal{M}_0^p(\Omega)$ of positive Borel measures not charging set of p-capacity zero, and a vector function $F : \Omega \times \mathbf{R}^M \to \mathbf{R}^M$, such that for every $f \in W^{-1,p'}(\Omega, \mathbf{R}^M)$ the sequence (u_n) of solutions of problems* (1.1) *converges weakly in $W_0^{1,p}(\Omega, \mathbf{R}^M)$ to the solution u of the variational problem*

$$\begin{cases} u \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_\mu(\Omega, \mathbf{R}^M)\,, \\ \displaystyle\int_\Omega a(x, Du)Dv\,dx + \int_\Omega F(x, u)v\,d\mu \;=\; \langle f, v\rangle \\ \forall v \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_\mu(\Omega, \mathbf{R}^M). \end{cases} \tag{1.2}$$

By $L^p_\mu(\Omega,\mathbf{R}^M)$ we denote the standard L^p spaces with respect to the measure μ. Note that in this general case the usual "extra term" is given by $\int_\Omega F(x,u)v\,d\mu$.

The problem considered in the present paper has been studied, under various degree of generality, by many authors, with several approaches and in different frameworks. Most of the known results are given under assumptions involving the geometry or the capacity of the closed sets $\Omega\setminus\Omega_n$, which in general imply that the measure μ in the limit problem is a Radon measure (see, for instance, [20], [22], and [7] for the linear case, and [24], [25], [26], [27], [21], and [3], for monotone operators).

The class $\mathcal{M}^p_0(\Omega)$ described above also includes measures which take the value $+\infty$ on large families of sets; in this way, Dirichlet problems in subdomains of Ω can be written in the form (1.2) for a suitable choice of μ. Indeed, it is easy to see that, if E is a closed subset of Ω and the measure μ is defined by

$$\mu(B)=\begin{cases}0 & \text{if } C_p(B\cap E)=0\\ +\infty & \text{otherwise,}\end{cases} \tag{1.3}$$

for every Borel subset B of Ω, where C_p denotes the p-capacity, then problem (1.2) is equivalent to

$$u\in W^{1,p}_0(\Omega\setminus E,\mathbf{R}^M)\,,\qquad Au=f\quad\text{in }\Omega\setminus E.$$

In view of the latter remark, the compactness result above will be proved in a more general formulation (see Theorem 6.4) for a sequence of problems of the type

$$\begin{cases}u_n\in W^{1,p}_0(\Omega,\mathbf{R}^M)\cap L^p_{\mu_n}(\Omega,\mathbf{R}^M)\,,\\[4pt] \displaystyle\int_\Omega a(x,Du_n)Dv\,dx+\int_\Omega F_n(x,u_n)v\,d\mu_n\;=\;\langle f,v\rangle\\[4pt] \forall v\in W^{1,p}_0(\Omega,\mathbf{R}^M)\cap L^p_{\mu_n}(\Omega,\mathbf{R}^M)\,,\end{cases} \tag{1.4}$$

which for a suitable choice of (μ_n) in $\mathcal{M}^p_0(\Omega)$ reduce to (1.1), and includes also Schrödinger systems with positive oscillating potentials. A further motivation for the study of problem (1.4) is given by the recent applications to a relaxed formulation of some optimal design problems (see, for instance, [2]).

The compactness result in the setting of (1.4) was first proved for the scalar case $M=1$, using Γ-convergence techniques, in [13] and [14] when $p=2$ and A is a symmetric linear elliptic operator, and in [10] if A is $p-1$ homogeneous, under the assumption that it is the subdifferential of a convex functional. These results were generalized using Tartar's energy method in [11] for the general scalar linear case, and subsequently for the nonlinear case under an assumption of homogeneity of order $p-1$ for the operator A (see [15] and [16]). In these cases the extra term which appears in the limit problem is proved to be of the form $\int_\Omega |u|^{p-2}uv\,,d\mu$. The case of systems is much less investigated. Previous results have been obtained only in the framework of linear symmetric elliptic operators in [18]. Further reference on this subject can be found in the book [9] and in the papers [11] and [16], which contain a wide bibliography.

Our result provides a description of the limiting behavior of sequences of Dirichlet boundary value problems not only for monotone operators of Leray–Lions type, but also covering the case of systems related to linear possibly nonsymmetric operators or nonlinear homogeneous operators, which were not included in previous results. The proof follows the lines of [3], where Theorem 1.1 is obtained in the scalar case, under some additional assumptions on the sequence (Ω_n) which imply in particular that the measure μ in the limit problem is bounded. The idea of the proof is essentially to compare our sequence of problems with a sequence of model problems for which the behavior is known (for instance scalar problems with the p-Laplace operator).

In section 2 we recall some preliminary results and notation and in section 3 we state some known results in the study of the asymptotic behavior of scalar problems with the p-Laplace operator.

Section 4 is dedicated to a careful study of the behavior of a sequence of "correctors" for the p-Laplace operator, as introduced in [16]. In section 5 we state the problem and we prove, following the line of [1] and [16], that a sequence of solutions of problems (1.4) which converges weakly in $W^{1,p}(\Omega, \mathbf{R}^M)$ converges also strongly in $W^{1,r}(\Omega, \mathbf{R}^M)$ for every $r < p$ (see Proposition 5.4). In section 6 we prove the compactness result. In section 7 we prove a correctors result, in the general context of nonlinear monotone vector operators. Indeed, the sequence of gradients (Du_n) of solutions of problems (1.1) converges to Du a priori only weakly in L^p by Theorem 1.1. Hence to obtain a strong convergence it is necessary to add a further sequence which depends only on the limit function u. The construction of such a sequence is provided by Theorem 7.1 and is new also in the case of linear systems. For previous correctors results, see, e.g., [7], [11], [3]. Section 8 is devoted to the analysis of some special cases. In particular we obtain a simpler form for the extra term and for the correctors in the linear case and in the homogeneous case, in agreement with the previous scalar results. The structure of the extra term is proved to depend only on the asymptotic behavior of the function $a(x, \xi)$ for $\xi \to \infty$ (see section 9). In the last section our result is applied also to the treatment of asymptotic problems in a class of pseudomonotone operators. The extension to the general pseudomonotone operators for the scalar case can be found in [5]. Throughout the paper we treat in detail only the case $p \geq 2$. The case $1 \leq p < 2$ can be treated in a similar way, after proper modification on the growth and coerciveness hypotheses for the operator A. The changes in the proofs can easily be performed using Proposition 3.2 of [17].

2. Notation and preliminaries.

Let N and M be two positive integers, $N \geq 2$; by $\mathbf{M}^{M\times N}$ we denote the space of $M \times N$ real matrices.

Let Ω be a bounded open subset of $\mathbf{R}^N$. We denote by $W_0^{1,p}(\Omega, \mathbf{R}^M)$ and $W^{1,p}(\Omega, \mathbf{R}^M)$, $1 < p < +\infty$, the usual Sobolev spaces (of $\mathbf{R}^M$-valued functions) and by $W^{-1,p'}(\Omega, \mathbf{R}^M)$, $1/p' + 1/p = 1$, the dual of $W_0^{1,p}(\Omega, \mathbf{R}^M)$. By $W_c^{1,p}(\Omega, \mathbf{R}^M)$ and $W_{\mathrm{loc}}^{1,p}(\Omega, \mathbf{R}^M)$ we denote respectively the space of all functions in $W^{1,p}(\Omega, \mathbf{R}^M)$ with compact support in Ω and the space of all functions which belong to $W^{1,p}(U, \mathbf{R}^M)$ for every open set $U \subset\subset \Omega$. When $p = 2$ we adopt the standard notation $H^1(\Omega, \mathbf{R}^M)$, $H_0^1(\Omega, \mathbf{R}^M)$, and $H^{-1}(\Omega, \mathbf{R}^M)$.

By $L^p_\mu(\Omega, \mathbf{R}^M)$, $1 \leq p \leq +\infty$, we denote the usual Lebesgue space with respect to the measure μ. If μ is the Lebesgue measure, we use the standard notation $L^p(\Omega, \mathbf{R}^M)$.

When we consider space of scalar functions ($M = 1$), we omit $\mathbf{R}^M$ in the notations above.

Let $u \in W^{1,p}(\Omega)$ and $k \in \mathbf{R}$. By $T_k u$ we shall denote the truncation at the level k which is the function in $W^{1,p}(\Omega)$ defined by $T_k u = (-k) \wedge u \vee k$.

Let A be an open set in $\mathbf{R}^N$, $u : A \to \mathbf{R}^M$ and $a, b \in \mathbf{R}$; we shall denote by $\{a \leq |u| \leq b\}_A$ the set of all $x \in A$ such that $a \leq |u(x)| \leq b$. When $A = \Omega$ we shall omit Ω in the notation above.

We shall use $o_{m,n}$ (respectively, o_n) to denote a sequence of real numbers such that $\lim_{m\to\infty} \lim_{n\to\infty} o_{m,n} = 0$ (respectively, $\lim_{n\to\infty} o_n = 0$).

If $E \subseteq \Omega$, the (*harmonic*) *p-capacity* of E in Ω, denoted by $C_p(E)$, is defined as the infimum of

$$\int_\Omega |Du|^p \, dx$$

over the set of all functions $u \in W_0^{1,p}(\Omega)$ such that $u \geq 1$ almost everywhere (a.e.) in a neighborhood of E.

We say that a property $\mathcal{P}(x)$ holds *p-quasi everywhere* (abbreviated as p-q.e.) in a set E if it holds for all $x \in E$ except for a subset N of E of p-capacity zero. The expression *μ-almost everywhere* (abbreviated as μ-a.e.) refers, as usual, to the analogous property for a Borel measure μ.

A function $u \colon \Omega \to \mathbf{R}^M$ is said to be *p-quasi continuous* if for every $\varepsilon > 0$ there exists a set $A \subseteq \Omega$, with $C_p(A) < \varepsilon$, such that the restriction of u to $\Omega \backslash A$ is continuous.

It is well known that every $u \in W^{1,p}(\Omega, \mathbf{R}^M)$ has a p-quasi continuous representative, which is uniquely defined up to a set of p-capacity zero. In the following we shall always identify u with its p-quasi continuous representative, so that the pointwise values of a function $u \in W^{1,p}(\Omega, \mathbf{R}^M)$ are defined p-q.e. in Ω.

A subset A of Ω is said to be *p-quasi open* in Ω if for every $\varepsilon > 0$ there exists an open subset A_ε of Ω, with $C_p(A_\varepsilon) < \varepsilon$, such that $A \cup A_\varepsilon$ is open. It is easy to see that if a function $u \colon \Omega \to \mathbf{R}$ is p-quasi continuous, then the set $\{u > c\}$ is p-quasi open for every $c \in \mathbf{R}$. For all these properties of p-quasi continuous representatives of Sobolev functions we refer to [28, Chapter 3].

By a nonnegative *Borel measure* in Ω we mean a countably additive set function defined in the Borel σ-field of Ω and with values in $[0, +\infty]$. By a nonnegative *Radon measure* in Ω we mean a nonnegative Borel measure which is finite on every compact subset of Ω. We shall always identify a nonnegative Borel measure with its completion.

We say that a Radon measure ν on Ω belongs to $W^{-1,p'}(\Omega)$ if there exists $f \in W^{-1,p'}(\Omega)$ such that

$$\langle f, \varphi \rangle = \int_\Omega \varphi \, d\nu \qquad \forall \, \varphi \in C_0^\infty(\Omega) \,, \tag{2.1}$$

where $\langle \cdot, \cdot \rangle$ denotes the duality pairing between $W^{-1,p'}(\Omega)$ and $W_0^{1,p}(\Omega)$. We shall always identify f and ν. Note that, by the Riesz theorem, for every positive functional $f \in W^{-1,p'}(\Omega)$, there exists a Radon measure ν such that (2.1) holds.

We denote by $\mathcal{M}_0^p(\Omega)$ the class of all Borel measures which vanish on the sets of p-capacity zero and satisfy the following condition:

$$\mu(B) = \inf\{\mu(A) \; : \; A \; p\text{-quasi open}, \; B \subseteq A \subseteq \Omega\}$$

for every Borel set $B \subseteq \Omega$. It is well known that every Radon measure which belongs to $W^{-1,p'}(\Omega)$ belongs also to $\mathcal{M}_0^p(\Omega)$ (see [28, section 4.7]).

3. Preliminary results on the relaxed Dirichlet problem with the p-Laplace operator. Let Ω be a bounded open subset of $\mathbf{R}^N$, $N \geq 2$. Let $2 \leq p < +\infty$ and let $\mu \in \mathcal{M}_0^p(\Omega)$. In the following we shall consider the space $W_0^{1,p}(\Omega) \cap L_\mu^p(\Omega)$ of all functions $u \in W_0^{1,p}(\Omega)$ such that $\int_\Omega |u|^p d\mu < +\infty$. With the norm

$$\|u\|_{W_0^{1,p}(\Omega) \cap L_\mu^p(\Omega)} \; = \left(\int_\Omega |Du|^p dx + \int_\Omega |u|^p d\mu \right)^{\frac{1}{p}}$$

the space $W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega)$ is a reflexive Banach space.

Let f be a functional belonging to $(W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega))'$ (the dual space of $W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega)$) and let us consider the following variational problem:

$$\tag{3.1} \begin{cases} u \in W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega), \\ \displaystyle\int_\Omega |Du|^{p-2} Du Dv \, dx + \int_\Omega |u|^{p-2} uv \, d\mu \; = \; \langle f, v \rangle \\ \forall \, v \in W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega). \end{cases}$$

Since the operator from $W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega)$ to $(W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega))'$ mapping $u \in W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega)$ to the functional defined by $\int_\Omega |Du|^{p-2} Du Dv \, dx + \int_\Omega |u|^{p-2} uv \, d\mu$ for every $v \in W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega)$ is a maximal monotone operator and the space $W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega)$ is reflexive, we get that there exists a unique solution u of problem (3.1).

Remark 3.1. It is easy to see that the dual of $W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega)$, $(W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega))'$, coincides with $W^{-1,p'}(\Omega) + L^{p'}_\mu(\Omega)$, so that, in particular, an element of the space $W^{-1,p'}(\Omega)$ can be seen as an element of $(W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega))'$. In what follows, with a slight abuse of notation, $\langle f, v \rangle$ will denote the duality pairing between $(W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega))'$ and $W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega)$, in the general case $f \in (W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega))'$, and the duality pairing between $W^{-1,p'}(\Omega)$ and $W_0^{1,p}(\Omega)$, in the case $f \in W^{-1,p'}(\Omega)$.

Many results similar to those given in the linear case (comparison principle, compactness, etc.) have been proved by Dal Maso and Murat (see [16] and [15]) for nonlinear problems of the type (3.1) (in general for nonlinear homogeneous operators).

PROPOSITION 3.2. *Let f_1, $f_2 \in W^{-1,p'}(\Omega)$ and let μ_1, $\mu_2 \in \mathcal{M}_0^p(\Omega)$. Let u_1, $u_2 \in W_0^{1,p}(\Omega)$ be the solutions of problem* (3.1) *corresponding to f_1, μ_1 and to f_2, μ_2. If $0 \le f_1 \le f_2$ and $\mu_2 \le \mu_1$ in Ω, then $0 \le u_1 \le u_2$ p-q.e. in Ω.*

Proof. See [15, Proposition 2.7]. □

In the space $\mathcal{M}_0^p(\Omega)$ it is possible to introduce a notion of convergence relative to the p-Laplace operator, $\Delta_p u = \operatorname{div}(|Du|^{p-2} Du)$.

DEFINITION 3.3. *Let (μ_n) be a sequence of measures of $\mathcal{M}_0^p(\Omega)$ and let $\mu \in \mathcal{M}_0^p(\Omega)$. We say that (μ_n) $\gamma^{-\Delta_p}$-converges to the measure μ if, for every $f \in W^{-1,p'}(\Omega)$, the sequence (u_n) of solutions of problems*

$$\tag{3.2} \begin{cases} u_n \in W_0^{1,p}(\Omega) \cap L^p_{\mu_n}(\Omega), \\ \displaystyle\int_\Omega |Du_n|^{p-2} Du_n Dv \, dx + \int_\Omega |u_n|^{p-2} u_n v \, d\mu_n \; = \; \langle f, v \rangle \\ \forall \, v \in W_0^{1,p}(\Omega) \cap L^p_{\mu_n}(\Omega) \end{cases}$$

converges weakly in $W_0^{1,p}(\Omega)$ to the solution u of problem (3.1).

THEOREM 3.4. *Every sequence of measures in $\mathcal{M}_0^p(\Omega)$ contains a $\gamma^{-\Delta_p}$-convergent subsequence.*

Proof. See [10, Theorem 2.1] or [15, Theorem 6.5]. □

Many properties of the measure $\mu \in \mathcal{M}_0^p(\Omega)$ can be studied by means of the solution w of the problem

$$\begin{cases} w \in W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega), \\ \displaystyle\int_\Omega |Dw|^{p-2} Dw Dv \, dx + \int_\Omega |w|^{p-2} wv \, d\mu \; = \; \int_\Omega v \, dx \\ \forall \, v \in W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega). \end{cases} \tag{3.3}$$

By the comparison principle (Proposition 3.2), the function w is bounded in $L^\infty(\Omega)$ by a constant which does not depend on μ (see [15, section 2]) and satisfies $w \geq 0$ p-q.e. in Ω.

THEOREM 3.5. *Let $\mu \in \mathcal{M}_0^p(\Omega)$, let w be the solution of problem* (3.3) *and let $\nu = 1 + \Delta_p w$ in the sense of $W^{-1,p'}(\Omega)$. Then ν is a nonnegative Radon measure of $W^{-1,p'}(\Omega)$ and*

$$\nu(B \cap \{w > 0\}) \; = \; \int_B w^{p-1} d\mu \tag{3.4}$$

for every Borel set $B \subseteq \Omega$. Reciprocally, we have

$$\mu(B) \; = \; \begin{cases} \displaystyle\int_B \frac{1}{w^{p-1}} d\nu & \textit{if } C_p(B \cap \{w = 0\}) = 0, \\ +\infty & \textit{if } C_p(B \cap \{w = 0\}) > 0 \end{cases}$$

for any Borel set $B \subseteq \Omega$.

Proof. See [15, Theorem 5.1] and [11, Proposition 3.4] for the linear case. □

The next proposition gives two density results which will be useful in what follows.

PROPOSITION 3.6. *Let $\mu \in \mathcal{M}_0^p(\Omega)$ and let w the solution of problem* (3.3). *Then*

(a) *the set $\{w\psi : \psi \in C_0^\infty(\Omega)\}$ is dense in $W_0^{1,p}(\Omega) \cap L^p_\mu(\Omega)$ and hence in $W^{1,p}_{\text{loc}}(\Omega) \cap L^p_\mu(\Omega)$.*

(b) *the set Λ of all functions of the form $w \sum_{i=1}^l a_i 1_{K_i}$ where $a_i \in \mathbf{R}$ and K_i are closed subsets of Ω such that $w = 0$ μ-a.e. on $K_i \cap K_j$, with $i \neq j$, is dense in $L^p_\mu(\Omega)$.*

Proof. The proof of part (a) is given in [15, Proposition 5.5]. In order to prove part (b), we consider the measure $\lambda = w^p \mu$. Since w belongs to $L^p_\mu(\Omega)$, the measure λ is a Borel bounded measure and therefore the set of all step functions of the form $\sum_{i=1}^l a_i 1_{K_i}$, where $a_i \in \mathbf{R}$ and K_i are closed subsets of Ω such that, for $i \neq j$, $\lambda(K_i \cap K_j) = 0$, is dense in $L^p_\lambda(\Omega)$. If u belongs to $L^p_\mu(\Omega)$, then u/w belongs to $L^p_\lambda(\Omega)$, and for every $\zeta \in \Lambda$ we have

$$\int_\Omega \left| \zeta - \frac{u}{w} \right|^p d\lambda = \int_\Omega |w\zeta - u|^p \, d\mu$$

which gives part (b). □

Finally the solutions of problems (3.3) are useful to characterize the $\gamma^{-\Delta_p}$-convergence in $\mathcal{M}_0^p(\Omega)$. Let (μ_n) be a sequence of measures in $\mathcal{M}_0^p(\Omega)$, and let w_n be the solutions of the problems

$$\begin{cases} w_n \in W_0^{1,p}(\Omega) \cap L^p_{\mu_n}(\Omega), \\ \displaystyle\int_\Omega |Dw_n|^{p-2} Dw_n Dv \, dx + \int_\Omega |w_n|^{p-2} w_n v \, d\mu_n \; = \; \int_\Omega v \, dx \\ \forall \, v \in W_0^{1,p}(\Omega) \cap L^p_{\mu_n}(\Omega). \end{cases} \tag{3.5}$$

The following result characterizes the $\gamma^{-\Delta_p}$-convergence in terms of the convergence of the functions w_n.

Theorem 3.7. *The following conditions are equivalent:*

(a) *(w_n) converges to w weakly in $W_0^{1,p}(\Omega)$;*

(b) *(μ_n) $\gamma^{-\Delta_p}$-converges to μ.*

Proof. See [15, Theorem 6.3] and [11, Theorem 4.3] for the linear case. □

Remark 3.8. If (μ_n) $\gamma^{-\Delta_p}$-converges to μ, then the sequence (w_n) converges to w strongly in $W_0^{1,r}(\Omega)$ for every $1 \le r < p$ and hence, a subsequence of (Dw_n) converges to Dw pointwise a.e. in Ω (see [15, Theorem 6.8]).

4. Sequences in the spaces $W^{1,p}\cap L^p_{\mu_n}$.

In this section (μ_n) will be a sequence of $\mathcal{M}_0^p(\Omega)$ which $\gamma^{-\Delta_p}$-converges to a measure $\mu \in \mathcal{M}_0^p(\Omega)$. We shall use the sequence (w_n) of the solutions of problems (3.5) to investigate the behavior of an arbitrary sequence (u_n), with $u_n \in W^{1,p}(\Omega) \cap L^p_{\mu_n}(\Omega)$, which converges weakly in $W^{1,p}(\Omega)$. By Remark 3.8 we may assume that (w_n) and (Dw_n), respectively, converge to w and Dw pointwise a.e. in Ω.

Let us prove some technical lemmas that will be useful in the remainder of this paper.

Lemma 4.1. *Let Ω' be an open subset of Ω. For every $\varphi \in W_0^{1,p}(\Omega') \cap L^\infty(\Omega')$ we have*

$$\lim_{n\to\infty}\Big(\int_{\Omega'} |Dw_n|^p\varphi\,dx + \int_{\Omega'} |w_n|^p\varphi\,d\mu_n\Big) = \int_{\Omega'} |Dw|^p\varphi\,dx + \int_{\Omega'} |w|^p\varphi\,d\mu. \tag{4.1}$$

Proof. Let $\varphi \in W_0^{1,p}(\Omega') \cap L^\infty(\Omega')$ and let us extend φ to Ω by setting $\varphi = 0$ in $\Omega \setminus \Omega'$. Thus $w_n\varphi$ belongs to $W_0^{1,p}(\Omega)$, and we can take it as test function in (3.3). Therefore by Remark 3.8 we obtain

$$\begin{aligned}
&\lim_{n\to\infty}\Big(\int_{\Omega'} |Dw_n|^p\varphi\,dx + \int_{\Omega'} |w_n|^p\varphi\,d\mu_n\Big)\\
&\quad = \lim_{n\to\infty}\Big(\int_{\Omega'} w_n\varphi\,dx - \int_{\Omega'} |Dw_n|^{p-2}Dw_nD\varphi\,w_n dx\Big)\\
&\quad = \int_{\Omega'} w\varphi\,dx - \int_{\Omega} |Dw|^{p-2}DwD\varphi\,w\,dx = \int_{\Omega'} |Dw|^p\varphi\,dx + \int_{\Omega'} |w|^p\varphi\,d\mu,
\end{aligned}$$

which concludes the proof. □

Lemma 4.2. *Let Ω' be an open subset of Ω. For every $\varphi, \psi \in W^{1,p}(\Omega') \cap L^\infty(\Omega')$, with φ or ψ in $W_0^{1,p}(\Omega')$, we have*

$$\lim_{n\to\infty}\Big(\int_{\Omega'} |D(w_n\psi)|^p\varphi\,dx + \int_{\Omega'} |w_n\psi|^p\varphi\,d\mu_n\Big) = \int_{\Omega'} |D(w\psi)|^p\varphi\,dx + \int_{\Omega'} |w\psi|^p\varphi\,d\mu. \tag{4.2}$$

Proof. Let $\varphi, \psi \in W^{1,p}(\Omega') \cap L^\infty(\Omega')$, with φ or ψ in $W_0^{1,p}(\Omega')$. Since for every $\xi_1, \xi_2 \in \mathbf{R}^N$ and for every $p \ge 2$ the following inequality holds

$$\big||\xi_1|^p - |\xi_2|^p\big| \le p\big(|\xi_1| + |\xi_2|\big)^{p-1}|\xi_1 - \xi_2|, \tag{4.3}$$

we have

$$\big||\psi Dw_n + w_nD\psi|^p - |\psi Dw_n|^p\big| \le p\big(|\psi Dw_n + w_nD\psi| + |\psi Dw_n|\big)^{p-1}|w_nD\psi|,$$

where by Remark 3.8 the left-hand side converges pointwise to $\big||\psi Dw + wD\psi|^p - |\psi Dw|^p\big|$ and the right-hand side is uniformly integrable. Then $(|D(w_n\psi)|^p - |\psi Dw_n|^p)$ converges to $|D(w\psi)|^p - |\psi Dw|^p$ strongly in $L^1(\Omega')$. This implies that

$$\int_{\Omega'} |D(w_n\psi)|^p\varphi\,dx = \int_{\Omega'} |D(w\psi)|^p\varphi\,dx - \int_{\Omega'} |Dw|^p|\psi|^p\varphi\,dx + \int_{\Omega'} |Dw_n|^p|\psi|^p\varphi\,dx + o_n$$

and therefore the conclusion follows from Lemma 4.1. □

Lemma 4.3. *Let Ω' be an open subset of Ω, let $u \in W^{1,p}(\Omega') \cap L^p_\mu(\Omega')$, and let (ψ_m) be a sequence of functions in $C^\infty_0(\Omega')$ such that $(w\psi_m)$ converges to u strongly in $W^{1,p}_{\text{loc}}(\Omega') \cap L^p_\mu(\Omega')$. Then*

$$\lim_{m\to\infty}\lim_{n\to\infty}\Big(\int_{\Omega'} |D(w_n\psi_m - u)|^p\varphi\,dx + \int_{\Omega'} |w_n\psi_m|^p\varphi\,d\mu_n\Big) = \int_{\Omega'} |u|^p\varphi\,d\mu \tag{4.4}$$

for every $\varphi \in W^{1,p}_c(\Omega') \cap L^\infty(\Omega')$.

Proof. As in the proof of Lemma 4.2, $\big(|D(w_n\psi_m - u)|^p - |D(w_n\psi_m)|^p\big)$ converges to $|D(w\psi_m - u)|^p - |D(w\psi_m)|^p$ strongly in $L^1(\Omega')$ as $n \to \infty$. Let $\varphi \in W^{1,p}_c(\Omega') \cap L^\infty(\Omega')$; thus, by Lemma 4.2, we get

$$\begin{aligned}\int_{\Omega'} |D(w_n\psi_m - u)|^p\varphi\,dx + \int_{\Omega'} |w_n\psi_m|^p\varphi\,d\mu_n &= \int_{\Omega'} \big(|D(w_n\psi_m - u)|^p - |D(w_n\psi_m)|^p\big)\varphi\,dx\\ + \int_{\Omega'} |D(w_n\psi_m)|^p\varphi\,dx + \int_{\Omega'} |w_n\psi_m|^p\varphi\,d\mu_n &= \int_{\Omega'} \big(|D(w\psi_m - u)|^p - |D(w\psi_m)|^p\big)\varphi\,dx\\ + \int_{\Omega'} |D(w\psi_m)|^p\varphi\,dx + \int_{\Omega'} |w\psi_m|^p\varphi\,d\mu + o_n &= \int_{\Omega'} |u|^p\varphi\,d\mu + o_{m,n}.\end{aligned}$$

The conclusion follows by taking the limit first as $n \to \infty$ and then as $m \to \infty$. □

Let Ω' be an open subset of Ω. The following theorem shows that if a sequence (u_n), with $u_n \in W^{1,p}(\Omega') \cap L^p_{\mu_n}(\Omega')$, converges weakly in $W^{1,p}(\Omega')$ to a function $u \in W^{1,p}(\Omega')$, and there exists a constant $C > 0$ such that

$$\int_{\Omega'} |u_n|^p d\mu_n \le C \tag{4.5}$$

for every $n \in \mathbf{N}$, then the function u belongs to $L^p_\mu(\Omega')$.

Theorem 4.4. *Let (u_n) be a sequence such that $u_n \in W^{1,p}(\Omega') \cap L^p_{\mu_n}(\Omega')$. Suppose that (u_n) converges weakly in $W^{1,p}(\Omega')$ to some function u. Then*

$$\liminf_{n\to\infty}\Big(\int_{\Omega'} |Du_n|^p dx + \int_{\Omega'} |u_n|^p d\mu_n\Big) \ge \int_{\Omega'} |Du|^p dx + \int_{\Omega'} |u|^p d\mu. \tag{4.6}$$

In particular, if (4.5) *holds, then $u \in W^{1,p}(\Omega') \cap L^p_\mu(\Omega')$.*

The result of Theorem 4.4 can be obtained as a direct consequence of the Γ-convergence of the functionals $\int_{\Omega'} |Du_n|^p dx + \int_{\Omega'} |u_n|^p d\mu_n$ to the functional $\int_{\Omega'} |Du|^p dx + \int_{\Omega'} |u|^p d\mu$ proved in [10]. For the sake of completeness we shall give an alternative proof of Theorem 4.4 which does not involve Γ-convergence theory. Before proving Theorem 4.4, let us prove two preliminary lemmas.

Lemma 4.5. *Let (u_n) be a sequence such that $u_n \in W^{1,p}(\Omega') \cap L^p_{\mu_n}(\Omega')$ and such that* (4.5) *holds. Suppose that (u_n) converges weakly in $W^{1,p}(\Omega')$ to some function u. Then $\{u = 0\}_{\Omega'} \supseteq \{w = 0\}_{\Omega'}$.*

Proof. Taking into account the decomposition $u_n = u_n^+ - u_n^-$, where u_n^+ and u_n^- denote respectively the positive and the negative part of u_n, it is not restrictive to assume $u_n \geq 0$ p-q.e. in Ω'.

We shall prove first the result in the special case where the functions u_n and u belong to $W_0^{1,p}(\Omega')$, and we shall suppose, also, that there exists a constant $K > 0$ such that $u_n \leq K$ p-q.e. in Ω' and hence $u \leq K$ p-q.e. in Ω'.

For every $m \in \mathbf{N}$ let us consider the sequence (u_n^m) of the solutions of the problems

$$\text{(4.7)} \qquad \begin{cases} u_n^m \in W_0^{1,p}(\Omega') \cap L^p_{\mu_n}(\Omega'), \\ \displaystyle\int_{\Omega'} |Du_n^m|^{p-2} Du_n^m Dv\,dx + \int_{\Omega'} |u_n^m|^{p-2} u_n^m v\,d\mu_n \\ \qquad = m \displaystyle\int_{\Omega'} \big(|u_n|^{p-2}u_n - |u_n^m|^{p-2}u_n^m\big) v\,dx \\ \forall\, v \in W_0^{1,p}(\Omega') \cap L^p_{\mu_n}(\Omega'), \end{cases}$$

which, extended to Ω by setting $u_n^m = 0$ in $\Omega \backslash \Omega'$, are also the solutions of the following equivalent problems:

$$\text{(4.8)} \qquad \begin{cases} u_n^m \in W_0^{1,p}(\Omega) \cap L^p_{\hat{\mu}_n}(\Omega), \\ \displaystyle\int_{\Omega} |Du_n^m|^{p-2} Du_n^m Dv\,dx + \int_{\Omega} |u_n^m|^{p-2} u_n^m v\,d\hat{\mu}_n \\ \qquad = m \displaystyle\int_{\Omega} \big(|u_n|^{p-2}u_n - |u_n^m|^{p-2}u_n^m\big) v\,dx \\ \forall\, v \in W_0^{1,p}(\Omega) \cap L^p_{\hat{\mu}_n}(\Omega), \end{cases}$$

where $\hat{\mu}_n$ is the measure defined by

$$\hat{\mu}_n(B) = \begin{cases} \mu_n(B) & \text{if } C_p(B \cap (\Omega \setminus \Omega')) = 0, \\ +\infty & \text{if } C_p(B \cap (\Omega \setminus \Omega')) > 0 \end{cases}$$

for any Borel set $B \subseteq \Omega$. By the comparison principle (Proposition 3.2) we have that

$$\text{(4.9)} \qquad 0 \leq u_n^m \leq m^{\frac{1}{p-1}} K w_n \qquad p\text{-q.e. in } \Omega.$$

By taking in (4.7) $u_n^m - u_n$ as a test function we get

$$\text{(4.10)} \qquad \begin{aligned} &\int_{\Omega'} \big(|Du_n^m|^{p-2}Du_n^m - |Du_n|^{p-2}Du_n\big) D(u_n^m - u_n)\,dx \\ &\quad + \int_{\Omega'} \big(|u_n^m|^{p-2}u_n^m - |u_n|^{p-2}u_n\big)(u_n^m - u_n)\,d\mu_n \\ &\quad + m \int_{\Omega'} \big(|u_n^m|^{p-2}u_n^m - |u_n|^{p-2}u_n\big)(u_n^m - u_n)\,dx \\ = &- \int_{\Omega'} |Du_n|^{p-2}Du_n D(u_n^m - u_n)\,dx - \int_{\Omega'} |u_n|^{p-2}u_n(u_n^m - u_n)\,d\mu_n. \end{aligned}$$

Since for every $\xi_1, \xi_2 \in \mathbf{R}^N$ and for every $p \geq 2$ we have

$$\text{(4.11)} \qquad (|\xi_1|^{p-2}\xi_1 - |\xi_2|^{p-2}\xi_2)(\xi_1 - \xi_2) \geq 2^{2-p}|\xi_1 - \xi_2|^p,$$

applying Young's inequality in (4.10) we get

$$\begin{aligned}2^{2-p}\int_{\Omega'}|D(u_n^m-u_n)|^p dx+2^{2-p}\int_{\Omega'}|u_n^m-u_n|^p d\mu_n+2^{2-p}m\int_{\Omega'}|u_n^m-u_n|^p dx\\ \le\frac{1}{\varepsilon^{p'}p'}\Big(\int_{\Omega'}|Du_n|^p dx+\int_{\Omega'}|u_n|^p d\mu_n\Big)\\ +\frac{\varepsilon^p}{p}\Big(\int_{\Omega'}|D(u_n^m-u_n)|^p dx+\int_{\Omega'}|u_n^m-u_n|^p d\mu_n\Big),\end{aligned}$$

where $\varepsilon>0$ is an arbitrary real number. Since (u_n) is bounded in $W_0^{1,p}(\Omega')$ and (4.5) holds, by choosing ε small enough we obtain that there exists a constant $C>0$ such that

$$\int_{\Omega'}|D(u_n^m-u_n)|^p dx+m\int_{\Omega'}|u_n^m-u_n|^p dx\ \le\ C. \tag{4.12}$$

By (4.12) we have that the sequence (u_n^m) is bounded in $W_0^{1,p}(\Omega')$, uniformly in m and n. Then for every $m\in\mathbf{N}$ there exists a subsequence of (u_n^m) (we can choose the subsequence independent of m) which converges to a function u^m weakly in $W_0^{1,p}(\Omega')$. By the weak lower semicontinuity of the norm, the sequence (u^m) is also bounded in $W_0^{1,p}(\Omega')$. Moreover by (4.12) we get

$$\int_{\Omega'}|u^m-u|^p dx\ =\ \lim_{n\to\infty}\int_{\Omega'}|u_n^m-u_n|^p dx\ \le\ \frac{C}{m},$$

and hence (u^m) converges weakly to u in $W_0^{1,p}(\Omega')$. By (4.9) we have that $|u^m|\le m^{1/(p-1)}Kw$ p-q.e. in Ω' and hence u^m belongs to the set $\mathcal{K}=\{v\in W_0^{1,p}(\Omega'):v=0\ p\text{-q.e. in }\{w=0\}_{\Omega'}\}$. Since $\mathcal{K}$ is convex and closed in $W_0^{1,p}(\Omega')$, it is weakly closed. Therefore $u\in\mathcal{K}$ and hence $\{u=0\}_{\Omega'}\supseteq\{w=0\}_{\Omega'}$.

Finally let us consider the general case where the sequence (u_n) is not bounded in $L^\infty(\Omega')$ but $u_n\in W^{1,p}(\Omega')\cap L^p_{\mu_n}(\Omega')$, satisfies (4.5), and converges weakly in $W^{1,p}(\Omega')$ to u. Let Φ be a function in $W_0^{1,\infty}(\Omega')$, with $\Phi>0$ in Ω', and for every $n\in\mathbf{N}$ let T_1u_n be the truncation at the level 1 of u_n. Since $\Phi T_1u_n\in W_0^{1,p}(\Omega')\cap L^p_{\mu_n}(\Omega')$ and the sequence (ΦT_1u_n) satisfies (4.5), is bounded in $L^\infty(\Omega')$, and converges weakly in $W_0^{1,p}(\Omega')$ to ΦT_1u, by the previous step we can conclude that $\{\Phi T_1u=0\}_{\Omega'}\supseteq\{w=0\}_{\Omega'}$ and hence $\{u=0\}_{\Omega'}\supseteq\{w=0\}_{\Omega'}$. □

Lemma 4.6. *Let (v_n), with $v_n\in W^{1,p}(\Omega')\cap L^p_{\mu_n}(\Omega')$, be a sequence which converges to a function v weakly in $W^{1,p}(\Omega')$, and suppose that there exists a constant $C>0$ such that*

$$\int_{\Omega'}|v_n|^p d\mu_n\ \le\ C \tag{4.13}$$

for every $n\in\mathbf{N}$. Then we have

$$\begin{aligned}\lim_{n\to\infty}\Big(\int_{\Omega'}\varphi|D(w_n\psi)|^{p-2}D(w_n\psi)Dv_n\,dx+\int_{\Omega'}\varphi|w_n\psi|^{p-2}w_n\psi v_n\,d\mu_n\Big)\\ =\int_{\Omega'}\varphi|D(w\psi)|^{p-2}D(w\psi)Dv\,dx+\int_{\Omega'}\varphi|w\psi|^{p-2}w\psi v\,d\mu\end{aligned} \tag{4.14}$$

for every $\psi\in W^{1,p}(\Omega')\cap L^\infty(\Omega')$ and for every $\varphi\in W_0^{1,p}(\Omega')\cap L^\infty(\Omega')$.

Proof. Let $\psi \in W^{1,p}(\Omega') \cap L^\infty(\Omega')$ and $\varphi \in W_0^{1,p}(\Omega') \cap L^\infty(\Omega')$. Since for every $p \geq 2$ the following inequality holds

$$\big||\xi_1|^{p-2}\xi_1 - |\xi_2|^{p-2}\xi_2\big| \leq (p-1)(|\xi_1| + |\xi_2|)^{p-2}|\xi_1 - \xi_2| \tag{4.15}$$

for every $\xi_1, \xi_2 \in \mathbf{R}^N$, as in Lemma 4.2, we can conclude that $\big(|D(w_n\psi)|^{p-2}D(w_n\psi) - |\psi Dw_n|^{p-2}\psi Dw_n\big)$ converges to $|D(w\psi)|^{p-2}D(w\psi) - |\psi Dw|^{p-2}\psi Dw$ strongly in $L^{p'}(\Omega', \mathbf{R}^N)$. Thus

$$\begin{aligned} &\lim_{n\to\infty}\Big(\int_{\Omega'} \varphi|D(w_n\psi)|^{p-2}D(w_n\psi)Dv_n\,dx - \int_{\Omega'}\varphi|\psi Dw_n|^{p-2}\psi Dw_n Dv_n\,dx\Big) \\ &\qquad = \int_{\Omega'}\big(|D(w\psi)|^{p-2}D(w\psi) - |\psi Dw|^{p-2}\psi Dw\big)Dv\,\varphi\,dx. \end{aligned} \tag{4.16}$$

In order to conclude the proof it is enough to show that

$$\begin{aligned} &\lim_{n\to\infty}\Big(\int_{\Omega'}\varphi|\psi Dw_n|^{p-2}\psi Dw_n Dv_n\,dx + \int_{\Omega'}\varphi|w_n\psi|^{p-2}w_n\psi v_n\,d\mu_n\Big) \\ &\qquad = \int_{\Omega'}\varphi|\psi Dw|^{p-2}\psi Dw Dv\,dx + \int_{\Omega'}\varphi|\psi|^{p-2}\psi v\,d\nu, \end{aligned} \tag{4.17}$$

where $\nu \in W^{-1,p'}(\Omega)$ is the Radon measure defined in Theorem 3.5. Indeed, since by Lemma 4.5 we have that $\{v = 0\}_{\Omega'} \supseteq \{w = 0\}_{\Omega'}$, by (3.4) we get

$$\int_{\Omega'}\varphi|\psi|^{p-2}\psi v\,d\nu = \int_{\{w>0\}_{\Omega'}}\varphi|\psi|^{p-2}\psi v\,d\nu = \int_{\Omega'}\varphi w^{p-1}|\psi|^{p-2}\psi v\,d\mu;$$

therefore the conclusion follows from (4.16) and (4.17).

It remains to prove (4.17). Let us consider $\phi \in W_0^{1,\infty}(\Omega')$. Taking $\phi v_n \in W_0^{1,p}(\Omega') \cap L^p_{\mu_n}(\Omega') \subset W_0^{1,p}(\Omega) \cap L^p_{\mu_n}(\Omega)$ as a test function in problem (3.5), and taking into account that $\nu = 1 + \Delta_p w$ in $W^{-1,p'}(\Omega)$ (Theorem 3.5), we obtain

$$\begin{aligned} &\lim_{n\to\infty}\int_{\Omega'}\phi|Dw_n|^{p-2}Dw_n Dv_n\,dx + \int_{\Omega'}\phi|w_n|^{p-2}w_n v_n\,d\mu_n \\ &\qquad = \lim_{n\to\infty}\int_{\Omega'}\phi v_n\,dx - \int_{\Omega'}|Dw_n|^{p-2}Dw_n D\phi\, v_n\,dx \\ &= \int_{\Omega'}\phi v\,dx - \int_{\Omega'}|Dw|^{p-2}Dw D\phi\, v\,dx = \int_{\Omega'}\phi|Dw|^{p-2}Dw Dv\,dx + \int_{\Omega'}\phi v\,d\nu. \end{aligned} \tag{4.18}$$

We have to prove that (4.18) holds for every $\phi \in W_0^{1,p}(\Omega') \cap L^\infty(\Omega')$. Let $\phi \in W_0^{1,p}(\Omega') \cap L^\infty(\Omega')$. Since ν is a Radon measure in $W^{-1,p'}(\Omega)$, it is possible to construct a sequence (ϕ_m) of functions in $W_0^{1,\infty}(\Omega')$ bounded in $L^\infty(\Omega')$, which converges to ϕ a.e. and ν-a.e. in Ω'. By (4.18) we have

$$\begin{aligned} &\Big|\int_{\Omega'}\phi|Dw_n|^{p-2}Dw_n Dv_n\,dx + \int_{\Omega'}\phi|w_n|^{p-2}w_n v_n\,d\mu_n - \int_{\Omega'}\phi|Dw|^{p-2}Dw Dv\,dx - \int_{\Omega'}\phi v\,d\nu\Big| \\ &\qquad \leq \Big|\int_{\Omega'}(\phi - \phi_m)|Dw_n|^{p-2}Dw_n Dv_n\,dx + \int_{\Omega'}(\phi - \phi_m)|w_n|^{p-2}w_n v_n\,d\mu_n\Big| \\ &\qquad\qquad + \Big|\int_{\Omega'}(\phi_m - \phi)|Dw|^{p-2}Dw Dv\,dx + \int_{\Omega'}(\phi_m - \phi)v\,d\nu\Big| + o_n. \end{aligned} \tag{4.19}$$

By the dominated convergence theorem the limit as $m \to \infty$ of the second term in the right-hand side of (4.19) is zero. It remains to estimate the first term of the right-hand side of (4.19). Since (ϕ_m) is bounded in $L^\infty(\Omega')$, by Hölder's inequality, (4.13), and Lemma 4.1 we obtain

$$\begin{aligned} &\Big|\int_{\Omega'} (\phi - \phi_m)|Dw_n|^{p-2} Dw_n Dv_n\, dx + \int_{\Omega'} (\phi - \phi_m)|w_n|^{p-2} w_n v_n\, d\mu_n\Big| \\ &\le C\Big(\int_{\Omega'} |Dw_n|^p |\phi - \phi_m|^{\frac{p}{(p-1)}}\, dx + \int_{\Omega'} |w_n|^p |\phi - \phi_m|^{\frac{p}{(p-1)}}\, d\mu_n\Big)^{\frac{p-1}{p}} \\ &= C\Big(\int_{\Omega'} |Dw|^p |\phi - \phi_m|^{\frac{p}{(p-1)}}\, dx + \int_{\Omega'} |w|^p |\phi - \phi_m|^{\frac{p}{(p-1)}}\, d\mu\Big)^{\frac{p-1}{p}} + o_n = o_{m,n}, \end{aligned}$$

where C is a positive constant independent of n and m and where for the last limit we used the dominated convergence theorem. Finally (4.17) follows immediately from (4.18) by choosing $\phi = \varphi|\psi|^{p-2}\psi$. □

We are now in a position to prove Theorem 4.4.

Proof of Theorem 4.4. If $\liminf_{n\to\infty} \int_{\Omega'} |u_n|^p d\mu_n = +\infty$, then inequality (4.6) is trivially satisfied; otherwise it is not restrictive to suppose that (4.5) holds. Let $\psi \in W^{1,p}(\Omega') \cap L^\infty(\Omega')$, and let $\varphi \in W_0^{1,p}(\Omega') \cap L^\infty(\Omega')$ with $\varphi \ge 0$. Since for every $\xi_1, \xi_2 \in \mathbf{R}^N$, by the convexity of the function $|\cdot|^p$, the following inequality holds:

$$|\xi_1|^p - |\xi_2|^p \ \ge\ p|\xi_2|^{p-2}\xi_2(\xi_1 - \xi_2), \tag{4.20}$$

we have

$$\begin{aligned} &\int_{\Omega'} \varphi|Du_n|^p dx + \int_{\Omega'} \varphi|u_n|^p d\mu_n \ \ge\ \int_{\Omega'} \varphi|D(w_n\psi)|^p dx + \int_{\Omega'} \varphi|w_n\psi|^p d\mu_n \\ &+ p\int_{\Omega'} |D(w_n\psi)|^{p-2} D(w_n\psi) D(u_n - w_n\psi)\varphi\, dx + p\int_{\Omega'} |w_n\psi|^{p-2} w_n\psi(u_n - w_n\psi)\varphi\, d\mu_n. \end{aligned}$$

By Lemmas 4.2 and 4.6 we get

$$\begin{aligned} &\liminf_{n\to\infty}\Big(\int_{\Omega'} \varphi|Du_n|^p dx + \int_{\Omega'} \varphi|u_n|^p d\mu_n\Big) \\ &\ge \int_{\Omega'} \varphi|D(w\psi)|^p dx + \int_{\Omega'} \varphi|w\psi|^p d\mu \\ &+ p\int_{\Omega'} |D(w\psi)|^{p-2} D(w\psi) D(u - w\psi)\varphi\, dx + p\int_{\Omega'} |w\psi|^{p-2} w\psi(u - w\psi)\varphi\, d\mu. \end{aligned} \tag{4.21}$$

Assume that $u \in L^\infty(\Omega')$. Let $\varepsilon > 0$ and let us choose in (4.21) $\psi = \frac{u}{w \vee \varepsilon}$ and $\varphi = \phi R_\varepsilon(w)$, with $0 \le \phi \le 1$, $\phi \in W_0^{1,p}(\Omega') \cap L^\infty(\Omega')$, and $R_\varepsilon : \mathbf{R} \mapsto \mathbf{R}$ defined by

$$R_\varepsilon(s) = \begin{cases} 0 & \text{if } s \le \varepsilon, \\ \frac{s}{\varepsilon} - 1 & \text{if } \varepsilon \le s \le 2\varepsilon, \\ 1 & \text{if } 2\varepsilon \le s < +\infty. \end{cases}$$

Since $w\psi = u$ p-q.e. in $\{w > \varepsilon\}$ and $\phi R_\varepsilon(w) = 0$ p-q.e. in $\{w \le \varepsilon\}$, by (4.21) we have

$$\begin{aligned} &\liminf_{n\to\infty}\Big(\int_{\Omega'} |Du_n|^p dx + \int_{\Omega'} |u_n|^p d\mu_n\Big) \\ &\ge \int_{\Omega' \cap \{w > \varepsilon\}} R_\varepsilon(w)\phi|Du|^p dx + \int_{\Omega' \cap \{w > \varepsilon\}} R_\varepsilon(w)\phi|u|^p d\mu, \end{aligned}$$

which, by the monotone convergence theorem, implies

$$\text{(4.22)}\qquad \begin{aligned}&\liminf_{n\to\infty}\Big(\int_{\Omega'}|Du_n|^p dx+\int_{\Omega'}|u_n|^p d\mu_n\Big)\\ &\qquad\geq\int_{\Omega'\cap\{w>0\}}\phi|Du|^p dx+\int_{\Omega'\cap\{w>0\}}\phi|u|^p d\mu\end{aligned}$$

for every $\phi\in W_0^{1,p}(\Omega')\cap L^\infty(\Omega')$ with $0\leq\phi\leq 1$. Since $Du=0$ a.e. in $\{u=0\}_{\Omega'}$ and by Lemma 4.5 $\{u=0\}_{\Omega'}\supseteq\{w=0\}_{\Omega'}$, estimate (4.23) may be written as

$$\liminf_{n\to\infty}\Big(\int_{\Omega'}|Du_n|^p dx+\int_{\Omega'}|u_n|^p d\mu_n\Big)\;\geq\;\int_{\Omega'}\phi|Du|^p dx+\int_{\Omega'}\phi|u|^p d\mu.$$

Thus, by the monotone convergence theorem, we deduce that $u\in L^p_\mu(\Omega')$ and (4.6) holds. If u does not belong to $L^\infty(\Omega')$, it is enough to apply the previous step to the sequence of truncations $T_k(u_n)$ with $k\in\mathbf{N}$. Then we have

$$\begin{aligned}\liminf_{n\to\infty}\Big(\int_{\Omega'}|Du_n|^p dx+\int_{\Omega'}|u_n|^p d\mu_n\Big)\;&\geq\;\liminf_{n\to\infty}\Big(\int_{\Omega'}|DT_k(u_n)|^p dx+\int_{\Omega'}|T_k(u_n)|^p d\mu_n\Big)\\ &\geq\;\int_{\Omega'}|DT_k(u)|^p dx+\int_{\Omega'}|T_k(u)|^p d\mu.\end{aligned}$$

We conclude the proof by the monotone convergence theorem, taking the limit as $k\to\infty$. □

5. Relaxed Dirichlet problems with monotone operators. Let A be the monotone operator defined from $W^{1,p}(\Omega,\mathbf{R}^M)$ to $W^{-1,p'}(\Omega,\mathbf{R}^M)$, with $2\leq p<+\infty$ and $M\geq 2$, mapping $u\in W^{1,p}(\Omega,\mathbf{R}^M)$ in $Au=-\mathrm{div}\big(a(x,Du)\big)\in W^{-1,p'}(\Omega,\mathbf{R}^M)$, where $a\colon\Omega\times\mathbf{M}^{M\times N}\mapsto\mathbf{M}^{M\times N}$ is a Carathéodory function. We shall assume that the function a satisfies the following conditions:

(i) there exists a constant $\alpha>0$ such that

$$(a(x,\xi_1)-a(x,\xi_2))(\xi_1-\xi_2)\geq\alpha|\xi_1-\xi_2|^p$$

for every $\xi_1,\xi_2\in\mathbf{M}^{M\times N}$ and for a.e. $x\in\Omega$;

(ii) there exists a constant $\beta>0$ and a function $h\in L^{\frac{p}{p-2}}(\Omega)$ such that

$$|a(x,\xi_1)-a(x,\xi_2)|\;\leq\;\beta(h(x)+\big(|\xi_1|+|\xi_2|)^{p-2}\big)|\xi_1-\xi_2|$$

for every $\xi_1,\xi_2\in\mathbf{M}^{M\times N}$ and for a.e. $x\in\Omega$;

(iii) $a(x,0)=0$ a.e. in Ω.

These hypotheses imply in particular that the following conditions hold:

(iv) there exists a constant $\eta>0$ and a function $k\in L^{p'}(\Omega)$ such that

$$|a(x,\xi)|\leq k(x)+\eta|\xi|^{p-1}$$

for every $\xi\in\mathbf{M}^{M\times N}$ and for a.e. $x\in\Omega$;

(v) $a(x,\xi)\xi\;\geq\;\alpha|\xi|^p$ for every $\xi\in\mathbf{M}^{M\times N}$ and a.e. $x\in\Omega$.

We shall see in section 10 that the results proved in what follows hold for a class of operators which satisfy more general conditions than (i)–(iv) above.

Given three positive constants c_1, c_2, and σ, with $0<\sigma\leq 1$, let us define the class $\mathcal{F}(c_1,c_2,\sigma)$ of all vector functions $F\colon\Omega\times\mathbf{R}^M\mapsto\mathbf{R}^M$ such that the following properties are satisfied:

(I) $F(x,s)$ is a Borel function;

(II) for every $s_1, s_2 \in \mathbf{R}^M$ and for every $x \in \Omega$ we have

$$(F(x,s_1) - F(x,s_2))(s_1 - s_2) \geq c_1 |s_1 - s_2|^p;$$

(III) for every $s_1, s_2 \in \mathbf{R}^M$ and for every $x \in \Omega$ we have

$$|F(x,s_1) - F(x,s_2)| \leq c_2(|s_1| + |s_2|)^{p-1-\sigma}|s_1 - s_2|^\sigma;$$

(IV) $F(x,0) = 0$ for every $x \in \Omega$.

As consequence of properties (III) and (IV) we have that the function F also satisfies

(V) $|F(x,s)| \leq c_2|s|^{p-1}$ for every $s \in \mathbf{R}^M$ and for every $x \in \Omega$,

and by properties (II) and (IV) we get

(VI) $F(x,s)s \geq c_1|s|^p$ for every $s \in \mathbf{R}^M$ and for every $x \in \Omega$.

In the following we shall fix a constant $L > 0$ and we shall denote by $\mathcal{F}(L)$ the class $\mathcal{F}(\alpha, L, 1)$, where α is the positive constant which appears in condition (i) above.

From now on by C we shall denote a positive constant, depending only on α, β, L, and p, which can change from line to line.

Let $f \in W^{-1,p'}(\Omega, \mathbf{R}^M)$, let (μ_n) be a sequence of $\mathcal{M}_0^p(\Omega)$, and let $F_n \in \mathcal{F}(L)$. Let us consider the following nonlinear systems with boundary Dirichlet condition:

$$\text{(5.1)} \qquad \begin{cases} u_n \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega, \mathbf{R}^M), \\ \displaystyle\int_\Omega a(x, Du_n)Dv\,dx + \int_\Omega F_n(x,u_n)v\,d\mu_n \;=\; \langle f, v\rangle \\ \forall\, v \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega, \mathbf{R}^M). \end{cases}$$

Since by Remark 3.1 $\langle f, \cdot\rangle$ is a functional in $(W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega, \mathbf{R}^M))'$, by assumptions (i)–(v) and (I)–(VI) the theory of monotone operators (see [23]) assures the existence of a unique solution u_n of problem (5.1). From (v) and (VI), taking u_n as a test function in (5.1), it is easy to see that the sequence (u_n) is bounded in $W_0^{1,p}(\Omega, \mathbf{R}^M)$ for any choice of (μ_n) and (F_n). Thus, up to a subsequence, the sequence (u_n) converges weakly in $W_0^{1,p}(\Omega, \mathbf{R}^M)$ to some function $u \in W_0^{1,p}(\Omega, \mathbf{R}^M)$. Our goal is to find the variational problem satisfied by the function u. To this aim we shall consider special sequences of test functions $v_n \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega, \mathbf{R}^M)$ which converge weakly to some function $v \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_\mu(\Omega, \mathbf{R}^M)$, and we shall try to take the limit in problem (5.1). This is the energy method of L. Tartar.

In order to prove that the structure of the limit problem is local (i.e., it does not depend on the choice of the domain Ω and of the boundary data), in what follows, we shall consider a more general situation. Namely, we shall study the asymptotic behavior of an arbitrary sequence (u_n) of solutions of the problems

$$\text{(5.2)} \qquad \begin{cases} u_n \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} a(x, Du_n)Dv\,dx + \int_{\Omega'} F_n(x,u_n)v\,d\mu_n \;=\; \langle f_n, v\rangle \\ \forall\, v \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M), \end{cases}$$

where Ω' is an open subset of Ω, $f_n \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M))'$. We do not require any boundary data for u_n, while we assume that the sequence (u_n) is bounded in $W^{1,p}(\Omega',\mathbf{R}^M)$, which implies in particular that, up to a subsequence, (u_n) converges weakly to some u in $W^{1,p}(\Omega',\mathbf{R}^M)$. For the sequence (f_n), we shall assume a notion of convergence specified by the following definition.

Definition 5.1. *Let (μ_n) be a sequence of $\mathcal{M}_0^p(\Omega)$ which $\gamma^{-\Delta_p}$-converges to a measure μ. Let (f_n) be a sequence of functionals, with $f_n \in (W_0^{1,p}(\Omega',\mathbf{R}^M) \cap L^p_{\mu_n}(\Omega',\mathbf{R}^M))'$, and let $f \in (W_0^{1,p}(\Omega',\mathbf{R}^M) \cap L^p_\mu(\Omega',\mathbf{R}^M))'$. We shall say that the sequence (f_n) converges to f in the sense of $(\mathcal{H}_{\Omega'})$ if the following condition is satisfied:*

$(\mathcal{H}_{\Omega'})$ *If $v \in W_0^{1,p}(\Omega',\mathbf{R}^M) \cap L^p_\mu(\Omega',\mathbf{R}^M)$, $v_n \in W_0^{1,p}(\Omega',\mathbf{R}^M) \cap L^p_{\mu_n}(\Omega',\mathbf{R}^M)$ for every n, and (v_n) converges to v weakly in $W_0^{1,p}(\Omega',\mathbf{R}^M)$, then $\langle f_n, v_n\rangle \to \langle f, v\rangle$.*

The next lemma gives an estimate of the norm in $(W_0^{1,p}(\Omega',\mathbf{R}^M)\cap L^p_{\mu_n}(\Omega',\mathbf{R}^M))'$ of a sequence of functionals (f_n) which converges in the sense of $(\mathcal{H}_{\Omega'})$, while Proposition 5.3 gives a local estimate of the norm in $L^p_{\mu_n}(\Omega',\mathbf{R}^M)$ of the corresponding solutions u_n of problem (5.2).

Lemma 5.2. *Let $f \in (W_0^{1,p}(\Omega',\mathbf{R}^M)\cap L^p_\mu(\Omega',\mathbf{R}^M))'$, and let $f_n \in (W_0^{1,p}(\Omega',\mathbf{R}^M)\cap L^p_{\mu_n}(\Omega',\mathbf{R}^M))'$ for every n. If (f_n) converges to f in the sense of $(\mathcal{H}_{\Omega'})$, then $(\|f_n\|)$ converges to $\|f\|$, where the norm of f_n (resp., f) is taken in the space $(W_0^{1,p}(\Omega',\mathbf{R}^M) \cap L^p_{\mu_n}(\Omega',\mathbf{R}^M))'$ (resp., $(W_0^{1,p}(\Omega',\mathbf{R}^M) \cap L^p_\mu(\Omega',\mathbf{R}^M))'$).*

Proof. Let (ζ_n) be a sequence such that $\zeta_n \in W_0^{1,p}(\Omega',\mathbf{R}^M) \cap L^p_{\mu_n}(\Omega',\mathbf{R}^M)$, with unit norm and $\|f_n\| = \langle f_n,\zeta_n\rangle$. Then, up to a subsequence, (ζ_n) converges weakly in $W_0^{1,p}(\Omega',\mathbf{R}^M)$ to some function ζ, by Theorem 4.4 $\zeta \in W_0^{1,p}(\Omega',\mathbf{R}^M) \cap L^p_\mu(\Omega',\mathbf{R}^M)$, and $\|\zeta\| \le 1$. Since (f_n) converges in the sense of $(\mathcal{H}_{\Omega'})$ we have that

$$\lim_{n\to\infty} \|f_n\| \,=\, \lim_{n\to\infty}\langle f_n,\zeta_n\rangle \,=\, \langle f,\zeta\rangle \,\le\, \|f\|.$$

In order to prove the opposite inequality let us consider the function ζ such that $\zeta \in W_0^{1,p}(\Omega',\mathbf{R}^M) \cap L^p_\mu(\Omega',\mathbf{R}^M)$, with unit norm, $\|f\| = \langle f,\zeta\rangle$, and let (ψ_m) be a sequence in $C_0^\infty(\Omega',\mathbf{R}^M)$ such that $(w\psi_m)$ converges strongly to ζ in $W_0^{1,p}(\Omega',\mathbf{R}^M)\cap L^p_\mu(\Omega',\mathbf{R}^M)$. By Lemma 4.2 we have that the norm in the space $W_0^{1,p}(\Omega',\mathbf{R}^M) \cap L^p_{\mu_n}(\Omega',\mathbf{R}^M)$ of the functions $w_n\psi_m$ converges to the norm of $w\psi_m$ in the space $W_0^{1,p}(\Omega',\mathbf{R}^M)\cap L^p_\mu(\Omega',\mathbf{R}^M)$. Thus, since $(w_n\psi_m)$ converges weakly in $W_0^{1,p}(\Omega',\mathbf{R}^M)$ to $w\psi_m$, we have

$$\begin{aligned}\|f\| \,=\, \langle f,\zeta\rangle \,&=\, \lim_{m\to\infty}\lim_{n\to\infty}\langle f_n, w_n\psi_m\rangle \\ \le\, \lim_{m\to\infty}\liminf_{n\to\infty}\|f_n\|\,\|w_n\psi_m\| \,&=\, \liminf_{n\to\infty}\|f_n\|\,\|\zeta\| \,=\, \liminf_{n\to\infty}\|f_n\|. \qquad \square\end{aligned}$$

Proposition 5.3. *Let (u_n) be a sequence of solutions of problems* (5.2). *If the sequence (u_n) is bounded in $W^{1,p}(\Omega',\mathbf{R}^M)$, then*

$$\int_{\Omega'} |u_n|^p\varphi\, d\mu_n \,\le\, M \tag{5.3}$$

for every $\varphi \in C_0^1(\Omega')$, with $\varphi \ge 0$, where the constant M depends on the norm in $C_0^1(\Omega')$ of φ.

Proof. The proof follows immediately, taking $u_n\varphi$ as test function in (5.2), by Lemma 5.2 and conditions (v) and (VI). $\square$

The following proposition shows that, without any additional assumption, the sequence (u_n) converges strongly in $W^{1,r}(\Omega',\mathbf{R}^M)$ for every $1 \le r < p$.

Proposition 5.4. *Let (u_n), with $u_n \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M)$, be a sequence which converges to some function u weakly in $W^{1,p}(\Omega', \mathbf{R}^M)$. Suppose that there exists a sequence (f_n), with $f_n \in (W^{1,p}_0(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M))'$, which converges to $f \in (W^{1,p}_0(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M))'$ in the sense of $(\mathcal{H}_{\Omega'})$, such that u_n satisfies problem* (5.2). *Then (u_n) converges to u strongly in $W^{1,r}(\Omega', \mathbf{R}^M)$ for every $r < p$, and hence a subsequence of (Du_n) converges to Du pointwise a.e. in Ω'.*

Proof. The proof follows the lines of the one given in [16] (see also [1]).

In the course this proof we shall denote by C a positive constant independent on n. Let $\Psi : \mathbf{R} \mapsto \mathbf{R}$ be a C^1 function which satisfies the following properties:

$$\begin{aligned} &\Psi(t) = 1 \quad \text{if } |t| < 1, \quad \Psi(t) = 0 \quad \text{if } |t| \geq 2, \\ &|\Psi(t)| \leq 1 \quad \forall t \in \mathbf{R}, \quad |\Psi'(t)| \leq 2 \quad \forall t \in \mathbf{R}, \end{aligned}$$

and let $\Phi(y) = \Psi(|y|)y$. Let $\delta > 0$ and, for every $n \in \mathbf{N}$, let $\delta_n \leq \delta$ be a positive real number that we shall fix later. For every such a δ_n we define the function $\Phi_{\delta_n}(y) = \delta_n \Phi(y/\delta_n)$. Given $\varphi \in C^1_0(\Omega')$, with $\varphi \geq 0$, we can take $(\Phi_{\delta_n}(u_n) + w_n \Phi_{\delta_n}(u_n - u))\varphi$ as test function in problem (5.2), and we obtain

$$\begin{aligned} &\int_{\Omega'} a(x, Du_n) D\Phi_{\delta_n}(u_n) Du_n \varphi \, dx \\ &+ \int_{\Omega'} \big(a(x, Du_n) - a(x, Du)\big) D\Phi_{\delta_n}(u_n - u) D(u_n - u) w_n \varphi \, dx \\ &+ \int_{\Omega'} a(x, Du_n) \big(\Phi_{\delta_n}(u_n) \otimes D\varphi + \Phi_{\delta_n}(u_n - u) \otimes D(w_n \varphi)\big) \, dx \\ &+ \int_{\Omega'} F_n(x, u_n)(w_n \Phi_{\delta_n}(u_n - u) + \Phi_{\delta_n}(u_n))\varphi \, d\mu_n \\ &= \langle f_n, (w_n \Phi_{\delta_n}(u_n - u) + \Phi_{\delta_n}(u_n))\varphi \rangle \\ &- \int_{\Omega'} a(x, Du) D\Phi_{\delta_n}(u_n - u) D(u_n - u) w_n \varphi \, dx. \end{aligned} \tag{5.4}$$

Since (u_n) is bounded in $W^{1,p}(\Omega', \mathbf{R}^M)$, (w_n) is bounded in $W^{1,p}(\Omega)$, and $|\Phi_{\delta_n}| \leq 2\delta_n \leq 2\delta$, by condition (iv), we have

$$\Big| \int_{\Omega'} a(x, Du_n) \big(\Phi_{\delta_n}(u_n) \otimes D\varphi + \Phi_{\delta_n}(u_n - u) \otimes D(w_n \varphi)\big) \, dx \Big| \leq C\delta. \tag{5.5}$$

From property (V), Hölder's inequality, and Proposition 5.3 it follows that

$$\Big| \int_{\Omega'} F_n(x, u_n) \Phi_{\delta_n}(u_n - u) w_n \varphi \, d\mu_n \Big| \leq C\delta, \tag{5.6}$$

while from property (VI) and the definition of the function Φ we get

$$\int_{\Omega'} F_n(x, u_n) \Phi_{\delta_n}(u_n) \varphi \, d\mu_n \geq 0. \tag{5.7}$$

Since $(\Phi_{\delta_n}(u_n - u) w_n \varphi)$ converges weakly to zero in $W^{1,p}_0(\Omega, \mathbf{R}^M)$ and (f_n) converges in the sense of $(\mathcal{H}_{\Omega'})$, we have

$$\langle f_n, w_n \Phi_{\delta_n}(u_n - u)\varphi \rangle = o_n. \tag{5.8}$$

Moreover, as $0 < \delta_n \leq \delta$ and the sequence (Φ_{δ_n}) is uniformly Lipschitz, it is easy to see that there exists a positive number $\tilde{\delta} \leq \delta$ such that

$$\limsup_{n \to \infty} \langle f_n, \Phi_{\delta_n}(u_n)\varphi\rangle \;=\; \langle f, \Phi_{\tilde{\delta}}(u)\varphi\rangle. \tag{5.9}$$

Finally, since $(D\Phi_{\delta_n}(u_n - u)D(u_n - u))$ converges weakly to zero in $L^p(\Omega', \mathbf{R}^M)$ we also obtain that

$$\int_{\Omega'} a(x, Du) D\Phi_{\delta_n}(u_n - u)D(u_n - u) w_n \varphi \, dx \;=\; o_n. \tag{5.10}$$

Thus, by assumptions (i)–(v), by (5.4)–(5.10), and by the definition of the function Φ, we get

$$\begin{aligned} &\int_{\{|u_n| < \delta_n\}_{\Omega'}} |Du_n|^p \varphi \, dx, + \int_{\{|u_n - u| < \delta_n\}_{\Omega'}} |D(u_n - u)|^p w_n \varphi \, dx \\ &\leq C \int_{\{\delta_n \leq |u_n - u| < 2\delta_n\}_{\Omega'}} (h + |Du| + |Du_n|)^{p-2} |D(u_n - u)|^2 \, dx \\ &+ C \int_{\{\delta_n \leq |u_n| < 2\delta_n\}_{\Omega'}} (k + \eta |Du_n|^{p-1})|Du_n| \, dx + \langle f, \Phi_{\tilde{\delta}}(u)\varphi\rangle + C\delta + o_n, \end{aligned} \tag{5.11}$$

where we also used the fact that the sequence (w_n) is bounded in $L^\infty(\Omega)$. Now, since (u_n) is bounded in $W^{1,p}(\Omega', \mathbf{R}^M)$, there exists a positive constant K such that

$$\int_{\Omega'} (h + |Du| + |Du_n|)^{p-2} |D(u_n - u)|^2 \, dx + \int_{\Omega'} (k + \eta |Du_n|^{p-1})|Du_n| \, dx \;\leq\; K.$$

In particular, if we fix $J \in \mathbf{N}$ and $\gamma > 0$, then we have

$$\begin{aligned} \sum_{j=1}^{J} \Big(&\int_{\{2^{j-1}\gamma \leq |u_n - u| < 2^j\gamma\}_{\Omega'}} (h + |Du| + |Du_n|)^{p-2} |D(u_n - u)|^2 \, dx \\ &+ \int_{\{2^{j-1}\gamma \leq |u_n| < 2^j\gamma\}_{\Omega'}} (k + \eta |Du_n|^{p-1})|Du_n| \, dx \Big) \;\leq\; K; \end{aligned}$$

so that, for every $n \in \mathbf{N}$, there exists $j(n) \in \{1, \ldots, J\}$ such that

$$\begin{aligned} &\int_{\{2^{j(n)-1}\gamma \leq |u_n - u| < 2^{j(n)}\gamma\}_{\Omega'}} (h + |Du| + |Du_n|)^{p-2} |D(u_n - u)|^2 \, dx \\ &\quad + \int_{\{2^{j(n)-1}\gamma \leq |u_n| < 2^{j(n)}\gamma\}_{\Omega'}} (k + \eta |Du_n|^{p-1})|Du_n| \, dx \;\leq\; \frac{K}{J}. \end{aligned}$$

If in (5.11) we take $\delta = 2^J\gamma$ and $\delta_n = 2^{j(n)-1}\gamma$, then we get

$$\begin{aligned} &\int_{\{|u_n| < \gamma\}_{\Omega'}} |Du_n|^p \varphi \, dx + \int_{\{|u_n - u| < \gamma\}_{\Omega'}} |D(u_n - u)|^p w_n \varphi \, dx \\ &\qquad \leq\; \frac{C}{J} + C2^J\gamma \;+\; \langle f, \Phi_{\tilde{\delta}}(u)\varphi\rangle \;+\; o_n, \end{aligned} \tag{5.12}$$

where we used the fact that $\delta_n \geq \gamma$ for every $n \in \mathbf{N}$. By Rellich's theorem the sequence (u_n) converges to u strongly in $L^p_{\text{loc}}(\Omega', \mathbf{R}^M)$, and hence, up to a subsequence, pointwise a.e. in Ω'. Thus, by Egorov's theorem, for every $\sigma > 0$ there exists a subset S of Ω', with $|S| < \sigma$, such that (u_n) converges to u uniformly on $\Omega' \setminus S$.

Now let $\varepsilon > 0$. If we choose $J \in \mathbf{N}$ and $\gamma > 0$ such that $1/J < \varepsilon$ and $\delta = 2^J\gamma = \varepsilon$, then by (5.12) we have

$$\limsup_{n\to\infty}\Big(\int_{\{|u_n|<\gamma\}_{\Omega'}} |Du_n|^p\varphi\,dx + \int_{\{|u_n-u|<\gamma\}_{\Omega'}} |D(u_n-u)|^p w_n\varphi\,dx\Big) \le C\varepsilon + \langle f, \Phi_{\tilde\delta}(u)\varphi\rangle.$$

Moreover, for n large enough we have that $\Omega' \setminus S \subseteq \{|u_n - u| < \gamma\}_{\Omega'}$ and $\{u = 0\}_{\Omega'} \setminus S \subseteq \{|u_n| < \gamma\}_{\Omega'}$, so that we get

$$\begin{aligned}\text{(5.13)}\qquad &\limsup_{n\to\infty}\Big(\int_{\{u=0\}_{\Omega'}\setminus S} |Du_n|^p\varphi\,dx + \int_{\Omega'\setminus S} |D(u_n-u)|^p w_n\varphi\,dx\Big)\\ &\quad\le C\varepsilon + \langle f, \Phi_{\tilde\delta}(u)\varphi\rangle,\end{aligned}$$

which, by using that $0 \le \tilde\delta \le \delta = \varepsilon$ and $\Phi_{\tilde\delta}(u)\varphi$ converges strongly to zero in $W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_\mu(\Omega, \mathbf{R}^M)$ as ε tends to zero, gives

$$\text{(5.14)}\qquad \lim_{n\to\infty}\Big(\int_{\{u=0\}_{\Omega'}\setminus S} |Du_n|^p\varphi\,dx + \int_{\Omega'\setminus S} |D(u_n-u)|^p w_n\varphi\,dx\Big) = 0.$$

By the arbitrariness of σ, we get, up to a subsequence, that $(D(u_n - u)w_n)$ and $(Du_n 1_{\{|u|=0\}_{\Omega'}})$ converges to zero pointwise a.e. in Ω'. Moreover, since (w_n) converges to w strongly in $L^p(\Omega', \mathbf{R}^M)$ and by Lemma 4.5 $\{w > 0\} \supseteq \{|u| > 0\}_{\Omega'}$, this implies that (Du_n) converges pointwise to Du a.e. in $\{|u| > 0\}_{\Omega'}$ and hence, as $|Du| = 0$ a.e. in $\{|u| = 0\}_{\Omega'}$, (Du_n) converges pointwise to Du a.e. in Ω'.

Finally, since (u_n) is bounded in $W^{1,p}(\Omega', \mathbf{R}^M)$, we obtain that (u_n) converges to u strongly in $W^{1,r}(\Omega', \mathbf{R}^M)$ for every $r < p$. □

Remark 5.5. Under the same assumptions of Proposition 5.4, by (v) and Proposition 5.4 we have that $(a(x, Du_n))$ converges to $a(x, Du)$ weakly in $L^{p'}(\Omega', \mathbf{M}^{M\times N})$ and strongly in $L^r(\Omega', \mathbf{M}^{M\times N})$ for every $1 \le r < p'$. Similarly we deduce that $(a(x, D(u_n - u)))$ converges to zero weakly in $L^{p'}(\Omega', \mathbf{M}^{M\times N})$ and strongly in $L^r(\Omega', \mathbf{M}^{M\times N})$ for every $1 \le r < p'$.

6. The limit problem. In this section we shall prove the main result of this paper (Theorem 6.4). We shall consider a sequence (u_n) of solutions of problems (5.2), with $F_n \in \mathcal{F}(L)$ and $\mu_n \in \mathcal{M}_0^p(\Omega)$, which satisfies

$$\text{(6.1)}\qquad \int_{\Omega'} |Du_n|^p dx + \int_{\Omega'} |u_n|^p d\mu_n \le M,$$

where M is a positive constant which depends on the sequence (u_n). We shall show that a cluster point u of such a sequence is a solution of a variational problem similar to (5.2). Namely we shall prove that the limit problem will be of the form

$$\text{(6.2)}\qquad \begin{cases} u \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_\mu(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} a(x, Du)Dv\,dx + \int_{\Omega'} F(x, u)v\,d\mu = \langle f, v\rangle \\ \forall\, v \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_\mu(\Omega', \mathbf{R}^M), \end{cases}$$

where μ is a measure in $\mathcal{M}_0^p(\Omega)$ and $F(x, s)$ is a vector function in $\mathcal{F}(\alpha, C, 1/(p-1))$ for a constant C which depends only on α, β, L, N, and p.

Remark 6.1. Let $\mu \in \mathcal{M}_0^p(\Omega)$ and let $\tilde{F}, F \in \mathcal{F}(c_1, c_2, \sigma)$ be two functions such that for every $s \in \mathbf{R}^M$ $F(x,s) = \tilde{F}(x,s)$ μ-a.e. in $\{w > 0\}$, where w is the solution of problem (3.3). If in problem (6.2) we change F by $\tilde{F}$ we obtain an equivalent problem. In particular the function $F(x,s)$ can be defined arbitrarily in the set $\{w = 0\}$.

Let us introduce now a notion of convergence in the space $\mathcal{M}_0^p(\Omega) \times \mathcal{F}(c_1, c_2, \sigma)$, with $c_1 > 0$, $c_2 > 0$, and $0 < \sigma \le 1$.

Definition 6.2. *Let (μ_n) be a sequence in $\mathcal{M}_0^p(\Omega)$, let (F_n) be a sequence in $\mathcal{F}(c_1, c_2, \sigma)$, let $\mu \in \mathcal{M}_0^p(\Omega)$ and $F \in \mathcal{F}(c_1, c_2, \sigma)$. We say that the pairs (μ_n, F_n) γ^A-converge (in Ω) to the pair (μ, F) if the following property holds: for any open set $\Omega' \subseteq \Omega$, for any sequence of functionals (f_n) with $f_n \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M))'$, which converges to some $f \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M))'$ in the sense of $(\mathcal{H}_{\Omega'})$ (according with Definition* 5.1*), and for any sequence (u_n) of solutions of problems* (5.2) *satisfying* (6.1)*, all cluster points of the sequence (u_n) in the weak topology of $W^{1,p}(\Omega', \mathbf{R}^M)$ satisfy problem* (6.2).

The most important property of the γ^A convergence is the following result.

Proposition 6.3. *Let $((\mu_n, F_n))$ be a sequence in $\mathcal{M}_0^p(\Omega) \times \mathcal{F}(c_1, c_2, \sigma)$ which γ^A-converges to a pair (μ, F). Then for any open set $\Omega' \subseteq \Omega$ and for any sequence (f_n), with $f_n \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M))'$, which converges to some $f \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M))'$ in the sense of $(\mathcal{H}_{\Omega'})$, the unique solution u_n of the problem*

$$(6.3) \qquad \begin{cases} u_n \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} a(x, Du_n) Dv \, dx + \int_{\Omega'} F_n(x, u_n) v \, d\mu_n = \langle f_n, v \rangle \\ \forall\, v \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M) \end{cases}$$

converges weakly in $W_0^{1,p}(\Omega', \mathbf{R}^M)$ to the unique solution u of the problem

$$(6.4) \qquad \begin{cases} u \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} a(x, Du) Dv \, dx + \int_{\Omega'} F(x, u) v \, d\mu = \langle f, v \rangle \\ \forall\, v \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M). \end{cases}$$

Proof. By using u_n as a test function in (6.3) and by taking into account Lemma 5.2, we deduce that the sequence (u_n) satisfies (6.1). This implies in particular that there exists a subsequence of (u_n) which converges weakly in $W_0^{1,p}(\Omega', \mathbf{R}^M)$ to a function $u \in W_0^{1,p}(\Omega', \mathbf{R}^M)$. By the definition of γ^A-convergence, the function u satisfies (6.4). Since this problem has a unique solution, the whole sequence (u_n) converges to u. □

The following theorem gives a compactness result for the γ^A-convergence.

Theorem 6.4. *Let (μ_n) be a sequence of measures in $\mathcal{M}_0^p(\Omega)$ and let (F_n) be a sequence in $\mathcal{F}(L)$, with $L > 0$. Then there exist an increasing sequence of integers (n_j), a measure $\mu \in \mathcal{M}_0^p(\Omega)$, and a function $F \in \mathcal{F}(\alpha, C, 1/(p-1))$ such that the pairs (μ_{n_j}, F_{n_j}) γ^A-converge to (μ, F) in Ω (according to Definition* 6.2*), where C is a positive constant which depends only on α, β, L, N, and p.*

Remark 6.5. The compactness result stated in Theorem 6.4 can be proved under more general assumptions on (F_n). Namely, if the sequence (F_n) belongs to

$\mathcal{F}(c_1, c_2, \sigma)$, for some constants $c_1 > 0$, $c_2 > 0$, and $0 < \sigma \le 1$, then there exist an increasing sequence of integers (n_j), a measure $\mu \in \mathcal{M}_0^p(\Omega)$, and a function $F \in \mathcal{F}(c_1', c_2', \sigma')$ such that the pairs (μ_{n_j}, F_{n_j}) γ^A-converge to (μ, F) in Ω. The positive constants c_1 and c_2 depend only on α, β, c_1, c_2, N, p, and σ; while $\sigma' = \min\{\sigma, 1/(p-\sigma)\}$.

In order to simplify the exposition of the proof, we shall prove only the compactness result as stated in Theorem 6.4 (the proof of the general case stated in Remark 6.5 being analogous). Before proving Theorem 6.4 we need additional information on the behavior of the sequence (u_n) of solutions of problems (5.2). To this aim we shall compare (u_n) with the sequences $(w_n \psi_m)$, $\psi_m \in C_0^\infty(\Omega, \mathbf{R}^M)$, of correctors for the p-Laplacian, studied in section 4.

In Lemma 6.6 and Propositions 6.7 and 6.8, we shall consider an open set $\Omega' \subseteq \Omega$, a sequence of measures (μ_n), a sequence of functions (F_n), two sequences of functionals (f_n), (g_n), two sequences of functions (u_n), (z_n), a measure μ, two functionals f, g, and two functions u and z such that

$$\begin{cases} \mu_n, \mu \in \mathcal{M}_0^p(\Omega), \qquad F_n \in \mathcal{F}(L), \\ (\mu_n)\ \gamma^{-\Delta_p}\text{-converges to } \mu, \end{cases} \tag{6.5}$$

$$\begin{cases} f_n, g_n \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M))', \\ f, g \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M))', \\ f_n \to f \ \text{ in the sense of } (\mathcal{H}_{\Omega'}), \\ g_n \to g \ \text{ in the sense of } (\mathcal{H}_{\Omega'}), \end{cases} \tag{6.6}$$

$$\begin{cases} u_n, z_n \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M), \\ u, z \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M), \\ u_n \rightharpoonup u \ \text{ in } W^{1,p}(\Omega', \mathbf{R}^M), \\ z_n \rightharpoonup z \ \text{ in } W^{1,p}(\Omega', \mathbf{R}^M), \end{cases} \tag{6.7}$$

$$\begin{cases} \int_{\Omega'} a(x, Du_n) Dv\, dx + \int_{\Omega'} F_n(x, u_n) v\, d\mu_n = \langle f_n, v \rangle \\ \qquad \forall\, v \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M), \\ \int_{\Omega'} a(x, Dz_n) Dv\, dx + \int_{\Omega'} F_n(x, z_n) v\, d\mu_n = \langle f_n, v \rangle \\ \qquad \forall\, v \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M). \end{cases} \tag{6.8}$$

Lemma 6.6. *Assume that* (6.5), (6.6), (6.7), *and* (6.8) *hold. Then for every function $\varphi \in C_c^\infty(\Omega')$, with $\varphi \ge 0$, we have the estimates*

$$\limsup_{n\to\infty} \Big(\int_{\Omega'} |D(u_n - u)|^p \varphi\, dx + \int_{\Omega'} |u_n|^p \varphi\, d\mu_n \Big) \le C \int_{\Omega'} |u|^p \varphi\, d\mu \tag{6.9}$$

and

$$\begin{aligned} &\limsup_{n\to\infty} \Big(\int_{\Omega'} |D((u_n - z_n) - (u - z))|^p \varphi\, dx + \int_{\Omega'} |u_n - z_n|^p \varphi\, d\mu_n \Big) \\ &\qquad \le C \Big(\int_{\Omega'} |u|^p \varphi\, d\mu + \int_{\Omega'} |z|^p \varphi\, d\mu \Big)^{\frac{p-2}{p-1}} \Big(\int_{\Omega'} |u - z|^p \varphi\, d\mu \Big)^{\frac{1}{p-1}}, \end{aligned} \tag{6.10}$$

where C is a positive constant which depends only on α, β, L, N, and p.

Proof. By Theorem 4.4 we have that u and z belong to $W^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_\mu(\Omega, \mathbf{R}^M)$. Let $\varphi \in C_c^\infty(\Omega')$, with $\varphi \ge 0$, let w_n and w be the solutions of problems (3.5) and (3.3). By Proposition 3.6 there exists a sequence (ψ_m) in $C_0^\infty(\Omega', \mathbf{R}^M)$ such that $(w\psi_m)$ converges to $u - z$ strongly in $W^{1,p}_{\text{loc}}(\Omega') \cap L^p_\mu(\Omega')$. Thus, taking $(u_n - z_n - w_n\psi_m)\varphi$

as a test function in the difference of the equations in (6.8), we get

$$
\begin{aligned}
&\int_{\Omega'}[a(x,Du_n)-a(x,Dz_n)]D(u_n-z_n-w_n\psi_m)\varphi\,dx\\
&\quad+\int_{\Omega'}[F_n(x,u_n)-F_n(x,z_n)](u_n-z_n-w_n\psi_m)\varphi\,d\mu_n\\
&=-\int_{\Omega'}[a(x,Du_n)-a(x,Dz_n)](u_n-z_n-w_n\psi_m)\otimes D\varphi\,dx\\
&\quad+\langle f_n-g_n,(u_n-z_n-w_n\psi_m)\varphi\rangle\;=\;o_{m,n}.
\end{aligned}
\tag{6.11}
$$

Let us estimate the terms which appear in (6.11). By using assumption (ii) and Proposition 5.4, the sequences $(|a(x,Du_n)-a(x,D(u_n-u)|^{p'})$ and $(|a(x,Dz_n)-a(x,D(z_n-z)|^{p'})$ are uniformly integrable and pointwise convergent respectively to $|a(x,Du)|^{p'}$ and $|a(x,Dz)|^{p'}$. Therefore they converge strongly in $L^1(\Omega',\mathbf{M}^{M\times N})$ and hence, from (6.11), we deduce

$$
\begin{aligned}
&\int_{\Omega'}[a(x,D(u_n-u))-a(x,D(z_n-z))]D(u_n-z_n-(u-z))\varphi\,dx\\
&\quad+\int_{\Omega'}[F_n(x,u_n)-F_n(x,z_n)](u_n-z_n)\varphi\,d\mu_n\\
&=o_{m,n}-\int_{\Omega'}[a(x,Du)-a(x,Dz)]D(u_n-z_n-w_n\psi_m)\varphi\,dx\\
&+\int_{\Omega'}[a(x,D(u_n-u))-a(x,D(z_n-z))]D(w_n\psi_m-(u-z))\varphi\,dx\\
&\quad+\int_{\Omega'}[F_n(x,u_n)-F_n(x,z_n)]w_n\psi_m\varphi\,d\mu_n.
\end{aligned}
$$

Since

$$
\int_{\Omega'}[a(x,Du)-a(x,Dz)]D(u_n-z_n-w_n\psi_m)\varphi\,dx\;=\;o_{m,n}
$$

by properties (i) and (ii) of a and properties (II) and (III) of F_n, we get

$$
\begin{aligned}
&\alpha\int_{\Omega'}|D(u_n-z_n-(u-z))|^p\varphi\,dx+\alpha\int_{\Omega'}|u_n-z_n|^p\varphi\,d\mu_n\\
&\le\beta\int_{\Omega'}(h+|D(u_n-u)|+|D(z_n-z)|)^{p-2}|D(u_n-z_n-(u-z))|\,|D(w_n\psi_m-(u-z))|\varphi\,dx\\
&\quad+L\int_{\Omega'}(|u_n|+|z_n|)^{p-2}|u_n-z_n|\,|w_n\psi_m|\varphi\,d\mu_n+o_{m,n}\\
&=\beta\int_{\Omega'}(|D(u_n-u)|+|D(z_n-z)|)^{p-2}|D(u_n-z_n-(u-z))|\,|D(w_n\psi_m-(u-z))|\varphi\,dx\\
&\quad+L\int_{\Omega'}(|u_n|+|z_n|)^{p-2}|u_n-z_n|\,|w_n\psi_m|\varphi\,d\mu_n+o_{m,n}.
\end{aligned}
\tag{6.12}
$$

Using Young's inequality and then Hölder's inequality in (6.12), we obtain

$$\begin{aligned}
&\int_{\Omega'} |D((u_n - z_n) - (u - z))|^p \varphi\, dx + \int_{\Omega'} |u_n - z_n|^p \varphi\, d\mu_n \\
&\leq C\Big(\int_{\Omega'} (|D(u_n - u)| + |D(z_n - z)|)^p \varphi\, dx\Big)^{\frac{p-2}{p-1}} \Big(\int_{\Omega'} |D(w_n\psi_m - (u - z))|^p \varphi\, dx\Big)^{\frac{1}{p-1}} \\
&\quad + C\Big(\int_{\Omega'} \big(|u_n| + |z_n|\big)^p \varphi\, d\mu_n\Big)^{\frac{p-2}{p-1}} \Big(\int_{\Omega'} |w_n\psi_m|^p \varphi\, d\mu_n\Big)^{\frac{1}{p-1}} + o_{m,n}.
\end{aligned} \tag{6.13}$$

Taking $z_n = z = 0$ (and then $g_n = 0$), in estimate (6.13), by Young's inequality, we get

$$\begin{aligned}
&\int_{\Omega'} |D(u_n - u)|^p \varphi\, dx + \int_{\Omega'} |u_n|^p \varphi\, d\mu_n \\
&\quad \leq C \int_{\Omega'} |D(w_n\psi_m - u)|^p \varphi\, dx + C \int_{\Omega'} |w_n\psi_m|^p \varphi\, d\mu_n + o_{m,n},
\end{aligned}$$

which by Lemma 4.3 implies (6.9).

Finally, in order to get (6.10), it is enough to apply, in estimate (6.13), estimate (6.9) for u_n and z_n, and Lemma 4.3. □

The following proposition gives a first version of the limit problem satisfied by u.

PROPOSITION 6.7. *Let us assume* (6.5), (6.6), (6.7), *and* (6.8). *Then there exists a $w\mu$-measurable vector function H, uniquely defined μ-a.e. in Ω', such that the function u satisfies the problem*

$$\begin{cases} u \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_\mu(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} a(x, Du) Dv\, dx + \int_{\Omega'} Hv\, d\mu = \langle f, v\rangle \\ \forall\, v \in W^{1,p}_0(\Omega', \mathbf{R}^M) \cap L^p_\mu(\Omega', \mathbf{R}^M), \end{cases} \tag{6.14}$$

and

$$|H| \leq C|u|^{p-1} \qquad \mu\text{-}a.e.\ in\ \Omega'. \tag{6.15}$$

Moreover, for every $\phi \in C^\infty_c(\Omega', \mathbf{R}^M)$ we have

$$\begin{aligned}
&\int_{\Omega'} Hw\phi\, d\mu \\
&= \lim_{n\to\infty} \Big[\int_{\Omega'} a(x, D(u_n - u))\phi \otimes D(w_n - w)\, dx + \int_{\Omega'} F_n(x, u_n) w_n \phi\, d\mu_n\Big],
\end{aligned} \tag{6.16}$$

where w_n and w are the solutions of problems (3.5) *and* (3.3).

Proof. Given $\phi \in C^\infty_c(\Omega', \mathbf{R}^M)$, we take $w_n\phi$ as the test function in the equation satisfied by u_n (see (6.8)) and we get

$$\begin{aligned}
&\int_{\Omega'} a(x, Du_n)\phi \otimes Dw_n\, dx + \int_{\Omega'} a(x, Du_n) D\phi\, w_n dx \\
&\quad + \int_{\Omega'} F_n(x, u_n) w_n \phi\, d\mu_n = \langle f_n, w_n\phi\rangle.
\end{aligned} \tag{6.17}$$

By Remark 5.5 we have

$$\lim_{n\to\infty}\Big(\langle f_n, w_n\phi\rangle - \int_{\Omega'} a(x,Du_n)D\phi\, w_n dx\Big) \;=\; \langle f, w\phi\rangle - \int_{\Omega'} a(x,Du)D\phi\, w dx.$$

Let us define a distribution T in Ω' by

$$\begin{aligned}\langle T,\phi\rangle \;=\; \lim_{n\to\infty}\Big[&\int_{\Omega'} a(x,Du_n)\phi\otimes Dw_n\,dx\\ &- \int_{\Omega'} a(x,Du)\phi\otimes Dw\,dx \;+\; \int_{\Omega'} F_n(x,u_n)w_n\phi\,d\mu_n\Big]\end{aligned}$$

for every $\phi\in C_c^\infty(\Omega',\mathbf{R}^M)$. Since the norm of w_n in $W_0^{1,p}(\Omega)\cap L^p_{\mu_n}(\Omega)$ is bounded, by (6.1) and property (V) we have

$$\int_\Omega |a(x,Du_n)||Dw_n|\,dx \;+\; \int_\Omega |F_n(x,u_n)||w_n|\,d\mu_n \;\le\; C,$$

and hence T is continuous with respect to the uniform convergence and it can be represented by a vector Radon measure $(T_1,\dots,T_M)$ such that

$$\langle T,\phi\rangle \;=\; \sum_{i=1}^M\int_{\Omega'}\phi_i dT_i \qquad \forall\,\phi\in C_c^\infty(\Omega',\mathbf{R}^M), \tag{6.18}$$

where $\phi_1,\dots,\phi_M$ are the components of the vector function ϕ. Thus taking the limit in (6.17) we obtain

$$\int_{\Omega'} a(x,Du)D(w\phi)\,dx \;+\; \langle T,\phi\rangle \;=\; \langle f, w\phi\rangle. \tag{6.19}$$

Since by conditions (ii) and (iv) and Proposition 5.4, $a(x,Du_n)-a(x,D(u_n-u))$ converges to $a(x,Du)$ strongly in $L^{p'}(\Omega,\mathbf{M}^{M\times N})$, we can write

$$\langle T,\phi\rangle \;=\; \lim_{n\to\infty}\Big[\int_{\Omega'} a(x,D(u_n-u))\phi\otimes D(w_n-w)\,dx \;+\; \int_{\Omega'} F_n(x,u_n)w_n\phi\,d\mu_n\Big]. \tag{6.20}$$

Let us prove (6.16). For every $\phi\in C_c^\infty(\Omega',\mathbf{R}^M)$, with $\phi\ge 0$, by assumptions (V) and (v), Proposition 5.4, Hölder's inequality, Lemma 4.3, and estimate (6.9), we have

$$\begin{aligned}|\langle T,\phi\rangle| \;&\le\; C\limsup_{n\to\infty}\Big[\int_{\Omega'}(k(x)+\eta|D(u_n-u)|^{p-1})|D(w_n-w)||\phi|\,dx\\ &\qquad + \int_{\Omega'}|F_n(x,u_n)|w_n|\phi|\,d\mu_n\Big]\\ &\le\; C\limsup_{n\to\infty}\Big[\int_\Omega |D(u_n-u)|^{p-1}|D(w_n-w)||\phi|\,dx + \int_{\Omega'}|u_n|^{p-1}w_n|\phi|\,d\mu_n\Big]\\ &\le\; C\limsup_{n\to\infty}\Big[\Big(\int_{\Omega'}|D(u_n-u)|^p|\phi|\,dx\Big)^{\frac{p-1}{p}}\Big(\int_\Omega|D(w_n-w)|^p|\phi|\,dx\Big)^{\frac1p}\\ &\qquad +\Big(\int_{\Omega'}|u_n|^p|\phi|\,d\mu_n\Big)^{\frac{p-1}{p}}\Big(\int_{\Omega'}|w_n|^p|\phi|\,d\mu_n\Big)^{\frac1p}\Big]\\ &\le\; C\Big(\int_{\Omega'}|u|^p|\phi|\,d\mu\Big)^{\frac{p-1}{p}}\Big(\int_{\Omega'}|w|^p|\phi|\,d\mu\Big)^{\frac1p}.\end{aligned} \tag{6.21}$$

Let us denote by $|T_i|$ the total variation of the measures T_i, $i = 1\dots, M$. Taking into account that for every open subset A of Ω' we have

$$|T_i|(A) \,=\, \sup\{\langle T_i, \varphi\rangle \,:\, \varphi \in C_0^\infty(A),\ \sup|\varphi| \le 1\},$$

by (6.21) we get

$$|T_i|(A) \,\le\, C\Big(\int_A |u|^p d\mu\Big)^{\frac{p-1}{p}}\Big(\int_A |w|^p d\mu\Big)^{\frac{1}{p}} \tag{6.22}$$

for every open subset A of Ω'. Since $|u|^p\mu$, $|w|^p\mu$, and $|T_i|$ are finite measures, (6.22) holds for every Borel subset of Ω'. This implies that the measures T_i are absolutely continuous with respect to the measure $|w|^p\mu$, and hence to the measure $w\mu$. Since $w\mu$ is a σ-finite measure we can apply the Radon–Nikodým derivation theorem and we find a $w\mu$-measurable vector function $H = (H_1, \dots, H_M)$ such that

$$T_i(A) \,=\, \int_A H_i w d\mu$$

for every Borel subset A of Ω' and $i = 1, \dots, M$, so that, by (6.20) and (6.18), (6.16) holds. We can suppose that

$$H_i(x) = 0 \qquad \text{for } \mu\text{-a.e. } x \text{ in } \{w = 0\} \qquad \forall\, i = 1, \dots, M. \tag{6.23}$$

Thus by (6.22) we get

$$\int_A |H_i| w d\mu \,\le\, C\Big(\int_A |u|^p d\mu\Big)^{\frac{p-1}{p}}\Big(\int_A |w|^p d\mu\Big)^{\frac{1}{p}}$$

for every Borel subset A of Ω'. Using Young's inequality, we obtain

$$\int_A |H_i| w d\mu \,\le\, C\Big(\frac{1}{p'\varepsilon^{p'}}\int_A |u|^p d\mu + \frac{\varepsilon^p}{p}\int_A |w|^p d\mu\Big)$$

for every Borel subset A of Ω' and for every $\varepsilon > 0$. Thus (first reasoning for $\varepsilon \in \mathbf{Q}$ and then arguing by density) we get

$$|H_i(x)| w(x) \,\le\, C\Big(\frac{1}{p'\varepsilon^{p'}}|u(x)|^p + \frac{\varepsilon^p}{p}|w(x)|^p\Big) \tag{6.24}$$

for μ-a.e. x in Ω' and for every $\varepsilon > 0$. If $x \in \Omega'$ satisfies $w(x) > 0$ and (6.24) holds true for any ε, by choosing $\varepsilon = |u(x)|^{\frac{p-1}{p}}/|w(x)|^{\frac{p-1}{p}}$ in (6.24) and taking into account (6.23), we get

$$|H_i(x)| \,\le\, C|u(x)|^{p-1}, \qquad \mu\text{-a.e. } x \in \Omega',$$

and hence (6.15) is proved. Condition (6.14) follows from (6.19), (6.18), and the density result given by Proposition 3.6. Finally the vector function H is uniquely determined μ-a.e. in Ω' by (6.14) and (6.15). Indeed, by (6.14) H is uniquely determined μ-a.e. in $\{w > 0\}$, and by (6.15) we have $H = 0$ μ-a.e. in $\{|u| = 0\}_{\Omega'}$. Then the conclusion follows by Lemma 4.5. □

In order to study the dependence of the function H on the function u, let us consider a sequence of functionals (g_n) and a sequence of functions (z_n) which satisfy

(6.6), (6.7), and (6.8). By Proposition 6.7, applied to (z_n), we get that there exists a $w\mu$-measurable vector function H', uniquely defined μ-a.e. in Ω', such that

$$\text{(6.25)}\qquad \begin{cases} z \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_\mu(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} a(x, Dz)Dv\,dx + \int_{\Omega'} H'v\,d\mu = \langle g, v\rangle \\ \forall\, v \in W^{1,p}_0(\Omega', \mathbf{R}^M) \cap L^p_\mu(\Omega', \mathbf{R}^M), \end{cases}$$

$$\text{(6.26)}\qquad |H'| \le C|z|^{p-1}, \qquad \mu\text{-a.e. in } \Omega',$$

and

$$\text{(6.27)}\qquad \begin{aligned} &\int_{\Omega'} H'w\phi\,d\mu \\ &= \lim_{n\to\infty}\Big[\int_{\Omega'} a(x, D(z_n - z))\phi \otimes D(w_n - w)\,dx + \int_{\Omega'} F_n(x, z_n)w_n\phi\,d\mu_n\Big]. \end{aligned}$$

The following proposition compares the function H with the function H'.

PROPOSITION 6.8. *The vector functions H and H' satisfy*

$$\text{(6.28)}\qquad |H - H'| \le C\big(|u| + |z|\big)^{p\frac{p-2}{p-1}}|u - z|^{\frac{1}{p-1}}, \qquad \mu\text{-a.e. in } \Omega'$$

and

$$\text{(6.29)}\qquad (H - H')(u - z) \ge \alpha|u - z|^p, \qquad \mu\text{-a.e. in } \Omega'.$$

Proof. Let us first prove (6.28). Consider $\phi \in C^\infty_c(\Omega', \mathbf{R}^M)$ and let w_n and w be the solutions of problems (3.5) and (3.3). By (6.16), (6.27), and by assumptions (ii) and (III), we have

$$\text{(6.30)}\qquad \begin{aligned} &\Big|\int_{\Omega'} (H - H')w\phi\,d\mu\Big| \\ &\le \Big|\int_{\Omega'} (a(x, D(u_n - u)) - a(x, D(z_n - z)))\phi \otimes D(w_n - w)\,dx\Big| \\ &\qquad + \Big|\int_{\Omega'} (F_n(x, u_n) - F_n(x, z_n))w_n\phi\,d\mu_n\Big| + o_n \\ &\le C\int_{\Omega'} \big(h + |D(u_n - u)| + |D(z_n - z)|\big)^{p-2}|D((u_n - z_n) - (u - z))|\,|D(w_n - w)|\,|\phi|\,dx \\ &\qquad + C\int_{\Omega'} (|u_n| + |z_n|)^{p-2}|u_n - z_n|\,|\phi|w_n\,d\mu_n + o_n \\ &\le C\int_{\Omega'} \big(|D(u_n - u)| + |D(z_n - z)|\big)^{p-2}|D((u_n - z_n) - (u - z))|\,|D(w_n - w)|\,|\phi|\,dx \\ &\qquad + C\int_{\Omega'} (|u_n| + |z_n|)^{p-2}|u_n - z_n|\,|\phi|w_n\,d\mu_n + o_n. \end{aligned}$$

By using Hölder's inequality, (6.9), applied to u_n and z_n and (6.10), we get

$$\begin{aligned} &\Big|\int_{\Omega'} (H - H')w\phi\,d\mu\Big| \\ &\le C\Big(\int_{\Omega'} |u|^p|\phi|\,d\mu + \int_{\Omega} |z|^p|\phi|\,d\mu\Big)^{\frac{p-2}{p-1}}\Big(\int_{\Omega'} |u - z|^p|\phi|\,d\mu\Big)^{\frac{1}{p(p-1)}}\Big(\int_{\Omega'} |w|^p|\phi|\,d\mu\Big)^{\frac{1}{p}}. \end{aligned}$$

Then we conclude as in the proof of Proposition 6.7 and we obtain (6.28).

In order to prove (6.29), let us consider a function $\varphi \in C_c^\infty(\Omega')$, with $\varphi \geq 0$. Using $(u_n - z_n)\varphi$ as a test function in the difference of the two equations in (6.8), we obtain

$$\begin{aligned}
&\int_{\Omega'} [a(x, Du_n) - a(x, Dz_n)] D(u_n - z_n)\varphi\, dx \\
&+ \int_{\Omega'} [a(x, Du_n) - a(x, Dz_n)](u_n - z_n) \otimes D\varphi\, dx \\
&+ \int_{\Omega'} [F_n(x, u_n) - F_n(x, z_n)](u_n - z_n)\varphi\, d\mu_n \;=\; \langle f_n - g_n, (u_n - z_n)\varphi\rangle.
\end{aligned}$$

We can rewrite this formula as

$$\begin{aligned}
&\int_{\Omega'} \big([a(x, Du_n) - a(x, Dz_n)] D(u_n - z_n) - \alpha |D(u_n - z_n)|^p\big)\varphi\, dx \\
&+ \alpha \int_{\Omega'} |D(u_n - z_n)|^p \varphi\, dx + \int_{\Omega'} [F_n(x, u_n) - F_n(x, z_n)](u_n - z_n)\varphi\, d\mu_n \\
&+ \int_{\Omega'} [a(x, Du_n) - a(x, Dz_n)](u_n - z_n) \otimes D\varphi\, dx \;=\; \langle f_n - g_n, (u_n - z_n)\varphi\rangle.
\end{aligned} \tag{6.31}$$

By assumption (II) and Theorem 4.4, we have

$$\begin{aligned}
&\alpha \int_{\Omega'} |D(u_n - z_n)|^p \varphi\, dx + \int_{\Omega'} [F_n(x, u_n) - F_n(x, z_n)](u_n - z_n)\varphi\, d\mu_n \\
&\qquad \geq\; \alpha \int_{\Omega'} |D(u - z)|^p \varphi\, dx \;+ \alpha \int_{\Omega'} |u - z|^p \varphi\, d\mu \;+\; o_n.
\end{aligned}$$

Moreover, by Remark 5.5, the sequence $(a(x, Du_n) - a(x, Dz_n))$ converges to $a(x, Du) - a(x, Dz)$ pointwise a.e. in Ω' and weakly in $L^{p'}(\Omega', \mathbf{M}^{M\times N})$. Then by condition (i) we can apply Fatou's lemma to the first integrand of (6.31) and, taking the limit, we obtain

$$\begin{aligned}
&\int_{\Omega'} \big([a(x, Du) - a(x, Dz)] D(u - z) - \alpha |D(u - z)|^p\big)\varphi\, dx \\
&\qquad + \alpha \int_{\Omega'} |D(u - z)|^p \varphi\, dx + \alpha \int_{\Omega'} |u - z|^p \varphi\, d\mu \\
&+ \int_{\Omega'} [a(x, Du) - a(x, Dz)](u - z) \otimes D\varphi\, dx \;\leq\; \langle f - g, (u - z)\varphi\rangle,
\end{aligned}$$

that is,

$$\int_{\Omega'} [a(x, Du) - a(x, Dz)] D\big(\varphi(u - z)\big)\, dx + \alpha \int_{\Omega'} |u - z|^p \varphi\, d\mu \;\leq\; \langle f - g, (u - z)\varphi\rangle.$$

Thus by (6.14) and (6.25) we get

$$\int_{\Omega'} (H - H')(u - z)\varphi\, d\mu \;\geq\; \alpha \int_{\Omega'} |u - z|^p \varphi\, d\mu$$

for every $\varphi \in C_c^\infty(\Omega')$, with $\varphi \geq 0$. This implies (6.29). □

Proposition 6.8 will imply that the function H defined by (6.16) depends on u only through its pointwise values, i.e., there exists a function $F(x, s)$ such that

$H(x) = F(x, u(x))$ μ-a.e. in Ω. This construction allows us to define the function $F(x, s)$ only on the pairs (x, s) such that $s = u(x)$, where u is the limit of a sequence of solutions of problems (5.2). We shall prove a penalization result (Theorem 6.9) which shows that, in some sense, it is possible to obtain any real number s as the "limit" of a sequence of solutions.

THEOREM 6.9. *Let $s \in \mathbf{R}^M$. For every $m \in \mathbf{N}$, let s_n^m be the unique solution of the problem*

$$\begin{cases} s_n^m \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega, \mathbf{R}^M), \\ \displaystyle\int_\Omega a(x, Ds_n^m) Dv\, dx + \int_\Omega F_n(x, s_n^m) v\, d\mu_n \\ \displaystyle\quad = m \int_\Omega (|w_n s|^{p-2} w_n s - |s_n^m|^{p-2} s_n^m) v\, dx \\ \forall\, v \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega, \mathbf{R}^M). \end{cases} \tag{6.32}$$

Then there exists an increasing sequence of indices (n_j) such that for every m the sequence $(s_{n_j}^m)_{j \in \mathbf{N}}$ converges to some function s^m weakly in $W_0^{1,p}(\Omega, \mathbf{R}^M)$. The sequence (s^m) converges to ws strongly in $W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_\mu(\Omega, \mathbf{R}^M)$ and satisfies

$$\lim_{m \to \infty} m \int_\Omega |s^m - ws|^p\, dx = 0.$$

Moreover, there exists a unique $w\mu$-measurable function H_s^m, with

$$|H_s^m| \le C|s^m|^{p-1}, \qquad \mu\text{-a.e. in } \Omega, \tag{6.33}$$

such that the function s^m satisfies the problem

$$\begin{cases} s^m \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_{\mu}(\Omega, \mathbf{R}^M), \\ \displaystyle\int_\Omega a(x, Ds^m) Dv\, dx + \int_\Omega H_s^m v\, d\mu \\ \displaystyle\quad = m \int_\Omega (|w_n \psi|^{p-2} w_n \psi - |s^m|^{p-2} s^m) v\, dx \\ \forall\, v \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_{\mu}(\Omega, \mathbf{R}^M). \end{cases} \tag{6.34}$$

The sequence (H_s^m) converges in $L^{p'}_\mu(\Omega, \mathbf{R}^M)$ to a function H_s which satisfies

$$|H_s| \le C|s^m|^{p-1}, \qquad \mu\text{-a.e. in } \Omega. \tag{6.35}$$

Proof. Let $s \in \mathbf{R}^M$ and let $s_n^m \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega, \mathbf{R}^M)$ be the solution of problem (6.32). Taking $(s_n^m - w_n s)$ as the test function in (6.32) we get

$$\begin{aligned}(6.36)\qquad &\int_\Omega \big(a(x, Ds_n^m) - a(x, D(w_n s))\big) D(s_n^m - w_n s)\, dx \\ &\quad + \int_\Omega \big(F(x, s_n^m) - F(x, w_n s)\big)(s_n^m - w_n s)\, d\mu_n \\ &\quad + m \int_\Omega (|s_n^m|^{p-2} s_n^m - |w_n s|^{p-2} w_n s)(s_n^m - w_n s)\, dx \\ &= -\int_\Omega a(x, D(w_n s)) D(s_n^m - w_n s)\, dx - \int_\Omega F(x, w_n s)(s_n^m - w_n s)\, d\mu_n.\end{aligned}$$

Using assumptions (i) and (iv) of a, (II) and (V) of F_n, and (4.3) we obtain

$$\begin{aligned}&\alpha \int_\Omega |D(s_n^m - w_n s)|^p dx + \alpha \int_\Omega |s_n^m - w_n s|^p d\mu_n + m 2^{2-p} \int_\Omega |s_n^m - w_n s|^p dx \\ &\le \int_\Omega \big(k(x) + \eta |D(w_n s)|^{p-1}\big) |D(s_n^m - w_n s)|\, dx + L \int_\Omega |w_n s|^{p-1} |s_n^m - w_n s| d\mu_n.\end{aligned} \tag{6.37}$$

Then, by Young's inequality and the fact that $\int_\Omega |Dw_n|^p dx + \int_\Omega |w_n|^p d\mu_n$ is bounded, it is easy to see that there exists a constant C such that

$$\int_\Omega |D(s_n^m - w_n s)|^p dx + \int_\Omega |s_n^m - w_n s|^p d\mu_n + m \int_\Omega |s_n^m - w_n s|^p dx \le C|s|^p. \tag{6.38}$$

Then there exists an increasing sequence of indices (n_j) which, by a diagonal procedure, we can assume independent on m, such that for every $m \in \mathbf{N}$ the sequence $(s_{n_j}^m)_{j\in\mathbf{N}}$ converges to some function s^m weakly in $W_0^{1,p}(\Omega, \mathbf{R}^M)$. Moreover, by Theorem 4.4 we have

$$\int_\Omega |D(s^m - ws)|^p dx + \int_\Omega |s^m - ws|^p d\mu + m \int_\Omega |s^m - ws|^p dx \le C|s|^p. \tag{6.39}$$

This implies that (s^m) converges weakly in $W_0^{1,p}(\Omega, \mathbf{R}^M)$ to ws. In particular $|s^m - ws|$ converges to zero weakly in $W_0^{1,p}(\Omega)$, and by Theorem 3.5 we get

$$\lim_{m\to\infty} \int_\Omega |s^m - ws| w^{p-1} d\mu = \lim_{m\to\infty} \int_\Omega |s^m - ws| d\nu = 0.$$

Thus up to a subsequence (s^m) converges to ws ν-a.e. in Ω and hence by Lemma 4.5 μ-a.e. in Ω. Moreover, since by (6.39) (s^m) is bounded in $L_\mu^p(\Omega, \mathbf{R}^M)$, it converges to ws weakly in $L_\mu^p(\Omega, \mathbf{R}^M)$.

By Proposition 6.7, for every $m \in \mathbf{N}$, there exists a $w\mu$-measurable vector function H_s^m, uniquely defined μ-a.e. in Ω, which satisfies (6.33) and such that s^m is the solution of the problem (6.34). By Proposition 6.8, for every $m, k \in \mathbf{N}$, we have

$$|H_s^m - H_s^k| \le C\big(|s^m| + |s^k|\big)^{p\frac{p-2}{p-1}} |s^m - s^k|^{\frac{1}{p-1}}, \qquad \mu\text{-a.e. in } \Omega. \tag{6.40}$$

This implies that there exists a function H_s, which satisfies (6.35), such that H_s^m converges to H_s μ-a.e. in Ω. Moreover, by Proposition 6.8, for every $m, k \in \mathbf{N}$, we have

$$(H_s^m - H_s^k)(s^m - s^k) \ge \alpha |s^m - s^k|^p, \qquad \mu\text{-a.e. in } \Omega,$$

and then, taking the limit as $k \to \infty$, we obtain

$$(H_s^m - H_s)(s^m - ws) \geq \alpha |s^m - ws|^p, \qquad \mu\text{-a.e. in } \Omega. \tag{6.41}$$

Now, taking $(s^m - ws)$ as a test function in (6.34), we get

$$\begin{aligned}\int_\Omega \big(a(x, Ds^m) - a(x, D(ws))\big) D(s^m - ws)\, dx + \int_\Omega (H_s^m - H_s)(s^m - ws)\, d\mu \\ + m \int_\Omega (|s^m|^{p-2} s^m - |ws|^{p-2} ws)(s^m - ws)\, dx \\ = - \int_\Omega a(x, D(ws)) D(s^m - ws)\, dx - \int_\Omega H_s(s^m - ws)\, d\mu.\end{aligned}$$

Then by (6.41), assumption (i), and the inequality (4.3), we obtain

$$\begin{aligned}\alpha \int_\Omega |D(s^m - ws)|^p dx + \alpha \int_\Omega |s^m - ws|^p d\mu \\ \leq - \int_\Omega a(x, D(ws)) D(s^m - ws)\, dx - \int_\Omega H_s(s^m - ws)\, d\mu.\end{aligned}$$

The conclusion follows by the weak convergence of (s^m) to ws in $W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L_\mu^p(\Omega, \mathbf{R}^M)$. □

We are now in a position to prove Theorem 6.4.

Proof of Theorem 6.4. We start by defining the sequence (n_j), the measure μ, and the function F. By Theorem 3.4 we can suppose that there exists a measure $\mu \in \mathcal{M}_0^p(\Omega)$ such that the sequence (μ_n) $\gamma^{-\Delta_p}$-converges to a measure μ. This measure will be the measure which appears in the statement.

For any $q \in \mathbf{Q}^M$, let q_n^m be the solutions of the problems

$$\begin{cases} q_n^m \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L_\mu^p(\Omega, \mathbf{R}^M), \\[2ex] \displaystyle\int_\Omega a(x, Dq_n^m) Dv\, dx + \int_\Omega F_n(x, q_n^m) v\, d\mu_n \\[2ex] \displaystyle\qquad = m \int_\Omega (|w_n q|^{p-2} w_n q - |q_n^m|^{p-2} q_n^m) v\, dx \\[2ex] \forall\, v \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L_\mu^p(\Omega, \mathbf{R}^M). \end{cases} \tag{6.42}$$

By Theorem 6.9 and a diagonal argument, there exists an increasing sequence (n_j) such that for every $q \in \mathbf{Q}^M$, the sequence $(q_{n_j}^m)$ converges weakly in $W_0^{1,p}(\Omega, \mathbf{R}^M)$ to a function $q^m \in W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L_\mu^p(\Omega, \mathbf{R}^M)$ when j tends to infinity, and the sequence (q^m) converges strongly in $W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L_\mu^p(\Omega, \mathbf{R}^M)$ to qw when m tends to infinity. Moreover, there exists a sequence (H_q^m) in $L_\mu^{p'}(\Omega, \mathbf{R}^M)$ such that the sequence (q^m)

satisfies the problem

$$(6.43)\qquad \begin{cases} q^m \in W_0^{1,p}(\Omega,\mathbf{R}^M)\cap L^p_\mu(\Omega,\mathbf{R}^M), \\[2mm] \displaystyle\int_\Omega a(x,Dq^m)Dv\,dx + \int_\Omega H_q^m v\,d\mu \\[2mm] \displaystyle\quad = m\int_\Omega (|w_n q|^{p-2}w_n q - |q^m|^{p-2}q^m)v\,dx \\[2mm] \forall\, v\in W_0^{1,p}(\Omega,\mathbf{R}^M)\cap L^p_\mu(\Omega,\mathbf{R}^M) \end{cases}$$

and such that it converges strongly in $L^{p'}_\mu(\Omega,\mathbf{R}^M)$ to a function H_q which satisfies

$$(6.44)\qquad |H_q| \le C|wq|^{p-1}, \qquad \mu\text{-a.e. in } \Omega.$$

Applying Proposition 6.8 to q_n^m and $(q')_n^m$ and then taking the limit in H_q^m and $H_{q'}^m$, we also have

$$(6.45)\qquad \begin{aligned} &|H_q(x)-H_{q'}(x)| \le C\big(|q|+|q'|\big)^{p\frac{p-2}{p-1}}|q-q'|^{\frac{1}{p-1}}w(x)^{p-1} \\ &\quad \forall\, q,q'\in\mathbf{Q}^M,\ \mu\text{-a.e. } x \text{ in } \Omega \end{aligned}$$

and

$$(6.46)\qquad (H_q(x)-H_{q'}(x))(q-q') \ge \alpha|q-q'|^p w(x)^p \qquad \forall\, q,q'\in\mathbf{Q}^M,\ \mu\text{-a.e. } x \text{ in } \Omega.$$

We define a function $G:\Omega\times\mathbf{Q}^M\mapsto\mathbf{R}^M$ by

$$(6.47)\qquad G(x,q) = H_q(x) \qquad \forall\, q\in\mathbf{Q}^M,\ \mu\text{-a.e. } x \text{ in } \Omega$$

and then we extend G to $\Omega\times\mathbf{R}^M$ by continuity (see (6.45)). The function G satisfies

$$(6.48)\qquad \begin{cases} |G(x,s)| \le C|s|^{p-1}w(x)^{p-1}, \\ |G(x,s)-G(x,s')| \le C(|s|+|s'|)^{p\frac{p-2}{p-1}}|s_1-s_2|^{\frac{1}{p-1}}w(x)^{p-1}, \\ (G(x,s)-G(x,s'))(s-s') \ge \alpha|s-s'|^p w(x)^p \end{cases}$$

for every s and s' in $\mathbf{R}^M$ and for μ-almost every x in Ω, and it is a Carathéodory function with respect to the σ-finite measure $w\mu$. Therefore, there exists a Borel function $F:\Omega\times\mathbf{R}^M\to\mathbf{R}^M$ such that

$$(6.49)\qquad F(x,s) = G\left(x,\frac{s}{w(x)}\right)1_{\{w>0\}}(x) + \alpha|s|^{p-2}s1_{\{w=0\}} \qquad \forall\, s\in\mathbf{R}^M,\ \mu\text{-a.e. } x \text{ in } \Omega,$$

so that, by (6.48), $F\in\mathcal{F}(\alpha,C,1/(p-1))$.

In order to prove Theorem 6.4 it remains only to show that the pairs (μ_{n_j},F_{n_j}) γ^A-converge to (μ,F). To carry this out, consider an open subset Ω' of Ω and a sequence of functionals (f_{n_j}), with $f_{n_j}\in(W_0^{1,p}(\Omega',\mathbf{R}^M)\cap L^p_{\mu_{n_j}}(\Omega',\mathbf{R}^M))'$, which converges in the sense of $(\mathcal{H}_{\Omega'})$ to a functional $f\in(W_0^{1,p}(\Omega',\mathbf{R}^M)\cap L^p_\mu(\Omega',\mathbf{R}^M))'$. We have to prove that if $u_{n_j}\in W_0^{1,p}(\Omega',\mathbf{R}^M)\cap L^p_{\mu_{n_j}}(\Omega',\mathbf{R}^M)$ satisfies (5.2) and (6.1) (with n replaced by n_j), then any cluster point u of u_{n_j} in the weak topology of $W^{1,p}(\Omega', \mathbf{R}^M)$ satisfies (6.2). To simplify the notation, let us assume that the whole sequence (u_{n_j}) converges weakly in $W^{1,p}(\Omega', \mathbf{R}^M)$ to u.

By Proposition 6.7, there exists a function $H \in L^{p'}_\mu(\Omega', \mathbf{R}^M)$ such that u satisfies (6.14). Estimate (6.28), applied with u_n and z_n replaced by u_{n_j} and $q^m_{n_j}$, gives

$$|H - H^m_q| \,\le\, C\big(|u| + |q^m|\big)^{p\frac{p-2}{p-1}} |u - q^m|^{\frac{1}{p-1}}, \qquad \mu\text{-a.e. in } \Omega',$$

and therefore, taking the limit as m tends to infinity we obtain

$$|H - F(x, qw)| \,\le\, C\big(|u| + |qw|\big)^{p\frac{p-2}{p-1}} |u - qw|^{\frac{1}{p-1}}, \qquad \mu\text{-a.e. in } \Omega',$$

which implies that for any step function $\zeta = \sum_{i=i}^m q_i 1_{B_i}$, with B_i Borel subset of Ω' and q_i in $\mathbf{Q}^M$, we get

$$|H - F(x, \zeta w)| \,\le\, C\big(|u| + |\zeta w|\big)^{p\frac{p-2}{p-1}} |u - \zeta w|^{\frac{1}{p-1}}, \qquad \mu\text{-a.e. in } \Omega'.$$

Finally, Proposition 3.6 and the continuity property (III) of F imply that $H(x) = F(x, u(x))$ μ-a.e. in Ω', which concludes the proof. □

7. Corrector. In this section, we shall fix the sequence (μ_n) in $\mathcal{M}^p_0(\Omega)$ and the sequence (F_n) in $\mathcal{F}(L)$, with $L > 0$, and we shall assume that (μ_n) $\gamma^{-\Delta_p}$-converges to μ and the pairs (μ_n, F_n) γ^A-converge to (μ, F), where $\mu \in \mathcal{M}^p_0(\Omega)$ and $F \in \mathcal{F}(\alpha, C, 1/(p-1))$. This implies that in Theorem 6.9 the solutions s^m_n of the problems (6.32) converge weakly in $W^{1,p}_0(\Omega, \mathbf{R}^M)$ to s^m when n tends to infinity without extracting any subsequence. Let us define $R^m_n : \Omega \times \mathbf{R}^M \mapsto \mathbf{M}^{M\times N}$ by

$$R^m_n(x, s) = Ds^m_n - D(sw). \tag{7.1}$$

The following result gives an approach in $L^p(\Omega, \mathbf{M}^{M\times N})$ of the gradient of the solution u_n of problem (5.2).

THEOREM 7.1. *Let Ω' be an open subset of Ω. Let (u_n) be a sequence, with $u_n \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M)$, which converges to a function u weakly in $W^{1,p}(\Omega', \mathbf{R}^M)$ and satisfies* (6.1). *Suppose there exists a sequence (f_n), with $f_n \in (W^{1,p}_0(\Omega) \cap L^p_{\mu_n}(\Omega))'$, which converges to $f \in (W^{1,p}_0(\Omega) \cap L^p_{\mu_n}(\Omega))'$ in the sense of $(\mathcal{H}_{\Omega'})$ and such that u_n satisfies problem* (5.2).

Then, for every function $\zeta = \sum_{i=1}^l s_i 1_{K_i}$ with s_i in $\mathbf{R}^M$ and K_i closed subsets of Ω' such that $w = 0$ μ-a.e. on $K_i \cap K_j$ for $i \neq j$, we have

$$\begin{aligned} &\limsup_{m\to\infty} \lim_{n\to\infty} \int_K |Du_n - Du - R^m_n(x, \zeta)|^p dx \\ &\quad\le C\Big(\int_K |u|^p \, d\mu + \int_K |w\zeta|^p \, d\mu\Big)^{\frac{p-2}{p-1}} \Big(\int_K |u - w\zeta|^p \, d\mu\Big)^{\frac{1}{p-1}}, \end{aligned} \tag{7.2}$$

where $K = \bigcup_{i=i}^l K_i$ and C is a positive constant which depends only on α, β, and L.

Remark 7.2. The heuristic idea of Theorem 7.1 is to show that the sequence of the gradients of u_n is, except for a sequence which converges strongly to zero in $L^p(\Omega, \mathbf{R}^M)$, equal to the gradient of u plus a sequence of nonlinear functions of the variables x and $u(x)$. This explains the nonlinearity of the function F. If it were possible to apply (7.2) by replacing ζ by u/w, we would get

$$\lim_{k\to\infty} \limsup_{n\to\infty} \int_\Omega \Big|Du_n - Du - R^m_n\Big(x, \frac{u}{w}\Big)\Big|^p \, dx = 0.$$

But the choice $\zeta = u/w$ in (7.2) is not possible since we do not know, a priori, if $R_n^m(x,s)$ is a Carathéodory function; so $R_n^m(x,u(x))$ may not even be measurable. We avoid this problem using the function $w\zeta$ to approach u. This approach is always possible by Proposition 3.6 part b.

Remark 7.3. When we consider $R_n^m(x,\zeta)$, the value of ζ on $K_i \cap K_j$, $i \neq j$, is not relevant. Indeed by taking in (7.2) $u_n = u = 0$ (then $f_n = 0$) and $\zeta = s1_{K_i \cap K_j}$ we deduce

$$\limsup_{m\to\infty}\limsup_{n\to\infty}\int_{K_i\cap K_j} R_n^m(x,s)\,dx = 0 \qquad \forall\, s \in \mathbf{R}^M.$$

Remark 7.4. If K is a compact subset of Ω' such that $\mu(K) = 0$, estimate (7.2) with $\zeta = 0$ implies that Du_n converges strongly to Du in $L^p(K, \mathbf{R}^M)$.

Proof of Theorem 7.1. Let $s \in \mathbf{R}^M$ and let K be a closed subset of Ω'. By Lemma 6.6, for every $\varphi \in C_c^\infty(\Omega', \mathbf{R}^M)$, with $\varphi \geq 1_K$ in Ω', we have

$$\tag{7.3} \begin{aligned} &\limsup_{n\to\infty}\int_K |D((u_n - s_n^m) - (u - s^m))|^p\,dx \\ &\leq C\Big(\int_{\Omega'} |u|^p\varphi\,d\mu + \int_{\Omega'} |s^m|^p\varphi\,d\mu\Big)^{\frac{p-2}{p-1}}\Big(\int_{\Omega'} |u - s^m|^p\varphi\,d\mu\Big)^{\frac{1}{p-1}}. \end{aligned}$$

If φ now decreases to 1_K, by the fact that (s^m) tends to sw strongly in $W_0^{1,p}(\Omega, \mathbf{R}^M) \cap L^p_\mu(\Omega, \mathbf{R}^M)$ and from (7.3) we deduce

$$\tag{7.4} \begin{aligned} &\limsup_{m\to\infty}\limsup_{n\to\infty}\int_K |D((u_n - s_n^m) - (u - s^m))|^p\,dx \\ &\leq C\Big(\int_K |u|^p\,d\mu + \int_K |sw|^p\,d\mu\Big)^{\frac{p-2}{p-1}}\Big(\int_K |u - sw|^p\,d\mu\Big)^{\frac{1}{p-1}}. \end{aligned}$$

Moreover, by inequality

$$\big||\xi_1|^p - |\xi_2|^p\big| \leq p(|\xi_1|^{p-1} + |\xi_2|^{p-1})|\xi_1 - \xi_2| \qquad \forall\, \xi_1, \xi_2 \in \mathbf{M}^{M\times N},$$

we get

$$\begin{aligned} &\Big||D((u_n - s_n^m) - (u - s^m))|^p - |D((u_n - s_n^m) - (u - sw))|^p\Big| \\ &\leq p\Big(|D((u_n - s_n^m) - (u - s^m))|^{p-1} + |D((u_n - s_n^m) - (u - sw))|^{p-1}\Big)|D(s^m - sw)|, \end{aligned}$$

and then by the strong convergence of (s^m) in $W_0^{1,p}(\Omega, \mathbf{R}^M)$ we deduce

$$\lim_{m\to\infty}\limsup_{n\to\infty}\int_K\Big||D((u_n - s_n^m) - (u - s^m))|^p\,dx - |D((u_n - s_n^m) - (u - sw))|^p\Big|\,dx = 0.$$

Thus by (7.4) and the definition of R_n^m, we get

$$\tag{7.5} \begin{aligned} &\limsup_{m\to\infty}\limsup_{n\to\infty}\int_K |D(u_n - u - R_n^m(x,s))|^p\,dx \\ &\leq C\Big(\int_K |u|^p\,d\mu + \int_K |sw|^p\,d\mu\Big)^{\frac{p-2}{p-1}}\Big(\int_K |u - sw|^p\,d\mu\Big)^{\frac{1}{p-1}}. \end{aligned}$$

Consider now $\zeta = \sum_{i=1}^{l} s_i 1_{K_i}$, with $s_i \in \mathbf{R}^M$ and K_i closed subsets of Ω' such that $w = 0$ μ-a.e. on $K_i \cap K_j$, for $i \neq j$. By Lemma 4.5, we also have $|u| = 0$ μ-a.e. on $K_i \cap K_j$, for $i \neq j$. Then, if $K = \bigcup_{i=1}^{l} K_i$, by using (7.5) and Hölder's inequality we get

$$\begin{aligned}
&\limsup_{m\to\infty}\limsup_{n\to\infty}\int_K |Du_n - Du - R_n^m(x,\zeta)|^p\,dx \\
&\le \limsup_{m\to\infty}\limsup_{n\to\infty}\sum_{i=1}^{l}\int_{K_i} |D(u_n - u - R_n^m(x,s_i))|^p\,dx \\
&\le C\sum_{i=1}^{l}\Big(\int_{K_i}|u|^p\,d\mu + \int_{K_i}|ws_i|^p\,d\mu\Big)^{\frac{p-2}{p-1}}\Big(\int_{K_i}|u - ws_i|^p\,d\mu\Big)^{\frac{1}{p-1}} \\
&= C\Big(\int_K |u|^p\,d\mu + \int_K |w\zeta|^p\,d\mu\Big)^{\frac{p-2}{p-1}}\Big(\int_K |u - w\zeta|^p\,d\mu\Big)^{\frac{1}{p-1}},
\end{aligned}$$

which concludes the proof. □

8. Particular cases. In this section, we shall prove that some assumptions on the function a, as homogeneity or linearity, are inherited by function F. In [6] we construct an example which shows that the function F in general can be nonlinear and nonhomogeneous.

Homogeneous case. Let a be a function which satisfies conditions (i)–(v), as at the beginning of section 5. Let us assume in addition that a satisfies the following homogeneity condition:

(vi) for a.e. $x \in \Omega$, for every $t \in \mathbf{R}$, and for every $\xi \in \mathbf{M}^{M\times N}$,

$$a(x, t\xi) = |t|^{p-2} t a(x, t\xi).$$

Moreover, let (μ_n) be a sequence in $\mathcal{M}_0^p(\Omega)$, and let (F_n) be a sequence of functions in $\mathcal{F}(L)$ which satisfies the following condition:

(VII) for every $x \in \Omega$, for every $t \in \mathbf{R}$, and for every $s \in \mathbf{R}^M$,

$$F_n(x, ts) = |t|^{p-2} t F_n(x, s).$$

Under these assumptions we have the following result.

THEOREM 8.1. *If the function a satisfies conditions* (i)–(vi) *and the sequence (F_n) satisfies conditions* (I)–(VII), *then in Theorem* 6.4 *the function F can be chosen satisfying*

$$F(x, ts) = |t|^{p-2} t F(x, s)$$

for every $x \in \Omega$, for every $t \in \mathbf{R}$, and for every $s \in \mathbf{R}^M$.

Proof. Assumptions (vi) and (VII) imply that for every $t \in \mathbf{R}$ and for every $q \in \mathbf{Q}^M$, the solution q_n^m of (6.42) satisfies

$$(tq)_n^m = tq_n^m, \qquad \mu\text{-a.e. in } \Omega,$$

where $(tq)_n^m$ is the solution of problem (6.42) with q replaced by tq, which converges, according with Theorem 6.9, to some function $(tq)^m$ weakly in $W_0^{1,p}(\Omega, \mathbf{R}^M)$ for every $m \in \mathbf{N}$. Then taking the limit as $n \to \infty$ we have

$$(tq)^m = tq^m, \qquad \mu\text{-a.e. in } \Omega.$$

Therefore, the functions H_q^m and H_{tq}^m defined by (6.43) satisfy

$$H_{tq}^m = tH_q^m, \qquad \mu\text{-a.e. in } \Omega$$

for every $t \in \mathbf{R}$ and for every $q \in \mathbf{Q}^M$. Thus, using that for every $q \in \mathbf{Q}^M$, the function $G(x,q)$ in the proof of Theorem 6.4 is defined as the limit in m of H_q^m, the continuity of $G(x,s)$ with respect to the variable s and that the function $F(x,s)$ satisfies (6.49), we conclude the proof. □

In this special case we have the following result for the correctors defined by (7.1).

THEOREM 8.2. *Assume that the function a and the sequence* (F_n) *satisfy, respectively, properties* (vi) *and* (VII). *Then, the function* R_n^m *defined by* (7.1) *satisfies*

$$R_n^m(x,ts) = tR_n^m(x,s) \tag{8.1}$$

for almost every $x \in \Omega$, *for every* $s \in \mathbf{R}^M$, *and for every* $t \in \mathbf{R}$.

Proof. Assumptions (vi) and (VII) imply that, for every $t \in \mathbf{R}$ and for every $s \in \mathbf{R}^M$, $(ts)_n^m = ts_n^m$, where s_n^m is the solution of (6.32) and $(ts)_n^m$ is the solution of problem (6.32) with s replaced by ts. Thus the conclusion follows by the definition of R_n^m. □

Linear case. Let us consider now the linear case, i.e., let us assume, with slight abuse of notation, that the function $a(x,\xi)$ is of the form $a(x)\xi$, where $a(x)$ is a measurable function from Ω on the linear applications from $\mathbf{M}^{M\times N}$ to $\mathbf{M}^{M\times N}$ which satisfies these hypotheses:

(i$_l$) there exists a constant $\alpha > 0$ such that for every $\xi \in \mathbf{M}^{M\times N}$ and for a.e. $x \in \Omega$, we have

$$a(x)\xi\xi \geq \alpha|\xi|^2;$$

(ii$_l$) there exists a constant $\beta > 0$ such that for every $\xi \in \mathbf{M}^{M\times N}$ and for a.e. $x \in \Omega$, we have

$$|a(x)\xi| \leq \beta|\xi|.$$

Remark 8.3. Hypotheses (i$_l$) and (ii$_l$) imply (i)–(v) at the beginning of section 5 for $p = 2$.

Let us denote by $\mathcal{F}_l(L)$, with $L > 0$, the class of all vector functions from $\Omega \times \mathbf{R}^M$ to $\mathbf{R}^M$ which are linear in the second argument (i.e., of the form $F(x)s$) and which satisfy the following two conditions:

(I$_l$) for every $s \in \mathbf{R}^M$ and for every $x \in \Omega$ we have

$$F(x)ss \geq \alpha|s|^2;$$

(II$_l$) for every $s \in \mathbf{R}^M$ and for every $x \in \Omega$ we have

$$|F(x)s| \leq L|s|.$$

Remark 8.4. It is easy to see that the class $\mathcal{F}_l(L)$ defined above is contained in the class $\mathcal{F}(L)$ defined in section 5.

We are now in a position to state the following result.

THEOREM 8.5. *Assume that in Theorem* 6.4, $Au = -\text{div}\,(a(x)Du)$, *with* $a(x)$ *satisfying* (i$_l$) *and* (ii$_l$), *and that the sequence* (F_n) *belongs to* $\mathcal{F}_l(L)$. *Then, the function F which appears in the statement of Theorem* 6.4 *can be chosen in the class* $\mathcal{F}_l(L')$, *with* $L' > 0$ *different, in general, from L.*

Proof. We have already shown in Theorem 8.1 that F is homogeneous in its second argument. The additivity of F can be proved essentially with the same argument. □

For the corrector result, as in section 7, let us assume that (μ_n) $\gamma^{-\Delta}$-converges to μ and that the pairs (μ_n, F_n) γ^A-converge to (μ, F) according with Definition 6.2 (where $Au = -\mathrm{div}\,(a(x)Du)$). In this case the function $R_n^m : \Omega \times \mathbf{R}^M \to \mathbf{M}^{M\times N}$ is given by $R_n^m(x,s) = Ds_n^m(x) - D(ws)(x)$, where for every $s \in \mathbf{R}^M$, s_n^m is the solution of the problem

$$\tag{8.2} \begin{cases} s_n^m \in H_0^1(\Omega, \mathbf{R}^M) \cap L^2_{\mu_n}(\Omega, \mathbf{R}^M), \\ \displaystyle\int_\Omega a(x) Ds_n^m Dv\,dx + \int_\Omega F_n(x) s_n^m v\,d\mu_n \;=\; m\int_\Omega (w_n s - s_n^m) v\,dx \\ \forall\, v \in H_0^1(\Omega, \mathbf{R}^M) \cap L^2_{\mu_n}(\Omega, \mathbf{R}^M). \end{cases}$$

Clearly, the functions R_n^m are linear in their second argument, and hence they are Carathéodory functions. This allows us to improve Theorem 7.1.

Theorem 8.6. *Let Ω' be an open subset of Ω. Let (u_n), with $u_n \in H^1(\Omega', \mathbf{R}^M) \cap L^2_{\mu_n}(\Omega', \mathbf{R}^M)$, be a sequence which converges weakly in $H^1(\Omega', \mathbf{R}^M)$ to some function u and satisfies* (6.1). *Assume also that there exists a sequence (f_n), with f_n belonging to $(H_0^1(\Omega', \mathbf{R}^M) \cap L^2_{\mu_n}(\Omega', \mathbf{R}^M))'$, converging to some functional $f \in (H_0^1(\Omega, \mathbf{R}^M) \cap L^2_\mu(\Omega, \mathbf{R}^M))'$ in the sense of $(\mathcal{H}_{\Omega'})$, such that (u_n) satisfies the following problem:*

$$\tag{8.3} \begin{cases} u_n \in H^1(\Omega', \mathbf{R}^M) \cap L^2_{\mu_n}(\Omega', \mathbf{R}^M), \\ \displaystyle\int_\Omega a(x) Du_n Dv\,dx + \int_\Omega F_n(x) u_n v\,d\mu_n \;=\; \langle f_n, v\rangle \\ \forall\, v \in H_0^1(\Omega', \mathbf{R}^M) \cap L^2_{\mu_n}(\Omega', \mathbf{R}^M). \end{cases}$$

Then, for every function $\psi \in H^1(\Omega', \mathbf{R}^M) \cap L^\infty(\Omega', \mathbf{R}^M)$ and for every closed set $K \subset \Omega$, we have

$$\tag{8.4} \limsup_{m\to\infty} \limsup_{n\to\infty} \int_K |Du_n - Du - R_n^m(x)\psi|^2 dx \;\le\; C\int_K |u - w\psi|^2\,d\mu.$$

In particular, if u/w belongs to $L^\infty(K, \mathbf{R}^M)$, then we have

$$\tag{8.5} \limsup_{m\to\infty} \limsup_{n\to\infty} \int_K \left| Du_n - Du - R_n^m(x)\frac{u}{w}\right|^2 dx \;=\; 0.$$

In order to prove Theorem 8.6, we need some preliminary lemmas.

Lemma 8.7. *Let $W = \sup\{\|w_n\|_{L^\infty(\Omega)}\}$. Then for every $s \in \mathbf{R}^M$, the solutions s_n^m of* (8.2) *satisfy*

$$\tag{8.6} \limsup_{m\to\infty} \limsup_{n\to\infty} \int_{\{|s_n^m| \ge 2^k W|s|\}} |D\, s_n^m|^2 dx \le C\frac{|s|^2}{k} \qquad \forall\, k \in \mathbf{N}.$$

Proof. For any $j \in \mathbf{N}$, let us consider the function $\Phi_j : \mathbf{R}^M \mapsto \mathbf{R}^M$ defined by

$$\tag{8.7} \Phi_j(\zeta) = \begin{cases} 0 & \text{if } |\zeta| \le 2^{j-1}W|s|, \\ \dfrac{|\zeta| - 2^{j-1}W|s|}{2^{j-1}W|s|}\zeta & \text{if } 2^{j-1}W|s| < |\zeta| < 2^j W|s|, \\ \zeta & \text{if } |\zeta| \ge 2^j W|s|. \end{cases}$$

Taking $\Phi_j(s_n^m)$ as a test function in (8.2), we get

$$\int_\Omega a(x)Ds_n^m D[\Phi_j(s_n^m)]\,dx + \int_\Omega F_n(x)s_n^m\Phi_j(s_n^m)\,d\mu_n + m\int_\Omega (s_n^m - w_n s)\Phi_j(s_n^m)\,dx = 0,$$

which implies

$$\begin{aligned}\alpha\int_{\{|s_n^m|\geq 2^j W|s|\}} &|D\,s_n^m|^2\,dx\\ \leq -\int_{\{2^{j-1}W|s|\leq|s_n^m|<2^jW|s|\}} &a(x)Ds_n^m D[\Phi_j(s_n^m)]\,dx + m\int_\Omega |s_n^m - w_n s||\Phi_j(s_n^m)|\,dx\\ \leq C\int_{\{2^{j-1}W|s|\leq|s_n^m|<2^jW|s|\}} &|Ds_n^m|^2\,dx + m\int_\Omega |s_n^m - w_n s||\Phi_1(s_n^m)|\,dx,\end{aligned} \tag{8.8}$$

where we used that $|\Phi_j(s_n^m)| \leq |\Phi_1(s_n^m)|$ for every $j\in\mathbf{N}$, and the fact that, in the set $\{2^{j-1}W|s| \leq |s_n^m| < 2^jW|s|\}$, we have $D[\Phi_j(s_n^m)] = Ds_n^m(2|s_n^m|-2^{j-1}W|s|)/2^{j-1}W|s|$, and hence $|D[\Phi_j(s_n^m)]| \leq 3|Ds_n^m|$.

On the other hand, by (6.38) we can see that for every $k\in\mathbf{N}$ we have

$$\sum_{j=1}^k \int_{\{2^{j-1}W|s|\leq|s_n^m|<2^jW|s|\}} |Ds_n^m|^2\,dx \;\leq\; \int_\Omega |Ds_n^m|^2\,dx \;\leq\; C|s|^2$$

and therefore, for every $k\in\mathbf{N}$, there exists $j(k)$, with $1\leq j(k)\leq k$, such that

$$\int_{\{2^{j(k)-1}W|s|\leq|s_n^m|<2^{j(k)}W|s|\}} |Ds_n^m|^2\,dx \;\leq\; C\frac{|s|^2}{k}.$$

By (8.8), applied with $j(k)$, we deduce that for any $k\in\mathbf{N}$ we have

$$\begin{aligned}&\int_{\{|s_n^m|\geq 2^kW|s|\}} |D\,s_n^m|^2\,dx\\ &\quad\leq \int_{\{|s_n^m|\geq 2^{j(k)}W|s|\}} |D\,s_n^m|^2\,dx \leq C\frac{|s|^2}{k} + m\int_\Omega |s_n^m - w_n s||\Phi_1(s_n^m)|\,dx,\end{aligned}$$

thus taking the limit as $n\to\infty$ and using that $\Phi_1(ws)=0$, we obtain

$$\begin{aligned}\limsup_{n\to\infty}\int_{\{|s_n^m|\geq 2^kW|s|\}} |D\,s_n^m|^2\,dx \;&\leq\; C\frac{|s|^2}{k} + m\int_\Omega |s^m - ws||\Phi_1(s^m)-\Phi_1(ws)|\,dx\\ &\leq\; C\frac{|s|^2}{k} + Cm\int_\Omega |s^m - ws|^2\,dx.\end{aligned}$$

Since, by Theorem 6.9, the second term on the right-hand side tends to zero when m tends to infinity, estimate (8.6) is proved. □

Lemma 8.8. *For every function $\varphi\in H_0^1(\Omega)\cap L^\infty(\Omega)$, with $\varphi\geq 0$, we have*

$$\limsup_{m\to\infty}\limsup_{n\to\infty}\int_\Omega |R_n^m(x)|^2\varphi\,dx \;\leq\; C\int_\Omega w^2\varphi\,d\mu. \tag{8.9}$$

Proof. Let $s\in\mathbf{R}^M$, with $|s|\leq 1$. Let us define $\Psi_k:\mathbf{R}^M\mapsto\mathbf{R}^M$ by $\Psi_k(\zeta) = \zeta - \Phi_k(\zeta)$, where Φ_k is the function defined by (8.7). Taking $\Psi_k(s_n^m - w_n s)\varphi$, with

$\varphi \in H_0^1(\Omega) \cap L^\infty(\Omega)$ and $\varphi \geq 0$, as a test function in (8.2), we have

$$\begin{aligned}&\int_\Omega a(x) Ds_n^m D[\Psi_k(s_n^m - w_n s)]\varphi\, dx + \int_\Omega a(x) Ds_n^m \Psi_k(s_n^m - w_n s) \otimes D\varphi\, dx\\&+ m\int_\Omega (s_n^m - w_n s)\Psi_k(s_n^m - w_n s)\varphi\, dx + \int_\Omega F_n(x) s_n^m \Psi_k(s_n^m - w_n s)\varphi\, d\mu_n = 0,\end{aligned}$$

where the second term tends to zero when n and then m tend to infinity and where the third term in the left-hand side is positive. This permits us to write

$$\begin{aligned}&\alpha\int_{\{|s_n^m - w_n s| \leq 2^{k-1}W|s|\}} |D(s_n^m - w_n s)|^2\varphi\, dx + \int_\Omega F_n(x)(s_n^m - w_n s)\Psi_k(s_n^m - w_n s)\varphi\, d\mu_n\\&\qquad \leq C\int_{\{2^{k-1}W|s| < |s_n^m - w_n s| < 2^k W|s|\}} |Ds_n^m||D(s_n^m - w_n s)|\varphi\, dx\\&\qquad + C\int_{\{|s_n^m - w_n s| \leq 2^{k-1}W|s|\}} |D(w_n s - ws)||D(s_n^m - w_n s)|\varphi\, dx\\&\qquad + C\int_{\{|s_n^m - w_n s| \leq 2^{k-1}W|s|\}} |Dws||D(s_n^m - w_n s)|\varphi\, dx\\&\qquad + C\int_\Omega |w_n s||\Psi_k(s_n^m - w_n s)|\varphi\, d\mu_n + o_{m,n}.\end{aligned} \tag{8.10}$$

Since for $k \geq 2$

$$|s_n^m| \geq |s_n^m - w_n s| - |w_n s| \geq |s_n^m - w_n s| - W|s| \geq 2^{k-2}W|s| \tag{8.11}$$

in the set $\{|s_n^m - w_n s| \geq 2^{k-1}W|s|\}$, by Hölder's inequality, (6.38), and Lemma 8.7, we obtain

$$\int_{\{2^{k-1}W|s| < |s_n^m - w_n s| < 2^k W|s|\}} |Ds_n^m||D(s_n^m - w_n s)|\varphi\, dx \leq C\frac{\|\varphi\|_{L^\infty(\Omega)}}{\sqrt{k-2}}|s|^2 + o_{m,n}.$$

By the definition of Ψ_k and (I_l), we have

$$\begin{aligned}\int_\Omega F_n(x)(s_n^m - w_n s)\Psi_k(s_n^m - w_n s)\varphi\, d\mu_n &\geq \alpha\int_\Omega (s_n^m - w_n s)\Psi_k(s_n^m - w_n s)\varphi\, d\mu_n\\&\geq \alpha\int_\Omega |\Psi_k(s_n^m - w_n s)|^2\varphi\, d\mu_n.\end{aligned}$$

Therefore, using Young's inequality in (8.10) and taking into account that $|s| \leq 1$ and that the third term of the right-hand side of (8.10) tends to zero when n and m tend to infinity, we get

$$\begin{aligned}&\int_{\{|s_n^m - w_n s| \leq 2^{k-1}W|s|\}} |D(s_n^m - w_n s)|^2\varphi\, dx + \int_\Omega |\Psi_k(s_n^m - w_n s)|^2\varphi\, d\mu_n\\&\leq C\left[\frac{\|\varphi\|_{L^\infty(\Omega)}}{\sqrt{k-2}} + \int_\Omega |D(w_n s - ws)|^2\varphi\, dx + \int_\Omega |w_n s|^2\varphi\, d\mu_n\right] + o_{m,n}\\&\qquad \leq C\frac{\|\varphi\|_{L^\infty(\Omega)}}{\sqrt{k-2}} + C\int_\Omega w^2\varphi\, d\mu + o_{m,n},\end{aligned} \tag{8.12}$$

where in the last inequality we used Lemma 4.2. Thus by (8.12), (8.11), and Lemmas 8.7 and 4.2, we have

$$\int_\Omega |R_n^m(x)s|^2\varphi\,dx \;=\; \int_\Omega |D(s_n^m - ws)|^2\varphi\,dx$$

$$\le\; 2\int_{\{|s_n^m-w_ns|\le 2^{k-1}W|s|\}} |D(s_n^m-w_ns)|^2\varphi\,dx+2\int_{\{|s_n^m-w_ns|\le 2^{k-1}W|s|\}} |D(w_ns-ws)|^2\varphi\,dx$$

$$+2\int_{\{|s_n^m-w_ns|> 2^{k-1}W|s|\}} |Ds_n^m|^2\varphi\,dx+2\int_{\{|s_n^m-w_ns|> 2^{k-1}W|s|\}} |D(ws)|^2\varphi\,dx$$

$$\le\; C\|\varphi\|_{L^\infty(\Omega)}\Big(\frac{1}{\sqrt{k-2}}+\frac{1}{k-2}\Big)+C\int_\Omega w^2\varphi\,d\mu+o_{m,n},$$

which by the arbitrariness of k implies

$$\limsup_{m\to\infty}\limsup_{n\to\infty}\int_\Omega |R_n^m(x)s|^2\varphi\,dx \;\le\; C\int_\Omega w^2\varphi\,d\mu.$$

Since

$$|R_n^m(x)| = \max\{|R_n^m(x)s| : |s|\le 1\} \le \sum_{i=1}^N |R_n^m(x)e_i|,$$

where $\{e_i : i \le i \le N\}$ is the canonical basis of $\mathbf{R}^N$, Lemma 8.8 is proved. □

Remark 8.9. If in Lemma 8.8, φ belongs to $C_c^\infty(\Omega)$, then estimate (8.9) may be easily deduced from estimate (6.9) in Lemma 6.6. Remark also that Lemmas 8.7 and 8.8 can be easily generalized to the nonlinear case.

Proof of Theorem 8.6. By Lemma 8.8, for every closed $K \subset \Omega'$ and for every function $\psi \in H^1(\Omega', \mathbf{R}^M)$, with $\psi \ge 0$, we have

$$\limsup_{m\to\infty}\limsup_{n\to\infty}\int_K |R_m^n(x)|^2\psi\,dx \;\le\; C\int_K w^2\psi\,d\mu. \tag{8.13}$$

Indeed it is enough in (8.9) to take φ equals to $\varphi_n\psi$, with $\varphi_n \in H_0^1(\Omega', \mathbf{R}^M) \cap L^\infty(\Omega', \mathbf{R}^M)$ decreasing to the characteristic function of K.

Consider $\psi \in H^1(\Omega', \mathbf{R}^M) \cap L^\infty(\Omega', \mathbf{R}^M)$ and let K be a closed subset of Ω'. By Theorem 7.1, for any function $\zeta = \sum_{i=1}^l s_i 1_{K_i}$, with $s_i \in \mathbf{R}$ and K_i closed subsets of Ω', such that $K = \bigcup_{i=1}^l K_i$ and $w = 0$ μ-a.e. on $K_i \cap K_j$, for $i \ne j$, we have

$$\int_K |Du_n - Du - R_n^m(x)\psi|^2\,dx$$

$$\le\; 2\int_K |Du_n - Du - R_n^m(x)\zeta|^2\,dx + 2\int_K |R_n^m(x)|^2|\psi-\zeta|^2\,dx$$

$$\le\; C\int_K |u-w\zeta|^2\,d\mu + 2\sum_{i=1}^l\int_{K_i} |R_n^m(x)|^2|\psi - s_i|^2\,dx + o_{m,n} \tag{8.14}$$

$$\le\; C\int_K |u-w\zeta|^2\,d\mu + C\sum_{i=1}^l\int_{K_i} |w\psi - s_iw|^2\,d\mu + o_{m,n}$$

$$=\; C\int_K |u-w\zeta|^2\,d\mu + C\int_K |w\psi - w\zeta|^2\,d\mu + o_{m,n},$$

where we used (8.13). In order to obtain (8.4), it is enough to take $\zeta = \zeta_k$, where (ζ_k) is a sequence of step functions such that $(w\zeta_k)$ converges strongly to $w\psi$ in $L^2_\mu(\Omega', \mathbf{R}^M)$.

Assume now that u/w belongs to $L^\infty(K, \mathbf{R}^M)$ and take $\varepsilon > 0$. By estimates (8.4) and (8.13), we get

$$\begin{aligned}
&\int_K \left| Du_n - Du - R_n^m(x)\frac{u}{w}\right|^2 dx \\
&\le \int_K \left| Du_n - Du - R_n^m(x)\frac{u}{w+\varepsilon}\right|^2 dx + \int_K |R_n^m(x)|^2 \left|\frac{u}{w+\varepsilon} - \frac{u}{w}\right|^2 dx \\
&\le \int_K \left| u - \frac{wu}{w+\varepsilon}\right|^2 d\mu + C\varepsilon^2 \left\|\frac{u}{w}\right\|^2_{L^\infty(K,\mathbf{R}^M)} \int_K |R_n^m(x)|^2 \frac{1}{(w+\varepsilon)^2}\, d\mu + o_{m,n} \\
&\le \int_K \left| u - \frac{wu}{w+\varepsilon}\right|^2 d\mu + C\varepsilon^2 \left\|\frac{u}{w}\right\|^2_{L^\infty(K,\mathbf{R}^M)} \int_K \frac{w^2}{(w+\varepsilon)^2}\, d\mu + o_{m,n}.
\end{aligned} \tag{8.15}$$

By using that u belongs to $L^2_\mu(\Omega, \mathbf{R}^M)$ and the dominated convergence theorem, the first integral of the right-hand side of (8.15) tends to zero when ε tends to zero. Since

$$\frac{\varepsilon w}{(w+\varepsilon)^2} = \frac{\varepsilon}{w+\varepsilon}\frac{w}{w+\varepsilon} \le 1,$$

and hence by the fact that $\nu = w^{p-1}\mu$ is a Radon measure,

$$\varepsilon \int_K \frac{w^2}{(w+\varepsilon)^2}\, d\mu \le \int_K w\, d\mu < +\infty,$$

we get that the second integral on the right-hand side of (8.15) tends to zero when ε tends to zero. We deduce (8.5) taking the limit in n, m, and then in ε. □

9. Asymptotically equivalent operators. We saw in the previous sections that the properties of the function F which appears in the limit problem (6.2) are strictly related to the properties of the function a which define the differential operator A. The next proposition shows, in some sense, how the function F depends on the behavior of $a(x, \xi)$ when $|\xi|$ is large.

Let $\tilde{a} : \Omega \times \mathbf{M}^{M\times N} \to \mathbf{M}^{M\times N}$ be a Carathéodory function which satisfies conditions (i)–(v), and suppose that the following property

$$\lim_{|\xi|\to\infty} \frac{|a(x,\xi) - \tilde{a}(x,\xi)|}{|\xi|^{p-1}} = 0 \tag{9.1}$$

holds uniformly with respect to x in Ω. Let $\tilde{A}$ be the differential operator given by $\tilde{A}u = -\mathrm{div}\,(\tilde{a}(x, Du))$.

PROPOSITION 9.1. *Suppose that the pair* (μ_n, F_n)*, according to Definition* 6.2*,* γ^A*-converges to* (μ, F)*.*

If the functions a and $\tilde{a}$ satisfy condition (9.1)*, then we also have that* (μ_n, F_n) $\gamma^{\tilde{A}}$*-converges to* (μ, F)*.*

Proof. According to the definition of the $\gamma^{\tilde{A}}$-convergence, we have to show that for any open subset Ω' of Ω, for any sequence of functionals (f_n), with $f_n \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M))'$, which converges to some $f \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap$

$L^p_\mu(\Omega', \mathbf{R}^M))'$ in the sense of $(\mathcal{H}_{\Omega'})$, and for any sequence (u_n) which satisfies (6.1) and

$$\begin{cases} u_n \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} \tilde{a}(x, Du_n) Dv\, dx + \int_{\Omega'} F_n(x, u_n) v\, d\mu_n \;=\; \langle f_n, v\rangle \\ \forall\, v \in W^{1,p}_0(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M), \end{cases} \tag{9.2}$$

every cluster point of the sequence (u_n) in the weak topology of $W^{1,p}(\Omega', \mathbf{R}^M)$ satisfies problem

$$\begin{cases} u \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} \tilde{a}(x, Du) Dv\, dx + \int_{\Omega'} F(x, u) v\, d\mu \;=\; \langle f, v\rangle \\ \forall\, v \in W^{1,p}_0(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M). \end{cases} \tag{9.3}$$

If u_n satisfies (9.2), then it also satisfies

$$\begin{cases} u_n \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} a(x, Du_n) Dv\, dx + \int_{\Omega'} F_n(x, u_n) v\, d\mu_n \;=\; \langle g_n, v\rangle \\ \forall\, v \in W^{1,p}_0(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M), \end{cases}$$

where $g_n = f_n - \mathrm{div}\,[a(x, Du_n) - \tilde{a}(x, Du_n)]$. Therefore, once we show that $(\mathrm{div}\,[a(x, Du_n) - \tilde{a}(x, Du_n)])$ converges in the sense of $(\mathcal{H}_{\Omega'})$ to $\mathrm{div}\,[a(x, Du) - \tilde{a}(x, Du)]$, by the γ^A-convergence of (μ_n, F_n) to (μ, F), we can deduce that u satisfies (9.3).

In order to prove that $(-\mathrm{div}\,[\tilde{a}(x, Du_n) - a(x, Du_n)])$ converges in the sense of $(\mathcal{H}_{\Omega'})$, let us consider $v_n \in W^{1,p}_0(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M)$ such that (v_n) converges weakly to some v in $W^{1,p}_0(\Omega', \mathbf{R}^M)$. Since by Proposition 5.4 the sequence (Du_n) converges to Du pointwise a.e. in Ω', by Egorov's theorem, for every $\delta > 0$, there exists a set $E \subseteq \Omega'$, with $|E| < \delta$, such that (Du_n) converges uniformly to Du in $\Omega' \setminus E$. Thus we get

$$\begin{aligned} &\lim_{n\to\infty} \int_{\Omega'} [\tilde{a}(x, Du_n) - a(x, Du_n)] Dv_n\, dx \\ &= \int_{\Omega' \setminus E} [\tilde{a}(x, Du) - a(x, Du)] Dv\, dx + \lim_{n\to\infty} \int_E [\tilde{a}(x, Du_n) - a(x, Du_n)] Dv_n\, dx. \end{aligned} \tag{9.4}$$

Let us estimate the last limit in (9.4). By (9.1), for every $\varepsilon > 0$ there exists $M > 0$ such that

$$|\tilde{a}(x, \xi) - a(x, \xi)| \;\le\; \varepsilon |\xi|^{p-1}$$

whenever $|\xi| > M$. Thus, since (v_n) and (u_n) are bounded in $W^{1,p}(\Omega', \mathbf{R}^M)$, by

Hölder's inequality, we get

$$\begin{aligned}
&\lim_{n\to\infty}\Big|\int_E [\tilde a(x,Du_n)-a(x,Du_n)]Dv_n\,dx\Big| \\
&\qquad\le \lim_{n\to\infty}\int_{E\cap\{|Du_n|>M\}_{\Omega'}} |\tilde a(x,Du_n)-a(x,Du_n)||Dv_n|\,dx \qquad (9.5)\\
&\quad+\int_{E\cap\{|Du_n|\le M\}_{\Omega'}} |\tilde a(x,Du_n)-a(x,Du_n)||Dv_n|\,dx \;\le\; C(\varepsilon+M^{p-1}\delta^{(p-1)/p}).
\end{aligned}$$

Now taking the limit as δ goes to zero and then the limit as M goes to infinity, by (9.4) and (9.5) we obtain

$$\lim_{n\to\infty}\int_{\Omega'}[\tilde a(x,Du_n)-a(x,Du_n)]Dv_n\,dx \;=\; \int_{\Omega'}[\tilde a(x,Du)-a(x,Du)]Dv\,dx,$$

which concludes the proof. □

Corollary 9.2. *Let (F_n) be a sequence in $\mathcal{F}(L)$ which satisfies condition* (VI) *and assume that the function a satisfies the following condition: There exists a Carathéodory function $\tilde a$ such that*

$$\lim_{t\to\infty}\frac{a(x,t\xi)}{|t|^{p-2}t} \;=\; \tilde a(x,\xi) \qquad (9.6)$$

uniformly in x, for every $\xi\in\mathbf{M}^{M\times N}$.

Suppose that the pair (μ_n,F_n), according to Definition 6.2, *γ^A-converges to (μ,F). Then the function F also satisfies condition* (VI).

Proof. It is easy to see that $\tilde a$ satisfies conditions (i)–(vi) and that condition (9.6) implies condition (9.1). Thus by the previous theorem the sequence of pairs (F_n,μ_n) $\gamma^{\tilde A}$-converges to (μ,F) and by Theorem 8.1 the function F satisfies condition (VI). □

10. General operators. In this section we shall prove that the results given in the previous sections hold for a class of more general operators. Actually, let $2\le p<+\infty$ and let $b:\Omega\times\mathbf{R}^M\times\mathbf{M}^{M\times N}\mapsto\mathbf{M}^{M\times N}$ be a Carathéodory function such that:

(i′) there exists a constant $\alpha>0$ such that

$$(b(x,0,\xi_1)-b(x,0,\xi_2))(\xi_1-\xi_2)\ge\alpha|\xi_1-\xi_2|^p$$

for every $s\in\mathbf{R}^M$, for every $\xi_1,\xi_2\in\mathbf{M}^{M\times N}$, and for a.e. $x\in\Omega$;

(ii′) there exists a constant $\beta>0$ and a function $h\in L^{\frac{p}{p-2}}(\Omega)$ $(p/(p-2)=+\infty$ if $p=2)$ such that

$$|b(x,0,\xi_1)-b(x,0,\xi_2)| \;\le\; \beta(h(x)+(|\xi_1|+|\xi_2|)^{p-2})|\xi_1-\xi_2|$$

for every $\xi_1,\xi_2\in\mathbf{M}^{M\times N}$ and for a.e. $x\in\Omega$;

(iii′) there exists a constant $\gamma>0$ and a function $k\in L^{p'}(\Omega)$ such that

$$|b(x,s_1,\xi)-b(x,s_2,\xi)| \;\le\; \gamma\big(k(x)+(|s_1|+|s_2|)^q+|\xi|^r\big)\min\{|s_1-s_2|,1\}$$

for every $s_1,s_2\in\mathbf{R}^M$, for every $\xi\in\mathbf{M}^{M\times N}$ and for a.e. $x\in\Omega$, where q and r are constants which satisfy $0\le q<N(p-1)/(N-p)$ if $p<N$, $q\ge0$ if $p\ge N$ and $0\le r<p-1$.

(iv′) $b(\cdot, 0, 0) \in L^{p'}(\Omega)$.

Under these hypotheses on the operator $Bu = -\mathrm{div}(b(x, u, Du))$, we have the following generalizations of Definition 6.2 and Theorem 6.4.

Definition 10.1. Let (μ_n) be a sequence in $\mathcal{M}_0^p(\Omega)$, let (F_n) be a sequence in $\mathcal{F}(c_1, c_2, \sigma)$, let $\mu \in \mathcal{M}_0^p(\Omega)$ and $F \in \mathcal{F}(c_1, c_2, \sigma)$. We say that the pairs (μ_n, F_n) γ^B-*converge (in* Ω*)* to the pair (μ, F) if the following property holds: for any open set $\Omega' \subseteq \Omega$, for any sequence of functionals (f_n), with $f_n \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M))'$, which converges to some $f \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M))'$ in the sense of $(\mathcal{H}_{\Omega'})$ (according to Definition 5.1), and for any sequence (u_n) of solutions of the problems

$$\tag{10.1} \begin{cases} u_n \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} b(x, u_n, Du_n) Dv\, dx + \int_{\Omega'} F_n(x, u_n) v\, d\mu_n \,=\, \langle f_n, v\rangle \\ \forall\, v \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_n}(\Omega', \mathbf{R}^M) \end{cases}$$

satisfying (6.1), all cluster points of the sequence (u_n) in the weak topology of $W^{1,p}(\Omega', \mathbf{R}^M)$ satisfy the following problem:

$$\tag{10.2} \begin{cases} u \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} b(x, u, Du) Dv\, dx \,+ \int_{\Omega'} F(x, u) v\, d\mu \,=\, \langle f, v\rangle \\ \forall\, v \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M). \end{cases}$$

Remark 10.2. If (u_n) is a sequence of solutions of problems (10.1) then the assertion of Proposition 5.4 can be proved using the same argument.

Theorem 10.3. *Let (μ_n) be a sequence of measures in $\mathcal{M}_0^p(\Omega)$ and let (F_n) be a sequence in $\mathcal{F}(L)$, with $L > 0$. Then there exists an increasing sequence of integers (n_j), a measure $\mu \in \mathcal{M}_0^p(\Omega)$, and a function $F \in \mathcal{F}(\alpha, C, 1/(p-1))$ such that the pairs (μ_{n_j}, F_{n_j}) γ^B-converge to (μ, F) in Ω (according to Definition* 10.1*).*

Proof. The above hypotheses on $b(x, s, \xi)$ imply that the application $a : \Omega \times \mathbf{M}^{M\times N} \mapsto \mathbf{M}^{M\times N}$ defined by $a(x, \xi) = b(x, 0, \xi) - b(x, 0, 0)$ satisfies conditions (i)–(v) in section 5 and then, by Theorem 6.4, there exists an increasing sequence of integers (n_j), a measure $\mu \in \mathcal{M}_0^p(\Omega)$, and a function $F \in \mathcal{F}(\alpha, C, 1/(p-1))$ such that the pairs (μ_{n_j}, F_{n_j}) γ^A-converge to (μ, F) in Ω (according to Definition 6.2). Let us see that the pairs (μ_{n_j}, F_{n_j}) γ^B-converge to (μ, F) in Ω (according to Definition 10.1). Let us consider a sequence of functionals (f_{n_j}), with $f_{n_j} \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_{n_j}}(\Omega', \mathbf{R}^M))'$, which converges to some $f \in (W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu}(\Omega', \mathbf{R}^M))'$ in the sense of $(\mathcal{H}_{\Omega'})$, a sequence (u_{n_j}) which satisfies (10.1) (with n replaced by n_j) and (6.1), and a cluster point u of the sequence (u_{n_j}) in the weak topology of $W^{1,p}(\Omega', \mathbf{R}^M)$. We have to prove that u satisfies problem (10.2). In order to simplify the notation, we shall still denote by (u_{n_j}) the subsequence of (u_{n_j}) which converges weakly in $W^{1,p}(\Omega', \mathbf{R}^M)$ to u. By (10.1), the sequence (u_{n_j}) satisfies

$$\tag{10.3} \begin{cases} u_{n_j} \in W^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_{n_j}}(\Omega', \mathbf{R}^M), \\ \displaystyle\int_{\Omega'} a(x, Du_{n_j}) Dv\, dx \,+ \int_{\Omega'} F(x, u_{n_j}) v\, d\mu \,=\, \langle f_{n_j}, v\rangle \,-\, \langle g_{n_j}, v\rangle \\ \forall\, v \in W_0^{1,p}(\Omega', \mathbf{R}^M) \cap L^p_{\mu_{n_j}}(\Omega', \mathbf{R}^M), \end{cases}$$

where $g_{n_j} = -\mathrm{div}\big(b(x, u_{n_j}, Du_{n_j}) - b(x, 0, Du_{n_j}) - b(x, 0, 0)\big)$. To conclude the proof it is enough to show that the sequence (g_{n_j}) converges in the sense of $(\mathcal{H}_{\Omega'})$ to the functional $g = -\mathrm{div}\big(b(x, u, Du) - b(x, 0, Du) - b(x, 0, 0)\big)$. By (iii$'$) we have

$$\big|b(x, u_{n_j}, Du_{n_j}) - b(x, 0, Du_{n_j})\big| \leq \gamma(k + |u_{n_j}|^q + |Du_{n_j}|^r)|u_{n_j}|. \tag{10.4}$$

By Remark 10.2, Du_{n_j} converges pointwise to Du, and then the left-hand side of (10.4) converges pointwise to $b(x, u, Du) - b(x, 0, Du)$, and the power p' of the right-hand side is uniformly integrable. This implies that $(b(x, u_{n_j}, Du_{n_j}) - b(x, 0, Du_{n_j}))$ converges strongly in $L^{p'}(\Omega')$ to $b(x, u, Du) - b(x, 0, Du)$, which concludes the proof. □

SCATTERING THEORY AND SELF-SIMILAR SOLUTIONS FOR THE NONLINEAR SCHRÖDINGER EQUATION*

THIERRY CAZENAVE[†] AND FRED B. WEISSLER[‡]

Abstract. We study a certain class of mild solutions of the nonlinear Schrödinger equation $iu_t + \Delta u = \gamma |u|^\alpha u$. In particular, we develop a scattering theory in this class of solutions. As a consequence, we characterize self-similar solutions in $L^{\alpha+2}$ whose gradient is in L^2. In addition, we prove the existence of classical H^1 global solutions having various specified rates of decay as $t \to \infty$.

Key words. nonlinear Schrödinger equation, self-similar solution, scattering theory

1. Introduction.

This paper is devoted to the study of a certain class of mild solutions of the nonlinear Schrödinger equation

$$iu_t + \Delta u = \gamma |u|^\alpha u, \tag{1.1}$$

where $u = u(t,x) \in \mathbb{C}$, $t > 0$, $x \in \mathbb{R}^N$, γ is a fixed real number, and $\alpha > 0$. As usual, a mild solution refers to a solution of the corresponding integral equation. Since we consider solutions of (1.1) for $t > 0$, i.e., without specifying an initial value, the corresponding integral equation has $u(\tau)$ as "initial value" for any $\tau > 0$. See Definition 3.1 for the precise formulation. In particular, the solution must be in $L^\infty_{\text{loc}}((0,\infty), L^{\alpha+2}(\mathbb{R}^N))$.

Historically, (1.1) has been studied in $H^1(\mathbb{R}^N)$, often with the additional restriction that α be "subcritical", i.e.,

$$\alpha < \frac{4}{N-2} \quad (\alpha < \infty \text{ if } N = 1,2).$$

In this case, the natural energy of a solution

$$E(u(t)) = \frac{1}{2}\int_{\mathbb{R}^N} |\nabla u(t,x)|^2\,dx + \frac{\gamma}{\alpha+2}\int_{\mathbb{R}^N} |u(t,x)|^{\alpha+2}\,dx$$

is well defined.

On the other hand, H^1 is not well adapted for the study of self-similar solutions of (1.1), i.e., solutions u of the form

$$u(t,x) = t^{-\frac{p}{2}} f\Big(\frac{x}{\sqrt{t}}\Big),$$

where $p \in \mathbb{C}$ and $\operatorname{Re} p = 2/\alpha$. Conservation laws for H^1 solutions of (1.1) combined with the dilation properties of self-similar solutions show that nontrivial H^1 self-similar solutions of (1.1) could only exist if $\alpha = 4/N$. And even if $\alpha = 4/N$, no radially

symmetric nontrivial H^1 self-similar solutions exist (see [7], [9]). As far as we are aware, however, the existence of nontrivial self-similar solutions with $\nabla f \in L^2(\mathbb{R}^N)$ and $f \in L^{\alpha+2}(\mathbb{R}^N)$ is an open question; see [10].

If $u(t,x) = t^{-\frac{p}{2}} f(\frac{x}{\sqrt{t}})$, where $\operatorname{Re} p = 2/\alpha$ and $f \in L^{\alpha+2}(\mathbb{R}^N)$, then

$$\|u(t)\|_{L^{\alpha+2}} = t^{-\beta}\|f\|_{L^{\alpha+2}},$$

where

$$\beta = \frac{4-(N-2)\alpha}{2\alpha(\alpha+2)}. \tag{1.2}$$

(Note that $\beta > 0$ precisely when α is subcritical.) Thus, we are motivated to consider the class of mild solutions u of (1.1) such that

$$u \in X_\alpha \equiv \{u \in L^\infty_{\text{loc}}((0,\infty), L^{\alpha+2}(\mathbb{R}^N));\ \sup_{t>0} t^\beta \|u(t)\|_{L^{\alpha+2}} < \infty\}. \tag{1.3}$$

We believe this to be a natural space in which to study solutions of (1.1). As we shall see, this study will yield new results about H^1 solutions.

In a previous article [4] we proved that if

$$\alpha_0 < \alpha < \frac{4}{N-2}, \tag{1.4}$$

where α_0 is the positive root of the polynomial $N\alpha^2 + (N-2)\alpha - 4$, and if $\varphi : \mathbb{R}^N \to \mathbb{C}$ is small enough in the space

$$W_\alpha = \{\varphi \in \mathcal{S}'(\mathbb{R}^N);\ \sup_{t>0} t^\beta \|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}} < \infty\}, \tag{1.5}$$

where

$$\mathcal{T}(t) = e^{it\Delta}$$

is the Schrödinger group on $\mathbb{R}^N$, then φ is the initial value of a (mild) solution $u \in X_\alpha$ of (1.1). If, in addition, $\varphi \in H^1(\mathbb{R}^N)$, then the resulting solution coincides with the "classical" H^1 solution. Furthermore, we showed that the resulting set of solutions includes a class of nontrivial self-similar solutions, and, if $\alpha < 4/N$, it includes a class of H^1 solutions which are asymptotically self-similar as $t \to \infty$.

In this paper, we continue the study of X_α solutions of (1.1). Section 2 gives the technical preliminaries, including information about X_α and W_α and related spaces. In section 3 below (Proposition 3.3) we prove that if α satisfies (1.4), then every solution $u \in X_\alpha$ of (1.1) has an initial value $\varphi \in W_\alpha$ and a scattering state $u^+ \in W_\alpha$. If, in addition, $\alpha > 4/N$ and u is an H^1 solution, then u^+ is also a scattering state in H^1 (Proposition 3.10). Furthermore, we obtain stronger estimates on the initial value, the scattering state, and decay of the integral term in case the solution $u \in X_\alpha$ in fact decays as $t \to \infty$ as $t^{-\mu}$ for some $\mu > \beta$. See Propositions 3.6, 3.7, and 3.8, Corollary 3.9, and Proposition 3.10 (iv).

In section 4 we show that the scattering state u^+ of the X_α solution u is (essentially) the Fourier transform of the initial value ψ of the function $v(s,y)$ related to $u(t,x)$ by the pseudoconformal transformation.

In section 5 we prove that if α satisfies (1.4) and u^+ is sufficiently small in W_α, then there exists a solution $u \in X_\alpha$ of (1.1) which has scattering state u^+. The results of this section, along with those of section 3 and [4], construct a "low energy" scattering theory for (1.1) in the space W_α. We also show (Proposition 5.3) that if, in addition, $\alpha > 4/N$ and $u^+ \in H^1(\mathbb{R}^N)$, then the resulting solution $u(t)$ is an H^1 solution. Moreover (Proposition 5.4), if α satisfies (1.4) and $u^+ \in H^1(\mathbb{R}^N) \cap W_\alpha$ is sufficiently small in W_α, and if $\|\mathcal{T}(t)u^+\|_{L^{\alpha+2}}$ decays like $t^{-\mu}$ for some $\mu > \beta$, then the resulting solution $u(t)$ is an H^1 solution. The smallness condition is not needed if $\gamma > 0$ or $\alpha < 4/N$ (Proposition 5.5).

We should point out that while the solution $u \in X_\alpha$ uniquely determines its initial value $\varphi \in W_\alpha$ and scattering state $u^+ \in W_\alpha$, the converse is not necessarily true. If u^+ (respectively, φ) is sufficiently small in W_α, then there is a solution $u \in X_\alpha$ with scattering state u^+ (respectively, with initial value φ). We know this solution to be unique among functions $u \in X_\alpha$ with $\sup_{t>0} t^\beta \|u(t)\|_{L^{\alpha+2}} \le M$ for some specific M determined by the parameters and W_α norm of u^+ (respectively, φ). It is conceivable (though we have no example) that another larger solution $\widetilde{u} \in X_\alpha$ of (1.1) will have the same scattering state (respectively, initial value). Indeed, for a solution $u \in X_\alpha$ of (1.1) we have not shown that $u^+ = 0$ (or $\varphi = 0$) implies $u \equiv 0$. See Proposition 3.8 for a partial result. Furthermore, we show in section 6 (Proposition 6.3) that if $u(t,x) = t^{-\frac{p}{2}} f(x/\sqrt{t})$ with $\operatorname{Re} p = 2/\alpha$ is a self-similar solution of (1.1), and if $f \in L^{\alpha+2}(\mathbb{R}^N)$ and $\nabla f \in L^2(\mathbb{R}^N)$, then its scattering state u^+ must be zero. In other words, if (1.4), a nontrivial finite energy self-similar solution of (1.1) would provide an example of a nontrivial X_α solution of (1.1) with $u^+ = 0$. Proposition 6.8 shows a partial converse: any radially symmetric self-similar solution $u \in X_\alpha$ of (1.1) (whose profile is also in a certain $L^q(\mathbb{R}^N)$; see the statement of Proposition 6.8) must be of finite energy.

The last section (before the appendix) is concerned with the comparison between scattering states and the asymptotic form of a solution as $t \to \infty$. As we shall see, different solutions of (1.1) in X_α can have the same asymptotic form as $t \to \infty$. On the other hand, at least among the solutions constructed by the "low energy" scattering theory in X_α, there is a one-to-one correspondence between solution and scattering state. Thus, the scattering state is a more precise description of the solution. In this section (section 7), we construct H^1 solutions of (1.1) which are asymptotic as $t \to \infty$ to various self-similar solutions of the linear Schrödinger equation. Indeed, if $\psi(x)$ is C^∞ away from the origin and homogeneous of degree $-q$, $0 < \operatorname{Re} q < N$, then the solution of the linear Schrödinger equation in $\mathcal{S}'(\mathbb{R}^N)$ given by $v(t) = \mathcal{T}(t)\psi$ is self-similar in that $\lambda^q v(\lambda^2 t, \lambda x) \equiv v(t,x)$. If we further require

$$\frac{\alpha+2}{\alpha+1} < \frac{N}{\operatorname{Re} q} < \alpha + 2,$$

then $\mathcal{T}(t)\psi \in L^{\alpha+2}(\mathbb{R}^N)$ for all $t > 0$, and so $v \in X_\alpha$. (See [4, 5, 12, 13]. This last reference shows that C^∞ can be replaced by lesser regularity.) Under the additional assumption that

$$\operatorname{Re} q > \min\Big\{\frac{N}{2}, \frac{2}{\alpha}\Big\},$$

we prove the existence of initial values and scattering states in $W_\alpha \cap H^1(\mathbb{R}^N)$ which give rise to solutions $u \in X_\alpha \cap C([0,\infty), H^1(\mathbb{R}^N))$, asymptotic as $t \to \infty$ to a linear self-similar solution of the above form. For such solutions, we are able to show that as $t \to \infty$

$$0 < a \le t^\nu \|u(t)\|_{L^{\alpha+2}} \le b < \infty$$

for certain $\nu > \beta$. We also obtain estimates on the difference $u(t) - \mathcal{T}(t)u^+$ in $L^{\alpha+2}(\mathbb{R}^N)$ and $H^1(\mathbb{R}^N)$ as $t \to \infty$. For similar results for the nonlinear heat equation, but in terms of the decay rate of $\|u(t)\|_{L^\infty}$, see Theorem 3.8 in [11].

We will have occasion to use the following property of the Schrödinger group on $\mathcal{S}'(\mathbb{R}^N)$: If $u_n \to u$ in $\mathcal{S}'(\mathbb{R}^N)$ and if $t_n \to t$, then $\mathcal{T}(t_n)u_n \to \mathcal{T}(t)u$ in $\mathcal{S}'(\mathbb{R}^N)$. Indeed, given $\theta \in \mathcal{S}(\mathbb{R}^N)$,

$$\langle \mathcal{T}(t_n)u_n, \theta\rangle_{\mathcal{S}',\mathcal{S}} = \langle u_n, \mathcal{T}(-t_n)\theta\rangle_{\mathcal{S}',\mathcal{S}} \to \langle u, \mathcal{T}(-t)\theta\rangle_{\mathcal{S}',\mathcal{S}} = \langle \mathcal{T}(t)u, \theta\rangle_{\mathcal{S}',\mathcal{S}},$$

since $u_n \to u$ in $\mathcal{S}'(\mathbb{R}^N)$ and $\mathcal{T}(-t_n)\theta \to \mathcal{T}(-t)\theta$ in $\mathcal{S}(\mathbb{R}^N)$ (see [14, Theorem 2.17, p. 52]).

2. Function spaces and preliminary estimates. In this section, we establish various estimates of the integral

$$\mathcal{G}(\tau, \sigma, t, u) = \int_\tau^\sigma \mathcal{T}(t-s)|u(s)|^\alpha u(s)\, ds. \tag{2.1}$$

Here, $\alpha > 0$, $0 \le \tau < \infty$, $0 \le \sigma \le \infty$, and $t \in \mathbb{R}$. All these estimates rely on the elementary property

$$\|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}} \le |t|^{-\frac{N\alpha}{2(\alpha+2)}}\|\varphi\|_{L^{\frac{\alpha+2}{\alpha+1}}}, \tag{2.2}$$

which holds for all $t \ne 0$ and all $\varphi \in L^{\frac{\alpha+2}{\alpha+1}}(\mathbb{R}^N)$ and

$$L^{\frac{\alpha+2}{\alpha+1}}(\mathbb{R}^N) \hookrightarrow H^{-\frac{N\alpha}{2(\alpha+2)}}, \tag{2.3}$$

which follows by duality from the Sobolev embedding $H^{\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N) \hookrightarrow L^{\alpha+2}(\mathbb{R}^N)$. We begin with a simple observation.

Lemma 2.1. *The following properties hold:*

(i) *If $u \in L^{\alpha+1}_{\mathrm{loc}}((0,\infty), L^{\alpha+2}(\mathbb{R}^N))$ and if $0 < \tau \le \sigma < \infty$, then for every $t \in \mathbb{R}$ the integral in* (2.1) *is absolutely convergent in $H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N)$ and*

$$\|\mathcal{G}(\tau,\sigma,t,u)\|_{H^{-\frac{N\alpha}{2(\alpha+2)}}} \le C\int_\tau^\sigma \|u(s)\|^{\alpha+1}_{L^{\alpha+2}}\, ds \tag{2.4}$$

for some constant $C = C(N,\alpha)$. If $u \in L^{\alpha+1}_{\mathrm{loc}}([0,\infty), L^{\alpha+2}(\mathbb{R}^N))$, then the integral is also convergent for $\tau = 0$ and the estimate (2.4) *holds.*

(ii) *Under the assumptions of* (i) *above, $\mathcal{G}(\tau,\sigma,t,u)$ depends continuously in $H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N)$ on τ,σ,t. Moreover, for all $t,t' \in \mathbb{R}$, $\mathcal{T}(t')\mathcal{G}(\tau,\sigma,t,u) = \mathcal{G}(\tau,\sigma,t+t',u)$.*

(iii) *If $u \in L^{\alpha+1}_{\mathrm{loc}}((0,\infty), L^{\alpha+2}(\mathbb{R}^N))$ and if $0 < \tau \le \sigma < \infty$, then for every $t \notin [\tau,\sigma]$ the integral in* (2.1) *is absolutely convergent in $L^{\alpha+2}(\mathbb{R}^N)$. If $u \in L^{\alpha+1}_{\mathrm{loc}}([0,\infty), L^{\alpha+2}(\mathbb{R}^N))$, then the same property holds for $\tau = 0$. If we assume that $\alpha < 4/(N-2)$ (so that $\frac{N\alpha}{2(\alpha+2)} < 1$) and that $u \in L^\infty_{\mathrm{loc}}((0,\infty), L^{\alpha+2}(\mathbb{R}^N))$, then the integral is also convergent for every $t \in [\tau,\sigma]$ such that $t+\tau > 0$.*

(iv) *If u,v both satisfy the assumptions of* (iii) *above, then*

$$\begin{aligned} &\|\mathcal{G}(\tau,\sigma,t,u) - \mathcal{G}(\tau,\sigma,t,v)\|_{L^{\alpha+2}} \\ &\quad \le C\textstyle\int_\tau^\sigma |t-s|^{-\frac{N\alpha}{2(\alpha+2)}}(\|u(s)\|^\alpha_{L^{\alpha+2}} + \|v(s)\|^\alpha_{L^{\alpha+2}})\|u(s)-v(s)\|_{L^{\alpha+2}}\, ds, \end{aligned} \tag{2.5}$$

for some constant $C = C(\alpha)$.

Proof. By (2.3), $\| |u|^\alpha u\|_{H^{-\frac{N\alpha}{2(\alpha+2)}}} \le C\|u\|_{L^{\alpha+2}}^{\alpha+1}$. Properties (i) and (ii) follow immediately, since $(\mathcal{T}(t))_{t\in\mathbb{R}}$ is a group of isometries in $H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N)$. The other properties are immediate consequences of (2.2) and Hölder's inequality. □

We next introduce the various spaces of initial values and time-dependent functions which we will use to study the Schrödinger equation (1.1). Suppose (1.2) and (1.4), so that

$$\beta(\alpha+1) < 1, \quad \frac{N\alpha}{2(\alpha+2)} < 1, \tag{2.6}$$

and

$$\frac{N\alpha}{2(\alpha+2)} + \alpha\beta = 1. \tag{2.7}$$

The spaces W_α and X_α defined by (1.5) and (1.3) with the norms

$$\|\varphi\|_{W_\alpha} = \sup_{t>0} t^\beta \|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}}, \quad \|u\|_{X_\alpha} = \sup_{t>0} t^\beta \|u(t)\|_{L^{\alpha+2}}$$

are Banach spaces. We observe that $W_\alpha = \{\varphi \in \mathcal{S}'(\mathbb{R}^N);\ \mathcal{T}(\cdot)\varphi \in X_\alpha\}$. Moreover, it is clear that for all $t \ge 0$, $\mathcal{T}(t) : W_\alpha \to W_\alpha$ with

$$\|\mathcal{T}(t)\|_{\mathcal{L}(W_\alpha)} \le 1. \tag{2.8}$$

Given α as above and $\mu \ge 0$, we also define

$$\mathcal{W}_{\alpha,\mu} = \{\varphi \in \mathcal{S}'(\mathbb{R}^N);\ \sup_{t>0} t^\mu \|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}} < \infty\} \tag{2.9}$$

and

$$\mathcal{X}_{\alpha,\mu} = \{u \in L^\infty_{\mathrm{loc}}((0,\infty), L^{\alpha+2}(\mathbb{R}^N));\ \sup_{t>0} t^\mu \|u(t)\|_{L^{\alpha+2}} < \infty\}. \tag{2.10}$$

It is clear that $\mathcal{W}_{\alpha,\mu}$ and $\mathcal{X}_{\alpha,\mu}$ are Banach spaces with the norms

$$\|\varphi\|_{\mathcal{W}_{\alpha,\mu}} = \sup_{t>0} t^\mu \|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}} \quad \text{and} \quad \|u\|_{\mathcal{X}_{\alpha,\mu}} = \sup_{t>0} t^\mu \|u(t)\|_{L^{\alpha+2}}.$$

We observe that $\mathcal{W}_{\alpha,\mu} = \{\varphi \in \mathcal{S}'(\mathbb{R}^N);\ \mathcal{T}(\cdot)\varphi \in \mathcal{X}_{\alpha,\mu}\}$. Moreover, it is clear that for all $t \ge 0$, $\mathcal{T}(t) : \mathcal{W}_{\alpha,\mu} \to \mathcal{W}_{\alpha,\mu}$ with

$$\|\mathcal{T}(t)\|_{\mathcal{L}(\mathcal{W}_{\alpha,\mu})} \le 1. \tag{2.11}$$

It is also clear that $\mathcal{W}_{\alpha,\beta} = W_\alpha$ and $\mathcal{X}_{\alpha,\beta} = X_\alpha$, where β is defined by (2.6).

Remark 2.2. Note that the definitions of W_α and $\mathcal{W}_{\alpha,\mu}$ make sense for any $\alpha > 0$. On the other hand, if $\alpha > 4/(N-2)$, then $\beta < 0$; thus $W_\alpha = \{0\}$ because $\|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}} \to 0$ as $t \downarrow 0$. Moreover, if $\alpha < \alpha_0$ then Proposition 8.1 also implies that $W_\alpha = \{0\}$. This result has been proved independently by Oru [12, Theorem V.2–5]. Furthermore, if $\mu > \frac{N\alpha}{2(\alpha+2)}$, then Proposition 8.1 implies that $\mathcal{W}_{\alpha,\mu} = \{0\}$.

We next estimate $\mathcal{G}(\tau,\sigma,t,u)$ for $u \in X_\alpha$ in the case $\sigma < \infty$.

Proposition 2.3. *If* (1.2) *and* (1.4), *then the following properties hold:*

(i) *For all* $u \in X_\alpha$ *and all* $0 \le \tau \le \sigma < \infty$ *and* $t \in \mathbb{R}$*, the integral in* (2.1) *is absolutely convergent in* $H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N)$*. If* $|t| + \tau > 0$*, it is also absolutely convergent in* $L^{\alpha+2}(\mathbb{R}^N)$*. Moreover,*

$$\mathcal{T}(t')\mathcal{G}(\tau, \sigma, t, u) = \mathcal{G}(\tau, \sigma, t' + t, u) \tag{2.12}$$

for all $0 \le \tau \le \sigma < \infty$ *and all* $t, t' \in \mathbb{R}$*. Furthermore,* $\mathcal{G}(\tau, \sigma, t, u)$ *depends continuously in* $H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N)$ *on* τ, σ, t *as above.*

(ii) *If* $u, v \in X_\alpha$ *and if* $u - v \in \mathcal{X}_{\alpha,\mu}$ *for some* $\mu \in (0, 1 - \alpha\beta)$*, then* $\mathcal{G}(\tau, \sigma, t, u) - \mathcal{G}(\tau, \sigma, t, v) \in \mathcal{W}_{\alpha,\mu}$ *for all* $\tau, \sigma, t \ge 0$*. Moreover,* $\mathcal{G}(\tau, \sigma, \cdot, u) - \mathcal{G}(\tau, \sigma, \cdot, v) \in \mathcal{X}_{\alpha,\mu}$ *and*

$$\begin{aligned} &\|\mathcal{G}(\tau, \sigma, t, u) - \mathcal{G}(\tau, \sigma, t, v)\|_{\mathcal{W}_{\alpha,\mu}} + \|\mathcal{G}(\tau, \sigma, \cdot, u) - \mathcal{G}(\tau, \sigma, \cdot, v)\|_{\mathcal{X}_{\alpha,\mu}} \\ &\qquad \le C(\|u\|^\alpha_{X_\alpha} + \|v\|^\alpha_{X_\alpha})\|u - v\|_{\mathcal{X}_{\alpha,\mu}}, \end{aligned} \tag{2.13}$$

where $C = C(N, \alpha, \mu)$*.*

Proof. By (2.6), property (i) follows from Lemma 2.1. Now let $\mu \in (0, 1 - \alpha\beta)$ and let $u, v \in X_\alpha$ be such that $u - v \in \mathcal{X}_{\alpha,\mu}$. Given $\theta \ge 0$, it follows from (2.12) that $\mathcal{T}(\theta)\mathcal{G}(\tau, \sigma, t, u) = \mathcal{G}(\tau, \sigma, \theta + t, u)$. Therefore, applying (2.5), we obtain

$$\begin{aligned} &\|\mathcal{T}(\theta)(\mathcal{G}(\tau, \sigma, t, u) - \mathcal{G}(\tau, \sigma, t, v))\|_{L^{\alpha+2}} \\ &\qquad \le C(\|u\|^\alpha_{X_\alpha} + \|v\|^\alpha_{X_\alpha})\|u - v\|_{\mathcal{X}_{\alpha,\mu}} \Big| \int_\tau^\sigma |\theta + t - s|^{-\frac{N\alpha}{2(\alpha+2)}} s^{-\alpha\beta-\mu}\, ds \Big|. \end{aligned} \tag{2.14}$$

On the other hand, we deduce from (2.7) and (2.6) that

$$\begin{aligned} \int_0^\infty |\theta + t - s|^{-\frac{N\alpha}{2(\alpha+2)}} s^{-\alpha\beta-\mu}\, ds &= (\theta + t)^{-\mu} \int_0^\infty |1 - s|^{-\frac{N\alpha}{2(\alpha+2)}} s^{-\alpha\beta-\mu}\, ds \\ &= (\theta + t)^{-\mu} C(N, \alpha, \mu). \end{aligned} \tag{2.15}$$

Property (ii) follows from (2.14) and (2.15). □

We now estimate $\mathcal{G}(\tau, \infty, t, u)$ for $u \in X_\alpha$.

Proposition 2.4. *If* (1.2) *and* (1.4)*, then the following properties hold:*

(i) *Given* $u \in X_\alpha$*, the integral in* (2.1) *with* $\sigma = \infty$ *is absolutely convergent in* $L^{\alpha+2}(\mathbb{R}^N)$ *for all* $0 \le \tau < \infty$ *and* $t \in \mathbb{R}$ *such that* $|t| + \tau > 0$*. For* $t = \tau = 0$*, it converges in* $H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N) + L^{\alpha+2}(\mathbb{R}^N)$*. Moreover,*

$$\mathcal{G}(\tau, \infty, t, u) - \mathcal{G}(\tau, \sigma, t, u) = \mathcal{G}(\sigma, \infty, t, u) \underset{\sigma \to \infty}{\longrightarrow} 0 \tag{2.16}$$

in $L^{\alpha+2}(\mathbb{R}^N)$ *for* $\tau \ge 0$ *and* $t \in \mathbb{R}$*, and*

$$\mathcal{T}(t')\mathcal{G}(\tau, \infty, t, u) = \mathcal{G}(\tau, \infty, t' + t, u) \tag{2.17}$$

for all $0 \le \tau < \infty$ *and all* $t, t' \in \mathbb{R}$*.*

(ii) *If* $u, v \in X_\alpha$ *and if* $u - v \in \mathcal{X}_{\alpha,\mu}$ *for some* $\mu \in (0, 1 - \alpha\beta)$*, then* $\mathcal{G}(\tau, \infty, t, u) - \mathcal{G}(\tau, \infty, t, v) \in \mathcal{W}_{\alpha,\mu}$ *for all* $\tau, t \ge 0$*. Moreover,* $\mathcal{G}(\tau, \infty, \cdot, u) - \mathcal{G}(\tau, \infty, \cdot, v) \in \mathcal{X}_{\alpha,\mu}$ *and*

$$\begin{aligned} &\|\mathcal{G}(\tau, \infty, t, u) - \mathcal{G}(\tau, \infty, t, v)\|_{\mathcal{W}_{\alpha,\mu}} + \|\mathcal{G}(\tau, \infty, \cdot, u) - \mathcal{G}(\tau, \infty, \cdot, v)\|_{\mathcal{X}_{\alpha,\mu}} \\ &\qquad \le C(\|u\|^\alpha_{X_\alpha} + \|v\|^\alpha_{X_\alpha})\|u - v\|_{\mathcal{X}_{\alpha,\mu}}, \end{aligned} \tag{2.18}$$

where $C = C(N, \alpha, \mu)$*.*

(iii) *If* $u, v \in X_\alpha$ *and if* $u - v \in \mathcal{X}_{\alpha,\mu}$ *for some* $\mu > 0$*, then*

$$\|\mathcal{G}(\,\cdot\,, \infty, \,\cdot\,, u) - \mathcal{G}(\,\cdot\,, \infty, \,\cdot\,, v)\|_{\mathcal{X}_{\alpha,\mu}} \le C(\|u\|^\alpha_{X_\alpha} + \|v\|^\alpha_{X_\alpha})\|u - v\|_{\mathcal{X}_{\alpha,\mu}}, \tag{2.19}$$

where $C = C(N, \alpha, \mu)$.

Proof. Let $u \in X_\alpha$. We first observe that

$$\begin{aligned}(2.20)\qquad &\|\mathcal{T}(t-s)|u(s)|^\alpha u(s)\|_{L^{\alpha+2}} \\ &\quad \le |t-s|^{-\frac{N\alpha}{2(\alpha+2)}}\|u(s)\|_{L^{\alpha+2}}^{\alpha+1} \le |t-s|^{-\frac{N\alpha}{2(\alpha+2)}} s^{-\alpha\beta-\beta}\|u\|_{X_\alpha}^{\alpha+1}.\end{aligned}$$

It follows from (2.7) that $\|\mathcal{T}(t-s)|u(s)|^\alpha u(s)\|_{L^{\alpha+2}}$ is integrable as $s \to \infty$. The other singularities are $|t-s|^{-\frac{N\alpha}{2(\alpha+2)}}$ at $s = t$ and $s^{-\alpha\beta-\beta}$ at $s = 0$. By (2.6) both are integrable provided $t \neq 0$. Thus we see that the integral in (2.1) is absolutely convergent in $L^{\alpha+2}(\mathbb{R}^N)$ for all $0 \le \tau < \infty$ and $t \in \mathbb{R}$ such that $|t| + \tau > 0$. For $t = \tau = 0$, we write

$$\int_0^\infty \mathcal{T}(-s)|u(s)|^\alpha u(s)\,ds = \int_0^1 \mathcal{T}(-s)|u(s)|^\alpha u(s)\,ds + \int_1^\infty \mathcal{T}(-s)|u(s)|^\alpha u(s)\,ds.$$

The second integral on the right-hand side is absolutely convergent in $L^{\alpha+2}(\mathbb{R}^N)$ by the previous argument, and the first one is absolutely convergent in $H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N)$ by Proposition 2.3 (i). This proves the first part of (i), and (2.16) is an immediate consequence. To prove (2.17), we observe that on the one hand,

$$\mathcal{T}(t')\mathcal{G}(\tau,\sigma,t,u) \underset{\sigma\to\infty}{\longrightarrow} \mathcal{T}(t')\mathcal{G}(\tau,\infty,t,u)$$

in $\mathcal{S}'(\mathbb{R}^N)$ by (2.16). On the other hand, by (2.12) and (2.16),

$$\mathcal{T}(t')\mathcal{G}(\tau,\sigma,t,u) = \mathcal{G}(\tau,\sigma,t'+t,u) \underset{\sigma\to\infty}{\longrightarrow} \mathcal{G}(\tau,\infty,t'+t,u)$$

in $\mathcal{S}'(\mathbb{R}^N)$.

Turning now to (ii), we let $u, v \in X_\alpha$ be such that $u - v \in \mathcal{X}_{\alpha,\mu}$ for some $\mu \in (0, 1-\alpha\beta)$. By (2.17) and (2.16), we may let $\sigma \to \infty$ in (2.13) and we obtain (2.18).

Finally, let $u, v \in X_\alpha$ be such that $u - v \in \mathcal{X}_{\alpha,\mu}$ for some $\mu > 0$. It follows from (2.2) and Hölder's inequality that

$$\begin{aligned}&\|\mathcal{G}(t,\infty,t,u) - \mathcal{G}(t,\infty,t,v)\|_{L^{\alpha+2}} \\ &\qquad \le C(\|u\|_{X_\alpha}^\alpha + \|v\|_{X_\alpha}^\alpha)\|u-v\|_{\mathcal{X}_{\alpha,\mu}} \int_t^\infty |t-s|^{-\frac{N\alpha}{2(\alpha+2)}} s^{-\alpha\beta-\mu}\,ds \\ &\qquad = Ct^{-\mu}(\|u\|_{X_\alpha}^\alpha + \|v\|_{X_\alpha}^\alpha)\|u-v\|_{\mathcal{X}_{\alpha,\mu}} \int_1^\infty |1-s|^{-\frac{N\alpha}{2(\alpha+2)}} s^{-\alpha\beta-\mu}\,ds.\end{aligned}$$

This proves property (iii). □

3. Mild solutions of the nonlinear Schrödinger equation in $L^{\alpha+2}(\mathbb{R}^N)$.

Throughout this paper, we consider solutions of (1.1) in the following sense.

Definition 3.1. *Given* $u \in L^\infty_{\mathrm{loc}}((0,\infty), L^{\alpha+2}(\mathbb{R}^N))$, *we say that* u *is a solution of* (1.1) *if*

$$(3.1)\qquad u(t) = \mathcal{T}(t-\tau)u(\tau) - i\gamma\int_\tau^t \mathcal{T}(t-s)|u(s)|^\alpha u(s)\,ds$$

for all $t, \tau > 0$.

Remark 3.2. At first sight, it seems that Definition 3.1 does not make sense since u is only defined almost everywhere; and so (3.1) could only be required to hold for almost all $t, \tau > 0$. One can show, however, that if $u \in L^\infty_{\text{loc}}((0,\infty), L^{\alpha+2}(\mathbb{R}^N))$ satisfies (3.1) for almost all $t, \tau > 0$, then u can be modified on a set of measure 0 in t so that $u \in C((0,\infty), \mathcal{S}'(\mathbb{R}^N))$ and satisfies (3.1) for all $t, \tau > 0$. Indeed, given any $\tau > 0$, it follows from Lemma 2.1 that the right-hand side of (3.1) is a continuous function of $t > 0$ with values in $\mathcal{S}'(\mathbb{R}^N)$. Fix $\tau_0 > 0$ such that (3.1) holds for almost all $t > 0$ and redefine u to be equal everywhere to the right-hand side of (3.1) with $\tau = \tau_0$. Given now any $t, \tau > 0$, using (3.1) with (τ, t) replaced successively by (τ_0, τ) and (τ_0, t), we see that u satisfies (3.1) at (t, τ). It is understood that we always consider this continuous representative of the solution u.

Proposition 3.3. *Suppose* (1.2) *and* (1.4). *If $u \in X_\alpha$ is a solution of* (1.1), *then the following properties hold:*

(i) *$u(t) \in W_\alpha$ for all $t > 0$ and $\sup_{t>0} \|u(t)\|_{W_\alpha} \le \|u\|_{X_\alpha} + C\|u\|_{X_\alpha}^{\alpha+1}$.*

(ii) *$\mathcal{T}(-t)u(t) \in W_\alpha$ for all $t > 0$ and $\sup_{t>0} \|\mathcal{T}(-t)u(t)\|_{W_\alpha} \le \|u\|_{X_\alpha} + C\|u\|_{X_\alpha}^{\alpha+1}$.*

(iii) *There exists $\varphi \in W_\alpha$ such that $u(t) \to \varphi$ as $t \downarrow 0$ in $\mathcal{S}'(\mathbb{R}^N)$ and*

$$u(t) = \mathcal{T}(t)\varphi - i\gamma \int_0^t \mathcal{T}(t-s)|u(s)|^\alpha u(s)\, ds \tag{3.2}$$

for all $t \ge 0$. The integral in (3.2) *makes sense in $H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N)$. Furthermore,*

$$\|u(t) - \mathcal{T}(t)\varphi\|_{H^{-\frac{N\alpha}{2(\alpha+2)}}} \le Ct^{1-\beta(\alpha+1)}\|u\|_{X_\alpha}^{\alpha+1} \tag{3.3}$$

for all $t \ge 0$. Moreover, $u : [0,\infty) \to \mathcal{S}'(\mathbb{R}^N)$ is continuous and $u : (0,\infty) \to L^{\alpha+2}(\mathbb{R}^N)$ is weakly continuous.

(iv) *There exists $u^+ \in W_\alpha$ such that $\mathcal{T}(-t)u(t) \to u^+$ as $t \to \infty$ in $\mathcal{S}'(\mathbb{R}^N)$ and equation*

$$\mathcal{T}(\tau - t)u(t) = \mathcal{T}(\tau)u^+ + i\gamma \int_t^\infty \mathcal{T}(\tau - s)|u(s)|^\alpha u(s)\, ds \tag{3.4}$$

holds for all $t, \tau \ge 0$. If $t + \tau > 0$, the integral in (3.4) *makes sense in $L^{\alpha+2}(\mathbb{R}^N)$. (If $t = \tau = 0$, the integral makes sense in $L^{\alpha+2}(\mathbb{R}^N) + H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N)$.) Finally,*

$$\|\mathcal{T}(-t)u(t) - u^+\|_{L^{\alpha+2}} \le Ct^{-\beta}\|u\|_{X_\alpha}^{\alpha+1} \tag{3.5}$$

for all $t > 0$.

Proof. We begin by showing statement (ii). It follows from (3.1) that

$$\mathcal{T}(t-\tau)u(\tau) = u(t) + i\gamma \int_\tau^t \mathcal{T}(t-s)|u(s)|^\alpha u(s)\, ds. \tag{3.6}$$

Consider a fixed $\tau > 0$. It follows from (3.6) and (2.13) applied with $v = 0$, $\sigma = t$, and $\mu = \beta$ that

$$\|\mathcal{T}(\cdot - \tau)u(\tau)\|_{X_\alpha} \le \|u\|_{X_\alpha} + \gamma\|\mathcal{G}(\tau, \cdot, \cdot, u)\|_{X_\alpha} \le \|u\|_{X_\alpha}(1 + C\|u\|_{X_\alpha}^\alpha).$$

Since $\|\mathcal{T}(\cdot - \tau)u(\tau)\|_{X_\alpha} = \|\mathcal{T}(-\tau)u(\tau)\|_{W_\alpha}$, we deduce statement (ii). Property (i) follows from property (ii) and (2.8).

We turn to property (iii). We deduce from (3.1) and (2.12) that

$$\mathcal{T}(-t)u(t) - \mathcal{T}(-\tau)u(\tau) = -i\gamma \int_\tau^t \mathcal{T}(-s)|u(s)|^\alpha u(s)\, ds. \tag{3.7}$$

Next, we let $\tau \downarrow 0$. The right-hand side converges to an element of $H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N)$ by Lemma 2.1. Since $\mathcal{T}(-t)u(t)$ is a fixed element of $\mathcal{S}'(\mathbb{R}^N)$, we see that there exists $\varphi \in \mathcal{S}'(\mathbb{R}^N)$ such that $\mathcal{T}(-\tau)u(\tau) \to \varphi$ in $\varphi \in \mathcal{S}'(\mathbb{R}^N)$ as $\tau \downarrow 0$. This implies that $u(\tau) \to \varphi$ in $\varphi \in \mathcal{S}'(\mathbb{R}^N)$ as $\tau \downarrow 0$. We then find

$$\mathcal{T}(-t)u(t) = \varphi - i\gamma \int_0^t \mathcal{T}(-s)|u(s)|^\alpha u(s)\, ds \tag{3.8}$$

for all $t \geq 0$. We may then apply $\mathcal{T}(t)$ and we obtain (3.2). Here again, the right-hand side makes sense in $H^{-\frac{N\alpha}{2(\alpha+2)}}(\mathbb{R}^N)$. Furthermore, it follows from (2.4) that

$$\|u(t) - \mathcal{T}(t)\varphi\|_{H^{-\frac{N\alpha}{2(\alpha+2)}}} \leq C\|u\|_{X_\alpha}^{\alpha+1} \int_0^t s^{-(\alpha+1)\beta}\, ds,$$

and the estimate (3.3) follows. Using (3.2) and the estimate (2.13) with $\tau = 0$, $\sigma = t$, $\mu = \beta$, and $v = 0$, we see that $\varphi \in W_\alpha$ and $\|\varphi\|_{W_\alpha} \leq \|u\|_{W_\alpha} + C\|u\|_{W_\alpha}^{\alpha+1}$. Since $\mathcal{T}(\cdot)\varphi : [0,\infty) \to \mathcal{S}'(\mathbb{R}^N)$ is continuous, it follows from Proposition 2.3 (i) that $u : [0,\infty) \to \mathcal{S}'(\mathbb{R}^N)$ is continuous, and this proves (iii).

We now construct u^+. We fix $\tau > 0$ and we let $t \to \infty$ in (3.7). It follows from (2.16) that the right-hand side of (3.7) converges to $-i\gamma\mathcal{G}(\tau, \infty, 0, u)$ in $L^{\alpha+2}(\mathbb{R}^N)$ as $t \to \infty$, and thus $\mathcal{T}(-t)u(t)$ converges in $\mathcal{S}'(\mathbb{R}^N)$ to a limit that we call u^+. Thus we obtain (3.4) with $\tau = 0$. The general case of (3.4) now follows from applying $\mathcal{T}(\tau)$ (which is possible by (2.17)). It follows from (3.4) applied with $\tau = 0$ and Proposition 2.4 (ii) that $u^+ \in W_\alpha$. Finally, since

$$\begin{aligned} &\Big\|\int_t^\infty \mathcal{T}(-s)|u(s)|^\alpha u(s)\, ds\Big\|_{L^{\alpha+2}} \\ &\qquad \leq C\|u\|_{X_\alpha}^{\alpha+1} \int_t^\infty s^{-\frac{N\alpha}{2(\alpha+2)}} s^{-\beta(\alpha+1)}\, ds \leq C\|u\|_{X_\alpha}^{\alpha+1} t^{-\beta}, \end{aligned} \tag{3.9}$$

we obtain (3.5). This proves (iv). □

REMARK 3.4. It follows from (2.13) and (2.18) that φ and u^+ depend continuously on u. More precisely, given two solutions u_1 and u_2 of (1.1),

$$\|\varphi_1 - \varphi_2\|_{W_\alpha} + \|u_1^+ - u_2^+\|_{W_\alpha} \leq \|u_1 - u_2\|_{X_\alpha} + C(\|u_1\|_{X_\alpha}^\alpha + \|u_2\|_{X_\alpha}^\alpha)\|u_1 - u_2\|_{X_\alpha}, \tag{3.10}$$

where φ_j and u_j^+ are the corresponding initial values and scattering states.

REMARK 3.5. In principle, we could have considered solutions of (1.1) in X_α without requiring $\alpha > \alpha_0$. It is not too hard to check that Proposition 3.3 would still be true, except for the construction of the initial value φ. The reason for this is that the condition $\beta(\alpha + 1) < 1$ is needed only for the convergence of integrals at 0. In particular, $u^+ \in W_\alpha$ and $u(t) \in W_\alpha$ for all $t > 0$. On the other hand, if $\alpha < \alpha_0$, then $W_\alpha = \{0\}$ by Remark 2.2. Thus, if $\alpha < \alpha_0$ then (1.1) has no nontrivial solutions in X_α and in particular no nontrivial self-similar solutions with profile in $L^{\alpha+2}(\mathbb{R}^N)$.

PROPOSITION 3.6. *Suppose* (1.2) *and* (1.4) *and let* $\mu > 0$. *If* $u_1, u_2 \in X_\alpha$ *are two solutions of* (1.1) *with initial values* $\varphi_1, \varphi_2 \in W_\alpha$ *and scattering states* $u_1^+, u_2^+ \in W_\alpha$, *respectively, and if in addition* $u_1 - u_2 \in \mathcal{X}_{\alpha,\mu}$, *then* $u_1^+ - u_2^+ \in \mathcal{W}_{\alpha,\mu}$ *and*

$$\|u_1^+ - u_2^+\|_{\mathcal{W}_{\alpha,\mu}} \leq \|u_1 - u_2\|_{\mathcal{X}_{\alpha,\mu}} + C(\|u_1\|_{X_\alpha}^\alpha + \|u_2\|_{X_\alpha}^\alpha)\|u_1 - u_2\|_{\mathcal{X}_{\alpha,\mu}} \tag{3.11}$$

for some constant C *independent of* u_1 *and* u_2. *If, furthermore,* $\alpha\beta + \mu < 1$, *then* $\varphi_1 - \varphi_2 \in \mathcal{W}_{\alpha,\mu}$ *and* $u_1(t) - u_2(t) \in \mathcal{W}_{\alpha,\mu}$ *for all* $t > 0$, *and*

$$\begin{aligned} &\max\{\|\varphi_1 - \varphi_2\|_{\mathcal{W}_{\alpha,\mu}}, \sup_{t>0} \|u_1(t) - u_2(t)\|_{\mathcal{W}_{\alpha,\mu}}\} \\ &\qquad \leq \|u_1 - u_2\|_{\mathcal{X}_{\alpha,\mu}} + C(\|u_1\|_{X_\alpha}^\alpha + \|u_2\|_{X_\alpha}^\alpha)\|u_1 - u_2\|_{\mathcal{X}_{\alpha,\mu}} \end{aligned} \tag{3.12}$$

for some constant C independent of u_1 and u_2.

Proof. It follows from (3.4) with $\tau = t$ that

$$\mathcal{T}(t)(u_1^+ - u_2^+) = u_1(t) - u_2(t) - i\gamma(\mathcal{G}(t,\infty,t,u_1) - \mathcal{G}(t,\infty,t,u_2)),$$

so (3.11) follows from (2.19). Next, assume $\alpha\beta + \mu < 1$ and consider (3.4) with a fixed value of $t > 0$, i.e.,

$$\mathcal{T}(\cdot)\mathcal{T}(-t)(u_1(t) - u_2(t)) = \mathcal{T}(\cdot)(u_1^+ - u_2^+) + i\gamma(\mathcal{G}(t,\infty,\cdot,u_1) - \mathcal{G}(t,\infty,\cdot,u_2)).$$

It follows from (3.11) and (2.18) that

$$\|\mathcal{T}(-t)(u_1(t) - u_2(t))\|_{\mathcal{W}_{\alpha,\mu}} \le \|u_1 - u_2\|_{\mathcal{X}_{\alpha,\mu}} + C(\|u_1\|_{X_\alpha}^\alpha + \|u_2\|_{X_\alpha}^\alpha)\|u_1 - u_2\|_{\mathcal{X}_{\alpha,\mu}}.$$

We deduce the second estimate in (3.12) by applying (2.11). Next, it follows from (3.2) that $\mathcal{T}(t)(\varphi_1 - \varphi_2) = u_1(t) - u_2(t) + i\gamma(\mathcal{G}(0,t,t,u_1) - \mathcal{G}(0,t,t,u_2))$; and so the first estimate in (3.12) is a consequence of (2.13). □

PROPOSITION 3.7. *Suppose* (1.2) *and* (1.4). *Let $u \in X_\alpha$ be a solution of* (1.1) *with initial value $\varphi \in W_\alpha$ and scattering state $u^+ \in W_\alpha$. If $u \in \mathcal{X}_{\alpha,\mu}$ for some $\mu > \beta$, then the following properties hold:*

(i) $t^\mu \|u(t) - \mathcal{T}(t)u^+\|_{L^{\alpha+2}} \le C\|u\|_{\mathcal{X}_{\alpha,\mu}}^{\alpha+1} t^{-\alpha(\mu-\beta)}$ *for all $t > 0$.*

(ii) $t^\mu \|u(t) - \mathcal{T}(t)\varphi\|_{L^{\alpha+2}} \le C\|u\|_{\mathcal{X}_{\alpha,\mu}}^{\alpha+1} t^{-\alpha(\mu-\beta)}$ *for all $t > 0$, provided $(\alpha+1)\mu < 1$.*

(iii) $t^\mu \|\mathcal{T}(-t)u(t) - u^+\|_{L^{\alpha+2}} \le C\|u\|_{\mathcal{X}_{\alpha,\mu}}^{\alpha+1} t^{-\alpha(\mu-\beta)}$ *for all $t > 0$.*

(iv) $\|\mathcal{T}(-t)u(t) - u^+\|_{H^{-\frac{N\alpha}{2(\alpha+2)}}} \le C\|u\|_{\mathcal{X}_{\alpha,\mu}}^{\alpha+1} t^{1-(\alpha+1)\mu}$ *for all $t > 0$, provided $(\alpha + 1)\mu > 1$.*

(v) $t^\mu \|\mathcal{T}(t)(\varphi - u^+)\|_{L^{\alpha+2}} \le C\|u\|_{\mathcal{X}_{\alpha,\mu}}^{\alpha+1} t^{-\alpha(\mu-\beta)}$ *for all $t > 0$, provided $(\alpha + 1)\mu < 1$.*

Proof. All these results follow from the various integral equations, where in the integral term $\|u(s)\|_{L^{\alpha+2}}$ is always estimated by $s^{-\mu}\|u\|_{\mathcal{X}_{\alpha,\mu}}$. □

PROPOSITION 3.8. *Suppose* (1.2) *and* (1.4). *Let $u \in X_\alpha$ be a solution of* (1.1) *with scattering state $u^+ \in W_\alpha$. If $u \in \mathcal{X}_{\alpha,\mu}$ for some $\mu > \beta$ and if $u^+ = 0$, then $u(t) \equiv 0$.*

Proof. We apply (3.4) with $\tau = t$ and we deduce that

$$\|u(t)\|_{L^{\alpha+2}} \le C \int_t^\infty (s-t)^{-\frac{N\alpha}{2(\alpha+2)}} \|u(s)\|_{L^{\alpha+2}}^{\alpha+1}\, ds;$$

and so, setting $f(t) = \sup_{s \ge t} \|u(s)\|_{L^{\alpha+2}}$,

$$\|u(t)\|_{L^{\alpha+2}} \le Cf(t) \int_t^\infty (s-t)^{-\frac{N\alpha}{2(\alpha+2)}} s^{-\mu\alpha}\, ds = Cf(t)t^{-\alpha(\mu-\beta)} \tag{3.13}$$

by (2.7). Since the right-hand side of (3.13) is nonincreasing, we see that $f(t) \le Cf(t)t^{-\alpha(\mu-\beta)}$. Thus $f(t) = 0$ for t sufficiently large. Fix now t_0 large enough so that $u(t) = 0$ for $t \ge t_0$. We deduce from (3.6) that

$$u(t) = i\gamma \int_t^{t_0} \mathcal{T}(t-s)|u(s)|^\alpha u(s)\, ds \tag{3.14}$$

for all $t \ge 0$. Fix $0 < \varepsilon < t_0$. Since $\sup_{\varepsilon \le s \le t_0} \|u(s)\|_{L^{\alpha+2}} < \infty$, we deduce from (3.14) that

$$\|u(t)\|_{L^{\alpha+2}} \le C \int_t^{t_0} |t-s|^{-\frac{N\alpha}{2(\alpha+2)}} \|u(s)\|_{L^{\alpha+2}}\, ds$$

for $\varepsilon \le t \le t_0$, and by a singular Gronwall-type argument, $u(t) = 0$ for all $\varepsilon \le t \le t_0$. The result follows by letting $\varepsilon \downarrow 0$. □

COROLLARY 3.9. *Suppose* (1.2) *and* (1.4). *If* $\mu > \frac{N\alpha}{2(\alpha+2)}$ *and if* u *is a solution of* (1.1) *in* $X_\alpha \cap \mathcal{X}_{\alpha,\mu}$, *then* $u \equiv 0$.

Proof. By Proposition 3.6, $u^+ \in \mathcal{W}_{\alpha,\mu}$. Since $\mathcal{W}_{\alpha,\mu} = \{0\}$ by Remark 2.2, the result follows from Proposition 3.8. □

We conclude this section by considering solutions of (1.1) that are both in X_α and $H^1(\mathbb{R}^N)$.

PROPOSITION 3.10. *Suppose* (1.2) *and* (1.4) *and let* $u \in X_\alpha$ *be a solution of* (1.1) *in the sense of Definition* 3.1 *with scattering state* u^+. *If* $u(t_0) \in H^1(\mathbb{R}^N)$ *for some* $t_0 > 0$, *then the following properties hold:*

(i) $u(t) \in H^1(\mathbb{R}^N)$ *for all* $t > 0$ *and* u *is the "classical"* H^1 *solution determined by* $u(t_0)$.

(ii) $u^+ \in H^1(\mathbb{R}^N)$.

(iii) *If* $\alpha > 4/N$, *or if* $\alpha = 4/N$ *and* $\|u(t_0)\|_{H^1}$ *is sufficiently small, then* $\mathcal{T}(-t)u(t) \to u^+$ *in* $H^1(\mathbb{R}^N)$ *as* $t \to \infty$ *and* $\|u(t) - \mathcal{T}(t)u^+\|_{H^1} \le Ct^{-\beta(\alpha+2)\frac{N\alpha-4}{N\alpha}}$.

(iv) *If* $u \in \mathcal{X}_{\alpha,\mu}$ *for some* $\mu > \beta$, *then* $\mathcal{T}(-t)u(t) \to u^+$ *in* $H^1(\mathbb{R}^N)$ *as* $t \to \infty$ *and* $\|u(t) - \mathcal{T}(t)u^+\|_{H^1} \le Ct^{-\alpha(\mu-\beta)}$.

Proof. Let v be the H^1 solution of (1.1) with the initial value $v(t_0) = u(t_0)$, which is defined on the maximal interval $(t_0 - T_*, t_0 + T^*)$. It follows that

$$u(t) - v(t) = -i\mathcal{G}(t_0, t, t, u) + i\mathcal{G}(t_0, t, t, v)$$

for $t_0 < t < t_0 + T^*$. By applying (2.5), we deduce that

$$\begin{aligned} &\|u(t) - v(t)\|_{L^{\alpha+2}} \\ &\quad \le C \sup_{t_0 \le s \le t} (\|u(s)\|_{L^{\alpha+2}} + \|v(s)\|_{L^{\alpha+2}})^\alpha \int_{t_0}^t |t-s|^{-\frac{N\alpha}{2(\alpha+2)}} \|u(s) - v(s)\|_{L^{\alpha+2}}\, ds. \end{aligned}$$

It now follows from a singular Gronwall argument that $u(t) = v(t)$ for $t_0 \le t < t_0 + T^*$. Since $\sup_{t \ge t_0} \|u(t)\|_{L^{\alpha+2}} < \infty$, it follows from conservation of energy that $\sup_{t_0 \le t < t_0 + T^*} \|u(t)\|_{H^1} < \infty$, so that $T^* = \infty$. For $t_0 - T_* < t < t_0$, we have $u(t) - v(t) = i\mathcal{G}(t, t_0, t, u) + i\mathcal{G}(t, t_0, t, v)$ and a similar argument shows that $T_* \ge t_0$ and that $v(t) = u(t)$ for all $0 < t < t_0$. This proves (i).

We now observe that $\|u(t)\|_{L^{\alpha+2}}$ is bounded as $t \to \infty$. By conservation of energy, this implies that $\|u(t)\|_{H^1}$ is bounded as $t \to \infty$. Thus $\|\mathcal{T}(-t)u(t)\|_{H^1}$ is bounded, which implies that $u^+ \in H^1(\mathbb{R}^N)$. Hence (ii).

Next, we prove (iii). When $\gamma \ge 0$ and $\alpha > 4/N$, the result follows from [6]; and when $\alpha \ge 4/N$ with $\|u(t_0)\|_{H^1}$ small, the result follows from [8]. Regardless of the sign of γ, it is known that if $u \in C((0,\infty), H^1(\mathbb{R}^N))$ is a solution of (1.1) such that $\|u(t)\|_{L^{\alpha+2}} \to 0$ as $t \to \infty$ and if $4/N < \alpha < 4/(N-2)$ (or if $\alpha = 4/N$ and $\|u(t_0)\|_{H^1}$ is small for some $t_0 \ge 0$), then $\mathcal{T}(-t)u(t)$ has a limit in $H^1(\mathbb{R}^N)$ as $t \to \infty$. We give the proof of this last property for completeness. We first show that

$$u \in L^q((1,\infty), W^{1,r}(\mathbb{R}^N)) \tag{3.15}$$

with $r = \alpha + 2$ and $q = 4(\alpha+2)/N\alpha$. First observe that $u \in L^q_{\text{loc}}((0,\infty), W^{1,r}(\mathbb{R}^N))$ (see [1, Theorem 5.3.1 and Remark 5.3.5]). Fix now $S > 0$ to be chosen large enough. It follows from (3.1) that

$$u(t+S) = \mathcal{T}(t)u(S) - i\gamma \int_0^t \mathcal{T}(t-s)(|u|^\alpha u)(s+S)\, ds.$$

It follows from Strichartz' estimate (see, e.g., [1, Theorem 3.2.5]) that

$$\|u\|_{L^q((S,T),W^{1,r})} \le C\|u(S)\|_{H^1} + C\| \, |u|^\alpha u\|_{L^{q'}((S,T),W^{1,r'})}$$

for all $S < T < \infty$, where C is independent of S and T. On the other hand, it follows from Hölder's inequality that

$$\| \, |u|^\alpha u\|_{L^{q'}((S,T),W^{1,r'})} \le C(\sup_{t\ge S} \|u(t)\|_{L^{\alpha+2}})^{\left(1-\frac{4}{N\alpha}\right)(\alpha+2)} \|u\|^{1+\frac{2(4-(N-2)\alpha)}{N\alpha}}_{L^q((S,T),W^{1,r})}. \tag{3.16}$$

Since by conservation of energy $\|u(S)\|_{H^1}^2 \to \|u(t_0)\|_{L^2}^2 + 2E(u(t_0))$ as $S \to \infty$, we deduce from the above inequalities that there exists C, independent of S large and $T > S$, such that

$$\begin{aligned}\|u\|_{L^q((S,T),W^{1,r})} \le C(\|u(t_0)\|_{L^2}^2 + 2E(u(t_0)))^{\frac12}& \\ +C(\sup_{t\ge S} \|u(t)\|_{L^{\alpha+2}})^{\left(1-\frac{4}{N\alpha}\right)(\alpha+2)} &\|u\|^{1+\frac{2(4-(N-2)\alpha)}{N\alpha}}_{L^q((S,T),W^{1,r})}.\end{aligned}$$

It follows, either by choosing S large enough if $\alpha > 4/N$, or by assuming $\|u(t_0)\|_{H^1}$ small enough if $\alpha = 4/N$, that

$$\|u\|_{L^q((S,T),W^{1,r})} \le C,$$

independent of $T > S$. We obtain (3.15) by letting $T \to \infty$. We now set $v(t) = \mathcal{T}(-t)u(t)$ and we observe that

$$v(\tau) - v(t) = -i\gamma \int_t^\tau \mathcal{T}(-s)(|u|^\alpha u)(s)\, ds$$

for all $0 < t < \tau < \infty$. Applying Strichartz' estimate, (3.16), and (3.15), we obtain that

$$\begin{aligned}\|v(\tau) - v(t)\|_{H^1} &\le C\| \, |u|^\alpha u\|_{L^{q'}((t,\tau),W^{1,r'})} \\ &\le C(\sup_{s\ge t} \|u(s)\|_{L^{\alpha+2}})^{\left(1-\frac{4}{N\alpha}\right)(\alpha+2)} \|u\|^{1+\frac{2(4-(N-2)\alpha)}{N\alpha}}_{L^q((t,\infty),W^{1,r})} \\ &\le Ct^{-\beta(\alpha+2)\frac{N\alpha-4}{N\alpha}},\end{aligned}$$

and (iii) follows. (If $\alpha = 4/N$, note that $\|u\|_{L^q((t,\infty),W^{1,r})} \to 0$ as $t \to \infty$.)

Finally, we prove (iv). The proof follows the same outline as for part (iii), except that instead of (3.16) we use the inequality

$$\| \, |u|^\alpha u\|_{L^{q'}((S,T),W^{1,r'})} \le C\|u\|^\alpha_{L^{\frac{1}{\beta}}((S,T),L^{\alpha+2})} \|u\|_{L^q((S,T),W^{1,r})}, \tag{3.17}$$

and we observe that

$$\|u\|_{L^{\frac{1}{\beta}}((S,T),L^{\alpha+2})} \le \Big(\frac{\beta}{\mu-\beta}\Big)^\beta S^{-(\mu-\beta)} \|u\|_{\mathcal{X}_{\alpha,\mu}}. \tag{3.18}$$

This completes the proof. □

Remark 3.11. As is well known, an H^1 scattering theory (global when $\gamma \ge 0$ and "low energy" when $\gamma < 0$) was developed by Ginibre and Velo [6].

Remark 3.12. The previous proof shows that (3.15) under the hypotheses of Proposition 3.10 (iii). It follows that $\liminf_{t\to\infty} t^{\frac{N\alpha}{4(\alpha+2)}}\|u(t)\|_{L^{\alpha+2}} = 0$, and in particular $\liminf_{t\to\infty} t^{\beta}\|u(t)\|_{L^{\alpha+2}} = 0$.

Proposition 3.13. *Suppose* $4/N < \alpha < 4/(N-2)$ *and let* $u \in X_\alpha$ *be a solution of* (1.1) *with initial value* φ. *If* $u(t) \in H^1(\mathbb{R}^N)$ *for all* $t > 0$ *and* $\varphi = 0$, *then* $u(t) \equiv 0$.

Proof. By standard interpolation,

$$\|u(t)\|_{L^2} \le C\|u(t)\|^{\theta}_{H^{-\frac{N\alpha}{2(\alpha+2)}}}\|u(t)\|^{1-\theta}_{H^1}$$

with $\theta\frac{N\alpha}{2(\alpha+2)} = 1-\theta$. Using formula (3.3) and conservation of charge and energy, we deduce that

$$\begin{aligned}\|u(t)\|_{L^2} &\le Ct^{\theta(1-\beta(\alpha+1))} + Ct^{\theta(1-\beta(\alpha+1))}\|u(t)\|^{(1-\theta)\frac{\alpha+2}{2}}_{L^{\alpha+2}}\\ &\le Ct^{\theta(1-\beta(\alpha+1))} + Ct^{\theta(1-\beta(\alpha+1))-\beta(1-\theta)\frac{\alpha+2}{2}}.\end{aligned}$$

Since $\alpha > 4/N$, the powers of t are positive, which contradicts the conservation of charge as $t \downarrow 0$. □

4. Pseudoconformally equivalent solutions. In this paragraph, we consider solutions v of a nonautonomous nonlinear Schrödinger equation obtained from (1.1) by the pseudoconformal transformation. In particular, we give an explicit relationship between the scattering state u^+ and the initial value $v(0)$.

For the rest of this section, we assume that $u, v \in L^\infty_{\text{loc}}((0,\infty), L^{\alpha+2}(\mathbb{R}^N))$ are related by the following formula:

$$v(s,y) = s^{-\frac{N}{2}}e^{i\frac{|y|^2}{4s}}\overline{u}\Big(\frac{1}{s},\frac{y}{s}\Big) = t^{\frac{N}{2}}e^{i\frac{|x|^2}{4t}}\overline{u}(t,x), \tag{4.1}$$

where $s, t > 0$, $x, y \in \mathbb{R}^N$ with $s = 1/t$ and $x = y/s = ty$. It follows (see Lemma 5.9 of [4]) that u is a solution of (1.1) in the sense of Definition 3.1 if and only if v is a solution of

$$v(s) = \mathcal{T}(s-\sigma)v(\sigma) - i\gamma\int_\sigma^s \mathcal{T}(s-\theta)\theta^{\frac{N\alpha-4}{2}}|v(\theta)|^\alpha v(\theta)\,d\theta \tag{4.2}$$

for all $0 < \sigma \le s < \infty$. Moreover, an elementary calculation shows that

$$t^{\beta}\|u(t)\|_{L^{\alpha+2}} = s^{\delta}\|v(s)\|_{L^{\alpha+2}}, \tag{4.3}$$

where

$$\delta = \frac{N\alpha^2 + (N-2)\alpha - 4}{2\alpha(\alpha+2)}. \tag{4.4}$$

In particular, $u \in X_\alpha$ if and only if $v \in \mathcal{X}_{\alpha,\delta}$. More generally,

$$t^{\mu}\|u(t)\|_{L^{\alpha+2}} = s^{\frac{N\alpha}{2(\alpha+2)}-\mu}\|v(s)\|_{L^{\alpha+2}} \tag{4.5}$$

for all $\mu \in \mathbb{R}$.

Proposition 4.1. *Suppose* (1.4). *Let* $v \in \mathcal{X}_{\alpha,\delta}$ *be a solution of* (4.2). *It follows that there exists* $\psi \in \mathcal{W}_{\alpha,\delta}$ *such that* $v(s) \to \psi$ *in* $\mathcal{S}'(\mathbb{R}^N)$ *as* $s \downarrow 0$ *and* v *satisfies*

$$v(s) = \mathcal{T}(s)\psi - i\gamma\int_0^s \mathcal{T}(s-\theta)\theta^{\frac{N\alpha-4}{2}}|v(\theta)|^\alpha v(\theta)\,d\theta \tag{4.6}$$

for all $s > 0$. *Moreover,*

$$\mathcal{F}\psi = i^{\frac{N}{2}} D_{4\pi}\overline{u^+}, \tag{4.7}$$

where $\mathcal{F}$ *denotes the Fourier transform*

$$\mathcal{F}\phi(x) = \int_{\mathbb{R}^N} e^{-2\pi i x\cdot y}\phi(y)\,dy,$$

and D_μ *denotes the dilation operator defined by* $D_\mu\phi(x) = \mu^{\frac{N}{2}}\phi(\mu x)$.

Proof. The first part of the proposition is proved in the same way as statement (iii) in Proposition 3.3. The second statement is a consequence of Lemma 4.2 below. Indeed, note that formula (4.1) can be written as $\overline{u}(t) = M_{-s}D_s v(s)$. Lemma 4.2 therefore implies that

$$\overline{\mathcal{T}(-t)u(t)} = \mathcal{T}(t)\overline{u}(t) = \mathcal{T}\Big(\frac{1}{s}\Big)M_{-s}D_s v(s) = i^{-\frac{N}{2}}D_{\frac{1}{4\pi}}\mathcal{F}\mathcal{T}(-s)v(s).$$

The result follows by letting $s \downarrow 0$ and thus $t \to \infty$. Indeed, $\mathcal{T}(-s)v(s) \to \psi$ in $\mathcal{S}'(\mathbb{R}^N)$ as $s \downarrow 0$ by construction of ψ. □

Lemma 4.2. *For all* $s > 0$,

$$T\Big(\frac{1}{s}\Big)M_{-s}D_s\mathcal{T}(s) = i^{-\frac{N}{2}}D_{\frac{1}{4\pi}}\mathcal{F},$$

where the multiplication operator M_s *is defined by* $M_s\phi(x) = e^{i\frac{s|x|^2}{4}}\phi(x)$.

Proof. Starting with formula (3.5) in [2] we derive that

$$\begin{aligned}\mathcal{T}\Big(\frac{1}{s}\Big)M_{-s}D_s\mathcal{T}(s) &= i^{-\frac{N}{2}}M_s D_{\frac{s}{4\pi}}\mathcal{F}D_s\mathcal{T}(s) = i^{-\frac{N}{2}}M_s D_{\frac{s}{4\pi}}D_{\frac{1}{s}}\mathcal{F}\mathcal{T}(s)\\ &= i^{-\frac{N}{2}}M_s D_{\frac{1}{4\pi}}M_{-16\pi^2 s}\mathcal{F} = i^{-\frac{N}{2}}D_{\frac{1}{4\pi}}\mathcal{F}.\end{aligned}$$

This completes the proof. □

Remark 4.3. Formula (4.7) is analogous to formula (3.11) in [2] as well as the last formula in Proposition 3.14 in [3]. The difference between this paper and the papers [2], [3] is the specific form of the pseudoconformal transformation used. In [2], [3] the transformation fixed $t = 0$ and brought ∞ to $t = 1$. In the present paper, the transformation we use exchanges $t = \infty$ and $t = 0$. Moreover, the class of solutions considered in the present paper is different.

5. Wave operators and their properties. In this section, we prove that, given a scattering state u^+ sufficiently small in the space W_α, there is a unique solution u of (1.1) sufficiently small in X_α which has u^+ as a scattering state. The construction is similar to Theorem 2.1 in [4] where we prove that sufficiently small initial values $\varphi \in W_\alpha$ give rise to solutions of (1.1) in X_α. As a result, we will have constructed a "low energy" scattering theory for (1.1) in the space W_α.

Theorem 5.1. *Suppose* (1.2) *and* (1.4). *Assume* $\rho, M > 0$ *satisfy the inequality*

$$\rho + KM^{\alpha+1} \le M,$$

where $K = K(\alpha,\gamma)$ *is given by* (5.5) *below. Let* $u^+ \in W_\alpha$ *be such that* $\|u^+\|_{W_\alpha} \le \rho$. *It follows that there exists a unique solution* $u \in X_\alpha$ *of* (1.1) *in the sense of Definition* 3.1

such that $\|u\|_{X_\alpha} \le M$ *and* $\mathcal{T}(-t)u(t) \to u^+$ *in* $\mathcal{S}'(\mathbb{R}^N)$ *as* $t \to \infty$*. Furthermore, the following properties hold:*

(i) *Let* $u^+, v^+ \in W_\alpha$ *with* $\|u^+\|_{W_\alpha}, \|v^+\|_{W_\alpha} \le \rho$ *and let* u *and* v *be the resulting solutions of* (1.1)*. It follows that* $\|u - v\|_{X_\alpha} \le C\|u^+ - v^+\|_{W_\alpha}$*, for some constant* C *independent of* u^+ *and* v^+*.*

(ii) *Let* $u^+, v^+ \in W_\alpha$ *with* $\|u^+\|_{W_\alpha}, \|v^+\|_{W_\alpha} \le \rho$ *and let* u *and* v *be the resulting solutions of* (1.1)*. Given* $\mu > 0$*, there exists* $\rho_1 = \rho_1(\alpha, \gamma, \mu) > 0$ *such that if* $\|u^+\|_{W_\alpha} + \|u^+\|_{W_\alpha} \le \rho_1$ *and* $u^+ - v^+ \in \mathcal{W}_{\alpha,\mu}$*, then* $u - v \in \mathcal{X}_{\alpha,\mu}$*.*

(iii) *Let* $u^+ \in W_\alpha$ *with* $\|u^+\|_{W_\alpha} \le \rho$ *and let* u *be the resulting solution of* (1.1)*. Given* $\mu > 0$*, there exists* $\rho_2 = \rho_2(\alpha, \gamma, \mu) > 0$ *such that if* $\|u^+\|_{W_\alpha} \le \rho_2$ *and* $u^+ \in \mathcal{W}_{\alpha,\mu}$*, then* $u \in \mathcal{X}_{\alpha,\mu}$*.*

Proof. The basic idea of the proof is to use a contraction mapping argument to prove global existence of solutions of the equation

$$u(t) = \mathcal{T}(t)u^+ + i\gamma \int_t^\infty \mathcal{T}(t-s)|u(s)|^\alpha u(s)\, ds \tag{5.1}$$

for all $t > 0$, which is equation (3.4) with $\tau = t$.

For $u^+ \in W_\alpha$ and $u \in X_\alpha$, we set

$$(\mathcal{Q}_{u^+}u)(t) = \mathcal{T}(t)u^+ + i\gamma \int_t^\infty \mathcal{T}(t-s)|u(s)|^\alpha u(s)\, ds \tag{5.2}$$

for all $t > 0$. In other words, $(\mathcal{Q}_{u^+}u)(t) = \mathcal{T}(t)u^+ + i\gamma\mathcal{G}(t, \infty, t, u)$. This definition makes sense by Proposition 2.4. In particular, it follows from (2.18) applied with $v = 0$ and $\mu = \beta$ that $\mathcal{Q}_{u^+}u \in X_\alpha$ and

$$\|\mathcal{Q}_{u^+}u\|_{X_\alpha} \le \|u^+\|_{W_\alpha} + C_1\|u\|_{X_\alpha}^{\alpha+1}. \tag{5.3}$$

Moreover, if $u^+, v^+ \in W_\alpha$ and $u, v \in X_\alpha$, then it follows also from (2.18) that

$$\|\mathcal{Q}_{u^+}u - \mathcal{Q}_{v^+}v\|_{X_\alpha} \le \|u^+ - v^+\|_{W_\alpha} + C_2 \max\{\|u\|_{X_\alpha}, \|v\|_{X_\alpha}\}^\alpha \|u - v\|_{X_\alpha}. \tag{5.4}$$

It is clear now that if $M, \rho > 0$ satisfy $\rho + KM^{\alpha+1} \le M$ with

$$K = K(\alpha, \gamma) = \max\{C_1, C_2\}, \tag{5.5}$$

then given $u^+ \in W_\alpha$ with $\|u^+\|_{W_\alpha} \le \rho$, $\mathcal{Q}_{u^+}$ is a strict contraction on the set $B_M = \{u \in X_\alpha;\ \|u\|_{X_\alpha} \le M\}$ equipped with the distance induced by the norm in X_α. Thus $\mathcal{Q}_{u^+}$ has a unique fixed point, which is the unique solution of (5.1) in B_M. We also obtain the estimate of property (i).

Next we show that u is a solution of (1.1) in the sense of Definition 3.1. We observe first that by (2.17), we may commute $\mathcal{T}(t)$ with the integral in (5.1); and so, u satisfies

$$\mathcal{T}(-t)u(t) = u^+ + i\gamma \int_t^\infty \mathcal{T}(-s)|u(s)|^\alpha u(s)\, ds. \tag{5.6}$$

The integral converges strongly in $L^{\alpha+2}(\mathbb{R}^N)$ and it follows in particular that

$$\mathcal{T}(-t)u(t) - u^+ \underset{t\to\infty}{\longrightarrow} 0 \tag{5.7}$$

in $L^{\alpha+2}(\mathbb{R}^N)$. Furthermore, (5.6) implies that

$$\mathcal{T}(-t)u(t) - \mathcal{T}(-\tau)u(\tau) = i\gamma \int_t^\tau \mathcal{T}(-s)|u(s)|^\alpha u(s)\,ds$$

for all (finite) $t, \tau > 0$, where now the integral converges in both $L^{\alpha+2}(\mathbb{R}^N)$ and $H^{-\frac{N\alpha}{2(\alpha+2)}}$. By applying $\mathcal{T}(t)$, we see that u is a solution of (1.1) in the sense of Definition 3.1. This completes the proof of the main statement of the theorem and property (i).

Finally, we prove property (ii) (property (iii) being a special case). If $u^+, v^+ \in W_\alpha$ with $u^+ - v^+ \in \mathcal{W}_{\alpha,\mu}$ and if $u, v \in X_\alpha$ with $u - v \in \mathcal{X}_{\alpha,\mu}$, then it follows from (2.19) that $\mathcal{Q}_{u^+}u - \mathcal{Q}_{v^+}v \in \mathcal{X}_{\alpha,\mu}$ and

$$(5.8)\quad \|\mathcal{Q}_{u^+}u - \mathcal{Q}_{v^+}v\|_{\mathcal{X}_{\alpha,\mu}} \le \|u^+ - v^+\|_{\mathcal{W}_{\alpha,\mu}} + C_3 \max\{\|u\|_{X_\alpha}, \|v\|_{X_\alpha}\}^\alpha \|u - v\|_{\mathcal{X}_{\alpha,\mu}}$$

with $C_3 = C_3(\alpha, \gamma, \mu)$. To prove the statement, we fix $0 < \rho_1 \le \rho$ and $0 < M_1 \le M$ small enough so that

$$\rho_1 + K(\alpha, \gamma) M_1^{\alpha+1} \le M_1 \quad \text{and} \quad C_3 M_1^\alpha < 1.$$

Assuming $\|v^+\|_{W_\alpha} \le \rho_1$, it follows that the corresponding solution v satisfies $\|v\|_{X_\alpha} \le M_1$. Next, assuming also that $\|u^+\|_{W_\alpha} \le \rho_1$, we carry out a new contraction mapping argument in the set

$$\widetilde{B} = \{w \in X_\alpha;\, w - v \in \mathcal{X}_{\alpha,\mu}, \|w\|_{X_\alpha} \le M_1, \|w - v\|_{\mathcal{X}_{\alpha,\mu}} \le L_1\}$$

with

$$L_1 = \frac{\|u^+ - v^+\|_{\mathcal{W}_{\alpha,\mu}}}{1 - C_3 M_1^\alpha}.$$

$\widetilde{B}$ is a complete metric space using the distance induced by the norm in X_α. The only new element in the contraction mapping argument is to show that $\|\mathcal{Q}_{u^+}w - v\|_{\mathcal{X}_{\alpha,\mu}} \le L_1$ for all $w \in \widetilde{B}$. This is an immediate consequence of (5.8) and the definition of L_1, and the fact that $\mathcal{Q}_{v^+}v = v$. The resulting solution u of (1.1) is clearly the same as obtained in B_M since $\widetilde{B} \subset B_M$. □

Remark 5.2. In fact, the proof of Theorem 5.1 never uses the fact that $\alpha > \alpha_0$, which is the same as the condition $\beta(\alpha + 1) < 1$. Indeed, this last condition is needed only when the integrand in (3.1) needs to be estimated as $s \downarrow 0$. On the other hand, the theorem is vacuous if $\alpha < \alpha_0$ since $W_\alpha = \{0\}$.

Proposition 5.3. *Suppose* (1.2) *and* (1.4). *Let* $u^+ \in W_\alpha$ *be such that* $\|u^+\|_{W_\alpha} \le \rho$ *as in Theorem* 5.1 *and let* u *be the resulting solution of* (1.1). *If, in addition,* $u^+ \in H^1(\mathbb{R}^N)$ *and* $\alpha \ge 4/N$, *then* $u(t) \in H^1(\mathbb{R}^N)$ *for all* $t > 0$.

Proof. Let ρ, M be as in Theorem 5.1 and let u^+ and u be as above. Let $r = \alpha + 2$ and $q = 4(\alpha + 2)/N\alpha$ and observe that by Strichartz' estimate $\mathcal{T}(\cdot)u^+ \in L^q(\mathbb{R}, W^{1,r}(\mathbb{R}^N))$. Given $T > 0$, consider the set

$$B_M^T = \Big\{u \in L^\infty((T,\infty), L^{\alpha+2}(\mathbb{R}^N)) \cap L^q((T,\infty), W^{1,r}(\mathbb{R}^N));$$
$$\sup_{t \ge T} t^\beta \|u(t)\|_{L^{\alpha+2}} \le M, \|u\|_{L^q((T,\infty),W^{1,r})} \le 2\|\mathcal{T}(\cdot)u^+\|_{L^q((T,\infty),W^{1,r})}\Big\}.$$

It is clear that B_M^T equipped with the distance $d(u,v) = \sup_{t\ge T} t^\beta \|u(t) - v(t)\|_{L^{\alpha+2}}$ is a complete metric space. On the other hand, it follows from (5.3), (5.4), and (5.5) that (with $\mathcal{Q}$ defined by (5.2))

$$\sup_{t\ge T} t^\beta \|\mathcal{Q}_{u^+} u\|_{L^{\alpha+2}} \le \rho + KM^{\alpha+1} \le M, \tag{5.9}$$

$$d(\mathcal{Q}_{u^+} u, \mathcal{Q}_{u^+} v) \le KM^\alpha d(u,v) \tag{5.10}$$

for all $u, v \in B_M^T$. Furthermore, it follows from Strichartz' estimate (see, e.g., [1, Theorem 3.2.5]) that

$$\begin{aligned}\|\mathcal{Q}_{u^+} u\|_{L^q((T,\infty),W^{1,r})} &\le \|\mathcal{T}(\cdot)u^+\|_{L^q((T,\infty),W^{1,r})} + C\| \, |u|^\alpha u\|_{L^{q'}((T,\infty),W^{1,r'})} \\ &\le \|\mathcal{T}(\cdot)u^+\|_{L^q((T,\infty),W^{1,r})} + C\left(\sup_{t\ge T}\|u(t)\|_{L^{\alpha+2}}\right)^{\left(1-\frac{4}{N\alpha}\right)(\alpha+2)} \|u\|_{L^q((T,\infty),W^{1,r})}^{1+\frac{2(4-(N-2)\alpha)}{N\alpha}},\end{aligned}$$

where the last inequality follows from (3.16). Therefore,

$$\begin{aligned}\|\mathcal{Q}_{u^+} u\|_{L^q((T,\infty),W^{1,r})} \le{}& \|\mathcal{T}(\cdot)u^+\|_{L^q((T,\infty),W^{1,r})} \\ &+CT^{-\beta\left(1-\frac{4}{N\alpha}\right)(\alpha+2)}(2\|\mathcal{T}(\cdot)u^+\|_{L^q((T,\infty),W^{1,r})})^{1+\frac{2(4-(N-2)\alpha)}{N\alpha}} \\ \le{}& 2\|\mathcal{T}(\cdot)u^+\|_{L^q((T,\infty),W^{1,r})}\end{aligned} \tag{5.11}$$

if T is large enough. (5.9), (5.10), and (5.11) imply that $\mathcal{Q}_{u^+}$ has a unique fixed point in B_M^T, which clearly coincides with the solution constructed in Theorem 5.1 by (5.10). Thus $u \in L^q((T,\infty), W^{1,r}(\mathbb{R}^N))$ for T large enough. Applying again Strichartz' inequality, we now see that $u \in C([T,\infty), H^1(\mathbb{R}^N))$. The result now follows from Proposition 3.10 (i). □

PROPOSITION 5.4. *Suppose* (1.2) *and* (1.4). *Let* $u^+ \in W_\alpha \cap \mathcal{W}_{\alpha,\mu}$ *for some* $\mu > \beta$. *Suppose* $\|u^+\|_{W_\alpha} \le \min\{\rho, \rho_1\}$ *as in Theorem* 5.1 *parts* (i) *and* (iii) *and let u be the resulting solution of* (1.1). *If, in addition,* $u^+ \in H^1(\mathbb{R}^N)$, *then* $u(t) \in H^1(\mathbb{R}^N)$ *for all* $t > 0$.

Proof. The proof is similar to the proof of Proposition 5.3 above, except that instead of the inequality (3.16), we use the inequalities (3.17) and (3.18). □

PROPOSITION 5.5. *Suppose* (1.2) *and* (1.4). *Let* $u^+ \in H^1(\mathbb{R}^N) \cap \mathcal{W}_{\alpha,\mu}$ *for some* $\mu > \beta$. *Suppose* $\gamma > 0$ *or* $\alpha < 4/N$. *Then there exists a unique solution* $u \in C([0,\infty), H^1(\mathbb{R}^N)) \cap \mathcal{X}_{\alpha,\mu}$ *of* (1.1) *whose scattering state is* u^+.

Proof. The proof is again similar to the proof of Proposition 5.3 above, and we use the same notation. Fix $M \ge 2\sup_{t>0} t^\mu \|\mathcal{T}(t)u^+\|_{L^{\alpha+2}}$, $M \ge 2\|\mathcal{T}(\cdot)u^+\|_{L^q(\mathbb{R},W^{1,r})}$. Given $T, M > 0$, consider the set

$$B_M^T = \left\{ u \in L^\infty((T,\infty), L^{\alpha+2}(\mathbb{R}^N)) \cap L^q((T,\infty), W^{1,r}(\mathbb{R}^N)); \right. \\ \left. \sup_{t\ge T} t^\mu \|u(t)\|_{L^{\alpha+2}} \le M, \|u\|_{L^q((T,\infty),W^{1,r})} \le M \right\}.$$

It is clear that B_M^T equipped with the distance $d(u,v) = \sup_{t\ge T} t^\mu \|u(t) - v(t)\|_{L^{\alpha+2}}$ is a complete metric space. Using (3.17) and (3.18) instead of (3.16), we still obtain the final inequality in (5.11), i.e., if T is large enough, then

$$\|\mathcal{Q}_{u^+} u\|_{L^q((T,\infty),W^{1,r})} \le 2\|\mathcal{T}(\cdot)u^+\|_{L^q(\mathbb{R},W^{1,r})} \le M. \tag{5.12}$$

Next,

$$\sup_{t\geq T} t^{\mu}\|\mathcal{Q}_{u^+}\|_{L^{\alpha+2}} \leq \sup_{t\geq T} t^{\mu}\|\mathcal{T}(t)u^+\|_{L^{\alpha+2}} + \gamma M^{\alpha+1}\sup_{t\geq T} t^{\mu}\int_t^{\infty}|t-s|^{-\frac{N\alpha}{2(\alpha+2)}}s^{-\mu(\alpha+1)}\,ds \leq \sup_{t\geq T} t^{\mu}\|\mathcal{T}(t)u^+\|_{L^{\alpha+2}} + C\gamma M^{\alpha+1}T^{1-\frac{N\alpha}{2(\alpha+2)}-\alpha\mu}.$$

Since $1-\frac{N\alpha}{2(\alpha+2)}-\alpha\mu < 1-\frac{N\alpha}{2(\alpha+2)}-\alpha\beta = 0$,

$$\sup_{t\geq T} t^{\mu}\|\mathcal{Q}_{u^+}\|_{L^{\alpha+2}} \leq M \tag{5.13}$$

if T is large enough. In a similar way, we see that

$$d(\mathcal{Q}_{u^+}(u),\mathcal{Q}_{u^+}(v)) \leq C\gamma M^{\alpha}T^{1-\frac{N\alpha}{2(\alpha+2)}-\alpha\mu}d(u,v) \leq \frac{1}{2}d(u,v) \tag{5.14}$$

if T is large enough. By (5.12), (5.13), and (5.14), $\mathcal{Q}_{u^+}$ has a unique fixed point $u \in B_T^M$ for T large enough. By Strichartz' inequality, we see that $u \in C([T,\infty),H^1(\mathbb{R}^N))$. Since $\gamma > 0$ or $\alpha < 4/N$, all H^1 solutions of (1.1) are global, so that u can be extended to a solution $u \in C([0,\infty),H^1(\mathbb{R}^N))$. Since $u \in B_M^T$, and $H^1(\mathbb{R}^N) \hookrightarrow L^{\alpha+2}(\mathbb{R}^N)$, we clearly have $u \in \mathcal{X}_{\alpha,\mu}\cap X_{\alpha}$. We conclude as in Theorem 5.1 that u^+ is the scattering state of u.

Finally we show uniqueness. Consider two solutions $u,v \in C([0,\infty),H^1(\mathbb{R}^N))\cap \mathcal{X}_{\alpha,\mu}$ of (1.1) with the same scattering state $u^+ \in H^1(\mathbb{R}^N)\cap\mathcal{W}_{\alpha,\mu}$. It follows (see the proof of Proposition 3.10 (iv)) that $u,v \in L^q((0,\infty),W^{1,r}(\mathbb{R}^N))$. Consider now the set B_M^T with M sufficiently large so that

$$M \geq \max\{\|u\|_{\mathcal{X}_{\alpha,\mu}},\|v\|_{\mathcal{X}_{\alpha,\mu}},\|u\|_{L^q((0,\infty),W^{1,r})},\|v\|_{L^q((0,\infty),W^{1,r})}\}.$$

In particular, $u,v \in B_M^T$ for all $T>0$. Applying (5.14) with this choice of M, we see that $u(t)=v(t)$ for t sufficiently large. By uniqueness of H^1 solutions, we conclude that $u=v$. □

6. Self-similar solutions. Let $p \in \mathbb{C}$ with $\operatorname{Re} p = 2/\alpha$. Given $\lambda > 0$ and $u \in \mathcal{S}'((0,\infty)\times\mathbb{R}^N)$, let $u_\lambda(t,x) = \lambda^p u(\lambda^2 t,\lambda x)$. (Even if u is not a function, this is obviously defined by duality.) If $u \in X_\alpha$, then it follows that $u_\lambda \in X_\alpha$ and $\|u_\lambda\|_{X_\alpha} = \|u\|_{X_\alpha}$. Moreover, if $u \in X_\alpha$ is a solution of (1.1), then u_λ is also a solution. In addition, if φ and u^+ are the initial values and scattering states of u and φ_λ and u_λ^+ are the initial values and scattering states of u_λ, then $\varphi_\lambda(x) = \lambda^p\varphi(\lambda x)$ and $u_\lambda^+(x) = \lambda^p u^+(\lambda x)$.

We recall that a solution $u \in X_\alpha$ of (1.1) is self-similar if $u_\lambda = u$ for all $\lambda > 0$.

PROPOSITION 6.1. *Suppose* (1.4) *and let* $p \in \mathbb{C}$ *with* $\operatorname{Re} p = 2/\alpha$.

(i) *If* $u \in X_\alpha$ *is a self-similar solution of* (1.1), *it follows that the initial value* φ *and the scattering state* u^+ *are homogeneous tempered distributions of degree* $-p$.

(ii) *Let* $u^+ \in W_\alpha$ *be such that* $\|u^+\|_{W_\alpha} \leq \rho$ *as in Theorem* 5.1. *Let* u *be the resulting solution of* (1.1) *with scattering state* u^+ *as provided by Theorem* 5.1. *If in addition* u^+ *is a homogeneous tempered distribution of degree* $-p$, *then* u *is a self-similar solution of* (1.1).

Proof. (i) follows from formula (3.4) with $\tau = 0$ and from formula (3.8) by a straightforward calculation using $u = u_\lambda$ and the commutation relation $(\mathcal{T}(t)\psi)_\lambda = \mathcal{T}(t/\lambda^2)(\psi_\lambda)$ for all $t \in \mathbb{R}$ and $\lambda > 0$.

The proof of statement (ii) is the same as the proof of the analogous statement in Proposition 4.3 of [4] for initial values. For each $\lambda > 0$, u_λ and u are both solutions of (1.1) with $\|u_\lambda\|_{X_\alpha} = \|u\|_{X_\alpha} \le M$ as in Theorem 5.1 with the same scattering state. By the uniqueness part of Theorem 5.1, $u_\lambda = u$. □

Remark 6.2. Let $f \in L^1_{\mathrm{loc}}(\mathbb{R}^N)$, let $p \in \mathbb{C}$ with $\operatorname{Re} p = 2/\alpha$, and set $u(t,x) = t^{-\frac{p}{2}} f(x/\sqrt{t})$ for $t > 0$ and $x \in \mathbb{R}^N$. It follows that $f \in L^{\alpha+2}(\mathbb{R}^N)$ if and only if $u \in X_\alpha$.

Proposition 6.3. *In addition to* (1.4)*, suppose $N \ge 3$. Let $p \in \mathbb{C}$ with* $\operatorname{Re} p = 2/\alpha$. *Let $u \in X_\alpha$ be a self-similar solution of* (1.1) *with the profile f, i.e., $u(t,x) = t^{-\frac{p}{2}} f(x/\sqrt{t})$. If $\nabla f \in L^2(\mathbb{R}^N)$, then $u^+ = 0$.*

Proof. We first show that

$$\mathcal{T}(-t)u(t) \in L^{\frac{2N}{N-2}}(\mathbb{R}^N) \tag{6.1}$$

for all $t > 0$. Set $w = \mathcal{T}(-t)u(t)$. Since $w \in W_\alpha$ by Proposition 3.3, it follows that for $\tau > 0$,

$$\mathcal{T}(\tau)w \in L^{\alpha+2}(\mathbb{R}^N). \tag{6.2}$$

Since $\nabla f \in L^2(\mathbb{R}^N)$, it is clear that $\nabla u(t) \in L^2(\mathbb{R}^N)$. Thus

$$\nabla \mathcal{T}(\tau)w \in L^2(\mathbb{R}^N). \tag{6.3}$$

It follows from (6.2), (6.3), and an obvious truncation argument that

$$\|\mathcal{T}(\tau)w\|_{L^{\frac{2N}{N-2}}} \le C\|\nabla \mathcal{T}(\tau)w\|_{L^2} = C\|\nabla w\|_{L^2}.$$

We obtain (6.1) by letting $\tau \downarrow 0$.

It therefore follows from (3.4) with $\tau = 0$, from (6.1), and from (3.9) that $u^+ \in L^{\frac{2N}{N-2}}(\mathbb{R}^N) + L^{\alpha+2}(\mathbb{R}^N)$. Since u^+ is homogeneous of degree $-p$ by Proposition 6.1, and since $N\alpha/2 < \alpha + 2 < 2N/(N-2)$, u^+ must be 0, as shown by Lemma 6.4 below. □

Lemma 6.4. *Let $1 \le r \le \infty$ and let $v \in L^r_{\mathrm{loc}}(\mathbb{R}^N)$. If v is homogeneous of degree $-k + i\omega$ with $k \ge N/r$ and $k > 0$ if $r = \infty$, then $v \equiv 0$.*

Proof. Let $0 < \lambda < 1$. Since $\lambda^k |v(\lambda x)| \equiv |v(x)|$, it follows that

$$\|v\|_{L^r(\{|x|<1\})} = \lambda^{k-\frac{N}{r}} \|v\|_{L^r(\{|x|<\lambda\})}.$$

If $r < \infty$, then $\|v\|_{L^r(\{|x|<1\})} \le \|v\|_{L^r(\{|x|<\lambda\})}$, thus $v = 0$ on $\{\lambda < |x| < 1\}$. If $r = \infty$, then $\|v\|_{L^r(\{|x|<1\})} < \|v\|_{L^r(\{|x|<1\})}$, thus $v = 0$ on $\{|x| < 1\}$. By homogeneity, we deduce in both cases that $v \equiv 0$. □

Corollary 6.5. *Under the assumptions of Proposition* 6.3*, let $u \in X_\alpha$ be a self-similar solution of* (1.1) *with the profile $f \in L^{\alpha+2}(\mathbb{R}^N)$, $f \not\equiv 0$. If $\|f\|_{L^{\alpha+2}} \le M$ with M as in the statement of Theorem* 5.1*, then $\nabla f \notin L^2(\mathbb{R}^N)$.*

Proof. If $\nabla f \in L^2(\mathbb{R}^N)$, then by Proposition 6.3 $u^+ = 0$, and by Theorem 5.1 it follows that $u(t) \equiv 0$ (note that $\|u\|_{X_\alpha} = \|f\|_{L^{\alpha+2}}$). □

Remark 6.6. Remark 3.12 shows that if $\alpha = 4/N$, then there is no H^1 self-similar solution of (1.1) with small H^1 norm. (If $N \ge 3$, this is also a consequence of Corollary 6.5.) It follows from [9] that there is no *radially symmetric* H^1 self-similar solution of (1.1).

Remark 6.7. If $u \in X_\alpha$ is a self-similar solution of (1.1) with profile f and if $\mathcal{T}(-1)f \in L^{\frac{N\alpha}{2}}_{\mathrm{loc}}(\mathbb{R}^N)$, then the proof of Proposition 6.3 shows that $u^+ = 0$. This is true in particular if $f \in L^r(\mathbb{R}^N)$ for some $r \le 2$ in the case $\alpha \le 4/N$ and $r \le N\alpha/(N\alpha - 2)$ in the case $\alpha > 4/N$. This is also true if $f \in \dot{H}^s(\mathbb{R}^N)$ for some $s \ge 0$ in the case $\alpha \le 4/N$ and $s \ge N/2 - 2/\alpha$ in the case $\alpha > 4/N$.

We now establish a partial converse of Proposition 6.3.

Proposition 6.8. *In addition to* (1.4), *suppose* $N \ge 3$. *Let* $p \in \mathbb{C}$ *with* $\operatorname{Re} p = 2/\alpha$. *Let* $u \in X_\alpha$ *be a self-similar solution of* (1.1) *with the profile* f, *i.e.,* $u(t,x) = t^{-\frac{p}{2}} f(x/\sqrt{t})$. *Suppose further that* f *is radially symmetric and that* $f \in L^\rho(\mathbb{R}^N)$ *for some* $\alpha + 1 \le \rho < \frac{2N}{N+2}(\alpha+1)$. *If* $u^+ = 0$, *then* $\nabla f \in L^2(\mathbb{R}^N)$.

Remark 6.9. Note that $\frac{N\alpha}{2} < \frac{2N}{N+2}(\alpha+1) < \alpha + 2$, since $\alpha < 4/(N-2)$.

Proof of Proposition 6.8. Set

$$v = \int_1^\infty \mathcal{T}(-s)|u(s)|^\alpha u(s)\, ds.$$

By formula (3.4), it suffices to show that $\nabla v \in L^2(\mathbb{R}^N)$.

Let $g = \mathcal{T}(-1)|f|^\alpha f$. Since $f \in L^{\alpha+2}(\mathbb{R}^N)$, $g \in L^{\alpha+2}(\mathbb{R}^N)$; and since $f \in L^\rho(\mathbb{R}^N)$, $g \in L^{\frac{\rho}{\rho-\alpha-1}}(\mathbb{R}^N)$. (Note that $q := \frac{\rho}{\rho-\alpha-1} > \frac{2N}{N-2}$.) It follows from the scaling properties of $(\mathcal{T}(t))_{t\in\mathbb{R}}$ with respect to dilations that

$$v(r) = \int_1^\infty s^{-1-\frac{p}{2}} g\Big(\frac{r}{\sqrt{s}}\Big)\, ds,$$

where $r = |x|$. Setting $\sigma = r/\sqrt{s}$, this implies

$$v(r) = 2r^{-p} \int_0^r \sigma^{p-1} g(\sigma)\, d\sigma.$$

Thus,

$$\partial_r v = 2r^{-1} g(r) - 2pr^{-p-1} \int_0^r \sigma^{p-1} g(\sigma)\, d\sigma = 2r^{-1} g(r) - h(r).$$

We now estimate the right-hand side in $L^2(\mathbb{R}^N)$.

$$\|r^{-1} g(r)\|_{L^2(\{|x|>1\})} \le \|g\|_{L^{\alpha+2}} \|r^{-1}\|_{L^{\frac{2(\alpha+2)}{\alpha}}(\{|x|>1\})} < \infty,$$

since $\alpha < 4/(N-2)$; and

$$\|r^{-1} g(r)\|_{L^2(\{|x|<1\})} \le \|g\|_{L^q} \|r^{-1}\|_{L^{\frac{2q}{q-2}}(\{|x|<1\})} < \infty,$$

since $q > 2N/(N-2)$. Thus, $r^{-1} g(r) \in L^2(\mathbb{R}^N)$. Next, we have

$$\Big| \int_0^r \sigma^{p-1} g(\sigma)\, d\sigma \Big| \le C r^{\frac{2}{\alpha} - \frac{N}{\alpha+2}} \|g\|_{L^{\alpha+2}}.$$

Since $-\frac{2}{\alpha} - 1 + \frac{2}{\alpha} - \frac{N}{\alpha+2} < -\frac{N}{2}$, it follows that $h \in L^2(\{|x| > 1\})$. A similar calculation where $\|g\|_{L^q}$ is used in place of $\|g\|_{L^{\alpha+2}}$ shows that $h \in L^2(\{|x| < 1\})$. □

7. Scattering theory versus asymptotically self-similar solutions. In this section we exhibit various classes of scattering states u^+ and initial values φ in $W_\alpha \cap H^1(\mathbb{R}^N)$ for which the asymptotic rate of decay of $\|u(t)\|_{L^{\alpha+2}}$ as $t \to \infty$ can be precisely determined. These classes are determined either by the asymptotic behavior of $u^+(x)$ or $\varphi(x)$ as $|x| \to \infty$ or by the asymptotic behavior of $\widehat{u^+}(\xi)$ or $\widehat{\varphi}(\xi)$ as $|\xi| \to 0$.

As usual, we assume (1.4). In addition, we consider $q \in \mathbb{C}$ such that

$$\frac{\alpha+2}{\alpha+1} < \frac{N}{\operatorname{Re} q} < \alpha + 2. \tag{7.1}$$

Note that if $\operatorname{Re} q = 2/\alpha$, then (7.1) is the same as (1.4). However, in what follows we explicitly exclude this possibility by requiring the following additional conditions:

$$\operatorname{Re} q > \frac{2}{\alpha}, \tag{7.2}$$

$$\operatorname{Re} q > \frac{N}{2}. \tag{7.3}$$

Suppose that $\psi(x)$ is C^∞ away from the origin and homogeneous of degree $-q$. (It follows that $\widehat{\psi}(\xi)$ is also C^∞ away from the origin and homogeneous of degree $q - N$. See [15, p. 262].) By (the proof of) Theorem V.1–3 in [12] (see also Proposition 3.9 in [4], Lemma 3.2 in [5], and Theorem 3 in [13]), (7.1) implies that $\mathcal{T}(t)\psi \in L^{\alpha+2}(\mathbb{R}^N)$ for all $t > 0$; and so,

$$t^\nu \|\mathcal{T}(t)\psi\|_{L^{\alpha+2}} = \|\mathcal{T}(1)\psi\|_{L^{\alpha+2}} \tag{7.4}$$

for all $t > 0$ with

$$\nu = \frac{\operatorname{Re} q}{2} - \frac{N}{2(\alpha+2)} = \beta + \frac{\operatorname{Re} q}{2} - \frac{1}{\alpha} > \beta \tag{7.5}$$

by formula (3.6) in [4]. Note that

$$\nu < \frac{N\alpha}{2(\alpha+2)}, \tag{7.6}$$

by (7.1). Note also that $\mathcal{T}(t)\psi$ is a self-similar solution of the linear Schrödinger equation, with a different homogeneity than the self-similar solutions of (1.1) in the previous section. More precisely, $v(t,x) = \mathcal{T}(t)\psi(x)$ satisfies $\lambda^q v(\lambda^2 t, \lambda x) = v(t,x)$ for all $\lambda > 0$ and all $t \geq 0$, $x \in \mathbb{R}^N$.

Let $\eta \in C_{\mathrm{c}}^\infty(\mathbb{R}^N)$ and $\eta(x) \equiv 1$ in a neighborhood of the origin, and set

$$\Psi = (1 - \eta)\psi. \tag{7.7}$$

Note that $\eta\psi = \psi - \Psi \in L^{\frac{\alpha+2}{\alpha+1}}(\mathbb{R}^N)$ by (7.1). Also, we define Θ by

$$\widehat{\Theta} = \eta\widehat{\psi}. \tag{7.8}$$

Note that, by the arguments on pp. 88–89 in [12], we have that $\psi - \Theta \in L^{\frac{\alpha+2}{\alpha+1}}(\mathbb{R}^N)$.

We begin with the following lemma.

Lemma 7.1. *Assume* (1.4), (7.1), (7.2), *and* (7.3) *and let* Ψ *and* Θ *be as above. It follows that* $\Psi, \Theta \in H^1(\mathbb{R}^N) \cap W_\alpha \cap \mathcal{W}_{\alpha,\nu}$ *with* ν *defined by* (7.5).

Proof. We consider first Ψ. It follows from (7.3) and the homogeneity of ψ that $\Psi \in H^1(\mathbb{R}^N)$; and so

$$\sup_{t\geq 0} \|\mathcal{T}(t)\Psi\|_{L^{\alpha+2}} \leq C \sup_{t\geq 0} \|\mathcal{T}(t)\Psi\|_{H^1} \leq C\|\Psi\|_{H^1} < \infty. \tag{7.9}$$

On the other hand, since $\psi - \Psi = \eta\psi \in L^{\frac{\alpha+2}{\alpha+1}}(\mathbb{R}^N)$,

$$\|\mathcal{T}(t)\Psi\|_{L^{\alpha+2}} \leq \|\mathcal{T}(t)(\Psi-\psi)\|_{L^{\alpha+2}} + \|\mathcal{T}(t)\psi\|_{L^{\alpha+2}} \leq Ct^{-\frac{N\alpha}{2(\alpha+2)}} + Ct^{-\nu},$$

where we also used (7.4). Applying (7.6), we deduce that

$$\sup_{t\geq 1} t^\nu \|\mathcal{T}(t)\Psi\|_{L^{\alpha+2}} < \infty. \tag{7.10}$$

The result now follows from (7.5), (7.9), and (7.10).

Next we turn to Θ. By (7.3) and the homogeneity of $\widehat{\psi}$, we have that $\eta\widehat{\psi} \in L^2(\mathbb{R}^N)$ and $\xi\eta(\xi)\widehat{\psi}(\xi) \in L^2(\mathbb{R}^N)$, and so $\Theta \in H^1(\mathbb{R}^N)$. Furthermore, since $\varphi - \Theta \in L^{\frac{\alpha+2}{\alpha+1}}(\mathbb{R}^N)$, it follows that

$$\|\mathcal{T}(t)\Theta\|_{L^{\alpha+2}} \leq \|\mathcal{T}(t)(\Theta-\psi)\|_{L^{\alpha+2}} + \|\mathcal{T}(t)\psi\|_{L^{\alpha+2}} \leq Ct^{-\frac{N\alpha}{2(\alpha+2)}} + Ct^{-\nu};$$

and we conclude as we did for Ψ. □

Proposition 7.2. *Assume* (1.4), (7.1), (7.2), *and* (7.3). *Let* Ψ *be given by* (7.7) *and let* $u^+ = c\Psi$ *where the constant* c *is small enough so that* u^+ *satisfies the hypotheses of part* (iii) *of Theorem* 5.1 *with* $\mu = \nu$ *and let* $u \in X_\alpha \cap \mathcal{X}_{\alpha,\nu} \cap C([0,\infty), H^1(\mathbb{R}^N))$ *be the resulting solution of* (1.1). *It follows that*

$$t^\nu \|u(t) - \mathcal{T}(t)u^+\|_{L^{\alpha+2}} + t^\nu \|\mathcal{T}(-t)u(t) - u^+\|_{L^{\alpha+2}} \leq Ct^{-\alpha(\nu-\beta)}, \tag{7.11}$$

and

$$t^\nu \|u(t) - c\mathcal{T}(t)\psi\|_{L^{\alpha+2}} \leq C\max\{t^{-\alpha(\nu-\beta)}, t^{-\frac{N\alpha}{2(\alpha+2)}+\nu}\} \tag{7.12}$$

for all $t > 0$. *In particular,*

$$0 < \liminf_{t\to\infty} t^\nu \|u(t)\|_{L^{\alpha+2}} \leq \limsup_{t\to\infty} t^\nu \|u(t)\|_{L^{\alpha+2}} < \infty. \tag{7.13}$$

In addition,

$$\|u(t) - \mathcal{T}(t)u^+\|_{H^1} \leq Ct^{-\alpha(\nu-\beta)}. \tag{7.14}$$

The same is true if $u^+ = c\Theta$ *where* Θ *is given by* (7.8) *and* c *is sufficiently small.*

Proof. Recall that $u \in C([0,\infty), H^1(\mathbb{R}^N))$ by Proposition 5.4. The first estimate is a consequence Proposition 3.7 (i) and (iii). Furthermore, since $c\psi = u^+ + c\eta\psi$, it follows that

$$\begin{aligned} t^\nu \|u(t) - \mathcal{T}(t)c\psi\|_{L^{\alpha+2}} &\leq t^\nu \|u(t) - \mathcal{T}(t)u^+\|_{L^{\alpha+2}} + t^\nu \|\mathcal{T}(t)c\eta\psi\|_{L^{\alpha+2}} \\ &\leq Ct^{-\alpha(\nu-\beta)} \|u\|_{\mathcal{X}_{\alpha,\nu}} + Ct^{-\frac{N\alpha}{2(\alpha+2)}+\nu} \|\eta\psi\|_{L^{\frac{\alpha+2}{\alpha+1}}}. \end{aligned}$$

This proves the second estimate, which immediately implies the third. The last one follows from Proposition 3.10 (iv). If $u^+ = c\Theta$, the same argument works using $c\psi = u^+ + c(\psi - \Theta)$. $\square$

REMARK 7.3. (7.13) gives the precise decay rate of $\|u(t)\|_{L^{\alpha+2}}$ as $t \to \infty$. Notice that for different choices of q, we obtain H^1 solutions of (1.1) with different decay rates. By (7.1), (7.2), and (7.3), the decay rates which can be realized by Proposition 7.2 are

$$\beta < \nu < \frac{N\alpha}{2(\alpha+2)} \quad \text{if} \quad \alpha_0 < \alpha \le \frac{4}{N} \tag{7.15}$$

and

$$\frac{N\alpha}{4(\alpha+2)} < \nu < \frac{N\alpha}{2(\alpha+2)} \quad \text{if} \quad \frac{4}{N} \le \alpha < \frac{4}{N-2}. \tag{7.16}$$

Note that $\frac{N\alpha\alpha}{4(\alpha+2)} < \beta$ precisely when $\alpha < 4/N$. We can make the following additional comments on the optimality of (7.15) and (7.16).

(i) The right-hand limit $\nu = \frac{N\alpha}{2(\alpha+2)}$ in (7.15) and (7.16) can be achieved for solutions with initial values $\varphi \in H^1(\mathbb{R}^N) \cap L^2(\mathbb{R}^N, |x|^2 dx)$ (see [16] and [3]). On the other hand, Corollary 3.9 shows that it cannot be improved.

(ii) If $\alpha > 4/N$, then Remark 3.12 shows that the lower bound in (7.16) cannot even be attained.

(iii) We conjecture that the lower bound in (7.15) is not sharp. Indeed, if $\alpha_0 < \alpha < 4/N$ and $N/2 < \operatorname{Re} q < 2/\alpha$, then Ψ defined by (7.7) is in $H^1(\mathbb{R}^N)$ but not in W_α. Thus the resulting (global) solution is not in X_α. On the other hand, by Corollary 7.4.6 in [1], at least in the radially symmetric case and when $\gamma > 0$, $\|u(t)\|_{L^{\alpha+2}} \to 0$ as $t \to \infty$.

REMARK 7.4. Under the hypotheses of Proposition 7.2, (1.1) has a large class of solutions, corresponding to different choices of the cut-off function η, all of which are asymptotic as $t \to \infty$ to the same self-similar solution of the linear Schrödinger equation (whose scaling properties are different from those of (1.1)). See Theorems 1.4 and 1.5 in [17] for similar results for the "two-power" nonlinear Schrödinger equation.

REMARK 7.5. If, in addition to the hypotheses of Proposition 7.2, we assume $\alpha > 4/N$, then the property that $u(t) - \mathcal{T}(t)u^+ \to 0$ in $H^1(\mathbb{R}^N)$ is a well-known result of the "classical" H^1 theory of Ginibre and Velo [6]. The precise decay estimates (7.11), (7.13), and (7.14) are new as far as we are aware. In other words, new information about H^1 solutions of (1.1) has been obtained by studying X_α solutions.

Applying Proposition 5.5 instead of Theorem 5.1, we obtain the following analogue of Proposition 7.2, where we do not need the smallness condition, but instead we assume $\gamma > 0$ or $\alpha < 4/N$.

PROPOSITION 7.6. *Assume* (1.4), (7.1), (7.2), *and* (7.3). *Suppose in addition* $\gamma > 0$ *or* $\alpha < 4/N$. *Let* Ψ *be given by* (7.7) *and let* $u^+ = c\Psi$ *for some* $c \in \mathbb{C}$. *Let* $u \in C([0,\infty), H^1(\mathbb{R}^N)) \cap \mathcal{X}_{\alpha,\nu}$ *be the resulting solution of* (1.1), *as given by Proposition* 5.5. *It follows that* (7.11), (7.12), (7.13), *and* (7.14) *hold. The same is true if* $u^+ = c\Theta$, *where* Θ *is given by* (7.8).

The next proposition is the analogue of Proposition 7.2 for initial values instead of scattering states. Its proof uses Theorem 2.1 in [4] to guarantee the existence of global solutions u of (1.1) in $X_\alpha \cap \mathcal{X}_{\alpha,\nu}$. This theorem requires the additional condition $\alpha\beta + \nu < 1$ in order to conclude $u \in \mathcal{X}_{\alpha,\nu}$. In the present situation, this condition is automatic, since by (7.6) and (2.7) $\nu < \frac{N\alpha}{2(\alpha+2)} = 1 - \alpha\beta$.

Proposition 7.7. *Assume* (1.4), (7.1), (7.2), *and* (7.3). *Let Ψ be given by* (7.7) *and $\varphi = c\Psi$ where the constant c is small enough so that φ satisfies the hypotheses of Theorem* 2.1 *in* [4] *with $\delta = \nu - \beta$. Let $u \in X_\alpha \cap \mathcal{X}_{\alpha,\nu}$ be the resulting solution of* (1.1), *which is also a "classical" H^1 solution by Proposition* 2.3 *in* [4]. *It follows that*

$$t^\nu \|u(t) - c\mathcal{T}(t)\psi\|_{L^{\alpha+2}} = O(t^{-\varepsilon}) \tag{7.17}$$

as $t \to \infty$ for some $\varepsilon > 0$. In particular, u satisfies (7.13). *Moreover, u satisfies* (7.11) *and* (7.14), *where u^+ is the scattering state of u. These results are true if $\varphi = c\Theta$ where Θ is given by* (7.8) *and c is sufficiently small.*

Proof. If $(\alpha+1)\nu < 1$, the proof of (7.17) is similar to the proof of (7.12) using part (ii) of Proposition 3.7. If $(\alpha+1)\nu \geq 1$, fix $\nu' \in (\beta, \nu)$ such that $(\alpha+1)\nu' < 1$. By using part (ii) of Proposition 3.7 again, we obtain

$$\begin{aligned} t^\nu \|u(t) - \mathcal{T}(t)c\psi\|_{L^{\alpha+2}} &\leq t^\nu \|u(t) - \mathcal{T}(t)\varphi\|_{L^{\alpha+2}} + t^\nu \|\mathcal{T}(t)c\eta\psi\|_{L^{\alpha+2}} \\ &\leq Ct^{\nu-\nu'-\alpha(\nu'-\beta)} \|u\|^{\alpha+1}_{\mathcal{X}_{\alpha,\nu'}} + Ct^{-\frac{N\alpha}{2(\alpha+2)}+\nu} \|\eta\psi\|_{L^{\frac{\alpha+2}{\alpha+1}}}. \end{aligned}$$

It follows from (7.6) that $-\frac{N\alpha}{2(\alpha+2)} + \nu < 0$ and that

$$\nu - \nu' - \alpha(\nu' - \beta) = \nu - (\alpha+1)\nu' + 1 - \frac{N\alpha}{2(\alpha+2)} < 0$$

if $(\alpha+1)\nu'$ is sufficiently close to 1. This proves (7.17). (7.11) follows from Proposition 3.7 (i) and (iii), and (7.14) follows from Proposition 3.10 (iv). This completes the proof if $\varphi = c\Psi$. The proof for $\varphi = c\Theta$ is analogous. □

8. Appendix.

In this appendix, we give some properties of the linear Schrödinger equation.

Proposition 8.1. *If $\varphi \in \mathcal{S}'(\mathbb{R}^N)$, $\varphi \neq 0$, then*

$$\liminf_{t\to\infty} t^{\frac{N\alpha}{2(\alpha+2)}} \|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}} > 0$$

for all $\alpha \geq 0$. Here, we use the convention that $\|\psi\|_{L^{\alpha+2}} = +\infty$ if $\psi \in \mathcal{S}'(\mathbb{R}^N)$, $\psi \notin L^{\alpha+2}(\mathbb{R}^N)$.

Proof. We claim that

$$\mathcal{T}(-t)\mathcal{F}\psi = i^{\frac{N}{2}} D_{\frac{1}{4\pi t}} M_{-16\pi^2 t} \mathcal{T}\Big(\frac{1}{16\pi^2 t}\Big)\psi \tag{8.1}$$

for all $t > 0$ and all $\psi \in \mathcal{S}'(\mathbb{R}^N)$, where the dilation D_ℓ and the multiplier M_μ are defined by

$$(D_\ell\theta)(x) = \ell^{\frac{N}{2}}\theta(\ell x), \quad (M_\mu\theta)(x) = e^{i\frac{\mu|x|^2}{4}}\theta(x)$$

for all $\theta \in \mathcal{S}(\mathbb{R}^N)$ and by duality for all $\theta \in \mathcal{S}'(\mathbb{R}^N)$. Indeed, by density it suffices to establish (8.1) for $\psi \in \mathcal{S}(\mathbb{R}^N)$. Since $\mathcal{T}(t) = \mathcal{F}M_{-16\pi^2 t}\mathcal{F}^{-1}$ (take the inverse Fourier transform of the Schrödinger equation satisfied by $\mathcal{T}(t)\psi$), it follows that $\mathcal{T}(-t)\mathcal{F} = \mathcal{F}M_{16\pi^2 t}$. Next, we use the following formula (see formula (3.5) in [2]) which can be verified by a direct calculation with the kernel of $\mathcal{T}(t)$,

$$\mathcal{F}M_{16\pi^2 t} = i^{\frac{N}{2}} D_{\frac{1}{4\pi t}} M_{-16\pi^2 t} \mathcal{T}\Big(\frac{1}{16\pi^2 t}\Big).$$

(8.1) follows. We now deduce from (8.1) that

$$\|\mathcal{T}(-t)\mathcal{F}\psi\|_{L^{\alpha+2}} = (4\pi t)^{-\frac{N\alpha}{2(\alpha+2)}} \Big\|\mathcal{T}\Big(\frac{1}{16\pi^2 t}\Big)\psi\Big\|_{L^{\alpha+2}} \tag{8.2}$$

for all $\psi \in \mathcal{S}'(\mathbb{R}^N)$.

Finally, suppose by contradiction that there exist $\alpha \geq 0$ and a sequence $\tau_n \to \infty$ such that

$$\tau_n^{\frac{N\alpha}{2(\alpha+2)}} \|\mathcal{T}(\tau_n)\varphi\|_{L^{\alpha+2}} \underset{n\to\infty}{\longrightarrow} 0.$$

Applying (8.2) with $t = (16\pi^2\tau_n)^{-1}$, we deduce that

$$\Big\|\mathcal{T}\Big(-\frac{1}{16\pi^2\tau_n}\Big)\mathcal{F}\varphi\Big\|_{L^{\alpha+2}} \underset{n\to\infty}{\longrightarrow} 0.$$

Since $\tau_n \to \infty$, this implies that $\mathcal{F}\varphi = 0$ in $\mathcal{S}'(\mathbb{R}^N)$, thus $\varphi = 0$. □

Remark 8.2. For every $\alpha > 0$, the following properties hold:

(i) Given $0 < \nu < \frac{N\alpha}{2(\alpha+2)}$, there exists $\varphi \in \mathcal{S}'(\mathbb{R}^N)$ such that $t^\nu \|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}} = 1$ for all $t > 0$. Indeed, let $\varphi(x) = c|x|^{-2\nu - \frac{N}{\alpha+2}}$ and apply Proposition 3.7 in [4].

(ii) Given $\frac{N\alpha}{4(\alpha+2)} < \nu < \frac{N\alpha}{2(\alpha+2)}$, there exist $0 < a < b < \infty$ and $\varphi \in H^\infty(\mathbb{R}^N)$ such that $a \leq t^\nu \|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}} \leq b$ for all $t \geq 1$. Indeed, let $\varphi(x) = c|x|^{-2\nu-\frac{N}{\alpha+2}}\theta(x)$ with $\theta \in C^\infty(\mathbb{R}^N)$, $\theta(x) = 0$ for $|x| \leq 1$, and $\theta(x) = 1$ for $|x| \geq 2$.

Remark 8.3. Here are a few observations on the structure of the Banach space $\mathcal{W}_{\alpha,\mu}$.

(i) $(\mathcal{T}(t))_{t\geq 0}$ is a semigroup of contractions on $\mathcal{W}_{\alpha,\mu}$, but if $0 < \mu < \frac{N\alpha}{2(\alpha+2)}$, then $(\mathcal{T}(t))_{t\geq 0}$ is **not** continuous. More precisely, if $\varphi \in \mathcal{W}_{\alpha,\mu}$, then one verifies easily that

$$\|\mathcal{T}(\tau)\varphi - \varphi\|_{\mathcal{W}_{\alpha,\mu}} \geq \liminf_{t\downarrow 0} t^\mu \|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}}$$

for all $\tau > 0$. In particular, if $\varphi(x) = |x|^{-2\mu-\frac{N}{\alpha+2}}$, then $\|\mathcal{T}(\tau)\varphi - \varphi\|_{\mathcal{W}_{\alpha,\mu}} \geq \|\varphi\|_{\mathcal{W}_{\alpha,\mu}} > 0$ for all $\tau > 0$ by Remark 8.2 (i).

(ii) If $0 < \mu < \frac{N\alpha}{2(\alpha+2)}$, then $\mathcal{S}(\mathbb{R}^N)$ is **not** dense in $\mathcal{W}_{\alpha,\mu}$. More precisely, if $\varphi(x) = |x|^{-2\mu-\frac{N}{\alpha+2}}$ and $\theta \in \mathcal{S}(\mathbb{R}^N)$, then $\|\varphi - \theta\|_{\mathcal{W}_{\alpha,\mu}} \geq \|\varphi\|_{\mathcal{W}_{\alpha,\mu}} > 0$. Indeed, by Remark 8.2 (i),

$$t^\mu\|\mathcal{T}(t)(\varphi-\theta)\|_{L^{\alpha+2}} \geq t^\mu\|\mathcal{T}(t)\varphi\|_{L^{\alpha+2}} - t^\mu\|\mathcal{T}(t)\theta\|_{L^{\alpha+2}} = \|\varphi\|_{\mathcal{W}_{\alpha,\mu}} - t^\mu\|\mathcal{T}(t)\theta\|_{L^{\alpha+2}},$$

and the conclusion follows by letting $t \downarrow 0$. We do not know what is the closure of $\mathcal{S}(\mathbb{R}^N)$ in $\mathcal{W}_{\alpha,\mu}$.

(iii) If $0 < \mu < \frac{N\alpha}{2(\alpha+2)}$, then $\mathcal{W}_{\alpha,\mu}$ is **not** separable. To see this, let $\varphi(x) = |x|^{-2\mu-\frac{N}{\alpha+2}}$ and, given $v \in \mathbb{R}^N$, set $\varphi_v(x) = e^{i\frac{v\cdot x}{2}}\varphi(x)$. If $v \neq w$, we claim that $\|\varphi_v - \varphi_w\|_{\mathcal{W}_{\alpha,\mu}} \geq \|\varphi\|_{\mathcal{W}_{\alpha,\mu}}$, which implies the result. Indeed, by Galilean invariance, $(\mathcal{T}(t)\varphi_v)(x) = e^{-it\frac{|v|^2}{4}}e^{i\frac{v\cdot x}{2}}(\mathcal{T}(t)\varphi)(x - tv)$. Thus $\varphi_v \in \mathcal{W}_{\alpha,\mu}$ and $\|\varphi_v\|_{\mathcal{W}_{\alpha,\mu}} = \|\varphi\|_{\mathcal{W}_{\alpha,\mu}}$. Moreover, if f is the profile associated with φ, then

$$\mathcal{T}(t)(\varphi_v - \varphi_w)(x) = t^{-\mu-\frac{N}{2(\alpha+2)}}\left[e^{-it\frac{|v|^2}{4}}e^{i\frac{v\cdot x}{2}}f\Big(\frac{x-tv}{\sqrt{t}}\Big) - e^{-it\frac{|w|^2}{4}}e^{i\frac{w\cdot x}{2}}f\Big(\frac{x-tw}{\sqrt{t}}\Big)\right].$$

In particular,

$$t^{\mu}\|\mathcal{T}(t)(\varphi_v - \varphi_w)\|_{L^{\alpha+2}(\{|x-tv|<1\})} \geq \|f\|_{L^{\alpha+2}(\{|x|<\sqrt{t}\})} - \|f\|_{L^{\alpha+2}(\{|x|>\sqrt{t}|v-w|-1\})}.$$

Letting $t \to \infty$, we see that

$$\liminf_{t\to\infty} t^{\mu}\|\mathcal{T}(t)(\varphi_v - \varphi_w)\|_{L^{\alpha+2}(\{|x-tv|<1\})} \geq \|f\|_{L^{\alpha+2}},$$

and the claim follows.

AN ELLIPTIC REGULARITY RESULT FOR A COMPOSITE MEDIUM WITH "TOUCHING" FIBERS OF CIRCULAR CROSS-SECTION[*]

ERIC BONNETIER[†] AND MICHAEL VOGELIUS[‡]

Abstract. In this paper we consider the elliptic equation $\nabla \cdot a\nabla u = 0$ in a two dimensional domain Ω, which contains a finite number of circular inhomogeneities (cross-sections of fibers). The coefficient, a, takes two constant values, one in all the inhomogeneities and one in the part of Ω which lies outside the inhomogeneities. A number of the inhomogeneities may possibly touch, but in spite of this we prove that any variational solution u (with sufficiently smooth boundary data) is in $W^{1,\infty}$. For this very interesting, particular type of coefficient, our result improves a classical regularity result due to DeGiorgi and Nash, which asserts that the solution is in the Hölder class C^γ for some positive exponent γ.

1. Introduction.

Consider a domain $\Omega \subset \mathbb{R}^2$, representing the cross-section of a three dimensional body. We suppose the three dimensional body is occupied by a fiber-reinforced composite and we suppose the cross-section is taken perpendicular to the finitely many (identical) cylindrical fibers. Frequently in composites, the fibers are very closely spaced and may even touch. We suppose the strength of the fibers is different from that of the material between the fibers (the so-called matrix). When we talk about strength this could, for instance, refer to the shear modulus (for a problem of antiplane shear) or the conductivity (for a problem of heat or electric conduction). In all three cases the corresponding scalar variable, u, (the out of plane displacement, the temperature or the voltage potential) satisfies the elliptic equation

$$\nabla \cdot a\nabla u = 0 \quad \text{in } \Omega, \tag{1}$$

with, for instance, a given Dirichlet boundary condition

$$u = \phi \quad \text{on } \partial\Omega. \tag{2}$$

The coefficient $0 < a < \infty$ takes two constant values, one in the fibers and one in the matrix. The aim of this paper is to study the behavior of u and, in particular, its gradient near points where the fibers touch. Because the cross-section is perpendicular to the fibers, these appear as disks of identical radii. We may without loss of generality restrict attention to a situation with only two touching disks (fibers); for simplicity we take these to lie strictly inside Ω. We may also rescale the strength, a, so that

$$\begin{aligned} &a(x) = 1 \quad \text{for } x \text{ outside the two disks,} \\ &a(x) = a_0 \quad \text{for } x \text{ inside the two disks.} \end{aligned} \tag{3}$$

In the context of antiplane shear it is probably physically most relevant to think of a_0 as being larger than 1—after all, the fibers are there for reinforcement. However, in the context of heat or electrical conduction there are no physical reasons why we might not have $a_0 < 1$ as well. We may, without loss of generality, suppose that the point where the two disks touch is located at the origin. We may also suppose that the domain Ω is of class C^∞ and symmetric in the x_1-axis, and that the boundary data ϕ is in $C^\infty(\partial\Omega)$. If not, we can simply take such a smooth domain inside Ω, containing the two fiber cross-sections and rely on elliptic regularity to get that the (new) Dirichlet data is C^∞. The geometric situation is illustrated in Figure 1. For simplicity of illustration, we have drawn $\partial\Omega$ in the shape of a circle—a convention we shall follow throughout this paper. The solution u is defined variationally by the requirements that u be in $H^1(\Omega)$ with $u|_{\partial\Omega} = \phi$ and

$$\int_\Omega a(x)\nabla u \nabla v \, dx = 0 \quad \forall v \in H_0^1(\Omega).$$

In two dimensions (as we are here) Sobolev's imbedding theorem states that elements of $H^s(\Omega)$, $1 < s$ are automatically continuous. This is not true for all elements of $H^1(\Omega)$. However, a regularity result of DeGiorgi and Nash (cf. [3], [10], or [4]) asserts that any H^1 solution to a divergence form, scalar elliptic equation with bounded measurable coefficients such as (1), is indeed Hölder continuous inside Ω. Near $\partial\Omega$, the coefficent a is constant, and the boundary, as well as the boundary data ϕ, are C^∞, so standard elliptic boundary regularity results immediately imply that u is C^∞ there. Indeed, away from the origin (where the two disks touch) standard elliptic regularity results (for operators with constant, or piecewise constant coefficients) very easily imply that the gradient of u is bounded. The origin, however, presents a serious problem. Neither standard elliptic regularity results nor the DeGiorgi–Nash result assert anything about the boundedness of the gradient. Such boundedness is guaranteed by the main result of this paper.

Theorem. *The solution u is in $W^{1,\infty}(\Omega)$ for any fixed $0 < a_0 < \infty$.*

Since the gradient of the solution u is generically discontinuous at the interfaces between the fibers and the matrix, this theorem is optimal in terms of global regularity.

We have assumed that the circular fiber cross-sections have the same radius. It is worthwhile to point out that this assumption is for convenience only. A configuration with two touching disks of different radii (say, r_1 and r_2) may quite easily be mapped conformally to a configuration consisting of two identical touching disks: pick the x_1-axis to be the common tangent for the two disks (they touch at the origin) and let $z = \Phi(x)$ denote the conformal mapping $\Phi(x_1, x_2) = (x_1/(x_1^2 + x_2^2), x_2/(x_1^2 + x_2^2))$. Let T_c denote the vertical translation $T(z_1, z_2) = (z_1, z_2 + c)$. With an appropriate choice of c $(= \pm(r_2 - r_1)/4r_1r_2)$ the conformal mapping $\Psi = \Phi^{-1} \circ T_c \circ \Phi$ maps the configuration with the two different disks to a configuration with two identical touching disks (of radius $2r_1r_2/(r_1 + r_2)$). This mapping is furthermore smooth at the origin. The validity of the above theorem for two identical disks now immediately implies its validity for different disks as well: the "push-forward" $w = u \circ \Psi^{-1}$ of the function u is in $W^{1,\infty}$ near the origin (since it pertains to a configuration of two identical disks) and due to the regularity of Ψ the same can therefore be said about u. This "push-forward" technique works for any configuration which is conformally equivalent to two touching disks. It should be extremely interesting to study the regularity issue for configurations that are not conformally equivalent to two touching disks.

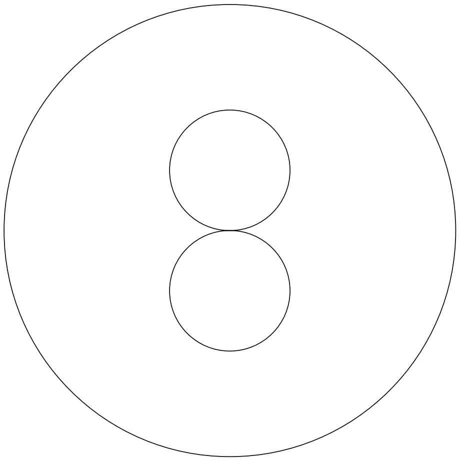

FIG. 1. *Two touching fibers.*

In the context of antiplane shear, $a\nabla u$ represents the stresses (internal forces). Most linear fracture models suppose that fracturing will occur at points with extreme stress concentrations. The fact that the (shear) stresses remain bounded, even near points where the fibers touch, strongly indicates that separation between circular fibers and the matrix is not a likely mechanism for the onset of fracture. The result proven in this paper only applies to a scalar equation; it would be of utmost interest to extend this to the full system of linear elasticity.

To indicate that the behavior of u near the origin is not entirely obvious (and not always the same) let us change to the (conformally) different situation shown in Figure 2: two conical shapes symmetrically touching, with $a = a_0$ inside the two shapes, $a = 1$ outside. For a fixed a_0, the solution is in C^γ with γ uniformly bounded away from zero (independently of the size of the interior angle of the conical shapes). This is consistent with the result of DeGiorgi and Nash, which asserts that u is of a minimal Hölder class that only depends on the aspect ratio of the coefficients. The actual Hölder exponent γ is "generically" smallest when the conical shapes have interior angles $\alpha = \pi/2$. Corresponding to this exponent there is locally near the origin an H^1 solution to (1), which in polar coordinates has the form

$$r^\gamma(A\cos\gamma\theta + B\sin\gamma\theta),$$

with a different pair of constants (A, B) in each of the four sectors. γ is the smallest exponent for which a solution of this form exists in H^1. γ is very easily characterized as the smallest positive solution to a certain determinant identity (expressing that the system of linear equations for the coefficient pairs (A, B) has a nontrivial solution). An analysis very similar to that found in [5] would show that near the origin any solution has, generically, the same behavior as this special solution. Figure 3 shows the "generic γ" ($\alpha = \pi/2$) as a function of $a_0 \neq 1$ for the two possible symmetries of the solution u: one where u is odd with respect to the x_1 axis, and one where u is even with respect to the x_1 axis. It is clear from the graph that a general solution u, which contains elements of both symmetries, is never in $W^{1,\infty}$ (except when $a_0 = 1$); indeed, depending on a_0, its regularity may not be better than C^γ for any arbitrarily small positive γ.

The fact that u is not in $W^{1,\infty}(\Omega)$ in this situation can be explained in terms of

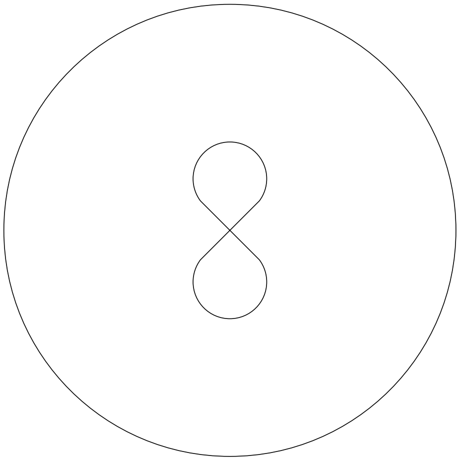

FIG. 2. *Two touching conical shapes.*

a "corner effect." Consider the geometric situation where the two convex shapes are $\epsilon > 0$ apart vertically. The solution will then have two singularities which arise due to the corners in the interfaces. Each corner has an angle of $\pi/2$. Figure 4 shows the generic Hölder coefficient for any solution corresponding to an interface with angle $\pi/2$ (and conductivity ratio $1 : a_0$). Figure 4 corresponds to the lower half of Figure 3; if we had considered solutions with a special symmetry, the curve on the right side (of $a_0 = 1$) would continue smoothly into the left quadrant, and vice versa. It is clear that, for $\epsilon > 0$, a general solution is never in $W^{1,\infty}(\Omega)$ (except when $a_0 = 1$), and it is quite natural to expect that this does not in any way improve in the limit $\epsilon \to 0$, when the two shapes touch.

But the "corner effect" is not the whole story in Figure 3. The regularity situation has clearly become significantly worse when compared to that in Figure 4. For fixed $\epsilon > 0$, Figure 4 clearly indicates that any solution will at least be in $C^{2/3}(\Omega)$, independently of a_0. However, when the shapes touch (for $\epsilon = 0$) Figure 3 clearly indicates that the regularity may not be better than C^γ for any arbitrarily small positive γ, depending on the size of a_0. The touching may thus induce a loss of almost a factor of 2/3 in terms of differentiability.

We now return to the case of (identical) circular fibers. The extreme situations that formally correspond to $a_0 = 0$ and $a_0 = \infty$ are somewhat particular. The corresponding solutions are now (essentially) only defined in $\Omega \setminus \{\text{the fibers}\}$. If the boundary point where the two fibers touch (the origin) is thought of as two different boundary points of $\Omega \setminus \{\text{the fibers}\}$, then these solutions are always C^∞ in the interior and up to the boundary of $\Omega \setminus \{\text{the fibers}\}$. With this convention we also have that all the derivatives of order ≥ 1 vanish at the origin. In the case $a_0 = 0$, we generically have that the solution u^0 is multivalued at the origin, i.e., it has a different limit when approaching the origin from the cusp on the left than when approaching the origin from the cusp on the right. For $a_0 = \infty$, the solution u^∞ is always single valued at the origin. We refer the reader to the appendix, where these issues are discussed in more detail.

An interesting project would be to consider the case where the fibers are very close but not touching. Say, the circular (unit size) cross-sections are ϵ apart vertically. For the case of $a_0 = 0$ (as well as $a_0 = \infty$) the discontinuity mentioned above gives the

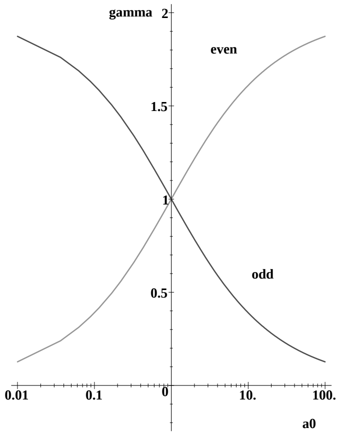

FIG. 3. *The generic γ as a function of a_0 for symmetrically touching conical shapes of interior angle $\pi/2$.*

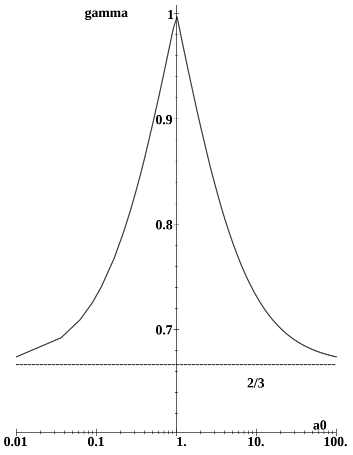

FIG. 4. *The generic γ as a function of a_0 for a single conical shape of interior angle $\pi/2$.*

existence of solutions, the gradients of which become unbounded at the origin as the distance ϵ approaches zero. This phenomenon has been noted and studied in detail by several authors (cf. [2], [9], and [6]). We again refer to the appendix, where some of this work is discussed in a little more detail. For fixed $0 < a_0 < \infty$, we conjecture that the gradient near the origin stays bounded independently of ϵ. We base this conjecture, among other things, on some very accurate calculations communicated to us by Börje Andersson of the Aeronautical Research Institute of Sweden [1]. For circular cross-sections and special boundary conditions, such as those corresponding to the solutions considered in [2] and [9], it is not unlikely that the mapping technique used there would make it possible to establish this uniform boundedness. However, for general boundary conditions or for more general (smooth) fiber cross-sections, entirely different techniques will be required to prove the conjecture.[1]

2. A reduced problem. Since Ω is symmetric in the x_1-axis, the boundary condition $u|_{\partial\Omega} = \phi(x)$ may also be written as $u|_{\partial\Omega} = \frac{1}{2}(\phi(x) - \phi(\overline{x})) + \frac{1}{2}(\phi(x) + \phi(\overline{x}))$, where $\overline{x} = (x_1, -x_2)$ denotes the reflection of the point $x = (x_1, x_2)$. As a consequence, we may separate our boundary value problem into one of two cases: (1) the solution u is odd in the x_1-axis; (2) the solution u is even in the x_1-axis.

In case the boundary data (and thus the solution, u) is even in the x_1-axis, consider the a-harmonic conjugate to u. This function, v, is related to u by

$$a\nabla u = \nabla v^{\perp} = \begin{pmatrix} -\frac{\partial v}{\partial x_2} \\ \frac{\partial v}{\partial x_1} \end{pmatrix}, \tag{4}$$

and it solves

$$\nabla \cdot a^{-1}(x)\nabla v = 0 \quad \text{in } \Omega.$$

From (4) it follows immediately that on $\partial\Omega$

$$\begin{aligned} a^{-1}\nabla v \cdot n &= -a^{-1}\nabla v \cdot \tau^{\perp} \\ &= a^{-1}\nabla v^{\perp} \cdot \tau \\ &= \frac{\partial u}{\partial \tau}, \end{aligned}$$

where τ denotes the counterclockwise tangent. Since u is even it now follows that v (normalized by $\int_\Omega v\,dx = 0$) is odd in the x_1-axis.

In the rest of this paper we shall concentrate on the case where u is odd in the x_1-axis and prove that the gradient of u is bounded. The exact same argument that we present could of course be applied to the (odd) function v (the only difference being that a_0, the conductivity inside the two fibers, gets replaced by a_0^{-1}), thus proving that the gradient of v stays bounded in Ω. Because of the relationship (4) this immediately implies that ∇u is also bounded in Ω in the case where u is even in the x_1-axis. By means of the splitting introduced at the beginning of this section, this now verifies the boundedness of ∇u in the general case (without any symmetry assumptions).

Under the assumption that u is odd in the x_1-axis it indeed suffices to consider the boundary value problem in the half-domain, $\Omega_+ = \{(x_1, x_2) \in \Omega : 0 < x_2\}$, with the additional boundary condition $u = 0$ at $x_2 = 0$ (cf. Figure 5). For simplicity we shall from now on assume that the fiber has radius 1, so that its boundary is given by the equation $x_1^2 + (x_2^2 - 1)^2 = 1$.

[1] Quite recently Y.-Y. Li and M. Vogelius have developed such techniques and among other results established that the conjecture is indeed true; see [8].

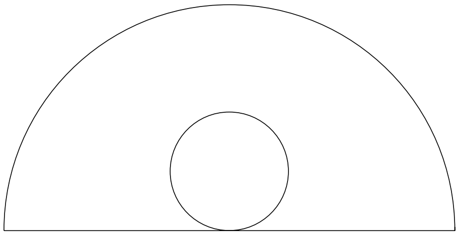

FIG. 5. *The reduced geometric setup.*

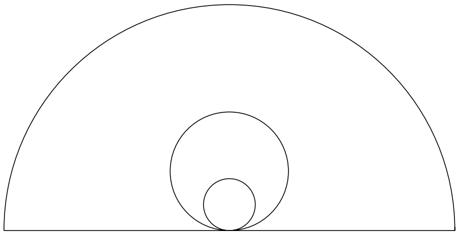

FIG. 6. *The geometric situation with the "auxiliary" boundary.*

3. An auxiliary boundary value problem. Let D_ϵ denote the disk $D_\epsilon = \{(x_1, x_2) : x_1^2 + (x_2 - \epsilon)^2 \le \epsilon^2\}$, centered at $(0, \epsilon)$, with radius ϵ. For small, positive ϵ we introduce an auxiliary function u_ϵ as the solution to the boundary value problem

$$\begin{aligned} \nabla \cdot a(x)\nabla u_\epsilon = 0 &\quad \text{in } \Omega_+ \setminus D_\epsilon, \\ u_\epsilon = \phi &\quad \text{on } \partial\Omega_+ \setminus \{x_2 = 0\}, \\ u_\epsilon = 0 &\quad \text{on } \{x_2 = 0\} \text{ and on } \partial D_\epsilon. \end{aligned}$$

For a geometric illustration, see Figure 6.
The conductivity, a, is as given before. The solution, u, whose gradient we are trying to bound, solves the corresponding "limiting" boundary value problem

$$\begin{aligned} \nabla \cdot a(x)\nabla u = 0 &\quad \text{in } \Omega_+, \\ u = \phi &\quad \text{on } \partial\Omega_+ \setminus \{x_2 = 0\}, \\ u = 0 &\quad \text{on } \{x_2 = 0\}. \end{aligned}$$

A fairly direct argument shows the following proposition.

PROPOSITION 3.1. *Let u_ϵ and u be as defined above, with u_ϵ extended to all of Ω_+ by setting it to zero on D_ϵ. Then $u_\epsilon \to u$ in $H^1(\Omega_+)$ as $\epsilon \to 0$. Let K denote a compact subset of $\overline{\Omega_+} \setminus \{x_1^2 + (x_2 - 1)^2 = 1\}$. Then $u_\epsilon \to u$ in $C^\infty(K)$ as $\epsilon \to 0$.*

Proof. Let $0 \le \psi \le 1$ be in $C^\infty(\mathbb{R}^2)$ with

$$\psi(y) = 0 \quad \text{for } |y| \le 1 \quad \text{and } \psi(y) = 1 \quad \text{for } |y| \ge 2$$

and define the function v_ϵ by

$$v_\epsilon(x) = u(x)\psi\Big(\frac{x_1}{\epsilon}, \frac{x_2 - \epsilon}{\epsilon}\Big).$$

The function $v_\epsilon \in H^1(\Omega_+)$ satisfies

$$\begin{aligned} v_\epsilon = \phi &\quad \text{on } \partial\Omega_+ \setminus \{x_2 = 0\}, \\ v_\epsilon = 0 &\quad \text{on } \{x_2 = 0\} \quad \text{and on } \partial D_\epsilon. \end{aligned}$$

Thus, due to Dirichlet's principle,

$$\begin{aligned}\left[\int_{\Omega_+\setminus D_\epsilon} a|\nabla u_\epsilon|^2\,dx\right]^{1/2} &\le \left[\int_{\Omega_+\setminus D_\epsilon} a|\nabla v_\epsilon|^2\,dx\right]^{1/2}\\ &\le \left[\int_{\Omega_+\setminus D_\epsilon} a|\nabla u|^2\,dx\right]^{1/2} + \frac{1}{\epsilon}\left[\int_{\Omega_+\setminus D_\epsilon} a|u|^2|\nabla\psi(\frac{x_1}{\epsilon},\frac{x_2-\epsilon}{\epsilon})|^2\,dx\right]^{1/2}\\ &= \left[\int_{\Omega_+\setminus D_\epsilon} a|\nabla u|^2\,dx\right]^{1/2} + o(1).\end{aligned}$$

For the last estimate we have used the fact that $\nabla\psi(y)$ vanishes for $|y|\ge 2$, and the fact that u is continuous at 0 with $u(0)=0$ (due to the result of DeGiorgi and Nash) to conclude that

$$\left[\int_{\Omega_+\setminus D_\epsilon} a|u|^2|\nabla\psi(\frac{x_1}{\epsilon},\frac{x_2-\epsilon}{\epsilon})|^2\,dx\right]^{1/2} \le C\epsilon \max_{\Omega_+\cap\{x_1^2+(x_2-\epsilon)^2\le 4\epsilon^2\}} |u| = o(\epsilon).$$

Since u_ϵ has been extended to be zero on D_ϵ, and since u is in $H^1(\Omega_+)$, it follows that

$$\int_{\Omega_+} a|\nabla u_\epsilon|^2\,dx \le \int_{\Omega_+} a|\nabla u|^2\,dx + o(1). \tag{5}$$

On the other hand, Dirichlet's principle also gives

$$\int_{\Omega_+} a|\nabla u|^2\,dx \le \int_{\Omega_+} a|\nabla u_\epsilon|^2\,dx. \tag{6}$$

A combination of (5) and (6) yields

$$\int_{\Omega_+} a|\nabla u_\epsilon|^2\,dx = \int_{\Omega_+} a|\nabla u|^2\,dx + o(1). \tag{7}$$

It is easy to see that

$$\int_{\Omega_+} a|\nabla(u_\epsilon - u)|^2\,dx = \int_{\Omega_+} a|\nabla u_\epsilon|^2\,dx - \int_{\Omega_+} a|\nabla u|^2\,dx,$$

and therefore by insertion of (7)

$$\int_{\Omega_+} a|\nabla(u_\epsilon - u)|^2\,dx \to 0 \quad \text{as } \epsilon\to 0.$$

Since $u_\epsilon = u = 0$ on $\{x_2=0\}$, it follows immediately that $u_\epsilon \to u$ in $H^1(\Omega_+)$.

The statement about C^∞ convergence follows from elliptic regularity theory and from the fact that ϕ comes from an odd C^∞ function on all of $\partial\Omega$. We have to exclude the curve $\{x_1^2+(x_2-1)^2=1\}$, since the coefficient a is discontinuous across it. □

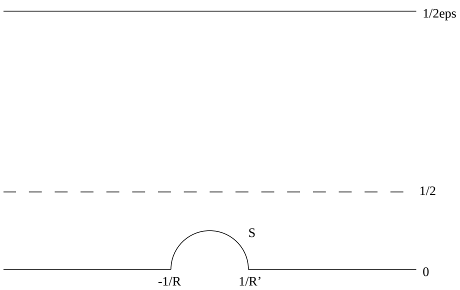

FIG. 7. *The geometric situation in the z-coordinates.*

4. Preliminary estimates. It turns out to be somewhat simpler to work with the variables $(z_1, z_2) = \Phi(x_1, x_2)$ given by the conformal transformation

$$\Phi(x_1, x_2) = \left(\frac{x_1}{x_1^2 + x_2^2}, \frac{x_2}{x_1^2 + x_2^2} \right).$$

The geometric situation is now as illustrated in Figure 7. The "outer" boundary $\partial\Omega \cap \{x_2 > 0\}$ maps to the "inner" boundary S. The circle $\{x_1^2 + (x_2 - 1)^2 = 1\}$ (the fiber) and the circle $\{x_1^2 + (x_2 - \epsilon)^2 = \epsilon^2\}$ (the additional boundary for u_ϵ) map to the horizontal straight lines $z_2 = 1/2$ and $z_2 = 1/2\epsilon$, respectively. The inside of these circles map to the halfplanes $z_2 > 1/2$ and $z_2 > 1/2\epsilon$, respectively. The lower boundary $\{x_2 = 0, -R < x_1 < R'\}$ maps to the straight part of the lower boundary, $\{z_2 = 0, z_1 < -1/R \text{ or } 1/R' < z_1\}$. Since Φ is a conformal mapping, it follows immediately that

$$\int_{\Omega_+} a(x)|\nabla_x v|^2 \, dx = \int_{\Phi(\Omega_+)} A(z)|\nabla_z V|^2 \, dz, \forall v \in H^1(\Omega_+). \tag{8}$$

Here A and V are related to a and v by

$$V(z) = v \circ \Phi^{-1}(z), \quad A(z) = a \circ \Phi^{-1}(z).$$

The transformed solutions $U(z) = u \circ \Phi^{-1}(z)$ and $U_\epsilon(z) = u_\epsilon \circ \Phi^{-1}(z)$ satisfy the differential equations

$$\nabla \cdot A(z)\nabla U = 0 \text{ for } z \in \Phi(\Omega_+)$$

and

$$\nabla \cdot A(z)\nabla U_\epsilon = 0 \text{ for } z \in \Phi(\Omega_+), \quad z_2 < 1/2\epsilon.$$

The transformed conductivity $A(z) = A(z_2)$ has the form

$$A(z) = 1 \text{ for } z_2 < 1/2, \quad A(z) = a_0 \text{ for } z_2 > 1/2.$$

On the "inner" boundary S the functions U and U_ϵ satisfy the boundary conditions

$$U(z) = U_\epsilon(z) = \phi \circ \Phi^{-1}(z).$$

Furthermore, U satisfies

$$U = 0 \text{ on the lower straight boundary } \{z_2 = 0, \quad z_1 < -1/R \text{ or } 1/R' < z_1\},$$

and U_ϵ satisfies

$U_\epsilon = 0$ on the lower straight boundary $\{z_2 = 0, \quad z_1 < -1/R \text{ or } 1/R' < z_1\}$, and on $\{z_2 = 1/2\epsilon\}$.

From the energy identity (8) and the fact that $u, u_\epsilon \in H^1(\Omega_+)$, with $u_\epsilon \to u$, it follows immediately that

(9)
$$\int_{\Phi(\Omega_+)} |\nabla U|^2 \, dz < \infty \quad \text{and} \quad \int_{\Phi(\Omega_+)\cap\{z_2<1/2\epsilon\}} |\nabla U_\epsilon|^2 \, dz < C \text{ independently of } \epsilon.$$

The function $U(z)$ tends to zero as $|z| \to \infty$ (this follows from the fact that u is continuous and has the value 0 at the origin). A simple calculation, using separation of variables, shows that the auxiliary function, U_ϵ, has the expansion

$$U_\epsilon(z) = \sum_{n=1}^{\infty} \beta_{n,\epsilon}\phi_{n,\epsilon}(z_2)e^{-\sqrt{\lambda_{n,\epsilon}}\ z_1} \quad \text{for } z_1 \text{ sufficiently positive,} \tag{10}$$

$$U_\epsilon(z) = \sum_{n=1}^{\infty} \beta'_{n,\epsilon}\phi_{n,\epsilon}(z_2)e^{\sqrt{\lambda_{n,\epsilon}}\ z_1} \quad \text{for } z_1 \text{ sufficiently negative,} \tag{11}$$

where $\lambda_{n,\epsilon} > 0$ and $\phi_{n,\epsilon}(\cdot)$ are the eigenvalues and the eigenvectors of the two point boundary value problem

$$\begin{aligned} -(A(\cdot)\phi')' &= \lambda A(\cdot)\phi \qquad \text{in } (0, 1/2\epsilon), \\ \phi(0) &= \phi(1/2\epsilon) = 0. \end{aligned} \tag{12}$$

Since the coefficient A is bounded from above and is bounded away from zero, it is not difficult to see that

$$d(n\epsilon)^2 \le \lambda_{n,\epsilon} \le D(n\epsilon)^2$$

for some constants $0 < d < D$, independent of n and ϵ. We assume the $\phi_{n,\epsilon}$ are normalized by $\|\phi_{n,\epsilon}\|_{L^2(0,1/2\epsilon)} = 1$. Note that there are no exponentially increasing terms in either of the representations (10) and (11) due to the second inequality from (9). Using the same inequality from (9) (and a standard trace theorem) it follows that there exists $z_1^* > 0$, such that

$$\begin{aligned} \sum_{n=1}^{\infty}(\beta_{n,\epsilon})^2 e^{-2\sqrt{\lambda_{n,\epsilon}}\ z_1^*} &\le C\|U_\epsilon|_{z_1=z_1^*}\|^2_{L^2(0,1/2\epsilon)} \\ &\le C_\epsilon \int_{\Phi(\Omega_+)\cap\{0\le z_1\le z_1^*, 0\le z_2\le 1/2\epsilon\}} |\nabla U_\epsilon|^2 \, dz \\ &< \infty \end{aligned}$$

for any fixed $\epsilon > 0$. Similarly we get that

$$\sum_{n=1}^{\infty}(\beta'_{n,\epsilon})^2 e^{-2\sqrt{\lambda_{n,\epsilon}}\ z_1^*} < \infty$$

for any fixed $\epsilon > 0$. As a consequence of these two bounds and the fact that $d(n\epsilon)^2 \leq \lambda_{n,\epsilon} \leq D(n\epsilon)^2$, it follows immediately that

$$|U_\epsilon(z)| \leq C_\epsilon e^{-c_\epsilon |z_1|}$$

for $|z_1|$ sufficiently large, uniformly in $0 < z_2 < 1/2\epsilon$. That is, for a fixed ϵ, the function U_ϵ converges exponentially to zero as $|z_1| \to \infty$.

Consider the restriction of U_ϵ to the horizontal line $z_2 = 1$ (supposing $\epsilon < 1/2$). By simple integration by parts and Hölder's inequality,

$$\int_{z_2=1} U_\epsilon^2 \, dz_1 \leq C \left(\int_{\Phi(\Omega_+)\cap\{z_2<1\}} \left(\frac{\partial}{\partial z_2} U_\epsilon \right)^2 dz + \int_S U_\epsilon^2 \, ds_z \right).$$

Using the energy bound (9) for U_ϵ and the boundedness of the boundary values of U_ϵ on S, we now obtain

$$\int_{z_2=1} U_\epsilon^2 \, dz_1 \leq C \left(\int_{\Phi(\Omega_+)\cap\{z_2<1\}} |\nabla U_\epsilon|^2 \, dz + \int_S \left(\phi \circ \Phi^{-1}\right)^2 ds_z \right) \;\; \leq \;\; C. \tag{13}$$

The fact that $U_\epsilon(z)$ approaches 0 exponentially fast as $z_1 \to \pm\infty$ along the line $z_2 = 1$ translates into the fact that the function $u_\epsilon(x)$, restricted to the corresponding circle $\{x_1^2 + (x_2 - 1/2)^2 = 1/4\}$, is C^∞, with its value and all the values of its tangential derivatives vanishing at zero. Let v_ϵ denote the solution to

$$\begin{aligned} \triangle v_\epsilon = 0 \quad & \text{in } \{x_1^2 + (x_2 - 1/2)^2 < 1/4\}, \\ v_\epsilon = u_\epsilon \quad & \text{on } \{x_1^2 + (x_2 - 1/2)^2 = 1/4\}. \end{aligned}$$

We introduce one more auxiliary function $V_\epsilon(z)$, the "push-forward" of the function v_ϵ:

$$V_\epsilon(z) = v_\epsilon \circ \Phi^{-1}(z).$$

V_ϵ is defined on the halfplane $\{z_2 > 1\}$. V_ϵ, together with all its derivatives with respect to z_1, converges to zero as $|z| \to \infty$, and it satisfies

$$\triangle V_\epsilon = 0 \quad \text{in } \{z_2 > 1\}, \; V_\epsilon = U_\epsilon \quad \text{on } \{z_2 = 1\}.$$

We have the following representation for V_ϵ:

$$V_\epsilon(z_1, z_2) = \frac{(z_2 - 1)}{\pi} \int_{-\infty}^{\infty} \frac{U_\epsilon(s, 1)}{(z_1 - s)^2 + (z_2 - 1)^2} \, ds,$$

from which it immediately follows that

$$\begin{aligned} |V_\epsilon(z_1, z_2)| &\leq C(z_2 - 1) \|U_\epsilon(\cdot, 1)\|_{L^p(-\infty,\infty)} \| \frac{1}{(z_1 - \cdot)^2 + (z_2 - 1)^2} \|_{L^q(-\infty,\infty)} \\ &\leq C(z_2 - 1)^{-\frac{1}{p}} \|U_\epsilon(\cdot, 1)\|_{L^p(-\infty,\infty)}. \end{aligned} \tag{14}$$

Here $1 \leq p \leq \infty$, and $\frac{1}{p} + \frac{1}{q} = 1$. Note that, since it is continuous as a function of z_1 and since it decreases exponentially to zero as $z_1 \to \infty$, $U_\epsilon(z_1, 1)$ belongs to $L^p(-\infty, \infty)$ for all $1 \leq p \leq \infty$. For any integer $k \geq 1$, we similarly get

$$\left| \left(\frac{\partial}{\partial z_1} \right)^k V_\epsilon(z_1, z_2) \right| \leq C(z_2 - 1)^{-k-\frac{1}{p}} \|U_\epsilon(\cdot, 1)\|_{L^p(-\infty,\infty)}. \tag{15}$$

The estimates (13), (14), and (15) (the latter two for $p = 2$) lead to the following lemma.

LEMMA 4.1. *Let $0 < \alpha$. Then there exists a constant C, independent of ϵ, such that*

$$|U_\epsilon(z)| \le C|z|^{-1/2}, \quad \left|\frac{\partial}{\partial z_1}U_\epsilon(z)\right| \le C|z|^{-3/2}, \quad \textit{and} \ \left|\left(\frac{\partial}{\partial z_1}\right)^2 U_\epsilon(z)\right| \le C|z|^{-5/2}$$

for $z \in \{\max(2, \alpha|z_1|) \le z_2 \le 1/2\epsilon\}$.

Proof. Let V_ϵ be as above. The function $U_\epsilon - V_\epsilon$ satisfies

$$\begin{aligned} \triangle(U_\epsilon - V_\epsilon) = 0 \quad &\text{in } \{1 < z_2 < 1/2\epsilon\}, \\ U_\epsilon - V_\epsilon = 0 \quad &\text{on } \{z_2 = 1\}, \\ |U_\epsilon - V_\epsilon| \le C\sqrt{\epsilon} \quad &\text{on } \{z_2 = 1/2\epsilon\}. \end{aligned} \tag{16}$$

The estimate of $U_\epsilon - V_\epsilon$ on $\{z_2 = 1/2\epsilon\}$ follows from (13) and (14) with $p = 2$. For any fixed ϵ we also have that $(U_\epsilon - V_\epsilon)(z) \to 0$ as $|z_1| \to \infty$ (uniformly on $1 \le z_2 \le 1/2\epsilon$). An application of the maximum principle to (16) now yields

$$|(U_\epsilon - V_\epsilon)(z)| \le C\sqrt{\epsilon} \quad \text{on } \{1 \le z_2 \le 1/2\epsilon\},$$

and therefore, based on (13) and (14) with $p = 2$

$$|U_\epsilon(z)| \le C(\sqrt{\epsilon} + z_2^{-1/2}) \quad \text{on } \{2 \le z_2 \le 1/2\epsilon\}.$$

It follows from this that

$$|U_\epsilon(z)| \le C|z|^{-1/2} \quad \text{on } \{\max(2, \alpha|z_1|) \le z_2 \le 1/2\epsilon\},$$

as desired. A similar argument may be used to derive the desired estimates for $\frac{\partial}{\partial z_1}U_\epsilon$ and $\left(\frac{\partial}{\partial z_1}\right)^2 U_\epsilon$, the only difference being that one applies (15) with $k = 1$ and 2 in place of (14). ☐

The following result will prove convenient both here and later.

LEMMA 4.2. *Let $0 < M_0$, $0 < \gamma$ and $0 < \alpha$, with $\arctan\alpha < \frac{\pi}{2(\gamma+1)}$. Suppose W_ϵ is continuous on $\{M_0 \le z_1, \ \ 0 \le z_2 \le \frac{1}{2\epsilon}\}$, continuously differentiable on each of the sets $\{M_0 \le z_1, \frac{1}{2} \le z_2 \le \frac{1}{2\epsilon}\}$ and $\{M_0 \le z_1, 0 \le z_2 \le \frac{1}{2}\}$, and satisfies, in a weak sense,*

$$\begin{aligned} \nabla \cdot A(z)\nabla W_\epsilon = 0 \quad &\textit{in } \{M_0 < z_1, \ \ 0 < z_2 < 1/2\epsilon\} \\ W_\epsilon = 0 \quad &\textit{on } \{M_0 \le z_1, \ \ z_2 = 1/2\epsilon\} \textit{ and } \{M_0 \le z_1, z_2 = 0\}. \end{aligned}$$

Suppose furthermore that $|W_\epsilon(M_0, z_2)| \le K_0$ for $0 \le z_2 \le \alpha M_0$, and that, for fixed ϵ, $W_\epsilon(z)z_1^\gamma \to 0$ as $z_1 \to \infty$, uniformly on $0 \le z_2 \le 1/2\epsilon$. Then

$$|W_\epsilon(z)| \le C_0|z|^{-\gamma} \textit{ on } \{z_2 = \alpha z_1, \ \ \alpha M_0 \le z_2 \le 1/2\epsilon\}$$

implies that

$$|W_\epsilon(z)| \le C_0'|z|^{-\gamma} \textit{ on } \{M_0 \le z_1, \ \ 0 \le z_2 \le \min(\alpha z_1, \ 1/2\epsilon)\},$$

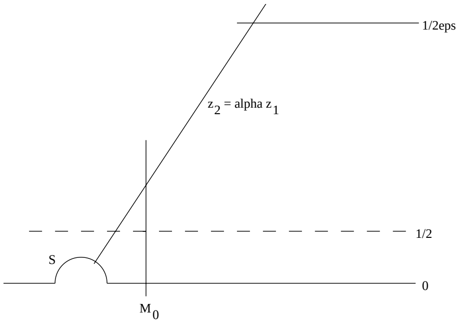

FIG. 8. *The semi-infinite strip. The dashed line represents the conductivity discontinuity at* $z_2 = 1/2$. *The "inner" boundary* S *is illustrated as a semicircle.*

with C_0' *depending on* C_0, M_0, K_0, α, *and* γ *but otherwise independent of* W_ϵ *(and* ϵ*).*

Proof. The proof differs slightly depending on whether $a_0 < 1$ or $a_0 > 1$. We start by considering the case $a_0 < 1$. Let $\mu(z)$ denote the function

$$\mu(z) = r^{-\gamma} \sin \gamma(\theta + \delta),$$

where (r, θ) denotes polar coordinates centered at the origin. Let P_ϵ denote the semi-infinite strip bounded by the four lines $\{z_2 = 0\}$, $\{z_1 = M_0\}$, $\{z_2 = \alpha z_1\}$, and $\{z_2 = 1/2\epsilon\}$ (see Figure 8).

The function μ is clearly harmonic in P_ϵ. We also calculate

$$\begin{aligned}\frac{\partial \mu}{\partial z_2} = \sin\theta \frac{\partial \mu}{\partial r} + \frac{\cos\theta}{r}\frac{\partial \mu}{\partial \theta} &= -\gamma r^{-\gamma-1}(\sin\theta \sin\gamma(\theta+\delta) - \cos\theta\cos\gamma(\theta+\delta)) \\ &= \gamma r^{-\gamma-1}\cos((\gamma+1)\theta + \gamma\delta).\end{aligned}$$

Due to the condition $\arctan \alpha < \frac{\pi}{2(\gamma+1)}$, it follows that $0 \le \theta \le \arctan\alpha < \frac{\pi}{2(\gamma+1)}$ on $\overline{P_\epsilon}$. By selecting $0 < \delta$ sufficiently small we may thus obtain

$$0 < (\gamma+1)\theta + \gamma\delta < \pi/2 \quad \text{on } \overline{P_\epsilon}.$$

It follows immediately that

$$\mu(z) > 0 \quad \text{for } z \in \overline{P_\epsilon} \quad \text{ and } \quad \frac{\partial \mu}{\partial z_2}(z) > 0 \quad \text{for } z \in P_\epsilon. \tag{17}$$

Now consider the function

$$w_\epsilon(z) = \frac{W_\epsilon(z)}{\mu(z)}.$$

A simple calculation gives that

$$\triangle w_\epsilon + 2\frac{1}{\mu}\nabla\mu \cdot \nabla w_\epsilon = 0 \quad \text{in } P_\epsilon \setminus \{z_2 = 1/2\} \tag{18}$$

and

$$a_0 \frac{\partial w_\epsilon}{\partial z_2}^+ - \frac{\partial w_\epsilon}{\partial z_2}^- = (1-a_0)\frac{1}{\mu}\frac{\partial \mu}{\partial z_2} w_\epsilon \quad \text{on the half-line } \{z_2 = 1/2\} \cap P_\epsilon\ . \tag{19}$$

Equation (18), the fact that w_ϵ attains the value 0 on ∂P_ϵ, and the fact that $w_\epsilon(z) \to 0$ as $z_1 \to \infty$ imply that w_ϵ attains it extremal values (min and max) on ∂P_ϵ or on the half-line $\{z_2 = 1/2\} \cap P_\epsilon$. The condition (19) rules out the possibility that an extremal value can be attained on $\{z_2 = 1/2\} \cap P_\epsilon$ unless w_ϵ is constant (= 0): if a maximum was attained at $z_0 \in \{z_2 = 1/2\} \cap P_\epsilon$ then $w_\epsilon(z_0) \geq 0$ and thus, according to (17) and (19),

$$a_0 \frac{\partial w_\epsilon}{\partial z_2}^+ (z_0) - \frac{\partial w_\epsilon}{\partial z_2}^- (z_0) \geq 0.$$
